THE GENERIC NUMBER OF INVARIANT ZEROS OF A STRUCTURED LINEAR SYSTEM*

JACOB VAN DER WOUDE†

Abstract. In this paper we consider a structured linear system represented by means of a directed graph. We present a graph theoretic method to compute the generic number of invariant zeros of the corresponding Rosenbrock matrix. The method is based on a fundamental decomposition of the directed graph representing the structured system. The generic number of invariant zeros is important in generic versions of problems involving controllability and pole placement.

Key words. graph theory, linking, separating subset, linear system, invariant zeros

1. Introduction.

This paper deals with a method to compute the generic number of invariant zeros of a structured system. This number of zeros has already been studied in various papers (see, for instance, [10], [11]) and also in the book [7]. However, in none of the cited references was the most general case treated or was a complete solution given. In this paper we aim for the most general case and we present a graph theoretic method to compute the generic number of invariant zeros of a general structured linear system. Fundamental in our approach is a decomposition of the directed graph representing the structured system into a number of structured subsystems.

The material in this paper on separators and (separator-based) decompositions is largely based on results in [5] on M-decompositions. In [5] M-decompositions are developed in order to hierarchically decompose a (large) set of (algebraic) equations into a number of smaller sets of equations such that the solvability of the original set of equations can be investigated by checking the solvability of the smaller sets of equations individually and by using their hierarchical ordering.

In this paper we use only a simplified version of the M-decomposition and we apply it on linear structured systems described by differential equations. We show that after applying the simplified M-like decomposition, we obtain in principle three essentially different linear structured subsystems that each have their own specific properties. These properties can be used to compute the generic number of invariant zeros of each of the subsystems individually. By combining the obtained results for the subsystems we get the generic number of invariant zeros of the original system. In [16] the subsystems with their specific properties are used to investigate the generic solvability of the disturbance decoupling problem with pole placement for structured systems.

For the sake of completeness and the readers' interest, we have included some illustrative results on separators and separator-based decompositions. Also we present a simple and straightforward algorithm for the decomposition used in this paper.

We want to also point out that we can apply a general version of the M-decomposition on linear structured systems described by differential equations. In principle, this will yield a minimal inconsistent part, a number of consistent parts, and a maximal inconsistent part (see [5]). Two of the three subsystems mentioned above can be obtained directly from the minimal part and the maximal inconsistent part, respectively. The third subsystem is obtained by aggregating all the components of the consistent parts.

The main goal of our paper is the presentation of the three different subsystems with their specific properties and their use for computing the generic number of invariant zeros of a structured linear system. Since the subsystems can already be obtained by means of our simplified version of the M-decomposition, we have refrained from using a more general version of this decomposition. For more details on a general version of the M-decomposition, we refer to [5].

The outline of this paper is as follows. In section 2 we give the mathematical formulation of the problem of the paper. In section 3 we explain how a structured system can be represented by means of a directed graph. In section 4 we present some simplifying assumptions that in the context of this paper can be made without harming the generality and we present the decomposition of a graph on which this paper is based. In section 5 we present results that are crucial for this paper. These results are combined to yield our main result: a graph theoretic method for computing the generic number of invariant zeros of a general structured system. In section 6 we illustrate the method by means of an elementary example. In section 7 we present some conclusions and remarks. We give (sketches of) proofs of some of the results of this paper in the appendix.

2. Problem formulation.

2.1. Systems and number of zeros. In this paper we study the following linear time-invariant system:

$$\Sigma: \quad \left\{ \begin{array}{rcl} \dot{x}(t) &=& Ax(t) + Bu(t), \\ y(t) &=& Cx(t) + Du(t), \end{array} \right. \tag{1}$$

with state $x(t) \in \mathbb{R}^n$, input $u(t) \in \mathbb{R}^m$, and output $y(t) \in \mathbb{R}^p$. The matrices A, B, C, and D are real and have dimensions $n \times n$, $n \times m$, $p \times n$, and $p \times m$, respectively. With I_n the $n \times n$ identity matrix, we write the *system pencil* of system (1) as (see [8])

$$P(s) = \begin{pmatrix} A - sI_n & B \\ C & D \end{pmatrix}.$$

From the next subsection on we assume that system (1) is *structured* in the sense that only the zero/nonzero structure of the matrices A, B, C, and D is known. However, here we still assume that system (1) is numerically specified. Then, regarding $P(s)$ as a rational matrix, we call its rank the *normal-rank* and we denote this normal-rank by n-rank $P(s)$. For a particular complex value $\hat{s}$, we denote the *rank* of the constant (complex) matrix $P(\hat{s})$ by rank $P(\hat{s})$. It is well known that if n-rank $P(s) = q$, then rank $P(\hat{s}) = q$ for almost all values $\hat{s} \in \mathbb{C}$ and $\max_{\hat{s} \in \mathbb{C}}$ rank $P(\hat{s}) = q$ (see [13]). Given that n-rank $P(s) = q$, there may exist numbers $\hat{s} \in \mathbb{C}$ such that rank $P(\hat{s}) < q$. We call such numbers the *invariant zeros* of the system (see [1]). Formally, if n-rank $P(s) = q$, we have the following definition.

DEFINITION 2.1. *The number $s_0 \in \mathbb{C}$ is an invariant zero of system* (1) *if rank* $P(s_0) < q$.

For certain applications, for instance, applications involving pole placement, the *number* of invariant zeros of system (1) is important (see [8]), where the number of zeros is counted with multiplicity. See also [16] for an application of the results of this paper.

In this paper we study methods to compute *the number of invariant zeros*. Our goal is to compute the number of invariant zeros for *structured systems*. For numerically specified (nonstructured) systems, we have various methods available to compute the number of invariant zeros. In the following we review some cases that will illustrate the approach followed in this paper:

Special Cases.

1. We begin by considering the case when $p = m$. Then $P(s)$ is square with dimensions $(n + p) \times (n + p)$. If in addition n-rank $P(s) = n + p$, then $P(s)$ is invertible as a rational matrix. The number of invariant zeros of system (1) then equals the degree of the determinant of $P(s)$.

2. Next we consider the case when $p < m$. If in addition n-rank $P(s) = n + p$, then $P(s)$ has a right inverse, seen as a rational matrix. Now if s_0 is an invariant zero of (1), then rank $P(s_0) < n + p$. Hence, any $(n + p) \times (n + p)$ submatrix of $P(s_0)$ has zero determinant. Therefore, s_0 is a zero of any $(n + p)$th order minor of $P(s)$, implying that s_0 is a zero of the greatest common divisor of all these minors. Conversely, if s_0 is a zero of the greatest common divisor of all $(n+p)$th order minors of $P(s)$, then any $(n+p)\times(n+p)$ submatrix of $P(s)$ has zero determinant for $s = s_0$, implying that rank $P(s_0) < n + p$ and that s_0 is an invariant zero of (1). Therefore, if $p < m$ and n-rank $P(s) = n + p$, then the number of invariant zeros of system (1) is equal to the degree of the greatest common divisor of all $(n + p)$th order minors of $P(s)$.

3. Similarly as above, we can treat the case when $m < p$ with n-rank $P(s) = n + m$.

4. We now consider the case that by row and column permutations the system pencil $P(s)$ is transformed into $\tilde{P}(s)$ given by

$$\tilde{P}(s) = \begin{pmatrix} \tilde{P}_1(s) & \tilde{Q}_{12}(s) \\ 0 & \tilde{P}_2(s) \end{pmatrix},$$

with

- $\tilde{P}_i(s)$ *system pencils like* $P(s)$ *of dimensions* $a_i \times b_i$ *for* $i = 1, 2$,
- *n-rank* $\tilde{P}_1(s) = a_1$,
- *n-rank* $\tilde{P}_2(s) = b_2$.

Hence, seen as rational matrices, we have that $\tilde{P}_1(s)$ has full row rank and $\tilde{P}_2(s)$ has full column rank. Then using some basic calculus for rational matrices we can show that n-rank $P(s)$ = n-rank $\tilde{P}(s) = q$ with $q = a_1 + b_2$. The $a_1 \times b_2$ polynomial matrix $\tilde{Q}_{12}(s)$ is not relevant in this context. By simple reasoning it is easy to prove that any invariant zero of $\tilde{P}(s)$ is an invariant zero of $\tilde{P}_1(s)$ and/or $\tilde{P}_2(s)$, and also the converse is true. Any invariant zero of $\tilde{P}_1(s)$ and/or $\tilde{P}_2(s)$ is also an invariant zero of $\tilde{P}(s)$. Moreover, counting the zeros with multiplicities it can be shown that the number of invariant zeros of $\tilde{P}(s)$ is equal to the sum of the number of invariant zeros of $\tilde{P}_1(s)$ and the number of invariant zeros of $\tilde{P}_2(s)$. Therefore, to compute the number of invariant zeros of $\tilde{P}(s)$, we can compute the number of invariant zeros of the smaller matrices $\tilde{P}_1(s)$ and $\tilde{P}_2(s)$ and add them together. Since row and column

permutations are of no influence, we then also have obtained the number of invariant zeros of $P(s)$.

2.2. Structured systems and generic number of zeros. In the previous subsection we considered systems that are numerically specified. However, in this paper we mainly treat systems (1) that are not numerically specified. Indeed, in the rest of this paper we assume that we know only the *zero/nonzero* structure of the matrices A, B, C, and D. This means that of each entry in these matrices we know only whether its value is fixed to zero, in which case we call it a *fixed zero*, or that it has an unknown real value, in which case we call the entry a *free parameter*. We say that a system (1) is *structured* if only the zero/nonzero structure of the matrices A, B, C, and D is given.

In a structured system (1) with l nonzero entries in the matrices A, B, C, and D, we can parametrize these entries by a scalar real parameters λ_i, $i = 1, 2, \ldots, l$, together forming a parameter vector $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_l)^\top \in \mathbb{R}^l$, where $^\top$ means transpose.

We denote the matrices obtained by replacing the nonzeros in A, B, C, and D by the corresponding parameters λ_i, $i = 1, 2, \ldots, l$, by A_λ, B_λ, C_λ, and D_λ, respectively. Following this notation we also write

$$P_\lambda(s) = \begin{pmatrix} A_\lambda - sI_n & B_\lambda \\ C_\lambda & D_\lambda \end{pmatrix}.$$

For each value of $\lambda \in \mathbb{R}^l$, we have a numerically specified system with system pencil $P_\lambda(s)$ of which we can compute the n-rank and the number of invariant zeros. It turns out that the n-rank of $P_\lambda(s)$ will have the same value for almost all parameter values $\lambda \in \mathbb{R}^l$ (see [7], [14]). This is the so-called *generic n-rank* of $P(s)$ and will be denoted by g-n-rank $P(s)$.

If the g-n-rank of $P(s)$ is equal to q, it can be shown that the degree of each qth order minor of $P(s)$ individually will have the same value for almost all parameter values (see [7]). The same applies to the degree of the greatest common divisor of the qth order minors of $P(s)$. This means that for almost all parameter values the number of invariant zeros of $P(s)$ is the same. Therefore, we can refer to this number as the *generic number of invariant zeros* of $P(s)$.

Above, each of the expressions "for almost all" is to be understood as "for all except for those in some proper algebraic variety in $\mathbb{R}^l$" (see [12]).

2.3. Approach followed in this paper. In this paper we develop a method to determine the generic number of invariant zeros of a structured system (1). Basically, the method consists of two steps.

In the first step the system pencil of a structured system

$$P(s) = \begin{pmatrix} A - sI_n & B \\ C & D \end{pmatrix}$$

is transformed using row and column permutations into the next form

$$P(s) = \begin{pmatrix} P_1(s) & Q_{12}(s) & Q_{13}(s) \\ 0 & P_2(s) & Q_{23}(s) \\ 0 & 0 & P_3(s) \end{pmatrix},$$

in which $P_i(s)$, $i = 1, 2, 3$, are system pencils like $P(s)$, such that

- $P_1(s)$ *generically has full row rank (even after deleting an arbitrary column; see in the later sections),*
- $P_2(s)$ *is generically invertible, and*
- $P_3(s)$ *generically has full column rank (even after deleting an arbitrary row; see in the later sections).*

In the second step, as in subsection 2.1, we determine the generic number of invariant zeros of the structured system (1) by adding the generic number of invariant zeros of the structured subsystems characterized by the system pencils $P_1(s)$, $P_2(s)$, and $P_3(s)$.

The generic number of invariant zeros of the structured subsystem characterized by $P_2(s)$ is simply the generic degree of the determinant of $P_2(s)$. The generic number of invariant zeros of the structured subsystem characterized by $P_1(s)$ equals the generic degree of the greatest common divisor of all maximum order minors of $P_1(s)$. Similarly, the generic number of invariant zeros of the structured subsystem is characterized by $P_3(s)$.

Using graph theory we are able to determine row and column permutations such that $P(s)$ is transformed into the above triangular form. In addition to obtaining the above triangular form, the permutations are such that $P_1(s)$ has special properties that enable us to determine the generic degree of the greatest common divisor of all maximum order minors of $P_1(s)$ in a straightforward way. This also holds for the generic degree of the greatest common divisor of all maximum order minors of $P_3(s)$.

3. Graph representation of structured systems.

3.1. Graphs, paths, linkings, and cycles families. We introduce the graph $G = (V, E)$ of a structured system of the form (1). The vertex set V of the graph is given by $U \cup X \cup Y$ with $U = \{u_1, \dots, u_m\}$ the set of input vertices, $X = \{x_1, \dots, x_n\}$ the set of state vertices, $Y = \{y_1, \dots, y_p\}$ the set of output vertices. Hence, V consists of $n + m + p$ vertices. The indices n, m, and p come from system (1) and denote the dimension of the state space, the input space, and the output space, respectively. Denoting (v, v') for a directed edge from the vertex $v \in V$ to the vertex $v' \in V$, the edge set E of the graph is described by $E_A \cup E_B \cup E_C \cup E_D$ with $E_A = \{(x_j, x_i) | A_{ij} \neq 0\}$, $E_B = \{(u_j, x_i) | B_{ij} \neq 0\}$, $E_C = \{(x_j, y_i) | C_{ij} \neq 0\}$, $E_D = \{(u_j, y_i) | D_{ij} \neq 0\}$. In the latter, for instance, $A_{ij} \neq 0$ means that the (i, j)th entry of the matrix A is a free parameter (a nonzero). An example of a graph is given in section 6.

Let W, W' be two nonempty subsets of the vertex set V of the graph G. We say that there exists a *path* from W to W', if there is an integer t and there are vertices $w_0, w_1, \dots, w_t \in V$ such that $w_0 \in W$, $w_t \in W'$, and $(w_{i-1}, w_i) \in E$ for $i = 1, 2, \dots t$. We call the vertex w_0 the *begin vertex* of the path and w_t the *end vertex*. We say that the path consists of the vertices $w_0, w_1, \dots, w_t$, where it may happen that some of the vertices occur more than once. We also say that each of the vertices in $w_0, w_1, \dots, w_t$ is contained in the path. We call the path *simple* if every vertex on the path occurs only once. Occasionally, we denote a path by the sequence of directed edges it consists of, i.e., by $(w_0, w_1), (w_1, w_2), \dots, (w_{t-1}, w_t)$. If $(w_0, w_1), \dots, (w_{i-1}, w_i), (w_i, w_{i+1}), \dots, (w_{j-1}, w_j), (w_j, w_{j+1}), \dots, (w_{t-1}, w_t)$ is a path from the vertex w_0 to the vertex w_t, first along the vertex w_i and then along the vertex w_j, the part from the vertex w_i to the vertex w_j is called a *subpath* of the original path.

We say that two paths from W to W' are *disjoint* if they consist of disjoint sets of vertices. We call l paths from W to W' disjoint if they are mutually disjoint, i.e., each of the two of them are disjoint. We call a set of l *disjoint* and *simple* paths from

W to W' a *linking from W to W' of size l*. Since there are only a finite number of linkings, there obviously exist linkings consisting of a maximum number of disjoint paths. We call such linkings *maximum (size) linkings*.

We call a *simple* path a *U-rooted path* if the path has its begin vertex in U. We call a number of mutually disjoint U-rooted paths a *U-rooted path family*.

We call a *closed* and *simple* path a *cycle*, i.e., a cycle is a path of the form $(w_0, w_1), (w_1, w_2), \ldots, (w_{t-1}, w_0)$, consisting of distinct vertices $w_0, w_1, \ldots, w_{t-1}$. We call two cycles *disjoint* if they consist of disjoint sets of vertices. We say that l cycles are disjoint if they are mutually disjoint. We call such a set of l disjoint cycles a *cycle family of size l*.

We say that the union of a linking, a U-rooted path family and a cycle family is *disjoint* if they mutually have no vertices in common.

3.2. Separators, essential vertices, and subgraphs. Given the graph $G = (V, E)$ we call a set of vertices $S \subseteq V$ a *separator* between the sets U and Y if every path from U to Y contains at least one vertex in S. The number of vertices in a separator is called the *size* of the separator. Since there are only a finite number of separators between U and Y, there clearly exist such separators having the smallest size. We call such separators *minimum (size) separators* between U and Y. We denote the family of all minimum separators between U and Y by $\mathcal{S}$.

The following theorem is now well known (see [5]).

THEOREM 3.1 (Menger). *The size of a maximum linking from U to Y is equal to the size of a minimum separator between U and Y.*

Next we assume that the maximum size of a linking from U to Y is equal to k and we concentrate on linkings of size k from U to Y. We define the set of so-called *essential vertices* as follows.

DEFINITION 3.2. *$V_{ess} = \{v \in V |$ v is included in every linking of size k from U to Y $\}$.*

We have the following property which is proved in the report version of this paper [15].

PROPOSITION 3.3. *$V_{ess} = \cup\{S | S \in \mathcal{S}\}$.*

Thus, V_{ess} consists of all vertices that are present in minimum size separators between U and Y. The following observations are immediate.

COROLLARY 3.4.

- *$S \subseteq V_{ess}$ for all $S \in \mathcal{S}$,*
- *V_{ess} is a separator between U and Y.*

We now introduce subgraphs of the original graph G. However, before doing this we observe that input vertices (vertices in U) can be seen as vertices from which only edges are coming out and to which no edges are going into. Similarly, output vertices (vertices in Y) can be seen as vertices from which no edges are coming out and to which only edges are going into.

Introducing a class of subgraphs we occasionally want to change the role of vertices. For instance, we may want to think of a state vertex $x \in X$ as an input vertex. To do so, we simply ignore the edges that are going into x and concentrate on the edges that are coming out of x. Similarly, if we want to think of x as an output vertex, we simply ignore the edges that are coming out of x and concentrate on the edges that are going into x. In the same manner we can think of an output vertex $y \in Y$ as an input vertex by ignoring the edges that are going into y, yielding a vertex y that is isolated (to which no edges are going into or from which no edges are coming out). Similarly, an input vertex $u \in U$ can be thought of as an output vertex by ignoring

the edges that are coming out of u, yielding a vertex u that is isolated. We discuss these isolated vertices in some more detail later.

Now we let W and $\tilde{W}$ be two nonempty subsets of the vertex set V and we concentrate on all so-called *IO-paths* in G from W to $\tilde{W}$. Here, an IO-path from W to $\tilde{W}$ is a path from W to $\tilde{W}$ where we think of the vertices in W as input vertices (only outgoing edges) and of the vertices in $\tilde{W}$ as output vertices (only incoming edges). Hence, we have the following definition.

DEFINITION 3.5. *An IO-path in G from W to $\tilde{W}$ is a path from W to $\tilde{W}$ that only has one vertex in W (the begin vertex) and only one vertex in $\tilde{W}$ (the end vertex).*

Given the sets W and $\tilde{W}$ we collect the vertices on all IO-paths from W to $\tilde{W}$ in the set V' and we collect all the edges in E between vertices in V' in the set E'. The combination of V' and E' then defines the subgraph G', i.e., $G' = (V', E')$. To indicate that the subgraph G' is obtained by concentrating on all IO-paths in G from W to $\tilde{W}$ we write $G' = H(G; W, \tilde{W})$. We note that we do not require that the sets W and $\tilde{W}$ have an empty intersection. If $v \in W \cap \tilde{W}$, then the vertex v is at the same time seen as an input vertex and an output vertex. As we explained above, all the edges that are coming out of v and all the edges that are going into v, respectively, are then ignored in G'. Hence, the vertex v in G' is an isolated vertex.

Given two pairs of subsets $(W_1, \tilde{W}_1)$ and $(W_2, \tilde{W}_2)$ in V, we can compare (partially order) the associated subgraphs $G_i = H(G; W_i, \tilde{W}_i)$, $i = 1, 2$, in the following way.

DEFINITION 3.6. *Given two pairs of subsets $(W_1, \tilde{W}_1)$ and $(W_2, \tilde{W}_2)$ in V, defining two subgraphs $G_i = H(G; W_i, \tilde{W}_i)$, $i = 1, 2$, of the graph G. Then $G_1 \preceq G_2$ if any IO-path from W_2 to $\tilde{W}_2$ contains a subpath that is an IO-path from W_1 to $\tilde{W}_1$.*

Put differently, $G_1 \preceq G_2$ if and only if any IO-path from W_1 to $\tilde{W}_1$ can be extended (in both directions if necessary) to an IO-path from W_2 to $\tilde{W}_2$. With this ordering of subgraphs we have the following important result. For a proof we refer to [15].

THEOREM 3.7. *There exist two uniquely determined minimum separators between U and Y, denoted as S^* and S_*, such that*

- *$H(G; U, S_*) \preceq H(G; U, S)$ for all $S \in \mathcal{S}$,*
- *$H(G; S^*, Y) \preceq H(G; S, Y)$ for all $S \in \mathcal{S}$.*

To give some intuition for the minimum separators S^* and S_*, we consider a simple path P from $u \in U$ to $y \in Y$ and a minimum separator $S \in \mathcal{S}$. Clearly, the path must contain a vertex in S, say, s. Next we think of the first part of the path from u to s as an IO-path in $H(G; U, S)$. According to the above theorem there is a begin part of this IO-path that can be seen as an IO-path in $H(G; U, S_*)$, say, from u to $s_* \in S_*$. As S_* is the "smallest" with respect to the ordering $\preceq$ introduced above, the previous means that when following any path from U to Y the first vertex in a minimum separator must be a vertex in S_*. Similarly, the last vertex on any path P from U to Y in a minimum separator must be a vertex in S^*.

As $S_* \in \mathcal{S}$ and $V_{ess} = \cup\{S | S \in \mathcal{S}\}$ it follows that $S_* \subseteq V_{ess}$. It also follows that any path from U to V_{ess} has to end in some $S \in \mathcal{S}$ and has to pass through S_*. Thus, any IO-path from U to V_{ess} is in fact an IO-path from U to S_*. The latter implies the following corollary.

COROLLARY 3.8.

- $H(G; U, V_{ess}) = H(G; U, S_*)$,
- $H(G; V_{ess}, Y) = H(G; S^*, Y)$.

Hence, we can compute S_* by considering the set of output vertices of the subgraph $H(G; U, V_{ess})$, where vertices of V_{ess} in U are also considered as output vertices

for the moment. Similarly, we can compute S^* by considering the set of input vertices of the subgraph $H(G; V_{ess}, Y)$. The subset V_{ess} can be computed beforehand by applying algorithms based on the computation of the maximum flow through an associated network.

4. Simplifying assumptions and graph decomposition.

4.1. Simplifying assumptions and basic result. We consider a structured system of the type (1) with the graph $G = (V, E)$ with $V = U \cup X \cup Y$. In the context of this paper we can make the following assumptions on the graph G without harming the generality. We recall that U, X, and Y denote the set of input, state, and output vertices, respectively.

ASSUMPTION 4.1.

- *Every vertex in U is the begin vertex of an edge that ends in a vertex in $X \cup Y$,*
- *Every vertex in Y is the end vertex of an edge that begins in a vertex in $U \cup X$,*
- *Every vertex in X is contained in a path (not necessarily simple) from U to Y.*

We can motivate the assumptions as follows. Following the definition of the graph we see that there is no edge from input vertex u_j to a state or output vertex if and only if the jth column of the compound matrix $\binom{B}{D}$ consists of fixed zeros only. In case of such a zero column the jth input has no effect at all on the system and therefore can be ignored without loss of generality.

Similarly, we see that there is no edge that ends in the output vertex y_i and that starts in a state or input vertex if and only if the ith row of the compound matrix $\begin{pmatrix} C & D \end{pmatrix}$ consists of only zeros. In case of such a zero row the ith output has no information at all on the system and therefore can be ignored without loss of generality. This explains the two first assumptions.

Now we come to the third assumption. The next proposition is well known (see [2], [4], [9]).

PROPOSITION 4.2. *Every state vertex $x \in X$ is the end vertex of some U-rooted path if and only if the pair (A, B) is not reducible, where we say that the pair (A, B) is* reducible *if there is a permutation matrix Q such that*

$$QAQ^{-1} = \begin{pmatrix} A_{11} & 0 \\ A_{21} & A_{22} \end{pmatrix}, \qquad QB = \begin{pmatrix} 0 \\ B_2 \end{pmatrix},$$

with A_{11}, A_{22}, and B_2 are matrices of dimensions $n_1 \times n_1$, $n_2 \times n_2$, and $n_2 \times m$, respectively, with $n_1 + n_2 = n$ and $n_1 > 0$.

Proposition 4.2 states that if there is a state vertex $x \in X$ that is not the end vertex of a U-rooted path, there is a permutation matrix Q such that the system pencil $P(s)$ transforms into

$$\begin{pmatrix} A_{11} - sI_{n_1} & 0 & 0 \\ A_{21} & A_{22} - sI_{n_2} & B_2 \\ C_1 & C_2 & D \end{pmatrix},$$

where $CQ^{-1} = (C_1 \;\; C_2)$. From the latter we immediately see that every eigenvalue of A_{11} is an invariant zero of the original $P(s)$. This means that the generic number of invariant zeros of $P(s)$ is equal to n_1 plus the generic number of invariant zeros of

$$\begin{pmatrix} A_{22} - sI_{n_2} & B_2 \\ C_2 & D \end{pmatrix}.$$

Therefore, as far as the generic number of invariant zeros of $P(s)$ is concerned we may assume without loss of generality that we have split off the "reducible part" and that we may concentrate on the "nonreducible remainder." Inspired by Proposition 4.2 and the above decomposition this means that we just may concentrate on those structured subsystems of which all state vertices are end vertices of U-rooted paths.

Similarly, if there are state vertices that are not begin vertices of paths ending in Y, we can reorder the state vertices in the graph and split off the vertices that are not begin vertices of paths ending in Y. Similarly as before with n_1, only the *number* of those vertices is relevant for the generic number of invariant zeros. Once this number is known the associated vertices can be ignored. We therefore may concentrate on those structured subsystems of which all state vertices are begin vertices of paths ending in Y.

Thus, we can say that without loss of generality we may focus on graphs of which the state vertices are end vertices of paths beginning in U as well as begin vertices of paths ending in Y. Put differently, we may focus on those graphs of which the state vertices are contained in a path from U to Y, which is our third assumption.

To conclude this subsection we recall a well known result (see [13] for a similar result for systems without D matrix). The results relates the g-n-rank of the system pencil with the existence of a maximum size linking from U to Y. See also [15] for a proof.

THEOREM 4.3. *Let $P(s)$ be the system pencil of the structured system* (1)*. Then the n-rank of $P(s)$ is generically equal to n* plus *the* maximum *size of a linking from U to Y.*

4.2. Separator-based decomposition. In this subsection we present a decomposition of the graph $G = (V, E)$ based on a minimum separator between U and Y. We assume that the maximum size of a linking from U to Y is equal to k. Further, we let S be a minimum separator between U and Y. According to the theorem of Menger we know that the set S has to consist of k vertices. Finally, we assume Assumption 4.1 to be valid.

First we consider the subgraph $H(G; U, S)$ of the graph G. As we want to think of the vertices in S as new output vertices, the vertices in $U \cap S$ have to play a double role, i.e., at the same time they have be both input and output vertices. These vertices then have an unclear system theoretic interpretation and have to be treated specially. We do this by first considering only the IO-paths from U to S that have positive length. In this way we first ignore the vertices in $U \cap S$.

We collect all the vertices on the positive length IO-paths from U to S in the set V_α. To distinguish the various vertices in V_α we adopt the following general notation: if K, L are sets then $K\backslash L$ denotes the set of elements in K that are not in L, i.e., $K\backslash L = \{v \in K | v \notin L\}$. With this notation we now define the next new input, output, and state vertex sets

$$U_\alpha = V_\alpha \cap U, \;\; Y_\alpha = V_\alpha \cap S, \;\; X_\alpha = V_\alpha \backslash (U_\alpha \cup Y_\alpha).$$

Due to Assumption 4.1 every vertex in U is the begin vertex of a path from U to Y. Hence, we have that every vertex in U is the begin vertex of an IO-path from U to S. Moreover, since we exclude IO-paths of zero length, it follows that $U_\alpha = U\backslash S$. Furthermore, since S is a separator of minimum size, every vertex of S is the end vertex of at least one IO-path from U to S. Concentrating on positive length IO-paths only we obtain that $Y_\alpha = S\backslash U = S \cap (X \cup Y)$. Therefore

$$U_\alpha = U\backslash S, \;\; Y_\alpha = S\backslash U = S \cap (X \cup Y), \;\; X_\alpha = V_\alpha \backslash (U_\alpha \cup Y_\alpha).$$

By construction $X_\alpha \cap U_\alpha = \emptyset$ and $X_\alpha \cap Y_\alpha = \emptyset$. From the above it follows directly that also $U_\alpha \cap Y_\alpha = \emptyset$. Hence, the collection $\{U_\alpha, Y_\alpha, X_\alpha\}$ forms a partitioning of V_α, meaning that the union of the subsets in the collection is V_α and that the intersection of any two subsets in the collection is empty.

In the above we thought of the vertices in S as new output vertices. However, we can also think of these vertices as new input vertices. Then the vertices in $S \cap Y$ have to be treated in a special way. In view of the above we collect all vertices on positive length IO-paths from S to Y into the set V_β. Then we can define new output, input, and state vertex sets as follows:

$$Y_\beta = V_\beta \cap Y, \;\; U_\beta = V_\beta \cap S, \;\; X_\beta = V_\beta \backslash (U_\beta \cup Y_\beta).$$

Due to Assumption 4.1 every vertex in Y is the end vertex of a path from U to Y. Similarly as above it follows that

$$Y_\beta = Y \backslash S, \;\; U_\beta = S \backslash Y = S \cap (X \cup U), \;\; X_\beta = V_\beta \backslash (U_\beta \cup Y_\beta).$$

The collection $\{U_\beta, Y_\beta, X_\beta\}$ forms a partitioning of V_β.

We now consider both V_α and V_β simultaneously. Hence, we have the graph $G = (V, E)$ with $V = U \cup X \cup Y$ and we consider the subgraphs $G_\alpha = (V_\alpha, E_\alpha)$ and $G_\beta = (V_\beta, E_\beta)$, where V_α and V_β are defined as above and the edge sets E_α and E_β are obtained by restricting the edge set E to V_α and V_β, respectively.

It easily follows that $U \subseteq U_\alpha \cup U_\beta$ and $Y \subseteq Y_\alpha \cup Y_\beta$. We next observe that the intersection of V_α and V_β must be contained in S, i.e., $V_\alpha \cap V_\beta \subseteq S$. Indeed, suppose that $v \in V_\alpha \cap V_\beta$, but that $v \notin S$. Because $v \in V_\alpha$, the vertex v is contained in an IO-path from U to S. Since $v \notin S$ the part from U to v of such an IO-path does not contain any vertex in S. Similarly, since $v \in V_\beta$, there is a part of an IO-path from S to Y forming a path from v to Y that does not contain any vertex in S. Combining these two subpaths results in a path from U to Y along v that does not contain any vertex in S. However, this is in contradiction with the fact that S is a separator between U and Y and, consequently, must contain at least one vertex of any path from U to Y. Thus, we have proved that

$$V_\alpha \cap V_\beta \subseteq S.$$

Intersecting both sides with $V_\alpha \cap V_\beta$ we obtain that $V_\alpha \cap V_\beta = S \cap (V_\alpha \cap V_\beta) = (S \cap V_\alpha) \cap (S \cap V_\beta) = Y_\alpha \cap U_\beta$. This implies that $V_\alpha \cap V_\beta = (S \backslash U) \cap (S \backslash Y) = S \backslash (U \cup Y) = S \cap X$.

To come to a complete partitioning of the vertex set V we define

$$X_\delta = V \backslash (V_\alpha \cup V_\beta).$$

The notation suggests that $X_\delta \subseteq X$. As $U \subseteq U_\alpha \cup U_\beta$ and $Y \subseteq Y_\alpha \cup Y_\beta$ it is obvious that this is indeed true. From above it now immediately follows that the next collection of subsets forms a partitioning of V

$$\{X_\alpha, X_\beta, X_\delta, U_\alpha, Y_\beta, S \cap X, S \cap U, S \cap Y\}.$$

Indeed, by construction $\{V_\alpha \cup V_\beta, X_\delta\}$ is a partitioning of V. Observe further that $Y_\alpha = S \backslash U = (S \cap X) \cup (S \cap Y)$ and $U_\beta = S \backslash Y = (S \cap X) \cup (S \cap U)$, where clearly $\{S \cap X, S \cap Y\}$ is a partitioning of Y_α and $\{S \cap X, S \cap U\}$ is a partitioning of U_β. This implies that $\{X_\alpha, U_\alpha, S \cap X, S \cap Y\}$ is a partitioning of V_α, $\{X_\beta, Y_\beta, S \cap X, S \cap U\}$ is

a partitioning of V_β, and because $V_\alpha \cap V_\beta = S \cap X$ that $\{X_\alpha, X_\beta, U_\alpha, Y_\beta, S \cap X, S \cap U, S \cap Y\}$ is a partitioning of $V_\alpha \cup V_\beta$.

Moreover, it is easy to see that the collection $\{X_\alpha, X_\beta, X_\delta, U_\alpha, U_\beta\}$ is a partitioning of $X \cup U$ and $\{X_\alpha, X_\beta, X_\delta, Y_\alpha, Y_\beta\}$ is a partitioning of $X \cup Y$.

4.3. Properties of separator-based decomposition. Given the above partitioning of V into the subsets $\{X_\alpha,\ X_\beta,\ X_\delta,\ U_\alpha,\ Y_\beta,\ S \cap X,\ S \cap U,\ S \cap Y\}$ we can prove the following result of which a proof can be found in the appendix.

PROPOSITION 4.4. *Let S be a minimum separator between U and Y and let $V = U \cup X \cup Y$ be partitioned as above. Then there are no edges*

- *from $X_\alpha \cup U_\alpha$ to $X_\beta \cup Y_\beta$,*
- *from $X_\alpha \cup U_\alpha$ to X_δ,*
- *from X_δ to $X_\beta \cup Y_\beta$.*

The partitioning of the vertex sets $X \cup U$ and $X \cup Y$ induces a partitioning of the system matrix $P(s)$. To see this, we first consider the matrix $P(s)$ for $s = 0$,

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix},$$

and think of it to act on the vector $\left(\begin{smallmatrix} x \\ u \end{smallmatrix}\right)$ to yield the vector $\left(\begin{smallmatrix} \dot{x} \\ y \end{smallmatrix}\right)$. Next, we reorder the components of these vectors in accordance to the partitionings $\{X_\alpha, U_\alpha, X_\delta, X_\beta, U_\beta\}$ and $\{X_\alpha, Y_\alpha, X_\delta, X_\beta, Y_\beta\}$, respectively, to obtain

$$\begin{pmatrix} x_\alpha \\ u_\alpha \\ x_\delta \\ x_\beta \\ u_\beta \end{pmatrix} \text{ and } \begin{pmatrix} \dot{x}_\alpha \\ y_\alpha \\ \dot{x}_\delta \\ \dot{x}_\beta \\ y_\beta \end{pmatrix}, \text{respectively.}$$

For instance, the vector x_α contains all components of the vector x in X_α. Similarly for the other subvectors. Since there is no edge from $X_\alpha \cup U_\alpha$ to $X_\delta \cup X_\beta \cup Y_\beta$ and no edge from $X_\alpha \cup U_\alpha \cup X_\delta$ to $X_\beta \cup Y_\beta$, there are row and column permutations that transform the matrix $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$ into the upper block triangular matrix

$$\begin{pmatrix} A_\alpha & B_\alpha & * & * & * \\ C_\alpha & D_\alpha & * & * & * \\ 0 & 0 & A_\delta & * & * \\ 0 & 0 & 0 & A_\beta & B_\beta \\ 0 & 0 & 0 & C_\beta & D_\beta \end{pmatrix},$$

where all matrices have suitable dimensions and with the $*$'s denoting matrices that are not relevant in the present context.

For the matrix $P(s)$, the above triangular matrix means that using a suitable row and column permutation $P(s)$ can be transformed into

$$\begin{pmatrix} A_\alpha - sI_{n_\alpha} & B_\alpha & * & * & * \\ C_\alpha & D_\alpha & * & * & * \\ 0 & 0 & A_\delta - sI_{n_\delta} & * & * \\ 0 & 0 & 0 & A_\beta - sI_{n_\beta} & B_\beta \\ 0 & 0 & 0 & C_\beta & D_\beta \end{pmatrix},$$

where all matrices are as before and n_i denotes the number of vertices in X_i, $i = \alpha, \delta, \beta$.

Given the above block triangular form of the matrix $P(s)$ we can prove the following result. For a proof, we refer to the appendix.

PROPOSITION 4.5. *Let the system pencil $P(s)$ be transformed into the upper block triangular form as given above. Then the following hold:*

- *The subsystem pencil*

$$P_\alpha(s) = \begin{pmatrix} A_\alpha - sI_{n_\alpha} & B_\alpha \\ C_\alpha & D_\alpha \end{pmatrix}$$

  generically has full row rank.
- *The subsystem pencil*

$$\begin{pmatrix} A_\delta - sI_{n_\delta} & * & * \\ 0 & A_\beta - sI_{n_\beta} & B_\beta \\ 0 & C_\beta & D_\beta \end{pmatrix}$$

  generically has full column rank.
- *If in the above $S = S_*$, the subsystem pencil $P_\alpha(s)$ generically has full row rank, even after deleting an arbitrary column.*

5. Main results. In this section we present the main results of this paper.

5.1. Fundamental results for special cases. In this subsection we first consider a square structured system of type (1) that is generically invertible. The following theorem indicates how the number of invariant zeros can be computed.

THEOREM 5.1. *Assume that $m = p$, and let $P(s)$ be generically invertible. Then the degree of the determinant of $P(s)$ is generically equal to $n+p$* minus *the* minimum *number of edges in a maximum size (size p) linking from U to Y.*

A proof of Theorem 5.1 is given in the appendix where it is related to one of the results in [14].

Next we assume that $m > p$ and that $P(s)$ generically has full row rank, even after the deletion of an arbitrary column. Then we have the following important result.

THEOREM 5.2. *Let $P(s)$ generically have full row n-rank, even after the deletion of an arbitrary column. Then the greatest common divisor of all the $(n+p)$th order minors of $P(s)$ generically is a monomial in s with a degree equal to $n+p$* minus *the* maximum *number of edges in the disjoint union of a*

- *linking of size p from U to Y,*
- *a U-rooted path family,*
- *a cycle family in X.*

A sketch of a proof of Theorem 5.2 will be given in the appendix. A full proof can be found in [15]. Theorem 5.2 is an extension of one of the main results in [3]. Theorems 5.1 and 5.2 will be illustrated in the next section.

5.2. Partitioning of a structured system. In this subsection we consider a structured system of the type (1) and we assume that Assumption 4.1 is satisfied. The next result states how in general a structured system can be seen as the combination of three smaller subsystems each having properties that are useful for computing the generic number of invariant zeros.

THEOREM 5.3. *There exist row and column permutations such that the system pencil $P(s)$ of a structured system* (1) *with matrices A, B, C, and D can be trans-*

formed into the block triangular form,

$$\begin{pmatrix} A_1 - sI_{n_1} & B_1 & * & * & * & * \\ C_1 & D_1 & * & * & * & * \\ 0 & 0 & A_2 - sI_{n_2} & B_2 & * & * \\ 0 & 0 & C_2 & D_2 & * & * \\ 0 & 0 & 0 & 0 & A_3 - sI_{n_3} & B_3 \\ 0 & 0 & 0 & 0 & C_3 & D_3 \end{pmatrix},$$

with A_i, B_i, C_i, and D_i structured matrices of dimensions $n_i \times n_i$, $n_i \times m_i$, $p_i \times n_i$, and $p_i \times m_i$, respectively, $i = 1, 2, 3$, such that, if present

- $\left(\begin{smallmatrix} A_1 - sI_{n_1} & B_1 \\ C_1 & D_1 \end{smallmatrix}\right)$ *generically has full row n-rank, even after the deletion of an arbitrary column;*
- $\left(\begin{smallmatrix} A_2 - sI_{n_2} & B_2 \\ C_2 & D_2 \end{smallmatrix}\right)$ *generically is invertible (as a rational matrix);*
- $\left(\begin{smallmatrix} A_3 - sI_{n_3} & B_3 \\ C_3 & D_3 \end{smallmatrix}\right)$ *generically has full column n-rank, even after the deletion of an arbitrary row.*

In the above block triangular form the $*$'s denote matrices (matrix pencils) that are not relevant in the context of this paper. A sketch of a proof of Theorem 5.3 is given in the appendix. It is based on Propositions 4.4 and 4.5, combined with the minimum separators S_* and S^*.

5.3. Algorithm. In this subsection we present an algorithm to compute the generic number of invariant zeros of a structured system. The algorithm consists of a first part in which the graph of the system is split into smaller subgraphs for which the generic number of invariant zeros can be computed by Theorems 5.1 and 5.2. This is done in the second part of the algorithm. The results are then taken together and yield the generic number of invariant zeros of the original system.

ALGORITHM 5.4.

- *Make a directed graph of the structured system as explained in subsection* 3.1.
- *Check if the assumptions in subsection* 4.1 *are valid. If not, do preliminary computations as explained in subsection* 4.1 *that result in a smaller structured system for which the assumptions in subsection* 4.1 *are valid.*
- *Using, for instance, Menger's theorem determine the set of essential vertices V_{ess} and the sets S_* and S^* using the subgraphs $H(G; U, V_{ess})$ and $H(G; V_{ess}, Y)$, respectively.*
- *Construct the subgraphs G_1 and G_3 by considering all IO-paths with positive length from U to S_* and from S^* to Y, respectively. Let the subgraph G_2 be determined by considering the vertices in S_* as input vertices, the vertices in S^* as output vertices, and all the remaining vertices of V that are not present in G_1 or G_3.*
- *Using Theorems* 5.1, 5.2, *and the dual of Theorem* 5.2 *compute the generic number of invariant zeros of the subsystems corresponding to the obtained partitioning.*
- *Add the obtained generic numbers to get the generic number of invariant zeros of the original structured system.*

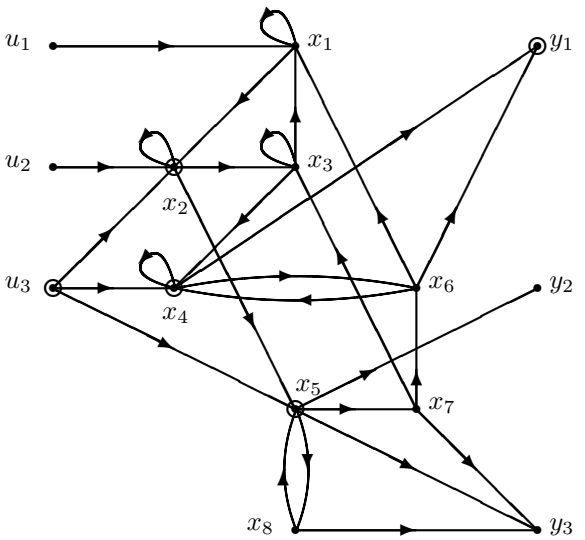

FIG. 6.1. *The graph G with the vertices in V_{ess} already encircled.*

6. Example. We consider the structured system of type (1) as depicted in Figure 6.1. We can parametrize the matrices of the structured system by a parameter $\lambda \in \mathbb{R}^{27}$ as follows.

$$A_\lambda = \begin{pmatrix} \lambda_1 & 0 & \lambda_3 & 0 & 0 & \lambda_4 & 0 & 0 \\ \lambda_5 & \lambda_7 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \lambda_{10} & \lambda_9 & 0 & 0 & 0 & \lambda_{11} & 0 \\ 0 & 0 & \lambda_{12} & \lambda_{15} & 0 & \lambda_{14} & 0 & 0 \\ 0 & \lambda_{16} & 0 & 0 & 0 & 0 & 0 & \lambda_{18} \\ 0 & 0 & 0 & \lambda_{19} & 0 & 0 & \lambda_{20} & 0 \\ 0 & 0 & 0 & 0 & \lambda_{23} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \lambda_{24} & 0 & 0 & 0 \end{pmatrix}, B_\lambda = \begin{pmatrix} \lambda_2 & 0 & 0 \\ 0 & \lambda_6 & \lambda_8 \\ 0 & 0 & 0 \\ 0 & 0 & \lambda_{13} \\ 0 & 0 & \lambda_{17} \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

$$C_\lambda = \begin{pmatrix} 0 & 0 & 0 & \lambda_{22} & 0 & \lambda_{21} & 0 & 0 \\ 0 & 0 & 0 & 0 & \lambda_{25} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \lambda_{28} & 0 & \lambda_{26} & \lambda_{27} \end{pmatrix}, D_\lambda = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

By Figure 6.1 it can be easily verified that Assumption 4.1 is valid. Hence, we are in the position to directly apply our main result and we do not need to perform some preliminary computations. From Figure 6.1 we can conclude that the maximum size of a linking from U to Y is 2. To see this, we note that the following two paths from U to Y are disjoint: (u_2, x_2),(x_2, x_5),(x_5, y_2) and (u_3, x_4),(x_4, y_1). Furthermore, we note that paths from u_1 to Y and paths from u_2 to Y always contain x_2, and, therefore, never can be disjoint. As there are only three input vertices it follows that the maximum size of a linking from U to Y has to be 2.

Further, from the above two paths we know already that the vertices u_1, x_1, x_3, x_6, x_7, x_8, and y_3 are not contained in V_{ess}. In fact, it is easy to see that V_{ess} is given by $\{u_3, x_2, x_4, x_5, y_1\}$. In Figure 6.1 we have already encircled the vertices in V_{ess}.

Next we concentrate on the subgraphs $H(G; U, V_{ess}) = H(G; U, S_*)$ and $H(G; V_{ess}\ , Y) = H(G; S^*, Y)$; see Corollary 3.8. From Figure 6.1 it is easy to see

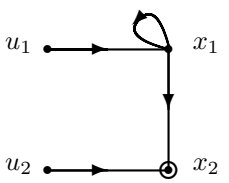

FIG. 6.2a G_1.

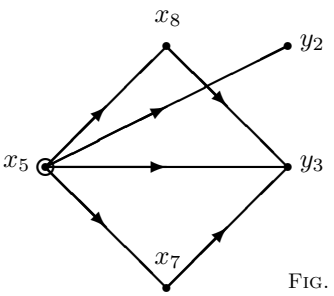

FIG. 6.2b G_3.

that $S_* = \{u_3, x_2\}$ and $S^* = \{x_5, y_1\}$, respectively. In Figures 6.2a and 6.2b we have depicted the subgraphs G_1 and G_3, respectively. We have obtained the subgraph G_1 by concentrating on all IO-paths from U to V_{ess} (or S_*) that have a positive length or, alternatively, by just deleting from $H(G; U, V_{ess})$ all isolated vertices. The subgraph G_3 is obtained in a similar way from $H(G; V_{ess}, Y)$. Finally, we collect all vertices on IO-paths in G from S_* to S^* in the subgraph G_2. We have depicted G_2 in Figure 6.3.

As a consequence of the above we can conclude that with a suitable row and column permutation the system matrix of system (1) can be transformed into the next form

$$\left(\begin{array}{ccc|ccccc|ccc}
-s+\lambda_1 & \lambda_2 & 0 & \lambda_3 & 0 & \lambda_4 & 0 & 0 & 0 & 0 & 0 \\
\lambda_5 & 0 & \lambda_6 & 0 & 0 & 0 & -s+\lambda_7 & \lambda_8 & 0 & 0 & 0 \\
\hline
0 & 0 & 0 & -s+\lambda_9 & 0 & 0 & \lambda_{10} & 0 & \lambda_{11} & 0 & 0 \\
0 & 0 & 0 & \lambda_{12} & -s+\lambda_{15} & \lambda_{14} & 0 & \lambda_{13} & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & \lambda_{19} & -s & 0 & 0 & \lambda_{20} & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \lambda_{16} & \lambda_{17} & 0 & \lambda_{18} & -s \\
0 & 0 & 0 & 0 & \lambda_{22} & \lambda_{21} & 0 & 0 & 0 & 0 & 0 \\
\hline
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -s & 0 & \lambda_{23} \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -s & \lambda_{24} \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_{25} \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_{26} & \lambda_{27} & \lambda_{28}
\end{array}\right).$$

In this block triangular form we can distinguish the three subsystems corresponding to the three subgraphs G_1, G_2, and G_3, respectively. These subgraphs G_1, G_2, and G_3 correspond to the following system pencils:

$$P_1(s) = \begin{pmatrix} A_1 - sI_{n_1} & B_1 \\ C_1 & D_1 \end{pmatrix} = \begin{pmatrix} -s+\lambda_1 & \lambda_2 & 0 \\ \lambda_5 & 0 & \lambda_6 \end{pmatrix}$$

with $n_1 = 1, m_1 = 2, p_1 = 1$,

$$P_2(s) = \begin{pmatrix} A_2 - sI_{n_2} & B_2 \\ C_2 & D_2 \end{pmatrix} = \begin{pmatrix} -s+\lambda_9 & 0 & 0 & \lambda_{10} & 0 \\ \lambda_{12} & -s+\lambda_{15} & \lambda_{14} & 0 & \lambda_{13} \\ 0 & \lambda_{19} & -s & 0 & 0 \\ 0 & 0 & 0 & \lambda_{16} & \lambda_{17} \\ 0 & \lambda_{22} & \lambda_{21} & 0 & 0 \end{pmatrix}$$

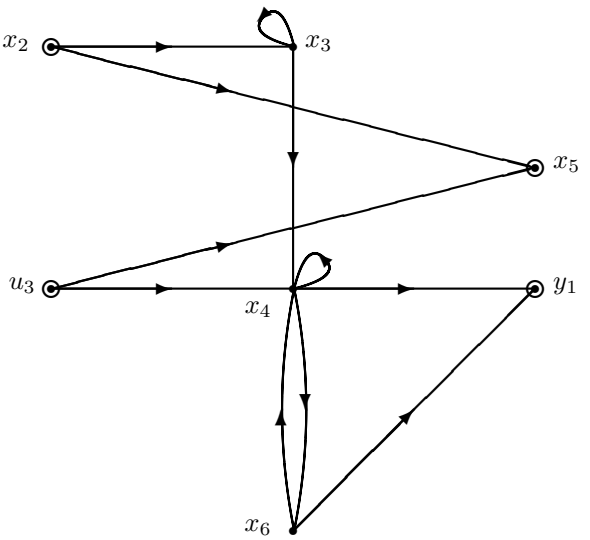

FIG. 6.3. G_2

with $n_2 = 3, m_2 = 2, p_2 = 2$, and

$$P_3(s) = \begin{pmatrix} A_3 - sI_{n_3} & B_3 \\ C_3 & D_3 \end{pmatrix} = \begin{pmatrix} -s & 0 & \lambda_{23} \\ 0 & -s & \lambda_{24} \\ 0 & 0 & \lambda_{25} \\ \lambda_{26} & \lambda_{27} & \lambda_{28} \end{pmatrix}$$

with $n_3 = 2, m_3 = 1, p_3 = 2$, respectively.

Applying Theorem 5.1 on graph G_2 it follows that the generic number of invariant zeros is equal to 2, namely, $n_2 + p_2$ minus the minimum number of edges in a size p_2 linking from U_2 $(= \{x_2, u_3\})$ to Y_2 $(= \{x_5, y_1\})$ in G_2. Since $n_2 = 3$, $p_2 = 2$ and any size 2 linking from U_2 to Y_2 in G_2 contains at least 3 edges, the generic number of invariant zeros of the subsystem corresponding to the graph G_2 equals $3 + 2 - 3 = 2$.

For the graph G_1, the application of Theorem 5.2 yields that the generic number of invariant zeros is equal to 0, being $n_1 + p_1$ minus the maximum number of edges in the disjoint union of a linking of size p_1 from U_1 $(= \{u_1, u_2\})$ to Y_1 $(= \{x_2\})$, a U_1-rooted path family, and a cycle family in X_1 $(= \{x_1\})$. Here $n_1 = 1$, $p_1 = 1$, and it is easy to see that the number of edges in a disjoint union just described is at most 2. For instance, the disjoint union of the size 1 linking from U_1 to Y_1 given by the edge (u_2, x_2) and the U_1-rooted path family given by the edge (u_1, x_1) contains 2 edges. The same applies to all other such unions. Using Theorem 5.2 it, therefore, follows that the generic number of invariant zeros of the subsystem corresponding to the graph G_1 equals $1 + 1 - 2 = 0$.

For the graph G_3, the application of Theorem 5.2 in transposed form yields that the generic number of invariant zeros is equal to $3 - 2 = 1$. This is left to the reader.

Combining the above we can now conclude that the generic number of invariant zeros of the original structured system (1) is $0 + 2 + 1 = 3$.

7. Conclusions. In this paper we studied structured systems and we presented a graph theoretical method to compute the generic number of invariant zeros of such

systems. The method uses elementary and efficient network algorithms. We think that the results in the paper are of an elementary and basic nature, and we believe that they are important in the many areas of systems theory that involve pole placement issues when only the zero/nonzero structure is known.

Appendix. In this appendix we give the proofs of some of the results of this paper.

Proof of Proposition 4.4. To prove the first part of the proposition, we take $v \in X_\alpha \cup U_\alpha$ and $w \in X_\beta \cup Y_\beta$ and we assume that there is an edge from v to w, i.e., $(v, w) \in E$. From the definition of X_α and U_α it is clear that $v \notin S$. Similarly, it follows from the definitions of X_β and Y_β that $w \notin S$. Since $v \in V_\alpha$ and $v \notin S$, there is an IO-path from U to v that does not contain any vertex in S. Similarly, because $w \in V_\beta$ and $w \notin S$ there is an IO-path from w to Y that does not contain any vertex in S. Connecting these two paths by the edge between v and w, i.e., by (v, w), we obtain a path from U to Y that does not contain any vertex in S. However, this is in contradiction with the fact that S is a separator between U and Y. Thus, we must conclude that there does not exists an edge from v to w, implying that there can not be an edge from $X_\alpha \cup U_\alpha$ to $X_\beta \cup Y_\beta$.

To prove the second part of the proposition, we again take a vertex $v \in X_\alpha \cup U_\alpha$. But we now consider a vertex $w \in X_\delta$ and we assume that there is an edge from v to w, i.e., $(v, w) \in E$. From the proof of the first part of the proposition we know that there exists a path, say, P_1, from U to v that does not contain any vertex in S. Since we assume that every state vertex is contained in a path from U to Y, there is a simple path from U to Y that contains the vertex $w \in X_\delta$. We denote this path by P and we denote the part of P from w to Y by P_2. Now there are two possibilities.

- P_2 does not contain any vertex in S,
- P_2 does contain a vertex in S.

In the first case the combination of the path P_1, the edge (v, w), and the path P_2 yields a path from U to Y that does not contain any vertex in S. This is in contradiction with the fact that S is a separator between U and Y. In the second case denote the first vertex on P_2 starting from w that is contained in S by w' and denote the part of P_2 from w to w' by P_2'. Recall that $w \in X_\delta$. Now consider the combination of the path P_1, the edge (v, w) and the path P_2'. This combination establishes an IO-path from U to S. Indeed, only the end vertex w' is in S. Since w is contained in the combined path made up of the path P_1, the edge (v, w) and the path P_2' it follows by construction that $w \in V_\alpha$. This is not possible since V_α and X_δ have empty intersection.

Since both cases are not possible, we must conclude that there does not exist an edge from v to w, implying that there can not be an edge from $X_\alpha \cup U_\alpha$ to X_δ.

The third part of the proposition can be proved analogously to the second part.

This concludes the proof of Proposition 4.4. □

Proof of Proposition 4.5. We recall that the number of vertices in a minimum separator S is k. We denote k_U, k_X, and k_Y for the number of vertices in the sets $S \cap U$, $S \cap X$ and $S \cap Y$, respectively, so that $k_U + k_X + k_Y = k$. The number of vertices in V_α is given by the sum of the number of vertices in X_α, $U_\alpha = U \backslash S$, and $Y_\alpha = S \backslash U$. The number of vertices in V_α is therefore given by the expression $n_\alpha + (m - k_U) + (k - k_U)$.

We observe that a linking of size k from U to Y in G induces a linking of size $(k - k_U)$ from U_α to Y_α. Indeed, restrict the paths of the linking to the subpaths that begin in U and end in S, and of these subpaths take the $(k - k_U)$ subpaths that have

a positive length. According to Theorem 4.3 it follows now that the generic rank of the system pencil

$$\begin{pmatrix} A_\alpha - sI_{n_\alpha} & B_\alpha \\ C_\alpha & D_\alpha \end{pmatrix}$$

is equal to $n_\alpha + (k - k_U)$, implying that the pencil generically has full row rank. This completes the proof of the first statement of Proposition 4.5.

In the same way we can prove that the pencil

$$\begin{pmatrix} A_\beta - sI_{n_\beta} & B_\beta \\ C_\beta & D_\beta \end{pmatrix}$$

generically has full column rank equal to $n_\beta + (k - k_Y)$. As $(A_\delta - sI_{n_\delta})$ (generically) has full rank the second statement of Proposition 4.5 easily follows.

If $S = S_*$, we have that $H(G; U, S) = H(G; U, V_{ess})$; see Corollary 3.8. Concentrating on $H(G; U, V_{ess})$ we have that in this subgraph there is a linking of size k from U to V_{ess}. We recall that $G_\alpha = (V_\alpha, E_\alpha)$ can be obtained from $H(G; U, V_{ess})$ by just ignoring the isolated vertices in $U \cap V_{ess}$. As by definition vertices in X_α and U_α are therefore not contained in V_{ess}, they are not essential and each of them can be deleted without decreasing the maximum size of a linking from U to V_{ess}. Also in G_α the deletion of a single vertex from U_α or X_α does not decrease the maximum size of a linking from U_α to Y_α. We note that instead of the deletion of vertices and incident edges we can also delete the outgoing edges from these vertices alone.

Deletion of vertex u_i in U_α corresponds to the deletion of the column $n_\alpha + i$ from $P_\alpha(s)$. Deletion of the outgoing edges of vertex x_i corresponds to the deletion of the column i from $P_\alpha(s)$. As in both cases a linking of size $(k - k_U)$ from U_α to Y_α still is possible, it follows that the generic rank of $P_\alpha(s)$ is $n_\alpha + (k - k_U)$ even after the deletion of an arbitrary column from $P_\alpha(s)$. This completes the proof of the third statement of Proposition 4.5. □

Proof of Theorem 5.1. In the case of the matrix $D = 0$, i.e, D consists of fixed zeros only, Theorem 5.1 is formulated and proved in [14] as Theorem 6.2. For general D a proof of Theorem 5.1 can be given by a straightforward modification of the proof in [14]. This is left for the reader. To conclude this proof we note that in Theorem 5.1 the number of edges is counted, while in Theorem 6.2 in [14] state vertices are counted. This explains the difference in formulation of Theorem 5.1 here and Theorem 6.2 in [14]. This concludes the proof of Theorem 5.1. □

Sketch of proof of Theorem 5.2. A full proof can be found in [15]. Here we have divided the proof into a number of steps.

1. Assuming that g-n-rank $P(s) = n + p$, we first indicate that the rank of $P(s)$ for $s = 0$ generically is equal $n + p$ if and only if there is a disjoint union of
   - a linking of size p from U to Y,
   - a U-rooted path family,
   - a cycle family in X

that contains $n + p$ (the largest possible number) edges.

2. Next we prove that under the conditions of Theorem 5.2 the greatest common divisor of all the $(n + p)$th order minors of $P(s)$ generically is a monomial in s (a single power in s). See also [5], Lemma 14.5, or Proposition A.1 in [17].

3. Then we may follow the line of thought in [3] and we define

$$\mu = \min \left\{ s | \exists i_1, i_2, \ldots, i_s : \begin{pmatrix} A & B \\ C & D \end{pmatrix}^{(i_1, i_2, \ldots, i_s)}_{(i_1, i_2, \ldots, i_s)} \text{ generically has full row rank} \right\},$$

where we assume that $1 \leq i_1 < i_2 < \cdots < i_s \leq n$, and where we have written

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^{(i_1,i_2,\ldots,i_s)}_{(i_1,i_2,\ldots,i_s)}$$

for the matrix obtained from $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$ by deleting all rows and all columns with index in $\{i_1, i_2, \ldots, i_s\}$. We note that $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)^{(i_1,i_2,\ldots,i_s)}_{(i_1,i_2,\ldots,i_s)}$ itself defines a system with an $n-s$ dimensional state. The input vector remains m dimensional and the output vector p dimensional.

In the spirit of [3] we can prove that every $(n+p)$th order minor of $P(s)$ can be divided by s^μ. Furthermore, we can indicate that at least one $(n+p)$th order minor can be found by specifying the values of the nonzeros in $P(s)$ that contains a term of the form as^μ with $a \neq 0$. The existence of such a minor can be proved in the same way as a similar result is proved in [3].

Finally, combining Steps 2 and 3 we obtain that

- the greatest common divisor of all the $(n+p)$th order minors of $P(s)$ is generically a monomial in s;
- every $(n+p)$th order minor of $P(s)$ can be divided by s^μ, while there is an $(n+p)$th order minor of $P(s)$ that can not be divided by $s^{\mu+1}$.

Hence, the greatest common divisor of all the $(n+p)$th order minors of $P(s)$ is generically of the form as^μ with $a \neq 0$. Combining the definition of μ with Step 1, we obtain that μ is the minimal number of vertices that have to be deleted from the graph G such that in the remaining graph there exists a disjoint union of a linking of size p from U to Y, a U-rooted path family, and a cycle family in X that contains $(n-\mu)+p$ edges.

Instead of trying to take μ minimal we can try to take $(n-\mu)+p$ maximal. Suppose that the maximal number of edges in a disjoint union as above is ρ. Then $\rho = (n-\mu)+p$ or $\mu = (n+p)-\rho$, and we can conclude that the greatest common divisor of all the $(n+p)$th order minors of $P(s)$ is generically a monomial with a degree equal to $(n+p)$ minus the maximal number of edges in a disjoint union of

- a linking of size p from U to Y,
- a U-rooted path family,
- a cycle family in X,

which completes the proof of Theorem 5.2. □

Proof of Theorem 5.3. Theorem 5.3 is in fact a consequence of the combination of Propositions 4.4 and 4.5 and the sets S_* and S^*. Below a sketch of the proof of Theorem 5.3 is given.

First the decomposition of subsection 4.2 is considered for $S = S_*$. This decomposition is based on $H(G; U, V_{ess})$ and yields a subgraph $G_1 = (V_1, E_1)$ of G, where V_1 denotes the set of all vertices contained in IO-paths from U to S_* that have a positive length. Note that we use the index 1 instead of the index α as in subsection 4.2. The vertex set can be partitioned as $V_1 = U_1 \cup X_1 \cup Y_1$, where

$$U_1 = U \backslash S_*, \;\; Y_1 = S_* \backslash U, \;\; X_1 = V_1 \backslash (U_1 \cup Y_1).$$

In the spirit of sections 4.2 and 4.3 define $\bar{V}$ as the set of all vertices contained in IO-paths from S_* to Y that have a positive length. (In terms of subsection 4.2 this means that $\bar{V} = V_\beta$.) Furthermore, we define

$$\tilde{U} = S_* \backslash Y, \; \tilde{Y} = Y \backslash S_*, \; \tilde{X} = (\bar{V} \backslash (\tilde{U} \cup \tilde{Y})) \cup (V \backslash (V_1 \cup \bar{V})), \; \tilde{V} = \tilde{U} \cup \tilde{X} \cup \tilde{Y}.$$

Then according to the results of subsections 4.2 and 4.3 there are row and column permutations such that the system pencil $P(s)$ can be transformed into

$$\begin{pmatrix} P_1(s) & * \\ 0 & \tilde{P}(s) \end{pmatrix},$$

with $P_1(s)$ a subsystem pencil of the form

$$\begin{pmatrix} A_1 - sI_{n_1} & B_1 \\ C_1 & D_1 \end{pmatrix},$$

generically having full row rank, even after deleting an arbitrary column, and with $\tilde{P}(s)$ a subsystem pencil of the form

$$\begin{pmatrix} \tilde{A} - sI_{\tilde{n}} & \tilde{B} \\ \tilde{C} & \tilde{D} \end{pmatrix},$$

generically having full column rank.

In terms of the decomposition of subsection 4.2 with $S = S_*$, we have that $P_1(s)$ in fact equals

$$\begin{pmatrix} A_\alpha - sI_{n_\alpha} & B_\alpha \\ C_\alpha & D_\alpha \end{pmatrix}$$

and that $\tilde{P}(s)$ equals

$$\begin{pmatrix} A_\delta - sI_{n_\delta} & * & * \\ 0 & A_\beta - sI_{n_\beta} & B_\beta \\ 0 & C_\beta & D_\beta \end{pmatrix}.$$

Next we use the set S^* to decompose the subsystem pencil $\tilde{P}(s)$. For instance, it can be shown that $S^* \subseteq \tilde{V} \cup S_*$ and that $S^* \backslash (Y \cap S_*)$ is the "largest" minimum separator between $\tilde{U}$ and $\tilde{Y}$ in $\tilde{G}$ (see [15]). This implies that we can apply the decomposition of section 4.2 in a dual way on $\tilde{P}(s)$. We then obtain row and column permutations such that $\tilde{P}(s)$ is transformed into

$$\begin{pmatrix} A_2 - sI_{n_2} & B_2 & * & * \\ C_2 & D_2 & * & * \\ 0 & 0 & A_3 - sI_{n_3} & B_3 \\ 0 & 0 & C_3 & D_3 \end{pmatrix},$$

with $P_2(s)$ a subsystem pencil of the form

$$\begin{pmatrix} A_2 - sI_{n_2} & B_2 \\ C_2 & D_2 \end{pmatrix},$$

generically having full row rank and with $P_3(s)$ a subsystem pencil of the form

$$P_3(s) = \begin{pmatrix} A_3 - sI_{n_3} & B_3 \\ C_3 & D_3 \end{pmatrix},$$

generically having full column rank, even after deleting an arbitrary row. As $\tilde{P}(s)$ generically has full column rank, it immediately follows that $P_2(s)$ is square and generically invertible.

Combining the previous two decompositions we have shown that there are row and column permutations such that the system pencil $P(s)$ transforms into the block triangular form described in Theorem 5.3. □

DESIGN OF HOMOGENEOUS TIME-VARYING STABILIZING CONTROL LAWS FOR DRIFTLESS CONTROLLABLE SYSTEMS VIA OSCILLATORY APPROXIMATION OF LIE BRACKETS IN CLOSED LOOP*

PASCAL MORIN†, JEAN-BAPTISTE POMET†, AND CLAUDE SAMSON†

Abstract. A constructive method for time-varying stabilization of smooth driftless controllable systems is developed. It provides time-varying homogeneous feedback laws that are continuous and smooth away from the origin. These feedbacks make the closed-loop system globally exponentially asymptotically stable if the control system is homogeneous with respect to a family of dilations and, using local homogeneous approximation of control systems, locally exponentially asymptotically stable otherwise.

The method uses some known algorithms that construct oscillatory control inputs to approximate motion in the direction of iterated Lie brackets that we adapt to the closed-loop context.

Key words. nonlinear control, stabilization, time-varying stabilization, controllability, Lie brackets

1. Introduction.

1.1. Related work and contribution. Stabilization by continuous time-varying feedback laws of nonlinear systems that cannot be stabilized by time-invariant continuous feedback laws has been an ongoing subject of research in the past few years.

The fact that for many controllable systems no continuous stabilizing feedback exists was first pointed out by Sussmann [23]. A simple necessary condition was given by Brockett [1], since known as "Brockett's condition." It allows us to identify a wide class of controllable systems for which no continuous stabilizing feedback exists; these include most controllable driftless systems. More recently, Coron gave a stronger necessary condition [2].

A possible way of stabilizing systems for which these necessary conditions are violated is to use discontinuous (time-invariant) control laws. This has been explored in the literature, but the present work does not go in this direction at all.

The possibility of stabilizing nonlinear controllable systems via *continuous time-varying feedback control laws* was first noticed in the very detailed study of stabilization of one-dimensional systems by Sontag and Sussmann [21]. More recently, smooth stabilizing control laws for some nonholonomic mechanical systems were given by Samson [18]; this was the starting point of a systematic study of time-varying stabilization. Coron [3] proved that all controllable driftless systems may be stabilized by continuous (and even smooth) time-varying feedback and that "most" controllable systems (even with drift) can also be stabilized by continuous time-varying feedback [4]. Pomet deals with a less general class of controllable driftless systems [15].

From here on, only driftless systems are considered in this paper. After the general existence result given in [3], studies on the subject have focused on methods to *construct* continuous time-varying stabilizing feedback laws and on obtaining feedback laws that provide sufficiently fast convergence.

As far as the constructiveness aspect is concerned, for simplicity let us divide the construction methods into two kinds. The first kind of method applies to rather large classes of controllable driftless systems, such as the work of Coron [3] (general controllable driftless systems; the paper is not oriented toward construction of the control, but a method can be extracted from the proofs), Pomet [15] (controllable driftless systems for which the control Lie algebra is generated by a specific set of vector fields), or of M'Closkey and Murray [12] (same conditions as in [15]). These studies all share the following feature: they use the solution of a linear PDE, or the expression of the flow of a vector field, to construct the control law. This solution, or this flow, has to be calculated beforehand, either analytically or numerically, and this introduces, especially when no analytical solution is available, a degree of complication which may not be necessary. The second kind of method found in the literature provides explicit expressions. Its drawback is that it applies only to specific subclasses of driftless systems, such as models of mobile robots or systems in the "chain form" or "power-form," like the work of Samson [18], Teel, Murray, and Walsh [27], and Sépulchre, Campion, and Vertz [20], among others.

Alternatively, a need to improve the speed of convergence came out of the slow convergence associated with the *smooth* control laws that were first proposed. This concern motivated several studies, starting with the work by M'Closkey and Murray [11], yielding continuous control laws which are not smooth, or even Lipschitz everywhere, but are homogeneous with respect to some dilation, and thus exponentially stabilizing, not in the standard sense but with respect to some homogeneous norm (this notion was introduced by Kawski [7]). See, for instance, further work by the authors of this paper [16, 14] or by M'Closkey and Murray [12], who have also proposed recently a procedure that transforms a given smooth stabilizing control law into a homogeneous one [13]. Except for this last reference, which requires that a smooth stabilizing control law has been designed beforehand, the construction of homogeneous exponentially stabilizing control laws in the literature is restricted to specific subclasses of driftless systems.

The design method described in the present paper has the advantage of being totally explicit, in the sense that it requires only ordinary differentiation and linear algebraic operations, while it applies to general controllable systems and provides exponential stability. This method gives homogeneous feedbacks, which ensure global stability if the control vector fields are homogeneous and local stability otherwise. The fact that it relates controllability with the construction of a stabilizing control law in a more direct way than previous designs also makes it conceptually appealing, all the more so as it may be viewed as converting the open-loop control techniques reported by Liu and Sussmann in [25] and Liu [9] into closed-loop techniques.

However, the generality of the method also has a price. When applied to particular systems for which explicit solutions have long been available, the present method often yields solutions which are significantly more complicated. This comes partly from the complexity of the approximation algorithm proposed in [25, 9], which we use. This is also a consequence of the modifications that we have made to adapt this algorithm to our feedback control objective.

1.2. Outline of the method. Nonlinear controllability results were first derived for driftless systems; see, for instance, the work by Lobry [10], where it is shown that such systems are controllable if and only if any direction in the state space can be obtained as a linear combination of iterated Lie brackets of the control vector fields, at least in real-analytic cases. It was also shown very early on by Haynes and Hermes [5] that, under this same condition, *any* curve in the state-space can be approached by open-loop solutions of the controlled system. (Note that this property is not shared by all controllable systems, but rather is specific to driftless systems.) In these studies the key element is that, in addition to the directions of motion corresponding to the control vector fields, motion along other directions corresponding to iterated Lie brackets is also possible by quickly switching motions along the original control vector fields. Take, for example, a system with two controls

$$\dot{x} \;=\; u_1\, b_1(x) \;+\; u_2\, b_2(x) \tag{1.1}$$

with state x in $\mathbb{R}^5$, and assume that at each point x the vectors

$$b_1(x)\,,\; b_2(x)\,,\; [b_1,b_2](x)\,,\; [b_1,[b_1,b_2]](x)\,,\; [b_2,[b_1,b_2]](x) \tag{1.2}$$

are linearly independent, and thus span $\mathbb{R}^5$. The idea in [5] is the following: first, it is clear that *any* (e.g., differentiable) parameterized curve $t \mapsto \gamma(t)$ is a possible solution of the "extended" system with five controls:

$$\begin{aligned}\dot{x} = v_1\, b_1(x) \;+\; v_2\, b_2(x) \;+\; v_3\, [b_1,b_2](x)\\ +\; v_4\, [b_1,[b_1,b_2]](x) \;+\; v_5\, [b_2,[b_1,b_2]](x)\end{aligned} \tag{1.3}$$

(simply decompose $\dot{\gamma}(t)$ on the basis (1.2) to obtain the controls). Then it is proved in [5] that there exists a sequence of (oscillatory) controls $u_1(\varepsilon, t, v_1, v_2, v_3, v_4, v_5)$ and $u_2(\varepsilon, t, v_1, v_2, v_3,\; v_4, v_5)$ such that the system (1.1) "converges to" the system (1.3) when $\varepsilon \to 0$ in the sense that the solutions of (1.1) with these controls u_k converge uniformly on finite time intervals to the solutions of (1.3). The proof in [5] does not give a process to build these sequences of approximating sequence of oscillatory control, and although the case of a simple bracket (approximating $[b_1, b_2]$ by switching between b_1 and b_2) is elementary and well known, the case above of brackets of order 3 is more complex. The more recent work by Liu [9] and Sussmann and Liu [25] gives an explicit construction of the approximating sequence. The process of building this sequence is amazingly intricate compared to the simplicity of the existence proof in [5]. Of course, the controls u_k are not defined for $\varepsilon = 0$, and both their frequency and their amplitude tend to infinity when ε goes to zero.

Being aware of these results, and faced with the problem of proving that any controllable driftless system may be stabilized by means of a periodic feedback, the most natural idea is probably the following, which we illustrate for (1.1) (5 states, 2 controls):

(a) Stabilize the extended system (1.3) by a control law $v_i(x)$. This is very easy, and $\dot{x}$ may even be assigned to be any desired function, for instance, $-x$.

(b) Use the approximation results and build the controls $u_k(\varepsilon, t, v_1(x), v_2(x), v_3(x),\; v_4(x),\; v_5(x))$, according to the process given in [25, 9] so that when ε tends to zero, the system (1.1) controlled with these controls "tends to" the extended system (1.3) controlled with the controls $v_i(x)$.

(c) Since the limit system is asymptotically stable (for instance, $\dot{x} = -x$), and asymptotic stability is somehow robust, the constructed control laws are, it is to be hoped, stabilizing for ε nonzero but small enough. For instance, one may take $\|x\|^2$ as a Lyapunov function for the limit system, its time-derivative along the limit system is $-2\|x\|^2$, and it is tempting to believe that its time-derivative along the original system controlled by $u_k(\varepsilon, t, v_1(x), v_2(x), v_3(x), v_4(x), v_5(x))$ is no larger than $-\|x\|^2$ for ε small enough.

Unfortunately, these arguments, which would have been somewhat simpler than those in [3], are not rigorous as they stand. The meaning of "tends to" in point (b) is very imprecise. In [5], and in [25, 9], only uniform convergence of the trajectories on finite-time intervals are considered. This is not adequate for asymptotic stabilization. The Lyapunov function-based argument in point (c) does not work because, in general, when ε tends to zero, the time derivative of a given function along the system (1.1) in feedback with the controls u_k from point (b) does not tend to the time-derivative of this function along the "limit" system (1.3). In addition, the fact that feedback controls are considered instead of open-loop controls complicates the proofs because the controls depend on the state and therefore may have a very high derivative with respect to time not only through the high frequencies and amplitudes built into the approximation process but also through their dependence on the state, whose speed is proportional to these high amplitudes.

However, we show in the present paper that the above sketch is basically correct, provided that homogeneous controls associated with a homogeneous Lyapunov function are used and that the construction of the approximating sequence is modified to take into account the closed-loop nature of the controls. An argument of the type of point (c) is possible based on a notion of approximation that is not in terms of uniform convergence of trajectories, but in terms of the differential operator defined by derivation along the system.

This paper is organized as follows. After a brief recall of technical material in section 2, we state in section 3 the control objective, make homogeneity assumptions, and explain how they will yield local results for general controllable systems. The design method is developed in section 4 through four steps: choice of the "useful" Lie brackets, construction of the stabilizing controls for the extended system (system (1.3) in the above example), construction of the "state dependent" amplitudes for the feedback law, and construction of the oscillatory controls by the method exposed in [9]; the material from these steps is then gathered to give the control law, and the stabilization result is stated. We present in this section all that is needed for the construction of the control law, but the proofs of some properties needed at each steps, and of the theorem, are given separately in section 7. Section 6 is devoted to a convergence result needed in the proof of the stability theorem; it is a translation in terms of differential operators (instead of trajectories) of the averaging results presented in [25, 9, 26] and in [8]. An illustrative example is given in section 5.

2. Background on homogeneous vector fields. For any $\lambda > 0$, the "dilation operator" δ_λ associated with a "weight vector" $r = (r_1, \ldots, r_n)$ $(r_i > 0)$ is defined on $\mathbb{R}^n$ by

$$\delta_\lambda(x_1, \ldots, x_n) = (\lambda^{r_1} x_1, \ldots, \lambda^{r_n} x_n).$$

A function $f \in C^o(\mathbb{R}^n; \mathbb{R})$ is said to be homogeneous of degree τ with respect to the family of dilations (δ_λ) if

$$\forall \lambda > 0, \quad f(\delta_\lambda(x)) = \lambda^\tau f(x)\,.$$

A *homogeneous norm* is any proper continuous positive function that is homogeneous of degree 1.

A continuous vector field X on $\mathbb{R}^n$ is said to be homogeneous of degree σ with respect to the family of dilations (δ_λ) if one of the following equivalent properties is satisfied:

(1) For any $i = 1, \ldots, n$, its ith component, i.e., the function $x \mapsto X_i(x)$, is homogeneous of degree $r_i + \sigma$.
(2) For any function h homogeneous of degree $\tau > 0$ with respect to the same dilation, the function $L_X h$ (its Lie derivative along X) is homogeneous of degree $\sigma + \tau$.
(3) For all positive constant λ, the vector field $((\delta_\lambda)_* X)$, conjugate of X by the diffeomorphism δ_λ —away from the origin— satisfies $((\delta_\lambda)_* X)(x) = \lambda^{-\sigma} X(x)$ for $x \neq 0$.

The previous definitions of homogeneity can be extended to time-varying functions and vector fields by considering an "extended dilation":

$$\delta_\lambda(x_1, \ldots, x_n, t) = (\lambda^{r_1} x_1, \ldots, \lambda^{r_n} x_n, t).$$

Finally, let $f \in C^0(\mathbb{R}^n \times \mathbb{R}; \mathbb{R}^n)$, with $f(x, .)$ T-periodic, defining a homogeneous vector field of degree zero with respect to a family of dilations (δ_λ). Then, the two following properties are equivalent (see [7] for the autonomous case):

(i) the origin $x = 0$ of the system $\dot{x} = f(x, t)$ is locally asymptotically stable.
(ii) $x = 0$ is globally *ρ-exponentially asymptotically stable*, i.e., for any homogeneous norm ρ, there exist $K, \gamma > 0$ such that, for any solution $x(.)$ of the system,

$$\rho(x(t)) \leq K \rho(x(0)) e^{-\gamma t}.$$

In what follows, when using the expression *exponentially asymptotically stable*, we will refer to the ρ-exponential asymptotic stability defined above.

3. Problem statement. Consider a smooth driftless controllable system

$$\dot{x} = \sum_{i=1}^{m} u_i f_i(x). \tag{3.1}$$

In general, there does not exist a dilation with respect to which the control vector fields are homogeneous. However, controllability implies that after some adequate change of coordinates, there exist a dilation and a controllable *homogeneous approximation* [6, 7]—with respect to this dilation—of the system (3.1) around the origin. Different methods exist to find such a change of coordinates and dilation. For instance, a constructive method (i.e., requiring only algebraic computations and derivations) is given in [22]. Using this method, one obtains a driftless control system with control vector fields homogeneous of degree -1. Moreover, any homogeneous feedback law that asymptotically stabilizes this system also locally asymptotically stabilizes the original system.

The present work constructs a homogeneous feedback that ensures global exponential stabilization for homogeneous systems. Applied to the homogeneous approximation of a general system (3.1), it provides *local* exponential stabilization of (3.1).

Throughout this paper, we always consider a system

$$\dot{x} = \sum_{i=1}^{m} u_i b_i(x), \tag{3.2}$$

where the b_i's are smooth vector fields and the system of coordinates is such that there exist some integers $(r_1, \dots, r_n)$ such that

(1) each vector field b_i is homogeneous of degree -1 with respect to the family of dilations δ_λ with weights $(r_1, \dots, r_n)$;
(2) the rank at the origin of the Lie algebra generated by the b_i's is n:

$$\text{Rank}(\text{Lie}\{b_1, \dots, b_m\}(0)\ ) \ = \ n. \tag{3.3}$$

The integer valued weights $r_1, \dots, r_n$ are now fixed, and we denote

$$P \ = \ \text{Max}\,\{r_i;\ i = 1, \dots, n\}. \tag{3.4}$$

Our objective is to design feedback laws $u = (u_1, \dots, u_m) \in C^0(\mathbb{R} \times \mathbb{R}^n; \mathbb{R}^m)$ such that the origin $x = 0$ of the closed-loop system (3.2) is exponentially asymptotically stable.

Remark 3.1. We require only full rank control Lie algebra at the origin, but controllability follows, because homogeneity allows us to deduce the same rank condition everywhere.

Remark 3.2. We assume that the degrees are all equal to -1. These are the degrees given by the construction of a homogeneous approximation in [22]. If a system is naturally homogeneous, but the degrees are not all equal (if they are equal, a simple scaling makes them all equal to -1), it might be better to use this natural homogeneity than to construct a different homogeneous approximation that will have all the degrees equal to -1. The present method can be adapted to the case when the degrees of homogeneity are not all equal; this requires only a modification of the first step (see Remark 4.3).

4. Controller design. The control design consists of four steps described below.

Step 1 *(selection of Lie brackets).*

In this step, we select some vector fields $\tilde{b}_j$ $(j = 1, \dots, N)$, obtained as Lie brackets of the control vector fields $b_1, \dots, b_m$. The $\tilde{b}_j$ are chosen recursively as follows. For any $p = 1, \dots, P$ (with P defined by (3.4)),

(1) compute all brackets of length p made from the control vector fields b_i $(i = 1, \dots, m)$;
(2) select among the vector fields so obtained a maximal number of vector fields independent[1] over $\mathbb{R}$. These vector fields are the $\tilde{b}_j$ $(m_{p-1} + 1 \le j \le m_p)$. (We set $m_0 = 0$ so that all the integers m_p $(p = 0, \dots, P)$ are defined, with $N = m_P$.)

It follows from this construction that with each vector field $\tilde{b}_j$ we can associate a Lie bracket of some b_i's, i.e.,

$$\tilde{b}_j \ = \ \mathcal{C}_j(b_{\tau_j^1}, \dots, b_{\tau_j^{\ell(j)}})\,, \tag{4.1}$$

with

- $\mathcal{C}_j$ a formal bracket and $b_{\tau_j^1}, \dots, b_{\tau_j^{\ell(j)}}$ the elements that are bracketed (listed in the order they appear in the bracket);
- $\ell(j)$ the number of vector fields that are bracketed in (4.1), i.e.,

$$\ell(j) = p \quad \Leftrightarrow \quad m_{p-1} + 1 \le j \le m_p.$$

[1] Recall that some vector fields $X_1, \cdots, X_r$ are said to be *linearly independent over* $\mathbb{R}$ if and only if for any $(\lambda_1, \dots, \lambda_r)$ in $\mathbb{R}^r$, the vector field $\lambda_1 X_1 + \cdots + \lambda_r X_r$ is identically zero on $\mathbb{R}^n$ only if $\lambda_1 = \cdots = \lambda_r = 0$.

For instance, if we choose a vector field $\tilde{b}_6 = [[b_2, b_1], [b_1, [b_1, b_2]]]$, then we encode this as (4.1) with $\ell(6) = 5$, $\tau_6^2 = \tau_6^3 = \tau_6^4 = 1$, $\tau_6^1 = \tau_6^5 = 2$, and the symbol $\mathcal{C}_6$ defined by $\mathcal{C}_6(z_1, z_2, z_3, z_4, z_5) = [[z_1, z_2], [z_3, [z_4, z_5]]]$. This notation is sloppy but avoids using formal Lie brackets and the evaluation operator (see [24]) from a free Lie algebra to vector fields, which would make the exposition uselessly heavy. Of course, the decomposition (4.1) is not unique in general. From now on, we consider that one decomposition has been chosen and that the $\mathcal{C}_j$'s and τ_j^k's have been defined accordingly.

Remark 4.1. (1) In Step 1 above, we do not need to compute all brackets of length p. More precisely, let $\mathcal{F}$ denote the free Lie algebra generated by some indeterminates $s_1, \ldots, s_m$. Then, one can select a basis $\mathcal{B}$ of this Lie algebra (for instance a P. Hall basis, as used by Sussmann and Liu [25, 26] and Liu [9]). If $\mathcal{B}_p$ denotes the elements of $\mathcal{B}$ of order p, then it is clearly sufficient to consider Lie brackets of the b_i obtained by *evaluating* (in the sense of [24]) the elements of $\mathcal{B}_p$ at $s_i = b_i$ $(i = 1, \ldots, m)$. One usually takes this into account when checking controllability.

(2) Since the vector fields b_i $(i = 1, \ldots, m)$ are homogeneous of degree -1, each bracket of length p of these vector fields is homogeneous of degree $-p$. Moreover, the weights of the dilation being integers, any smooth vector field homogeneous of integer degree is, in fact, polynomial. Using a (finite) basis of the polynomials homogeneous of degree k ($k \in \{0, \ldots, P-1\}$), selecting Lie brackets of a given length consists only of computing a basis of a finite dimensional vector space.

(3) We do not need to consider brackets of order larger than P because they are identically zero; indeed, all components of these vector fields are homogeneous of negative degree and, therefore, they would tend to infinity at the origin if they were not identically zero.

Example. Let us illustrate this step on the following academic example:

$$\begin{aligned} \dot{x}_1 &= u_1, \\ \dot{x}_2 &= x_3^2(u_1 + u_2), \\ \dot{x}_3 &= u_3, \end{aligned}$$

which is of the form (3.2) with $m = 3$ and

$$b_1 = \frac{\partial}{\partial x_1} + x_3^2 \frac{\partial}{\partial x_2}, \quad b_2 = x_3^2 \frac{\partial}{\partial x_2}, \quad b_3 = \frac{\partial}{\partial x_3}.$$

The control vector fields are homogeneous of degree -1 with respect to the dilation with weights $r_1 = 1$, $r_2 = 3$, and $r_3 = 1$.

For the brackets of length 1, i.e., the control vector fields, b_1 and b_3 are independent at the origin while b_2 is zero at the origin but independent from b_1 and b_3 away from $x_3 = 0$. Hence $m_1 = 3$, and one can take $\tilde{b}_1 = b_1 = \mathcal{C}_1(b_1)$, $\tilde{b}_2 = b_2 = \mathcal{C}_2(b_2)$, and $\tilde{b}_3 = b_3 = \mathcal{C}_3(b_3)$.

At length 2 all the brackets vanish at the origin, but they are not identically zero: $[b_2, b_3] = -2x_3 \frac{\partial}{\partial x_2}$, and $[b_3, b_1] = -[b_2, b_3]$. Since $[b_1, b_2] = 0$, we have $m_2 = 4$. We define, for instance, $\tilde{b}_4 = [b_2, b_3] = \mathcal{C}_4(b_2, b_3)$.

Finally, since $[b_3, [b_2, b_3]] = -2\frac{\partial}{\partial x_2}$, $m_3 = 5$ with, for instance, $\tilde{b}_5 = [b_3, [b_2, b_3]] = \mathcal{C}_5(b_3, b_2, b_3)$. Note that here, due to the origin being a singular point for the distributions spanned by the control vector fields and by the brackets of order at most 2, N is strictly larger than n.

With this general construction, we have the following proposition.

PROPOSITION 4.2. *For any family* $(\tilde{b}_j)_{j=1,\dots,N}$ *defined as above, we have the following:*

(a) *Let* $j_1, \dots, j_n$ *be such that* $\mathrm{Span}\{\tilde{b}_{j_1}(0), \dots, \tilde{b}_{j_n}(0)\} = \mathbb{R}^n$. *Then*

$$\forall x \in \mathbb{R}^n, \quad \mathrm{Span}\{\tilde{b}_{j_1}(x), \dots, \tilde{b}_{j_n}(x)\} = \mathbb{R}^n .$$

(b) *Any vector field* b *that can be written as a Lie bracket of order* p *of some* b_i*'s is a linear combination of the* $\tilde{b}_j$*'s with* $\ell(j) = p$, *i.e.,*

$$b = \sum_{j=m_{p-1}+1}^{m_p} \lambda_j \tilde{b}_j = \sum_{\ell(j)=p} \lambda_j \tilde{b}_j$$

for some real numbers $\lambda_j \in \mathbb{R}$.

(c) *The vector fields* $\{\tilde{b}_j\}_{j=1,\dots,N}$ *are linearly independent over* $\mathbb{R}$.

(The proof is in section 7.1.)

Remark 4.3. If the degrees of the vector fields b_i are not all equal, the above construction has to be modified. More precisely, in the recursive construction of the family $(\tilde{b}_j)_{j=1,\dots,N}$, we have to consider an induction on the degree of homogeneity instead of an induction on the length of the Lie brackets. (Note that this is just a generalization of the above construction, since for vector fields of the same degree -1 the set of Lie brackets of length p is the same as the set of Lie brackets of degree $-p$.) This means that at each step, we have to compute the set of Lie brackets of a certain degree and select from among them a finite number of vector fields that form a basis of this set.

Step 2 *(stabilization of the extended system).*

Let a be a smooth vector field, homogeneous of degree zero with respect to the family of dilations (δ_λ), and such that the origin $x = 0$ of the system $\dot{x} = a(x)$ is asymptotically stable. One may take, for instance, $a(x) = -x$. In view of Proposition 4.2(a), the $n \times n$ matrix whose columns are $\tilde{b}_{j_1}(x), \dots, \tilde{b}_{j_n}(x)$ is invertible for all x. Define the functions $\tilde{u}_j$ $(j = 1, \dots, N)$ by

$$\bullet \begin{pmatrix} \tilde{u}_{j_1}(x) \\ \vdots \\ \tilde{u}_{j_n}(x) \end{pmatrix} = \left(\tilde{b}_{j_1}(x), \dots, \tilde{b}_{j_n}(x)\right)^{-1} a(x), \tag{4.2}$$

$$\bullet\ \tilde{u}_j = 0 \quad \forall j \notin \{j_1, \dots, j_n\}.$$

These functions are obviously such that

$$a = \sum_{j=1}^{N} \tilde{u}_j \, \tilde{b}_j, \tag{4.3}$$

and furthermore, we may state this proposition.

PROPOSITION 4.4. *For any* $j = 1, \dots, N$, *the above-constructed function* $\tilde{u}_j$ *is in* $C^\infty(\mathbb{R}^n - \{0\}; \mathbb{R}) \cap C^0(\mathbb{R}^n; \mathbb{R})$ *and is homogeneous of degree* $\ell(j)$.

Proof. Continuity and smoothness away from the origin are inherited from the vector fields $\tilde{b}_j$ and the vector field a. Each $\tilde{u}_{j_k}$ is homogeneous of degree $\ell(j_k)$ because the lth component of the vector field a is homogeneous of degree r_l and the element (k, l) of the matrix $(\tilde{b}_{j_1}(x), \dots, \tilde{b}_{j_n}(x))^{-1}$ is homogeneous of degree $\ell(j_k) - r_l$. This

last statement is true because the element (k,l) of the matrix $(\tilde{b}_{j_1}(x),\dots,\tilde{b}_{j_n}(x))$ is homogeneous of degree $r_l-\ell(j_k)$ for the vector field; $\tilde{b}_{j_k}$ is an iterated Lie bracket of $\ell(j_k)$ homogeneous vector fields of degree -1 and hence is homogeneous of degree $-\ell(j_k)$. □

Step 3 *(construction of the state-dependent amplitudes).*

This step consists of finding some functions $v_j^k \in C^\infty(\mathbb{R}^n-\{0\};\mathbb{R})\cap C^0(\mathbb{R}^n;\mathbb{R})$ $(j=1,\dots,N,\ k=1,\dots\ell(j))$ homogeneous of degree one and such that

$$\sum_{j=1}^{N}\tilde{u}_j\,\mathcal{C}_j(b_{\tau_j^1},\dots,b_{\tau_j^{\ell(j)}})=\sum_{j=1}^{N}\mathcal{C}_j(b_{\tau_j^1}v_j^1,\dots,b_{\tau_j^{\ell(j)}}v_j^{\ell(j)}). \tag{4.4}$$

Recall that the $\mathcal{C}_j$'s, defined in Step 1, are the brackets associated with the $\tilde{b}_j$'s, i.e.,

$$\tilde{b}_j=\mathcal{C}_j(b_{\tau_j^1},\dots,b_{\tau_j^{\ell(j)}})\,. \tag{4.5}$$

The construction of the functions v_j^k is based on the following lemma.

LEMMA 4.5. *Let $\mathcal{C}(b_{i_1},\dots,b_{i_p})$ $(i_k\in\{1,\dots,m\})$ be any Lie bracket of some vector fields b_{i_k} $(i_k\in\{1,\dots,m\})$, and $v_k\in C^\infty(\mathbb{R}^n-\{0\};\mathbb{R})\cap C^0(\mathbb{R}^n;\mathbb{R})$ $(k=1,\dots,p)$ some functions homogeneous of degree* 1*. Then,*

(i) $\mathcal{C}(b_{i_1}v_1,\dots,b_{i_p}v_p)=v_1\dots v_p\,\mathcal{C}(b_{i_1},\dots,b_{i_p})-\sum_{j=1}^{m_{p-1}}h_j\ \tilde{b}_j$;

(ii) *for any $j=1,\dots,m_{p-1}$, $h_j\in C^\infty(\mathbb{R}^n-\{0\};\mathbb{R})\cap C^0(\mathbb{R}^n;\mathbb{R})$ is homogeneous of degree $\ell(j)$.*

The proof of this lemma, left to the reader, follows from Proposition 4.2(b) by a direct induction on the length p of the bracket $\mathcal{C}(b_{i_1}v_1,\dots,b_{i_p}v_p)$. It is a generalization of the fact that for two functions v_1 and v_2, and vector fields b_{i_1} and b_{i_2}, $[v_1b_{i_1},v_2b_{i_2}]=v_1v_2[b_{i_1},b_{i_2}]-v_2(L_{b_{i_2}}v_1)b_{i_1}+v_1(L_{b_{i_1}}v_2)b_{i_2}$.

Note that the functions h_j in Lemma 4.5 can be explicitly computed by expressing brackets of order not larger than $p-1$ as linear combinations of $\tilde{b}_1,\dots,\tilde{b}_{m_{p-1}}$.

Based on Lemma 4.5, the functions v_j^k can be constructed recursively as follows.

Step $p=P$: For any $j\in\{m_{P-1}+1,\dots,m_P\}$, we define

$$v_j^P=\frac{\tilde{u}_j}{\rho^{P-1}}\ \text{ and }\ v_j^k=\rho\ (k=1,\dots,P-1)\,, \tag{4.6}$$

with ρ any homogeneous norm in $C^\infty(\mathbb{R}^n-\{0\};\mathbb{R})\cap C^0(\mathbb{R}^n;\mathbb{R})$ (for instance, one may take $\rho(x)=(\sum|x_i|^{\frac{q}{r_i}})^{\frac{1}{q}}$ with $q=2\prod_{i=1}^n r_i$).

In view of (4.5), (4.6), and Lemma 4.5, we have

$$\sum_{j=m_{P-1}+1}^{m_P}\mathcal{C}_j(b_{\tau_j^1}v_j^1,\dots,b_{\tau_j^P}v_j^P)\ =\ \sum_{j=m_{P-1}+1}^{m_P}\tilde{u}_j\tilde{b}_j-\sum_{j=1}^{m_{P-1}}h_j^P\tilde{b}_j \tag{4.7}$$

with h_j^P $(j=1,\dots,m_{P-1})$ obtained by expanding the brackets in the left-hand side of (4.7) with respect to the variables v_j^k and their derivatives.

Step $1\le p<P$: Assume that the functions v_j^k $(j=m_p+1,\dots,m_P,\ k=1,\dots,\ell(j))$ and h_j^k $(j=m_p+1,\dots,m_P,\ k=p+1,\dots,P)$ have been computed in Steps P to $p+1$ and satisfy the induction assumption

$$\sum_{j=m_p+1}^{N}\mathcal{C}_j(b_{\tau_j^1}v_j^1,\dots,b_{\tau_j^{\ell(j)}}v_j^{\ell(j)})\ =\ \sum_{j=m_p+1}^{N}\tilde{u}_j\tilde{b}_j-\sum_{j=1}^{m_p}h_j^{p+1}\tilde{b}_j\,. \tag{4.8}$$

We define, for any $j \in \{m_{p-1}+1, \dots, m_p\}$,

$$v_j^p = \frac{1}{\rho^{p-1}}(\tilde{u}_j + h_j^{p+1}) \text{ and } v_j^k = \rho \ (k = 1, \dots, p-1)\,. \tag{4.9}$$

In view of (4.5), (4.9), and Lemma 4.5, we have

$$\sum_{j=m_{p-1}+1}^{m_p} \mathcal{C}_j(b_{\tau_j^1} v_j^1, \dots, b_{\tau_j^p} v_j^p) = \sum_{j=m_{p-1}+1}^{m_p} (\tilde{u}_j + h_j^{p+1})\tilde{b}_j + \sum_{j=1}^{m_{p-1}} (h_j^{p+1} - h_j^p)\tilde{b}_j \tag{4.10}$$

for an adequate choice of the h_j^p $(j = m_{p-1}+1, \dots, m_p)$ obtained again by expanding the brackets in the left-hand side of (4.7) with respect to the variables v_j^k and their derivatives. In view of (4.8) and (4.10), we have

$$\sum_{j=m_{p-1}+1}^{N} \mathcal{C}_j(b_{\tau_j^1} v_j^1, \dots, b_{\tau_j^{\ell(j)}} v_j^{\ell(j)}) = \sum_{j=m_{p-1}+1}^{N} \tilde{u}_j \tilde{b}_j - \sum_{j=1}^{m_{p-1}} h_j^p \tilde{b}_j \tag{4.11}$$

so that the induction assumption (4.8) on Steps P to $p+1$ is also true for Steps P to p.

The computation of the functions v_j^k and h_j^k ends after Step $p = 1$ has been performed. Let us remark that in the last step ($p = 1$), there is no function h_j^p to compute. With this construction, we have the next proposition.

PROPOSITION 4.6. *Consider the functions v_j^k defined above. Then*

(a) *each v_j^k $(j = 1, \dots, N,\ k = 1, \dots, \ell(j))$ belongs to $C^\infty(\mathbb{R}^n - \{0\}; \mathbb{R}) \cap C^0(\mathbb{R}^n; \mathbb{R})$ and is homogeneous of degree 1;*

(b) *(4.4) is satisfied.*

Proof. Point (b) is a direct consequence of (4.11) with $p = 1$. Point (a) is an easy consequence of Proposition 4.4, equations (4.6) and (4.9), and Lemma 4.5. ∎

Step 4 (oscillatory approximation of Lie brackets).

The last step of our construction relies on the work of Liu [9] and Sussmann and Liu [25, 26]. More precisely, consider a control system

$$\dot{x} = \sum_{\alpha=1}^{A} u_\alpha X_\alpha(x) \tag{4.12}$$

with $X_1, \dots, X_A$ some smooth vector fields on a smooth n-dimensional manifold, a "Lie bracket extended" system

$$\dot{x} = \sum_{\beta=1}^{B} w_\beta X_\beta(x) \qquad (B \geq A), \tag{4.13}$$

where the A first vector fields are the same as in (4.12), and the other vector fields are Lie brackets of $X_1, \dots, X_A$. In [9], an algorithm is given that builds, for any set of integrable functions of time w_β $(\beta = 1, \dots, B)$, some "highly oscillatory" functions of time u_α^ε such that the trajectories of (4.12), with $u_\alpha = u_\alpha^\varepsilon$, approximate those of (4.13).

We do not describe this algorithm here, though we use the notation

$$u_\alpha^\varepsilon = \mathcal{F}(\alpha, \varepsilon, (w_\beta)_{1 \leq \beta \leq B}), \tag{4.14}$$

where $\mathcal{F}$ is a function described algorithmically in [9]. It depends only on which Lie brackets have to be performed to obtain the vector fields $X_{A+1}, \ldots, X_B$ from the vector fields $X_1, \ldots, X_A$. It is of the form

$$u_\alpha^\varepsilon(t) \;=\; \eta_{\alpha,0}(t) + \varepsilon^{-\frac{1}{2}} \sum_{\omega\in\Omega(2,\alpha)} \eta_{\omega,\alpha}(t) e^{i\omega t/\varepsilon} + \sum_{n=3}^{N} \varepsilon^{\frac{n-1}{n}} \sum_{\omega\in\Omega(n,\alpha)} \eta_\omega(t) e^{i\omega t/\varepsilon}, \tag{4.15}$$

with N the length of the higher order bracket X_β in (4.13), $\eta_{\alpha,0}, \eta_{\omega,\alpha}$, and η_ω some functions, and $\Omega_{2,\alpha}$, $\Omega_{n,\alpha}$ some finite subsets of $\mathbb{R}$, that are all built precisely in [9]. In particular, the construction of the "approximating inputs" u_α^ε given in [9] implies the following.

THEOREM 4.7 (see [9]). *For any T $(0 < T < +\infty)$ and any family w_β $(\beta = 1, \ldots, B)$ of integrable functions on $[0,T]$, the functions u_α^ε $(\alpha = 1, \ldots, A)$ given by (4.14), where $\mathcal{F}$ symbolizes the algorithm described in [9], are integrable and are such that the trajectories of (4.12)–(4.15) converge to the trajectories of (4.13) in the following sense: For any $p \in \mathbb{R}^n$, if the system (4.13) with $x(0) = p$ has a unique solution x^∞ defined on $[0,T]$ and if x_ε is a maximal solution of system (4.12)–(4.15) with $x(0) = p$, then x_ε is defined on $[0,T]$ for ε small enough and converges uniformly to x^∞ on $[0,T]$ as $\varepsilon \to 0$.*

Remark 4.8. (1) The functions u_α^ε in (4.15) are real-valued because each $\Omega_{n,\alpha}$ $(n = 2, \ldots, N)$ is symmetric $(\omega \in \Omega_{n,\alpha} \Rightarrow -\omega \in \Omega_{n,\alpha})$, $\eta_{-\omega} = \overline{\eta_\omega}$, and $\eta_{-\omega,\alpha} = \overline{\eta_{\omega,\alpha}}$.

(2) If the functions w_β in (4.13) are constant, the functions $\eta_{\alpha,0}, \eta_{\omega,\alpha}$, and η_ω are also constant.

Consider now the following two systems:

$$\dot{x} = \sum_{j=1}^{N} \sum_{s=1}^{\ell(j)} u_{j,s} b_{\tau_j^s} v_j^s\,, \tag{4.16}$$

$$\dot{x} = \sum_{j=1}^{N} \mathcal{C}_j(b_{\tau_j^1} v_j^1, \ldots, b_{\tau_j^{\ell(j)}} v_j^{\ell(j)})\,. \tag{4.17}$$

Systems (4.16) and (4.17) are of the same form as (4.12) and (4.13), respectively, with the vector fields X_α being the $b_{\tau_j^s} v_j^s$'s (with α a double index (j,s)), the vector fields X_β being these plus the brackets in (4.17), i.e., $\mathcal{C}_j(X_{j,1}, \ldots, X_{j,\ell(j)})$, $1 \le j \le N$, and each w_β in (4.13) being constant: 0 in front of the X_β's that are also X_α's and 1 in front of the added brackets. Note that since each original vector field from (3.2) appears many times in the brackets selected in Step 1, we consider here as independent control vector fields in (4.12) some vector fields that are in fact "multiples" of each other: for instance if the vector field b_1 appears more than one time, we have $\tau_j^s = \tau_{j'}^{s'} = 1$ for some $(j,x) \neq (j',s')$, and $v_j^s b_1$ and $v_{j'}^{s'} b_1$ are distinct control vector fields X_α in (4.12).

Following Liu's algorithm, we construct some functions

$$u_{j,s}^\varepsilon \;=\; \mathcal{F}\left((j,s), \varepsilon, (0, \ldots, 0, 1, \ldots, 1)\right),$$

where $\mathcal{F}$ is the notation introduced in (4.14), such that the trajectories of (4.16)–(4.18) (which exist on any time interval because the system is degree zero homogeneous) converge uniformly on any time interval $[0,T]$ to those of (4.17), as ε tends to zero.

Recall (see (4.15)) that they are of the form

$$u^\varepsilon_{j,s}(t) = \eta_{j,s,0} + \varepsilon^{-\frac{1}{2}} \sum_{\omega\in\Omega(2,j,s)} \eta_{\omega,j,s} e^{i\omega t/\varepsilon} + \sum_{n=3}^{P} \varepsilon^{\frac{n-1}{n}} \sum_{\omega\in\Omega(n,j,s)} \eta_\omega e^{i\omega t/\varepsilon}\,. \tag{4.18}$$

Note that the functions η in (4.18) are constant in view of Remark 4.8 above. We rewrite system (4.16)–(4.18) as

$$\dot{x} = \sum_{i=1}^{m} \left(\sum_{(j,s):\tau^s_j=i} u^\varepsilon_{j,s}(t) v^s_j(x) \right) b_i(x)\,. \tag{4.19}$$

Our final control laws are defined by

$$u^\varepsilon_i(x,t) = \sum_{(j,s):\tau^s_j=i} u^\varepsilon_{j,s}(t) v^s_j(x)\,. \tag{4.20}$$

As stated in the following theorem, they ensure asymptotic stability of system (3.2) for "sufficiently large" frequencies.

THEOREM 4.9. *Let the controls u^ε_i be these described above. Then, the vector field in the right-hand side of the time-varying closed-loop system*

$$\dot{x} = \sum_{i=1}^{m} u^\varepsilon_i(x,t)\, b_i(x) \tag{4.21}$$

is homogeneous of degree zero and, for $\varepsilon > 0$ sufficiently small, the origin is exponentially uniformly asymptotically stable. (See the proof in section 7.3.)

Remark 4.10. Our construction a priori implies uniform convergence of the trajectories of (4.21) to those of (4.17), the origin of which is asymptotically stable from (4.3) to (4.5). However, this is not enough to infer asymptotic stability of (4.21). In the proofs, and in section 6, we introduce a stronger kind of convergence (DO-convergence), sufficient to infer asymptotic stability of (4.21). However, we quote uniform convergence here (instead of the DO-convergence, which we really need) because we base our construction on [9]. It makes the present construction clearer. (To construct the controls, one needs only to follow the algorithm in [9]; the kind of convergence does not matter.) Also, using the convergence result from [9] (Theorem 4.7) provides a shortcut in the proof on DO-convergence. This may make the paper less self-contained, but it avoids reproducing some difficult calculations made in [9].

5. An illustrative example. We now illustrate the control design method shown in section 4. Let us consider the following system in $\mathbb{R}^4$:

$$\dot{x} = b_1 u_1 + b_2 u_2\,, \tag{5.1}$$

with $b_1 = \frac{\partial}{\partial x_1} + x_3 \frac{\partial}{\partial x_2} + x_4 \frac{\partial}{\partial x_3}$ and $b_2 = \frac{\partial}{\partial x_4}$, which can be used to model the kinematic equations of a car-like mobile robot. One easily verifies that the vector fields b_1 and b_2 are homogeneous of degree -1 with respect to the family of dilations of weight $r = (1,3,2,1)$, and that this system is controllable. We follow this example with the four steps of our control design procedure.

Step 1. Since $[b_1,b_2] = -\frac{\partial}{\partial x_3}$, $[b_1,[b_1,b_2]] = \frac{\partial}{\partial x_2}$, and $[b_2,[b_2,b_1]] = 0$, the family $(\tilde{b}_j)$ is directly given by

$$\begin{aligned}(\tilde{b}_j) = (\tilde{b}_1,\tilde{b}_2,\tilde{b}_3,\tilde{b}_4) &= (b_1, b_2, [b_1,b_2], [b_1,[b_1,b_2]]) \\ &= (\mathcal{C}_1(b_{\tau^1_1}), \mathcal{C}_2(b_{\tau^1_2}), \mathcal{C}_3(b_{\tau^1_3}, b_{\tau^2_3}), \mathcal{C}_4(b_{\tau^1_4}, b_{\tau^2_4}, b_{\tau^3_4})).\end{aligned} \tag{5.2}$$

This implies that $\tau_1^1 = 1, \tau_2^1 = 2, \tau_3^1 = 1, \tau_3^2 = 2, \tau_4^1 = \tau_4^2 = 1, \tau_4^3 = 2$, and that $m_1 = 2$, $m_2 = 3$, and $m_3 = N = 4$.

Step 2. Let us, for instance, define the vector field a by $a(x) = -x$. (The origin $x = 0$ of $\dot{x} = a(x)$ is obviously asymptotically stable.) Then the integers j_k are simply defined by $j_k = k$ $(k = 1, \ldots, 4)$. By a direct computation, one obtains the following expression for the functions $\tilde{u}_j$:

$$\begin{aligned}(\tilde{u}_1, \tilde{u}_2, \tilde{u}_3, \tilde{u}_4)^T(x) &= (\tilde{b}_1, \tilde{b}_2, \tilde{b}_3, \tilde{b}_4)^{-1}(x)\, a(x) \\ &= (-x_1, -x_4, -x_1x_4 + x_3, x_1x_3 - x_2)^T\,.\end{aligned} \tag{5.3}$$

Step 3. From Step 1, the brackets $\mathcal{C}_k$ are defined by

$$\mathcal{C}_1(x_1) = x_1, \mathcal{C}_2(x_2) = x_2, \mathcal{C}_3(x_1, x_2) = [x_1, x_2], \mathcal{C}_4(x_1, x_1, x_2) = [x_1, [x_1, x_2]]\,.$$

We now follow the procedure exposed in section 4.

Step $p = P = 3$: The functions v_4^1, v_4^2, and v_4^3 are given, in view of (4.6), by

$$v_4^1 = v_4^2 = \rho, \quad v_4^3 = \frac{\tilde{u}_4}{\rho^2}\,, \tag{5.4}$$

with $\rho \in C^\infty(\mathbb{R}^4 - \{0\}; \mathbb{R}) \cap C^0(\mathbb{R}^4; \mathbb{R})$ a homogeneous norm. (For instance, one may take $\rho(x) = (x_1^{12} + x_2^4 + x_3^6 + x_4^{12})^{\frac{1}{12}}$.)

We also compute the functions h_j^P involved in (4.7). A tedious but simple calculation gives

$$\begin{aligned} h_1^3 &= v_4^2 v_4^3 L_{[b_1,b_2]} v_4^1 + v_4^2 L_{b_1} v_4^3 L_{b_2} v_4^1 + v_4^1 L_{b_1}(v_4^3 L_{b_2} v_4^2) - v_4^3 L_{b_1} v_4^1 L_{b_2} v_4^2\,, \\ h_2^3 &= -v_4^1 L_{b_1}(v_4^2 L_{b_1} v_4^3)\,, \\ h_3^3 &= -v_4^1 L_{b_1} v_4^2 v_4^3 - v_4^1 v_4^2 L_{b_1} v_4^3\,. \end{aligned} \tag{5.5}$$

Step $p = 2$: The functions v_3^1 and v_3^2 are given, in view of (4.9), by

$$v_3^1 = \rho, \quad v_3^2 = \frac{(\tilde{u}_3 + h_3^3)}{\rho}\,. \tag{5.6}$$

The functions h_1^2 and h_2^2 defined by (4.10) can be computed using (5.6):

$$\begin{aligned} h_1^2 &= h_1^3 + v_3^2 L_{b_2} v_3^1\,, \\ h_2^2 &= h_2^3 - v_3^1 L_{b_1} v_3^2\,. \end{aligned} \tag{5.7}$$

Step $p = 1$: Finally, the functions v_1^1 and v_2^1 are defined, from (4.9) again, by

$$v_1^1 = \tilde{u}_1 + h_1^2, \quad v_2^1 = \tilde{u}_2 + h_2^2\,. \tag{5.8}$$

Step 4. First, we need to find functions $u_{j,s}\,(j = 1, \ldots, 4\,, s = 1, \ldots, \ell(j))$ such that the trajectories of the system

$$\dot{x} = \sum_{j=1}^{4} \sum_{s=1}^{\ell(j)} u_{j,s} b_{\tau_j^s} v_j^s \tag{5.9}$$

converge uniformly to those of the system

$$\dot{x} = \sum_{j=1}^{4} \mathcal{C}_j(b_{\tau_j^1} v_j^1, \ldots, b_{\tau_j^{\ell(j)}} v_j^{\ell(j)})\,. \tag{5.10}$$

We remark that, in view of (5.2), (5.4), and (5.6), the vector fields $b_{\tau_3^1} v_3^1, b_{\tau_4^1} v_4^1$, and $b_{\tau_4^2} v_4^2$ are in fact identical. As a consequence, there are only 5—not 7 (the number of terms in the sum (5.9))—different vector fields in (5.9) or (5.10). Therefore, the system (5.9) can be rewritten as

$$\dot{x} = \sum_{i=1}^{5} u_i X_i \tag{5.11}$$

with $X_1 = b_1 v_1^1, X_2 = b_2 v_2^1, X_3 = b_1 v_3^1 = b_1 v_4^1 = b_1 v_4^2, X_4 = b_2 v_3^2$, and $X_5 = b_2 v_4^3$, and u_1, u_2, u_3, u_4, u_5 standing, respectively, for $u_{1,1}$, $u_{2,1}$, $u_{3,1} + u_{4,1} + u_{4,2}$, $u_{3,2}$, and $u_{4,3}$, and the system (5.10) can then be rewritten as

$$\dot{x} = X_1 + X_2 + [X_3, X_4] + [X_3, [X_3, X_5]]\,. \tag{5.12}$$

We choose some candidate functions u_i, for the approximation of trajectories of (5.12) by solutions of (5.11), of the following form:

$$\left\{ \begin{array}{rcl} u_1(t) &=& \eta_{1,0}\,, \\ u_2(t) &=& \eta_{2,0}\,, \\ u_3(t) &=& \varepsilon^{-\frac{1}{2}} \eta_{\omega_{1,1}} \cos \omega_{1,1} t/\varepsilon + \varepsilon^{-\frac{2}{3}} \left(\eta_{\omega_{2,1}} \cos \omega_{2,1} t/\varepsilon + \eta_{\omega_{2,2}} \cos \omega_{2,2} t/\varepsilon \right), \\ u_4(t) &=& \varepsilon^{-\frac{1}{2}} \eta_{\omega_{1,2}} \sin \omega_{1,2} t/\varepsilon, \\ u_5(t) &=& \varepsilon^{-\frac{2}{3}} \eta_{\omega_{2,3}} \cos \omega_{2,3} t/\varepsilon \end{array} \right. \tag{5.13}$$

with $\omega_{k,j}$ defined for instance by

$$\begin{array}{rcl} \Omega_1 &=& \{\omega_{1,1}, \omega_{1,2}\} = \{\frac{7}{2}, -\frac{7}{2}\} \\ \text{and} \quad \Omega_2 &=& \{\omega_{2,1}, \omega_{2,2}, \omega_{2,3}\} = \{2, 3, -5\}. \end{array}$$

Note in particular that each set Ω_k is "minimally cancelling" (MC) in the sense of [9, 25, 26]. Using [9, Theorem 5.1] (see also [9, section 8]), where a very similar example is treated), one can show that the trajectories of system (5.11)–(5.13) converge to those of the system

$$\dot{x} = \eta_{1,0} X_1 + \eta_{2,0} X_2 - \frac{\eta_{\omega_{1,1}} \eta_{\omega_{1,2}}}{2\omega_{1,1}} [X_3, X_4] - \frac{\eta_{\omega_{2,1}} \eta_{\omega_{2,2}} \eta_{\omega_{2,3}}}{4\omega_{2,1}\omega_{2,2}} [X_3, [X_3, X_5]]\,. \tag{5.14}$$

In order to identify system (5.12) with system (5.14), one can, for instance, define

$$\eta_{1,0} = \eta_{2,0} = \eta_{\omega_{1,1}} = \eta_{\omega_{2,1}} = \eta_{\omega_{2,2}} = 1$$

and

$$\eta_{\omega_{1,2}} = -2\omega_{1,1},\ \eta_{\omega_{2,3}} = -4\omega_{2,1}\omega_{2,2}\,.$$

Expressing the right-hand term of (5.11) as a function of the control vector fields b_1 and b_2, we finally obtain the expression of our stabilizing feedbacks:

$$\left\{ \begin{array}{rcl} u_1^\varepsilon(x,t) &=& u_1(t/\varepsilon) v_1^1(x) + u_3(t/\varepsilon) v_3^1(x), \\ u_2^\varepsilon(x,t) &=& u_2(t/\varepsilon) v_2^1(x) + u_4(t/\varepsilon) v_3^2(x) + u_5(t/\varepsilon) v_4^3(x) \end{array} \right. \tag{5.15}$$

with the u_i's defined by (5.13) and the v_j^s's defined by (5.4), (5.6), and (5.8).

Although the above expression of the control laws appears quite simple, it is, in fact, quite involved due to the terms contained in the v_j^s's, and in particular due to the functions h_j^p defined by (5.5) and (5.7). This is a negative aspect of our construction: solving the equation (4.4) in the v_j^s's leads to heavy computations.

6. Convergence of highly oscillatory vector fields as differential operators. As explained in the introduction (section 1.2), the convergence results which are implicitly contained in [5], and explicitly in [25, 9] or [8], in terms of uniform convergence of solutions on finite time intervals, are not sufficient here. In this section, we state separately the convergence result that is used to prove Theorem 4.9. The word convergence is perhaps a bit farfetched since there is no notion of limit in the topological sense; the convergence is more of an algebraic nature: we simply decompose the operator as the sum of a nonoscillating term (the "limit") and a term which is a differential operator—of order higher than 1—whose coefficients are, when ε goes to zero and x remains in a compact set, $\mathcal{O}(\varepsilon^\gamma)$, with $\gamma > 0$. However, this result will prove to be sufficient for our needs. It is also sufficient to recover the uniform convergence stated in [5, 8, 25, 9]. In what follows, $\mathcal{T}$ denotes any time interval (possibly infinite).

DEFINITION 6.1. *Let $F^\varepsilon\,(\varepsilon \in (0,\varepsilon_0]\,\varepsilon_0 > 0)$ and F^0 be vector fields on $\mathbb{R}^{1+n}$, defined by $F^\varepsilon(t,x) = \frac{\partial}{\partial t} + f(\varepsilon,t,x)$ and $F^0(t,x) = \frac{\partial}{\partial t} + f^0(t,x)$ with $f \in \mathcal{C}^0((0,\varepsilon_0]\times\mathcal{T}\times\mathbb{R}^n;\mathbb{R}^n)\cap\mathcal{C}^\infty((0,\varepsilon_0]\times\mathcal{T}\times(\mathbb{R}^n-\{0\});\mathbb{R}^n)$, and $f^0 \in \mathcal{C}^0(\mathcal{T}\times\mathbb{R}^n;\mathbb{R}^n)\cap\mathcal{C}^\infty(\mathcal{T}\times(\mathbb{R}^n-\{0\});\mathbb{R}^n)$.*

We say that F^ε converges as a differential operator of order one on functions of t and x, in brief "DO-converges," to F^0, as $\varepsilon \longrightarrow 0$, if

$$F^\varepsilon = F^0 + \varepsilon^{\gamma_1}\left(F^\varepsilon D_1^\varepsilon - D_1^\varepsilon\frac{\partial}{\partial t}\right) + \varepsilon^{\gamma_2} D_2^\varepsilon\,. \tag{6.1}$$

The above equality is understood as an equality of differential operators. γ_1 and γ_2 are strictly positive reals, and D_1^ε and D_2^ε are differential operators whose coefficients are continuous, smooth outside the origin, and locally uniformly bounded when $\varepsilon \to 0$, i.e., there exists $\varepsilon_0 > 0$ such that for all compact subset K of $\mathbb{R}^n$, each component of these differential operators is bounded for $(\varepsilon,t,x) \in (0,\varepsilon_0]\times\mathcal{T}\times K$.

This kind of convergence carries with it two important properties.

PROPOSITION 6.2. *Suppose that a vector field F^ε DO-converges, as $\varepsilon \longrightarrow 0$, to a vector field F^0 on a time interval $\mathcal{T}$. Then we have the following.*

1. *The trajectories of $\dot{x} = f(\varepsilon,t,x)$ converge uniformly to those of $\dot{x} = f^0(t,x)$ on finite time intervals. More precisely, let $[0,T] \subset \mathcal{T}$, and let x^0 be the (unique) solution of*

$$\begin{aligned}\dot{x} &= f^0(t,x),\\ x(0) &= x_0\,.\end{aligned} \tag{6.2}$$

Then, for ε small enough, the unique solution x^ε of

$$\begin{aligned}\dot{x} &= f(\varepsilon,t,x),\\ x(0) &= x_0\end{aligned} \tag{6.3}$$

is defined on $[0,T]$, and $x^\varepsilon(t)$ converges to $x^0(t)$ uniformly on $[0,T]$.

2. *If $\mathcal{T} = [0,+\infty)$, and if all vector fields in (6.1) are homogeneous of degree zero and f^0 is autonomous, then, if the origin of*

$$\dot{x} = f^0(x) \tag{6.4}$$

is asymptotically stable, the origin of

$$\dot{x} = f(\varepsilon,t,x) \tag{6.5}$$

is (exponentially) asymptotically stable too for $\varepsilon > 0$ sufficiently small.

Proof. We prove (1). First, we rewrite (6.1) as

$$F^\varepsilon(I - \varepsilon^{\gamma_1} D_1^\varepsilon) = F^0 - \varepsilon^{\gamma_1} D_1^\varepsilon \frac{\partial}{\partial t} \; + \; \varepsilon^{\gamma_2} D_2^\varepsilon \, .$$

This is an equality between differential operators. We apply each side to the coordinate functions x_i. $D_1^\varepsilon x_i$ and $D_2^\varepsilon x_i$ are simply the coefficients in front of $\frac{\partial}{\partial x_i}$ in the expression of the differential operator D_1^ε or D_2^ε. This implies (coordinate by coordinate) that the differential equation (6.3) can be rewritten

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(x \, - \, \varepsilon^{\gamma_1} d_1(\varepsilon, t, x)\right) \;\; = \;\; f^0(t,x) \; + \; \varepsilon^{\gamma_2} d_2(\varepsilon, t, x), \tag{6.6}$$

where $d_i(\varepsilon, t, x)$ $(i \in \{1, 2\})$ is the vector whose jth component is the coefficient of $\frac{\partial}{\partial x_j}$ in D_i^ε. This implies that the difference between $x^0(t) - x^\varepsilon(t)$ satisfies

$$\begin{aligned} \|x^\varepsilon(t) - x^0(t)\| \leq \varepsilon^{\gamma_1} \|d_1(\varepsilon, t, x^0(t))\| \; + \; \varepsilon^{\gamma_1} \|d_1(\varepsilon, t, x_0)\| \\ + \; \int_0^t \|f^0(\tau, x^\varepsilon(\tau)) - f^0(\tau, x^0(\tau))\| \mathrm{d}\tau \; + \; \varepsilon^{\gamma_2} \int_0^t \|d_2(\varepsilon, \tau, x^\varepsilon(\tau))\| \mathrm{d}\tau. \end{aligned}$$

The standard Gronwall lemma then yields, $\forall\, \varepsilon \in (0, \varepsilon_0]$ and $\forall\, t \in [0, T]$ such that x^ε remains in the interior of a certain compact neighborhood K of the trajectory x^0, the estimate $\|x^\varepsilon(t) - x^0(t)\| \leq (2\varepsilon^{\gamma_1} + T\varepsilon^{\gamma_2}) M e^{\lambda t}$, where λ is a Lipschitz constant (with respect to x) of F on $[0, T] \times K$ and M is an upperbound on $(0, \varepsilon_0] \times [0, T] \times K$ for both $\|d_1\|$ and $\|d_2\|$. This proves (1).

Let us prove (2). Since the right-hand side of (6.4) is homogeneous of degree zero, there exists [17] a *homogeneous* and autonomous Lyapunov function V, positive definite, whose derivative along (6.4) is given by

$$\dot{V}_{(6.4)} \; = \; F^0 V \; = \; -W. \tag{6.7}$$

Here $X\,V$, for X a vector field, denotes the Lie derivative of V along X with W homogeneous positive definite of the same degree as V, i.e.,

$$W(x) \; \geq \; c\, V(x). \tag{6.8}$$

Let us now compute the derivative of V along system (6.5). From (6.1) and (6.7),

$$\dot{V}_{(6.5)} \; = \; F^\varepsilon V \;\; = \;\; -\, W \; + \; \varepsilon^{\gamma_1} F^\varepsilon D_1^\varepsilon V \; - \; \varepsilon^{\gamma_1} D_1^\varepsilon \frac{\partial V}{\partial t} \; + \; \varepsilon^{\gamma_2} D_2^\varepsilon V,$$

which can be rewritten, since V is autonomous, as

$$F^\varepsilon V_\varepsilon \;\; = \;\; -\, W \; + \; \varepsilon^{\gamma_2} D_2^\varepsilon V, \tag{6.9}$$

with

$$V_\varepsilon \;\; = \;\; V \; - \; \varepsilon^{\gamma_1} D_1^\varepsilon V. \tag{6.10}$$

Since, by assumption, the operators D_1^ε and D_2^ε are homogeneous of degree zero, and locally uniformly bounded with respect to $\varepsilon > 0$, one has, since V is positive definite,

$$|D_1^\varepsilon V| \; \leq \; k\, V, \quad |D_2^\varepsilon V| \; \leq \; k\, V$$

$\forall\ \varepsilon > 0$. Hence, for ε sufficiently small, V_ε is arbitrarily close to V and hence positive definite, and also

$$\dot{V}_\varepsilon \;=\; F^\varepsilon V_\varepsilon \;\leq\; -\frac{c}{2} V. \tag{6.11}$$

Therefore, for ε small enough, V_ε is a strict Lyapunov function for system (6.5). This ends the proof of 2 via Lyapunov's first method. □

Before stating our convergence result, we recall two definitions introduced in [25, 9].

DEFINITION 6.3 (see [25, 9]). *Let Ω be a finite subset of $\mathbb{R}$ and $|\Omega|$ denote the number of elements of Ω. The set Ω is said to be MC if and only if*

(i) $\sum_{\omega\in\Omega} \omega = 0$;

(ii) *this is the only zero sum with at most $|\Omega|$ terms taken in Ω with possible repetitions:*

$$\left.\begin{array}{c} \displaystyle\sum_{\omega\in\Omega} \lambda_\omega \omega = 0 \\ (\lambda_\omega)_{\omega\in\Omega} \in \mathbb{Z}^{|\Omega|} \\ \displaystyle\sum_{\omega\in\Omega} |\lambda_\omega| \leq |\Omega| \end{array}\right\} \Longrightarrow \left\{\begin{array}{lll} (\lambda_\omega)_{\omega\in\Omega} & = & (0,\dots,0), \\ & or & (1,\dots,1), \\ & or & (-1,\dots,-1). \end{array}\right. \tag{6.12}$$

For example, a set $\{\omega_1, \omega_2\}$ is MC if and only if $\omega_2 = -\omega_1$ with $\omega_1 \neq 0$, a set $\{\omega_1, \omega_2, \omega_3\}$ is MC if and only if $\omega_3 = -\omega_1 - \omega_2$ with $\omega_1 \neq 0$, $\omega_2 \neq 0$, $\omega_1 + \omega_2 \neq 0$, $\omega_1 - \omega_2 \neq 0$, $\omega_1 + 2\omega_2 \neq 0$, $2\omega_1 + \omega_2 \neq 0$, $\omega_1 - 2\omega_2 \neq 0$, $2\omega_1 - \omega_2 \neq 0 \dots$.

DEFINITION 6.4 (see [25, 9]). *Let $(\Omega_\alpha)_{\alpha\in I}$ be a finite family of finite subsets Ω_α of $\mathbb{R}$. The family $(\Omega_\alpha)_{\alpha\in I}$ is said to be "independent with respect to p" if and only if*

$$\left.\begin{array}{l} \bullet\ \displaystyle\sum_{\alpha\in I}\sum_{\omega\in\Omega_\alpha} \lambda_\omega \omega = 0 \\ \bullet\ (\lambda_\omega)_{\omega\in\Omega_\alpha, \alpha\in I} \in \mathbb{Z}^{\Sigma|\Omega_\alpha|} \\ \bullet\ \displaystyle\sum_{\alpha\in I}\sum_{\omega\in\Omega} |\lambda_\omega| \leq p \end{array}\right\} \Longrightarrow \sum_{\omega\in\Omega_\alpha} \lambda_\omega \omega = 0 \quad \forall \alpha \in I. \tag{6.13}$$

For example, the sets $(\{\omega_1, \omega_2, \omega_3\}, \{\omega_4, \omega_5\})$ are both MC and independent with respect to 2 if and only if $\omega_3 = -\omega_1 - \omega_2$ and $\omega_5 = -\omega_4$ with $\omega_1 \neq 0$, $\omega_2 \neq 0$, $\omega_1 + \omega_2 \neq 0$, $\omega_1 - \omega_2 \neq 0$, $\omega_1 + 2\omega_2 \neq 0$, $2\omega_1 + \omega_2 \neq 0$, $\omega_1 - 2\omega_2 \neq 0$, $2\omega_1 - \omega_2 \neq 0$, $\omega_4 \neq 0$ (this is MC), and $\omega_1 + \omega_4 \neq 0$, $\omega_1 - \omega_4 \neq 0$, $\omega_2 + \omega_4 \neq 0$, $\omega_2 - \omega_4 \neq 0$, $\omega_1 + \omega_2 + \omega_4 \neq 0$, $\omega_1 + \omega_2 - \omega_4 \neq 0$ (this is independence).

We are now ready to state our convergence result.

THEOREM 6.5. *Let N be a positive integer and consider, for $j = 1, \dots, N$,*

- *some vector fields $X_j^s \in C^\infty(\mathbb{R}^n - \{0\}; \mathbb{R}^n) \cap C^0(\mathbb{R}^n; \mathbb{R}^n)$ $(s = 1, \dots, \ell(j))$,*
- *some smooth complex valued functions of time η_j^s $(s = 1, \dots, \ell(j))$ such that, for some M,*

$$\left|\eta_j^s(t)\right| \leq M \text{ and } \left|\dot{\eta}_j^s(t)\right| \leq M \quad \forall t \in \mathcal{T}, \tag{6.14}$$

- *some sets $\Omega_j = \{\omega_j^1, \dots, \omega_j^{\ell(j)}\}$ of real numbers such that $\omega_j^s = 0$ if $\ell(j) = 1$, Ω_j is MC if $\ell(j) \geq 2$, and the family (Ω_j) $(\ell(j) \geq 2)$ is independent with respect to $P \triangleq \mathrm{Max}_j \ell(j)$.*

Then the vector field

$$F^\varepsilon \;=\; \frac{\partial}{\partial t} + \sum_{j=1}^{N}\sum_{s=1}^{\ell(j)} \alpha^s_{j,\varepsilon} X^s_j\,, \tag{6.15}$$

with

$$\alpha^s_{j,\varepsilon}(t) = 2\varepsilon^{-\frac{\ell(j)-1}{\ell(j)}} \Re\left(\eta^s_j(t)\, e^{i\omega^s_j t/\varepsilon}\right), \tag{6.16}$$

DO-converges, as $\varepsilon \to 0$, to the vector field

$$F^0 = \frac{\partial}{\partial t} + \sum_{j=1}^{N} \frac{2}{\ell(j)} \Re\left(\frac{\eta^1_j \cdots \eta^{\ell(j)}_j}{i^{\ell(j)-1}}\right) B_j \tag{6.17}$$

$$\text{with}\quad B_j \;=\; \sum_{\sigma\in\mathfrak{S}(\ell(j))} \frac{[X^{\sigma(1)}_j, [X^{\sigma(2)}_j, [\ldots, X^{\sigma(\ell(j))}_j]\ldots]]}{\omega^{\sigma(1)}_j(\omega^{\sigma(1)}_j + \omega^{\sigma(2)}_j)\ldots(\omega^{\sigma(1)}_j + \ldots + \omega^{\sigma(\ell(j)-1)}_j)}\,.$$

Furthermore, if all the vector fields X^s_j are homogeneous of degree zero, then all the differential operators in (6.1) *are homogeneous of degree zero also.*

Remark 6.6. This result is very much related to the theory of "normal forms" for time-varying differential equations, as shown, for instance, in [19, Chapter 6]. Let us recall (see [19] for details) that a vector field $\frac{\partial}{\partial t} + \varepsilon f^0(t,x)\frac{\partial}{\partial x}$ is said to be in normal form if and only if $[\frac{\partial}{\partial t}, f^0\frac{\partial}{\partial x}] = 0$, i.e., if f^0 does not depend on t. For a system

$$(\Sigma_\varepsilon) \qquad \dot{x} \;=\; f(\varepsilon, t, x),$$

finding a normal form means finding a change of coordinates $x \mapsto y = x + \alpha(\varepsilon, x)$ that transforms (Σ_ε) into

$$(\Sigma_0) \qquad \dot{y} \;=\; \varepsilon f_0(y).$$

In general, deciding whether a normal form exists for a system, and then possibly finding this normal form, is a difficult problem and there are no systematic tools available.

Let us, however, rephrase Theorem 6.5 in the terms of [19]. By a time-scaling $t \mapsto \varepsilon t$, the system $\dot{x} = f(\varepsilon, x, t)$, where f is defined by $F^\varepsilon = \frac{\partial}{\partial t} + f\frac{\partial}{\partial x}$, with F^ε given by (6.15), is rewritten as

$$(\Sigma'_\varepsilon) \qquad \dot{x} \;=\; \varepsilon f_1(t,x) \,+\, \varepsilon^{1/2} f_2(t,x) \,+\, \cdots \,+\, \varepsilon^{1/P} f_P(t,x).$$

In the context of "normal forms," Theorem 6.5 states that (Σ_0), with f^0 defined by $F^0 = \frac{\partial}{\partial t} + f^0\frac{\partial}{\partial x}$ and F^0 given by (6.17), is a normal form for (Σ'), up to terms of higher order in ε.

7. Proofs.

7.1. Proof of Proposition 4.2 (section 4). Point (b) is strictly a consequence of the construction. Point (c) follows from the fact that if a linear combination of all the vector fields $\tilde{b}_j$ with constant real coefficients is identically zero, then homogeneity implies that each linear combination where only the terms corresponding to the brackets of same length must also be zero, and since by construction all the brackets

$\tilde{b}_j$ of same length are linearly independent over $\mathbb{R}$, this implies that all the coefficients are zero.

Let us prove point (a). Recall that any Lie bracket of length $p > P$ made with the vector fields b_i is identically zero (see Remark 4.1). From this fact, the controllability assumption (3.3), and the construction itself, there clearly exist integers $j_1, \ldots, j_n \in \{1, \ldots, N\}$ such that $\{\tilde{b}_{j_1}(0), \ldots, \tilde{b}_{j_n}(0)\}$ is a basis of $\mathbb{R}^n$. Hence $\{\tilde{b}_{j_1}(x), \ldots, \tilde{b}_{j_n}(x)\}$ is a basis of $\mathbb{R}^n$ for x in some neighborhood W of the origin. Let us show that this is true for any x in $\mathbb{R}^n$. Let x be outside W. There exist $\lambda > 0$ such that $\bar{x} = \delta_\lambda(x)$ is in W and hence $\{\tilde{b}_{j_1}(\bar{x}), \ldots, \tilde{b}_{j_n}(\bar{x})\}$ is a basis of $\mathbb{R}^n$. This implies, since δ_λ is a local diffeomorphism from a neighborhood of x to a neighborhood of $\bar{x}$, that

$$\left\{ \left((\delta_\lambda^{-1})_* \tilde{b}_{j_1} \right)(x), \ldots, \left((\delta_\lambda^{-1})_* \tilde{b}_{j_n} \right)(x) \right\}$$

is also a basis of $\mathbb{R}^n$. Now, from the homogeneity, $(\delta_\lambda^{-1})_* \tilde{b}_{j_k} = \lambda^{-\ell(j_k)} \tilde{b}_{j_k}$. This proves point (a). □

7.2. Proof of Theorem 6.5. In [5, 8, 25, 9], the main ingredient of the proof was iterated integrations by parts. Here we mimic these integrations by parts but at the level of products of differential operators instead of integrals along the solutions. The closed-loop vector field F^ε can be rewritten as

$$\begin{aligned} F^\varepsilon = & \frac{\partial}{\partial t} + \sum_{\substack{1 \le j \le N \\ \ell(j)=1}} 2\eta_j^1 X_j^1 \\ & + \sum_{\substack{1 \le j \le N \\ \ell(j) \ge 2}} \sum_{s=1}^{\ell(j)} \varepsilon^{-\frac{\ell(j)-1}{\ell(j)}} \left(\eta_j^s e^{i\omega_j^s t/\varepsilon} + \overline{\eta_j^s} e^{-i\omega_j^s t/\varepsilon} \right) X_j^s. \end{aligned} \tag{7.1}$$

Let us make some conventions and definitions, used only in the present proof. We define the sets of indices

$$J = \{j \in \{1, \ldots, N\}, \ell(j) \ge 2\} = \{m_1 + 1, \ldots, N\}, \tag{7.2}$$

$$J_l = \{j \in \{1, \ldots, N\}, \ell(j) = l\} = \{m_{l-1} + 1, \ldots, m_l\}, \tag{7.3}$$

$$K_j = \{-\ell(j), -\ell(j) - 1, \ldots, -1, 1, 2, \ldots \ell(j)\} \tag{7.4}$$

and the sets of pairs of indices

$$I = \{(j, s), j \in J, s \in K_j\} = \bigcup_{j \in J} \{j\} \times K_j, \tag{7.5}$$

$$I_l = \{(j, s) \in I, \ell(j) = l\} = \bigcup_{j \in J_l} \{j\} \times K_j. \tag{7.6}$$

We call F_1 the vector field

$$F_1 = \sum_{\substack{1 \le j \le N \\ \ell(j)=1}} 2\eta_j^1 X_j^1 = \sum_{(j,s) \in I_1} 2\eta_j^s X_j^s. \tag{7.7}$$

Clearly, if we define, for $s < 0$, the real numbers ω_j^s, the complex numbers η_j^s, and the vector fields X_j^s by

$$\left.\begin{aligned} \omega_j^{-s} &= -\omega_j^s \\ \eta_j^{-s} &= \overline{\eta_j^s} \\ X_j^{-s} &= X_j^s \end{aligned}\right\} \text{ for } j \in J\,,\ s \in K_j\,,\ s > 0, \tag{7.8}$$

the vector field F^ε from (7.1) may be rewritten as

$$F^\varepsilon = \frac{\partial}{\partial t} \;+\; F_1 \;+\; \sum_{(j,s)\in I} \varepsilon^{-\frac{\ell(j)-1}{\ell(j)}}\, \eta_j^s e^{i\omega_j^s t/\varepsilon} X_j^s \tag{7.9}$$

$$= \frac{\partial}{\partial t} \;+\; F_1 \;+\; \varepsilon^{-\frac{1}{2}}\, F_2^\varepsilon \;+\; \varepsilon^{-\frac{2}{3}}\, F_3^\varepsilon \;+\; \cdots \;+\; \varepsilon^{-\frac{P-1}{P}}\, F_P^\varepsilon, \tag{7.10}$$

where

$$F_l^\varepsilon \;=\; \sum_{(j,s)\in I_l} \eta_j^s e^{i\omega_j^s t/\varepsilon} X_j^s. \tag{7.11}$$

Note that the interest of (7.10) is that the negative powers of ε are written apart, and the vector fields F_j^ε have the "boundedness" property that their coefficients are continuous functions of x and t, smooth outside $x = 0$, indexed by $\varepsilon > 0$, and locally uniformly bounded with respect to $\varepsilon > 0$. (It is not the case of F^ε itself because of the negative powers of ε.) In the remainder of the proof, we shall always write the negative powers of ε apart so that all the differential operators written as capital letters never contain coefficients that are unbounded when ε goes to zero.

We now define a certain number of differential operators $F^\varepsilon_{p_1,p_2,\ldots,p_d}$ of order d for d between 1 and P, and for all d-tuple $(p_1, p_2, \ldots, p_d)$ of integers such that

$$\left\{\begin{array}{rcl} 1 \le p_k \le P \;\; \text{for } 1 \le k \le d, \\ \frac{1}{p_1} + \cdots + \frac{1}{p_{d-1}} \le 1, \\ (p_1, p_2) \;\neq\; (2,2), \\ (p_1, p_2, p_3) \;\neq\; (3,3,3), \\ \vdots \\ (p_1, \ldots, p_{d-1}) \;\neq\; (d-1, \ldots, d-1). \end{array}\right. \tag{7.12}$$

We define $F^\varepsilon_{p_1,p_2,\ldots,p_d}$ to be equal to

$$\sum_{((j_1,s_1),\ldots,(j_d,s_d))\,\in\, I^d(p_1,\ldots,p_d)} \frac{\eta_{j_1}^{s_1}\eta_{j_2}^{s_2}\cdots\eta_{j_d}^{s_d} e^{i(\omega_{j_1}^{s_1}+\cdots+\omega_{j_d}^{s_d})\frac{t}{\varepsilon}}\, X_{j_d}^{s_d} X_{j_{d-1}}^{s_{d-1}} \ldots X_{j_1}^{s_1}}{i^{(d-1)}\omega_{j_1}^{s_1}(\omega_{j_1}^{s_1}+\omega_{j_2}^{s_2})\cdots(\omega_{j_1}^{s_1}+\cdots+\omega_{j_{d-1}}^{s_{d-1}})}, \tag{7.13}$$

where $I^d(p_1, \ldots, p_d)$ is the set of d-tuples of indices $((j_1, s_1), \ldots, (j_d, s_d))$ such that $\ell(j_k) = p_k$, and which are neither a collection of $\frac{d}{2}$ pairs of the form (j, s), $(j, -s)$ nor such that, for some (even) k, $2 \le k \le d$, $((j_1, s_1), \ldots, (j_k, s_k))$ would be a collection of $\frac{k}{2}$ pairs of the form (j, s), $(j, -s)$. More precisely, $I^d(p_1, \ldots, p_d)$ may be defined recursively by $I^1(p) = I_1$ and

$$((j_1, s_1), \ldots, (j_d, s_d)) \;\in\; I^d(p_1, \ldots, p_d)$$

$$\Leftrightarrow \left\{\begin{array}{l} \bullet\; (j_k, s_k) \;\in\; I_{p_k} \;\forall\; k, \\ \bullet\; ((j_1, s_1), \ldots, (j_{d-1}, s_{d-1})) \;\in\; I^{d-1}(p_1, \ldots, p_{d-1}), \\ \bullet\; \text{there exists no permutation } \tau \in \mathfrak{S}(d) \\ \quad \text{such that } \;(j_{\tau(k)}, s_{\tau(k)}) \;=\; (j_k, -s_k). \end{array}\right. \tag{7.14}$$

With the above definition of the sets of indices $I^d(p_1,\dots,p_d)$, the denominators in (7.13) cannot be zero because of the following lemma.

LEMMA 7.1. *Let* $((j_1,s_1),\dots,(j_d,s_d)) \in I^d$ *(see the definition of* I *in* (7.5)*) be such that* $\omega_{j_1}^{s_1}+\dots+\omega_{j_d}^{s_d} = 0$. *Then*

- *either* $(\ell(j_1),\dots,\ell(j_d)) = (d,\dots,d)$ *and there exists a permutation* $\sigma\in\mathfrak{S}(d)$ *such that the p-tuple* $((j_1,s_1),\dots,(j_d,s_d))$ *is exactly equal to* $((j,\sigma(1)),\dots,(j,\sigma(p)))$ *or* $((j,-\sigma(1)),\dots,(j,-\sigma(p)))$ *(with* $j_1=\dots=j_d=j$*),*
- *or* $\frac{1}{\ell(j_1)}+\dots+\frac{1}{\ell(j_d)} > 1$,
- *or there exists a permutation* $\tau\in\mathfrak{S}(d)$ *such that* $(j_{\tau(k)},s_{\tau(k)}) = (j_k,-s_k)\ \forall\ k$.

Proof. The equality $\omega_{j_1}^{s_1}+\dots+\omega_{j_d}^{s_d}=0$ may be rewritten as

$$\sum_{\substack{j\in\{1,\dots,N\}\\ \ell(j)\geq 2}}\ \sum_{s=1}^{\ell(j)}\lambda_j^s\omega_j^s \ = \ 0, \tag{7.15}$$

where the integer λ_j^s is equal to the number of times that (j,s) appears in $((j_1,s_1),\dots,(j_d,s_d))$ minus the number of times $(j,-s)$ appears. Of course, (7.15) may be rewritten as

$$\sum_{j\in J}\sum_{\omega\in\Omega_j}\lambda_\omega\omega = 0$$

with $\lambda_{\omega_j^s}=\lambda_j^s$. Note that

$$\sum_{\omega}|\lambda_w| \ = \ \sum_{j,s}|\lambda_j^s| \ \leq \ d \ \leq \ P.$$

Hence, from the assumption that the sequences of frequencies are mutually "independent with respect to P" and are all MC (see (6.12)–(6.13)), each $(\lambda_j^1,\dots,\lambda_j^{\ell(j)})$ is equal to either $(0,\dots,0)$, $(1,\dots,1)$, or $(-1,\dots,-1)$. If it is different from $(0,\dots,0)$ for at least one j, then all the couples $(j,1),\dots,(j,\ell(j))$ or all the couples $(j,-1),\dots,(j,-\ell(j))$ appear in $((j_1,s_1),\dots,(j_d,s_d))$. If $d=\ell(j)$ for this j, i.e., if $((j_1,s_1),\dots,(j_d,s_d))$ is a reordering of $((j,1),\dots,(j,\ell(j)))$, or of $((j,-1),\dots,(j,-\ell(j)))$, then we are in the first case of the lemma; if $d>\ell(j)$, then there is at least another couple (j',s') in $((j_1,s_1),\dots,(j_d,s_d))$ and hence the sum $\frac{1}{\ell(j_1)}+\dots+\frac{1}{\ell(j_d)}$ can be no less than $1+\frac{1}{\ell(j')}$ and we are in the second case of the lemma. Let us now examine the case where all the $(\lambda_j^1,\dots,\lambda_j^{\ell(s)})$'s are equal to $(0,\dots,0)$. This means that for all j,s, the couple (j,s) and the couple $(j,-s)$ appear the same number of times in $((j_1,s_1),\dots,(j_d,s_d))$. This allows one to build the permutation having the property required in the third point of the lemma: it is the one that exchanges 1 with the first k_1 such that $(j_{k_1},s_{k_1})=(j_1,-s_1)$, 2 (3 if $k_1=2$) with the first $k_2\neq k_1$ such that $(j_{k_2},s_{k_2})=(j_2,-s_2)$, and so on. □

We shall now prove the following two facts.

Fact 1. For all q, $1\leq q\leq P$, there exist $\gamma_{1,q}$ and $\gamma_{2,q}$ strictly positive such that

$$F^\varepsilon = \frac{\partial}{\partial t} \ + \ F_1 \ + \ \sum_{p=2}^{q}(-1)^{p-1}F^\varepsilon_{\underbrace{p,p,\dots,p}_{p\text{ times}}} + \varepsilon^{\gamma_{1,q}}\left(F^\varepsilon D^\varepsilon_{1,q} \ - \ D^\varepsilon_{1,q}\frac{\partial}{\partial t}\right) \ + \ \varepsilon^{\gamma_{2,q}}\,D^\varepsilon_{2,q} \tag{7.16}$$

$$+ \sum_{\substack{(p_1,\dots,p_q)\in\{2,\dots,P\}^q,\\ \frac{1}{p_1}+\dots+\frac{1}{p_q}\le 1,\\ (p_1,\dots,p_q)\neq(q,\dots,q)}} (-1)^{q-1}\varepsilon^{-\left(1-\frac{1}{p_1}-\dots-\frac{1}{p_q}\right)} F^{\varepsilon}_{p_1,\dots,p_q}$$

Fact 2. For all p, $1 \le p \le P$, there exist $\gamma'_{1,p}$ and $\gamma'_{2,p}$ strictly positive such that

$$F^{\varepsilon}_{\underbrace{p,p,\dots,p}_{p \text{ times}}} = 2\,\frac{(-1)^{p-1}}{p} \sum_{j\in J_p} \Re\left(\frac{\eta_j^1\cdots\eta_j^p}{i^{(p-1)}}\right) B_j + \varepsilon^{\gamma'_{1,p}}\left(F^{\varepsilon} D'^{\varepsilon}_{1,p} - D'^{\varepsilon}_{1,p}\frac{\partial}{\partial t}\right) + \varepsilon^{\gamma'_{2,p}} D'^{\varepsilon}_{2,p} \tag{7.17}$$

with

$$B_j = \sum_{\sigma\in\mathfrak{S}(\ell(j))} \frac{[X_j^{\sigma(1)},[X_j^{\sigma(2)},[\dots,X_j^{\sigma(\ell(j))}]\dots]]}{\omega_j^{\sigma(1)}(\omega_j^{\sigma(1)}+\omega_j^{\sigma(2)})\cdots(\omega_j^{\sigma(1)}+\cdots+\omega_j^{\sigma(\ell(j)-1)})}. \tag{7.18}$$

These two facts imply Theorem 6.5. Indeed, for $q = P$, the last sum in (7.16) is empty since $\frac{1}{p_1}+\cdots+\frac{1}{p_P} \le 1$ with all the integers p_j no larger that P implies $(p_1,\dots,p_P) = (P,\dots,P)$. Hence for $q = P$, (7.16) reads

$$F^{\varepsilon} = \frac{\partial}{\partial t} + F_1 + \sum_{p=2}^{P}(-1)^{p-1} F^{\varepsilon}_{\underbrace{p,p,\dots,p}_{p \text{ times}}} + \varepsilon^{\gamma_{1,P}}\left(F^{\varepsilon} D^{\varepsilon}_{1,P} - D^{\varepsilon}_{1}\frac{\partial}{\partial t}\right) + \varepsilon^{\gamma_{2,P}} D^{\varepsilon}_{2,P}. \tag{7.19}$$

Substituting in the above the expression of $F^{\varepsilon}_{p,\dots,p}$ given by (7.17), one clearly gets (6.1) with the appropriate differential operators D^{ε}_1 and D^{ε}_2 and the appropriate positive real numbers γ_1 and γ_2.

Proof of Fact 1. We prove (7.16) by induction on q, from $q = 1$ to $q = P$.

For $q = 1$, the sum on the first line of (7.16) is empty, one may take $D^{\varepsilon}_{1,1}, D^{\varepsilon}_1$, and $D^{\varepsilon}_{2,1}$ to be zero, and (7.16) is simply (7.10).

Let us now suppose that (7.16) holds for a certain $q \ge 1$ and let us prove it for $q+1$. This is done through a manipulation on differential operators that more or less mimics an integration by parts. Since we shall use it elsewhere, let us explain it on a "general" differential operator Y before applying it.

Consider a differential operator of order d on functions of t and x that does not contain derivations with respect to t:

$$Y = \sum_{\text{multi-indices } I \text{ of length } d} \eta_I(t) a_I(t,x) \frac{\partial^{|I|}}{\partial x_I}. \tag{7.20}$$

Define $Y^{[-1]}$ and $Y^{[1]}$ to be

$$Y^{[-1]} = \sum_{\text{multi-indices } I \text{ of length } d} \eta_I(t)\left(\int_*^t a_I(\tau,x)\mathrm{d}\tau\right)\frac{\partial^{|I|}}{\partial x_I}, \tag{7.21}$$

$$Y^{[1]} = \sum_{\text{multi-indices } I \text{ of length } d} \frac{\mathrm{d}\eta_I}{\mathrm{d}t}(t)\left(\int_*^t a_I(\tau,x)\mathrm{d}\tau\right)\frac{\partial^{|I|}}{\partial x_I}. \tag{7.22}$$

Note that these are defined up to a function of x (through the initial time in the integrals) and that $Y^{[1]}$ is zero if the η's are constants. The derivative with respect to t of $Y^{[-1]}$ is $Y + Y^{[1]}$ in the following sense:

$$Y + Y^{[1]} \;=\; \left[\, \frac{\partial}{\partial t}\,,\, Y^{[-1]} \,\right] \;=\; \frac{\partial}{\partial t}\, Y^{[-1]} \;-\; Y^{[-1]}\, \frac{\partial}{\partial t}. \tag{7.23}$$

Indeed it is obvious that for any smooth function h of x and t, one has

$$Y.h\,(t,x) \;+\; Y^{[1]}.h\,(t,x) \;=\; \frac{\partial}{\partial t}\,\Big(Y^{[-1]}.h\,(t,x)\Big) \;-\; Y^{[-1]}.\frac{\partial h}{\partial t}\,(t,x), \tag{7.24}$$

simply because $\frac{\partial}{\partial t}$ commutes with $\frac{\partial}{\partial^{|I|}x_I}$. Then we rewrite (7.23) in the following way:

$$\begin{aligned} Y &= \left[\, \frac{\partial}{\partial t}\,,\, Y^{[-1]} \,\right] \;-\; Y^{[1]} \\ &= F^{\varepsilon}\, Y^{[-1]} \;-\; \left(\sum_{r=1}^{P} \varepsilon^{-\frac{r-1}{r}} F_r^{\varepsilon}\right) Y^{[-1]} \;-\; Y^{[-1]}\, \frac{\partial}{\partial t} \;-\; Y^{[1]}. \end{aligned} \tag{7.25}$$

In order to prove that if (7.16) holds for q, it also holds for $q+1$, we apply the identity (7.25) with

$$\begin{aligned} Y &= F^{\varepsilon}_{p_1,\dots,p_q}, \\ Y^{[-1]} &= \varepsilon\, G^{\varepsilon}_{p_1,\dots,p_q}, \\ Y^{[1]} &= \varepsilon\, H^{\varepsilon}_{p_1,\dots,p_q}, \end{aligned}$$

for

$$(p_1,\dots,p_q) \neq (q,\dots,q) \;\text{ and }\; \frac{1}{p_1} + \dots + \frac{1}{p_q} \leq 1, \tag{7.26}$$

where $G^{\varepsilon}_{p_1,\dots,p_q}$ and $H^{\varepsilon}_{p_1,\dots,p_q}$ are given by

$$G^{\varepsilon}_{p_1,\dots,p_q} = \sum_{((j_1,s_1),\dots,(j_q,s_q)) \,\in\, I^q(p_1,\dots,p_q)} \frac{\eta_{j_1}^{s_1} \cdots \eta_{j_q}^{s_q} e^{i(\omega_{j_1}^{s_1} + \dots + \omega_{j_q}^{s_q})t/\varepsilon}\, X_{j_q}^{s_q} X_{j_{q-1}}^{s_{q-1}} \dots X_{j_1}^{s_1}}{i^q \omega_{j_1}^{s_1} (\omega_{j_1}^{s_1} + \omega_{j_2}^{s_2}) \dots (\omega_{j_1}^{s_1} + \dots + \omega_{j_q}^{s_q})} \tag{7.27}$$

$$H^{\varepsilon}_{p_1,\dots,p_q} = \sum_{((j_1,s_1),\dots,(j_q,s_q)) \in I^q(p_1,\dots,p_q)} \frac{\left(\frac{d}{dt}\left(\eta_{j_1}^{s_1} \cdots \eta_{j_q}^{s_q}\right)\right) e^{i(\omega_{j_1}^{s_1} + \dots + \omega_{j_q}^{s_q})t/\varepsilon}\, X_{j_q}^{s_q} X_{j_{q-1}}^{s_{q-1}} \dots X_{j_1}^{s_1}}{i^q \omega_{j_1}^{s_1} (\omega_{j_1}^{s_1} + \omega_{j_2}^{s_2}) \dots (\omega_{j_1}^{s_1} + \dots + \omega_{j_q}^{s_q})}. \tag{7.28}$$

Note that the denominators are nonzero because, from Lemma 7.1, the definition (7.14) of the set of indices $I^q(p_1,\dots,p_q)$ precisely removes the terms where the denominators would be zero.

Then (7.25) with the above expressions for Y, $Y^{[1]}$, and $Y^{[-1]}$ yields

$$F^{\varepsilon}_{p_1,\dots,p_q} \;=\; -\sum_{r=1}^{P} \varepsilon^{\frac{1}{r}} F_r^{\varepsilon} G^{\varepsilon}_{p_1,\dots,p_q} + \varepsilon\, F^{\varepsilon} G^{\varepsilon}_{p_1,\dots,p_q} - \varepsilon\, G^{\varepsilon}_{p_1,\dots,p_q} \frac{\partial}{\partial t} \;-\; \varepsilon\, H^{\varepsilon}_{p_1,\dots,p_q}. \tag{7.29}$$

From (7.27) and (7.11) we have

$$\begin{aligned} &F_r^{\varepsilon} G^{\varepsilon}_{p_1,\dots,p_q} \\ &\quad= \sum_{\substack{((j_1,s_1),\dots,(j_q,s_q)) \;\in\; I^q(p_1,\dots,p_q) \\ (j_{q+1},s_{q+1}) \,\in\, I_r}} \frac{\eta_{j_1}^{s_1} \cdots \eta_{j_{q+1}}^{s_{q+1}} e^{i(\omega_{j_1}^{s_1} + \dots + \omega_{j_{q+1}}^{s_{q+1}})t/\varepsilon}\, X_{j_{q+1}}^{s_{q+1}} X_{j_q}^{s_q} \dots X_{j_1}^{s_1}}{i^q \omega_{j_1}^{s_1} (\omega_{j_1}^{s_1} + \omega_{j_2}^{s_2}) \dots (\omega_{j_1}^{s_1} + \dots + \omega_{j_q}^{s_q})}. \end{aligned}$$

From (7.14), the $(q+1)$-tuples $((j_1,s_1),\dots,(j_{q+1},s_{q+1}))$, which are in $I^q(p_1,\dots,p_q)\times I_r$ but not in $I^{q+1}(p_1,\dots,p_q,r)$, are such that there exists a permutation τ of the set of integers $\{1,\dots,q+1\}$ for which

$$\begin{aligned}((j_{\tau(1)},s_{\tau(1)}),(j_{\tau(2)},s_{\tau(2)}),\dots,(j_{\tau(q+1)},s_{\tau(q+1)}))\\ =((j_1,-s_1),(j_2,-s_2),\dots,(j_{q+1},-s_{q+1})),\end{aligned}\tag{7.30}$$

and this is possible only if q is odd. Equations (7.8) (for X and ω, not for η) and (7.30) imply that the term corresponding to $((j_1,-s_1),(j_2,-s_2),\dots,(j_{q+1},-s_{q+1}))$ is equal to

$$\frac{\eta_{j_{\tau(1)}}^{s_{\tau(1)}}\cdots\eta_{j_{\tau(q+1)}}^{s_{\tau(q+1)}}e^{i(\omega_{j_{\tau(1)}}^{s_{\tau(1)}}+\cdots+\omega_{j_{\tau(q+1)}}^{s_{\tau(q+1)}})t/\varepsilon}\,X_{j_{q+1}}^{s_{q+1}}X_{j_q}^{s_q}\cdots X_{j_1}^{s_1}}{i^q(-\omega_{j_1}^{s_1})(-\omega_{j_1}^{s_1}-\omega_{j_2}^{s_2})\dots(-\omega_{j_1}^{s_1}-\cdots-\omega_{j_q}^{s_q})}$$

which, since q must be odd (if not, there is no such term), is equal to

$$-\frac{\left(\prod_{k=1}^{q+1}\eta_{j_{\tau(k)}}^{s_{\tau(k)}}\right)e^{i(\omega_{j_1}^{s_1}+\cdots+\omega_{j_{q+1}}^{s_{q+1}})t/\varepsilon}\,X_{j_{q+1}}^{s_{q+1}}X_{j_q}^{s_q}\cdots X_{j_1}^{s_1}}{i^q\omega_{j_1}^{s_1}(\omega_{j_1}^{s_1}+\omega_{j_2}^{s_2})\cdots(\omega_{j_1}^{s_1}+\cdots+\omega_{j_q}^{s_q})}$$

and τ gives the change of index in the product allowing us to say that this is the opposite of the term corresponding to $((j_1,s_1),(j_2,s_2),\dots,(j_{q+1},s_{q+1}))$. Hence these terms sum to zero in the above sum. From (7.14), this implies $F_r^\varepsilon G_{p_1,\dots,p_q}^\varepsilon = F_{p_1,\dots,p_q,r}^\varepsilon$. Substituting this in (7.29) yields (we rename r as p_{q+1})

$$F_{p_1,\dots,p_q}^\varepsilon = -\sum_{p_{q+1}=1}^{P}\varepsilon^{\frac{1}{p_{q+1}}}F_{p_1,\dots,p_q,p_{q+1}}^\varepsilon+\varepsilon\,F^\varepsilon G_{p_1,\dots,p_q}^\varepsilon-\varepsilon\,G_{p_1,\dots,p_q}^\varepsilon\frac{\partial}{\partial t}-\varepsilon\,H_{p_1,\dots,p_q}^\varepsilon.$$

Hence (7.16) yields

$$\begin{aligned}F^\varepsilon = \frac{\partial}{\partial t}+F_1+\sum_{p=2}^{q}(-1)^{p-1}F^\varepsilon_{\underbrace{p,p,\dots,p}_{p\text{ times}}}\\ +\varepsilon^{\gamma_{1,q}}\left(F^\varepsilon D_{1,q}^\varepsilon-D_1^\varepsilon\frac{\partial}{\partial t}\right)+\varepsilon^{\gamma_{2,q}}D_{2,q}^\varepsilon\\ +(-1)^q\sum_{\substack{(p_1,\dots,p_q)\in\{2,\dots,P\}^q\\ \frac{1}{p_1}+\cdots+\frac{1}{p_q}\le 1\\ (p_1,\dots,p_q)\neq(q,\dots,q)\\ p_{q+1}\in\{1,\dots,P\}}}\varepsilon^{-\left(1-\frac{1}{p_1}-\cdots-\frac{1}{p_{q+1}}\right)}F^\varepsilon_{p_1,\dots,p_q,p_{q+1}}\\ +(-1)^{q-1}\sum_{\substack{(p_1,\dots,p_q)\in\{2,\dots,P\}^q,\\ \frac{1}{p_1}+\cdots+\frac{1}{p_q}\le 1\\ (p_1,\dots,p_q)\neq(q,\dots,q)}}\varepsilon^{\frac{1}{p_1}+\cdots+\frac{1}{p_q}}\left(F^\varepsilon G^\varepsilon_{p_1,\dots,p_q}-G^\varepsilon_{p_1,\dots,p_q}\frac{\partial}{\partial t}-H^\varepsilon_{p_1,\dots,p_q}\right).\end{aligned}\tag{7.31}$$

The term corresponding to $(p_1,\dots,p_{q+1})=(q+1,\dots,q+1)$ in the sum on the third line is $(-1)^qF^\varepsilon_{q+1,\dots,q+1}$, it adds to the sum on the first line and this yields the first line of (7.16) for $q+1$. The other terms in this sum such that $\frac{1}{p_1}+\cdots+\frac{1}{p_{q+1}}\le 1$ yield exactly the third line of (7.16) for $q+1$, and the terms in this sum such that

$\frac{1}{p_1} + \cdots + \frac{1}{p_{q+1}} > 1$, as well as all the last sum, add up with the second line to give the second line (the "small" terms) of (7.16) for $q+1$. This proves (7.16) for $q+1$ and ends the proof by induction of Fact 1.

Proof of Fact 2. From the definition (7.13) of $F^\varepsilon_{p_1,p_2,\ldots,p_d}$, we have

(7.32)
$$F^\varepsilon_{\underbrace{p,\ldots,p}_{p \text{ times}}} = \sum_{\substack{((j_1,s_1),\ldots,(j_p,s_p)) \in I^p(p,\ldots,p) \\ \omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p}=0}} \frac{\eta_{j_1}^{s_1}\eta_{j_2}^{s_2}\cdots\eta_{j_p}^{s_p} X_{j_p}^{s_p} X_{j_{p-1}}^{s_{p-1}} \ldots X_{j_1}^{s_1}}{i^{(p-1)}\omega_{j_1}^{s_1}(\omega_{j_1}^{s_1}+\omega_{j_2}^{s_2})\ldots(\omega_{j_1}^{s_1}+\cdots+\omega_{j_{p-1}}^{s_{p-1}})}$$
$$+ \sum_{\substack{((j_1,s_1),\ldots,(j_p,s_p)) \in I^p(p,\ldots,p) \\ \omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p}\neq 0}} \frac{\eta_{j_1}^{s_1}\eta_{j_2}^{s_2}\cdots\eta_{j_p}^{s_p} e^{i(\omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p})t/\varepsilon} X_{j_p}^{s_p} X_{j_{p-1}}^{s_{p-1}} \ldots X_{j_1}^{s_1}}{i^{(p-1)}\omega_{j_1}^{s_1}(\omega_{j_1}^{s_1}+\omega_{j_2}^{s_2})\ldots(\omega_{j_1}^{s_1}+\cdots+\omega_{j_{p-1}}^{s_{p-1}})}.$$

Now, apply (7.20), (7.21), (7.22), and (7.25) with Y equal to the second sum, and therefore

$$Y^{[-1]} \;=\; \varepsilon\, G^\varepsilon_{p,\ldots,p}, \quad Y^{[1]} \;=\; \varepsilon\, H^\varepsilon_{p,\ldots,p},$$

with

(7.33)
$$G^\varepsilon_{\underbrace{p,\ldots,p}_{p \text{ times}}} = \sum_{\substack{((j_1,s_1),\ldots,(j_p,s_p)) \in I^p(p,\ldots,p) \\ \omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p}\neq 0}} \frac{\eta_{j_1}^{s_1}\cdots\eta_{j_p}^{s_p} e^{i(\omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p})t/\varepsilon} X_{j_p}^{s_p} X_{j_{p-1}}^{s_{p-1}} \cdots X_{j_1}^{s_1}}{i^{p}\omega_{j_1}^{s_1}(\omega_{j_1}^{s_1}+\omega_{j_2}^{s_2})\ldots(\omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p})};$$

(7.34)
$$H^\varepsilon_{\underbrace{p,\ldots,p}_{p \text{ times}}} = \sum_{\substack{((j_1,s_1),\ldots,(j_p,s_p)) \in I^p(p\ldots p) \\ \omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p}\neq 0}} \frac{\left(\frac{\mathrm{d}}{\mathrm{d}t}\left(\eta_{j_1}^{s_1}\cdots\eta_{j_p}^{s_p}\right)\right) e^{i(\omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p})t/\varepsilon} X_{j_p}^{s_p} X_{j_{p-1}}^{s_{p-1}} \cdots X_{j_1}^{s_1}}{i^{p}\omega_{j_1}^{s_1}(\omega_{j_1}^{s_1}+\omega_{j_2}^{s_2})\ldots(\omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p})}.$$

This allows us to rewrite the second sum in (7.32) as

$$\varepsilon\, F^\varepsilon\, G^\varepsilon_{p,\ldots,p} \;-\; \varepsilon\, G^\varepsilon_{p,\ldots,p}\,\frac{\partial}{\partial t} \;-\; \varepsilon\, H^\varepsilon_{p,\ldots,p} \;-\; \sum_{r=1}^{P} \varepsilon^{\frac{1}{r}} F^\varepsilon_{p,\ldots,p,r}$$

with

(7.35)

$$F^{\varepsilon}_{\underbrace{p,\dots,p,r}_{p \text{ times}}} = \sum_{\substack{((j_1,s_1),\dots,(j_p,s_p)) \ \in \ I^p(p,\dots,p) \\ \omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p}\neq 0 \\ (j_{p+1},s_{p+1})\in I_r}} \frac{\eta_{j_1}^{s_1}\cdots\eta_{j_{p+1}}^{s_{p+1}} e^{i(\omega_{j_1}^{s_1}+\cdots+\omega_{j_{p+1}}^{s_{p+1}})t/\varepsilon}\, X_{j_{p+1}}^{s_{p+1}} X_{j_p}^{s_p}\dots X_{j_1}^{s_1}}{i^p\omega_{j_1}^{s_1}(\omega_{j_1}^{s_1}+\omega_{j_2}^{s_2})\dots(\omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p})}.$$

Let us now consider the *first* sum in (7.32). From Lemma 7.1 and the fact that, from (7.14), a p-tuple that is in $I^p(p,\dots,p)$ cannot be of the type described in the third item of this lemma, all the p-tuples $((j_1,s_1),\dots,(j_p,s_p))$ in $I^p(p,\dots,p)$ such that $\omega_{j_1}^{s_1}+\cdots+\omega_{j_p}^{s_p}=0$ are exactly of the form $((j,\sigma(1)),\dots,(j,\sigma(p)))$ or $((j,-\sigma(1)),\dots,(j,-\sigma(p)))$ with $\ell(j)=p$ and $\sigma\in\mathfrak{S}(p)$. Hence the first sum may be rewritten (recall that $X_j^{-s}=X_j^s$) as

$$2\sum_{j\in J_p}\Re\left(\frac{\eta_j^1\cdots\eta_j^p}{i^{p-1}}\right)C_j$$

with

$$C_j = \sum_{\sigma\in\mathfrak{S}(p)}\frac{X_j^{\sigma(p)}X_j^{\sigma(p-1)}\cdots X_j^{\sigma(1)}}{\omega_j^{\sigma(1)}(\omega_j^{\sigma(1)}+\omega_j^{\sigma(2)})\cdots(\omega_j^{\sigma(1)}+\cdots+\omega_j^{\sigma(p-1)})}. \tag{7.36}$$

If one replaces in the above sum σ by $\sigma\circ\tau$, where τ is the permutation that sends $(1,2,\dots,p)$ on $(p,p-1,\dots,1)$ (change of indices in the summation), one gets

$$C_j = \sum_{\sigma\in\mathfrak{S}(p)}\frac{X_j^{\sigma(1)}X_j^{\sigma(2)}\cdots X_j^{\sigma(p)}}{(\omega_j^{\sigma(p)}+\cdots+\omega_j^{\sigma(2)})(\omega_j^{\sigma(p)}+\cdots+\omega_j^{\sigma(3)})\cdots(\omega_j^{\sigma(p)}+\omega_j^{\sigma(p-1)})\omega_j^{\sigma(p)}}.$$

Since $\omega_j^1+\cdots+\omega_j^p=0$, the denominator may be transformed:

$$C_j = (-1)^{p-1}\sum_{\sigma\in\mathfrak{S}(p)}\frac{X_j^{\sigma(1)}X_j^{\sigma(2)}\dots X_j^{\sigma(p)}}{\omega_j^{\sigma(1)}(\omega_j^{\sigma(1)}+\omega_j^{\sigma(2)})\cdots(\omega_j^{\sigma(1)}+\cdots+\omega_j^{\sigma(p-1)})}.$$

Finally, a combinatorial computation in the free Lie algebra (see [8], or [9] in which this identity is also obtained but in a less computational way) gives

$$\sum_{\sigma\in\mathfrak{S}(p)}\frac{X_j^{\sigma(1)}X_j^{\sigma(2)}\dots X_j^{\sigma(p)}}{\omega_j^{\sigma(1)}(\omega_j^{\sigma(1)}+\omega_j^{\sigma(2)})\cdots(\omega_j^{\sigma(1)}+\cdots+\omega_j^{\sigma(p-1)})} = \frac{1}{p}\sum_{\sigma\in\mathfrak{S}(p)}\frac{[X_j^{\sigma(1)},[X_j^{\sigma(2)},[\cdots,X_j^{\sigma(p)}]\cdots]]}{\omega_j^{\sigma(1)}(\omega_j^{\sigma(1)}+\omega_j^{\sigma(2)})\cdots(\omega_j^{\sigma(1)}+\cdots+\omega_j^{\sigma(p-1)})}.$$

Hence $C_j = \frac{(-1)^{p-1}}{p} B_j$ with B_j given by (7.18). Substituting the above in (7.32) yields

$$F^{\varepsilon}_{\underbrace{p,\dots,p}_{p \text{ times}}} = \frac{2\,(-1)^{p-1}}{p} \sum_{j \in J_p} \Re\left(\frac{\eta_j^1 \cdots \eta_j^p}{i^{p-1}}\right) B_j + \varepsilon \left(F^{\varepsilon}\, G^{\varepsilon}_{\underbrace{p,\dots,p}_{p \text{ times}}} - G^{\varepsilon}_{\underbrace{p,\dots,p}_{p \text{ times}}} \frac{\partial}{\partial t} \right) - \varepsilon\, H^{\varepsilon}_{p,\dots,p} - \sum_{r=1}^{P} \varepsilon^{\frac{1}{r}} F^{\varepsilon}_{\underbrace{p,\dots,p,r}_{p \text{ times}}}. \tag{7.37}$$

This clearly yields (7.17), ends the proof of Fact 2, and hence ends the proof of Theorem 6.5.

7.3. Proof of Theorem 4.9. Let $F^{\varepsilon} = \frac{\partial}{\partial t} + f^{\varepsilon}$ with f^{ε} the vector field associated with the right-hand side of (4.21), and let $G = \frac{\partial}{\partial t} + g$ with g the vector field associated with the right-hand side of (4.17). First, we show that F^{ε} DO-converges (see Definition 6.1) to G as ε tends to zero.

Since (4.21) is the same as (4.16) with $u_{j,s} = u^{\varepsilon}_{j,s}$ given by (4.18), F^{ε} can be expressed in the form (6.15), with all X^s_j's homogeneous of degree zero because each X^s_j corresponds to one of the $b_{\tau^s_j} v^s_j$'s and, from Proposition 4.6, all vector fields $b_{\tau^s_j} v^s_j$ are homogeneous of degree zero. We can apply Theorem 6.5 because the sets $\Omega_{n,\alpha}$ ($n = 2,\dots,N$) in the construction of Theorem 4.7 are MC and linearly independent with respect to P (see [9, section 5]). It implies that F^{ε} DO-converges, as ε tends to zero, to a vector field $F^0 = \frac{\partial}{\partial t} + f^0$ of the form (6.17), and in the definition (6.1) of DO-convergence, all differential operators are homogeneous of degree zero. We claim that $G = F^0$. Indeed, from Proposition 6.2, the property of DO-convergence implies the uniform convergence of the trajectories on finite time intervals. Therefore, the trajectories of (4.21) converge to those of $\dot{x} = f^0(t,x)$; however, from Theorem 4.7 (recall that (4.21) is the same as (4.16)–(4.18)), they converge to the trajectories of (4.17). This implies that the systems $\dot{x} = g(t,x)$ and $\dot{x} = f^0(t,x)$ are the same because they have the same trajectories. Hence, $F^0 = G$.

Finally, since F^{ε} DO-converges to $G = \frac{\partial}{\partial t} + g$ (with g autonomous) and since all differential operators in the definition of DO-convergence are homogeneous of degree zero, the asymptotic stability of the origin of (4.21), for $\varepsilon > 0$ small enough, will follow from Proposition 6.2 if we can show that the origin of (4.17) is asymptotically stable. This is a direct consequence of (4.3) to (4.5). ∎

SENSITIVITY OF SOLUTIONS TO VARIATIONAL INEQUALITIES ON BANACH SPACES*

ADAM B. LEVY†

Abstract. We analyze the sensitivity of parameterized variational inequalities for convex polyhedric sets in reflexive Banach spaces. We compute a generalized derivative of the solution mapping where the formula for the derivative is given in terms of the solutions to an auxiliary variational inequality. These results are distinguished from other work in this area by the fact that they do not depend on the uniqueness of the solutions to the variational inequalities. To obtain our results, we use second-order epi-derivatives to analyze the second-order properties of polyhedric sets. We apply our results to sensitivity analyses of stationary points and KKT pairs associated with constrained infinite-dimensional optimization problems.

Key words. variational inequality, sensitivity analysis, polyhedric set, parameterized optimization, second-order epi-derivative, protoderivative

1. Introduction.

Variational inequalities have been studied widely in infinite-dimensional optimization, particularly because they can represent solutions or solution-multiplier pairs associated with optimal control problems. In this paper, we analyze the sensitivity of solutions x in a reflexive Banach space X to variational inequalities of the form

$$\langle v - F(x,u), c - x\rangle \leq 0 \quad \forall\, c \in C, \tag{1.1}$$

where v is a parameter in the dual space X^*, u is a parameter in a Banach space U, $F : X \times U \to X^*$ is a (single-valued) mapping, and $C \subseteq X$ is a closed, nonempty, convex polyhedric set.

DEFINITION 1.1. *A subset C of a Banach space is called* polyhedric at $\bar{x} \in C$ for $x^* \in X^*$ *if the identity holds that*

$$\overline{(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C-\bar{x})} = (x^*)^\perp \bigcap \overline{\cup_{\lambda>0}\lambda(C-\bar{x})},$$

where the overbar denotes the strong closure of the set.

Polyhedric sets are an infinite-dimensional generalization of finite-dimensional polyhedral sets; sets that are polyhedric at all their points were first studied in a Hilbert space setting [10], [4], where projections onto these sets were shown to be semidifferentiable. It is a fact that the point x is the projection of $G(u)$ onto the set C if and only if the variational inequality $\langle G(u) - x, c - x\rangle \leq 0$ for all $c \in C$ is satisfied. The authors in [10] and [4] used this fact to apply their results about projections to analyze the sensitivity of variational inequalities (1.1) of the special form where $F(x,u) = G(u) - x$, $U = \mathbb{R}$, and $v = 0$. Notice that this form of variational inequality automatically has a unique solution $x(u)$ for each u, since the projection of $G(u)$ onto the convex set C is a unique point. From their results about the semidifferentiability of projections, these authors showed that the solution function

†Department of Mathematics, Bowdoin College, Brunswick, ME 04011 (alevy@bowdoin.edu).

$x(u)$ is semidifferentiable with respect to u. In [14] and [8], the results in [4] and [10] were applied to the sensitivity analysis of solutions and solution-multiplier pairs associated with parameterized optimization problems on Hilbert spaces. This work is complemented by [9], where the sensitivity of variational inequalities associated with convex polyhedric cones C was analyzed under a "strong regularity" assumption which involves unique and Lipschitz continuous solutions to a linearized version of the variational inequality. All of these papers include examples of polyhedric sets arising in variational inequalities associated with optimal control problems. The main result of the present paper complements these results by quantifying the sensitivity of the solutions to (1.1) without relying on some of the strong conditions found in the works of previous authors.

THEOREM 1.1. *Consider fixed parameters $\bar{v} \in X^*$ and $\bar{u} \in U$ together with a solution $\bar{x}$ to the variational inequality* (1.1) *corresponding to these parameters. If C is a convex set that is polyhedric at $\bar{x} \in C$ for $\bar{v} - F(\bar{x}, \bar{u})$ and F is semidifferentiable at $(\bar{x}, \bar{u})$ (with derivative mapping $DF(\bar{x}, \bar{u}) : X \times U \to X^*$), then the solution mapping*

$$S(u, v) := \{x \in C : \langle v - F(x, u), c - x\rangle \leq 0 \quad \forall\, c \in C\}$$

is protodifferentiable at $(\bar{u}, \bar{v})$ for $\bar{x}$ with protoderivative mapping $DS(\bar{u}, \bar{v}|\bar{x}) : U \times X^* \rightrightarrows X$ given by

$$DS(\bar{u}, \bar{v}|\bar{x})(u, v) = \{x \in C' : \langle v - DF(\bar{x}, \bar{u})(x, u), c' - x\rangle \leq 0 \quad \forall\, c' \in C'\},$$

where $C' \subseteq X$ is defined by

$$C' := \overline{(\bar{v} - F(\bar{x}, \bar{u}))^{\perp} \bigcap \cup_{\lambda > 0} \lambda(C - \bar{x})}.$$

Theorem 1.1 is distinguished from previous work in this area in that it involves no explicit assumptions about the uniqueness (or even existence) of the solutions to the variational inequality. This is representative of a fundamental shift in how sensitivity analysis can be approached: By utilizing a generalized derivative like the protoderivative, we can focus on differential properties of solutions without having to simultaneously consider properties like uniqueness and continuity. These other important properties can then be studied separately and the results combined when a combination of the properties is desired. Our approach is fruitful since the protoderivative gives important sensitivity information even when uniqueness and continuity are not present. In particular, we show that the images of the protoderivative mapping are the sets of "directional derivatives" obtained by considering different curves tangential to a direction. Moreover, nothing is lost with this approach as we show that the protoderivative is the same as the usual directional derivative for continuous functions (here called the "semiderivative").

As a precursor to our main result, we analyze the second-order properties of convex polyhedric sets C by considering their associated "indicator functions" $\delta_C : X \to \mathbb{R} \cup \{\infty\}$ defined by

$$\delta_C(x) = \begin{cases} 0 & \text{if } x \in C, \\ \infty & \text{otherwise.} \end{cases}$$

We show that δ_C is "twice Mosco epi-differentiable at $\bar{x}$ for x^*" with second-order epi-derivative equal to the indicator function associated with the set

$$\overline{(x^*)^{\perp} \bigcap \cup_{\lambda > 0} \lambda(C - \bar{x})},$$

but the second-order directional derivative along a fixed direction is the indicator function associated with the set

$$(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C-\bar{x}).$$

These results are interesting in their own right, since they quantify the "straightness" of the boundaries of polyhedric sets in a way that distinguishes them from finite-dimensional polyhedral sets.

In the final two sections, we apply our results to abstract constrained optimization problems and we obtain results that complement those in [14] and [8]. Because our sensitivity analysis does not depend on the uniqueness of solutions, we avoid some of the strong conditions needed in [14] and [8]. Of course, the stronger conditions used by other authors give stronger consequences too. (For example, in [8] the existence, uniqueness, and Lipschitz continuity of solutions is obtained.) The abstract models that we study cover many important problems in infinite-dimensional optimization, including problems in parameterized optimal control.

2. Second-order analysis of convex polyhedric sets. The results in this section hold when X is any Banach space (not necessarily reflexive). To analyze the second-order properties of a closed, nonempty, convex polyhedric set $C \subseteq X$ at a point $\bar{x} \in C$, we fix a point x^* in the dual space X^* and construct the second-order difference quotient functions $\Delta_t^2(\bar{x}|x^*) : X \to \mathbb{R} \cup \{\infty\}$ as follows:

$$\Delta_t^2(\bar{x}|x^*)(x) := \frac{\delta_C(\bar{x}+tx) - \delta_C(\bar{x}) - t\langle x^*, x\rangle}{t^2/2}.$$

Notice that the term $\delta_C(\bar{x})$ contributes nothing since the point $\bar{x}$ is in the set C; however, we include this term so that the difference quotient will look familiar. The generalized second-order derivatives that we employ in this paper are defined as the Mosco epi-limits of the difference quotients $\Delta_t^2(\bar{x}|x^*)$. Recall from [2] that a family of functions $\Delta_t : X \to \mathbb{R} \cup \{\infty\}$ *Mosco epi-converges as* $t \downarrow 0$ to $\Delta : X \to \mathbb{R} \cup \{\infty\}$ if for every sequence of scalars $t_n \downarrow 0$, and every element $x \in X$, the two conditions hold that

$$\Delta(x) \leq \inf_{x_n \overset{w}{\to} x} \liminf_n \Delta_{t_n}(x_n),$$

$$\Delta(x) \geq \inf_{x_n \overset{s}{\to} x} \limsup_n \Delta_{t_n}(x_n),$$

where the superscripts w and s indicate weak and strong convergence, respectively. We say that the indicator function $\delta_C : X \to \mathbb{R} \cup \{\infty\}$ is *twice Mosco epi-differentiable at* $\bar{x}$ *for* x^* with second-order epi-derivative function $\delta_C''(\bar{x}|x^*) : X \to \mathbb{R} \cup \{\infty\}$ if the second-order difference quotients $\Delta_t^2(\bar{x}|x^*)$ Mosco epi-converge as $t \downarrow 0$ to $\delta_C''(\bar{x}|x^*)$ with $\delta_C''(\bar{x}|x^*)(0) = 0$. The second-order epi-derivative detects the curvature of the set C, as the following finite-dimensional example from [12] illustrates.

Example. Consider the half-disk in $\mathbb{R}^2$

$$C = \{x = (x_1, x_2) \in \mathbb{R}^2 : x_1^2 + x_2^2 \leq 2, x_1 - x_2 \leq 0\}$$

and its corner point $\bar{x} = (1,1)$. If we consider the point $x^* = (2,2)$ which solves the variational inequality $\langle x^*, c - \bar{x}\rangle \leq 0$ for all $c \in C$, we see that the second-order epi-derivative at $\bar{x}$ for x^* is

$$\delta_C''(\bar{x}|x^*)(x) = (x_1^2 + x_2^2) + \delta_{\{\lambda(-1,1):\lambda\geq 0\}}(x).$$

The $(x_1^2 + x_2^2)$ term is evidence that the second-order epi-derivative for the vector x^* in this case detects the curving on the semicircular boundary of C. In contrast, consider instead the point $x^* = (2, -2)$ which also solves the variational inequality $\langle x^*, c - \bar{x}\rangle \leq 0$ for all $c \in C$. In this case, the second-order epi-derivative at $\bar{x}$ for x^* is

$$\delta''_C(\bar{x}|x^*)(x) = \delta_{\{\lambda(-1,-1):\lambda\geq 0\}}(x).$$

The second-order epi-derivative for this vector x^* detects only the straight side of C.

Recall that a convex set C in $\mathbb{R}^n$ is called *polyhedral* if it can be specified by finitely many linear constraints. The boundaries of such sets thus consist of finitely many straight pieces. It can be deduced from [12, Exercise 13.17] that for any convex polyhedral set $C \subseteq \mathbb{R}^n$, the indicator function δ_C is twice (Mosco) epi-differentiable at any point $\bar{x} \in C$ for any point $x^* \in X^*$ solving the variational inequality $\langle x^*, c-x\rangle \leq 0$ for all $c \in C$. Moreover, the second-order epi-derivative in this case is the indicator function associated with the set

$$\overline{(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C - \bar{x})},$$

so the second-order epi-derivative in this case detects the (lack of) curvature of the set C. The following theorem shows that this property extends to polyhedric sets on Banach spaces, a result which supports the claim that polyhedric sets are a reasonable generalization of polyhedral sets.

THEOREM 2.1. *Consider a closed, nonempty, convex set C in a Banach space X that is polyhedric at $\bar{x} \in C$ and a point $x^* \in X^*$ satisfying $\langle x^*, c-\bar{x}\rangle \leq 0$ for all $c \in C$. Then the indicator function $\delta_C : X \to \mathbb{R} \cup \{\infty\}$ is twice Mosco epi-differentiable at $\bar{x}$ for x^* and the second-order epi-derivative $\delta''_C(\bar{x}|x^*)$ satisfies*

$$\delta''_C(\bar{x}|x^*)(x) = \begin{cases} 0 & \text{if } x \in \overline{(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C - \bar{x})}, \\ \infty & \text{otherwise.} \end{cases}$$

Proof. To prove this result, we need to verify that for any $t_n \downarrow 0$ and any $x_n \xrightarrow{w} x$, the difference quotient functions $\Delta_t^2(\bar{x}|x^*)$ satisfy

$$\liminf_n \Delta^2_{t_n}(\bar{x}|x^*)(x_n) \geq \begin{cases} 0 & \text{if } x \in \overline{(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C - \bar{x})}, \\ \infty & \text{otherwise.} \end{cases} \tag{2.1}$$

From the definition of the difference quotient functions, it is clear that $\Delta^2_{t_n}(\bar{x}|x^*)(x_n)$ equals infinity unless $\bar{x} + t_n x_n \in C$, so if there is no sequence $\{x_n\}$ weakly converging to x and satisfying $\bar{x} + t_n x_n \in C$, then the limit inferior in (2.1) is infinity for all weakly converging sequences $x_n \xrightarrow{w} x$, and the inequality (2.1) is verified. We thus assume that there exists a sequence $x_n \xrightarrow{w} x$ with $\bar{x} + t_n x_n \in C$. In this case, according to the assumption about the point x^*, the inner product $\langle x^*, t_n x_n\rangle$ is nonpositive. It follows that the value of the difference quotient for t_n evaluated at x_n always satisfies

$$\Delta^2_{t_n}(\bar{x}|x^*)(x_n) \geq 0. \tag{2.2}$$

Thus, the only part of inequality (2.1) that needs to be verified is that the limit inferior of $\Delta^2_{t_n}(\bar{x}|x^*)(x_n)$ equals infinity when $x \notin \overline{(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C - \bar{x})}$. Since C is polyhedric at $\bar{x}$ for x^*, the set $\overline{(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C - \bar{x})}$ is the same as the set

$(x^*)^\perp \bigcap \overline{\cup_{\lambda>0}\lambda(C-\bar{x})}$, so to verify the inequality (2.1) in this case, we assume either that x is not perpendicular to x^* or that x is not an element of the set $\overline{\cup_{\lambda>0}\lambda(C-\bar{x})}$. We show first that this latter case cannot occur.

Case. $x \notin \overline{\cup_{\lambda>0}\lambda(C-\bar{x})}$ cannot occur. Since we have assumed throughout that $\bar{x}+t_n x_n \in C$ with $x_n \stackrel{w}{\to} x$, it follows that $x_n \in \cup_{\lambda>0}\lambda(C-\bar{x})$ so that x is in the weak closure of the set $\cup_{\lambda>0}\lambda(C-\bar{x})$. However, the set $\cup_{\lambda>0}\lambda(C-\bar{x})$ is convex (since C is convex) so its weak closure is the same as its strong closure $\overline{\cup_{\lambda>0}\lambda(C-\bar{x})}$. We conclude that $x \in \overline{\cup_{\lambda>0}\lambda(C-\bar{x})}$.

Case. $\langle x^*, x\rangle \neq 0$. Since $\bar{x}+t_n x_n \in C$, the difference quotient for t_n evaluated at x_n satisfies

$$\Delta^2_{t_n}(\bar{x}|x^*)(x_n) = \frac{-t_n\langle x^*, x_n\rangle}{t_n^2/2}. \tag{2.3}$$

However, since the term $\langle x^*, x_n\rangle$ converges to $\langle x^*, x\rangle$ which is nonzero in this case, it follows from (2.3) and the inequality (2.2) that the limit inferior of the difference quotient for t_n evaluated at x_n is infinity.

This establishes the inequality (2.1), so we will be finished if we can also verify that for any $t_n \downarrow 0$, there exists $x_n \stackrel{s}{\to} x$ satisfying the inequality

$$\limsup_n \Delta^2_{t_n}(\bar{x}|x^*)(x_n) \leq \begin{cases} 0 & \text{if } x \in \overline{(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C-\bar{x})}, \\ \infty & \text{otherwise.} \end{cases} \tag{2.4}$$

It follows immediately that we need only consider the case

$$x \in \overline{(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C-\bar{x})},$$

which implies that there exists a sequence $\xi_n \stackrel{s}{\to} x$ satisfying $\langle x^*, \xi_n\rangle = 0$ and with $\xi_n \in \lambda_n(C-\bar{x})$ for some positive scalars λ_n. For any $t \in [0, 1/\lambda_n]$, we can write

$$\bar{x}+t\xi_n = (1-t\lambda_n)\bar{x} + t\lambda_n(\bar{x}+\xi_n/\lambda_n),$$

which is a convex combination of elements in C. From the convexity of C, we conclude that any such points $\bar{x}+t\xi_n$ are contained in C. We construct a sequence of points x_n from the sequence $\{\xi_n\}$ in the following manner. We set $x_1 = \xi_1$, $x_2 = \xi_1, \ldots, x_n = \xi_1$ for all n until t_n is smaller than $1/\lambda_2$, at which point we begin setting $x_n = \xi_2$ for all n until t_n is less than $1/\lambda_3$ and continue this process ad infinitum. The resulting sequence $\{x_n\}$ converges strongly to x, satisfies $\langle x^*, x_n\rangle = 0$, and has $\bar{x}+t_n x_n \in C$ for all n larger than the one where we began using ξ_2. It follows that the difference quotient for t_n evaluated at these x_n equals zero, so that its limit superior satisfies the inequality (2.4).

The second-order epi-derivative proposed in this case equals zero when evaluated at zero, so the proof is complete. □

In order to see how the second-order epi-derivative compares to a more classical notion of second-order directional derivative, we consider a point $\bar{x} \in C$ and a point $x^* \in X^*$ satisfying $\langle x^*, c-\bar{x}\rangle \leq 0$ for all $c \in C$, and take the limit as $t \downarrow 0$ of the difference quotient functions $\Delta^2_t(\bar{x}|x^*)$ in a fixed direction x:

$$\lim_{t\downarrow 0} \frac{\delta_C(\bar{x}+tx) - \delta_C(\bar{x}) - t\langle x^*, x\rangle}{t^2/2}. \tag{2.5}$$

PROPOSITION 2.1. *Consider a closed, nonempty, convex set C in the Banach space X, a point $\bar{x} \in C$ and a point $x^* \in X^*$ satisfying $\langle x^*, c - \bar{x}\rangle \leq 0$ for all $c \in C$. Then the second-order directional derivative along any fixed direction $x \in X$ satisfies*

$$\lim_{t \downarrow 0} \frac{\delta_C(\bar{x} + tx) - \delta_C(\bar{x}) - t\langle x^*, x\rangle}{t^2/2} = \begin{cases} 0 & \text{if } x \in (x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C - \bar{x}), \\ \infty & \text{otherwise.} \end{cases}$$

Proof. Just as in the proof of Theorem 2.1, if $x \in \lambda(C - \bar{x})$, then we know that $\bar{x} + tx \in C$ for all $t \in [0, 1/\lambda]$. It follows that if x is an element of the intersection $(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C - \bar{x})$, then the limit (2.5) is equal to zero. Moreover, the difference quotient in (2.5) is always nonnegative (again according to an argument similar to the one in the proof of Theorem 2.1), so if x is not perpendicular to x^*, then the limit (2.5) is infinite. Finally, if x is not in the set $\cup_{\lambda>0}\lambda(C - \bar{x})$ it follows that the term $\delta_C(\bar{x} + tx)$ is infinite for all $t > 0$, so the limit (2.5) is infinite too. ∎

It follows from Theorem 2.1 and Proposition 2.1 that the second-order epi-derivative is the same as the second-order directional derivative along a fixed direction if and only if the set $(x^*)^\perp \bigcap \cup_{\lambda>0}\lambda(C - \bar{x})$ is closed. This always occurs when C is a polyhedral set in $\mathbb{R}^n$, so that the two second-order derivatives agree in the case of polyhedral C. However, this is not necessarily true for polyhedric sets in Banach spaces, as the following example shows.

Example. Consider the Banach space X of continuous functions on the interval $[-1, 1]$ under the supremum norm

$$\| x \| := \sup_{\tau \in [-1,1]} |x(\tau)|,$$

the set $C = \{x \in X : x(\tau) \leq 0 \text{ for all } \tau \in [-1, 1]\}$, and the function $\bar{x} \in C$ defined by $\bar{x}(\tau) = -\tau^4$. This set C is trivially polyhedric at $\bar{x}$ for $x^* = 0 \in X^*$ (any set is polyhedric at all of its points for $x^* = 0$). Now consider the function $x \in X$ defined by $x(\tau) = \tau^2$. In order for x to be an element of the set $\cup_{\lambda>0}\lambda(C - \bar{x})$, there must be some $\lambda > 0$ with $\tau^2 \leq \lambda\tau^4$ for all $\tau \in [-1, 1]$. Since no such λ exists, we conclude that x is not in the set $\cup_{\lambda>0}\lambda(C - \bar{x})$. However, if we define the continuous functions x_n on $[-1, 1]$ by

$$x_n(\tau) := \begin{cases} n\tau^4 & \text{for } \tau \in \left[-\sqrt{\frac{1}{n}}, \sqrt{\frac{1}{n}}\right], \\ \tau^2 & \text{for } \tau < -\sqrt{\frac{1}{n}} \text{ or } \tau > \sqrt{\frac{1}{n}}, \end{cases}$$

then these converge to x as $n \to \infty$ and satisfy $x_n \in n(C - \bar{x})$. Therefore, x is contained in $\overline{\cup_{\lambda>0}\lambda(C - \bar{x})}$. It follows that the second-order epi-derivative satisfies $\delta''_C(\bar{x}|x^*)(x) = 0$, while the second-order directional derivative along the fixed direction x (2.5) is infinite.

This example highlights the fact that polyhedric sets in Banach spaces have properties distinct from polyhedral sets in $\mathbb{R}^n$. In particular, polyhedric sets C in Banach spaces have "straight" boundaries as detected by the second-order epi-derivative $\delta''_C(\bar{x}|x^*)$. However, this straightness is not the same as it is for polyhedral sets whose boundary "straightness" is also detected by the second-order directional derivative along fixed directions (2.5).

3. Protoderivatives of solutions to variational inequalities. It is convenient to represent the solutions to the variational inequality (1.1) as the values of the multifunction $S : U \times X^* \rightrightarrows X$ defined by

$$S(u, v) := \{x : v - F(x, u) \in N_C(x)\}, \tag{3.1}$$

where the normal cone mapping $N_C : X \rightrightarrows X^*$ associated with the set C is defined for $x \in X$ by

$$N_C(x) := \begin{cases} \{x^* : \langle x^*, c - x\rangle \le 0 \text{ for all } c \in C\} & \text{if } x \in C, \\ \emptyset & \text{otherwise.} \end{cases} \tag{3.2}$$

"Protoderivatives" of these kinds of solution multifunctions have been studied in [6], where they are shown to depend on the protodifferentiability of the normal cone mapping N_C. The protoderivative of any multifunction $S : Z \rightrightarrows Y$ between two Banach spaces can be defined in terms of the contingent cone to the graph of S at $(\bar{z}, \bar{y}) \in \operatorname{gph} S$:

$$T_{\operatorname{gph} S}(\bar{z}, \bar{y}) := \limsup_{t \downarrow 0} \frac{\operatorname{gph} S - (\bar{z}, \bar{y})}{t},$$

defined in terms of "$\limsup_{t \downarrow 0}$" denoting the outer set limit as $t \downarrow 0$, which is the set of all points obtained as limits of points in the sets $\big(\operatorname{gph} S - (\bar{z}, \bar{y})\big)/t_n$ for some sequence $t_n \downarrow 0$. The multifunction $S : Z \rightrightarrows Y$ is *protodifferentiable at $\bar{z}$ for $\bar{y}$* if every element in the contingent cone $T_{\operatorname{gph} S}(\bar{z}, \bar{y})$ can actually be obtained as a limit

$$\lim_{t \downarrow 0} \frac{\xi(t) - (\bar{z}, \bar{y})}{t} \tag{3.3}$$

for some selection mapping $\xi : [0, \epsilon] \to \operatorname{gph} S$ with $\epsilon > 0$. Under these circumstances, the protoderivative of S at $\bar{z}$ for $\bar{y}$ is the multifunction $DS(\bar{z}|\bar{y}) : Z \rightrightarrows Y$ whose graph is the contingent cone $T_{\operatorname{gph} S}(\bar{z}, \bar{y})$. The following is a consequence of the second-order Mosco epi-differentiability demonstrated in Theorem 2.1.

THEOREM 3.1. *Consider a closed, nonempty, convex set C in a reflexive Banach space X that is polyhedric at $\bar{x} \in C$ and a point $x^* \in X^*$ satisfying $\langle x^*, c - \bar{x}\rangle \le 0$ for all $c \in C$. Then the normal cone mapping $N_C : X \rightrightarrows X^*$ is protodifferentiable at $\bar{x}$ for x^* with protoderivative equal to the normal cone mapping associated with the set*

$$C' := \overline{(x^*)^\perp \bigcap \cup_{\lambda > 0} \lambda(C - \bar{x})}.$$

Proof. This follows from Theorem 2.1 and [11, Theorem 5] since the normal cone mapping associated with a convex set is the convex subdifferential of the indicator function. □

Remark. The result [11, Theorem 5] used in the proof of Theorem 3.1 is based on Attouch's theorem [1], which connects the epi-convergence of convex functions on reflexive Banach spaces with the graphical convergence of their subgradient mappings. Because of this connection, Theorem 3.1 itself must be stated in terms of reflexive Banach spaces instead of the more general Banach spaces considered in section 2. Our main result, Theorem 1.1, follows immediately from results now obtained.

Proof of Theorem 1.1. This follows immediately from Theorem 3.1 and [6, Theorem 4.1]. The latter result gave the protodifferentiability of general solution mappings of the form

$$S(u, v) := \{x : v - F(x, u) \in M(x, u)\}$$

as long as F is semidifferentiable and the set-valued mapping M is protodifferentiable. According to Theorem 3.1, the normal cone mapping N_C studied here is one example

of a protodifferentiable set-valued mapping M, so the protodifferentiability of the solution mapping (3.1) follows from [6, Theorem 4.1]. Moreover, a formula was given in [6, Theorem 4.1] for the protoderivative of the general solution mapping, and this formula specializes in the case of (3.1) to the formula claimed in the statement of Theorem 1.1. □

Remark. Note that it is important that the parameter $v \in X^*$ appear in the variational inequality (1.1) if we are to deduce protodifferentiability from [6, Theorem 4.1]. If the solution mapping (3.1) does not depend explicitly on v, we can obtain estimates for related generalized derivatives called "outer graphical derivatives" via [5].

Protoderivatives for multifunctions between two Euclidean spaces have been studied widely (see [12] for a survey), where they have been shown to have many useful properties. In the case when S is a (single-valued) continuous function, the protoderivative is related closely to the "semiderivative." A continuous function $S : Z \to Y$ between two Banach spaces is *semidifferentiable at $\bar{z}$ with semiderivative $DS(\bar{z}) : Z \to Y$* if for every $\phi : \mathbb{R}^+ \to Z$ for which $(\phi(t) - \bar{z})/t$ converges to some point $z \in Z$, the limit exists

$$DS(\bar{z})(z) = \lim_{t \downarrow 0} \frac{S(\phi(t)) - S(\bar{z})}{t}.$$

(See [13] for a discussion of equivalent definitions of this derivative which the author calls the "Hadamard" directional derivative.) It was shown in [7] that a locally Lipschitzian mapping $S : \mathbb{R}^n \to \mathbb{R}^m$ is protodifferentiable at $\bar{z}$ for $\bar{y} = S(\bar{z})$ if and only if it is semidifferentiable at $\bar{z}$. (An equivalent derivative called the "B-derivative" was used in [7].) The following proposition clarifies the relationship between the protoderivative and the semiderivative in the case of continuous functions between two Banach spaces.

PROPOSITION 3.1. (i) *If the continuous function $S : Z \to Y$ is semidifferentiable at $\bar{z}$, then S is protodifferentiable at $\bar{z}$ for $\bar{y} = S(\bar{z})$ with protoderivative $DS(\bar{z}|\bar{y})$ equal to the semiderivative $DS(\bar{z})$.*

(ii) *If the multifunction $S : Z \to Y$ is protodifferentiable at $\bar{z}$ for $\bar{y} = S(\bar{z})$, then for any $\phi : \mathbb{R}^+ \to Z$ with $(\phi(t) - \bar{z})/t \to z$ and $\big(S(\phi(t)) - S(\bar{z})\big)/t \to y$ as $t \downarrow 0$, the limit y is in the image of the protoderivative $DS(\bar{z}|\bar{y})(z)$.*

Proof. (i) We consider any pair (z, y) in the contingent cone to the graph of S at $(\bar{z}, \bar{y})$. Then there exist sequences $t_n \downarrow 0$ and $(z_n, y_n) \to (z, y)$ which satisfy

$$y_n \in \frac{S(\bar{z} + t_n z_n) - \bar{y}}{t_n}.$$

Since S is semidifferentiable at $\bar{z}$, it follows that y must be equal to the semiderivative evaluated in the direction z, so the protoderivative (if it exists) is equal to the semiderivative. Moreover, if we define the selection mapping $\xi(t) := (\bar{z} + tz, S(\bar{z} + tz))$, the limit (3.3) satisfies

$$\lim_{t \downarrow 0} \frac{\xi(t) - (\bar{z}, S(\bar{z}))}{t} = \left(z, \lim_{t \downarrow 0} \frac{S(\bar{z} + tz) - S(\bar{z})}{t} \right) = (z, y),$$

so S is protodifferentiable at $\bar{z}$ for $\bar{y} = S(\bar{z})$.

(ii) For any sequence $t_n \downarrow 0$, the sequences $z_n := (\phi(t_n) - \bar{z})/t_n$ and $y_n := \big(S(\phi(t_n) - S(\bar{z})\big)/t_n$ satisfy

$$(z_n, y_n) \in \frac{\operatorname{gph} S - (\bar{z}, \bar{y})}{t_n}$$

and converge to z and y, respectively. It follows that the pair (z, y) is in the contingent cone to $\operatorname{gph} S$ at $(\bar{z}, \bar{y})$, which is the same as the graph of the protoderivative $DS(\bar{z}|\bar{y})$. □

According to the definition of the protoderivative, each element in the set $DS(\bar{z}|\bar{y})(z)$ can be obtained as the limit of $\big(S(\phi(t)) - \bar{z}\big)/t$ for some ϕ as in (ii) of Theorem 3.1. This fact together with part (ii) of Theorem 3.1 shows that the image of the protoderivative $DS(\bar{z}|\bar{y})(z)$ is precisely the set of "directional derivatives" obtained by considering different curves ϕ tangential to the direction z.

4. Sensitivity of stationary points. We consider the optimization problem

$$\min\ g_0(x, u) - \langle v, x\rangle \text{ over all } x \in C, \tag{4.1}$$

where C is a closed, nonempty, convex set in a reflexive Banach space X, and the functional $g_0 : X \times U \to \mathbb{R}$ is continuously differentiable with respect to x. The stationary points associated with this problem for parameters $u \in U$ and $v \in X^*$ are the solutions to the variational inequality

$$v - \nabla_x g_0(x, u) \in N_C(x),$$

this being a first-order necessary condition for optimality in (4.1).

THEOREM 4.1. *Consider the parameters $\bar{v} \in X^*$ and $\bar{u} \in U$ together with a stationary point $\bar{x} \in C$ satisfying $\bar{v} - \nabla_x g_0(\bar{x}, \bar{u}) \in N_C(\bar{x})$. If the gradient mapping $\nabla_x g_0$ is semidifferentiable at $(\bar{x}, \bar{u})$ and the set C is polyhedric at $\bar{x}$ for $\bar{v} - \nabla_x g_0(\bar{x}, \bar{u})$, then the stationary point mapping*

$$S(u, v) := \{x \in C : v - \nabla_x g_0(x, u) \in N_C(x)\}$$

is protodifferentiable at $(\bar{u}, \bar{v})$ for $\bar{x}$ with protoderivative mapping $DS(\bar{u}, \bar{v}|\bar{x}) : U \times X^* \rightrightarrows X$ given by

$$DS(\bar{u}, \bar{v}|\bar{x})(u, v) = \big\{x \in C' : v - D\big(\nabla_x g_0\big)(\bar{x}, \bar{u})(x, u) \in N_{C'}(x)\big\},$$

where $C' \subseteq X$ is defined by

$$C' := \overline{(\bar{v} - \nabla_x g_0(\bar{x}, \bar{u}))^\perp \bigcap \cup_{\lambda>0} \lambda(C - \bar{x})}.$$

Proof. This follows immediately from Theorem 1.1. □

Theorem 4.1 compares to [14, Theorem 2], where an abstract optimal control problem is shown to have semidifferentiable solutions. In contrast to Theorem 4.1, however, strong second-order conditions were needed in [14, Theorem 2] to ensure unique solutions to the variational inequality.

5. Sensitivity of Karush–Kuhn–Tucker pairs. Our results also apply to solution-multiplier pairs associated with optimization problems like

$$\min\ g_0(x, u) - \langle v_1, x\rangle \text{ over all } x \in C(u, v_2), \tag{5.1}$$

where the constraint set $C(u, v_2)$ is defined for parameters $u \in U$ and $v_2 \in Y^*$ by

$$C(u, v_2) := \{x \in C : v_2 + g(x, u) \in K\}$$

for a mapping $g : X \times U \to Y^*$ that is continuously differentiable with respect to x, a closed, nonempty, convex set C in a reflexive Banach space X and a closed, nonempty,

convex cone K (with vertex at the origin) in a reflexive Banach space Y. For such an optimization problem, we can construct the Lagrangian

$$L(x,u,y) := g_0(x,u) + \langle y, g(x,u)\rangle,$$

in terms of which we can represent the Karush–Kuhn–Tucker (KKT) pairs $(x,y) \in C \times K^*$ (where K^* is polar cone to K, containing the elements $y^* \in Y^*$ which satisfy $\langle y^*, y\rangle \le 0$ for all $y \in K$) for the problem (5.1) which satisfy

$$v_1 - \nabla_x L(x,u,y) \in N_C(x), \quad v_2 + g(x,u) \in N_{K^*}(y). \tag{5.2}$$

The set of KKT pairs satisfying (5.2) for parameters (u, v_1, v_2) is the same as the image of the mapping

$$\begin{aligned} S(u,v_1,v_2) := \{(x,y) \in C \times K^* : (v_1,v_2) \\ - \big(\nabla_x L(x,u,y), -g(x,u)\big) \in N_{C\times K^*}(x,y)\big\}. \end{aligned} \tag{5.3}$$

This follows since the product set $N_C(x) \times N_{K^*}(y)$ is the same as the normal cone of the product $C \times K^*$ at the point (x,y).

THEOREM 5.1. *Consider the parameters $\bar v = (\bar v_1, \bar v_2) \in V := X^* \times Y^*$ and $\bar u \in U$ together with a KKT pair $(\bar x, \bar y) \in C \times K^*$. If the gradient mapping $\nabla_x L$ is semidifferentiable at $(\bar x, \bar u, \bar y)$, the mapping g is semidifferentiable at $(\bar x, \bar u)$, and the set $C \times K^*$ is polyhedric at $(\bar x, \bar y)$ for $\bar v - \big(\nabla_x L(\bar x, \bar u, \bar y), -g(\bar x, \bar u)\big)$, then the KKT-pair mapping* (5.3) *is protodifferentiable at $(\bar u, \bar v)$ for $(\bar x, \bar y)$ with protoderivative $DS(\bar u, \bar v|\bar x, \bar y) : U \times V \rightrightarrows X \times Y$ given by*

$$\begin{aligned} &DS(\bar u, \bar v|\bar x, \bar y)(u,v) \\ &\quad = \Big\{(x,y) \in C' : v - \Big(D\big(\nabla_x L\big)(\bar x, \bar u, \bar y)(x,u,y), -Dg(\bar x, \bar u)(x,u)\Big) \in N_{C'}(x,y)\Big\}, \end{aligned}$$

where $C' \subseteq X \times Y$ is defined by

$$C' := \overline{\Big(\bar v - \big(\nabla_x L(\bar x, \bar u, \bar y), -g(\bar x, \bar u)\big)\Big)^{\perp} \bigcap \cup_{\lambda>0} \lambda\big(C \times K^* - (\bar x, \bar y)\big)}.$$

Proof. This follows from Theorem 1.1 since under our assumptions, the mapping

$$(x,u,y) \mapsto \big(\nabla_x L(x,u,y), -g(x,u)\big)$$

is semidifferentiable at $(\bar x, \bar u, \bar y)$ with semiderivative

$$\Big(D\big(\nabla_x L\big)(\bar x, \bar u, \bar y)(x,u,y), -Dg(\bar x, \bar u)(x,u)\Big). \qquad \square$$

This result compares to results in [8] and [9], where second-order conditions and regularity conditions were used to guarantee unique KKT pairs that are Lipschitz continuous and semidifferentiable. Related results are given in [3], where similar but weaker conditions were used to study the directional stability of nearly optimal solution selections.

RISK-SENSITIVE CONTROL OF DISCRETE-TIME MARKOV PROCESSES WITH INFINITE HORIZON*

G. B. DI MASI† AND L. STETTNER‡

Abstract. In this paper we study existence of solutions to the Bellman equation corresponding to risk-sensitive ergodic control of discrete-time Markov processes using three different approaches. Also, for particular classes of systems, asymptotics for vanishing risk factor is investigated, showing that in the limit the optimal value for an average cost per unit time is obtained.

Key words. controlled discrete-time Markov processes, exponential ergodic performance criterion, Bellman equation

PII. S0363012997320614

1. Introduction.

On a probability space $(\Omega, \mathcal{F}, P)$ consider a controlled Markov process $X = (x_n)$ taking values on a complete separable metric state space E endowed with the Borel σ-algebra $\mathcal{E}$. Assume that x_n has a controlled transition operator $P^{a_n}(x_n, \cdot)$, where a_n is the control at time n taking values on a compact metric space U and adapted to the σ-algebra $\sigma\{x_0, x_1, \ldots, x_n\}$.

Let $c : E \times U \to R^+$ be a continuous and bounded function. Our aim is to minimize the following exponential ergodic performance criterion:

$$J_x\big((a_n)\big) = \lim_{n\to\infty} \sup \frac{1}{n} \log E_x \left\{ \exp \left\{ \sum_{i=0}^{n-1} c(x_i, a_i) \right\} \right\}. \tag{1.1}$$

Consider the following assumption:

(B1) $\forall f \in C(E)$ the mapping $E \times U \ni (x, a) \mapsto P^a f(x)$ is continuous.

In (B1) and in what follows we shall denote by $C(E)$ the space of continuous bounded real valued functions on E endowed with the uniform norm $||\cdot||$.

The following result that is proved in [10, Theorem 2.1] for countable state space can be easily extended to our general state space model.

PROPOSITION 1.1. *If there exists a function $w \in C(E)$ and a constant λ such that for $x \in E$,*

$$e^{w(x)+\lambda} = \inf_{a\in U} \left[e^{c(x,a)} \int_E e^{w(y)} P^a(x, dy) \right], \tag{1.2}$$

then under (B1)

$$\lambda = \inf_{(a_n)} J_x\big((a_n)\big) = J_x\big(u(x_n)\big), \tag{1.3}$$

where $u : E \to U$ is a Borel function for which the inf *in* (1.2) *is attained.*

Infinite horizon risk-sensitive problems were studied for linear diffusions with exponential quadratic cost in a series of papers (see, e.g., [15], [8], [13], and references therein). General diffusion models were studied in [11] and [7]. Risk-sensitive control of Markov processes with cost criterion (1.1) was studied only in [9] and [6].

Our work was motivated by [9], where the existence of solutions to the Bellman equation (1.2) is proved for countable state space under the assumption of the existence of a uniformly (with respect to all stationary Markov controls and initial states) positive recurrent state.

In this paper we show the existence of solutions to the Bellman equation under different assumptions and using different approaches. In particular, in section 2 we show the existence of a unique solution using a certain span-norm contraction. In section 3 we study the discounted exponential cost criterion and prove the convergence of the solution to the discounted Bellman equation to the solution of (1.2) when the discount factor approaches 1. In section 4 we show the existence of solutions to the Bellman equation using the so-called stochastic discounted game approach. We then complete the paper studying in section 5 the asymptotic behavior for vanishing risk factor and showing that the limit corresponds to the average cost per unit time problem. Although we formulate our results for general states, the assumptions imposed in this paper seem to be rather restrictive if the state space is not compact. We also assume that the cost function $c(x, a)$ is bounded, similarly as in the span approach to risk neutral problems in section 3.3 of [10]. Nevertheless we think that this paper could motivate further research on extending the results under weaker assumptions.

2. Span contraction approach. Notice first that due to Lemma 3.3 in [9] or Proposition 2.3 in [3], (1.2) can be written in the following equivalent form:

$$w(x) + \lambda = \inf_{a \in U} \sup_{\mu \in \mathcal{P}(E)} \left[c(x,a) + \int_E w(y)\mu(dy) - I\big(\mu, P^a(x,\cdot)\big) \right], \tag{2.1}$$

where $\mathcal{P}(E)$ is the space of probability measures on E and $I(\mu, \nu)$, called mutual entropy of μ and ν is defined as follows:

$$I(\mu,\nu) = \begin{cases} \displaystyle\int_E \log \tfrac{d\mu}{d\nu}\, \mu\,(dx) & \text{when } \mu \text{ is absolutely continuous with respect to } \nu, \\ +\infty & \text{otherwise.} \end{cases}$$

Moreover, the sup in (2.1) is attained for

$$\mu^*(dz) = \frac{e^{w(z)} P^a(x, dz)}{\int_E e^{w(y)} P^a(x, dy)}.$$

Remark 2.1. The function w in (2.1) corresponds to the upper value in a two person stochastic dynamic game when the first player (minimizer) chooses at each step a control parameter a while the second player chooses the system dynamics, given by the measure μ, so as to maximize the reward function

$$\limsup_{n\to\infty} n^{-1} E_x \left\{ \sum_{i=0}^{n-1} \Big(c(x_i, a_i) - I\big(\mu_i, P^{a_i}(x_i, \cdot)\big) \Big) \right\} \tag{2.2}$$

(see [9], where a similar discounted game was considered).

The following assumption (A1) is frequently imposed for studying average cost per unit time problems (see, e.g., [10]):

(A1) $\exists_{\delta<1}$ such that $\forall_{x,x'\in E}$, $\forall_{a,a'\in U}$, $\forall_{B\in\mathcal{E}}$

$$P^a(x,B) - P^{a'}(x',B) \le \delta.$$

For $g \in C(E)$ define the operator

$$Tg(x) = \inf_{a\in U}\left[c(x,a) + \log\int_E e^{g(y)}P^a(x,dy)\right] \tag{2.3}$$

which, by Lemma 3.3 in [9] or Proposition 2.3 in [3], takes the equivalent form

$$Tg(x) = \inf_{a\in U}\sup_{\mu\in\mathcal{P}(E)}\left[c(x,a) + \int_E g(y)\mu(dy) - I\big(\mu, P^a(x,\cdot)\big)\right]. \tag{2.4}$$

The sup in (2.4) is attained for

$$\mu^*(B) = \frac{\int_B e^{g(z)}P^a(x,dz)}{\int_E e^{g(z)}P^a(x,dz)}. \tag{2.5}$$

PROPOSITION 2.2. *Under* (A1) *and* (B1) *the operator* T *is a local contraction in* $C(E)$ *endowed with the span norm* $||g||_{sp} = \sup_{x\in E} g(x) - \inf_{x\in E} g(x)$*; namely, for each* $M > 0$*, there exists a constant* $\alpha(M) < 1$ *such that for each* $g_1, g_2 \in C(E)$ *with* $||g_1||_{sp} \le M$ *and* $||g_2||_{sp} \le M$ *we have*

$$||Tg_1 - Tg_2||_{sp} \le \alpha(M)||g_1 - g_2||_{sp}. \tag{2.6}$$

Proof. Because of assumption (B1) formula (2.3) shows that T transforms $C(E)$ into itself and the inf is attained.

For given functions g_1, g_2 in $C(E)$ and $x_1, x_2 \in E$, let a_1, a_2 be such that

$$Tg_i(x_i) = \sup_{\mu\in\mathcal{P}(E)}\left\{c(x_i,a_i) + \int g_i(y)\mu(dy) - I\big(\mu, P^{a_i}(x_i,\cdot)\big)\right\}.$$

Moreover, let

$$\mu_1(B) = \frac{\int_B e^{g_2(z)}P^{a_1}(x_1,dz)}{\int_E e^{g_2(z)}P^{a_1}(x_1,dz)},$$
$$\mu_2(B) = \frac{\int_B e^{g_1(z)}P^{a_2}(x_2,dz)}{\int_E e^{g_1(z)}P^{a_2}(x_2,dz)}.$$

Then

$$
\begin{aligned}
&Tg_1(x_2) - Tg_2(x_2) - \big(Tg_1(x_1) - Tg_2(x_1)\big) \\
&\le \sup_{\mu\in\mathcal{P}(E)} \left\{ c(x_2,a_2) + \int_E g_1(y)\mu(dy) - I\big(\mu, P^{a_2}(x_2,\cdot)\big) \right\} \\
&- \sup_{\mu\in\mathcal{P}(E)} \left\{ c(x_2,a_2) + \int_E g_2(y)\mu(dy) - I\big(\mu, P^{a_2}(x_2,\cdot)\big) \right\} \\
&- \sup_{\mu\in\mathcal{P}(E)} \left\{ c(x_1,a_1) + \int_E g_1(y)\mu(dy) - I\big(\mu, P^{a_1}(x_1,\cdot)\big) \right\} \\
&+ \sup_{\mu\in\mathcal{P}(E)} \left\{ c(x_1,a_1) + \int_E g_2(y)\mu(dy) - I\big(\mu, P^{a_1}(x_1,\cdot)\big) \right\} \\
&\le c(x_2,a_2) + \int_E g_1(y)\mu_2(dy) - I\big(\mu_2, P^{a_2}(x_2,\cdot)\big) \qquad (2.7)\\
&-c(x_2,a_2) - \int_E g_2(y)\mu_2(dy) + I\big(\mu_2, P^{a_2}(x_2,\cdot)\big) \\
&-c(x_1,a_1) - \int_E g_1(y)\mu_1(dy) + I\big(\mu_1, P^{a_1}(x_1,\cdot)\big) \\
&+c(x_1,a_1) + \int_E g_2(y)\mu_1(dy) - I\big(\mu_1, P^{a_1}(x_1,\cdot)\big) \\
&= \int_E \big(g_1(y) - g_2(y)\big)(\mu_2-\mu_1)(dy) \le \sup_{y\in E}\big(g_1(y) - g_2(y)\big)(\mu_2-\mu_1)(\Gamma) \\
&+ \inf_{y\in E}\big(g_1(y) - g_2(y)\big)(\mu_2-\mu_1)(\Gamma^c) = ||g_1 - g_2||_{sp}(\mu_2-\mu_1)(\Gamma),
\end{aligned}
$$

where the set Γ comes from the Hahn–Jordan decomposition of $\mu_2 - \mu_1$.

Consequently, taking sup over $x_1, x_2 \in E$ in (2.7) we have

$$
||Tg_1 - Tg_2||_{sp} \le ||g_1 - g_2||_{sp} \sup_{B\in\mathcal{E}} \sup_{x,x'\in E} \sup_{a,a'\in U} (\mu_{xag_1} - \mu_{x'a'g_2})(B), \tag{2.8}
$$

where

$$
\mu_{xag}(B) = \frac{\int_B e^{g(z)} P^a(x,dz)}{\int_E e^{g(z)} P^a(x,dz)}.
$$

To complete the proof it then remains to show that

$$
\sup_{g_1,g_2;||g_1||_{sp},||g_2||_{sp}\le M} \sup_{B\in\mathcal{E}} \sup_{x,x'\in E} \sup_{a,a'\in U} (\mu_{xag_1} - \mu_{x'a'g_2})(B) = \alpha(M) < 1. \tag{2.9}
$$

Suppose (2.9) does not hold. Then there exist sequences (g_{1n}), (g_{2n}) with $||g_{1n}||_{sp}$, $||g_{2n}||_{sp} \le M$, (B_n), $B_n \in \mathcal{E}$, (x_n), (x'_n) and (a_n), (a'_n) such that

$$
\left(\mu_{x_n a_n g_{1n}} - \mu_{x'_n a'_n g_{2n}}\right)(B_n) \to 1 \quad \text{as} \quad n \to \infty.
$$

Therefore

$$
\mu_{x_n a_n g_{1n}}(B_n) \to 1
$$

and

$$
\mu_{x'_n a'_n g_{2n}}(B_n) \to 0 \quad \text{as} \quad n \to \infty.
$$

Since

$$e^{-||g||_{sp}} P^a(x, B) \le \mu_{xag}(B),$$

we have

$$P^{a'_n}(x'_n, B_n) \to 0 \quad \text{and} \quad P^{a_n}(x_n, B_n^c) \to 0.$$

Consequently

$$\lim_{n\to\infty} P^{a_n}(x_n, B_n) - P^{a'_n}(x'_n, B_n) = 1,$$

which contradicts assumption (A1). □

We get immediately the following corollary.

COROLLARY 2.3. *Under* (A1) *and* (B1) *there exists at most one (up to an additive constant) function* $w \in C(E)$ *and a unique constant* λ *for which the Bellman equation* (1.2) *is satisfied.* □

The following assumption (A2) will be shown to guarantee that in a suitable subset of $C(E)$ the operator T is in fact a global contraction.

(A2) There exists $\eta \in \mathcal{P}(E)$ and a Borel function $E \times E \times A \ni (x, y, a) \mapsto p(x, y, a)$ such that $\forall_{x\in E}$, $\forall_{a\in U}$, $\forall_{B\in\mathcal{E}}$,

$$P^a(x, B) = \int_B p(x, y, a)\eta(dy)$$

and

$$\sup_{x,x'\in E} \sup_{y\in E} \sup_{a\in U} \frac{p(x, y, a)}{p(x', y, a)} = \mathcal{K} < \infty. \tag{2.10}$$

Remark 2.4. If in addition to the existence of a density $p(x, y, a)$ with respect to a probability measure η we have that

(B2) $E \times U \ni (x, a) \mapsto p(x, \cdot, a) \in L^1(\eta)$ is continuous,

then

(B3) the mapping $E \times U \ni (x, a) \mapsto P^a(x, \cdot)$ is continuous in the variation norm of $\mathcal{P}(E)$ and, in particular, (B1) also holds.

Furthermore, if

(A3) $p(x, y, a)$ in (A2) satisfies the stronger form of (2.10), namely,

$$\sup_{x,x'\in E} \sup_{y\in E} \sup_{a,a'\in U} \frac{p(x, y, a)}{p(x', y, a')} < +\infty,$$

then (A1) holds.

Remark 2.5. The assumptions (A2) and (A3) require mutual equivalence of transition probabilities for different values of initial states and controls and existence of a uniformly bounded away from 0 their Radon–Nikodým derivatives. These kinds

of assumption restrict the class of models in locally compact state space; however, they appear acceptable in the case of compact or countable state spaces.

THEOREM 2.6. *Under* (B1), (A1), *and* (A2) *the operator* T *defined in* (2.3) *and* (2.4) *maps* $C(E)$ *into* $C_L(E)$, *where* $C_L(E) \subset C(E)$ *is the set of continuous functions with span norm bounded by* $L = \log \mathcal{K} + ||c||$, *and consequently there is a unique (up to an additive constant) function* $w \in C(E)$ *which is in fact in* $C_L(E)$ *and a constant* λ *such that Bellman equation* (1.2) *is satisfied.*

Proof. Notice that for $g \in C(E)$ we have

$$Tg(x) - Tg(x') \le \sup_{a\in U}\left[c(x,a) - c(x',a) + \log \frac{\int_E e^{g(y)}P^a(x,dy)}{\int_E e^{g(y)}P^a(x',dy)}\right]$$

$$\le ||c|| + \sup_{a\in U} \log \frac{\int_E e^{g(y)}\frac{p(x,y,a)}{p(x',y,a)}p(x',y,a)\eta(dy)}{\int_E e^{g(y)}p(x',y,a)\eta(dy)} \le ||c|| + \log \mathcal{K}.$$

Therefore $||Tg||_{sp} \le L$ and T is a global contraction in the span norm in $C_L(E)$, so that it has a fixed point w in $C_L(E)$ and w, which is (up to an additive constant) unique, and the constant $\lambda = w - Tw$ are solutions to (1.2). □

Let $b\mathcal{B}(E)$ denote the set of bounded Borel measurable functions on E, and let $\mathcal{U} = \{u : E \to U, \text{ Borel measurable}\}$.

Given $u \in \mathcal{U}$, for $g \in b\mathcal{B}(E)$ define

$$T_u g(x) = c\big(x, u(x)\big) + \log \int_E e^{g(y)}P^{u(x)}(x,dy) \tag{2.11}$$

or in its equivalent form (see [9, Lemma 3.3] or [2, Proposition 2.3])

$$T_u g(x) = \sup_{\mu\in\mathcal{P}(E)}\left[c\big(x,u(x)\big) + \int_E g(y)\mu(dy) - I\big(\mu, P^{u(x)}(x,\cdot)\big)\right], \tag{2.12}$$

where the sup is attained for

$$\mu_u^*(B) = \frac{\int_B e^{g(y)}P^{u(x)}(x,dy)}{\int_E e^{g(y)}P^{u(x)}(x,dy)}.$$

PROPOSITION 2.7. *Under* (A1) *and* (A2) *for any* $u \in \mathcal{U}$ *the operator* T_u *in* (2.11) *and* (2.12) *transforms* $b\mathcal{B}(E)$ *into* $b\mathcal{B}_L(E)$, *where* $b\mathcal{B}_L(E) \subset b\mathcal{B}(E)$ *consists of functions with span norm bounded by* $L = \log \mathcal{K} + ||c||$. *Furthermore* T_u *is a global contraction in* $b\mathcal{B}_L(E)$, *and consequently there exists a unique (up to an additive constant) function* $w_u \in b\mathcal{B}_L(E)$ *and a unique constant* λ_u *such that*

$$w_u(x) + \lambda_u = \left[c\big(x,u(x)\big) + \log \int_E e^{w_u(y)}P^{u(x)}(x,dy)\right]. \tag{2.13}$$

Proof. Let $g_1, g_2 \in b\mathcal{B}(E)$, $x_1, x_2 \in E$. Then

$$\begin{aligned} &T_u g_1(x_2) - T_u g_2(x_2) - \big(T_u g_1(x_1) - T_u g_2(x_1)\big) \\ &= \sup_{\mu\in\mathcal{P}(E)}\left[\int_E g_1(y)\mu(dy) - I\big(\mu, P^{u(x_2)}(x_2,\cdot)\big)\right] \\ &- \sup_{\mu\in\mathcal{P}(E)}\left[\int_E g_2(y)\mu(dy) - I\big(\mu, P^{u(x_2)}(x_2,\cdot)\big)\right] \end{aligned}$$

$$
\begin{aligned}
&- \sup_{\mu\in\mathcal{P}(E)} \left[\int_E g_1(y)\mu(dy) - I\big(\mu, P^{u(x_1)}(x_1,\cdot)\big)\right] \\
&+ \sup_{\mu\in\mathcal{P}(E)} \left[\int_E g_2(y)\mu(dy) - I\big(\mu, P^{u(x_1)}(x_1,\cdot)\big)\right] \\
&\le \int_E (g_1-g_2)(y)\left(\mu_{x_2u(x_2)g_1} - \mu_{x_1u(x_1)g_2}\right)(dy) \\
&\le ||g_1-g_2||_{sp} \sup_{B\in\mathcal{E}} \left(\mu_{x_2u(x_2)g_1} - \mu_{x_1u(x_1)g_2}\right)(B),
\end{aligned}
$$

where $\mu_{xu(x)g}$ is as defined below (2.8).

Similarly to what has been done in the proof of Proposition 2.2, it is possible to show that

$$
\sup_{x_1,x_2\in E} \sup_{B\in\mathcal{E}} \left(\mu_{x_2u(x_2)g_1} - \mu_{x_1u(x_1)g_2}\right)(B) \le \alpha(M) < 1
$$

provided that $||g_1||_{sp}$, $||g_2||_{sp} \le M$.

Furthermore, by arguments similar to those used in the proof of Theorem 2.6, it is easily seen that under (A2) the operator T_u transforms $b\mathcal{B}(E)$ into $b\mathcal{B}_L(E)$ and consequently T_u is a global contraction in the space $b\mathcal{B}_L(E)$. Existence and uniqueness of the solution to (2.13) then follow as in Theorem 2.6. □

Two important consequences of Proposition 2.7 are given below.

COROLLARY 2.8. *Under* (A1) *and* (A2) *for each* $\varepsilon > 0$ *there exists a positive integer* n_0 *such that for* $n \ge n_0$

$$
\sup_{x\in E} \sup_{u\in\mathcal{U}} \left| n^{-1}\log E_x\left\{\exp\left\{\sum_{i=0}^{n-1} c\big(x_i,u(x_i)\big)\right\}\right\} - \lambda_u \right| < \varepsilon. \tag{2.14}
$$

Proof. Recalling that by Proposition 2.7, $||w_u||_{sp} \le L$, and iterating (2.13), namely,

$$
e^{w_u(x)} = E_x\left\{\exp\left\{\sum_{i=0}^{n-1}\Big(c\big(x_i,u(x_i)\big) - \lambda_u\Big)\right\} e^{w_u(x_n)}\right\},
$$

we obtain

$$
e^{-L} \le e^{-||w_u||_{sp}} \le E_x\left\{\exp\left\{\sum_{i=0}^{n-1}\Big(c\big(x_i,u(x_i)\big) - \lambda_u\Big)\right\}\right\} \le e^{||w_u||_{sp}} \le e^L
$$

and therefore

$$
-\frac{L}{n} \le n^{-1}\log E_x\left\{\exp\left\{\sum_{i=0}^{n-1} c\big(x_i,u(x_i)\big)\right\}\right\} - \lambda_u \le \frac{L}{n}
$$

from which the result follows. □

COROLLARY 2.9. *If* E *and* U *are finite, under* (A1) *and* (A2) *the policy iteration algorithm works and can be performed through the following steps:*

(1) *Fix* $z \in E$ *and take any* $u \in \mathcal{U}$.

(2) *Solve* (2.13) *with* $w_u(z) = 0$.

(3) *If for a point* $\overline{x} \in E$ *we have*

$$w_u(\overline{x}) + \lambda_u > \inf_{a \in U} \left[c(\overline{x}, a) + \log \int_E e^{w_u(y)} P^a(\overline{x}, dy) \right], \tag{2.15}$$

where the inf *is attained at* $\overline{a}$*, then put* $\overline{u}(\overline{x}) = \overline{a}$*,* $\overline{u}(x) = u(x)$ *for* $x \neq \overline{x}$*, and go to point* 2 *with* $u = \overline{u}$*. If* $\forall x \in E$ (2.15) *holds as an equality, then* u *is an optimal control.*

Proof. It follows from the fact that for E and U finite the class $\mathcal{U}$ is also finite, taking into account that by (2.13) and (2.15) we have $\forall x \in E$

$$w_u(x) + \lambda_u \geq c\big(x, \overline{u}(x)\big) + \log \int e^{w_u(y)} P^{\overline{u}(x)}(x, dy)$$

from which by interation we obtain

$$w_u(x) + n\lambda_u \geq \log E_x \left\{ \exp \left\{ \sum_{i=0}^{n-1} c\big(x_i, \overline{u}(x_i)\big) \right\} e^{w_u(x_n)} \right\}$$

and consequently $\lambda_{\overline{u}} \leq \lambda_u$. □

Remark 2.10. The previous corollaries provide us with two feasible methods to solve risk-sensitive ergodic problems. In particular, Corollary 2.8 suggests a finite horizon approximation, which is uniform in the class of stationary Markov controls $\mathcal{U}$, for general state and control spaces.

On the other hand, for finite state and control spaces, Corollary 2.9 provides a version of the well-known Howard improvement algorithm (see, e.g., [10]), which in a finite number of steps leads to an optimal control.

3. Discounted cost asymptotics. For $\beta \in (0, 1)$ and $\gamma \in [0, d]$ consider the exponential discounted cost criterion (see, e.g., [2])

$$J^{\beta}_{x,\gamma}\big((a_n)\big) = E_x \left\{ \exp \left\{ \gamma \sum_{i=0}^{\infty} \beta^i c(x_i, a_i) \right\} \right\}. \tag{3.1}$$

Let $w_\beta(x, \gamma)$ be the corresponding value function

$$w_\beta(x, \gamma) = \inf_{(a_n)} E_x \left\{ \exp \left\{ \gamma \sum_{i=0}^{\infty} \beta^i c(x_i, a_i) \right\} \right\}. \tag{3.2}$$

Proposition 3.1. *Under* (B1) *there exists a unique* $w_\beta \in C(E \times [0, d])$ *such that the equation*

$$w_\beta(x, \gamma) = \inf_{a \in U} \left[e^{\gamma c(x,a)} \int_E w_\beta(y, \gamma\beta) P^a(x, dy) \right] \tag{3.3}$$

with boundary condition

$$\lim_{\gamma \to 0} \sup_{x \in E} |w_\beta(x, \gamma) - 1| = 0 \tag{3.4}$$

holds.

Moreover $w_\beta(x, \gamma)$ *is the optimal value for the cost function* (3.1) *defined in* (3.2).

Proof. We split the proof into several steps.

Step 1. Let for $g \in C(E \times [0,d])$

$$T_\beta g(x,\gamma) = \inf_{a\in U}\left[e^{\gamma c(x,a)}\int_E g(y,\gamma\beta)P^a(x,dy)\right]. \tag{3.5}$$

Notice that by (B1) T_β transforms $C(E\times[0,d])$ into itself. Furthermore, if g satisfies the boundary condition

$$\lim_{\gamma\to 0}\sup_{x\in E}|g(x,\gamma)-1| = 0, \tag{3.6}$$

then (3.6) holds also for $T_\beta g(x,\gamma)$ since

$$\begin{aligned}|T_\beta g(x,\gamma)-1| &\le \sup_{a\in U}\left[|e^{\gamma c(x,a)}-1|\int_E |g(y,\gamma\beta)|P^a(x,dy)\right]\\ &+\sup_{a\in U}\left[\int_E |g(y,\gamma\beta)-1|P^a(x,dy)\right]\to 0\end{aligned}$$

uniformly in x as $\gamma\to 0$.

Step 2. Notice that T_β preserves the order in the sense that if $\forall_{x\in E}$, $\forall_{\gamma\in[0,d]}$ $g_1(x,\gamma)\ge g_2(x,\gamma)$, then $T_\beta g_1(x,\gamma)\ge T_\beta g_2(x,\gamma)$.

Therefore since for $\underline{g}(x,\gamma)\equiv 1$, $T_\beta\underline{g}(x,\gamma)\ge 1\equiv\underline{g}(x,\gamma)$ we have that $T_\beta^n\underline{g}(x,\gamma)$ is an increasing sequence. On the other hand, since for $\overline{g}(x,\gamma)=e^{\gamma\frac{||c||}{1-\beta}}$

$$T_\beta\overline{g}(x,\gamma)=\inf_{a\in U}\left[e^{\gamma c(x,a)}e^{\gamma\beta\frac{||c||}{1-\beta}}\right]\le e^{\gamma\frac{||c||}{1-\beta}}=\overline{g}(x,\gamma),$$

we have that $T_\beta^n\overline{g}(x,\gamma)$ is a decreasing sequence and

$$1\le T_\beta^n\underline{g}(x,\gamma)\le T_\beta^n\overline{g}(x,\gamma)\le e^{\gamma\frac{||c||}{1-\beta}}. \tag{3.7}$$

Step 3. For $g\in C(E\times[0,d])$ we have the representation formula for $n=1,2,\dots,$

$$T_\beta^n g(x,\gamma)=\inf_{(a_n)}E_x\left\{\exp\left\{\gamma\sum_{i=0}^{n-1}\beta^i c(x_i,a_i)\right\}g(x_n,\gamma\beta^n)\right\}, \tag{3.8}$$

and therefore uniformly in $x\in E$ and $\gamma\in[0,d]$

$$\begin{aligned}&|T_\beta^n\overline{g}(x,\gamma)-T_\beta^n\underline{g}(x,\gamma)|\\ &\le\sup_{(a_n)}E_x\left\{e^{\gamma\sum_{i=0}^{n-1}\beta^i c(x_i,a_i)}\left|e^{\frac{\gamma\beta^n||c||}{1-\beta}}-1\right|\right\}\to 0\end{aligned}$$

as $n\to\infty$.

Thus there exists a function $w_\beta(x,\gamma)$ which is a uniform (in $x\in E$ and $\gamma\in[0,d]$) limit of $T_\beta^n\overline{g}(x,\gamma)$ and $T_\beta^n\underline{g}(x,\gamma)$. Consequently $w_\beta(x,\gamma)\in C(E\times[0,d])$ and is a solution to (3.3) with boundary condition (3.4) (using Step 1). The uniqueness is guaranteed by the representation (3.8) together with the boundary condition (3.4). □

Remark 3.2. An optimal strategy (a_n) for the cost functional $J^\beta_{x,\gamma}$ in (3.1) is of the form $a_n=u(x_n,\gamma\beta^n)$, where $u: E\times[0,d]\to U$ is a function for which the inf in (3.3) is attained. Notice that the above strategy is not a stationary one since it depends on time n through the power n of β.

We shall need the following assumption.

(A4) There exists $\eta \in \mathcal{P}(E)$ and a positive integer N such that for any Markov strategy $V = (a_n)$, where $a_n = u_n(x_n)$ with $u_n \in \mathcal{U}$ and for any $x \in E$ the measures $P_x^V\{x_N \in \cdot\}$ are absolutely continuous with respect to η with densities $p_N^V(x,y)$ satisfying

$$\sup_V \sup_{x,x' \in E} \sup_{y \in E} \frac{p_N^V(x,y)}{p_N^V(x',y)} \le \overline{\mathcal{K}} < \infty.$$

Clearly (A2) implies (A4) with $N = 1$.

Define for fixed $z \in E$

$$h_\beta(x,\gamma) = \frac{w_\beta(x,\gamma)}{w_\beta(z,\gamma)};$$

then we have the following theorem.

THEOREM 3.3. *Under* (A1), (A4), *and* (B3), *there exists a unique constant* λ *and for fixed* $z \in E$ *a unique function* $w \in C(E)$ *with* $w(z) = 0$ *which satisfy the Bellman equation*

$$w(x) + \lambda = \inf_a \left[\gamma c(x,a) + \log \int_E e^{w(y)} P^a(x,dy)\right]. \tag{3.9}$$

Furthermore, for each $x \in E$ *and each* $\gamma \in [0,d]$,

$$\lim_{\beta \uparrow 1} \frac{w_\beta(x,\gamma)}{w_\beta(x,\gamma\beta)} = e^\lambda,$$
$$\lim_{\beta \uparrow 1} h_\beta(x,\gamma) = e^{w(x)},$$

where the last convergence is uniform on compact sets of E.

Proof. For the optimal Markov strategy $V = (a_n)$ with $a_n = u_n(x_n, \gamma\beta^n)$ (see Remark 2.10) we obtain using (A4)

$$\begin{aligned}
\frac{w_\beta(x,\gamma)}{w_\beta(z,\gamma)} &= \frac{E_x^V\left\{\exp\left\{\gamma \sum_{i=0}^{N-1} c(x_i,a_i)\beta^i\right\} w_\beta(x_N,\gamma\beta^N)\right\}}{E_z^V\left\{\exp\left\{\gamma \sum_{i=0}^{N-1} c(x_i,a_i)\beta^i\right\} w_\beta(x_N,\gamma\beta^N)\right\}} \\
&\le e^{\gamma N||c||} \frac{\int_E w_\beta(y,\gamma\beta^N) p_N^V(z,y) \frac{p_N^V(x,y)}{p_N^V(z,y)} \eta(dy)}{\int_E w_\beta(y,\gamma\beta^N) p_N^V(z,y) \eta(dy)} \\
&\le \overline{\mathcal{K}} e^{\gamma N||c||}.
\end{aligned}$$

Similarly

$$\frac{w_\beta(x,\gamma)}{w_\beta(z,\gamma)} \ge \overline{\mathcal{K}}^{-1} e^{-\gamma N||c||}$$

so that

$$\overline{\mathcal{K}}^{-1} e^{-\gamma N||c||} \le h_\beta(x,\gamma) \le \overline{\mathcal{K}} e^{\gamma N||c||}. \tag{3.10}$$

By (3.3) we then have

$$h_\beta(x,\gamma) \cdot \frac{w_\beta(z,\gamma)}{w_\beta(z,\gamma\beta)} = \inf_{a \in U} \left[e^{\gamma c(x,a)} \int_E h_\beta(y,\gamma\beta) P^a(x,dy)\right]. \tag{3.11}$$

Using (3.10), we obtain from (3.11)

$$1 \le \frac{w_\beta(x,\gamma)}{w_\beta(x,\gamma\beta)} \le e^{\gamma||c||}\frac{||h_\beta(\cdot,\gamma\beta)||}{h_\beta(x,\gamma\beta)}$$
$$\le e^{\gamma||c||}\overline{\mathcal{K}}^2 e^{2\gamma\beta N||c||} \le \overline{\mathcal{K}}^2 e^{\gamma||c||(2N+1)}.$$

By (B3) and (3.10), for each $\gamma \in [0,d]$ and any positive integer m, $T_\beta h_\beta(x,\gamma\beta^m)$ is continuous in x, uniformly in β, and is bounded.

For a fixed γ, using a diagonal procedure, by the Ascoli–Arzelà theorem [12, Theorem 8.33] one can find a sequence $\beta_n \uparrow 1$, constants λ_m, and functions $w_m(x,\gamma)$ such that for $m = 0,1,2,\ldots,$

$$\frac{w_{\beta_n}(z,\gamma\beta_n^m)}{w_{\beta_n}(z,\gamma\beta_n^{m+1})} \to e^{\lambda_m} \tag{3.12}$$

and

$$T_{\beta_n} h_{\beta_n}(x,\gamma\beta_n^m) \to e^{w_m(x,\gamma)+\lambda_m} \tag{3.13}$$

uniformly in x on compact subsets of E.

By (3.11) we then have for $m = 0,1,2,\ldots,$

$$\lim_{n\to\infty} h_{\beta_n}(x,\gamma\beta_n^{m+1}) = e^{w_m(x,\gamma)} \tag{3.14}$$

uniformly in x on compact subsets of E.

Furthermore, from (3.10) and (3.14),

$$-\log\overline{\mathcal{K}} - N\gamma||c|| \le w_m(x,\gamma) \le \log\overline{\mathcal{K}} + N\gamma||c||. \tag{3.15}$$

Consequently, from (3.13) and (3.14), we have

$$e^{w_m(x,\gamma)}e^{\lambda_m} = \lim_{n\to\infty}\left\{\inf_{a\in U}\left[e^{\gamma\beta_n^m c(x,a)}\int_E h_{\beta_n}(y,\gamma\beta_n^{m+1})P^a(x,dy)\right]\right\}$$
$$= \inf_{a\in U}\left[e^{\gamma c(x,a)}\int_E e^{w_m(y,\gamma)}P^a(x,dy)\right]. \tag{3.16}$$

Notice that $w_m(z,\gamma) = 0$ and $||w_m(\cdot,\gamma)||_{sp} \le 2(\log\overline{\mathcal{K}} + N\gamma||c||)$.

Let, for $g \in C(E\times[0,d])$,

$$Tg(x,\gamma) = \inf_{a\in U}\left[\gamma c(x,a) + \log\int_E e^{g(y,\gamma)}P^a(x,dy)\right].$$

From (3.16) it is clear that $Tw_m = w_m + \lambda_m$.

Since $w_m(z,\gamma) = w_{m+1}(z,\gamma) = 0$ by Corollary 2.3, we have $w_m(z,\gamma) = w(z,\gamma)$ for $m = 0,1,2,\ldots,$ and consequently $\lambda_0 = \lambda_1 = \cdots = \lambda_m = \lambda$.

Since by Corollary 2.3, adapting the procedure described above, from any sequence $\beta_n \uparrow 1$ one can choose a further subsequence β_{n_k} (to simplify notation denoted again by β_n) such that

$$\lim_{n\to\infty}\log\frac{w_{\beta_n}(z,\gamma)}{w_{\beta_n}(z,\gamma\beta_n)} = \lambda$$

and

$$\lim_{n\to\infty} \log h_{\beta_n}(x,\gamma) = w(x),$$

where λ and $w(x)$ are unique solutions of the Bellman equation (3.9), then the above convergences hold for any sequence $\beta \uparrow 1$.

Finally, since λ is unique (see Corollary 2.3), it does not depend on the choice of the initial point z as stated in the theorem. □

Remark 3.4. Following the proof of Theorem 3.3, notice that we can obtain the existence of a constant λ and $w \in C(E)$ for which (3.9) is satisfied using only assumptions (A4) and (B3). From Proposition 1.1, λ is then the optimal cost of the risk-sensitive problem (see (1.3)) and is therefore unique.

4. Discounted game approach. For $\beta \in (0,1)$ consider the following equation:

$$e^{w_\beta(x)} = \inf_{a\in U}\left\{e^{c(x,a)}\int_E e^{\beta w_\beta(y)}P^a(x,dy)\right\}. \tag{4.1}$$

The function w_β in (4.1) can be interpreted as the upper value of a certain discounted stochastic dynamic game (see [9] for details). We have the following proposition.

PROPOSITION 4.1. *Under* (B1), *for* $\beta \in (0,1)$ *there exists a unique* $w_\beta \in C(E)$ *for which the equation is satisfied. Moreover*

$$0 \le w_\beta(x) \le \frac{||c||}{1-\beta}. \tag{4.2}$$

Proof. Notice that under (B1) the operator

$$T^\beta g(x) = \inf_{a\in U}\left[c(x,a) + \log\int_E e^{\beta g(y)}P^a(x,dy)\right] \tag{4.3}$$

transforms $C(E)$ into itself. Furthermore, for $g_1, g_2 \in C(E)$,

$$T^\beta g_1(x) - T^\beta g_2(x) \le \sup_{a\in U}\left[\log\frac{\int_E e^{\beta g_1(y)}P^a(x,dy)}{\int_E e^{\beta g_2(y)}P^a(x,dy)}\right]$$
$$\le \sup_{a\in U}\left[\log\frac{\int_E e^{\beta||g_1-g_2||+\beta g_2(y)}P^a(x,dy)}{\int_E e^{\beta g_2(y)}P^a(x,dy)}\right] \le \beta||g_1-g_2||$$

and changing the role of g_1 and g_2 we obtain that

$$||T^\beta g_1 - T^\beta g_2|| \le \beta||g_1-g_2||,$$

which means that T^β is a contraction in $C(E)$. In addition for $\underline{g}(x) \equiv 0$ and $\overline{g}(x) = \frac{||c||}{1-\beta}$ we have $T^\beta\underline{g} \ge \underline{g}$ and $T^\beta\overline{g} \le \overline{g}$ so that by the contraction principle, analogous to what has been done in Proposition 3.1, $(T^\beta)^n\underline{g}$ and $(T^\beta)^n\overline{g}$ approximate w_β from below and from above, respectively, from which (4.2) follows. □

Fix $z \in E$ and let $k_\beta(x) = w_\beta(x) - w_\beta(z)$.

From (4.1) we then have

$$k_\beta(x) + (1-\beta)w_\beta(z) = T^\beta k_\beta(x) \tag{4.4}$$

with the operator T_β defined in (4.3).

THEOREM 4.2. *Under* (A2) *and* (B3) *there exist a function* $w \in C(E)$ *and a unique constant* λ *for which* (1.2) *holds. Moreover*

$$\lim_{\beta\uparrow 1}(1-\beta)w_\beta(x) = \lambda. \tag{4.5}$$

Assuming additionally that (A1) *holds, we have then that* w *is the unique function in* $C(E)$ *such that* $w(z) = 0$ *for which* (1.2) *holds and furthermore*

$$\lim_{\beta\uparrow 1} k_\beta(x) = w(x) \tag{4.6}$$

uniformly on compact subsets of E.

Proof. Let us notice first that similar to the proof of Theorem 2.6, under (A2) and (B3) the operator T^β transforms $C(E)$ into $C_L(E)$. Consequently, since $w_\beta = T_\beta w_\beta$ we have that $||k_\beta|| \le L$. Furthermore, by (B3) the function $T^\beta k_\beta(x)$ is uniformly in $\beta \in (0,1)$ continuous and bounded.

Therefore, taking into account (4.2), there exist $\lambda \in R$ and $w \in C(E)$ and a sequence $\beta_n \uparrow 1$ such that

$$\lim_{n\to\infty}(1-\beta_n)w_{\beta_n}(z) = \lambda$$

and

$$\lim_{n\to\infty} T^{\beta_n}k_{\beta_n}(x) = w(x) + \lambda$$

uniformly in x from compact subsets of E.

Then from (4.4)

$$\lim_{n\to\infty} k_{\beta_n}(x) = w(x)$$

uniformly on compact subsets of E and consequently from (4.3) and (2.3)

$$\lim_{n\to\infty} T^{\beta_n}k_{\beta_n}(x) = Tw(x)$$

so that, letting $\beta_n \uparrow 1$ in (4.4) we have that $w(x)$ and λ satisfy (1.2).

The uniqueness of λ as well as the convergence (4.5) for all $x \in E$ is guaranteed by Proposition 1.1. The uniqueness of $w(x)$ is guaranteed by Corollary 2.3 and therefore we have (4.6). □

5. Risk-sensitive asymptotics. In this section we shall study the asymptotics of the value functions corresponding to the cost functionals

$$J_{x,\gamma}\big((a_n)\big) = \gamma^{-1}\limsup_{n\to\infty} n^{-1}\log\left(E_x\left\{\exp\left\{\sum_{i=0}^{n-1}\gamma c(x_i,a_i)\right\}\right\}\right) \tag{5.1}$$

as the risk factor $\gamma \downarrow 0$, assuming that E is a locally compact separable metric space.

Notice that by the Jensen inequality we have

$$J_{x,\gamma}\big((a_n)\big) \ge \limsup_{n\to\infty} n^{-1}E_x\left\{\sum_{i=0}^{n-1} c(x_i,a_i)\right\} := \overline{J}_x\big((a_n)\big). \tag{5.2}$$

Furthermore, again by the Jensen inequality, for $\gamma_1 \le \gamma_2$ we have

$$J_{x,\gamma_1}\big((a_n)\big) \le J_{x,\gamma_2}\big((a_n)\big), \tag{5.3}$$

which means that the optimal values of the cost $J_{x,\gamma}$ are decreasing as $\gamma \to 0$ and greater than the optimal value of $\overline{J}_x$. We shall in fact show that the latter value is reached in the limit.

We impose the following assumption.

(A5) There exists $\eta \in \mathcal{P}(E)$ such that for $x \in E$, $a \in U$, $B \in \mathcal{E}$

$$P^a(x,B) = \int_B p(x,y,a)\eta(dy),$$

where $p(x,y,a) > 0$, the mapping $(x,y,a) \to p(x,y,a)$ is continuous and (A3) holds, i.e.,

$$\sup_{x,x' \in E} \sup_{y \in E} \sup_{a,a' \in U} \frac{p(x,y,a)}{p(x',y,a')} = \tilde{\mathcal{K}} < +\infty.$$

For the proof of the main theorem we shall need the following result.

LEMMA 5.1. *Under* (A5) *we have that*

$$\overline{\lambda} = \inf_{u \in \mathcal{U}_c} \overline{J}_x\big(u(x_n)\big), \tag{5.4}$$

where $\mathcal{U}_c$ *is the subclass of* $\mathcal{U}$ *consisting of continuous functions* $u : E \to U$, *and* $\overline{\lambda} = \inf_{(a_n)} \overline{J}_x\big((a_n)\big)$.

Proof. Since E is locally compact there is an increasing sequence of compact sets K_m such that $\bigcup_{m=1}^{\infty} K_m = E$. We can also require that $\eta(\partial K_m) = 0$. Consider now a sequence of partitions $(E_1^m, E_2^m, \dots, E_{d_m}^m)$, $m = 1,2,\dots$, of E with representative elements $\{e_1^m, e_2^m, \dots, e_{d_m}^m\}$ such that $E = \bigcup_{i=1}^{d_m} E_i^m$, $E_i^m \cap E_j^m = \emptyset$ for $i \neq j$, $\eta(\partial E_i^m) = 0$ the diameter of E_i^m is not greater than $\frac{1}{m}$ for $i = 1,2,\dots,d_m - 1$, $E_{d_m}^m = E \setminus K_m$; furthermore $\{E_1^{m+1}, E_2^{m+1}, \dots, E_{d_{m+1}}^{m+1}\}$ is a partition finer than $\{E_1^m, E_2^m, \dots, E_{d_m}^m\}$ and $\{e_1^m, e_2^m, \dots, e_{d_m}^m\} \subset \{e_1^{m+1}, \dots, e_{d_{m+1}}^{m+1}\}$.

Let $P_m^a(x,\cdot) = P^a(e_l^m,\cdot)$, for $x \in E_l^m$, $l = 1,2,\dots,d_m, m = 1,2,\dots$

Consider a Markov process $X^m = (x_n^m)$ with transition kernel $P_m^a(x,\cdot)$. For $u \in \mathcal{U}$ define

$$\lambda_m^u = \limsup_{n\to\infty} n^{-1} E_x^u \left\{ \sum_{i=0}^{n-1} c((x_i^m), u(x_i^m)) \right\}.$$

Similarly for a Markov process $X = (x_n)$ with transition kernel $P^a(x,\cdot)$ let

$$\lambda^u = \limsup_{n\to\infty} n^{-1} E_x^u \left\{ \sum_{i=0}^{n-1} c((x_i), u(x_i)) \right\}.$$

By (A5), using the ergodicity results of section 3.3 of [10] we obtain that there are a positive integer N and a constant M such that for $n \geq N$ and $m = 1,2,\dots$ we have

$$\sup_u \sup_{x \in E} \left| \lambda_m^u - n^{-1} E_x^u \left\{ \sum_{i=0}^{n-1} c((x_i^m), u(x_i^m)) \right\} \right| \leq \frac{M}{n}$$

and

$$\sup_u \sup_{x\in E} \left| \lambda^u - n^{-1} E_x^u \left\{ \sum_{i=0}^{n-1} c((x_i), u(x_i)) \right\} \right| \le \frac{M}{n} \tag{5.5}$$

with supremum taken over all $u \in \mathcal{U}$.

Since

$$\sup_{a\in U} \; ||P_m^a(x,\cdot) - P^a(x,\cdot)||_{var} \to 0$$

as $m \to \infty$ uniformly in x on compact subsets, where $||\ ||_{var}$ stands for variation norm, we have that

$$\sup_u |\lambda_m^u - \lambda^u| \to 0$$

as $m \to \infty$.

For each controlled Markov process X^m piecewise constant controls (i.e., the controls constant on each set of the partition $E_1^m, \dots, E_{d_m}^m$) are optimal. Therefore the class of piecewise constant controls is also nearly optimal for the controlled Markov process X. Consequently to complete the proof of Lemma 5.1 it remains to show that each piecewise constant (on our partition) function u can be approximated by continuous functions $u_l : E \to U$ in the sense that

$$|\lambda^{u_l} - \lambda^u| \to 0.$$

Choose a sequence u_l of continuous functions from E into U such that

$$\eta(\{z \in E : u_l(z) \neq u(z)\}) \to 0$$

as $l \to \infty$.

Therefore

$$\eta\{z \in E : \exists_{y\in E}\ p(z,y,u_l(z)) \neq p(z,y,u(z))\} \to 0$$

as $l \to \infty$, or in other words,

$$\eta\{z \in E :\ ||P^{u_l(z)}(z,\cdot) - P^{u(z)}(z,\cdot)||_{var} > 0\} \to 0$$

as $l \to \infty$.

Consequently for each n

$$\left| E_x^{u_l} \left\{ \sum_{i=0}^{n-1} c(x_i, u_l(x_i)) \right\} - E_x^u \left\{ \sum_{i=0}^{n-1} c(x_i, u(x_i)) \right\} \right| \to 0$$

as $l \to \infty$ for η almost all $x \in E$.

By (5.5) (as above) we obtain then that $|\lambda^{u_l} - \lambda^u| \to 0$, as $l \to \infty$, which completes the proof. □

The main result of this section can be stated as follows.

THEOREM 5.2. *Under* (A5) *we have*

$$\lim_{\gamma\downarrow 0} \inf_{(a_n)} \sup_{x\in E} J_{x,\gamma}\big((a_n)\big) = \overline{\lambda}. \tag{5.6}$$

Proof. Notice first that by (5.2), for $\gamma > 0$,

$$\inf_{(a_n)} \sup_{x\in E} J_{x,\gamma}\big((a_n)\big) \geq \overline{\lambda}$$

so that, using also the monotonicity property (5.3),

$$\lim_{\gamma\downarrow 0} \inf_{(a_n)} \sup_{x\in E} J_{x,\gamma}\big((a_n)\big) \geq \overline{\lambda}. \tag{5.7}$$

By Theorem 6.9 and Corollary 7.21 of [14] we have that for $u \in \mathcal{U}_c$

$$\begin{aligned} &\lim_{n\to\infty} \sup_{x\in E} \frac{1}{n}\frac{1}{\gamma} \log E\left\{\exp\left\{\sum_{i=0}^{n-1} \gamma c\big(x_i, u(x_i)\big)\right\}\right\} \\ &\leq \sup_{\nu\in\mathcal{P}(E)} \left[\int_E c\big(z, u(z)\big)\nu(dz) - \frac{1}{\gamma} I^u(\nu)\right], \end{aligned} \tag{5.8}$$

where

$$I^u(\nu) = -\inf_{h\in H} \int_E \log \frac{P^u h(x)}{h(x)} \nu(dx),$$

$P^u h(x) = \int h(y) P^{u(x)}(x, dy)$, and H is the set of all bounded functions $h : E \to R^+$ such that $\frac{1}{h(x)}$ is also bounded.

Since I^u is lower semicontinuous, if E is compact there is for each γ a $\nu_\gamma \in \mathcal{P}(E)$ such that

$$\begin{aligned} &\sup_{\nu\in\mathcal{P}(E)} \left[\int_E c\big(z, u(z)\big)\nu(dz) - \frac{1}{\gamma} I^u(\nu)\right] \\ &= \int_E c\big(z, u(z)\big)\nu_\gamma(dz) - \frac{1}{\gamma} I^u(\nu_\gamma). \end{aligned} \tag{5.9}$$

If E is compact, there is a sequence $\gamma_m \to 0$ and a measure $\overline{\nu} \in P(E)$ such that $\nu_{\gamma_m} \to \overline{\nu}$ weakly. Since

$$\frac{1}{n}\frac{1}{\gamma}\left|\log E\left\{\exp\left\{\sum_{i=0}^{n-1} \gamma c\big(x_i, u(x_i)\big)\right\}\right\}\right| \leq ||c||,$$

by (5.8) and (5.9) we have that $\limsup_{m\to\infty} I^u(\nu_{\gamma_m}) = 0$.

By lower semicontinuity of I^u we then have that $\liminf_{m\to\infty} I^u(\nu_{\gamma_m}) \geq I^u(\overline{\nu})$ and therefore $I^u(\overline{\nu}) = 0$.

By Lemma 2.5 of [4], $I^u(\overline{\nu}) = 0$ if and only if $\overline{\nu} = \pi_u$, the unique invariant measure corresponding to the transition operator $P^{u(x)}(x, dy)$.

Consequently

$$\begin{aligned} &\lim_{m\to\infty} \left[\int_E c\big(z, u(z)\big)\nu_{\gamma_m}(dz) - \frac{1}{\gamma_m} I^u(\nu_{\gamma_m})\right] \\ &\leq \int_E c\big(z, u(z)\big)\pi_u(dz) = \overline{J}_x\big(u(x_n)\big) \end{aligned}$$

and taking into account (5.2) and (5.8) we have that

$$\lim_{m\to\infty}\lim_{n\to\infty}\sup_{x\in E}\frac{1}{n}\frac{1}{\gamma_m}\log E\left\{\exp\left\{\sum_{i=0}^{n-1}\gamma_m c\big(x_i,u(x_i)\big)\right\}\right\}$$

(5.10)

$$=\lim_{m\to\infty}\left[\int_E c\big(z,u(z)\big)\nu_{\gamma_m}(dz)-\frac{1}{\gamma_m}I^u(\nu_{\gamma_m})\right]=\overline{J}_x\big(u(x_n)\big).$$

Since from any sequence $\gamma_m\downarrow 0$ one can choose a further subsequence $\gamma_{m_k}\downarrow 0$ such that we have the convergence result (5.10) with γ_m replaced by γ_{m_k}, we finally have

$$\lim_{m\to\infty}\lim_{n\to\infty}\sup_{x\in E}\frac{1}{n}\frac{1}{\gamma_m}\log E\left\{\exp\left\{\sum_{i=0}^{n-1}\gamma_m c\big(x_i,u(x_i)\big)\right\}\right\}=\overline{J}_x\big(u(x_n)\big)$$

from which, by (5.7) and (5.8), we obtain (5.6) in the case of compact E.

In the case when E is only locally compact we construct a continuous function $\psi: E\to R$, $\psi(x)\geq 1$ for $x\in E$ such that the mapping

$$E\ni x\mapsto\int_E\psi(y)P^{u(x)}(x,dy)$$

is bounded on compact subsets of E and for each $m>0$ the set

$$K_m^u=\left\{x\in E:\frac{\psi(x)}{\int_E\psi(y)P^{u(x)}(x,dy)}\leq m\right\}$$

is compact.

Indeed, by local compactness of E for fixed $\overline{x}\in E$ and $\overline{a}\in U$ one can find an increasing sequence of compact subsets $K_n\subset K_{n+1}$, $\partial K_n\subset \mathrm{Int}K_{n+1}$ such that

$$\int_{K_n^c}p(\overline{x},y,\overline{a})\eta(dy)\leq\frac{1}{(n+1)^3}$$

and a continuous function ψ taking values from the interval $[n,n+1]$, for $x\in K_{n+1}\setminus K_n$. Then by (A5) for $x\in E$ and $u\in\mathcal{U}$ we have

$$0<\frac{1}{\tilde{\mathcal{K}}}E_{\overline{x}}^{\overline{a}}\{\psi(x_q)\}\leq E_x^u\{\psi(x_1)\}$$

$$\leq\tilde{\mathcal{K}}E_{\overline{x}}^{\overline{a}}\{\psi(x_1)\}\leq\tilde{\mathcal{K}}\sum_{n=1}^{\infty}(n+1)\frac{1}{(n+1)^3}<\infty$$

and therefore K_m^u is a compact set.

Consequently, by Lemma 4.2 of [5], for each $m>0$ the set

$$C_m^u=\{\nu\in\mathcal{P}(E):I^u(\nu)\leq m\}$$

is compact in $\mathcal{P}(E)$ and we can adapt the proof of the case when E is compact. □

SAMPLE-PATH OPTIMALITY AND VARIANCE-MINIMIZATION OF AVERAGE COST MARKOV CONTROL PROCESSES*

ONÉSIMO HERNÁNDEZ-LERMA†, OSCAR VEGA-AMAYA‡, AND GUADALUPE CARRASCO§

Abstract. This paper studies several average-cost criteria for Markov control processes on *Borel spaces* with possibly *unbounded costs*. Under suitable hypotheses we show (i) the existence of a *sample-path average cost* (SPAC-) optimal stationary policy; (ii) a stationary policy is SPAC-optimal if and only if it is *expected average cost* (EAC-) optimal; and (iii) within the class of stationary SPAC-optimal (equivalently, EAC-optimal) policies there exists one with a minimal limiting *average variance*.

Key words. (discrete-time) Markov control processes, average cost criteria, sample-path average cost, expected average cost, canonical policies, average variance

1. Introduction.

We study several average cost (AC) criteria for Markov control processes on *Borel spaces* with possibly *unbounded costs*. Under suitable hypotheses, we show (i) the existence of a *sample-path average cost* (SPAC-) optimal stationary policy; (ii) a stationary policy is SPAC-optimal if and only if it is *expected average cost* (EAC-) optimal; (iii) within the class of stationary SPAC-optimal policies there exists one with minimal limiting *average variance*.

Discrete-time Markov control processes (MCPs) with AC criteria are among the most widely studied stochastic control problems. However, as can be seen in [1, 2, 4, 7, 8, 15, 16, 23, 32, 33, 34] and their extensive bibliographies, most of the related literature is concentrated on the EAC criterion, especially for MCPs with denumerable state space and/or bounded costs. In contrast, for the SPAC case there are a lot fewer works. For instance, for *finite state* MCPs, we should mention the pioneering works by Mandl [28, 29, 30]; see also [23, pp. 161–162]. For the *countable state* case, see [3, 4, 5], whereas for MCPs on *Borel spaces* we know only of [1, Theorem 6.3(v), (vi)] for bounded costs and [26, 35, 36] for unbounded costs. Finally, to the best of our knowledge, for the variance minimization the only previous works are those by Mandl [28, 29, 30] for *finite state* MCPs and by Kurano [24] for the Borel case with *bounded costs*. The reader should be warned, however, that several authors have studied a "variance minimization problem" for a quantity which is not the "real" variance—see, for instance, [21] and [32, p. 408]. Here, our definition (12) [see also (45)] of limiting average variance is the one used in the *central limit theorem for Markov chains*, as in [7, Corollaire 7.III.2] or [31, Theorem 17.0.1].

To obtain the results (i), (ii), (iii) mentioned in the first paragraph, we introduce hypotheses (Assumptions 3.1, 3.2, 3.4) already used in [18]—see also [36]—to study several undiscounted cost criteria, including EAC-optimality. It turns out that the results (i), (ii), (iii)—stated precisely in Theorems 3.7 and 3.8—can be obtained by adding a mild "second order" condition, Assumption 3.6. This setting combines several tools and proof techniques of common use in stochastic control and probability theory. For example, the "Lyapunov condition" in Assumption 3.2(b) is a suitable variant of conditions previously used by many authors, for instance, [5, 6, 7, 9, 12, 13, 17, 18, 19, 20, 22, 23, 25, 31]. Moreover, the "Lyapunov function" W in Assumptions 3.1 and 3.2 is also required to act as a "weight" (or "bounding") function, which allows us to introduce appropriate weighted norms for functions and measures, as in (14) and (58). The use of weight functions in stochastic control problems goes back (at least) to the 1970s—for earlier references see, for example, [6, 12, 13, 16, 17, 20]. On the other hand, a key step in our proof of SPAC-optimality (see Lemma 4.4) uses the law of large numbers for martingales, also known as the martingale stability theorem [7, 14, 23, 27], which is in the spirit of the proof in [1, Theorem 6.3; 24, 28, 29, 30]. This is different from the "tightness" approach followed by other authors, in which an important intermediate step is to give conditions for a certain set, say M, of occupation (or empirical) measures to be tight. To make sure that M is tight, one can, for instance, compactify the underlying space(s), as in [3, 4] (see also [5]) or impose conditions on the cost function, as in [26, 35, 36]. This has also been done in other works for different kinds of control problems—see, for example, the references in [10, 11, 16, p. 122], where the tightness approach is referred to as the "direct approach."

The remainder of the paper is organized as follows. In section 2 we introduce the Markov control model and the AC criteria we are interested in. In section 3 we introduce our hypotheses and state our main results, Theorems 3.7 and 3.8, which are proved in section 4 and section 5, respectively. We close in section 6 with some important remarks. In particular, in Remark 6.1 we mention hypotheses that can be used in lieu of the "stability" Assumptions 3.2 and 3.4.

2. The Markov control processes. The material in this section is quite standard—see [1, 4, 8, 15, 16, 32, 33, 34].

We shall consider the usual discrete-time, stationary, Markov control model $(\mathbf{X}, \mathbf{A}, \{A(x) : x \in \mathbf{X}\}, Q, C)$ with state space $\mathbf{X}$ and control (or action) set $\mathbf{A}$, both assumed to be Borel spaces with σ-algebras $\mathcal{B}(\mathbf{X})$ and $\mathcal{B}(\mathbf{A})$, respectively. For each state $x \in \mathbf{X}$, $A(x) \in \mathcal{B}(\mathbf{A})$ is the (nonempty) set of feasible control actions in x. We assume that the set

$$\mathbf{K} := \{(x, a) : x \in \mathbf{X}, a \in A(x)\}$$

of feasible state-action pairs is a Borel subset of $\mathbf{X} \times \mathbf{A}$. Finally, Q [or $Q(B|x, a)$ for $B \in \mathcal{B}(\mathbf{X})$ and $(x, a) \in \mathbf{K}$] denotes the transition law, and $C : \mathbf{K} \to \mathbb{R}$ is a measurable function that stands for the cost-per-stage function.

The class of measurable functions $f : \mathbf{X} \to \mathbf{A}$ such that $f(x)$ is in $A(x)$ for every $x \in \mathbf{X}$ is denoted by $\mathbf{F}$, and we suppose that it is nonempty.

Control policies. Let $\mathbf{H}_0 := \mathbf{X}$ and $\mathbf{H}_n := \mathbf{K}^n \times \mathbf{X}$ for $n = 1, 2, \ldots$. A *control policy* is a sequence $\pi = \{\pi_n\}$ of stochastic kernels on $\mathbf{A}$ given $\mathbf{H}_n$ satisfying the constraint $\pi_n(A(x_n)|h_n) = 1$ for every "history" $h_n = (x_0, a_0, \ldots, x_{n-1}, a_{n-1}, x_n)$ in $\mathbf{H}_n$, and $n = 0, 1, \ldots$. The class of all policies is denoted by Π.

A policy $\pi = \{\pi_n\}$ is said to be a (deterministic) *stationary policy* if there exists $f \in \mathbf{F}$ such that $\pi_n(\cdot|h_n)$ is concentrated at $f(x_n)$ for each history $h_n \in \mathbf{H}_n$ and $n =$

$0, 1, \ldots$. Following a standard convention, we identify $\mathbf{F}$ with the class of stationary policies.

For notational ease, for a stationary policy $f \in \mathbf{F}$ we write

$$C_f(x) := C(x, f(x)) \quad \text{and} \quad Q_f(\cdot|x) := Q(\cdot|x, f(x)) \quad \forall x \in \mathbf{X}. \tag{1}$$

Let $(\Omega, \mathcal{F})$ be the (canonical) measurable space consisting of the sample space $\Omega := (\mathbf{X} \times \mathbf{A})^\infty$ and its product σ-algebra $\mathcal{F}$. Then, for each policy π and "initial state" $x \in \mathbf{X}$, a stochastic process $\{(x_n, a_n)\}$ and a probability measure P_x^π are defined on $(\Omega, \mathcal{F})$ in a canonical way, where x_n and a_n represent the state and control at time n, $n = 0, 1, \ldots$. The expectation operator with respect to P_x^π is denoted by E_x^π.

AC criteria. For each $n = 1, 2, \ldots$, let

$$J_n^0(\pi, x) := \sum_{t=0}^{n-1} C(x_t, a_t) \tag{2}$$

be the *n-stage sample-path cost* when using the policy π, given the initial state $x \in \mathbf{X}$. The long-run SPAC is then defined as

$$J^0(\pi, x) := \limsup_{n\to\infty} \frac{1}{n} J_n^0(\pi, x). \tag{3}$$

DEFINITION 2.1. *A policy $\pi^* \in \Pi$ is said to be SPAC-optimal if there exists a constant $\widehat{\rho}$ such that*

$$J^0(\pi^*, x) = \widehat{\rho} \quad P_x^{\pi^*} - a.s. \quad \forall x \in \mathbf{X},$$

and

$$J^0(\pi, x) \geq \widehat{\rho} \quad P_x^\pi - a.s. \quad \forall \pi \in \Pi, x \in \mathbf{X}.$$

The constant $\widehat{\rho}$ is called the optimal SPAC.

The "expected" analogs of (2) and (3) are, respectively, the *n-stage expected cost*

$$J_n(\pi, x) := E_x^\pi \sum_{t=0}^{n-1} C(x_t, a_t)$$

and the long-run EAC

$$J(\pi, x) := \limsup_{n\to\infty} \frac{1}{n} J_n(\pi, x). \tag{4}$$

Among the EAC-related optimality concepts we are interested in are the following.

DEFINITION 2.2. (a) *A policy $\pi^* \in \Pi$ is said to be EAC-optimal if*

$$J(\pi^*, x) = J^*(x) \quad \forall x \in \mathbf{X}, \tag{5}$$

where

$$J^*(x) := \inf_{\pi\in\Pi} J(\pi, x) \quad \textit{for} \quad x \in \mathbf{X} \tag{6}$$

is the optimal expected average cost.

(b) *A stationary policy $f_* \in \mathbf{F}$ is called canonical (or, more explicitly, EAC-canonical) if there exist a constant ρ_* and a measurable function $h_* : \mathbf{X} \to \mathbb{R}$ such that*

$$\rho_* + h_*(x) = \min_{a \in A(x)} \left[C(x,a) + \int_{\mathbf{X}} h_*(y) Q(dy|x,a) \right] \quad \forall x \in \mathbf{X}, \tag{7}$$

and $f_*(x) \in A(x)$ attains the minimum on the right-hand side of (7) *for every $x \in \mathbf{X}$, that is (using the notation* (1)*),*

$$\rho_* + h_*(x) = C_{f_*}(x) + \int_{\mathbf{X}} h_*(y) Q_{f_*}(dy|x) \quad \forall x \in \mathbf{X}. \tag{8}$$

If (7) and (8) are satisfied, it is then said that (ρ_*, h_*, f_*) is a *canonical triplet*, a concept introduced by Yushkevich [37] (see also [1, 8, 12, 16, 18]). The connection between parts (a) and (b) in Definition 2.2 is that if (ρ_*, h_*, f_*) is a canonical triplet and, in addition, h_* satisfies that

$$\lim_{n \to \infty} \frac{1}{n} E_x^\pi h_*(x_n) = 0 \quad \forall \pi \in \Pi, x \in \mathbf{X}, \tag{9}$$

then f_* *is EAC-optimal and ρ_* is the optimal expected average cost*, i.e.,

$$J(f_*, x) = J^*(x) = \rho_* \quad \forall x \in \mathbf{X}. \tag{10}$$

Thus, in this case we have

$$\mathbf{F}_{cp} \subset \mathbf{F}_{eac}, \tag{11}$$

where $\mathbf{F}_{cp}$ is the class of canonical policies and $\mathbf{F}_{eac} \subset \mathbf{F}$ is the class of stationary EAC-optimal policies.

In the following sections we show, among other things, the existence of stationary policies that are optimal in the sense of Definitions 2.1 and 2.2, and, moreover, the existence of a stationary policy that minimizes the limiting average variance in the class $\mathbf{F}_{eac}$. In other words, for each $f \in \mathbf{F}$ and $x \in \mathbf{X}$, consider the *n-stage variance*

$$V_n(f,x) := \text{var}\ \left[J_n^0(f,x) \right] = E_x^f \left[J_n^0(f,x) - J_n(f,x) \right]^2$$

and the limiting *average variance*

$$V(f,x) := \limsup_{n \to \infty} \frac{1}{n} V_n(f,x). \tag{12}$$

Then we shall prove that there exists a stationary policy $\widehat{f}$ such that $\widehat{f}$ is EAC-optimal and

$$V(\widehat{f}, x) = \inf_{f \in \mathbf{F}_{eac}} V(f,x) \quad \forall x \in \mathbf{X}. \tag{13}$$

3. Main results. We first require two sets of hypotheses. The first one, Assumption 3.1, is a combination of the usual continuity/compactness requirements (to ensure, for instance, the existence of "measurable minimizers") together with a growth condition on the one-step cost C.

ASSUMPTION 3.1. *For each state $x \in \mathbf{X}$,*

(a) $A(x)$ *is a compact subset of* $\mathbf{A}$*;*

(b) $C(x,\cdot)$ *is lower semicontinuous on* $A(x)$*;*

(c) $\int_{\mathbf{X}} u(y)Q(dy|x,\cdot)$ *is continuous on* $A(x)$ *for every bounded measurable function* u *on* $\mathbf{X}$;

(d) *there exists a measurable function* $W \geq 1$ *on* $\mathbf{X}$ *and a constant* r_1 *such that*

(d1) $|C(x,a)| \leq r_1 W(x) \quad \forall (x,a) \in \mathbf{K}$ *and*

(d2) $\int_{\mathbf{X}} W(y)Q(dy|x,\cdot)$ *is continuous on* $A(x)$.

The second set of hypotheses we need is to guarantee that the MCP has a nice "stable" behavior uniformly in $\mathbf{F}$. Here, to fix ideas we shall impose Assumptions 3.2 and 3.4 below, which are an adaptation to MCPs of a Lyapunov-like condition used in Markov chain theory—see [9] or [31, p. 367]. However, the reader should keep in mind that, as noted in Remark 6.1, there are other hypotheses that yield the same stable behavior.

ASSUMPTION 3.2. *For each stationary policy* $f \in \mathbf{F}$,

(a) *there exists positive constants* $B_f < 1$ *and* $b_f < \infty$, *and a petite subset* K_f *of* $\mathbf{X}$ *such that (using the notation* (1)*)*

$$\int_{\mathbf{X}} W(y)Q_f(dy|x) \leq B_f W(x) + b_f \mathbf{I}_{K_f}(x) \quad \forall x \in \mathbf{X},$$

where $W \geq 1$ *is the function in Assumption* 3.1(d), *and* $\mathbf{I}_K(\cdot)$ *denotes the indicator function of* K;

(b) *the state processes* $\{x_n\}$*—which under* $f \in \mathbf{F}$ *is a Markov chain with transition kernel* Q_f [16, *Proposition* 2.3.5]*—is* φ*-irreducible and aperiodic for some* σ*-finite measure* φ *on* $\mathbf{X}$.

To state some consequences of Assumption 3.2, let us first introduce the following notation: $B_W(\mathbf{X})$ denotes the normed linear space of measurable functions u on $\mathbf{X}$ with a finite W*-norm* $||u||_W$, which is defined as

$$||u||_W := \sup_{x \in \mathbf{X}} |u(x)|/W(x). \tag{14}$$

We shall write $\int_{\mathbf{X}} u(y)\mu(dy)$ as $\mu(u)$, i.e.,

$$\mu(u) := \int_{\mathbf{X}} u(y)\mu(dy).$$

REMARK 3.3 (see [31, Theorem 16.0.1]). *Under Assumption* 3.2, *for each stationary policy* $f \in \mathbf{F}$ *we have the following:*

(a) *The Markov chain* $\{x_n\}$ *induced by* f *is positive Harris-recurrent, and, moreover, its unique invariant probability measure* μ_f *satisfies that* $\mu_f(W) < \infty$;

(b) $\{x_n\}$ *is* W*-geometrically ergodic; that is, there exist positive constants* $\gamma < 1$ *and* $M_f < \infty$ *such that*

$$\left| \int_{\mathbf{X}} u(y)Q_f^n(dy|x) - \mu_f(u) \right| \leq ||u||_W M_f \gamma_f^n W(x) \tag{15}$$

for each $u \in B_W(\mathbf{X}), x \in \mathbf{X}$, *and* $n = 0, 1, \ldots$.

The next assumption concerns the constants M_f and γ_f in (15).

ASSUMPTION 3.4. $M := \sup_f M_f$ *and* $\gamma := \sup_f \gamma_f$ *are such that* $M < \infty$ *and* $\gamma < 1$.

Assumptions 3.1, 3.2, and 3.4 have been used in [18] and [36] to study several undiscounted cost criteria, such as overtaking optimality, bias optimality, and others. In particular, the following result was established.

REMARK 3.5 (see [18, Theorem 3.5], [36, Theorem 4.5.3]). *Under Assumptions* 3.1, 3.2, *and* 3.4, *there exists a canonical triplet* (ρ_*, h_*, f_*), *where* h_* *is a function in* $B_W(\mathbf{X})$ *that satisfies* (9)*; hence* (10) *holds.*

In others words, we already have a canonical policy $f_* \in \mathbf{F}_{cp} \subset \mathbf{F}_{eac}$ [see (11)]. It turns out that by suitably strengthening Assumption 3.1 we can also obtain SPAC-optimal policies with minimal average variance in $\mathbf{F}_{eac}$. Thus, consider the following.

ASSUMPTION 3.6. *There exists a constant* r_2 *such that*

$$C^2(x,a) \le r_2 W(x) \quad \forall (x,a) \in \mathbf{K}. \tag{16}$$

We can now state our first main result, which is proved in section 4.

THEOREM 3.7. *Suppose that Assumptions* 3.1, 3.2, 3.4, *and* 3.6 *are satisfied, and let* ρ_* *be as in* (10). *Then*

(a) *for each* $\pi \in \Pi$ *and* $x \in \mathbf{X}$

$$J^0(\pi,x) \ge \liminf_{n\to\infty} \frac{1}{n} J_n^0(\pi,x) \ge \rho_* \quad P_x^\pi - a.s.; \tag{17}$$

(b) *a stationary policy is EAC-optimal if and only if it is SPAC-optimal; hence (by* (17) *and Remark* 3.5*) there exists a SPAC-optimal policy* $f_* \in \mathbf{F}$, *and* ρ_* *is the optimal sample path average cost. That is,* $\rho_* = \widehat{\rho}$ *where* $\widehat{\rho}$ *is the constant in Definition* 2.1.

It is worth noting that Theorem 3.7(b) and the second inequality in (17) state that $f_* \in \mathbf{F}$ is in fact *strong SPAC-optimal*, where "strong" means that $f_* = \pi^*$ satisfies Definition 2.1 (with $\widehat{\rho} = \rho_*$) when the "lim-sup" SPAC in (3) is replaced by *lim-inf SPAC*

$$\underline{J}^0(\pi,x) := \liminf_{n\to\infty} \frac{1}{n} J_n^0(\pi,x). \tag{18}$$

On the other hand, denoting by $\mathbf{F}_{spac} \subset \mathbf{F}$ the class of SPAC-optimal stationary policies, we may rewrite the first statement in Theorem 3.7(b) as

$$\mathbf{F}_{eac} = \mathbf{F}_{spac}. \tag{19}$$

The reader should note that a priori neither one of the relations $\mathbf{F}_{eac} \subset \mathbf{F}_{spac}$ and $\mathbf{F}_{eac} \supset \mathbf{F}_{spac}$ is obvious!

To state our second main result we need some notation: For each $x \in \mathbf{X}$, let $A^*(x) \subset A(x)$ the set of control actions $a \in A(x)$ that attain the minimum in (7), i.e.,

$$A^*(x) := \left\{ a \in A(x) : \rho_* + h_*(x) = C(x,a) + \int_{\mathbf{X}} h_*(y) Q(dy|x,a) \right\}. \tag{20}$$

Observe that, by (8), a *policy* $f \in \mathbf{F}$ *is canonical* ($f \in \mathbf{F}_{cp}$) *if and only if* $f(x) \in A^*(x)$ $\forall\, x \in \mathbf{X}$. Moreover, consider the function Φ on $\mathbf{K}$ defined as

$$\Phi(x,a) := \int_{\mathbf{X}} h_*^2(y) Q(dy|x,a) - \left[\int_{\mathbf{X}} h_*(y) Q(dy|x,a) \right]^2. \tag{21}$$

As in (1), for $f \in \mathbf{F}$ and $x \in \mathbf{X}$ we write

$$\Phi_f(x) := \Phi(x, f(x)).$$

With this notation we can state our variance-minimization result as follows. (The proof is given in section 5.)

THEOREM 3.8. *Suppose that Assumptions* 3.1, 3.2, 3.4, *and* 3.6 *are satisfied. Then there exists a constant* $\sigma_*^2 \geq 0$, *a canonical policy* $f_* \in \mathbf{F}_{cp}$, *and a function* $V^*(\cdot)$ *in* $B_W(\mathbf{X})$ *such that, for each* $x \in \mathbf{X}$,

$$\begin{aligned} \sigma_*^2 + V^*(x) &= \min_{a \in A^*(x)} \left[\Phi(x,a) + \textstyle\int_{\mathbf{X}} V^*(y) Q(dy|x,a)\right] \\ &= \Phi_{f_*}(x) + \textstyle\int_{\mathbf{X}} V^*(y) Q_{f_*}(dy|x). \end{aligned} \tag{22}$$

Furthermore, f_* *satisfies* (13) *and* $V(f_*, \cdot) = \sigma_*^2$; *in fact,*

$$V(f_*, x) = \mu_{f_*}(\Phi_{f_*}) = \sigma_*^2 \quad \forall x \in X \tag{23}$$

and

$$\sigma_*^2 \leq V(f,x) \quad \forall f \in \mathbf{F}_{eac}, x \in \mathbf{X}. \tag{24}$$

Note the similarity between (22) and (7)–(8). This similarity is crucial in the proof of Theorem 3.8 (see section 5).

4. Proof of Theorem 3.7. The assumptions of Theorem 3.7 are supposed to hold throughout the following.

The proof of Theorem 3.7 requires some preliminary results, stated in the following lemmas. Let us first note that by Assumption 3.1(d1), the function C_f in (1) is in $B_W(\mathbf{X})$ for every $f \in \mathbf{F}$. Hence, as $\mu_f(W) < \infty$ (Remark 3.3(a)), the (finite) constants

$$J_f := \mu_f(C_f) \quad \text{for} \quad f \in \mathbf{F}$$

are well defined.

LEMMA 4.1. *Let* $f \in \mathbf{F}$ *be an arbitrary stationary policy. Then for each* $x \in \mathbf{X}$

$$J(f,x) = \lim_{n\to\infty} \frac{1}{n} J_n(f,x) = J_f \tag{25}$$

and also

$$J^0(f,x) = \lim_{n\to\infty} \frac{1}{n} J_n^0(f,x) = J_f \quad P_x^f - a.s. \tag{26}$$

Moreover, the function

$$h_f(x) := E_x^f \sum_{t=0}^{\infty} [C_f(x_t) - J_f] \tag{27}$$

belongs to $B_W(\mathbf{X})$ *and is such that the pair* (J_f, h_f) *satisfies the Poisson equation*

$$J_f + h_f(x) = C_f(x) + \int_{\mathbf{X}} h_f(y) Q_f(dy|x) \quad \forall x \in \mathbf{X}. \tag{28}$$

Proof. In (15) replace $u(\cdot)$ with $C_f(\cdot)$. Then (15) and Assumption 3.4 yield

$$\left|E_x^f C_f(x_n) - J_f\right| \leq r_1 M \gamma^n W(x) \quad \forall x \in \mathbf{X}, n = 0, 1, \ldots, \tag{29}$$

where r_1 is the constant in Assumption 3.1(d1), and clearly (25) follows from (29) and the definition (4) of the long-run EAC. Observe, on the other hand, that (29) yields

$$|h_f(x)| \leq r_1 M(1-\gamma)^{-1} W(x) \quad \forall x \in \mathbf{X},$$

so that h_f is indeed in $B_W(\mathbf{X})$, whereas writing (27) as

$$h_f(x) = C_f(x) - J_f + E_x^f \sum_{t=1}^{\infty} [C_f(x_t) - J_f]$$

and then using the Markov property, we obtain (28).

Finally, (26) is a consequence of Remark 3.3(a) and the strong law of large numbers for Markov chains—see, for instance, [31, p. 411]. □

Let us now consider the function $w(x) := W(x)^{1/2}$. By Jensen's inequality and Assumption 3.2(a),

$$\int_{\mathbf{X}} w(y) Q_f(dy|x) \leq B_f' w(x) + b_f' \mathbf{I}_{K_f}(x) \quad \forall f \in \mathbf{F}, x \in \mathbf{X}, \tag{30}$$

with $B_f' := B_f^{1/2} < 1$ and $b_f' := b_f^{1/2} < \infty$. Therefore, by Assumptions 3.2 and 3.4, we see the following from Remark 3.3(b).

LEMMA 4.2. *For each stationary policy $f \in \mathbf{F}$,*

(a) $\{x_n\}$ *is w-geometrically ergodic; that is,*

$$\left| \int_{\mathbf{X}} u(y) Q_f^n(dy|x) - \mu_f(u) \right| \leq ||u||_w M \gamma^n w(x) \tag{31}$$

for each $x \in \mathbf{X}, n = 0, 1, \ldots,$ and $u \in B_w(\mathbf{X})$, where $B_w(\mathbf{X})$ is the normed linear space of measurable functions u on $\mathbf{X}$ such that

$$||u||_w := \sup_{x \in \mathbf{X}} |u(x)|/w(x) < \infty;$$

(b) *the function h_f in* (27) *belongs to $B_w(\mathbf{X})$ (since* (16*) yields the w-analogue of Assumption* 3.1(d1) : $|C(x,a)| \leq r_2^{1/2} w(x)$ $\forall$ $(x,a) \in \mathbf{K}$).

The next two lemmas are crucial for the proof of (17).

LEMMA 4.3. *For each policy $\pi \in \Pi$ and initial state $x \in \mathbf{X}$ we have*

(a) $E_x^\pi \sum_{t=1}^{\infty} t^{-2} W(x_t) < \infty$;

hence the following statements hold $P_x^\pi-$ a.s.:

(b) $\sum_{t=1}^{\infty} t^{-2} W(x_t) < \infty$;

(c) $t^{-2} W(x_t) \to 0$;

(d) $t^{-1} w(x_t) \to 0$.

Proof. As $W \geq w \geq 1$, it is evident that $(a) \Rightarrow$ (b) $\Rightarrow$ (c) $\Rightarrow$ (d). Thus, it suffices to prove (a).

To prove (a), let us note that by Assumption 3.1 and a well-known measurable selection theorem (see, for instance, [16, Proposition D.5, p. 182]), there exists $g \in \mathbf{F}$ such that

$$\sup_{a \in A(x)} \int_{\mathbf{X}} W(y) Q(dy|x,a) = \int_{\mathbf{X}} W(y) Q_g(dy|x) \quad \forall x \in \mathbf{X},$$

which together with Assumption 3.2(a) yields

$$\int_{\mathbf{X}} W(y)Q(dy|x,a) \le B_g W(x) + b_g \mathbf{I}_{K_g}(x) \quad \forall (x,a) \in \mathbf{K}. \tag{32}$$

Now let $\pi \in \Pi$ and $x_0 = x \in \mathbf{X}$ be arbitrary, and let $\mathcal{F}_t$ be the $\sigma-$algebra generated by the state and control variables up to time t, that is,

$$\mathcal{F}_t := \sigma\{x_0, a_0, \cdots, x_t, a_t\} \quad \text{for} \quad t = 0, 1, \ldots. \tag{33}$$

Then, by the properties of the induced probability measure P_x^π [15, p. 4], [16, p. 16]

$$\begin{aligned} E_x^\pi \left[W(x_{t+1})|\mathcal{F}_t\right] &= \textstyle\int_{\mathbf{X}} W(y)Q(dy|x_t, a_t) \\ &\le B_g W(x_t) + b_g \quad [\text{by (32)}]. \end{aligned} \tag{34}$$

This implies

$$E_x^\pi W(x_{t+1}) \le B_g E_x^\pi W(x_t) + b_g \quad \forall t = 0, 1, \ldots.$$

Therefore

$$E_x^\pi W(x_t) \le B_g^t W(x) + b_g/(1 - B_g) \quad \forall t = 0, 1, \ldots, \tag{35}$$

and (a) follows. □

As in the previous proof, let $\pi \in \Pi$ and $x_0 = x \in \mathbf{X}$ be arbitrary, and let $\mathcal{F}_t$ be the σ-algebra in (33). Moreover, let h_* be the function in Remark 3.5 (see (7)), and define the random variables

$$Y_t(\pi, x) := h_*(x_t) - E_x^\pi \left[h_*(x_t)|\mathcal{F}_{t-1}\right] \quad \text{for} \quad t = 1, 2, \ldots \tag{36}$$

and

$$M_n(\pi, x) := \sum_{t=1}^{n} Y_t(\pi, x) \quad \text{for} \quad t = 1, 2, \ldots. \tag{37}$$

LEMMA 4.4. *For each policy $\pi \in \Pi$ and each initial state $x_0 = x \in \mathbf{X}$, the sequence $\{M_n(\pi, x)\}$ is a P_x^π-martingale with respect to the filtration $\{\mathcal{F}_n\}$, and*

$$\lim_{n\to\infty} \frac{1}{n} M_n(\pi, x) = 0 \quad P_x^\pi - a.s. \tag{38}$$

Proof. Choose an arbitrary policy $\pi \in \Pi$ and an arbitrary initial state x. Now note that (ρ_*, h_*) is a solution to the Poisson equation (8) (cf. (28)), so that, by Lemma 4.2(b),

$$h_* \text{ is in } B_w(\mathbf{X}); \text{ that is, } |h_*(\cdot)| \le ||h_*||_w w(\cdot). \tag{39}$$

Then, by (36),

$$\begin{aligned} |Y_t(\pi, x)| &\le |h_*(x_t)| + E_x^\pi \left[|h_*(x_t)| \,|\mathcal{F}_{t-1}\,\right] \\ &\le ||h_*||_w \left\{w(x_t) + E_x^\pi \left[w(x_t) \mid \mathcal{F}_{t-1}\right]\right\}, \end{aligned} \tag{40}$$

and it follows that

$$E_x^\pi |Y_t(\pi, x)| \leq 2||h_*||_w E_x^\pi w(x_t).$$

This inequality and (35) show that $M_n(\pi, x)$ is P_x^π-integrable for every n. On the other hand, it is clear that $M_n(\pi, x)$ is $\mathcal{F}_n$-measurable and that

$$E_x^\pi \left[M_{n+1}(\pi, x) - M_n(\pi, x) \mid \mathcal{F}_n \right] = 0 \quad P_x^\pi - \text{a.s.}, \ \forall n;$$

therefore, $\{M_n(\pi, x)\}$ is a martingale.

Thus, (38) will follow from the law of large numbers for martingales (or martingale stability theorem) [14, Theorem 2.18, p. 35], [23, p. 161], [27, p. 53] provided that

$$\sum_{t=1}^{\infty} t^{-2} E_x^\pi \left[|Y_t(\pi, x)|^2 \mid \mathcal{F}_{t-1} \right] < \infty \quad P_x^\pi - \text{a.s.} \tag{41}$$

To prove (41), first we use the elementary inequality

$$(a + b)^2 \leq 2(a^2 + b^2) \quad \forall a, b \in \mathbb{R}$$

and the fact that $w^2 := W$ to see that (40) yields

$$|Y_t(\pi, x)|^2 \leq 2||h_*||_w^2 \left\{ W(x_t) + E_x^\pi \left[W(x_t) \mid \mathcal{F}_{t-1} \right] \right\}$$

so that

$$E_x^\pi \left[|Y_t(\pi, x)|^2 \mid \mathcal{F}_{t-1} \right] \leq 4||h_*||_w^2 E_x^\pi \left[W(x_t) \mid \mathcal{F}_{t-1} \right].$$

Thus, by (34),

$$E_x^\pi \left[|Y_t(\pi, x)|^2 \mid \mathcal{F}_{t-1} \right] \leq 4||h_*||_w^2 (B_g + b_g) W(x_{t-1}).$$

This inequality and Lemma 4.3(b) yield (41) because

$$\sum_{t=1}^{\infty} t^{-2} W(x_t) \leq W(x_0) + \sum_{t=2}^{\infty} (t-1)^{-2} W(x_{t-1}) < \infty \qquad P_x^\pi - \text{a.s.}$$

This completes the proof of Lemma 4.4. □

We are now ready to prove Theorem 3.7 itself.

Proof of Theorem 3.7. (a). Fix $\pi \in \Pi$ and $x_0 = x \in \mathbf{X}$ arbitrary, and consider Mandl's [30] *discrepancy function* $D : \mathbf{K} \to \mathbb{R}$ defined as

$$D(x, a) := C(x, a) + \int_{\mathbf{X}} h_*(y) Q(dy|x, a) - h_*(x) - \rho_*.$$

By Remark 3.5 and (7), D is *nonnegative*. On the other hand, rewriting (36) as

$$Y_t(\pi, x) = h_*(x_t) - \int_{\mathbf{X}} h_*(y) Q(dy|x_{t-1}, a_{t-1}),$$

we see that (37) becomes

$$M_n(\pi, x) = h_*(x_n) - h_*(x_0) - \sum_{t=0}^{n-1} D(x_t, a_t) + J_n^0(\pi, x) - n\rho_*,$$

and so

$$J_n^0(\pi, x) \geq n\rho_* + M_n(\pi, x) - h_*(x_n) + h_*(x_0). \tag{42}$$

Finally, multiply both sides of (42) by $1/n$ and then take lim inf as $n \to \infty$ to obtain the second inequality in (17) [from (38), (39), and Lemma 4.3(d)]. As the first inequality in (17) is obvious, (a) follows.

(b) Suppose that $f \in \mathbf{F}$ is EAC-optimal. Then from (26) we get

$$J^0(f, x) = \rho_* \qquad P_x^f - \text{a.s.} \quad \forall x \in \mathbf{X},$$

which together with (17) yields that f is SPAC-optimal. (In other words, $\mathbf{F}_{eac} \subset \mathbf{F}_{spac}$—see (19).)

Conversely, suppose that $f \in \mathbf{F}$ is SPAC-optimal. That is,

$$J^0(f, x) = J_f \qquad P_x^f - \text{a.s.} \quad \forall x \in \mathbf{X}$$

and

$$J^0(\pi, x) \geq J_f \quad P_x^\pi - \text{a.s.} \quad \forall \pi \in \Pi, x \in \mathbf{X}.$$

In particular, the latter inequality and (26) yield

$$J_g \geq J_f \quad \forall g \in \mathbf{F}.$$

Hence, by Remark 3.5, $J_f = \rho_*$; that is, f is EAC-optimal. (In other words, $\mathbf{F}_{spac} \subset \mathbf{F}_{eac}$.) □

5. Proof of Theorem 3.8. We shall first state some preliminary facts.

By Lemma 4.2(b), the function h_f is in $B_w(\mathbf{X})$ for each $f \in \mathbf{F}$, and so the function

$$\Psi_f(x) := \int_{\mathbf{X}} h_f^2(y) Q_f(dy|x) - \left[\int_{\mathbf{X}} h_f(y) Q_f(dy|x)\right]^2 \quad \text{for} \quad x \in \mathbf{X} \tag{43}$$

belongs to $B_W(\mathbf{X})$. Thus, as $\mu_f(W) < \infty$ (Remark 3.3(a)), the (finite) constants

$$\sigma_f^2 := \mu_f(\Psi_f) \quad \text{for} \quad f \in \mathbf{F} \tag{44}$$

are well defined, and they coincide with the limiting average variance in (12). More explicitly, by the central limit theorem for Markov chains we have the following (see, for instance, [7, p. 302]; [31, pp. 411, 436]).

LEMMA 5.1. *For each* $f \in \mathbf{F}$

$$V(f, x) = \lim_{n \to \infty} \frac{1}{n} E_x^f \sum_{t=0}^{n-1} \Psi_f(x_t) = \sigma_f^2 \quad \forall x \in \mathbf{X}. \tag{45}$$

On the other hand, if $f \in \mathbf{F}$ is a *canonical policy*, then the corresponding solution $(J_f, h_f) = (\rho_*, h_f)$ to the Poisson equation (28) is such that h_f coincides with h_* except perhaps for an additive constant, that is [18, 36],

$$h_f(\cdot) = h_*(\cdot) + k_f \quad \forall f \in \mathbf{F}_{cp} \tag{46}$$

for some constant k_f. Therefore, comparing (43) and (21), we obtain

$$\Phi_f(\cdot) = \Psi_f(\cdot) \quad \forall f \in \mathbf{F}_{cp}. \tag{47}$$

We will next prove, in particular, that (46) and (47) hold μ_f-a.e. for all stationary EAC-optimal policies $f \in \mathbf{F}_{eac}$. (Recall (11).)

LEMMA 5.2. *Let f be a stationary policy in $\mathbf{F}_{eac}\backslash\mathbf{F}_{cp}$. Then*

(a) $h_f(\cdot) = h_*(\cdot) + k_f \quad \mu_f$*-a.e. for some constant* k_f;

(b) *there exists a canonical policy $\widehat{f} \in \mathbf{F}_{cp}$ such that $\mu_{\widehat{f}} = \mu_f$, and*

$$V(\widehat{f}, x) = V(f, x) = \sigma_f^2 \quad \forall x \in \mathbf{X}, \tag{48}$$

where σ_f^2 is the constant in (44), (45).

Proof. (a) From the so-called average cost optimality equation (7), we have

$$\rho_* + h_*(x) \le C_f(x) + \int_{\mathbf{X}} h_*(y) Q_f(dy|x) \quad \forall x \in \mathbf{X}. \tag{49}$$

On the other hand, we also have $J_f = \rho_*$ because f is EAC-optimal, and so the Poisson equation (28) for f becomes

$$\rho_* + h_f(x) = C_f(x) + \int_{\mathbf{X}} h_f(y) Q_f(dy|x) \quad \forall x \in \mathbf{X}. \tag{50}$$

From (49) and (50), it follows that the function $u(\cdot) = h_f(\cdot) - h_*(\cdot)$ is super-harmonic with respect to Q_f, i.e.,

$$u(x) \ge \int_{\mathbf{X}} u(y) Q_f(dy|x) \quad \forall x \in \mathbf{X}.$$

Iterating this inequality, we see that

$$u(x) \ge \int_{\mathbf{X}} u(y) Q_f^n(dy|x) \quad \forall x \in \mathbf{X}, n = 0, 1, \ldots,$$

and if we let $n \to \infty$, (31) yields

$$u(x) \ge \int_{\mathbf{X}} u(y) \mu_f(dy) \quad \forall x \in \mathbf{X}. \tag{51}$$

Now let $k_f := \inf_{x \in \mathbf{X}} u(x)$. Then, by (51), $\int_{\mathbf{X}} u(y)\mu_f(dy) = k_f$, which implies

$$u(\cdot) = k_f \quad \mu_f\text{-a.e.}$$

Thus, as $u := h_f - h_*$, (a) follows with $k_f = \inf_{x \in \mathbf{X}} u(x) = \int_{\mathbf{X}} u(y)\mu_f(dy)$.

(b) By (a), there exists a Borel set $N \in \mathcal{B}(\mathbf{X})$ such that $\mu_f(N) = 0$ and

$$h_f(x) = h_*(x) + k_f \quad \forall x \in N^c := \mathbf{X}\backslash N. \tag{52}$$

Now let $g \in \mathbf{F}_{cp}$ be a canonical policy (whose existence is ensured by Remark 3.5), and define a new policy $\widehat{f}$ as $\widehat{f} := g$ on N and $\widehat{f} := f$ on N^c. Then, $\widehat{f}$ is canonical, and $Q_f(\cdot|x) = Q_{\widehat{f}}(\cdot|x)$ on N^c, that is,

$$Q_f(\cdot|x) = Q_{\widehat{f}}(\cdot|x) \quad \mu_f - \text{a.e.} \tag{53}$$

Hence, on the one hand, (53) yields

$$\mu_f(\cdot) = \mu_{\widehat{f}}(\cdot), \tag{54}$$

and, on the other hand, (53) and (52) give (from (43) and (21))

$$\Psi_f(\cdot) = \Phi_f(\cdot) \quad \mu_f\text{-a.e.} \tag{55}$$

Therefore, (48) follows from (44)–(45) and (54)–(55). □

We are now ready for the proof of Theorem 3.8.

Proof of Theorem 3.8. Let $A^*(x)$ and $\Phi(x,a)$ be as in (20) and (21), respectively, and consider the new Markov control model

$$(\mathbf{X}, \mathbf{A}, \{A^*(x) : x \in \mathbf{X}\}, Q, \widehat{C})$$

with $\widehat{C}(x,a) := \Phi(x,a)$. It is easy to check that this control model satisfies Assumptions 3.1, 3.2, and 3.4, replacing C and $A(\cdot)$ with $\widehat{C}$ and $A^*(\cdot)$, respectively. Consequently, by Remark 3.5, there exists a constant $\sigma_*^2 \geq 0$, a function $V^*(\cdot)$ in $B_W(\mathbf{X})$, and a canonical policy $f_* \in \mathbf{F}_{cp}$ that satisfy (22). Then, by standard arguments it follows that

$$\sigma_*^2 = \mu_{f_*}(\Phi_{f_*}) = V(f_*, x) \quad \forall x \in \mathbf{X} \tag{56}$$

and

$$\sigma_*^2 \leq \mu_f(\Phi_f) = V(f,x) \quad \forall f \in \mathbf{F}_{cp}, x \in \mathbf{X}, \tag{57}$$

where the last equality in (56) and (57) follows from (47) and (45). Finally, from (57) and Lemma 5.2(b) we conclude that

$$\sigma_*^2 \leq \sigma_f^2 = V(f,x) \quad \forall f \in \mathbf{F}_{eac}, x \in \mathbf{X}.$$

This completes the proof of Theorem 3.8. □

6. Additional comments. In this section we briefly discuss alternative forms of the stability Assumptions 3.2 and 3.4, as well as examples related to our main results.

In addition to the space of functions $B_W(\mathbf{X})$ with the W-norm (14), where $W \geq 1$ is the "weight" function in Assumption 3.1(d), we shall consider the normed linear space $M_W(\mathbf{X})$ of the finite signed measures with a finite W-norm

$$||\mu||_W := \int_{\mathbf{X}} W(y)|\mu|(dy), \tag{58}$$

where $|\mu| := \mu^+ + \mu^-$ denotes the *total variation of* μ.

REMARK 6.1. *Suppose that Assumption* 3.1 *holds. Then from the proofs in* [18, *Theorem* 3.5] *and* [36, *Theorem* 4.5.3] *one can see that the result mentioned in Remark* 3.5 *holds provided that*

(I) *the* W*-geometric ergodicity* (15) *holds, with constants* M_f *and* γ_f *that satisfy Assumption* 3.4; *and*

(II) *The transition kernel* Q_f *is* φ*-irreducible for each* $f \in \mathbf{F}$, *where* φ *is a* σ*-finite measure on* X *independent of* $f \in \mathbf{F}$.

These two conditions were obtained in section 3 from Assumptions 3.2 and 3.4. However, there are other ways of getting I. For example, Assumptions 3.2 and 3.4 may be replaced by the following hypotheses used in [12, 13].

(a) For each stationary policy $f \in \mathbf{F}$ the kernel Q_f (in (1)) admits a unique invariant probability measure μ_f.

(b) There exists a probability measure ν in $M_W(\mathbf{X})$ and positive constants $\alpha < \infty$ and $\beta < 1$ for which the following holds: for each $f \in \mathbf{F}$ there exists a measurable function $0 \leq l_f \leq 1$ such that

(b1) $Q_f(B|x) \geq l_f(x)\nu(B) \quad \forall x \in \mathbf{X}, B \in \mathcal{B}(\mathbf{X})$;

(b2) $\nu(l_f) \geq \alpha$, and $\nu(W) = ||\nu||_W < \infty$;

(b3) $\int_{\mathbf{X}} W(y)Q_f(dy|x) \leq \beta W(x) + l_f(x)\nu(W) \quad \forall x \in \mathbf{X}$.

These conditions, (a) and (b), are an adaptation to MCPs of ideas used by Kartashov [22] to obtain the W-geometric ergodicity in (15). In fact, under (a) and (b), our present Assumption 3.4 is satisfied and one can also obtain estimates of the constants M and γ—see [22, Theorem 3.6] and [12, Lemmas 3.3 and 3.4]—in Assumption 3.4.

Similarly, instead of (a) and (b), one could adapt to MCPs the "contraction" property in [22, Corollary 2.1], which in our notation would be of the form $||\theta Q_f||_W \leq \rho||\theta||_W$ for every signed measure θ in $M_W(\mathbf{X})$ with $\theta(\mathbf{X}) = 0$, for some positive constant $\rho < 1$. On the other hand, as was already noted in [18, Remark 2.10], if the cost function $C(x, a)$ is *bounded*, then the "weight" function $W \geq 1$ may be bounded and (15) can be obtained from *Doeblin's condition*—see [31, Theorem 16.0.2].

To conclude, we should mention that the examples in [13] and [18] (see also [36, Chapter 4]) also hold in our present case. For instance, the example in [18, section 6], consists of an inventory system with state space $\mathbf{X} := [0, \infty)$ and a compact control set $\mathbf{A} \subset \mathbb{R}$, in which the one-step cost $C(x, a)$ is *piecewise-linear* in $x \in \mathbf{X}$ and $a \in \mathbf{A}$. Therefore, as the weight function is *exponential*, say

$$W(x) := k \exp(rx) \quad \forall x \in \mathbf{X},$$

with $k, r > 0$, our Assumption 3.6 will trivially hold for some $r_2 > 0$ sufficiently large. A similar comment holds for the queueing system in [13, section 5], except that this reference uses the conditions (a) and (b) in Remark 6.1 in lieu of Assumptions 3.2 and 3.4.

ACTOR-CRITIC–TYPE LEARNING ALGORITHMS FOR MARKOV DECISION PROCESSES*

VIJAYMOHAN R. KONDA† AND VIVEK S. BORKAR‡

Abstract. Algorithms for learning the optimal policy of a Markov decision process (MDP) based on simulated transitions are formulated and analyzed. These are variants of the well-known "actor-critic" (or "adaptive critic") algorithm in the artificial intelligence literature. Distributed asynchronous implementations are considered. The analysis involves two time scale stochastic approximations.

Key words. reinforcement learning, Markov decision processes, actor-critic algorithms, stochastic approximation, asynchronous iterations

AMS subject classifications. 93E35, 68T05, 62L20

1. Introduction.

Recently there has been a lot of interest in simulation-based algorithms for MDPs. In these, one takes as the starting point one of the classical iterative algorithms for computing the value function: the value iteration or policy iteration. The conditional expectation term in these is then replaced by its integrand evaluated at an actual simulated transition. The algorithm is expected to "see" the conditional expectation through an averaging effect achieved by using stochastic approximationlike step sizes. These schemes are very useful when the exact dynamics is unknown or complicated but simulation is "easy." An instance would be a large communication network where an exact analytic model is hard to derive but simulating a typical transition using local dynamics is easy.

The simulation-based scheme derived from value iteration is called Q-learning and has been extensively analyzed [26, 24, 1, 2]. The scheme derived from policy iteration is called adaptive critic [3] and has eluded a satisfactory convergence analysis (see [27]). This is because policy iteration involves two loops. The inner loop computes the "value function" for a stationary policy and the outer one updates the latter. If both are done recursively, ideally the outer update should wait for the convergence of the inner loop. The aim of this paper is to propose several variants of the adaptive critic method where the above difficulty is circumvented by a two time scale stochastic approximation. That is, we use different step size schedules for different components of the iteration. Recall that the traditional stochastic approximation algorithm asymptotically tracks an associated ODE [17]. The two time scale algorithm correspondingly tracks a singular ODE. As in the case of singular ODEs, the fast component sees the slow component as quasi-constant, while the slow component sees the fast one as essentially equilibrated. Thus operating the outer loop of our algorithm on a slower (virtual) time scale than the inner loop achieves the desired effect. These

qualitative remarks will be made precise later. Another important feature of our work is the distributed, asynchronous iterations typical in applications. (Unfortunately, we have to stick to the synchronous iterations for one of the time scales in the case of the average cost problems, due to some technical difficulties; see [11].)

The reader is referred to [6, 14] for extensive accounts of earlier work on simulation-based algorithms. Two time scale stochastic approximations are studied in [8]. Our approach to asynchronous algorithms follows [9].

The paper is organized as follows. The next section proposes and analyzes a prototypical algorithm without any reference to MDPs. All the algorithms we propose will be variants of this. Section 3 introduces the MDP framework and the associated algorithms. These are analyzed in sections 5 and 6 for discounted and average cost, respectively, following some preliminaries in section 4. The last section concludes with some relevant remarks. Algorithm 2 was also presented in [10]. It is included here for the sake of completeness.

2. General algorithm.

2.1. Notation. Let l, $m \geq 1$, $I = \{1, \ldots, l\}$, $I' = \{1, \ldots, m\}$. Let e_i denote a unit l-vector whose ith component is one. Let $I_1, I_2, \ldots, I_K$ be a partition of I, and let $G_1, G_2, \ldots, G_K$ be closed convex subsets of R^l such that $G_i \subset H_i \stackrel{\Delta}{=} \text{span}\{e_k | k \in I_i\}$ and $G = \{\sum_i x_i : x_j \in G_j \ \forall j\}$ is compact. Let $\pi_i : R^l \to H_i$ denote the projection map; let $P_i : H_i \to G_i$ and $P : R^l \to G$ denote the projections given by $P_i(x) = y$ subject to $y \in G_i$, $\|y - x\| = \inf_{z \in G_i} \|z - x\|$, $P(x) = y$ s.t. $\|y - x\| = \inf_{z \in G} \|z - x\|$. It is then easy to see the following:

(1) For each $x \in R^l$, $x = \sum_{k=1}^K \pi_k(x)$.

(2) For each $i = 1, 2, \ldots, K$, $G_i = \pi_i(G)$.

For each $x \in R^l$, $P(x) = \sum_{i=1}^K P_i(\pi_i(x))$. We further assume that $\{G_i\}$ are of the form

$$G_i = \{x \in H_i : q_{ij}(\pi_i(x)) \leq 0, \quad 1 \leq j \leq K_i$$

for some continuously differentiable functions $\{q_{ij}(\cdot)\}$.

Let $f : G \times R^m \to R^m$, $g : G \times R^m \to R^l$ be prescribed Lipschitz maps such that for each $x \in G$, $f(x, y) = 0$ has a unique solution $y = \lambda(x)$. Assume that $\lambda(\cdot)$ is Lipschitz. Define

$$\bar{P}_x(g(x, \lambda(x))) = \lim_{\Delta \downarrow 0} \frac{P(x + \Delta g(x, \lambda(x))) - x}{\Delta}.$$

The algorithm proposed below aims to find the solution of $\bar{P}_x(g(x, \lambda(x))) = 0$ based on noisy samples. We describe this next.

Let $\{\bar{X}_n, \bar{Y}_n\}$ be set-valued random processes taking values in the subsets of I, I', respectively, and set

$$\nu_1(i, n) = \sum_{k=0}^{n-1} I\{i \in \bar{X}_k\}, \quad \nu_1(i, 0) = 0, \quad 1 \leq i \leq l,$$

$$\nu_2(j, n) = \sum_{k=0}^{n-1} I\{j \in \bar{Y}_k\}, \quad \nu_2(j, 0) = 0, \quad 1 \leq j \leq m.$$

Let $\{a(n)\}$ be positive sequences satisfying

$$\sum_n a(n) = \sum_n b(n) = \infty, \quad \sum_n a(n)^2 < \infty, \quad \sum_n b(n)^2 < \infty. \tag{2.1}$$

Then the algorithm is as follows: For $1 \leq k \leq K$, $1 \leq i \leq m$,

(2.2)
$$\pi_k(X(n+1)) = P_k\left(\pi_k(X(n)) + \sum_{j \in I_k} a(\nu_1(j,n))(g_j(\tilde{X}^j(n), \tilde{Y}^j(n)) + M_j(n))I\{j \in \bar{X}_n\}e_j\right),$$

$$Y_i(n+1) = Y_i(n) + b(\nu_2(i,n))(f_i(\hat{X}^i(n), \hat{Y}^i(n)) + M'_i(n))I\{i \in \bar{Y}_n\}. \tag{2.3}$$

Here $\{M(n)\}$, $\{M'(n)\}$ are vector martingale difference sequences and

$$\begin{aligned}
\tilde{X}^j(n) &= [X_1(n - \tau_{j1}(n)), \ldots, X_l(n - \tau_{jl}(n))]^T, \\
\tilde{Y}^j(n) &= [Y_1(n - \bar{\tau}_{j1}(n)), \ldots, Y_m(n - \bar{\tau}_{jm}(n))]^T, \\
\hat{X}^i(n) &= [X_1(n - \rho_{i1}(n)), \ldots, X_l(n - \rho_{il}(n))]^T, \\
\hat{Y}^i(n) &= [Y_1(n - \bar{\rho}_{i1}(n)), \ldots, Y_m(n - \bar{\rho}_{im}(n))]^T,
\end{aligned}$$

for nonnegative random "delays" $\{\tau_{ij}(\cdot)\}$, $\{\bar{\tau}_{ij}(\cdot)\}$, $\{\rho_{ij}(\cdot)\}$, $\{\bar{\rho}_{ij}(\cdot)\}$.

The interpretation is as follows: $\bar{Y}_n$ is the set of indices i such that $Y_i(n)$ gets updated at time n. Similarly, $\bar{X}_n$ is the set of indices j such that the noisy sample $(g_j(\tilde{X}^j(n), \tilde{Y}^j(n)) + M_j(n))$ is used to update $X(n)$. Each component of $X(\cdot)$, $Y(\cdot)$ is assigned to a unique processor which receives the outputs of other processors with some random delays and updates all the components assigned to it. Each component of $Y(\cdot)$ is assigned to a separate processor. Two components X_i, X_j of $X(\cdot)$ are assigned to the same processor and experience the same communication delays if there exists $1 \leq k \leq K$ such that $i, j \in I_k$. $\{M(n)\}$, $\{M'(n)\}$ are martingale difference sequences (with respect to the "natural" σ-fields generated by processes under consideration) representing measurement noise. $\nu_1(i,n)$ (respectively, $\nu_2(i,n)$) is the number of times the ith component of $X(\cdot)$ (respectively, $Y(\cdot)$) was updated up to time n. These are known to the respective processors who need not know n (the global "clock"). See [9] for a further discussion of this paradigm.

2.2. Assumptions. We shall make the following assumptions:

(A1) *Ideal step size.* Letting $c(n)$ stand for either $a(n)$ or $b(n)$, we assume, in addition to (2.1), that $c(n)$ is eventually decreasing and the following hold:

1. $a(n) = o(b(n))$.
2. For $x \in (0,1)$,
$$\sup_n c([xn])/c(n) < \infty, \tag{2.4}$$
where $[\cdots]$ stands for the integer part of "...".
3. For $x \in (0,1)$ and $A(n) = \sum_{i=0}^{n} c(i)$,
$$A([yn])/A(n) \to 1 \tag{2.5}$$
uniformly in $y \in [x,1]$.

Examples are $c(n) = \frac{1}{n}$, $\frac{1}{n \log n}$ for $n \geq 2$ with suitable modifications for $n = 0, 1$.

(A2) *Boundedness of iterates.* $\sup_n \|Y(n)\| < \infty$.

(A3) *ODE stability.* For each $x \in G$, the ODE
$$\dot{y}(t) = f(x, y(t)), \qquad y(0) = y,$$

has a unique globally asymptotically stable equilibrium point $\lambda(x)$, where $\lambda(\cdot)$ is Lipschitz. (Note that this means that the ODE $\dot{x}(t) = 0$, $\dot{y}(t) = f(x(t), y(t))$ has $\text{graph}(\lambda) \stackrel{\Delta}{=} \{(x, \lambda(x)) : x \in G\}$ as the globally asymptotically stable set.) Also, the ODE

$$\dot{x}(t) = \bar{P}_{x(t)}(g(x(t), \lambda(x(t)))), \qquad x(0) = x,$$

has a strict Liapunov function, i.e., a twice continuously differentiable function $L(\cdot) : G \to R$ such that

$$\nabla L(x) \cdot \bar{P}_x(g(x, \lambda(x))) < 0$$

whenever $\bar{P}_x(g(x, \lambda(x))) \neq 0$.

(A4) *Ideal noise.* $\{M(n)\}$, $\{M'(n)\}$ are square integrable and satisfy

$$\sup_n \|M(n)\|, \sup_n \|M'(n)\| < \infty \text{ almost surely},$$

$$\mathrm{E}[M(n)|\mathcal{F}_n] = \mathrm{E}[M'(n)|\mathcal{F}_n] = 0 \text{ a.s.},$$

$$\sup_n \mathrm{E}[\|M(n)\|^2|\mathcal{F}_n], \sup_n \mathrm{E}[\|M'(n)\|^2|\mathcal{F}_n] < \infty \text{ a.s.},$$

where $\mathcal{F}_n = \sigma(X(k), Y(k), \{\tau_{ij}(k)\}, \{\bar{\tau}_{ij}(k)\}, \{\rho_{ij}(k)\}, \{\bar{\rho}_{ij}(k)\}, k \leq n, M(k), M'(k), k < n), n \geq 0$.

(A5) *Bounded delays.* All interprocessor delays are bounded by a common deterministic constant D.

(A6) *Frequent updates.* $\bar{X}_n$, $\bar{Y}_n \neq \emptyset$ $\forall n$ and there exists an $\bar{\eta} > 0$ such that

$$\liminf_{n\to\infty} \frac{\nu_1(i,n)}{n} \geq \bar{\eta},$$

$$\liminf_{n\to\infty} \frac{\nu_2(j,n)}{n} \geq \bar{\eta}$$

a.s. $\forall i, j$.

Furthermore, if, for $\bar{a}(\cdot), \bar{b}(\cdot)$ defined as in section 4.2 below,

$$N(n,x) = \min\left\{m > n : \sum_{i=n+1}^{m} \bar{a}(i) \geq x\right\},$$

$$N'(n,x) = \min\left\{m > n : \sum_{i=n+1}^{m} \bar{b}(i) \geq x\right\},$$

for $x > 0$, then the limits

$$\lim_{n\to\infty} \frac{\sum_{j=\nu_1(i,n)}^{\nu_1(i,N(n,x))} a(j)}{\sum_{j=\nu_1(k,n)}^{\nu_1(k,N(n,x))} a(j)}, \tag{2.6}$$

$$\lim_{n\to\infty} \frac{\sum_{j=\nu_2(i,n)}^{\nu_2(i,N'(n,x))} b(j)}{\sum_{j=\nu_2(k,n)}^{\nu_2(k,N'(n,x))} b(j)} \tag{2.7}$$

exist a.s. (Together, these conditions imply that the components are updated "comparably often" in an "evenly spread" manner.) In section 6 where we consider learning algorithms for the average cost problems, we strengthen this to $\nu_2(j,n) = n$, i.e., $\bar{Y}_n = I'$.

3. Algorithms for MDPs.

3.1. MDPs. We shall consider MDPs on a finite state space $S = \{1, 2, \ldots, s\}$ with a finite action space $A = \{a_0, \ldots, a_r\}$. $\mathcal{P}(A)$ will denote the set of probability vectors on A. Also given is a transition function $p : S \times S \times A \to [0, 1]$ satisfying

$$\sum_j p(i, j, a) = 1 \ \forall i, a.$$

The MDP is an S-valued process $\{X_n\}$ satisfying a.s.

$$P(X_{n+1} = j | X_k, Z_k, k \le n) = p(X_n, j, Z_n), \qquad n \ge 0,$$

where $\{Z_n\}$ is an A-valued "control" process. If $Z_n = v(X_n)\ \forall n$ for some $v : S \to A$, call $\{Z_n\}$ or, by abuse of terminology, the map v itself, a stationary policy. More generally, if for each n, Z_n is conditionally independent of $\{X_m, Z_m, m < n\}$, given X_n, and Z_n has the same conditional law given X_n for each n, then we call it a stationary randomized policy and identify it with the map $\varphi : S \to \mathcal{P}(A)$ which gives the conditional law of Z_n given X_n. For $i \in S$, $a \in A$, let $\pi(i, a)$ denote the ath component of $\varphi(i)$. Under a stationary policy v (respectively, a stationary randomized policy φ), $\{X_n\}$ is a time-homogeneous Markov chain with transition probabilities $[[p(i, j, v(i))]]$ (respectively, $[[q(i, j, \varphi(i))]]$ where $q(i, j, \varphi(i)) = \sum_a p(i, j, a)\pi(i, a)$). By a further abuse of terminology, we identify the stationary randomized policy φ with the vector $\pi = [\pi(i, a)]$, where the elements are ordered lexicographically. Let $k : S \times A \to R$ be a prescribed "running cost" function and $\alpha \in (0, 1)$ a "discount factor." The two control problems we consider follow in sections 3.2 and 3.3.

3.2. The infinite horizon discounted cost problem. Here the aim is to minimize over all admissible $\{Z_n\}$ the quantity $\mathrm{E}[\sum_{n=0}^{\infty} \alpha^n k(X_n, Z_n)]$. Define the value function $V_\alpha : S \to R$ by

$$V_\alpha(i) = \inf \mathrm{E}\left[\sum_{n=0}^{\infty} \alpha^n k(X_n, Z_n) | X_0 = i\right],$$

where the infimum is over all admissible $\{Z_n\}$. Then $V_\alpha(\cdot)$ is the unique solution to the equation

$$V_\alpha(i) = \min_a \left[k(i, a) + \alpha \sum_j p(i, j, a) V_\alpha(j)\right], \qquad i \in S, \tag{3.1}$$

and $\{Z_n\}$ is optimal if and only if $Z_n \in \mathrm{Arg\ min}(k(X_n, \cdot) + \alpha \sum_j p(X_n, j, \cdot) V_\alpha(j))$ a.s. $\forall n$. In particular, a stationary policy v (respectively, stationary randomized policy φ) is optimal if and only if $v(i) \in \mathrm{Arg\ min}(k(i, \cdot) + \alpha \sum_j p(i, j, \cdot) V_\alpha(j))$ (respectively, $\mathrm{support}(\varphi(i)) \subset \mathrm{Arg\ min}(k(i, \cdot) + \alpha \sum_j p(i, j, \cdot) V_\alpha(j)))\ \forall i$ that are visited with positive probability. Thus the existence of a stationary policy $v(\cdot)$ follows, as well as a recipe for finding it, viz., by minimizing the right-hand side (RHS) of (3.1) to find $v(i)$; see [21] for this and related results.

For future reference, we also associate with a stationary randomized policy $\varphi = [[\pi(i, a)]]$ a "stationary value function" $V_\pi : S \to R$ defined by

$$V_\pi(i) = \mathrm{E}\left[\sum_{n=0}^{\infty} \alpha^n k(X_n, Z_n) | X_0 = i\right], \qquad i \in S,$$

where $\{Z_n\} \approx \varphi$. This is easily seen to be the unique solution of the linear equation

$$V_\pi(i) = \sum_a \pi(i,a) \left[k(i,a) + \alpha \sum_j p(i,j,a) V_\pi(j) \right], \qquad i \in S. \tag{3.2}$$

3.3. Average expected cost problem. Here the aim is to minimize

$$\limsup_{N\to\infty} \frac{1}{N} \mathrm{E} \left[\sum_{n=0}^{N-1} k(X_n, Z_n) \right]$$

over all admissible $\{Z_n\}$. We assume that $\{X_n\}$ is an irreducible Markov chain under every stationary policy. Under this condition, it can be shown that there exists a pair $(h(\cdot), \lambda^*)$, $h : S \to R$, $\lambda^* \in R$, satisfying

$$\lambda^* + h(i) = \min_a \left[k(i,a) + \sum_j p(i,j,a) h(j) \right]. \tag{3.3}$$

Furthermore, λ^* is uniquely specified as the optimal cost, equal to the cost of an optimal stationary policy guaranteed to exist and characterized by $v(i) \in \mathrm{Arg}\ \min(k(i,\cdot) + \sum_j p(i,j,\cdot) h(j))$. A stationary randomized policy φ is optimal if and only if support of $\varphi(i)$ lies in the above Argmin. The vector h is unique up to an additive constant; i.e., if h, h' satisfy (3.3), then $h(i) - h'(i)$ is independent of i. We shall denote by h^* the unique solution satisfying $h^*(i_0) = \lambda^*$ for a prescribed $i_0 \in S$. For future reference, we also associate with a stationary randomized policy $\varphi = [[\pi(i,a)]]$ the corresponding cost λ_π and the function $h_\pi : S \to R$ uniquely specified by $h_\pi(i_0) = \lambda_\pi$ and

$$\lambda_\pi + h_\pi(i) = \sum_a \pi(i,a) \left[k(i,a) + \sum_j p(i,j,a) h_\pi(j) \right], \qquad i \in S.$$

3.4. Policy iteration. A popular iterative scheme for solving (3.1) or (3.3) is policy iteration, known to converge to the desired solution in finitely many steps [21]. Consider (3.1). One starts with an initial guess for optimal stationary policy, say, $v_0(\cdot)$. At nth iteration, one performs the following two steps: Given current candidate $v_n(\cdot)$ for the stationary optimal policy,

Step 1. Compute the stationary value function $V_n \triangleq V_{v_n}$.

Step 2. Pick $v_{n+1}(i) \in \mathrm{Argmin}(k(i,\cdot) + \alpha \sum_j p(i,j,\cdot) V_n(j))$.

Step 1 involves solution of a linear system. We may replace it by an "inner loop" that computes V_n iteratively via a "stationary value iteration": Step 1′: $V_n^{m+1}(i) = k(i, v_n(i)) + \alpha \sum_j p(i,j,v_n(i)) V_n^m(j)$ for $m = 0, 1, 2, \ldots$.

This entails that Step 2 wait till the inner loop iterations converge. Among other things, the algorithms we propose work around this difficulty by using two time scales.

The policy iteration for the average expected cost reads exactly the same except that the linear system in question now is

$$h_n(i) + h_n(i_0) = k(i, v_n(i)) + \sum_j p(i,j,v_n(i)) h_n(j), \qquad i \in S,$$

to be solved for $h_n(\cdot)$. An iterative scheme for this, replacing Step 1 above, is

$$h_n^{m+1}(i) = k(i, v_n(i)) + \sum_j p(i, j, v_n(i)) h_n^m(j) - h_n^m(i_0),$$

where $i_0 \in S$ is a prescribed state as before. Step 2 is as before with $\alpha = 1$. This is the "relative value iteration" scheme [21]. It is known to converge to h^*.

3.5. Learning algorithms for MDPs. In this section, we introduce simulation-based learning algorithms based on policy iteration. As already mentioned, the key point in simulation-based algorithms is that the transition probabilities $p(i, \cdot, a)$ are not available, but it is possible to simulate a transition according to any of these probabilities. Thus one replaces the conditional average of candidate V (or h, as the case may be) with respect to a given transition probability by an evaluation of the same function at the state reached by a simulated transition as per the said probability. Nevertheless, in order for the algorithm to mimic the classical iterative algorithms of the previous subsection, it must "see" the appropriate conditional average through an averaging effect. This is achieved by using a stochastic approximationlike step size schedule.

The "learning" variants of policy iteration were introduced by Barto, Sutton, and Anderson [3] and dubbed "adaptive critic" algorithms. Our formulations differ in that we explicitly use two time scales to simulate the two (i.e., inner and outer) loops of iterations. The outer loop operates on a slower scale and thus sees the inner loop as essentially equilibrated, while the inner (fast) loop sees the outer one as quasi-static. In addition, we allow for a distributed asynchronous implementation, as is usually the case in practice. All in all, our algorithms will fit the framework of the "general algorithm" discussed in the last section.

We shall denote by $V_n(\cdot)$, $\pi_n(\cdot, \cdot)$ the current estimate for the value function and optimal stationary randomized policy, respectively. Let I_1, I_2 be a collection of nonempty subsets of S, $S \times (A \backslash \{a_0\})$, respectively. Let $\{Y_n\}$, $\{Z_n\}$ be I_1, I_2-valued random processes, respectively, with the interpretation that $Y_n =$ the set of $i \in S$ for which $V_n(i)$ gets updated at time n, $Z_n =$ the set of $(i, a) \in S \times (A \backslash \{a_0\})$ for which $\pi_n(i, a)$ gets updated at time n. (Note that $\pi_n(i, a_0) = 1 - \sum_{a \neq a_0} \pi_n(i, a)$.) Define $\nu_1(i, n)$, $\nu_2(i, a, n)$ by

$$\nu_1(i, 0) = 0, \qquad \nu_1(i, n) = \sum_{m=0}^{n-1} I\{i \in Y_m\}, \qquad n > 0,$$

$$\nu(i, a, 0) = 0, \qquad \nu_2(i, a, n) = \sum_{m=0}^{n-1} I\{(i, a) \in Z_m\}, \qquad n > 0.$$

We assume the following throughout the counterpart of (A6). For a deterministic $\Delta > 0$,

$$\liminf_{n \to \infty} \frac{\nu_1(i, n)}{n} \geq \Delta, \qquad \text{a.s. } \forall i \in S,$$

$$\liminf_{n \to \infty} \frac{\nu_2(i, a, n)}{n} \geq \Delta, \qquad \text{a.s. } \forall i \in S, \quad a \in A.$$

Also, the appropriate analogues of (2.6), (2.7) are assumed to hold.

Introduce delays $\tau_n(i, j)$, $\bar{\tau}_n(i, j)$, $\hat{\tau}_n(i)$. The processor updating $V_n(i)$ receives at time n, $V_{n - \tau_n(i,j)}(j)$ instead of $V_n(j)$ and $\pi_{n - \hat{\tau}_n(i)}(i, a)$ instead of $\pi_n(i, a)$. Similarly

the processor updating $\pi_n(i,\cdot)$ at time n receives $V_{n-\bar\tau_n(i,j)}(j)$ instead of $V_n(j)$. These delays are assumed to be bounded a.s. by a deterministic $T > 0$. No messages are lost. Thus, for example, for $j \neq i$, each $\{V_m(j)\}$ is received by the processor that updated $V_m(i)$, albeit with a delay of at most T and not necessarily in the order sent. Let $\{\xi_n(i,a)\}$, $\{\eta_n(i,a)\}$, $i \in S$, $a \in A$, be independent families of independently and identically distributed (i.i.d.) random variables with law $p(i,\cdot,a)$. Let $\varphi_n(i)$ be an A-valued random variable whose conditional law given $\mathcal{F}_n \stackrel{\Delta}{=} \sigma(V_m(\cdot), \pi_m(\cdot), \xi_n(\cdot,\cdot), \eta_m(\cdot,\cdot), \tau_m(\cdot,\cdot), \bar\tau_m(\cdot,\cdot), \hat\tau_m(\cdot),\ m \le n)$ is $\pi_{n-\hat\tau_n(i)}(i,\cdot)$. (Note that this is available to the processor updating $V_n(i)$ at time n.)

Let $PS \subset R^r$ be the simplex defined by

$$PS = \left\{ (x_1,\dots,x_r) : x_i \ge 0; \forall i = 1,\dots,r \text{ and } \sum_{i=1}^r x_i \le 1 \right\}.$$

Let P be the projection from R^r to PS. A stationary randomized policy π can be identified with a $\hat\pi \in PS^s$ with $\hat\pi = [[\pi(i,a)]]$, $i \in S$, $a \in A\backslash\{a_0\}$ (because $\pi(i,a_0)$ gets automatically specified $\forall i$). In particular $\pi \approx \hat\pi$ is thus an element in $(PS)^s$. We shall use $\hat\pi(i)$ and $\hat\pi(i,\cdot)$ interchangeably. The algorithms update $\hat\pi$ rather than π. In what follows, $\{a(n)\}$, $\{b(n)\}$ are as in the preceding section. The updating scheme for V_n is the same in Algorithms 1–3 and therefore is mentioned only once.

3.6. Algorithm 1.

$$\begin{aligned} V_{n+1}(i) = V_n(i) &+ b(\nu_1(i,n))[k(i,\varphi_n(i)) + \alpha V_{n-\tau_n(i,\xi_n(i,\varphi_n(i)))}(\xi_n(i,\varphi_n(i))) \\ &- V_n(i)]I\{i \in Y_n\}, \end{aligned}$$

$$\begin{aligned} \hat\pi_{n+1}(i) = P\Bigg(\hat\pi_n(i) + \sum_{l=1}^r a(\nu_2(i,a_l,n))[k(i,a_0) - k(i,a_l) + \alpha(V_{n-\bar\tau(i,\eta_n(i,a_0))}(\eta_n(i,a_0)) \\ - V_{n-\bar\tau(i,\eta_n(i,a_l))}(\eta_n(i,a_l)))]I\{(i,a_l) \in Z_n\}e_l \Bigg), \end{aligned}$$

where e_l is the unit vector in lth coordinate direction.

3.7. Algorithm 2. Let $\{\psi_{il}(n)\}_{i\in S, a_l \in A}$ denote zero mean i.i.d. noise satisfying the following: For $M_n(i,l) \stackrel{\Delta}{=} \alpha\pi_n(i,a_l)(\sum_k p(i,k,a_l)V_n(k) - V_{n-\bar\tau(i,\eta_n(i,a_l))}(\eta_n(i,a_l)))$, the following holds:

$$\inf_{\theta\in R^r, \|\theta\|=1} \mathrm{E}\left[\max\left(0, \left\langle \theta, \sum_l (M_n(i,l) + \psi_{il}(n))e_l \right\rangle \right)\right] > 0.$$

This condition is difficult to verify. Crudely speaking, it requires that the noise intensity uniformly dominate the effect of the "error" term $M_n(\cdot,\cdot)$ in all directions. In simulations, simple ad hoc "noise" schemes seem to work well. We shall have more to say on this in the following section. The algorithm is as follows: $\{V_n\}$ is updated as above and

$$\begin{aligned} \hat\pi_{n+1}(i) = P\Bigg(\hat\pi_n(i) + \sum_{l=1}^r a(\nu_2(i,a_l,n))[(V_{n-\bar\tau_n(i,i)}(i) - k(i,a_l) \\ - \alpha V_{n-\bar\tau_n(i,\eta_n(i,a_l))}(\eta_n(i,a_l)))\hat\pi_n(i,a_l) + \psi_{il}(n)]I\{(i,a_l) \in Z_n\}e_l \Bigg). \end{aligned}$$

3.8. Algorithm 3. In this, we parametrize $\pi(\cdot,\cdot)$ by parameters $\beta(\cdot,\cdot)$ according to

$$\pi_\beta(i,a) = \frac{\exp(\beta(i,a))}{\sum_{a'} \exp(\beta(i,a'))}, \quad i \in S, \quad a \in A.$$

Each $\beta(i,a)$ is updated by a separate processor. The setup is as before except that the conditional distribution of $\varphi_n(i)$ now is

$$\frac{\exp(\beta_{n-\hat{\tau}_n(i)}(i,\cdot))}{\sum_a \exp(\beta_{n-\hat{\tau}_n(i)}(i,a))}$$

and Z_n is an $S \times A$-valued process.

The algorithm is as follows: $\{V_n\}$ is updated as above and

$$\begin{aligned}\beta_{n+1}(i,a) = P_{\beta_0}(\beta_n(i,a) + a(\nu_2(i,a,n))[V_{n-\bar{\tau}(i,i)}(i) - k(i,a) \\ - \alpha V_{n-\bar{\tau}(i,\eta_n(i,a))}(\eta_n(i,a))]I\{(i,a) \in Z_n\}),\end{aligned}$$

where $P_{\beta_0} : R \to R$, $\beta_0 > 0$ is defined by

$$P_{\beta_0}(x) = \begin{cases} -\beta_0 & \text{for} \quad x \le -\beta_0, \\ x & \text{for} \quad -\beta_0 < x < \beta_0, \\ \beta_0 & \text{otherwise.} \end{cases} \tag{3.4}$$

The next three algorithms deal with the average expected cost problem and are exact counterparts of the above. The delays are defined as before, with h_n replacing V_n. Because of some technical difficulties that will become apparent later in section 5, we require all components of $\{h_n\}$ to sit on the same processor and get updated synchronously. The algorithms are as follows.

3.9. Algorithm 4.

$$h_{n+1}(i) = h_n(i) + b(n)[k(i,\varphi_n(i)) + h_n(\xi_n(i,\varphi_n(i))) - h_n(i) - h_n(i_0)], \tag{3.5}$$

$$\begin{aligned}\hat{\pi}_{n+1}(i) = P\Bigg(\hat{\pi}_n(i) + \sum_{l=1}^{r} a(\nu_2(i,a_l,n))[k(i,a_0) - k(i,a_l) + (h_{n-\bar{\tau}(i,\eta_n(i,a_0))}(\eta_n(i,a_0)) \\ - h_{n-\bar{\tau}(i,\eta_n(i,a_l))}(\eta_n(i,a_l)))]I\{(i,a_l) \in Z_n\}e_l\Bigg).\end{aligned}$$

3.10. Algorithm 5. $\{h_n\}$ is updated as above and

$$\begin{aligned}\hat{\pi}_{n+1}(i) = P\Bigg(\hat{\pi}_n(i) + \sum_{l=1}^{r} a(\nu_2(i,a_l,n))[(h_{n-\bar{\tau}_n(i,i_0)}(i_0) + h_{n-\bar{\tau}(i,i)}(i) - k(i,a_l) \\ - h_{n-\bar{\tau}(i,\eta_n(i,a_l))}(\eta_n(i,a_l)))\hat{\pi}_n(i,a_l) + \psi_{il}(n)]I\{(i,a_l) \in Z_n\}e_l\Bigg).\end{aligned}$$

3.11. Algorithm 6. Here π is parameterized by $\beta(\cdot,\cdot)$ as before. $\{h_n\}$ is updated as above and

$$\beta_{n+1}(i,a) = P_{\beta_0}(\beta_n(i,a) + a(\nu_2(i,a,n))[h_n(i_0) + h_{n-\bar{\tau}(i,i)}(i) - k(i,a) - h_{n-\bar{\tau}(i,\eta_n(i,a))}(\eta_n(i,a))]I\{(i,a) \in Z_n\}).$$

We now briefly describe the intuition behind the three schemes for updating $\hat{\pi}(\cdot)$. Note that ideally $\hat{\pi}$ should concentrate on Argmin of the quantity in square brackets in (3.1), which we call the "Q-value." This suggests that $\hat{\pi}$ should be incrementally adjusted in the direction of lowering the average Q-value with respect to $\hat{\pi}$. This is achieved by comparing Q-values of, say, (i,a) with that of (i,a_0) and using the difference as the "reinforcement signal" for adjusting $\hat{\pi}(i,a)$ in the appropriate direction. (Note that $\hat{\pi}(i,a_0)$ gets automatically adjusted.) This is the philosophy behind Algorithms 1 and 4.

In Algorithms 2 and 5, on the other hand, we take as reinforcement signal the offset between value function and the Q-value, keeping in mind that the former should ideally be the minimum of the latter over a. The additional multiplication by $\hat{\pi}(i,a)$ on the RHS ensures that the iterates "sort of" remain within the desired simplex. (They do exactly so in an asymptotic sense.)

Algorithms 3 and 6 are different in a crucial way. They parametrize $\hat{\pi}$ by hypothesizing a Gibbsian form parametrized by a parameter vector and update the latter rather than $\hat{\pi}$ itself. This search is on a restricted subdomain of the simplex; thus only near optimality can be hoped for. But this parametric form leads to simple algorithms with the possibility of alleviating the "curse of dimensionality" by interfacing with low-dimensional parametrizations.

4. Convergence analysis for the general algorithm.

4.1. Preliminary lemmas. This section sets forth some key technical results underlying the convergence analysis to follow. To start with, consider the ODE

$$\dot{x} = h(x(t),t), \qquad t \geq 0, \tag{4.1}$$

with $h : R^d \times [0,\infty) \to R^d$ measurable and the set $J \stackrel{\Delta}{=} \{x : h(x,t) = 0\}$ compact and independent of t. A continuously differentiable function $V : R^d \to R$ is said to be a strict Liapunov function for (4.1) if

1. $V(x) \to \infty$ as $\|x\| \to \infty$, uniformly in $\|x\|$;

2. $H(x,t) \stackrel{\Delta}{=} \nabla V(x) \cdot h(x,t) \leq 0 \ \forall x,t$ with equality holding only when $x \in J$.

Define $J^\epsilon = \{x : \|x - y\| < \epsilon \text{ for some } y \in J\}$, $\epsilon > 0$. We further assume that $\inf_{t\geq 0, x\notin B} |H(x,t)|$ is nonzero for every open set B containing J.

DEFINITION 4.1. *Given T, $\delta > 0$, a (T,δ)-perturbation of ODE* (4.1) *is a bounded measurable function $y : [0,\infty) \to R^d$ such that there exist $0 = T_0 < T_1 < \cdots T_n \uparrow \infty$ and solutions $x^j(t)$, $t \in [T'_j, T'_{j+1}]$, $j \geq 0$, of* (4.1) *such that $T'_{j+1} - T'_j = T_{j+1} - T_j \geq T$ for $j \geq 0$ and $\|y(t) - x^j(T'_j + t - T_j)\| < \delta$, $T_j \leq t \leq T_{j+1}$, $j \geq 0$.*

The following is a small extension of [13, Theorem 1, p. 339].

LEMMA 4.2. *For any T, $\epsilon > 0$, there exists a $\delta_0 = \delta_0(T,\epsilon) > 0$ such that for any $\delta \in (0,\delta_0)$, any (T,δ)-perturbation of* (4.1) *will converge to J^ϵ.*

Proof. Let $y(\cdot)$ be a (T,δ)-perturbation of (4.1). For $\eta > 0$, define

$$B(\eta) = \{x : |V(x) - V(y)| < \eta \text{ for some } y \in J\}.$$

Let B be a ball large enough so that it contains both $\{y(t), t \geq 0\}$ and $B(\eta)$ for some η chosen so that $B(\eta) \subset J^\epsilon$. Define K, Δ by

$$K = \sup_{x \in \bar{B}} \|\nabla V(x)\|, \qquad \Delta = \inf_{t \geq 0} \inf_{x \in \bar{B} \setminus B(\eta)} |H(x,t)|.$$

Call the restriction of $y(\cdot)$ to $[T_j, T_{j+1}]$ the jth patch of $y(\cdot)$. Let $\delta < \frac{\Delta T}{4K}$. It is easily seen that $V(y(T_j)) - V(y(T_{j+1})) + 2\delta K \geq V(x^j(T'_j)) - V(x^j(T'_{j+1})) \geq \Delta T$ whenever $x^j(t)$, $t \in [T'_j, T'_{j+1}]$, does not intersect $B(\eta)$. But then

$$V(y(T_j)) - V(y(T_{j+1})) \geq \Delta T/2. \tag{4.2}$$

This can occur for at most finitely many consecutive j's because $V(\cdot)$ is bounded from below. Also, if the jth patch of $y(\cdot)$ does not intersect $B(\eta + \delta K)$, $x^j(\cdot)$ cannot intersect $B(\eta)$. We conclude that eventually $x^j(\cdot)$ and the jth patch of $y(\cdot)$ must intersect $B(\eta)$, $B(\eta + \delta K)$, respectively. Now, for all j,

$$V(x^j(t)) \leq V(x^j(s)) \ \forall s, \quad t \in [T'_j, T'_{j+1}], \quad t \geq s.$$

So

$$V(y(t)) \leq V(y(s)) + 2\delta K \ \forall s, \quad t \in [T_j, T_{j+1}], \quad t \geq s.$$

Therefore, the patch of $y(\cdot)$ that intersects $B(\eta + \delta K)$ remains in $B(\eta + \delta K + 2\delta K)$ after hitting $B(\eta + \delta K)$. Since $2\delta K < \Delta T/2$, (4.2) implies that the subsequent patch must hit $B(\eta + \delta K)$. It follows that $y(\cdot)$ remains in $B(\eta + \delta K + 2\delta K)$ once it hits $B(\eta + \delta K)$. Pick η, δ sufficiently small so that $B(\eta + \delta K + 2\delta K) \subset J^\epsilon$. This completes the proof. □

COROLLARY 4.3. *For $X(\cdot) \in C([0,\infty); R^d)$, $0 \leq t(n) \uparrow \infty$, if $\{X(t(n) + \cdot)\}$ is conditionally compact in $C([0,\infty); R^d)$ and all the limit points of $\{X(t(n) + \cdot)\}$ in $C([0,\infty); R^d)$ as $n \to \infty$ satisfy (4.1), then $X(t)$ converges to J as $t \to \infty$.*

Proof. Let $T > 0$. Let $\delta > 0$ be such that $X(t(n) + \cdot)$ is not a (T, δ)-perturbation of (4.1) for any n. Then there exists sequence $n_1, n_2, \ldots, n_i \uparrow \infty$ such that

$$\sup_{t \in [0,t]} \|X(t(n_i) + t) - z(t)\| \geq \delta \ \forall i > 0,$$

for all $z(\cdot)$ satisfying ODE (4.1). This means that there cannot exist a subsequence of $\{X^{n_i}(\cdot)\}$ that converges to a solution of ODE (4.1). Thus for all $\delta > 0$, there exists n sufficiently large such that $X(t(n) + \cdot)$ is a (T, δ)-perturbation of (4.1). This, by Lemma 4.2, implies that $X(t)$ converges to J as $t \to \infty$. □

Next define U^d as the space of $[0,1]^d$-valued trajectories $\bar{\mu} = \{\mu_t, t \geq 0\}$ with the coarsest topology that renders continuous the maps $\bar{\mu} \mapsto \int_0^T h(t)\mu_t(i)dt$ for $T > 0$, $1 \leq i \leq d$, $h \in L_2[0,T]$. Using the Banach–Alaoglu theorem, it is easily verified that U^d is compact metrizable and, hence, Polish. For $\bar{\mu} \in U^d$ let $M^{\bar{\mu}}(t)$ denote the diagonal matrix $\text{diag}(\mu_t(1), \ldots, \mu_t(d))$, $t \geq 0$. For $\mu \in [0,1]^d$ define $M^\mu = \text{diag}(\mu(1), \ldots, \mu(d))$.

LEMMA 4.4. *Let $\{X^n(\cdot)\} \subset C([0,\infty); R^d)$ be uniformly bounded with $X^n(\cdot) \to X^\infty(\cdot)$ and $\{\bar{\mu}^n\} \subset U^d$ such that $\bar{\mu}^n \to \bar{\mu}^\infty$. Then for every $h \in C(R^d; R^d)$,*

$$\lim_{n \to \infty} \int_0^t M^{\bar{\mu}^n}(s) h(X^n(s)) ds = \int_0^t M^{\bar{\mu}^\infty}(s) h(X^\infty(s)) ds.$$

Proof.

$$\begin{aligned}
&\left\| \int_0^t M^{\bar{\mu}^\infty}(s) h(X^\infty(s)) ds - \int_0^t M^{\bar{\mu}^n}(s) h(X^n(s)) ds \right\| \\
&\quad \leq \left\| \int_0^t M^{\bar{\mu}^n}(s) (h(X^\infty(s)) - h(X^n(s))) ds \right\| \\
&\qquad + \left\| \int_0^t M^{\bar{\mu}^\infty}(s) h(X^\infty(s)) ds - \int_0^t M^{\bar{\mu}^n}(s) h(X^\infty(s)) ds \right\| \\
&\quad \leq \int_0^t \| h(X^\infty(s)) - h(X^n(s)) \| ds \\
&\qquad + \left\| \int_0^t M^{\bar{\mu}^\infty}(s) h(X^\infty(s)) ds - \int_0^t M^{\bar{\mu}^n}(s) h(X^\infty(s)) ds \right\|.
\end{aligned}$$

Given our hypotheses, it is easy to see that both terms on the right go to zero. ∎

The last lemma of this subsection concerns the noise sequence.

LEMMA 4.5. $\sum_n a(\nu_1(i,n)) M_i(n) I\{i \in \bar{X}_n\}$, $\sum_n b(\nu_2(j,n)) M'_j(n) I\{j \in \bar{Y}_n\}$ *converge a.s.*

Proof. Note that in each case the partial sums form a square integrable $\{\mathcal{F}_n\}$-martingale. By (A4) and the fact that $\forall i, j$,

$$\sum_n a(\nu_1(i,n))^2 I\{i \in \bar{X} n\}, \qquad \sum_n b(\nu_2(j,n))^2 I\{j \in \bar{Y}_n\} < \infty \text{ a.s.},$$

it follows that the quadratic variation process for these martingales remain bounded a.s. The claim now follows from [18, Proposition VII-3(c), pp. 149–150]. ∎

4.2. Convergence analysis. We shall proceed through a sequence of lemmas. Define

$$\begin{aligned}
\bar{b}(n) &= \max_{i \in \bar{Y}_n} b(\nu_2(i,n)), \\
\bar{a}(n) &= \max_{j \in \bar{X}_n} a(\nu_1(j,n)).
\end{aligned}$$

Let $t(0) = 0$, $t(n) = \sum_{k=0}^{n-1} \bar{b}(k)$, $n > 0$ and define sequences $\{\mu'_n\}$, $\{\mu_n\}$ in $[0,1]^m$, $[0,1]^l$ by the following: For $n \geq 0$,

$$\begin{aligned}
\mu'_n(i) &= b(\nu_2(i,n)) I\{i \in \bar{Y}_n\} / \bar{b}(n), \qquad 1 \leq i \leq m, \\
\mu_n(j) &= a(\nu_1(j,n)) I\{j \in \bar{X}_n\} / \bar{a}(n)
\end{aligned}$$

for $1 \leq j \leq l$. Then rewrite the algorithm (2.2)–(2.3) as

$$X(n+1) = P(X(n) + \bar{a}(n) M^{\mu_n}(W(n) + M(n))), \tag{4.3}$$

$$Y(n+1) = Y(n) + \bar{b}(n) M^{\mu'_n}(W'(n) + M'(n)), \tag{4.4}$$

where $W_i(n) = g_i(\tilde{X}^i(n), \tilde{Y}^i(n))$, $W'_j(n) = f_j(\hat{X}^j(n), \hat{Y}^j(n))$ for $1 \leq i \leq m$, $1 \leq j \leq l$.

LEMMA 4.6. $\bar{b}(n), \bar{a}(n) \to 0$ *and* $\bar{a}(n) = o(\bar{b}(n))$ *a.s.*

Proof. By assumption (A1) $\hat{a} = \sup_n \sup_{y \in [x,1]} a([yn])/a(n)$ is finite $\forall x \in (0,1]$. Let $\bar{\eta} > \epsilon > 0$, where $\bar{\eta}$ is as in (A6). By (A6), a.s., $\nu_1(i,n)/n > \bar{\eta} - \epsilon$ eventually.

Setting $x = \bar{\eta} - \epsilon$ in the above, $a(\nu_1(i,n))/a(n) \leq \hat{a} + \delta$ eventually a.s. for any $\delta > 0$. Since $a(n) \to 0$ it follows that $\bar{a}(n) \to 0$; $\bar{b}(n) \to 0$ is proved similarly. Now, for large n,

$$\frac{\bar{a}(n)}{\bar{b}(n)} \leq \frac{a([n(\bar{\eta} - \epsilon)])}{b(n)} \leq \hat{a}\frac{a(n)}{b(n)}$$

by (A1). □

LEMMA 4.7. $\|g(X(n), Y(n)) - W(n)\|, \|f(X(n), Y(n)) - W'(n)\| \to 0$ *a.s.*

Proof. Let C be a bound on the $\{g_i(X^i(n), Y^i(n))\}$ (cf. (A2)). For D as in (A5) and $1 \leq i \leq K$, we have, for $n \geq D$ and suitable $C_1 > 0$ depending on C,

$$\begin{aligned}\|X(n) - \tilde{X}^i(n)\| &\leq C_1 \sum_{k=n-D}^{n} \bar{a}(k) + \sum_{k=n-D}^{n} \|\bar{a}(k)M(k)\| \\ &\leq (D+1)\left(C_1 \sup_{k \geq n-D} \bar{a}(k) + \sup_{k \geq n-D} \|\bar{a}(k)M(k)\|\right).\end{aligned}$$

Using Lemma 4.5 and (A4) we conclude that the r.h.s. above tends to zero a.s. Similarly, one proves that a.s.

$$\|\hat{X}^i(n) - X(n)\|, \quad \|\hat{Y}^i(n) - Y(n)\|, \quad \|\tilde{Y}^j(n) - Y(n)\| \to 0.$$

The claim follows from (A2) and continuity of $f(\cdot,\cdot)$, $g(\cdot,\cdot)$. □

Define $\bar{\mu} \in U^m$ by the following: $\mu_t = \mu'_n$, $t \in [t(n), t(n+1))$, $n \geq 0$. Let $\bar{\mu}^n = \{\mu_{t+t(n)}, t \geq 0\}$. In the following lemma, it is worth keeping in mind that the convergence of $\bar{\mu}^n$'s along a subsequence to μ^* (say) is with respect to the topology on U^m defined above. That is, for each $T > 0$, $f \in L_2[0,T], i \in S$,

$$\int_0^T f(t)\mu_t^n(i)dt \to \int_0^T f(t)\mu_t^*(i)dt.$$

LEMMA 4.8. *Almost surely, every limit point $\bar{\mu}^*$ of $\{\bar{\mu}^n\}$ in U^m satisfies the following: $\mu_t^*(i) = c(t)/m$ almost every t (a.e.t) for some bounded measurable function $c(\cdot) : [0,\infty) \to [1,\infty)$.*

Proof. Let $h(\cdot)$ be an eventually decreasing smooth function $[0,\infty) \to [0,\infty)$ such that $h(t(n)) = b(n)$ $\forall n$. Note that

$$\begin{aligned}\lim_{t\to\infty} \frac{\int_z^t \mu_s(j)ds}{\int_z^t \mu_s(i)ds} &= \lim_{n\to\infty} \frac{\sum_{k=0}^{\nu_1(j,n)} b(k)}{\sum_{k=0}^{\nu_1(i,n)} b(k)} = \lim_{n\to\infty} \frac{\int_0^{\nu_1(j,n)} h(s)ds}{\int_0^{\nu_1(i,n)} h(s)ds} \\ &= \lim_{n\to\infty} \frac{\int_0^{\nu_1(j,n)} h(s)ds}{\int_0^n h(s)ds} \frac{\int_0^n h(s)ds}{\int_0^{\nu_1(i,n)} h(s)ds} \\ &= 1 \ a.s.,\end{aligned}$$

uniformly in z for $z \leq C$ (say), by virtue of (A1)(3) and (A6). Then for $x > 0$,

$$\lim_{t\to\infty} \frac{\int_0^x \int_0^t \mu_{s+y}(j)dsdy}{\int_0^x \int_0^t \mu_{s+y}(i)dsdy} = \lim_{t\to\infty} \frac{\int_0^t \int_0^x \mu_{s+y}(j)dyds}{\int_0^t \int_0^x \mu_{s+y}(i)dyds} = 1 \ a.s.$$

By l'Hôpital's rule,

$$\lim_{t\to\infty} \frac{\int_0^x \mu_{t+y}(j)dy}{\int_0^x \mu_{t+y}(i)dy} = 1 \text{ a.s.}$$

(That this limit is known to exist a priori follows from the second half of assumption (A6).) Thus, a.s., any limit point $\bar{\mu}^*$ of $\{\bar{\mu}^n\}$ must satisfy

$$\frac{\int_0^x \mu_t^*(j)dt}{\int_0^x \mu_t^*(i)dt} = 1 \text{ a.s.}$$

Since x was arbitrary, we have $\mu_t^*(j)/\mu_t^*(i) = 1$ for a.e.t. This along with the fact that $m \geq \sum_i \mu_t(i) \geq 1$ for all t implies the above claim. □

The proofs of the next two lemmas are given in outline, as the details are lengthy but routine.

LEMMA 4.9. $\|\lambda(X(n)) - Y(n)\| \to 0$ a.s.

Proof (sketch). Fix a sample point outside the zero probability set where the foregoing lemmas and assumptions fail. Rewrite the algorithm as

$$X(n+1) = X(n) + \bar{b}(n)\left(\frac{\bar{a}(n)}{\bar{b}(n)}\right) M^{\mu_n}(W(n) + M(n))$$

$$+ \bar{b}(n)\left(\frac{P(X(n) + \bar{a}(n)M^{\mu_n}(W(n) + M(n))) - X(n) - \bar{a}(n)M^{\mu_n}(W(n) + M(n))}{\bar{b}(n)}\right),$$

$$Y(n+1) = Y(n) + \bar{b}(n)M^{\mu_n'}(f(X(n), Y(n)) + ((W'(n) - f(X(n), Y(n))) + M'(n))).$$

Using our definition of $P(\cdot)$, it follows that

$$\left\| \frac{P(X(n) + \bar{a}(n)M^{\mu_n}(W(n) + M(n))) - X(n) - \bar{a}(n)M^{\mu_n}(W(n) + M(n))}{\bar{b}(n)} \right\|$$

$$\leq \left(\frac{\bar{a}(n)}{\bar{b}(n)}\right) \|W(n) + M(n)\|.$$

Since $\|W(n) + M(n)\|$ remains bounded, we have, by Lemma 4.6,

$$X(n+1) = X(n) + \bar{b}(n)Z(n),$$

where $Z(n)$ is $o(1)$. Define $\tilde{X}(\cdot) : [0, \infty) \to R^l$, $\tilde{Y}(\cdot) : [0, \infty) \to R^m$ by $\tilde{X}(t(n)) = X(n)$, $\tilde{Y}(t(n)) = Y(n)$, with linear interpolation on $[t(n), t(n+1)]$, $n \geq 0$. In view of Lemmas 4.4–4.8, a standard argument using the discrete Gronwall inequality shows that for any T, $\delta > 0$, $\tilde{X}(t(n) + \cdot)$, $\tilde{Y}(t(n) + \cdot)$ is, for sufficiently large n, (see, e.g., [9, p. 847]) a (T, δ)-perturbation of the ODE (for a suitable $c : R^+ \to [1, \infty)$)

$$\dot{x}(t) = 0, \qquad \dot{y}(t) = \frac{c(t)}{m} f(x(t), y(t)).$$

By Lemma 4.2, $(X(n), Y(n)) \to \text{graph}(\lambda)$. The claim follows from the uniform continuity of $\lambda(x)$. □

Now define the sequence $s(n) \uparrow \infty$ by $s(0) = 0$, $s(n) = \sum_{k=0}^{n-1} \bar{a}(k)$, $n > 0$. Redefine $\bar{\mu} \in U^l$ by $\mu_t = \mu_n$, $t \in [s(n), s(n+1))$, $n \geq 0$.

LEMMA 4.10. $(X(n), Y(n)) \to \{(x, y) : \bar{P}_x(g(x, \lambda(x))) = 0 \text{ and } y = \lambda(x)\}$ *a.s.*

Proof (sketch). Fix ω outside a zero probability set where any of the foregoing assumptions and lemmas fail. Note that

$$\begin{aligned} X(n+1) = X(n) &+ \bar{a}(n)M^{\mu_n}(g(X(n), \lambda(X(n))) + M(n) \\ &+ ([g(X(n), Y(n)) - g(X(n), \lambda(X(n)))] \\ &+ [W(n) - g(X(n), Y(n))])) + r(n), \end{aligned} \tag{4.5}$$

where

$$r(n) = P(X(n) + \bar{a}(n)M^{\mu_n}(W(n) + M(n))) - (X(n) + \bar{a}(n)M^{\mu_n}(W(n) + M(n))).$$

Let $\tilde{\mu}^n = \{\mu_{s(n)+t}, t \geq 0\}$, $n \geq 0$. It is easily verified that Lemma 4.8 applies to $\{\tilde{\mu}^n\}$ as well. Define $\tilde{X}(\cdot) : [0, \infty) \to R^l$ by $\tilde{X}(s(n)) = X(n)$, with linear interpolation on $[s(n), s(n+1)], n \geq 0$. A standard argument along the lines of [16, 17] using Lemmas 4.4–4.9 and Corollary 4.3 shows that for any T, $\delta > 0$, $\tilde{X}(s(n) + \cdot)$ is a (T, δ)-perturbation of the ODE

$$\dot{x}(t) = \frac{c(t)}{l} \bar{P}_{x(t)}(g(x(t), \lambda(x(t))))$$

for sufficiently large n, where $c(\cdot)$ is a scalar measurable function on $[0, \infty)$ satisfying $c(t) \geq 1$ $\forall t$. (The only differences from [9] are the following: (i) the nonautonomous term $c(t)$ arising from the asymptotics of $\{\mu_{s(n)+\cdot}\}$, which is handled as in the preceding lemma (see [9] for details of this limiting argument); (ii) the additional "error" terms in the square brackets in (4.5), whose contribution is asymptotically negligible in view of the foregoing lemmas; and (iii) the term $r(n)$ due to projection operator which can be handled along the lines of [17, section 5.3]—see [16] for details.) Now invoke Lemma 4.2 to conclude. □

5. Convergence analysis for discounted cost.

5.1. Preliminaries. The convergence analysis of this and the next section rests on verifying that the algorithms in question fit the general model of section 2. For this purpose, we start with the following minor variant of a result from [24]. Consider the following iterations in R^d for computing $X(n)$, $n \geq 0$, $X(\cdot) = [X_1(\cdot), \ldots X_d(\cdot)]^T$: For $1 \leq i \leq d$,

$$X_i(n+1) = X_i(n) + a_i(n)(F_i^n(\tilde{X}^i(n)) - X_i(n) + w_i(n)),$$

where $\tilde{X}^i(n)$ is a d-vector whose jth component is $X_j(n - \tau_{ij}(n))$ for some random delays $\{\tau_{ij}(\cdot)\}$ and $\{w_i(n)\}$ is a stochastic process. We make the following assumptions.

1. For $1 \leq i \leq d$, $\{a_i(n)\} \subset [0, \infty)$ are random with $\sum_n a_i(n) = \infty$ a.s., $\sum_n a_i(n)^2 \leq \bar{C}$ a.s. for a finite constant $\bar{C} > 0$.
2. $\{a_i(n)\}$, $\{w_i(n-1)\}$, $\{\tau_{ij}(n)\}$, $\{X_i(n)\}$ are $\{\mathcal{F}_n\}$-adapted for an increasing family of σ-fields $\{\mathcal{F}_n\}$ with

$$\mathrm{E}[w_i(n)|\mathcal{F}_n] = 0, \qquad \mathrm{E}[w_i^2(n)|\mathcal{F}_n] \leq A + B \max_j \max_{k \leq n} |X_j(k)|^2 \ \forall i,$$

   a.s. for suitable A, $B > 0$.
3. $\|F^n(x)\|_\infty \leq \beta \|x\|_\infty + D$ $\forall x$, for suitable $\beta \in (0, 1)$, $D > 0$ and

$$\|F^n(x) - F^n(y)\|_\infty \leq \bar{\beta} \|x - y\|_\infty \forall x, y$$

   for some $\bar{\beta} \in (0, 1)$.

LEMMA 5.1. *Under the above hypotheses,* $\sup_n \|X(n)\| < \infty$ *a.s.*

This is precisely [24, Theorem 2.1] with one small modification that does not affect its proof: [24] has a fixed $F(\cdot)$ in place of $\{F^n(\cdot)\}$.

COROLLARY 5.2. *In Algorithms* 1–3, $\{V_n\}$ *is bounded a.s.*

Proof. Make the following correspondence with the above lemma:

$$a_i(n) = b(\nu_1(i,n))I\{i \in Y_n\},$$
$$\mathcal{F}_n = \sigma(\xi_m(i,a), \eta_m(i,a), \varphi_m(i), m < n, i \in S, a \in A,$$
$$Y_m, Z_m, V_m, \pi_m, \tau_m(i,j), \bar{\tau}_m(i,j), \hat{\tau}_m(i), m \le n, i,j \in S, a \in A),$$
$$F_i^n(V) = \sum_a \pi_{n-\hat{\tau}_n(i)}(i,a)\left[k(i,a) + \alpha \sum_j p(i,j,a)V(j)\right],$$
$$w_i(n) = [k(i,\varphi_n(i)) + \alpha V_{n-\tau_n(i,\xi_n(i,\varphi_n(i)))}(\xi_n(i,\varphi_n(i))) - V_n(i)]$$
$$- \mathrm{E}[[k(i,\varphi_n(i)) + \alpha V_{n-\tau_n(i,\xi_n(i,\varphi_n(i)))}(\xi_n(i,\varphi_n(i))) - V_n(i)]|\mathcal{F}_n].$$

Note that $w(n)$ corresponds to "$M(n)$" in (A4). The claim follows easily. □

This verifies (A2). Assumptions (A1), (A5), and (A6) are already built in. Assumption (A4) follows easily from the a.s. boundedness of $\{V_n(\cdot)\}$. We now verify (A3). Consider the ODE

$$\dot{V}(t) = F(\pi, V(t)) - V(t), \tag{5.1}$$

where $F(\cdot,\cdot) = [F_1(\cdot,\cdot), \ldots, F_s(\cdot,\cdot)]^T$ is defined by

$$F_i(\pi, x) = \sum_a \pi(i,a)k(i,a) + \alpha \sum_{aj} \pi(i,a)p(i,j,a)x_j$$

for $\pi = [[\pi(i,a)]]$, $i \in S$, $a \in A$ with $\pi(i,\cdot) \in \mathcal{P}(A)$ $\forall i$, $x = [x_1, \ldots, x_s] \in R^s$. Note that π is a fixed parameter in (5.1).

LEMMA 5.3. *V_π is the unique asymptotically stable equilibrium point for* (5.1).

Proof. Direct verification shows that the ODE in question is an asymptotically stable linear system of the form

$$\dot{x}(t) = Ax(t) + B$$

with the desired equilibrium point as its unique globally asymptotically stable equilibrium. □

Note that V_π for given $\pi = [[\pi(i,a)]]$ is obtained by solving a linear system. Writing it explicitly using Cramer's rule, one verifies that it is a C^1 function of $[[\pi(i,a)]]$, in particular Lipschitz. This verifies the first part of (A3). The second part is specific to each algorithm and will be verified separately.

In what follows, we shall say that $\hat{G}(\cdot)$ is a vector field on $(PS)^s$ when it is so with the latter viewed as a compact manifold with boundary (i.e., when the corresponding integral curves do not leave $(PS)^s$). Such a $\hat{G}(\cdot)$ will also define a unique vector field $G(\cdot)$ on $(\mathcal{P}(A))^s$ given by

$$G_{ia}(\pi) = \hat{G}_{ia}(\hat{\pi}) \ \forall i \in S, a \in A \backslash \{a_0\},$$

$$G_{ia_0}(\pi) = -\sum_{a \neq a_0} \hat{G}_{ia}(\pi).$$

Define vectors $G_i = [G_i.], \hat{G}_i = [\hat{G}_i.]$ in R^{r+1}, R^r, respectively. Define $K : (\mathcal{P}(A))^s \to R^{s \times (r+1)}$ by $K(\pi) = [[K_{ia}(\pi)]]$ for $i \in S$, $a \in A$, where

$$K_{ia}(\pi) = k(i,a) + \alpha \sum_j p(i,j,a)V_\pi(j) - V_\pi(i).$$

Note that

$$\sum_a K_{ia}(\pi)\pi(i,a) = 0 \ \forall i \in S. \tag{5.2}$$

Define $\hat{K} : (PS)^s \to R^{s\times r}$ as

$$\hat{K}_{ia}(\hat{\pi}) = K_{ia}(\pi) - K_{ia_0}(\pi), \quad i \in S, \quad a \in A\backslash\{a_0\}$$

and the vectors corresponding to K: $K_i = [K_i.]$, $\hat{K}_i = [\hat{K}_i.]$.

LEMMA 5.4. *If G satisfies*

$$G_i(\pi) \cdot K_i(\pi) \leq 0 \qquad \forall i \in S, \tag{5.3}$$

then

$$D_G V_\pi(i) \leq G_i(\pi) \cdot K_i(\pi) \leq 0 \ \forall i \in S,$$

where D_G represents the directional derivative along G.

Proof. Define the operator $T_\pi : R^s \to R^s$ by $T_\pi(\cdot) = F(\pi, \cdot)$. From the geometry of $\mathcal{P}(A)^s$, it is clear that if G is a vector field on $\mathcal{P}(A)^s$, then for every $\pi \in \text{int}(\mathcal{P}(A)^s)$ there exists $\delta_0(\pi)$ such that for all $0 \leq \delta \leq \delta_0(\pi)$, $\pi + \delta G \in \mathcal{P}(A)^s$. Pick $\delta > 0$ so that $\pi + \delta G \in (\mathcal{P}(A))^s$. Simple algebra, using the facts that $T_\pi V_\pi = V_\pi$ and $\sum_a G_{ia}(\pi) = 0$, leads to

$$T_{\pi+\delta G} V_\pi(i) - V_\pi(i) = \delta \sum_a K_{ia}(\pi) G_{ia}(\pi) \leq 0.$$

Iterating, $T^n_{\pi+\delta G} V_\pi \leq T^{n-1}_{\pi+\delta G} V_\pi \leq \cdots \leq V_\pi$. Also

$$\frac{(T^n_{\pi+\delta G} V_\pi)(i) - V_\pi(i)}{\delta} \leq \sum_a K_{ia}(\pi) G_{ia}(\pi) \text{ for } n > 1.$$

Since $T^n_{\pi'} V_0 \to V_{\pi'}, \forall \pi', V_0$, by the contraction mapping principle, we may let $n \to \infty$ in the above inequality to obtain

$$\frac{V_{\pi+\delta G}(i) - V_\pi(i)}{\delta} \leq \sum_a K_{ia}(\pi) G_{ia}(\pi).$$

For π on the boundary of $\mathcal{P}(A)^s$, the claim follows by continuity. To conclude, we let $\delta \downarrow 0$. □

The lemma can be equivalently stated as follows: if $\hat{G}$ satisfies

$$\hat{G}_i(\hat{\pi}) \cdot \hat{K}_i(\hat{\pi}) \leq 0 \ \forall i \in S,$$

then

$$\nabla V_\pi(i) \cdot \hat{G}(\hat{\pi}) \leq \hat{G}_i(\hat{\pi}) \cdot \hat{K}_i(\hat{\pi}) \leq 0 \ \forall i \in S.$$

COROLLARY 5.5. *If in addition, $\hat{G}_i(\hat{\pi}) \cdot \hat{K}_i(\hat{\pi}) = 0$ for all $i \in S$ only if $\hat{G}(\hat{\pi}) = 0$ (i.e., only on equilibrium points of the vector field), then $\sum_{i\in S} V_\pi(i)$ serves as a strict Liapunov function for ODE $\dot{\hat{\pi}}(t) = G(\hat{\pi}(t))$.*

5.2. Convergence of Algorithm 1. We start with Algorithm 1. The key step is to verify that it fits the format of the "general algorithm" with $(\hat{\pi}_n, V_n)$ replacing $(X(n), Y(n))$. Thus corresponding g is $g = [[g_{ia}]]$ with

$$g_{ia}(\hat{\pi}, V) = k(i, a_0) - k(i, a) + \alpha \sum_j (p(i, j, a_0) - p(i, j, a))V(j), \quad i \in S, \quad a \in A\backslash\{a_0\},$$

with $M(n), M'(n)$ appropriately defined. (Note that this does not depend on π.) To verify the rest of (A3), consider the ODE

$$\dot{\hat{\pi}}(i) = \bar{P}_{\hat{\pi}}(g_i(\hat{\pi}, V_\pi)), \qquad i \in S, \tag{5.4}$$

with

$$g_i(\hat{\pi}, V_\pi) = [g_i.(\hat{\pi}, V_\pi n)],$$

$$\bar{P}_{\hat{\pi}}(g_i(\hat{\pi}_i, V_\pi)) = \lim_{\Delta \downarrow 0} \frac{P(\hat{\pi}(i) + \Delta g_i(\hat{\pi}, V_\pi)) - \hat{\pi}(i)}{\Delta},$$

where P is the projection into PS. Write K, $\hat{K}$ for $K(\pi)$, $\hat{K}(\hat{\pi})$, respectively, for the sake of simplicity.

LEMMA 5.6. *$\sum_{i \in S} V_\pi(i)$ is a strict Liapunov functions for ODE* (5.4).

Proof. Make the correspondence $\hat{G}_i = \bar{P}_{\hat{\pi}}(g_i(\hat{\pi}, V_\pi)) = g_i(\hat{\pi}, V_\pi) + r_i(\hat{\pi})$ $\forall i$, where $r_i(\cdot)$ is the correction term at boundary due to projection. Note that $\|g_i(\hat{\pi}, V_\pi)\| \geq \|r_i(\hat{\pi})\|$ $\forall i$ with equality holding only when $g_i(\hat{\pi}, V_\pi) = -r_i(\hat{\pi})$. Also $g_i(\hat{\pi}, V_\pi) = -\hat{K}_i(\hat{\pi})$ by definition. Thus $\forall i$,

$$\begin{aligned} \hat{G}_i \cdot \hat{K}_i &= g_i \cdot \hat{K}_i + r_i \cdot \hat{K}_i \\ &= -\|\hat{K}_i\|^2 + r_i \cdot \hat{K}_i \\ &\leq -\|\hat{K}_i\|^2 + \|r_i\| \, \|\hat{K}_i\| \\ &\leq 0 \end{aligned}$$

with equality if and only if $g_i = -r_i$. This means that $D_G V_\pi(i) = 0$ for all $i \in S$ only on equilibrium points of (5.4). The claim follows (cf. Corollary 5.5). □

LEMMA 5.7. *If $\hat{\pi}$ is an equilibrium point of* (5.4)*, then $V_\pi = V_\alpha$.*

Proof. Fix $i \in S$. Let $KT(i)$ denote $\{\hat{\pi} \in PS^s : g_i(\hat{\pi}, V_\pi) = -r_i(\hat{\pi})\}$ (the "Kuhn–Tucker points") and $e_a \in R^r$ the unit vector whose elements are indexed by elements of $A\backslash\{a_0\}$ and are zero, except for the one with index a. Since on the boundary of PS, r_i is normal to the active constraints among constraints defining PS and directed toward the interior, we have

$$r_i = \sum_{a \neq a_0} \lambda_a e_a - \lambda_{a_0} \sum_{a \neq a_0} e_a,$$

for some $\lambda_a \geq 0$, such that λ_a is zero when $\pi(i, a) > 0$. Thus, a $\hat{\pi} \in KT(i)$ will satisfy

$$\hat{K}_i = \sum_{a \neq a_0} \lambda_a e_a - \lambda_{a_0} \sum_{a \neq a_0} e_a, \qquad \lambda_a \geq 0,$$

with $\lambda_a = 0$ when $\pi(i, a) > 0$. To start with, let $\lambda_{a_0} = 0$; then $\hat{K}_i = \sum_{a \neq a_0} \lambda_a e_a$. Thus for $a \neq a_0$ and $\pi(i, a) > 0$, $\hat{K}_{ia} = 0$, i.e.,

$$k(i, a_0) + \alpha \sum_j p(i, j, a_0) V_\pi(j) = k(i, a) + \alpha \sum_j p(i, j, a) V_\pi(j).$$

Also, for $a \neq a_0$ and $\pi(i,a) = 0$, $\hat{K}_{ia} = \lambda_a \geq 0$, i.e.,

$$k(i,a_0) + \alpha \sum_j p(i,j,a_0) V_\pi(j) \leq k(i,a) + \alpha \sum_j p(i,j,a) V_\pi(j).$$

Therefore,

$$\begin{aligned} V_\pi(i) &= \sum_a \pi(i,a) \left[k(i,a) + \alpha \sum_j p(i,j,a) V_\pi(j) \right] \\ &= \left[k(i,a_0) + \alpha \sum_j p(i,j,a_0) V_\pi(j) \right] \\ &= \min_a \left[k(i,a) + \alpha \sum_j p(i,j,a) V_\pi(j) \right]. \end{aligned}$$

Now suppose $\lambda_{a_0} \neq 0$. Then $\pi(i,a_0) = 0$. Note that

$$V_\pi(i) = \min_a \left[k(i,a) + \alpha \sum_j p(i,j,a) V_\pi(j) \right] \tag{5.5}$$

would also follow if we show that

$$\begin{aligned} \pi(i,a) = 0 &\Rightarrow K_{ia} \geq 0, \\ \pi(i,a) > 0 &\Rightarrow K_{ia} = 0. \end{aligned}$$

For $a \neq a_0$ and $\pi(i,a) > 0$, $\hat{K}_{ia} = -\lambda_{a_0}$, i.e., $K_{ia} = K_{ia_0} - \lambda_{a_0}$. For $a \neq a_0$, $\pi(i,a) = 0$, we have $K_{ia} = K_{ia_0} - \lambda_{a_0} + \lambda_a$. Using $\pi(i,a_0) = 0$ and (5.2), we have

$$\sum_{a \neq a_0} K_{ia} \pi(i,a) = K_{ia_0} - \lambda_{a_0} = 0,$$

implying $K_{ia_0} \geq 0$. For $a \neq a_0$, $\pi(i,a) = 0$, we then have

$$K_{ia} = K_{ia_0} - \lambda_{a_0} + \lambda_a = \lambda_a \geq 0$$

and for $a \neq a_0$ and $\pi(i,a) > 0$ we have

$$K_{ia} = K_{ia_0} - \lambda_{a_0} = 0.$$

Thus (5.5) holds. The set of equilibria is precisely $KT = \cap_{i \in S} KT(i)$, which therefore contains only optimal $\hat{\pi}$. □

The following then is a consequence of the results of section 2.

THEOREM 5.8. $(\hat{\pi}_n, V_n) \to \{(\hat{\pi}, V_\pi) : V_\pi = V_\alpha\}$ *a.s.*

5.3. Convergence of Algorithm 2. For Algorithm 2, consider (5.4) with g redefined by

$$g_{ia}(\hat{\pi}, V) = \pi(i,a) \left(V(i) - k(i,a) - \alpha \sum_j p(i,j,a) V(j) \right), \quad i \in S, \quad a \in A \backslash \{a_0\}.$$

Note that $g_{ia}(\hat{\pi}, V_\pi) = -\pi(i,a)K_{ia}$ and $\bar{P}_{\hat{\pi}}(g_i(\hat{\pi}, V_\pi)) = g_i(\hat{\pi}, V_\pi)$, so $\bar{P}_{\hat{\pi}}(\cdot)$ can be dropped in (5.4). The equilibrium points of (5.4) are now characterized by

$$\pi(i,a)\left(V(i) - k(i,a) - \alpha\sum_j p(i,j,a)V(j)\right) = 0 \ \forall i,a.$$

(Note that this does depend on π.) It is easy to see that the stable equilibria are precisely those for which $V_\pi = V_\alpha$.

THEOREM 5.9. *$(\hat{\pi}_n, V_n)$ converges to $\{(\hat{\pi}, V_\pi) : V_\pi = V_\alpha\}$ a.s.*

Proof. Setting

$$G_{ia}(\pi) = g_{ia}(\pi, V_\pi) = -\pi(i,a)K_{ia},$$

we have $G_i \cdot K_i = -\sum_a \pi(i,a)K_{ia}^2 \le 0$ with equality only at equilibria of (5.4). Thus $\sum_i V_\pi(i)$ serves as a strict Liapunov function as before, implying asymptotic stability of $\{\pi : G(\pi) = 0\}$. To claim that the convergence is in fact to the stable equilibrium a.s., argue as in [19], which is possible due to our assumptions on the external noise $\{\psi_{ij}(n)\}$. Unlike the isolated unstable equilibria of [19], we now have unstable faces, but essentially the same argument as [19] goes through. □

Remark. The condition on $\{\psi(n)\}$ is rather awkward, since it seems to imply that a "large" noise input is required in order to avoid unstable equilibria. In simulation studies, however, simple ad hoc schemes such as adding a small noise only at the boundary to push the process into the interior of $(PS)^s$ seemed to do quite well.

5.4. Convergence of Algorithm 3. Here we work with $\{\beta_n\}$ instead of $\{\pi_n\}$. Redefine g as

$$g_{ia}(\beta, V) = V(i) - k(i,a) - \alpha\sum_j p(i,j,a)V(j), \quad i \in S, \quad a \in A\backslash\{a_0\}.$$

(Note that this does not depend on π.) It is easy to see that $g_{ia}(\beta, V_{\pi_\beta}) = -K_{ia}(\pi_\beta)$. (5.4) gets replaced by

$$\dot{\beta}(i,a) = \bar{P}_{\beta_0}(g_{ia}(\beta, V_{\pi_\beta})), \quad i \in S, \quad a \in A, \tag{5.6}$$

with

$$\bar{P}_{\beta_0}(g_{ia}(\beta, V_{\pi_\beta})) = \lim_{\Delta\downarrow 0}\frac{P_{\beta_0}(\beta(i,a) + \Delta g_{ia}(\beta, V_{\pi_\beta})) - \beta(i,a)}{\Delta}$$

and P_{β_0} is as before.

LEMMA 5.10. *$\sum_{i\in S} V_{\pi_\beta}(i)$ are strict Liapunov functions for* (5.6).

Proof. By explicit differentiation, we get

$$\begin{aligned} G_{ia}(\pi_\beta) &\triangleq \dot{\pi}_\beta(i,a) \\ &= \frac{\exp(\beta(i,a))\dot{\beta}(i,a)}{\sum_{a'}\exp(\beta(i,a'))} - \frac{\exp(\beta(i,a))\sum_{a'}\dot{\beta}(i,a')\exp(\beta(i,a'))}{(\sum_{a'}\exp(\beta(i,a')))^2} \\ &= \pi_\beta(i,a)\bar{P}_{\beta_0}(g_{ia}(\beta, V_{\pi_\beta})) - \pi_\beta(i,a)\sum_{a'}\pi_\beta(i,a')\bar{P}_{\beta_0}(g_{ia'}(\beta, V_{\pi_\beta})). \end{aligned}$$

Let

$$\gamma_{ia}(\beta) = \begin{cases} 0 & \text{if} \quad \beta(i,a) = \beta_0 \quad \text{and} \quad K_{ia}(\pi_\beta) \le 0, \\ & \text{or} \quad \beta(i,a) = -\beta_0 \quad \text{and} \quad K_{ia}(\pi_\beta) \ge 0, \\ 1 & \text{otherwise.} \end{cases}$$

Then $\bar{P}_{\beta_0}(g_{ia}(\beta, V_{\pi_\beta})) = -K_{ia}(\pi_\beta)\gamma_{ia}(\beta)$ and a simple computation using (5.2) leads to

$$\sum_a K_{ia}(\pi_\beta) G_{ia}(\pi_\beta) = -\sum_a \pi_\beta(i,a) K_{ia}(\pi_\beta)^2 \gamma_{ia}(\beta) \le 0$$

with equality only at equilibrium points of (5.6). The claim follows. □

Since π_β always remains in a proper subset of $\mathcal{P}(A)^s$, the algorithm may not converge to optimal policies. Nevertheless, the following results show that we can get an ϵ-optimal solution for any $\epsilon > 0$ by choosing β_0 sufficiently large. Define the operator $T_\alpha : R^s \to R^s$ by

$$[T_\alpha(x)]_i = \min_a \left[k(i,a) + \alpha \sum_j p(i,j,a) x_j \right], \quad x = [x_1, \ldots, x_s] \in R^s, \quad 1 \le i \le s.$$

LEMMA 5.11. $\|V - V_\alpha\|_\infty \le (1-\alpha)^{-1} \|T_\alpha V - V\|_\infty$.

Proof Consider

$$\begin{aligned} \|V - V_\alpha\|_\infty &\le \|V - T_\alpha V\|_\infty + \|T_\alpha V - V_\alpha\|_\infty \\ &= \|V - T_\alpha V\|_\infty + \|T_\alpha V - T_\alpha V_\alpha\|_\infty \\ &\le \|V - T_\alpha V\|_\infty + \alpha \|V - V_\alpha\|_\infty. \end{aligned}$$

The claim follows. □

LEMMA 5.12. *For any $\epsilon > 0$ there exists sufficiently large $\bar{\beta}$ such that for all $\beta_0 \ge \bar{\beta}$ the following holds true: If β is an equilibrium point of* (5.6)*, then $V_\alpha(i) \le V_{\pi_\beta}(i) \le V_\alpha(i) + \epsilon \ \forall i \in S$*

Proof. Let $K^-_{ia}(\pi) = \max(0, -K_{ia}(\pi)), K^+_{ia}(\pi) = \max(0, K_{ia}(\pi))$. Note that

$$\|T_\alpha V_\pi - V_\pi\|_\infty = \max_{i,a} K^-_{ia}(\pi). \tag{5.7}$$

If β is an equilibrium point of (5.6), one has

$$\begin{aligned} -\beta_0 < \beta(i,a) < \beta_0 &\Rightarrow K_{ia}(\pi_\beta) = 0 \\ \beta(i,a) = -\beta_0 &\Rightarrow K_{ia}(\pi_\beta) \ge 0, \\ \beta(i,a) = \beta_0 &\Rightarrow K_{ia}(\pi_\beta) \le 0. \end{aligned}$$

Thus

$$\pi_\beta(i,a) K_{ia}(\pi\beta) = \frac{\exp(-\beta_0) K^+_{ia}(\pi\beta) - \exp(\beta_0) K^-_{ia}(\pi\beta)}{\sum_a \exp \beta(i,a)},$$

which, with (5.2), leads to

$$\sum_a K^-_{ia}(\pi_\beta) = \exp(-2\beta_0) \sum_a K^+_{ia}(\pi_\beta). \tag{5.8}$$

Let $K = \|k(\cdot,\cdot)\|_\infty$. Then $\|V_\pi\|_\infty \le K(1-\alpha)^{-1}\ \forall \pi$. Hence

$$\begin{aligned}|K_{ia}(\pi)| &\le |k(i,a)| + \alpha \sum_j p(i,j,a)|V_\pi(j)| + |V_\pi(i)| \\ &\le K + \frac{\alpha K}{1-\alpha} + \frac{K}{1-\alpha} \\ &= K\left(\frac{2+\alpha}{1-\alpha}\right).\end{aligned}$$

With (5.7), (5.8), this leads to

$$\|T_\alpha V_{\pi_\beta} - V_{\pi_\beta}\|_\infty \le (r+1)K\exp(-2\beta_0)\left(\frac{2+\alpha}{1-\alpha}\right).$$

Choose β_0 such that

$$(r+1)K\exp(-2\beta_0)\left(\frac{1+\alpha}{(1-\alpha)^2}\right) \le \epsilon.$$

The claim follows. □

THEOREM 5.13. *For any $\epsilon > 0$ there exists $\bar\beta = \bar\beta(\epsilon)$ such that for all $\beta_0 \ge \bar\beta$, (β_n, V_n) converges to the set $\{(\beta, V_{\pi_\beta}) : V_\alpha(i) \le V_{\pi_\beta}(i) \le V_\alpha(i) + \epsilon\ \forall i \in S\}$ a.s.*

6. Convergence analysis for average cost.

6.1. Preliminaries. Recall that in addition to all the assumptions underlying the preceding section, we also assume now that S is irreducible under every stationary randomized policy. As in section 4, we begin with verification of (A2), (A3). First we verify the first half of (A2) and (A3), as they are common for all the algorithms. Because the rest are algorithm specific, we deal with them individually. Our approach to verification of boundedness of h_n follows [7]. Define span seminorm $\|\cdot\|_s$ on R^s by

$$\|x\|_s = \max_i x_i - \min_i x_i.$$

Then $\|x\|_s = 0$ if and only if x is a multiple of $[1,\dots,1] \in R^s$. Rewrite (3.5) as

$$h_{n+1}(i) = h_n(i)(1-b(n)) + b(n)[k(i,\varphi_n(i)) + h_n(\xi_n(i,\varphi_n(i))) - h_n(i_0)]. \tag{6.1}$$

Let $\{h'_n\}$, $\{h''_n\}$ denote iterates of (6.1) with identical $\{(\psi_n,\varphi_n,\xi_n)\}$ but with different initial conditions.

LEMMA 6.1. $\sup_n \|h'_n - h''_n\|_s < \infty$.

Proof. Let $A(n) = \max_{m\le n}\|h'_m - h''_m\|_s$. From (6.1), one has $A(n+1) \le A(n)\ \forall n$. The claim follows. □

COROLLARY 6.2. *If the iterates of* (6.1) *remain bounded for one initial condition, they do so for all initial conditions (sample pathwise).*

Proof. From Lemma 6.1, it follows that $\|h_n\|_s$ remains bounded for all initial conditions if $\|h_n\|_\infty$ (and hence $\|h_n\|_s$) does so for one initial condition. Then it suffices to verify that one component of $\{h_n\}$ remains bounded. Letting $K_1 = \sup_n \|h_n\|_s$, $K_2 = \max_{i,a}|k(i,a)|$, we have

$$h_{n+1}(i_0) = h_n(i_0)(1-b(n)) + b(n)[k(i_0,\varphi_n(i_0)) + h_n(\xi_n(i_0,\varphi_n(i_0))) - h_n(i_0)].$$

Thus

$$|h_{n+1}(i_0)| \leq |h_n(i_0)|(1 - b(n)) + b(n)(K_1 + K_2).$$

It follows by induction that $\sup_n |h_n(i_0)| < \infty$. □

Next, consider the ODE in R^s:

$$\dot{x}(t) = F^\pi(x(t)) - x(t), \tag{6.2}$$

where $F^\pi(\cdot) = [F_1^\pi(\cdot), \ldots, F_s^\pi(\cdot)]^T : R^s \to R^s$ is defined by

$$F_i^\pi(x) = \sum_a \pi(i,a)k(i,a) + \sum_{a,j} \pi(i,a)p(i,j,a)x_j - x_{i_0}, \qquad i \in S$$

for $x = [x_1, \ldots, x_s]^T$.

LEMMA 6.3. *h_π is the unique globally asymptotically stable equilibrium point of* (6.2).

Proof. Direct verification shows that the ODE in question is an asymptotically stable linear system of the form

$$\dot{x}(t) = Ax(t) + B$$

with the desired equilibrium points as its unique globally asymptotically stable equilibrium. □

Remark. Note that asymptotic stability implies the existence of a smooth strict Liapunov function [28]. See [12] for related results.

This verifies the first half of (A3). We still need to complete our verification of (A2). For this purpose, note that h_π, being the unique solution of a well-posed linear system whose coefficients depend smoothly on π, varies continuously with π, which varies over a compact set. Thus the set Q of h_π as π varies over stationary randomized policies is compact. Take a ball $B \subset R^s$ large enough so that it contains the ϵ-neighborhood of Q (for a prescribed $\epsilon > 0$) in its interior. Let $\{h_n\}$ denote our original iterates and $\{h'_n\}$ modified iterates obtained by resetting to h_{π_n} every time it exits from B, otherwise it is identical, i.e., driven by the same random sequences.

LEMMA 6.4. *$\{h_n\}$ remains bounded a.s.*

Proof (sketch). Note that $\{h'_n\}$ is bounded a.s. by construction. Writing its iteration between two consecutive resets in the standard form

$$h'_{n+1} = h'_n + b(n)(G(h'_n) + M_n + e(n))$$

for an appropriately defined $G(\cdot)$, an "error" term $e(n)$, and a martingale difference term M_n, one verifies that $\{e(n)\}$, $\{M_n\}$ are a.s. bounded because $\{h'_n\}$ is. Thus the appropriate piecewise linear interpolation of $\{h'_n\}$ between two consecutive resets becomes a better and better approximation of trajectories of (6.2) as $n \to \infty$. Now argue as in the proof of Lemma 4.2 to conclude that with probability one, eventually the reset trajectory of $\{h'_n\}$ will not exit the ϵ-neighborhood of Q, and therefore the number of resets is a.s. finite. The claim now follows from Corollary 6.2. □

The remaining assumptions are straightforward, except for the second half of (A3), which is to be verified separately for each algorithm as before.

Next, we set up the counterpart of the results of the preceding section for the average cost problem. For this purpose, redefine $K : \mathcal{P}(\mathcal{A})^s \to R^{s \times (r+1)}$ as $K(\pi) = [[K_{ia}(\pi)\|$, where

$$K_{ia}(\pi) = k(i,a) + \sum_j p(i,j,a)h_\pi(j),$$

and $\hat{K} : (PS)^s \to R^{s\times r}$ by

$$\hat{K}_{ia}(\hat{\pi}) = K_{ia_0} \ \forall a \neq a_0, i.$$

Define vectors $K_i = [K_i.], \hat{K}_i = [\hat{K}_i.]$ correspondingly. Let G denote a vector field on $\mathcal{P}(A)^s$.

LEMMA 6.5. *If G satisfies*

$$G_i(\pi) \cdot K_i(\pi) \leq 0 \ \forall i \in S, \tag{6.3}$$

then

$$D_G \lambda_\pi \leq 0.$$

Furthermore, equality holds if and only if it does so in the former inequality for all i.

Proof. Consider $\delta_0 > 0$ small enough so that $\pi' = \pi + \delta G \in \mathcal{P}(A)^s \ \forall \delta \in (0, \delta_0)$. Let $\{X_n\}$, $\{X'_n\}$ be the chains controlled by stationary randomized policies π, π', respectively, and $\{Z'_n\}$ the control process corresponding to the latter. Then

$$\begin{aligned}
\mathrm{E}[h_\pi(X'_n)|X'_{n-1}] &= \sum_a \sum_j \pi'(X'_{n-1}, a) p(X'_{n-1}, j, a) h_\pi(j) \\
&= \delta \sum_a \sum_j G_{X'_{n-1}a}(\pi) p(X'_{n-1}, j, a) h_\pi(j) \\
&\quad + \sum_a \sum_j \pi(X'_{n-1}, a) p(X'_{n-1}, j, a) h_\pi(j) \\
&= \delta \sum_a \sum_j G_{X'_{n-1}a}(\pi) p(X'_{n-1}, j, a) h_\pi(j) \\
&\quad + \lambda_\pi + h_\pi(X'_{n-1}) - \sum_a \pi(X'_{n-1}, a) k(X'_{n-1}, a) \\
&= \delta \sum_a G_{X'_{n-1}a}(\pi) \left[k(X'_{n-1}, a) + \sum_j p(X'_{n-1}, j, a) h_\pi(j) \right] \\
&\quad + \lambda_\pi + h_\pi(X'_{n-1}) - \sum_a \pi'(X'_{n-1}, a) k(X'_{n-1}, a).
\end{aligned}$$

Therefore,

$$\begin{aligned}
&\frac{1}{N} \sum_{n=1}^{N} \mathrm{E}[(h(X'_n) - h(X'_{n-1}))|X'_{n-1}] - \lambda_\pi + \frac{1}{N} \sum_{n=1}^{N} \mathrm{E}[k(X'_{n-1}, Z'_{n-1})|X'_{n-1}] \\
&= \delta \frac{1}{N} \sum_{n=0}^{N-1} \sum_a G_{X'_{n-1}a}(\pi) \left[k(X'_{n-1}, a) + \sum_j p(X'_{n-1}, j, a) h_\pi(X'_{n-1}) \right].
\end{aligned}$$

Take expectations on both sides and let $N \to \infty$ to obtain

$$\begin{aligned}
\frac{\lambda_{\pi'} - \lambda_\pi}{\delta} &= \lim_{N\to\infty} \frac{1}{N} \sum_{n=0}^{N-1} \mathrm{E}[K_{X'_n}(\pi) \cdot G_{X'_n}(\pi)] \\
&= \mathrm{E}[K_{\bar{X}_n}(\pi) \cdot G_{\bar{X}_n}(\pi)],
\end{aligned}$$

where $\{\tilde{X}_n\}$ is the stationary process under π'. Now let $\delta \to 0$ and use continuous dependence of stationary distribution on π to obtain

$$D_G\lambda_\pi = \mathrm{E}[K_{\hat{X}_n}(\pi) \cdot G_{\hat{X}_n}(\pi)],$$

where $\{\hat{X}_n\}$ is the stationary process under π. Recall that stationary distribution under π assigns strictly positive probability to each state in S. The rest is easy. □

In terms of $\hat{K}$, $\hat{G}$, the above can be recast as follows: If $\hat{G}$ satisfies

$$\hat{G}_i(\hat{\pi}) \cdot \hat{K}_i(\hat{\pi}) \leq 0 \ \forall i \in S, \tag{6.4}$$

then

$$\nabla\lambda_\pi \cdot \hat{G}(\hat{\pi}) \leq 0$$

with equality in the latter if and only if equality holds in the former inequality for all i.

COROLLARY 6.6. *If* (6.3) (*respectively,* (6.4)) *holds with equality if and only if* $G(\pi) = 0$ (*respectively,* $\hat{G}(\hat{\pi}) = 0$), *then* λ_π *is a strict Liapunov function for the ODE*

$$\dot{\pi}(t) = G(\pi(t)),$$
$$(\textit{respectively}, \ \dot{\hat{\pi}}(t) = \hat{G}(\hat{\pi}(t))).$$

The treatment of Algorithms 4–6 closely parallels that of algorithms 1–3, so we shall only outline the essentials.

6.2. Convergence analysis of Algorithm 4. For this, define the corresponding "g" by

$$g_{ia}(\hat{\pi}, h) = k(i, a_0) - k(i, a) + \sum_j (p(i, j, a_0) - p(i, j, a))h(j)$$

for $i \in S$, $a \neq a_0$. Consider, for $\hat{\pi}_i(\cdot) \stackrel{\Delta}{=} [\hat{\pi}_{ia}(\cdot)]_{a \neq a_0}$,

$$\dot{\hat{\pi}}_i(t) = \bar{P}_{\hat{\pi}(t)}(g_i.(\hat{\pi}(t), h_{\pi(t)})), \qquad i \in S, \tag{6.5}$$

$$g_i(\hat{\pi}, h_\pi) = [g_i(\hat{\pi}, h_\pi)],$$

$$\bar{P}(g_i(\hat{\pi}, h_\pi)) = \lim_{\Delta \downarrow 0} \frac{P(\hat{\pi}(i) + \Delta g_i(\hat{\pi}, h_\pi)) - \hat{\pi}(i)}{\Delta},$$

and P is the projection into PS. Note that $g_i(\hat{\pi}, h_\pi) = -\hat{K}_i(\hat{\pi})$. Now argue as for Algorithm 1 to conclude.

THEOREM 6.7. λ_π *is a strict Liapunov function for* (6.5), *whose equilibrium points correspond to optimal* π *(i.e., such that* $\lambda_\pi = \lambda^*$*).*

COROLLARY 6.8. $(\hat{\pi}_n, h_n) \to \{(\hat{\pi}, h_\pi) : \lambda_\pi = \lambda^*\}$ *a.s.*

6.3. Convergence analysis of Algorithm 5. Change g to

$$g_{ia}(\hat{\pi}, h) = \pi(i,a)\left(h(i_0) + h(i) - k(i,a) - \sum_j p(i,j,a)h(j)\right)$$

for $i \in S$, $a \neq a_0$. The corresponding ODE is

$$\begin{aligned}\dot{\hat{\pi}}_i &= \bar{P}_{\hat{\pi}}(g_i(\hat{\pi}, h_\pi)) \\ &= g_i(\hat{\pi}(t), h_\pi(t)).\end{aligned}$$

Then it is easily checked that

$$G_i(\pi) \cdot K_i(\pi) = -\sum_a \pi(i,a)(\lambda_\pi + h_\pi(i) - K_{ia}(\pi))^2.$$

Thus we have the following analogues of the results for Algorithm 2.

THEOREM 6.9. *λ_π is a strict Liapunov function for* (6.6), *whose stable equilibrium points satisfy $\lambda_\pi = \lambda^*$.*

COROLLARY 6.10. *$(\hat{\pi}_n, h_n) \to \{(\hat{\pi}, h_\pi) : \lambda_\pi = \lambda^*\}$ a.s.*

6.4. Convergence analysis of Algorithm 6. Define π_β as before and

$$g_{ia}(\beta, h) = h(i_0) + h(i) - k(i,a) - \sum_j p(i,j,a)h(j)$$

for $i \in S$, $a \in A$. Consider the ODE

$$\dot{\beta}(i,a) = \bar{P}_{\beta_0}(g_{ia}(\beta, h_{\pi_\beta})), \tag{6.6}$$

where

$$\bar{P}_{\beta_0}(g_{ia}(\beta, h_{\pi_\beta})) = \lim_{\Delta \downarrow 0} \frac{P_{\beta_0}(\beta(i,a) + \Delta g_{ia}(\beta, h_{\pi_\beta})) - \beta(i,a)}{\Delta}$$

and P_{β_0} is as before.

LEMMA 6.11. *λ_{π_β} is a strict Liapunov function for* (6.6).

Proof Define $G(\cdot) = [[G_{ia}(\cdot)]]$ by

$$\begin{aligned}G_{ia}(\pi_\beta) &= \dot{\pi}_\beta(i,a) \\ &= \pi_\beta(i,a)\bar{P}_{\beta_0}(g_{ia}(\beta, h_{\pi_\beta})) - \pi_\beta(i,a)\sum_{a'} \pi_\beta(i,a')\bar{P}_{\beta_0}(g_{ia'}(\beta, h_{\pi_\beta})).\end{aligned}$$

Note that $\bar{P}_{\beta_0}(g_{ia}(\beta, h_{\pi_\beta})) = (\lambda_{\pi_\beta} + h_{\pi_\beta}(i) - K_{ia}(\pi_\beta))\gamma_{ia}(\beta)$, where

$$\gamma_{ia}(\beta) = \begin{cases} 0 & \text{if} \quad \beta(i,a) = \beta_0 \quad \text{and} \quad K_{ia}(\pi_\beta) \leq \lambda_{\pi_\beta} + h_{\pi_\beta}(i), \\ & \text{or} \quad \beta(i,a) = -\beta_0 \quad \text{and} \quad K_{ia}(\pi_\beta) \geq \lambda_{\pi_\beta} + h_{\pi_\beta}(i), \\ 1 & \text{otherwise.} \end{cases}$$

One verifies that

$$\begin{aligned}G_i(\pi_\beta) \cdot K_i(\pi_\beta) &= \sum_a K_{ia}(\pi_\beta)G_{ia}(\pi_\beta) \\ &= -\sum_a \pi_\beta(i,a)\gamma_{ia}(\beta)(\lambda_{\pi_\beta} + h_{\pi_\beta}(i) - K_{ia}(\pi_\beta))^2 \\ &\leq 0.\end{aligned}$$

Since $\pi_\beta(i,a) > 0$ always, equality holds for all $i \in S$ only at equilibrium points of (6.6). The rest is routine. □

The following results characterize the equilibrium points of (6.6). As before, let $e = [1, \ldots, 1]^T$ and define the operator $T : R^s \to R^s$ by

$$(Tu)(i) = \min_a \left[k(i,a) + \sum_j p(i,j,a)u(j) \right].$$

LEMMA 6.12. *If a stationary randomized policy π satisfies $\|Th_\pi - h_\pi - \lambda_\pi e\|_\infty \leq \epsilon$ for some $\epsilon > 0$, then $\lambda^* \leq \lambda_\pi \leq \lambda^* + \epsilon$.*

Proof. Let $\{X_n\}$, $\{Z_n\}$ denote, respectively, the state and control processes under some stationary randomized policy μ. Define the vector $r \in R^s$ by

$$r(i) = \lambda_\pi + h_\pi(i) - \min_a \left[k(i,a) + \sum_j p(i,j,a)h_\pi(j) \right]$$

. By hypothesis $\epsilon \geq r(i) \geq 0 \ \forall i$. Also,

$$\begin{aligned}
\mathrm{E}[h_\pi(X_{n+1})|X_n, Z_n] &= \sum_j p(X_n, j, Z_n)h_\pi(j) \\
&= \left[k(X_n, Z_n) + \sum_j p(X_n, j, Z_n)h_\pi(j) \right] - k(X_n, Z_n) \\
&\geq \min_a \left[k(X_n, a) + \sum_j p(X_n, j, a)h_\pi(j) \right] - k(X_n, Z_n) \\
&= \lambda_\pi + h_\pi(X_n) - r(X_n) - k(X_n, Z_n).
\end{aligned}$$

Hence

$$\frac{1}{N}\sum_{n=0}^{N-1} \mathrm{E}[(h_\pi(X_{n+1}) - h_\pi(X_n))|X_n, Z_n] \geq \lambda_\pi - \frac{1}{N}\sum_{n=0}^{N-1} r(X_n) - \frac{1}{N}\sum_{n=0}^{N-1} k(X_n, Z_n).$$

Take expectations on both sides and let $N \to \infty$ to obtain

$$\lambda_\pi \leq \lambda_\mu + \lim_{N\to\infty} \frac{1}{N}\sum_{n=0}^{N-1} \mathrm{E}[r(X_n)].$$

Since μ was arbitrary and $\|r\|_\infty \leq \epsilon$, the claim follows. □

LEMMA 6.13. *For any $\epsilon > 0$ there exists $\bar\beta = \bar\beta(\epsilon)$ such that for all $\beta_0 \geq \bar\beta$, every equilibrium point β of (6.6) satisfies $\lambda^* \leq \lambda_{\pi_\beta} \leq \lambda^* + \epsilon$.*

Proof. From continuous dependence of solutions of well-posed linear equations on data, we have $\pi \mapsto h_\pi$ continuous. Thus $\{h_\pi\}$ remains bounded. The rest of the proof closely mimics the proof of Lemma 5.12. □

THEOREM 6.14. *For any $\epsilon > 0$ there exists $\bar\beta > 0$ such that for $\beta_0 \geq \bar\beta$, $(\beta_n, h_n) \to \{(\beta, h_{\pi_\beta}) : \lambda^* \leq \lambda_{\pi_\beta} \leq \lambda^* + \epsilon\}$ a.s.*

7. Conclusions. The techniques used in this paper are quite general and can be used to derive the corresponding learning algorithm, given a policy iteration algorithm. In particular, learning algorithms for the stochastic shortest path (SSP) problem based on its policy iteration (see [5]) can be easily derived. The connection shown by Bertsekas [4] between SSP and average cost problem can be exploited to change our update of h_n in the algorithms for average cost problems, so that our algorithms become three time scale asynchronous algorithms, which allow general delays as in the discounted case.

There are many other interesting directions that need to be explored.

Average cost problems. In our analysis of these, we were obliged to make a part of the iterations synchronous, because Lemma 5.1 fails otherwise. Our analysis does, however, show that in the asynchronous case, one would have the desired convergence a.s. on the set of sample paths for which the iterates remain bounded. Thus the missing link is precisely a proof of a.s. boundedness for the general asynchronous case. It is our pleasure to note that while this paper was under review, this issue was settled by a novel stability test developed by Borkar and Meyn [11].

Approximation issues. Tsitsiklis and Van Roy [25] consider several approximation schemes based on compact representations in Q-learning. The idea is to directly approximate $V_n(\cdot)$ by a function belonging to a parametrized family and update the parameter in question rather than updating $V_n(\cdot)$ directly. In the actor-critic scheme, however, there is an additional iteration for $\pi_n(\cdot,\cdot)$. One can conceivably write a function approximation scheme for $\pi(\cdot,\cdot)$ using a parametrized family (such as a neural network, e.g., see [22]) and update the probabilities recursively. These possibilities need to be explored.

Feedback implementations. The algorithms we consider in this work are "off-line"; i.e., they are based on a simulation run rather than an actual system being controlled in real time. One can convert these into on-line (or feedback) adaptive control algorithms for a controlled Markov chain X_n, $n \geq 0$, by setting $Y_n = \{X_n\}$, $Z_n = \{(X_n, \varphi_n(X_n))\}$ $\forall n$ and letting $\varphi_n(X_n)$ be the actual randomized control law being implemented.

A natural question then is whether the scheme is asymptotically optimal. (For the appropriate concept of "asymptotically optimal" in the discounted framework, see [23].) Recall that the convergence of the algorithm to desired limits requires that all state-action pairs be tried sufficiently often. For states, this may happen automatically if suitable irreducibility conditions are met, even in the feedback case. But if the $\pi_n(\cdot,\cdot)$ converge rapidly (to the desired limit or otherwise) all the state-action pairs may not get updated frequently enough. A simple way out of this conflict is to modify the feedback law to a convex combination of $\varphi_n(\cdot)$ and the uniform distribution on A so as to ensure a minimum probability $\epsilon > 0$ of each $a \in A$ being picked. For $\epsilon > 0$ sufficiently small, the scheme will be nearly optimal within a prescribed tolerance. However, too small an ϵ may slow down convergence. Thus there is a trade-off involved. A potentially promising scheme is to start with a large $\epsilon \in (0, 1/r]$ (to ensure all state-action pairs being tried frequently) and then reduce it "slowly" enough to ensure optimality. (Recall the simulated annealing algorithm for global optimization.) It is, however, a nontrivial task to capture the optimal rate of decrease of ϵ in a precise manner. These issues need further study. One should also add that presence of interprocessor communication delays causes nontrivial complications in the feedback case.

Rate of convergence. We have not provided any theoretical analysis of convergence

rate. Since a stochastic approximation algorithm eventually tracks the associated ODE, the convergence of its interpolated version to a given neighborhood of the asymptotically stable limit of the ODE (assuming one exists) will closely mimic that of the ODE itself. The rate of the latter could be gauged from the Liapunov function approach. One must invert the time scaling $n \to t(n)$ to get the convergence behavior of the original algorithm.

Even this may be worthless if "eventually" is in too distant a future. There are problems, too: The ODE captures the averaging affect of the algorithm akin to the law of large numbers. But there can be fluctuations around the average behavior of the "central limit theorem" variety. For a two time scale algorithm, the time scales should be separated enough so that the slow one does not get swamped by the fluctuations of the fast one.

A related issue is the generally high variance of the stochastic approximation algorithms. An additional averaging can reduce this; see, e.g., [20]. This and other issues pertaining to improving the performance of the algorithms need careful study.

Constant ratio step sizes. We have $a(n)/b(n) \to 0$ in order to simulate the "singular ODE" effect. However Theorem 3.4, p. 516, in [15] suggests that there exists $\epsilon^* > 0$ such that for all $\epsilon \in (0, \epsilon^*) a(n) = \epsilon b(n)$ suffices for convergence of our algorithms. It would be interesting to obtain lower bounds on ϵ^* and see if there are any situations in which $\epsilon^* > 1$. The latter situation may arise when, among the limiting coupled ODEs, the rate of convergence to equilibrium for one is naturally much faster than the other without the crutches of separated time scales.

Acknowledgments. The authors are grateful to an anonymous referee for an outstanding job of refereeing, which uncovered subtle errors that had escaped our notice.

LIPSCHITZ-TYPE STABILITY IN NONSMOOTH CONVEX PROGRAMS*

ROBERT JANIN† AND JACQUES GAUVIN‡

Abstract. This paper deals with upper Lipschitzian continuity of the optimal solution to parametrized convex programs with linear equality and inequality constraints and with a convex nondifferentiable objective function. Under quadratic growth conditions for the objective function, some accurate bound for the rate of the upper Lipschitzian continuity is provided.

Key words. convex minimization, stability, sensitivity analysis

1. Introduction.

Consider some elementary convex mathematical program of the following form:

$$\min f(x), x \in \mathbb{R}^n,$$
$$\text{subject to (s.t.)} Ax \in y + K,$$

where the function f is convex and continuous but possibly nondifferentiable, the operator A is linear from $\mathbb{R}^n$ into $\mathbb{R}^m$, and the set K is some polyhedral convex cone of $\mathbb{R}^m$. The parameter is denoted by y (as in [14]) and will also be called perturbation. Does the strong convexity of the objective function f imply the Lipschitz-type stability of the optimal solution?

The local Lipschitz dependence, with respect to parameters, of the optimal solution to minimization problems has been studied much. When the function f is twice differentiable, the answer for the question is positive; when the function f is nondifferentiable, the answer for the question may be negative. It was shown in [3] that a necessary condition for upper Lipschitzian continuity of the optimal solution is that the linearized problem has some optimal solution. By upper Lipschitzian continuity we mean there is some constant k such that $\| x(y) - x(y_o) \| \leq k \| y - y_o \|$ for any perturbation y. Here we denote by $\| x \|$ the euclidean norm of the vector x, the norm for the linear operator A is defined by $\| A \| = \sup_{\|x\|=1} \| Ax \|$. If in addition to the above condition some condition denoted by (A) in [18] is assumed, then the upper Lipschitzian stability of the optimal solution holds.

The purpose of the present paper is to show how the nonsmoothness of the objective function steps into the loss of Lipschitzian stability by means of subgradients and Lagrange–Kuhn and Tucker multipliers and to give some accurate bound for the rate of upper Lipschitzian continuity. For the sake of a clear result, the minimization program has been taken as simple as possible.

In the present paper the elements of $\mathbb{R}^p$ are represented by column vectors, the linear mappings are represented by their associate matrix in the canonical basis, the

superscript T means transposition, and the subspace $E^{\perp}$ is the orthogonal complement of the subspace E. The polyhedral convex cone K we consider here has the form

$$K = \{y \in \mathbb{R}^m : y_i = 0 (1 \leq i \leq r), y_i \geq 0 (r+1 \leq i \leq m)\},$$

and we assume that the so-called Mangasarian–Fromovitz regularity condition (MFC) holds at the optimal solution x_o for the parameter $y_o = 0$:

$$\text{(MFC)} \quad \begin{cases} \text{(i) the rows } A^i \ (1 \leq i \leq r) \text{ of the matrix } A \text{ are linearly independent;} \\ \text{(ii) there exists some vector } z \in \mathbb{R}^n \text{ such that} \\ A^i z = 0 \ (1 \leq i \leq r),\ A^i z > 0 \ (i \in I(x_o)), \end{cases}$$

where $I(x) = \{i : r+1 \leq i \leq m \ , \ A^i x = 0\}$. The regularity condition MFC is a particular case of Robinson's condition [15]. On the other hand, assume that the independence of the family $A^i (i = 1, 2, \ldots, m,\ A^i x_o = 0)$ is a particular case of the MFC. Assuming that x_o is some optimal solution and the MFC holds at the point x_o, then there exists some multiplier vector $\lambda \in K^+ = \{\lambda \in \mathbb{R}^m : \lambda^T u \geq 0,\ u \in K\}$ such that

$$0 \in \partial f(x_o) \ - A^T \lambda \text{ and } \lambda^T A x_o = 0; \tag{1}$$

that is,

$$\lambda_i \geq 0, i \in I(x_o),\ \sum_{i=1}^{m} \lambda_i A^{iT} \in \partial f(x_o), \text{ and } \lambda_i A^i x_o = 0 \ (1 \leq i \leq m). \tag{2}$$

Here we denote by $\partial f(x_o)$ the subdifferential of the convex function f at the point x_o, the elements of the subdifferential of the function f at the point x_o are called subgradients of f. The directional derivative and the subdifferential of the function f at the point x_o are related by the relationship

$$Df(x; y) = \lim_{t \searrow 0} \frac{1}{t}[f(x + ty) - f(x)] \geq \xi^T . y \ \forall \xi \in \partial f(x),$$

and if we assume the function f is continuous at the point x then we have

$$Df(x; y) = \max_{\xi \in \partial f(x)} \xi^T y. \tag{3}$$

In the study of asymptotic properties of the optimal solution, the first approach, to our knowledge, has been based upon implicit function theorems applied to the system of $m + n$ equations with $m + n$ unknowns

$$\begin{gathered} \sum_{i=1}^{m} \lambda_i A^i - \nabla f(x_o) \ = 0, \\ A^i x = y^i \qquad (1 \leq i \leq r), \\ \lambda_i (A^i x - y^i) = 0 \qquad (r+1 \leq i \leq m). \end{gathered}$$

For smooth functions, assuming the independence of the gradients of binding constraints and nonzero Lagrange–Kuhn and Tucker multipliers corresponding to binding inequality constraints ($\lambda_i > 0$ for $i \in I(x_o)$, strict complementarity condition) Pallu de la Barrière [13, Thm. 6, p. 296] and Fiacco and McCormick [6] presented the

differentiability of the optimal solution with respect to the parameter y; Jittorntrum [12] obtained directional derivatives without strict complementarity condition.

For a more general constraint set, Robinson [16] presented some generalized implicit function theorem and got the Lipschitzian stability of the solution of the generalized equation:

$$0 \in g(\xi, y) + \partial\Omega_F(\xi), \tag{4}$$

where $\Omega_F(.)$ is the indicator function of the closed constraints set F and g is differentiable with respect to the variable ξ and Lipschitz continuous with respect to the variable y; similar results are presented in [1], [17], [5], [11]. The problem we consider here may be reformulated in the framework of generalized equations; define, for $\xi = (x, \lambda)$, the Lagrangian function of the program:

$$L(\xi, y) = L(x, \lambda, y) = f(x) - \sum_{i=1}^{m} \lambda_i (A^i x - y^i),\ \lambda_i \geq 0\ (r+1 \leq i \leq m). \tag{5}$$

Then, assuming the MFC is satisfied, the above conditions, necessary for optimality, are formulated by the following generalized equations:

$$\begin{cases} 0 \in \partial_x L(\xi, y) = \partial f(x) - \sum \lambda_i A^i, \\ 0 \in \partial_\lambda L(\xi, y) = -Ax + y \ + \ K_\lambda, \end{cases} \tag{6}$$

where $K_\lambda = \{z \in K^+ : \lambda^T.z = 0\}$. Since the program is convex (6) are also sufficient for the point x to be optimal; the relationship with (4) is clear with

$$g(\xi, y) = g(x, \lambda, y) = \begin{pmatrix} \partial f(x) - \sum \lambda_i A^i \\ -Ax + y \end{pmatrix}$$

and with the feasible set

$$F = \{\xi = (x, \lambda) \in \mathbb{R}^n \times R^m :\ \lambda_i \geq 0\ i = r+1, r+2, \ldots, m\}.$$

Because in the present paper the function f is not smooth, then the function g is possibly multivalued and cannot be differentiable with respect to the variable $\xi = (x, \lambda)$. Therefore, the above method does not apply.

In recent years a different method has given important improvements in sensitivity analysis and in the study of the asymptotic expansion of the optimal solution. The method is very common in the study of partial differential equations to obtain a priori bounds for the solution u of the variational equation

$$a(u, v) = \langle h, v \rangle,\ v \in V,$$

where V is some Hilbert space, a is some real functional on $V \times V$, and h is some element of the dual V'; for $v \in V$, the number $h(v)$ is denoted by $\langle h, v \rangle$ and satisfies the inequality $| \langle h, v \rangle | \leq \| h \|_{V'} . \| v \|_V\ (\forall v \in V, \forall h \in V')$.

Assume that the functional a is coercive, i.e., there is some positive number c such that

$$a(v, v) \geq c \| v \|_V^2\ (\forall v \in V),$$

and assume $u \in V$ is some solution of the problem. Then

$$c \parallel u \parallel_V^2 \leq \parallel h \parallel_{V'} \parallel u \parallel_V \quad \text{and} \quad \parallel u \parallel_V \leq \frac{1}{c} \parallel h \parallel_{V'} . \tag{7}$$

The inequality (7) then gives some upper bound for the rate of Lipschitzian continuity for the solution u with respect to the parameter h.

The above method has been introduced into sensitivity analysis independently by Shapiro [19] and by Gauvin and Janin [7], [8]: the coercivity condition is related to second-order sufficient optimality condition, and the inequality of pairing is related to upper estimates on the optimal value function. This idea is then developed particularly in [2], [20], [18], [3], and for nonisolated minima in [4]. We follow this method in our paper.

Authors [19], [1], [7], [2], [20], [3], [4] have generally related the Lipschitzian continuity of the optimal solution to the only second-order derivative (in classical or generalized sense) of the Lagrangian function (5) of the program . In reference [10], we have considered the most simple case where constraints are equalities $Ax = y$; we have shown that, for nonsmooth function f, the rate of upper Lipschitzian continuity, when it holds, is also related to some part of the subdifferential of the objective function at the optimal point, namely the set

$$\sum = \{\sigma \in \partial f(x_o) : \ \sigma^T A^{\#} y > \lambda^T y \text{ for any } \lambda \text{ satisfying (2)}\}.$$

For any full row ranked matrix A we denote by $A^{\#} = A^T(AA^T)^{-1}$ the least square sense inverse of A. If the MFC is satisfied, then the matrix A is not full row ranked but convenient full row ranked submatrices will be characterized.

2. Illustrative example. For $\varepsilon \geq 0$ consider the program

$$\begin{gathered} \min f(x_1, x_2) = \min \mid x_2 - \varepsilon x_1 \mid + \tfrac{1}{2}(x_1^2 + x_2^2) \\ \text{s.t. } x_2 = y. \end{gathered}$$

Here $n = 2, m = 1$, $K = \{0\}$ with $K^+ = \mathbb{R}$, $A = [0\ 1]$ with $A^{\#} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$.

For any ε and for $y = 0$, the optimal solution is

$$x_o = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

For $\varepsilon > 0$, the first-order optimality condition (2) is satisfied with the unique multiplier $\lambda = 0$:

$$\begin{bmatrix} 0 \\ 1 \end{bmatrix} [0] = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \in \partial f(0,0) = \left\{ (1-2t) \begin{bmatrix} \varepsilon \\ -1 \end{bmatrix} \ : 0 \leq t \leq 1 \right\}.$$

Then, for $y > 0$, we have

$$\sum = \{\sigma \in \partial f(0,0) : \sigma^T A^{\#} y > 0\} = \left\{ (1-2t) \begin{bmatrix} \varepsilon \\ -1 \end{bmatrix} : t \in \left]\frac{1}{2}, 1\right[\right\}.$$

The result obtained in [10] is the following:

$$\parallel x(y) - x_o \parallel \leq \sqrt{\parallel A^{\#} \parallel^2 + \sup_{\sigma \in \Sigma} \frac{\parallel (\sigma - \sigma_o)^T A^{\#} \parallel^2}{\parallel (\mathbf{1} - A^{\#}A)(\sigma - \sigma_o) \parallel^2}}\, y = \sqrt{1 + \frac{1}{\varepsilon^2}}\, y.$$

For $-\varepsilon^2 \leq y \leq \varepsilon^2$, we have the optimal solution: $x(y) = \begin{bmatrix} y/\varepsilon \\ y \end{bmatrix}$, for which the rate of Lipschitz continuity is exactly the number given by the above formula.

On the other hand, for $\varepsilon = 0$, the first-order optimality condition is satisfied with any $\lambda \in [-1, +1]$:

$$\begin{bmatrix} 0 \\ 1 \end{bmatrix} [\lambda] = \begin{bmatrix} 0 \\ \lambda \end{bmatrix} \in \partial f(0,0) = \{0\} \times [-1, +1] \ .$$

Here we have $\Sigma = \emptyset$; the result, given in [7], becomes

$$\| \, x(y) - x_o \, \| \leq \| \, A^{\#} \, \| \quad | \, y \, | = | \, y \, | \ .$$

For this case, the optimal solution is $\begin{bmatrix} 0 \\ y \end{bmatrix}$, and the rate of Lipschitz continuity is again the number given in the above formula.

Our aim is now to extend the results of [10] for the more general case of equality and inequality constraints.

3. Assumptions. The objective function $f : \mathbb{R}^n \to \mathbb{R}$ is assumed to be convex and finite, and we denote by x_o the optimal solution corresponding to the parameter $y = 0$ and we assume the MFC holds at the point x_o. We assume moreover that the following local conditions are satisfied.

1. *Superquadratic growth condition*: there is $\rho > 0$ such that
   $f(x) \geq f(x_o) + Df(x_o; x - x_o) + \frac{\rho}{2} \, \| \, x - x_o \, \|^2$, $x \in x_o + B$.
2. *Subquadratic growth condition*: there is $\Gamma \geq \rho$ such that
   $f(x) \leq f(x_o) + Df(x_o; x - x_o) + \frac{\Gamma}{2} \, \| \, x - x_o \, \|^2$, $x \in x_o + B$,
   where the set B is some compact convex neighborhood of 0.

REMARK 1. *Let γ be some univariate convex increasing function and consider the program*

$$\begin{array}{c} \min \gamma[f(x)], x \in \mathbb{R}^n, \\ \text{s.t. } Ax \in y + K. \end{array}$$

The value function $v(y) = \inf_{Ax \in y+K} f(x)$ becomes $\gamma[v(y)]$ but the optimal solution remains the same. Therefore the above conditions 1 *and* 2 *may not be satisfied for a given f but satisfied by $\gamma[f]$ for a convenient function γ. By example the function $f(x_1, x_2) = (x_1^2 + x_2^2)^{\frac{3}{4}}$ does not satisfy condition* 2*, but for $\gamma(t) = t^{\frac{4}{3}}$ it is clear that both conditions hold for the function*

$$\gamma[f](x_1, x_2) = f(x_1, x_2)^{\frac{4}{3}} = x_1^2 + x_2^2.$$

REMARK 2. *As remarked by one of the referees of this article, the subquadratic growth condition does correspond to the upper estimate of the value function and it has to be compared with conditions which deal with upper estimates of the value function. The parametric optimization problem considered here can be formulated in the following form:*

$$\min_{(x,\alpha) \in \mathbb{R}^n \times \mathbb{R}} \alpha \ \text{ s.t. } G((x, \alpha), y) \in C, \tag{8}$$

where $G((x, \alpha), y) = ((x, \alpha), Ax - y)$, $C = (epi \, f) \times K$, and epi $f = \{(x, \alpha) \in \mathbb{R}^n \times R : \alpha \geq f(x)\}$. In such a formulation the nonsmoothness of the objective function has

been removed and it is hidden now in the convex set C. Consider the "linearized" problem, here the problem

$$\min_h Df(x_o;h) \text{ s.t. } Ah - \delta y \in T_K(Ax_o)$$

and in the other formulation

$$\min_{(h,\delta\alpha)\in\mathbb{R}^n\times\mathbb{R}} \delta\alpha$$

$$\text{s.t. } G((h,\delta\alpha),\delta y) \in T_C((x_o,f(x_o)),0) = T_{epif}(x_o,f(x_o)) \times T_K(Ax_o),$$

where $T_C(z)$ is the contingent cone to the set C at the point z_o. The assumption (A) in [18] *which gives the upper estimate consists mainly in the following: there exists some optimal solution (ξ,β) of the linearized problem such that*

$$dist\{G((x_o+t\xi, f(x_o)+t\beta),\ t\delta y), C\} = O(t^2).$$

It is clear that $\beta = Df(x_o,\xi)$ and that the assumption (A) of [18] *becomes*

$$f(x_o+t\xi) = f(x_o) + tDf(x_o,\xi) + O(t^2).$$

That is precisely, for only one direction, our subquadratic growth condition. Some subquadratic-growth-type condition can be also identified in [3] *each time the condition $T_C^2(\xi,\beta) \neq \emptyset$ holds, as in Proposition* 2.2 *of* [3]. *Here (ξ,β) are as above, $\beta = Df(x_o;\xi)$, and*

$$T_C^2(z,d) = \left\{k :\ dist\left\{z+td+\frac{t^2}{2}k, C\right\} = o(t^2)\right\}.$$

The condition $T_C^2(\xi,\beta)\neq\emptyset$ is slightly stronger than the assumption (A) in [18] *because of $o(t^2)$ instead of $O(t^2)$.*

REMARK 3. *On the other hand the superquadratic growth condition corresponds to the lower estimate obtained by means of second-order sufficient optimality conditions (assumption (B) of* [18]*). The formulation* (8) *is not convenient for assumption (B) in* [18] *since the second-order derivatives of the objective function cancel.*

4. Second-order marginal analysis result. The optimal value function $v(.)$ is convex and the subgradients at the point zero are optimal solutions of the dual program; thus the subgradients of the value function v are precisely the Lagrange–Kuhn and Tucker multipliers of the program and the following first-order marginal result holds under the MFC [14, Thm. 29.1, p. 298]:

$$\partial v(0) = \left\{\lambda\in\mathbb{R}^m : \lambda_i \geq 0\ (i\in I(x_o)), \sum_{i=1}^m \lambda_i A^{iT} \in \partial f(x_o), \lambda^T Ax_o = 0\right\}. \tag{9}$$

We are interested here with the second-order term of the power series of the value function $v(.)$ near the point $y=0$. Denote by $X(y)$ the set of optimal solutions for the value y of the perturbation; the following lemma states precisely the continuity of $X(.)$ at $y=0$.

LEMMA 4.1. *Assume that the superquadratic growth condition and the MFC are satisfied. Then the multivalued mapping*

$$y \longrightarrow X(y)$$

is continuous at the point $y = 0$.

Proof. If the MFC is satisfied, then there exists some vector $\xi \in \mathbb{R}^n$ such that

$$\begin{aligned} &A^{iT}\xi = 0 \quad (1 \le i \le r), \\ &A^{iT}\xi > 0 \quad (r+1 \le i \le m, A^{iT}x_o = 0). \end{aligned}$$

The family of linear forms $A^i (1 \le i \le r)$ is linearly independent; there is then some linear mapping $A^\natural$ from $\mathbb{R}^r$ into $\mathbb{R}^n$ such that $A^{iT}A^\natural z = z^i (1 \le i \le r)$.

Denote by y_r the projection of the vector $y \in \mathbb{R}^m$ onto the subspace $\mathbb{R}^r \times \{0\}_{m-r}$, and define the continuous mapping $\xi(y) = x_o + A^\natural y_r + k \|y\| \xi$, where k is some constant to be determined in order for the point $\xi(y)$ to be a feasible solution for any perturbation y. We prove now that such a number k exists.

Since $A^{iT}A^\natural y_r = y^i$ and $A^{iT}\xi = 0$ $(1 \le i \le r)$,

$$A^{iT}\xi(y) = y^i (1 \le i \le r).$$

On the other hand, for $r+1 \le i \le m$ such that $A^{iT}x_o = 0$, we have

$$A^{iT}\xi(y) - y^i = A^{iT}A^\natural y_r - y^i + k \|y\| A^{iT}\xi;$$

since there exists some positive number l_i such that $A^{iT}A^\natural y_r - y^i \ge -l_i \|y\|$ and $A^{iT}\xi > 0$, there exists a number k_i such that

$$A^{iT}\xi(y) - y^i \ge -l_i \|y\| + k_i \|y\| A^{iT}\xi \ge 0 \text{ for any perturbation } y,$$

taking k as the maximum of the numbers $k_i (\, r+1 \le i \le m \,, A^{iT}x_o = 0)$, the point $\xi(y)$ is some feasible solution for any perturbation y close to zero. Since $\lim_{y \to O} \xi(y) = x_o$, there exists then some neighborhood V of the null perturbation such that

$$\forall y \in V \Longrightarrow \ \xi(y) \in B,$$

which shows that for any $y \in V$ the program has feasible solutions in the set B.

Consider the extended value function

$$\begin{aligned} &f_B(x) = f(x) \text{ for } x \in B, \\ &f_B(x) = +\infty \text{ for } x \notin B. \end{aligned}$$

Denote by $X_B(y)$ the set of optimal solutions of the program where f has been replaced by f_B; for any $y \in V$, and for any $x \in X_B(y)$, we have

$$f(x) = f_B(x) \le f_B(\xi(y)) = f(\xi(y)) < +\infty.$$

Denote by $x(y)$ some selection of $X_B(y)$. Consider now some cluster point $\widetilde{x}$ of $x(.)$ as the perturbation y tends to zero, taking some subsequence $x_i = x(y_i)$ tending to $\widetilde{x}$ we have the following:

$$f(\widetilde{x}) = \lim_i f(x(y_i)) \ \le \lim_{y_i \to 0} f(\xi(y_i)) = .f(x_o).$$

Since $\widetilde{x} \in B$ and is some feasible solution for the null perturbation, $f(\,\widetilde{x}) = f(x_o)$, and because of superquadratic growth condition, the point x_o is the only optimal solution for the null perturbation. Then we have $\widetilde{x} = x_o$.

Since x_o is the only cluster point of $x(y)$ as y tends to zero, we have

$$\lim_{y\to 0} X_B(y) = x_o.$$

That is to say, for any open subset Ω containing x_o there exists some neighborhood W of the perturbation 0 such that

$$y \in W \Longrightarrow X_B(y) \subset \Omega;$$

taking for Ω the interior of B denoted by int(B), there exists some neighborhood W of zero such that

$$X_B(y) \subset \text{int}(B)\ (\forall y \in W).$$

We show now that, for any $y \in W$, the convex compact set $X_B(y)$ is the set $X(y)$ of optimal solutions for the original program with the objective function f. Consider some feasible solution x such that $x \notin X_B(y)$ and

$$f(x) \leq f(x') \text{ for any } x' \in X_B(y).$$

Consider the point $x_t = (1-t)x' + tx$ for $0 \leq t \leq 1$; there exist two positive numbers t_1 and t_2 such that $x_t \in B$ and $x_t \notin X_B(y)$ for $t_1 \leq t \leq t_2$, but by the inequality of convexity $f_B(x_t) \leq f_B(x')$ which cannot hold because $x' \in X_B(y)$ and $x_t \notin X_B(y)$. Such a feasible solution x cannot exist and $X(y) = X_B(y)$; then $\lim_{y\to 0} X(y) = x_o$.

LEMMA 4.2. *Suppose the assumption of subquadratic growth condition holds and the MFC is satisfied; then there is some $\varepsilon > 0$ such that, for $\| y \| \leq \varepsilon$, the optimal value $v(y)$ satisfies*

$$v(y) \leq v(0) + \min_{A\xi \in y + K_o} Df(x_o; \xi) + \frac{\Gamma}{2} \| \xi \|^2,$$

where $K_o = \{y \in \mathbb{R}^m : y_i = 0 (1 \leq i \leq r), y_i \geq 0\ (i \in I(x_o))\}$.

Proof. Let $\delta > 0$ be some positive number to be chosen later but such that the ball B_δ with radius δ is contained in the neighborhood where subquadratic growth condition holds; because of the continuous dependence of the optimal solutions at the point 0, there exists $\varepsilon_1 > 0$ such that for $\|y\| < \varepsilon_1$, any optimal solution $x(y)$ is contained in $x_o + B_\delta$ and $v(y)$ is attained by some point in $x_o + B_\delta$.

Because of the subquadratic growth condition, for any $\xi \in B_\delta$ such that $A(x_o + \xi) \in y + K$, we have the following:

$$v(y) \leq f(x_o + \xi) \leq f(x_o) + Df(x_o; \xi) + \frac{\Gamma}{2}\|\xi\|^2.$$

Minimizing now with respect to ξ we get

$$v(y) - v(0) \leq \min_{\xi \in B_\delta\ ,\ A(x_o+\xi)\in y+K} Df(x_o; \xi) + \frac{\Gamma}{2}\|\xi\|^2.$$

Now we choose the radius δ such that

$$\{x : Ax \in y + K_o, x \in x_o + B_\delta\} = \{x : Ax \in y + K, x \in x_o + B_\delta\}.$$

The second set is a priori contained in the first set; we show now the converse. The number $\alpha = \min_{i\notin I(x_o)} A^{iT} x_o$ is positive. Take $\varepsilon_2 = \frac{\alpha}{3}$ and r such that $| A^{iT}(x - x_o) | < \frac{\alpha}{3}$ for any $i \notin I(x_o)$ and for any x such that $\| x - x_o \| < \delta$.

Consider some perturbation y with $\| y \| < \varepsilon_2$ and some x with $\| x - x_o \| < \delta$ and $Ax \in y + K_o$; then for $i \notin I(x_o)$

$$A^{iT}x - y^i = A^{iT}x_o - y^i + A^{iT}(x - x_o) \geq \alpha - \frac{\alpha}{3} - \frac{\alpha}{3} > 0.$$

We then have

$$Ax \in y + K.$$

Take $\varepsilon_3 = \min\{\varepsilon_1, \varepsilon_2\}$; then, for $\|y\| \leq \varepsilon_3$, we have

$$v(y) - v(0) \leq \min_{\xi \in B_\delta, A(x_o+\xi) \in y+K_o} Df(x_o; \xi) + \frac{\Gamma}{2}\|\xi\|^2.$$

Since $-Ax_o \in K_o$, $-Ax_o + K_o = K_o$, and the following holds:

$$v(y) - v(0) \leq \min_{\xi \in B_\delta, A\xi \in y+K_o} Df(x_o; \xi) + \frac{\Gamma}{2}\|\xi\|^2.$$

Since the optimal $\xi(y)$ in the minimization of the right-hand side is continuous with respect to y at the point $y = 0$, and since $\lim_{y\to 0} \xi(y) = 0$, there exists $\varepsilon_4 > 0$ such that $\|\xi(y)\| < \delta$ for $\|y\| < \varepsilon_4$. The result follows.

The next lemma refines the result of the above lemma.

LEMMA 4.3. *Suppose the assumptions of superquadratic and subquadratic growth conditions hold and the MFC is satisfied; then there exists $\varepsilon > 0$ such that for all perturbation $y \in \mathbb{R}^m$ with $\| y \| \leq \varepsilon$, the optimal value $v(y)$ satisfies the following:*

$$v(y) \leq v(0) + \max_{\sigma \in \partial f(x_o)} \min_{A\xi \in y+K_o} \frac{\Gamma}{2} \left(\left\| \xi + \frac{\sigma}{\Gamma} \right\|^2 - \left\| \frac{\sigma}{\Gamma} \right\|^2 \right). \tag{10}$$

Proof. The function f is continuous at the point x_o; then by (3)

$$v(y) \leq v(0) + \min_{A\xi \in y+K_o} \max_{\sigma \in \partial f(x_o)} \left(\sigma^T \xi + \frac{\Gamma}{2} \| \xi \|^2 \right).$$

The function $\xi \to \sigma^T \xi + \frac{\Gamma}{2} \| \xi \|^2$ is convex and tends to $+\infty$ as $\| \xi \|$ tends to $+\infty$; on the other hand the function $\sigma \to \sigma^T \xi + \frac{\Gamma}{2} \| \xi \|^2$ is concave on the compact set $\partial f(x_o)$. By the saddle point theorem, Theorem VII 4.3.1, in [9] we have

$$v(y) \leq v(0) + \max_{\sigma \in \partial f(x_o)} \min_{A\xi \in y+K_o} \left(\sigma^T \xi + \frac{\Gamma}{2} \| \xi \|^2 \right);$$

since we have

$$\sigma^T \xi + \frac{\Gamma}{2} \| \xi \|^2 = \frac{\Gamma}{2} \left(\left\| \xi + \frac{\sigma}{\Gamma} \right\|^2 - \left\| \frac{\sigma}{\Gamma} \right\|^2 \right),$$

the assertion holds.

The following result gives some precision about the second-order term of the power series of the marginal function $v(y)$.

THEOREM 4.4. *Suppose the assumptions of superquadratic and subquadratic growth conditions hold and the MFC is satisfied, then there exists $\varepsilon > 0$ such that for all perturbation $y \in \mathbb{R}^m$ with $\| y \| \leq \varepsilon$, there exist $\sigma_o \in \partial f(x_o)$ and $\lambda \in \mathbb{R}^s$, $\lambda_i \geq 0$ $(i \in I(x_o))$, and some full row ranked submatrix A_L such that*

1. $\operatorname{rank}(A_L) = \operatorname{rank}(A)$, $A_L^T\lambda = \sigma_o$, $\lambda^T A_L x_o = 0$, *and* $Dv(0;y) = \lambda^T y = \sigma_o^T A_L^{\#} y$,
2. *if* $\Sigma = \{\sigma \in \partial f(x_o) : \sigma T A_L^{\#} y > Dv(0;y)\}$ *then the following alternative holds: either* $\Sigma = \emptyset$, *in which case*

$$v(y) - v(0) \le Dv(0;y) + \frac{\Gamma}{2} \parallel A_L^{\#} y \parallel^2,$$

or $\Sigma \neq \emptyset$, *in which case*

$$v(y) - v(0) \le Dv(0;y) + \frac{\Gamma}{2}\left(\parallel A_L^{\#} y \parallel^2 + \sup_{\sigma\in\Sigma} \frac{\mid (\sigma - \sigma_o)^T A_L^{\#} y \mid^2}{\parallel (\mathbf{1} - A_L^{\#} A_L)(\sigma - \sigma_o) \parallel^2} \right).$$

Proof. Following [9] we have

$$\begin{aligned} Dv(0;y) &= \max\{\lambda^T y : \lambda \text{ satisfies (2)}\} \\ &= \max\{\lambda^T y : A^T\lambda = \sigma, \sigma \in \partial f(x_o), \lambda^i \ge 0 \ (i \in I(x_o))\}. \end{aligned}$$

There exists $\sigma_o \in \partial f(x_o)$ such that

$$Dv(0;y) = \max\{\lambda^T y : A^T\lambda = \sigma_o, \lambda^i \ge 0 \ (i \in I(x_o))\}.$$

The right-hand-side maximization is a linear program which is feasible and bounded above. The dual program

$$\begin{aligned} &\text{Min } \sigma_o^T \xi \\ &\text{s.t.} \begin{cases} A^i\xi = y^i & (1 \le i \le r), \\ A^i\xi \ge y^i & (i \in I(x_o)) \end{cases} \end{aligned}$$

also has optimal solutions. The set $\mathcal{S}$ of feasible solutions is polyhedral convex and closed. It may be written

$$\mathcal{S} = \mathcal{S} \cap F + \ker A,$$

where F is some complement of $\ker A$; take, for example, $F = \operatorname{range}(A^T) = \ker(A)^{\perp}$. The function to be minimized is linear, then there is at least one minimizer, denoted by ξ_o, in $\mathcal{S}\cap F$, which is an extremal point of $\mathcal{S}\cap F$. The point ξ_o satisfies $s = \operatorname{rank}(A^T) = \operatorname{rank}(A)$ independent constraints. Denote by A_L the corresponding submatrix of the matrix A; then

$$\xi_o = A_L^{\#} y \text{ and } A_L^{\#} y + \ker A \subset \{\xi : A\xi \in y + K_o\}.$$

Following (10) we have

$$v(y) \le v(0) + \max_{\sigma\in\partial f(x_o)} \min_{\xi \in A_L^{\#} y + \ker A} \frac{\Gamma}{2}\left(\left\| \xi + \frac{\sigma}{\Gamma} \right\|^2 - \left\| \frac{\sigma}{\Gamma} \right\|^2 \right).$$

The optimal ξ in the right-hand side is the projection of $-\frac{\sigma}{\Gamma}$ on $A_L^{\#} y + \ker A$,

$$\xi = -\frac{\sigma}{\Gamma} + A_L^{\#} A_L \frac{\sigma}{\Gamma} + A_L^{\#} y,$$

and by Pythagoras's theorem

$$v(y) - v(0) \leq \max_{\sigma \in \partial f(x_o)} \frac{\Gamma}{2} \parallel A_L^{\#} y \parallel^2 + \sigma^T A_L^{\#} y - \frac{1}{2\Gamma} \parallel (\mathbf{1} - A_L^{\#} A_L)\sigma \parallel^2 . \tag{11}$$

The subgradient σ_o which has been characterized above is such that

$$Dv(0; y) = \sigma_o^T A_L^{\#} y,$$

and since $\sigma_o \in \text{range}(A_L^T) = \ker(A_L)^{\perp}$ we have $(\mathbf{1} - A_L^{\#} A_L)\sigma_o = 0$

$$A_L^{\#} A_L \sigma_o = \sigma_o.$$

The inequality (11) then gives

$$v(y) - v(0) \leq \sigma_o^T A_L^{\#} y \; + \frac{\Gamma}{2} \parallel A_L^{\#} y \parallel^2$$

$$+ \max_{\sigma \in \partial f(x_o)} (\sigma^T - \sigma_o^T) A_L^{\#} y - \frac{1}{2\Gamma} \parallel (\mathbf{1} - A_L^{\#} A_L)(\sigma - \sigma_o) \parallel^2 . \tag{12}$$

Consider the expression

$$E = \max_{\sigma \in \partial f(x_o)} (\sigma^T - \sigma_o^T) A_L^{\#} y - \frac{1}{2\Gamma} \parallel (\mathbf{1} - A_L^{\#} A_L)(\sigma - \sigma_o) \parallel^2 .$$

The maximum with respect to $\sigma \in \partial f(x_o)$ is certainly lower than the sup extended to the cone $\sigma_o + \mathbb{R}^+(\partial f(x_o) - \sigma_o)$:

$$E \leq \sup_{\sigma \in \partial f(x_o)} \sup_{s \geq 0} \{ s(\sigma - \sigma_o)^T A_L^{\#} y - \tfrac{s^2}{2\Gamma} \parallel (\mathbf{1} - A_L^{\#} A_L)(\sigma - \sigma_o) \parallel^2 \}$$

$$\leq \begin{cases} 0 \text{ if } (\sigma - \sigma_o)^T A_L^{\#} y \leq 0, \\ \frac{\Gamma}{2} \frac{|(\sigma - \sigma_o)^T A_L^{\#} y|^2}{\|(\mathbf{1} - A_L^{\#} A_L)(\sigma - \sigma_o)\|^2} \text{ otherwise.} \end{cases}$$

This, in (12), completes the proof.

REMARK 4. *The operator* $\mathbf{1} - A_L^{\#} A_L$ *is the orthogonal projection on* $\ker A_L$*; then we have* $(\mathbf{1} - A_L^{\#} A_L)\sigma = 0$ *if and only if* $\sigma \in \text{range}(A_L^{\#}) = \text{range}(A_L^T)$*. On the other hand, following optimality conditions* (2)*, any* $\sigma \in \Sigma$ *which is an element of* $\partial f(x_o)$ *cannot be an element of range*(A_L^T)*. Then* $(\mathbf{1} - A_L^{\#} A_L)(\sigma - \sigma_o) = (\mathbf{1} - A_L^{\#} A_L)\sigma \neq 0$ *for any* $\sigma \in \Sigma$*.*

5. Lipschitz-type stability of the optimal solution. We are now ready for the main result.

THEOREM 5.1. *Suppose the assumptions of superquadratic and subquadratic growth conditions hold and the MFC is satisfied. Then there exists* $\varepsilon > 0$ *such that for all perturbations* $y \in \mathbb{R}^m, \parallel y \parallel \leq \varepsilon$*, there exist* $\sigma_o \in \partial f(x_o)$ *and some full row ranked submatrix* A_L *such that the following holds:*

1. $\text{rank}(A_L) = \text{rank}(A)$*,* $\sigma_o \in \text{range}(A_L)$*, and* $Dv(0; y) = \sigma_o^T A_L^{\#} y$*,*
2. *if* $\Sigma = \{\sigma \in \partial f(x_o) : \sigma^T A_L^{\#} y > Dv(0; y)\}$*, then for any optimal solution* $x(y)$*, the following alternative holds: either* $\Sigma = \emptyset$*, in which case*

$$\parallel x(y) - x(0) \parallel \leq \sqrt{\frac{\Gamma}{\rho}} \parallel A_L^{\#} \parallel \parallel y \parallel,$$

or $\Sigma \neq \emptyset$, *in which case*

$$\| x(y) - x(0) \| \leq \sqrt{\frac{\Gamma}{\rho}\left(\| A_L^{\#} \|^2 + \sup_{\sigma \in \Sigma} \frac{\| (\sigma - \sigma_o)^T A_L^{\#} \|^2}{\| (\mathbf{1} - A_L^{\#} A_L)(\sigma - \sigma_o) \|^2} \right)} \ \| y \| .$$

Proof. For any $\sigma \in \partial f(x_o)$, by the superquadratic growth condition

$$\frac{\rho}{2} \| x(y) - x_o \|^2 \leq f(x(y)) - f(x_o) - \sigma^T (x(y) - x_o).$$

By (9), σ may be chosen such that $\sigma = A^T \lambda$, where $\lambda \in \partial v(0)$; taking into account that $f(x(y)) = v(y)$ and $f(x_o) = v(0)$

$$\frac{\rho}{2} \| x(y) - x_o \|^2 \leq v(y) - v(0) - \lambda^T A(x(y) - x_o).$$

The multiplier λ and some submatrix A_L may be chosen as in Theorem 4.4; then

$$\frac{\rho}{2} \| x(y) - x_o \|^2 \leq v(y) - v(0) - Dv(0; y)$$

$$\leq \begin{cases} \frac{\Gamma}{2} \| A_L^{\#} \|^2 \| y \|^2 & \text{if } \Sigma = \emptyset, \\ \frac{\Gamma}{2} (\| A_L^{\#} \|^2 + \sup_{\sigma \in \Sigma} \frac{\| (\sigma - \sigma_o)^T A_L^{\#} \|^2}{\| (\mathbf{1} - A_L^{\#} A_L)(\sigma - \sigma_o) \|^2}) \| y \|^2 & \text{otherwise.} \end{cases}$$

This completes the proof.

REMARK 5. *The submatrix* A_L *is not known a priori, but the index set* L *includes* $\{1, 2, \ldots, r\}$ *and indices of binding constraints such that* $\lambda_i > 0$ $(r + 1 \leq i \leq m)$, *for some* λ *such that* $\lambda^T y = Dv(0; y)$. *In the following classical smooth case, the matrix* A *is known. Suppose that the assumptions of superquadratic and subquadratic growth conditions hold, assume the function* f *is differentiable at the point* x_o, *and assume that the so-called independence condition holds. The family* $A^i (1 \leq i \leq m,\ A^i x_o = 0)$ *is linearly independent; then any optimal solution* $x(y)$ *is upper Lipschitz continuous with respect to the parameter* y *at the point* $y_o = 0$, *with the rate*

$$\| x(y) - x_o \| \ \leq \sqrt{\frac{\Gamma}{\rho}} \| A^{\#} \| \| y \|,$$

where A *is the matrix corresponding to active constraints. If the function* f *is twice continuously differentiable, then* Γ *and* ρ *are related to the highest and the lowest eigenvalues of the Hessian matrix of the function* f.

COROLLARY 5.2. *Suppose the assumptions of superquadratic and subquadratic growth conditions hold and the MFC is satisfied; assume* $f = \max_{1 \leq j \leq p} f_j$, *where the functions* f_j *are differentiable, and assume that the independence condition holds; then the optimal solution is upper Lipschitz continuous with respect to the parameter* y *at the point* 0 *with the rate, in case* $\Sigma = \emptyset$:

$$\| x(y) - x_o \| \ \leq \sqrt{\frac{\Gamma}{\rho}} \| A^{\#} \| \| y \|$$

and with the rate, in case $\Sigma \neq \emptyset$:

$$\| x(y) - x_o \| \ \leq \sqrt{\frac{\Gamma}{\rho}\left(\| A^{\#} \|^2 + \max_{\sigma \in \Sigma} \frac{\| (\sigma - \sigma_o)^T A^{\#} \|^2}{\| (\mathbf{1} - A^{\#} A)\sigma \|^2} \right)} \ || y || .$$

Here A *denotes the matrix corresponding to active constraints.*

5.1. Examples. Now we will answer two questions by examples.

1. In the case $\Sigma \neq \emptyset$ the upper bound may be $+\infty$; does there then exist any program with no upper Lipschitz continuity at the point 0?
2. Is it possible to relax the subquadratic growth assumption in the case where the function f is assumed to be differentiable?

We will answer both questions with the help of the following example in $\mathbb{R}^2$. We denote

$$w(x_1, x_2) = x_1 + \sqrt{x_1^2 + x_2^2}.$$

The subdifferential of w at that point $(0,0)$ is the closed disc C with center at $(0,1)$ and with radius 1.

For $\alpha \geq 1$, consider the program

$$\min f(x_1, x_2) = w(x_1, x_2)^\alpha + \frac{1}{2}(x_1^2 + x_2^2) \text{ s.t. } x_2 = y.$$

The objective function f is differentiable for $\alpha > 1$ and $\partial f(0,0) = C$ for $\alpha = 1$. On the other hand the quadratic growth conditions hold for $\alpha = 1$ but the subquadratic growth condition vanishes for $2 > \alpha > 1$. For $y = 0$, the optimal solution is $(0,0)$ and the unique subgradient which takes part in the optimality conditions is

$$\sigma_o = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

1. For the case where $\alpha = 1$, $y > 0$ we have

$$\sup_{\sigma \in \Sigma} \frac{\| \sigma - \sigma_o \|}{\| (\mathbf{1} - A^{\#}A)\sigma \|} = +\infty$$

because the sup is taken on the upper half disc. Optimal solutions are easily built by geometrical argument. Optimality holds at $(x_1, x_2) \neq (0,0)$ as the gradient of f

$$\nabla f(x_1, x_2) = \begin{bmatrix} 1 + x_1 + \frac{x_1}{\sqrt{x_1^2 + x_2^2}} \\ x_2 + \frac{x_2}{\sqrt{x_1^2 + x_2^2}} \end{bmatrix}$$

is normal to the line $\{x_2 = y\}$; therefore

$$1 + x_1 + \frac{x_1}{\sqrt{x_1^2 + x_2^2}} = 0$$

or else, with polar coordinates by taking $x_1 = \rho \cos\theta$ and $x_2 = \rho \sin\theta$, we have the following:

$$\rho = -1 - \frac{1}{\cos\theta}.$$

The unique optimal solution for the perturbation y stands at the intersection with the line $\{x_2 = y\}$. Since the curve is tangent to the half line $\{x_2 = 0, x_1 < 0\}$ for $\theta = \pi$, it is clear that the optimal solution cannot be upper Lipschitz continuous at $y = 0$. This example answers the first question in showing that the bound $+\infty$ is reached.

We can also remark that the linearized program has no optimal solution and by [3] we know that upper Lipschitzian continuity cannot hold.

2. For the case where $\alpha = \frac{3}{2}$ the optimal solutions stand at the crossing of the line $\{x_2 = y\}$ and the curve

$$\rho = \frac{9}{4}\frac{(1+\cos\theta)^2}{\cos^2\theta} \qquad \left(-\frac{\pi}{2} < \theta < \frac{3\pi}{2}\right).$$

Once again the optimal solution stands on the curve which is tangent at $(0,0)$ to the first axis, there is then no upper Lipschitz continuity at $\{y = 0\}$. This shows that the subquadratic growth condition cannot be relaxed, which was the second question.

Acknowledgments. We are thankful to both referees for their helpful comments and particularly to the one who helped us for organizing our results with respect to related works by [3] and [18].

INDIRECT OBSTACLE CONTROL PROBLEM FOR SEMILINEAR ELLIPTIC VARIATIONAL INEQUALITIES*

QIHONG CHEN†

Abstract. An optimal control problem for a coupled system of a semilinear elliptic equation and an obstacle variational inequality is considered. Existence and optimality conditions of optimal triple are established.

Key words. optimal control, existence, optimality condition, elliptic obstacle variational inequality

AMS subject classifications. 49J20, 49K20

1. Introduction.

In this paper, we investigate an optimal control problem in which the state y is governed by a controlled semilinear elliptic obstacle variational inequality,

$$\begin{cases} y \in H^2(\Omega) \cap H_0^1(\Omega), & \\ Ay \geq f(x,y,u) & \text{in} \quad \Omega, \\ y \geq \varphi & \text{in} \quad \Omega, \\ (Ay - f)(y - \varphi) = 0 & \text{in} \quad \Omega, \end{cases} \tag{1.1}$$

where the obstacle φ solves another semilinear elliptic equation with distributed control,

$$\begin{cases} A\varphi = g(x,\varphi,u) & \text{in} \quad \Omega, \\ \varphi|_{\partial\Omega} = 0, \end{cases} \tag{1.2}$$

and the cost functional is given by

$$J(y,\varphi,u) = \int_\Omega L(x,y(x),\varphi(x),u(x))dx, \tag{1.3}$$

where (y,φ,u) is a triple of state and control satisfying (1.1) and (1.2). Hence, the control problem is

$$\text{minimize} \quad J(y,\varphi,u) \quad \text{subject to}\,(1.1),(1.2) \qquad \text{and} \quad u(x) \in U \,\text{a.e. in}\,\Omega. \tag{1.4}$$

Optimal control problems for variational inequalities have been discussed by many authors in different aspects. See [2], [3], [4], [8], [9], [13], [15], [17], and [19] for examples. Some standard results for variational inequalities can be found in [7], [12], [16], and [18].

Recently, the obstacle control problem has been studied in [1], where the obstacle is taken to be the control and the solution to the obstacle problem is taken to be the state; existence, uniqueness, and some characterizations of the optimal pairs were established based on the properties of the homogeneous state equation.

In our problem, if f does not explicitly depend on u, the action of control is *indirect* in the following sense: the control u acts upon the state y by means of the obstacle φ, the solution of controlled equation (1.2). This amounts to a design of the shape of the string by choosing a suitable "curvature" of the obstacle, if the one-dimensional obstacle problem of the string is considered. Although our problem setting is mathematically presented, our state system (1.1)–(1.2) is meaningful in practice. For instance, some free boundary problems such as the problem of the filtration of water through a homogeneous porous dam and the stationary water cone problem arising in the production of oil from a reservoir with bottom water, etc., after a Baiocchi-type transformation, can be reformulated in terms of the elliptic variational unilateral problem (cf. [16] and [20]). Also, a parabolic counterpart of (1.1)–(1.2) may appear in the studying of mathematical finance (such as the pricing of interest rate derivatives, etc.; cf. [11]).

The plan of this paper is as follows. In section 2, we state the main hypotheses and results, establish a $W^{2,p}$-estimate of state, and prove the continuity of the state with respect to the control variable. Section 3 is devoted to the existence of optimal triples. We study the approximate problems in section 4 and derive the optimality conditions (in the form of Pontryagin's principle) in section 5. Finally, section 6 is concerned with the case in which the control domain is convex.

2. State equation.

2.1. Main hypotheses and results. First, we introduce the following assumptions.

(H_1) $\Omega \subset \mathbb{R}^n$ is a bounded region with $C^{1,1}$ boundary $\partial\Omega$, U is a Polish space (a separable complete metric space), and

$$\mathcal{U} = \{u\colon \Omega \to U \,|\, u(\cdot) \text{ is measurable}\}. \tag{2.1}$$

(H_2) Operator A is defined by

$$Ay(x) = -\sum_{i,j=1}^{n} D_j(a_{ij}(x)D_i y(x)) \tag{2.2}$$

with $a_{ij} \in C^1(\overline{\Omega})$, $a_{ij} = a_{ji}$, $1 \le i, j \le n$, and for some $\lambda > 0$,

$$\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \ge \lambda \sum_{i=1}^{n} |\xi_i|^2 \quad \forall x \in \Omega,\ (\xi_1, \xi_2, \dots, \xi_n) \in \mathbb{R}^n. \tag{2.3}$$

(H_3) The functions $f, g\colon \Omega \times \mathbb{R} \times U \to \mathbb{R}$ have the following properties: $f(\cdot, y, u)$, $g(\cdot, \varphi, u)$ are measurable on Ω, and $f(x, \cdot, u), g(x, \cdot, u)$ are in $C^1(\mathbb{R})$ with $f(x, \cdot, \cdot)$, $f_y(x, \cdot, \cdot)$, $g(x, \cdot, \cdot)$, and $g_\varphi(x, \cdot, \cdot)$ continuous on $\mathbb{R} \times U$. Moreover, there exists a constant $K > 0$, such that

$$-K \le f_y,\ g_\varphi \le 0 \quad \text{on} \quad \Omega \times \mathbb{R} \times U \tag{2.4}$$

and

$$|f(x, 0, u)| + |g(x, 0, u)| \le K \quad \text{on} \quad \Omega \times U. \tag{2.5}$$

(H_4) The function $L: \Omega \times \mathbb{R} \times \mathbb{R} \times U \to \mathbb{R}$ satisfies the following: $L(\cdot, y, \varphi, u)$ is measurable on Ω, $L(x, \cdot, \cdot, u)$ is in $C^1(\mathbb{R} \times \mathbb{R})$ with $L(x, \cdot, \cdot, \cdot), L_y(x, \cdot, \cdot, \cdot)$, and $L_\varphi(x, \cdot, \cdot, \cdot)$ continuous on $\mathbb{R} \times \mathbb{R} \times U$, and for any $R > 0$, there exists a constant $K_R > 0$, such that

$$|L| + |L_y| + |L_\varphi| \le K_R \quad \text{on} \quad \Omega \times [-R, R] \times [-R, R] \times U. \tag{2.6}$$

Under (H_2), the operator A is associated with a positive symmetric bilinear form $a(\cdot, \cdot)$: $H_0^1(\Omega) \times H_0^1(\Omega) \to \mathbb{R}$

$$a(y, z) = \sum_{i,j=1}^{n} \int_\Omega a_{ij}(x) D_i y(x) D_j z(x) dx. \tag{2.7}$$

The weak solution of obstacle problem (1.1) can be defined as follows.

DEFINITION 2.1. *Given $u \in \mathcal{U}$ and $\varphi \in H_0^1(\Omega)$, a function $y \in H_0^1(\Omega)$ is called a weak solution of obstacle problem* (1.1)*, if*

$$\begin{cases} y \in K(\varphi), \\ a(y, z - y) \ge \int_\Omega f(x, y(x), u(x))(z - y) dx \quad \forall z \in K(\varphi), \end{cases} \tag{2.8}$$

where

$$K(\varphi) = \{ z \in H_0^1(\Omega) |\, z \ge \varphi \quad \text{a.e. in } \Omega \} \tag{2.9}$$

is a convex and closed subset of $H_0^1(\Omega)$.

Any element $u \in \mathcal{U}$ is referred to as a control. Any triple $(y, \varphi, u) \in H_0^1(\Omega) \times H_0^1(\Omega) \times \mathcal{U}$ satisfying (2.8) and (1.2) is called a feasible triple, and the corresponding (y, φ) and u will be referred to as a feasible state and a feasible control, respectively. The set of all feasible triples is denoted by $\mathcal{A}$. Clearly, under (H_1)–(H_4), $\mathcal{U}$ coincides with the set of all feasible controls, and for each $u \in \mathcal{U}$, there corresponds a unique feasible state (y, φ), and the cost functional (1.3) is well defined. Hereafter, we always assume (H_1)–(H_4). Thus, we can write $J(y, \varphi, u)$ as $J(u)$ without any ambiguity, and we will use $J(u)$ for convenience. Also we restate the control problem (1.4) as follows.

Problem (C). Find a feasible control $\overline{u} \in \mathcal{U}$, such that

$$J(\overline{u}) = \inf_{u \in \mathcal{U}} J(u). \tag{2.10}$$

If such a $\overline{u}$ exists, we call it an optimal control. Accordingly, the corresponding state $(\overline{y}, \overline{\varphi})$ and the feasible triple $(\overline{y}, \overline{\varphi}, \overline{u}) \in \mathcal{A}$ will be called an optimal state and triple, respectively.

Our main results on Problem (C) are the following two (see also Theorem 3.4 and Theorem 5.2).

EXISTENCE THEOREM. *In addition to* (H_1)–(H_4)*, we let the so-called Cesari property (see section* 3 *for details) hold. Then Problem* (C) *admits an optimal control $\overline{u} \in \mathcal{U}$.*

Pontryagin's principle. Let (H_1)–(H_4) hold and $(\overline{y}, \overline{\varphi}, \overline{u}) \in \mathcal{A}$ be an optimal triple for Problem (C). Then there exist $\overline{p}, \overline{q} \in H_0^1(\Omega)$ and $\overline{\mu} \in H^{-1}(\Omega) \cap \mathcal{M}(\overline{\Omega})$, such that

$$\operatorname{supp} \overline{\mu} \subset \{ x \in \Omega |\, \overline{y}(x) = \overline{\varphi}(x) \},$$

$$\begin{cases} A\overline{p} - f_y(x,\overline{y},\overline{u})\overline{p} = L_y(x,\overline{y},\overline{\varphi},\overline{u}) - \overline{\mu} & \text{in} \quad \Omega, \\ A\overline{q} - g_\varphi(x,\overline{\varphi},\overline{u})\overline{q} = L_\varphi(x,\overline{y},\overline{\varphi},\overline{u}) + \overline{\mu} & \text{in} \quad \Omega, \\ \overline{p}|_{\partial\Omega} = 0, \qquad \overline{q}|_{\partial\Omega} = 0, \end{cases}$$

and

$$H(x,\overline{y}(x),\overline{\varphi}(x),\overline{u}(x),\overline{p}(x),\overline{q}(x)) = \min_{u\in U} H(x,\overline{y}(x),\overline{\varphi}(x),u,\overline{p}(x),\overline{q}(x)) \quad \text{a.e. } x\in\Omega,$$

where $\mathcal{M}(\overline{\Omega})$ is the set of all regular signed measures on $\overline{\Omega}$, and

$$H(x,y,\varphi,u,p,q) = pf(x,y,u) + qg(x,\varphi,u) + L(x,y,\varphi,u)$$

for any $(x,y,\varphi,u,p,q)\in\Omega\times\mathbb{R}\times\mathbb{R}\times U\times\mathbb{R}\times\mathbb{R}$.

2.2. $W^{2,p}$-estimate of state. Let us start with a $W^{2,p}$-estimate of state, which is useful in what follows.

PROPOSITION 2.2. *Let $(y,\varphi,u)\in\mathcal{A}$. Then for any $p\geq 2$,*

$$\|y\|_{W^{2,p}(\Omega)} \leq C_p, \tag{2.11}$$

$$\|\varphi\|_{W^{2,p}(\Omega)} \leq C_p, \tag{2.12}$$

where C_p is a constant independent of the control variable u.

Proof. Under (H_1)–(H_3), (2.12) is easily obtained from the standard L^p-estimate of elliptic equations (cf. [10]).

To prove (2.11), we define

$$\beta(r) = \begin{cases} 0, & 0\leq r<+\infty, \\ -r^2, & -\frac{1}{2}\leq r<0, \\ r+\frac{1}{4}, & -\infty<r<-\frac{1}{2}, \end{cases} \tag{2.13}$$

and we introduce a family of approximation of state equation (2.8):

$$\begin{cases} Ay_\varepsilon + \frac{1}{\varepsilon}\beta(y_\varepsilon-\varphi) = f(x,y_\varepsilon,u) & \text{in} \quad \Omega, \\ y_\varepsilon|_{\partial\Omega} = 0, \end{cases} \tag{2.14}$$

where φ solves (1.2).

It is seen that, for any given $u\in\mathcal{U}$, $\varphi\in W_0^{1,p}(\Omega)$, and $\varepsilon>0$, $(2.14)_\varepsilon$ is uniquely solvable in $W^{2,p}(\Omega)\cap W_0^{1,p}(\Omega)$. The set of all triples $(y_\varepsilon,\varphi,u)\in H_0^1(\Omega)\times H_0^1(\Omega)\times\mathcal{U}$ satisfying $(2.14)_\varepsilon$ and (1.2) will be denoted by $\mathcal{A}_\varepsilon$.

The estimate (2.11) results from the following two lemmas.

LEMMA 2.3. *Let $(y_\varepsilon,\varphi,u)\in\mathcal{A}_\varepsilon$. Then for any $p\geq 2$,*

$$\|\beta(y_\varepsilon-\varphi)\|_{L^p(\Omega)} \leq \varepsilon C_p, \tag{2.15}$$

and consequently,

$$\|y_\varepsilon\|_{W^{2,p}(\Omega)} \leq C_p, \tag{2.16}$$

where C_p is a constant independent of $\varepsilon>0$ and $u\in\mathcal{U}$.

Proof. Define, for $r\in\mathbb{R}$, $B(r) = |\beta(r)|^{p-2}\beta(r)$. Then we have

$$B(r)\leq 0 \quad \text{in}\,\mathbb{R} \quad \text{and} \quad B(r) = 0 \quad \text{in} \quad \mathbb{R}^+, \tag{2.17}$$

$$B'(r) = (p-1)|\beta(r)|^{p-2}\beta'(r) \geq 0, \tag{2.18}$$

and, as $p \geq 2$, $\beta(0) = 0$, and $y_\varepsilon, \varphi \in W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega)$,

$$B(y_\varepsilon - \varphi) \in W_0^{1,p}(\Omega) \hookrightarrow W_0^{1,p'}(\Omega), \tag{2.19}$$

where $p' = \frac{p}{p-1} \leq p$ is the conjugate number of p.

Multiplying $(2.14)_\varepsilon$ by $\varepsilon B(y_\varepsilon - \varphi)$ and integrating by parts, we obtain

$$\varepsilon a(y_\varepsilon, B(y_\varepsilon - \varphi)) + \int_\Omega |\beta(y_\varepsilon - \varphi)|^p dx = \varepsilon \int_\Omega f(x, y_\varepsilon, u) B(y_\varepsilon - \varphi) dx. \tag{2.20}$$

From (2.3), (2.17), (2.18), and the monotony of $f(x, \cdot, u)$, we see that

$$\int_\Omega f(x, y_\varepsilon, u) B(y_\varepsilon - \varphi) dx \leq \int_\Omega f(x, \varphi, u) B(y_\varepsilon - \varphi) dx \tag{2.21}$$

and

$$a(y_\varepsilon - \varphi, B(y_\varepsilon - \varphi)) \geq 0. \tag{2.22}$$

Then, by (1.2), (2.20)–(2.22), and Hölder's inequality, we have

$$\begin{aligned} &\|\beta(y_\varepsilon - \varphi)\|_{L^p(\Omega)}^p \\ &\leq \varepsilon \left\{ \int_\Omega f(x, \varphi, u) B(y_\varepsilon - \varphi) dx - a(\varphi, B(y_\varepsilon - \varphi)) \right\} \\ &= \varepsilon \int_\Omega [f(x, \varphi, u) - g(x, \varphi, u)] B(y_\varepsilon - \varphi) dx \\ &\leq \varepsilon \|f(\cdot, \varphi(\cdot), u(\cdot)) - g(\cdot, \varphi(\cdot), u(\cdot))\|_{L^p(\Omega)} \|\beta(y_\varepsilon - \varphi)\|_{L^p(\Omega)}^{p-1}. \end{aligned} \tag{2.23}$$

Thus, using (2.12) and (H_3), we get the desired estimate (2.15) with

$$C_p = \|f(\cdot, \varphi(\cdot), u(\cdot)) - g(\cdot, \varphi(\cdot), u(\cdot))\|_{L^p(\Omega)},$$

which is independent of $\varepsilon > 0$ and $u \in \mathcal{U}$.

Estimate (2.16) follows immediately from (2.15) and the elliptic L^p- estimate. □

LEMMA 2.4. *Let $(y_\varepsilon, \varphi, u) \in \mathcal{A}_\varepsilon$ and $(y, \varphi, u) \in \mathcal{A}$. Then, as $\varepsilon \to 0$,*

$$y_\varepsilon \to y \quad \textit{weakly in} W^{2,p}(\Omega) \textit{ and strongly in} W_0^{1,p}(\Omega).$$

The proof of Lemma 2.4 is similar to that in [1, Proposition 2.2(i)] with some suitable modifications. □

2.3. Continuous dependence of state on control. In the control set $\mathcal{U}$, we define the distance, called Ekeland's distance, as

$$d(u, v) = m(\{x \in \Omega | u(x) \neq v(x)\}) \quad \forall u, v \in \mathcal{U}, \tag{2.24}$$

where m denotes the Lebesgue measure. We can show that $(\mathcal{U}, d)$ is a complete metric space (cf. [13]).

The following result is concerned with the continuity of the state (y, φ) with respect to the control u under the above metric.

PROPOSITION 2.5. *Let* $(y,\varphi,u),(y_k,\varphi_k,u_k)\in\mathcal{A}\,(k=1,2,\ldots)$. *If* $d(u_k,u)\to 0$, *then for any* $p\geq 2$,

$$\|y_k-y\|_{W^{1,p}(\Omega)}\to 0 \tag{2.25}$$

and

$$\|\varphi_k-\varphi\|_{W^{1,p}(\Omega)}\to 0. \tag{2.26}$$

Proof. The convergence (2.26) is a known result in [13]. Here, we give a sketch of the proof for the reader's convenience.

Since the difference $\varphi_k-\varphi$ satisfies

$$\begin{cases} A(\varphi_k-\varphi)+a_k(x)(\varphi_k-\varphi)=g(x,\varphi,u_k)-g(x,\varphi,u),\\ (\varphi_k-\varphi)|_{\partial\Omega}=0, \end{cases} \tag{2.27}$$

where

$$a_k(x)=-\int_0^1 g_\varphi(x,\varphi(x)+\tau(\varphi_k(x)-\varphi(x)),u_k(x))d\tau,$$

satisfying (by (H_3))

$$0\leq a_k(x)\leq K\qquad\forall k, \tag{2.28}$$

we obtain, from the L^p-estimate for elliptic equations of divergence form,

$$\|\varphi_k-\varphi\|_{W^{1,p}(\Omega)}\leq C\|g(\cdot,\varphi(\cdot),u_k(\cdot))-g(\cdot,\varphi(\cdot),u(\cdot))\|_{W^{-1,p}(\Omega)}. \tag{2.29}$$

By Sobolev embedding and the duality, we have

$$\begin{cases} L^{\frac{np}{n+p}}(\Omega)\hookrightarrow W^{-1,p}(\Omega) & \text{for}\quad p>\frac{n}{n-1},\\ L^q(\Omega)\hookrightarrow W^{-1,p}(\Omega) & \text{for}\quad p=\frac{n}{n-1}. \end{cases} \tag{2.30}$$

Then, (2.29), together with (2.30), (2.12), and (H_3), gives

$$\|\varphi_k-\varphi\|_{W^{1,p}(\Omega)}\leq\begin{cases} C_p d(u_k,u)^{\frac{n+p}{np}} & \text{if}\quad p>\frac{n}{n-1},\\ C_{p,q}d(u_k,u)^{\frac{1}{q}}\quad\forall q>0 & \text{if}\quad p=\frac{n}{n-1}, \end{cases} \tag{2.31}$$

where the constants C_p and $C_{p,q}$ are independent of u and $u_k(k=1,2,\ldots)$. This proves (2.26).

From Proposition 2.2, we know that, for some subsequence,

$$y_k\to y^*\qquad\text{weakly in}\,W^{2,p}(\Omega),\quad\text{strongly in}\,W_0^{1,p}(\Omega).$$

Clearly,

$$y^*(x)\geq\varphi(x)\qquad\text{a.e.}\quad x\in\Omega. \tag{2.32}$$

Now, for any $z\in K(\varphi)$, let $z_k=z\vee\varphi_k$; we have $z_k\in K(\varphi_k)$ and $z_k\to z$ strongly in $H_0^1(\Omega)$. Note that

$$\begin{aligned}&\|f(\cdot,y_k(\cdot),u_k(\cdot))-f(\cdot,y^*(\cdot),u(\cdot))\|_{L^2(\Omega)}\\ &\leq\|f(\cdot,y_k(\cdot),u_k(\cdot))-f(\cdot,y_k(\cdot),u(\cdot))\|_{L^2(\Omega)}+\|f(\cdot,y_k(\cdot),u(\cdot))-f(\cdot,y^*(\cdot),u(\cdot))\|_{L^2(\Omega)}\\ &\leq C\{d(u_k,u)^{\frac{1}{2}}+\|y_k-y^*\|_{L^2(\Omega)}\}\to 0.\end{aligned}$$

Passing to the limit in (2.8), in which u, y, and z are replaced by u_k, y_k, and z_k, respectively, we obtain

$$a(y^*, z - y^*) \geq \int_\Omega f(x, y^*(x), u(x))(z - y^*)dx.$$

This, combined with (2.32), means that y^* is a solution of (2.8). By the uniqueness, we must have that $y^* = y$, and the whole sequence $\{y_k\}$ converges to y strongly in $W_0^{1,p}(\Omega)$. □

COROLLARY 2.6. *$J(u)$ is continuous on $(\mathcal{U}, d)$.*

3. Existence.

3.1. Cesari property and measurable selection theorem. Let us first recall the following.

DEFINITION 3.1 (see [5], [13]). *Let Y be a Banach space and Z be a metric space. Let $\Lambda\colon Z \to 2^Y$ be a multifunction. We say that Λ possesses the Cesari property at $z \in Z$ if*

$$\cap_{\delta>0} \overline{co}\Lambda(O_\delta(z)) = \Lambda(z), \tag{3.1}$$

where $\overline{co}E$ stands for the closed convex hull of the set E and $O_\delta(z)$ is the δ-neighborhood of the point z. If Λ has the Cesari property at every point $z \in Z$, we simply say that Λ has the Cesari property on Z.

DEFINITION 3.2. *Let $\Omega \subset \mathbb{R}^n$ be some Lebesgue measurable set and U be a Polish space. Let $\Gamma\colon \Omega \to 2^U$ be a multifunction. Function $u\colon \Omega \to U$ is called a selection of $\Gamma(\cdot)$ if*

$$u(x) \in \Gamma(x) \quad a.e. \quad x \in \Omega. \tag{3.2}$$

If such a u is measurable, then u is called a measurable selection of $\Gamma(\cdot)$.

The following gives the existence of measurable selections.

THEOREM 3.3. *Let $\Gamma\colon \Omega \to 2^U$ be measurable, taking closed set values. Then $\Gamma(\cdot)$ admits a measurable selection.*

We refer the readers to [13, pp. 100–101] for the proof of Theorem 3.3.

3.2. Existence of optimal controls. To establish the existence for problem (C), we first introduce the following set:

$$\Lambda(x, y, \varphi) = \{(\xi, \eta, \zeta) \in \mathbb{R}^3 | \, \xi \geq L(x, y, \varphi, u), \eta = f(x, y, u), \zeta = g(x, \varphi, u), u \in U\}. \tag{3.3}$$

We make the following assumption:

(H_5) For almost all $x \in \Omega$, the mapping $(y, \varphi) \mapsto \Lambda(x, y, \varphi)$ has the Cesari property on $\mathbb{R}^2$.

THEOREM 3.4. *Let (H_1)–(H_5) hold. Then Problem (C) admits at least one optimal control $\overline{u} \in \mathcal{U}$.*

Proof. Let $\{u_k\} \subset \mathcal{U}$ be a minimizing sequence satisfying

$$J(u_k) \leq \inf_{u \in \mathcal{U}} J(u) + \frac{1}{k}. \tag{3.4}$$

Take $p > \max\{\frac{n}{2}, 2\}$. By Proposition 2.2, we know that the corresponding state (y_k, φ_k) satisfies

$$\|y_k\|_{W^{2,p}(\Omega)} + \|\varphi_k\|_{W^{2,p}(\Omega)} \leq C_p, \tag{3.5}$$

with C_p being independent of k. Thus, we may let, extracting some subsequence if necessary,

$$\left\{\begin{array}{l} y_k \to \overline{y}, \\ \varphi_k \to \overline{\varphi}, \end{array}\right. \tag{3.6}$$

weakly in $W^{2,p}(\Omega)$, strongly in $W_0^{1,p}(\Omega)$, and $C^\alpha(\overline{\Omega})$ for some $\alpha \in (0,1)$ and some $(\overline{y},\overline{\varphi}) \in [W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega)]^2$. By (3.5) and ($H_3$), the functions $f(\cdot, y_k(\cdot), u_k(\cdot))$ and $g(\cdot, \varphi_k(\cdot), u_k(\cdot))$ are uniformly bounded. Hence, we may further assume

$$\left\{\begin{array}{ll} f(\cdot, y_k(\cdot), u_k(\cdot)) \to \overline{f}(\cdot) & \text{weakly in} \quad L^p(\Omega), \\ g(\cdot, \varphi_k(\cdot), u_k(\cdot)) \to \overline{g}(\cdot) & \text{weakly in} \quad L^p(\Omega) \end{array}\right. \tag{3.7}$$

for some $\overline{f}, \overline{g} \in L^\infty(\Omega)$. Then, by the Mazur theorem, we can find $\alpha_{ij} \geq 0$, $\sum_{i\geq 1} \alpha_{ij} = 1 \, \forall j$, such that

$$\left\{\begin{array}{ll} \eta_j(\cdot) = \sum_{i\geq 1} \alpha_{ij} f(\cdot, y_{i+j}(\cdot), u_{i+j}(\cdot)) \to \overline{f}(\cdot) & \text{strongly in} \quad L^p(\Omega), \\ \zeta_j(\cdot) = \sum_{i\geq 1} \alpha_{ij} g(\cdot, \varphi_{i+j}(\cdot), u_{i+j}(\cdot)) \to \overline{g}(\cdot) & \text{strongly in} \quad L^p(\Omega). \end{array}\right. \tag{3.8}$$

Set

$$\xi_j(\cdot) = \sum_{i\geq 1} \alpha_{ij} L(\cdot, y_{i+j}(\cdot), \varphi_{i+j}(\cdot), u_{i+j}(\cdot)) \tag{3.9}$$

and

$$\overline{L}(x) = \underline{\lim}_{j\to\infty} \xi_j(x) \qquad \text{a.e. } x \in \Omega. \tag{3.10}$$

The convergence (3.6) implies that, for any $\delta > 0$, there exists a j_0 such that for $j \geq j_0$,

$$(\xi_j(x), \eta_j(x), \zeta_j(x)) \in co\Lambda(x, O_\delta((\overline{y}(x), \overline{\varphi}(x)))) \qquad \text{a.e. } x \in \Omega. \tag{3.11}$$

Thus, for any $\delta > 0$, we have

$$(\overline{L}(x), \overline{f}(x), \overline{g}(x)) \in \overline{co}\Lambda(x, O_\delta((\overline{y}(x), \overline{\varphi}(x)))) \qquad \text{a.e. } x \in \Omega, \tag{3.12}$$

and then, by (H_5),

$$(\overline{L}(x), \overline{f}(x), \overline{g}(x)) \in \Lambda(x, \overline{y}(x), \overline{\varphi}(x)) \qquad \text{a.e. } x \in \Omega. \tag{3.13}$$

Now, making use of Theorem 3.3, we can find a $\overline{u} \in \mathcal{U}$ such that

$$\left\{\begin{array}{l} \overline{L}(x) \geq L(x, \overline{y}(x), \overline{\varphi}(x), \overline{u}(x)) \\ \overline{f}(x) = f(x, \overline{y}(x), \overline{u}(x)) \\ \overline{g}(x) = g(x, \overline{\varphi}(x), \overline{u}(x)) \end{array}\right. \qquad \text{a.e. } x \in \Omega. \tag{3.14}$$

We claim that $(\overline{y}(x), \overline{\varphi}(x))$ is the state corresponding to $\overline{u}$, i.e.,

$$(\overline{y}, \overline{\varphi}, \overline{u}) \in \mathcal{A}. \tag{3.15}$$

In fact, since $(y_k, \varphi_k, u_k) \in \mathcal{A}$, from the convergence (3.6), (3.7), and (3.14), we have

$$\left\{\begin{array}{ll} A\overline{\varphi} = g(x, \overline{\varphi}, \overline{u}) & \text{in} \quad \Omega, \\ \overline{\varphi}|_{\partial\Omega} = 0 \end{array}\right. \tag{3.16}$$

and

$$\overline{y}(x) \geq \overline{\varphi}(x) \qquad \text{a.e. } x \in \Omega. \tag{3.17}$$

For any $z \in K(\overline{\varphi})$, we have $z \vee \varphi_k \in K(\varphi_k)$ and

$$z \vee \varphi_k \to z \qquad \text{strongly in} \quad H_0^1(\Omega). \tag{3.18}$$

Then, the feasibility of (y_k, φ_k, u_k) gives

$$a(y_k, z \vee \varphi_k - y_k) \geq \int_\Omega f(x, y_k, u_k)(z \vee \varphi_k - y_k)dx \quad \forall k, \tag{3.19}$$

and the convergence (3.6), (3.7), (3.14), and (3.18) yields

$$a(\overline{y}, z - \overline{y}) \geq \int_\Omega f(x, \overline{y}, \overline{u})(z - \overline{y})dx. \tag{3.20}$$

Thus, by (3.16), (3.17), and (3.20), the feasibility (3.15) is verified.

Finally, we can deduce from (3.14), (3.10), (3.9), (3.4), and Fatou's lemma that

$$\begin{aligned}
J(\overline{u}) &= \int_\Omega L(x, \overline{y}(x), \overline{\varphi}(x), \overline{u}(x))dx \\
&\leq \int_\Omega \overline{L}(x)dx = \int_\Omega \underline{\lim}_{j\to\infty} \xi_j(x)dx \\
&\leq \underline{\lim}_{j\to\infty} \int_\Omega \xi_j(x)dx = \underline{\lim}_{j\to\infty} \sum_{i\geq 1} \alpha_{ij} J(u_{i+j}) \\
&\leq \underline{\lim}_{j\to\infty} \sum_{i\geq 1} \alpha_{ij} (\inf_{u\in\mathcal{U}} J(u) + \frac{1}{j}) = \underline{\lim}_{j\to\infty} (\inf_{u\in\mathcal{U}} J(u) + \frac{1}{j}) \\
&= \inf_{u\in\mathcal{U}} J(u).
\end{aligned}$$

Hence $\overline{u}$ is an optimal control of Problem (C). □

4. Analysis of approximate problems.

4.1. Approximate functional. Let us introduce a family of approximate functional

$$J_\varepsilon(u) = J(y_\varepsilon, \varphi, u) = \int_\Omega L(x, y_\varepsilon(x), \varphi(x), u(x))dx, \tag{4.1}$$

where $(y_\varepsilon, \varphi, u) \in \mathcal{A}_\varepsilon$.

Proposition 4.1.

$$\begin{aligned}
&\text{(i)} \quad \text{For any fixed } \varepsilon > 0,\ J_\varepsilon(u) \text{is continuous on } (\mathcal{U}, d); \\
&\text{(ii)} \quad \text{For any given } u \in \mathcal{U}, \lim_{\varepsilon\to 0} J_\varepsilon(u) = J(u).
\end{aligned} \tag{4.2}$$

Proof. (i) It suffices to prove the continuous dependence of y_ε on u. Let $(y_\varepsilon, \varphi, u)$, $(y_{\varepsilon,k}, \varphi_k, u_k) \in \mathcal{A}_\varepsilon (k = 1, 2, \ldots)$. Supposing $d(u_k, u) \to 0$, we have already had that, for any $p \geq 2$, $\|\varphi_k - \varphi\|_{W^{1,p}(\Omega)} \to 0$ (see (2.26)). Adapting the proof of (2.26) to $y_{\varepsilon,k} - y_\varepsilon$, we can obtain

(4.3)

$$\|y_{\varepsilon,k} - y_\varepsilon\|_{W^{1,p}(\Omega)} \leq C \left\{ \frac{1}{\varepsilon} \|\varphi_k - \varphi\|_{L^p(\Omega)} + \|f(\cdot, y_\varepsilon(\cdot), u_k(\cdot)) - f(\cdot, y_\varepsilon(\cdot), u(\cdot))\|_{W^{-1,p}(\Omega)} \right\}.$$

Recalling (2.30), (2.16), and (H_3), we see that

$$\begin{aligned} &\|f(\cdot, y_\varepsilon(\cdot), u_k(\cdot)) - f(\cdot, y_\varepsilon(\cdot), u(\cdot))\|_{W^{-1,p}(\Omega)} \\ &\leq \begin{cases} C_p d(u_k, u)^{\frac{n+p}{np}} & \text{if} \quad p > \frac{n}{n-1}, \\ C_{p,q} d(u_k, u)^{\frac{1}{q}} \quad \forall q > 1 & \text{if} \quad p = \frac{n}{n-1}. \end{cases} \end{aligned} \tag{4.4}$$

Thus, we have

$$\|y_{\varepsilon,k} - y_\varepsilon\|_{W^{1,p}(\Omega)} \to 0. \tag{4.5}$$

(ii) (4.2) is an immediate consequence of Lemma 2.4 and (H_4). □

4.2. Taylor expansion. We note that for each $(y_\varepsilon, \varphi, u) \in \mathcal{A}_\varepsilon$, (y_ε, φ) is the solution of semilinear elliptic system $(2.14)_\varepsilon$ and (1.2). Using an argument similar to that in [13], we can present a sort of "Taylor expansion" formula for (y_ε, φ) and the approximate functional $J_\varepsilon(u)$.

PROPOSITION 4.2. *Let $(y_\varepsilon, \varphi, u) \in \mathcal{A}_\varepsilon$ and $v \in \mathcal{U}$ be fixed. Then, for any $\rho \in (0,1)$, there exists a measurable set $E^\rho \subset \Omega$ with $m(E^\rho) = \rho m(\Omega)$, such that if $u^\rho \in \mathcal{U}$ is defined by*

$$u^\rho(x) = \begin{cases} u(x) & \text{if} \quad x \in \Omega \setminus E^\rho, \\ v(x) & \text{if} \quad x \in E^\rho \end{cases} \tag{4.6}$$

and $(y_\varepsilon^\rho, \varphi^\rho, u^\rho) \in \mathcal{A}_\varepsilon$, then it holds that

$$\begin{cases} y_\varepsilon^\rho = y_\varepsilon + \rho z + r^\rho, \\ \lim_{\rho \to 0} \frac{1}{\rho} \|r^\rho\|_{W^{1,p}(\Omega)} = 0; \end{cases} \tag{4.7}$$

$$\begin{cases} \varphi^\rho = \varphi + \rho\zeta + \omega^\rho, \\ \lim_{\rho \to 0} \frac{1}{\rho} \|\omega^\rho\|_{W^{1,p}(\Omega)} = 0; \end{cases} \tag{4.8}$$

$$\begin{cases} J_\varepsilon(u^\rho) = J_\varepsilon(u) + \rho j + e^\rho, \\ \lim_{\rho \to 0} \frac{1}{\rho} |e^\rho| = 0; \end{cases} \tag{4.9}$$

where z, ζ, and j satisfy the following:

$$\begin{cases} Az - f_y(x, y_\varepsilon, u)z + \frac{1}{\varepsilon}\beta'(y_\varepsilon - \varphi)(z - \zeta) = f(x, y_\varepsilon, v) - f(x, y_\varepsilon, u) & \text{in } \Omega, \\ A\zeta - g_\varphi(x, \varphi, u)\zeta = g(x, \varphi, v) - g(x, \varphi, u) & \text{in } \Omega, \\ z|_{\partial\Omega} = 0, \qquad \zeta|_{\partial\Omega} = 0 \end{cases} \tag{4.10}$$

and

$$j = \int_\Omega [L_y(x, y_\varepsilon, \varphi, u)z + L_\varphi(x, y_\varepsilon, \varphi, u)\zeta + L(x, y_\varepsilon, \varphi, v) - L(x, y_\varepsilon, \varphi, u)]dx. \tag{4.11}$$

4.3. Convergence theorem. The main result of this section is the following convergence theorem.

THEOREM 4.3. *Let $\overline{J}_\varepsilon = \inf_{u \in \mathcal{U}} J_\varepsilon(u)$ and $\overline{J} = \inf_{u \in \mathcal{U}} J(u)$. Then*

$$\lim_{\varepsilon \to 0} \overline{J}_\varepsilon = \overline{J}. \tag{4.12}$$

To prove Theorem 4.3, we need the following:

LEMMA 4.4. *Let* $\{u_\varepsilon\} \subset \mathcal{U}$ *be any sequence,* $(y_\varepsilon, \varphi_\varepsilon, u_\varepsilon) \in \mathcal{A}_\varepsilon$, *and* $(y^\varepsilon, \varphi_\varepsilon, u_\varepsilon) \in \mathcal{A}$. *Then*

$$\lim_{\varepsilon \to 0} \|y_\varepsilon - y^\varepsilon\|_{H_0^1(\Omega)} = 0. \tag{4.13}$$

Proof. By Proposition 2.2 and Lemma 2.3, we have that, for any $p \geq 2$,

$$\|y_\varepsilon\|_{W^{2,p}(\Omega)} + \|\varphi_\varepsilon\|_{W^{2,p}(\Omega)} + \|y^\varepsilon\|_{W^{2,p}(\Omega)} \leq C_p, \tag{4.14}$$

with C_p independent of $\varepsilon > 0$. Thus, we may assume that, for some subsequence,

$$\begin{cases} y_\varepsilon \to y & \text{strongly in} \quad H_0^1(\Omega), \\ \varphi_\varepsilon \to \varphi & \text{strongly in} \quad H_0^1(\Omega) \end{cases} \tag{4.15}$$

and

$$\|y^\varepsilon\|_{H^1(\Omega) \cap L^\infty(\Omega)} \leq C \quad \text{with } C \text{ independent of } \varepsilon > 0. \tag{4.16}$$

For any $\eta \in H_0^1(\Omega)$ with $\eta \geq 0$ a.e. in Ω, we have from $(2.14)_\varepsilon$ that

$$0 \leq -\int_\Omega \beta(y_\varepsilon - \varphi_\varepsilon)\eta dx = \varepsilon \left\{ a(y_\varepsilon, \eta) - \int_\Omega f(x, y_\varepsilon, u_\varepsilon)\eta dx \right\} \to 0, \tag{4.17}$$

because the terms in $\{\,\}$ are bounded. Then, by Fatou's lemma,

$$\int_\Omega \beta(y - \varphi)\eta dx = 0 \quad \forall \eta \in H_0^1(\Omega) \text{ with } \eta \geq 0 \text{ a.e. in } \Omega. \tag{4.18}$$

This implies that

$$\beta(y - \varphi) = 0 \quad \text{a.e. in} \quad \Omega, \tag{4.19}$$

and, by the definition of $\beta(\cdot)$,

$$y \geq \varphi \quad \text{a.e. in} \quad \Omega. \tag{4.20}$$

Now, letting $z_\varepsilon = y_\varepsilon \vee \varphi_\varepsilon$, we have

$$z_\varepsilon \to y \qquad \text{strongly in} \quad H_0^1(\Omega), \tag{4.21}$$

and consequently,

$$\|z_\varepsilon - y_\varepsilon\|_{H_0^1(\Omega)} \to 0. \tag{4.22}$$

Recalling that y_ε and y^ε solve $(2.14)_\varepsilon$ and (2.8), respectively, we have

$$\begin{aligned} &a(y_\varepsilon, y_\varepsilon - y^\varepsilon) \\ &= -\tfrac{1}{\varepsilon} \int_\Omega \beta(y_\varepsilon - \varphi_\varepsilon)(y_\varepsilon - y^\varepsilon)dx + \int_\Omega f(x, y_\varepsilon, u_\varepsilon)(y_\varepsilon - y^\varepsilon)dx \end{aligned} \tag{4.23}$$

and

$$a(y^\varepsilon, z_\varepsilon - y^\varepsilon) \geq \int_\Omega f(x, y^\varepsilon, u_\varepsilon)(z_\varepsilon - y^\varepsilon)dx. \tag{4.24}$$

By the monotonicity of $f(x,\cdot,u)$ and $\beta(\cdot)$, we see that

$$\int_\Omega [f(x, y_\varepsilon, u_\varepsilon) - f(x, y^\varepsilon, u_\varepsilon)](y_\varepsilon - y^\varepsilon)dx \leq 0 \tag{4.25}$$

and

$$\int_\Omega \beta(y_\varepsilon - \varphi_\varepsilon)(y_\varepsilon - y^\varepsilon)dx \geq 0. \tag{4.26}$$

Here, we have used the fact that $y^\varepsilon \geq \varphi_\varepsilon > y_\varepsilon$ when $y_\varepsilon < \varphi_\varepsilon$. From (4.23)–(4.26), we may deduce that

$$a(y_\varepsilon - y^\varepsilon, y_\varepsilon - y^\varepsilon) \leq a(y^\varepsilon, z_\varepsilon - y_\varepsilon) - \int_\Omega f(x, y^\varepsilon, u_\varepsilon)(z_\varepsilon - y_\varepsilon)dx \leq C\|z_\varepsilon - y_\varepsilon\|_{H^1(\Omega)} \to 0,$$

where (4.16) and (4.22) have been used. This and (2.3) prove (4.13). □

Remark. The above lemma can be strengthened. As a matter of fact, using Lions's interpolation theorem (cf. [14]), we can deduce from (4.13) and (4.14) that, for any $p \geq 2$,

$$\lim_{\varepsilon \to 0} \|y_\varepsilon - y^\varepsilon\|_{W^{1,p}(\Omega)} = 0. \tag{4.27}$$

From Lemma 4.4 and (H_4), we easily get the following corollary.

COROLLARY 4.5. *For any sequence* $\{u_\varepsilon\} \subset \mathcal{U}$,

$$\lim_{\varepsilon \to 0}[J_\varepsilon(u_\varepsilon) - J(u_\varepsilon)] = 0. \tag{4.28}$$

Proof of Theorem 4.3. For any $\varepsilon > 0$, one can find $u_\varepsilon \in \mathcal{U}$, such that

$$J_\varepsilon(u_\varepsilon) < \overline{J}_\varepsilon + \varepsilon. \tag{4.29}$$

Then, by Corollary 4.5, we have

$$\underline{\lim}_{\varepsilon \to 0}\overline{J}_\varepsilon \geq \underline{\lim}_{\varepsilon \to 0} J_\varepsilon(u_\varepsilon) = \underline{\lim}_{\varepsilon \to 0}[J(u_\varepsilon) + J_\varepsilon(u_\varepsilon) - J(u_\varepsilon)] = \underline{\lim}_{\varepsilon \to 0} J(u_\varepsilon) \geq \overline{J}. \tag{4.30}$$

On the other hand, let $u_\delta \in \mathcal{U}$ be such that

$$J(u_\delta) < \overline{J} + \delta. \tag{4.31}$$

Then, using Corollary 4.5 again, we have

$$\overline{\lim}_{\delta \to 0}\overline{J}_\delta \leq \overline{\lim}_{\delta \to 0} J_\delta(u_\delta) = \overline{\lim}_{\delta \to 0}[J(u_\delta) + J_\delta(u_\delta) - J(u_\delta)] = \overline{\lim}_{\delta \to 0} J(u_\delta) \leq \overline{J}. \tag{4.32}$$

Hence, (4.12) follows from (4.30) and (4.32). □

5. Optimality condition. In this section, we first recall Ekeland's variational principle and then use it to derive some necessary conditions for optimal controls of Problem (C).

THEOREM 5.1 (Ekeland's variational principle; see [6]). *Let (V, d) be a complete metric space and $J: V \to (-\infty, +\infty]$ be a proper lower semicontinuous function bounded from below. Let $\alpha > 0, \overline{v} \in V$ such that*

$$J(\overline{v}) \le \inf_{v \in V} J(v) + \alpha^2.$$

Then there exists a $v_\alpha \in V$ satisfying

$$J(v_\alpha) \le J(\overline{v}), \tag{5.1}$$

$$d(v_\alpha, \overline{v}) \le \alpha, \tag{5.2}$$

$$-\alpha d(v, v_\alpha) \le J(v) - J(v_\alpha) \quad \forall v \in V. \tag{5.3}$$

THEOREM 5.2. *Let (H_1)–(H_4) hold and $(\overline{y}, \overline{\varphi}, \overline{u}) \in \mathcal{A}$ be an optimal triple for Problem (C). Then there exist $\overline{p}, \overline{q} \in H_0^1(\Omega)$ and $\overline{\mu} \in H^{-1}(\Omega) \cap \mathcal{M}(\overline{\Omega})$, such that*

$$\operatorname{supp} \overline{\mu} \subset \{\, x \in \Omega |\ \overline{y}(x) = \overline{\varphi}(x) \,\}, \tag{5.4}$$

$$\begin{cases} A\overline{p} - f_y(x, \overline{y}, \overline{u})\overline{p} = L_y(x, \overline{y}, \overline{\varphi}, \overline{u}) - \overline{\mu} & in\, \Omega, \\ A\overline{q} - g_\varphi(x, \overline{\varphi}, \overline{u})\overline{q} = L_\varphi(x, \overline{y}, \overline{\varphi}, \overline{u}) + \overline{\mu} & in\, \Omega, \\ \overline{p}|_{\partial\Omega} = 0, \qquad \overline{q}|_{\partial\Omega} = 0, \end{cases} \tag{5.5}$$

and

$$H(x, \overline{y}(x), \overline{\varphi}(x), \overline{u}(x), \overline{p}(x), \overline{q}(x)) = \min_{u \in U} H(x, \overline{y}(x), \overline{\varphi}(x), u, \overline{p}(x), \overline{q}(x)) \qquad a.e.\ x \in \Omega, \tag{5.6}$$

where $\mathcal{M}(\overline{\Omega})$ is the set of all regular signed measures on $\overline{\Omega}$, and

$$H(x, y, \varphi, u, p, q) = pf(x, y, u) + qg(x, \varphi, u) + L(x, y, \varphi, u)$$

for any $(x, y, \varphi, u, p, q) \in \Omega \times \mathbb{R} \times \mathbb{R} \times U \times \mathbb{R} \times \mathbb{R}$.

Condition (5.4) is understood as the following: For any $\eta \in C(\overline{\Omega})$ with $\operatorname{supp} \eta \subset \Omega_0$,

$$\langle \overline{\mu},\ \eta \rangle_{\mathcal{M}(\overline{\Omega}), C(\overline{\Omega})} = 0,$$

where

$$\Omega_0 = \{\, x \in \Omega |\ \overline{y}(x) > \overline{\varphi}(x) \,\}. \tag{5.7}$$

Proof. Given $\varepsilon > 0$ and

$$\alpha_\varepsilon = (J_\varepsilon(\overline{u}) - \overline{J}_\varepsilon + \varepsilon)^{1/2} > 0. \tag{5.8}$$

From (4.2) and (4.12), we see that (note $J(\overline{u}) = \overline{J}$)

$$\alpha_\varepsilon \to 0. \tag{5.9}$$

Since $J_\varepsilon(u)$ is continuous on $(\mathcal{U}, d)$ and

$$J_\varepsilon(\overline{u}) \le \overline{J}_\varepsilon + \alpha_\varepsilon^2 = \inf_{u\in\mathcal{U}} J_\varepsilon(u) + \alpha_\varepsilon^2 \tag{5.10}$$

by Ekeland's variational principle, there exists a $u_\varepsilon \in \mathcal{U}$, such that

$$d(u_\varepsilon, \overline{u}) \le \alpha_\varepsilon, \tag{5.11}$$

$$-\alpha_\varepsilon d(u, u_\varepsilon) \le J_\varepsilon(u) - J_\varepsilon(u_\varepsilon) \quad \forall u \in \mathcal{U}. \tag{5.12}$$

Let $(y_\varepsilon, \varphi_\varepsilon, u_\varepsilon) \in \mathcal{A}_\varepsilon$ and $v \in \mathcal{U}$ be fixed. By Proposition 4.2 we know that, for any $\rho \in (0,1)$, there exists a measurable set $E^\rho \subset \Omega$ with $m(E^\rho) = \rho m(\Omega)$, such that if we define

$$u_\varepsilon^\rho(x) = \begin{cases} u_\varepsilon(x) & \text{if} \quad x \in \Omega \setminus E^\rho, \\ v(x) & \text{if} \quad x \in E^\rho \end{cases} \tag{5.13}$$

and let $(y_\varepsilon^\rho, \varphi_\varepsilon^\rho, u_\varepsilon^\rho) \in \mathcal{A}_\varepsilon$, then

$$\begin{cases} y_\varepsilon^\rho = y_\varepsilon + \rho z_\varepsilon + r_\varepsilon^\rho, \\ \varphi_\varepsilon^\rho = \varphi_\varepsilon + \rho\zeta_\varepsilon + \omega_\varepsilon^\rho, \\ J_\varepsilon(u_\varepsilon^\rho) = J_\varepsilon(u_\varepsilon) + \rho j_\varepsilon + e_\varepsilon^\rho, \end{cases} \tag{5.14}$$

where $z_\varepsilon, \zeta_\varepsilon$, and j_ε satisfy the following:

(5.15)
$$\begin{cases} Az_\varepsilon - f_y(x, y_\varepsilon, u_\varepsilon)z_\varepsilon + \frac{1}{\varepsilon}\beta'(y_\varepsilon - \varphi_\varepsilon)(z_\varepsilon - \zeta_\varepsilon) = f(x, y_\varepsilon, v) - f(x, y_\varepsilon, u_\varepsilon) & \text{in } \Omega, \\ A\zeta_\varepsilon - g_\varphi(x, \varphi_\varepsilon, u_\varepsilon)\zeta_\varepsilon = g(x, \varphi_\varepsilon, v) - g(x, \varphi_\varepsilon, u_\varepsilon) & \text{in } \Omega, \\ z_\varepsilon|_{\partial\Omega} = 0, \qquad \zeta_\varepsilon|_{\partial\Omega} = 0 \end{cases}$$

and

(5.16)
$$j_\varepsilon = \int_\Omega [L_y(x, y_\varepsilon, \varphi_\varepsilon, u_\varepsilon)z_\varepsilon + L_\varphi(x, y_\varepsilon, \varphi_\varepsilon, u_\varepsilon)\zeta_\varepsilon + L(x, y_\varepsilon, \varphi_\varepsilon, v) - L(x, y_\varepsilon, \varphi_\varepsilon, u_\varepsilon)]dx,$$

with

$$\lim_{\rho\to 0} \frac{1}{\rho}\|r_\varepsilon^\rho\|_{W^{1,p}(\Omega)} = \lim_{\rho\to 0} \frac{1}{\rho}\|\omega_\varepsilon^\rho\|_{W^{1,p}(\Omega)} = \lim_{\rho\to 0} \frac{1}{\rho}|e_\varepsilon^\rho| = 0. \tag{5.17}$$

Now, we take $u = u_\varepsilon^\rho$ in (5.12). It follows that

$$-\alpha_\varepsilon m(\Omega) \le \frac{1}{\rho}[J_\varepsilon(u_\varepsilon^\rho) - J_\varepsilon(u_\varepsilon)] \to j_\varepsilon \qquad (\rho \to 0). \tag{5.18}$$

Let $(p_\varepsilon, q_\varepsilon) \in H_0^1(\Omega) \times H_0^1(\Omega)$ be the unique solution of the following system:

$$\begin{cases} Ap_\varepsilon + [\frac{1}{\varepsilon}\beta'(y_\varepsilon - \varphi_\varepsilon) - f_y(x, y_\varepsilon, u_\varepsilon)]p_\varepsilon = L_y(x, y_\varepsilon, \varphi_\varepsilon, u_\varepsilon) & \text{in } \Omega, \\ Aq_\varepsilon - g_\varphi(x, \varphi_\varepsilon, u_\varepsilon)q_\varepsilon - \frac{1}{\varepsilon}\beta'(y_\varepsilon - \varphi_\varepsilon)p_\varepsilon = L_\varphi(x, y_\varepsilon, \varphi_\varepsilon, u_\varepsilon) & \text{in } \Omega, \\ p_\varepsilon|_{\partial\Omega} = 0, \qquad q_\varepsilon|_{\partial\Omega} = 0. \end{cases} \tag{5.19}$$

Then, we may deduce from (5.16) and (5.18) that

$$\int_\Omega [H(x, y_\varepsilon, \varphi_\varepsilon, v, p_\varepsilon, q_\varepsilon) - H(x, y_\varepsilon, \varphi_\varepsilon, u_\varepsilon, p_\varepsilon, q_\varepsilon)]dx \ge -\alpha_\varepsilon m(\Omega). \tag{5.20}$$

In what follows, we are going to take the limits to get the final result.

Noting that $\beta' \geq 0, f_y \leq 0$, and $g_\varphi \leq 0$, we can apply the standard elliptic estimation to the system (5.19) and get

$$\|p_\varepsilon\|_{H_0^1(\Omega)} + \|q_\varepsilon\|_{H_0^1(\Omega)} \leq C. \tag{5.21}$$

Then, from (5.19), we further get

$$\|\beta'(y_\varepsilon - \varphi_\varepsilon)p_\varepsilon\|_{H^{-1}(\Omega)} \leq C\varepsilon. \tag{5.22}$$

Moreover, let $S_\delta(r) \in C^1(\mathbb{R})$ be a family of smooth approximation to $sign\ r$, satisfying the following:

$$S'_\delta(r) \geq 0 \quad \forall r \in \mathbb{R} \tag{5.23}$$

and

$$S_\delta(r) = \begin{cases} 1 & \text{if} \quad r > \delta, \\ 0 & \text{if} \quad r = 0, \\ -1 & \text{if} \quad r < -\delta. \end{cases} \tag{5.24}$$

Multiplying the first equation of (5.19) by $\varepsilon S_\delta(p_\varepsilon)$ and integrating it over Ω, we can get

$$\int_\Omega \beta'(y_\varepsilon - \varphi_\varepsilon)p_\varepsilon S_\delta(p_\varepsilon)dx \leq C\varepsilon. \tag{5.25}$$

Letting $\delta \to 0$, we have

$$\|\beta'(y_\varepsilon - \varphi_\varepsilon)p_\varepsilon\|_{L^1(\Omega)} \leq C\varepsilon. \tag{5.26}$$

In estimates (5.21), (5.22), and (5.26), the constant C is independent of $\varepsilon > 0$. Hence we may let, extracting some subsequence if necessary,

$$\begin{cases} p_\varepsilon \to \overline{p} & \text{weakly in } H_0^1(\Omega), \text{ strongly in } L^2(\Omega), \\ q_\varepsilon \to \overline{q} & \text{weakly in } H_0^1(\Omega), \text{ strongly in } L^2(\Omega), \\ \frac{1}{\varepsilon}\beta'(y_\varepsilon - \varphi_\varepsilon)p_\varepsilon \to \overline{\mu} & \text{weakly star in } H^{-1}(\Omega) \cap \mathcal{M}(\overline{\Omega}). \end{cases}$$

Let $(y^\varepsilon, \varphi_\varepsilon, u_\varepsilon) \in \mathcal{A}$. By (5.9), (5.11), and Proposition 2.5, we have, for any $p \geq 2$,

$$\begin{cases} \|y^\varepsilon - \overline{y}\|_{W^{1,p}(\Omega)} \to 0, \\ \|\varphi_\varepsilon - \overline{\varphi}\|_{W^{1,p}(\Omega)} \to 0 \end{cases} \tag{5.27}$$

and

$$\|y_\varepsilon - \overline{y}\|_{W^{1,p}(\Omega)} \to 0, \tag{5.28}$$

where the convergence $\|y_\varepsilon - y^\varepsilon\|_{W^{1,p}(\Omega)} \to 0$ (see (4.27)) has been utilized.

For any $\eta \in C(\overline{\Omega})$ with $\operatorname{supp}\eta \subset \Omega_0$, the convergence (5.27)–(5.28), combined with the compactness of $\operatorname{supp}\eta$, ensures that, for some $\varepsilon_0 > 0$,

$$y_\varepsilon(x) - \varphi_\varepsilon(x) > 0 \quad \forall x \in supp\,\eta,\ 0 < \varepsilon < \varepsilon_0,$$

which yields

$$\begin{aligned}\langle \overline{\mu},\ \eta\rangle_{\mathcal{M}(\overline{\Omega}),C(\overline{\Omega})} &= \lim_{\varepsilon\to 0}\int_\Omega \frac{1}{\varepsilon}\beta'(y_\varepsilon-\varphi_\varepsilon)p_\varepsilon\eta dx\\ &= \lim_{\varepsilon\to 0}\int_{\operatorname{supp}\eta} \frac{1}{\varepsilon}\beta'(y_\varepsilon-\varphi_\varepsilon)p_\varepsilon\eta dx\\ &= 0.\end{aligned}$$

Thus, (5.4) holds.

Passing to the limit in (5.19) and (5.20), we obtain (5.5) and

$$\int_\Omega [H(x,\overline{y}(x),\overline{\varphi}(x),v(x),\overline{p}(x),\overline{q}(x)) - H(x,\overline{y}(x),\overline{\varphi}(x),\overline{u}(x),\overline{p}(x),\overline{q}(x))]dx \geq 0.$$

Finally, by the separability of U and the continuity of the Hamiltonian H in the variable v, noting also that $v\in\mathcal{U}$ is arbitrary, we obtain the optimality condition (5.6). □

6. Convex case. In the previous sections, the control domain U is just a metric space and does not necessarily have any algebraic structure. Thus we do not talk about the convexity of U, and accordingly, we use spike perturbations in the derivation of optimality conditions.

This section will be concerned with the case in which $\mathcal{U}=L^2(\Omega)$, and then the convex variation can be performed, and a stronger regularity of optimal control can be obtained. □

6.1. Problem setting. Let all the assumptions in (H_1) and (H_2) be unchanged except for U and $\mathcal{U}$. In addition, we assume that

($\tilde{H}_3$) The function $f\colon\Omega\times\mathbb{R}\to\mathbb{R}$, has the following properties: $f(\cdot,y)$ is measurable on Ω, $f(x,\cdot)$ is in $C^1(\mathbb{R})$, and there exists a constant $K>0$, such that

$$-K\leq f_y\leq 0 \quad \text{on} \quad \Omega\times\mathbb{R}, \tag{6.1}$$

$$|f(x,0)|\leq K \quad \text{on} \quad \Omega. \tag{6.2}$$

Given $y_d\in L^2(\Omega)$, we introduce the following quadratic cost functional which we try to minimize on $u\in L^2(\Omega)$:

$$J(u)=\frac{1}{2}\int_\Omega [(y-y_d)^2+u^2]dx. \tag{6.3}$$

In (6.3), the state y is the solution of the following semilinear elliptic obstacle problem:

$$\begin{cases} y\in K(\varphi),\\ a(y,z-y)\geq \displaystyle\int_\Omega f(x,y)(z-y)dx \quad \forall z\in K(\varphi),\end{cases} \tag{6.4}$$

where $K(\varphi)$ and $a(\cdot,\cdot)$ are defined as before (see (2.9) and (2.7)) and the obstacle φ solves (1.2) with $g(x,\varphi,u)=u$, i.e.,

$$\begin{cases} A\varphi = u & \text{in} \quad \Omega,\\ \varphi|_{\partial\Omega}=0.\end{cases} \tag{6.5}$$

Obviously, the cost functional (6.3) is well defined since, under (H_1), (H_2), and ($\tilde{H}_3$), (6.4) and (6.5) are uniquely solvable for any $u \in L^2(\Omega)$.

The feasible set, denoted by $\tilde{\mathcal{A}}$, consists of all triples $(y, \varphi, u) \in H_0^1(\Omega) \times H_0^1(\Omega) \times L^2(\Omega)$ satisfying (6.4) and (6.5). Any triple $(y, \varphi, u) \in \tilde{\mathcal{A}}$ is called a feasible triple, and the corresponding (y, φ) and u are referred to as a feasible state and control, respectively. Clearly, $L^2(\Omega)$ coincides with the set of all feasible controls.

Now, we pose the following optimal control problem.

Problem ($\tilde{C}$). Find a $\overline{u} \in L^2(\Omega)$, such that

$$J(\overline{u}) = \inf_{u \in L^2(\Omega)} J(u). \tag{6.6}$$

Such a $\overline{u} \in L^2(\Omega)$, if it exists, is called an optimal control and the corresponding triple $(\overline{y}, \overline{\varphi}, \overline{u}) \in \tilde{\mathcal{A}}$ is called an optimal triple.

6.2. Compactness and existence.

PROPOSITION 6.1.

(i) *There is a unique triple* $(y, \varphi, u) \in \tilde{\mathcal{A}}$ *corresponding to each* $u \in L^2(\Omega)$, *and there exists a constant* $C > 0$, *independent of* u, *such that*

$$\|\varphi\|_{H^2(\Omega)} \leq C\|u\|_{L^2(\Omega)}, \tag{6.7}$$

$$\|y\|_{H_0^1(\Omega)} \leq C(1 + \|u\|_{L^2(\Omega)}). \tag{6.8}$$

(ii) *The solution operator* $S: u \mapsto (y, \varphi)$ *of* (6.4)–(6.5) *is compact.*

Proof. The proof of (i) is classic. For the proof of (ii), it suffices to show that if $u_k \to u$ weakly in $L^2(\Omega)$, then

$$\begin{cases} \varphi_k \to \varphi & \text{strongly in } H_0^1(\Omega), \\ y_k \to y & \text{strongly in } H_0^1(\Omega), \end{cases} \tag{6.9}$$

where (y, φ, u), $(y_k, \varphi_k, u_k) \in \tilde{\mathcal{A}}\,(k = 1, 2, \ldots)$.

In fact, by estimates (6.7) and (6.8) and the uniqueness of limit point, we have the convergence (cf. the proof of Proposition 2.5):

$$\varphi_k \to \varphi \quad \text{strongly in } H_0^1(\Omega), \tag{6.10}$$

$$y_k \to y \quad \text{weakly in } H_0^1(\Omega), \text{strongly in } L^2(\Omega). \tag{6.11}$$

To prove the strong convergency of y_k in $H_0^1(\Omega)$, we note that $z_k = y \vee \varphi_k \in K(\varphi_k)$, and

$$z_k \to y \quad \text{strongly in } H_0^1(\Omega). \tag{6.12}$$

Hence, by (6.4), convergence (6.11), and (6.12),

$$a(z_k - y_k, z_k - y_k) \leq a(z_k, z_k - y_k) - \int_\Omega f(x, y_k)(z_k - y_k)dx \to 0. \tag{6.13}$$

This implies $\|z_k - y_k\|_{H_0^1(\Omega)} \to 0$, and consequently,

$$\|y_k - y\|_{H_0^1(\Omega)} \to 0. \qquad \square \tag{6.14}$$

The existence of Problem ($\tilde{C}$) is readily obtained from the compactness of the solution operator and the lower semicontinuity of the cost functional $J(u)$.

THEOREM 6.2. *Let* (H_1), (H_2), *and* ($\tilde{H}_3$) *hold. Then Problem* ($\tilde{C}$) *admits an optimal control* $\overline{u} \in L^2(\Omega)$.

6.3. Approximate control problems. Let $(\overline{y}, \overline{\varphi}, \overline{u})$ be a fixed optimal triple of Problem $(\tilde{\mathrm{C}})$.

In this subsection, we will introduce a family of approximate control problems. First we define

$$J_\varepsilon(u) = \frac{1}{2}\int_\Omega [(y_\varepsilon - y_d)^2 + u^2 + (u - \overline{u})^2]dx, \tag{6.15}$$

where y_ε is the approximate state solving

$$\begin{cases} Ay_\varepsilon + \frac{1}{\varepsilon}\beta(y_\varepsilon - \varphi) = f(x, y_\varepsilon) & \text{in} \quad \Omega, \\ y_\varepsilon|_{\partial\Omega} = 0, \end{cases} \tag{6.16}_\varepsilon$$

with φ being the solution of (6.5) and $\beta(\cdot)$ being given in (2.13).

The set of all triples $(y_\varepsilon, \varphi, u) \in H_0^1(\Omega) \times H_0^1(\Omega) \times L^2(\Omega)$ satisfying $(6.16)_\varepsilon$ and (6.5) will be denoted by $\tilde{\mathcal{A}}_\varepsilon$.

Our approximate control problems can be stated as follows.

Problem $(\tilde{\mathrm{C}})_\varepsilon$. Find a $u_\varepsilon \in L^2(\Omega)$, such that

$$J_\varepsilon(u_\varepsilon) = \inf_{u \in L^2(\Omega)} J_\varepsilon(u). \tag{6.17}$$

It is easy to see the following.

PROPOSITION 6.3. *There exists an optimal triple* $(y_\varepsilon, \varphi_\varepsilon, u_\varepsilon) \in \tilde{\mathcal{A}}_\varepsilon$ *to Problem* $(\tilde{\mathrm{C}})_\varepsilon$.

PROPOSITION 6.4. *For any fixed* $\varepsilon > 0$, *the solution mapping* $T_\varepsilon : u \mapsto (y_\varepsilon, \varphi)$ *of* $(6.16)_\varepsilon$ *and* (6.5) *is differentiable in the following sense: Given* $u, h \in L^2(\Omega)$, *there exists a pair* $(\xi, \eta) \in H_0^1(\Omega) \times H_0^1(\Omega)$, *such that, as* $\delta \to 0$,

$$\frac{1}{\delta}[T_\varepsilon(u + \delta h) - T_\varepsilon(u)] \to (\xi, \eta) \quad \textit{weakly in } H_0^1(\Omega) \times H_0^1(\Omega).$$

Furthermore, (ξ, η) *solves*

$$\begin{cases} A\xi - f_y(x, y_\varepsilon)\xi + \frac{1}{\varepsilon}\beta'(y_\varepsilon - \varphi)(\xi - \eta) = 0 & \textit{in } \Omega, \\ A\eta = h & \textit{in } \Omega, \\ \xi|_{\partial\Omega} = 0, \quad \eta|_{\partial\Omega} = 0. \end{cases} \tag{6.18}$$

From above proposition, we can derive the characterization of optimal triples of the approximate Problem $(\tilde{\mathrm{C}})_\varepsilon$.

PROPOSITION 6.5. *Let* $(y_\varepsilon, \varphi_\varepsilon, u_\varepsilon)$ *be an optimal triple of Problem* $(\tilde{\mathrm{C}})_\varepsilon$. *Then there exists an adjoint pair* $(p_\varepsilon, q_\varepsilon) \in H_0^1(\Omega) \times H_0^1(\Omega)$, *such that*

$$\begin{cases} Ap_\varepsilon + [\frac{1}{\varepsilon}\beta'(y_\varepsilon - \varphi_\varepsilon) - f_y(x, y_\varepsilon)]p_\varepsilon = y_\varepsilon - y_d & \textit{in } \Omega, \\ Aq_\varepsilon - \frac{1}{\varepsilon}\beta'(y_\varepsilon - \varphi_\varepsilon)p_\varepsilon = 0 & \textit{in } \Omega, \\ p_\varepsilon|_{\partial\Omega} = 0, \quad q_\varepsilon|_{\partial\Omega} = 0 \end{cases} \tag{6.19}$$

and

$$q_\varepsilon + 2u_\varepsilon - \overline{u} = 0 \quad \textit{a.e. in} \quad \Omega. \tag{6.20}$$

6.4. Necessary condition. In deriving the necessary conditions of the optimal control for the original Problem ($\tilde{\mathrm{C}}$), the following lemmas are crucial.

LEMMA 6.6. *Let* $(y_\varepsilon, \varphi_\varepsilon, u_\varepsilon) \in \tilde{\mathcal{A}}_\varepsilon$. *If* $u_\varepsilon \to u$ *weakly in* $L^2(\Omega)$, *for some* $u \in L^2(\Omega)$ *(in particular, this is the case if* $u_\varepsilon = u$*), then*

$$\begin{cases} y_\varepsilon \to y & \text{strongly in } H_0^1(\Omega), \\ \varphi_\varepsilon \to \varphi & \text{strongly in } H_0^1(\Omega) \end{cases} \tag{6.21}$$

with $(y, \varphi, u) \in \tilde{\mathcal{A}}$.

Proof. The proof is quite similar to that of Proposition 6.1 (ii) with some minor modifications. □

LEMMA 6.7. *Let* $(\overline{y}, \overline{\varphi}, \overline{u})$ *be an optimal triple of the original Problem* ($\tilde{\mathrm{C}}$) (*given at the beginning of subsection* 6.3), *and* $(y_\varepsilon, \varphi_\varepsilon, u_\varepsilon)$ *be optimal triples for (approximate) Problem* $(\tilde{\mathrm{C}})_\varepsilon$. *Then*

$$u_\varepsilon \to \overline{u} \quad \text{weakly in} \quad L^2(\Omega), \tag{6.22}$$

$$y_\varepsilon \to \overline{y} \quad \text{strongly in} \quad H_0^1(\Omega), \tag{6.23}$$

and

$$\varphi_\varepsilon \to \overline{\varphi} \quad \text{strongly in} \quad H_0^1(\Omega). \tag{6.24}$$

Proof. First, we note that

$$\|u_\varepsilon\|^2_{L^2(\Omega)} \le 2J_\varepsilon(u_\varepsilon) \le 2J_\varepsilon(\overline{u}) \to 2J(\overline{u}) \qquad (\varepsilon \to 0). \tag{6.25}$$

Thus, $\{u_\varepsilon\}$ is bounded in $L^2(\Omega)$. For some subsequence, still denoted by $\{u_\varepsilon\}$, we have

$$u_\varepsilon \to u \qquad \text{weakly in } L^2(\Omega) \text{ for some } u \in L^2(\Omega). \tag{6.26}$$

Then, by Lemma 6.6,

$$y_\varepsilon \to y \qquad \text{strongly in} \quad H_0^1(\Omega), \tag{6.27}$$

$$\varphi_\varepsilon \to \varphi \qquad \text{strongly in} \quad H_0^1(\Omega) \tag{6.28}$$

with $(y, \varphi, u) \in \tilde{\mathcal{A}}$.

Next, we have the following:

$$\begin{aligned} & J(\overline{u}) \le J(u) \\ &= \tfrac{1}{2} \int_\Omega [(y - y_d)^2 + u^2] dx \\ &\le \tfrac{1}{2} \int_\Omega [(y - y_d)^2 + u^2 + (u - \overline{u})^2] dx \\ &\le \underline{\lim}_{\varepsilon \to 0} \tfrac{1}{2} \int_\Omega [(y_\varepsilon - y_d)^2 + u_\varepsilon^2 + (u_\varepsilon - \overline{u})^2] dx \\ &= \underline{\lim}_{\varepsilon \to 0} J_\varepsilon(u_\varepsilon) \\ &\le \underline{\lim}_{\varepsilon \to 0} J_\varepsilon(\overline{u}) = J(\overline{u}). \end{aligned} \tag{6.29}$$

Thus, all the equalities in (6.29) must hold. This means $J(u) = J(\overline{u})$, and $\int_\Omega (u - \overline{u})^2 dx = 0$. Hence we obtain $u = \overline{u}$ and, by uniqueness, $y = \overline{y}$ and $\varphi = \overline{\varphi}$. This completes the proof. □

Using an argument analogous to section 5, we may prove the following theorem.

THEOREM 6.8. *Let* $(\overline{y}, \overline{\varphi}, \overline{u})$ *be an optimal triple of Problem* $(\tilde{\mathrm{C}})$. *Then there exists an adjoint pair* $(\overline{p}, \overline{q}) \in H_0^1(\Omega) \times H_0^1(\Omega)$ *and* $\overline{\mu} \in H^{-1}(\Omega) \cap \mathcal{M}(\overline{\Omega})$, *such that*

$$\begin{cases} A\overline{p} - f_y(x, \overline{y})\overline{p} = \overline{y} - y_d - \overline{\mu} & \text{in } \Omega, \\ A\overline{q} = \overline{\mu} & \text{in } \Omega, \\ \overline{p}|_{\partial\Omega} = 0, \quad \overline{q}|_{\partial\Omega} = 0 \end{cases} \tag{6.30}$$

and

$$\overline{q} + \overline{u} = 0 \quad \text{a.e. in } \Omega. \tag{6.31}$$

Remark. From (6. 31), we see that any optimal control $\overline{u}$ must be an element of $H_0^1(\Omega)$. Moreover, $\overline{u}$ is the strong limit point of the corresponding approximate optimal controls u_ε in $L^2(\Omega)$. More precisely, we can deduce from (6.20) and (6.31) that

$$u_\varepsilon \to \overline{u} \qquad \text{weakly in } H_0^1(\Omega) \quad \text{and strongly in } L^2(\Omega).$$

Acknowledgments. The author is grateful to Prof. Xunjing Li and Prof. Jiongmin Yong for their instructive suggestions and also to Prof. Lishang Jiang for his helpful advice.

SOME RESULTS ON THE BELLMAN EQUATION OF ERGODIC CONTROL*

HIROAKI MORIMOTO† AND MASAMI OKADA‡

Abstract. We study the multidimensional Bellman equation of ergodic control for diffusion processes without invariant measures and establish the existence of a unique solution in a certain class.

Key words. ergodic control, Bellman equation, polynomial growth, convex

AMS subject classifications. 49C20, 93E20

1. Introduction.

We deal with the d-dimensional Bellman equation of the form

$$\lambda = \frac{1}{2}\Delta\phi(x) + F(D\phi(x)) + h(x), \qquad x \in \mathbf{R^d}, \tag{1}$$

where

$$\begin{aligned} F(\xi) &= \min\{|p|^2 + (\xi, p) : |p| \le 1\} \\ &= \begin{cases} -|\xi|^2/4 & \text{if } |\xi| \le 2, \\ -|\xi| + 1 & \text{if } |\xi| > 2, \end{cases} \end{aligned} \tag{2}$$

and $|\cdot|, (,)$, and D denote the norm, the inner product of vectors, and the gradient, respectively. Now we are given a convex function $h(x)$ with polynomial growth, and the unknown is the pair of a constant λ and a C^2-function $\phi(x)$ on $\mathbf{R^d}$.

Generally speaking, the linear ergodic control problem has been investigated for the stochastic differential systems with invariant measures [3], [5]. The corresponding Bellman equation is given by

$$\lambda = \frac{1}{2}\Delta\phi + (Ax, D\phi) + F(D\phi) + h,$$

and the matrix A is assumed to satisfy a kind of Lyapunov-type stability condition for the existence result of a unique solution.

Equation (1) is related to the study of ergodic control in the linear systems without invariant measures such as manufacturing systems in the production planning problems [14]. Also, this is an extension of [9] by means of direct calculations, and [10] recently treated this from the point of view of reducing (1) to an equivalent integral equation in the 1-dimensional case.

Our aim is to show that the Bellman equation (1) admits a unique solution $(\lambda, \phi) \in \mathbf{R} \times C^2(\mathbf{R^d})$ in a certain class. To solve (1), we consider the Bellman equation for the

control problem with discounted rate $\alpha > 0$:

$$\alpha u_\alpha(x) = \frac{1}{2}\Delta u_\alpha(x) + F(Du_\alpha(x)) + h(x), \qquad x \in \mathbf{R^d}. \tag{3}$$

We apply the technique of [4] to (1) with the Lipschitz continuous term $F(\xi)$, and we are focused on studying the limit of (3) as $\alpha \to 0$. The solution (λ, ϕ) is given by the limit

$$\alpha \min u_\alpha \quad \to \quad \lambda, \tag{4}$$

$$u_\alpha(x) - \min u_\alpha \quad \to \quad \phi(x). \tag{5}$$

It is known in [12] that (3) has a unique solution u_α. However, the crucial point for establishing (4), (5), and (1) is that u_α becomes a convex function with polynomial growth and we can obtain the gradient estimates of u_α in the whole space $\mathbf{R^d}$ uniformly in α.

Let us mention the works [4], [7] on the Bellman equation of ergodic control without convex and polynomial growth hypotheses and the linear quadratic case, in which $F(\xi)$ is replaced by $\min\{|p|^2 + (\xi, p) : p \in \mathbf{R^d}\}$. We refer to [13] for ergodic control of reflected diffusions.

The content of this paper is as follows. In section 2 we show the existence of a unique solution u_α to Bellman equation (3) under the convexity assumption on $h(x)$. Further, in section 3, we study the limit of u_α as $|x| \to \infty$ and the polynomial growth property. Section 4 is devoted to a priori estimates of $u_\alpha - \min u_\alpha$ for the approximation problem. Section 5 deals with the existence of the unique solution of (1). Finally, in section 6, we present an application of our results to an ergodic control problem of linear stochastic differential systems without invariant measures.

2. Bellman equations of discounted cost control. We study the existence of a unique solution u_α with polynomial growth to the Bellman equation:

$$\alpha u_\alpha(x) = \frac{1}{2}\Delta u_\alpha(x) + F(Du_\alpha(x)) + h(x), \qquad x \in \mathbf{R^d}, \tag{6}$$

where $0 < \alpha < 1/2$. We assume

$$h : \text{nonnegative, convex on } \mathbf{R^d}, \tag{7}$$

h satisfies the polynomial growth condition, i.e.,

$$\exists C > 0, \qquad m \in \mathbf{N}_+; \quad h(x) \le C(1 + |x|^m), \quad x \in \mathbf{R^d}, \tag{8}$$

$$h \in C^1(\mathbf{R^d}). \tag{9}$$

To simplify the notation, we make use of the following quantity:

$$[f]_{\delta, B_r} = \sup_{x \in B_r} |f(x)| + \sup_{x, y \in B_r,\ x \neq y} \frac{|f(x) - f(y)|}{|x - y|^\delta},$$

where $f(x)$ is the bounded Hölder continuous function with exponent δ on a ball $B_r = B_r(0)$ of $\mathbf{R^d}$. Let $t_n \in C_c^\infty(\mathbf{R^d})$ be a sequence such that $t_n = 1$ on B_n, 0 outside B_{2n} and $0 \le t_n \le 1, |Dt_n| \le C/n$, and set $h_n = t_n h \in C_c^1(\mathbf{R^d})$. It is clear that $h_n \to h$ and $0 \le h_n \le h$.

Now let us consider the Bellman equation

$$\alpha u_n(x) = \frac{1}{2}\Delta u_n(x) + F(Du_n(x)) + h_n(x), \qquad x \in \mathbf{R^d}. \tag{10}$$

Then we have Theorem 2.1.

THEOREM 2.1. *Under* (7), (8), *and* (9), *equation* (10) *admits a unique solution* $u_n \in C_0(\mathbf{R^d}) \cap C^2(\mathbf{R^d})$, *which satisfies*

$$\sup_n [u_n]_{\delta,B_r} < \infty, \tag{11}$$

$$\sup_n \sum_i [D_i u_n]_{\delta,B_r} < \infty, \tag{12}$$

$$\sup_n \sum_{i,j} [D_{ij} u_n]_{\delta,B_r} < \infty \tag{13}$$

for some $0 < \delta < 1$.

Proof. It is well known [2] that, for every $n \in \mathbf{N}_+$, (10) has a unique solution u_n of the form

$$u_n(x) = \inf \left\{ E\left[\int_0^\infty e^{-\alpha t}(h_n(x(t)) + |p(t)|^2)dt \right] : |p(t)| \le 1 \right\} \tag{14}$$

in the class $C_0(\mathbf{R^d})$ of continuous functions vanishing at infinity, where $x(t)$ is a solution of the stochastic differential equation

$$dx(t) = p(t)dt + dw(t), \qquad x(0) = x \in \mathbf{R^d},$$

defined on some probability space $(\Omega, \mathcal{F}, P; \{\mathcal{F}_t\})$ carrying a d-dimensional standard Brownian motion $w(t)$, and the infimum is taken over the class of all $\mathcal{F}_t$-progressively measurable processes $p(t)$ with $|p(t)| \le 1$.

Since the similar proof of the assertions is needed later, we shall divide it into several steps.

Step 1. We note $u_n \ge 0$ by (14) and (7). Let $\nu \ge 1$ and we shall show that

$$2\alpha \int u_n^{\nu+1}\Theta dx + \int |Du_n|^2 \nu u_n^{\nu-1}\Theta dx \le 2\int (h_n + 1)u_n^\nu \Theta dx, \tag{15}$$

where $\Theta(x) = e^{-\theta|x|}$ for a positive constant θ chosen later. Multiplying both sides of (10) by $u_n^\nu\Theta$ and integrating over $\mathbf{R^d}$, we have

$$2\alpha \int u_n^{\nu+1}\Theta dx - \int \Delta u_n u_n^\nu \Theta dx - 2\int F(Du_n)u_n^\nu\Theta dx = 2\int h_n u_n^\nu \Theta dx.$$

The second term of the left-hand side can be rewritten as

$$\begin{aligned}\int (Du_n, D(u_n^\nu\Theta))dx &= \int \left[|Du_n|^2 \nu u_n^{\nu-1}\Theta - \theta u_n^\nu \left(Du_n, \frac{x}{|x|} \right)\Theta \right] dx \\ &\ge \int [|Du_n|^2 \nu u_n^{\nu-1} - \theta u_n^\nu |Du_n|]\Theta dx.\end{aligned}$$

Since $|\xi| + 1 \ge -F(\xi) \ge |\xi| - 1$, we get (15) for a choice of θ with $0 < \theta < 2$.

Step 2. By Step 1, we have

$$\begin{aligned}\alpha \int u_n^{\nu+1}\Theta dx &\le \int (h_n + 1)u_n^\nu \Theta dx \\ &\le \int (|h| + 1)u_n^\nu \Theta dx \\ &\le \left(\int (|h| + 1)^{\nu+1}\Theta dx \right)^{1/(\nu+1)} \left(\int (u_n^\nu)^{(\nu+1)/\nu}\Theta dx \right)^{\nu/(\nu+1)}\end{aligned}$$

from which

$$\alpha\left(\int u_n^{\nu+1}\Theta dx\right)^{1/(\nu+1)} \le \left(\int (|h|+1)^{\nu+1}\Theta dx\right)^{1/(\nu+1)}.$$

Step 3. Here we take $\nu = 1$ in (15). Then

$$\begin{aligned}\alpha\int (u_n^2+|Du_n|^2)\Theta dx &\le \int (h_n+1)u_n\Theta dx\\ &\le \left(\int (|h|+1)^2\Theta dx\right)^{1/2}\left(\int u_n^2\Theta dx\right)^{1/2}\\ &\le \left(\int (|h|+1)^2\Theta dx\right)^{1/2}\left(\int (u_n^2+|Du_n|^2)\Theta dx\right)^{1/2}.\end{aligned}$$

Hence

$$\sup_n \int (u_n^2+|Du_n|^2)\Theta dx < \infty,$$

and thus,

$$\sup_n(|u_n|_{L^2(B_r)}+|Du_n|_{L^2(B_r)}) < \infty \quad \text{for each } r>0.$$

By the regularity result [11, Thm 8.8, p. 183], there exists $C>0$ such that

$$|u_n|_{W^{2,2}(B_r)} \le C(|u_n|_{W^{1,2}(B_{r+1})}+|\Delta u_n|_{L^2(B_{r+1})}).$$

Therefore, we get by (10)

$$\sup_n |u_n|_{W^{2,2}(B_r)} < \infty.$$

Step 4. We show that

$$\sup_n |u_n|_{W^{2,k}(B_r)} < \infty \qquad \text{for all } k > d. \tag{16}$$

Due to the Sobolev inequality [6, Thm IX.16, p. 169], (16) follows immediately in the case of $d = 1, 2$. Further, assuming $d > 2$, we have

$$\sup_n |Du_n|_{L^q(B_{r+1})} \le \sup_n C|Du_n|_{W^{1,2}(B_{r+1})} < \infty, \qquad \frac{1}{q} = \frac{1}{2}-\frac{1}{d}.$$

By Step 2 and (10)

$$\sup_n |\Delta u_n|_{L^q(B_{r+1})} < \infty.$$

Moreover, we know by [1] that

$$|u_n|_{W^{2,q}(B_r)} \le C(|u_n|_{W^{1,q}(B_{r+1})}+|\Delta u_n|_{L^q(B_{r+1})}).$$

Hence,

$$\sup_n |u_n|_{W^{2,q}(B_r)} < \infty.$$

By a bootstrap argument, we can obtain (16).

Step 5. Using the Sobolev inequality again, we have

$$\sup_n |u_n|_{L^\infty(B_r)} \le \sup_n C|u_n|_{W^{1,k}(B_r)} < \infty.$$

Now, we apply the Morrey theorem [6, Thm IX.12, p. 166 or p. 169],

$$|u_n(x) - u_n(y)| \le C|u_n|_{W^{1,k}(B_r)}|x-y|^\delta \qquad \forall x, y \in B_r, \qquad \delta = 1 - d/k,$$

to obtain (11). Similarly, by Step 4, we deduce (12).

Step 6. We can easily see by (9) that the derivative $D_i u_n$ satisfies

$$\alpha D_i u_n = \frac{1}{2}\Delta D_i u_n + (DF(Du_n), DD_i u_n) + D_i h_n.$$

Since $DF(\xi)$ is bounded, we have

$$\sup_n |\Delta D_i u_n|_{L^k(B_r)} < \infty,$$

and by virtue of [1]

$$\sup_n |Du_n|_{W^{2,k}(B_r)} < \infty.$$

Thus, by the same argument as Step 5, we deduce (13). The proof is complete. □

To show the existence of u_α of (6) with polynomial growth, we consider the stochastic differential equation

$$dz(t) = G(z(t))dt + dw(t), \qquad z(0) = x \in \mathbf{R^d}, \tag{17}$$

where

$$G(z) = \begin{cases} -z/|z| \text{ if } z \in \mathbf{R^d}\backslash\{0\}, \\ 0 \qquad \text{if } z = 0. \end{cases}$$

LEMMA 2.2. *For each $n \in \mathbf{N}_+$, there exists $C > 0$ such that*

$$\alpha E\left[\int_0^\infty e^{-\alpha t}|z(t)|^{2n} dt\right] \le C(1 + |x|^{2n+2}). \tag{18}$$

Proof. By an application of Ito's formula to $e^{-\alpha t}|z|^{2n+2}$, we have

$$\begin{aligned} E[e^{-\alpha t}|z(t)|^{2n+2}] - |x|^{2n+2} &= E\bigg[\int_0^t e^{-\alpha s}\{-\alpha|z(s)|^{2n+2} + (2n+2)(G(z(s)), z(s))|z(s)|^{2n} \\ &\qquad + (n+1)(2n+d)|z(s)|^{2n}\}ds\bigg] \\ &\le E\bigg[\int_0^t e^{-\alpha s}\{-2(n+1)|z(s)|^{2n+1} \\ &\qquad + (n+1)(2n+d)|z(s)|^{2n}\}ds\bigg]. \end{aligned}$$

Hence

$$E\left[\int_0^\infty e^{-\alpha s}\ g(z(s))\ ds\right] \le |x|^{2n+2},$$

where $g(z) = 2(n+1)|z|^{2n+1} - (n+1)(2n+d)|z|^{2n}$. We choose $\zeta > 0$ such that $|z|^{2n} \le g(z)$ for all $|z| \ge \zeta$. Then

$$\begin{aligned} E\left[\int_0^\infty e^{-\alpha t}|z(t)|^{2n}dt\right] &= \int_0^\infty e^{-\alpha t}E[|z(t)|^{2n}1_{(|z(t)|<\zeta)} + |z(t)|^{2n}1_{(|z(t)|\ge\zeta)}]dt \\ &\le \int_0^\infty e^{-\alpha t}\{\zeta^{2n} + E[g(z(t))]\}dt \\ &\le \zeta^{2n}/\alpha + |x|^{2n+2}. \end{aligned}$$

Thus we get (18) with $C > 0$ independent of α.

THEOREM 2.3. *Assume* (7), (8), (9). *Then there exists a unique solution* $u_\alpha \in C^2(\mathbf{R^d})$ *of equation* (6) *such that* u_α *is convex and satisfies*

$$0 \le \alpha u_\alpha(x) \le C(1+|x|^{m+3}), \qquad x \in \mathbf{R^d}, \tag{19}$$

for some constant $C > 0$.

Proof. By Theorem 2.1, it is evident that the sequences $\{u_n\}, \{Du_n\}$, and $\{\Delta u_n\}$ are uniformly bounded and equicontinuous on every B_r. By the Ascoli–Arzelà theorem, we have

$$\begin{aligned} u_n &\to u_\alpha \in C^2(\mathbf{R^d}), \\ Du_n &\to Du_\alpha, \\ \Delta u_n &\to \Delta u_\alpha \quad \text{uniformly on } B_r, \end{aligned}$$

taking a subsequence if necessary. Passing to the limit in (10), we can obtain (6).

To prove (19), we recall (14). Hence, by (8) and Lemma 2.2,

$$\begin{aligned} 0 \le \alpha u_n(x) &\le \alpha E\left[\int_0^\infty e^{-\alpha t}(h_n(z(t)) + |G(z(t))|^2)dt\right] \\ &\le C\left(1 + \alpha E\left[\int_0^\infty e^{-\alpha t}(1+|z(t)|^m)dt\right]\right) \\ &\le C(1+|x|^{m+3}). \end{aligned}$$

This implies that u_α satisfies (19). Due to (19), we have

$$E[e^{-\alpha t}u_\alpha(x(t))] \to 0 \quad \text{as} \quad t \to \infty.$$

Hence, by Ito's formula

$$u_\alpha(x) = \inf\left\{E\left[\int_0^\infty e^{-\alpha t}(h(x(t)) + |p(t)|^2)dt\right] : |p(t)| \le 1\right\}, \tag{20}$$

where the infimum is attained by the feedback law $\rho(Du_\alpha)$ with $\rho(\xi) = \arg\min F(\xi)$. Thus the convexity of u_α follows (cf. [8, p. 204]). The proof is complete. □

Remark. In the case of $d = 1$, the theorem is verified without (9), because h is Lipschitz continuous and (12) implies (13).

3. Limit at infinity and polynomial growth. We consider the limit of the solution u_α to Bellman equation (6) as $|x| \to \infty$ and also the polynomial growth property of $u_\alpha - \min u_\alpha$, denoted by v_α. We make the following assumption:

$$\text{There exists } C_0 > 0 \text{ such that } \ h(x) \geq C_0|x|. \tag{21}$$

Our objective in this section is to prove the following result.

THEOREM 3.1. *We assume* (7), (8), (9), (21). *Then we have*

$$u_\alpha(x) \quad \to \quad \infty \quad \textit{as} \quad |x| \quad \to \quad \infty \quad \textit{uniformly in } \alpha, \tag{22}$$

$$v_\alpha(x) \leq C(1 + |x|^{m+1}) \tag{23}$$

for some constant $C > 0$.

LEMMA 3.2. *If* $d = 1$, *then the assertions of Theorem* 3.1 *hold.*

Proof. By (6), (2), and the convexity of $u_\alpha \geq 0$, we have

$$\begin{aligned} h(x) &\leq \alpha u_\alpha(x) + |u_\alpha'(x)| + 1 \\ &\leq \alpha(|u_\alpha'(x)||x| + u_\alpha(0)) + |u_\alpha'(x)| + 1. \end{aligned}$$

Hence, by (21)

$$\begin{aligned} |u_\alpha'(x)| &\geq (h(x) - 1 - \alpha u_\alpha(0))/(|x| + 1) \\ &\geq C_0/2 \quad \text{for sufficiently large } x, \end{aligned}$$

and then

$$u_\alpha(x) \quad \to \quad \infty \quad \text{as} \quad |x| \quad \to \infty.$$

Thus, by convexity, we can find $C > 0$ independent of α such that $u_\alpha(x) \geq C|x| - 1/C$. This implies (22).

Now we can define $\gamma_\alpha \in \mathbf{R}$ by $u_\alpha(\gamma_\alpha) = \min_x u_\alpha(x)$. Since $u_\alpha'(\gamma_\alpha) = 0$, it is easy to see that

$$h(\gamma_\alpha) \leq \alpha u_\alpha(\gamma_\alpha) \leq \alpha u_\alpha(0).$$

By (19) and (21), this yields that

$$\sup_\alpha |\gamma_\alpha| < \infty. \tag{24}$$

Moreover,

$$\sup_\alpha \alpha \min u_\alpha < \infty.$$

From (6) it follows that

$$\alpha v_\alpha = \frac{1}{2} v_\alpha'' + F(v_\alpha') + (h - \alpha \min u_\alpha),$$

and by (2),

$$0 \leq v_\alpha'' - 2|v_\alpha'| + 2(1 + h - \alpha \min u_\alpha).$$

By (19) we note that $\lim_{y\to\infty} e^{-2y}v_\alpha(y) = 0$.

Integrating over $[x, y]$ and letting $y \to \infty$, we have

$$\begin{aligned} 0 \le v_\alpha'(x) &\le \int_0^\infty 2(1 + h(s+x) - \alpha \min u_\alpha)e^{-2s}ds \\ &\le C(1 + |x|^m) \qquad \text{for} \qquad x \ge \gamma_\alpha. \end{aligned}$$

Hence

$$0 \le v_\alpha(x) \le C(1 + |x|^{m+1}) \qquad \text{for} \qquad x \ge \gamma_\alpha.$$

By the same calculation as above over $(-\infty, \gamma_\alpha]$, we deduce (23). □

Proof of Theorem 3.1. We prove the theorem, comparing (6) with

$$\alpha v_i = \frac{1}{2}\Delta v_i + F_i(Dv_i) + h_i, \quad i = 1, 2, \tag{25}$$

where

$$F_1(\xi) = \sum_{j=1}^d \min_{|p_j|\le 1}(p_j^2 + p_j\xi_j), \qquad h_1(x) = \sum_{j=1}^d \eta_1|x_j|,$$

$$F_2(\xi) = \sum_{j=1}^d \min_{|p_j|\le 1/d}(p_j^2 + p_j\xi_j), \qquad h_2(x) = \sum_{j=1}^d \{\eta_2(|x_j|^m + 1) - \alpha \min u_\alpha\},$$

and each positive constant η_i will be chosen later. Here we note that the summation of F_i can be interchanged with the minimization on p_j. By virtue of Theorem 2.3, each equation has a unique solution v_i. Further, we can easily see that v_i is of the form

$$v_i(x) = \sum_{j=1}^d w_j^{(i)}(x_j)$$

for the solution $w_j^{(i)}(x_j)$ to (25) in the case $d = 1$. Hence, by Lemma 3.2, the following relations are fulfilled:

$$\begin{aligned} &v_1(x) \quad \to \quad \infty \quad \text{as} \quad |x| \quad \to \quad \infty \ \text{ uniformly in } \alpha, \\ &v_2(x) - \min v_2 \le \sum_j (w_j^{(2)}(x_j) - \min w_j^{(2)}) \le C(1 + |x|^{m+1}) \end{aligned}$$

for sufficiently large $\eta_2 > 0$ with $C_0|x| \le h_2$. Along the same line as (20), we have

$$v_\alpha(x) = \inf\left\{E\left[\int_0^\infty e^{-\alpha t}(h(x(t)) - \alpha \min u_\alpha + |p(t)|^2)dt\right] : |p(t)| \le 1\right\},$$

$$v_1(x) = \inf\left\{E\left[\int_0^\infty e^{-\alpha t}(h_1(x(t)) + |p(t)|^2)dt\right] : |p_j(t)| \le 1\right\},$$

$$v_2(x) - \min v_2 = \inf\left\{E\left[\int_0^\infty e^{-\alpha t}(h_2(x(t)) - \alpha \min v_2 + |p(t)|^2)dt\right] : |p_j(t)| \le 1/d\right\}.$$

Since $\{p : |p_j| \le 1/d\} \subset \{p : |p| \le 1\} \subset \{p : |p_j| \le 1\}$, we can obtain

$$\begin{aligned} u_\alpha &\ge v_1, \\ v_\alpha &\le v_2 - \min v_2 \end{aligned}$$

for a convenient choice of each η_i such that $h_1 \le h$ and $h - \alpha \min u_\alpha \le h_2 - \alpha \min v_2$. Thus the theorem is established.

4. A priori estimates for approximation. For the approximation problem of (1), we consider here the gradient estimates of v_α satisfying

$$\alpha v_\alpha = \frac{1}{2}\Delta v_\alpha + F(Dv_\alpha) + (h - \alpha \min u_\alpha), \tag{26}$$

which follows from (6).

THEOREM 4.1. *Assume* (7), (8), (9), (21). *Then there exists* $0 < \delta < 1$ *such that*

$$\sup_{0<\alpha<1/2} [v_\alpha]_{\delta,B_r} < \infty, \tag{27}$$

$$\sup_{0<\alpha<1/2} \sum_i [D_i v_\alpha]_{\delta,B_r} < \infty, \tag{28}$$

$$\sup_{0<\alpha<1/2} \sum_{i,j} [D_{ij} v_\alpha]_{\delta,B_r} < \infty \tag{29}$$

for every $r > 0$.

Proof. Multiplying both sides of (26) by $v_\alpha(x)\Theta(x)$ and integrating over $\mathbf{R^d}$, we have

$$2\int \alpha v_\alpha^2 \Theta dx - \int (\Delta v_\alpha) v_\alpha \Theta dx - 2\int F(Dv_\alpha) v_\alpha \Theta dx = 2\int (h - \alpha \min u_\alpha) v_\alpha \Theta dx,$$

where Θ is as in the proof of Theorem 2.1. The second term of the left-hand side can be rewritten as

$$\begin{aligned}\int (Dv_\alpha, D(v_\alpha\Theta))dx &= \int \left[|Dv_\alpha|^2\Theta - \theta v_\alpha \left(Dv_\alpha, \frac{x}{|x|} \right) \Theta \right] dx \\ &\geq \int [|Dv_\alpha|^2 - \theta v_\alpha |Dv_\alpha|]\Theta dx.\end{aligned}$$

By the choice of θ with $2 > \theta > 0$, we get

$$\int |Dv_\alpha|^2 \Theta dx \leq 2\int (h - \alpha \min u_\alpha + 1) v_\alpha \Theta dx.$$

Since

$$v_\alpha(\bar\gamma_\alpha) - v_\alpha(x) \geq (Dv_\alpha(x), \bar\gamma_\alpha - x) \quad \text{for} \quad \bar\gamma_\alpha := \arg\min v_\alpha,$$

and $\{\bar\gamma_\alpha\}$ is bounded by analogy with (24), we have

$$0 \leq v_\alpha(x) \leq C|Dv_\alpha(x)|(|x| + 1). \tag{30}$$

Then by the Schwarz inequality

$$\int |Dv_\alpha|^2 \Theta dx \leq 2C \left(\int (h - \alpha \min u_\alpha + 1)^2 (|x| + 1)^2 \Theta dx \right)^{1/2} \left(\int |Dv_\alpha|^2 \Theta dx \right)^{1/2}.$$

Therefore, we deduce

$$\sup_\alpha \int |Dv_\alpha|^2 \Theta dx < \infty.$$

Now we can find a constant $C > 0$ independent of α such that

$$|Dv_\alpha|_{L^2(B_r)} \leq C,$$

and by (30)

$$|v_\alpha|_{L^2(B_r)} \le C.$$

Along the same line as Step 3 of Theorem 2.1, we can obtain

$$\sup_\alpha |v_\alpha|_{W^{2,2}(B_r)} < \infty.$$

Finally, by the same bootstrap argument as Step 4 of Theorem 2.1,

$$\sup_\alpha |v_\alpha|_{W^{2,k}(B_r)} < \infty \qquad \text{for all } k > d.$$

Further, repeating Steps 5 and 6 of Theorem 2.1, we can deduce (27), (28), (29). □

5. Bellman equation of ergodic control.

5.1. Existence. In this section we shall show the existence of a unique solution $(\lambda, \phi) \in \mathbf{R} \times C^2(\mathbf{R^d})$ to the Bellman equation

$$\lambda = \frac{1}{2}\Delta\phi(x) + F(D\phi(x)) + h(x), \qquad x \in \mathbf{R^d}. \tag{31}$$

THEOREM 5.1. *We assume* (7), (8), (9), (21). *Then there exists a subsequence* $\alpha \to 0$ *such that*

$$\alpha \min u_\alpha \quad \to \quad \lambda \in \mathbf{R}_+, \tag{32}$$

$$v_\alpha(x) \quad \to \quad \phi(x) \in C^2(\mathbf{R^d}) \quad \textit{uniformly on each } B_r. \tag{33}$$

The limit (λ, ϕ) *satisfies Bellman equation* (31) *and, furthermore,*

$$\phi : \textit{convex on } \mathbf{R^d}, \tag{34}$$

$$\phi(x) \quad \to \quad \infty \quad \textit{as} \quad |x| \quad \to \quad \infty, \tag{35}$$

$$0 \le \phi(x) \le C(1 + |x|^{m+1}) \tag{36}$$

for some constant $C > 0$.

Proof. From Theorem 4.1 it follows that $\{v_\alpha\}$ and $\{Dv_\alpha\}$ are uniformly bounded and equicontinuous on each B_r, and so is $\{D^2 v_\alpha\}$. By the Ascoli–Arzelà theorem, we get

$$\begin{aligned} v_\alpha \quad &\to \quad \phi, \\ Dv_\alpha \quad &\to \quad D\phi, \\ D^2 v_\alpha \quad &\to \quad D^2\phi \qquad \text{uniformly on } B_r, \end{aligned}$$

taking a subsequence if necessary. Moreover,

$$\alpha v_\alpha(x) \quad \to \quad 0, \qquad \alpha \min u_\alpha \quad \to \quad \lambda,$$

since $\{\alpha \min u_\alpha\}$ is bounded. Passing to the limit in (26), we deduce (31). The assertions (34), (35), and (36) follow from Theorems 2.3 and 3.1 immediately. □

5.2. Uniqueness. Before going into the proof of uniqueness, we need the following property of the stochastic differential equation

$$dx^*(t) = \rho(D\phi(x^*(t)))dt + dw(t), \qquad x^*(0) = x, \tag{37}$$

where $\rho(\xi) = \arg\min F(\xi)$, i.e.,

$$\rho(\xi) = \begin{cases} -\xi/2 & \text{if } |\xi| \le 2, \\ -\xi/|\xi| & \text{if } |\xi| > 2. \end{cases} \tag{38}$$

LEMMA 5.2. *For any $n \in \mathbf{N}_+$, there exists $C > 0$ such that*

$$E[|x^*(t)|^{2n}] \le C(1+t). \tag{39}$$

Proof. We remark by (31) and (21) that

$$-F(D\phi(x)) \ge h(x) - \lambda \quad \to \quad \infty,$$

and hence

$$|D\phi(x)| \quad \to \quad \infty \quad \text{as} \quad |x| \quad \to \quad \infty.$$

Now, let us show that

$$\left(x, \frac{D\phi(x)}{|D\phi(x)|}\right) \quad \to \quad \infty \quad \text{as} \quad |x| \quad \to \quad \infty. \tag{40}$$

Suppose it were not true. Then there exists a sequence $x_k \to \infty$ such that

$$\left(x_k, \frac{D\phi(x_k)}{|D\phi(x_k)|}\right) \le C \quad \text{for some } C > 0.$$

Define $S_k = \{x : \ \phi(x) < \phi(x_k)\}$, and let T_k be the tangent plane of S_k at x_k. Since 0 belongs to S_k, we can easily find $y_k \in T_k$ such that the vector y_k coincides with $|y_k|D\phi(x_k)/|D\phi(x_k)|$. By the definition of T_k,

$$(y_k - x_k, D\phi(x_k)) = 0.$$

Hence

$$|y_k| \le C.$$

On the other hand, since S_k is convex, we have

$$\phi(y_k) \ge \phi(x_k),$$

and hence

$$\phi(y_k) \quad \to \quad \infty \quad \text{as} \quad k \quad \to \quad \infty.$$

This is a contradiction, and thus we get (40).

Next, we have by Ito's formula

$$E[|x^*(t)|^{2n}] - |x|^{2n} = E\Bigg[\int_0^t \{2n|x^*(s)|^{2(n-1)}(x^*(s), \rho(D\phi(x^*(s))) + n(d + 2(n-1))|x^*(s)|^{2(n-1)}\}ds\Bigg].$$

By (40), we can choose $R > 0$ such that

$$2(x, \rho(D\phi(x))) + d + 2(n-1) \leq 0 \quad \text{for} \quad |x| \geq R.$$

Therefore, we deduce (39). The proof is complete. □

THEOREM 5.3. *We make the assumptions of Theorem* 5.1. *Let* $(\lambda_j, \phi_j) \in \mathbf{R} \times C^2(\mathbf{R^d}), j = 1, 2,$ *be two solutions of* (31) *satisfying* (34), (35), (36). *Then we have*

$$\lambda_1 = \lambda_2, \tag{41}$$

$$D\phi_1 = D\phi_2. \tag{42}$$

Proof. We first show (41). By (31) and (38) we have

$$\lambda_1 = \frac{1}{2}\Delta\phi_1 + |\rho(D\phi_1)|^2 + (\rho(D\phi_1), D\phi_1) + h,$$
$$\lambda_2 \leq \frac{1}{2}\Delta\phi_2 + |\rho(D\phi_1)|^2 + (\rho(D\phi_1), D\phi_2) + h.$$

Denoting $\hat{\phi} = \phi_1 - \phi_2$, we get

$$\frac{1}{2}\Delta\hat{\phi} + (\rho(D\phi_1), D\hat{\phi}) \leq \lambda_1 - \lambda_2. \tag{43}$$

We apply Ito's formula to the solution $\hat{x}(t)$ of (37) with ϕ_1 replacing ϕ. Then

$$E[e^{-\alpha(t\wedge\sigma_n)}\hat{\phi}(\hat{x}(t\wedge\sigma_n))] = \hat{\phi}(x) + E\Bigg[\int_0^{t\wedge\sigma_n} \Big\{ -\alpha e^{-\alpha s}\hat{\phi}(\hat{x}(s))ds + e^{-\alpha s}(\rho(D\phi_1), D\hat{\phi})(\hat{x}(s)) + e^{-\alpha s}\frac{1}{2}\Delta\hat{\phi}(\hat{x}(s))\Big\}ds\Bigg],$$

where $\{\sigma_n\}$ is a sequence of localizing times for the local martingale. Note that

$$|\hat{x}(t)| \leq |x| + t + |w(t)|. \tag{44}$$

Letting $n \to \infty$, we have by the dominated convergence theorem

$$E[e^{-\alpha t}\hat{\phi}(\hat{x}(t))] - \hat{\phi}(x) \leq E\left[\int_0^t e^{-\alpha s}\{-\alpha\hat{\phi}(\hat{x}(s)) + (\lambda_1 - \lambda_2)\}ds\right].$$

Moreover, letting $t \to \infty$, we get

$$-\hat{\phi}(x) \leq E\left[\int_0^\infty e^{-\alpha s}\{-\alpha\hat{\phi}(\hat{x}(s))\}ds\right] + (\lambda_1 - \lambda_2)/\alpha$$

or, equivalently,

$$\lambda_1 - \lambda_2 \geq \alpha\left(\alpha E\left[\int_0^\infty e^{-\alpha s}\hat{\phi}(\hat{x}(s))ds\right] - \hat{\phi}(x)\right).$$

By (36) and Lemma 5.2 we have

$$\begin{aligned} |E[\hat{\phi}(\hat{x}(t))]| &\leq C(1 + E[|\hat{x}(t)|^{m+1}]) \\ &\leq C(1 + (E[|\hat{x}(t)|^{2(m+1)}])^{1/2}) \\ &\leq C(1 + (C(t+1))^{1/2}). \end{aligned} \tag{45}$$

Hence

$$\left|\alpha^2 E\left[\int_0^\infty e^{-\alpha s}\hat{\phi}(\hat{x}(s))ds\right]\right| \le C\left(\alpha+\alpha^2\int_0^\infty e^{-\alpha s}s^{1/2}ds\right)\to 0 \quad \text{as} \quad \alpha\to 0.$$

Passing to the limit, we can deduce $\lambda_1 \ge \lambda_2$, and thus (41).

Next, in order to prove (42), it is sufficient to show that ϕ admits a representation

$$\phi(x)-\phi(0)=\lim_{r\to 0+}\inf\left\{E\left[\int_0^{\tau_r}((h(x(t))+|p(t)|^2)-\lambda)dt\right] \;:\; |p(t)|\le 1\right\}, \tag{46}$$

where $\tau_r=\inf\{t : x(t)\in B_r\}$ for the response $x(t)$ to each control $p(t)$. By (31) and (37), it is obvious that

$$\phi(x^*(t))+\int_0^t (h(x^*(s))+|p^*(s)|^2-\lambda)ds \text{ is a local martingale,}$$

where $p^*(t)=\rho(D\phi(x^*(t)))$. Taking into account (44), we see that

$$\phi(x)=E\left[\int_0^{\tau_r\wedge t}(h(x^*(s))+|p^*(s)|^2-\lambda)ds+\phi(x^*(\tau_r\wedge t))\right].$$

Letting $t\to\infty$, we have by Fatou's lemma

$$\phi(x)\ge E\left[\int_0^{\tau_r}(h(x^*(s))+|p^*(s)|^2-\lambda)ds+\phi(x^*(\tau_r))\right].$$

Here, we note that $x^*(t)$ becomes a Brownian motion by the Girsanov transformation of probability measure P. Then $P(\tau_r<\infty)=1$ and hence $P(|x^*(\tau_r)|=r)=1$. Thus

$$\phi(x)-\inf_{|x|=r}\phi(x)\ge E\left[\int_0^{\tau_r}(h(x^*(s))+|p^*(s)|^2-\lambda)ds\right] \quad \text{for } |x|>r. \tag{47}$$

Letting $r\to 0$, we get (46) with $\ge$ replacing $=$.

On the other hand, by (26), it is easy to see that

$$e^{-\alpha t}v_\alpha(x(t))+\int_0^t e^{-\alpha s}(h(x(s))+|p(t)|^2-\alpha\min u_\alpha)ds \text{ is a submartingale.}$$

Hence

$$v_\alpha(x)\le E\left[\int_0^{\tau_r\wedge t}e^{-\alpha s}(h(x(s))+|p(s)|^2-\alpha\min u_\alpha)ds+e^{-\alpha(\tau_r\wedge t)}v_\alpha(x(\tau_r\wedge t))\right],$$

from which

$$v_\alpha(x)\le E\left[\int_0^{\tau_r}e^{-\alpha s}(h(x(s))+|p(s)|^2-\alpha\min u_\alpha)ds+e^{-\alpha\tau_r}v_\alpha(x(\tau_r))\right].$$

Let (λ_2,ϕ_2) be the limit of (32) and (33). Tending α to 0, we get

$$\phi_2(x)-\sup_{|x|=r}\phi_2(x)\le E\left[\int_0^{\tau_r}(h(x(s))+|p(s)|^2-\lambda_2)ds\right].$$

Thus we can obtain

$$\phi_2(x) - \phi_2(0) = \lim_{r\to 0+} \inf \left\{ E\left[\int_0^{\tau_r} ((h(x(t)) + |p(t)|^2) - \lambda_2) dt \right] \ : \ |p(t)| \le 1 \right\},$$
$$\phi_1(x) - \phi_1(0) \ge \phi_2(x) - \phi_2(0),$$

taking $\phi = \phi_2$ and $\phi = \phi_1$ in (47), respectively.

Define $\bar{\phi}(x) = \phi_1(x) - \phi_1(0) - (\phi_2(x) - \phi_2(0)) \ge 0$. Then, by (43)

$$\frac{1}{2}\Delta\bar{\phi} + (\rho(D\phi_1), D\bar{\phi}) \le 0.$$

By the maximal principle [11, Thm 3.5, p. 35], we have

$$\bar{\phi} = 0 \qquad \text{on } B_R \quad \forall R,$$

since $\bar{\phi}$ achieves its minimum at $x = 0$. Therefore, we conclude (46), completing the proof. □

6. An application to ergodic control. We shall study the ergodic control problem to minimize the cost

$$J(p) = \limsup_{T\to\infty} \frac{1}{T} E\left[\int_0^T \{h(x(t)) + |p(t)|^2\} dt \right] \tag{48}$$

over all $\mathcal{P}$ subject to the state equation

$$dx(t) = p(t)dt + dw(t), \qquad x(0) = x, \tag{49}$$

where $\mathcal{P}$ denotes the set of all progressively measurable $\mathcal{F}_t$-adapted processes $p(t)$ such that

$$|p(t)| \le 1,$$

$$\lim_{T\to\infty} \frac{1}{T} E[|x(t)|^{m+1}] = 0 \quad \text{for the response } x(t) \text{ to } p(t)\ . \tag{50}$$

THEOREM 6.1. *We assume* (7), (8), (9), (21). *Then the optimal control* $p^*(t)$ *is given by*

$$p^*(t) = \rho(D\phi(x^*(t)))$$

and the value is given by

$$J(p^*) = \lambda,$$

where $x^*(t)$ *is defined by* (37).

Proof. By (31) and Ito's formula, we have

$$\begin{aligned} E[\phi(x^*(T))] - \phi(x) &= E\left[\int_0^T \left\{ (D\phi(x^*(t)), \rho(D\phi(x^*(t)))) + \frac{1}{2}\Delta\phi(x^*(t)) \right\} dt \right] \\ &= E\left[\int_0^T \left(F(D\phi(x^*(t))) \ - |\rho(D\phi(x^*(t)))|^2 + \frac{1}{2}\Delta\phi(x^*(t)) \right) \ dt \right] \\ &= E\left[\int_0^T (\lambda - h(x^*(t)) - |\rho(D\phi(x^*(t)))|^2) \ dt \right]. \end{aligned}$$

In view of Lemma 5.2 and (45),

$$\lim_{T\to\infty}\frac{1}{T}E[\phi(x^*(T))]=0,$$

and also p^* belongs to $\mathcal{P}$. Hence dividing both sides by T and letting $T\to\infty$, we get

$$J(p^*)=\lim_{T\to\infty}\frac{1}{T}E\left[\int_0^T(h(x^*(t))+|p^*(t)|^2)dt\right]=\lambda.$$

Next, let $p\in\mathcal{P}$ be arbitrary. Along the same line as above, we have

$$E[\phi(x(T))]-\phi(x)\geq E\left[\int_0^T(\lambda-h(x(t))-|p(t)|^2)dt\right].$$

Also, by (36) and (50)

$$\lim_{T\to\infty}\frac{1}{T}E[\phi(x(T))]=0.$$

Thus, we deduce $J(p)\geq\lambda$, which completes the proof. □

7. Concluding remarks. In this paper we have analyzed the Bellman equation of ergodic control problems for diffusion processes that may not possess invariant measures. We have also showed that the gradient estimate of the solution to the Bellman equation in discounted cost problems is bounded in discounted rates, and the equation can be solved without the Lyapunov-type stability conditions discussed in many other sources. It should be noted that the convexity and the polynomial growth property inherited from h play important roles for the existence of a unique solution to the Bellman equation and further for a synthesis of optimal control. We can verify the optimality for the sake of preserving the moment of the optimal trajectory less than the order of time t.

The present paper is a generalization completely covering the results of earlier papers in the 1-dimensional case. The method gives some useful suggestions such that the control problem will be solvable for the long-run average cost defined on a rather wider class of admissible controls than what is known, for which the stochastic system is made unstable, even if it contains the stabilizing matrix A. It is also applicable to solve the Bellman equation with $\min\{(x,p):|p|\leq 1\}$ replacing $F(\xi)$.

The result of this paper provides an answer for some applications to the ergodic production planning problems in unstable manufacturing systems with sales returns, constant demand, and no breakdown. However, the ergodic control of the hybrid system requires the solution to the simultaneous equations with respect to the state of random demands. We need to study the convexity and the polynomial growth property of such Bellman equations.

Acknowledgments. We would like to thank anonymous referees for helpful comments that enabled us to improve the manuscript.

H^2 AND H^∞ DESIGN OF SAMPLED-DATA SYSTEMS USING LIFTING. PART I: GENERAL FRAMEWORK AND SOLUTIONS*

LEONID MIRKIN†, HÉCTOR P. ROTSTEIN‡, AND ZALMAN J. PALMOR†

Abstract. This paper presents a complete solution to the H^2 and H^∞ problems for sampled-data systems. As opposed to previous works in the area, it is assumed here that all or some of the sampling function, the discrete-time controller, and the hold function are available for design.

The solution is obtained by transforming the problem to discrete time using the well-known lifting technique. It is then shown that the desired components of the sampled-data controller can be "peeled-off" from the inherently infinite-dimensional description in the lifted-domain. The procedure for doing this last step is central to the approach in this paper.

Both new and revised solutions are presented in this paper. The solution to the H^2 problems is completely new. The solution to the H^∞ problems is presented in a unifying framework and is more transparent than the previous existing solutions in the literature. Transparency pays in the form of clearer results. In particular, a separation structure is established between the design of (sub)optimal hold and sampler.

Key words. sampled-data control, generalized sampler and hold, H^2 optimization, H^∞ optimization, lifting technique

1. Introduction.

Since the early 90's, much attention has been paid to H^2 and H^∞ optimal control of continuous-time systems using a sampled-data controller, namely, a controller implemented by a digital computer connected to a plant via A/D (sampler) and D/A (hold) converters. See [17, 4, 30, 8, 16, 27, 3, 25, 29] for an introduction to the subject and pointers to relevant literature. In a great majority of these works, only the discrete part of the sampled-data controller is designed; the sampler and the hold, on the other hand, are selected without taking into consideration the plant dynamics or the control objectives. In most cases, an approximate "ideal" sampler is used to obtain the discrete-time measurements, while zero- or first-order holds are the devices of choice for converting the output of the discrete part of the controller to a continuous-time control signal. Having fixed sampler and hold has several advantages: the behavior of these devices is fairly well understood and hence can be incorporated (at least heuristically) in the controller design process, the design of hardware is considerably simplified, and adequate simulation tools exist, etc. At the same time, fixing the sampler and hold devices irrespective of control considerations may limit the closed-loop performance, especially when the sampling rate is not "fast" enough with respect to the plant dynamics.

Numerous attempts have been made to incorporate the sampler and, especially, the hold into the design process specially by considering the discrete-time performance [15, 1]. Loosely speaking, these designs are based on the open-loop compensation of undesirable plant dynamics (e.g., nonminimum-phase zeros) and manage to achieve

†Faculty of Mechanical Engineering, Technion—IIT, Haifa 32000, Israel (mersglm@tx.technion.ac.il, palmor@tx.technion.ac.il). The work of the first author was partially supported by the Theodore and Mina Bargman Academic Lectureship.

‡RAFAEL and Department of Electrical Engineering, Technion—IIT, Haifa 32000, Israel (hector@ee.technion.ac.il).

significant improvements of discrete-time performance, usually at the expense of a poor intersampling behavior. As a consequence, these works give rise to criticism [10, 7] and the suspicion that, for instance, a generalized hold device will generically exhibit undesirable robustness properties. It becomes apparent that the design of sampling and/or hold devices should take into account intersampling behavior, even when sampling is fast.

The design of A/D and D/A converters on the basis of continuous-time performance poses some serious technical difficulties. It is not surprising then that few results in this direction are available in the literature. For instance, LQG design of the hold function was discussed by Juan and Kabamba [14] (see also [12]) assuming that the discrete-time part of the controller is fixed. The necessary conditions for optimality of the hold function derived in [14] are quite involved and apply only when rather restrictive constraints (fixed monodromy) on the hold function are imposed. The design of the H^∞ suboptimal hold function is considered by Başar [6] for the state-feedback and by Sun, Nagpal, and Khargonekar [26] for the output feedback cases. In a remarkable work, Tadmor [27] treated the sampled-data H^∞ problem in a general setting, including the design of sampling and/or hold functions. In a more restrictive setting, [22] proposed a simple approach to the H^∞ control when *both* sampler *and* hold are design parameters. In all the H^∞ results above, explicit formulae for the suboptimal sampler and/or hold are obtained. Finally, Bamieh [2] proposed an approximate solution to the ℓ^1 design of the sampling and hold functions.

An important breakthrough in the treatment of sampled-data systems was the introduction of "lifting," an operation that reduces the time-varying sampled data problem into a time-invariant, albeit inherently infinite-dimensional, discrete-time one. The idea is conceptually simple and involves three steps: (i) lift the problem to the discrete time, (ii) solve the resulting formal discrete-time problem in the so-called lifted domain, and (iii) "peel-off" the result back to continuous time. The complexity of dealing with systems in the lifted domain thus far has prevented finding a complete solution to the relevant design problems. The main contribution of the current research is to show how the three design steps can effectively be carried out. In order to do this, a better understanding of the lifted domain and its connection with continuous time is required. In order to streamline the presentation, we have divided the paper into two parts. In the first one, the framework is described and the main solutions are presented, based on the technical results derived in the second part. The second part presents some technical developments which are relevant for the problems under consideration, but also have independent interest.[1] For clarity, we have tried to make the two parts as self-contained as possible. We believe that with this structure we have achieved an adequate tradeoff between readability of the material and completeness.

This paper is organized as follows. In section 2 the problems to be considered throughout the paper are formulated. The next two sections are devoted to the solutions of these problems in the lifted domain. In particular, in section 3 it is shown how a wide class of sampled-data problems can be reduced to a unified "standard problem" in the lifted domain, while in section 4 the lifted solutions to the sampled-data H^2 (section 4.1) and H^∞ (section 4.2) problems are presented and some interesting properties of these solutions are discussed (section 4.3). The lifted solutions are then "peeled-off" (based on the technical results obtained in the companion paper [23]) in

[1] This order reflects our personal taste; a reader needing all facts established before proceeding forward may want to read Part II first.

section 5, which contains complete solutions to the sampled-data H^2 and H^∞ problems, including the (sub)optimal sampling and hold. In section 6 various properties and interpretations of the optimal sampling and hold functions are discussed. In section 6.1 some qualitative conjectures concerning the control oriented design of the D/A converters are also presented.

1.1. Notation. The notation throughout the paper is as follows. As usual, $\mathbb{C}^-$ and $\mathbb{D}$ stand for the open left half plane and the open unit disc, respectively. $\mathbb{R}^n$ denotes the n-dimensional Euclidean space and $L_n^2[0,h]$ denotes the (Hilbert) space of square integrable $\mathbb{R}^n$-valued functions on the interval $[0,h]$. When the dimensions are irrelevant the dimension index is dropped, by simply writing $\mathbb{R}$ and $L^2[0,h]$. For operators on $\mathbb{R} \oplus L^2[0,h]$, $\|\cdot\|_2$ denotes the induced operator norm, while $\|\cdot\|_{HS}$ — the Hilbert–Schmidt operator norm. M' means the transpose of a matrix M and O^* — the adjoint of a Hilbert space operator O. The notations $\sigma(M)$, $\rho(M)$, and $\bar{\sigma}(M)$ stand for the spectrum, the spectral radius, and the maximum singular value of a square matrix M, respectively. $O^{1/2}$ means the square root of $O = O^* \geq 0$.

A "bar" above a variable ($\bar{\zeta}$) denotes discrete-time signals in $\mathbb{R}^n$, while "breve" ($\breve{\zeta}$) denotes discrete-time signals in the lifted domain. Also, we put forward the following operator notation which improves the readability of formulae when both finite- and infinite-dimensional input/output spaces are involved: a bar indicates an operator $\bar{O}$ with both input and output spaces finite dimensional; grave accent — $\grave{O}$, when the input space is finite-dimensional and the output infinite-dimensional one; acute accent — $\acute{O}$, when the input space is infinite-dimensional and the output finite-dimensional one; and finally breve — $\breve{O}$, when both input and output spaces are infinite dimensional.

The compact block notation

$$\left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right]$$

denotes (matrix- or operator-valued) transfer functions either in s or in z domain in terms of their state–space realization. To distinguish linear time-invariant (LTI) systems in the time domain from the corresponding transfer functions, the former are denoted by script capital letters, so $G(s)$ implies the transfer function of a continuous-time LTI system $\mathcal{G}$. The lower linear fractional transformation of $\mathcal{K}$ over $\mathcal{P}$ is denoted as $\mathcal{F}_\ell(\mathcal{P},\mathcal{K})$. Finally, $Ric_{\mathbb{C}^-}$ and $Ric_{\mathbb{D}}$ denote the continuous- and discrete-time Riccati functions. These functions are not the standard ones usually found in the literature [32], but rather are defined over product spaces:

$$Ric_{\mathbb{S}} : \mathbb{R}^{(2n+m)\times(2n+m)} \times \mathbb{R}^{(2n+m)\times(2n+m)} \to \mathbb{R}^{n\times n} \times \mathbb{R}^{m\times n},$$

where $\mathbb{S} = \mathbb{C}^-$ or $\mathbb{D}$. There are good reasons for considering these generalized forms; see, for instance, [24, 13] and the Appendix in the companion paper [23] for definitions and properties. The functions $Ric_{\mathbb{S}}$ are not defined over the whole $\mathbb{R}^{(2n+m)\times(2n+m)}$ but rather on a subset called $\operatorname{dom} Ric_{\mathbb{S}}$. It is worth stressing that the function $Ric_{\mathbb{S}}$ has a one-to-one correspondence with the stabilizing solution of appropriate Riccati equations.

2. Problem statement. Consider the single rate sampled-data control systems illustrated in Figure 1, where $\mathcal{P}_c$ is a continuous-time generalized plant and w, z, y, and u are (continuous-time) exogenous input, regulated output, measured output,

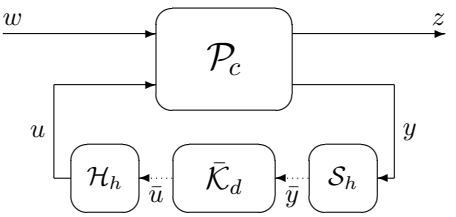

FIG. 1. *General sampled-data setup in time domain.*

and control input, respectively. The sampled-data controller consists of a discrete-time part $\bar{\mathcal{K}}_d$, a sampler $\mathcal{S}_h$, and a hold $\mathcal{H}_h$, assumed to be synchronized and with a sampling period h. Throughout this paper the generalized plant $\mathcal{P}_c$ is assumed to be LTI with the following state–space realization:

$$P_c(s) = \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & 0 & D_{12} \\ C_2 & D_{21} & 0 \end{array}\right]. \tag{1}$$

The matrices D_{11} and D_{22} are both taken to be zero; this assumption both simplifies the derivations and leads to more transparent results. Moreover, for the H^2 problem the assumption $D_{11} = 0$ is also a necessary condition for the cost function to be finite.

The hold and sampler act on the output of the controller $\bar{u}[k]$ and the measurement $y(t)$, respectively, to generate [15, 1]

$$\big(\mathcal{H}_h \bar{u}\big)(kh + \tau) = \phi_H(\tau)\bar{u}[k] \qquad \forall \tau \in [0, h) \tag{2a}$$

and

$$\big(\mathcal{S}_h y\big)[k] = \int_0^{h^-} \phi_S(\tau) y(kh^- - \tau)\, d\tau. \tag{2b}$$

Here $\phi_H(\tau)$ and $\phi_S(\tau)$ are generalized hold and sampling functions, respectively, defined on the interval $[0, h)$. During the intersample, the hold function shapes the form of the control signal while the sampling function is used to weight the measurements. Note that the integration limit for $\mathcal{S}_h$ is chosen to be h^- rather than h. This is motivated by the fact that any implementable $\bar{\mathcal{K}}_d$ cannot process information instantaneously. As shown in [22], this assumption considerably simplifies the treatment of sampled-data systems.

Depending on whether the sampler and hold devices are considered as design variables or not, there are four possible classes of sampled-data control problems:

C_a: Both sampler and hold are free for design;
C_b: The sampler is fixed but the hold is to be designed;
C_c: The sampler is to be designed but the hold is fixed;
C_d: Both sampler and hold are fixed.

The last case has been extensively treated in the literature, especially when $\mathcal{S}_h$ is the ideal sampler and $\mathcal{H}_h$ is the zero-order hold (see [8] and the references therein). For the class C_d the solutions usually are based on conversions of the sampled-data problem into an equivalent pure discrete one; the latter problem can then be solved by using known techniques. Such an approach requires several intermediate steps and does not give rise to closed-form solutions to the sampled-data H^∞ problem. Hence,

although this paper addresses basically cases C_{a-c}, which involve the design of the sampling and/or hold functions, the results for C_d will also be presented.

The control problems to be dealt with in the paper are the H^2 and H^∞ optimization problems. Under minor reasonable constraints on the functions ϕ_S and ϕ_H in (2) and any LTI $\bar{\mathcal{K}}_d$, the system in Figure 1 is h-periodic in continuous time. For such systems the notions of the H^2 and H^∞ system norms can be introduced in a natural manner [8]. Thus, the following optimization problems can be posed:

OP_{H^2}: Find an LTI $\bar{\mathcal{K}}_d$ and, possibly, a sampling function $\phi_S(\tau)$ and/or a hold function $\phi_H(\tau)$ so that the resulting sampled-data controller internally stabilizes the system in Figure 1 and minimizes the H^2 norm of the closed-loop operator from w to z.

OP_{H^∞}: Given a scalar $\gamma > 0$, find (if they exist) an LTI $\bar{\mathcal{K}}_d$ and, possibly, a sampling function $\phi_S(\tau)$ and/or a hold function $\phi_H(\tau)$ so that the resulting sampled-data controller internally stabilizes the system in Figure 1 and makes the H^∞ norm of the closed-loop operator from w to z less than γ.

Remark 2.1. It is worth stressing that the discrete-time part $\bar{\mathcal{K}}_d$ of the sampled-data controller is always a design parameter. This is in contrast to the approach in [14, 12], where the generalized hold is designed for a fixed $\bar{\mathcal{K}}_d$. Nevertheless, the $\mathcal{H}_h$ and $\mathcal{S}_h$ resulting from the solution to OP_{H^2} and OP_{H^∞} are referred to as H^2-*optimal* and H^∞-*suboptimal* hold and sampler, respectively. The H^2-optimality of $\mathcal{H}_h$ ($\mathcal{S}_h$) here is understood as the ability to design $\bar{\mathcal{K}}_d$ and, possibly, $\mathcal{S}_h$ ($\mathcal{H}_h$) so that the H^2 performance achieved by the sampled-data controller $\mathcal{H}_h\bar{\mathcal{K}}_d\mathcal{S}_h$ supersedes the one achieved using any other hold (sampling) device. Similarly, H^∞-suboptimal hold (sampler) refers to the feasibility of designing $\bar{\mathcal{K}}_d$ and, possibly, $\mathcal{S}_h$ ($\mathcal{H}_h$) so that the overall sampled-data controller be γ-suboptimal.

3. Lifted "standard problem." The treatment of OP_{H^2} and OP_{H^∞} is complicated by their hybrid continuous/discrete nature and their inherent periodicity. To circumvent these difficulties the so-called *lifting technique* of [31, 5, 3] (see also [28, 27]) can be applied.

The notion of lifting is based on a conversion of real valued signals in continuous time into *functional space valued* sequences, that is, sequences that take values not from $\mathbb{R}$ but rather from some general Banach space ($L^2[0,h]$ in this paper). Formally, let $\ell_{L^2[0,h]}$ be the space of sequences of the form $\{\breve{\xi}[k]\}$, where each $\breve{\xi}[k]$ is a function in $L^2[0,h]$, that is,

$$\ell_{L^2[0,h]} = \left\{ \breve{\xi} : \breve{\xi}[k] \in L^2[0,h] \quad \forall k \in \mathbb{Z}_+ \right\}.$$

Then, given any $h > 0$, the lifting operator $\mathcal{W}_h : L^2_e \mapsto \ell_{L^2[0,h]}$ is defined [5, 3] through

$$\breve{\xi} = \mathcal{W}_h\xi \quad \Longleftrightarrow \quad \big(\breve{\xi}[k]\big)(\tau) = \xi(kh+\tau) \quad \forall \tau \in [0,h].$$

It is easy to see that the lifting operator is a linear bijection between L^2_e and $\ell_{L^2[0,h]}$. Moreover, if the domain of $\mathcal{W}_h$ is restricted to the Hilbert space L^2, then the lifting operator can be made an isometry by endowing $\ell_{L^2[0,h]}$ with an appropriate norm. Hence, treating a system $\zeta = \mathcal{G}\omega$ not as a mapping from ω to ζ but rather as a mapping from $\breve{\omega}$ to $\breve{\zeta}$ gives essentially the same system (as an input–output mapping). Indeed, since lifting preserves stability and induced norms, the system $\mathcal{G}$ and its *lifting*,

$$\breve{\mathcal{G}} \doteq \mathcal{W}_h\mathcal{G}\mathcal{W}_h^{-1} : \ell_{L^2[0,h]} \mapsto \ell_{L^2[0,h]},$$

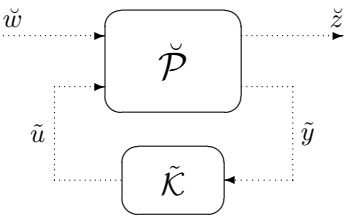

FIG. 2. *"Standard problem" in the lifted domain.*

are equivalent. The advantage of treating systems in the lifting domain stems from the fact that $\breve{\mathcal{G}}$ is time-invariant in discrete time even if $\mathcal{G}$ is h-periodic in continuous time. Hence, any periodic problem in continuous time can be made time-invariant in discrete time.

The application of this idea to the sampled-data setup in Figure 1 is straightforward. In order to convert this setup to a pure discrete time-invariant one, one of the operators $\mathcal{P}_c$, $\mathcal{S}_h$, and $\mathcal{H}_h$ in Figure 1 should be lifted to $\breve{\mathcal{P}}_c \doteq \mathcal{W}_h \mathcal{P}_c \mathcal{W}_h^{-1}$, $\acute{\mathcal{S}}_h \doteq \mathcal{S}_h \mathcal{W}_h^{-1}$, and $\grave{\mathcal{H}}_h \doteq \mathcal{W}_h \mathcal{H}_h$, respectively. The lifted plant $\breve{\mathcal{P}}_c$ is LTI and has a state–space realization

$$\breve{P}_c(z) = \left[\begin{array}{c|cc} \bar{A} & \acute{B}_1 & \acute{B}_2 \\ \hline \grave{C}_1 & \breve{D}_{11} & \breve{D}_{12} \\ \grave{C}_2 & \breve{D}_{21} & \breve{D}_{22} \end{array}\right]. \tag{3}$$

Notice that although $\bar{A}$ is a square matrix with the same dimensions as A, the remaining entries in this state–space representation are operators acting from or/and to infinite-dimensional spaces. The lifted hold $\grave{\mathcal{H}}_h$ is a *memoryless* gain with transfer function

$$\grave{H}_h(z) = \grave{\Phi}_H,$$

while the lifted sampler includes a backward shift [22]:

$$\acute{S}_h(z) = z^{-1} \acute{\Phi}_S.$$

The expressions for the parameters of the plant $\breve{\mathcal{P}}_c$, the hold $\grave{\mathcal{H}}_h$, and the sampler $\acute{\mathcal{S}}_h$ can be derived using standard lifting arguments [3, 21]. They, however, are not essential for the discussion in this section and hence are postponed to the companion paper [23].

What is important in the discussion that follows is the fact that lifting puts all blocks in Figure 1 on equal footing, making them discrete-time LTI systems. Consequently, the four cases $\mathsf{C}_{a\text{–}d}$ of the sampled-data interconnection in Figure 1 with generalized sampler and hold can be reduced to the standard setup of the linear optimal control in Figure 2, where the generalized plant $\breve{\mathcal{P}}$ is *given*, while the controller $\tilde{\mathcal{K}}$ is *to be designed*. The lifted sampler $\acute{\mathcal{S}}_h$ and hold $\grave{\mathcal{H}}_h$ can be absorbed either into the generalized plant or to the controller, depending on whether they are fixed or treated as free design parameters. The only fixed part that will always be absorbed into the controller is the backward shift z^{-1} of $\acute{\mathcal{S}}_h$. The reason for this is twofold: first, the state–space dimension of $\breve{\mathcal{P}}$ is preserved, and second, the characterization of $\tilde{\mathcal{K}}$ is considerably simplified if the operator is *strictly* causal [22]. An optimization problem can therefore always be formulated as a "standard problem," with a *strictly*

proper controller. More specifically, for the four cases considered above, one gets the following:

C_a: Here, both $\acute{\Phi}_S$ and $\grave{\Phi}_H$ are absorbed into the controller, giving

$$\breve{P}(z) = \breve{P}_c(z) \qquad \text{and} \qquad \tilde{K}(z) = \breve{K}(z) \doteq z^{-1}\grave{\Phi}_H \bar{K}_d(z)\acute{\Phi}_S.$$

Any designed controller can always be factorized as follows:

$$\breve{K}(z) = \left[\begin{array}{c|c} \bar{A}_K & \acute{B}_K \\ \hline \grave{C}_K & 0 \end{array}\right] = \grave{\Phi}_H \left[\begin{array}{c|c} \bar{A}_K & \bar{B}_K \\ \hline C_K & 0 \end{array}\right] \acute{\Phi}_S,$$

where $\grave{\Phi}_H$ and $\bar{C}_K$ are any operators of appropriate dimensions such that $\grave{\Phi}_H \bar{C}_K = \grave{C}_K$ and $\bar{B}_K$ and $\acute{\Phi}_S$ are such that $\bar{B}_K \acute{\Phi}_S = \acute{B}_K$. This yields $\bar{\mathcal{K}}_d$, $\mathcal{H}_h$, and $\mathcal{S}_h$.

C_b: In this case $\acute{\Phi}_S$ is absorbed into the lifted plant, but $\grave{\Phi}_H$ is absorbed into the controller, giving

$$\breve{P}(z) = \left[\begin{array}{c|cc} \bar{A} & \acute{B}_1 & \acute{B}_2 \\ \hline \grave{C}_1 & \breve{D}_{11} & \breve{D}_{12} \\ \bar{C}_2 & \acute{D}_{21} & \acute{D}_{22} \end{array}\right] \qquad \text{and} \qquad \tilde{K}(z) = \grave{K}(z) \doteq z^{-1}\grave{\Phi}_H \bar{K}_d(z),$$

where

$$\left[\begin{array}{ccc} \bar{C}_2 & \acute{D}_{21} & \acute{D}_{22} \end{array}\right] \doteq \acute{\Phi}_S \left[\begin{array}{ccc} \grave{C}_2 & \breve{D}_{21} & \breve{D}_{22} \end{array}\right].$$

Any designed controller can always be factorized as follows:

$$\grave{K}(z) = \left[\begin{array}{c|c} \bar{A}_K & \bar{B}_K \\ \hline \grave{C}_K & 0 \end{array}\right] = \grave{\Phi}_H \left[\begin{array}{c|c} \bar{A}_K & \bar{B}_K \\ \hline C_K & 0 \end{array}\right],$$

where $\grave{\Phi}_H$ and $\bar{C}_K$ are any operators of appropriate dimensions such that $\grave{\Phi}_H \bar{C}_K = \grave{C}_K$. This yields both $\bar{\mathcal{K}}_d$ and $\mathcal{H}_h$.

C_c: Now $\grave{\Phi}_H$ is absorbed into the lifted plant, but $\acute{\Phi}_S$ is absorbed into the controller, giving

$$\breve{P}(z) = \left[\begin{array}{c|cc} \bar{A} & \acute{B}_1 & \bar{B}_2 \\ \hline \grave{C}_1 & \breve{D}_{11} & \grave{D}_{12} \\ \grave{C}_2 & \breve{D}_{21} & \grave{D}_{22} \end{array}\right] \qquad \text{and} \qquad \tilde{K}(z) = \acute{K}(z) \doteq z^{-1}\bar{K}_d(z)\acute{\Phi}_S,$$

where

$$\left[\begin{array}{c} \bar{B}_2 \\ \grave{D}_{12} \\ \grave{D}_{22} \end{array}\right] \doteq \left[\begin{array}{c} \acute{B}_2 \\ \breve{D}_{12} \\ \breve{D}_{22} \end{array}\right] \grave{\Phi}_H.$$

Any designed controller can always be factorized as follows:

$$\acute{K}(z) = \left[\begin{array}{c|c} \bar{A}_K & \acute{B}_K \\ \hline C_K & 0 \end{array}\right] = \left[\begin{array}{c|c} \bar{A}_K & \bar{B}_K \\ \hline C_K & 0 \end{array}\right] \acute{\Phi}_S,$$

where $\bar{B}_K$ and $\acute{\Phi}_S$ are any operators of appropriate dimensions such that $\bar{B}_K \acute{\Phi}_S = \acute{B}_K$. This yields both $\bar{\mathcal{K}}_d$ and $\mathcal{S}_h$.

C_d: In this case, both $\acute{\Phi}_S$ and $\grave{\Phi}_H$ are absorbed into the lifted plant, giving

$$\breve{P}(z) = \left[\begin{array}{c|cc} \bar{A} & \acute{B}_1 & \bar{B}_2 \\ \hline \grave{C}_1 & \breve{D}_{11} & \grave{D}_{12} \\ \bar{C}_2 & \acute{D}_{21} & \bar{D}_{22} \end{array}\right] \qquad \text{and} \qquad \tilde{K}(z) = \bar{K}(z) \doteq z^{-1}\bar{K}_d(z),$$

where

$$\bar{D}_{22} \doteq \acute{\Phi}_S \breve{D}_{22} \grave{\Phi}_H.$$

Given a designed $\bar{\mathcal{K}}$, the discrete-time part of the controller is

$$\bar{K}_d(z) = z\bar{K}(z).$$

Thus a designed $\tilde{\mathcal{K}}$ now contains information not only about $\bar{\mathcal{K}}_d$, but also possibly about $\grave{\Phi}_H$ and/or $\acute{\Phi}_S$. If the hold function is the design parameter, then it is completely characterized by the "C"-part of the controller. Likewise, if the sampling function is the design parameter, then it is completely characterized by the "B"-part of the controller.

It is worth stressing that although for all the cases above the problem fits into the unified framework in Figure 2, it is seen that some of the parameters of $\breve{\mathcal{P}}$ and $\tilde{\mathcal{K}}$ might have either finite- or infinite-dimensional input and/or output spaces depending on the situation. In this respect, it is assumed here that the generalized plant takes the form

$$\breve{P}(z) = \left[\begin{array}{c|cc} \bar{A} & \acute{B}_1 & \tilde{B}_2 \\ \hline \grave{C}_1 & \breve{D}_{11} & \tilde{D}_{12} \\ \tilde{C}_2 & \tilde{D}_{21} & \tilde{D}_{22} \end{array}\right] = \left[\begin{array}{c|cc} \bar{A} & \acute{B}_1 & \tilde{B}_2 \\ \hline \grave{C} & \breve{D}_{\bullet 1} & \tilde{D}_{\bullet 2} \end{array}\right] = \left[\begin{array}{c|c} \bar{A} & \acute{B} \\ \hline \grave{C}_1 & \breve{D}_{1\bullet} \\ \tilde{C}_2 & \tilde{D}_{2\bullet} \end{array}\right], \tag{4}$$

while a designed controller is necessarily of the form

$$\tilde{K}(z) = \left[\begin{array}{c|c} \bar{A}_K & \tilde{B}_K \\ \hline \tilde{C}_K & 0 \end{array}\right].$$

The tilde is used to highlight that the corresponding operators may have either finite or infinite dimension depending on whether $\mathcal{S}_h$ and $\mathcal{H}_h$ are fixed or not.

4. Optimal design in the lifted domain. Having reduced the sampled-data setup to the discrete-time LTI "standard problem" in Figure 2, the next step is to reformulate and solve OP_{H^∞} and OP_{H^2} in terms of $\breve{\mathcal{P}}$ and $\tilde{\mathcal{K}}$. This is the purpose of this section.

Start by imposing the following assumptions on the generalized plant (4):

(A1): The operator $\left[\begin{array}{cc} \bar{A} - \lambda I & \tilde{B}_2 \end{array}\right]$ is right invertible $\forall\, |\lambda| \geq 1$.

(A2): The operator $\left[\begin{smallmatrix} \bar{A} - \lambda I \\ \tilde{C}_2 \end{smallmatrix}\right]$ is left invertible $\forall\, |\lambda| \geq 1$.

(A3): The operator $\left[\begin{smallmatrix} \bar{A} - e^{j\theta} I & \tilde{B}_2 \\ \grave{C}_1 & \tilde{D}_{12} \end{smallmatrix}\right]$ is left invertible $\forall \theta \in [0, 2\pi)$.

(A4): The operator $\left[\begin{smallmatrix} \bar{A} - e^{j\theta} I & \acute{B}_1 \\ \tilde{C}_2 & \tilde{D}_{21} \end{smallmatrix}\right]$ is right invertible $\forall \theta \in [0, 2\pi)$.

These assumptions are the counterparts of the standard assumptions imposed on a discrete-time generalized plant, to guarantee input–output stabilizability and nonsingularity of the H^2 and H^∞ problems. Furthermore, the following assumption about $\breve{\mathcal{P}}$ has to be made:

(A5): $\tilde{D}_{21}$ is a bounded operator.

For the standard discrete-time systems with matrix valued parameters this assumption is obviously redundant. For lifted systems, however, this is not always true since sampling operations might be unbounded in the L^2 sense [8, Theorem 9.3.1]. Thus the assumption (A5), together with the assumption $D_{22} = 0$, guarantees that $\mathcal{S}_h$ operates over "proper" signals. Actually, it means that prefiltering by an anti-aliasing filter is provided if necessary.

4.1. H^2 optimization. The notion of the H^2 system norm can be extended in a natural manner to LTI systems in the lifted domain [4] (see also [17]) although it is not an induced norm. More specifically, the H^2 norm of an LTI system $\breve{\mathcal{G}} : \ell_{L^2[0,h]} \mapsto \ell_{L^2[0,h]}$ is defined as follows:

$$\|\breve{\mathcal{G}}\|_{H^2}^2 \doteq \frac{1}{h}\int_0^{2\pi} \|\breve{G}(e^{j\theta})\|_{HS}^2 \, d\theta.$$

This definition is consistent with both the deterministic and the stochastic interpretations of the H^2 system norm in the time domain, and reduces to the usual definition when $\breve{\mathcal{G}}$ is the lifting of an LTI continuous-time system [4].

Thus, OP_{H^2} can now be reformulated in the lifted domain as follows:
$\mathsf{OP}_{H^2}^{eq}$: For the plant $\breve{\mathcal{P}}$ given in (4), find a *strictly causal* $\tilde{\mathcal{K}}$ which internally stabilizes $\breve{\mathcal{P}}$ and minimizes the performance index:

$$J_{H^2} \doteq \|\mathcal{F}_\ell\big(\breve{\mathcal{P}}, \tilde{\mathcal{K}}\big)\|_{H^2}^2.$$

The solution to this H^2 problem is presented next without a proof. This is because, in principle, problem $\mathsf{OP}_{H^2}^{eq}$ is a discrete-time LTI H^2 problem which can be solved by using existing techniques [8, 30]. Detailed treatment of the H^2 problem in the lifted domain in the case when both sampler and hold are fixed and the controller is not constrained to be strictly proper can be found in [20].

The solution of $\mathsf{OP}_{H^2}^{eq}$ requires the following two H^2 DAREs:

$$\begin{aligned}(5a)\quad \bar{X} &= \bar{A}'\bar{X}\bar{A} + \grave{C}_1^*\grave{C}_1 \\ &\quad - (\tilde{B}_2^*\bar{X}\bar{A} + \tilde{D}_{12}^*\grave{C}_1)^*(\tilde{D}_{12}^*\tilde{D}_{12} + \tilde{B}_2^*\bar{X}\tilde{B}_2)^{-1}(\tilde{B}_2^*\bar{X}\bar{A} + \tilde{D}_{12}^*\grave{C}_1)\end{aligned}$$

and

$$\begin{aligned}(5b)\quad \bar{Y} &= \bar{A}\bar{Y}\bar{A}' + \acute{B}_1\acute{B}_1^* \\ &\quad - (\bar{A}\bar{Y}\tilde{C}_2^* + \acute{B}_1\tilde{D}_{21}^*)(\tilde{D}_{21}\tilde{D}_{21}^* + \tilde{C}_2\bar{Y}\tilde{C}_2^*)^{-1}(\bar{A}\bar{Y}\tilde{C}_2^* + \acute{B}_1\tilde{D}_{21}^*)^*.\end{aligned}$$

Notice that for all the four cases described in section 3, both $\bar{X}$ and $\bar{Y}$ of (5) are square matrices (e. g., *finite dimensional*) with the same dimensions as $\bar{A}$. Also, observe that the choice of the hold device affects only the control Riccati equation (5a), while the choice of sampler affects only the filtering Riccati equation (5b).

The main result for the $\mathsf{OP}_{H^2}^{eq}$ can now be stated.

THEOREM 1. *Let* (A1)–(A5) *be satisfied. Then the DAREs* (5) *have the stabilizing solutions* $\bar{X}_2 \geq 0$ *and* $\bar{Y}_2 \geq 0$*, the optimal value of the performance index* J_{H^2} *is*

$$J_{H^2}^{opt} = \frac{1}{h}\Big(\|\breve{D}_{11}\|_{HS}^2 + \mathrm{tr}\big\{\bar{X}_2\acute{B}_1\acute{B}_1^* + \grave{C}_1^*\grave{C}_1\bar{Y}_2 + (\bar{A}'\bar{X}_2\bar{A} - \bar{X}_2)\bar{Y}_2\big\}\Big),$$

and the unique strictly proper controller which achieves the optimal cost $J_{H^2}^{opt}$ *has the state–space representation*

$$\tilde{K}_2(z) = \left[\begin{array}{c|c} \bar{A} + \tilde{B}_2\tilde{F}_2 + \tilde{L}_2\tilde{C}_2 + \tilde{L}_2\tilde{D}_{22}\tilde{F}_2 & -\tilde{L}_2 \\ \hline \tilde{F}_2 & 0 \end{array}\right],$$

where

$$\tilde{F}_2 \doteq -\big(\tilde{D}_{12}^*\tilde{D}_{12} + \tilde{B}_2^*\bar{X}_2\tilde{B}_2\big)^{-1}(\tilde{B}_2^*\bar{X}_2\bar{A} + \tilde{D}_{12}^*\grave{C}_1), \tag{6a}$$

$$\tilde{L}_2 \doteq -(\bar{A}\bar{Y}_2\tilde{C}_2^* + \acute{B}_1\tilde{D}_{21}^*)\big(\tilde{D}_{21}\tilde{D}_{21}^* + \tilde{C}_2\bar{Y}_2\tilde{C}_2^*\big)^{-1}. \tag{6b}$$

Note again that although the parameters of $\breve{\mathcal{P}}$ might be infinite dimensional, the solutions to the Riccati equations as well as the "A" parameter of the optimal controller are always finite-dimensional matrices. The state feedback $\tilde{F}_2$ and the output injection $\tilde{L}_2$ "gains," however, might operate over *infinite-dimensional* output and input spaces, respectively. Consider, for instance, the operator $\tilde{F}_2$. When $\mathcal{H}_h$ is fixed (cases C_c and C_d), the operator compositions $\tilde{D}_{12}^*\grave{C}_1 = \grave{D}_{12}^*\grave{C}_1$ and $\tilde{D}_{12}^*\tilde{D}_{12} = \grave{D}_{12}^*\grave{D}_{12}$, as well as the operator $\tilde{B}_2 = \bar{B}_2$, are finite-dimensional matrices, which can easily be computed [4, 21]. Yet when $\mathcal{H}_h$ is to be designed (cases C_a and C_b), both (5a) and $\tilde{F}_2$ involve quite complicated infinite-dimensional operators. The Riccati equations, like (5a), can in principle be dealt with via the associated Hamiltonians [9], that enables to circumvent some problems. Nevertheless, in order to obtain the optimal state feedback "gain" one has to handle infinite-dimensional operators like $\breve{D}_{12}^*\breve{D}_{12} + \acute{B}_2^*\bar{X}\acute{B}_2$. The techniques for performing such manipulations over the lifted operators were developed recently in [21]. As shown in the companion paper [23], the resulting $\grave{F}_2$ (and $\acute{L}_2$) can be obtained in an elegant form.

4.2. H^∞ optimization. Since for continuous-time systems the H^∞ norm is the induced L^2/L^2 norm, the notion of the H^∞ system norm can be extended to sampled-data systems by defining it as the $\ell^2_{L^2[0,h]}/\ell^2_{L^2[0,h]}$-induced operator norm. As shown in [3], the H^∞ norm can be defined in the frequency domain as follows:

$$\|\breve{\mathcal{G}}\|_{H^\infty} \doteq \max_{\theta\in[0,2\pi)} \|\breve{G}(e^{j\theta})\|_2.$$

Correspondingly, the lifted equivalent of OP_{H^∞} for the setup in Figure 2 takes the following form:

$\mathsf{OP}_{H^\infty}^{eq}$: For the plant $\breve{\mathcal{P}}$ given in (4) and a number $\gamma > 0$, find a *strictly causal* internally stabilizing controller $\tilde{\mathcal{K}}$ such that

$$\|\mathcal{F}_\ell(\breve{\mathcal{P}}, \tilde{\mathcal{K}})\|_{H^\infty} < \gamma,$$

or show that no such controller exists.

Using the same reasoning as in the $\mathsf{OP}_{H^2}^{eq}$ case, the $\mathsf{OP}_{H^\infty}^{eq}$ problem is a discrete-time LTI H^∞ problem [5], with the additional constraint that the controller must be strictly proper. This type of problem was discussed in detail for the case of finite-dimensional parameters in [19].

The solution of the $\mathsf{OP}_{H^\infty}^{eq}$ requires the following two H^∞ DAREs:

$$\begin{aligned}\bar{X} = {} & \bar{A}'\bar{X}\bar{A} + \grave{C}_1^*\grave{C}_1 \\ & - (\breve{D}_{1\bullet}^*\grave{C}_1 + \acute{B}^*\bar{X}\bar{A})^*(\breve{D}_{1\bullet}^*\breve{D}_{1\bullet} - \gamma^2 E_{11} + \acute{B}^*\bar{X}\acute{B})^{-1}(\breve{D}_{1\bullet}^*\grave{C}_1 + \acute{B}^*\bar{X}\bar{A})\end{aligned} \tag{7a}$$

and

$$\text{(7b)}\quad \bar{Y} = \bar{A}\bar{Y}\bar{A}' + \acute{B}_1\acute{B}_1^* - (\acute{B}_1\breve{D}_{\bullet 1}^* + \bar{A}\bar{Y}\grave{C}^*)(\breve{D}_{\bullet 1}\breve{D}_{\bullet 1}^* - \gamma^2 E_{11} + \grave{C}\bar{Y}\grave{C}^*)^{-1}(\acute{B}_1\breve{D}_{\bullet 1}^* + \bar{A}\bar{Y}\grave{C}^*)^*,$$

where $E_{11} \doteq \left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right]$. As in the H^2 case, both $\bar{X}$ and $\bar{Y}$ solving the H^∞ DAREs (7) are square matrices of the same dimension as $\bar{A}$. Also, the choices of $\mathcal{H}_h$ and $\mathcal{S}_h$ affect only (7a) and (7b), respectively.

Using (7), necessary and sufficient conditions for the existence of a solution to the OP_{H^∞} as well as a particular solution may be established:

THEOREM 2. *Given plant* (4) *such that the assumptions* (A1)–(A5) *hold, then the following statements are equivalent:*

(i) *There exists a controller* $\tilde{\mathcal{K}}$ *which solves the* $\mathsf{OP}_{H^\infty}^{eq}$.

(ii) *The DAREs* (7) *have stabilizing solutions* $\bar{X}_\gamma \geq 0$ *and* $\bar{Y}_\gamma \geq 0$ *such that*

$$\text{(8)}\qquad \left\| \begin{bmatrix} \bar{X}_\gamma^{1/2} & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} \bar{A} & \acute{B}_1 \\ \grave{C}_1 & \breve{D}_{11} \end{bmatrix} \begin{bmatrix} \bar{Y}_\gamma^{1/2} & 0 \\ 0 & I \end{bmatrix} \right\|_2 < \gamma.$$

Given that the conditions of part (ii) *hold, then the matrix* $\bar{Z}_\gamma \doteq (I - \gamma^{-2}\bar{Y}_\gamma\bar{X}_\gamma)^{-1}$ *is well defined and one controller which solves* $\mathsf{OP}_{H^\infty}^{eq}$ *is*

$$\tilde{K}_\gamma(z) = \left[\begin{array}{c|c} \bar{A} + \acute{B}\grave{F}_\gamma + \bar{Z}_\gamma\tilde{L}_{\gamma 2}(\tilde{C}_2 + \tilde{D}_{2\bullet}\grave{F}_\gamma) & -\bar{Z}_\gamma\tilde{L}_{\gamma 2} \\ \hline \tilde{F}_{\gamma 2} & 0 \end{array}\right],$$

where

$$\text{(9a)}\qquad \grave{F}_\gamma \doteq -(\breve{D}_{1\bullet}^*\breve{D}_{1\bullet} - \gamma^2 E_{11} + \acute{B}^*\bar{X}_\gamma\acute{B})^{-1}(\breve{D}_{1\bullet}^*\grave{C}_1 + \acute{B}^*\bar{X}_\gamma\bar{A}) = \begin{bmatrix} \grave{F}_{\gamma 1} \\ \tilde{F}_{\gamma 2} \end{bmatrix},$$

$$\text{(9b)}\qquad \acute{L}_\gamma \doteq -(\acute{B}_1\breve{D}_{\bullet 1}^* + \bar{A}\bar{Y}_\gamma\grave{C}^*)(\breve{D}_{\bullet 1}\breve{D}_{\bullet 1}^* - \gamma^2 E_{11} + \grave{C}\bar{Y}_\gamma\grave{C}^*)^{-1} = \begin{bmatrix} \acute{L}_{\gamma 1} & \tilde{L}_{\gamma 2} \end{bmatrix}.$$

As seen, the direct solution to the H^∞ problem involves infinite-dimensional operators even when both sampling and hold functions are fixed (case C_d above). Nevertheless, as shown in the companion paper [23] the techniques developed in [21] enable the reduction of all these operator compositions to finite-dimensional matrices, which can be easily computed.

4.3. Discussion. Although the lifted solutions of Theorems 1 and 2 are not readily implementable, some insight into the solutions to OP_{H^2} and OP_{H^∞} can be gained already at this stage. This is shown by the following remarks.

Remark 4.1. As noted in section 3, if the hold (sampling) function is the design parameter, then it is characterized by the "C" ("B")-part of the lifted controller. Hence, the H^2-optimal hold is characterized by the operator $\tilde{F}_2$, which becomes $\grave{F}_2$ in that case, while the H^2-optimal sampler — by the operator $\tilde{L}_2$ ($\acute{L}_2$). By inspecting (6) and (5) one can see that $\tilde{F}_2$ depends only on the subsystem from $\tilde{u}$ to $\breve{z}$, while $\tilde{L}_2$ is completely characterized by the properties of the subsystem from $\breve{w}$ to $\tilde{y}$. Therefore, there is complete separation between the design of $\mathcal{H}_h$ and $\mathcal{S}_h$ in the H^2 case. This separation is reminiscent of that between the state feedback and the state estimation in the standard H^2 (LQG) design and thus is not a surprise.

Remark 4.2. More surprising is the fact that similar separation arguments apply to the design of the H^∞ suboptimal hold and sampler as well. This fact is worth

stressing, given the coupling which exists between the full information and the output estimation problems in the H^∞ output feedback control [32]. Although the "B"-part of the lifted H^∞ suboptimal controller contains the coupling term $\bar{Z}_\gamma$, the latter is *finite dimensional* and hence can always be absorbed into the discrete-time part of the controller. Consequently, the H^∞ suboptimal hold and sampler are characterized by the operators $\tilde{F}_{\gamma 2}$ and $\tilde{L}_{\gamma 2}$, respectively. It is seen from (9) and (7) that these operators are not completely independent, since both of them are affected by the subsystem from $\breve{w}$ to $\breve{z}$. Nevertheless, $\tilde{F}_{\gamma 2}$ does *not* depend on the measurement $\tilde{y}$ and $\tilde{L}_{\gamma 2}$ does *not* depend on the control $\tilde{u}$. Hence, *both* the hold *and* the sampling functions can be designed independently from one another in the H^∞ case also. This is in contrast to previous works in the literature [28, 22], where the H^∞ suboptimal sampler depended on the hold and it is not clear how to recover the separation.

Remark 4.3. It is not difficult to verify that as $\gamma \to \infty$ the H^∞ Riccati equations (7) reduce to the corresponding H^2 ones (5). Moreover, as $\gamma \to \infty$, the conditions of statement (ii) of Theorem 2 hold automatically, $\bar{Z}_\gamma = I$ (since both $\bar{X}_\gamma$ and $\bar{Y}_\gamma$ are uniformly bounded),

$$\lim_{\gamma\to\infty} \grave{F}_\gamma = \begin{bmatrix} 0 \\ \tilde{F}_2 \end{bmatrix} \quad \text{and} \quad \lim_{\gamma\to\infty} \acute{L}_\gamma = \begin{bmatrix} 0 & \tilde{L}_2 \end{bmatrix}.$$

Thus in the limit case $\gamma \to \infty$ the H^∞-suboptimal controller $\tilde{K}_\gamma(z)$ approaches $\tilde{K}_2(z)$, the H^2-optimal one.

5. Main results. The solutions to the OP_{H^2} and OP_{H^∞} can now be presented. Again, these solutions are strongly based on the technical machinery developed in the companion paper, so that some readers may prefer to read the material there before proceeding. To keep the presentation clear, it is assumed that a zero-order hold is used in cases C_c and C_d, while an ideal sampler is used in cases C_b and C_d. From Remarks 4.1 and 4.2 it follows that such simplifications do not affect the results concerning the (sub)optimal sampler and hold. More general $\mathcal{S}_h$ and $\mathcal{H}_h$ can be treated in a similar fashion. Also, as follows from Remark 4.3, the solution of Theorem 2 approaches that of Theorem 1 as $\gamma \to \infty$. For that reason, only the H^∞ results are presented below. The H^2 results can be obtained from the H^∞ ones by the simple substitution $\gamma^{-1} = 0$. The only part of the H^2 solution which needs to be treated independently is the calculation of the optimal performance $J^{opt}_{H^2}$. See section 5.5 for further details.

Let

$$\Gamma_X \doteq \begin{bmatrix} -D_{12}'C_1 & -B_2' & -D_{12}'D_{12} \\ A & \gamma^{-2}B_1B_1' & B_2 \\ -C_1'C_1 & -A' & -C_1'D_{12} \end{bmatrix},$$

$$\Gamma_Y \doteq \begin{bmatrix} -D_{21}B_1' & -C_2 & -D_{21}D_{21}' \\ A' & \gamma^{-2}C_1'C_1 & C_2' \\ -B_1B_1' & -A & -B_1D_{21}' \end{bmatrix},$$

and

$$\Sigma \doteq \exp\left(\begin{bmatrix} 0 & -D_{12}'C_1 & -B_2' & -D_{12}'D_{12} \\ 0 & A & \gamma^{-2}B_1B_1' & B_2 \\ 0 & -C_1'C_1 & -A' & -C_1'D_{12} \\ 0 & 0 & 0 & 0 \end{bmatrix} h\right) = \begin{bmatrix} I & \Sigma_{12} & \Sigma_{13} & \Sigma_{14} \\ 0 & \Sigma_{22} & \Sigma_{23} & \Sigma_{24} \\ 0 & \Sigma_{32} & \Sigma_{33} & \Sigma_{34} \\ 0 & 0 & 0 & I \end{bmatrix}.$$

Define the matrices

$$\Sigma_X \doteq \begin{bmatrix} \Sigma_{12} & \Sigma_{13} & \Sigma_{14} \\ \Sigma_{22} & \Sigma_{23} & \Sigma_{24} \\ \Sigma_{32} & \Sigma_{33} & \Sigma_{34} \end{bmatrix},$$

$$\Sigma_Y \doteq \begin{bmatrix} 0 & C_2 & 0 \\ \Sigma'_{22} & -\gamma^{-2}\Sigma'_{32} & \Sigma'_{22}C'_2 \\ -\gamma^2\Sigma'_{23} & \Sigma'_{33} & -\gamma^2\Sigma'_{23}C'_2 \end{bmatrix},$$

and the matrix function of an argument $\nu \in \mathbb{Z}^+$

$$\Lambda_\nu \doteq \begin{bmatrix} 0 & 0 & 0 \\ I_n & 0 & 0 \\ 0 & I_n & 0 \end{bmatrix} \in \mathbb{R}^{(\nu+2n)\times(2n+\nu)}.$$

The following quantity is also required:

$$\gamma_0 \doteq \|\mathcal{P}_{c,11}\|_{L^2[0,h]}, \tag{10}$$

where $P_{c,11}(s) = C_1(sI - A)^{-1}B_1$ (in other words, γ_0 is the $L^2[0,h]$-induced norm of the subsystem from w to z). This quantity can be computed as described in [8, Section 13.5] or [11]. Since $\gamma_0 = \|\breve{D}_{11}\|_2$, it is clear that γ_0 is the lower bound for the achievable H^∞ performance in sampled-data systems under any choice of $\mathcal{S}_h$ and $\mathcal{H}_h$. Hence it is natural to consider only the cases where $\gamma > \gamma_0$.

Assumptions (A1)–(A5) are formulated in terms of the system description in the lifted domain. Results in the companion paper [23] allow us to replace them with more readily checkable conditions. In particular, when $\mathcal{H}_h$ is the design parameter, assumptions (A1) and (A3) can be equivalently formulated as

(A1′): The pair (A, B_2) is $\mathbb{C}^-$-stabilizable;

(A3′): The matrix $\left[\begin{smallmatrix} A-j\omega I & B_2 \\ C_1 & D_{12} \end{smallmatrix}\right]$ is left invertible $\forall\omega \in \mathbb{R}$ and $D'_{12}D_{12} > 0$,

while when $\mathcal{H}_h$ is the zero-order hold ($\phi_H(\tau) = I$) they can be replaced with

(A1″): The pair $(\Sigma_{22}, \Sigma_{24})$ is $\mathbb{D}$-stabilizable for any $\gamma > \gamma_0$;

(A3″): The matrix

$$\begin{bmatrix} \Sigma_{12} & \Sigma_{14} \\ \Sigma_{22} - e^{j\theta}I & \Sigma_{24} \\ \Sigma_{32} & \Sigma_{34} \end{bmatrix}$$

is left invertible $\forall\theta \in [0, 2\pi)$ and any $\gamma > \gamma_0$.

Analogously, when $\mathcal{S}_h$ is is the design parameter, assumptions (A2) and (A4) can be equivalently expressed as

(A2′): The pair (C_2, A) is $\mathbb{C}^-$-detectable;

(A4′): The matrix $\left[\begin{smallmatrix} A-j\omega I & B_1 \\ C_2 & D_{21} \end{smallmatrix}\right]$ is right invertible $\forall\omega \in \mathbb{R}$ and $D_{21}D'_{21} > 0$

and (A5) is redundant, while when it is the ideal sampler ($\phi_S(\tau) = \delta(\tau)$), (A2) and (A4) can be replaced with

(A2″): The pair (C_2, Σ_{22}) is $\mathbb{D}$-detectable for any $\gamma > \gamma_0$;

(A4″): The matrix $\left[\begin{smallmatrix} \Sigma_{22}-e^{j\theta}I & \gamma^2\Sigma_{23} \\ C_2 & 0 \end{smallmatrix}\right]$ is right invertible $\forall\theta \in [0, 2\pi)$ and any $\gamma > \gamma_0$;

(A5″): $D_{21} = 0$.

The following remarks are in order.

Remark 5.1. Although (A1″) is equivalent to (A1) only when $\gamma \to \infty$, OP_{H^∞} will have no solutions whenever (A1″) is violated. Hence, (A1) can be replaced by (A1″)

without loss of generality. Just note that unless $\gamma = \infty$, the violation of (A1″) does not necessarily imply that $(\bar{A}, \bar{B}_2)$ is not $\mathbb{D}$-stabilizable. The same is true regarding (A2″) and the $\mathbb{D}$-detectability of $(\bar{C}_2, \bar{A})$.

Remark 5.2. Assumptions (A1″)–(A4″) are expressed in terms of the parameters of the matrix exponential Σ. This, in principle, does not complicate the computations, since Σ is required for the solution of OP_{H^2} and OP_{H^∞} in any case. In some cases, however, it is possible to verify (A1)–(A4) directly in terms of the parameters of the continuous-time plant $\mathcal{P}$. In particular, if the sampling period h is nonpathological with respect to the eigenvalues of A [8], then (A1) and (A2) are equivalent to (A1′) and (A2′), respectively, even when $\mathcal{H}_h$ and $\mathcal{S}_h$ are fixed. Furthermore, it is shown in [30, section 5] that

- if the continuous-time subsystem from u to z, $\mathcal{P}_{12}$, is left invertible and $\mathcal{H}_h$ is the zero-order hold, then (A3″) holds iff (C_2, A) has no unobservable $j\omega$-axis eigenvalues and 0 is not a zero of $P_{12}(s)$;
- if the continuous-time subsystem from w to y is right invertibe and $\mathcal{S}_h$ is the ideal sampler, then (A4″) holds iff (A, B_2) has no unobservable $j\omega$-axis eigenvalues.

It is worth stressing, however, that (A1) and/or (A2) may hold even if h is pathological and (A3) ((A4)) may hold even if the continuous-time subsystem from u to z (from w to y) is not left (right) invertible.

5.1. Both hold and sampler are free. In case C_a the solution to OP_{H^∞} is as follows.

THEOREM 3 (C_a). *Given plant* (1) *such that assumptions* (A1′)–(A4′) *hold, then for any* $\gamma > \gamma_0$ *the matrix* Σ_{33} *is nonsingular and the following statements are equivalent:*

(i) *There exist* $\bar{\mathcal{K}}_d$, $\mathcal{H}_h$, *and* $\mathcal{S}_h$ *which solve* OP_{H^∞}.

(ii) $(\Gamma_X, \Lambda_m) \in \mathrm{dom}(Ric_{\mathbb{C}^-})$ *and* $(\Gamma_Y, \Lambda_r) \in \mathrm{dom}(Ric_{\mathbb{C}^-})$ *and the following conditions hold:*

(a) $X_\gamma \ge 0$ *and* $\rho(X_\gamma \Sigma_{23} \Sigma_{33}^{-1}) < 1$,

(b) $Y_\gamma \ge 0$ *and* $\rho(\Sigma_{33}^{-1} \Sigma_{32} Y_\gamma) < \gamma^2$,

(c) $\rho\big(Y_\gamma(\Sigma_{33} + \gamma^{-2}\Sigma_{32}Y_\gamma)^{-1} X_\gamma (\Sigma'_{33} - \Sigma'_{23}X_\gamma)^{-1}\big) < \gamma^2$,

where $(X_\gamma, F_\gamma) = Ric_{\mathbb{C}^-}(\Gamma_X, \Lambda_m)$ *and* $(Y_\gamma, L'_\gamma) = Ric_{\mathbb{C}^-}(\Gamma_Y, \Lambda_r)$.

Furthermore, if the conditions of part (ii) *hold, then* $Z_\gamma \doteq (I - \gamma^{-2} Y_\gamma X_\gamma)^{-1}$ *is well defined, and one possible choice for* $\bar{\mathcal{K}}_d$, $\mathcal{H}_h$, *and* $\mathcal{S}_h$ *is*

$$\bar{K}_d(z) = z\left[\begin{array}{c|c} Z_\gamma \Theta_{12} + \Theta_{22} & Z_\gamma \\ \hline I & 0 \end{array}\right],$$

where

$$\left[\begin{array}{cc} \Theta_{11} & \Theta_{12} \\ 0 & \Theta_{22} \end{array}\right] \doteq \exp\left(\left[\begin{array}{cc} A + \gamma^{-2} Y_\gamma C_1' C_1 + L_\gamma C_2 & L_\gamma (C_2 + \gamma^{-2} D_{21} B_1' X_\gamma) \\ 0 & A + \gamma^{-2} B_1 B_1' X_\gamma + B_2 F_\gamma \end{array}\right] h\right)$$

and

$$\phi_H(\tau) = F_\gamma\, e^{(A + \gamma^{-2} B_1 B_1' X_\gamma + B_2 F_\gamma)\tau}, \tag{11a}$$

$$\phi_S(\tau) = -e^{(A + \gamma^{-2} Y_\gamma C_1' C_1 + L_\gamma C_2)\tau}\, L_\gamma. \tag{11b}$$

Proof (outline). Actually, it suffices to prove that the solution given in the theorem is equivalent to the one in Theorem 2. To this end, note that by [23, Lemma 3]

and its dual, the DAREs (7) have stabilizing solutions iff $(\Gamma_X, \Lambda_m) \in \mathrm{dom}(Ric_{\mathbb{C}^-})$ and $(\Gamma_Y, \Lambda_r) \in \mathrm{dom}(Ric_{\mathbb{C}^-})$. Then items (a)–(c) are equivalent to (8) by [23, Lemma 8].

Now consider the lifted controller $\bar{K}_\gamma(z)$ $(= \breve{K}_\gamma(z))$ in Theorem 2. It is clear that $\grave{\Phi}_H = \grave{F}_{\gamma 2}$ and $\acute{\Phi}_S = \acute{L}_{\gamma 2}$ can be chosen. Then (11) follow directly from [23, Lemma 3] and its dual. It also follows from that lemma that

$$\bar{A} + \acute{B}\grave{F}_\gamma = \Theta_{22} \qquad \text{and} \qquad \acute{L}_2(\grave{C}_2 + \breve{D}_{2\bullet}\grave{F}_\gamma) = \Theta_{12},$$

from which the formula for $\bar{K}_d(z)$ follows. □

Note that the H^∞ problem for case C_a was already treated by Tadmor [27] (see also [22]). The solution in Theorem 3, however, is simpler and has the intriguing separation structure between $\mathcal{H}_h$ and $\mathcal{S}_h$ (the suboptimal sampler in [27] does depend on the suboptimal hold).

5.2. Free hold and fixed sampler. In case C_b the solution to OP_{H^∞} is as follows.

THEOREM 4 (C_b). *Given plant* (1) *such that assumptions* (A1′), (A2″), (A3′), (A4″), (A5″) *hold and let the sampling function be* $\phi_S(\tau) = \delta(\tau)$. *Then for any* $\gamma > \gamma_0$ *the following statements are equivalent:*

(i) *There exist* $\bar{\mathcal{K}}_d$ *and* $\mathcal{H}_h$ *which solve* OP_{H^∞}.

(ii) $(\Gamma_X, \Lambda_m) \in \mathrm{dom}(Ric_{\mathbb{C}^-})$ *and* $(\Sigma_Y, \Lambda_r) \in \mathrm{dom}(Ric_{\mathbb{D}})$ *and the following conditions hold:*

(a) $X_\gamma \geq 0$ *and* $\rho(X_\gamma \Sigma_{23} \Sigma_{33}^{-1}) < 1$,

(b) $\bar{Y}_\gamma \geq 0$ *and* $\rho(\Sigma_{33}^{-1}\Sigma_{32}\bar{Y}_\gamma) < \gamma^2$,

(c) $\rho\big(\bar{Y}_\gamma(\Sigma_{33} + \gamma^{-2}\Sigma_{32}\bar{Y}_\gamma)^{-1} X_\gamma (\Sigma'_{33} - \Sigma'_{23}X_\gamma)^{-1}\big) < \gamma^2$,

where $(X_\gamma, F_\gamma) = Ric_{\mathbb{C}^-}(\Gamma_X, \Lambda_m)$ *and* $(\bar{Y}_\gamma, \bar{L}'_\gamma) = Ric_{\mathbb{D}}(\Sigma_Y, \Lambda_r)$.

Furthermore, if the conditions of part (ii) *hold, then* $Z_\gamma \doteq (I - \gamma^{-2}\bar{Y}_\gamma X_\gamma)^{-1}$ *is well defined and one possible choice for* $\bar{\mathcal{K}}_d$ *and* $\mathcal{H}_h$ *is*

$$\bar{K}_d(z) = z\left[\begin{array}{c|c} (I + Z_\gamma \bar{L}_\gamma C_2) e^{(A+\gamma^{-2}B_1B_1'X_\gamma + B_2F_\gamma)h} & -Z_\gamma \bar{L}_\gamma \\ \hline I & 0 \end{array}\right]$$

and $\phi_H(\tau)$ *as in* (11a).

Proof (outline). The first part can be proven in a similar fashion as the first part of Theorem 3, except that the DARE (7b) is solved by using [23, Lemma 7]. To get $\bar{K}_d(z)$ just note that if $\mathcal{S}_h$ is the ideal sampler and $D_{21} = 0$, then

$$\left[\begin{array}{cc} \bar{C}_2 & \acute{D}_{2\bullet} \end{array}\right] = C_2 \left[\begin{array}{cc} \bar{A} & \acute{B} \end{array}\right], \tag{12}$$

which completes that proof. □

The H^∞ problem for case C_b was considered in [26], where the suboptimal hold function has also the form (11a). Yet the Riccati equations there are nontrivially coupled and the existence conditions are computationally more complicated than conditions (a)–(c) in Theorem 4. In particular, the nonsingularity of a matrix function of time t on the whole interval $[0, h]$ should be verified in [26] for each γ. On the other hand, a similar test in our case is to be performed only once, when γ_0 is calculated [8, section 13.5].

5.3. Fixed hold and free sampler. In case C_c, the solution to OP_{H^∞} is as follows.

THEOREM 5 (C_c). *Given plant* (1) *such that assumptions* (A1″), (A2′), (A3″), (A4′) *hold and let the hold function be* $\phi_H(\tau) = I$. *Then for any* $\gamma > \gamma_0$ *the following statements are equivalent:*

(i) *There exist* $\bar{\mathcal{K}}_d$ *and* $\mathcal{S}_h$ *which solve* OP_{H^∞}.
(ii) $(\Sigma_X, \Lambda_m) \in \mathrm{dom}(Ric_{\mathbb{D}})$ *and* $(\Gamma_Y, \Lambda_r) \in \mathrm{dom}(Ric_{\mathbb{C}^-})$ *and the following conditions hold:*
  (a) $\bar{X}_\gamma \geq 0$ *and* $\rho(\bar{X}_\gamma \Sigma_{23} \Sigma_{33}^{-1}) < 1$,
  (b) $Y_\gamma \geq 0$ *and* $\rho(\Sigma_{33}^{-1} \Sigma_{32} Y_\gamma) < \gamma^2$,
  (c) $\rho\big(Y_\gamma(\Sigma_{33} + \gamma^{-2}\Sigma_{32}Y_\gamma)^{-1}\bar{X}_\gamma(\Sigma'_{33} - \Sigma'_{23}\bar{X}_\gamma)^{-1}\big) < \gamma^2$,
  where $(\bar{X}_\gamma, \bar{F}_\gamma) = Ric_{\mathbb{D}}(\Sigma_X, \Lambda_m)$ *and* $(Y_\gamma, L'_\gamma) = Ric_{\mathbb{C}^-}(\Gamma_Y, \Lambda_r)$.

Furthermore, if the conditions of part (ii) *hold, then* $Z_\gamma \doteq (I - \gamma^{-2} Y_\gamma \bar{X}_\gamma)^{-1}$ *is well defined and one possible choice for* $\bar{\mathcal{K}}_d$ *and* $\mathcal{S}_h$ *is*

$$\bar{K}_d(z) = z\left[\begin{array}{c|c} \Psi_{11} + \Psi_{12}\bar{F}_\gamma Z_\gamma & I \\ \hline \bar{F}_\gamma Z_\gamma & 0 \end{array}\right],$$

where

$$\left[\begin{array}{cc} \Psi_{11} & \Psi_{12} \\ 0 & I \end{array}\right] \doteq \exp\left(\left[\begin{array}{cc} A + \gamma^{-2} Y_\gamma C_1' C_1 + L_\gamma C_2 & B_2 + \gamma^{-2} Y_\gamma C_1' D_{12} \\ 0 & 0 \end{array}\right] h\right)$$

and $\phi_S(\tau)$ *as in* (11b).

Proof (outline). The first part can be proven in a way similar to the first part of Theorem 3, except that the DARE (7a) is solved by [23, Lemma 7]. In order to obtain the formula for $\bar{K}_d(z)$ it is more convenient to use the dual form of the H^∞ suboptimal controller, i.e.,

$$\tilde{K}(z) = \left[\begin{array}{c|c} \bar{A} + \acute{L}_\gamma \grave{C} + (\tilde{B}_2 + \acute{L}_\gamma \tilde{D}_{\bullet 2})\tilde{F}_{\gamma 2}\bar{Z}_\gamma & -\tilde{L}_{\gamma 2} \\ \hline \tilde{F}_{\gamma 2}\bar{Z}_\gamma & 0 \end{array}\right]$$

(which becomes $\acute{K}(z)$ in this case). Then, using the dual result to [23, Lemma 3] one can get that

$$\bar{A} + \acute{L}_\gamma \grave{C} = \Psi_{11} \qquad \text{and} \qquad \bar{B}_2 + \acute{L}_\gamma \grave{D}_{\bullet 2} = \Psi_{12},$$

from which the formula for $\bar{K}_d(z)$ follows. □

5.4. Both hold and sampler are fixed. In case C_d the solution to OP_{H^∞} is as follows.

THEOREM 6 (C_d). *Given plant* (1) *such that assumptions* ($\mathsf{A1}''$)–($\mathsf{A5}''$) *hold and let the hold function be* $\phi_H(\tau) = I$ *and the sampling function be* $\phi_S(\tau) = \delta(\tau)$. *Then for any* $\gamma > \gamma_0$ *the following statements are equivalent:*
(i) *There exists* $\bar{\mathcal{K}}_d$ *which solves* OP_{H^∞}.
(ii) $(\Sigma_X, \Lambda_m) \in \mathrm{dom}(Ric_{\mathbb{D}})$ *and* $(\Sigma_Y, \Lambda_r) \in \mathrm{dom}(Ric_{\mathbb{D}})$ *and the following conditions hold:*
  (a) $\bar{X}_\gamma \geq 0$ *and* $\rho(\bar{X}_\gamma \Sigma_{23} \Sigma_{33}^{-1}) < 1$,
  (b) $\bar{Y}_\gamma \geq 0$ *and* $\rho(\Sigma_{33}^{-1} \Sigma_{32} \bar{Y}_\gamma) < \gamma^2$,
  (c) $\rho\big(\bar{Y}_\gamma(\Sigma_{33} + \gamma^{-2}\Sigma_{32}\bar{Y}_\gamma)^{-1}\bar{X}_\gamma(\Sigma'_{33} - \Sigma'_{23}\bar{X}_\gamma)^{-1}\big) < \gamma^2$,
  where $(\bar{X}_\gamma, \bar{F}_\gamma) = Ric_{\mathbb{D}}(\Sigma_X, \Lambda_m)$ *and* $(\bar{Y}_\gamma, \bar{L}'_\gamma) = Ric_{\mathbb{D}}(\Sigma_Y, \Lambda_r)$.

Furthermore, if the conditions of part (ii) *hold, then* $Z_\gamma \doteq (I - \gamma^{-2} \bar{Y}_\gamma \bar{X}_\gamma)^{-1}$ *is well defined and one possible choice for* $\bar{\mathcal{K}}_d$ *is*

$$\bar{K}_d(z) = z\left[\begin{array}{c|c} (I + Z_\gamma \bar{L}_\gamma C_2)(\Sigma_{22} + \Sigma_{23}\bar{X}_\gamma + \Sigma_{24}\bar{F}_\gamma) & -Z_\gamma \bar{L}_\gamma \\ \hline \bar{F}_\gamma & 0 \end{array}\right].$$

Proof (outline). The first part can be proven in a way similar to the first part of Theorem 3, except that instead of [23, Lemma 3] one has to use [23, Lemma 7]. The formula for $\bar{K}_d(z)$ then follows by (12) and the equality

$$\bar{A} + \acute{B}\grave{F}_\gamma = \Sigma_{22} + \Sigma_{23}\bar{X}_\gamma + \Sigma_{24}\bar{F}_\gamma,$$

which, in turn, follows from the fact that $(\bar{X}_\gamma, \bar{F}_\gamma) = Ric_{\mathbb{D}}(\Sigma_X, \Lambda_m)$. □

Although this case has been extensively studied in the literature in both H^2 and H^∞ cases (see the references in [8]), the conventional approach to the solution is based on the following two-step procedure: first, a sampled-data problem is converted to an equivalent discrete-time finite-dimensional one; and second, the latter problem is solved for $\bar{\mathcal{K}}_d$ using standard discrete H^2 or H^∞ methods. The available solutions thus are quite involved. Moreover, because of the presence of the intermediate step, the effect of the original parameters of the continuous-time problem is difficult to trace back.

To the best of our knowledge, Theorem 6 yields the first closed-form solution to the sampled-data H^∞ problem. It is worth stressing that from the computational point of view the solutions to both H^2 and H^∞ sampled-data problems given in Theorem 6 are compatible with those for pure discrete-time treatments.

5.5. The optimal H^2 performance. In this subsection the formula for the H^2 optimal performance index $J^{opt}_{H^2}$ given in Theorem 1, is expressed in terms of the matrices A, B_1, and C_1. Such a formula can, in principle, be assembled from the results in [4, p. 11]. The result below, however, is simpler in the sense that the matrix exponential of smaller dimension is to be computed.

Form the matrix exponential

$$\Delta \doteq \exp\left(\begin{bmatrix} -A' & C_1'C_1 & 0 \\ 0 & A & B_1B_1' \\ 0 & 0 & -A' \end{bmatrix} h\right) = \begin{bmatrix} \Delta_{11} & \Delta_{12} & \Delta_{13} \\ 0 & \Delta_{22} & \Delta_{23} \\ 0 & 0 & \Delta_{11} \end{bmatrix}.$$

Then this lemma follows.

LEMMA 1. *Let X_2 and Y_2 be the stabilizing solutions to the Riccati equations* (5)*, then the optimal value of the performance index J_{H^2} is*

$$J^{opt}_{H^2} = \tfrac{1}{h}\operatorname{tr}\big(\Delta_{22}'(\Delta_{13} + X_2\Delta_{23} + \Delta_{12}Y_2 + X_2\Delta_{22}Y_2) - X_2Y_2\big).$$

Proof. As follows from [23, Props. 8 and 9] (subject to (s.t.) $B_\gamma = 0$) and their duals:

$$\bar{A} = \Delta_{22}, \quad \acute{B}_1\acute{B}_1^* = \Delta_{23}\Delta_{22}', \quad \text{and} \quad \grave{C}_1^*\grave{C}_1 = \Delta_{22}'\Delta_{12}.$$

Then, using the integral expression for the Hilbert–Schmidt norm [4] one can write

$$\begin{aligned} \|\breve{D}_{11}\|^2_{HS} &= \operatorname{tr}\left(\int_0^h \int_0^t C_1 e^{A(t-s)}B_1B_1'e^{A'(t-s)}C_1' ds\, dt\right) \\ &= \operatorname{tr}\left(e^{A'h}\int_0^h e^{-A'(h-t)}C_1' \int_0^t C_1 e^{A(t-s)}B_1B_1'e^{-A's} ds\, dt\right) \\ &= \operatorname{tr}\big(\Delta_{22}'\Delta_{13}\big), \end{aligned}$$

where the latter equality follows from the fact that the second trace above is just the trace of the impulse response of a continuous-time system with the following transfer matrix:

$$\left[\begin{array}{c|c} -A' & C' \\ \hline \Delta_{22}' & 0 \end{array}\right]\left[\begin{array}{c|c} A & B \\ \hline C & 0 \end{array}\right]\left[\begin{array}{c|c} -A' & I \\ \hline B' & 0 \end{array}\right]$$

at $t = h$. This completes the proof. □

6. Discussion. Theorems 3–5 give not only the discrete-time part $\bar{\mathcal{K}}_d$ of the sampled-data controller, but also the H^∞ suboptimal (or the H^2 optimal) sampling and/or hold functions[2]. The purpose of the present section is to present some generic properties of the (sub)optimal sampler and hold functions, together with their interpretation. The first property is the separation between the design of the sampler and the hold, which has already been discussed in section 4.3. The separation property has a clear explanation: both sampler and hold are, in a sense, open-loop devices. Consequently, the design of the hold does not depend on the measurement $y(t)$ and the design of the sampler does not depend on the control action $u(t)$. The remaining properties refer to the $\mathcal{S}_h$ and $\mathcal{H}_h$, which are discussed separately below.

6.1. Optimal hold. Consider the H^∞ control CARE

$$0 = A'X + XA + C_1'C_1 + \tfrac{1}{\gamma^2}XB_1B_1'X - (B_2'X + D_{12}'C_1)'(D_{12}'D_{12})^{-1}(B_2'X + D_{12}'C_1), \tag{13}$$

which reduces to the H^2 one as $\gamma \to \infty$. The H^∞ state feedback gain is then

$$F_2 \doteq -(D_{12}'D_{12})^{-1}(B_2'X + D_{12}'C_1).$$

The following corollary can be derived from Theorems 3 and 4.

COROLLARY 1. *Let $X = X' \geq 0$ be the stabilizing solution to the CARE* (13). *Then one possible H^∞ suboptimal hold function is*

$$\phi_H(\tau) = F_2\, e^{(A+\gamma^{-2}B_1B_1'X+B_2F_2)\tau} \quad \forall \tau \in [0, h), \tag{14}$$

independent of the choice of the sampler and the measured output $y(t)$. When $\gamma^{-2} = 0$, this becomes the unique H^2 optimal solution.

The following remarks are in order.

Remark 6.1. Notice that the optimal hold for the *nonsingular* H^2 and H^∞ problems is always "asymptotically stable," in the sense that its "A" matrix is Hurwitz. In other words, the continuation of the hold in (14) over the whole interval $[0, \infty)$ belongs to L^2. The "stability" property is intuitively reasonable: the generalized hold being an "open-loop" device, it should prevent any source of instability during the intersample.

Remark 6.2. As a curious corollary to the previous remark, the standard zero-order hold (ZOH) can *never* appear as part of an optimal hold for nonsingular problems; this is because the "A" matrix of a ZOH is the zero-matrix. The ZOH does appear as part of an optimal hold for *singular* H^2 and H^∞ problems, for which $A + \gamma^{-2}B_1B_1'X + B_2F_2$ has an eigenvalue at the origin. Such problems may arise when integral control is required; see [32, section 17.3]. In the sampled-data case, the

[2]See Remark 2.1 for what is meant by *optimal* sampling and hold functions.

integral control action is actually "redistributed" between the discrete-time part of the controller $\bar{\mathcal{K}}_d$ and the hold $\mathcal{H}_h$.

Remark 6.3. It is worth mentioning that the design of H^2 and H^∞ (sub)optimal holds does *not* depend on the sampling period h. The optimal hold function remains the same for all h and only the interval changes on which $\phi_H(\tau)$ is defined. Also, it can easily be verified that with the optimal $\mathcal{H}_h$ the system is stabilizable *for all* h. In other words, if $\mathcal{H}_h$ is either H^2 or H^∞ optimal, then no sampling period can result in a loss of controllability and hence there exists no *pathological sampling*.

The stability property discussed in Remarks 6.1 and 6.2 becomes particularly interesting when compared with previous works on the design of generalized hold functions. Indeed, for most hold devices designed in the literature from the discrete-time performance point of view (see [1] and the references therein), the continuation of ϕ_H on the whole $\mathbb{R}^+$ does *not* necessarily belong to L^2 (and even L^∞). For example, if the hold function of the form $\phi_H(\tau) = C_H e^{A_H \tau} B_H$ is designed, then the typical choice is $A_H = -A'$, where A is the "A" matrix of a plant. Hence, the stability of such a hold depends on the open-loop plant dynamics. In the face of the previous remark, it is desirable to understand what is the underlying reason that rules out the use of "unstable" hold functions. To this end, consider the continuous-time LQR problem for the process

$$\dot{x}(t) = Ax(t) + B_2 u(t)$$

and the cost function

$$\mathcal{J} = \int_0^\infty \big(C_1 x(t) + D_{12} u(t)\big)' \big(C_1 x(t) + D_{12} u(t)\big) dt.$$

The solution to the problem of minimizing $\mathcal{J}$ is given by the feedback law [18] $u(t) = F_2 x(t)$, so that for a given t_k and any $\tau > 0$, the closed-loop state vector satisfies the equation

$$x(t_k + \tau) = e^{(A + B_2 F_2)\tau} x(t_k).$$

Substituting this equation into the formula for the control signal gives

$$u(t_k + \tau) = F_2 e^{(A + B_2 F_2)\tau} x(t_k).$$

On the other hand, it follows from (2a) and (14) that the H^2 optimal hold produces the control signal

$$u(kh + \tau) = F_2 e^{(A + B_2 F_2)\tau} \bar{u}_k \qquad \forall \tau \in [0, h).$$

The comparison of the latter two expressions prompts the following interpretation of the H^2 optimal hold.

INTERPRETATION 1. *The H^2 optimal hold, given by* (14) *subject to $\gamma^{-1} = 0$, attempts to "reconstruct" the LQR feedback control law, assuming that $\bar{\mathcal{K}}_d$ produces at the kth sampling instant an estimation of state vector of the plant at $t = kh$.*

Similarly to the H^2 case, the interpretation of the H^∞ suboptimal hold can be obtained from the continuous-time H^∞ state feedback problem as follows.

INTERPRETATION 2. *The H^∞ suboptimal hold, given by* (14)*, attempts to "reconstruct" the H^∞ suboptimal state feedback control law assuming that* (i) *$\bar{\mathcal{K}}_d$ produces at the kth sampling instant an estimate of the state vector of the plant at $t = kh$; and* (ii) *the disturbance w is the worst-case one (in an H^∞ sense), i.e., $w(t) = \frac{1}{\gamma^2} B_1' X\, x(t)$.*

These interpretations explain the "stability" of the optimal hold. Indeed, optimal continuous-time control must guarantee the internal stability of the closed-loop system. Consequently, the reconstruction of the continuous-time control signal in an open-loop fashion lead to the "stable dynamics" of the hold. When the integral control results from the continuous-time design, the "A" matrix of the hold function has an eigenvalue at the origin. This is consistent with the discussion in Remark 6.2.

The main conclusion of the previous interpretations is that the optimal hold attempts to reconstruct a "good" LTI continuous-time control law. Notice that this differs from some previous approaches to the design of $\mathcal{H}_h$, which seek to circumvent basic limitations of linear continuous-time control and attempt to outperform a continuous-time controller. The results in this paper suggest that the design of the hold should be based on the understanding that the optimal continuous-time control is the "best" possible choice; consequently, the sampled-data controller should mimic it as good as possible. We believe that this idea can be extended for designing controllers in problems with no known analytic solution but with computable optimal continuous-time controller. For example, the H^2 or H^∞ problems when $\mathcal{H}_h$ or $\mathcal{S}_h$ are constrained to be scalar.

6.2. Optimal sampler. Consider now the H^∞ filtering CARE

$$0 = AY + YA' + B_1B_1' + \tfrac{1}{\gamma^2}YC_1'C_1Y - (YC_2' + B_1D_{21}')(D_{21}D_{21}')^{-1}(YC_2' + B_1D_{21}')', \tag{15}$$

which again reduces to the H^2 one when $\gamma \to \infty$. The H^∞ filter gain is then as follows:

$$L_2 \doteq -(YC_2' + B_1D_{21}')(D_{21}D_{21}')^{-1}.$$

The following corollary can be derived from Theorems 3 and 5.

COROLLARY 2. *Let $Y = Y' \geq 0$ be the stabilizing solution of the CARE* (15). *Then one possible H^∞ suboptimal sampling function is*

$$\phi_S(\tau) = -e^{(A+\gamma^{-2}YC_1'C_1+L_2C_2)\tau}\,L_2 \quad \forall \tau \in [0,h), \tag{16}$$

independent of the choice of the hold and the control input $u(t)$. When $\gamma^{-2} = 0$, this becomes the unique H^2 optimal solution.

The following remarks are in order.

Remark 6.4. Analogously to the optimal hold case, the optimal sampling function (16) is asymptotically stable in the sense defined in Remark 6.1. Moreover, the design of $\mathcal{S}_h$ does not depend on the sampling period and it produces a detectable system for all h. In other words, if $\mathcal{S}_h$ is either H^2 or H^∞ optimal, then no sampling period can lead to the loss of observability and hence there exists no *pathological sampling*.

Remark 6.5. Another interesting property of the optimal sampler is that is does not require prefiltering of the measurement output $y(t)$ by an anti-aliasing filter. This is because, loosely speaking, the sampler itself serves as an anti-aliasing filter. Mathematically, this means that the generalized sampler $\mathcal{S}_h$ with sampling function (16) is bounded as an operator $L^2 \mapsto \ell^2$.

Remark 6.6. The anti-aliasing capability of the optimal sampler is actually a consequence of the fact that the ideal sampler (the sampling function $\phi_S(\tau) = \delta(\tau)$) can never appear as a part of an optimal sampler for *nonsingular* H^2 and H^∞ problems. The crucial assumption here is the full row rank of the matrix D_{21}. The latter

means that all of the measurement channels are corrupted by noise. For such a $y(t)$ the instantaneous sampling is an illegal operation that accounts for the absence of the impulse component in the optimal sampling function. In the case when an anti-aliasing filter is present, the matrix D_{21} necessarily loses row rank and the problem becomes singular. It can be shown that in such a case the optimal sampler is of the form $D_S\delta(\tau) + C_S e^{A_S\tau}$ for some A_S, C_S, and $D_S \neq 0$ (but still, $D_S D_{21} = 0$). This result gives rise to an interesting observation. It is well known that if $\mathcal{S}_h$ contains the ideal sampler, then the measured output must be prefiltered by an anti-aliasing filter. The discussion above implies that the opposite is also true: *whenever the measured output is prefiltered by an anti-aliasing filter, an optimal sampler contains the ideal sampler.*

7. Concluding remarks. This paper proposes a framework for treating a rather general class of sampled-data control problems. The cases considered were those in which the sampler, the hold, or both the sampler and the hold are available for design. For all these cases, necessary and sufficient conditions for the existence of controllers as well as state–space formulas for all the blocks involved have been provided. Conditions and the formulas for state–space matrices can be readily implemented in a computer.

The essence of this framework is to convert the hybrid periodically time-varying problems to a unified discrete-time LTI "standard problem" via the lifting transformation. The solution of the problem is then found directly in the lifted domain. The lifting procedure is then carried one step forward by peeling off the representations in the lifted domain back to continuous, or more specifically sampled-data, time. The sampled-data problems completely solved in this paper are the following:

- The sampled-data H^2 problems when sampling and/or hold functions are the design parameters. The solution to this problem is, to the best of our knowledge, completely new.
- The sampled-data H^∞ problems under similar conditions. These solutions, although not new, are considerably more transparent than the ones previously existing in the literature. In exchange for this transparency, we have found out that: (a) a separation structure between the design of H^∞ suboptimal sampler and hold; and (b) a solution to the H^∞ problem which, to the best of our knowledge, is the first closed-form solution.

In the final section, several comments which reconcile and compare the present result with some previous approaches to the design of generalized hold functions are discussed.

This paper is complemented with [23], where all the technical results required to establish the main results in this paper are developed. The reader is therefore referred to this work for details and interesting additional results concerning sampled-data systems in the lifted domain.

H^2 AND H^∞ DESIGN OF SAMPLED-DATA SYSTEMS USING LIFTING. PART II: PROPERTIES OF SYSTEMS IN THE LIFTED DOMAIN*

LEONID MIRKIN†, HÉCTOR P. ROTSTEIN‡, AND ZALMAN J. PALMOR†

Abstract. An important class of sampled-data systems becomes time-invariant when the systems are "lifted" into an appropriate domain. The purpose of the present paper is to study some basic properties of systems represented by state space equations in the lifted domain. Hidden modes, invariant zeros, and Riccati equations are investigated, and the connection between representations in continuous and lifted domains are clarified. The material treated here is important for solving optimal control problems of generalized sampled-data systems.

Key words. sampled-data control, lifting technique, generalized sampler and hold

1. Introduction.

In the companion paper [12], the authors presented a solution to the H^2 and H^∞ problems for a general class of sampled-data systems, including the cases of sampling and/or the hold functions available for design. The steps involved in the solution were the following: (i) lift the problem to the "discrete-time" lifted domain; (ii) find a formal solution to the resulting discrete-time problem; and (iii) "peel-off" the result back to continuous time. Although this approach is conceptually straightforward, it presents some technical difficulties, particularly when attempting to perform the calculations involved in step (iii). For this reason, the approach has rarely been followed in the literature, with the exception of [2] and [9], where sampled-data H^∞ analysis and H^2 design problems were solved, respectively, both for the case of fixed sampler and hold. Also note that Tadmor in [15, section 4] performed the H^∞ design directly for the lifted system, yet his solution was left in the lifted domain and no hint was given of how to "peel-off" the resulting solution.

One of the reasons that make the third step problematic is numerous properties that are well known for continuous and discrete-time systems have not been worked out for the representation of continuous-time systems in the lifted domain. It is worth mentioning that these properties are not directly inherited from the continuous-time representations and that the connection between a continuous-time representation and its lifted counterpart has not completely been clarified. The purpose of this paper is to bridge this gap.

Let $\mathcal{G}$, $\mathcal{H}_h$, and $\mathcal{W}_h$ denote a linear time-invariant (LTI) continuous-time system, a generalized hold with period h and the so-called LTI hold function of the form $\phi_H(\tau) = D_H\delta(\tau) + C_H e^{A_H\tau}B_H$, and the lifting operator, respectively (see [12]). This paper focuses on the LTI lifted systems $\check{\mathcal{G}} \doteq \mathcal{W}_h\mathcal{G}\mathcal{W}_h^{-1}$ and $\dot{\mathcal{G}} \doteq \mathcal{W}_h\mathcal{G}\mathcal{H}_h$; the aim is to characterize the hidden modes and invariant zeros of the state-space realizations obtained when lifting the continuous-time representations and to study the discrete

algebraic Riccati equations (DAREs) associated with these systems. Corresponding results for systems of the form $\acute{\mathcal{G}} \doteq \mathcal{S}_h \mathcal{G} \mathcal{W}_h^{-1}$, where $\mathcal{S}_h$ is a generalized sampler, follow from those for $\grave{\mathcal{G}}$ by duality arguments. (To this end, $\mathcal{H}_h$ includes the impulse action $D_H \delta(\tau)$; this enables one to cover corresponding results for the ideal sampler.)

Since the systems $\mathcal{G}$ and $\breve{\mathcal{G}}$ are equivalent in an input-output sense [1], one would expect a close connection between the properties of their state-space realizations. However, establishing these connections is far from straightforward, since the properties cannot always be characterized adequately in terms of input-output relations. To illustrate the difficulties, recall that [10] establishes that a DARE associated with $\breve{\mathcal{G}}$ may have more solutions than the corresponding continuous-time algebraic Riccati equation (CARE) associated with $\mathcal{G}$. This result suggests that the connections between state-space properties of continuous-time LTI systems and their lifted counterparts are indeed worth study. In spite of this remark, this paper shows that a strong connection between state-space properties of $\mathcal{G}$ and $\breve{\mathcal{G}}$ does exist, much like the connection between their poles. In particular, it will be shown that any hidden mode (invariant zero) λ_i of $\mathcal{G}$ corresponds to the hidden mode (invariant zero) $e^{\lambda_i h}$ of $\breve{\mathcal{G}}$, even when their state-space realizations are not minimal.

Contrary to $\breve{\mathcal{G}}$, the operator $\grave{\mathcal{G}}$ has a finite rank. Consequently, hidden modes and invariant zeros of $\grave{\mathcal{G}}$ can, in principle, be routinely characterized in terms of matrix-valued parameters of the *finite-dimensional* operator $\grave{\mathcal{G}}^* \grave{\mathcal{G}}$ [3]. Such an approach fits well into the H^2 problem, since computations are based on precisely the same matrices. Unfortunately, the same is not true for the sampled-data H^∞ problem. For that reason, in this paper a new characterization of singularities of $\grave{\mathcal{G}}$ is proposed in terms of the H^∞ data. Although the derivations in this case are more involved, the final formulae are not more complicated than those based on the H^2 data. As it turns out, Riccati equations play an important role in the characterization of certain properties of systems in the lifted-domain, and consequently they are also investigated. It will be shown that the treatment of DAREs in terms of extended symplectic pairs (ESPs) associated with a *lifted* system enables one to obtain surprisingly simple solutions. In particular, the H^∞ DARE associated with $\grave{\mathcal{G}}$ reduces to ESP, which is not more complicated than the ESP associated with the H^2 DARE.

The material considered here was originally intended for solving the optimization problems presented in [12]; however, the results have independent interest since numerous important properties of systems in the lifted-domain are studied. The reader is referred to [12] for an introduction to lifting and additional motivation.

This paper consists of four sections and an appendix. Section 2 reviews the representation for lifted systems introduced in [11]. Section 3 studies a continuous-time system in the lifted domain, including the connection between the continuous-time and the lifted domain descriptions. Section 4 studies the cascade of a continuous time system and a generalized hold, also in the lifted-domain. Section 5 discusses the meaning of the coupling condition for H^∞. When studying the properties of systems in the lifted domain, one is naturally led to considering the DARE. For completeness, an appendix has been included, which reviews relevant results collected from various sources.

1.1. Notation. The notation throughout the paper is consistent with that of [12], with the following additions. The Redheffer star product [13] of two suitably partitioned 2×2 block operators O and P is denoted as

$$O \star P \doteq \begin{bmatrix} \mathcal{F}_\ell(O, P_{22}) & O_{12}(I - P_{22}O_{22})^{-1}P_{21} \\ P_{12}(I - O_{22}P_{22})^{-1}O_{21} & \mathcal{F}_\ell(P, O_{22}) \end{bmatrix}.$$

Continuous, discrete, or lifted LTI system $\tilde{\mathcal{G}}$ will be represented by the transfer function

$$\tilde{G}(\cdot) = \left[\begin{array}{c|c} \tilde{A} & \tilde{B} \\ \hline \tilde{C} & \tilde{D} \end{array}\right],$$

such that $\tilde{A} \in \mathbb{R}^{n\times n}$, associated with a state-space realization. This realization is in turn associated with the following pencils: the *controllability pencil*

$$\boldsymbol{C}_{\tilde{\mathcal{G}}}(\lambda) \doteq \left[\begin{array}{cc} \tilde{A} - \lambda I & \tilde{B} \end{array}\right]$$

and the *system pencil*

$$\boldsymbol{S}_{\tilde{\mathcal{G}}}(\lambda) \doteq \left[\begin{array}{cc} \tilde{A} - \lambda I & \tilde{B} \\ \tilde{C} & \tilde{D} \end{array}\right].$$

As is conventional, $z \in \mathbb{C}$ is said to be (a) an uncontrollable mode of $\tilde{A}$ if $\operatorname{rank} \boldsymbol{C}_{\tilde{\mathcal{G}}}(z) < n$ and (b) an invariant zero of the realization of $\tilde{\mathcal{G}}$ if $\operatorname{rank} \boldsymbol{S}_{\tilde{\mathcal{G}}}(z) < \operatorname{normalrank} \boldsymbol{S}_{\tilde{\mathcal{G}}}(\lambda)$. Finally, the special matrices $E_1 \doteq \left[\begin{smallmatrix} I \\ 0 \end{smallmatrix}\right]$, $E_2 \doteq \left[\begin{smallmatrix} 0 \\ I \end{smallmatrix}\right]$, $E_{11} \doteq \left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right]$, and $E_{22} \doteq \left[\begin{smallmatrix} 0 & 0 \\ 0 & I \end{smallmatrix}\right]$ are used. (The block dimensions are always clear from the context.)

2. A representation of lifted systems. This section presents a brief exposition of the results of [11] concerning the representation of the parameters of lifted systems. This representation plays a central role in the reasonings that follow. Conventionally [17, 2, 1, 3], the parameters of lifted systems are described by integral operators over $L^2[0,h]$. This representation follows naturally from the lifting procedure but unfortunately makes manipulations quite cumbersome. To remedy this difficulty, [11] considered a different representation of the parameters of the lifted systems, which considerably simplifies manipulations over these parameters. This representation builds on three components: systems with two-point boundary conditions (STPBC) operating on the time interval $[0,h]$, the impulse operator $\mathcal{I}_\theta$, and the sampling operator $\mathcal{I}_\theta^*$.

(i) STPBC are linear continuous-time operators $\breve{O} : L^2[0,h] \mapsto L^2[0,h]$, described by the state equations [7, 4]:

$$\breve{O} : \left\{\begin{array}{ll} \dot{x}(t) = Ax(t) + B\omega(t), & \Omega x(0) + \Upsilon x(h) = 0, \\ \zeta(t) = Cx(t) + D\omega(t), & \end{array}\right. \tag{2.1}$$

where the square matrices Ω and Υ shape the boundary conditions of the state vector x. The boundary conditions are said to be well-posed if $\det(\Omega + \Upsilon e^{Ah}) \neq 0$ and in this case the map $\zeta = \breve{O}\omega$ is well defined $\forall \omega \in L^2[0,h]$, namely,

$$\zeta(t) = D\omega(t) + Ce^{At}(\Omega + \Upsilon e^{Ah})^{-1}\left(\Omega \int_0^t e^{-As}B\omega(s)ds - \Upsilon \int_t^h e^{A(h-s)}B\omega(s)ds\right).$$

In this paper, STPBC are denoted by using the compact block notation:

$$\breve{O} = \left(\begin{array}{c|c|c} A & \boxed{\Omega \rightleftharpoons \Upsilon} & B \\ \hline C & & D \end{array}\right).$$

The term STPBC is reserved for systems with well-posed boundary conditions only. In the case when $\Omega = I$ and $\Upsilon = 0$, the boundary condition window can be omitted so that the notation becomes $\left(\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right)$. Notice that this case corresponds to a causal STPBC.

(ii) The impulse operator $\mathcal{I}_\theta$ transforms a vector $\eta \in \mathbb{R}^n$ into a modulated δ-impulse:

$$\big(\mathcal{I}_\theta \eta\big)(t) = \delta(t-\theta)\eta.$$

(iii) The sampling operator[1] $\mathcal{I}_\theta^*$ transforms a function $\zeta \in C_n[0,h]$ into a vector from $\mathbb{R}^n$:

$$\mathcal{I}_\theta^* \zeta = \zeta(\theta).$$

With the aid of these operators, we now consider the representation of basic components of sampled-data systems in the lifted domain. Let $\mathcal{G}$ be an LTI continuous-time system with the transfer matrix

$$G(s) = \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right], \tag{2.2}$$

$\mathcal{H}_h$ be a generalized zero-order hold of the form [12, eq. 2a] with the hold function

$$\phi_H(\tau) = D_H \delta(\tau) + C_H e^{A_H \tau} B_H, \tag{2.3}$$

and $\mathcal{S}_h$ be a generalized zero-order sampler of the form [12, eq. 2b] with the sampling function

$$\phi_S(\tau) = D_S \delta(\tau) + C_S e^{A_S \tau} B_S. \tag{2.4}$$

The systems $\breve{\mathcal{G}} \doteq \mathcal{W}_h \mathcal{G} \mathcal{W}_h^{-1}$, $\grave{\mathcal{H}}_h \doteq \mathcal{W}_h \mathcal{H}_h$, and $\acute{\mathcal{S}}_h \doteq \mathcal{S}_h \mathcal{W}_h^{-1}$ are LTI with transfer functions

$$\breve{G}(z) = \left[\begin{array}{c|c} \bar{A} & \acute{B} \\ \hline \grave{C} & \breve{D} \end{array}\right],$$

$$\grave{H}_h(z) = \left[\begin{array}{c|c} 0 & 0 \\ \hline 0 & \grave{\Phi}_H \end{array}\right],$$

and

$$\acute{S}_h(z) = \left[\begin{array}{c|c} 0 & \acute{\Phi}_S \\ \hline I & 0 \end{array}\right],$$

respectively, where

$$\left[\begin{array}{cc} \bar{A} & \acute{B} \\ \grave{C} & \breve{D} \end{array}\right] = \left[\begin{array}{cc} \mathcal{I}_h^* & 0 \\ 0 & I \end{array}\right] \left(\begin{array}{c|cc} A & I & B \\ \hline I & 0 & 0 \\ C & 0 & D \end{array}\right) \left[\begin{array}{cc} \mathcal{I}_0 & 0 \\ 0 & I \end{array}\right],$$

$$\grave{\Phi}_H = \left(\begin{array}{c|c} A_H & B_H \\ \hline C_H & D_H \end{array}\right) \mathcal{I}_0,$$

and

$$\acute{\Phi}_S = \mathcal{I}_h^* \left(\begin{array}{c|c} A_S & B_S \\ \hline C_S & D_S \end{array}\right).$$

[1] It is worth stressing that $\mathcal{I}_\theta^*$ is not the adjoint of $\mathcal{I}_\theta$. See [11] for a justification of this abuse of notation.

The representation via STPBC has several advantages. First, algebraic manipulations over STPBC can be performed in state space, much like manipulations over standard LTI systems. This fact is established in the next proposition.

PROPOSITION 2.1 (see [11]). *Let*

$$\breve{O}_i = \left(\begin{array}{c|c|cc} A_i & \Omega_i \rightleftharpoons \Upsilon_i & B_{i_1} & B_{i_2} \\ \hline C_{i_1} & & D_{i_{11}} & D_{i_{12}} \\ C_{i_2} & & D_{i_{21}} & D_{i_{22}} \end{array}\right), \qquad i = 1, 2.$$

Then

$$\breve{O}_1 \star \breve{O}_2 = \left(\begin{array}{c|c|c} A_\star & \Omega_\star \rightleftharpoons \Upsilon_\star & B_\star \\ \hline C_\star & & D_\star \end{array}\right),$$

where

$$\begin{aligned}
A_\star &\doteq \begin{bmatrix} A_1 & 0 \\ B_{2_2}C_{1_2} & A_2 \end{bmatrix} + \begin{bmatrix} B_{1_2} \\ B_{2_2}D_{1_{22}} \end{bmatrix}(I - D_{2_{22}}D_{1_{22}})^{-1}\begin{bmatrix} D_{2_{22}}C_{1_2} & C_{2_2} \end{bmatrix}, \\
B_\star &\doteq \begin{bmatrix} B_{1_1} & 0 \\ B_{2_2}D_{1_{21}} & B_{2_1} \end{bmatrix} + \begin{bmatrix} B_{1_2} \\ B_{2_2}D_{1_{22}} \end{bmatrix}(I - D_{2_{22}}D_{1_{22}})^{-1}\begin{bmatrix} D_{2_{22}}D_{1_{21}} & D_{2_{21}} \end{bmatrix}, \\
C_\star &\doteq \begin{bmatrix} C_{1_1} & 0 \\ D_{2_{12}}C_{1_2} & C_{2_1} \end{bmatrix} + \begin{bmatrix} D_{1_{12}} \\ D_{2_{12}}D_{1_{22}} \end{bmatrix}(I - D_{2_{22}}D_{1_{22}})^{-1}\begin{bmatrix} D_{2_{22}}C_{1_2} & C_{2_2} \end{bmatrix}, \\
D_\star &\doteq \begin{bmatrix} D_{1_{11}} & 0 \\ D_{2_{12}}D_{1_{21}} & D_{2_{11}} \end{bmatrix} + \begin{bmatrix} D_{1_{12}} \\ D_{2_{12}}D_{1_{22}} \end{bmatrix}(I - D_{2_{22}}D_{1_{22}})^{-1}\begin{bmatrix} D_{2_{22}}D_{1_{21}} & D_{2_{21}} \end{bmatrix}, \\
\Omega_\star &\doteq \begin{bmatrix} \Omega_1 & 0 \\ 0 & \Omega_2 \end{bmatrix}, \\
\Upsilon_\star &\doteq \begin{bmatrix} \Upsilon_1 & 0 \\ 0 & \Upsilon_2 \end{bmatrix},
\end{aligned}$$

and the star product exists iff $\det(I - D_{2,22}D_{1,22}) \neq 0$ *and* $\det(\Omega_\star + \Upsilon_\star e^{A_\star h}) \neq 0$.

REMARK 2.1. *Since addition, multiplication, inversion, and LFT operations are just special cases of the star product, Proposition* 2.1 *covers a wide spectrum of manipulations over STPBC. In particular, it follows from Proposition* 2.1 *that* $\breve{O}_1 + \breve{O}_2$ *and* $\breve{O}_1\breve{O}_2$ *are well defined for every* $\breve{O}_1$ *and* $\breve{O}_2$ *of appropriate dimensions, and a square STPBC given by* (2.1) *is invertible iff* $\det(D) \neq 0$ *and* $\det(\Omega + \Upsilon e^{(A - BD^{-1}C)h}) \neq 0$.

Second, the operators $\mathcal{I}_\theta$ and $\mathcal{I}_\theta^*$ fit nicely into the state-space framework. In particular, the adjoint of any composition of STPBC, $\mathcal{I}_\theta$ and $\mathcal{I}_\theta^*$ can be computed componentwise. For instance,

$$\begin{bmatrix} \bar{A} & \acute{B} \\ \grave{C} & \breve{D} \end{bmatrix}^* = \begin{bmatrix} \mathcal{I}_0^* & 0 \\ 0 & I \end{bmatrix}\left(\begin{array}{c|c|cc} -A' & 0 \rightleftharpoons I & I & C' \\ \hline -I & & 0 & 0 \\ -B' & & 0 & D' \end{array}\right)\begin{bmatrix} \mathcal{I}_h & 0 \\ 0 & I \end{bmatrix}.$$

Moreover, the operators $\mathcal{I}_\theta$ and $\mathcal{I}_\theta^*$ can be absorbed into STPBC in an elegant manner.

PROPOSITION 2.2 (see [11]). *Let*

$$\begin{bmatrix} \acute{B}_i \\ \breve{D}_i \end{bmatrix} \doteq \begin{bmatrix} \mathcal{I}_h^* & 0 \\ 0 & I \end{bmatrix}\left(\begin{array}{c|c} A & B_i \\ \hline I & 0 \\ C & D_i \end{array}\right), \qquad i = 1, 2.$$

Then for any appropriately dimensioned matrix M

$$\breve{D}_1^*\breve{D}_2 + \acute{B}_1^* M \acute{B}_2 = \left(\begin{array}{cc|c|c} A & 0 & \left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right] \rightleftharpoons \left[\begin{smallmatrix} 0 & 0 \\ -M & I \end{smallmatrix}\right] & B_2 \\ -C'C & -A' & & -C'D_2 \\ \hline D_1'C & B_1' & & D_1'D_2 \end{array}\right).$$

Finally, the computations of matrices involving infinite-dimensional parameters of lifted systems can be reduced to the computation of matrix exponentials.

PROPOSITION 2.3 (see [11]).

$$\left[\begin{smallmatrix} \mathcal{I}_h^* \\ \mathcal{I}_0^* \end{smallmatrix}\right]\left(\begin{array}{c|c|c} A & \Omega \rightleftharpoons \Upsilon & B \\ \hline C & & 0 \end{array}\right)\left[\begin{smallmatrix} \mathcal{I}_0 & \mathcal{I}_h \end{smallmatrix}\right] = \left[\begin{smallmatrix} Ce^{Ah} \\ C \end{smallmatrix}\right](\Omega + \Upsilon e^{Ah})^{-1}\left[\begin{smallmatrix} \Omega B & -\Upsilon B \end{smallmatrix}\right],$$

where $CB = 0$ is assumed for the $(2,1)$ and the $(1,2)$ entries to guarantee well-posedness.

3. System of the form $\mathcal{W}_h\mathcal{G}\mathcal{W}_h^{-1}$. The system $\breve{\mathcal{G}} \doteq \mathcal{W}_h\mathcal{G}\mathcal{W}_h^{-1}$ has a natural state space representation inherited from the state space representation of $\mathcal{G}$. The purpose of this section is to study the relationship between the uncontrollable modes and invariant zeros of the two representations. It is clear that such a relationship must exist. After all, $\mathcal{G}$ and $\breve{\mathcal{G}}$ are equivalent in an *input-output* sense, and the state vector of $\breve{\mathcal{G}}$ is the sampled state vector of $\mathcal{G}$. However, as shown next, some subtleties are involved and the topic must be investigated with care. For the sake of completeness, a result from [10] is also reviewed, stating that an H^∞ DARE associated with $\breve{\mathcal{G}}$ and an H^∞ CARE associated with $\mathcal{G}$ are actually equivalent.

3.1. Preliminary results. For given matrices A_a, B_a, and C_a of appropriate dimensions and a scalar h form the Hamiltonian matrix

$$H_a \doteq \left[\begin{smallmatrix} A_a & -B_aB_a' \\ -C_a'C_a & -A_a' \end{smallmatrix}\right] = \left[\begin{smallmatrix} H_{a,11} & H_{a,12} \\ H_{a,21} & H_{a,22} \end{smallmatrix}\right]$$

and the symplectic matrix

$$S_a \doteq e^{H_a h} = \left[\begin{smallmatrix} S_{a,11} & S_{a,12} \\ S_{a,21} & S_{a,22} \end{smallmatrix}\right].$$

The following two propositions will be useful later.

PROPOSITION 3.1. *The block $S_{a,22}$ verifies* $\det S_{a,22} \neq 0$.

Proof. Consider the STPBC

$$\breve{O}_a \doteq \left(\begin{array}{c|c} A_a & B_a \\ \hline C_a & 0 \end{array}\right).$$

From here, the operator $I + \breve{O}_a\breve{O}_a^*$ has the representation

$$I + \breve{O}_a\breve{O}_a^* = \left(\begin{array}{cc|c|c} A_a & -B_aB_a' & \left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right] \rightleftharpoons \left[\begin{smallmatrix} 0 & 0 \\ 0 & I \end{smallmatrix}\right] & 0 \\ 0 & -A_a' & & C_a' \\ \hline C_a & 0 & & I \end{array}\right),$$

and the STPBC in the right-hand side above is invertible iff the matrix

$$E_{11} + E_{22}\exp\left(\left(\left[\begin{smallmatrix} A_a & -B_aB_a' \\ 0 & -A_a' \end{smallmatrix}\right] - \left[\begin{smallmatrix} 0 \\ C_a' \end{smallmatrix}\right]\left[\begin{smallmatrix} C_a & 0 \end{smallmatrix}\right]\right)h\right) = \left[\begin{smallmatrix} I & 0 \\ S_{a,21} & S_{a,22} \end{smallmatrix}\right]$$

is nonsingular. On the other hand, the operator $I+\breve{O}_a\breve{O}_a^*$ is invertible by construction. This concludes the proof. □

PROPOSITION 3.2. *The following two statements are equivalent:*

(i) *The pencil* $\left[\begin{smallmatrix} H_{a,11}-sI \\ H_{a,21}\end{smallmatrix}\right]$ *has reduced column rank at* $s=\lambda+j\frac{2\pi}{h}k$ *for some* $k\in\mathbb{Z}$.

(ii) *The pencil* $\left[\begin{smallmatrix} S_{a,11}-zI \\ S_{a,21}\end{smallmatrix}\right]$ *has reduced column rank at* $z=e^{\lambda h}$.

Proof. Let $P_H(s)$ and $P_S(z)$ denote the pencils in (i) and (ii), respectively.

(i)⇒(ii): Assume that $P_H(\lambda)$ has reduced column rank. Then there exists a vector $\eta\neq 0$ so that $P_H(\lambda)\eta=0$. It means that $E_1\eta$ is the eigenvector of H_a associated with the eigenvalue λ. Hence, $E_1\eta$ is also the eigenvector of $e^{H_a h}$ associated with the eigenvalue $e^{\lambda h}$, which in turn leads to $P_S(e^{\lambda h})\eta=0$.

(ii) ⇒ (i): Assume that $P_S(e^{\lambda h})$ has reduced column rank. Then there exists a vector $\eta\neq 0$ so that $P_S(e^{\lambda h})\eta=0$. Since an eigenvector of $e^{H_a h}$ is not necessarily an eigenvector of H_a [5, §2.11], one cannot now apply the same reasoning as in the first part of the proof. Instead, the STPBC arguments are used below. To this end, we introduce the following operators:

$$\left[\begin{array}{cc}\grave{C}_a & \breve{D}_a\end{array}\right] \doteq \left(\begin{array}{c|cc} A_a & I & B_a \\ \hline C_a & 0 & 0\end{array}\right)\left[\begin{array}{cc}\mathcal{I}_0 & 0\\ 0 & I\end{array}\right].$$

Then

$$\begin{aligned}\grave{C}_a^*(I+\breve{D}_a\breve{D}_a^*)^{-1}\grave{C}_a &= \left[\begin{array}{cc} I & 0\end{array}\right]\left(\left[\begin{array}{cc}0 & \grave{C}_a^*\\ 0 & -\breve{D}_a^*\end{array}\right]\star\left[\begin{array}{cc}0 & 0\\ \grave{C}_a & \breve{D}_a\end{array}\right]\right)\left[\begin{array}{c}0\\ I\end{array}\right]\\ &= \mathcal{I}_0^*\left(\begin{array}{c|c|c} H_a & E_{11}\rightleftharpoons E_{22} & E_1\\ \hline E_2' & & 0\end{array}\right)\mathcal{I}_0 \qquad \text{(by Proposition 2.1)}\\ &= -S_{a,22}^{-1}S_{a,21} \qquad \text{(by Proposition 2.3)}\end{aligned}$$

and hence $\ker S_{a,21}=\ker\grave{C}_a$. Since $\eta\in\ker S_{a,21}$, then $C_a e^{A_a\tau}\eta\equiv 0$. Therefore, η belongs to the unobservable subspace of the pair (C_a,A_a). Now, it can be shown (e.g., by using the Kalman canonical decomposition of (C_a,A_a)) that there exists a $k\in\mathbb{Z}$ so that $P_H(\lambda+j\frac{2\pi}{h}k)\eta=0$. □

Now, assume that $\det D'D\neq 0$, and associate with the systems $\mathcal{G}$ and $\breve{\mathcal{G}}$ the following Hamiltonian matrices:

$$H \doteq \left[\begin{array}{cc} A & 0\\ -C'C & -A'\end{array}\right]-\left[\begin{array}{c} B\\ -C'D\end{array}\right](D'D)^{-1}\left[\begin{array}{cc} D'C & B'\end{array}\right]=\left[\begin{array}{cc} H_{11} & H_{12}\\ H_{21} & H_{22}\end{array}\right] \tag{3.1a}$$

and

$$\bar{H} \doteq \left[\begin{array}{cc} \bar{A} & 0\\ -\grave{C}^*\grave{C} & -\bar{A}'\end{array}\right]-\left[\begin{array}{c} \acute{B}\\ -\grave{C}^*\breve{D}\end{array}\right](\breve{D}^*\breve{D})^{-1}\left[\begin{array}{cc} \breve{D}^*\grave{C} & \acute{B}^*\end{array}\right]=\left[\begin{array}{cc} \bar{H}_{11} & \bar{H}_{12}\\ \bar{H}_{21} & \bar{H}_{22}\end{array}\right]. \tag{3.1b}$$

The next proposition establishes a relationship between H and $\bar{H}$.

PROPOSITION 3.3. *If* $\det D'D\neq 0$, *then the matrix* $\bar{H}$ *is well defined and can be expressed as*

$$\bar{H}=\left[\begin{array}{cc} S_{11} & S_{12}\\ 0 & -I\end{array}\right]\left[\begin{array}{cc} I & 0\\ S_{21} & S_{22}\end{array}\right]^{-1}=\left[\begin{array}{cc} I & S_{12}\\ 0 & S_{22}\end{array}\right]^{-1}\left[\begin{array}{cc} S_{11} & 0\\ S_{21} & -I\end{array}\right],$$

where S_{ij} *are the subblocks of the matrix* $S\doteq e^{Hh}$.

Proof. Consider the 2×2 operator

$$\breve{O} \doteq \left(\begin{array}{c|cc} A & I & B \\ \hline I & 0 & 0 \\ \left[\begin{array}{c} C \\ 0 \end{array}\right] & \left[\begin{array}{c} 0 \\ 0 \end{array}\right] & \left[\begin{array}{c} D \\ I \end{array}\right] \end{array}\right).$$

Then it is straightforward to verify that

$$\begin{aligned} \bar{H} &= \left[\begin{array}{cc} \mathcal{I}_h^* & 0 \\ 0 & -\mathcal{I}_0^* \end{array}\right] \breve{O} \star \breve{O}^* \left[\begin{array}{cc} \mathcal{I}_0 & 0 \\ 0 & \mathcal{I}_h \end{array}\right] \\ &= \left[\begin{array}{cc} \mathcal{I}_h^* & 0 \\ 0 & -\mathcal{I}_0^* \end{array}\right] \left(\begin{array}{c|c|c} H & \boxed{E_{11} \rightleftharpoons E_{22}} & I \\ \hline I & & 0 \end{array}\right) \left[\begin{array}{cc} \mathcal{I}_0 & 0 \\ 0 & -\mathcal{I}_h \end{array}\right] \qquad \text{(by Proposition 2.1)} \end{aligned}$$

and the proof is now completed by applying Proposition 2.3. ∎

3.2. Uncontrollable modes. From the input-output equivalence, a strong correspondence exists between the poles of $\mathcal{G}$ and those of $\breve{\mathcal{G}}$. This is clearly exhibited by the fact that the "A" matrix of the realization of $\breve{\mathcal{G}}$ inherited from a corresponding one of $\mathcal{G}$ is $\bar{A} = e^{Ah}$. Consequently, $e^{\lambda h}$ is a pole of the realization of $\breve{\mathcal{G}}$ iff either of $\lambda + j\frac{2\pi}{h}k$, $k \in \mathbb{Z}$, is a pole of the realization of $\mathcal{G}$. The lemma below establishes that precisely the same relationship holds between the uncontrollable modes of the realizations of $\mathcal{G}$ and $\breve{\mathcal{G}}$.

LEMMA 3.4. *$\boldsymbol{C}_{\breve{\mathcal{G}}}(e^{\lambda h})$ is right invertible iff $\boldsymbol{C}_{\mathcal{G}}(\lambda + j\frac{2\pi}{h}k)$ is right invertible $\forall k \in \mathbb{Z}$.*

Proof. Without loss of generality, assume that $C = 0$ and $D = I$. Then in (3.1a) $H_{21} = S_{21} = 0$ and then, for any μ

$$\left[\begin{array}{cc} S_{11} - \mu I & S_{12} \end{array}\right] = \boldsymbol{C}_{\breve{\mathcal{G}}}(\mu) \left[\begin{array}{cc} I & 0 \\ 0 & \acute{B}^* \end{array}\right] \left[\begin{array}{cc} I & 0 \\ 0 & -S_{22} \end{array}\right]$$

by Proposition 3.3. Together with Proposition 3.1, this leads to the equality

$$\operatorname{rank} \boldsymbol{C}_{\breve{\mathcal{G}}}(\mu) = \operatorname{rank} \left[\begin{array}{cc} S_{11} - \mu I & S_{12} \end{array}\right].$$

The same arguments show that for any μ

$$\operatorname{rank} \boldsymbol{C}_{\mathcal{G}}(\mu) = \operatorname{rank} \left[\begin{array}{cc} H_{11} - \mu I & H_{12} \end{array}\right].$$

Thus, the lemma follows by applying Proposition 3.2 to $A_a = A'$, $B_a = 0$, and $C_a = B'$. ∎

The following two corollaries to Lemma 3.4 are of particular interest for the solutions of the sampled-data H^2 and H^∞ problems with free hold or sampler, respectively:

COROLLARY 3.5. *The pair $(\bar{A}, \acute{B})$ is $\mathbb{D}$-stabilizable iff the pair (A, B) is $\mathbb{C}^-$-stabilizable.*

COROLLARY 3.6. *The pair $(\grave{C}, \bar{A})$ is $\mathbb{D}$-detectable iff the pair (C, A) is $\mathbb{C}^-$-detectable.*

3.3. Invariant zeros. The relationship between the invariant zeros of the realizations of $\mathcal{G}$ and $\breve{\mathcal{G}}$ is given in the next lemma.

LEMMA 3.7. *$\boldsymbol{S}_{\breve{\mathcal{G}}}(e^{\lambda h})$ is left invertible iff $\det D'D \neq 0$ and $\boldsymbol{S}_{\mathcal{G}}(\lambda + j\frac{2\pi}{h}k)$ is left invertible $\forall k \in \mathbb{Z}$.*

Proof. First, note that the operator $\boldsymbol{S}_{\breve{\mathcal{G}}}(z)$ is left invertible only if $\breve{O}_D \doteq \breve{D}^*\breve{D} + \acute{B}^*\acute{B}$ is invertible on $L^2[0,h]$. It follows from Proposition 2.2 that

$$\breve{O}_D = \left(\begin{array}{cc|c|c} A & 0 & \left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right] \rightleftharpoons \left[\begin{smallmatrix} 0 & 0 \\ -I & I \end{smallmatrix}\right] & B \\ -C'C & -A' & & -C'D \\ \hline D'C & B' & & D'D \end{array}\right),$$

from which the necessity of $D'D > 0$ for the left invertibility of $\boldsymbol{S}_{\breve{\mathcal{G}}}(z)$ is established.

If D is left invertible, then so is $\breve{D}$ and for any z the equation

$$\begin{bmatrix} \bar{H}_{11} - zI & ? \\ \bar{H}_{21} & ? \\ 0 & \breve{D}^*\breve{D} \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & \grave{C}^* \\ 0 & \breve{D}^* \end{bmatrix} \boldsymbol{S}_{\breve{\mathcal{G}}}(z) \begin{bmatrix} I & 0 \\ -(\breve{D}^*\breve{D})^{-1}\breve{D}^*\grave{C} & I \end{bmatrix}$$

holds. Therefore, taking into account the relationship between $\bar{H}$ and S from Proposition 3.3,

$$\dim\ker \boldsymbol{S}_{\breve{\mathcal{G}}}(z) = \dim\ker \begin{bmatrix} \bar{H}_{11} - zI \\ \bar{H}_{21} \end{bmatrix} = \dim\ker \begin{bmatrix} S_{11} - zI \\ S_{21} \end{bmatrix}.$$

Analogously, for any $s \in \mathbb{C}$

$$\dim\ker \boldsymbol{S}_{\mathcal{G}}(s) = \dim\ker \begin{bmatrix} H_{11} - sI \\ H_{21} \end{bmatrix}.$$

The proof is now completed by applying Proposition 3.2 to matrices $A_a = A - B(D'D)^{-1}D'C$, $B_a = B(D'D)^{-1/2}$, and $C_a = (I - D(D'D)^{-1}D')^{1/2}C$. □

In the solution of the sampled-data H^2 and H^∞ problems one is concerned with invariant zeros on the unit circle only. Consequently, the following two corollaries of Lemma 3.7 are formulated.

COROLLARY 3.8. *$\boldsymbol{S}_{\breve{\mathcal{G}}}(e^{j\theta})$ is left invertible $\forall\theta \in [0, 2\pi]$ iff $\det D'D \neq 0$ and $\boldsymbol{S}_{\mathcal{G}}(j\omega)$ is left invertible $\forall\omega \in \mathbb{R}$.*

COROLLARY 3.9. *$\boldsymbol{S}_{\breve{\mathcal{G}}}(e^{j\theta})$ is right invertible $\forall\theta \in [0, 2\pi]$ iff $\det DD' \neq 0$ and $\boldsymbol{S}_{\mathcal{G}}(j\omega)$ is right invertible $\forall\omega \in \mathbb{R}$.*

3.4. Riccati equation. The last topic of this section is to study the H^∞ DARE associated with $\breve{\mathcal{G}}$. For that purpose, consider the operator

$$\begin{bmatrix} \acute{B}_\gamma \\ \breve{D}_\gamma \end{bmatrix} \doteq \begin{bmatrix} \mathcal{I}_h^* & 0 \\ 0 & I \end{bmatrix} \left(\begin{array}{c|c} A & B_\gamma \\ \hline I & 0 \\ C & 0 \end{array}\right), \tag{3.2}$$

where B_γ is a given matrix of appropriate dimensions. Now, augment the "B" and "D" parameters of $\breve{\mathcal{G}}$ as follows:

$$\acute{B}_\alpha \doteq \begin{bmatrix} \acute{B}_\gamma & \acute{B} \end{bmatrix} \qquad \text{and} \qquad \breve{D}_\alpha \doteq \begin{bmatrix} \breve{D}_\gamma & \breve{D} \end{bmatrix}.$$

Consider the H^∞ DARE:

$$X = \bar{A}'X\bar{A} + \grave{C}^*\grave{C} - (\breve{D}_\alpha^*\grave{C} + \acute{B}_\alpha^*X\bar{A})^*(\breve{D}_\alpha^*\breve{D}_\alpha - E_{11} + \acute{B}_\alpha^*X\acute{B}_\alpha)^{-1}(\breve{D}_\alpha^*\grave{C} + \acute{B}_\alpha^*X\bar{A}), \tag{3.3}$$

where the partitioning of E_{11} corresponds to that of $\breve{D}_\alpha^* \breve{D}_\alpha$. It can be verified that, if $B_\gamma = 0$, then (3.3) becomes the standard H^2 DARE associated with $\breve{\mathcal{G}}$. Define the two matrices

$$M_\gamma \doteq \begin{bmatrix} -D'C & -B' & -D'D \\ A & B_\gamma B_\gamma' & B \\ -C'C & -A' & -C'D \end{bmatrix}$$

and

$$N_\gamma \doteq \begin{bmatrix} 0 & 0 & 0 \\ I & 0 & 0 \\ 0 & I & 0 \end{bmatrix}.$$

The relevant result can now be expressed as follows.

LEMMA 3.10. *The pair (M_γ, N_γ) is an extended Hamiltonian pair and the following statements are equivalent:*

(i) *The DARE* (3.3) *has a stabilizing solution X.*

(ii) $(M_\gamma, N_\gamma) \in \mathrm{dom}(Ric_{\mathbb{C}^-})$.

Moreover, if either of these conditions holds, then $(X, F_2) = Ric_{\mathbb{C}^-}(M_\gamma, N_\gamma)$,

$$\begin{bmatrix} \grave{F}_1 \\ \grave{F}_2 \end{bmatrix} \doteq -(\breve{D}_\alpha^* \breve{D}_\alpha - E_{11} + \acute{B}_\alpha^* X \acute{B}_\alpha)^{-1}(\breve{D}_\alpha^* \grave{C} + \acute{B}_\alpha^* X \bar{A})$$

$$= \left(\begin{array}{c|c} A + B_\gamma B_\gamma' X + BF_2 & I \\ \hline B_\gamma' X & 0 \\ F_2 & 0 \end{array} \right) \mathcal{I}_0,$$

and $\bar{A} + \acute{B}_\gamma \grave{F}_1 + \acute{B} \grave{F}_2 = e^{(A + B_\gamma B_\gamma' X + BF_2)h}$.

Proof. The proof is contained in [10]. □

REMARK 3.1. *It follows from Lemma* A.2 *that $(X, F_2) = Ric_{\mathbb{C}^-}(M_\gamma, N_\gamma)$ implies that X is actually the stabilizing solution of the H^∞* continuous-time *algebraic Riccati equation*

$$A'X + XA + C'C + XB_\gamma B_\gamma' X - (D'C + BX)'(D'D)^{-1}(D'C + BX) = 0$$

and $F_2 = -(D'D)^{-1}(D'C + BX)$. Thus, the DARE (3.3) *associated with the system $\breve{\mathcal{G}}$, augmented by $\acute{B}_\gamma$ and $\breve{D}_\gamma$ is, in a sense, equivalent to the CARE associated with $\mathcal{G}$, augmented by B_γ.*

4. System of the form $\mathcal{W}_h \mathcal{G} \mathcal{H}_h$. This section is concerned with systems of the form $\grave{\mathcal{G}} \doteq \mathcal{W}_h \mathcal{G} \mathcal{H}_h$, where $\mathcal{G}$ and $\mathcal{H}_h$ are given by (2.2) and (2.3), respectively. The transfer function of $\grave{\mathcal{G}}$ can be expressed as

$$\grave{G}(z) = \left[\begin{array}{c|c} \bar{A} & \bar{B} \\ \hline \grave{C} & \grave{D} \end{array} \right].$$

Here $\bar{A}$ and $\grave{C}$ are the same as for $\breve{\mathcal{G}}$, while $\bar{B} = \acute{B} \grave{\Phi}_H$ and $\grave{D} = \breve{D} \grave{\Phi}_H$. To ensure that the operator $\grave{D}$ is well defined as a mapping $\mathbb{R} \mapsto L^2[0, h]$, assume that

$$DD_H = 0.$$

The purpose of this section is to study the singularities of $\boldsymbol{S}_{\grave{\mathcal{G}}}(z)$ and $\boldsymbol{C}_{\grave{\mathcal{G}}}(z)$ and the H^∞ DARE associated with $\grave{\mathcal{G}}$. In particular, it is shown that, under the assumption

$\|\breve{D}_\gamma\|_2 < 1$, both the invariant zeros of $\grave{\mathcal{G}}$ and the stabilizing solution of its associated DARE can be characterized in terms of the matrices

$$\Sigma \doteq \exp\left(\begin{bmatrix} -A'_H & -C'_H D'C & -C'_H B' & -C'_H D' D C_H \\ 0 & A & B_\gamma B'_\gamma & BC_H \\ 0 & -C'C & -A' & -C'DC_H \\ 0 & 0 & 0 & A_H \end{bmatrix} h\right) = \begin{bmatrix} \Sigma_{11} & \Sigma_{12} & \Sigma_{13} & \Sigma_{14} \\ 0 & \Sigma_{22} & \Sigma_{23} & \Sigma_{24} \\ 0 & \Sigma_{32} & \Sigma_{33} & \Sigma_{34} \\ 0 & 0 & 0 & \Sigma_{44} \end{bmatrix}, \tag{4.1}$$

where B_γ is as defined in the previous section, and

$$M_H \doteq \begin{bmatrix} I & BD_H \\ 0 & B_H \end{bmatrix}.$$

When B_γ is sufficiently "small," including the case $B_\gamma = 0$, the uncontrollable modes of $\grave{\mathcal{G}}$ can also be expressed in terms of these matrices.

4.1. Preliminary results on $\mathcal{W}_h\mathcal{G}\mathcal{H}_h$. To study the properties of $\grave{\mathcal{G}}$, it is convenient to develop some preliminary results.

PROPOSITION 4.1. $\det \Sigma_{33} \neq 0$ *for any* B_γ *such that* $\|\breve{D}_\gamma\|_2 < 1$.

Proof. This is Theorem 13.5.1 in [3]. □

In order to formulate the next lemma, assume that $\|\breve{D}_\gamma\|_2 < 1$ and define the matrices

$$M_A \doteq \begin{bmatrix} \Sigma_{22} & \Sigma_{24} \end{bmatrix} - \Sigma_{23}\Sigma_{33}^{-1}\begin{bmatrix} \Sigma_{32} & \Sigma_{34} \end{bmatrix}, \tag{4.2a}$$

$$M_{12} \doteq -\begin{bmatrix} \Sigma_{33} & 0 \\ \Sigma_{13} & \Sigma_{11} \end{bmatrix}^{-1}\begin{bmatrix} \Sigma_{32} & \Sigma_{34} \\ \Sigma_{12} & \Sigma_{14} \end{bmatrix}, \tag{4.2b}$$

$$M_{21} \doteq \Sigma_{23}\Sigma_{33}^{-1}. \tag{4.2c}$$

PROPOSITION 4.2. *If* $\|\breve{D}_\gamma\|_2 < 1$, *then*

$$\begin{bmatrix} \bar{A} & \bar{B} \end{bmatrix} + \acute{B}_\gamma \breve{D}_\gamma^*(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\begin{bmatrix} \grave{C} & \grave{D} \end{bmatrix} = M_A M_H,$$

$$\begin{bmatrix} \grave{C}^* \\ \grave{D}^* \end{bmatrix}(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\begin{bmatrix} \grave{C} & \grave{D} \end{bmatrix} = M'_H M_{12} M_H,$$

and

$$\acute{B}_\gamma(I - \breve{D}_\gamma^*\breve{D}_\gamma)^{-1}\acute{B}_\gamma^* = M_{21}.$$

Proof. Under the additional assumption that $D_H = 0$, this lemma was established in section IV of [11]. The same arguments used there can be applied to establish the more general result. □

As shown next, manipulations with subblocks are facilitated by the symplectic structure of the matrix Σ.

PROPOSITION 4.3. *If* $\|\breve{D}_\gamma\|_2 < 1$, *then*

$$\begin{bmatrix} \Sigma_{33}^{-1} & 0 \\ 0 & \Sigma_{14} \end{bmatrix}' = \begin{bmatrix} I & 0 \\ -\Sigma'_{34} & \Sigma'_{44} \end{bmatrix}\left(\begin{bmatrix} \Sigma_{22} & \Sigma_{24} \\ \Sigma_{12} & \Sigma_{14} \end{bmatrix} - \begin{bmatrix} \Sigma_{23} \\ \Sigma_{13} \end{bmatrix}\Sigma_{33}^{-1}\begin{bmatrix} \Sigma_{32} & \Sigma_{34} \end{bmatrix}\right)\begin{bmatrix} I & \Sigma'_{13} \\ 0 & \Sigma'_{11} \end{bmatrix}.$$

Proof. From [18, section 21.3], two relevant properties hold for any symplectic matrix

$$S = \begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{bmatrix}$$

such that $\det S_{22} \neq 0$: *a)* $S_{11} = (S'_{22})^{-1} + S_{12}S_{22}^{-1}S_{21}$ and *b)* $S_{22}^{-1}S_{21}$ is symmetric. On the other hand, it is easy to see that the matrix

$$\begin{bmatrix} \Sigma_{22} & \Sigma_{24} & \Sigma_{23} & 0 \\ 0 & \Sigma_{44} & 0 & 0 \\ \Sigma_{32} & \Sigma_{34} & \Sigma_{33} & 0 \\ \Sigma_{12} & \Sigma_{14} & \Sigma_{13} & \Sigma_{11} \end{bmatrix} = \exp\left(\begin{bmatrix} A & BC_H & B_\gamma B'_\gamma & 0 \\ 0 & A_H & 0 & 0 \\ -C'C & -C'DC_H & -A' & 0 \\ -C'_H D'C & -C'_H D'DC_H & -C'_H B' & -A'_H \end{bmatrix} h \right)$$

is symplectic. Then, from the nonsingularity of Σ_{33} and $\Sigma_{11} = e^{-A'_H h}$, the formula in the proposition can be derived from (a) and (b). ∎

PROPOSITION 4.4. *If* $\|\breve{D}_\gamma\|_2 < 1$, *then*

$$\Upsilon \doteq -(\Sigma_{23}\Sigma_{33}^{-1})^{1/2}\Sigma_{33}\begin{bmatrix} I & 0 \end{bmatrix}\left(-\begin{bmatrix} \Sigma_{33} & 0 \\ \Sigma_{13} & \Sigma_{11} \end{bmatrix}^{-1}\begin{bmatrix} \Sigma_{32} & \Sigma_{34} \\ \Sigma_{12} & \Sigma_{14} \end{bmatrix}\right)^{1/2}$$

is a contraction, i.e., $\bar{\sigma}(\Upsilon) < 1$.

Proof. The matrix Υ is a contraction iff

$$I - \Upsilon\Upsilon' = I + (\Sigma_{23}\Sigma_{33}^{-1})^{1/2}\Sigma_{32}\Sigma'_{33}(\Sigma_{23}\Sigma_{33}^{-1})^{1/2} > 0.$$

Without loss of generality, the pair (A, B_γ) can be assumed to be controllable. (Otherwise the problem can be easily reduced to the one with controllable (A, B_γ) by an appropriate change of basis [3, section 13.5].) Since $\acute{B}_\gamma\acute{B}^*_\gamma = \int_0^h e^{A\tau}B_\gamma B'_\gamma e^{A'\tau}d\tau$, the controllability of (A, B_γ) and Proposition 4.2 yield $M_{21} > 0$. Then

$$\begin{aligned} I - \Upsilon\Upsilon' &= M_{21}^{-1/2}M_{21}(I + \Sigma_{32}\Sigma'_{23})M_{21}^{-1/2} \\ &= M_{21}^{-1/2}\Sigma_{22}(\Sigma_{22}^{-1}\Sigma_{23})\Sigma'_{22}M_{21}^{-1/2}, \end{aligned}$$

where the latter equality is obtained by using $I + \Sigma_{32}\Sigma'_{23} = \Sigma_{33}\Sigma'_{22}$, which, in turn, follows from Proposition 4.3.

Now, to prove the proposition one needs to prove that $\det \Sigma_{23} \neq 0$. To this end, introduce the operators

$$\begin{bmatrix} \grave{C}_a & \breve{D}_a \end{bmatrix} \doteq \left(\begin{array}{c|cc} -A' & I & C' \\ \hline B'_\gamma & 0 & 0 \end{array}\right)\begin{bmatrix} \mathcal{I}_0^* & 0 \\ 0 & I \end{bmatrix}.$$

By applying Proposition 4.2, one gets that $\grave{C}^*_a(I - \breve{D}_a\breve{D}^*_a)^{-1}\grave{C}_a = \Sigma_{22}^{-1}\Sigma_{23}$. Since $\grave{C}^*_a\grave{C}_a = \int_0^h e^{-A\tau}B_\gamma B'_\gamma e^{-A'\tau}d\tau$, the controllability of (A, B_γ) yields $I - \Upsilon\Upsilon' > 0$. ∎

4.2. Uncontrollable modes. The pencil $\boldsymbol{C}_{\grave{\mathcal{G}}}(z)$ is finite dimensional, and consequently its singularities can be characterized by calculating the matrices $\bar{A}$ and $\bar{B}$. This calculation follows from a direct corollary to Proposition 4.2.

LEMMA 4.5. *If* $B_\gamma = 0$, *then the matrix* $\boldsymbol{C}_{\grave{\mathcal{G}}}(z)$ *is right invertible iff* $[\Sigma_{22} - zI \;\; zBD_H + \Sigma_{24}B_H\,]$ *is right invertible.*

Lemma 4.5 gives a complete characterization of the uncontrollable modes of $\grave{\mathcal{G}}$ by calculating Σ under the assumption $B_\gamma = 0$. It turns out that this assumption is associated with the solution of an H^2 optimization, while the solution of the a corresponding H^∞ is based on Σ for a nonzero B_γ. Hence, the verification of stabilizability (and observability) of the system of interest in the H^∞ case might require additional computations. It is then of interest to characterize the stabilizability of $(\bar{A}, \bar{B})$ in terms of Σ for a $B_\gamma \neq 0$. To this end, for a given matrix F define the system

$$\breve{\mathcal{G}}_F \doteq \left[\begin{array}{c|c} \bar{A} + \bar{B}F & \acute{B}_\gamma \\ \hline \grave{C} + \grave{D}F & \breve{D}_\gamma \end{array}\right].$$

Lemma 4.6. *Whenever B_γ is such that $\|\breve{D}_\gamma\|_2 < 1$, the matrix $\boldsymbol{C}_{\hat{\mathcal{G}}}(z)$ is right invertible $\forall |z| \geq 1$ and there exists a matrix F such that $\|\breve{\mathcal{G}}_F\|_{H^\infty} < 1$ only if the matrix $\left[\begin{array}{cc} \Sigma_{22} - zI & zBD_H + \Sigma_{24}B_H \end{array}\right]$ is right invertible $\forall |z| \geq 1$.*

Proof. Denote by $\mathcal{S}_{sc}$ the set of all (discrete-time with either finite- or infinite-dimensional input-output spaces) systems, which are internally stable and have H^∞ norm < 1. Standard loop shifting and orthogonal projection arguments [1] give

$$\breve{\mathcal{G}}_F \in \mathcal{S}_{sc} \iff \mathcal{F}_\ell\big(\breve{\Theta}_\gamma, \breve{\mathcal{G}}_F\big) \in \mathcal{S}_{sc} \iff \bar{\mathcal{G}}_F \in \mathcal{S}_{sc},$$

where the unitary operator

$$\breve{\Theta}_\gamma \doteq \left[\begin{array}{cc} -\breve{D}_\gamma & (I - \breve{D}_\gamma \breve{D}_\gamma^*)^{1/2} \\ (I - \breve{D}_\gamma^* \breve{D}_\gamma)^{1/2} & \breve{D}_\gamma^* \end{array}\right] = (\breve{\Theta}_\gamma^*)^{-1}$$

is well defined and

$$\bar{\mathcal{G}}_F \doteq \left[\begin{array}{c|c} M_A M_H M_F & M_{21}^{1/2} \\ \hline M_{12}^{1/2} M_H M_F & 0 \end{array}\right],$$

where $M_F \doteq \left[\begin{smallmatrix} I \\ F \end{smallmatrix}\right]$. Since the matrix Υ defined in Proposition 4.4 is a contraction, there always exists a unitary dilation of Υ, say

$$\bar{\Theta} \doteq \left[\begin{array}{cc} ? & ? \\ ? & \Upsilon \end{array}\right] = (\bar{\Theta}')^{-1}.$$

Then,

$$\bar{\mathcal{G}}_F \in \mathcal{S}_{sc} \iff \mathcal{F}_\ell\big(\bar{\Theta}, \bar{\mathcal{G}}_F\big) \in \mathcal{S}_{sc}.$$

The corresponding "A"-matrix of $\mathcal{F}_\ell\big(\bar{\Theta}, \bar{\mathcal{G}}_F\big)$ is just

$$\left[\begin{array}{cc} \Sigma_{22} & \Sigma_{24} \end{array}\right] M_H M_F = \Sigma_{22} + \left[\begin{array}{cc} \Sigma_{22} & \Sigma_{24} \end{array}\right] \left[\begin{array}{c} BD_H \\ B_H \end{array}\right] F,$$

which implies that $(\bar{A}, \bar{B})$ is stabilizable and there exists F such that $\|\breve{\mathcal{G}}_F\|_{H^\infty} < 1$ only if the pair $(\Sigma_{22}, \Sigma_{22}BD_H + \Sigma_{24}B_H)$ is stabilizable. The latter, in turn, is equivalent to the right invertibility of the matrix pencil

$$\left[\begin{array}{cc} \Sigma_{22} - zI & \Sigma_{22}BD_H + \Sigma_{24}B_H \end{array}\right] = \left[\begin{array}{cc} \Sigma_{22} - zI & zBD_H + \Sigma_{24}B_H \end{array}\right] \left[\begin{array}{cc} I & BD_H \\ 0 & I \end{array}\right]$$

$\forall |z| \geq 1$, which proves the lemma. □

Lemma 4.6 actually establishes that the absence of the generalized eigenvalues outside the open unit disk of the pencil $\left[\begin{array}{cc} \Sigma_{22}-zI & zBD_H+\Sigma_{24}B_H \end{array}\right]$ is necessary to solve the (state feedback) H^∞ problem for the system

$$\left[\begin{array}{c|cc} \bar{A} & \acute{B}_\gamma & \bar{B} \\ \hline \grave{C} & \breve{D}_\gamma & \grave{D} \\ I & 0 & 0 \end{array}\right].$$

Since the solvability of the latter problem is necessary for the solvability of the corresponding H^∞ output feedback problem with a strictly proper controller, the $\mathbb{D}$-stabilizability of $(\bar{A},\bar{B})$ can be replaced with the condition above without loss of generality. Note also that the pencil above has exactly the same form as the corresponding pencil in Lemma 4.5. Thus, as $B_\gamma \to 0$ the condition of Lemma 4.6 becomes sufficient.

4.3. Invariant zeros. In principle, the invariant zeros of the natural realization of $\grave{\mathcal{G}}$ can be characterized by noting that

$$\ker \boldsymbol{S}_{\grave{\mathcal{G}}}(z) = \ker \left[\begin{array}{cc} \bar{A}-zI & \bar{B} \\ \grave{C}^*\grave{C} & \grave{C}^*\grave{D} \\ \grave{D}^*\grave{C} & \grave{D}^*\grave{D} \end{array}\right].$$

The matrices $\bar{A}$, $\bar{B}$, $\grave{C}^*\grave{C}$, $\grave{C}^*\grave{D}$, and $\grave{D}^*\grave{D}$ are given by Proposition 4.2 when $B_\gamma = 0$. These matrices are precisely the same calculated for the solution of the sampled-data H^2 problems. Unfortunately, as noticed in the discussion after Lemma 4.5, such an approach does not fit well into H^∞ optimization, since the matrices above are not required for the solution. Consequently, it is of interest to express singularities of $\boldsymbol{S}_{\grave{\mathcal{G}}}(z)$ in terms of the H^∞ data, i.e., in terms of Σ when $B_\gamma \neq 0$. Although incorporating a nonzero B_γ into the computations makes the derivations more involved, the final formulae are not more complicated than those obtained in the H^2 case. Moreover, when $B_\gamma = 0$ the formulae reduce to the H^2 ones.

LEMMA 4.7. *Whenever B_γ is such that $\|\breve{D}_\gamma\|_2 < 1$, the operator $\boldsymbol{S}_{\grave{\mathcal{G}}}(z)$ is left invertible iff the matrix*

$$\left[\begin{array}{cc} \Sigma_{22}-zI & zBD_H+\Sigma_{24}B_H \\ B_H'\Sigma_{44}'\Sigma_{12} & B_H'\Sigma_{44}'\Sigma_{14}B_H \\ \Sigma_{32} & \Sigma_{34}B_H \end{array}\right]$$

is left invertible.

Proof. It is clear that if $\|\breve{D}_\gamma\|_2 < 1$ then $\boldsymbol{S}_{\grave{\mathcal{G}}}(z)$ is left invertible iff the matrix

$$\left[\begin{array}{cc} I & \acute{B}_\gamma\breve{D}_\gamma \\ 0 & \grave{C}^* \\ 0 & \grave{D} \end{array}\right]\left[\begin{array}{cc} I & 0 \\ 0 & (I-\breve{D}_\gamma\breve{D}_\gamma^*)^{-1} \end{array}\right]\left[\begin{array}{cc} \bar{A}-zI & \bar{B} \\ \grave{C} & \grave{D} \end{array}\right] = \left[\begin{array}{c} M_AM_H - z\left[\begin{array}{cc} I & 0 \end{array}\right] \\ M_H'M_{12}M_H \end{array}\right]$$

is left invertible. Using (4.2) one can verify that the latter matrix is just the Schur complement of Σ_{33} in

$$M_e \doteq \left[\begin{array}{ccc} \Sigma_{22}-zI & \Sigma_{22}BD_H+\Sigma_{24}B_H & ? \\ 0 & 0 & I \\ -B_H'\Sigma_{44}'\Sigma_{12} & -B_H'\Sigma_{44}'\Sigma_{12}BD_H - B_H'\Sigma_{44}'\Sigma_{14}B_H & ? \\ \Sigma_{32} & \Sigma_{32}BD_H+\Sigma_{34}B_H & \Sigma_{33} \end{array}\right],$$

where ? denotes irrelevant blocks. Therefore, and as $\det \Sigma_{33} \neq 0$, the left invertibility of the operator of interest is equivalent to the left invertibility of M_e. The latter, in turn, is equivalent to the left invertibility of the Schur complement of the identity I in M_e, i.e.,

$$\begin{bmatrix} \Sigma_{22} - zI & zBD_H + \Sigma_{24}B_H \\ -B'_H\Sigma'_{44}\Sigma_{12} & -B'_H\Sigma'_{44}\Sigma_{14}B_H \\ \Sigma_{32} & \Sigma_{34}B_H \end{bmatrix} \begin{bmatrix} I & BD_H \\ 0 & I \end{bmatrix}.$$

This completes the proof. □

REMARK 4.1. *The test in Lemma* 4.7 *can be simplified if additional assumptions are made about the hold function* ϕ_H. *In particular, when* B_H *is square and invertible and* $D_H = 0$, *the pencil reduces to*

$$\begin{bmatrix} \Sigma_{22} - zI & \Sigma_{24} \\ \Sigma_{12} & \Sigma_{14} \\ \Sigma_{32} & \Sigma_{34} \end{bmatrix},$$

while, when $B_H = 0$ *and* $D_H = I$, *the pencil becomes*

$$\begin{bmatrix} \Sigma_{22} - zI & zB \\ \Sigma_{32} & 0 \end{bmatrix}.$$

4.4. Riccati equation. The final derivations of the section are again devoted to the Riccati equation associated with the system. Consider the DARE

$$\begin{aligned} X &= \bar{A}'X\bar{A} + \grave{C}^*\grave{C} \\ &\quad - (\breve{D}^*_\beta\grave{C} + \acute{B}^*_\beta X\bar{A})^*(\breve{D}^*_\beta\breve{D}_\beta - E_{11} + \acute{B}^*_\beta X\acute{B}_\beta)^{-1}(\breve{D}^*_\beta\grave{C} + \acute{B}^*_\beta X\bar{A}), \end{aligned} \tag{4.3}$$

where $\acute{B}_\beta \doteq \begin{bmatrix} \acute{B}_\gamma & \bar{B} \end{bmatrix}$ and $\breve{D}_\beta \doteq \begin{bmatrix} \breve{D}_\gamma & \grave{D} \end{bmatrix}$. This DARE appears when treating the H^∞ problem with fixed hold. Although the equation can be made finite dimensional by computing an LU-decomposition of the operator $\breve{D}^*_\beta\breve{D}_\beta - E_{11} + \acute{B}^*_\beta X\acute{B}_\beta$, the intermediate steps involved in the calculations severely limit any further analysis. Instead, (4.3) can be replaced by an extended symplectic matrix pair, with the advantage that the stabilizing solution can be characterized in terms of the subblocks of the matrix Σ. Moreover, this approach allows the derivation of the formula for the "gain"

$$\grave{F} \doteq -(\breve{D}^*_\beta\breve{D}_\beta - E_{11} + \acute{B}^*_\beta X\acute{B}_\beta)^{-1}(\breve{D}^*_\beta\grave{C} + \acute{B}^*_\beta X\bar{A}) = \begin{bmatrix} \grave{F}_1 \\ \bar{F}_2 \end{bmatrix},$$

required for the lifted solution in [12].

To this end we define the following two matrices:

$$M_\gamma \doteq \begin{bmatrix} B'_H\Sigma'_{44}\Sigma_{12} & B'_H\Sigma'_{44}\Sigma_{13} & B'_H\Sigma'_{44}\Sigma_{14} \\ \Sigma_{22} & \Sigma_{23} & \Sigma_{24} \\ \Sigma_{32} & \Sigma_{33} & \Sigma_{34} \end{bmatrix} \begin{bmatrix} I & 0 & BD_H \\ 0 & I & 0 \\ 0 & 0 & B_H \end{bmatrix} - \begin{bmatrix} 0 & D'_HB' & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

and

$$N_\gamma \doteq \begin{bmatrix} 0 & 0 & 0 \\ I & 0 & 0 \\ 0 & I & 0 \end{bmatrix}.$$

The main results concerning the DARE (4.3) can now be stated.

LEMMA 4.8. *Whenever B_γ is such that $\|\breve{D}_\gamma\|_2 < 1$, the pair (M_γ, N_γ) is an extended symplectic pair, and the following statements are equivalent:*

(i) *The DARE* (4.3) *has a stabilizing solution X.*

(ii) $(M_\gamma, N_\gamma) \in \mathrm{dom}(Ric_{\mathbb{D}})$.

Moreover, if either of these conditions holds, then $(X, \bar{F}_2) = Ric_{\mathbb{D}}(M_\gamma, N_\gamma)$,

$$\grave{F}_1 = \left(\begin{array}{ccc|c} A & B_\gamma B_\gamma' & BC_H & I + BD_H\bar{F}_2 \\ -C'C & -A' & -C'DC_H & X \\ 0 & 0 & A_H & B_H\bar{F}_2 \\ \hline 0 & B_\gamma' & 0 & 0 \end{array}\right)\mathcal{I}_0, \tag{4.4}$$

and $\bar{A} + \acute{B}_\gamma\grave{F}_1 + \bar{B}\bar{F}_2 = \Sigma_{22} + \Sigma_{23}X + (\Sigma_{22}BD_H + \Sigma_{24}B_H)\bar{F}_2$.

Proof. As follows from Lemma A.1, the solvability of the DARE (4.3) is equivalent to the condition $(M_a, N_a) \in \mathrm{dom}(Ric_{\mathbb{D}})$, where

$$M_a \doteq \begin{bmatrix} \bar{A} + \acute{B}_\gamma\breve{D}_\gamma^*(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\grave{C} & 0 & \bar{B} + \acute{B}_\gamma\breve{D}_\gamma^*(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\grave{D} \\ \grave{C}^*(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\grave{C} & -I & \grave{C}^*(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\grave{D} \\ \grave{D}^*(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\grave{C} & 0 & \grave{D}^*(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\grave{D} \end{bmatrix}$$

and

$$N_a \doteq \begin{bmatrix} I & -\acute{B}_\gamma(I - \breve{D}_\gamma^*\breve{D}_\gamma)^{-1}\acute{B}_\gamma^* & 0 \\ 0 & -(\bar{A} + \acute{B}_\gamma\breve{D}_\gamma^*(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\grave{C})' & 0 \\ 0 & -(\bar{B} + \acute{B}_\gamma\breve{D}_\gamma^*(I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1}\grave{D})' & 0 \end{bmatrix}.$$

Denote by (M_b, N_b) the matrix pair obtained by the permutation of the second and the third columns of (M_a, N_a). Then, using Proposition 4.2, we have that

$$(M_b, N_b) = \left(\begin{bmatrix} M_A M_H & 0 \\ M_H' M_{12} M_H & -E_1 \end{bmatrix}, \begin{bmatrix} E_1' & -M_{21} \\ 0 & -M_H' M_A' \end{bmatrix}\right).$$

Furthermore, using Proposition 4.3,

$$M_A' = \begin{bmatrix} I \\ -\Sigma_{11}^{-1}\Sigma_{13} \end{bmatrix}\Sigma_{33}^{-1}.$$

Then, taking into account (4.2) and the fact that $\Sigma_{11}^{-1} = \Sigma_{44}'$, one verifies

$$\begin{gathered} M_A - \Sigma_{23}E_1'M_{12} = \begin{bmatrix} \Sigma_{22} & \Sigma_{24} \end{bmatrix}, \\ M_{21} - \Sigma_{23}E_1'M_A' = 0, \\ MM_H'M_{12} = -\begin{bmatrix} I & 0 \\ 0 & B_H'\Sigma_{44}' \end{bmatrix}\begin{bmatrix} \Sigma_{32} & \Sigma_{34} \\ \Sigma_{12} & \Sigma_{14} \end{bmatrix}, \end{gathered}$$

and

$$MM_H'M_A' = E_1,$$

where

$$M \doteq \begin{bmatrix} \Sigma_{33} & 0 \\ B_H'\Sigma_{44}'\Sigma_{13} & I \end{bmatrix}\begin{bmatrix} I & 0 \\ -D_H'B' & I \end{bmatrix}.$$

With these formulae, the equivalence of $Ric_{\mathbb{D}}(M_a, N_a)$ and $Ric_{\mathbb{D}}(M_\gamma, N_\gamma)$ follows by premultiplying the pair (M_b, N_b) by the (nonsingular) matrix $\left[\begin{smallmatrix} I & -\Sigma_{23}E_1' \\ 0 & -M \end{smallmatrix}\right]$ and permuting the second and the third block columns of the resulting pair.

Consider now the operator $\grave{F}_1$ which, by Lemma A.1 in the appendix, is given by

$$\grave{F}_1 = \big(I - \breve{D}_\gamma^* \breve{D}_\gamma - \acute{B}_\gamma^* X \acute{B}_\gamma\big)^{-1}\big(\breve{D}_\gamma^* \grave{C} + \acute{B}_\gamma^* X \bar{A} + (\breve{D}_\gamma^* \grave{D} + \grave{B}_\gamma^* X \bar{B})\bar{F}_2\big),$$

where the operator to be inverted is nonsingular. Note, that $\bar{B} = \acute{B}\grave{\Phi}_H$ and $\grave{D} = \breve{D}\grave{\Phi}_H$ and introduce the following two operators:

$$\begin{aligned} \breve{O}_1 &\doteq \breve{D}_\gamma^* \breve{D}_\gamma + \acute{B}_\gamma^* X \acute{B}_\gamma, \\ \breve{O}_2 &\doteq \breve{D}_\gamma^* \left[\begin{smallmatrix} \grave{C} & \breve{D} \end{smallmatrix}\right] + \acute{B}_\gamma^* X \left[\begin{smallmatrix} \bar{A} & \acute{B} \end{smallmatrix}\right]. \end{aligned}$$

Applying Proposition 2.2 to these operators,

$$\breve{O}_1 = \left(\begin{array}{cc|c|c} A & 0 & \left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right] \rightleftharpoons \left[\begin{smallmatrix} 0 & 0 \\ -X & I \end{smallmatrix}\right] & B_\gamma \\ -C'C & -A' & & 0 \\ \hline 0 & B_\gamma' & & 0 \end{array}\right),$$

$$\breve{O}_2 = \left(\begin{array}{cc|c|cc} A & 0 & \left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right] \rightleftharpoons \left[\begin{smallmatrix} 0 & 0 \\ -X & I \end{smallmatrix}\right] & I & B \\ -C'C & -A' & & 0 & -C'D \\ \hline 0 & B_\gamma' & & 0 & 0 \end{array}\right) \left[\begin{smallmatrix} \mathcal{I}_0 & 0 \\ 0 & I \end{smallmatrix}\right]$$

and then, according to Proposition 2.1,

$$(I - \breve{O}_1)^{-1}\breve{O}_2 = \left(\begin{array}{cc|c|cc} A & B_\gamma B_\gamma' & \left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right] \rightleftharpoons \left[\begin{smallmatrix} 0 & 0 \\ -X & I \end{smallmatrix}\right] & I & B \\ -C'C & -A' & & 0 & -C'D \\ \hline 0 & B_\gamma' & & 0 & 0 \end{array}\right) \left[\begin{smallmatrix} \mathcal{I}_0 & 0 \\ 0 & I \end{smallmatrix}\right]$$

and the nonsingularity of $I - \breve{O}_1$ is equivalent to the nonsingularity of $\Sigma_{33} - X\Sigma_{23}$. Since

$$\left[\begin{smallmatrix} \mathcal{I}_0 & 0 \\ 0 & I \end{smallmatrix}\right] \left[\begin{smallmatrix} I \\ \grave{\Phi}_H \bar{F}_2 \end{smallmatrix}\right] = \left(\begin{array}{c|c} A_H & B_H\bar{F}_2 \\ \hline 0 & I \\ C_H & D_H\bar{F}_2 \end{array}\right)\mathcal{I}_0$$

and $DD_H = 0$, one gets

$$\grave{F}_1 = \left(\begin{array}{ccc|c|c} A & B_\gamma B_\gamma' & BC_H & \left[\begin{smallmatrix} I & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & I \end{smallmatrix}\right] \rightleftharpoons \left[\begin{smallmatrix} 0 & 0 & 0 \\ -X & I & 0 \\ 0 & 0 & 0 \end{smallmatrix}\right] & I + BD_H\bar{F}_2 \\ -C'C & -A' & -C'DC_H & & 0 \\ 0 & 0 & A_H & & B_H\bar{F}_2 \\ \hline 0 & B_\gamma' & 0 & & 0 \end{array}\right)\mathcal{I}_0.$$

Now (4.4) follows from

$$X = -(\Sigma_{33} - X\Sigma_{23})^{-1}\big((\Sigma_{32} - X\Sigma_{22})(I + BD_H\bar{F}_2) + (\Sigma_{34} - X\Sigma_{24})B_H\bar{F}_2\big),$$

which, in turn, can easily be derived form the fact that $\operatorname{Im}\left[\begin{smallmatrix} I & X & \bar{F}_2' \end{smallmatrix}\right]'$ is the stable deflating subspace of the pencil $M_\gamma - \lambda N_\gamma$. The latter fact also leads to the equality for $\bar{A} + \acute{B}_\beta \grave{F}$. □

REMARK 4.2. *As in the cases of the uncontrollable modes and invariant zeros, additional assumptions on the hold function ϕ_H may substantially simplify the form of the matrix M_γ. In the case where $D_H = 0$ and $B_H = I$ it becomes*

$$M_\gamma = \begin{bmatrix} \Sigma_{12} & \Sigma_{13} & \Sigma_{14} \\ \Sigma_{22} & \Sigma_{23} & \Sigma_{24} \\ \Sigma_{32} & \Sigma_{33} & \Sigma_{34} \end{bmatrix},$$

while for $D_H = I$ and $B_H = 0$

$$M_\gamma = \begin{bmatrix} 0 & B' & 0 \\ \Sigma_{22} & \Sigma_{23} & \Sigma_{22}B \\ \Sigma_{32} & \Sigma_{33} & \Sigma_{32}B \end{bmatrix}.$$

5. Coupling condition. Consider the inequality

$$\left\| \begin{bmatrix} X^{1/2} & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} \bar{A} & \acute{B}_\gamma \\ \grave{C} & \breve{D}_\gamma \end{bmatrix} \begin{bmatrix} Y^{1/2} & 0 \\ 0 & I \end{bmatrix} \right\|_2 < 1, \tag{5.1}$$

where $X = X' \geq 0$ and $Y = Y' \geq 0$ are given matrices and

$$\begin{bmatrix} \bar{A} & \acute{B}_\gamma \\ \grave{C} & \breve{D}_\gamma \end{bmatrix} = \begin{bmatrix} \mathcal{I}_h^* & 0 \\ 0 & I \end{bmatrix} \left(\begin{array}{c|cc} A & I & B_\gamma \\ \hline I & 0 & 0 \\ C & 0 & 0 \end{array} \right) \begin{bmatrix} \mathcal{I}_0 & 0 \\ 0 & I \end{bmatrix}.$$

This is actually the coupling condition for the solutions X and Y of the H^∞ DAREs, which appears in the solution of the sampled-data H^∞ problem (see [12, Theorem 2]). The purpose of this section is to express inequality (5.1) in terms of the matrix

$$\begin{bmatrix} \Sigma_{22} & \Sigma_{23} \\ \Sigma_{32} & \Sigma_{33} \end{bmatrix},$$

defined by (4.1), which can be readily computed.

LEMMA 5.1. *Whenever B_γ is such that $\|\breve{D}_\gamma\|_2 < 1$, inequality* (5.1) *holds iff the following three inequalities hold:*

(a) $\rho(X\,\Sigma_{23}\Sigma_{33}^{-1}) < 1$*;*

(b) $\rho(\Sigma_{33}^{-1}\Sigma_{32}Y) < 1$*;*

(c) $\rho(Y(\Sigma_{33} + \Sigma_{32}Y)^{-1}X(\Sigma'_{33} - \Sigma'_{23}X)^{-1}) < 1$.

Proof. Consider the following two operators: $\acute{O}_X \doteq X^{1/2}\acute{B}_\gamma(I - \breve{D}_\gamma^*\breve{D}_\gamma)^{-1/2}$ and $\grave{O}_Y \doteq (I - \breve{D}_\gamma\breve{D}_\gamma^*)^{-1/2}\grave{C}Y^{1/2}$. By standard dilation theory [18, section 2.11], the inequality (5.1) holds iff the matrix

$$M_a \doteq (I - \acute{O}_X\acute{O}_X^*)^{-1/2}(X^{1/2}\bar{A}Y^{1/2} + \acute{O}_X\breve{D}_\gamma^*\grave{O}_Y)(I - \grave{O}_Y^*\grave{O}_Y)^{-1/2}$$

is well defined and a contraction, i.e., $\bar{\sigma}(M_a) < 1$. By Proposition 4.2,

$$\acute{O}_X\acute{O}_X^* = X^{1/2}\Sigma_{23}\Sigma_{33}^{-1}X^{1/2} \qquad \text{and} \qquad \grave{O}_Y^*\grave{O}_Y = -Y^{1/2}\Sigma_{33}^{-1}\Sigma_{32}Y^{1/2}.$$

Consequently, M_a is well defined iff conditions (a) and (b) hold. Using Propositions 4.2 and 4.3 one gets

$$X^{1/2}\bar{A}Y^{1/2} + \acute{O}_X\breve{D}_\gamma^*\grave{O}_Y = X^{1/2}(\Sigma'_{33})^{-1}Y^{1/2}.$$

Then, since for any matrices M_1 and M_2 of appropriate dimensions $\rho(M_1M_2) = \rho(M_2M_1)$ and the matrix $\Sigma_{23}\Sigma_{33}^{-1}$ is symmetric,

$$\rho(M_aM_a') = \rho\big(Y(\Sigma_{33} + \Sigma_{32}Y)^{-1}X(\Sigma'_{33} - \Sigma'_{23}X)^{-1}\big).$$

The equality $\bar{\sigma}(M_a) = \rho(M_aM_a')$ concludes the proof. ∎

6. Conclusions. In this paper, several properties of systems represented in the lifted domain have been presented. The material considered was originally worked out for solving H^2 and H^∞ optimization problems for sampled-data systems. Eventually, it evolved to include results about systems in the lifted domain of independent general interest.

Appendix. The Riccati operators. The role of extended symplectic and Hamiltonian matrix pairs for solving algebraic Riccati equations has been extensively considered in the literature. See, for instance, [16, 14, 6]. The purpose of this appendix is to present a brief introduction to the results used in the paper.

Recall that the ordered pair of $(2n+m)\times(2n+m)$ matrices (M,N) is called an extended symplectic matrix pair (ESMP) if the associated matrix pencil $M-\lambda N$ verifies the following:

(a) $\det(M-\lambda N)\not\equiv 0$.

(b) If $\lambda\notin\{0,\infty\}$ is a generalized eigenvalue of $M-\lambda N$ of multiplicity r, then so is $\frac{1}{\lambda}$.

(c) If 0 is an eigenvalue of M of multiplicity r, then it is an eigenvalue of N of multiplicity $r+m$.

An ESMP is said to be *dichotomic* if the associated matrix pencil has no generalized eigenvalues on the unit circle. If an ESMP (M,N) is dichotomic, then the pencil $M-\lambda N$ has n eigenvalues in $\mathbb{D}$. Consider the n-dimensional deflating subspace $\mathcal{X}_{\mathbb{D}}(M,N)$ corresponding to eigenvalues in $\mathbb{D}$. It is obvious that

$$\mathcal{X}_{\mathbb{D}}(M,N)=\operatorname{Im}\begin{bmatrix}X_1\\X_2\\X_3\end{bmatrix},$$

where $X_1,X_2\in\mathbb{R}^{n\times n}$, $X_3\in\mathbb{R}^{m\times n}$, and

$$M\begin{bmatrix}X_1\\X_2\\X_3\end{bmatrix}=N\begin{bmatrix}X_1\\X_2\\X_3\end{bmatrix}A_{st},\qquad \sigma(A_{st})\in\mathbb{D}.$$

A dichotomic ESMP is said to be disconjugate if the matrix X_1 is nonsingular. When an ESMP is disconjugate, it is possible to set $X\doteq X_2X_1^{-1}$ and $F\doteq X_3X_1^{-1}$. Since X and F can be uniquely determined from (M,N), it is possible to define the function $Ric_{\mathbb{D}}:(M,N)\to(X,F)$, and set $(X,F)=Ric_{\mathbb{D}}(M,N)$. The domain of $Ric_{\mathbb{D}}$, denoted $\operatorname{dom}(Ric_{\mathbb{D}})$, then consists of all disconjugate ESMP.

Consider now the following DARE, associated with the state feedback H^∞ (or H^2, when $\gamma=\infty$) control problem:

$$X=A'XA+C'C-(D'C+B'XA)'R_\gamma(X)^{-1}(D'C+B'XA), \tag{A.1}$$

where $B\doteq\begin{bmatrix}B_1 & B_2\end{bmatrix}$ and $D\doteq\begin{bmatrix}D_1 & D_2\end{bmatrix}$, and

$$R_\gamma(X)\doteq D'D-\gamma^2E_{11}+B'XB.$$

A solution X_γ of (A.1) is said to be *stabilizing* if $X_\gamma=X_\gamma'$, the matrix $R_\gamma(X_\gamma)$ is nonsingular, and the matrix $A+BF_\gamma$ is Schur, where

$$F_\gamma\doteq-R_\gamma(X_\gamma)^{-1}(D'C+B'X_\gamma A)=\begin{bmatrix}F_{\gamma1}\\F_{\gamma2}\end{bmatrix}.$$

The next lemma, borrowed from [8], establishes a strong equivalence between the stabilizing solution of the DARE (A.1) and an associated ESMP.

LEMMA A.1. *Assume that* $\bar{\sigma}(D_1) < \gamma$ *and form the matrix pair*

$$(M_\gamma, N_\gamma) \doteq \left(\begin{bmatrix} A_\gamma & 0 & B_\gamma \\ C'R_\gamma C & -I & C'R_\gamma D_2 \\ D_2'R_\gamma C & 0 & D_2'R_\gamma D_2 \end{bmatrix}, \begin{bmatrix} I & -B_1\tilde{R}_\gamma B_1' & 0 \\ 0 & -A_\gamma' & 0 \\ 0 & -B_\gamma' & 0 \end{bmatrix} \right),$$

where $R_\gamma \doteq (I - \gamma^{-2}D_1D_1')^{-1}$, $\tilde{R}_\gamma \doteq (\gamma^2 I - D_1'D_1)^{-1}$, *and*

$$\begin{bmatrix} A_\gamma & B_\gamma \end{bmatrix} \doteq \begin{bmatrix} A & B_2 \end{bmatrix} + \gamma^{-2}B_1D_1'R_\gamma \begin{bmatrix} C & D_2 \end{bmatrix}.$$

Then (M_γ, N_γ) *is ESMP and the following two statements are equivalent:*

(i) $(M_\gamma, N_\gamma) \in \mathrm{dom}(Ric_{\mathbb{D}})$.

(ii) *The DARE* (A.1) *has a (unique) stabilizing solution* X_γ.

Moreover, if either of these conditions holds, then $\det(\gamma^2 I - D_1'D_1 - B_1'X_\gamma B_1) \neq 0$,

$$(X_\gamma, F_{\gamma 2}) = Ric_{\mathbb{D}}(M_\gamma, N_\gamma),$$

and

$$F_{\gamma 1} = (\gamma^2 I - D_1'D_1 - B_1'X_\gamma B_1)^{-1}\big(D_1'C + B_1'X_\gamma A + (D_1'D_2 + B_1'X_\gamma B_2)F_{\gamma 2}\big).$$

The ordered pair of $(2n+m) \times (2n+m)$ matrices (M, N) is called an *extended Hamiltonian matrix pair* (EHMP) if the associated matrix pencil $M - \lambda N$ verifies the following.

(a) $\det(M - \lambda N) \not\equiv 0$.

(b) If $\lambda \neq \infty$ is a generalized eigenvalue of $M - \lambda N$ of multiplicity r, then so is $-\lambda$.

(c) 0 is an eigenvalue of N of multiplicity m.

By an analogy with ESMP, an EHMP is said to be *dichotomic* if the associated matrix pencil has no generalized eigenvalues on the imaginary axis. When the EHMP (M, N) is dichotomic, the pencil $M - \lambda N$ has n eigenvalues in $\mathbb{C}^-$. Consider the n-dimensional deflating subspace $\mathcal{X}_{\mathbb{C}^-}(M, N)$ corresponding to eigenvalues in $\mathbb{C}^-$, and write

$$\mathcal{X}_{\mathbb{C}^-}(M, N) = \mathrm{Im} \begin{bmatrix} X_1 \\ X_2 \\ X_3 \end{bmatrix},$$

where $X_1, X_2 \in \mathbb{R}^{n\times n}$, $X_3 \in \mathbb{R}^{m\times n}$, and

$$M \begin{bmatrix} X_1 \\ X_2 \\ X_3 \end{bmatrix} = N \begin{bmatrix} X_1 \\ X_2 \\ X_3 \end{bmatrix} A_{st}, \qquad \sigma(A_{st}) \in \mathbb{C}^-.$$

A dichotomic EHMP is said to be *disconjugate* if the matrix X_1 is nonsingular. For a disconjugate EHMP, set $X \doteq X_2X_1^{-1}$ and $F \doteq X_3X_1^{-1}$, and define the function $Ric_{\mathbb{C}^-} : (M, N) \to (X, F)$; thus $(X, F) = Ric_{\mathbb{C}^-}(M, N)$. The domain of $Ric_{\mathbb{C}^-}$, denoted $\mathrm{dom}(Ric_{\mathbb{C}^-})$, then consists of all disconjugate EHMP.

Hamiltonian pairs play a role in the analysis of CAREs similar to the one ESMPs play in the analysis of DAREs. Consider a CARE in general form:

$$A'X + XA + C'C - (B'X + D'C)'\big(D'D - \gamma^2 E_{11}\big)^{-1}(B'X + D'C) = 0, \tag{A.2}$$

where, again, $B \doteq \begin{bmatrix} B_1 & B_2 \end{bmatrix}$ and $D \doteq \begin{bmatrix} D_1 & D_2 \end{bmatrix}$. For finite γ this equation is the so-called H^∞ CARE, while as $\gamma \to \infty$ (A.2) becomes the H^2 CARE, associated with the state feedback problems. A solution X_γ of (A.2) is said to be *stabilizing* if $X_\gamma = X'_\gamma$, and the matrix $A + BF_\gamma$ is Hurwitz, where

$$F_\gamma \doteq -\big(D'D - \gamma^2 E_{11}\big)^{-1}(D'C + B'X_\gamma) = \begin{bmatrix} F_{\gamma 1} \\ F_{\gamma 2} \end{bmatrix}.$$

The following lemma, which establishes a strong equivalence between the stabilizing solution of the CARE (A.2) and an associated EHMP, can be formulated.

LEMMA A.2. *Assume that $\bar\sigma(D_1) < \gamma$ and form the matrix pair*

$$(M_\gamma, N_\gamma) \doteq \left(\begin{bmatrix} A_\gamma & B_1\tilde R_\gamma B_1' & B_\gamma \\ -C'R_\gamma C & -A'_\gamma & -C'R_\gamma D_2 \\ -D_2'R_\gamma C & -B'_\gamma & -D_2'R_\gamma D_2 \end{bmatrix}, \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & 0 \end{bmatrix} \right),$$

where $R_\gamma \doteq (I - \gamma^{-2}D_1D_1')^{-1}$, $\tilde R_\gamma \doteq (\gamma^2 I - D_1'D_1)^{-1}$, and

$$\begin{bmatrix} A_\gamma & B_\gamma \end{bmatrix} \doteq \begin{bmatrix} A & B_2 \end{bmatrix} + \gamma^{-2}B_1D_1'R_\gamma \begin{bmatrix} C & D_2 \end{bmatrix}.$$

Then (M_γ, N_γ) is EHMP and the following two statements are equivalent:

(i) $(M_\gamma, N_\gamma) \in \mathrm{dom}(Ric_{\mathbb{C}^-})$.

(ii) *D_2 has full column rank and the CARE* (A.2) *has a (unique) stabilizing solution X_γ.*

Moreover, if either of these conditions holds, then

$$(X_\gamma, F_{\gamma 2}) = Ric_{\mathbb{C}^-}(M_\gamma, N_\gamma)$$

and

$$F_{\gamma 1} = (\gamma^2 I - D_1'D_1)^{-1}\big(D_1'(C + D_2F_{\gamma 2}) + B_1'X_\gamma\big).$$

WEAK SHARP MINIMA: CHARACTERIZATIONS AND SUFFICIENT CONDITIONS*

MARCIN STUDNIARSKI† AND DOUG E. WARD‡

Abstract. The problem of identifying weak sharp minima of order m, an important class of (possibly) nonisolated minima, is investigated in this paper. Some sufficient conditions for weak sharp minimality in nonsmooth mathematical programming are presented, and some characterizations of weak sharp minimality are obtained, with special attention given to orders one and two. It is also demonstrated that two of these sufficient conditions guarantee exactness of an l_1 penalty function. A key role in this paper is played by two geometric concepts: the limiting proximal normal cone and a generalization of the contingent cone.

Key words. weak sharp minimizer of order m, normal cone, contingent cone, directional derivative, subdifferential, exact penalty function

1. Introduction.

This paper is devoted to the study of a special type of minimizer for the mathematical program

$$\min\{f(x) \mid x \in C\}, \tag{1.1}$$

where $f : \mathbb{R}^n \to \overline{\mathbb{R}} := [-\infty, +\infty]$ and C is a nonempty subset of $\mathbb{R}^n$.

DEFINITION 1.1 (see [7]). *Let $\|\cdot\|$ be the Euclidean norm on $\mathbb{R}^n$. Suppose that f is finite and constant on the set $S \subset \mathbb{R}^n$, and let $\bar{x} \in S \cap C$ and $m \geq 1$. For $x \in \mathbb{R}^n$, let*

$$\operatorname{dist}^m(x, S) := \inf\big\{ \|y - x\|^m \mid y \in S \big\}.$$

(a) *We say that $\bar{x}$ is a* weak sharp minimizer of order m *for* (1.1) *if there exists $\beta > 0$ such that*

$$f(x) - f(\bar{x}) \geq \beta \operatorname{dist}^m(x, S) \quad \forall x \in C. \tag{1.2}$$

(b) *For $\varepsilon > 0$, let $B(x, \varepsilon) := \{y \in \mathbb{R}^n \mid \|y - x\| \leq \varepsilon\}$. We say that $\bar{x}$ is a* weak sharp local minimizer of order m *for* (1.1) *if there exist $\beta > 0$ and $\varepsilon > 0$ such that*

$$f(x) - f(\bar{x}) \geq \beta \operatorname{dist}^m(x, S) \quad \forall x \in C \cap B(\bar{x}, \varepsilon). \tag{1.3}$$

As an illustration of Definition 1.1, consider $f : \mathbb{R}^2 \to \mathbb{R}$ defined by $f(x, y) = |x|^m$ for $m \geq 1$. Let $C = \mathbb{R}^2$ and $S = \{(0, y) \mid y \in \mathbb{R}\}$. Then each element of S is a weak sharp minimizer of order m for (1.1).

Weak sharp minima occur in many optimization problems. For example, every minimizer of a linear program is a weak sharp minimizer of order one. Burke and

Ferris [7] have shown that solutions of certain convex quadratic programs and linear complementarity problems are weak sharp minima of order one and that many optimization algorithms exhibit finite termination at weak sharp minima. Weak sharp minima of higher order are of great interest in sensitivity analysis in nonlinear programming [4], [5], [14], [15], [23], [24]; in particular, the presence of weak sharp minima in a parametric nonlinear program leads to Hölder continuity properties of the solution set multifunction [15].

In the case where S is the singleton $\{\bar{x}\}$, Definition 1.1 reduces to a familiar concept (see [2], [17], [26], [27], [28], and references therein). In this case, we will call $\bar{x}$ a *strict minimizer of order* m. When $m = 2$, such minimizers are also called strong minimizers, and when $m = 1$, they are called sharp minimizers or strongly unique minimizers.

How can weak sharp minima be identified? It is well known that standard sufficient conditions for minimality (e.g., [10, Theorem 4] for $m = 2$) are sufficient for strict minimality of order m; in fact, they often characterize strict minimality of order m in the presence of a constraint qualification [3], [25], [28]. For the more difficult case of nonisolated minima, this question has been the focus of much recent attention. Burke and Ferris [7] have developed general necessary conditions for weak sharp minima of order one and have shown that those conditions provide characterizations of weak sharp minimality of order one when f, C, and S are convex. Bonnans and Ioffe [4], [5] have derived sufficient conditions and characterizations for weak sharp minimality of order two in the case where f is a pointwise maximum of C^2 functions. In addition, Ward [28] has given some necessary conditions for weak sharp minimality of order m.

In this paper, we present sufficient conditions and characterizations for weak sharp minimality of order m in nonsmooth programming, continuing a line of research begun in [26] and [28]. As in those papers, we start by giving a characterization of weak sharp minimality that requires no differentiability assumptions. We then go on to consider simpler sufficient conditions and to apply our general results in important special cases.

An outline of this paper is as follows. We begin in section 2 by deriving a general characterization of weak sharp minimality of order m in the unconstrained case ($C = \mathbb{R}^n$ in (1.1)). Since our characterization is rather complicated, we then give a simpler sufficient condition for weak sharp minimality and discuss situations in which this sufficient condition provides a characterization. Both the characterization and sufficient condition involve the normal cone of Mordukhovich [18] to the set S at $\bar{x}$, a geometric object that seems to arise naturally in attempts to formulate conditions sufficient for weak sharp minimality. The sufficient condition also involves a special variant of the contingent epiderivative of f [1], a directional derivative that plays a key role in sufficient conditions for strict minimality.

In section 3, we apply the results of section 2 to produce sufficient conditions for weak sharp minimality of orders one and two in constrained problems. We pay particular attention to problems with inequality and/or equality constraints and give a special result for the case of linear constraints. We again mention situations in which sufficient conditions give actual characterizations. In section 4, we show that our sufficient optimality conditions for inequality-constrained problems are also sufficient for exactness of a standard l_1 penalty function. Finally in section 5, we adapt an idea of Auslender [2] to establish another set of sufficient conditions for weak sharp minimality of order one. We then compare these sufficient conditions, which involve

the subdifferential of Mordukhovich [18], [19], [20], [21] rather than a contingent-type epiderivative, with the corresponding conditions from sections 2 and 3.

We conclude this section with a compilation of some notation and definitions that will be useful throughout the paper. For a set $S \subset \mathbb{R}^n$, we denote the *closure* of S by $\operatorname{cl} S$, the *interior* of S by $\operatorname{int} S$, and the *boundary* of S by $\operatorname{bd} S$. The *indicator function* of S is the function i_S defined by $i_S(x) = 0$ for $x \in S$ and $i_S(x) = +\infty$ for $x \in \mathbb{R}^n \backslash S$.

Let $\langle \cdot, \cdot \rangle$ denote the usual inner product on $\mathbb{R}^n$. For a cone $S \subset \mathbb{R}^n$, the *polar* of S is the closed convex cone defined by

$$S^0 := \big\{ y \in R^n \mid \langle x, y \rangle \leq 0 \ \forall x \in S \big\}.$$

For a function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$, the *epigraph* of f is the set

$$\operatorname{epi} f := \big\{ (x, r) \mid f(x) \leq r \big\}.$$

We say that f is *proper* if $\operatorname{epi} f$ is nonempty and f never takes on the value $-\infty$, and that f is *lower semicontinuous* (l.s.c.) if $\operatorname{epi} f$ is closed. If f is finite at x, we say that f is *strictly differentiable* at x [7] if there exists a linear mapping $\nabla f(x) : \mathbb{R}^n \to \mathbb{R}$ such that $\forall y \in \mathbb{R}^n$,

$$\lim_{(v,w,t) \to (x,y,0^+)} \big(f(w + tv) - f(w) \big) / t = \langle \nabla f(x), y \rangle .$$

For $i = 1, 2$, we say that f is C^i at x if f is i times differentiable on a neighborhood of x and the i th derivative function is continuous at x. We will say that f is $C^{1,1}$ at x if f is C^1 at x and the derivative function ∇f is Lipschitzian near x.

2. The unconstrained case. We begin our study of weak sharp minima by examining the case where $C = \mathbb{R}^n$ in (1.1). In this case, we will refer to a weak sharp local minimizer of order m for (1.1) as a *weak sharp local minimizer of order m for f*.

The following concept of normal cone will play a major role in our optimality conditions.

DEFINITION 2.1. *Let $S \subset \mathbb{R}^n$ be nonempty.*

(a) *For $x \in \mathbb{R}^n$, call*

$$P(S, x) := \big\{ w \in \operatorname{cl} S \mid \|x - w\| = \operatorname{dist}(x, S) \big\}.$$

(b) *Let $\bar{x} \in \operatorname{cl} S$. The* normal cone *to S at $\bar{x}$ is defined by*

$$N(S, \bar{x}) := \big\{ y \mid \exists \{y_j\} \to y,\ \{x_j\} \to \bar{x},\ \{t_j\} \subset (0, +\infty),\ \{s_j\} \subset R^n \\ \text{with } s_j \in P(S, x_j) \text{ and } y_j = (x_j - s_j)/t_j \big\}.$$

The normal cone $N(S, \bar{x})$ is often called the Mordukhovich normal cone or limiting proximal normal cone. For information on its properties, see [13], [19], [20], [21], and references therein. In terms of $N(S, \bar{x})$, we can obtain a general characterization of weak sharp local minimality of order m.

THEOREM 2.2. *Let $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ be finite and constant on a closed set $S \subset \mathbb{R}^n$, and let $\bar{x} \in S$ and $m \geq 1$. The following are equivalent:*

(a) *$\bar{x}$ is a weak sharp local minimizer of order m for f.*

(b) *$\forall y \in N(S, \bar{x})$ with $\|y\| = 1$, $\forall$ sequences $\{x_j\} \to \bar{x}$, $\{s_j\}$ with $s_j \in P(S, x_j)$, $\{(x_j - s_j)/\|x_j - s_j\|\} \to y$ and*

$$\liminf_{j \to \infty} \big(f(x_j) - f(s_j) \big) / \|x_j - s_j\|^{m-1} \leq 0,$$

we have

$$\liminf_{j\to\infty} \big(f(x_j) - f(s_j)\big)/\left\|x_j - s_j\right\|^m > 0.$$

(c) $\forall y \in N(S,\bar{x})$ *with* $\|y\| = 1$, $\forall$ *sequences* $\{x_j\} \to \bar{x}$, $\{s_j\}$ *with* $s_j \in P(S,x_j)$ *and* $\{(x_j - s_j)/\left\|x_j - s_j\right\|\} \to y$, *we have*

$$\liminf_{j\to\infty} \big(f(x_j) - f(s_j)\big)/\left\|x_j - s_j\right\|^m > 0.$$

Proof. (a) $\Rightarrow$ (c). Suppose that (a) holds. Let $y \in N(S,\bar{x})$ with $\|y\| = 1$, and let $\{x_j\} \to \bar{x}$, $\{s_j\}$ with $\{(x_j - s_j)/\left\|x_j - s_j\right\|\} \to y$ and $s_j \in P(S,x_j)$. Since S is closed, each $s_j \in S$. By (a), there exists $\beta > 0$ such that for j large enough,

$$f(x_j) - f(s_j) = f(x_j) - f(\bar{x}) \geq \beta \operatorname{dist}^m(x_j,S) = \beta \left\|x_j - s_j\right\|^m.$$

Thus

$$\liminf_{j\to\infty} \big(f(x_j) - f(s_j)\big)/\left\|x_j - s_j\right\|^m \geq \beta,$$

and (c) holds.

(c) $\Rightarrow$ (b). This implication is obvious.

(b) $\Rightarrow$ (a) (by contraposition). Suppose that $\bar{x}$ is not a weak sharp local minimizer of order m for f. Then there exists a sequence $\{x_j\} \to \bar{x}$ such that

$$f(x_j) - f(\bar{x}) < \operatorname{dist}^m(x_j,S)/j.$$

For each j, let $s_j \in P(S,x_j)$. Since S is closed, each $s_j \in S$; and since $\|x_j - s_j\| \leq \|x_j - \bar{x}\|$, we have $\|x_j - s_j\| \to 0$. Taking a subsequence if necessary, we may assume without loss of generality that the sequence $\{(x_j - s_j)/\left\|x_j - s_j\right\|\}$ converges to some y. Then $y \in N(S,\bar{x}), \|y\| = 1$, and

$$f(x_j) - f(s_j) = f(x_j) - f(\bar{x}) < \operatorname{dist}^m(x_j,S)/j = \left\|x_j - s_j\right\|^m/j.$$

Hence

$$\liminf_{j\to\infty} \big(f(x_j) - f(s_j)\big)/\left\|x_j - s_j\right\|^{m-1} \leq 0$$

and

$$\liminf_{j\to\infty} \big(f(x_j) - f(s_j)\big)/\left\|x_j - s_j\right\|^m \leq 0.$$

Therefore (b) does not hold, and the proof is complete. ∎

Theorem 2.2 gives very general, albeit rather complicated, characterizations of weak sharp local minima of order m for f. Are there simpler conditions that imply Theorem 2.2(c) and still provide a characterization in a wide variety of circumstances? Next we propose one answer to this question based on the following concept of directional derivative.

DEFINITION 2.3. *Let S be a nonempty closed subset of $\mathbb{R}^n$, and let $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ be finite on* $\operatorname{bd} S$. *For $x \in \operatorname{bd} S$ and $y \in \mathbb{R}^n$, define*

$$\underline{d}_S^m f(x;y) := \liminf_{\substack{s\to \operatorname{bd} S\, x \\ (t,v)\to(0^+,y)}} \big(f(s+tv) - f(s)\big)/t^m,$$

where "$s \to_{\mathrm{bd}\, S} x$" means that $s \to x$ with each $s \in \mathrm{bd}\, S$. (In particular, (x, y) is an allowable choice of (s, v).)

Definition 2.3 gives a sort of generalization of the directional derivative

$$\underline{d}^m f(x; y) := \liminf_{(t,v)\to(0^+,y)} \big(f(x + tv) - f(x)\big)/t^m,$$

which was used to study strict local minima of order m in [26], [28]. Observe that when $S = \{x\}$, then $\underline{d}^m_S f(x; y)$ reduces to $\underline{d}^m f(x; y)$. It is also worth noting that $\underline{d}^m_S f(x; y)$ and $\underline{d}^m f(x; y)$ may coincide if f is sufficiently smooth.

LEMMA 2.4. *Let $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ be finite on $\mathrm{bd}\, S$, and let $x \in \mathrm{bd}\, S$.*

(a) *If f is strictly differentiable at x with derivative $\nabla f(x)$, then $\forall y \in \mathbb{R}^n$,*

$$\underline{d}^1_S f(x; y) = \langle \nabla f(x), y\rangle = \underline{d}^1 f(x; y).$$

(b) *If f is C^2 at x and there exists $\varepsilon > 0$ with $\nabla f(s) = 0$ $\forall s \in \mathrm{bd}\, S \cap B(x, \varepsilon)$, then $\forall y \in \mathbb{R}^n$,*

$$\underline{d}^2_S f(x; y) = \nabla^2 f(x)(y, y)/2 = \underline{d}^2 f(x; y).$$

Proof. Part (a) follows easily from the definition of strict differentiability. To prove part (b), note that if f is C^2 at x with $\nabla f(s) = 0$ $\forall s \in \mathrm{bd}\, S \cap B(x, \varepsilon)$, then $\forall y \in \mathbb{R}^n$, we have by Taylor's formula that

$$\begin{aligned}\underline{d}^2_S f(x; y) &= \liminf_{\substack{s\to_{\mathrm{bd}\, S} x\\ (t,v)\to(0^+,y)}} \big(f(s + tv) - f(s)\big)/t^2\\ &= \liminf_{\substack{s\to_{\mathrm{bd}\, S} x\\ (t,v)\to(0^+,y)}} \nabla^2 f(s)(v, v)/2 = \nabla^2 f(x)(y, y)/2.\end{aligned}$$

Similarly, $\nabla^2 f(x)(y, y)/2 = \underline{d}^2 f(x; y)$, and so part (b) is true. ∎

The directional derivative $\underline{d}^m_S f(x; \cdot)$ has a number of properties in common with $\underline{d}^m f(x; \cdot)$. In particular, $\underline{d}^m_S f(x; \cdot)$ is l.s.c. as a function of the direction y. From the definition of $\underline{d}^m_S f(x; \cdot)$, it follows easily that if $\underline{d}^m_S f(x; y) > -\infty$ and $\underline{d}^m_S g(x; y) > -\infty$, then

$$\underline{d}^m_S (f + g)(x; y) \geq \underline{d}^m_S f(x; y) + \underline{d}^m_S g(x; y); \tag{2.1}$$

and if in addition there exist $c \in \mathbb{R}$ and $\delta > 0$ such that

$$f(z) = g(z) = c \quad \forall z \in \mathrm{bd}\, S \cap B(\bar{x}, \delta),$$

then for $h(x) := \max\{f(x), g(x)\}$,

$$\underline{d}^m_S h(\bar{x}; y) \geq \max\big\{\underline{d}^m_S f(\bar{x}; y), \underline{d}^m_S g(\bar{x}; y)\big\}. \tag{2.2}$$

We will take advantage of these properties later in this paper.

Making use of Theorem 2.2, we can deduce sufficient conditions for weak sharp minimality in terms of our new directional derivatives.

THEOREM 2.5. *Let $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ be finite and constant on a closed set $S \subset \mathbb{R}^n$, and let $\bar{x} \in \mathrm{bd}\, S$. If $m \geq 1$ and*

$$\underline{d}^m_S f(\bar{x}; y) > 0 \quad \forall y \in N(S, \bar{x})\backslash\{0\}, \tag{2.3}$$

then $\bar{x}$ is a weak sharp local minimizer of order m for f.

Proof. Let $m \geq 1$, and let $y \in N(S, \bar{x})$ with $\|y\| = 1$. Let $\{x_j\} \to \bar{x}$, $\{s_j\}$ with $s_j \in P(S, x_j)$ and $\{(x_j - s_j)/\|x_j - s_j\|\} \to y$. Then $x_j \notin S$, and so $s_j \in \operatorname{bd} S$. Define $t_j := \|x_j - s_j\|$ and $y_j := (x_j - s_j)/t_j$. As noted in the proof of Theorem 2.2, $t_j \to 0^+$. By (2.3), it follows that

$$\begin{aligned}\liminf_{j\to\infty} &\big(f(x_j) - f(s_j)\big)/\|x_j - s_j\|^m \\ &= \liminf_{j\to\infty} \big(f(s_j + t_j y_j) - f(s_j)\big)/t_j^m \geq \underline{d}_S^m f(\bar{x}; y) > 0.\end{aligned}$$

Hence $\bar{x}$ is a weak sharp minimizer of order m for f by Theorem 2.2. ∎

Condition (2.3) is not a general characterization of weak sharp minimality, mainly because Definition 2.3 does not specify that $s \in P(S, s + tv)$. (In the proof that (a) $\Rightarrow$ (c) in Theorem 2.2, the fact that $s_j \in P(S, x_j)$ plays an essential role.) The following example illustrates that the sufficient conditions of Theorem 2.5 are not always necessary conditions.

Example 2.1. Define $f : \mathbb{R}^2 \to \overline{\mathbb{R}}$ by

$$f(x, y) := \begin{cases} x^m & \text{if } x \geq 0,\ 0 \leq y \leq 1, \\ +\infty & \text{otherwise,} \end{cases}$$

and let $S = \{(0, y) \mid 0 \leq y \leq 1\}$. Then each element of S is a weak sharp minimizer of order m for f. When $0 < y < 1$, $N(S, (0, y)) = \{(z, 0) \mid z \in \mathbb{R}\}$. Since

$$\underline{d}_S^m f\big((0, y); (z, 0)\big) = \begin{cases} z^m & \text{if } z \geq 0, \\ +\infty & \text{if } z < 0, \end{cases}$$

(2.3) is satisfied at $\bar{x} = (0, y)$, $0 < y < 1$.

However, $N(S, (0, 0)) = \{(x, y) \mid y \leq 0\}$ and $\underline{d}_S^m\ f((0, 0); (0, -1)) = 0$, so (2.3) does not hold at $\bar{x} = (0, 0)$. Similarly, $N(S, (0, 1)) = \{(x, y) \mid y \geq 0\}$ and $\underline{d}_S^m$ $f((0, 1); (0, 1)) = 0$, so (2.3) is not satisfied at $\bar{x} = (0, 1)$. In general, (2.3) will not hold in situations where S is a convex set that contains more than one point but has empty interior and $\bar{x}$ is not in the relative interior of S.

It is interesting to compare Theorem 2.5 with the necessary conditions for weak sharp minima that were derived in [7], [28]. These necessary conditions are stated in terms of $\underline{d}^m f(\bar{x}; \cdot)$ and the *contingent cone,* which is defined for $C \subset \mathbb{R}^n$ and $\bar{x} \in C$ by

$$K(C, x) := \big\{y \in R^n \mid \exists (t_j, y_j) \to (0^+, y) \text{ with } x + t_j y_j \in C\big\}.$$

In particular, Theorem 2.6 below is a special case of [28, Theorem 4.1] (or, for $m = 1$, [7, Theorem 2.2]).

THEOREM 2.6 (see [28]). *Let $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ be finite and constant on $S \subset \mathbb{R}^n$, and let $\bar{x} \in S$ be a weak sharp local minimizer of order m for f. Then there exists $\beta > 0$ such that*

$$\underline{d}^m f(\bar{x}; y) \geq \beta \operatorname{dist}^m \big(y, K(S, \bar{x})\big) \quad \forall y \in R^n. \tag{2.4}$$

By comparing Theorems 2.5 and 2.6, we can determine assumptions under which condition (2.3) characterizes weak sharp minima.

THEOREM 2.7. *Let $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ be finite and constant on a closed set $S \subset \mathbb{R}^n$, and let $\bar{x} \in \operatorname{bd} S$. If $K(S, \bar{x}) \cap N(S, \bar{x}) = \{0\}$ and*

$$\underline{d}^m f(\bar{x}; y) = \underline{d}_S^m f(\bar{x}; y) \quad \forall y \in N(S, \bar{x}) \backslash \{0\}, \tag{2.5}$$

then $\bar{x}$ is a weak sharp local minimizer of order m for f if and only if (2.3) *holds.*

Proof. Suppose that $\bar{x}$ is a weak sharp minimizer of order m for f, $K(S,\bar{x}) \cap N(S,\bar{x}) = \{0\}$, and $\underline{d}^m f(\bar{x};y) = \underline{d}^m_S f(\bar{x};y)\ \forall y \in N(S,\bar{x})\backslash\{0\}$. Let $y \in N(S,\bar{x})\backslash\{0\}$. Then $y \notin K(S,\bar{x})$, and by (2.4), $\underline{d}^m f(\bar{x};y) > 0$. Hence $\underline{d}^m_S f(\bar{x};y) > 0$ and so (2.3) holds. On the other hand, (2.3) implies that $\bar{x}$ is a weak sharp minimizer of order m for f by Theorem 2.5. □

Remark 2.1. (a) The assumption

$$K(S,\bar{x}) \cap N(S,\bar{x}) = \{0\} \tag{2.6}$$

in Theorem 2.7 holds, in particular, if S is convex. Indeed, if S is convex, then $N(S,\bar{x}) = K(S,\bar{x})^0$ [13], [19], [20], so that if $y \in K(S,\bar{x}) \cap N(S,\bar{x})$, it follows that $\langle y,y\rangle \le 0$. If S is the set of all global minimizers of f, then S will be convex, for example, whenever f is quasi-convex.

However, (2.6) may not hold if S is not convex. For example, if $S = \{(x,y) \mid y = -|x|\}$ and $\bar{x} = (0,0)$, then $S \subset K(S,\bar{x}) \cap N(S,\bar{x})$.

(b) In Example 2.1, we saw that (2.3) does not hold at the points $(0,0)$ and $(0,1)$. Observe that (2.5) is not satisfied at these points since

$$\underline{d}^m_S f\big((0,0);(0,-1)\big) = \underline{d}^m_S f\big((0,1);(0,1)\big) = 0,$$

while

$$\underline{d}^m f\big((0,0);(0,-1)\big) = \underline{d}^m f\big((0,1);(0,1)\big) = +\infty.$$

3. Optimality conditions for constrained problems. In this section, we apply the results of section 2 to deduce optimality conditions for problems with inequality, equality, and abstract set constraints, concentrating on sufficient conditions for weak sharp minima of orders one and two. In stating these conditions, we will use a variation of the contingent cone that takes the set S into account. For $C \subset \mathbb{R}^n$ and $x \in C$, we define this new tangent cone by

$$K_S(C,x) := \big\{y \mid \exists (t_j,y_j) \to (0^+,y),\ \exists x_j \to_{\mathrm{bd}\, S} x \text{ with } x_j + t_j y_j \in C\big\}.$$

Observe that when $S = \{x\}$, then $K_S(C,x) = K(C,x)$. It is also easy to see that $K_S(C,x)$ is defined precisely so that if S is closed and $\bar{x} \in \mathrm{bd}\, S$, then

$$\underline{d}^m_S i_C(\bar{x};\cdot) = i_{K_S(C,\bar{x})}(\cdot) \quad \forall m \ge 1. \tag{3.1}$$

We can use Theorem 2.5 and our new tangent cone to derive sufficient conditions for weak sharp minimality in (1.1).

THEOREM 3.1. *Let $C \subset \mathbb{R}^n$, and let $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ be finite and constant on a closed set S with $\bar{x} \in \mathrm{bd}\, S \cap C$. If $\underline{d}^m_S f(\bar{x};\cdot)$ is proper and*

$$\underline{d}^m_S f(\bar{x};y) > 0 \quad \forall y \in \big(N(S,\bar{x}) \cap K_S(C,\bar{x})\big)\backslash\{0\}, \tag{3.2}$$

then $\bar{x}$ is a weak sharp local minimizer of order m for (1.1).

Proof. Suppose that (3.2) holds, and let $y \in N(S,\bar{x})\backslash\{0\}$. Then by (3.1) and (3.2), we have

$$\underline{d}^m_S (f + i_C)(\bar{x};y) \ge \underline{d}^m_S f(\bar{x};y) + i_{K_S(C,\bar{x})}(y) > 0; \tag{3.3}$$

and so by Theorem 2.5, $\bar{x}$ is a weak sharp local minimizer of order m for $f+i_C$. Hence $\bar{x}$ is a weak sharp local minimizer of order m for (1.1). □

We next present sufficient conditions for weak sharp minimality of order one in the problem

$$\min\big\{f(x) \mid g_i(x) \le 0,\ i \in J,\ h_i(x) = 0,\ i \in L,\ x \in \Omega\big\}, \tag{3.4}$$

where Ω is a nonempty subset of $\mathbb{R}^n$, $J := \{1,\dots,p\}$, $L := \{1,\dots,q\}$, $g_i : \mathbb{R}^n \to \overline{\mathbb{R}}$, $i \in J$, and $h_i : \mathbb{R}^n \to \overline{\mathbb{R}}$, $i \in L$. In (3.4), we define

$$C := \big\{x \in \mathbb{R}^n \mid g_i(x) \le 0,\ i \in J,\ h_i(x) = 0,\ i \in L,\ x \in \Omega\big\}$$

and let Γ be a closed subset of C on which f is finite and constant, with $f(x) = \alpha$ $\forall x \in \Gamma$. For $x \in C$, we single out the set of indices

$$I(x) := \big\{i \in J \mid g_i(x) = 0\big\};$$

and for $\bar{x} \in \Gamma$, we define

$$I^*(\bar{x}) := \big\{i \in I(\bar{x}) \mid \exists \delta > 0 \text{ with } i \in I(y)\ \forall y \in B(\bar{x},\delta) \cap \Gamma\big\}$$

and

$$S(\bar{x}) := \big\{x \mid g_i(x) = 0,\ i \in I^*(\bar{x}),\ h_i(x) = 0,\ i \in L,\ f(x) = \alpha\big\}.$$

Our sufficient conditions can now be stated as follows.

THEOREM 3.2. *Let $\bar{x} \in \Gamma$, and let $S \subset S(\bar{x})$ be closed with $\bar{x} \in \operatorname{bd} S$. Suppose that h_i is strictly differentiable at $\bar{x}$ for each $i \in L$. If $\underline{d}^1_S f(\bar{x};\cdot)$ is proper and*

$$\begin{aligned} &\underline{d}^1_S f(\bar{x};y) > 0 \quad \forall y \in \big(N(S,\bar{x}) \cap K_S(\Omega,\bar{x})\big) \setminus \{0\} \text{ with} \\ &\underline{d}^1_S g_i(\bar{x};y) \le 0 \quad \forall i \in I^*(\bar{x}), \langle \nabla h_i(\bar{x}), y\rangle = 0\ \forall i \in L, \end{aligned} \tag{3.5}$$

then $\bar{x}$ is a weak sharp local minimizer of order one for (3.4)*).*

Proof. The result will follow directly from Theorem 3.1 and the inclusion

$$K_S(C,\bar{x}) \subset \big\{y \in K_S(\Omega,\bar{x}) \mid \underline{d}^1_S g_i(\bar{x};y) \le 0\ \forall i \in I^*(\bar{x}), \langle \nabla h_i(\bar{x}), y\rangle = 0\ \forall i \in L\big\}.$$

To verify this inclusion, let $y \in K_S(C,\bar{x})$. Then there exist sequences $\{x_j\} \subset \operatorname{bd} S$ with $\{x_j\} \to \bar{x}, \{t_j\} \to 0^+$, and $\{y_j\} \to y$ such that $x_j + t_j y_j \in C$. In particular, $x_j + t_j y_j \in \Omega$, and so $y \in K_S(\Omega,\bar{x})$. For $i \in L$, $h_i(x_j + t_j y_j) = 0$ and $h_i(x_j) = 0$ since $S \subset S(\bar{x})$, and because h_i is strictly differentiable at $\bar{x}$, we have $\langle \nabla h_i(\bar{x}), y\rangle = 0$. Finally, for $i \in I^*(\bar{x})$, $g_i(x_j) = 0$ and $g_i(x_j + t_j y_j) \le 0$ $\forall j$, so that $\underline{d}^1_S g_i(\bar{x};y) \le 0$. □

Our next example illustrates Theorem 3.2, highlighting the importance of the choice of S in condition (3.5).

Example 3.1. In problem (3.4), let $n = 2$, $\Omega = \mathbb{R}^2$, $J = \{1,2\}$, $L = \emptyset$, and define $f(x,y) = x$, $g_1(x,y) = -x$, $g_2(x,y) = -y$. Then each element of $S = \{(0,y) \mid y \ge 0\}$ is a weak sharp minimizer of order one for (3.4).

For $y > 0$ and $\bar{x} = (0,y)$, $N(S,\bar{x}) = \{(z,0) \mid z \in \mathbb{R}\}$, $I(\bar{x}) = I^*(\bar{x}) = \{1\}$, and $\underline{d}^1_S g_1(\bar{x};(z,0)) \le 0$ for $z \ge 0$. Since

$$\underline{d}^1_S f\big(\bar{x};(z,0)\big) = z > 0 \quad \forall z > 0,$$

(3.5) holds for $\bar{x} = (0, y)$, $y > 0$. However, for $\bar{x} = (0, 0)$, $N(S, \bar{x}) = \{(x, y) \mid y \le 0\}$, while $I(\bar{x}) = \{1, 2\}$ and $I^*(\bar{x}) = \{1\}$. Since $(0, -1) \in N(S, \bar{x})$ and $\underline{d}^1_S\, g_1(\bar{x}; (0, -1)) = 0$, while $\underline{d}^1_S\, f(\bar{x}; (0, -1)) = 0$, (3.5) is not satisfied at $\bar{x}$.

On the other hand, if we let $S := \{0\} \times \mathbb{R}$, then (3.5) holds with $\bar{x} = (0, y)$ for any $y \ge 0$.

One can also prove sufficient conditions for weak sharp local minima of order two in terms of Lagrangian functions. In the remainder of this section, we present such conditions.

We first set some notation. For $\lambda_i \ge 0$, $i \in J$, $\mu_i \in \mathbb{R}$, $i \in L$, we define the Lagrangian function

$$L(x) := f(x) + \sum_{i \in J} \lambda_i g_i(x) + \sum_{i \in L} \mu_i h_i(x)$$

and single out a set of directions

$$D^*(\bar{x}) := \big\{ v \mid \langle \nabla f(\bar{x}), v \rangle \le 0, \langle \nabla g_i(\bar{x}), v \rangle \le 0 \ \forall i \in I^*(\bar{x}), \langle \nabla h_i(\bar{x}), v \rangle = 0 \ \forall i \in L \big\}$$

and a set of multipliers

$$\Lambda^*(\bar{x}) := \big\{ (\lambda, \mu) \in \mathbb{R}^p \times \mathbb{R}^q \mid \nabla L(\bar{x}) = 0,\ \lambda_i \ge 0,\ i \in J,\ \lambda_i = 0 \ \forall i \notin I^*(\bar{x}) \big\}.$$

In terms of these concepts, we can derive second-order sufficient conditions for problem (3.4) with $\Omega = \mathbb{R}^n$.

THEOREM 3.3. *In problem* (3.4)*, let* $\Omega = \mathbb{R}^n$*. Let* $S \subset \Gamma$ *be closed, and suppose that* f, g_i*,* $i \in J$*, and* h_i*,* $i \in L$*, are strictly differentiable at* $\bar{x} \in \operatorname{bd} S$*. If there exists* $(\lambda, \mu) \in \Lambda(\bar{x})$ *with*

$$\underline{d}^2_S L(\bar{x}; y) > 0 \quad \forall y \in \big(N(S, \bar{x}) \cap D^*(\bar{x})\big) \backslash \{0\}, \tag{3.6}$$

then $\bar{x}$ *is a weak sharp local minimizer of order two for* (3.4)*.*

Proof. We prove the contrapositive. If $\bar{x}$ is not a weak sharp local minimizer of order two for (3.4), there exists a sequence $\{x_j\} \to_C \bar{x}$ such that

$$f(x_j) - f(\bar{x}) < \operatorname{dist}^2(x_j, S)/j.$$

Then each $x_j \notin S$, so there exists $s_j \in \operatorname{bd} S$ with $s_j \in P(S, x_j)$. Call $t_j := \|x_j - s_j\|$ and $y_j := (x_j - s_j)/t_j$. As in the proof of Theorem 2.2, $\{t_j\} \to 0^+$; and we may assume, taking a subsequence if necessary, that $\{y_j\} \to y$ for some $y \ne 0$. Then $y \in N(S, \bar{x}) \backslash \{0\}$. For j large enough, we have

$$\begin{aligned} \big(g_i(x_j) - g_i(s_j)\big)/t_j &\le 0 \quad \forall i \in I^*(\bar{x}), \\ \big(h_i(x_j) - h_i(s_j)\big)/t_j &= 0 \quad \forall i \in L, \end{aligned}$$

and

$$\big(f(x_j) - f(s_j)\big)/t_j < t_j/j.$$

Thus $y \in D^*(\bar{x})$. Now let $\lambda \in \Lambda^*(\bar{x})$. Then for j large enough,

$$\big(L(x_j) - L(s_j)\big)/t_j^2 \le \big(f(x_j) - f(s_j)\big)/t_j^2 \le 1/j.$$

Therefore

$$\underline{d}_S^2 L(\bar{x}; y) \le \liminf_{j\to\infty} \big(L(x_j) - L(s_j)\big)/t_j^2 \le 0. \qquad \square$$

By comparing Theorem 3.3 with the necessary conditions given in [28, section 4], we can formulate a characterization of weak sharp local minimality of order two. To do so, we first define the set of multipliers

$$\Lambda(\bar{x}) := \big\{(\lambda,\mu) \in \mathbb{R}^p \times \mathbb{R}^q \mid \nabla L(\bar{x}) = 0,\ \lambda_i \ge 0,\ \lambda_i g_i(\bar{x}) = 0\ \forall i \in J\big\};$$

and for $(\lambda,\mu) \in \Lambda(\bar{x})$ we single out the sets of indices

$$M(\bar{x}) := \big\{i \in I(\bar{x}) \mid \lambda_i > 0\big\}$$

and

$$N(\bar{x}) := \big\{i \in I(\bar{x}) \mid \lambda_i = 0\big\},$$

and define the set of directions

$$D(\bar{x}) := \big\{v \mid \langle \nabla g_i(\bar{x}), v\rangle = 0\ \forall i \in M(\bar{x}),\ \langle \nabla g_i(\bar{x}), v\rangle \le 0\ \forall i \in N(\bar{x}),\ \langle \nabla h_i(\bar{x}), v\rangle = 0\ \forall i \in L\big\}.$$

Our characterization involves the following constraint qualification.

DEFINITION 3.4. *Let f, g_i, $i \in J$, h_i, $i \in L$, be C^1 at $\bar{x}$, and suppose that $(\lambda,\mu) \in \Lambda(\bar{x})$. We say that the strict Mangasarian–Fromovitz constraint qualification (SMFCQ) is satisfied at $(\bar{x},\lambda,\mu)$ if*

(i) *$\nabla g_i(\bar{x})$, $i \in M(\bar{x})$, $\nabla h_i(\bar{x})$, $i \in L$, are linearly independent;*

(ii) *there exists $z \in \mathbb{R}^n$ such that*

$$\langle \nabla g_i(\bar{x}), z\rangle < 0,\ i \in N(\bar{x});\ \langle \nabla g_i(\bar{x}), z\rangle = 0,\ i \in M(\bar{x});\ \langle \nabla h_i(\bar{x}), z\rangle = 0,\ i \in L.$$

Observe that if $I(\bar{x}) = M(\bar{x})$, then condition SMFCQ coincides with the familiar linear independence constraint qualification. Kyparisis [16] has shown that SMFCQ is necessary and sufficient for $\Lambda(\bar{x})$ to be a singleton. In [28], Ward used this constraint qualification in developing necessary conditions for weak sharp minimality of order two. In particular, Proposition 3.5 below is a special case of [28, Corollary 4.2] (taking into account [28, Lemma 3.1(i)]).

PROPOSITION 3.5. *Let $\Omega = \mathbb{R}^n$ in (3.4), let $S \subset \Gamma$ be closed, and let $\bar{x} \in \operatorname{bd} S$ be a weak sharp local minimizer of order two for (3.4). Suppose that f, g_i, $i \in J$, and h_i, $i \in L$, are $C^{1,1}$ at $\bar{x}$, and assume that SMFCQ is satisfied at $(\bar{x},\lambda,\mu)$. Then there exists $\beta > 0$ such that*

$$\underline{d}^2 L(\bar{x}; y) \ge \beta \operatorname{dist}^2\big(y, K(S,\bar{x})\big) \quad \forall y \in D(\bar{x}). \tag{3.7}$$

Theorem 3.3 and Proposition 3.5 yield the following characterization of local weak sharp minimality of order two for a program with $C^{1,1}$ data.

THEOREM 3.6. *In problem (3.4), let $\Omega = \mathbb{R}^n$, let $S \subset \Gamma$ be closed, and suppose that f, g_i, $i \in J$, and h_i, $i \in L$, are $C^{1,1}$ at $\bar{x} \in \operatorname{bd} S$. Assume that $K(S,\bar{x}) \cap N(S,\bar{x}) = \{0\}$, $D(\bar{x}) = D^*(\bar{x})$, SMFCQ is satisfied at $(\bar{x},\lambda,\mu)$ with $(\lambda,\mu) \in \Lambda^*(\bar{x})$,*

and $\underline{d}^2_S L(\bar{x};\cdot) = \underline{d}^2 L(\bar{x};\cdot)$. *Then* $\bar{x}$ *is a weak sharp local minimizer of order two for* (3.4) *if and only if*

$$\underline{d}^2 L(\bar{x};y) > 0 \quad \forall y \in \big(N(S,\bar{x}) \cap D(\bar{x})\big)\backslash\{0\}. \tag{3.8}$$

Proof. By our assumptions and Theorem 3.3, (3.8) implies that $\bar{x}$ is a weak sharp local minimizer of order two . On the other hand, suppose that $\bar{x}$ is a weak sharp local minimizer of order two for (3.4), and let $y \in (N(S,\bar{x}) \cap D(\bar{x}))\backslash\{0\}$. Since $N(S,\bar{x}) \cap K(S,\bar{x}) = \{0\}$, $y \notin K(S,\bar{x})$, and by (3.7), $\underline{d}^2 L(\bar{x};y) > 0$. Therefore (3.8) holds. □

In the case in which f, g_i, and h_i are C^2, Theorem 3.6 reduces to a slightly simpler result.

COROLLARY 3.7. *In problem* (3.4), *let* $\Omega = \mathbb{R}^n$. *Let* $S \subset \Gamma$ *be closed, and suppose that* f, g_i, $i \in J$, *and* h_i, $i \in L$, *are* C^2 *at* $\bar{x} \in \operatorname{bd} S$. *Assume that* $K(S,\bar{x}) \cap N(S,\bar{x}) = \{0\}$, $D(\bar{x}) = D^*(\bar{x})$, *SMFCQ is satisfied at* $(\bar{x},\lambda,\mu)$ *with* $(\lambda,\mu) \in \Lambda^*(\bar{x})$, *and there exists* $\delta > 0$ *such that* $\nabla L(s) = 0$ $\forall s \in \operatorname{bd} S \cap B(\bar{x},\delta)$. *Then* $\bar{x}$ *is a weak sharp local minimizer of order two for* (3.4) *if and only if*

$$\nabla^2 L(\bar{x})(y,y) > 0 \quad \forall y \in \big(N(S,\bar{x}) \cap D(\bar{x})\big)\backslash\{0\}. \tag{3.9}$$

Proof. This result follows immediately from Theorem 3.6 and Lemma 2.4(b). □

Remark 3.1. In Theorem 3.6 and Corollary 3.7, one condition under which $D(\bar{x}) = D^*(\bar{x})$ and $\Lambda(\bar{x}) = \Lambda^*(\bar{x})$ is the assumption that $I(\bar{x}) = I^*(\bar{x})$, since

$$D(\bar{x}) = \big\{v \mid \langle \nabla f(\bar{x}), v\rangle \le 0, \langle \nabla g_i(\bar{x}), v\rangle \le 0 \ \forall i \in I(\bar{x}), \langle \nabla h_i(\bar{x}), v\rangle = 0 \ \forall i \in L\big\}$$

by [11, Theorem 3.5].

We conclude this section with a discussion of an interesting special case of Theorem 3.2. In problem (3.4), let $\Omega = R^n$, $g_i(x) = \langle a_i, x\rangle - b_i$, $i \in J$, and $h_i(x) = \langle c_i, x\rangle - d_i$, $i \in L$, where each $a_i, c_i \in \mathbb{R}^n$, $b_i, d_i \in \mathbb{R}$; and suppose that f is constant on the set

$$S = \big\{x \in \mathbb{R}^n \mid \langle a_i, x\rangle = b_i,\ i \in J_1, \langle c_i, x\rangle = d_i,\ i \in L\big\} \tag{3.10}$$

for some $J_1 \subset J$. In this case of linear constraints, we have the following result.

PROPOSITION 3.8. *In problem* (3.4), *define* C *as above and suppose* f *is constant on the set* S *in* (3.10). *Let* $\bar{x} \in \Gamma = S \cap C$ *be such that* $I^*(\bar{x}) = J_1$, *and assume that* a_i, $i \in J_1$, c_i, $i \in L$, *are linearly independent. Suppose that* f *is strictly differentiable at* $\bar{x}$ *and there exists* $\lambda \in \Lambda(\bar{x})$ *such that* $M(\bar{x}) = J_1$. *Then* $\bar{x}$ *is a weak sharp local minimizer of order one for* (3.4).

Proof. Let $y \in N(S,\bar{x})$ be such that $\underline{d}^1_S f(\bar{x};y) \le 0$, $\underline{d}^1_S g_i(\bar{x};y) \le 0$ $\forall i \in J_1$, and $\langle \nabla h_i(\bar{x}), y\rangle = 0$ $\forall i \in L$. Since there exists $\lambda \in \Lambda(\bar{x})$ with $M(\bar{x}) = J_1$, it follows (in view of Lemma 2.4) that $\langle a_i, y\rangle = 0$ $\forall i \in J_1$ and $\langle c_i, y\rangle = 0$ $\forall i \in L$. Let A be a matrix whose rows are a_i, $i \in J_1$, and c_i, $i \in L$. Then $Ay = 0$. In addition, it is easy to calculate that $N(S,\bar{x}) = \operatorname{Range} A^T$, and so $y = A^T w$ for some w. Hence

$$0 = Ay = AA^T w,$$

and since A has linearly independent rows, we conclude that $w = 0$. Therefore $y = 0$, and (3.5) holds. By Theorem 3.2, $\bar{x}$ is a weak sharp local minimizer of order one for (3.4). □

We illustrate Proposition 3.8 with an example.

Example 3.2. Consider the problem

$$\min\{x^2 - 2y - 3z \mid x + 2y + 3z \le 6,\ x \ge 0,\ y \ge 0,\ z \ge 0\}.$$

Here the objective function is clearly constant on the set

$$S = \{(x, y, z) \mid x + 2y + 3z = 6,\ x = 0\}.$$

Let $\bar{x} = (0, y, z)$ be an element of $S \cap C$. It is easy to verify that $(1, 1, 0, 0) \in \Lambda(\bar{x})$, giving $M(\bar{x}) = J_1 = \{1, 2\}$. Since

$$A = \begin{bmatrix} 1 & 2 & 3 \\ -1 & 0 & 0 \end{bmatrix}$$

has independent rows, the hypotheses of Proposition 3.8 are satisfied, and we conclude that $\bar{x}$ is a weak sharp local minimizer of order one for this problem.

4. Sufficient conditions and exactness of penalties. One way to approach the solution of constrained optimization problems is via associated unconstrained problems. For example, under fairly general conditions, a minimizer of

$$\min\{f(x) \mid g_i(x) \le 0,\ i \in J,\ x \in \Omega\} \tag{4.1}$$

will also be a minimizer of the problem

$$\min\left\{f(x) + p\sum_{i\in J} \max(g_i(x), 0) \mid x \in \Omega\right\} \tag{4.2}$$

for sufficiently large values of $p > 0$. (See [6], [9], [11], and references therein.) When minimizers of (4.1) and (4.2) are related in this way, the *penalty function*

$$\theta_p(x) := f(x) + p\sum_{i\in J} \max\big(g_i(x), 0\big)$$

is said to be *exact*.

One type of hypothesis that often guarantees exactness of θ_p is a sufficient condition for strict local minimality of order m. (See, for instance, [6], [11], [12], [22], [27].) In this section, we prove similar results for weak sharp minimality. First, we generalize [27, Theorem 4.1] for $m = 1$ and the penalty function θ_p by showing that condition (3.5) of Theorem 3.2 (in the case $L = \emptyset$) implies exactness of θ_p.

In this section, we let $L = \emptyset$ in (3.4) and let $S \subset \Gamma$ be closed. To state our main result, we introduce notation similar to that of [22] and [27], defining

$$K^*(\bar{x}) := \big\{y \in N(S, \bar{x}) \cap K_S(\Omega, \bar{x}) \mid \|y\| = 1,\ \underline{d}^1_S f(\bar{x}; y) \le 0\big\},$$
$$b(\bar{x}) := \min\big\{\underline{d}^1_S f(\bar{x}; y) \mid \|y\| = 1,\ y \in N(S, \bar{x}) \cap K_S(\Omega, \bar{x})\big\},$$

and

$$a(\bar{x}) := \min\left\{\sum_{I^*(\bar{x})} \max\big(0, \underline{d}^1_S g_i(\bar{x}; y)\big) \mid y \in K^*(\bar{x})\right\}.$$

We note that since $\underline{d}^1_S\, f(\bar{x}; \cdot)$ is l.s.c., the set $K^*(\bar{x})$ is compact, although possibly empty. It follows that the minima in the definitions of $b(\bar{x})$ and $a(\bar{x})$ are attained if the constraint sets in those definitions are nonempty.

We can now prove a result on exactness of θ_p.

THEOREM 4.1. *Let $\bar{x} \in \operatorname{bd} S$, and suppose that $\underline{d}^1_S g_i(\bar{x};\cdot)$ is proper for each $i \in I(\bar{x})$. Define*

$$\rho_0 := \begin{cases} -b(\bar{x})/a(\bar{x}) & \text{if } K^*(\bar{x}) \neq \emptyset, \\ 0 & \text{else.} \end{cases}$$

Suppose that $\underline{d}^1_S f(\bar{x};\cdot)$ is proper and

$$\underline{d}^1_S f(\bar{x};y) > 0 \ \forall y \in \big(N(S,\bar{x}) \cap K_S(\Omega,\bar{x})\big)\backslash\{0\} \text{ with } \underline{d}^1_S g_i(\bar{x};y) \leq 0 \ \forall i \in I^*(\bar{x}). \tag{4.3}$$

Then $\forall p > \rho_0$, $\bar{x}$ is a weak sharp local minimizer of order one for (4.2).

Proof. We first observe that if (4.3) is satisfied and $K^*(\bar{x}) \neq \emptyset$, then $a(\bar{x}) > 0$ and $b(\bar{x}) \leq 0$, so that ρ_0 is well defined and nonnegative. To prove our assertion, let $p > \rho_0$, and let $y \in (N(S,\bar{x}) \cap K_S(\Omega,\bar{x}))\backslash\{0\}$. By Theorem 3.1, it suffices to show that $\underline{d}^1_S \theta_p(\bar{x};y) > 0$. Without loss of generality, we may assume that $\|y\| = 1$. Since $\underline{d}^1_S f(\bar{x};\cdot)$ and $\underline{d}^1_S g_i(\bar{x};\cdot)$, $i \in I(\bar{x})$, are proper and

$$\underline{d}^1_S \max\{g_i, 0\}(\bar{x};y) \geq 0 \quad \forall i \in I(\bar{x})\backslash I^*(\bar{x}),$$

it follows from (2.1) and (2.2) that

$$\underline{d}^1_S \theta_p(\bar{x};y) \geq \underline{d}^1_S f(\bar{x};y) + p \sum_{I^*(\bar{x})} \max\big(0, \underline{d}^1_S g_i(\bar{x};y)\big). \tag{4.4}$$

If $K^*(\bar{x}) = \emptyset$, it follows from (4.4) that $\underline{d}^1_S \theta_p(\bar{x};y) > 0$. If $K^*(\bar{x}) \neq \emptyset$, then if $\underline{d}^1_S f(\bar{x};y) > 0$, we again have $\underline{d}^1_S\ \theta\ _p(\bar{x};y) > 0$; while if $y \in K^*(\bar{x})$, the definition of ρ_0 implies that

$$p \sum_{I^*(\bar{x})} \max\big(0, \underline{d}^1_S g_i(\bar{x};y)\big) > -b(\bar{x}),$$

and hence

$$\underline{d}^1_S \theta_p(\bar{x};y) > \underline{d}^1_S f(\bar{x};y) - b(\bar{x}) \geq 0.$$

Therefore $\bar{x}$ is a weak sharp local minimizer of order 1 for (4.2). ∎

Theorem 4.1 generalizes part of [27, Theorem 4.1] to cover the case where S is not necessarily a singleton. We illustrate Theorem 4.1 with an example in which [27, Theorem 4.1] is not applicable.

Example 4.1. In problem (4.1), let $n = 2$, $\Omega = \mathbb{R}^2$, $J = \{1\}$, and define $f(x,y) = x$, $g_1(x,y) = -x + 1$. Then each element of $S = \{(1,y) \mid y \in \mathbb{R}\}$ is a weak sharp minimizer of order 1 for (4.1). For $\bar{x} \in S$, $N(S,\bar{x}) = \{(z,0) \mid z \in \mathbb{R}\}$, $I(\bar{x}) = I^*(\bar{x}) = \{1\}$, and $\underline{d}^1_S g_1(\bar{x};(z,0)) \leq 0$ for $z \geq 0$. Since $\underline{d}^1_S f(\bar{x};(z,0)) = z\ \forall z > 0$, (4.3) holds. It is easy to calculate that $K^*(\bar{x}) = \{(-1,0)\}$, $b(\bar{x}) = -1$, and $a(\bar{x}) = 1$, so by Theorem 4.1, each $\bar{x} \in S$ is a weak sharp local minimizer of order one for (4.2) whenever $p > 1$.

Analogues of Theorem 4.1 can be formulated for other nonsmooth penalty functions of the class considered in [27]. Moreover, it is possible to accommodate equality constraints in Theorem 4.1 by treating them as pairs of inequality constraints.

The second-order sufficient conditions of Theorem 3.3 also imply exactness of θ_p. We now demonstrate this for problem (4.1) with $\Omega = \mathbb{R}^n$.

THEOREM 4.2. *In problem* (4.1)*, let* $\Omega = \mathbb{R}^n$*. Let* $S \subset \Gamma$ *be closed, and suppose that* f *and* g_i*,* $i \in J$*, are strictly differentiable at* $\bar{x} \in \operatorname{bd} S$ *and* $\lambda \in \Lambda^*(\bar{x})$*. If*

$$\underline{d}^2_S L(\bar{x}; y) > 0 \quad \forall y \in \big(N(S, \bar{x}) \cap D^*(\bar{x})\big) \backslash \{0\}, \tag{4.5}$$

then $\bar{x}$ *is a weak sharp local minimizer of order two for* θ_p $\forall p > \max_{i \in J} \lambda_i$*.*

Proof. Let $p > \max_{i \in J} \lambda_i$ and $y \in N(S, \bar{x}) \backslash \{0\}$. By Theorem 2.5, it suffices to show that $\underline{d}^2_S \theta_p(\bar{x}; y) > 0$. Since $\underline{d}^2_S \theta_p(\bar{x}; y) \geq \underline{d}^1_S \theta_p(\bar{x}; y)$, we may assume that $\underline{d}^1_S \theta_p(\bar{x}; y) \leq 0$. Then, as in (4.4), we have

$$0 \geq \underline{d}^1_S \theta_p(\bar{x}; y) \geq \langle \nabla f(\bar{x}), y \rangle + p \sum_{I^*(\bar{x})} \max\big(0, \langle \nabla g_i(\bar{x}), y \rangle\big),$$

and so $\langle \nabla f(\bar{x}), y \rangle \leq 0$. Since $\nabla L(\bar{x}) = 0$, it follows that

$$\sum_{I^*(\bar{x})} \lambda_i \langle \nabla g_i(\bar{x}), y \rangle \geq p \sum_{I^*(\bar{x})} \max\big(0, \langle \nabla g_i(\bar{x}), y \rangle\big). \tag{4.6}$$

Observe that (4.6) and the fact that $p > \max_{i \in J} \lambda_i$ imply that $y \in D^*(\bar{x})$. By (4.5), $\underline{d}^2_S L(\bar{x}; y) > 0$. Finally, note that since $\lambda \in \Lambda^*(\bar{x})$, we have $L(s) = \theta_p(s) = f(\bar{x})$ for $s \in \operatorname{bd} S$ sufficiently close to $\bar{x}$. Hence

$$\underline{d}^2_S \theta_p(\bar{x}; y) \geq \underline{d}^2_S L(\bar{x}; y) > 0,$$

and the proof is complete. □

Theorem 4.2 is a weak sharp analogue of results for strict local minima of order two like [6, Theorem 4.7] and the related theorems cited on page 986 of [6].

5. More sufficient conditions for weak sharp minima of order one. In this section, we present sufficient conditions for weak sharp minimality of order one which are different from those of sections 2 and 3. These conditions involve the Mordukhovich subdifferential [18], [19], [20], [21], [13] instead of the directional derivative $\underline{d}^1_S f(x; \cdot)$. We begin by reviewing some essential definitions.

DEFINITION 5.1. *Let* $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ *be finite at* $x \in \mathbb{R}^n$*.*

(a) *The* Mordukhovich subdifferential *(or* approximate subdifferential*) of* f *at* x *is the set*

$$\partial f(x) := \big\{x^* \in \mathbb{R}^n \mid (x^*, -1) \in N\big(\operatorname{epi} f, (x, f(x))\big)\big\}.$$

(b) *The* singular Mordukhovich subdifferential *of* f *at* x *is the set*

$$\partial^\infty f(x) := \big\{x^* \in \mathbb{R}^n \mid (x^*, 0) \in N\big(\operatorname{epi} f, (x, f(x))\big)\big\}.$$

Much information about ∂f and $\partial^\infty f$ is given in [18], [19], [20], [21], [13], and references therein. We mention here that if f is convex, then ∂f coincides with the subdifferential of convex analysis, and if f is strictly differentiable at x, then $\partial f(x) = \{\nabla f(x)\}$. The singular subdifferential $\partial^\infty f$ is used to describe conditions under which calculus rules for ∂f are valid; an important thing to remember about $\partial^\infty f$ is that $\partial^\infty f(x) = \{0\}$ if and only if f is Lipschitzian near x.

We now give sufficient conditions for weak sharp minimality of order one in the unconstrained case. Our proof makes use of a technique of [2, Theorem 1.1].

THEOREM 5.2. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be continuous, and let $\bar{x} \in \mathbb{R}^n$. Suppose that there exists $\delta > 0$ such that $f(\bar{x}) \le f(x)\ \forall x \in B(\bar{x}, \delta)$. Define $S := \{x \in B(\bar{x}, \delta) \mid f(x) = f(\bar{x})\}$. Suppose that there exists $c > 0$ such that*

$$\|z\| \ge c \quad \forall z \in \partial f(x),\ \forall x \in B(\bar{x}, \delta) \backslash S. \tag{5.1}$$

Then there exists $\mu \in (0, \delta)$ such that

$$f(x) \ge f(\bar{x}) + c\,\mathrm{dist}(x, S) \quad \forall x \in B(\bar{x}, \mu). \tag{5.2}$$

Proof. Let $F(x) := f(x) - f(\bar{x})$. For $\rho \in [0, \delta]$, define

$$h(\rho) := \max\{F(x) \mid x \in B(\bar{x}, \rho)\}/c.$$

Since F is continuous, there exists $\rho^* \in (0, \delta)$ such that

$$F(x) \le F(\bar{x}) + c\delta/2 \quad \forall x \in B(\bar{x}, \rho^*),$$

and so

$$h(\rho) \le \delta/2 \quad \forall \rho \in [0, \rho^*]. \tag{5.3}$$

We claim that (5.2) is true with $\mu := \rho^*/4$. Indeed, if (5.2) does not hold with $\mu := \rho^*/4$, there exists $u \in B(\bar{x}, \rho^*/4)$ such that

$$\mathrm{dist}(u, S) > F(u)/c,$$

and so for some $t \in (1, 1.5)$,

$$\mathrm{dist}(u, S) > \gamma := tF(u)/c.$$

Since $F(u) \ge 0$, we have $\mathrm{dist}(u, S) > 0$, and it follows that $u \notin S$. Hence $\gamma > 0$. Moreover, (5.3) and the definition of h imply that

$$\gamma \le th(\rho^*/4) \le t\delta/2 < .75\delta. \tag{5.4}$$

Now since $\gamma c/t = F(u)$ and $F(x) \ge 0\ \forall x \in B(\bar{x}, \delta)$, we have

$$F(u) \le \inf\{F(x) \mid x \in B(\bar{x}, \delta)\} + \gamma c/t.$$

Applying Ekeland's variational principle [8, Theorem 7.5.1] to the l.s.c. function F with $V := B(\bar{x}, \delta), \varepsilon := \gamma c/t$ and $\lambda := \gamma$, we deduce that there exists $u_\gamma \in B(\bar{x}, \delta)$ such that

$$\|u - u_\gamma\| \le \gamma, \tag{5.5}$$

$$F(w) + c\,\|w - u_\gamma\|/t > F(u_\gamma) \quad \forall w \in V \backslash \{u_\gamma\}. \tag{5.6}$$

By (5.6), u_γ minimizes the function $\psi(w) := F(w) + c\,\|w - u_\gamma\|/t$ on V. Conditions (5.4) and (5.5) imply that

$$\|u_\gamma - \bar{x}\| \le \|u_\gamma - u\| + \|u - \bar{x}\| \le .75\delta + .25\rho^* < \delta,$$

which means that u_γ lies in the interior of V, and so u_γ is a local minimizer for ψ. By the sum formula for subdifferentials (e.g., [20, Corollary 4.6]),

$$0 \in \partial\psi(u_\gamma) \subset \partial F(u_\gamma) + \frac{c}{t}\partial(\|\cdot - u_\gamma\|)(u_\gamma).$$

Hence there exists $z_\gamma \in \partial f(u_\gamma)$ such that $z_\gamma = cy_\gamma/t$ for some y_γ with $\|y_\gamma\| \leq 1$. Finally, since $\operatorname{dist}(u, S) > \gamma$, (5.5) implies that $u_\gamma \notin S$. Thus by (5.1),

$$c \leq \|z_\gamma\| = c\,\|y_\gamma\|\,/t \leq c/t < c,$$

which is a contradiction. □

We observe that any subdifferential with a calculus rule like [20, Corollary 4.6] could be used in place of ∂f in (5.1). One reason to choose the Mordukhovich subdifferential in (5.1) is that ∂f is the smallest possible subdifferential having a sum rule and some other desirable properties [13].

We illustrate Theorem 5.2 with a simple example.

Example 5.1. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by $f(x, y) := |y|$, and let $\bar{x} := (0, 0)$ and $\delta > 0$. Then $S = \{(0, y) \mid -\delta \leq y \leq \delta\}$ and $\|z\| = 1\ \forall z \in \partial f(x, y)$ with $(x, y) \in B(\bar{x}, \delta)\backslash S$. Hence (5.1) holds with $c = 1$, and $\bar{x}$ is a weak sharp minimum of order one for f.

The following example shows that (5.1) is not necessary for weak sharp minimality of order one. It also shows that (2.3) may hold even when (5.1) is not satisfied.

Example 5.2. Define $f : \mathbb{R} \to \mathbb{R}$ by

$$f(x) := \begin{cases} 0 & \text{if } x \leq 0, \\ 2^{-n} & \text{if } 2^{-n-1} \leq x \leq 2^{-n},\ n \text{ an odd integer}, \\ 3x - 2^{-n} & \text{if } 2^{-n-1} \leq x \leq 2^{-n},\ n \text{ an even integer}, \end{cases}$$

and let $\bar{x} = 0$. The function f is continuous (Lipschitzian, in fact), and for $\delta > 0$, $S = \{x \mid -\delta \leq x \leq 0\}$. Since $f(x) \geq x\ \forall x \geq 0$, (5.2) holds with $c = 1$ and any $\mu \in (0, \delta)$. However, $0 \in \partial f(x)$ for $x = 3/2^{2n+1}$, $n = 0, 1, 2, \ldots$, so (5.1) does not hold for any $c > 0$.

On the other hand, $N(S, \bar{x}) = \{y \mid y \geq 0\}$ and

$$\underline{d}^1_S f(\bar{x}; y) = \underline{d}^1 f(\bar{x}; y) = y \quad \forall y \geq 0,$$

so (2.3) holds at $\bar{x} = 0$. In this example, condition (2.3) identifies a weak sharp minimizer of order one that is not detected by (5.1).

Since Theorem 5.2 specifies that f be continuous, it is not possible to use indicator functions, as in section 3, to derive further optimality conditions for constrained problems. However, other standard techniques can be used to extend Theorem 5.2 to the constrained case. We illustrate one such technique for an inequality-constrained problem in Corollary 5.3.

COROLLARY 5.3. *Let $g_i : \mathbb{R}^n \to \mathbb{R}$, $i = 0, 1, \ldots, m$, be continuous, and define $C := \{x \in \mathbb{R}^n \mid g_i(x) \leq 0,\ i = 1, \ldots, m\}$. Suppose that $\bar{x} \in C$ and $g_0(\bar{x}) \leq g_0(x)$ $\forall x \in C \cap B(\bar{x}, \delta)$. Call $S := \{x \in C \cap B(\bar{x}, \delta) \mid g_0(x) = g_0(\bar{x})\}$. Assume that the following conditions are satisfied $\forall x \in B(\bar{x}, \delta)\backslash S$:*

(i) *If $x_i^* \in \partial^\infty g_i(x)$, $i \in \{0\} \cup I(x)$, and $\sum x_i^* = 0$, then $x_i^* = 0\ \forall i$.*

(ii) *There exists $c > 0$ such that*

$$\bigcup \left\{ \sum_{i \in 0 \cup I(x)} \lambda_i \circ \partial g_i(x) \mid \lambda_i \geq 0,\ \sum \lambda_i = 1 \right\} \cap \operatorname{int} B(0, c) = \emptyset,$$

where we define $\lambda \circ \partial g(x)$ *to be* $\lambda \partial g(x)$ *for* $\lambda > 0$ *and* $\partial^\infty g(x)$ *for* $\lambda = 0$.

Then there exists $\mu \in (0, \delta)$ *such that*

$$g_0(x) \geq g_0(\bar{x}) + c\,\mathrm{dist}(x, S) \quad \forall x \in B(\bar{x}, \mu) \cap C. \tag{5.7}$$

Proof. Define $f(x) := \max\{g_0(x) - g_0(\bar{x}), g_1(x), \ldots, g_m(x)\}$. Then $S = \{x \in B(\bar{x}, \delta) \mid f(x) = f(\bar{x})\}$. Since (i) is satisfied, Theorem 7.5 of [21] implies that

$$\partial f(x) \subset \bigcup \left\{ \sum_{i \in 0 \cup I(x)} \lambda_i \circ \partial g_i(x) \mid \lambda_i \geq 0, \sum \lambda_i = 1 \right\}$$

$\forall x \in B(\bar{x}, \delta) \backslash S$. Condition (ii) then guarantees that (5.1) holds. By Theorem 5.2, we conclude that (5.7) holds. □

It is possible for Corollary 5.3 to identify weak sharp minima of order one that are not recognized by Theorem 3.2. We revisit Example 3.1 to demonstrate this fact.

Example 5.3. Let $n = 2$, $m = 2$ in Corollary 5.3. For $(x, y) \in \mathbb{R}^2$, define $g_0(x, y) = x$, $g_1(x, y) = -x$, $g_2(x, y) = -y$. As noted in Example 3.1, each element of $S = \{(0, y) \mid y \geq 0\}$ is a weak sharp minimizer of order one for this problem, but $(0, 0)$ is not identified by Theorem 3.2. We observe that (i) of Corollary 5.3 is satisfied $\forall (x, y) \in \mathbb{R}^2$ since each g_i is Lipschitzian. For $\bar{x} = (0, y)$ and $y > 0$, $I(z) = \emptyset$ $\forall z \in \mathbb{R}^2 \backslash S$ near $\bar{x}$, and (ii) is satisfied with $c = 1$ since $\partial g_0(z) = \{(1, 0)\}$. For $\bar{x} = (0, 0)$ and $z \in \mathbb{R}^2 \backslash S$ near $\bar{x}$, either $I(z) = \emptyset$ or $I(z) = \{2\}$. In either case, (ii) is satisfied. Hence Corollary 5.3 identifies each element of S as a weak sharp local minimizer of order one.

Examples 5.2 and 5.3 show that the optimality conditions of Theorem 5.2 and Corollary 5.3 are, in general, neither weaker nor stronger than the corresponding parts of Theorems 2.5 and 3.2.

6. Conclusion. In this paper, we have developed a number of sufficient conditions and characterizations of weak sharp minimality in nonsmooth programming, in many cases generalizing known results for strict minimality. Several questions merit further investigation. For example, can more be said about the relationship between $\underline{d}^m_S f(x; \cdot)$ and $\underline{d}^m f(x; \cdot)$? Can our results be applied fruitfully to the study of sensitivity analysis in nonlinear programming? We hope to address such questions in future work.

ON THE MINIMUM PROBLEM FOR A CLASS OF NONCOERCIVE NONCONVEX FUNCTIONALS*

GRAZIANO CRASTA†

Abstract. We are concerned with the problem of existence of solutions to the variational problem

$$\min\left\{\int_0^R g(t,v'(t))\,dt;\ v\in AC([0,R]),\ v(R)=0\right\},$$

with only one fixed endpoint prescribed. The map $g\colon [0,R]\times\mathbb{R}\to\overline{\mathbb{R}}$ is a normal integrand, for which neither convexity nor superlinear growth conditions are assumed.

As an application, we give an existence result for the radially symmetric variational problem

$$\min_{u\in W_0^{1,1}(B_R)}\int_{B_R}\left[f\left(|x|,|\nabla u(x)|\right)+a(|x|)\,u(x)\right]dx,$$

where B_R is the ball of $\mathbb{R}^n$ centered at the origin and with radius $R>0$, the map $f\colon [0,R]\times[0,+\infty[\to\overline{\mathbb{R}}$ is a normal integrand, and $a\in L^1(0,R)$. Again, neither convexity nor superlinear growth conditions are made on f.

These kinds of problems, with nonconvex Lagrangians with respect to ∇u, arise in different fields of mathematical physics such as optimal design and nonlinear elasticity.

Key words. calculus of variations, existence, radially symmetric solutions, nonconvex problems, noncoercive problems

1. Introduction.

We study the existence of solutions to the variational problem

$$\min_{v\in V}\Gamma(v),\quad \Gamma(v)\doteq\int_0^R g(t,v'(t))\,dt, \tag{1}$$

where $V\doteq\{v\in AC([0,R]);\ v(R)=0\}$. The map $g\colon [0,R]\times\mathbb{R}\to\overline{\mathbb{R}}$ is a normal integrand for which neither convexity nor superlinear growth conditions are assumed. Furthermore, we remark that only one fixed endpoint is prescribed.

As customary, we consider the relaxed problem associated with (1), namely,

$$\min_{v\in V}\overline{\Gamma}(v),\quad \overline{\Gamma}(v)\doteq\int_0^R g^{**}(t,v'(t))\,dt, \tag{2}$$

where $g^{**}(t,\cdot)$ is the bipolar of the map $\xi\mapsto g(t,\xi)$.

If g is assumed to be superlinear, then a solution to (2) can be found using the direct method of the calculus of variations (see, for example, [14]). From the properties of this solution, one can often deduce the existence (or nonexistence) of a solution to the nonconvex problem (1).

In our case we follow a different approach based on the indirect method described below. As a first step we prove that there exists a nonempty closed interval $J \subseteq \mathbb{R}$ such that the fixed endpoints variational problem

$$\min_{v \in V(\alpha)} \overline{\Gamma}(v), \qquad V(\alpha) \doteq \{v \in V;\, v(0) = -\alpha\}, \tag{3}$$

has a solution for every $\alpha \in J$. Next, we show that the extended real-valued function $\overline{\phi}(\alpha) \doteq \inf\left\{\overline{\Gamma}(v);\ v \in V(\alpha)\right\}$ attains its minimum in a point $\overline{a} \in J$. Using the properties of the set of integrals of a decomposable family of integrable functions, we prove that the map $\phi(\alpha) \doteq \inf\{\Gamma(v);\ v \in V(\alpha)\}$ coincides with $\overline{\phi}$, and that the nonconvex fixed endpoints variational problem

$$\min_{v \in V(\alpha)} \Gamma(v) \tag{4}$$

has a solution for $\alpha = \overline{a}$ (see section 2 for the definition of decomposable family and Theorem 2.1 for the properties of the set of integrals of such a family). Finally, from the analysis above, we conclude that problem (1) has a solution.

The issue of the existence of solutions to fixed endpoints variational problems, either with nonconvex or noncoercive integrands, was also considered in [11, 12, 13, 15, 18, 19, 20].

As an application, we prove that there exists a solution to the radially symmetric variational problem

$$\min_{u \in W_0^{1,1}(B_R)} \int_{B_R} \left[f\left(|x|, |\nabla u(x)|\right) + a(|x|)\, u(x)\right] dx, \tag{5}$$

where B_R is the ball of $\mathbb{R}^n$ centered at the origin and with radius $R > 0$, the map $f\colon [0,R] \times [0,+\infty[\to \overline{\mathbb{R}}$ is a normal integrand, and $a \in L^1(0,R)$. We emphasize again the fact that f is not required to be convex nor superlinear with respect to ∇u. Nonconvex radially symmetric functionals were considered in [7] for a more general framework on the integrand, assuming superlinear growth with respect to ∇u. For related results we mention also [6, 24].

These kinds of problems arise in different fields of mathematical physics. Among others, we cite [16, 17] and [2, 3, 21, 24], respectively, for problems of optimal design and nonlinear elasticity.

The plan of the paper is the following. In section 3 we state the main result concerning problem (1), and we give some examples. Then, in sections 4 and 6, respectively, we give applications to the existence of solutions to problem (5) and to a minimization problem involving the Laplacian. The proofs of the results stated in sections 3 and 4 are given, respectively, in sections 7 and 5.

2. Preliminaries. We shall denote by $\operatorname{int} A$, $\overline{A}$, $\operatorname{co} A$, $\overline{\operatorname{co}}\, A$, respectively, the interior, the closure, the convex hull, and the closure of the convex hull of a set A. Given a function $\psi\colon X \to \overline{\mathbb{R}} \doteq]-\infty, +\infty]$, we denote by $\operatorname{epi}\psi$ and $\operatorname{graph}\psi$, respectively, its epigraph and its graph, and by ψ^* and ψ^{**}, respectively, its polar and bipolar functions. If ψ admits an affine minorant, then we have that $\operatorname{epi}\psi^{**} = \overline{\operatorname{co}}\operatorname{epi}\psi$ (see [14, Prop. 3.2]).

We say that $\phi\colon [0,R] \times \mathbb{R} \to \overline{\mathbb{R}}$ is a normal integrand if $\phi(t,\cdot)$ is lower semicontinuous for almost every (a.e.) $t \in [0,R]$, and there exists a Borel function $\hat{\phi}\colon [0,R] \times [0,+\infty[\to \overline{\mathbb{R}}$ such that $\hat{\phi}(t,\cdot) = \phi(t,\cdot)$ for a.e. $t \in [0,R]$ (see [14, Def. VIII.1.1]). We

shall denote by ϕ^* and ϕ^{**}, respectively, the polar and the bipolar of the function $\phi(t,\cdot)$.

A convex function $\psi\colon \mathbb{R} \to \overline{\mathbb{R}}$ is proper if its essential domain $\operatorname{Dom}\psi \doteq \{\xi \in \mathbb{R};\ \psi(\xi) < +\infty\}$ is not empty. As customary, the subgradient of ψ at ξ will be denoted by $\partial\psi(\xi)$. For the definition and the main properties of the subgradient we refer to [14, 22]. We recall that, if $\xi \in \operatorname{Dom}\psi$, then $\partial\psi(\xi) = [\psi'_-(\xi), \psi'_+(\xi)]$, where $\psi'_-(\xi)$ and $\psi'_+(\xi)$ denote, respectively, the left and right derivatives of ψ at ξ. If we extend $\psi'_\pm$ beyond the interval $\operatorname{Dom}\psi$ by setting both $+\infty$ for points lying to the right of $\operatorname{Dom}\psi$ and both $-\infty$ for points lying to the left, then $\psi'_\pm$ are monotone nondecreasing functions on $\mathbb{R}$, finite in $\operatorname{int}\operatorname{Dom}\psi$, and for every ξ one has

$$\begin{aligned} &\lim_{\eta\searrow\xi} \psi'_+(\eta) = \psi'_+(\xi), \quad \lim_{\eta\nearrow\xi} \psi'_+(\eta) = \psi'_-(\xi), \\ &\lim_{\eta\searrow\xi} \psi'_-(\eta) = \psi'_+(\xi), \quad \lim_{\eta\nearrow\xi} \psi'_-(\eta) = \psi'_-(\xi) \end{aligned} \tag{6}$$

(see [22, Thm. 24.1]). For notational convenience, if ψ depends on two variables (t,ξ), we denote by $\partial\psi(t,\xi)$ the subgradient of the function $\xi \mapsto \psi(t,\xi)$ at (t,ξ).

We say that a convex function ψ is strictly convex at infinity if $\operatorname{Dom}\psi = \mathbb{R}$ and its graph contains no halflines. It is easy to check that ψ is strictly convex at infinity if and only if for every $r_1 > 0$ there exists $r_2 > 0$ such that, for all $p \in \mathbb{R}$, $\partial\psi^*(p) \cap \overline{B}_{r_1} \neq \emptyset$ implies $\partial\psi^*(p) \subseteq B_{r_2}$ (see [10, Def. 2.1]). We recall that, if ϕ is any function such that ϕ^{**} is strictly convex at infinity, then the convex hull of the epigraph of ϕ is closed (see [13, Thm. 3.6]). As a consequence, ϕ^{**} coincides with the convexification of ϕ, that is, $\phi^{**} = \sup\{\psi \le \phi;\ \psi \text{ convex}\}$.

Another result which will be used in the following concerns the set of integrals of a decomposable family of integrable functions. More precisely, given a set $K \subset L^1([0,R],\mathbb{R}^m)$, we shall denote by $I(K)$ the set of integrals of the elements of K, that is,

$$I(K) \doteq \left\{ \int_0^R w(t)dt;\ w \in K \right\}. \tag{7}$$

We say that K is decomposable if, for every measurable set $E \subset [0,R]$ and all $u, v \in K$, one has $u \cdot \chi_E + v \cdot \chi_{[0,R]\setminus E} \in K$, where χ_E denotes the characteristic function of the set E.

Now we recall an extension of the classical Lyapunov theorem on the range of nonatomic vector-valued measures (see [19, Thm. 3]).

THEOREM 2.1. *If $K \subset L^1([0,R],\mathbb{R}^m)$ is decomposable, then $I(K)$ is convex and $I(K) = I(\operatorname{co} K)$. If, in addition, K is strongly closed in the L^1 topology, then $I(K)$ contains the compact extremal faces of $\overline{I(K)}$.*

3. The main result. In this section we state the main theorem of the paper, and we give some examples. The proof will be postponed to section 7.

We collect here the hypotheses that will be used in the rest of the paper. Conditions (G1)–(G3) will be enough to prove the existence of a solution to the convex problem (2). In order to obtain a solution to (1) we also need the hypotheses (G4) and (G5).

(G1) The map $g\colon [0,R]\times[0,+\infty[\to \overline{\mathbb{R}}$ is a normal integrand, and $\operatorname{Dom} g^{**}(t,\cdot) = \mathbb{R}$ for a.e. $t \in [0,R]$.

(G2) The map $t \mapsto g^{**}(t,0)$ is integrable on $[0,R]$.

(G3) There exist a positive constant m and a function $b \in L^1(0,R)$ such that

$$g^{**}(t,\xi) \geq m|\xi| - b(t) \quad \text{a.e. } t \in [0,R] \ \forall \xi \in \mathbb{R}. \tag{8}$$

(G4) For every $r_1 > 0$ there exists $r_2 > 0$ such that, for a.e. $t \in [0,R]$ and every $p \in \mathbb{R}$, if $\partial g^*(t,p) \cap \overline{B}_{r_1} \neq \emptyset$ then $\partial g^*(t,p) \subseteq B_{r_2}$.

(G5) The map $t \mapsto g(t,\xi)$ is integrable on $[0,R]$ for every $\xi \in \mathbb{R}$.

Remark 3.1. 1. It is easy to prove that, if (G2) holds, then (G3) is equivalent to

(G3′) There exists a positive constant m such that $g^*(\cdot,p) \in L^1(0,R)$ for every $p \in [-m,m]$.

Indeed, let us assume that (G3) holds, and let $p \in [-m,m]$. From (G3) and the definition of g^* we deduce that

$$-g^{**}(t,0) \leq g^*(t,p) \leq b(t) \quad \text{a.e. } t \in [0,R]; \tag{9}$$

hence, from (G2), we conclude that $g^*(\cdot,p) \in L^1(0,R)$. Conversely, assume that the condition (G3′) holds. Then it is easy to check that (G3) holds with $b(t) \doteq \max\{g^*(t,m),\, g^*(t,-m)\}$.

2. Assumption (G3) looks similar to other growth conditions found in literature, suitable to minimize fixed endpoint variational problems (see, for example, [8, §10.4, §11.1]). The main difference is that these conditions require that for every $m \in \mathbb{R}$ (and not only for a fixed one) there exists an integrable function $b = b_m$ such that (8) holds. For example, let us consider a function g satisfying the bounds $a_1|\xi| - a_2 \leq g(t,\xi) \leq c_1|\xi| + c_2$ for some positive constants a_j, c_j, $j = 1,2$. It is clear that (G3) holds with $m = a_1$, whereas (8) cannot hold if $m > c_1$. It should be noted that the weaker growth condition (G3) is sufficient since only one fixed endpoint is prescribed.

3. It is easy to see that, if (G4) holds, then $g^{**}(t,\xi)$ is strictly convex at infinity with respect to ξ for almost every fixed $t \in [0,R]$. Furthermore, from Proposition 2.2 in [10], we have that (G4) holds if, for example, the function $g^{**}(t,\xi)$ is continuous on $[0,R] \times \mathbb{R}$ and strictly convex at infinity with respect to ξ for every fixed $t \in [0,R]$.

4. If g is coercive, that is, if $g(t,\xi) \geq \psi(|\xi|)$ where $\psi\colon [0,+\infty[\to \mathbb{R}$ is a continuous increasing function satisfying $\lim_{s\to+\infty} \psi(s)/s = +\infty$, then g satisfies (G3) and (G4).

5. From (G3) it follows that the functional $\overline{\Gamma}$ defined in (2) is bounded from below.

6. It is worth rewriting conditions (G1)–(G5) when $g \equiv g(\xi)$ does not depend on t. It is easy to see that assumptions (G1)–(G3) and (G4)–(G5) can be replaced, respectively, by (g1)–(g2) and (g3) below.

(g1) $g\colon \mathbb{R} \to \overline{\mathbb{R}}$ is a lower semicontinuous function, and $\operatorname{Dom} g^{**} = \mathbb{R}$.

(g2) There exist positive constants m and b such that $g^{**}(\xi) \geq m|\xi| - b$ for every $\xi \in \mathbb{R}$.

(g3) g^{**} is strictly convex at infinity, and $g(\xi) \in \mathbb{R}$ for every $\xi \in \mathbb{R}$.

THEOREM 3.2. *Assume that* (G1)–(G3) *hold. Then the convex problem* (2) *admits a solution* $\bar{v} \in V$ *satisfying the Euler–Lagrange inclusion*

$$0 \in \partial g^{**}(t, \bar{v}'(t)) \quad \text{a.e. } t \in [0,R]. \tag{10}$$

If, in addition, (G4) *and* (G5) *hold, then* $\bar{v}$ *satisfies*

$$g(t,\bar{v}'(t)) = g^{**}(t,\bar{v}'(t)) \qquad \text{a.e. } t \in [0,R], \tag{11}$$

thus providing a solution to the nonconvex problem (1).

Remark 3.3. Notice that, if assumption (G5) holds, then for every $\alpha \in \mathbb{R}$ the set $\{v \in V(\alpha);\ \overline{\Gamma}(v) < +\infty\}$ is not empty (we recall that $V(\alpha)$ is the set defined in (4)). Hence, if (G1)–(G3) and (G5) hold, from Corollary 1 in [23] we can infer that $\bar{v}$ is a solution to problem (2) if and only if it satisfies the Euler–Lagrange inclusion (10).

Example 3.4. Let $n = 1$, and consider the function $g(t, \xi) \doteq g_0(|\xi|) - t\,\xi$, where

$$g_0(s) \doteq \begin{cases} s - \sqrt{s} & \text{if } s > 1/4, \\ -1/4 & \text{if } 0 \le s \le 1/4. \end{cases}$$

It is easy to show that the assumptions (G1), (G2), (G4), and (G5) are satisfied, whereas (G3) is satisfied if and only if $R < 1$ (it is enough to choose $m = 1 - R$).

We are going to show that, if $R \ge 1$, then the variational problem (1) has no solution. Let $R \ge 1$, and assume by contradiction that $u \in V$ is a solution to (1). It is easy to check that $\xi \mapsto g_0(|\xi|)$ is continuously differentiable and $g_0'(s) = 1 - s^{-1/2}/2$ if $s > 1/4$, while $g_0'(s) = 0$ if $0 \le s \le 1/4$. From the Euler–Lagrange necessary conditions (10) we deduce that $g_0'(|u'(t)|)\,\operatorname{sign} u'(t) = t$ for a.e. $t \in [0, R]$. Since $|g_0'(s)| < 1$ for every s, this relation cannot be satisfied a.e. if $R > 1$. In the case $R = 1$ we deduce that $u'(t) = \left[4(1-t)^2\right]^{-1}$ for a.e. $t \in [0, 1]$. But now $u' \notin L^1(0, 1)$, giving a contradiction.

Example 3.5. Let $n = 1$, $g(t, \xi) \doteq \sqrt{1 + \xi^2} - t\,\xi$. Again, (G1), (G2), (G4), and (G5) are satisfied, whereas (G3) holds if and only if $R < 1$, choosing $m = 1 - R$. It is easy to see that, in this case, for every $R > 1$ problem (1) does not have a solution. Indeed, if u is a solution, then from the Euler–Lagrange necessary conditions (10) we have that $u'(t)/\sqrt{1 + u'(t)^2} = t$ for a.e. $t \in [0, R]$. Since the left-hand side is strictly less than 1 for every t, this condition cannot be satisfied if $R > 1$.

4. Application to radially symmetric problems. In this section we give an application of Theorem 3.2 to radially symmetric variational problems of the form (5).

We collect here the assumptions on f and a. Conditions (H1)–(H4) will be enough to prove the existence of a solution to the relaxed problem

$$\min_{u \in W_0^{1,1}(B_R)} \int_{B_R} \left[f^{**}\left(|x|, |\nabla u(x)|\right) + a(|x|)\, u(x) \right] dx. \tag{12}$$

In order to obtain a solution to the nonconvex problem (5) we also need the hypotheses (H5) and (H6).

(H1) The map $f\colon [0, R] \times [0, +\infty[\to \overline{\mathbb{R}}$ is a normal integrand, and $\operatorname{Dom} f^{**}(t, \cdot) = \mathbb{R}$ for a.e. $t \in [0, R]$.

(H2) The map $x \mapsto f^{**}(|x|, 0)$ is integrable on B_R; that is, $t \mapsto t^{n-1} f^{**}(t, 0)$ is integrable on $[0, R]$.

(H3) The function $A\colon [0, R] \to \mathbb{R}$ defined by $A(0) \doteq 0$, $A(t) \doteq t^{1-n} \int_0^t s^{n-1} a(s)\, ds$, $t \in]0, R]$, belongs to $L^\infty(0, R)$.

(H4) There exists a constant $M > \|A\|_{L^\infty}$ such that for every $\rho \in [0, M[$ there exists a function $c_\rho \in L^1(0, R)$ such that

$$f^{**}(t, \xi) \ge \rho\,|\xi| - t^{1-n} c_\rho(t) \quad \text{a.e. } t \in [0, R],\ \xi \in \mathbb{R}.$$

(H5) For every $r_1 > 0$ there exists $r_2 > 0$ such that, for every $(t, p) \in [0, T] \times \mathbb{R}$, if $\partial f^*(t, p) \cap \overline{B}_{r_1} \ne \emptyset$, then $\partial f^*(t, p) \subseteq B_{r_2}$.

(H6) The map $t \mapsto t^{n-1} f(t, s)$ is integrable on $[0, R]$ for every $s \in [0, +\infty[$.

Remark 4.1. From (H4) we deduce that $M \le \operatorname{ess\,inf}_{t\in[0,R]} M(t)$, where $M(t) \doteq \lim_{s\to+\infty} f^{**}(t,s)/s$.

We are now in a position to state the main theorem concerning radially symmetric problems. The proof will be postponed to section 5.

THEOREM 4.2. *Assume that* (H1)–(H4) *hold. Then the convex problem* (12) *has at least one radially symmetric solution* $\tilde u(x) = \bar u(|x|)$, *and* $\bar u$ *satisfies the Euler–Lagrange inclusion*

$$\bar u'(t) \in \partial f^*(t, A(t)) \quad \text{a.e. } t \in [0,R]. \tag{13}$$

Furthermore, if either $a(t) > 0$ *(resp.,* < 0*) for a.e.* $t \in [0,R]$ *or* $f^{**}(t,\cdot)$ *has a strict minimum at* 0 *for a.e.* $t \in [0,R]$, *then every solution to* (12) *is radially symmetric.*

If, in addition, (H5) *and* (H6) *hold, then* $\tilde u$ *satisfies*

$$f(|x|, |\nabla \tilde u(x)|) = f^{**}(|x|, |\nabla \tilde u(x)|) \qquad \text{for a.e. } x \in B_R, \tag{14}$$

thus providing a solution to the nonconvex problem (5).

For the reader's convenience, we state Theorem 4.2 in the case $f = f(|\xi|)$ does not depend explicitly on x.

THEOREM 4.3. *Assume the following:*

(i) $f\colon [0,+\infty[\to \overline{\mathbb{R}}$ *is a lower semicontinuous function, and* $\operatorname{Dom} f^{**} = \mathbb{R}$;

(ii) $M \doteq \lim_{s\to+\infty} f^{**}(s)/s > 0$;

(iii) $a \in L^1(0,R)$ *and* $\sup_{t\in]0,R]} \left| t^{1-n} \int_0^t s^{n-1}\, a(s)\, ds \right| < M$.

Then the variational problem

$$\min_{u\in W_0^{1,1}(B_R)} \int_{B_R} \left[f^{**}\left(|\nabla u(x)|\right) + a(|x|)\, u(x) \right] dx \tag{15}$$

has a radially symmetric solution. If, in addition,

(iv) f^{**} *is strictly convex at infinity,*

then the nonconvex problem

$$\min_{u\in W_0^{1,1}(B_R)} \int_{B_R} \left[f\left(|\nabla u(x)|\right) + a(|x|)\, u(x) \right] dx \tag{16}$$

has a radially symmetric solution.

Remark 4.4. In the particular case $a(t) \equiv 1$, condition (iii) becomes

(iii′) $R < nM$.

In this case the bound $R < nM$ is optimal, in the sense explained in Example 3.4.

Example 4.5. We discuss here an example treated in [5, 25, 4] without the symmetry assumption on the domain. Let $a(t) \equiv 1$, and let $f\colon [0,+\infty[\to \overline{\mathbb{R}}$ be a lower semicontinuous function satisfying $f(L) = 0$ for some $L > 0$, and

$$f(s) \ge \max\{0, \lambda(s-L)\} \quad \forall s \ge 0$$

for some $\lambda > 0$. It easy to see that $f^{**}(\xi) = 0$ if $|\xi| \le L$, while $f^{**}(\xi) \ge \lambda(|\xi| - L)$ if $|\xi| \ge L$, so that $M \ge \lambda$.

Now we want to apply Theorem 4.3. Conditions (i) and (ii) are satisfied by f^{**}, while (iii′) is certainly satisfied if $R < n\lambda$. Thus, if $R < n\lambda$, there exists a solution $\tilde u(x) = \bar u(|x|)$ to (15), and $\bar u(t)$ satisfies (13), that is,

$$\frac{t}{n} \in \partial f^{**}(\bar u'(t)) \quad \text{a.e. } t \in [0,R]. \tag{17}$$

This implies that $\bar{u}'(t) \geq 0$ for a.e. t. It is easy to check that

$$\partial f^{**}(s) \begin{cases} = \{0\} & \text{if } 0 \leq s < L, \\ \supseteq [0, \lambda] & \text{if } s = L, \\ \subseteq [\lambda, +\infty[& \text{if } s > L. \end{cases} \tag{18}$$

Furthermore, the condition $R < n\lambda$ implies that $0 < t/n < \lambda$ for every $t \in]0, R]$, so that from (17) and (18) we necessarily have $\bar{u}'(t) = L$ a.e. $t \in [0, R]$; that is, $\bar{u}(t) = -L(R - t)$, $t \in [0, R]$. Thus a solution $\tilde{u}$ to (15) is given by $\tilde{u}(x) \doteq -L \operatorname{dist}(x, \partial B_R)$. Since $f^{**}(L) = f(L)$, $\tilde{u}$ provides a solution to (16) even if f is not convex. In [5, 25] it was proved that there exists a solution whenever $R \leq n\lambda$.

5. Proof of Theorem 4.2. We collect here some results that will be used in order to reduce (12) to a one-dimensional problem (see [7, Thms. 1 and 2]).

PROPOSITION 5.1. *Problem* (12) *has a solution if and only if it admits at least one radially symmetric solution. Furthermore, if either* $a(t) > 0$ *(resp.,* < 0*) for a.e.* $t \in [0, R]$ *or* $f^{**}(t, \cdot)$ *has a strict minimum at* 0 *for a.e.* $t \in [0, R]$*, then every solution to* (12) *is radially symmetric.*

Proposition 5.1 implies that problem (12) is equivalent to

$$\min_{u \in W} \int_0^R t^{n-1} \left[f^{**}(t, u'(t)) + a(t)\, u(t) \right] dt, \tag{19}$$

where

$$W \doteq \left\{ u \in AC_{loc}(]0, R]);\ u(R) = 0,\ t \mapsto t^{n-1} u'(t) \in L^1(0, R) \right\}, \tag{20}$$

in the sense that (12) has a solution if and only if (19) has a solution.

In order to treat problem (19), we need a further reduction. We begin by proving an integration-by-parts lemma involving functions in the set W defined in (20).

LEMMA 5.2. *Let* $a \in L^1(0, R)$*,* $u \in W$*. Then the maps* $t \mapsto t^{n-1} a(t) u(t)$ *and* $t \mapsto B(t) u'(t)$*,* $B(t) \doteq \int_0^t s^{n-1} a(s)\, ds$*, are integrable on* $[0, R]$*, and the following integration-by-parts formula holds:*

$$\int_0^R t^{n-1} a(t) u(t)\, dt = -\int_0^R B(t) u'(t)\, dt. \tag{21}$$

Proof. Since $u \in W$, there exists $k \in L^1(0, R)$ such that $u'(t) = t^{1-n} k(t)$ a.e. $t \in [0, R]$; that is, $u(t) = -\int_t^R s^{1-n} k(s)\, ds$. Clearly we have

$$|u(t)| \leq t^{1-n} \|k\|_{L^1} \qquad \text{a.e. } t \in [0, R], \tag{22}$$

so that $|t^{n-1}\, a(t)\, u(t)| \leq \|k\|_{L^1} |a(t)| \in L^1(0, R)$. Furthermore, from the trivial estimate

$$|B(t)| \leq t^{n-1} \int_0^t |a(s)|\, ds, \qquad t \in [0, R], \tag{23}$$

we deduce that $|B(t) u'(t)| \leq \|a\|_{L^1} |k(t)| \in L^1(0, R)$. In order to prove (21), from the properties of the Lebesgue integral it suffices to show that

$$\lim_{\varepsilon \to 0+} \int_\varepsilon^R t^{n-1} a(t) u(t)\, dt = -\lim_{\varepsilon \to 0+} \int_\varepsilon^R B(t) u'(t)\, dt.$$

Integrating by parts we have that

$$\int_\varepsilon^R t^{n-1}a(t)u(t)\,dt = -B(\varepsilon)u(\varepsilon) - \int_\varepsilon^R B(t)u'(t)\,dt.$$

It remains to prove that $\lim_{\varepsilon\to 0+} B(\varepsilon)u(\varepsilon) = 0$. From (22) and (23) we infer that $|B(\varepsilon)u(\varepsilon)| \le \|k\|_{L^1}\int_0^\varepsilon |a(s)|\,ds$, and from the absolute continuity of the integral the last term tends to zero as $\varepsilon \to 0^+$. □

Using Lemma 5.2, we can integrate by parts the term $a(t)\,u(t)$ in (19), so that the integral in (19) is equal to $\int_0^R t^{n-1}\left[f^{**}(t,u'(t)) - A(t)\,u'(t)\right]\,dt$, where A is the function defined in (H3). With every $u \in W$ we associate a function $v \in V$ in the following way:

$$v(t) \doteq -\int_t^R s^{n-1}u'(s)\,ds.$$

It is easy to see that the map $u \in W \mapsto v \in V$ is a bijection; hence problem (19) is equivalent to problem (2), with

$$g(t,\xi) \doteq t^{n-1} f\left(t, \frac{|\xi|}{t^{n-1}}\right) - A(t)\,\xi, \tag{24}$$

in the sense that (19) has a solution if and only if (2) has a solution.

It remains to prove that the assumptions of Theorem 3.2 are satisfied. Clearly, (G1), (G2), and (G4), respectively, are equivalent to (H1), (H2), and (H5). It is also easy to verify that (H3) and (H6) imply (G5). Furthermore, from (H3) and (H4) we deduce that for every $\rho \in [0, M[$ there exists $c_\rho \in L^1(0,R)$ such that

$$g^{**}(t,\xi) \ge \rho|\xi| - c_\rho(t) - A(t)\xi \quad \text{a.e. } t \in [0,R]\ \forall \xi \in \mathbb{R}.$$

Now, from (H4), it is clear that (G3) holds choosing $m \in]0, M - \|A\|_{L^\infty}[$.

6. A minimization problem involving the Laplacian. Consider the minimization problem

$$\min_{u\in W_*} \int_{B_R} \left[f(|x|, \triangle u(x)) + a(|x|)\,u(x)\right]\,dx, \tag{25}$$

where $W_* \doteq \{u \in W^{2,1}(B_R) \cap W_0^{1,1}(B_R);\ \frac{\partial u}{\partial n} = 0 \text{ on } \partial B_R\}$. This kind of problem was considered in [6] for superlinear Lagrangians. In that paper it was proved that the corresponding relaxed problem

$$\min_{u\in W_*} \int_{B_R} \left[f^{**}(|x|, \triangle u(x)) + a(|x|)\,u(x)\right]\,dx \tag{26}$$

has a solution if and only if it admits at least one radially symmetric solution.

We recall that, if $\tilde u \in W_*$ is radially symmetric, that is, $\tilde u(x) = \bar u(|x|)$ for some $\bar u \in W_S \doteq \{u \in W^{2,1}_{loc}(]0,R]);\ \exists v \in W_* \text{ s.t. } u(|x|) = v(x)\}$, then, for $x \neq 0$, one has

$$\triangle\tilde u(x) = |x|^{1-n}\frac{d}{dt}\left[t^{n-1}\bar u'(t)\right]_{t=|x|}. \tag{27}$$

Let us define $V_* \doteq \left\{w \in W^{2,1}([0,R]);\ w(R) = 0,\ w'(R) = 0\right\}$. To every $u \in W_S$ we can associate a $w \in V_*$ by setting $w'(t) = t^{n-1}u'(t)$, $t \in]0,R]$.

Now, let $B(t) \doteq \int_0^t s^{n-1}a(s)\,ds$, $A(t) \doteq -\int_0^t s^{1-n}B(s)\,ds$, $t \in [0,R]$. Let $u \in W_S$, and let w be the corresponding function in V_*. Integrating twice by parts (see Lemma 5.2) we deduce that

$$\int_0^R t^{n-1}a(t)\,u(t)\,dt = -\int_0^R B(t)\,u'(t)\,dt$$
$$= -\int_0^R t^{1-n}w'(t)\,B(t)\,dt = -\int_0^R A(t)\,w''(t)\,dt.$$

Recalling (27), this implies that (26) is equivalent to

$$\min_{w\in V_*}\int_0^R \left[t^{n-1}f^{**}(t,t^{1-n}w''(t)) - A(t)\,w''(t)\right]\,dt, \tag{28}$$

in the sense that (26) has a solution if and only if (28) has a solution.

We can make a further reduction, associating with every $w \in V_*$ a function $v \in V$ such that $w' = v$, obtaining the minimization problem (2). Thus we can conclude that the following existence theorem for (25) holds.

THEOREM 6.1. *Assume that* (H1) *and* (H2) *hold, that the function*

$$A(t) \doteq \int_0^t s^{1-n}\left(\int_0^s \sigma^{n-1}a(\sigma)\,d\sigma\right)\,ds, \qquad t \in [0,R],$$

belongs to $L^\infty(0,R)$, *and* (H4) *is satisfied. Then problem* (26) *has at least one radially symmetric solution. If, in addition,* (H5) *and* (H6) *hold, then the nonconvex problem* (25) *has a radially symmetric solution.*

7. Proof of Theorem 3.2. In the first part of this section we shall study the convex problem (2), so that only conditions (G1)–(G3) will be assumed to hold. Finally, starting from Lemma 7.13 below, we shall prove that, under the additional conditions (G4) and (G5), the nonconvex problem (1) has a solution.

LEMMA 7.1. *Assume that* (G1)–(G3) *hold. Then the set*

$$H \doteq \left\{p \in \mathbb{R} :\ g^*(\cdot,p) \in L^1(0,R)\right\} \tag{29}$$

is an interval, and $[-m,m] \subseteq H$.

Proof. Let $p,q \in H$ and define $p_\lambda \doteq \lambda p + (1-\lambda)q$, $\lambda \in [0,1]$. From (G2) and the inequality

$$-g^{**}(t,0) \le g^*(t,p_\lambda) \le \lambda g^*(t,p) + (1-\lambda)g^*(t,q) \quad \text{a.e. } t \in [0,R]\ \forall \lambda \in [0,1],$$

it follows that $p_\lambda \in H$ for every $\lambda \in [0,1]$, and this proves that H is an interval. The inclusion $[-m,m] \subseteq H$ follows from (G3′). □

LEMMA 7.2. *Assume that* (G1)–(G3) *hold. Then, for every* $p \in]-m,m[$, *the set* S *of all measurable selections of the multifunction* $t \mapsto \partial g^*(t,p)$ *is integrably bounded.*

Proof. Choose $\varepsilon > 0$ such that $\overline{B}_\varepsilon(p) \subset]-m,m[$. Let $h \in S$. From the inequality

$$g^*(t,q) - g^*(t,p) \ge h(t)(q-p) \quad \forall q \in \mathbb{R} \text{ a.e. } t \in [0,R],$$

we get

$$-\varepsilon^{-1}\left[g^*(t,p-\varepsilon) - g^*(t,p)\right] \le h(t) \le \varepsilon^{-1}\left[g^*(t,p+\varepsilon) - g^*(t,p)\right],$$

and the conclusion now follows from Lemma 7.1. □

The first part of Theorem 3.2 can be already proved at this stage.

THEOREM 7.3. *Assume that* (G1)–(G3) *hold. Then problem* (2) *has a solution. More precisely, if* ξ *is a measurable selection of* $\partial g^*(\cdot,0)$*, then the function* $\bar v(t) \doteq -\int_t^R \xi(s)\,ds$ *provides a solution to* (2).

Proof. Since $0 \in]-m,m[$, from Lemma 7.2 we have that $\xi \in L^1(0,R)$, so that the function $\bar v(t) \doteq -\int_t^R \xi(s)\,ds$, $t \in]0,R]$, belongs to V. It is easy to see that $\bar v$ is a solution to (2). Indeed, since $0 \in \partial g^{**}(t,\bar v'(t))$ a.e. $t \in [0,R]$, we have that $\overline\Gamma(v) - \overline\Gamma(\bar v) \geq 0$ for every $v \in V$. □

In order to proceed with the analysis of problem (1), we need a further reduction. More precisely, for every $\alpha \in \mathbb{R}$ let us consider the functions

$$\phi(\alpha) \doteq \inf_{v\in V(\alpha)} \Gamma(v), \qquad \overline\phi(\alpha) \doteq \inf_{v\in V(\alpha)} \overline\Gamma(v), \tag{30}$$

where $V(\alpha)$ is the set defined in (3), with the convention $\inf\emptyset = +\infty$ (we recall that, at this stage, we are not assuming (G5), so that the maps ϕ and $\overline\phi$ may well assume the value $+\infty$ at some point). Now it is easy to see that (1) has a solution if and only if there exists $\overline a \in \mathbb{R}$ such that $\phi(\overline a) = \min_\alpha \phi(\alpha)$, and the fixed endpoints variational problem (4) has a solution for $\alpha = \overline a$. The same conclusion holds for the functional $\overline\Gamma$ and the associated function $\overline\phi$.

First we shall prove that the problem (3) has a solution for every $\alpha \in J$, where J is a nonempty (possibly unbounded) closed interval of $\mathbb{R}$. Then we shall prove that $\overline\phi$ attains its minimum in a point $\overline a \in J$, so that (2) has a solution. In order to prove that (1) has a solution, we shall show that $\phi \equiv \overline\phi$, and that (4) has a solution for $\alpha = \overline a$. For the analysis of noncoercive nonconvex problems like (4) see also [11, 12]. Necessary and sufficient conditions for the existence of solutions to the convex problem (3) can be found in [18], in the case $g^{**}(t,\cdot)$ continuously differentiable for a.e. t.

We recall a weak form of the Euler–Lagrange inclusion that will be used in the sequel (see [1, Thm. 3.1]).

THEOREM 7.4. *If* v *is a solution to* (3)*, then there exists* $p \in \mathbb{R}$ *such that*

$$p \in \partial g^{**}(t,v'(t)) \qquad \text{a.e. } t \in [0,R]. \tag{31}$$

Remark 7.5. If $h \in L^1(0,R)$ is an integrable selection of $\partial g^*(\cdot,p)$ for some p, then the function $v(t) \doteq -\int_t^R h(s)\,ds$ solves (2) for $\alpha = \int_0^R h(s)\,ds$. Namely,

$$\overline\Gamma(w) - \overline\Gamma(v) = \int_0^R \left[g^{**}(t,w'(t)) - g^{**}(t,v'(t))\right]\,dt \geq p\int_0^R \left[w'(t) - v'(t)\right]\,dt = 0$$

for every $w \in V(\alpha)$.

Let $h_1, h_2 \colon [0,R] \to [-\infty,+\infty]$ be the measurable functions defined by

$$h_1(t) \doteq \lim_{p\to -m+} (g^*)'_-(t,p), \quad h_2(t) \doteq \lim_{p\to m-} (g^*)'_+(t,p). \tag{32}$$

We remark that these limits exist, finite or infinite, for every $t \in [0,R]$, since the maps $p \mapsto (g^*)'_\pm(t,p)$ are monotone nondecreasing. Let us define $\alpha_j \doteq \int_0^R h_j(t)\,dt$, $j = 1,2$. Clearly $\alpha_1 \leq \alpha_2$, and, by Lemma 7.2, $\alpha_1 \in [-\infty,+\infty[$, $\alpha_2 \in]-\infty,+\infty]$. Let us define the closed interval

$$J \doteq \{\alpha \in \mathbb{R};\ \alpha_1 \leq \alpha \leq \alpha_2\}. \tag{33}$$

Remark 7.6. If $\alpha_1 \in \mathbb{R}$, then by definition $h_1 \in L^1(0,R)$. Furthermore, from (6), $h_1(t) = (g^*)'_+(t,-m)$ for a.e. $t \in [0,R]$. Now, from Remark 7.5, we can conclude that problem (3) has a solution for $\alpha = \alpha_1$. The same argument works for α_2 if $\alpha_2 \in \mathbb{R}$.

THEOREM 7.7. *Assume that* (G1)–(G3) *hold. Then problem* (3) *has a solution for every* $\alpha \in J$.

Proof. If $\alpha_j \in \mathbb{R}$ for some $j \in \{1,2\}$ and $\alpha = \alpha_j$, then the proof follows from Remark 7.6. Now let us assume that $\alpha \in]\alpha_1, \alpha_2[$. The maps $I^{\pm}\colon]-m,m[\to \mathbb{R}$,

$$I^{\pm}(p) \doteq \int_0^R (g^*)'_{\pm}(t,p)\,dt,$$

are monotone nondecreasing and $I^-(p) \le I^+(p)$ for every $p \in]-m,m[$. Furthermore, from the monotone convergence theorem and the fact that

$$\lim_{p\to -m+} (g^*)'_-(t,p) = \lim_{p\to -m+} (g^*)'_+(t,p),$$
$$\lim_{p\to m-} (g^*)'_-(t,p) = \lim_{p\to m-} (g^*)'_+(t,p),$$

one gets

$$\lim_{p\to -m+} I^{\pm}(p) = \alpha_1, \qquad \lim_{p\to m-} I^{\pm}(p) = \alpha_2.$$

Hence there exists $p \in]-m,m[$ such that $I^-(p) \le \alpha \le I^+(p)$. Let S be the set of all measurable selections of $\partial g^*(\cdot,p)$. Since $p \in]-m,m[$, from Lemma 7.2 S is integrably bounded; hence by Aumann's theorem (see [9, Thm. 7.2.1]) we obtain $\{\int_0^R h(t)\,dt;\ h \in S\} = [I^-(p), I^+(p)]$. Thus we can conclude that there exists $h \in S$ such that $\int_0^R h(t)\,dt = \alpha$, so that, recalling Remark 7.5, the proof is complete. ∎

Now we prove some properties of the maps ϕ and $\overline{\phi}$ defined in (30). We recall that, from Remark 3.1(5), these maps are bounded from below.

LEMMA 7.8. *The maps* $\overline{\phi}$ *and* ϕ *are convex.*

Proof. Let us define

$$K_1 \doteq \left\{(u,v) \in L^1(0,R)\times L^1(0,R);\ v(t) \ge g^{**}(t,u(t)) \text{ a.e. } t\right\}, \tag{34}$$

$$K_2 \doteq \left\{(u,v) \in L^1(0,R)\times L^1(0,R);\ v(t) \ge g(t,u(t)) \text{ a.e. } t\right\}. \tag{35}$$

Since the sets K_j are decomposable, from Theorem 2.1 we deduce that the sets $I(K_j)$, $j = 1,2$, defined in (7), are convex subsets of $\mathbb{R}^2$. From the very definition of $\overline{\phi}$ and ϕ we infer that

$$\begin{aligned} &I(K_1) \subseteq \operatorname{epi}\overline{\phi} \subseteq \overline{I(K_1)}, \quad I(K_2) \subseteq \operatorname{epi}\phi \subseteq \overline{I(K_2)},\\ &\operatorname{epi}\overline{\phi} \setminus \operatorname{graph}\overline{\phi} \subset I(K_1), \quad \operatorname{epi}\phi \setminus \operatorname{graph}\phi \subset I(K_2). \end{aligned} \tag{36}$$

Let us prove that $\overline{\phi}$ is convex. Assume by contradiction that there exist $\alpha,\beta \in \mathbb{R}$, $\lambda \in]0,1[$, and $\varepsilon > 0$ such that $\overline{\phi}(\lambda\alpha + (1-\lambda)\beta) = \lambda\overline{\phi}(\alpha) + (1-\lambda)\overline{\phi}(\beta) + 2\varepsilon$. Since $(\alpha, \overline{\phi}(\alpha)+\varepsilon)$, $(\beta, \overline{\phi}(\beta)+\varepsilon) \in I(K_1)$, from the convexity of $I(K_1)$ we deduce that $(\lambda\alpha + (1-\lambda)\beta, \lambda\overline{\phi}(\alpha) + (1-\lambda)\overline{\phi}(\beta) + \varepsilon) \in I(K_1)$. By the definition of $I(K_1)$ and $\overline{\phi}$, this implies that $\overline{\phi}(\lambda\alpha + (1-\lambda)\beta) \le \lambda\overline{\phi}(\alpha) + (1-\lambda)\overline{\phi}(\beta) + \varepsilon$, a contradiction. The convexity of ϕ can be proved in the same way. ∎

LEMMA 7.9. *There exists a constant* $c \in \mathbb{R}$ *such that* $\overline{\phi}(\alpha) \ge m|\alpha| - c$ *for every* $\alpha \in \mathbb{R}$. *In particular*

$$\lim_{|\alpha|\to+\infty} \overline{\phi}(\alpha) = +\infty. \tag{37}$$

Proof. Let us define $c \doteq \|b\|_{L^1} + 1$, where $b \in L^1(0,R)$ is the function given in (G3). By the very definition of $\overline{\phi}$ we have that, for every fixed $\alpha \in \operatorname{Dom}\overline{\phi}$, there exists $v \in V(\alpha)$ such that $\overline{\Gamma}(v) \le \overline{\phi}(\alpha) + 1$; hence, from (G3),

$$\overline{\phi}(\alpha) \ge \overline{\Gamma}(v) - 1 \ge m\,\|v'\|_{L^1} - c \ge m\left|\int_0^R v'(t)\,dt\right| - c = m|\alpha| - c. \tag{38}$$

Since this inequality is trivially satisfied if $\alpha \notin \operatorname{Dom}\overline{\phi}$, the lemma is proved. □

Remark 7.10. If (G5) holds, then from Lemma 7.8 we deduce that ϕ and $\overline{\phi}$ are finite convex maps on $\mathbb{R}$; hence they are continuous on $\mathbb{R}$. In general, $\operatorname{Dom}\phi$ and $\operatorname{Dom}\overline{\phi}$ can be proper subsets of $\mathbb{R}$.

LEMMA 7.11. *The map $\overline{\phi}$ is continuous relative to J.*

Proof. Since $\overline{\phi}$ is a convex function and, by Theorem 7.7, $J \subseteq \operatorname{Dom}\overline{\phi}$, we have that $\overline{\phi}$ is upper semicontinuous relative to J (see [22, Thm. 10.2]); hence it is enough to prove that it is lower semicontinuous relative to the same interval.

Let $(a_k)_k \subset \operatorname{Dom}\overline{\phi}$, $\lim_k a_k = \alpha \in J$. From Theorem 7.7 there exist $v \in V(\alpha)$, $v_k \in V(a_k)$, $k \in \mathbb{N}$, such that $\overline{\Gamma}(v) = \overline{\phi}(\alpha)$, $\overline{\Gamma}(v_k) \le \overline{\phi}(a_k) + 1/k$, $k \in \mathbb{N}$. From Theorem 7.4 there exists $p \in \mathbb{R}$ such that $p \in \partial g^{**}(t, v'(t))$ a.e. $t \in [0,R]$ so that, for every $k \in \mathbb{N}$,

$$g^{**}(t, v_k'(t)) - g^{**}(t, v(t)) \ge p(v_k'(t) - v'(t)) \quad \text{a.e. } t \in [0,R].$$

Integrating this inequality we get, for every $k \in \mathbb{N}$,

$$\overline{\phi}(a_k) - \overline{\phi}(\alpha) + \frac{1}{k} \ge \overline{\Gamma}(v_k) - \overline{\Gamma}(v) \ge p\int_0^R [v_k'(t) - v'(t)]\,dt = p(a_k - \alpha).$$

Taking the $\liminf$ for $k \to +\infty$ we obtain $\overline{\phi}(\alpha) \le \liminf_k \overline{\phi}(a_k)$, which concludes the proof. □

PROPOSITION 7.12. *The map $\overline{\phi}$ attains its minimum in J; that is,*

$$\inf_{\alpha\in\mathbb{R}} \overline{\phi}(\alpha) = \min_{\alpha\in J} \overline{\phi}(\alpha). \tag{39}$$

Proof. Let us assume that $\alpha_1 \in \mathbb{R}$. Let $v(t) \doteq -\int_t^R h_1(s)\,ds$, $t \in [0,R]$, where h_1 is the function defined in (32). From Remark 7.6 we easily infer that $v \in V(\alpha_1)$, $\overline{\Gamma}(v) = \overline{\phi}(\alpha_1)$, and $h_1(t) \in \partial g^*(t,-m)$ for a.e. $t \in [0,R]$.

Let us fix $\alpha \in \operatorname{Dom}\overline{\phi}$. For every $\varepsilon > 0$ there exists $v_\varepsilon \in V(\alpha)$ such that $\overline{\Gamma}(v_\varepsilon) \le \overline{\phi}(\alpha) + \varepsilon$; hence, recalling that $v'(t) = h_1(t) \in \partial g^*(t,-m)$,

$$\begin{aligned}\overline{\phi}(\alpha) - \overline{\phi}(\alpha_1) &\ge \overline{\Gamma}(v_\varepsilon) - \overline{\Gamma}(v) - \varepsilon \\ &\ge -m\int_0^R [v_\varepsilon'(t) - v'(t)]\,dt - \varepsilon = -m(\alpha - \alpha_1) - \varepsilon.\end{aligned}$$

Since $\varepsilon > 0$ is arbitrary we deduce that

$$\overline{\phi}(\alpha) - \overline{\phi}(\alpha_1) \ge -m(\alpha - \alpha_1) \qquad \forall \alpha \in \mathbb{R}; \tag{40}$$

hence

$$\overline{\phi}(\alpha) - \overline{\phi}(\alpha_1) \ge 0 \qquad \forall \alpha \le \alpha_1. \tag{41}$$

Similarly, if $\alpha_2 \in \mathbb{R}$, with the same argument given above one can prove that

$$\overline{\phi}(\alpha) - \overline{\phi}(\alpha_2) \geq m(\alpha - \alpha_2) \qquad \forall \alpha \in \mathbb{R}; \tag{42}$$

hence

$$\overline{\phi}(\alpha) - \overline{\phi}(\alpha_2) \geq 0 \qquad \forall \alpha \geq \alpha_2. \tag{43}$$

Now (39) follows from (41), (43) and Lemmas 7.9 and 7.11. □

Notice that the analysis above provides an alternative proof of Theorem 7.3. Indeed, from Proposition 7.12, $\overline{\phi}$ reaches its minimum value in a point $\overline{a} \in J$. Let $\bar{v} \in V(\overline{a})$ be such that $\overline{\Gamma}(\bar{v}) = \overline{\phi}(\overline{a})$. For every $v \in V$, setting $\alpha = -v(0)$, we have that $\overline{\Gamma}(\bar{v}) = \overline{\phi}(\overline{a}) \leq \overline{\phi}(\alpha) \leq \overline{\Gamma}(v)$; hence $\bar{v}$ provides a solution to (2).

Now we start studying the nonconvex problem (1). In the following technical lemmas we shall denote by $\overline{G}$ the functional defined by $\overline{G}(u) \doteq \int_0^R g^{**}(t, u(t))\, dt$, $u \in L^1(0, R)$.

LEMMA 7.13. *Assume that* (G1)–(G3) *hold. Let $u \in L^1(0, R)$, and assume that $\overline{G}(u) < +\infty$. Then for every $\varepsilon > 0$ there exists $u_\varepsilon \in L^\infty(0, R)$ such that*

$$\|u_\varepsilon - u\|_{L^1} < \varepsilon, \qquad |\overline{G}(u_\varepsilon) - \overline{G}(u)| < \varepsilon.$$

Proof. For every $k \in \mathbb{N}$ let us define the truncated function $u_k \doteq (u \wedge k) \vee (-k)$. Since $u \in L^1(0, R)$, from the dominated convergence theorem we deduce that $\lim_k \|u_k - u\|_{L^1} = 0$. Furthermore, from (G3) it follows that the convex map $\xi \mapsto g^{**}(t, \xi) + b(t)$ is nonnegative for a.e. $t \in [0, R]$; hence, for every $k \in \mathbb{N}$,

$$0 \leq g^{**}(t, u_k(t)) + b(t) \leq g^{**}(t, u(t)) + g^{**}(t, 0) + 2\, b(t) \quad \text{a.e. } t \in [0, R]. \tag{44}$$

From (G2) and the facts that $\overline{G}(u) < +\infty$ and $b \in L^1(0, R)$, we deduce that the right-hand side of (44) is an integrable function on $[0, R]$. Hence, from the dominated convergence theorem, we conclude that $\lim_k \overline{G}(u_k) = \overline{G}(u)$, completing the proof. □

LEMMA 7.14. *Assume that* (G1) *and* (G4) *hold. Then for every $u_0 \in L^\infty(0, R)$ there exist $u_1, u_2 \in L^\infty(0, R)$ and a measurable function $\lambda\colon [0, R] \to [0, 1]$ such that*

$$u_0(t) = \lambda(t) u_1(t) + (1 - \lambda(t)) u_2(t) \quad \text{a.e. } t \in [0, R], \tag{45}$$

$$g^{**}(t, u_0(t)) = \lambda(t) g(t, u_1(t)) + (1 - \lambda(t)) g(t, u_2(t)) \quad \text{a.e. } t \in [0, R]. \tag{46}$$

Proof. From (G4) and Corollary 3.8 in [13] we have that there exist measurable functions u_1, u_2, and λ satisfying (45) and (46). It remains to prove that $u_1, u_2 \in L^\infty(0, R)$.

From (45) and (46) we have that, for a.e. $t \in [0, R]$, the points $u_j(t)$, $j = 0, 1, 2$, belong to the same face of $\operatorname{epi} g^{**}(t, \cdot)$. In particular, for a.e. $t \in [0, R]$ there exists $p = p(t) \in \mathbb{R}$ such that

$$u_j(t) \in \partial g^*(t, p), \quad j = 0, 1, 2. \tag{47}$$

Choosing $r_1 = \|u_0\|_{L^\infty}$, from (47) and (G4) there exists $r_2 > 0$ such that $\|u_j\|_{L^\infty} \leq r_2$, $j = 1, 2$, concluding the proof. □

PROPOSITION 7.15. *Assume that* (G1)–(G5) *hold. Then $\phi = \overline{\phi}$, and $\overline{I(K_1)} = \overline{I(K_2)}$.*

Proof. The second part of the theorem is a direct consequence of the first one. Since $g \geq g^{**}$ we have the trivial inequality $\phi \geq \overline{\phi}$. Assume by contradiction that there exists a point $\alpha \in \mathbb{R}$ such that $\phi(\alpha) > \overline{\phi}(\alpha)$. Since, from (G5), ϕ and $\overline{\phi}$ are continuous on $\mathbb{R}$, there exists $\varepsilon > 0$ such that

$$\phi(x) \geq \overline{\phi}(\alpha) + 3\varepsilon \quad \forall x \in [\alpha - \varepsilon, \alpha + \varepsilon]. \tag{48}$$

From the very definition of $\overline{\phi}$ there exists $u \in L^1(0,R)$ such that $\int_0^R u(t)\,dt = \alpha$, and $\overline{G}(u) \leq \overline{\phi}(\alpha) + \varepsilon$. From Lemma 7.13 there exists $u_0 \in L^\infty(0,R)$ such that, if $x \doteq \int_0^R u_0(t)\,dt$, then $|x - \alpha| < \varepsilon$ and

$$\overline{G}(u_0) \leq \overline{G}(u) + \varepsilon \leq \overline{\phi}(\alpha) + 2\varepsilon. \tag{49}$$

From Lemma 7.14 there exist functions $u_1, u_2 \in L^\infty(0,R)$ and a measurable map $\lambda\colon [0,R] \to [0,1]$ such that (45) and (46) hold. Since $u_j \in L^\infty(0,R)$, $j = 0,1,2$, it is easy to check that (G3) and (G5) imply that the maps $t \mapsto g^{**}(t, u_j(t))$, $j = 0,1,2$, belong to $L^1(0,R)$. Furthermore, from (46) we deduce that $g(t,u_j(t)) = g^{**}(t,u_j(t))$, $j = 1,2$, for a.e. $t \in [0,R]$; hence the maps $t \mapsto g(t,u_j(t))$, $j = 1,2$, belong to $L^1(0,R)$ too.

From Lyapunov's theorem on the range of nonatomic vector-valued measures (see, for example, [8, Thm. 16.1.v]), there exists a measurable set $E \subseteq [0,R]$ such that, denoting $E^C \doteq [0,R] \setminus E$,

$$\int_0^R [\lambda(t)u_1(t) + (1-\lambda(t))u_2(t)]\,dt = \int_E u_1(t)\,dt + \int_{E^C} u_2(t)\,dt, \tag{50}$$

$$\begin{aligned}\int_0^R [\lambda(t)g(t,u_1(t)) + (1-\lambda(t))g(t,u_2(t))]\,dt \\ = \int_E g(t,u_1(t))\,dt + \int_{E^C} g(t,u_2(t))\,dt.\end{aligned} \tag{51}$$

Let us define $\tilde{u} \doteq u_1\chi_E + u_2\chi_{E^C}$. From (45) and (50) we have that

$$\int_0^R \tilde{u}(t)\,dt = \int_0^R u_0(t)\,dt = x, \tag{52}$$

while from (51), (46), and (49) we deduce that

$$\int_0^R g(t,\tilde{u}(t))\,dt = \int_0^R g^{**}(t,u_0(t))\,dt = \overline{G}(u_0) \leq \overline{\phi}(\alpha) + 2\varepsilon. \tag{53}$$

From (52) and (53) we thus conclude that $\phi(x) \leq \overline{\phi}(\alpha) + 2\varepsilon$. Since $|x - \alpha| < \varepsilon$, this is in contradiction with (48). ∎

We are now in a position to conclude the proof of Theorem 3.2. Let us assume that (G1)–(G5) hold. Since K_2 is decomposable and strongly closed in the L^1 topology, from Theorem 2.1 it follows that $I(K_2)$ is a convex subset of $\mathbb{R}^2$ that contains every extremal compact face of $\overline{I(K_2)}$. From Propositions 7.12 and 7.15 there exists a point $\overline{a} \in J$ where ϕ attains its minimum value. Furthermore, from Lemma 7.9 we have that $\lim_{|\alpha|\to\infty} \phi(\alpha) = +\infty$, so that the point $(\overline{a}, \phi(\overline{a}))$ must belong to a compact extremal face of $\operatorname{epi}\phi = \overline{I(K_2)}$. Henceforth $(\overline{a}, \phi(\overline{a})) \in I(K_2)$; that is, there exists $\bar{v} \in V(\overline{a})$ such that $\Gamma(\bar{v}) = \phi(\overline{a})$, and $\bar{v}$ provides a solution to (1). Finally, the relation (11) follows from the equality $\Gamma(\bar{v}) = \overline{\Gamma}(\bar{v})$. ∎

Remark 7.16. The necessity of the approximation process developed in Lemmas 7.13 and 7.14, and used in Proposition 7.15, depends on the fact that, given $u_0 \in L^1(0,R)$, conditions (G1)–(G5) are not sufficient to provide the existence of integrable functions u_1 and u_2 satisfying (45) and (46).

Indeed, we shall give below an example of a function $g\colon \mathbb{R} \to \mathbb{R}$ satisfying (G1)–(G5) for which the following holds: There exists a function $u_0 \in L^1(0,1)$ such that, for every choice of functions u_1, u_2 satisfying (45) and (46), then at least one of these functions is not integrable on $[0,1]$.

Let us define $a_0 = 0$, $a_k = 2^{k^2}/k^2$ $(k = 1, 2, \dots)$, and let $(b_k)_k$ be the sequence defined by the recurrence relations $b_0 = 0$, $b_{k+1} = b_k + [1 - 1/(k+1)](a_{k+1} - a_k)$, $k = 0, 1, \dots$. It is easy to verify that $(a_k)_k$ is a strictly monotone increasing sequence, and $\lim_k a_k = +\infty$. Let $g\colon \mathbb{R} \to \mathbb{R}$ be a continuous function satisfying the following properties: $g(-\xi) = g(\xi)$ for every ξ, $g(a_k) = b_k$ for every $k \in \mathbb{N}$, and

$$g(\lambda a_k + (1-\lambda)a_{k+1}) > \lambda b_k + (1-\lambda)b_{k+1} \quad \forall \lambda \in]0,1[\ \forall k \in \mathbb{N}. \tag{54}$$

It is easy to show that g^{**} is a piecewise affine function such that

$$\partial g^{**}(\xi) = \begin{cases} \left\{1 - \dfrac{1}{k}\right\} & \text{if } |\xi| \in]a_{k-1}, a_k[,\ k \in \mathbb{N}, \\ \left[1 - \dfrac{1}{k}, 1 - \dfrac{1}{k+1}\right] & \text{if } |\xi| = a_k,\ k = 1, 2, \dots, \\ \{0\} & \text{if } \xi = 0, \end{cases}$$

and, from (54),

$$g^{**}(\xi) = g(\xi) \quad \text{if and only if} \quad |\xi| = a_k \text{ for some } k \in \mathbb{N}. \tag{55}$$

Furthermore, g satisfies (G1)–(G5): concerning (G3), it is enough to choose $m = 1/2$ and $b = 1$.

Since $a_{k+1} > a_k$ for every $k \in \mathbb{N}$ and $\lim_k (a_{k+1} - a_k) = +\infty$, there exists $\varepsilon > 0$ such that $a_k + \varepsilon < a_{k+1}$ for all $k \in \mathbb{N}$. Let us define the function

$$u_0 \doteq \sum_{k=0}^{\infty} (a_k + \varepsilon)\chi_{I_k}, \qquad I_k \doteq \left]2^{-(k+1)^2},\ 2^{-k^2}\right].$$

We claim that $u_0 \in L^1(0,1)$. Indeed, $u_0 \geq 0$, and

$$\begin{aligned} \int_0^1 u_0(t)\,dt &= \sum_{k=0}^{\infty} (a_k + \varepsilon) meas(I_k) \\ &= \sum_{k=0}^{\infty} \left(\frac{2^{k^2}}{k^2} + \varepsilon\right)\left[2^{-k^2} - 2^{-(k+1)^2}\right] < +\infty. \end{aligned}$$

Furthermore, $0 \leq g(\xi) \leq |\xi|$, so that $\overline{G}(u_0) < +\infty$. Now let u_1 and u_2 be two functions satisfying (45) and (46). Since $u_0(t) \in]a_k, a_{k+1}[$ for every $t \in I_k$, from (55) we deduce that, for a.e. $t \in I_k$, either $u_1(t) = a_k$, $u_2(t) = a_{k+1}$ or $u_1(t) = a_{k+1}$,

$u_2(t) = a_k$. Hence

$$\int_0^1 [u_1(t) + u_2(t)]\, dt = \sum_{k=0}^{\infty} (a_k + a_{k+1})\ meas(I_k) \geq \sum_{k=0}^{\infty} a_{k+1}\, meas(I_k)$$
$$= \sum_{k=0}^{\infty} \frac{2^{(k+1)^2}}{(k+1)^2} \left[2^{-k^2} - 2^{-(k+1)^2}\right] = \sum_{k=0}^{\infty} \frac{2^{2k+1} - 1}{(k+1)^2} = +\infty.$$

Thus we can conclude that at least one of the functions u_1, u_2 is not integrable on $[0, 1]$.

Acknowledgments. The author wishes to thank Annalisa Malusa for the helpful discussions during the preparation of the manuscript and the anonymous referees for making suggestions that improved the presentation of the paper.

MINIMAX CONTROL OF PARABOLIC SYSTEMS WITH STATE CONSTRAINTS*

NADIR ARADA† AND JEAN-PIERRE RAYMOND†

Abstract. In this paper we study a minimax control problem for parabolic equations in the presence of pointwise state constraints. The terminology minimax here refers to a cost functional defined with a L^∞-norm. The directional derivatives of the L^∞-norm are elements of $(L^\infty)'$. Therefore, the adjoint equation may involve finitely additive measures in place of Radon measures. To overcome this difficulty, we introduce a compactification (of Stone–Čech type). We prove necessary optimality conditions which are new, both in the case with no state constraints and in the case with state constraints. Under some convexity conditions, these optimality conditions are also sufficient.

Key words. control problems, minimax, supremum norm, pointwise state constraints, compactification

1. Introduction. In this paper, we consider an optimal control problem with a cost functional of the form

$$J(y,u) = ||F(y,u)||_{\infty,Q} = \text{ess-sup}_{(x,t)\in Q}|F(y(x,t),u(x,t))|.$$

The pair $(y,u) \in C(\overline{Q}) \times L^\infty(Q)$ (the state and control variables) satisfies a semilinear parabolic equation

$$\frac{\partial y}{\partial t} + Ay + \Phi(\cdot,y,u) = 0 \quad \text{in } Q, \quad y = \Psi|_\Sigma \quad \text{on } \Sigma, \quad y(0) = \Psi|_{\Omega\times\{0\}} \quad \text{in } \Omega, \tag{1}$$

where Ω is a bounded domain in $\mathbb{R}^N$, $Q = \Omega\times]0,T[$, $\Sigma = \Gamma\times]0,T[$, Γ is the boundary of Ω, $T > 0$, A is a second-order elliptic operator, $\Psi \in C(\overline{\Sigma} \cup (\Omega \times \{0\}))$. The set U_{ad} of admissible controls is a convex subset of $L^\infty(Q)$. Pointwise constraints of the form

$$g(x,t,y(x,t)) \le 0 \qquad \text{for all } (x,t) \in \overline{Q} \tag{2}$$

are imposed on the state variable. In this setting g is a function from $\overline{Q} \times \mathbb{R}$ into $\mathbb{R}$. The paper is concerned with the following control problem:

$$(\mathcal{P}) \qquad \inf\{J(y,u) \mid (y,u) \in C(\overline{Q}) \times U_{ad}, \ (y,u) \text{ satisfies (1) and (2)}\}.$$

As in [5], [13], we here use the terminology minimax because the cost functional is defined by an L^∞-norm. Let us mention that the same terminology is often used in the literature in the game-theoretical sense, that is, minimization with respect to control variables and maximization with respect to disturbances [11]. There is a growing interest in studying problems for functionals defined by a supremum norm [5], [9], [13], [14]. A survey of the existing literature for control problems involving supremum norm functionals, and governed by ordinary differential equations, is given

in the introduction of [5]. For problems governed by partial differential equations, the interest is more recent [9]. To understand the difficulties in deriving optimality conditions, consider the following control problem with no state constraints:

$$(\mathcal{P}_c) \qquad \inf\{I(y,u) = ||G(y,u)||_{C(\overline{Q})} \;\mid\; (y,u) \in C(\overline{Q}) \times U_c, \quad (y,u) \text{ satisfies (1)}\},$$

where U_c is a closed convex set in $C(\overline{Q})$. In this case, for a regular function G, we can prove that if $(\bar{y},\bar{u})$ is an optimal solution of $(\mathcal{P}_c)$, then there exists a Radon measure $\bar{\eta}$ on $\overline{Q}$, that is, a regular Borel measure such that

$$\int_Q \bar{p}\ \Phi'_u(\cdot,\bar{y},\bar{u})(u-\bar{u})\,dx\,dt + \Big\langle \bar{\eta}, G'_u(\bar{y},\bar{u})(u-\bar{u})\Big\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} \geq 0$$

for all $u \in U_c$, where the adjoint state $\bar{p} \in L^1(0,T;W_0^{1,1}(\Omega))$ satisfies

$$(3) \qquad \begin{cases} -\dfrac{\partial \bar{p}}{\partial t} + A^*\bar{p} + \Phi'_y(\cdot,\bar{y},\bar{u})\bar{p} + G'_y(\bar{y},\bar{u})^*\bar{\eta}|_Q = 0 & \text{in } Q, \\ \\ \bar{p}(\cdot,T) + G'_y(\bar{y},\bar{u})^*\bar{\eta}|_{\Omega_T} = 0 & \text{in } \Omega, \end{cases}$$

and

$$\bar{\eta} \neq 0, \qquad \Big\langle \bar{\eta}, z\Big\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} \leq 0 \quad \text{for all } z \in \Big\{ y \in C(\overline{Q}) \mid\; [G(\bar{y},\bar{u});y] < 0\Big\},$$

where $[G(\bar{y},\bar{u});y]$ stands for the derivative of the mapping $z \longrightarrow ||z||_{C(\overline{Q})}$ at $G(\bar{y},\bar{u})$ in the direction y (see section 2). Similar results are obtained by W. Yu for some identification problems [14]. Now, if the set of admissible controls is a subset of $L^\infty(Q)$, it is natural to consider functionals of the form of J. In this case, the main difficulty to derive optimality conditions comes from that the directional derivatives of the mapping $z \longrightarrow ||z||_{\infty,Q}$ are elements of $(L^\infty(Q))'$. Therefore, the corresponding adjoint equation may involve finitely additive measures in place of Radon measures. Contrary to (3), such an equation cannot be studied with the classical tools of distribution theory. To overcome this difficulty, we suggest following the method developed in [1], [3]. By introducing a compactification of the domain Q, we are able to prove a representation theorem for finitely additive measures belonging to $(L^\infty(Q))'$ (Theorem 4.1). Roughly speaking, with each element of $(L^\infty(Q))'$, we associate a Radon measure on $\overline{Q}$ and a bounded linear transformation. With these tools, we obtain new optimality conditions for minimax control problems with (or without) pointwise state constraints. Due to the representation theorem of elements of $(L^\infty(Q))'$, the adjoint equation is written in a classical form (with Radon measures as source terms). The bounded linear transformation intervenes only in optimality conditions for the distributed control.

In Theorem 4.2, optimality conditions are obtained in a Lagrangian form and not in the form of a Pontryagin's principle. Let us explain why. To prove a Pontryagin's principle, we need continuity properties of the cost functional with respect to diffuse perturbations of controls (see [9], [2], [6]). These continuity properties are not satisfied for J (because J is defined by a L^∞-norm). A classical way to overcome this difficulty is to approximate the L^∞-norm by a L^r-norm and to write approximate optimality conditions. But the passage to the limit when r tends to infinity can only be carried out for a subclass of admissible controls [5], [9], [13]. In this case (see [9, p. 203]), it is not obvious to verify if optimality conditions are trivial or not.

By using Lagrangian perturbations, we recover continuity properties for the cost functional, and optimality conditions are stated in Lagrangian form, but they give nontrivial information. In particular, we are able to derive some interesting corollaries (Corollaries 5.4–5.7) from the general result stated in Theorem 4.2.

In the case where $U_{ad} \subset C(\overline{Q})$, we recover classical optimality conditions (Corollary 5.4). For problems with no state constraints, optimality conditions are obtained in qualified form (Corollary 5.1). Moreover, if F is convex, necessary optimality conditions are also sufficient (Corollary 5.2). For problems with state constraints, optimality conditions in qualified form are also sufficient if F is convex (Theorem 4.5).

2. Examples and assumptions. For simplicity, we have considered only an equation with a distributed control. But the results of our paper may be extended to problems with controls on the boundary and in the initial condition. Let us give elementary examples for which optimality conditions of the paper may be applied.

EXAMPLE 1. *Let y_d be a given function in $C(\overline{Q})$. Set*

$$J(y) = ||y - y_d||_{C(\overline{Q})},$$

$$U_{ad} = \{u \in L^\infty(Q) \mid a \le u \le b\}, \qquad a \in L^\infty(Q), \qquad b \in L^\infty(Q).$$

Let y_u be the solution of

$$\frac{\partial y}{\partial t} - \Delta y = u + f \quad \text{in } Q, \quad y = 0 \quad \text{on } \Sigma, \quad y(0) = \Psi \quad \text{in } \Omega,$$

with $f \in L^q(Q)$ $(q > \frac{N}{2} + 1)$, and $\Psi \in C_o(\Omega)$. Suppose that there exists $u \in U_{ad}$ such that $z_1 \le y_u \le z_2$, where z_1, z_2 are two functions in $C(\overline{Q})$. The problem

$$\inf\{J(y_u) \ \mid \ u \in U_{ad}, \quad z_1 \le y_u \le z_2\}$$

admits solutions. Optimality conditions may be deduced from Corollary 5.7.

EXAMPLE 2. *Let y_d be a given function in $L^\infty(Q)$. Define U_{ad} as in Example* 1. *Let y_u be the solution to*

$$\frac{\partial y}{\partial t} - \Delta y + uy = f \quad \text{in } Q, \quad y = 0 \quad \text{on } \Sigma, \quad y(0) = \Psi \quad \text{in } \Omega,$$

where f and Ψ are as in Example 1. *The identification problem*

$$\textit{Minimize} \quad ||y_u - y_d||_{\infty,Q}, \quad u \in U_{ad}$$

admits solutions. Optimality conditions may be deduced from Corollary 5.1.

EXAMPLE 3. *Let us give an example with two controls $u_1 \in L^\infty(Q)$ and $u_2 \in L^\infty(Q)$. Consider the problem*

$$\textit{Minimize} \quad ||y + u_1 - y_d||_{\infty,Q},$$

subject to

$$\frac{\partial y}{\partial t} - \Delta y = u_2 + f \quad \text{in } Q, \quad y = 0 \quad \text{on } \Sigma, \quad y(0) = \Psi \quad \text{in } \Omega,$$

$$-\varepsilon \le u_1 \le \varepsilon, \qquad a \le u_2 \le b,$$

where ε is a positive number, f, Ψ, a, b are as in Example 1. *The control u_1 may play the role of a noise with level ε. The above problem admits solutions. Optimality conditions for this problem may be obtained by adapting the result of Corollary* 5.1 *to the case of two control variables.*

Assumptions and notation. Throughout the paper, Ω denotes a bounded, open, and connected subset in $\mathbb{R}^N$ ($N \geq 2$) of class $C^{2+\gamma}$ for some $0 < \gamma \leq 1$. We denote by Ω_0 (resp., Ω_T) the set $\Omega \times \{0\}$ (resp., $\Omega \times \{T\}$). The second-order elliptic operator A is of the form $Ay(x) = -\sum_{i,j=1}^N D_i(a_{ij}(x)D_j y(x))$. ($D_i$ denotes the partial derivative with respect to x_i.) The coefficients a_{ij} belong to $C^{1+\gamma}(\overline{\Omega})$ and satisfy the conditions

$$a_{ij}(x) = a_{ji}(x) \qquad \text{for every } \ i,j \in \{1,\dots,N\}, \qquad m_0|\chi|^2 \leq \sum_{i,j=1}^N a_{ij}(x)\chi_i\chi_j$$

for all $\chi \in \mathbb{R}^N$ and for all $x \in \overline{\Omega}$, with $m_0 > 0$. For every $1 \leq \ell \leq \infty$, the usual norms in the spaces $L^\ell(Q)$, $L^\ell(\Sigma)$, will be denoted by $||\cdot||_{\ell,Q}$, $||\cdot||_{\ell,\Sigma}$. Throughout the paper $\langle\cdot,\cdot\rangle_{*,Q}$ denotes the duality pairing between the spaces $(L^\infty(Q))'$ and $L^\infty(Q)$. If E is a locally compact subset of $\overline{Q}$, $\mu \in \mathcal{M}_b(E)$ (the space of bounded Radon measures on E) and $y \in C_b(E)$, we set $\langle \mu, y\rangle_{b,E} = \int_E y(x,t)d\mu(x,t)$. We denote by int $\mathcal{C}$, the interior of $\mathcal{C}$ for the usual topology of $C(\overline{Q})$ and by $\mathbf{cl}_\infty S$, the closure of $S \subset L^\infty(Q)$ for the usual topology of $L^\infty(Q)$. For z and χ in $L^\infty(Q)$, we set

$$[z;\chi] = \lim_{\rho \searrow 0} \frac{||z+\rho\chi||_{\infty,Q} - ||z||_{\infty,Q}}{\rho}.$$

The previous limit exists for all z and for all χ, because the mapping $||\cdot||_{\infty,Q}$ is convex and the function $\rho \longrightarrow \frac{||z+\rho\chi||_{\infty,Q}-||z||_{\infty,Q}}{\rho}$ is nondecreasing on $\mathbb{R}_+^*$. Moreover, we can easily see that the mapping $\chi \longrightarrow [z;\chi]$ is Lipschitz of rank 1 from $L^\infty(Q)$ into $\mathbb{R}$ (see [8, Chapter 7]).

A1. Φ is a Carathéodory function from $Q \times \mathbb{R}^2$ into $\mathbb{R}$ (i.e., $\Phi(\cdot,y,u)$ is measurable for all $(y,u) \in \mathbb{R}^2$ and $\Phi(x,t,\cdot)$ is continuous for almost all $(x,t) \in Q$). For almost all $(x,t) \in Q$, $\Phi(x,t,\cdot)$ is of class C^1. Moreover, the following estimates hold:

$$|\Phi(x,t,0,u)| \leq \eta(|u|), \quad 0 \leq \Phi'_y(x,t,y,u) \leq \eta(|y|)\eta(|u|), \quad |\Phi'_u(x,t,y,u)| \leq \eta(|y|)\eta(|u|),$$

where η is a nondecreasing function from $\mathbb{R}^+$ into $\mathbb{R}^+$.

A2. F is of class C^1 on $\mathbb{R}^2$. Moreover, the following estimate holds:

$$|F(y,u)| + |F'_y(y,u)| + |F'_u(y,u)| \leq \eta(|u|)\eta(|y|).$$

A3. U_{ad} is a bounded closed convex subset in $L^\infty(Q)$.

A4. g is continuous on $\overline{Q} \times R$ and, for every $(x,t) \in \overline{Q}$, $g(x,t,\cdot)$ is differentiable and g'_y is continuous on $\overline{Q} \times R$. Moreover, we suppose that there exists $\theta_o > 0$ such that $g(x,t,\Psi(x,t)) \leq -\theta_o$ for all $(x,t) \in \overline{\Sigma} \cup \Omega_0$. ($\Psi$ is the function appearing in (1).)

3. State equation and adjoint equation.

3.1. State equation.

The following result is proved in [2, Proposition 3.9].

PROPOSITION 3.1. *Let a be a nonnegative function in $L^q(Q)$ ($q > \frac{N}{2} + 1$), let ϕ be in $L^q(Q)$, and ψ be in $C(\overline{\Sigma} \cup \Omega_0)$. The solution y of*

$$\frac{\partial y}{\partial t} + Ay + ay = \phi \quad \text{in } Q, \quad y = \psi|_\Sigma \quad \text{on } \Sigma, \quad y(\cdot,0) = \psi(0) \quad \text{in } \Omega, \tag{4}$$

belongs to $C(\overline{Q})$ and satisfies the following estimate:

$$||y||_{C(\overline{Q})} \leq C\Big(||\phi||_{q,Q} + ||\psi||_{C(\overline{\Sigma}\cup\Omega_0)}\Big) \qquad \text{for all } q > \frac{N}{2} + 1,$$

where $C \equiv C(M, \Omega, T, N, q)$.

THEOREM 3.2 (see [2, Theorem 3.11]). *Let* u *be in* $L^\infty(Q)$. *Equation* (1) *admits a unique solution* $y_u \in C(\overline{Q})$ *satisfying*

$$||y_u||_{C(\overline{Q})} \leq C\Big(||u||_{q,Q} + ||\Psi||_{C(\overline{\Sigma}\cup\Omega_0)} + 1\Big) \qquad \text{for all } q > \frac{N}{2} + 1,$$

where $C \equiv C(T, \Omega, N, q)$. *Moreover, the mapping* $u \longrightarrow y_u$ *is continuous from* $L^\infty(Q)$ *into* $C(\overline{Q})$.

3.2. Adjoint equation. Let a be a nonnegative function in $L^\infty(Q)$. Consider the equation

$$-\frac{\partial p}{\partial t} + Ap + ap = \mu|_Q \quad \text{in } Q, \quad p = 0 \quad \text{on } \Sigma, \quad p(T) = \mu|_{\Omega_T} \quad \text{in } \Omega, \tag{5}$$

where $\mu = \mu|_Q + \mu|_{\Omega_T}$ is a bounded Radon measure on $Q \cup \Omega_T$, $\mu|_Q$ is the restriction of μ to Q, and $\mu|_{\Omega_T}$ the restriction of μ to Ω_T.

DEFINITION 3.3. *A function* $p \in L^1(0, T; W_0^{1,1}(\Omega))$ *is a weak solution to* (5) *if and only if*

$$\int_Q \left(-p\frac{\partial z}{\partial t} + \sum_{i,j=1}^N a_{ij} D_j p D_i z + azp \right) dx\, dt = \langle \mu, z \rangle_{b, Q\cup\Omega_T}$$

for all $z \in C^1(\overline{Q}) \cap C_0(Q \cup \Omega_T)$.

THEOREM 3.4 (see [2, Theorem 4.2]). *Let* a *be a nonnegative function in* $L^\infty(Q)$ *and let* $\mu \in \mathcal{M}_b(Q \cup \Omega_T)$. *Equation* (5) *admits a unique weak solution* p *in* $L^1(0, T; W_0^{1,1}(\Omega))$. *The function* p *belongs to* $L^\delta(0, T; W_0^{1,d}(\Omega))$, *for every* (δ, d) *satisfying* $\delta \geq 1$, $d \geq 1$, $\frac{N}{2d} + \frac{1}{\delta} > \frac{N+1}{2}$ *and satisfies*

$$||p||_{L^\delta(0,T;W^{1,d}(\Omega))} \leq C||\mu||_{\mathcal{M}_b(Q\cup\Omega_T)},$$

where $C \equiv C(\Omega, T, \delta, d)$ *is independent of* a. *Moreover, there exist a function* $\frac{\partial p}{\partial n_A} \in L^1(\Sigma)$ *and a function* $p(0) \in L^1(\Omega)$ *such that*

$$\int_Q \left(\frac{\partial z}{\partial t} + Az + az \right) p\, dx\, dt = \langle \mu, z \rangle_{b, Q\cup\Omega_T} + \int_\Sigma z \frac{\partial p}{\partial n_A}\, ds\, dt - \int_\Omega z(0)p(0)\, dx$$

for all $z \in Y_q = \{y \in C_b(Q\cup\Omega_T) \mid \frac{\partial y}{\partial t} + Ay \in L^q(Q),\ y|_\Sigma \in L^\infty(\Sigma),\ \text{and } y(0) \in C(\overline{\Omega})\}$.

4. Statement of the main results. Every $\zeta \in (L^\infty(Q))'$ is identified with a measure $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{Q} \times Q^\#)$, where $Q^\#$ is a compactification of Q (see section 6). For notational simplicity, $\hat{\hat{\zeta}}$ will still be denoted by ζ. We denote by $\mathcal{B}$ the canonical projection from $\mathcal{M}(\overline{Q} \times Q^\#)$ onto $\mathcal{M}(\overline{Q})$ defined by

$$\mathcal{B} : \zeta \in \mathcal{M}(\overline{Q} \times Q^\#) \longrightarrow \mathcal{B}(\zeta) \in \mathcal{M}(\overline{Q}),$$

$$\Big\langle \mathcal{B}(\zeta), \phi \Big\rangle_{\mathcal{M}(\overline{Q}), C(\overline{Q})} = \Big\langle \zeta, \phi \Big\rangle_{\mathcal{M}(\overline{Q}\times Q^\#), C(\overline{Q}\times Q^\#)} \qquad \text{for all } \phi \in C(\overline{Q}).$$

Throughout the paper, for any $\zeta \in (L^\infty(Q))'$, $|\zeta|$ stands for the total variation of ζ, $\mathcal{B}(|\zeta|)$ is the canonical projection of $|\zeta|$ onto $\mathcal{M}(\overline{Q})$, and $L^\infty_{\mathcal{B}(|\zeta|)}(\overline{Q})$ denotes the space of $\mathcal{B}(|\zeta|)$-essentially bounded $\mathcal{B}(|\zeta|)$-measurable functions on $\overline{Q}$. The proofs of the following theorems are given in sections 6 and 7.

THEOREM 4.1. *Let $\zeta \in (L^\infty(Q))'$. There exists a bounded linear transformation $\Lambda_\zeta : L^\infty(Q) \longrightarrow L^\infty_{\mathcal{B}(|\zeta|)}(\overline{Q})$ such that*

$$(6)\quad \Big\langle \zeta, h\phi \Big\rangle_{*,Q} = \int_{\overline{Q}} \Lambda_\zeta(h)\phi \; d\mathcal{B}(|\zeta|) \qquad \textit{for all } h \in L^\infty(Q) \;\; \textit{and for all } \phi \in C(\overline{Q}).$$

If $\mathcal{A}$ is an open subset of $\overline{Q}$, then we have

$$(7)\qquad \int_{\overline{Q}} \Lambda_\zeta(\tilde{h}) \; d\mathcal{B}(|\zeta|) = \Big\langle \mathcal{B}(\zeta), \tilde{h} \Big\rangle_{b,\mathcal{A}} + \int_{\overline{Q}\setminus\mathcal{A}} \Lambda_\zeta(\tilde{h}) \; d\mathcal{B}(|\zeta|)$$

for all $\tilde{h} \in C_b(\mathcal{A}) \cap L^\infty(Q)$. Moreover,

$$(8)\quad \Big\langle \ell^*\zeta, \phi \Big\rangle_{*,Q} = \Big\langle \mathcal{B}(\zeta), \ell\phi \Big\rangle_{b,\mathcal{A}} + \Big\langle \mathcal{B}(\ell^*\zeta), \phi \Big\rangle_{b,\overline{Q}\setminus\mathcal{A}}$$

for all $\phi \in C(\overline{Q})$ and for all $\ell \in (C_b(\mathcal{A}) \cap L^\infty(Q))$, where $\ell^*\zeta$ is the measure defined by

$$\Big\langle \ell^*\zeta, h \Big\rangle_{*,Q} = \Big\langle \zeta, \ell h \Big\rangle_{*,Q} \qquad \textit{for all } h \in L^\infty(Q).$$

We shall say that $(\bar{y}, \bar{u})$ satisfies the regularity condition **(R)** if there exists (z_o, u_o) in $C(\overline{Q}) \times U_{ad}$ such that

$$g(\cdot, \bar{y}) + g'_y(\cdot, \bar{y}) \; z_o \in \operatorname{int} \mathcal{C},$$

$$\frac{\partial z_o}{\partial t} + Az_o + \Phi'_y(\cdot, \bar{y}, \bar{u})z_o = -\Phi'_u(\cdot, \bar{y}, \bar{u})(u_o - \bar{u}) \; \textit{in } Q,$$

$$z_o = 0 \qquad \textit{on } \Sigma, \qquad z_o(0) = 0 \qquad \textit{in } \Omega.$$

Throughout the paper, we suppose that $(\bar{y}, \bar{u})$ is an admissibe solution for $(\mathcal{P})$, satisfying $||F(\bar{y}, \bar{u})||_{\infty,Q} > 0$.

THEOREM 4.2. *If* A1–A4 *are fulfilled, and if $(\bar{y}, \bar{u})$ is a solution of $(\mathcal{P})$, then there exist $\bar{\mu} \in \mathcal{M}(\overline{Q})$, $\bar{\zeta} \in (L^\infty(Q))'$, and $\bar{p} \in L^1(0, T; W_0^{1,1}(\Omega))$ such that the following conditions hold*:

- *Nontriviality condition*:

$$(9)\qquad (\bar{\zeta}, \bar{\mu}|_{Q\cup\Omega_T}) \neq (0, 0), \qquad \bar{\mu} \geq 0.$$

- *Complementary conditions:*

$$(10)\qquad \Big\langle \bar{\mu}, z - g(\cdot, \bar{y}) \Big\rangle_{\mathcal{M}(\overline{Q}), C(\overline{Q})} \leq 0 \quad \textit{for all } z \in \mathcal{C},$$

$$(11)\qquad \Big\langle \bar{\zeta}, \chi \Big\rangle_{*,Q} \leq 0 \quad \textit{for all } \chi \in \mathbf{cl}_\infty \Big\{ y \in L^\infty(Q) \mid [F(\bar{y}, \bar{u}); y] < 0 \Big\}.$$

$$(12)\;\; \textit{If } \bar{\mu}|_{Q\cup\Omega_T} = 0, \textit{ then } \langle \bar{\zeta}, \chi \rangle_{*,Q} < 0 \quad \textit{for all } \chi \in \Big\{ y \in L^\infty(Q) \mid [F(\bar{y}, \bar{u}); y] < 0 \Big\}.$$

- *Adjoint equation:*

$$(13)\qquad \begin{cases} -\dfrac{\partial \bar p}{\partial t} + A\bar p + \Phi'_y(\cdot,\bar y,\bar u)\bar p + g'_y(\cdot,\bar y)^*\bar\mu|_Q + \mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta)|_Q = 0 & \text{in } Q,\\ \bar p(\cdot,T) + g'_y(\cdot,\bar y)^*\bar\mu|_{\Omega_T} + \mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta)|_{\Omega_T} = 0 & \text{in } \Omega. \end{cases}$$

- *Optimality condition for $\bar u$:*

$$(14)\qquad \int_Q \bar p\ \Phi'_u(x,t,\bar y,\bar u)(u-\bar u)\,dx\,dt + \Big\langle \bar\zeta, F'_u(\bar y,\bar u)(u-\bar u)\Big\rangle_{*,Q} \ge 0 \qquad \text{for all } u\in U_{ad},$$

where $g'_y(\cdot,\bar y)^*\bar\mu\,|_Q$ is the restriction of $g'_y(\cdot,\bar y)^*\bar\mu$ to Q, $g'_y(\cdot,\bar y)^*\bar\mu\,|_{\Omega_T}$ is the restriction of $g'_y(\cdot,\bar y)^*\bar\mu$ to Ω_T, $\mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta)\,|_Q$ is the restriction of $\mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta)$ to Q, $\mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta)|_{\Omega_T}$ is the restriction of $\mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta)$ to Ω_T, $g'_y(\cdot,\bar y)^*\bar\mu$ and $F'_y(\bar y,\bar u)^*\bar\zeta$ are defined by

$$\Big\langle g'_y(\cdot,\bar y)^*\bar\mu, z\Big\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} = \Big\langle \bar\mu, g'_y(\cdot,\bar y)z\Big\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} \quad \text{for all } z\in C(\overline{Q}),$$

$$\Big\langle F'_y(\bar y,\bar u)^*\bar\zeta, h\Big\rangle_{*,Q} = \Big\langle \bar\zeta, F'_y(\bar y,\bar u)h\Big\rangle_{*,Q} \quad \text{for all } h\in L^\infty(Q).$$

Moreover, if $(\bar y,\bar u)$ satisfies the regularity condition (**R**)*, then $\bar\zeta\neq 0$.*

REMARK 4.3. (i) Notice that for every $\varepsilon\in]0,1[$, we have

$$\Big[F(\bar y,\bar u); -\varepsilon F(\bar y,\bar u)\Big] = -\varepsilon\ ||F(\bar y,\bar u)||_{\infty,Q} < 0.$$

It follows that 0 belongs to $\mathbf{cl}_\infty\{\chi\in L^\infty(Q)\mid [F(\bar y,\bar u);\chi]<0\}$.

(ii) In the same way, if $z\in L^\infty(Q)$ satisfies $z\neq 0$ and $||z||_{\infty,Q}\le ||F(\bar y,\bar u)||_{\infty,Q}$, then there exists $(z_\varepsilon)_\varepsilon\subset L^\infty(Q)$ such that

$$||z_\varepsilon||_{\infty,Q} < ||z||_{\infty,Q}\le ||F(\bar y,\bar u)||_{\infty,Q} \quad \text{and} \quad ||z_\varepsilon - z||_{\infty,Q}\longrightarrow 0 \ \text{ when } \varepsilon\to 0.$$

It is easy to see that $(z_\epsilon - F(\bar y,\bar u))_\varepsilon\subset\{\chi\in L^\infty(Q)\mid [F(\bar y,\bar u);\chi]<0\}$. Therefore, $z-F(\bar y,\bar u)$ belongs to $\mathbf{cl}_\infty\{\chi\in L^\infty(Q)\mid [F(\bar y,\bar u);\chi]<0\}$. Due to (11), we have

$$(15)\qquad \Big\langle \bar\zeta, z-F(\bar y,\bar u)\Big\rangle_{*,Q}\le 0 \quad \text{for all } z \text{ satisfying } ||z||_{\infty,Q}\le ||F(\bar y,\bar u)||_{\infty,Q}.$$

REMARK 4.4. Notice that $\bar\mu$ is a measure on $\overline{Q}$, but the nontriviality condition is stated with the restriction of μ to $Q\cup\Omega_T$.

THEOREM 4.5 (sufficient optimality conditions). *Suppose that* A1–A4 *are fulfilled. Suppose in addition that Φ is of the form $\Phi(\cdot,y,u)=\beta(\cdot)\,y-u$, that $g(\cdot,y)=y$, and that F is convex. If $(\bar y,\bar u,\bar p)\in C(\overline{Q})\times U_{ad}\times L^1(0,T;W^{1,1}(\Omega))$ satisfies* (1)–(2) *together with* (9)–(14) *for $\bar\zeta\neq 0$, then $(\bar y,\bar u)$ is an optimal pair for problem $(\mathcal{P})$.*

REMARK 4.6. This result is still true with obvious modifications for constraints of the form $y\in\mathcal{C}$, where $\mathcal{C}$ is a closed convex subset of $C(\overline{Q})$, with nonempty interior in $C(\overline{Q})$. The proof of Theorem 4.5 is similar to the one given in Corollary 5.2.

5. Some applications.

5.1. Problems with no state constraints. In this section, we are interested in the following control problem:

$$(\widetilde{\mathcal{P}}) \qquad \inf\{J(y,u) \ \mid \ (y,u) \in C(\overline{Q}) \times U_{ad}, \ \ (y,u) \text{ satisfies (1)}\}.$$

Since there is no state constraints stated in $(\widetilde{\mathcal{P}})$, we are able to give necessary optimality conditions in qualified form.

COROLLARY 5.1. *If* A1–A3 *are fulfilled and if* $(\bar{y},\bar{u})$ *is a solution of* $(\widetilde{\mathcal{P}})$*, then there exist* $\bar{\zeta} \in (L^\infty(Q))'$ *and* $\bar{p} \in L^1(0,T;W_0^{1,1}(\Omega))$ *such that the following conditions hold*:

$$\bar{\zeta} \neq 0, \tag{16}$$

$$\left\langle \bar{\zeta}, y \right\rangle_{*,Q} < 0 \quad \textit{for all } y \in \left\{ \chi \in L^\infty(Q) \mid [F(\bar{y},\bar{u});\chi] < 0 \right\}, \tag{17}$$

$$\begin{cases} -\dfrac{\partial \bar{p}}{\partial t} + A\bar{p} + \Phi'_y(x,t,\bar{y},\bar{u})\bar{p} + \mathcal{B}(F'_y(\bar{y},\bar{u})^*\zeta)|_Q = 0 & \textit{in } Q, \\ \bar{p}(x,T) + \mathcal{B}(F'_y(\bar{y},\bar{u})^*\zeta)|_{\Omega_T} = 0 & \textit{in } \Omega, \end{cases} \tag{18}$$

$$\int_Q \bar{p}\ \Phi'_u(x,t,\bar{y},\bar{u})(u-\bar{u})\,dx\,dt + \left\langle \bar{\zeta}, F'_u(\bar{y},\bar{u})(u-\bar{u}) \right\rangle_{*,Q} \geq 0 \tag{19}$$

for all $u \in U_{ad}$.

Proof. Due to Theorem 4.2, there exist $\bar{\mu} \in \mathcal{M}(\overline{Q})$, $\bar{\zeta} \in (L^\infty(Q))'$, and $\bar{p} \in L^1(0,T;W_0^{1,1}(\Omega))$ such that (9)–(14) hold. From (10), we deduce

$$\left\langle \bar{\mu}, z - g(\cdot,\bar{y}) \right\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} \leq 0 \quad \text{for all } z \in C(\overline{Q}).$$

Therefore, we obtain

$$\langle \bar{\mu}, z \rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} \leq 0 \quad \text{for all } z \in C(\overline{Q}),$$

and thus $\bar{\mu} \equiv 0$. Taking (9) and (12) into account, we deduce (16) and (17). ∎

COROLLARY 5.2 (sufficient optimality conditions). *Suppose that* A1–A3 *are fulfilled. Suppose in addition that* Φ *is of the form* $\Phi(\cdot,y,u) = \beta(\cdot)\ y - u$ *and that* F *is convex. If* $(\bar{y},\bar{u},\bar{p},\bar{\zeta}) \in C(\overline{Q}) \times U_{ad} \times L^1(0,T;W_0^{1,1}(\Omega)) \times (L^\infty(Q))'$ *satisfies* (1) *together with* (16)–(19)*, then* $(\bar{y},\bar{u})$ *is an optimal pair for the problem* $(\widetilde{\mathcal{P}})$.

Proof. Let $(\bar{y},\bar{u},\bar{p},\bar{\zeta})$ be in $C(\overline{Q}) \times U_{ad} \times L^1(0,T;W_0^{1,1}(\Omega)) \times (L^\infty(Q))'$, satisfying (1) together with (16)–(19). Due to Theorem 3.4, $\bar{p}$ satisfies

$$\int_Q \bar{p}\left(\frac{\partial z}{\partial t} + Az + \beta z\right) dx\,dt - \int_\Sigma \frac{\partial \bar{p}}{\partial n_A} z\ \ ds\,dt + \int_\Omega \bar{p}(0)z(0)\ \ dx \tag{20}$$

$$= -\left\langle \mathcal{B}(F'_y(\bar{y},\bar{u})^*\bar{\zeta}), z \right\rangle_{b,Q\cup\Omega_T} \qquad \text{for all } z \in Y_q.$$

Let u be in U_{ad} and let y_u be the solution of (1) corresponding to u. Since the function $\bar{y} - y_u$ belongs to $C_0(Q \cup \Omega_T)$, by setting $z = \bar{y} - y_u$ in (20), we obtain

$$\int_Q p(\bar u-u)dx\,dt=\int_Q p\left(\frac{\partial(\bar y-y_u)}{\partial t}+A(\bar y-y_u)+\beta(\bar y-y_u)\right)dx\,dt$$
$$=-\Big\langle\mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta),\bar y-y_u\Big\rangle_{b,Q\cup\Omega_T}=-\Big\langle\mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta),\bar y-y_u\Big\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})}$$
$$=-\Big\langle\bar\zeta,F'_y(\bar y,\bar u)(\bar y-y_u)\Big\rangle_{*,Q}.$$

Consequently, from (19), it follows that

$$\Big\langle\bar\zeta,F'_y(\bar y,\bar u)(y_u-\bar y)+F'_u(\bar y,\bar u)(u-\bar u)\Big\rangle_{*,Q}\geq 0. \tag{21}$$

On the other hand, for $\rho\in]0,1[$ and $u\in U_{ad}$, let us set $u_\rho=\bar u+\rho(u-\bar u)$, and let y_{u_ρ} be the solution of (1) corresponding to u_ρ. It is clear that (y_{u_ρ},u_ρ) is admissible for $(\widetilde{\mathcal{P}})$. By applying Lemma 7.1, and using the convexity of F, we obtain

$$\lim_{\rho\searrow 0}\frac{J(y_{u_\rho},u_\rho)-J(\bar y,\bar u)}{\rho}=\Big[F(\bar y,\bar u);\ F'_y(\bar y,\bar u)(y_u-\bar y)+F'_u(\bar y,\bar u)(u-\bar u)\Big]$$
$$\leq J(y_u,u)-J(\bar y,\bar u).$$

We claim that $[F(\bar y,\bar u);\ F'_y(\bar y,\bar u)(y_u-\bar y)+F'_u(\bar y,\bar u)(u-\bar u)]\geq 0$. Argue by contradiction and suppose the contrary. From (17), it follows that

$$\Big\langle\bar\zeta,F'_y(\bar y,\bar u)(y_u-\bar y)+F'_u(\bar y,\bar u)(u-\bar u)\Big\rangle_{*,Q}<0,$$

which contradicts (21). Therefore $J(y_u,u)\geq J(\bar y,\bar u)$. □

5.2. Problems with partially continuous controls. In this section, we are concerned with problems of the form $(\mathcal{P})$ when the admissible controls are continuous on an open set $\mathcal{A}$ of $\overline{Q}$. In particular, when $\mathcal{A}=\overline{Q}$, we recover the result stated in the introduction for the problem $(\mathcal{P}_c)$ (see Remark 5.5). In this case, the multiplier $\bar\zeta\in(L^\infty(Q))'$ may be replaced by $\mathcal{B}(\bar\zeta)$, that is, a Radon measure on $\overline{Q}$. If the set of admissible controls are continuous on an open subset $\mathcal{A}\subset\overline{Q}$, then we show that the operator $\Lambda_{\bar\zeta}$ intervenes only on $\overline{Q}\setminus\mathcal{A}$.

COROLLARY 5.3. *Assume that* A1–A4 *are fulfilled and that* $U_{ad}\subset C(\overline{Q})$. *If* $(\bar y,\bar u)$ *is a solution of* $(\mathcal{P})$, *then there exist* $\bar\mu\in\mathcal{M}(\overline{Q})$ *and* $\bar\eta\in\mathcal{M}(\overline{Q})$ *such that* $(\bar\mu,\bar\eta,\bar p)$ *satisfies* (9), (10), (11), (12), *and* (22), *where* $\bar p\in L^1(0,T;W_0^{1,1}(\Omega))$ *is the solution of*

$$\begin{cases}-\dfrac{\partial\bar p}{\partial t}+A\bar p+\Phi'_y(\cdot,\bar y,\bar u)\bar p+g'_y(\cdot,\bar y)^*\bar\mu|_Q+F'_y(\bar y,\bar u)^*\bar\eta|_Q=0 & \text{in } Q,\\[2ex] \bar p(T)+g'_y(\cdot,\bar y)^*\bar\mu|_{\Omega_T}+F'_y(\bar y,\bar u)^*\bar\eta|_{\Omega_T}=0 & \text{in } \Omega.\end{cases}$$

Proof. The proof is based on arguments similar to those of Corollary 5.4 and is omitted. The corollary corresponds to the case when $\mathcal{A}=\overline{Q}$. □

COROLLARY 5.4. *Let* $\mathcal{A}$ *be an open subset of* $\overline{Q}$. *Assume that* A1–A4 *are fulfilled and that* $U_{ad}\subset(C_b(\mathcal{A})\cap L^\infty(Q))$. *If* $(\bar y,\bar u)$ *is a solution of* $(\mathcal{P})$, *then there exist* $\bar\mu\in\mathcal{M}^+(\overline{Q})$ *and* $\bar\zeta\in(L^\infty(Q))'$ *such that* $(\bar\mu,\bar\zeta)$ *satisfies* (9), (10), (11), *and* (12),

$$\int_Q\bar p\ \Phi'_u(x,t,\bar y,\bar u)(u-\bar u)\,dx\,dt \tag{22}$$

$$+\Big\langle \mathcal{B}(\bar\zeta), F'_u(\bar y,\bar u)(u-\bar u)\Big\rangle_{b,\mathcal{A}} + \int_{\overline{Q}\setminus\mathcal{A}} \Lambda_{\bar\zeta}\Big(F'_u(\bar y,\bar u)(u-\bar u)\Big)\, d\mathcal{B}(|\bar\zeta|) \ge 0$$

for all $u \in U_{ad}$, where $\Lambda_{\bar\zeta}$ is the operator associated with $\bar\zeta$ and defined in Theorem 4.1 *and $\bar p \in L^1(0,T;W_0^{1,1}(\Omega))$ is the solution of*

$$\begin{cases} -\dfrac{\partial \bar p}{\partial t} + A\bar p + \Phi'_y(\cdot,\bar y,\bar u)\bar p + g'_y(\cdot,\bar y)^*\bar\mu|_Q + F'_y(\bar y,\bar u)^*\mathcal{B}(\bar\zeta)|_{\mathcal{A}} \\ \\ +\mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta)|_{Q\setminus\mathcal{A}} = 0 \qquad \text{in } Q, \\ \\ \bar p(T) + g'_y(\cdot,\bar y)^*\bar\mu|_{\Omega_T} + \mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta)|_{\Omega_T} = 0 \qquad \text{in } \Omega. \end{cases}$$

Proof. Due to Theorem 4.2, there exist $\bar\mu \in \mathcal{M}(\overline{Q})$, $\bar\zeta \in (L^\infty(Q))'$, and $\bar p \in L^1(0,T;W_0^{1,1}(\Omega))$ such that (9)–(14) hold. Since $U_{ad} \subset C_b(\mathcal{A}) \cap L^\infty(Q)$, for every $u \in U_{ad}$ and every $z \in C(\overline{Q})$, the functions $F'_y(\bar y,\bar u)z$ and $F'_u(\bar y,\bar u)u$ belong to $C_b(\mathcal{A}) \cap L^\infty(Q)$. From Theorem 4.1, it follows that

$$\Big\langle \bar\zeta, F'_u(\bar y,\bar u)u\Big\rangle_{*,Q} = \Big\langle \mathcal{B}(\bar\zeta), F'_u(\bar y,\bar u)u\Big\rangle_{b,\mathcal{A}} + \int_{\overline{Q}\setminus\mathcal{A}} \Lambda_{\bar\zeta}\Big(F'_u(\bar y,\bar u)u\Big)\, d\mathcal{B}(|\zeta|)$$

for all $u \in U_{ad}$. On the other hand, with the definition of $\bar p$ and with (8), we have

$$\begin{aligned} &\int_Q \left(\bar p\frac{\partial z}{\partial t} + \sum_{i,j} a_{ij}D_i z D_j \bar p + \Phi'_y(x,t,\bar y,\bar u)\bar p z\right) dx\,dt \\ &= -\Big\langle g'_y(\cdot,\bar y)^*\bar\mu + \mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta), z\Big\rangle_{b,Q\cup\Omega_T} = -\Big\langle \bar\mu, g'_y(\cdot,\bar y)z\Big\rangle_{b,Q\cup\Omega_T} \\ &-\Big\langle F'_y(\bar y,\bar u)^*\mathcal{B}(\bar\zeta), z\Big\rangle_{b,\mathcal{A}} - \Big\langle \mathcal{B}(F'_y(\bar y,\bar u)^*\bar\zeta), z\Big\rangle_{b,(Q\setminus\mathcal{A})\cup\Omega_T} \end{aligned}$$

for every $z \in C^1(\overline{Q}) \cap C_0(Q\cup\Omega_T)$. The proof is complete. ∎

REMARK 5.5. If there are no state constraints, by using Corollaries 5.1 and 5.3, we recover the optimality conditions stated in the introduction for problem $(\mathcal{P}_c)$.

5.3. Comparison with other results. In this section, we apply our general result to problem $(\mathcal{P})$ when the function F is assumed to satisfy the following additional assumption.

A6. There exists a positive constant a such that $a \le F(y,u)$ for all $(y,u) \in \mathbb{R}^2$.

This kind of assumption is used in [9, p. 198], [13], and [5].

COROLLARY 5.6. *Assume that* A1–A4 *and* A6 *are fulfilled. If $(\bar y,\bar u)$ is a solution of $(\mathcal{P})$, then there exist $\bar\mu \in \mathcal{M}(\overline{Q})$, $\bar\zeta \in (L^\infty(Q))'$, and $\bar p \in L^1(0,T;W_0^{1,1}(\Omega))$ such that the conditions* (9)–(14) *hold. Moreover, we have*

$$\bar\zeta \ge 0,$$

$$\int_{Q_0} \bar p\ \Phi'_u(x,t,\bar y,\bar u)(u-\bar u)\,dx\,dt \ge 0 \qquad \text{for all } u \in U_0, \tag{23}$$

where

$$Q_0 = \{(x,t) \in Q \mid F(\bar y(x,t),\bar u(x,t)) < ||F(\bar y,\bar u)||_{\infty,Q}\},$$

$$U_0 = \{u \in U_{ad} \mid u(x,t) = \bar{u}(x,t) \quad \textit{for almost all } (x,t) \in Q \setminus Q_0\}.$$

Proof. Due to Theorem 4.2, there exist $\bar{\mu} \in \mathcal{M}(\overline{Q})$, $\bar{\zeta} \in (L^\infty(Q))'$, and $\bar{p} \in L^1(0,T;W_0^{1,1}(\Omega))$ such that (9)–(14) hold.

• Let us prove that $\bar{\zeta} \geq 0$. Let $\phi \in L^\infty(Q)$ be such that $\phi \geq 0$ and $||\phi||_{\infty,Q} \neq 0$. It is clear that

$$0 \leq \frac{\phi(x,t)}{||\phi||_{\infty,Q}}\, a \leq a \leq F(\bar{y}(x,t), \bar{u}(x,t)) \qquad \text{for all } (x,t) \in Q.$$

Taking (15) into account, and since $0 < a \leq F$, we have

$$\left\langle \bar{\zeta}, \frac{\phi\ a}{||\phi||_{\infty,Q}} \right\rangle_{*,Q} = \left\langle \bar{\zeta}, F(\bar{y},\bar{u}) - \left(F(\bar{y},\bar{u}) - \frac{\phi\ a}{||\phi||_{\infty,Q}} \right) \right\rangle_{*,Q} \geq 0.$$

Therefore, $\langle \bar{\zeta}, \phi \rangle_{*,Q} \geq 0$ for all nonnegative functions $\phi \in L^\infty(Q)$.

• Let us prove (23). Suppose that meas $(Q_0) > 0$, and let $\epsilon > 0$ be such that $Q_\epsilon = \{(x,t) \in Q \mid F(\bar{y}(x,t), \bar{u}(x,t)) \leq ||F(\bar{y},\bar{u})||_{\infty,Q} - \epsilon\} \neq \emptyset$.

Let us set

$$U_\epsilon = \{u \in U_{ad} \mid u(x,t) = \bar{u}(x,t) \ \text{ for almost all } (x,t) \in Q \setminus Q_\epsilon\}.$$

First, we prove that $\bar{\zeta}(Q_\epsilon) = 0$ for all $\epsilon > 0$. Suppose that $\bar{\zeta}(Q_\epsilon) > 0$ for some $\epsilon > 0$, and consider

$$F_\epsilon(s,t) = \begin{cases} F(\bar{y}(x,t), \bar{u}(x,t)) & \text{in } Q \setminus Q_\epsilon, \\ \\ F(\bar{y}(x,t), \bar{u}(x,t)) + \frac{\epsilon}{2} & \text{in } Q_\epsilon. \end{cases}$$

Due to the definition of Q_ϵ, we have

$$||F_\epsilon||_{\infty,Q} = \max\left(||F_\epsilon||_{\infty,Q\setminus Q_\epsilon}, ||F_\epsilon||_{\infty,Q_\epsilon} \right)$$

$$= \max\left(||F(\bar{y},\bar{u})||_{\infty,Q\setminus Q_\epsilon}, ||F(\bar{y},\bar{u}) + \frac{\epsilon}{2}||_{\infty,Q_\epsilon} \right)$$

$$\leq \max\left(||F(\bar{y},\bar{u})||_{\infty,Q\setminus Q_\epsilon}, ||F(\bar{y},\bar{u})||_{\infty,Q} - \frac{\epsilon}{2} \right) \leq ||F(\bar{y},\bar{u})||_{\infty,Q}.$$

By using (15), we obtain

$$\frac{\epsilon}{2}\ \bar{\zeta}(Q_\epsilon) = \left\langle \bar{\zeta}, F_\epsilon - F(\bar{y},\bar{u}) \right\rangle_{*,Q} \leq 0.$$

This contradicts $\bar{\zeta}(Q_\epsilon) > 0$. Consequently, $\bar{\zeta}(Q_\epsilon) = 0$ for all $\epsilon > 0$. Therefore, from the definition of U_ϵ, we deduce that

$$\left\langle \bar{\zeta}, F'_u(\bar{y},\bar{u})(u-\bar{u}) \right\rangle_{*,Q} = 0 \qquad \text{for all } u \in U_\epsilon \text{ and for all } \epsilon > 0.$$

The optimality condition (14) can be rewritten as

$$\int_{Q_\epsilon} \bar{p}\ \Phi'_u(x,t,\bar{y},\bar{u})(u-\bar{u})\, dx\, dt \geq 0 \qquad \text{for all } u \in U_\epsilon \text{ and for all } \ \epsilon > 0.$$

Since $Q_0 = \cup_{\epsilon>0}\ Q_\epsilon$ and $U_0 = \cap_{\epsilon>0}\ U_\epsilon$, it follows that

$$\int_{Q_0} \bar{p}\ \Phi'_u(x,t,\bar{y},\bar{u})(u-\bar{u})\, dx\, dt \geq 0 \qquad \text{for all } u \in U_0.$$

The proof is complete. ∎

In the case when F does not explicitly depend on u, we have the following result.

COROLLARY 5.7. *Assume that* A1–A4 *are fulfilled. Assume in addition that* $F \equiv F(y)$. *If* $(\bar{y}, \bar{u})$ *is a solution of* $(\mathcal{P})$, *then there exist* $\bar{\mu} \in \mathcal{M}(\overline{Q})$, $\bar{\nu} \in \mathcal{M}(\overline{Q})$, *and* $\bar{p} \in L^1(0,T; W_0^{1,1}(\Omega))$ *such that the following conditions hold:*

$(\bar{\nu}, \bar{\mu})$ *satisfies* (9)–(12),

$$\begin{cases} -\dfrac{\partial \bar{p}}{\partial t} + A\bar{p} + \Phi'_y(\cdot, \bar{y}, \bar{u})\bar{p} + g'_y(\cdot, \bar{y})^* \bar{\mu}|_Q + F'_y(\bar{y})^* \bar{\nu}|_Q = 0 & \text{in } Q, \\ \bar{p}(T) + g'_y(\cdot, \bar{y})^* \bar{\mu}|_{\Omega_T} + F'_y(\bar{y})^* \bar{\nu}|_{\Omega_T} = 0 & \text{in } \Omega, \end{cases}$$

$$\int_Q \bar{p}\ \Phi'_u(x,t,\bar{y},\bar{u})(u - \bar{u})\, dx\, dt \geq 0 \qquad \text{for all } u \in U_{ad}.$$

Moreover, if $||F(\Psi)||_{C(\overline{\Sigma} \cup \Omega_0)} \neq ||F(\bar{y})||_{C(\overline{Q})}$, *then* $\bar{\nu}|_{Q \cup \Omega_T} \neq 0$.

Proof. Due to Theorem 4.2, there exist $\bar{\mu} \in \mathcal{M}(\overline{Q})$, $\bar{\zeta} \in (L^\infty(Q))'$, and $\bar{p} \in L^1(0,T; W_0^{1,1}(\Omega))$ such that (9)–(14) hold. Due to Theorem 4.1, for all $\phi \in C(\overline{Q})$, we have

$$\Big\langle \zeta, \phi \Big\rangle_{*,Q} = \Big\langle \mathcal{B}(\zeta), \phi \Big\rangle_{\mathcal{M}(\overline{Q}), C(\overline{Q})},$$

$$\Big\langle F'_y(\bar{y})^* \zeta, \phi \Big\rangle_{*,Q} = \Big\langle \zeta, F'_y(\bar{y})\phi \Big\rangle_{*,Q} = \Big\langle \mathcal{B}(\zeta), F'_y(\bar{y})\phi \Big\rangle_{\mathcal{M}(\overline{Q}), C(\overline{Q})}$$
$$= \Big\langle F'_y(\bar{y})^* \mathcal{B}(\zeta), \phi \Big\rangle_{\mathcal{M}(\overline{Q}), C(\overline{Q})}.$$

The result follows from these properties by setting $\mathcal{B}(\bar{\zeta}) = \bar{\nu}$. It remains to prove that $(\bar{\mu}|_{Q \cup \Omega_T}, \bar{\nu}|_{Q \cup \Omega_T}) \neq 0$. Argue by contradiction and suppose that $\bar{\mu}|_{Q \cup \Omega_T} = \bar{\nu}|_{Q \cup \Omega_T} = 0$. From (9), it follows that $\bar{\nu}|_{\overline{\Sigma} \cup \Omega_0} \neq 0$. Consider the solution z_F of

$$\frac{\partial z}{\partial t} + Az = 0 \quad \text{in } Q, \quad z = F(\Psi)|_\Sigma \quad \text{in } \Sigma, \quad z(0) = F(\Psi)|_{\Omega \times \{0\}} \quad \text{in } \Omega.$$

The function $z_F - F(\bar{y})$ belongs to $C_0(Q \cup \Omega_T)$, and

$$\Big\langle \bar{\nu}, z_F - F(\bar{y}) \Big\rangle_{\mathcal{M}(\overline{Q}), C(\overline{Q})} = \Big\langle \bar{\nu}, z_F - F(\bar{y}) \Big\rangle_{b, Q \cup \Omega_T} = 0. \tag{24}$$

On the other hand, since $||z_F||_{C(\overline{Q})} = ||F(\Psi)||_{C_b(\overline{\Sigma} \cup \Omega_0)} < ||F(\bar{y})||_{C(\overline{Q})}$, we can easily see that $z_F - F(\bar{y})$ belongs to $\{\chi \in C(\overline{Q}) \mid [F(\bar{y}); \chi] < 0\}$. Due to (12), it follows that

$$\Big\langle \bar{\nu}, z_F - F(\bar{y}) \Big\rangle_{\mathcal{M}(\overline{Q}), C(\overline{Q})} = \Big\langle \bar{\nu}, z_F - F(\bar{y}) \Big\rangle_{b, Q \cup \Omega_T} < 0.$$

This contradicts (24). The proof is complete. ∎

6. The compactification of Q. Let $\mathcal{O}$ be a locally compact subset of $\overline{Q}$ and let $L^\infty(\mathcal{O})$ be the space of essentially bounded measurable functions on $\mathcal{O}$. Denote by $(L^\infty(\mathcal{O}))'$ the dual space of $L^\infty(\mathcal{O})$.

THEOREM 6.1 (see [7, Theorem 11, p. 445]). *There exist a compact Hausdorff space* $\mathcal{O}^\#$ *and an isometric homomorphism* τ *from* $L^\infty(\mathcal{O})$ *onto* $C(\mathcal{O}^\#)$. *The isomor-*

phism τ maps nonnegative functions into nonnegative functions. Moreover, τ is an algebraic isomorphism in the sense that if $h = h_1 h_2$ almost everywhere on $\mathcal{O}$, then $\tau(h) = \tau(h_1)\tau(h_2)$. If f is an arbitrary real continuous function and h is in $L^\infty(\mathcal{O})$, then $\tau(f(h)) = f(\tau(h))$.

REMARK 6.2 (see [7, Theorem 26, p. 278]). Since τ is an algebraic homomorphism from $C(\overline{\mathcal{O}})$ into $C(\mathcal{O}^\#)$, there exists a continuous mapping i, from $\mathcal{O}^\#$ into $\overline{\mathcal{O}}$, such that

$$\tau(\phi) = \phi \circ i \qquad \text{for all } \phi \in C(\overline{\mathcal{O}}).$$

Moreover, observe that τ^{-1} (the inverse of τ) satisfies

$$\tau^{-1}(h\ell) = \tau^{-1}(h)\ \tau^{-1}(\ell) \qquad \text{for all } h \in C(\mathcal{O}^\#) \text{ and for all } \ell \in C(\mathcal{O}^\#).$$

The set $C(\overline{\mathcal{O}}) \otimes C(\mathcal{O}^\#)$, of linear combinations of functions of the form $\phi\psi$, where $\phi \in C(\overline{\mathcal{O}})$ and $\psi \in C(\mathcal{O}^\#)$, is a subspace of $C(\overline{\mathcal{O}} \times \mathcal{O}^\#)$. The following result gives interesting properties for the elements of $\mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^\#)$ (the dual space of $C(\overline{\mathcal{O}} \times \mathcal{O}^\#)$).

LEMMA 6.3. *Let η be a Radon measure on $\overline{\mathcal{O}} \times \mathcal{O}^\#$, let $\mathcal{B}(\eta) \in \mathcal{M}(\overline{\mathcal{O}})$ be the projection of η on $\overline{\mathcal{O}}$, and let $\mathcal{B}(|\eta|) \in \mathcal{M}^+(\overline{\mathcal{O}})$ be the projection of $|\eta|$ on $\overline{\mathcal{O}}$. There exists a bounded linear tranformation $\Lambda_\eta : C(\mathcal{O}^\#) \longrightarrow L^\infty_{\mathcal{B}(|\eta|)}(\overline{\mathcal{O}})$ such that*

$$\left\langle \eta, \phi\psi \right\rangle_\# = \int_{\overline{\mathcal{O}}} \Lambda_\eta(\psi)\phi \, d\mathcal{B}(|\eta|) \quad \textit{for all } (\phi, \psi) \in C(\overline{\mathcal{O}}) \times C(\mathcal{O}^\#). \tag{25}$$

($\langle \cdot, \cdot \rangle_\#$ is the duality pairing between $\mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^\#)$ and $C(\overline{\mathcal{O}} \times \mathcal{O}^\#)$, τ is defined in Theorem 6.1.)

Proof. The proof is word for word the same as the proof of Lemma 4.4 in [1]. □

Due to Theorem 6.1, the measure $\zeta \in (L^\infty(\mathcal{O}))'$ can be identified with $\hat{\zeta} \in \mathcal{M}(\mathcal{O}^\#)$ via the formula

$$\left\langle \hat{\zeta}, \xi \right\rangle_{\mathcal{M}(\mathcal{O}^\#), C(\mathcal{O}^\#)} = \left\langle \zeta, \tau^{-1}(\xi) \right\rangle_{(L^\infty(\mathcal{O}))', L^\infty(\mathcal{O})} \qquad \text{for all } \xi \in C(\mathcal{O}^\#). \tag{26}$$

Let i be the continuous mapping defined in Remark 6.2 and let e be the continuous mapping, from $\mathcal{O}^\#$ into $\overline{\mathcal{O}} \times \mathcal{O}^\#$, defined by

$$e(q^\#) = (i(q^\#), q^\#) \qquad \text{for all } q^\# \in \mathcal{O}^\#.$$

To each $\hat{\zeta} \in \mathcal{M}(\mathcal{O}^\#)$ (defined by (26)), we associate $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^\#)$ defined by

$$\left\langle \hat{\hat{\zeta}}, \psi \right\rangle_\# = \left\langle \hat{\zeta}, \psi \circ e \right\rangle_{\mathcal{M}(\mathcal{O}^\#), C(\mathcal{O}^\#)} = \left\langle \zeta, \tau^{-1}(\psi \circ e) \right\rangle_{(L^\infty(\mathcal{O}))', L^\infty(\mathcal{O})} \tag{27}$$

for all $\psi \in C(\overline{\mathcal{O}} \times \mathcal{O}^\#)$.

THEOREM 6.4. *Let $\zeta \in (L^\infty(\mathcal{O}))'$ and let $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^\#)$ be the measure associated with ζ. There exists a bounded linear transformation $\Lambda_{\hat{\hat{\zeta}}} : C(\mathcal{O}^\#) \longrightarrow L^\infty_{\mathcal{B}(|\hat{\hat{\zeta}}|)}(\overline{\mathcal{O}})$ such that*

$$\left\langle \hat{\hat{\zeta}}, \phi\tau(h) \right\rangle_\# = \left\langle \mathcal{B}(\hat{\hat{\zeta}}), \phi h \right\rangle_{b,\mathcal{A}} + \int_{\overline{\mathcal{O}} \setminus \mathcal{A}} \phi \Lambda_{\hat{\hat{\zeta}}}(\tau(h)) \, d\mathcal{B}(|\hat{\hat{\zeta}}|) \tag{28}$$

for all $(\phi, h) \in C(\overline{\mathcal{O}}) \times (C_b(\mathcal{A}) \cap L^\infty(\mathcal{O}))$ and for all open subsets $\mathcal{A}$ of $\overline{\mathcal{O}}$.

Proof. See the proof of Theorem 4.7 in [1]. □

THEOREM 6.5. *Let ζ be in $(L^\infty(\mathcal{O}))'$. For $\ell \in L^\infty(\mathcal{O})$, define the measure $\ell^*\zeta \in (L^\infty(\mathcal{O}))'$ by*

$$\Big\langle \ell^*\zeta, h\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \zeta, \ell h\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} \qquad \textit{for all } h \in L^\infty(\mathcal{O}).$$

Then, the measures $\hat{\hat{\zeta}}$ and $\widehat{\widehat{\ell^*\zeta}}$, respectively, associated with ζ and $\ell^*\zeta$ via (27)*, satisfy*

$$\Big\langle \widehat{\widehat{\ell^*\zeta}}, \psi\Big\rangle_{\#} = \Big\langle \tau(\ell)^*\hat{\hat{\zeta}}, \psi\Big\rangle_{\#} \qquad \textit{for all } \psi \in C(\overline{\mathcal{O}} \times \mathcal{O}^{\#}). \tag{29}$$

Proof. With (27), we can identify the measure $\ell^*\mu$ with $\widehat{\widehat{\ell^*\mu}} \in \mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$. Moreover,

$$\Big\langle \widehat{\widehat{\ell^*\zeta}}, \psi\Big\rangle_{\#} = \Big\langle \ell^*\zeta, \tau^{-1}(\psi \circ e)\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \zeta, \ell\tau^{-1}(\psi \circ e)\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})}$$

$$= \Big\langle \zeta, \tau^{-1}\tau(\ell)\ \tau^{-1}(\psi \circ e)\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \zeta, \tau^{-1}\Big(\tau(\ell)(\psi \circ e)\Big)\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})}$$

$$= \Big\langle \zeta, \tau^{-1}\Big((\tau(\ell)\psi) \circ e\Big)\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \hat{\hat{\zeta}}, \tau(\ell)\psi\Big\rangle_{\#} = \Big\langle \tau(\ell)^*\hat{\hat{\zeta}}, \psi\Big\rangle_{\#}$$

for all $\psi \in C(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$. □

COROLLARY 6.6. *Let $\ell \in L^\infty(\mathcal{O})$, $\zeta \in (L^\infty(\mathcal{O}))'$ and let $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$ be the measure associated with ζ. Then,*

$$\Big\langle \zeta, \phi h\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \hat{\hat{\zeta}}, \phi\tau(h)\Big\rangle_{\#} \qquad \textit{for all } (\phi, h) \in C(\overline{\mathcal{O}}) \times L^\infty(\mathcal{O}), \tag{30}$$

$$\Big\langle \ell^*\zeta, \phi h\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \tau(\ell)^*\hat{\hat{\zeta}}, \phi\ \tau(h)\Big\rangle_{\#} \quad \textit{for all } (\phi, h) \in C(\overline{\mathcal{O}}) \times L^\infty(\mathcal{O}).$$

In particular, we have

$$\Big\langle \ell^*\zeta, \phi\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \tau(\ell)^*\hat{\hat{\zeta}}, \phi\Big\rangle_{\#} = \Big\langle \mathcal{B}\Big(\tau(\ell)^*\hat{\hat{\zeta}}\Big), \phi\Big\rangle_{\mathcal{M}(\overline{\mathcal{O}}),C(\overline{\mathcal{O}})}$$

for all $\phi \in C(\overline{\mathcal{O}})$.

Proof. To prove (30), it is sufficient to observe that

$$\Big\langle \zeta, \phi h\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \zeta, \tau^{-1}\tau(\phi h)\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \hat{\zeta}, \tau(\phi h)\Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}),C(\mathcal{O}^{\#})}$$

$$= \Big\langle \hat{\zeta}, \tau(\phi)\tau(h)\Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}),C(\mathcal{O}^{\#})} = \Big\langle \hat{\zeta}, (\phi \circ i)\ \tau(h)\Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}),C(\mathcal{O}^{\#})}$$

$$= \Big\langle \hat{\zeta}, (\phi\ \tau(h)) \circ e\Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}),C(\mathcal{O}^{\#})} = \Big\langle \hat{\hat{\zeta}}, \phi\tau(h)\Big\rangle_{\#} \qquad \text{for all } (\phi, h) \in C(\overline{\mathcal{O}}) \times L^\infty(\mathcal{O}).$$

By taking (30) and (29) into account, it follows that

$$\Big\langle \ell^*\zeta, \phi h\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \widehat{\widehat{\ell^*\zeta}}, \phi\ \tau(h)\Big\rangle_{\#} = \Big\langle \tau(\ell)^*\hat{\hat{\zeta}}, \phi\ \tau(h)\Big\rangle_{\#}.$$

The proof is complete. □

PROPOSITION 6.7. *Let $\ell \in (L^\infty(\mathcal{O}) \cap C_b(\mathcal{A}))$, where $\mathcal{A}$ is an open subset of $\overline{\mathcal{O}}$. Let $\zeta \in (L^\infty(\mathcal{O}))'$ and let $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^\#)$ be the measure associated with ζ. Then,*

$$\Big\langle \zeta, \phi h\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \tau(\ell)^*\hat{\hat{\zeta}}, \phi\Big\rangle_{\#} = \Big\langle \mathcal{B}(\hat{\hat{\zeta}}), \ell\phi\Big\rangle_{b,\mathcal{A}} + \Big\langle \mathcal{B}(\tau(\ell)^*\hat{\hat{\zeta}}), \phi\Big\rangle_{b,\overline{\mathcal{O}}\setminus\mathcal{A}}$$

for all $\phi \in C(\overline{\mathcal{O}})$.

Proof. From Corollary 6.6 and from (28), for all $\phi \in C(\overline{\mathcal{O}})$, we have

$$\Big\langle \zeta, \phi h\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \tau(\ell)^*\hat{\hat{\mu}}, \phi\Big\rangle_{\#} = \Big\langle \mathcal{B}\Big(\tau(\ell)^*\hat{\hat{\zeta}}\Big), \phi\Big\rangle_{\mathcal{M}(\overline{\mathcal{O}}),C(\overline{\mathcal{O}})} \tag{31}$$

$$= \Big\langle \mathcal{B}\Big(\tau(\ell)^*\hat{\hat{\zeta}}\Big), \phi\Big\rangle_{b,\mathcal{A}} + \Big\langle \mathcal{B}\Big(\tau(\ell)^*\hat{\hat{\zeta}}\Big), \phi\Big\rangle_{b,\overline{\mathcal{O}}\setminus\mathcal{A}}.$$

Let $(f_k)_k$ be a sequence of continuous functions with compact support in $\mathcal{A}$, with values in $[0,1]$, and converging to 1 on every compact subset included in $\mathcal{A}$. For $\phi \in C(\overline{\mathcal{O}})$, the integrals $\int_{\mathcal{A}} \phi\ d[\mathcal{B}(\tau(\ell)^*\hat{\hat{\zeta}})]$ and $\int_{\mathcal{A}} \ell\phi\ d\mathcal{B}(\hat{\hat{\zeta}})$ are obtained by passing to the limit in $\int_{\mathcal{A}} \phi f_k\ d[\mathcal{B}(\tau(\ell)^*\hat{\hat{\mu}})]$ and in $\int_{\mathcal{A}} \ell\phi f_k\ d\mathcal{B}(\hat{\hat{\zeta}})$. Let us still denote by f_k the extension of f_k by zero to $\overline{\mathcal{O}} \setminus \mathcal{A}$. Since the functions ϕf_k and $\ell\phi f_k$ belong to $C(\overline{\mathcal{O}})$, we have

$$\int_{\mathcal{A}} \phi f_k\, d\Big[\mathcal{B}\Big(\tau(\ell)^*\hat{\hat{\zeta}}\Big)\Big] = \Big\langle \mathcal{B}\Big(\tau(\ell)^*\hat{\hat{\zeta}}\Big), \phi f_k\Big\rangle_{\mathcal{M}(\overline{\mathcal{O}}),C(\overline{\mathcal{O}})} = \Big\langle \hat{\hat{\zeta}}, \tau(\ell)\ \phi f_k\Big\rangle_{\#}$$

$$= \Big\langle \zeta, \ell\phi f_k\Big\rangle_{(L^\infty(\mathcal{O}))',L^\infty(\mathcal{O})} = \Big\langle \mathcal{B}\Big(\hat{\hat{\zeta}}\Big), \ell\phi f_k\Big\rangle_{\mathcal{M}(\overline{\mathcal{O}}),C(\overline{\mathcal{O}})} = \int_{\mathcal{A}} \ell\phi f_k\, d\,\mathcal{B}\Big(\hat{\hat{\zeta}}\Big).$$

It follows that

$$\int_{\mathcal{A}} \phi\, d\Big[\mathcal{B}\Big(\tau(\ell)^*\hat{\hat{\zeta}}\Big)\Big] = \int_{\mathcal{A}} \ell\phi\, d\,\mathcal{B}\Big(\hat{\hat{\zeta}}\Big). \tag{32}$$

The conclusion follows from (31) and (32). □

Proof of Theorem 4.1. Let us identify the measure $\zeta \in (L^\infty(Q))'$ with $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{Q} \times Q^\#)$. By setting $\Lambda_\zeta = \Lambda_{\hat{\hat{\zeta}}} \circ \tau$, the properties (6) and (7) follow from (25) and (28). Assertion (8) follows from Proposition 6.7. □

7. Proof of necessary optimality conditions. To obtain optimality conditions, we prove some differential calculus rules stated below.

LEMMA 7.1. *For every $0 < \rho < 1$ and every $u_1,\ u_2 \in L^\infty(Q)$, we set $u_\rho = u_1 + \rho u_2$. If y_ρ and y_1 are the solutions of* (1) *corresponding to u_ρ and u_1, then*

$$y_\rho = y_1 + \rho z + r_\rho \qquad \textit{with} \quad \lim_{\rho\to 0} \frac{1}{\rho} ||r_\rho||_{C(\overline{Q})} = 0, \tag{33}$$

$$F(y_\rho, u_\rho) = F(y_1, u_1) + \rho(F'_y(y_1, u_1)z + F'_u(y_1, u_1)u_2) + \tilde{r}_\rho, \quad \lim_{\rho\to 0} \frac{1}{\rho} ||\tilde{r}_\rho||_{\infty,Q} = 0, \tag{34}$$

where z is the weak solution of

$$\frac{\partial z}{\partial t} + Az + \Phi'_y(\cdot, y_1, u_1)z = -\Phi'_u(\cdot, y_1, u_1)u_2 \quad in\ Q,\ z = 0\ on\ \Sigma,\ z(0) = 0\ in\ \Omega.$$

Proof. The function $\zeta_\rho = \frac{y_\rho - y_1}{\rho} - z$ is the weak solution in $C(\overline{Q})$ of

$$\frac{\partial \zeta}{\partial t} + A\zeta + a_\rho \zeta = (a - a_\rho)z + (b - b_\rho)u_2 \ \text{ in } Q, \quad \zeta = 0 \quad \text{on } \Sigma, \quad \zeta(0) = 0 \quad \text{in } \Omega,$$

where $a_\rho = \int_0^1 \Phi'_y(\cdot, y_1 + \theta(y_\rho - y_1), u_\rho)d\theta$, $b_\rho = \int_0^1 \Phi'_u(\cdot, y_1, u_1 + \theta(u_\rho - u_1))d\theta$, $a = \Phi'_y(\cdot, y_1, u_1)$, and $b = \Phi'_u(\cdot, y_1, u_1)$. Moreover, by Proposition 3.1, we have

$$||\zeta_\rho||_{C(\bar{Q})} \le C(||a - a_\rho||_{q,Q} + ||b - b_\rho||_{q,Q}) \quad \text{for all } q > \frac{N}{2} + 1,$$

where $C \equiv C(T, \Omega, N, q)$ is a constant independent of ρ. Since $(u_\rho)_\rho$ converges to u_1 in $L^\infty(Q)$, the sequence $(y_\rho)_\rho$ converges to y_1 in $C(\overline{Q})$ and $(a_\rho, b_\rho)_\rho$ converges to (a, b) in $L^\theta(Q) \times L^\theta(Q)$ for all $\theta < \infty$. We have established (33). To prove (34), observe that

$$\frac{F(y_\rho, u_\rho) - F(y_1, u_1)}{\rho}$$

$$= \frac{F(y_\rho, u_\rho) - F(y_1 + \rho z, u_\rho)}{\rho} + \frac{F(y_1 + \rho z, u_\rho) - F(y_1, u_\rho)}{\rho} + \frac{F(y_1, u_\rho) - F(y_1, u_1)}{\rho}.$$

Due to (33) and A2, we have

$$\lim_{\rho \searrow 0} \Big|\Big| \frac{F(y_\rho, u_\rho) - F(y_1 + \rho z, u_\rho)}{\rho} \Big|\Big|_{\infty,Q} = \lim_{\rho \searrow 0} \Big(||\tilde{F}_\rho||_{\infty,Q} \ \frac{||r_\rho||_{\infty,Q}}{\rho} \Big) = 0,$$

where $\tilde{F}_\rho = \int_0^1 F'_y(\theta y_\rho + (1 - \theta)(y_1 + \rho z), u_\rho)d\theta$. Therefore,

$$\lim_{\rho \searrow 0} \Big|\Big| \frac{F(y_\rho, u_\rho) - F(y_1, u_1)}{\rho} - (F'_y(y_1, u_1)z + F'_u(y_1, u_1)u_2) \Big|\Big|_{\infty,Q}$$

$$\le \lim_{\rho \searrow 0} \Big|\Big| \frac{F(y_1 + \rho z, u_\rho) - F(y_1, u_\rho)}{\rho} - F'_y(y_1, u_1)z \Big|\Big|_{\infty,Q}$$

$$+ \lim_{\rho \searrow 0} \Big|\Big| \frac{F(y_1, u_\rho) - F(y_1, u_1)}{\rho} - F'_u(y_1, u_1)u_2 \Big|\Big|_{\infty,Q} = 0.$$

The proof is complete. □

For $u \in U_{ad}$, let us denote by z_u the solution of

$$\frac{\partial z}{\partial t} + Az + \Phi'_y(\cdot, \bar{y}, \bar{u})z = -\Phi'_u(\cdot, \bar{y}, \bar{u})\ u \ \text{ in } Q, \quad z = 0 \ \text{ on } \Sigma, \ \ z(0) = 0 \ \text{ in } \Omega.$$

LEMMA 7.2. *Assume that* A1–A4 *are fulfilled. Let $(\bar{y}, \bar{u})$ be a solution of $(\mathcal{P})$. Let us set*

$$\mathcal{S} = \Big\{ (\xi, \chi) \in C(\overline{Q}) \times L^\infty(Q) \mid \textit{there exists } u \in U_{ad} \textit{ such that}$$

$$\xi = g(\cdot, \bar{y}) + g'_y(\cdot, \bar{y})(z_u - z_{\bar{u}}) \quad \chi = F'_y(\bar{y}, \bar{u})\ (z_u - z_{\bar{u}}) + F'_u(\bar{y}, \bar{u})(u - \bar{u}) \Big\},$$

$$\mathcal{D} = \text{ int } \mathcal{C} \times \{\chi \in L^\infty(Q) \mid [F(\bar y, \bar u); \chi] < 0\}.$$

Then there exist $\bar\mu \in \mathcal{M}(\overline{Q})$ *and* $\bar\zeta \in (L^\infty(Q))'$ *such that*

$$\langle \bar\mu, \xi_1\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} + \langle \bar\zeta, \chi_1\rangle_{*,Q} > \langle \bar\mu, \xi_2\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} + \langle \bar\zeta, \chi_2\rangle_{*,Q} \tag{35}$$

for all $(\xi_1, \chi_1) \in \mathcal{S}$ *and for all* $(\xi_2, \chi_2) \in \mathcal{D}$ *and*

$$\langle \bar\mu, \xi_1\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} + \langle \bar\zeta, \chi_1\rangle_{*,Q} \geq \langle \bar\mu, \xi_2\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} + \langle \bar\zeta, \chi_2\rangle_{*,Q} \tag{36}$$

for all $(\xi_1, \chi_1) \in \mathcal{S}$ *and for all* $(\xi_2, \chi_2) \in \overline{\mathcal{D}} = \mathcal{C} \times \mathbf{cl}_\infty\{\chi \in L^\infty(Q) \mid [F(\bar y, \bar u); \chi] < 0\}$.

Proof. The sets $\mathcal{S}$ and $\mathcal{D}$ are convex, and $\mathcal{D}$ is open. Let us prove that $\mathcal{S} \cap \mathcal{D} = \emptyset$. Argue by contradiction and suppose that there exists $u_o \in U_{ad}$ such that

$$g(\cdot, \bar y) + g'_y(\cdot, \bar y)(z_{u_o} - z_{\bar u}) \in \text{ int } \mathcal{C}, \tag{37}$$

$$\Big[F(\bar y, \bar u); F'_y(\bar y, \bar u)\ (z_{u_o} - z_{\bar u}) + F'_u(\bar y, \bar u)(u_o - \bar u)\Big] < 0. \tag{38}$$

Let $u_\rho = \bar u + \rho(u_o - \bar u)$, $g_\rho = g(\cdot, \bar y) + \frac{1}{\rho}(g(y_\rho) - g(\bar y))$, where y_ρ is the solution of (1) corresponding to u_ρ. From (37), (38), and Lemma 7.1, it follows that

$$\lim_{\rho \searrow 0} g_\rho \in \text{ int } \mathcal{C} \quad \text{and} \quad \lim_{\rho \searrow 0} \frac{||F(y_\rho, u_\rho)||_{\infty,Q} - ||F(\bar y, \bar u)||_{\infty,Q}}{\rho} < 0.$$

Therefore, there exists $\rho_o > 0$ such that, for every $0 < \rho \leq \rho_o < 1$, we have

$$g(\cdot, y_\rho) = \rho\ g_\rho + (1 - \rho)\ g(\bar y) \in \text{ int } \mathcal{C} \quad \text{and} \quad J(y_\rho, v_\rho) < J(\bar y, \bar v).$$

This contradicts the optimality of $(\bar y, \bar u)$ and proves that $\mathcal{S} \cap \mathcal{D} = \emptyset$. From a geometric version of the Hahn–Banach theorem (the Eidelheit theorem [12]), there exists $(\bar\mu, \bar\zeta) \in \mathcal{M}(\overline{Q}) \times (L^\infty(Q))'$ such that

$$\inf_{(\xi_1,\chi_1)\in\mathcal{S}} \Big(\langle \bar\mu, \xi_1\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} + \langle \bar\zeta, \chi_1\rangle_{*,Q}\Big)$$

$$> \ \langle \bar\mu, \xi_2\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} + \langle \bar\zeta, \chi_2\rangle_{*,Q} \quad \text{for all } (\xi_2, \chi_2) \in \mathcal{D}$$

and

$$\inf_{(\xi_1,\chi_1)\in\mathcal{S}} \Big(\langle \bar\mu, \xi_1\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} + \langle \bar\zeta, \chi_1\rangle_{*,Q}\Big)$$

$$\geq \sup_{(\xi_2,\chi_2)\in\overline{\mathcal{D}}} \Big(\langle \bar\mu, \xi_2\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} + \langle \bar\zeta, \chi_2\rangle_{*,Q}\Big).$$

The proof is complete. □

7.1. Proof of Theorem 4.2. Let z_{θ_o} be a function belonging to int $\mathcal{C}$ and satisfying $z_{\theta_o} \equiv g(\cdot, \bar\Psi)$ in $\overline{\Sigma} \cup \overline{\Omega}_0$. (The existence of such a function follows from A4.)

• If we set $\chi_1 = 0$, $\xi_1 = g(\cdot, \bar y)$, and $\xi_2 = z_{\theta_o}$ in (35), we obtain

$$\Big\langle \bar\mu, g(\cdot, \bar y) - z_{\theta_o}\Big\rangle_{\mathcal{M}(\overline{Q}),C(\overline{Q})} = \Big\langle \bar\mu, g(\cdot, \bar y) - z_{\theta_o}\Big\rangle_{b,Q\cup\Omega_T} > \Big\langle \bar\zeta, \chi\Big\rangle_{*,Q}$$

for all $\chi \in \{y \in L^\infty(Q) \mid [F(\bar y, \bar u); y] < 0\}$. Conditions (9) and (12) easily follow from this inequality.

• The following is a direct consequence of Remark 4.3:

(i) If we set $\xi_1 = g(\cdot, \bar{y})$, $\xi_2 = z \in \mathcal{C}$ fixed, and $\chi_1 = \chi_2 = 0$ in (36), we obtain (10).

(ii) If we set $\xi_1 = \xi_2 = g(\cdot, \bar{y})$ and $\chi_1 = 0$ in (36), we obtain (11).

(iii) Let $u \in U_{ad}$. By setting $\xi_1 = g(\cdot, \bar{y}) + g'_y(\cdot, \bar{y})(z_u - z_{\bar{u}})$, $\chi_1 = F'_y(\bar{y}, \bar{u})\ (z_u - z_{\bar{u}}) + F'_u(\bar{y}, \bar{u})(u - \bar{u})$, $\chi_2 = 0$, and $\xi_2 = g(\cdot, \bar{y})$ in (36), we obtain

$$\left\langle \bar{\mu}, g'_y(\cdot, \bar{y})(z_u - z_{\bar{u}}) \right\rangle_{\mathcal{M}(\overline{Q}), C(\overline{Q})} + \left\langle \bar{\zeta}, F'_y(\bar{y}, \bar{u})(z_u - z_{\bar{u}}) + F'_u(\bar{y}, \bar{u})(u - \bar{u}) \right\rangle_{*,Q} \geq 0. \tag{39}$$

Let $\bar{p}$ be the weak solution of (13). With the Green formula of Theorem 3.4 and with Theorem 4.1, we obtain

$$\left\langle \bar{\mu}, g'_y(\cdot, \bar{y})(z_u - z_{\bar{u}}) \right\rangle_{\mathcal{M}(\overline{Q}), C(\overline{Q})} + \left\langle \bar{\zeta}, F'_y(\bar{y}, \bar{u})(z_u - z_{\bar{u}}) \right\rangle_{*,Q}$$

$$= \left\langle g'_y(\cdot, \bar{y})^* \bar{\mu} + \mathcal{B}(F'_y(\bar{y}, \bar{u})^* \bar{\zeta}), z_u - z_{\bar{u}} \right\rangle_{b, Q \cup \Omega_T} = \int_Q \bar{p}\ \Phi'_u(x, t, \bar{y}, \bar{u})(u - \bar{u})\, dx\, dt.$$

This equality, with (39), gives (14). The proof is complete. □

INEXACT SQP INTERIOR POINT METHODS AND LARGE SCALE OPTIMAL CONTROL PROBLEMS*

F. LEIBFRITZ† AND E. W. SACHS‡

Abstract. Optimal control problems with partial differential equations lead to large scale nonlinear optimization problems with constraints. An efficient solver which takes into account the structure and also the size of the problem is an inexact sequential quadratic programming method where the quadratic problems are solved iteratively. Based on a reformulation as a mixed nonlinear complementarity problem we give a measure of when to terminate the iterative quadratic program solver. For the latter we use an interior point algorithm. Under standard assumptions, local linear, superlinear, and quadratic convergence can be proved. The numerical application is an optimal control problem from nonlinear heat conduction.

Key words. inexact SQP method, interior point method, optimal control, partial differential equations

1. Introduction.

In this paper we consider large scale optimization problems with equality and inequality constraints which occur, for instance, from the discretization of optimal control problems with partial differential equations and state constraints.

As an example we use a problem which arises in the control of heating processes of industrial kilns. The goal is to heat the furnace such that the interior of the metal ingots or ceramic charges inside the kiln follows a prescribed temperature profile. Furthermore, constraints on the temperature, so-called state constraints, are imposed during the heating process. This problem can be formulated as an optimal control problem with a nonlinear diffusion equation which is controlled through the boundary. The objective function is given in a least squares framework. The state constraints are upper bounds on the temperature and are so-called hard constraints, in contrast to constraints on the controls. It is well known that control problems with state constraints require advanced numerical methods for their solution.

We present a method from *sequential quadratic programming* (SQP) for the solution of the resulting finite-dimensional optimization problem. In general, SQP methods reduce the nonlinear problem to a sequence of quadratic subproblems. For large problems, the solution of a single quadratic program might be very expensive. Even for small problems, the computational effort in SQP methods is dominated by solving the quadratic subproblems. In the view of global and local convergence properties of the SQP methods, it is advisable to solve each of the quadratic subproblems by

an efficient algorithm only up to a certain accuracy. Furthermore, the structure of the matrices occurring in each quadratic subproblem should be taken into account. Moreover, the presence of inequality constraints poses a further difficulty for these algorithms. In our work we use an interior point algorithm for the solution of the quadratic subproblems (cf. [6], [12], [23], [24], and the references therein). Since this is an iterative method it has two major advantages which can be used in the context of large scale optimization problems. First, the sparsity of the matrices can be used in an efficient way. Second, the quadratic subproblems can be solved only approximately. In other words, the inner iterative process can be terminated during the first iterations of the outer SQP method when one is still far away from a solution at an early stage, saving computing time. Then one can adaptively tighten the accuracy of the solutions of the quadratic problems as the iteration progresses. This leads to an inexact SQP approach which offers a trade-off between the accuracy of solving each subproblem and the amount of work for solving them (cf. [3], [4], and [19]). An immediate question is just how accurately should the subproblems be solved? And is there a measure when to terminate the iterative quadratic program solver? Furthermore, does an inexact SQP approach possess the same asymptotic convergence behavior as an exact SQP method? We will show that theoretical and practical answers to the above questions are available (cf. [5], [8], [10], [14, section 7], [16], [17], [22], and the references therein).

Converting the Karush–Kuhn–Tucker conditions of the nonlinear optimization problem into a mixed nonlinear complementarity problem enables us to define a quantity which gives a practical measure of how close a given vector is at a solution of the considered problem. This quantity determines how accurately the quadratic subproblems will be solved. Moreover, we prove under standard assumptions that a linear, superlinear, or quadratic rate of the outer SQP method is retained, although the quadratic subproblems are not solved exactly. Furthermore, the interior point algorithm itself can be shown to be superlinearly or quadratically convergent. The linear systems of the interior point approach are solved by an iterative equation solver like GMRES, in order to make use of the inherent sparsity structure, also with an adaptive termination criterion. All the convergence results will be verified by numerical results for a discretized control problem, as mentioned above.

Note that the convergence results for the inexact SQP method are of a local nature and no globalization strategies are incorporated. These require second order sufficiency conditions for optimality at the solution. This implies that the corresponding quadratic subproblems to be solved by interior point methods exhibit the proper convexity requirements.

In section 2 we state the finite-dimensional optimization problem with nonlinear equality and inequality constraints. The corresponding Karush–Kuhn–Tucker conditions will be restated into a mixed nonlinear complementarity problem. After that we present the inexact SQP algorithm for determining a solution of the mixed nonlinear complementarity problem. Furthermore, we discuss the notion of a regular solution and state some sufficient conditions for the regularity of this problem class.

Essential to an inexact SQP method is a practical measure of how close a given vector is to being a solution of the mixed nonlinear complementarity problem. Therefore, in section 3 we give a quantity which can be used as a measure of inexactness. Some results will justify the use of this quantity.

The local convergence analysis for the inexact SQP algorithm can be found in section 4. Under standard assumptions we prove that this method achieves the same

asymptotic convergence rates as an exact SQP approach. A similar result can be found in Pang [19] for nonmixed complementarity problems.

In section 5 an interior point method is described which is an iterative scheme to solve the quadratic subproblems, or, equivalently, the mixed linear complementarity problems occurring in the inexact SQP iteration. Furthermore, we state some local convergence results. In particular, the first result yields a superlinear convergence rate of the Karush–Kuhn–Tucker system of the quadratic subproblem to zero. Second, under stronger assumptions we obtain locally the quadratic convergence of the generated sequence to a solution of the subproblem.

Finally, in section 6, we use a discretized parabolic state-constrained control problem to support our theoretical results. It shows that the combination of an inexact SQP method with an interior point algorithm works very well for the considered problem class.

Throughout this paper we use the following notation. If $\varphi : \mathbb{R}^n \to \mathbb{R}^m$ is a continuously differentiable function, we use the notation

$$\varphi_z(z) = [(\varphi_1)_z(z), \dots, (\varphi_m)_z(z)] \in \mathbb{R}^{n\times m}.$$

Thus, the matrix $\varphi_z(z)$ has as columns the gradients $(\varphi_1)_z(z), \dots, (\varphi_m)_z(z)$ and is the transpose of the Jacobian matrix of the function φ. For vectors $\zeta \in \mathbb{R}^n$ and $\vartheta \in \mathbb{R}^n$ we also use

$$\min(\zeta) = \min_{1\le i\le n} \zeta_i, \quad \max(\zeta) = \max_{1\le i\le n} \zeta_i, \quad \chi = \min(\zeta, \vartheta), \quad \chi = \max(\zeta, \vartheta),$$

where $\chi \in \mathbb{R}^n$ is vector valued with the "min" ("max") interpreted as componentwise minimum (maximum). The index l will be used as the inexact SQP iteration counter and the index k denotes the interior point iteration counter of the considered algorithms.

2. Inexact SQP method for nonlinear optimization problems. In this section we consider a local inexact SQP method for the solution of the following finite-dimensional minimization problem with nonlinear equality and inequality constraints:

$$\text{(NP)} \qquad \min_z \ F(z) \quad \text{s.t.} \quad f(z) = 0, \quad g(z) \le 0,$$

where $z \in \mathbb{R}^n, F : \mathbb{R}^n \to \mathbb{R}, f : \mathbb{R}^n \to \mathbb{R}^{m_e}, g : \mathbb{R}^n \to \mathbb{R}^m$. We make the following assumptions on (NP):

Assumption 2.1.

(i) There exists an optimal solution z^* of (NP).

(ii) The functions F, f, g are twice continuously differentiable in an open ball $U(z^*)$.

(iii) The linear independent constraint qualification is fulfilled, i.e., the gradients of the active constraints are linearly independent at z^*.

Using the Karush–Kuhn–Tucker theorem, Assumption 2.1 implies that there exist $w^* \in \mathbb{R}^{m_e}$ and $y^* \in \mathbb{R}^m$, $y^* \ge 0$, such that (z^*, w^*, y^*) satisfies the first order necessary optimality conditions for (NP), i.e.,

$$F_z(z^*) + f_z(z^*)w^* + g_z(z^*)y^* = 0, \tag{2.1}$$

$$f(z^*) = 0, \tag{2.2}$$

$$g(z^*) \le 0, \tag{2.3}$$

$$(y^*)^T g(z^*) = 0. \tag{2.4}$$

These conditions can be converted into a *mixed nonlinear complementarity problem* due to the fact that some variables (z and w) are not restricted to be nonnegative (cf., for example, [9], [19], [20], or [21]). The mixed nonlinear complementarity problem, defined in terms of two mappings $h_1 : \mathbb{R}^{n+m_e+m} \to \mathbb{R}^{n+m_e}$ and $h_2 : \mathbb{R}^{n+m_e+m} \to \mathbb{R}^m$, is to determine a triple of vectors $(z, w, y) \in \mathbb{R}^{n+m_e+m}$ such that

$$h_1(z,w,y) = 0, \quad h_2(z,w,y) \geq 0, \quad y \geq 0, \quad \text{and} \quad y^T h_2(z,w,y) = 0. \tag{2.5}$$

If we define the functions by

$$h_1(z,w,y) = \begin{bmatrix} F_z(z) + f_z(z)\, w + g_z(z)\, y \\ f(z) \end{bmatrix} \quad \text{and} \quad h_2(z,w,y) = -g(z), \tag{2.6}$$

then the Karush–Kuhn–Tucker conditions (2.1)–(2.4) correspond precisely to the mixed nonlinear complementarity problem (2.5). In the following, we look for a solution $(z^*, w^*, y^*) \in \mathbb{R}^{n+m_e+m}$ such that

$$\begin{aligned} y^* \geq 0, \quad & {y^*}^T g(z^*) = 0, \\ h_1(z^*, w^*, y^*) = 0, \quad & \text{and} \quad h_2(z^*, w^*, y^*) \geq 0, \end{aligned} \tag{MNCP}$$

where the mappings h_1 and h_2 are given by (2.6).

SQP methods reduce the solution of the nonlinear problem (NP) to the numerical solution of a sequence of quadratic subproblems. In particular, a SQP method for a problem with equality constraints determines the step as the solution of a subproblem with quadratic objective function and linear constraints. For $w \in \mathbb{R}^{m_e}$, $y \in \mathbb{R}^m$, define the Lagrangian function by

$$\mathcal{L}(z,w,y) = F(z) + w^T f(z) + y^T g(z). \tag{2.7}$$

A common variant of the SQP algorithm for (NP) including inequality constraints obtains a new iterate $(z^{l+1}, w^{l+1}, y^{l+1})$ from the current iterate (z^l, w^l, y^l) by solving at each stage the quadratic program

$$\begin{aligned} \min_{\Delta z} \ & \tfrac{1}{2}\, \Delta z^T\, \mathcal{L}_{zz}(z^l, w^l, y^l)\, \Delta z + F_z^T(z^l)\, \Delta z \\ \text{s.t.} \ & f_z^T(z^l)\, \Delta z + f(z^l) = 0, \\ & g_z^T(z^l)\, \Delta z + g(z^l) \leq 0. \end{aligned} \tag{QP}_l$$

Then the new iterate z^{l+1} is set to $z^l + \Delta z$ and the new Lagrange multipliers w^{l+1}, y^{l+1} are obtained from the multipliers at the solution of $(\mathrm{QP})_l$. The necessary optimality conditions for this subproblem can be restated as a *mixed linear complementarity problem*, i.e.,

$$\begin{aligned} & \text{find } (z,w,y) \text{ such that} \\ & y \geq 0, \quad -g_z^T(z^l)(z - z^l) - g(z^l) \geq 0, \\ & y^T \left(-g_z^T(z^l)(z - z^l) - g(z^l)\right) = 0, \\ & \begin{bmatrix} F_z(z^l) \\ f(z^l) \end{bmatrix} + \begin{bmatrix} \mathcal{L}_{zz}(z^l, w^l, y^l) & f_z(z^l) & g_z(z^l) \\ f_z^T(z^l) & O & O \end{bmatrix} \begin{bmatrix} z - z^l \\ w \\ y \end{bmatrix} = 0. \end{aligned} \tag{MLCP}_l$$

For $\Delta z = z^{l+1} - z^l$ the point $(\Delta z, w^{l+1}, y^{l+1})$ satisfies the Karush–Kuhn–Tucker conditions of $(\mathrm{QP})_l$. Hence, it is also a solution vector of the mixed linear complementarity problem.

Under suitable regularity conditions the sequence $\{(z^l, w^l, y^l)\}$ generated by a SQP approach is well defined and locally convergent. A drawback of this method is the cost of solving the quadratic subproblem, or, equivalently, the mixed linear complementarity problem at each iteration. Computing the exact solution can be expensive if the number of unknowns is large and may not be justified when far from a solution. Therefore, one is led to use an iterative method, e.g., an interior point algorithm, and to solve the subproblem only approximately. This observation leads to an inexact SQP method which offers a trade-off between the accuracy of solving the subproblems and the amount of work involved in solving them (cf. [3], [4], and [19]).

Pang [19] suggests an inexact Newton method for solving a nonmixed nonlinear complementarity problem of the following form. Find a vector $\xi \in \mathbb{R}^n$ such that

$$\xi \geq 0, \quad \varphi(\xi) \geq 0, \quad \xi^T \varphi(\xi) = 0.$$

In this paper we formulate an inexact SQP algorithm for determining a solution of the mixed nonlinear complementarity problem (MNCP). If we define the mixed nonlinear complementarity function $\hat{h} : \mathbb{R}^{n+m_e+m} \to \mathbb{R}^{n+m_e+m}$ (cf. [11]) by

$$\hat{h}(z, w, y) = \begin{bmatrix} \mathcal{L}_z(z, w, y) \\ f(z) \\ \min(y, -g(z)) \end{bmatrix} \tag{2.8}$$

and its linearization at a given point (z^l, w^l, y^l) near the solution (z^*, w^*, y^*) by

$$\hat{h}^l(z, w, y) = \begin{bmatrix} F_z(z^l) + f_z(z^l)w + g_z(z^l)y + \mathcal{L}_{zz}(z^l, w^l, y^l)(z - z^l) \\ f(z^l) + f_z^T(z^l)(z - z^l) \\ \min(y, -g(z^l) - g_z^T(z^l)(z - z^l)) \end{bmatrix}, \tag{2.9}$$

where the *min*-operator is interpreted as the componentwise minimum of the vector-valued entries, then we obtain the following algorithm.

Algorithm 2.2. Inexact SQP Method.

Choose a local starting point (z^0, w^0, y^0) and a termination criterion $\varepsilon > 0$.

For $l = 0, 1, 2, \ldots$ until $||\hat{h}(z^l, w^l, y^l)|| \leq \varepsilon$ do

(I) Choose $\lambda_l > 0$ and find a vector (z, w, y) of $(\text{MLCP})_l$ which satisfies

$$||\hat{h}^l(z, w, y)|| \leq \lambda_l \, ||\hat{h}(z^l, w^l, y^l)||. \tag{2.10}$$

(II) Set $(z^{l+1}, w^{l+1}, y^{l+1}) = (z, w, y)$.

The inexact SQP method of Algorithm 2.2 generates in every iteration a new point $(z^{l+1}, w^{l+1}, y^{l+1})$ according to the *approximation rule* (2.10). The nonnegative sequence $\{\lambda_l\}$ controls the level of accuracy and will be specified later.

The approximation rule (2.10) as a measure of inexactness will be motivated in the next section. Pang [19] introduced this error bound in the context of nonlinear complementarity problems. Furthermore, the rule (2.10) is similar to the residual rule used in [3] for the solution of nonlinear equations with an inexact Newton method.

In order to state the convergence of the inexact SQP method and to motivate the usefulness of (2.10) as a measure of inexactness, we discuss the notion of a *regular solution*, which was introduced by Robinson [21] in the context of generalized equations.

For our purpose, we define regularity in terms of the mixed nonlinear complementarity problem (MNCP).

DEFINITION 2.3 (cf. [21, p. 45]). *Let* (z^*, w^*, y^*) *be a solution of* (MNCP). *Then* (z^*, w^*, y^*) *is called regular if there exists a neighborhood* U_δ^* *of* (z^*, w^*, y^*) *and a scalar* $\gamma^* > 0$ *such that for every perturbation vector* $\rho = (\rho_1, \rho_2, \rho_3)^T \in \mathbb{R}^{n+m_e+m}$ *with* $||\rho|| < \gamma^*$, *there is a unique solution* $(z(\rho), w(\rho), y(\rho)) \in U_\delta^*$ *that solves the perturbed mixed linear complementarity problem defined by*

$$(\text{MLCP})_\rho \qquad \begin{array}{c} y(\rho) \geq 0, \quad y(\rho)^T \left(-g_z^T(z^*)(z(\rho) - z^*) - g(z^*) - \rho_3\right) = 0 \\ -g_z^T(z^*)(z(\rho) - z^*) - g(z^*) - \rho_3 \geq 0, \end{array}$$

$$\begin{bmatrix} F_z(z^*) \\ f(z^*) \end{bmatrix} + \begin{bmatrix} \mathcal{L}_{zz}(z^*, w^*, y^*) & f_z(z^*) & g_z(z^*) \\ f_z^T(z^*) & O & O \end{bmatrix} \begin{bmatrix} z(\rho) - z^* \\ w(\rho) \\ y(\rho) \end{bmatrix} - \begin{bmatrix} \rho_1 \\ \rho_2 \end{bmatrix} = 0.$$

Moreover, the solution $(z(\rho), w(\rho), y(\rho))$ *is Lipschitz continuous in* ρ; *i.e., there is a constant* $L > 0$ *such that for every* $\rho, \hat{\rho}$ *with* $||\rho|| < \gamma^*, ||\hat{\rho}|| < \gamma^*$ *we have*

$$\|(z(\rho), w(\rho), y(\rho)) - (z(\hat{\rho}), w(\hat{\rho}), y(\hat{\rho}))\| \leq L \, \|\rho - \hat{\rho}\|.$$

This regularity condition can be considered a generalization of the requirement that the Jacobian matrix be nonsingular in the case of solving systems of nonlinear equations. Robinson [21] states some sufficient conditions for the regularity of (MNCP). In particular, he proved under Assumption 2.4 that (z^*, w^*, y^*) is a regular solution of (MNCP). Hence, the mixed nonlinear complementarity problem is locally solvable in a vicinity of (z^*, w^*, y^*). Without loss of generality, $g(z^*)$ and y^* can be partitioned as

$$(g_+(z^*), g_0(z^*), g_-(z^*))^T \in \mathbb{R}^{r+s+t}, \qquad \left(y_+^*, y_0^*, y_-^*\right)^T \in \mathbb{R}^{r+s+t},$$

where $m = r + s + t$ and

$$\begin{array}{rcl@{\qquad}rcl} g_+(z^*) & = & 0, & y_+^* & > & 0, \\ g_0(z^*) & = & 0, & y_0^* & = & 0, \\ g_-(z^*) & < & 0, & y_-^* & = & 0. \end{array} \tag{2.11}$$

With this partition we can formulate a special strong second order sufficiency condition and a linear independence condition. We make the following assumption.

Assumption 2.4.

(i) The matrix $[f_z^T(z^*)\,(g_+)_z^T(z^*)\,(g_0)_z^T(z^*)]^T$ has full row rank.

(ii) For all $\Delta z \neq 0$, $\Delta z \in \mathbb{R}^n$ satisfying $\Delta z^T f_z(z^*) = 0$ and $\Delta z^T (g_+)_z(z^*) = 0$:

$$\Delta z^T \, \mathcal{L}_{zz}(z^*, w^*, y^*) \, \Delta z > 0.$$

With these conditions one can show the following result.

THEOREM 2.5 (see Robinson [21, Theorem 4.1]). *Let Assumption* 2.1(ii) *and Assumption* 2.4 *be fulfilled. Furthermore, let* (z^*, w^*, y^*) *be a solution of* (MNCP). *Then,* (z^*, w^*, y^*) *is a regular solution of* (MNCP).

If a solution of (MNCP) satisfies the conditions of Assumption 2.4, then Theorem 2.5 guarantees the regularity of the problem. In this case we know from Definition 2.3 that there is a unique solution of $(\text{MLCP})_\rho$ in a vicinity of (z^*, w^*, y^*). Hence, we can locally determine a solution of the mixed nonlinear complementarity problem

with the inexact SQP method of Algorithm 2.2. Furthermore, the regular solution (z^*, w^*, y^*) of (MNCP) is also an optimal solution of (NP). In particular, we can state the following result.

THEOREM 2.6 (cf. Bertsekas [1, Theorem 1.30]). *Let Assumption* 2.1(ii) *and Assumption* 2.4 *be fulfilled. Furthermore, let* (z^*, w^*, y^*) *be a solution of* (MNCP). *Then,* z^* *is a strict local minimum of the nonlinear problem* (NP).

3. Measure of inexactness. The main advantage of the approximation rule (2.10) is the savings in the computational effort during the early iterations; i.e., at each stage of the inexact SQP method of Algorithm 2.2 a new iterate is defined as an inaccurate solution of the subproblem $(\text{MLCP})_l$. The use of an inexact method raises the question of how to measure the accuracy of the approximate solution to a mixed nonlinear complementarity problem, or, in other words, how close is a given vector to a solution of (MNCP)?

For the motivation of the approximation rule (2.10) as a *measure of inexactness*, first, we consider the mixed linear complementarity problem $(\text{MLCP})_l$. Second, similar results will be given for the mixed nonlinear complementarity problem (MNCP).

We assume that $(z^l, w^l, y^l), l \geq 0$, is fixed and given. For such a point, we define the matrix $M \in \mathbb{R}^{(n+m_e+m)\times(n+m_e+m)}$ and the vectors $r_1, s_1 \in \mathbb{R}^{n+m_e}$ by

$$M = \begin{bmatrix} \nabla h_1(z^l, w^l, y^l) \\ \nabla h_2(z^l, w^l, y^l) \end{bmatrix}, \; r_1 = \begin{bmatrix} F_z(z^l) \\ f(z^l) \end{bmatrix}, \; s_1 = \begin{bmatrix} z - z^l \\ w \end{bmatrix},$$

where

$$\begin{aligned} \nabla h_1(z^l, w^l, y^l) &= \begin{bmatrix} \mathcal{L}_{zz}(z^l, w^l, y^l) & f_z(z^l) & g_z(z^l) \\ f_z^T(z^l) & O & O \end{bmatrix}, \\ \nabla h_2(z^l, w^l, y^l) &= \begin{bmatrix} -g_z^T(z^l) & O & O \end{bmatrix}, \end{aligned}$$

and rewrite $(\text{MLCP})_l$ as

$$\begin{aligned} & y \geq 0, \quad y^T \left(-g_z^T(z^l)(z - z^l) - g(z^l)\right) = 0, \\ & -g_z^T(z^l)(z - z^l) - g(z^l) \geq 0, \quad r_1 + \nabla h_1(z^l, w^l, y^l) \begin{bmatrix} s_1 \\ y \end{bmatrix} = 0. \end{aligned} \tag{3.1}$$

Obviously, a vector $(\tilde{z}, \tilde{w}, \tilde{y})$ is an exact solution of $(\text{MLCP})_l$, or, equivalently, of (3.1) if and only if the linearized complementarity function (2.9) is equal to zero.

LEMMA 3.1. *Let* (z^l, w^l, y^l) *be fixed. Furthermore, let* $\hat{h}^l$ *be defined by* (2.9). *Then*

$$\hat{h}^l(\tilde{z}, \tilde{w}, \tilde{y}) \equiv 0 \quad \Longleftrightarrow \quad (\tilde{z}, \tilde{w}, \tilde{y}) \quad \textit{is a solution of } (\text{MLCP})_l.$$

Thus, the quantity $||\hat{h}^l(z, w, y)||$ is a practical measure of how close a given vector is to being a solution of $(\text{MLCP})_l$. The following result justifies the use of the above quantity as a measure of inexactness, which can be proved by a simple modification of the proof of [19, Lemma 1].

PROPOSITION 3.2. *Let* (z^l, w^l, y^l) *be fixed. Furthermore, let* $(\tilde{z}, \tilde{w}, \tilde{y})$ *be a regular solution of* (3.1). *Then there exists a neighborhood* $U_{\tilde{\delta}}$ *of* $(\tilde{z}, \tilde{w}, \tilde{y})$ *and* $\hat{\lambda} > 0$ *such that for all* $(z, w, y) \in U_{\tilde{\delta}}$, *we obtain*

$$||(z, w, y) - (\tilde{z}, \tilde{w}, \tilde{y})|| \leq \hat{\lambda} \, ||\hat{h}^l(z, w, y)||.$$

Under the assumption of regularity Proposition 3.2 guarantees that the quantity $||\hat{h}^l||$ is a good measure of the inexactness in a neighborhood of a solution to the mixed linear complementarity problem. One can expect that the smaller $||\hat{h}^l||$ is, the closer a point (z, w, y) is to the solution $(\tilde{z}, \tilde{w}, \tilde{y})$ of (3.1).

Similar to the above discussion, we can show that an iterate (z^l, w^l, y^l) is an exact solution of the mixed nonlinear complementarity problem (MNCP) if and only if the complementarity function (2.8) is zero. In particular, we state the following result.

LEMMA 3.3. *Let $\hat{h}$ be defined by* (2.8). *Then*

$$\hat{h}(z^*, w^*, y^*) \equiv 0 \quad \Longleftrightarrow \quad (z^*, w^*, y^*) \quad \textit{is a solution of} \text{ (MNCP)}.$$

Thus, the quantity $||\hat{h}(z^l, w^l, y^l)||$ measures how close the current iterate is to being a solution of (MNCP). We can expect that the larger $||\hat{h}(z^l, w^l, y^l)||$ is, the further away the current point is from an exact solution of the mixed nonlinear complementarity problem. On the other hand, the smaller it is, the more accurately the next subproblem is solved. In particular, we have the following proposition.

PROPOSITION 3.4. *Let (z^*, w^*, y^*) be a regular solution of the mixed nonlinear complementarity problem* (MNCP). *Then there exists a neighborhood U^* of (z^*, w^*, y^*) and a positive scalar $\hat{\lambda}_l$ such that whenever a point (z^l, w^l, y^l) is in U^*, we obtain*

$$||(z^l, w^l, y^l) - (z^*, w^*, y^*)|| \leq \hat{\lambda}_l \, ||\hat{h}(z^l, w^l, y^l)||.$$

Proof. Let $L > 0$, $\gamma^* > 0$, and U^*_δ be specified as in Definition 2.3. From the continuity of $\hat{h}$ we obtain the existence of a neighborhood U^* of (z^*, w^*, y^*) such that for all points (z^l, w^l, y^l) in U^* we get

$$v^l = \Big((z^l, w^l, y^l) - (\hat{h}_1(z^l, w^l, y^l), \hat{h}_2(z^l, w^l, y^l), \hat{h}_3(z^l, w^l, y^l))\Big)^T \in U^*_\delta, \quad ||\rho^l|| < \gamma^*,$$

where $\rho^l = (I - M)\hat{h}(z^l, w^l, y^l)$. Then, by the definition of $\hat{h}$ and $\hat{h}^l(z^l, w^l, y^l) = \hat{h}(z^l, w^l, y^l)$, it follows that $\hat{h}^l(v^l; \rho^l) = 0$, where $\hat{h}^l(v; \rho) := \hat{h}^l(v) - \rho$ denotes the perturbed linearized complementarity function according to $(\text{MLCP})_\rho$. Hence, the vector $v^l \in U^*_\delta$ is a solution of a perturbed mixed linear complementarity problem of the form $(\text{MLCP})_\rho$. Furthermore, the exact solution (z^*, w^*, y^*) of (MNCP) is regular. Then, by Definition 2.3 we know that $||(v^l_1, v^l_2, v^l_3) - (z^*, w^*, y^*)|| \leq L \, ||(I - M)\hat{h}(z^l, w^l, y^l)||$. Therefore, with $\hat{\lambda}_l = 1 + L \, ||I - M||$, we can deduce the desired result. ∎

4. Convergence rate for the inexact SQP method. In this section we state a local convergence result for the inexact SQP Algorithm 2.2. This method produces at every stage a new iterate according to the approximation rule (2.10). From the discussion of the previous section, we know that an iterate (z^l, w^l, y^l) is an exact solution of the mixed nonlinear complementarity problem (MNCP) if and only if the mixed nonlinear complementarity function (2.8) is equal to zero. Thus, the quantity $||\hat{h}(z^l, w^l, y^l)||$ measures how close the current iterate is to being a solution of (MNCP). As in Proposition 3.4 we can expect that the larger $||\hat{h}(z^l, w^l, y^l)||$ is, the further away the current point is from an exact solution of (MNCP). On the other hand, the smaller it is, the more accurately the next subproblem is solved.

We need two lemmas to establish the local convergence result. The first lemma is easy to prove and guarantees that under a sufficient differentiability assumption on

F, f, and g, the mixed nonlinear complementarity function $\hat{h}$ is Lipschitz continuous. The second lemma is a consequence of regularity. It states under the sole assumption of regularity that for sufficiently small perturbations the perturbed mixed linear complementarity problems are uniquely solvable in a vicinity of a regular solution of (MNCP). This result is a special case of Robinson [21, Theorem 2.4].

LEMMA 4.1. *Let F, f, and g be twice continuously differentiable. Then the mixed complementarity function $\hat{h}$ defined in* (2.8) *is Lipschitz continuous; i.e., there exist positive constants c_f, c_g, and $c_{\mathcal{L}}$ such that for all $(z^1, w^1, y^1), (z^2, w^2, y^2) \in \mathbb{R}^{n+m_e+m}$ we have*

$$||\hat{h}(z^1, w^1, y^1) - \hat{h}(z^2, w^2, y^2)|| \leq \hat{L}\, ||(z^1, w^1, y^1) - (z^2, w^2, y^2)||, \tag{4.1}$$

where $\hat{L} := c_{\mathcal{L}} + 2\, \max(1, c_f) + 2\, \sqrt{m}\, \max(1, c_g)$.

LEMMA 4.2. *Let (z^*, w^*, y^*) be a solution of* (MNCP). *Furthermore, suppose that Assumption* 2.1(ii) *and Assumption* 2.4 *are fulfilled. Then there exist a scalar $\gamma^* > 0$, two neighborhoods $U^*_{\delta_1}$ and $U^*_{\delta_2}$ of (z^*, w^*, y^*), and a Lipschitz constant $L > 0$ such that for all $(z, w, y) \in U^*_{\delta_1}$ and every perturbation $\rho = (\rho_1, \rho_2, \rho_3)^T \in \mathbb{R}^{n+m_e+m}$ with $||\rho|| < \gamma^*$, there is a unique solution vector*

$$\xi(z, w, y; \rho) := (\xi_1, \xi_2, \xi_3)^T \in U^*_{\delta_2}$$

depending on z, w, y, and ρ that solves the perturbed mixed linear complementarity problem defined by

$$\begin{gathered}
\xi_3 \geq 0, \quad \xi_3^T \left(-g_z^T(z)(\xi_1 - z) - g(z) - \rho_3\right) = 0, \\
-g_z^T(z)(\xi_1 - z) - g(z) - \rho_3 \geq 0, \\
\begin{bmatrix} F_z(z) \\ f(z) \end{bmatrix} + \begin{bmatrix} \mathcal{L}_{zz}(z, w, y) & f_z(z) & g_z(z) \\ f_z^T(z) & O & O \end{bmatrix} \begin{bmatrix} \xi_1 - z \\ \xi_2 \\ \xi_3 \end{bmatrix} - \begin{bmatrix} \rho_1 \\ \rho_2 \end{bmatrix} = 0.
\end{gathered}$$

Moreover, if $||\rho|| < \gamma^*$ and $||\hat{\rho}|| < \gamma^*$, then

$$||(\xi_1, \xi_2, \xi_3) - (\hat{\xi}_1, \hat{\xi}_2, \hat{\xi}_3)|| \leq L\, ||\rho - \hat{\rho}||,$$

where $\hat{\xi}(z, w, y; \hat{\rho}) := (\hat{\xi}_1, \hat{\xi}_2, \hat{\xi}_3)$ depends on z, w, y, and $\hat{\rho}$.

Now we are ready to show the local convergence result. A similar result can be found in Pang [19] for nonmixed nonlinear complementarity problems. For mixed nonlinear complementarity problems, i.e., those with equality as well as inequality relations, considered in this paper, the problem formulation, the definition of $\hat{h}$, and other relations have to be modified as described above. In particular, we are able to prove the following theorem.

THEOREM 4.3. *Let (z^*, w^*, y^*) be a solution triple of* (MNCP). *Furthermore, suppose that Assumption* 2.1(ii) *and Assumption* 2.4 *are fulfilled. Let $\hat{L} > 0$ be the Lipschitz constant specified in Lemma* 4.1 *and let $L > 0$ be the scalar as given in Lemma* 4.2. *Moreover, assume that for all l we have for some $\lambda \in (0, 1)$ and $\tilde{\lambda} > 1$*

$$\lambda_l \leq \lambda / \tilde{\lambda}, \tag{4.2}$$

where $\tilde{\lambda} = \max(1, \hat{L})\, (\, 1 + \max(1, L)\, c\,)$ and $c > 0$ is a given constant satisfying (4.8). *Then*

(i) *There exists an open ball* U^* *including* (z^*, w^*, y^*) *such that for all starting data* $(z^0, w^0, y^0) \in U^*$, *the sequence* $\{(z^l, w^l, y^l)\}$ *generated by the inexact SQP Algorithm* 2.2 *is well defined and converges to* (z^*, w^*, y^*) *with a linear rate; i.e., there is a constant* $r \in (0, 1)$ *such that*

$$||(z^{l+1}, w^{l+1}, y^{l+1}) - (z^*, w^*, y^*)|| \leq r\ ||(z^l, w^l, y^l) - (z^*, w^*, y^*)||; \tag{4.3}$$

(ii) *If, in addition to the assumptions in* (i), $\lim_{l\to\infty} \lambda_l = 0$, *then the rate of convergence is superlinear;*

(iii) *Suppose, in addition to the assumptions in* (i), *that the second derivatives of* F, f, *and* g *satisfy a Lipschitz condition in a neighborhood of* z^*. *Then, if*

$$\lambda_l \leq \hat{\beta}\ \|\hat{h}(z^l, w^l, y^l)\| \tag{4.4}$$

for some $\hat{\beta} > 0$, *the convergence of* $\{(z^l, w^l, y^l)\}$ *to* (z^*, w^*, y^*) *is quadratic.*

Proof. Let $U^*_{\delta_1}$, $U^*_{\delta_2}$, $\gamma^* > 0$, and $L > 0$ be specified as in Lemma 4.2. Since $\hat{h}(z^*, w^*, y^*) = 0$, Lemma 4.1 implies that with the Lipschitz constant $\hat{L} > 0$,

$$\left\|\hat{h}(z, w, y)\right\| = \left\|\hat{h}(z, w, y) - \hat{h}(z^*, w^*, y^*)\right\| \leq \hat{L}\ \|(z, w, y) - (z^*, w^*, y^*)\| \tag{4.5}$$

holds for all $(z, w, y) \in U^*_{\delta_1}$. By restricting $U^*_{\delta_1}$, if necessary, we can assume that

$$\lambda\ \|(z, w, y) - (z^*, w^*, y^*)\| < \gamma^* \quad \forall\, (z, w, y) \in U^*_{\delta_1} \text{ and } \lambda \in (0, 1). \tag{4.6}$$

Since h_1 and h_2 are continuously differentiable functions, we can assume, by restricting $U^*_{\delta_1}$ further, the existence of constant $\varepsilon > 0$ such that

$$\left\| \begin{bmatrix} h_1(z^*, w^*, y^*) \\ h_2(z^*, w^*, y^*) \end{bmatrix} - \begin{bmatrix} h_1(z, w, y) \\ h_2(z, w, y) \end{bmatrix} - \begin{bmatrix} \nabla h_1(z, w, y) \\ \nabla h_2(z, w, y) \end{bmatrix} ((z^*, w^*, y^*) - (z, w, y))^T \right\|$$

$$\leq \varepsilon\ \|(z, w, y) - (z^*, w^*, y^*)\| < \gamma^* \quad \forall\, (z, w, y) \in U^*_{\delta_1} \tag{4.7}$$

and $r := L\,\varepsilon + \lambda < 1$. Moreover, the norm of the gradient of h_1 and h_2 is bounded for all points in a vicinity of the regular solution (z^*, w^*, y^*). Hence, there is a constant $c > 0$ such that

$$\left\| \begin{bmatrix} I_1 & O \\ O & I_2 \end{bmatrix} - \begin{bmatrix} \nabla h_1(z, w, y) \\ \nabla h_2(z, w, y) \end{bmatrix} \right\| \leq c \quad \forall\, (z, w, y) \in U^*_{\delta_1}. \tag{4.8}$$

(i) We interpret the residual vector $\hat{h}^l$ as perturbation $\tilde{\rho}$ for solving $(\text{MLCP})_l$ at the lth stage of the inexact SQP algorithm and show that $(z^{l+1}, w^{l+1}, y^{l+1})$ solves a perturbed mixed linear complementarity problem. Then, choosing two perturbations ρ, $\hat{\rho}$ and perturbing $(z^{l+1}, w^{l+1}, y^{l+1})$ by $\tilde{\rho}$ (denoted by ξ^{l+1}), we conclude that ξ^{l+1} and (z^*, w^*, y^*) each solve a perturbed mixed linear complementarity problem. Finally, using the Lipschitz continuity of these solutions with respect to the perturbations and adding $0 = \tilde{\rho} - \tilde{\rho}$ to the left-hand side of (4.3), we show that (4.3) holds.

Let (z^0, w^0, y^0) be chosen in $U^*_{\delta_1}$. In general, assume that the point (z^l, w^l, y^l) lies in $U^*_{\delta_1}$. Let $(z^{l+1}, w^{l+1}, y^{l+1})$ be generated by the inexact SQP Algorithm 2.2; i.e., $(z^{l+1}, w^{l+1}, y^{l+1})$ is an approximate solution of $(\text{MLCP})_l$ satisfying (2.10). Setting $\tilde{\rho} := (\tilde{\rho}_1, \tilde{\rho}_2, \tilde{\rho}_3)^T = \hat{h}^l(z^{l+1}, w^{l+1}, y^{l+1})$, then it follows by (2.10), (4.2), and (4.5) that

$$||\tilde{\rho}|| \leq \lambda_l \hat{L} ||(z^l, w^l, y^l) - (z^*, w^*, y^*)|| \leq \frac{\lambda ||(z^l, w^l, y^l) - (z^*, w^*, y^*)||}{1 + \max(1, L)c}. \tag{4.9}$$

Thus, (4.9), together with (4.6), implies $||\tilde{\rho}|| < \gamma^*$. Using Lemma 4.2, we deduce that $(z^{l+1}, w^{l+1}, y^{l+1}) \in U^*_{\delta_2}$ satisfies uniquely the following perturbed mixed linear complementarity problem:

$$
\begin{aligned}
y^{l+1} \geq 0, \quad & \left(y^{l+1}\right)^T \left(-g_z^T(z^l)(z^{l+1} - z^l) - g(z^l) - \tilde{\rho}_3\right) = 0, \\
& -g_z^T(z^l)(z^{l+1} - z^l) - g(z^l) - \tilde{\rho}_3 \geq 0, \\
& \begin{bmatrix} F_z(z^l) \\ f(z^l) \end{bmatrix} + \nabla h_1(z^l, w^l, y^l) \begin{bmatrix} z^{l+1} - z^l \\ w^{l+1} \\ y^{l+1} \end{bmatrix} - \begin{bmatrix} \tilde{\rho}_1 \\ \tilde{\rho}_2 \end{bmatrix} = 0.
\end{aligned} \tag{4.10}
$$

Defining $\xi^{l+1} := \left(\xi_1^{l+1}, \xi_2^{l+1}, \xi_3^{l+1}\right)^T = \left((z^{l+1}, w^{l+1}, y^{l+1}) - (\tilde{\rho}_1, \tilde{\rho}_2, \tilde{\rho}_3)\right)^T$ and

$$
\rho := (\rho_1, \rho_2, \rho_3)^T = \left(\begin{bmatrix} I_1 & O \\ O & I_2 \end{bmatrix} - \begin{bmatrix} \nabla h_1(z^l, w^l, y^l) \\ \nabla h_2(z^l, w^l, y^l) \end{bmatrix} \right) \tilde{\rho},
$$

it follows by (4.6), (4.8), and (4.9), that $||\rho|| < \gamma^*$. Then, with the definition of $\tilde{\rho}$, ξ^{l+1}, ρ, and $y^{l+1} \geq \tilde{\rho}_3$, the vector ξ^{l+1} solves

$$
\begin{aligned}
\xi_3^{l+1} \geq 0, \quad & \left(\xi_3^{l+1}\right)^T \left(-g_z^T(z^l)(\xi_1^{l+1} - z^l) - g(z^l) - \rho_3\right) = 0, \\
& -g_z^T(z^l)(\xi_1^{l+1} - z^l) - g(z^l) - \rho_3 \geq 0, \\
& \begin{bmatrix} F_z(z^l) \\ f(z^l) \end{bmatrix} + \nabla h_1(z^l, w^l, y^l) \begin{bmatrix} \xi_1^{l+1} - z^l \\ \xi_2^{l+1} \\ \xi_3^{l+1} \end{bmatrix} - \begin{bmatrix} \rho_1 \\ \rho_2 \end{bmatrix} = 0.
\end{aligned} \tag{4.11}
$$

Hence, the continuity of $\hat{h}^l$, $\tilde{\rho} = \hat{h}^l(z^{l+1}, w^{l+1}, y^{l+1})$ and Lemma 4.2 imply that the vector $\xi^{l+1} \in U^*_{\delta_2}$ is the unique solution of (4.11). Setting $\hat{\rho} = [\hat{\rho}_{1,2}\ \hat{\rho}_3]^T$, where

$$
\begin{bmatrix} \hat{\rho}_{1,2} \\ \hat{\rho}_3 \end{bmatrix} = \begin{bmatrix} h_1(z^*, w^*, y^*) \\ h_2(z^*, w^*, y^*) \end{bmatrix} - \begin{bmatrix} h_1(z^l, w^l, y^l) \\ h_2(z^l, w^l, y^l) \end{bmatrix} - \begin{bmatrix} \nabla h_1(z^l, w^l, y^l) \\ \nabla h_2(z^l, w^l, y^l) \end{bmatrix} \begin{bmatrix} z^* - z^l \\ w^* - w^l \\ y^* - y^l \end{bmatrix},
$$

then by (4.7) we obtain $||\hat{\rho}|| \leq \varepsilon ||(z^*, w^*, y^*) - (z^l, w^l, y^l)|| < \gamma^*$. Since

$$
\begin{aligned}
h_1(z^*, w^*, y^*) &= h_1(z^l, w^l, y^l) + \hat{\rho}_{1,2} + \nabla h_1(z^l, w^l, y^l)((z^*, w^*, y^*) - (z^l, w^l, y^l))^T = 0, \\
h_2(z^*, w^*, y^*) &= h_2(z^l, w^l, y^l) + \hat{\rho}_3 + \nabla h_2(z^l, w^l, y^l)((z^*, w^*, y^*) - (z^l, w^l, y^l))^T \geq 0,
\end{aligned}
$$

it follows that the regular solution (z^*, w^*, y^*) satisfies the following perturbed mixed linear complementarity problem:

$$
\begin{aligned}
y^* \geq 0, \quad & \left(y^*\right)^T \left(-g_z^T(z^l)(z^* - z^l) - g(z^l) + \hat{\rho}_3\right) = 0, \\
& -g_z^T(z^l)(z^* - z^l) - g(z^l) + \hat{\rho}_3 \geq 0, \\
& h_1(z^l, w^l, y^l) + \hat{\rho}_{1,2} + \nabla h_1(z^l, w^l, y^l)((z^*, w^*, y^*) - (z^l, w^l, y^l))^T = 0.
\end{aligned} \tag{4.12}
$$

Then, Lemma 4.2 guarantees the Lipschitz continuity of the above solutions with respect to the perturbations; i.e., we obtain

$$
||(\xi_1^{l+1}, \xi_2^{l+1}, \xi_3^{l+1}) - (z^*, w^*, y^*)|| \leq L\, ||\rho - \hat{\rho}||. \tag{4.13}
$$

Hence, with $||\hat{\rho}|| \le \varepsilon||(z^*, w^*, y^*) - (z^l, w^l, y^l)||$, (2.10), (4.2), (4.8), (4.9), and (4.13), we have

$$\begin{aligned}||(z^{l+1}, w^{l+1}, y^{l+1}) - (z^*, w^*, y^*)|| &\le (\lambda_l \hat{L}(1 + Lc) + L\varepsilon)||(z^l, w^l, y^l) - (z^*, w^*, y^*)|| \\ &\le (\lambda + L\varepsilon)||(z^l, w^l, y^l) - (z^*, w^*, y^*)||.\end{aligned}$$

Since $r := \lambda + L\,\varepsilon < 1$ and $(z^l, w^l, y^l) \in U^*_{\delta_1}$ we obtain $(z^{l+1}, w^{l+1}, y^{l+1}) \in U^*_{\delta_1}$. Then, it follows that the point $(z^{l+1}, w^{l+1}, y^{l+1})$ generated by the inexact SQP Algorithm 2.2 is well defined, and by induction, we can conclude that the sequence $\{(z^l, w^l, y^l)\}$ is well defined. Furthermore, $\{(z^l, w^l, y^l)\}$ converges to (z^*, w^*, y^*) with a linear rate.

(ii) Suppose, in addition, that $\lim_{l\to\infty} \lambda_l = 0$. If we replace in (4.7) $r := L\,\varepsilon + \lambda < 1$, the constant ε by $\varepsilon_l > 0$ with $\lim_{l\to\infty} \varepsilon_l = 0$, then the same analysis as in (i) yields

$$||(z^{l+1}, w^{l+1}, y^{l+1}) - (z^*, w^*, y^*)|| \le r_l\, ||(z^l, w^l, y^l) - (z^*, w^*, y^*)||,$$

where $r_l = \lambda_l\, \hat{L}\, (1 + L\, c) + L\, \varepsilon_l \to 0$. But this implies the superlinear convergence.

(iii) Let, in addition, the assumptions in (iii) be fulfilled. The differentiability of h_1, h_2, and the Lipschitz condition imply in a neighborhood of (z^*, w^*, y^*) the Lipschitz continuity of ∇h_1 and ∇h_2. Then, by [18, Theorem 3.2.12], there exists $\beta > 0$ such that $||\hat{\rho}|| \le (\beta/2)\, ||(z^l, w^l, y^l) - (z^*, w^*, y^*)||^2 \quad \forall\, (z^l, w^l, y^l) \in U^*_{\delta_1}$. Thus, the same analysis as in (i) yields

$$||(z^{l+1}, w^{l+1}, y^{l+1}) - (z^*, w^*, y^*)|| \le \alpha\, ||(z^l, w^l, y^l) - (z^*, w^*, y^*)||^2,$$

where $\alpha = \hat{\beta}\, \hat{L}^2\, (1 + L\, c) + (L\, \beta/2)$. This and $(z^l, w^l, y^l) \to (z^*, w^*, y^*)$ establish the quadratic convergence rate of the considered sequence. □

This theorem shows that it is sufficient for the local convergence behavior to solve the quadratic subproblem, or, equivalently, the mixed linear complementarity problem only up to a certain accuracy. Dependent on the choice of the control sequence $\{\lambda_l\}$ in (2.10), this results in a linear, superlinear, or quadratic rate of convergence.

5. Interior point method for solving the quadratic subproblem. We have seen in the previous section that the quadratic subproblem, or, equivalently, the mixed linear complementarity problem in the inexact SQP method of Algorithm 2.2 should be solved by an iterative scheme. Since there are inequality constraints involved, we use an *interior point method*.

In order to describe the primal-dual interior point approach for the quadratic subproblem in general, we define

$$\begin{aligned} &A = f_z^T(z^l), \quad C = g_z^T(z^l), \quad Q = \mathcal{L}_{zz}(z^l, w^l, y^l), \\ &b = -f(z^l), \quad c = F_z(z^l), \quad d = -g(z^l), \quad \text{and} \quad \xi = \Delta z = z - z^l, \end{aligned} \tag{5.1}$$

where (z^l, w^l, y^l), $l = 0, 1, 2, \ldots$, is a given SQP iterate and $A \in \mathbb{R}^{m_e \times n}, C \in \mathbb{R}^{m \times n}, Q \in \mathbb{R}^{n \times n}, b \in \mathbb{R}^{m_e}, c \in \mathbb{R}^n, d \in \mathbb{R}^m$, and $\xi \in \mathbb{R}^n$. Then, the subproblem $(\mathrm{QP})_l$ can be rewritten as a general quadratic program, i.e.,

$$\min_{\xi}\ \frac{1}{2}\, \xi^T\, Q\, \xi + c^T \xi \quad \text{s.t.} \quad A\xi - b = 0, \quad C\xi - d \le 0. \tag{QP}$$

Let ξ^* be an optimal solution of (QP) and let the inequality constraints and μ^* be partitioned as

$$\nu_{\mathcal{A}^*} = d_{\mathcal{A}^*} - C_{\mathcal{A}^*}\, \xi^* = 0, \quad \mu^*_{\mathcal{A}^*} > 0 \quad \text{and} \quad \nu_{\mathcal{I}^*} = d_{\mathcal{I}^*} - C_{\mathcal{I}^*}\, \xi^* > 0, \quad \mu^*_{\mathcal{I}^*} = 0, \tag{5.2}$$

where $\mathcal{A}^*$ denotes the index set of the active and $\mathcal{I}^*$ denotes the index set of the nonbinding constraints at an optimal solution of (QP), and $\mu^* \in \mathbb{R}^m, \mu^* \geq 0$ denotes the Lagrange multiplier of the inequality constraints of (QP). With this partition we can formulate Assumption 5.1, which should hold throughout this section at an optimal solution ξ^* of (QP).

Assumption 5.1.

(i) There exists an optimal solution ξ^* of (QP).

(ii) Q is symmetric and positive definite on the null space $\mathcal{N}^*$ at ξ^*, where

$$\mathcal{N}^* := \{\xi \in \mathbb{R}^n \mid A\xi = 0, C_{\mathcal{A}^*}\xi = 0\}. \tag{5.3}$$

(iii) The matrix $[A\ C_{\mathcal{A}^*}]^T$ has full rank at the solution ξ^* of (QP).

For the special case (5.1) the following statement can be made. If Assumption 2.4 is fulfilled, we obtain that Assumption 5.1 holds in a neighborhood of ξ^*. In particular, Assumption 5.1(ii) is a convexity condition for the quadratic program and, together with Assumption 5.1(iii), a regularity condition, which guarantees the local solvability of (QP). Using the Karush–Kuhn–Tucker theorem, this assumption implies the existence of $\pi^* \in \mathbb{R}^{m_e}$ and $\mu^* \in \mathbb{R}^m, \mu^* \geq 0$, such that the point (ξ^*, π^*, μ^*) satisfies the Karush–Kuhn–Tucker conditions for (QP). Introducing a slack variable $\nu \in \mathbb{R}^m$, defined by $\nu = d - C\xi \geq 0$, the necessary optimality conditions can be restated as a mixed linear complementarity problem.

We arrive at the following nonlinear system with nonnegativity constraints on the variables μ and ν:

$$J(\xi, \pi, \mu, \nu) = \begin{pmatrix} Q\xi + A^T\pi + C^T\mu + c \\ A\xi - b \\ C\xi + \nu - d \\ NMe \end{pmatrix} = 0, \quad (\mu, \nu) \geq 0, \tag{5.4}$$

where $J : \mathbb{R}^{n+m_e+2m} \to \mathbb{R}^{n+m_e+2m}$ and $e = (1, \ldots, 1)^T \in \mathbb{R}^m$ and diagonal matrices $N, M \in \mathbb{R}^{m \times m}$

$$N = \operatorname{diag}(\nu_1, \ldots, \nu_m) \quad \text{and} \quad M = \operatorname{diag}(\mu_1, \ldots, \mu_m).$$

We denote the primal-dual feasibility set defined by

$$\mathcal{F} := \{(\xi, \pi, \mu, \nu) \in \mathbb{R}^{n+m_e+2m} \mid (\xi, \pi, \mu, \nu) \,\text{satisfies}\, (5.4)\} \tag{5.5}$$

and impose the following assumption.

Assumption 5.2. The interior of the primal-dual feasibility set is nonempty, i.e.,

$$\mathcal{F}^+ = \{(\xi, \pi, \mu, \nu) \in \mathcal{F} \mid \mu > 0, \nu > 0\} \neq \emptyset.$$

We say that points in the set $\mathcal{F}$ are feasible for (5.4) and strictly feasible, if they are elements of $\mathcal{F}^+$.

The interior point algorithm we consider in this paper is motivated by the application of the logarithmic barrier approach (cf. [7]) to the quadratic program. The unique minimum of the corresponding logarithmic barrier problem, if it exists, is characterized by the Karush–Kuhn–Tucker condition

$$J(\xi, \pi, \mu, \nu) - \begin{pmatrix} 0 \\ 0 \\ 0 \\ \eta e \end{pmatrix} = 0, \quad (\mu, \nu) > 0, \tag{5.6}$$

where $\eta > 0$ is the logarithmic barrier parameter and the function J is defined in (5.4).

The primal-dual interior point framework can now be formulated (cf., for example, [12] or [24] and the references therein). Recall that J is given by (5.4).

ALGORITHM 5.3. INTERIOR POINT METHOD.

Choose a starting point $(\xi^0, \pi^0, \mu^0, \nu^0) \in \mathcal{F}^+$.

For $k = 0, 1, 2, \ldots$ *until convergence do*

(I) *Choose* $\sigma_k \in [0, 1)$ *and set* $\eta_k = \sigma_k ({\mu^k}^T \nu^k)/m$.

(II) *Generate the search direction* $(\delta\xi^k, \delta\pi^k, \delta\mu^k, \delta\nu^k)$ *by solving the following system of equations:*

$$J'(\xi^k, \pi^k, \mu^k, \nu^k) \begin{pmatrix} \delta\xi^k \\ \delta\pi^k \\ \delta\mu^k \\ \delta\nu^k \end{pmatrix} = -J(\xi^k, \pi^k, \mu^k, \nu^k) + \begin{pmatrix} 0 \\ 0 \\ 0 \\ \eta_k e \end{pmatrix}. \tag{5.7}$$

(III) *Choose* $\tau_k \in (0, 1)$ *and compute the step length by*

$$\theta_k = \frac{-\tau_k}{\min_{1 \le i \le m}([(M^k)^{-1}\delta\mu^k]_i, [(N^k)^{-1}\delta\nu^k]_i, -\tau_k)}. \tag{5.8}$$

(IV) *Set* $(\xi^{k+1}, \pi^{k+1}, \mu^{k+1}, \nu^{k+1}) = (\xi^k, \pi^k, \mu^k, \nu^k) + \theta_k(\delta\xi^k, \delta\pi^k, \delta\mu^k, \delta\nu^k)$.

The following proposition guarantees the nonsingularity of the Jacobian matrix J' of the perturbed Newton system (5.7) in a neighborhood of the solution of (5.4).

PROPOSITION 5.4. *Let Assumption* 5.1 *be fulfilled. If* $\mu^k > 0$, $\nu^k > 0$, *and* $(\xi^k, \pi^k, \mu^k, \nu^k) \to (\xi^*, \pi^*, \mu^*, \nu^*)$, *then the Jacobian*

$$J'(\xi^k, \pi^k, \mu^k, \nu^k) = \begin{bmatrix} Q & A^T & C^T & O \\ A & O & O & O \\ C & O & O & I \\ O & O & N^k & M^k \end{bmatrix} \tag{5.9}$$

of the perturbed system (5.7) *is nonsingular for* k *sufficiently large.*

Proposition 5.4 ensures that the iterates produced by the interior point method of Algorithm 5.3 are locally well defined. Its proof is a direct consequence of the following result. Hence, we omit the proof.

A variant of the interior point method of Algorithm 5.3 generates a search direction by solving the following reduced symmetric, indefinite system of equations:

$$\begin{bmatrix} Q & A^T & C^T \\ A & O & O \\ C & O & -(M^k)^{-1}N^k \end{bmatrix} \begin{bmatrix} \delta\xi^k \\ \delta\pi^k \\ \delta\mu^k \end{bmatrix} = \begin{bmatrix} -Q\xi^k - A^T\pi^k - C^T\mu^k - c \\ -A\xi^k + b \\ -\eta_k(M^k)^{-1}e - C\xi^k + d \end{bmatrix}. \tag{5.10}$$

The eliminated variable $\delta\nu^k$ is set to

$$\delta\nu^k = \eta_k(M^k)^{-1}e - N^k e - (M^k)^{-1}N^k\delta\mu^k. \tag{5.11}$$

If we replace the perturbed Newton system (5.7) by (5.10) and (5.11), we can prove that the iterates produced by this variant of Algorithm 5.3 are locally well defined.

PROPOSITION 5.5. *Let Assumption* 5.1 *be fulfilled,* $\mu^k > 0$, $\nu^k > 0$, *and let* $D^k = (M^k)^{-1}N^k$ *be positive definite. If* $(\mu^k, \nu^k) \to (\mu^*, \nu^*)$ *then the matrix*

$$\hat{J}^k = \begin{bmatrix} Q & A^T & C^T \\ A & O & O \\ C & O & -D^k \end{bmatrix} \tag{5.12}$$

is nonsingular for k *sufficiently large.*

Proof. Let the assumptions be fulfilled and let $D^k = (M^k)^{-1}N^k$. Without loss of generality, the matrices C, D^k can be partitioned as

$$C = [C_{\mathcal{A}^*}\ C_{\mathcal{I}^*}]^T \quad \text{and} \quad D^k = \operatorname{diag}(D^k_{\mathcal{A}^*}, D^k_{\mathcal{I}^*}),$$

where $\mathcal{A}^*$ corresponds with the index set of the active and $\mathcal{I}^*$ with the index set of the nonbinding constraints at the solution of (QP). Note that the submatrices $D^k_{\mathcal{A}^*}$ and $D^k_{\mathcal{I}^*}$ are positive definite and that $\lim_{k\to\infty} D^k_{\mathcal{A}^*} = D^*_{\mathcal{A}^*} = 0$ and $\lim_{k\to\infty}(D^k_{\mathcal{I}^*})^{-1} = (D^*_{\mathcal{I}^*})^{-1} = 0$.

Assume that a subsequence $\{\hat{J}^{k_i}\}$ of $\{\hat{J}^k\}$ is singular. Then there exists a subsequence $\{(\mu^{k_i}, \nu^{k_i})\}$ of $\{(\mu^k, \nu^k)\}$ such that for $(z^{k_i}, w^{k_i}, y^{k_i}_{\mathcal{A}^*}, y^{k_i}_{\mathcal{I}^*}) \neq 0$

$$\begin{aligned} Qz^{k_i} + A^T w^{k_i} + C^T_{\mathcal{A}^*} y^{k_i}_{\mathcal{A}^*} + C^T_{\mathcal{I}^*} y^{k_i}_{\mathcal{I}^*} &= 0, \\ Az^{k_i} &= 0, \\ C_{\mathcal{A}^*} z^{k_i} - D^{k_i}_{\mathcal{A}^*} y^{k_i}_{\mathcal{A}^*} &= 0 \iff y^{k_i}_{\mathcal{A}^*} = (D^{k_i}_{\mathcal{A}^*})^{-1} C_{\mathcal{A}^*} z^{k_i}, \\ C_{\mathcal{I}^*} z^{k_i} - D^{k_i}_{\mathcal{I}^*} y^{k_i}_{\mathcal{I}^*} &= 0 \iff y^{k_i}_{\mathcal{I}^*} = (D^{k_i}_{\mathcal{I}^*})^{-1} C_{\mathcal{I}^*} z^{k_i}. \end{aligned} \tag{5.13}$$

If $z^{k_i} = 0$, we can conclude from the last equation of (5.13) that $y^{k_i}_{\mathcal{I}^*} = 0$. This, together with Assumption 5.1(iii), implies $w^{k_i} = 0$ and $y^{k_i}_{\mathcal{A}^*} = 0$. Hence, $z^{k_i} \neq 0$. From this sequence we can extract a subsequence, i.e., $\{(1/||z^{k_i}||)(z^{k_i}, w^{k_i}, y^{k_i}_{\mathcal{A}^*}, y^{k_i}_{\mathcal{I}^*})\}$, which we denote by $\{(z^{k_i}, w^{k_i}, y^{k_i}_{\mathcal{A}^*}, y^{k_i}_{\mathcal{I}^*})\}$, where $\lim_{i\to\infty} z^{k_i} = z^*$ and $||z^{k_i}|| = 1$ for some z^*. Then we have

$$\begin{aligned} Qz^{k_i} + C^T_{\mathcal{A}^*}(D^{k_i}_{\mathcal{A}^*})^{-1} C_{\mathcal{A}^*} z^{k_i} + C^T_{\mathcal{I}^*}(D^{k_i}_{\mathcal{I}^*})^{-1} C_{\mathcal{I}^*} z^{k_i} + A^T w^{k_i} &= 0, \\ Az^{k_i} &= 0. \end{aligned} \tag{5.14}$$

Premultiplying the first equation in (5.14) by $(z^{k_i})^T$ we deduce from (5.14) that

$$(z^{k_i})^T Q z^{k_i} + (z^{k_i})^T C^T_{\mathcal{A}^*}(D^{k_i}_{\mathcal{A}^*})^{-1} C_{\mathcal{A}^*} z^{k_i} + (z^{k_i})^T C^T_{\mathcal{I}^*}(D^{k_i}_{\mathcal{I}^*})^{-1} C_{\mathcal{I}^*} z^{k_i} = 0. \tag{5.15}$$

Then we obtain

$$(z^{k_i})^T C^T_{\mathcal{A}^*}(D^{k_i}_{\mathcal{A}^*})^{-1} C_{\mathcal{A}^*}\ z^{k_i} = -\ (z^{k_i})^T Q\ z^{k_i} - (z^{k_i})^T C^T_{\mathcal{I}^*}(D^{k_i}_{\mathcal{I}^*})^{-1} C_{\mathcal{I}^*}\ z^{k_i}.$$

Note that for all k_i we have

$$(z^{k_i})^T \left(C^T_{\mathcal{A}^*}(D^{k_i}_{\mathcal{A}^*})^{-1} C_{\mathcal{A}^*} \right) z^{k_i} \geq 0 \quad \text{and} \quad (z^{k_i})^T \left(C^T_{\mathcal{I}^*}(D^{k_i}_{\mathcal{I}^*})^{-1} C_{\mathcal{I}^*} \right) z^{k_i} \geq 0.$$

Moreover, for the subsequence $\{(\mu^{k_i}, \nu^{k_i})\}$ of $\{(\mu^k, \nu^k)\}$ we know that $D^{k_i}_{\mathcal{A}^*} \to 0$ and $(D^{k_i}_{\mathcal{I}^*})^{-1} \to 0$ if $i \to \infty$. Then we can conclude that

$$\limsup_{i\to\infty}\ (z^{k_i})^T C^T_{\mathcal{A}^*}(D^{k_i}_{\mathcal{A}^*})^{-1} C_{\mathcal{A}^*}\ z^{k_i} \leq -\ (z^*)^T Q\ z^*.$$

Since $D^{k_i}_{\mathcal{A}^*} \to 0$, we obtain $C_{\mathcal{A}^*}\, z^{k_i} \to C_{\mathcal{A}^*}\, z^* = 0$. Now, we deduce from (5.15) that $(z^*)^T Q z^* \leq 0$, which is a contradiction to Assumption 5.1 (ii). ∎

In the last part of this section we state some local convergence results for the interior point method of Algorithm 5.3. The first theorem yields a superlinear convergence rate of the Karush–Kuhn–Tucker system J to zero without the assumption of nonsingularity of the Jacobian J' at the solution of (5.4). Then, Theorem 5.6 can be obtained by making straightforward modifications to Theorems 3.1 and 3.3 of Zhang, Potra, and Tapia [24]. Its proof is omitted.

THEOREM 5.6. *Let $\{(\xi^k, \pi^k, \mu^k, \nu^k)\}$ be a sequence generated by the interior point method of Algorithm* 5.3 *and assume that $(\xi^k, \pi^k, \mu^k, \nu^k)$ converge to $(\xi^*, \pi^*, \mu^*, \nu^*)$. Furthermore, suppose that*

(i) *strict complementarity holds at the solution of* (5.4)*, i.e., that for all $i = 1, \ldots, m$ we have either $\mu_i^* > 0$ and $\nu_i^* = 0$ or $\mu_i^* = 0$ and $\nu_i^* > 0$;*
(ii) *the sequence $\{\kappa_k\}$ is bounded, where $\kappa_k = {\mu^k}^T \nu^k / (m \min(M^k N^k e))$;*
(iii) *Q is symmetric and positive semidefinite on $\mathcal{N}^*$;*
(iv) *$\sigma_k \to 0$ and $\tau_k \to 1$.*

Then for k sufficiently large the convergence of the sequence $\{J(\xi^k, \pi^k, \mu^k, \nu^k)\}$ to zero is superlinear and the point $(\xi^*, \pi^*, \mu^*, \nu^*)$ solves problem (5.4).

With some additional work, we can actually demonstrate that the complementarity sequence $\{M^k N^k e\}$ componentwise converges to zero with a superlinear rate.

Theorem 5.8 states the quadratic convergence of the sequence $\{(\xi^k, \pi^k, \mu^k, \nu^k)\}$ to $(\xi^*, \pi^*, \mu^*, \nu^*)$ in a vicinity of the solution. To obtain this result we have to assume the nonsingularity of the Jacobian matrix J' at the solution of (5.4). In particular, we state the following lemma, which is a direct consequence of Proposition 5.5.

LEMMA 5.7. *Let $(\xi^*, \pi^*, \mu^*, \nu^*)$ be a solution of* (5.4) *and assume that*

(i) *strict complementarity holds at the solution of* (5.4)*, i.e., that for all $i = 1, \ldots, m$ we have either $\mu_i^* > 0$ and $\nu_i^* = 0$ or $\mu_i^* = 0$ and $\nu_i^* > 0$;*
(ii) *the matrix $[A\ C_{\mathcal{A}^*}]^T$ has full rank at ξ^*;*
(iii) *Q is symmetric and positive definite on the null space $\mathcal{N}^*$ at ξ^*.*

Then the Jacobian matrix $J'(\xi^*, \pi^*, \mu^*, \nu^*)$ is nonsingular.

In particular, we have the following quadratic convergence result, which is attributed to Zhang, Tapia, and Dennis [23] in the context of linear programming, and it can be proved by making straightforward modifications to [23, Theorem 4.3]. Its proof is omitted.

THEOREM 5.8. *Let $\{(\xi^k, \pi^k, \mu^k, \nu^k)\}$ be a sequence generated by the interior point method of Algorithm* 5.3 *and assume that $(\xi^k, \pi^k, \mu^k, \nu^k)$ converges to $(\xi^*, \pi^*, \mu^*, \nu^*)$. Furthermore, suppose that*

(i) *strict complementarity holds at the solution of* (5.4)*, i.e., that for all $i = 1, \ldots, m$ we have either $\mu_i^* > 0$ and $\nu_i^* = 0$ or $\mu_i^* = 0$ and $\nu_i^* > 0$;*
(ii) *the matrix $[A\ C_{\mathcal{A}^*}]^T$ has full rank at ξ^*;*
(iii) *Q is symmetric and positive definite on the null space $\mathcal{N}^*$;*
(iv) *the parameters σ_k and τ_k satisfy in every iteration*

$$0 \leq \sigma_k \leq \min(\sigma, c_1 {\mu^k}^T \nu^k) \quad \text{and} \quad \max(\tau, 1 - c_2 {\mu^k}^T \nu^k) \leq \tau_k < 1,$$

where $\sigma \in [0, 1)$, $\tau \in (0, 1)$, and c_1, c_2 are positive constants.

Then the convergence of the sequence $\{(\xi^k, \pi^k, \mu^k, \nu^k)\}$ to $(\xi^*, \pi^*, \mu^*, \nu^*)$ is quadratic.

6. Numerical solution of a parabolic state-constrained control problem. As an example for an application of the inexact SQP interior point method we use a

parabolic control problem that has already been presented in the literature. Burger and Pogu [2] use Newton's method and a conjugate gradient method. In order to avoid the repeated solution of a nonlinear parabolic boundary value problem, Kupfer and Sachs [13] apply a reduced SQP method. Both consider an unconstrained parabolic control problem. In Leibfritz and Sachs [15] a state-constrained problem is solved by an exact SQP approach combined with an interior point solver for the quadratic subproblems and a band LR decomposition for the linear systems. In [16] the authors present implementation details of an inexact SQP interior point method and some numerical results.

For motivation we formulate the control problem in infinite dimension. The goal is to solve the discretized counterpart with our inexact SQP interior point algorithm. For further details we refer to Leibfritz and Sachs [15], [16]. Let $\phi(x,t)$ denote the temperature at time $t \in [0,T]$ and at $x \in [0,1]$, where $x = 0$ is on the boundary and $x = 1$ is inside the probe. Furthermore, we use the following notation:

C:	heat capacity,	λ:	heat conduction,
q:	source term,	p:	reference profile,
u:	control,	ϕ:	state,
$\tilde{\phi}_0$:	initial temperature distribution,	$\phi_{\max}$:	maximal temperature.

Then the parabolic state-constrained optimal control problem for a diffusion equation with boundary inputs and state constraints is given as follows:

$$\text{Minimize} \int_0^T (\phi(1,t) - p(t))^2 \, dt + \alpha \int_0^T u^2(t) \, dt, \tag{6.1}$$

subject to all $(\phi(x,t), u(t))$ satisfying the diffusion equation

$$C(\phi(x,t))\phi_t(x,t) - [\lambda(\phi(x,t))\phi_x(x,t)]_x = q(x,t), \quad (x,t) \in (0,1) \times (0,T), \tag{6.2}$$

with initial and boundary conditions

$$\begin{aligned} \lambda(\phi(0,t))\phi_x(0,t) &= g[\phi(0,t) - u(t)], & t \in (0,T), \\ \lambda(\phi(1,t))\phi_x(1,t) &= 0, & t \in (0,T), \\ \phi(x,0) &= \tilde{\phi}_0(x), & x \in (0,1), \end{aligned} \tag{6.3}$$

and the state constraint,

$$\phi(x,t) \leq \phi_{\max}, \quad (x,t) \in (0,1) \times (0,T). \tag{6.4}$$

Note that the optimal control problem has inequality constraints on the state which avoids overheating during the process. The positive constant α imposes a penalty on large values of the control. In Figure 6.1 we see that for the unconstrained problem, after the start of the process at $t = 0$, the heating leads to rather large temperatures at the boundary, where the probe is heated. This effect can be removed by an upper limit on these temperatures (see, e.g., Figure 6.2), which leads to the state constraint (6.4).

In the numerical tests we use the following parameters for the state-constrained optimal control problem:

$$T = 12.0, \quad \tilde{\phi}_0(x) \equiv 0, \quad x \in (0,1), \quad \phi_{\max} = 2.2, \quad \alpha = 1.0 \cdot 10^{-4}, \quad g = 1.0.$$

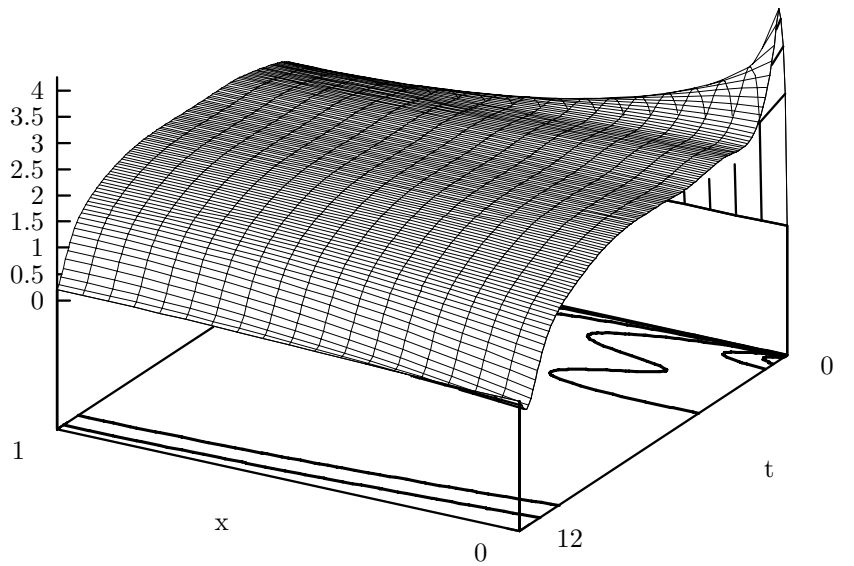

FIG. 6.1. *Unconstrained temperature distribution.*

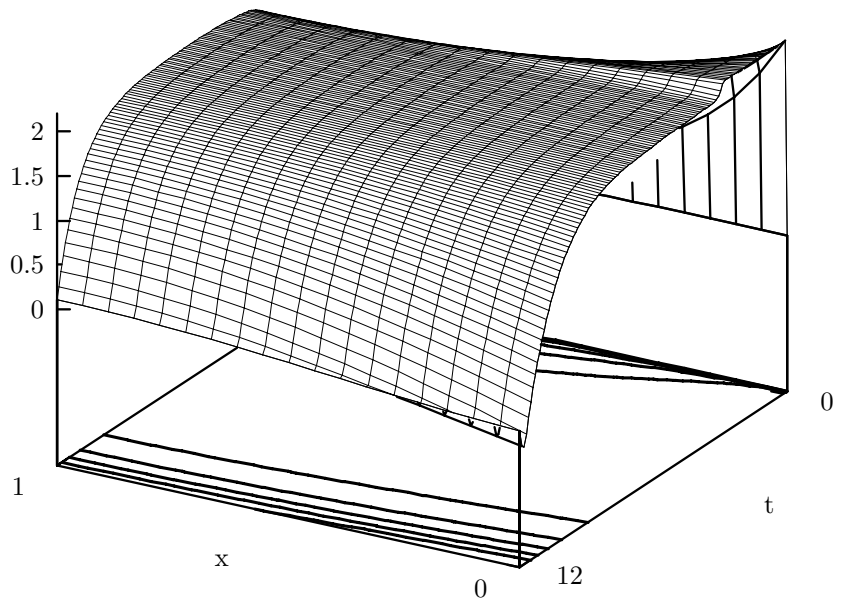

FIG. 6.2. *Computed temperature distribution* $\phi(x,t)$ *with* $\phi_{\max} = 2.2$.

For the discretization parameters N of the space grid and M of the time grid we use different values. The nonlinearities in the diffusion equation are described by

$$C(t) = q_1 + q_2 t, \quad \lambda(t) = r_1 + r_2 t,$$

and the source term at $(x,t) \in (0,1) \times (0,T)$ is given by

$$\begin{aligned} q(x,t) = &\left[\rho(q_1 + 2q_2) + \pi^2(r_1 + 2r_2)\right] \exp(\rho t) \cos(\pi x) \\ &- r_2 \pi^2 \exp(2\rho t) + \left(2r_2\pi^2 + \rho q_2\right) \exp(2\rho t) \cos(\pi x)^2, \end{aligned}$$

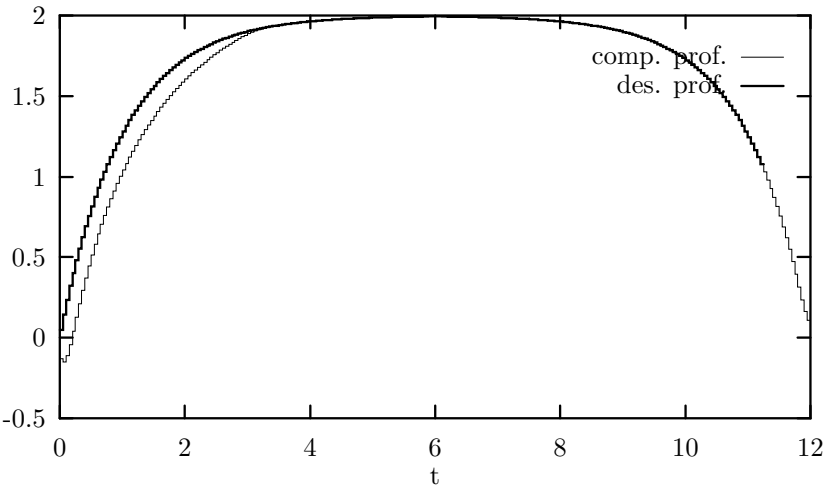

FIG. 6.3. *Temperature profile $p(t)$ and computed temperature profile $\phi(1,t)$.*

where $q_1 = r_1 = 4.0$, $q_2 = 1.0$, $r_2 = -1.0$, and $\rho = -1.0$. The temperature profile, which should be reached at $x = 1$ for $t \in (0,T)$, is defined by

$$p(t) = \begin{cases} 2 - 2\exp(\rho t), & 0 \le t \le 6, \\ 2 - 2\exp(\rho(T-t)), & 6 < t \le T, \\ 0, & t > T. \end{cases}$$

The graph in Figure 6.2 shows that the temperature is reduced at the right boundary and that the constraint is active for a certain time period. Furthermore, this figure demonstrates that the introduction of the inequality constraint avoids overheating of the whole process.

The desired and the achieved temperature distributions inside the probe at $x = 1$ are illustrated in Figure 6.3 and indicate that the approximation is satisfactory. In the time interval between $t = 0.0$ and $t \approx 3.0$, where the constraints are active on the right boundary, the computed temperature profile lies below the desired reference profile. After that, the profiles match each other. This profile exhibits a typical structure. During the time interval $[0,T]$ there is a heating phase followed by a phase where the temperature is kept nearly constant. Then the process is concluded by a cooling down phase.

The optimal control, which is due to the upper bound imposed on the temperature at the other boundary, is displayed in Figure 6.4.

4	–	–	6	$3.565 \cdot 10^{-8}$	6	$5.210 \cdot 10^{-8}$

In the last part of this section, we present several numerical tables for the state-

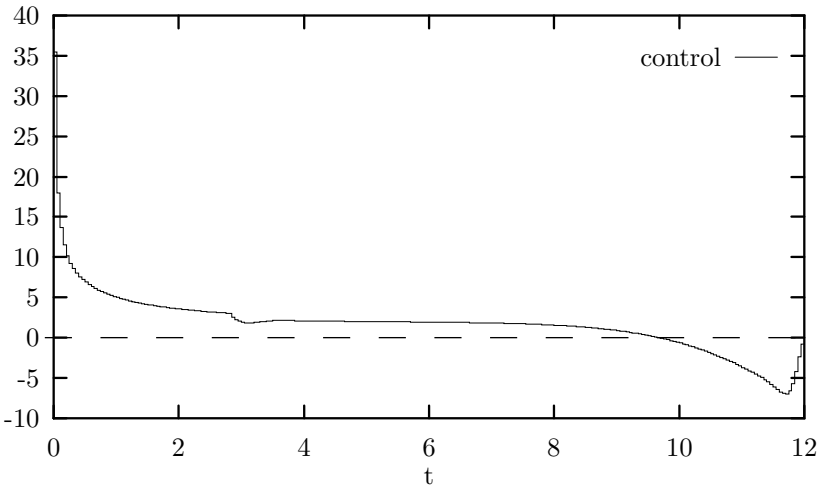

FIG. 6.4. *Computed optimal control $u(t)$ at $x = 0$.*

constrained parabolic control problem. All computations were performed in double-precision Fortran-77 on a Sun Sparcstation 10. In all numerical tests we have initialized our local inexact SQP Algorithm 2.2 with an approximate solution of the unconstrained control problem (cf. Figure 6.1). The forcing sequence $\{\lambda_l\}$ of the inexact SQP Algorithm 2.2 is chosen by (4.4). Then one can expect that the sequence $\{(z^l, w^l, y^l)\}$ generated by the inexact SQP Algorithm 2.2 converges locally to (z^*, w^*, y^*) with a quadratic rate (cf. Theorem 4.3). In every inexact SQP iteration, we solve the subproblems with the interior point method of Algorithm 5.3. There, we have chosen the parameters σ_k and τ_k as in Theorem 5.8 (iv) and we have used the constants

$$c_1 = c_2 = 1.0, \quad \sigma = 0.001, \quad \text{and} \quad \tau = 0.99995.$$

TABLE 6.2
Quadratic convergence rate of the interior point algorithm.

	$N = 18\ M = 120$			$N = 18\ M = 240$

4	5	$3.286 \cdot 10^{-10}$	–	5	$1.357 \cdot 10^{-09}$	–
	6	$4.317 \cdot 10^{-19}$	$1.080 \cdot 10^{-19}$	6	$6.196 \cdot 10^{-18}$	$1.841 \cdot 10^{-18}$

The interior point algorithm will be terminated if the approximation rule (2.10) is satisfied and the linear system (5.10) is solved iteratively by GMRES. Finally, we terminate the inexact SQP approach if $\varepsilon_l = ||\hat{h}(z^l, w^l, y^l)|| \leq 10^{-08} \cdot \sqrt{M(3N+4)}$.

Table 6.1 shows the convergence rate of the inexact SQP method. There, IP indicates the number of interior point iterations for each inexact SQP iteration. We

observe that the inexact SQP approach locally achieves a quadratic rate of convergence according to Theorem 4.3. The results clearly demonstrate numerically the theoretical properties of the inexact SQP algorithm. Furthermore, we see that this approach achieves asymptotically the same convergence rates as an exact SQP method. In Table 6.2 we illustrate the quadratic convergence of the sequence generated by the interior point method during the last few inner iterations. During the first inexact SQP iteration the interior point algorithm terminates before achieving the vicinity of the solution of (QP), where we can observe the asymptotic rates. After that, we obtain a quadratic rate during the last few iterations according to Theorem 5.8. Furthermore, this table indicates that each quadratic subproblem is solved more accurately the more the iteration progresses. Finally, Table 6.3 shows the superlinear convergence of the duality gap during the last few iterations of the interior point algorithm according to Theorem 5.6.

TABLE 6.3
Superlinear convergence of the duality gap.

ON THE LAGRANGE–NEWTON–SQP METHOD FOR THE OPTIMAL CONTROL OF SEMILINEAR PARABOLIC EQUATIONS*

FREDI TRÖLTZSCH†

Abstract. A class of Lagrange–Newton–SQP methods is investigated for optimal control problems governed by semilinear parabolic initial-boundary value problems. Distributed and boundary controls are given, restricted by pointwise upper and lower bounds. The convergence of the method is discussed in appropriate Banach spaces. Based on a weak second order sufficient optimality condition for the reference solution, local quadratic convergence is proved. The proof is based on the theory of Newton methods for generalized equations in Banach spaces.

1. Introduction.

This paper is concerned with the numerical analysis of a sequential quadratic programming (SQP) method for optimal control problems governed by semilinear parabolic equations. We extend convergence results obtained in the author's papers [31] and [32] for simplified cases. Here, we allow for distributed and boundary control. Moreover, terminal, distributed, and boundary observation are included in the objective functional. In contrast to the former papers, where a semigroup approach was chosen to deal with the parabolic equations, the theory is now presented in the framework of weak solutions relying on papers by Casas [7], Raymond and Zidani [28], and Schmidt [30]. We refer also to Heinkenschloss and Tröltzsch [15], where the convergence of an SQP method is proved for the optimal control of a phase field model. Including first order sufficient optimality conditions in the considerations, we are able to essentially weaken the second order sufficient optimality conditions needed to prove the convergence of the method. These sufficient conditions tighten the gap to the associated necessary ones. However, the approach requires a quite extensive analysis.

SQP methods for the optimal control of ODEs have already been the subject of many papers. We refer, for instance, to the discussion of quadratic convergence and the associated numerical examples by Alt [1], [2], Alt and Malanowski [5], [6], to the mesh independence principle in Alt [3], and to the numerical application by Machielsen [27]. Moreover, we refer to the more extensive references therein. For a paper standing in some sense between the control of ODEs and PDEs we refer to Alt, Sontag and Tröltzsch [4], who investigated the control of weakly singular Hammerstein integral equations. The case of semilinear elliptic PDEs was considered by Unger [34].

Following recent developments for ordinary differential equations, we adopt here the relation between the SQP method and a generalized Newton method. This approach makes the whole theory more transparent. We are able to apply known results on the convergence of generalized Newton methods in Banach spaces assuming the so

called strong regularity at the optimal reference point. In this way, the convergence analysis is shorter, and we are able to concentrate on specific questions arising from the presence of partial differential equations.

Once the convergence of the Newton method is shown, we still need an extensive analysis to make the theory complete. We have to ensure the strong regularity by sufficient conditions and to show that the Newton steps can be performed by solving linear-quadratic control problems (SQP-method). This interplay between the Newton method and the SQP method is a specific feature, which cannot be derived from general results in Banach spaces, since we have to discuss pointwise relations.

We should underline that this paper does not aim to discuss the numerical application of the method. Any computation has to be connected with a discretization of the problem. This gives rise to consider approximation errors, stability estimates, the interplay between mesh adaption and precision (particularly delicate for PDEs), and the numerical implementation. Besides the fact that some of these questions are still unsolved, the presentation of the associated theory would go far beyond the scope of one paper. We understand the analysis of our paper as a general line applicable to any proof of convergence for these numerical methods. Some test examples close to this paper were presented by Goldberg and Tröltzsch [11], [12]. The fast convergence of the SQP method is demonstrated there by examples in spatial domains of dimension one and two relying on a fine discretization of the problems. Lagrange–Newton-type methods were also discussed for PDEs by Heinkenschloss and Sachs [14], Ito and Kunisch [16], [17], Kelley and Sachs [19], [20], [21], Kupfer and Sachs [23], Heinkenschloss [13], and Kunisch and Volkwein [22], who report in much more detail on the numerical details needed for an effective implementation.

The paper is organized as follows. Section 2 is concerned with existence and uniqueness of weak solutions for the equation of state. After stating the problem and associated necessary and sufficient optimality conditions in section 3, the generalized Newton method is established in section 4. The strong stability of the generalized equation is discussed in section 5, while section 6 is concerned with performing the Newton steps by SQP steps.

2. The equation of state. The dynamics of our control system are described by the semilinear parabolic initial-boundary value problem

$$\begin{aligned} y_t(x,t) + \ \text{div}\ (\mathcal{A}(x)\,\text{grad}_x y(x,t)) + d(x,t,y(x,t),v(x,t)) &= 0 \quad \text{in } Q, \\ \partial_\nu y(x,t) + b(x,t,y(x,t),u(x,t)) &= 0 \quad \text{on } \Sigma, \\ y(x,0) - y_0(x) &= 0 \quad \text{on } \Omega\,. \end{aligned} \tag{2.1}$$

This system is considered in $Q = \Omega \times (0,T)$, where $\Omega \subset \mathbb{R}^N (N \geq 2)$ is a bounded domain and $T > 0$ a fixed time. By ∂_ν the co-normal derivative $\partial y/\partial \nu_A = -\nu^\top \mathcal{A} \nabla y$ is denoted, where ν is the outward normal on Γ. The functions u and v denote *boundary* and *distributed control*, $\Sigma = \Gamma \times (0,T)$, $\Gamma = \partial\Omega$, and y_0 is a fixed initial state function. Following [7] and [28], we impose the following assumptions on the data.

(A1) Γ is of class $C^{2,\alpha}$ for some $\alpha \in (0,1]$. The coefficients a_{ij} of the matrix $\mathcal{A} = (a_{ij})_{i,j=1,\ldots,N}$ belong to $C^{1,\alpha}(\overline{\Omega})$, and there is $m_0 > 0$ such that

$$-\xi^\top \mathcal{A}(x)\,\xi \geq m_0\,|\xi|^2 \quad \forall \xi \in \mathbb{R}^N \qquad \forall x \in \overline{\Omega}. \tag{2.2}$$

$\mathcal{A}(x)$ is (w.l.o.g.) symmetric .

(A2) The "distributed" nonlinearity $d = d(x,t,y,v)$ is defined on $\overline{Q} \times \mathbb{R}^2$ and satisfies the following Carathéodory-type condition:

(i) For all $(y,v) \in \mathbb{R}^2$, $d(\cdot,\cdot,y,v)$ is Lebesgue measurable on Q.
(ii) For almost all $(x,t) \in Q$, $d(x,t,\cdot,\cdot)$ is of class $C^{2,1}(\mathbb{R}^2)$.
The "boundary" nonlinearity $b = b(x,t,y,u)$ is defined on $\Sigma \times \mathbb{R}^2$ and is supposed to fulfill (i), (ii) with Σ substituted for Q.

In our setting, the controls u, v will be uniformly bounded by a certain constant K.

(A3) The functions d, b fulfill the *assumptions of boundedness and monotonicity*
(i)

$$|d(x,t,0,v)| \le d_K(x,t) \quad \forall (x,t) \in Q, |v| \le K, \tag{2.3}$$

where $d_K \in L^q(Q)$ and $q > \frac{N}{2} + 1$. There is a number $c_0 \in \mathbb{R}$ and a nondecreasing function $\eta : \mathbb{R}_+ \to \mathbb{R}_+$ such that

$$c_0 \le d_y(x,t,y,v) \le \eta(|y|) \tag{2.4}$$

for almost everywhere (a.e.) $(x,t) \in Q$, all $y \in \mathbb{R}$, all $|v| \le K$.
(ii)

$$|b(x,t,0,u)| \le b_K(x,t) \quad \forall (x,t) \in \Sigma, |u| \le K \tag{2.5}$$

and

$$c_0 \le b_y(x,t,y,u) \le \eta(|y|) \tag{2.6}$$

for a.e. $(x,t) \in \Sigma$, all $y \in \mathbb{R}$, all $|u| \le K$, where $b_K \in L^r(\Sigma)$, $r > N+1$.

The assumptions imply those supposed in [7], [28], since our controls are uniformly bounded. The $C^{2,1}$-assumption on d, b is not necessary for the discussion of the equation of state. We shall need it for the Lagrange–Newton method. Although the discussion of existence and uniqueness for the nonlinear system (2.1) is not necessary for our analysis we quote the following result from [7], [28].

THEOREM 2.1. *Suppose that* (A1)–(A3) *are satisfied,* $y_0 \in C(\overline{\Omega})$, $v \in L^\infty(Q)$, $u \in L^\infty(\Sigma)$. *Then the system* (2.1) *admits a unique weak solution* $y \in L^2(0,T;H^1(\Omega)) \cap C(\overline{Q})$.

A *weak solution* of (2.1) is a function y of $L^2(0,T;H^1(\Omega)) \cap C(\overline{Q})$ such that

$$\begin{aligned} &-\int_Q (y \cdot p_t + (\nabla_x y)^\top \mathcal{A}(x) \nabla_x p)\, dxdt + \int_Q d(x,t,y,v)\ p\ dxdt \\ &\quad + \int_\Sigma b(x,t,y,u)\ p\ dSdt - \int_\Omega y_0(x) p(x,0) dx = 0 \end{aligned} \tag{2.7}$$

holds $\forall p \in W_2^{1,1}(Q)$ satisfying $p(x,T) = 0$ [24]. In (2.7) we have assumed that $y \in C(\overline{Q})$ to make the nonlinearities d, b well defined. Theorem 2.1 was shown by a detailed discussion of regularity for an associated linear equation. This linear version of Theorem 2.1 is more important for our analysis. In what follows, we shall use the symbol $A = \operatorname{div}(\mathcal{A} \operatorname{grad} y)$. Moreover, we need the space $W(0,T) = \{y \in L^2(0,T;H^1(\Omega)) | y_t \in L^2(0,T;H^1(\Omega)')\}$[25], [26]. Regard the linear initial-boundary value problem

$$\begin{aligned} y_t + A\,y + a\,y &= v && \text{on } Q, \\ \partial_\nu y + b\,y &= u && \text{on } \Sigma, \\ y(0) &= y_0 && \text{on } \Omega. \end{aligned} \tag{2.8}$$

THEOREM 2.2. *Suppose that $a \in L^\infty(Q)$, $b \in L^\infty(\Sigma)$, $q > N/2+1$, $r > N+1$, $a(x,t) \geq c_0$, $b(x,t) \geq c_0$ a.e. on Q and Σ, respectively, and $y_0 \in C(\overline{\Omega})$. Then there is a constant $c_l = c(c_0, q, r, m_0, \Omega, T)$ not depending on a, b, v, u, y_0 such that*

$$\|y\|_{L^2(0,T;H^1(\Omega))} + \|y\|_{C(\overline{Q})} \leq c_l \left(\|v\|_{L^q(Q)} + \|u\|_{L^r(\Sigma)} + \|y_0\|_{C(\overline{\Omega})}\right) \tag{2.9}$$

holds for the weak solution of the linear system (2.8).

For the proof we refer to [7] or [28]. Equation (2.9) yields a similar estimate for $b \cdot y$. Regarding the linear system (2.8) with right-hand sides $v - ay$, $u - by$, and y_0, respectively, the L^2-theory of linear parabolic equations applies to derive

$$\|y\|_{W(0,T)} \leq c'(\|v\|_{L^q(Q)} + \|u\|_{L^r(\Sigma)} + \|y_0\|_{C(\overline{\Omega})}), \tag{2.10}$$

where c_l' depends also on $\|a\|_{L^\infty(Q)}, \|b\|_{L^\infty(\Sigma)}$. We shall work in the state space $Y = \{y \in W(0,T) \,|\, y_t + Ay \in L^q(Q),\ \partial_\nu y \in L^r(\Sigma)\, y(0) \in C(\overline{\Omega})\}$ endowed with the norm $\|y\|_Y := \|y\|_{W(0,T)} + \|y_t + Ay\|_{L^q(Q)} + \|\partial_\nu y\|_{L^r(\Sigma)} + \|y(0)\|_{C(\overline{\Omega})}$. Y is known to be continuously embedded into $C(\overline{Q})$. From (2.9) and (2.10) we get

$$\|y\|_Y \leq \tilde{c}_l \left(\|v\|_{L^q(Q)} + \|u\|_{L^r(\Sigma)} + \|y_0\|_{C(\overline{\Omega})}\right), \tag{2.11}$$

where $\tilde{c}_l$ depends on $c_0, q, r, m_0, \Omega, T, \|a\|_{L^\infty(Q)}, \|b\|_{L^\infty(\Sigma)}$. Further on, we shall need the Hilbert space $H = W(0,T) \times L^2(\Omega) \times L^2(\Sigma)$ equipped with the norm $\|(y,v,u)\|_H := (\|y\|^2_{W(0,T)} + \|v\|^2_{L^2(Q)} + \|u\|^2_{L^2(\Sigma)})^{1/2}$.

3. Optimal control problem and SQP method. Let $\varphi : \Omega \times \mathbb{R} \to R$, $f : Q \times \mathbb{R}^2 \to \mathbb{R}$, and $g : \Sigma \times \mathbb{R}^2 \to \mathbb{R}$ be given functions specified below. Consider the problem (P) to minimize

$$J(y,v,u) = \int_\Omega \varphi(x, y(x,T))dx + \int_Q f(x,t,y,v)dxdt + \int_\Sigma g(x,t,y,u)dSdt \tag{3.1}$$

subject to the state equation (2.1) and to the pointwise constraints on the control

$$v_a \leq v(x,t) \leq v_b \quad \text{a.e. on } Q, \tag{3.2}$$

$$u_a \leq u(x,t) \leq u_b \quad \text{a.e. on } \Sigma, \tag{3.3}$$

where v_a, v_b, u_a, u_b are given functions of $L^\infty(Q)$ and $L^\infty(\Sigma)$, respectively, such that $v_a \leq v_b$ a.e. on Q and $u_a \leq u_b$ a.e. on Σ. The *controls* v and u belong to the *sets of admissible controls*

$$V_{ad} = \{v \in L^\infty(Q) \,|\, v \text{ satisfies } (3.2)\}, \qquad U_{ad} = \{u \in L^\infty(\Sigma) \,|\, u \text{ satisfies } (3.3)\}.$$

(P) is a nonconvex programming problem, hence different local minima will possibly occur. Numerical methods will deliver a local minimum close to their starting point. Therefore, we do not restrict our investigations to global solutions of (P). We will assume later that a fixed *reference solution* is given satisfying certain first and second order optimality conditions (ensuring local optimality of the solution). For the same reason, we shall not discuss the problem of existence of global (optimal) solutions for (P).

In the next assumptions, D^2 will denote Hessian matrices of functions. The functions φ, f, d, g, and b are assumed to satisfy the following assumptions on smoothness and growth. Here, $\|\cdot\|$ denotes any useful norm for 2×2 matrices.

(A4) For all $x \in \Omega$, $\varphi(x,\cdot)$ belongs to $C^{2,1}(\mathbb{R})$ with respect to $y \in \mathbb{R}$, while $\varphi(\cdot,y)$, $\varphi_y(\cdot,y)$, and $\varphi_{yy}(\cdot,y)$ are bounded and measurable on Ω. There is a constant $c_K > 0$ such that

$$|\varphi_{yy}(x,y_1) - \varphi_{yy}(x,y_2)| \le c_K\,|y_1 - y_2| \tag{3.4}$$

holds $\forall\, y_i \in \mathbb{R}$ such that $|y_j| \le K$, $i = 1,2$.
For all $(x,t) \in Q$, $f(x,t,\cdot,\cdot)$ is of class $C^{2,1}(\mathbb{R}^2)$ with respect to $(y,v) \in \mathbb{R}^2$, while f, f_y, f_v, f_{yy}, f_{yv}, and f_{vv}, all depending on $(\cdot,\cdot,y,v)$, are bounded and measurable with respect to $(x,t) \in Q$. There is a constant $f_K > 0$ such that

$$\|D^2 f(x,t,y_1,v_1) - D^2 f(x,t,y_2,v_2)\| \le f_K\,(|y_1 - y_2| + |v_1 - v_2|) \tag{3.5}$$

holds $\forall\, y_i, v_i$ satisfying $|y_i| \le K$, $|v_i| \le K$, $i = 1,2$, and almost all $(x,t) \in Q$.
For d we require the same except the boundedness of $d(\cdot,\cdot,y,v)$.
The functions g and d satisfy analogous assumptions on $\Sigma \times \mathbb{R}^2$. In particular,

$$\|D^2 g(x,t,y_1,u_1) - D^2 g(x,t,y_2,u_2)\| \le g_K\,(|y_1 - y_2| + |u_1 - u_2|) \tag{3.6}$$

holds $\forall\, y_i, u_i$ satisfying $|y_i| \le K$, $|u_i| \le K$, $i = 1,2$, and almost all $(x,t) \in \Sigma$.

Let us recall the known standard *first order necessary optimality system* for a local minimizer (y,v,u) of (P). The triplet (y,v,u) has to satisfy, together with an *adjoint state* $p \in W(0,T)$, the state system (2.1), the constraints $v \in V_{ad}$, $u \in U_{ad}$, the *adjoint equation*

$$\begin{aligned} -p_t + A\,p + d_y(x,t,y,v)\,p &= f_y(x,t,y,v) && \text{in } Q,\\ \partial_\nu p + b_y(x,t,y,u)\,p &= g_y(x,t,y,u) && \text{on } \Sigma,\\ p\,(x,T) &= \varphi_y(x,y(x,T)) && \text{in } \Omega, \end{aligned} \tag{3.7}$$

and the *variational inequalities*

$$\int_Q (f_v(x,t,y,v) - d_v(x,t,y,v)\cdot p)(z - v)\,dxdt \ge 0 \quad \forall z \in V_{ad}, \tag{3.8}$$

$$\int_\Sigma (g_u(x,t,y,u) - b_u(x,t,y,u)\cdot p)(z - u)\,dSdt \ge 0 \quad \forall z \in U_{ad}. \tag{3.9}$$

We introduce for convenience the *Lagrange function* $\mathcal{L}$,

$$\begin{aligned} \mathcal{L}(y,v,u;p) &= J(y,v,u) - \int_Q \{(y_t + Ay + d(x,t,y,v)\}\,p\,dxdt\\ &\quad - \int_\Sigma \{\partial_\nu y + b(x,t,y,v)\}\,p\,dSdt, \end{aligned} \tag{3.10}$$

defined on $Y \times L^\infty(Q) \times L^\infty(\Sigma) \times W(0,T)$. $\mathcal{L}$ is of class $C^{2,1}$ with respect to (y,v,u) in $Y \times L^\infty(Q) \times L^\infty(\Sigma)$. Moreover, we define the *Hamilton functions*

$$H^Q = H^Q(x,t,y,p,v) = f(x,t,y,v) - p\,d(x,t,y,v), \tag{3.11}$$

$$H^\Sigma = H^\Sigma(x,t,y,p,u) = g(x,t,y,u) - p\,b(x,t,y,u), \tag{3.12}$$

containing the "nondifferential" parts of $\mathcal{L}$. Then the relations (3.7)–(3.9) imply

$$\mathcal{L}_y(y,v,u;p)h = 0 \quad \forall h \in W(0,T) \text{ satisfying } h(0) = 0, \tag{3.13}$$

$$\mathcal{L}_v(y,v,u;p)(z - v) = \int_Q H^Q_v(x,t,y,p,v)(z - v)\,dxdt \ge 0 \quad \forall z \in V_{ad}, \tag{3.14}$$

$$\mathcal{L}_u(y,v,u;p)(z - u) = \int_\Sigma H^\Sigma_u(x,t,y,p,u)(z - u)dSdt \ge 0 \quad \forall z \in U_{ad}. \tag{3.15}$$

Let us suppose once and for all that a fixed *reference triplet* $(\overline{y}, \overline{v}, \overline{u}) \in Y \times L^\infty(Q) \times L^\infty(\Sigma)$ is given satisfying together with $\overline{p} \in W(0,T)$ the optimality system. This system is not sufficient for local optimality. Therefore, we shall assume some kind of *second order sufficient conditions*. We have to consider them along with a *first order sufficient condition*. Following Dontchev, et al. [10], the sets

$$Q(\sigma) = \{(x,t) \in Q \,|\, |\, H_v^Q(x,t,\overline{y}(x,t),\overline{v}(x,t),\overline{p}(x,t))\,| \geq \sigma\}, \tag{3.16}$$

$$\Sigma(\sigma) = \{(x,t) \in \Sigma \,|\, |\, H_u^\Sigma(x,t,\overline{y}(x,t),\overline{u}(x,t),\overline{p}(x,t))\,| \geq \sigma\} \tag{3.17}$$

are defined for arbitrarily small but fixed $\sigma > 0$. On these sets, the controls $\overline{u}$ and $\overline{v}$ are uniquely defined by the first order optimality conditions; they attain the lower or upper bound of their control set. Here we do not need second order information, since first order sufficiency applies. Although the same holds for all points, where $|H_v^Q|$ and $|H_u^\Sigma|$ are positive, we need the level $\sigma > 0$ to make this property stable with respect to small perturbations. The sets $Q(\sigma)$ and $\Sigma(\sigma)$ define strongly active control constraints in the sense of optimization theory, since $|H_v^Q|$ and $|H_u^\Sigma|$ are Lagrange multipliers associated to the control constraints. However, we shall not need this interpretation. D^2H^Q and D^2H^Σ denote the Hessian matrices of H^Q, H^Σ with respect to (y,v) and (y,u) respectively, taken at the reference point. For instance,

$$D^2H^Q(x,t) = \begin{pmatrix} H_{yy}^Q(x,t,\overline{y}(x,t),\overline{v}(x,t),\overline{p}(x,t)) & H_{yv}^Q(x,t,\overline{y}(x,t),\overline{v}(x,t),\overline{p}(x,t)) \\ H_{vy}^Q(x,t,\overline{y}(x,t),\overline{v}(x,t),\overline{p}(x,t)) & H_{vv}^Q(x,t,\overline{y}(x,t),\overline{v}(x,t),\overline{p}(x,t)) \end{pmatrix}.$$

D^2H^Σ is defined analogously. Moreover, we introduce a quadratic form B depending on $h_i = (y_i, v_i, u_i) \in Y \times L^\infty(Q) \times L^\infty(\Sigma),\ i = 1,2$, by

$$\begin{aligned} B[h_1,h_2] \;=\; & \int_\Omega \varphi_{yy}(x,\overline{y}(x,T))y_1(x,T)y_2(x,T)\,dx + \int_Q (y_1,v_1)D^2H^Q(y_2,v_2)^\top\,dxdt \\ & + \int_\Sigma (y_1,u_1)D^2H^\Sigma(y_2,u_2)^\top\,dSdt. \end{aligned} \tag{3.18}$$

The *second order sufficient optimality condition* is defined as follows:

(SSC) There are $\delta > 0, \sigma > 0$ such that

$$B[h,h] \geq \delta \cdot \|h\|_H^2 \tag{3.19}$$

holds $\forall\, h = (y,v,u) \in W(0,T) \times L^2(Q) \times L^2(\Sigma)$, where $v \in V_{ad}, v(x,t) = 0$ on $Q(\sigma), u \in U_{ad}, u = 0$ on $\Sigma(\sigma)$, and y is the associated weak solution of the linearized equation

$$\begin{aligned} y_t + A\,y + d_y(\overline{y},\overline{v})\,y + d_v(\overline{y},\overline{v})\,v &= 0, \\ \partial_\nu y + b_y(\overline{y},\overline{u})\,y + b_u(\overline{y},\overline{u})\,u &= 0, \\ y(0) &= 0. \end{aligned} \tag{3.20}$$

Next we introduce the SQP method to solve the problem (P) iteratively. Let us first assume that the controls are unrestricted, that is $V_{ad} = L^\infty(Q)$, $U_{ad} = L^\infty(\Sigma)$. Then the optimality system (2.1), (3.7), (3.8), (3.9) is a nonlinear system of equations for the unknown functions v, p, y, u, which can be treated by the Newton method. (For unrestricted controls, the variational inequalities are equivalent to the equations

$f_v - d_v p = 0$ and $g_u - b_u p = 0$.) In each step of the method, a linear system of equations is to be solved. This linear system is the optimality system of a linear-quadratic optimal control problem without constraints on the controls, which can be solved instead of the linear system of equations.

Now consider again the constraints on the control. Then the optimality system is no longer a system of equations, since it contains the two variational inequalities (3.8) and (3.9). However, it is not difficult to generalize the linear-quadratic control problems by adding the control-constraints. This idea leads to the following iterative method: Suppose that (y_i, p_i, v_i, u_i), $i = 1, \dots, n$, have already been determined. Then $(y_{n+1}, v_{n+1}, u_{n+1})$ is computed by solving the following linear-quadratic optimal control problem (QP_n) :

(QP_n) Minimize

$$
\begin{aligned}
J_n(y,v,u) = &\int_\Omega \varphi_y^n \cdot y(T)dx + \int_Q (f_y^n \cdot y + f_v^n \cdot v)\, dxdt + \int_\Sigma (g_y^n\ y + g_u^n\ u) dSdt \\
&+\tfrac{1}{2}\int_\Omega \varphi_{yy}^n\ (y(T) - y_n(T))^2 dx + \frac{1}{2}\int_Q (y - y_n, v - v_n) D^2 H^{Q,n} \begin{pmatrix} y - y_n \\ v - v_n \end{pmatrix} dxdt \\
&+\tfrac{1}{2}\int_\Sigma (y - y_n, u - u_n) D^2 H^{\Sigma,n} \begin{pmatrix} y - y_n \\ u - u_n \end{pmatrix} dSdt
\end{aligned}
$$

(3.21)

subject to

$$
\begin{aligned}
y_t + A\, y + d^n + d_y^n\, (y - y_n) + d_v^n\, (v - v_n) &= 0, \\
\partial_\nu y + b^n + b_y^n\, (y - y_n) + b_u^n\, (u - u_n) &= 0, \\
y(0) &= y_0
\end{aligned}
\tag{3.22}
$$

and to

$$
v \in V_{ad}, u \in U_{ad}. \tag{3.23}
$$

In this setting, the notation $\varphi_y^n = \varphi_y(x, y_n(x,T))$, $\varphi_{yy}^n = \varphi_{yy}^n(x, y_n(x,T))$, $f_y^n = f_y^n(x,t,y_n(x,t),v_n(x,t))$, $D^2 H^{Q,n} = D^2 H_{(y,v,u)}(x,t,y_n(x,t),v_n(x,t),p_n(x,t))$ etc., was used. The associated adjoint state p_{n+1} is determined from

$$
\begin{aligned}
-p_t + A\, p + d_y^n\, (p - p_n) &= H_y^{Q,n} + H_{yy}^{Q,n}(y_{n+1} - y_n) + H_{yv}^{Q,n}(v_{n+1} - v_n), \\
p(T) &= \varphi_y^n + \varphi_{yy}^n\ (y_{n+1} - y_n)(T), \\
\partial_\nu p + b_y^n\, (p - p_n) &= H_y^{\Sigma,n} + H_{yy}^{\Sigma,n}(y_{n+1} - y_n) + H_{yu}^{\Sigma,n}(u_{n+1} - u_n).
\end{aligned}
\tag{3.24}
$$

In this way, a sequence of quadratic optimization problems is to be solved, giving the method the name sequential quadratic programming (SQP) method. The main aim of this paper is to show that this process exhibits a local quadratic convergence. We shall transform the optimality system into a *generalized equation*. Then we are able to interpret the SQP method as a Newton method for a generalized equation. This approach gives direct access to known results on the convergence of Newton methods. In the analysis, a specific difficulty arises from the fact that (QP_n) might be non-convex. It therefore may have multiple local minima. We shall have to restrict the control set to a sufficiently small neighborhood around the reference solution.

4. Generalized equation and Newton method. To transform the optimality system into a generalized equation, we reformulate the variational inequalities (3.8)–(3.9) as generalized equations, too.

Therefore, we define the *cones*

$$N^Q(v) = \begin{cases} \{z \in L^\infty(Q) \mid \int_Q z(\tilde{v} - v)dxdt \le 0 \quad \forall \tilde{v} \in V_{ad}\} \text{ if } v \in V_{ad}, \\ \emptyset \text{ if } v \notin V_{ad}, \end{cases} \tag{4.1}$$

$$N^\Sigma(u) = \begin{cases} \{z \in L^\infty(\Sigma) \mid \int_\Sigma z(\tilde{u} - u)dSdt \le 0 \quad \forall \tilde{u} \in U_{ad}\} \text{ if } u \in U_{ad}, \\ \emptyset \text{ if } u \notin U_{ad}. \end{cases} \tag{4.2}$$

Then (3.8) and (3.9) read $-H_v^Q(y,p,v) \in N^Q(v)$, $-H_u^\Sigma(y,p,u) \in N^\Sigma(u)$, or

$$0 \in H_v^Q(y,p,v) + N^Q(v), \tag{4.3}$$

$$0 \in H_u^\Sigma(y,p,u) + N^\Sigma(u). \tag{4.4}$$

(H_v^Q and H_u^Σ are Nemytskii operators defined analogously to H_y^Q, H_y^Σ.) The set-valued mappings $T_1 : v \mapsto N^Q(v)$ from $L^\infty(Q)$ to $2^{L^\infty(Q)}$ and $T_2 : u \mapsto N^\Sigma(u)$ from $L^\infty(\Sigma)$ to $2^{L^\infty(\Sigma)}$ have closed graph. We introduce now the subspace E of $\tilde{E} = L^\infty(Q) \times L^\infty(\Sigma) \times C(\overline{\Omega}))^2 \times L^\infty(Q) \times L^\infty(\Sigma)$, which contains all $\eta \in \tilde{E}$ of the form $\eta = (e_Q, e_\Sigma, 0, \gamma_Q, \gamma_\Sigma, \gamma_\Omega, \gamma_v, \gamma_u)$ and is endowed with the norm $\|\eta\|_E = \|e_Q\|_{L^\infty(Q)} + \|e_\Sigma\|_{L^\infty(\Sigma)} + \|\gamma_Q\|_{L^\infty(Q)} + \|\gamma_\Sigma\|_{L^\infty(\Sigma)} + \|\gamma_\Omega\|_{C(\overline{\Omega})} + \|\gamma_v\|_{L^\infty(Q)} + \|\gamma_u\|_{L^\infty(\Sigma)}$. We also need the space $W = Y \times Y \times L^\infty(Q) \times L^\infty(\Sigma)$ equipped with the norm $\|(y,p,v,u)\|_W = \|y\|_Y + \|p\|_Y + \|v\|_{L^\infty(\Omega)} + \|u\|_{L^\infty(\Sigma)}$. Moreover, define the set-valued mapping $T : W \to 2^E$ by

$$T(w) = (\{0\}, \{0\}, \{0\}, \{0\}, \{0\}, \{0\}, N^Q(v)N^\Sigma(u))$$

and $F : W \to E$ by $F(w) = (F_1(w), ..., F_8(w))$, where

$$\begin{aligned} F_1(w) &= y_t + A\,y + d(y,v), \\ F_2(w) &= \partial_\nu y + b(y,u), \\ F_3(w) &= y(0) - y_0, \\ F_4(w) &= -p_t + A\,p - H_y^Q(y,p,v), \\ F_5(w) &= \partial_\nu p - H_y^\Sigma(y,p,u), \\ F_6(w) &= p(T) - \varphi_y(y(T)), \\ F_7(w) &= H_v^Q(y,p,v), \\ F_8(w) &= H_u^\Sigma(y,p,u). \end{aligned}$$

In the definition of E, the third component is vanishing, since it will correspond to the initial condition $y(0) - y_0 = 0$, which is kept fixed in the generalized Newton method. The optimality system is clearly equivalent to the generalized equation

$$0 \in F(w) + T(w), \tag{4.5}$$

where F is of class $C^{1,1}$, and the set-valued mapping T has closed graph. Obviously, the reference solution $\overline{w} = (\overline{y}, \overline{p}, \overline{v}, \overline{u})$ satisfies (4.5). The *generalized Newton method* for solving (4.5) is similar to the Newton method for equations in Banach spaces.

Suppose that we have already computed $w_1, \dots, w_n$. Then w_{n+1} is to be determined by the generalized equation

$$0 \in F(w_n) + F'(w_n)(w - w_n) + T(w). \tag{4.6}$$

The convergence analysis of this method is closely related to the notion of *strong regularity* of (4.5). See Robinson [29]. The generalized equation (4.5) is said to be *strongly regular at* $\overline{w}$ if there are constants $r_1 > 0, r_2 > 0$, and $c_L > 0$ such that for all perturbations $e \in \mathcal{B}_{r_1}(0_E)$ the *linearized equation*

$$e \in F(\overline{w}) + F'(\overline{w})(w - \overline{w}) + T(w) \tag{4.7}$$

has in $\mathcal{B}_{r_2}(\overline{w})$ a unique solution $w = w(e)$, and the Lipschitz property

$$\|w(e_1) - w(e_2)\|_W \le c_L \|e_1 - e_2\|_E \tag{4.8}$$

holds $\forall\, e_1, e_2 \in \mathcal{B}_{r_1}(0_E)$. In the case of an equation $F(w) = 0$, we have $F(\overline{w}) = 0, T(w) = \{0\}$, and strong regularity means the existence and boundedness of $(F'(\overline{w}))^{-1}$. For other aspects of L-stability we refer to [9]. The following result gives a first answer to the convergence analysis of the generalized Newton method.

THEOREM 4.1. *Suppose that* (4.5) *is strongly regular at* $\overline{w}$. *Then there are* $r_{\mathcal{N}} > 0$ *and* $c_{\mathcal{N}} > 0$ *such that for each starting element* $w_1 \in \mathcal{B}_{r_{\mathcal{N}}}(\overline{w})$ *the generalized Newton method generates a unique sequence* $\{w_n\}_{n=1}^{\infty}$. *This sequence remains in* $\mathcal{B}_{r_{\mathcal{N}}}(\overline{w})$, *and it holds that*

$$\|w_{n+1} - \overline{w}\|_W \le c_{\mathcal{N}} \|w_n - \overline{w}\|_W^2 \qquad \forall n \in \mathbb{N}. \tag{4.9}$$

This result was apparently shown first by Josephy [18]. Generalizations can be found in Dontchev [8] and Alt [1], [2]. We refer in particular to the recent publication by Alt [3], where a mesh-independence principle was shown for numerical approximation of (4.5). We shall verify that the second order condition (SSC) implies strong regularity of the generalized equation at $\overline{w} = (\overline{y}, \overline{p}, \overline{v}, \overline{u})$ in certain subsets $\widehat{V}_{ad} \subset V_{ad}$, $\widehat{U}_{ad} \subset U_{ad}$. Then Theorem 4.1 yields the quadratic convergence of the generalized Newton method in these subsets.

5. Strong regularity. To investigate the strong regularity of the generalized equation (4.5) at $\bar{w}$, we have to consider the perturbed generalized equation (4.7). Once again, we are able to interpret this equation as the optimality system of a linear-quadratic control problem. This problem is not necessarily convex, therefore we study the behavior of the following auxiliary linear-quadratic problem associated with the perturbation e:

($\widehat{\mathrm{QP}_e}$) Minimize

$$\begin{aligned} J_e(y,v,u) = {} & \int_\Omega (\bar\varphi_y + \gamma_\Omega)\, y(T)\, dx + \int_Q (\bar f_y + \gamma_Q)\, y\, dxdt + \int_Q (\bar f_v + \gamma_v)\, v\, dxdt \\ & + \int_\Sigma (\bar g_y + \gamma_\Sigma)\, y\, dSdt + \int_\Sigma (\bar g_u + \gamma_u)\, u\, dSdt + \frac{1}{2}\int_\Omega \bar\varphi_{yy}(y(T) - \bar y(T))^2 dx \\ & + \tfrac{1}{2}\int_Q \begin{pmatrix} y - \bar y \\ v - \bar v \end{pmatrix}^\top D^2 \bar H^Q \begin{pmatrix} y - \bar y \\ v - \bar v \end{pmatrix} dxdt + \tfrac{1}{2}\int_\Sigma \begin{pmatrix} y - \bar y \\ u - \bar u \end{pmatrix}^\top D^2 \bar H^\Sigma \begin{pmatrix} y - \bar y \\ u - \bar u \end{pmatrix} dSdt \end{aligned} \tag{5.1}$$

subject to

$$\begin{aligned} y_t + A\,y + d(\bar y, \bar v) + \bar d_y\,(y - \bar y) + \bar d_v\,(v - \bar v) &= e_Q && \text{in } Q, \\ \partial_\nu y + b(\bar y, \bar u) + \bar b_y\,(y - \bar y) + \bar b_u\,(u - \bar u) &= e_\Sigma && \text{on } \Sigma, \\ y(0) &= y_0 && \text{in } \Omega \end{aligned} \tag{5.2}$$

and to the constraints on the control

$$\begin{array}{rcl} v \in \widehat{V}_{ad} & = & \{v \in V_{ad} \,|\, v(x,t) = \bar{v}(x,t) \text{ on } Q(\sigma)\}, \\ u \in \widehat{U}_{ad} & = & \{u \in U_{ad} \,|\, u(x,t) = \bar{u}(x,t) \text{ on } \Sigma(\sigma)\}. \end{array} \tag{5.3}$$

In this setting, the perturbation vector $e = (e_Q, e_\Sigma, 0, \gamma_Q, \gamma_\Sigma, \gamma_\Omega, \gamma_v, \gamma_u)$ belongs to E. The hat in $(\widehat{\mathrm{QP}}_e)$ indicates that v and u are taken equal to $\bar{v}$ and $\bar{u}$ on the strongly active sets $Q(\sigma)$ and $\Sigma(\sigma)$, respectively.

Remark. The generalized equation (4.7) is equivalent to the optimality system of the problem (QP_e) obtained from $(\widehat{\mathrm{QP}}_e)$ on substituting V_{ad} for $\widehat{V}_{ad}$ and U_{ad} for $\widehat{U}_{ad}$, respectively.

In the space of perturbations E we need another norm

$$\begin{array}{rcl} \|e\|_2 & = & \|e_Q\|_{L^2(Q)} + \|e_\Sigma\|_{L^2(\Sigma)} + \|\gamma_Q\|_{L^2(Q)} + \|\gamma_\Sigma\|_{L^2(\Sigma)} \\ & & + \|\gamma_\Omega\|_{L^2(\Omega)} + \|\gamma_v\|_{L^2(Q)} + \|\gamma_u\|_{L^2(\Sigma)}. \end{array}$$

Moreover, in W we shall also use the norm

$$\|(y,p,v,u)\|_2 = \|y\|_{W(0,T)} + \|p\|_{W(0,T)} + \|v\|_{L^2(Q)} + \|u\|_{L^2(\Sigma)}.$$

The next results follow from the author's paper [33].

LEMMA 5.1. *Suppose that the second order sufficient optimality condition* (SSC) *is satisfied at* $(\bar{y}, \bar{v}, \bar{u})$ *with associated adjoint state* $\bar{p}$. *Then for each* $e \in E$, *the problem* $(\widehat{\mathrm{QP}}_e)$ *has a unique solution* (y_e, v_e, u_e) *with associated adjoint state* p_e. *Let* (y_i, v_i, u_i) *and* $p_i, i = 1, 2$, *be the solutions and adjoint states to* $e_i \in E, i = 1, 2$. *There is a constant* $l_2 > 0$, *not depending on* e_i, *such that*

$$\|(y_1,p_1,v_1,u_1) - (y_2,p_2,v_2,u_2)\|_2 \le l_2 \|e_1 - e_2\|_2 \tag{5.4}$$

holds $\forall\, e_i \in E, i = 1, 2$.

By continuity, (5.4) extends to perturbations e_i of L^2. It was shown in [33] that the second order condition (SSC) implies the following strong *Legendre–Clebsch* condition:

$$\begin{array}{lll} H^Q_{vv}(x,t,\bar{y}(x,t),\bar{p}(x,t),\bar{v}(x,t)) \ge \delta & a.e. \text{ on } & Q, \\ H^\Sigma_{uu}(x,t,\bar{y}(x,t),\bar{p}(x,t),\bar{u}(x,t)) \ge \delta & a.e. \text{ on } & \Sigma. \end{array} \tag{LC}$$

THEOREM 5.2. *Let the assumptions of Lemma* 5.1 *be satisfied. Then there is a constant* $l_\infty > 0$, *not depending on* e_i, *such that*

$$\|(y_1,p_1,v_1,u_1) - (y_2,p_2,v_2,u_2)\|_W \le l_\infty \|e_1 - e_2\|_E \tag{5.5}$$

holds for (y_i, v_i, u_i, p_i), *and* $e_i, i = 1, 2$, *introduced in Lemma* 5.1.

This theorem follows from [33, Thm. 5.2]. (Notice that $v_i = \bar{v}$ and $u_i = \bar{u}$ on $Q(\sigma)$ and $\Sigma(\sigma)$, respectively. This can be expressed by taking $u_a := u_b := \bar{u}$ and $v_a := v_b := \bar{v}$ on these sets. Then [33, Thm. 5.2] is easy to apply.)

Unfortunately, (5.5) holds only for $\widehat{V}_{ad}$ and $\widehat{U}_{ad}$. We are not able to prove (5.5) in V_{ad}, U_{ad}. In this case, J_e might be nonconvex and (QP_e) may have multiple solutions, if solvable at all. However, formulating Theorem 5.2 in the context of our generalized equation, we already have obtained the following result on strong regularity.

THEOREM 5.3. *Suppose that* $\bar{w} = (\bar{y}, \bar{p}, \bar{v}, \bar{u})$ *satisfies the first order optimality system* (2.1), (3.2)–(3.3), (3.7)–(3.9) *together with the second order sufficient condition*

(SSC). *Then the generalized equation* (4.5) *is strongly regular at* $\bar{w}$*, provided that the control sets* $\widehat{V}_{ad}, \widehat{U}_{ad}$ *are substituted for* V_{ad}, U_{ad} *in the definition of* $T(w)$.

Remark. The last assumption means that the cones $N^Q(v)$ and $N^\Sigma(u)$ are defined on using $\widehat{V}_{ad}$ and $\widehat{U}_{ad}$, respectively.

To complete the discussion of the Newton method, the following questions have yet to be answered: How can we solve the generalized equation (4.6) in $\widehat{V}_{ad}$ and $\widehat{U}_{ad}$, and how do we get rid of the artificial restriction $v = \bar{v}$ on $Q(\sigma)$ and $u = \bar{u}$ on $\Sigma(\sigma)$?

We shall show that the SQP method, restricted to a sufficiently small neighborhood around $\bar{v}$ and $\bar{u}$, will solve both the problems: If the region is small enough, then the SQP method delivers a unique solution $w_n = (y_n, p_n, v_n, u_n)$, where $v_n = \bar{v}, u_n = \bar{u}$ is automatically satisfied on $Q(\sigma), \Sigma(\sigma)$. Moreover, this w_n is a solution of the generalized equation (4.5), that is, a solution of the optimality system for (P).

6. The linear-quadratic subproblems (QP_n). The presentation of the SQP method is still quite formal. We do not know whether the quadratic subproblem (QP_n) defined by (3.21)–(3.23) is solvable at all. Moreover, if solutions exist, we are not able to show their uniqueness. There might exist multiple stationary solutions, i.e., solutions satisfying the optimality system for (QP_n). Notice that the objective J_n of (QP_n) is only convex on a subspace. Owing to this, we have to restrict (QP_n) to a sufficiently small neighborhood around the reference solution $(\bar{v}, \bar{u})$. This region is defined by

$$\begin{aligned} V_{ad}^\varrho &= \{v \in V_{ad} \,|\, \|v - \bar{v}\|_{L^\infty(Q)} \le \varrho\}, \\ U_{ad}^\varrho &= \{u \in U_{ad} \,|\, \|u - \bar{u}\|_{L^\infty(\Sigma)} \le \varrho\}, \end{aligned}$$

where $\varrho > 0$ is a sufficiently small radius. To avoid the unknown reference solution $(\bar{v}, \bar{u})$ in the definition of the neighborhood, we shall later replace this neighborhood by a ball around the initial iterate (v_1, u_1) .

Let us denote by (QP_n^ϱ) the problem (QP_n) restricted to V_{ad}^ϱ, U_{ad}^ϱ and by ($\widehat{\mathrm{QP}}_n$) the same problem restricted to $\widehat{V}_{ad}$, $\widehat{U}_{ad}$, respectively. To analyze ($\widehat{\mathrm{QP}}_n$) in a first step, we need some auxiliary results.

LEMMA 6.1. *For all* $K > 0$ *there is a constant* $c_L = c_L(K)$ *such that*

$$\mathcal{E} \le c_L(K) \|w_n - \bar{w}\|_W \tag{6.1}$$

holds $\forall\, w_n \in W$ *with* $\|w_n - \bar{w}\|_W \le K$*, where the expression* $\mathcal{E}$ *is defined by*

$$\begin{aligned} \mathcal{E} = \max \{ &\|f_v^n - \bar{f}_v\|_{L^\infty(Q)}, \|f_y^n - \bar{f}_y\|_{L^\infty(Q)}, \|g_v^n - \bar{g}_u\|_{L^\infty(\Sigma)}, \|g_y^n - \bar{g}_y\|_{L^\infty(\Sigma)}, \\ &\| d_y^n - \bar{d}_y\|_{L^\infty(Q)}, \|d_v^n - \bar{d}_v\|_{L^\infty(Q)}, \|b_y^n - \bar{b}_y\|_{L^\infty(\Sigma)}, \|b_u^n - \bar{b}_u\|_{L^\infty(\Sigma)}, \|\varphi_y^n - \bar{\varphi}_y\|_{C(\bar{\Omega})}, \\ &\| \varphi_{yy}^n - \bar{\varphi}_{yy}\|_{C(\bar{\Omega})}, \|D^2 H^{Q,n} - D^2 \bar{H}^Q\|_{L^\infty(Q)}, \|D^2 H^{\Sigma,n} - D^2 \bar{H}^\Sigma\|_{L^\infty(Q)} \}. \end{aligned}$$

Proof. The estimate follows from the assumptions (A2)–(A4) imposed on the functions f, g, φ, b, d in sections 2 and 3. For instance, the mean value theorem yields

$$\begin{aligned} \|f_v^n - \bar{f}_v\|_{L^\infty(Q)} &= \sup_{(x,t)\in Q} \operatorname{ess} |f_{vy}(y^\vartheta, v^\vartheta)(y_n - \bar{y}) + f_{vv}(v^\vartheta, v^\vartheta)(v_n - \bar{v})| \\ &\le c(K) \sup_{(x,t)\in Q} \operatorname{ess} (|y_n - \bar{y}| + |v_n - \bar{v}|) \end{aligned}$$

by (3.5), where $y^\vartheta = \bar{y} + \vartheta(y_n - \bar{y})$, $v^\vartheta = \bar{v} + \vartheta(v_n - \bar{v})$, and $\vartheta = \vartheta(x,t)$ belongs to $(0,1)$. (Consider, for example, the estimation

$$\begin{aligned} |f_{vy}(y^\vartheta, v^\vartheta)| &\le |f_{yv}(0,0)| + |f_{vy}(y^\vartheta, v^\vartheta) - f_{vy}(0,0)| \le c_1 + c(K)\,(|y^\vartheta| + |v^\vartheta|) \\ &\le c_1 + c(K) \cdot K, \end{aligned}$$

which follows from (3.5).) The other terms in $\mathcal{E}$ are handled analogously. ∎

We shall denote the quadratic part of the functional J_n by

$$\begin{aligned} B_n[(y_1,v_1,u_1),(y_2,v_2,u_2)] \;=\; & \int_\Omega \varphi^n_{yy}\; y_1(T)y_2(T)\,dx + \int_Q (y_1,v_1)D^2H^{Q,n}(y_2,v_2)^\top\,dxdt \\ & + \int_\Sigma (y_1,u_1)D^2H^{\Sigma,n}(y_2,u_2)^\top\,dSdt \end{aligned} \tag{6.2}$$

and write for short $B_n[(y,v,u),(y,v,u)] = B_n[y,v,u]^2$.

LEMMA 6.2. *Suppose that the second order sufficient optimality condition* (SSC) *is satisfied. Then there is $\varrho_1 > 0$ with the following property: If $\|w_n - \bar w\|_W \le \varrho_1$, then*

$$B_n[y,v,u]^2 \ge \frac{\delta}{2}\|(y,v,u)\|^2_H \tag{6.3}$$

holds $\forall\,(y,v,u) \in H$ satisfying $v = 0$ on $Q(\sigma)$, $u = 0$ on $I^u(\sigma)$ together with

$$\begin{aligned} y_t + A\,y + d^n_y\; y + d^n_v\; v &= 0, \\ \partial_\nu y + b^n_y\; y + b^n_u\; u &= 0, \\ y(0) &= 0. \end{aligned} \tag{6.4}$$

Proof. Let z denote the weak solution of the parabolic equation obtained from (6.4) on substituting $\bar d_y, \bar d_v, \bar b_y, \bar b_u$ for d^n_y, d^n_v, b^n_y, b^n_u, respectively. Then

$$\begin{aligned} (y-z)_t + A\,(y-z) + \bar d_y\,(y-z) &= (\bar d_y - d^n_y)\,y + (\bar d_v - d^n_v)\,v, \\ \partial_\nu(y-z) + \bar b_y\,(y-z) &= (\bar b_y - b^n_y)\,y + (\bar b_u - b^n_u)\,u, \\ (y-z)(0) &= 0. \end{aligned}$$

We have $\bar d_y \ge c_0, \bar b_y \ge c_0$. The differences on the right-hand sides can be estimated by Lemma 6.1, where $K = \|\bar w\|_W + \varrho_1$; hence parabolic L^2-regularity yields

$$\begin{aligned} \|y-z\|_{W(0,T)} &\le c\,(\|\bar d_y - d^n_y\|_{L^\infty(Q)}\|y\|_{L^2(Q)} + \|\bar d_y - d^n_v\|_{L^\infty(Q)}\|v\|_{L^2(Q)} \\ &\quad + \|\bar b_y - b^n_y\|_{L^\infty(\Sigma)}\|y\|_{L^2(\Sigma)} + \|\bar b_u - b^n_u\|\|u\|_{L^2(\Sigma)}) \\ &\le c\,\varrho_1(\|y\|_{W(0,T)} + \|v\|_{L^2(Q)} + \|u\|_{L^2(\Sigma)}) \le c\,\varrho_1\|(y,v,u)\|_H. \end{aligned} \tag{6.5}$$

Substituting $y = z + (y-z)$ in B_n,

$$\begin{aligned} B_n[y,v,u]^2 &= B_n[z+(y-z),v,u]^2 \\ &= B[z,v,u]^2 + (B_n - B)[z,v,u]^2 + 2B_n[(z,v,u),(y-z,0,0)] \\ &\quad + B_n[y-z,0,0]^2 \end{aligned}$$

is obtained. (SSC) applies to the first expression B, while the second is estimated by Lemma 6.1. In the remaining two parts, we use the uniform boundedness of all coefficients. Therefore, by (6.5)

$$\begin{aligned} B_n[y,v,u]^2 &\ge \delta\,\|(z,v,u)\|^2_H - c\,\varrho_1\|(z,v,u)\|^2_H - c\,\|(z,v,u)\|_H\|y-z\|_{W(0,T)} \\ &\quad - c\,\|y-z\|^2_{W(0,T)} \\ &\ge \frac{3}{4}\delta\,\|(z,v,u)\|^2_H - c\varrho_1\|(z,v,u)\|_H\|(y,v,u)\|_H - c\varrho_1^2\|(y,v,u)\|^2_H \end{aligned}$$

if ϱ_1 is sufficiently small. Next we resubstitute $z = y + (z - y)$ and apply (6.5) again. In this way, the desired estimate (6.3) is easily verified for sufficiently small $\varrho_1 > 0$. □

COROLLARY 6.3. *If $\|w_n - \bar{w}\|_W \le \varrho_1$ and* (SSC) *is satisfied at $\bar{w}$, then $(\widehat{\mathrm{QP}}_n)$ has a unique optimal pair of controls $(\hat{v}, \hat{u})$ with associated state $\hat{y}$.*

Proof. The functional J_n to be minimized in $(\widehat{\mathrm{QP}}_n)$ has the form (see (3.21))

$$J_n(y, v, u) = a_n(y, v, u) + \frac{1}{2} B_n[y - y_n, v - v_n, u - u_n]^2,$$

where a_n is a linear integral functional. J_n is uniformly convex on the feasible region of $(\widehat{QP}_n)$. By Lemma 6.2, the sets $\widehat{V}_{ad}$ and $\widehat{U}_{ad}$ are weakly compact in $L^2(Q)$ and $L^2(\Sigma)$, respectively. Therefore, the corollary follows from standard arguments. □

Let us return to the discussion of the relation between Newton method and SQP method. In what follows, we shall denote by $\hat{w}_n = (\hat{y}_n, \hat{p}_n, \hat{v}_n, \hat{u}_n)$ the sequence of iterates generated by the SQP method performed in $\widehat{V}_{ad}$, $\widehat{U}_{ad}$ (provided that this sequence is well defined). The iterates of the generalized Newton method are denoted by w_n. Consider now both methods initiating from the same element $w_n = \hat{w}_n$.

If $\|w_n - \bar{w}\|_W \le \varrho_1$, then Corollary 6.3 shows the existence of a unique solution $(\hat{y}_{n+1}, \hat{v}_{n+1}, \hat{u}_{n+1})$ of $(\widehat{\mathrm{QP}}_n)$ having the associated adjoint state $\hat{p}_{n+1}$. The element $\hat{w}_{n+1}$ solves the optimality system corresponding to $(\widehat{\mathrm{QP}}_n)$. By convexity (Lemma 6.2), any other solution of this system solves $(\widehat{\mathrm{QP}}_n)$; hence it is equal to $\hat{w}_{n+1}$. On the other hand, the optimality system is equivalent to the generalized equation (4.6) at w_n (based on the sets $\widehat{V}_{ad}, \widehat{U}_{ad}$). For $\|w_n - \bar{w}\|_W \le r_{\mathcal{N}}$, one step of the generalized Newton method delivers the unique solution w_{n+1} of (4.6). As w_{n+1} solves the optimality system for $(\widehat{\mathrm{QP}}_n)$, it has to coincide with $\hat{w}_{n+1}$. Suppose further that $\|w_n - \bar{w}\|_W \le \min\{r_{\mathcal{N}}, \varrho_1\}$. Then Theorem 4.1 implies that $w_{n+1} = \hat{w}_{n+1}$ remains in $\mathcal{B}_{min\{r_{\mathcal{N}}, \varrho_1\}}(\overline{w})$, so that $\|\hat{w}_{n+1} - \bar{w}\|_W \le \min\{r_{\mathcal{N}}, \varrho_1\}$. Consequently, we are able to perform the next step in both the methods. Moreover, in $\widehat{V}_{ad}, \widehat{U}_{ad}$ each step of the Newton method is equivalent to solving $(\widehat{\mathrm{QP}}_n)$, which always has a unique solution. In other words, the Newton method and the SQP method are identical in $\widehat{V}_{ad}, \widehat{U}_{ad}$.

THEOREM 6.4. *Let $\bar{w} = (\bar{y}, \bar{p}, \bar{v}, \bar{u})$ satisfy the first order optimality system* (2.1), (3.2)–(3.3), (3.7)–(3.9) *together with the second order sufficient optimality conditions* (SSC). *Suppose that $w_1 = (y_1, p_1, v_1, u_1) \in W$ is given such that $\|w_1 - \bar{w}\|_W \le min\{\varrho_1, r_{\mathcal{N}}\}$, $v_1 \in \widehat{V}_{ad}$, and $u_1 \in \widehat{U}_{ad}$. Then in $\widehat{V}_{ad}, \widehat{U}_{ad}$, the generalized Newton method is equivalent to the SQP method: The solution of the generalized equation* (4.6) *is given by the unique solution of $(\widehat{\mathrm{QP}}_n)$ along with the associated adjoint state.*

The result follows from Theorem 5.3 (strong regularity) and the considerations above.

Remark. It is easy to verify that $\hat{w}_n$, the solution of $(\widehat{\mathrm{QP}}_n)$, obeys the optimality system for (P) in the original sets V_{ad}, U_{ad} (cf. also Corollary 6.9).

Next, we discuss the optimality system for $(\widehat{\mathrm{QP}}_n)$ and $(\mathrm{QP}_n^{\varrho})$. Let us denote the associated Hamilton functions by $\tilde{H}$ to distinguish them from H, which belongs to (P):

$$\begin{aligned}
\tilde{H}^Q(x,t,y,p,v) &= f_y^n(y - y_n) + f_v^n(v - v_n) - p\,(d^n + d_y^n(y - y_n) + d_v^n(v - v_n)) \\
&\quad + \tfrac{1}{2}(y - y_n, v - v_n) D^2 H^{Q,n}(y - y_n, v - v_n)^\top, \\
\tilde{H}^\Sigma(x,t,y,p,u) &= g_y^n(y - y_n) + g_u^n(u - u_n) - p\,(b^n + b_y^n(y - y_n) + b_u^n(u - u_n)) \\
&\quad + \tfrac{1}{2}(y - y_n, u - u_n) D^2 H^{\Sigma,n}(y - y_n, u - u_n)^\top,
\end{aligned}$$

where y, v, p, u are real numbers and (x,t) appears in the quantities depending on n. Notice that these Hamiltonians coincide for $(\widehat{\mathrm{QP}}_n), (\mathrm{QP}_n^\varrho)$, and (QP_n), since these problems differ only in the underlying sets of admissible controls. We consider the problems defined at $w_n = (y_n, p_n, v_n, u_n)$. In what follows, we denote solutions of the optimality system corresponding to (QP_n^ϱ) by (y^+, v^+, u^+). The optimality system for (QP_n^ϱ) consists of

$$\int_Q \tilde{H}_v^Q(y^+, p^+, v^+)(v - v^+)\, dxdt \geq 0 \quad \forall v \in V_{ad}^\varrho, \tag{6.6}$$

$$\int_\Sigma \tilde{H}_u^\Sigma(y^+, p^+, u^+)(u - u^+)\, dSdt \geq 0 \quad \forall u \in U_{ad}^\varrho, \tag{6.7}$$

where the associated adjoint state p^+ is defined by

$$\begin{aligned} -p_t^+ + A\,p^+ &= \tilde{H}_y^Q = f_y^n + H_{yy}^{Q,n}(y^+ - y_n) + H_{yv}^{Q,n}(v^+ - v_n) - d_y^n p^+, \\ p(T) &= \varphi_y^n + \varphi_{yy}^n(y^+(T) - y(T)), \\ \partial_\nu p &= \tilde{H}_y^\Sigma = g_y^n + H_{yy}^{\Sigma,n}(y^+ - y_n) + H_{yv}^{\Sigma,n}(u^+ - u_n) - b_y^n p^+. \end{aligned} \tag{6.8}$$

The state equation (3.22) for y^+ and the constraints $v^+ \in V_{ad}^\varrho, u^+ \in U_{ad}^\varrho$ are included in the optimality system too. The optimality system of $(\widehat{\mathrm{QP}}_n)$ has the same principal form as (6.6)–(6.8) and is obtained on replacing (y^+, p^+, v^+, u^+) by $(\hat{y}_{n+1}, \hat{p}_{n+1}, \hat{v}_{n+1}, \hat{u}_{n+1})$. Moreover, $\widehat{V}_{ad}$, $\widehat{U}_{ad}$ is to be substituted for V_{ad}^ϱ, U_{ad}^ϱ there.

In the further analysis, we shall perform the following steps. First we prove by a sequence of results that the solution $(\hat{v}_n, \hat{u}_n)$ of $(\widehat{\mathrm{QP}}_n)$ satisfies the optimality system of (QP_n^ϱ) for sufficiently small ϱ. Moreover, we prove that (QP_n^ϱ) has at least one optimal pair, if w_n is sufficiently close to $\bar{w}$. Finally, relying on (SSC), we verify uniqueness for the optimality system of (QP_n^ϱ). Therefore, $(\hat{v}_n, \hat{u}_n)$ can be obtained as the unique global solution of (QP_n^ϱ). Notice that (QP_n^ϱ) might be nonconvex; hence the optimality of $(\hat{v}_n, \hat{u}_n)$ does not follow directly from fulfilling the optimality system.

LEMMA 6.5. *There is $\varrho_2 > 0$ with the following property: If $\varrho \leq \varrho_2$, $w_n \in W$ fulfills $\|w_n - \bar{w}\|_W \leq \varrho_2$, and (y^+, v^+, u^+) satisfies the constraints of (QP_n^ϱ) with associated adjoint state p^+, then*

$$\textit{sign}\ \tilde{H}_v^Q(y^+, p^+, v^+)(x,t) = \textit{sign}\ H_v^Q(\bar{y}, \bar{p}, \bar{v})(x,t) \quad \textit{a.e. on}\ \ Q(\sigma), \tag{6.9}$$

$$\textit{sign}\ \tilde{H}_u^\Sigma(y^+, p^+, u^+)(x,t) = \textit{sign}\ H_u^\Sigma(\bar{y}, \bar{p}, \bar{u})(x,t) \quad \textit{a.e. on}\ \ \Sigma(\sigma), \tag{6.10}$$

$$|\tilde{H}_v^Q(y^+, p^+, v^+)(x,t)| \geq \frac{\sigma}{2} \quad \textit{a.e. on}\ \ Q(\sigma), \tag{6.11}$$

$$|\tilde{H}_u^\Sigma(y^+, p^+, u^+)(x,t)| \geq \frac{\sigma}{2} \quad \textit{a.e. on}\ \ \Sigma(\sigma). \tag{6.12}$$

Proof. Let us discuss $\tilde{H}_v^Q$; the proof is analogous for $\tilde{H}_u^\Sigma$. We have

$$\begin{aligned} \tilde{H}_v^Q &= f_v^n + H_{yv}^{Q,n}(y^+ - y_n) + H_{vv}^{Q,n}(v^+ - v_n) - p^+ d_v^n \\ &= \bar{f}_v - \bar{p}\bar{d}_v + \{f_v^n - \bar{f}_v + (f_{yv}^n - p_n d_{yv}^n)(y^+ - y_n) \\ &\quad + (f_{vv}^n - p_n d_{vv}^n)(v^+ - v_n) + (\bar{p}\bar{d}_v - p^+ d_v^n)\} = \bar{H}_v^Q + \{\ldots\} \geq \sigma - |\{\ldots\}| \end{aligned}$$

a.e. on $Q(\sigma)$. Lemma 6.1 applies to estimate $|\{\ldots\}| \leq c \cdot \varrho_2$, where c does not depend on w_n, y^+, p^+, u^+, v^+, provided that we are able to prove that $\|p^+ - \bar{p}\|_{C(\bar{Q})} \leq c\ \varrho_2$ and

$\|y^+ - \bar{y}\|_{C(\bar{Q})} \le c\ \varrho_2$ holds with an associated constant c. Let us sketch the estimation of $y^+ - \bar{y} =: y$. This function satisfies

$$\begin{aligned} y_t + A\,y + d_y^n y &= -d_v^n(v^+ - \bar{v}) + (d_y^n - d_y^\vartheta)(y_n - \bar{y}) + (d_v^n - d_v^\vartheta)(v_n - \bar{v}) \\ \partial_\nu y + b_y^n y &= -d_u^n(u^+ - \bar{u}) + (b_y^n - b_y^\vartheta)(y_n - \bar{y}) + (b_u^n - b_u^\vartheta)(u_n - \bar{u}) \\ y(0) &= 0, \end{aligned}$$

where $d_y^\vartheta = d_y(\bar{y} + \vartheta(y_n - \bar{y}), \bar{v} + \vartheta(v_n - \bar{v}))$, $\vartheta = \vartheta(x,t) \in (0,1)$, and the other quantities are defined accordingly. We have $\max\{\|v^+ - \bar{v}\|_{L^\infty(Q)}, \|u^+ - \bar{u}\|_{L^\infty(\Sigma)}\} \le \varrho, \max\{\|y_n - \bar{y}\|_{C(\bar{Q})}, \|u_n - \bar{u}\|_{L^\infty(\Sigma)}, \|v_n - \bar{v}\|_{L^\infty(Q)}\} \le \varrho_2$. Thus the right-hand sides of the PDE and its boundary condition are estimated by $c \cdot \varrho_2$. The estimate for $\|y^+ - \bar{y}\|$ follows from Theorem 2.2. The difference $p^+ - \bar{p}$ is handled in the same way. □

COROLLARY 6.6. *If* $\max\{\|w_n - \bar{w}\|_W, \varrho\} \le \varrho_2$, *then the relations*

$$\begin{aligned} v^+(x,t) &= \bar{v}(x,t) \quad \text{a.e. on } Q(\sigma), \\ u^+(x,t) &= \bar{u}(x,t) \quad \text{a.e. on } \Sigma(\sigma) \end{aligned}$$

hold for all controls (v^+, u^+) *of* (QP_n^ϱ), *satisfying together with the associated state* y^+ *and the adjoint state* p^+ *the optimality systems* (6.6)–(6.8), (3.22).

Proof. On $Q(\sigma)$ we have $\bar{v}(x,t) = v_b$, where $\bar{H}_v^Q(x,t) \le -\sigma$, and $\bar{v}(x,t) = v_a$, where $\bar{H}_v^Q(x,t) \ge \sigma$. Therefore, $v \in V_{ad}^\varrho$ means $v(x,t) \in [v_b - \varrho, v_b]$ or $v(x,t) \in [v_a, v_a + \varrho]$, respectively. Lemma 6.5 yields $\tilde{H}_v^Q \le -\sigma/2$ or $\tilde{H}_v^Q \ge \sigma/2$ on $Q(\sigma)$, hence the variational inequality (6.6) gives $v^+ = v_b$ or $v^+ = v_a$, respectively. In this way, we have shown $v^+ = \bar{v}$ on $Q(\sigma)$; u^+ is handled analogously. □

COROLLARY 6.7. *Let the assumptions of Theorem* 6.4 *be satisfied and suppose that* $\|w_1 - \bar{w}\|_W \le \varrho := \min\{r_{\mathcal{N}}, \varrho_1, \varrho_2\}$. *Then* $\|\hat{w}_n - \bar{w}\|_W \le \varrho$ *holds* $\forall\ n \in N$. *In particular,* $\hat{v}_n \in V_{ad}^\varrho, \hat{u}_n \in U_{ad}^\varrho$.

This is obtained by Theorem 4.1 and the convergence estimate (4.9).

COROLLARY 6.8. *Under the assumptions of Corollary* 6.7, *the sign-conditions* (6.9)–(6.12) *hold true for* $(y^+, p^+, v^+, u^+) := (\hat{y}_n, \hat{p}_n, \hat{v}_n, \hat{u}_n)$.

(Corollary 6.7 yields $\hat{v}_n \in V_{ad}^{\varrho_2}, \hat{u}_n \in U_{ad}^{\varrho_2}$, hence the result follows from Lemma 6.5.)

COROLLARY 6.9. *Under the assumptions of Corollary* 6.7, *the solution* $(\hat{v}_n, \hat{u}_n)$ *of* $(\widehat{QP}_n)$ *satisfies the optimality system of* (QP_n), *too.*

Proof. The optimality systems for $(\widehat{\mathrm{QP}}_n)$ and (QP_n) differ only in the variational inequalities. From the optimality system of $(\widehat{\mathrm{QP}}_n)$ we know that

$$\int_Q \tilde{H}_v^Q(\hat{y}_n, \hat{p}_n, \hat{v}_n)(v - \hat{v}_n)\,dxdt \ge 0 \quad \forall v \in \widehat{V}_{ad}. \tag{6.13}$$

On $Q(\sigma), \hat{v}_n = \bar{v} = v_a$, if $\bar{H}_v^Q \ge \sigma$ and $\hat{v}_n = \bar{v} = v_b$, if $\bar{H}_v^Q \le -\sigma$. Lemma 6.5 and Corollary 6.8 yield $\tilde{H}_v^Q(\hat{y}_n, \hat{p}_n, \hat{v}_n) \ge \sigma/2$ or $\tilde{H}_v^Q(\hat{y}_n, \hat{p}_n, \hat{v}_n) \le -\sigma/2$, respectively. Therefore, $\tilde{H}_v^Q(\hat{y}_n, \hat{v}_n, \hat{p}_n)(v - \hat{v}_n) \ge 0$ holds on $Q(\sigma)$ for all real numbers $v \in [v_a, v_b]$. On the complement $Q \setminus Q(\sigma)$, the controls of $\widehat{V}_{ad}$ are not restricted to be equal to $\bar{v}$; hence in (6.13) v was arbitrary in $[u_a, u_b]$. This yields

$$\int_Q \tilde{H}_v^Q(v - \hat{v}_n)\,dxdt = \int_{Q\setminus Q(\sigma)} \tilde{H}_v^Q(v - \hat{v}_n)\,dxdt + \int_{Q(\sigma)} \tilde{H}_v^Q(v - \hat{v}_n)\,dxdt \ge 0 \qquad \forall v \in V_{ad},$$

where the nonnegativity of the first term follows from (6.13). The variational inequality for $\hat{u}_n$ is discussed in the same way. ∎

COROLLARY 6.10. *Let the assumptions of Corollary* 6.7 *be fulfilled. Then* $(\hat{v}_n, \hat{u}_n)$, *the solution of* $(\widehat{\mathrm{QP}}_n)$, *satisfies the optimality system for* (QP_n^ϱ).

Proof. By Corollary 6.9, $(\hat{v}_n, \hat{u}_n)$ satisfies the variational inequality (6.13) $\forall\, v \in V_{ad}, u \in U_{ad}$, in particular $\forall\, v \in V_{ad}^\varrho, u \in U_{ad}^\varrho$. Moreover, $\hat{v}_n \in V_{ad}^\varrho, \hat{u}_n \in U_{ad}^\varrho$ is granted by Corollary 6.9. ∎

LEMMA 6.11. *Assume that* $\bar{w} = (\bar{y}, \bar{p}, \bar{v}, \bar{u})$ *satisfies the second order condition* (SSC). *If* $\varrho_3 > 0$ *is taken sufficiently small, and* $\|w_n - \bar{w}\|_W \le \varrho_3$, *then for all* $\varrho > 0$ *the problem* (QP_n^ϱ) *has at least one pair of (globally) optimal controls* (v, u).

Proof. If $\|w_n - \bar{w}\|_W \le \varrho_3$ and $\varrho_3 > 0$ is sufficiently small, then

$$H_{vv}^Q(x,t,y_n(x,t),p_n(x,t),v_n(x,t)) \ge \frac{\delta}{2} \quad \text{a.e. on } Q, \tag{6.14}$$

$$H_{uu}^\Sigma(x,t,y_n(x,t),p_n(x,t),u_n(x,t)) \ge \frac{\delta}{2} \quad \text{a.e. on } \Sigma \tag{6.15}$$

follow from (LC), $\|y_n - \bar{y}\|_{C(\bar{Q})} + \|p_n - \bar{p}\|_{C(\bar{Q})} + \|v_n - \bar{v}\|_{L^\infty(Q)} + \|u_n - \bar{u}\|_{L^\infty(\Sigma)} \le \varrho_3$, and the Lipschitz properties of H_{vv}^Q, H_{vv}^Σ. Notice that w_n belongs to a set of diameter $K := \|\bar{w}\|_W + \varrho_3$, hence the Lipschitz estimates (3.5) and (3.6) apply. Therefore, (QP_n^ϱ) has the following properties. It is a linear-quadratic problem with linear equation of state. In the objective, the controls appear linearly and convex-quadratically (with convexity following from (6.14)–(6.15)). The control-state mapping $(v, u) \mapsto y$ is compact from $L^2(Q) \times L^2(\Sigma)$ to Y. Moreover, $V_{ad}^\varrho, U_{ad}^\varrho$ are nonempty weakly compact sets of L^2. Now the existence of at least one optimal pair of controls follows by standard arguments. Here, it is essential that the quadratic control-part of J_n is weakly l.s.c. with respect to the controls and that products of the type $y \cdot v$ or $y \cdot u$ lead to sequences of the type "strongly convergent times weakly convergent sequence," so that $y_n \to y$ and $v_n \rightharpoonup v$ implies $y_n v_n \rightharpoonup yv$. ∎

Remark. Alternatively, this result can be deduced also from the fact that $(\hat{y}_n, \hat{v}_n, \hat{u}_n)$ satisfies together with $\hat{p}_n$ the first and second order necessary conditions for (QP_n^ϱ) and that the optimality system of (QP_n^ϱ) is uniquely solvable (cf. Thm. 6.12).

THEOREM 6.12. *Let* $\bar{w} = (\bar{y}, \bar{p}, \bar{v}, \bar{u})$ *fulfill the first order necessary conditions* (2.1), (3.2)–(3.3), (3.7)–(3.9) *together with the second order sufficient optimality condition* (SSC). *If* $w_n = (y_n, p_n, v_n, u_n) \in W$ *is given such that* $\max\{\, \|w_n - \bar{w}\|_W, \varrho\} \le \min\{r_{\mathcal{N}}, \varrho_1, \varrho_2, \varrho_3\}$, *then the solution* $(\hat{v}_n, \hat{u}_n)$ *of* $(\widehat{\mathrm{QP}}_n)$ *is (globally) optimal for* (QP_n^ϱ). *Together with* $\hat{y}_n, \hat{p}_n$, *it delivers the unique solution of the optimality system of* (QP_n^ϱ).

Proof. Denote by (v^+, u^+) the solution of (QP_n^ϱ), which exists according to Lemma 6.11. Therefore, $(y^+, p^+, v^+, u^+) = w^+$ has to satisfy the associated optimality system. On the other hand, also $\hat{w}_n = (\hat{y}_n, \hat{p}_n, \hat{v}_n, \hat{u}_n)$ fulfills this optimality system by Corollary 6.10. We show that the solution of the optimality system is unique, and then the theorem is proven.

Let us assume that another $\hat{w} = (\hat{y}, \hat{p}, \hat{v}, \hat{u})$ obeys the optimality system too. Inserting $(\hat{v}, \hat{u})$ in the variational inequalities for (v^+, u^+), while (v^+, u^+) is inserted in the corresponding ones for $(\hat{v}, \hat{u})$, we arrive at

$$\begin{aligned} &\int_Q \{\tilde{H}_v^Q(y^+, p^+, v^+)(\hat{v} - v^+) + \tilde{H}_v^Q(\hat{y}, \hat{p}, \hat{v})(v^+ - \hat{v})\}\, dxdt \\ &\quad + \int_\Sigma \{\tilde{H}_u^\Sigma(y^+, p^+, u^+)(\hat{u} - u^+) + \tilde{H}_u^\Sigma(\hat{y}, \hat{p}, \hat{u})(u^+ - \hat{u})\}\, dSdt \ge 0. \end{aligned} \tag{6.16}$$

The expressions under the integral over Q in (6.16) have the form

$$f_v^n(\hat v-v^+)+H_{yv}^{Q,n}(y^+-y_n)(\hat v-v^+)+H_{vv}^{Q,n}(v^+-v_n)(\hat v-v^+)-p^+d_v^n(\hat v-v^+)$$
$$+f_v^n(v^+-\hat v)+H_{yv}^{Q,n}(\hat y-y_n)(v^+-\hat v)+H_{vv}^{Q,n}(\hat v-v_n)(v^+-\hat v)-\hat p\,d_v^n(v^+-\hat v);$$

the other terms look similar. Simplifying (6.16), we get, after setting $y=\hat y-y^+$, $v=\hat v-v^+$, $u=\hat u-u^+$, $p=\hat p-p^+$,

$$\begin{aligned}0 \;\le\; & -\int_Q \{H_{yv}^{Q,n}yv+H_{vv}^{Q,n}v^2+p\;d_v^n\;v\}\,dxdt\\ & -\int_\Sigma \{H_{yu}^{\Sigma,n}yu+H_{uu}^{\Sigma,n}u^2+p\;b_u^n\;u\}\,dSdt.\end{aligned}\tag{6.17}$$

The difference $p=\hat p-p^+$ obeys

$$\begin{aligned}-p_t+Ap &= H_{yy}^{Q,n}y+H_{yv}^{Q,n}v-d_y^np,\\ \partial_\nu p &= H_{yy}^{\Sigma,n}y+H_{yu}^{\Sigma,n}u-b_y^np,\\ p(T) &= \varphi_{yy}^n y(T).\end{aligned}\tag{6.18}$$

Multiplying the PDE in (6.18) by y and integrating over Q we find, after an integration by parts,

$$\begin{aligned}&-\int_\Omega p(T)y(T)dx+\int_0^T(y_t,p)_{H^1(\Omega)',H^1(\Omega)}dt+\int_Q\langle\mathcal{A}\nabla p,\nabla y\rangle dxdt\\ =\;&\int_Q(H_{yy}^{Q,n}y^2+H_{yv}^{Q,n}yv-d_y^n\;p\,y)\,dxdt+\int_\Sigma(H_{yy}^{\Sigma,n}y^2+H_{yu}^{\Sigma,n}yu-b_y^n\;p\;y)\,dSdt.\end{aligned}\tag{6.19}$$

This description of the procedure was formal, as the definition of the weak solution of (6.18) requires the test function y to be zero at $t=T$. To make (6.19) precise we have to use the information that $p\in W(0,T), y\in W(0,T)$ along with the integration by parts formula

$$\int_0^T(p_t,y)_{H^1(\Omega)',H^1(\Omega)}dt=\int_\Omega(p(T)y(T)-p(0)y(0))dx-\int_0^T(y_t,p)_{H^1(\Omega)',H^1(\Omega)}dt.$$

Next, we invoke the state equation for $y=\hat y-y^+$ and the condition for $p(T)$ to obtain from (6.19)

$$\begin{aligned}-\int_\Omega\varphi_{yy}^n y(T)^2dx \;&-\; \int_Q(H_{yy}^{Q,n}y^2+H_{yv}^{Q,n}yv)\,dxdt\\ -\int_\Sigma(H_{yy}^{\Sigma,n}y^2\;&+\;H_{yu}^{\Sigma,n}yu)\,dSdt=\int_Q d_v^n\;v\;p\;dxdt+\int_\Sigma d_u^n\;u\;p\;dSdt.\end{aligned}\tag{6.20}$$

Adding (6.20) to (6.17) yields

$$0\le-\int_\Omega\varphi_{yy}^n y(T)^2dx-\int_Q(y,v)D^2H^{Q,n}(y,v)^\top dxdt-\int_\Sigma(y,u)D^2H^{\Sigma,n}(y,u)^\top dSdt;$$

that is, $0\le -B^n[y,v,u]^2$. As $\max\{\,\|w_n-\bar w\|_W,\varrho\}\le\varrho_2$, Corollary 6.6 yields $v=0$ on $Q(\sigma)$ and $u=0$ on $\Sigma(\sigma)$. Therefore, Lemma 6.2 applies to conclude $\delta/2\,\|(y,v,u)\|_H^2\le 0$, i.e., $v=0, u=0$. In other words, $\hat v=v^+$, $\hat u=u^+$, completing the proof. □

Now we are able to formulate the main result of this paper.

THEOREM 6.13. *Let $\bar{w} = (\bar{y}, \bar{p}, \bar{v}, \bar{u})$ satisfy the assumptions of Theorem* 6.12 *and define $\varrho_{\mathcal{N}} = min\{r_{\mathcal{N}}, \varrho_1, \varrho_2, \varrho_3\}$. If $\max\{\varrho, \|w_1 - \bar{w}\|\} \le \varrho_{\mathcal{N}}$, then the sequence $\{w_n\} = \{(y_n, p_n, v_n, u_n)\}$ generated by the SQP method by solving (QP_n^{ϱ}) coincides with the sequence $\hat{w}_n$ obtained by solving $(\widehat{\mathrm{QP}}_n)$. Therefore, w_n converges q-quadratically to $\bar{w}$ according to the convergence estimate* (4.9).

Thanks to this theorem, we are justified to solve $(\mathrm{QP}_n^{\varrho})$ instead of $(\widehat{\mathrm{QP}}_n)$ to obtain the same (unique) solution. This result is still not completely satisfactory, as the unknown element $\bar{w}$ was used to define $(\mathrm{QP}_n^{\varrho})$.

However, an analysis of this section reveals that any convex, closed set $\tilde{V}_{ad}, \tilde{U}_{ad}$ can be taken instead of $V_{ad}^{\varrho}, U_{ad}^{\varrho}$, if the following properties are satisfied:

$\tilde{V}_{ad} \subset V_{ad}^{\varrho_{\mathcal{N}}}, \tilde{U}_{ad} \subset U_{ad}^{\varrho_{\mathcal{N}}}$, and $\tilde{V}_{ad} \supset V_{ad}^{\varrho_0}, \tilde{U}_{ad} \supset U_{ad}^{\varrho_0}$ for some $\varrho_0 > 0$. (The last condition is needed to guarantee $\hat{v}_n = \bar{v}$ on $Q(\sigma), \hat{u}_n = \bar{u}$ on $\Sigma(\sigma)$ and, last but not least, to make the convergence $\hat{v}_n \to \bar{v}, \hat{u}_n \to \bar{u}$ possible.)

Define, for instance, $\varrho_0 = \|\bar{w} - w_1\|_W$, where $\varrho_0 \le \frac{1}{3}\varrho_{\mathcal{N}}$,

$$\tilde{V}_{ad} = \{v \in V_{ad} |\ \|v - v_1\|_{L^\infty(Q)} \le 2\varrho_0\},$$

$$\tilde{U}_{ad} = \{u \in U_{ad} |\ \|u - u_1\|_{L^\infty(\Sigma)} \le 2\varrho_0\},$$

where $\varrho_0 = \|\bar{w} - w_1\|_W$ is the distance of the starting element of the SQP method to $\bar{w}$. Then $V_{ad}^{\varrho_0} \subset \tilde{V}_{ad} \subset V_{ad}^{\varrho_{\mathcal{N}}}$. The same property holds for $\tilde{U}_{ad}$. In that case, the SQP method will deliver the same solution in $\tilde{V}_{ad}, \tilde{Q}_{ad}$ as in $V_{ad}^{\varrho_{\mathcal{N}}}, U_{ad}^{\varrho_{\mathcal{N}}}$. This however, is the solution in $\widehat{V}_{ad}, \widehat{U}_{ad}$.

Remark. The restriction of the admissible sets to V_{ad}^{ϱ}, U_{ad}^{ϱ} might appear artificial, since restrictions of this type are not known from the theory of SQP methods in spaces of finite dimension. However, it is indispensable. In finite dimensions, the set of active constraints is detected after one step, provided that the starting value was chosen sufficiently close to the reference solution. The further analysis can rely on this. Here, we cannot determine the active set in finitely many steps unless we assume this a priori as in the definition of $\widehat{\mathrm{QP}}_n$.

ON THE STRONG STABILIZABILITY OF MIMO n-DIMENSIONAL LINEAR SYSTEMS*

JIANG QIAN YING†

Abstract. A plant is *strongly stabilizable* if there exists a *stable* compensator to stabilize it. Based on some theorems in complex analysis of several variables proved in this paper, we present necessary conditions for the strong stabilizability of complex and real n-D multi-input multi-output (MIMO) shift-invariant linear plants. For the real case, the condition is a generalization of the *parity interlacing property* of Youla, Bongiorno, and Lu [*Automatica J. IFAC*, 10 (1974), pp. 159–173] for the strong stabilizability of a real one-dimensional MIMO plant.

These conditions are also sufficient for the cases of n-D plants with a single output (MISO) or with a single input (SIMO). For general n-D MIMO plants, we do not know if the conditions are sufficient or not. A useful sufficient, but not necessary, condition for the strong stabilizability of a class of n-D ($n \geq 2$) MIMO plants is given.

Key words. multidimensional system, feedback stabilization, strong stabilizability, sign condition

1. Introduction.

Let $\bar{U}^n = \{z \in \mathbf{C}^n \mid |z_1| \leq 1, \ldots, |z_n| \leq 1\}$ be the closed unit polydisc in $\mathbf{C}^n$. In this paper a polynomial in z is said to be *Hurwitz* if it is free from 0 in $\bar{U}^n$. A rational function with a Hurwitz denominator is regular (analytic) over $\bar{U}^n$ and will be said to be *stable*.

An n-dimensional (n-D) multi-input multi-output (MIMO) linear shift invariant plant with l inputs and m outputs can be described by a transfer matrix with entries of rational functions in $z = (z_1, \ldots, z_n)$:

$$P(z) = \begin{bmatrix} p_{11}(z) & \cdots & p_{1l}(z) \\ \vdots & \ldots & \vdots \\ p_{m1}(z) & \cdots & p_{ml}(z) \end{bmatrix}. \tag{1.1}$$

The system is called *real* if the entries are real rational functions and *complex* if they are complex rational functions. See [4] for more materials on n-D systems theory.

$P(z)$ is *stable* by definition if all its entries are stable. For an unstable plant $P(z)$, one may try to use a stabilizing compensator $C(z)$ in some feedback configuration to obtain a stable feedback system. In a standard feedback configuration [23, 22, 15], the stability of the feedback system is equivalent to the stability of the following system:

$$H(P,C) = \begin{bmatrix} I - P(I+CP)^{-1}C & -P(I+CP)^{-1} \\ (I+CP)^{-1}C & (I+CP)^{-1} \end{bmatrix} \tag{1.2}$$

*Received by the editors March 16, 1998; accepted for publication (in revised form) February 8, 1999; published electronically December 21, 1999.

†Division of Regional Policy, Faculty of Regional Studies, Gifu University, 1-1 Yanagido, Gifu 501, Japan (ying@cc.gifu-u.ac.jp).

$$= \begin{bmatrix} (I+PC)^{-1} & -(I+PC)^{-1}P \\ C(I+PC)^{-1} & I - C(I+PC)^{-1}P \end{bmatrix}. \tag{1.3}$$

P is said to be *stabilizable* if such a C (complex or real) exists to make $H(P,C)$ stable. Stabilizability conditions and stabilizing compensator construction methods have been given in [22, 16, 15]. For real stabilizable systems, the compensators can always be constructed real.

In the case that the compensator $C(z)$ itself can be chosen stable, P is said to be *strongly stabilizable*. Furthermore, for a real system P, if C can be chosen real and stable, we say that P is *real strongly stabilizable*.

For an MIMO one-dimensional (1-D) linear system described by a real rational transfer matrix, Youla, Bongiorno, and Lu [27] in the early seventies gave a constructive condition for the existence of a stable real compensator. It can be easily derived from the works of [27], [20], and [25] that 1-D systems are always strongly stabilizable in the sense that a *complex* stable compensator always exists. See Appendix A of this paper for details.

Youla, Bongiorno, and Lu's work at the same time solved the problem of simultaneously stabilizing two 1-D plants with a single (not necessarily stable) compensator. In general, k 1-D plants can be simultaneously stabilized by a single compensator if certain other $k-1$ plants can be stabilized by a single *stable* compensator. However, the general simultaneous stabilization problem is rather complicated, as indicated by a recent result due to Blondel which says that for some *three* 1-D single-input single-output (SISO) plants, it is not rationally decidable whether or not they can be simultaneously stabilized by a single compensator [2, 3].

On the other hand, the extension of Youla, Bongiorno, and Lu's result to n-D systems or even more general linear systems over a commutative ring has also been a long standing open problem [23, Section 8.3]. For the problem of strong stabilization of n-D linear systems, recently a topological condition for strong stabilizability of an n-D SISO complex system was given by Shankar [20] and a computable equivalent was given by Ying [25]. By introducing a concept of "sign" of real functions on complex varieties, Ying gave a necessary and sufficient condition for real strong stabilizability of a real n-D SISO system [25]. But in the literature nothing significant has been known concerning the strong stabilizability of MIMO n-D systems.

In this paper we present new results concerning strong stabilizability of MIMO n-D systems. The main contributions are some mathematical theorems that extend Shankar and Ying's results. Applying these theorems, we are able to give necessary conditions for the strong stabilizability of MIMO systems. For two special classes of systems, i.e., MISO (multi-input single-output) and SIMO (single-input multi-output) systems, these conditions are also sufficient.

The concept of the sign of a real polynomial function on a complex variety, which has been first formulated in [25] and will also be involved in the part of this paper that concerns the real strong stabilizability of systems, along with the key theorems in several complex variables theory, will be stated in the next section. Readers who feel lack of motivation for the pure mathematical materials of section 2 may start directly with section 3 and look back to section 2 when necessary.

In section 3, necessary conditions for strong stabilizability of n-D MIMO systems are presented. Some examples are given at the end. In section 4, the sufficiency of the conditions for MISO and SIMO systems are proved. In section 5, a useful sufficient, but not necessary, condition for the strong stabilizability of a complex MIMO system is given. The difficulty in applying existing algebraic methods for establishing a

sufficient condition for strong stabilizability, and for stable compensator construction, is briefly discussed for general MIMO n-D systems.

2. Main mathematical theorems. Throughout this paper, by saying that a function is analytic on a *closed* set in $\mathbf{C}^n$, we mean that the function is defined and analytic in some open neighborhood of the closed set. See, e.g., [12, 13] for the theory of analytic functions of complex variables.

In this section we give solutions to the following questions:

Let $g(z)$, $\alpha_1(z), \ldots, \alpha_M(z)$ be complex polynomials.

(i) What is the condition for the existence of M stable complex rational functions $h_1(z), \ldots, h_M(z)$ such that

$$g(z) + h_1(z)\alpha_1(z) + \cdots + h_M(z)\alpha_M(z) \neq 0 \quad \text{on } \bar{U}^n? \tag{2.1}$$

(ii) When $g(z)$, $\alpha_1(z), \ldots, \alpha_M(z)$ are real polynomials and the above inequality (2.1) has a solution, what is the condition for $h_1, \ldots, h_M$ to be real?

For the special case when $M = 1$, questions (i) and (ii) were answered by Shankar [20] and Ying [25], respectively, from which necessary and sufficient conditions for the strong stabilizability of complex and real n-D SISO plants were derived. In the following we present answers for the general case.

2.1. Complex stable rational functions. Clearly, a necessary condition for the existence of $h_1, \ldots, h_M$ such that the inequality (2.1) holds is that $g, \alpha_1, \ldots, \alpha_M$ do not have common zero in $\bar{U}^n$. It can be derived from Cartan's Theorems A or B (see, e.g., [12, 13, 21]) that this condition is also sufficient for the existence of $M + 1$ rational functions analytic on $\bar{U}^n$: $f_0(z), f_1(z), \ldots, f_M(z)$, such that

$$f_0(z)g(z) + f_1(z)\alpha_1(z) + \cdots + f_M(z)\alpha_M(z) \neq 0 \quad \text{on } \bar{U}^n.$$

In the following a stronger condition is given such that $f_0(z)$ can be fixed to a nonzero constant. Before this we review some necessary topological concepts.

Recall that the winding number of a cycle (a closed curve) γ in $\mathbf{C}^* = \mathbf{C}\backslash\{0\}$ is defined as

$$W(\gamma) = \frac{1}{2\pi i}\int_\gamma \frac{d\xi}{\xi} = \frac{1}{2\pi i}\int_\gamma d(\log \xi).$$

It is the number of times that γ winds around the origin counterclockwise. A single-valued logarithmic function $\log \xi$ can be defined in some subset Σ of $\mathbf{C}^*$ if and only if Σ does not contain any cycle with a nonzero winding number.

In general, for a subset Σ in some complex space, an analytic function $g : \Sigma \longrightarrow \mathbf{C}^*$ has a single-valued logarithmic function $\log g$ on Σ if and only if g maps any cycle in Σ into a cycle with winding number 0 in $\mathbf{C}^*$, i.e., $W(g(\gamma)) = 0$. This property is equivalent to that g induces a 0 homomorphism from the first homology group of Σ to that of $\mathbf{C}^*$ (see, e.g., [9]). If this is satisfied, we say that g is 0-*homotopic* on Σ.

For some positive real number r, an open polydisc in $\mathbf{C}^n$ of radius r is defined as

$$\Delta(0; r) = \{z = (z_1, \ldots, z_n) \in \mathbf{C}^n \mid |z_1| < r, \ldots, |z_n| < r\}.$$

Let I be the ideal generated by $\alpha_1, \ldots, \alpha_M$ in $\mathbf{C}[z]$, the ring of complex polynomials, and let

$$V(I) \cap \bar{U}^n = \left\{z \in \bar{U}^n \mid f(z) = 0 \quad \forall f(z) \in I\right\}.$$

THEOREM 2.1. *Let $g(z), \alpha_1(z), \ldots, \alpha_M(z)$ be complex polynomials. A necessary and sufficient condition for the existence of analytic functions $h_1, \ldots, h_M$ on an open polydisc $\Omega = \Delta(0; r)$ containing $\bar{U}^n$, such that*

$$g(z) + \sum_{1 \le j \le M} h_j \alpha_j \neq 0 \quad \text{on } \bar{U}^n \tag{2.2}$$

is that $g(z)$ is 0-homotopic on $V(I) \cap \bar{U}^n$; or equivalently, $g(z)$ has a single-valued logarithmic function $\log g(z)$ on $V(I) \cap \bar{U}^n$.

Proof. Let $\mathcal{I}$ be the ideal sheaf generated by $(\alpha_1, \ldots, \alpha_M)$ in the sheaf $\mathcal{O}$ of analytic functions on some open polydisc $\Omega \supset \bar{U}^n$. We have the following exact sequence of sheaves:

$$0 \to \mathcal{I} \to \mathcal{O} \to \mathcal{O}/\mathcal{I} \to 0, \tag{2.3}$$

which induces a long exact sequence of modules over the ring of analytic functions

$$0 \to \Gamma(\mathcal{I}, \Omega) \to \Gamma(\mathcal{O}, \Omega) \xrightarrow{\varphi} \Gamma(\mathcal{O}/\mathcal{I}, \Omega) \to H^1(\mathcal{I}) \to \cdots . \tag{2.4}$$

The assumption that $\log g(z)$ is defined over $V(I)$ means that $\log g(z)$ is a global section of the quotient sheaf $\mathcal{O}/\mathcal{I}$ on Ω, that is, $\log g(z) \in \Gamma(\mathcal{O}/\mathcal{I}, \Omega)$.

Now $\mathcal{I}$ is finitely generated; thus it is a coherent sheaf. By Cartan's Theorem B, we have $H^1(\mathcal{I}) = 0$, which means that φ is surjective and there exists a $G(z) \in \Gamma(\mathcal{O}, \Omega)$ such that $\varphi(G(z)) = \log g(z)$.

Clearly, $\varphi(g(z)) = e^{\log g(z)}$ and $\varphi(e^{G(z)}) = e^{\varphi(G(z))}$ in $\Gamma(\mathcal{O}/\mathcal{I}, \Omega)$. We have

$$\varphi\big(e^{G(z)} - g(z)\big) = 0 \quad \text{in } \Gamma(\mathcal{O}/\mathcal{I}, \Omega); \tag{2.5}$$

therefore

$$e^{G(z)} - g(z) \in \Gamma(\mathcal{I}, \Omega). \tag{2.6}$$

That is, there exist $h_j(z) \in \Gamma(\mathcal{O}, \Omega)$, $j = 1, \ldots, M$, such that

$$e^{G(z)} = g(z) + \sum_{1 \le j \le M} h_j(z)\alpha_j(z) \neq 0 \quad \text{on } \Omega. \tag{2.7}$$

Since analytic functions can be approximated to any precision by polynomials on $\bar{U}^n$, thus also by stable rational functions, the inequality

$$g(z) + \sum_{1 \le j \le M} h_j(z)\alpha_j(z) \neq 0$$

still holds if the h_i's are replaced with their rational approximators. This proves the sufficiency of the condition.

For necessity, let

$$G(z) = \log\left(g(z) + \sum_{1 \le j \le M} h_j(z)\alpha_j(z)\right),$$

the restriction of $G(z)$ on $V(I) \cap \bar{U}^n$ is a logarithm of $g(z)$. This completes the proof. ∎

2.2. Concept of signs of real polynomial functions. Suppose that $g(z)$, $\alpha_1(z), \ldots, \alpha_M(z)$ are real and that there exist real stable rational functions $h_1(z)$, $\ldots, h_M(z)$ such that

$$g(z) + h_1(z)\alpha_1(z) + \cdots + h_M(z)\alpha_M(z) \neq 0 \quad \text{on } \bar{U}^n.$$

This is a real valued continuous mapping on $\bar{U}^n \cap \mathbf{R}^n$ and

$$g(z) + h_1(z)\alpha_1(z) + \cdots + h_M(z)\alpha_M(z) \neq 0 \quad \text{on } \bar{U}^n \cap \mathbf{R}^n. \tag{2.8}$$

The left side of 2.8 must have an invariant sign on the connected set $\bar{U}^n \cap \mathbf{R}^n$. Therefore g has an invariant sign, either $+$ or $-$, over $V(I) \cap \bar{U}^n \cap \mathbf{R}^n$, where I denotes the ideal generated by $\alpha_1, \ldots, \alpha_M$ in $\mathbf{C}[z]$.

Here we extend this condition to a stronger one which is concerned with the complex components which may not possess a real point. Recall that a connected component, or simply a component, is defined as a connected subset which is not contained in any larger connected subset; see, e.g., [9].

In the following we use "-" to denote a complex conjugation operator. From the context there should be no confusion with the "-" in the notation "$\bar{U}^n$" which means the closedness of the polydisc. We first make clear an important aspect of the structure of a connected component X of $V(I) \cap \bar{U}^n$. Let $z_0 \in X$; if $\overline{z_0} \in X$, then for any $z \in X$, $\overline{z} \in X$. In fact, since z_0, $\overline{z_0}$, and z are all in X, there exist a path γ_0 connecting z_0 to $\overline{z_0}$ and a path γ connecting z_0 to z. The path $\overline{\gamma}$ defined as $t \to \overline{\gamma(t)}$ then connects $\overline{z_0}$ to $\overline{z}$; hence we have $\bar{z} \in X$. In this case X is identical to $\overline{X} = \{\overline{z} \mid z \in X\}$ and is said to be *self-conjugate* in this paper.

On the other hand, if $X \neq \bar{X}$, then $X \cap \bar{X} = \phi$. In this case both X and $\bar{X}$ are non-self-conjugate components.

It is evident from the above argument that a connected component containing a real point is self-conjugate. Now suppose that X is a component containing a real point z_0. We reformulate the above sign consistency condition into one which is independent of the real point. We assume $g(z_0) > 0$. Let G_0 be a real number such that

$$e^{G_0} = g(z_0).$$

For an arbitrary point $z \in X$, let γ be a path in X connecting z_0 to z, define

$$G(z) = G_0 + \int_\gamma \frac{dg}{g}.$$

G is an analytic function on X. Let $\overline{\gamma}$ be the path defined as

$$\overline{\gamma}(t) = \overline{\gamma(t)} \quad \text{for } t \in [0, 1].$$

We have

$$\overline{G(z)} = \overline{G_0} + \int_\gamma \frac{d\overline{g(z)}}{\overline{g(z)}} = \overline{G_0} + \int_\gamma \frac{dg(\overline{z})}{g(\overline{z})} = G_0 + \int_{\overline{\gamma}} \frac{dg(z)}{g(z)} = G(\overline{z}).$$

To summarize, $G(z)$ is an analytic function on X such that

$$e^{G(z)} = g(z) \quad \text{and} \quad \overline{G(z)} = G(\overline{z}) \quad \forall z \in X. \tag{2.9}$$

On the other hand, the existence of such a $G(z)$ implies that $g(z) = e^{G(z)} > 0$ for $z \in X \cap \mathbf{R}^n$, because $G(z)$ is real on $\mathbf{R}^n$. The case $g(z_0) < 0$ can be proved similarly.

DEFINITION 2.2. *Let X be a self-conjugate connected component of $V(I) \cap \bar{U}^n$. Then g is said to have a* positive sign *on X if there exists an analytic function G on X such that*

$$e^{G(z)} = g(z) \quad \textit{and} \quad \overline{G(z)} = G(\overline{z}) \quad \forall z \in X;$$

g is said to have a negative sign *on X if $-g$ has a positive sign on X.*

The following proposition asserts that g either has a positive sign or has a negative sign on X.

PROPOSITION 2.3. *Let $g(z), \alpha_1(z), \ldots, \alpha_M(z)$ be real polynomials. Let I denote the ideal generated by $\alpha_1(z), \ldots, \alpha_M(z)$ in $\mathbf{C}[z]$. Assume that $g(z)$ has logarithm on $V(I) \cap \bar{U}^n$. Let X be a self-conjugate component of $V(I) \cap \bar{U}^n$, and let γ_0 be a path in X connecting a point $z_0 \in X$ to its conjugate $\overline{z_0}$. Let G_0 be a complex (possibly real) number such that*

$$e^{G_0} = g(z_0).$$

Then

$$\int_{\gamma_0} \frac{dg}{g} = \overline{G_0} - G_0 + m2\pi i, \tag{2.10}$$

where m is an integer. Moreover, g has a positive sign if m is an even number and g has a negative sign if m is an odd number.

Proof. Let

$$\tilde{G_0} = G_0 + \int_{\gamma_0} \frac{dg}{g};$$

then we have

$$e^{\tilde{G_0}} = g(\overline{z_0}) = e^{\overline{G_0}},$$

and hence

$$\tilde{G_0} = \overline{G_0} + m2\pi i$$

for some integer m. Therefore

$$\int_{\gamma_0} \frac{dg}{g} = \tilde{G_0} - G_0 = \overline{G_0} - G_0 + m2\pi i.$$

If $m = 2k$, for an integer k, we set

$$G_{z_0} = G_0 - k2\pi i.$$

It then follows that

$$G_{z_0} + \int_{\gamma_0} \frac{dg}{g} = G_0 - k2\pi i + \overline{G_0} - G_0 + m2\pi i = \overline{G_0} + k2\pi i = \overline{G_{z_0}}.$$

For any $z \in X$, let γ be a path connecting z_0 to z; from the assumption of the proposition, the integral

$$G(z) = G_{z_0} + \int_{\gamma} \frac{dg}{g}$$

is independent of the path and therefore defines a function $G(z)$ in z on X.

If γ is a path connecting z_0 to z, then $\overline{\gamma}$ is a path connecting $\overline{z_0}$ to $\overline{z}$, and the concatenation $\gamma_0\overline{\gamma}$, then connects z_0 to $\overline{z}$,

$$G(\overline{z}) = G_{z_0} + \int_{\gamma_0\overline{\gamma}} \frac{dg}{g} = \overline{G_{z_0}} + \int_{\overline{\gamma}} \frac{dg}{g} = \overline{G_{z_0} + \int_{\gamma} \frac{dg}{g}} = \overline{G(z)}.$$

In this case g has a positive sign on X.

Else if $m = 2k - 1$ for an integer k, we set

$$G_0' = G_0 - (2k-1)\pi i.$$

We have

$$-g(z_0) = -e^{G_0} = e^{G_0'},$$
$$G_0' + \int_{\gamma_0} \frac{d(-g)}{(-g)} = G_0 - (2k-1)\pi i + \overline{G_0} - G_0 + m2\pi i = \overline{G_0'}.$$

In this case $-g$ has a positive sign and hence g has a negative sign on X. □

Let X be a non-self-conjugate component of $V(I) \cap \bar{U}^n$. Then $\bar{X}$ is also a non-self-conjugate component since $X \cap \bar{X} = \phi$. If some analytic function $G(z)$ is defined on X such that

$$e^{G(z)} = g(z) \quad \forall z \in X,$$

then we can extend it to the union $X \cup \bar{X}$ by letting

$$G(\xi) = \overline{G(\bar{\xi})}, \quad \xi \in \bar{X}.$$

It is clear that $G(z)$ satisfies

$$e^{G(z)} = g(z), \quad \text{and} \quad \overline{G(z)} = G(\bar{z}) \quad \forall z \in X \cup \bar{X}.$$

In this sense, we say that $g(z)$ has a positive sign on $X \cup \bar{X}$. On the other hand, since the above argument also holds exactly for $-g(z)$, we may also say that $g(z)$ simultaneously has a negative sign on $X \cup \bar{X}$.

Therefore we are justified to make the following definition.

DEFINITION 2.4. *$g(z)$ is said to have a positive (negative, respectively) sign on $V(I) \cap \bar{U}^n$ if $g(z)$ has a positive (negative, respectively) sign over the union of the self-conjugate components of $V(I) \cap \bar{U}^n$.*

It is clear that $g(z)$ has a positive (negative, respectively) sign on $V(I) \cap \bar{U}^n$ if there exists an analytic function G on $V(I) \cap \bar{U}^n$ such that

$$e^{G(z)} = g(z)\big(e^{G(z)} = -g(z), \text{ respectively}\big) \quad \text{and} \quad \overline{G(z)} = G(\bar{z}) \quad \forall z \in V(I) \cap \bar{U}^n.$$

In particular, this is true if there is no self-conjugate component at all.

2.3. Real stable rational functions. We are now able to answer the second question proposed at the beginning of this section.

THEOREM 2.5. *Let $g(z), \alpha_1(z), \ldots, \alpha_M(z)$ be real polynomials. Let I denote the ideal generated by $\alpha_1(z), \ldots, \alpha_M(z)$ in $\mathbf{C}[z]$. A necessary and sufficient condition for the existence of real stable rational functions $h_1, \ldots, h_M$, such that*

$$g(z) + \sum_{1 \le j \le M} h_j \alpha_j \neq 0 \quad \text{on } \bar{U}^n \tag{2.11}$$

is that $g(z)$ is 0-homotopic on $V(I) \cap \bar{U}^n$ and that $g(z)$ has an invariant sign on $V(I) \cap \bar{U}^n$.

Proof. For proof of sufficiency, clearly it suffices to treat the case when $g(z)$ has a positive sign on $V(I) \cap \bar{U}^n$, as will be assumed in the following. From the statement at the end of section 2.2, it is seen that an analytic logarithmic function $\log g(z)$ can be constructed such that

$$\overline{\log g(z)} = \log g(\bar{z}) \quad \text{on } V(I) \cap \bar{U}^n. \tag{2.12}$$

Let Ω be an open polydisc containing $\bar{U}^n$ small enough so that $\log g(z)$ can be extended to $V(I) \cap \Omega$, where the above equation still holds. From the proof of Theorem 2.1, we have an analytic function $G(z)$ on Ω such that

$$e^{G(z)} = \log g(z) \quad \forall z \in V(I) \cap \Omega.$$

Then the analytic function defined as

$$W(z) = \big(G(z) + \overline{G(\bar{z})}\,\big)/2, \quad z \in \Omega, \tag{2.13}$$

satisfies

$$\varphi\big(W(z)\big) = \log g(z) \quad \text{in } \Gamma(\mathcal{O}/\mathcal{I}, \Omega),$$

where $\varphi : \Gamma(\mathcal{O}, \Omega) \to \Gamma(\mathcal{O}/\mathcal{I}, \Omega)$ is the canonical map. It follows that there exist $h_j(z) \in \Gamma(\mathcal{O}, \Omega)$, $j = 1, \ldots, M$, such that

$$e^{W(z)} = g(z) + \sum_{1 \le j \le M} h_j(z)\alpha_j(z) \neq 0 \quad \text{on } \bar{U}^n. \tag{2.14}$$

Now $W(z)$ satisfies

$$\overline{W(z)} = W(\bar{z}) \tag{2.15}$$

and can be chosen as a power series with real coefficients convergent on Ω. It is thus clear that $h_1(z), \ldots, h_M(z)$ can be chosen as a power series with real coefficients convergent on Ω and can be approximated by real stable rational functions.

For necessity, suppose that real stable rational functions $h_1(z), \ldots, h_M(z)$ have been given such that

$$u(z) = g(z) + \sum_{1 \le j \le M} h_j(z)\alpha_j(z) \neq 0 \quad \text{on } \Omega.$$

If $u(0) > 0$, let $\log u(0)$ be defined as a real number. Define

$$W(z) = \log u(0) + \int_\gamma \frac{du(z)}{u(z)} \tag{2.16}$$

for any γ connecting 0 to z in $\bar{U}^n$. Now W satisfies

$$\overline{W(z)} = W(\bar{z}), \qquad e^{W(z)} = g(z) \quad \forall z \in V(I) \cap \bar{U}^n;$$

$g(z)$ therefore has a positive sign on $V(I) \cap \bar{U}^n$.

Similarly, it could be shown that $g(z)$ has a negative sign if $u(0) < 0$. □

3. Necessary conditions for strong stabilizability of MIMO systems. In this section we will adopt the *matrix fraction description* (MFD) approach for describing a system. A *left* MFD of P is defined as

$$P(z) = D^{-1}(z)N(z),$$

where D is an $m \times m$ and N an $m \times l$ polynomial matrix:

$$D = \begin{bmatrix} d_{11} & \cdots & d_{1m} \\ \vdots & \ldots & \vdots \\ d_{m1} & \cdots & d_{mm} \end{bmatrix}, \qquad N = \begin{bmatrix} n_{11} & \cdots & n_{1l} \\ \vdots & \ldots & \vdots \\ n_{m1} & \cdots & n_{ml} \end{bmatrix}, \tag{3.1}$$

where d_{jk} and n_{jk} are polynomials in z with real or complex coefficients, corresponding to a real or a complex system, respectively. Let

$$F = [D\ N] = \begin{bmatrix} d_{11} & \cdots & d_{1m} & n_{11} & \cdots & n_{1l} \\ \vdots & \ldots & \vdots & \vdots & \ldots & \vdots \\ d_{m1} & \cdots & d_{mm} & n_{m1} & \cdots & n_{ml} \end{bmatrix}. \tag{3.2}$$

Let $M = \binom{m+l}{l}$. Let $\alpha_1, \alpha_2, \ldots, \alpha_M$ denote the M maximal order minors of F, with $\alpha_1 = \det D$.

An MFD is said to be *minor coprime* if the α_i's have no nonunit common factor. Similarly, a minor coprime *right* MFD is defined as a matrix fraction YX^{-1} such that the maximal order minors of $\left[\begin{smallmatrix} X \\ Y \end{smallmatrix}\right]$ have no common nonunit factor. A minor coprime MFD (either left or right) can always be constructed for a 1-D and a two-dimensional (2-D) transfer matrix, but not generally for an n-D ($n \geq 3$) matrix [28, 14].

In the following we will first treat MIMO systems with a minor coprime MFD because of their simplicity, although they will turn out to be special instances of a more general case treated subsequently.

3.1. Necessary conditions for strong stabilizability of MIMO systems with a minor coprime MFD. It is known that if $D^{-1}N$ is a minor coprime MFD for a plant P, then P is stable if and only if $\det D(z) \neq 0$ for $z \in \bar{U}^n$; see, e.g., [14, proof of Theorem 3.4].

If $D^{-1}N$ is a minor coprime MFD for an unstable plant P, consider a compensator C with minor coprime right MFD $C = YX^{-1}$. C stabilizes P if and only if the determinant of

$$D(z)X(z) + N(z)Y(z)$$

is free from zero in $\bar{U}^n$. See, e.g., [11, p. 77] for the 2-D case and [15, Theorem 2] for the general case.

By the Cauchy–Binet theorem, we have

$$\det[DX + NY] = \sum_{i=1}^{M} \alpha_i \beta_i,$$

where $\beta_1, \ldots, \beta_M$ are the maximal minors of $\begin{bmatrix} X \\ Y \end{bmatrix}$, with $\beta_1 = \det X$.

It follows obviously that a necessary condition for $P = D^{-1}N$ to be stabilizable is that there exist $M = \binom{m+l}{m}$ polynomials $\beta_1(z), \ldots, \beta_M(z)$ such that

$$\sum_{i=1}^{M} \alpha_i(z)\beta_i(z) \neq 0 \quad \text{for } z \in \bar{U}^n. \tag{3.3}$$

This condition is equivalent to that $\alpha_1, \ldots, \alpha_M$ have no common zero in $\bar{U}^n$ [11, 21].

Conversely, if such polynomials exist, a compensator $C = YX^{-1}$ can be constructed such that [23, 10, 11, 15]

$$\det[DX + NY] = \sum_{i=1}^{M} \alpha_i\beta_i \neq 0 \quad \text{on } \bar{U}^n. \tag{3.4}$$

It then follows that for a plant $P = D^{-1}N$ to be stabilizable it is necessary and sufficient that $\alpha_1, \ldots, \alpha_M$ have no common zero in $\bar{U}^n$. From the construction [11] of the compensator, it can be seen that a real compensator can always be found for a real plant which satisfies this condition.

For a 1-D system, minor coprimeness is equivalent to *zero coprimeness* [28] which means that the α_i's have no common zero at all. This implies that a 1-D system described with a minor coprime MFD is always stabilizable.

If the compensator $C = YX^{-1}$ itself can be chosen stable, then as a necessary condition $\beta_1(z)$ in (3.3) must be able to be chosen stable. Therefore we have the following theorem.

THEOREM 3.1. *Assume that P has a minor coprime MFD $P = D^{-1}N$.*

(i) *Let α_j, $j = 1, \ldots, M$, $M = \binom{m+l}{m}$ be the maximal order minors of $[D\ N]$ with $\alpha_1 = \det D$. A necessary condition for $P = D^{-1}N$ to be strongly stabilizable is that there are stable rational functions $h_2, \ldots, h_M$ such that*

$$\det D + \sum_{2 \leq j \leq M} h_j\alpha_j \neq 0 \quad \textit{on } \bar{U}^n.$$

(ii) *If $P = D^{-1}N$ is strongly stabilizable and is real, then a necessary condition for the existence of a real stable compensator is that the above h_j's can be chosen real.*

Recalling Theorems 2.1 and 2.5 gives the following theorem.

THEOREM 3.2. *Assume that P has a minor coprime MFD $P = D^{-1}N$. Let I be the ideal generated by $\alpha_2, \ldots, \alpha_M$ in $\mathbf{C}[z]$.*

(i) *A necessary condition for P to be strongly stabilizable is that $\det D(z)$ is 0-homotopic on $V(I) \cap \bar{U}^n$.*

(ii) *If P is strongly stabilizable and is real, then a necessary condition for the existence of a real stable compensator is that $\det D$ has an invariant sign on $V(I) \cap \bar{U}^n$.*

The following lemmas say that, instead of $V(I)$, it is equivalent to investigate the behavior of $\det D(z)$ on another variety $V(J)$, where J is the ideal generated by $n_{jk}(z)$, $1 \leq j \leq m, 1 \leq k \leq l$, the entries of $N(z)$.

LEMMA 3.3. *Assume $D^{-1}N$ is a minor coprime MFD for a stabilizable plant. Let $\alpha_1 = \det D, \alpha_2, \ldots, \alpha_M$ be the maximal order minors of $[D\ N]$, let I be the ideal generated by $\alpha_2, \ldots, \alpha_M$, and J be the ideal generated by n_{ij}, $1 \leq j \leq m, 1 \leq k \leq l$, the entries of $N(z)$. Then*

$$V(I) \backslash V(\det D) = V(J) \backslash V(\det D).$$

Proof. It is clear that

$$V(J) \subseteq V(I);$$

hence

$$V(J)\backslash V(\det D) \subseteq V(I)\backslash V(\det D).$$

Assume that

$$z_0 \in V(I)\backslash V(\det D).$$

If $z_0 \notin V(J)$, then there is an n_{jk} that is not zero at z_0. Since $\det D(z_0) \neq 0$, there are some $m-1$ columns of $D(z_0)$ independent of the kth column

$$[n_{1k}(z_0) \cdots n_{mk}(z_0)]^t$$

of $N(z_0)$. The corresponding minor of $[D\ N]$ is then not 0 at z_0. Thus $z_0 \notin V(I)$. This contradicts the assumption. Therefore

$$V(I)\backslash V(\det D) \subseteq V(J)\backslash V(\det D). \qquad \square$$

LEMMA 3.4. *With the same notations and assumptions as in Lemma* 3.3*, we have*

$$V(I) \cap \bar{U}^n = V(J) \cap \bar{U}^n.$$

Proof. Since $D^{-1}N$ is assumed to be a minor coprime MFD of a stabilizable plant, the maximum order minors necessarily do not have common zero on $\bar{U}^n$. In our notation, I is the ideal generated by all the minors excluding $\det D$; therefore we have

$$V(I) \cap \bar{U}^n \cap V(\det D) = \phi,$$
$$V(I) \cap \bar{U}^n = V(I) \cap \bar{U}^n\backslash V(\det D) = V(J) \cap \bar{U}^n\backslash V(\det D) \subseteq V(J) \cap \bar{U}^n.$$

On the other hand,

$$V(J) \cap \bar{U}^n \subseteq V(I) \cap \bar{U}^n.$$

This completes the proof. $\square$

The following theorem is obvious from Lemma 3.4 and Theorem 3.2.

THEOREM 3.5. *Suppose that P has a minor coprime MFD $D^{-1}N$. Let J be the ideal generated by the entries of N in $\mathbf{C}[z]$.*

(i) *A necessary condition for P to be strongly stabilizable is that* $\det D(z)$ *is* 0*-homotopic on $V(J) \cap \bar{U}^n$.*

(ii) *If P is strongly stabilizable and is real, then a necessary condition for the existence of a real stable compensator is that* $\det D$ *has an invariant sign on $V(J) \cap \bar{U}^n$.*

This theorem applies to all 1-D and 2-D systems, for which minor coprime MFDs always exist. For the 1-D case, the condition of (i) is trivial, because $V(I)$ consists of a finite number of discrete points. Furthermore, since the only self-conjugate components of $V(I) \cap \bar{U}^n$ are the real points, condition (ii) means exactly that $\det D$ has an invariant sign on $V(I) \cap \bar{U}^n \cap \mathbf{R}^n$. This is equivalent to the well-known *parity interlacing property* of Youla, Bongiorno, and Lu [27] and is sufficient for the existence of a real stable compensator; see Appendix A for more details.

Unfortunately, for 2-D and general n-D systems, we do not know if the conditions of (i) and (ii) in Theorems 3.2 and 3.5 are sufficient or not.

3.2. Necessary conditions for strong stabilizability of general MIMO systems. Let P be an n-D transfer matrix with a (not necessarily minor coprime) left MFD $D^{-1}N$. Let $F = [D\ N]$.

Let $\alpha_1, \alpha_2, \ldots, \alpha_M$ denote the $M = \binom{m+l}{l}$ maximal order minors of F, with $\alpha_1 = \det D$. Let d be the greatest common divisor of the $\alpha_i's$. The polynomials

$$b_1 = \frac{\alpha_1}{d}, \ldots, b_M = \frac{\alpha_M}{d} \tag{3.5}$$

are called *generating polynomials* of P and are independent of the choices of F up to a nonzero constant [14]. The following two propositions establish the stability and stabilizability conditions of an n-D system in terms of the generating polynomials.

PROPOSITION 3.6 (see [14]). *P is stable if and only if the first generating polynomial b_1 is free from 0 in $\bar{U}^n$.*

PROPOSITION 3.7 (see [15, 22]). *P is stabilizable if and only if the generating polynomials do not share a common zero in $\bar{U}^n$.*

In the following we assume the stabilizability of $P(z)$.

Let $e_1, \ldots, e_M$ be the generating polynomials of the compensator C. It is shown in [15] that the first generating polynomial of the resultant feedback system is

$$b_{H1} = r \sum_{j=1}^{M} b_j e_j, \tag{3.6}$$

where r is a nonzero constant.

If $P = D^{-1}N$ is strongly stabilizable, then the compensator C can be chosen stable. This implies that both e_1 and b_{H1} in the above equation are free from 0 in $\bar{U}^n$. Dividing the equation by e_1 and r, we have

$$\frac{b_{H1}}{re_1} = b_1 + \sum_{j=2}^{M} b_j \frac{e_j}{e_1}. \tag{3.7}$$

This leads to the following theorem.

THEOREM 3.8. (i) *Let b_j, $j = 1, \ldots, M$, $M = \binom{m+l}{m}$ be the generating polynomials of $P = D^{-1}N$. A necessary condition for P to be strongly stabilizable is that there exist stable rational functions $h_2, \ldots, h_M$ such that*

$$b_1 + \sum_{2 \le j \le M} h_j b_j \neq 0 \quad \text{on } \bar{U}^n.$$

(ii) *If $P = D^{-1}N$ is strongly stabilizable and is real, then a necessary condition for the existence of a real stable compensator is that the above h_j's can be chosen real.*

In view of Theorems 2.1 and 2.5 of section 2, we have the following theorem.

THEOREM 3.9. *Let $b_1, b_2, \ldots, b_M$ be the generating polynomials of $P = D^{-1}N$, and I' be the ideal generated by $b_2, \ldots, b_M$ in $\mathbf{C}[z]$.*

(i) *A necessary condition for P to be strongly stabilizable is that b_1 is 0-homotopic on $V(I') \cap \bar{U}^n$.*

(ii) *If P is strongly stabilizable and is real, then a necessary condition for the existence of a real stable compensator is that b_1 has an invariant sign on $V(I') \cap \bar{U}^n$.*

If $P = D^{-1}N$ is a *minor coprime* MFD, then the generating polynomials are exactly the maximal order minors of $[D\ N]$. In this case Theorems 3.8 and 3.9 reduce to Theorems 3.1 and 3.2, respectively.

3.3. Examples.

Example 1 (real strongly stabilizable).

$$F = [D\ N] = \begin{bmatrix} z_2^2 & 1 & z_1 & z_2 \\ -1 & z_3^2 & z_3 & 0 \end{bmatrix}.$$

The minors are

$$(\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6) = \big(1 + z_2^2 z_3^2, z_1 + z_2^2 z_3, z_2, z_3 - z_1 z_3^2, -z_2 z_3^2, -z_2 z_3\big).$$

Obviously $D^{-1}N$ is minor coprime. In accordance with our previous notations, $I = (\alpha_1, \ldots, \alpha_6)$, $J = (z_1, z_2, z_3)$. We have

$$V(I) \cap \bar{U}^3 = V(J) \cap \bar{U}^3 = \{(0, 0, 0)\}.$$

The necessary conditions of Theorems 3.2 and 3.5 are satisfied. For this plant we have the following stable real compensator $C = YX^{-1}$ with

$$\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ z_2 & 0 \\ -z_1 & z_3 \end{bmatrix}.$$

Example 2 (strongly stabilizable, but not real strongly stabilizable).

$$F = \big[z_1, z_1^2 + z_2 z_3 - z_2 - 2, z_3\big].$$
$$V(J) \cap \bar{U}^3 = V\big(z_1^2 + z_2 z_3 - z_2 - 2, z_3\big) \cap \bar{U}^3 = \{(-1, -1, 0), (1, -1, 0)\}$$

is a discrete point set, and the condition (i) for strong stabilizability of Theorem 3.5 is trivial. By trial, we found a *complex* stable compensator $C = YX^{-1}$,

$$\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} 0.5z_1 + i \\ -1 \\ z_2 \end{bmatrix}.$$

In fact, it is not difficult to check that the polynomial

$$(0.5z_1 + i)z_1 - \big(z_1^2 + z_2 z_3 - z_2 - 2\big) + z_2 z_3 = -0.5z_1^2 + iz_1 + z_2 + 2$$

is free from 0 in $\bar{U}^2$ and hence in $\bar{U}^3$. However, z_1 has opposite signs at the two discrete points of $\bar{U}^3 \cap V(J)$, thus violating condition (ii) in Theorem 3.5. There is no real stable compensator. Using the Gröbner basis method [5, 11, 24], we can find a real compensator $\left[\begin{smallmatrix} z_1 \\ -1 \\ z_2 \end{smallmatrix}\right]$, which is, however, not stable.

Example 3 (not minor coprime MFD).

$$F = \begin{bmatrix} d(z_1, z_2, z_3) & 0 & z_1 z_2 \\ 0 & d(z_1, z_2, z_3) & 1 \end{bmatrix},$$
$$d = z_1^2 + z_2^2 + z_3^2 - 1.$$

The minors are

$$\alpha_1 = d^2, \qquad \alpha_2 = d, \qquad \alpha_3 = -dz_1 z_2.$$

$D^{-1}N$ is not minor coprime. The generating polynomials are

$$(b_1, b_2, b_3) = (d, 1, -z_1 z_2).$$

We have

$$1 \cdot b_1 + 5 \cdot b_2 = z_1^2 + z_2^2 + z_3^2 + 4,$$

a Hurwitz polynomial. Using the method of [10, 15], one can find a compensator $C = YX^{-1}$,

$$\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} d+5 & -z_1 z_2 \\ 0 & d \\ 0 & 5d \end{bmatrix}.$$

$YX^{-1} = [0\ 5]$ is a right MFD of a stable system.

Example 4 (stabilizable, but not strongly stabilizable).

$$P = \frac{1 - 4z_1 z_2}{z_1} \begin{bmatrix} z_2 + 1 & z_2 \\ z_1 & z_1 \end{bmatrix},$$
$$F = \begin{bmatrix} z_1 & 0 & (z_2+1)f & z_2 f \\ 0 & z_1 & z_1 f & z_1 f \end{bmatrix},$$

where $f = 1 - 4z_1 z_2$. The 2×2 minors are

$$(\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6) = \big(z_1^2, z_1^2 f, z_1^2 f, -z_1(z_2+1)f, -z_1 z_2 f, z_1 f^2\big).$$

The generating polynomials are

$$(b_1, b_2, b_3, b_4, b_5, b_6) = \big(z_1, z_1 f, z_1 f, -(z_2+1)f, -z_2 f, f^2\big).$$

The plant is stabilizable because

$$V(b_1, b_6) \cap \bar{U}^2 = \phi.$$

But

$$V(b_2, \ldots, b_6) \cap \bar{U}^2 = V(1 - 4z_1 z_2) \cap \bar{U}^2$$

has a cycle

$$\gamma : t \longrightarrow \left(\frac{1}{2} e^{i2\pi t}, \frac{1}{2} e^{-i2\pi t}\right), \quad t \in [0, 1]$$

which is mapped by z_1 to a cycle $\{\frac{1}{2} e^{i2\pi t},\ 0 \le t \le 1\}$ in $\mathbf{C}^*$, which has winding number 1 around the origin. Thus the system is not strongly stabilizable.

4. MISO and SIMO systems. For two special classes of n-D systems, the MISO and SIMO systems, the necessary conditions for strong stabilizability given in Theorems 3.8 and 3.9 are actually sufficient. In the following theorem, the conditions are reformed for convenience of exposition. Their equivalence with that given in Theorem 3.9 is not difficult to verify.

THEOREM 4.1. *Let $P(z)$ be either an m-input/1-output or a 1-input/m-output system, described by the following corresponding transfer matrices:*

$$P(z) = d^{-1}(z)\big[n_1(z)\cdots n_m(z)\big] \quad \textit{and} \tag{4.1}$$

$$P(z) = \begin{bmatrix} n_1(z) \\ \vdots \\ n_m(z) \end{bmatrix} d^{-1}(z). \tag{4.2}$$

Let J be the ideal generated by $n_1(z), \ldots, n_m(z)$. Then

(i) *P is strongly stabilizable (by a complex compensator) if and only if $d(z)$ is 0-homotopic on $V(J) \cap \bar{U}^n$;*

(ii) *if P is a strongly stabilizable real plant, then a real stable compensator exists if and only if $d(z)$ has an invariant sign on the self-conjugate components of $V(J) \cap \bar{U}^n$.*

Proof. We give a proof for the SIMO case. Necessity: P has a left MFD

$$P = D^{-1}N = \begin{bmatrix} d & 0 & \cdots & 0 \\ 0 & d & & \vdots \\ \vdots & & \ddots & 0 \\ 0 & \cdots & 0 & d \end{bmatrix}^{-1} \begin{bmatrix} n_1 \\ \vdots \\ n_m \end{bmatrix}.$$

The maximal order minors of $[D\ N]$ are

$$d^m, d^{m-1}n_1, \ldots, d^{m-1}n_m,$$

and the generating polynomials are

$$d, n_1, \ldots, n_m.$$

The necessary part of the conditions is then obvious by Theorem 3.9. Sufficiency: By Theorems 2.1 and 2.5, there exist $y(z)(\neq 0 \text{ on } \bar{U}^n)$, $x_1(z), \ldots, x_m(z)$, real under condition (ii), such that

$$y(z)d(z) + x_1(z)n_1(z) + \cdots + x_m(z)n_m(z) \neq 0 \quad \text{on } \bar{U}^n.$$

Let

$$C(z) = y^{-1}X = y^{-1}(z)\big[x_1(z)\cdots x_m(z)\big].$$

It suffices to show that $H(P, C)$ in (1.2) is stable. $H(P, C)$ is stable if and only if

$$\begin{aligned} H'(P,C) &= \begin{bmatrix} P(I+CP)^{-1}C & P(I+CP)^{-1} \\ (I+CP)^{-1}C & (I+CP)^{-1} \end{bmatrix} \\ &= \begin{bmatrix} N(yd+XN)^{-1}X & N(yd+XN)^{-1}y \\ d(yd+XN)^{-1}X & d(yd+XN)^{-1}y \end{bmatrix} \\ &= \begin{bmatrix} N \\ d \end{bmatrix} (yd + x_1n_1 + \cdots + x_mn_m)^{-1} [Xy] \end{aligned} \tag{4.3}$$

is stable. Actually it is stable from the conditions. Therefore $C(z)$ is a stable compensator, real under condition (ii).

The proof for the MISO case is similar by using the alternate expression (1.3) in section 1 for $H(P, C)$. □

5. On sufficient conditions for strong stabilizability of MIMO systems. Based on the fact that all stable complex (or real) rational functions in one variable form a Euclidean domain, the necessary conditions in Theorem 3.5 have been constructively proven to be sufficient for 1-D systems, too; see Appendix A and [23, section 4.4]. The construction of a stable compensator for a 1-D system relies essentially on the Euclidean division algorithm in the domains of one-variable stable rational functions. But the domains of stable rational functions in two or more variables are no longer Euclidean and the method of [23] cannot be applied. Although we have not met any counterexample which disproves the sufficiency of the necessary conditions in Theorems 3.1, 3.2, 3.5, 3.8, and 3.9, we have not been able to prove the sufficiency.

In this section, by extending the analytic method used in section 2.1, we give a condition which is sufficient, but not necessary, for the strong stabilizability of a certain class of complex MIMO n-D plants. We also discuss some difficulties in adopting existing algebraic methods for the construction of stable compensators for MIMO n-D systems.

5.1. A sufficient condition for complex strong stabilizability.

THEOREM 5.1. *Let $D(z)$ and $N(z)$ be two complex polynomial $m \times m$ matrices. A sufficient condition for the existence of a complex polynomial $m \times m$ matrix $X(z)$ such that*

$$\det\big[D(z) + N(z)X(z)\big] \neq 0 \quad \text{on } \bar{U}^n \tag{5.1}$$

is that $D(z)$ has a single-valued logarithmic matrix function $\log D(z)$ on $V(\det N(z)) \cap \bar{U}^n$.

Proof. Let $\mathcal{O}$ be the sheaf of germs of analytic functions on some open polydisc $\Omega \supset \bar{U}^n$. Let $\mathcal{O}^{m\times m}$ be a free sheaf of modules of rank $m \times m$ over $\mathcal{O}$; let $\mathcal{N} = N \cdot \mathcal{O}^{m\times m}$ be a subsheaf of $\mathcal{O}^{m\times m}$ obtained by matrix multiplication with N, which is finitely generated. We have the following exact sequence of sheaves:

$$0 \to \mathcal{N} \to \mathcal{O}^{m\times m} \to \mathcal{O}^{m\times m}/\mathcal{N} \to 0, \tag{5.2}$$

which induces a long exact sequence of modules over the ring of analytic functions

$$0 \to \Gamma(\mathcal{N}, \Omega) \to \Gamma(\mathcal{O}^{m\times m}, \Omega) \xrightarrow{\varphi} \Gamma(\mathcal{O}^{m\times m}/\mathcal{N}, \Omega) \to H^1(\mathcal{N}) \to \cdots . \tag{5.3}$$

Since $\mathcal{N}$ is finitely generated, it is a coherent analytic sheaf. Therefore we have

$$H^1(\mathcal{N}) = 0, \tag{5.4}$$

and φ is a surjective mapping.

By assumption $\log D(z)$ is defined over $V(\det N)$. This can be analytically extended to an open neighborhood U_0 containing $V(\det N)$. Let

$$U_1 = \Omega \backslash V(\det N).$$

Consider the $m \times m$ zero matrix $\mathbf{0}$ as a section of $\mathcal{O}^{m\times m}$ over U_1. On $U_0 \cap U_1$, we have

$$\log D(z) - \mathbf{0} = N(z)\big(N(z)^{-1} \log D(z)\big).$$

This implies that $\log D(z)$ can actually be viewed as a global section of the quotient sheaf $\mathcal{O}^{m\times m}/\mathcal{N}$ on Ω, which satisfies

$$e^{\log D(z)} = D(z) \quad \text{for } z \in V(\det N) \cap \Omega. \tag{5.5}$$

Since φ is surjective, there exists a global section $G(z)$ of $\mathcal{O}^{m\times m}$ on Ω, such that

$$\varphi\big(G(z)\big) = \log D(z) \quad \text{for } z \in V(\det N) \cap \Omega. \tag{5.6}$$

Clearly, $\varphi(D(z)) = e^{\log D(z)}$ and $\varphi(e^{G(z)}) = e^{\varphi(G(z))}$ in $\Gamma(\mathcal{O}^{m\times m}/\mathcal{N}, \Omega)$, we have

$$\varphi\big(e^{G(z)} - D(z)\big) = 0 \quad \text{in } \Gamma\big(\mathcal{O}^{m\times m}/\mathcal{N}, \Omega\big); \tag{5.7}$$

therefore

$$e^{G(z)} - D(z) \in \Gamma(\mathcal{N}, \Omega). \tag{5.8}$$

That is, there exists an $H(z) \in \Gamma(\mathcal{O}^{m\times m}, \Omega)$ such that

$$e^{G(z)} = D(z) + N(z) \cdot H(z) \quad \text{on } \Omega. \tag{5.9}$$

Since $\det e^{G(z)} \neq 0$, approximating $H(z)$ by a complex polynomial matrix $X(z)$, we have

$$\det\big[D(z) + N(z) \cdot X(z)\big] \neq 0 \quad \text{on } \bar{U}^n.$$

This completes the proof. □

As an immediate consequence of this theorem, we have the following sufficient condition for strong stabilizability.

COROLLARY 5.2. *Let $D(z)^{-1}N(z)$ be a minor coprime MFD of a complex $m \times l$ plant $P(z)$, $l \geq m$. If there is some $m \times m$ submatrix $N_0(z)$ of $N(z)$, such that $D(z)$ has a single-valued logarithmic matrix function $\log D(z)$ on $V(\det N_0(z)) \cap \bar{U}^n$, then $P(z)$ is strongly stabilizable.*

In Example 1 of section 3.3,

$$[D\ N] = \begin{bmatrix} z_2^2 & 1 & z_1 & z_2 \\ -1 & z_3^2 & z_3 & 0 \end{bmatrix}.$$

It can be verified (e.g., by using the theory of operational calculus [7]; see Appendix B of this paper) that $D(z) = \left[\begin{smallmatrix} z_2^2 & 1 \\ -1 & z_3^2 \end{smallmatrix}\right]$ has a single-valued analytic logarithmic function over $V(\det N) \cap \bar{U}^3 = V(-z_2 z_3) \cap \bar{U}^3$.

If $D(z) = \operatorname{diag}(d_1(z), \ldots, d_m(z))$, a diagonal matrix, then its logarithmic function can be defined as

$$\log D(z) = \operatorname{diag}\big(\log d_1(z), \ldots, \log d_m(z)\big).$$

This yields the following simpler criterion for a strong stabilizability test for a class of plants that have a special form of minor coprime MFD.

COROLLARY 5.3. *Let $D(z)^{-1}N(z)$ be a minor coprime MFD of a complex $m \times l$ plant $P(z)$, $l \geq m$ with $D(z) = \operatorname{diag}\big(d_1(z), \ldots, d_m(z)\big)$, a diagonal matrix. If there is some $m \times m$ submatrix $N_0(z)$ of $N(z)$, such that, for each $i = 1, \ldots, m$, $d_i(z)$ has a single-valued logarithmic function $\log d_i(z)$ on $V(\det N_0(z)) \cap \bar{U}^n$; or equivalently, each $d_i(z)$ is 0-homotopic on $V(\det N_0(z)) \cap \bar{U}^n$, then $P(z)$ is strongly stabilizable.*

Example 5.

$$[D\ N] = \begin{bmatrix} 1-4z_1z_2 & 0 & z_2+1 & z_2 \\ 0 & 1 & z_1 & z_1 \end{bmatrix}.$$

$\det N = z_1$. The condition of Corollary 5.3 is satisfied. We actually have a stable compensator $C = YX^{-1}$ with

$$\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 4z_1 & 0 \end{bmatrix}.$$

However, both conditions of the above corollaries are not necessary, as demonstrated by the following example.

Example 6.

$$F = [D\ N] = \begin{bmatrix} z_1 & 0 & 1 & 0 \\ 0 & z_2 & 0 & 1-4z_1z_2 \end{bmatrix}.$$

We have $\det D(z) + \frac{1}{4}\det N(z) = z_1z_2 + \frac{1}{4}(1-4z_1z_2) = \frac{1}{4}$. But it is not possible to define a single-valued $\log D(z)$ on $V(\det N(z)) \cap \bar{U}^2$ (see Appendix B). Nevertheless, for this plant, we have the following stable real compensator $C = YX^{-1}$ with

$$\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 3z_1 & 1 \\ --1 & 0 \end{bmatrix}.$$

Actually, $\det\left([D\ N]\left[\begin{smallmatrix} X \\ Y \end{smallmatrix}\right]\right) = \det[DX+NY] = \det\left[\begin{smallmatrix} 4z_1 & 1 \\ -1+4z_1z_2 & z_2 \end{smallmatrix}\right] = 1$. Note that while $\det\left[\begin{smallmatrix} 4z_1 & 1 \\ -1+4z_1z_2 & z_2 \end{smallmatrix}\right] = 1$, and has a logarithmic function 0 on $\bar{U}^2$, $\left[\begin{smallmatrix} 4z_1 & 1 \\ -1+4z_1z_2 & z_2 \end{smallmatrix}\right]$ does not have a logarithmic function on $\bar{U}^2$, even though $\bar{U}^2$ is simply connected. In fact, it can be shown that $\left[\begin{smallmatrix} 4z_1 & 1 \\ 0 & z_2 \end{smallmatrix}\right]$ does not have a logarithmic function on $V(-1+4z_1z_2)\cap\bar{U}^2$ (see Appendix B). Theorem 5.1 actually requires the resulting matrix have a logarithmic function. This is stronger than what we need for strong stabilizability, as is illustrated by the above example.

5.2. Difficulties in an algebraic approach. Surely it is desirable to establish a method that not only gives a sufficient *and* necessary condition for strong stabilizability, but also constructs a stable compensator when it exists. However, even when an n-D MIMO system *is* strongly stabilizable, existing algebraic methods for constructing a compensator do not ensure the resulting compensator be stable itself. For instance, the method of [10], applied to Example 1 of section 3.3, goes as follows:

$$\alpha_1 + z_2z_3\alpha_6 = \det D + z_2z_3 \det N = 1.$$

Let D^{adj} and N^{adj} denote the adjoint matrices of D and N, respectively. Let

$$\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} D^{adj} \\ \mathbf{0} \end{bmatrix} + z_2z_3 \begin{bmatrix} \mathbf{0} \\ N^{adj} \end{bmatrix} = \begin{bmatrix} z_3^2 & -1 \\ 1 & z_2^2 \\ 0 & -z_2^2z_3 \\ -z_2z_3^2 & z_1z_2z_3 \end{bmatrix},$$

$[DX + NY] = DD^{adj} + z_2 z_3 N N^{adj} = (\alpha_1 + z_2 z_3 \alpha_6)\left[\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right] = \left[\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right]$. $X^{-1}Y$ is the resulting compensator, which is itself unstable.

A possible approach by making use of the existing algebraic method for constructing a stable compensator for 1-D system is as follows. Let

$$D^{-1}N = D(z_1, z_2)^{-1} N(z_1, z_2)$$

be a 2-D system. Let

$$\alpha_1 = \det D, \quad \alpha_2, \ldots, \alpha_M$$

be the maximum order minors of [D N]. Assume there exist polynomials $\beta_2, \ldots, \beta_M$, such that

$$\det D + \beta_2 \alpha_2 + \cdots + \beta_M \alpha_M = u(z_1, z_2) \neq 0 \quad \forall (z_1, z_2) \in \bar{U}^2.$$

Viewing the entries of D and N, and $u(z_1, z_2)$ as elements of $K(z_1)[z_2]$, $K = \mathbf{C}$ or $\mathbf{R}$, the ring of polynomials in a single variable z_2 over the field of rational functions $K(z_1)$. Since $K(z_1)[z_2]$ is a Euclidean domain, the algorithm of [23] can be used to give a matrix $Y'(z_1, z_2)$ such that

$$\det \left[D(z_1, z_2) + N(z_1, z_2) Y'(z_1, z_2) \right] = u(z_1, z_2).$$

There $Y'(z_1, z_2)$ has entries belonging to $K(z_1)[z_2]$ and can be written as

$$Y'(z_1, z_2) = \frac{1}{d(z_1)} Y(z_1, z_2),$$

with $d(z_1)$ in $K[z_1]$ and the entries of $Y(z_1, z_2)$ in $K[z_1, z_2]$.

If $d(z_1)$ is a 1-D Hurwitz polynomial, then Y' is already a stable compensator. In general, $d(z_1)$ may have zeros in $\bar{U}^1$. In this case, if we have a method that can remove the zeros of $d(z_1)$ in $\bar{U}^1$ from $Y'(z_1, z_2)$, while keeping the resulting determinant $u(z_1, z_2)$ to be nonzero over $\bar{U}^2$, then we will be able to construct a stable compensator. Unfortunately, after much effort, we have not been able to find such a method.

6. Conclusion. We conclude this paper with open problems for future research.

1. For a finitely generated ideal J, the set $V(J) \cap \bar{U}^n$ can be viewed as a semi-algebraic set and its homology groups can be computed by the *cylindrical algebraic decomposition* [6, 1, 19]. For the case that the ideal J is generated by one polynomial, computational procedures for testing the criterion in Theorem 2.1 and the sign consistency condition in Theorem 2.5 have been given based on the cylindrical algebraic decomposition [25, 26]. The extension to the general case (J be generated by a finite number of polynomials) is straightforward.

Unfortunately, our method is not constructive in that it does not give a solution to inequality (2.1) in section 2. The development of an algorithmic method to solve inequality (2.1) remains open.

2. Though it is also possible to explore further advanced analysis method to fill the gap between the necessary conditions and the sufficient one presented in this paper, it is desirable to have an algebraic constructive method, as that for a 1-D MIMO system.

We believe that an adequate preparation has been made by our work for the final solution of the problem of the strong stabilizability of n-D MIMO systems, which is

most likely to be achieved by a fundamentally new algebraic approach that considers standard representations of MIMO n-D systems, analogous in function to that for conventional 1-D systems, such as the Smith–McMillan forms, which have played an essential role in stable compensator construction.

On the other hand, the application of the Euclidean algorithm has been indispensable to the construction of the Smith–McMillan forms, as well as to the construction of stable compensators for 1-D systems. Therefore a novel promising algebraic framework to address the above issue in linear MIMO n-D systems should be one in which adequate algorithms can be applied. In the recent behavioral approach to the study of n-D systems [18, 8, 29, 17], it seems relatively easy to apply the Gröbner basis algorithms, which are in a sense alternatives of Euclidean algorithm for dealing with algorithmic problems in multivariate polynomials and modules. However, we are not sure if this approach can be easily adapted for solving our problems.

To conclude, it is an interesting topic for future research to establish a new algebraic framework to solve old open problems, as the one remains unsolved in this paper.

Appendix A. Strong stabilizability of 1-D systems. Let $P(z)$ be a 1-D system with a minor coprime left MFD

$$P(z) = D^{-1}N = \begin{bmatrix} d_{11} & \cdots & d_{1m} \\ \vdots & \cdots & \vdots \\ d_{m1} & \cdots & d_{mm} \end{bmatrix}^{-1} \begin{bmatrix} n_{11} & \cdots & n_{1l} \\ \vdots & \cdots & \vdots \\ n_{m1} & \cdots & n_{ml} \end{bmatrix}.$$

Let $b(z)$ be the greatest common divisor of $n_{ij}(z), 1 \le i \le m, 1 \le j \le l$. Then $b(z)$ is the single generator of the ideal $J = (n_{ij}(z), 1 \le i \le m, 1 \le j \le l) \subset \mathbf{C}[z]$. $b(z)$ is equal to the *smallest invariant factor* of $P(z)$, which is defined as the smallest of the numerators when $P(z)$ is written in the Smith–McMillan form [23, p. 401]. Note that b can be chosen real if P is real.

Let $a(z) = \det D(z)$. The minor coprimeness of $D(z)^{-1}N(z)$ implies that $a(z)$ and $b(z)$ have no common zero. Since $V(b)$ is discrete, by Theorem 2.1, there exists a *complex* stable rational function $r(z)$ such that

$$a(z) + b(z)r(z) \neq 0 \quad \text{for } z \in \bar{U}^1.$$

The following lemma is easy to prove.

LEMMA A.1. (i) *Let*

$$S_{\boldsymbol{C}} = \{f(z)/g(z) : f(z),\ g(z) \in \boldsymbol{C}[z],\ g(z) \neq 0 \text{ on } \bar{U}^1\} \subset \boldsymbol{C}(z),$$

the ring of all stable complex rational functions. For each $s \in S_{\boldsymbol{C}}$, define the degree $\deg s$= *the number of zeros of s in $\bar{U}^1$. Then with this degree $S_{\boldsymbol{C}}$ is a Euclidean domain.*

(ii) *Let*

$$S_{\boldsymbol{R}} = S_{\boldsymbol{C}} \cap \boldsymbol{R}(z),$$

the ring of real stable rational functions. Then with the degree induced from that defined in $S_{\boldsymbol{C}}$, $S_{\boldsymbol{R}}$ is a Euclidean domain.

Based on the Euclidean property of $S_{\boldsymbol{C}}$, a complex stable rational matrix $R(z)$ can be constructed such that [23, section 4.4]

$$\det\big[D(z) + N(z)R(z)\big] = a(z) + b(z)r(z).$$

This means that P is stabilized by the stable compensator $R(z)$.

If $P = D^{-1}N$ is a real plant, the condition that $\det D$ has an invariant sign on $V(J) = V(b)$ guarantees the existence of a real stable rational function $r(z)$, such that

$$a(z) + b(z)r(z) \neq 0 \quad \text{for } z \in \bar{U}^1.$$

Using the Euclidean property of $S_{\mathbf{R}}$, one can construct a real stable rational matrix R such that

$$\det\big[D(z) + N(z)R(z)\big] = a(z) + b(z)r(z) \neq 0 \quad \text{for } z \in \bar{U}^1.$$

It is easy to see that $a(z) = \det D(z)$ is the least common denominator of the entries of $P(z)$ [23, p. 90] and that the zeros of the plant $P(z)$ are exactly the zeros of $b(z)$ [23, 27].

The condition that $a(z)$ has an invariant sign at the real zeros of $b(z)$ in $\bar{U}^1$ is equivalent to that the numbers of poles of $P(z)$ lying between two adjacent zeros on the interval $[-1, 1]$ are always even. This is the *parity interlacing property* on the interval $[-1, 1]$. By transforming the unit disc to the right halfplane, one obtains the same property on the right half real line [27, 25].

Appendix B. Operational calculus on matrix. For some z, consider $D(z)$ as a linear operator on a finite-dimensional linear space. Let $\sigma(D(z)) \subset \mathbf{C}^*$ denote the set of its eigenvalues. As an inverse of the exponential map, an analytic logarithmic function of $D(z)$ can be defined by the following integral:

$$\log D(z) = \frac{1}{2\pi i}\int_B \log(\lambda)\big(\lambda I - D(z)\big)^{-1} d\lambda, \tag{B.1}$$

where B is the boundary of some domain which contains the closure of some open set containing $\sigma(D(z))$ and consists of a finite number of closed rectifiable Jordan curves. Clearly, $\log D(z)$ is single valued if the domain with boundary B does not contain the origin in $\mathbf{C}^*$.

In Example 1, $D(z) = \left[\begin{smallmatrix} z_2^2 & 1 \\ -1 & z_3^2 \end{smallmatrix}\right]$ and $N(z) = \left[\begin{smallmatrix} z_1 & z_2 \\ z_3 & 0 \end{smallmatrix}\right]$. The eigenvalues of $D(z)$ are

$$\lambda = \frac{1}{2}\left(z_2^2 + z_3^3 \pm \sqrt{\big(z_2^2 - z_3^3\big)^2 - 4}\right). \tag{B.2}$$

It is easy to see that the union of the sets of eigenvalues $\cup_{z \in V(z_2 z_3) \cap \bar{U}^3} \sigma(D(z))$ does not intersect with the real axis, and can be contained in a simply connected open domain not containing the origin in $\mathbf{C}^*$. With B being the boundary of this domain, $\log D(z)$ defined in (B.1) is a single-valued analytic logarithmic function in z because λ in (B.2) varies analytically in z.

On the other hand, if $\log D(z)$ is defined as a single-valued matrix function, then by the *spectral mapping theorem* [7, p. 569], the eigenvalues of $D(z)$ have single-valued logarithms which are the eigenvalues of $\log D(z)$.

In Example 6, the eigenvalues of $D(z)$ are z_1 and z_2, which are not 0-homotopic on $V(\det N(z)) \cap \bar{U}^2 = V(1 - 4z_1 z_2) \cap \bar{U}^2$. Therefore $D(z)$ does not have a single-valued logarithm on $V(\det N(z)) \cap \bar{U}^2$. For the same reason, $\left[\begin{smallmatrix} 4z_1 & 1 \\ -1+4z_1 z_2 & z_2 \end{smallmatrix}\right]$ does not have a logarithm on $V(1 - 4z_1 z_2) \cap \bar{U}^2$.

BOUNDARY CONTROLLABILITY OF THERMOELASTIC PLATES VIA THE FREE BOUNDARY CONDITIONS*

GEORGE AVALOS† AND IRENA LASIECKA‡

Abstract. Controllability properties of a partial differential equation (PDE) model describing a thermoelastic plate are studied. The PDE is composed of a Kirchoff plate equation coupled to a heat equation on a bounded domain, with the coupling taking place on the interior and boundary of the domain. The coupling in this PDE is parameterized by $\alpha > 0$. Boundary control is exerted through the (two) free boundary conditions of the plate equation and through the Robin boundary condition of the temperature. These controls have the physical interpretation of inserted forces and moments and prescribed temperature, respectively, all of which act on the edges of the plate. The main result here is that under such boundary control, and with initial data in the basic space of well-posedness, one can simultaneously control the displacement of the plate *exactly* and the temperature *approximately*. Moreover, the thermal control may be taken to be arbitrarily smooth in time and space, and the thermal control region may be any nonempty subset of the boundary. This controllability holds for arbitrary values of the coupling parameter α, with the optimal controllability time in line with that seen for uncoupled Kirchoff plates.

Key words. partial differential equations, exact-approximate controllability

1. Introduction.

1.1. Statement of the problem. Throughout, Ω will be a bounded open subset of $\mathbb{R}^2$ with sufficiently smooth boundary $\Gamma = \overline{\Gamma_0} \cup \overline{\Gamma_1}$, with both Γ_0 and Γ_1 being open, with Γ_0 being possibly empty, and satisfying $\overline{\Gamma_0} \cap \overline{\Gamma_1} = \varnothing$. Furthermore, Γ_2 will be any open and nonempty subset of Γ_1. With this geometry, we shall consider here the following thermoelastic system on finite time $(0, T)$:

$$
\left\{
\begin{array}{l}
\left\{ \begin{array}{l} \omega_{tt} - \gamma \Delta \omega_{tt} + \Delta^2 \omega + \alpha \Delta \theta = 0 \\ \beta \theta_t - \eta \Delta \theta + \sigma \theta - \alpha \Delta \omega_t = 0 \end{array} \right. \quad \text{on } (0,T) \times \Omega; \\
\\
\omega = \dfrac{\partial \omega}{\partial \nu} = 0 \ \text{ on } (0,T) \times \Gamma_0; \\
\\
\left\{ \begin{array}{l} \Delta \omega + (1-\mu) B_1 \omega + \alpha \theta = u_1 \\ \dfrac{\partial \Delta \omega}{\partial \nu} + (1-\mu) \dfrac{\partial B_2 \omega}{\partial \tau} - \gamma \dfrac{\partial \omega_{tt}}{\partial \nu} + \alpha \dfrac{\partial \theta}{\partial \nu} = u_2 \end{array} \right. \quad \text{on } (0,T) \times \Gamma_1; \\
\\
\dfrac{\partial \theta}{\partial \nu} + \lambda \theta = \left\{ \begin{array}{ll} u_3 & \text{on } (0,T) \times \Gamma_2, \\ 0 & \text{on } (0,T) \times \Gamma \backslash \Gamma_2, \end{array} \right. \qquad \lambda \geq 0; \\
\\
\omega(t=0) = \omega_0,\ \omega_t(t=0) = \omega_1,\ \theta(t=0) = \theta_0 \quad \text{on } \Omega.
\end{array}
\right. \tag{1.1}
$$

Here, α, β, η, and σ are positive constants. The positive constant γ is proportional to the thickness of the plate and assumed to be small with $0 < \gamma \leq M$. The boundary operators B_i are given by

$$B_1\omega \equiv 2\nu_1\nu_2\frac{\partial^2\omega}{\partial x\partial y} - \nu_1^2\frac{\partial^2\omega}{\partial y^2} - \nu_2^2\frac{\partial^2\omega}{\partial x^2} \text{ and } B_2\omega \equiv (\nu_1^2 - \nu_2^2)\frac{\partial^2\omega}{\partial x\partial y} + \nu_1\nu_2\left(\frac{\partial^2\omega}{\partial y^2} - \frac{\partial^2\omega}{\partial x^2}\right). \tag{1.2}$$

The constant $\mu \in (0, \frac{1}{2})$ is the familiar Poisson ratio, and $\nu = [\nu_1, \nu_2]$ denotes the outward unit normal to the boundary. Here and throughout we shall make the following geometric assumption on the (uncontrolled) portion of the boundary Γ_0:

$$\text{with } \overline{h}(x,y) \equiv [x - x_0, y - y_0], \exists\ \{x_0, y_0\} \in \mathbb{R}^2 \text{ such that } \overline{h}(x,y)\cdot\nu \leq 0 \text{ on } \Gamma_0. \tag{1.3}$$

The PDE model (1.1), with boundary functions $u_1 = u_2 = 0$ and $u_3 = 0$, mathematically describes an uncontrolled Kirchoff plate subjected to a thermal damping, with the displacement of the plate represented by the function $\omega(t,x,y)$ and the temperature given by the function $\theta(t,x,y)$ (see [11] for a derivation of this model). The given control variables $u_1(t,x)$ and $u_2(t,x)$ are defined on the portion of the boundary $(0,T)\times\Gamma_1$; the control $u_3(t,x)$ is defined on $(0,T)\times\Gamma_2$.

Making the denotation

$$H^k_{\Gamma_0}(\Omega) \equiv \left\{\varpi \in H^k(\Omega) : \left.\frac{\partial^j\varpi}{\partial\nu^j}\right|_{\Gamma_0} = 0 \text{ for } j = 0, ..., k-1\right\}, \tag{1.4}$$

we will throughout take the initial data $[\omega_0, \omega_1, \theta_0]$ to be in $H^2_{\Gamma_0}(\Omega)\times H^1_{\Gamma_0}(\Omega)\times L^2(\Omega)$. For initial data in these spaces and controls $u_1 = u_2 = 0$ and $u_3 = 0$, one can show the well-posedness of (1.1) with the corresponding solution $[\omega, \omega_t, \theta]$ being in $C([0,T]; H^2_{\Gamma_0}(\Omega)\times H^1_{\Gamma_0}(\Omega)\times L^2(\Omega))$ (see, e.g., [11] and [2]). In this paper, we will study controllability properties of solutions of (1.1) under the influence of boundary control functions in the following spaces:

$$[u_1, u_2, u_3] \in L^2(0,T; L^2(\Gamma_1)\times H^{-1}(\Gamma_1))\times C^r(\Sigma_{2,T}), \text{ where } r > 0 \text{ and } \Sigma_{2,T} = (0,T)\times\Gamma_2. \tag{1.5}$$

For arbitrary $[u_1, u_2, u_3]$ of such smoothness, the corresponding solution $[\omega, \omega_t, \theta]$ will be in the "large" space $C([0,T]; [D(\mathcal{A}^*_\gamma)]')$ (see the definition of $D(\mathcal{A}^*_\gamma)$ in (1.49)). In particular, we intend to address, on the finite time interval $[0,T]$, the question of *exact-approximate controllability* (this term being originally coined in [6]). That is to say, for given data $[\omega_0, \omega_1, \theta_0]$ (initial) and $\left[\omega_0^T, \omega_1^T, \theta_0^T\right]$ (terminal) in $H^2_{\Gamma_0}(\Omega)\times H^1_{\Gamma_0}(\Omega)\times L^2(\Omega)$, and arbitrary $\epsilon > 0$, is there a suitable control triple $[u_1, u_2, u_3] \in L^2(0,T; L^2(\Gamma_1)\times H^{-1}(\Gamma_1))\times C^r(\Sigma_{2,T})$ such that the corresponding solution $[\omega, \omega_t, \theta]$ of (1.1) satisfies the following steering property at terminal time T:

$$[\omega(T), \omega_t(T)] = \left[\omega_0^T, \omega_1^T\right] \text{ and } \left\|\theta(T) - \theta_0^T\right\|_{L^2(\Omega)} \leq \epsilon?$$

In this regard, we post our main result here for which we need the number

$$T^* \equiv 2\sqrt{\gamma}\cdot\max\left\{\sqrt{\frac{2}{1-\mu}}\max_{[x,y]\in\overline{\Omega}}\left|\overline{h}(x,y)\right|, \sup_{[x,y]\in\Omega} d\left([x,y],\Gamma_2\right)\right\}, \tag{1.6}$$

where, above, $d([x,y],\Gamma_2)$ denotes the distance between $[x,y]$ and Γ_2.

THEOREM 1.1. *Let assumptions* (1.3) *and* (1.6) *stand. Then for* $T > T^*$, *the following controllability property holds true: For given initial data* $[\omega_0, \omega_1, \theta_0]$ *and terminal data* $\left[\omega_0^T, \omega_1^T, \theta_0^T\right]$ *in the space* $H^2_{\Gamma_0}(\Omega) \times H^1_{\Gamma_0}(\Omega) \times L^2(\Omega)$, *and arbitrary* $\epsilon > 0$, *one can find control functions* $[u_1^*, u_2^*, u_3^*] \in L^2(0,T; L^2(\Gamma_1) \times H^{-1}(\Gamma_1)) \times C^r(\Sigma_{2,T})$ *(where arbitrary* $r \geq 0$*) such that the corresponding solution* $[\omega^*, \omega_t^*, \theta^*]$ *to* (1.1) *satisfies at terminal time* T,

$$[\omega^*(T), \omega_t^*(T)] = \left[\omega_0^T, \omega_1^T\right],$$

$$\left\|\theta^*(T) - \theta_0^T\right\|_{L^2(\Omega)} < \epsilon.$$

Theorem 1.1 is almost a corollary from the following controllability result for the mechanical variable only, which comprises the bulk of our effort here.

THEOREM 1.2. *With the coupling parameter* α *in* (1.1) *being arbitrary, and* (1.3), (1.6) *in place, then for* $T > T^*$, *the following property holds true: For all initial data* $[\omega_0, \omega_1, \theta_0] \in H^2_{\Gamma_0}(\Omega) \times H^1_{\Gamma_0}(\Omega) \times L^2(\Omega)$ *and terminal data* $\left[\omega_0^T, \omega_1^T\right] \in H^2_{\Gamma_0}(\Omega) \times H^1_{\Gamma_0}(\Omega)$, *there exists* $[u_1, u_2, u_3] \in L^2(0,T; L^2(\Gamma_1) \times H^{-1}(\Gamma_1)) \times H^s(\Sigma_{2,T})$, *where arbitrary* $s \geq 0$, *such that the corresponding solution* $[\omega, \omega_t, \theta]$ *to* (1.1) *satisfies* $[\omega(T), \omega_t(T)] = \left[\omega_0^T, \omega_1^T\right]$.

Remark 1.3. Note that the point $[x_0, y_0]$ can be selected in such a way so that $2 \max_{[x,y] \in \overline{\Omega}} \left|\overline{h}(x,y)\right| \leq diam\,(\Omega)$, and so, ultimately, T^* in (1.6) can be rechosen as $T^* = 2\sqrt{\gamma}\ diam\,(\Omega)$.

Remark 1.4. Note that in our statement of controllability, no geometric conditions are imposed on the controlled region of the boundary Γ_1 , only on the (possibly void) boundary portion Γ_0.

1.2. Literature. To date, the only work dealing with the *boundary* control of thermoelastic plates, in dimension greater than one, had been that of J. Lagnese in [12] (indeed, this present paper is principally motivated by [12]). In this paper, Lagnese shows that if the coupling parameter α is small enough and the boundary Γ is "star shaped," then the boundary controlled system (1.1) is (partially) exactly controllable with respect to the mechanical variables $[\omega, \omega_t]$. Also in [22], a boundary-controlled system of thermoelastic waves is studied, with a coupling parameter α likewise present therein, and a result of partial exact controllability for this PDE is cited (again, controllability with respect to the hyperbolic component). This controllability result is quoted in [22] to be valid for all sizes of α; however, in the erratum [23], the author of [22] has acknowledged a flaw in the controllability proof, the correction of which will necessitate a smallness criterion on α. Ultimately, then, the paper [22] produces a controllability result if the coupling parameter is small enough, a result in the style of [12]. The chief contribution of the present paper is to remove restrictions on the size of α (see Theorem 1.2 above). For a one-dimensional version of (1.1), S. Hansen and B. Zhang in [8], via a moment problem approach, show the system's exact null controllability with boundary control in either the plate or the thermal component.

Other controllability results for the thermoelastic system, which do not assume any "smallness" condition on the coupling parameters, involve the implementation of *distributed/internal* controls subject to clamped or hinged boundary conditions. These results include that in [6], in which interior control is placed in the Kirchoff plate component subject to *clamped* boundary conditions.

With such control, one obtains exact controllability for the plate $[\omega, \omega_t]$ and approximate controllability for the temperature θ (i.e., exact-approximate controllability). In addition, the work in [19] deals with obtaining a result of null controllability for a linear system of thermoelasticity, in which both the hyperbolic and the parabolic components can be driven to zero by means of interior control placed in the hyperbolic (wave) component.

Another result of internal control for the thermoelastic PDE (1.1) is in [5], wherein interior control is placed in the heat equation only (i.e., $\beta\theta_t - \eta\Delta\theta + \sigma\theta - \alpha\Delta\omega_t = u$) so as to obtain exact controllability for *both* components ω and θ. The novelty of this result is that this (total) exact controllability obtains for all values of the rotational inertia parameter $\gamma \geq 0$: in the limiting case $\gamma = 0$, one is then presented with a result of exact controllability for a PDE modeled by the generator of an analytic semigroup (see [18]). This controllability holds for all values of α.

Again, the main contribution of this paper is that we consider *boundary* controls acting via the higher order *free* mechanical boundary conditions, and we do not assume any size restriction on the coupling parameter α. Moreover, we do not impose any geometric "star-shaped" conditions on the controlled portion of the geometry.

At this point, we attempt to compare the degree of difficulty in obtaining controllability results for thermoelastic plates under mechanical interior control with lower-order mechanical boundary conditions enforced (such as *clamped* or *hinged*), versus that involved in the present study, where, again, boundary control is exerted upon the second and third order free boundary conditions. This comparison is appropriate, since the novelty of our work is touted to be (mechanical) exact controllability for the PDE (1.1), whatever α may be; and excluding the paper [5], the only other available controllability results for thermoelastic systems, which require no size constraints on α, concerned thermoelastic systems under (distributed) interior mechanical control and with lower mechanical boundary conditions in place.

An underlying strategy in control theoretic studies of thermoelastic plates has been to exploit, if possible, previously known controllability results for (uncoupled) Kirchoff plates. To this end, one attempts to treat the thermoelastic system as a sort of perturbation of the Kirchoff plate. It is well known that if the underlying controllability map can be decomposed into the sum of a compact map and a surjective controllability map, corresponding to a (simpler) subcomponent of the PDE system, then the exact controllability of the original problem is equivalent to its approximate controllability. This favorable scenario occurs in equations of thermoelasticity with either *clamped* or *hinged* boundary conditions and *interior*, *distributed* controls (see, e.g., [20]). Indeed, the part of the simpler component is played by the classical and much-studied Kirchoff plate, for which many results on exact controllability are already available in the literature. Taking the boundary conditions to be clamped or hinged allows for a known structural decomposition of the thermoelastic system into a group (associated with the Kirchoff plate) and a compact perturbation. Combining this decomposition with the boundedness of interior control actions immediately yields the desired decomposition of the original controllability map into the sum of a surjective controllability map (corresponding to the Kirchoff plate) and a compact perturbation. This popular strategy was used in [6], where an *exact-approximate* controllability result was established for the thermoelastic system with clamped homogeneous boundary conditions and internal controls.

The situation is drastically different in the present paper, involving the case of *boundary controls*. Here, in this case of *free* mechanical boundary conditions, the

corresponding controllability operator *cannot* be taken to be a compact perturbation of the controllability map for the (uncoupled) boundary-controlled Kirchoff plate. In the first place, the associated input→state space map, defined explicitly in (1.42), is an inherently *unbounded* operator with respect to the natural energy space (see [17] for recent sharp regularity results for corresponding solutions, which are still, however, below the level of energy). Moreover, in the present case of *free* boundary conditions, there is a decomposition of the underlying thermoelastic semigroup, but it is into the sum of a Kirchoff plate semigroup and an *unbounded*—not compact—operator (see [16]). This complication is due to the fact that the Lopatinski conditions are not satisfied for the Kirchoff model under free boundary conditions, and to the intrinsic nature of the coupling between the mechanical and thermal variables within the free boundary conditions. These two complications above, again an artifact of the "free case," explain why there have been so few results regarding the boundary control of thermoelastic plates and why a "decoupling" of the thermoelastic PDE into a sole Kirchoff plate can only go so far.

Our goal here is to dispense with this smallness assumption and, in addition, show that a control can be constructed that provides exact controllability of the mechanical variables and approximate controllability of the thermal component. We note that the thermal control u_3 present in (1.1)—wholly absent in [12]—plays no part at all in the removal of the size restriction on α; it is in place only to exploit, in a compactness-uniqueness argument, recently obtained approximate controllability properties of the thermoelastic plate under the action of boundary control in the free mechanical boundary conditions (see [10]). At this point in time, the thermoelastic system cannot be shown to be approximately controllable with control in the free boundary conditions only (and no thermal control). Therefore, the presence of the thermal boundary control here is not an artificiality; it appears to be necessary for approximate controllability. (We do not know if the future will bring a unique continuation result for the thermoelastic plate in the absence of the thermal component.) However, the result of Theorem 1.1 says that the thermal control may be taken to be very smooth and with arbitrarily small support Γ_2. Again, this benign situation is a consequence of our employing thermal control at the compactness-uniqueness level only; it plays no part whatsoever in generating the main observability estimate (estimate (2.5) of Theorem 2.1), this being free of any size restrictions on α.

The strategy adopted in this paper consists of the following steps. Initially, a suitable transformation of variables is made and applied to (1.1); subsequently, a multiplier method is invoked with respect to the transformed equation. The mulitiplers employed here are the differential multipliers used in the study of exact controllability for the Kirchoff plate model (inspired by [11]), together with the nonlocal (ΨDO) multipliers used in the study of thermoelastic plates in [3] and [4]. The controllability time T^* in Theorem 1.1 ultimately depends in part upon the radial vector field associated with the differential Kirchoff multipliers (see Lemma 2.5 below). This multiplier method allows the attainment of preliminary estimates for the energy of the system. However, these estimates are "polluted" by certain boundary terms that are not majorized by the energy. To cope with these, we use the sharp trace estimates established in [15] for Kirchoff plates. The use of this PDE result introduces lower order terms into the energy estimate, which are eventually eliminated with the help of a new unique continuation result in [10]. It is *only* at the level of invoking this uniqueness result that the thermal control u_3 on Γ_2 must be introduced. The controllability time T^* in (1.6) is optimal.

1.3. Operator theoretic formulation and analysis.

1.3.1. Preliminary definitions. In obtaining our controllability result Theorem 1.1, it will be useful to consider the PDE system (1.1) as an abstract evolution equation in a certain Hilbert space, to which end we introduce the following definitions and notation.

- With $H^k_{\Gamma_0}(\Omega)$ as defined in (1.4), we define $\mathring{\mathbf{A}}$: $L^2(\Omega) \supset D\left(\mathring{\mathbf{A}}\right) \to L^2(\Omega)$ to be $\mathring{\mathbf{A}} = \Delta^2$, with domain

$$D(\mathring{\mathbf{A}}) = \Big\{\omega \in H^4(\Omega) \cap H^2_{\Gamma_0}(\Omega) : \Delta\omega + (1-\mu)B_1\omega = 0 \text{ on } \Gamma_1 \text{ and } \frac{\partial \Delta\omega}{\partial \nu} + (1-\mu)\frac{\partial B_2\omega}{\partial \tau} = 0 \text{ on } \Gamma_1\Big\}. \tag{1.7}$$

- $\mathring{\mathbf{A}}$ is then positive definite and self-adjoint, and consequently from [7] we have the characterizations

$$\begin{aligned} D\left(\mathring{\mathbf{A}}^{\frac{1}{4}}\right) &= H^1_{\Gamma_0}(\Omega), \\ D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) &= H^2_{\Gamma_0}(\Omega), \\ D\left(\mathring{\mathbf{A}}^{\frac{3}{4}}\right) &= \left\{\omega \in H^3(\Omega) \cap H^2_{\Gamma_0}(\Omega) : \Delta\omega + (1-\mu)B_1\omega = 0 \text{ on } \Gamma_1\right\}. \end{aligned} \tag{1.8}$$

Note that without loss of generality, we are here taking Γ_0 to be nonempty in order to have the equivalence of the $H^2(\Omega)$ norm with that induced by the $D(\mathring{\mathbf{A}}^{\frac{1}{2}})$. In the case that $\Gamma_0 = \emptyset$, we would simply modify $D(\mathring{\mathbf{A}})$ by enforcing $\frac{\partial \Delta\omega}{\partial \nu} + (1-\mu)\frac{\partial B_2\omega}{\partial \tau}|_{\Gamma_1} = \omega|_{\Gamma_1}$ (instead of $\frac{\partial \Delta\omega}{\partial \nu} + (1-\mu)\frac{\partial B_2\omega}{\partial \tau}|_{\Gamma_1} = 0$ in (1.7)). This modification would not change the problem.

Moreover, using Green's formula in [11], we have that for ω, $\widehat{\omega}$ "smooth enough,"

$$\begin{aligned} \int_\Omega (\Delta^2\omega)\widehat{\omega}d\Omega = a(\omega,\widehat{\omega}) + \int_\Gamma \left[\frac{\partial \Delta\omega}{\partial \nu} + (1-\mu)\frac{\partial B_2\omega}{\partial \tau}\right]\widehat{\omega}d\Gamma \\ - \int_\Gamma \left[\Delta\omega + (1-\mu)B_1\omega\right]\frac{\partial \widehat{\omega}}{\partial \nu}d\Gamma, \end{aligned} \tag{1.9}$$

where $a(\cdot,\cdot)$ is defined by

$$a(\omega,\widehat{\omega}) \equiv \int_\Omega \left[\omega_{xx}\widehat{\omega}_{xx} + \omega_{yy}\widehat{\omega}_{yy} + \mu\left(\omega_{xx}\widehat{\omega}_{yy} + \omega_{yy}\widehat{\omega}_{xx}\right) + 2(1-\mu)\omega_{xy}\widehat{\omega}_{xy}\right]d\Omega. \tag{1.10}$$

In particular, this formula and the second characterization in (1.8) give that for all ω, $\widehat{\omega} \in D(\mathring{\mathbf{A}}^{\frac{1}{2}})$,

$$\begin{aligned} \left\langle \mathring{\mathbf{A}}\omega, \widehat{\omega}\right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]' \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} &= \left(\mathring{\mathbf{A}}^{\frac{1}{2}}\omega, \mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\omega}\right)_{L^2(\Omega)} = a(\omega,\widehat{\omega})_{L^2(\Omega)}, \\ \|\omega\|^2_{D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} &= \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} = a(\omega,\omega). \end{aligned} \tag{1.11}$$

- We define $A_D : L^2(\Omega) \supset D(A_D) \to L^2(\Omega)$ to be $A_D = -\Delta$, with Dirichlet boundary conditions, viz.,

$$D(A_D) = H^2(\Omega) \cap H^1_0(\Omega). \tag{1.12}$$

A_D is also positive definite, self-adjoint, and by [7]

$$D\left(A_D^{\frac{1}{2}}\right) = H_0^1(\Omega). \tag{1.13}$$

- We denote the operator $A_R : L^2(\Omega) \supset D(A_R) \to L^2(\Omega)$ by the following second order elliptic operator:

$$A_R = -\Delta + \frac{\sigma}{\eta}\mathbf{I}, \text{ with } D(A_R) = \left\{\vartheta \in H^2(\Omega) : \frac{\partial \vartheta}{\partial \nu} + \lambda\vartheta = 0\right\}. \tag{1.14}$$

A_R is self-adjoint, positive definite on $L^2(\Omega)$, with its fractional powers therefore being well defined. In particular, we have again by [7] that for $s \in \left[0, \frac{3}{4}\right)$,

$$\begin{aligned} &D(A_R^s) = H^{2s}(\Omega), \\ &\left(\vartheta, \widetilde{\vartheta}\right)_{H^1(\Omega)} = \left(A_R^{\frac{1}{2}}\vartheta, A_R^{\frac{1}{2}}\widetilde{\vartheta}\right)_{L^2(\Omega)} \\ &= \left(\nabla\vartheta, \nabla\widetilde{\vartheta}\right)_{L^2(\Omega)} + \lambda\left(\vartheta, \widetilde{\vartheta}\right)_{L^2(\Gamma)} + \frac{\sigma}{\eta}\left(\vartheta, \widetilde{\vartheta}\right)_{L^2(\Omega)}. \end{aligned} \tag{1.15}$$

- We denote the operator $A_N : L^2(\Omega) \supset D(A_N) \to L^2(\Omega)$ by the following second order elliptic operator:

$$A_N = -\Delta, \text{ with } D(A_N) = \left\{\vartheta \in H^2(\Omega) : \vartheta|_{\Gamma_0} = \left.\frac{\partial \vartheta}{\partial \nu}\right|_{\Gamma_1} = 0\right\}. \tag{1.16}$$

Once again by [7], we have for $s \in \left(\frac{1}{4}, \frac{3}{4}\right)$

$$D(A_N^s) = \left\{\vartheta \in H^{2s}(\Omega) \text{ such that } \vartheta|_{\Gamma_0} = 0\right\}. \tag{1.17}$$

- (γ_0, γ_1) will denote the classical Sobolev trace maps, which yield for $f \in C^\infty(\overline{\Omega})$

$$\gamma_0 f = f|_\Gamma\,;\, \gamma_1 f = \left.\frac{\partial f}{\partial \nu}\right|_\Gamma. \tag{1.18}$$

- We define the elliptic operators G_1, G_2, and D as follows:

$$G_1 h = v \Longleftrightarrow \begin{cases} \Delta^2 v = 0 \quad \text{on } \Omega, \\ v = \dfrac{\partial v}{\partial \nu} = 0 \quad \text{on } \Gamma_0, \\ \begin{cases} \Delta v + (1-\mu)B_1 v = h \\ \dfrac{\partial \Delta v}{\partial \nu} + (1-\mu)\dfrac{\partial B_2 v}{\partial \tau} = 0 \end{cases} \quad \text{on } \Gamma_1, \end{cases} \tag{1.19}$$

$$G_2 h = v \Longleftrightarrow \begin{cases} \Delta^2 v = 0 \quad \text{on } \Omega, \\ v = \dfrac{\partial v}{\partial \nu} = 0 \quad \text{on } \Gamma_0, \\ \begin{cases} \Delta v + (1-\mu)B_1 v = 0 \\ \dfrac{\partial \Delta v}{\partial \nu} + (1-\mu)\dfrac{\partial B_2 v}{\partial \tau} = h \end{cases} \quad \text{on } \Gamma_1, \end{cases}$$

$$Dh = v \Longleftrightarrow \begin{cases} \Delta v = 0 & \text{on } \Omega, \\ v|_{\Gamma} = h & \text{on } \Gamma; \end{cases} \quad Rh = v \Longleftrightarrow \begin{cases} \left(-\Delta + \frac{\sigma}{\eta}\mathbf{I}\right) v = 0 & \text{on } \Omega, \\ \dfrac{\partial v}{\partial \nu} + \lambda v = h & \text{on } \Gamma_2, \\ \dfrac{\partial v}{\partial \nu} + \lambda v = 0 & \text{on } \Gamma \backslash \Gamma_2. \end{cases} \tag{1.20}$$

The classic regularity results of [21, p. 152] then provide that for all q real,

$$\begin{cases} D \in \mathcal{L}\left(H^q(\Gamma), H^{q+\frac{1}{2}}(\Omega)\right), \\ R \in \mathcal{L}\left(H_0^q(\Gamma_2), H^{q+\frac{3}{2}}(\Omega)\right), \\ G_1 \in \mathcal{L}\left(H_0^q(\Gamma_1), H^{q+\frac{5}{2}}(\Omega)\right), \\ G_2 \in \mathcal{L}\left(H_0^{q-\frac{1}{2}}(\Gamma_1), H^{q+3}(\Omega)\right). \end{cases} \tag{1.21}$$

Denoting the topological dual of H^q as $[H^q]'$ (pivotal with respect to the L^2-inner product), then with the elliptic operators A_R and R as defined above, one can show that for $q \geq -\frac{1}{2}$, the (Banach space) adjoint $R^* A_R \in \mathcal{L}(D(A_R^{\frac{1}{2}}), [H^q(\Gamma_2)]')$ satisfies

$$R^* A_R \vartheta = \vartheta|_{\Gamma_2} \quad \text{for all } \vartheta \in D\left(A_R^{\frac{1}{2}}\right). \tag{1.22}$$

Moreover, with the operators $\mathring{\mathbf{A}}$ and G_i as defined above, one can readily show with the use of Green's formula (1.9) that $\forall\ \varpi \in D(\mathring{\mathbf{A}}^{\frac{1}{2}})$ the (Banach space) adjoints $G_i^* \mathring{\mathbf{A}} \in \mathcal{L}(D(\mathring{\mathbf{A}}^{\frac{1}{2}}), H^{i-\frac{1}{2}}(\Gamma_1))$ satisfy for $i = 1, 2$,

$$G_i^* \mathring{\mathbf{A}} \varpi = \begin{cases} (-1)^{i-1}\ \gamma_{2-i}\varpi|_{\Gamma_1} & \text{on } \Gamma_1, \\ 0 & \text{on } \Gamma_0. \end{cases} \tag{1.23}$$

- With A_N given by (1.16), we define the operator $P_\gamma : D(P_\gamma) \subset L^2(\Omega) \to L^2(\Omega)$ by

$$P_\gamma \equiv \mathbf{I}\ + \gamma A_N. \tag{1.24}$$

(i) With the parameter $\gamma > 0$, we define a space $H^1_{\Gamma_0,\gamma}(\Omega)$ equivalent to $H^1_{\Gamma_0}(\Omega)$ with inner product

$$(\omega_1, \omega_2)_{H^1_{\Gamma_0,\gamma}(\Omega)} \equiv (\omega_1, \omega_2)_{L^2(\Omega)} + \gamma\, (\nabla\omega_1, \nabla\omega_2)_{L^2(\Omega)} \quad \forall\, \omega_1, \omega_2 \in H^1_{\Gamma_0}(\Omega) \tag{1.25}$$

and with its dual denoted as $H^{-1}_{\Gamma_0,\gamma}(\Omega)$. After recalling that $H^1_{\Gamma_0}(\Omega) = D(A_N^{\frac{1}{2}})$ (by (1.17)), two extensions by continuity will then yield that

$$\begin{aligned} &P_\gamma \in \mathcal{L}\left(H^1_{\Gamma_0,\gamma}(\Omega), H^{-1}_{\Gamma_0,\gamma}(\Omega)\right) \\ &\text{with } \langle P_\gamma \omega_1, \omega_2 \rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega) \times H^1_{\Gamma_0,\gamma}(\Omega)} = (\omega_1, \omega_2)_{H^1_{\Gamma_0,\gamma}(\Omega)}. \end{aligned} \tag{1.26}$$

Furthermore, the obvious $H^1_{\Gamma_0,\gamma}(\Omega)$-ellipticity of P_γ and Lax–Milgram give us that $P_\gamma \in \mathcal{L}(H^1_{\Gamma_0,\gamma}(\Omega), H^{-1}_{\Gamma_0,\gamma}(\Omega))$is boundedly invertible, with

$$P_\gamma^{-1} \in \mathcal{L}\left(H^{-1}_{\Gamma_0,\gamma}(\Omega), H^1_{\Gamma_0,\gamma}(\Omega)\right). \tag{1.27}$$

Moreover, because P_γ is positive definite and self-adjoint as an operator $P_\gamma : L^2(\Omega) \supset D(P_\gamma) \to L^2(\Omega)$, the square root $P_\gamma^{\frac{1}{2}}$ is consequently well defined with $D(P_\gamma^{\frac{1}{2}}) = H^1_{\Gamma_0,\gamma}(\Omega)$, by (1.17). It then follows from (1.25) and (1.26) that for ω and $\widehat{\omega} \in H^1_{\Gamma_0,\gamma}(\Omega)$,

$$\left\| P_\gamma^{\frac{1}{2}} \omega \right\|^2_{L^2(\Omega)} = \|\omega\|^2_{L^2(\Omega)} + \gamma \|\nabla \omega\|^2_{L^2(\Omega)} = \|\omega\|^2_{H^1_{\Gamma_0,\gamma}(\Omega)}, \tag{1.28}$$

$$\left(P_\gamma^{\frac{1}{2}} \omega, P_\gamma^{\frac{1}{2}} \widehat{\omega} \right)_{L^2(\Omega)} = (\omega, \widehat{\omega})_{H^1_{\Gamma_0,\gamma}(\Omega)}. \tag{1.29}$$

(ii) Finally, by Green's formula we have for ω, $\widehat{\omega} \in D(\mathring{\mathbf{A}}^{\frac{1}{2}})$,

$$\begin{aligned} &\gamma \left\langle \left(\Delta + \mathring{\mathbf{A}} G_2 \gamma_1\right) \omega, \widehat{\omega} \right\rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega) \times H^1_{\Gamma_0,\gamma}(\Omega)} \\ &= -\gamma \left(\nabla \omega, \nabla \widehat{\omega}\right)_{L^2(\Omega)} + \gamma \left(\frac{\partial \omega}{\partial \nu}, \widehat{\omega} \right)_{L^2(\Gamma_1)} + \gamma \left(\gamma_1 \omega, G_2^* \mathring{\mathbf{A}} \widehat{\omega} \right)_{L^2(\Gamma_1)} \\ &= -\gamma \left(\nabla \omega, \nabla \widehat{\omega}\right)_{L^2(\Omega)} = -\gamma \left\langle A_N \omega, \widehat{\omega} \right\rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega) \times H^1_{\Gamma_0,\gamma}(\Omega)} \end{aligned} \tag{1.30}$$

after using (1.23). We thus obtain after two extensions by continuity to $H^1_{\Gamma_0,\gamma}(\Omega)$ that

$$P_\gamma = \mathbf{I} - \gamma \left(\Delta + \mathring{\mathbf{A}} G_2 \gamma_1\right) \text{ as elements of } \mathcal{L}\left(H^1_{\Gamma_0,\gamma}(\Omega), H^{-1}_{\Gamma_0,\gamma}(\Omega) \right). \tag{1.31}$$

In obtaining the equality above, we have used implicitly the fact that for every $\varpi^* \in H^{-1}_{\Gamma_0,\gamma}(\Omega)$ and $\varpi \in D(\mathring{\mathbf{A}}^{\frac{1}{2}})$,

$$\langle \varpi^*, \varpi \rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega) \times H^1_{\Gamma_0,\gamma}(\Omega)} = \langle \varpi^*, \varpi \rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}} \right) \right]' \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}} \right)} \tag{1.32}$$

- We denote the Hilbert space $\mathbf{H}_\gamma$ to be

$$\mathbf{H}_\gamma \equiv D\left(\mathring{\mathbf{A}}^{\frac{1}{2}} \right) \times H^1_{\Gamma_0,\gamma}(\Omega) \times L^2(\Omega), \tag{1.33}$$

with the inner product

$$\begin{aligned} \left(\begin{bmatrix} \omega_1 \\ \omega_2 \\ \theta \end{bmatrix}, \begin{bmatrix} \widehat{\omega}_1 \\ \widehat{\omega}_2 \\ \widehat{\theta} \end{bmatrix} \right)_{\mathbf{H}_\gamma} &= \left(\mathring{\mathbf{A}}^{\frac{1}{2}} \omega_1, \mathring{\mathbf{A}}^{\frac{1}{2}} \widehat{\omega}_1 \right)_{L^2(\Omega)} \\ &\quad + \left(P_\gamma^{\frac{1}{2}} \omega_2, P_\gamma^{\frac{1}{2}} \widehat{\omega}_2 \right)_{L^2(\Omega)} + \beta \left(\theta, \widehat{\theta} \right)_{L^2(\Omega)}. \end{aligned} \tag{1.34}$$

- With the above definitions, and making the denotation

$$(\clubsuit) \equiv A_R - \frac{\sigma}{\eta} - \mathring{\mathbf{A}} G_1 \gamma_0 + \lambda \mathring{\mathbf{A}} G_2 \gamma_0, \tag{1.35}$$

we then set $\mathcal{A}_\gamma : \mathbf{H}_\gamma \supset D(\mathcal{A}_\gamma) \to \mathbf{H}_\gamma$ to be

$$\begin{aligned} \mathcal{A}_\gamma &\equiv \begin{pmatrix} \mathbf{I} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & P_\gamma^{-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{I} \end{pmatrix} \begin{pmatrix} 0 & \mathbf{I} & 0 \\ -\mathring{\mathbf{A}} & 0 & \alpha(\clubsuit) \\ 0 & -\dfrac{\alpha}{\beta} A_D (\mathbf{I} - D\gamma_0) & -\dfrac{\eta}{\beta} A_R \end{pmatrix} \\ &\text{with } D(\mathcal{A}_\gamma) = \Big\{ [\omega_0, \omega_1, \theta_0] \in D\left(\mathring{\mathbf{A}}^{\frac{1}{2}} \right) \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}} \right) \times D(A_R)) \\ &\qquad \text{such that } \mathring{\mathbf{A}} \omega_0 + \alpha \mathring{\mathbf{A}} G_1 \gamma_0 \theta_0 \in H^{-1}_{\Gamma_0,\gamma}(\Omega) \Big\}. \end{aligned} \tag{1.36}$$

- We make the following denotations for the space of controllability:

$$\begin{aligned} U_s &= L^2(\Gamma_1) \times H^{-1}(\Gamma_1) \times H^s(\Gamma_2), \\ \mathcal{U}_s &= L^2(0,T; L^2(\Gamma_1) \times H^{-1}(\Gamma_1)) \times H^s((0,T) \times \Gamma_2), \end{aligned} \tag{1.37}$$

where $s \geq 0$. We define the control operator $\mathcal{B}$ on U_s by having for every $\overline{u} = [u_1, u_2, u_3] \in U_s$,

$$\mathcal{B}\overline{u} = \begin{bmatrix} 0 \\ P_\gamma^{-1}[\mathring{\mathbf{A}} G_1 u_1 + \mathring{\mathbf{A}} G_2 u_2] \\ \dfrac{\eta}{\beta} A_R R u_3 \end{bmatrix}. \tag{1.38}$$

Note that a priori the mapping $\mathcal{B}$ only makes sense as an element of $\mathcal{L}(U_s, [D(\mathcal{A}_\gamma^*)]')$, where $\mathbf{H}_\gamma \subset [D(\mathcal{A}_\gamma^*)]'$. Indeed, for fixed $\overline{u} = [u_1, u_2, u_3] \in U_s$ one has, upon using the expression for the inverse $\mathcal{A}_\gamma^{-1}$ given in (4.2) below, and the definition of the elliptic operators G_1, G_2, and R in (1.19) and (1.20) above, that

$$\begin{aligned} \mathcal{B}\overline{u} &= \mathcal{A}_\gamma \mathcal{A}_\gamma^{-1} \begin{bmatrix} 0 \\ P_\gamma^{-1}[\mathring{\mathbf{A}} G_1 u_1 + \mathring{\mathbf{A}} G_2 u_2] \\ \dfrac{\eta}{\beta} A_R R u_3 \end{bmatrix} \\ &= \mathcal{A}_\gamma \begin{bmatrix} -G_1 u_1 - G_2 u_2 - \alpha \mathring{\mathbf{A}}^{-1}(\clubsuit) R u_3 \\ 0 \\ -R u_3 \end{bmatrix} \in \left[D(\mathcal{A}_\gamma^*)\right]', \end{aligned} \tag{1.39}$$

where ($\clubsuit$) is as defined in (1.35).

- By duality, we have

$$\begin{aligned} U_s^* &= L^2(\Gamma_1) \times H^1(\Gamma_1) \times [H^s(\Gamma_2)]', \\ \mathcal{U}_s^* &= L^2(0,T; L^2(\Gamma_1) \times H^1(\Gamma_1)) \times \left[H^s(0,T; L^2(\Gamma_2))\right]', \end{aligned} \tag{1.40}$$

and $\mathcal{B}^* \in \mathcal{L}\left(D(\mathcal{A}_\gamma^*), U_s^*\right)$.

1.3.2. Abstract operator formulation. If we take the initial data $[\omega_0, \omega_1, \theta_0]$ to be in $\mathbf{H}_\gamma$, and control $\overline{u} \in \mathcal{U}_s$, where $\mathcal{U}_s$ is as defined in (1.37), then considering the operator definitions above, the coupled system (1.1) can be rewritten a fortiori as the operator theoretic model

$$\frac{d}{dt}\begin{bmatrix} \omega(t) \\ \omega_t(t) \\ \theta(t) \end{bmatrix} = \mathcal{A}_\gamma \begin{bmatrix} \omega(t) \\ \omega_t(t) \\ \theta(t) \end{bmatrix} + \mathcal{B}\overline{u}(t), \qquad \begin{bmatrix} \omega(0) \\ \omega_t(0) \\ \theta(0) \end{bmatrix} = \begin{bmatrix} \omega_0 \\ \omega_1 \\ \theta_0 \end{bmatrix}, \tag{1.41}$$

with this equation having sense in $\left[D(\mathcal{A}_\gamma^*)\right]'$ (a space strictly larger than $\mathbf{H}_\gamma$). Given the operator definitions for $\mathcal{A}_\gamma$ and $\mathcal{B}$ above, the solution $[\omega, \omega_t, \theta]$ to the ODE (1.41) (and so to the PDE (1.1)) is given by

$$\begin{bmatrix} \omega(\cdot) \\ \omega_t(\cdot) \\ \theta(\cdot) \end{bmatrix} = e^{\mathcal{A}_\gamma(\cdot)} \begin{bmatrix} \omega_0 \\ \omega_1 \\ \theta_0 \end{bmatrix} + \int_0^{(\cdot)} e^{\mathcal{A}_\gamma(\cdot - s)} \mathcal{B}\overline{u}(s) ds, \tag{1.42}$$

which by (1.39) and the convolution theorem is an element of $C([0,T];[D(\mathcal{A}_\gamma^*)]')$. With this representation of the solution $[\omega,\omega_t,\theta]$ in mind, we define the *input* $\to$ *terminal state* map $\mathcal{L}_T \in \mathcal{L}(\mathcal{U}_s, \left[D(\mathcal{A}_\gamma^*)\right]')$ as

$$\mathcal{L}_T\overline{u} = \int_0^T e^{\mathcal{A}_\gamma(T-s)}\mathcal{B}\overline{u}(s)ds. \tag{1.43}$$

Taken as an unbounded operator from $\mathcal{U}_s$ into $\mathbf{H}_\gamma$, then $\mathcal{L}_T : D(\mathcal{L}_T) \subset \mathcal{U}_s \to \mathbf{H}_\gamma$ is closed and densely defined, with its domain of definition $D(\mathcal{L}_T)$ given to be

$$D(\mathcal{L}_T) = \{\overline{u} \in \mathcal{U}_s : \mathcal{L}_T\overline{u} \in \mathbf{H}_\gamma\}. \tag{1.44}$$

Its adjoint $\mathcal{L}_T^* : D(\mathcal{L}_T^*) \subset \mathbf{H}_\gamma \to \mathcal{U}_s^*$, where $\mathcal{U}_s^*$ is as given in (1.40), is likewise closed and densely defined, with

$$D(\mathcal{L}_T^*) = \left\{ [\phi_0,\phi_1,\psi_0] \in \mathbf{H}_\gamma : \mathcal{L}_T^* \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \in \mathcal{U}_s^* \right\}. \tag{1.45}$$

As we are concerned with obtaining exact controllability of the displacement $[\omega,\omega_t]$ only, we accordingly define the projection operator $\Pi : \mathbf{H}_\gamma \to D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)$ by

$$\Pi \begin{bmatrix} \varpi_0 \\ \varpi_1 \\ \vartheta_0 \end{bmatrix} = \begin{bmatrix} \varpi_0 \\ \varpi_1 \end{bmatrix}. \tag{1.46}$$

Henceforth, the work here will be concerned with determining the surjectivity of the closed operator $\Pi\mathcal{L}_T$, $D(\Pi\mathcal{L}_T) \subset \mathcal{U}_s \to D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)$, with

$$\Pi\mathcal{L}_T\overline{u} = \Pi \int_0^T e^{\mathcal{A}_\gamma(T-s)}\mathcal{B}\overline{u}(s)ds, \tag{1.47}$$

and with $D(\Pi\mathcal{L}_T) = D(\mathcal{L}_T)$. Determining the surjectivity of the operator $\Pi\mathcal{L}_T$ for some $T > 0$ becomes our concern here, since it is equivalent to showing the exact controllability of the mechanical component $[\omega,\omega_t]$ to (1.1) (Theorem 1.2). This surjectivity for $\Pi\mathcal{L}_T$ is in turn equivalent to the existence of a certain observability inequality pertaining to the range of the adjoint $\mathcal{L}_T^*\Pi^*$ (the inequality (2.1) below), where $\mathcal{L}_T^*\Pi^* : D(\mathcal{L}_T^*\Pi^*) \subset D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega) \to \mathbf{H}_\gamma$ is likewise a closed densely defined operator (as $\mathcal{L}_T^*$ is), with its domain given by

$$D(\mathcal{L}_T^*\Pi^*) = \left\{ [\phi_0,\phi_1] \in D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times H^1_{\Gamma_0}(\Omega) : [\phi_0,\phi_1,0] \in D(\mathcal{L}_T^*) \right\}. \tag{1.48}$$

It is the injectivity condition (2.1) that we intend to directly verify. In order to rewrite this abstract inequality in "PDE form" (i.e., as the inequality (2.2) below), we need the following two propositions, the first of which is proved in the appendix below.

PROPOSITION 1.5. *The Hilbert space adjoint $\mathcal{A}_\gamma^*$ of $\mathcal{A}_\gamma$, as defined in* (1.36)*, is given to be*

$$\mathcal{A}_\gamma^* = \begin{pmatrix} \mathbf{I} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & P_\gamma^{-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{I} \end{pmatrix} \begin{pmatrix} \mathbf{0} & -\mathbf{I} & \mathbf{0} \\ \mathring{\mathbf{A}} & \mathbf{0} & -\alpha(\clubsuit) \\ \mathbf{0} & \dfrac{\alpha}{\beta}A_D(\mathbf{I}-D\gamma_0) & -\dfrac{\eta}{\beta}A_R \end{pmatrix},$$

$$\text{with } D(\mathcal{A}_\gamma^*) = \left\{ [\phi_0,\phi_1,\psi_0] \in D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times D(A_R) \right.$$

$$\left. \text{such that } \mathring{\mathbf{A}}\phi_0 + \alpha\mathring{\mathbf{A}}G_1\gamma_0\psi_0 \in H^{-1}_{\Gamma_0,\gamma}(\Omega) \right\} \tag{1.49}$$

(above, (♣) is the same denotation made in (1.35)*).*

Remark 1.6. Using the semigroup $\{e^{\mathcal{A}_\gamma^* t}\}_{t\geq 0}$ generated by $\mathcal{A}_\gamma^*$, then for terminal data $[\phi_0, \phi_1, \psi_0] \in \mathbf{H}_\gamma$,

$$\begin{bmatrix} \phi(t) \\ \phi_t(t) \\ \psi(t) \end{bmatrix} = e^{\mathcal{A}_\gamma^*(T-t)} \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \in C([0,T];\ \mathbf{H}_\gamma) \tag{1.50}$$

is the solution to the following backward problem:

$$\begin{cases} \begin{cases} \phi_{tt} - \gamma\Delta\phi_{tt} + \Delta^2\phi + \alpha\Delta\psi = 0 \\ \beta\psi_t + \eta\Delta\psi - \sigma\psi - \alpha\Delta\phi_t = 0 \end{cases} \text{ on } (0,\infty)\times\Omega, \\ \phi = \dfrac{\partial\phi}{\partial\nu} = 0 \ \text{ on } (0,\infty)\times\Gamma_0, \\ \begin{cases} \Delta\phi + (1-\mu)B_1\phi + \alpha\psi = 0 \\ \dfrac{\partial\Delta\phi}{\partial\nu} + (1-\mu)\dfrac{\partial B_2\phi}{\partial\tau} - \gamma\dfrac{\partial\phi_{tt}}{\partial\nu} + \alpha\dfrac{\partial\psi}{\partial\nu} = 0 \end{cases} \text{ on } (0,\infty)\times\Gamma_1, \\ \dfrac{\partial\psi}{\partial\nu} + \lambda\psi = 0 \ \text{ on } (0,\infty)\times\Gamma,\ \lambda\geq 0, \\ [\phi(T), \phi_t(T), \psi(T)] = [\phi_0, \phi_1, \psi_0]\,. \end{cases} \tag{1.51}$$

Remark 1.7. For terminal data $[\phi_0, \phi_1, \psi_0]$ in $D(\mathcal{A}_\gamma^*)$, the two equations of (1.51) may be written pointwise as

$$P_\gamma\phi_{tt} = -\mathring{\mathbf{A}}\phi - \alpha\mathring{\mathbf{A}}G_1\gamma_0\psi + \alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\psi - \alpha\Delta\psi \ \text{ in } H^{-1}_{\Gamma_0,\gamma}(\Omega), \tag{1.52}$$

$$\beta\psi_t = -\eta\Delta\psi + \sigma\psi + \alpha\Delta\phi_t \ \text{ in } L^2(\Omega), \tag{1.53}$$

$$[\phi(T), \phi_t(T), \psi(T)] = [\phi_0, \phi_1, \psi_0]\,. \tag{1.54}$$

Remark 1.8. Since $\overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset$, and Γ is smooth, we can assume throughout that $D(\mathcal{A}_\gamma^*)$ is dense in the graph topology of $D(\mathcal{L}_T^*)$.

Proposition 1.9. *The adjoint $\mathcal{L}_T^* : D(\mathcal{L}_T^*) \subset \mathbf{H}_\gamma \to \mathcal{U}_s^*$ of $\mathcal{L}_T$ is computed to be*

$$\mathcal{L}_T^* \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} = \begin{bmatrix} \dfrac{\partial\phi_t}{\partial\nu}\Big|_{\Gamma_1}, -\phi_t|_{\Gamma_1}, \eta\,\psi|_{\Gamma_2} \end{bmatrix} \ \textit{for all} \ \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \in D(\mathcal{L}_T^*)\,, \tag{1.55}$$

where $[\frac{\partial\phi_t}{\partial\nu}|_{\Gamma_1}, \phi_t|_{\Gamma_1}, \psi|_{\Gamma_2}]$ are boundary "traces" of the solution $[\phi, \phi_t, \psi]$ to the coupled system (1.51).

Proof. By Remark 1.8, it is enough to show the characterization in (1.55) for $[\phi_0, \phi_1, \psi_0] \in D(\mathcal{A}_\gamma^*)$. With this in mind, one has readily the classic representation

$$\mathcal{L}_T^* \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} = \mathcal{B}^* e^{\mathcal{A}_\gamma^*(T-t)} \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \quad \text{for every} \quad \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \in D\left(\mathcal{A}_\gamma^*\right), \tag{1.56}$$

where again, $\mathcal{B}^* \in \mathcal{L}\left(D\left(\mathcal{A}_\gamma^*\right), U_s^*\right)$ is the adjoint of $\mathcal{B}$. We must show that the right-hand side of this equality may be written explicitly in "PDE form" as (1.55). To this end, for every $[u_1, u_2, u_3] \in \mathcal{U}_s$ and $[\phi_0, \phi_1, \psi_0] \in D\left(\mathcal{A}_\gamma^*\right)$, we have

(1.57)

$$
\begin{aligned}
&\left\langle \mathcal{L}_T \begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix}, \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \right\rangle_{[D(\mathcal{A}_\gamma^*)]' \times D(\mathcal{A}_\gamma^*)} \\
&= \left\langle \int_0^T e^{\mathcal{A}_\gamma (T-s)} \mathcal{B} \begin{bmatrix} u_1(s) \\ u_2(s) \\ u_3(s) \end{bmatrix} ds, \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \right\rangle_{[D(\mathcal{A}_\gamma^*)]' \times D(\mathcal{A}_\gamma^*)} \\
&= \int_0^T \left\langle e^{\mathcal{A}_\gamma (T-s)} \mathcal{A}_\gamma \mathcal{A}_\gamma^{-1} \mathcal{B} \begin{bmatrix} u_1(s) \\ u_2(s) \\ u_3(s) \end{bmatrix}, \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \right\rangle_{[D(\mathcal{A}_\gamma^*)]' \times D(\mathcal{A}_\gamma^*)} ds \\
&= \int_0^T \left(\mathcal{A}_\gamma^{-1} \mathcal{B} \begin{bmatrix} u_1(s) \\ u_2(s) \\ u_3(s) \end{bmatrix}, e^{\mathcal{A}_\gamma^* (T-s)} \mathcal{A}_\gamma^* \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \right)_{\mathbf{H}_\gamma} ds \\
&= \int_0^T \left(\begin{bmatrix} -G_1 u_1(s) - G_2 u_2(s) - \alpha \mathring{\mathbf{A}}^{-1} (\clubsuit) R u_3 \\ 0 \\ -R u_3 \end{bmatrix}, \mathcal{A}_\gamma^* e^{\mathcal{A}_\gamma^* (T-s)} \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \right)_{\mathbf{H}_\gamma} ds.
\end{aligned}
$$

Noting that

$$
\begin{bmatrix} \phi(t) \\ \phi_t(t) \\ \psi(t) \end{bmatrix} \equiv e^{\mathcal{A}_\gamma^* (T-t)} \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix}
$$

gives the solution to the backward problem (1.51), we then use this relation, the definition of the adjoint $\mathcal{A}_\gamma^*$ in (1.49), and Proposition 4.1 of the appendix to obtain

(1.58)

$$
\begin{aligned}
&\left\langle \mathcal{L}_T \begin{bmatrix} u_1(s) \\ u_2(s) \\ u_3(s) \end{bmatrix}, \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \right\rangle_{[D(\mathcal{A}_\gamma^*)]' \times D(\mathcal{A}_\gamma^*)} \\
&= \int_0^T \left(\begin{bmatrix} -G_1 u_1(s) - G_2 u_2(s) - \alpha \mathring{\mathbf{A}}^{-1} (\clubsuit) R u_3 \\ 0 \\ -R u_3 \end{bmatrix}, \right. \\
&\qquad \left. \begin{bmatrix} -\phi_t \\ P_\gamma^{-1} \mathring{\mathbf{A}} \phi - \alpha P_\gamma^{-1} (\clubsuit) \psi \\ \dfrac{\alpha}{\beta} A_D (\mathbf{I} - D\gamma_0) \phi_t - \dfrac{\eta}{\beta} A_R \psi \end{bmatrix} \right)_{\mathbf{H}_\gamma} ds \\
&= \int_0^T \left[\left(\mathring{\mathbf{A}}^{\frac{1}{2}} G_1 u_1, \mathring{\mathbf{A}}^{\frac{1}{2}} \phi_t \right)_{L^2(\Omega)} + \left(\mathring{\mathbf{A}}^{\frac{1}{2}} G_2 u_2, \mathring{\mathbf{A}}^{\frac{1}{2}} \phi_t \right)_{L^2(\Omega)} + \eta \left(R u_3, A_R \psi \right)_{L^2(\Omega)} \right] dt \\
&= \int_0^T \left[\left(u_1, G_1^* \mathring{\mathbf{A}} \phi_t \right)_{L^2(\Gamma_1)} + \left\langle u_2, G_2^* \mathring{\mathbf{A}} \phi_t \right\rangle_{H^{-1}(\Gamma_1) \times H^1(\Gamma_1)} \right] dt + \int_0^T \eta \left(u_3, \psi \right)_{L^2(\Gamma_2)} dt \\
&= \int_0^T \left[\left(u_1, \frac{\partial \phi_t}{\partial \nu} \right)_{L^2(\Gamma_1)} - \left\langle u_2, \phi_t \right\rangle_{H^{-1}(\Gamma_1) \times H^1(\Gamma_1)} \right] dt + \eta \left\langle u_3, \psi \right\rangle_{H^s((0,T)\Gamma_2) \times [H^s((0,T) \times \Gamma_2)]'},
\end{aligned}
$$

thereby completing the proof of Proposition 1.9. □

Immediately, we have Corollary 1.10.

COROLLARY 1.10. *The adjoint operator* $\mathcal{L}_T^*\Pi^* : D(\mathcal{L}_T^*\Pi^*) \subset D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega) \to \mathcal{U}_s^*$ *is given by*

$$\mathcal{L}_T^*\Pi^* \begin{bmatrix} \phi_0 \\ \phi_1 \end{bmatrix} = \left[\left. \frac{\partial \phi_t}{\partial \nu} \right|_{\Gamma_1}, -\phi_t|_{\Gamma_1}, \eta\psi|_{\Gamma_2} \right] \tag{1.59}$$

for all $[\phi_0, \phi_1] \in D(\mathcal{L}_T^*\Pi^*)$, *where* $[\frac{\partial \phi_t}{\partial \nu}|_{\Gamma_1}, \phi_t|_{\Gamma_1}, \psi|_{\Gamma_2}]$ *are boundary traces of the solution* $[\phi, \phi_t, \psi]$ *to the following (backward) system:*

$$\begin{cases} \begin{cases} \phi_{tt} - \gamma\Delta\phi_{tt} + \Delta^2\phi + \alpha\Delta\psi = 0 \\ \beta\psi_t + \eta\Delta\psi - \sigma\psi - \alpha\Delta\phi_t = 0 \end{cases} & \text{on } (0,\infty)\times\Omega, \\ \phi = \dfrac{\partial\phi}{\partial\nu} = 0 \quad \text{on } (0,\infty)\times\Gamma_0, \\ \begin{cases} \Delta\phi + (1-\mu)B_1\phi + \alpha\psi = 0 \\ \dfrac{\partial\Delta\phi}{\partial\nu} + (1-\mu)\dfrac{\partial B_2\phi}{\partial\tau} - \gamma\dfrac{\partial\phi_{tt}}{\partial\nu} + \alpha\dfrac{\partial\psi}{\partial\nu} = 0 \end{cases} & \text{on } (0,\infty)\times\Gamma_1, \\ \dfrac{\partial\psi}{\partial\nu} + \lambda\psi = 0 \quad \text{on } (0,\infty)\times\Gamma,\ \lambda \geq 0, \\ [\phi(T), \phi_t(T), \psi(T)] = [\phi_0, \phi_1, 0]\,. \end{cases} \tag{1.60}$$

We conclude this section with a regularity result for the thermal component of the solution $[\phi, \phi_t, \psi]$ to (1.51) , this being originally derived in [11] and [2] for the forward problem (1.1). Assuming terminal data $[\phi_0, \phi_1, \psi_0] \in D(\mathcal{A}_\gamma^*)$, we have, by using (1.50), the equality

$$\frac{d}{dt}\left\| \begin{bmatrix} \phi(t) \\ \phi_t(t) \\ \psi(t) \end{bmatrix} \right\|^2_{\mathbf{H}_\gamma} = -2\left(\mathcal{A}_\gamma^* \begin{bmatrix} \phi(t) \\ \phi_t(t) \\ \psi(t) \end{bmatrix}, \begin{bmatrix} \phi(t) \\ \phi_t(t) \\ \psi(t) \end{bmatrix} \right)_{\mathbf{H}_\gamma}. \tag{1.61}$$

Integrating this equation from 0 to T, performing computations similar to those performed for the proof of Proposition 1.9, recalling the characterization (1.15), and subsequently invoking a density argument, we have the following proposition.

PROPOSITION 1.11. *With terminal data* $[\phi_0, \phi_1, \psi_0] \in \mathbf{H}_\gamma$, *we have that the component* ψ *of the solution of* (1.51) *is an element of* $L^2(0,\infty; D(A_R^{\frac{1}{2}}))$. *Indeed, we have the following relation valid for all* $T > 0$:

$$\left\| \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \right\|^2_{\mathbf{H}_\gamma} - \left\| \begin{bmatrix} \phi(0) \\ \phi_t(0) \\ \psi(0) \end{bmatrix} \right\|^2_{\mathbf{H}_\gamma} = 2\eta \int_0^T \left\| A_R^{\frac{1}{2}}\psi \right\|^2_{L^2(\Omega)} dt. \tag{1.62}$$

2. Proof of Theorem 1.2.

2.1. The necessary inequality. As stated above, showing the partial exact controllability of the system (1.1) for some time $T > 0$ is equivalent to showing the surjectivity of the operator $\Pi\mathcal{L}_T : D(\mathcal{L}_T) \subset \mathcal{U}_s \to D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)$, where $\Pi\mathcal{L}_T$ is as defined in (1.47) and with $D(\mathcal{L}_T)$ as defined in (1.44). Using the classical functional

analysis (e.g., couple Lemma 3.8.18(i) and Theorem 6.5.10(ii) of [9]), the surjectivity of $\Pi\mathcal{L}_T$ for some time $T > 0$ is tantamount to the existence of a constant $C_T > 0$ such that following inequality is satisfied for all $[\phi_0, \phi_1] \in D(\mathcal{L}_T^*\Pi^*)$, where $D(\mathcal{L}_T^*\Pi^*)$ is as defined in (1.48):

$$\left\| \mathcal{L}_T^* \begin{bmatrix} \phi_0 \\ \phi_1 \\ 0 \end{bmatrix} \right\|_{\mathcal{U}_s^*} \geq C_T \left\| \begin{bmatrix} \phi_0 \\ \phi_1 \end{bmatrix} \right\|_{D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times H^1_{\Gamma_0,\gamma}(\Omega)}. \tag{2.1}$$

Corollary 1.10 then gives that this abstract inequality above may be rewritten by having for all $[\phi_0, \phi_1] \in D(\mathcal{L}_T^*\Pi^*)$,

$$\int_0^T \left[\|\phi_t\|^2_{H^1(\Gamma_1)} + \left\| \frac{\partial \phi_t}{\partial \nu} \right\|^2_{L^2(\Gamma_1)} \right] dt + \eta \|\psi\|^2_{[H^s((0,T)\times\Gamma_2)]'} \geq C_T \left\| \begin{bmatrix} \phi_0 \\ \phi_1 \end{bmatrix} \right\|^2_{D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times H^1_{\Gamma_0,\gamma}(\Omega)}, \tag{2.2}$$

where $[\frac{\partial \phi_t}{\partial \nu}|_{\Gamma_1}, \phi_t|_{\Gamma_1}, \psi|_{\Gamma_2}]$ are traces of the solution $[\phi, \phi_t, \psi]$ to the backward system (1.60) (this being "adjoint" with respect to (1.1)). So to prove the statement of partial exact controllability of the thermoelastic system (Theorem 1.2), it will hence suffice to establish the inequality (2.2) for $T > 0$ large enough. With this end in mind, we make the following denotation for the mechanical "energy" of the system for $0 \leq t \leq T$:

$$E_\phi(t) = \frac{1}{2} \left[\left\| \mathring{\mathbf{A}}^{\frac{1}{2}} \phi(t) \right\|^2_{L^2(\Omega)} + \left\| P_\gamma^{\frac{1}{2}} \phi_t(t) \right\|^2_{L^2(\Omega)} \right], \tag{2.3}$$

where again $[\phi, \phi_t, \psi]$ solve the backward system (1.60). In addition, we will denote by $\mathsf{l.o.t.}(\phi, \phi_t, \psi)$ ("lower order terms") any sum of terms that obey the following estimate for some constant C_T:

$$\begin{aligned} \mathsf{l.o.t.}(\phi, \phi_t, \psi) \leq C_T \Bigg(& \|\phi\|^2_{L^\infty\left(0,T;H^{\frac{3}{2}+\epsilon}(\Omega)\right)} + \|\phi_t\|^2_{L^\infty\left(0,T;H^{\frac{1}{2}+\epsilon}(\Omega)\right)} \\ & + \|\psi\|^2_{L^2\left(0,T;H^{\frac{1}{2}+\epsilon}(\Omega)\right)} + \|\psi\|^2_{L^\infty\left(0,T;H^{-\frac{1}{2}+\epsilon}(\Omega)\right)} \Bigg). \end{aligned} \tag{2.4}$$

By way of establishing (2.2), the bulk of the work will entail the derivation of the following estimate.

THEOREM 2.1. *For $T > 0$ large enough, the solution $[\phi, \phi_t, \psi]$ to (1.51) with terminal data $[\phi_0, \phi_1, \psi_0] \in D(\mathcal{L}_T^*)$ satisfies the following inequality:*

$$\begin{aligned} & \int_0^T \left[E_\phi(t) + \left\| A_R^{\frac{1}{2}} \psi \right\|^2_{L^2(\Omega)} \right] dt + E_\phi(0) \\ & \leq C_T \left(\|\psi_0\|^2_{L^2(\Omega)} + \int_0^T \|\nabla \phi_t\|^2_{L^2(\Gamma_1)}\, dt + \mathsf{l.o.t.}(\phi, \phi_t, \psi) \right). \end{aligned} \tag{2.5}$$

This theorem will follow from a chain of results. Given the density of $D(\mathcal{A}_\gamma^*)$ in $D(\mathcal{L}_T^*)$ (see Remark 1.8) and the fact that the solution of (1.51) has the representation

$$\begin{bmatrix} \phi(t) \\ \phi_t(t) \\ \psi(t) \end{bmatrix} = e^{\mathcal{A}_\gamma^*(T-t)} \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix}, \tag{2.6}$$

it will be enough to show inequality (2.5) for solutions $[\phi, \phi_t, \psi]$ to (1.51) corresponding to terminal data in $D(\left[\mathcal{A}_\gamma^*\right]^2)$. Taking $[\phi_0, \phi_1, \psi_0] \in D(\left[\mathcal{A}_\gamma^*\right]^2)$, we then have that $[\phi, \phi_t, \psi]$ is an element of $C^2([0,T]; \mathbf{H}_\gamma) \cap C^1([0,T]; D(\mathcal{A}_\gamma^*)) \cap C([0,T]; D(\left[\mathcal{A}_\gamma^*\right]^2))$ and as such has the additional regularity (see [3, Theorem 2] and also [12]):

$$\begin{aligned} &\phi \in C([0,T]; H^4(\Omega)); \ \phi_t \in C([0,T]; H^3(\Omega)); \ \phi_{tt} \in C\left([0,T]; D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right), \\ &\psi_t \in C([0,T]; D(A_R)), \\ &\phi - \gamma G_2 \gamma_1 \phi_{tt} + \alpha G_1 \gamma_0 \psi - \alpha\lambda G_2 \gamma_0 \psi \in C([0,T]; D(\mathring{\mathbf{A}})). \end{aligned} \tag{2.7}$$

This extra regularity of $[\phi, \phi_t, \psi]$, corresponding to smooth initial data, will justify the computations to be done below.

2.2. Proof of Theorem 2.1. As mentioned above, the terminal data $[\phi_0, \phi_1, \psi_0]$ will be considered to be in $D(\left[\mathcal{A}_\gamma^*\right]^2)$; accordingly the corresponding solution $[\phi, \phi_t, \psi]$ of (1.51) will be a classical one, with the regularity posted in (2.7). With the end in mind of deriving the estimate (2.2), we start by making the substitution

$$\widehat{\phi}(t) = e^{-\xi t}\phi(t) \text{ and } \widehat{\psi}(t) = e^{-\xi t}\psi(t), \tag{2.8}$$

where parameter $\xi \in \mathbb{R}$ is to be determined. Necessarily then $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ solves the coupled (backward) system

$$\begin{cases} \begin{cases} \left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t + \widehat{\phi}_{tt}\right) - \gamma\Delta\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t + \widehat{\phi}_{tt}\right) + \Delta^2\widehat{\phi} + \alpha\Delta\widehat{\psi} = 0 \\ \beta\left(\xi\widehat{\psi} + \widehat{\psi}_t\right) + \eta\Delta\widehat{\psi} - \sigma\widehat{\psi} - \alpha\Delta\left(\xi\widehat{\phi} + \widehat{\phi}_t\right) = 0 \end{cases} & \text{on } (0,\infty)\times\Omega, \\ \widehat{\phi} = \dfrac{\partial\widehat{\phi}}{\partial\nu} = 0 \ \text{ on } (0,\infty)\times\Gamma_0, \\ \begin{cases} \Delta\widehat{\phi} + (1-\mu)B_1\widehat{\phi} + \alpha\widehat{\psi} = 0 \\ \dfrac{\partial\Delta\widehat{\phi}}{\partial\nu} + (1-\mu)\dfrac{\partial B_2\widehat{\phi}}{\partial\tau} - \gamma\dfrac{\partial}{\partial\nu}\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t + \widehat{\phi}_{tt}\right) + \alpha\dfrac{\partial\widehat{\psi}}{\partial\nu} = 0 \end{cases} & \text{on } (0,\infty)\times\Gamma_1, \\ \dfrac{\partial\widehat{\psi}}{\partial\nu} + \lambda\widehat{\psi} = 0 \ \text{ on } (0,\infty)\times\Gamma, \ \lambda \geq 0, \\ \left[\widehat{\phi}(T), \widehat{\phi}_t(T), \widehat{\psi}(T)\right] = \left[e^{-\xi T}\phi_0, -\xi e^{-\xi T}\phi_0 + e^{-\xi T}\phi_1, e^{-\xi T}\psi_0\right]. \end{cases} \tag{2.9}$$

Since $[\phi_0, \phi_1, \psi_0] \in D(\left[\mathcal{A}_\gamma^*\right]^2)$, the extra regularity in (2.7) gives that $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ is a classical (not just weak) solution of (2.9); accordingly, we can rewrite (2.9) abstractly as (see Remark 1.7 and (1.31))

$$\begin{aligned} &\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t + \widehat{\phi}_{tt}\right) - \gamma\Delta\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t + \widehat{\phi}_{tt}\right) - \gamma\mathring{\mathbf{A}}G_2\gamma_1\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t + \widehat{\phi}_{tt}\right) \\ &\qquad + \mathring{\mathbf{A}}\widehat{\phi} + \alpha\mathring{\mathbf{A}}G_1\gamma_0\widehat{\psi} - \alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\widehat{\psi} + \alpha\Delta\widehat{\psi} = 0 \text{ in } H^{-1}_{\Gamma_0,\gamma}(\Omega), \end{aligned} \tag{2.10}$$

$$\beta\left(\xi\widehat{\psi} + \widehat{\psi}_t\right) + \eta\Delta\widehat{\psi} - \sigma\widehat{\psi} - \alpha\Delta\left(\xi\widehat{\phi} + \widehat{\phi}_t\right) = 0 \text{ in } L^2(\Omega), \tag{2.11}$$

$$\left[\widehat{\phi}(T), \widehat{\phi}_t(T), \widehat{\psi}(T)\right] = \left[e^{-\xi T}\phi_0, -\xi e^{-\xi T}\phi_0 + e^{-\xi T}\phi_1, e^{-\xi T}\psi_0\right]. \tag{2.12}$$

Now multiplying the heat equation (2.11) by $\frac{\alpha}{\eta}$ and adding it to the Kirchoff plate (2.10), and subsequently taking the parameter ξ to be $\xi \equiv \frac{\alpha^2}{2\gamma\eta}$, we obtain the single equation

$$\begin{aligned}\widehat{\phi}_{tt} - \gamma\Delta\widehat{\phi}_{tt} + \mathring{\mathbf{A}}\widehat{\phi} - \gamma\mathring{\mathbf{A}}G_2\gamma_1\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t + \widehat{\phi}_{tt}\right) + \alpha\mathring{\mathbf{A}}G_1\gamma_0\widehat{\psi} - \alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\widehat{\psi}\\ = c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}\,, \qquad (2.13)\end{aligned}$$

$$\left[\widehat{\phi}(T), \widehat{\phi}_t(T), \widehat{\psi}(T)\right] = \left[e^{-\xi T}\phi_0, -\xi e^{-\xi T}\phi_0 + e^{-\xi T}\phi_1, e^{-\xi T}\psi_0\right], \qquad (2.14)$$

where the constants $c_0 = \frac{\alpha^3\beta}{2\gamma\eta^2} - \frac{\alpha\sigma}{\eta}$, $c_1 = \frac{\alpha\beta}{\eta}$, $c_2 = -\frac{\alpha^4}{4\gamma^2\eta^2}$, $c_3 = -\frac{\alpha^2}{\gamma\eta}$, and $c_4 = -\frac{\alpha^4}{4\gamma\eta^2}$. (Note that the particular choice of ξ made here eliminates the higher order term $\Delta\widehat{\phi}_t$.) System (2.13)–(2.14) may be rewritten in PDE form as the Kirchoff plate equation

$$\begin{cases} \widehat{\phi}_{tt} - \gamma\Delta\widehat{\phi}_{tt} + \Delta^2\widehat{\phi} = c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi} \quad \text{on } (0,\infty)\times\Omega, \\ \widehat{\phi} = \dfrac{\partial\widehat{\phi}}{\partial\nu} = 0 \ \text{ on } (0,\infty)\times\Gamma_0, \\ \begin{cases} \Delta\widehat{\phi} + (1-\mu)B_1\widehat{\phi} = -\alpha\widehat{\psi} \\ \dfrac{\partial\Delta\widehat{\phi}}{\partial\nu} + (1-\mu)\dfrac{\partial B_2\widehat{\phi}}{\partial\tau} - \gamma\dfrac{\partial\widehat{\phi}_{tt}}{\partial\nu} = \gamma\dfrac{\partial}{\partial\nu}\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t\right) - \alpha\dfrac{\partial\widehat{\psi}}{\partial\nu} \end{cases} \text{on } (0,\infty)\times\Gamma_1, \\ \left[\widehat{\phi}(T), \widehat{\phi}_t(T), \widehat{\psi}(T)\right] = \left[e^{-\xi T}\phi_0, -\xi e^{-\xi T}\phi_0 + e^{-\xi T}\phi_1, e^{-\xi T}\psi_0\right]. \end{cases} \qquad (2.15)$$

As $\widehat{\phi} - \gamma G_2\gamma_1(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t + \widehat{\phi}_{tt}) + \alpha G_1\gamma_0\widehat{\psi} - \alpha\lambda G_2\gamma_0\widehat{\psi} \in C([0,T]; D(\mathring{\mathbf{A}}))$ (using the last containment in (2.7)), then $[\widehat{\phi}, \widehat{\phi}_t]$ is a classical solution of (2.15).

We note at this point that one can readily derive the trace estimate Lemma 4.5 (of the appendix below) for the plate component $\Delta\widehat{\phi}|_{\Gamma_0}$ of the solution $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ of (2.9). The proof of this is relegated to the appendix, since it is entirely analogous to that shown for the forward problem in [3] and [4]. This estimate will be critical in the proof of the following lemma, which gives an energy relation for the mechanical variable.

LEMMA 2.2. (a) *The solution* $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ *to* (2.9) *satisfies the following relation for all* s *and* $\tau \in [0,T]$*:*

$$E_{\widehat{\phi}}(t)\Big|_{t=s}^{t=\tau} = \mathcal{F}(s,\tau), \qquad (2.16)$$

where $E_{\widehat{\phi}}(\tau)$ *is the mechanical energy function defined in* (2.3) *and* $\mathcal{F}(\cdot,\cdot)$ *is a function (defined below in* (2.34)*) that obeys the following estimate for all* s *and* $\tau \in [0,T]$ *and* $\epsilon > 0$*:*

$$\begin{aligned}\mathcal{F}(s,\tau) \le C_\epsilon\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt + \epsilon\int_0^T \left[E_{\widehat{\phi}}(t) + \left\|A_R^{\frac{1}{2}}\widehat{\psi}(t)\right\|^2_{L^2(\Omega)}\right] dt\\ +\epsilon\left(E_{\widehat{\phi}}(s) + E_{\widehat{\phi}}(\tau)\right) + \text{l.o.t.}(\widehat{\phi}, \widehat{\phi}_t\widehat{\psi}). \qquad (2.17)\end{aligned}$$

(b) *For* $\epsilon > 0$ *small enough, the solution* $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ *to* (2.9) *satisfies the following*

estimate for all s and $\tau \in [0,T]$:

$$E_{\widehat{\phi}}(\tau) \leq \left(\frac{1+\epsilon}{1-\epsilon}\right) E_{\widehat{\phi}}(s) + C_\epsilon \int_0^T \left\|\nabla \widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt$$
$$+\frac{\epsilon}{1-\epsilon}\int_0^T \left[E_{\widehat{\phi}}(t) + \left\|A_R^{\frac{1}{2}}\widehat{\psi}(t)\right\|^2_{L^2(\Omega)}\right] dt + \mathsf{l.o.t.}(\widehat{\phi}, \widehat{\phi}_t\widehat{\psi}). \tag{2.18}$$

Above, the constant C_ϵ is independent of time.

Proof. We take the duality pairing of the abstract equation (2.13) with $\widehat{\phi}_t$ and integrate in time and space so as to get

(2.19)

$$\int_s^\tau \left[\left\langle \widehat{\phi}_{tt} - \gamma\Delta\widehat{\phi}_{tt} - \gamma \mathring{\mathbf{A}} G_2\gamma_1\widehat{\phi}_{tt}, \widehat{\phi}_t\right\rangle_{H^{-1}_{\Gamma_0}(\Omega)\times H^1_{\Gamma_0}(\Omega)} + \left\langle \mathring{\mathbf{A}}\widehat{\phi}, \widehat{\phi}_t\right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]'\times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)}\right] dt$$
$$= \int_s^\tau \left\langle \gamma\mathring{\mathbf{A}}G_2\gamma_1\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t\right) - \alpha\mathring{\mathbf{A}}G_1\gamma_0\widehat{\psi} + \alpha\lambda\ \mathring{\mathbf{A}}G_2\gamma_0\widehat{\psi}, \widehat{\phi}_t\right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]'\times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} dt$$
$$+ \int_s^\tau \left(c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \widehat{\phi}_t\right)_{L^2(\Omega)} dt.$$

(Note that here we are using implicitly the fact that the terminal data $[\phi_0, \phi_1, \psi_0]$ being in $D(\mathcal{A}^*_\gamma)$ implies that $\mathring{\mathbf{A}}\widehat{\phi} + \gamma\mathring{\mathbf{A}}G_2\gamma_1(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t + \widehat{\phi}_{tt}) - \alpha\mathring{\mathbf{A}}G_1\gamma_0\widehat{\psi} + \alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\widehat{\psi}$ is an element of $C([0,T]; H^{-1}_{\Gamma_0}(\Omega))$.) Second, denoting A_D^{-1} to be the inverse of the elliptic operator defined in (1.12), we multiply the PDE (2.15) by $-\frac{c_1}{\gamma}A_D^{-1}\widehat{\psi}$, and subsequently integrate in time and space so as to get

$$-\frac{c_1}{\gamma}\int_s^\tau \left(\widehat{\phi}_{tt} - \gamma\Delta\widehat{\phi}_{tt} + \Delta^2\widehat{\phi} - \left[c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}\right], A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)} dt = 0. \tag{2.20}$$

(A1) *Rewriting* (2.19). Using equality (1.31) and the characterizations in (1.23), we have upon the taking of adjoints that (2.19) may be rewritten as

$$E_{\widehat{\phi}}(t)\Big|_{t=s}^{t=\tau} = \int_s^\tau \left(c_0\widehat{\psi} + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \widehat{\phi}_t\right)_{L^2(\Omega)} dt + \int_s^\tau c_1\left(\widehat{\psi}_t, \widehat{\phi}_t\right)_{L^2(\Omega)} dt$$
$$-\int_s^\tau \left[\left(\gamma\xi^2\frac{\partial\widehat{\phi}}{\partial\nu} + 2\gamma\xi\frac{\partial\widehat{\phi}_t}{\partial\nu} + \alpha\lambda\gamma_0\widehat{\psi}, \widehat{\phi}_t\right)_{L^2(\Gamma_1)} + \alpha\left(\widehat{\psi}, \frac{\partial\widehat{\phi}_t}{\partial\nu}\right)_{L^2(\Gamma_1)}\right] dt\,. \tag{2.21}$$

(A2) *Rewriting* (2.20). (i) An integration by parts, the use of the heat equation (2.11), and the fact that $A_R\widehat{\psi} = -\Delta\widehat{\psi} + \Delta D\gamma_0\widehat{\psi} + \frac{\sigma}{\eta}\widehat{\psi} = A_D(\ \mathbf{I} - D\gamma_0)\widehat{\psi} + \frac{\sigma}{\eta}\widehat{\psi}$ yield

(2.22)

$$\int_s^\tau -\frac{c_1}{\gamma}\left(\widehat{\phi}_{tt}, A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)} dt = \left[-\frac{c_1}{\gamma}\left(\widehat{\phi}_t, A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)}\right]_s^\tau$$
$$+\frac{c_1}{\gamma}\int_s^\tau \left(\widehat{\phi}_t, A_D^{-1}\widehat{\psi}_t\right)_{L^2(\Omega)} dt$$

$$= \left[-\frac{c_1}{\gamma} \left(\widehat{\phi}_t, A_D^{-1} \widehat{\psi} \right)_{L^2(\Omega)} \right]_s^\tau$$
$$+ \frac{c_1}{\gamma} \int_s^\tau \left(\widehat{\phi}_t, \left(\frac{\sigma}{\beta} - \xi \right) A_D^{-1} \widehat{\psi} + \frac{\eta}{\beta} \left(\mathbf{I} - D\gamma_0 \right) \widehat{\psi} \right)_{L^2(\Omega)} dt$$
$$- \frac{c_1}{\gamma} \int_s^\tau \left(\widehat{\phi}_t, \frac{\alpha\xi}{\beta} \left(\mathbf{I} - D\gamma_0 \right) \widehat{\phi} + \frac{\alpha}{\beta} \left(\mathbf{I} - D\gamma_0 \right) \widehat{\phi}_t \right)_{L^2(\Omega)} dt.$$

(ii) An integration by parts and employment of Green's theorem yield

(2.23)

$$\int_s^\tau c_1 \left(\Delta \widehat{\phi}_{tt}, A_D^{-1} \widehat{\psi} \right)_{L^2(\Omega)} dt = - \int_s^\tau c_1 \left(\nabla \widehat{\phi}_{tt}, \nabla A_D^{-1} \widehat{\psi} \right)_{L^2(\Omega)} dt$$
$$= -c_1 \left[\left(\nabla \widehat{\phi}_t, \nabla A_D^{-1} \widehat{\psi} \right)_{L^2(\Omega)} \right]_s^\tau + c_1 \int_s^\tau \left(\nabla \widehat{\phi}_t, \nabla A_D^{-1} \widehat{\psi}_t \right)_{L^2(\Omega)} dt$$
$$= - c_1 \left[\left(\nabla \widehat{\phi}_t, \nabla A_D^{-1} \widehat{\psi} \right)_{L^2(\Omega)} \right]_s^\tau + c_1 \int_s^\tau \left(\widehat{\phi}_t, A_D A_D^{-1} \widehat{\psi}_t \right)_{L^2(\Omega)} dt$$
$$+ c_1 \int_s^\tau \left(\widehat{\phi}_t, \frac{\partial A_D^{-1} \widehat{\psi}_t}{\partial \nu} \right)_{L^2(\Gamma_1)} dt$$
$$= -c_1 \left[\left(\nabla \widehat{\phi}_t, \nabla A_D^{-1} \widehat{\psi} \right)_{L^2(\Omega)} \right]_s^\tau + c_1 \int_s^\tau \left(\widehat{\phi}_t, \widehat{\psi}_t \right)_{L^2(\Omega)} dt$$
$$+ c_1 \int_s^\tau \left(\widehat{\phi}_t, \left(\frac{\sigma}{\beta} - \xi \right) \frac{\partial A_D^{-1} \widehat{\psi}}{\partial \nu} + \frac{\eta}{\beta} \frac{\partial (\mathbf{I} - D\gamma_0) \widehat{\psi}}{\partial \nu} \right)_{L^2(\Gamma_1)} dt$$
$$- c_1 \int_s^\tau \left(\widehat{\phi}_t, \frac{\alpha\xi}{\beta} \frac{\partial (\mathbf{I} - D\gamma_0) \widehat{\phi}}{\partial \nu} + \frac{\alpha}{\beta} \frac{\partial (\mathbf{I} - D\gamma_0) \widehat{\phi}_t}{\partial \nu} \right)_{L^2(\Gamma_1)} dt.$$

(iii) Through the use of Green's theorem (1.9) and the boundary conditions in (2.15), we obtain

(2.24)

$$- \int_s^\tau \frac{c_1}{\gamma} \left(\Delta^2 \widehat{\phi}, A_D^{-1} \widehat{\psi} \right)_{L^2(\Omega)} dt$$
$$= - \frac{c_1}{\gamma} \int_s^\tau a \left(\widehat{\phi}, A_D^{-1} \widehat{\psi} \right) dt - \frac{\alpha c_1}{\gamma} \int_s^\tau \left(\widehat{\psi}, \frac{\partial A_D^{-1} \widehat{\psi}}{\partial \nu} \right)_{L^2(\Gamma_1)} dt$$
$$+ \frac{c_1}{\gamma} \int_s^\tau \left(\Delta \widehat{\phi}, \frac{\partial A_D^{-1} \widehat{\psi}}{\partial \nu} \right)_{L^2(\Gamma_0)} dt$$

(where we have used the fact that $\widehat{\phi}|_{\Gamma_0} = \frac{\partial \widehat{\phi}}{\partial \nu}|_{\Gamma_0} = 0$ implies $B_1 \widehat{\phi}|_{\Gamma_0} = 0$; see [11]).

Jointly then, equalities (2.20) and (2.22)–(2.24) give the relation

(2.25)

$$0 = -c_1 \int_s^\tau \left(\widehat{\phi}_t, \widehat{\psi}_t\right)_{L^2(\Omega)} dt - \frac{c_1}{\gamma} \int_s^\tau \left(\widehat{\phi}_t, \left(\frac{\sigma}{\beta} - \xi\right) A_D^{-1}\widehat{\psi} + \frac{\eta}{\beta}\left(\mathbf{I} - D\gamma_0\right)\widehat{\psi}\right)_{L^2(\Omega)} dt$$
$$+ \frac{c_1}{\gamma} \int_s^\tau \left(\widehat{\phi}_t, \frac{\alpha\xi}{\beta}\left(\mathbf{I} - D\gamma_0\right)\widehat{\phi} + \frac{\alpha}{\beta}\left(\mathbf{I} - D\gamma_0\right)\widehat{\phi}_t\right)_{L^2(\Omega)} dt$$
$$- c_1 \int_s^\tau \left(\widehat{\phi}_t, \left(\frac{\sigma}{\beta} - \xi\right)\frac{\partial A_D^{-1}\widehat{\psi}}{\partial\nu} + \frac{\eta}{\beta}\frac{\partial(\mathbf{I} - D\gamma_0)\widehat{\psi}}{\partial\nu}\right)_{L^2(\Gamma_1)} dt$$
$$+ c_1 \int_s^\tau \left(\widehat{\phi}_t, \frac{\alpha\xi}{\beta}\frac{\partial(\mathbf{I} - D\gamma_0)\widehat{\phi}}{\partial\nu} + \frac{\alpha}{\beta}\frac{\partial(\mathbf{I} - D\gamma_0)\widehat{\phi}_t}{\partial\nu}\right)_{L^2(\Gamma_1)} dt$$
$$+ \frac{c_1}{\gamma} \int_s^\tau a\left(\widehat{\phi}, A_D^{-1}\widehat{\psi}\right) dt + \frac{\alpha c_1}{\gamma} \int_s^\tau \left(\widehat{\psi}, \frac{\partial A_D^{-1}\widehat{\psi}}{\partial\nu}\right)_{L^2(\Gamma_1)} dt$$
$$- \frac{c_1}{\gamma} \int_s^\tau \left(\Delta\widehat{\phi}, \frac{\partial A_D^{-1}\widehat{\psi}}{\partial\nu}\right)_{L^2(\Gamma_0)} dt$$
$$- \int_s^\tau \left(c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \frac{c_1}{\gamma}A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)} dt$$
$$+ c_1\left[\left(\nabla\widehat{\phi}_t, \nabla A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)} + \frac{1}{\gamma}\left(\widehat{\phi}_t, A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)}\right]_s^\tau.$$

Summing the relations (2.21) and (2.25), we obtain

(2.26)

$$E_{\widehat{\phi}}(t)\Big|_{t=s}^{t=\tau} = \int_s^\tau \left(c_0\widehat{\psi} + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \widehat{\phi}_t - \frac{c_1}{\gamma}A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)} dt$$
$$- \int_s^\tau \left[\left(\gamma\xi^2\frac{\partial\widehat{\phi}}{\partial\nu} + 2\gamma\xi\frac{\partial\widehat{\phi}_t}{\partial\nu} + \alpha\lambda\gamma_0\widehat{\psi}, \widehat{\phi}_t\right)_{L^2(\Gamma_1)} + \alpha\left(\widehat{\psi}, \frac{\partial\widehat{\phi}_t}{\partial\nu}\right)_{L^2(\Gamma_1)}\right] dt$$
$$- \frac{c_1}{\gamma} \int_s^\tau \left(\widehat{\phi}_t, \left(\frac{\sigma}{\beta} - \xi\right) A_D^{-1}\widehat{\psi} + \frac{\eta}{\beta}\left(\mathbf{I} - D\gamma_0\right)\widehat{\psi}\right)_{L^2(\Omega)} dt + c_1\left[\left(\nabla\widehat{\phi}_t, \nabla A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)}\right]_s^\tau$$
$$+ c_1 \int_s^\tau \left[\left(\frac{\widehat{\phi}_t}{\gamma}, \frac{\alpha\xi}{\beta}\left(\mathbf{I} - D\gamma_0\right)\widehat{\phi} + \frac{\alpha}{\beta}\left(\mathbf{I} - D\gamma_0\right)\widehat{\phi}_t\right)_{L^2(\Omega)}\right.$$
$$\left. - \left(\widehat{\phi}_t, \left(\frac{\sigma}{\beta} - \xi\right)\frac{\partial A_D^{-1}\widehat{\psi}}{\partial\nu} + \frac{\eta}{\beta}\frac{\partial(\mathbf{I} - D\gamma_0)\widehat{\psi}}{\partial\nu}\right)_{L^2(\Gamma_1)}\right] dt$$
$$+ c_1 \int_s^\tau \left(\widehat{\phi}_t, \frac{\alpha\xi}{\beta}\frac{\partial(\mathbf{I} - D\gamma_0)\widehat{\phi}}{\partial\nu} + \frac{\alpha}{\beta}\frac{\partial(\mathbf{I} - D\gamma_0)\widehat{\phi}_t}{\partial\nu}\right)_{L^2(\Gamma_1)} dt + \frac{c_1}{\gamma} \int_s^\tau a\left(\widehat{\phi}, A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)} dt$$
$$+ \frac{c_1}{\gamma} \int_s^\tau \left[\left(\alpha\widehat{\psi}, \frac{\partial A_D^{-1}\widehat{\psi}}{\partial\nu}\right)_{L^2(\Gamma_1)} - \left(\Delta\widehat{\phi}, \frac{\partial A_D^{-1}\widehat{\psi}}{\partial\nu}\right)_{L^2(\Gamma_0)}\right] dt + \frac{c_1}{\gamma}\left[\left(\widehat{\phi}_t, A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)}\right]_s^\tau$$

(note the cancellation of the high order term $\int_s^\tau (\widehat{\psi}_t, \widehat{\phi}_t)_{L^2(\Omega)} dt$).

We now proceed to estimate the right-hand side of this relation. In so doing, we will be using implicitly, in (B1)–(B7) below, the inequality $ab \leq \epsilon a^2 + C_\epsilon b^2$.

(B1) We have by trace theory

$$-\int_s^\tau \left[\left(\gamma\xi^2\frac{\partial\widehat{\phi}}{\partial\nu}+2\gamma\xi\frac{\partial\widehat{\phi}_t}{\partial\nu}+\alpha\lambda\gamma_0\widehat{\psi},\widehat{\phi}_t\right)_{L^2(\Gamma_1)}+\alpha\left(\widehat{\psi},\frac{\partial\widehat{\phi}_t}{\partial\nu}\right)_{L^2(\Gamma_1)}\right]dt$$

$$\leq C\int_0^T\left\|\frac{\partial\widehat{\phi}_t}{\partial\nu}\right\|^2_{L^2(\Gamma_1)}dt+\text{l.o.t.}\left(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}\right). \tag{2.27}$$

(B2) As A_D^{-1} is a bounded operator, we have

$$\int_s^\tau\left(c_0\widehat{\psi}+c_2\widehat{\phi}+c_3\widehat{\phi}_t+c_4\Delta\widehat{\phi},\widehat{\phi}_t-\frac{c_1}{\gamma}A_D^{-1}\widehat{\psi}\right)dt$$

$$\leq\frac{\epsilon}{6}\int_0^T\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2_{L^2(\Omega)}dt+\text{l.o.t.}\left(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}\right). \tag{2.28}$$

(B3) As $D\gamma_0\in\mathcal{L}(H^s(\Omega))$ for $s>\frac{1}{2}$ (by standard elliptic theory), and $A_D^{-1}\in\mathcal{L}(L^2(\Omega),D(A_D))$, we then have in conjunction with trace theory

(2.29)

$$-\frac{c_1}{\gamma}\int_s^\tau\left(\widehat{\phi}_t,\left(\frac{\sigma}{\beta}-\xi\right)A_D^{-1}\widehat{\psi}+\frac{\eta}{\beta}\left(\mathbf{I}-D\gamma_0\right)\widehat{\psi}\right)_{L^2(\Omega)}dt$$

$$+\frac{c_1}{\gamma}\int_s^\tau\left(\widehat{\phi}_t,\frac{\alpha\xi}{\beta}\left(\mathbf{I}-D\gamma_0\right)\widehat{\phi}+\frac{\alpha}{\beta}\left(\mathbf{I}-D\gamma_0\right)\widehat{\phi}_t\right)_{L^2(\Omega)}dt$$

$$-c_1\int_s^\tau\left(\widehat{\phi}_t,\left(\frac{\sigma}{\beta}-\xi\right)\frac{\partial A_D^{-1}\widehat{\psi}}{\partial\nu}\right)_{L^2(\Gamma_1)}dt$$

$$+\frac{c_1}{\gamma}\int_s^\tau a\left(\widehat{\phi},A_D^{-1}\widehat{\psi}\right)dt+\frac{\alpha c_1}{\gamma}\int_s^\tau\left(\widehat{\psi},\frac{\partial A_D^{-1}\widehat{\psi}}{\partial\nu}\right)_{L^2(\Gamma_1)}dt$$

$$\leq\frac{\epsilon}{6}\int_0^T\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2_{L^2(\Omega)}dt+\text{l.o.t.}\left(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}\right).$$

(B4) Using the fact that $D\gamma_0\in\mathcal{L}(H^s(\Omega))$ for $s>\frac{1}{2}$, and $\frac{\partial\widehat{\psi}}{\partial\nu}(t)|_\Gamma=-\lambda\widehat{\psi}(t)|_\Gamma$, we have along with trace theory that

$$c_1\int_s^\tau\left(\widehat{\phi}_t,-\frac{\eta}{\beta}\frac{\partial\widehat{\psi}}{\partial\nu}+\frac{\alpha\xi}{\beta}\frac{\partial(\mathbf{I}-D\gamma_0)\widehat{\phi}}{\partial\nu}+\frac{\alpha}{\beta}\frac{\partial\widehat{\phi}_t}{\partial\nu}\right)_{L^2(\Gamma_1)}dt$$

$$\leq C\int_0^T\left\|\frac{\partial\widehat{\phi}_t}{\partial\nu}\right\|^2_{L^2(\Gamma_1)}dt+\text{l.o.t.}\left(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}\right). \tag{2.30}$$

(B5) By [1, p. 311, Theorem 3] and trace theory we deduce that $\frac{\partial}{\partial\nu}D\gamma_0\in\mathcal{L}(H^1(\Omega),H^{-\frac{1}{2}}(\Gamma))$, and so accordingly we have

$$c_1\int_s^\tau\left(\widehat{\phi}_t,\frac{\eta}{\beta}\frac{\partial D\gamma_0\widehat{\psi}}{\partial\nu}-\frac{\alpha}{\beta}\frac{\partial D\gamma_0\widehat{\phi}_t}{\partial\nu}\right)_{L^2(\Gamma_1)}dt\leq C_\epsilon\int_0^T\left\|\widehat{\phi}_t\right\|^2_{H^{\frac{1}{2}}(\Gamma_1)}dt$$

$$+\frac{\epsilon}{6}\int_0^T\left[\left\|P_\gamma^{\frac{1}{2}}\widehat{\phi}_t\right\|^2_{L^2(\Omega)}+\left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)}\right]dt. \tag{2.31}$$

(B6) As $A_D^{-1} \in \mathcal{L}(H^{-1}(\Omega), H_0^1(\Omega))$, by the characterizations of elliptic operators given in [7] , we then have for all $t \in [0,T]$

$$\begin{aligned}\left(\nabla\widehat{\phi}_t(t), \nabla A_D^{-1}\widehat{\psi}(t)\right)_{L^2(\Omega)} &\leq C \left\|\nabla\widehat{\phi}_t(t)\right\|_{L^2(\Omega)} \left\|\nabla A_D^{-1}\widehat{\psi}(t)\right\|_{L^2(\Omega)} \\ &\leq \frac{\epsilon}{6}\left\|P_\gamma^{\frac{1}{2}}\widehat{\phi}_t(t)\right\|_{L^2(\Omega)}^2 + \text{l.o.t.}\left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}\right).\end{aligned}$$

We thus have

$$\begin{aligned}&c_1\left[\left(\nabla\widehat{\phi}_t(t), \nabla A_D^{-1}\widehat{\psi}\right)_{L^2(\Omega)}\right]_{t=s}^{t=\tau} + \left[\frac{c_1}{\gamma}\left(\widehat{\phi}_t(t), A_D^{-1}\widehat{\psi}(t)\right)_{L^2(\Omega)}\right]_{t=s}^{t=\tau} \\ &\leq \frac{\epsilon}{6}\left(\left\|P_\gamma^{\frac{1}{2}}\widehat{\phi}_t(\tau)\right\|_{L^2(\Omega)}^2 + \left\|P_\gamma^{\frac{1}{2}}\widehat{\phi}_t(s)\right\|_{L^2(\Omega)}^2\right) + \text{l.o.t.}\left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}\right). \qquad (2.32)\end{aligned}$$

(B7) Finally, we can use the trace result Lemma 4.5 of the appendix and the fact that $A_D^{-1} \in \mathcal{L}(H^{-\frac{1}{2}+\epsilon}(\Omega), H^{\frac{3}{2}+\epsilon}(\Omega)$ (again by [7]) to have

(2.33)

$$\begin{aligned}&-\frac{c_1}{\gamma}\int_s^\tau \left(\Delta\widehat{\phi}, \frac{\partial A_D^{-1}\widehat{\psi}}{\partial\nu}\right)_{L^2(\Gamma_0)} dt \\ &\leq C\int_s^\tau \left\|\Delta\widehat{\phi}\right\|_{L^2(\Gamma_0)}\left\|\widehat{\psi}\right\|_{H^{-\frac{1}{2}+\epsilon}(\Omega)} dt \leq \frac{\epsilon}{6C_0}\int_s^\tau \left\|\Delta\widehat{\phi}\right\|_{L^2(\Gamma_0)}^2 dt + C_\epsilon\int_0^T \left\|\widehat{\psi}\right\|_{H^{-\frac{1}{2}+\epsilon}(\Omega)}^2 dt \\ &\text{(where the constant } C_0 \text{ above is the very same as that in (4.13))} \\ &\leq \frac{\epsilon}{3}\int_0^T E_{\widehat{\phi}}(t)dt + \frac{\epsilon}{3}\left[E_{\widehat{\phi}}(s) + E_{\widehat{\phi}}(\tau)\right] + \text{l.o.t.}\left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}\right).\end{aligned}$$

Therefore, if we define $\mathcal{F}(s,\tau)$ to be

$$\mathcal{F}(s,\tau) \equiv \text{right-hand side of (2.26)}, \qquad (2.34)$$

estimates (2.27)–(2.33), then we have

$$\begin{aligned}\mathcal{F}(s,\tau) \leq C_\epsilon\int_0^T \left\|\nabla\widehat{\phi}_t\right\|_{L^2(\Gamma_1)}^2 dt + \epsilon\int_0^T \left[E_{\widehat{\phi}}(t) + \left\|A_R^{\frac{1}{2}}\widehat{\psi}(t)\right\|_{L^2(\Omega)}^2\right] dt \\ +\epsilon\left[E_{\widehat{\phi}}(s) + E_{\widehat{\phi}}(\tau)\right] + \text{l.o.t.}\left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}\right), \qquad (2.35)\end{aligned}$$

where the constant C_ϵ does not depend on time T. This and equality (2.26) prove (a).

To prove (b), we combine (2.16) and (2.17) and subsequently take $\epsilon > 0$ small enough. The proof of Lemma 2.2 is concluded. □

With the radial vector field $\overline{h}$ defined in (1.3) , one has the following relation, which is essentially demonstrated in [12] (the complete proof is carried out in Proposition 4.6 of the appendix below).

PROPOSITION 2.3. *With the vector field $\overline{h}$ as defined in* (1.3)*, the solution $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ to* (2.15)*, corresponding to terminal data $[\phi_0, \phi_1, \psi_0] \in D([\mathcal{A}_\gamma^*]^2)$, satisfies the following equality for arbitrary $\epsilon_0 \in [0,T)$:*

(2.36)

$$\int_{\epsilon_0}^{T-\epsilon_0} E_{\widehat{\phi}}(t)dt = \int_{\epsilon_0}^{T-\epsilon_0} \left(c_0\widehat{\psi} + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi} \right)_{L^2(\Omega)} dt$$

$$- c_1 \int_{\epsilon_0}^{T-\epsilon_0} \left(\widehat{\psi}, \overline{h}\cdot\nabla\widehat{\phi}_t - \frac{1}{2}\widehat{\phi}_t \right)_{L^2(\Omega)} dt + \frac{1}{2}\int_{\epsilon_0}^{T-\epsilon_0}\int_{\Gamma_1} \overline{h}\cdot\nu \left(\widehat{\phi}_t^2 + \gamma \left| \nabla\widehat{\phi}_t \right|^2 \right) d\Gamma dt$$

$$- \int_{\epsilon_0}^{T-\epsilon_0} \left\| \widehat{\phi}_t \right\|^2_{L^2(\Omega)} dt + \frac{1}{2}\int_{\epsilon_0}^{T-\epsilon_0}\int_{\Gamma_0} \overline{h}\cdot\nu \left(\Delta\widehat{\phi} \right)^2 d\Gamma dt$$

$$- \int_{\epsilon_0}^{T-\epsilon_0} \left[\alpha \left(\widehat{\psi}, \frac{\partial}{\partial\nu}\left(\overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi} \right) \right)_{L^2(\Gamma_1)} \right.$$

$$\left. + \left(\gamma\frac{\partial}{\partial\nu}\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t \right) - \alpha\frac{\partial\widehat{\psi}}{\partial\nu}, \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi} \right)_{L^2(\Gamma_1)} \right] dt$$

$$- \left[(\widehat{\phi}_t, \overline{h}\cdot\nabla\widehat{\phi})_{L^2(\Omega)} + \gamma\left(\nabla\widehat{\phi}_t, \nabla\left(\overline{h}\cdot\nabla\widehat{\phi} \right) \right)_{L^2(\Omega)} - \frac{1}{2}(\widehat{\phi}_t, \widehat{\phi})_{L^2(\Omega)} \right]_{t=\epsilon_0}^{t=T-\epsilon_0}$$

$$+ \left[\frac{\gamma}{2}\left(\nabla\widehat{\phi}_t, \nabla\widehat{\phi} \right)_{L^2(\Omega)} + c_1\left(\widehat{\psi}, \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi} \right)_{L^2(\Omega)} \right]_{t=\epsilon_0}^{t=T-\epsilon_0}$$

$$- \int_{\epsilon_0}^{T-\epsilon_0}\int_{\Gamma_1} \frac{\overline{h}\cdot\nu}{2} \left[\left(\frac{\partial^2\widehat{\phi}}{\partial x^2} \right)^2 + \left(\frac{\partial^2\widehat{\phi}}{\partial y^2} \right)^2 \right.$$

$$\left. + 2\mu\left(\frac{\partial^2\widehat{\phi}}{\partial x^2} \right)\left(\frac{\partial^2\widehat{\phi}}{\partial y^2} \right) + 2(1-\mu)\left(\frac{\partial^2\widehat{\phi}}{\partial x\partial y} \right)^2 \right] dtd\Gamma.$$

So as to derive another intermediate energy inequality, we will now estimate the right-hand side of the relation (2.36). In the course of this work, we will make critical use of the following trace estimate for (uncoupled) Kirchoff plates, which was derived in [15]. It is this regularity result that allows the controlled portion Γ_1 of the boundary to be free of geometric constraints.

TRACE THEOREM (see [15]). *Let the function $\varphi(t,x)$ satisfy the following Kirchoff equation on an open, bounded domain $\Omega \subset \mathbb{R}^n$, with smooth boundary Γ, $\Gamma = \Gamma_0 \cup \Gamma_1$, where each Γ_i is open and nonempty, with $\overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset$:*

$$\text{(2.37)} \qquad \begin{cases} \varphi_{tt} - \gamma\Delta\varphi_{tt} + \Delta^2\varphi = f \quad \text{on } (0,T)\times\Omega, \\ \varphi = \dfrac{\partial\varphi}{\partial\nu} = 0 \quad \text{on } (0,T)\times\Gamma_0, \\ \begin{cases} \Delta\varphi + (1-\mu)B_1\varphi = g_1 \\ \dfrac{\partial\Delta\varphi}{\partial\nu} + (1-\mu)\dfrac{\partial B_2\varphi}{\partial\tau} - \gamma\dfrac{\partial\varphi_{tt}}{\partial\nu} = g_2 \end{cases} \quad \text{on } (0,T)\times\Gamma_1 \end{cases}$$

(here the boundary operators B_1 and B_2 are as given in (1.2)). Let $0 < \epsilon_0 < \frac{T}{2}$ and $\epsilon > 0$ be arbitrary. Then the following inequality holds true for the solution φ:

(2.38)

$$\int_{\epsilon_0}^{T-\epsilon_0} \left[\left\| \frac{\partial^2\varphi}{\partial\tau^2} \right\|^2_{L^2(\Gamma_1)} + \left\| \frac{\partial^2\varphi}{\partial\nu^2} \right\|^2_{L^2(\Gamma_1)} + \left\| \frac{\partial^2\varphi}{\partial\tau\partial\nu} \right\|^2_{L^2(\Gamma_1)} \right] dt$$

$$\leq C_{T,\epsilon_0,\gamma}\left\{\left[\int_0^T \|f\|^2_{[H^{\frac{3}{2}-\epsilon}(\Omega)]'} + \|g_1\|^2_{L^2(\Gamma_1)} + \|\varphi\|^2_{H^{\frac{3}{2}+\epsilon}(\Gamma_1)} + \||\nabla\varphi_t|\|^2_{L^2(\Gamma_1)} + \|\varphi_t\|^2_{L^2(\Gamma_1)}\right]dt + \|g_2\|^2_{H^{-1}(0,T\times\Gamma_1)}\right\}.$$

Remark 2.4. In the original statement of this theorem (see Theorem 2.1 in [15]), the term $\int_0^T \|f\|^2_{[H^{\frac{3}{2}-\epsilon}(\Omega)]'}\,dt$ in the inequality (2.38) is replaced by $\|f\|^2_{[H^q(0,T\times\Omega)]'}$, where $q < \frac{1}{2}$. However, if one replaces the $H^{-q}(0,T\times\Omega)$ spaces with $L^2(0,T;[H^q(\Omega)]')$, the values of allowed parameters extend to $q < 3/2 + \epsilon$. This is in line with elliptic theory corresponding to free boundary conditions.

By the use of this trace result in part, we have the following energy estimate.

LEMMA 2.5. *For all $\epsilon_0 \in (0, \frac{T}{2})$ and $\widetilde{\epsilon} > 0$ arbitrary, the solution $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ to* (2.15) *satisfies*

$$\int_{\epsilon_0}^{T-\epsilon_0} E_{\widehat{\phi}}(t)dt \leq C^*\left(E_{\widehat{\phi}}(T-\epsilon_0) + E_{\widehat{\phi}}(\epsilon_0)\right)$$
$$+ C_T\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} + \widetilde{\epsilon}\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)} + \text{l.o.t.}\ (\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}), \tag{2.39}$$

where the (time independent) constant $C^* \geq \sqrt{\frac{2\gamma}{1-\mu}}\max_{[x,y]\in\overline{\Omega}}\left|\overline{h}(x,y)\right|$ (where, again, μ is Poisson's ratio and $\overline{h}$ satisfies 1.3*).*

Proof. We proceed to majorize the right-hand side of (2.36).

(A.1) Handling the term $\int_{\epsilon_0}^{T-\epsilon_0}(c_0\widehat{\psi} + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi})_{L^2(\Omega)}dt$: First, by Green's theorem and the fact that $\nabla \in \mathcal{L}\left(H^s(\Omega), H^{s-1}(\Omega)\right)$ and $\nabla\left(\overline{h}\cdot\nabla\right) \in \mathcal{L}\left(H^s(\Omega), H^{s-2}(\Omega)\right)$, we obtain

$$\begin{aligned}\left(\Delta\widehat{\phi}, \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}\right)_{L^2(\Omega)} &= -\left(\nabla\widehat{\phi}, \nabla\left(\overline{h}\cdot\nabla\widehat{\phi}\right) - \frac{1}{2}\widehat{\nabla\phi}\right)_{L^2(\Omega)} \\ &\quad + \left(\frac{\partial\widehat{\phi}}{\partial\nu}, \nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}\right)_{L^2(\Gamma_1)} \\ &= -\left(\nabla\widehat{\phi}, \nabla\left(\overline{h}\cdot\nabla\widehat{\phi}\right) - \frac{1}{2}\widehat{\nabla\phi}\right)_{H^\epsilon(\Omega)\times H^{-\epsilon}(\Omega)} + \left(\frac{\partial\widehat{\phi}}{\partial\nu}, \nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}\right)_{L^2(\Gamma_1)} \\ &\leq \text{l.o.t.}\left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}\right),\end{aligned}$$

where in the last step we have also used Cauchy–Schwarz and the trace theory. We thus have

$$\int_{\epsilon_0}^{T-\epsilon_0}\left(c_0\widehat{\psi} + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}\right)_{L^2(\Omega)}dt \leq \text{l.o.t.}\left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}\right). \tag{2.40}$$

(A.2) Likewise using Sobolev trace theory, the fact that $\frac{\partial\widehat{\psi}}{\partial\nu} = -\lambda\widehat{\psi}$, and the divergence theorem, we have

(2.41)

$$
\begin{aligned}
&- \int_{\epsilon_0}^{T-\epsilon_0} \left[c_1 \left(\widehat{\psi}, \overline{h} \cdot \nabla \widehat{\phi}_t - \frac{1}{2} \widehat{\phi}_t \right)_{L^2(\Omega)} + \left\| \widehat{\phi}_t \right\|^2_{L^2(\Omega)} \right] dt \\
&+ \int_{\epsilon_0}^{T-\epsilon_0} \left[- \left(\gamma \frac{\partial}{\partial \nu} \left(\xi^2 \widehat{\phi} + 2\xi \widehat{\phi}_t \right) - \alpha \frac{\partial \widehat{\psi}}{\partial \nu}, \overline{h} \cdot \nabla \widehat{\phi} - \frac{1}{2} \widehat{\phi} \right)_{L^2(\Gamma_1)} + \frac{\alpha}{2} \left(\widehat{\psi}, \frac{\partial \widehat{\phi}}{\partial \nu} \right)_{L^2(\Gamma_1)} \right] dt \\
&\leq c_1 \int_{\epsilon_0}^{T-\epsilon_0} \left(\widehat{\psi}, h_1 \widehat{\phi}_{tx} + h_2 \widehat{\phi}_{ty} \right)_{L^2(\Omega)} dt + C \int_0^T \left\| \nabla \widehat{\phi}_t \right\|^2_{L^2(\Gamma_1)} dt + \text{l.o.t. } (\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}) \\
&= -c_1 \int_{\epsilon_0}^{T-\epsilon_0} \int_\Omega \operatorname{div} \left(\widehat{\psi h} \right) \widehat{\phi}_t d\Omega dt \\
&\quad + c_1 \int_{\epsilon_0}^{T-\epsilon_0} \int_{\Gamma_1} \overline{h} \cdot \nu \, \widehat{\psi} \widehat{\phi}_t d\Gamma dt + C \int_0^T \left\| \nabla \widehat{\phi}_t \right\|^2_{L^2(\Gamma_1)} dt + \text{l.o.t. } (\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}) \\
&\leq C \int_0^T \left\| \nabla \widehat{\phi}_t \right\|^2_{L^2(\Gamma_1)} dt + \widetilde{\epsilon} \int_0^T \left\| A_R^{\frac{1}{2}} \widehat{\psi} \right\|^2_{L^2(\Omega)} + \text{l.o.t. } (\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}).
\end{aligned}
$$

(A.3) Using (1.3), we have

$$
\frac{1}{2} \int_{\epsilon_0}^{T-\epsilon_0} \int_{\Gamma_0} \overline{h} \cdot \nu \left(\Delta \widehat{\phi} \right)^2 \leq 0. \tag{2.42}
$$

(A.4) We now estimate the terms

$$
\begin{aligned}
&- \left[(\widehat{\phi}_t, \overline{h} \cdot \nabla \widehat{\phi})_{L^2(\Omega)} + \gamma \left(\nabla \widehat{\phi}_t, \nabla \left(\overline{h} \cdot \nabla \widehat{\phi} \right) \right)_{L^2(\Omega)} - \frac{1}{2} (\widehat{\phi}_t, \widehat{\phi})_{L^2(\Omega)} \right]_{t=\epsilon_0}^{t=T-\epsilon_0} \\
&+ \left[\frac{\gamma}{2} \left(\nabla \widehat{\phi}_t, \nabla \widehat{\phi} \right)_{L^2(\Omega)} + c_1 \left(\widehat{\psi}, \overline{h} \cdot \nabla \widehat{\phi} - \frac{1}{2} \widehat{\phi} \right)_{L^2(\Omega)} \right]_{t=\epsilon_0}^{t=T-\epsilon_0}.
\end{aligned} \tag{2.43}
$$

First, as $\overline{h} \cdot \nabla \widehat{\phi}(t) \in H^{\frac{1}{2}-\epsilon}(\Omega)$ for all $t \in [0,T]$, we have

(2.44)

$$
\begin{aligned}
&\left(\widehat{\psi}(t), \overline{h} \cdot \nabla \widehat{\phi}(t) - \frac{1}{2} \widehat{\phi}(t) \right)_{L^2(\Omega)} = \left\langle \widehat{\psi}(t), \overline{h} \cdot \nabla \widehat{\phi}(t) - \frac{1}{2} \widehat{\phi}(t) \right\rangle_{H^{-\frac{1}{2}+\epsilon}(\Omega) \times H^{\frac{1}{2}-\epsilon}(\Omega)} \\
&\leq \text{l.o.t.} \left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi} \right).
\end{aligned}
$$

Second, we have pointwise in time

$$
\begin{aligned}
&\gamma \left(\nabla \widehat{\phi}_t, \nabla \left(\overline{h} \cdot \nabla \widehat{\phi} \right) \right)_{L^2(\Omega)} + \frac{\gamma}{2} \left(\nabla \widehat{\phi}_t, \nabla \widehat{\phi} \right)_{L^2(\Omega)} \\
&= \sqrt{\gamma} \int_\Omega \sqrt{\gamma} \nabla \widehat{\phi}_t(x,y) \cdot [(x-x_0)\phi_{xx} + (y-y_0)\phi_{xy}, (x-x_0)\phi_{xy} + (y-y_0)\phi_{yy}] \, dxdy \\
&\quad + \frac{3\gamma}{2} \left(\nabla \widehat{\phi}_t, \nabla \widehat{\phi} \right)_{L^2(\Omega)}.
\end{aligned} \tag{2.45}
$$

Now, to handle the first term on the right-hand side of (2.45), we use the inequality $ab \leq \frac{\delta}{2} a^2 + \frac{1}{2\delta} b^2$ with $\delta \equiv \sqrt{2(1-\mu)}$ (where, again, Poisson's ratio $\mu \in (0, \frac{1}{2})$)

(2.46)

$$\begin{aligned}
&\int_\Omega \sqrt{\gamma}\nabla\widehat{\phi}_t(x,y)\cdot[(x-x_0)\phi_{xx}+(y-y_0)\phi_{xy},(x-x_0)\phi_{xy}+(y-y_0)\phi_{yy}]\,dxdy\\
&=\int_\Omega (x-x_0)\sqrt{\gamma}\nabla\widehat{\phi}_t\cdot[\phi_{xx},\phi_{xy}]\,dxdy+\int_\Omega (y-y_0)\sqrt{\gamma}\nabla\widehat{\phi}_t\cdot[\phi_{xy},\phi_{yy}]\,dxdy\\
&\leq \max_{[x,y]\in\overline{\Omega}}\left|\overline{h}(x,y)\right|\left\{\frac{\gamma}{\sqrt{2\,(1-\mu)}}\int_\Omega |\nabla\phi_t|^2\,d\Omega+\frac{\sqrt{(1-\mu)}}{\sqrt{2}}\int_\Omega\left[\phi_{xx}^2+\phi_{yy}^2\right]d\Omega\right.\\
&\qquad\qquad\left.+\ \sqrt{2\,(1-\mu)}\int_\Omega\phi_{xy}^2 d\Omega\right\}\\
&\leq \frac{1}{\sqrt{2\,(1-\mu)}}\max_{[x,y]\in\overline{\Omega}}\left|\overline{h}(x,y)\right|\left\{\left\|P_\gamma^{\frac{1}{2}}\widehat{\phi}_t\right\|_{L^2(\Omega)}^2+(1-\mu)\int_\Omega\left[\phi_{xx}^2+\phi_{yy}^2\right]d\Omega\right.\\
&\qquad\qquad\left.+2(1-\mu)\int_\Omega\phi_{xy}^2 d\Omega\right\}.
\end{aligned}$$

From this inequality, the definition of $a(\cdot,\cdot)$ in (1.10), and the characterization in (1.11), we obtain

(2.47)

$$\begin{aligned}
&\int_\Omega \sqrt{\gamma}\nabla\widehat{\phi}_t(x,y)\cdot[(x-x_0)\phi_{xx}+(y-y_0)\phi_{xy},(x-x_0)\phi_{xy}+(y-y_0)\phi_{yy}]\,dxdy\\
&\leq \frac{1}{\sqrt{2\,(1-\mu)}}\max_{[x,y]\in\overline{\Omega}}\left|\overline{h}(x,y)\right|\left\{\left\|P_\gamma^{\frac{1}{2}}\widehat{\phi}_t\right\|_{L^2(\Omega)}^2+\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|_{L^2(\Omega)}^2\right\}.
\end{aligned}$$

To deal with the second term on the right-hand side of (2.45), we can use the fact that $\nabla\in\mathcal{L}\left(H^s(\Omega),H^{1-s}(\Omega)\right)$ for all real s, so as to have

$$\begin{aligned}
&\left(\nabla\widehat{\phi}_t(t),\nabla\widehat{\phi}(t)\right)_{L^2(\Omega)}=\left\langle\nabla\widehat{\phi}_t(t),\nabla\widehat{\phi}(t)\right\rangle_{H^{-\epsilon}(\Omega)\times H^{\epsilon}(\Omega)}\\
&\leq C\left\|\widehat{\phi}_t(t)\right\|_{H^{1-\epsilon}(\Omega)}\left\|\widehat{\phi}(t)\right\|_{H^{1+\epsilon}(\Omega}\leq\ \mathsf{l.o.t.}\left(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}\right).
\end{aligned}\tag{2.48}$$

Combining (2.45), (2.47), and (2.48) with the definition of $E_{\widehat{\phi}}$ in (2.3), we then obtain

$$\begin{aligned}
&\gamma\left(\nabla\widehat{\phi}_t(t),\nabla\left(\overline{h}\cdot\nabla\widehat{\phi}(t)\right)\right)_{L^2(\Omega)}+\frac{\gamma}{2}\left(\nabla\widehat{\phi}_t(t),\nabla\widehat{\phi}(t)\right)_{L^2(\Omega)}\\
&\leq\sqrt{\frac{2\gamma}{1-\mu}}\max_{(x,y)\in\overline{\Omega}}\left|\overline{h}(x,y)\right|E_{\widehat{\phi}}(t)+\mathsf{l.o.t.}\ \left(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}\right).
\end{aligned}\tag{2.49}$$

Coupling (2.44) and (2.49) in turn, we arrive at the estimate

(2.50)

$$(2.43)\leq\sqrt{\frac{2\gamma}{1-\mu}}\left\{\max_{(x,y)\in\overline{\Omega}}\left|\overline{h}(x,y)\right|\right\}\left(E_{\widehat{\phi}}(T-\epsilon_0)+E_{\widehat{\phi}}(\epsilon_0)\right)+\mathsf{l.o.t.}\left(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}\right).$$

(A.5) Handling the term $-\int_{\epsilon_0}^{T-\epsilon_0}\alpha(\widehat{\psi},\frac{\partial}{\partial\nu}(\overline{h}\cdot\nabla\widehat{\phi}))$ and noting that

$$\begin{aligned}
\frac{\partial}{\partial\nu}\left(\overline{h}\cdot\nabla\widehat{\phi}\right)&=\nu_1\widehat{\phi}_x+\nu_1\,(x-x_0)\,\widehat{\phi}_{xx}\ +\nu_1\,(y-y_0)\,\widehat{\phi}_{xy}+\nu_2\,(x-x_0)\,\widehat{\phi}_{xy}\\
&\quad+\nu_2\widehat{\phi}_y+\nu_2\,(y-y_0)\,\widehat{\phi}_{yy},
\end{aligned}\tag{2.51}$$

we then have by Cauchy–Schwarz, the trace estimate (2.38) for the Kirchoff plates above, the use of the forcing data in (2.15), and the standard Sobolev trace theory that

(2.52)

$$
\begin{aligned}
&-\int_{\epsilon_0}^{T-\epsilon_0} \alpha\left(\widehat{\psi}, \frac{\partial}{\partial \nu}\left(\overline{h}\cdot\nabla\widehat{\phi}\right)\right)_{L^2(\Gamma_1)} dt \\
&\le C\int_{\epsilon_0}^{T-\epsilon_0}\left[\left\|\widehat{\psi}\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)} + \left\|\widehat{\phi}_{xx}\right\|^2_{L^2(\Gamma_1)} + \left\|\widehat{\phi}_{yy}\right\|^2_{L^2(\Gamma_1)} + 2\left\|\widehat{\phi}_{xy}\right\|^2_{L^2(\Gamma_1)}\right. \\
&\qquad\left. + \left\|\widehat{\phi}_x\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)} + \left\|\widehat{\phi}_y\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)}\right] dt \\
&= C\int_{\epsilon_0}^{T-\epsilon_0}\left[\left\|\widehat{\psi}\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)} + \left\|\frac{\partial^2\widehat{\phi}}{\partial\tau^2}\right\|^2_{L^2(\Gamma_1)} + \left\|\frac{\partial^2\widehat{\phi}}{\partial\nu^2}\right\|^2_{L^2(\Gamma_1)} + 2\left\|\frac{\partial^2\widehat{\phi}}{\partial\tau\partial\nu}\right\|^2_{L^2(\Gamma_1)}\right. \\
&\qquad\left. + \left\|\widehat{\phi}_x\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)} + \left\|\widehat{\phi}_y\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)}\right] dt \\
&\le C_T\left(\int_0^T\left[\left\|c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}\right\|^2_{\left[H^{\frac{3}{2}-\epsilon}(\Omega)\right]'} + \left\|\widehat{\psi}\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)}\right.\right. \\
&\qquad\left. + \left\|\gamma\frac{\partial}{\partial\nu}\left(\xi^2\widehat{\phi} + 2\xi\widehat{\phi}_t\right)\right\|^2_{L^2(\Gamma_1)}\right] dt \\
&\qquad\left. + \int_0^T\left[\left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} + \left\|\widehat{\phi}\right\|^2_{H^{\frac{3}{2}+\epsilon}(\Omega)} + \left\|\widehat{\phi}_t\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)}\right] dt\right) \\
&\le C_T\int_0^T\left[\left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} + \left\|c_1\widehat{\psi}_t + c_4\Delta\widehat{\phi}\right\|^2_{\left[H^{\frac{3}{2}-\epsilon}(\Omega)\right]'} + \right] dt + \text{l.o.t.}\left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}\right).
\end{aligned}
$$

To handle the term $\int_0^T \|c_1\widehat{\psi}_t + c_4\Delta\widehat{\phi}\|^2_{[H^{\frac{3}{2}-\epsilon}(\Omega)]'} dt$, we use Proposition 4.4 in the appendix below and the fact that $\widehat{\psi}_t = -\xi\widehat{\psi}(t) + e^{-\xi t}\psi_t(t)$ and $\widehat{\phi}(t) = e^{-\xi t}\phi(t)$ to have

(2.53)

$$
\begin{aligned}
&\int_0^T \left\|c_1\widehat{\psi}_t + c_4\Delta\widehat{\phi}\right\|^2_{\left[H^{\frac{3}{2}-\epsilon}(\Omega)\right]'} dt \\
&= \int_0^T \left\|-\xi c_1\widehat{\psi}(t) + c_1 e^{-\xi t}\psi_t(t) + c_4 e^{-\xi t}\Delta\phi(t)\right\|^2_{\left[H^{\frac{3}{2}-\epsilon}(\Omega)\right]'} dt \\
&\le C\int_0^T\left[\left\|\widehat{\psi}\right\|^2_{L^2(\Omega)} + \|\phi\|^2_{H^{\frac{3}{2}+\epsilon}(\Omega)} + \|\psi\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)} + \|\phi_t\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)} + \left\|\frac{\partial\phi_t}{\partial\nu}\right\|^2_{L^2(\Gamma_1)}\right] dt \\
&\le C_T\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt + \text{l.o.t.}\left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}\right).
\end{aligned}
$$

Collectively, estimates (2.52) and (2.53) then give

$$
\begin{aligned}
&-\int_{\epsilon_0}^{T-\epsilon_0} \alpha \left(\widehat{\psi}, \frac{\partial}{\partial \nu} \left(\overline{h} \cdot \nabla \widehat{\phi} \right) \right)_{L^2(\Gamma_1)} dt \\
&\leq C_T \int_0^T \left\| \nabla \widehat{\phi}_t \right\|^2_{L^2(\Gamma_1)} dt + \text{l.o.t.} \left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi} \right). \qquad (2.54)
\end{aligned}
$$

(A.6) In the same way as in (A.5) we have

(2.55)

$$
\begin{aligned}
&-\int_{\epsilon_0}^{T-\epsilon_0} \int_{\Gamma_1} \frac{\overline{h} \cdot \nu}{2} \left[\left(\frac{\partial^2 \widehat{\phi}}{\partial x^2} \right)^2 + \left(\frac{\partial^2 \widehat{\phi}}{\partial y^2} \right)^2 + 2\mu \left(\frac{\partial^2 \widehat{\phi}}{\partial x^2} \right) \left(\frac{\partial^2 \widehat{\phi}}{\partial y^2} \right) \right. \\
&\qquad \left. + \ 2(1-\mu) \left(\frac{\partial^2 \widehat{\phi}}{\partial x \partial y} \right)^2 \right] dt d\Gamma \\
&\leq C_T \int_0^T \left\| \nabla \widehat{\phi}_t \right\|^2_{L^2(\Gamma_1)} + \text{l.o.t.} \left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi} \right).
\end{aligned}
$$

(A.7) Finally,

(2.56)

$$
\frac{1}{2} \int_{\epsilon_0}^{T-\epsilon_0} \int_{\Gamma_1} \overline{h} \cdot \nu \left(\widehat{\phi}_t^2 + \gamma \left| \nabla \widehat{\phi}_t \right|^2 \right) d\Gamma dt \leq C \int_0^T \left\| \nabla \widehat{\phi}_t \right\|^2_{L^2(\Gamma_1)} dt + \text{l.o.t.} \ \left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi} \right).
$$

Estimate (2.39) now comes about by stringing together (2.36), (2.40)–(2.42), (2.50), and (2.56), and taking $\epsilon > 0$ small enough. □

LEMMA 2.6. *For $T > T_0 \equiv 2\sqrt{\frac{2\gamma}{1-\mu}} \max_{(x,y)\in\overline{\Omega}} |\overline{h}(x,y)|$, the solution $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ of* (2.15) *satisfies the following estimate:*

$$
\begin{aligned}
&\int_0^T E_{\widehat{\phi}}(t) dt + E_{\widehat{\phi}}(T) + \int_0^T \left\| A_R^{\frac{1}{2}} \widehat{\psi} \right\|^2_{L^2(\Omega)} dt \\
&\leq C_T \left(\|\psi_0\|^2_{L^2(\Omega)} + \int_0^T \left\| \nabla \widehat{\phi}_t \right\|^2_{L^2(\Gamma_1)} dt \right) + \text{l.o.t.} \left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi} \right). \qquad (2.57)
\end{aligned}
$$

Proof. We have for any $\epsilon_0 \in (0, T)$,

$$
\begin{aligned}
&\int_0^T E_{\widehat{\phi}}(t) dt = \int_0^{\epsilon_0} E_{\widehat{\phi}}(t) dt + \int_{T-\epsilon_0}^T E_{\widehat{\phi}}(t) dt + \int_{\epsilon_0}^{T-\epsilon_0} E_{\widehat{\phi}}(t) dt \\
&\leq \frac{2\epsilon_0 (1+\epsilon)}{1-\epsilon} E_{\widehat{\phi}}(T) + \frac{2\epsilon_0 \epsilon}{1-\epsilon} \int_0^T \left[E_{\widehat{\phi}}(t) + \left\| A_R^{\frac{1}{2}} \widehat{\psi}(t) \right\|^2_{L^2(\Omega)} \right] dt + \int_{\epsilon_0}^{T-\epsilon_0} E_{\widehat{\phi}}(t) dt \\
&\quad + C_\epsilon \int_0^T \left\| \nabla \widehat{\phi}_t \right\|^2_{L^2(\Gamma_1)} dt + \text{l.o.t.}(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}) \\
&\quad \text{(after applying Lemma 2.2(b) twice)} \\
&\leq C^* \left(E_{\widehat{\phi}}(T - \epsilon_0) + E_{\widehat{\phi}}(\epsilon_0) \right) + \frac{2\epsilon_0 (1+\epsilon)}{1-\epsilon} E_{\widehat{\phi}}(T) + \frac{2\epsilon_0 \epsilon}{1-\epsilon} \int_0^T E_{\widehat{\phi}}(t) dt \\
&(2.58) + \frac{2\epsilon (1+\epsilon_0)}{1-\epsilon} \int_0^T \left\| A_R^{\frac{1}{2}} \widehat{\psi} \right\|^2_{L^2(\Omega)} dt + C_{T,\epsilon} \int_0^T \left\| \nabla \widehat{\phi}_t \right\|^2_{L^2(\Gamma_1)} dt + \text{l.o.t.}(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}),
\end{aligned}
$$

after applying Lemma 2.5 with $C^* \geq \sqrt{\frac{2\gamma}{1-\mu}} \max_{[x,y]\in\overline{\Omega}} \left|\overline{h}(x,y)\right|$, and $\widetilde{\epsilon} \equiv \frac{2\epsilon}{1-\epsilon}$ therein. Applying Lemma 2.2(b) twice more to the right-hand side of (2.58) yields now

(2.59)
$$\begin{aligned}\int_0^T E_{\widehat{\phi}}(t)dt \leq\ & 2\left(\epsilon_0 + C^*\right)\frac{1+\epsilon}{1-\epsilon}E_{\widehat{\phi}}(T) + \frac{2\epsilon\left(\epsilon_0 + C^*\right)}{1-\epsilon}\int_0^T E_{\widehat{\phi}}(t)dt \\ &+ \frac{2\epsilon\left(1+\epsilon_0 + C^*\right)}{1-\epsilon}\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)} dt + C_{T,\epsilon}\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt \\ &+ \mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}).\end{aligned}$$

Moreover, we have by (2.16)

$$\int_0^T E_{\widehat{\phi}}(t)dt = TE_{\widehat{\phi}}(T) + \int_0^T \mathcal{F}(T,t)dt, \tag{2.60}$$

where the function $\mathcal{F}$ is as defined in (2.34). Combining (2.59) and (2.60) yields

(2.61)
$$\begin{aligned}TE_{\widehat{\phi}}(T) + \int_0^T \mathcal{F}(T,t)dt \leq\ & 2\left(\epsilon_0 + C^*\right)\frac{1+\epsilon}{1-\epsilon}E_{\widehat{\phi}}(T) + \frac{2\epsilon\left(\epsilon_0 + C^*\right)}{1-\epsilon}\int_0^T E_{\widehat{\phi}}(t)dt \\ &+ \frac{2\epsilon\left(1+\epsilon_0 + C^*\right)}{1-\epsilon}\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)} dt + C_{T,\epsilon}\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt + \mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}).\end{aligned}$$

To use this inequality, we integrate both sides of (2.17) (with $s = T$ therein) so as to have

$$\begin{aligned}\int_0^T \mathcal{F}(T,t)dt \leq\ & \epsilon\left(T+1\right)\int_0^T E_{\widehat{\phi}}(t)dt + \epsilon T E_{\widehat{\phi}}(T) + \epsilon T\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)} dt \\ &+ C_{T,\epsilon}\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt + \mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}).\end{aligned} \tag{2.62}$$

Combining (2.61) and (2.62), we thus obtain

(2.63)
$$\begin{aligned}TE_{\widehat{\phi}}(T) \leq\ & \left[\frac{2\left(\epsilon_0 + C^*\right)\left(1+\epsilon\right)}{1-\epsilon} + \epsilon T\right]E_{\widehat{\phi}}(T) \\ &+ \epsilon\left[\frac{2\left(\epsilon_0 + C^*\right)}{1-\epsilon} + \left(T+1\right)\right]\int_0^T E_{\widehat{\phi}}(t)dt \\ &+ \epsilon\left[\frac{2\left(1+\epsilon_0 + C^*\right)}{1-\epsilon} + T\right]\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)} dt + C_{T,\epsilon}\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt \\ &+ \mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}).\end{aligned}$$

Taking now $T > \frac{2(\epsilon_0+C^*)(1+\epsilon)}{(1-\epsilon)^2}$, or what is the same, $T > 2C^*$ for ϵ and ϵ_0 small enough, we then have

$$\begin{aligned}E_{\widehat{\phi}}(T) \leq\ & C_{T,\epsilon}\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt + \epsilon\widetilde{C}_T\left[\int_0^T E_{\widehat{\phi}}(t)dt + \int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)} dt\right] \\ &+ \mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}),\end{aligned} \tag{2.64}$$

where throughout $\widetilde{C}_T$ will denote a constant independent of ϵ and ϵ_0 (small enough).

In turn, applying this to (2.59), we have

$$\int_0^T E_{\widehat{\phi}}(t)dt \leq C_{T,\epsilon}\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)}dt + \frac{2\epsilon\left(\epsilon_0+C^*\right)\left[\left(1+\epsilon\right)\widetilde{C}_T+1\right]}{1-\epsilon}\int_0^T E_{\widehat{\phi}}(t)dt$$
$$+\frac{2\epsilon\left[\left(\epsilon_0+C^*\right)\left(1+\epsilon\right)\widetilde{C}_T+\left(1+\epsilon_0+C^*\right)\right]}{1-\epsilon}\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)}dt + \mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi})$$

from which follows the estimate, for $\epsilon,\epsilon_0>0$ small enough,

(2.65)
$$\int_0^T E_{\widehat{\phi}}(t)dt \leq C_{T,\epsilon}\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)}dt + \epsilon\widetilde{C}_T\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)}dt + \mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}).$$

Coupling together (2.64) and (2.65), we have the following preliminary inequality for the mechanical energy, again for $T>2C^*$:

$$\int_0^T E_{\widehat{\phi}}(t)dt + E_{\widehat{\phi}}(T)$$
$$\leq C_{T,\epsilon}\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)}dt + \epsilon\widetilde{C}_T\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)}dt + \mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}). \tag{2.66}$$

It remains to estimate the thermal component. To this end, we can multiply (2.11) by $\widehat{\psi}$, integrate in time and space, use the characterization (1.15) and (2.8) to have

$$\eta\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)}dt = \left[\frac{\beta}{2}\left\|e^{-\xi t}\psi(t)\right\|^2_{L^2(\Omega)}\right]_{t=0}^{t=T} + \xi\int_0^T\left(\beta\widehat{\psi}-\alpha\Delta\widehat{\phi},\widehat{\psi}\right)_{L^2(\Omega)}dt$$
$$+\alpha\int_0^T\left[\left(\nabla\widehat{\phi}_t,\nabla\widehat{\psi}\right)_{L^2(\Omega)} - \left(\frac{\partial\widehat{\phi}_t}{\partial\nu},\widehat{\psi}\right)_{L^2(\Gamma_1)}\right]dt. \tag{2.67}$$

Majorizing this expression results in

$$\eta\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)}dt \leq C_{\underset{\epsilon}{\sim}}\left(\|\psi_0\|^2_{L^2(\Omega)} + \int_0^T\left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)}dt + \int_0^T E_{\widehat{\phi}}(t)dt\right)$$
$$+\widetilde{\epsilon}\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)}dt + \mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}),$$

and taking $\widetilde{\epsilon}>0$ small enough above, this becomes

$$\int_0^T \left\|A_R^{\frac{1}{2}}\widehat{\psi}\right\|^2_{L^2(\Omega)}dt \leq C_1\left(\|\psi_0\|^2_{L^2(\Omega)} + \int_0^T\left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)}dt + \int_0^T E_{\widehat{\phi}}(t)dt\right)$$
$$+\mathsf{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}), \tag{2.68}$$

where $C_1=\frac{C_{\widetilde{\epsilon}}}{\eta-\widetilde{\epsilon}}$.

Combining (2.66) and (2.68), we have

(2.69)

$$\int_0^T E_{\widehat{\phi}}(t)dt + E_{\widehat{\phi}}(T)$$
$$\leq C_{T,\epsilon}\int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt + \epsilon\widetilde{C}_T C_1\left(\|\psi_0\|^2_{L^2(\Omega)} + \int_0^T E_{\widehat{\phi}}(t)dt\right) + \text{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}),$$

from which we obtain for $\epsilon > 0$ small enough

(2.70)
$$\int_0^T E_{\widehat{\phi}}(t)dt + E_{\widehat{\phi}}(T) \leq C_{T,\epsilon}\left(\|\psi_0\|^2_{L^2(\Omega)} + \int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt\right) + \text{l.o.t.}(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}).$$

The final estimate (2.57) finally comes about by combining (2.70) and (2.68). □

Conclusion of the proof of Theorem 2.1. Assume initially that $[\phi_0,\phi_1,\psi_0] \in D(\mathcal{A}^*_\gamma)$. Through the change of variable $\widehat{\phi}(t) = e^{-\xi t}\phi(t)$ and $\widehat{\psi}(t) = e^{-\xi t}\psi(t)$, where again $[\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}]$ solves (2.15) and $\xi \equiv \frac{\alpha^2}{2\gamma\eta} > 0$, we have for $T > T_0 \equiv 2\sqrt{\frac{2\gamma}{1-\mu}}\max_{[x,y]\in\overline{\Omega}}\left|\overline{h}(x,y)\right|$

(2.71)
$$\int_0^T E_\phi(t)dt + \int_0^T \left\|A_R^{\frac{1}{2}}\psi(t)\right\|^2_{L^2(\Omega)} dt + E_\phi(T)$$
$$= \int_0^T \left[\left\|\mathring{\mathbf{A}}^{\frac{1}{2}} e^{\xi t}\widehat{\phi}(t)\right\|^2_{L^2(\Omega)} + \left\|P_\gamma^{\frac{1}{2}}\left(e^{\xi t}\widehat{\phi}_t(t) + \xi e^{\xi t}\widehat{\phi}(t)\right)\right\|^2_{L^2(\Omega)} + \left\|A_R^{\frac{1}{2}} e^{\xi t}\widehat{\psi}(t)\right\|^2_{L^2(\Omega)}\right] dt$$
$$+ \left\|\mathring{\mathbf{A}}^{\frac{1}{2}} e^{\xi T}\widehat{\phi}(T)\right\|^2_{L^2(\Omega)} + \left\|P_\gamma^{\frac{1}{2}}\left(e^{\xi T}\widehat{\phi}_t(T) + \xi e^{T}\widehat{\phi}(T)\right)\right\|^2_{L^2(\Omega)}$$
$$\leq C_T\left(\|\psi_0\|^2_{L^2(\Omega)} + \int_0^T \left\|\nabla\widehat{\phi}_t\right\|^2_{L^2(\Gamma_1)} dt\right) + \text{l.o.t.}\left(\widehat{\phi},\widehat{\phi}_t,\widehat{\psi}\right)$$
(after using estimate (2.57))
$$\leq C_T\left(\|\psi_0\|^2_{L^2(\Omega)} + \int_0^T \left\|\nabla\left(e^{-\xi t}\phi_t(t) - \xi e^{-\xi t}\phi(t)\right)\right\|^2_{L^2(\Gamma_1)} dt\right)$$
$$+ \text{l.o.t.}\left(e^{-\xi t}\phi, e^{-\xi t}\phi_t - \xi e^{-\xi t}\phi, e^{-\xi t}\psi\right)$$
$$\leq C_T\left(\|\psi_0\|^2_{L^2(\Omega)} + \int_0^T \|\nabla\phi_t(t)\|^2_{L^2(\Gamma_1)}\, dt\right) + \text{l.o.t.}\left(\phi,\phi_t,\psi\right).$$

This gives the desired inequality (2.5). □

2.3. Conclusion of the proof of Theorem 1.2. For $[\phi_0,\phi_1] \in D(\mathcal{L}^*_T\Pi^*)$, we immediately have from Theorem 2.1 the following corollary.

COROLLARY 2.7. *For $[\phi_0,\phi_1] \in D(\mathcal{L}^*_T\Pi^*)$ and $T > T_0 \equiv 2\sqrt{\frac{2\gamma}{1-\mu}}\max_{[x,y]\in\overline{\Omega}}\left|\overline{h}(x,y)\right|$, the corresponding solution $[\phi,\phi_t,\psi]$ of (1.60) satisfies the following inequality:*

(2.72)
$$\int_0^T E_\phi(t)dt + E_\phi(T) + \int_0^T \left\|A_R^{\frac{1}{2}}\psi\right\|^2_{L^2(\Omega)} dt \leq C_T\int_0^T \|\nabla\phi_t\|^2_{L^2(\Gamma_1)}\, dt + \text{l.o.t.}\left(\phi,\phi_t,\psi\right).$$

We will have the desired inequality (2.2) upon the elimination of the tainting lower order terms in (2.72). To this end, we invoke a (by now) classical compactness–uniqueness argument (see, e.g., [13] and [2]), which makes crucial use of the new Holmgren-type uniqueness result for the thermoelastic system recently derived by Isakov in [10]. It is at this point that the boundary trace $\psi|_{\Gamma_2}$, corresponding to the control u_3, comes into play.

LEMMA 2.8. *Let T^* be as defined in* (1.6). *Then for $T > T^*$ and initial data $[\phi_0, \phi_1] \in D(\mathcal{L}_T^* \Pi^*)$, there exists a C_T such that the following estimate holds true for the solution of* (1.60):

$$\begin{aligned} &\|\phi\|^2_{L^\infty(0,T;H^{\frac{3}{2}+\epsilon}(\Omega))} + \|\phi_t\|^2_{L^\infty(0,T;H^{\frac{1}{2}+\epsilon}(\Omega))} + \|\psi\|^2_{L^\infty(0,T;H^{-\frac{1}{2}+\epsilon}(\Omega))} + \int_0^T \|\psi\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)}\, dt \\ &\qquad \leq C_T \left(\int_0^T \|\nabla \phi_t\|^2_{L^2(\Gamma_1)}\, dt + \|\psi\|^2_{[H^s((0,T)\times\Gamma_2)]'} \right). \end{aligned} \tag{2.73}$$

Proof. If the proposition is false, then there exists a sequence $\{[\phi_0^{(n)}, \phi_1^{(n)}]\}_{n=1}^\infty \subseteq D(\mathcal{L}_T^* \Pi^*)$, and a corresponding solution sequence $\{[\phi^{(n)}, \phi_t^{(n)}, \psi^{(n)}]\}_{n=1}^\infty$ to (1.60), which satisfies

$$\begin{aligned} &\left\|\phi^{(n)}\right\|^2_{L^\infty\left(0,T;H^{\frac{3}{2}+\epsilon}(\Omega)\right)} + \left\|\phi_t^{(n)}\right\|^2_{L^\infty\left(0,T;H^{\frac{1}{2}+\epsilon}(\Omega)\right)} + \left\|\psi^{(n)}\right\|^2_{L^\infty\left(0,T;H^{-\frac{1}{2}+\epsilon}(\Omega)\right)} \\ &\qquad + \int_0^T \left\|\psi^{(n)}\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)} dt = 1 \ \ \forall\, n, \end{aligned} \tag{2.74}$$

$$\lim_{n\to\infty} \int_0^T \left\|\nabla \phi_t^{(n)}\right\|^2_{L^2(\Gamma_1)} dt + \left\|\psi^{(n)}\right\|^2_{[H^s((0,T)\times\Gamma_2)]'} = 0. \tag{2.75}$$

As $T > 2\sqrt{\frac{2\gamma}{1-\mu}} \max_{[x,y]\in\overline{\Omega}} \left|\overline{h}(x,y)\right|$, we have the existence of the inequality (2.72). This and (2.74)–(2.75) then imply the boundedness of the sequence

$$\begin{aligned} &\left\{ \int_0^T \left[\left\| \begin{bmatrix} \phi^{(n)}(t) \\ \phi_t^{(n)}(t) \end{bmatrix} \right\|^2_{D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\times H^1_{\Gamma_0,\gamma}(\Omega)} + \left\| A_R^{\frac{1}{2}} \psi^{(n)}(t) \right\|^2_{L^2(\Omega)} \right] dt \right. \\ &\qquad \left. + \left\| \begin{bmatrix} \phi_0^{(n)} \\ \phi_1^{(n)} \end{bmatrix} \right\|^2_{D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\times H^1_{\Gamma_0,\gamma}(\Omega)} \right\}_{n=1}^\infty. \end{aligned} \tag{2.76}$$

There thus exists a subsequence, still denoted here as $\{[\phi_0^{(n)}, \phi_1^{(n)}]\}_{n=1}^\infty$, and $[\widetilde{\phi}_0, \widetilde{\phi}_1] \in D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)$, such that

$$\phi_0^{(n)} \to \widetilde{\phi}_0 \ \text{ in } D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \text{ weakly}, \tag{2.77}$$

$$\phi_1^{(n)} \to \widetilde{\phi}_1 \ \text{ in } H^1_{\Gamma_0,\gamma}(\Omega) \text{ weakly}. \tag{2.78}$$

If we further denote $[\widetilde{\phi}, \widetilde{\phi}_t, \widetilde{\psi}]$ as the solution to (1.60), corresponding to initial data $[\widetilde{\phi}_0, \widetilde{\phi}_1, 0]$, then a fortiori,

$$\left[\phi^{(n)}, \phi_t^{(n)}, \psi^{(n)}\right] \to \left[\widetilde{\phi}, \widetilde{\phi}_t, \widetilde{\psi}\right] \ \text{ in } L^\infty(0,T;\mathbf{H}_\gamma) \text{ weak star}. \tag{2.79}$$

From Proposition 4.3 of the appendix, we have that $\{\phi_{tt}^{(n)}\}_{n=1}^{\infty}$ is bounded in $L^{\infty}(0,T;[D(\mathring{\mathbf{A}}^{\frac{1}{2}}P_{\gamma}^{-1})]')$, inasmuch as $\{\|[\phi_0^{(n)},\phi_1^{(n)}]\|_{D(\mathring{\mathbf{A}}^{\frac{1}{2}})\times H^1_{\Gamma_0,\gamma}(\Omega)}\}_{n=1}^{\infty}$ is bounded in $D(\mathring{\mathbf{A}}^{\frac{1}{2}})\times H^1_{\Gamma_0,\gamma}(\Omega)$. Also, from Proposition 4.4 we have that $\psi_t^{(n)}\in L^2(0,T;[H^{\frac{3}{2}-\epsilon}(\Omega)]')$ for all n, with the estimate

$$\int_0^T \left\|\psi_t^{(n)}\right\|^2_{[H^{\frac{3}{2}-\epsilon}(\Omega)]'} dt \le C\int_0^T \left\|\nabla\phi_t^{(n)}\right\|^2_{L^2(\Gamma_1)} dt + \text{l.o.t.}\,(\phi,\phi_t,\psi)\,, \tag{2.80}$$

and this combined with (2.74)–(2.75) yields that $\{\psi_t^{(n)}\}_{n=1}^{\infty}$ is bounded in $L^2(0,T;[H^{\frac{3}{2}-\epsilon}(\Omega)]')$. This boundedness of $\{[\phi_{tt}^{(n)},\psi_t^{(n)}]\}_{n=1}^{\infty}$, and that for the sequence posted in (2.76), allows us to deduce through a compactness result of Simon's in [24] that

$$\begin{aligned}
&\phi^{(n)}\to\widetilde{\phi} \ \text{ strongly in } L^{\infty}(0,T;H^{\frac{3}{2}+\epsilon}(\Omega)),\\
&\phi_t^{(n)}\to\widetilde{\phi}_t \ \text{ strongly in } L^{\infty}(0,T;H^{\frac{1}{2}+\epsilon}(\Omega)),\\
&\psi^{(n)}\to\widetilde{\psi} \ \text{ strongly in } L^{2}(0,T;H^{\frac{1}{2}+\epsilon}(\Omega)),\\
&\psi^{(n)}\to\widetilde{\psi} \ \text{ strongly in } L^{\infty}(0,T;H^{-\frac{1}{2}+\epsilon}(\Omega)).
\end{aligned}$$

These convergences and (2.74) thus give

$$\begin{aligned}
&\left\|\widetilde{\phi}\right\|^2_{L^{\infty}\left(0,T;H^{\frac{3}{2}+\epsilon}(\Omega)\right)} + \left\|\widetilde{\phi}_t\right\|^2_{L^{\infty}\left(0,T;H^{\frac{1}{2}+\epsilon}(\Omega)\right)} + \left\|\widetilde{\psi}\right\|^2_{L^{\infty}\left(0,T;H^{-\frac{1}{2}+\epsilon}(\Omega)\right)}\\
&\qquad + \int_0^T \left\|\widetilde{\psi}\right\|^2_{H^{\frac{1}{2}+\epsilon}(\Omega)} dt = 1.
\end{aligned} \tag{2.81}$$

Moreover, the explicit representation of $\mathcal{L}_T^*\Pi^*$ in (1.59) and the convergences posted in (2.75) and (2.77)–(2.79) give that $[\widetilde{\phi}_0,\widetilde{\phi}_1]\in D(\mathcal{L}_T^*\Pi^*)$, with

$$\int_0^T \left\|\nabla\widetilde{\phi}_t\right\|^2_{H^1(\Gamma_1)} dt + \left\|\widetilde{\psi}\right\|^2_{[H^s((0,T)\times\Gamma_2)]'} = 0. \tag{2.82}$$

Now if we make the change of variable

$$z=\widetilde{\phi}_t, \qquad v=\widetilde{\psi}_t,$$

then using (2.82), $[z,v]$ solve the system

$$\begin{cases}
\begin{cases} z_{tt}-\gamma\Delta z_{tt}+\Delta^2 z+\alpha\Delta v=0\\ \beta v_t+\eta\Delta v-\sigma v-\alpha\Delta z_t=0\end{cases} & \text{on } (0,\infty)\times\Omega,\\[2ex]
z=\dfrac{\partial z}{\partial\nu}=0 \ \text{ on } (0,\infty)\times\Gamma,\\[2ex]
\begin{cases}\Delta z+(1-\mu)B_1 z+\alpha v=0\\ \dfrac{\partial\Delta z}{\partial\nu}+(1-\mu)\dfrac{\partial B_2 z}{\partial\tau}-\gamma\dfrac{\partial z_{tt}}{\partial\nu}+\alpha\dfrac{\partial v}{\partial\nu}=0\end{cases} & \text{on } (0,\infty)\times\Gamma_1,\\[2ex]
\dfrac{\partial v}{\partial\nu}+\lambda v=0 \ \text{ on } (0,\infty)\times\Gamma,\\[2ex]
v=0 \ \text{ on } (0,\infty)\times\Gamma_2.
\end{cases} \tag{2.83}$$

Now by Isakov's theorem in [10, p. 3, Corollary 1.2], we have for

$$T > 2\sqrt{\gamma} \cdot \sup_{[x,y]\in\Omega} d\left([x,y],\Gamma_2\right)$$

that the uniqueness property for the thermoelastic system is obtained, so that the solution $[z, v]$ of (2.83) is necessarily zero. Consequently $\widetilde{\phi}$ and $\widetilde{\psi}$ are each constants. From the essential boundary condition on Γ_0 in (1.60), we then have $\widetilde{\phi} = 0$ on $(0,T)\times\Omega$. In turn, the free boundary conditions on Γ_1 give that $\widetilde{\psi} = 0$ on $(0,T)\times\Omega$. Thus $[\widetilde{\phi}, \widetilde{\psi}] = [0,0]$, which contradicts the equality given in (2.81). This concludes the proof of the lemma. □

Corollary 2.7 and Lemma 2.8 in combination give inequality (2.2), the establishment of which verifies the surjectivity of the control to partial state map $\Pi\mathcal{L}_T : D(\mathcal{L}_T) \subset \mathcal{U}_s \to D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)$. This completes the proof of Theorem 1.2.

3. The proof of Theorem 1.1. Given the space $C^r(\Sigma_{2,T})$, we consider system (1.1) under the influence of boundary controls in $\mathcal{U}_{r+1}$, as defined in (1.37). The controlled PDE is then approximately controllable in $\mathcal{U}_{r+1}$ for $T > 2\sqrt{\gamma}\cdot\sup_{[x,y]\in\Omega} d\left([x,y],\Gamma_2\right)$. Indeed, if we take arbitrary $[\phi_0,\phi_1,\psi_0]$ from the null space of $\mathcal{L}_T^*$, then using the form of this operator given in (1.55), we have necessarily that $\phi_t|_{\Gamma_1} = \frac{\partial\phi_t}{\partial\nu}|_{\Gamma_1} = 0$, and $\psi|_{\Gamma_2} = 0$, where $[\phi,\phi_t,\psi]$ is the solution to (1.51). We can then use the uniqueness theorem of Isakov, in a fashion similar to that employed in Lemma 2.8, to show that $[\phi,\phi_t,\psi] = [0,0,0]$ on $(0,T)\times\Omega$ and, in particular, $[\phi_0,\phi_1,\psi_0] = [0,0,0]$.

A preliminary step (a regularity property of $\mathcal{L}_T$). With the designated control space $\mathcal{U}_{r+1}$ we then take $T > T^*$ so as to ensure both the approximate controllability of the entire system (1.1) and the exact controllability with respect to the displacement (see Theorem 1.2). In this event, we have the observability inequality (2.2), and therewith one can show in a manner identical to that done in [14, Appendix B] that the operator

$$\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^* \text{ is an isomorphism from } D(\mathcal{L}_T^*\Pi^*) \text{ into } [D(\mathcal{L}_T^*\Pi^*)]', \tag{3.1}$$

where the projection Π onto $D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)$ is as defined in (1.46). Consequently, we have

$$\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\left(\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\right)^{-1}\Pi \in \mathcal{L}\left(\mathbf{H}_\gamma, D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)\right). \tag{3.2}$$

Moreover, if we denote the maps $\mathcal{L}^{(1)}$, $\mathcal{L}^{(2)}$ by

$$\mathcal{L}^{(1)}\begin{bmatrix} u_1 \\ u_2 \end{bmatrix}(t) = \int_0^t e^{\mathcal{A}_\gamma(t-s)}\mathcal{B}\begin{bmatrix} u_1(s) \\ u_2(s) \\ 0 \end{bmatrix},$$

$$\mathcal{L}^{(2)}u(t) = \int_0^t e^{\mathcal{A}_\gamma(t-s)}\mathcal{B}\begin{bmatrix} 0 \\ 0 \\ u(s) \end{bmatrix}$$

(cf. (1.42)), then by a standard energy method one can show that

$$\mathcal{L}^{(2)} : L^2(0,T;H^{-\frac{1}{2}}(\Gamma_2)) \to C([0,T];\mathbf{H}_\gamma) \text{ continuously.} \tag{3.3}$$

To handle $\mathcal{L}^{(1)}$ on the other hand, one must appeal to a new regularity result in [17], which gives

$$\mathcal{L}^{(1)} : L^2(0,T;L^2(\Gamma_1)\times H^{-1}(\Gamma_1)) \to C([0,T];H^{\frac{3}{2}}(\Omega)\times H^{\frac{1}{2}}(\Omega)\times L^2(\Omega)) \quad \text{continuously.} \tag{3.4}$$

Combining (3.3) and (3.4) (at terminal time T) with (3.2), we thus deduce that the mapping

$$(\mathbb{I}-\Pi^*\Pi)\,\mathcal{L}_T\mathcal{L}_T^*\Pi^*\left(\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\right)^{-1}\Pi \in \mathcal{L}\left(\mathbf{H}_\gamma\right), \tag{3.5}$$

where $\mathbb{I}:\mathbf{H}_\gamma \to \mathbf{H}_\gamma$ denotes the identity.

Combining (3.2) and (3.5) thus gives

$$\mathcal{L}_T\mathcal{L}_T^*\Pi^*\left(\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\right)^{-1}\Pi \in \mathcal{L}(\mathbf{H}_\gamma). \tag{3.6}$$

Step 1. For arbitrary $\epsilon>0$ we select a $\overline{u}_1 \in D(\mathcal{L}_T) \subset \mathcal{U}_{r+1}$, so that for arbitrary terminal state $[\omega_0^T,\omega_1^T,\theta_0^T] \in \mathbf{H}_\gamma$, the corresponding solution $[\omega^{(1)}(t),\omega_t^{(1)}(t),\theta^{(1)}(t)]$ to (1.1), with $[u_1,u_2,u_3]\equiv\overline{u}_1$ and zero initial data, satisfies

$$\begin{aligned}&\left\|\begin{bmatrix}\omega^{(1)}(T)-\omega_0^T\\ \omega_t^{(1)}(T)-\omega_1^T\\ \theta^{(1)}(T)-\theta_0^T\end{bmatrix}+e^{\mathcal{A}_\gamma T}\begin{bmatrix}\omega_0\\ \omega_1\\ \theta_0\end{bmatrix}\right\|_{\mathbf{H}_\gamma}\\ &\qquad<\frac{\epsilon}{1+\left\|(\mathbb{I}-\Pi^*\Pi)\mathcal{L}_T\mathcal{L}_T^*\Pi^*\left(\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\right)^{-1}\Pi\right\|_{\mathcal{L}(\mathbf{H}_\gamma)}}\end{aligned} \tag{3.7}$$

(where the fact that $(\mathbb{I}\text{-}\Pi^*\Pi)\mathcal{L}_T\mathcal{L}_T^*\Pi^*\left(\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\right)^{-1}\Pi$ is due to (3.6)).

Step 2. We now select $\overline{u}_2 \in D(\mathcal{L}_T)$ to be the "minimal norm steering control" with respect to the (partial) terminal state $[\omega_0^T-\omega^{(1)}(T),\omega_1^T-\omega_t^{(1)}(T)]$. That is to say, $\overline{u}_2$ satisfies

$$\Pi\mathcal{L}_T\overline{u}_2+\Pi e^{\mathcal{A}_\gamma T}\begin{bmatrix}\omega_0\\ \omega_1\\ \theta_0\end{bmatrix}=\begin{bmatrix}\omega_0^T-\omega^{(1)}(T)\\ \omega_1^T-\omega_t^{(1)}(T)\end{bmatrix} \tag{3.8}$$

and minimizes the functional $\frac{1}{2}\|\overline{u}\|_{\mathcal{U}_s}^2$, over all $\overline{u}\in\mathcal{U}_s$, which satisfies

$$\Pi\mathcal{L}_T\overline{u}=\begin{bmatrix}\omega_0^T-\omega^{(1)}(T)\\ \omega_1^T-\omega_t^{(1)}(T)\end{bmatrix}-\Pi e^{\mathcal{A}_\gamma T}\begin{bmatrix}\omega_0\\ \omega_1\\ \theta_0\end{bmatrix}.$$

(By Theorem 1.2. we know there exists at least one such $\overline{u}$.) By convex optimization theory and Lax–Milgram, the minimizer $\overline{u}_2$ can be given explicitly by

$$\overline{u}_2=\mathcal{L}_T^*\Pi^*\left(\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\right)^{-1}\Pi\left(\begin{bmatrix}\omega_0^T-\omega^{(1)}(T)\\ \omega_1^T-\omega_t^{(1)}(T)\\ \theta_0^T-\theta^{(1)}(T)\end{bmatrix}-e^{\mathcal{A}_\gamma T}\begin{bmatrix}\omega_0\\ \omega_1\\ \theta_0\end{bmatrix}\right) \tag{3.9}$$

(see (B.20) of [14, p. 288]). With this representation, we then have from (3.7) the norm bound

$$\|(\mathbb{I}-\Pi^*\Pi)\mathcal{L}_T\overline{u}_2\|_{\mathbf{H}_\gamma}\le\frac{\left\|(\mathbb{I}-\Pi^*\Pi)\mathcal{L}_T\mathcal{L}_T^*\Pi^*\left(\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\right)^{-1}\Pi\right\|_{\mathcal{L}(\mathbf{H}_\gamma)}\cdot\epsilon}{1+\left\|(\mathbb{I}-\Pi^*\Pi)\mathcal{L}_T\mathcal{L}_T^*\Pi^*\left(\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\right)^{-1}\Pi\right\|_{\mathcal{L}(\mathbf{H}_\gamma)}}. \tag{3.10}$$

Step 3. Set the control $\overline{u}^* = \overline{u}_1 + \overline{u}_2$. Consequently, there is the equality

$$\begin{aligned}\mathcal{L}_T\overline{u}^* + e^{\mathcal{A}_\gamma T}\begin{bmatrix}\omega_0\\ \omega_1\\ \theta_0\end{bmatrix} &= \mathcal{L}_T\overline{u}_1 + \mathcal{L}_T\overline{u}_2 + e^{\mathcal{A}_\gamma T}\begin{bmatrix}\omega_0\\ \omega_1\\ \theta_0\end{bmatrix} = \begin{bmatrix}\omega_0^T\\ \omega_1^T\\ \theta^{(1)}(T)\end{bmatrix}\\ &\quad + (\mathbb{I} - \Pi^*\Pi)\left[\mathcal{L}_T\overline{u}_2 + e^{\mathcal{A}_\gamma T}\begin{bmatrix}\omega_0\\ \omega_1\\ \theta_0\end{bmatrix}\right]. \end{aligned} \tag{3.11}$$

Letting $[\omega^*, \omega_t^*, \theta^*]$ denote the solution of (1.1) corresponding to the chosen control $\overline{u}^*$, we then have from (3.11) that $[\omega^*(T), \omega_t^*(T)] = [\omega_0^T, \omega_1^T]$. Moreover, from (3.11), (3.7), and (3.10) we obtain the estimate

$$\begin{aligned}\left\|\theta^*(T) - \theta_0^T\right\|_{L^2_{\sigma+\lambda}(\Omega)} &\le \left\|\begin{bmatrix}0\\ 0\\ \theta^{(1)}(T) - \theta_0^T\end{bmatrix} + (\mathbb{I} - \Pi^*\Pi)\left[e^{\mathcal{A}_\gamma T}\begin{bmatrix}\omega_0\\ \omega_1\\ \theta_0\end{bmatrix}\right]\right\|_{\mathbf{H}_\gamma}\\ &\quad + \|(\mathbb{I} - \Pi^*\Pi)\mathcal{L}_T\overline{u}_2\|_{\mathbf{H}_\gamma}\\ &< \frac{\epsilon}{1 + \left\|(\mathbb{I} - \Pi^*\Pi)\mathcal{L}_T\mathcal{L}_T^*\Pi^*\left(\Pi\mathcal{L}_T\mathcal{L}_T^*\Pi^*\right)^{-1}\Pi\right\|_{\mathcal{L}(\mathbf{H}_\gamma)}} + \|(\mathbb{I} - \Pi^*\Pi)\mathcal{L}_T\overline{u}_2\|_{\mathbf{H}_\gamma} < \epsilon. \end{aligned} \tag{3.12}$$

Thus, the constructed control $\overline{u}^* = [u_1^*, u_2^*, u_3^*] \in \mathcal{U}_{r+1}$ satisfies the desired exact–approximate controllability property. Moreover, the Sobolev embedding theorem gives that $u_3^* \in C^r(\Sigma_{2,T})$. This concludes the proof of Theorem 1.1.

4. Appendix.

PROPOSITION 4.1. *The operator* $A_R - \frac{\sigma}{\eta} + \lambda\mathring{\mathbf{A}}G_2\gamma_0 - \mathring{\mathbf{A}}G_1\gamma_0$ *is an element of* $\mathcal{L}(L^2(\Omega), [D(\mathring{\mathbf{A}}^{\frac{1}{2}})]')$ *and* $(A_R - \frac{\sigma}{\eta} + \lambda\mathring{\mathbf{A}}G_2\gamma_0 - \mathring{\mathbf{A}}G_1\gamma_0)^* = A_D(I - D\gamma_0)$ *as elements of* $\mathcal{L}(D(\mathring{\mathbf{A}}^{\frac{1}{2}}), L^2(\Omega))$.

Proof. For every $\vartheta \in D(A_R)$ and $\varpi \in D(\mathring{\mathbf{A}}^{\frac{1}{2}})$, we have

$$\begin{aligned}&\left\langle\left(A_R - \frac{\sigma}{\eta} + \lambda\mathring{\mathbf{A}}G_2\gamma_0 - \mathring{\mathbf{A}}G_1\gamma_0\right)\vartheta, \varpi\right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]'\times D|\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)}\\ &= (-\Delta\vartheta, \varpi)_{L^2(\Omega)} + \left\langle\lambda\mathring{\mathbf{A}}G_2\gamma_0\vartheta, \varpi\right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]'\times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} - \left\langle\mathring{\mathbf{A}}G_1\gamma_0\vartheta, \varpi\right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]'\times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)}\\ &= (\nabla\vartheta, \nabla\varpi)_{L^2(\Omega)} - \left(\frac{\partial\vartheta}{\partial\nu}, \varpi\right)_{L^2(\Gamma_1)} + \lambda\left(\gamma_0\vartheta, G_2^*\mathring{\mathbf{A}}\varpi\right)_{L^2(\Gamma_1)} - \left(\gamma_0\vartheta, G_1^*\mathring{\mathbf{A}}\varpi\right)_{L^2(\Gamma_1)}\\ &\quad \text{(after the use of Green's formula and the taking of adjoints)}\\ &= (\nabla\vartheta, \nabla\varpi)_{L^2(\Omega)} - \left(\gamma_0\vartheta, G_1^*\mathring{\mathbf{A}}\varpi\right)_{L^2(\Gamma_1)} = (\vartheta, -\Delta\varpi)_{L^2(\Omega)}\\ &\quad \text{(after one more use of Green's theorem and the characterization (1.23))}\\ &= (\vartheta, A_D(I - D\gamma_0)\varpi)_{L^2(\Omega)}. \end{aligned}$$

As $D(A_R)$ is dense in $L^2(\Omega)$, this equality proves the assertion. ∎

LEMMA 4.2. *The Hilbert space adjoint $\mathcal{A}_\gamma^*$ of $\mathcal{A}_\gamma$, as defined in* (1.36)*, is given to be*

$$\mathcal{A}_\gamma^* = \begin{pmatrix} \mathbf{I} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & P_\gamma^{-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{I} \end{pmatrix} \begin{pmatrix} \mathbf{0} & -\mathbf{I} & \mathbf{0} \\ \mathring{\mathbf{A}} & \mathbf{0} & -\alpha(\clubsuit) \\ \mathbf{0} & \dfrac{\alpha}{\beta} A_D(\mathbf{I} - D\gamma_0) & -\dfrac{\eta}{\beta} A_R \end{pmatrix},$$

$$\text{with } D(\mathcal{A}_\gamma^*) = \Big\{ [\phi_0, \phi_1, \psi_0] \in D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times D(A_R) \\ \text{such that } \mathring{\mathbf{A}}\phi_0 + \alpha \mathring{\mathbf{A}} G_1 \gamma_0 \psi_0 \in H^{-1}_{\Gamma_0,\gamma}(\Omega) \Big\}$$

(above, $(\clubsuit)$ is the same denotation made in (1.35)*).*

Proof. We define $\mathcal{S} \subseteq \mathbf{H}_\gamma$ to be

$$\mathcal{S} \equiv \Big\{ [\phi_0, \phi_1, \psi_0] \in D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times D(A_R) \\ \text{such that } \mathring{\mathbf{A}}\omega_1 + \alpha\ \mathring{\mathbf{A}} G_1 \gamma_0 \theta \in H^{-1}_{\Gamma_0,\gamma}(\Omega) \Big\}$$

and proceed to show that $D(\mathcal{A}_\gamma^*) = \mathcal{S}$. Indeed, if $[\omega_1, \omega_2, \theta] \in D(\mathcal{A}_\gamma)$ and $[\widetilde{\omega}_1, \widetilde{\omega}_2, \widetilde{\theta}] \in \mathcal{S}$, we have by using (1.36)

$$\begin{aligned}
&\left(\mathcal{A}_\gamma \begin{bmatrix} \omega_1 \\ \omega_2 \\ \theta \end{bmatrix}, \begin{bmatrix} \widetilde{\omega}_1 \\ \widetilde{\omega}_2 \\ \widetilde{\theta} \end{bmatrix} \right)_{\mathbf{H}_\gamma} \\
&= \left(\mathring{\mathbf{A}}^{\frac{1}{2}} \omega_2, \mathring{\mathbf{A}}^{\frac{1}{2}} \widetilde{\omega}_1 \right)_{L^2(\Omega)} \\
&\quad + \left(P_\gamma^{-1} \left(-\mathring{\mathbf{A}}\omega_1 + \alpha A_R \theta - \frac{\alpha\sigma}{\eta}\theta - \alpha \mathring{\mathbf{A}} G_1 \gamma_0 \theta + \alpha\lambda \mathring{\mathbf{A}} G_2 \gamma_0 \theta \right), \widetilde{\omega}_2 \right)_{H^1_{\Gamma_0,\gamma}(\Omega)} \\
&\quad - \left(\alpha A_D (I - D\gamma_0)\omega_2, \widetilde{\theta} \right)_{L^2(\Omega)} - \frac{\eta\beta}{\beta} \left(A_R \theta, \widetilde{\theta} \right)_{L^2(\Omega)} \\
&= \left\langle \omega_2, \mathring{\mathbf{A}} \widetilde{\omega}_1 \right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \right]' \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} - \left\langle \omega_1,\ \mathring{\mathbf{A}} \widetilde{\omega}_2 \right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \right]' \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} - \alpha \left(\Delta\theta, \widetilde{\omega}_2 \right)_{L^2(\Omega)} \\
&\quad - \alpha \left\langle \mathring{\mathbf{A}} G_1 \gamma_0 \theta, \widetilde{\omega}_2 \right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \right]' \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} + \alpha\lambda \left\langle \mathring{\mathbf{A}} G_2 \gamma_0 \theta, \widetilde{\omega}_2 \right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \right]' \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} \\
&\quad + \alpha \left(\Delta\omega_2, \widetilde{\theta} \right)_{L^2(\Omega)} - \beta \left(\theta, \frac{\eta}{\beta} A_R \widetilde{\theta} \right)_{L^2(\Omega)} \\
&\quad \text{(after using the equality posted in (1.32))} \\
&= \left\langle \omega_2, \mathring{\mathbf{A}} \widetilde{\omega}_1 \right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \right]' \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} - \left\langle \omega_1,\ \mathring{\mathbf{A}} \widetilde{\omega}_2 \right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \right]' \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} + \alpha \left(\nabla\theta, \nabla\widetilde{\omega}_2 \right)_{L^2(\Omega)} \\
&\quad - \alpha \left(\frac{\partial\theta}{\partial\nu}, \gamma_0 \widetilde{\omega}_2 \right)_{L^2(\Gamma_1)} - \alpha \left(\gamma_0\theta, \frac{\partial\widetilde{\omega}_2}{\partial\nu} \right)_{L^2(\Gamma_1)} - \alpha\lambda \left(\gamma_0\theta, \gamma_0\widetilde{\omega}_2 \right)_{L^2(\Gamma_1)} \\
&\quad - \alpha \left(\nabla\omega_2, \nabla\widetilde{\theta} \right)_{L^2(\Omega)} + \alpha \left(\frac{\partial\omega_2}{\partial\nu}, \gamma_0\widetilde{\theta} \right)_{L^2(\Gamma_1)} - \beta \left(\theta, \frac{\eta}{\beta} A_R \widetilde{\theta} \right)_{L^2(\Gamma_1)} \\
&\quad \text{(after using Green's theorem and (1.23))} \\
&= - \left(\mathring{\mathbf{A}}^{\frac{1}{2}} \omega_1, \mathring{\mathbf{A}}^{\frac{1}{2}} \widetilde{\omega}_2 \right)_{L^2(\Omega)} + \left\langle \omega_2, \mathring{\mathbf{A}} \widetilde{\omega}_1 \right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \right]' \times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)} + \beta \left(\theta, -\frac{\alpha}{\beta} \Delta\widetilde{\omega}_2 \right)_{L^2(\Omega)}
\end{aligned}$$

$$
\begin{aligned}
&+\alpha\left(\omega_2,\Delta\widetilde{\theta}\right)_{L^2(\Omega)}-\alpha\left(\gamma_0\omega_2,\frac{\partial\widetilde{\theta}}{\partial\nu}\right)_{L^2(\Gamma_1)}+\alpha\left(G_1^*\mathring{\mathbf{A}}\omega_2,\gamma_0\widetilde{\theta}\right)_{L^2(\Gamma_1)}\\
&-\beta\left(\theta,\frac{\eta}{\beta}A_R\widetilde{\theta}\right)_{L^2(\Gamma_1)}\\
=&-\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\omega_1,\mathring{\mathbf{A}}^{\frac{1}{2}}\widetilde{\omega}_2\right)_{L^2(\Omega)}+\left\langle\omega_2,\mathring{\mathbf{A}}\widetilde{\omega}_1\right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]'\times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)}\\
&+\alpha\left(\omega_2,-A_R\widetilde{\theta}+\frac{\sigma}{\eta}\widetilde{\theta}\right)_{L^2(\Omega)}-\alpha\lambda\left(G_2^*\mathring{\mathbf{A}}\omega_2,\gamma_0\widetilde{\theta}\right)_{L^2(\Gamma_1)}\\
&+\alpha\left\langle\omega_2,\mathring{\mathbf{A}}G_1\gamma_0\widetilde{\theta}\right\rangle_{\left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]'\times D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)}+\beta\left(\theta,\frac{\alpha}{\beta}A_D(I-D\gamma_0)\widetilde{\omega}_2\right)_{L^2(\Omega)}\\
&-\beta\left(\theta,\frac{\eta}{\beta}A_R\widetilde{\theta}\right)_{L^2(\Gamma_1)}\\
=&-\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\omega_1,\mathring{\mathbf{A}}^{\frac{1}{2}}\widetilde{\omega}_2\right)_{L^2(\Omega)}\\
&+\left(P_\gamma^{\frac{1}{2}}\omega_2,P_\gamma^{\frac{1}{2}}P_\gamma^{-1}\left[\mathring{\mathbf{A}}\widetilde{\omega}_1+\alpha\left(-A_R\widetilde{\theta}+\frac{\sigma}{\eta}\widetilde{\theta}+\mathring{\mathbf{A}}G_1\gamma_0\widetilde{\theta}-\lambda\mathring{\mathbf{A}}G_2\gamma_0\widetilde{\theta}\right)\right]\right)_{L^2(\Omega)}\\
&+\beta\left(\theta,\frac{\alpha}{\beta}A_D(I-D\gamma_0)\widetilde{\omega}_2\right)_{L^2(\Omega)}-\beta\left(\theta,\frac{\eta}{\beta}A_R\widetilde{\theta}\right)_{L^2(\Gamma_1)}\\
&\text{(after again using (1.32), (1.23), and the fact that } \left[\widetilde{\omega}_1,\widetilde{\omega}_2,\widetilde{\theta}\right]\in\mathcal{S})\\
=&\left(\begin{bmatrix}\omega_1\\ \omega_2\\ \theta\end{bmatrix},\mathcal{T}\begin{bmatrix}\widetilde{\omega}_1\\ \widetilde{\omega}_2\\ \widetilde{\theta}\end{bmatrix}\right)_{\mathbf{H}_\gamma},
\end{aligned}
$$

where

$$
\mathcal{T}\equiv\begin{pmatrix}\mathbf{I}&\mathbf{0}&\mathbf{0}\\ \mathbf{0}&P_\gamma^{-1}&\mathbf{0}\\ \mathbf{0}&\mathbf{0}&\mathbf{I}\end{pmatrix}\begin{pmatrix}\mathbf{0}&-\mathbf{I}&\mathbf{0}\\ \mathring{\mathbf{A}}&\mathbf{0}&-\alpha(\clubsuit)\\ \mathbf{0}&\frac{\alpha}{\beta}A_D(\mathbf{I}-D\gamma_0)&-\frac{\eta}{\beta}A_R\end{pmatrix}.
$$

Thus,

$$
\mathcal{S}\subseteq D(\mathcal{A}_\gamma^*)\text{ and }\mathcal{A}_\gamma^*\big|_{\mathcal{S}}=\mathcal{T}. \tag{4.1}
$$

To show the opposite containment, one can straightforwardly compute the inverse $\mathcal{A}_\gamma^{-1}\in\mathcal{L}(\mathbf{H}_\gamma,D(\mathcal{A}_\gamma))$ as

$$
\mathcal{A}_\gamma^{-1}=\begin{pmatrix}-\frac{\alpha^2}{\eta}\mathring{\mathbf{A}}^{-1}(\clubsuit)A_R^{-1}A_D(I-D\gamma_0)&-\mathring{\mathbf{A}}^{-1}P_\gamma&-\frac{\alpha\beta}{\eta}\mathring{\mathbf{A}}^{-1}(\clubsuit)A_R^{-1}\\ \mathbf{I}&\mathbf{0}&\mathbf{0}\\ -\frac{\alpha}{\eta}A_R^{-1}A_D(I-D\gamma_0)&\mathbf{0}&-\frac{\beta}{\eta}A_R^{-1}\end{pmatrix}. \tag{4.2}
$$

In turn, one can use this quantity and Proposition 4.1 to compute the Hilbert space

adjoint $\left(\mathcal{A}_\gamma^*\right)^{-1}$ of $\mathcal{A}_\gamma^{-1}$ as

$$(4.3)\quad \left(\mathcal{A}_\gamma^*\right)^{-1} = \begin{pmatrix} -\frac{\alpha^2}{\eta}\mathring{\mathbf{A}}^{-1}(\clubsuit)A_R^{-1}A_D(I-D\gamma_0) & \mathring{\mathbf{A}}^{-1}P_\gamma & -\frac{\alpha\beta}{\eta}\mathring{\mathbf{A}}^{-1}(\clubsuit)A_R^{-1} \\ -\mathbf{I} & \mathbf{0} & \mathbf{0} \\ -\frac{\alpha}{\eta}A_R^{-1}A_D(I-D\gamma_0) & \mathbf{0} & -\frac{\beta}{\eta}A_R^{-1} \end{pmatrix}.$$

With this quantity in hand, we then have that for arbitrary $[\phi_0,\phi_1,\psi_0]\in D(\mathcal{A}_\gamma^*)$ and corresponding

$$\begin{bmatrix} \omega_0 \\ \omega_1 \\ \theta_0 \end{bmatrix} = \mathcal{A}_\gamma^* \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \in \mathbf{H}_\gamma,$$

$$\begin{aligned} \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} &= \left(\mathcal{A}_\gamma^*\right)^{-1} \begin{bmatrix} \omega_0 \\ \omega_1 \\ \theta_0 \end{bmatrix} \\ &= \begin{bmatrix} -\frac{\alpha^2}{\eta}\mathring{\mathbf{A}}^{-1}(\clubsuit)A_R^{-1}A_D(I-D\gamma_0)\omega_0 + \mathring{\mathbf{A}}^{-1}P_\gamma\omega_1 - \frac{\alpha\beta}{\eta}\mathring{\mathbf{A}}^{-1}(\clubsuit)A_R^{-1}\theta_0 \\ -\omega_0 \\ -\frac{\alpha}{\eta}A_R^{-1}A_D(I-D\gamma_0)\omega_0 - \frac{\beta}{\eta}A_R^{-1}\theta_0 \end{bmatrix}. \end{aligned}$$

(4.4)

A fortiori then, $[\phi_0,\phi_1]\in[D(\mathring{\mathbf{A}}^{\frac12})]^2$ and $\psi_0\in D(A_R)$. Moreover, (4.4) and the definition of the operator $(\clubsuit)$ in (1.35) gives

$$(4.5)\qquad \mathring{\mathbf{A}}\phi_0 + \alpha\mathring{\mathbf{A}}G_1\gamma_0\phi_1 \in H^1_{\Gamma_0,\gamma}(\Omega).$$

Thus, $D(\mathcal{A}_\gamma^*)\subseteq\mathcal{S}$, and this combined with (4.1) concludes Lemma 4.2. □

PROPOSITION 4.3. *For arbitrary terminal data $[\phi_0,\phi_1,\psi_0]\in\mathbf{H}_\gamma$, the solution $[\phi,\phi_t,\psi]$ to (1.51) has the following additional regularity:*

$$\|\phi_{tt}\|_{L^\infty(0,T;[D(\mathring{\mathbf{A}}^{\frac12}P_\gamma^{-1})]')} \le C\,\|[\phi_0,\phi_1,\psi_0]\|_{\mathbf{H}_\gamma},$$

where $\mathring{\mathbf{A}}^{\frac12}P_\gamma^{-1}$ is taken as a closed and densely defined operator, $\mathring{\mathbf{A}}^{\frac12}P_\gamma^{-1}: D(\mathring{\mathbf{A}}^{\frac12}P_\gamma^{-1})\subset L^2(\Omega)\to L^2(\Omega)$, with $D(\mathring{\mathbf{A}}^{\frac12}P_\gamma^{-1}) = \{\varphi\in L^2(\Omega): P_\gamma^{-1}\varphi\in D(\mathring{\mathbf{A}}^{\frac12})\}$.

Proof. For terminal data $[\phi_0,\phi_1,\psi_0]\in D(\mathcal{A}_\gamma^*)$, we have for all $\varpi\in L^1(0,T;D(\mathring{\mathbf{A}}^{\frac12}P_\gamma^{-1}))$, upon using the abstract equation (1.52), the characterizations in (1.23) , the fact that $P_\gamma^{-1}\varpi\in L^1(0,T;D(\mathring{\mathbf{A}}^{\frac12})\cap D(A_N))$ (recall the definition of A_N in (1.16) and P_γ in (1.24)), and $\frac{\partial\psi}{\partial\nu}|_\Gamma = -\lambda\psi|_\Gamma$, that

(4.6)

$$\begin{aligned} &\int_0^T (\varpi,\phi_{tt})_{L^2(\Omega)}\,dt = \int_0^T \left(\varpi, P_\gamma^{-1}\left[-\mathring{\mathbf{A}}\phi - \alpha\mathring{\mathbf{A}}G_1\gamma_0\psi + \alpha\lambda\ \mathring{\mathbf{A}}G_2\gamma_0\psi - \alpha\Delta\psi\right]\right)_{L^2(\Omega)}dt \\ &= \int_0^T \left[-\left(\mathring{\mathbf{A}}^{\frac12}P_\gamma^{-1}\varpi, \mathring{\mathbf{A}}^{\frac12}\phi\right)_{L^2(\Omega)} - \alpha\left(G_1^*\mathring{\mathbf{A}}P_\gamma^{-1}\varpi, \gamma_0\psi\right)_{L^2(\Gamma_1)}\right. \end{aligned}$$

$$
\begin{aligned}
&+ \alpha\lambda \left(G_2^* \, \mathring{\mathbf{A}} P_\gamma^{-1}\varpi, \gamma_0\psi\right)_{L^2(\Gamma_1)} - \alpha\left(P_\gamma^{-1}\varpi, \Delta\psi\right)_{L^2(\Omega)}\Big] \, dt \\
&= \int_0^T \left[\left(-\mathring{\mathbf{A}}^{\frac{1}{2}} P_\gamma^{-1}\varpi, \mathring{\mathbf{A}}^{\frac{1}{2}}\phi\right)_{L^2(\Omega)} + \alpha\left(P_\gamma^{-1}\varpi, \frac{\partial\psi}{\partial\nu}\right)_{L^2(\Gamma_1)} - \alpha\left(P_\gamma^{-1}\varpi, \Delta\psi\right)_{L^2(\Omega)}\right] dt \\
&= \int_0^T \left[\left(-\mathring{\mathbf{A}}^{\frac{1}{2}} P_\gamma^{-1}\varpi, \mathring{\mathbf{A}}^{\frac{1}{2}}\phi\right)_{L^2(\Omega)} + \alpha\left(\nabla P_\gamma^{-1}\varpi, \nabla\psi\right)_{L^2(\Omega)}\right] dt \\
&= \int_0^T \left[\left(-\mathring{\mathbf{A}}^{\frac{1}{2}} P_\gamma^{-1}\varpi, \mathring{\mathbf{A}}^{\frac{1}{2}}\phi\right)_{L^2(\Omega)} - \alpha\left(\Delta P_\gamma^{-1}\varpi, \psi\right)_{L^2(\Omega)}\right] dt.
\end{aligned}
$$

Estimating the far side of this expression by using the fact that $P_\gamma^{-1} \in \mathcal{L}(L^2(\Omega), D(A_N))$, followed by the contraction of the semigroup $\{e^{\mathcal{A}_\gamma^* t}\}_{t\geq 0}$, one has the estimate

$$
\int_0^T (\varpi, \phi_{tt})_{L^2(\Omega)} \, dt \leq C \left\| \begin{bmatrix} \phi_0 \\ \phi_1 \\ \psi_0 \end{bmatrix} \right\|_{\mathbf{H}_\gamma} \|\varpi\|_{L^1(0,T;D(\mathring{\mathbf{A}}^{\frac{1}{2}} P_\gamma^{-1}))} \, dt. \tag{4.7}
$$

A density argument concludes the proof. □

PROPOSITION 4.4. *If $[\phi, \phi_t, \psi]$ denotes the solution to* (1.51)*, corresponding to terminal data $[\phi_0, \phi_1, \psi_0]$, we have the following estimates.*

1. *The map $[\phi_0, \phi_1, \psi_0] \to \Delta\phi$ is an element of $\mathcal{L}(\mathbf{H}_\gamma, L^2(0,T;[H^1(\Omega)]'))$, with the norm bound*

$$
\|\Delta\phi\|_{L^2(0,T;[H^1(\Omega)]')} \leq \mathsf{l.o.t.}\,(\phi, \phi_t, \psi)\,. \tag{4.8}
$$

2. *The map $[\phi_0, \phi_1, \psi_0] \to [\Delta\phi_t, \psi_t]$ is an element of $\mathcal{L}(D(\mathcal{L}_T^*), [L^2(0,T;[H^{\frac{3}{2}-\epsilon}(\Omega)]')]^2)$, with the norm bound*

$$
\|[\Delta\phi_t, \psi_t]\|_{\left[L^2\left(0,T;\left[H^{\frac{3}{2}-\epsilon}(\Omega)\right]'\right)\right]^2} \leq C \|\nabla\phi_t\|_{L^2(0,T;L^2(\Gamma_1))} + \mathsf{l.o.t.}\,(\phi, \phi_t, \psi)\,. \tag{4.9}
$$

Proof of (i). For all $\varpi \in L^2(0,T;H^1(\Omega))$, we easily have

$$
\begin{aligned}
&\int_0^T (\Delta\phi, \varpi)_{L^2(\Omega)} \, dt = -\int_0^T (\nabla\phi, \nabla\varpi)_{L^2(\Omega)} \, dt + \int_0^T \left(\frac{\partial\phi}{\partial\nu}, \varpi\right)_{L^2(\Gamma_1)} dt \\
&\leq C \int_0^T \left[\|\nabla\phi\|_{L^2(\Omega)} \|\nabla\varpi\|_{L^2(\Omega)} + \|\phi\|_{H^{\frac{3}{2}+\epsilon}(\Omega)} \|\varpi\|_{H^1(\Omega)}\right] dt \\
&\leq C \|\phi\|_{L^2\left(0,T;H^{\frac{3}{2}+\epsilon}(\Omega)\right)} \|\varpi\|_{L^2(0,T;H^1(\Omega))}\,,
\end{aligned} \tag{4.10}
$$

and this estimate gives the asserted result.

Proof of (ii). If $[\phi_0, \phi_1, \psi_0] \in D(\mathcal{A}_\gamma^*)$, then $[\phi, \phi_t, \psi] \in C([0,T]; D(\mathcal{A}_\gamma^*)) \cap C^1([0,T]; \mathbf{H}_\gamma)$, and so in particular $\Delta\phi_t \in L^2(0,T;L^2(\Omega))$. Taking the L^2-inner product with respect to arbitrary $\varpi \in L^2(0,T;H^{\frac{3}{2}-\epsilon}(\Omega))$, we have upon the use of Green's theorem and the definition of A_R in (1.14) that

(4.11)

$$
\begin{aligned}
&-\int_0^T (\Delta\phi_t, \varpi)_{L^2(\Omega)}\, dt \\
&= \int_0^T \left(A_R^{\frac{1}{2}}\phi_t, A_R^{\frac{1}{2}}\varpi\right)_{L^2(\Omega)} dt \\
&\quad - \int_0^T \left[\lambda\,(\phi_t, \varpi)_{L^2(\Gamma)} + \frac{\sigma}{\eta}\,(\phi_t, \varpi)_{L^2(\Omega)} + \left(\frac{\partial\phi_t}{\partial\nu}, \varpi\right)_{L^2(\Gamma_1)}\right] dt \\
&= \int_0^T \left(A_R^{\frac{1}{4}+\frac{\epsilon}{2}}\phi_t, A_R^{\frac{3}{4}-\frac{\epsilon}{2}}\varpi\right)_{L^2(\Omega)} dt \\
&\quad - \int_0^T \left[\lambda\,(\phi_t, \varpi)_{L^2(\Gamma)} + \frac{\sigma}{\eta}\,(\phi_t, \varpi)_{L^2(\Omega)} + \left(\frac{\partial\phi_t}{\partial\nu}, \varpi\right)_{L^2(\Gamma_1)}\right] dt \\
&\le \int_0^T \left(\left\|A_R^{\frac{1}{4}+\frac{\epsilon}{2}}\phi_t\right\|_{L^2(\Omega)} \left\|A_R^{\frac{3}{4}-\frac{\epsilon}{2}}\varpi\right\|_{L^2(\Omega)}\right. \\
&\qquad \left. + \left(C\,\|\nabla\phi_t\|_{L^2(0,T;L^2(\Gamma_1))} + \text{l.o.t.}\,(\phi, \phi_t, \psi)\right)\|\varpi\|_{H^{\frac{1}{2}+\epsilon}(\Omega)}\right) dt \\
&\le \left(C\,\|\nabla\phi_t\|_{L^2(0,T;L^2(\Gamma_1))} + \text{l.o.t.}\,(\phi, \phi_t, \psi)\right)\|\varpi\|_{L^2\left(0,T;H^{\frac{3}{2}-\epsilon}(\Omega)\right)}.
\end{aligned}
$$

Moreover, as $[\phi_0, \phi_1, \psi_0] \in D(\mathcal{A}_\gamma^*)$, we can take the L^2-inner product of ψ_t with arbitrary $\varpi \in L^2(0,T;H^{\frac{3}{2}-\epsilon}(\Omega))$ and use (1.53) and (4.11) to obtain

$$
\begin{aligned}
&\int_0^T (\psi_t, \varpi)_{L^2(\Omega)}\, dt = \beta^{-1}\int_0^T (\eta A_R\psi + \alpha\Delta\phi_t, \varpi)_{L^2(\Omega)}\, dt \\
&= \beta^{-1}\int_0^T \left[\left(\eta A_R^{\frac{1}{4}+\frac{\epsilon}{2}}\psi, A_R^{\frac{3}{4}-\frac{\epsilon}{2}}\varpi\right)_{L^2(\Omega)} + (\alpha\Delta\phi_t, \varpi)_{L^2(\Omega)}\right] dt \\
&\le \left(C\,\|\nabla\phi_t\|_{L^2(0,T;L^2(\Gamma_1))} + \text{l.o.t.}\,(\phi, \phi_t, \psi)\right)\|\varpi\|_{L^2\left(0,T;H^{\frac{3}{2}-\epsilon}(\Omega)\right)}. \qquad (4.12)
\end{aligned}
$$

Having obtained estimates (4.11) and (4.12) with smooth data $[\phi_0, \phi_1, \psi_0]$, a density argument (see Remark 1.8) and a recollection of the form of the adjoint $\mathcal{L}_T^*$ in (1.55) will allow us to obtain the norm bound (4.9) for all terminal data in $D(\mathcal{L}_T^*)$. □

LEMMA 4.5. *Concerning the component $\widehat{\phi}$ of the solution $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ of (2.9), one has that $\Delta\widehat{\phi}|_{\Gamma_0} \in L^2(0,T;L^2(\Gamma_0))$ with the following estimate valid for all s and $\tau \in [0,T]$:*

$$
\int_s^\tau \left\|\Delta\widehat{\phi}\right\|^2_{L^2(\Gamma_0)} dt \le C_0\left(\int_0^T E_{\widehat{\phi}}(t)dt + E_{\widehat{\phi}}(s) + E_{\widehat{\phi}}(\tau)\right) + \text{l.o.t.}\left(\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}\right). \qquad (4.13)
$$

Proof. So as to obtain the inequality (4.13), we multiply the first equation of (2.15) by the quantity $\overline{m}\cdot\nabla\widehat{\phi}$, where $\overline{m}(x,y) \equiv [m_1(x,y), m_2(x,y)]$ is a $\left[C^2(\overline{\Omega})\right]^2$ vector field,[1] which satisfies

$$
\overline{m}|_\Gamma = \begin{cases} [\nu_1, \nu_2] & \text{on } \Gamma_0, \\ 0 & \text{on } \Gamma_1, \end{cases} \qquad (4.14)
$$

[1] Here we make use of the fact that Γ_0 and Γ_1 are separated.

and follow this by an integration from s to τ; i.e., we will work with the equation

$$\begin{aligned}&\int_s^\tau \left(\widehat{\phi}_{tt} - \gamma\Delta\widehat{\phi}_{tt} + \Delta^2\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt \\ &\qquad = \int_s^\tau \left(c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt. \end{aligned} \tag{4.15}$$

To handle the left-hand side of (4.15), perform the following steps.

(i) First,

(4.16)

$$\begin{aligned}&\int_s^\tau \left(\widehat{\phi}_{tt}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt = \left(\widehat{\phi}_t, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)}\Big|_s^\tau - \int_s^\tau \left(\widehat{\phi}_t, \overline{m}\cdot\nabla\widehat{\phi}_t\right)_{L^2(\Omega)} dt \\ &= \left(\widehat{\phi}_t, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)}\Big|_s^\tau - \frac{1}{2}\int_s^\tau\int_\Omega \operatorname{div}\left(\widehat{\phi}_t^2\overline{m}\right) dtd\Omega \\ &\quad + \frac{1}{2}\int_s^\tau\int_\Omega \widehat{\phi}_t^2\left[m_{1x} + m_{2y}\right] dtd\Omega \\ &= \left(\widehat{\phi}_t, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)}\Big|_s^\tau + \frac{1}{2}\int_s^\tau\int_\Omega \widehat{\phi}_t^2\left[m_{1x} + m_{2y}\right] dtd\Omega, \end{aligned}$$

after making use of the divergence theorem and the fact that $\widehat{\phi}_t = 0$ on Γ_0.

(ii) Next,

(4.17)

$$\begin{aligned}&\int_s^\tau \left(-\Delta\widehat{\phi}_{tt}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt = \left(\nabla\widehat{\phi}_t, \nabla\left(\overline{m}\cdot\nabla\widehat{\phi}\right)\right)_{L^2(\Omega)}\Big|_s^\tau \\ &\quad - \int_s^\tau \left(\nabla\widehat{\phi}_t, \nabla\left(\overline{m}\cdot\nabla\widehat{\phi}_t\right)\right)_{L^2(\Omega)} dt \\ &= \left(\nabla\widehat{\phi}_t, \nabla\left(\overline{m}\cdot\nabla\widehat{\phi}\right)\right)_{L^2(\Omega)}\Big|_s^\tau - \frac{1}{2}\int_s^\tau\int_\Omega \operatorname{div}\left(\left|\nabla\widehat{\phi}_t\right|^2\overline{m}\right) dtd\Omega \\ &\quad - \int_s^\tau\int_\Omega \left[\frac{\widehat{\phi}_{tx}^2 m_{1x}}{2} + \frac{\widehat{\phi}_{ty}^2 m_{2y}}{2}\right] dtd\Omega - \int_s^\tau\int_\Omega \left[\widehat{\phi}_{tx}\widehat{\phi}_{ty}m_{2x} + \widehat{\phi}_{tx}\widehat{\phi}_{ty}m_{1y}\right] dtd\Omega \\ &\quad + \int_s^\tau\int_\Omega \left[\frac{\widehat{\phi}_{tx}^2 m_{2y}}{2} + \frac{\widehat{\phi}_{ty}^2 m_{1x}}{2}\right] dtd\Omega \\ &= \left(\nabla\widehat{\phi}_t, \nabla\left(\overline{m}\cdot\nabla\widehat{\phi}\right)\right)_{L^2(\Omega)}\Big|_s^\tau \\ &\quad + \int_s^\tau\int_\Omega \left[\frac{\widehat{\phi}_{tx}^2 m_{2y}}{2} + \frac{\widehat{\phi}_{ty}^2 m_{1x}}{2} - \frac{\widehat{\phi}_{tx}^2 m_{1x}}{2} - \frac{\widehat{\phi}_{ty}^2 m_{2y}}{2}\right] dtd\Omega \\ &\quad - \int_s^\tau\int_\Omega \left[\widehat{\phi}_{tx}\widehat{\phi}_{ty}m_{2x} + \widehat{\phi}_{tx}\widehat{\phi}_{ty}m_{1y}\right] dtd\Omega, \end{aligned}$$

after again using the divergence theorem and the fact that $\int_\Omega \operatorname{div}(|\nabla\widehat{\phi}_t|^2\overline{m})d\Omega = \int_{\Gamma_0} |\nabla\widehat{\phi}_t|^2 d\Gamma_0 = 0$ (as $\widehat{\phi}_t(t) \in H^2_{\Gamma_0}(\Omega)$).

(iii) To handle the biharmonic term, we use Green's theorem (1.9), the given boundary conditions of (2.15), (4.14), and the fact that $\widehat{\phi} \in H^2_{\Gamma_0}(\Omega)$ to obtain

(4.18)
$$\int_s^\tau \left(\Delta^2\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt = \int_s^\tau a\left(\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right) dt$$
$$+\alpha\int_s^\tau\int_{\Gamma_1}\widehat{\psi}\cdot\frac{\partial\overline{m}\cdot\nabla\widehat{\phi}}{\partial\nu}\,d\Gamma_1 dt \;-\int_s^\tau\int_{\Gamma_0}\left(\Delta\widehat{\phi}+(1-\mu)B_1\widehat{\phi}\right)\frac{\partial^2\widehat{\phi}}{\partial\nu^2}d\Gamma_0 dt.$$

We note at this point that we can rewrite the first term on the right-hand side of (4.18) as

(4.19)
$$\begin{aligned}&\int_s^\tau a\left(\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right) dt\\ &= \frac{1}{2}\int_s^\tau\int_\Omega \overline{m}\cdot\nabla\left[\widehat{\phi}_{xx}^2+\widehat{\phi}_{yy}^2+2\mu\widehat{\phi}_{xx}\widehat{\phi}_{yy}+2(1-\mu)\widehat{\phi}_{xy}^2\right]dtd\Omega\\ &\quad+\mathcal{O}\left(\int_0^T\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2_{L^2(\Omega)}dt\right),\end{aligned}$$

where $\mathcal{O}(\int_0^T \|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\|^2_{L^2(\Omega)}dt)$ denotes a series of terms that can be majorized by the $L^2(0,T;D(\mathring{\mathbf{A}}^{\frac{1}{2}}))$-norm of $\widehat{\phi}$. We consequently have by the divergence theorem that

(4.20)
$$\begin{aligned}&\int_s^\tau a\left(\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right) dt\\ &= \frac{1}{2}\int_s^\tau\int_\Omega \overline{m}\cdot\nabla\left[\widehat{\phi}_{xx}^2+\widehat{\phi}_{yy}^2+2\mu\widehat{\phi}_{xx}\widehat{\phi}_{yy}+2(1-\mu)\widehat{\phi}_{xy}^2\right]dtd\Omega\\ &\quad+\mathcal{O}\left(\int_0^T\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2_{L^2(\Omega)}dt\right)\\ &= \frac{1}{2}\int_s^\tau\int_\Omega \operatorname{div}\left\{\overline{m}\left[\widehat{\phi}_{xx}^2+\widehat{\phi}_{yy}^2+2\mu\widehat{\phi}_{xx}\widehat{\phi}_{yy}+2(1-\mu)\widehat{\phi}_{xy}^2\right]\right\}dtd\Omega\\ &\quad+\mathcal{O}\left(\int_0^T\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2_{L^2(\Omega)}dt\right)\\ &= \frac{1}{2}\int_s^\tau\int_{\Gamma_0}\left[\widehat{\phi}_{xx}^2+\widehat{\phi}_{yy}^2+2\mu\widehat{\phi}_{xx}\widehat{\phi}_{yy}+2(1-\mu)\widehat{\phi}_{xy}^2\right]dtd\Gamma_0\\ &\quad+\mathcal{O}\left(\int_0^T\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2_{L^2(\Omega)}dt\right)\\ &= \frac{1}{2}\int_s^\tau\int_{\Gamma_0}\left(\Delta\widehat{\phi}\right)^2dt+\mathcal{O}\left(\int_0^T\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2_{L^2(\Omega)}dt\right),\end{aligned}$$

where in the last step above, we have used the fact (as reasoned in [11, Chapter 4]) that $\widehat{\phi}|_{\Gamma_0} = \frac{\partial\widehat{\phi}}{\partial\nu}|_{\Gamma_0} = 0$ implies that $\widehat{\phi}_{xx}^2+\widehat{\phi}_{yy}^2+2\mu\widehat{\phi}_{xx}\widehat{\phi}_{yy}+2(1-\mu)\widehat{\phi}_{xy}^2 = (\Delta\widehat{\phi})^2$ on Γ_0.

To handle the last term on the right-hand side of (4.18), we note that $B_1\widehat{\phi} = 0$ on Γ_0, which implies that

$$\Delta\widehat{\phi} = \Delta\widehat{\phi} + (1-\mu)B_1\widehat{\phi} = \frac{\partial^2\widehat{\phi}}{\partial\nu^2} \text{ on } \Gamma_0 \ . \tag{4.21}$$

We consequently have upon the insertion of (4.20) into (4.18), followed by the consideration of (4.21) that

$$\begin{aligned}\int_s^\tau \left(\Delta^2\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt &= -\frac{1}{2}\int_s^\tau \left\|\Delta\widehat{\phi}\right\|^2_{L^2(\Gamma_0)} dt \\ &+ \alpha\int_s^\tau\int_{\Gamma_1} \widehat{\psi}\cdot\frac{\partial\overline{m}\cdot\nabla\widehat{\phi}}{\partial\nu}\, d\Gamma_1 dt \ + \ \mathcal{O}\left(\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2_{L^2(\Omega)} dt\right).\end{aligned} \tag{4.22}$$

(iv) To handle the right-hand side of (4.15), an integration by parts yields

$$\begin{aligned}&\int_s^\tau \left(c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt \\ &= c_1\left[\left(\widehat{\psi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)}\right]_s^\tau - c_1\int_s^\tau \left(\widehat{\psi}, \overline{m}\cdot\nabla\widehat{\phi}_t\right)_{L^2(\Omega)} dt \\ &\quad + \int_s^\tau \left(c_0\widehat{\psi} + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt.\end{aligned}$$

As $\overline{m}\cdot\nabla\widehat{\phi} \in C([0,T]; H^1_{\Gamma_0,\gamma}(\Omega))$, we have for all $t \in [0,T]$,

$$\left(\widehat{\psi}(t), \overline{m}\cdot\nabla\widehat{\phi}(t)\right)_{L^2(\Omega)} = \left\langle\widehat{\psi}(t), \overline{m}\cdot\nabla\widehat{\phi}(t)\right\rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega)\times H^1_{\Gamma_0,\gamma}(\Omega)}.$$

Accordingly, we have

$$\begin{aligned}&\int_s^\tau \left(c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt \\ &\quad = c_1\left[\left\langle\widehat{\psi}, \overline{m}\cdot\nabla\widehat{\phi}\right\rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega)\times H^1_{\Gamma_0,\gamma}(\Omega)}\right]_s^\tau \\ -c_1&\int_s^\tau \left(\widehat{\psi}, \overline{m}\cdot\nabla\widehat{\phi}_t\right)_{L^2(\Omega)} dt + \int_s^\tau \left(c_0\widehat{\psi} + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt.\end{aligned} \tag{4.23}$$

To finish the proof, we rewrite (4.15) by collecting the relations given above in (4.16), (4.17), (4.22), and (4.23) to attain

$$\begin{aligned}&\frac{1}{2}\int_s^\tau \left\|\Delta\widehat{\phi}\right\|^2_{L^2(\Gamma_0)} dt = \alpha\int_s^\tau\int_{\Gamma_1} \widehat{\psi}\cdot\frac{\partial\overline{m}\cdot\nabla\widehat{\phi}}{\partial\nu}\, d\Gamma_1 dt \\ &+ \ \mathcal{O}\left(\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2_{L^2(\Omega)} dt\right) + \frac{1}{2}\int_s^\tau\int_\Omega \widehat{\phi}_t^2\left[m_{1x} + m_{2y}\right] dt d\Omega\end{aligned} \tag{4.24}$$

$$
\begin{aligned}
&- \int_s^\tau \left(c_0\widehat{\psi} + c_2\widehat{\phi} + c_3\widehat{\phi}_t + c_4\Delta\widehat{\phi}, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} dt \\
&+ \gamma \int_s^\tau \int_\Omega \left[\frac{\widehat{\phi}_{tx}^2 m_{2y}}{2} + \frac{\widehat{\phi}_{ty}^2 m_{1x}}{2} - \frac{\widehat{\phi}_{tx}^2 m_{1x}}{2} - \frac{\widehat{\phi}_{ty}^2 m_{2y}}{2}\right] dt d\Omega \\
&- \gamma \int_s^\tau \int_\Omega \left[\widehat{\phi}_{tx}\widehat{\phi}_{ty} m_{2x} + \widehat{\phi}_{tx}\widehat{\phi}_{ty} m_{1y}\right] dt d\Omega + c_1 \int_s^\tau \left(\widehat{\psi}, \overline{m}\cdot\nabla\widehat{\phi}_t\right)_{L^2(\Omega)} dt \\
&+ \left[\left(\widehat{\phi}_t, \overline{m}\cdot\nabla\widehat{\phi}\right)_{L^2(\Omega)} + \gamma\left(\nabla\widehat{\phi}_t, \nabla\left(\overline{m}\cdot\nabla\widehat{\phi}\right)\right)_{L^2(\Omega)} - c_1\left\langle\widehat{\psi}, \overline{m}\cdot\nabla\widehat{\phi}\right\rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega)\times H^1_{\Gamma_0,\gamma}(\Omega)}\right]_s^\tau.
\end{aligned}
$$

The desired inequality (4.13) now comes about by majorizing the right-hand side of this expression (note that in this majorization we are using implicitly the fact that $\frac{\partial\overline{m}\cdot\nabla\widehat{\phi}}{\partial\nu}|_{\Gamma_1}$ is a "lower order term," as $\overline{m}|_{\Gamma_1} = 0$). □

PROPOSITION 4.6. *With the vector field $\overline{h}$ as defined in* (1.3)*, the solution $[\widehat{\phi}, \widehat{\phi}_t, \widehat{\psi}]$ to* (2.15)*, corresponding to terminal data $[\phi_0, \phi_1, \psi_0] \in D([\mathcal{A}_\gamma^*]^2)$, satisfies equality* (2.36) *for arbitrary $\epsilon_0 \in [0, T)$.*

Proof. We multiply (2.15) by $\overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}$ and subsequently integrate in time and space; i.e., we will consider the equation

$$
\int_{\epsilon_0}^{T-\epsilon_0} \left(\widehat{\phi}_{tt} - \gamma\Delta\widehat{\phi}_{tt} + \Delta^2\widehat{\phi} - \left[c_0\widehat{\psi} + c_1\widehat{\psi}_t + c_2\widehat{\phi} + c_3\widehat{\phi}_t\right], \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}\right)_{L^2(\Omega)} dt = 0. \tag{4.25}
$$

First, using directly the computations performed in [12] for the quantity $\int_{\epsilon_0}^{T-\epsilon_0}(\widehat{\phi}_{tt} - \gamma\Delta\widehat{\phi}_{tt} + \Delta^2\widehat{\phi}, \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi})_{L^2(\Omega)}dt$, in the case that $\overline{h}$ is a radial vector field (see the relations (3.12) and (3.16) of [12]), we have

(4.26)

$$
\begin{aligned}
&\int_{\epsilon_0}^{T-\epsilon_0} \left(\widehat{\phi}_{tt} - \gamma\Delta\widehat{\phi}_{tt} + \Delta^2\phi, \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}\right)_{L^2(\Omega)} dt \\
&= \left[(\widehat{\phi}_t, \overline{h}\cdot\nabla\widehat{\phi})_{L^2(\Omega)} + \gamma\left(\nabla\widehat{\phi}_t, \nabla\left(\overline{h}\cdot\nabla\widehat{\phi}\right)\right)_{L^2(\Omega)} - \frac{1}{2}(\widehat{\phi}_t, \widehat{\phi})_{L^2(\Omega)}\right]_{t=\epsilon_0}^{t=T-\epsilon_0} \\
&\quad - \left[\frac{\gamma}{2}\left(\nabla\widehat{\phi}_t, \nabla\widehat{\phi}\right)_{L^2(\Omega)}\right]_{t=\epsilon_0}^{t=T-\epsilon_0} - \frac{1}{2}\int_{\epsilon_0}^{T-\epsilon_0}\int_{\Gamma_1} \overline{h}\cdot\nu\left(\widehat{\phi}_t^2 + \gamma\left|\nabla\widehat{\phi}_t\right|^2\right) d\Gamma dt \\
&\quad + \int_{\epsilon_0}^{T-\epsilon_0} \left[\frac{1}{2}\left\|P_\gamma^{\frac{1}{2}}\widehat{\phi}_t\right\|_{L^2(\Omega)}^2 + \left\|\widehat{\phi}_t\right\|_{L^2(\Omega)}^2 - \gamma\left(\overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}, \frac{\partial\widehat{\phi}_{tt}}{\partial\nu}\right)_{L^2(\Gamma_1)}\right] dt \\
&\quad + \int_{\epsilon_0}^{T-\epsilon_0} \left[\frac{1}{2}\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\phi}\right\|^2 + \frac{1}{2}\int_{\Gamma_0} \overline{h}\cdot\nu\left(\Delta\widehat{\phi}\right)^2 d\Gamma - \left(\Delta\widehat{\phi}, \frac{\partial}{\partial\nu}\left(\overline{h}\cdot\nabla\widehat{\phi}\right)\right)_{L^2(\Gamma_0)}\right] dt \\
&\quad + \int_{\epsilon_0}^{T-\epsilon_0} \left[\left(\frac{\partial\Delta\widehat{\phi}}{\partial\nu} + (1-\mu)\frac{\partial B_2\widehat{\phi}}{\partial\tau}, \overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}\right)_{L^2(\Gamma_1)}\right. \\
&\qquad \left. - \left(\Delta\widehat{\phi} + (1-\mu)B_1\widehat{\phi}, \frac{\partial}{\partial\nu}\left(\overline{h}\cdot\nabla\widehat{\phi} - \frac{1}{2}\widehat{\phi}\right)\right)_{L^2(\Gamma_1)}\right] dt
\end{aligned}
$$

$$+\int_{\epsilon_0}^{T-\epsilon_0}\int_{\Gamma_1}\frac{\overline{h}\cdot\nu}{2}\left[\left(\frac{\partial^2\widehat{\phi}}{\partial x^2}\right)^2+\left(\frac{\partial^2\widehat{\phi}}{\partial y^2}\right)^2+2\mu\left(\frac{\partial^2\widehat{\phi}}{\partial x^2}\right)\left(\frac{\partial^2\widehat{\phi}}{\partial y^2}\right)+2(1-\mu)\left(\frac{\partial^2\widehat{\phi}}{\partial x\partial y}\right)^2\right]dtd\Gamma.$$

Using the boundary conditions in (2.15) and the fact that $\frac{\partial(\overline{h}\cdot\nabla\phi)}{\partial\nu}|_{\Gamma_0}=(\overline{h}\cdot\nu)\Delta\phi|_{\Gamma_0}$, this equation becomes

(4.27)

$$\begin{aligned}
&\int_{\epsilon_0}^{T-\epsilon_0}\left(\widehat{\phi}_{tt}-\gamma\Delta\widehat{\phi}_{tt}+\Delta^2\phi,\overline{h}\cdot\nabla\widehat{\phi}-\frac{1}{2}\widehat{\phi}\right)_{L^2(\Omega)}dt=\frac{1}{2}\int_{\epsilon_0}^{T-\epsilon_0}E_{\widehat{\phi}}(t)dt\\
&+\left[(\widehat{\phi}_t,\overline{h}\cdot\nabla\widehat{\phi})_{L^2(\Omega)}+\gamma\left(\nabla\widehat{\phi}_t,\nabla\left(\overline{h}\cdot\nabla\widehat{\phi}\right)\right)_{L^2(\Omega)}-\frac{1}{2}(\widehat{\phi}_t,\widehat{\phi})_{L^2(\Omega)}\right]_{t=\epsilon_0}^{t=T-\epsilon_0}\\
&-\left[\frac{\gamma}{2}\left(\nabla\widehat{\phi}_t,\nabla\widehat{\phi}\right)_{L^2(\Omega)}\right]_{t=\epsilon_0}^{t=T-\epsilon_0}-\frac{1}{2}\int_{\epsilon_0}^{T-\epsilon_0}\int_{\Gamma_1}\overline{h}\cdot\nu\left(\widehat{\phi}_t^2+\gamma\left|\nabla\widehat{\phi}_t\right|^2\right)d\Gamma dt\\
&+\int_{\epsilon_0}^{T-\epsilon_0}\left[\left\|\widehat{\phi}_t\right\|_{L^2(\Omega)}^2-\frac{1}{2}\int_{\Gamma_0}\overline{h}\cdot\nu\left(\Delta\widehat{\phi}\right)^2d\Gamma\right]dt\\
&+\int_{\epsilon_0}^{T-\epsilon_0}\left[\alpha\left(\widehat{\psi},\frac{\partial}{\partial\nu}\left(\overline{h}\cdot\nabla\widehat{\phi}-\frac{1}{2}\widehat{\phi}\right)\right)_{L^2(\Gamma_1)}\right.\\
&\qquad\left.+\left(\gamma\frac{\partial}{\partial\nu}\left(\xi^2\widehat{\phi}+2\xi\widehat{\phi}_t\right)-\alpha\frac{\partial\widehat{\psi}}{\partial\nu},\overline{h}\cdot\nabla\widehat{\phi}-\frac{1}{2}\widehat{\phi}\right)_{L^2(\Gamma_1)}\right]dt\\
&+\int_{\epsilon_0}^{T-\epsilon_0}\int_{\Gamma_1}\frac{\overline{h}\cdot\nu}{2}\left[\left(\frac{\partial^2\widehat{\phi}}{\partial x^2}\right)^2+\left(\frac{\partial^2\widehat{\phi}}{\partial y^2}\right)^2+2\mu\left(\frac{\partial^2\widehat{\phi}}{\partial x^2}\right)\left(\frac{\partial^2\widehat{\phi}}{\partial y^2}\right)\right.\\
&\qquad\left.+2(1-\mu)\left(\frac{\partial^2\widehat{\phi}}{\partial x\partial y}\right)^2\right]dtd\Gamma.
\end{aligned}$$

Second, we multiply $[c_0\widehat{\psi}+c_1\widehat{\psi}_t+c_2\widehat{\phi}+c_3\widehat{\phi}_t+c_4\Delta\widehat{\phi}]$ by $\overline{h}\cdot\nabla\widehat{\phi}-\frac{1}{2}\widehat{\phi}$ and integrate by parts to obtain

(4.28)

$$\begin{aligned}
&\int_{\epsilon_0}^{T-\epsilon_0}\left(c_0\widehat{\psi}+c_1\widehat{\psi}_t+c_2\widehat{\phi}+c_3\widehat{\phi}_t+c_4\Delta\widehat{\phi},\overline{h}\cdot\nabla\widehat{\phi}-\frac{1}{2}\widehat{\phi}\right)_{L^2(\Omega)}dt\\
&=c_1\left[\left(\widehat{\psi},\overline{h}\cdot\nabla\widehat{\phi}-\frac{1}{2}\widehat{\phi}\right)_{L^2(\Omega)}\right]_{t=\epsilon_0}^{t=T-\epsilon_0}\\
&\quad-c_1\int_{\epsilon_0}^{T-\epsilon_0}\left(\widehat{\psi},\overline{h}\cdot\nabla\widehat{\phi}_t-\frac{1}{2}\widehat{\phi}_t\right)_{L^2(\Omega)}dt
\end{aligned}$$

$$+\int_{\epsilon_0}^{T-\epsilon_0}\left(c_0\widehat{\psi}+c_2\widehat{\phi}+c_3\widehat{\phi}_t+c_4\Delta\widehat{\phi},\overline{h}\cdot\nabla\widehat{\phi}-\frac{1}{2}\widehat{\phi}\right)_{L^2(\Omega)}dt.$$

To now obtain (2.36), we combine the expressions (4.25) and (4.27)–(4.28) and follow this by a rearrangement of terms. □

MINIMIZATION OF FUNCTIONALS OF THE GRADIENT BY BAIRE'S THEOREM*

SANDRO ZAGATTI†

Abstract. We give sufficient conditions for the existence of solutions of the minimum problem

$$\mathcal{P}_{u_0}: \qquad \text{Minimize} \quad \int_\Omega g(Du(x))dx, \quad u \in u_0 + W_0^{1,p}(\Omega,\mathbb{R}),$$

based on the structure of the epigraph of the lower convex envelope of g, which is assumed be lower semicontinuous and to grow at infinity faster than the power p with p larger than the dimension of the space. No convexity conditions are required on g, and no assumptions are made on the boundary datum $u_0 \in W_0^{1,p}(\Omega,\mathbb{R})$.

1. Introduction.

Consider the problem

$$\mathcal{P}_{u_0}: \qquad \text{Minimize} \ \ \mathcal{I}(u) = \int_\Omega g(Du(x))dx$$

on $u \in u_0 + W_0^{1,1}(\Omega,\mathbb{R})$, where Ω is an open and bounded subset of $\mathbb{R}^n$ and $g : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ is lower semicontinuous and satisfies $g(y) \geq \phi(|y|)$ for some continuous function ϕ with superlinear growth at infinity. As the theorem quoted below shows clearly, for $n > 1$, if we do not assume the convexity of g, in general $\mathcal{P}_{u_0}$ fails to have solutions since $\mathcal{I}$ is not weak lower semicontinuous on $W^{1,1}(\Omega,\mathbb{R})$. However, if the boundary datum u_0 is assumed to be affine, i.e., $u_0 = A_\xi := \langle \xi, \cdot \rangle$ for some $\xi \in \mathbb{R}^n$, the existence of minimum points for $\mathcal{I}$ on $A_\xi + W_0^{1,p}(\Omega,\mathbb{R})$ can be completely characterized by the following result, due to Cellina [C1], [C2].

THEOREM. *Problem $\mathcal{P}_{A_\xi}$ admits at least one solution if and only if either $g(\xi) = g^{**}(\xi)$ or the point $(\xi, g^{**}(\xi))$ belongs to the relative interior of an n-dimensional proper face of* epi(g^{**})*, where g^{**} is the lower convex envelope of g and* epi(g^{**}) *denotes its epigraph.*

By the lower semicontinuity of g, if $(y, g^{**}(y))$ is an extreme point of epi(g^{**}), then necessarily $g^{**}(y) = g(y)$; hence Cellina's result implies in particular that if g^{**} satisfies hypothesis (H) (the dimension of any proper face of the epigraph of g^{**} is either 0 or n), then problem $\mathcal{P}_{A_\xi}$ admits at least one solution for any affine boundary datum A_ξ.

In this paper we prove that under condition (H), if the n-dimensional faces of epi(g^{**}) are finitely many and pairwise disjoint and if $\phi(|y|) = a|y|^p - b$ for some positive constant a, b and for $p > n$, problem $\mathcal{P}_{u_0}$ admits at least one solution for any $u_0 \in W^{1,p}(\Omega,\mathbb{R})$.

To prove this result we make use of Baire's theorem, considering the nonempty set $\mathcal{S}$ of solutions of the minimum problem for the relaxed functional

$$\overline{\mathcal{P}}_{u_0}: \qquad \text{Minimize } \overline{\mathcal{I}}(u) = \int_\Omega g^{**}(Du(x))dx, \quad u \in u_0 + W_0^{1,p}(\Omega, \mathbb{R}),$$

endowed with a distance with respect to which it is a complete metric space, and introducing suitable open and dense subsets $\mathcal{S}_k \subseteq \mathcal{S}$ such that, for any element u of $\bigcap_k \mathcal{S}_k$, $g^{**}(Du) = g(Du)$ almost everywhere in Ω. Consequently there exists (a dense subset of) $v \in \mathcal{S}$ such that $\mathcal{I}(v) = \overline{\mathcal{I}}(v)$, and, since the infimum of $\mathcal{I}$ equals the minimum of $\overline{\mathcal{I}}$, v solves $\mathcal{P}_{u_0}$.

To do this we use techniques introduced in the framework of differential inclusions (see, for example, [B], [BF], [DP1] and the references quoted there) and more recently implemented in the study of existence of generalized solutions for Hamilton–Jacobi equations [DM1], [DM2], [DP2], [Z].

2. Preliminaries and notation. In this paper an element x of $\mathbb{R}^n$ is written $x = (x_1, \dots, x_n)$ and we denote by $\langle \cdot, \cdot \rangle$ and by $|\cdot|$, respectively, the scalar product and the Euclidean norm in $\mathbb{R}^n$; for $x \in \mathbb{R}^n$ and $r > 0$, $B(x, r)$ is the open ball centered in x of radius r. If x and y are elements of $\mathbb{R}^n$ by $[x, y]$ we mean the closed line segment of endpoints x and y, i.e., $[x, y] = \{z \in \mathbb{R}^n : z = (1 - t)x + ty, t \in [0, 1]\}$. Given $A \subseteq \mathbb{R}^n$, ∂A, $\text{int}(A)$, $\overline{A}$, $\text{diam}(A)$, $\text{Ls}(A)$, $\text{co}(A)$, and χ_A, $m_n(A)$, respectively, denote the boundary, the interior, the closure, the diameter, the linear span, the convex hull, the characteristic function, and the n-dimensional Lebesgue measure of A; by $\dim(A)$ we mean the dimension of $\text{Ls}(A)$. The relative interior of A (r.i.(A)) and the relative boundary of A (r.b.(A)) are the interior and the boundary of A relative to $\text{Ls}(A)$. Given two sets A and B, $A \triangle B$ is the symmetric difference $(A - B) \cup (B - A)$.

We need the notion of *face* of a convex set. Given a convex subset C of $\mathbb{R}^n$, a face of C is a convex subset C' of C such that every closed line segment in C whose relative interior intersects C' has both endpoints in C'. A face of C different from C itself is said to be a *proper face*. The zero-dimensional faces of C are actually singletons and are called *extreme points* of C. The set of extreme points of C is denoted by $\text{extr}(C)$. The following facts are well known (see [R, pp. 162–169]).

PROPOSITION 2.1. *Let $C \subseteq \mathbb{R}^n$ be a convex set.*

(i) *If C'' is a face of C' and C' is a face of C, then C'' is a face of C.*

(ii) *A proper face C' of C is entirely contained in the relative boundary of C so that, in particular, $\dim(C') < \dim(C)$.*

(iii) *The collection of the relative interiors of the faces of C is a partition of C itself.*

A family $\mathcal{V}$ of closed subsets of $\mathbb{R}^n$ is said to cover a set $A \subseteq \mathbb{R}^n$ in the Vitali sense (or to be a Vitali covering of E) if for any $x \in A$ there exist a positive number $r(x) > 0$, a sequence of n-dimensional balls $(B(x, \rho_k))_{k \in \mathbb{N}}$, with $\rho_k \to 0$ as $k \to \infty$, and a sequence $(V_k)_{k \in \mathbb{N}}$ in $\mathcal{V}$ such that $V_k \subseteq B(x, \rho_k)$ for any k and

$$\frac{m_n(V_k)}{m_n(B(x, \rho_k))} > r(x) \qquad \forall k \in \mathbb{N}.$$

According to the Vitali covering theorem (see [F, pp. 205–207]) given a Vitali covering $\mathcal{V}$ and a positive ϵ, there exists a finite subfamily $\{V_k, k = 1, \dots, m\}$ of $\mathcal{V}$ such that $V_k \bigcap V_j = \emptyset$ for $j \neq k$ and $m_n\left(A - \bigcup_{k=1}^m V_k\right) \leq \epsilon$.

We recall (see for example [WZ, p. 107]) that, given a measurable subset A of $\mathbb{R}^n$, almost every point x in A is a point of density, i.e.,

$$\lim_{\rho\to 0}\frac{m_n(A\cap B(x,\rho))}{m_n(B(x,\rho))}=1.$$

For a map $u:\Omega(\subseteq\mathbb{R}^n)\to\mathbb{R}$, Du denotes the gradient of u: $Du=(\frac{\partial u}{\partial x_1},\dots,\frac{\partial u}{\partial x_n})$. We shall use the spaces $L^\infty(\Omega,\mathbb{R})$, $L^1(\Omega,\mathbb{R})$, $W^{1,p}(\Omega,\mathbb{R})$, $W_0^{1,p}(\Omega,\mathbb{R})$, $W^{1,\infty}(\Omega,\mathbb{R})$, and $W_0^{1,\infty}(\Omega,\mathbb{R})$ endowed with their usual topologies.

We recall (see [KS, p. 50]) the following well-known proposition.

PROPOSITION 2.2. *Let $\Omega\subseteq\mathbb{R}^n$ and $u\in W^{1,q}(\Omega,\mathbb{R})$ $(1\le q\le+\infty)$; set*

$$v(x):=\max\{0,u(x)\}.$$

Then v belongs to $W^{1,q}(\Omega,\mathbb{R})$, and

$$Dv(x)=\begin{cases}Du(x) & \text{a.e. in } \{x\in\Omega:u(x)>0\},\\ 0 & \text{a.e. in } \{x\in\Omega:u(x)\le 0\}.\end{cases}$$

Let $g:\mathbb{R}^n\to\mathbb{R}\cup\{+\infty\}$; we set $\mathrm{dom}(g)=\{y\in\mathbb{R}^n:g(y)\in\mathbb{R}\}$ and denote by g^{**} the lower convex envelope of g (see, for example, [ET]), remarking that the epigraph of g^{**}, $\mathrm{epi}(g^{**}):=\{(y,t)\in\mathbb{R}^n\times\mathbb{R}:t\ge g^{**}(y)\}$ is a closed convex subset of $\mathbb{R}^n\times\mathbb{R}$.

DEFINITION 2.3. *Let $g:\mathbb{R}^n\to\mathbb{R}\cup\{+\infty\}$ be lower semicontinuous. We say that g satisfies condition* (A) *if*

(A.i) *there exist two positive constant a,b such that*

$$g(y)\ge a|y|^p-b\qquad\forall y\in\mathbb{R}^n,$$

where $p>n$.

(A.ii) *There exist $F^1,\dots,F^N$ proper nonvertical faces of* $\mathrm{epi}(g^{**})$ *such that* $\dim(F^i)=n$ *for any $i=1,\dots,N$, $F^i\bigcap F^j=\emptyset$ when $i\ne j$ and any proper face $F\ne F^i$ for any $i\in\{1,\dots,N$ has dimension equal to zero, i.e., is an extreme point.*

Remark 2.4. For any $i=1,\dots,N$, $F^i\subseteq\partial(\mathrm{epi}(g^{**}))$ and any extreme point of $\mathrm{epi}(g^{**})$ is of the form $(y,g^{**}(y))$.

DEFINITION 2.5. *For any n-dimensional face F^i $(i=1,\dots,N)$ of* $\mathrm{epi}(g^{**})$ *we set*

$$F_0^i:=\{y\in\mathbb{R}^n:(y,g^{**}(y))\in F^i\}.$$

Example. Let $n=3$ and $g(y):=(|y|^2-1)^2$. The map g satisfies (A.i) and (A.ii). Indeed we may choose $a=\frac{1}{2}$, $b=3$, and $p=4$; moreover, any point $(y,g^{**}(y))$ such that $|y|\ge 1$ is an extreme point of $\mathrm{epi}(g^{**})$ and $F^1:=\{(y,0),|y|\le 1\}$, which is a n-dimensional set, is the unique proper face of $\mathrm{epi}(g^{**})$ having nonzero dimension. In this case we have $F_0^1=\overline{B}(0,1)$.

We collect now some properties of $\mathrm{epi}(g^{**})$ that will be useful in the following.

PROPOSITION 2.6. *Let g satisfy* (A). *Then*

(i) *F^i is a compact convex subset of $\mathbb{R}^n\times\mathbb{R}$ for any $i=1,\dots,N$.*

(ii) *F_0^i is a compact convex subset of $\mathbb{R}^n$ with nonempty interior for any $i=1,\dots,N$.*

(iii) $\mathrm{r.b.}(F^i)=\mathrm{extr}(F^i)\subseteq\mathrm{extr}(\mathrm{epi}(g^{**}))$ *for any $i=1,\dots,N$.*

(iv) $\mathrm{extr}(F_0^i)=\partial(F_0^i)$ *and, if $i\ne j$, $F_0^i\bigcap F_0^j=\emptyset$.*

(v) *The set* $\{y \in \mathbb{R}^n : g(y) = g^{**}(y)\}$ *is contained in the set* $(\mathbb{R}^n - \bigcup_{i=1}^N \operatorname{int}(F_0^i))$.

(vi) *The map* g^{**} *is affine on each* F_0^i*; i.e., there exist* $\alpha_i \in \mathbb{R}^n$, $\beta_i \in \mathbb{R}$, *such that* $g^{**}(y) = \langle \alpha_i, y\rangle + \beta_i$ *for any* $y \in F_0^i$ *and for any* $i = 1, \dots, N$.

(vii) *Let* $y_1, y_2 \in \mathbb{R}^n$, $y_1 \neq y_2$ *be such that either* $y_1, y_2 \in \mathbb{R}^n - \bigcup_{i=1}^N F_0^i$ *or* $y_1 \in F_0^j$ *for some* j *and* $y_2 \in \mathbb{R}^n - F_0^j$. *Then, for any* $\lambda \in]0,1[$,

$$g^{**}((1-\lambda)y_1 + \lambda y_2) < (1-\lambda)g^{**}(y_1) + \lambda g^{**}(y_2). \tag{2.1}$$

Proof. Statement (i) is an obvious consequence of the definition of face and of the growth condition expressed in point (A.i) of Definition 2.3. Moreover it implies obviously (ii).

To prove (iii) take $z \in$ r.b.(F^i). By point (i) and (iii) of Proposition 2.1 z belongs to the relative interior of a proper face F of F^i and, by point (ii) of the same proposition, $\dim(F) < n$; but, again by point (i) of Proposition 2.1, F is a face of $\operatorname{epi}(g^{**})$ and this implies, by assumption (A.ii) of Definition 2.3, that $\dim(F) = 0$.

Point (iv) is a consequence of the fact that

$$\operatorname{extr}(F_0^i) = \{y \in \mathbb{R}^n : (y, g^{**}(y)) \in \operatorname{extr}(F^i)\}$$

of previous point (iii) and of the fact that $F^i \bigcap F^j = \emptyset$.

Point (v) follows from (iv), from Remark 2.4, and from the lower semicontinuity of g. To prove (vi) see [ET, Chap. 2] or [C1].

To prove point (vii) assume by contradiction that for some $\lambda \in]0,1[$ equality holds in equation (2.1) instead of strict inequality. This means that the point $P_\lambda = ((1-\lambda)y_1 + \lambda y_2), g^{**}((1-\lambda)y_1 + \lambda y_2)$, which belongs to the relative interior of the line segment $L = [(y_1, g^{**}(y_1)), (y_2, g^{**}(y_2))] \subseteq \operatorname{epi}(g^{**})$, belongs to $\partial(\operatorname{epi}(g^{**}))$; then P_λ belongs to some proper face H of $\operatorname{epi}(g^{**})$ and, by the definition of face, both endpoints of the line segment L lie in H. But H must have dimension larger than one, since it contains L, and this, recalling that by Definition 2.3 the only faces of $\operatorname{epi}(g^{**})$ having dimension larger than zero are the n-dimensional faces F_0^i, implies that $(y_1, g^{**}(y_1))$ and $(y_2, g^{**}(y_2))$ belongs to F^j for some $j \in \{1, \dots, N\}$, which is a contradiction in both cases. ∎

DEFINITION 2.7. *Let* $E \subseteq \mathbb{R}^n$ *be measurable and* $K \subseteq \mathbb{R}^n$ *compact and convex. We define the map* $h(\cdot, K) : \mathbb{R}^n \to \mathbb{R} \cup \{-\infty\}$ *by*

$$h(\xi, K) = \begin{cases} \sup\left\{ \left(\int_0^1 |\phi(y) - \xi|^2 dy\right)^{\frac{1}{2}}, \phi : [0,1] \to K, \int_0^1 \phi(y)dy = \xi \right\}, & \xi \in K, \\ -\infty, & \xi \in \mathbb{R}^n - K, \end{cases}$$

and the likelihood functional

$$\mathcal{L}(V, E) := \int_E h(V(x), K)dx$$

for $V \in L^\infty(E, \mathbb{R}^n)$.

PROPOSITION 2.8.

(i) *The map* $\xi \to h(\xi, K)$ *is upper semicontinuous and strictly concave.*

(ii) $h(\xi, K) \geq 0$ *for any* $\xi \in K$ *and* $h(\xi, K) = 0$ *if and only if* $\xi \in \operatorname{extr}(K)$.

(iii) $|h(\xi, K)| \leq \operatorname{diam}(K)$.

(iv) *The functional* $\mathcal{L}(\cdot, E)$ *is upper semicontinuous with respect to weak* topology of* $L^\infty(E, \mathbb{R}^n)$*; i.e., for any sequence* $\{V_k\}_{k\in\mathbb{N}}$ *such that* $V_k \overset{*}{\rightharpoonup} V$ *in* $L^\infty(E, \mathbb{R}^n)$, *we have*

$$\mathcal{L}(V, E) \geq \limsup_{k\to\infty} \mathcal{L}(V_k, E).$$

For the proof of (i), (ii), and (iii) see [B]. To prove (iv) see Theorem 1.2, p. 49, of [D].

3. Statement of the result. Throughout this paper we assume that Ω is an open bounded subset of $\mathbb{R}^n$, $g : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ satisfies condition (A), and u_0 denotes an element of $W^{1,p}(\Omega, \mathbb{R})$.

We define the set of admissible functions

$$\mathcal{W} := u_0 + W_0^{1,p}(\Omega, \mathbb{R})$$

and the functionals

$$\mathcal{I}(u) := \int_\Omega g(Du(x))dx, \qquad \overline{\mathcal{I}}(u) := \int_\Omega g^{**}(Du(x))dx,$$

and we consider the problems

$$\mathcal{P}: \quad \text{Minimize } \mathcal{I}(u), \qquad u \in \mathcal{W},$$

and

$$\overline{\mathcal{P}}: \quad \text{Minimize } \overline{\mathcal{I}}(u), \qquad u \in \mathcal{W}.$$

Clearly for some boundary data u_0 we could have $\mathcal{I}(u) = \overline{\mathcal{I}}(u) = +\infty$ for any $u \in \mathcal{W}$. To avoid triviality, we shall assume, however, that the functionals are finite for some $u \in \mathcal{W}$.

The following is a well-known fact (see, for example, [ET, Chap. IX] or [D, Chap. 3]).

THEOREM 3.1. *$\overline{\mathcal{I}}$ is coercive and weak lower semicontinuous on $W^{1,p}(\Omega, \mathbb{R})$. Consequently $\overline{\mathcal{P}}$ admits at least one solution. Moreover,*

$$m := \min\{\overline{\mathcal{I}}(u), u \in \mathcal{W}\} \le \inf\{\mathcal{I}(u), u \in \mathcal{W}\}.$$

The main result of this paper, which will be proved in the next section, is the following theorem.

THEOREM 3.2. *$\mathcal{P}$ admits at least one solution.*

4. Proof of Theorem 3.2.

DEFINITION 4.1. *We set $\mathcal{S}(\overline{\mathcal{P}}) := \{u \in \mathcal{W} : u \text{ is a solution of } \overline{\mathcal{P}}\}$.*

DEFINITION 4.2. *Let $u \in \mathcal{S}(\overline{\mathcal{P}})$ and $i \in \{1, \dots, N\}$; we set*

$$E_u^i := \{x \in \Omega : Du(x) \in F_0^i\}.$$

Remark 4.3. The sets E_u^i are measurable.

PROPOSITION 4.4. *Let $u, v \in \mathcal{S}(\overline{\mathcal{P}})$, $i, j \in \{1, \dots, N\}$, $i \neq j$. Then*

$$m_n(E_u^i \triangle E_v^i) = 0, \tag{4.1}$$

$$m_n(E_u^i \cap E_u^j) = 0. \tag{4.2}$$

Proof. We prove that $m_n(E_u^i - E_v^i) = 0$; then (4.1) follows interchanging u with v. Assume, by contradiction, $m_n(E_u^i - E_v^i) > 0$ and set $G = E_u^i - E_v^i$. For almost

every $x \in G$, $Du(x) \in F_0^i$, and $Dv(x) \in \mathbb{R}^n - (F_0^i)$; hence, recalling point (vii) of Proposition 2.6, for any $\lambda \in]0,1[$, we have

$$g^{**}((1-\lambda)Du(x) + \lambda Dv(x)) < (1-\lambda)g^{**}(Du(x)) + \lambda g^{**}(Dv(x))$$

almost everywhere in G. Define the map $w := (1-\lambda)u + \lambda v$. Clearly w belongs to $\mathcal{W}$ and, by the convexity of g^{**} and the above inequality, we have

$$\begin{aligned}
\overline{\mathcal{I}}(w) &= \int_G g^{**}(Dw(x))dx + \int_{\Omega - G} g^{**}(Dw(x))dx \\
&< (1-\lambda)\int_G g^{**}(Du(x))dx + \lambda \int_G g^{**}(Dv(x))dx + \int_{\Omega-G} g^{**}(Dw(x))dx \\
&\leq (1-\lambda)\int_G g^{**}(Du(x))dx + \lambda \int_G g^{**}(Dv(x))dx \\
&\quad + (1-\lambda)\int_{\Omega-G} g^{**}(Du(x))dx + \lambda \int_{\Omega-G} g^{**}(Dv(x))dx \\
&= (1-\lambda)\overline{\mathcal{I}}(u) + \lambda\overline{\mathcal{I}}(v) = m,
\end{aligned}$$

which is a contradiction.

To prove the second assertion assume $m_n(E_u^i \bigcap E_u^j) > 0$. This implies that given any representative of u there exists some $x \in E_u^i \bigcap E_u^j$ such that $Du(x) \in F_0^i \bigcap F_0^j$, and this contradicts point (iv) of Proposition 2.6. □

DEFINITION 4.5. *Take $u \in \mathcal{S}(\overline{\mathcal{P}})$ and set*

$$E^i := E_u^i, \qquad E := \bigcup_{i=1}^N E^i.$$

Remark 4.6.

(i) In view of (4.1) the sets E^i are defined modulo null sets in the sense that, given any $v \in \mathcal{S}(\overline{\mathcal{P}})$, $Dv(x) \in F_0^i$ for almost every $x \in E^i$, and then, choosing a suitable representative of v, we may assume

$$E_v^i = E^i \quad \forall v \in \mathcal{S}(\overline{\mathcal{P}}) \quad \forall i \in \{1, \dots, N\}. \tag{4.3}$$

(ii) By (4.2) we may also assume

$$E^i \bigcap E^j = \emptyset, \tag{4.4}$$

observing that the sets E^i may be empty.

PROPOSITION 4.7. *Let $u, v \in \mathcal{S}(\overline{\mathcal{P}})$. Then $Du(x) = Dv(x)$ for almost every $x \in \Omega - E$.*

Proof. First, we remark that by the definition of E, $Du(x), Dv(x) \in \mathbb{R}^n - \left(\bigcup_{i=1}^s F_0^i\right)$ for almost every $x \in \Omega - E$.

Assume that there exists $G \subseteq \Omega - E$ with positive measure such that $Du(x) \neq Dv(x)$ for $x \in G$; recalling point (iii) of Proposition 2.6 we have, for any $\lambda \in]0,1[$,

$$g^{**}((1-\lambda)Du(x) + \lambda Dv(x)) < (1-\lambda)g^{**}(Du(x)) + \lambda g^{**}(Dv(x)), \quad x \in G.$$

Then we define $w := (1-\lambda)u + \lambda v \in \mathcal{W}$ and, by the same computations of the proof of Proposition 4.4, get

$$\overline{\mathcal{I}}(w) = \int_G g^{**}(Dw(x))dx + \int_{\Omega-G} g^{**}(Dw(x))dx < m,$$

which is a contradiction. □

DEFINITION 4.8.

(i) *For any $i \in \{1, \dots, N\}$ we define the functional*

$$\mathcal{L}(u, E^i) := \int_{E^i} h(Du(x), F_0^i)dx, \qquad u \in \mathcal{S}(\overline{\mathcal{P}}),$$

where h is given by Definition 4.1 *and the first argument of the integrand is intended as the restriction to E^i of the $L^1(\Omega, \mathbb{R}^n)$-map Du. By Remark* 4.6 *and by the boundedness of F_0^i such a restriction belongs to $L^\infty(E^i, \mathbb{R}^n)$.*

(ii) *For any $\alpha > 0$ we define the sets*

$$\mathcal{S}_\alpha := \{u \in \mathcal{S}(\overline{\mathcal{P}}) : \mathcal{L}(u, E^i) < \alpha \text{ for every } i \in \{1, \dots, N\}\}.$$

Remark 4.9. By Propositions 2.8 and 4.4, for any $u \in \mathcal{S}(\overline{\mathcal{P}})$ and for any $i \in \{1, \dots, N\}$, we have that $\mathcal{L}(u, E^i) \geq 0$ and that $\mathcal{L}(u, E^i) = 0$ if and only if $Du(x) \in \mathrm{extr}(F_0^i) = \partial F_0^i$ for almost every $x \in E^i$.

DEFINITION 4.10. *Letting $u, v \in \mathcal{S}(\overline{\mathcal{P}})$ we set $d(u, v) := \|u - v\|_{L^1(\Omega)}$.*

PROPOSITION 4.11. *The pair $\big(\mathcal{S}(\overline{\mathcal{P}}), d\big)$ is a complete metric space.*

Proof. We prove that $\mathcal{S}(\overline{\mathcal{P}})$ is a closed subset of $L^1(\Omega)$. For this purpose take a sequence $(u_k)_{k\in\mathbb{N}}$ in $\mathcal{S}(\overline{\mathcal{P}})$ such that $u_k \to u$ in $L^1(\Omega)$; we have to show that u is a solution of $\overline{\mathcal{P}}$.

Recalling the growth condition expressed in (A.ii) of Definition 2.3, we have

$$\int_\Omega |Du(x)|^p dx \leq M \quad \text{for any } k \in \mathbb{N}$$

for some positive constant M; hence, by the superlinear growth of ϕ, there exist a subsequence $\big(u_{k_j}\big)_{j\in\mathbb{N}}$ and $v \in W^{1,p}(\Omega, \mathbb{R})$ such that

$$u_{k_j} \rightharpoonup v \quad \text{in } W^{1,p}(\Omega, \mathbb{R}). \tag{4.5}$$

By weak lower semicontinuity of $\overline{\mathcal{I}}$ (Theorem 3.1), v belongs to $\mathcal{S}(\overline{\mathcal{P}})$. By Proposition 4.7, $Du_{k_j} = Dv$ almost everywhere in $\Omega - E$ and, for almost every $x \in E$, $Du_{k_j}(x), Dv(x) \in \big(\bigcup_{i=1}^s F_0^i\big) \subseteq B(0, R)$ for some $R > 0$; hence the sequence $\big(u_{k_j} - v\big)_{j\in\mathbb{N}}$ belongs to $W_0^{1,\infty}(\Omega, \mathbb{R})$ and $\|u_{k_j} - v\|_{W_0^{1,\infty}(\Omega,\mathbb{R})} \leq R$. Consequently we may extract a subsequence that we still call $(u_{k_j} - v)$, weakly* converging in $W_0^{1,\infty}(\Omega, \mathbb{R})$; by (4.5) its weak* limit must be zero and then, by the Rellich–Kondrachov compactness theorem we have $(u_{k_j} - v) \to 0$ in $L^\infty(\Omega, \mathbb{R})$ as $j \to \infty$. This implies $u(x) = v(x)$ for almost every $x \in \Omega$ and then u is a solution of $\overline{\mathcal{P}}$. □

PROPOSITION 4.12. *For every $\alpha > 0$, $\mathcal{S}_\alpha$ is relatively open in $\mathcal{S}(\overline{\mathcal{P}})$.*

Proof. Fix $\alpha > 0$; we prove that $\mathcal{S}(\overline{\mathcal{P}}) - \mathcal{S}_\alpha$ is closed. Let $(u_k)_{k\in\mathbb{N}}$ be a sequence in $\mathcal{S}(\overline{\mathcal{P}}) - \mathcal{S}_\alpha$ converging in $L^1(\Omega, \mathbb{R})$ to some u. Extracting if necessary a subsequence, we may assume that for some $j \in \{1, \dots, N\}$, $\mathcal{L}(u_k, E^j) \geq \alpha$ for every $k \in \mathbb{N}$. By the same argument used in the proof of Proposition 4.11 we infer the existence of a subsequence that we still call $(u_k)_{k\in\mathbb{N}}$ such that $u_k \rightharpoonup u$ in $W^{1,p}(\Omega, \mathbb{R})$. Hence u belongs to $\mathcal{S}(\overline{\mathcal{P}})$ and $\|Du_k - Du\|_{L^\infty(\Omega,\mathbb{R})} \leq R$, where $R > 0$ is the radius of a ball containing $\cup_{i=1}^N F_0^i$. Extracting if necessary a subsequence we may assume that $(Du_k - Du) \overset{*}{\rightharpoonup} 0$ in $L^\infty(\Omega, \mathbb{R})$ so that, in particular, remarking that $|Du_k|$ and $|Du|$ are bounded by R on each set E^i ($i \in \{1, \dots, N\}$), $(Du_k)\big|_{E^j} \overset{*}{\rightharpoonup} (Du)\big|_{E^j}$ in $L^\infty(E^j, \mathbb{R})$. Hence, by point (iv) of Proposition 2.8,

$$\mathcal{L}(u, E^j) \geq \limsup_{k\to\infty} \mathcal{L}(u_k, E^j) \geq \alpha.$$

Hence u belongs to $\mathcal{S}(\overline{\mathcal{P}}) - \mathcal{S}_\alpha$ and the statement is proved. □

In the following we shall consider $\mathcal{S}(\overline{\mathcal{P}})$ endowed with the distance $d(\cdot,\cdot)$.

The following proposition is an adaptation of our case of the approximation lemma proved in [DP2].

PROPOSITION 4.13. *Let $u \in \mathcal{S}(\overline{\mathcal{P}})$, $j \in \{1,\dots,N\}$. Assume that the set*

$$H^j = \{x \in \Omega : Du(x) \in \operatorname{int}(F_0^j)\}$$

has positive measure.

Then there exists $E_0^j \subseteq H^j$ with $m_n(H^j - E_0^j) = 0$ such that, given $\epsilon > 0$, the following conditions hold:

(i) *For any $y \in E_0^j$ there exist $s_y^0 > 0$, a family $\{A_{(y,s)}, s \in (0, s_y^0)\}$ of compact subsets of E^j, and a family $\{u_{(y,s)}, s \in (0, s_y^0)\}$ of elements of $\mathcal{S}(\overline{\mathcal{P}})$, satisfying the following properties:*

$$u_{(y,s)} - u \in W_0^{1,\infty}(\Omega, \mathbb{R}) \qquad \forall s \in (0, s_y^0), \tag{4.6}$$

$$u_{(y,s)} = u \text{ a.e. in } \Omega - A_{(y,s)} \qquad \forall s \in (0, s_y^0), \tag{4.7}$$

$$\|u_{(y,s)} - u\|_{L^\infty(\Omega)} \le \epsilon \qquad \forall s \in (0, s_y^0), \tag{4.8}$$

$$Du_{(y,s)} = Du \quad \text{a.e. in } \Omega - A_{(y,s)} \qquad \forall s \in (0, s_y^0), \tag{4.9}$$

$$Du_{(y,s)} \in \operatorname{extr}(K) \quad \text{a.e. in } A_{(y,s)} \qquad \forall s \in (0, s_y^0), \tag{4.10}$$

$$\int_\Omega Du_{(y,s)}(x)dx = \int_\Omega Du(x)dx \qquad \forall s \in (0, s_y^0). \tag{4.11}$$

(ii) *The family $\{A_{(y,s)}, s \in (0, s_y^0), y \in A_0\}$ is a Vitali covering of E_0^j.*

Proof. First, we suppress the dependence on j and set

$$E_0 := \{y \in H : u \text{ is differentiable at } y\}. \tag{4.12}$$

By Theorem 1, p. 235, of [EG], $m_n(H - E_0) = 0$. We fix $y \in E_0$ and proceed to the construction of $A_{(y,s)}$ and of $u_{(y,s)}$; for the sake of simplicity we omit the dependence on y writing s^0, A_s, and u_s instead of s_y^0, $A_{(y,s)}$, and $u_{(y,s)}$, respectively.

Let $\rho > 0$ be such that $B(y,\rho) \subseteq \Omega$. Since $Du(y) \in \operatorname{int}(F_0)$, by Carathéodory's theorem (see [R, p. 155]) there exists a set

$$\{v_j, j = 0, 1, \dots, n\} \subseteq \operatorname{extr}(F_0) \tag{4.13}$$

such that $Du(y) \in \operatorname{int}(\operatorname{co}(\{v_j, j = 0, 1, \dots, n\}))$.

Define the set

$$P_1 := \{z \in \mathbb{R}^n : \langle v_j - Du(y), z\rangle \le 1, j = 0, \dots, n\}$$

and, for any $r > 0$, set $P_r = rP_1 := \{w \in \mathbb{R}^n : w = rz, z \in P_1\}$. We notice that

$$\begin{aligned} P_r &= \{z \in \mathbb{R}^n : \langle v_j - Du(y), z\rangle \le r, j = 0, \dots, n\}, \\ \partial P_r &= \{z \in \mathbb{R}^n : \langle v_j - Du(y), z\rangle = r \text{ for some } j = 0, \dots, n\}. \end{aligned} \tag{4.14}$$

It is easy to see that, for any $r > 0$, P_r is a compact neighborhood of the origin, and, in particular, there exist two positive numbers d, D such that

$$0 < d < 1 < D \qquad \text{and} \qquad B(0,d) \subseteq P_1 \subseteq B(0,D). \tag{4.15}$$

Now, for $s > 0$, we define the map $w_s : \mathbb{R}^n \to \mathbb{R}$ by setting

$$w_s(x) := \max_{0\le j\le n} \{\langle v_j - Du(y), x - y\rangle\} - s. \tag{4.16}$$

It is easy to check that w_s is a piecewise affine continuous map belonging to $W^{1,\infty}_{\mathrm{loc}}(\mathbb{R}^n, \mathbb{R})$; moreover, recalling (4.13) and (4.14) we have that

$$\begin{aligned} &w_s(x) \le 0 \quad \text{if and only if} \quad x \in y + P_s, \\ &w_s(x) = 0 \quad \text{if and only if} \quad x \in y + \partial P_s. \end{aligned} \tag{4.17}$$

In addition

$$w_s(x) \ge s \qquad \forall x \in y + \partial P_{2s}, \tag{4.18}$$

while (see [C1])

$$Dw_s(x) \in \{v_j - Du(y), j = 0, 1, \dots, n\} \quad \text{for a.e. } x \in \mathbb{R}^n. \tag{4.19}$$

Claim 4.14. There exists $s_1 > 0$ such that, for every $s \in (0, s_1)$ and $\forall x \in y + \partial P_{2s}$,

$$u(x) < u(y) + \langle Du(y), x - y\rangle + w_s(x). \tag{4.20}$$

Proof of Claim 4.14. Since u is differentiable at y (recall (4.12)) we may choose $s_1 > 0$ in such a way that $\forall x \in B(y, 2s_1 D)$,

$$\left| \frac{u(x) - u(y) - \langle Du(y), x - y\rangle}{|x - y|} \right| \le \frac{1}{4D}.$$

Hence, for any $s \in (0, s_1)$, remarking that $y + P_{2s} \subseteq B(y, 2sD) \subseteq B(y, 2s_1 D)$,

$$u(x) - u(y) - \langle Du(y), x - y\rangle \le \frac{1}{4D}(2sD) = \frac{s}{2} \qquad \forall x \in y + P_{2s}.$$

Since, by (4.18), $w_s(x) \ge s$ for any $x \in y + \partial P_{2s}$, the claim is proved.

Now we fix a positive s^0 such that

$$s^0 < \min\left\{ s_1, \frac{\rho}{2D}, \frac{\epsilon}{4\mathrm{diam}(F_0)D} \right\}$$

and define the map $\tilde{u}_s : y + P_{2s} \to \mathbb{R}$, by

$$\tilde{u}_s(x) := \min\left\{u(x), u(y) + \langle Du(y), x - y\rangle + w_s(x)\right\}, \quad x \in y + P_{2s}. \tag{4.21}$$

We set also

$$A_s := \left\{x \in y + P_{2s} : \tilde{u}_s(x) = u(y) + \langle Du(y), x - y\rangle + w_s(x)\right\}. \tag{4.22}$$

First, we notice that, by Proposition 2.1, $\tilde{u}_s$ belongs to $W^{1,p}(\Omega, \mathbb{R})$. We recall that $y + P_{2s} \subseteq B(y, 2sD)$, that $s < s^0$, and that $B(y, 2s^0 D) \subseteq B(y, \rho) \subseteq \Omega$; hence $y + \mathrm{int}(P_{2s}) \subseteq \Omega$ and, by Proposition 2.1, $\tilde{u}_s$ belongs to $W^{1,p}((y + P_{2s}), \mathbb{R})$. Then it is continuous and, consequently, the set A_s turns out to be a compact subset of $y + P_{2s}$. Moreover

$$\partial A_s \subseteq \{x \in y + P_{2s} : \tilde{u}_s(x) = u(x)\}$$

and

$$A_s \subseteq y + \mathrm{int}(P_{2s}). \tag{4.23}$$

Indeed, assuming by contradiction the existence of some $\overline{x} \in A_s \cap (y + \partial P_{2s})$ we would have, by (4.20) and (4.23),

$$u(y) + \langle Du(y), \overline{x} - y\rangle + w_s(\overline{x}) = \tilde{u}(\overline{x}) < u(y) + \langle Du(y), \overline{x} - y\rangle + w_s(\overline{x}).$$

We have so proved that u and $\tilde{u}_s$ agree on the open set $\mathrm{int}(y + P_{2s}) - A_s \subseteq \Omega$; hence, by (4.21), (4.22), and (4.24),

$$\tilde{u}_s - u \in W_0^{1,p}(y + \mathrm{int}(P_{2s}), \mathbb{R}). \tag{4.24}$$

Moreover, by Proposition 2.1, we have

$$D\tilde{u}_s(x) = \begin{cases} Du(x), & x \in (y + P_{2s}) - A_s, \\ \\ Du(y) + Dw_s(x), & x \in A_s. \end{cases} \tag{4.25}$$

Now we define the map u_s by setting

$$u_s(x) := \begin{cases} \tilde{u}_s(x), & x \in (y + P_{2s}), \\ \\ u(x), & x \in \Omega - (y + P_{2s}). \end{cases} \tag{4.26}$$

Claim 4.15. The families $\{A_s, s \in (0, s^0)\}$ and $\{u_s, s \in (0, s^0)\}$ satisfy (4.6)–(4.11).

Proof of Claim 4.15. By (4.23), (4.24), and (4.26), prolonging the map $\tilde{u}_s - u$ by zero outside $(y + P_{2s})$ we may write $u_s = u + (u_s - u)\chi_{(y+P_{2s})}$. Consequently, u_s belongs to $W^{1,p}(\Omega, \mathbb{R})$ and

$$u_s - u \in W_0^{1,p}(\Omega, \mathbb{R}). \tag{4.27}$$

Hence u_s belongs to $\mathcal{S}(\overline{\mathcal{P}})$ and (4.7) follows easily from (4.21), (4.23), and (4.26).

Moreover, by Proposition 2.1, we have

$$Du_s(x) := \begin{cases} D\tilde{u}_s(x), & x \in (y + P_{2s}), \\ \\ Du(x), & x \in \Omega - (y + P_{2s}). \end{cases} \tag{4.28}$$

Hence (4.9) holds trivially, while (4.19), (4.25), and (4.28) imply (4.10).

By (4.27) and (4.9), applying the divergence theorem, we have

$$\int_\Omega (Du_s(x) - Du(x))\, dx = \int_{A_s} (Du_s(x) - Du(x))\, dx = 0,$$

i.e., (4.11). This last fact implies that u_s belongs to $\mathcal{S}(\overline{\mathcal{P}})$; indeed recalling (4.25), (4.28), and that g^{**} is affine on F_0, we have, by Jensen's inequality,

$$\begin{aligned} \frac{1}{m_n(A_s)} \int_{A_s} g^{**}(Du_s(x))dx &= g^{**}\left(\frac{1}{m_n(A_s)} \int_{A_s} Du_s(x)dx\right) \\ &= g^{**}\left(\frac{1}{m_n(A_s)} \int_{A_s} Du(x)dx\right) \le \left(\frac{1}{m_n(A_s)} \int_{A_s} g^{**}(Du(x))dx\right). \end{aligned}$$

Hence

$$\begin{aligned}\overline{\mathcal{I}}(u_s) &= \int_{\Omega - A_s} g^{**}(Du_s(x))dx + \int_{A_s} g^{**}(Du_s(x))dx \\ &\leq \int_{\Omega - A_s} g^{**}(Du(x))dx + \int_{A_s} g^{**}(Du(x))dx = m.\end{aligned}$$

Since u_s belongs to $\mathcal{S}(\overline{\mathcal{P}})$ and $Du_s(x) \in F_0$ for almost every $x \in A_s$ it follows that $A_s \subseteq E$. Hence we may infer that $u_s - u$ belongs to $W_0^{1,\infty}(\Omega, \mathbb{R})$ and that $|Du_s(x) - Du(x)| \leq 2\text{diam}(F_0)$ for almost every $x \in \Omega$. Then, recalling that $Du_s(x) - Du(x) \neq 0$ only for $x \in y + P_{2s} \subseteq B(y, 2sD)$, we have, for every $s \in (0, s^0)$,

$$|u_s(x) - u(x)| \leq 4\text{diam}(F_0)sD \leq \epsilon.$$

Hence (4.6) and (4.8) are proved.

Claim 4.16. Point (ii) of Proposition 4.13 holds true.

Proof of Claim 4.16. First note that, given $\eta > 0$, we have that

$$w_s(x) \geq \eta s - s \qquad \forall x \in y + P_{\eta s}.$$

Choose η_0 sufficiently small so that

$$\left| \frac{u(x) - u(y) - \langle Du(y), x - y \rangle}{|x - y|} \right| \leq 1$$

for any $x \in B(y, \eta_0 sD)$. Then fix $\eta < \min\{\eta_0, \frac{1}{2+2D}\}$; we have, for any $x \in y + P_{\eta s} \subseteq B(y, \eta sD) \subseteq B(y, \eta_0 sD)$,

$$u(x) - u(y) - \langle Du(y), x - y \rangle - w_s(x) \geq -\eta sD - \eta s + s \geq \frac{s}{2}.$$

This implies that any $x \in y + P_{\eta s}$ belongs to A_s; hence,

$$B(y, \eta sd) \subseteq y + P_{\eta s} \subseteq A_s \subseteq y + P_{2s} \subseteq B(y, 2sD) \qquad \forall s \in (0, s^0). \tag{4.29}$$

Now we recall that the construction depends on $y \in E_0$ and set

$$A_{(y,s)} := A_s \qquad \text{and} \qquad u_{(y,s)} := u_s.$$

In general (4.29) takes the form

$$B(y, \eta_y s d_y) \subseteq y + P_{\eta_y s} \subseteq A_{(y,s)} y + P_{2s} \subseteq B(y, 2sD_y) \qquad \forall s \in (0, s_y^0), \tag{4.30}$$

where η_y, d_y, D_y, and s_y^0 are suitable positive numbers satisfying the same requirements of η, d, D, and s^0. Now we observe that for any $y \in E_0$, $A_{(y,s)}$ is a compact subset of Ω and that, by (4.30),

$$\frac{m_n(A_{(y,s)})}{m_n(B(y, 2sD))} \geq \frac{m_n(B(y, \eta_y s d_y))}{m_n(B(y, 2sD))} \geq \left(\frac{\eta_y d_y}{2D_y} \right)^n \qquad \forall s \in (0, s_y^0).$$

This inequality, together with (4.30), shows that $\{A_{(y,s)}, s \in (0, s_y^0), y \in E_0\}$ is a Vitali covering of E_0. □

PROPOSITION 4.17. *For any $\alpha > 0$ the set $\mathcal{S}_\alpha$ is dense in $\mathcal{S}(\overline{\mathcal{P}})$.*

Proof. Let $\epsilon > 0$ and $u \in \mathcal{S}(\overline{\mathcal{P}})$ be given. We want to construct $v \in \mathcal{S}_\alpha$ such that $\|u - v\|_{L^1(\Omega,\mathbb{R})} \leq \epsilon$. Suppose first that, for any $i \in \{1, \dots, N\}$,

$$m_n\left(\{x \in E^i : Du(x) \in \mathrm{int}(F_0^i)\}\right) = 0. \tag{4.31}$$

Recalling the definition of E^i and point (iv) of Proposition 2.6, we imply that $Du \in \mathrm{extr}(F_0^i)$ almost everywhere in E^i and then, by point (ii) of Proposition 2.8, $\mathcal{L}(u, E^i) = 0$ for any $i \in \{1, \dots, N\}$. In this case we set $v = u$ and there is nothing to prove.

Suppose now that (4.31) does not hold. Renumbering the indices, we may assume that for some $P \leq N$,

$$m_n\left(\{x \in E^i : Du(x) \in \mathrm{int}F_0^i\}\right) > 0 \quad \text{for any } i \in \{1, \dots, P\} \tag{4.32}$$

and that

$$m_n\left(\{x \in \Omega : Du(x) \in \mathrm{int}F_0^i\}\right) = 0 \quad \text{for any } i \in \{P+1, \dots, N\}.$$

This last inequality implies, as above, that $\mathcal{L}(u, E^i) = 0$ for any $i \in \{P+1, \dots, N\}$. We consider then the other indices. Set

$$H^i := \{x \in E^i : Du(x) \in \mathrm{int}F_0^i\}, \qquad i \in \{1, \dots, P\}.$$

For any $i \in \{1, \dots, P\}$ we apply Proposition 4.13, with $\frac{\epsilon}{m_n(\Omega)}$ in place of ϵ, obtaining sets $E_0^i \subseteq H^i$ such that

$$m_n(H^i - E_0^i) = 0 \tag{4.33}$$

and families

$$\left\{A^i_{(y,s)}, s \in (0, s_y^0), y \in E_0^i, \right\}, \qquad i \in \{1, \dots, P\},$$

$$\left\{u^i_{(y,s)}, s \in (0, s_y^0), y \in E_0^i, \right\}, \qquad i \in \{1, \dots, P\},$$

satisfying (4.6)–(4.11), so that, in particular,

$$\|u^i_{(y,s)} - u\|_{L^\infty}(\Omega) \leq \frac{\epsilon}{m_n(\Omega)}. \tag{4.34}$$

By the Vitali covering theorem there exists a finite subfamily

$$\left\{A^i_{(y_j,s_j)}, s \in (0, s^0_{y_j}), y_j \in E_0^i, j \in \{1, \dots, \ell_i\}, \right\}, \qquad i \in \{1, \dots, P\},$$

such that

$$A^i_{(y_j,s_j)} \bigcap A^i_{(y_k,s_k)} = \emptyset \qquad \forall j, k \in \{1, \dots, \ell_i\}, \quad j \neq k, \tag{4.35}$$

and

$$m_n\left(E_0^i - G^i\right) \leq \frac{\alpha}{2\mathrm{diam}(F_0^i)}, \tag{4.36}$$

where we have set

$$G^i := \bigcup_{j=1}^{\ell_i} A^i_{(y_j,s_j)}. \tag{4.37}$$

Claim 4.18. Let $i, m \in \{1, \dots, P\}$, $i \neq m$. Then

$$A^i_{(y_j,s_j)} \bigcap A^m_{(y_k,s_k)} = \emptyset \qquad \forall j \in \{1, \dots, \ell_i\} \quad \forall k \in \{1, \dots, \ell_m\}. \tag{4.38}$$

Proof of Claim 4.18. Keeping the index i fixed, we define

$$v^i(x) := \begin{cases} u(x) & \text{for } x \in \Omega - G^i, \\ u^i_{(y_j,s_j)}(x) & \text{for } x \in A^i_{(y_j,s_j)} \text{ for some index } j \in \{1, \dots, \ell_i\}. \end{cases}$$

We have to show that this definition is well posed, i.e., that v^i belongs to $W^{1,p}(\Omega, \mathbb{R})$. By (4.35), recalling the compactness of the sets $A^i_{(y,s)}$, we may find open disjoint sets Λ^i_j, $j \in \{1, \dots, \ell_i\}$ such that

$$A^i_{(y_j,s_j)} \subseteq \Lambda^i_j \subseteq \overline{\Lambda^i_j} \subseteq \Omega.$$

Recalling (4.6) and (4.7), we have

$$W^{1,p}(\Omega, \mathbb{R}) \ni u^i_{(y_j,s_j)} = u + (u^i_{(y_j,s_j)} - u) = u + (u^i_{(y_j,s_j)} - u)\chi_{\Lambda^i_j};$$

hence $(u^i_{(y_j,s_j)} - u)\chi_{\Lambda^i_j} \in W^{1,p}(\Omega, \mathbb{R})$ and, consequently,

$$v^i = u + \sum_{j=1}^{\ell_i} (u^i_{(y_j,s_j)} - u)\chi_{\Lambda^i_j}$$

belongs to $W^{1,p}(\Omega, \mathbb{R})$. Moreover, by (4.6) and (4.35), $v^i - u \in W^{1,\infty}_0(\Omega, \mathbb{R})$ and then v^i belongs to $\mathcal{W}$.

Recalling (4.28), we have

$$Dv^i(x) := \begin{cases} Du(x) & \text{for } x \in \Omega - G^i, \\ Du^i_{(y_j,s_j)}(x) & \text{for } x \in A^i_{(y_j,s_j)} \text{ for some index } j \in \{1, \dots, \ell_i\}, \end{cases}$$

and, by (4.11),

$$\int_{A^i_{(y_j,s_j)}} Dv^i(x)dx = \int_{A^i_{(y_j,s_j)}} Du(x)dx.$$

This implies that

$$\int_{G^i} Dv^i(x)dx = \sum_{j=1}^{\ell_i} \int_{A^i_{(y_j,s_j)}} Dv^i(x)dx = \sum_{j=1}^{\ell_i} \int_{A^i_{(y_j,s_j)}} Du(x)dx = \int_{G^i} Du(x)dx. \tag{4.39}$$

By (4.10) we have that

$$Dv^i(x) \in \operatorname{extr}(F^i_0) \quad \text{for a.e. } x \in G^i; \tag{4.40}$$

recalling that g^{**} is affine on F_0^i (point (vi) of Proposition 2.6), we have, by Jensen's inequality by (4.39) and (4.40),

$$\begin{aligned}\frac{1}{m_n(G^i)}\int_{G^i} g^{**}(Dv^i(x))dx &= g^{**}\left(\frac{1}{m_n(G^i)}\int_{G^i} Dv^i(x)dx\right)\\ &= g^{**}\left(\frac{1}{m_n(G^i)}\int_{G^i} Du(x)dx\right)\\ &\le \frac{1}{m_n(G^i)}\int_{G^i} g^{**}(Du(x))dx;\end{aligned}$$

i.e.,

$$\int_{G^i} g^{**}(Dv^i(x))dx \le \int_{G^i} g^{**}(Du(x))dx.$$

This last inequality, the definition of v^i, and the convexity of g^{**} imply that

$$\overline{\mathcal{I}}(v^i) = \int_{G^i} g^{**}(Dv^i(x))dx + \int_{\Omega - G^i} g^{**}(Du(x))dx \le \int_{\Omega} g^{**}(Du(x))dx = m.$$

Hence v^i belongs to $\mathcal{S}(\overline{\mathcal{P}})$ and, by (4.40) and point (ii) of Remark 4.6,

$$G^i \subseteq E_v^i \subseteq E^i; \tag{4.41}$$

i.e., by (4.37),

$$A^i_{(y_j,s_j)} \subseteq E^i \quad \forall j \in \{1,\dots,\ell_i\}.$$

Recalling (4.4) we conclude that $A^i_{(y_j,s_j)} \cap E^m = \emptyset$ for any $j \in \{1,\dots,\ell_i\}$ and, conversely, that $A^m_{(y_k,s_k)} \cap E^i = \emptyset$ for any $k \in \{1,\dots,\ell_m\}$. Hence, again by (4.4), (4.38) holds true, and the claim is proved.

Now we define

$$v(x) := \begin{cases} u(x) & \text{for } x \in \Omega - \left(\bigcup_{i=1}^P G^i\right),\\ u^i_{(y_j,s_j)}(x) & \text{for } x \in A^i_{(y_j,s_j)}\\ & \text{for some indices } j \in \{1,\dots,\ell_i\} \text{ and } i \in \{1,\dots,P\}.\end{cases}$$

By virtue of Claim 4.18 we may apply to v the same argument used for map v^i in the proof of Claim 4.19, obtaining that v belongs to $\mathcal{S}(\overline{\mathcal{P}})$.

Claim 4.19. The map v belongs to $\mathcal{S}_\alpha$ and $\|u - v\|_{L^1(\Omega,\mathbb{R})} \le \epsilon$.

Proof of Claim 4.19. By the definition of v and by point (4.6) of Proposition 4.12 we have that $u - v$ belongs to $W_0^{1,\infty}(\Omega,\mathbb{R})$; moreover, by (4.8) and (4.34),

$$\|u^i_{(y_j,s_j)} - v\|_{L^\infty(\Omega,\mathbb{R})} \le \frac{\epsilon}{m_n(\Omega)} \quad \forall j \in \{1,\dots,\ell_i\} \quad \forall i \in \{1,\dots,P\}.$$

Hence $\|u - v\|_{L^1(\Omega,\mathbb{R})} \le \epsilon$.

We have to prove now that

$$\mathcal{L}(v, E^i) < \alpha \quad \forall i \in \{1,\dots,N\}.$$

By (4.33), recalling Remark 4.9, we have that

$$\mathcal{L}(v, E^i) = 0 \quad \forall i \in \{P+1, \dots, N\}.$$

Take then $i \in \{1, \dots, P\}$. By the definition of v, by (4.10) and (4.32), we have that

$$Dv(x) \in \operatorname{extr}(F_0^i) \quad \text{for a.e. } x \in G^i \cup (E^i - H^i);$$

hence, again by Proposition 2.8,

$$\int_{G^i} h(Dv(x), F_0^i)dx = \int_{E^i - H^i} h(Dv(x), F_0^i)dx = 0. \tag{4.42}$$

Then, by (4.33), (4.36), (4.41), and (4.42),

$$\begin{aligned}
\mathcal{L}(v, E^i) &= \int_{E^i} h(Dv(x), F_0^i)dx \\
&\le \int_{E^i - H^i} h(Dv(x), F_0^i)dx + \int_{H^i - E_0^i} h(Dv(x), F_0^i)dx \\
&\quad + \int_{E_0^i - G^i} h(Dv(x), F_0^i)dx + \int_{G^i} h(Dv(x), F_0^i)dx \\
&= \int_{E_0^i - G^i} h(Dv(x), F_0^i)dx \\
&\le \operatorname{diam}(F_0^i) m_n(E_0^i - G^i) \le \frac{\alpha}{2} < \alpha. \qquad \square
\end{aligned}$$

Proof of Theorem 3.2. By Baire's theorem and by Propositions 4.11, 4.12, and 4.13, we have that

$$\mathcal{S}_0 := \bigcap_{k \in \mathbb{N}} \mathcal{S}_{\frac{1}{k}}$$

is a dense subset of $\mathcal{S}(\overline{\mathcal{P}})$. Take an element $\overline{u} \in \mathcal{S}_0$. Clearly $\mathcal{L}(\overline{u}, E^i) = 0$ for any $i \in \{1, \dots, N\}$; hence, recalling Remark 4.9,

$$D\overline{u}(x) \in \operatorname{extr}(F_0^i) \qquad \text{for a.e. } x \in E^i. \tag{4.43}$$

Moreover, by Definition 4.5 and Proposition 4.7,

$$D\overline{u}(x) \in \mathbb{R}^n - \bigcup_{i=1}^N F_0^i \qquad \text{for a.e. } x \in \Omega - E. \tag{4.44}$$

Putting together (4.43) and (4.44) we have that

$$D\overline{u}(x) \in \mathbb{R}^n - \bigcup_{i=1}^N \operatorname{int}(F_0^i) \qquad \text{for a.e. } x \in \Omega$$

and then, by point (iv) of Proposition 2.6,

$$g(D\overline{u}(x)) = g^{**}(D\overline{u}(x)) \qquad \text{for a.e. } x \in \Omega.$$

Since $\overline{u}$ is a solution of $\overline{\mathcal{P}}$, this implies that

$$\mathcal{I}(\overline{u}) = \overline{\mathcal{I}}(\overline{u}),$$

and, recalling Theorem 3.1, we conclude that $\overline{u}$ is a solution of $\mathcal{P}$. $\square$

SECOND ORDER HAMILTON–JACOBI EQUATIONS IN HILBERT SPACES AND STOCHASTIC BOUNDARY CONTROL*

FAUSTO GOZZI†, ELISABETH ROUY‡, AND ANDRZEJ ŚWIĘCH§

Abstract. The paper is concerned with fully nonlinear second order Hamilton–Jacobi–Bellman–Isaacs equations of elliptic type in separable Hilbert spaces which have unbounded first and second order terms. The viscosity solution approach is adapted to the equations under consideration and the existence and uniqueness of viscosity solutions are proved. A stochastic optimal control problem driven by a parabolic stochastic PDE with control of Dirichlet type on the boundary is considered. It is proved that the value function of this problem is the unique viscosity solution of the associated Hamilton–Jacobi–Bellman equation.

Key words. stochastic boundary control, Hamilton–Jacobi equations, viscosity solutions

1. Introduction.

In this paper we study second order infinite dimensional Hamilton–Jacobi–Bellman–Isaacs equations

$$\lambda v(x) + \big\langle Ax, Dv(x)\big\rangle + H\big(x, Dv(x), D^2v(x)\big) = 0, \qquad x \in X, \tag{1.1}$$

and their relationship with stochastic optimal control problems. Above, X is a real, separable Hilbert space, D denotes the Fréchet derivative, λ is a positive number, and $-A : D(A) \subset X \to X$ is a closed linear operator that generates an analytic C_0–semigroup e^{-tA} on X. Moreover, we assume that A is positive and self-adjoint and has compact resolvent $R(\mu, A)$, and that $H : X_1 \to \mathbb{R}$, where $X_1 \subset X \times X \times \Sigma(X)$ (Σ denotes the space of all bounded, self-adjoint linear operators from X to itself). X_1 will be specified later. We call such equations *unbounded*.

Equations of this type arise in stochastic optimal control problems driven by parabolic stochastic PDE, for instance, when the control is given at the boundary with Dirichlet or Neumann type conditions (see section 5.4) and the stochastic term is given by the so-called "white noise." This has been one of the main motivations of our study. Our approach is very flexible since the model control problem we study in section 5 includes both distributed and boundary controls and applies also to cases with purely distributed controls (infinite or finite dimensional). In this paper we define a suitable notion of solution of (1.1), prove existence and uniqueness of solutions, and show that if (1.1) comes from a stochastic optimal control problem the value function is its unique solution. These results are general and apply also to equations with no

"sup" structure, in particular to Isaacs' equations. Therefore, instead of studying a boundary control problem in section 5 we could study a differential game problem.

To have an idea of what we have in mind let us look at the following stochastic optimal control problem (P_0) that we will study in detail in section 5.4. Let $\Omega \subset \mathbb{R}^n$ be an open, connected, and bounded set with smooth boundary. Consider the stochastic controlled PDE

$$\begin{cases} \dfrac{\partial x}{\partial t}(t,\xi) = \Delta_\xi x(t,\xi) + f_1\big(x(t,\xi),\alpha_1(t,\xi)\big) \\ \qquad\qquad + f_2\big(x(t,\xi),\alpha_1(t,\xi)\big)\dot{W}_Q(t,\xi) & \text{in } (0,\infty)\times\Omega, \\ x(0,\xi) = x_0(\xi) & \text{on } \Omega, \\ x(t,\xi) = \alpha_2(t,\xi) & \text{on } (0,\infty)\times\partial\Omega, \end{cases} \tag{1.2}$$

where W_Q is a Wiener process with values in $L^2(\Omega)$ and with covariance operator Q, $x_0 \in L^2(\Omega)$, and the controls $\alpha_1 : (0,\infty) \to L^2(\Omega)$, $\alpha_2 : (0,\infty) \to L^2(\partial\Omega)$ are measurable and adapted to the Wiener process W_Q, and $f_1, f_2 : \mathbb{R}^2 \to \mathbb{R}$. In this equation we have two control functions. The first, indicated by α_1, is the "distributed" control, while the other, indicated by α_2, is the "boundary" control. The Cauchy problem (1.2) may be rewritten in an abstract form as explained in section 5.

Consider now the problem of minimizing the cost functional

$$J(x_0;\alpha_1,\alpha_2) = \mathbb{E}\int_0^{+\infty} e^{-\lambda t} L\big(x(t;x_0,\alpha_1,\alpha_2),\alpha_1(t),\alpha_2(t)\big)\,dt,$$

where $\lambda > 0$, $L : L^2(\Omega)\times L^2(\Omega)\times L^2(\partial\Omega) \to \mathbb{R}$ is a bounded, uniformly continuous function and $x(\cdot\,;x_0,\alpha)$ is the solution of the Cauchy problem (1.2). The value function of this problem is defined as

$$v(x) = \inf J(x;\alpha_1,\alpha_2),$$

where the infimum is taken over all admissible controls (α_1,α_2) considered above. We expect that the function v is a solution (in a suitable sense) of (1.1), where the Hamiltonian H depends on the data of the problem (see section 5.3). We point out here that the presence of the boundary control term in the state equation (1.2) causes $H(x,Dv(x),D^2v(x))$ to be defined only if $Dv(x) \in D(A^\beta)$, where A is the Laplace operator with Dirichlet boundary conditions and $\beta \in (\frac{3}{4},1)$. Clearly, in the case of different boundary conditions, different values of β have to be considered; for example, the case of Neumann boundary conditions (which also fits in our assumptions) gives $\beta \in (\frac{1}{4},1)$. This "bad behavior" appears as a result of "transforming" the boundary control into a distributed one, as it is explained, e.g., in Bensoussan et al. [3] and Cannarsa and Tessitore [10].

To deal with the difficulties posed by this problem we introduce a change of variables which is similar to the one used by Cannarsa and Tessitore in [10] to study a first order Hamilton–Jacobi equation associated with a boundary control problem with Dirichlet boundary conditions. Given a solution $x(\cdot)$ of the state equation (1.2), we set $y(\cdot) = A^{-\frac{\beta}{2}}x(\cdot)$ for a chosen $\beta \in (0,1)$, and we study a new control problem (P_1) with cost $J(A^{\frac{\beta}{2}}y,\alpha)$ and state $y(\cdot)$. We then obtain a different Hamilton–Jacobi–Bellman equation,

$$\lambda u(y) + \langle Ay, Du(y)\rangle + H\left(A^{\frac{\beta}{2}}y, A^{-\frac{\beta}{2}}Du(y), A^{-\frac{\beta}{2}}D^2u(y)A^{-\frac{\beta}{2}}\right) = 0, \tag{1.3}$$

which can also be obtained directly from (1.1) by making the change of variable $y = A^{-\frac{\beta}{2}}x$ and setting $u(y) = v(A^{\frac{\beta}{2}}y)$. This equation contains fewer unbounded terms and is easier to handle in spite of the additional difficulty created by the presence of the unbounded term $A^{\frac{\beta}{2}}y$. For (1.3) we are able to prove existence and uniqueness of viscosity solutions. Then, since (1.1) and (1.3) are related by the change of variable $u(y) = v(A^{\frac{\beta}{2}}y)$, we define a viscosity solution of (1.1) as a function v such that $u(\cdot) \overset{def}{=} v(A^{\frac{\beta}{2}}\cdot)$ is a viscosity solution of (1.3). The function v is uniquely determined once u has been characterized on $D(A^{\frac{\beta}{2}})$. This is the idea behind the definition of viscosity solution we employ and we will make it rigorous in section 3. The definition is meaningful since in the case when (1.1) comes from a stochastic control problem, v and u can be respectively characterized as the value functions of problems (P_0) and (P_1).

The techniques of this paper could also be employed to study evolution equations of parabolic type and stochastic boundary control problems with finite horizon (see Cannarsa and Tessitore [9] for an analogue in the first order case). Moreover, some of the assumptions made throughout the paper can be relaxed but we do not attempt to do so here.

Finally we observe that the problems of optimality conditions and synthesis of optimal controls for stochastic control problems in infinite dimensions when the value function is not regular are open. Even in the case of finite dimensional stochastic control problems very few results are available (see [37]). These questions will be studied in the future. We briefly discuss what is known in section 5.5.

There is an increasing interest in and a growing literature on Hamilton–Jacobi equations in infinite dimensions. These equations were first studied by Barbu and Da Prato (see, e.g., [2]), setting the problem in classes of convex functions and using semigroup and perturbation methods (see also Da Prato [15] and Havarneanu [28]). Much progress has been made recently due to the introduction of the notion of viscosity solutions. We refer the reader to Crandall and Lions [14], Ishii [31], Soner [42], and Tataru [44, 45, 46] for the first order equations. As regards the second order, "bounded" equations have been investigated by P.-L. Lions in [39, Parts I and III], and "unbounded" in [39, Part II], Ishii [32], Kocan and Święch [34], and Święch [43]. Except for [32] the unboundedness in the studied equations was always coming from the term $\langle Ax, Du\rangle$. This paper is concerned with equations that exhibit "bad behavior" in the Hamiltonian H also in Du and D^2u.

To compare our work with the existing literature let us look at the following model equation:

$$\lambda v(x) - \frac{1}{2}\operatorname{Tr} QD^2v(x) + \big\langle Ax, Dv(x)\big\rangle + H\big(x, Dv(x)\big) = 0, \quad x \in X, \tag{1.4}$$

where $Q : X \to X$ is a self-adjoint nonnegative linear operator. Leaving aside the unboundedness of the term $\langle Ax, Dv(x)\rangle$ that has been investigated in various cases, let us concentrate our attention on the other terms. If Q is a nuclear operator, the term $\operatorname{Tr} QC$ is well defined for all $C \in \Sigma(X)$, and (1.4) is well studied. If Q is not nuclear, $\operatorname{Tr} QC$ does not make sense for many operators, notably for $C = I$. However, equations like this arise in stochastic optimal control of infinite dimensional systems driven by "nondegenerate processes," in particular by the so-called "white noise" (see Albeverio and Röckner [1], and Jona Lasinio and Mitter [33]). Concerning the "bad behavior" with respect to Dv, in the case of Bellman equations (1.4) associated with stochastic boundary control problems, H is well defined only on $X \times D(A^\beta)$

(where $D(A^\beta)$ denotes the domain of the β-fractional power of A for a suitable $\beta \in (0,1)$), and hence the term $H(x, Dv(x))$ is not well defined even if v is Fréchet differentiable. To our knowledge equations of this kind have been studied only in the first order case (i.e., when $Q = 0$) by Cannarsa, Gozzi and Soner [8] and Cannarsa and Tessitore [10].

In the case when Q is not nuclear and H is continuous in $X \times X$, Hamilton–Jacobi equations (1.4) and their parabolic analogues have been recently studied by Cannarsa and Da Prato [4, 5, 7], Gozzi [25, 26], and Gozzi and Rouy [27] from the point of view of strong solutions (which are in particular differentiable in the space variable x). The theory is based on stochastic representation of solutions and uses techniques related to properties of transition semigroups in infinite dimensions recently developed by Da Prato and Zabczyk [17, 18]. Another approach to second order Hamilton–Jacobi equations in infinite dimensions is presented by Chow and Menaldi in [11].

The plan of the paper is the following. In section 2 we give some preliminaries. In section 3 and section 4 we present the definition of a viscosity solution and we prove a general uniqueness and existence result for the transformed equation (1.3) and for the original one (1.1), respectively. Section 5 is devoted to the control problem (P_0). In sections 5.1 and 5.2 we introduce the problem and we prove various estimates for the solutions of the transformed state equation. In section 5.3 we prove that the value function of the control problem (P_0) is the unique viscosity solution of the associated Hamilton–Jacobi–Bellman equation, while in section 5.4 we present examples of stochastic boundary control problems. Finally, in section 5.5 we briefly discuss the relationship between the notions of viscosity and strong solutions and the problem of synthesis of optimal controls.

We refer the reader to the survey paper of Crandall, Ishii, and Lions [12] for the introduction to the notion of viscosity solutions and a complete treatment of finite dimensional equations and to the book of Fleming and Soner [24] for the connection with stochastic optimal control.

2. Notation and preliminaries. Throughout this paper X will denote a real separable Hilbert space endowed with the inner product $\langle \cdot, \cdot \rangle$ and the norm $|\cdot|$. We denote by $\mathcal{L}(X)$ the Banach space of the continuous linear operators $T : X \to X$ with the operator norm $\|\cdot\|$, and we set

$$\Sigma(X) = \big\{T \in \mathcal{L}(X),\ T \text{ self-adjoint}\big\}.$$

Moreover, we denote by $\mathcal{L}_2(X)$ the set of all Hilbert–Schmidt operators $T : X \to X$. It is well known that $\mathcal{L}_2(X)$ is a Hilbert space with the norm

$$\|T\|^2_{\mathcal{L}_2(X)} = \sum_{k=1}^{\infty} |Te_k|^2,$$

where $\{e_k\}_{k\in\mathbb{N}}$ is any orthonormal basis of X.

For any Hilbert spaces X and Y, we denote by $B(X,Y)$, $UC(X,Y)$, and $BUC(X,Y)$ the Banach space of all functions $\varphi : X \to Y$ which are, respectively, bounded, uniformly continuous, uniformly continuous and bounded on X with the usual norm

$$\|\varphi\| = \sup_{x\in X} |\varphi(x)|_Y.$$

For $k \in \mathbb{N}$, we denote by $BUC^k(X,Y)$ the set of all functions $\varphi : X \to Y$ which are uniformly continuous and bounded on X together with all their Fréchet derivatives up to the order k. If $Y = \mathbb{R}$, then we write $BUC^k(X)$ instead of $BUC^k(X,\mathbb{R})$.

We say that a function $\rho : [0,+\infty) \to [0,+\infty)$ is a modulus if ρ is continuous, nondecreasing, subadditive, and $\rho(0) = 0$. Subadditivity in particular implies that for all $\varepsilon > 0$, there exists $C_\varepsilon > 0$ such that

$$\rho(r) \le \varepsilon + C_\varepsilon r \quad \text{for every } r \ge 0.$$

Moreover, a function $\rho : [0,+\infty) \times [0,+\infty) \to [0,+\infty)$ is a local modulus if ρ is continuous, nondecreasing in both variables, subadditive in the first variable, and $\rho(0,r) = 0$ for every $r \ge 0$.

For any $\varphi \in UC(X)$, we denote by ρ_φ a continuity modulus of φ, i.e., a modulus such that $|\varphi(x) - \varphi(y)| \le \rho_\varphi(|x-y|)$ for every $x, y \in X$. We recall that, if $\varphi \in UC(X,Y)$, then its modulus of continuity always exists and so there exist positive constants C_0, C_1 such that

$$|\varphi(x)|_Y \le C_0 + C_1|x| \quad \text{for every } x \in X.$$

We now briefly recall some properties of the stochastic convolution. Let $(\Omega, \mathcal{F}, \mathcal{F}_t, \mathbf{P})$ be a complete probability space with a normal filtration $\{\mathcal{F}_t : t \ge 0\}$, and let W be a cylindrical Wiener process with respect to $\mathcal{F}_t$ (see [17, Chapter 4], for the definition and properties of a cylindrical Wiener process W).

Given $T \in (0,+\infty]$, let us denote by $M^0(0,T;X)$ the space of all X-valued processes measurable on $(0,T)$ and adapted to the filtration $\mathcal{F}_t$ and by $M^2(0,T;X)$ the space of the X-valued processes x such that $x \in M^0(0,T;X)$ and

$$\mathbb{E}\left(\int_0^T |x(s)|^2\, ds\right) < +\infty.$$

The result below can be found in [17, Theorem 7.6] and [18, Chapter 5].

PROPOSITION 2.1. *Let $A : D(A) \subset X \to X$ be the generator of a strongly continuous semigroup e^{tA} on X. Assume that $B : [0,T] \times X \times \Omega \to \mathcal{L}(X)$ is a strongly continuous predictable process such that $e^{tA}B(s,x,\omega)$ is a Hilbert–Schmidt operator for all $s,t \in (0,T]$, $x \in X$, $\omega \in \Omega$ and*

$$\mathbb{E}\int_0^T \left\|e^{tA}B(s,x)\right\|^2_{\mathcal{L}_2(X)} dt < +\infty$$

uniformly in $(s,x) \in [0,T] \times X$. Then, setting

$$\bar{W}(t,x) = \int_0^t e^{(t-s)A}B(s,x)\, dW(s),$$

we have that, for every $x \in X$,

(i) *the process $\bar{W}(\cdot,x)$ is mean square continuous,*
(ii) *the process $\bar{W}(\cdot,x)$ has $\mathbf{P}$-almost surely (a.s.) square integrable trajectories and $\bar{W}(\cdot,x) \in M^2(0,T;X)$,*
(iii) *if for some $\delta > 0$*

$$\mathbb{E}\int_0^T t^{-\delta}\left\|e^{tA}B(s,x)\right\|^2_{\mathcal{L}_2} dt < +\infty \tag{2.1}$$

uniformly in $(s,x) \in [0,T] \times X$, *then* $\bar{W}(\cdot,x)$ *has continuous trajectories and*

$$\mathbb{E}\left(\sup_{0\le t\le T} |\bar{W}(t,x)|^2\right) < +\infty.$$

3. Definition of viscosity solution and a general existence and uniqueness result for the transformed equation. In this section we study the "transformed" equation (1.3). Note that, for the purpose of studying (1.1), we need only to solve the transformed problem on $D(A^{\beta/2})$, but since Hamilton–Jacobi equations of this kind may be of independent interest, we investigate a general equation

$$\lambda u(y) + \langle Ay, Du(y)\rangle + G\big(y, Du(y), D^2u(y)\big) = 0, \quad y \in X. \tag{3.1}$$

We assume the following.

HYPOTHESIS 3.1. $A : D(A) \subset X \to X$ *is a self-adjoint operator, there exists* $a > 0$ *such that* $\langle Ax, x\rangle \ge a|x|^2$ *for all* $x \in D(A)$, *and* A^{-1} *is compact.*

Remark 3.2. Hypothesis 3.1 implies in particular that $-A$ is the infinitesimal generator of an analytic semigroup with compact resolvent satisfying $\|e^{-tA}\| \le e^{-at}$ for all $t \ge 0$ and that there is an orthonormal basis of X made of eigenvectors of A such that the corresponding sequence of eigenvalues diverges to $+\infty$ as $n \to \infty$. It also follows that for every $\theta \in [0,1]$ there exists a constant $M_\theta > 0$ such that

$$\big|A^\theta e^{-tA}x\big| \le M_\theta \frac{e^{-ta}}{t^\theta}|x| \quad \text{for every } t > 0,\ x \in X. \tag{3.2}$$

Moreover, for $\gamma \in (0,1]$ and $\alpha \in (0,\gamma)$, a well known interpolation inequality (see, e.g., [41, pp. 73–74]) states that for every $\sigma > 0$ there exists $C_\sigma > 0$ such that

$$|A^\alpha x| \le \sigma |A^\gamma x| + C_\sigma |x| \quad \text{for every } x \in D(A^\gamma). \tag{3.3}$$

Let $X_1 \subset X_2 \subset \cdots$ be finite dimensional subspaces of X generated by eigenvectors of A such that $\overline{\bigcup_{N=1}^\infty X_N} = X$. Given $N \in \mathbb{N}$, denote by P_N the orthogonal projection onto X_N, let $Q_N = I - P_N$, and let $X_N^\perp = Q_N X$. We then have an orthogonal decomposition $X = X_N \times X_N^\perp$ and we will denote by x_N an element of X_N and by $x_N^\perp$ an element of $X_N^\perp$. For $x \in X$ we will write $x = (P_N x, Q_N x)$. For $\gamma > 0$ we denote by $X_{-\gamma}$ the completion of X in the norm $|x|_{-\gamma} = |A^{-\frac{\gamma}{2}}x|$. We make the following assumptions about G.

HYPOTHESIS 3.3.

(A0) *There exists* $\beta \in (0,1)$ *such that the function* $G : D(A^{\frac{\beta}{2}}) \times D(A^{\frac{\beta}{2}}) \times \Sigma(X) \to \mathbb{R}$ *is continuous (in the topology of* $D(A^{\frac{\beta}{2}}) \times D(A^{\frac{\beta}{2}}) \times \Sigma(X)$*).*

(A1)
$$G(x,p,S_1) \le G(x,p,S_2) \quad \text{if } S_1 \ge S_2$$
for all $x, p \in D(A^{\frac{\beta}{2}})$.

(A2) *There exists a modulus* ρ *such that*
$$\begin{aligned}&\big|G(x,p,S_1) - G(x,q,S_2)\big| \\ &\qquad \le \rho\Big(\big(1 + \big|A^{\frac{\beta}{2}}x\big|\big)|A^{\frac{\beta}{2}}(p-q)| + \big(1 + |A^{\frac{\beta}{2}}x|^2\big)\|S_1 - S_2\|\Big)\end{aligned}$$
for all $x, p, q \in D(A^{\frac{\beta}{2}})$ *and* $S_1, S_2 \in \Sigma(X)$.

(A3) *There exist* $0 < \eta < 1 - \beta$ *and a modulus* ω *such that, for all* $N \geq 1$,

$$G\Big(x, \frac{A^{-\eta}(x-y)}{\varepsilon}, Z\Big) - G\Big(y, \frac{A^{-\eta}(x-y)}{\varepsilon}, Y\Big) \geq -\omega\Big(|A^{\frac{\beta}{2}}(x-y)|\Big(1 + \frac{|A^{\frac{\beta}{2}}(x-y)|}{\varepsilon}\Big)\Big)$$

for all $x, y \in D(A^{\frac{\beta}{2}})$ *and* $Z, Y \in \Sigma(X_N)$ *such that*

$$\begin{pmatrix} Z & 0 \\ 0 & -Y \end{pmatrix} \leq \frac{2}{\varepsilon} \begin{pmatrix} P_N A^{-\eta} P_N & -P_N A^{-\eta} P_N \\ -P_N A^{-\eta} P_N & P_N A^{-\eta} P_N \end{pmatrix}. \tag{3.4}$$

(A4) *For every* $R < +\infty, |\lambda| \leq R$, $p, x \in D(A^{\frac{\beta}{2}})$

$$\sup\big\{|G(x,p,S+\lambda Q_N) - G(x,p,S)| : \|S\| \leq R, S = P_N S P_N\big\} \to 0 \quad \text{as } N \to \infty. \tag{3.5}$$

Remark 3.4. By the properties of moduli, condition (A2) guarantees that there exists a constant C such that, for every x, p, S,

$$\big|G(x,p,S)\big| \leq C\Big(1 + \big(1 + |A^{\frac{\beta}{2}}x|\big)\big|A^{\frac{\beta}{2}}p\big| + \big(1 + |A^{\frac{\beta}{2}}x|^2\big)\|S\|\Big) + \big|G(x,0,0)\big|. \tag{3.6}$$

Some of the conditions above can be weakened; however, we want to keep the technicalities down. We refer the reader to [43] for techniques leading to possible generalizations.

The definition of viscosity solution is motivated by [10].

DEFINITION 3.5. *We say that a function* φ *belongs to the space* $\tilde{C}^2_-(X)$ *(resp.,* $\tilde{C}^2_+(X)$*) if*

(i) $\varphi \in C^2(X)$ *and is weakly sequentially lower (resp., upper) semicontinuous on* X.
(ii) $D\varphi \in UC(X,X) \cap UC(D(A^{\frac{1}{2}-\varepsilon}), D(A^{\frac{1}{2}}))$ *for some* $\varepsilon = \varepsilon(\varphi) > 0$.
(iii) $D^2\varphi \in BUC(X, \Sigma(X))$.

DEFINITION 3.6. *Given* $\delta > 0$ *and* $w, \varphi : X \to \mathbb{R}$ *we say that a point* $y_0 \in X$ *belongs to the set* $M^+_\delta(w,\varphi)$ *if* y_0 *is a point of a local maximum for the function*

$$w - \varphi - \frac{\delta}{2}|\cdot|^2.$$

Similarly, we say that y_0 *belongs to* $M^-_\delta(w,\varphi)$ *if* y_0 *is a point of a local minimum for the function*

$$w - \varphi + \frac{\delta}{2}|\cdot|^2.$$

DEFINITION 3.7. *We say that a function* $w : X \to \mathbb{R}$ *is a viscosity subsolution of* (3.1) *if* w *is weakly sequentially upper semicontinuous on* X*, and for every* $\varphi \in \tilde{C}^2_-(X)$ *and* $\delta > 0$,

(i) $M^+_\delta(w,\varphi) \subset D(A^{\frac{1}{2}})$,
(ii) *for all* $y \in M^+_\delta(w,\varphi)$,

$$\lambda w(y) + \langle A^{\frac{1}{2}} y, A^{\frac{1}{2}} D\varphi(y)\rangle + \delta |A^{\frac{1}{2}} y|^2 + G\left(y, D\varphi(y) + \delta y, D^2\varphi(y) + \delta I\right) \le 0.$$

We say that w is a viscosity supersolution of (3.1) *if w is weakly sequentially lower semicontinuous on X, and for every $\varphi \in \tilde{C}^2_+(X)$ and $\delta > 0$,*

(i) $M^-_\delta(w,\varphi) \subset D(A^{\frac{1}{2}})$,

(ii) *for all $y \in M^-_\delta(w,\varphi)$,*

$$\lambda w(y) + \langle A^{\frac{1}{2}} y, A^{\frac{1}{2}} D\varphi(y)\rangle - \delta \left|A^{\frac{1}{2}} y\right|^2 + G\left(y, D\varphi(y) - \delta y, D^2\varphi(y) - \delta I\right) \ge 0.$$

We say that w is a viscosity solution of (3.1) *if it is both a viscosity subsolution and a supersolution.*

THEOREM 3.8. *Let Hypotheses* 3.1 *and* 3.3 *be satisfied. Then we have the following.*

Comparison: Let $u, -v \le M$ for some constant M. If u is a viscosity subsolution of (3.1) *and v is a viscosity supersolution of* (3.1)*, then $u \le v$ on X. Moreover, if u is a viscosity solution then*

$$\left|u(x) - u(y)\right| \le m\left(|A^{-\frac{\eta}{2}}(x-y)|\right) \tag{3.7}$$

for all $x, y \in X$ and some modulus m, where η is the constant in (A3).

Existence: If

$$\sup_{x \in D\left(A^{\frac{\beta}{2}}\right)} \left|G(x,0,0)\right| = K < \infty, \tag{3.8}$$

then there exists a unique viscosity solution $u \in BUC(X_{-\eta})$ of (3.1).

Proof. Comparison. Let $\varepsilon, \delta > 0$. Put

$$\Phi(x,y) = u(x) - v(y) - \frac{\left|A^{-\frac{\eta}{2}}(x-y)\right|^2}{2\varepsilon} - \frac{\delta}{2}|x|^2 - \frac{\delta}{2}|y|^2.$$

Since $u - v$ is bounded from above and weakly upper-semicontinuous in $X \times X$, Φ must attain its maximum at some point $(\bar{x}, \bar{y})$ (which can be assumed to be strict by subtracting, for instance, $\mu(|A^{-1}(x-\bar{x})|^2 + |A^{-1}(y-\bar{y})|^2)$ and then letting $\mu \to 0$). Moreover, standard considerations (see, for instance, [32]) yield that

$$\lim_{\varepsilon \to 0} \limsup_{\delta \to 0} \left(\frac{|A^{-\frac{\eta}{2}}(\bar{x} - \bar{y})|^2}{\varepsilon} \right) = 0 \tag{3.9}$$

and

$$\lim_{\delta \to 0} \left(\delta |\overline{x}|^2 + \delta |\overline{y}|^2\right) = 0 \quad \text{for every fixed } \varepsilon > 0. \tag{3.10}$$

We now fix $N \in \mathbb{N}$. Then obviously

$$\langle A^{-\eta}(x-y), x-y\rangle = \langle P_N A^{-\eta} P_N (x-y), x-y\rangle + \left|A^{-\frac{\eta}{2}} Q_N (x-y)\right|^2,$$

and we have

$$\begin{aligned}\left|A^{-\frac{\eta}{2}} Q_N (x-y)\right|^2 \le{}& 2\langle Q_N A^{-\eta} Q_N(\bar{x} - \bar{y}), x - y\rangle - \langle Q_N A^{-\eta} Q_N(\bar{x} - \bar{y}), \bar{x} - \bar{y}\rangle \\ &+ 2\left|A^{-\frac{\eta}{2}} Q_N (x - \bar{x})\right|^2 + 2\left|A^{-\frac{\eta}{2}} Q_N (y - \bar{y})\right|^2\end{aligned}$$

with equality if $x = \bar{x}, y = \bar{y}$. Therefore, if we define

$$u_1(x) = u(x) - \frac{\langle x, Q_N A^{-\eta} Q_N(\bar{x} - \bar{y})\rangle}{\varepsilon} + \frac{\langle Q_N A^{-\eta} Q_N(\bar{x} - \bar{y}), \bar{x} - \bar{y}\rangle}{2\varepsilon} - \frac{\left|A^{-\frac{\eta}{2}} Q_N(x - \bar{x})\right|^2}{\varepsilon} - \frac{\delta}{2}|x|^2$$

and

$$v_1(y) = v(y) - \frac{\langle y, Q_N A^{-\eta} Q_N(\bar{x} - \bar{y})\rangle}{\varepsilon} + \frac{\left|A^{-\frac{\eta}{2}} Q_N(y - \bar{y})\right|^2}{\varepsilon} + \frac{\delta}{2}|y|^2,$$

it follows that the function

$$\widetilde{\Phi}(x, y) \stackrel{def}{=} u_1(x) - v_1(y) - \frac{\langle P_N A^{-\eta} P_N(x - y), x - y\rangle}{2\varepsilon} \tag{3.11}$$

always satisfies $\widetilde{\Phi} \leq \Phi$ and attains a strict global maximum at $\bar{x}, \bar{y}$, where $\widetilde{\Phi}(\bar{x}, \bar{y}) = \Phi(\bar{x}, \bar{y})$. We now define, for $x_N,\ y_N \in X_N$, the functions

$$\tilde{u}_1(x_N) = \sup_{x_N^\perp \in X_N^\perp} u_1\big(x_N, x_N^\perp\big), \qquad \tilde{v}_1(y_N) = \inf_{y_N^\perp \in X_N^\perp} v_1\big(y_N, y_N^\perp\big).$$

Since u_1 and $-v_1$ are weakly upper semicontinuous on X, $\tilde{u}_1$ and $-\tilde{v}_1$ are upper semicontinuous on X_N (see [13]). Moreover, by definition of u_1 and $-v_1$ and by the form of $\widetilde{\Phi}$, it follows that

$$\tilde{u}_1(P_N\bar{x}) = u_1(\bar{x}), \qquad \tilde{v}_1(P_N\bar{y}) = v_1(\bar{y}). \tag{3.12}$$

Defining now the map $\Phi_N : X_N \times X_N \to \mathbb{R}$ as

$$\begin{aligned}\Phi_N(x_N, y_N) &= \tilde{u}_1(x_N) - \tilde{v}_1(y_N) - \frac{\langle P_N A^{-\eta} P_N(x_N - y_N), x_N - y_N\rangle}{2\varepsilon} \\ &= \sup_{x_N^\perp,\, y_N^\perp \in X_N^\perp} \widetilde{\Phi}\left(\big(x_N, x_N^\perp\big), \big(y_N, y_N^\perp\big)\right),\end{aligned}$$

it is not difficult to check that Φ_N attains a strict global maximum over $X_N \times X_N$ at $(\bar{x}_N, \bar{y}_N) = (P_N\bar{x}, P_N\bar{y})$. By a finite dimensional result (see [12]) for every $n \in \mathbb{N}$ there exist points $x_N^n,\ y_N^n \in X_N$ such that

$$x_N^n \to \bar{x}_N, y_N^n \to \bar{y}_N, \qquad \tilde{u}_1(x_N^n) \to \tilde{u}_1(\bar{x}_N), \qquad \tilde{v}_1(y_N^n) \to \tilde{v}_1(\bar{y}_N) \quad \text{as } n \to \infty \tag{3.13}$$

and there exist functions $\varphi_n, \psi_n \in C^2(X_N)$ such that $\tilde{u}_1 - \varphi_n$, and $-\tilde{v}_1 + \psi_n$ have unique, strict, global maxima at x_N^n, and y_N^n respectively, and

$$\begin{aligned} D\varphi_n(x_N^n) &\to \frac{1}{\varepsilon} P_N A^{-\eta} P_N(\bar{x}_N - \bar{y}_N), \\ D\psi_n(y_N^n) &\to \frac{1}{\varepsilon} P_N A^{-\eta} P_N(\bar{x}_N - \bar{y}_N), \end{aligned} \tag{3.14}$$

$$D^2\varphi_n(x_N^n) \to Z_N, \qquad D^2\psi_n(y_N^n) \to Y_N, \tag{3.15}$$

where Z_N, Y_N satisfy (3.4). Consider finally the map $\Phi_N^n : X \times X \to \mathbb{R}$ defined as

$$\Phi_N^n(x,y) = u_1(x) - v_1(y) - \varphi_n(P_N x) + \psi_n(P_N y). \tag{3.16}$$

This map has the variables split and, by the definition of u_1 and v_1, attains its global maximum (which we can assume to be strict) at some point $(\hat{x}^n, \hat{y}^n)$. This point depends also on N but we will drop this dependence since N is now fixed. Setting now

$$\overline{\varphi}_{N,n}(x) \stackrel{def}{=} \frac{\langle x, Q_N A^{-\eta} Q_N(\bar{x}-\bar{y})\rangle}{\varepsilon} + \frac{\left|A^{-\frac{\eta}{2}} Q_N(x-\bar{x})\right|^2}{\varepsilon} + \varphi_n(P_N x),$$

we easily see that $\overline{\varphi}_{N,n} \in \tilde{C}^2_-(X)$ and we have from (3.16) that $u(x) - \overline{\varphi}_{N,n}(x) - \frac{\delta}{2}|x|^2$ has a maximum at $\hat{x}^n$. Therefore, by the definition of viscosity subsolution, $\hat{x}^n \in D(A^{\frac{1}{2}})$ and

$$\begin{aligned}
&\lambda u(\hat{x}^n) + \left\langle A^{\frac{1}{2}}\hat{x}^n, A^{\frac{1}{2}} D\varphi_n(P_N\hat{x}^n) + \frac{A^{\frac{1}{2}-\eta} Q_N(\bar{x}-\bar{y})}{\varepsilon} + \frac{2A^{\frac{1}{2}-\eta} Q_N(\hat{x}^n-\bar{x})}{\varepsilon}\right\rangle \\
&\quad + \delta|A^{\frac{1}{2}}\hat{x}^n|^2 + G\Bigg(\hat{x}^n, D\varphi_n(P_N\hat{x}^n) + \frac{A^{-\eta} Q_N(\bar{x}-\bar{y})}{\varepsilon} + \frac{2A^{-\eta} Q_N(\hat{x}^n-\bar{x})}{\varepsilon} \\
&\qquad\qquad + \delta\hat{x}^n, D^2\varphi_n(P_N\hat{x}^n) + \frac{2A^{-\eta}Q_N}{\varepsilon} + \delta I\Bigg) \le 0.
\end{aligned} \tag{3.17}$$

We now would like to pass to the limit as $n \to \infty$ in the above inequality keeping ε, δ, N fixed. To do this we have to justify a lot of convergencies. We start by observing that setting

$$\hat{x}^n = (P_N\hat{x}^n, Q_N\hat{x}^n), \qquad \hat{y}^n = (P_N\hat{y}^n, Q_N\hat{y}^n) \quad \text{for every } x_N^\perp,\ y_N^\perp \in X_N^\perp,$$

we have

$$\begin{aligned}
&\tilde{u}_1(P_N\hat{x}^n) - \tilde{v}_1(P_N\hat{y}^n) - \varphi_n(P_N\hat{x}^n) + \psi_n(P_N\hat{y}^n) \\
&\quad \ge u_1(P_N\hat{x}^n, Q_N\hat{x}^n) - v_1(P_N\hat{y}^n, Q_N\hat{y}^n) - \varphi_n(P_N\hat{x}^n) + \psi_n(P_N\hat{y}^n) \\
&\quad \ge u_1(x_N^n, x_N^\perp) - v_1(y_N^n, y_N^\perp) - \varphi_n(x_N^n) + \psi_n(y_N^n).
\end{aligned}$$

Therefore taking suprema over $x_N^\perp$ and $y_N^\perp$ in the above inequality we obtain

$$\begin{aligned}
&\tilde{u}_1(P_N\hat{x}^n) - \tilde{v}_1(P_N\hat{y}^n) - \varphi_n(P_N\hat{x}^n) + \psi_n(P_N\hat{x}^n) \\
&\quad \ge u_1(P_N\hat{x}^n, Q_N\hat{x}^n) - v_1(P_N\hat{y}^n, Q_N\hat{y}^n) - \varphi_n(P_N\hat{x}^n) + \psi_n(P_N\hat{y}^n) \\
&\quad \ge \tilde{u}_1(x_N^n) - \tilde{v}_1(y_N^n) - \varphi_n(x_N^n) + \psi_n(y_N^n).
\end{aligned}$$

This implies that

$$P_N\hat{x}^n = x_N^n, \qquad P_N\hat{y}^n = y_N^n, \qquad u_1(\hat{x}^n) = \tilde{u}_1(x_N^n), \qquad v_1(\hat{y}^n) = \tilde{v}_1(y_N^n),$$

which, together with (3.13) and (3.12), yields

$$u_1(\hat{x}^n) \longrightarrow u_1(\bar{x}), \qquad v_1(\hat{y}^n) \longrightarrow u_1(\bar{y}) \tag{3.18}$$

as $n \to +\infty$. Finally, since

$$u_1(\hat{x}^n) = \tilde{u}_1(P_N\hat{x}^n), \quad v_1(\hat{y}^n) = \tilde{v}_1(P_N\hat{y}^n)$$

and

$$u_1(\bar{x}) = \tilde{u}_1(P_N\bar{x}), \quad v_1(\bar{y}) = \tilde{v}_1(P_N\bar{y}),$$

formula (3.18), together with the weak upper semicontinuity of u_1 and the weak lower semicontinuity of v_1, implies

$$\hat{x}^n \longrightarrow \bar{x}, \qquad \hat{y}^n \longrightarrow \bar{y} \tag{3.19}$$

as $n \to +\infty$. Therefore, using (3.19), (3.18), (3.6), (A0), and (3.3), it follows from (3.17) that $|A^{\frac{1}{2}}\hat{x}^n|$ are bounded independently of n which implies, thanks to (3.19), that $\bar{x} \in D(A^{\frac{1}{2}})$ and

$$A^{\frac{1}{2}}\hat{x}^n \rightharpoonup A^{\frac{1}{2}}\bar{x} \tag{3.20}$$

as $n \to +\infty$. Since $A^{\frac{\beta-1}{2}}$ and $A^{-\frac{\eta}{2}}$ are compact we conclude that, as $n \to +\infty$,

$$A^{\frac{\beta}{2}}\hat{x}^n = A^{\frac{\beta-1}{2}}\big(A^{\frac{1}{2}}\hat{x}^n\big) \to A^{\frac{\beta}{2}}\bar{x} \qquad \text{and} \qquad A^{\frac{1-\eta}{2}}\hat{x}^n \to A^{\frac{1-\eta}{2}}\bar{x}. \tag{3.21}$$

Using (3.14), (3.15), (3.20), (3.21), and the weak lower semicontinuity of norm we thus obtain that

$$\begin{aligned}
&\left\langle A^{\frac{1-\eta}{2}}\bar{x}, \frac{A^{\frac{1-\eta}{2}}(\bar{x}-\bar{y})}{\varepsilon}\right\rangle + \delta|A^{\frac{1}{2}}\bar{x}|^2 \\
&\qquad \le \liminf_{n\to\infty}\left[\left\langle A^{\frac{1}{2}}\hat{x}^n, A^{\frac{1}{2}}D\varphi_n(P_N\hat{x}^n) + \frac{A^{\frac{1}{2}-\eta}Q_N(\bar{x}-\bar{y})}{\varepsilon} + \frac{2A^{\frac{1}{2}-\eta}Q_N(\hat{x}^n-\bar{x})}{\varepsilon}\right\rangle\right. \\
&\qquad\qquad \left. + \delta|A^{\frac{1}{2}}\hat{x}^n|^2\right].
\end{aligned}$$

Therefore, letting $n \to \infty$ in (3.17) yields

$$\begin{aligned}
&\lambda u(\bar{x}) + \left\langle A^{\frac{1-\eta}{2}}\bar{x}, \frac{A^{\frac{1-\eta}{2}}(\bar{x}-\bar{y})}{\varepsilon}\right\rangle + \delta|A^{\frac{1}{2}}\bar{x}|^2 \\
&\qquad + G\left(\bar{x}, \frac{A^{-\eta}(\bar{x}-\bar{y})}{\varepsilon} + \delta\bar{x}, Z_N + \frac{2\|A^{-\eta}\|Q_N}{\varepsilon} + \delta I\right) \le 0.
\end{aligned} \tag{3.22}$$

We now eliminate terms with δ and N. Using (A2) we have

$$\begin{aligned}
&G\left(\bar{x}, \frac{A^{-\eta}(\bar{x}-\bar{y})}{\varepsilon}, Z_N + \frac{2\|A^{-\eta}\|Q_N}{\varepsilon}\right) - \rho\Big(d\delta\big(1+|A^{\frac{\beta}{2}}\bar{x}|^2\big)\Big) \\
&\qquad \le G\left(\bar{x}, \frac{A^{-\eta}(\bar{x}-\bar{y})}{\varepsilon} + \delta\bar{x}, Z_N + \frac{2\|A^{-\eta}\|Q_N}{\varepsilon} + \delta I\right)
\end{aligned} \tag{3.23}$$

for some constant $d > 0$. Now, given $\tau > 0$, let K_τ be such that $\rho(s) \le \tau + K_\tau s$. Applying (3.3) with $\alpha = \beta/2$ and $\gamma = 1/2$ we obtain that

$$\rho\big(d\delta\big(1+|A^{\frac{\beta}{2}}\bar{x}|^2\big)\big) \le \frac{\delta}{2}|A^{\frac{1}{2}}\bar{x}|^2 + \delta C_\tau|\bar{x}|^2 + \tau + K_\tau\, d\delta$$

for some constant $C_\tau > 0$ independent of δ and ε. It then follows from (3.10) that

$$\limsup_{\delta\to 0}\Big(\rho\big(d\delta\big(1+|A^{\frac{\beta}{2}}\bar{x}|^2\big)\big) - \delta|A^{\frac{1}{2}}\bar{x}|^2\Big) \le 0. \tag{3.24}$$

Using this, (3.23), and (3.5) in (3.22), we therefore obtain

(3.25)
$$\lambda u(\bar{x}) + \left\langle A^{\frac{1-\eta}{2}}\bar{x}, \frac{A^{\frac{1-\eta}{2}}(\bar{x}-\bar{y})}{\varepsilon}\right\rangle + G\left(\bar{x}, \frac{A^{-\eta}(\bar{x}-\bar{y})}{\varepsilon}, Z_N\right) \le \omega_1(N;\delta,\varepsilon) + \omega_2(\delta,\varepsilon),$$

where $\lim_{N\to\infty}\omega_1(N;\delta,\varepsilon) = 0$ if ε, δ are fixed and ω_2 is a local modulus. Similarly we obtain

(3.26)
$$\lambda v(\bar{y}) + \left\langle A^{\frac{1-\eta}{2}}\bar{y}, \frac{A^{\frac{1-\eta}{2}}(\bar{x}-\bar{y})}{\varepsilon}\right\rangle + G\left(\bar{y}, \frac{A^{-\eta}(\bar{x}-\bar{y})}{\varepsilon}, Y_N\right) \ge -\omega_1(N;\delta,\varepsilon) - \omega_2(\delta,\varepsilon).$$

We now subtract (3.26) from (3.25), use (A3), and then let $N \to \infty$. We then conclude that

$$\lambda\big(u(\bar{x}) - v(\bar{y})\big) \le \omega\left(\big|A^{\frac{\beta}{2}}(\bar{x}-\bar{y})\big|\left(1 + \frac{|A^{\frac{\beta}{2}}(\bar{x}-\bar{y})|}{\varepsilon}\right)\right) - \frac{|A^{\frac{1-\eta}{2}}(\bar{x}-\bar{y})|^2}{\varepsilon} + 2\omega_2(\delta,\varepsilon).$$

Set $r = |A^{\frac{1-\eta}{2}}(\bar{x}-\bar{y})|$, and let $\sigma > 0$. Using the interpolation inequality (3.3), the fact that $|A^{\frac{\beta}{2}}(\bar{x}-\bar{y})| \le c|A^{\frac{1-\eta}{2}}(\bar{x}-\bar{y})|$ for some $c > 0$ and the property of the moduli, we have that, for all $\alpha,\ \sigma > 0$, there exist $C_\sigma,\ K_\alpha > 0$ such that

$$\lambda\big(u(\bar{x}) - v(\bar{y})\big) \le \alpha + cK_\alpha\left(\sigma\frac{r^2}{\varepsilon} + C_\sigma\frac{\big|A^{-\frac{\eta}{2}}(\bar{x}-\bar{y})\big|}{\varepsilon}r + r\right) - \frac{r^2}{\varepsilon} + 2\omega_2(\delta,\varepsilon).$$

For α fixed, we chose σ such that $cK_\alpha\sigma < 1$. Then, in the right-hand side of the previous inequality, we have a polynomial of order 2 in $r/\sqrt{\varepsilon}$ which is bounded from above and we get

$$\lambda\big(u(\bar{x}) - v(\bar{y})\big) \le \alpha + \frac{K_\alpha^2 c^2\left(\sqrt{\varepsilon} + C_\sigma\frac{|A^{-\frac{\eta}{2}}(\bar{x}-\bar{y})|}{\sqrt{\varepsilon}}\right)^2}{4(1 - K_\alpha c\sigma)} + 2\omega_2(\delta,\varepsilon). \tag{3.27}$$

By using (3.9), this yields

$$\limsup_{\varepsilon\to 0}\limsup_{\delta\to 0}\big(u(\bar{x}) - v(\bar{y})\big) \le \alpha$$

for all $\alpha > 0$, which implies $u \le v$ in X since for all $x \in X$, we have

$$\Phi(x,x) \le \Phi(\bar{x},\bar{y}) \le u(\bar{x}) - v(\bar{y}).$$

Now, let u be a solution. We can set $u = v$ in the preceding proof and we obtain that for all x, y in X

$$u(x) - u(y) - \frac{|A^{-\frac{\eta}{2}}(x-y)|^2}{2\varepsilon} = \limsup_{\delta\to 0}\Phi(x,y) \le \limsup_{\delta\to 0}\big(u(\bar{x}) - u(\bar{y})\big) \le \rho_1(\epsilon)$$

for some modulus ρ_1 in light of (3.27). This proves (3.7).

Existence. Consider the approximating equation

$$\lambda u_N + \langle Ax, Du_N\rangle + G(x, Du_N, D^2u_N) = 0 \quad \text{in } X_N. \tag{3.28}$$

We notice that (3.28) satisfies the assumptions of the comparison part of the theorem with constants and moduli independent of N. By the finite dimensional theory (3.28) has a solution u_N (for every N) such that $\|u_N\|_\infty \le K/\lambda$. We will prove that there exists a modulus σ independent of N such that

$$\big|u_N(x) - u_N(y)\big| \le \sigma\big(|x-y|_{-\eta}\big)$$

for all $x, y \in X_N$. To do this we adapt the technique of [30] which was also used in [43].

For every $\varepsilon > 0$ let K_ε be such that $\omega(r) \le \lambda\varepsilon/2 + K_\varepsilon r$. For $L > K/\lambda + 1$ we set

$$\psi_L(r) = 2L2^{1-\frac{1}{2L}} r^{\frac{1}{2L}}.$$

The function $\psi_L \in C^2(0,\infty)$ is increasing and concave, $\psi_L'(r) \ge 1$ for $0 < r \le 2$, $\psi_L(0) = 0$, $\psi_L(1) > 2(K/\lambda + 1)$, and

$$\psi_L(r) > L\big(\psi_L'(r)r + r\big) \quad \text{for } 0 \le r \le 2. \tag{3.29}$$

We will show that for every $\varepsilon > 0$ there exists $L = L_\varepsilon$ such that

$$u_N(x) - u_N(y) \le \psi_L\big(|A^{-\frac{\eta}{2}}(x-y)|\big) + \varepsilon \quad \text{for every } x, y \in X. \tag{3.30}$$

Denoting by $\Delta = \{(x,y) \in X \times X : |A^{-\frac{\eta}{2}}(x-y)| < 1\}$ it is clear, from the properties of ψ_L, that for $(x,y) \notin \Delta$ (3.30) is always satisfied independently of L. Assume now by contradiction that (3.30) is false. Then, given any $L > \frac{K}{\lambda} + 1$ we have, for small $\delta > 0$, that

$$\sup_{(x,y)\in X\times X} \left(u_N(x) - u_N(y) - \psi_L(|A^{-\frac{\eta}{2}}(x-y)|) - \varepsilon - \frac{\delta}{2}|x|^2 - \frac{\delta}{2}|y|^2\right) > 0 \tag{3.31}$$

and the supremum is attained at $(\bar x, \bar y) \in \Delta$ such that $\bar x \ne \bar y$. Denote $s = |A^{-\frac{\eta}{2}}(\bar x - \bar y)|$. Using Lemma 2.3 in [43] (see the proof of Proposition 2.5 in [43]) and then repeating arguments from the just-finished proof of comparison we obtain that there exist $Z, Y \in \Sigma(X_N)$ such that

$$\begin{pmatrix} Z & 0 \\ 0 & -Y \end{pmatrix} \le \frac{2\psi_L'(s)}{s} \begin{pmatrix} P_N A^{-\eta} P_N & -P_N A^{-\eta} P_N \\ -P_N A^{-\eta} P_N & P_N A^{-\eta} P_N \end{pmatrix}$$

and

$$\begin{aligned}
\lambda(u_N(\bar x) - u_N(\bar y)) &\le -\frac{\psi_L'(s)}{s}|A^{\frac{1-\eta}{2}}(\bar x - \bar y)|^2 + G\left(\bar y, \frac{\psi_L'(s)}{s}A^{-\eta}(\bar x - \bar y), Y\right) \\
&\quad - G\left(\bar x, \frac{\psi_L'(s)}{s}A^{-\eta}(\bar x - \bar y), Z\right) + \rho(\delta, L) \\
&\le -\frac{\psi_L'(s)}{s}\big|A^{\frac{1-\eta}{2}}(\bar x - \bar y)\big|^2 + \frac{\lambda\varepsilon}{2} \\
&\quad + K_\varepsilon\left(\big|A^{\frac{\beta}{2}}(\bar x - \bar y)\big|\left(1 + \frac{\psi_L'(s)}{s}\big|A^{\frac{\beta}{2}}(\bar x - \bar y)\big|\right)\right) + \rho(\delta, L)
\end{aligned}$$

for some local modulus ρ. Therefore, using (3.3) with a sufficiently small σ, it follows that

$$\begin{aligned}
\lambda(u_N(\bar x) - u_N(\bar y)) &\le -\frac{\psi_L'(s)}{2s}\big|A^{\frac{1-\eta}{2}}(\bar x - \bar y)\big|^2 + \frac{\lambda\varepsilon}{2} \\
&\quad + C_\varepsilon\big(\psi_L'(s)s + s\big) + \frac{c}{2}|A^{\frac{1-\eta}{2}}(\bar x - \bar y)| + \rho(\delta, L),
\end{aligned}$$

where C_ε depends only on K_ε and the interpolation constant (but not on L), and c is such that $|A^{\frac{1-\eta}{2}}x| \geq c|A^{-\frac{\eta}{2}}x|$ for all $x \in H$. Thus, we eventually have

$$\lambda\big(u_N(\bar{x}) - u_N(\bar{y})\big) \leq \frac{\lambda\varepsilon}{2} + C_\varepsilon\big(\psi_L'(s)s + s\big) + \rho(\delta, L),$$

which becomes, choosing $L = C_\varepsilon/\lambda$ and letting $\delta \to 0$,

$$u_N(\bar{x}) - u_N(\bar{y}) \leq \frac{\varepsilon}{2} + L\big(\psi_L'(s)s + s\big).$$

This leads to a contradiction in light of (3.29) since we obviously have by (3.31)

$$\psi_L(s) + \varepsilon \leq u_N(\bar{x}) - u_N(\bar{y}).$$

Hence, we obtain the required modulus of continuity.

Now set $v_N(x) = u_N(P_N x)$. Since $A^{-\frac{\eta}{2}}$ is compact we are in a position to apply the Arzelà–Ascoli theorem to find a subsequence (still denoted by v_N) converging uniformly on bounded sets of X to a function u that obviously satisfies the same estimates as u_N's (see [14, Part IV] and [43] for more). It remains to show that u solves the limiting equation (3.1). Let $\varphi \in C^2_-(X)$ and let $u(x) - \varphi(x) - \frac{\delta}{2}|x|^2$ have a maximum at $\hat{x}$ which we may assume to be strict. It follows that there exists a sequence $\hat{x}_N = P_N\hat{x}_N \to \hat{x}$ as $N \to \infty$ such that, for every $x \in X_N$,

$$v_N(x) - \varphi(x) - \frac{\delta}{2}|x|^2 \leq v_N(\hat{x}_N) - \varphi(\hat{x}_N) - \frac{\delta}{2}|\hat{x}_N|^2.$$

Therefore, since $AP_N = P_N A$,

$$\begin{aligned}\lambda u_N(\hat{x}_N) + \big\langle A^{\frac{1}{2}}\hat{x}_N, A^{\frac{1}{2}}D\varphi(\hat{x}_N)\big\rangle + \delta\big|A^{\frac{1}{2}}\hat{x}_N\big|^2 \\ + G\left(\hat{x}_N, P_N D\varphi(\hat{x}_N) + \delta\hat{x}_N, P_N(D^2\varphi(\hat{x}_N) + \delta I)P_N\right) \leq 0.\end{aligned} \tag{3.32}$$

Since $\hat{x}_N \in X_N$ and φ is a test function we have

$$\big|A^{\frac{1}{2}}D\varphi(\hat{x}_N)\big| \leq B + C\big|A^{\frac{1}{2}-\varepsilon}\hat{x}_N\big| \tag{3.33}$$

for some independent constants B, C. Also, by (3.33), (3.3), (3.6), and (3.8),

$$\begin{aligned}&\big|G\big(\hat{x}_N, P_N D\varphi(\hat{x}_N) + \delta\hat{x}_N, P_N(D^2\varphi(\hat{x}_N) + \delta I)P_N\big)\big| \\ &\qquad \leq C_1\Big(1 + |A^{\frac{\beta}{2}}\hat{x}_N|^2 + |A^{\frac{1}{2}-\varepsilon}\hat{x}_N|^2\Big) \leq C_2 + \frac{\delta}{4}|A^{\frac{1}{2}}\hat{x}_N|^2.\end{aligned}$$

Using this, (3.33), and the interpolation inequality (3.3), we therefore obtain from (3.32) that

$$\big|A^{\frac{1}{2}}\hat{x}_N\big| \leq C_3$$

for some constant C_3 independent of N. Thus, $A^{\frac{1}{2}}\hat{x}_N \rightharpoonup A^{\frac{1}{2}}\hat{x}$ (so $\hat{x} \in D(A^{\frac{1}{2}})$) and hence

$$A^{\frac{\beta}{2}}\hat{x}_N \to A^{\frac{\beta}{2}}\hat{x}, \qquad \text{and} \qquad A^{\frac{1}{2}}D\varphi(\hat{x}_N) \to A^{\frac{1}{2}}D\varphi(\hat{x}).$$

These convergencies and Lemma 2.8 in [43] allow us to pass to the limit in (3.32) as $N \to \infty$ to conclude that

$$\lambda u(\hat{x}) + \big\langle A^{\frac{1}{2}}\hat{x}, A^{\frac{1}{2}}D\varphi(\hat{x})\big\rangle + \delta\big|A^{\frac{1}{2}}\hat{x}\big|^2 + G\left(\hat{x}, D\varphi(\hat{x}) + \delta\hat{x}, D^2\varphi(\hat{x}) + \delta I\right) \leq 0. \qquad \square$$

Remark 3.9. If instead of (A2) we assume that there exist $\gamma < 1$ and a modulus ρ such that

$$\big|G(x,p,S_1) - G(x,q,S_2)\big| \le \rho\left(\big(1+|A^{\frac{\beta}{2}}x|^{\gamma}\big)\big|A^{\frac{\beta}{2}}(p-q)\big| + \big(1+|A^{\frac{\beta}{2}}x|^{2\gamma}\big)\|S_1-S_2\|\right)$$

for all $x,p,q \in D(A^{\frac{\beta}{2}})$ and $S_1, S_2 \in \Sigma(X)$, then the conclusion of the comparison part of Theorem 3.8 holds if we replace the assumption that $u, -v \le M$ by the assumption that

$$\big|u(x)-u(y)\big|, \big|v(x)-v(y)\big| \le m\big(|A^{-\frac{\eta}{2}}(x-y)|\big)$$

for some modulus m. The same proof applies except that an analogue of (3.24) has to be justified differently and instead of (3.10) we now obtain (by a standard argument) that

$$\frac{\big|A^{-\frac{\eta}{2}}(\bar{x}-\bar{y})\big|^2}{\varepsilon} \le t_\varepsilon \to 0 \quad \text{as } \varepsilon \to 0.$$

4. Viscosity solutions of the original equation. We now briefly explain how to define the viscosity solution of the original equation

$$\lambda v(x) + \big\langle Ax, Dv(x)\big\rangle + H\big(x, Dv(x), D^2v(x)\big) = 0, \quad x \in X, \tag{4.1}$$

where we assume that Hypothesis 3.1 and the following hold.

HYPOTHESIS 4.1. *The function $H : X \times D(A^\beta) \times A^{-\frac{\beta}{2}}\Sigma(X)A^{-\frac{\beta}{2}} \to \mathbb{R}$ is such that, if we define*

$$G_H(z,p,S) \stackrel{def}{=} H\left(A^{\frac{\beta}{2}}z, A^{-\frac{\beta}{2}}p, A^{-\frac{\beta}{2}}SA^{-\frac{\beta}{2}}\right),$$

then G_H satisfies Hypothesis 3.3.

Remark 4.2. The last hypothesis could also be written more explicitly by translating Hypothesis 3.3. We used the above formulation for brevity and also because it can be easily checked by the change of variable.

If we apply the change of variable $y = A^{-\frac{\beta}{2}}x$ and set $u(y) \stackrel{def}{=} v(A^{\frac{\beta}{2}}y)$, (4.1) for v formally becomes the following equation for u:

$$\lambda u(y) + \big\langle Ay, Du(y)\big\rangle + G_H\big(y, Du(y), D^2u(y)\big) = 0, \quad y \in X. \tag{4.2}$$

The function v is uniquely determined, once u has been characterized on $D(A^{\frac{\beta}{2}})$. Therefore we are driven to the following definition of viscosity solution for equation (4.1).

DEFINITION 4.3. *A bounded continuous function $v : X \to \mathbb{R}$ is said to be a viscosity solution of equation* (4.1) *if and only if the function*

$$u(y) \stackrel{def}{=} v\big(A^{\frac{\beta}{2}}y\big)$$

is a viscosity solution of the transformed equation (4.2). *Similarly we define a viscosity subsolution and a supersolution of* (4.1).

From Theorem 3.8 we have the following.

THEOREM 4.4. *Let Hypotheses* 3.1 *and* 4.1 *be satisfied. If*

$$\sup_{x\in X} |H(x,0,0)| = K < \infty, \tag{4.3}$$

then there exists a unique viscosity solution $v \in BUC(X_{-(\beta+\eta)})$ of (4.1).

5. The stochastic boundary control problem.

5.1. The state equation. Let X, U_1, and U_2 be real separable Hilbert spaces. Let $\tilde{U}_2$ be a given closed bounded subset of U_2 with $R = \sup_{h\in\tilde{U}_2}|h|$ and define $U \stackrel{def}{=} U_1 \times \tilde{U}_2$. Let $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\geq 0}, \mathbf{P})$ and W be respectively the stochastic base and the cylindrical Brownian motion on X defined in section 2.

Consider a stochastic dynamical system governed by the following stochastic differential equation in X:

(5.1)
$$\begin{cases} dx(t) = \left[-Ax(t) + b(x(t),\alpha_1(t)) + A^\beta C\alpha_2(t)\right]dt + B(x(t),\alpha_1(t))dW(t), \quad t>0, \\ x(0) = x_0 \in X, \end{cases}$$

where we assume that Hypothesis 3.1 holds. We also assume the following.

HYPOTHESIS 5.1.

(i) $\alpha \stackrel{def}{=} (\alpha_1,\alpha_2) \in \mathcal{U}_{ad}(0,T;U) \stackrel{def}{=} M^0(0,T;U_1)\times M^0(0,T;\tilde{U}_2)$ *for every* $T>0$.

(ii) *The function* b *is continuous from* $X\times U_1$ *to* X *and there exists a constant* $c_0>0$ *such that*

$$|b(x,\alpha_1)| \leq c_0(1+|x|) \quad \textit{for all } x\in X,\ \alpha_1\in U_1,$$
$$|b(x_1,\alpha_1)-b(x_2,\alpha_1)| \leq c_0|x_1-x_2| \quad \textit{for all } x_1,x_2\in X,\ \alpha_1\in U_1.$$

(iii) $C\in\mathcal{L}(U_2,X)$ *and* $\beta\in(\frac{3}{4},1)$.

(iv) B *is a mapping from* $X\times U_1$ *into* $\mathcal{L}(X)$ *such that* $A^{-\frac{\beta}{2}}B : X\times U_1 \to \mathcal{L}_2(X)$ *is continuous, and moreover, there exists a constant* $K_1>0$ *such that*

$$\|A^{-\frac{\beta}{2}}B(x,\alpha_1)\|_{\mathcal{L}_2(X)} \leq K_1(1+|x|) \quad \textit{for all } x\in X,\ \alpha_1\in U_1,$$
$$\|A^{-\frac{\beta}{2}}[B(x_1,\alpha_1)-B(x_2,\alpha_1)]\|_{\mathcal{L}_2(X)} \leq K_1|x_1-x_2| \quad \textit{for all } x_1,x_2\in X,\ \alpha_1\in U_1.$$

(v) *For all* $x\in X$,

$$\lim_{N\to+\infty}\sup_{\alpha_1\in U_1}\left\|Q_N A^{-\frac{\beta}{2}}B(x,\alpha_1)\right\|_{\mathcal{L}_2(X)} = 0.$$

Remark 5.2.

- Hypotheses 5.1(iv), (v) are satisfied if we assume, for example, that there exists a constant $K_2>0$ such that

$$\|B(x,\alpha_1)\| \leq K_2(1+|x|) \quad \text{for all } x\in X,\ \alpha_1\in U_1,$$
$$\|B(x_1,\alpha_1)-B(x_2,\alpha_1)\| \leq K_2|x_1-x_2| \quad \text{for all } x_1,x_2\in X,\ \alpha_1\in U_1,$$

  and if the operator $A^{-\beta}$ is trace class.
- Hypothesis 5.1(v) is satisfied if, for instance, for every $x\in X$ there exists $\eta\in(0,\beta/2)$ such that $A^{-\eta}B(x,\alpha_1)$ is bounded in $\mathcal{L}_2(X)$ independently of $\alpha_1\in U_1$.

Equation (5.1) contains terms that are not well defined in general. However it is possible to give sense to its integral form. For this reason we introduce the concept of mild solution of (5.1) (see, e.g., [17]).

DEFINITION 5.3. *An* $\mathcal{F}_t$*-adapted process* $x(t)$, $t\geq 0$, *is said to be a mild solution of* (5.1) *if*

$$\mathbf{P}\left(\int_0^t |x(s)|^2 ds < +\infty\right) = 1 \quad \textit{for all } t\geq 0$$

and if it satisfies the integral equation

$$
\begin{aligned}
x(t) = e^{-tA}x_0 &+ \int_0^t e^{-(t-s)A} b\big(x(s), \alpha_1(s)\big)\, ds + A^\beta \int_0^t e^{-(t-s)A} C\alpha_2(s)\, ds \\
&+ \int_0^t e^{-(t-s)A} B\big(x(s), \alpha_1(s)\big)\, dW(s), \quad \mathbf{P}\text{a.s., } t \geq 0.
\end{aligned} \tag{5.2}
$$

Equation (5.2) *will be called the mild form of* (5.1).

If, given $T \geq 0$, we denote by $\mathcal{H}_{2,T}$ the Banach space of all (equivalence classes of) predictable X-valued processes $z(t)$, $t \geq 0$ such that

$$
\|z\|_{\mathcal{H}_{2,T}} \stackrel{def}{=} \sup_{s\in[0,T]} \big(\mathbb{E}|z(s)|^2\big)^{\frac{1}{2}} < +\infty,
$$

then we have the following result (see [17, Chapter 7] and [18, Chapter 5]).

THEOREM 5.4. *Assume that Hypotheses* 3.1 *and* 5.1(i)–(iv) *hold. Then, for any initial condition x_0 there exists a unique mild solution $x(\cdot) = x(\cdot; x_0, \alpha)$ of* (5.1) *such that for every $T > 0$ $x(\cdot) \in \mathcal{H}_{2,T}$ and there exists a constant C_T independent of x_0 such that*

$$
\sup_{s\in[0,T]} \mathbb{E}|x(s)|^2 \leq C_T\big(1 + |x_0|^2\big).
$$

Finally, the solution has continuous trajectories $\mathbf{P}$*-a.s.*

Proof. The proof is completely similar to the one given in [17, Chapter 7] and [18, Chapter 5]. The only differences between (5.2) and those treated in the results above are the presence of the term

$$
A^\beta \int_0^t e^{-(t-s)A} C\alpha_2(s)\, ds \tag{5.3}
$$

and the nonstandard assumption 5.1(iv). The term (5.3) does not influence the proof of the theorem, since, when α_2 is bounded a.s., we have for some constant $C_0 > 0$,

$$
\mathbb{E}\left| A^\beta \int_0^t e^{-(t-s)A} C\alpha_2(s)\, ds \right|^2 \leq C_0 R^2 \left(\int_0^t \frac{e^{-a(t-s)}}{(t-s)^\beta}\, ds \right)^2.
$$

Moreover, the stochastic convolution can be estimated by writing

$$
\int_0^t e^{-(t-s)A} B\big(x(s), \alpha_1(s)\big)\, dW(s) = \int_0^t A^{\frac{\beta}{2}} e^{-(t-s)A} A^{-\frac{\beta}{2}} B\big(x(s), \alpha_1(s)\big)\, dW(s)
$$

so that, thanks to (3.2),

$$
\begin{aligned}
\mathbb{E}\left| \int_0^t e^{-(t-s)A} B\big(x(s), \alpha_1(s)\big)\, dW(s) \right|^2 & \\
\leq \int_0^t \frac{M_{\frac{\beta}{2}}^2 e^{-2a(t-s)}}{(t-s)^\beta} \mathbb{E}\big\| A^{-\frac{\beta}{2}} B\big(x(s), \alpha_1(s)\big)\big\|^2_{\mathcal{L}_2(X)}\, ds. &
\end{aligned}
$$

In particular this ensures also that (2.1) holds as well as the continuity of trajectories of the solution. □

5.2. Change of variables and main estimates. As we said in the introduction, we transform (5.1) by the change of variables

$$y(t) = A^{-\frac{\beta}{2}} x(t). \tag{5.4}$$

Then the function $y(\cdot) = y(\cdot; y_0, \alpha) = A^{-\frac{\beta}{2}} x(\cdot; x_0, \alpha)$ satisfies the equation

$$\begin{cases} dy(t) = \big[-Ay(t) + A^{-\frac{\beta}{2}} b(A^{\frac{\beta}{2}} y(t), \alpha_1(t)) + A^{\frac{\beta}{2}} C\alpha_2(t) \big] dt \\ \qquad\quad + A^{-\frac{\beta}{2}} B\big(A^{\frac{\beta}{2}} y(t), \alpha_1(t)\big)\, dW(t), \\ y(0) = y_0 = A^{-\frac{\beta}{2}} x_0 \in X. \end{cases}$$

Again, the above equation has to be understood in its mild form

$$\begin{aligned} y(t) &= e^{-tA} y_0 + A^{-\frac{\beta}{2}} \int_0^t e^{-(t-s)A} b\big(A^{\frac{\beta}{2}} y(s), \alpha_1(s)\big)\, ds \\ &\quad + A^{\frac{\beta}{2}} \int_0^t e^{-(t-s)A} C\alpha_2(s)\, ds + A^{-\frac{\beta}{2}} \int_0^t e^{-(t-s)A} B\big(A^{\frac{\beta}{2}} y(s), \alpha_1(s)\big)\, dW(s). \end{aligned} \tag{5.5}$$

When $y_0 \in D(A^{\frac{\beta}{2}})$, the last equation is nothing else but a different form of (5.1) obtained by the change of variables (5.4), and so the function

$$y(\cdot\,; y_0, \alpha) = A^{-\frac{\beta}{2}} x\big(\cdot\,; A^{\frac{\beta}{2}} y_0, \alpha\big)$$

is a mild solution of (5.5), and the following estimate holds:

$$\big\| A^{\frac{\beta}{2}} y \big\|^2_{\mathcal{H}_{2,T}} \le C_T \big(1 + |A^{\frac{\beta}{2}} y_0|^2\big).$$

However, one can also find a solution of (5.5) for a general initial condition $y_0 \in X$.

Denote by $M^2(a, b; D(A^\gamma))$, for $\gamma \in [0, 1]$, the Banach space of all (equivalence classes of) predictable X-valued processes $z(t)$, for $t \ge 0$, such that

$$\|z\|_{2,\gamma} \stackrel{def}{=} \left(\mathbb{E} \int_a^b |A^\gamma z(s)|^2 ds \right)^{\frac{1}{2}} < +\infty.$$

By a careful application of the arguments used in the proof of Theorem 5.4 we get the following result.

PROPOSITION 5.5. *Assume that Hypotheses* 3.1 *and* 5.1 *hold. Then for every* $y_0 \in X$, *equation* (5.5) *has a unique solution* $y(\cdot) = y(\cdot\,; y_0, \alpha)$ *such that for every* $T > 0$, $y \in M^2(0, T; D(A^{\frac{\beta}{2}}))$. *Moreover,* y *has continuous trajectories to* 0.

Proof. The proof of existence and uniqueness follows by applying the contraction mapping principle in a suitable way. Let $y_0 \in X$; for $y \in M^2(0, T; D(A^{\frac{\beta}{2}}))$, we define a map Λ on $M^2(0, T; D(A^{\frac{\beta}{2}}))$ by

$$\begin{aligned} [\Lambda y](t) &= e^{-tA} y_0 + A^{-\frac{\beta}{2}} \int_0^t e^{-(t-s)A} b\big(A^{\frac{\beta}{2}} y(s), \alpha_1(s)\big)\, ds + A^{\frac{\beta}{2}} \int_0^t e^{-(t-s)A} C\alpha_2(s)\, ds \\ &\quad + A^{-\frac{\beta}{2}} \int_0^t e^{-(t-s)A} B\big(A^{\frac{\beta}{2}} y(s), \alpha_1(s)\big)\, dW(s). \end{aligned}$$

First, we prove that Λ maps $M^2(0,T;D(A^{\frac{\beta}{2}}))$ into itself. For $y \in M^2(0,T;D(A^{\frac{\beta}{2}}))$, we have

$$\begin{aligned} A^{\frac{\beta}{2}}[\Lambda y](t) &= A^{\frac{\beta}{2}} e^{-tA} y_0 + \int_0^t e^{-(t-s)A} b\big(A^{\frac{\beta}{2}} y(s), \alpha_1(s)\big)\, ds \\ &\quad + A^{\beta} \int_0^t e^{-(t-s)A} C\alpha_2(s)\, ds \\ &\quad + A^{\frac{\beta}{2}} \int_0^t e^{-(t-s)A} A^{-\frac{\beta}{2}} B\big(A^{\frac{\beta}{2}} y(s), \alpha_1(s)\big)\, dW(s) \end{aligned}$$

so that, for suitable constants $C_1, C_2 > 0$,

$$\begin{aligned} \big|A^{\frac{\beta}{2}}[\Lambda y](t)\big| &\le \big|A^{\frac{\beta}{2}} e^{-tA} y_0\big| + C_1 \int_0^t e^{-a(t-s)} \big[1 + |A^{\frac{\beta}{2}} y(s)|\big]\, ds \\ &\quad + C_2 R \int_0^t \frac{e^{-a(t-s)}}{(t-s)^{\beta}} ds + \left| \int_0^t A^{\frac{\beta}{2}} e^{-(t-s)A} A^{-\frac{\beta}{2}} B\big(A^{\frac{\beta}{2}} y(s), \alpha_1(s)\big)\, dW(s) \right|. \end{aligned}$$

Then, taking the mean value of the square of the terms of this last inequality and using the isometry formula for stochastic integrals, we get

$$\begin{aligned} \mathbb{E}\Big|A^{\frac{\beta}{2}}[\Lambda y](t)\Big|^2 &\le C_3 \Big[\big|A^{\frac{\beta}{2}} e^{-tA} y_0\big|^2 + \int_0^t \big[1 + \mathbb{E}\big|A^{\frac{\beta}{2}} y(s)\big|^2\big]\, ds \\ &\quad + R^2 + \int_0^t \frac{1}{(t-s)^{\beta}} \big[1 + \mathbb{E}\big|A^{\frac{\beta}{2}} y(s)\big|^2\big]\, ds \Big], \end{aligned} \tag{5.6}$$

where $C_3 > 0$ is a suitable constant, since

$$\int_0^t \frac{e^{-a(t-s)}}{(t-s)^{\beta}}\, ds$$

is bounded independently of $t > 0$. Integrating over $[0,T]$ we obtain, for suitable $C_4 > 0$,

$$\begin{aligned} \|\Lambda y\|^2_{M^2\left(0,T;D\left(A^{\frac{\beta}{2}}\right)\right)} &= \int_0^T \mathbb{E}\left|A^{\frac{\beta}{2}}[\Lambda y](t)\right|^2 dt \\ &\le C_4 \Big[|y_0|^2 T^{1-\beta} + T^2 + T + T^{2-\beta} \\ &\quad + \int_0^T \int_0^t \left[1 + \frac{1}{(t-s)^{\beta}}\right] \mathbb{E}\big|A^{\frac{\beta}{2}} y(s)\big|^2\, ds \Big]. \end{aligned}$$

Moreover, since

$$\begin{aligned} \int_0^T \int_0^t \left[1 + \frac{1}{(t-s)^{\beta}}\right] \mathbb{E}\big|A^{\frac{\beta}{2}} y(s)\big|^2 ds\, dt &= \int_0^T \mathbb{E}\big|A^{\frac{\beta}{2}} y(s)\big|^2 \int_s^T \left[1 + \frac{1}{(t-s)^{\beta}}\right] dt\, ds \\ &= \int_0^T \mathbb{E}|A^{\frac{\beta}{2}} y(s)|^2 \left[T - s + \frac{(T-s)^{1-\beta}}{1-\beta}\right] ds, \end{aligned}$$

it finally follows that, for some modulus ω,

$$\|\Lambda y\|^2_{M^2\left(0,T;D\left(A^{\frac{\beta}{2}}\right)\right)} \le \omega(T) \left[1 + |y_0|^2 + \|y\|^2_{M^2\left(0,T;D\left(A^{\frac{\beta}{2}}\right)\right)}\right].$$

We now prove that Λ is a contraction on $M^2(0,T;D(A^{\frac{\beta}{2}}))$ when T is sufficiently small. Let $y_1(\cdot), y_2(\cdot) \in M^2(0,T;D(A^{\frac{\beta}{2}}))$. Then, arguing as above, we have

$$\mathbb{E}\left|A^{\frac{\beta}{2}}\big(\Lambda y_1(t) - \Lambda y_2(t)\big)\right|^2 \le C_4 \int_0^t \left(1 + \frac{1}{(t-s)^\beta}\right) \mathbb{E}\left|A^{\frac{\beta}{2}}\big(y_1(s) - y_2(s)\big)\right|^2 ds$$

for some constant $C_4 > 0$, which implies

$$\|\Lambda y_1 - \Lambda y_2\|_{M^2\left(0,T;D\left(A^{\frac{\beta}{2}}\right)\right)} \le \omega_1(T)\, \|y_1 - y_2\|_{M^2\left(0,T;D\left(A^{\frac{\beta}{2}}\right)\right)}$$

for some modulus ω_1. This implies that Λ is a contraction on $M^2(0,T;D(A^{\frac{\beta}{2}}))$ for small T. The existence of a unique solution in $M^2(0,T;D(A^{\frac{\beta}{2}}))$ for general $T > 0$ follows by repeating the argument a finite number of times. Finally this implies the existence of a unique solution $y(\cdot\,; y_0, \alpha)$ of (5.5) defined on $[0,+\infty)$ and such that $y(\cdot\,; y_0, \alpha) \in M^2(0,T;D(A^{\frac{\beta}{2}}))$ for every $T > 0$. The proof of continuity of trajectories is exactly the same as in the proof of Theorem 5.4. □

We conclude this section with some estimates for the solution of (5.5). First we recall a well-known generalization of the Gronwall lemma (see [29, p. 188]).

LEMMA 5.6. *Let $T \in (0,+\infty]$ and let $a_0 : [0,T] \to \mathbb{R}$ be a locally integrable function. Assume that $\varphi : [0,T] \to \mathbb{R}$ is a locally integrable function satisfying the inequality, for some $\eta \in (0,1)$,*

$$\varphi(t) \le a_0(t) + b_0 \int_0^t \Big[1 + \frac{1}{(t-s)^\eta}\Big]\varphi(s)\, ds$$

for a given constant $b_0 > 0$. Then there exists a positive constant $C_0 = C_0(b_0,\eta)$ such that

$$\varphi(t) \le a_0(t) + C_0 \int_0^t \frac{e^{C_0(t-s)}}{(t-s)^\eta} a_0(s)\, ds.$$

PROPOSITION 5.7. *Assume that Hypothesis 5.1 holds. Let $T > 0$, $y_0 \in X$. Then there exists a constant $C(T,y_0)$ such that, for all $t \in (0,T]$ and all $\alpha \in \mathcal{U}_{ad}(0,+\infty;U)$, we have*

$$\mathbb{E}\big|A^{\frac{\beta}{2}} y(t;y_0,\alpha)\big|^2 \le C(T,y_0)\left(1 + \frac{1}{t^\beta}\right). \tag{5.7}$$

Moreover, for every $\gamma \in (0, 1-\beta)$, there exists a constant $C_\gamma(T,y_0) > 0$ such that, for all $t \in (0,T]$ and $\alpha \in \mathcal{U}_{ad}(0,+\infty;U)$, we have

$$\int_0^t \left(1 + \frac{1}{(t-s)^{\beta+\gamma}}\right) \mathbb{E}\big|A^{\frac{\beta}{2}} y(s;y_0,\alpha)\big|^2 ds \le C_\gamma(T,y_0)\left(1 + \frac{1}{t^\beta}\right). \tag{5.8}$$

Proof. We use the arguments from the proof of Proposition 5.5. Let $y_0 \in X$, $T > 0$, $\alpha \in \mathcal{U}_{ad}(0,T;U)$, $y(\cdot) = y(\cdot;y_0,\alpha)$ and $t \in (0,T]$. The estimate (5.6) implies that there exist some $C > 0$ and then some $C(T) > 0$ such that

$$\begin{aligned}\mathbb{E}\big|A^{\frac{\beta}{2}} y(t)\big|^2 &\le C\left[1 + t + t^{1-\beta} + \big|A^{\frac{\beta}{2}} e^{-tA} y_0\big|^2 + \int_0^t \left(1 + \frac{1}{(t-s)^\beta}\right) \mathbb{E}\big|A^{\frac{\beta}{2}} y(s)\big|^2 ds\right] \\ &\le C(T)\left(1 + \frac{|y_0|^2}{t^\beta} + \int_0^t \left(1 + \frac{1}{(t-s)^\beta}\right) \mathbb{E}\big|A^{\frac{\beta}{2}} y(s)\big|^2 ds\right).\end{aligned}$$

We apply Lemma 5.6 and we obtain for a suitable $\overline{C}(T, y_0) > 0$ that

$$\begin{aligned}\mathbb{E}\big|A^{\frac{\beta}{2}} y(t)\big|^2 &\le \overline{C}(T, y_0)\left(1 + \frac{1}{t^\beta} + \int_0^t \frac{1}{(t-s)^\beta}\left(1 + \frac{1}{s^\beta}\right) ds\right) \\ &= \overline{C}(T, y_0)\left(1 + \frac{1}{t^\beta} + \frac{t^{1-\beta}}{1-\beta} + \int_0^t \frac{1}{(t-s)^\beta}\frac{1}{s^\beta}\, ds\right).\end{aligned}$$

However,

$$\int_0^t \frac{1}{(t-s)^\beta}\frac{1}{s^\beta}\, ds = t^{1-2\beta}\int_0^1 \frac{1}{(1-s)^\beta}\frac{1}{s^\beta}\, ds,$$

and this last integral is bounded so that, since $t^{1-2\beta} \le t^{-\beta}T^{1-\beta}$, we obtain the desired result.

Now, let $\gamma \in (0, 1-\beta)$. We have by (5.7)

$$\int_0^t \frac{1}{(t-s)^{\beta+\gamma}}\mathbb{E}\big|A^{\frac{\beta}{2}} y(s)\big|^2\, ds \le C(T, y_0)\int_0^t \frac{1}{(t-s)^{\beta+\gamma}}\left(1 + \frac{1}{s^\beta}\right) ds.$$

We proceed as above and the result follows. □

5.3. Properties of the value function. We now consider the stochastic optimal control problem of minimizing the functional

$$J(x_0; \alpha) = \mathbb{E}\int_0^{+\infty} e^{-\lambda t} L\big(x(t; x_0, \alpha), \alpha(t)\big)\, dt, \qquad x_0 \in X \tag{5.9}$$

over all functions $\alpha \in \mathcal{U}_{ad}(0, +\infty; U)$ (called controls). Here $x(\cdot; x_0, \alpha)$ is the mild solution of equation (5.1), i.e., the solution of the integral equation (5.2). The discount factor λ is positive and L satisfies the following assumptions:

$$\begin{aligned}&\text{(i)} \quad L \in C(X \times U), \ \ |L(x, \alpha)| \le C_L \quad \text{for all } (x, \alpha) \in X \times U; \\ &\text{(ii)} \quad |L(x_1, \alpha) - L(x_2, \alpha)| \le \omega_L(|x_1 - x_2|) \quad \text{for all } \alpha \in U, \ x_1, x_2 \in X,\end{aligned} \tag{5.10}$$

for some positive constant C_L and some modulus ω_L.

The value function

$$v(x_0) = \inf\big\{J(x_0; \alpha);\ \alpha \in \mathcal{U}_{ad}(0, +\infty; U)\big\}, \quad x_0 \in X \tag{5.11}$$

should solve the associated Hamilton–Jacobi equation

$$\lambda v(x) + \big\langle Ax, Dv(x)\big\rangle + H\big(x, Dv(x), D^2 v(x)\big) = 0 \quad \text{for } x \in X, \tag{5.12}$$

where the Hamiltonian $H : X \times D(A^\beta) \times A^{-\frac{\beta}{2}}\Sigma(X)A^{-\frac{\beta}{2}} \to \mathbb{R}$ is given by

$$\begin{aligned}H(x, p, S) = \sup_{\alpha \in U}\Big\{ &-\frac{1}{2}\operatorname{Tr}\big[B^*(x, \alpha_1)SB(x, \alpha_1)\big] \\ &- \big\langle b(x, \alpha_1), p\big\rangle - \big\langle C\alpha_2, A^\beta p\big\rangle - L(x, \alpha)\Big\}.\end{aligned}$$

The connection between the control problem introduced above and stochastic boundary control problems is discussed in section 5.4.

By inserting the change of variable (5.4) in the cost functional (5.9), we obtain a new optimal control problem whose value function u is given by

$$u(y_0) = \inf_{\alpha(\cdot)\in\mathcal{U}_{ad}(0,+\infty;U)} \mathbb{E}\int_0^{+\infty} e^{-\lambda t} L\big(A^{\frac{\beta}{2}} y(t;y_0,\alpha),\alpha(t)\big)\,dt. \tag{5.13}$$

The value functions u and v are related by the formula

$$v(x) = u\big(A^{-\frac{\beta}{2}}x\big) \quad \text{for all } x\in X. \tag{5.14}$$

But if v solves (5.12) then u should solve

$$\lambda u(y) + \big\langle Ay, Du(y)\big\rangle + H\big(A^{\frac{\beta}{2}}y, A^{-\frac{\beta}{2}}Du(y), A^{-\frac{\beta}{2}}D^2u(y)A^{-\frac{\beta}{2}}\big) = 0. \tag{5.15}$$

By setting $G_H(y,q,S) = H(A^{\frac{\beta}{2}}y, A^{-\frac{\beta}{2}}q, A^{-\frac{\beta}{2}}SA^{-\frac{\beta}{2}})$, (5.15) can be written as

$$\lambda u(y) + \big\langle Ay, Du(y)\big\rangle + G_H\big(y, Du(y), D^2u(y)\big) = 0 \tag{5.16}$$

where now $G_H : D(A^{\frac{\beta}{2}}) \times D(A^{\frac{\beta}{2}}) \times \Sigma(X) \to \mathbb{R}$ and

$$G_H(y,q,S) = \sup_{\alpha\in U}\Big\{ -\frac{1}{2}\operatorname{Tr}\Big[\Big(A^{-\frac{\beta}{2}}B\big(A^{\frac{\beta}{2}}y,\alpha_1\big)\Big)^* S\Big(A^{-\frac{\beta}{2}}B\big(A^{\frac{\beta}{2}}y,\alpha_1\big)\Big)\Big] - \big\langle b\big(A^{\frac{\beta}{2}}y,\alpha_1\big), A^{-\frac{\beta}{2}}q\big\rangle - \big\langle C\alpha_2, A^{\frac{\beta}{2}}q\big\rangle - L\big(A^{\frac{\beta}{2}}y,\alpha_1\big)\Big\}.$$

The goal of this section is to prove that v is the unique viscosity solution of (5.12). In fact we will prove more. We will prove that u is the unique viscosity solution of (5.16) and that it satisfies the dynamic programming principle in X. To obtain the latter for v we require only that the dynamic programming principle for u be satisfied on $D(A^{\frac{\beta}{2}})$. Therefore in fact we prove that the transformed problem itself has a control interpretation and we think that this fact may be of independent interest.

THEOREM 5.8. *Assume that Hypotheses* 3.1 *and* 5.1 *and* (5.10) *hold. Then the value function v defined in* (5.11) *is the unique $BUC(X_{-\eta})$ viscosity solution (for every $\eta\in(0,1)$) of the Hamilton–Jacobi equation* (5.12). *Moreover, the dynamic programming principle holds for u and v, i.e., for $x\in X$ and all $T>0$,*

$$v(x) = \inf_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)} \mathbb{E}\left\{\int_0^T e^{-\lambda t}L\big(x(t;x,\alpha),\alpha(t)\big)\,dt + e^{-\lambda T}v\big(x(T;x,\alpha)\big)\right\}$$

and

$$u(y) = \inf_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)} \mathbb{E}\left\{\int_0^T e^{-\lambda t}L\big(A^{\frac{\beta}{2}}y(t;y,\alpha),\alpha(t)\big)\,dt + e^{-\lambda T}u\big(y(T;y,\alpha)\big)\right\}.$$

We will prove this theorem by the approximation argument used in the proof of the existence of Theorem 3.8. We need a preliminary lemma.

DEFINITION 5.9. *Let $N\ge 1$ and $y_0\in X$. For a given $\alpha\in\mathcal{U}_{ad}(0,+\infty;U)$, we define $y_N(\cdot;y_0,\alpha)\in M^2(0,+\infty;D(A^{\frac{\beta}{2}}))$ to be the solution of*

$$\begin{aligned} y_N(t) &= e^{-tA}P_Ny_0 + A^{-\frac{\beta}{2}}\int_0^t e^{-(t-s)A}P_Nb\big(A^{\frac{\beta}{2}}y_N(s),\alpha_1(s)\big)\,ds \\ &\quad + A^{\frac{\beta}{2}}\int_0^t e^{-(t-s)A}P_NC\alpha_2(s)\,ds \\ &\quad + A^{-\frac{\beta}{2}}\int_0^t e^{-(t-s)A}P_NB(A^{\frac{\beta}{2}}y_N(s),\alpha_1(s))\,dW(s). \end{aligned} \tag{5.17}$$

LEMMA 5.10. *Let $y_0 \in X$, and for $\alpha \in \mathcal{U}_{ad}(0,+\infty;U)$ denote by $y(\cdot;y_0,\alpha)$ the solution of (5.5). Then, for all $T>0$, we have*

$$\lim_{N\to+\infty} \sup_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)} \left\|y_N(\cdot;y_0,\alpha)-y(\cdot;y_0,\alpha)\right\|_{M^2\left(0,T;D\left(A^{\frac{\beta}{2}}\right)\right)} = 0.$$

Proof. Let $\alpha \in \mathcal{U}_{ad}(0,+\infty;U)$, $y_N(\cdot)=y_N(\cdot;y_0,\alpha)$, and $y(\cdot)=y(\cdot;y_0,\alpha)$. Fix γ in $(0,1-\beta)$. Then, for $t\in(0,T)$, we have

$$\begin{aligned}
A^{\frac{\beta}{2}}\big(y_N(t)-y(t)\big) &= -A^{\frac{\beta}{2}}e^{-tA}Q_Ny_0 - Q_NA^{-\frac{\gamma}{2}}\int_0^t A^{\frac{\gamma}{2}}e^{-(t-s)A}Q_Nb\big(A^{\frac{\beta}{2}}y(s),\alpha_1(s)\big)\,ds\\
&\quad - Q_NA^{-\frac{\gamma}{2}}\int_0^t A^{\beta+\frac{\gamma}{2}}e^{-(t-s)A}Q_NC\alpha_2(s)\,ds\\
&\quad - Q_NA^{-\frac{\gamma}{2}}\int_0^t A^{\frac{\beta+\gamma}{2}}e^{-(t-s)A}A^{-\frac{\beta}{2}}Q_NB\big(A^{\frac{\beta}{2}}y(s),\alpha_1(s)\big)\,dW(s)\\
&\quad + \int_0^t e^{-(t-s)A}P_N\big[b\big(A^{\frac{\beta}{2}}y_N(s),\alpha_1(s)\big)-b\big(A^{\frac{\beta}{2}}y(s),\alpha_1(s)\big)\big]\,ds\\
&\quad + \int_0^t A^{\frac{\beta}{2}}e^{-(t-s)A}A^{-\frac{\beta}{2}}P_N\big[B\big(A^{\frac{\beta}{2}}y_N(s),\alpha_1(s)\big)\\
&\qquad\qquad - B\big(A^{\frac{\beta}{2}}y(s),\alpha_1(s)\big)\big]\,dW(s)
\end{aligned}$$

which yields, for a suitable $C_\gamma(T)>0$,

$$\begin{aligned}
&\mathbb{E}\big|A^{\frac{\beta}{2}}\big(y_N(t)-y(t)\big)\big|^2\\
&\quad\le C_\gamma(T)\left[\frac{1}{t^\beta}\big|Q_Ny_0\big|^2 + \big\|Q_NA^{-\frac{\gamma}{2}}\big\|^2\left(1+\int_0^t\left(1+\frac{1}{(t-s)^{\beta+\gamma}}\right)\mathbb{E}|A^{\frac{\beta}{2}}y(s)|^2ds\right)\right.\\
&\qquad\left.+\int_0^t\left(1+\frac{1}{(t-s)^\beta}\right)\mathbb{E}\big|A^{\frac{\beta}{2}}\big(y_N(s)-y(s)\big)\big|^2ds\right].
\end{aligned}$$

Since $A^{-\gamma/2}$ is compact, $\|Q_NA^{-\gamma/2}\|\to 0$ as $N\to+\infty$, and by using (5.8) we can rewrite the above inequality as follows:

$$\begin{aligned}
\mathbb{E}\big|A^{\frac{\beta}{2}}\big(y_N(t)-y(t)\big)\big|^2 &\le C_{\gamma,N}(T,y_0)\left(1+\frac{1}{t^\beta}\right)\\
&\quad+\int_0^t\left(1+\frac{1}{(t-s)^\beta}\right)\mathbb{E}\big|A^{\frac{\beta}{2}}\big(y_N(s)-y(s)\big)\big|^2\,ds,
\end{aligned}$$

where $C_{\gamma,N}(T,y_0)\to 0$ as $N\to+\infty$. Using Lemma 5.6 and arguing as in the proof of Proposition 5.7, we finally obtain, for a suitable $C>0$,

$$\mathbb{E}\big|A^{\frac{\beta}{2}}\big(y_N(t)-y(t)\big)\big|^2 \le C_{\gamma,N}(T,y_0)C\left(1+\frac{1}{t^\beta}\right), \tag{5.18}$$

so that

$$\sup_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)}\|y_N-y\|_{M^2\left(0,T;D\left(A^{\frac{\beta}{2}}\right)\right)}\to 0 \quad\text{as } N\to+\infty. \qquad \square$$

Proof of Theorem 5.8. We notice that under our assumptions (5.16) has a unique viscosity solution in $BUC(X_{-\eta})$ for every $\eta\in(0,1-\beta)$. To verify that the value

function (5.13) is the solution, we consider the approximating problems

$$\lambda u_N + \langle Ax, Du_N\rangle + G_H(x, Du_N, D^2u_N) = 0 \quad \text{in } X_N. \tag{5.19}$$

Equation (5.19) is the one used in the proof of Theorem 3.8 and it is easy to see that it is the equation in X_N corresponding to the control problem with evolution given by (5.17). Therefore, by the finite dimensional theory (see [24, 35, 38] for results and techniques that adapt to our situation to obtain the dynamic programming principle and Theorem 3.8), the function

$$u_N(y_0) = \inf_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)} \mathbb{E}\int_0^{+\infty} e^{-\lambda t} L\big(A^{\frac{\beta}{2}} y_N(t; y_0, \alpha), \alpha(t)\big)\, dt \tag{5.20}$$

is the unique viscosity solution of (5.19) in X_N and the dynamic programming principle holds for u_N, i.e., for every $y_0 \in X$, $T \geq 0$,

$$\begin{aligned} u_N(y_0) = \inf_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)} \mathbb{E}\Big\{ &\int_0^T e^{-\lambda t} L\big(A^{\frac{\beta}{2}} y_N(t; y_0, \alpha), \alpha(t)\big)\, dt \\ &+ e^{-\lambda T} u_N\big(y_N(T; y_0, \alpha)\big)\Big\}. \end{aligned} \tag{5.21}$$

Since for every $y_0 \in X$ $y_N(t; y_0, \alpha) = P_N y_N(t; P_N y_0, \alpha)$, extending u_N to X by putting $u_N(y) = u_N(P_N y)$ we obtain (5.20) and (5.19) for every $y_0 \in X$. Moreover, from the proof of existence of Theorem 3.8, we know that for every $\eta \in (0, 1-\beta)$ and $N \geq 1$,

$$\|u_N\|_\infty \leq \frac{K}{\lambda}, \qquad \big|u_N(x) - u_N(y)\big| \leq \sigma_\eta\big(|x-y|_{-\eta}\big) \tag{5.22}$$

for some modulus σ_η and $u_N \to \overline{u}$ uniformly on bounded sets, where $\overline{u}$ is the unique viscosity solution of (5.16). Therefore it remains to show that $u = \overline{u}$ which is an immediate consequence of the following lemma.

LEMMA 5.11. *u_N converges pointwise to u as $N \to \infty$.*

Proof. Let $y_0 \in X$, $N \in \mathbb{N}$. For every $T > 0$,

$$\begin{aligned} &\big|u_N(y_0) - u(y_0)\big| \\ &\quad\leq \sup_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)} \int_0^T e^{-\lambda t}\mathbb{E}\,\omega_L\big(|A^{\frac{\beta}{2}}(y_N(t; y_0, \alpha) - y(t; y_0, \alpha))|\big)\, dt + 2C_L\frac{e^{-\lambda T}}{\lambda}. \end{aligned}$$

Let $\varepsilon > 0$. There exists $T_\varepsilon > 0$ such that, for all N,

$$\begin{aligned} &\big|u_N(y_0) - u(y_0)\big| \\ &\quad\leq \sup_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)} \int_0^{T_\varepsilon} e^{-\lambda t}\mathbb{E}\,\omega_L\big(|A^{\frac{\beta}{2}}(y_N(t; y_0, \alpha) - y(t; y_0, \alpha))|\big)\, dt + \varepsilon. \end{aligned}$$

Now, by using the properties of moduli and Schwarz inequality, we know that for all $\sigma > 0$, there exists $C_\sigma > 0$ such that

$$\begin{aligned} &\int_0^{T_\varepsilon} e^{-\lambda t}\mathbb{E}\,\omega_L\big(|A^{\frac{\beta}{2}}(y_N(t; y_0, \alpha) - y(t; y_0, \alpha))|\big)\, dt \\ &\qquad\leq \frac{\sigma}{\lambda} + C_\sigma\sqrt{T_\varepsilon}\big\|y_N(\cdot; y_0, \alpha) - y(\cdot; y_0, \alpha)\big\|_{M^2\left(0,T_\varepsilon;D\left(A^{\frac{\beta}{2}}\right)\right)} \end{aligned}$$

for all $N \in \mathbb{N}$ and all $\alpha \in \mathcal{U}_{ad}(0,+\infty;U)$. By letting N go to infinity, then σ to 0, and finally ε to 0, we conclude the proof of the Lemma 5.11. □

To finish the proof of Theorem 5.8 we only have to show the dynamic programming principle for u. By (5.21), we have

$$\begin{aligned}\Big|u_N(y_0) - \inf_{\alpha\in\mathcal{U}_{ad}} \mathbb{E}\Big\{ \int_0^T e^{-\lambda t} L\big(A^{\frac{\beta}{2}} y(t;y_0,\alpha),\alpha(t)\big)\,dt + e^{-\lambda T} u\big(y(T;y_0,\alpha)\big)\Big\}\Big| \\ \le \sup_{\alpha\in\mathcal{U}_{ad}} \mathbb{E}\int_0^T e^{-\lambda t}\omega_L\big(|A^{\frac{\beta}{2}}(y_N(t;y_0,\alpha) - y(t;y_0,\alpha))|\big)\,dt \\ + e^{-\lambda T}\sup_{\alpha\in\mathcal{U}_{ad}} \mathbb{E}\big|u_N\big(y_N(T;y_0,\alpha)\big) - u\big(y(T;y_0,\alpha)\big)\big|.\end{aligned}$$

As in the proof of Lemma 5.11, the first term of the right-hand side converges to 0 when N goes to infinity. For the second term, we proceed as follows:

$$\begin{aligned}\mathbb{E}\big|u_N\big(y_N(T;y_0,\alpha)\big) - u\big(y(T;y_0,\alpha)\big)\big| \le \mathbb{E}\big|u_N\big(y_N(T;y_0,\alpha)\big) - u_N\big(y(T;y_0,\alpha)\big)\big| \\ + \mathbb{E}\big|u_N\big(y(T;y_0,\alpha)\big) - u\big(y(T;y_0,\alpha)\big)\big|.\end{aligned}$$

The first term of the right-hand side converges uniformly to 0 when N goes to infinity by (5.18) and (5.22). It remains to prove that

$$\sup_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)} \mathbb{E}\big|u_N\big(y(T;y_0,\alpha)\big) - u\big(y(T;y_0,\alpha)\big)\big|$$

goes to 0 when N goes to infinity. By Proposition 5.7, estimate (5.7), $\mathbb{E}|y(T;y_0,\alpha)|^2$ is bounded by a constant $C(T,y_0) > 0$ which does not depend on $\alpha \in \mathcal{U}_{ad}(0,+\infty;U)$. Hence, for all $R > 0$,

$$\mathbf{P}\big\{\big|y(T;y_0,\alpha)\big| > R\big\} \le \frac{C(T,y_0)}{R^2}.$$

Let $\varepsilon > 0$ and choose $R_\varepsilon > 0$ sufficiently large so that this probability will be smaller than ε. Then

$$\sup_{\alpha\in\mathcal{U}_{ad}(0,+\infty;U)} \mathbb{E}\big|u_N\big(y(T;y_0,\alpha)\big) - u\big(y(T;y_0,\alpha)\big)\big| \le \frac{2C_L}{\lambda}\varepsilon + \sup_{|y|\le R_\varepsilon}\big|u_N(y) - u(y)\big|.$$

We conclude by letting $N \to +\infty$ since ε was arbitrary. □

5.4. Examples of stochastic boundary control problems. We now present examples of problems where the operator A is the Laplacian with Dirichlet boundary conditions, reminding that our results also hold true for the case of Laplacian with Neumann boundary conditions (which is in some sense easier to treat since it gives rise to a lower exponent β in the Bellman equation). For further examples we refer to the book of Lasiecka and Triggiani [36]. This book deals with deterministic boundary control problems. However, it can be checked that our results apply to suitable stochastic perturbations of examples belonging to the "first abstract class" treated in the book.

We refer the reader to the papers of Tessitore [47, 48] and Duncan, Maslowski, and Pasik-Duncan [19, 20] for more about stochastic boundary control problems and to Da Prato and Ichikawa [16], Flandoli [22, 23], Fattorini [21], and Zabczyk [49] for deterministic boundary control problems. However, to the best of our knowledge, the results presented in our paper are the first of this kind in the literature.

Example. Let $\Omega \subset \mathbb{R}^N$ be an open, connected, and bounded set with smooth boundary. Consider, as in the introduction, the following stochastic controlled PDE

(5.23)
$$\begin{cases} \dfrac{\partial x}{\partial t}(t,\xi) = \Delta_\xi x(t,\xi) \\ \qquad\qquad +f_1\left(x(t,\xi),\alpha_1(t,\xi)\right) + f_2\left(x(t,\xi),\alpha_1(t,\xi)\right)\dot{W}_Q(t,\xi) \quad \text{in } (0,\infty)\times\Omega, \\ x(0,\xi) = x_0(\xi) \qquad \text{on } \Omega, \\ x(t,\xi) = \alpha_2(t,\xi) \quad \text{on } (0,\infty)\times\partial\Omega, \end{cases}$$

where W_Q is a Wiener process with values in $L^2(\Omega)$ and with covariance operator Q, $x_0 \in L^2(\Omega)$, and the controls are $\alpha_1 \in M^0(0,\infty;L^2(\Omega))$, $\alpha_2 \in M^0(0,\infty;L^2(\partial\Omega))$, with $\|\alpha_2(s)\|_{L^2(\partial\Omega)} \le C_1$ for a given $C_1 > 0$. Moreover, $f_1 : \mathbb{R}^2 \to \mathbb{R}$ is a continuous function, Lipschitz continuous in the first variable, uniformly with respect to the second one. Assumptions on f_2 and Q will be specified later. Here we have two control functions. The first, indicated by α_1, is the "distributed" control, while the other, indicated by α_2, is the "boundary" control.

Using a standard procedure which can be found, e.g., in [3] and [10] for the deterministic case (the stochastic case does not need any substantial change), problem (5.23) may be rewritten in an abstract form by finding an equation similar to the one treated in section 5.1. Let $X = L^2(\Omega)$ be the state space, let $U_1 = L^2(\Omega), U_2 = L^2(\partial\Omega)$ be the spaces of control parameters, and let $\tilde{U}_2$ be the closed ball of U_2 of radius C_1. Let $U = U_1 \times \tilde{U}_2$. Then (5.23) becomes

(5.24)
$$\begin{cases} dx(s) = \left[-Ax(s) + b\big(x(s),\alpha_1(s)\big) + A\overline{C}\alpha_2(s)\right]ds + B\big(x(s),\alpha_1(s)\big)\,dW(s), \\ \qquad 0 < s < +\infty, \\ x(0) = x_0, \quad x_0 \in X, \end{cases}$$

where $\alpha \in M^0(0,\infty;U)$, A is the Laplace operator with zero Dirichlet boundary conditions, and $b : X \times U_1 \to X$ and $B : X \times U_1 \to \mathcal{L}(X)$ are defined as

$$\begin{aligned} b(x,\alpha_1)(\xi) &= f_1\big(x(\xi),\alpha_1(\xi)\big), \\ \big[B(x,\alpha_1)y\big](\xi) &= f_2\big(x(\xi),\alpha_1(\xi)\big)\big[[Q^{\frac{1}{2}}y](\xi)\big] \quad \text{for all } \xi \in \Omega,\ y \in L^2(\Omega), \end{aligned}$$

and finally $\overline{C} : U_2 \to X$ is a continuous linear operator, the Dirichlet operator.

Since f_1 is Lipschitz continuous in the first variable, uniformly with respect to the second one, b satisfies Hypothesis 5.1(ii). As for the diffusion term, we assume here that f_2 and Q are such that Hypotheses 5.1(iv) and (v) are satisfied. This is true, for example, if $N = 1, Q = I$, and f_2 is Lipschitz continuous in the first variable, uniformly with respect to the second one. Indeed, taking the orthonormal basis $\{e_k\}$ of eigenvectors of A (which is uniformly bounded in $L^\infty(\Omega)$), we have, for suitable $C_0 > 0$,

$$\left\|A^{-\frac{\beta}{2}}B(x,\alpha_1)\right\|^2_{\mathcal{L}_2(X)} = \sum_{k=1}^{+\infty}\left|A^{-\frac{\beta}{2}}B(x,\alpha_1)e_k\right|^2 = C_0\sum_{k=1}^{+\infty}\sum_{h=1}^{+\infty}h^{-2\beta}\big\langle B(x,\alpha_1)e_k,e_h\big\rangle^2.$$

Now, since B is self-adjoint,

$$\begin{aligned}\left\|A^{-\frac{\beta}{2}}B(x,\alpha_1)\right\|^2_{\mathcal{L}_2(X)} &= C_0\sum_{h=1}^{+\infty} h^{-2\beta}\left|B(x,\alpha_1)e_h\right|^2\\ &= C_0\sum_{h=1}^{+\infty} h^{-2\beta}\int_\Omega \left|f_2(x(\xi),\alpha_1(\xi))e_h(\xi)\right|^2 d\xi\end{aligned}$$

so, since $\|e_h(\xi)\|_\infty \le C_1$ for some positive constant C_1, we easily get that, for suitable $C_2 > 0$,

$$\left\|A^{-\frac{\beta}{2}}B(x,\alpha_1)\right\|^2_{\mathcal{L}_2(X)} \le C_2\big[1+|x|^2\big],$$

since $\beta > 3/4$. We can check similarly the other assumptions in Hypotheses 5.1(iv), (v). For $N \ge 2$ we need stronger assumptions on f_2. Furthermore, since Im $\overline{C} \subset D(A^\eta)$ (see, e.g., [40]) for $\eta \in (0, \frac{1}{4})$, setting $C = A^\eta\overline{C}$ we have that C is a continuous linear operator and $A\overline{C}\alpha_2 = A^\beta C\alpha_2$ for $\beta \in (\frac{3}{4}, 1)$, $\beta = 1-\eta$, so that we obtain an equation that falls into the class discussed in section 5.1.

Equation (5.24) makes sense only in the mild form, as explained in section 5.1, due to the presence of the unbounded term $A^\beta C\alpha_2$. Given $\lambda > 0$ and $l \in BUC(\mathbb{R}^2)$, we now define

$$L(x,\alpha_1) = \int_\Omega l\big(x(\xi),\alpha_1(\xi)\big)\,d\xi,$$

(assumptions (5.10) are then satisfied) and consider the problem of minimizing the cost functional

$$J(x_0;\alpha_1,\alpha_2) = \mathbb{E}\int_0^{+\infty} e^{-\lambda t}L\left(x(t;x_0,\alpha_1,\alpha_2),\alpha_1(t)\right)\,dt, \tag{5.25}$$

where $x(\cdot\,;x_0,\alpha)$ is the mild solution of the stochastic differential equation 5.24. The cost functional can be more general. The associated Hamilton–Jacobi–Bellman equation is now (1.1) where the Hamiltonian H is given by

$$\begin{aligned}&H(x,p,S)\\ &= \sup_{\alpha=(\alpha_1,\alpha_2)\in U}\left\{-\frac{1}{2}\mathrm{Tr}\ B^*(x,\alpha_1)SB(x,\alpha_1) - \langle b(x,\alpha_1),p\rangle - \langle C\alpha_2, A^\beta p\rangle - L(x,\alpha_1)\right\}.\end{aligned}$$

When f_2 is constant (and thus so is B) Hypothesis 5.1 holds in the following case.

HYPOTHESIS 5.12. *Let $\{e_k\}$ be an orthonormal basis in X, let B be linear and independent of x and α_1. Let A and B satisfy*

$$Ae_k = -\alpha_k e_k, \qquad BB^*e_k = \lambda_k e_k, \quad k \in \mathbb{N},$$

where $\{\alpha_k\}$ is a sequence of positive numbers increasing to $+\infty$ while $\{\lambda_k\}$ is a bounded sequence of nonnegative real numbers.

PROPOSITION 5.13. *Assume that Hypothesis* 5.12 *holds. Then Hypothesis* 5.1 *is satisfied if*

$$\sum_{k=1}^{\infty}\frac{\lambda_k}{\alpha_k^\beta} < +\infty. \tag{5.26}$$

For $\Omega = [0,\pi]^N$, the Laplace operator A satisfies Hypothesis 5.12 by taking, for $(n_1,\dots,n_N) \in \mathbb{N}^N$,

$$e_{n_1,\dots,n_N}(\xi) = \left(\frac{2}{\pi}\right)^{\frac{N}{2}} \sin n_1\xi_1 \cdots \sin n_N\xi_N \qquad \text{and} \qquad \alpha_{n_1,\dots,n_N}(\xi) = n_1^2 + \cdots + n_N^2$$

so that, by ordering the eigenvalues, we obtain

$$\alpha_k \approx k^{\frac{2}{N}} \quad \text{as } k \to +\infty.$$

Therefore condition 5.26 is fulfilled if for some small $\varepsilon > 0$ $\lambda_k = o(k^{\frac{2\beta}{N}-1-\varepsilon})$. When B is invertible this is possible only for $N = 1$. We remark that, differently from the case studied in [27], we can allow B to vary in a wider class, in particular B can have finite rank.

5.5. Concluding remarks. Second order Hamilton–Jacobi equations with second order terms being trace class have been studied in various papers (see, e.g., [2, 15, 28]). In some cases (e.g., when the second order term is linear and hypoelliptic) it is possible to prove existence and uniqueness of differentiable solutions, while in the general fully nonlinear case a theory of viscosity solutions is available (see [31, 39, 43]).

When the second order terms are not trace class there are no results about existence and uniqueness of viscosity solutions. However, in the papers [4, 7, 25] and [26] for the evolution case and [27] for the stationary case, it is proved that in some special cases these equations can be solved by using regularizing properties of transition semigroups associated with suitable Markov processes: in this way existence and uniqueness of differentiable solutions is proved and the theory finds applications to stochastic control problems allowing to prove existence of feedback controls. The stationary case is also treated in [11] where existence and uniqueness of a certain kind of weak solution is proved using variational methods in Gauss–Sobolev spaces. The assumptions in [11] are different from ours. The question arises naturally if it is possible to extend the theory of viscosity solutions to include the equations studied in [11, 27], and if the viscosity solution coincides with solutions proposed there. An answer to this question, though incomplete, is given by Theorem 5.14 below. The types of equations studied in [27] and here overlap, but neither of them contains the other. The main advantage of our approach is that it allows us to handle fully nonlinear equations. However, we pay the price of rather strong assumptions on the operator A.

To be more precise, we recall that in [27] the equation

$$\lambda v(x) = \frac{1}{2}\big[QD^2v(x)\big] + \big\langle Ax + F(x), Dv(x)\big\rangle - H_0\big(Dv(x)\big) + \psi(x), \quad x \in X \tag{5.27}$$

was considered (see [27] for the precise setting). By combining the results and techniques of this paper and [27] the following result holds, which we state here without a proof.

THEOREM 5.14. *Assume that $-A$ satisfies Hypothesis* 3.1 *and moreover that the operator $A^{-\beta}Q$ is nuclear for some $\beta \in (0,1)$. Assume also that F is Lipschitz continuous and H_0 is uniformly continuous on bounded subsets of X. Then, for every $\lambda > 0$ and $\psi \in BUC(X)$, there exists a unique $BUC(X_{-\eta})$ viscosity solution (for every $\eta < 1$) of 5.27. Moreover, if the hypotheses of Theorems* 3.3 *and* 3.11 *in* [27]

hold then the viscosity solution is Fréchet differentiable with respect to x and coincides with the mild-strong one of the above theorems.

It is proved in [27, Theorem 5.7] that the solution v can be used to construct an optimal control in feedback form given by

$$\alpha^*(s) = DH_0\big(Dv\big(y^*(t)\big)\big),$$

where $y^*(\cdot)$ solves a closed-loop equation. To our knowledge this is the only nontrace class infinite dimensional case when the solution is regular enough to allow construction of an optimal control. Moreover there are no general results available about optimality conditions (see [37] for the finite dimensional case). It is an open problem if such results can be proved in cases of boundary control or stronger nonlinearities in the Bellman equation, i.e., the cases tractable only by viscosity solutions introduced here. We plan to come back to these questions in the future.

Acknowledgments. The authors would like to thank Prof. G. Da Prato for his hospitality and for providing excellent conditions for work in Scuola Normale Superiore di Pisa. We also wish to thank Prof. J. Zabczyk for helpful suggestions and remarks on the paper.

A MODIFIED FORWARD-BACKWARD SPLITTING METHOD FOR MAXIMAL MONOTONE MAPPINGS*

PAUL TSENG†

Abstract. We consider the forward-backward splitting method for finding a zero of the sum of two maximal monotone mappings. This method is known to converge when the inverse of the forward mapping is strongly monotone. We propose a modification to this method, in the spirit of the extragradient method for monotone variational inequalities, under which the method converges assuming only the forward mapping is (Lipschitz) continuous on some closed convex subset of its domain. The modification entails an additional forward step and a projection step at each iteration. Applications of the modified method to decomposition in convex programming and monotone variational inequalities are discussed.

Key words. maximal monotone mapping, forward-backward splitting method, extragradient method, variational inequality, convex programming, decomposition

1. Introduction.

Let $\mathcal{H}$ be a real Hilbert space with inner product $\langle x, y\rangle$ and induced norm $\|x\| = \sqrt{\langle x, x\rangle}$ for $x, y \in \mathcal{H}$. (In the case of $\mathcal{H} = \Re^n$, the space of n-dimensional real column-vectors, $\langle \cdot, \cdot \rangle$ is the Euclidean inner product.) A set-valued mapping (also called "operator") T on $\mathcal{H}$, which is written as $T : \mathcal{H} \rightrightarrows \mathcal{H}$, associates each point $x \in \mathcal{H}$ with a subset $T(x)$ of $\mathcal{H}$. Denote $\mathrm{dom}T = \{x \in \mathcal{H} : T(x) \neq \emptyset\}$. The mapping T is called *monotone* if

$$\langle x - x', y - y' \rangle \geq 0 \qquad \text{for all } x, x' \in \mathrm{dom}T, y \in T(x), y' \in T(x'),$$

and T is called *maximal monotone* if its graph

$$\mathrm{gph}T = \{(x, y) \in \mathcal{H} \times \mathcal{H} : y \in T(x)\}$$

is not properly contained in the graph of any other monotone mapping on $\mathcal{H}$. The inverse mapping T^{-1} defined by $T^{-1}(y) = \{x \in \mathcal{H} : y \in T(x)\}$ is, by symmetry, maximal monotone on $\mathcal{H}$ whenever T is. Maximal monotone mappings have been well studied by Minty, Moreau, Rockafellar, and others (see [4, 36, 38, 61], [47, Chap. 12], and references therein). One well-known example of such a mapping is $T = \partial f$, where ∂f is the subdifferential of a proper closed convex function $f : \mathcal{H} \mapsto (-\infty, \infty]$ [43]. Then, $0 \in \partial f(x)$ if and only if x is a minimizer of f. Another example is $T = F + N_C$, where C is a nonempty closed convex set in $\mathcal{H}$, F is a maximal monotone mapping that is single-valued and continuous on C, and N_C is the normal cone mapping $N_C(x) = \{y \in \mathcal{H} : \langle y, x' - x\rangle \leq 0 \text{ for all } x' \in C\}$ for $x \in C$ and is empty otherwise. Then, $0 \in F(x) + N_C(x)$ if and only if $x \in C$ satisfies the variational inequalities of $\langle F(x), x' - x\rangle \geq 0$ for all $x' \in C$.

In general, we are interested in finding, for a given maximal monotone mapping T on $\mathcal{H}$, an $x \in \mathcal{H}$ satisfying $0 \in T(x)$. A classical method for doing this is the proximal point algorithm, proposed by Martinet [27, 28] and generalized by Rockafellar [44, 45]:

$$x^{k+1} = (I + \alpha_k T)^{-1}(x^k), \qquad k = 0, 1, \ldots,$$

where $\alpha_k > 0$. This method and its dual version in the context of convex programming, the method of multipliers of Hesteness and Powell, have been extensively studied (see [1, 15, 18, 21] and references therein) and are known to yield as special cases decomposition methods such as the method of partial inverses [48, 53], the Douglas–Rachford splitting method, and the alternating direction method of multipliers [8, 9, 10, 22]. In the case of $T = A + B$, where A and B are maximal monotone mappings on $\mathcal{H}$ with A single-valued on $\mathrm{dom}A \supset \mathrm{dom}B$, the forward-backward (F-B) splitting method

$$x^{k+1} = (I + \alpha_k B)^{-1}(I - \alpha_k A)(x^k), \qquad k = 0, 1, \ldots,$$

where $\alpha_k > 0$, was proposed by Lions and Mercier [22], by Passty [37], and, in a dual form for convex programming, by Han and Lou [16]. In the case where $B = N_C$, with C a nonempty closed convex set in $\mathcal{H}$, this method reduces to a projection method proposed by Sibony [49] for monotone variational inequalities and, in the further case where F is the gradient of a differentiable convex function, it reduces to a gradient projection method of Goldstein and of Levitin and Polyak [1]. This method was extensively analyzed by Mercier [30] and Gabay [13] and was further studied in [5, 6, 20, 33, 34, 39, 56, 57]. In particular, Mercier and Gabay showed that if A^{-1} is strongly monotone with modulus $\gamma > 0$, then the iterates x^k converge weakly to a solution, provided, α_k is constant and less than 2γ. And if in addition A is strongly monotone, then x^k converge strongly to the unique solution [30, p. 24], [13, Thm. 6.1] (also see [12, Chap. 6], [34], and, for the case of nonconstant α_k, [6, 57]). If A is Lipschitz continuous on $\mathrm{dom}A = \mathcal{H}$ and T is strongly monotone, Chen and Rockafellar [6] showed that the iterates x^k converge strongly at a linear rate to the unique solution provided α_k is less than some threshold depending on the Lipschitz constant and the modulus of strong monotonicity (also see Chen's thesis [5] and, for the case A is Lipschitz continuous and strongly monotone, see [30, p. 26], [39, Prop. 3.2]). Moreover, their method incorporates scaling and they derive an explicit formula for the convergence ratio in terms of the constants and the stepsize, from which a minimum-ratio stepsize was calculated. If neither A^{-1} nor T is assumed to be strongly monotone, Passty [37] showed that a weighted average of the iterates x^k, weighted by the stepsize α_k, converges weakly to a solution, provided $A(x^k)$ is bounded (it need not be single-valued even) and α_k is square summable but not absolutely summable. However, such ergodic convergence does not seem very useful in practice. For further discussions of splitting methods and applications, see [9, 11, 14, 30, 34] and references therein.

A nice feature of the F-B method is that the backward (i.e., proximal) step involves B only, so the "dense" portion of T can be put into A to facilitate problem decomposition. And, as a referee noted, the splitting is even more attractive if in addition any ill-conditioned portion of T can be put into B. In contrast, other splitting methods have backward step(s) that involve A also, possibly limiting the level of problem decomposition achievable. Some studies of this in the context of discrete-time optimal control problems are given in [5, 9, 48, 56]. (Of course, problem decomposition is not the only consideration. Convergence rate is another.) On the other hand, the

F-B method has the drawback that it requires either A^{-1} to be strongly monotone, implying A is Lipschitz continuous on $\mathrm{dom}A = \mathcal{H}$ (see [4, Cor. 2.4], [41]), or A to be Lipschitz continuous on $\mathrm{dom}A = \mathcal{H}$ and T to be strongly monotone. These requirements limit the choice of the splitting $T = A + B$ and rule out the kind of applications considered in section 4. Furthermore, choosing a good stepsize may be difficult since it entails estimating the modulus of A^{-1} or the Lipschitz constant of A and the modulus of A or B.

In this paper, we propose a simple modification to the F-B method that removes the requirement of A^{-1} or T being strongly monotone for convergence. The modification is motivated by the extragradient method of Korpelevich [19] for monotone variational inequalities, which modifies the projection method of Sibony by performing an additional forward step and a projection step at each iteration. By adaptively choosing the stepsize, this method has been shown to converge for monotone continuous mappings in the case $\mathcal{H} = \Re^n$ [17, 26, 54]. Our proposed modified method is in the same spirit as the extragradient method, performing an additional forward step and projection step onto some closed convex set $X \subset \mathrm{dom}A$ at each iteration (see (2.3)) and using an adaptive stepsize rule (see (2.4)). The modified method, when specialized to the case of variational inequalities, coincides with the extragradient method when the problem is unconstrained but otherwise seems to be new (see Example 2 in section 4). We show that if (i) A is Lipschitz continuous on $X \cup \mathrm{dom}B$ or if (ii) A is locally (in the weak topology) uniformly continuous on $X \subset \mathrm{dom}B$ and $x \mapsto \min_{w \in T(x)} \|w\|$ is locally (in the weak topology) bounded on X, then the iterates generated by this method converge weakly to a solution. Under additional assumptions on T, namely, T is strongly monotone or T^{-1} has a (local) Lipschitzian property, linear rate of convergence is also shown (see Theorem 3.4). Applications of the method to decomposition in convex programming and variational inequalities are discussed in section 4.

Throughout this paper, we denote by I either the identity mapping on $\mathcal{H}$ or the identity matrix. By a closed set C in $\mathcal{H}$, we mean C is closed in the weak topology. For any nonempty closed convex set $X \subset \mathcal{H}$, we denote the nearest-point projection of $y \in \mathcal{H}$ onto X by $P_X[y] = \arg\min_{x \in X} \|x - y\|$. A mapping $S : \mathcal{H} \rightrightarrows \mathcal{H}$ is said to be strongly monotone with modulus $\gamma > 0$ if

$$\langle x - x', y - y' \rangle \geq \gamma \|x - x'\|^2 \qquad \text{for all } x, x' \in \mathrm{dom}S, y \in S(x), y' \in S(x').$$

A mapping $A : \mathcal{H} \rightrightarrows \mathcal{H}$ that is single-valued on some set $Y \subset \mathcal{H}$ is said to be Lipschitz continuous on a set X with constant $\lambda \geq 0$, where $X \subset Y$, if

$$\|A(x) - A(x')\| \leq \lambda \|x - x'\| \qquad \text{for all } x, x' \in X$$

and is said to be locally uniformly continuous on $X \subset Y$ if

$$\|A(x^k) - A(y^k)\| \to 0 \text{ whenever } x^k \in X, y^k \in Y \text{ converge weakly and } \|x^k - y^k\| \to 0. \tag{1.1}$$

A function $\phi : X \mapsto \Re$, where $X \subset \mathcal{H}$, is said to be locally bounded on X if $\phi(x^k)$ is bounded whenever $x^k \in X$ converges weakly. (Here $\{x^k\}$ and $\{y^k\}$ are sequences.)

2. Method description. Let $A : \mathcal{H} \rightrightarrows \mathcal{H}$ and $B : \mathcal{H} \rightrightarrows \mathcal{H}$ be maximal monotone mappings with A single-valued on $\mathrm{dom}A \supset \mathrm{dom}B$ and with $T^{-1}(0) \neq \emptyset$, where $T = A + B$. In this section we describe the modified F-B splitting method for finding an element of $T^{-1}(0)$. For convenience, we denote the F-B mapping by

$$J(x, \alpha) = (I + \alpha B)^{-1}(I - \alpha A)(x) \qquad \text{for all } x \in \mathrm{dom}A, \text{ for all } \alpha > 0. \tag{2.1}$$

It is well known (see Minty [32]) that $(I+\alpha B)^{-1}$ is a single-valued mapping from $\mathcal{H}$ to dom$B$. Thus, $J(\cdot,\alpha)$ is a single-valued mapping from dom$A$ to dom$B$.

Modified F-B splitting method. *Assume $X \subset \mathrm{dom}A$ is a closed convex set such that $X \cap T^{-1}(0) \neq \emptyset$ and either A is Lipschitz continuous on $X \cup \mathrm{dom}B$ or A is continuous (from the strong topology to the strong topology) on* dom$B$ *and $X \subset \mathrm{dom}B$. Choose any $x^0 \in X$. For $k = 0, 1, \ldots$, we generate x^{k+1} from x^k by choosing an $\alpha_k \in (0,\infty)$ and letting*

$$\bar{x}^k = J(x^k, \alpha_k), \tag{2.2}$$

$$x^{k+1} = P_X[\bar{x}^k - \alpha_k(A(\bar{x}^k) - A(x^k))]. \tag{2.3}$$

Since $J(\cdot,\alpha)$ maps dom$A$ to dom$B \subset$ dom$A$ and $x^0 \in X \subset$ dom$A$, an induction argument yields $x^k \in X$ and $\bar{x}^k \in$ dom$B$, so $A(x^k)$ and $A(\bar{x}^k)$ are nonempty for all $k = 0, 1, \ldots$. The projection onto X in (2.3) is needed to ensure that $A(x^k)$ is nonempty and that α_k can be chosen by the stepsize rule below (see the proof of Theorem 3.4(a)).

There are various choices for the set X. If A is Lipschitz continuous on a closed convex subset of dom$A$ that contains dom$B$, then we can choose X to be this set. If dom$B$ is closed, then a result of Minty [31] (also see [4, Rem. 2.1]) implies dom$B$ is convex and we can choose $X =$ dom$B$. This occurs, for example, when the constraints are explicit, so that $B = G + N_C$, with C a nonempty closed convex set in $\mathcal{H}$ and $G : \mathcal{H} \rightrightarrows \mathcal{H}$ a maximal monotone mapping with dom$G \supset C$. (See section 4 for specific choices of X in some applications.) In some cases, such as when dom$B$ is unbounded, there may be an advantage in choosing X to be a bounded subset of dom$B$. Also, we can more generally work with a dynamically changing set X^k, provided $(\cap_{k=0}^{\infty} X^k) \cap T^{-1}(0) \neq \emptyset$. This does not affect our convergence result and allows for X^k to be adjusted so to better approximate $T^{-1}(0)$. For example, if A is Lipschitz continuous on dom$A = \mathcal{H}$ with constant $\lambda \geq 0$, then following a cutting-plane approach of Solodov and Svaiter [50], we can choose X^k to be the half-space

$$X^k = \{x \in \mathcal{H} : \langle \bar{w}^k, x - \bar{x}^k \rangle \leq 0\},$$

where $\bar{w}^k = (x^k - \bar{x}^k)/\alpha_k - A(x^k) + A(\bar{x}^k)$. Using $\bar{w}^k \in T(\bar{x}^k)$ (see (3.12)) and monotonicity of T, it can be seen that $T^{-1}(0) \subset X^k$, and if $\alpha_k < 1/\lambda$, then $x^k \notin X^k$.

Choosing α_k requires some care, for it cannot be too large (or the method might diverge) nor can it be too small (or the convergence might be too slow). If A is Lipschitz continuous on $X \cup$ dom$B$, then α_k can be chosen to be a constant (see Theorem 3.4(a)). However, it is more practical to choose α_k dynamically using an Armijo–Goldstein-type stepsize rule. Specifically, we will choose α_k to be the largest $\alpha \in \{\sigma, \sigma\beta, \sigma\beta^2, \ldots\}$ satisfying

$$\alpha \|A(J(x^k,\alpha)) - A(x^k)\| \leq \theta \|J(x^k,\alpha) - x^k\|, \tag{2.4}$$

where $\beta \in (0,1)$ and $\theta \in (0,1)$ and $\sigma > 0$ are constants. As a referee noted, in the optimization context, the acceptance criterion (2.4) involves function gradients, not function values, which distinguishes it from the classical Armijo–Goldstein criteria, e.g., [1, pp. 20, 57]. We will show that (2.4) is satisfied by all α sufficiently small, so α_k is well defined (see Theorem 3.4(a)). Alternatively, we can choose α_k to be the largest $\alpha \in \{\alpha_{k-1}, \alpha_{k-1}\beta, \alpha_{k-1}\beta^2, \ldots\}$ satisfying (2.4), with α_{-1} chosen arbitrarily. The resulting α_k, though more conservative, is cheaper to find since typically $\alpha = \alpha_{k-1}$ will satisfy (2.4). Our convergence results below hold for this alternative stepsize rule

also. The above stepsize rules are motivated by, but are simpler than, those given in [59] for an alternating projection-proximal method. These stepsize rules contrast with those for F-B splitting methods, which require the stepsize to be less than a constant depending on the modulus of A^{-1} or the Lipschitz constant of A and the modulus of A or B, so the latter need to be known or estimated. Related stepsize rules in the context of projection-type methods for variational inequalities are discussed in [17, 26, 52, 54]. In the case where $\mathrm{dom}A = \mathrm{dom}B = \mathcal{H} = X$, the modified F-B method may be viewed as an instance of a hybrid approximate extragradient-proximal point algorithm proposed recently by Solodov and Svaiter [51].

3. Convergence analysis. In this section we analyze the convergence and the rate of convergence of the method in the previous section. We begin with the following lemma, showing that the algorithmic mapping for the modified F-B method has a nonexpansive property analogous to those for projection and proximal methods.

LEMMA 3.1. *Consider any maximal monotone mappings $A : \mathcal{H} \rightrightarrows \mathcal{H}$ and $B : \mathcal{H} \rightrightarrows \mathcal{H}$ and any closed convex set $X \subset \mathrm{dom}A$ such that A is single-valued on $\mathrm{dom}A \supset \mathrm{dom}B$ and $\Sigma = X \cap (A+B)^{-1}(0)$ is nonempty. For any $\alpha > 0$, any $x \in \mathrm{dom}A$, and any $x^* \in \Sigma$, the vectors $\bar{x} = J(x,\alpha)$ and $z = \bar{x} - \alpha(A(\bar{x}) - A(x))$, where J is given by (2.1), together with some $\eta \geq 0$ satisfy*

$$\|P_X[z] - x^*\|^2 \leq \|z - x^*\|^2 = \|x - x^*\|^2 + \alpha^2\|A(\bar{x}) - A(x)\|^2 - \|\bar{x} - x\|^2 - 2\alpha\eta, \tag{3.1}$$

with η having the property that, if $A+B$ is strongly monotone on $\mathrm{dom}B$ with modulus $\gamma > 0$, then $\eta \geq \gamma\|\bar{x} - x^*\|^2$.

Proof. We have from the definition of $\bar{x}$ and z that

$$\bar{x} + \alpha\bar{v} = x - \alpha u, \quad z = \bar{x} - \alpha(\bar{u} - u), \quad u = A(x), \quad \bar{u} = A(\bar{x}), \quad \exists \bar{v} \in B(\bar{x}) \tag{3.2}$$

and from $0 \in A(x^*) + B(x^*)$ that

$$u^* + v^* = 0, \qquad u^* = A(u^*), \quad \exists v^* \in B(x^*). \tag{3.3}$$

Then,

$$\begin{aligned}
\|x - x^*\|^2 &= \|x - \bar{x} + \bar{x} - z + z - x^*\|^2 \\
&= \|x - \bar{x}\|^2 + \|\bar{x} - z\|^2 + \|z - x^*\|^2 + 2\langle x - \bar{x}, \bar{x} - x^*\rangle + 2\langle \bar{x} - z, z - x^*\rangle \\
&= \|x - \bar{x}\|^2 - \|\bar{x} - z\|^2 + \|z - x^*\|^2 + 2\langle x - z, \bar{x} - x^*\rangle \\
&= \|x - \bar{x}\|^2 - \alpha^2\|A(\bar{x}) - A(x)\|^2 + \|z - x^*\|^2 + 2\alpha\langle \bar{u} + \bar{v}, \bar{x} - x^*\rangle \\
&= \|x - \bar{x}\|^2 - \alpha^2\|A(\bar{x}) - A(x)\|^2 + \|z - x^*\|^2 + 2\alpha\langle \bar{u} - u^* + \bar{v} - v^*, \bar{x} - x^*\rangle,
\end{aligned}$$

where the fourth equality uses (3.2) and the fifth equality uses (3.3). This proves the equality in (3.1) with $\eta = \langle \bar{u} - u^* + \bar{v} - v^*, \bar{x} - x^*\rangle$. Since A and B are monotone, it follows from (3.2) and (3.3) that $\eta = \langle \bar{u} - u^* + \bar{v} - v^*, \bar{x} - x^*\rangle$ is nonnegative. And if in addition $A + B$ is strongly monotone on $\mathrm{dom}B$ with modulus $\gamma > 0$, then $\eta \geq \gamma\|\bar{x} - x^*\|^2$. The inequality in (3.1) follows from $x^* = P_X[x^*]$ (since $x^* \in X$) and the nonexpansive property of P_X [60, Eq. (1.8)]. □

The next lemma is well known (see [4, p. 27], [36, p. 105]) and a proof is included for completeness.

LEMMA 3.2. *Consider any maximal monotone mapping $S : \mathcal{H} \rightrightarrows \mathcal{H}$. If $\{x^k\}$ is a sequence in $\mathcal{H}$ bounded in norm and converging weakly to some x and $\{w^k\}$ is a sequence in $\mathcal{H}$ converging strongly to some w and $w^k \in S(x^k)$ for all k, then $w \in S(x)$.*

Proof. For any $x' \in \mathrm{dom}S$ and any $w' \in S(x')$, we have $0 \le \langle w'-w^k, x'-x^k\rangle = \langle w'-w^k, x'-x\rangle + \langle w'-w, x-x^k\rangle + \langle w-w^k, x-x^k\rangle \le \langle w'-w^k, x'-x\rangle + \langle w'-w, x-x^k\rangle + \|w-w^k\|\|x-x^k\| \to \langle w'-w, x'-x\rangle$. The maximality of S then implies $w \in S(x)$. □

In a Hilbert space, a weakly convergent sequence is automatically bounded in norm (see, e.g., [36, p. 2]), but we will not need this fact. The following lemma extends a basic result about the backward mapping $(I+\alpha B)^{-1}$ (see [4, Prop. 2.6]) to the F-B mapping J.

LEMMA 3.3. *Consider any maximal monotone mappings $A : \mathcal{H} \rightrightarrows \mathcal{H}$ and $B : \mathcal{H} \rightrightarrows \mathcal{H}$ such that A is single-valued on* $\mathrm{dom}A \supset \mathrm{dom}B$. *Let J be given by* (2.1). *Then,*

$$\|J(x,\alpha)-x\|/\alpha \le \min_{w\in A(x)+B(x)} \|w\| \qquad \textit{for all } x \in \mathrm{dom}B, \ \textit{for all } \alpha > 0. \tag{3.4}$$

Proof. Fix any $x \in \mathrm{dom}B$ and any $\alpha > 0$. Let $z = J(x,\alpha)$. Then, (2.1) implies $(x-z)/\alpha \in A(x)+B(z)$ so that, for any $w \in A(x)+B(x)$, the monotonicity of B implies

$$\langle ((x-z)/\alpha - A(x)) - (w - A(x)), z-x\rangle \ge 0.$$

Simplifying and rearranging terms give

$$\|x-z\|^2/\alpha \le \langle w, x-z\rangle \le \|w\|\|x-z\|,$$

and (3.4) is proven. (The minimum in (3.4) is attained uniquely since $A(x)+B(x)$ is a closed convex set.) □

The inequality in (3.4) is sharp as $\alpha \to 0$. To see this, note that, by (3.4), $J(x,\alpha)$ converges strongly to x as $\alpha \to 0$ and $w_\alpha = (x - J(x,\alpha))/\alpha$ is bounded in norm. Choose any sequence $\{\alpha_k\} \to 0$ such that $\|w_{\alpha_k}\| \to \liminf_{\alpha\to 0}\|w_\alpha\|$. By Alaoglu's theorem [36, p. 2], $\{w_{\alpha_k}\}$ has a weak cluster point and, by $w_\alpha \in A(x)+B(J(x,\alpha))$ and Lemma 3.2 with $S = B^{-1}$, any such weak cluster point w is in $A(x)+B(x)$. This together with $\|w_\alpha\|^2 = \|w_\alpha - w\|^2 + \|w\|^2 + 2\langle w_\alpha - w, w\rangle \ge \|w\|^2 + 2\langle w_\alpha - w, w\rangle \to \|w\|^2$ as $\alpha \to 0$ implies

$$\liminf_{\alpha\to 0} \|J(x,\alpha)-x\|/\alpha = \lim_k \|w_{\alpha_k}\| \ \ge \min_{w\in A(x)+B(x)} \|w\|. \tag{3.5}$$

By (3.4), the inequality in (3.5) holds with equality. The mapping $x \mapsto \arg\min_{w\in T(x)}\|w\|$ has been much studied; see, e.g., [4, Chap. 2].

Below we state and prove our main convergence result, showing that, under mild assumptions on A and B, the modified F-B method with α_k determined by the Armijo–Goldstein-type stepsize rule (2.4) generates well-defined iterates x^k that converge weakly to a solution. Moreover, if T is strongly monotone or T^{-1} has a (local) Lipschitzian property (see (3.7)) and if the stepsizes α_k are bounded away from zero, then the iterates have (local) linear rate of convergence. The proof entails using Lemma 3.3 to show that (2.4) holds for all α sufficiently small, so that α_k is well defined. Then, Lemmas 3.1 and 3.2 are used to show, respectively, that x^k are bounded in norm and every weak cluster point is a solution.

THEOREM 3.4. *Consider any maximal monotone mappings $A : \mathcal{H} \rightrightarrows \mathcal{H}$ and $B : \mathcal{H} \rightrightarrows \mathcal{H}$ such that A is single-valued on* $\mathrm{dom}A \supset \mathrm{dom}B$, *and $T = A + B$ is maximal monotone with $T^{-1}(0) \ne \emptyset$. Assume $X \subset \mathrm{dom}A$ is a closed convex set such*

that $\Sigma = X \cap T^{-1}(0) \neq \emptyset$ *and either* A *is Lipschitz continuous on* $X \cup \mathrm{dom}B$ *or* A *is continuous on* $\mathrm{dom}B \supset X$. *Let* $\{(x^k, \bar{x}^k)\}_{k=0,1,\ldots}$ *be generated by the modified F-B method* (2.2)–(2.3) *with* α_k *chosen to be the largest* $\alpha \in \{\sigma, \sigma\beta, \sigma\beta^2, \ldots\}$ *satisfying* (2.4), *where* $\beta \in (0,1)$, $\theta \in (0,1)$, *and* $\sigma > 0$. *Then the following hold.*

(a) α_k *is well defined for all* k. *If* A *is Lipschitz continuous on* $X \cup \mathrm{dom}B$ *with constant* $\lambda \geq 0$, *then* $\alpha_k \geq \min\{\sigma, \theta\beta/\lambda\}$.

(b) *For every* $x^* \in \Sigma$ *and every* $k \in \{0, 1, \ldots\}$, *we have*

$$\|x^{k+1} - x^*\|^2 \leq \|x^k - x^*\|^2 - (1-\theta^2)\|\bar{x}^k - x^k\|^2 - 2\alpha_k \eta^k \tag{3.6}$$

for some $\eta^k \geq 0$ *with the property that, if* T *is strongly monotone on* $\mathrm{dom}B$ *with modulus* $\gamma > 0$, *then* $\eta^k \geq \gamma\|\bar{x}^k - x^*\|^2$. *If either* (i) $\liminf_{k\to\infty}\alpha_k > 0$ *or* (ii) A *is locally uniformly continuous on* $X \subset \mathrm{dom}B$ *(see* (1.1)*) and the function* $x \mapsto \min_{w\in T(x)}\|w\|$ *is locally bounded on* X, *then* $\{x^k\}$ *converges weakly to an element of* Σ.

(c) *If* T *is strongly monotone on* $\mathrm{dom}B$ *with modulus* $\gamma > 0$, *then*

$$\|x^{k+1} - x^*\| \;\leq\; (1 - \min\{1-\theta^2, 2\alpha_k\gamma\}/2)^{1/2}\|x^k - x^*\|$$

for all k, *where* x^* *denotes the unique element of* Σ.

(d) *If there exist* $\tau > 0$ *and* $\delta > 0$ *such that*

$$(X + \delta\mathbb{B}) \cap T^{-1}(w) \subset \Sigma + \tau\|w\|\mathbb{B} \quad \textit{for all } w \in \mathcal{H} \textit{ with } \|w\| \leq \delta, \tag{3.7}$$

where $\mathbb{B} = \{x \in \mathcal{H} : \|x\| \leq 1\}$, *and either* $\liminf_{k\to\infty}\alpha_k > 0$ *or* $\delta = \infty$, *then there exists an index* $\bar{k}$ *such that*

$$d\left(x^{k+1}, \Sigma\right) \;\leq\; d\left(x^k, \Sigma\right)/(1 + \rho\alpha_k^2)^{1/2}$$

for all $k \geq \bar{k}$, *where we denote* $d(x, \Sigma) = \min_{x^*\in\Sigma}\|x - x^*\|$ *and* $\rho = (1 - \theta^2)/((\sigma+\tau)\theta + \tau)^2$. *If* $\delta = \infty$, *then* $\bar{k} = 0$. *(The minimum is attained uniquely since* Σ *is a closed convex set.)*

Proof. (a) Suppose A is Lipschitz continuous on $X \cup \mathrm{dom}B$ with constant $\lambda \geq 0$. For each $k \in \{0, 1, \ldots\}$, since $x^k \in X$ and $J(x^k, \alpha) \in \mathrm{dom}B$, it follows from the Lipschitz continuity of A that (2.4) holds for all $\alpha \leq \theta/\lambda$, so α_k is well defined. Moreover, either $\alpha_k = \sigma$ or else (2.4) fails to hold for $\alpha = \alpha_k/\beta$. In the latter case, we must have $\alpha_k/\beta > \theta/\lambda$.

Suppose A is continuous on $\mathrm{dom}B$ and $X \subset \mathrm{dom}B$. Fix any $k \in \{0, 1, \ldots\}$. If $x^k \in \Sigma$, then $\alpha_k = \sigma$ (since both sides of (2.4) equal zero for any $\alpha > 0$). Now suppose $x^k \notin \Sigma$. Since $x^k \in X \subset \mathrm{dom}B$, applying Lemma 3.3 with $x = x^k$ yields

$$\|J(x^k, \alpha) - x^k\|/\alpha \leq \min_{w\in T(x^k)}\|w\| \quad \text{for all } \alpha > 0, \tag{3.8}$$

so $J(x^k, \alpha)$ converges strongly to x^k as $\alpha \to 0$ and the continuity of A on $\mathrm{dom}B$ implies

$$\|A(J(x^k, \alpha)) - A(x^k)\| \to 0 \quad \text{as } \alpha \to 0.$$

By (2.1), we have $(x^k - J(x^k, \alpha))/\alpha \in A(x^k) + B(J(x^k, \alpha))$. If $\liminf_{\alpha\to 0}\|x^k - J(x^k, \alpha)\|/\alpha = 0$, then since $J(x^k, \alpha)$ converges strongly to x^k, Lemma 3.2 with $S = B$ would yield $0 \in A(x^k) + B(x^k)$, contradicting $x^k \notin \Sigma$. Thus,

$$\liminf_{\alpha\to 0}\|x^k - J(x^k, \alpha)\|/\alpha > 0.$$

The preceding two relations show that (2.4) holds whenever α is sufficiently small, so α_k is well defined.

(b) For every $x^* \in \Sigma$ and every $k \in \{0, 1, \ldots\}$, we have from (2.2), (2.3), and applying Lemma 3.1 that (3.1) holds with $\alpha = \alpha_k$, $x = x^k$, $\bar{x} = \bar{x}^k$, $P_X[z] = x^{k+1}$, and $\eta = \eta^k$, for some $\eta^k \geq 0$ having the desired property. Hence

$$\|x^{k+1} - x^*\|^2 \leq \|x^k - x^*\|^2 + (\alpha_k)^2 \|A(\bar{x}^k) - A(x^k)\|^2 - \|\bar{x}^k - x^k\|^2 - 2\alpha_k \eta^k.$$

Since $\alpha = \alpha_k$ satisfies (2.4) so that, by (2.2), $\alpha_k \|A(\bar{x}^k) - A(x^k)\| \leq \theta \|\bar{x}^k - x^k\|$, this yields (3.6). Thus, (3.6) holds for $k = 0, 1, \ldots$ and any $x^* \in \Sigma$. Then the sequence $\{x^k\}_{k=0,1,\ldots}$ is bounded in norm and, by Alaoglu's theorem [36, p. 2], has at least one weak cluster point.

Let x^∞ be any weak cluster point of $\{x^k\}$, and we will show that $x^\infty \in \Sigma$. Consider any subsequence $\{x^k\}_{k \in K}$ ($K \subset \{0, 1, 2, \ldots\}$) converging weakly to x^∞. Since $x^k \in X$ and X is closed, then $x^\infty \in X$. Suppose $\liminf_{k \to \infty} \alpha_k > 0$. Since (3.6) implies $\|\bar{x}^k - x^k\| \to 0$, this together with $\alpha = \alpha_k$ in (2.4) and (2.2) yields $\|A(\bar{x}^k) - A(x^k)\| \to 0$. By (2.1) and (2.2), we also have

$$(x^k - \bar{x}^k)/\alpha_k + A(\bar{x}^k) - A(x^k) \in A(\bar{x}^k) + B(\bar{x}^k) = T(\bar{x}^k) \tag{3.9}$$

for all k. It follows that the left-hand side of (3.9) converges strongly to 0 as $k \in K$, $k \to \infty$. Since $\{\bar{x}^k\}_{k \in K}$ is bounded in norm and converges weakly to x^∞, Lemma 3.2 with $S = T$ yields $0 \in T(x^\infty)$. Thus, $x^\infty \in \Sigma$. Suppose instead A is locally uniformly continuous on $X \subset \mathrm{dom} B$ and the function $x \mapsto \min_{w \in T(x)} \|w\|$ is locally bounded on X. If $\{\alpha_k\}_{k \in K}$ contains a subsequence that is bounded below by a positive scalar, then an argument analogous to that used above would yield $x^\infty \in \Sigma$. Otherwise, suppose $\{\alpha_k\}_{k \in K} \to 0$. Then for all $k \in K$ sufficiently large, we have $\alpha_k < \sigma$, so our choice of α_k implies (2.4) fails to hold for $\alpha = \bar{\alpha}_k$, where $\bar{\alpha}_k = \alpha_k / \beta$, i.e.,

$$\theta \|J(x^k, \bar{\alpha}_k) - x^k\| / \bar{\alpha}_k < \|A(J(x^k, \bar{\alpha}_k)) - A(x^k)\|. \tag{3.10}$$

Applying Lemma 3.3 with $x = x^k$ and $\alpha = \bar{\alpha}_k$ yields

$$\|J(x^k, \bar{\alpha}_k) - x^k\| / \bar{\alpha}_k \ \leq \ \min_{w \in T(x^k)} \|w\|$$

for all $k \in K$. Since x^k is in X and converges weakly to x^∞ as $k \in K, k \to \infty$, the right-hand side is bounded for all $k \in K$, implying $\{J(x^k, \bar{\alpha}_k)\}_{k \in K}$ is bounded in norm and converges weakly to x^∞. By (2.1) and $T = A + B$, we have

$$w^k = (x^k - J(x^k, \bar{\alpha}_k))/\bar{\alpha}_k + A(J(x^k, \bar{\alpha}_k)) - A(x^k) \in T(J(x^k, \bar{\alpha}_k))$$

for all $k \in K$. If $\liminf_{k \in K, k \to \infty} \|w^k\| = 0$, then Lemma 3.2 with $S = T$ would imply $0 \in T(x^\infty)$, so $x^\infty \in \Sigma$. Otherwise suppose $\liminf_{k \in K, k \to \infty} \|w^k\| > 0$. Since $x^k \in X$ and $J(x^k, \bar{\alpha}_k) \in \mathrm{dom} B$ converge weakly and $\|J(x^k, \bar{\alpha}_k) - x^k\| \to 0$ as $k \in K, k \to \infty$, we have from the local uniform continuity of A on $X \subset \mathrm{dom} B$ that $\{\|A(J(x^k, \bar{\alpha}_k)) - A(x^k)\|\}_{k \in K} \to 0$, and hence $\liminf_{k \in K, k \to \infty} \|x^k - J(x^k, \bar{\alpha}_k)\| / \bar{\alpha}_k = \liminf_{k \in K, k \to \infty} \|w^k\| > 0$. This contradicts the fact that (3.10) holds for all $k \in K$ sufficiently large.

We now show, by an argument used in [3] and in [44, p. 885], that $\{x^k\}$ has no more than one weak cluster point. Suppose x_1^∞ and x_2^∞ are two weak cluster points of $\{x^k\}$. Then, as we just showed above, for $i = 1, 2$, we have $x_i^\infty \in \Sigma$, so letting

$x^* = x_i^\infty$ in (3.6) yields $\{\|x^k - x_i^\infty\|^2\}$ is monotonically decreasing and hence converges to a limit, say, υ_i. Since

$$\|x^k - x_1^\infty\|^2 = \|x^k - x_2^\infty\|^2 + \|x_2^\infty - x_1^\infty\|^2 + 2\langle x^k - x_2^\infty, x_1^\infty - x_2^\infty\rangle$$

for all k, passing to the limit along any subsequence of $\{x^k\}$ converging weakly to x_2^∞ yields $\upsilon_1 = \upsilon_2 + \|x_2^\infty - x_1^\infty\|^2$. A symmetric argument yields $\upsilon_2 = \upsilon_1 + \|x_1^\infty - x_2^\infty\|^2$. Adding these two equalities gives $\|x_1^\infty - x_2^\infty\| = 0$.

(c) Suppose that T is strongly monotone on dom$B$ with modulus $\gamma > 0$. Then (b) implies (3.6) holds and $\eta^k \geq \gamma\|\bar{x}^k - x^*\|^2$, so that

$$\begin{aligned}\|x^{k+1} - x^*\|^2 &\leq \|x^k - x^*\|^2 - (1-\theta^2)\|\bar{x}^k - x^k\|^2 - 2\alpha_k\gamma\|\bar{x}^k - x^*\|^2 \\ &\leq \|x^k - x^*\|^2 - \min\{1-\theta^2, 2\alpha_k\gamma\}(\|\bar{x}^k - x^k\|^2 + \|\bar{x}^k - x^*\|^2) \\ &\leq \|x^k - x^*\|^2 - \frac{1}{2}\min\{1-\theta^2, 2\alpha_k\gamma\}\|x^k - x^*\|^2,\end{aligned}$$

where the last inequality follows from $\|x^k - x^*\|^2 \leq (\|x^k - \bar{x}^k\| + \|\bar{x}^k - x^*\|)^2 \leq 2\|x^k - \bar{x}^k\|^2 + 2\|\bar{x}^k - x^*\|^2$.

(d) Suppose that there exist $\tau > 0$ and $\delta > 0$ such that (3.7) holds. It can be seen that (3.7) is equivalent to

$$d(x, \Sigma) \leq \tau \min_{w \in T(x)} \|w\| \quad \text{for all } x \in \text{dom}T \cap (X + \delta\mathbb{B}) \text{ with } \min_{w \in T(x)} \|w\| \leq \delta. \tag{3.11}$$

(The minimum is attained uniquely since $T(x)$ is a closed convex set.) Also, we have from (3.9) that the vector $z^k = \bar{x}^k - \alpha_k(A(\bar{x}^k) - A(x^k))$ satisfies

$$(x^k - z^k)/\alpha_k = (x^k - \bar{x}^k)/\alpha_k - A(x^k) + A(\bar{x}^k) \in B(\bar{x}^k) + A(\bar{x}^k) = T(\bar{x}^k) \tag{3.12}$$

for all k. Suppose $\liminf_{k\to\infty}\alpha_k > 0$. Since (3.6) implies $\{\|\bar{x}^k - x^k\|\} \to 0$, we have from (2.4) with $\alpha = \alpha_k$ and (2.2) that $\{\|A(\bar{x}^k) - A(x^k)\|\} \to 0$. Thus, there exists an index $\bar{k}$ such that the left-hand side of (3.12) and $\bar{x}^k - x^k$ are both below δ in norm for all $k \geq \bar{k}$, in which case $x^k \in X$ and (3.11) yield

$$d\left(\bar{x}^k, \Sigma\right) \leq \tau\|x^k - z^k\|/\alpha_k.$$

Then, for $x^* \in \Sigma$ satisfying $\|\bar{x}^k - x^*\| = d(\bar{x}^k, \Sigma)$, we have

$$\begin{aligned}d\left(x^{k+1}, \Sigma\right) &\leq \|x^{k+1} - x^*\| \\ &= \|P_X[z^k] - P_X[x^*]\| \\ &\leq \|z^k - x^*\| \\ &\leq \|z^k - \bar{x}^k\| + \|\bar{x}^k - x^*\| \\ &\leq \|z^k - \bar{x}^k\| + \tau\|x^k - z^k\|/\alpha_k \\ &\leq \|z^k - \bar{x}^k\| + \tau(\|x^k - \bar{x}^k\| + \|\bar{x}^k - z^k\|)/\alpha_k \\ &= (\alpha_k + \tau)\|A(\bar{x}^k) - A(x^k)\| + \tau\|x^k - \bar{x}^k\|/\alpha_k \\ &\leq ((\alpha_k + \tau)\theta + \tau)\|x^k - \bar{x}^k\|/\alpha_k,\end{aligned}$$

where the first equality uses (2.3), the second inequality uses the nonexpansive property of P_X [60, Eq. (1.8)], and the last inequality uses (2.2) and (2.4) with $\alpha = \alpha_k$.

Then, for $x^* \in \Sigma$ satisfying $\|x^k - x^*\| = d(x^k, \Sigma)$, inequality (3.6) and the above inequality yield

$$\begin{aligned} d\left(x^{k+1}, \Sigma\right)^2 &\leq \|x^{k+1} - x^*\|^2 \\ &\leq \|x^k - x^*\|^2 - (1-\theta^2)\|\bar{x}^k - x^k\|^2 \\ &\leq \|x^k - x^*\|^2 - \frac{(1-\theta^2)\alpha_k^2}{((\alpha_k+\tau)\theta+\tau)^2} d\left(x^{k+1}, \Sigma\right)^2 \\ &= d\left(x^k, \Sigma\right)^2 - \frac{(1-\theta^2)\alpha_k^2}{((\alpha_k+\tau)\theta+\tau)^2} d\left(x^{k+1}, \Sigma\right)^2. \end{aligned}$$

This holds for all $k \geq \bar{k}$ and, since $\alpha_k \leq \sigma$, the desired inequality follows. The case of $\delta = \infty$ is treated similarly with $\bar{k} = 0$. □

Sufficient conditions for the sum of two maximal monotone mappings $T = A + B$ to be maximal are given in [42]. The assumption made in Theorem 3.4(b) on the local uniform continuity of A on $X \subset \mathrm{dom}B$ holds if either A is continuous (from the weak topology to the strong topology) on $\mathrm{dom}B$ or A is uniformly continuous (from the strong topology to the strong topology) on $\mathrm{dom}B$. The other assumption that $x \mapsto \min_{w \in T(x)} \|w\|$ be locally bounded on X is reasonably mild. If A is continuous, from the weak topology to the strong topology, on X and $B = G + N_C$, with $G : \mathcal{H} \rightrightarrows \mathcal{H}$ maximal monotone and C a nonempty closed convex subset of $\mathrm{int}(\mathrm{dom}G)$, then this assumption holds. This is because G is locally bounded on $\mathrm{int}(\mathrm{dom}G)$ [41] (also see [4, Prop. 2.9]). However, in general, this assumption may fail to hold. For example, for $B = \partial f$, where f is the proper closed convex function on $\Re^2$ defined by

$$f(x) = f(x_1, x_2) = \begin{cases} \max\{-\sqrt{1 - x_1^2 - x_2^2}, x_1 - 1\} & \text{if } x_1^2 + x_2^2 \leq 1, \\ \infty & \text{else,} \end{cases}$$

it can be checked that $x \mapsto \min_{v \in B(x)} \|v\|$ is not locally bounded at $(1, 0) \in \mathrm{dom}B$. The assumption (3.7) made in Theorem 3.4(d) is weaker than the Lipschitzian assumption made in [44, Eq. (3.1)] as it does not require $T^{-1}(0)$ to be a singleton. This assumption has been much studied and is known to hold when T is polyhedral [40] (also see [47, Chap. 9] for related discussions). In the case of variational inequalities, corresponding to $T = F + N_C$ with F single-valued on a nonempty closed convex set C, we have $\min_{w \in T(x)} \|w\| = \|F(x) + v\|$ for some $v \in N_C(x)$, implying

$$\|x - P_C[x - F(x)]\| = \|P_C[x+v] - P_C[x - F(x)]\| \leq \|(x+v) - (x - F(x))\| = \min_{w \in T(x)} \|w\|.$$

Thus, the Lipschitzian property (3.7) and its equivalent formulation as an error bound (3.11) can be inferred from corresponding results for the projection residual $R(x) = x - P_C[x - F(x)]$, as studied in [23, 24, 35, 58] and references therein. Also, as in [7, 8, 9, 44, 50], it may be worthwhile to consider inexact evaluation of the backward mapping $(I + \alpha B)^{-1}$.

In the case where A is Lipschitz continuous on $\mathrm{dom}A = \mathcal{H}$ with constant λ and T is strongly monotone with modulus γ, parts (a) and (c) of Theorem 3.4 imply that x^k converge strongly at linear rate to the unique element of $T^{-1}(0)$ and the convergence ratio is at most

$$(1 - \min\{1 - \theta^2, 2\gamma\sigma, 2\gamma\theta\beta/\lambda\}/2)^{1/2}.$$

Assuming λ and γ are known, one can choose $\sigma > 0$ and $\theta \in (0, 1)$ to minimize the above estimate and obtain

$$1/\sqrt{1 + \beta\kappa/(1 + (\beta\kappa)^2)^{1/2}},$$

where $\kappa = \gamma/\lambda$. This can be compared with an analogous estimate by Chen and Rockafellar [6, Cor. 2.5] for the F-B method:

$$1/\sqrt{1+\kappa^2/(1-(\gamma_1/\lambda)^2)},$$

where γ_1 is the modulus of A (with $\gamma_1 = 0$ allowed). Which estimate is smaller depends on κ, β, and γ_1/λ, and whether these estimates reflect the methods' behavior in practice remains to be seen.

4. Applications. Below we derive new decomposition methods by applying the modified F-B method appropriately to special cases of convex programming and variational inequalities. Throughout this paper, for any matrix $D \in \Re^{m\times n}$, we denote its transpose by D^T and its operator norm by $\|D\| = \max_{x\in\Re^n:\|x\|=1}\|Dx\|$. For any function $f : \Re^n \mapsto (-\infty,\infty]$, we denote its effective domain by $\mathrm{dom}f = \{x \in \Re^n : f(x) < \infty\}$.

Example 1. Consider the following convex program studied in [57, Sec. 4]:

$$\begin{array}{ll} \text{minimize} & f_1(x_1) + f_2(x_2) \\ \text{subject to} & Dx_1 + Ex_2 = b, \end{array} \tag{4.1}$$

where f_1 and f_2 are closed proper convex functions on, respectively, $\Re^{n_1}$ and $\Re^{n_2}$ and $D \in \Re^{m\times n_1}$, $E \in \Re^{m\times n_2}$, $b \in \Re^m$. We assume that f_1 is strictly convex and cofinite [43, p. 116], so that $(\partial f_1)^{-1}$ is single-valued and continuous on $\Re^{n_1}$. (Roughly speaking, f_1 being cofinite means it grows faster than linear. If f_1 is strongly convex or if $\mathrm{dom}f_1$ is bounded, then f_1 is cofinite.) We also assume that there exists $(x_1, x_2) \in \mathrm{ri}(\mathrm{dom}f_1) \times \mathrm{ri}(\mathrm{dom}f_2)$ satisfying $Dx_1 + Ex_2 = b$ and that there does not exist $x_2 \in \mathrm{dom}f_2$ and $z \in \Re^{n_2}$ satisfying $Ez = 0$ and $f_2(x_2 + tz) < f_2(x_2)$ for all $t > 0$. Then, it can be argued similarly as in [57] that the above convex program has an optimal solution and a Kuhn–Tucker vector $y \in \Re^m$ associated with the constraints $Dx_1 + Ex_2 = b$. Moreover, y is a Kuhn–Tucker vector if and only if y satisfies $0 \in A(y) + B(y)$, where A and B are the maximal monotone mappings:

$$A(y) = D(\partial f_1)^{-1}(D^T y), \qquad B(y) = E(\partial f_2)^{-1}(E^T y) - b.$$

Notice that A is single-valued and continuous on $\Re^m$. Applying the modified F-B method with this choice of A and B and with X being a suitable closed convex subset of $\mathrm{dom}B$ (or $X = \Re^m$, if $(\partial f_1)^{-1}$ is Lipschitz continuous on $\Re^{n_1}$), we obtain the following modification to the alternating minimization algorithm in [57]:

$$\begin{aligned} \bar{x}_1^k &= \arg\min_{x_1\in\Re^{n_1}} \{f_1(x_1) - \langle y^k, Dx_1\rangle\}, \\ \bar{x}_2^k &= \arg\min_{x_2\in\Re^{n_2}} \{f_2(x_2) - \langle y^k, Ex_2\rangle + \alpha_k\|D\bar{x}_1^k + Ex_2 - b\|^2/2\}, \\ \bar{y}^k &= y^k + \alpha_k(b - D\bar{x}_1^k - E\bar{x}_2^k), \\ x_1^{k+1} &= \arg\min_{x_1\in\Re^{n_1}} \{f_1(x_1) - \langle \bar{y}^k, Dx_1\rangle\}, \\ y^{k+1} &= P_X[\bar{y}^k - \alpha_k(Dx_1^{k+1} - D\bar{x}_1^k)], \end{aligned}$$

for $k = 0, 1, \ldots$ In contrast to the original method, the modified method does not require f_1 to be strongly convex for convergence, so f_1 can include functions such as $x \ln x$, which are strictly convex and cofinite, but not strongly convex. On the other hand, the modified method requires an additional minimization in x_1 and a projection

onto the set X. If f_2 has a separable structure and $E = -I$, as considered in [7], then X can be chosen to have a corresponding Cartesian product structure and the projection onto X would decompose accordingly. Alternatively, if f_2 is cofinite so that $\mathrm{dom}(\partial f_2)^{-1} = \Re^{n_2}$, then X can be chosen to be $\mathrm{dom}B = \Re^m$ and the projection would be vacuous.

Example 2. Consider the variational inequality problem of finding an $x \in \mathcal{H}$ satisfying $0 \in F(x) + N_C(x)$, where C is a nonempty closed convex set in $\mathcal{H}$ and F is a maximal monotone mapping that is single-valued and continuous on C. This is equivalent to $0 \in A(x) + B(x)$, where A and B are the maximal monotone mappings:

$$A(x) = F(x), \qquad B(x) = N_C(x).$$

Applying the modified F-B method with this choice of A and B and with $X = C$ (or $X = \mathcal{H}$, if A is Lipschitz continuous on $\mathrm{dom}A = \mathcal{H}$), we obtain the following (new) double-projection method:

$$\bar{x}^k = P_C[x^k - \alpha_k F(x^k)], \tag{4.2}$$

$$x^{k+1} = P_X[\bar{x}^k - \alpha_k(F(\bar{x}^k) - F(x^k))], \tag{4.3}$$

for $k = 0, 1, \ldots$ This method differs from the extragradient method [17, 19, 26, 54], whose second equation is

$$x^{k+1} = P_C[x^k - \alpha_k F(\bar{x}^k)]. \tag{4.4}$$

It also differs from a modified projection-type method [52] (also see [55] for a similar method) whose second equation is

$$x^{k+1} = x^k - \gamma_k(x^k - \bar{x}^k + \alpha_k(F(\bar{x}^k) - F(x^k))) \tag{4.5}$$

with $\gamma_k > 0$ a quantity depending on $x^k, \bar{x}^k, \alpha_k$. If $X = \mathcal{H}$, then (4.3) and (4.5) would coincide whenever $\gamma_k = 1$. If in addition $C = \mathcal{H}$, then (4.3) and (4.4) would also coincide. In this case, the three methods differ only in their stepsize rules for choosing α_k. While the method (4.2)–(4.3) has similar theoretical convergence properties as the other two methods, its practical performance remains to be determined from numerical testing. Notice that (4.3) involves projection onto X rather than onto C as in (4.4), which can be advantageous when X has a simpler structure than C. Other projection-type methods, including the method of Sibony, require stronger assumptions, such as F^{-1} being strongly monotone, for convergence (see [2, 25, 29, 49] and references therein).

Example 3. Consider the convex program (4.1), where f_1 and f_2 are closed proper convex functions on, respectively, $\Re^{n_1}$ and $\Re^{n_2}$ and $D \in \Re^{m\times n_1}$, $E \in \Re^{m\times n_2}$, $b \in \Re^m$. The case of $E = -I$ and $b = 0$ corresponds to the problem studied in [7]. We assume there exists $(x_1, x_2) \in \mathrm{ri}(\mathrm{dom}f_1)\times\mathrm{ri}(\mathrm{dom}f_2)$ satisfying $Dx_1 + Ex_2 = b$ but, in contrast to Example 1, we do not assume f_1 is strictly convex or cofinite. Then, this problem has an optimal solution if and only if $0 \in A(x_1, x_2, y) + B(x_1, x_2, y)$ has a solution [42, Chap. 28], where A and B are the maximal monotone mappings:

$$A(x_1, x_2, y) = (D^T y, E^T y, -Dx_1 - Ex_2), \qquad B(x_1, x_2, y) = \partial f_1(x_1) \times \partial f_2(x_2) \times \{b\}.$$

Notice that A is Lipschitz continuous on $\Re^{m+n_1+n_2}$ with constant

$$\lambda = \sqrt{\|D^T\|^2 + \|D\|^2 + \|E^T\|^2 + \|E\|^2}.$$

Applying the modified F-B method with this choice of A and B and with $X = \Re^{m+n_1+n_2}$, we obtain (in case of $E = -I$ and $b = 0$) the following variant of a decomposition method of Chen and Teboulle [7]:

$$\begin{aligned}
\bar{x}_1^k &= \arg\min_{x_1 \in \Re^{n_1}} \{f_1(x_1) + \langle y^k, Dx_1\rangle + \|x_1 - x_1^k\|^2/(2\alpha_k)\},\\
\bar{x}_2^k &= \arg\min_{x_2 \in \Re^{n_2}} \{f_2(x_2) + \langle y^k, Ex_2\rangle + \|x_2 - x_2^k\|^2/(2\alpha_k)\},\\
\bar{y}^k &= y^k + \alpha_k(Dx_1^k + Ex_2^k - b),\\
x_1^{k+1} &= \bar{x}_1^k - \alpha_k D^T(\bar{y}^k - y^k),\\
x_2^{k+1} &= \bar{x}_2^k - \alpha_k E^T(y^k - \bar{y}^k),\\
y^{k+1} &= \bar{y}^k + \alpha_k(D\bar{x}_1^k + E\bar{x}_2^k - Dx_1^k - Ex_2^k),
\end{aligned}$$

for $k = 0, 1, \ldots$ This method has the same minimization subproblems as the Chen–Teboulle method and, in particular, the subproblems have strongly convex objective function and decompose according to the separable structure of f_1 and f_2.

Example 4. Consider the inclusion problem $0 \in A(x_1, x_2, y) + B(x_1, x_2, y)$, where

$$A(x_1, x_2, y) = (D^T y, E^T y, -Dx_1 - Ex_2), \qquad B(x_1, x_2, y) = T_1(x_1) \times T_2(x_2) \times \{b\},$$

and T_1 and T_2 are maximal monotone mappings on $\Re^{n_1}$ and $\Re^{n_2}$, respectively, and $D \in \Re^{m\times n_1}$, $E \in \Re^{m\times n_2}$, $b \in \Re^m$. Then, A and B are maximal monotone and A is Lipschitz continuous on $\Re^{m+n_1+n_2}$ with constant

$$\lambda = \sqrt{\|D^T\|^2 + \|D\|^2 + \|E^T\|^2 + \|E\|^2}.$$

The special case where $T_1 = \partial f_1$, $T_2 = \partial f_2$ yields the convex program (4.1). The special case where $n_1 = n_2$, $D = -E = I$, and $b = 0$ yields the inclusion $0 \in T_1(x) + T_2(x)$. Applying the modified F-B method with this choice of A and B and with $X = \Re^{m+n_1+n_2}$, we obtain the following variant of a splitting method in [59, Ex. 3]:

$$\begin{aligned}
\bar{x}_1^k &= (I + \alpha_k T_1)^{-1}(x^k - \alpha_k D^T y^k),\\
\bar{x}_2^k &= (I + \alpha_k T_2)^{-1}(x^k - \alpha_k E^T y^k),\\
\bar{y}^k &= y^k + \alpha_k(Dx_1^k + Ex_2^k - b),\\
x_1^{k+1} &= \bar{x}_1^k - \alpha_k D^T(\bar{y}^k - y^k),\\
x_2^{k+1} &= \bar{x}_2^k - \alpha_k E^T(\bar{y}^k - y^k),\\
y^{k+1} &= \bar{y}^k + \alpha_k(D\bar{x}_1^k + E\bar{x}_2^k - Dx_1^k - Ex_2^k),
\end{aligned}$$

for $k = 0, 1, \ldots$.

Example 5. Consider the minimax problem:

$$\min_{x\in\Re^n} \max_{y\in Y} \{f(x) - g(y) + \langle y, Dx\rangle\},$$

where f is a closed proper convex functions on $\Re^n$, g is a continuously differentiable convex function on $\Re^m$, Y is a nonempty closed convex set in $\Re^m$, and $D \in \Re^{m\times n}$. Under a suitable constraint qualification [42, Chap. 37], this problem is equivalent to $0 \in A(x, y) + B(x, y)$, where A and B are the maximal monotone mappings

$$A(x, y) = (D^T y, \nabla g(y) - Dx), \qquad B(x, y) = \partial f(x) \times N_Y.$$

Applying the modified F-B method with this choice of A and B and with $X = X_1 \times Y$, where $X_1 = \Re^n$ if ∇g is Lipschitz continuous on $\Re^m$ and otherwise X_1 is a suitable closed convex subset of $\mathrm{dom}\partial f$, we obtain the following variant of a method in [59, Ex. 4]:

$$\begin{aligned}
\bar{x}^k &= \arg\min_{x\in\Re^n}\{f(x) + \langle y^k, Dx\rangle + \|x - x^k\|^2/(2\alpha_k)\},\\
\bar{y}^k &= P_Y[y^k + \alpha_k(Dx^k - \nabla g(y^k))],\\
x^{k+1} &= P_{X_1}[\bar{x}^k - \alpha_k D^T(\bar{y}^k - y^k)],\\
y^{k+1} &= P_Y[y^k + \alpha_k(D\bar{x}^k - \nabla g(\bar{y}^k) - Dx^k + \nabla g(y^k))],
\end{aligned}$$

for $k = 0, 1, \ldots$. As in the method of [59], if Y has a Cartesian product structure or f has a separable structure (e.g., $f(x_1, \ldots, x_n) = f_1(x_1) + \cdots + f_n(x_n)$ for some functions $f_1, \ldots, f_n$ on $\Re$), as in certain discrete-time deterministic optimal control problem [5, 46] and in the scheduling of hydroelectric power generation under uncertainty [48], then X_1 can be chosen to have a corresponding product structure and the computation of $\bar{x}^k$ and x^{k+1} decompose accordingly. See [59] for further discussions of the advantages of such decomposition methods.

Under additional assumptions on the problems, convergence and linear convergence of the methods in Examples 1–5 can be established by appropriately applying Theorem 3.4. (For $\mathcal{H} = \Re^n$, weak convergence and strong convergence are equivalent.) Additional applications are discussed in [5, 13, 56, 57]. Notice that the inclusion $0 \in A(x) + B(x)$ may be reformuated as $0 \in F(x, y_1, y_2) \times G(x, y_1, y_2)$, where

$$F(x, y_1, y_2) = (B(x) - y_2), \qquad G(x, y_1, y_2) = (A(y_1) + y_2) \times \{x - y_1\}.$$

Then, provided A is single-valued and continuous on $\mathcal{H} = \Re^n$, the method in [59] may be applied to this reformulated problem to obtain a method that has similar computation and convergence properties as, but is more complicated than, the modified F-B method. (The analysis in [59] is for the case $\mathcal{H} = \Re^n$, although extension to a Hilbert space setting seems possible.) Last, there recently has been much study of proximal point methods using a nonquadratic proximal term (see [18] and references therein), and it would be interesting to extend the modified F-B method to this setting.

THE O.D.E. METHOD FOR CONVERGENCE OF STOCHASTIC APPROXIMATION AND REINFORCEMENT LEARNING*

V. S. BORKAR† AND S. P. MEYN‡

Abstract. It is shown here that stability of the stochastic approximation algorithm is implied by the asymptotic stability of the origin for an associated ODE. This in turn implies convergence of the algorithm. Several specific classes of algorithms are considered as applications. It is found that the results provide (i) a simpler derivation of known results for reinforcement learning algorithms; (ii) a proof for the first time that a class of asynchronous stochastic approximation algorithms are convergent without using any a priori assumption of stability; (iii) a proof for the first time that asynchronous adaptive critic and Q-learning algorithms are convergent for the average cost optimal control problem.

Key words. stochastic approximation, ODE method, stability, asynchronous algorithms, reinforcement learning

1. Introduction.

The stochastic approximation algorithm considered in this paper is described by the d-dimensional recursion

$$X(n+1) = X(n) + a(n)\big[h\big(X(n)\big) + M(n+1)\big], \quad n \geq 0, \tag{1.1}$$

where $X(n) = [X_1(n), \ldots, X_d(n)]^T \in \mathbb{R}^d$, $h : \mathbb{R}^d \to \mathbb{R}^d$, and $\{a(n)\}$ is a sequence of positive numbers. The sequence $\{M(n) : n \geq 0\}$ is uncorrelated with zero mean.

Though more than four decades old, the stochastic approximation algorithm is now of renewed interest due to novel applications to reinforcement learning [20] and as a model of learning by boundedly rational economic agents [19]. Traditional convergence analysis usually shows that the recursion (1.1) will have the desired asymptotic behavior provided that the iterates remain bounded with probability one, or that they visit a prescribed bounded set infinitely often with probability one [3, 14]. Under such stability or recurrence conditions one can then approximate the sequence $\boldsymbol{X} = \{X(n) : n \geq 0\}$ with the solution to the ordinary differential equation (ODE)

$$\dot{x}(t) = h\big(x(t)\big) \tag{1.2}$$

with identical initial conditions $x(0) = X(0)$.

The recurrence assumption is crucial, and in many practical cases this becomes a bottleneck in applying the ODE method. The most successful technique for establishing stochastic stability is the stochastic Lyapunov function approach (see, e.g.,

[14]). One also has techniques based upon the contractive properties or homogeneity properties of the functions involved (see, e.g., [20] and [12], respectively).

The main contribution of this paper is to add to this collection another general technique for proving stability of the stochastic approximation method. This technique is inspired by the fluid model approach to stability of networks developed in [9, 10], which is itself based upon the multistep drift criterion of [15, 16]. The idea is that the usual stochastic Lyapunov function approach can be difficult to apply due to the fact that time-averaging of the noise may be necessary before a given positive valued function of the state process will decrease towards zero. In general such time-averaging of the noise will require infeasible calculation. In many models, however, it is possible to combine time-averaging with a limiting operation on the magnitude of the initial state, to replace the stochastic system of interest with a simpler deterministic process.

The scaling applied in this paper to approximate the model (1.1) with a deterministic process is similar to the construction of the fluid model of [9, 10]. Suppose that the state is scaled by its initial value to give $\widetilde{X}(n) = X(n)/\max(|X(0)|, 1)$, $n \geq 0$. We then scale time to obtain a continuous function $\phi : \mathbb{R}_+ \to \mathbb{R}^d$ which interpolates the values of $\{\widetilde{X}(n)\}$. At a sequence of times $\{t(j) : j \geq 0\}$ we set $\phi(t(j)) = \widetilde{X}(j)$, and for arbitrary $t \geq 0$, we extend the definition by linear interpolation. The times $\{t(j) : j \geq 0\}$ are defined in terms of the constants $\{a(j)\}$ used in (1.1). For any $r > 0$, the scaled function $h_r : \mathbb{R}^d \to \mathbb{R}^d$ is given by

$$h_r(x) = h(rx)/r, \quad x \in \mathbb{R}^d. \tag{1.3}$$

Then through elementary arguments we find that the stochastic process $\boldsymbol{\phi}$ approximates the solution $\widehat{\phi}$ to the associated ODE

$$\dot{x}(t) = h_r\big(x(t)\big), \quad t \geq 0, \tag{1.4}$$

with $\widehat{\phi}(0) = \phi(0)$ and $r = \max(|X(0)|, 1)$.

With our attention on stability considerations, we are most interested in the behavior of $\boldsymbol{X}$ when the magnitude of the initial condition $|X(0)|$ is large. Assuming that the limiting function $h_\infty = \lim_{r\to\infty} h_r$ exists, for large initial conditions we find that ϕ is approximated by the solution ϕ^∞ of the limiting ODE

$$\dot{x}(t) = h_\infty\big(x(t)\big), \tag{1.5}$$

where again we take identical initial conditions $\phi^\infty(0) = \phi(0)$.

Thus, for large initial conditions all three processes are approximately equal,

$$\phi \approx \widehat{\phi} \approx \phi^\infty.$$

Using these observations we find in Theorem 2.1 that the stochastic model (1.1) is stable in a strong sense provided the origin is asymptotically stable for the limiting ODE (1.5). Equation (1.5) is precisely the fluid model of [9, 10].

Thus, the major conclusion of this paper is that the ODE method can be extended to establish both the stability *and* convergence of the stochastic approximation method, as opposed to only the latter. The result [14, Theorem 4.1, p. 115] arrives at a similar conclusion: if the ODE (1.2) possesses a "global" Lyapunov function with bounded partial derivatives, then this will serve as a stochastic Lyapunov function, thereby establishing recurrence of the algorithm. Though similar in flavor, there are

significant differences between these results. First, in the present paper we consider a scaled ODE, not the usual ODE (1.2). The former retains only terms with dominant growth and is frequently simpler. Second, while it is possible that the stability of the scaled ODE and the usual one go hand in hand, this does not imply that a Lyapunov function for the latter is easily found. The reinforcement learning algorithms for ergodic-cost optimal control and asynchronous algorithms, both considered as applications of the theory in this paper, are examples where the scaled ODE is conveniently analyzed.

Though the assumptions made in this paper are explicitly motivated by applications to reinforcement learning algorithms for Markov decision processes, this approach is likely to find a broader range of applications.

The paper is organized as follows. The next section presents the main results for the stochastic approximation algorithm with vanishing stepsize or with bounded, nonvanishing stepsize. Section 2 also gives a useful error bound for the constant stepsize case and briefly sketches an extension to asynchronous algorithms, omitting details that can be found in [6]. Section 3 gives examples of algorithms for reinforcement learning of Markov decision processes to which this analysis is applicable. The proofs of the main results are collected together in section 4.

2. Main results. Here we collect together the main general results concerning the stochastic approximation algorithm. Proofs not included here may be found in section 4.

We shall impose the following additional conditions on the functions $\{h_r : r \geq 1\}$ defined in (1.3) and the sequence $\boldsymbol{M} = \{M(n) : n \geq 1\}$ used in (1.1). Some relaxations of assumption (A1) are discussed in section 2.4.

(A1) The function h is Lipschitz, and there exists a function $h_\infty : \mathbb{R}^d \to \mathbb{R}^d$ such that

$$\lim_{r\to\infty} h_r(x) = h_\infty(x), \quad x \in \mathbb{R}^d.$$

Furthermore, the origin in $\mathbb{R}^d$ is an asymptotically stable equilibrium for the ODE (1.5).

(A2) The sequence $\{M(n), \mathcal{F}_n : n \geq 1\}$, with $\mathcal{F}_n = \sigma(X(i), M(i), i \leq n)$, is a martingale difference sequence. Moreover, for some $C_0 < \infty$ and any initial condition $X(0) \in \mathbb{R}^d$,

$$\mathsf{E}\big[\|M(n+1)\|^2 \mid \mathcal{F}_n\big] \leq C_0\big(1 + \|X(n)\|^2\big), \quad n \geq 0.$$

The sequence $\{a(n)\}$ is deterministic and is assumed to satisfy one of the following two assumptions. Here TS stands for "tapering stepsize" and BS for "bounded stepsize."

(TS) The sequence $\{a(n)\}$ satisfies $0 < a(n) \leq 1,\ n \geq 0$, and

$$\sum_n a(n) = \infty, \qquad \sum_n a(n)^2 < \infty.$$

(BS) The sequence $\{a(n)\}$ satisfies for some constants $1 > \overline{\alpha} > \underline{\alpha} > 0$,

$$\underline{\alpha} \leq a(n) \leq \overline{\alpha}, \quad n \geq 0.$$

2.1. Stability and convergence. The first result shows that the algorithm is stabilizing for both bounded and tapering step sizes.

THEOREM 2.1. *Assume that* (A1) *and* (A2) *hold. Then we have the following:*

(i) *Under* (TS), *for any initial condition* $X(0) \in \mathbb{R}^d$,

$$\sup_n \|X(n)\| < \infty \qquad \textit{almost surely (a.s.).}$$

(ii) *Under* (BS) *there exist* $\alpha^* > 0$ *and* $C_1 < \infty$ *such that for all* $0 < \overline{\alpha} < \alpha^*$ *and* $X(0) \in \mathbb{R}^d$,

$$\limsup_{n\to\infty} \mathsf{E}\big[\big\|X(n)\big\|^2\big] \le C_1. \qquad \square$$

An immediate corollary to Theorem 2.1 is convergence of the algorithm under (TS). The proof is a standard application of the Hirsch lemma (see [11, Theorem 1, p. 339] or [3, 14]), but we give the details below for sake of completeness.

THEOREM 2.2. *Suppose that* (A1), (A2), *and* (TS) *hold and that the ODE* (1.2) *has a unique globally asymptotically stable equilibrium* x^*. *Then* $X(n) \to x^*$ *a.s. as* $n \to \infty$ *for any initial condition* $X(0) \in \mathbb{R}^d$.

Proof. We may suppose that $X(0)$ is deterministic without any loss of generality so that the conclusion of Theorem 2.1 (i) holds that the sample paths of $\boldsymbol{X}$ are bounded with probability one. Fixing such a sample path, we see that $\boldsymbol{X}$ remains in a bounded set H, which may be chosen so that $x^* \in \operatorname{int}(H)$.

The proof depends on an approximation of $\boldsymbol{X}$ with the solution to the primary ODE (1.2). To perform this approximation, first define $t(n) \uparrow \infty$, $T(n) \uparrow \infty$ as follows: Set $t(0) = T(0) = 0$ and for $n \ge 1$, $t(n) = \sum_{i=0}^{n-1} a(i)$. Fix $T > 0$ and define inductively

$$T(n+1) = \min\big\{t(j) : t(j) > T(n) + T\big\}, \quad n \ge 0.$$

Thus $T(n) = t(m(n))$ for some $m(n) \uparrow \infty$ and $T \le T(n+1) - T(n) \le T + 1$ for $n \ge 0$. We then define two functions from $\mathbb{R}_+$ to $\mathbb{R}^d$:

(a) $\{\psi(t), t > 0\}$ is defined by $\psi(t(n)) = X(n)$ with linear interpolation on $[t(n), t(n+1)]$ for each $n \ge 0$.

(b) $\{\widehat{\psi}(t), t > 0\}$ is piecewise continuous, defined so that, for any $j \ge 0$, $\widehat{\psi}$ is the solution to (1.2) for $t \in [T(j), T(j+1))$, with the initial condition $\widehat{\psi}(T(j)) = \psi(T(j))$.

Let $\epsilon > 0$ and let $B(\epsilon)$ denote the open ball centered at x^* of radius ϵ. We may then choose the following:

(i) $0 < \delta < \epsilon$ such that $x(t) \in B(\epsilon)$ for all $t \ge 0$ whenever $x(\,\cdot\,)$ is a solution of (1.2) satisfying $x(0) \in B(\delta)$.

(ii) $T > 0$ so large that for any solution of (1.2) with $x(0) \in H$ we have $x(t) \in B(\delta/2)$ for all $t \ge T$. Hence, $\widehat{\psi}(T(j)-) \in B(\delta/2)$ for all $j \ge 1$.

(iii) An application of the Bellman Gronwall lemma as in Lemma 4.6 below that leads to the limit

$$\big\|\psi(t) - \widehat{\psi}(t)\big\| \to 0 \qquad \text{a.s.}, \quad t \to \infty. \tag{2.1}$$

Hence we may choose $j_0 > 0$ so that we have

$$\big\|\psi\big(T(j) - \big) - \widehat{\psi}\big(T(j) - \big)\big\| \le \delta/2, \quad j \ge j_0.$$

Since $\psi(\,\cdot\,)$ is continuous, we conclude from (ii) and (iii) that $\psi(T(j)) \in B(\delta)$ for $j \ge j_0$. Since $\widehat{\psi}(T(j)) = \psi(T(j))$, it then follows from (i) that $\widehat{\psi}(t) \in B(\epsilon)$ for all $t \ge T(j_0)$. Hence by (2.1),

$$\limsup_{t\to\infty} \|\psi(t) - x^*\| \le \epsilon \qquad \text{a.s.}$$

This completes the proof since $\epsilon > 0$ was arbitrary. □

We now consider (BS), focusing on the absolute error defined by

$$e(n) := \|X(n) - x^*\|, \qquad n \ge 0. \tag{2.2}$$

THEOREM 2.3. *Assume that* (A1), (A2), *and* (BS) *hold, and suppose that* (1.2) *has a globally asymptotically stable equilibrium point* x^*.

Then for any $0 < \alpha \le \alpha^*$, *where* α^* *is introduced in Theorem* 2.1 (ii),

(i) *for any* $\epsilon > 0$, *there exists* $b_1 = b_1(\epsilon) < \infty$ *such that*

$$\limsup_{n\to\infty} \mathsf{P}\big(e(n) \ge \epsilon\big) \le b_1 \overline{\alpha};$$

(ii) *if* x^* *is a globally exponentially asymptotically stable equilibrium for the ODE* (1.2), *then there exists* $b_2 < \infty$ *such that for every initial condition* $X(0) \in \mathbb{R}^d$,

$$\limsup_{n\to\infty} \mathsf{E}\big[e(n)^2\big] \le b_2 \overline{\alpha}. \qquad \square$$

2.2. Rate of convergence. A uniform bound on the mean square error $\mathsf{E}[e(n)^2]$ for $n \ge 0$ can be obtained under slightly stronger conditions on $\boldsymbol{M}$ via the theory of ψ-irreducible Markov chains. We find that this error can be bounded from above by a sum of two terms: the first converges to zero as $\alpha \downarrow 0$, while the second decays to zero exponentially as $n \to \infty$.

To illustrate the nature of these bounds, consider the linear recursion

$$X(n+1) = X(n) + \alpha\big[-\big(X(n) - x^*\big) + W(n+1)\big], \quad n \ge 0,$$

where $\{W(n)\}$ is independently and identically distributed (i.i.d.) with mean zero and variance σ^2. This is of the form (1.1) with $h(x) = -(x - x^*)$ and $M(n) = W(n)$. The error $e(n+1)$ defined in (2.2) may be bounded as follows:

$$\begin{aligned}\mathsf{E}\big[e(n+1)^2\big] &\le \alpha^2\sigma^2 + (1-\alpha)^2\mathsf{E}\big[e(n)^2\big] \\ &\le \alpha\sigma^2/(2-\alpha) + \exp(-2\alpha n)\mathsf{E}\big[e(0)^2\big], \quad n \ge 0.\end{aligned}$$

For a deterministic initial condition $X(0) = x$ and any $\epsilon > 0$, we thus arrive at the formal bound,

$$\mathsf{E}[e(n)^2 \mid X(0) = x] \le B_1(\alpha) + B_2\big(\|x\|^2 + 1\big)\exp\big(-\epsilon_0(\alpha)n\big), \tag{2.3}$$

where B_1, B_2, and ϵ_0 are positive-valued functions of α. The bound (2.3) is of the form that we seek: the first term on the right-hand side (r.h.s.) decays to zero with α, while the second decays exponentially to zero with n. However, the rate of convergence for the second term becomes vanishingly small as $\alpha \downarrow 0$. Hence to maintain a small probability of error the variable α should be neither too small nor too large. This recalls the well-known trade-off between mean and variance that must be made in the application of stochastic approximation algorithms.

A bound of this form carries over to the nonlinear model under some additional conditions. For convenience, we take a Markov model of the form

$$X(n+1) = X(n) + \alpha\big[h\big(X(n)\big) + m\big(X(n), W(n+1)\big)\big], \tag{2.4}$$

where again $\{W(n)\}$ is i.i.d. and also independent of the initial condition $X(0)$. We assume that the functions $h : \mathbb{R}^d \to \mathbb{R}^d$ and $m : \mathbb{R}^d \times \mathbb{R}^q \to \mathbb{R}^d$ are smooth (C^1) and that assumptions (A1) and (A2) continue to hold. The recursion (2.4) then describes a Feller–Markov chain with stationary transition kernel to be denoted by P.

Let $V\colon \mathbb{R}^d \to [1,\infty)$ be given. The Markov chain $\boldsymbol{X}$ with transition function P is called *V-uniformly ergodic* if there is a unique invariant probability π, an $R < \infty$, and $\rho < 1$ such that for any function g satisfying $|g(x)| \le V(x)$,

$$\big|\mathsf{E}\big[g\big(X(n)\big) \mid X(0) = x\big] - \mathsf{E}_\pi\big[g\big(X(n)\big)\big]\big| \le RV(x)\rho^n, \qquad x \in \mathbb{R}^d, \quad n \ge 0, \tag{2.5}$$

where $\mathsf{E}_\pi[g(X(n))] = \int g(x)\,\pi(dx)$, $n \ge 0$.

The following result establishes bounds of the form (2.3) using V-ergodicity of the model. Assumptions (2.6) and (2.7) below are required to establish ψ-irreducibility of the model in Lemma 4.10.

There exists a $w^* \in \mathbb{R}^q$ with $m(x^*, w^*) = 0$, and for a continuous function $p : \mathbb{R}^q \to [0,1]$ with $p(w^*) > 0$,

$$\mathsf{P}\big(W(1) \in A\big) \ge \int_A p(z)dz, \quad A \in \mathcal{B}(\mathbb{R}^q). \tag{2.6}$$

The pair of matrices (F, G) is controllable with

$$F = \frac{d}{dx}h(x^*) + \frac{\partial}{\partial x}m(x^*, w^*) \quad \textit{and} \quad G = \frac{\partial}{\partial w}m(x^*, w^*). \tag{2.7}$$

THEOREM 2.4. *Suppose that* (A1), (A2), (2.6), *and* (2.7) *hold for the Markov model* (2.4) *with $0 < \alpha \le \alpha^*$. Then the Markov chain $\boldsymbol{X}$ is V-uniformly ergodic, with $V(x) = \|x\|^2 + 1$, and we have the following bounds:*

(i) *There exist positive-valued functions A_1 and ϵ_0 of α and a constant A_2 independent of α, such that*

$$\mathsf{P}\big\{e(n) \ge \epsilon \mid X(0) = x\big\} \le A_1(\alpha) + A_2\big(\|x\|^2 + 1\big)\exp\big(-\epsilon_0(\alpha)n\big).$$

The functions satisfy $A_1(\alpha) \to 0$, $\epsilon_0(\alpha) \to 0$ as $\alpha \downarrow 0$.

(ii) *If in addition the ODE* (1.2) *is exponentially asymptotically stable, then the stronger bound* (2.3) *holds, where again $B_1(\alpha) \to 0$, $\epsilon_0(\alpha) \to 0$ as $\alpha \downarrow 0$, and B_2 is independent of α.*

Proof. The V-uniform ergodicity is established in Lemma 4.10.

From Theorem 2.3 (i) we have, when $X(0) \sim \pi$,

$$\mathsf{P}_\pi\big(e(n) \ge \epsilon\big) = \mathsf{P}_\pi\big(e(0) \ge \epsilon\big) \le b_1\overline{\alpha},$$

and hence from V-uniform ergodicity,

$$\begin{aligned}\mathsf{P}\big(e(n) \ge \epsilon \mid X(0) = x\big) &\le \mathsf{P}_\pi\big(e(n) \ge \epsilon\big) + \big|\mathsf{P}\big(e(n) \ge \epsilon \mid X(0) = x\big) - \mathsf{P}_\pi\big(e(n) \ge \epsilon\big)\big| \\ &\le b_1\alpha + RV(x)\rho^n, \quad n \ge 0.\end{aligned}$$

This and the definition of V establishes (i). The proof of (ii) is similar.

The fact that $\rho = \rho_\alpha \to 1$ as $\alpha \downarrow 0$ is discussed in section 4.3. ∎

2.3. The asynchronous case. The conclusions above also extend to the model of asynchronous stochastic approximation analyzed in [6]. We now assume that each component of $X(n)$ is updated by a separate processor. We postulate a set-valued process $\{Y(n)\}$ taking values in the set of subsets of $\{1, 2, \dots, d\}$, with the interpretation: $Y(n) = \{\text{indices of the components updated at time } n\}$. For $n \geq 0$, $1 \leq i \leq d$, define

$$\nu(i, n) = \sum_{m=0}^{n} I\{i \in Y(m)\},$$

the number of updates executed by the ith processor up to time n. A key assumption is that there exists a deterministic $\Delta > 0$ such that for all i,

$$\liminf_{n\to\infty} \frac{\nu(i, n)}{n} \geq \Delta \qquad \text{a.s.}$$

This ensures that all components are updated comparably often. Furthermore, if

$$N(n, x) = \min\left\{m > n : \sum_{k=n+1}^{m} a(n) > x\right\}$$

for $x > 0$, the limit

$$\lim_{n\to\infty} \frac{\sum_{k=v(i,n)}^{v(i,N(n,x))} a(k)}{\sum_{k=v(j,n)}^{v(j,N(n,x))} a(k)}$$

exists a.s. for all i, j.

At time n, the kth processor has available the following data:

(i) Processor (k) is given $\nu(k, n)$, but it may not have n, the "global clock."

(ii) There are interprocessor communication delays $\tau_{kj}(n), 1 \leq k, j \leq d, n \geq 0$, so that at time n, processor (k) may use the data $X_j(m)$ only for $m \leq n - \tau_{kj}(n)$.

We assume that $\tau_{kk}(n) = 0$ for all n and that $\{\tau_{kj}(n)\}$ have a common upper bound $\overline{\tau} < \infty$ ([6] considers a slightly more general situation).

To relate the present work to [6], we recall that the "centralized" algorithm of [6] is

$$X(n+1) = X(n) + a(n) f\big(X(n), W(n+1)\big),$$

where $\{W(n)\}$ are i.i.d. and $\{f(\cdot, y)\}$ are uniformly Lipschitz. Thus $F(x) := \mathsf{E}[f(x, W(1))]$ is Lipschitz. The correspondence with the present set up is obtained by setting $h(x) = F(x)$ and

$$M(n+1) = f\big(X(n), W(n+1)\big) - F\big(X(n)\big)$$

for $n \geq 0$. The asynchronous version then is

$$\begin{aligned} X_i(n+1) = X_i(n) + a\big(\nu(i,n)\big) f\big(&X_1(n - \tau_{i1}(n)), X_2\big(n - \tau_{i2}(n)\big), \\ &\dots, X_d\big(n - \tau_{id}(n)\big), W(n+1)\big) I\{i \in Y(n)\}, \quad n \geq 0, \end{aligned} \tag{2.8}$$

for $1 \leq i \leq d$. Note that this can be executed by the ith processor without any knowledge of the global clock which, in fact, can be a complete artifice as long as causal relationships are respected.

The analysis presented in [6] depends upon the following additional conditions on $\{a(n)\}$:

(i) $a(n+1) \le a(n)$ eventually;

(ii) for $x \in (0,1)$, $\sup_n a([xn])/a(n) < \infty$;

(iii) for $x \in (0,1)$,

$$\left(\sum_{i=0}^{[xn]} a(i)\right) \Big/ \left(\sum_{i=0}^{n} a(i)\right) \to 1,$$

where $[\,\cdot\,]$ stands for "the integer part of $(\,\cdot\,)$."

A fourth condition is imposed in [6], but this becomes irrelevant when the delays are bounded. Examples of $\{a(n)\}$ satisfying (i)–(iii) are $a(n) = 1/(n+1)$ or $1/(1 + n\log(n+1))$.

As a first simplifying step, it is observed in [6] that $\{Y(n)\}$ may be assumed to be singletons without any loss of generality. We shall do likewise. What this entails is simply unfolding a single update at time n into $|Y(n)|$ separate updates, each involving a single component. This blows up the delays at most d-fold, which does not affect the analysis in any way.

The main result of [6] is the analog of our Theorem 2.2 *given* that the conclusions of our Theorem 2.1 hold. In other words, stability implies convergence. Under (A1) and (A2), our arguments above can be easily adapted to show that the conclusions of Theorem 2.2 also hold for the asynchronous case. One argues exactly as above and in [6] to conclude that the suitably interpolated and rescaled trajectory of the algorithm tracks an appropriate ODE. The only difference is a scalar factor $1/d$ multiplying the r.h.s. of the ODE (i.e., $\dot{x}(t) = (1/d)h(x(t))$). This factor, which reflects the asynchronous sampling, amounts to a time-scaling that does not affect the qualitative behavior of the ODE.

THEOREM 2.5. *Under the conditions of Theorem* 2.2 *and the above hypotheses on* $\{a(n)\}$, $\{Y(n)\}$, *and* $\{\tau_{ij}(n)\}$, *the asynchronous iterates given by* (3.7) *remain a.s. bounded and (therefore) converge to* x^* *a.s.* □

2.4. Further extensions. Although satisfied in all of the applications treated in section 3, in some other models assumption (A1) that $h_r \to h_\infty$ pointwise may be violated. If this convergence does not hold, then we may abandon the fluid model and replace (A1) by

(A1′) The function h is Lipschitz, and there exists $T > 0$, $R > 0$ such that

$$\left|\widehat{\phi}(t)\right| \le \frac{1}{2}, \quad t \ge T,$$

for any solution to (1.4) with $r \ge R$ and with initial condition satisfying $|\widehat{\phi}(0)| = 1$.

Under the Lipschitz condition on h, at worst we may find that the pointwise limits of $\{h_r : r \ge 1\}$ will form a family Λ of Lipschitz functions on $\mathbb{R}^d$. That is, $h_\infty \in \Lambda$ if and only if there exists a sequence $\{r_i\} \uparrow \infty$ such that

$$h_{r_i}(x) \to h_\infty(x), \quad i \to \infty,$$

where the convergence is uniform for x in compact subsets of $\mathbb{R}^d$. Under (A1′) we then find, using the same arguments as in the proof of Lemma 4.1, that the family Λ is uniformly stable.

LEMMA 2.6. *Under* (A1′) *the family of ODEs defined via* Λ *is uniformly exponentially asymptotically stable in the following sense. For some* $b < \infty$, $\delta > 0$, *and any solution* ϕ^∞ *to the ODE* (1.5) with $h_\infty \in \Lambda$,

$$|\phi^\infty(t)| \le be^{-\delta t}|\phi^\infty(0)|, \quad t \ge 0. \qquad \square$$

Using this lemma the development of section 4 goes through with virtually no changes, and hence Theorems 2.1–2.5 are valid with (A1) replaced by (A1′).

Another extension is to broaden the class of scalings. Consider a nonlinear scaling defined by a function $g\colon \mathbb{R}_+ \to \mathbb{R}_+$ satisfying $g(r)/r \to \infty$ as $r \to \infty$, and suppose that $h_r(\cdot)$ redefined as $h_r(x) = h(rx)/g(r)$ satisfies

$$h_r(x) \to h_\infty(x) \text{ uniformly on compacts as } r \to \infty.$$

Then, assuming that the a.s. boundedness of rescaled iterates can be separately established, a completely analogous development of the stochastic algorithm is possible. An example would be a "stochastic gradient" scheme, where $h(\cdot)$ is the gradient of an even degree polynomial, with degree, say, $2n$. Then $g(r) = r^{2n-1}$ will do. We do not pursue this further because the reinforcement learning algorithms we consider below do conform to the case $g(r) = r$.

3. Reinforcement learning. As both an illustration of the theory and an important application in its own right, in this section we analyze reinforcement learning algorithms for Markov decision processes. The reader is referred to [4] for a general background of the subject and to other references listed below for further details.

3.1. Markov decision processes. We consider a Markov decision process $\boldsymbol{\Phi} = \{\Phi(t) : t \in \mathbb{Z}\}$ taking values in a finite state space $S = \{1, 2, \dots, s\}$ and controlled by a control sequence $\boldsymbol{Z} = \{Z(t) : t \in \mathbb{Z}\}$ taking values in a finite action space $A = \{a_0, \dots, a_r\}$. We assume that the control sequence is *admissible* in the sense that $Z(n) \in \sigma\{\Phi(t) : t \le n\}$ for each n. We are most interested in stationary policies of the form $Z(t) = w(\Phi(t))$, where the *feedback law* w is a function $w\colon S \to A$. The controlled transition probabilities are given by $p(i, j, a)$ for $i, j \in S, a \in A$.

Let $c : S \times A \to R$ be the one-step cost function, and consider first the infinite horizon discounted cost control problem of minimizing over all admissible $\boldsymbol{Z}$ the total discounted cost

$$J(i, \boldsymbol{Z}) = \mathsf{E}\left[\sum_{t=0}^{\infty} \beta^t c\big(\Phi(t), Z(t)\big) \mid \Phi(0) = i\right],$$

where $\beta \in (0, 1)$ is the discount factor. The minimal value function is defined as

$$V(i) = \min J(i, \boldsymbol{Z}),$$

where the minimum is over all admissible control sequences $\boldsymbol{Z}$. The function V satisfies the dynamic programming equation

$$V(i) = \min_a \left[c(i, a) + \beta \sum_j p(i, j, a)V(j)\right], \qquad i \in S,$$

and the optimal control minimizing J is given as the stationary policy defined through the feedback law w^* given as any solution to

$$w^*(i) := \arg\min_a \left[c(i, a) + \beta \sum_j p(i, j, a)V(j)\right], \quad i \in S.$$

The value iteration algorithm is an iterative procedure to compute the minimal value function. Given an initial function $V_0 \colon S \to \mathbb{R}_+$ one obtains a sequence of functions $\{V_n\}$ through the recursion

$$V_{n+1}(i) = \min_a \left[c(i,a) + \beta \sum_j p(i,j,a) V_n(j) \right], \quad i \in S, \quad n \geq 0. \tag{3.1}$$

This recursion is convergent for any initialization $V_0 \geq 0$. If we define *Q-values* via

$$Q(i,a) = c(i,a) + \beta \sum_j p(i,j,a) V(j), \qquad i \in S, \quad a \in A,$$

then $V(i) = \min_a Q(i,a)$ and the matrix Q satisfies

$$Q(i,a) = c(i,a) + \beta \sum_j p(i,j,a) \min_b Q(j,b), \qquad i \in S, \quad a \in A.$$

The matrix Q can also be computed using the equivalent formulation of value iteration,

$$Q_{n+1}(i,a) = c(i,a) + \beta \sum_j p(i,j,a) \min_b Q_n(j,b), \qquad i \in S, \quad a \in A, \quad n \geq 0, \tag{3.2}$$

where $Q_0 \geq 0$ is arbitrary.

The value iteration algorithm is initialized with a function $V_0 \colon S \to \mathbb{R}_+$. In contrast, the *policy iteration algorithm* is initialized with a feedback law w^0 and generates a sequence of feedback laws $\{w^n : n \geq 0\}$. At the nth stage of the algorithm a feedback law w^n is given and the value function for the resulting control sequence $\boldsymbol{Z}^n = \{w^n(\Phi(0)), w^n(\Phi(1)), w^n(\Phi(2)), \dots\}$ is computed to give

$$J_n(i) = J\big(i, \boldsymbol{Z}^n\big), \qquad i \in S.$$

Interpreted as a column vector in $\mathbb{R}^s$, the vector J_n satisfies the equation

$$\big(I - \beta P_n\big) J_n = c_n, \tag{3.3}$$

where the $s \times s$ matrix P_n is defined by $P_n(i,j) = p(i,j,w^n(i))$, $i,j \in S$, and the column vector c_n is given by $c_n(i) = c(i, w^n(i))$, $i \in S$. Equation (3.3) can be solved for fixed n by the "fixed-policy" version of value iteration given by

$$J_n(i+1) = \beta P_n J_n(i) + c_n, \quad i \geq 0, \tag{3.4}$$

where $J_n(0) \in \mathbb{R}^s$ is given as an initial condition. Then $J_n(i) \to J_n$, the solution to (3.3), at a geometric rate as $i \to \infty$.

Given J_n, the next feedback law w^{n+1} is then computed via

$$w^{n+1}(i) = \arg\min_a \left[c(i,a) + \beta \sum_j p(i,j,a) J_n(j) \right], \quad i \in S. \tag{3.5}$$

Each step of the policy iteration algorithm is computationally intensive for large state spaces since the computation of J_n requires the inversion of the $s \times s$ matrix $I - \beta P_n$.

In the average cost optimization problem one seeks to minimize over all admissible $\boldsymbol{Z}$,

$$\limsup_{n \to \infty} \frac{1}{n} \sum_{t=0}^{n-1} \mathsf{E}\big[c\big(\Phi(t), Z(t)\big)\big]. \tag{3.6}$$

The policy iteration and value iteration algorithms to solve this optimization problem remain unchanged with three exceptions. One is that the constant β must be set equal to unity in (3.1) and (3.5). Second, in the policy iteration algorithm the value function J_n is replaced by a solution J_n to Poisson's equation

$$\sum p\big(i,j,w^n(i)\big)J_n(j) = J_n(i) - c\big(i,w^n(i)\big) + \eta_n, \quad i \in S,$$

where η_n is the steady state cost under the policy w^n. The computation of J_n and η_n again involves matrix inversions via

$$\pi_n\big(I - P_n + ee'\big) = e', \qquad \eta_n = \pi_n c_n, \qquad \big(I - P_n + ee'\big)J_n = c_n,$$

where $e \in \mathbb{R}^s$ is the column vector consisting of all ones and the row vector π_n is the invariant probability for P_n. The introduction of the outer product ensures that the matrix $(I - P_n + ee')$ is invertible, provided that the invariant probability π_n is unique.

Lastly, the value iteration algorithm is replaced by the "relative value iteration," where a common scalar offset is subtracted from all components of the iterates at each iteration (likewise for the Q-value iteration). The choice of this offset term is not unique. We shall be considering one particular choice, though others can be handled similarly (see [1]).

3.2. *Q*-learning. If the matrix Q defined in (3.2) can be computed via value iteration or some other scheme, then the optimal control is found through a simple minimization. If transition probabilities are unknown so that value iteration is not directly applicable, one may apply a stochastic approximation variant known as the *Q-learning algorithm* of Watkins [1, 20, 21]. This is defined through the recursion

$$Q_{n+1}(i,a) = Q_n(i,a) + a(n)\Big[\beta \min_b Q_n(\Psi_{n+1}(i,a),b) + c(i,a) - Q_n(i,a)\Big],$$

$i \in S, a \in A$, where $\Psi_{n+1}(i,a)$ is an independently simulated S-valued random variable with law $p(i,\cdot,a)$.

Making the appropriate correspondences with our set up, we have $X(n) = Q_n$ and $h(Q) = [h_{ia}(Q)]_{i,a}$ with

$$h_{ia}(Q) = \beta \sum_j p(i,j,a) \min_b Q(j,b) + c(i,a) - Q(i,a), \qquad i \in S, \quad a \in A.$$

The martingale is given by $M(n+1) = [M_{ia}(n+1)]_{i,a}$ with

$$M_{ia}(n+1) = \beta \left(\min_b Q_n(\Psi_{n+1}(i,a),b) - \sum_j p(i,j,a)\Big(\min_b Q_n(j,b)\Big) \right), \quad i \in S, \quad a \in A.$$

Define $F(Q) = [F_{ia}(Q)]_{i,a}$ by

$$F_{ia}(Q) = \beta \sum_j p(i,j,a) \min_b Q(j,b) \ + \ c(i,a).$$

Then $h(Q) = F(Q) - Q$ and the associated ODE is

$$\dot{Q} = F(Q) - Q := h(Q). \tag{3.7}$$

The map $F : \mathbb{R}^{s\times(r+1)} \to \mathbb{R}^{s\times(r+1)}$ is a contraction with respect to the max norm $\|\cdot\|_\infty$. The global asymptotic stability of its unique equilibrium point is a special case of the results of [8]. This $h(\cdot)$ fits the framework of our analysis, with the (i,a)th component of $h_\infty(Q)$ given by

$$\beta \sum_j p(i,j,a) \min_b Q(j,b) - Q(i,a), \quad i \in S, \quad a \in A.$$

This also is of the form $h_\infty(Q) = F_\infty(Q) - Q$ where $F_\infty(\cdot)$ is an $\|\cdot\|_\infty$- contraction, and thus the asymptotic stability of the unique equilibrium point of the corresponding ODE is guaranteed (see [8]). We conclude that assumptions (A1) and (A2) hold, and hence Theorems 2.1–2.4 also hold for the Q-learning model.

3.3. Adaptive critic algorithm. Next we shall consider the *adaptive critic algorithm*, which may be considered as the reinforcement learning analog of policy iteration (see [2, 13] for a discussion). There are several variants of this, one of which, taken from [13], is as follows. For $i \in S$, we define

$$V_{n+1}(i) = V_n(i) + b(n)\big[c\big(i,\psi_n(i)\big) + \beta V_n\big(\Psi_n\big(i,\psi_n(i)\big)\big) - V_n(i)\big], \tag{3.8}$$

from which the policies are updated according to

$$\widehat{w}_{n+1}(i) = \Gamma\left\{\widehat{w}_n(i) + a(n)\sum_{\ell=1}^{r}\Big(\big[c(i,a_0) + \beta V_n\big(\eta_n(i,a_0)\big)\big] - [c(i,a_\ell) + \beta V_n(\eta_n(i,a_\ell))]e_\ell\Big)\right\}. \tag{3.9}$$

Here $\{V_n\}$ are s-vectors and for each $i, \{\widehat{w}_n(i)\}$ are r-vectors lying in the simplex $\{x \in \mathbb{R}^r \mid x = [x_1,\dots,x_r], x_i \ge 0, \sum_i x_i \le 1\}$. $\Gamma(\cdot)$ is the projection onto this simplex. The sequences $\{a(n)\}, \{b(n)\}$ satisfy

$$\sum_n a(n) = \sum_n b(n) = \infty, \qquad \sum_n \big(a(n)^2 + b(n)^2\big) < \infty, \qquad a(n) = o\big(b(n)\big).$$

The rest of the notation is as follows. For $1 \le \ell \le r, e_\ell$ is the unit r-vector in the ℓth coordinate direction. For each i, n, $w_n(i) = w_n(i,\cdot)$ is a probability vector on A defined by the following. For $\widehat{w}_n(i) = [\widehat{w}_n(i,1),\dots,\widehat{w}_n(i,r)]$,

$$w_n(i,a_\ell) = \begin{cases} \widehat{w}_n(i,\ell) & \text{for } \ell \ne 0, \\ 1 - \displaystyle\sum_{j\ne 0}\widehat{w}_n(i,j) & \text{for } \ell = 0. \end{cases}$$

Given $w_n(i)$, $\psi_n(i)$ is an A-valued random variable independently simulated with law $w_n(i)$. Likewise, $\Psi_n(i,\psi_n(i))$ are S-valued random variables which are independently simulated (given $\psi_n(i)$) with law $p(i,\cdot,\psi_n(i))$ and $\{\eta_n(i,a_\ell)\}$ are S-valued random variables independently simulated with law $p(i,\cdot,a_\ell)$, respectively.

To see why this is based on policy iteration, recall that policy iteration alternates between two steps. One step solves the linear system of (3.3) to compute the fixed-policy value function corresponding to the current policy. We have seen that solving (3.3) can be accomplished by performing the fixed-policy version of value iteration given in (3.4). The first step (3.8) in the above iteration is indeed the "learning" or

"simulation-based stochastic approximation" analog of this fixed-policy value iteration. The second step in policy iteration updates the current policy by performing an appropriate minimization. The second iteration (3.9) is a particular search algorithm for computing this minimum over the simplex of probability measures on A. This search algorithm is by no means unique; the paper [13] gives two alternative schemes. However, the first iteration (3.8) is common to all.

The different choices of stepsize schedules for the two iterations (3.8) and (3.9) induces the "two time-scale" effect discussed in [5]. The first iteration sees the policy computed by the second as nearly static, thus justifying viewing it as a fixed-policy iteration. In turn, the second sees the first as almost equilibrated, justifying the search scheme for minimization over A. See [13] for details.

The boundedness of $\{\widehat{w}_n\}$ is guaranteed by the projection $\Gamma(\,\cdot\,)$. For $\{V_n\}$, the fact that $b(n) = o(a(n))$ allows one to treat $\widehat{w}_n(i)$ as constant, say, $\overline{w}(i)$; see, e.g., [13]. The appropriate ODE then turns out to be

$$\dot{v} = G(v) - v := h(v), \tag{3.10}$$

where $G : \mathbb{R}^s \to \mathbb{R}^s$ is defined by

$$G_i(x) = \sum_{\ell} \overline{w}(i, a_\ell) \left[\beta \sum_j p(i, j, a_\ell) x_j + c(i, a_\ell) \right] - x_i, \quad i \in S.$$

Once again, $G(\,\cdot\,)$ is an $\|\,\cdot\,\|_\infty$-contraction and it follows from the results of [8] that (3.10) is globally asymptotically stable. The limiting function $h_\infty(x)$ is again of the form $h_\infty(x) = G_\infty(x) - x$ with $G_\infty(x)$ defined so that its ith component is

$$\sum_{\ell} \overline{w}(i, a_\ell) \left[\beta \sum_j p(i, j, a_\ell) x_j \right] - x_i.$$

We see that G_∞ is also a $\|\,\cdot\,\|_\infty$-contraction and the global asymptotic stability of the origin for the corresponding limiting ODE follows as before from the results of [8].

3.4. Average cost optimal control. For the average cost control problem, we impose the additional restriction that the chain $\mathbf{\Phi}$ has a *unique* invariant probability measure under any stationary policy so that the steady state cost (3.6) is independent of the initial condition.

For the average cost optimal control problem, the Q-learning algorithm is given by the recursion

$$Q_{n+1}(i, a) = Q_n(i, a) + a(n)\Big(\min_b Q_n(\Psi_n(i, a), b) + c(i, a) - Q_n(i, a) - Q_n(i_0, a_0)\Big),$$

where $i_0 \in S$, $a_0 \in A$ are fixed a priori. The appropriate ODE now is (3.7) with $F(\,\cdot\,)$ redefined as $F_{ia}(Q) = \sum_j p(i, j, a) \min_b Q(j, b) + c(i, a) - Q(i, a) - Q(i_0, a_0)$. The global asymptotic stability for the unique equilibrium point for this ODE has been established in [1]. Once again this fits our framework with $h_\infty(x) = F_\infty(x) - x$ for F_∞ defined the same way as F, except for the terms $c(\cdot, \cdot)$ which are dropped. We conclude that (A1) and (A2) are satisfied for this version of the Q-learning algorithm.

Another variant of Q-learning for average cost, based on a "stochastic shortest path" formulation, is presented in [1]. This also can be handled similarly.

In [13], three variants of the adaptive critic algorithm for the average cost problem are discussed, differing only in the $\{\widehat{w}_n\}$ iteration. The iteration for $\{V_n\}$ is common to all and is given by

$$V_{n+1}(i) = V_n(i) + b(n)\big[c\big(i,\psi_n(i)\big) + V_n\big(\Psi_n\big(i,\psi_n,(i)\big)\big) - V_n(i) - V_n(i_0)\big], \quad i \in S,$$

where $i_0 \in S$ is a fixed state prescribed beforehand. This leads to the ODE (3.10) with G redefined as

$$G_i(x) = \sum_{\ell} \overline{w}(i,a_\ell)\left(\sum_j p(i,j,a_\ell)x_j + c(i,a_\ell)\right) - x_i - x_{i_0}, \quad i \in S.$$

The global asymptotic stability of the unique equilibrium point of this ODE has been established in [7]. Once more, this fits our framework with $h_\infty(x) = G_\infty(x) - x$ for G_∞ defined just like G, but without the $c(\cdot,\cdot)$ terms.

Asynchronous versions of all the above can be written down along the lines of (3.7). Then by Theorem 2.5, they have bounded iterates a.s. The important point to note here is that to date, a.s. boundedness for Q-learning and adaptive critic is proved by other methods for centralized algorithms [1, 12, 20]. For asynchronous algorithms, it is proved for discounted cost only [1, 13, 20] or by introducing a projection to enforce stability [14].

4. Derivations. Here we provide proofs for the main results given in section 2. Throughout this section we assume that (A1) and (A2) hold.

4.1. Stability. The functions $\{h_r, r \geq 1\}$ and the limiting function h_∞ are Lipschitz with the same Lipschitz constant as h under (A1). It follows from Ascoli's theorem that the convergence $h_r \to h_\infty$ is uniform on compact subsets of $\mathbb{R}^d$. This observation is the basis of the following lemma.

LEMMA 4.1. *Under* (A1)*, the ODE* (1.5) *is globally exponentially asymptotically stable.*

Proof. The function h_∞ satisfies

$$h_\infty(cx) = ch_\infty(x), \qquad c > 0, \quad x \in \mathbb{R}^d.$$

Hence the origin $\theta \in \mathbb{R}^d$ is an equilibrium for (1.5), i.e., $h_\infty(\theta) = \theta$. Let $B(\epsilon)$ be the closed ball of radius ϵ centered at θ with ϵ chosen so that $x(t) \to \theta$ as $t \to \infty$ uniformly for initial conditions in $B(\epsilon)$. Thus there exists a $T > 0$ such that $\|x(T)\| \leq \epsilon/2$ whenever $\|x(0)\| \leq \epsilon$. For an arbitrary solution $x(\,\cdot\,)$ of (1.5), $y(\,\cdot\,) = \epsilon x(\,\cdot\,)/\|x(0)\|$ is another, with $\|y(0)\| = \epsilon$. Hence $\|y(T)\| < \epsilon/2$, implying $\|x(T)\| \leq \frac{1}{2}\|x(0)\|$. The global exponential asymptotic stability follows. ∎

With the scaling parameter r given by $r(j) = \max(1, \|X(m(j))\|)$, $j \geq 0$, we define three piecewise continuous functions from $\mathbb{R}_+$ to $\mathbb{R}^d$ as in the introduction:

(a) $\{\phi(t) : t \geq 0\}$ is an interpolated version of $\boldsymbol{X}$ defined as follows. For each $j \geq 0$, define a function ϕ_j on the interval $[T(j), T(j+1)]$ by

$$\phi_j\big(t(n)\big) = X(n)/r(j), \quad m(j) \leq n \leq m(j+1),$$

with $\phi_j(\,\cdot\,)$ defined by linear interpolation on the remainder of $[T(j), T(j+1)]$ to form a piecewise linear function.

We then define ϕ to be the piecewise continuous function

$$\phi(t) = \phi_j(t), \qquad t \in \big[T(j), T(j+1)\big), \quad j \geq 0.$$

(b) $\{\widehat{\phi}(t) : t \geq 0\}$ is continuous on each interval $[T(j), T(j+1))$, and on this interval it is the solution to the ODE

$$\dot{x}(t) = h_{r(j)}\big(x(t)\big), \tag{4.1}$$

with initial condition $\widehat{\phi}(T(j)) = \phi(T(j))$, $j \geq 0$.

(c) $\{\phi^\infty(t) : t \geq 0\}$ is also continuous on each interval $[T(j), T(j+1))$, and on this interval it is the solution to the "fluid model" (1.5) with the same initial condition

$$\phi^\infty\big(T(j)\big) = \widehat{\phi}\big(T(j)\big) = \phi\big(T(j)\big) \quad j \geq 0.$$

Boundedness of $\widehat{\phi}(\,\cdot\,)$ and $\phi^\infty(\,\cdot\,)$ is crucial in deriving useful approximations.

LEMMA 4.2. *Under* (A1) *and* (A2) *and either* (TS) *or* (BS), *there exists* $\bar{C} < \infty$ *such that for any initial condition* $X(0) \in \mathbb{R}^d$

$$\widehat{\phi}(t) \leq \bar{C} \quad \textit{and} \quad \phi^\infty(t) \leq \bar{C}, \qquad t \geq 0.$$

Proof. To establish the first bound use the Lipschitz continuity of h to obtain the bound

$$\frac{d}{dt}\big\|\widehat{\phi}(t)\big\|^2 = 2\widehat{\phi}(t)^T h_{r(j)}\big(\widehat{\phi}(t)\big) \leq C\big(\big\|\widehat{\phi}(t)\big\|^2 + 1\big), \quad T(j) \leq t < T(j+1),$$

where C is a deterministic constant, independent of j. The claim follows with $\bar{C} = 2\exp((T+1)C)$ since $\|\widehat{\phi}(T(j))\| \leq 1$. The proof of the second bound is therefore identical. ∎

The following version of the Bellman Gronwall lemma will be used repeatedly.

LEMMA 4.3.

(i) *Suppose* $\{\alpha(n)\}$, $\{A(n)\}$ *are nonnegative sequences and* $\beta > 0$ *such that*

$$A(n+1) \leq \beta + \sum_{k=0}^{n} \alpha(k)A(k), \quad n \geq 0.$$

Then for all $n \geq 1$,

$$A(n+1) \leq \exp\left(\sum_{k=1}^{n} \alpha(k)\right)\big(\alpha(0)A(0) + \beta\big).$$

(ii) *Suppose* $\{\alpha(n)\}$, $\{A(n)\}$, $\{\gamma(n)\}$ *are nonnegative sequences such that*

$$A(n+1) \leq \big(1 + \alpha(n)\big)A(n) + \gamma(n), \quad n \geq 0.$$

Then for all $n \geq 1$,

$$A(n+1) \leq \exp\left(\sum_{k=1}^{n} \alpha(k)\right)\big(\big(1 + \alpha(0)\big)A(0) + \beta(n)\big),$$

where $\beta(n) = \sum_0^n \gamma(k)$.

Proof. Define $\{R(n)\}$ inductively by $R(0) = A(0)$ and

$$R(n+1) = \beta + \sum_{k=0}^{n} \alpha(k)R(k), \quad n \geq 0.$$

A simple induction shows that $A(n) \le R(n), \ \ n \ge 0$. An alternative expression for $R(n)$ is

$$R(n) = \left(\prod_{k=1}^{n} (1 + \alpha(k)) \right) \big(\alpha(0)A(0) + \beta \big).$$

The inequality (i) then follows from the bound $1 + x \le e^x$.

To see (ii) fix $n \ge 0$ and observe that on summing both sides of the bound

$$A(k+1) - A(k) \le \alpha(k)A(k) + \gamma(k)$$

over $0 \le k \le \ell$ we obtain for all $0 \le \ell < n$,

$$A(\ell + 1) \le A(0) + \beta(n) + \sum_{k=0}^{\ell} \alpha(k)A(k).$$

The result then follows from (i). □

The following lemmas relate the three functions $\phi(\cdot)$, $\widehat{\phi}(\cdot)$, and $\phi^\infty(\cdot)$.

LEMMA 4.4. *Suppose that* (A1) *and* (A2) *hold. Given any $\epsilon > 0$, there exist $T, R < \infty$ such that for any $r > R$ and any solution to the ODE* (1.4) *satisfying $\|x(0)\| \le 1$, we have $\|x(t)\| \le \epsilon$ for $t \in [T, T+1]$.*

Proof. By global asymptotic stability of (1.5) we can find $T > 0$ such that $\|\phi^\infty(t)\| \le \epsilon/2$, $t \ge T$, for solutions $\phi^\infty(\cdot)$ of (1.5) satisfying $\|\phi^\infty(0)\| \le 1$.

With T fixed, choose R so large that $|\widehat{\phi}(t) - \phi^\infty(t)| \le \epsilon/2$ whenever $\widehat{\phi}$ is a solution to (1.4) satisfying $\widehat{\phi}(0) = \phi^\infty(0)$; $|\widehat{\phi}(0)| \le 1$; and $r \ge R$. This is possible since, as we have already observed, $h_r \to h_\infty$ as $r \to \infty$ uniformly on compact sets. The claim then follows from the triangle inequality. □

Define the following: For $j \ge 0$, $m(j) \le n < m(j+1)$,

$$\widetilde{X}(n) := X(n)/r(j),$$
$$\widetilde{M}(n+1) := M(n+1)/r(j),$$

and for $n \ge 1$,

$$\xi(n) := \sum_{m=0}^{n-1} a(m)\widetilde{M}(m+1).$$

LEMMA 4.5. *Under* (A1), (A2), *and either* (TS) *or* (BS), *for each initial condition $X(0) \in \mathbb{R}^d$ satisfying $\mathsf{E}[\|X(0)\|^2] < \infty$, we have the following:*

(i) $\sup_{n \ge 0} \mathsf{E}[\|\widetilde{X}(n)\|^2] < \infty$.

(ii) $\sup_{j \ge 0} \mathsf{E}[\|X(m(j+1))/r(j)\|^2] < \infty$.

(iii) $\sup_{j \ge 0, T(j) \le t \le T(j+1)} \mathsf{E}[\|\phi(t)\|^2] < \infty$.

(iv) *Under* (TS) *the sequence $\{\xi(n), \mathcal{F}_n\}$ is a square integrable martingale with*

$$\sup_{n \ge 0} \mathsf{E}[\|\xi(n)\|^2] < \infty.$$

Proof. To prove (i) note first that under (A2) and the Lipschitz condition on h there exists $C < \infty$ such that for all $n \ge 1$,

$$\mathsf{E}\big[\|X(n)\|^2 \mid \mathcal{F}_{n-1}\big] \le \big(1 + Ca(n-1)\big)\|X(n-1)\|^2 + Ca(n-1), \quad n \ge 0. \tag{4.2}$$

It then follows that for any $j \geq 0$ and any $m(j) < n < m(j+1)$,

$$\mathsf{E}\big[\big\|\widetilde{X}(n)\big\|^2 \mid \mathcal{F}_{n-1}\big] \leq \big(1 + Ca(n-1)\big)\big\|\widetilde{X}(n-1)\big\|^2 + Ca(n-1),$$

so that by Lemma 4.3 (ii), for all such n,

$$\begin{aligned}\mathsf{E}\big[\big\|\widetilde{X}(n+1)\big\|^2\big] &\leq \exp\big(C(T+1)\big)\big(2\mathsf{E}\big[\big\|\widetilde{X}(m(j))\big\|^2\big] + C(T+1)\big)\\ &\leq \exp\big(C(T+1)\big)\big(2 + C(T+1)\big).\end{aligned}$$

Claim (i) follows, and claim (ii) follows similarly. We then obtain claim (iii) from the definition of $\phi(\,\cdot\,)$. From (i), (ii), and (A2), we have $\sup_n \mathsf{E}[\|\widetilde{M}(n)\|^2] < \infty$. Using this and the square summability of $\{a(n)\}$ assumed in (TS), the bound (iv) immediately follows. □

LEMMA 4.6. *Suppose* $\mathsf{E}[\|X(0)\|^2] < \infty$. *Under* (A1), (A2), *and* (TS), *with probability one,*

(i) $\|\phi(t) - \widehat{\phi}(t)\| \to 0$ *as* $t \to \infty$,

(ii) $\sup_{t\geq 0}\|\phi(t)\| < \infty$.

Proof. Express $\widehat{\phi}(\,\cdot\,)$ as follows: For $m(j) \leq n < m(j+1)$,

$$\begin{aligned}\widehat{\phi}(t(n+1)-) &= \widehat{\phi}(T(j)) + \sum_{i=m(j)}^{n}\int_{t(i)}^{t(i+1)} h_{r(j)}\big(\widehat{\phi}(s)\big)ds\\ &= \widehat{\phi}(T(j)) + \epsilon_1(j) + \sum_{i=m(j)}^{n} a(i)h_{r(j)}\big(\widehat{\phi}(t(i))\big),\end{aligned} \tag{4.3}$$

where $\epsilon_1(j) = O(\sum_{i=m(j)}^{m(j+1)} a(i)^2) \to 0$ as $j \to \infty$. The "$-$" covers the case where $t(n+1) = t(m(j+1)) = T(j+1)$.

We also have by definition

$$\phi\big(t(n+1)-\big) = \phi\big(T(j)\big) + \sum_{i=m(j)}^{n} a(i)\big[h_{r(j)}\big(\phi\big(t(i)\big)\big) + \widetilde{M}(i+1)\big]. \tag{4.4}$$

For $m(j) \leq n \leq m(j+1)$, let $\varepsilon(n) = \|\phi(t(n)-) - \widehat{\phi}(t(n)-)\|$. Combining (4.3), (4.4), and the Lipschitz continuity of h, we have

$$\varepsilon(n+1) \leq \varepsilon\big(m(j)\big) + \epsilon_1(j) + \|\xi(n+1) - \xi(m(j))\| + C\sum_{i=m(j)}^{n} a(i)\varepsilon(i),$$

where $C < \infty$ is a suitable constant. Since $\varepsilon(m(j)) = 0$, we can use Lemma 4.3 (i) to obtain

$$\varepsilon(n) \leq \exp\big(C(T+1)\big)\big(\epsilon_1(j) + \epsilon_2(j)\big), \qquad m(j) \leq n \leq m(j+1),$$

where $\epsilon_2(j) = \max_{m(j)\leq n\leq m(j+1)} \|\xi(n+1) - \xi(m(j))\|$. By (iv) of Lemma 4.5 and the martingale convergence theorem [18, p. 62], $\{\xi(n)\}$ converges a.s.; thus $\epsilon_2(j) \to 0$ a.s., as $j \to \infty$. Since $\epsilon_1(j) \to 0$ as well,

$$\sup_{m(j)\leq n\leq m(j+1)} \big\|\phi(t(n)-) - \widehat{\phi}(t(n)-)\big\| = \sup_{m(j)\leq n\leq m(j+1)} \varepsilon(n) \to 0$$

as $j \to \infty$, which implies the first claim.

Result (ii) then follows from Lemma 4.2 and the triangle inequality. □

LEMMA 4.7. *Under* (A1), (A2), *and* (BS), *there exists a constant* $C_2 < \infty$ *such that for all* $j \geq 0$,

(i) $\sup_{j\geq 0, T(j)\leq t\leq T(j+1)} \mathsf{E}[\|\phi(t) - \widehat{\phi}(t)\|^2 \mid \mathcal{F}_{n(j)}] \leq C_2\overline{\alpha}$,

(ii) $\sup_{j\geq 0, T(j)\leq t\leq T(j+1)} \mathsf{E}[\|\phi(t)\|^2 \mid \mathcal{F}_{n(j)}] \leq C_2$.

Proof. Mimic the proof of Lemma 4.6 to obtain

$$\varepsilon(n+1) \leq \sum_{i=m(j)}^{n} Ca(i)\varepsilon(i) + \epsilon_0(j), \qquad m(j) \leq n < m(j+1),$$

where $\varepsilon(n) = \mathsf{E}[\|\phi(t(n)-) - \widehat{\phi}(t(n)-)\|^2 \mid \mathcal{F}_{m(j)}]^{1/2}$ for $m(j) \leq n \leq m(j+1)$, and the error term has the upper bound

$$|\epsilon_0(j)| = O(\overline{\alpha}),$$

where the bound is deterministic. By Lemma 4.3 (i) we obtain the bound,

$$\varepsilon(n) \leq \exp\big(C(T+1)\big)\epsilon_0(j), \qquad m(j) \leq n \leq m(j+1),$$

which proves (i). We, therefore, obtain (ii) using Lemma 4.2, (i), and the triangle inequality. □

Proof of Theorem 2.1. (i) By a simple conditioning argument, we may take $X(0)$ to be deterministic without any loss of generality. In particular, $\mathsf{E}[\|X(0)\|^2] < \infty$ trivially. By Lemma 4.6 (ii), it now suffices to prove that $\sup_n \|X(m(n))\| < \infty$ a.s. Fix a sample point outside the zero probability set where Lemma 4.6 fails. Pick $T > 0$ as above and $R > 0$ such that for every solution $x(\,\cdot\,)$ of the ODE (1.4) with $\|x(0)\| \leq 1$ and $r \geq R$, we have $\|x(t)\| \leq \frac{1}{4}$ for $t \in [T, T+1]$. This is possible by Lemma 4.4.

Hence by Lemma 4.6 (i) we can find an $j_0 \geq 1$ such that whenever $j \geq j_0$ and $\|X(m(j))\| \geq R$,

$$\frac{\|X(m(j+1))\|}{\|X(m(j))\|} = \phi\big(T(j+1) - \big) \leq \frac{1}{2}. \tag{4.5}$$

This implies that $\{X(m(j)) : j \geq 0\}$ is a.s. bounded, and the claim follows.

(ii) For $m(j) < n \leq m(j+1)$,

(4.6)

$$\begin{aligned}
\mathsf{E}\big[\big\|X(n)\big\|^2 \mid \mathcal{F}_{m(j)}\big]^{1/2} &= \mathsf{E}\big[\big\|\phi\big(t(n)-\big)\big\|^2 \mid \mathcal{F}_{m(j)}\big]^{1/2}\big(\big\|X(m(j))\big\| \vee 1\big) \\
&\leq \mathsf{E}\big[\big\|\phi\big(t(n)-\big) - \widehat{\phi}\big(t(n)-\big)\big\|^2 \mid \mathcal{F}_{m(j)}\big]^{1/2}\big(\big\|X\big(m(j)\big)\big\| \vee 1\big) \\
&\quad + \mathsf{E}\big[\big\|\widehat{\phi}(t(n)-)\big\|^2 \mid \mathcal{F}_{m(j)}\big]^{1/2}\big(\|X\big(m(j)\big)\| \vee 1\big).
\end{aligned}$$

Let $0 < \eta < \frac{1}{2}$, and let $\alpha^* = \eta/(2C_2)$, for C_2 as in Lemma 4.7. We then obtain for $\overline{\alpha} \leq \alpha^*$,

$$\begin{aligned}
\mathsf{E}\big[\big\|X(n)\big\|^2 \mid \mathcal{F}_{m(j)}\big]^{1/2} &\leq (\eta/2)\big(\big\|X\big(m(j)\big)\big\| \vee 1\big) \\
&\quad + \mathsf{E}\big[\big\|\widehat{\phi}\big(t(n)-\big)\big\|^2 \mid \mathcal{F}_{m(j)}\big]^{1/2}\big(\big\|X\big(m(j)\big)\big\| \vee 1\big).
\end{aligned} \tag{4.7}$$

Choose $R, T > 0$ such that for any solution $x(\cdot)$ of the ODE (1.4), $\|x(t)\| < \eta/2$ for $t \in [T, T+1]$, whenever $\|x(0)\| < 1$ and $r \geq R$. When $\|X(m(j))\| \geq R$, we then obtain

$$\mathsf{E}\big[\big\|X\big(m(j+1)\big)\big\|^2 \mid \mathcal{F}_{m(j)}\big]^{1/2} \leq \eta \big\|X\big(m(j)\big)\big\|, \tag{4.8}$$

while by Lemma 4.7 (ii) there exists a constant C such that the left-hand side (l.h.s.) of the inequality above is bounded by C a.s. when $\|X(m(j))\| \leq R$. Thus,

$$\mathsf{E}\big[\big\|X\big(m(j+1)\big)\big\|^2\big] \leq 2\eta^2 \mathsf{E}\big[\big\|X\big(m(j)\big)\big\|^2\big] + 2C^2.$$

This establishes boundedness of $\mathsf{E}[\|X(m(j+1))\|^2]$, and the proof then follows from (4.7) and Lemma 4.2. □

4.2. Convergence for (BS). LEMMA 4.8. *Suppose that* (A1), (A2), *and* (BS) *hold and that* $\overline{\alpha} \leq \alpha^*$. *Then for some constant* $C_3 < \infty$,

$$\sup_{t \geq 0} \mathsf{E}\big[\big\|\widehat{\psi}(t) - \psi(t)\big\|^2\big] \leq C_3 \overline{\alpha}.$$

Proof. By (A2) and Theorem 2.1 (ii),

$$\sup_n \mathsf{E}\big[\big\|X(n)\big\|^2\big] < \infty, \quad \sup_n \mathsf{E}\big[\big\|M(n)\big\|^2\big] < \infty.$$

The claim then follows from familiar arguments using the Bellman Gronwall lemma exactly as in the proof of Lemma 4.6. □

Proof of Theorem 2.3. (i) We apply Theorem 2.1 which allows us to choose an $R > 0$ such that

$$\sup_n \mathsf{P}\big(\|X(n)\| > R\big) < \overline{\alpha}.$$

Let $B(c)$ denote the ball centered at x^* of radius $c > 0$ and let $0 < \mu < \epsilon/2$ be such that if a solution $x(\cdot)$ of (1.2) satisfies $x(0) \in B(\mu)$, then $x(t) \in B(\epsilon/2)$ for $t \geq 0$. Pick $T > 0$ such that if a solution $x(\cdot)$ of (1.2) satisfies $\|x(0)\| \leq R$, then $x(t) \in B(\mu/2)$ for $t \in [T, T+1]$. Then for all $j \geq 0$,

$$\begin{aligned}
\mathsf{P}\big(e\big(m(j+1)\big) \geq \mu\big) &= \mathsf{P}\Big(e\big(m(j+1)\big) \geq \mu, \big\|X\big(m(j)\big)\big\| > R\Big) \\
&\quad + \mathsf{P}\Big(e\big(m(j+1)\big) \geq \mu, \|X(m(j))\| \leq R\Big) \\
&\leq \overline{\alpha} + \mathsf{P}\Big(\psi\big(T(j+1)\big) \notin B(\mu), \widehat{\psi}\big(T(j+1)\big) \in B(\mu/2)\Big) \\
&\leq \overline{\alpha} + \mathsf{P}\Big(\|\psi\big(T(j+1)\big) - \widehat{\psi}\big(T(j+1)\big)\| > \mu/2\Big) \\
&\leq O(\overline{\alpha})
\end{aligned}$$

by Lemma 4.8. Then for $m(j) \leq n < m(j+1)$,

$$\begin{aligned}
\mathsf{P}\big(e(n) \geq \epsilon\big) &= \mathsf{P}\big(e(n) \geq \epsilon, e\big(m(j)\big) \geq \mu\big) \\
&\quad + \mathsf{P}\big(e(n) \geq \epsilon, e\big(m(j)\big) \leq \mu\big) \\
&\leq O(\overline{\alpha}) + \mathsf{P}\big(\psi\big(t(n)\big) \notin B(\epsilon), \widehat{\psi}\big(t(n)\big) \in B\big(\epsilon/2\big)\big) \\
&\leq O(\overline{\alpha}) + \mathsf{P}\big(\|\psi\big(t(n)\big) - \widehat{\psi}\big(t(n)\big)\| > \epsilon/2\big) \\
&\leq O(\overline{\alpha}).
\end{aligned}$$

Since the bound on the r.h.s. is uniform in n, the claim follows.

(ii) We first establish the bound with $n = m(j+1)$, $j \to \infty$. We have for any j,

$$\begin{aligned}\mathsf{E}\big[e\big(m(j+1)\big)^2\big]^{1/2} &\le \mathsf{E}\big[\big\|\psi\big(T(j+1)-\,\big) - \widehat{\psi}\big(T(j+1)-\,\big)\big\|^2\big]^{1/2} \\ &\quad + \mathsf{E}\big[\big\|\widehat{\psi}\big(T(j+1)-\,\big) - x^*\big\|^2\big]^{1/2}. \end{aligned} \tag{4.9}$$

By exponential stability there exist $C < \infty$, $\delta > 0$ such that for all $j \ge 0$,

$$\begin{aligned}\big\|\widehat{\psi}\big(T(j+1)-\,\big) - x^*\big\| &\le C\exp\big(-\delta\big[T(j+1)-T(j)\big]\big)\big\|\widehat{\psi}\big(T(j)\big) - x^*\big\| \\ &\le C\exp(-\delta T)\big\|\widehat{\psi}\big(T(j)\big) - x^*\big\|.\end{aligned}$$

Choose T so large that $C\exp(-\delta T) \le \frac{1}{2}$ so that

$$\begin{aligned}\mathsf{E}\big[\big\|\widehat{\psi}\big(T(j+1)-\,\big) - x^*\big\|^2\big]^{1/2} &\le \frac{1}{2}\mathsf{E}\big[\big\|\widehat{\psi}\big(T(j)\big) - x^*\big\|^2\big]^{1/2} \\ &\le \frac{1}{2}\mathsf{E}\big[e\big(m(j)\big)^2\big]^{1/2} + \frac{1}{2}\mathsf{E}\big[\big\|\psi\big(T(j)\big) - \widehat{\psi}\big(T(j)\big)\big\|^2\big]^{1/2}. \end{aligned} \tag{4.10}$$

Combining (4.9) and (4.10) with Lemma 4.8 gives

$$\mathsf{E}\big[e\big(m(j+1)\big)^2\big]^{1/2} \le \frac{1}{2}\mathsf{E}\big[e\big(m(j)\big)^2\big]^{1/2} + 2\sqrt{C_3\overline{\alpha}},$$

which shows that

$$\limsup_{j\to\infty} \mathsf{E}\big[e\big(m(j)\big)^2\big] \le 16C_3\overline{\alpha}.$$

The result follows from this and Lemma 4.7 (ii). □

Proof of Theorem 2.5. The details of the proof, though pedestrian in the light of the foregoing and [6], are quite lengthy, not to mention the considerable overhead of additional notation, and are therefore omitted. We briefly sketch below a single point of departure in the proof.

In Lemma 4.6 we compare two functions $\phi(\,\cdot\,)$ and $\widehat{\phi}(\,\cdot\,)$ on the interval $[T(j), T(j+1)]$. The former in turn involved the iterates $\widetilde{X}(n)$ for $m(j) \le n < m(j+1)$ or, equivalently, $X(n)$ for $m(j) \le n < m(j+1)$. Here $X(n+1)$ was computed in terms of $X(n)$ and the "noise" $M(n+1)$. In the asynchronous case, however, the evaluation of $X_j(n+1)$ can involve $X_j(n)$ for $n - \overline{\tau} \le m \le n$, $j \ne i$. Therefore the argument leading to Lemma 4.6 calls for a slight modification. While computing $X(n), m(j) \le n < m(j+1)$, we plug into the iteration as and when required $\widetilde{X}_i(m) = X_i(m)/r(j)$. Note, however, that if the same $X_i(m)$ also features in the computation of $X_k(l)$ for $m(q) \le \ell < m(q+1)$, say, with $q \ne j$, then $\widetilde{X}_i(m)$ should be redefined there as $X_i(m)/r(q)$. Thus the definition of $\widetilde{X}_i(m)$ now becomes context-dependent.

With this minor change, the proofs of [6] can be easily combined with the arguments used in the proofs of Theorems 2.1 and 2.2 to draw the desired conclusions. □

4.3. The Markov model. The bounds that we obtain for the Markov model (2.4) are based upon the theory of ψ-irreducible Markov chains.

A subset $S \subset \mathbb{R}^d$ is called *petite* if there exists a probability measure ν on $\mathbb{R}^d$ and $\delta > 0$ such that the resolvent kernel K satisfies

$$K(x, A) := \sum_{k=0}^{\infty} 2^{-k-1} P^k(x, A) \ge \delta\nu(A), \quad x \in S,$$

for any measurable $A \subset \mathbb{R}^d$. Under assumptions (2.6) and (2.7) we show below that every compact subset of $\mathbb{R}^d$ is petite, so that $\mathbf{\Phi}$ is a ψ-irreducible T-*chain*. We refer the reader to [16] for further terminology and notation.

LEMMA 4.9. *Suppose that* (A1), (A2), (2.6), *and* (2.7) *hold and that* $\alpha \le \alpha^*$. *Then all compact subsets of* $\mathbb{R}^d$ *are petite for the Markov chain* $\boldsymbol{X}$, *and hence the chain is* ψ*-irreducible.*

Proof. The conclusions of the theorem will be satisfied if we can find a function s which is bounded from below on compact sets and a probability ν such that the resolvent kernel K satisfies the bound

$$K(x, A) \ge s(x)\nu(A)$$

for every $x \in \mathbb{R}^d$ and any measurable subset $A \subset \mathbb{R}^d$. This bound is written succinctly as $K \ge s \otimes \nu$.

The first step of the proof is to apply the implicit function theorem together with (2.6) and (2.7) to obtain a bound of the form

$$P^d(x, A) = \mathsf{P}(X(d) \in A \mid X(0) = x) \ge \epsilon\nu(A), \quad x \in O,$$

where O is an open set containing $x^*, \epsilon > 0$, and ν is the uniform distribution on O. The set O can be chosen independent of α, but the constant ϵ may depend on α. For details on this construction, see Chapter 7 of [16].

To complete the proof it is enough to show that $K(x, O) > 0$. To see this, suppose that $\alpha \le \alpha^*$ and that $W(n) = w^*$ for all n. Then the foregoing stability analysis shows that $X(n) \in O$ for all n sufficiently large. Since w^* is in the support of the marginal distribution of $\{W(n)\}$, it then follows that $K(x, O) > 0$.

From these two bounds, we then have

$$K(x, A) \ge 2^{-d} \int K(x, dy) P^d(y, A) \ge 2^{-d} \epsilon K(x, O)\nu(A).$$

This is of the form $K \ge s \otimes \nu$ with s lower semicontinuous and positive everywhere. The function s is therefore bounded from below on compact sets, which proves the claim. ∎

The previous lemma together with Theorem 2.1 allows us to establish a strong form of ergodicity for the model.

LEMMA 4.10. *Suppose that* (A1), (A2), (2.6), *and* (2.7) *hold and that* $\alpha \le \alpha^*$.

(i) *There exists a function* $V_\alpha : \mathbb{R}^d \to [1, \infty)$ *and constants* $b, L < \infty$ *and* $\epsilon_0 > 0$ *independent of* α *such that*

$$PV_\alpha(x) \le \exp(-\epsilon_0\alpha)V_\alpha(x) + bI_C(x),$$

where $C = \{x : \|x\| \le L\}$. *While the function* V_α *will depend upon* α, *it is uniformly bounded as follows,*

$$\gamma^{-1}(\|x\|^2 + 1) \le V_\alpha(x) \le \gamma(\|x\|^2 + 1),$$

where $\gamma \ge 1$ *does not depend upon* α.

(ii) *The chain is* V*-uniformly ergodic, with* $V(x) = \|x\|^2 + 1$.

Proof. Using (4.8) we may construct T and L independent of $\alpha \le \alpha^*$ such that

$$\mathsf{E}\big[\big\|X(k_0)\big\|^2 + 1 \mid X(0) = x\big] \le (1/2)(\|x\|^2 + 1), \quad \|x\| \ge L,$$

where $k_0 = [T/\alpha] + 1$. We now set

$$V_\alpha(x) = \alpha \sum_{k=0}^{k_0-1} \mathsf{E}\left[\left\|X(k)\right\|^2 + 1 \mid X(0) = x\right] 2^{k/k_0}.$$

From the previous bound, it follows directly that the desired drift inequality holds with $\epsilon_0 = \log(2)/T$. Lipschitz continuity of the model gives the bounds on V_α. This proves (i).

The V-uniform ergodicity then follows from Lemma 4.9 and Theorem 16.0.1 of [16]. □

We note that for small α and large x, the Lyapunov function V_α approximates V_∞ plus a constant, where

$$V_\infty(x) = \int_0^T \left(\|x(s)\|^2 + 1\right) 2^{s/T} ds; \quad x(0) = x,$$

and $x(\,\cdot\,)$ is a solution to (1.5). If this ODE is asymptotically stable then the function V_∞ is in fact a Lyapunov function for (1.5), provided $T > 0$ is chosen sufficiently large.

In [17] a bound is obtained on the rate of convergence ρ given in (2.5) for a chain satisfying the drift condition

$$PV_\alpha(x) \le \lambda V(x) + bI_C(x).$$

The bound depends on the "petiteness" of the set C and the constants $b < \infty$ and $\lambda < 1$. The bound on ρ obtained in [17] also tends to unity with vanishing α since in the preceding lemma we have $\lambda = \exp(-\epsilon_0\alpha) \to 1$ as $\alpha \to 0$. From the structure of the algorithm this is not surprising, but this underlines the fact that care must be taken in the choice of the stepsize α.

UNIQUENESS OF LOWER SEMICONTINUOUS VISCOSITY SOLUTIONS FOR THE MINIMUM TIME PROBLEM*

OLIVIER ALVAREZ†, SHIGEAKI KOIKE‡, AND ISAO NAKAYAMA‡

Abstract. We obtain the uniqueness of lower semicontinuous (LSC) viscosity solutions of the transformed minimum time problem assuming that they converge to zero on a "reachable" part of the target in appropriate directions. We present a counter-example which shows that the uniqueness does not hold without this convergence assumption.

It was shown by Soravia that the uniqueness of LSC viscosity solutions having a "subsolution property" on the target holds. In order to verify this subsolution property, we show that the dynamic programming principle (DPP) holds inside for any LSC viscosity solutions.

In order to obtain the DPP, we prepare appropriate approximate PDEs derived through Barles' inf-convolution and its variant.

Key words. semicontinuous viscosity solutions, dynamic programming principle, minimum time problem

1. Introduction.

In this manuscript, we discuss the minimum time problem of deterministic optimal control, which has been studied via viscosity solution approach by many authors. As the first result, we refer to Bardi [Ba]. See also [EJ], [BF], [BS], and [BSo], who also treated the minimum time problem of differential games.

In those works, they characterized the value function of the minimum time problem to reach a given target as the unique viscosity solution of a first-order PDE. However, they treated the case only when the resulting value functions are continuous since those uniqueness results imply the continuity of solutions. We note that there often appear discontinuous value functions for practical minimum time problems.

The breakthrough to treat semicontinuous solutions for first-order PDEs was done by Barron and Jensen [BJ1]. Indeed, they introduced a new definition of semicontinuous viscosity solutions for Cauchy problems with convex Hamiltonians, which arise when we deal with optimal control problems. Under their setting, it was shown in [BJ2] that the semicontinuous value function is the unique solution of the associated PDE. We note that if we restrict ourselves to treat continuous viscosity solutions, then their definition is equivalent to that of the standard one.

Afterward, Barles [B1] discussed semicontinuous solutions for stationary problems utilizing "Barles"-convolution. With this idea, Soravia [S1] studied the Dirichlet-type problems. More precisely, he imposed a "subsolution" property on the boundary of the target, under which the uniqueness of LSC viscosity solutions for the (transformed) minimum time problem was obtained. See also [K] and [BL] for related topics. Recently, Cârjă, Mignanego, and Pieri in [CMP] (see also [C]) studied LSC viscosity

solutions of the minimum time problem assuming that they converge to the Dirichlet data from inside.

For the viscosity solution theory of first-order Hamilton–Jacobi equations, we refer to a new book by Bardi and Capuzzo Dolcetta [BC].

On the other hand, in nonsmooth analysis, LSC solutions have been studied in optimal control theory. For the first result, we refer to Frankowska [F]. More recently, Wolenski and Zhuang [WZ] have proved the uniqueness of LSC solutions of the minimum time problem assuming the subsolution property on the target as in [S1], which the value function satisfies. We note that their definition of solutions is slightly different from that of viscosity solutions. It is worth mentioning that in [WZ], to show the uniqueness, they compared the other LSC solution (if it exists) with the value function by the so-called invariance theory while, in the literature of the viscosity solution theory, we have shown it via comparison principle for a boundary value problem of PDEs.

Our aim here is to obtain a uniqueness result without assuming the subsolution property on the target. In fact, we will derive such a property from the definition of solutions under some continuity assumption on a "reachable" part of the boundary. Then, we will be able to apply Soravia's argument in [S1] to get the uniqueness.

Moreover, we will mention that our continuity condition is equivalent to Soravia's one. In fact, to show that the Soravia's condition implies the continuity condition, we give a direct proof, although we can prove it using the uniqueness of solutions.

In an example, we will see that this continuity assumption is necessary to obtain the uniqueness result.

Here, we shall recall the original minimum time problem. Consider the state equation associated with controls

$$\alpha \in \mathcal{A} \equiv \{\alpha : [0,\infty) \to A \text{ measurable}\},$$

where A is a compact set in $\mathbf{R}^m$ (for some $m \in \mathbf{N}$). For $x \in \mathbf{R}^n$,

$$\begin{cases} \dfrac{dX}{dt}(t) = g(X(t), \alpha(t)) \quad \text{for } t > 0, \\ X(0) = x, \end{cases} \tag{1.1}$$

where $g : \mathbf{R}^n \times A \to \mathbf{R}^n$ is a given function and $x \in \mathbf{R}^n$ is fixed.

We shall denote, under appropriate hypotheses, by $X(\cdot; x, \alpha)$ the (unique) solution of (1.1). We will also denote by $X(\cdot; x, \xi(\cdot))$ the unique solution for a vector field $\xi \in W^{1,\infty}(\mathbf{R}^n; \mathbf{R}^n)$:

$$\begin{cases} \dfrac{dX}{dt}(t) = \xi(X(t)) \quad \text{for } t > 0, \\ X(0) = x. \end{cases}$$

For simplicity, we shall suppose that

$$\mathcal{T} \subset \mathbf{R}^n \text{ is compact.} \tag{$A0$}$$

With these notations, we recall the value function of the minimum time problem:

$$V(x) = \inf_{\alpha \in \mathcal{A}} T_x^\alpha,$$

where $T_x^\alpha = \inf\{t \geq 0 \mid X(t; x, \alpha) \in \mathcal{T}\}$.

Since $V(x)$ might be infinity in a subregion of $\Omega \equiv \mathbf{R}^n \backslash \mathcal{T}$, we will have to study the free boundary problem:

$$\max_{a\in A}\{-\langle g(x,a), DV(x)\rangle - 1\} = 0 \quad \text{in } \mathcal{R} \equiv \{x \in \Omega \mid V(x) < \infty\}. \tag{1.2}$$

Since we cannot expect that $\mathcal{R}$ is open in general, as we will see, we meet some difficulty if we treat (1.2) directly. Therefore, in this paper, following the previous works, we shall consider the transformed value function by Kruzkov transformation:

$$u(x) = \inf_{\alpha\in\mathcal{A}} \left(1 - e^{-T_x^\alpha}\right).$$

Then, we can expect u to be a solution of

$$u(x) + \max_{a\in A}\{-\langle g(x,a), Du(x)\rangle\} = 1 \quad \text{in } \Omega. \tag{1.3}$$

Thus, once we verify that u is the unique solution of (1.3), we will be able to derive the reachable set by $\mathcal{R} = \{x \in \Omega \mid u(x) < 1\}$.

This paper is organized as follows. Section 2 is devoted to our definition of the minimum time problem and the DPP which implies the subsolution property. We present our uniqueness result and examples in section 3. Also, we discuss the equivalence of boundary conditions in section 3. In the final section, we prove the DPP in section 2.

2. DPP. Our hypothesis on the regularity of given functions is as follows:

$$(A1) \qquad g \in C\big(\mathbf{R}^n \times A; \mathbf{R}^n\big) \qquad \text{and} \qquad \sup_{a\in A} \|g(\cdot,a)\|_{W^{1,\infty}(\mathbf{R}^n;\mathbf{R}^n)} < \infty.$$

For later convenience, we shall consider the following general first-order PDE in a set $\Sigma \subset \mathbf{R}^n$:

$$u(x) + \max_{a\in A}\{-\langle g(x,a), Du(x)\rangle - f(x,a)\} = 0 \quad \text{in } \Sigma, \tag{2.1}$$

where $f : \mathbf{R}^n \times A \to \mathbf{R}$ is a given continuous function.

For simplicity, we shall use the notation

$$H(x,r,p) \equiv r + \max_{a\in A}\{-\langle g(x,a), p\rangle - f(x,a)\}.$$

We will suppose the following regularity on given functions in (2.1):

$$(A1') \qquad \begin{cases} g \in C\big(\mathbf{R}^n \times A; \mathbf{R}^n\big),\ f \in C\big(\mathbf{R}^n \times A; \mathbf{R}\big), \text{ and} \\ \sup\limits_{a\in A} \big\{\|g(\cdot,a)\|_{W^{1,\infty}(\mathbf{R}^n;\mathbf{R}^n)} + \|f(\cdot,a)\|_{W^{1,\infty}(\mathbf{R}^n;\mathbf{R})}\big\} < \infty. \end{cases}$$

Following [BJ1] (also [B1]), we present our definition of solutions of (2.1).

DEFINITION. *For a function $u : \Sigma \to \mathbf{R}$, we call it a subsolution (resp., supersolution) of* (2.1) *if u is LSC in Σ, and*

$$H(x,u(x),p) \le (\textit{resp.},\ \ge)\ 0 \quad \textit{for } x \in \Sigma \textit{ and } p \in D^-u(x),$$

where $D^-u(x)$ denotes the standard subdifferential of u at $x \in \Sigma$.

$$D^-u(x) = \{p \in \mathbf{R}^n \mid u(y) \ge u(x) + \langle p, y-x\rangle + o(|y-x|) \textit{ as } y \to x\}.$$

For a function $u : \Sigma \to \mathbf{R}$, we also call it a solution of (2.1) *if u is both a sub- and a supersolution of* (2.1)

We characterize the set of reachable controls in the following way. For $x \in \partial\mathcal{T}$,

$$A(x) \equiv \left\{ a \in A \;\middle|\; \begin{array}{c} \text{There exists } t > 0 \text{ such that} \\ X(s; x, -g(\cdot, a)) \in \Omega \text{ for } s \in (0, t) \end{array} \right\}.$$

We shall derive the "subsolution" properties on $\partial\mathcal{T}$ for solutions through the following propositions.

LEMMA 2.1. *Assume that* (A1) *holds. Let u be a solution of* (1.3). *Assume also that $u = 0$ on $\mathcal{T}$. Then, for $x \in \partial\mathcal{T}$ and $p \in D^- u(x)$, we have*

$$-\langle g(x, a), p\rangle \le 0 \quad \textit{provided } a \in A \backslash A(x).$$

Proof. Choose $\phi \in C^1$ such that $u - \phi$ attains its minimum over $\mathbf{R}^n$ at $x \in \partial\mathcal{T}$, $u(x) = \phi(x) = 0$, and $D\phi(x) = p$. Set $X(\cdot) \equiv X(\cdot; x, -g(\cdot, a))$.

Since $a \in A\backslash A(x)$, there exists $\{t_k > 0\}_{k=1}^{\infty}$, such that $\lim_{k\to\infty} t_k = 0$ and $X(t_k) \in \mathcal{T}$ $(k = 1, 2, \dots)$. Hence,

$$\phi(X(t_k)) - \phi(x) \le u(X(t_k)) = 0.$$

Therefore, dividing t_k and then sending $k \to \infty$, we conclude the assertion. □

For simplicity, we shall suppose that

(A0′) $\qquad \Sigma$ is open and $\partial\Sigma$ is compact.

For $\delta > 0$, we define an open subset

$$\Sigma_\delta \equiv \{x \in \Sigma \mid \operatorname{dist}(x, \partial\Sigma) > \delta\}.$$

Also, for an open subset $O \subset \Sigma$ and $x \in O$, we use the notation

$$\tau_O^{x,\alpha} = \inf\{t \ge 0 \mid X(t; x, \alpha) \notin O\}.$$

We present the DPP for (2.1), whose proof will be given in the final section since it is rather complicated.

THEOREM 2.2 (cf. [L]). *Assume that* (A0′) *and* (A1′) *hold. Let $u : \overline{\Sigma} \to \mathbf{R}$ be a bounded solution of*

$$H(x, u, Du) = 0 \quad \textit{in } \Sigma.$$

Then, for $\delta > 0$ and $x \in \Sigma_\delta$,

$$u(x) = \inf_{\alpha\in\mathcal{A}} \left\{ \int_0^{\tau_{\Sigma_\delta}^{x,\alpha}} e^{-s} f(X(s; x, \alpha), \alpha(s)) ds + e^{-\tau_{\Sigma_\delta}^{x,\alpha}} u(X(\tau_\delta^{x,\alpha}; x, \alpha)) \right\}.$$

COROLLARY 2.3. *Assume that* (A0) *and* (A1) *hold. Fix $x \in \partial\mathcal{T}$. Let $u : \overline{\Omega} \to \mathbf{R}$ be a bounded solution of*

$$u(x) + \max_{a\in A}\{-\langle g(x, a), Du(x)\rangle\} - 1 = 0 \quad \textit{in } \Omega.$$

Assume also that $u = 0$ on $\mathcal{T}$ and, for any $x \in \partial\mathcal{T}$ and $a \in A(x)$,

$$\liminf_{s\to t} u(X(s; x_t, a)) = u(x) \textit{ holds,}$$

where $x_t \equiv X(t; x, -g(\cdot, a))$ *for* $t \geq 0$.

Then,

$$u(x) - \langle g(x,a), p\rangle \leq 1 \quad \textit{for } p \in D^- u(x).$$

Proof of Corollary 2.3. Let $x \in \partial\mathcal{T}, p \in D^- u(x)$, and $a \in A(x)$ in the hypothesis. We then set $x_t = X(t; x, -g(\cdot, a)) \in \Omega$ for small $t > 0$.

Choose $\phi \in C^1$ such that $u(x) = \phi(x)$, $u \geq \phi$ in $\mathbf{R}^n$, and $D\phi(x) = p$.

Fix small $t > 0$ and choose $\delta(t) > 0$ such that $x_t \in \Omega_\delta$ for $\delta \in (0, \delta(t))$.

By Theorem 2.2, we have

$$u(x_t) \leq 1 - e^{-\tau_{\Omega_\delta}^{x_t,a}} + e^{-\tau_{\Omega_\delta}^{x_t,a}} u(X(\tau_{\Omega_\delta}^{x_t,a}; x_t, a)),$$

where a stands for the constant control; $\alpha(\cdot) \equiv a$.

We note that $\lim_{\delta\to 0} \tau_{\Omega_\delta}^{x_t,a} = t$.

We also note that the uniqueness of solutions of (1.1) yields $X(\tau_{\Omega_\delta}^{x_t,a}; x_t, a) = x_{t-\tau_{\Omega_\delta}^{x_t,a}}$. Take the limit infimum, as $\delta \to 0$, together with these in the above to get

$$\phi(x_t) - e^{-t}\phi(x) \leq u(x_t) - e^{-t}u(x) \leq 1 - e^{-t}.$$

Dividing $t > 0$ and then, sending $t \to 0$ in the above, we conclude the proof. □

3. Main results. In order to obtain the uniqueness result, we will suppose the following continuity assumption. Letting u be an LSC function in $\overline{\Omega}$, we will suppose that, for any $x \in \mathcal{T}$ and $a \in A(x)$,

$$\liminf_{s\to t} u(X(s; x_t, a)) = 0 \quad \text{for small } t > 0, \tag{A2}$$

where $x_t = X(t; x, -g(\cdot, a))$.

Notice that we do not suppose that $A(x) \neq \emptyset$ in this hypothesis.

Our uniqueness result for (1.3) is as follows.

THEOREM 3.1. *Assume that* (A0) *and* (A1) *hold. Let* u *and* $v : \mathbf{R}^n \to \mathbf{R}$ *be bounded solutions of* (1.3) *and satisfy* (A2). *Assume also that* $u = v = 0$ *on* $\mathcal{T}$. *Then,* $u = v$ *in* $\mathbf{R}^n$.

Proof of Theorem 3.1. In view of Lemma 2.1 and Corollary 2.3, we see that

$$u(x) + \max_{a\in A}\{-\langle g(x,a), p\rangle\} \leq 1 \quad \text{for } x \in \partial\mathcal{T} \text{ and } p \in D^- u(x). \tag{3.1}$$

This property enables us to apply Soravia's result, Theorem 3.1 in [S1], to conclude the proof. □

Thanks to the above theorem, it is easy to show that the relaxed value function is the unique bounded viscosity solution of (1.3) satisfying (A2). To this end, let us introduce the unique solution $\hat{X}(\cdot; x, \mu)$ of the associated state equation:

$$\hat{X}(t) = x + \int_0^t \int_A g\big(\hat{X}(s), a\big) d\mu[s](a) ds, \tag{3.2}$$

where $s \in [0, \infty) \to \mu[s] \in M(A)$ is measurable. Here, $M(A)$ is the set of all Radon probability measures on A. We shall denote by $\hat{\mathcal{A}}$ the set of such maps μ.

The relaxed value function is as follows:

$$\hat{V}(x) = \inf_{\mu\in\hat{\mathcal{A}}} \left(1 - e^{-\hat{T}_x^\mu}\right),$$

where $\hat{T}_x^\mu = \inf\{t \geq 0 \mid \hat{X}(t;x,\mu) \in \mathcal{T}\}$.

THEOREM 3.2. *Assume that* (A0) *and* (A1) *hold. Then,* $\hat{V}$ *is the unique bounded solution of* (1.3) *satisfying* (A2).

Proof of Theorem 3.2. Following the argument in [BJ2], we see that $\hat{V}$ is LSC and satisfies (1.3) in our sense in Ω.

To check that A2 holds for $\hat{V}$, we observe that, for $x \in \partial\mathcal{T}$ and $a \in A(x)$,

$$\hat{V}(X(s;X(t;x,-g(\cdot,a)),a)) \leq 1 - e^{-(t-s)}.$$

Hence, since $\hat{V}(x) = 0$, sending $s \to t$, we obtain (A2) for $\hat{V}$. We remark here that the nonnegativity of $\hat{V}$ indeed yields

$$\lim_{s\to t} \hat{V}(X(s;X(t;x,-g(\cdot,a)),a)) = 0.$$

Therefore, Theorem 3.1 immediately implies the assertion. □

Remark. If we have an LSC solution u of (1.3) satisfying (3.1), then $u(x) = \hat{V}(x)$ in $\mathbf{R}^n$. Hence, (A2) holds true for u by Soravia's argument in [S1] since $\hat{V}$ also satisfies (3.1). Thus, through the above theorem, the condition (3.1) is equivalent to (A2). See [WZ] for the same argument.

Now, we shall show that condition (3.1) implies a bit stronger assertion than (A2).

THEOREM 3.3. *Assume that* (A0) *and* (A1) *hold. Let* $u : \overline{\Omega} \to [0,\infty)$ *be a bounded subsolution of* (1.3), *satisfying* (3.1) *and* $u = 0$ *on* $\mathcal{T}$. *Then, for each* $x \in \partial\mathcal{T}$, $a \in A(x)$, *and small* $t > 0$, *we have*

$$\lim_{s\to t} u(X(s;X(t;x,-g(\cdot,a)),a)) = 0.$$

Proof of Theorem 3.3. Fix $x \in \partial\mathcal{T}$ and $a \in A(x)$. As usual, we may suppose $x = 0$ and $g(0,a) = -e_n$, where $e_n = (0,\dots,0,1)$. Furthermore, we may suppose that $g(\cdot,a) = -e_n$ near the origin. Indeed, setting $v(y) = v(y_1,\dots,y_n) = u(X(y_n;(y_1,\dots,y_{n-1},0),-g(\cdot,a)))$, we have

$$v(y) + \frac{\partial v}{\partial y_n}(y) = u(X) - \langle g(X,a), Du(X)\rangle.$$

Define $Q_\eta^h = \{x = (x',x_n) \mid -1 < x_n < h, |x'| < \eta\}$ for small $h,\eta \in (0,1)$, and $\phi(x',x_n) = 2(x_n - |x'|^2/\eta^2)$. Since $\min_{\overline{Q_\eta^h}}(u-\phi) \leq (u-\phi)(0) = 0$, the minimum point $\hat{x} \in \overline{Q_\eta^h}$ can be attained at $\hat{x} = (\hat{x}',h)$. Indeed, otherwise, we have four possibilities:

(1) In the case when $\hat{x}_n = -1$, we immediately see $(u-\phi)(\hat{x}) \geq 2 > (u-\phi)(0)$.

(2) In the case when $|\hat{x}'| = \eta$ holds, we also have $(u-\phi)(\hat{x}) > 0 = (u-\phi)(0)$.

(3) In the case when $\hat{x} = (\hat{x}',\hat{x}_n) \in Q_\eta^h \backslash \overline{\Omega}$, there is $\epsilon > 0$ such that $(u-\phi)(\hat{x} + \epsilon e_n) < (u-\phi)(\hat{x})$.

In the above three cases, we get a contradiction to the choice of the minimum point $\hat{x}$. The remaining case is as follows:

(4) In the case when $\hat{x} \in \overline{\Omega} \cap Q_\eta^h$, the definition of solutions yields

$$1 \geq u(\hat{x}) + \frac{\partial \phi}{\partial x_n}(\hat{x}) \geq 2,$$

which is a contradiction.

Therefore, taking $\eta \to 0$ along a subsequence if necessary, by the lower semicontinuity of u, we find $u(0,\dots,0,h) \leq 2h$, which concludes the assertion. □

Remark. Recently, P. Soravia kindly let us know that we can easily obtain the above assertion using the optimality principle in [S2], [S3].

The following example is due to Soravia.

EXAMPLE 3.4. *For $\mathcal{T} \equiv [-1, 1]$, consider the PDE*

$$u + \left|\frac{\partial u}{\partial x}\right| = 1 \quad \text{in } \Omega \equiv \mathbf{R}\backslash\mathcal{T}. \tag{3.3}$$

It is easy to show that the unique (continuous) solution is given by

$$V(x) = \begin{cases} 1 - e^{-|x|+1} & \text{for } |x| \geq 1, \\ 0 & \text{for } |x| < 1. \end{cases}$$

On the other hand, we observe that the following function satisfies (3.3) *in* Ω:

$$\hat{V}(x) = \begin{cases} 1 - e^{x+1} & \text{for } x < -1, \\ 0 & \text{for } |x| \leq 1, \\ 1 & \text{for } x > 1. \end{cases}$$

Notice that $\hat{V}$ does not satisfy $(A2)$ *at $x = 1$. Thus, this example indicates that it is necessary for the uniqueness result to suppose* $(A2)$.

We also note that, by Theorem 3.1, *$\hat{V}$ is the unique LSC solution of*

$$u - \frac{\partial u}{\partial x} = 1 \quad \text{in } \Omega.$$

We next give an example, in which the reachable set is not open and the discontinuity appears in Ω.

EXAMPLE 3.5. *For $\mathcal{T} \equiv \{x = (0, x_2) \in \mathbf{R}^2 \mid 0 \leq x_2 \leq 1\}$,*

$$u + \max\left\{\left|\frac{\partial u}{\partial x_1}\right|, -a(x_2)\frac{\partial u}{\partial x_2}\right\} = 1 \quad \text{in } \Omega \equiv \mathbf{R}^2\backslash\mathcal{T}, \tag{3.4}$$

where

$$a(x_2) = \begin{cases} 1 & \text{for } x_2 \geq -1, \\ x_2 + 2 & \text{for } x_2 \in (-2, -1), \\ 0 & \text{for } x_2 \leq -2. \end{cases}$$

We easily verify that the reachable set $\mathcal{R} = \{x \in \Omega \mid V(x) < 1\}$ is given by

$$\{(x_1, x_2) \in \Omega \mid -2 < x_2 \leq 1\}.$$

Moreover, it is not hard to calculate the value function:

$$V(x_1, x_2) = \begin{cases} 1 & \text{for } x_2 > 1 \text{ or } x_2 \leq -2, \\ 1 - e^{-|x_1|} & \text{for } x_2 \in (0, 1], \\ 1 - e^{-|x_1|+x_2} & \text{for } x_2 \in (-1, 0], \\ 1 - (x_2 + 2)e^{-|x_1|-1} & \text{for } x_2 \in (-2, -1]. \end{cases}$$

Notice that the discontinuity of V occurs at $(x_1, 1) \in \Omega$.

4. Proof of Theorem 2.2. The basic idea of our proof was obtained by Lions in [L] for second-order PDEs. We also refer to [EI] and [BSo]. But, in their argument, we need some regularity of solutions. Hence, we will adapt some approximation techniques.

Let u be a solution of (2.1). We shall extend u (with the same notation) to the whole space by setting $u(x) = \infty$ for $x \notin \overline{\Sigma}$.

We fix any $T > 0$.

We first approximate u by locally Lipschitz continuous functions. For $\epsilon > 0$ and $(x,t) \in \mathbf{R}^n \times (0,T)$, we define

$$u_\epsilon(x,t) = \inf_{y \in \mathbf{R}^n} \left(u(y) + e^{-\mu t} \frac{|x-y|^2}{\epsilon^2} \right)$$

and

$$u^\epsilon(x,t) = \inf_{y \in \mathbf{R}^n} \left(u(y) + e^{\mu t} \frac{|x-y|^2}{\epsilon^2} \right).$$

Here, we fix $\mu > 2 + 2\max_{a \in A} \|Dg(\cdot,a)\|_\infty$. Notice that the first one is Barles' convolution but the second one has an opposite sign of the power on the exponential.

It is immediate to see that $u_\epsilon \le u^\epsilon$ in $\mathbf{R}^n \times [0,T]$.

We can easily show the properties:

$$\text{(4.1)} \qquad \begin{cases} |x-y| \le \epsilon e^{\mu t/2} (2\|u\|_\infty)^{1/2} & \text{if } u_\epsilon(x,t) = u(y) + e^{-\mu t} \dfrac{|x-y|^2}{\epsilon^2}, \\ |x-y| \le \epsilon e^{-\mu t/2} (2\|u\|_\infty)^{1/2} & \text{if } u^\epsilon(x,t) = u(y) + e^{\mu t} \dfrac{|x-y|^2}{\epsilon^2}. \end{cases}$$

In view of these facts, we define the constant $\hat{c} = \hat{c}(T) \equiv e^{\mu T/2} (2\|u\|_\infty)^{1/2}$.

We claim that the following properties hold. For some C_1 and $C_1' > 0$ independent of ϵ and $\mu > 0$,

$$\text{(4.2)} \qquad \begin{cases} 0 \ge u_\epsilon(x,t) + q + \max\limits_{a \in A} \{ -\langle g(x,a), p \rangle - f(x,a) \} - C_1 \epsilon^2 e^{\mu t} \\ \qquad \text{for } (x,t) \in \Sigma_{\hat{c}\epsilon} \times (0,T) \text{ and } (p,q) \in D^+ u_\epsilon(x,t) \end{cases}$$

and

$$\text{(4.3)} \qquad \begin{cases} 0 \le u^\epsilon(x,t) + q + \max\limits_{a \in A} \{ -\langle g(x,a), p \rangle - f(x,a) \} + C_1' \epsilon^2 e^{-\mu t} \\ \qquad \text{for } (x,t) \in \Sigma_{\hat{c}\epsilon} \times (0,T) \text{ and } (p,q) \in D^- u^\epsilon(x,t). \end{cases}$$

Here, $D^+ u_\epsilon(x,t) = -D^-(-u_\epsilon)(x,t)$.

We note that (4.3) holds in a larger set than $\Sigma_{\hat{c}\epsilon}$ but this is sufficient to conclude the proof.

Although it is not hard to show (4.2) and (4.3) by the argument in [B1] together with (4.1), we give a brief proof for the reader's convenience.

Since (4.3) can be obtained easily by remarking the sign of the power on e, we shall only show (4.2). See also our proof for (4.2) below.

Let us recall the Barron–Jensen lemma, which will be needed also for checking the sign of q in (4.2).

LEMMA 4.1 (See [BJ1] or [K]). *Fix $(x,t) \in \mathbf{R}^n \times (0,T)$ and $(p,q) \in D^+ u_\epsilon(x,t)$. For any $\alpha > 0$, there exist $(x_k^\alpha, t_k^\alpha) \in \mathbf{R}^n \times (0,T)$, $(p_k^\alpha, q_k^\alpha) \in D^- u_\epsilon(x_k^\alpha, t_k^\alpha)$ for $k \in$*

$\{1, 2, \dots, n(\alpha)\}$ *(with some* $n(\alpha) \in \mathbf{N}$*),* $(x^\alpha, t^\alpha) \in \mathbf{R}^n \times (0, T)$*,* $C_0 > 0$*, and* $\{\theta_k^\alpha \in [0,1]\}_{k=1}^{n(\alpha)}$ *such that*

$$
\begin{cases}
\text{(i)} & \displaystyle\lim_{\alpha\to 0} \frac{|x_k^\alpha - x^\alpha|}{\alpha} = 0, \\
\text{(ii)} & \displaystyle\lim_{\alpha\to 0} \big(x^\alpha, t_k^\alpha\big) = (x,t) \quad \big(\forall k = 1, \dots, n(\alpha)\big), \\
\text{(iii)} & \alpha |p_k^\alpha| \le C_0 \quad \big(\forall \alpha > 0,\ k = 1, \dots, n(\alpha)\big), \\
\text{(iv)} & \displaystyle\sum_{k=1}^{n(\alpha)} \theta_k^\alpha = 1 \quad (\forall \alpha > 0), \\
\text{(v)} & \displaystyle\lim_{\alpha\to 0} \sum_{k=1}^{n(\alpha)} \theta_k^\alpha (p_k^\alpha, q_k^\alpha) = (p,q).
\end{cases} \tag{4.4}
$$

For $(x,t) \in \Sigma_{\hat{c}\epsilon} \times (0,T)$ and $(p,q) \in D^+ u_\epsilon(x,t)$ in (4.2), we shall choose (x_k^α, t_k^α), etc., in Lemma 4.1.

Since we may suppose $x_k^\alpha \in \Sigma_{\hat{c}\epsilon}$ for small $\alpha > 0$, in view of (4.1), we can choose $y_k^\alpha \in \Sigma$ such that

$$
u_\epsilon(x_k^\alpha, t_k^\alpha) = u(y_k^\alpha) + e^{-\mu t_k^\alpha} \frac{|x_k^\alpha - y_k^\alpha|^2}{\epsilon^2}. \tag{4.5}
$$

Since $p_k^\alpha \in D^- u(y_k^\alpha)$, the definition yields

$$
0 = u(y_k^\alpha) + \max_{a\in A}\{-\langle g(y_k^\alpha, a), p_k^\alpha\rangle - f(y_k^\alpha, a)\}.
$$

Noting $p_k^\alpha = e^{-\mu t_k^\alpha} \frac{2(x_k^\alpha - y_k^\alpha)}{\epsilon^2}$, we calculate in the following way:

$$
\begin{aligned}
0 &\ge u(y_k^\alpha) + \max_{a\in A}\{-\langle g(x_k^\alpha, a), p_k^\alpha\rangle - f(y_k^\alpha, a)\} \\
&\quad - 2 \max_{a\in A} \|Dg(\cdot, a)\|_\infty e^{-\mu t_k^\alpha} \frac{|x_k^\alpha - y_k^\alpha|^2}{\epsilon^2} \\
&\ge u(y_k^\alpha) + \max_{a\in A}\{-\langle g(x^\alpha, a), p_k^\alpha\rangle - f(x_k^\alpha, a)\} \\
&\quad - \max_{a\in A} \|Dg(\cdot, a)\|_\infty \left(2e^{-\mu t_k^\alpha} \frac{|x_k^\alpha - y_k^\alpha|^2}{\epsilon^2} + |x_k^\alpha - x^\alpha||p_k^\alpha|\right) \\
&\quad - \max_{a\in A} \|Df(\cdot, a)\|_\infty |x_k^\alpha - y_k^\alpha|.
\end{aligned}
$$

Since we may also suppose $\mu e^{-\mu t_k^\alpha} \frac{|x_k^\alpha - y_k^\alpha|^2}{\epsilon^2} + q_k^\alpha = 0$ for small $\alpha > 0$, by (4.5) and (iii) of (4.4), we can find $C_1 > 0$ such that

$$
\begin{aligned}
0 &\ge u_\epsilon(x_k^\alpha, t_k^\alpha) + q_k^\alpha + \max_{a\in A}\{-\langle g(x^\alpha, a), p_k^\alpha\rangle - f(x_k^\alpha, a)\} \\
&\quad - C_0 \max_{a\in A} \|Dg(\cdot, a)\|_\infty \frac{|x_k^\alpha - x^\alpha|}{\alpha} - C_1 \epsilon^2 e^{\mu t_k^\alpha} \\
&\quad + \left\{\mu - 2 \max_{a\in A} \|Dg(\cdot, a)\|_\infty - 2\right\} e^{-\mu t_k^\alpha} \frac{|x_k^\alpha - y_k^\alpha|^2}{\epsilon^2}.
\end{aligned}
$$

From the choice of $\mu > 0$, we see that the last term on the right-hand side of the above is nonnegative.

Taking the convex combination with $\{\theta_k^\alpha\}_{k=1}^{n(\alpha)}$ and then sending $\alpha \to 0$ with (i), (ii), (iv), and (v) of (4.4) in the above, we have

$$0 \geq u_\epsilon(x,t) + q + \max_{a\in A}\{-\langle g(x,a),p\rangle - f(x,a)\} - C_1\epsilon^2 e^{\mu t}.$$

Now, for $\delta > 0$, we choose $\eta_\delta \in C^\infty(\mathbf{R}^n)$ such that

$$0 \leq \eta_\delta \leq 1 \quad \text{in } \mathbf{R}^n, \qquad \eta_\delta = 1 \quad \text{in } \overline{\Sigma_\delta}, \qquad \text{and} \qquad \eta_\delta = 0 \quad \text{in } \left(\Sigma_{\delta/2}\right)^c.$$

We set the functions

$$\begin{cases} g_\delta(x,a) = \eta_\delta(x) g(x,a), \\ f_{\epsilon,\delta}(x,t,a) = \eta_\delta(x)(f(x,a) + C_1\epsilon^2 e^{\mu t}) + (1-\eta_\delta(x))u_\epsilon(x,t), \\ f^{\epsilon,\delta}(x,t,a) = \eta_\delta(x)(f(x,a) - C_1'\epsilon^2 e^{-\mu t}) + (1-\eta_\delta(x))u^\epsilon(x,t). \end{cases}$$

We then consider the problems: For $(x,t,p,q) \in \mathbf{R}^n \times (0,T) \times \mathbf{R}^n \times \mathbf{R}$,

$$u + u_t + H_{\epsilon,\delta}(x,t,Du) = 0 \tag{4.6}$$

and

$$u + u_t + H^{\epsilon,\delta}(x,t,Du) = 0, \tag{4.7}$$

where

$$\begin{cases} H_{\epsilon,\delta}(x,t,p) = \max_{a\in A}\{-\langle g_\delta(x,a),p\rangle - f_{\epsilon,\delta}(x,t,a)\}, \\ H^{\epsilon,\delta}(x,t,p) = \max_{a\in A}\{-\langle g_\delta(x,a),p\rangle - f^{\epsilon,\delta}(x,t,a)\}. \end{cases}$$

In what follows, we suppose that $\delta > \frac{\epsilon}{2\hat{c}}$.

We claim that u_ϵ and u^ϵ, respectively, are the standard viscosity subsolution and supersolution of $u + u_t + H_{\epsilon,\delta} = 0$ and $u + u_t + H^{\epsilon,\delta} = 0$ in $\mathbf{R}^n \times (0,T)$. For $(x,t) \in \mathbf{R}^n \times (0,T)$,

$$u_\epsilon(x,t) + q + H_{\epsilon,\delta}(x,t,p) \leq 0 \quad \text{provided } (p,q) \in D^+u_\epsilon(x,t) \tag{4.8}$$

and

$$u^\epsilon(x,t) + q + H^{\epsilon,\delta}(x,t,p) \geq 0 \quad \text{provided } (p,q) \in D^-u^\epsilon(x,t). \tag{4.9}$$

Indeed, it is immediate to check that u_ϵ and u^ϵ, respectively, satisfy that, for $(x,t) \in \mathbf{R}^n \times (0,T)$,

$$u_\epsilon(x,t) + \eta_\delta(x)q + H_{\epsilon,\delta}(x,t,p) \leq 0 \quad \text{provided } (p,q) \in D^+u_\epsilon(x,t)$$

and

$$u^\epsilon(x,t) + \eta_\delta(x)q + H^{\epsilon,\delta}(x,t,p) \geq 0 \quad \text{provided } (p,q) \in D^-u^\epsilon(x,t).$$

Here, we have used the fact $\eta_\delta(x) = 0$ for $x \notin \Sigma_{\hat{c}\epsilon}$.

We first show (4.9).

Since $(p,q) \in D^-u^\epsilon(x,t)$, from the definition, we have $q = \mu e^{\mu t}\frac{|x-y|^2}{\epsilon^2} \geq 0$ for some $y \in \Sigma$. Hence, we conclude our claim because $\eta_\delta \geq 0$.

Thus, for (4.8), it is sufficient to show that $q \le 0$ provided $(p,q) \in D^+u_\epsilon(x,t)$. This is not straightforward unlike (4.9).

However, in view of (iv) and (v) of Lemma 4.1, q can be approximated by $\sum_{k=1}^{n(\alpha)} \theta_k^\alpha q_k^\alpha$ (as $\alpha \to 0$) for $(p_k^\alpha, q_k^\alpha) \in D^- u_\epsilon(x_k^\alpha, t_k^\alpha)$ with appropriate (x_k^α, t_k^α). Hence, we can see that $q_k^\alpha = -\mu e^{-\mu t_k^\alpha} \frac{|x_k^\alpha - y|^2}{\epsilon^2} \le 0$ for some y. Therefore, $q \le 0$.

Now, we shall give the value functions $u_{\epsilon,\delta}$ and $u^{\epsilon,\delta}$, respectively, for (4.6) and (4.7) with initial condition $u_\epsilon(\cdot,0)$ and $u^\epsilon(\cdot,0)$:

$$u_{\epsilon,\delta}(x,t) = \inf_{\alpha\in\mathcal{A}} \left\{ \int_0^t e^{-s} f_{\epsilon,\delta}(X(s;x,\alpha), t-s, \alpha(s))ds + e^{-t} u_\epsilon(X(t;x,\alpha),0) \right\}$$

and

$$u^{\epsilon,\delta}(x,t) = \inf_{\alpha\in\mathcal{A}} \left\{ \int_0^t e^{-s} f^{\epsilon,\delta}(X(s;x,\alpha), t-s, \alpha(s))ds + e^{-t} u^\epsilon\big(X(t;x,\alpha),0\big) \right\}.$$

Since $f_{\epsilon,\delta}(x,t) \le f^{\epsilon,\delta}(x,t) + \epsilon^2(C_1 e^{\mu t} + C_1' e^{-\mu t})$ and $u_\epsilon \le u^\epsilon$, there exists $C_2 > 0$ such that

$$u_{\epsilon,\delta}(x,t) \le u^{\epsilon,\delta}(x,t) + C_2\epsilon^2 e^{\mu t} \quad \text{in } \mathbf{R}^n \times [0,T]. \tag{4.10}$$

We also remark that $u_{\epsilon,\delta}$ and $u^{\epsilon,\delta}$ are bounded and continuous. Hence, the standard comparison principle yields that

$$u_\epsilon(x,t) \le u_{\epsilon,\delta}(x,t) \qquad \text{and} \qquad u^{\epsilon,\delta}(x,t) \le u^\epsilon(x,t) \quad \text{in } \mathbf{R}^n \times [0,T]. \tag{4.11}$$

Fix $x \in \Sigma$ and choose $\delta > 0$ so that $x \in \Sigma_\delta$.

Then, the DPP for $u_{\epsilon,\delta}$ at (x,T) with (4.10) and (4.11) implies that

$$\begin{aligned}
u_\epsilon(x,T) &\le \inf_{\alpha\in\mathcal{A}} \left\{ \begin{array}{c} e^{-\tau_{\Sigma_\delta}^{x,\alpha}\wedge T} u_{\epsilon,\delta}\big(X(\tau_{\Sigma_\delta}^{x,\alpha}\wedge T;x,\alpha), (T-\tau_{\Sigma_\delta}^{x,\alpha})^+\big) \\ + \displaystyle\int_0^{\tau_{\Sigma_\delta}^{x,\alpha}\wedge T} e^{-s} f\big(X(s;x,\alpha),\alpha(s)\big)ds \end{array} \right\} \\
&\le \inf_{\alpha\in\mathcal{A}} \left\{ \begin{array}{c} e^{-\tau_{\Sigma_\delta}^{x,\alpha}\wedge T} u^{\epsilon,\delta}\big(X(\tau_{\Sigma_\delta}^{x,\alpha}\wedge T;x,\alpha), (T-\tau_{\Sigma_\delta}^{x,\alpha})^+\big) \\ + \displaystyle\int_0^{\tau_{\Sigma_\delta}^{x,\alpha}\wedge T} e^{-s} f\big(X(s;x,\alpha),\alpha(s)\big)ds \end{array} \right\} + C_2\epsilon^2 e^{\mu T} \qquad (4.12) \\
&\le u^\epsilon(x,T) + C_2\epsilon^2 e^{\mu T}.
\end{aligned}$$

We note that, for each $\alpha \in \mathcal{A}$, (4.10) and (4.11) imply

$$\begin{aligned}
u(X(\tau_{\Sigma_\delta}^{x,\alpha}\wedge T;x,\alpha)) &= \lim_{\epsilon\to 0} u_{\epsilon,\delta}(X(\tau_{\Sigma_\delta}^{x,\alpha}\wedge T;x,\alpha), (T-\tau_{\Sigma_\delta}^{x,\alpha})^+) \\
&= \lim_{\epsilon\to 0} u^{\epsilon,\delta}(X(\tau_{\Sigma_\delta}^{x,\alpha}\wedge T;x,\alpha), (T-\tau_{\Sigma_\delta}^{x,\alpha})^+).
\end{aligned} \tag{4.13}$$

Therefore, sending $\epsilon \to 0$ with (4.13) in (4.12), we have

$$u(x) = \inf_{\alpha\in\mathcal{A}} \left\{ \begin{array}{c} e^{-\tau_{\Sigma_\delta}^{x,\alpha}\wedge T} u\big(X(\tau_{\Sigma_\delta}^{x,\alpha}\wedge T;x,\alpha)\big) \\ + \displaystyle\int_0^{\tau_{\Sigma_\delta}^{x,\alpha}\wedge T} e^{-s} f\big(X(s;x,\alpha),\alpha(s)\big)ds \end{array} \right\}.$$

Finally, sending $T \to \infty$, we conclude the proof. □

Acknowledgments. We wish to thank Professor E. N. Barron for informing us of the manuscript [WZ]. We also wish to thank Professor M. Bardi for letting us know an interesting example (see Example 3.4) due to P. Soravia.

We finally wish to thank the referees for their suggestions on the first draft.

OBSERVATIONS PREPROCESSING AND QUANTIZATION FOR NONLINEAR FILTERS*

NIGEL J. NEWTON†

Abstract. Methods of *preprocessing* the observations for nonlinear filters are investigated, the aim being to reduce the computational labor involved in their implementation. An example of preprocessing is *quantization*, which involves the replacement of real-valued observation samples by discrete values. Because the resulting likelihood functions have finite support, they can be held in "look-up" tables kept in some type of rapid access memory, which renders their "real-time" evaluation trivial. Preprocessed observations of this sort carry less information than *raw* observations. This loss of information is characterized here for filters with substantially noisy observation samples by means of a functional central limit theorem. Among other things, this supplies an asymptotic, effective signal-to-noise ratio for preprocessed filters.

Methods of optimizing preprocessing operations with respect to this quantified information loss are developed. In particular, optimal quantization thresholds are found for observations that are contaminated by Gaussian noise, and it is shown that the loss of information for quite coarse quantization schemes is small; for example, the asymptotic, effective signal-to-noise ratio for a filter with one-bit quantized observations is $2/\pi$ times that for the same filter with raw observations. Simulations on two examples demonstrate the validity of the asymptotic characterization, even when the observation samples are only modestly contaminated by noise.

Key words. nonlinear filtering, quantization, approximation, weak convergence, hidden Markov models

1. Introduction.

Nonlinear filtering concerns methods for progressively estimating the value of a *signal* process from the available history of a related *observations* process, where, typically, the dynamics of both processes are nonlinear and influenced by random noise. The theory of such filters, in a fairly general context, is well understood (see [2], [4], [7], [8], [11], [18], and [19]), as are aspects of their approximation, in particular those relating to continuous-time filters (see, for example, [1], [3], [5], [12], [14], and [17]), but their implementation in many areas of potential application remains difficult. This is due largely to the computational complexity of the algorithms involved, which is often orders of magnitude greater than for linear filters. One aspect of implementation is the evaluation of likelihood functions for the observations, and this can be simplified by means of *preprocessing*. An example of preprocessing, which motivated this study, is *quantization*; this involves the replacement of real-valued observation samples by discrete samples. The likelihood functions for these discrete observations can be held in "look-up" tables kept in some type of rapid access memory, which renders their "real-time" evaluation trivial. Another example of preprocessing is *dimension reduction*, where an observation sample from a high-dimensional space is replaced by one from a space of lower dimension, with obvious computational advantages. Of course, such preprocessing operations reduce the information content of the observations, making the filters that subsequently use them less accurate than those using raw observations. The primary concern of this

†Department of Electronic Systems Engineering, University of Essex, Wivenhoe Park, Colchester, CO4 3SQ, UK (njn@essex.ac.uk).

article is to quantify this loss and so enable the design of preprocessing operations that minimize it within various sets of constraints. In particular, methods for determining the optimal placement of thresholds in quantization schemes are developed.

Attention is restricted, here, to filters for Markov chain signals. Preprocessing techniques for estimators of continuous-state signals (including filters for diffusions) are considered in a companion paper [16]. All the results concern filters for which the observation samples are substantially contaminated by noise. This includes not only discrete-time filters with inherently noisy observation sequences but also continuous-time filters that have been discretized in time with a small time step. For example, suppose we wish to estimate a signal, $(X_t;\, t \in [0,\infty))$, modeled by a Markov chain with rate matrix A, from continuous-time observations modeled by

$$Z_t = \int_0^t g(X_s)ds + W_t \qquad \text{for } t \in [0,\infty), \tag{1.1}$$

where g is an $\mathbb{R}^n$-valued function and $(W_t;\, t \in [0,\infty))$ is an n-dimensional standard Brownian motion; then, modulo some technical assumptions, we can calculate the posterior probabilities that X_t occupies the various states, given the observations up to time t, by means of Wonham's filter [18],

$$d\pi_t = \left(A - \sum_{j=1}^{n} (G_j - \bar{g}_{t,j} I)\, \bar{g}_{t,j} \right) \pi_t\, dt + \sum_{j=1}^{n} (G_j - \bar{g}_{t,j} I)\, \pi_t\, dZ_{t,j}, \tag{1.2}$$

where

$$\begin{aligned} \pi_t &= \mathrm{vec}_i \left\{ P(X_t = x_i \mid Z_s;\, 0 \le s \le t) \right\}, \\ G_j &= \mathrm{diag}_i \{ g_j(x_i) \}, \\ \bar{g}_t &= \sum_i g(x_i) \pi_{t,i}, \end{aligned}$$

and I is the matrix identity. ($\mathrm{vec}_i(y_i)$ is used to indicate the column vector, whose components are the elements y_i.) Time discretizations of (1.2), with time step Δt, typically involve the sampled (and, here, normalized) observations

$$\begin{aligned} Y_k &= \Delta t^{-1} (Z_{(k+1)\Delta t} - Z_{k\Delta t}) \qquad \text{for } k = 0, 1, \ldots \\ &\approx g(X_{k\Delta t}) + \Delta t^{-1} (W_{(k+1)\Delta t} - W_{k\Delta t}), \end{aligned}$$

which become increasingly noisy as Δt decreases.

In the next section, preprocessing operations for the observation sequences of discrete-time Markov chain filters are characterized by a central limit theorem. The limit is taken over sequences of filters with worsening observation noise and slowing signal dynamics. The slowing of the signal dynamics compensates for the worsening of the noise in such a way that the performance of the filters converges to that of a continuous-time limit filter. Section 3 develops applications of this result to the time discretization of filters for continuous-time Markov chain signals. The limit filter for both discrete and continuous-time cases is characterized by a matrix-valued signal-to-noise ratio, H. In section 4, this is related to other measures of performance such as error probability and mean-square error. The results of some simulations are presented in section 5. These suggest that the approach of optimizing preprocessing operations with respect to the performance measure of the limit problem is a useful

one, in that the performance measures for the limit filter closely approximate those for the filters in the sequence, even when the observation noise is only modest. This is true over a wide range of filter performances, as demonstrated by the simulations in Example 1 of section 5.

The key feature of filters that are well approximated by the limit filter is that, as a result of a combination of observation noise level and signal switching rate, they act "long term"; i.e., they make significant use of a long history of observation samples, taking little notice of a single sample. Another asymptotic performance measure appropriate for such filters is obtained if the signal dynamics are slowed but the observation noise remains fixed. In that case, the performance of the filters improves asymptotically—in particular, the error probability converges to zero. An asymptotic analysis for the steady-state error probability for filters based on raw observations is developed in [9] and [10]. This can be adapted for filters based on preprocessed observations and used as a basis for optimizing the preprocessing operations with respect to the specific performance criterion of error probability. This approach is complementary to that of section 2 in that it provides asymptotic analysis for filters with any level of observation noise, but is useful only if the filters have small error probabilities. In the context of quantization it prescribes optimal thresholds that differ from those derived in section 4 when the level of observation noise is low. Of course, for filters with high levels of observation noise and small error probabilities the two approaches yield equivalent results.

However, it is not clear how useful this alternative asymptotic analysis is for filters with low levels of observation noise. Like the analysis developed here, it relies on the filters acting "long term," which means that, when the level of observation noise is low, it is useful only if the signal switching rate is extremely low. In Example 1 of section 5, the analysis of [10] corresponds to the limit as the parameter a goes to zero. The optimal thresholds according to the two asymptotic performance measures broadly coincide for this example for values of δ (the reciprocal of the noise standard deviation) less than 1. For values of δ greater than 1 the performance of the filter is dominated by "short-term" effects (even when $a = 0.0001$). The value of a would need to be extremely small for a "window" of noise intensities, lower than those for which the high-noise asymptotic used here applies, but higher than those for which short-term effects dominate the filter performance, to open. The asymptotic analysis in [10], applied to preprocessing, may allow the fine tuning of operations for certain examples with low observation noise intensities and very low error probabilities, but this is not investigated further here.

2. An asymptotic characterization of preprocessing operations. In this section, the information lost through preprocessing operations used in conjunction with Markov chain filters is estimated by means of a central limit theorem.

Let $\{(\Omega^\delta, \mathcal{F}^\delta, P^\delta, (X_k^\delta \in \{x_1, x_2, \dots, x_m\};\ k = 0, 1, \dots), Q^\delta, p); \delta \in (0, 1]\}$ be a family of discrete-time, time-homogeneous, Markov chains parametrized by δ, and having transition probability matrices Q^δ and common initial law p $(= \mathrm{vec}_i\{P(X_0^\delta = i)\})$. For each δ, let $(Y_k^{h,\delta} \in M;\ k = 1, 2, \dots)$ be a *preprocessed* observation sequence whose terms take values in some measurable space $(M, \mathcal{M})$ and are defined by

$$Y_k^{h,\delta} = h\left(\delta g(X_k^\delta) + \zeta_k^\delta\right) \quad \text{for } k = 1, 2, \dots, \tag{2.1}$$

where $(\zeta_k^\delta \in \mathbb{R}^n;\ k = 1, 2, \dots)$ is a sequence of independent random variables (noises), defined on $(\Omega^\delta, \mathcal{F}^\delta, P^\delta)$, that are independent of $(X_k^\delta;\ k = 0, 1, \dots)$ and have com-

mon distribution $P_\zeta(dz)$, g is an $\mathbb{R}^n$-valued function on $\{x_1, x_2, \ldots, x_m\}$, and h is a measurable (preprocessing) function from $\mathbb{R}^n$ to M. (For example, quantization.)

For $z \in \mathbb{R}^n$, let $q(dy, z)$ be the probability measure induced on $(M, \mathcal{M})$ by $h(z+\zeta)$ and suppose that:

(H1) there exists a constant $\theta > 0$ such that

$$q(dy, z) \ll q(dy, 0) \quad \text{if } \|z\| < \theta.$$

Let $r(y, z)$ be a version of the associated Radon–Nikodým derivative, i.e.,

$$r(y, z) = \frac{q(dy, z)}{q(dy, 0)} \quad \text{almost everywhere (a.e.)} - q(dy, 0).$$

For sufficiently small δ, the discrete-time nonlinear filter for estimating X_k^δ from the observations $(Y_1^{h,\delta}, Y_2^{h,\delta}, \ldots, Y_k^{h,\delta})$ can be expressed recursively as follows. (Note that, for large values of δ, it may be possible within the constraints of (H1), for the measures $q(dy, g(x_i)\delta)$ and $q(dy, g(x_j)\delta)$ to be mutually singular for one or more pairs of states (x_i, x_j). A recursive expression for the nonlinear filter would then necessarily be different from the following.) Let

$$\pi_k^{h,\delta} = \mathrm{vec}_i \left\{ P^\delta \left(X_k^\delta = x_i \mid Y_1^{h,\delta}, Y_2^{h,\delta}, \ldots, Y_k^{h,\delta} \right) \right\}; \tag{2.2}$$

then from Bayes' formula it follows that

$$\begin{aligned} \pi_0^{h,\delta} &= p, \\ \pi_{k+1}^{h,\delta} &= S\left(R(Y_{k+1}^{h,\delta}, \delta) Q^\delta \pi_k^{h,\delta} \right) \quad \text{for } k = 0, 1, \ldots, \end{aligned} \tag{2.3}$$

where

$$R(y, \delta) = \mathrm{diag}_i \{ r(y, g(x_i)\delta) \},$$

and $S : \mathbb{R}^m \to \mathbb{R}^m$ is the following normalization function:

$$S_i(u) = \begin{cases} \left(\sum_{j=1}^m |u_j| \right)^{-1} u_i & \text{if } u \neq 0 \\ 0 & \text{if } u = 0 \end{cases} \qquad \text{for } i = 1, 2, \ldots, m. \tag{2.4}$$

THEOREM 2.1. *Suppose that, in addition to* (H1),

(H2) *for almost every* y $(q(dy, 0))$, $r(y, \cdot)$ *has continuous first and second derivatives in some neighborhood of the origin (in what follows,* $r_z(y, \cdot)$ *and* $r_{zz}(y, \cdot)$ *will represent, respectively, the corresponding row-vector Jacobian and the Hessian matrix);*

(H3) *there exists an* $\epsilon > 0$ *such that*

$$\int \|r_z(y, 0)\|^{3+\epsilon} \, q(dy, 0) < \infty;$$

(H4) *there exist* $\epsilon, \theta > 0$ *such that*

$$\sup_{\|z\| < \theta} \int \|r_{zz}(y, z)\|^{3+\epsilon} \, q(dy, 0) < \infty;$$

(H5) *there exists an $m \times m$ Markov rate matrix, A, such that, for all δ,*

$$Q^\delta = I + A\delta^2 + o(\delta^2),$$

where $o(\cdot)$ (and, for later use, $O(\cdot)$) have their usual (Landau) meanings.
Let $(\Omega, \mathcal{F}, P, (X_t \in \{x_1, x_2, \ldots, x_m\};\, t \in [0,\infty)), A, p)$ be a continuous-time Markov process with rate matrix A and the same initial law, p, as (X_k^δ). Let H be the $n \times n$ matrix

$$H = \int r_z'(y,0) r_z(y,0) q(dy, 0), \tag{2.5}$$

and let $(Z_t^H;\, t \in [0,\infty))$ be the observations process

$$Z_t^H = H \int_0^t g(X_s) ds + B_t^H, \tag{2.6}$$

where g is as in (2.1) and $(B_t^H;\, t \in [0,\infty))$ is an n-dimensional Brownian motion on $(\Omega, \mathcal{F}, P)$, independent of $(X_t;\, t \in [0,\infty))$, and with covariance matrix H. Let $(\pi_t^H;\, t \in [0,\infty))$ be the nonlinear filter for (X_t) given (Z_t^H), i.e.,

$$\pi_t^H = \mathrm{vec}_i \left\{ P\left(X_t = x_i \mid Z_s^H;\, s \in [0,t] \right) \right\}. \tag{2.7}$$

Then the piecewise constant extension of $(\pi_k^{h,\delta};\, k = 0, 1, \ldots)$, $(\pi_{[\delta^{-2}t]}^{h,\delta};\, t \in [0,\infty))$, considered as a family of random variables in the Skorohod space $D_{\mathbb{R}^m}[0,\infty)$, converges weakly to $(\pi_t^H;\, t \in [0,\infty))$ as $\delta \to 0$. ($[x]$ signifies the integer part of x.)

Remark 1. If the rank, d, of H is nonzero, then $(Z_t^H;\, t \in [0,\infty))$ is equivalent to the following d-vector observations process:

$$\tilde{Z}_t^L = L \int_0^t g(X_s) ds + W_t,$$

where L is any $d \times n$ matrix such that $L'L = H$, and $(W_t;\, t \in [0,\infty))$ is a standard d-dimensional Brownian motion. Thus H can be interpreted as the (matrix-valued) signal-to-noise ratio of the limit filter (2.7), which is itself the weak limit of the discrete-time filters of (2.3) as the signal dynamics slow, (H5), and the observation noise worsens, (2.1).

Remark 2. The statement of the theorem remains true if the signal process is *controlled* in the sense that the matrix of transition probabilities, Q^δ, depends on $(\pi_k^{h,\delta})$, in which case $(X_k^\delta,\, \pi_k^{h,\delta})$ is Markov and

$$P^\delta \left(X_{k+1}^\delta = x_i \mid X_k^\delta = x_j,\, \pi_k^{h,\delta} \right) = Q_{i,j}^\delta(\pi_k^{h,\delta}).$$

Hypothesis (H5) is replaced by the following.

(H5′) There exists a Lipschitz continuous Markov rate function, $A : S_m \to \mathbb{R}^{m \times m}$ (where S_m is the simplex $\{x \in [0,1]^m : \sum_i x_i = 1\}$), such that, for all δ,

$$Q^\delta(p) = I + A(p)\delta^2 + o(\delta^2) \qquad \text{uniformly in } p \in S_m;$$

the requirement that the observation noise, $(\zeta_k^\delta;\, k = 1, 2, \ldots)$, be independent of the signal, $(X_k^\delta;\, k = 0, 1, \ldots)$, is replaced by the requirement that $(\zeta_{k+1}^\delta, \zeta_{k+2}^\delta, \ldots)$ be

independent of X_k^δ for each k, and the limit filter is that for the *controlled*, continuous-time process $(X_t,\ A(\pi_t^H))$, given the observations (2.6), where X_s and $B_t^H - B_s^H$ are independent for all $0 \le s \le t < \infty$. The steps in the proof are the same as those for the uncontrolled case but involve more complex notation.

Proof of Theorem 2.1. The *unnormalized* version of the discrete-time filters (2.3),

$$\begin{aligned}\rho_0^{h,\delta} &= p,\\ \rho_{k+1}^{h,\delta} &= R(Y_{k+1}^{h,\delta},\delta)Q^\delta \rho_k^{h,\delta} \quad \text{for } k = 0,1,\dots\end{aligned}$$

is first expanded in terms of δ. Because of (H2), for sufficiently small δ, the Radon–Nikodým derivatives, $r(y, g(x_i)\delta)$, can be expanded as follows:

$$r(y, g(x_i)\delta) = 1 + r_z(y,0)g(x_i)\delta + f(y,x_i,\delta)\delta^2,$$

where

$$f(y,x_i,\delta) = g'(x_i)\int_0^1\int_0^\beta r_{zz}(y,\alpha g(x_i)\delta)d\alpha\, d\beta\, g(x_i).$$

This, together with (H5), gives

$$\rho_{k+1}^{h,\delta} = \rho_k^{h,\delta} + F(Y_{k+1}^{h,\delta},\delta)\rho_k^{h,\delta},$$

where

$$\begin{aligned}F(y,\delta) = A\delta^2 &+ \operatorname{diag}_i\{r_z(y,0)g(x_i)\}\delta + \operatorname{diag}_i\{f(y,x_i,\delta)\}O(\delta^2)\\ &+ (I + \operatorname{diag}_i\{r_z(y,0)g(x_i)\})\, o(\delta^2).\end{aligned}$$

Now, $(\rho_k^{h,\delta})$ is a Markov process in $\mathbb{R}^m$ with (time-homogeneous) transition function $\mu(u,B)$ given by

$$\mu(u,B) = P_u\left(u + F(Y,\delta)u \in B\right),$$

where

$$Y = h(\delta g(X) + \zeta),$$

X ($\in \{x_1, x_2, \dots, x_m\}$), and ζ ($\in \mathbb{R}^n$) are independent random variables with distributions $S(Q^\delta u)$ and $P_\zeta(dz)$, respectively, defined on some probability space $(\Omega_u, \mathcal{F}_u, P_u)$, and S is the normalization function defined in (2.4). Because of (H3) and (H4), for sufficiently small δ,

$$\begin{aligned}\mathbf{E}_u\|F(Y,\delta)\|^{2+\epsilon} &= \sum_j \int \|F(y,\delta)\|^{2+\epsilon} q(dy, g(x_j)\delta)(Q^\delta S(u))_j\\ &= \sum_j \int \|F(y,\delta)\|^{2+\epsilon}\left(1 + r_z(y,0)g(x_j)\delta + f(y,x_j,\delta)\delta^2\right)\\ &\qquad\qquad \times q(dy,0)(Q^\delta S(u))_j\\ &= O(\delta^{2+\epsilon}) \qquad \text{uniformly in } u,\end{aligned}$$

and so by Markov's inequality, for any $\theta > 0$,

$$\begin{aligned}\delta^{-2}P_u\left(\|F(Y,\delta)\| > \theta\right) &\le \theta^{-(2+\epsilon)}\delta^{-2}\mathbf{E}_u\|F(Y,\delta)\|^{2+\epsilon}\\ &= O(\delta^\epsilon) \quad \text{uniformly in } u.\end{aligned} \tag{2.8}$$

Again, for sufficiently small δ,

$$\begin{aligned}\mathbf{E}_u r_z(Y,0) &= \sum_j \int r_z(y,0) q(dy, g(x_j)\delta)(Q^\delta S(u))_j \\ &= \sum_j \int r_z(y,0)\left(1 + r_z(y,0)g(x_j)\delta + f(y,x_j,\delta)\delta^2\right) q(dy,0)(Q^\delta S(u))_j \\ &= \bar{g}'(u)H\delta + O(\delta^2) \qquad \text{uniformly in } u,\end{aligned}$$

where

$$\bar{g}(u) = \sum_j g(x_j)(S(u))_j.$$

Similarly, for θ as defined in (H4),

$$\sup_{\|z\|<\theta} \mathbf{E}_u r_{zz}(Y,z) = O(\delta) \qquad \text{uniformly in } u,$$

and so

$$\begin{aligned}\mathbf{E}_u F(Y,\delta) &= A\delta^2 + \operatorname{diag}_i\{\bar{g}'(u)Hg(x_i)\}\delta^2 + o(\delta^2) \\ &= A\delta^2 + \sum_{l=1}^n (H\bar{g}(u))_l G_l \delta^2 + o(\delta^2)\end{aligned} \tag{2.9}$$

uniformly in u, where $G_l = \operatorname{diag}_i\{g_l(x_i)\}$. Also, for sufficiently small δ,

$$\begin{aligned}\mathbf{E}_u F(Y,\delta)uu'F'(Y,\delta) &= \mathbf{E}_u \operatorname{diag}_i\{r_z(Y,0)g(x_i)\}uu' \operatorname{diag}_i\{r_z(Y,0)g(x_i)\}\delta^2 + O(\delta^3) \\ &= \sum_{k,l=1}^n H_{k,l}G_k uu' G_l \delta^2 + O(\delta^3)\end{aligned} \tag{2.10}$$

uniformly on compacts.

The continuous-time filter (2.7) is Wonham's filter, which can be expressed recursively in unnormalized form as follows:

$$\begin{aligned}\rho_0^H &= p, \\ d\rho_t^H &= A\rho_t^H dt + \sum_{l=1}^n G_l \rho_t^H dZ_{t,l}^H \\ &= \left(A + \sum_{l=1}^n \left(H\bar{g}\left(\rho_t^H\right)\right)_l G_l\right)\rho_t^H dt + \sum_{l=1}^n G_l \rho_t^H d\nu_{t,l}^H, \\ \pi_t^H &= S(\rho_t^H),\end{aligned} \tag{2.11}$$

where

$$\nu_t^H := Z_t^H - \int_0^t H\bar{g}(\rho_s)ds$$

is the associated *innovations process*.

The coefficients in (2.11) fulfill Itô's Lipschitz continuity and linear growth conditions and so (2.11) has a unique strong solution. It follows that the associated

martingale problems for each initial law on $(\mathbb{R}^m, \mathcal{B}^m)$ all have unique solutions. This, and properties (2.8), (2.9), and (2.10) of the transition function, $\mu(u, B)$, allow the application of a functional central limit theorem (a simple variation of Lemma 4.2 on p. 355 of [6]) showing that, for any sequence $\delta_l \to 0$,

$$\left(\rho^{h,\delta_l}_{[\delta_l^{-2}t]}\right) \Rightarrow \left(\rho^H_t\right) \quad \text{in } D_{\mathbb{R}^m}[0,\infty).$$

The theorem now follows from the a.e. (with respect to the distribution of (ρ^H_t)) continuity of the mapping

$$\Gamma : D_{\mathbb{R}^m}[0,\infty) \to D_{\mathbb{R}^m}[0,\infty),$$

defined by

$$\Gamma_t(v) = S(v_t) \qquad \text{for all } t \in [0,\infty). \qquad \square$$

The following examples illustrate some preprocessing operations and noise distributions that fulfill (H1)–(H4), and give the corresponding signal-to-noise ratios for the limit filter.

Example 1. Lossless preprocessing. If h is 1–1, and the noise distribution, $P_\zeta(dz)$, has a density, $p(z)$, with the following properties:

(H1-1) $p(z) > 0$ for all z;

(H2-1) $p(z)$ has continuous first and second derivatives (denoted $p_z(z)$ and $p_{zz}(z)$);

(H3-1) there exists an $\epsilon > 0$ such that

$$\int \frac{\|p_z(u)\|^{3+\epsilon}}{p^{2+\epsilon}(u)} du < \infty;$$

(H4-1) there exist $\epsilon, \theta > 0$ such that

$$\sup_{\|z\|<\theta} \int \frac{\|p_{zz}(u-z)\|^{3+\epsilon}}{p^{2+\epsilon}(u)} du < \infty;$$

then $(h, P_\zeta(dz))$ fulfills (H1)–(H4), and

$$H = \int \frac{p'_z(u) p_z(u)}{p(u)} du.$$

Two specific examples of noise distributions satisfying the above are Gaussian,

$$p(z) = \frac{1}{(2\pi)^{n/2}|V|^{1/2}} \exp\left(-\tfrac{1}{2}(z-\mu)' V^{-1}(z-\mu)\right)$$

for which $H = V^{-1}$, and Cauchy (with $n = 1$),

$$p(z) = \frac{a}{\pi(1+(az)^2)}$$

for which $H = a^2$. This latter example illustrates an important difference between linear and nonlinear filtering. At first sight, it would seem reasonable to estimate a slowly varying signal given a large number of noisy observations by some sort of linear, moving-average filter. However, this would be completely fruitless in this case, where the noise distribution is "heavy tailed." The nonlinear filter does use a moving average

technique but applies it to the log-likelihood function of the observations, rather than the observations themselves. This example also illustrates that the discrete-time filters (2.3) need not themselves have signal-to-noise ratios in the mean-square sense in order for Theorem 2.1 to apply.

Of course, the preprocessing in this example is artificial in that it does not sacrifice any information, and so the signal-to-noise ratio of the limit filter, H, is that corresponding to the *raw* observations.

Example 2. Quantization. Let h be the discrete-valued function

$$h(z) = \sum_{i=1}^{N} b_i \chi_{B_i}(z),$$

where N could be infinite, the b_i are distinct elements of M, the B_i are disjoint Borel sets in $\mathbb{R}^n$ with nonzero Lebesgue measure whose union is $\mathbb{R}^n$, and χ_{B_i} is the indicator function of the set B_i. If $P_\zeta(dz)$ has a density, $p(z)$, with the following properties:

(H1-2) $p(z) > 0$ for all z;

(H2-2) $p(z)$ has continuous first and second derivatives ($p_z(z)$ and $p_{zz}(z)$);

(H3-2) there exists an $\epsilon > 0$ such that

$$\sum_i \left\| \int_{B_i} p_z(u)du \right\|^{3+\epsilon} P_\zeta(B_i)^{-(2+\epsilon)} < \infty;$$

(H4-2) there exist $\epsilon, \theta > 0$ such that

$$\sup_{\|z\|<\theta} \sum_i \left\| \int_{B_i} p_{zz}(u-z)du \right\|^{3+\epsilon} P_\zeta(B_i)^{-(2+\epsilon)} < \infty;$$

then $(h, P_\zeta(dz))$ fulfills (H1)–(H4), and

$$H = \sum_i \int_{B_i} \int_{B_i} p_z'(u) p_z(v) du\, dv\, P_\zeta(B_i)^{-1}.$$

The conditions on $P_\zeta(dz)$ can be weakened if the sets B_i are sufficiently regular. For example, there is no need for $P_\zeta(dz)$ to have a density at all interior points of the B_i.

Example 3. Rectangular quantization. Let h be the discrete-valued function

$$h(z) = \sum_{j_1=0}^{N_1} \sum_{j_2=0}^{N_2} \cdots \sum_{j_n=0}^{N_n} b_J \chi_{B_J}(z),$$

where $N_i < \infty$ for all i, $J = (j_1, j_2, \ldots, j_n)$, the b_J are distinct elements of M, and the B_J are the following n-dimensional rectangles:

$$B_J = (t_{1,j_1}, t_{1,j_1+1}) \times (t_{2,j_2}, t_{2,j_2+1}) \times \cdots \times (t_{n,j_n}, t_{n,j_n+1}).$$

Here, for each i,

$$-\infty = t_{i,0} < t_{i,1} < \cdots < t_{i,N_i} < t_{i,N_i+1} = \infty.$$

Let A be the set of boundaries

$$A = \mathbb{R}^n - \cup_J B_J.$$

If, for some $\alpha > 0$, $P_\zeta(dz)$ has a density, $p(z)$, in the neighborhood

$$N_\alpha := \{z \in \mathbb{R}^n : \|z - a\| < \alpha \quad \text{for some } a \in A\},$$

with the following properties:

(H1-3) $p(z) > 0$ for all $z \in N_\alpha$;

(H2-3) $p(z)$ has a continuous first derivative on N_α ($p_z(z)$); then (H1)–(H4) are satisfied, and

$$H = \sum_{j_1=0}^{N_1} \sum_{j_2=0}^{N_2} \cdots \sum_{j_n=0}^{N_n} \operatorname{vec}_i \{\lambda_{J,i}(t_{i,j_i}) - \lambda_{J,i}(t_{i,j_i+1})\} \times \operatorname{vec}_i' \{\lambda_{J,i}(t_{i,j_i}) - \lambda_{J,i}(t_{i,j_i+1})\} P_\zeta(B_J)^{-1},$$

where

$$\lambda_{J,i}(t) = \begin{cases} \displaystyle\int_{\bar{B}_J \cap \{z_i = t\}} p(z)\, dz_1\, dz_2 \ldots dz_{i-1}\, dz_{i+1} \ldots dz_n & \text{if } t \text{ is finite,} \\ 0 & \text{if } t \text{ is infinite,} \end{cases}$$

and $\bar{B}_J$ is the closure of B_J. In particular, if $n = 1$,

$$H = \frac{p(t_1)^2}{P_\zeta((-\infty, t_1))} + \sum_{j=1}^{N-1} \frac{(p(t_j) - p(t_{j+1}))^2}{P_\zeta((t_j, t_{j+1}))} + \frac{p(t_N)^2}{P_\zeta((t_N, \infty))}. \tag{2.12}$$

Example 4. Linear dimension reduction. If $M = \mathbb{R}^d$, $h(z) = Bz$ for some $d \times n$ matrix, B, with rank d ($< n$), and the noise distribution has a density, $p(z)$, with the following properties:

(H1-4) $\int_{\mathbb{R}^{n-d}} p(Vv - UU'z)dv > 0$ for all z;

(H2-4) $p(z)$ has continuous first and second derivatives ($p_z(z)$ and $p_{zz}(z)$);

(H3-4) there exists an $\epsilon > 0$ such that

$$\int_{\mathbb{R}^d} \frac{\left\| \int_{\mathbb{R}^{n-d}} p_z(Vv + Uu)dv \right\|^{3+\epsilon}}{\left(\int_{\mathbb{R}^{n-d}} p(Vv + Uu)dv \right)^{2+\epsilon}} du < \infty;$$

(H4-4) there exist $\epsilon, \theta > 0$ such that

$$\sup_{\|z\| < \theta} \int_{\mathbb{R}^d} \frac{\left\| \int_{\mathbb{R}^{n-d}} p_{zz}(Vv + Uu - UU'z)dv \right\|^{3+\epsilon}}{\left(\int_{\mathbb{R}^{n-d}} p(Vv + Uu)dv \right)^{2+\epsilon}} du < \infty;$$

where V and U are, respectively, $n \times (n-d)$- and $n \times d$-dimensional matrices whose columns form orthonormal bases for, respectively, the kernel of B and its orthogonal complement, then $(h, P_\zeta(dz))$ fulfills (H1)–(H4) and

$$H = UU' \int_{\mathbb{R}^d} \frac{\int_{\mathbb{R}^{n-d}} p_z'(Vv + Uu)dv \int_{\mathbb{R}^{n-d}} p_z(Vv + Uu)dv}{\int_{\mathbb{R}^{n-d}} p(Vv + Uu)dv} du\, UU'.$$

3. Continuous-time filters. Theorem 2.1 concerns discrete-time, discrete-state filters. Suppose now that $(\Omega, \mathcal{F}, P, (X_t \in \{x_1, x_2, \ldots, x_m\};\ t \in [0,\infty)), A, p)$ is a continuous-time Markov chain with rate matrix A and initial law p that we wish to estimate from observations of the continuous-time, n-vector process

$$Z_t = \int_0^t g(X_s)ds + W_t,$$

where $(W_t;\ t \in [0,\infty))$ is a standard n-dimensional Brownian motion on $(\Omega, \mathcal{F}, P)$, independent of $(X_t;\ t \in [0,\infty))$. One step in an implementation of the nonlinear filter for this problem is discretization in time. With a step size of δ^2, this yields (normalized) raw discrete-time observations of the following form:

$$\begin{aligned} Z_k^\delta &= \delta^{-1}(Z_{(k+1)\delta^2} - Z_{k\delta^2}) \\ &= \delta g(X_{k\delta^2}) + \delta^{-1}(V^\delta_{(k+1)\delta^2} - V^\delta_{k\delta^2}), \end{aligned}$$

where

$$V_t^\delta = \int_0^t g^\delta(X,s)ds + W_t$$

and

$$g^\delta(X,t) = g(X_t) - g(X_{[\delta^{-2}t]\delta^2}).$$

These observations differ from the raw observations of (2.1) in that the noise terms, $\delta^{-1}(V^\delta_{(k+1)\delta^2} - V^\delta_{k\delta^2})$, are statistically dependent on the discrete-time signal process, $(X_{k\delta^2};\ k = 0, 1, \ldots)$. However, the process $(g^\delta(X,t);\ t \in [0,\infty))$ is bounded, and so Girsanov's theorem can be used to define new probability measures on $(\Omega, \mathcal{F})$ under which the noise terms *are* independent of $(X_{k\delta^2};\ k = 0, 1, \ldots)$. (See, for example, Theorem 6.2 in [15].) In fact, if P_T^δ is defined by

$$\begin{aligned} \frac{dP_T^\delta}{dP} &= \exp\left(-\int_0^T g^\delta(X,t)'dW_t - \frac{1}{2}\int_0^T \|g^\delta(X,t)\|^2 dt\right) \\ &=: M_T^\delta, \end{aligned}$$

then P_T^δ is a probability measure under which the distribution of $(X_t;\ t \in [0,T])$ is unaltered but $(V_t^\delta;\ t \in [0,T])$ becomes a standard Brownian motion, independent of $(X_t;\ t \in [0,\infty))$. Thus Theorem 2.1 provides, under P_T^δ, a weak limit for the nonlinear filters for the discrete-time Markov chains, $(\Omega, \mathcal{F}, P_T^\delta, (X_{k\delta^2};\ k = 0, 1, \ldots), \exp(A\delta^2), p)$, given the preprocessed observations

$$Y_k^{h,\delta} = h(Z_k^\delta).$$

In fact, $(\pi^{h,\delta}_{[\delta^{-2}t]};\ t \in [0,\infty))$, defined by (2.2)–(2.4) with P^δ replaced by P_T^δ, and $Y_k^{h,\delta}$ as defined above, converges weakly in $D_{\mathbb{R}^m}[0,\infty)$ to the continuous-time filter of (2.5)–(2.7), i.e., the original continuous-time filter of this section, but with the new signal-to-noise ratio, H. What is not immediately apparent is that the same can be said for the nonlinear filter for $(X_{k\delta^2};\ k = 0, 1, \ldots)$ under the "true" measure, P, $(\tilde\pi^{h,\delta}_{[\delta^{-2}t]};\ t \in [0,\infty))$, where

$$\tilde\pi_k^{h,\delta} := \mathrm{vec}_i\left\{P\left(X_{k\delta^2} = x_i \mid Y_1^{h,\delta}, Y_2^{h,\delta}, \ldots, Y_k^{h,\delta}\right)\right\} \qquad \text{for } k = 0, 1, \ldots.$$

The following proposition addresses this issue and shows that the filters, $(\pi_k^{h,\delta};\ k = 0,1,\ldots)$, are strong approximations to the filters with respect to the true measure. This is of independent interest as the former are easier to implement than the latter. For example, in the case of n-bit quantization, the one-step update of the former filters consists of multiplication by one of 2^n precomputed matrices.

PROPOSITION 3.1.

(i) *For any $T < \infty$ and any $\theta \in (0,\infty)$,*

$$\lim_{\delta\to 0} \mathbf{E} \sup_{k\le \delta^{-2}T} \left\| \tilde{\pi}_k^{h,\delta} - \pi_k^{h,\delta} \right\|^\theta = 0.$$

(ii) *For any $T < \infty$ and any sequence $(\delta_l \in (0,1];\ l = 1,2,\ldots)$ with the property*

$$\sum_l \delta_l^{2-\epsilon} < \infty \qquad \textit{for some } \epsilon > 0, \tag{3.1}$$

$$\lim_{l\to\infty} \sup_{k\le \delta_l^{-2}T} \|\tilde{\pi}_k^{h,\delta_l} - \pi_k^{h,\delta_l}\| = 0 \qquad \textit{almost surely (a.s.).}$$

(iii) $(\tilde{\pi}^{h,\delta}_{[\delta^{-2}t]};\ t \in [0,\infty))$*, considered as a family of random variables in the Skorohod space $D_{\mathbb{R}^m}[0,\infty)$, converges weakly to the continuous-time filter of* (2.5)–(2.7).

Proof. For each k, let $\mathcal{Y}_k^{h,\delta}$ be the σ-field generated by $Y_1^{h,\delta}, Y_2^{h,\delta}, \ldots, Y_k^{h,\delta}$. From the basic properties of conditional expectation it follows that, for any $k < \infty$, any $C \in \mathcal{Y}_k^{h,\delta}$, and any $1 \le i \le m$,

$$\int_C \pi_{k,i}^{h,\delta} dP_T^\delta = \int_C \mathbf{E}\left(\chi_{\{x_i\}}(X_{k\delta^2}) M_T^\delta \mid \mathcal{Y}_k^{h,\delta}\right) \mathbf{E}_T^\delta\left((M_T^\delta)^{-1} \mid \mathcal{Y}_k^{h,\delta}\right) dP_T^\delta,$$

and so

$$\begin{aligned}\pi_{k,i}^{h,\delta} - \tilde{\pi}_{k,i}^{h,\delta} = {} & \mathbf{E}\left(\chi_{\{x_i\}}(X_{k\delta^2}) M_T^\delta \mid \mathcal{Y}_k^{h,\delta}\right) \mathbf{E}_T^\delta\left((M_T^\delta)^{-1} - 1 \mid \mathcal{Y}_k^{h,\delta}\right) \\ & + \mathbf{E}\left(\chi_{\{x_i\}}(X_{k\delta^2})(M_T^\delta - 1) \mid \mathcal{Y}_k^{h,\delta}\right) \qquad \text{a.s.},\end{aligned}$$

from which the triangle and Jensen's inequalities yield

$$\begin{aligned}\left\|\pi_k^{h,\delta} - \tilde{\pi}_k^{h,\delta}\right\| \le {} & \mathbf{E}\left(M_T^\delta \mid \mathcal{Y}_k^{h,\delta}\right) \mathbf{E}_T^\delta\left(|(M_T^\delta)^{-1} - 1| \mid \mathcal{Y}_k^{h,\delta}\right) \\ & + \mathbf{E}\left(|M_T^\delta - 1| \mid \mathcal{Y}_k^{h,\delta}\right).\end{aligned} \tag{3.2}$$

Since $g^\delta(X,t)$ is bounded,

$$\sup_{\delta\in(0,1]} \mathbf{E}(M_T^\delta)^{2j} < \infty \qquad \text{for all integers } j \text{ (positive or negative).} \tag{3.3}$$

Also, for any $\theta \in (0,\infty)$, there exists a $K < \infty$ such that

$$\begin{aligned}\sup_{t\in[0,\infty)} \mathbf{E}\|g^\delta(X,t)\|^\theta &\le K \sup_{t\in[0,\delta^2]} \sum_{i\ne j} \|g(x_j) - g(x_i)\|^\theta \left|\exp(At)_{i,j}\right| \\ &= O(\delta^2).\end{aligned}$$

Now, for some $\alpha \in (0,1)$,

$$M_T^\delta - 1 = -\left(\int_0^T g^\delta(X,t)' dW_t + \frac{1}{2} \int_0^T \|g^\delta(X,t)\|^2 dt \right) (M_T^\delta)^\alpha,$$

and so Hölder's inequality, (3.3), and a standard result on the moments of stochastic integrals (see, for example, Lemma 4.12 in [15]) show that, for any $\theta \in (0,\infty)$, there exists a $K < \infty$ such that

$$\begin{aligned} \mathbf{E}|M_T^\delta - 1|^\theta &\le K \left(\mathbf{E} \left| \int_0^T g^\delta(X,t)' dW_t + \frac{1}{2} \int_0^T \|g^\delta(X,t)\|^2 dt \right|^{\theta p} \right)^{1/p} \\ &= O(\delta^{2/p}), \end{aligned}$$

where $p = \min\{\alpha > 1 : \theta\alpha/2 \text{ is an integer}\}$. Similarly,

$$\mathbf{E}_T^\delta |(M_T^\delta)^{-1} - 1|^\theta = O(\delta^{2/p}).$$

Hölder's and Jensen's inequalities, when applied to (3.2), show that, for any $\theta \in [1,\infty)$ and any $q \in (1,\infty)$,

$$\begin{aligned} \mathbf{E} \sup_{k \le \delta^{-2} T} \left\| \pi_k^{h,\delta} - \tilde{\pi}_k^{h,\delta} \right\|^\theta &\le 2^{\theta-1} \left(\mathbf{E} \sup_k \mathbf{E} \left((M_T^\delta)^{\theta q/(q-1)} \mid \mathcal{Y}_k^{h,\delta} \right) \right)^{(q-1)/q} \\ &\quad \times \left(\mathbf{E} \sup_k \mathbf{E}_T^\delta \left(|(M_T^\delta)^{-1} - 1|^{\theta q} \mid \mathcal{Y}_k^{h,\delta} \right) \right)^{1/q} \\ &\quad + 2^{\theta-1} \left(\mathbf{E} \sup_k \mathbf{E} \left(|M_T^\delta - 1|^\theta \mid \mathcal{Y}_k^{h,\delta} \right) \right). \end{aligned} \tag{3.4}$$

Another application of Hölder's and Jensen's inequalities and Doob's submartingale inequality shows that

$$\begin{aligned} \mathbf{E} \sup_k \mathbf{E}_T^\delta \left(|(M_T^\delta)^{-1} - 1|^{\theta q} \mid \mathcal{Y}_k^{h,\delta} \right) &\le \left(\mathbf{E}_T^\delta (M_T^\delta)^{-q/(q-1)} \right)^{(q-1)/q} \\ &\quad \times \left(\mathbf{E}_T^\delta \sup_k \mathbf{E}_T^\delta \left(|(M_T^\delta)^{-1} - 1|^{\theta q^2} \mid \mathcal{Y}_k^{h,\delta} \right) \right)^{1/q} \\ &\le K \left(\mathbf{E}_T^\delta |(M_T^\delta)^{-1} - 1|^{\theta q^2} \right)^{1/q} \end{aligned}$$

for some $K < \infty$. A similar treatment of the other terms in the right-hand side of (3.4) shows that, for some $K < \infty$,

$$\begin{aligned} \mathbf{E} \sup_{k \le \delta^{-2} T} \left\| \tilde{\pi}_k^{h,\delta} - \pi_k^{h,\delta} \right\|^\theta &\le K \left(\mathbf{E}_T^\delta |(M_T^\delta)^{-1} - 1|^{\theta q^2} \right)^{1/q^2} + K \mathbf{E} |M_T^\delta - 1|^\theta \\ &= O(\delta^{2/p}), \end{aligned}$$

where p is as defined above. This proves (i). It also shows that, for any $0 < \epsilon < 1$,

$$\mathbf{E} \sup_{k \le \delta^{-2} T} \left\| \tilde{\pi}_k^{h,\delta} - \pi_k^{h,\delta} \right\|^{2-\epsilon} = O(\delta^{2-\epsilon}),$$

and this, together with (3.1) and the Borel–Cantelli lemma, proves (ii).

Now let

$$e_t^\delta = \left\| \pi^{h,\delta}_{[\delta^{-2}t]} - \tilde{\pi}^{h,\delta}_{[\delta^{-2}t]} \right\|.$$

For any $0 \le h \le t \le T - h$, if $\delta > \sqrt{2h}$,

$$\left|e_t^\delta - e_{t+h}^\delta\right| \left|e_t^\delta - e_{t-h}^\delta\right| = 0,$$

and so, from (i) and Hölder's inequality,

$$\begin{aligned}\sup_{\delta<1} \mathbf{E}\left(\left|e_t^\delta - e_{t+h}^\delta\right|^{\theta/2} \left|e_t^\delta - e_{t-h}^\delta\right|^{\theta/2}\right) &= \sup_{\delta\le\sqrt{2h}} \mathbf{E}\left(\left|e_t^\delta - e_{t+h}^\delta\right|^{\theta/2} \left|e_t^\delta - e_{t-h}^\delta\right|^{\theta/2}\right) \\ &= O(h^{1/p}),\end{aligned}$$

where p is as defined above. An application of the theorems on pages 137–139 in [6] now shows that the family $\{(\pi^{h,\delta}_{[\delta^{-2}t]} - \tilde{\pi}^{h,\delta}_{[\delta^{-2}t]}) : \delta \in (0,1]\}$ is relatively compact. This and part (i) of the proposition establish part (iii). □

Results of this type, but for a more general class of nonlinear estimation problems (including filters for diffusions), can be found in [16].

4. The rank ordering of preprocessing operations. As discussed earlier, the matrix H is the signal-to-noise ratio of the limit filter of Theorem 2.1, which we clearly want to be large in some sense. In fact, we typically want to choose h such that a cost of the following form is small:

$$\begin{aligned} C_\phi(h,\delta,k) &:= J_\phi(\pi_k^{h,\delta}) \\ &= \mathbf{E}\phi(\pi_k^{h,\delta}), \end{aligned} \tag{4.1}$$

where J_ϕ is the cost function corresponding to a continuous, convex (upward) function ϕ. A variation to this fixed-time cost criterion that is appropriate if $\pi_k^{h,\delta}$ has a steady-state distribution is a cost criterion with respect to this distribution:

$$C_\phi(h,\delta) = \lim_{k\to\infty} C_\phi(h,\delta,k).$$

For example, if we wanted to choose a value for X^δ from its range with the minimal probability of being in error, then an appropriate function, ϕ, would be

$$\phi(p) = -\max_i\{p_i\},$$

whereas, if we wanted to estimate a moment $\mathbf{E}f(X_k^\delta)$ with minimal mean-square error, then an appropriate ϕ would be

$$\phi(p) = -\left(\sum_i f(x_i)p_i\right)^2.$$

Theorem 2.1 shows that, under hypotheses (H1)–(H5), for any continuous ϕ,

$$J_\phi\left(\pi^{h,\delta}_{[\delta^{-2}t]}\right) \to J_\phi(\pi_t^H) \qquad \text{for all } t \in [0,\infty),$$

where (π_t^H) is the limit filter of the theorem, i.e., the costs for the discrete-time filters according to a given criterion converge to the cost for the limit filter according to the same criterion.

If $(\pi_k^{h,\delta})$ is an approximation to a continuous-time filter based on sampled and preprocessed observations, then it is appropriate for it to inherit the cost function of the continuous-time filter, in which case the cost for $(\pi_k^{h,\delta})$ will converge to the original cost for the continuous-time filter, but with the new signal-to-noise ratio, H.

Clearly, given a limit cost $J_\phi(\pi_t^H)$, we could, at least in principle, optimize the parameters of preprocessing operations for filters where δ is small. In practice, though, this can be difficult, and we may not have such a precise notion of cost if, for example, we need to estimate several features of the signal with no clear weighting of importance. However, there is still a partial ordering of preprocessing operations, which holds for all reasonable cost functions.

PROPOSITION 4.1. *Let $(X_t;\, t \in [0,\infty))$ be the continuous-time Markov chain of Theorem* 2.1, *and $(\pi_t^{H_1};\, t \in [0,\infty))$ and $(\pi_t^{H_2};\, t \in [0,\infty))$ the nonlinear filters for estimating it from observations $(Z_t^{H_1};\, t \in [0,\infty))$ and $(Z_t^{H_2};\, t \in [0,\infty))$, respectively, defined by* (2.6) *with matrices H_1 and H_2, and independent noises, $(B_t^{H_1};\, t \in [0,\infty))$ and $(B_t^{H_2};\, t \in [0,\infty))$. If $H_1 - H_2$ is positive semidefinite, then*

$$J_\phi(\pi_t^{H_1}) \le J_\phi(\pi_t^{H_2})$$

for all $t \in [0,\infty)$ and all cost functions of the form (4.1) *for which ϕ is continuous and convex upward.*

Proof. Set $H_3 = H_1 - H_2$, and let $(Z_t^{H_3};\, t \in [0,\infty))$ be a corresponding observations process with a noise process, $(B_t^{H_3})$, which is independent of $(B_t^{H_2})$. Examination of the nonlinear filtering equations (2.7) shows that the filter for (X_t), given the $2n$-dimensional observation process $(Z_t^{H_2}, Z_t^{H_3};\, t \in [0,\infty))$, involves only the sum

$$\begin{aligned} Z_t^{H_2} + Z_t^{H_3} &= (H_2 + H_3) \int_0^t g(X_s)ds + B_t^{H_2} + B_t^{H_3} \\ &= H_1 \int_0^t g(X_s)ds + B_t^{H_2} + B_t^{H_3}. \end{aligned}$$

Now $B_t^{H_2} + B_t^{H_3}$ is an n-dimensional Brownian motion with covariance matrix H_1, and so $(Z_t^{H_2} + Z_t^{H_3})$ is equivalent to $(Z_t^{H_1})$ for the filtering problem. Thus, by Jensen's inequality, setting $\mathcal{Z}_t^{H_2} = \sigma(Z_s^{H_2};\, s \in [0,t])$, etc.,

$$\begin{aligned} \mathbf{E}\phi\left(\pi_t^{H_1}\right) &= \mathbf{E}\phi\left(\mathrm{vec}_i\left\{P\left(X_t = x_i \mid \mathcal{Z}_t^{H_2} \vee \mathcal{Z}_t^{H_3}\right)\right\}\right) \\ &\le \mathbf{E}\mathbf{E}\left(\phi\left(\mathrm{vec}_i\left\{P\left(X_t = x_i \mid \mathcal{Z}_t^{H_2}\right)\right\}\right) \mid \mathcal{Z}_t^{H_3}\right) \\ &= \mathbf{E}\phi\left(\pi_t^{H_2}\right). \qquad \square \end{aligned}$$

The partial ordering of Proposition 4.1 becomes a complete ordering if the components of the noise process $(\zeta_i;\, i = 1, 2 \ldots, n)$ are independent, and the preprocessing function, h, consists of n separate functions of the n components of the raw observation. In particular, this is true if $n = 1$. Thus the choice of thresholds t_j in (2.12) that maximize H will be asymptotically optimal for the nonlinear filtering problem in terms of any of the cost functions of (4.1).

The optimal thresholds for zero-mean, unit-variance Gaussian noise (with a number of different degrees of quantization) are given, along with the corresponding values

TABLE 4.1
Optimal quantization thresholds for standard Gaussian noise (to three decimal places).

Number of bits	Thresholds								H
1	0								0.637
2	0	±0.982							0.883
3	0	±0.501	±1.050	±1.748					0.965
4	0	±0.258	±0.522	±0.800	±1.100	±1.437	±1.844	±2.401	0.990

for H in Table 4.1. The reduction in the signal-to-noise ratio of the limit filter arising through the use of 1-bit quantization is a factor of only $2/\pi$, and the reduction factors rapidly approach unity as the number of bits in the quantization increases. Clearly, if the noise has a nonstandard Gaussian distribution, then the thresholds should all be shifted by its mean and scaled by its standard deviation. The optimal thresholds of Table 4.1 are also pertinent to the quantization of multidimensional observations if the components of the noise are independent and Gaussian, and the components of the observations are quantized separately.

The asymptotic signal-to-noise ratio for 1-bit quantization is similar to that obtained by Kushner in [13] for a continuous-time system comprising a limiter, a gain control, and a linear filter. The input to this system is taken to be the sum of a (useful) signal and wide-band Gaussian noise. As the bandwidth of the noise increases, the output of the system converges weakly to the output that would be obtained if the limiter and gain control were removed, except that the signal-to-noise ratio is reduced by a factor that depends on the nature of the signal and the limiting behavior of the noise. If the signal is sinusoidal and the noise correlation is exponential, then the reduction factor obtained by Kushner is $2/(\pi \ln 2)$. The problem is somewhat different from that considered here, although both problems concern some form of accumulating larger and larger numbers of samples of an increasingly noise corrupted signal. Kushner's problem can be interpreted in this way by time scaling.

A generalization of the techniques discussed here includes *feedback* from the filter to the preprocessing operation, i.e., uses preprocessing operations of the following form:

$$Y_k^{h,\delta} = h\left(\delta g(X_k^\delta) + \zeta_k, \pi_{k-1}^{h,\delta}\right).$$

For example, we might use a quantization scheme with thresholds that change when $\pi_k^{h,\delta}$ moves between different regions of its range. The functions $h(z + \cdot, p)$ induce a two-parameter family of distributions on $(M, \mathcal{M})$, $q(dy, z, p)$, with corresponding Radon–Nikodým derivatives, $r(y, z, p)$. Theorem 2.1 extends to this case showing that the discrete-time filters converge to a continuous-time filter with observations process given by (2.6), but with a *time-varying*, signal-to-noise ratio of $H(\pi_t^H)$, where

$$H(p) = \int r_z'(y, 0, p) r_z(y, 0, p) q(dy, 0, p).$$

(Sufficient conditions are that (H1)–(H4) be true *uniformly in* p and that $H(p)$ be Lipschitz continuous.) In principle, we could optimize within classes of such feedback preprocessing operations according to cost functions of the form (4.1) but, once again, this is not easy, except in special cases. A simple variation of Proposition 4.1 shows that, if, for two feedback preprocessing operations h_1 and h_2, the limit signal-to-noise

ratio functions, $H_1(\cdot)$ and $H_2(\cdot)$, are such that $H_1(p) - H_2(p)$ is positive semidefinite for all p, then

$$J_\phi\left(\pi_t^{H_1(\cdot)}\right) \leq J_\phi\left(\pi_t^{H_2(\cdot)}\right)$$

for all $t \in [0, \infty)$ and all cost functions of the form (4.1). Thus, we may partially order the feedback preprocessing operations. If the components of the raw observations process are perturbed by independent noises and are preprocessed separately (in particular if the raw observations process is scalar), then the *instantaneous*, asymptotic signal-to-noise ratios, $H(p)$, of a feedback preprocessing operation will be completely ordered in the above sense. There is, therefore, nothing to be gained by the use of feedback in such cases; the optimal feedback preprocessing operation is clearly the feedback-less operation, $h(\cdot, p*)$, where $p*$ is the parameter that optimizes $H(p)$.

5. Examples. The optimal quantization techniques for observations perturbed by Gaussian noise, described above, were used with the following two examples. In both cases, the filters were based on raw observations, and 1- and 2-bit quantized observations were simulated. The quantization levels used throughout are those given in Table 4.1. An ergodic simulation technique was used involving the time averaging of variates obtained from the posterior distributions provided by the various filters. A number of the results were checked against results obtained from direct simulations. The filters were allowed to reach steady-state before data recording started, and so the cost functions concerned are relative to the invariant distributions of the filters. All simulations were run until all the sample standard deviations were less than 0.32% of their corresponding statistics. Error bars have been omitted from the graphs for the sake of clarity.

Example 5. Binary signal. In this example $(X_k^\delta \in \{-1, +1\}, k = 0, 1, \ldots)$ is a binary Markov process with the following matrix of transition probabilities,

$$Q^\delta = \begin{bmatrix} 1 - a\delta^2 & a\delta^2 \\ a\delta^2 & 1 - a\delta^2 \end{bmatrix},$$

and the raw observations are given by

$$Z_k^\delta = \delta X_k^\delta + \zeta_k, \tag{5.1}$$

where $(\zeta_k;\ k = 1, 2, \ldots)$ is an independently and identically distributed (i.i.d.) standard Gaussian sequence, independent of (X_k^δ).

Figures 5.1 and 5.2 show the steady-state error probabilities for the associated nonlinear filters based on the variously quantized observations, for values of the normalized switching rate, a, of 0.1 and 0.0001. The three disconnected points on the left-hand sides of the figures are the asymptotic error probabilities for the filters predicted by Theorem 2.1. These were calculated from the (known) steady-state distribution of the nonlinear filter for a continuous-time binary Markov process, given observations (2.6). (The values of H used for the quantized filters are those given in Table 4.1, and a value of 1 was used for the filter based on raw observations.) As the figures show, not only do the error probabilities approach the predicted limits, but they do so for fairly large values of δ. Thus, at least in this example, the use of quantization thresholds optimized with respect to limit cost functions appears to be justified.

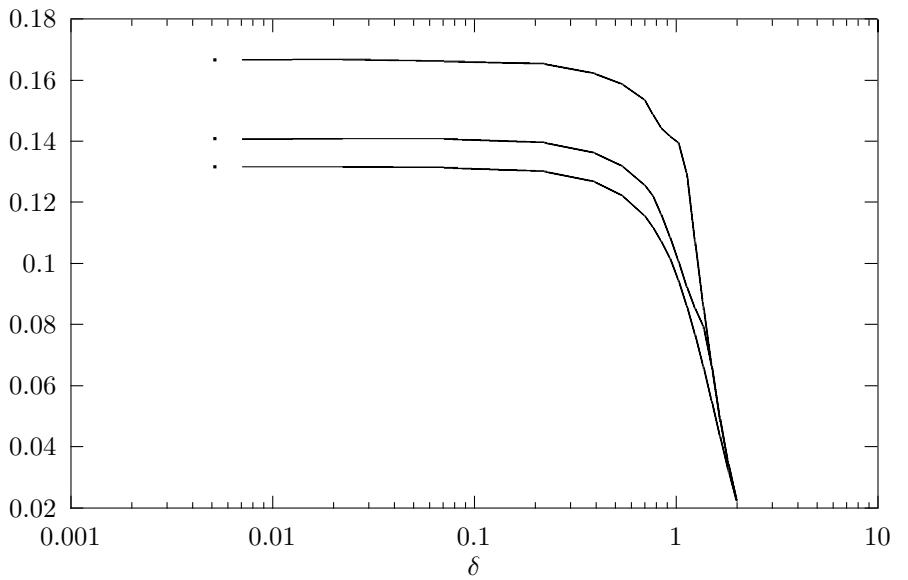

FIG. 5.1. *Filter error probabilities for Example* 1 *(*$a = 0.1$*). Bottom curve: raw observations; middle curve:* 2*-bit quantized observations; top curve:* 1*-bit quantized observations.*

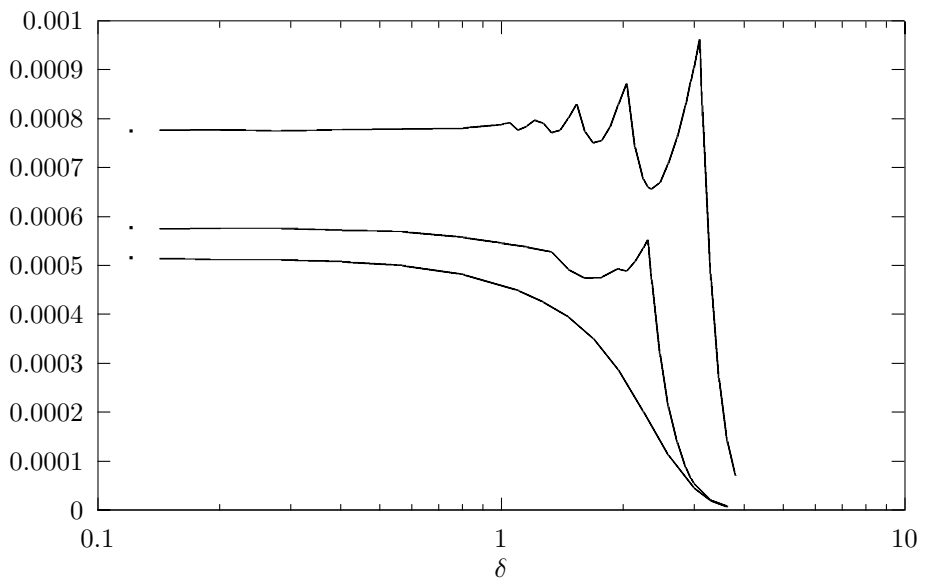

FIG. 5.2. *Filter error probabilities for Example* 1 *(*$a = 0.0001$*). Bottom curve: raw observations; middle curve:* 2*-bit quantized observations; top curve:* 1*-bit quantized observations.*

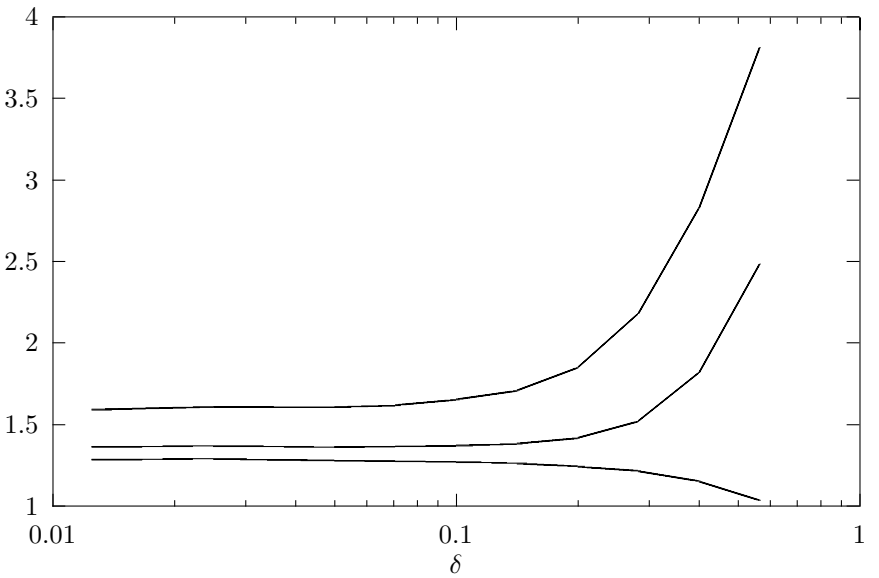

FIG. 5.3. *Mean-square filter errors for Example* 2 *(*$a = 1.0$*). Bottom curve: raw observations; middle curve:* 2*-bit quantized observations; top curve:* 1*-bit quantized observations.*

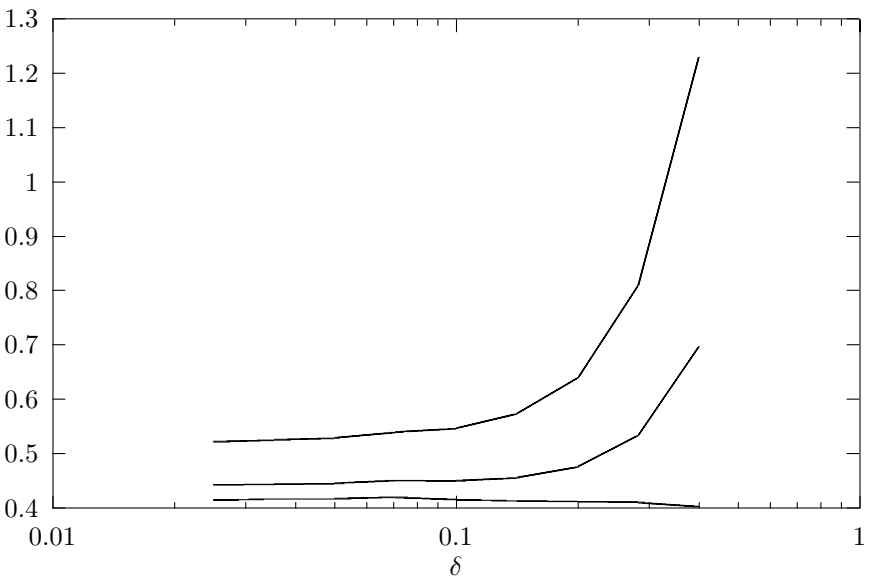

FIG. 5.4. *Mean-square filter errors for Example* 2 *(*$a = 0.1$*). Bottom curve: raw observations; middle curve:* 2*-bit quantized observations; top curve:* 1*-bit quantized observations.*

Example 6. Birth-death approximation to a diffusion. In this example the signal, $(X_k^\delta \in \{\pm 0.5, \pm 1.5, \pm 2.5 \ldots, \pm 9.5\},\ k = 0, 1, \ldots)$, is a 20-state birth-death process with transition probabilities

$$P^\delta(X_{k+1} = y \mid X_k = x) = \begin{cases} a\delta^2 & \text{if } y = x + 1 \text{ and } x \le 8.5, \\ & \text{or } y = x - 1 \text{ and } x \ge -8.5, \\ 1 - 2a\delta^2 & \text{if } -8.5 \le y = x \le 8.5, \\ 1 - a\delta^2 & \text{if } y = x = -9.5 \text{ or } 9.5, \\ 0 & \text{for all other } x, y, \end{cases}$$

and the raw observations are given by (5.1). The signal here can be interpreted as a discrete-state, weak approximation to a diffusion process with zero drift term and a diffusion coefficient that rapidly approaches zero for arguments beyond ±9 but is constant elsewhere.

Figures 5.3 and 5.4 show the mean-square error in the posterior mean of X obtained from the filters with the same three preprocessing operations as were used with Example 5, for values of a of 1.0 and 0.1. Once again, the graphs suggest that the weak limit is approached for fairly large values of δ.

DYNAMIC DOMAIN DECOMPOSITION IN APPROXIMATE AND EXACT BOUNDARY CONTROL IN PROBLEMS OF TRANSMISSION FOR WAVE EQUATIONS*

J. E. LAGNESE† AND G. LEUGERING‡

Abstract. This paper is concerned with dynamic domain decomposition for optimal boundary control and for approximate and exact boundary controllability of wave propagation in heterogeneous media. We consider a cost functional which penalizes the deviation of the final state of the solution of the global problem from a specified target state. For any fixed value of the penalty parameter, optimality conditions are derived for both the global optimal control problem and for local optimal control problems obtained by a domain decomposition and a saddle-point–type iteration. Convergence of the iterations to the solution of the global optimality system is established. We then pass to the limit in the iterations as the penalty parameter increases without bound and show that the limiting local iterations converge to the solution of the optimality system associated with the problem of finding the minimum norm control that drives the solution of the global problem to a specified target state.

Key words. domain decomposition, optimal control, controllability, saddle-point iteration

1. Introduction.

This paper explores optimal boundary final-value control as well as approximate and exact boundary controllability for scalar wave equations in heterogeneous media by means of domain decomposition. Indeed, we consider the situation where the material properties are piecewise constant within a material body which occupies a bounded domain $\Omega \in \mathbb{R}^d$ and hence deal with a *transmission problem*. It is assumed that the subdomains Ω_i, $i = 1, \dots, m$, within which the material properties are constant satisfy

$$\Omega_i \cap \Omega_j = \emptyset, \quad i \neq j, \quad \overline{\Omega}_i \subset \Omega, \quad i = 1, \dots, m-1, \quad \Omega_m = \Omega \setminus \bigcup_{i=1}^{m-1} \overline{\Omega}_i,$$

and that $\partial\Omega$, $\partial\Omega_i$, $i = 1, \dots, m$, are smooth. However, our results will hold for other decompositions $\{\Omega_i\}_{i=1}^m$ of Ω and for less regular boundaries if it is known that solutions of the global and local problems considered below have sufficient regularity.

The basic idea of domain decomposition in the present context is to handle the constant coefficient subdomain problems individually, with the impact on the environment of such a subdomain being modeled through some inhomogeneities, and to then assemble the controlled local processes into the global one by means of some iteration. Obviously, the communication between the local problems via transmission conditions has to be restored in the limit of the iteration. In this sense, we consider the present problem a paradigm and the procedure given in this paper as a general

tool to handle more complex multilink flexible structures as discussed in Lagnese, Leugering, and Schmidt [19].

The motivation for the approach considered in this paper is twofold. On the one hand, controllability properties and optimal control laws (feedbacks, etc.) are more readily available at the local subdomain level. Consequently, there is good reason to believe that it may be possible to construct suitable control laws for the global, more complex, structure by iteration, even in situations where such control properties are not a priori known at the global level. On the other hand, and perhaps more importantly, the approach is motivated by its *numerical potential:* complex heterogeneous structures or media, after some discretization, inevitably lead to very large systems to be solved numerically. In typical applications, such as to flexible structures, structural elements of different kinds (strings, beams, membranes, plates and/or shells) are coupled through joints and interfaces. Such transmission problems are usually very difficult to handle numerically at the global level. It seems very natural, therefore, to decompose such structures into their canonical constituents (structural elements, subdomains) to discretize those and to run the computations *in parallel* with the communications between subdomains taking place once an iteration step is completed. The local problems can be treated numerically as in Glowinski and J.-L. Lions ([14], [15]).

There is extensive literature on domain decomposition methods for direct simulation of static or transient problems (see, for instance, [10], [30], [16] as examples of very recent expositions and [31] for textbook material in the context of numerical domain decomposition); comparatively little is known about such methods in the context of optimal control problems. Let us mention the work by Benamou [2], [3], [4], [5], [6], [7] and Benamou and Després [8], where elliptic, parabolic, and hyperbolic problems with constant coefficients in Ω are considered together with a cost functional which involves the entire state over space and time (in addition to the control). In these papers the authors use an extension of P. L. Lions's method [27], originally obtained for elliptic problems. Regarding transmission problems, the principle of extension of domain decomposition in optimal control of heterogeneous materials was already mentioned in [8] in connection with the Hemholtz equation. Let us also mention the work of Bamberger, Glowinski, and Tran [1], where a domain decomposition technique is introduced for the computation of the acoustic wave equation in which the bulk modulus and density fields are allowed to be discontinuous across an interface.

In fact, the nonoverlapping Schwarz alternating method in [27] has been shown by Glowinski and LeTallec [13] to be equivalent to an augmented Lagrangian saddle-point iteration. This analogy has been used by Bounaim [9] to extend the domain decomposition to elliptic optimal control problems. The idea pursued there is to add the cost function to the augmented Lagrangian interpretation of the underlying domain decomposition. The corresponding saddle-point problem, however, is solved by a gradient method rather than on the basis of the Uzawa-type iteration obtained after elimination of the Lagrange multipliers and artificial interface parameters. Very recently, J. L. Lions and Pironneau [25] (based on [26]) have considered a Lagrangian approach for both overlapping and nonoverlapping domain decompositions for elliptic and parabolic problems with a possible extension to hyperbolic problems. Their approach is similar to Bounaim's [9] method with the difference that they consider the original Lagrange functional to match the continuity at the artificial interfaces and use conjugate gradients. The augmented Lagrangian point of view was also used in [22] in order to devise a domain decomposition for mechanical networks of one-dimensional elements, where *multiple* nodes naturally appear. In that context the basic Lagrangian

approach, pursued in [25], could be utilized as well. Also in that work, the numerical implementation was discussed and simulations were presented. It should be mentioned that in all of the works [2], [3], [4], [5], [6], [7], [8], [22], the proof of convergence of the decomposition utilizes ideas inspired by Després [11].

To our best knowledge, this paper is the first to apply a dynamic domain decomposition method to state constrained optimal control problems. (For domain decomposition in optimal control of elliptic equations with control constraints, see [4].) Generalizations to more complex multiply connected structures as well as the numerical implementation of the algorithms given in this paper are presently under investigation. The only numerical study of dynamic domain decomposition in optimal control problems in dimension greater than one that is known to us is the preprint by Benamou [6] (see also [7]), where a scalar constant coefficient wave equation on a square is considered. In that work a *complete* decomposition down to the finite element level is used. Quadrilateral elements, a leap-frog scheme in time, and numerical integration leading to lumped masses are employed. In addition, various relaxations are used to speed up convergence.

Let us now formulate more precisely the problems to be studied. Set

$$\Gamma_{ij} = \partial\Omega_i \cap \partial\Omega_j = \Gamma_{ji}, \quad i \neq j, \quad \Gamma = \partial\Omega.$$

It is assumed that Γ_{ij} is either empty or has a nonempty interior. The exterior unit normal vector to Ω_i is denoted by ν_i. Introduce the Hilbert spaces

$$H = L^2(\Omega) = \prod_{i=1}^{m} L^2(\Omega_i),$$

$$\begin{aligned} V &= \{(\phi_1, \dots, \phi_m) : \phi_i \in H^1(\Omega_i),\ \phi_i = \phi_j \text{ on } \Gamma_{ij}\} \\ &= \{(\phi_1, \dots, \phi_m) : \phi_i = \phi|_{\Omega_i},\ \phi \in H^1(\Omega)\} \end{aligned}$$

with respective norms

$$\|(\phi_1, \dots, \phi_m)\| = \left(\sum_{i=1}^{m} \int_{\Omega_i} |\phi_i|^2 dx \right)^{1/2},$$

$$\|(\phi_1, \dots, \phi_m)\|_V = \left(\sum_{i=1}^{m} \int_{\Omega_i} (a_i |\nabla \phi_i|^2 + |\phi_i|^2) dx \right)^{1/2},$$

where $a_i > 0$. Let V' denote the dual space of V with respect to H, $(\cdot, \cdot)_{V'}$ the scalar product in the $V' - V$ duality, and A the Riesz isomorphism of V onto V'.

Let $T > 0$ and set

$$Q_i = \Omega_i \times (0, T), \quad \Sigma_{ij} = \Gamma_{ij} \times (0, T), \quad \Sigma = \Gamma \times (0, T).$$

Let $f \in L^2(\Sigma)$. We consider the following transmission problem: for $i = 1, \dots, m$,

$$\begin{aligned} y_{i,tt} - a_i \Delta y_i &= 0 \quad \text{in } Q_i, \\ a_m \frac{\partial y_m}{\partial \nu_m} &= f \quad \text{on } \Sigma, \\ y_i = y_j, \quad a_i \frac{\partial y_i}{\partial \nu_i} + a_j \frac{\partial y_j}{\partial \nu_j} &= 0 \quad \text{on } \Sigma_{ij}, \\ y_i(0) = y_{i,t}(0) &= 0 \quad \text{in } \Omega_i. \end{aligned} \tag{1.1}$$

For each $f \in \mathcal{U} := L^2(\Sigma)$, (1.1) has a unique solution $\mathbf{Y} := (y_1, \dots, y_m)$ with

$$\mathbf{Y} \in C([0,T]; H) \cap C^1([0,T]; V'),$$

and the map $f \mapsto (\mathbf{Y}, \mathbf{Y}_{,t}) : \mathcal{U} \mapsto C([0,T]; H \times V')$ is continuous. The solution of (1.1) may be interpreted in the sense of transposition (cf. Komornik [17, Theorem 4.7]):

$$(\mathbf{Y}_{,t}(t), \Phi(t))_{V'} - (\mathbf{Y}(t), \Phi_{,t}(t)) = \int_0^t \int_\Gamma f \phi_m \, d\Gamma \, dt, \quad \forall (\Phi^0, \Phi^1) \in V \times H,\ 0 \le t \le T, \tag{1.2}$$

where $\Phi := (\phi_1, \dots, \phi_m)$ is the solution of the problem

$$\begin{aligned} \phi_{i,tt} - a_i \Delta \phi_i &= 0 \quad \text{in } Q_i,\ i = 1, \dots, m, \\ a_m \frac{\partial \phi_m}{\partial \nu_m} &= 0 \quad \text{on } \Sigma, \\ \phi_i = \phi_j, \quad a_i \frac{\partial \phi_i}{\partial \nu_i} + a_j \frac{\partial \phi_j}{\partial \nu_j} &= 0 \quad \text{on } \Sigma_{ij}, \\ \Phi(0) = \Phi^0 \in V, \quad \Phi_{,t}(0) &= \Phi^1 \in H. \end{aligned} \tag{1.3}$$

One has $(\Phi, \Phi_{,t}) \in C([0,T]; V \times H)$ and

$$\|(\Phi, \Phi_{,t})\|_{L^\infty(0,T;V\times H)} \le C \|(\Phi^0, \Phi^1)\|_{V \times H}.$$

It is a consequence of Holmgren's theorem that the system (1.1) is *approximately controllable* for T sufficiently large, that is,

$$\mathcal{R}_T := \{(\mathbf{Y}(T), \mathbf{Y}_{,t}(T)) :\ f \in \mathcal{U}\} \quad \text{is dense in } H \times V'.$$

(This remains true for controls which vanish outside $\mathcal{O} \times (0,T)$, where $\mathcal{O}$ is a fixed, nonempty open set in Γ.) Further, (1.1) is known to be *exactly controllable* to $V \times H$, that is, $V \times H \subset \mathcal{R}_T$, provided certain conditions on the geometries of the regions Ω_i and the elastic parameters a_i are satisfied. For example, exact controllability holds if all of the a_i are the same. Exact controllability also holds if (i) $\Omega_1 = \omega_1$, $\Omega_{i+1} = \omega_{i+1} \backslash \overline{\omega}_i$ for $i = 1, \dots, m-1$, where ω_i are open sets such that $\overline{\omega_i} \subset \omega_{i+1}$, $i = 1, \dots, m-1$, $\omega_m = \Omega$; (ii) there is a point $x_0 \in \Omega_1$ such that $(x - x_0) \cdot \nu_i \ge 0$, $\forall x \in \partial\omega_i$, for $i = 1, \dots, m$; and (iii) $a_i \ge a_{i+1}$ for $i = 1, \dots, m-1$ (cf. [24, Chap. VI] and [18]).

Let $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T) \in H \times V'$, and consider the optimal control problem

$$J(f) = \frac{1}{2} \int_\Sigma |f|^2 d\Sigma + \frac{k}{2} (\|\mathbf{Y}(T) - \mathbf{Y}_T\|^2 + \|\mathbf{Y}_{,t}(T) - \dot{\mathbf{Y}}_T\|^2_{V'}) \to \inf \tag{1.4}$$

subject to (1.1), where the infimum is taken over $\mathcal{U}$. Standard theory gives the existence of a unique minimizer f characterized by

$$0 = \int_\Sigma f g \, d\Sigma + k(\mathbf{U}(T), \mathbf{Y}(T) - \mathbf{Y}_T) + k(\mathbf{U}_{,t}(T), A^{-1}(\mathbf{Y}_{,t}(T) - \dot{\mathbf{Y}}_T))_{V'} \quad \forall g \in \mathcal{U},$$

where $\mathbf{U} = \mathbf{U}_g \in C([0,T];H) \cap C^1([0,T];V')$ is the solution of (1.1) with f replaced by g. Introduce the adjoint state $\mathbf{P} = (p_1, \dots, p_m)$ as the solution of the system

$$\begin{aligned} p_{i,tt} - a_i \Delta p_i &= 0 \quad \text{in } Q_i,\ i = 1, \dots, m, \\ a_m \frac{\partial p_m}{\partial \nu_m} &= 0 \quad \text{on } \Sigma, \\ p_i = p_j, \quad a_i \frac{\partial p_i}{\partial \nu_i} + a_j \frac{\partial p_j}{\partial \nu_j} &= 0 \quad \text{on } \Sigma_{ij}, \end{aligned} \tag{1.5}$$

$$\mathbf{P}(T) = kA^{-1}(\mathbf{Y}_{,t}(T) - \dot{\mathbf{Y}}_T), \quad \mathbf{P}_{,t}(T) = -k(\mathbf{Y}(T) - \mathbf{Y}_T). \tag{1.6}$$

For any $f \in \mathcal{U}$, (1.5), (1.6) has a unique solution with $(\mathbf{P}, \mathbf{P}_{,t}) \in C([0,T];V \times H)$. From (1.2) we have

$$0 = (\mathbf{U}_{,t}(T), \mathbf{P}(T))_{V'} - (\mathbf{U}(T), \mathbf{P}_{,t}(T)) - \int_\Sigma g p_m \, d\Sigma \quad \forall g \in \mathcal{U},$$

from which it follows that the optimal control is given by

$$f = -p_m|_\Sigma. \tag{1.7}$$

The optimality system is therefore (1.1), (1.5)–(1.7).

Remark 1.1. The solution of (1.1), (1.5)–(1.7) satisfies $(\mathbf{Y}, \mathbf{Y}_{,t}) \in C([0,T];V \times H)$. In fact, the optimal control $f = -p_m|_\Sigma \in C([0,T];H^{1/2}(\Gamma))$ so that the conclusion follows by localization and a result of Miyatake [28], taking into account the above assumptions on the regions Ω_i. It then follows that if $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T) \in V \times H$, we have $(\mathbf{P}(T), \mathbf{P}_{,t}(T)) \in D(A) \times V$, where

$$\begin{aligned} D(A) = \{\Phi \in V \,|\, A\Phi \in H\} = \Big\{ &(\phi_1, \dots, \phi_m) \,|\, \phi_i \in H^2(\Omega_i), \\ &\phi_i = \phi_j,\ a_i \frac{\partial \phi_i}{\partial \nu_i} + a_j \frac{\partial \phi_j}{\partial \nu_j} = 0 \text{ on } \Gamma_{ij},\ \ a_m \frac{\partial \phi_m}{\partial \nu_m} = 0 \text{ on } \Gamma \Big\}. \end{aligned}$$

As a consequence, $p_m|_\Sigma \in C^1([0,T];H^{1/2}(\Gamma))$, so that $(\mathbf{Y}_{,t}, \mathbf{Y}_{,tt}) \in C([0,T];V \times H)$, and therefore $y_i \in C([0,T], H^2(\Omega_i))$, $i = 1, \dots, m$. In particular, the transmission conditions hold in the sense of traces on Γ_{ij}.

Remark 1.2. The first condition in (1.6) is the elliptic transmission problem

$$\begin{aligned} -a_i \Delta p_i(T) + p_i(T) &= k(y_{i,t}(T) - \dot{y}_{iT}) \quad \text{in } \Omega_i, \\ a_m \frac{\partial p_m(T)}{\partial \nu_m} &= 0 \quad \text{on } \Gamma, \\ p_i(T) = p_j(T), \quad a_i \frac{\partial p_i(T)}{\partial \nu_i} + a_j \frac{\partial p_j(T)}{\partial \nu_j} &= 0 \quad \text{on } \Gamma_{ij}. \end{aligned} \tag{1.8}$$

In (1.8),

$$y_{i,t}(T) - \dot{y}_{iT} := A_i[A^{-1}(\mathbf{Y}_{,t}(T) - \dot{\mathbf{Y}}_T)|_{\Omega_i}] \in (H^1(\Omega_i))',$$

where A_i is the Riesz isomorphism of $H^1(\Omega_i)$ onto its dual with the norm on $H^1(\Omega_i)$ given by

$$\|\phi\|_{H^1(\Omega_i)} := \left(\int_{\Omega_i} (a_i |\nabla \phi|^2 + |\phi|^2) dx \right)^{1/2}.$$

This is because

$$A(\phi_1, \ldots, \phi_m) = (A_1\phi_1, \ldots, A_m\phi_m), \ \ \forall (\phi_1, \ldots, \phi_m) \in V.$$

If $\mathbf{Y}(\cdot\,; k)$ denotes the solution of (1.1) corresponding to the optimal control (1.7), and if T is sufficiently large, it is easy to see that

$$(\mathbf{Y}(T; k), \mathbf{Y}_t(T; k)) \to (\mathbf{Y}_T, \dot{\mathbf{Y}}_T) \quad \text{in } H \times V' \text{ as } k \to \infty.$$

Therefore, a control that steers the solution to a neighborhood of $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T)$ at time T may be obtained via the optimality system (1.1), (1.5)–(1.7) with k sufficiently large. On the other hand, if (1.1) is exactly controllable to $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T) \in V \times H$ at time T, the minimum $L^2(\Sigma)$ norm control that steers the solution of (1.1) to $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T)$ at time T is the solution of the optimal control problem

$$\inf_{f \in \mathcal{U}} \int_\Sigma |f|^2 d\Sigma$$

subject to (1.1) and the state constraint

$$\mathbf{Y}(T) = \mathbf{Y}_T, \quad \mathbf{Y}_{,t}(T) = \dot{\mathbf{Y}}_T.$$

It is well known that the optimality system for this problem is given by (1.1), (1.5),

$$\mathbf{P}(T) = \mathbf{P}_T, \quad \mathbf{P}_{,t}(T) = \dot{\mathbf{P}}_T, \tag{1.9}$$

where $(\mathbf{P}_T, \dot{\mathbf{P}}_T) \in H \times V'$ is the solution of the equation

$$((\mathbf{P}_T, \dot{\mathbf{P}}_T), (-\dot{\mathbf{Y}}_T, \mathbf{Y}_T))_{H \times V'} = \int_\Sigma |p_m|^2 d\Sigma, \tag{1.10}$$

with the optimal control again given by (1.7).

The main object of this paper is to present domain decomposition methods (DDMs) for both the approximate controllability and exact controllability problems. Each DDM is based on an *under* of the nonoverlapping Schwarz alternating algorithm and the introduction of skew-symmetric, Robin, iterative transmission conditions between the subdomains Ω_i that couple the direct and adjoint states in the optimality systems associated with the approximate, resp., the exact, controllability problem. The use of this type of decomposition, without relaxation, in problems of optimal control was first proposed by Benamou [2], [3], [4], [5], [6], [7]. The introduction of relaxation in conjunction with the nonoverlapping Schwarz alternating algorithm has been previously investigated in [11] for direct approximation and in [8] in conjunction with some optimal control problems related to the Helmholtz equation. The transmission conditions (3.3) below may be viewed as a generalization of those in [8] to optimal control problems involving penalization of the final state. Let us comment that the convergence of our DDMs *without relaxation* remains an open question.

For both the approximate and exact controllability problems, the corresponding DDM is a sequence of boundary value problems on the region Q_i. In the case of approximate controllability, these problems, denoted by $\{D_i^n(k)\}_{n=1}^\infty$, depend on the penalty parameter k. We denote the DDM for the exact controllability problem by $\{D_i^n(\infty)\}_{n=1}^\infty$. Let us denote by $y_i^n(\cdot\,; k)$, $p_i^n(\cdot\,; k)$ the solution of $D_i^n(k)$; by $y_i^n(\cdot\,; \infty)$,

$p_i^n(\cdot\,;\infty)$ the solution of $D_i^n(\infty)$; by $\{y_i(\cdot\,;k), p_i(\cdot\,;k)\}_{i=1}^m$ the solution of the optimality system (1.1), (1.5)–(1.7); and by $\{y_i(\cdot\,;\infty), p_i(\cdot\,;\infty)\}_{i=1}^m$ the solution of (1.1), (1.5), (1.7), (1.9), and (1.10). We wish to determine under what conditions the following diagram is valid in appropriate norms:

$$\begin{array}{ccc} (y_i^n(\cdot\,;k), p_i^n(\cdot\,;k)) & \xrightarrow{\;n\to\infty\;} & (y_i(\cdot\,;k), p_i(\cdot\,;k)) \\ {\scriptstyle k\to\infty}\big\downarrow & & {\scriptstyle k\to\infty}\big\downarrow \\ (y_i^n(\cdot\,;\infty), p_i^n(\cdot\,;\infty)) & \xrightarrow{\;n\to\infty\;} & (y_i(\cdot\,;\infty), p_i(\cdot\,;\infty)) \end{array} \tag{1.11}$$

Assuming that $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T) \in V \times H$, it will be proved that the top limit is always true and that the remaining ones are also valid if (1.1) is exactly controllable to $V \times H$.

As is to be expected from the works of Benamou and of Leugering cited above, for fixed n, the boundary value problem $D_i^n(k)$ is in fact the optimality system for a certain local optimal control problem on the region Q_i. (The same is true for $D_i^n(\infty)$.) The local optimal control problem associated with $D_i^n(k)$ is introduced in the next section. In section 3 the convergence $(y_i^n(\cdot\,;k), p_i^n(\cdot\,;k)) \to (y_i(\cdot\,;k), p_i(\cdot\,;k))$ as $n \to \infty$ is established. In section 4 it is proved that $(y_i(\cdot\,;k), p_i(\cdot\,k)) \to (y_i(\cdot\,;\infty), p_i(\cdot\,\infty))$ as $k \to \infty$, while in section 5 it is shown that $(y_i^n(\cdot\,;k), p_i^n(\cdot\,;k)) \to (y_i^n(\cdot\,;\infty), p_i^n(\cdot\,;\infty))$ as $k \to \infty$. Finally, in the last section it is established that $(y_i^n(\cdot\,;\infty), p_i^n(\cdot\,;\infty)) \to (y_i(\cdot\,;\infty), p_i(\cdot\,\infty))$ as $n \to \infty$.

2. The local optimal control problems. For $i = 1, \dots, m$ we set

$$\gamma_i = \bigcup_{j:\Gamma_{ij}\neq\emptyset} \Gamma_{ij}, \quad \Gamma_i = \begin{cases} \emptyset, & i \neq m, \\ \Gamma, & i = m, \end{cases} \quad S_i = \gamma_i \times (0,T), \quad \Sigma_i = \Gamma_i \times (0,T).$$

Then $\partial\Omega_i = \gamma_i \cup \Gamma_i$. We also set $H_i = L^2(\Omega_i)$, $V_i = H^1(\Omega_i)$ endowed with the norm

$$\|\phi\|_{V_i} = \left(\int_{\Omega_i} (a_i |\nabla\phi|^2 + |\phi|^2) dx + \alpha \int_{\gamma_i} |\phi|^2 d\Gamma \right)^{1/2}, \quad \alpha > 0,$$

and denote by V_i' the dual space of V_i with respect to H_i. Of course, V_i' and $(H^1(\Omega_i))'$ are the same as sets and have equivalent norms, but the Riesz isomorphism $\mathcal{A}_i$ of V_i onto V_i' is not the same as the Riesz isomorphism A_i defined above. (However, they are connected through the bounded invertible mapping B_i on V_i defined by $(\phi,\psi)_{H^1(\Omega_i)} = (B_i\phi, \psi)_{V_i}\ \forall \phi, \psi \in V_i$.)

Set $y_{iT} = \mathbf{Y}_T|_{\Omega_i} \in H_i$, $\dot{y}_{iT} = A_i(A^{-1}\dot{\mathbf{Y}}_T|_{\Omega_i}) \in V_i'$ (see Remark 1.2). Suppose that λ_i, μ_i are given in $L^2(S_i)$ and τ_i is given in $L^2(\gamma_i)$. We define $\sigma_i \in V_i'$ by

$$(\sigma_i, \phi)_{V_i'} = \int_{\gamma_i} \tau_i \phi \, d\Gamma \quad \forall \phi \in V_i,$$

and consider the optimal control problems

$$\begin{aligned} J_i(f_1, f_2) = {} & \frac{1}{2} \int_{\Sigma_i} |f_2|^2 d\Sigma + \frac{1}{2\beta} \int_{S_i} (|f_1|^2 + |\beta z_i + \mu_i|^2) d\Sigma \\ & + \frac{k}{2} (\|z_i(T) - y_{iT}\|_{H_i}^2 + \|z_{i,t}(T) - \dot{y}_{iT} + k^{-1}\sigma_i\|_{V_i'}^2) \to \inf, \end{aligned}$$

where $\beta > 0$, subject to

$$
\begin{aligned}
z_{i,tt} - a_i \Delta z_i &= 0 \quad \text{in } Q_i, \\
a_i \frac{\partial z_i}{\partial \nu_i} &= f_1 + \lambda_i \quad \text{on } S_i, \\
a_i \frac{\partial z_i}{\partial \nu_i} &= f_2 \quad \text{on } \Sigma_i, \\
z_i(0) = z_{i,t}(0) &= 0 \quad \text{in } \Omega_i,
\end{aligned} \tag{2.1}
$$

where the infimum is taken over $f_1 \in L^2(S_i)$ and $f_2 \in L^2(\Sigma_i)$. This optimal control problem is well posed since the solution of (2.1) satisfies

$$z_i|_{S_i} \in L^2(S_i), \quad z_i|_{\Sigma_i} \in L^2(\Sigma_i),$$

(see Lasiecka–Triggiani [20]). In fact, from [20] we have $(z_i, z_{i,t}) \in C([0,T]; H^\alpha(\Omega_i) \times H^{\alpha-1}(\Omega_i))$, $z_i|_{\Sigma_{ij}} \in H^{2\alpha-1}(\Sigma_{ij})$, $z_i|_{\Sigma_i} \in H^{2\alpha-1}(\Sigma_i)$, where $\alpha = 3/5 - \varepsilon \ \forall \varepsilon > 0$, and

$$
\begin{aligned}
&\|z_i\|_{H^{2\alpha-1}(\Sigma_i)} + \sum_{j:\Gamma_{ij} \neq \emptyset} \|z_i\|_{H^{2\alpha-1}(\Sigma_{ij})} + \|(z_i, z_{i,t})\|_{L^\infty(0,T;H^\alpha(\Omega_i)\times H^{\alpha-1}(\Omega_i))} \\
&\quad \le C\big(\|f_1 + \lambda_i\|_{L^2(S_i)} + \|f_2\|_{L^2(\Sigma_i)}\big).
\end{aligned}
$$

From Tataru [33] we have the even stronger regularity result

$$z_i \in H^{2/3}(Q_i), \quad z_i|_{\Sigma_{ij}} \in H^{1/3}(\Sigma_{ij}), \quad z_i|_{\Sigma_i} \in H^{1/3}(\Sigma_i).$$

The unique optimal solution f_1, f_2 of the above problem is characterized by the variational equation

$$
\begin{aligned}
0 = &\int_{\Sigma_i} f_2 g_2 \, d\Sigma + \int_{S_i} [\beta^{-1} f_1 g_1 + (\beta z_i + \mu_i) u_i] d\Sigma \\
&+ k[(u_i(T), z_i(T) - y_{iT})_{H_i} + (u_{i,t}(T), \mathcal{A}_i^{-1}(z_{i,t}(T) - \dot{y}_{iT} + k^{-1}\sigma_i))_{V_i'}] \\
&\quad \forall g_1 \in L^2(S_i),\ g_2 \in L^2(\Sigma_i),
\end{aligned}
$$

where $\mathcal{A}_i$ is the Riesz isomorphism of V_i onto V_i' and where u_i is the solution of

$$
\begin{aligned}
u_{i,tt} - a_i \Delta u_i &= 0 \quad \text{in } Q_i, \\
a_i \frac{\partial u_i}{\partial \nu_i} &= g_1 \quad \text{on } S_i, \\
a_i \frac{\partial u_i}{\partial \nu_i} &= g_2 \quad \text{on } \Sigma_i, \\
u_i(0) = u_{i,t}(0) &= 0 \quad \text{in } \Omega_i.
\end{aligned}
$$

Introduce the adjoint state as the solution of

$$
\begin{aligned}
q_{i,tt} - a_i \Delta q_i &= 0 \quad \text{in } Q_i, \\
a_i \frac{\partial q_i}{\partial \nu_i} &= \beta z_i + \mu_i \quad \text{on } S_i, \\
a_i \frac{\partial q_i}{\partial \nu_i} &= 0 \quad \text{on } \Sigma_i, \\
q_i(T) = k\mathcal{A}_i^{-1}(z_{i,t}(T) - \dot{y}_{iT} + k^{-1}\sigma_i) &\in V_i, \\
q_{i,t}(T) = -k(z_i(T) - y_{iT}) &\in H_i.
\end{aligned} \tag{2.2}
$$

The solutions z_i, u_i, q_i all possess the same regularity and after an integration by parts (which can be justified by virtue of the regularity of u_i and q_i) we obtain

$$0 = (u_{i,t}(T), q_i(T))_{V_i'} - (u_i(T), q_{i,t}(T))_{H_i} - \int_{\Sigma_i} q_i g_2 d\Sigma - \int_{S_i} [q_i g_1 - (\beta z_i + \mu_i) u_i] d\Sigma, \quad \forall g_1 \in L^2(S_i),\ g_2 \in L^2(\Sigma_i). \tag{2.3}$$

It follows that

$$f_1 = -\beta q_i|_{S_i}, \quad f_2 = -q_i|_{\Sigma_i}.$$

The optimality system is therefore (2.2) and

$$\begin{aligned} z_{i,tt} - a_i \Delta z_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} + \beta q_i &= \lambda_i \quad \text{on } S_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} + q_i &= 0 \quad \text{on } \Sigma_i, \\ z_i(0) = z_{i,t}(0) &= 0 \quad \text{in } \Omega_i. \end{aligned} \tag{2.4}$$

Remark 2.1. Note that $q_i(T)$ is the solution of the elliptic boundary value problem

$$\begin{aligned} -a_i \Delta q_i(T) + q_i(T) &= k(z_{i,t}(T) - \dot{y}_{iT}) \quad \text{in } \Omega_i, \\ a_i \frac{\partial q_i(T)}{\partial \nu_i} + \alpha q_i(T) &= \tau_i \quad \text{on } \gamma_i, \\ a_i \frac{\partial q_i(T)}{\partial \nu_i} &= 0 \quad \text{on } \Gamma_i. \end{aligned}$$

For purposes of studying convergence of the domain decomposition in the next section, we introduce a space $\mathcal{X}$ and a bounded linear operator on $\mathcal{X}$ as follows:

$$\mathcal{X} := \prod_{i=1}^{m} L^2(S_i) \times L^2(S_i) \times L^2(\gamma_i)$$

with norm $\|\cdot\|_{\mathcal{X}}$ given by

$$\|X\|_{\mathcal{X}}^2 = \sum_{i=1}^{m} \left\{ \frac{1}{\beta} \int_{S_i} (|\lambda_i|^2 + |\mu_i|^2) d\Sigma + \frac{1}{\alpha k} \int_{\gamma_i} |\tau_i|^2 d\Gamma \right\},$$

where $X = \{(\lambda_i, \mu_i, \tau_i) : i = 1, \dots, m\}$. Now let $X \in \mathcal{X}$ and define a linear mapping $\mathcal{T} : \mathcal{X} \mapsto \mathcal{X}$ as follows: let (z_i, q_i) be the solutions of the local optimality systems (2.2), (2.4) corresponding to X, where $y_{iT} = \dot{y}_{iT} = 0$, $i = 1, \dots, m$ (this is done for purposes of the proof of Theorem 3.1 below). Set

$$(\mathcal{T}X)_{ij} = \left(\left(-a_j \frac{\partial z_j}{\partial \nu_j} + \beta q_j \right) |_{\Sigma_{ij}}, \left(-a_j \frac{\partial q_j}{\partial \nu_j} - \beta z_j \right) |_{\Sigma_{ij}}, \left(-a_j \frac{\partial q_j(T)}{\partial \nu_j} + \alpha q_j(T) \right) |_{\gamma_{ij}} \right),$$

$$(\mathcal{T}X)_i = \{(\mathcal{T}X)_{ij} : j : \Gamma_{ij} \neq \emptyset\}, \quad \mathcal{T}X = \{(\mathcal{T}X)_i : i = 1, \dots, m\}. \tag{2.5}$$

Note that X is a fixed point of $\mathcal{T}$ if and only if $\{(z_i, q_i) : i = 1, \dots, m\}$ is a solution of the global optimality system (1.1), (1.5)–(1.7). It follows that $\mathcal{T}$ has a unique fixed point. Since the solution of the optimal control problem (1.1), (1.4) corresponding to $\mathbf{Y}_T = \dot{\mathbf{Y}}_T = 0$ is clearly $f = 0$, it follows that this fixed point is $X = 0$. The following result shows that $\mathcal{T}$ is nonexpansive.

LEMMA 2.2. *For any* $X \in \mathcal{X}$,

$$\|\mathcal{T}X\|_{\mathcal{X}}^2 = \|X\|_{\mathcal{X}}^2 - \frac{4}{k}\sum_{i=1}^{m}\big[\|q_i(T)\|_{H^1(\Omega_i)}^2 + \|q_{i,t}(T)\|_{L^2(\Omega_i)}^2\big] - 4\int_\Sigma |q_m|^2 d\Sigma.$$

Proof. One has

$$\begin{aligned}
\|X\|_{\mathcal{X}}^2 &= \sum_{i=1}^{m}\bigg\{\frac{1}{\beta}\int_{S_i}\bigg[\bigg|a_i\frac{\partial z_i}{\partial \nu_i} + \beta q_i\bigg|^2 + \bigg|a_i\frac{\partial q_i}{\partial \nu_i} - \beta z_i\bigg|^2\bigg]\,d\Sigma \\
&\qquad + \frac{1}{\alpha k}\int_{\gamma_i}\bigg|a_i\frac{\partial q_i(T)}{\partial \nu_i} + \alpha q_i(T)\bigg|^2 d\Gamma\bigg\} \\
&= \sum_{i=1}^{m}\frac{1}{\beta}\bigg\{\int_{S_i}\bigg[\bigg|a_i\frac{\partial z_i}{\partial \nu_i}\bigg|^2 + \bigg|a_i\frac{\partial q_i}{\partial \nu_i}\bigg|^2 + \beta^2(|z_i|^2 + |q_i|^2) \\
&\qquad + 2\beta\bigg(q_i a_i\frac{\partial z_i}{\partial \nu_i} - z_i a_i\frac{\partial q_i}{\partial \nu_i}\bigg)\bigg]\,d\Sigma \\
&\qquad + \frac{1}{\alpha k}\int_{\gamma_i}\bigg[\bigg|a_i\frac{\partial q_i(T)}{\partial \nu_i}\bigg|^2 + \alpha^2|q_i(T)|^2 + 2\alpha q_i(T)a_i\frac{\partial q_i(T)}{\partial \nu_i}\bigg]d\Gamma\bigg\},
\end{aligned}$$

$$\begin{aligned}
\|\mathcal{T}X\|_{\mathcal{X}}^2 = \sum_{i=1}^{m}\sum_{j:\Gamma_{ij}\neq\emptyset}\bigg\{&\frac{1}{\beta}\int_{\Sigma_{ij}}\bigg[\bigg|-a_j\frac{\partial z_j}{\partial \nu_j} + \beta q_j\bigg|^2 + \bigg|a_j\frac{\partial q_j}{\partial \nu_j} + \beta z_j\bigg|^2\bigg]\,d\Sigma \\
&+ \frac{1}{\alpha k}\int_{\Gamma_{ij}}\bigg|-a_j\frac{\partial q_j(T)}{\partial \nu_j} + \alpha q_j(T)\bigg|^2 d\Gamma\bigg\}.
\end{aligned}$$

Since $\sum_{i=1}^m\sum_{j:\Gamma_{ij}\neq\emptyset} = \sum_{j=1}^m\sum_{i:\Gamma_{ji}\neq\emptyset}$, the last equation may be written

$$\begin{aligned}
\|\mathcal{T}X\|_{\mathcal{X}}^2 = \sum_{j=1}^{m}\bigg\{&\frac{1}{\beta}\int_{\Sigma_j}\bigg[\bigg|-a_j\frac{\partial z_j}{\partial \nu_j} + \beta q_j\bigg|^2 + \bigg|a_j\frac{\partial q_j}{\partial \nu_j} + \beta z_j\bigg|^2\bigg]\,d\Sigma \\
&+ \frac{1}{\alpha k}\int_{\gamma_j}\bigg|-a_j\frac{\partial q_j(T)}{\partial \nu_j} + \alpha q_j(T)\bigg|^2 d\Gamma\bigg\}.
\end{aligned}$$

Therefore

$$\begin{aligned}
(2.6)\quad \|\mathcal{T}X\|_{\mathcal{X}}^2 - \|X\|_{\mathcal{X}}^2 = -4\sum_{i=1}^{m}\bigg\{&\int_{S_i}\bigg(q_i a_i\frac{\partial z_i}{\partial \nu_i} - z_i a_i\frac{\partial q_i}{\partial \nu_i}\bigg)d\Sigma \\
&+\frac{1}{k}\int_{\gamma_i} q_i(T)a_i\frac{\partial q_i(T)}{\partial \nu_i}\bigg\}d\Gamma.
\end{aligned}$$

From (2.3) we have

$$\begin{aligned}
(2.7)\qquad 0 = (z_{i,t}(T), q_i(T))_{V_i'} - (z_i(T), q_{i,t}(T))_{H_i} - \int_{\Sigma_i} q_i a_i\frac{\partial z_i}{\partial \nu_i}\,d\Sigma \\
- \int_{S_i}\bigg(q_i a_i\frac{\partial z_i}{\partial \nu_i} - z_i a_i\frac{\partial q_i}{\partial \nu_i}\bigg)d\Sigma.
\end{aligned}$$

From (2.2),

$$(z_{i,t}(T), q_i(T))_{V_i'} - (z_i(T), q_{i,t}(T))_{H_i} = \frac{1}{k}\big(\|q_i(T)\|^2_{H^1(\Omega_i)} + \|q_{i,t}(T)\|^2_{L^2(\Omega_i)}\big) - \frac{1}{k}\int_{\gamma_i} q_i(T) a_i \frac{\partial q_i(T)}{\partial \nu_i}\, d\Gamma. \tag{2.8}$$

Lemma 2.2 follows from (2.6)–(2.8). □

Lemma 2.2. can be regarded as an extension to optimality systems of the isometry Lemma 2.4 of Després [12]. Later on we shall use the following result of Opial [29, Theorem 3].

PROPOSITION 2.3. *Let $\mathcal{C}$ be a closed convex set in a uniformly convex Banach space $\mathcal{X}$ having a weakly continuous duality mapping, and let $\mathcal{T} : \mathcal{C} \mapsto \mathcal{C}$ be a nonexpansive mapping with at least one fixed point. Set $\mathcal{T}_\epsilon = \epsilon I + (1-\epsilon)\mathcal{T}$. Then, for any $X \in \mathcal{C}$ and any $\epsilon \in (0,1)$, the sequence of successive approximations $\{\mathcal{T}_\epsilon^n X\}$ is weakly convergent to a fixed point of $\mathcal{T}$.*

3. Domain decomposition. For $i = 1, \dots, m$ and for $n = 0, 1, \dots$, consider the problem

$$\begin{aligned} y_{i,tt}^{n+1} - a_i \Delta y_i^{n+1} &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial y_i^{n+1}}{\partial \nu_i} + \beta p_i^{n+1} &= \lambda_{ij}^n \quad \text{on } \Sigma_{ij}, \\ a_i \frac{\partial y_i^{n+1}}{\partial \nu_i} + p_i^{n+1} &= 0 \quad \text{on } \Sigma_i, \\ y_i^{n+1}(0) = y_{i,t}^{n+1}(0) &= 0, \end{aligned} \tag{3.1}$$

$$\begin{aligned} p_{i,tt}^{n+1} - a_i \Delta p_i^{n+1} &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial p_i^{n+1}}{\partial \nu_i} - \beta y_i^{n+1} &= \mu_{ij}^n \quad \text{on } \Sigma_{ij}, \\ a_i \frac{\partial p_i^{n+1}}{\partial \nu_i} &= 0 \quad \text{on } \Sigma_i, \\ p_i^{n+1}(T) = k\mathcal{A}_i^{-1}(y_{i,t}^{n+1}(T) - \dot{y}_{iT} + k^{-1}\sigma_i^n), \\ p_{i,t}^{n+1}(T) &= -k(y_i^{n+1}(T) - y_{iT}), \end{aligned} \tag{3.2}$$

where λ_{ij}^0, $\mu_{ij}^0 \in L^2(\Sigma_{ij})$ and, for $n = 1, 2, \dots$ and fixed $\epsilon \in [0, 1)$,

$$\begin{aligned} \lambda_{ij}^n &= (1-\epsilon)\left(-a_j \frac{\partial y_j^n}{\partial \nu_j} + \beta p_j^n\right)|_{\Sigma_{ij}} + \epsilon\left(a_i \frac{\partial y_i^n}{\partial \nu_i} + \beta p_i^n\right)|_{\Sigma_{ij}}, \\ \mu_{ij}^n &= (1-\epsilon)\left(-a_j \frac{\partial p_j^n}{\partial \nu_j} - \beta y_j^n\right)|_{\Sigma_{ij}} + \epsilon\left(a_i \frac{\partial p_i^n}{\partial \nu_i} - \beta y_i^n\right)|_{\Sigma_{ij}}, \end{aligned} \tag{3.3}$$

and where $\sigma_i^n \in V_i'$ is defined by

$$(\sigma_i^n, \phi)_{V_i'} = \sum_{j:\Gamma_{ij} \neq \emptyset} \int_{\Gamma_{ij}} \tau_{ij}^n \phi \, d\Gamma \quad \forall \phi \in V_i, \tag{3.4}$$

with $\tau_{ij}^0 \in L^2(\Gamma_{ij})$ arbitrary and for $n = 1, 2, \ldots,$

$$\tau_{ij}^n = (1-\epsilon)\left(-a_j \frac{\partial p_j^n(T)}{\partial \nu_j} + \alpha p_j^n(T)\right)|_{\Gamma_{ij}} + \epsilon\left(a_i \frac{\partial p_i^n(T)}{\partial \nu_i} + \alpha p_i^n(T)\right)|_{\Gamma_{ij}}. \tag{3.5}$$

Note that the iteration on $p_i^{n+1}(T)$ is a relaxation of the nonoverlapping Schwarz alternating method applied to the global elliptic transmission problem (1.8) for the final state $p(T)$. Written as an elliptic boundary value problem, it is

$$\begin{aligned} -a_i \Delta p_i^{n+1}(T) + p_i^{n+1}(T) &= k(y_{i,t}^{n+1}(T) - \dot{y}_{iT}) \quad \text{in } \Omega_i, \\ a_i \frac{\partial p_i^{n+1}(T)}{\partial \nu_i} + \alpha p_i^{n+1}(T) &= \tau_{ij}^n \quad \text{on } \Gamma_{ij}, \\ a_i \frac{\partial p_i^{n+1}(T)}{\partial \nu_i} &= 0 \quad \text{on } \Gamma_i \end{aligned} \tag{3.6}$$

(see Remark 2.1). Note also that (3.1), (3.2) is the optimality system for the local optimal control problem on Q_i considered in the previous section with λ_i, μ_i and τ_i replaced by $(\lambda_{ij}^n)_{j:\Gamma_{ij}\neq\emptyset}$, $(\mu_{ij}^n)_{j:\Gamma_{ij}\neq\emptyset}$, and $(\tau_{ij}^n)_{j:\Gamma_{ij}\neq\emptyset}$, resp. The parameter ϵ is a relaxation parameter; when $\epsilon = 0$ the iterations at the interfaces Σ_{ij} are exactly those introduced by Benamou [2], [3], [4], [5], [6], [7].

If λ_{ij}^n, $\mu_{ij}^n \in L^2(\Sigma_{ij})$, $\tau_{ij}^n \in L^2(\Gamma_{ij})$, $i = 1, \ldots, m$, $j : \Gamma_{ij} \neq \emptyset$, then because of the regularity possessed by the solutions y_i^{n+1}, p_i^{n+1}, $i = 1, \ldots, m$, we have

$$\lambda_{ij}^{n+1} \in L^2(\Sigma_{ij}), \quad \mu_{ij}^{n+1} \in L^2(\Sigma_{ij}), \quad \tau_{ij}^{n+1} \in L^2(\Gamma_{ij}).$$

If, therefore, $\lambda_{ij}^0 \in L^2(\Sigma_{ij})$, $\mu_{ij}^0 \in L^2(\Sigma_{ij})$, $\tau_{ij}^0 \in L^2(\Gamma_{ij})$, then (3.1), (3.2) is well set for each $n = 0, 1, \ldots$.

Consider now the global optimality system (1.1), (1.5)–(1.7). If we set

$$\begin{aligned} \lambda_{ij} &= (1-\epsilon)\left(-a_j \frac{\partial y_j}{\partial \nu_j} + \beta p_j\right)|_{\Sigma_{ij}} + \epsilon\left(a_i \frac{\partial y_i}{\partial \nu_i} + \beta p_i\right)|_{\Sigma_{ij}}, \\ \mu_{ij} &= (1-\epsilon)\left(-a_j \frac{\partial p_j}{\partial \nu_j} - \beta y_j\right)|_{\Sigma_{ij}} + \epsilon\left(a_i \frac{\partial p_i}{\partial \nu_i} - \beta y_i\right)|_{\Sigma_{ij}}, \\ \tau_{ij} &= (1-\epsilon)\left(-a_j \frac{\partial p_j(T)}{\partial \nu_j} + \alpha p_j(T)\right)|_{\Gamma_{ij}} + \epsilon\left(a_i \frac{\partial p_i(T)}{\partial \nu_i} + \alpha p_i(T)\right)|_{\Gamma_{ij}}, \\ (\sigma_i, \phi)_{V_i'} &= \sum_{j:\Gamma_{ij}\neq\emptyset} \int_{\Gamma_{ij}} \tau_{ij}\phi \, d\Gamma \quad \forall \phi \in V_i, \end{aligned}$$

then it is seen that y_i, p_i is formally a solution of (3.1), (3.2) with $\lambda_{ij}^n, \mu_{ij}^n, \tau_{ij}^n$ replaced by $\lambda_{ij}, \mu_{ij}, \tau_{ij}$, resp., and y_i, p_i is an actual solution if it is known that

$$\lambda_{ij} \in L^2(\Sigma_{ij}), \quad \mu_{ij} \in L^2(\Sigma_{ij}), \quad \tau_{ij} \in L^2(\Gamma_{ij}).$$

This amounts to requiring that

$$\frac{\partial y_j}{\partial \nu_j}|_{\Sigma_{ij}} \in L^2(\Sigma_{ij}), \quad \frac{\partial p_j}{\partial \nu_j}|_{\Sigma_{ij}} \in L^2(\Sigma_{ij}), \quad \frac{\partial p_j(T)}{\partial \nu_j}|_{\Gamma_{ij}} \in L^2(\Gamma_{ij}), \tag{3.7}$$

which will hold if it is assumed that $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T) \in V \times H$ (see Remark 1.1.).

We will prove the following convergence result.

THEOREM 3.1. *Assume that* $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T) \in V \times H$ *and* $\epsilon \in (0,1)$. *Let* $\mathbf{Y} = (y_1, \dots, y_m)$, $\mathbf{P} = (p_1, \dots, p_m)$ *be the solution of the global optimality system* (1.1), (1.5)–(1.7), *and* y_i^n, p_i^n *be the solutions of the local optimality systems* (3.1), (3.2), $i = 1, \dots, m$. *Set* $\mathbf{Y}^n = (y_1^n, \dots, y_m^n)$, $\mathbf{P}^n = (p_1^n, \dots, p_m^n)$. *Then as* $n \to \infty$,

$$\mathbf{Y}^n \to \mathbf{Y}, \quad \mathbf{P}^n \to \mathbf{P} \quad \text{in } C\Big([0,T]; \prod_{i=1}^m L^2(\Omega_i)\Big),$$
$$\mathbf{Y}^n_{,t} \to \hat{\mathbf{Y}}, \quad \mathbf{P}^n_{,t} \to \hat{\mathbf{P}} \quad \text{in } C\Big([0,T]; \prod_{i=1}^m (H^1(\Omega_i))'\Big),$$

where $\hat{\mathbf{Y}}(t)|_V = \mathbf{Y}_{,t}(t)$, $\hat{\mathbf{P}}(t)|_V = \mathbf{P}_{,t}(t)$, $0 \le t \le T$,

$$p_m^n|_\Sigma \to p_m|_\Sigma \quad \text{strongly in } L^2(\Sigma),$$
$$y_i^n|_{S_i} \to y_i|_{S_i}, \quad p_i^n|_{S_i} \to p_i|_{S_i} \quad \text{strongly in } L^2(S_i),$$
$$\frac{\partial y_i^n}{\partial \nu_i}|_{S_i} \to \frac{\partial y_i}{\partial \nu_i}|_{S_i}, \quad \frac{\partial p_i^n}{\partial \nu_i}|_{S_i} \to \frac{\partial p_i}{\partial \nu_i}|_{S_i} \quad \text{weakly in } L^2(S_i),$$
$$\mathbf{P}^n(T) \to \mathbf{P}(T) \quad \text{strongly in } \prod_{i=1}^m V_i,$$
$$\mathbf{P}^n_{,t}(T) \to \mathbf{P}_{,t}(T) \quad \text{strongly in } H,$$
$$\frac{\partial p_i^n(T)}{\partial \nu_i}|_{\gamma_i} \to \frac{\partial p_i(T)}{\partial \nu_i}|_{\gamma_i} \quad \text{weakly in } L^2(\gamma_i).$$

Remark 3.2. The proof of convergence for the case without relaxation ($\epsilon = 0$) is an open problem.

Proof. For $n = 1, 2, \dots$, set

$$\tilde{y}_i^n = y_i^n - y_i, \quad \tilde{p}_i^n = p_i^n - p_i,$$
$$\tilde{\lambda}_{ij}^n = \lambda_{ij}^n - \lambda_{ij} = (1-\epsilon)\left(-a_j \frac{\partial \tilde{y}_j^n}{\partial \nu_j} + \beta \tilde{p}_j^n\right)|_{\Sigma_{ij}} + \epsilon\left(a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} + \beta \tilde{p}_i^n\right)|_{\Sigma_{ij}},$$
$$\tilde{\mu}_{ij}^n = \mu_{ij}^n - \mu_{ij} = (1-\epsilon)\left(-a_j \frac{\partial \tilde{p}_j^n}{\partial \nu_j} - \beta \tilde{y}_j^n\right)|_{\Sigma_{ij}} + \epsilon\left(a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} - \beta \tilde{y}_i^n\right)|_{\Sigma_{ij}},$$
$$\tilde{\tau}_{ij}^n = \tau_{ij}^n - \tau_{ij} = (1-\epsilon)\left(-a_j \frac{\partial \tilde{p}_j^n(T)}{\partial \nu_j} + \alpha \tilde{p}_j^n(T)\right)|_{\Gamma_{ij}} + \epsilon\left(a_i \frac{\partial \tilde{p}_i^n(T)}{\partial \nu_i} + \alpha \tilde{p}_i^n(T)\right)|_{\Gamma_{ij}},$$
$$\tilde{\sigma}_i^n = \sigma_i^n - \sigma_i.$$

The pair $(\tilde{y}_i^n, \tilde{p}_i^n)$ satisfies

$$\begin{aligned}
&\tilde{y}_{i,tt}^{n+1} - a_i \Delta \tilde{y}_i^{n+1} = 0, \quad \tilde{p}_{i,tt}^{n+1} - a_i \Delta \tilde{p}_i^{n+1} = 0 \quad \text{in } Q_i,\\
&a_i \frac{\partial \tilde{y}_i^{n+1}}{\partial \nu_i} + \beta \tilde{p}_i^{n+1} = \tilde{\lambda}_{ij}^n, \quad a_i \frac{\partial \tilde{p}_i^{n+1}}{\partial \nu_i} - \beta \tilde{y}_i^{n+1} = \tilde{\mu}_{ij}^n \quad \text{on } \Sigma_{ij},\\
&a_i \frac{\partial \tilde{y}_i^{n+1}}{\partial \nu_i} + \tilde{p}_i^{n+1} = 0, \quad a_i \frac{\partial \tilde{p}_i^{n+1}}{\partial \nu_i} = 0 \quad \text{on } \Sigma_i,\\
&\tilde{y}_i^{n+1}(0) = \tilde{y}_{i,t}^{n+1}(0) = 0,\\
&\tilde{p}_i^{n+1}(T) = k\mathcal{A}_i^{-1}(\tilde{y}_{i,t}^{n+1}(T) + k^{-1}\tilde{\sigma}_i^n), \quad \tilde{p}_{i,t}^{n+1}(T) = -k\tilde{y}_i^{n+1}(T).
\end{aligned} \tag{3.8}$$

It is important to note that the iterations on the interfaces Σ_{ij} may be expressed in terms of the mapping $\mathcal{T}$ defined in the last section as follows. Set

$$X_i^n := \left(\left(a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} + \beta \tilde{p}_i^n \right) |_{\Sigma_i}, \left(a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} - \beta \tilde{y}_i^n \right) |_{\Sigma_i}, \left(a_i \frac{\partial \tilde{p}_i^n(T)}{\partial \nu_i} + \alpha \tilde{p}_i^n(T) \right) |_{\gamma_i} \right),$$
$$X^n = \{X_i^n\}_{i=1}^m.$$

Then the interface conditions may be expressed as the relaxed fixed point iteration

$$X^{n+1} = (1-\epsilon)\mathcal{T}X^n + \epsilon X^n. \tag{3.9}$$

It follows from Lemma 2.2 and Proposition 2.3 that if $0 < \epsilon < 1$, X^n converges weakly in $\mathcal{X}$ to a fixed point X of $\mathcal{T}$. This fixed point must be $X = 0$ as was noted above (immediately preceding the statement of Lemma 2.2). Thus $X^n \to 0$ and $\mathcal{T}X^n \to 0$ weakly in $\mathcal{X}$, from which follows that

$$\tilde{y}_i^n|_{S_i} \to 0, \quad \tilde{p}_i^n|_{S_i} \to 0, \quad \frac{\partial \tilde{y}_i^n}{\partial \nu_i}|_{S_i} \to 0, \quad \frac{\partial \tilde{p}_i^n}{\partial \nu_i}|_{S_i} \to 0$$

weakly in $L^2(S_i)$, and

$$\tilde{p}_i^n(T)|_{\gamma_i} \to 0, \quad \frac{\partial \tilde{p}_i^n(T)}{\partial \nu_i}|_{\gamma_i} \to 0$$

weakly in $L^2(\gamma_i)$.

From (3.9) and Lemma 2.2 we have

$$\begin{aligned} \|X^{n+1}\|_{\mathcal{X}}^2 &= (1-\epsilon)^2 \|\mathcal{T}X^n\|_{\mathcal{X}}^2 + \epsilon^2 \|X^n\|_{\mathcal{X}}^2 + 2\epsilon(1-\epsilon)(X^n, \mathcal{T}X^n)_{\mathcal{X}} \\ &= ((1-\epsilon)^2 + \epsilon^2)\|X^n\|_{\mathcal{X}}^2 - \frac{4(1-\epsilon)^2}{k} \sum_{i=1}^m \mathcal{E}_i(\tilde{p}_i^n(T)) \\ &\quad - 4(1-\epsilon)^2 \int_\Sigma |\tilde{p}_m^n|^2 d\Sigma + 2\epsilon(1-\epsilon)(X^n, \mathcal{T}X^n)_{\mathcal{X}}, \end{aligned} \tag{3.10}$$

where

$$\mathcal{E}_i(\phi) = \|\phi\|_{H^1(\Omega_i)}^2 + \|\phi_{,t}\|_{L^2(\Omega_i)}^2.$$

By the same calculation as in the proof of Lemma 2.2, we obtain

$$\begin{aligned} \|X^n\|_{\mathcal{X}}^2 = \sum_{i=1}^m \Bigg\{ &\frac{1}{\alpha k} \int_{\gamma_i} \left(\alpha^2 |\tilde{p}_i^n(T)|^2 + \left| a_i \frac{\partial \tilde{p}_i^n(T)}{\partial \nu_i} \right|^2 \right) d\Gamma \\ &+ \frac{1}{\beta} \int_{S_i} \left(\beta^2 (|\tilde{y}_i^n|^2 + |\tilde{p}_i^n|^2) + \left| a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} \right|^2 + \left| a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} \right|^2 \right) d\Sigma \Bigg\} \\ &+ \frac{2}{k} \sum_{i=1}^m \mathcal{E}_i(\tilde{p}_i^n(T)) + 2 \int_\Sigma |\tilde{p}_m^n|^2 d\Sigma. \end{aligned} \tag{3.11}$$

It follows from (3.10), (3.11) that

$$\begin{aligned} \|X^{n+1}\|_{\mathcal{X}}^2 = ((1-\epsilon)^2 + \epsilon^2)E^n - \frac{2}{k}(1-2\epsilon) \sum_{i=1}^m \mathcal{E}_i(\tilde{p}_i^n(T)) \\ - 2(1-2\epsilon) \int_\Sigma |\tilde{p}_m^n|^2 d\Sigma + 2\epsilon(1-\epsilon)(X^n, \mathcal{T}X^n)_{\mathcal{X}}, \end{aligned} \tag{3.12}$$

where

$$E^n := \sum_{i=1}^{m} \left\{ \frac{1}{\alpha k} \int_{\gamma_i} \left(\alpha^2 |\tilde{p}_i^n(T)|^2 + \left| a_i \frac{\partial \tilde{p}_i^n(T)}{\partial \nu_i} \right|^2 \right) d\Gamma \right.$$
$$\left. + \frac{1}{\beta} \int_{S_i} \left(\beta^2 (|\tilde{y}_i^n|^2 + |\tilde{p}_i^n|^2) + \left| a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} \right|^2 + \left| a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} \right|^2 \right) d\Sigma \right\}.$$

From (3.12) and (3.11) with n replaced by $n+1$ we obtain

$$E^{n+1} = ((1-\epsilon)^2 + \epsilon^2) E^n - \frac{2}{k} \sum_{i=1}^{m} [(1-2\epsilon)\mathcal{E}_i(\tilde{p}_i^n(T)) + \mathcal{E}_i(\tilde{p}_i^{n+1}(T))] \tag{3.13}$$
$$- 2 \int_{\Sigma} [(1-2\epsilon)|\tilde{p}_m^n|^2 + |\tilde{p}_m^{n+1}|^2] d\Sigma + 2\epsilon(1-\epsilon)(X^n, \mathcal{T}X^n)_{\mathcal{X}}.$$

We have

$$(X^n, \mathcal{T}X^n)_{\mathcal{X}} = \sum_{i=1}^{m} \sum_{j:\Gamma_{ij} \neq \emptyset} \left\{ \frac{1}{\beta} \int_{\Sigma_{ij}} \left[\left(a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} + \beta \tilde{p}_i^n \right) \left(-a_j \frac{\partial \tilde{y}_j^n}{\partial \nu_j} + \beta \tilde{p}_j^n \right) \right.\right.$$
$$\left. - \left(a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} - \beta \tilde{y}_i^n \right) \left(a_j \frac{\partial \tilde{p}_j^n}{\partial \nu_j} + \beta \tilde{y}_j^n \right) \right] d\Sigma$$
$$\left. + \frac{1}{\alpha k} \int_{\Gamma_{ij}} \left(a_i \frac{\partial \tilde{p}_i^n(T)}{\partial \nu_i} + \alpha \tilde{p}_i^n(T) \right) \left(-a_j \frac{\partial \tilde{p}_j^n(T)}{\partial \nu_i} + \alpha \tilde{p}_j^n(T) \right) d\Gamma \right\}$$
$$= \sum_{i=1}^{m} \sum_{j:\Gamma_{ij} \neq \emptyset} \left\{ \frac{1}{\beta} \int_{\Sigma_{ij}} \left[-a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} a_j \frac{\partial \tilde{y}_j^n}{\partial \nu_j} - a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} a_j \frac{\partial \tilde{p}_j^n}{\partial \nu_j} \right.\right.$$
$$+ \beta^2 (\tilde{p}_i^n \tilde{p}_j^n + \tilde{y}_i^n \tilde{y}_j^n) + \beta \left(\tilde{p}_j^n a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} - \tilde{p}_i^n a_j \frac{\partial \tilde{y}_j^n}{\partial \nu_j} \right)$$
$$\left. -\beta \left(\tilde{y}_j^n a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} - \tilde{y}_i^n a_j \frac{\partial \tilde{p}_j^n}{\partial \nu_j} \right) \right] d\Sigma$$
$$+ \frac{1}{\alpha k} \int_{\Gamma_{ij}} \left[-a_i \frac{\partial \tilde{p}_i^n(T)}{\partial \nu_i} a_j \frac{\partial \tilde{p}_j^n(T)}{\partial \nu_j} + \alpha^2 \tilde{p}_i^n(T) \tilde{p}_j^n(T) \right.$$
$$\left. \left. + \alpha \left(\tilde{p}_j^n(T) a_i \frac{\partial \tilde{p}_i^n(T)}{\partial \nu_i} - \tilde{p}_i^n(T) a_j \frac{\partial \tilde{p}_j^n(T)}{\partial \nu_j} \right) \right] d\Gamma \right\}.$$

One has

$$\sum_{i=1}^{m} \sum_{j:\Gamma_{ij} \neq \emptyset} \int_{\Sigma_{ij}} \left(\tilde{p}_j^n a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} - \tilde{p}_i^n a_j \frac{\partial \tilde{y}_j^n}{\partial \nu_j} \right) d\Sigma = 0,$$

and similarly for the other integrals with mixed terms. Therefore

$$(X^n, \mathcal{T}X^n)_{\mathcal{X}} = \sum_{i=1}^{m} \sum_{j:\Gamma_{ij} \neq \emptyset} \left\{ \frac{1}{\beta} \int_{\Sigma_{ij}} \left[- a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} a_j \frac{\partial \tilde{y}_j^n}{\partial \nu_j} - a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} a_j \frac{\partial \tilde{p}_j^n}{\partial \nu_j} \right.\right.$$
$$\left. + \beta^2 (\tilde{p}_i^n \tilde{p}_j^n + \tilde{y}_i^n \tilde{y}_j^n) \right] d\Sigma$$
$$\left. + \frac{1}{\alpha k} \int_{\Gamma_{ij}} \left[-a_i \frac{\partial \tilde{p}_i^n(T)}{\partial \nu_i} a_j \frac{\partial \tilde{p}_j^n(T)}{\partial \nu_j} + \alpha^2 \tilde{p}_i^n(T) \tilde{p}_j^n(T) \right] d\Gamma \right\}.$$

Since

$$\sum_{i=1}^{m}\int_{S_i}|f_i|^2d\Sigma=\sum_{i=1}^{m-1}\sum_{\substack{j:\Gamma_{ij}\neq\emptyset\\ j>i}}\int_{\Sigma_{ij}}(|f_i|^2+|f_j|^2)\,d\Sigma,$$

$$\sum_{i=1}^{m}\sum_{j:\Gamma_{ij}\neq\emptyset}\int_{\Sigma_{ij}}f_if_j\,d\Sigma=2\sum_{i=1}^{m-1}\sum_{\substack{j:\Gamma_{ij}\neq\emptyset\\ j>i}}\int_{\Sigma_{ij}}f_if_j\,d\Sigma,$$

we have

(3.14)

$$\begin{aligned}
&((1-\epsilon)^2+\epsilon^2)E^n+2\epsilon(1-\epsilon)(X^n,\mathcal{T}X^n)_{\mathcal{X}}\\
&=\sum_{i=1}^{m}\sum_{\substack{j:\Gamma_{ij}\neq\emptyset\\ j>i}}\left\{\frac{1}{\beta}\int_{\Sigma_{ij}}\left[((1-\epsilon)^2+\epsilon^2)\left(\left|a_i\frac{\partial\tilde y_i^n}{\partial\nu_i}\right|^2+\left|a_j\frac{\partial\tilde y_j^n}{\partial\nu_j}\right|^2\right.\right.\right.\\
&\quad+\left.\left|a_i\frac{\partial\tilde p_i^n}{\partial\nu_i}\right|^2+\left|a_j\frac{\partial\tilde p_j^n}{\partial\nu_j}\right|^2\right)-4\epsilon(1-\epsilon)\left(a_i\frac{\partial\tilde y_i^n}{\partial\nu_i}a_j\frac{\partial\tilde y_j^n}{\partial\nu_j}+a_i\frac{\partial\tilde p_i^n}{\partial\nu_i}a_j\frac{\partial\tilde p_j^n}{\partial\nu_j}\right)\\
&\quad\left.+\beta^2((1-\epsilon)^2+\epsilon^2)(|\tilde y_i^n|^2+|\tilde y_j^n|^2+|\tilde p_i^n|^2+|\tilde p_j^n|^2)+4\beta^2\epsilon(1-\epsilon)(\tilde y_i^n\tilde y_j^n+\tilde p_i^n\tilde p_j^n)\right]d\Sigma\\
&\quad+\frac{1}{\alpha k}\int_{\Gamma_{ij}}\left[((1-\epsilon)^2+\epsilon^2)\left(\left|a_i\frac{\partial\tilde p_i^n(T)}{\partial\nu_i}\right|^2+\left|a_j\frac{\partial\tilde p_j^n(T)}{\partial\nu_j}\right|^2\right.\right.\\
&\quad\left.+\alpha^2(|\tilde p_i^n(T)|^2+|\tilde p_j^n(T)|^2)\right)\\
&\quad\left.-4\epsilon(1-\epsilon)a_i\frac{\partial\tilde p_i^n(T)}{\partial\nu_i}a_j\frac{\partial\tilde p_j^n(T)}{\partial\nu_j}+4\alpha^2\epsilon(1-\epsilon)\tilde p_i^n(T)\tilde p_j^n(T)\right]d\Gamma\Bigg\}\\
&\le[(1-\epsilon)^2+\epsilon^2+2\epsilon(1-\epsilon)]E^n=E^n.
\end{aligned}$$

Substitution of (3.14) into (3.13) yields

$$\begin{aligned}
E^{n+1}\le E^n-\frac{2}{k}\sum_{i=1}^{m}[\mathcal{E}_i(\tilde p_i^{n+1}(T))+(1-2\epsilon)\mathcal{E}_i(\tilde p_i^n(T))]\\
-2\int_\Sigma(|\tilde p_m^{n+1}|^2+(1-2\epsilon)|\tilde p_m^n|^2)\,d\Sigma.
\end{aligned}$$

By iteration we obtain

$$E^{n+1}\le E^1-2\sum_{\ell=1}^{n+1}\left[\frac{1}{k}\sum_{i=1}^{m}c_\ell(\epsilon)\mathcal{E}_i(\tilde p_i^\ell(T))-\int_\Sigma c_\ell(\epsilon)|\tilde p_m^\ell|^2d\Sigma\right],\tag{3.15}$$

where

$$c_1(\epsilon)=1-2\epsilon,\quad c_{n+1}(\epsilon)=1,\quad c_\ell(\epsilon)=2(1-\epsilon),\ \ell=2,\dots,n.$$

It follows from (3.15) that for $0\le\epsilon<1$,

$$\sum_{\ell=1}^{\infty}\sum_{i=1}^{m}\mathcal{E}_i(\tilde p_i^\ell(T))<\infty,\qquad\sum_{\ell=1}^{\infty}\int_\Sigma|\tilde p_m^\ell|^2d\Sigma<\infty$$

so that

$$\tilde{p}_m^n|_\Sigma \to 0 \quad \text{strongly in } L^2(\Sigma), \;\; \mathcal{E}_i(\tilde{p}_i^n(T)) \to 0, \quad i = 1, \dots, m,$$

from the second of which follows that

$$\begin{aligned} \tilde{p}_i^n(T) &\to 0 \quad \text{in } V_i, \\ \tilde{p}_{i,t}^n(T) &\to 0 \quad \text{in } L^2(\Omega_i), \quad i = 1, \dots, m. \end{aligned} \tag{3.16}$$

The boundedness of $\{E^n\}_{n=1}^\infty$, together with (3.16) and the regularity results of Lasiecka–Triggiani [20, Theorems 2.0, 2.1] mentioned above, allow us to conclude that

$$\begin{aligned} &\{\tilde{y}_i^n\}_{n=1}^\infty, \quad \{\tilde{p}_i^n\}_{n=1}^\infty \quad \text{are bounded in } C([0,T]; H^{3/5-\varepsilon}(\Omega_i)), \\ &\{\tilde{y}_{i,t}^n\}_{n=1}^\infty, \quad \{\tilde{p}_{i,t}^n\}_{n=1}^\infty \quad \text{are bounded in } C([0,T]; (H^{2/5+\varepsilon}(\Omega_i))'), \\ &\{\tilde{y}_{i,tt}^n\}_{n=1}^\infty, \quad \{\tilde{p}_{i,tt}^n\}_{n=1}^\infty \quad \text{are bounded in } L^2(0,T; (H^{7/5+\varepsilon}(\Omega_i))'). \end{aligned} \tag{3.17}$$

In particular, $\tilde{y}_i^n|_{S_i}$, $\tilde{p}_i^n|_{S_i}$ are bounded in $L^\infty(0,T; H^{1/10-\varepsilon}(\gamma_i))$. Since they converge weakly to zero in $L^2(S_i)$ when $0 < \epsilon < 1$, a compactness result of Simon [32, Corollary 5] shows that the convergence is *strong* in that space (in fact, it is strong in $L^\infty(0,T; L^2(\gamma_i))$). The same result also implies that on a subsequence we have

$$\begin{aligned} \tilde{y}_i^n \to \tilde{y}_i, \quad \tilde{p}_i^n \to \tilde{p}_i \quad &\text{in } C([0,T]; L^2(\Omega_i)), \\ \tilde{y}_{i,t}^n \to \tilde{y}_{i,t}, \quad \tilde{p}_{i,t}^n \to \tilde{p}_{i,t} \quad &\text{in } C([0,T]; (H^1(\Omega_i))'), \end{aligned}$$

where $\tilde{y}_i$, $\tilde{p}_i$ is the solution of

$$\begin{aligned} \tilde{y}_{i,tt} - a_i \Delta \tilde{y}_i = 0, \quad \tilde{p}_{i,tt} - a_i \Delta \tilde{p}_i = 0 \quad &\text{in } Q_i, \\ a_i \frac{\partial \tilde{y}_i}{\partial \nu_i} = 0, \quad a_i \frac{\partial \tilde{p}_i}{\partial \nu_i} = 0 \quad &\text{on } S_i, \\ a_i \frac{\partial \tilde{y}_i}{\partial \nu_i} = 0, \quad a_i \frac{\partial \tilde{p}_i}{\partial \nu_i} = 0 \quad &\text{on } \Sigma_i, \\ \tilde{y}_i(0) = \tilde{y}_{i,t}(0) = \tilde{p}_i(T) = \tilde{p}_{i,t}(T) = 0. & \end{aligned}$$

It follows that $\tilde{y}_i = \tilde{p}_i = 0$ in Q_i, $i = 1, \dots, m$. □

4. The limit of the global optimality system. In this section we study the limiting behavior as $k \to \infty$ of the solution of the global optimality system (1.1), (1.5)–(1.7) under the assumption that the global problem (1.1) is exactly controllable to $V \times H$ for T sufficiently large. As is to be expected, the limit of the global optimality system is the optimality system for the state constrained optimal control problem

$$J(f) = \frac{1}{2} \int_\Sigma |f|^2 d\Sigma \to \inf \tag{4.1}$$

subject to (1.1) and

$$\mathbf{Y}(T) = \mathbf{Y}_T, \quad \mathbf{Y}_{,t}(T) = \dot{\mathbf{Y}}_T. \tag{4.2}$$

We denote by $J_k(f)$ the cost functional in (1.4) and by $\mathbf{Y}(\cdot\,; k)$, $\mathbf{P}(\cdot\,; k)$ the solution of the optimality system (1.1), (1.5)–(1.7). Let Φ be the solution of (1.3), where $(\Phi^0, \Phi^1) \in V \times H$. The assumption that $V \times H$ lies in the range of the control-to-state

mapping $f \mapsto (\mathbf{Y}(T), \mathbf{Y}_{,t}(T)) : L^2(\Sigma) \mapsto H \times V'$ for T sufficiently large is equivalent to the assumption that (1.3) is *continuously observable* from Σ for T sufficiently large in the following sense: there exists $T_0 > 0$ such that

$$\|\Phi^0\|_H^2 + \|\Phi^1\|_{V'}^2 \le C_T \int_\Sigma |\phi_m|^2 d\Sigma, \quad T > T_0, \tag{4.3}$$

for some constant C_T independent of (Φ^0, Φ^1).

We shall prove the following result.

THEOREM 4.1. *Suppose that* (4.3) *holds,* $T > T_0$, *and let* $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T) \in V \times H$. *Then as* $k \to \infty$ *the solution of the optimality system* (1.1), (1.5)–(1.7) *satisfies*

$$\begin{gathered}
\mathbf{Y}(\cdot\,; k) \to \mathbf{Y}(\cdot), \quad \mathbf{P}(\cdot\,; k) \to \mathbf{P}(\cdot) \quad \text{strongly in } C([0,T]; H), \\
\mathbf{Y}_{,t}(\cdot\,; k) \to \mathbf{Y}_{,t}(\cdot), \quad \mathbf{P}_{,t}(\cdot\,; k) \to \mathbf{P}_{,t}(\cdot) \quad \text{strongly in } C([0,T]; V'), \\
p_m(\cdot\,; k)|_\Sigma \to p_m(\cdot)|_\Sigma \quad \text{strongly in } L^2(\Sigma),
\end{gathered}$$

where $\mathbf{Y} = (y_1, \dots, y_m)$, $\mathbf{P} = (p_1, \dots, p_m)$ *satisfy*

$$\begin{gathered}
y_{i,tt} - a_i \Delta y_i = 0, \quad p_{i,tt} - a_i \Delta p_i = 0 \quad \text{in } Q_i, \\
y_i = y_j, \quad a_i \frac{\partial y_i}{\partial \nu_i} + a_j \frac{\partial y_j}{\partial \nu_j} = 0 \quad \text{on } \Sigma_{ij}, \\
p_i = p_j, \quad a_i \frac{\partial p_i}{\partial \nu_i} + a_j \frac{\partial p_j}{\partial \nu_j} = 0 \quad \text{on } \Sigma_{ij}, \\
a_m \frac{\partial y_m}{\partial \nu_m} = -p_m, \quad a_m \frac{\partial p_m}{\partial \nu_m} = 0 \quad \text{on } \Sigma, \\
\mathbf{Y}(0) = \mathbf{Y}_{,t}(0) = 0, \quad \mathbf{P}(T) = \mathbf{P}_T, \quad \mathbf{P}_{,t}(T) = \dot{\mathbf{P}}_T, \\
\mathbf{Y}(T) = \mathbf{Y}_T, \quad \mathbf{Y}_{,t}(T) = \dot{\mathbf{Y}}_T,
\end{gathered} \tag{4.4}$$

and where $(\mathbf{P}_T, \dot{\mathbf{P}}_T) \in H \times V'$ *is the unique solution of*

$$((\mathbf{P}_T, \dot{\mathbf{P}}_T), (-\dot{\mathbf{Y}}_T, \mathbf{Y}_T))_{H \times V'} = \int_\Sigma |p_m|^2 d\Sigma. \tag{4.5}$$

The system (4.4) *is the optimality system for the problem* (4.1) *subject to* (1.1) *and* (4.2).

Proof. Let $T > T_0$ and $f_k(\cdot) = -p_m(\cdot\,; k)|_\Sigma$ be the optimal control for the optimal control problem (1.1), (1.4). Let f_0 be any $L^2(\Sigma)$ control such that the solution of (1.1) satisfies (4.2). Then

$$J_k(f_k) \le J_k(f_0) = \frac{1}{2} \|f_0\|_{L^2(\Sigma)}; \tag{4.6}$$

hence

$$\begin{gathered}
\{f_k\} \quad \text{is bounded in } L^2(\Sigma), \\
\sqrt{k}(\mathbf{Y}(T; k) - \mathbf{Y}_T) \quad \text{is bounded in } H, \\
\sqrt{k}(\mathbf{Y}_{,t}(T; k) - \dot{\mathbf{Y}}_T) \quad \text{is bounded in } V'.
\end{gathered}$$

Therefore

$$\begin{aligned}
&\lim_{k \to \infty} \mathbf{Y}(T; k) = \mathbf{Y}_T \quad \text{strongly in } H, \\
&\lim_{k \to \infty} \mathbf{Y}_{,t}(T; k) = \dot{\mathbf{Y}}_T \quad \text{strongly in } V',
\end{aligned} \tag{4.7}$$

and, as $k \to \infty$ through an appropriate subnet of $k > 0$,

$$f_k \to f_\infty \quad \text{weakly in } L^2(\Sigma)$$

for some $f_\infty \in L^2(\Sigma)$ that satisfies

$$\|f_\infty\|_{L^2(\Sigma)} \le \liminf \|f_k\|_{L^2(\Sigma)}. \tag{4.8}$$

The solution $\mathbf{Y}(\cdot\,;k)$ satisfies

$$\|(\mathbf{Y}(\cdot,;k), \mathbf{Y}_{,t}(\cdot\,;k))\|_{C([0,T];H\times V')} \le C\|f_k\|_{L^2(\Sigma)}, \tag{4.9}$$

where C is independent of k, and therefore we may extract a subnet of $k > 0$ on which as $k \to \infty$,

$$\begin{aligned} \mathbf{Y}(\cdot\,;k) &\to \mathbf{Y}(\cdot) \quad \text{weakly}^* \text{ in } L^\infty(0,T;H), \\ \mathbf{Y}_{,t}(\cdot\,;k) &\to \mathbf{Y}_{,t}(\cdot) \quad \text{weakly}^* \text{ in } L^\infty(0,T;V') \end{aligned}$$

for some $\mathbf{Y} \in C([0,T];H) \cap C^1([0,T];V')$. It follows from (1.2) and (4.7) that $\mathbf{Y}$ satisfies

$$\begin{aligned} (\mathbf{Y}_{,t}(t), \Phi(t))_{V'} - (\mathbf{Y}(t), \Phi_{,t}(t)) &= \int_0^t \int_\Gamma f_\infty \phi_m \, d\Gamma dt, \\ (\mathbf{Y}_{,t}(T) - \dot{\mathbf{Y}}_T, \Phi(T))_{V'} - (\mathbf{Y}(T) - \mathbf{Y}_T, \Phi_{,t}(T)) &= 0 \quad \forall (\Phi^0, \Phi^1) \in V \times H, \end{aligned}$$

where Φ is the solution of (1.3). Therefore $\mathbf{Y}$ is the solution of (1.1) corresponding to $f = f_\infty$ and $\mathbf{Y}$ satisfies (4.2). Set

$$\mathcal{U}_{\text{ad}} = \{f \in L^2(\Sigma) : \mathbf{Y} \text{ satisfies (1.1) and (4.2)}\}.$$

We have

$$J_k(f_k) \le \inf_{f\in\mathcal{U}_{\text{ad}}} J_k(f) = \frac{1}{2} \inf_{f\in\mathcal{U}_{\text{ad}}} \|f\|^2_{L^2(\Sigma)}. \tag{4.10}$$

It follows from (4.8) that f_∞ is the control of minimum $L^2(\Sigma)$ norm in $\mathcal{U}_{\text{ad}}$. Because this control is unique (since $\mathcal{U}_{\text{ad}}$ is closed and convex and the mapping $f \mapsto J(f)$ is continuous on $L^2(\Sigma)$), it follows from (4.8) and (4.10) that

$$f_k \to f_\infty \quad \text{strongly in } L^2(\Sigma) \text{ as } k \to \infty \tag{4.11}$$

and that

$$\|f_\infty\|_{L^2(\Sigma)} = \inf_{f\in\mathcal{U}_{\text{ad}}} \|f\|_{L^2(\Sigma)}.$$

From (4.9) we then obtain

$$(\mathbf{Y}(\cdot\,;k), \mathbf{Y}_{,t}(\cdot\,;k)) \to (\mathbf{Y}(\cdot), \mathbf{Y}_{,t}(\cdot)) \quad \text{in } C([0,T];H\times V').$$

As $f_k = -p_m(\cdot\,;k)|_\Sigma$, assumption (4.3) together with (4.11) shows that

$$(\mathbf{P}(T;k), \mathbf{P}_{,t}(T;k)) \to (\mathbf{P}_T, \dot{\mathbf{P}}_T) \quad \text{strongly in } H\times V'$$

for some $(\mathbf{P}_T, \dot{\mathbf{P}}_T)$. Since the linear map $(\mathbf{P}(T;k), \mathbf{P}_{,t}(T;k)) \mapsto (\mathbf{P}(\cdot\,;k), \mathbf{P}_{,t}(\cdot\,;k)) : H \times V' \mapsto C([0,T];H \times V')$ is continuous we have

$$\begin{aligned} \mathbf{P}(\cdot\,;k) &\to \mathbf{P}(\cdot) \quad \text{in } C([0,T];H), \\ \mathbf{P}_{,t}(\cdot\,;k) &\to \mathbf{P}_{,t}(\cdot) \quad \text{in } C([0,T];V'), \end{aligned}$$

where $\mathbf{P} = (p_1, \dots, p_m)$ is the unique solution in $C([0,T];H) \cap C^1([0,T];V')$ of

$$\begin{gathered} p_{i,tt} - a_i \Delta p_i = 0 \quad \text{in } Q_i, \\ p_i = p_j, \quad a_i \frac{\partial p_i}{\partial \nu_i} + a_j \frac{\partial p_j}{\partial \nu_j} = 0 \quad \text{on } \Sigma_{ij}, \\ a_m \frac{\partial p_m}{\partial \nu_m} = 0 \quad \text{on } \Sigma, \\ \mathbf{P}(T) = \mathbf{P}_T, \quad \mathbf{P}_{,t}(T) = \dot{\mathbf{P}}_T. \end{gathered} \tag{4.12}$$

Since $\mathbf{P}(\cdot\,;k) \to \mathbf{P}(\cdot)$ strongly in $C([0,T];H)$ and $p_m(\cdot\,;k)|_\Sigma \to -f_\infty$ strongly in $L^2(\Sigma)$, by definition

$$p_m|_\Sigma = -f_\infty.$$

For $i = 1, 2, \dots$, we may choose that $\hat{f}_i \in L^2(\Sigma)$ be such that $\hat{f}_i \to f_\infty$ strongly in $L^2(\Sigma)$ and the corresponding solution $\hat{\mathbf{Y}}_i$ of (1.1) satisfies $(\hat{\mathbf{Y}}_i, \hat{\mathbf{Y}}_{i,t}) \in C([0,T]; V \times H)$. One then has

$$(\hat{\mathbf{Y}}_i, \hat{\mathbf{Y}}_{i,t}) \to (\mathbf{Y}, \mathbf{Y}_{,t}) \quad \text{in } C([0,T]; H \times V').$$

An integration by parts gives

$$0 = (\mathbf{P}_{,t}(T;k), \hat{\mathbf{Y}}_i(T)) - (\mathbf{P}(T;k), \hat{\mathbf{Y}}_{i,t}(T)) + \int_\Sigma p_m(\cdot\,;k) \hat{f}_i \, d\Sigma.$$

Upon passing to the limit first in i and then in k we obtain

$$(\dot{\mathbf{P}}_T, \mathbf{Y}_T)_{V'} - (\mathbf{P}_T, \dot{\mathbf{Y}}_T) = \int_\Sigma |p_m|^2 d\Sigma,$$

that is, $(\mathbf{P}_T, \dot{\mathbf{P}}_T)$ is the unique solution of the equation

$$((\mathbf{P}_T, \dot{\mathbf{P}}_T), (-\dot{\mathbf{Y}}_T, \mathbf{Y}_T))_{H \times V'} = \int_\Sigma |p_m|^2 d\Sigma. \tag{4.13}$$

□

Remark 4.2. Of course, the solution $(\mathbf{P}_T, \dot{\mathbf{P}}_T)$ of (4.13) is exactly the one obtained from the Hilbert uniqueness method. Suppose that $(\mathbf{P}_T, \dot{\mathbf{P}}_T) \in V \times H$, and let $\mathbf{Y}$, $\mathbf{P}$ be the solution of the global problem (4.4), omitting the condition on $(\mathbf{Y}(T), \mathbf{Y}_{,t}(T))$. By Holmgren's theorem, for $T > T_0$ one may define a norm $\|(\mathbf{P}_T, \dot{\mathbf{P}}_T)\|_F$ by setting

$$\|(\mathbf{P}_T, \dot{\mathbf{P}}_T)\|_F^2 = \int_\Sigma |p_m|^2 d\Sigma,$$

and a corresponding Hilbert space

$$F = \text{ completion of } V \times H \text{ in } \| \cdot \|_F.$$

By (4.3) we have $F \subset H \times V'$, so $H \times V \subset F'$. Then (4.13) is the same as

$$(\mathbf{P}_T, \dot{\mathbf{P}}_T) = \Lambda^{-1}(-\dot{\mathbf{Y}}_T, \mathbf{Y}_T),$$

where Λ is the canonical isomorphism $F \mapsto F'$.

5. The limit of the local optimality system. In this section we wish to study the limiting behavior as $k \to \infty$ of the solution $y_i^{n+1}(\cdot\,;k)$, $p_i^{n+1}(\cdot\,;k)$ of the local problem (3.1)–(3.5). To this end we first consider the limiting behavior as $k \to \infty$ of the solution $z_i(\cdot\,;k)$, $q_i(\cdot\,;k)$ of the system

$$\begin{aligned} z_{i,tt} - a_i \Delta z_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= f_1^k + \lambda_i(\cdot\,;k) \quad \text{on } S_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= f_2^k \quad \text{on } \Sigma_i, \\ z_i(0;k) = z_{i,t}(0;k) &= 0, \end{aligned} \tag{5.1}$$

$$\begin{aligned} q_{i,tt} - a_i \Delta q_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= \beta z_i + \mu_i(\cdot\,;k) \quad \text{on } S_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= 0 \quad \text{on } \Sigma_i, \\ q_i(T;k) &= k\mathcal{A}_i^{-1}(z_{i,t}(T;k) - \dot{y}_{iT} + k^{-1}\sigma_i(k)), \\ q_{i,t}(T;k) &= -k(z_i(T;k) - y_{iT}), \end{aligned} \tag{5.2}$$

$$f_1^k = -\beta q_i(\cdot\,;k)|_{S_i}, \quad f_2^k = -q_i(\cdot\,;k)|_{\Sigma_i}, \tag{5.3}$$

where $\lambda_i(\cdot\,;k)$, $\mu_i(\cdot\,;k) \in L^2(S_i)$, $\tau_i(\cdot\,;k) \in L^2(\gamma_i)$ and $\sigma_i(k) \in V_i'$ is defined by

$$(\sigma_i(k), \phi)_{V_i'} = \int_{\gamma_i} \tau_i(\cdot\,;k)\phi(\cdot)\, d\Gamma \quad \forall \phi \in V_i.$$

The system (5.1)–(5.3) is the optimality system for the problem

$$\begin{aligned} J_i^k(f_1, f_2) = \frac{1}{2}\int_{\Sigma_i} |f_2|^2 d\Sigma + \frac{1}{2\beta}\int_{S_i} (|f_1|^2 + |\beta z_i(\cdot\,;k) + \mu_i(\cdot\,;k)|^2) d\Sigma \\ + \frac{k}{2}(\|z_i(T;k) - y_{iT}\|_{H_i}^2 + \|z_{i,t}(T;k) - \dot{y}_{iT} + k^{-1}\sigma_i(k)\|_{V_i'}^2) \to \inf \end{aligned}$$

subject to

$$\begin{aligned} z_{i,tt} - a_i \Delta z_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= f_1 + \lambda_i(\cdot\,;k) \quad \text{on } S_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= f_2 \quad \text{on } \Sigma_i, \\ z_i(0) = z_{i,t}(0) &= 0 \quad \text{in } \Omega_i, \end{aligned} \tag{5.4}$$

where the infimum is taken over $f_1 \in L^2(S_i)$ and $f_2 \in L^2(\Sigma_i)$.

Let ϕ_i be the solution of

$$\begin{aligned} \phi_{i,tt} - a_i \Delta \phi_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial \phi_i}{\partial \nu_i} &= 0 \quad \text{on } S_i \cup \Sigma_i, \\ \phi_i(0) = \phi_i^0, &\quad \phi_{i,t}(0) = \phi_i^1. \end{aligned} \tag{5.5}$$

It is assumed that (5.5) is continuously observable for $T > T_0$ for some $T_0 > 0$:

(5.6)
$$\|\phi_i^0\|_{H_i}^2 + \|\phi_i^1\|_{V_i'}^2 \le C_T \left(\int_{S_i} |\phi_i|^2 d\Sigma + \int_{\Sigma_i} |\phi_i|^2 d\Sigma \right) \quad \forall (\phi_i^0, \phi_i^1) \in V_i \times H_i,$$

for some constant C_T. It is known that under mild conditions on Γ and γ_i (for example, if they are sufficiently smooth), (5.6) holds for $T > (2/\sqrt{a_i})\mathrm{diam}(\Omega_i)$. It follows from (5.6) that if $(y_{iT}, \dot{y}_{iT}) \in V_i \times H_i$ there are controls $f_1 \in L^2(S_i)$, $f_2 \in L^2(\Sigma_i)$ such that the solution of (5.4) satisfies

$$z_i(T;k) = y_{iT}, \quad z_{i,t}(T;k) = \dot{y}_{iT}. \tag{5.7}$$

THEOREM 5.1. *Suppose that* (5.6) *holds,* $T > T_0$, *and let* $(y_{iT}, \dot{y}_{iT}) \in V_i \times H_i$. *Suppose further that as* $k \to \infty$

$$\begin{gathered} \lambda_i(\cdot\,;k) \to \lambda_i^\infty(\cdot), \quad \mu_i(\cdot\,;k) \to \mu_i^\infty(\cdot) \quad \textit{strongly in } L^2(S_i), \\ \left\{ \frac{1}{\sqrt{k}} \tau_i(\cdot\,;k) \right\} \quad \textit{is bounded in } L^2(\gamma_i). \end{gathered} \tag{5.8}$$

Then the solution of (5.1)–(5.3) *satisfies*

$$\begin{gathered} z_i(\cdot\,;k) \to z_i(\cdot), \quad q_i(\cdot\,;k) \to q_i(\cdot) \quad \textit{in } C([0,T];H_i), \\ z_{i,t}(\cdot\,;k) \to z_{i,t}(\cdot), \quad q_{i,t}(\cdot\,;k) \to q_{i,t}(\cdot) \quad \textit{in } C([0,T];V_i'), \\ z_i(\cdot\,;k)|_{S_i} \to z_i(\cdot)|_{S_i}, \quad q_i(\cdot\,;k)|_{S_i} \to q_i(\cdot)|_{S_i} \quad \textit{strongly in } L^2(S_i), \\ q_i(\cdot\,;k)|_{\Sigma_i} \to q_i(\cdot)|_{\Sigma_i} \quad \textit{strongly in } L^2(\Sigma_i), \end{gathered}$$

where z_i, q_i *are the solution of*

$$\begin{gathered} z_{i,tt} - a_i \Delta z_i = 0 \quad \textit{in } Q_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} = -\beta q_i + \lambda_i^\infty \quad \textit{on } S_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} = -q_i \quad \textit{on } \Sigma_i, \\ z_i(0) = z_{i,t}(0) = 0, \qquad z_i(T) = y_{iT}, \;\; z_{i,t}(T) = \dot{y}_{iT}, \end{gathered} \tag{5.9}$$

$$\begin{gathered} q_{i,tt} - a_i \Delta q_i = 0 \quad \textit{in } Q_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} = \beta z_i + \mu_i^\infty \quad \textit{on } S_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} = 0 \quad \textit{on } \Sigma_i, \\ q_i(T) = q_{iT}, \quad q_{i,t}(T) = \dot{q}_{iT}, \end{gathered} \tag{5.10}$$

and where $(q_{iT}, \dot{q}_{iT}) \in H_i \times V_i'$ *is the unique solution of*

$$\begin{aligned} &((q_{iT}, \dot{q}_{iT}), (-\dot{y}_{iT}, y_{iT}))_{H_i \times V_i'} \\ &\quad = \int_{S_i} [\beta(|q_i|^2 + |z_i|^2) - \lambda_i^\infty q_i + \mu_i^\infty z_i] \, d\Sigma + \int_{\Sigma_i} |q_i|^2 d\Sigma. \end{aligned} \tag{5.11}$$

Proof. Let $T > T_0$ and $f_1^0 \in L^2(S_i)$, $f_2^0 \in L^2(\Sigma_i)$ be such that the solution $\hat{z}_i$ of

$$\begin{aligned} \hat{z}_{i,tt} - a_i \Delta \hat{z}_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial \hat{z}_i}{\partial \nu_i} &= f_1^0 \quad \text{on } S_i, \\ a_i \frac{\partial \hat{z}_i}{\partial \nu_i} &= f_2^0 \quad \text{on } \Sigma_i, \\ \hat{z}_i(0) = \hat{z}_{i,t}(0) &= 0 \quad \text{in } \Omega_i \end{aligned}$$

satisfies (5.7), and set $\hat{f}_1^k(\cdot\,;k) = f_1^0(\cdot) - \lambda(\cdot\,;k)$. Then

$$\begin{aligned} J_i^k(f_1^k, f_2^k) \le J_i^k(\hat{f}_1^k, f_2^0) = \frac{1}{2}\|f_2^0\|^2_{L^2(\Sigma_i)} + \frac{1}{2\beta}\|\hat{f}_1^k\|_{L^2(S_i)} \\ + \frac{1}{2\beta}\int_{S_i} |\beta \hat{z}_i(\cdot) + \mu_i(\cdot\,;k)|^2 d\Sigma + \frac{1}{2k}\|\sigma_i(k)\|^2_{V_i'}. \end{aligned}$$

It follows that

$$\begin{aligned} \{f_1^k\}, \quad \{z_i(\cdot\,;k)|_{S_i}\} \quad &\text{are bounded in } L^2(S_i), \\ \{f_2^k\} \quad &\text{is bounded in } L^2(\Sigma_i), \\ \sqrt{k}(z_i(T;k) - y_{iT}) \quad &\text{is bounded in } H_i, \\ \sqrt{k}(z_{i,t}(T;k) - \dot{y}_{iT} + k^{-1}\sigma_i(k)) \quad &\text{is bounded in } V_i'. \end{aligned}$$

Therefore

$$\begin{aligned} z_i(T;k) &\to y_{iT} \quad \text{strongly in } H_i, \\ z_{i,t}(T;k) &\to \dot{y}_{iT} \quad \text{strongly in } V_i', \end{aligned} \tag{5.12}$$

and on a certain subsequence

$$\begin{aligned} f_1^k &\to f_1^\infty \quad \text{weakly in } L^2(S_i), \\ f_2^k &\to f_2^\infty \quad \text{weakly in } L^2(\Sigma_i), \\ z_i(\cdot\,;k)|_{S_i} &\to z_i^\infty(\cdot) \quad \text{weakly in } L^2(S_i). \end{aligned} \tag{5.13}$$

It follows from (5.8), (5.13), the regularity results of [20], and the compactness result [32] utilized above that

$$\begin{aligned} z_i(\cdot\,;k) &\to z_i(\cdot) \quad \text{in } C([0,T]; L^2(\Omega_i)), \\ z_{i,t}(\cdot\,;k) &\to z_{i,t}(\cdot) \quad \text{in } C([0,T]; (H^1(\Omega_i))'), \end{aligned} \tag{5.14}$$

where z_i satisfies

$$\begin{aligned} z_{i,tt} - a_i \Delta z_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= f_1^\infty + \lambda_i^\infty \quad \text{on } S_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= f_2^\infty \quad \text{on } \Sigma_i, \\ z_i(0) = z_{i,t}(0) = 0, \qquad z_i(T) &= y_{iT}, \;\; z_{i,t}(T) = \dot{y}_{iT}. \end{aligned} \tag{5.15}$$

We have

$$\begin{aligned}(5.16)\quad &\frac{1}{\beta}\|f_1^\infty\|^2_{L^2(S_i)} + \|f_2^\infty\|^2_{L^2(\Sigma_i)} + \frac{1}{\beta}\|\beta z_i^\infty + \mu_i^\infty\|^2_{L^2(S_i)} \\ &\quad \le \liminf\Big(\frac{1}{\beta}\|f_1^k\|^2_{L^2(S_i)} + \|f_2^k\|^2_{L^2(\Sigma_i)} + \frac{1}{\beta}\|\beta z_i(\cdot\,;k) + \mu_i^k(\cdot)\|^2_{L^2(S_i)}\Big) \\ &\quad \le 2\liminf J_i^k(f_1^k, f_2^k).\end{aligned}$$

Set

$$\begin{aligned}\mathcal{U}_{\rm ad} = \{&f_1 \in L^2(S_i),\ f_2 \in L^2(\Sigma_i) : \\ &\text{the solution of (2.1) with } \lambda_i = \lambda_i^\infty \text{ satisfies (5.7)}\}.\end{aligned}$$

For all $f_1, f_2 \in \mathcal{U}_{\rm ad}$ we have

$$\begin{aligned}J_i^k(f_1^k, f_2^k) \le J_i^k(f_1, f_2) &= \frac{1}{2}\|f_2\|^2_{L^2(\Sigma_i)} + \frac{1}{2\beta}\|f_1\|^2_{L^2(S_i)} \\ &\quad + \frac{1}{2\beta}\int_{S_i} |\beta z_i(\cdot\,;k) + \mu_i^k(\cdot)|^2 d\Sigma + \frac{1}{2k}\|\sigma_i(k)\|^2_{V_i'},\end{aligned}$$

where $z_i(\cdot\,;k)$ is the solution of (5.4). Since $\lambda_i(\cdot\,;k) \to \lambda_i^\infty(\cdot)$ strongly in $L^2(S_i)$,

$$z_i(\cdot\,;k)|_{S_i} \to z_i(\cdot)|_{S_i} \quad \text{strongly in } L^2(S_i),$$

where $z_i(\cdot)$ is the solution of (2.1) with $\lambda_i = \lambda_i^\infty$. Therefore

$$\begin{aligned}(5.17)\qquad \limsup J_i^k(f_1^k, f_2^k) &\le \frac{1}{2}\|f_2\|^2_{L^2(\Sigma_i)} + \frac{1}{2\beta}\|f_1\|^2_{L^2(S_i)} \\ &\quad + \frac{1}{2\beta}\int_{S_i} |\beta z_i + \mu_i^\infty|^2 d\Sigma \quad \forall (f_1, f_2) \in \mathcal{U}_{\rm ad}.\end{aligned}$$

It follows from (5.13), (5.16), and (5.17) that as $k \to \infty$,

$$\begin{aligned}(5.18)\qquad f_1^k &\to f_1^\infty \quad \text{strongly in } L^2(S_i), \\ f_2^k &\to f_2^\infty \quad \text{strongly in } L^2(\Sigma_i), \\ z_i(\cdot\,;k)|_{S_i} &\to z_i^\infty \quad \text{strongly in } L^2(S_i)\end{aligned}$$

and that

$$J_i(f_1^\infty, f_2^\infty) \le J_i(f_1, f_2) \quad \forall (f_1, f_2) \in \mathcal{U}_{\rm ad},$$

where

$$J_i(f_1, f_2) = \frac{1}{2}\|f_2\|^2_{L^2(\Sigma_i)} + \frac{1}{2\beta}\|f_1\|^2_{L^2(S_i)} + \frac{1}{2\beta}\int_{S_i} |\beta z_i + \mu_i^\infty|^2 d\Sigma$$

and where z_i satisfies

$$\begin{aligned}z_{i,tt} - a_i \Delta z_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= f_1 + \lambda_i^\infty \quad \text{on } S_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= f_2 \quad \text{on } \Sigma_i, \\ z_i(0) = z_{i,t}(0) = 0 \quad z_i(T) &= y_{iT}, \quad z_{i,t}(T) = \dot{y}_{iT}.\end{aligned}$$

The solution $q_i(\cdot\,;k)$ of (5.2) may be expressed as $q_i = r_i + s_i$, where r_i satisfies (5.2) except that

$$r_i(T;k) = r_{i,t}(T;k) = 0,$$

and s_i satisfies (5.2) except that

$$a_i \frac{\partial s_i}{\partial \nu_i} = 0 \quad \text{on } S_i.$$

By virtue of the regularity results in [20] we have

$$\|r_i(\cdot\,;k)\|^2_{L^2(\Sigma_i)} + \|r_i(\cdot\,;k)\|^2_{L^2(S_i)} \le C_T \int_{S_i} |\beta z_i(\cdot\,;k) + \mu_i(\cdot\,;k)|^2 d\Sigma, \tag{5.19}$$

and by virtue of the observability assumption (5.6) we have, for $T > T_0$,

$$\|q_i(T;k)\|^2_{H_i} + \|q_{i,t}(T;k)\|^2_{V_i'} \le C_T \left(\int_{S_i} |s_i|^2 d\Sigma + \int_{\Sigma_i} |s_i|^2 d\Sigma \right). \tag{5.20}$$

It follows from (5.19), (5.20) that

$$\begin{aligned} &\|q_i(T;k)\|^2_{H_i} + \|q_{i,t}(T;k)\|^2_{V_i'} \\ &\quad \le C_T \left(\int_{S_i} (|q_i(\cdot\,;k)|^2 + |\beta z_i(\cdot\,;k) + \mu_i(\cdot\,;k)|^2) d\Sigma + \int_{\Sigma_i} |q_i(\cdot\,;k)|^2 d\Sigma \right) \\ &\quad = C_T \left(\int_{S_i} (|f_1^k|^2 + |\beta z_i(\cdot\,;k) + \mu_i(\cdot\,;k)|^2) d\Sigma + \int_{\Sigma_i} |f_2^k|^2 d\Sigma \right). \end{aligned} \tag{5.21}$$

From (5.8), (5.18), and (5.21) we may conclude that

$$\begin{aligned} q_i(T;k) &\to q_{iT} \quad \text{strongly in } H_i, \\ q_{i,t}(T;k) &\to \dot{q}_{iT} \quad \text{strongly in } V_i' \end{aligned}$$

for some $(q_{iT}, \dot{q}_{iT}) \in H_i \times V_i'$ and then that

$$\begin{aligned} q_i(\cdot\,;k) &\to q_i(\cdot) \quad \text{in } C([0,T];H_i), \\ q_{i,t}(\cdot\,;k) &\to q_{i,t}(\cdot) \quad \text{in } C([0,T];V_i'), \end{aligned}$$

where q_i is the solution of

$$\begin{aligned} q_{i,tt} - a_i \Delta q_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= \beta z_i + \mu_i^\infty \quad \text{on } S_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= 0 \quad \text{on } \Sigma_i, \\ q_i(T) = q_{iT}, &\quad q_{i,t}(T) = \dot{q}_{iT}. \end{aligned}$$

Further,

$$\begin{aligned} \beta q_i(\cdot\,;k)|_{S_i} = -f_1^k &\to -f_1^\infty \quad \text{strongly in } L^2(S_i), \\ q_i(\cdot\,;k)|_{\Sigma_i} = -f_2^k &\to -f_2^\infty \quad \text{strongly in } L^2(\Sigma_i), \end{aligned}$$

so, by definition,

$$\beta q_i|_{S_i} = -f_1^\infty, \quad q_i|_{\Sigma_i} = -f_2^\infty.$$

A formal integration by parts (which may be justified by approximating f_1^∞, f_2^∞, μ_i^∞, λ_i^∞ by smoother data) gives

$$0 = (\dot{y}_{iT}, q_{iT})_{H_i} - (\dot{q}_{iT}, y_{iT})_{V_i'} - \int_{S_i} \left(q_i a_i \frac{\partial z_i}{\partial \nu_i} - z_i a_i \frac{\partial q_i}{\partial \nu_i} \right) d\Sigma - \int_{\Sigma_i} q_i a_i \frac{\partial z_i}{\partial \nu_i}\, d\Sigma,$$

that is,

$$\begin{aligned} (5.22) \qquad & ((q_{iT}, \dot{q}_{iT}), (-\dot{y}_{iT}, y_{iT}))_{H_i \times V_i'} \\ & = \int_{S_i} [\beta(|q_i|^2 + |z_i|^2) - \lambda_i^\infty q_i + \mu_i^\infty z_i] d\Sigma + \int_{\Sigma_i} |q_i|^2 d\Sigma. \qquad \square \end{aligned}$$

Remark 5.2. The above analysis shows that (5.9), (5.10), (5.11) is the optimality system for the problem $\inf_{(f_1,f_2)\in\mathcal{U}_{\text{ad}}} J_i(f_1, f_2)$.

Let us comment further on (5.22). The pair $(q_{iT}, \dot{q}_{iT})$ may be calculated in a manner reminiscent of the Hilbert uniqueness method. In fact, this pair is chosen so that the solution of

$$\begin{aligned} (5.23) \qquad z_{i,tt} - a_i \Delta z_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= -\beta q_i + \lambda_i^\infty \quad \text{on } S_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= -q_i \quad \text{on } \Sigma_i, \\ z_i(0) = z_{i,t}(0) &= 0, \end{aligned}$$

$$\begin{aligned} (5.24) \qquad q_{i,tt} - a_i \Delta q_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= \beta z_i + \mu_i^\infty \quad \text{on } S_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= 0 \quad \text{on } \Sigma_i, \\ q_i(T) = q_{iT}, \quad & q_{i,t}(T) = \dot{q}_{iT} \end{aligned}$$

satisfies

$$(5.25) \qquad z_i(T) = y_{iT}, \qquad z_{i,t}(T) = \dot{y}_{iT}.$$

For arbitrary $(q_{iT}, \dot{q}_{iT}) \in V_i \times H_i$, the system (5.23), (5.24) has a unique solution since it is the optimality system for the problem

$$\inf_{f\in L^2(S_i)} \left(\frac{1}{2\beta} \int_{S_i} (|f|^2 + |\beta q_i - \lambda_i^\infty|^2)\, d\Sigma + \frac{1}{2} \int_{\Sigma_i} |q_i|^2 d\Sigma \right)$$

subject to

$$\begin{aligned} q_{i,tt} - a_i \Delta q_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= f + \mu_i^\infty \quad \text{on } S_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= 0 \quad \text{on } \Sigma_i, \\ q_i(T) = q_{iT}, \quad & q_{i,t}(T) = \dot{q}_{iT}. \end{aligned}$$

The solution of (5.23), (5.24) may be written $z_i = z_i^1 + z_i^2$, $q_i = q_i^1 + q_i^2$, where

$$(z_i^1, q_i^1) \text{ is the solution corresponding to } \lambda_i^\infty = \mu_i^\infty = 0,$$
$$(z_i^2, q_i^2) \text{ is the solution corresponding to } q_{iT} = \dot{q}_{iT} = 0.$$

By Holmgren's theorem, we may define a norm $\|(q_{iT}, \dot{q}_{iT})\|_{F_i}$ by setting

$$\|(q_{iT}, \dot{q}_{iT})\|_{F_i}^2 := \int_{S_i} \beta(|q_i^1|^2 + |z_i^1|^2) d\Sigma + \int_{\Sigma_i} |q_i^1|^2 d\Sigma,$$

and a corresponding Hilbert space

$$F_i = \text{ completion of } V_i \times H_i \text{ in } \| \cdot \|_{F_i}.$$

For $T > T_0$, one has (cf. (5.19)–(5.21))

$$\|(q_{iT}, \dot{q}_{iT})\|_{H_i \times V_i'} \le C_T \|(q_{iT}, \dot{q}_{iT})\|_{F_i};$$

hence $F_i \subset H_i \times V_i'$, $H_i \times V_i \subset F_i'$. In addition, by Green's formula we have

$$((q_{iT}, \dot{q}_{iT}), (-z_{i,t}^1(T), z_i^1(T))) = \|(q_{iT}, \dot{q}_{iT})\|_{F_i}^2.$$

Therefore, if $(-\dot{z}_{iT}, z_{iT}) \in F_i'$ and if we set

$$(q_{iT}, \dot{q}_{iT}) = \Lambda_i^{-1}(-\dot{z}_{iT}, z_{iT}),$$

where Λ_i is the canonical isomorphism $F_i \mapsto F_i'$, then we will have

$$z_i^1(T) = z_{iT}, \qquad z_{i,t}^1(T) = \dot{z}_{iT}.$$

It follows that (5.25) will be satisfied by choosing

$$(q_{iT}, \dot{q}_{iT}) = \Lambda_i^{-1}((-\dot{y}_{iT}, y_{iT}) - (-z_{i,t}^2(T), z_i^2(T))). \tag{5.26}$$

It may be checked that (5.26) is exactly the same as (5.22).

5.1. Application of Theorem 5.1 to domain decomposition. We now apply Theorem 5.1 to the solution $y_i^{n+1}(\cdot\,; k)$, $p_i^{n+1}(\cdot\,; k)$ of the optimality system (3.1), (3.2), where $\lambda_{ij}^n(\cdot\,; k)$, $\mu_{ij}^n(\cdot\,; k)$, $\tau_{ij}^n(\cdot\,; k)$ are given by (3.3), (3.5) and $\sigma_i^n(k)$ by (3.4). We assume that

$$\lambda_{ij}^0, \quad \mu_{ij}^0, \quad \tau_{ij}^0 \quad \text{are independent of } k. \tag{5.27}$$

Then, as $k \to \infty$ the solution $y_i^1(\cdot\,; k)$, $p_i^1(\cdot\,; k)$ converges in the manner described in Theorem 5.1 to the solution $y_i^1(\cdot)$, $p_i^1(\cdot)$ of the system

$$y_{i,tt}^1 - a_i \Delta y_i^1 = 0, \quad p_{i,tt}^1 - a_i \Delta p_i^1 = 0 \quad \text{in } Q_i,$$
$$a_i \frac{\partial y_i^1}{\partial \nu_i} + \beta p_i^1 = \lambda_{ij}^0, \quad a_i \frac{\partial p_i^1}{\partial \nu_i} - \beta y_i^1 = \mu_{ij}^0 \quad \text{on } \Sigma_{ij},$$
$$a_i \frac{\partial y_i^1}{\partial \nu_i} + p_i^1 = 0, \quad a_i \frac{\partial p_i^1}{\partial \nu_i} = 0 \quad \text{on } \Sigma_i,$$
$$y_i^1(0) = y_{i,t}^1(0) = 0, \quad p_i^1(T) = p_{iT}^1, \quad p_{i,t}(T) = \dot{p}_{iT}^1,$$
$$y_i^1(T) = y_{iT}, \quad y_{i,t}^1(T) = \dot{y}_{iT},$$

where $(p^1_{iT}, \dot{p}^1_{iT}) \in H_i \times V_i'$ is the solution of

$$((p^1_{iT}, \dot{p}^1_{iT}), (-\dot{y}_{iT}, y_{iT}))_{H_i \times V_i'}$$
$$= \sum_{j:\Gamma_{ij} \neq \emptyset} \int_{\Sigma_{ij}} [\beta(|p^1_i|^2 + |y^1_i|^2) d\Sigma - \lambda^0_{ij} p^1_i + \mu^0_{ij} y^1_i] d\Sigma + \int_{\Sigma_i} |p^1_i|^2 d\Sigma.$$

According to Theorem 5.1,

$$y^1_i(\cdot\,; k)|_{S_i} \to y^1_i(\cdot)|_{S_i}, \quad p^1_i(\cdot\,; k)|_{S_i} \to p^1_i(\cdot)|_{S_i} \quad \text{strongly in } L^2(S_i),$$

and therefore

$$a_i \frac{\partial y^1_i(\cdot\,; k)}{\partial \nu_i} \to \lambda^0_{ij}(\cdot) - \beta p^1_i(\cdot) = a_i \frac{\partial y^1_i(\cdot)}{\partial \nu_i},$$
$$a_i \frac{\partial p^1_i(\cdot\,; k)}{\partial \nu_i} \to \mu^0_{ij}(\cdot) + \beta y^1_i(\cdot) = a_i \frac{\partial p^1_i(\cdot)}{\partial \nu_i} \quad \text{strongly in } L^2(\Sigma_{ij}).$$

As a result,

$$\begin{aligned} \lambda^1_{ij}(\cdot\,; k) &\to (1-\epsilon)\left(- a_j \frac{\partial y^1_j(\cdot)}{\partial \nu_j} + \beta p^1_j(\cdot)\right)|_{\Sigma_{ij}} + \epsilon \left(a_i \frac{\partial y^1_i(\cdot)}{\partial \nu_i} + \beta p^1_i(\cdot)\right)|_{\Sigma_{ij}} \\ &:= \lambda^1_{ij}(\cdot) \quad \text{strongly in } L^2(\Sigma_{ij}), \\ \mu^1_{ij}(\cdot\,; k) &\to (1-\epsilon)\left(- a_j \frac{\partial p^1_j(\cdot)}{\partial \nu_j} - \beta y^1_j(\cdot)\right)|_{\Sigma_{ij}} + \epsilon \left(a_i \frac{\partial p^1_i(\cdot)}{\partial \nu_i} - \beta y^1_i(\cdot)\right)|_{\Sigma_{ij}} \\ &:= \mu^1_{ij}(\cdot) \quad \text{strongly in } L^2(\Sigma_{ij}). \end{aligned} \tag{5.28}$$

The proof of Theorem 5.1 showed that

$$\sqrt{k}(y^1_{i,t}(T; k) - \dot{y}_{iT} + k^{-1}\sigma^0_i(k))$$

is bounded in V_i' and therefore

$$\frac{1}{\sqrt{k}} p^1_i(T; k) = \mathcal{A}_i^{-1}[\sqrt{k}(y^1_{i,t}(T; k) - \dot{y}_{iT} + k^{-1}\sigma^0_i(k))] \quad \text{is bounded in } V_i.$$

In particular,

$$\frac{1}{\sqrt{k}} p^1_i(T; k)|_{\gamma_i} \quad \text{is bounded in } L^2(\gamma_i).$$

Since (see Remark 2.1)

$$a_i \frac{\partial p^1_i(T; k)}{\partial \nu_i} + \alpha p^1_i(T; k) = \tau^0_{ij}(\cdot) \quad \text{on } \Gamma_{ij},$$

it follows that

$$\frac{1}{\sqrt{k}} a_i \frac{\partial p^1_i(T; k)}{\partial \nu_i} \quad \text{is bounded in } L^2(\gamma_i);$$

hence

$$\begin{aligned} \frac{1}{\sqrt{k}} \tau^1_{ij}(\cdot\,; k) = {} & \frac{1-\epsilon}{\sqrt{k}} \left(-a_j \frac{\partial p^1_j(T; k)}{\partial \nu_j} + \alpha p^1_j(T; k)\right)\Big|_{\Gamma_{ij}} \\ & + \frac{\epsilon}{\sqrt{k}} \left(a_i \frac{\partial p^1_i(T; k)}{\partial \nu_i} + \alpha p^1_i(T; k)\right)\Big|_{\Gamma_{ij}} \quad \text{is bounded in } L^2(\Gamma_{ij}). \end{aligned}$$

We may now apply Theorem 5.1 to conclude that as $k \to \infty$ the solution $y_i^2(\cdot\,;k)$, $p_i^2(\cdot\,;k)$ of (3.1), (3.2) with $n+1=2$ converges in the manner described in that theorem to the solution $y_i^2(\cdot)$, $p_i^2(\cdot)$ of

$$\begin{gathered}
y_{i,tt}^2 - a_i \Delta y_i^2 = 0, \quad p_{i,tt}^2 - a_i \Delta p_i^2 = 0 \quad \text{in } Q_i, \\
a_i \frac{\partial y_i^2}{\partial \nu_i} + \beta p_i^2 = \lambda_{ij}^1, \quad a_i \frac{\partial p_i^2}{\partial \nu_i} - \beta y_i^2 = \mu_{ij}^1 \quad \text{on } \Sigma_{ij}, \\
a_i \frac{\partial y_i^2}{\partial \nu_i} + p_i^2 = 0, \quad a_i \frac{\partial p_i^2}{\partial \nu_i} = 0 \quad \text{on } \Sigma_i, \\
y_i^2(0) = y_{i,t}^2(0) = 0, \quad p_i^2(T) = p_{iT}^2, \quad p_{i,t}(T) = \dot{p}_{iT}^2, \\
y_i^2(T) = y_{iT}, \quad y_{i,t}^2(T) = \dot{y}_{iT},
\end{gathered}$$

where λ_{ij}^1, μ_{ij}^1 are given by (5.28) and where $(p_{iT}^2, \dot{p}_{iT}^2)$ is the solution of

$$\begin{aligned}
&((p_{iT}^2, \dot{p}_{iT}^2), (-\dot{y}_{iT}, y_{iT}))_{H_i \times V_i'} \\
&\quad = \sum_{j:\Gamma_{ij} \neq \emptyset} \int_{\Sigma_{ij}} [\beta(|p_i^2|^2 + |y_i^2|^2) d\Sigma - \lambda_{ij}^1 p_i^2 + \mu_{ij}^1 y_i^2] d\Sigma + \int_{\Sigma_i} |p_i^2|^2 d\Sigma.
\end{aligned}$$

One may now proceed inductively to obtain the following result.

THEOREM 5.3. *Assume* (5.6) *and* (5.27), *and let* $(y_{iT}, \dot{y}_{iT}) \in V_i \times H_i$. *Then as* $k \to \infty$ *the solutions* $\{y_i^{n+1}(\cdot\,;k), p_i^{n+1}(\cdot\,;k)\}_{n=0}^{\infty}$ *converge in the sense of Theorem* 5.1 *to the solutions* $\{y_i^{n+1}(\cdot), p_i^{n+1}(\cdot)\}_{n=0}^{\infty}$ *of*

$$\begin{gathered}
y_{i,tt}^{n+1} - a_i \Delta y_i^{n+1} = 0 \quad \textit{in } Q_i, \\
a_i \frac{\partial y_i^{n+1}}{\partial \nu_i} + \beta p_i^{n+1} = \lambda_{ij}^n \quad \textit{on } \Sigma_{ij}, \\
a_i \frac{\partial y_i^{n+1}}{\partial \nu_i} + p_i^{n+1} = 0 \quad \textit{on } \Sigma_i, \\
y_i^{n+1}(0) = y_{i,t}^{n+1}(0) = 0,
\end{gathered} \tag{5.29}$$

$$\begin{gathered}
p_{i,tt}^{n+1} - a_i \Delta p_i^{n+1} = 0 \quad \textit{in } Q_i, \\
a_i \frac{\partial p_i^{n+1}}{\partial \nu_i} - \beta y_i^{n+1} = \mu_{ij}^n \quad \textit{on } \Sigma_{ij}, \\
a_i \frac{\partial p_i^{n+1}}{\partial \nu_i} = 0 \quad \textit{on } \Sigma_i, \\
p_i^{n+1}(T) = p_{iT}^{n+1}, \quad p_{i,t}^{n+1}(T) = \dot{p}_{iT}^{n+1},
\end{gathered} \tag{5.30}$$

$$y_i^{n+1}(T) = y_{iT}, \quad y_{i,t}^{n+1}(T) = \dot{y}_{iT}, \tag{5.31}$$

where

$$\begin{aligned}
\lambda_{ij}^n &= (1-\epsilon)\left(-a_j \frac{\partial y_j^n}{\partial \nu_j} + p_j^n\right)|_{\Sigma_{ij}} + \epsilon\left(a_i \frac{\partial y_i^n}{\partial \nu_i} + p_i^n\right)|_{\Sigma_{ij}}, \\
\mu_{ij}^n &= (1-\epsilon)\left(-a_j \frac{\partial p_j^n}{\partial \nu_j} - y_j^n\right)|_{\Sigma_{ij}} + \epsilon\left(a_i \frac{\partial p_i^n}{\partial \nu_i} - y_i^n\right)|_{\Sigma_{ij}},
\end{aligned} \tag{5.32}$$

and where $(p_{iT}^{n+1}, \dot{p}_{iT}^{n+1}) \in H_i \times V_i'$ *is the solution of*

$$((p_{iT}^{n+1}, \dot{p}_{iT}^{n+1}), (-\dot{y}_{iT}, y_{iT}))_{H_i \times V_i'} = \int_{\Sigma_i} |p_i^{n+1}|^2 d\Sigma + \sum_{j:\Gamma_{ij} \neq \emptyset} \int_{\Sigma_{ij}} [\beta(|p_i^{n+1}|^2 + |y_i^{n+1}|^2) d\Sigma - \lambda_{ij}^n p_i^{n+1} + \mu_{ij}^n y_i^{n+1}] d\Sigma. \tag{5.33}$$

6. Convergence to the solution of the global optimality system. In this section it is proved that the solution of (5.29)–(5.33) converges as $n \to \infty$ to the solution of (4.4), (4.5). The proof follows the same lines as the proof of Theorem 3.1. First we introduce the space

$$\mathcal{X} := \prod_{i=1}^{m} L^2(S_i) \times L^2(S_i)$$

with norm $\|\cdot\|_{\mathcal{X}}$ given by

$$\|X\|_{\mathcal{X}}^2 = \sum_{i=1}^{m} \frac{1}{\beta} \int_{S_i} (|\lambda_i|^2 + |\mu_i|^2) d\Sigma,$$

where $X = \{(\lambda_i, \mu_i) : i = 1, \dots, m\}$. For $X \in \mathcal{X}$ define a linear mapping $\mathcal{T} : \mathcal{X} \mapsto \mathcal{X}$ as follows. Let (z_i, q_i) be the solution of

$$\begin{aligned} z_{i,tt} - a_i \Delta z_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= -\beta q_i + \lambda_i \quad \text{on } S_i, \\ a_i \frac{\partial z_i}{\partial \nu_i} &= -q_i \quad \text{on } \Sigma_i, \\ z_i(0) = z_{i,t}(0) &= 0, \end{aligned}$$

$$\begin{aligned} q_{i,tt} - a_i \Delta q_i &= 0 \quad \text{in } Q_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= \beta z_i + \mu_i \quad \text{on } S_i, \\ a_i \frac{\partial q_i}{\partial \nu_i} &= 0 \quad \text{on } \Sigma_i, \\ q_i(T) = q_{iT}, &\quad q_{i,t}(T) = \dot{q}_{iT}, \end{aligned}$$

where $(q_{iT}, \dot{q}_{iT})$ is chosen so that (see (5.26))

$$z_i(T) = z_{i,t}(T) = 0. \tag{6.1}$$

Set

$$\mathcal{T}X = \left\{ \left(\left(-a_j \frac{\partial z_j}{\partial \nu_j} + \beta q_j \right) |_{\Sigma_{ij}}, \left(-a_j \frac{\partial q_j}{\partial \nu_j} - \beta z_j \right) |_{\Sigma_{ij}} \right) : i = 1, \dots, m;\ j : \Gamma_{ij} \neq \emptyset \right\}.$$

We note that $\mathcal{T}X = X$ if and only if the global transmission conditions on Σ_{ij} are satisfied for all i, j. Clearly $X = 0$ is a fixed point of $\mathcal{T}$. By the same calculation as in the proof of Lemma 2.1, we have

$$\|\mathcal{T}X\|_{\mathcal{X}}^2 = \|X\|_{\mathcal{X}}^2 - 4 \int_{\Sigma} |q_m|^2 d\Sigma, \tag{6.2}$$

so that $\mathcal{T}$ is nonexpansive.

We introduce λ_{ij}, μ_{ij}, $\tilde{y}_j^n$, $\tilde{p}_j^n$, $\tilde{\lambda}_{ij}^n$, $\tilde{\mu}_{ij}^n$ as above, and set

$$\tilde{p}_{iT}^n = p_{iT}^n - p_{iT}, \quad \tilde{q}_{iT}^n = \dot{p}_{iT}^n - \dot{p}_{iT},$$

where $p_{iT} = \mathbf{P}_T|_{\Omega_i} \in H_i$, $\dot{p}_{iT} = \mathcal{A}_i(A^{-1}\dot{\mathbf{P}}_T|_{\Omega_i}) \in V_i'$. Then $\tilde{y}_j^n$, $\tilde{p}_j^n$ satisfy

$$\begin{gathered}
\tilde{y}_{i,tt}^{n+1} - a_i\Delta\tilde{y}_i^{n+1} = 0, \quad \tilde{p}_{i,tt}^{n+1} - a_i\Delta\tilde{p}_i^{n+1} = 0 \quad \text{in } Q_i,\\
a_i\frac{\partial\tilde{y}_i^{n+1}}{\partial\nu_i} + \beta\tilde{p}_i^{n+1} = \tilde{\lambda}_{ij}^n, \quad a_i\frac{\partial\tilde{p}_i^{n+1}}{\partial\nu_i} - \beta\tilde{y}_i^{n+1} = \tilde{\mu}_{ij}^n \quad \text{on } \Sigma_{ij},\\
a_i\frac{\partial\tilde{y}_i^{n+1}}{\partial\nu_i} + \tilde{p}_i^{n+1} = 0, \quad a_i\frac{\partial\tilde{p}_i^{n+1}}{\partial\nu_i} = 0 \quad \text{on } \Sigma_i,\\
\tilde{y}_i^{n+1}(0) = \tilde{y}_{i,t}^{n+1}(0) = \tilde{y}_i^{n+1}(T) = \tilde{y}_{i,t}^{n+1}(T) = 0,\\
\tilde{p}_i^{n+1}(T) = \tilde{p}_{iT}^{n+1}, \quad \tilde{p}_{i,t}^{n+1}(T) = \tilde{q}_{iT}^{n+1}.
\end{gathered} \tag{6.3}$$

We observe that the iterations on Σ_{ij} may be expressed as the fixed point iteration

$$X^{n+1} = (1-\epsilon)\mathcal{T}X^n + \epsilon X^n.$$

According to Proposition 2.1, if $0 < \epsilon < 1$, then $X^n \to X$ weakly in $\mathcal{X}$, where X is a fixed point of $\mathcal{T}$.

THEOREM 6.1. *Assume that* (4.3) *and* (5.6) *hold,* $T > T_0$, $0 < \epsilon < 1$, *and let* $(\mathbf{Y}_T, \dot{\mathbf{Y}}_T) \in V \times H$. *Then as* $n \to \infty$ *we have*

$$\begin{gathered}
\tilde{y}_i^n \to 0 \quad \textit{in } C([0,T];H_i),\\
\tilde{y}_{i,t}^n \to 0 \quad \textit{in } C([0,T];V_i'),\\
\tilde{p}_i^n \to 0 \quad \textit{weakly}^* \textit{ in } L^\infty(0,T;H_i),\\
\tilde{p}_{i,t}^n \to 0 \quad \textit{weakly}^* \textit{ in } L^\infty(0,T;V_i'),\\
\tilde{p}_m^n|_\Sigma \to 0 \quad \textit{strongly in } L^2(\Sigma).
\end{gathered}$$

Proof. We proceed as in the proof of Theorem 3.1 and calculate with the aid of (6.2) that

$$\begin{aligned}
\|X^{n+1}\|_{\mathcal{X}}^2 &= (1-\epsilon)^2\|\mathcal{T}X^n\|_{\mathcal{X}}^2 + \epsilon^2\|X^n\|_{\mathcal{X}}^2 + 2\epsilon(1-\epsilon)(X^n, \mathcal{T}X^n)_{\mathcal{X}}\\
&= ((1-\epsilon)^2+\epsilon^2)\|X^n\|_{\mathcal{X}}^2 - 4(1-\epsilon)^2\int_\Sigma |\tilde{p}_m^n|^2 d\Sigma + 2\epsilon(1-\epsilon)(X^n, \mathcal{T}X^n)_{\mathcal{X}}.
\end{aligned} \tag{6.4}$$

Again, by the same calculation as in Lemma 2.2, we obtain

$$\begin{aligned}
\|X^n\|_{\mathcal{X}}^2 = \sum_{i=1}^m \frac{1}{\beta}\int_{S_i}\left(\beta^2(|\tilde{y}_i^n|^2 + |\tilde{p}_i^n|^2) + \left|a_i\frac{\partial\tilde{y}_i^n}{\partial\nu_i}\right|^2 + \left|a_i\frac{\partial\tilde{p}_i^n}{\partial\nu_i}\right|^2\right)d\Sigma\\
+ 2\int_\Sigma |\tilde{p}_m^n|^2 d\Sigma.
\end{aligned} \tag{6.5}$$

Therefore

$$\begin{aligned}
\|X^{n+1}\|_{\mathcal{X}}^2 = ((1-\epsilon)^2+\epsilon^2)E^n\\
- 2(1-2\epsilon)\int_\Sigma |\tilde{p}_m^n|^2 d\Sigma + 2\epsilon(1-\epsilon)(X^n, \mathcal{T}X^n)_{\mathcal{X}},
\end{aligned} \tag{6.6}$$

where

$$E^n := \sum_{i=1}^m \frac{1}{\beta} \int_{S_i} \left(\beta^2 (|\tilde{y}_i^n|^2 + |\tilde{p}_i^n|^2) + \left| a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} \right|^2 + \left| a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} \right|^2 \right) d\Sigma.$$

From (6.6) and (6.5) with n replaced by $n+1$ we obtain

$$\begin{aligned} E^{n+1} &= ((1-\epsilon)^2 + \epsilon^2) E^n \\ &\quad - 2 \int_\Sigma [(1-2\epsilon)|\tilde{p}_m^n|^2 + |\tilde{p}_m^{n+1}|^2] d\Sigma + 2\epsilon(1-\epsilon)(X^n, \mathcal{T} X^n)_{\mathcal{X}}. \end{aligned} \tag{6.7}$$

One has

$$\begin{aligned} (X^n, \mathcal{T} X^n)_{\mathcal{X}} = \sum_{i=1}^m \sum_{j:\Gamma_{ij} \neq \emptyset} \frac{1}{\beta} \int_{\Sigma_{ij}} \Bigg[& -a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} a_j \frac{\partial \tilde{y}_j^n}{\partial \nu_j} - a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} a_j \frac{\partial \tilde{p}_j^n}{\partial \nu_j} \\ & + \beta^2 (\tilde{p}_i^n \tilde{p}_j^n + \tilde{y}_i^n \tilde{y}_j^n) \Bigg] d\Sigma, \end{aligned}$$

so that

(6.8)

$$\begin{aligned} & ((1-\epsilon)^2 + \epsilon^2) E^n + 2\epsilon(1-\epsilon)(X^n, \mathcal{T} X^n)_{\mathcal{X}} \\ & = \sum_{i=1}^m \sum_{\substack{j:\Gamma_{ij} \neq \emptyset \\ j>i}} \frac{1}{\beta} \int_{\Sigma_{ij}} \Bigg[((1-\epsilon)^2 + \epsilon^2) \left(\left| a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} \right|^2 + \left| a_j \frac{\partial \tilde{y}_j^n}{\partial \nu_j} \right|^2 \right. \\ & \quad \left. + \left| a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} \right|^2 + \left| a_j \frac{\partial \tilde{p}_j^n}{\partial \nu_j} \right|^2 \right) - 4\epsilon(1-\epsilon) \left(a_i \frac{\partial \tilde{y}_i^n}{\partial \nu_i} a_j \frac{\partial \tilde{y}_j^n}{\partial \nu_j} + a_i \frac{\partial \tilde{p}_i^n}{\partial \nu_i} a_j \frac{\partial \tilde{p}_j^n}{\partial \nu_j} \right) \\ & \quad + \beta^2 ((1-\epsilon)^2 + \epsilon^2)(|\tilde{y}_i^n|^2 + |\tilde{y}_j^n|^2 + |\tilde{p}_i^n|^2 + |\tilde{p}_j^n|^2) + 4\beta^2 \epsilon(1-\epsilon)(\tilde{y}_i^n \tilde{y}_j^n + \tilde{p}_i^n \tilde{p}_j^n) \Bigg] d\Sigma \\ & \leq [(1-\epsilon)^2 + \epsilon^2 + 2\epsilon(1-\epsilon)] E^n = E^n. \end{aligned}$$

Substitution of (6.8) into (6.7) yields

$$E^{n+1} \leq E^n - 2 \int_\Sigma (|\tilde{p}_m^{n+1}|^2 + (1-2\epsilon)|\tilde{p}_m^n|^2)\, d\Sigma,$$

and so, by iteration,

$$E^{n+1} \leq E^1 - \sum_{\ell=1}^{n+1} \int_\Sigma c_\ell(\epsilon) |\tilde{p}_m^\ell|^2 d\Sigma, \tag{6.9}$$

where

$$c_1(\epsilon) = 1 - 2\epsilon, \quad c_{n+1}(\epsilon) = 1, \quad c_\ell(\epsilon) = 2(1-\epsilon),\ \ell = 2, \ldots, n.$$

In particular, for $0 \leq \epsilon < 1$ we have

$$\sum_{\ell=1}^\infty \int_\Sigma |\tilde{p}_m^\ell|^2 d\Sigma < \infty$$

so that

$$\tilde{p}_m^n|_\Sigma \to 0 \quad \text{strongly in } L^2(\Sigma) \text{ as } n \to \infty. \tag{6.10}$$

We also deduce from (6.9) that on a subsequence

$$\tilde{p}_i^\ell|_{S_i} \to \tilde{p}_i^\infty, \quad \tilde{y}_i^\ell|_{S_i} \to \tilde{y}_i^\infty, \quad a_i \frac{\partial \tilde{y}_i^\ell}{\partial \nu_i}\bigg|_{S_i} \to \tilde{Y}_i, \quad a_i \frac{\partial \tilde{p}_i^\ell}{\partial \nu_i}\bigg|_{S_i} \to \tilde{P}_i \tag{6.11}$$

weakly in $L^2(S_i)$. Since for $0 < \epsilon < 1$ we know that X^n converges weakly in $\mathcal{X}$ to a fixed point of $\mathcal{T}$, it follows from (6.3) that

$$\tilde{P}_i - \tilde{y}_i^\infty = -\tilde{P}_j - \tilde{y}_j^\infty, \quad \tilde{Y}_i + \tilde{p}_i^\infty = -\tilde{Y}_j + \tilde{p}_j^\infty \quad \text{on } \Sigma_{ij}$$

and then that

$$\tilde{Y}_i + \tilde{Y}_j = 0, \quad \tilde{P}_i + \tilde{P}_j = 0, \quad \tilde{y}_i^\infty = \tilde{y}_j^\infty, \quad \tilde{p}_i^\infty = \tilde{p}_j^\infty \quad \text{on } \Sigma_{ij}. \tag{6.12}$$

From (5.6) and (6.11) it is seen that

$$(\tilde{p}_{iT}^n, \tilde{q}_{iT}^n) \quad \text{is bounded in } H_i \times V_i'$$

and then that

$$(\tilde{p}_i^n, \tilde{p}_{i,t}^n) \quad \text{is bounded in } C([0,T]; H_i \times V_i').$$

Therefore, on a subsequence,

$$\begin{gathered}(\tilde{p}_{iT}^\ell, \tilde{q}_{iT}^\ell) \to (\tilde{p}_{iT}, \tilde{q}_{iT}) \quad \text{weakly in } H_i \times V_i', \\ \tilde{p}_i^\ell \to \tilde{p}_i \quad \text{weakly}^* \text{ in } L^\infty(0,T; H_i), \\ \tilde{p}_{i,t}^\ell \to \tilde{p}_{i,t} \quad \text{weakly}^* \text{ in } L^\infty(0,T; V_i').\end{gathered}$$

In addition, it follows as in the proof of Theorem 3.1 that on a subsequence

$$\begin{gathered}\tilde{y}_i^\ell \to \tilde{y}_i \quad \text{in } C([0,T]; H_i), \\ \tilde{y}_{i,t}^\ell \to \tilde{y}_{i,t} \quad \text{in } C([0,T]; V_i').\end{gathered}$$

The functions $\tilde{y}_i$, $\tilde{p}_i$ satisfy

$$\begin{gathered}\tilde{y}_{i,tt} - a_i \Delta \tilde{y}_i = 0, \quad \tilde{p}_{i,tt} - a_i \Delta \tilde{p}_i = 0 \quad \text{in } Q_i, \\ a_i \frac{\partial \tilde{y}_i}{\partial \nu_i} = -\tilde{Y}_i, \quad a_i \frac{\partial \tilde{p}_i}{\partial \nu_i} = -\tilde{P}_i \quad \text{on } S_i, \\ a_i \frac{\partial \tilde{y}_i}{\partial \nu_i} = 0, \quad a_i \frac{\partial \tilde{p}_i}{\partial \nu_i} = 0 \quad \text{on } \Sigma_i, \\ \tilde{y}_i(0) = \tilde{y}_{i,t}(0) = 0, \quad \tilde{p}_i(T) = \tilde{p}_{iT}, \quad \tilde{p}_{i,t}(T) = \tilde{q}_{iT},\end{gathered} \tag{6.13}$$

and

$$\tilde{p}_i|_{S_i} = \tilde{p}_i^\infty, \quad \tilde{y}_i|_{S_i} = \tilde{y}_i^\infty.$$

By virtue of (6.12) it is seen that $\tilde{\mathbf{Y}} := (\tilde{y}_1, \dots, \tilde{y}_m)$ is the solution of (1.1) with $f = 0$, and therefore $\tilde{\mathbf{Y}}(t) = 0$, $\tilde{\mathbf{Y}}_t(t)|_V = 0$, $0 \le t \le T$. In addition, $\tilde{\mathbf{P}} := (\tilde{p}_1, \dots, \tilde{p}_m)$ is the solution of

$$
\begin{gathered}
\tilde{p}_{i,tt} - a_i \Delta \tilde{p}_i = 0 \quad \text{in } Q_i,\ i = 1, 2, \\
\tilde{p}_i = \tilde{p}_j, \quad a_i \frac{\partial \tilde{p}_i}{\partial \nu_i} + a_j \frac{\partial \tilde{p}_j}{\partial \nu_j} = 0 \quad \text{on } \Sigma_{ij}, \\
a_i \frac{\partial \tilde{p}_i}{\partial \nu_i} = 0 \quad \text{on } \Sigma_i, \\
\tilde{\mathbf{P}}(T) = \tilde{\mathbf{P}}_{iT}, \quad \tilde{\mathbf{P}}_{,t}(T) = \tilde{\mathbf{Q}}_{iT},
\end{gathered}
\tag{6.14}
$$

where

$$
\tilde{\mathbf{P}}_{iT} = (\tilde{p}_{1T}, \dots, \tilde{p}_{mT}), \quad \tilde{\mathbf{Q}}_{iT} = (\tilde{q}_{1T}, \dots, \tilde{q}_{mT}).
$$

From (6.10) and (6.13) we have

$$
\tilde{p}_m|_\Sigma = 0,
$$

and then (4.3) gives $\tilde{\mathbf{P}}_{iT} = \tilde{\mathbf{Q}}_{iT} = 0$, hence $\tilde{\mathbf{P}}(t) = 0$, $0 \le t \le T$. □

STRONG CONVERGENCE OF BLOCK-ITERATIVE OUTER APPROXIMATION METHODS FOR CONVEX OPTIMIZATION*

PATRICK L. COMBETTES†

Abstract. The strong convergence of a broad class of outer approximation methods for minimizing a convex function over the intersection of an arbitrary number of convex sets in a reflexive Banach space is studied in a unified framework. The generic outer approximation algorithm under investigation proceeds by successive minimizations over the intersection of convex supersets of the feasibility set determined in terms of the current iterate and variable blocks of constraints. The convergence analysis involves flexible constraint approximation and aggregation techniques as well as relatively mild assumptions on the constituents of the problem. Various well-known schemes are recovered as special realizations of the generic algorithm and parallel block-iterative extensions of these schemes are devised within the proposed framework. The case of inconsistent constraints is also considered.

Key words. block-iterative, convex feasibility problem, convex programming, constrained minimization, cutting plane, fixed point, inconsistent constraints, outer approximation, projection onto an intersection of convex sets, reflexive Banach space, surrogate cut, uniformly convex function

1. Introduction.

Let $\mathcal{X}$ be a real reflexive Banach space, let $J\colon \mathcal{X} \to]-\infty,+\infty]$ be a proper function, and let $(S_i)_{i\in I}$ be an arbitrary family of closed convex subsets of $\mathcal{X}$. We investigate a broad class of block-iterative outer approximation methods for solving the program

$$\text{(P)} \qquad \text{find } \overline{x} \in S \triangleq \bigcap_{i\in I} S_i \quad \text{such that } J(\overline{x}) = \inf_{x\in S} J(x) \triangleq \overline{J}$$

under the following assumptions:

(A1) J is lower semicontinuous and convex.

(A2) For some closed convex set $E \supset S$, there exists a point $u \in S \cap \operatorname{dom} J$ such that the set $C \triangleq \{x \in E \mid J(x) \leq J(u)\}$ is bounded and J is uniformly convex with modulus of convexity c on C, i.e., [53], [54]

$$(1.1) \qquad \big(\forall (x,y) \in C^2\big) \quad J\left(\frac{x+y}{2}\right) \leq \frac{J(x)+J(y)}{2} - c(\|x-y\|),$$

where $c\colon \mathbb{R}_+ \to \mathbb{R}_+$ is nondecreasing and $(\forall \tau \in \mathbb{R}_+)\ c(\tau) = 0 \Leftrightarrow \tau = 0$.

(A3) For every $i \in I$, $S_i = \{x \in \mathcal{X} \mid g_i(x) \leq 0\}$, where g_i belongs to the class $\mathcal{G}$ of

all functions $g\colon \mathcal{X} \to]-\infty, +\infty]$ such that

$$\text{(1.2)} \qquad \begin{cases} \text{(i) } \{x \in \mathcal{X} \mid g(x) \leq 0\} \text{ is nonempty and convex.} \\ \text{(ii) For every sequence } (y_n)_{n\geq 0} \subset \mathcal{X} \\ \qquad \begin{cases} y_n \overset{n}{\rightharpoonup} y \\ \overline{\lim}_n g(y_n) \leq 0 \end{cases} \quad \Rightarrow \quad g(y) \leq 0. \end{cases}$$

Assumptions (A1)–(A2) are rather standard and ensure in particular that (P) admits a unique solution $\overline{x}$ [1]. Assumption (A3) provides an explicit description of the constraint sets $(S_i)_{i\in I}$ as lower level sets of functions $(g_i)_{i\in I} \subset \mathcal{G}$. As will be seen in section 2, the class $\mathcal{G}$ is quite broad, and (A3) therefore covers a wide range of constraints encountered in convex optimization problems.

In the past four decades, various outer approximation methods for constrained minimization problems have been proposed, following their introduction by Cheney and Goldstein [8] and Kelley [31] in the form of cutting plane algorithms. The underlying principle is to replace (P) by a sequence of minimizations over simple closed convex supersets $(Q_n)_{n\geq 0}$ of the feasibility set S. Typically, the approximation at iteration n can be written as $Q_n = D_n \cap H_n$, where D_n and H_n are two closed convex supersets of S, the latter being termed a cut. Outer approximation methods can be divided into two main categories, namely, cutoff methods and constraints disintegration methods. In cutoff method [37], $D_{n+1} = Q_n$ and Q_{n+1} therefore results from the accumulation of all previous cuts. Several classical algorithms fit in this framework that differ in the way the cuts are defined, e.g., [8], [30], [31], [52], [55]. Naturally, a limitation of cutoff methods is that the minimization of J over the sets $(Q_n)_{n\geq 0}$ becomes increasingly demanding in terms of both computational load and storage requirements. This shortcoming prompted the development of filtered cutoff methods in which some of the old cuts can be discarded under various hypotheses, thereby keeping the complexity of the outer approximations manageable, e.g., [5], [16], [19], [49], [50]. These methods are cumulative in the sense that every cut must be retained until it is definitely dropped. By contrast, in the somewhat less well known constraints disintegration methods, D_n is a half-space depending solely on x_n and a subgradient of J at x_n. Such schemes were first proposed by Haugazeau in the 1960s for the minimization of quadratic forms in Hilbert spaces [26] and several variants have since been proposed for this particular problem [14], [27], [41], [44], [45]. The extension to convex functions was dealt with in [35] in Banach spaces and rediscovered in Euclidean spaces in [29] and [39].

The goal of the present work is to develop a general framework for outer approximation methods that captures and extends the above algorithms. Our investigation will not only provide a unified strong convergence analysis of existing outer approximation methods for solving (P) but also yield flexible generalizations of these methods in the form of parallel block-iterative algorithms.

The paper is built around the following generic outer approximation scheme. For brevity, $\mathfrak{m}(A)$ denotes the minimizer of J over a convex set A and $\mathfrak{C}(A)$ the family of all closed convex supersets of A.

ALGORITHM 1.1. *A sequence $(x_n)_{n\geq 0}$ is constructed as follows, where E is supplied by* (A2).

Step 0. *Set $D_0 = E$, $x_0 = \mathfrak{m}(D_0)$, and $n = 0$.*

Step 1. *Take a nonempty finite index set $I_n \subset I$ and generate H_n such that*

$$H_n \in \mathfrak{C}\left(\bigcap_{i\in I_n} S_i\right). \tag{1.3}$$

Step 2. *Set $Q_n = E \cap D_n \cap H_n$ and $x_{n+1} = \mathfrak{m}(Q_n)$.*
Step 3. *Generate D_{n+1} such that*

$$D_{n+1} \in \mathfrak{C}(S) \quad \text{and} \quad x_{n+1} = \mathfrak{m}(D_{n+1}). \tag{1.4}$$

Step 4. *Set $n = n + 1$ and go to Step* 1.

Associated with this algorithm is the following terminology.

DEFINITION 1.1. *Let H_n and D_{n+1} be two subsets of $\mathcal{X}$. Then H_n (respectively, D_{n+1}) will be said to be a* cut *(respectively, a* base*) for Algorithm* 1.1 *at iteration n if* (1.3) *(respectively,* (1.4)*) holds.*

At iteration n, x_n and an outer approximation D_n to S are given such that x_n minimizes J over D_n. A finite block of sets $(S_i)_{i\in I_n}$ is then selected and H_n is constructed as an outer approximation to their intersection. The update x_{n+1} is the minimizer of J over $Q_n = E \cap D_n \cap H_n$. We observe that, since $u \in Q_n$, x_{n+1} is the minimizer of J over $Q_n \cap C$. Consequently, since J is weakly lower semicontinuous (by (A1)) and since $Q_n \cap C$ is nonempty and weakly compact (bounded, closed, and convex by (A1)–(A2) in the reflexive space $\mathcal{X}$), the existence of x_{n+1} follows from Weierstrass' theorem [1, Thm. 2.1.1]; its uniqueness follows from the strict convexity of J over $Q_n \cap C$, which is secured by (A2). The iteration is completed by generating a new outer approximation D_{n+1} to S over which J achieves its infimum at x_{n+1}.

The remainder of the paper is divided into six sections. In section 2 basic notation and definitions are introduced and assumptions (A1)–(A3) are illustrated through specific examples. In section 3 we establish the strong convergence of Algorithm 1.1 to the solution $\overline{x}$ of (P) for two types of control sequence $(I_n)_{n\geq 0}$ under certain "tightness" conditions. Four frameworks are then considered individually. In section 4, two general cut construction techniques are described, namely, exact-constraint cuts in section 4.1 and surrogate cuts in section 4.2. In the former case, the cuts are drawn directly from the pool of constraint sets $(S_i)_{i\in I}$, whereas in the latter they are constructed as surrogate half-spaces based on approximate projections of the current iterate onto the selected block of sets. Section 5 is devoted to the construction of bases. In section 5.1 the bases are cumulative, as in cutoff methods, whereas in section 5.2 the bases are instantaneous, as in constraints disintegration methods. By coupling a cut construction strategy from section 4.1 or 4.2 with a base construction strategy from section 5.1 or 5.2, we obtain in section 6 four general realizations of the abstract Algorithm 1.1. In each case, strong convergence theorems are given and existing methods are exhibited as special cases. As a by-product, a block-iterative algorithm for projecting onto an intersection of convex sets in a Hilbert space is presented in detail. Finally, problems with inconsistent constraints and feasibility problems are discussed in section 7.

2. Preliminaries.

2.1. Notation, definitions, and basic facts. The definitions and results stated hereafter can be found in [1].

$\mathbb{N}$ is the set of nonnegative integers, $\mathbb{N}^*$ the set of positive integers, $\mathbb{R}_+$ the set of nonnegative reals, $\mathbb{R}_+^*$ the set of positive reals, and $\mathbb{R}^N$ the standard N-dimensional

Euclidean space. $\mathcal{X}$ is a real reflexive Banach space, and Id its identity operator. $\operatorname{bd} A$ denotes the boundary of a set $A \subset \mathcal{X}$, A° its interior, $\mathfrak{m}(A)$ the minimizer of J over A (i.e., $\mathfrak{m}(A) \in A$ and $(\forall x \in A)\ J(\mathfrak{m}(A)) \leq J(x)$) provided such a point exists and is unique, and $\mathfrak{C}(A)$ the family of all closed convex supersets of A. The norm of $\mathcal{X}$ and that of its topological dual $\mathcal{X}'$ is denoted by $\|\cdot\|$, the associated distance by d, and the canonical bilinear form on $\mathcal{X} \times \mathcal{X}'$ by $\langle \cdot, \cdot \rangle$. The expressions $x_n \overset{n}{\rightharpoonup} x$ and $x_n \overset{n}{\to} x$ denote, respectively, the weak and strong convergence to x of a sequence $(x_n)_{n\geq 0}$ and $\mathfrak{W}(x_n)_{n\geq 0}$ its set of weak cluster points. The closed ball of center x and radius γ in $\mathcal{X}$ or $\mathcal{X}'$ is denoted by $B(x, \gamma)$ and the normalized duality mapping of $\mathcal{X}$ by Δ, i.e.,

$$(\forall x \in \mathcal{X}) \quad \Delta(x) = \big\{x' \in \mathcal{X}' \mid \|x\|^2 = \langle x, x' \rangle = \|x'\|^2\big\}. \tag{2.1}$$

It follows from the reflexivity of $\mathcal{X}$ that Δ is surjective ($\Delta^{-1}(x') \neq \emptyset$ for every $x' \in \mathcal{X}'$). Δ is single valued if $\mathcal{X}'$ is strictly convex.

Let $F\colon \mathcal{X} \to]-\infty, +\infty]$ be a proper function, i.e., $\operatorname{dom} F = \{x \in \mathcal{X} \mid F(x) < +\infty\} \neq \emptyset$. F is subdifferentiable at $x \in \operatorname{dom} F$ if its subdifferential at this point,

$$\partial F(x) = \big\{t' \in \mathcal{X}' \mid\ (\forall y \in \mathcal{X})\ \langle y - x, t' \rangle + F(x) \leq F(y)\big\}, \tag{2.2}$$

is not empty. A subgradient of F at x is an element of $\partial F(x)$. The lower level set of F at height $\lambda \in \mathbb{R}$ is $\operatorname{lev}_{\leq \lambda} F = \{x \in \mathcal{X} \mid F(x) \leq \lambda\}$. F is quasi-convex if its lower level sets $(\operatorname{lev}_{\leq \lambda} F)_{\lambda \in \mathbb{R}}$ are convex and it is (respectively, weakly) lower semicontinuous if they are (respectively, weakly) closed. Now suppose that $A \subset \mathcal{X}$ is a nonempty convex set and that F is convex and continuous at a point in $A \cap \operatorname{dom} F$, and let $p \in A$. Then

$$F(p) = \inf_{y \in A} F(y) \quad \Leftrightarrow \quad \big(\exists t' \in \partial F(p)\big)(\forall y \in A) \quad \langle p - y, t' \rangle \leq 0. \tag{2.3}$$

In particular, fix $x \in \mathcal{X}$ and let $F\colon y \mapsto \|x - y\|^2/2$. Then (2.3) yields

$$\|x - p\| = d(x, A) \quad \Leftrightarrow \quad \big(\exists q' \in \Delta(x - p)\big)(\forall y \in A) \quad \langle y - p, q' \rangle \leq 0 \tag{2.4}$$

and p is called a projection of x onto A. Such a point exists if A is closed and it is unique if in addition $\mathcal{X}$ is strictly convex, as is the case when $\mathcal{X}$ is uniformly convex, i.e.,

$$(\forall \epsilon \in]0, 2])(\exists \delta \in]0, 2])\big(\forall (x, y) \in B(0, 1)^2\big) \quad \|x - y\| \geq \epsilon \Rightarrow \|x + y\| \leq 2 - \delta, \tag{2.5}$$

and a fortiori when $\mathcal{X}$ is a Hilbert space.

If $\mathcal{X}$ is a Hilbert space, the identifications $\mathcal{X}' = \mathcal{X}$ and $\Delta = \mathrm{Id}$ will be made and the scalar product of $\mathcal{X}$ will also be denoted by $\langle \cdot, \cdot \rangle$. Thus, expressions such as $\langle x, y' \rangle$, where $(x, y) \in \mathcal{X}^2$ and $y' \in \Delta(y)$, will reduce to $\langle x, y \rangle$.

2.2. On assumptions (A1)–(A3). We first describe basic scenarios covered by assumptions (A1)–(A2). It should be noted at this point that the boundedness of C in (A2) is mentioned only for the sake of clarity and that it is actually implicit. Indeed, if $F\colon \mathcal{B} \to]-\infty, +\infty]$ is lower semicontinuous and uniformly convex on a closed convex set $A \subset \mathcal{B}$, where $\mathcal{B}$ is a reflexive Banach space, then $A \cap \operatorname{lev}_{\leq F(w)} F$ is bounded for every $w \in A \cap \operatorname{dom} F$ [53, Thm. 1(1)].

PROPOSITION 2.1. *Assumptions* (A1) *and* (A2) *are satisfied in each of the following cases.*

(i) *J is lower semicontinuous and convex and, for some $E \in \mathfrak{C}(S)$, there exists $u \in S \cap \operatorname{dom} J$ such that $C = E \cap \operatorname{lev}_{\leq J(u)} J$ is compact and J is strictly convex and continuous on C.*

(ii) $\mathcal{X} = \mathbb{R}^N$, *$J$ is finite and strictly convex, and either of the following conditions is fulfilled:*
  (a) *$E = \mathcal{X}$ and, for some $\overline{\lambda} \in \mathbb{R}$, $\operatorname{lev}_{\leq \overline{\lambda}} J$ is nonempty and bounded.*
  (b) *$E \in \mathfrak{C}(S)$ is bounded.*

(iii) *$\mathcal{X}$ is a Hilbert space, $E = \mathcal{X}$, and J is a coercive quadratic form, i.e., $J\colon x \mapsto a(x,x)/2 - \langle x, b\rangle$, where $b \in \mathcal{X}$ and a is a symmetric bounded bilinear form on $\mathcal{X}^2$ that satisfies*

$$\big(\exists \gamma \in \mathbb{R}_+^*\big)(\forall x \in \mathcal{X}) \quad a(x,x) \geq \gamma \|x\|^2. \tag{2.6}$$

(iv) *$\mathcal{X}$ is uniformly convex, $E = \mathcal{X}$, and $J\colon x \mapsto \int_0^{\|x-w\|} \varphi(t)dt$, where $w \in \mathcal{X}$ and $\varphi\colon \mathbb{R}_+ \to \mathbb{R}_+$ is increasing.*

(v) *Let $(\Omega, \mathcal{F}, \mu)$ be a complete finite measure space, let $p \in]1, +\infty[$, and let X be a separable, real reflexive Banach space with norm $\|\cdot\|_{\mathsf{X}}$ and Borel σ-algebra $\mathcal{B}$. $\mathcal{X} = \mathbf{L}^p_{\mathsf{X}}$ is the Lebesgue space of (equivalence classes of μ — almost everywhere (a.e.) equal) measurable functions $x\colon (\Omega, \mathcal{F}) \to (\mathsf{X}, \mathcal{B})$ such that $\int_\Omega \|x(\omega)\|^p_{\mathsf{X}} \mu(d\omega) < +\infty$ and $J\colon x \mapsto \int_\Omega \varphi(\omega, x(\omega))\mu(d\omega)$, where the integrand $\varphi\colon \Omega \times \mathsf{X} \to]-\infty, +\infty]$ fulfills the following conditions:*
  (a) *φ is measurable relative to the product σ-algebra $\mathcal{F} \times \mathcal{B}$.*
  (b) *$(\forall x \in \mathcal{X})$ $\int_\Omega |\varphi(\omega, x(\omega))|\mu(d\omega) < +\infty$.*
  (c) *The functions $(\varphi(\omega, \cdot))_{\omega \in \Omega}$ are lower semicontinuous, proper, and uniformly convex on X with common modulus of convexity c_0, hence*

$$(\forall \omega \in \Omega)(\forall (\mathsf{x}, \mathsf{y}) \in \big(\operatorname{dom} \varphi(\omega, \cdot)\big)^2) \quad \varphi\left(\omega, \frac{\mathsf{x}+\mathsf{y}}{2}\right) \leq \frac{\varphi(\omega, \mathsf{x}) + \varphi(\omega, \mathsf{y})}{2} - c_0(\|\mathsf{x}-\mathsf{y}\|_{\mathsf{X}}). \tag{2.7}$$

Moreover, c_0 is continuous and $\underline{\lim}_{\tau \to +\infty} c_0(\tau)/\tau^p > 0$.

Proof. (i) is a consequence of [36, Thm. 4.1.8.(1)]. (ii) $\Rightarrow$ (i): J is convex and, by [46, Cor. 10.1.1], continuous. Moreover, for any $u \in S$, $E \cap \operatorname{lev}_{\leq J(u)} J$ is compact. This follows from the compactness of $\operatorname{lev}_{\leq \lambda} J$ for any $\lambda \in \mathbb{R}$ in (a) [46, Cor. 8.7.1] and from that of E in (b). (iii): $a(\cdot,\cdot)$ is a scalar product on $\mathcal{X}$ with associated norm $|||\cdot|||\colon x \mapsto \sqrt{a(x,x)}$. The parallelogram identity applied to $|||\cdot|||$ and (2.6) then shows its uniform convexity on $\mathcal{X}$ with modulus of convexity $\alpha \mapsto \gamma\alpha^2/4$. Hence, $|||\cdot|||$ satisfies (A1)–(A2) and so does J. (iv): Without loss of generality, let $w = 0$. The function $\psi\colon \alpha \mapsto \int_0^\alpha \varphi(t)dt$ is well defined, finite, increasing, convex, and continuous on $\mathbb{R}_+$ [46, Thm. 24.2]. Hence, $J = \psi \circ \|\cdot\|$ is convex and continuous, and (A1) is satisfied. Finally, (A2) is satisfied due to the uniform convexity of J on any closed ball [54, Thm. 4.1(ii)] and therefore on $\operatorname{lev}_{\leq J(u)} J$ for any $u \in S$. (v): $\mathcal{X}$ is a reflexive Banach space with norm $\|\cdot\|\colon x \mapsto (\int_\Omega \|x(\omega)\|^p_{\mathsf{X}} \mu(d\omega))^{1/p}$ [20, Thm. 8.20.5]. Moreover, J is finite, continuous, and convex on $\mathcal{X}$ [47, Thm. 22(a)], which gives (A1). As regards (A2), we claim that J is uniformly convex on $\mathcal{X}$. Indeed, take arbitrarily $(x, y) \in \mathcal{X}^2$. Then it follows from (b) that $\varphi(\cdot, x(\cdot)) < +\infty$ and $\varphi(\cdot, y(\cdot)) < +\infty$ μ-a.e. Consequently, by virtue of (2.7), for μ almost every $\omega \in \Omega$, it holds that

$$\varphi\left(\omega, \frac{x(\omega)+y(\omega)}{2}\right) \leq \frac{\varphi(\omega, x(\omega)) + \varphi(\omega, y(\omega))}{2} - c_0\left(\|x(\omega) - y(\omega)\|_{\mathsf{X}}\right), \tag{2.8}$$

where, under our assumptions, the function $\omega \mapsto c_0(\|x(\omega) - y(\omega)\|_{\mathsf{X}})$ is measurable. Upon integrating (2.8), we obtain

$$J\left(\frac{x+y}{2}\right) \leq \frac{J(x)+J(y)}{2} - \int_{\Omega} c_0\left(\|x(\omega)-y(\omega)\|_{\mathsf{X}}\right)\mu(d\omega). \tag{2.9}$$

Now fix $\varepsilon \in \mathbb{R}_+^*$ arbitrarily. Then, since $\mu(\Omega) < +\infty$ and $\underline{\lim}_{\tau\to+\infty} c_0(\tau)/\tau^p > 0$, it follows from [54, Lem. 4.4] that there exists $c \in \mathbb{R}_+^*$ depending only on ε such that $\int_\Omega c_0(\|x(\omega)-y(\omega)\|_{\mathsf{X}})\mu(d\omega) \geq c$ whenever $\|x-y\| \geq \varepsilon$. This proves the claim. ∎

Scenario (ii) is an important practical instance of (i) in which (P) takes the form of a semi-infinite convex program, as commonly found in numerical applications. In scenario (iii), since there exists $w \in \mathcal{X}$ such that $(\forall x \in \mathcal{X})\langle x, b\rangle = a(x,w)$ [7, Chap. V], we can write $J\colon x \mapsto a(x-w,x-w)/2 - a(w,w)/2$. (P) can therefore be looked upon as the problem of finding the projection of w onto the intersection of the closed convex sets $(S_i)_{i\in I}$ relative to the norm $|||\cdot|||\colon x \mapsto \sqrt{a(x,x)}$. Alternatively, since for every $y \in \mathcal{X}$ $\langle y, \nabla J(\overline{x})\rangle = a(y,\overline{x}) - \langle y, b\rangle$ [15, Chap. VII], (2.3) shows that (P) is equivalent to solving the variational inequality

$$\text{find}\,\overline{x} \in S = \bigcap_{i\in I} S_i \quad \text{such that } (\forall x \in S) \quad a(x-\overline{x},\overline{x}) \geq \langle x-\overline{x}, b\rangle, \tag{2.10}$$

which arises in numerous areas of mathematical sciences [1], [7], [15]. Next, scenario (iv) describes the problem of projecting w onto the intersection of the closed convex sets $(S_i)_{i\in I}$ in a uniformly convex Banach space. It is noted that if $J\colon x \mapsto \|x-w\|^2/2$, then $\partial J\colon x \mapsto \Delta(x-w)$ [1]. Finally, scenario (v) is of interdisciplinary interest and covers problems in areas such as stochastic programming, economics, and control theory; see, e.g., [1], [43], [47]. It should be added that $t' \in \partial J(x) \Leftrightarrow t'(\cdot) \in \partial\varphi(\cdot, x(\cdot))$ μ — a.e. [47, Thm. 22(c)] and that $\mathcal{X}$ is a Hilbert space if X is a Hilbert space and $p = 2$.

We now turn to assumption (A3). The motivation for introducing the class of functions $\mathcal{G}$ stems from its ability to capture in the convenient form of functional inequalities a wide range of convex constraints arising in theoretical and practical optimization problems. As illustrated below, constraint sets in the form of lower level sets of quasi-convex functions or of fixed point sets of quasi-nonexpansive operators, as found for instance in [4], [10], [11], [12], [29], [34], [35], and [51], are included. Let us also call attention to the fact that (1.2)(ii) implies that $\text{lev}_{\leq 0} g$ is weakly closed for every $g \in \mathcal{G}$.

PROPOSITION 2.2. *Let $g\colon \mathcal{X} \to]-\infty,+\infty]$ be a function such that, for some $w \in \mathcal{X}$, $g(w) \leq 0$. Then $g \in \mathcal{G}$ if one of the conditions below is fulfilled.*

(i) *$\text{lev}_{\leq 0} g$ is convex and g is weakly lower semicontinuous.*

(ii) *g is lower semicontinuous and quasi-convex.*

(iii) *$\text{lev}_{\leq 0} g$ is closed and convex and the constraint "$g(x) \leq 0$" is correct* [37]*:*

$$\left(\forall (y_n)_{n\geq 0} \subset \mathcal{X}\right)\ \overline{\lim}_n\, g(y_n) \leq 0 \Rightarrow \underline{\lim}_n\, d(y_n, \text{lev}_{\leq 0} g) = 0. \tag{2.11}$$

(iv) *$g\colon x \mapsto \|Tx - x\|$ is the displacement function of an operator $T\colon \mathcal{X} \to \mathcal{X}$ whose fixed point set $\text{Fix}\, T \triangleq \{x \in \mathcal{X} \mid Tx = x\}$ is convex and such that $T - \text{Id}$ is demiclosed at the origin:*

$$\left(\forall (y_n)_{n\geq 0} \subset \mathcal{X}\right) \quad \begin{cases} y_n \overset{n}{\rightharpoonup} y \\ Ty_n - y_n \overset{n}{\to} 0 \end{cases} \quad \Rightarrow \quad y \in \text{Fix}\, T. \tag{2.12}$$

These conditions are fulfilled in each of the following cases.

(a) $\mathcal{X}$ *is uniformly convex and* T *is nonexpansive:* $(\forall (x,y)\in\mathcal{X}^2)\ \|Tx-Ty\| \leq \|x-y\|$.

(b) $\operatorname{Fix} T$ *is closed and convex and, for every sequence* $(y_n)_{n\geq 0}\subset\mathcal{X}$, $Ty_n - y_n \stackrel{n}{\to} 0 \Rightarrow \varliminf_n d(y_n, \operatorname{Fix} T) = 0$.

(c) $T-\operatorname{Id}$ *is demiclosed at the origin and there exists* $\eta\in\mathbb{R}_+^*$ *such that*

$$(\forall x\in\mathcal{X})\big(\exists z'\in\Delta(x-Tx)\big)(\forall y\in\operatorname{Fix} T)\quad \langle x-y, z'\rangle \geq \eta\|Tx-x\|^2. \tag{2.13}$$

(d) $\mathcal{X}$ *is a Hilbert space,* $T-\operatorname{Id}$ *is demiclosed at the origin, and* T *is quasi-nonexpansive:*

$$\big(\forall (x,y)\in\mathcal{X}\times\operatorname{Fix} T\big)\quad \|Tx-y\|\leq\|x-y\|. \tag{2.14}$$

(e) $\mathcal{X}$ *is a Hilbert space and* T *is firmly nonexpansive:*

$$\big(\forall (x,y)\in\mathcal{X}^2\big)\quad \|Tx-Ty\|^2 \leq \|x-y\|^2 - \|(T-\operatorname{Id})x-(T-\operatorname{Id})y\|^2. \tag{2.15}$$

Proof. (i) Since g is weakly lower semicontinuous, $y_n \stackrel{n}{\rightharpoonup} y \Rightarrow g(y)\leq \varlimsup_n g(y_n)$. Hence (1.2) (ii) holds. (ii) $\Rightarrow$ (i) is immediate. (iii) Since $\operatorname{lev}_{\leq 0} g$ is convex, $d(\cdot, \operatorname{lev}_{\leq 0} g)$ is convex and Lipschitzian and therefore weakly lower semicontinuous. Accordingly,

$$y_n \stackrel{n}{\rightharpoonup} y \quad\Rightarrow\quad d(y,\operatorname{lev}_{\leq 0} g)\leq \varliminf_n d(y_n, \operatorname{lev}_{\leq 0} g). \tag{2.16}$$

Hence, if we further assume $\varlimsup_n g(y_n)\leq 0$, (2.11) gives $d(y,\operatorname{lev}_{\leq 0} g)=0$; i.e., $g(y)\leq 0$ since $\operatorname{lev}_{\leq 0} g$ is closed. (iv) is immediate. (a) is proved in [24, Lem. 3.4 and Thm. 8.4]. (b) follows from (iii). (c): Let

$$(\forall x\in\mathcal{X})\quad Q_x = \big\{y\in\mathcal{X}\mid \langle x-y, z'\rangle\geq\eta\|Tx-x\|^2\big\} \tag{2.17}$$

(z' being as in (2.13)) and $Q=\bigcap_{x\in\mathcal{X}} Q_x$. Then Q is convex as an intersection of half-spaces. Let us show $\operatorname{Fix} T = Q$. $\operatorname{Fix} T\subset Q$ results at once from (2.13). Conversely, let $x\in Q$. Then $x\in Q_x$ and therefore $0\geq\eta\|Tx-x\|^2$. Thus, $Tx=x$ and, in turn, $Q\subset\operatorname{Fix} T$. (d) $\Rightarrow$ (c): In Hilbert spaces, (2.13) becomes

$$\big(\forall (x,y)\in\mathcal{X}\times\operatorname{Fix} T\big)\quad \langle x-y, x-Tx\rangle\geq\eta\|Tx-x\|^2. \tag{2.18}$$

The identity $2\langle x-y, x-Tx\rangle = \|Tx-x\|^2+\|x-y\|^2-\|Tx-y\|^2$ shows that (2.18) is equivalent to

$$\big(\forall (x,y)\in\mathcal{X}\times\operatorname{Fix} T\big)\quad \|Tx-y\|^2\leq\|x-y\|^2-(2\eta-1)\|Tx-x\|^2, \tag{2.19}$$

which reduces to (2.14) for $\eta=1/2$. (e) $\Rightarrow$ (c): T is nonexpansive and $T-\operatorname{Id}$ is therefore demiclosed by (a). In addition, (2.15) $\Rightarrow$ (2.19) with $\eta=1$. ∎

3. Convergence analysis. This section is devoted to establishing the strong convergence of Algorithm 1.1 under suitable conditions. Our starting point is the following proposition, which collects some basic properties of the algorithm.

PROPOSITION 3.1. *Let* $(x_n)_{n\geq 0}$ *be an arbitrary orbit of Algorithm* 1.1. *Then:*

(i) $(\forall n\in\mathbb{N})\ J(x_n)\leq J(x_{n+1})\leq \overline{J}$.

(ii) $(x_n)_{n\geq 0}\subset C$.

(iii) $\mathfrak{W}(x_n)_{n\geq 0}\neq\varnothing$.

(iv) $(J(x_n))_{n\geq 0}$ *converges and* $\lim_n J(x_n) \leq \overline{J}$.
(v) $(\exists n \in \mathbb{N})\ x_n \in S \quad \Rightarrow \quad (\forall k \in \mathbb{N})\ x_{n+k} = \overline{x}$.
(vi) $\mathfrak{W}(x_n)_{n\geq 0} \subset S \quad \Rightarrow \quad x_n \stackrel{n}{\rightarrow} \overline{x}$.
(vii) $x_{n+1} - x_n \stackrel{n}{\rightarrow} 0$.
(viii) $d(x_n, H_n) \stackrel{n}{\rightarrow} 0$.

Proof. (i) results from the inclusions $(\forall n \in \mathbb{N})D_n \supset Q_n \supset S$. (ii), (iv), and (v) follow from (i). (ii) $\Rightarrow$ (iii): It follows from (A1)–(A2) and the reflexivity of $\mathcal{X}$ that C is weakly compact. (vi): Assume $\mathfrak{W}(x_n)_{n\geq 0} \subset S$ and take $x \in \mathfrak{W}(x_n)_{n\geq 0}$, say $x_{n_k} \stackrel{k}{\rightharpoonup} x$. By virtue of (A1), J is weakly lower semicontinuous and it follows from (iv) that $J(x) \leq \underline{\lim}_k J(x_{n_k}) = \lim_n J(x_n) \leq \overline{J}$. However, $x \in S$ and $\overline{x}$ is the unique solution to (P). Hence, $x = \overline{x}$, $\mathfrak{W}(x_n)_{n\geq 0} = \{\overline{x}\}$, and, since C is weakly compact, (ii) yields $x_n \stackrel{n}{\rightharpoonup} \overline{x}$. Repeating the above argument, we obtain $\overline{J} = J(\overline{x}) \leq \underline{\lim}_n J(x_n)$ and, by (iv), $J(x_n) \stackrel{n}{\rightarrow} \overline{J}$. Since $(x_n + \overline{x})/2 \stackrel{n}{\rightharpoonup} \overline{x}$, the weak lower semicontinuity of J and (1.1) yield

$$\begin{aligned} \overline{J} &\leq \underline{\lim}_n J\left(\frac{x_n + \overline{x}}{2}\right) \\ &\leq \overline{\lim}_n \frac{J(x_n) + \overline{J}}{2} - \overline{\lim}_n c(\|x_n - \overline{x}\|) \\ &= \overline{J} - \overline{\lim}_n c(\|x_n - \overline{x}\|). \end{aligned} \tag{3.1}$$

Hence, $c(\|x_n - \overline{x}\|) \stackrel{n}{\rightarrow} 0$ and, by (A2), $x_n \stackrel{n}{\rightarrow} \overline{x}$. (vii): For every $n \in \mathbb{N}$, $(x_n, x_{n+1}) \in D_n^2$ and therefore $y_n = (x_n + x_{n+1})/2 \in D_n$. Since $x_n = \mathfrak{m}(D_n)$, (1.1) then yields

$$J(x_n) \leq J(y_n) \leq \frac{J(x_n) + J(x_{n+1})}{2} - c(\|x_{n+1} - x_n\|). \tag{3.2}$$

Hence, (iv) implies $c(\|x_{n+1} - x_n\|) \stackrel{n}{\rightarrow} 0$ and, in turn, $x_{n+1} - x_n \stackrel{n}{\rightarrow} 0$. (vii) $\Rightarrow$ (viii): $(\forall n \in \mathbb{N})x_{n+1} \in H_n \Rightarrow \|x_{n+1} - x_n\| \geq d(x_n, H_n)$. ∎

Item (i) above shows that Algorithm 1.1 is an ascent method. On the other hand, item (vi) guarantees the strong convergence of any orbit to the solution of (P) as long as each of its weak cluster points satisfies all the constraints. In view of (1.3), for this condition to hold, the control sequence $(I_n)_{n\geq 0}$ determining the blocks of constraints activated over the course of the iterations must sweep through the index set I in a coherent fashion; three suitable control modes will be considered in Definition 3.1. In addition, the constraint sets $(S_i)_{i\in I}$ must be tightly approximated by the cuts $(H_n)_{n\geq 0}$ in a sense that will be made precise in Definition 3.2.

DEFINITION 3.1. *Algorithm* 1.1 *operates under*

- admissible *control if* I *is countable and there exist positive integers* $(M_i)_{i\in I}$ *such that*

$$\big(\forall (i,n) \in I \times \mathbb{N}\big) \quad i \in \bigcup_{k=n}^{n+M_i-1} I_k; \tag{3.3}$$

- chaotic *control if* I *is countable and*

$$I = \overline{\lim}_n I_n \triangleq \bigcap_{n\geq 0} \bigcup_{k\geq n} I_k; \tag{3.4}$$

- coercive *control if*

$$\left(\exists (\mathrm{i}(n))_{n\geq 0} \in \bigtimes_{n\geq 0} I_n\right) \quad \overline{\lim}_n g_{\mathrm{i}(n)}(x_n) \leq 0 \Rightarrow \overline{\lim}_n \sup_{i\in I} g_i(x_n) \leq 0. \tag{3.5}$$

In addition, Algorithm 1.1 *is* serial *if* $(I_n)_{n\geq 0}$ *reduces to a sequence of singletons* $(\{i(n)\})_{n\geq 0}$. *The above admissibility and coercivity conditions then read*

$$(\forall i \in I)(\exists M_i \in \mathbb{N}^*)(\forall n \in \mathbb{N}) \quad i \in \{\mathrm{i}(n), \ldots, \mathrm{i}(n+M_i-1)\} \tag{3.6}$$

and

$$\overline{\lim}_n g_{\mathrm{i}(n)}(x_n) \leq 0 \Rightarrow \overline{\lim}_n \sup_{i\in I} g_i(x_n) \leq 0, \tag{3.7}$$

respectively.

The coercive control mode is found in [13] with $(\forall i \in I)$ $g_i\colon x \mapsto d(x, S_i)$. The admissible and chaotic control modes have already been used at various levels of generality in convex feasibility problems [4], [10], [13], [34], [42].

DEFINITION 3.2. *Let* $(x_n)_{n\geq 0}$ *be an arbitrary orbit of Algorithm* 1.1. *Then the algorithm will be said to be*

- tight *if, for every* $i \in I$ *and every increasing sequence* $(n_k)_{k\geq 0} \subset \mathbb{N}$ *such that* $i \in \bigcap_{k\geq 0} I_{n_k}$, *we have* $\overline{\lim}_k g_i(x_{n_k}) \leq 0$;
- strongly tight *if* $\overline{\lim}_n \max_{i\in I_n} g_i(x_n) \leq 0$.

It is clear that strong tightness implies tightness. We show below that, when I is finite, the distinction between the two notions disappears.

PROPOSITION 3.2. *Suppose that* I *is finite. Then Algorithm* 1.1 *is tight if and only if it is strongly tight.*

Proof. To show necessity, take an arbitrary orbit $(x_n)_{n\geq 0}$ and suppose that the algorithm is not strongly tight, i.e., that $\epsilon \triangleq \overline{\lim}_n \max_{i\in I_n} g_i(x_n) > 0$. Define a sequence $(\mathrm{i}(n))_{n\geq 0} \subset I$ by $(\forall n \in \mathbb{N})$ $g_{\mathrm{i}(n)}(x_n) = \max_{i\in I_n} g_i(x_n)$. Then, since I is finite, there exists an index $i \in I$ and an increasing sequence $(n_k)_{k\geq 0} \subset \mathbb{N}$ such that $(\forall k \in \mathbb{N})$ $\mathrm{i}(n_k) = i$ and $g_i(x_{n_k}) \stackrel{k}{\to} \epsilon$, in contradiction of the tightness assumption. □

We are now ready to state and prove the following strong convergence result.

THEOREM 3.1. *Let* $(x_n)_{n\geq 0}$ *be an arbitrary orbit of Algorithm* 1.1 *generated under either of the following conditions:*

(i) *tightness, I countable, and admissible control;*

(ii) *strong tightness and coercive control.*

Then $x_n \stackrel{n}{\to} \overline{x}$.

Proof. By virtue of Proposition 3.1(vi), it suffices to show $\mathfrak{W}(x_n)_{n\geq 0} \subset S$. Fix arbitrarily $i \in I$ and $x \in \mathfrak{W}(x_n)_{n\geq 0}$, say $x_{n_k} \stackrel{k}{\to} x$. Then it is enough to show $x \in S_i$, i.e., that $g_i(x) \leq 0$. (i): By (3.3), there exist $M_i \in \mathbb{N}^*$ and an increasing sequence $(p_k)_{k\geq 0} \subset \mathbb{N}$ such that

$$(\forall k \in \mathbb{N}) \quad n_k \leq p_k \leq n_k + M_i - 1 \qquad \text{and} \qquad i \in I_{p_k}. \tag{3.8}$$

Hence

$$(\forall k \in \mathbb{N}) \quad \|x_{p_k} - x_{n_k}\| \leq \sum_{l=n_k}^{n_k+M_i-2} \|x_{l+1} - x_l\| \tag{3.9}$$

and Proposition 3.1(vii) yields $x_{p_k} - x_{n_k} \xrightarrow{k} 0$. Consequently, $x_{p_k} \xrightarrow{k} x$. On the other hand, the tightness condition gives $\overline{\lim}_k g_i(x_{p_k}) \leq 0$ and (A3) then yields $g_i(x) \leq 0$, as desired. (ii): The strong tightness condition gives $\overline{\lim}_n \max_{j\in I_n} g_j(x_n) \leq 0$. However, since the control is coercive, we obtain

$$\begin{aligned} \overline{\lim}_n \max_{j\in I_n} g_j(x_n) \leq 0 &\Rightarrow \overline{\lim}_n g_{\mathrm{i}(n)}(x_n) \leq 0 \\ &\Rightarrow \overline{\lim}_n \sup_{j\in I} g_j(x_n) \leq 0 \\ &\Rightarrow \overline{\lim}_k g_i(x_{n_k}) \leq 0, \end{aligned} \tag{3.10}$$

where the sequence $(\mathrm{i}(n))_{n\geq 0}$ is as in (3.5). It then follows from (A3) that $g_i(x) \leq 0$, which completes the proof. □

We conclude this section by supplying a theoretical condition under which Theorem 3.1(i) can be extended to the chaotic control mode (3.4).

PROPOSITION 3.3. *Suppose that Algorithm* 1.1 *is tight and that I is countable, and let $(x_n)_{n\geq 0}$ be any of its orbits generated under chaotic control. Then, if $(x_n)_{n\geq 0}$ admits at most one weak cluster point, $x_n \xrightarrow{n} \overline{x}$.*

Proof. It follows from Proposition 3.1(ii) and the weak compactness of C that if $(x_n)_{n\geq 0}$ admits at most one weak cluster point, then it converges weakly, say $x_n \xrightarrow{n} x$. Now, fix $i \in I$ arbitrarily. According to Proposition 3.1(vi), it remains to show $g_i(x) \leq 0$. By condition (3.4), there exists an increasing sequence $(n_k)_{k\geq 0} \subset \mathbb{N}$ such that $i \in \bigcap_{k\geq 0} I_{n_k}$. In turn, tightness implies $\overline{\lim}_k g_i(x_{n_k}) \leq 0$ and, since $x_{n_k} \xrightarrow{k} x$, (A3) yields $g_i(x) \leq 0$. □

The execution of iteration n of Algorithm 1.1 necessitates the construction of a cut H_n at Step 1 and of a base D_{n+1} at Step 3 (see Definition 1.1). This question is addressed in the next two sections.

4. Cut construction schemes. In this section, we describe two techniques to construct cuts for Algorithm 1.1 and provide examples of families of constraint functions $(g_i)_{i\in I}$ that yield tight and strongly tight algorithms in each case.

4.1. Exact-constraint cuts. Here, Algorithm 1.1 is assumed to operate under serial control, say $(\forall n \in \mathbb{N})\ I_n = \{\mathrm{i}(n)\}$. In view of Definition 1.1, the following observation is self-evident.

PROPOSITION 4.1. *The set $H_n = S_{i(n)}$ is a cut for Algorithm* 1.1 *at iteration n.*

When it operates under serial control with cuts generated as above, Algorithm 1.1 will be said to be implemented with *exact-constraint cuts*. We now proceed with some examples of families $(g_i)_{i\in I}$ that yield tight and strongly tight algorithms (see also Proposition 3.2). In Propositions 4.2 and 4.3, γ is the diameter of C in (A2) and $Q = B(u, 2\gamma)$.

PROPOSITION 4.2. *Algorithm* 1.1 *with exact-constraint cuts is tight if, for every $i \in I$, one of the following conditions holds.*

(i) *g_i is uniformly continuous on Q.*
(ii) *g_i is weakly continuous on Q.*
(iii) *$\mathcal{X} = \mathbb{R}^N$ and g_i is finite and convex.*
(iv) *g_i is the displacement function of an operator $T_i\colon \mathcal{X} \to \mathcal{X}$ which satisfies condition* (c) *(in particular* (d) *or* (e)*) in Proposition* 2.2(iv) *with constant $\eta_i \in \mathbb{R}_+^*$.*

Proof. Given an arbitrary orbit $(x_n)_{n\geq 0}$, Propositions 3.1(viii) and 4.1 give $d(x_n, S_{\mathrm{i}(n)}) \xrightarrow{n} 0$. Now take an index $i \in I$ and an increasing sequence $(n_k)_{k\geq 0} \subset \mathbb{N}$

such that, for every $k \in \mathbb{N}$, $i = \underline{\mathrm{i}}(n_k)$. Then $d(x_{n_k}, S_i) \stackrel{k}{\to} 0$ and, in view of Definition 3.2, it must be proved that $\overline{\lim}_k g_i(x_{n_k}) \leq 0$. (i) is similar to Proposition 4.3(i) and thus is omitted. (ii) $\Rightarrow$ (i) follows from the weak compactness of Q. (iii) $\Rightarrow$ (i): g_i is Lipschitzian on Q by [46, Thm. 10.4]. (iv): For every $k \in \mathbb{N}$, let $p_{i,k}$ be a projection of x_{n_k} onto S_i and suppose that (c) in Proposition 2.2(iv) holds with constant $\eta_i \in \mathbb{R}_+^*$. Then, there exists $z'_k \in \Delta(x_{n_k} - T_i x_{n_k})$ such that $\|T_i x_{n_k} - x_{n_k}\|^2 \leq \eta_i^{-1} \langle x_{n_k} - p_{i,k}, z'_k \rangle$. Consequently, $\|T_i x_{n_k} - x_{n_k}\|^2 \leq \eta_i^{-1} \|x_{n_k} - p_{i,k}\| \cdot \|z'_k\| = \eta_i^{-1} d(x_{n_k}, S_i) \cdot \|T_i x_{n_k} - x_{n_k}\|$ and we conclude $g_i(x_{n_k}) \leq \eta_i^{-1} d(x_{n_k}, S_i)$. □

PROPOSITION 4.3. *Algorithm* 1.1 *with exact-constraint cuts is strongly tight if one of the following conditions holds.*

(i) $(g_i)_{i \in I}$ *is uniformly equicontinuous on* Q.
(ii) $(g_i)_{i \in I}$ *is weakly equicontinuous on* Q*: For every* $(x, \epsilon) \in Q \times \mathbb{R}_+^*$*, there exists a weak neighborhood* V *of* x *such that* $(\forall y \in V)(\forall i \in I)\ |g_i(x) - g_i(y)| \leq \epsilon$.
(iii) $(g_i)_{i \in I}$ *is a family of affine functions associated with a family of pointwise bounded continuous linear functions.*
(iv) $\mathcal{X} = \mathbb{R}^N$ *and* $(g_i)_{i \in I}$ *is a family of pointwise bounded convex functions.*
(v) $(g_i)_{i \in I}$ *is a family of displacement functions of operators* $(T_i)_{i \in I}$ *as in Proposition* 4.2(iv) *with* $\eta \triangleq \inf_{i \in I} \eta_i > 0$ *(in particular, each* T_i *satisfies condition* (d) *or* (e) *in Proposition* 2.2(iv)*).*

Proof. Take an arbitrary orbit $(x_n)_{n \geq 0}$. Then, as above, $d(x_n, S_{\mathrm{i}(n)}) \stackrel{n}{\to} 0$ and, in view of Definition 3.2, it must be proved that $\overline{\lim}_n g_{\mathrm{i}(n)}(x_n) \leq 0$. (i): Fix $\epsilon \in \mathbb{R}_+^*$, extract a subsequence $(x_{n_k})_{k \geq 0}$ such that $(g_{\mathrm{i}(n_k)}(x_{n_k}))_{k \geq 0} \subset]0, +\infty]$ (if no such subsequence exists, the proof is complete), and let p_k be a projection of x_{n_k} onto $S_{\mathrm{i}(n_k)}$. Since $u \in S_{\mathrm{i}(n_k)}$ and $(x_{n_k}, u) \in C^2$, we have

$$\|p_k - u\| \leq \|x_{n_k} - u\| + \|x_{n_k} - p_k\| \leq 2\|x_{n_k} - u\| \leq 2\gamma \tag{4.1}$$

and, in turn, $p_k \in B(u, 2\gamma) = Q$. Next, as $x_{n_k} - p_k \stackrel{k}{\to} 0$ and $((x_{n_k}, p_k))_{k \geq 0} \subset Q^2$, the uniform equicontinuity of $(g_i)_{i \in I}$ on Q gives, for k sufficiently large, $\sup_{i \in I} |g_i(x_{n_k}) - g_i(p_k)| \leq \epsilon$ and, therefore, $0 < g_{\mathrm{i}(n_k)}(x_{n_k}) \leq \epsilon$. Since ϵ can be arbitrarily small, strong tightness ensues. (ii) $\Rightarrow$ (i) follows from the weak compactness of Q. (iii) $\Rightarrow$ (i): $(\forall i \in I) g_i \colon x \mapsto \langle x, z'_i \rangle + \alpha_i$, where $(z'_i, \alpha_i) \in \mathcal{X}' \times \mathbb{R}$ and $(\forall x \in \mathcal{X}) \sup_{i \in I} |\langle x, z'_i \rangle| < +\infty$. The uniform boundedness principle [1, Thm. 1.1.4] asserts that $\zeta \triangleq \sup_{i \in I} \|z'_i\| < +\infty$ and, therefore, that $(g_i)_{i \in I}$ is equi-Lipschitzian with constant ζ. (iv) $\Rightarrow$ (i): $(g_i)_{i \in I}$ is equi-Lipschitzian on Q by [46, Th. 10.6]. (v): Following the proof of Proposition 4.2(iv), we obtain $(\forall n \in \mathbb{N})\ g_{\mathrm{i}(n)}(x_n) \leq \eta^{-1} d(x_n, S_{\mathrm{i}(n)})$. □

It should be remarked that in Hilbert spaces, projectors are nonexpansive [24, Chap. 12]. Accordingly, the inequalities $\|p_k - u\| \leq \|x_{n_k} - u\| \leq \gamma$ can be used in lieu of (4.1), and one can take $Q = B(u, \gamma)$ in Propositions 4.2 and 4.3.

Next, we recover the framework proposed by Laurent and Martinet in [35].

EXAMPLE 4.1. *Under the strong tightness condition, Algorithm* 1.1 *implemented with coercive control and exact-constraint cuts contains the setting of* [35]. *There,* (P) *is investigated under assumptions* (A1)–(A2) *with* $E = \mathcal{X}$ *and the special instance of* (A3) *when the functions* $(g_i)_{i \in I}$ *are lower semicontinuous, convex, and satisfy the condition*

$$(\exists \Omega \in \mathbb{R}_+^*)\big(\forall (x, i) \in C \times I\big) \quad g_i(x) \leq \Omega d(x, S_i). \tag{4.2}$$

Furthermore, the serial control rule

$$(\forall n \in \mathbb{N})\ g_{\mathrm{i}(n)}(x_n) \geq \theta \sup_{i \in I} g_i(x_n) - \rho_n, \quad \text{where } 0 < \theta \leq 1 \text{ and } 0 \leq \rho_n \overset{n}{\to} 0 \tag{4.3}$$

is in force. Since $d(x_n, S_{\mathrm{i}(n)}) \overset{n}{\to} 0$, (4.2) $\Rightarrow \overline{\lim}_n g_{\mathrm{i}(n)}(x_n) \leq 0$, *which shows strong tightness. On the other hand, since* (4.3) $\Rightarrow$ (3.7), *the control is coercive. Hence,* [35, Thm. 1] *is a corollary of Theorem* 3.1(ii).

4.2. Surrogate cuts. In this section, the cut H_n at iteration n is constructed as a surrogate half-space (this terminology appears in [23]). The basic idea is, for every $i \in I_n$, to "linearize" g_i by approximating it by a continuous affine function $g_{i,n}$ (determined here geometrically via a projection onto a simple superset of S_i). A surrogate function $\widetilde{g}_n$ is then formed as a convex combination of the family $(g_{i,n})_{i \in I_n}$, and the cut is defined as $H_n = \mathrm{lev}_{\leq \gamma_n} \widetilde{g}_n$ for some $\gamma_n \in \mathbb{R}_+$. We formally define *surrogate cuts* as follows.

PROPOSITION 4.4. *Fix* $(\delta, \varepsilon) \in]0,1[^2$ *and let*

$$H_n = \left\{ x \in \mathcal{X} \mid \sum_{i \in I_n} w_{i,n} \langle x - p_{i,n}, q'_{i,n} \rangle \leq \gamma_n \right\}, \tag{4.4}$$

where the following conditions hold.

(C1) *For every* $i \in I_n$, $p_{i,n}$ *is a projection of* x_n *onto a set* $S_{i,n} \in \mathfrak{C}(S_i)$ *and* $q'_{i,n} \in \Delta(x_n - p_{i,n})$ *satisfies*

$$(\forall x \in S_{i,n}) \quad \langle x - p_{i,n}, q'_{i,n} \rangle \leq 0. \tag{4.5}$$

(C2) $(w_{i,n})_{i \in I_n} \subset [0,1]$, $\sum_{i \in I_n} w_{i,n} = 1$, *and*

$$(\exists j \in I_n) \quad \begin{cases} d(x_n, S_{j,n}) = \max\limits_{i \in I_n} d(x_n, S_{i,n}), \\ w_{j,n} \geq \delta. \end{cases}$$

(C3) $0 \leq \gamma_n \leq (1 - \varepsilon) \sum_{i \in I_n} w_{i,n} d(x_n, S_{i,n})^2$.

Then H_n *is a cut for Algorithm* 1.1 *at iteration* n.

Proof. Let us show that (1.3) holds. First, it is clear that H_n is closed and convex. Second, (C1) yields $S_i \subset S_{i,n} \subset \{x \in \mathcal{X} \mid \langle x - p_{i,n}, q'_{i,n} \rangle \leq 0\}$ for every $i \in I_n$. Hence, by virtue of (C2) and (C3), $H_n \in \mathfrak{C}(\bigcap_{i \in I_n} S_i)$. □

The existence of $(q'_{i,n})_{i \in I_n}$ in (C1) is guaranteed by (2.4), while (2.1) yields

$$(\forall i \in I_n) \quad \|q'_{i,n}\|^2 = d(x_n, S_{i,n})^2 = \langle x_n - p_{i,n}, q'_{i,n} \rangle. \tag{4.6}$$

On the other hand, $(p_{i,n})_{i \in I_n}$ and $(q'_{i,n})_{i \in I_n}$ are uniquely defined if $\mathcal{X}$ and $\mathcal{X}'$ are strictly convex, respectively [1]. In particular, if $\mathcal{X}$ is a Hilbert space, one can identify $q'_{i,n} = x_n - p_{i,n}$ hereafter, and (4.4) becomes

$$H_n = \left\{ x \in \mathcal{X} \mid \sum_{i \in I_n} w_{i,n} \langle x - p_{i,n}, x_n - p_{i,n} \rangle \leq \gamma_n \right\}. \tag{4.7}$$

Surrogate half-spaces have already been used—explicitly or implicitly—for solving convex feasibility problems in Hilbert spaces. Thus, in the methods of [10], [12], [13], [22], [32], [34], [40], [42], [45], the update x_{n+1} is obtained by (under/over) projecting the current iterate x_n onto a half-space whose general form is (4.7). This point will be reexamined in section 7.2.

An important feature of Algorithm 1.1 with surrogate cuts is that it does not require the ability to enforce exactly a constraint "$g_i(x) \leq 0$" selected at Step 1 but merely the ability to move the current iterate x_n toward S_i by means of a projection onto a superset $S_{i,n}$. A wide range of approximating supersets are acceptable, and the construction of $S_{i,n}$ can be adapted to the nature of the function g_i. In the two examples below, $S_{i,n}$ is constructed as an affine half-space and the expressions for $p_{i,n}$, $q'_{i,n}$, and $d(x_n, S_{i,n})$ are derived from the following facts.

LEMMA 4.1 (see [48, Lem. I.1.2]). *Given a nonzero functional $z' \in \mathcal{X}'$ and $\alpha \in \mathbb{R}$, consider the closed affine half-space $A = \{y \in \mathcal{X} \mid \langle y, z' \rangle \leq \alpha\}$. Take $x \notin A$ and let $p = x + (\alpha - \langle x, z' \rangle)z/\|z'\|^2$, where $z \in \Delta^{-1}(z')$. Then $d(x, A) = (\langle x, z' \rangle - \alpha)/\|z'\|$ and p is a projection of x onto A.*

EXAMPLE 4.2. *The function g_i is convex and lower semicontinuous, and subdifferentiable on C. Then, given $t'_{i,n} \in \partial g_i(x_n)$, the function $x \mapsto \langle x - x_n, t'_{i,n} \rangle + g_i(x_n)$ minorizes g_i by* (2.2). *Thus*

$$S_{i,n} = \{x \in \mathcal{X} \mid \langle x_n - x, t'_{i,n} \rangle \geq g_i(x_n)\} \tag{4.8}$$

lies in $\mathfrak{C}(S_i)$. If $x_n \notin S_i$, then $p_{i,n} = x_n - g_i(x_n)t_{i,n}/\|t'_{i,n}\|^2$, $q'_{i,n} = g_i(x_n)t'_{i,n}/\|t'_{i,n}\|^2$, and $d(x_n, S_{i,n}) = g_i(x_n)/\|t'_{i,n}\|$, where $t_{i,n} \in \Delta^{-1}(t'_{i,n})$.

Approximations of type (4.8) go back to [31] and have been used extensively; see, e.g., [4], [12], [29], [32], [34].

EXAMPLE 4.3. *The function g_i is the displacement function of an operator T_i as in Proposition* 2.2(iv)(c) *with constant $\eta_i \in \mathbb{R}_+^*$. Hence $S_i = \operatorname{Fix} T_i$ and, for some $z'_{i,n} \in \Delta(x_n - T_i x_n)$, we have $\langle x_n - x, z'_{i,n} \rangle \geq \eta_i \|T_i x_n - x_n\|^2$ for every $x \in S_i$. Therefore*

$$S_{i,n} = \big\{x \in \mathcal{X} \mid \langle x - x_n - \eta_i(T_i x_n - x_n), z'_{i,n} \rangle \leq 0\big\} \tag{4.9}$$

lies in $\mathfrak{C}(S_i)$. Furthermore, $p_{i,n} = x_n + \eta_i(T_i x_n - x_n)$, $q'_{i,n} = \eta_i z'_{i,n}$, and $d(x_n, S_{i,n}) = \eta_i \|T_i x_n - x_n\|$.

Further examples can be derived from Example 4.3 by considering the special cases (d) or (e) of (c) in Proposition 2.2(iv). For instance, if $\mathcal{X}$ is a Hilbert space and T_i is firmly nonexpansive, (4.9) reads as

$$S_{i,n} = \{x \in \mathcal{X} \mid \langle x - T_i x_n, x_n - T_i x_n \rangle \leq 0\}. \tag{4.10}$$

This particular approximation appears implicitly in [4] and [10], and explicitly in [34].

We preface our study of the tightness of Algorithm 1.1 with surrogate cuts with two basic facts.

PROPOSITION 4.5. $(\forall n \in \mathbb{N})\ \sum_{i\in I_n} w_{i,n}q'_{i,n} = 0 \Leftrightarrow x_n \in \bigcap_{i\in I_n} S_{i,n} \Leftrightarrow x_n \in H_n$.

Proof. Fix $(n,x) \in \mathbb{N}\times S$. Then (C2), (4.6), and (4.5) imply

$$\begin{aligned}\delta \max_{i\in I_n} d(x_n,S_{i,n})^2 &\le \sum_{i\in I_n} w_{i,n} d(x_n,S_{i,n})^2 = \sum_{i\in I_n} w_{i,n}\langle x_n - p_{i,n}, q'_{i,n}\rangle \\ &= \sum_{i\in I_n} w_{i,n}\langle x_n - x, q'_{i,n}\rangle + \sum_{i\in I_n} w_{i,n}\langle x - p_{i,n}, q'_{i,n}\rangle \\ &\le \left\langle x_n - x, \sum_{i\in I_n} w_{i,n}q'_{i,n}\right\rangle. \qquad (4.11)\end{aligned}$$

Hence, $\sum_{i\in I_n} w_{i,n}q'_{i,n} = 0 \Rightarrow \max_{i\in I_n} d(x_n,S_{i,n})^2 = 0 \Rightarrow x_n \in \bigcap_{i\in I_n} S_{i,n}$. The three other implications are easily obtained. □

PROPOSITION 4.6. $\max_{i\in I_n} d(x_n,S_{i,n}) \overset{n}{\to} 0$.

Proof. Fix $n \in \mathbb{N}$ and suppose $x_n \notin \bigcap_{i\in I_n} S_{i,n}$. Then Proposition 4.5, the convexity of $\|\cdot\|$, (C2), and (4.6) yield $0 \neq \|\sum_{i\in I_n} w_{i,n}q'_{i,n}\| \le \sum_{i\in I_n} w_{i,n}\|q'_{i,n}\| \le \max_{i\in I_n} d(x_n,S_{i,n})$. Consequently, we derive from (4.4), Lemma 4.1, (4.6), and (4.11) that

$$\begin{aligned} d(x_n,H_n) &= \frac{\sum_{i\in I_n} w_{i,n}\langle x_n - p_{i,n}, q'_{i,n}\rangle - \gamma_n}{\|\sum_{i\in I_n} w_{i,n}q'_{i,n}\|} \\ &\ge \varepsilon \frac{\sum_{i\in I_n} w_{i,n} d(x_n,S_{i,n})^2}{\max_{i\in I_n} d(x_n,S_{i,n})} \\ &\ge \delta\varepsilon \max_{i\in I_n} d(x_n,S_{i,n}). \qquad (4.12)\end{aligned}$$

On the other hand, if $x_n \in \bigcap_{i\in I_n} S_{i,n}$, then (4.12) is immediate. Since $d(x_n,H_n) \overset{n}{\to} 0$ by Proposition 3.1(viii), the assertion is proved. □

We observe in passing that when Algorithm 1.1 is implemented with surrogate cuts and satisfies the tightness condition then, for every index $i \in I$ and every suborbit $(x_{n_k})_{k\ge 0}$ such that $i \in \bigcap_{k\ge 0} I_{n_k}$, it follows from Proposition 4.6 that $d(x_{n_k},S_{i,n_k}) \overset{k}{\to} 0$ and from (A3) that $x_{n_k} \overset{k}{\to} x \Rightarrow x \in S_i$. This is essentially the *focusing* property introduced in [4].

We wind up this section by furnishing convenient criteria for tightness and strong tightness.

PROPOSITION 4.7. *Algorithm* 1.1 *with surrogate cuts is tight if, for every* $i \in I$ *and every suborbit* $(x_{n_k})_{k\ge 0}$ *such that* $i \in \bigcap_{k\ge 0} I_{n_k}$, *one of the following conditions is fulfilled.*

(i) *It holds that*

$$d\big(x_{n_k},S_{i,n_k}\big) \overset{k}{\to} 0 \quad \Rightarrow \quad d\big(x_{n_k},S_i\big) \overset{k}{\to} 0 \qquad (4.13)$$

and any of conditions (i)–(iii) *in Proposition* 4.2 *is satisfied.*

(ii) g_i *is as in Example* 4.2 *with the additional assumption that its subdifferential is bounded on* C, *i.e., that*

$$\big(\exists \zeta_i \in \mathbb{R}_+^*\big)(\forall x \in C) \quad \partial g_i(x) \subset B(0,\zeta_i), \qquad (4.14)$$

and the sets $(S_{i,n_k})_{k\ge 0}$ *are as in* (4.8).

(iii) *g_i is as in Example* 4.3 *and the sets $(S_{i,n_k})_{k\geq 0}$ are as in* (4.9).

Proof. Take an arbitrary orbit $(x_n)_{n\geq 0}$. Proposition 4.6 asserts that $\max_{i\in I_n} d(x_n, S_{i,n}) \stackrel{n}{\to} 0$. Hence, given $i \in I$ and an increasing sequence $(n_k)_{k\geq 0} \subset \mathbb{N}$ such that $i \in \bigcap_{k\geq 0} I_{n_k}$, we have $d(x_{n_k}, S_{i,n_k}) \stackrel{k}{\to} 0$ and must show $\overline{\lim}_k g_i(x_{n_k}) \leq 0$. (i): (4.13) yields $d(x_{n_k}, S_i) \stackrel{k}{\to} 0$. However, under condition (i) (and in particular condition (ii) or (iii)) of Proposition 4.2, $d(x_{n_k}, S_i) \stackrel{k}{\to} 0 \Rightarrow \overline{\lim}_k g_i(x_{n_k}) \leq 0$. (ii): $(\forall k \in \mathbb{N}) \max\{0, g_i(x_{n_k})\} = \|t'_{i,n_k}\| \cdot d(x_{n_k}, S_{i,n_k}) \leq \zeta_i d(x_{n_k}, S_{i,n_k})$ by (4.14). (iii): $(\forall k \in \mathbb{N})\ g_i(x_{n_k}) = \|T_i x_{n_k} - x_{n_k}\| = \eta_i^{-1} d(x_{n_k}, S_{i,n_k})$. □

PROPOSITION 4.8. *Algorithm* 1.1 *with surrogate cuts is strongly tight if one of the following conditions holds.*

(i) *For any of its orbits $(x_n)_{n\geq 0}$, we have*

$$\max_{i\in I_n} d(x_n, S_{i,n}) \stackrel{n}{\to} 0 \quad \Rightarrow \quad \max_{i\in I_n} d(x_n, S_i) \stackrel{n}{\to} 0, \tag{4.15}$$

and any of conditions (i)–(iv) *in Proposition* 4.3 *is satisfied.*

(ii) *$(g_i)_{i\in I}$ is as in Example* 4.2 *with the additional assumption that the subdifferentials are equibounded on C, i.e., that*

$$\big(\exists \zeta \in \mathbb{R}_+^*\big)(\forall i \in I)(\forall x \in C) \quad \partial g_i(x) \subset B(0, \zeta), \tag{4.16}$$

and the sets $((S_{i,n})_{i\in I_n})_{n\geq 0}$ are as in (4.8).

(iii) *$(g_i)_{i\in I}$ is as in Example* 4.3*, with the additional assumption that $\eta \triangleq \inf_{i\in I} \eta_i > 0$, and the sets $((S_{i,n})_{i\in I_n})_{n\geq 0}$ are as in* (4.9).

Proof. Take an arbitrary orbit $(x_n)_{n\geq 0}$. Then Proposition 4.6 entails $\max_{i\in I_n} d(x_n, S_{i,n}) \stackrel{n}{\to} 0$. Let us show $\overline{\lim}_n \max_{i\in I_n} g_i(x_n) \leq 0$. (i): Define a sequence $(\mathrm{i}(n))_{n\geq 0} \subset I$ by $(\forall n \in \mathbb{N})\ g_{\mathrm{i}(n)}(x_n) = \max_{i\in I_n} g_i(x_n)$. Then (4.15) $\Rightarrow d(x_n, S_{\mathrm{i}(n)}) \stackrel{n}{\to} 0$. However, under condition (i) (and in particular any of conditions (ii)–(iv)) of Proposition 4.3, $d(x_n, S_{\mathrm{i}(n)}) \stackrel{n}{\to} 0 \Rightarrow \overline{\lim}_n g_{\mathrm{i}(n)}(x_n) \leq 0$, as desired. (ii) and (iii): Fix $n \in \mathbb{N}$. Following the proof of Proposition 4.7(ii) and (iii), we obtain, respectively, $\max_{i\in I_n} g_i(x_n) \leq \zeta \max_{i\in I_n} d(x_n, S_{i,n})$ and $\max_{i\in I_n} g_i(x_n) = \max_{i\in I_n} \|T_i x_n - x_n\| \leq \eta^{-1} \max_{i\in I_n} d(x_n, S_{i,n})$. □

It is readily noted that (4.13) and (4.15) are satisfied in particular when exact projections onto the constraint sets are used instead of projections onto approximating supersets.

4.3. Comments. When compared with exact-constraint cuts, surrogate cuts display three advantages. First, they yield versatile block-iterative algorithms that offer great latitude in the selection of the constraints retained at each iteration. Since the pairs $(p_{i,n}, q'_{i,n})_{i\in I_n}$ can be computed simultaneously prior to their aggregation in (4.4), surrogate cuts therefore allow for flexible parallel implementations that can fully take advantage of multiprocessor systems. Second, the processing of a constraint does not require its exact enforcement. Rather, each constraint can be "linearized" by means of a projection onto an outer approximation to the corresponding constraint set. This procedure, illustrated in Examples 4.2 and 4.3, significantly lightens the computational burden of the algorithm when nonaffine constraints are present. Third, surrogate cuts are capable of producing deep cuts, as reported in various theoretical and numerical studies, e.g., [11], [12], [32], [44], [45]. In this connection, the problem of finding optimal weights $(w_{i,n})_{i\in I_n}$ in terms of maximizing $d(x_n, H_n)$ is addressed in [32] and [33].

5. Base construction schemes. Two approaches to the construction of bases for Algorithm 1.1 are described in this section.

5.1. Cumulative bases. Steps 2 and 3 of Algorithm 1.1 suggest an obvious candidate for a base at iteration n, namely, $D_{n+1} = Q_n = E \cap D_n \cap H_n$. This base can be rewritten as

$$D_{n+1} = E \cap \bigcap_{k=0}^{n} H_k. \tag{5.1}$$

In other words, the current base is the intersection of the initial base E with all the previous cuts. This principle is the basis for the cutting plane methods originally proposed in [8] and [31], and reconsidered from a more general viewpoint in [37]. As noted in section 1, a drawback of (5.1) is that the number of cuts accumulated to define the bases grows rapidly as the iterations proceed. In the next proposition, it is pointed out that in the present framework this phenomenon can be mitigated by discarding all the cuts that are inactive at iteration n in the construction of the subsequent bases $(D_{n+k})_{k\geq 1}$.

PROPOSITION 5.1. *Let* $\mathbb{K}_{-1} = \emptyset$ *and, for every* $n \in \mathbb{N}$, $\mathbb{A}_n = \{k \in \mathbb{K}_{n-1} \cup \{n\} \mid x_{n+1} \in \operatorname{bd} H_k\}$. *Then the set*

$$D_{n+1} = E \cap \bigcap_{k\in\mathbb{K}_n} H_k, \quad \text{where } \mathbb{A}_n \subset \mathbb{K}_n \subset \mathbb{K}_{n-1} \cup \{n\} \tag{5.2}$$

is a base for Algorithm 1.1 *at iteration* n.

Proof. We need to check that (1.4) holds for D_{n+1} as in (5.2). First, as $E \in \mathfrak{C}(S)$ and, by (1.3), $(H_k)_{k\in\mathbb{K}_n} \subset \mathfrak{C}(S)$, (5.2) implies $D_{n+1} \in \mathfrak{C}(S)$. Next, to show $x_{n+1} = \mathfrak{m}(D_{n+1})$, note that $x_{n+1} = \mathfrak{m}(Q_n)$ and $Q_n = E \cap D_n \cap H_n = E \cap \bigcap_{k\in\mathbb{K}_{n-1}\cup\{n\}} H_k = D_{n+1} \cap B_n$, where $B_n = \bigcap_{k\in(\mathbb{K}_{n-1}\cup\{n\})\smallsetminus\mathbb{K}_n} H_k$. However, it follows from the definition of $\mathbb{A}_n$ and the inclusion $\mathbb{A}_n \subset \mathbb{K}_n$ that $x_{n+1} \in B_n^\circ$ and therefore that B_n is inactive at x_{n+1}. Accordingly, $x_{n+1} = \mathfrak{m}(D_{n+1} \cap B_n) = \mathfrak{m}(D_{n+1})$. The proof is complete. ∎

In particular, if at every iteration $\mathbb{K}_n = \mathbb{K}_{n-1} \cup \{n\}$, then all the cuts are retained and (5.2) relapses to (5.1). At the other end of the spectrum, the simplest bases are obtained by discarding all the inactive cuts, i.e., by taking $\mathbb{K}_n = \mathbb{A}_n$ at every iteration.

5.2. Instantaneous bases. The construction of D_{n+1} described here was first proposed for quadratic forms in Hilbert spaces by Haugazeau in [26] and extended to the present setting in [35].

PROPOSITION 5.2. *Suppose that:*

(A4) *There exists a point* $v \in S \cap \operatorname{dom} J$ *at which* J *is continuous.*

Then, given $t'_{n+1} \in \partial J(x_{n+1})$ *such that* $(\forall x \in Q_n)\langle x_{n+1} - x, t'_{n+1}\rangle \leq 0$, *the set*

$$D_{n+1} = \big\{x \in \mathcal{X} \mid \langle x_{n+1} - x, t'_{n+1}\rangle \leq 0\big\} \tag{5.3}$$

is a base for Algorithm 1.1 *at iteration* n.

Proof. Since $S \subset Q_n$, (A4) asserts that J is continuous at $v \in Q_n \cap \operatorname{dom} J$, whence, as $x_{n+1} = \mathfrak{m}(Q_n)$, the existence of t'_{n+1} is guaranteed by (2.3). Moreover, the inclusion $Q_n \subset D_{n+1}$ shows that $D_{n+1} \in \mathfrak{C}(S)$. Finally, for $A = D_{n+1}$, (2.3) yields $x_{n+1} = \mathfrak{m}(D_{n+1})$. We have thus established (1.4). ∎

If t'_{n+1} is the zero functional (which may happen only when $x_{n+1} = \mathfrak{m}(\mathcal{X})$), then $D_{n+1} = \mathcal{X}$. On the other hand, if the Gâteaux-derivative, $\nabla J(x_{n+1})$, of J at x_{n+1} exists, then

$$D_{n+1} = \{x \in \mathcal{X} \mid \langle x_{n+1} - x, \nabla J(x_{n+1})\rangle \leq 0\}. \tag{5.4}$$

5.3. Comments. An advantage of cumulative bases is their wide applicability. However, they lead to increasingly complex outer approximations as the algorithm progresses. A partial remedy to this situation is to systematically discard all the inactive cuts. One should, however, beware of its potential side-effect, namely, slower convergence. By contrast, instantaneous bases are very attractive, for they take the form of half-spaces under the relatively mild assumption (A4). Their efficacy can, however, be limited by the search for an acceptable subgradient in (5.3). Of course, this limitation vanishes altogether when J is Gâteaux-differentiable on C, the base being then explicitly given by (5.4).

6. Examples. The analysis of the preceding sections gives rise to four general realizations of Algorithm 1.1 according to whether one selects, on the one hand, exact-constraint or surrogate cuts and, on the other hand, cumulative or instantaneous bases. In this section, these four realizations are presented and the theorems stating their strong convergence to the solution $\overline{x}$ of (P) under the standing assumptions (A1)–(A3) are given. A variety of outer approximation methods are exhibited as special cases and their convergence is deduced from the main theorems. Although we have restricted ourselves to known methods, it is clear that further convergence results can be generated by considering alternative schemes subsumed by Algorithms 6.1–6.4 below.

6.1. Exact-constraint cuts and cumulative bases. If the cuts are generated as in Proposition 4.1 and the bases as in Proposition 5.1, Algorithm 1.1 reads as follows.

ALGORITHM 6.1. *A sequence $(x_n)_{n\geq 0}$ is constructed as follows, where E is supplied by* (A2).

Step 0. *Set $D_0 = E$, $x_0 = \mathfrak{m}(D_0)$, $\mathbb{K}_{-1} = \emptyset$, and $n = 0$.*

Step 1. *Take $\mathrm{i}(n) \in I$.*

Step 2. *Set $x_{n+1} = \mathfrak{m}(D_n \cap S_{\mathrm{i}(n)})$ and $\mathbb{A}_n = \{k \in \mathbb{K}_{n-1} \cup \{n\} \mid x_{n+1} \in \operatorname{bd} S_{\mathrm{i}(k)}\}$.*

Step 3. *Take $\mathbb{A}_n \subset \mathbb{K}_n \subset \mathbb{K}_{n-1} \cup \{n\}$ and set $D_{n+1} = E \cap \bigcap_{k\in\mathbb{K}_n} S_{\mathrm{i}(k)}$.*

Step 4. *Set $n = n + 1$ and go to Step* 1.

The convergence result below is a direct application of Theorem 3.1.

THEOREM 6.1. *Let $(x_n)_{n\geq 0}$ be an arbitrary orbit of Algorithm* 6.1 *generated under either of the following conditions:* (i) *tightness, I countable, and admissible control; or* (ii) *strong tightness and coercive control. Then $x_n \stackrel{n}{\to} \overline{x}$.*

EXAMPLE 6.1 (see [5, Thm. 2.4]). *In Algorithm* 6.1, *$\mathcal{X} = \mathbb{R}^N$, E is bounded, J is finite and strictly convex, I is a compact metric space, $(g_i)_{i\in I}$ is a family of finite convex functions such that $(i, x) \mapsto g_i(x)$ is continuous on $I \times \mathcal{X}$, $\mathbb{K}_n = \mathbb{A}_n$ at Step* 3, *and the* most violated constraint *control mode*

$$(\forall n \in \mathbb{N}) \quad g_{\mathrm{i}(n)}(x_n) = \max_{i\in I} g_i(x_n) \tag{6.1}$$

is in force. Then $x_n \stackrel{n}{\to} \overline{x}$.

Proof. The conditions of Proposition 2.1(ii)(b) are fulfilled, and (A1)–(A2) are therefore satisfied. In addition, it follows from Proposition 2.2(ii) that (A3) is satisfied. For every $x \in \mathcal{X}$, the continuity of $i \mapsto g_i(x)$ on the compact space I yields $\sup_{i\in I} |g_i(x)| < +\infty$. Proposition 4.3(iv) then ensures the strong tightness of the algorithm, while (6.1) is a special instance of the coercive control mode (3.7). The claim is therefore a consequence of Theorem 6.1(ii). □

Examples 6.2 and 6.3 below are, respectively, infinite-dimensional formulations of Kelley's basic cutting plane algorithm [31] and of the Kaplan–Veinott supporting hyperplane algorithm [30], [52]. These algorithms were already shown in [35] to be special instances of the framework described in Example 4.1. The problem under consideration is to find the minimizer $\overline{x}$ of a function $J\colon \mathcal{X} \to]-\infty, +\infty]$ over a closed convex set S under assumptions (A1)–(A2). By expressing S as a suitable intersection of half-spaces $(S_i)_{i\in I}$, this problem will be recast in the form of (P).

EXAMPLE 6.2. *Suppose that $S = \mathrm{lev}_{\leq 0} g$, where $g\colon \mathcal{X} \to]-\infty, +\infty]$ is a lower semicontinuous convex function. Let E be a polyhedron and suppose that there exists $\zeta \in \mathbb{R}_+^*$ such that, for every $x \in C$, $\partial g(x) \subset B(0, \zeta)$. Let $x_0 = \mathfrak{m}(E)$ and define $(x_n)_{n\geq 0}$ by the recursion*

(6.2)
$$(\forall n \in \mathbb{N}) \quad x_{n+1} = \mathfrak{m}\Bigg(E \cap \bigcap_{k=0}^{n} \{x \in \mathcal{X} \mid \langle x_k - x, t_k' \rangle \geq g(x_k)\}\Bigg), \quad \text{where } t_n' \in \partial g(x_n).$$

Then $x_n \overset{n}{\to} \overline{x}$.

Proof. Let $I = \{(y, t') \in \mathcal{X} \times \mathcal{X}' \mid t' \in \partial g(y)\}$ be the graph of ∂g. For every $i = (y, t') \in I$, the continuous affine function $g_i\colon x \mapsto \langle x - y, t' \rangle + g(y)$ minorizes g by virtue of (2.2) with $g_i(y) = g(y)$ and it defines a closed affine half-space $S_i = \mathrm{lev}_{\leq 0} g_i$. We can then write $S = \bigcap_{i\in I} S_i$. Since at iteration $n \in \mathbb{N}$ the function $i \mapsto g_i(x_n)$ is maximized for $\mathrm{i}(n) = (x_n, t_n')$ where $t_n' \in \partial g(x_n)$, (6.2) appears as a particular realization of Algorithm 6.1 with $\mathbb{K}_n = \mathbb{K}_{n-1} \cup \{n\}$ at Step 3 and control rule (6.1). The control is therefore coercive since (6.1) $\Rightarrow$ (3.7). Moreover, if $x_n \notin S$, $g_{\mathrm{i}(n)}(x_n) = g(x_n) = \|t_n'\| \cdot d(x_n, S_{\mathrm{i}(n)}) \leq \zeta d(x_n, S_{\mathrm{i}(n)})$. However, Proposition 3.1(viii) states that $d(x_n, S_{\mathrm{i}(n)}) \overset{n}{\to} 0$. Thus, $\overline{\lim}_n g_{\mathrm{i}(n)}(x_n) \leq 0$ and the algorithm is strongly tight. The announced result then follows from Theorem 6.1(ii). □

EXAMPLE 6.3. *Suppose that $\mathcal{X}$ is a Hilbert space, that S is bounded with $S^\circ \neq \emptyset$, and that E is a polyhedron. Let $x_0 = \mathfrak{m}(E)$ and $w \in S^\circ$, and define $(x_n)_{n\geq 0}$ by the recursion*

$$(\forall n \in \mathbb{N}) \quad x_{n+1} = \mathfrak{m}\left(E \cap \bigcap_{k=0}^{n} H_k\right), \tag{6.3}$$

where $H_n \in \mathfrak{C}(S)$ is either the whole space $\mathcal{X}$ or an affine half-space whose boundary supports S at the point $y_n \in \mathrm{bd}\, S \cap [x_n, w]$, according to whether x_n lies in S or not. Then $x_n \overset{n}{\to} \overline{x}$.

Proof. Let $I = \{i \in \mathcal{X} \mid \|i\| = 1\}$ be the unit sphere in $\mathcal{X}$ and $\sigma\colon i \mapsto \sup_{x\in S} \langle x, i \rangle$ the support function of S. For every $i \in I$, define a closed affine half-space $S_i = \mathrm{lev}_{\leq 0} g_i$, where $g_i\colon x \mapsto \langle x, i \rangle - \sigma(i)$. Then $S = \bigcap_{i\in I} S_i$. By assumption, $B(w, \gamma) \subset S$ for some $\gamma \in \mathbb{R}_+^*$. Now suppose $x_n \notin S$ and let p_n be the projection of x_n onto $\mathrm{bd}\, H_n \ni y_n$. Then $\mathrm{bd}\, H_n = \{y \in \mathcal{X} \mid \langle y - y_n, p_n - x_n \rangle = 0\}$ and $d(w, \mathrm{bd}\, H_n) =$

$\langle w-y_n, p_n-x_n\rangle/\|p_n-x_n\|$. However, $y_n \in [x_n, w]$ and therefore $w-y_n = \alpha_n(y_n-x_n)$, where $\alpha_n = \|w-y_n\|/\|x_n-y_n\|$. Hence, $d(w, \operatorname{bd} H_n) = \alpha_n\langle y_n-x_n, p_n-x_n\rangle/\|p_n-x_n\|$ $= \alpha_n d(x_n, H_n)$. Consequently,

$$(\forall i \in I) \quad d(x_n, H_n) = \frac{d(w, \operatorname{bd} H_n)}{\|w-y_n\|} \cdot \|x_n-y_n\| \geq \eta d(x_n, S_i), \tag{6.4}$$

where $\eta = \gamma/\sup_{y\in\operatorname{bd} S}\|w-y\| > 0$. In addition, for every $i \in I$, $x_n \notin S_i \Rightarrow d(x_n, S_i) = g_i(x_n)$. Hence, $g_{\mathrm{i}(n)}(x_n) \geq \eta \sup_{i\in I} g_i(x_n)$, where $\mathrm{i}(n) \in I$ and $S_{\mathrm{i}(n)} = H_n$, from which it follows that (6.3) is a particular realization of Algorithm 6.1 with $\mathbb{K}_n = \mathbb{K}_{n-1} \cup \{n\}$ at Step 3 and coercive control rule (3.7). Since the affine family $(g_i)_{i\in I}$ is equi-Lipschitzian on $\mathcal{X}$ with constant 1, strong tightness follows from Proposition 4.3(i) and Theorem 6.1(ii) yields $x_n \overset{n}{\to} \overline{x}$. □

6.2. Exact-constraint cuts and instantaneous bases. Algorithm 6.2 below is derived from Algorithm 1.1 by coupling the cuts of Proposition 4.1 together with the bases of Proposition 5.2.

ALGORITHM 6.2. *A sequence $(x_n)_{n\geq 0}$ is constructed as follows, where E is supplied by* (A2).

Step 0. *Set $D_0 = E$, $x_0 = \mathfrak{m}(D_0)$, and $n = 0$.*

Step 1. *Take $\mathrm{i}(n) \in I$.*

Step 2. *Set $x_{n+1} = \mathfrak{m}(E \cap D_n \cap S_{\mathrm{i}(n)})$.*

Step 3. *Take $t'_{n+1} \in \partial J(x_{n+1})$ such that $(\forall x \in E \cap D_n \cap S_{\mathrm{i}(n)})$ $\langle x_{n+1}-x, t'_{n+1}\rangle \leq 0$ and set $D_{n+1} = \{x \in \mathcal{X} \mid \langle x_{n+1}-x, t'_{n+1}\rangle \leq 0\}$.*

Step 4. *Set $n = n+1$ and go to Step 1.*

Convergence follows at once from Theorem 3.1.

THEOREM 6.2. *Let $(x_n)_{n\geq 0}$ be an arbitrary orbit of Algorithm 6.2 generated under either of the following conditions:* (i) *tightness, I countable, and admissible control; or* (ii) *strong tightness and coercive control. Then $x_n \overset{n}{\to} \overline{x}$.*

EXAMPLE 6.4 (see [26, Thm. 2]). *In Algorithm 6.2, $\mathcal{X}$ is a Hilbert space, $E = \mathcal{X}$, J is a coercive quadratic form, $I = \{0, \ldots, M-1\}$ is finite, $(\forall i \in I)$ $g_i\colon x \mapsto d(x, S_i)$, and the* periodic *control mode*

$$(\forall n \in \mathbb{N}) \quad \mathrm{i}(n) = n \ (\text{modulo } M), \tag{6.5}$$

is in force. Then $x_n \overset{n}{\to} \overline{x}$.

Proof. The conditions of Proposition 2.1(iii) are satisfied and, consequently, so are (A1) and (A2). In addition, (A3) is secured by Proposition 2.2(ii) since $(g_i)_{i\in I}$ is a family of continuous and—by the convexity of the sets $(S_i)_{i\in I}$—convex functions. In addition, it follows from Proposition 3.1(viii) that $g_{\mathrm{i}(n)}(x_n) = d(x_n, S_{\mathrm{i}(n)}) \overset{n}{\to} 0$ and therefore that the algorithm is tight. Finally, since (6.5) $\Rightarrow$ (3.6), the control is admissible. Hence, the assertion follows from Theorem 6.2(i). □

EXAMPLE 6.5 (see [41]). *In Algorithm 6.2, $\mathcal{X}$ is a Hilbert space, $E = \mathcal{X}$, J is a coercive quadratic form, I is a compact metric space, $(g_i)_{i\in I}$ is a family of affine functions such that $(i, x) \mapsto g_i(x)$ is continuous on $I \times \mathcal{X}$, and the most violated constraint control mode* (6.1) *is in force. Then $x_n \overset{n}{\to} \overline{x}$.*

Proof. (A1)–(A2) hold by Proposition 2.1(iii). Now fix $i \in I$. Then $g_i\colon x \mapsto \langle x, z_i\rangle + \alpha_i$, where $z_i \in \mathcal{X}$ and $\alpha_i \in \mathbb{R}$, and (A3) holds. For every $x \in \mathcal{X}$, the continuity of $i \mapsto \langle x, z_i\rangle$ on the compact space I implies $\sup_{i\in I}|\langle x, z_i\rangle| < +\infty$. Therefore,

the algorithm is strongly tight by Proposition 4.3(iii) and, since (6.1) $\Rightarrow$ (3.7), it operates under coercive control. The desired conclusion is reached by invoking Theorem 6.2(ii). □

EXAMPLE 6.6 (see [39]). *In Algorithm* 6.2, $\mathcal{X} = \mathbb{R}^N$, J *is finite and strictly convex,* E *is bounded,* J *is strongly convex (i.e.,* $c : \tau \mapsto \kappa\tau^2$ *with* $\kappa \in \mathbb{R}_+^*$ *in* (A2) [36]*) and differentiable on* E, $I = \{0, \dots, M-1\}$ *is finite,* $(\forall i \in I)$ $g_i \colon x \mapsto d(x, S_i)$, *and either of the following conditions is fulfilled:* (i) *the periodic control mode* (6.5) *is in force; or* (ii) *the most violated constraint control mode* (6.1) *is in force. Then* $x_n \overset{n}{\to} \overline{x}$.

Proof. The conditions of Proposition 2.1(ii)(b)—and therefore (A1)–(A2)—hold. As in Example 6.4, (A3) also holds and the algorithm is (strongly) tight. Hence, (i) and (ii) follow from Theorem 6.2(i) and (ii), respectively. □

6.3. Surrogate cuts and cumulative bases. Algorithm 1.1 is implemented with the cuts of Proposition 4.4 and the bases of Proposition 5.1.

ALGORITHM 6.3. *A sequence* $(x_n)_{n\geq 0}$ *is constructed as follows, where* E *is supplied by* (A2).

Step 0. *Take* $(\delta, \varepsilon) \in]0,1[^2$ *and set* $D_0 = E$, $x_0 = \mathfrak{m}(D_0)$, $\mathbb{K}_{-1} = \emptyset$, *and* $n = 0$.

Step 1. *Take a finite index set* $\emptyset \neq I_n \subset I$ *and set* $H_n = \{x \in \mathcal{X} \mid \sum_{i\in I_n} w_{i,n}\langle x - p_{i,n}, q'_{i,n}\rangle \leq \gamma_n\}$, *where*

(C1) *For every* $i \in I_n$, $p_{i,n}$ *is a projection of* x_n *onto a set* $S_{i,n} \in \mathfrak{C}(S_i)$ *and* $q'_{i,n} \in \Delta(x_n - p_{i,n})$ *is such that* $(\forall x \in S_{i,n})$ $\langle x - p_{i,n}, q'_{i,n}\rangle \leq 0$.

(C2) $(w_{i,n})_{i\in I_n} \subset [0,1]$, $\sum_{i\in I_n} w_{i,n} = 1$, *and*

$$(\exists j \in I_n) \quad \begin{cases} d(x_n, S_{j,n}) = \max\limits_{i\in I_n} d(x_n, S_{i,n}), \\ w_{j,n} \geq \delta. \end{cases}$$

(C3) $0 \leq \gamma_n \leq (1-\varepsilon)\sum_{i\in I_n} w_{i,n} d(x_n, S_{i,n})^2$.

Step 2. *Set* $x_{n+1} = \mathfrak{m}(D_n \cap H_n)$ *and* $\mathbb{A}_n = \{k \in \mathbb{K}_{n-1} \cup \{n\} \mid x_{n+1} \in \operatorname{bd} H_k\}$.

Step 3. *Take* $\mathbb{A}_n \subset \mathbb{K}_n \subset \mathbb{K}_{n-1} \cup \{n\}$ *and set* $D_{n+1} = E \cap \bigcap_{k\in\mathbb{K}_n} H_k$.

Step 4. *Set* $n = n+1$ *and go to Step* 1.

Theorem 3.1 now reads as follows.

THEOREM 6.3. *Let* $(x_n)_{n\geq 0}$ *be an arbitrary orbit of Algorithm* 6.3 *generated under either of the following conditions:* (i) *tightness,* I *countable, and admissible control; or* (ii) *strong tightness and coercive control. Then* $x_n \overset{n}{\to} \overline{x}$.

It is noteworthy that Kelley's basic algorithm, presented in Example 6.2 as a special case of Algorithm 6.1, can also be viewed as a special case of Algorithm 6.3 with a single constraint set and cuts as in (4.8). Along the same lines, we present below a formulation of Kelley's algorithm with a finite number of constraints [31] under assumptions (A1)–(A2).

EXAMPLE 6.7. *In Algorithm* 6.3, I *is finite,* $(g_i)_{i\in I}$ *is a family of finite continuous convex functions satisfying* (4.16), *the approximations* (4.8) *are used, and the most violated constraint control mode* (6.1) *is in force. Then* $x_n \overset{n}{\to} \overline{x}$.

Proof. Proposition 4.8(ii) asserts that this particular realization of Algorithm 6.3 is strongly tight. Thus, since the control is coercive, the result follows from Theorem 6.3(ii). □

6.4. Surrogate cuts and instantaneous bases. The fourth implementation of Algorithm 1.1 is obtained by generating the cuts as in Proposition 4.4 and the bases as in Proposition 5.2.

ALGORITHM 6.4. *A sequence $(x_n)_{n\geq 0}$ is constructed as follows, where E is supplied by* (A2).

Step 0. *Take $(\delta,\varepsilon)\in]0,1[^2$ and set $D_0=E$, $x_0=\mathfrak{m}(D_0)$, and $n=0$.*

Step 1. *Take a finite index set $\varnothing\neq I_n\subset I$ and set $H_n=\{x\in\mathcal{X}\mid \sum_{i\in I_n}w_{i,n}\langle x-p_{i,n},q'_{i,n}\rangle\leq\gamma_n\}$, where*

(C1) *For every $i\in I_n$, $p_{i,n}$ is a projection of x_n onto a set $S_{i,n}\in\mathfrak{C}(S_i)$ and $q'_{i,n}\in\Delta(x_n-p_{i,n})$ is such that $(\forall x\in S_{i,n})\ \langle x-p_{i,n},q'_{i,n}\rangle\leq 0$.*

(C2) *$(w_{i,n})_{i\in I_n}\subset[0,1]$, $\sum_{i\in I_n}w_{i,n}=1$, and*

$$(\exists j\in I_n)\quad\begin{cases}d(x_n,S_{j,n})=\max\limits_{i\in I_n}d(x_n,S_{i,n}),\\ w_{j,n}\geq\delta.\end{cases}$$

(C3) *$0\leq\gamma_n\leq(1-\varepsilon)\sum_{i\in I_n}w_{i,n}d(x_n,S_{i,n})^2$.*

Step 2. *Set $x_{n+1}=\mathfrak{m}(E\cap D_n\cap H_n)$.*

Step 3. *Take $t'_{n+1}\in\partial J(x_{n+1})$ such that $(\forall x\in E\cap D_n\cap H_n)\langle x_{n+1}-x,t'_{n+1}\rangle\leq 0$ and set $D_{n+1}=\{x\in\mathcal{X}\mid\langle x_{n+1}-x,t'_{n+1}\rangle\leq 0\}$.*

Step 4. *Set $n=n+1$ and go to Step* 1.

The convergence conditions below are furnished by Theorem 3.1.

THEOREM 6.4. *Let $(x_n)_{n\geq 0}$ be an arbitrary orbit of Algorithm* 6.4 *generated under either of the following conditions:* (i) *tightness, I countable, and admissible control; or* (ii) *strong tightness and coercive control. Then $x_n\overset{n}{\to}\overline{x}$.*

EXAMPLE 6.8. *In Algorithm* 6.4, *$\mathcal{X}$ is a Hilbert space, I is finite, $J\colon x\mapsto\|x-w\|^2/2$ where $w\in\mathcal{X}$, $E=\mathcal{X}$, $(\forall i\in I)$ $g_i\colon x\mapsto d(x,S_i)$, $S_{i,n}=S_i$ in* (C1), *$\gamma_n=0$ in* (C3), *$x_0=w$, and one of the following conditions is fulfilled:*

(i) [27, Thm. 3-2] *The periodic control mode* (6.5) *is in force.*

(ii) [44, Thm. V.1] *The* static *control mode*

$$(\forall n\in\mathbb{N})\quad I_n=I \tag{6.6}$$

is in force and $(\forall i\in I)$ $w_{i,n}=1/\mathrm{card}I$ in (C2).

(iii) [14] *The control mode*

$$(\forall n\in\mathbb{N})\quad I_n=\Big\{i\in I\mid d(x_n,S_i)=\max_{j\in I}d(x_n,S_j)\Big\} \tag{6.7}$$

is in force and $(w_{i,n})_{i\in I_n}\subset]0,1]$ in (C2).

Then $x_n\overset{n}{\to}\overline{x}$.

Proof. First, the above setting fits into that of Proposition 2.1(iii), and therefore (A1)–(A2) hold. In addition, as in Example 6.4, (A3) holds. Furthermore, Proposition 4.6 yields $\max_{i\in I_n}g_i(x_n)=\max_{i\in I_n}d(x_n,S_{i,n})\overset{n}{\to}0$, which establishes the strong tightness of this implementation of Algorithm 6.4. Accordingly, since in (i) and (ii) the control conforms to the admissibility condition (3.3), the first two assertions follow from Theorem 6.4(i). Finally, since (6.7) is an instance of the coercive control mode (3.5) here, (iii) follows from Theorem 6.4(ii). □

EXAMPLE 6.9. *In Algorithm* 6.4, *$\mathcal{X}=\mathbb{R}^N$, J is finite, strictly convex, and differentiable with bounded lower level sets, $E=\mathcal{X}$, I is finite, $(g_i)_{i\in I}$ is a family of finite convex functions, the approximations* (4.8) *are used, and one of the following conditions is fulfilled:*

(i) [29, Thm. 1] *The most violated constraint control mode* (6.1) *is in force.*

(ii) [29, Thm. 2] *The serial admissible control mode* (3.6) *is in force.*
(iii) [29, Thm. 3] *The static control mode* (6.6) *is in force and* $(\forall (n,i) \in \mathbb{N} \times I),\ x_n \in S_i \Rightarrow w_{i,n} = 0$.

Then $x_n \overset{n}{\to} \overline{x}$.

Proof. Note that the conditions of Proposition 2.1(ii)(a) are satisfied and that (A1)–(A3) hold. Moreover, each g_i is continuous and subdifferentiable on $\mathcal{X}$ and (4.14) holds [46, Thm. 24.7]. Since I is finite, Propositions 3.2 and 4.7(ii) therefore imply that the algorithm is strongly tight. Hence, (i) follows from Theorem 6.4(ii), while (ii) and (iii) follow from Theorem 6.4(i). □

It emerges from the discussions of sections 4.3 and 5.3 that Algorithms 6.3 and 6.4, which employ surrogate cuts, are more advantageous numerically than Algorithms 6.1 and 6.2, which employ exact-constraint cuts. When instantaneous bases are easily generated, as is the case when J is differentiable on C, Algorithm 6.4 stands out as the most attractive implementation of Algorithm 1.1. Its chief asset is to generate at every iteration a simple outer approximation, namely, the intersection of two half-spaces (with the initial base E when $E \neq \mathcal{X}$). An application of Algorithm 6.4 to an important concrete problem is demonstrated next.

6.5. Projection onto an intersection of convex sets. Algorithm 6.4 is applied to the problem of finding the projection $\overline{x}$ of a point w onto the intersection of an arbitrary family of intersecting closed convex sets $(S_i)_{i\in I}$ conforming to (A3) in a real Hilbert space $\mathcal{X}$. As $J\colon x \mapsto \|x-w\|^2/2$ in (P), assumptions (A1) and (A4) are clearly satisfied and, in light of Proposition 2.1(iii), so is (A2) with $E = \mathcal{X}$.

Given $(x,y,z) \in \mathcal{X}^3$, it will be convenient to define

$$H(x,y) = \{h \in \mathcal{X} \mid \langle h - y, x - y\rangle \leq 0\} \tag{6.8}$$

and to denote by $\mathfrak{q}(x,y,z)$ the projection of x onto $H(x,y) \cap H(y,z)$. Thus, $H(x,x) = \mathcal{X}$ and, if $x \neq y$, $H(x,y)$ is a closed affine half-space onto which y is the projection of x.

ALGORITHM 6.5. *A sequence* $(x_n)_{n\geq 0}$ *is constructed as follows.*

Step 0. *Take* $(\delta,\varepsilon) \in]0,1[^2$ *and set* $x_0 = w$ *and* $n = 0$.

Step 1. *Take a finite index set* $\emptyset \neq I_n \subset I$ *and set* $z_n = x_n + \lambda_n(\sum_{i\in I_n} w_{i,n}p_{i,n} - x_n)$, *where*

(B1) *For every* $i \in I_n$, $p_{i,n}$ *is the projection of* x_n *onto a set* $S_{i,n} \in \mathfrak{C}(S_i)$.

(B2) $(w_{i,n})_{i\in I_n} \subset [0,1]$, $\sum_{i\in I_n} w_{i,n} = 1$, *and*

$$(\exists j \in I_n) \quad \begin{cases} d(x_n, S_{j,n}) = \max\limits_{i\in I_n} d(x_n, S_{i,n}), \\ w_{j,n} \geq \delta. \end{cases}$$

(B3) $\varepsilon L_n \leq \lambda_n \leq L_n \triangleq \begin{cases} \dfrac{\sum\limits_{i\in I_n} w_{i,n}\|p_{i,n} - x_n\|^2}{\left\|\sum\limits_{i\in I_n} w_{i,n}p_{i,n} - x_n\right\|^2}, & \text{if } x_n \notin \bigcap\limits_{i\in I_n} S_{i,n}, \\ 1 & \text{otherwise.} \end{cases}$

Step 2. *Set* $\pi_n = \langle x_0 - x_n, x_n - z_n\rangle$, $\mu_n = \|x_0 - x_n\|^2$, $\nu_n = \|x_n - z_n\|^2$, $\rho_n =$

$\mu_n\nu_n - \pi_n^2$, *and*

$$x_{n+1} = \mathfrak{q}(x_0, x_n, z_n) \tag{6.9}$$
$$= \begin{cases} z_n & \text{if } \rho_n = 0 \text{ and } \pi_n \geq 0, \\ x_0 + (1 + \pi_n/\nu_n)(z_n - x_n) & \text{if } \rho_n > 0 \text{ and } \pi_n\nu_n \geq \rho_n, \\ x_n + \dfrac{\nu_n}{\rho_n}(\pi_n(x_0 - x_n) + \mu_n(z_n - x_n)) & \text{if } \rho_n > 0 \text{ and } \pi_n\nu_n < \rho_n. \end{cases}$$

Step 3. *Set* $n = n + 1$ *and go to Step* 1.

In this algorithm, the update x_{n+1} is obtained in (6.9) as the projection of $x_0 = w$ onto the intersection of the half-spaces $H(x_0, x_n)$ and $H(x_n, z_n)$.

PROPOSITION 6.1. *In the present context, Algorithm* 6.4 *reduces to Algorithm* 6.5.

Proof. Since $E = \mathcal{X}$, we obtain $x_0 = \mathfrak{m}(\mathcal{X}) = w$ at Step 0 of Algorithm 6.4. Next, recall that the cut H_n at Step 1 of Algorithm 6.4 is given by (4.7). We shall now show $H_n = H(x_n, z_n)$. Assume $x_n \notin \bigcap_{i\in I_n} S_{i,n}$ and define $y_n = x_n - \sum_{i\in I_n} w_{i,n}p_{i,n}$ ($\neq 0$ by Proposition 4.5), $\sigma_n^2 = \sum_{i\in I_n} w_{i,n}d(x_n, S_{i,n})^2$, and $\lambda_n = (\sigma_n^2 - \gamma_n)/\|y_n\|^2$. Then $z_n = x_n - \lambda_n y_n$, $L_n = \sigma_n^2/\|y_n\|^2$, and (B3) $\Leftrightarrow$ (C3). Moreover, for every $x \in \mathcal{X}$, we have

$$\begin{aligned} x \in H_n &\Leftrightarrow \langle x, y_n\rangle \leq \sum_{i\in I_n} w_{i,n}\langle p_{i,n}, x_n - p_{i,n}\rangle + \gamma_n \\ &\Leftrightarrow \langle x, y_n\rangle \leq \langle x_n, y_n\rangle - \lambda_n\|y_n\|^2 \\ &\Leftrightarrow \langle x - z_n, y_n\rangle \leq 0 \\ &\Leftrightarrow \langle x - z_n, x_n - z_n\rangle \leq 0. \end{aligned} \tag{6.10}$$

Consequently, $H_n = H(x_n, z_n)$. Next, observe that (5.4) yields $D_n = H(x_0, x_n)$. Hence, as $E = \mathcal{X}$, (6.9) coincides with Step 2 of Algorithm 6.4; the expression for $\mathfrak{q}(x, y, z)$ in terms of x, y, and z is drawn from [27, Thm. 3-1]. Note that all the possible cases are exhausted in (6.9) since $\rho_n \geq 0$ and, as also shown in [27, Thm. 3-1], $H(x_0, x_n) \cap H(x_n, z_n) = \emptyset \Leftrightarrow \rho_n = 0$ and $\pi_n < 0$. ∎

Naturally, Algorithm 6.5 contains those described in Example 6.8 as particular instances. Unlike them, however, it can handle an infinite number of constraints, approximate projections, and flexible block-iterative control modes. Strong convergence conditions are given in Theorem 6.4.

For comparison purposes, let us now review alternative iterative schemes that generate sequences converging strongly to the sought projection $\overline{x}$. From an algorithmic standpoint, these schemes are initialized with $x_0 = w$ and operate either in the serial format

$$(\forall n \in \mathbb{N}) \quad \mathrm{i}(n) \in I \quad \text{and} \quad x_{n+1} = R_{\mathrm{i}(n),n}x_n \tag{6.11}$$

or in the static parallel format

$$(\forall n \in \mathbb{N}) \quad x_{n+1} = \sum_{i\in I} w_i R_{i,n}x_n \quad \text{with} \quad (w_i)_{i\in I} \subset]0, 1] \quad \text{and} \quad \sum_{i\in I} w_i = 1, \tag{6.12}$$

where I is assumed to be countable and $(R_{i,n})_{(i,n)\in I\times\mathbb{N}}$ is a family of operators from $\mathcal{X}$ into $\mathcal{X}$. Henceforth, $(P_i)_{i\in I}$ designates the family of projectors onto the sets $(S_i)_{i\in I}$.

(1) *Periodic projection method.* Suppose that $(S_i)_{i\in I}$ is a finite family of M closed vector subspaces and set $R_{i,n} = P_i$. Then it was shown in [25] that under the periodic control mode (6.5) the serial projection method (6.11) converges strongly to $\overline{x}$. This result remains valid in the case of closed affine subspaces and it coincides with von Neumann's alternating projection theorem for $M = 2$ (see [18] for further details).

(2) *Dykstra-like methods.* In [6], an extension of the preceding periodic projection method to finite families of closed convex sets was obtained by setting $R_{i,n}x_n = P_i(x_n + y_{i,n})$, where $y_{i,n}$ is the outward normal vector resulting from the previous projection onto S_i. In [21], this serial algorithm was examined from a dual perspective and given an elegant and natural interpretation; moreover, the convergence of its parallel counterpart (6.12) was established. (See also [3] for further analysis.) New developments were reported in [28], where a nonperiodic control mode was used in (6.11) and countably infinite families of sets were considered.

(3) *Anchor point methods.* Suppose that, for every $i \in I$, $S_i = \operatorname{Fix} T_i$ where $T_i\colon \mathcal{X} \to \mathcal{X}$ is firmly nonexpansive, i.e., satisfies (2.15). (Note that if, for some $i \in I$, T_i is merely nonexpansive, it can be replaced by the averaged mapping $T_i^{\mathrm{av}} = (T_i + \mathrm{Id})/2$ which is firmly nonexpansive [24, Thm. 12.1] and satisfies $\operatorname{Fix} T_i^{\mathrm{av}} = \operatorname{Fix} T_i$.) Anchor point methods operate with $R_{i,n}x_n = \alpha_n x_0 + (1-\alpha_n)T_i x_n$, where $(\alpha_n)_{n\geq 0} \subset]0,1]$ converges "slowly" to 0 (e.g., $\alpha_n = 1/(n+1)$ in [2] and [10]). Strong convergence was established in [2] and [38] for the serial version (6.11) under the periodic control rule (6.5) (and I finite) and in [10] for the parallel version (6.12) with I countably infinite.

(4) *Periodic quasi-projection method.* This method, proposed in [26], was described in Example 6.4 as an offspring of Algorithm 6.2. It is equivalent to executing (6.11) under the periodic control mode (6.5) and with $R_{\mathrm{i}(n),n}x_n$ as the "quasi-projection" of x_n onto $S_{\mathrm{i}(n)}$, i.e., the projection of x_n onto $S_{\mathrm{i}(n)} \cap H(x_0, x_n)$.

Overall, Algorithm 6.5 appears to enjoy more flexibility than the above methods in terms of parallel implementation and more versatility in terms of the types of constraints it can handle. Indeed, Dykstra-like and anchor point methods are not well suited for parallel block-processing due to their serial or static parallel structure. The scope of Dykstra-like methods is further limited by the fact that they require the ability to compute projections, which is possible only in special situations. In this regard, anchor point methods are somewhat less restrictive, as any firmly nonexpansive mapping admitting the set under consideration as fixed point set can be used. In addition, Dykstra-like methods require that a normal vector be carried along for each set (except for affine subspaces), which makes their implementation costly in terms of memory allocation and management. Finally, it is noted that the quasi-projection method is a rather conceptual one, the computation of quasi-projections being usually a serious obstacle to its implementability in practice.

7. Further results. In this section, we present convergence results for two variants of (P) in which the original assumptions are altered. $\mathcal{X}$ is assumed to be a Hilbert space.

7.1. Inconsistent constraints. It has been assumed so far that the constraints are consistent, i.e., that $S \neq \emptyset$ in (P). In this section, we place ourselves in the following context: S may be empty and I is finite. As before, $(P_i)_{i\in I}$ are the projectors onto the closed convex sets $(S_i)_{i\in I}$.

As in the convex feasibility problems of [9] and [17], the exact, but possibly empty, feasibility set S can be replaced by the set $\widetilde{S}$ of points which best approximate the constraints in an averaged squared-distance sense. Fix weights $(w_i)_{i\in I} \subset]0,1]$ such that $\sum_{i\in I} w_i = 1$, define a (continuous and convex) *proximity function* $\Phi\colon x \mapsto (1/2)\sum_{i\in I} w_i d(x,S_i)^2$, and let $\widetilde{S}$ be the (closed and convex) set of minimizers of Φ over $\mathcal{X}$. (P) is then replaced by

$$(\widetilde{\mathrm{P}}) \qquad \text{find } \widetilde{x} \in \widetilde{S} \quad \text{such that } J(\widetilde{x}) = \inf_{x\in\widetilde{S}} J(x)$$

under assumptions (A1) and

(A0) $\widetilde{S} \neq \emptyset$,

($\widetilde{\text{A2}}$) for some $\widetilde{E} \in \mathfrak{C}(\widetilde{S})$, there exists a point $\widetilde{u} \in \widetilde{S} \cap \operatorname{dom} J$ such that $\widetilde{C} \triangleq \widetilde{E} \cap \operatorname{lev}_{\leq J(\widetilde{u})} J$ is bounded and J is uniformly convex on $\widetilde{C}$.

Some remarks are in order. First, if $S \neq \emptyset$, then $\widetilde{S} = S$. Second, if $S = \emptyset$, then assumption (A0) holds when one of the sets in $(S_i)_{i\in I}$ is bounded or when they are all closed affine half-spaces [17]. Third, it follows from (A0), (A1), and ($\widetilde{\text{A2}}$) that ($\widetilde{\text{P}}$) admits a unique solution $\widetilde{x}$.

The next step is to regard ($\widetilde{\text{P}}$) as a program of the general form (P) with a single constraint set, namely $\widetilde{S}$. Consequently, ($\widetilde{\text{P}}$) can be solved via Algorithms 6.3 or 6.4 by constructing suitable surrogate cuts for $\widetilde{S}$.

THEOREM 7.1. *Let $(x_n)_{n\geq 0}$ be an arbitrary orbit of Algorithms* 6.3 *or* 6.4 *in which the cut at Step* 1 *is taken to be*

$$(7.1) \qquad H_n = \left\{ x \in \mathcal{X} \mid \left\langle x - \sum_{i\in I} w_i P_i x_n, x_n - \sum_{i\in I} w_i P_i x_n \right\rangle \leq \gamma_n \right\},$$

where $0 \leq \gamma_n \leq (1-\varepsilon)\|x_n - \sum_{i\in I} w_i P_i x_n\|^2$. Then $x_n \overset{n}{\to} \widetilde{x}$.

Proof. The claim follows from Theorems 6.3(i) and 6.4(i). Indeed, the control is admissible since only one constraint set is present. Next, let us show that (7.1) is a valid cut at iteration n. To this end, let $T = \sum_{i\in I} w_i P_i$. Then T is firmly nonexpansive and $\operatorname{Fix} T = \widetilde{S}$ [9]. Hence (A3) holds by Proposition 2.2(iv)(e) and (7.1) is drawn from (4.10). Finally, tightness follows from Proposition 4.7(iii). ∎

7.2. Convex feasibility problems. If, instead of (A2), it is assumed that J is constant on S, then (P) turns into the convex feasibility problem

$$(\mathrm{CFP}) \qquad \text{find } \overline{x} \in S = \bigcap_{i\in I} S_i.$$

A general strategy for solving (CFP) is to construct a sequence $(x_n)_{n\geq 0}$ in which x_{n+1} is a relaxed projection of x_n onto a cut H_n. An implementation of this outer approximation scheme with surrogate cuts leads to the following block-iterative algorithm.

ALGORITHM 7.1. *In Algorithm* 6.5, *pick x_0 arbitrarily at Step* 0, *extend the relaxation range in* (B3) *to "$\varepsilon \leq \lambda_n \leq (2-\varepsilon)L_n$," and reduce Step* 2 *to "$x_{n+1} = z_n$."*

THEOREM 7.2. *Let $(x_n)_{n\geq 0}$ be an arbitrary orbit of Algorithm* 7.1 *generated under either of the following conditions:* (i) *tightness, I countable, and admissible control or* (ii) *strong tightness and coercive control. Then $(x_n)_{n\geq 0}$ converges weakly to a point in S.*

Proof. A slight modification of the results of [13, section 2] shows that $x_{n+1} - x_n \overset{n}{\to} 0$, $\max_{i\in I_n} d(x_n, S_{i,n}) \overset{n}{\to} 0$, and $(x_n)_{n\geq 0}$ converges weakly to a point in S if $\mathfrak{W}(x_n)_{n\geq 0} \subset S$, from which, by arguing along the same lines as in Theorem 3.1(i) (respectively, Theorem 3.1(ii)), we obtain (i) (respectively, (ii)). □

It follows from Propositions 4.7 and 4.8 that Theorem 7.2 covers the weak convergence results of [10], [12], and [13]. A closely related algorithm is proposed in [34, section 11] with similar weak convergence results.

Acknowledgments. The author wishes to express his gratitude to the two anonymous referees for their valuable remarks.

VARIATIONAL PRINCIPLES AND WELL-POSEDNESS IN OPTIMIZATION AND CALCULUS OF VARIATIONS*

ALEXANDER D. IOFFE† AND ALEXANDER J. ZASLAVSKI†

Abstract. The concluding result of the paper states that variational problems are generically solvable (and even well-posed in a strong sense) without the convexity and growth conditions always present in individual existence theorems. This and some other generic well-posedness theorems are obtained as realizations of a general variational principle extending the variational principle of Deville–Godefroy–Zizler.

Key words. calculus of variations, variational principle, existence of solutions, well-posed optimization problem

1. Introduction.

The Tonelli existence theorem in the calculus of variations [1] and its subsequent modifications (e.g., [2, 3, 4, 6, 5, 7, 8]) are based on two fundamental hypotheses concerning the behavior of the integrand as a function of the last argument (derivative): (1) the integrand should grow superlinearly at infinity and (2) that it should be convex (or exhibit a more special convexity property in case of a multiple integral with vector-valued functions) with respect to the last variable. The first hypothesis guarantees relative weak compactness of level sets of the functional and the second (together with the first) that it is lower semicontinuous (l.s.c.) in the same weak topology. In the absence of the latter the existence can still be proved but for the convexified or relaxed problem, while in the absence of the first no existence can be established at all. A few exceptions (e.g., [9, 7, 10, 11]) with very restrictive additional requirements rather confirm the need of the assumptions for general *individual* existence theorems.

Surprisingly, none of these two fundamental hypotheses is needed *generically*, and not only for the existence but also for uniqueness of a solution and even for well-posedness of the problem in a very strong sense (with respect to some special topology in the space of integrands). This is the content of the concluding theorem of this paper which we call the *antirelaxation theorem*. This theorem extends to multiple integrals and to variational problems with extended-real-valued integrands, in particular, to variational problems with explicit (nonfunctional) constraints on state variables and their derivatives.

The possibility to get generic well-posedness (with respect to variations of the integrand of the integral functional) without the convexity assumption was for the first time established by the second author [12] for a class of optimal control problems satisfying the Cesari growth condition.[1] Meanwhile, the first author was for some

[1] In a certain specific situation this possibility was mentioned by Asplund as early as in 1968 in his seminal paper [13]. We are thankful to the referee who drew our attention to this part of Asplund's paper.

time involved in a search of a general variational principle [14]. The main stimulus for this study has come from understanding that a common ground for the quoted result of [12] and some other generic well-posedness theorems (e.g., [15, 16]) should be looked for in the form of some "universal" variational principle probably having its prototype in the most recent variational principle of Deville–Godefroy–Zizler [17].

The variational principle of Deville–Godefroy–Zizler can also be interpreted as a statement that for a certain class of functions the minimization problem is uniquely solvable generically, and a closer look at its proof allows the generic well-posedness of the problem to be distilled. In this interpretation, however, the principle applies to a rather narrow class of minimization problems and it turns out that the main restriction comes from the assumption that there must be a continuous bump function by which (or certain transformations of which) we can perturb the functions to be minimized. This assumption effectively excludes such classes of functions or problems as, say, convex functions or problems of calculus of variations.

The key result of this paper, the *generic variational principle* of Theorem 2.2, is a modification of Deville–Godefroy–Zizler's variational principle which allows a substantially broader class of perturbations. As consequences of the theorem we get the already mentioned antirelaxation theorem, the theorem of Beer–Lucchetti [15] about generic well-posedness of minimization for convex l.s.c. functions, its extension to quasi-convex functions (which is probably a new result), a simple proof of a genericity theorem of Asplund [13] along with a characterization of Asplund spaces basically due to Ekeland–Lebourg [18], extensions of some well-posedness theorems collected in [16], in particular a theorem of Revalski [19] dealing with restrictions of continuous functions to closed sets, and the variational principle of Deville–Godefroy–Zizler itself. None of these results, with the obvious exception of the last, follows from the principle of Deville–Godefroy–Zizler. (Note that our main results as well as the variational principles of Ekeland, Borwein–Preiss, and Deville–Godefroy–Zizler apply to arbitrary l.s.c. functions but need a metric or a uniform structure in the domain space. We refer to [20] for a survey of results concerning generic well-posedness of minimization for continuous functions on completely regular topological spaces. It is to be observed that in the context of well-posedness continuity is often a restrictive requirement. The calculus of variations is the most important example of that sort.)

The proofs of all mentioned applications of the main theorem are built according to more or less the same scheme which consists in verification in each case of some basic hypotheses (H) introduced in the next section. We understand that the same scheme can easily be applied to get various variations and strengthenings of the results presented in this paper. (For example, it is easy to extend the antirelaxation theorem to variational problems over functions with values in infinite-dimensional spaces.) But we have stated the main theorem with a number of more complicated and so far unsolved problems in mind; first of all, problems with functional constraints (e.g., the problem of Lagrange in the calculus of variations or optimal control problems) in which constraint functions and maps are also subjects of variation as well as the cost function.

2. Generic variational principle. We shall consider two complete metric spaces (X, ρ) and $(\mathcal{A}, d)$, the first being called the *domain space* and the second the *data space*. We shall further assume that with every $a \in \mathcal{A}$ an l.s.c. function f_a on X is associated with values in $\overline{\mathbb{R}} = [-\infty, \infty]$ and none of these functions is identical $+\infty$. The following is the basic hypotheses about the functions which we adopt in the theorem:

(H) *There is a dense subset $\mathcal{B} \subset \mathcal{A}$, such that for any $a \in \mathcal{B}$, any $\varepsilon > 0$, and any*

$\gamma > 0$ there exist a nonempty open set $U \subset \mathcal{A}$, $x \in X$, $\alpha \in \mathbb{R}$, and $\eta > 0$ such that for any $b \in U$

(i) *$d(a,b) < \varepsilon$ and $\inf f_b > -\infty$;*

(ii) *if $z \in X$ is such that $f_b(z) \le \inf f_b + \eta$, then $\rho(z,x) \le \gamma$ and $|f_b(z) - \alpha| \le \gamma$.*

DEFINITION 2.1. *Given an $a \in \mathcal{A}$, we say that the problem of minimization of f_a on X is well-posed with respect to data in $\mathcal{A}$ (or just with respect to $\mathcal{A}$) if*

(1) *$\inf f_a$ is finite and attained at a unique point $x_a \in X$;*

(2) *for any $\varepsilon > 0$ there is a $\delta > 0$ such that $\inf f_b > -\infty$ for any $b \in \mathcal{A}$ satisfying $d(a,b) < \delta$ and, moreover, any $z \in X$ for which $f_b(z) \le \inf f_b + \delta$ satisfies $\rho(z, x_a) < \varepsilon$, $|f_b(z) - f(x_a)| < \varepsilon$.*

(In a slightly different setting a similar property was introduced in [21].)

THEOREM 2.2 (generic variational principle). *Assume* (H). *Then, the minimization problem for f_a is well-posed with respect to $\mathcal{A}$ for a generic $a \in \mathcal{A}$. In other words, there is a dense G_δ subset $\mathcal{A}' \subset \mathcal{A}$ such that for any $a \in \mathcal{A}'$ the minimization problem for f_a is well-posed with respect to $\mathcal{A}$.*

Proof. Take an $a \in \mathcal{B}$. By (H) for any natural $n = 1, 2, \dots$ there is a nonempty open set $U(a,n) \subset \mathcal{A}$, $x(a,n) \in X$, and numbers $\alpha(a,n)$ and $\eta(a,n) > 0$ such that for any $b \in U(a,n)$ we have

$$d(a,b) < 1/n; \ \inf f_b > -\infty; \tag{2.1}$$

and, whenever $f_b(z) \le \inf f_b + \eta(a,n)$,

$$\rho(z, x(a,n)) < 1/n, \qquad |f_b(z) - \alpha(a,n)| < 1/n. \tag{2.2}$$

Consider the set

$$\mathcal{A}_n = \bigcup_{\substack{a \in \mathcal{B} \\ m \ge n}} U(a,m).$$

Clearly, this set is dense and open, so by the Baire category theorem $\mathcal{A}' = \bigcap \mathcal{A}_n$ is a dense G_δ subset of $\mathcal{A}$.

Let $a \in \mathcal{A}'$. Then there is a sequence $\{a_n\} \subset \mathcal{B}$ and a sequence $\{k_n\} \to \infty$ of natural numbers such that $a \in U(a_n, k_n) = U_n$. Set $x_n = x(a_n, k_n)$, $\alpha_n = \alpha(a_n, k_n)$, and $\eta_n = \eta(a_n, k_n)$. We assume without loss of generality that $\eta_n \to 0$ decreasingly. Let z_n be such that $f_a(z_n) < \inf f_a + \eta_n$. Then $f_a(z_n) < \inf f_a + \eta_m$ if $m \le n$, so by (2.2) $\rho(z_n, x_m) \le 1/m$. It follows that $\rho(z_n, z_{n+k}) \le 2/m$ whenever $n \ge m$, that is, $\{z_n\}$ is a Cauchy sequence. Set $x_a = \lim z_n$. As f_a is l.s.c., we have $f_a(x_a) = \inf f_a$. Clearly, f_a does not have another minimizer for otherwise we would be able to construct a nonconvergent sequence $\{z_n\}$. This proves the first part of the theorem. We further note that by (2.2) $f_a(x_a) = \lim \alpha_n$.

To prove the second part, consider a sequence $\{b_n\} \subset \mathcal{A}$ converging to a, and let w_n be such that $\xi_n = f_{b_n}(w_n) - \inf f_{b_n} \to 0$. Choose $n(m)$ such that $b_n \in U_m$ and $\xi_n \le \eta_m$ for $n \ge n(m)$. For such n we have by (2.2) $\rho(w_n, x_m) \le 1/m$ and $|f_{b_n}(w_n) - \alpha_m| \le 1/m$. As $x_m \to x_a$ and $\alpha_m \to f_a(x_a)$, it follows that $w_n \to x_a$ and $f_{b_n}(w_n) \to f_a(x_a)$. This completes the proof.

Remark 2.3. As follows from the proof, there is no need to require that $(\mathcal{A}, d)$ be a complete metric space; it is sufficient to assume that it is a *Baire* space, that is, a space in which the Baire category theorem holds.

To conclude the section we observe that the variational principle of Deville–Godefroy–Zizler [17] is an immediate consequence of the theorem. To prove this

we consider a Banach space $\mathcal{A}$ of bounded continuous functions on a Banach space X with the following three properties:

(a) the norm topology in $\mathcal{A}$ is not weaker than the topology of uniform convergence on X: $\|a\|_{\mathcal{A}} \geq \sup\{|a(x)| : x \in X\}$;

(b) $\mathcal{A}$ contains compositions of its elements with translations and homotheties of X and $\|a(t+\cdot)\|_{\mathcal{A}} = \|a\|_{\mathcal{A}}$ for each $a \in \mathcal{A}$ and each $t \in X$;

(c) $\mathcal{A}$ contains a bump function, that is to say, a function $\varphi(x)$ supported on the unit ball and satisfying $0 \leq \varphi(x) \leq 1 = \varphi(0)$.

Under these assumptions, the variational principle of Deville–Godefroy–Zizler states that *for any proper l.s.c. and bounded below function f on X the set of $a \in \mathcal{A}$ for which $f + a$ attains a unique minimum on X is a dense G_δ subset of $\mathcal{A}$.*

To prove the statement we set $f_a = f + a$ and, given $a \in \mathcal{A}$, $\varepsilon > 0, \gamma > 0$, choose $\varepsilon_0 \in (0, \min\{\varepsilon/4, \gamma/4\})$ such that $\varepsilon_0 \|\psi\|_{\mathcal{A}} < 4^{-1}\varepsilon$, where $\psi(x) = \varphi(\gamma^{-1}x)$, $x \in X$, take an $\bar{x} \in X$ with $f_a(\bar{x}) < \inf f_a + \varepsilon_0/5$, and set $\bar{a}(x) = a(x) - (4\varepsilon_0/5)\psi(x - \bar{x})$, $U = \{b \in \mathcal{A} : \|b - \bar{a}\|_{\mathcal{A}} < \varepsilon_0/10\}$, $\alpha = f_{\bar{a}}(\bar{x})$, and $\eta = \varepsilon_0/10$. It is an easy matter, then, to verify that for any $b \in U$ and $z \in X$ with $f_b(z) \leq \inf f_b + \eta$

$$\alpha - \varepsilon_0 \leq f_{\bar{a}}(z) < f_b(z) + \varepsilon_0/10 \leq \inf f_b + \varepsilon_0/5 \leq \inf f_{\bar{a}} + 3\varepsilon_0/10 \leq \alpha + 3\varepsilon_0/10 \leq \inf f_a,$$

which implies both $|\alpha - f_b(z)| \leq 2\varepsilon_0 < \gamma$ and $f_{\bar{a}}(z) < \inf f_a$. Then $\|z - \bar{x}\| \leq \gamma$ because otherwise by the definition of $\bar{a}$ $f_a(z) = f_{\bar{a}}(z)$, a contradiction.

We shall see that a similar chain of arguments works in many other cases.

3. Epi-distance topology. In what follows we shall fix a certain "zero element" $\theta \in X$, set $\|x\| = \rho(\theta, x)$, $B(r) = \{x : \|x\| \leq r\}$, and agree to call a set $C \subset X$ *bounded* if $C \subset B(r)$ for some r.

Let $\mathrm{LSC}(X)$ denote the collection of all l.s.c. functions on X with values in $\bar{\mathbb{R}} = [-\infty, \infty]$ which are not identically equal to ∞. We shall next introduce a suitable topological structure in LSC(x) which will allow us to apply Theorem 2.2 to several important classes of l.s.c. functions.

Definition 3.1 (see [22]). *The epi-distance topology in LSC(X) is defined by the uniform structure formed by the sets*

$$U(\varepsilon, K) = \{(f, g) : f, g \in \mathrm{LSC}(X) \text{ and } |\operatorname{dist}((\alpha, x), \operatorname{epi} f) - \operatorname{dist}((\alpha, x), \operatorname{epi} g)| < \varepsilon, \text{ if } |\alpha| \leq K, \ \|x\| \leq K\}.$$

Here we set $\operatorname{dist}((\alpha, x), (\beta, u)) = |\alpha - \beta| + \rho(x, u)$.

Clearly, the uniform space $\mathrm{LSC}(X)$ is metrizable by a complete metric $d(\cdot, \cdot)$. (See e.g., [22]—although the proof is given there only for the case when X is a Banach space, the proof for an arbitrary metric space is not much different.) The following lemma contains crucial information about the behavior of functions close in $\mathrm{LSC}(X)$.

Lemma 3.2. *Let $\bar{f} \in \mathrm{LSC}(X)$ be bounded below. Suppose $\delta \in (0, 1)$ and a $\lambda \in \mathbb{R}$ are such that $\lambda > \inf \bar{f} + \delta$. Set*

$$\mathcal{L}_\lambda = \{x : \bar{f}(x) \leq \lambda\}. \tag{3.1}$$

Then for any $\gamma > 0$, $R > 0$ there is an $\varepsilon > 0$ such that for any other $f \in \mathrm{LSC}(X)$ with $d(f, \bar{f}) \leq \varepsilon$ we have $\inf f \leq \lambda - \delta/2$ and for any $z \in X$ satisfying $f(z) \leq \inf f + \varepsilon$ either $\inf \bar{f} \leq f(z) + \gamma$ and $\rho(z, \mathcal{L}_\lambda) \leq \gamma$ or $\|z\| \geq R$.

Proof. Taking if necessary a larger R, we may assume that $R > |\lambda| + |\inf \bar{f}| + 1$. Set $\sigma = \min\{\delta/4, \gamma/2\}$. Take an x with $\bar{f}(x) < \inf \bar{f} + \sigma$ and choose $\epsilon \in (0, \sigma)$ so small that for f with $d(f, \bar{f}) < \epsilon$ we have

$$|\operatorname{dist}((\alpha, z), \operatorname{epi} f) - \operatorname{dist}((\alpha, z), \operatorname{epi} \bar{f})| < \sigma, \tag{3.2}$$

if $|\alpha| \le R + \|x\|, \|z\| \le R + \|x\|$.

Clearly, $x \in \mathcal{L}_\lambda$ and for any f within ε of $\bar{f}$ we have by (3.2) for $\alpha = \inf \bar{f} + \sigma$

$$\operatorname{dist}((\alpha, x), \operatorname{epi} f) < \sigma,$$

which means that

$$f(x') < \alpha + \sigma = \inf \bar{f} + 2\sigma$$

with some x'. It follows that $\inf f < \lambda - \delta/2$.

Now let z be such that $f(z) \le \inf f + \varepsilon$. If further $||z|| \le R$, then by (3.2)

$$\operatorname{dist}((\max\{f(z), \inf \bar{f} - 1\}, z), \operatorname{epi} \bar{f}) < \sigma.$$

It follows that

$$\bar{f}(u) \le \max\{f(z), \inf \bar{f} - 1\} + \sigma$$

for some u such that $\rho(u, z) < \sigma$. Thus (as $\bar{f}(u) > \inf \bar{f} - 1 + \sigma$)

$$\bar{f}(u) \le f(z) + \sigma < \inf f + \varepsilon + \sigma \le \inf f + \delta/2 < \lambda.$$

This inequality gives $u \in \mathcal{L}_\lambda$; hence $\rho(z, \mathcal{L}_\lambda) \le \rho(u, z) < \sigma \le \gamma$ and $\inf \bar{f} \le \bar{f}(u) \le \inf f + \gamma$ which completes the proof.

4. Generic well-posedness of minimization for three classes of l.s.c. functions. We shall first apply our main theorem to the simplest case when elements of the data space are the functions themselves. Namely, we are ready now to consider the minimization problem for three important classes of l.s.c. functions, namely, convex l.s.c. functions, quasi-convex l.s.c functions, and arbitrary l.s.c functions satisfying a certain uniform growth condition. To this end we first fix some complete metric $d(f, g)$ in $\mathrm{LSC}(X)$ which is compatible with the epi-distance topology.

THEOREM 4.1. *In each of the following three cases the minimization problem for a generic $f \in \mathcal{A}$ is well-posed with respect to the space $\mathcal{A}$:*

(a) *X is a Banach space and $\mathcal{A}$ is the set of all convex l.s.c. functions on X;*

(b) *X is a Banach space and $\mathcal{A}$ is the set of all quasi-convex l.s.c. functions on X;*

(c) *X is a complete metric space and $\mathcal{A}$ is a collection of elements of* $\mathrm{LSC}(X)$ *satisfying $f(x) \ge \varphi(x)$ for all x, where $\varphi \in \mathrm{LSC}(X)$ satisfies $\varphi(x) \to \infty$ as $\|x\| \to \infty$.*

Proof. It is an easy matter to verify in either case that $\mathcal{A}$ is a closed subset of $\mathrm{LSC}(X)$; hence a complete metric space itself.

Let $\tilde{\mathcal{A}}$ denote the collection of those elements of $\mathcal{A}$ which are bounded below. We first observe that $\tilde{\mathcal{A}}$ is dense in $\mathcal{A}$. Indeed, for each $f \in \mathcal{A}$ the functions $f_n(x) = \max\{f(x), -n\}$, $x \in X$, $n = 1, 2, \dots$ belong to $\tilde{\mathcal{A}}$ and converge to f in the epi-distance topology. Let $\mathcal{B}$ denote the collection of those elements of $\tilde{\mathcal{A}}$ which attains its minimum. It can easily be seen that $\mathcal{B}$ is dense in $\mathcal{A}$. Indeed, for each $f \in \tilde{\mathcal{A}}$ the functions $f_n(x) = \max\{f(x), f(x_n)\}$, $x \in X$, $n = 1, 2, \dots$ with $x_n \in X$ satisfying $f(x_n) \le \inf f + n^{-1}$ belong to $\mathcal{B}$ and converge to f. Therefore the theorem will be proved if we verify that (H) holds with the $\mathcal{B}$ defined above.

Thus let $f \in \mathcal{B}$, $\varepsilon > 0$, $\gamma > 0$. Let $\bar{x} \in X$, $f(\bar{x}) = \inf f$. Choose a small $\delta \in (0, 1)$ and set

$$\bar{f}(x) = \sup\{f(x), f(\bar{x}) + \delta\rho(x, \bar{x})\}.$$

We can choose δ so small that $d(f, \bar{f}) < \varepsilon/2$.

Next we take a sufficiently big R—its value will be specified in each of the three cases separately. Set $\lambda = f(\bar{x}) + \delta\gamma/2$ and let, as above, $\mathcal{L}_\lambda = \{x : \bar{f}(x) \le \lambda\}$. Then $\mathcal{L}_\lambda$ belongs to the closed ball of radius $\gamma/2$ around $\bar{x}$ (as $\bar{f}(x) \ge f(\bar{x}) + \delta\rho(x, \bar{x})$). By Lemma 3.2 we can find an $\bar{\varepsilon}$ such that for any $g \in \mathrm{LSC}(X)$ with $d(g, \bar{f}) \le \bar{\varepsilon}$ and any z satisfying $g(z) \le \inf g + \bar{\varepsilon}$ we have

$$\inf g \le \lambda - \delta\gamma/8 \tag{4.1}$$

and either

$$\rho(z, \mathcal{L}_\lambda) \le \gamma/2,\ g(z) \ge \inf \bar{f} - \gamma \tag{4.2}$$

or

$$\|z\| \ge R. \tag{4.3}$$

In the first case, when (4.2) holds, we have by (4.2) $\rho(\bar{x}, z) \le \gamma$ and $g(z) \ge f(\bar{x}) - \gamma$ as desired. (The inequality $g(z) \le f(\bar{x}) + \gamma$ follows from (4.1) and the definition of λ if we assume that $\delta < 2/3$ and $\bar{\varepsilon} < \gamma/4$ which, of course, is always possible.)

To complete the proof of the theorem we have to show that in each case R can be chosen to make (4.3) impossible. Then (H) holds with $U = \{g \in \mathrm{LSC}(X)$: $d(g, \bar{f}) < \bar{\varepsilon}\}$, $\eta = \bar{\varepsilon}$, $\alpha = f(\bar{x})$.

In case (c) this is obvious (as $\varphi(z) \le g(z) \le f(\bar{x}) + \gamma$). Therefore we concentrate on (a) and (b). To simplify the calculation we may assume that all small numbers involved are smaller than one and that g is so close to $\bar{f}$ that

$$|\operatorname{dist}((\beta, x), \operatorname{epi} \bar{f}) - \operatorname{dist}((\beta, x), \operatorname{epi} g)| < 1/2, \tag{4.4}$$

if $\delta\|x - \bar{x}\| \le 2$, $|\beta| \le |f(\bar{x})| + 2$.

It follows that $g(x) > f(\bar{x}) + 1$ whenever $\|x - \bar{x}\| = 2/\delta$. Indeed, assuming the contrary, we get from (4.4) for some x and $\beta = f(\bar{x}) + 1$ that $\operatorname{dist}((\beta, x), \operatorname{epi} \bar{f}) < 1/2$; that is, there is an x' with $\|x - x'\| < 1/2$ such that $\bar{f}(x') \le f(\bar{x}) + 3/2$. However,

$$\begin{aligned} \bar{f}(x') &\ge f(\bar{x}) + \delta\|x' - \bar{x}\| \\ &\ge f(\bar{x}) + \delta(\|x - \bar{x}\| - \|x - x'\|) \\ &\ge f(\bar{x}) + 2 - \delta/2 > f(\bar{x}) + 3/2 \end{aligned}$$

and we arrive at a contradiction. Thus $g(x) > f(\bar{x}) + 1$ for any x with $\|x - \bar{x}\| = 2/\delta$. Now take $R > \|\bar{x}\| + 2/\delta$ and assume that (4.3) holds. By the choice of z, we have $g(z) < f(\bar{x}) + 1$ and, as follows from (4.4) for $\beta = f(\bar{x}) = \bar{f}(\bar{x})$,

$$\operatorname{dist}((\beta, \bar{x}), \operatorname{epi} g) < 1/2,$$

which means that there is an x' with $\|x' - \bar{x}\| < 1/2$ such that $g(x') < f(\bar{x}) + 1/2$. As x' lies within the ball of radius $1/2$ around $\bar{x}$, the line segment joining z and x' contains a point x with $\|x - \bar{x}\| = 2/\delta$. For this point

$$g(x) > f(\bar{x}) + 1 \ge \max\{g(z), g(x')\},$$

which cannot be the case either in (a) or in (b). This completes the proof of the theorem.

Remark 4.2. The first statement of the theorem was proved in [15].

5. Perturbations by linear functions: A theorem of Asplund. It is well known that genericity is not hereditary. In other words, a property which is generic on a space may fail to be generic on a subspace. Therefore it is reasonable, in principle, to consider minimization problems corresponding to more restricted collections of data.

The following result was proved in [13]. *Let X be an Asplund space and X^* its dual; let $g(x^*)$ be a norm l.s.c. extended-real-valued function on X^*; and let $f(x)$ be the restriction to X of the Fenchel conjugate of g. Assume that* $\operatorname{int}\operatorname{dom} f \neq \emptyset$. *Then the problem of minimizing $g_x(x^*) = g(x^*) - \langle x^*, x\rangle$ on X^* is generically well-posed with respect to $x \in \operatorname{dom} f$.*

Here $g^*(x^{**}) = \sup_{x^*}(\langle x^{**}, x^*\rangle - g(x^*))$ is the Fenchel conjugate of g and for any extended-real-valued function f on X, $\operatorname{dom} f = \{x : |f(x)| < \infty\}$.

Recall that X is called an *Asplund* space if every continuous convex function on X is Fréchet differentiable on a dense G_δ-set. There are many known characterizations of Asplund spaces. One of them (which is crucial in the proof in [18] is that a space with a Fréchet differentiable bump function is Asplund) is that every continuous convex function on X is ε-differentiable on a dense set. (A convex function f is ε-differentiable at $\bar{x}$ if there is an $x^* \in X^*$ such that $f(x) \le f(\bar{x}) + \langle x^*, x - \bar{x}\rangle + \varepsilon\|x - \bar{x}\|$ for all x of a neighborhood of $\bar{x}$.)

We shall show that both the quoted well-posedness theorem and the characterization of Asplund spaces follow from the generic variational principle of Theorem 2.2.

THEOREM 5.1. *For any Banach space X the following three statements are equivalent:*

(a) *X is an Asplund space;*

(b) *for any $\varepsilon > 0$, any continuous convex function on X is ε-differentiable on a dense subset of X;*

(c) *for any norm l.s.c. function g on X^* such that the domain of the restriction of its Fenchel conjugate to X has nonempty interior, the problem of minimization of $g_x(x^*) = g(x^*) - \langle x^*, x\rangle$ is generically well-posed with respect to $x \in \operatorname{dom} g^* \bigcap X$.*

(We observe that under the assumptions, $\operatorname{dom} g^* \bigcap X$ belongs to the closure of its interior; hence it is a Baire space—see Remark 2.3.)

Proof. The implication (a)⇒(b) is trivial; (c)⇒(a) follows from Šmulyan's duality between differentiability and rotundity [23]. Under the conditions of (c), if we denote, as above, the restriction of g^* to X by f, this duality reduces to equivalence of the following two properties for any $\bar{x} \in X$ and any $\bar{x}^* \in X^*$ (see [13]):

(i) there is a nonnegative convex l.s.c. function $\xi(t)$ (extended-real-valued) on $[0, \infty)$ such that $\xi(t)/t \to 0$ as $t \to 0$ and

$$f(x) \le f(\bar{x}) + \langle \bar{x}^*, x - \bar{x}\rangle + \xi(\|x - \bar{x}\|)$$

for all x;

(ii) there exists a convex l.s.c. function $\delta(t)$ on $[0, \infty)$ equal to zero at zero and positive for positive t, such that

$$g(x^*) \ge g(\bar{x}^*) + \langle x^* - \bar{x}^*, \bar{x}\rangle + \delta(\|x^* - \bar{x}^*\|)$$

for all x^*.

We have, therefore, to show that (b)⇒(c). Thus assume that (b) holds and g and f are as in (c). This means that $f(x) = -\inf_{x^*} g_x(x^*)$. We claim that for any x belonging to $\operatorname{int}\operatorname{dom} f$ there are $\varepsilon > 0$ and $r > 0$ such that for any $u \in x + B(u, \varepsilon)$ there is a minimizing sequence for g_u which belongs to the ball of radius r (around the origin) in X^*. Indeed, being weak l.s.c., f is continuous at x, so we can choose ε

so small that the entire ball $B(x, 2\varepsilon)$ (of radius 2ε around x) belongs to $\operatorname{int}\operatorname{dom} f$ and f is bounded above on the ball. If the claim is not true, then for any n we can find $u_n \in B(x, \varepsilon)$ within ε and $\{x_n^*\}$ such that $g_{u_n}(x_n^*) \le \inf g_{u_n} + 1/n$ and $\|x_n^*\| \to \infty$. But then we can take an $h \in X$ with the norm less than ε such that $\langle x_n^*, h\rangle \to -\infty$ in which case $-f(u_n) \le g_{u_n+h}(x_n^*) \to -\infty$, which (as $u_n + h \in B(x, 2\varepsilon)$) contradicts to the fact that f is bounded above on the ball.

It follows that for any $x \in \operatorname{int}\operatorname{dom} f$ there is an $r > 0$ such that the Fenchel conjugate f^r of the restriction of g to the ball of radius r around the origin (that is, the function equal to $g(x^*)$ if $\|x^*\| \le r$ and $+\infty$ otherwise) coincides with f in a neighborhood of x. But f^r, being conjugate to a function with bounded domain and bounded below, is everywhere finite, hence continuous, and by (b) densely Fréchet differentiable.

Thus, for any $x \in \operatorname{dom} f$ and any $\varepsilon > 0$ there is an $\bar{x}$ such that $\|\bar{x} - x\| < \varepsilon$ and f is Fréchet differentiable at $\bar{x}$. Let $\bar{x}^*$ be the derivative of f at $\bar{x}$. Then the property (i) above holds and therefore the property (ii).

Now, given a $\gamma > 0$, we choose a $\sigma > 0$ so small that $\sigma < \gamma/2$ and $\delta(t) > 2\sigma t$ if $t > \gamma$ and define a neighborhood U as the open ball of radius σ around $\bar{x}$. For any $u \in U$ we have by (ii)

$$g_u(x^*) \ge g_u(\bar{x}^*) + \delta(\|x^* - \bar{x}^*\|) - \langle x^* - \bar{x}^*, u - \bar{x}\rangle,$$

so that for $u \in U$ we have $g_u(x^*) \ge g_u(\bar{x}^*) + \sigma\|x^* - \bar{x}^*\| \ge g_u(\bar{x}^*) + \sigma\gamma$ if $\|x^* - \bar{x}^*\| > \gamma$. Now taking $\eta < \sigma\gamma/2$, we verify (H).

Thus by Theorem 2.2 the problem of minimizing g_x is generically well-posed with respect to $x \in \operatorname{dom} f$, that is, (c) is true.

6. Minimization subject to a nonfunctional constraint. This section is devoted to minimization problems of the form

$$\text{(P)} \qquad \text{minimize} \quad f(x) \quad \text{subject to} \quad x \in A,$$

with $A \subset X$ closed and f continuous and bounded below. This problem of course reduces to minimization of the restriction $f|_A$ of f to A and therefore can be considered in the framework of unconstrained minimization of l.s.c. extended-real-valued functions. However it is more natural to consider the pair (f, A) as the given data, rather than $f|_A$, and in this context Theorem 4.1 does not allow one to make any conclusion about generic solvability and well-posedness of the problem (as perturbations of $f|_A$ in $\operatorname{LSC}(X)$ may not be represented as restrictions of continuous functions).

In this section we use the notation introduced in the beginning of section 3 with $\|x\|$ standing for the distance from x to a specified "zero" element. Denote by $S(X)$ the collection of all closed subsets of X. We shall consider two complete metrics in $S(X)$: the metric $h_1(A, B)$ compatible with the Hausdorff topology (which is a completely metrizable topology defined by the uniform structure with the base

$$W_1(\varepsilon) = \{(A, B) : \ \rho(x, B) \le \varepsilon,\ x \in A,\ \rho(y, A) \le \varepsilon,\ y \in B\})$$

and a weaker metric $h_2(A, B)$ compatible with the bounded Hausdorff (Attouch–Wets) topology (which is a completely metrizable topology defined by the uniform structure with the base (see, e.g., [22])

$$W_2(\varepsilon, R) = \{(A, B) : \ |\rho(x, A) - \rho(x, B)| < \varepsilon \quad \forall x \in X,\ \|x\| \le R\}.$$

Let $\mathrm{C}^+(X)$ further be the collection of all continuous real-valued functions on X bounded from below. As for sets, we shall consider two metric structures in $\mathrm{C}^+(X)$; the first (complete) metric $r_1(f,g)$ is compatible with the topology of uniform convergence of elements of $\mathrm{C}^+(X)$ on X and the second weaker metric $r_2(f,g)$ can be any metric compatible with the topology of uniform convergence of elements of $\mathrm{C}^+(X)$ on bounded subsets of X (that is, on balls $B(R)=\{x:\|x\|\le R\}$).

Finally, let $\varphi(x)$ be a function on X bounded below and such that $\varphi(x)\to\infty$ as $\|x\|\to\infty$. Set

$$\mathrm{C}(X,\varphi)=\{f(\cdot)\in\mathrm{C}^+(X):\ f(x)\ge\varphi(x)\ \forall x\in X\}.$$

It is a trivial matter to verify that $\mathrm{C}(X,\varphi)$ is a complete subspace of $(\mathrm{C}^+(X),r_2)$. (The latter itself may be incomplete.)

The data spaces to be considered consist of pairs $a=(f,A)$ and we write f_a for $f|_A$ (so that for $b=(g,B)$ we have $f_b=g|_B$). In the theorem below we consider two data spaces of this kind: $(\mathcal{A}_1,d_1(a,b))$, where $\mathcal{A}_1=\mathrm{C}^+(X)\times S(X)$, and $(\mathcal{A}_2,d_2(a,b))$, where $\mathcal{A}_2=\mathrm{C}(X,\varphi)\times S(X)$ and for $a=(f,A),\ b=(g,B)$ the ith distance $(i=1,2)$ $d_i(a,b)$ is defined by $d_i(a,b)=r_i(f,g)+h_i(A,B)$.

THEOREM 6.1. *The problem* (P) *is generically well-posed with respect to both* $\mathcal{A}_1$ *and* $\mathcal{A}_2$.

Proof. We have to verify that in either case (H) holds. Therefore let $a=(f,A),\ \gamma>0$, and a neighborhood V of a, either in $\mathcal{A}_1$ or in $\mathcal{A}_2$ be given. We may assume that in the first case

$$V=\{b=(g,B):\ |f(x)-g(x)|\le\varepsilon\ \ \forall x\in X,\ \rho(x,B)\le\varepsilon\ \ \forall x\in A,\ \rho(y,A)\le\varepsilon\ \ \forall y\in B\}$$

with some $\varepsilon>0$ and in the second case

$$V=\{b=(g,B):\ |f(x)-g(x)|\le\varepsilon,\ x\in B(K),\ (A,B)\in W_2(\varepsilon,K)\}$$

with some $\varepsilon,K>0$. We may assume that $\varepsilon,\gamma<1$.

We choose positive numbers $\delta_1,\ \varepsilon_1,\ \bar\varepsilon$, and an $\bar x\in X$ to make sure that

$$\begin{aligned}&\varepsilon_1,\delta_1<(1/8)\min\{\varepsilon,\gamma\};\\ &\rho(\bar x,A)<\varepsilon_1;\ f(\bar x)\le\inf\{f(x):\ \rho(x,A)<\varepsilon_1\}+\delta_1;\\ &\bar\varepsilon<(\varepsilon_1-\rho(\bar x,A))/4.\end{aligned}$$

Let $\lambda(x)$ be a continuous function on X assuming values between 1 and 0 and such that $\lambda(x)=1$ if $\rho(x,(A\cup\{\bar x\}))\le\bar\epsilon$ and $\lambda(x)=0$ if $\rho(x,A)\ge\varepsilon_1$. Set

$$\begin{aligned}&\bar A=A\bigcup\{\bar x\};\\ &\bar f(x)=(1-\lambda(x))f(x)+\lambda(x)\max\{f(x),f(\bar x)+2\delta_1\min\{1,\gamma^{-1}\rho(x,\bar x)\}\};\\ &\bar a=(\bar f,\bar A).\end{aligned}$$

As in the previous section, we see that

(6.1)

$$f_{\bar a}(\bar x)=f(\bar x)=\bar f(\bar x)=\min f_{\bar a};\ \bar f(x)\ge f(\bar x)+2\delta_1,\quad\text{if } \rho(x,\bar x)\ge\gamma \text{ and } \rho(x,\bar A)\le\bar\varepsilon.$$

It also follows from the definition of $\bar f$ and $\bar x$ that

(6.2)
$$|f(x)-\bar f(x)|\le 3\delta_1\quad\forall\, x\in X.$$

Clearly, there exist a neighborhood U_1 of $\bar{f}$ and a neighborhood U_2 of $\bar{A}$ such that $U_1 \times U_2 \subset V$. We will show that U_1 and U_2 can be chosen so small that (H) holds with

$$U = U_1 \times U_2, \quad x = \bar{x}; \quad \alpha = f(\bar{x}); \quad \eta = \delta_1.$$

Choose a positive number ε_2 such that

$$|\bar{f}(\bar{x}) - \bar{f}(u)| < \delta_1/4, \quad \text{if } \rho(u, \bar{x}) < \varepsilon_2.$$

We can choose U_1 and U_2 sufficiently small to make sure that

(a) for $g \in U_1$

$$|\bar{f}(u) - g(u)| < \delta_1/4$$

for all $u \in X$ in the first case and for all u within R of $\bar{x}$ in the second case, where $R > 4$ is big enough to make sure that $\varphi(x) > f(\bar{x}) + 8\delta_1$ if $\rho(x, \bar{x}) > R$. In the first case we set $R = \infty$,

(b) any $B \in U_2$ contains a point u with $\rho(u, \bar{x}) < \varepsilon_2$ and

(c) for each $B \in U_2$ and each $u \in B$ satisfying $\rho(u, \bar{x}) \le R$:

$$\rho(u, \bar{A}) \le 2^{-1}\bar{\varepsilon}. \tag{6.3}$$

Let $b = (g, B) \in U$. In either case there is $u \in B$ such that $\rho(u, \bar{x}) < \varepsilon_2$ at which

$$\inf f_b \le g(u) \le \bar{f}(u) + \delta_1/4 \le \bar{f}(\bar{x}) + \delta_1/2.$$

If now $z \in B$ is such that $g(z) \le \inf f_b + \delta_1$, then

$$g(z) \le \bar{f}(\bar{x}) + \delta_1/2 + \delta_1, \quad \rho(z, \bar{x}) \le R, \quad \bar{f}(z) \le g(z) + \delta_1/4 < \bar{f}(\bar{x}) + 2\delta_1.$$

As follows from (6.3) and (6.1)

$$\rho(z, \bar{A}) \le \bar{\varepsilon}/2, \ \rho(z, \bar{x}) \le \gamma.$$

Clearly, $|g(z) - f(\bar{x})| \le 2\delta_1 < \gamma$. The proof is completed.

Remark 6.2. For $\mathcal{A}_1$ the theorem was proved in [19].

7. Topology of uniform convergence modulo given growth. We shall now pass to the last application of the generic variational principle, the antirelaxation theorem. But before we have to consider in some details the space of integrands and certain special topologies in this space.

We consider here the collection $\mathrm{LSC}^+(X)$ of nonnegative l.s.c. proper functions on X with another topology (or, more precisely, a series of topologies). Namely, for any $p \ge 1$ we introduce a uniform structure in $\mathrm{LSC}^+(X)$ with the basis formed by the sets

$$U_p(\varepsilon) = \{(f, g) : \ |f(x) - g(x)| \le \varepsilon(\|x\|^p + 1) \quad \forall\, x \in X\}$$

with the convention that $\infty - \infty = 0$. (As above, $\|x\|$ is the distance from x to a "zero" element.) Verification that these sets form a basis of a uniform structure for any p is an easy matter. We shall denote $\mathrm{LSC}^+(X)$ with the corresponding topology by $\mathrm{LSC}_p{}^+(X)$.

Observe that $\mathrm{LSC}_p{}^+(X)$ is a "very" disconnected space. Indeed, fix an $f_0 \in \mathrm{LSC}_p{}^+(X)$ and let

$$\tilde{U} = \bigcup_{\varepsilon>0} \{g \in \mathrm{LSC}(X) :\ (g, f_0) \in U_p(\varepsilon)\}.$$

Clearly, $\tilde{U}$ is a open set. For any $f \notin \tilde{U}$ we have

$$\sup_x \frac{|f(x) - f_0(x)|}{\|x\|^p + 1} = \infty.$$

Therefore if $(g, f) \in U_p(\varepsilon)$ for some ε, the equality above will not change if we replace f by g which means that $g \notin \tilde{U}$. In other words, the complement of $\tilde{U}$ is also an open set. The above argument actually proves the following.

PROPOSITION 7.1. *Functions $f, g \in \mathrm{LSC}(X)$ belong to the same connected component of $\mathrm{LSC}_{\mathrm{p}}^+(X)$ if and only if $(g, f) \in U_p(\varepsilon)$ for some ε; in particular, in this case* $\mathrm{dom}\, f = \mathrm{dom}\, g$.

It is clear that $\mathrm{LSC}_p{}^+(X)$ is metrizable. Moreover it is complete as follows from the proposition below.

PROPOSITION 7.2. *The space $\mathrm{LSC}_p{}^+(X)$ is complete.*

Proof. Let $\{f_m\}$ be a fundamental sequence in $\mathrm{LSC}_p{}^+(X)$. This means that there is a sequence of positive numbers $\{\varepsilon_m\}$ converging to zero such that $(f_n, f_{n+k}) \in U_p(\varepsilon_m)$ for all $n \geq m$ and all k. Let $\mathcal{D}$ be the common domain of all f_m. Clearly, for every x the sequence of values $f_m(x)$ converges. Denote the pointwise limit function by $f(x)$. Its domain is also $\mathcal{D}$ and for any m the inequality

$$|f_m(x) - f(x)| \leq \varepsilon_m(\|x\|^p + 1) \tag{7.1}$$

holds.

It remains to verify that $f \in \mathrm{LSC}_p{}^+(X)$, that is to say, that f is proper and l.s.c. The first is obvious. The second is an immediate consequence of the inequality (7.1) as for any m any x and any sequence $\{x_n\}$ converging to x

$$\begin{aligned} \liminf_{n\to\infty} f(x_n) &\geq \liminf_{n\to\infty} f_m(x_n) - \varepsilon_m(\|x\|^p + 1) \\ &\geq f_m(x) - \varepsilon_m(\|x\|^p + 1) \geq f(x) - 2\varepsilon_m(\|x\|^p + 1). \end{aligned}$$

8. Spaces of integrands. Let (T, Ξ, μ) be a space with a positive measure (which can be infinite). By $\mathcal{I}_p^+(T, X)$ we denote the topological space whose elements are nonnegative extended-real-valued functions $f(t, x)$ on $T \times X$ with the following properties:

(P1) f is $\mathcal{L} \bigotimes \mathcal{B}$-measurable, that is to say, measurable with respect to the σ-algebra generated by products of elements of Ξ and Borel subsets of X;

(P2) $f(t, \cdot)$ is l.s.c. and proper for almost every $t \in T$;

(P3) there is an $x(\cdot) \in L_p(T, X)$ such that $f(t, x(t)) \in L_1$.

The topology in $\mathcal{I}_p^+(T, X)$ is generated by the uniform structure whose basis is formed by the sets

$$\begin{aligned} V_p(\varepsilon) = \{(f, g) :\ &\exists\ \varphi \in B(T, \Xi, \mu),\ \varphi(t) \geq 0 \text{ such that} \\ &|f(t, x) - g(t, x)| < \varepsilon(\|x\|^p + \varphi(t)) \quad \forall x \in X \text{ almost everywhere on } T\}, \end{aligned}$$

where $B(T, \Xi, \mu)$ is the unit ball in $L_1(T, \Xi, \mu)$.

To be more precise, we have to define elements of $\mathcal{I}_p^+(T,X)$ as classes of functions equivalent in the sense that $f \sim f'$ if and only if $f(t,\cdot) = f'(t,\cdot)$ for almost every t. Properties (P1) and (P2) of elements of $\mathcal{I}_p^+(T,X)$ mean that they are *normal integrands* [7].

In this definition, as above, we adopt the convention that $\infty - \infty = 0$; we also observe that φ in the definition may depend on f and g. Again, it is an easy matter to see that the sets $V_p(\varepsilon)$ form a basis of a metrizable uniform structure.

Every integrand $f \in \mathcal{I}_p^+(T,X)$ generates an integral functional

$$J_f(x(\cdot)) = \int_T f(t,x(t))dt$$

on $L_p(T,X)$.

PROPOSITION 8.1. *For any $f \in \mathcal{I}_p^+(T,X)$ the functional J_f is a proper l.s.c. function on $L_p(T,X)$ and $\operatorname{dom} J_f = \operatorname{dom} J_g$ whenever f and g belong to the same connected component of $\mathcal{I}_p^+(T,X)$.*

Proof. J_f is a proper function by (P3). Lower semicontinuity is an immediate consequence of Fatou's lemma and the equality of domains is verified as in the proof of Proposition 7.2.

PROPOSITION 8.2. *The space $\mathcal{I}_p^+(T,X)$ is complete.*

Proof. Let $\{f_m\}$ be a fundamental sequence in $\mathcal{I}_p^+(T,X)$. This means that there is a sequence $\{\varepsilon_m\}$ of positive numbers converging to zero and a (triple indexed) sequence $\{\varphi_{mnk}\}$ of elements of the unit ball of $L_1(T,\Xi,\mu)$ such that almost everywhere in T

$$|f_n(t,x) - f_k(t,x)| \le \varepsilon_m(\|x\|^p + \varphi_{mnk}(t)) \quad \forall x, \tag{8.1}$$

whenever $n \ge m,\ k \ge m$. The strategy of the proof this time will be the following: We shall show that any subsequence of $\{f_m\}$ contains a converging sub-subsequence and limits of any two converging subsequences of $\{f_m\}$ may differ only on a set whose projection to T has μ-measure zero.

Therefore consider an arbitrary subsequence $\{f_{m_s}\}$. Taking a further subsequence if necessary (and writing for convenience g_s instead of f_{m_s} and δ_s instead of ε_{m_s}), we may assume that the series $\sum \delta_s$ converges. Then the functions $\psi_s(t) = \sum_{r=s}^{\infty} \delta_r \varphi_{m_r m_r m_{r+1}}$ decreasingly converge to zero in L_1. As these functions are nonnegative, it follows from the theorem of B. Levi (see [24, p. 75]) that $\psi_s(t) \to 0$ on a set $T' \in \Xi$ whose complement has measure zero.

We have, setting $\gamma_s = \sum_{r=s}^{\infty} \delta_r$,

$$|g_s(t,x) - g_{s+k}(t,x)| \le \gamma_s \|x\|^p + \psi_s(t).$$

It follows that for every $t \in T'$ the sequence $\{g_s(t,\cdot)\}$ is fundamental in $\mathrm{LSC}_p{}^+(X)$. Therefore by Proposition 7.2 the limit function $g(t,\cdot)$ is well defined on $T' \times X$ and l.s.c. in x. Being a pointwise limit of $\mathcal{L} \bigotimes \mathcal{B}$-measurable nonnegative functions, it is also $\mathcal{L} \bigotimes \mathcal{B}$-measurable and nonnegative. We have furthermore

$$|g_s(t,x) - g(t,x)| \le \gamma_s \|x\|^p + \psi_s(t)$$

from which we conclude that g has property (P3); hence $g \in \mathcal{I}_p^+(T,X)$, and g_s converges to g in $\mathcal{I}_p^+(T,X)$.

Now let g and g' be limits of two subsequences of $\{f_m\}$. It follows from (8.1) that $J_g \equiv J_{g'}$ on $L_p(T,X)$. If we had assumed now that $g(t,x) \ne g'(t,x)$ on a set whose projection to T has positive measure, then we would conclude using the standard measurable selection arguments (e.g., [7]) that $J_g(x(\cdot)) \ne J_{g'}(x(\cdot))$ for some $x(\cdot) \in L_p(T,X)$. This completes the proof of the proposition.

9. Generalized Bolza problem: An antirelaxation theorem. We are ready now to state and prove the concluding result quoted at the very beginning of the introduction. Let Ω be a bounded domain in $\mathbb{R}^m$ with Lipschitz boundary. We shall consider the space

$$\mathcal{A}_p = \mathcal{I}_p^+(\partial\Omega, \mathbb{R}^n) \times \mathcal{I}_p^+(\Omega, \mathbb{R}^n \times \mathbb{R}^{mn})$$

with the product topology. (Here Ω is considered with the Lebesgue measure and $\partial\Omega$ with the $(m-1)$-dimensional Lebesgue measure in $\mathbb{R}^m$. As Ω is a bounded domain with Lipschitz boundary, the $(m-1)$-dimensional Lebesgue measure of $\partial\Omega$ is finite.) With every $a = (l, L) \in \mathcal{A}_p$ we associate the generalized Bolza problem of minimizing

$$J_a(x(\cdot)) = \int_{\partial\Omega} l(\xi, x(\xi))d\xi + \int_\Omega L(t, x(t), \nabla x(t))dt$$

over all $x(\cdot) \in W_{1,p}^n(\Omega)$, the latter being the standard Sobolev space. For convenience we shall interpret it as the closure with respect to the norm

$$\|x(\cdot)\|_{1,p} = \left(\int_{\partial\Omega} |x(\xi)|^p d\xi + \int_\Omega (|x(t)|^p + |\nabla x(t)|^p)dt\right)^{1/p}$$

of the collection of continuous $\mathbb{R}^n$-valued functions on $\Omega \bigcup \partial\Omega$ which are continuously differentiable on Ω. (Here we denote by $|\cdot|$ the Euclidean norms of vectors in $\mathbb{R}^m$ and operators $\mathbb{R}^n \mapsto \mathbb{R}^m$ (see, e.g., Theorem 3.4.5 in [5]).)

As in the preceding sections we verify that, given a component of $\mathcal{A}_p$, J_a is either identically equal to ∞ or is proper with the same domain for all a of the component. In the latter case we shall say, abusing the language slightly, that J_a is *proper on the corresponding component*.

THEOREM 9.1. *The generalized Bolza problem of minimizing J_a on $W_{1,p}^n$ is generically well-posed with respect to every component of $\mathcal{A}_p$ on which J_a is proper.*

Proof. Being a product of two complete metrizable uniform spaces, $\mathcal{A}_p$ is also a complete metrizable uniform space. As a basis for the uniform structure in $\mathcal{A}_p$ we can take the sets $U(\delta)$ of pairs (a, a') having the property that there are functions $\varphi(\cdot) \in L_1(\partial\Omega)$ and $\psi(\cdot) \in L_1(\Omega)$ with norms not greater than one such that for almost every t in $\partial\Omega$ and Ω, respectively, the inequalities below are valid:

$$|l(t,x) - l'(t,x)| < \delta(|x|^p + \varphi(t)) \ \forall x \in \mathbb{R}^n,$$
$$|L(t,x,w) - L'(t,x,w)| < \delta(|x|^p + |w|^p + \psi(t)) \ \forall x \in \mathbb{R}^n, \ \forall w \in \mathbb{R}^{mn}.$$

Fix a metric $d(a, b)$ in $\mathcal{A}_p$ compatible with the structure. We have to show that (H) is satisfied for $(\mathcal{A}_p, d)$, J_a, and $X = W_{1,p}^n$. As the set $\mathcal{B}$ of those $a \in \mathcal{A}_p$ for which $J_a(x(\cdot)) \to \infty$ as $\|x(\cdot)\|_{1,p} \to \infty$ is dense in $\mathcal{A}_p$, we need to verify properties (i), (ii) of (H) only for $a \in \mathcal{B}$.

Therefore let an $\varepsilon > 0$, a $\gamma > 0$, and an $a \in \mathcal{B}$ be given. Let K be such that $\|x(\cdot)\|_{1,p}^p \le K$ if $J_a(x(\cdot)) \le \inf J_a + 1$. Let further $1 > \delta_1 > 2^{2(p-1)}\delta_2 > 0$ be such that

$$\gamma > \frac{2\delta_2(2^p K + 3)}{2^{(1-p)}\delta_1 - 2^{(p-1)}\delta_2} \quad \text{and} \quad d(a,b) < \varepsilon/2, \text{ if } (a,b) \in U(\delta_1(K+1)). \tag{9.1}$$

If a belongs to a component of $\mathcal{A}_p$ whose elements generate proper functionals on $W_{1,p}^n$, then $\inf J_a < \infty$. Choose an $x(\cdot) \in X$ such that

$$J_a(x(\cdot)) \le \inf J_a + \delta_2 \tag{9.2}$$

and set

$$\alpha = J_a(x(\cdot)).$$

Set further

$$\begin{aligned}&\bar{l}(t,x) = l(t,x) + 2^{(1-p)}\delta_1|x - x(t)|^p;\\ &\bar{L}(t,x,w) = L(t,x,w) + 2^{(1-p)}\delta_1(|x - x(t)|^p + |w - \nabla x(t)|^p);\\ &\bar{a} = (\bar{l},\bar{L}).\end{aligned}$$

Then for any $y(\cdot) \in W^n_{1,1}$

$$J_{\bar{a}}(y(\cdot)) = J_a(y(\cdot)) + 2^{1-p}\delta_1\|y(\cdot) - x(\cdot)\|^p_{1,p} \tag{9.3}$$

and (as $\|x-y\|^p \le 2^{(p-1)}(\|x\|^p + \|y\|^p)$)

$$\begin{aligned}0 \le \bar{L}(t,x,w) - L(t,x,w) &\le \delta_1(|x|^p + |w|^p + |x(t)|^p + |\nabla x(t)|^p)\\ &\le \delta_1(K+1)(|x|^p + |w|^p + (K+1)^{-1}(|x(t)|^p + |\nabla x(t)|^p));\\ 0 \le \bar{l}(t,x) - l(t,x) &\le \delta_1(|x|^p + |x(t)|^p)\\ &\le \delta_1(K+1)(|x|^p + (K+1)^{-1}|x(t)|^p).\end{aligned}$$

The latter, in view of the choice of $x(\cdot)$ and δ_1, implies that $d(\bar{a},a) < \varepsilon/2$.

Now let $U = \{b \in \mathcal{A} : \ (\bar{a},b) \in U(\delta_2)\}$. Then U is an open set and by (9.1), $d(a,b) < \varepsilon$ for any $b \in U$. We have furthermore for any such b

$$|J_{\bar{a}}(y(\cdot)) - J_b(y(\cdot))| \le \delta_2(\|y(\cdot)\|^p + 2) \tag{9.4}$$

(which is immediate from the definition of $U(\delta)$).

Finally, choose a $z(\cdot)$ such that

$$J_b(z(\cdot)) \le \inf J_b + \delta_2.$$

Then by (9.4) (as $J_a(x(\cdot)) = J_{\bar{a}}(x(\cdot))$)

$$\begin{aligned}J_b(z(\cdot)) &\le \inf J_b + \delta_2 \le J_b(x(\cdot)) + \delta_2\\ &\le J_a(x(\cdot)) + \delta_2(K+3).\end{aligned} \tag{9.5}$$

On the other hand, by (9.3), (9.4) we get

$$\begin{aligned}J_b(z(\cdot)) &\ge J_{\bar{a}}(z(\cdot)) - \delta_2(\|z(\cdot)\|^p + 2)\\ &\ge J_a(z(\cdot)) + 2^{(1-p)}\delta_1\|z(\cdot) - x(\cdot)\|^p\\ &\qquad -2^{(p-1)}\delta_2(\|z(\cdot) - x(\cdot)\|^p + \|x(\cdot)\|^p + 2)\\ &\ge J_a(z(\cdot)) + (2^{(1-p)}\delta_1 - 2^{(p-1)}\delta_2)\|z(\cdot) - x(\cdot)\|^p - \delta_2(2^{(p-1)}K + 2).\end{aligned} \tag{9.6}$$

Comparing (9.5) and (9.6), we get

$$2\delta_2(2^{p-1}K + 3) \ge (2^{1-p}\delta_1 - 2^{p-1}\delta_2)\|z(\cdot) - x(\cdot)\|^p$$

from which we conclude by (9.1) that $\|z(\cdot) - x(\cdot)\|^p \le \gamma$, and also

$$|J_b(z(\cdot) - \alpha| \le \delta_2(2^{p-1}K + 3) < \gamma.$$

Thus, to conclude the proof, we need to take only $\eta \le \delta_2$.

The last result of the paper relates to the standard boundary value problem of calculus of variations:

$$\text{(P)} \qquad \text{minimize} \quad \int_\Omega L(t,x(t),\nabla x(t))dt, \qquad x(\cdot)\in W^n_{1,p}, \quad x|_{\partial\Omega}(\cdot)=0.$$

Let $\mathcal{I}_p(\Omega,\mathbb{R}^n\times\mathbb{R}^{mn})$ stand for the subspace of $\mathcal{I}^+_p(\Omega,\mathbb{R}^n\times\mathbb{R}^{mn})$ consisting of integrands $L(t,x,w)$ for which the infimum in (P) is finite. By Proposition 8.1 if $L\in\mathcal{I}_p(\Omega,\mathbb{R}^n\times\mathbb{R}^{mn})$, then the entire component of $\mathcal{I}^+_p(\Omega,\mathbb{R}^n\times\mathbb{R}^{mn})$ containing L belongs to $\mathcal{I}_p(\Omega,\mathbb{R}^n\times\mathbb{R}^{mn})$. Therefore, $\mathcal{I}_p(\Omega,\mathbb{R}^n\times\mathbb{R}^{mn})$ is a union of components of $\mathcal{I}^+_p(\Omega,\mathbb{R}^n\times\mathbb{R}^{mn})$; hence an open subspace and therefore a completely metrizable uniform space.

THEOREM 9.2. *The standard boundary value problem* (P) *of calculus of variations is generically well-posed with respect to* $\mathcal{I}_p(\Omega,\mathbb{R}^n\times\mathbb{R}^{mn})$.

Proof. Set

$$l_0(t,x)=\begin{cases}0 & \text{if } x=0;\\ \infty & \text{otherwise.}\end{cases}$$

Consider the family $\{\mathcal{C}_\alpha\}$ of all subsets of $\mathcal{A}$ such that every $\mathcal{C}_\alpha$ is the product of the component of $\mathcal{I}^+_p(\partial\Omega,\mathbb{R}^n)$ containing l_0 and a component of $\mathcal{I}_p(\Omega,\mathbb{R}^n\times\mathbb{R}^{mn})$. Then every $\mathcal{C}_\alpha$ is a component of $\mathcal{A}$, J_a is proper on every $\mathcal{C}_\alpha$, and the problem of minimizing J_a is generically well-posed on $\mathcal{C}_\alpha$ by Theorem 9.1.

Set $\mathcal{A}_0=\bigcup\mathcal{C}_\alpha$, and let for any α, $\mathcal{C}'_\alpha$ be a dense G_δ-subset of $\mathcal{C}_\alpha$ such that for any $a\in\mathcal{C}'_\alpha$ the problem of minimizing J_a is well-posed with respect to $\mathcal{C}_\alpha$. For any α, we have $\mathcal{C}'_\alpha=\bigcap_{i=1}^\infty U_{i,\alpha}$, where every $U_{i,\alpha}$ is an open set contained in $\mathcal{C}_\alpha$. Clearly, $\mathcal{A}'_0=\bigcup\mathcal{C}'_\alpha$ is a dense subset of $\mathcal{A}_0$ and on the other hand, as $U_{i,\alpha}\bigcap U_{j,\beta}=\emptyset$ if $\alpha\neq\beta$,

$$\mathcal{A}'_0=\bigcup_\alpha\left(\bigcap_i U_{i,\alpha}\right)=\bigcap_i\left(\bigcup_\alpha U_{i,\alpha}\right),$$

so that $\mathcal{A}'_0$ is also a G_δ subset of $\mathcal{A}$.

Thus, the problem of minimization of J_a on $W^n_{1,1}$ is by Theorem 9.1 generically well-posed with respect to $\mathcal{A}_0$. The theorem now follows from the observation that if l belongs to the component of $\mathcal{I}^+_p(\partial\Omega,\mathbb{R}^n)$ containing l_0, then $l(t,0)$ differs from $l_0(t,0)$ by a function $\varphi(t)$ which is summable on $\partial\Omega$ and $l(t,x)=\infty$ if $x\neq 0$. It follows that $\operatorname{dom}J_a\subset W^{1,1}_0$ for any $a\in\mathcal{A}_0$, and for any $x(\cdot)\in W^{1,1}_0$

$$J_a(x(\cdot))-\int_\Omega L(t,x(t),\nabla x(t))dt=\int_{\partial\Omega}\varphi(t)dt,$$

that is to say, the functional of (P) has the same domain as J_a and differs from the restriction of J_a to $\operatorname{dom}J_a$ by a constant.

STOCHASTIC CALCULUS FOR FRACTIONAL BROWNIAN MOTION I. THEORY*

TYRONE E. DUNCAN†, YAOZHONG HU†, AND BOZENNA PASIK-DUNCAN†

Abstract. In this paper a stochastic calculus is given for the fractional Brownian motions that have the Hurst parameter in (1/2, 1). A stochastic integral of Itô type is defined for a family of integrands so that the integral has zero mean and an explicit expression for the second moment. This integral uses the Wick product and a derivative in the path space. Some Itô formulae (or change of variables formulae) are given for smooth functions of a fractional Brownian motion or some processes related to a fractional Brownian motion. A stochastic integral of Stratonovich type is defined and the two types of stochastic integrals are explicitly related. A square integrable functional of a fractional Brownian motion is expressed as an infinite series of orthogonal multiple integrals.

Key words. fractional Brownian motion, stochastic calculus, Itô integral, Stratonovich integral, Itô formula, Wick product, Itô calculus, multiple Itô integrals, multiple Stratonovich integrals

1. Introduction.

Since the pioneering work of Hurst [14], [15] and Mandelbrot [18], the fractional Brownian motions have played an increasingly important role in many fields of application such as hydrology, economics, and telecommunications.

Let $0 < H < 1$. It is well known that there is a Gaussian stochastic process $(B_t^H, t \geq 0)$ such that

$$\mathbb{E}\left(B_t^H\right) = 0, \qquad \mathbb{E}\left(B_t^H B_s^H\right) = \frac{1}{2}\left\{|t|^{2H} + |s|^{2H} - |t-s|^{2H}\right\} \tag{1.1}$$

for all $s, t \in \mathbb{R}_+$. This process is called a (standard) fractional Brownian motion with Hurst parameter H.

If $H = 1/2$, then the corresponding fractional Brownian motion is the usual standard Brownian motion. If $H > 1/2$, then the process $(B_t^H, t \geq 0)$ exhibits a long-range dependence, that is, if $r(n) = \mathbb{E}[B_1^H(B_{n+1}^H - B_n^H)]$, then $\sum_{n=1}^{\infty} r(n) = \infty$. A fractional Brownian motion is also self-similar, that is, $(B_{\alpha t}^H, t \geq 0)$ has the same probability law as $(\alpha^H B_t^H, t \geq 0)$. A process satisfying this property is called a self-similar process with the Hurst parameter H.

Since in many problems related to network traffic analysis, mathematical finance, and many other fields the processes under study seem empirically to exhibit the self-similar properties, and the long-range dependent properties, and since the fractional Brownian motions are the simplest processes of this kind, it is important to have a systematic study of these processes and to use them to construct other stochastic processes. One way to approach this study is to follow, by analogy, the methods for Brownian motion. In the stochastic analysis, a Brownian motion can be used as the input (white) noise and many other processes (e.g., general diffusion processes) can

†Department of Mathematics, University of Kansas, 405 Snow Hall, Lawrence, KS 66045-2142 (duncan@math.ukans.edu, bozenna@math.ukans.edu).

be constructed as solutions of stochastic differential equations. One powerful tool for determining these solutions is the Itô formula.

However, it is also known that if a stochastic process $(\pi_t, t \geq 0)$ has the property that the stochastic integral $\int F_t \, d\pi_t$ is well defined for a large class of integrands $(F_t, t \geq 0)$, then this process $(\pi_t, t \geq 0)$ is a semimartingale, e.g., [20]. It is known that the fractional Brownian motions are not semimartingales. Therefore the beautiful classical theory of stochastic analysis [4] is not applicable to fractional Brownian motions for $H \neq 1/2$. It is a significant and challenging problem to extend the results in the classical stochastic analysis to these fractional Brownian motions. There have been a few papers in this direction. Lin [17] and Dai and Heyde [2] introduced stochastic integrals and extended the Itô formula to fractional Brownian motions. Their definitions of a stochastic integral give a stochastic integral of Stratonovich type, which is explained further in section 3. Their Itô formula is the usual chain rule for differentiation.

The stochastic integral $\int_0^t f_s \delta B_s^H$, with respect to the fractional Brownian motions introduced by Lin, Dai, and Heyde, does not satisfy in general the following property: $\mathbb{E} \int_0^t f_s \delta B_s^H = 0$. A new type of stochastic integral, $\int_0^t f_s \, dB_s^H$, is introduced, satisfying $\mathbb{E} \int_0^t f_s \, dB_s^H = 0$. This property seems to be important in the modeling problem by stochastic differential equations with fractional Gaussian noise as the driving random process. Consider the following type of differential equation:

$$dX_t = b(X_t)dt + \sigma(X_t)dB_t^H. \tag{1.2}$$

It is natural to consider that $b(X_t)$ is the mean rate of change of the system state X_t at time t and $\sigma(X_t)dB_t^H$ is the random perturbation. So the term $\sigma(X_t)dB_t^H$ should not contribute to the mean rate of change. The term $b(X_t)$ is used to represent the average or deterministic part of the problem and $\sigma(X_t)$ is used to represent the intensity of the random part of the problem. Therefore it is important to extend the classical interpretation of b and σ to the differential equation (1.2).

To introduce the new integral $\int f \, dB^H$, the Wick product or Wick calculus is used. The use of the Wick product is not anomalous because in white noise analysis the usual product has been associated with integrals of Stratonovich type and the Wick product has been associated with integrals of Itô type (e.g., [8], [12]).

A brief outline of the paper is as follows. In section 2, some description and terminology for the fractional Brownian motions are given. In section 3, a derivative in special directions is defined and a stochastic integral of Itô type is defined using the Wick product. Furthermore, a stochastic integral of Stratonovich type is defined and the two types of stochastic integrals are related. In section 4, some change of variables formulas (Itô formulas) are given for the two types of stochastic integrals. In section 5, two applications of the Itô formula are given. In section 6, multiple integrals of Itô type and Stratonovich type for a fractional Brownian motion are defined and the Hu-Meyer formula is extended to these multiple integrals. The relation between these two types of multiple integrals is given. A square integrable functional of a fractional Brownian motion is represented as an infinite sum of orthogonal terms.

If the integrand of a stochastic integral of Stratonovich type for a fractional Brownian motion with $H \in (1/2, 1)$ is smooth, then the integral can be defined as a limit of a sequence of Riemann sums, where the integrand can be evaluated at any point between each pair of partition points. It is well known that this choice of evaluation of the integrand is not valid if the integrator is Brownian motion, that is, $H = 1/2$.

If f is smooth, then an application of an Itô formula is

$$f(B_t^H) = f(0) + \int_0^t f'(B_s^H) dB_s^H + H \int_0^t s^{2H-1} f''(B_s^H) ds,$$

where prime denotes differentiation and $H \in (1/2, 1)$. It is interesting to note that if $H = 1/2$ is formally substituted in the equation, then the well-known Itô formula for Brownian motion is obtained.

2. Fractional Brownian motion. Let $\Omega = C_0(\mathbb{R}_+, \mathbb{R})$ be the space of real-valued continuous functions on $\mathbb{R}_+$ with the initial value zero and the topology of local uniform convergence. There is a probability measure P^H on $(\Omega, \mathcal{F})$, where $\mathcal{F}$ is the Borel σ-algebra such that on the probability space $(\Omega, \mathcal{F}, P^H)$ the coordinate process $B^H : \Omega \to \mathbb{R}$ defined as

$$B_t^H(\omega) = \omega(t), \quad \omega \in \Omega,$$

is a Gaussian process satisfying (1.1). The process $(B_t^H, t \geq 0)$ is called the canonical (standard) fractional Brownian motion with Hurst parameter H. In this paper only this canonical process and its associated probability space are used. Throughout this paper it is assumed that $H \in (\frac{1}{2}, 1)$ is arbitrary but fixed. Clearly if $H = 1/2$, the fractional Brownian motion is the standard Brownian motion.

It is elementary to verify that a fractional Brownian motion for $H \neq 1/2$ is not a semimartingale. It is known [20] that if the (usual) stochastic integral $\int_a^b f_s \, dX_s$ is well defined for a large family of integrands with respect to a process $(X_t, t \geq 0)$, then this process $(X_t, t \geq 0)$ is a semimartingale. Thus the well-developed classical theory for semimartingales cannot be applied here, and the stochastic integral with respect to fractional Brownian motions needs to be developed.

Let $\phi : \mathbb{R}_+ \times \mathbb{R}_+ \to \mathbb{R}_+$ be given by

$$\phi(s,t) = H(2H-1)|s-t|^{2H-2}. \tag{2.1}$$

Many results of this paper can be extended to a more general $\phi(s,t)$ that is symmetric and positive definite, so ϕ in (2.1) is given as a function of two variables and not their difference. Let $f : \mathbb{R}_+ \to \mathbb{R}$ be a Borel measurable (deterministic) function. The function f belongs to the Hilbert space $L^2_\phi(\mathbb{R}_+)$ if

$$|f|_\phi^2 := \int_0^\infty \int_0^\infty f(s) f(t) \phi(s,t) ds \, dt < \infty. \tag{2.2}$$

The inner product on the Hilbert space L^2_ϕ is denoted by $\langle \cdot, \cdot \rangle_\phi$.

The stochastic (Wiener) integral with respect to fractional Brownian motions for deterministic kernels is easily defined.

LEMMA 2.1. *If $f, g \in L^2_\phi(\mathbb{R}_+)$, then $\int_0^\infty f_s \, dB_s^H$ and $\int_0^\infty g_s \, dB_s^H$ are well defined zero mean, Gaussian random variables with variances $|f|_\phi^2$ and $|g|_\phi^2$, respectively, and*

$$\mathbb{E}\left(\int_0^\infty f_s \, dB_s^H \int_0^\infty g_s \, dB_t^H \right) = \int_0^\infty \int_0^\infty f(s) g(t) \phi(s,t) ds dt = \langle f, g \rangle_\phi. \tag{2.3}$$

This lemma is verified in [7]. It can be proved directly by verifying it for simple functions $\sum_{i=1}^n a_i \chi_{[t_i, t_{i+1}]}(s)$ and then proceeding with a passage to the limit.

3. Stochastic integration for fractional Brownian motions. Let $(\Omega,\mathcal{F},P^H)$ be the probability space from section 2 where a fractional Brownian motion with Hurst parameter H is well defined. The probability measure P^H depends on H. Throughout this paper the Hurst parameter H is fixed such that $1/2 < H < 1$. Since H is fixed, the probability measure is denoted by P.

Let $L^p(\Omega,\mathcal{F},P) = L^p$ be the space of all random variables $F:\Omega\to\mathbb{R}$ such that

$$\|F\|_p := (\mathbb{E}|F|^p)^{1/p} < \infty$$

and let $L^2_\phi(\mathbb{R}_+) = \{f | f:\mathbb{R}_+\to\mathbb{R},\ |f|^2_\phi := \int_0^\infty\int_0^\infty f_s f_t \phi(s,t)ds\,dt < \infty\}$. Often for notational simplicity $L^2_\phi(\mathbb{R}_+)$ is denoted by L^2_ϕ. For any $f\in L^2_\phi$, define $\varepsilon : L^2_\phi \to L^1(\Omega,\mathcal{F},P)$ as

$$\begin{aligned}\varepsilon(f) :&= \exp\left\{\int_0^\infty f_t\,dB^H_t - \frac{1}{2}\int_0^\infty\int_0^\infty f_s f_t\phi(s,t)ds\,dt\right\}\\ &= \exp\left[\int_0^\infty f_t\,dB^H_t - \frac{1}{2}|f|^2_\phi\right].\end{aligned}\tag{3.1}$$

If $f\in L^2_\phi$, then $\varepsilon(f)\in L^p(\Omega,\mathcal{F},P)$ for each $p\ge 1$ and $\varepsilon(f)$ is called an exponential function (e.g., [21]). The Hilbert space L^2_ϕ is naturally associated with the Gaussian process, fractional Brownian motion, from the formulation as an abstract Wiener space. The Hilbert space plays a basic role for questions of absolute continuity [6] and the exponential function (3.1) is a Radon–Nikodym derivative for a translate of the fractional Brownian motion.

Let $\mathcal{E}$ be the linear span of the exponentials, that is,

$$\mathcal{E} = \left\{\sum_{k=1}^n a_k\varepsilon(f_k),\ n\in\mathbb{N}, a_k\in\mathbb{R},\ f_k\in L^2_\phi(\mathbb{R}_+) \text{ for } k\in\{1,\dots,n\}\right\}.\tag{3.2}$$

THEOREM 3.1. *$\mathcal{E}$ is a dense set of $L^p(\Omega,\mathcal{F},P)$ for each $p\ge 1$. In particular, $\mathcal{E}$ is a dense set of $L^2(\Omega,\mathcal{F},P)$.*

Proof. A random variable $F:\Omega\to\mathbb{R}$ is said to be a polynomial of the fractional Brownian motion if there is a polynomial $p(x_1,x_2,\dots,x_n)$ such that

$$F = p\left(B^H_{t_1}, B^H_{t_2},\dots,B^H_{t_n}\right)$$

for some $0\le t_1 < t_2 < \cdots < t_n$. Since $(B^H_t, t\ge 0)$ is a Gaussian process it is well known that the set of all polynomial fractional Brownian functionals is dense in $L^p(\Omega,\mathcal{F},P)$ for $p\ge 1$. In this case, the denseness of the polynomials follows from the continuity of the process and the Stone–Weierstrass theorem. To prove the theorem it is only necessary to prove that any polynomial can be approximated by the elements in $\mathcal{E}$. Since the Wick product of exponentials is still an exponential it is easy to see that it is only necessary to show that for any $t>0$, B^H_t can be approximated by elements in $\mathcal{E}$.

Let $f_\delta(s) = \chi_{[0,t]}(s)\delta$. It is clear that for $\delta>0$, f_δ is in L^2_ϕ, and $\varepsilon(f_\delta) = c(\delta)e^{\delta B^H_t}$ for some positive constant $c(\delta)$. It is easy to see that

$$F_\delta = \frac{\varepsilon(f_\delta) - c(\delta)}{c(\delta)\delta} = \frac{e^{\delta B^H_t} - 1}{\delta}$$

is in $\mathcal{E}$. If $\delta \to 0$, then $F_\delta \to B_t^H$ in $L^p(\Omega, \mathcal{F}, P)$ for each $p \geq 1$. This completes the proof. □

THEOREM 3.2. *If $f_1, f_2, \dots, f_n$ are elements in L_ϕ^2 such that $|f_i - f_j|_\phi \neq 0$ for $i \neq j$, then $\varepsilon(f_1)$, $\varepsilon(f_2), \dots, \varepsilon(f_n)$ are linearly independent in L_ϕ^2.*

Proof. This theorem is known to be true if the fractional Brownian motion is replaced by a standard Brownian motion (e.g., [21]).

Let $f_1, f_2, \dots, f_k$ be distinct elements in L_ϕ^2. Let $\lambda_1, \lambda_2, \dots, \lambda_k$ be real numbers such that

$$|\lambda_1 \varepsilon(f_1) + \lambda_2 \varepsilon(f_2) + \cdots + \lambda_k \varepsilon(f_k)|_\phi = 0.$$

Thus for any $g \in L_\phi^2$,

$$\mathbb{E}[\{\lambda_1 \varepsilon(f_1) + \lambda_2 \varepsilon(f_2) + \cdots + \lambda_k \varepsilon(f_k)\}\varepsilon(g)] = 0.$$

By an elementary computation for Gaussian random variables it follows that

$$\lambda_1 e^{\langle f_1, g\rangle_\phi} + \lambda_2 e^{\langle f_2, g\rangle_\phi} + \cdots + \lambda_k e^{\langle f_k, g\rangle_\phi} = 0.$$

Replace g by δg for $\delta \in \mathbb{R}$ to obtain

$$\lambda_1 e^{\delta\langle f_1, g\rangle_\phi} + \lambda_2 e^{\delta\langle f_2, g\rangle_\phi} + \cdots + \lambda_k e^{\delta\langle f_k, g\rangle_\phi} = 0.$$

Expand the above identity in the powers of δ and compare the coefficients of δ^p for $p \in \{0, 1, \cdots, k-1\}$ to obtain the family of equations

$$\lambda_1 \langle f_1, g\rangle_\phi^p + \lambda_2 \langle f_2, g\rangle_\phi^p + \cdots + \lambda_k \langle f_k, g\rangle_\phi^p = 0$$

for $p = 0, 1, \cdots, k-1$. This is a linear system of k equations and k unknowns. By the Vandermonde formula, the determinant of this linear system is

$$\det\left(\langle f_i, g\rangle_\phi^p\right) = \prod_{i<j} \langle f_i - f_j, g\rangle_\phi^p.$$

For every pair (i, j) with $i \neq j$, the set $\{g \in L_\phi^2 : \langle f_i - f_j, g\rangle_\phi \neq 0\}$ is the complement of a hyperplane in L_ϕ^2. Since the intersection of finitely many complements of hyperplanes in L_ϕ^2 is not empty, there is a $g \in L_\phi^2$ such that $\langle f_i - f_j, g\rangle_\phi \neq 0$ for all pairs i and j such that $i \neq j$. Thus $\lambda_1 = \lambda_2 = \cdots = \lambda_k = 0$. This proves the theorem. □

The above two theorems reduce many verifications for functions in $L^2(\Omega, \mathcal{F}, P)$ to verifications of exponentials in $\mathcal{E}$.

The following result is an absolute continuity of measures for some translates of fractional Brownian motion.

THEOREM 3.3. *If $F : \Omega \to \mathbb{R}$ is a random variable such that $F \in L^p(\Omega, \mathcal{F}, P)$ for some $p \geq 1$, then*

(3.3)
$$\mathbb{E}\left\{F\left(B_\cdot^H + \int_0^\cdot (\Phi g)(s)ds\right)\right\} = \mathbb{E}\left\{F(B_\cdot^H) e^{\int_0^\infty g_s\, dB_s^H - \frac{1}{2}\int_0^\infty \int_0^\infty \phi(u,v) g_u g_v\, du\, dv}\right\},$$

where Φ is given by

$$(\Phi g)(t) = \int_0^\infty \phi(t, u) g_u\, du$$

and $g \in L^2_\phi$.

Proof. The term $F(B^H_\cdot)$ denotes $F(\omega)$. Let $k \in L^2_\phi$ and

$$F(B^H_\cdot) = \varepsilon(k) = e^{\int_0^\infty k_s dB^H_s - \frac{1}{2}\int_0^\infty \int_0^\infty \phi(u,v)k_u k_v \, du\, dv}.$$

Then

$$F\left(B^H_\cdot + \int_0^\cdot (\Phi g)_s \, ds\right) = F(B^H_\cdot) e^{\int_0^\infty k_u (\Phi g)_u \, du}.$$

So

$$\mathbb{E}\left\{F\left(B^H_\cdot + \int_0^\cdot (\Phi g)_s \, ds\right)\right\} = e^{\int_0^\infty k_u (\Phi g)_u \, du}.$$

Furthermore, it follows that

$$\mathbb{E}\left\{F\big(B^H_\cdot\big)\varepsilon(g)\right\} = e^{\int_0^\infty \int_0^\infty \phi(u,v)k_u g_v \, du\, dv} = e^{\int_0^\infty k_u (\Phi g)_u \, du}.$$

Thus the theorem is true if F is an exponential function $\varepsilon(f) \in \mathcal{E}$. A limiting argument completes the proof. □

Let a Radon–Nikodym derivative $\frac{d\tilde{P}}{dP}$ on $(\Omega, \mathcal{F}, P)$ be given by

$$\frac{d\tilde{P}}{dP} = e^{\int_0^\infty g_s \, dB^H_s - \frac{1}{2}\int_0^\infty \int_0^\infty \phi(u,v) g_u g_v \, du\, dv},$$

and denote the expectation with respect to $\tilde{P}$ by $\tilde{\mathbb{E}}$; then (3.3) is given by

$$\mathbb{E}F\left(B^H_\cdot + \int_0^\cdot (\Phi g)_s \, ds\right) = \tilde{\mathbb{E}}(F(B^H_\cdot)).$$

For a random variable F in $L^p(\Omega, \mathcal{F}, P)$ $(p \geq 1)$ and a function $g \in L^2_\phi$, the random variable $F(B^H_\cdot + \int_0^\cdot (\Phi g)(v) dv)$ is well defined. An analogue of the Malliavin derivative [23] is introduced.

Definition 3.4. *The ϕ-derivative of a random variable $F \in L^p$ in the direction of Φg where $g \in L^2_\phi$ is defined as*

$$D_{\Phi g} F(\omega) = \lim_{\delta \to 0} \frac{1}{\delta}\left\{F(\omega + \delta \int_0^\cdot (\Phi g)(u) du) - F(\omega)\right\} \tag{3.4}$$

if the limit exists in $L^p(\Omega, \mathcal{F}, P)$. Furthermore, if there is a process $(D^\phi F_s, s \geq 0)$ such that

$$D_{\Phi g} F = \int_0^\infty D^\phi F_s g_s \, ds \quad \textit{almost surely (a.s.)}$$

for all $g \in L^2_\phi$, then F is said to be ϕ-differentiable.

The higher order derivatives can be defined in a similar manner.

Definition 3.5. *Let $F : [0,T] \times \Omega \to \mathbb{R}$ be a stochastic process. The process F is said to be ϕ-differentiable if for each $t \in [0,T]$, $F(t,\cdot)$ is ϕ-differentiable and $D^\phi_s F_t$ is jointly measurable.*

It is easy to verify an elementary version of a chain rule, that is, if $f : \mathbb{R} \to \mathbb{R}$ is a smooth function and $F : \Omega \to \mathbb{R}$ is ϕ-differentiable, then $f(F)$ is also ϕ-differentiable and

$$D_{\Phi g} f(F) = f'(F) D_{\Phi g} F$$

and

$$D_s^\phi f(F) = f'(F) D_s^\phi F$$

and the iterated directional derivatives

$$D_{\Phi g_1} D_{\Phi g_2} f(F) = f'(F) D_{\Phi g_1} D_{\Phi g_2} F + f''(F) D_{\Phi g_1} F D_{\Phi g_2} F.$$

The following rules for differentiation, which can be verified as in the proof of Proposition 3.6, are useful later:

$$D_{\Phi g} \int_0^\infty f_s \, dB_s^H = \int_0^\infty \int_0^\infty \phi(u,v) f_u g_v \, du \, dv = \langle f, g \rangle_\phi; \tag{3.5}$$

$$D_s^\phi \int_0^\infty f_u \, dB_u^H = \int_0^\infty \phi(u,s) f_u \, du = (\Phi f)(s); \tag{3.6}$$

$$D_{\Phi g} \varepsilon(f) = \varepsilon(f) \int_0^\infty \int_0^\infty \phi(u,v) f_u g_v \, du \, dv = \varepsilon(f) \langle f, g \rangle_\phi; \tag{3.7}$$

$$D_s^\phi \varepsilon(f) = \varepsilon(f) \int_0^\infty \phi(u,s) f_u \, du = \varepsilon(f)(\Phi f)(s), \tag{3.8}$$

where $f, g \in L_\phi^2$.

Now the Wick product $\diamond$ of two functionals is introduced. To extend the theory of stochastic calculus for Brownian motions to the fractional Brownian motions, the Wick calculus for Gaussian processes (or Gaussian measures) is used. The Wick product of two exponentials $\varepsilon(f)$ and $\varepsilon(g)$ is defined as

$$\varepsilon(f) \diamond \varepsilon(g) = \varepsilon(f + g). \tag{3.9}$$

Since for distinct $f_1, f_2, \ldots, f_n$ in L_ϕ^2, $\varepsilon(f_1), \varepsilon(f_2), \ldots, \varepsilon(f_n)$ are linearly independent, this definition can be extended to define the Wick product $F \diamond G$ of two functionals F and G in $\mathcal{E}$.

Note that $\int_0^\infty g_s \, dB_s^H$ is not an element in $\mathcal{E}$. The Wick product is extended to more general functionals, including the functionals of the form $\int_0^\infty g_s \, dB_s^H$, where $g \in L_\phi^2$.

PROPOSITION 3.6. *If $g \in L_\phi^2$, $F \in L^2(\Omega, \mathcal{F}, P)$, and $D_{\Phi g} F \in L^2(\Omega, \mathcal{F}, P)$, then*

$$F \diamond \int_0^\infty g_s \, dB_s^H = F \int_0^\infty g_s \, dB_s^H - D_{\Phi g} F. \tag{3.10}$$

Proof. By the definition (3.9),

$$\varepsilon(f) \diamond \varepsilon(\delta g) = \varepsilon(f + \delta g). \tag{3.11}$$

Differentiate the above identity with respect to δ, and evaluate at $\delta = 0$ to obtain

$$\begin{aligned}\varepsilon(f) \diamond \int_0^\infty g_s \, dB_s^H &= \varepsilon(f) \left[\int_0^\infty g_s \, dB_s^H - \langle f, g \rangle_\phi \right] \\ &= \varepsilon(f) \int_0^\infty g_s \, dB_s^H - \varepsilon(f) \langle f, g \rangle_\phi. \end{aligned} \tag{3.12}$$

By (3.7), it follows that the last term of the above expression is $D_{\Phi g} \varepsilon(f)$. Thus, the following equality is satisfied:

$$\varepsilon(f) \diamond \int_0^\infty g_s \, dB_s^H = \varepsilon(f) \int_0^\infty g_s \, dB_s^H - D_{\Phi g} \varepsilon(f). \tag{3.13}$$

If $F \in \mathcal{E}$ is a finite linear combination of $\varepsilon(f_1)$, $\varepsilon(f_2), \ldots, \varepsilon(f_n)$, then extend (3.13) by linearity

$$\begin{aligned} F \diamond \int_0^\infty g_s \, dB_s^H &= F \int_0^\infty g_s \, dB_s^H - D_{\Phi g} F \\ &= F \int_0^\infty g_s \, dB_s^H - \int_0^\infty D_s^\phi F g_s \, ds. \end{aligned} \tag{3.14}$$

The proof of the proposition is completed by Theorem 3.1. □

Now the second moment of (3.10) is computed. Note that by a simple computation for Gaussian random variables, it follows that

$$\mathbb{E}(\varepsilon(f)\varepsilon(g)) = \exp\{\langle f, g \rangle_\phi\}.$$

Thus

$$\begin{aligned} \mathbb{E}\{(\varepsilon(f) \diamond \varepsilon(\gamma g))(\varepsilon(h) \diamond \varepsilon(\delta g))\} &= \mathbb{E}\{\varepsilon(f + \gamma g)\varepsilon(h + \delta g)\} \\ &= \exp\{\langle f + \gamma g, h + \delta g \rangle_\phi\}. \end{aligned}$$

Both sides of this equality are functions of γ and δ. Taking the partial derivative $\frac{\partial^2}{\partial \gamma \partial \delta}$, evaluated at $\gamma = \delta = 0$, it follows that

$$\begin{aligned} \mathbb{E}\left\{ \left(\varepsilon(f) \diamond \int_0^\infty g_s \, dB_s^H \right) \left(\varepsilon(h) \diamond \int_0^\infty g_s \, dB_s^H \right) \right\} \\ = \exp(\langle f, h \rangle_\phi) \{ \langle f, g \rangle_\phi \langle h, g \rangle_\phi + \langle g, g \rangle_\phi \} \\ = \mathbb{E}\{ D_{\Phi g} \varepsilon(f) D_{\Phi g} \varepsilon(h) + \varepsilon(f)\varepsilon(h) \langle g, g \rangle_\phi \}. \end{aligned}$$

Thus

$$\begin{aligned} \mathbb{E}\left\{ \left(\varepsilon(f) \diamond \int_0^\infty g_s \, dB_s^H \right) \left(\varepsilon(h) \diamond \int_0^\infty g_s \, dB_s^H \right) \right\} \\ = \mathbb{E}(D_{\Phi g} \varepsilon(f) D_{\Phi g} \varepsilon(h) + \varepsilon(f)\varepsilon(h) \langle g, g \rangle_\phi). \end{aligned}$$

By bilinearity, for any F and G in $\mathcal{E}$, the following equality is satisfied:

$$\mathbb{E}\left\{ \left(F \diamond \int_0^\infty g_s \, dB_s^H \right) \left(G \diamond \int_0^\infty g_s \, dB_s^H \right) \right\} = \mathbb{E}\{ D_{\Phi g} F D_{\Phi g} G + FG \langle g, g \rangle_\phi \}.$$

Let F be equal to G. Then

$$\mathbb{E}\left(F \diamond \int_0^\infty g_s \, dB_s^H\right)^2 = \mathbb{E}\big[(D_{\Phi g}F)^2 + F^2|g|_\phi^2\big].$$

This result is stated in the following theorem.

THEOREM 3.7. *Let $g \in L_\phi^2$ and let $\mathcal{E}_g$ be the completion of $\mathcal{E}$ under the norm*

$$\|F\|_g^2 = \mathbb{E}\Big\{(D_{\Phi g}F)^2 + F^2\Big\},$$

where F is a random variable. Then for any element $F \in \mathcal{E}_g$, $F \diamond \int_0^\infty g_s \, dB_s^H$ is well defined and

$$\mathbb{E}\left(F \diamond \int_0^\infty g_s \, dB_s^H\right)^2 = \mathbb{E}\Big\{(D_{\Phi g}F)^2 + F^2|g|_\phi^2\Big\}. \tag{3.15}$$

By the polarization technique [21], there is the following corollary:

COROLLARY 3.8. *Let $g, h \in L_\phi^2$ and $F, G \in \mathcal{E}$. Then*

$$\mathbb{E}\left(F \diamond \int_0^\infty g_s \, dB_s^H \; G \diamond \int_0^\infty h_s \, dB_s^H\right) = \mathbb{E}[D_{\Phi g}F D_{\Phi h}G + FG\langle g, h\rangle_\phi].$$

This equality is the starting point for the definition of the stochastic integral with respect to the fractional Brownian motions. Let $F \in \mathcal{E}$. The stochastic integral $\int_0^T F_s \, dB_s^H$ is defined, and some properties associated with this stochastic integral are studied.

Consider an arbitrary partition of $[0, T]$, $\pi : 0 = t_0 < t_1 < t_1 < \cdots < t_n = T$. First, the following Riemann sum is given using the Wick product introduced above:

$$S(F, \pi) = \sum_{i=0}^{n-1} F_{t_i} \diamond (B_{t_{i+1}}^H - B_{t_i}^H).$$

From (3.9), it easily follows that for any F and G in $\mathcal{E}$, $\mathbb{E}(F \diamond G) = \mathbb{E}(F)\mathbb{E}(G)$. This identity extends to more general F and G such that $F \diamond G$ is well defined (e.g. [8], p. 83). Thus for any partition π,

$$\begin{aligned}\mathbb{E}\left(\sum_{i=0}^{n-1} F_{t_i} \diamond (B_{t_{i+1}}^H - B_{t_i}^H)\right) &= \sum_{i=0}^{n-1} \mathbb{E}\left(F_{t_i} \diamond (B_{t_{i+1}}^H - B_{t_i}^H)\right) \\ &= \sum_{i=0}^{n-1} \mathbb{E}(F_{t_i})\mathbb{E}\Big(B_{t_{i+1}}^H - B_{t_i}^H\Big) = 0.\end{aligned}$$

To compute the L^2 norm of $S(F, \pi)$, denote

$$\sigma_{ij} = \mathbb{E}\left\{\left(F_{t_i} \diamond (B_{t_{i+1}}^H - B_{t_i}^H)\right)\left(F_{t_j} \diamond (B_{t_{j+1}}^H - B_{t_j}^H)\right)\right\}.$$

By Corollary 3.8, it follows that

$$\sigma_{ij} = \mathbb{E}\left\{\int_{t_i}^{t_{i+1}} D_s^\phi F_{t_i} \, ds \int_{t_j}^{t_{j+1}} D_t^\phi F_{t_j} \, dt + F_{t_i} F_{t_j} \int_{t_i}^{t_{i+1}} \int_{t_j}^{t_{j+1}} \phi(u, v) du dv\right\}.$$

Thus

$$\mathbb{E}S(F,\pi)^2 = \sum_{i,j=0}^{n-1} \mathbb{E}\Big\{ \int_{t_i}^{t_{i+1}} D_s^\phi F_{t_i}\, ds \int_{t_j}^{t_{j+1}} D_t^\phi F_{t_j}\, dt + F_{t_i}F_{t_j} \int_{t_i}^{t_{i+1}} \int_{t_j}^{t_{j+1}} \phi(u,v) du dv \Big\}.$$

Denote $|\pi| := \max_i (t_{i+1} - t_i)$ and $F_t^\pi = F_{t_i}$ if $t_i \le t < t_{i+1}$. Assume that as $|\pi| \to 0$, $\mathbb{E}|F^\pi - F|_\phi^2 \to 0$ and

$$\sum_{i=0}^{n-1} \mathbb{E}\left\{ \int_{t_i}^{t_{i+1}} |D_s^\phi F_{t_i} - D_s^\phi F_s| ds \right\}^2$$

converges to 0. Then from the above it is easy to see that if $(\pi_n, n \in \mathbb{N})$ is a sequence of partitions such that $|\pi_n| \to 0$ as $n \to \infty$, then $(S(F,\pi_n), n \in \mathbb{N})$ is a Cauchy sequence in $L^2(\Omega, \mathcal{F}, P)$. The limit of this sequence in $L^2(\Omega, \mathcal{F}, P)$ is defined as $\int_0^T F_s\, dB_s^H$: that is, define

$$\int_0^T F_s\, dB_s^H = \lim_{|\pi| \to 0} \sum_{i=0}^{n-1} F_{t_i}^\pi \diamond (B_{t_{i+1}}^H - B_{t_i}^H) \tag{3.16}$$

so that

$$\mathbb{E}\left| \int_0^T F_s\, dB_s^H \right|^2 = \mathbb{E}\left\{ \left(\int_0^T D_s^\phi F_s\, ds \right)^2 + |F|_\phi^2 \right\}.$$

Let $\mathcal{L}(0,T)$ be the family of stochastic processes on $[0,T]$ such that $F \in \mathcal{L}(0,T)$ if $\mathbb{E}|F|_\phi^2 < \infty$, F is ϕ-differentiable, the trace of $(D_s^\phi F_t, 0 \le s \le T, 0 \le t \le T)$ exists, $\mathbb{E}\int_0^T (D_s^\phi F_s)^2\, ds < \infty$, and for each sequence of partitions $(\pi_n, n \in \mathbb{N})$ such that $|\pi_n| \to 0$ as $n \to \infty$, the quantities

$$\sum_{i=0}^{n-1} \mathbb{E}\left\{ \int_{t_i^{(n)}}^{t_{i+1}^{(n)}} |D_s^\phi F_{t_i^{(n)}}^\pi - D_s^\phi F_s| ds \right\}^2$$

and

$$\mathbb{E}|F^\pi - F|_\phi^2$$

tend to 0 as $n \to \infty$, where $\pi_n : 0 = t_0^{(n)} < t_1^{(n)} < \cdots < t_{n-1}^{(n)} < t_n^{(n)} = T$.

The following result summarizes the above construction of a stochastic integral.

THEOREM 3.9. *Let $(F_t, t \in [0,T])$ be a stochastic process such that $F \in \mathcal{L}(0,T)$. The limit* (3.16) *exists and this limit is defined as $\int_0^T F_s\, dB_s^H$. Moreover, this integral satisfies $\mathbb{E}\int_0^T F_s\, dB_s^H = 0$ and*

$$\mathbb{E}\left| \int_0^T F_s\, dB_s^H \right|^2 = \mathbb{E}\left\{ \left(\int_0^T D_s^\phi F_s\, ds \right)^2 + |1_{[0,T]} F|_\phi^2 \right\}. \tag{3.17}$$

The following properties follow directly from the above theorem.

(1) If $F, G \in \mathcal{L}(0,T)$, then

$$\int_0^t \big(aF_s + bG_s\big)dB_s^H = a\int_0^t F_s\,dB_s^H + b\int_0^t G_s\,dB_s^H \quad \text{a.s.}$$

for any constants a and b and $t \in (0,T]$.

(2) If $F \in \mathcal{L}(0,T)$, $\mathbb{E}[\sup_{0\le s\le T} F_s]^2 < \infty$, and $\sup_{0\le s\le T}\mathbb{E}|D_s^\phi F_s|^2 < \infty$, then $(\int_0^t F_s\,dB_s^H, 0 \le t \le T)$ has a continuous version.

Property (1) is obvious. To show (2) let $Y_t = \int_0^t F_s\,dB_s^H, 0 \le t \le T$. By the equality (3.17), it follows that

$$\begin{aligned}
\mathbb{E}|Y_t - Y_s|^2 &= \mathbb{E}\left|\int_s^t F_u\,dB_u^H\right|^2 \\
&\le \mathbb{E}\left\{\left(\int_s^t D_u^\phi F_u\,du\right)^2 + \int_s^t\int_s^t F_uF_v\phi(u,v)dudv\right\} \\
&\le (t-s)\int_s^t \mathbb{E}|D_u^\phi F_u|^2\,du + \mathbb{E}[\sup_{0\le s\le T} F_s]^2\int_s^t\int_s^t \phi(u,v)dudv \\
&\le (t-s)^2 + C(t-s)^{2H}.
\end{aligned}$$

By the Kolmogorov lemma [22], property (2) is satisfied.

In Theorem 3.9, it is not assumed that the stochastic process $(F_s, s \in [0,T])$ is adapted to the fractional Brownian motion. Now assume that $D_s^\phi F_s = 0$ for all $s \in [0,T]$. Thus in this case,

$$\mathbb{E}\left|\int_0^T F_s\,dB_s^H\right|^2 = \mathbb{E}\left\{\int_0^T\int_0^T F_uF_v\phi(u,v)du\,dv\right\}.$$

This fact is stated in the following theorem.

THEOREM 3.10. *If $F \in \mathcal{L}(0,T)$ and if F satisfies $\mathbb{E}\int_0^T |D_s^\phi F_s|ds = 0$, then*

$$\mathbb{E}\left|\int_0^T F_s\,dB_s^H\right|^2 = \mathbb{E}\{|1_{[0,T]}F|_\phi^2\}.$$

An analogue of the stochastic integral of Stratonovich type $\int_0^t F_s\delta B_s^H$ is also introduced. This type of integral is related to the integrals introduced by Lin [17] and Dai and Heyde [2].

DEFINITION 3.11. *Let $(\pi_n, n \in \mathbb{N})$ be a sequence of partitions of $[0,t]$ such that $|\pi_n| \to 0$ as $n \to \infty$. If $\sum_{i=0}^{n-1} f(t_i^{(n)})(B^H(t_{i+1}^{(n)}) - B^H(t_i^{(n)}))$ converges in $L^2(\Omega,\mathcal{F},P)$ to the same limit for all such sequences $(\pi_n, n \in \mathbb{N})$, then this limit is called the stochastic integral of Stratonovich type and the limit is denoted by $\int_0^t f(s)\delta B^H(s)$.*

THEOREM 3.12. *If $F \in \mathcal{L}(0,t)$, then the stochastic integral of Stratonovich type $\int_0^t F_s\delta B_s^H$ exists and the following equality is satisfied:*

$$\int_0^t F_s\delta B_s^H = \int_0^t F_s\,dB_s^H + \int_0^t D_s^\phi F_s\,ds \quad a.s.$$

Proof. By Proposition 3.6,

$$\begin{aligned}
&\sum_{i=0}^{n-1} F_{t_i^{(n)}}\left(B^H\left(t_{i+1}^{(n)}\right) - B^H\left(t_i^{(n)}\right)\right) \\
&\quad = \sum_{i=0}^{n-1} F_{t_i^{(n)}} \diamond \left(B^H\left(t_{i+1}^{(n)}\right) - B^H\left(t_i^{(n)}\right)\right) + \sum_{i=0}^{n-1} D_{\Phi\chi_{\left[t_i^{(n)}, t_{i+1}^{(n)}\right]}} F_{t_i^{(n)}} \\
&\quad = \sum_{i=0}^{n-1} \left[F_{t_i^{(n)}} \diamond \left(B^H\left(t_{i+1}^{(n)}\right) - B^H\left(t_i^{(n)}\right)\right) + \int_{t_i^{(n)}}^{t_{i+1}^{(n)}} D_s^{\phi} F_{t_i^{(n)}}\, ds\right].
\end{aligned}$$

This equality proves the Theorem. □

These two types of stochastic integrals are both interesting:

(1) The expectation of $\int_0^t F_s\, dB_s^H$ is 0, but the chain rule for this type of integral is more complicated than for the integral of Stratonovich type.

(2) The chain rule for the integral of Stratonovich type is simple, but $\mathbb{E}\int_0^t F_s \delta B_s^H \neq 0$ in general.

An example is provided that shows that $\mathbb{E}\{\int_0^t F_s \delta B_s^H\}$ is not 0.

It is well known that if X is a standard normal random variable, $X \sim N(0,1)$, then

$$\mathbb{E}X^n = \begin{cases} \frac{n!}{(\sqrt{2})^n (n/2)!} & \text{if } n \text{ is even,} \\ 0 & \text{if } n \text{ is odd.} \end{cases}$$

Let $f(x) = x^n$. If n is odd, then

$$\begin{aligned}
\mathbb{E}\int_0^t f(B_s^H)\delta B_s^H &= \mathbb{E}\int_0^t D_s^{\phi} f(B_s^H) ds \\
&= \mathbb{E}\int_0^t f'(B_s^H) D_s^{\phi} B_s^H\, ds \\
&= \mathbb{E}\int_0^t f'(B_s^H) \int_0^s \phi(u,s) du\, ds \\
&= H\int_0^t s^{2H-1}\mathbb{E} f'(B_s^H) ds \\
&= nH\int_0^t s^{2H-1}\mathbb{E}((B_s^H)^{n-1}) ds \\
&= nH\int_0^t s^{2H-1}\mathbb{E}\left(\frac{B_s^H}{s^H}\right)^{n-1} s^{nH-H} ds \\
&= \frac{n! H t^{(n+1)H}}{2^{\frac{n-1}{2}}(n+1)H\left(\frac{n-1}{2}\right)!},
\end{aligned}$$

which is not 0. If n is even, then by the same computation,

$$\mathbb{E}\int_0^t (B_s^H)^n \delta B_s^H = 0.$$

Now another interesting phenomenon is shown. Let π be a partition of the interval $[0,T] : 0 = t_0 < t_1 < t_2 < \cdots < t_n = T$. Let $(f(s), s \geq 0)$ be a smooth stochastic

process on the probability space $(\Omega, \mathcal{F}, P)$. For the Brownian motion $(B_t, t \geq 0)$, the Itô integral can be defined as the limit of the Riemann sums $\sum_{i=0}^{n-1} f_{t_i}(B_{t_{i+1}} - B_{t_i})$ as the partition $|\pi| \to 0$. The Stratonovich integral is defined as the limit of the Riemann sums $\sum_{i=0}^{n-1} \frac{f_{t_i}+f_{t_{i+1}}}{2}(B_{t_{i+1}} - B_{t_i})$ as the partition $|\pi| \to 0$. It may seem to be more natural to define the Stratonovich integral for a fractional Brownian motion $(B_t^H, t \geq 0)$ in a similar way. It is shown that the above two limits are the same for a large class of stochastic processes.

Initially the following lemma is given.

LEMMA 3.13. *Let p be a positive even integer. Then*

$$\mathbb{E}(B_t^H - B_s^H)^p = \frac{p!}{2^{p/2}(p/2)!}|t-s|^{pH}. \tag{3.18}$$

Proof. By (1.1) it follows that

$$\begin{aligned}\mathbb{E}|B_t^H - B_s^H|^2 &= \mathbb{E}(B_t^H)^2 + \mathbb{E}(B_s^H)^2 - 2\mathbb{E}B_t^H B_s^H \\ &= t^{2H} + s^{2H} - (t^{2H} + s^{2H} - |t-s|^{2H}) = |t-s|^{2H}.\end{aligned}$$

Thus $\frac{B_t^H - B_s^H}{|t-s|^H}$ is a standard Gaussian random variable and

$$\begin{aligned}\mathbb{E}|B_t^H - B_s^H|^p &= |t-s|^{pH}\mathbb{E}\left(\frac{B_t^H - B_s^H}{|t-s|^H}\right)^p \\ &= \frac{p!}{2^{p/2}(p/2)!}|t-s|^{pH}.\end{aligned}$$

COROLLARY 3.14. *For each $\alpha > 1$, there is a $C_\alpha < \infty$ such that*

$$\mathbb{E}|B_t^H - B_s^H|^\alpha \leq C_\alpha |t-s|^{\alpha H}. \tag{3.19}$$

DEFINITION 3.15. *The process $(f_s, 0 \leq s \leq T)$ is said to be a bounded quadratic variation process if there are constants $p \geq 1$ and $0 < C_p < \infty$ such that for any partition $\pi : 0 = t_0 < t_1 < t_2 < \cdots < t_n = T$,*

$$\sum_{i=0}^{n-1} (\mathbb{E}|f_{t_{i+1}} - f_{t_i}|^{2p})^{1/p} \leq C_p.$$

Example. Let $f : \mathbb{R} \to \mathbb{R}$ be continuously differentiable with the first derivative bounded by C. Then $f(B_s^H)$ is a bounded quadratic variation process. In fact, for any $p \geq 1$ and partition π,

$$\begin{aligned}&\sum_{i=0}^{n-1} \left\{\mathbb{E}|f(B_{t_{i+1}}^H) - f(B_{t_i}^H)|^{2p}\right\}^{1/p} \\ &\quad= \sum_{i=0}^{n-1} \left\{\mathbb{E}\left(\int_0^1 f'\left(B_{t_i}^H + \theta(B_{t_{i+1}}^H - B_{t_i}^H)\right) d\theta (B_{t_{i+1}}^H - B_{t_i}^H)\right)^{2p}\right\}^{1/p} \\ &\quad\leq C\sum_{i=0}^{n-1} \mathbb{E}\left(|B_{t_{i+1}}^H - B_{t_i}^H|^{2p}\right)^{1/p} \\ &\quad\leq C\sum_{i=0}^{n-1} |t_{i+1} - t_i|^{2H} \leq CT.\end{aligned}$$

THEOREM 3.16. *Let $(f(t), 0 \le t \le T)$ be a bounded quadratic variation process. Let $(\pi_n, n \in \mathbb{N})$ be a sequence of partitions of $[0,T]$ such that $|\pi_n| \to 0$ as $n \to \infty$ and*

$$\left(\sum_{i=0}^{n-1} f\left(t_i^{(n)}\right) \left(B^H\left(t_{i+1}^{(n)}\right) - B^H\left(t_i^{(n)}\right)\right),\ n \in \mathbb{N} \right)$$

converges to a random variable G in $L^2(\Omega, \mathcal{F}, P)$, where $\pi_n = \left\{t_0^{(n)}, \dots, t_n^{(n)}\right\}$. Then

$$\left(\sum_{i=0}^{n-1} f\left(t_{i+1}^{(n)}\right) \left(B^H\left(t_{i+1}^{(n)}\right) - B^H\left(t_i^{(n)}\right)\right),\ n \in \mathbb{N} \right)$$

also converges to G in $L^2(\Omega, \mathcal{F}, P)$.

Proof. It suffices to show that $\sum_{i=0}^{n-1}(f_{t_{i+1}} - f_{t_i})(B^H_{t_{i+1}} - B^H_{t_i})$ converges to 0 in $L^2(\Omega, \mathcal{F}, P)$. Let p be a number as indicated in the definition of bounded quadratic variation for $(f_t, 0 \le t \le T)$:

$$\begin{aligned}
&\left(\mathbb{E}\left\{ \sum_{i=0}^{n-1} (f_{t_{i+1}} - f_{t_i}) \left(B^H_{t_{i+1}} - B^H_{t_i}\right) \right\}^2 \right)^{1/2} \\
&\qquad \le \sum_{i=0}^{n-1} \left(\mathbb{E}(f_{t_{i+1}} - f_{t_i})^2 \mathbb{E}\left(B^H_{t_{i+1}} - B^H_{t_i}\right)^2 \right)^{1/2} \\
&\qquad \le \sum_{i=0}^{n-1} \left(\mathbb{E}(f_{t_{i+1}} - f_{t_i})^{2p} \right)^{1/2p} \left(\mathbb{E}\left(B^H_{t_{i+1}} - B^H_{t_i}\right)^{2q} \right)^{1/2q} \\
&\qquad \le \left\{ \sum_{i=0}^{n-1} \left(\mathbb{E}(f_{t_{i+1}} - f_{t_i})^{2p} \right)^{1/p} \right\}^{1/2} \left\{ \sum_{i=0}^{n-1} \left(\mathbb{E}|B^H_{t_{i+1}} - B^H_{t_i}|^{2q} \right)^{1/q} \right\}^{1/2} \\
&\qquad \le C \left\{ \sum_{i=0}^{n-1} |t_{i+1} - t_i|^{2H} \right\}^{1/2} \\
&\qquad \le C \max_{0 \le i \le n-1} (t_{i+1} - t_i)^{H-1/2} \left\{ \sum_{i=0}^{n-1} |t_{i+1} - t_i| \right\}^{1/2} \\
&\qquad \le C\sqrt{T} \max_{0 \le i \le n-1} (t_{i+1} - t_i)^{H-1/2} \to 0 \quad (\ as\ |\pi| \to 0),
\end{aligned}$$

where $1/p + 1/q = 1$. ∎

It can also be shown with a slightly more lengthy argument that if $(f_s, s \ge 0)$ is a process with bounded quadratic variation and ξ_i is any point in $[t_i, t_{i+1}]$, then a sequence of the Riemann sums $\sum_{i=0}^{n-1} f_{\xi_i}(B^H_{t_{i+1}} - B^H_{t_i})$ converges in $L^2(\Omega, \mathcal{F}, P)$ to $\int_0^T f_s \delta B^H_s$, if it is true for any particular choice of such a family of points ξ_i.

4. An Itô formula. Now an analogue of the Itô formula is established, that is, a chain rule for the integral introduced in the last section. Let $f : \mathbb{R} \to \mathbb{R}$ be a twice continuously differentiable function with bounded second derivative. Then for

a partition $\{t_0, t_1, \dots, t_n\}$ of $[0,T]$, it follows by Taylor's formula that

$$\begin{aligned} f\left(B_T^H\right) - f(0) &= \sum_{i=0}^{n-1} \left[f\left(B_{t_{i+1}}^H\right) - f\left(B_{t_i}^H\right) \right] \\ &= \sum_{i=0}^{n-1} f'\left(B_{t_i}^H\right) \left[B_{t_{i+1}}^H - B_{t_i}^H \right] + \frac{1}{2} \sum_{i=0}^{n-1} f''(\xi_i) \left[B_{t_{i+1}}^H - B_{t_i}^H \right]^2 \\ &= \sum_{i=0}^{n-1} f'\left(B_{t_i}^H\right) \diamond \left[B_{t_{i+1}}^H - B_{t_i}^H \right] + \sum_{i=0}^{n-1} \int_{t_i}^{t_{i+1}} D_s^\phi f'\left(B_{t_i}^H\right) ds \\ &\quad + \frac{1}{2} \sum_{i=0}^{n-1} f''(\xi_i) \left[B_{t_{i+1}}^H - B_{t_i}^H \right]^2 \\ &= I_1 + I_2 + I_3, \end{aligned}$$

where $\xi_i \in (B_{t_i}^H, B_{t_{i+1}}^H)$. Since it is assumed that $H > 1/2$, it follows that $I_3 \to 0$ in $L^2(\Omega, \mathcal{F}, P)$. By the definition of the stochastic integral introduced in the preceding section, the first term I_1 converges to $\int_0^T f'(B_s^H) dB_s^H$ in L^2. By a version of the chain rule for the ϕ-differentiation operator, it follows that, for $s \in [t_i, t_{i+1})$,

$$\begin{aligned} D_s^\phi f'\left(B_{t_i}^H\right) &= f''\left(B_{t_i}^H\right) D_s^\phi B_{t_i}^H \\ &= f''\left(B_{t_i}^H\right) \int_0^{t_i} \phi(u,s) du \\ &= H f''\left(B_{t_i}^H\right) [s^{2H-1} - (s-t_i)^{2H-1}]. \end{aligned}$$

Thus the second sum in the three sums from Taylor's formula converges to $H \int_0^T s^{2H-1} f''(B_s^H) ds$ in L^2. The following chain rule formula is obtained.

THEOREM 4.1. *If $f : \mathbb{R} \to \mathbb{R}$ is a twice continuously differentiable function with bounded derivatives to order two, then*

$$f(B_T^H) - f(B_0^H) = \int_0^T f'(B_s^H) dB_s^H + H \int_0^T s^{2H-1} f''(B_s^H) ds \quad a.s. \tag{4.1}$$

It is interesting to note that this formula implies the usual Itô formula for Brownian motion when $H = 1/2$ is formally substituted in (4.1).

The following theorem shows how to compute the ϕ-derivative of a stochastic integral of Itô type. It can be verified from the product rule and the Riemann sum approximations to the stochastic integral.

THEOREM 4.2. *Let $(F_t, t \in [0,T])$ be a stochastic process in $\mathcal{L}(0,T)$ and $\sup_{0 \le s \le T} \mathbb{E}|D_s^\phi F_s|^2 < \infty$, and let $\eta_t = \int_0^t F_u \, dB_u^H$ for $t \in [0,T]$. Then, for $s, t \in [0,T]$,*

$$D_s^\phi \eta_t = \int_0^t D_s^\phi F_u \, dB_u^H + \int_0^t F_u \phi(s,u) du \quad a.s.$$

Now a more general Itô formula is given.

THEOREM 4.3. *Let $\eta_t = \int_0^t F_u \, dB_u^H$, where $(F_u, 0 \le u \le T)$ is a stochastic process in $\mathcal{L}(0,T)$. Assume that there is an $\alpha > 1 - H$ such that*

$$\mathbb{E}|F_u - F_v|^2 \le C|u-v|^{2\alpha},$$

where $|u-v| \le \delta$ *for some* $\delta > 0$ *and*

$$\lim_{0\le u,v\le t,|u-v|\to 0} \mathbb{E}|D_u^\phi(F_u - F_v)|^2 = 0.$$

Let $f : \mathbb{R}_+ \times \mathbb{R} \to \mathbb{R}$ *be a function having the first continuous derivative in its first variable and the second continuous derivative in its second variable. Assume that these derivatives are bounded. Moreover, it is assumed that* $\mathbb{E}\int_0^T |F_s D_s^\phi \eta_s| ds < \infty$ *and* $(f'(s,\eta_s)F_s, s \in [0,T])$ *is in* $\mathcal{L}(0,T)$*. Then, for* $0 \le t \le T$*,*

$$\begin{aligned} f(t,\eta_t) = f(0,0) &+ \int_0^t \frac{\partial f}{\partial s}(s,\eta_s)ds + \int_0^t \frac{\partial f}{\partial x}(s,\eta_s)F_s\, dB_s^H \\ &+ \int_0^t \frac{\partial^2 f}{\partial x^2}(s,\eta_s)F_s D_s^\phi \eta_s\, ds \quad a.s. \end{aligned} \tag{4.2}$$

Proof. Let π be a partition defined as above by replacing T by t. Then

$$\begin{aligned} f(t,\eta_t) - f(0,0) &= \sum_{k=0}^{n-1} [f(t_{k+1},\eta_{t_{k+1}}) - f(t_k,\eta_{t_k})] \\ &= \sum_{k=0}^{n-1} [f(t_{k+1},\eta_{t_{k+1}}) - f(t_k,\eta_{t_{k+1}})] \\ &\quad + \sum_{k=0}^{n-1} [f(t_k,\eta_{t_{k+1}}) - f(t_k,\eta_{t_k})]. \end{aligned}$$

By the mean value theorem, it is easy to see that the first sum converges to

$$\int_0^t \frac{\partial f}{\partial s}(s,\eta_s)ds$$

in L^2. Now consider the second sum. Using Taylor's formula, it follows that

$$f(t_k,\eta_{t_{k+1}}) - f(t_k,\eta_{t_k}) = \frac{\partial f}{\partial x}(t_k,\eta_{t_k})(\eta_{t_{k+1}} - \eta_{t_k}) + \frac{1}{2}\frac{\partial^2 f}{\partial x^2}(t_k,\tilde{\eta}_{t_k})\left(\eta_{t_{k+1}} - \eta_{t_k}\right)^2,$$

where $\tilde{\eta}_{t_k} \in (\eta_{t_k}, \eta_{t_{k+1}})$. An upper bound is obtained for $\mathbb{E}\left(\eta_{t_{k+1}} - \eta_{t_k}\right)^2$ as follows:

$$\begin{aligned} \mathbb{E}\left(\eta_{t_{k+1}} - \eta_{t_k}\right)^2 &= \mathbb{E}\left(\int_{t_k}^{t_{k+1}} D_s^\phi F_s\, ds\right)^2 + \mathbb{E}\int_{t_k}^{t_{k+1}}\int_{t_k}^{t_{k+1}} F_u F_v \phi(u,v)dudv \\ &\le (t_{k+1} - t_k)\int_{t_k}^{t_{k+1}} \mathbb{E}(D_s^\phi F_s)^2\, ds \\ &\quad + \int_{t_k}^{t_{k+1}}\int_{t_k}^{t_{k+1}} (\mathbb{E}F_u^2)^{1/2}(\mathbb{E}F_v^2)^{1/2}\phi(u,v)dudv \\ &\le C\left[(t_{k+1} - t_k)^2 + \int_{t_k}^{t_{k+1}}\int_{t_k}^{t_{k+1}} \phi(u,v)dudv\right] \\ &\le C(t_{k+1} - t_k)^2 + C(t_{k+1} - t_k)^{2H} \le C(t_{k+1} - t_k)^{2H}, \end{aligned}$$

where $t_{i+1} - t_i < 1$ and C is a constant independent of the partition π that may differ for different applications.

Thus

$$\mathbb{E}\sum_{k=0}^{n-1}\frac{\partial^2 f}{\partial x^2}(t_k,\tilde{\eta}_{t_k})\left(\eta_{t_{k+1}}-\eta_{t_k}\right)^2 \le C\sum_{k=0}^{n-1}\mathbb{E}\left(\eta_{t_{k+1}}-\eta_{t_k}\right)^2$$
$$\le C\sum_{k=0}^{n-1}(t_{k+1}-t_k)^{2H}\to 0 \quad \text{as } |\pi|\to 0.$$

On the other hand,

$$\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\left(\eta_{t_{k+1}}-\eta_{t_k}\right)=\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\left(F_{t_k}\diamond\left(B^H_{t_{k+1}}-B^H_{t_k}\right)\right)$$
$$+\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\left(\int_{t_k}^{t_{k+1}}(F_s-F_{t_k})dB^H_s\right).$$

The first term on the right-hand side can be expressed as

$$\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\left(F_{t_k}\diamond\left(B^H_{t_{k+1}}-B^H_{t_k}\right)\right)$$
$$=\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\left(F_{t_k}\left(B^H_{t_{k+1}}-B^H_{t_k}\right)-\int_{t_k}^{t_{k+1}}D^\phi_s F_{t_k}\,ds\right)$$
$$=\frac{\partial f}{\partial x}(t_k,\eta_{t_k})F_{t_k}\left(B^H_{t_{k+1}}-B^H_{t_k}\right)-\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\int_{t_k}^{t_{k+1}}D^\phi_s F_{t_k}\,ds$$
$$=\left[\frac{\partial f}{\partial x}(t_k,\eta_{t_k})F_{t_k}\right]\diamond\left(B^H_{t_{k+1}}-B^H_{t_k}\right)+\int_{t_k}^{t_{k+1}}D^\phi_s\left(\frac{\partial f}{\partial x}(t_k,\eta_{t_k})F_{t_k}\right)ds$$
$$-\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\int_{t_k}^{t_{k+1}}D^\phi_s F_{t_k}\,ds$$
$$=\left[\frac{\partial f}{\partial x}(t_k,\eta_{t_k})F_{t_k}\right]\diamond\left(B^H_{t_{k+1}}-B^H_{t_k}\right)+\int_{t_k}^{t_{k+1}}F_{t_k}D^\phi_s\frac{\partial f}{\partial x}(t_k,\eta_{t_k})ds.$$

Thus,

$$\sum_{k=0}^{n-1}\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\left(\eta_{t_{k+1}}-\eta_{t_k}\right)=\sum_{k=0}^{n-1}\left[\frac{\partial f}{\partial x}(t_k,\eta_{t_k})F_{t_k}\right]\diamond\left(B^H_{t_{k+1}}-B^H_{t_k}\right)$$
$$+\sum_{k=0}^{n-1}\int_{t_k}^{t_{k+1}}F_{t_k}D^\phi_s\frac{\partial f}{\partial x}(t_k,\eta_{t_k})ds.$$

As $|\pi|\to 0$, the first term converges to

$$\int_0^t F_s\frac{\partial f}{\partial x}(s,\eta_s)dB^H_s$$

in L^2, and the second term converges to

$$\int_0^t\frac{\partial^2 f}{\partial x^2}(s,\eta_s)D^\phi_s\eta_s F_s\,ds$$

in L^2. To prove the theorem, it is only necessary to show that as $|\pi|\to 0$,

$$\sum_{k=0}^{n-1}\mathbb{E}|\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\int_{t_k}^{t_{k+1}}(F_s-F_{t_k})dB^H_s|\to 0.$$

Since f has a bounded second derivative, it follows that

$$\left|\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\right| \le C(1+|\eta_{t_k}|).$$

Thus

$$\mathbb{E}|\frac{\partial f}{\partial x}(t_k,\eta_{t_k})|^2 \le C.$$

Furthermore,

$$\begin{aligned}
&\sum_{k=0}^{n-1}\mathbb{E}\left|\frac{\partial f}{\partial x}(t_k,\eta_{t_k})\int_{t_k}^{t_{k+1}}(F_s-F_{t_k})\,dB_s^H\right| \\
&\quad\le C\sum_{k=0}^{n-1}\left\{\mathbb{E}\left|\int_{t_k}^{t_{k+1}}(F_s-F_{t_k})\,dB_s^H\right|^2\right\}^{1/2} \\
&\quad= C\sum_{k=0}^{n-1}\left\{\mathbb{E}\left(\int_{t_k}^{t_{k+1}}\big(D_s^\phi(F_s-F_{t_k})\big)ds\right)^2\right. \\
&\qquad\qquad\left.+\,\mathbb{E}\int_{t_k}^{t_{k+1}}\int_{t_k}^{t_{k+1}}(F_u-F_{t_k})(F_v-F_{t_k})\phi(u,v)dudv\right\}^{1/2} \\
&\quad\le C\sum_{k=0}^{n-1}\left\{(t_{k+1}-t_k)\int_{t_k}^{t_{k+1}}\mathbb{E}\big(D_s^\phi(F_s-F_{t_k})\big)^2\,ds\right. \\
&\qquad\qquad\left.+\int_{t_k}^{t_{k+1}}\int_{t_k}^{t_{k+1}}\{\mathbb{E}(F_u-F_{t_k})^2\}^{1/2}\{\mathbb{E}(F_v-F_{t_k})^2\}^{1/2}\phi(u,v)dudv\right\}^{1/2} \\
&\quad\le C\sum_{k=0}^{n-1}\left[\sup_{t_k\le s\le t_{k+1}}\mathbb{E}|D_s^\phi(F_s-F_{t_k})|^2(t_{k+1}-t_k)^2\right. \\
&\qquad\qquad\left.+(t_{k+1}-t_k)^{2H}\left\{\sup_{t_k\le s\le t_{k+1}}\mathbb{E}(F_s-F_{t_k})^2\right\}\right]^{1/2} \\
&\quad\le C\left\{\sup_{t_k\le s\le t_{k+1}}\mathbb{E}|D_s^\phi(F_s-F_{t_k})|^2\right\}^{1/2}+C|\pi|^{H+\alpha-1}\to 0
\end{aligned}$$

as $|\pi|\to 0$. This proves the theorem. □

The equality (4.2) can be formally expressed as

$$df(t,\eta_t)=\frac{\partial f}{\partial t}(t,\eta_t)dt+\frac{\partial f}{\partial x}(t,\eta_t)F_t\,dB_t^H+\frac{\partial^2 f}{\partial x^2}(t,\eta_t)F_tD_t^\phi\eta_t\,dt.$$

If $F(s)=a(s)$ is a deterministic function, then (4.1) simplifies as follows.

COROLLARY 4.4. *Let $\eta_t=\int_0^t a_u\,dB_u^H$, where $a\in L_\phi^2$ and $f:\mathbb{R}_+\times\mathbb{R}\to\mathbb{R}$ satisfies the conditions in Theorem* 4.3. *Let $(\frac{\partial f}{\partial x}(s,\eta_s)a_s, s\in[0,T])$ be in $\mathcal{L}(0,T)$. Then*

$$\begin{aligned}
f(t,\eta_t)=f(0,0)&+\int_0^t\frac{\partial f}{\partial s}(s,\eta_s)ds+\int_0^t\frac{\partial f}{\partial x}(s,\eta_s)a_s\,dB_s^H \\
&+\int_0^t\frac{\partial^2 f}{\partial x^2}(s,\eta_s)\int_0^s\phi(s,v)a_v\,dvds\quad a.s.,
\end{aligned}$$

or formally,

$$df(t,\eta_t) = \frac{\partial f}{\partial t}(t,\eta_t)dt + \frac{\partial f}{\partial x}(t,\eta_t)a_t\,dB_t^H + \frac{\partial^2 f}{\partial x^2}(t,\eta_t)\int_0^t \phi(t,v)a_v\,dvdt.$$

If $a_s \equiv 1$, then Theorem 4.1 is obtained.

In the classical stochastic analysis, the stochastic integral can be defined for general semimartingales and an Itô formula can be given. By the Doob–Meyer decomposition [4], a semimartingale can be expressed as the sum of a martingale and a bounded variation process. A semimartingale $(X_t, t \geq 0)$ with respect to a Brownian motion can often be expressed as $X_t = X_0 + \int_0^t f_s\,dB_s + \int_0^t g_s\,ds$. An Itô formula in the analogous form with respect to fractional Brownian motions is given. This generalization of the Itô formula is useful in applications.

THEOREM 4.5. *Let $(F_u, u \in [0,T])$ satisfy the conditions of Theorem* 4.3*, and let $\mathbb{E}\sup_{0\leq s\leq T}|G_s| < \infty$. Denote $\eta_t = \xi + \int_0^t G_u\,du + \int_0^t F_u\,dB_u^H$, $\xi \in \mathbb{R}$ for $t \in [0,T]$. Let $(\frac{\partial f}{\partial x}(s,\eta_s)F_s, s \in [0,T]) \in \mathcal{L}(0,T)$. Then, for $t \in [0,T]$,*

$$\begin{aligned} f(t,\eta_t) = f(0,\xi) &+ \int_0^t \frac{\partial f}{\partial s}(s,\eta_s)ds + \int_0^t \frac{\partial f}{\partial x}(s,\eta_s)G_s\,ds \\ &+ \int_0^t \frac{\partial f}{\partial x}(s,\eta_s)F_s\,dB_s^H + \int_0^t \frac{\partial^2 f}{\partial x^2}(s,\eta_s)F_s D_s^\phi \eta_s\,ds \quad a.s. \end{aligned}$$

The proof is the same as for the above theorem.

Now the Itô formula for $\mathbb{R}^n$-valued processes is given.

THEOREM 4.6. *Let $(F_s^i, i = 1,\dots,n, s \in [0,T])$ satisfy the conditions of Theorem* 4.3 *for F. Let $\xi_t^k = \int_0^t F_s^k\,dB_s^H$, $k = 1,2,\dots,n$ for $t \in [0,T]$. For $k = 1,2,\dots,n$ let $(f_{x_k}(s,\xi_s^1,\dots,\xi_s^n)F_s^k,\ s \in [0,T])$ be in $\mathcal{L}(0,T)$. Let $f : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}$ be twice continuously differentiable with bounded derivatives to second order. Then*

$$\begin{aligned} f(t,\xi_t^1,\dots,\xi_t^n) = f(0,0,\dots,0) &+ \int_0^t f_s(s,\xi_s^1,\dots,\xi_s^n)ds \\ &+ \sum_{k=1}^n \int_0^t f_{x_k}(s,\xi_s^1,\dots,\xi_s^n)F_s^k\,dB_s^H \\ &+ \sum_{k,l=1}^n \int_0^t f_{x_k x_l}(s,\xi_s^1,\dots,\xi_s^n)F_s^k\ D_s^\phi \xi_s^l\,ds \quad a.s. \end{aligned}$$

Proof. The theorem is verified for $n = 2$. To simplify the notation, let $F^1 = F$ and $F^2 = G$. Let $\pi : 0 = t_0 < t_1 < t_2 < \cdots < t_n = t$ be a partition of the interval $[0,t]$. Then

$$\begin{aligned} f(t,\xi_t,\eta_t) - f(0,0,0) = &\sum_{k=0}^{n-1} \big(f(t_{k+1},\xi_{t_{k+1}},\eta_{t_{k+1}}) - f(t_k,\xi_{t_{k+1}},\eta_{t_{k+1}})\big) \\ &+ \sum_{k=0}^{n-1} \big(f(t_k,\xi_{t_{k+1}},\eta_{t_{k+1}}) - f(t_k,\xi_{t_k},\eta_{t_k})\big), \end{aligned} \tag{4.3}$$

where $\xi_t = \int_0^t F\,dB^H$ and $\eta_t = \int_0^t G\,dB^H$. It is easy to see that the first sum converges to $\int_0^t \frac{\partial f}{\partial t}ds$ in L^2 as $|\pi| \to 0$. To determine the limit of the second sum, consider each

term in the sum:

$$\begin{aligned}
&f(t_k,\xi_{t_{k+1}},\eta_{t_{k+1}}) - f(t_k,\xi_{t_k},\eta_{t_k}) \\
&\quad = f_x(t_k,\xi_{t_k},\eta_{t_k})\big(\xi_{t_{k+1}}-\xi_{t_k}\big) + f_y(t_k,\xi_{t_k},\eta_{t_k})\big(\eta_{t_{k+1}}-\eta_{t_k}\big) \\
&\qquad + \frac{1}{2}f_{xx}(t_k,\tilde{\xi}_{t_k},\tilde{\eta}_{t_k})\big(\xi_{t_{k+1}}-\xi_{t_k}\big)^2 + \frac{1}{2}f_{yy}(t_k,\tilde{\xi}_{t_k},\tilde{\eta}_{t_k})\left(\eta_{t_{k+1}}-\eta_{t_k}\right)^2 \\
&\qquad + f_{xy}(t_k,\tilde{\xi}_{t_k},\tilde{\eta}_{t_k})\left(\xi_{t_{k+1}}-\xi_{t_k}\right)\left(\eta_{t_{k+1}}-\eta_{t_k}\right),
\end{aligned}$$

where $\tilde{\xi}_{t_k} \in (\xi_{t_k},\xi_{t_{k+1}})$ and $\tilde{\eta}_{t_k} \in (\eta_{t_k},\eta_{t_{k+1}})$. Thus

$$\begin{aligned}
&\sum_{k=0}^{n-1}\big(f(t_k,\xi_{t_{k+1}},\eta_{t_{k+1}}) - f(t_k,\xi_{t_k},\eta_{t_k})\big) \\
&\quad = \sum_{k=0}^{n-1} f_x(t_k,\xi_{t_k},\eta_{t_k})\left(\xi_{t_{k+1}}-\xi_{t_k}\right) + \sum_{k=0}^{n-1} f_y(t_k,\xi_{t_k},\eta_{t_k})\big(\eta_{t_{k+1}}-\eta_{t_k}\big) \\
&\qquad + \frac{1}{2}\sum_{k=0}^{n-1} f_{xx}(t_k,\tilde{\xi}_{t_k},\tilde{\eta}_{t_k})\left(\xi_{t_{k+1}}-\xi_{t_k}\right)^2 \\
&\qquad + \frac{1}{2}\sum_{k=0}^{n-1} f_{yy}(t_k,\tilde{\xi}_{t_k},\tilde{\eta}_{t_k})\left(\eta_{t_{k+1}}-\eta_{t_k}\right)^2 \\
&\qquad + \sum_{k=0}^{n-1} f_{xy}(t_k,\tilde{\xi}_{t_k},\tilde{\eta}_{t_k})\left(\xi_{t_{k+1}}-\xi_{t_k}\right)\left(\eta_{t_{k+1}}-\eta_{t_k}\right) \\
&\quad = I_1^\pi + I_2^\pi + I_3^\pi + I_4^\pi + I_5^\pi.
\end{aligned}$$

In a similar way as the proof of Theorem 4.3, it can be shown that as $|\pi| \to 0$, I_k^π converges to 0 in L^2 for $k = 3,4,5$:

$$\begin{aligned}
f_x(t_k,\xi_{t_k},\eta_{t_k})\left(\xi_{t_{k+1}}-\xi_{t_k}\right) &= f_x(t_k,\xi_{t_k},\eta_{t_k})\left(F_{t_k} \diamond \left(B^H_{t_{k+1}} - B^H_{t_k}\right)\right) \\
&\quad + f_x(t_k,\xi_{t_k},\eta_{t_k})\left(\int_{t_k}^{t_{k+1}} (F_s - F_{t_k}) dB^H_s\right).
\end{aligned}$$

In a similar way to the proof of Theorem 4.3, the second sum does not contribute in the limit as $|\pi| \to 0$.

By the definition of the Wick product, it follows that

$$\begin{aligned}
&f_x(t_k,\xi_{t_k},\eta_{t_k})\left(F_{t_k} \diamond \left(B^H_{t_{k+1}} - B^H_{t_k}\right)\right) \\
&\quad = f_x(t_k,\xi_{t_k},\eta_{t_k})\left(F_{t_k}\left(B^H_{t_{k+1}} - B^H_{t_k}\right) - \int_{t_k}^{t_{k+1}} D^\phi_s F_{t_k}\, ds\right) \\
&\quad = f_x(t_k,\xi_{t_k},\eta_{t_k}) F_{t_k}\left(B^H_{t_{k+1}} - B^H_{t_k}\right) - f_x(t_k,\xi_{t_k},\eta_{t_k})\int_{t_k}^{t_{k+1}} D^\phi_s F_{t_k}\, ds \\
&\quad = (f_x(t_k,\xi_{t_k},\eta_{t_k})F_{t_k}) \diamond \left(B^H_{t_{k+1}} - B^H_{t_k}\right) + \int_{t_k}^{t_{k+1}} D^\phi_s (f_x(t_k,\xi_{t_k},\eta_{t_k})F_{t_k}) ds \\
&\qquad - f_x(t_k,\xi_{t_k},\eta_{t_k})\int_{t_k}^{t_{k+1}} D^\phi_s F_{t_k}\, ds \\
&\quad = (f_x(t_k,\xi_{t_k},\eta_{t_k})F_{t_k}) \diamond \left(B^H_{t_{k+1}} - B^H_{t_k}\right) + \int_{t_k}^{t_{k+1}} f_{xx}(t_k,\xi_{t_k},\eta_{t_k}) D^\phi_s \xi_{t_k} F_{t_k}\, ds
\end{aligned}$$

$$
\begin{aligned}
&+\int_{t_k}^{t_{k+1}} f_{xy}(t_k,\xi_{t_k},\eta_{t_k})D_s^\phi \eta_{t_k}F_{t_k}\,ds+\int_{t_k}^{t_{k+1}} f_x(t_k,\xi_{t_k},\eta_{t_k})D_s^\phi F_{t_k}\,ds\\
&-f_x(t_k,\xi_{t_k},\eta_{t_k})\int_{t_k}^{t_{k+1}} D_s^\phi F_{t_k}\,ds\\
&=\left(f_x\big(t_k,\xi_{t_k},\eta_{t_k}\big)F_{t_k}\right)\diamond\left(B_{t_{k+1}}^H-B_{t_k}^H\right)+\int_{t_k}^{t_{k+1}} f_{xx}(t_k,\xi_{t_k},\eta_{t_k})D_s^\phi \xi_{t_k}F_{t_k}\,ds\\
&+\int_{t_k}^{t_{k+1}} f_{xy}(t_k,\xi_{t_k},\eta_{t_k})D_s^\phi \eta_{t_k}F_{t_k}\,ds.
\end{aligned}
$$

In a similar way to the proof of Theorem 4.3, it can be shown that as $|\pi|\to 0$,

$$
\begin{aligned}
I_1^\pi \to &\int_0^t \frac{\partial f}{\partial x}(s,\xi_s,\eta_s)F_s\,dB_s^H+\int_0^t \frac{\partial^2 f}{\partial x^2}(s,\xi_s,\eta_s)D_s^\phi\xi_s F_s\,ds\\
&+\int_0^t \frac{\partial^2 f}{\partial x\partial y}(s,\xi_s,\eta_s)D_s^\phi\eta_s F_s\,ds
\end{aligned}
$$

and

$$
\begin{aligned}
I_2^\pi \to &\int_0^t \frac{\partial f}{\partial y}(s,\xi_s,\eta_s)G_s\,dB_s^H+\int_0^t \frac{\partial^2 f}{\partial y^2}(s,\xi_s,\eta_s)D_s^\phi\eta_s G_s\,ds\\
&+\int_0^t \frac{\partial^2 f}{\partial x\partial y}(s,\xi_s,\eta_s)D_s^\phi\xi_s G_s\,ds
\end{aligned}
$$

in L^2, proving the theorem. □

The Itô formula for the integrals of Stratonovich type is simpler.

THEOREM 4.7. *Let $(F_t, t\in[0,T])$ be a process such that the assumptions of Theorem 4.3 are satisfied. Let $\xi_t=\int_0^t F_s\delta B_s^H$. Let $g:\mathbb{R}_+\times\mathbb{R}\to\mathbb{R}$ be a twice continuously differentiable function with bounded derivatives to second order. Let $(\frac{\partial g}{\partial x}(s,\xi_s)F_s, s\in[0,T])$ be in $\mathcal{L}(0,T)$. Then, for $t\in[0,T]$,*

$$
g(t,\xi_t)=g(0,0)+\int_0^t \frac{\partial g}{\partial s}(s,\xi_s)ds+\int_0^t \frac{\partial g}{\partial x}(s,\xi_s)F_s\delta B_s^H \quad a.s. \tag{4.4}
$$

Proof. Note that $\tilde{\xi}_t=\int_0^t F_s\,dB_s^H$ also exists and

$$
\xi_t=\tilde{\xi}_t+\int_0^t D_s^\phi F_s\,ds.
$$

Using the Itô formula (4.2),

$$
\begin{aligned}
g(t,\xi_t)&=g\left(t,\tilde{\xi}_t+\int_0^t D_s^\phi F_s\,ds\right)\\
&=g(0,0)+\int_0^t \frac{\partial g}{\partial s}(s,\xi_s)ds+\int_0^t \frac{\partial g}{\partial x}(s,\xi_s)D_s^\phi F_s\,ds\\
&\quad+\int_0^t \frac{\partial g}{\partial x}(s,\xi_s)F_s\,dB_s^H+\int_0^t \frac{\partial^2 g}{\partial x^2}(s,\xi_s)D_s^\phi\xi_s F_s\,ds. \qquad (4.5)
\end{aligned}
$$

Now,

$$\begin{aligned}\int_0^t \frac{\partial g}{\partial x}(s,\xi_s)F_s\,dB_s^H &= \int_0^t g_x(s,\xi_s)F_s\delta B_s^H - \int_0^t D_s^\phi(g_x(s,\xi_s)F_s)ds\\ &= \int_0^t g_x(s,\xi_s)F_s\delta B_s^H - \int_0^t g_{xx}(s,\xi_s)D_s^\phi\xi_s F_s\,ds\\ &\quad - \int_0^t g_x(s,\xi_s)D_s^\phi F_s\,ds. \qquad (4.6)\end{aligned}$$

Combining the above two equalities, it follows that

$$g(t,\xi_t) = g(0,0) + \int_0^t \frac{\partial g}{\partial s}(s,\xi_s)ds + \int_0^t \frac{\partial g}{\partial x}(s,\xi_s)F_s\delta B_s^H,$$

proving the theorem. □

REMARK 1. *The equation* (4.4) *can be expressed formally as*

$$\delta g(t,\xi_t) = g_t(t,\xi_t)dt + g_x(t,\xi_t)\delta\xi_t$$

or more generally as

$$\begin{aligned}\delta g(t,\xi_t^1,\xi_t^2,\dots,\xi_t^n) &= \frac{\partial g}{\partial t}(t,\xi_t^1,\xi_t^2,\dots,\xi_t^n)dt + \frac{\partial g}{\partial x_1}(t,\xi_t^1,\xi_t^2,\dots,\xi_t^n)\delta\xi_t^1\\ &\quad + \cdots + \frac{\partial g}{\partial x_n}(t,\xi_t^1,\xi_t^2,\dots,\xi_t^n)\delta\xi_t^n.\end{aligned}$$

5. Two applications of the Itô formula. Two applications of the Itô formula for fractional Brownian motion are given. First, the so-called homogeneous chaos is extended to a fractional Brownian motion. Second, an L^p estimate of the (Itô type) stochastic integral for a fractional Brownian motion is given.

Let $H_n(x)$ be the Hermite polynomial of degree n, that is,

$$e^{tx-\frac{1}{2}t^2} = \sum_{n=0}^{\infty} t^n H_n(x).$$

Let

$$|f|_{\phi,t} = \left\{\int_0^t\int_0^t \phi(u,v)f_u f_v\,dudv\right\}^{1/2}.$$

Define

$$\tilde{f}_t = |f|_{\phi,t}^{-1}\int_0^t f_s\,dB_s^H$$

and

$$H_n^{\phi,f}(t) = |f|_{\phi,t}^n H_n\left(\tilde{f}_t\right).$$

THEOREM 5.1. *If* $f1_{[0,T]} \in L_\phi^2$, *then the following equality is satisfied:*

$$dH_n^{\phi,f}(t) = nH_{n-1}^{\phi,f}(t)f_t\,dB_t^H,$$

where d is the Itô type differential given in Theorem 4.3 *and* $t \in [0,T]$.

Proof. Fix n and denote $X_t = H_n^{\phi,f}(t)$ for $t \in [0,T]$. Using the Itô formula (Theorem 4.3) and prime for differentiation, it follows that

$$\begin{aligned}
dX_t &= n|f|_{\phi,t}^{n-2} f_t \int_0^t \phi(u,t) f_u \, du H_n\Big(\tilde{f}_t\Big) dt \\
&\quad - |f|_{\phi,t}^{n} f_t \int_0^t \phi(u,t) f_u \, du H_n'\Big(\tilde{f}_t\Big) |f|_{\phi,t}^{-3} \left(\int_0^t f_s \, dB_s^H \right) dt \\
&\quad + |f|_{\phi,t}^{n} H_n'\Big(\tilde{f}_t\Big) |f|_{\phi,t}^{-1} f_t \, dB_t^H \\
&\quad + |f|_{\phi,t}^{n} f_t \int_0^t \phi(u,t) f_u \, du H_n''\Big(\tilde{f}_t\Big) |f|_{\phi,t}^{-2} \, dt \\
&= n|f|_{\phi,t}^{n-1} H_{n-1}\Big(\tilde{f}_t\Big) f_t \, dB_t^H \\
&\quad + |f|_{\phi,t}^{n-2} f_t \int_0^t \phi(u,t) f_u du \cdot \Big\{ nH_n(\tilde{f}_t) - \tilde{f}_t H_n'(\tilde{f}_t) + H_n''(\tilde{f}_t) \Big\} \, dt.
\end{aligned}$$

It is well known that for each $n \in \mathbb{N}$ the Hermite polynomial satisfies

$$nH_n(x) - xH_n'(x) + H_n''(x) = 0$$

for each $x \in \mathbb{R}$. Thus the sum of the terms in the above { } equals 0. The first term is

$$nH_{n-1}^{\phi,f}(t) f_t \, dB_t^H.$$

Thus

$$dH_n^{\phi,f}(t) = nH_{n-1}^{\phi,f}(t) f_t \, dB_t^H,$$

proving the theorem. □

The following estimate for the L^p norm of a stochastic integral is useful in some applications.

THEOREM 5.2. *Let $(g_s, s \in [0,t])$ be a stochastic process satisfying the assumptions of Theorem* 4.3 *for F. Let $F_t := \int_0^t g_s \, dB_s^H$. If $\mathbb{E}\int_0^t |g_s|^p \, ds < \infty$, $\int_0^t \mathbb{E}|D_s^\phi F_s|^p \, ds < \infty$, and $F^{p-1} g \in \mathcal{L}(0,t)$, then*

$$\mathbb{E}F_t^p \le p^p \left\{ \int_0^t \Big(\mathbb{E}|g_s D_s^\phi F_s|^{p/2} \Big)^{2/p} ds \right\}^{p/2}. \tag{5.1}$$

Proof. Applying the Itô formula (Theorem 4.3) to F_t^p (by the assumption that $F^{p-1} g \in \mathcal{L}(0,t)$, the restriction on the boundedness of f to its second derivative in Theorem 4.3 can be removed), it follows that

$$F_t^p = p \int_0^t F_s^{p-1} g_s \, dB_s^H + p(p-1) \int_0^t F_s^{p-2} g_s D_s^\phi F_s \, ds.$$

Thus

$$\begin{aligned}
\mathbb{E}F_t^p &= p(p-1) \int_0^t \mathbb{E}(F_s^{p-2} g_s D_s^\phi F_s) ds. \\
\mathbb{E}F_t^p &\le p(p-1) \int_0^t \mathbb{E}|F_s^{p-2} g_s D_s^\phi F_s| ds \\
&\le p^2 \int_0^t (\mathbb{E}F_s^p)^{\frac{p-2}{p}} \Big(\mathbb{E}|g_s D_s^\phi F_s|^{\frac{p}{2}} \Big)^{\frac{2}{p}} ds.
\end{aligned}$$

By an inequality of Langenhop, (e.g. [1]), there is the inequality

$$\mathbb{E}F_t^p \le p^p \left\{ \int_0^t \left(\mathbb{E}|g_s D_s^\phi F_s|^{\frac{p}{2}} \right)^{\frac{2}{p}} ds \right\}^{\frac{p}{2}}.$$

This completes the proof of the theorem. □

COROLLARY 5.3. *Let the conditions of Theorem* 5.2 *be satisfied, and let* $p \ge 2$. *Then*

$$\mathbb{E}F_t^p \le p^p \left\{ \int_0^t (\mathbb{E}|g_s|^p)^{\frac{2}{p}} ds + \int_0^t (\mathbb{E}|D_s^\phi F_s|^p)^{\frac{2}{p}} ds \right\}^{\frac{p}{2}}.$$

Proof. From $|ab| \le a^2 + b^2$, it follows that

$$\mathbb{E}|g_s D_s^\phi F_s|^{\frac{p}{2}} \le \mathbb{E}|g_s|^p + \mathbb{E}|D_s^\phi F_s|^p.$$

Thus

$$\begin{aligned} \left(\mathbb{E}|g_s D_s^\phi F_s|^{\frac{p}{2}} \right)^{\frac{2}{p}} &\le (\mathbb{E}|g_s|^p + \mathbb{E}|D_s^\phi F_s|^p)^{\frac{2}{p}} \\ &\le (\mathbb{E}|g_s|^p)^{\frac{2}{p}} + (\mathbb{E}|D_s^\phi F_s|^p)^{\frac{2}{p}}. \end{aligned}$$

This verifies the corollary. □

6. Iterated integrals and multiple integrals. Let $f \in L_\phi^2(\mathbb{R}_+)$ be such that $|f|_\phi = 1$. Similar to [8] define $(\int_0^\infty f_s\, dB_s^H)^{\diamond n}$ as the nth Wick power of $\int_0^\infty f_s\, dB_s^H$, that is, denote formally

$$\begin{aligned} \left(\int_0^\infty f_s\, dB_s^H \right)^{\diamond n} &:= \left(\int_0^\infty f_s\, dB_s^H \right)^{\diamond(n-1)} \diamond \int_0^\infty f_s\, dB_s^H, \quad n = 2, 3, \dots \\ \exp^\diamond \left(\int_0^\infty f_s\, dB_s^H \right) &:= \sum_{n=0}^\infty \frac{1}{n!} \left(\int_0^\infty f_s\, dB_s^H \right)^{\diamond n}; \\ \log^\diamond \left(1 + \int_0^\infty f_s\, dB_s^H \right) &:= \sum_{n=1}^\infty \frac{(-1)^{n-1}}{n} \left(\int_0^\infty f_s\, dB_s^H \right)^{\diamond n}. \end{aligned}$$

LEMMA 6.1. *If* $|f|_\phi = 1$, *then* $(\int_0^\infty f_s\, dB_s^H)^{\diamond n}$ *is well defined for each* $n \in \mathbb{N}$ *and*

$$\left(\int_0^\infty f_s\, dB_s^H \right)^{\diamond n} = H_n \left(\int_0^\infty f_s\, dB_s^H \right), \tag{6.1}$$

where H_n *denotes the Hermite polynomial of degree* n.

Proof. The equality (6.1) is verified by induction.

It is easy to see that (6.1) is true for $n = 1$. Let (6.1) be true for $1, 2, \dots, n-1$.

Then,

$$\begin{aligned}\left(\int_0^\infty f_s\,dB_s^H\right)^{\diamond n} &= H_{n-1}\left(\int_0^\infty f_s\,dB_s^H\right)\diamond\int_0^\infty f_s\,dB_s^H\\ &= H_{n-1}\left(\int_0^\infty f_s\,dB_s^H\right)\int_0^\infty f_s\,dB_s^H - D_{\Phi f}\left\{H_{n-1}\left(\int_0^\infty f_s\,dB_s^H\right)\right\}\\ &= H_{n-1}\left(\int_0^\infty f_s\,dB_s^H\right)\int_0^\infty f_s dB_s^H - H'_{n-1}\left(\int_0^\infty f_s\,dB_s^H\right)|f|_\phi^2\\ &= H_{n-1}\left(\int_0^\infty f_s\,dB_s^H\right)\int_0^\infty f_s\,dB_s^H - H'_{n-1}\left(\int_0^\infty f_s\,dB_s^H\right)\\ &= H_n\left(\int_0^\infty f_s\,dB_s^H\right)\end{aligned}$$

by an identity for Hermite polynomials. This verifies (6.1). ∎

For an arbitrary, nonzero $f\in L_\phi^2(\mathbb{R}_+)$, the product defined in (6.1) is extended as

$$\left(\int_0^\infty f_s\,dB_s^H\right)^{\diamond n} = |f|_\phi^n\left(\frac{\int_0^\infty f_s\,dB_s^H}{|f|_\phi}\right)^{\diamond n} = |f|_\phi^n H_n\left(\int_0^\infty \frac{\int_0^\infty f_s\,dB_s^H}{|f|_\phi}\right).$$

LEMMA 6.2. *If $f\in L_\phi^2(\mathbb{R}_+)$, then $(\int_0^\infty f_s\,dB_s^H)^{\diamond n}$ is well defined for each $n\in\mathbb{N}$ and*

$$\left(\int_0^t f_s\,dB_s^H\right)^{\diamond n} = H_n^{\phi,f}(t).$$

Since $\int_0^\infty f_s\,dB_s^H$ is a Gaussian random variable, it is easy to estimate its moments and to show that the series defining $\exp^\diamond(\int_0^\infty f_s\,dB_s^H)$ is convergent in $L^2(\Omega,\mathcal{F},P)$. Moreover there is the following corollary.

COROLLARY 6.3. *If $f\in L_\phi^2(\mathbb{R}_+)$, then*

$$\exp^\diamond\left(\int_0^\infty f_s\,dB_s^H\right) = \varepsilon(f) = \exp\left(\int_0^\infty f_s\,dB_s^H - \frac{1}{2}|f|_\phi^2\right).$$

Proof. It follows that

$$\begin{aligned}\exp^\diamond\left(\int_0^\infty f_s\,dB_s^H\right) &= \sum_{n=0}^\infty \frac{1}{n!}\left(\int_0^\infty f_s\,dB_s^H\right)^{\diamond n}\\ &= \sum_{n=0}^\infty \frac{1}{n!}|f|_\phi^n H_n\left(\frac{\int_0^\infty f_s\,dB_s^H}{|f|_\phi}\right)\\ &= \exp\left(|f|_\phi\frac{\int_0^\infty f_s\,dB_s^H}{|f|_\phi} - \frac{1}{2}|f|_\phi^2\right)\\ &= \exp\left(\int_0^\infty f_s\,dB_s^H - \frac{1}{2}|f|_\phi^2\right).\end{aligned}$$

This completes the proof of the lemma. ∎

The following lemma is also easy to prove.

LEMMA 6.4. *For any two functions f and g in $L^2_\phi(\mathbb{R}_+)$ with $\langle f,g\rangle_\phi = 0$, the following equality is satisfied:*

$$\left(\int_0^\infty f_s\,dB_s^H\right)^{\diamond n}\diamond\left(\int_0^\infty g_s\,dB_s^H\right)^{\diamond m} = \left(\int_0^\infty f_s\,dB_s^H\right)^{\diamond n}\left(\int_0^\infty g_s\,dB_s^H\right)^{\diamond m} = H_n^{\phi,f}(\infty)H_m^{\phi,g}(\infty).$$

Since $\int_0^\infty f_s\,dB_s^H/|f|_\phi$ and $\int_0^\infty g_s\,dB_s^H/|g|_\phi$ are Gaussian random variables with mean 0 and variance 1, their covariance is

$$\mathbb{E}\left\{\left(\int_0^\infty f_s\,dB_s^H/|f|_\phi\right)\left(\int_0^\infty g_s\,dB_s^H/|g|_\phi\right)\right\} = \langle f/|f|_\phi, g/|g|_\phi\rangle_\phi.$$

It follows that

$$\begin{aligned}\mathbb{E}&\left\{\left(\int_0^\infty f_s\,dB_s^H\right)^{\diamond n}\left(\int_0^\infty g_s\,dB_s^H\right)^{\diamond m}\right\}\\ &= \mathbb{E}\left\{|f|_\phi^n|g|_\phi^m H_n\left(\int_0^\infty f_s\,dB_s^H/|f|_\phi\right)H_m\left(\int_0^\infty g_s\,dB_s^H/|g|_\phi\right)\right\}\\ &= \begin{cases}0 & \text{if } m\neq n,\\ |f|_\phi^n|g|_\phi^n\langle f/|f|_\phi, g/|g|_\phi\rangle_\phi^n & \text{if } m=n\end{cases}\\ &= \begin{cases}0 & \text{if } m\neq n,\\ \langle f,g\rangle_\phi^n & \text{if } m=n.\end{cases}\end{aligned}$$

By a polarization technique [21] it is easy to verify the following lemma.

LEMMA 6.5. *Let $f^1,\dots,f^n$, $g^1,\dots,g^m\in L^2_\phi(\mathbb{R}_+)$. The following equality is satisfied:*

$$\mathbb{E}\left\{\left(\int_0^\infty f_s^1\,dB_s^H\diamond\cdots\diamond\int_0^\infty f_s^n\,dB_s^H\right)\left(\int_0^\infty g_s^1\,dB_s^H\diamond\cdots\diamond\int_0^\infty g_s^m\,dB_s^H\right)\right\} = \begin{cases}0 & \text{if } n\neq m,\\ \frac{1}{n!}\sum_\sigma\langle f^1,g^{\sigma(1)}\rangle_\phi\langle f^2,g^{\sigma(2)}\rangle_\phi\cdots\langle f^n,g^{\sigma(n)}\rangle_\phi & \text{if } n=m,\end{cases}$$

where $\sum_\sigma$ denotes the sum over all permutations σ of $\{1,2,\dots,n\}$.

Let $e_1,e_2,\dots,e_n,\dots$ be a complete orthonormal basis of $L^2_\phi(\mathbb{R}_+)$. Consider the nth symmetric tensor product of $L^2_\phi(\mathbb{R}_+)$: $L^s_\phi(\mathbb{R}_+^n) := L^2_\phi(\mathbb{R}_+)\otimes\cdots\otimes L^2_\phi(\mathbb{R}_+)$. It is the completion of all functions of the following form:

$$f(s_1,\dots,s_n) = \sum_{1\le k_1,\dots,k_n\le k} a_{k_1\cdots k_n}e_{k_1}(s_1)e_{k_2}(s_2)\cdots e_{k_n}(s_n), \tag{6.2}$$

where f is a symmetric function of its variables $s_1,\dots,s_n$ and k is a positive integer. The set of all of the above finite sums is denoted $\mathcal{L}_n$. For an element of the form (6.2), its multiple integral is defined by

$$I_n(f) = \sum_{1\le k_1,\dots,k_n\le k} a_{k_1\cdots k_n}\int_0^\infty e_{k_1}(s)dB_s^H\diamond\int_0^\infty e_{k_2}(s)dB_s^H\diamond\cdots\diamond\int_0^\infty e_{k_n}(s)dB_s^H. \tag{6.3}$$

By Lemma 6.5, the norm of (6.3) is given by

$$\mathbb{E}|I_n(f)|^2 = \int_{\mathbb{R}_+^{2n}} \phi(u_1,v_1)\phi(u_2,v_2)\cdots\phi(u_n,v_n)f(u_1,u_2,\dots,u_n) \tag{6.4}$$
$$f(v_1,v_2,\dots,v_n)du_1\,du_2\cdots du_n\,dv_1\,dv_2\cdots dv_n.$$

Thus for any element f in

$$L_\phi^2(\mathbb{R}_+^n) = \{f:\mathbb{R}_+^n\to\mathbb{R}; f \text{ is symmetric with respect to its arguments},$$
$$|f|_\phi^2 := \langle f,f\rangle_\phi < \infty\},$$

where

$$\langle f,g\rangle_\phi = \int_{\mathbb{R}_+^{2n}} \phi(u_1,v_1)\phi(u_2,v_2)\cdots\phi(u_n,v_n)f(u_1,u_2,\dots,u_n)$$
$$g(v_1,v_2,\dots,v_n)du_1\,du_2\cdots du_n\,dv_1\,dv_2\cdots dv_n.$$

The multiple integral $I_n(f)$ can be defined by a limit from elements in $\mathcal{L}_n$, and it follows that

$$\mathbb{E}(|I_n(f)|^2) = |f|_\phi^2.$$

The following lemma can also be shown by the polarization technique.

LEMMA 6.6. *If $f\in L_\phi^2(\mathbb{R}_+^n)$ and $g\in L_\phi^2(\mathbb{R}_+^m)$, then*

$$\mathbb{E}(I_n(f)I_m(g)) = \begin{cases}\langle f,g\rangle_\phi & \text{if } n=m,\\ 0 & \text{if } n\neq m.\end{cases} \tag{6.5}$$

Let $f\in L_\phi^2(\mathbb{R}_+^n)$. The iterated integral can be defined by the recursive formula

$$\int_{0\le s_1<s_2<\cdots<s_n\le t} f(s_1,s_2,\dots,s_n)dB_{s_1}^H\,dB_{s_2}^H\cdots dB_{s_n}^H$$
$$= \int_0^t \left(\int_{0\le s_1<s_2<\cdots\le s_n} f(s_1,s_2,\dots,s_{n-1},s_n)dB_{s_1}^H\,dB_{s_2}^H\cdots dB_{s_{n-1}}^H\right) dB_{s_n}^H. \tag{6.6}$$

THEOREM 6.7. *If $f\in L_\phi^2(\mathbb{R}_+^n)$, then the iterated integral* (6.6) *exists and*

$$I_n(f) = n!\int_{0\le s_1<s_2<\cdots<s_n\le t} f(s_1,s_2,\dots,s_n)dB_{s_1}^H\,dB_{s_2}^H\cdots dB_{s_n}^H. \tag{6.7}$$

Proof. First let f have the special form $f=g^{\otimes n}$, that is, $f(s_1,s_2,\dots,s_n) = g(s_1)g_2(s_2)\cdots g(s_n)$. Then

$$I_n(f) = H_n^{\phi,g}(t),$$

and

$$\begin{aligned} dI_n(f) &= dH_n^{\phi,g}(t)\\ &= nH_{n-1}^{\phi,g}(t)g(t)dB_t^H\\ &= nI_{n-1}(g^{\otimes(n-1)})g(t)dB_t^H. \end{aligned}$$

This verifies (6.7) for the case where $f = g^{\otimes n}$. By the polarization technique [21], the theorem follows easily. □

REMARK 2. *For Brownian motion, a multiple integral was originally introduced by Wiener* [24]*; Wiener's original multiple integral is in fact a multiple integral of Stratonovich type. The multiple integral of Itô type was introduced in* [16].

For Brownian motion, the multiple Stratonovich integrals also have been widely used in the applications. Since the work of [9] and [10], it is known that the definition of multiple Stratonovich integrals is related to the definition of "trace." There has been much work on this topic. The reader is referred to [13] and the references therein.

A class of *traces* and *multiple Stratonovich integrals* are defined, and the Hu–Meyer formula is extended to the fractional Brownian motions.

As in [11], introduce the *ϕ-trace* Tr_ϕ for simple functions. This new type of trace extends the classical one and plays an important role in this section.

Let $f_1, f_2, \dots, f_m \in L^2_\phi(\mathbb{R}_+)$. Consider the simple functions in $L^2_\phi(\mathbb{R}^n_+)$ of the following form:

$$f(t_1, t_2, \dots, t_n) = \sum_{1 \le i_1, i_2, \dots, i_n \le m} a_{i_1, i_2, \dots, i_n} f_{i_1}(t_1) f_{i_2}(t_2) \cdots f_{i_n}(t_n). \tag{6.8}$$

If f is given by (6.8), then for $k \in \{1, 2, \dots, [\frac{n}{2}]\}$, define

$$\mathrm{Tr}^k_\phi f(t_1, \dots, t_{n-2k}) = \int_0^\infty \cdots \int_0^\infty f(s_1, s_2, \dots, s_{2k-1}, s_{2k}, t_1, \dots, t_{n-2k}) \phi(s_1, s_2)\phi(s_3, s_4) \cdots \phi(s_{2k-1}, s_{2k}) ds_1 \cdots ds_{2k}.$$

To define the trace for general functions, as in [11], let $\gamma_\varepsilon(s, t)$ be an approximation of the Dirac function, that is,

$$\lim_{\varepsilon \to 0} \int \gamma_\varepsilon(s, t) f(s) ds = f(t)$$

in some sense. Assume that

$$\int_0^\infty \int_0^\infty \gamma_\varepsilon(s, t)^2 ds\, dt < \infty.$$

For any function $f \in L^2_\phi(\mathbb{R}^n_+)$, the approximation

$$f^\varepsilon(t_1, t_2, \dots, t_n) = \int_0^\infty \cdots \int_0^\infty f(s_1, s_2, \dots, s_n) \gamma_\varepsilon(s_1, t_1) \gamma_\varepsilon(s_2, t_2) \cdots \gamma_\varepsilon(s_n, t_n) ds_1\, ds_2 \cdots ds_n,$$

is a simple function of type (6.8), and if f is symmetric, then f^ε is also symmetric. Let

$$\rho_\varepsilon(s, t) = \int_0^\infty \gamma_\varepsilon(s, u) \gamma_\varepsilon(t, u) du.$$

According to the definition of f^ε,

$$\mathrm{Tr}^k_\phi f^\varepsilon(t_1, \dots, t_{n-2k}) = \int_0^\infty \cdots \int_0^\infty f(s_1, s_2, \dots, s_n) \rho(s_1, s_2) \cdots \rho(s_{2k-1}, s_{2k}) \gamma_\varepsilon(s_{2k+1}, t_1) \cdots \gamma_\varepsilon(s_n, t_{n-2k}) ds_1\, ds_2 \cdots ds_n.$$

DEFINITION 6.8. *Let $f \in L^2_\phi(\mathbb{R}^n_+)$. The kth trace of f is said to exist if $\mathrm{Tr}^k_\phi f^\varepsilon(t_1,\dots,t_{n-2k})$ converges to a function in $L^2_\phi(\mathbb{R}^{n-2k}_+)$ as $\varepsilon \to 0$. The limiting function is called the kth trace of f, that is,*

$$\mathrm{Tr}^k_\phi f(t_1,\dots,t_{n-2k}) = \lim_{\varepsilon\to 0} \mathrm{Tr}^k_\phi f^\varepsilon(t_1,\dots,t_{n-2k}).$$

Now introduce the multiple Stratonovich integrals for fractional Brownian motions. Define $(B^H_t)^\varepsilon = \int_0^\infty \gamma_\varepsilon(t,s)dB^H_s$. Then $(B^H_t)^\varepsilon$ is differentiable. Let $f \in L^2_\phi(\mathbb{R}^n_+)$. Consider

$$S^\varepsilon_n(f) := \int_{\mathbb{R}^n_+} f(s_1,s_2,\dots,s_n)(\dot B^H_{s_1})^\varepsilon(\dot B^H_{s_2})^\varepsilon\cdots(\dot B^H_{s_n})^\varepsilon ds_1\,ds_2\cdots ds_n.$$

DEFINITION 6.9. *If $S^\varepsilon_n(f)$ converges in $L^2(\Omega,\mathcal{F},P)$ as $\varepsilon\to 0$, then the multiple Stratonovich integral is said to exist and is denoted by*

$$S_n(f) = \int_{\mathbb{R}^n_+} f(s_1,s_2,\dots,s_n)\delta B^H_{s_1}\delta B^H_{s_2}\cdots\delta B^H_{s_n}.$$

The remaining part of this section is devoted to giving conditions such that $S^\varepsilon_n(f)$ is convergent in $L^2(\Omega,\mathcal{F},P)$ as $\varepsilon\to 0$.

By the identity $x^n = \sum_{k\le[\frac{n}{2}]} \frac{n!}{2^k k!(n-2k)!} H_{n-2k}(x)$, it follows that

$$\begin{aligned}
\left(\int_0^\infty f_s dB^H_s\right)^n &= |f|^n_\phi \left(\frac{\int_0^\infty f_s\,dB^H_s}{|f|_\phi}\right)^n \\
&= |f|^n_\phi \sum_{k\le[\frac{n}{2}]} \frac{n!}{2^k k!(n-2k)!} H_{n-2k}\left(\frac{\int_0^\infty f_s\,dB^H_s}{|f|_\phi}\right) \\
&= \sum_{k\le[\frac{n}{2}]} \frac{n!}{2^k k!(n-2k)!} |f|^n_\phi \left(\frac{\int_0^\infty f_s\,dB^H_s}{|f|_\phi}\right)^{\diamond(n-2k)} \\
&= \sum_{k\le[\frac{n}{2}]} \frac{n!}{2^k k!(n-2k)!} |f|^{2k}_\phi \left(\int_0^\infty f_s\,dB^H_s\right)^{\diamond(n-2k)} \\
&= \sum_{k\le[\frac{n}{2}]} \frac{n!}{2^k k!(n-2k)!} |f|^{2k}_\phi I_{n-2k}(f^{\otimes(n-2k)}) \\
&= \sum_{k\le[\frac{n}{2}]} \frac{n!}{2^k k!(n-2k)!} I_{n-2k}\left(\mathrm{Tr}^k_\phi(f^{\otimes n})\right),
\end{aligned}$$

where $f^{\otimes n}$ is the symmetric tensor product of f, that is, $f^{\otimes n}(s_1,s_2,\dots,s_n) = f(s_1)f(s_2)\cdots f(s_n)$.

Let $f_1,f_2,\dots,f_n \in L^2_\phi(\mathbb{R}_+)$, and let f be the symmetrization of $f_1f_2\cdots f_n$. Then by a polarization technique,

$$\int_0^\infty f_1(s)dB^H_s\int_0^\infty f_2(s)dB^H_s\cdots\int_0^\infty f_n(s)dB^H_s = \sum_{k\le[\frac{n}{2}]} \frac{n!}{2^k k!(n-2k)!} I_{n-2k}\left(\mathrm{Tr}^k_\phi(f)\right).$$

Using this formula, it follows that

$$S_n^\varepsilon(f) = \sum_{k\le[\frac{n}{2}]} \frac{n!}{2^k k!(n-2k)!} \int_{\mathbb{R}_+^n} f(s_1,s_2,\dots,s_n)\rho_\varepsilon(s_1,s_2)\rho_\varepsilon(s_3,s_4)\cdots\rho_\varepsilon(s_{2k-1},s_{2k})$$
$$\gamma_\varepsilon(s_{2k+1},t_1)\cdots\gamma_\varepsilon(s_n,t_{n-2k})ds_1\cdots ds_n\, dB_{t_1}^H\cdots dB_{t_{n-2k}}^H.$$

It is easy to verify the following result.

THEOREM 6.10. *Let $f \in L_\phi^2(\mathbb{R}_+^n)$ be such that all of the traces exist in the following sense: For $1 \le k \le [\frac{n}{2}]$,*

$$\int_{\mathbb{R}_+^n} f(s_1,s_2,\dots,s_n)\rho_\varepsilon(s_1,s_2)\rho_\varepsilon(s_3,s_4)\cdots\rho_\varepsilon(s_{2k-1},s_{2k})\gamma_\varepsilon(s_{2k+1},t_1)$$
$$\cdots\gamma_\varepsilon(s_n,t_{n-2k})ds_1\cdots ds_n \tag{6.9}$$

converges to a function $\operatorname{Tr}_\phi^k f$ in $L_\phi^2(\mathbb{R}_+^{n-2k})$ as $\varepsilon\to 0$. Then the sequence $(S_n^\varepsilon(f), n\in\mathbb{N})$ converges in $L^2(\Omega,\mathcal{F},P)$, and the limit is given by the extended Hu-Meyer formula

$$S_n(f) = \sum_{k\le[\frac{n}{2}]} \frac{n!}{2^k k!(n-2k)!} I_{n-2k}(\operatorname{Tr}_\phi^k f). \tag{6.10}$$

REMARK 3. *It should be noted that the analogue of this theorem and in particular the formula* (6.10) *has been discussed extensively for the Brownian motion.*

As a consequence of Theorem 6.10, (6.10), a chaos expansion theorem is described. It is well known that the family of all polynomials in the random variables $B_{t_1}^H,\dots,B_{t_k}^H$, for $0\le t_1<\cdots<t_k$ and $k\in\mathbb{N}$, is dense in $L^2(\Omega,\mathcal{F},P)$. Since each of these polynomials is a finite sum of the monomials of the form $\int_0^\infty f_1(s_1)\delta B_{s_1}^H\cdots\int_0^\infty f_n(s_n)\delta B_{s_n}^H$, where $f_1,\dots,f_n\in L_\phi^2$, this product of integrals of Wiener type can be expressed as a multiple Stratonovich integral: $\int_0^\infty\cdots\int_0^\infty (f_1\otimes\cdots\otimes f_n)(s_1,\cdots,s_n)\times\delta B_{s_1}^H\cdots\delta B_{s_n}^H$. By the equality (6.10), this multiple integral of Stratonovich type can be expressed as a finite, linear combination of multiple integrals of Itô type. Thus the family of all linear combinations of multiple integrals of the form $\int_0^\infty\cdots\int_0^\infty (f_1\otimes\cdots\otimes f_n)(s_1,\dots,s_n)dB_{s_1}^H\cdots dB_{s_n}^H$ is dense in $L^2(\Omega,\mathcal{F},P)$. Thus

$$L^2(\Omega,\mathcal{F},P) = \Big\{F : F = F_0 + \sum_{n=1}^\infty \int_0^\infty\cdots\int_0^\infty f_n(s_1,\dots,s_n)dB_{s_1}^H\cdots dB_{s_n}^H,$$
$$F_0\in\mathbb{R}, f_n\in L^2(\mathbb{R}_+^n) \text{ and } \sum_{n=1}^\infty |f_n|_\phi^2<\infty\Big\}. \tag{6.11}$$

The equality (6.11) is described in the following theorem.

THEOREM 6.11. *If $F\in L^2(\Omega,\mathcal{F},P)$, then there is a sequence $(f_n\in L_\phi^2(\mathbb{R}_+^n), n\in\mathbb{N})$ such that $\sum_{n=1}^\infty |f_n|_\phi^2<\infty$ and*

$$F = \mathbb{E}(F) + \sum_{n=1}^\infty \int_{\mathbb{R}_+^n} f_n(s_1,\dots,s_n)dB_{s_1}^H\cdots dB_{s_n}^H. \tag{6.12}$$

REMARK 4. *The expansion* (6.12) *is an analogue of the Itô–Wiener chaos expansion which is extended to fractional Brownian motion. Replacing the multiple integrals by the iterated multiple integrals and summing the infinite series gives a stochastic integral representation for $F-\mathbb{E}F$. Note that the terms on the right-hand side of* (6.12) *are orthogonal.*

Acknowledgments. An earlier version of this paper was given to G. Kallianpur and he subsequently provided us with the preprint [3], where the multiple integrals of Stratonovich type are defined and their first and second moments are computed. After the submission of this paper, the authors became aware of [5], where some related work on fractional Brownian motion is done.

NONSMOOTH DUALITY, SANDWICH, AND SQUEEZE THEOREMS*

A. S. LEWIS† AND R. E. LUCCHETTI‡

Abstract. Given a nonlinear function h separating a convex and a concave function, we provide various conditions under which there exists an affine separating function whose graph is somewhere almost parallel to the graph of h. Such results blend Fenchel duality with a variational principle and are closely related to the Clarke–Ledyaev mean value inequality.

Key words. sandwich theorem, squeeze theorem, Fenchel duality, variational principle, mean value inequality, Clarke subdifferential

AMS subject classifications. 49J52, 90C46, 26D07

PII. S0363012998334213

1. Introduction. The central theorems in this paper blend two completely distinct types of result, both fundamental in optimization theory: Fenchel duality and variational principles. The simplest version of Fenchel duality states that for any convex functions f and g on $\mathbf{R}^n$ satisfying $f \geq -g$, a regularity condition implies the set

$$L \stackrel{\text{def}}{=} \{y \in \mathbf{R}^n : f^*(y) + g^*(-y) \leq 0\}$$

is nonempty (where f^* is the Fenchel conjugate of f). Geometrically, this means there exists an affine function sandwiched between f and $-g$. On the other hand, one of the easiest examples of a variational principle states that if h is a locally Lipschitz function bounded below on $\mathbf{R}^n$, then h has arbitrarily small Clarke subgradients:

$$0 \in \mathrm{cl}\,(\mathrm{Im}\ \partial h).$$

Geometrically, there are points where the graph of h is almost horizontal (in a certain nonsmooth sense).

The theorems we discuss here combine the features of both results above. We consider functions f, g, and h as before, now satisfying $f \geq h \geq -g$, and under various regularity conditions we prove

$$L \cap \mathrm{cl}\,(\mathrm{Im}\ \partial h) \neq \emptyset.$$

Geometrically, there are affine functions between f and $-g$ whose graphs are somewhere almost parallel to the graph of h.

As we show by means of various examples, the existence of a suitable affine separating function depends on both local and asymptotic properties of the three functions. Hence the regularity conditions we need to impose combine assumptions on the domains of the primal functions, f and g, and of their conjugates, f^* and g^*, as well as local and global growth conditions on h.

The key tool for our results is a recent, somewhat surprising mean value inequality of Clarke–Ledyaev [3], rephrased as a hybrid sandwich theorem in [6]. We illustrate the application of this type of result with two apparently simple but rather remarkable consequences. First, any convex function f and locally Lipschitz function $h \leq f$ satisfy

$$\operatorname{dom} f^* \cap \operatorname{cl}(\operatorname{Im} \partial h) \neq \emptyset.$$

Second (a "squeeze theorem"), any locally Lipschitz functions $p \geq h \geq q$ with $p(0) = h(0) = q(0)$ satisfy

$$\partial p(0) \cap \partial h(0) \cap \partial q(0) \neq \emptyset.$$

We have not been able to find simple proofs or references for either of these two results.[1]

With the exception of this last squeeze theorem, our results do not appear to be substantially easier with the assumption that h is smooth (in which case ∂h reduces to the singleton ∇h). We believe they provide further evidence of the depth, applicability, and fundamental nature of the Clarke–Ledyaev inequality in optimization theory.

2. Notation and preliminary results. We begin by reviewing some basic ideas from convex analysis (see [7]). Given a convex set $A \subset \mathbf{R}^n$, we denote by $\operatorname{aff} A$ the smallest affine space containing A and by $\operatorname{ri} A$ the set of the internal points of $A \subset \operatorname{aff} A$ (with the induced topology). Observe that $\operatorname{ri} A$ is a nonempty convex set. Given a function $f : \mathbf{R}^n \to [-\infty, \infty]$, we denote its *effective domain* by

$$\operatorname{dom} f \stackrel{\text{def}}{=} \{x \in \mathbf{R}^n : f(x) < \infty\}$$

and by $\operatorname{epi} f$ its epigraph, the set

$$\operatorname{epi} f \stackrel{\text{def}}{=} \{(x, r) \in \mathbf{R}^n \times \mathbf{R} : r \geq f(x)\},$$

a convex set if and only if f is convex. The hypograph of the function $-g$ is instead

$$\operatorname{hyp}(-g) \stackrel{\text{def}}{=} \{(x, r) \in \mathbf{R}^n \times \mathbf{R} : r \leq -g(x)\},$$

again a convex set if and only if g is convex. The epigraph of f is closed if and only if f is lower semicontinuous in the usual sense.

We shall write $f \in \Gamma_0$ to mean that $\operatorname{epi} f$ is nonempty, closed, and convex and does not contain vertical lines.

For a set A, let I_A be the indicator function of the set A,

$$I_A(x) = \begin{cases} 0 & \text{if } x \in A, \\ \infty & \text{otherwise.} \end{cases}$$

In particular, I_{kB} denotes the indicator function of the ball centered at $0 \in \mathbf{R}^n$ and with radius k.

[1] Subsequent investigations revealed alternative approaches to the last theorem independent of the Clarke–Ledyaev result [1]. Nonetheless, the original approach we present here remains attractive for its transparency.

The *Fenchel conjugate* of a function $f : \mathbf{R}^n \to [-\infty, \infty]$ is the function $f^* : \mathbf{R}^n \to [-\infty, \infty]$ defined by

$$f^*(y) \stackrel{\text{def}}{=} \sup_{x \in \mathbf{R}^n} \{\langle y, x\rangle - f(x)\},$$

a convex lower semicontinuous function (even if f is not) which belongs to Γ_0 if f does. Furthermore, $f = f^{**}$, providing $f \in \Gamma_0$.

The function f is said to be *cofinite* if its conjugate f^* satisfies dom $f^* = \mathbf{R}^n$. It is easy to see this is equivalent to saying that $\lim_{\|x\| \to \infty} \frac{f(x)}{\|x\|} = \infty$ [5, Chapter 10, Proposition 1.3.8].

The *subdifferential* of a convex function f at a point $x \in$ dom f is the closed convex set

$$\partial f(x) \stackrel{\text{def}}{=} \{y \in \mathbf{R}^n : f(z) \geq f(x) + \langle y, z - x\rangle \text{ for all } z \in \mathbf{R}^n\}.$$

The fundamental connection between the subdifferentials of a function and of its Fenchel conjugate is shown by the following *Fenchel identity*:

$$y \in \partial f(x) \Longleftrightarrow f(x) + f^*(y) = \langle y, x\rangle.$$

It follows, in particular, that $y \in \partial f(x)$ if and only if $x \in \partial f^*(y)$, providing $f \in \Gamma_0$.

Given two functions $p, q : \mathbf{R}^n \to [-\infty, \infty]$, we define the *infimal convolution* between them by

$$(p \square q)(x) = \inf_{y \in \mathbf{R}^n} \{p(y) + q(x - y)\},$$

a convex function if p and q are, possibly assuming the value $-\infty$, and that may fail to be lower semicontinuous. Finally, for a function $p \in \Gamma_0$, we denote by

$$p_k \stackrel{\text{def}}{=} p \square k\|\cdot\|,$$

the infimal convolution between p and $k\|\cdot\|$: this function is the largest k-Lipschitz function minorizing p. For more about convex functions, the interested reader is invited to consult [4], [5], [7].

Next we briefly consider the subdifferential of a locally Lipschitz function $h : U \to \mathbf{R}$, where U is an open subset of $\mathbf{R}^n$. This notion is not uniquely defined in the literature, and here we make the choice of the *Clarke subdifferential* (see [2]) which is more suited for our scopes, as an example in the final section will show. To define it, first let us introduce the notion of *generalized directional derivative* of h at the point x in the direction v:

$$h^\circ(x, v) \stackrel{\text{def}}{=} \limsup_{\substack{z \to x \\ t \searrow 0}} \frac{h(z + tv) - h(z)}{t}.$$

The function $v \mapsto h^\circ(x, v)$ is everywhere finite, subadditive, and positively homogeneous; hence, in particular, it is continuous and convex. Then the *subdifferential* of h at x is defined as

$$\partial h(x) \stackrel{\text{def}}{=} \{y \in \mathbf{R}^n : \langle y, v\rangle \leq h^\circ(x, v) \text{ for all } v \in \mathbf{R}^n\},$$

a nonempty closed convex set. Moreover, if k is a Lipschitz constant for h, the subdifferential is norm-bounded by k. In particular, the multifunction ∂h is bounded on

bounded sets. Observe that the Clarke subdifferential of h at x is the same set as the (convex) subdifferential of the function $v \mapsto h^\circ(x, v)$ at $v = 0$, a simple but useful property we shall use throughout this paper.

For more about nonsmooth analysis for locally Lipschitz functions, the interested reader is invited to consult [2].

In this paper we shall deal with two convex functions $f, g \in \Gamma_0$ and a locally Lipschitz function h such that $f \geq h \geq -g$. For a moment, let us focus on the problem of nonemptyness of the set

$$L \stackrel{\text{def}}{=} \{y \in \mathbf{R}^n : f^*(y) + g^*(-y) \leq 0\}.$$

This set can be characterized in a more geometric way, as the following easy proposition states.

PROPOSITION 2.1. *Let $f, g \in \Gamma_0$. Then, for $y \in \mathbf{R}^n$,*

$$f^*(y) + g^*(-y) \leq 0$$

if and only if there exists $a \in \mathbf{R}$ such that

$$f(x) \geq a + \langle y, x \rangle \geq -g(x) \quad \text{for all } x \in \mathbf{R}^n.$$

Thus the problem of nonemptyness of L is equivalent to finding an affine separator lying below f and above g. This can be stated in terms of a separation problem for the sets $\operatorname{epi} f$ and $\operatorname{hyp}(-g)$. The assumption $f \geq -g$ ensures that

$$\operatorname{ri} \operatorname{epi} f \cap \operatorname{ri} \operatorname{hyp}(-g) = \emptyset,$$

(see [4, Chapter 4, Proposition 1.1.9]) and this in turn implies that $\operatorname{epi} f$ and $\operatorname{hyp}(-g)$ can be separated by a hyperplane [4, Chapter 3, Theorem 4.1.4]. However, it can happen that the only separating hyperplane is vertical, which unfortunately says nothing about nonemptyness of L.

The first result stating that L is nonempty is the following well-known Fenchel duality theorem [7, Theorem 31.1], which in our setting can be rephrased in the following way.

THEOREM 2.1. *Let $f, g \in \Gamma_0$ be such that $f \geq -g$ and suppose*

$$\operatorname{ri}(\operatorname{dom} f) \cap \operatorname{ri}(\operatorname{dom} g) \neq \emptyset.$$

Then there exists $y \in \mathbf{R}^n$ such that

$$f^*(y) + g^*(-y) \leq 0.$$

We illustrate the role of the assumption on the domains of f and g with the help of the following four examples, where the set L is always empty.

EXAMPLE 2.1.

$$f(x) = \begin{cases} -\sqrt{x} & \text{if } x \geq 0, \\ \infty & \text{otherwise,} \end{cases}$$

$$g(x) = \begin{cases} 0 & \text{if } x = 0, \\ \infty & \text{otherwise.} \end{cases}$$

Here $\operatorname{ri}(\operatorname{dom} f) \cap \operatorname{ri}(\operatorname{dom} g) = \emptyset$.

EXAMPLE 2.2.

$$f(u,v) = \begin{cases} -1 & \text{if } uv \geq 1, u \geq 0, \\ \infty & \text{otherwise,} \end{cases}$$

$$g(u,v) = \begin{cases} 0 & \text{if } u \geq 0, v = 0, \\ \infty & \text{otherwise.} \end{cases}$$

Here we have $\operatorname{dom} f \cap \operatorname{dom} g = \emptyset$.

EXAMPLE 2.3.

$$f(u,v) = \begin{cases} u & \text{if } v = -1, \\ \infty & \text{otherwise,} \end{cases}$$

$$g(u,v) = \begin{cases} 0 & \text{if } v = 0, \\ \infty & \text{otherwise.} \end{cases}$$

Here the distance between $\operatorname{dom} f$ *and* $\operatorname{dom} g$ *is* 1.

In the last two examples the domains of f and g do not intersect, while in the first example a crucial role is played by the fact that $\inf(f+g) = 0$. In the following example $\inf(f+g) > 0$, and yet there is no affine separator. Observe that such an example could not be provided in one dimension [4, Chapter 1, Remark 3.3.4].

EXAMPLE 2.4.

$$f(u,v) = \begin{cases} 1 - 2\sqrt{uv} & \text{if } u, v \geq 0, \\ \infty & \text{otherwise,} \end{cases}$$

$$g(u,v) = \begin{cases} 1 - 2\sqrt{-uv} & \text{if } u \leq 0, v \geq 0, \\ \infty & \text{otherwise.} \end{cases}$$

A straightforward calculation shows

$$f^*(u^*,v^*) = \begin{cases} -1 & \text{if } u^* \leq 0, u^*v^* \geq 1, \\ \infty & \text{otherwise,} \end{cases}$$

$$g^*(u^*,v^*) = \begin{cases} -1 & \text{if } u^* \geq 0, u^*v^* \leq -1, \\ \infty & \text{otherwise.} \end{cases}$$

Thus the set L is empty.

3. Sandwich theorems. We turn now to the case of three functions f, g, and h, such that f and g are convex, h is locally or globally Lipschitz, and $f \geq h \geq -g$. Examples 2.2, 2.3, and 2.4 show that the existence of a locally Lipschitz function h between f and $-g$ (take $h(x,y) = -xy$ in all cases) does not change the situation: there is no affine separator.

First let us recall now some known results.

THEOREM 3.1 (see [6, Theorem 2]). *Let C be a nonempty convex compact set in $\mathbf{R}^n$. Let $f, g \in \Gamma_0$ and with domains contained in C. Let $h : \mathbf{R}^n \to \mathbf{R}$ be Lipschitz on a neighborhood of C. Suppose moreover $f \geq h \geq -g$ on C.*

Then there exist $c \in C$ and $y \in \partial h(c)$ such that

$$f^*(y) + g^*(-y) \leq 0.$$

Boundedness of C can be relaxed at the expense of requiring more about the functions f and g and/or about the function h. Specifically, we have the following two results.

THEOREM 3.2 (see [6, Theorem 7]). *Let C be a nonempty closed convex set in $\mathbf{R}^n$. Let $f, g \in \Gamma_0$ be cofinite, with domains contained in C. Moreover suppose*

$$\operatorname{int}(\operatorname{dom} f) \cap \operatorname{int}(\operatorname{dom} g) \neq \emptyset.$$

Let $h : \mathbf{R}^n \to \mathbf{R}$ be locally Lipschitz on a neighborhood of C and suppose $f \geq h \geq -g$ on C.

Then there exist $c \in C$ and $y \in \partial h(c)$ such that

$$f^*(y) + g^*(-y) \leq 0.$$

THEOREM 3.3 (see [6, Theorem 8]). *Let C be a nonempty closed convex set in $\mathbf{R}^n$. Let $f, g \in \Gamma_0$ be cofinite, with domains contained in C. Let $h : \mathbf{R}^n \to \mathbf{R}$ be globally Lipschitz on a neighborhood of C and suppose $f \geq h \geq -g$ on C.*

Then there exist $c \in C$ and $y \in \partial h(c)$ such that

$$f^*(y) + g^*(-y) \leq 0.$$

Observe one does not need a qualification condition on the domains of f and g if h is globally Lipschitz. In the last two theorems, however, cofiniteness is required, which can be regarded as a (strong) qualification condition on the domains of the conjugates.

The first result we want to prove deals simply with the existence of the affine separator. To prove it, we need the following proposition about regularizing Fenchel problems.

PROPOSITION 3.1. *Suppose $p, q \in \Gamma_0$ and*

$$(\bullet) \qquad \operatorname{ri}(\operatorname{dom} p) \cap \operatorname{ri}(\operatorname{dom} q) \neq \emptyset.$$

Then, for all large k, we have

$$\inf(p+q) = \inf(p_k + q_k)$$

and

$$\operatorname{argmin}(p+q) = \operatorname{argmin}(p_k + q_k).$$

Proof. To prove the first equality, we need to prove only $\inf(p+q) \leq \inf(p_k + q_k)$. There is nothing to prove if $\inf(p+q) = -\infty$. Therefore, let us assume it is finite. (It cannot be ∞ because of $(\bullet)$.) By Fenchel duality, there is $y \in \mathbf{R}^n$ such that

$$-\inf(p+q) = p^*(y) + q^*(-y).$$

Take $k > \|y\|$. Then

$$-\inf(p+q) = p^*(y) + q^*(-y) = (p^* + I_{kB})(y) + (q^* + I_{kB})(-y)$$

$$= (p_k)^*(y) + (q_k)^*(-y) \geq \inf_{z \in \mathbf{R}^n}((p_k)^*(z) + (q_k)^*(-z))$$

$$= -\inf(p_k + q_k) \geq -\inf(p+q).$$

This shows the first equality and also that y as above is optimal for the problem of minimizing, on $\mathbf{R}^n$, $(p_k)^*(\cdot) + (q_k)^*(-\cdot)$.

Now, writing down optimality conditions, we obtain, using $k > \|y\|$,

$$\begin{aligned} x \in \operatorname{argmin}(p+q) &\Leftrightarrow p(x) + q(x) = -p^*(y) - q^*(-y), \\ &\Leftrightarrow x \in \partial p^*(y) \cap \partial q^*(-y), \\ &\Leftrightarrow x \in \partial(p^* + I_{kB})(y) \cap \partial(q^* + I_{kB})(-y), \\ &\Leftrightarrow x \in \partial(p_k)^*(y) \cap \partial(q_k)^*(-y), \\ &\Leftrightarrow x \in \operatorname{argmin}(p_k + q_k). \qquad \square \end{aligned}$$

We begin our sequence of main results by proving some variants of Fenchel duality, where the usual regularity condition is replaced by the existence of a Lipschitz separator.

THEOREM 3.4. *For $f, g \in \Gamma_0$, suppose*

$$\operatorname{ri}(\operatorname{dom} f^*) \cap \operatorname{ri}(-\operatorname{dom} g^*) \neq \emptyset.$$

Suppose further there exists a locally Lipschitz function h such that $f \geq h \geq -g$. Then there is $y \in \mathbf{R}^n$ such that

$$f^*(y) + g^*(-y) \leq 0.$$

(Moreover, if $\inf(f+g) = 0$, then such a y can be found in the range of ∂h.)

Proof. From Proposition 3.1, applied to $p = f^*$ and $q(\cdot) = g^*(-\cdot)$, we have

$$\inf((f^*)_k(\cdot) + (g^*)_k(-\cdot)) = \inf(f^*(\cdot) + g^*(-\cdot))$$

and

$$\operatorname{argmin}((f^*)_k(\cdot) + (g^*)_k(-\cdot)) = \operatorname{argmin}(f^*(\cdot) + g^*(-\cdot))$$

for all large k. Apply Theorem 3.1 to the functions $f + I_{kB}$, h, and $g + I_{kB}$, for large k, and the set $C = kB$, to find $y_k \in \operatorname{Im} \partial h$ such that

$$(f^*)_k(y_k) + (g^*)_k(-y_k) \leq 0.$$

If

$$y_k \in \operatorname{argmin}((f^*)_k(\cdot) + (g^*)_k(-\cdot))$$

(as in the case when $\inf(f+g) = 0$), then we deduce $f^*(y_k) + g^*(-y_k) \leq 0$ and we conclude. Otherwise, for all large k,

$$0 > \inf((f^*)_k(\cdot) + (g^*)_k(-\cdot)) = \inf(f^*(\cdot) + g^*(-\cdot)).$$

Thus there is $y \in \mathbf{R}^n$ such that $f^*(y) + g^*(-y) \leq 0$, as required. □

We provided here the result when $\inf(f+g) = 0$ for the sake of completeness. However observe that under the assumptions of Theorem 3.4 $\inf f + g$ is attained. In this circumstance the squeeze theorem in the next section will provide a more precise result.

With respect to the role of the assumptions in Theorem 3.4, Example 2.1 shows the set L can be empty if we do not assume the existence of a locally Lipschitz function sandwiched between f and $-g$, while Example 2.2 shows the necessity of the qualification condition

$$\text{ri}\,(\text{dom } f^*) \cap \text{ri}\,(-\text{dom } g^*) \neq \emptyset.$$

We turn now to the problem of providing conditions under which the slope of an affine separator can be found in the closure of the range of the Clarke subdifferential of the separating function h. To do this, we prove first the following proposition.

PROPOSITION 3.2. *Suppose $f, g \in \Gamma_0$ satisfy $f \geq -g$. For $k = 1, 2, \ldots$, define*

$$L_k \stackrel{\text{def}}{=} \{y \in \mathbf{R}^n : (f^*)_k(y) + (g^*)_k(-y) \leq 0\}$$

and

$$L \stackrel{\text{def}}{=} \{y \in \mathbf{R}^n : f^*(y) + g^*(-y) \leq 0\}.$$

Then L_k is a decreasing collection of closed convex sets containing L, and

$$y_k \in L_k, \quad y_k \to y \quad \textit{implies} \quad y \in L.$$

If moreover the condition

$$0 \in \text{int}\,(\text{dom } f - \text{dom } g)$$

holds, then the sets L_k for large k are all contained in a compact set.

Proof. Since $(f^*)_k \leq (f^*)_{k+1} \leq f^*$, clearly $L \subset L_{k+1} \subset L_k$, for all $k > 0$. Let us prove that, if y_k is such that $y_k \to y$ and

$$(f^*)_k(y_k) + (g^*)_k(-y_k) \leq 0 \quad \text{for all } k,$$

then

$$f^*(y) + g^*(-y) \leq 0.$$

From Proposition 2.1 there exists $a_k \in \mathbf{R}$ such that

$$f(x) \geq a_k + \langle y_k, x\rangle \geq -g(x) \quad \text{for all } x \in kB.$$

It is easy to show the sequence $\{a_k\}$ is bounded, so it has some cluster $a \in \mathbf{R}$. (Use the boundedness of $\{y_k\}$ and the existence of an element $x \in \text{dom } f \cap \text{dom } g$.) It follows that

$$f(x) \geq a + \langle y, x\rangle \geq -g(x) \quad \text{for all } x \in \mathbf{R}^n,$$

so $y \in L$. We have proved the first part of the claim. Now define a function

$$v(w) = \inf_{x \in \mathbf{R}^n} (f(x+w) + g(x))$$

and a sequence of functions decreasing pointwise to v,

$$v^k(w) = \inf_{x\in\mathbf{R}^n}((f + I_{kB})(x + w) + (g + I_{kB})(x)).$$

Observe that $(v^k)^*(y) = (f^*)_k(y) + (g^*)_k(-y)$ and $v^*(y) = f^*(y) + g^*(-y)$ and that $\operatorname{dom} v = \operatorname{dom} f - \operatorname{dom} g$, so that $0 \in \operatorname{int}(\operatorname{dom} v)$.

Since v is continuous at 0, there exist reals $r > 0$ and α and a cube C such that $rB \subset C \subset \operatorname{int}(\operatorname{dom} v)$ and $v \le \alpha - 1$ on C. Hence, for large k we have $v^k \le \alpha$ on each vertex of C and hence on rB, so $(v^k)^*(w) \ge r\|w\| - \alpha$ for all points w in $\mathbf{R}^n$, and therefore $L_k \subset (\alpha/r)B$. □

We are now ready for a new result.

THEOREM 3.5. *For $f, g \in \Gamma_0$, and locally Lipschitz $h : \mathbf{R}^n \to \mathbf{R}$ satisfying $f \ge h \ge -g$, suppose*

$$0 \in \operatorname{int}(\operatorname{dom} f - \operatorname{dom} g).$$

Then

$$\exists y \in \operatorname{cl}(\operatorname{Im} \partial h) : f^*(y) + g^*(-y) \le 0.$$

Proof. Apply Theorem 3.1 to the functions $f + I_{kB} \ge h \ge -(g + I_{kB})$, for large k. Then there exists

$$y_k \in \operatorname{Im}(\partial h) : (f^*)_k(y_k) + (g^*)_k(-y_k) \le 0.$$

By Proposition 3.2 the sequence (y_k) clusters and any cluster point satisfies the required property. □

We intend now to prove that the constraint qualification in Theorem 3.5 can be replaced by an assumption involving the growth of f and h at infinity. To do this, we need the following proposition.

PROPOSITION 3.3. *For $f \in \Gamma_0$ and locally Lipschitz h satisfying $f \ge h$, suppose*

$$\liminf_{\|x\|\to\infty} \frac{f(x)}{\|x\|} > \max\left\{\limsup_{\|x\|\to\infty} \frac{h(x)}{\|x\|}, 0\right\}.$$

Then, for all large k, $f_k \ge h$.

Proof. Let $0 < a < b$ and c be such that

$$\frac{f(x)}{\|x\|} \ge b, \quad \frac{h(x)}{\|x\|} \le a,$$

for all x such that $\|x\| \ge c$. Then there exists $rbf \in \mathbf{R}$ such that

$$f(x) \ge r + b\|x\| \quad \text{for all } x \in \mathbf{R}^n,$$

and f has bounded level sets. For the sake of contradiction, suppose there exists, for each $k \in \mathbf{N}$, x_k such that $f_k(x_k) < h(x_k)$. Two cases can occur.

(i) (x_k) is unbounded. Taking a subsequence, we can suppose $\|x_k\| \to \infty$. For $k > b$, we have $f_k(x_k) \ge r + b\|x_k\|$. It follows that

$$a\|x_k\| \ge h(x_k) > f_k(x_k) \ge r + b\|x_k\|,$$

a contradiction.

(ii) (x_k) is bounded. Again taking a subsequence, we can suppose $x_k \to x$. Pick $m > \|x\|$ and r so that h is r-Lipschitz on mB. Since f has compact level sets, for each k there is y_k such that $h(x_k) > f_k(x_k) = f(y_k) + k\|x_k - y_k\|$. As $h(x_k) \to h(x)$, for large k one has

$$f(y_k) \leq f(y_k) + k\|x_k - y_k\| \leq h(x) + 1.$$

Thus (y_k) is bounded and, taking another subsequence, we can suppose $y_k \to y$. Since

$$k\|x_k - y_k\| \leq h(x) + 1 - \inf f \quad \text{for all } k,$$

we deduce $y = x$. Thus, for large k, $x_k, y_k \in mB$, so

$$h(x_k) \leq h(y_k) + r\|x_k - y_k\| \leq f(y_k) + k\|x_k - y_k\| < h(x_k),$$

a contradiction. □

THEOREM 3.6. *For $f, g \in \Gamma_0$ and locally Lipschitz $h : \mathbf{R}^n \to \mathbf{R}$ satisfying $f \geq h \geq -g$, suppose*

$$\liminf_{x\to\infty} \frac{f(x)}{\|x\|} > \max\left\{\limsup_{x\to\infty} \frac{h(x)}{\|x\|}, 0\right\}.$$

Then

$$\exists y \in \text{ cl}\,(\text{Im } \partial h) : f^*(y) + g^*(-y) \leq 0.$$

Proof. From Proposition 3.3, $f_k \geq h \geq -g$ for large k. Since we know $\text{dom } f_k - \text{dom } g = \mathbf{R}^n$, Theorem 3.5 implies there exists $y \in \text{cl Im } \partial h$ with

$$f^*(y) + g^*(-y) \leq (f_k)^*(y) + g^*(-y) \leq 0. \qquad \square$$

The proof of the theorem above relies on the fact that we are able to construct a function $p \in \Gamma_0$ such that $f \geq p \geq h$ and whose domain contains internal points. However, to do this is not always possible, as the following example shows.

EXAMPLE 3.1. *Let*

$$f(u, v) = \begin{cases} 0 & \text{if } v = 0, \\ \infty & \text{otherwise} \end{cases}$$

and $h(u, v) = |uv|$. Suppose the convex function p satisfies $f \geq p \geq h$. Then clearly $p(u, 0) = 0$ for all u. For any real u and v and positive integer r,

$$\begin{aligned} \frac{1}{r}p(u, v) &= \frac{1}{r}p(u, v) + \frac{r-1}{r}p(u, 0) \\ &\geq p\left(u, \frac{v}{r}\right) \\ &= p\left(u, \frac{v}{r}\right) + p(r, 0) \\ &\geq 2p\left(\frac{u+r}{2}, \frac{v}{2r}\right) \\ &\geq \left|\frac{(u+r)v}{2r}\right| \\ &\to \frac{|v|}{2} \end{aligned}$$

as $r \to \infty$. Hence $p(u,v) = +\infty$ whenever $v \neq 0$, so $p = f$.

The next result deals with the case of h being globally Lipschitz.

THEOREM 3.7. *For $f, g \in \Gamma_0$ and globally Lipschitz $h : \mathbf{R}^n \to \mathbf{R}$, suppose $f \geq h \geq -g$. Then*

$$\exists y \in \ \mathrm{cl}\,(\mathrm{Im}\ \partial h) : f^*(y) + g^*(-y) \leq 0.$$

Proof. Apply Theorem 3.3 to the functions $f + I_{kB}$, h, and $g + I_{kB}$ to obtain the existence of $y_k \in \mathrm{Im}\ \partial h$ such that

$$(f + I_{kB})^*(y_k) + (g + I_{kB})^*(-y_k) \leq 0.$$

Since h is globally Lipschitz, (y_k) has a cluster point y. Then we conclude with the help of Proposition 3.2. □

The next example shows that in general no $y \in \mathrm{Im}\ \partial h$ satisfies $f^*(y)+g^*(-y) \leq 0$.

EXAMPLE 3.2. *Let $f(x) = |x|$,*

$$g(x) = \begin{cases} 1 + x^2 & \text{if } x \geq 0, \\ \infty & \text{otherwise,} \end{cases}$$

$$h(x) = \begin{cases} x - \exp(-x) & \text{if } x \geq 0, \\ 2x - 1 & \text{otherwise.} \end{cases}$$

Then all the assumptions of Theorem 3.5 are fulfilled, and moreover h is globally Lipschitz.

We end the section by proving a unilateral result which can be regarded as a generalized variational principle.

THEOREM 3.8. *For $f \in \Gamma_0$ and locally Lipschitz $h : \mathbf{R}^n \to \mathbf{R}$, suppose $f \geq h$. Then*

$$\mathrm{cl}\,(\mathrm{Im}\,\partial h) \cap \mathrm{dom}\, f^* \neq \emptyset.$$

Proof. Choose any point $z \in \mathrm{dom}\ f$ and real $k > \|z\|$. Define $g(\cdot) = I_{kB}(\cdot) - \inf_{kB} h$ and apply Theorem 3.5. □

The special case $f = 0$ gives the well-known variational result that a locally Lipschitz function h which is bounded above satisfies $0 \in \mathrm{cl}\,(\mathrm{Im}\,\partial h)$.

4. Squeeze theorems. In this section we specialize the situation studied before. We shall make the further assumption that there is a point where the three functions are equal. In this case, as we shall see, we are able to provide more precise results.

We shall start with the following easy proposition, that we state without proof.

PROPOSITION 4.1. *For $f, g \in \Gamma_0$ satisfying $f \geq -g$, suppose there exists x such that $f(x) = -g(x)$. Then*

$$\{y : f^*(y) + g^*(-y) \leq 0\} = \partial f(x) \cap -\partial g(x).$$

We prove now a "convex" squeeze theorem.

THEOREM 4.1. *For $f, g \in \Gamma_0$ and locally Lipschitz $h : \mathbf{R}^n \to \mathbf{R}$ satisfying $f \geq h \geq -g$, suppose there exists $x \in \mathbf{R}^n$ such that $f(x) = -g(x)$. Then*

$$\partial f(x) \cap \partial h(x) \cap -\partial g(x) \neq \emptyset.$$

Proof. Without loss of generality, we can suppose $x = 0$. For each positive integer r, as $f \geq h \geq -g$ on $\frac{1}{r}B$, we can apply Theorem 3.1 to find $x_r \in \frac{1}{r}B$ and $y_r \in \partial h(x_r)$ with

$$(f + I_{\frac{1}{r}B})^*(y_r) + (g + I_{\frac{1}{r}B})^*(-y_r) \leq 0.$$

By Proposition 4.1

$$y_r \in \partial(f + I_{\frac{1}{r}B})(0) \cap -\partial(g + I_{\frac{1}{r}B})(0) = \partial f(0) \cap -\partial g(0).$$

Since ∂h is locally bounded, there exists a subsequence (y_{r_k}) of (y_r) converging to some y, and since $x_{r_k} \to 0$ and ∂h is closed, $y \in \partial h(0)$. □

The next squeeze theorem deals instead with three locally Lipschitz functions. To prove it, we need the following proposition.

PROPOSITION 4.2. *Let $f : \mathbf{R}^n \to \mathbf{R}$ be locally Lipschitz and suppose $\delta > 0$. Then*

$$f(0) + f^\circ(0, x) + \delta\|x\| > f(x)$$

for all small nonzero x.

Proof. Suppose that $f(0) = 0$, that f is k-Lipschitz near 0, and that, for the sake of contradiction, there is a sequence (x_r) such that $x_r \neq 0$ for all r and $x_r \to 0$, with

$$f^\circ(0, x_r) + \delta\|x_r\| \leq f(x_r).$$

Thus

$$f^\circ\left(0, \frac{x_r}{\|x_r\|}\right) + \delta \leq \frac{f(x_r)}{\|x_r\|}.$$

Suppose, without loss of generality, $\frac{x_r}{\|x_r\|} \to d$. Then

$$\begin{aligned}
\limsup_{r\to\infty} f^\circ\left(0, \frac{x_r}{\|x_r\|}\right) + \delta &\leq \limsup_{r\to\infty} \frac{f(x_r)}{\|x_r\|} \\
&= \limsup_{r\to\infty} \frac{f(\|x_r\|d) + f(x_r) - f(\|x_r\|d)}{\|x_r\|} \\
&\leq \limsup_{r\to\infty} \frac{f(\|x_r\|d) + k\|x_r - \|x_r\|d\|)}{\|x_r\|} \\
&\leq f^\circ(0, d).
\end{aligned}$$

It follows that

$$f^\circ(0, d) + \delta \leq f^\circ(0, d),$$

which is impossible. □

THEOREM 4.2. *Suppose $f, h, g : \mathbf{R}^n \to \mathbf{R}$ are three locally Lipschitz functions such that $f \geq h \geq g$. Moreover, suppose $f(x) = g(x)$ for some x. Then*

$$\partial f(x) \cap \partial h(x) \cap \partial g(x) \neq \emptyset.$$

Proof. Suppose, without loss of generality, $f(0) = h(0) = g(0) = 0$. By Proposition 4.2, for each $r \in \mathbf{N}$, there exists $\varepsilon_r > 0$ such that

$$f^\circ(0, x) + \frac{\|x\|}{r} \geq h(x) \geq -\left((-g)^\circ(0, x) + \frac{\|x\|}{r}\right)$$

for all x such that $\|x\| \le \varepsilon_r$. Now, take $\varepsilon < \varepsilon_r$. Then

$$f^\circ(0,x) + \frac{\|x\|}{r} + I_{\varepsilon B}(x) \ge h(x) \ge -\left((-g)^\circ(0,x) + \frac{\|x\|}{r} + I_{\varepsilon B}(x)\right)$$

for all $x \in \mathbf{R}^n$. We can then apply Theorem 4.1 to get an element y_r such that

$$\begin{aligned} y_r &\in \partial\left(f^\circ(0,\cdot) + \frac{\|\cdot\|}{r} + I_{\varepsilon B}(\cdot)\right)(0) \cap \partial h(0) \\ &\quad \cap -\partial\left((-g)^\circ(0,\cdot) + \frac{\|\cdot\|}{r} + I_{\varepsilon B}(\cdot)\right)(0) \\ &= \left(\partial f(0) + \frac{1}{r}B\right) \cap \partial h(0) \cap \left(\partial g(0) + \frac{1}{r}B\right). \end{aligned}$$

Since $y_r \in \partial h(0)$, the sequence (y_r) is bounded and any of its cluster points does the job. □

COROLLARY 4.1. *Let $f_1 \ge f_2 \ge \cdots f_k : \mathbf{R}^n \to \mathbf{R}$ be locally Lipschitz. Suppose $f_1(0) = \cdots = f_k(0)$. Then*

$$\bigcap_{i=1}^{k} \partial f_i(0) \ne \emptyset,$$

provided at least one of the following conditions holds:

- *$k = 1, 2, 3$;*
- *at least one f_i is smooth;*
- *$n = 1, 2$.*

Proof. The cases $k = 2$ and the case when f_i is smooth follow from the sum rule applied to $f_1 - f_2$ and $f_j - f_i$, respectively. The case $k = 3$ is Theorem 4.2 and the cases $n = 1, 2$ are consequences of Theorem 4.2 and Helly's theorem. □

5. Final remarks. We have seen some sandwich and squeeze theorems, dealing with convex and locally Lipschitz functions. While the convex subdifferential is standard, there are several notions of subdifferential for locally Lipschitz functions. Here we use the Clarke subdifferential rather than, for instance, the approximate subdifferential, because the latter is not suitable for the results we seek. Consider the following simple example.

EXAMPLE 5.1. *Let*

$$f(x) = I_{[-1,1]}(x),$$

$$g(x) = |x| + I_{[-1,1]}(x),$$

and

$$h(x) = -|x|.$$

Then $f \ge h \ge -g$ and h is (globally) Lipschitz. However

$$L = \{y : f^*(y) + g^*(y) \le 0\} = \{0\},$$

while the approximate subdifferential of h is the set $\{-1, 1\}$.

Finally, here is a list of questions we leave to the interested reader.

Question 1. Does

$$\operatorname{ri}(\operatorname{dom} f) \cap \operatorname{ri}(\operatorname{dom} g) \neq \emptyset$$

imply

$$L \cap \operatorname{cl}(\operatorname{Im} \partial h) \neq \emptyset?$$

Question 2. Does

$$\operatorname{ri}(\operatorname{dom} f^*) \cap \operatorname{ri}(-\operatorname{dom} g^*) \neq \emptyset$$

imply

$$L \cap \operatorname{cl}(\operatorname{Im} \partial h) \neq \emptyset?$$

Question 3.[2] Does the nonsmooth squeeze result of Corollary 4.1 hold more generally for any n, k?

A BEHAVIORAL APPROACH TO THE POLE STRUCTURE OF ONE-DIMENSIONAL AND MULTIDIMENSIONAL LINEAR SYSTEMS*

J. WOOD†, U. OBERST‡, E. ROGERS†, AND D. H. OWENS§

Abstract. We use the tools of behavioral theory and commutative algebra to produce a new definition of a (finite) pole of a linear system. This definition agrees with the classical one and allows a direct dynamical interpretation. It also generalizes immediately to the case of a multidimensional (nD) system. We make a natural division of the poles into controllable and uncontrollable poles. When the behavior in question has latent variables, we make a further division into observable and unobservable poles. In the case of a one-dimensional (1D) state-space model, the uncontrollable and unobservable poles correspond, respectively, to the input and output decoupling zeros, whereas the observable controllable poles are the transmission poles.

Most of these definitions can be interpreted dynamically in both the 1D and nD cases, and some can be connected to properties of kernel representations. We also examine the connections between poles, transfer matrices, and their left and right matrix fraction descriptions (MFDs). We find behavioral results which correspond to the concepts that a controllable system is precisely one with no input decoupling zeros and an observable system is precisely one with no output decoupling zeros. We produce a decomposition of a behavior as the sum of subbehaviors associated with various poles. This is related to the integral representation theorem, which describes every system trajectory as a sum of integrals of polynomial exponential trajectories.

Key words. pole, decoupling zero, behavioral approach, multidimensional systems, characteristic variety, polynomial exponential function, associated primes, primary decomposition, integral representation

1. Introduction.

This paper is about the pole structure of one-dimensional (1D) and multidimensional (nD) linear systems. Although it is motivated by the need to establish a cohesive theory of poles for nD systems, many of the results in the paper give a new perspective to the classical 1D theory. Furthermore, this paper places all of the classical results in the new and growing behavioral framework [39, 40, 41]. We consider only linear systems with constant coefficients; our results apply to both continuous and discrete cases.

The systematic theory of poles (and zeros) of 1D systems originated in the work of Rosenbrock [33] and others. Since then, a number of papers have reviewed, extended, and refined the theory (e.g., [8, 23, 35]; see also the references at the end of this paper).

An nD system is one in which information propagates in two or more independent directions. Such systems arise as the solutions of partial differential or difference

equations. Shankar and Sule [36, 37] have defined poles for SISO nD systems, using the ring of stable causal rational functions. As yet, to our knowledge, no theory of pole structure or even a definition of a pole has been proposed for nD MIMO systems. The primary aim of this paper is to fill that gap. Our secondary aim is to extend the behavioral theory of both 1D and nD systems by introducing into it concepts concerned with pole structure. Thirdly, we intend to shed new light on the existing 1D theory, both through our use of behaviors and by identifying correspondences between system-theoretic concepts and algebraic ones.

In accordance with the behavioral paradigm, we define poles (decoupling zeros, etc.) to be objects associated with a system's behavior, rather than with any given representation of it. One advantage of such definitions is that they are all intrinsic, as is also the case with the recent definitions of Bourlès and Fliess [4] and of Pommaret and Quadrat [31]. For example, the input decoupling zeros are not defined as the zeros eliminated by a reduction procedure as in [33], but are instead defined directly.

The algebraic definitions of Bourlès and Fliess [4] have been extended to the case of nD systems with variable coefficients by Pommaret and Quadrat [31]. Our definitions are equivalent to these in the 1D/ nD constant coefficients case, the relationship being given by module duality, which translates, for example, the definition of a pole given in terms of the finitely generated system module into a corresponding one in terms of the system's behavior. Our definitions are not directly related to those of Shankar and Sule [36].

One of our principal tools in this paper is the duality theory in [24] between finitely generated modules over a polynomial ring and nD behaviors described by linear partial differential or difference equations with constant coefficients. Consequently, we use a considerable amount of commutative algebra; see, for example, [3, 5, 7, 10] for background in this field.

The paper is structured as follows. We begin with an overview of relevant concepts from behavioral theory, with special emphasis on module duality (see section 2). Section 3 collects some results on nD behavioral theory which we need later in the paper.

In section 4 we review the concepts of exponential trajectories and the characteristic variety. Exponential trajectories are central to any understanding of system poles, and the characteristic variety is a geometric object which captures the essential structure of a behavior as regards its exponential trajectories. Based on these ideas, we define the poles of an nD system in section 5. We also define the concepts of controllable and uncontrollable poles. The controllable poles have properties which relate strongly to those of the system's transfer matrix, whereas the uncontrollable poles play the role of input decoupling zeros.

Section 6 considers the case where the behavior in question is a latent variable representation (e.g., a state-input-output behavior). We divide the system poles into observable and unobservable poles, which have natural interpretations. This leads naturally to a further breakdown in terms of controllable observable poles, etc., all of which correspond naturally to known sets of poles in the classical 1D context.

Finally, in section 7 we consider a decomposition which is dual to the standard algebraic concept of the primary decomposition of a module. This "polar decomposition" expresses the zero-input behavior of a system as the finite sum of subbehaviors associated with the distinct poles of the system. Using a similar decomposition we can write the system behavior itself as the sum of the controllable part and a finite set of subbehaviors associated with the system's uncontrollable poles (input decou-

pling zeros). This latter decomposition is a refinement of the well-known controllable-autonomous decomposition. Using the little-known but important integral representation theorem, it is possible to write any zero-input trajectory as a sum of integrals of polynomial exponential trajectories. In the case of a finite-dimensional behavior, every zero-input trajectory can be written as a sum of polynomial-weighted exponential trajectories with frequencies corresponding to the system poles, as in the 1D case.

We leave a number of important issues untouched, for example, the definition of multiplicity of a pole, the definition of an infinite pole, and the whole question of zeros. However, the basic structures which we uncover in this work should prove a good foundation for further developments of this type.

2. Behaviors, modules, and duality. This section provides an overview of behavioral theory and the duality between finitely generated modules and behaviors given by partial differential/difference equations.

2.1. The behavioral approach. The behavioral approach to 1D systems is due to Willems [39, 40, 41], and centers on the concept of the system's behavior, which is the set of associated trajectories. Formally, we define a *system* as a triple $(\mathcal{A}, q, \mathcal{B})$, where $\mathcal{A}$ is a set called the *signal space*, $q \in \mathbb{Z}^+$ is the number of components, and $\mathcal{B} \subseteq \mathcal{A}^q$ is the *behavior*. The elements of $\mathcal{B}$ are called *trajectories*. We will make little distinction between a system and its behavior. Note that the standard behavioral definition of a system as a triple $(T, W, \mathcal{B})$ (where T is the signal domain, W the signal value set, and $\mathcal{B} \subseteq W^T$) does not cover the important case of distributions.

In all cases of interest (as listed below), $\mathcal{A}$ will have the structure of a module over a suitable ring of differential or difference operators; in particular, $\mathcal{A}$ is always a vector space over a field k, which is taken to be $\mathbb{R}$ or $\mathbb{C}$. Specifically, throughout this paper $\mathcal{A}$ denotes one of the following signal spaces, with a module structure as described.

1. The discrete signal space $\mathcal{A} = k^{\mathbb{N}^n}$, $k = \mathbb{R}, \mathbb{C}$, which is a module over the polynomial ring $\mathcal{R} = k[\underline{\mathbf{z}}] = k[z_1, \ldots, z_n]$, where the action of z_i on a trajectory $w \in \mathcal{A}$ is taken to be the shift operator σ_i, defined by

$$(\sigma_i w)(t_1, \ldots, t_n) \;:=\; w(t_1, \ldots, t_{i-1}, t_i + 1, t_{i+1}, \ldots, t_n). \tag{2.1}$$

By extension, any element of $\mathcal{R}$ has an action on $\mathcal{A}$

$$\text{for all } p \in k[\underline{\mathbf{z}}], w \in \mathcal{A}, \qquad p(z_1, \ldots, z_n)w \;:=\; p(\sigma_1, \ldots, \sigma_n)(w). \tag{2.2}$$

2. The discrete signal space $\mathcal{A} = k^{\mathbb{Z}^n}$, $k = \mathbb{R}, \mathbb{C}$, which is a module over the Laurent polynomial ring $\mathcal{R} = k[\underline{\mathbf{z}}, \underline{\mathbf{z}}^{-1}] = k[z_1, \ldots, z_n, z_1^{-1}, \ldots, z_n^{-1}]$, where z_i acts as the shift operator σ_i and z_i^{-1} as the inverse shift σ_i^{-1}.

3. The signal space $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, k)$, $k = \mathbb{R}, \mathbb{C}$ of all k-valued $\mathcal{C}^\infty$ functions on $\mathbb{R}^n$, which is a module over $\mathcal{R} = k[\underline{\mathbf{z}}]$, where z_i acts as the partial derivative operator $\partial/\partial t_i$. This action is extended to $\mathcal{R}$ by

$$\text{for all } p \in k[\underline{\mathbf{z}}], w \in \mathcal{A}, \qquad p(z_1, \ldots, z_n)w \;:=\; p(\partial/\partial t_1, \ldots, \partial/\partial t_n)(w). \tag{2.3}$$

4. The signal space $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, k)$, $k = \mathbb{R}, \mathbb{C}$ of all k-valued distributions on $\mathbb{R}^n$, which is a module over $\mathcal{R} = k[\underline{\mathbf{z}}]$, where z_i again acts as the partial derivative operator $\partial/\partial t_i$.

Throughout the paper, we consider the behavior $\mathcal{B} \subseteq \mathcal{A}^q$ to be the solution space in $\mathcal{A}^q$ of a finite set of linear partial differential or difference equations in q dependent

variables with constant coefficients. Such behaviors will be called *differential behaviors* and *difference behaviors*, respectively. The term *autoregressive (AR) behavior* has formerly been used but is undesirable due to the inappropriate stochastic connotations.

The set of systems with differential/difference behaviors covers all linear time-invariant systems dealt with by the classical 1D state-space framework and its nD analogues. Differential and difference behaviors are, in particular, linear and shift-invariant and in the continuous case are also closed under partial differentiation. In each case any differential or difference behavior $\mathcal{B}$ is therefore a submodule of $\mathcal{A}^q$; the ring action is the componentwise application of (2.2) or (2.3).

It is convenient to describe differential/difference behaviors using polynomial matrices (Laurent polynomial matrices when $\mathcal{A} = k^{\mathbb{Z}^n}$). Thus let $E \in \mathcal{R}^{g,q}$; then the behavior described by E is the submodule of $\mathcal{A}^q$ consisting of all w satisfying $Ew = 0$, where the meaning of Ew is given by the action of the ring $\mathcal{R}$ on $\mathcal{A}$. For example, the three-dimensional (3D) difference behavior $\mathcal{B}$ in 2 variables described by the equations

$$w_1(t_1, t_2, t_3) - w_1(t_1, t_2 + 1, t_3 + 1) + 2w_2(t_1 + 1, t_2, t_3) = 0,$$
$$w_1(t_1 + 2, t_2, t_3 + 1) - w_2(t_1, t_2, t_3) + 3w_2(t_1, t_2 + 1, t_3) = 0$$

is given by the polynomial matrix

$$E \;=\; \begin{pmatrix} 1 - z_2 z_3 & 2z_1 \\ z_1^2 z_3 & -1 + 3z_2 \end{pmatrix}.$$

We say that E is a *kernel representation* of $\mathcal{B}$, and we write $\mathcal{B} = \ker_{\mathcal{A}} E$. For any matrix $E \in \mathcal{R}^{g,q}$, we also define the following modules:[1]

$$\operatorname{Ker}_{\mathcal{R}} E := \{v \in \mathcal{R}^{1,g} \;\mid\; vE = 0\}, \tag{2.4}$$
$$\operatorname{Im}_{\mathcal{R}} E := \{v \in \mathcal{R}^{1,q} \;\mid\; v = xE \text{ for some } x \in \mathcal{R}^{1,g}\}, \tag{2.5}$$
$$\operatorname{Coker}_{\mathcal{R}} E := \mathcal{R}^{1,q} / \operatorname{Im}_{\mathcal{R}} E, \tag{2.6}$$
$$\operatorname{im}_{\mathcal{A}} E := \{w \in \mathcal{A}^g \;\mid\; w = El \text{ for some } l \in \mathcal{A}^q\}. \tag{2.7}$$

Note the different subscripts used to denote different ring actions. Also, the modules $\operatorname{Ker}_{\mathcal{R}} E$, $\operatorname{Im}_{\mathcal{R}} E$, $\operatorname{Coker}_{\mathcal{R}} E$ are defined with respect to a left action of E, whereas $\ker_{\mathcal{A}} E$ and $\operatorname{im}_{\mathcal{A}} E$ are defined with respect to a right action.

2.2. Module duality. In this section we describe the duality between finitely generated $\mathcal{R}$-modules and differential/difference behaviors [24]. For the purposes of the next definition and the discussion immediately following only, the space $\mathcal{A}$ can be thought of as an arbitrary module.

DEFINITION 2.1. *Let M be a finitely generated $\mathcal{R}$-module and $\mathcal{A}$ an arbitrary $\mathcal{R}$-module. The* dual of M *with respect to $\mathcal{A}$, denoted $D(M)$, is defined by*

$$D(M) \;:=\; \operatorname{Hom}_{\mathcal{R}}(M, \mathcal{A}). \tag{2.8}$$

If $\phi : M \mapsto N$ is a morphism of finitely generated $\mathcal{R}$-modules, then the dual map $D(\phi) : D(N) \mapsto D(M)$ is given by

$$\text{for all } v \in D(N), \qquad (D(\phi))(v) \;:=\; v \circ \phi. \tag{2.9}$$

[1]Note that the modules $\operatorname{Ker}_{\mathcal{R}} E$, $\operatorname{Im}_{\mathcal{R}} E$, $\operatorname{Coker}_{\mathcal{R}} E$ are defined using row vectors and do not therefore require transposition of E, contrary to the first author's previous practice.

The action of $\mathcal{R}$ on the dual module $D(M)$ is given by

$$\text{for all } r \in \mathcal{R}, w \in D(M), \qquad (rw)(m) \;:=\; r \cdot w(m) \;=\; w(rm) \tag{2.10}$$

for all $m \in M$.

Note for any $q \in \mathbb{Z}^+$ that $D(\mathcal{R}^{1,q}) \cong \mathcal{A}^q$. Furthermore, it turns out that we have the following theorem.

THEOREM 2.2 (see [24, pp. 19–21]). *Differential/difference behaviors are precisely the dual modules of finitely generated $\mathcal{R}$-modules. Specifically, if $\mathcal{B} = \ker_{\mathcal{A}} E$, then $\mathcal{B} = D(M)$, where M is the finitely generated module* $\operatorname{Coker}_{\mathcal{R}} E$.

It is not hard to show [24, Cor. 2.57] that the dual action of a polynomial matrix map $E : \mathcal{R}^{1,g} \mapsto \mathcal{R}^{1,q}$, $v \mapsto vE$ is the map $E : \mathcal{A}^q \mapsto \mathcal{A}^g$, $w \mapsto Ew$ given by the ring action on $\mathcal{A}$ ((2.2) or (2.3) in our cases of interest).

DEFINITION 2.3. *A* complex *of modules is a set of maps $\phi_i : F_i \mapsto F_{i-1}$, $i \in \mathbb{Z}$, where $\phi_i \circ \phi_{i+1} = 0$ for all i. We represent a complex by a diagram of the form*

$$\cdots \xrightarrow{\phi_{i+2}} F_{i+1} \xrightarrow{\phi_{i+1}} F_i \xrightarrow{\phi_i} F_{i-1} \xrightarrow{\phi_{i-1}} \cdots.$$

The complex is said to be exact *and is called an* exact sequence*, if for every i we have that* $\ker \phi_i = \operatorname{im} \phi_{i+1}$.

Exact sequences are a compact way of expressing structural relationships. Exactness of the following two sequences express the injectivity and surjectivity, respectively, of the map ϕ:

$$0 \longrightarrow M \xrightarrow{\phi} N \qquad\qquad M \xrightarrow{\phi} N \longrightarrow 0.$$

The next exact sequence expresses that K is (isomorphic to) the kernel of ϕ and L is (isomorphic to) the cokernel:

$$0 \longrightarrow K \xrightarrow{\iota} M \xrightarrow{\phi} N \xrightarrow{\rho} L \longrightarrow 0.$$

Note that to any complex of modules, there is a corresponding dual complex, obtained by reversing the arrows and dualizing each module and each map, and conversely. The following crucial result shows that, in our cases of interest, the same can be said of exact sequences.

THEOREM 2.4 (see [24, Thm. 2.54, Cor. 2.43, 2.46, 2.47]). *Each module $\mathcal{A}$ listed in section* 2.1 *is an injective cogenerator of the category of $\mathcal{R}$-modules. This signifies that duality is contravariant and faithfully exact. In other words, given a complex of modules*

$$\cdots \xrightarrow{\phi_{i+2}} F_{i+1} \xrightarrow{\phi_{i+1}} F_i \xrightarrow{\phi_i} F_{i-1} \xrightarrow{\phi_{i-1}} \cdots \tag{2.11}$$

and its dual complex

$$\cdots \xrightarrow{D(\phi_{i-1})} D(F_{i-1}) \xrightarrow{D(\phi_i)} D(F_i) \xrightarrow{D(\phi_{i+1})} D(F_{i+1}) \xrightarrow{D(\phi_{i+2})} \cdots, \tag{2.12}$$

we have that (2.11) *is exact if and only if* (2.12) *is exact. In consequence, if $\mathcal{B} = \ker_{\mathcal{A}} E \subseteq \mathcal{A}^q$, then the* orthogonal module $\mathcal{B}^{\perp} \subseteq \mathcal{R}^{1,q}$ *(the module of all equations satisfied by the system $\mathcal{B}$) is equal to* $\operatorname{Im}_{\mathcal{R}} E$.

The module duality gives rise to a lattice duality $\mathcal{B} \mapsto \mathcal{B}^\perp$ between differential/difference behaviors and submodules of $\mathcal{R}^{1,q}$. This duality takes summation to intersection and vice versa [24, sect. 2.22], [42, Lem. 1]. Note also that $\mathcal{B} = D(M)$, where $M = \mathcal{R}^{1,q}/\mathcal{B}^\perp$. For any $\mathcal{R}$-matrix E it can easily be seen that $(\mathrm{im}_{\mathcal{A}}\, E)^\perp = \mathrm{Ker}_{\mathcal{R}}\, E$.

Now if $\mathcal{B} = \ker_{\mathcal{A}} E$ and $\mathcal{B}' = \ker_{\mathcal{A}} E$ are two behaviors with the same number of system variables, then $\mathcal{B}' \subseteq \mathcal{B}$ if and only if there exists an $\mathcal{R}$-matrix L with $E = LE'$ [24, sect. 2.61]. Another important consequence of Theorem 2.4 is that the dual of a submodule is a factor module of the dual, and vice versa. More precisely, given a finitely generated $\mathcal{R}$-module M and a submodule N, we have an exact sequence

$$0 \longrightarrow N \longrightarrow M \longrightarrow M/N \longrightarrow 0. \tag{2.13}$$

This dualizes to an exact sequence

$$0 \longrightarrow D(M/N) \longrightarrow D(M) \longrightarrow D(N) \longrightarrow 0, \tag{2.14}$$

which we can interpret as meaning that $D(M/N)$ is a submodule of $D(M)$, with factor module $D(N)$. Indeed, we identify $D(M/N)$ with the set of functions of $D(M)$ which are zero on N.

An immediate application of the duality theorem is the following [24, pp. 24–25].

LEMMA 2.5. *If $E \in \mathcal{R}^{g,q}$, then $\mathrm{im}_{\mathcal{A}}\, E = \mathcal{A}^g$ if and only if E has full row rank.*

Proof. The map $E : \mathcal{R}^{1,g} \mapsto \mathcal{R}^{1,q}$, $v \mapsto vE$ is monic if and only if the dual map $E : \mathcal{A}^q \mapsto \mathcal{A}^g$, $w \mapsto Ew$ is epic. ∎

We investigate some of the links between the theory of differential/difference behaviors and commutative algebra resulting from this duality in section 3.

Henceforth, $\mathcal{B} = \ker_{\mathcal{A}} E$ denotes a differential or difference behavior with kernel representation E, which is contained in $\mathcal{A}^q$ for one of the signal spaces $\mathcal{A}$ listed in section 2.1, and $M = \mathrm{Coker}_{\mathcal{R}}\, E$ denotes the finitely generated module to which $\mathcal{B}$ is dual:

$$E \in \mathcal{R}^{g,q}, \qquad M = \mathrm{Coker}_{\mathcal{R}}\, E, \qquad \mathcal{B} = D(M) = \ker_{\mathcal{A}} E \ \subseteq\ \mathcal{A}^q. \tag{2.15}$$

A similar behavioral and/or module-theoretic approach can be taken for linear systems with variable coefficients, as shown in the 1D case, for example, in [12, 14, 16, 34], using noncommutative techniques. The algebraic approach has been extended to nD variable coefficient systems by Pommaret and Quadrat [30, 31]. Recent work has indicated that it may be possible to use behavioral tools in the analysis of nonlinear systems [47].

Recall that the annihilator of a module M, denoted $\mathrm{ann}\, M$, is the ideal of all $r \in \mathcal{R}$ such that $rM = 0$. We denote the set of all elements of $\mathcal{B}$ annihilated by an ideal J (i.e., all elements w such that $rw = 0$ for all $r \in J$) by $[\mathcal{B} : J]$. The following properties of duality will be useful.

LEMMA 2.6. *Let J be an ideal of $\mathcal{R}$ and M a finitely generated $\mathcal{R}$-module with dual $\mathcal{B}$; then*

$$D(M/JM) \ =\ [\mathcal{B} : J]. \tag{2.16}$$

Also, $\mathrm{ann}\, M = \mathrm{ann}\, \mathcal{B}$.

Proof. Equation (2.16) is given in [24, Cor. 2.101]. Considering the case $J = (r)$ for some $r \in \mathcal{R}\backslash 0$, we now find that $D(M/rM) = [\mathcal{B} : (r)]$. If r is in the annihilator of M, then $M/rM = M$, so $[\mathcal{B} : (r)] = \mathcal{B}$, i.e., r is in the annihilator of $\mathcal{B}$. The converse is similar. ∎

3. Controllable, observable, and autonomous systems. In this section we recount relevant results from [24, 42, 46] and other sources, some of which are extended here from discrete to continuous systems. These results concern the characterization of controllable systems, observable systems, and autonomous systems using algebraic tools.

3.1. Free variables. The following definition is adapted from [15].

DEFINITION 3.1. *Let $\mathcal{B} \subseteq \mathcal{A}^q$. The set of variables $\{w_i \mid i \in \Phi\}$ for some subset Φ of $\{1, \ldots, q\}$ is said to be a* set of free variables *if the mapping $\rho : \mathcal{A}^q \mapsto \mathcal{A}^\Phi$, which projects a trajectory onto the components of Φ, is epic when restricted to $\mathcal{B}$.*

The maximum size of a set of free variables is called the number of free variables *of $\mathcal{B}$ and is denoted by $m(\mathcal{B})$.*

Thus a set of variables indexed by Φ is free if the corresponding components can take any value in $\mathcal{A}^\Phi$. Given a kernel representation $\mathcal{B} = \ker_{\mathcal{A}} E$ of $\mathcal{B}$, it can be shown that the number of free variables is equal to $q - \operatorname{rank} E$ [24, Thm. 2.69]. It can also be shown that the number of free variables is additive [42, remarks following Def. 6], i.e., given an exact sequence

$$0 \longrightarrow \mathcal{B}_1 \longrightarrow \mathcal{B}_2 \longrightarrow \mathcal{B}_3 \longrightarrow 0$$

of differential/difference behaviors, we have $m(\mathcal{B}_2) = m(\mathcal{B}_1) + m(\mathcal{B}_3)$. Consequently, if $\mathcal{B}_1, \mathcal{B}_2 \subseteq \mathcal{A}^q$ for some q, then we have

$$m(\mathcal{B}_1) + m(\mathcal{B}_2) \;=\; m(\mathcal{B}_1 + \mathcal{B}_2) + m(\mathcal{B}_1 \cap \mathcal{B}_2). \tag{3.1}$$

3.2. Autonomous systems. In the behavioral framework, an autonomous discrete system is defined as follows [15, 42].

DEFINITION 3.2. *A difference behavior $\mathcal{B}$ with signal domain T is called* autonomous *if there exists $T_1 \subseteq T$ such that any trajectory of $\mathcal{B}$ is determined by its values on T_1, and also $T \backslash T_1$ contains an n-dimensional cone.*

The main characterization of such behaviors [42, Thm. 2] follows; similar results or special cases have also appeared in [15, 46].

THEOREM 3.3 (see [15, 42, 46]). *Let $\mathcal{B} = D(M)$ be a difference behavior. The following are equivalent:*

1. *$\mathcal{B}$ is autonomous.*
2. *$\mathcal{B}$ has no free variables.*
3. *For any E with $\mathcal{B} = \ker_{\mathcal{A}} E$, E has full column rank.*
4. *$\operatorname{ann} \mathcal{B} = \operatorname{ann} M \neq 0$; equivalently, M is a torsion module.*

In the continuous case, Pillai and Shankar [29] have defined an autonomous system as one with a characteristic variety which is not equal to $\mathbb{C}^n$ [29, Def. 4.2]. We will discuss characteristic varieties in section 4; for now, let us use the following definition, which is easily seen to be equivalent to this condition and to the conditions of Theorem 3.3.

DEFINITION 3.4. *A differential behavior is called* autonomous *if* $\operatorname{ann} \mathcal{B} \neq 0$.

Recall that a behavior is said to be *finite-dimensional* or *strongly autonomous* if and only if it is finite-dimensional as a vector space over k [15, 29]. Note that this has nothing to do with the traditional use of the term "finite-dimensional" in classical systems theory.

3.3. Minimal left annihilators and generalized factor primeness. We will also need the concepts of a minimal left annihilator [32, p. 24] and generalized factor primeness [24, Thm. 7.21], [46].

DEFINITION 3.5. *Let $\mathcal{R} = k[\underline{\mathbf{z}}]$ or $k[\underline{\mathbf{z}}, \underline{\mathbf{z}}^{-1}]$, and suppose that $E \in \mathcal{R}^{g,q}$. Then E is called a* minimal left annihilator *(of F) if there exists a matrix $F \in \mathcal{R}^{q,h}$ for some h for which the following conditions hold:*

1. *$EF = 0$.*
2. *For any E' satisfying $E'F = 0$, there exists L with $E' = LE$.*

The matrix E is said to be factor left prime in the generalized sense (GFLP)*, if the existence of a $\mathcal{R}$-matrix factorization $E = LE_1$ (L not necessarily square) with* rank $E =$ rank E_1 *implies the existence of an $\mathcal{R}$-matrix L' with $E_1 = L'E$.*

It is shown in [24, Lem. 2.27], [42, Lem. 7] that E is a minimal left annihilator of F if and only if $\ker_{\mathcal{A}} E = \operatorname{im}_{\mathcal{A}} F$, or equivalently, $\operatorname{Im}_{\mathcal{R}} E = \operatorname{Ker}_{\mathcal{R}} F$. Every matrix over $\mathcal{R}$ has a minimal left annihilator [24, Lem. 2.27], [42, Lem. 7]. A matrix over $\mathcal{R}$ is a minimal left annihilator if and only if it is GFLP [42, Lem. 10].

3.4. Controllable systems. Any differential/difference behavior admits certain input/output structures. In this paper, as is traditional in control theory, the "inputs" are assumed to be a maximal set of free variables, and in consequence the outputs have no freedom once the inputs are determined. The more general situation, in which an input/output structure is an arbitrary partitioning of the system variables and which may be better suited to certain applications, is not considered in this paper. In [31], Pommaret and Quadrat extend some of the algebraic theory of this paper to this general case.

DEFINITION 3.6 (see [24, Thm. 2.69], [32, Def. IV.8], [42, Def. 12]). *An* input/output structure *on the behavior $\mathcal{B}$ is a partitioning of the system variables $w = (u, y)$, such that the set of variables u is free and the* zero-input behavior $\mathcal{B}_{0,y}$*, defined by*

$$\mathcal{B}_{0,y} \;=\; \{(u, y) \in \mathcal{B} \;\mid\; u = 0\} \tag{3.2}$$

is autonomous.

Equivalently, we can consider a partitioning $E = (-Q\ P)$ of any kernel representation E of $\mathcal{B}$ (to within a permutation), where the columns of Q correspond to the input variables u and the columns of P to the output variables y, and we have the condition

$$\text{rank } E \;=\; \text{rank } P \;=\; \text{number of columns of } P.$$

It is easy to show that the number of inputs is equal to m, the number of free variables. In particular, the number of inputs and number of outputs of a behavior is independent of the input/output structure.

If $\mathcal{B}$ has a kernel representation $(-Q\ P)$, where P is the submatrix corresponding to the output components, then $\mathcal{B}_{0,y}$ is (trivially) isomorphic to $\ker_{\mathcal{A}} P$. We usually make no distinction between these two behaviors.

For a given admissible input/output structure, any behavior $\mathcal{B}$ has a unique *transfer (function) matrix* $G \in k(\underline{\mathbf{z}})^{p,m}$ characterized by the equation $PG = Q$; see [24, Thm. 2.69] and also [32, p. 75] for the discrete case. Collecting together all behaviors with a given input/output structure and the same transfer matrix with respect to that input/output structure, we obtain a transfer class. The transfer class turns out to be independent of the input/output structure and resulting transfer matrix, and the transfer classes partition the set of behaviors. Furthermore, each transfer class has a unique element which is minimal with respect to set inclusion [24, Thm. 7.21], [32, p. 76]. Such a behavior will be called the *minimal realization* of the transfer matrix. The minimal realization has properties which are closely linked to those of the transfer matrix, as we will see later in the paper.

The concept of a minimal realization is related to controllability, which in the behavioral context is defined as follows.

DEFINITION 3.7 (see [29, 32, 42, 44]). *A differential behavior $\mathcal{B}$ is* controllable *if, for any two open sets $T_1, T_2 \subseteq \mathbb{R}^n$ with disjoint closures and for any two trajectories $w^{(1)}, w^{(2)} \in \mathcal{B}$, there exists a $w \in \mathcal{B}$ such that*

$$w(\underline{t}) \;=\; \begin{cases} w^{(1)}(\underline{t}) & \text{if } \underline{t} \in T_1, \\ w^{(2)}(\underline{t}) & \text{if } \underline{t} \in T_2. \end{cases} \tag{3.3}$$

A difference behavior $\mathcal{B}$ with signal domain $T = \mathbb{Z}^n$ or $T = \mathbb{N}^n$ is controllable *if there exists a real number $\rho > 0$ such that for any sets $T_1, T_2 \subseteq T$ with $d(T_1, T_2) > \rho$, for any $\underline{b}_1, \underline{b}_2 \in T$, and any two trajectories $w^{(1)}, w^{(2)} \in \mathcal{B}$, there exists a $w \in \mathcal{B}$ such that*

$$w(\underline{t}) \;=\; \begin{cases} w^{(1)}(\underline{t} - \underline{b}_1) & \text{if } \underline{t} \in T_1 \text{ and } \underline{t} - \underline{b}_1 \in T, \\ w^{(2)}(\underline{t} - \underline{b}_2) & \text{if } \underline{t} \in T_2 \text{ and } \underline{t} - \underline{b}_2 \in T. \end{cases} \tag{3.4}$$

In the discrete case, we can take $\underline{b}_1 = 0$ without loss of generality, and for $T = \mathbb{Z}^n$, we can also take $\underline{b}_2 = 0$. For both differential and difference behaviors, controllability expresses the idea of being able to join with a system trajectory any two system trajectories defined on regions which are sufficiently far apart.

The next result collects previous results in the literature on the characterization of nD behavioral controllability. In the 1D case, the equivalence of controllability and torsionfreeness is first due to Fliess [13], following an observation of Pommaret [30]. Special cases of the next result in the 1D and two-dimensional (2D) discrete cases are due, respectively, to Willems [40] and to Rocha [32].

THEOREM 3.8. *Let $\mathcal{B} = D(M) = \ker_{\mathcal{A}} E$. The following are equivalent:*

1. *$\mathcal{B}$ is controllable.*
2. *$\mathcal{B}$ is minimal in its transfer class.*
3. *$\mathcal{B}$ has an image representation.*
4. *E is GFLP.*
5. *$\mathcal{B}$ is a divisible module.*
6. *M is a torsionfree module.*
7. *$\mathcal{B}$ has no proper differential/difference subbehaviors with the same number of free variables.*

Proof. The equivalence of Parts 1 and 3 is given in [29, Prop. 3.4, Thm. 3.9] for differential behaviors, in [42, Thm. 5] for difference behaviors on $\mathbb{Z}^n$, and in [44] for general difference behaviors. The equivalence of Parts 3 and 4 is given in [42, Lem. 10] and also [46]. The equivalence of Parts 3 and 6 has been given in [30, Prop. VII.A.10], and the equivalence of Parts 2, 4, and 6 in [24, Thm. 7.21]. The equivalence of Parts 5 and 6 can be proved easily using the exactness of duality. Condition 7 is a direct interpretation of condition 4, as discussed following Definition 10 in [42]. □

Note that any differential/ difference behavior has a "controllable-autonomous decomposition" $\mathcal{B} = \mathcal{B}^c + \mathcal{B}^a$ [42, Thm. 7]; the argument given in that paper applies equally well to continuous systems. In this decomposition, the controllable behavior $\mathcal{B}^c \subseteq \mathcal{B}$ is uniquely determined as the minimal element of the transfer class of $\mathcal{B}$; henceforth we call this behavior the *controllable part* of $\mathcal{B}$. It is shown in [24, Thm. 7.21] that if $\mathcal{B} = D(M)$, then

$$\mathcal{B}^c \;=\; D(M/tM), \tag{3.5}$$

where tM denotes the torsion submodule of M. We will also find the behavior $\mathcal{B}/\mathcal{B}^c$ interesting. This behavior is dual to tM, as can be seen from (3.5) using basic duality principles (see (2.13) and (2.14)). Given a representation E^c for $\mathcal{B}^c$, we can see by considering the restriction of the map E^c to $\mathcal{B}$ that the behavior $E^c\mathcal{B}$ is naturally isomorphic to $\mathcal{B}/\mathcal{B}^c$.

The controllable-autonomous decomposition as defined above is in fact slightly more general (and less rich in structure) for a 1D system than as originally defined for 1D systems (see, e.g., [41]). This is because we do not require that the sum should be direct.

The controllable part of $\mathcal{B}$ has the same input/output structures as $\mathcal{B}$ itself (inevitably, since it can be defined with respect to any such input/output structure via the transfer matrix G). As we will see later in the paper, the zero-input behavior of the controllable part, $(\mathcal{B}^c)_{0,y}$, has an interesting structure. It has already been shown in [24, Cor. 7.29] that the corresponding orthogonal module has the following form:

$$((\mathcal{B}^c)_{0,y})^{\perp} \;=\; \{v \in \mathcal{R}^{1,p} \mid vG \in \mathcal{R}^{1,m}\}, \tag{3.6}$$

where we treat $(\mathcal{B}^c)_{0,y}$ as a subbehavior of $\mathcal{A}^p$ rather than of $\mathcal{A}^q$, p being the number of outputs.

The next result has not been explicitly proved in the literature before.

LEMMA 3.9. *Let $\mathcal{B}$ be a behavior with zero-input behavior $\mathcal{B}_{0,y}$ according to some input/output structure. Then $\mathcal{B}_{0,y}$ is an autonomous part of $\mathcal{B}$ in a controllable-autonomous decomposition.*

Proof. For any $(u, y) \in \mathcal{B}$, since the variables u are free in $\mathcal{B}^c$, there must exist a y^c with $(u, y^c) \in \mathcal{B}^c$. As $(0, y - y^c) \in \mathcal{B}_{0,y}$, we have the required decomposition $(u, y) = (u, y^c) + (0, y - y^c)$. □

DEFINITION 3.10. *A matrix $E \in \mathcal{R}^{g,q}$ is called* zero left prime *if its gth order minors generate $\mathcal{R}$. A behavior $\mathcal{B}$ is called* strongly controllable *if it has a zero left prime kernel representation.*

It is a straightforward consequence that $\mathcal{B} = D(M)$ is strongly controllable if and only if M is free. Definition 3.10 is not the definition originally given for strong controllability [32], which has not yet been usefully extended from the 2D to nD or to the continuous case.

3.5. Observable systems. We use the behavioral concept of observability [32, Defn. 19], [40]: given a behavior $\mathcal{B}_{l,w}$ involving two sets of variables l and w, the variables l are said to be *observable* from the variables w if for any two trajectories $(l_1, w_1), (l_2, w_2) \in \mathcal{B}_{l,w}$, it holds that $w_1 = w_2$ implies $l_1 = l_2$. When the variables l are latent variables in a latent variable description of the behavior $\mathcal{B}_w$ (see section 6.1), we say that the behavior $\mathcal{B}_{l,w}$ is *observable* if the latent variables l are observable from the manifest ones w. We have that $\mathcal{B}_{l,w}$ is observable if and only if $\mathcal{B}_{l,0} = 0$.

4. Exponential trajectories and the characteristic variety. We commence our main discussion by explaining the notion of the characteristic variety of a behavior, which is a geometric object describing the exponential trajectories contained in the behavior. To motivate this analysis, we first review the classical interpretation of a pole of a 1D continuous system (see, e.g., [8, 20]).

The point a is a pole of the system Σ if, when zero input $u(t)$ is fed to the system, there exists a nonzero initial condition $x(0)$ such that the resulting state trajectory has the form $x(t) = x(0)e^{at}$ [20]. This is sometimes rephrased by allowing $u(t)$ to be a finite sum of generalized delta functions which "kick the system" into the appropriate

initial condition $x(0)$. Note that as $y(t)$ is determined linearly by $x(t)$ ($u(t)$ being zero), $y(t)$ must also be of the form $y(0)e^{at}$.

This *trajectory interpretation* of a pole can be formalized in behavioral theory as follows. Let $\mathcal{B}_{x,u,y}$ denote the state-input-output behavior of our given state space representation of the system. Then a is a pole of the system (of $\mathcal{B}_{x,u,y}$) if there exists a nonzero trajectory of the form v_0e^{at} in $\mathcal{B}_{x,0,y}$, the set of zero-input trajectories. Exponential trajectories therefore play a crucial role in describing the poles of a system, indeed they are the motive for considering poles.

4.1. Polynomial exponential trajectories. The algebraic significance of a trajectory such as $w(t) = v_0e^{at}$ is that it is killed by the differential operator $d/dt - a$. In the module formalism we are using, $w(t)$ is annihilated by the maximal ideal $(z - a)$. The characterization of trajectories annihilated by maximal ideals, or more generally by powers of maximal ideals, has been done in full detail in [25, Eqs. (1.25–26), (5.26–29), (6.6), (6.10)]. Such trajectories turn out to be exponential trajectories, or more generally, polynomial exponential trajectories, in a sense appropriate to the underlying signal space. These are precisely the trajectories in which we are interested in our study of poles.

The description of exponential trajectories in [25] can be reformulated as in the next two results.

THEOREM AND DEFINITION 4.1 (see [25]). *Consider a scalar trajectory $w(\underline{t})$ in $\mathcal{A}$, where $\mathcal{A}$ is one of the signal spaces listed in section 2.1, which is a module over the ring $\mathcal{R} = k[\underline{\mathbf{z}}]$ or $k[\underline{\mathbf{z}}, \underline{\mathbf{z}}^{-1}]$. Let $\underline{a} \in \mathbb{C}^n$ or $(\mathbb{C}\backslash 0)^n$, respectively, according to $\mathcal{R}$, and let $I(\underline{a})$ denote the maximal ideal of all elements of $\mathcal{R}$ which vanish at $\underline{a}$. (Note that we may have $\underline{a} \notin k^n$, but $I(\underline{a})$ is still meaningful.)*

Then $w(\underline{t})$ is annihilated by $I(\underline{a})$ if and only if it is of the following form (dependent on the signal space):

1. *For $\mathcal{A} = \mathbb{C}^{\mathbb{N}^n}$ or $\mathcal{A} = \mathbb{C}^{\mathbb{Z}^n}$,*

$$w(\underline{t}) \;=\; \alpha a_1^{t_1} \cdots a_n^{t_n}$$

for some $\alpha \in \mathbb{C}$.

2. *For $\mathcal{A} = \mathbb{R}^{\mathbb{N}^n}$, write $a_i = r_i e^{\imath\theta_i}$, $\theta_i := 0$ for $a_i = 0$, $i = 1, \ldots, n$;*

$$w(\underline{t}) \;=\; r_1^{t_1} \cdots r_n^{t_n}(\alpha \cos(\theta_1 t_1 + \cdots + \theta_n t_n) + \beta \sin(\theta_1 t_1 + \cdots + \theta_n t_n))$$

for some $\alpha, \beta \in \mathbb{R}$.

3. *For $\mathcal{A} = \mathbb{R}^{\mathbb{Z}^n}$, write $a_i = r_i e^{\imath\theta_i}$, $i = 1, \ldots, n$;*

$$w(\underline{t}) \;=\; r_1^{t_1} \cdots r_n^{t_n}(\alpha \cos(\theta_1 t_1 + \cdots + \theta_n t_n) + \beta \sin(\theta_1 t_1 + \cdots + \theta_n t_n))$$

for some $\alpha, \beta \in \mathbb{R}$.

4. *For $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, \mathbb{C})$ or $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, \mathbb{C})$,*

$$w(\underline{t}) \;=\; \alpha e^{a_1 t_1 + \cdots + a_n t_n}$$

for some $\alpha \in \mathbb{C}$.

5. *For $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, \mathbb{R})$ or $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, \mathbb{R})$, with $a_i = g_i + \imath h_i$, $i = 1, \ldots, n$,*

$$w(\underline{t}) \;=\; e^{g_1 t_1 + \cdots + g_n t_n}(\alpha \cos(h_1 t_1 + \cdots + h_n t_n) + \beta \sin(h_1 t_1 + \cdots + h_n t_n))$$

for some $\alpha, \beta \in \mathbb{R}$.

A trajectory of $\mathcal{A}^q$ is annihilated by $I(\underline{a})$ if and only if every component is of the above form. Such a trajectory is called an exponential trajectory with frequency $\underline{a}$.

The full exponential-type properties of a behavior can however only be captured by considering trajectories of a more general form, as described in the next result. A trajectory $w \in \mathcal{A}$ is called *locally finite* if the submodule $\mathcal{R} \cdot w$ generated by w is finite-dimensional over k [25]. The $\mathcal{R}$-submodule of $\mathcal{A}$ consisting of all locally finite trajectories is denoted by $\mathcal{A}_{\mathrm{lf}}$.

THEOREM AND DEFINITION 4.2 (see [25]). *Define $a, I(\underline{a})$ as above. A trajectory $w(\underline{t}) \in \mathcal{A}$ is annihilated by some power of $I(\underline{a})$ if and only if it is of the following form (dependent on the signal space):*

1. *For $\mathcal{A} = \mathbb{C}^{\mathbb{N}^n}$, write $S = \{i \in \{1, \dots, n\} \,:\, a_i \neq 0\}$;*

$$w(\underline{t}) \;=\; p(\underline{t}) \prod_{i \in S} a_i^{t_i}$$

for some $p(\underline{t})$ which is the componentwise product of a polynomial function $p^{(1)}(\underline{t})$ of the parameters $t_i, i \in S$ only, and a finitely supported function $p^{(2)}(\underline{t})$ of the parameters $t_j, j \notin S$ only.

2. *For $\mathcal{A} = \mathbb{C}^{\mathbb{Z}^n}$,*

$$w(\underline{t}) \;=\; p(\underline{t}) a_1^{t_1} \cdots a_n^{t_n}$$

for some $p(\underline{t}) \in \mathbb{C}[\underline{t}]$.

3. *For $\mathcal{A} = \mathbb{R}^{\mathbb{N}^n}$, write $S = \{i \in \{1, \dots, n\} \,:\, a_i \neq 0\}$, and, for $i \in S$, define $r_i, \theta_i \in \mathbb{R}$ by $a_i = r_i e^{\imath \theta_i}$. For $i \notin S$, set $\theta_i = 0$.*

$$w(\underline{t}) \;=\; p(\underline{t}) \left(\prod_{i \in S} r_i^{t_i} \right) (\alpha \cos(\theta_1 t_1 + \cdots + \theta_n t_n) + \beta \sin(\theta_1 t_1 + \cdots + \theta_n t_n))$$

for some $\alpha, \beta \in \mathbb{R}$ and some $p(\underline{t})$ which is the componentwise product of a real polynomial function $p^{(1)}(\underline{t})$ of the parameters $t_i, i \in S$ only, and a finitely supported real function $p^{(2)}(\underline{t})$ of the parameters $t_j, j \notin S$ only.

4. *For $\mathcal{A} = \mathbb{R}^{\mathbb{Z}^n}$, for $i = 1, \dots, n$, define $r_i, \theta_i \in \mathbb{R}$ by $a_i = r_i e^{\imath \theta_i}$, $i = 1 \dots, n$;*

$$w(\underline{t}) \;=\; p(\underline{t}) r_1^{t_1} \cdots r_n^{t_n} (\alpha \cos(\theta_1 t_1 + \cdots + \theta_n t_n) + \beta \sin(\theta_1 t_1 + \cdots + \theta_n t_n))$$

for some $\alpha, \beta \in \mathbb{R}$ and some $p(\underline{t}) \in \mathbb{R}[\underline{t}]$.

5. *For $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, \mathbb{C})$ or $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, \mathbb{C})$,*

$$w(\underline{t}) \;=\; p(\underline{t}) e^{a_1 t_1 + \cdots + a_n t_n}$$

for some $p(\underline{t}) \in \mathbb{C}[\underline{t}]$.

6. *For $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, \mathbb{R})$ or $\mathcal{A} = \mathcal{D}'(\mathbb{R}^n, \mathbb{R})$, write $a_i = g_i + \imath h_i$, $g_i, h_i \in \mathbb{R}$, $i = 1, \dots, n$;*

$$w(\underline{t}) \;=\; p(\underline{t}) e^{g_1 t_1 + \cdots + g_n t_n} (\alpha \cos(h_1 t_1 + \cdots + h_n t_n) + \beta \sin(h_1 t_1 + \cdots + h_n t_n))$$

for some $p(\underline{t}) \in \mathbb{R}[\underline{t}]$.

Moreover,

$$\mathcal{A}_{\mathrm{lf}} \;=\; \bigoplus_{\underline{a}} \left\{ w \in \mathcal{A} \;\middle|\; I(\underline{a})^l \text{ annihilates } w \text{ for some } l \in \mathbb{Z}^+ \right\}, \tag{4.1}$$

where for $k = \mathbb{C}$ the direct sum runs over all $\underline{a}$ in either $\mathbb{C}^n$ or $(\mathbb{C}\backslash 0)^n$, according to $\mathcal{R}$; for $k = \mathbb{R}$ the direct sum runs over a set of representatives of the one- or two-element subsets $\{\underline{a}, \overline{\underline{a}}\}, \underline{a} \in \mathbb{C}^n$. Here $\overline{\underline{a}}$ denotes the componentwise complex conjugate of $\underline{a}$.

The locally finite trajectories in $\mathcal{A}_{\mathrm{lf}}^q$ for any q are called polynomial exponential functions/trajectories.

Note that a finite-dimensional behavior consists entirely of polynomial exponential trajectories, as it contains $\mathcal{R}w$ for each trajectory w, and so all trajectories are locally finite.

As discussed in [25], the space $\mathcal{A}_{\mathrm{lf}}$ is itself an injective cogenerator of the category of $\mathcal{R}$-modules, i.e., Theorem 2.4 applies with $D(M) = \mathrm{Hom}_{\mathcal{R}}(M, \mathcal{A})$ replaced by $D_{\mathrm{lf}}(M) = \mathrm{Hom}_{\mathcal{R}}(M, \mathcal{A}_{\mathrm{lf}})$. This enables the vast majority of the duality theory of [24] to be applied to differential/difference behaviors in $\mathcal{A}_{\mathrm{lf}}^q$. In particular, the equation

$$(\mathcal{B} \cap \mathcal{A}_{\mathrm{lf}}^q)^{\perp} \;=\; \mathrm{Im}_{\mathcal{R}}\, E \;=\; \mathcal{B}^{\perp}$$

for any $\mathcal{B} = \ker_{\mathcal{A}} E$ shows that *the subbehavior $\mathcal{B} \cap \mathcal{A}_{\mathrm{lf}}^q$ of polynomial exponential trajectories determines $\mathcal{B}$ uniquely.* More specifically, in the case of a $\mathcal{C}^\infty$ differential behavior, Hörmander gives the following result [18, Thm. 7.6.14].

THEOREM 4.3. *Let $\mathcal{B}$ be a differential behavior with signal space $\mathcal{C}^\infty(\mathbb{R}^n, \mathbb{C})$. Then $\mathcal{B}$ is equal to the closure of the set of its polynomial exponential trajectories.*

Even in the general case, we have seen that a differential or difference behavior is described fully by those trajectories annihilated by some power of an ideal $I(\underline{a})$, $\underline{a} \in \mathbb{C}^n$. As any differential/difference behavior containing such a trajectory must also contain a trajectory annihilated by $I(\underline{a})$ itself, from section 4.2 to section 6 we will discuss only exponential trajectories. In section 7 we will look briefly at the integral representation theorem, which for a behavior with signal space $\mathcal{C}^\infty(\mathbb{R}^n, \mathbb{C})$ describes how any system trajectory can be written as an integral of polynomial exponential trajectories.

4.2. The characteristic variety. We now look at the concept of the characteristic variety, which contains the essential information on the exponential trajectories of a behavior.

Let $J \subseteq k[\underline{\mathbf{z}}]$, $k = \mathbb{R}, \mathbb{C}$. Then we define the variety $V(J)$ as

$$V(J) \;:=\; \{\underline{a} \in \mathbb{C}^n \;\mid\; p(\underline{a}) = 0 \text{ for all } p \in J\}. \tag{4.2}$$

Note that $V(J)$ is defined as a subset of $\mathbb{C}^n$ even when $k = \mathbb{R}$. In the case where the ring of interest is $\mathcal{R} = k[\underline{\mathbf{z}}, \underline{\mathbf{z}}^{-1}]$, the definition is the same, except that only points $\underline{a} \in (\mathbb{C}\backslash 0)^n$ are considered. Henceforth we write $\underline{a} \in \mathbb{C}^n$ ($(\mathbb{C}\backslash 0)^n$), on the understanding that the former applies except when working with the signal space $\mathcal{A} = k^{\mathbb{Z}^n}$.

The next result and definition are fundamental to the paper and come from the theory of PDEs; see [2, p. 200, p. 340] and also [28, p. 138–139], where the term *variety associated with the finitely generated module M* is used. The characteristic variety is also investigated in [30, 31].

THEOREM AND DEFINITION 4.4. *Let $\mathcal{B} = D(M)$ be a behavior with kernel representation E. Let $\underline{a}$ be a point in $\mathbb{C}^n$ ($(\mathbb{C}\backslash 0)^n$). The following are equivalent:*

1. *$\underline{a} \in V(\mathrm{ann}\, \mathcal{B}) = V(\mathrm{ann}\, M)$.*
2. *$E(\underline{a})$ has less than full column rank.*
3. *$\mathcal{B}$ contains a nonzero exponential trajectory w with frequency $\underline{a}$.*

If $\underline{a}$ satisfies these conditions, then it is called a characteristic point *of $\mathcal{B}$ or of M. The variety $V(\operatorname{ann}\mathcal{B})$ of all such points is called the* characteristic variety *of $\mathcal{B}$ or of M.*

Proof. Let g be the number of rows of E. By Lemma 2.6, duality preserves the annihilator, so $V(\operatorname{ann}\mathcal{B}) = V(\operatorname{ann} M)$. Write $I(\underline{a})$ for the set of all polynomials of $\mathcal{R}$ which vanish at the complex point $\underline{a}$. $I(\underline{a})$ is a maximal ideal of $\mathcal{R}$. The equivalence of the first two conditions follow since ann M and $\operatorname{Fitt}_0 M$, the ideal of qth order minors of E, are known to have the same radical [10, Prop. 20.6] and therefore vanish at the same points. Now we have that $(\mathcal{R}/I(\underline{a}))^{1,q}/(\mathcal{R}/I(\underline{a}))^{1,g}E(\underline{a}) = M/I(\underline{a})M$, and by Lemma 2.6 we also have

$$D(M/I(\underline{a})M) \;=\; [\mathcal{B} : I(\underline{a})],$$

the set of trajectories of $\mathcal{B}$ annihilated by $I(\underline{a})$. Hence $E(\underline{a})$ has less than full column rank if and only if $D(M/I(\underline{a})M) \neq 0$, or if and only if $\mathcal{B}$ contains a nonzero trajectory annihilated by $I(a)$. Finally, apply Theorem 4.1. □

The first condition of Theorem 4.4 has the advantage of being succinct, algebraic, and representation-independent. The second condition, which considers the points where the kernel representation has less than full column rank, is familiar from the classical theory of poles. The third condition gives a dynamic (trajectory) interpretation of the point, the details of which depend upon the signal space. The equivalence of the first two conditions of Theorem 4.4 is well known.

The characteristic variety is interesting only for autonomous behaviors, for it is different from $\mathbb{C}^n$ ($(\mathbb{C}\backslash 0)^n$) precisely when $\mathcal{B}$ is autonomous.

In fact, for a given characteristic point $\underline{a}$ of a behavior $\mathcal{B} = \ker_{\mathcal{A}} E$, it is possible to construct explicitly a nonzero exponential trajectory with frequency $\underline{a}$ in $\mathcal{B}$. Such a trajectory is given, for example, in the continuous complex case by $v_0 e^{a_1 t_1 + \cdots + a_n t_n}$, where v_0 is any nonzero element of the kernel of $E(\underline{a})$, acting on $\mathbb{C}^q$ on the right. Conversely, over the field $\mathbb{C}$ if $v_0 e^{a_1 t_1 + \cdots + a_n t_n} \in \mathcal{B}$, then $E(\underline{a})v_0 = 0$, because when working over $\mathbb{C}$ we can easily show for any exponential trajectory w that $E(\underline{\mathbf{z}})w = E(\underline{a})w$.

Note that the characteristic points are defined over the algebraic closure $\mathbb{C}$ of k. In the case $k = \mathbb{R}$, the subset of characteristic points in $\mathbb{R}^n$ or $(\mathbb{R}\backslash 0)^n$ correspond to exponential trajectories of the form $v_0 e^{a_1 t_1 + \cdots + a_n t_n}$ (continuous case) or $v_0 a_1^{t_1} \cdots a_n^{t_n}$ (discrete case). However, the information contained in this subset of the characteristic variety is insufficient to describe the exponential phenomena which the system may exhibit.

Example 4.5. Consider the 1D behavior over $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R})$ given by the kernel representation:

$$\mathcal{B} \;=\; \ker_{\mathcal{A}} E, \qquad E \;=\; \begin{pmatrix} z-5 & -2 \\ z & z-1 \end{pmatrix}.$$

Now E loses rank nowhere in $\mathbb{R}$, for its determinant is $z^2 - 4z + 5$, which has no roots in $\mathbb{R}$. Over $\mathbb{C}$, we have the roots $2 + \imath$, $2 - \imath$, and indeed, $\mathcal{B}$ admits the trajectory

$$w(t) \;=\; \begin{pmatrix} e^{2t}(3\sin t - \cos t) \\ e^{2t}(3\cos t - 4\sin t) \end{pmatrix},$$

which is exponential with frequency $2 + \imath$. However, $\mathcal{B}$ has no trajectories of the form $w(t) = \alpha e^{at}$, $a \in \mathbb{R}$, and the exponentially increasing/decreasing trajectories can only be found by considering the characteristic points in $\mathbb{C}\backslash\mathbb{R}$.

4.3. Associated and coassociated primes. We will find it useful to consider objects which describe the structure of a behavior $\mathcal{B}$ in a similar but slightly more detailed manner than $\operatorname{ann}\mathcal{B}$ and its corresponding variety.

Recall that an $\mathcal{R}$-module M and a prime ideal J give rise to the *localization* $M_J = \{\frac{m}{s} \mid m \in M, s \in \mathcal{R}\backslash J\}$, which is a module over the local ring $R_J = \{\frac{r}{s} \mid r \in \mathcal{R}, s \in \mathcal{R}\backslash J\}$.

DEFINITION 4.6. *Let M be an $\mathcal{R}$-module. The* support $\operatorname{supp} M$ *of M is the set of prime ideals J such that $M_J \neq 0$. The set* $\operatorname{Ass} M$ *of* associated primes *of M is the set of prime ideals of $\mathcal{R}$ which are annihilators of elements of M. These will also be called the* coassociated primes *of $\mathcal{B} = D(M)$.*

The following standard result can be found in, e.g., [3, Prop. II.4.17, Thm. IV.1.2] or [10, Cor. 2.7, Thm. 3.1].

THEOREM 4.7. *Let M be a finitely generated nonzero $\mathcal{R}$-module. Then the support of M is the set of all prime ideals containing* $\operatorname{ann} M$*. The set* $\operatorname{Ass} M$ *is finite, nonempty, contained in* $\operatorname{supp} M$*, and contains all the minimal prime divisors of* $\operatorname{ann} M$*.*

From the first claim of Theorem 4.7, a point $\underline{a}$ is a characteristic point of $\mathcal{B} = D(M)$ if and only if $\operatorname{ann} M \subseteq I(\underline{a})$, or equivalently, if and only if $M_{I(\underline{a})} \neq 0$. Indeed, much of the theory in this paper can be expressed formally in the language of localization; we will however use it sparingly.

From the last claim of Theorem 4.7, we can write the characteristic variety of $\mathcal{B}$ as the union of the varieties $V(J)$, J a coassociated prime of $\mathcal{B}$. There is redundancy in this decomposition, as it is also possible to write the characteristic variety as the union of the varieties corresponding to the minimal prime divisors of $\operatorname{ann} M$, called the *minimal primes* of M, only. The remaining associated primes of M, called *embedded primes*, correspond to proper subvarieties of those corresponding to the minimal primes. It is however necessary to consider all associated primes, since this makes available the primary decomposition theorem, which will be applied in section 7. In general, the coassociated primes of a behavior contain more information than the characteristic variety.

The next standard result will prove invaluable in breaking down the set of poles into subsets (e.g., controllable poles) with certain properties.

LEMMA 4.8. *Let M, M', M'' denote finitely generated $\mathcal{R}$-modules which form an exact sequence*

$$0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0.$$

Then $V(\operatorname{ann} M) = V(\operatorname{ann} M') \cup V(\operatorname{ann} M'')$ *and* $\operatorname{Ass} M' \subseteq \operatorname{Ass} M \subseteq (\operatorname{Ass} M') \cup (\operatorname{Ass} M'')$.

Proof. The first claim is found in [3, Chap. II, sect. 4.4] and the second in [3, Chap. IV, sect. 1.2] or [10, p. 92]. □

5. Controllable and uncontrollable poles. In this section we present our new definition of a pole of an nD system and provide a decomposition of the set of poles into *controllable* and *uncontrollable* poles. The controllable poles are poles of the controllable part of the system and are associated with the transfer matrix. The uncontrollable poles play the role of input-decoupling zeros.

5.1. Controllable and uncontrollable poles. In our motivational discussion at the beginning of section 4, we discussed the classical interpretation of a pole, as a frequency $\underline{a}$ for which the zero-input behavior contains a nonzero exponential

trajectory. We then discussed the characterization of such points $\underline{a}$ using the notion of the characteristic variety. We now use this notion to define a pole (point) in the obvious way. However, we do not yet consider states; these are introduced under the guise of latent variables in section 6. Note also the distinction between "poles," which are prime ideals, and "pole points," which are points in real or complex space.

DEFINITION 5.1. *Let $\mathcal{B} = D(M)$ be a behavior with a given input/output structure and controllable part $\mathcal{B}^c$.*

1. *The* pole variety*,* pole points*, and* poles *of $\mathcal{B}$ are defined to be the characteristic variety, characteristic points, and coassociated primes, respectively, of the zero-input behavior $\mathcal{B}_{0,y}$.*

2. *The* controllable pole variety*,* controllable pole points*, and* controllable poles *of $\mathcal{B}$ are defined to be the characteristic variety, characteristic points, and coassociated primes, respectively, of the behavior $(\mathcal{B}^c)_{0,y}$.*

3. *The* uncontrollable pole variety*,* uncontrollable pole points*, and* uncontrollable poles *of $\mathcal{B}$ are defined to be the characteristic variety, characteristic points, and coassociated primes, respectively, of the behavior $\mathcal{B}/\mathcal{B}^c$.*

These definitions are all new and are not trivially equivalent to any previously given definitions of which we are aware. The behaviors concerned in Definition 5.1, and the corresponding finitely generated modules, can be captured in a dual pair of commutative exact diagrams (5.1)–(5.2); compare with the diagrams on page 14 of [31].
