Furthermore there exists a feedback law $F : \mathbb{R}^n \to W$ *satisfying* $F(x) \in W_x$ *and* $F(\Lambda_\alpha x) = \Delta_\alpha F(x)$ *for all* $x \in \mathbb{R}^n$ *and all* $\alpha \ge 0$ *such that the corresponding sampled closed loop system is either*

(i) *semiglobally stable (if $\tau > 0$), or*
(ii) *globally uniformly exponentially stable (if $\tau = 0$), or*
(iii) *globally practically exponentially stable (if $\tau < 0$) with fixed sampling rate.*

(b) *The analogous result holds for system* (2.5) *satisfying Definition* 2.2. *Here we obtain*

$$\min_{v \in \operatorname{co} f(x,U)} DV(x;v) \le -2\mu N^\tau(x) V(x),$$

$F(x) \in U$, and $F(\Lambda_\alpha x) = F(x)$ for all $x \in \mathbb{R}^n$ and all $\alpha > 0$.

We will prove part (b) in section 4 and then use this result in order to prove part (a) in section 6.

4. Stabilization of systems homogeneous-in-the-state. In this section we will construct a Lyapunov function and a stabilizing feedback for system (2.9). Afterwards we retranslate this stabilization result to general systems homogeneous-in-the-state from Definition 2.2.

We start by characterizing asymptotic controllability of (2.9). For this purpose we introduce the finite time exponential growth rate (cf. [11, 12])

$$\lambda^t(x_0, u(\cdot)) = \frac{1}{t} \ln \frac{\|x(t, x_0, u(\cdot))\|}{\|x_0\|}.$$

It follows immediately from (2.9) that $x(t, \alpha x_0, u(\cdot)) = \alpha x(t, x_0, u(\cdot))$ and thus the growth rates satisfy $\lambda^t(x_0, u(\cdot)) = \lambda^t(\alpha x_0, u(\cdot))$ for all $x_0 \in \mathbb{R}^d \setminus \{0\}$ and all $\alpha > 0$. The meaning of λ^t is described by the following proposition.

PROPOSITION 4.1. *System* (2.9) *is asymptotically controllable if and only if there exist a time $T > 0$ and some $\rho > 0$ such that for each $x \in \mathbb{R}^n \setminus \{0\}$ there exists $u_x(\cdot) \in \mathcal{U}$ with*

$$\lambda^t(x, u_x(\cdot)) < -\rho \text{ for all } t \ge T. \tag{4.1}$$

Proof. Obviously (4.1) implies exponential controllability and thus, in particular, asymptotic controllability.

For the converse implication, since $\lambda^t(x, u(\cdot)) = \lambda^t(\alpha x, u(\cdot))$ it is sufficient to show (4.1) for $\|x\| = 1$, i.e. $x \in \mathbb{S}^{n-1}$. Asymptotic controllability implies that for each $x \in \mathbb{S}^{n-1}$ there exist $\tilde{u}_x(\cdot) \in \mathcal{U}$, $\tilde{t}_x > 0$, and $C_x > 0$ such that $\|\varphi(\tilde{t}_x, x, \tilde{u}_x(\cdot))\| < 1/2$, and $\|\varphi(t, x, \tilde{u}_x(\cdot))\| < C_x$ for all $t \in [0, \tilde{t}_x]$. By compactness of $\mathbb{S}^{n-1}$ and continuous dependence on the initial value we can choose the controls such that $T_1 = \sup_{x \in \mathbb{S}^{n-1}} \tilde{t}_x$ and $C = \sup_{x \in \mathbb{S}^{n-1}} C_x$ are finite. Now for each $x \in \mathbb{S}^{n-1}$ we define $u_x(\cdot)$ and a sequence t_i inductively by $t_0 = 0$ and

$$t_{i+1} = t_i + \tilde{t}_{x_i}, \quad u_x(t) = \tilde{u}_{x_i}(t - t_i),\ t \in [t_i, t_{i+1}],$$

where $x_i = \varphi(t_i, x, u_x(\cdot))/\|\varphi(t_i, x, u_x(\cdot))\|$. Now consider an arbitrary $t > 0$. Choosing t_i maximal with $t_i \le t$ (i.e., $t - t_i < T_1$ and $t_i > t - T_1$) this implies

$$\lambda^t(x, u_x(\cdot)) = \frac{t_i}{t} \lambda^{t_i}(x, u_x(\cdot)) + \frac{t - t_i}{t} \lambda^{t - t_i}(x_i, u_x(t_i + \cdot)) \le \frac{t - T_1}{t} \ln \frac{1}{2} + \frac{T_1}{t} \ln C,$$

where the last expression is independent of x and negative for all $t \ge T$ for $T > 0$ sufficiently large, which yields the assertion. ∎

In fact, we can show something more than just the negativity of the finite time exponential growth rates. We define the *Lyapunov exponent* of each trajectory by

$$\lambda(x, u(\cdot)) := \limsup_{t\to\infty} \lambda^t(x, u(\cdot))$$

and the supremum with respect to the state and infimum with respect to the control over these exponents by

$$\sigma := \sup_{x\in\mathbb{R}^n\setminus\{0\}} \inf_{u(\cdot)\in\mathcal{U}} \lambda(x, u(\cdot)).$$

Lyapunov exponents for control systems have been utilized in the analysis of bilinear systems (see, e.g., [6] for some basic concepts and [7] for a detailed exposition) and for the global stabilization of semilinear and the local stabilization of differentiable nonlinear systems at singular points [11]. In the homogeneous setup we obtain the following characterization.

PROPOSITION 4.2. *Consider the system* (2.9) *and its* sup-inf *Lyapunov exponent* σ. *Then for each* $\rho \in (0, |\sigma|)$ *there exists* $T > 0$ *such that for each* $x \in \mathbb{R}^n \setminus \{0\}$ *there exists* $u_x(\cdot) \in \mathcal{U}$ *with*

$$\lambda^t(x, u_x(\cdot)) < -\rho \text{ for all } t \geq T.$$

Proof. The proof is exactly as [11, Proof of Proposition 3.4]. □

Since by Proposition 4.1 for our class (2.9) of homogeneous systems asymptotic controllability immediately implies $\sigma < 0$, we obtain from Proposition 4.2 that (2.9) is asymptotically controllable if and only if $\sigma < 0$; i.e., we obtain a characterization of asymptotic controllability by means of Lyapunov exponents.

We will now use Proposition 4.2 for the construction of a homogeneous Lyapunov function for system (2.9). First observe that the projection

$$s(t, s_0, u(\cdot)) := \frac{x(t, x_0, u(\cdot))}{\|x(t, x_0, u(\cdot))\|}, \quad s_0 = \frac{x_0}{\|x_0\|}$$

of (2.9) onto $\mathbb{S}^{n-1}$ is well defined due to the homogeneity of the system. A simple application of the chain rule shows that s is the solution of

$$\dot{s}(t) = f_{\mathbb{S}}(s(t), u(t)), \quad f_{\mathbb{S}}(s, u) = f(s, u) - \langle s, f(s, u)\rangle s$$

and that for $s_0 = x_0/\|x_0\|$ the exponential growth rate λ^t satisfies

$$\lambda^t(x_0, u(\cdot)) = \lambda^t(s_0, u(\cdot)) = \frac{1}{t}\int_0^t q(s(\tau, s_0, u(\cdot)), u(\tau))d\tau$$

with $q(s, u) = \langle s, f(s, u)\rangle$. Unfortunately, this averaged integral does not allow a direct construction of a suitable Lyapunov function. Therefore we make use of an approximation by discounted integrals: Defining

$$J_\delta(s_0, u(\cdot)) := \int_0^\infty e^{-\delta\tau} q(s(\tau, s_0, u(\cdot)), u(\tau))d\tau$$

and the corresponding optimal value function

$$v_\delta(s_0) := \inf_{u(\cdot)\in\mathcal{U}} J_\delta(s_0, u(\cdot))$$

from Propositions 4.1 and 4.2 and [11, Lemma 3.5(i)] we obtain that if system (2.9) is asymptotically controllable then for each $\rho \in (0, |\sigma|)$ there exists $\delta_\rho > 0$ such that for all $\delta \in (0, \delta_\rho]$ and all $s_0 \in \mathbb{S}^{n-1}$ the inequality

$$\delta v_\delta(s_0) < -\rho$$

holds.

Note that v_δ is Hölder continuous and bounded for each $\delta > 0$; cf., e.g., [1]. We now fix some $\rho \in (0, \sigma)$ and some $\delta \in (0, \delta_\rho]$ and define

$$V_0(x) := e^{2v_\delta(x/\|x\|)}\|x\|^2.$$

LEMMA 4.3. *The function V_0 is a CLF which is homogeneous with degree* 1 *(with respect to the standard dilation) and satisfies*

$$\min_{v \in \mathrm{co} f(x,U)} DV_0(x; v) \le -2\rho V_0(x).$$

Proof. Homogeneity, positive definiteness, and properness follow immediately from the definition. Now for each $t > 0$ the function v_δ satisfies the dynamic programming principle

$$v_\delta(s_0) = \inf_{u(\cdot)\in\mathcal{U}} \left\{ \int_0^t e^{-\delta\tau} q(s(\tau, s_0, u(\cdot)), u(\tau))d\tau + e^{-\delta t} v_\delta(s(t, s_0, u(\cdot))) \right\};$$

see, e.g., [1]. Abbreviating $q(t, s_0, u(\cdot)) = q(s(t, s_0, u(\cdot)), u(t))$ and using $e^{-\delta t} - 1 \ge -\delta t$ we obtain for the integral part of this equality

$$\int_0^t e^{-\delta\tau} q(\tau, s_0, u(\cdot))d\tau \ge \int_0^t q(\tau, s_0, u(\cdot)) + (e^{-\delta t} - 1)M_q d\tau \ge t\lambda^t(s_0, u(\cdot)) - M_q\delta\frac{t^2}{2},$$

where M_q denotes a bound of $|q|$. Thus with $s_0 = x_0/\|x_0\|$ we obtain

$$\begin{aligned}
V_0(x_0) &\ge \inf_{u(\cdot)\in\mathcal{U}} \exp[2t\lambda^t(x, u(\cdot)) - M_q\delta t^2 + 2e^{-\delta t} v_\delta(s(t, s_0, u(\cdot)))]\|x_0\|^2 \\
&= \inf_{u(\cdot)\in\mathcal{U}} e^{2t\lambda^t(x,u(\cdot))} e^{-M_q\delta t^2} e^{2(e^{-\delta t}-1)v_\delta(s(t,s_0,u(\cdot)))} e^{2v_\delta(s(t,s_0,u(\cdot)))}\|x_0\|^2 \\
&= \inf_{u(\cdot)\in\mathcal{U}} \frac{\|x(t, x_0, u(\cdot))\|^2}{\|x_0\|^2} e^{-M_q\delta t^2} e^{2(e^{-\delta t}-1)v_\delta(s(t,s_0,u(\cdot)))} e^{2v_\delta(s(t,s_0,u(\cdot)))}\|x_0\|^2 \\
&= \inf_{u(\cdot)\in\mathcal{U}} e^{-M_q\delta t^2 + 2(e^{-\delta t}-1)v_\delta(s(t,s_0,u(\cdot)))} V_0(x(t, x_0, u(\cdot))) \\
&\ge \inf_{u(\cdot)\in\mathcal{U}} e^{-M_q\delta t^2 + 2(1-e^{-\delta t})\rho/\delta} V_0(x(t, x_0, u(\cdot))).
\end{aligned}$$

Now for each $t > 0$ we choose $u_t(\cdot) \in \mathcal{U}$ such that the infimum of the last expression is attained up to t^2. Using $b - b^2 \le 1 - e^{-b} \le b$ for $b > 0$ we can conclude

$$\begin{aligned}
V_0(x(t, x_0, u_t(\cdot))) - V_0(x_0) &\le (1 - e^{-M_q\delta t^2 + 2(1-e^{-\delta t})\rho/\delta}) V_0(x(t, x_0, u_t(\cdot))) + t^2 \\
&\le (1 - e^{-M_q\delta t^2 + 2t\rho - 2\delta t^2\rho}) V_0(x(t, x_0, u_t(\cdot))) + t^2 \\
&\le (-2t\rho + (M_q + 2\rho)\delta t^2) V_0(x(t, x_0, u(\cdot))) + t^2
\end{aligned}$$

for all $t > 0$ sufficiently small. Denoting $v_t = (x(t, x_0, u_t(\cdot)) - x_0)/t$ we obtain

$$\frac{1}{t}\left(V_0(x_0 + tv_t) - V_0(x_0)\right) \leq -2\rho V_0(x(t, x_0, u(\cdot))) + (M_q + 2\rho)\delta t V_0(x(t, x_0, u(\cdot))) + t$$

and since by compactness of U there exists a $v \in \mathrm{co} f(x_0, U)$ and a sequence $t_i \to 0$ such that $v_{t_i} \to v$ as $i \to \infty$ the assertion follows by the definition of DV_0. □

Based on V_0 and using the techniques from [5] (but with a more careful evaluation of the constants involved) we can now construct the stabilizing feedback law for system (2.9). To this end, for $\beta > 0$ we consider the approximation of V_0 via the inf-convolution

$$V_\beta(x) = \inf_{y \in \mathbb{R}^n} \left\{ V_0(y) + \frac{\|x - y\|^2}{2\beta^2} \right\}. \tag{4.2}$$

Observe that V_β is locally Lipschitz and $V_\beta \to V_0$ as $\beta \to 0$.

PROPOSITION 4.4. *For each $\mu \in (0, \rho)$ there exists $\beta > 0$ such that the function V_β is a Lipschitz continuous CLF which is homogeneous with degree 1 (with respect to the standard dilation) and satisfies*

$$\min_{v \in \mathrm{co} f(x,U)} DV_\beta(x; v) \leq -2\mu V_\beta(x).$$

Furthermore there exists a feedback law $F : \mathbb{R}^n \to U$ satisfying $F(\alpha x) = F(x)$ for all $x \in \mathbb{R}^n$, $\alpha > 0$ and constants $h > 0$ and $C > 0$ such that any π-trajectory corresponding to some partition π with $d(\pi) \leq h$ satisfies

$$\|x_\pi(t, x_0, F)\| \leq Ce^{-\mu t}\|x_0\|. \tag{4.3}$$

Proof. By its definition V_β is obviously positive definite. Now for each $x \in \mathbb{R}^n$ we denote by $y_\beta(x)$ a point realizing the minimum on the right-hand side of (4.2). Since V_0 is homogeneous with degree 1 we have that

$$\left\{ V_0(\alpha y) + \frac{\|\alpha x - \alpha y\|^2}{2\beta^2} \right\} = \alpha^2 \left\{ V_0(y) + \frac{\|x - y\|^2}{2\beta^2} \right\}$$

and thus in particular V_β is also homogeneous with degree 1 and hence proper, and we can choose $y_\beta(x)$ in such a way that $y_\beta(\alpha x) = \alpha y_\beta(x)$. Since V_0 is strictly increasing along the rays αx in $\alpha > 0$ it follows that $\|y_\beta(x)\| \leq \|x\|$.

Now we define

$$\zeta_\beta(x) := \frac{x - y_\beta(x)}{2\beta^2}$$

which implies $\zeta_\beta(\alpha x) = \alpha \zeta_\beta(x)$.

By [5, Lemma III.1 and III.2] (or by straightforward calculations) for this vector we can deduce the inequalities

$$V_\beta(x + \tau v) \leq V_\beta(x) + \tau\langle \zeta_\beta(x), v\rangle + \frac{\tau^2\|v\|^2}{2\beta^2} \tag{4.4}$$

and

$$V_0(y_\beta(x) + \tau v) \geq V_0(y_\beta(x)) + \tau\langle \zeta_\beta(x), v\rangle - \frac{\tau^2\|v\|^2}{2\beta^2}; \tag{4.5}$$

i.e., $\zeta_\beta(x)$ is a proximal supergradient of V_β in x and a proximal subgradient of V_0 in $y_\beta(x)$ (see, e.g., [3] for an exposition of these concepts). We choose the feedback $F(x)$ in such a way that

$$\langle \zeta_\beta(x), f(x, F(x))\rangle = \inf_{u\in U}\langle \zeta_\beta(x), f(x,u)\rangle$$

and $F(\alpha x) = F(x)$ for all $x \in \mathbb{R}^n \setminus \{0\}$ and all $\alpha > 0$. The value $F(0)$ can be chosen arbitrarily.

Now consider points $x \in \mathbb{R}^n$ with $\|x\| = 1$, i.e. $x \in \mathbb{S}^{n-1}$. For these points the Hölder continuity of V_0 (which is inherited from the Hölder continuity of v_δ) and the definitions of V_β and ζ_β imply

$$\frac{1}{2\beta^2}\|y_\beta(x) - x\|^2 \le V_0(x) - V_0(y_\beta(x)) \le H\|y_\beta(x) - x\|^\nu$$

and thus

$$\|\zeta_\beta(x)\|\|y_\beta(x) - x\| \le \bar{H}\beta^{\frac{2\nu}{2-\nu}} \quad \text{with} \quad \bar{H} = 2^{\frac{2\nu-2}{2-\nu}} H^{\frac{2}{2-\nu}}, \tag{4.6}$$

where $H > 0$ and $\nu \in (0, 1]$ denote the Hölder constant and exponent of V_0 on $\{x \in \mathbb{R}^n \mid \|x\| \le 1\}$. From (4.6) and the definition of V_β we immediately obtain

$$|V_0(y_\beta(x)) - V_\beta(x)| \le \bar{H}\beta^{\frac{2\nu}{2-\nu}}. \tag{4.7}$$

Now the Lipschitz continuity of f implies that

$$\langle \zeta_\beta(x), f(x, F(x))\rangle \le \min_{u\in U}\langle \zeta_\beta(x), f(y_\beta(x), u)\rangle + L\|\zeta_\beta(x)\|\|y_\beta(x) - x\|$$

and by (4.5) and the definition of DV_0 it follows that $\langle \zeta_\beta(x), v\rangle \le DV_0(y_\beta(x), v)$ for all $v \in \mathbb{R}^n$. Thus by the linearity of the scalar product and Lemma 4.3 we can conclude

$$\min_{u\in U}\langle \zeta_\beta(x), f(y_\beta(x), u)\rangle = \min_{v\in \operatorname{co} f(y_\beta(x),U)}\langle \zeta_\beta(x), v\rangle \le -2\rho V_0(y_\beta(x)).$$

Combining these inequalities with (4.6) and (4.7) yields

$$\langle \zeta_\beta(x), f(x, F(x))\rangle \le -2\rho V_\beta(x) + 2\rho\bar{H}\beta^{\frac{2\nu}{2-\nu}} + L\bar{H}\beta^{\frac{2\nu}{2-\nu}}. \tag{4.8}$$

Defining

$$f_x^\tau := \frac{1}{\tau}\int_0^\tau f(x(t, x, F(x)), F(x))dt$$

and using $M := \sup_{\|x\|\le 2, u\in U} f(x, u)$ and the Lipschitz continuity of f for $\tau > 0$ sufficiently small we obtain

$$\|f_x^\tau - f(x, F(x))\| \le ML\tau, \quad \|f_x^\tau\| \le M.$$

Thus by (4.4), (4.8), and the fact that $\|\zeta_\beta(x)\| \le C_\beta$ for all $x \in \mathbb{S}^{n-1}$ and some suitable $C_\beta > 0$ we can conclude

$$\begin{aligned} V_\beta(x(\tau, x, F(x))) - V_\beta(x) &= V_\beta(x + \tau f_x^\tau) - V_\beta(x) \\ &\le \tau\langle \zeta_\beta(x), f_x^\tau\rangle + \frac{\tau^2\|f_x^\tau\|^2}{2\beta^2} \\ &\le \tau\langle \zeta_\beta(x), f(x, F(x))\rangle + ML\tau^2\|\zeta_\beta(x)\| + \frac{\tau^2 M^2}{2\beta^2} \\ &\le \tau(-2\rho V_\beta(x) + (2\rho + L)\bar{H}\beta^{\frac{2\nu}{2-\nu}}) + \tau^2\left(MLC_\beta + \frac{M^2}{2\beta^2}\right). \end{aligned}$$

Denoting

$$\gamma_\beta := \sup_{x\in\mathbb{S}^{n-1}} \frac{(2\rho+L)\bar{H}\beta^{\frac{2\nu}{2-\nu}}}{V_\beta(x)}, \quad \tilde{C}_\beta := \sup_{x\in\mathbb{S}^{n-1}} \frac{MLC_\beta}{V_\beta(x)} + \frac{M^2}{2\beta^2 V_\beta(x)}$$

and exploiting homogeneity of $x(\cdot,x,F(x))$ and V_β, we obtain for arbitrary $x\neq 0$

$$V_\beta(x(\tau,x,F(x))) - V_\beta(x) \le \tau(-2\rho+\gamma_\beta)V_\beta(x) + \tau^2\tilde{C}_\beta V_\beta(x).$$

Now let $\varepsilon = \rho-\mu$, choose $\beta>0$ such that $\gamma_\beta\le\varepsilon$, and $\Delta t>0$ such that $\Delta t\tilde{C}_\beta\le\varepsilon$. Then we obtain

$$V_\beta(x(\tau,x,F(x))) - V_\beta(x) \le -2\tau\mu V_\beta(x)$$

for all $\tau\in(0,\Delta t]$, which implies the first assertion, and by

$$V_\beta(x(\tau,x,F(x))) \le V_\beta(x) - 2\tau\mu V_\beta(x) \le e^{-2\tau\mu}V_\beta(x)$$

we obtain the second assertion by the homogeneity of degree 1 of V_β. □

This proposition shows the stabilization for systems of type (2.9). In order to prove Theorem 3.5(b) it remains to retranslate this result to general homogeneous-in-the-state systems.

Proof of Theorem 3.5(b). Obviously, if the system defined by f is asymptotically controllable, then the transformed system defined by $\bar{f}$ is asymptotically controllable. Thus from Proposition 4.4 we obtain $\bar{V}=V_\beta$ and $\bar{F}=F$ satisfying the assertion for $\bar{f}$ which is homogeneous-in-the-state with $\Lambda_\alpha=\alpha\mathrm{Id}$, $k=1$, and $\tau=0$.

We start by showing the result for the system defined by $\tilde{f}(x,u)=\bar{f}(x,u)\|x\|^\gamma$ being homogeneous-in-the-state with $\Lambda_\alpha=\alpha\mathrm{Id}$, $k=1$, and $\tau=\gamma$. Let $\tilde{V}(x)=\bar{V}(x)$. Then we immediately obtain

$$\min_{v\in\mathrm{co}\tilde{f}(x,U)} D\tilde{V}(x;v) = \|x\|^\gamma \min_{v\in\mathrm{co}\bar{f}(x,U)} D\tilde{V}(x;v) \le -\|x\|^\gamma 2\mu\tilde{V}(x).$$

Now observe that for each control function $u(\cdot)\in\mathcal{U}$ the trajectories $\tilde{x}$ and $\bar{x}$ of these systems satisfy

$$\tilde{x}(t,x_0,u(\cdot)) = \bar{x}(\bar{t}(t),x_0,u(\tilde{t}(\cdot))), \tag{4.9}$$

where $\tilde{t}(t)$ denotes the inverse of $\bar{t}(t)$ which is defined by

$$\bar{t}(t) = \int_0^t \|\tilde{x}(\tau,x_0,u(\cdot))\|^\gamma d\tau$$

and thus is well defined as long as the solution $\tilde{x}(t,x_0,u(\cdot))$ exists. If both $\tilde{x}$ and $\bar{x}$ uniquely exist for all $t\ge 0$ it is immediate that $\bar{t}(t)\to\infty$ as $t\to\infty$.

Setting $\tilde{F}(x)=\bar{F}(x)$ a $\tilde{\pi}$-trajectory $\tilde{x}_{\tilde{\pi}}(t,x_0,\tilde{F})$ of

$$\dot{\tilde{x}} = \tilde{f}(\tilde{x},\tilde{F}(\tilde{x})) \tag{4.10}$$

on some interval $[0,T]$ on which $\tilde{x}_\pi$ exists becomes a $\bar{\pi}$-trajectory $\bar{x}_{\bar{\pi}}(\bar{t}(t),x_0,\bar{F})$ of

$$\dot{\bar{x}} = \bar{f}(\bar{x},\bar{F}(\bar{x})), \tag{4.11}$$

where $\bar\pi = (\bar t_i)_{i\in\mathbb{N}_0}$ is given by $\bar t_i = \bar t(\tilde t_i)$ with $\tilde\pi = (\tilde t_i)_{i\in\mathbb{N}_0}$. Now we distinguish the three cases.

(i) $\gamma > 0$: By the choice of $\bar F$ there exist $C, \mu, h > 0$ such that inequality (4.3) holds for each $\bar\pi$-trajectory $\bar x_{\bar\pi}$ of (4.11) with $d(\bar\pi) \le h$ and each $x \in \mathbb{R}^n$. Now consider a compact set $K \subset \mathbb{R}^n$ with $0 \in \operatorname{int} K$. Let $C_K := \sup_{x\in K} \|x\|$, consider a $\tilde\pi$-trajectory $\tilde x_{\tilde\pi}(t, x_0, \tilde F)$ of (4.10) with $d(\tilde\pi) \le h(CC_K)^{-\gamma}$ and $x \in K$, and assume that there exists a (minimal) time $t^* > 0$ such that $\|\tilde x_{\tilde\pi}(t^*, x_0, \tilde F)\| = C\|x\|$. Without loss of generality we may assume $t^* = \tilde t_l \in \tilde\pi$ for some $l > 0$, otherwise we may reduce the sampling interval containing t^*. Then since $\|\tilde x_{\tilde\pi}(t, x_0, \tilde F)\| \le CC_K$ for all $t \in [0, \tilde t_l]$ the rescaled $\bar\pi$ satisfies $\bar t_i - \bar t_{i-1} \le h$ for all $i = 1, \dots, l$; thus we obtain

$$\|\tilde x_{\tilde\pi}(\tilde t_l, x_0, \tilde F)\| = \|\bar x_{\bar\pi}(\bar t_l, x_0, \bar F)\| \le Ce^{-\mu\bar t_l}\|x_0\| < C\|x_0\|$$

contradicting the choice of $t^* = \tilde t_l$. Thus $\|\tilde x_{\tilde\pi}(t, x_0, \tilde F)\| \le C\|x\|$ holds for all $t \ge 0$, and hence $d(\bar\pi) \le h$, implying

$$\|\tilde x_{\tilde\pi}(t, x_0, \tilde F)\| \le Ce^{-\mu\bar t(t)}\|x_0\|$$

which implies the desired stability estimate with $\beta(\|x\|, t) = Ce^{-\mu\bar t(t)}\|x\|$ which is of class $\mathcal{KL}$ because the corresponding trajectories stay inside some compact set, thus exist for all $t \ge 0$, and are unique since $\gamma > 0$, hence $\bar t(t) \to \infty$ as $t \to \infty$.

(ii) $\gamma = 0$: In this case the assumption follows immediately from Proposition 4.4.

(iii) $\gamma < 0$: As in case (i) there exist $C, \mu, h > 0$ such that inequality (4.3) holds for each $\bar\pi$-trajectory $\bar x_{\bar\pi}$ of (4.11) with $d(\bar\pi) \le h$ and each $x \in \mathbb{R}^n$. Consider a compact set $K \subset \mathbb{R}^n$ and an open set $B \subset \mathbb{R}^n$ with $0 \in B \subset K$. Let $C_K = \sup_{x\in K} \|x\|$, $C_B = \inf_{x\notin B} \|x\|/2 > 0$. By continuous dependence on the initial value and compactness we can choose $s > 0$ such that $\|\tilde x(t, x_0, u)\| \le 2C^{-1}C_B$ for all $\|x_0\| = C^{-1}C_B$, all $u \in U$, and all $t \in [0, s]$. Then (2.7) implies (recall $\tau = \gamma < 0$ and $\Lambda_\alpha = \alpha\mathrm{Id}$) the inequality $\|\tilde x(t, x_0, u)\| \le 2\|x_0\|$ for all $\|x_0\| \ge C^{-1}C_B$, all $u \in U$, and all $t \in [0, s]$.

Now pick an arbitrary $\tilde\pi$-trajectory $\tilde x_{\tilde\pi}(t, x_0, \tilde F)$ of (4.10) with $\tilde\pi$ satisfying $d(\tilde\pi) \le \min\{h(C^{-1}C_B)^{-\gamma}, s\}$ and $x_0 \in K$, $\|x_0\| \ge C^{-1}C_B$, and consider an interval $[t_*, t^*]$ such that $\|\tilde x_{\tilde\pi}(t, x, \tilde F)\| \ge C^{-1}C_B$ for all $t \in [t_*, t^*]$. Then we either have $t_* = 0 = \tilde t_0$ or there exist sampling times such that $t_* \in [\tilde t_{i-1}, \tilde t_i]$. In this case by $d(\tilde\pi) \le s$ and the choice of s we obtain $\|\tilde x_{\tilde\pi}(\tilde t_i, x_0, \tilde F)\| \le 2\|\tilde x_{\tilde\pi}(t_*, x_0, \tilde F)\|$.

Analogously to the case $\gamma > 0$ the choice of $d(\tilde\pi)$ now implies $d(\bar\pi) \le h$ and thus

$$\|\tilde x_{\tilde\pi}(t, x_0, \tilde F)\| \le Ce^{-\mu(\bar t(t) - \bar t(\tilde t_i))}\|\tilde x_{\tilde\pi}(\tilde t_i, x_0, \tilde F)\| \tag{4.12}$$

for all $t \in [\tilde t_i, t^*]$. This estimate implies that for each trajectory there exists a (minimal) time $T \ge 0$ such that the trajectory hits the set $\{x \in \mathbb{R}^n \mid \|x\| \le C^{-1}C_B\}$, and up to that time (4.12) implies the desired estimate with $\beta(\|x_0\|, t) = Ce^{-\mu\bar t(t)}\|x\| \le Ce^{-\mu(CC_K)^\gamma t}\|x_0\|$. After that time T, whenever the trajectory leaves this set at some time $t_* \ge T$ inequality (4.12) implies that it will enter again at some time $t^* > t_*$ and satisfies $\|\tilde x_{\tilde\pi}(t, x_0, \tilde F)\| \le 2CC^{-1}C_B = 2C_B$ for all $t \in [t_*, t^*]$. Hence $\|\tilde x_{\tilde\pi}(t, x_0, \tilde F)\| \le 2C_B$ for all $t \ge T$, and since $\|x\| \le 2C_B$ implies $x \in B$ we obtain the practical stability property.

So far we have shown the existence of $\tilde V$ and $\tilde F$ satisfying the assumptions of the theorem for $\tilde f$; hence it remains to translate the results to f. To this end we define $V(x) = \tilde V(\Psi(x))$ and $F(x) = \tilde F(\Psi(x))$. This implies

$$DV(x; f(x, u)) = D\tilde V(\Psi(x))\tilde f(\Psi(x), u)$$

and

$$x_\pi(t,x,F) = \tilde{x}_\pi(t,\Psi(x),\tilde{F})$$

and thus immediately the assertion since $\|\Psi(x)\| = N^k(x)$. □

5. Numerical approximation of V and F. In this section we briefly explain how a numerical approximation to the CLF V and the feedback law F can be computed.

Unfortunately, up to now no numerical method for the approximation of v_δ, V_0, or V_β is known, which also gives an approximation of the super- or subgradients and thus allows the approximation of F. However, if we slightly change our feedback concept (or, more precisely, the notion of a closed loop system) an approximation is possible. For this purpose we introduce the following definition.

DEFINITION 5.1. *Let $h : \mathbb{R}^n \to \mathbb{R}^+$ be an arbitrary map. A feedback law $F^h : \mathbb{R}^n \to U$ is called a* discrete feedback *if we apply it as a sampled feedback according to Definition* 3.2 *with fixed state dependent intersampling times $\Delta t_i = h(x_\pi(t_i, x_0, F^h))$.*

This definition generalizes the one given in [8] in the sense that the time step h may now depend on x. The name "discrete feedback" is motivated by the fact that the resulting system can be written as a discrete time system $x_{i+1} = x(h(x_i), x_i, F^h(x_i))$ for which F^h is a feedback law in the classical sense.

Returning to our simplified system (2.9), and again fixing some $\rho > 0$ and $\delta \in (0,\rho)$, we can apply the results from [8, 9], observing that the structural assumptions on the system in these references (i.e., bi- or semilinearity, accessibility, convexity of U) are needed only in order to show $v_\delta(x) < 0$. In particular, all the numerical approximation results remain valid; thus we can proceed as in [8, 9] and (i) approximate $\mathcal{U}$ by piecewise constant control functions, (ii) approximate the trajectories and the integral by numerical schemes, and (iii) compute an approximation of v_δ on a grid discretizing the state space $\mathbb{S}^{n-1}$. Proceeding this way for any given $\varepsilon > 0$ we find $h > 0$ and numerically computable functions $v_\delta^h : \mathbb{S}^{n-1} \to \mathbb{R}$ and $F_{\mathbb{S}}^h : \mathbb{S}^{n-1} \to U$ such that

$$v_\delta^h(s) \le -\rho + \varepsilon \tag{5.1}$$

and

$$v_\delta^h(s) + \varepsilon \ge \int_0^h q(s(t,s,F_{\mathbb{S}}^h(s)), F_{\mathbb{S}}^h(s))dt + e^{-\delta h} v_\delta^h(s(h,s,F_{\mathbb{S}}^h(s))) \tag{5.2}$$

hold for each $s \in \mathbb{S}^{n-1}$. This function v_δ^h is the function $\tilde{v}_\delta^a$ from [8]; inequality (5.1) follows from [8, Theorems 3.3, 5.3, and inequality (5.4)], inequality (5.2) is easily extracted from the proofs of [8, Lemma 5.1, Lemma 5.2, and Proposition 5.4] using again [8, inequality (5.4)]. The feedback $F_{\mathbb{S}}^h$ is defined by choosing a control value minimizing the right-hand side of (5.2) using the numerical approximations of the trajectory and the integral. Observe that the state space $\mathbb{S}^{n-1}$ to be discretized here is somewhat more difficult to handle than the projective space $\mathbb{P}^{n-1}$ appearing in [8, 9], since for $n \ge 3$ a single map cannot be sufficient for the parametrization of $\mathbb{S}^{n-1}$ without introducing singularities. Hence, numerically, one either needs to work directly on $\mathbb{S}^{n-1}$, or one has to compute the solution using two parametrizations (e.g., the stereographic projection from the north and south pole) and consequently two grids for the representation of v_δ^h in local coordinates. This method was used for the second example in section 7.

Defining $F^h(x) = F^h_{\mathbb{S}}(x/\|x\|)$ analogous to Proposition 4.3 we can conclude that the function

$$V^h(x) := e^{2v^h_\delta(x/\|x\|)}\|x\|$$

is homogeneous, proper, and positive definite and satisfies

$$V^h(x(h,x,F^h(x))) \le (1 - 2h\rho + M(\varepsilon + \varepsilon h + h^2))V^h(x)$$

for some suitable constant $M > 0$ independent of h and ε; i.e., for any $\rho' \in (0,\rho)$ there exist sufficiently small $h > 0$ and $\varepsilon > 0$ such that

$$V^h(x(h,x,F^h(x))) \le (1 - 2h\rho')V^h(x). \tag{5.3}$$

Thus the function V^h is a (discrete time) Lyapunov function for the system controlled by the discrete feedback F^h according to Definition 5.1 with $h(x) \equiv h$, which immediately implies (exponential) stability.

As in the proof of Theorem 3.5(b) we can retranslate this result to arbitrary homogeneous-in-the-state systems. Analogous to the proof of this theorem denote the functions obtained for (2.9) by $\bar F^h$, $\bar V^h$, and $\bar h$. For the retranslation from $\bar f$ to $\tilde f$ we can use $\tilde F^h = \bar F^h$ and $\tilde F^h = \bar V^h$; however, following (4.9) we now have to use $\tilde h(x) = \tilde t(\bar h, x)$ as intersampling times, where

$$\tilde t(\bar h, x) = \int_0^{\bar h} \|\bar x(\tau, x, F^h(x))\|^{-\gamma} d\tau.$$

Passing from $\tilde f$ to f we define—again analogously to the proof of Theorem 3.5(b)—the feedback $F^h(x) = \tilde F^h(\Psi(x))$, the Lyapunov function $V^h(x) = \tilde V^h(\Psi(x))$, and the intersampling time $h(x) = \tilde h(\Psi(x))$. This way it is straightforward to see that (5.3)—now for the x-dependent h—remains valid and thus stability follows.

Observe that the time steps $h(x)$ are bounded from below by some positive constant on each compact set if and only if $\tau \ge 0$, and they are bounded on each open set not containing the origin if and only if $\tau \le 0$. In this way they behave just like the sampling rate for the theoretical feedback law from Theorem 3.5(b); however, here the stability is only guaranteed for these fixed intersampling times $h(x)$ and not for smaller ones as allowed in Definition 3.4.

6. Stabilization of homogeneous systems. We now return to the homogeneous system from Definition 2.1. The idea of the proof of Theorem 3.5(a) lies in the fact that for any asymptotically controllable homogeneous system we can find an asymptotically controllable homogeneous-in-the-state system. For this we find a CLF and a stabilizing feedback law by Theorem 3.5(b), which—retranslated to the homogeneous system—have the properties as stated in Theorem 3.5(a).

For this purpose recall that for each homogeneous system (2.1) we find an associated homogeneous-in-the-state system by (2.8). The following proposition shows that this system inherits the asymptotic controllability property.

PROPOSITION 6.1. *Consider a system* (2.1) *satisfying Definition* 2.1. *Assume that the system is asymptotically controllable. Then there exists a compact set of control values $U \subset W$ such that the homogeneous-in-the-state system* (2.8) *is asymptotically controllable using control functions with values in U.*

Proof. First observe that due to (2.7) it is sufficient to show that there exists a compact $U \subset W$ and a time $T > 0$ such that any initial value x_0 with $N(x_0) = 1$ can

be steered to some point x_1 with $N(x_1) \le 1/2$ in some time $t < T$ using a measurable control $u(\cdot)$ with $u(t) \in U$ for almost all $t \ge 0$. With this property asymptotic controllability easily follows by induction from (2.7).

In order to show the existence of this U first observe that, denoting the trajectories of f and g by x_f and x_g, respectively, the equality

$$x_f(t, x_0, u(\cdot)) = x_g(t, x_0, w(\cdot)) \quad \text{with } u(t) = \Delta^{-1}_{N(x_g(t,x_0,w(\cdot)))} w(t) \tag{6.1}$$

holds. Now consider the initial values $x_0 \in N^{-1}(1)$. For each of these points there exists a control $w_{x_0}(\cdot) \in \mathcal{W}$ such that $N(x_g(t_{x_0}, x_0, w_{x_0}(\cdot))) = 1/3$. Now by continuous dependence of the solution on the initial value we obtain that for each x_0 there exists an open neighborhood $B_{x_0} \ni x_0$ such that

$$N(x_g(t_{x_0}, x, w_{x_0}(\cdot))) \le 1/2$$

for all $x \in B_{x_0}$. Since $N^{-1}(1)$ is compact and is covered by the B_{x_0} we find a finite number $M \in \mathbb{N}$ of points x_0^i, $i = 1, \dots, M$, such that the sets $U_{x_0^i}$, $i = 1, \dots, M$, cover $N^{-1}(1)$. Thus setting $t_i = t_{x_0^i}$ and $w_i(\cdot) = w_{x_0^i}(\cdot)$ for each $x_0 \in N^{-1}(1)$ there exists a number $i \in \{1, \dots, M\}$ such that

$$N(x_g(t_i, x_0, w_i(\cdot))) \le 1/2.$$

Now we choose $u_i(t) = \Delta^{-1}_{N(x_g(t,x_0,w_i(\cdot)))} w_i(t)$ for all $t \in [0, t_i]$, $u_i(t) \in W$ arbitrary for $t > t_i$. Then by (6.1) we immediately obtain

$$N(x_f(t_i, x, u_i(\cdot))) \le 1/2$$

for each $x_0 \in N^{-1}(1)$ and some suitable $i \in \{1, \dots, M\}$. Since the functions $w_i(\cdot)$ are locally essentially bounded, i.e., essentially bounded on $[0, t_i]$, we can conclude that the functions $u_i(\cdot)$ are essentially bounded. Thus $\|u_i(\cdot)\|_\infty$ is finite for each $i = 1, \dots, M$ and also $\sup_{i=1,\dots,M} \|u_i(\cdot)\|_\infty$ is finite; hence there exists a compact $U \subset W$ such that $u_i(t) \in U$ for almost all $t > 0$ and all $i = 1, \dots, M$. ∎

Now we can complete the proof of Theorem 3.5.

Proof of Theorem 3.5(a). Consider the system homogeneous-in-the-state as defined by (2.8) with $U \subset W$ from Proposition 6.1. For this system from part (b) of this theorem we obtain a CLF V_f and a feedback F_f. Setting $V = V_f$ and $F(x) = \Delta_{N(x)} F_f(x)$ we immediately obtain the assertion. ∎

7. Examples. Finally, let us illustrate our results by two examples. The first example

$$g(x, w) = \begin{pmatrix} x_1 + w \\ 3x_2 + x_1 w^2 \end{pmatrix} \tag{7.1}$$

for $x = (x_1, x_2)^T \in \mathbb{R}^2$, $w \in W = \mathbb{R}$, is taken from [24], where it has been shown that a stabilizing continuous and homogeneous feedback law cannot exist for this system.

The vector field g is homogeneous with $\Lambda_\alpha = \operatorname{diag}(\alpha, \alpha^3)$ and $\Delta_\alpha = \alpha$. Thus we obtain $N(x) = (x_1^6 + x_2^2)^{1/6}$. For system (7.1) a stabilizing discrete feedback F^h has been computed numerically using the techniques of section 5. Analyzing the switching curves of the numerical feedback in this case, it was easy to derive the feedback

$$F(x) = \begin{cases} N(x), & x_1 \le -x_2^3, \\ -N(x), & x_1 > -x_2^3, \end{cases}$$

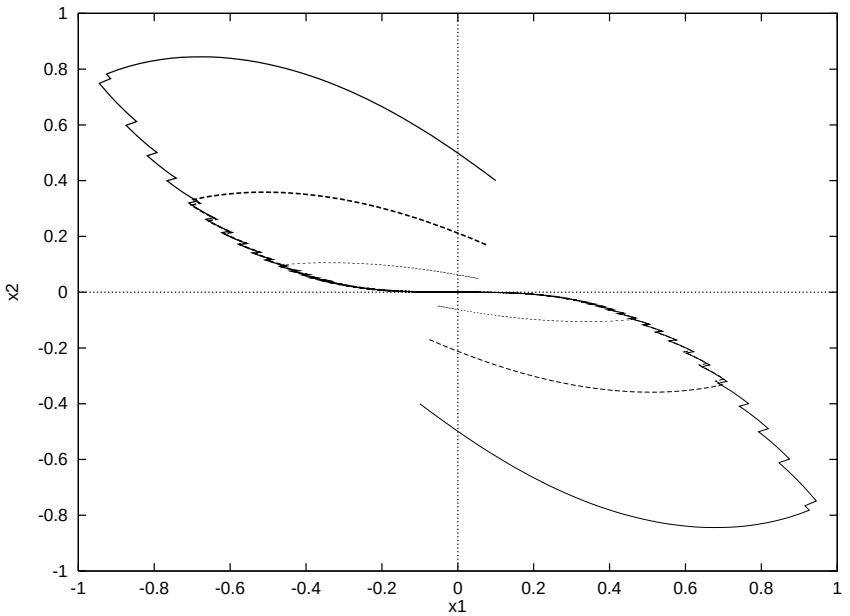

FIG. 7.1. *Trajectories for stabilized system* (7.1).

stabilizing the sampled system for all sufficiently small sampling rates. Figure 7.1 shows the corresponding (numerically simulated) sampled trajectories for some initial values; here the intersampling times have been chosen as $\Delta t_i = 0.01$ for all $i \in \mathbb{N}_0$.

The second example is the nonholonomic integrator given by Brockett [2] as an example for a system being asymptotically null controllable but not stabilizable by a continuous feedback law.

In suitable coordinates (cf. [26], where the physical meaning is also discussed) it reads

$$g(x,w) = \begin{pmatrix} w_1 \\ w_2 \\ x_1 w_2 \end{pmatrix} \tag{7.2}$$

for $x = (x_1, x_2, x_3)^T \in \mathbb{R}^3$, $w = (w_1, w_2)^T \in W = \mathbb{R}^2$. For this g we obtain homogeneity with $\Lambda_\alpha = \operatorname{diag}(\alpha, \alpha, \alpha^2)$ and $\Delta_\alpha = \operatorname{diag}(\alpha, \alpha)$, hence $N(x) = (x_1^4 + x_2^4 + x_3^2)^{1/4}$. Again a stabilizing discrete feedback law F_h has been computed numerically following section 5.

In this example it is also possible, in principle, to derive an explicit formula from the numerical results; it is, however, considerably more complicated, since a number of switching surfaces have to be identified. Hence we directly used the numerical approximation F^h of F for the simulation shown in Figures 7.2–7.4 in different projections; the time step is $h = 0.01$, and the control values were chosen as $U = \{-1, 1\}$.

ON THE EFFECT OF NEGLECTING SENSOR DYNAMICS IN PARAMETER IDENTIFICATION PROBLEMS*

ASEN L. DONTCHEV†, MICHAEL P. POLIS‡, AND VLADIMIR M. VELIOV§

Abstract. In this paper, we consider a deterministic parameter identification problem for a nonlinear control system subject to disturbances and with output measured by a sensor with fast dynamics. We study the effect of neglecting sensor dynamics on the set of parameter values that are consistent with the measurements. We show that when neglecting dynamics we must significantly modify the corresponding static model of the sensor in order to obtain a set of parameter values that contains the true value and is consistent with the measurements. We describe a correct model of the static sensor which is in a sense minimal.

Key words. deterministic parameter identification, sensor dynamics, nonlinear control, singular perturbations, invariance

1. Introduction.

In deterministic parameter identification the goal is to find a set of values of an unknown parameter vector which are consistent with the measurements; for a collection of recent papers in this field see [12]. In virtually all work in this field the dynamics of the sensor are ignored by assuming instantaneous response. This assumption considerably simplifies the model and improves the numerical tractability of the problem. In this paper, we show that ignoring the fast dynamics may lead to unsatisfactory effects. More specifically, we consider a nonlinear control system subject to disturbances whose output is measured by a sensor with fast dynamics described by a singularly perturbed ordinary differential equation. We show that when neglecting fast dynamics we must significantly modify the model of the sensor in order to obtain a set of parameter values that contains the true value. We describe a model of the static sensor which is in a sense minimal to obtain correct parameter identification results.

The effects of neglecting sensor/actuator dynamics have been studied by Leitmann, Ryan, and Steinberg [10], Corless, Leitmann, and Ryan [5], and Kenneth and Taylor [8], in the context of stabilization and observation problems. In the present paper we explore this effect from the point of view of parameter identification, a problem which, to the authors' knowledge, has not been considered in the literature. In our analysis, we use tools from the recently developed proximal approach in invariance (viability) theory [3, 4, 13].

We consider a nonlinear control system where the state equation is of the form

$$\dot{x}(t) = f(p, x(t), \mathcal{F}(y(\cdot))(t), v(t)), \quad x(0) = x_0. \tag{1.1}$$

Here $t \in [0,1]$ is the independent variable representing time, $x(t) \in \mathbb{R}^n$ is the state vector, $y(t) \in \mathbb{R}^m$ represents the output signal fed back into the system, $\mathcal{F}$ describes a feedback law, $v(t) \in \mathbb{R}^r$ is a disturbance, and $p \in \mathbb{R}^q$ is a parameter whose value is to be estimated. We assume that the initial state x_0 is known and the only information about the disturbance $v(\cdot)$ is that it is a Lebesgue measurable function on $[0,1]$ with values in V, a given closed subset of $\mathbb{R}^r$. The set of disturbance functions is denoted by $\mathcal{V}$. The state trajectory $x(\cdot)$ is regarded as an absolutely continuous function satisfying (1.1) almost everywhere (a.e.) in $[0,1]$. The output $y(t)$ is obtained through a sensor with dynamics described by the output equation

$$\varepsilon \dot{y}(t) = g(x(t), y(t), v(t)), \quad y(0) \in Y_0, \tag{1.2}$$

where ε is a "small" positive parameter describing the "fast" reaction of the sensor to changes of the state and the disturbance, and the set $Y_0 \subset \mathbb{R}^m$. The sensor with "neglected" dynamics is modeled by (1.2) with $\varepsilon = 0$, that is,

$$0 = g(x(t), y(t), v(t)). \tag{1.3}$$

We consider the following parameter identification problem. Let the a priori information for the value of the parameter p be represented by a set $P \subset \mathbb{R}^q$; that is, we know that $p \in P$. The goal is to find a subset of P, ideally, a single element—the true value of p, by measuring the output y. A "true" state trajectory $\hat{x}$ of the system associated with a function $\hat{v} \in \mathcal{V}$ representing the uncertainty (both unknown) results in a sensor "trajectory" $\hat{y}$ according to (1.2). We assume that a subset Δ of the interval $[0,1]$ is known such that the values of $\hat{y}(\cdot)$ are available at each moment of time $t \in \Delta$. In other words, the restriction $\hat{y}_{|\Delta}$ is the *exactly measured output* and, correspondingly, we suppose that the feedback law $\mathcal{F}(y(\cdot))$ uses only the values of y for $t \in \Delta$. Normally, $\mathcal{F}$ is a causal operator: its values $\mathcal{F}(y(\cdot))(t)$ depend only on the restriction of $y(\cdot)$ on $[0,t] \cap \Delta$, but the causality will not be essential for the considerations below. The data $\hat{y}(t)$, $t \in \Delta$ are used to reduce the uncertainty in the parameter p replacing the a priori estimation $p \in P$ by the a posteriori deterministic estimation $p \in P^{\varepsilon}_{\hat{y}(\cdot)}$, where

$$\begin{aligned} P^{\varepsilon}_{\hat{y}(\cdot)} \stackrel{def}{=} \{p \in P \mid &\text{there exist } v(\cdot) \in \mathcal{V} \text{ and a solution } (x(\cdot), y(\cdot)) \\ &\text{of (1.1)–(1.2) such that } y(t) = \hat{y}(t) \text{ for all } t \in \Delta\}. \end{aligned} \tag{1.4}$$

Observe that this estimation depends on the speed of the response represented by ε. Smaller values of ε correspond to faster responses. The sensor with an instantaneous response is modeled by (1.3), and applying this model to the parameter identification problem leads to the estimation $p \in P^0_{\hat{y}(\cdot)}$, where $P^0_{\hat{y}(\cdot)}$ is defined in the same way as $P^{\varepsilon}_{\hat{y}(\cdot)}$ but with (1.2) replaced by (1.3). Note that, due to the assumptions on the disturbance $v(\cdot)$, the output of the static sensor $y(\cdot)$ may be not absolutely continuous in time t.

If the set Δ consists of finitely many points (or more generally, has Lebesgue measure zero), then the values $v(t)$ in (1.3) can be chosen completely independently of the function $v(\cdot)$ in (1.1). In such a case, the static model can be written as

$$0 \in g(x(t), y(t), V) \tag{1.5}$$

or, equivalently, as

$$y \in K_0(x), \tag{1.6}$$

where

$$K_0(x) \stackrel{def}{=} \{y|\ 0 \in g(x,y,V)\}. \tag{1.7}$$

Taking into account that $\mathcal{F}(y(\cdot))(t)$ depends only on the values $y(s),\ s \in \Delta$, we can then describe the set $P^0_{\hat{y}(\cdot)}$ in the following way:

$$P^0_{\hat{y}(\cdot)} \stackrel{def}{=} \{p \in P|\ \text{there exist } v(\cdot) \in \mathcal{V} \text{ and an absolutely continuous solution } x(\cdot) \text{ of (1.1) corresponding to } \hat{y}(\cdot), v(\cdot) \text{ such that } \hat{y}(t) \in K_0(x(t)) \text{ for } t \in \Delta\}. \tag{1.8}$$

The estimation (1.8), however, can be totally wrong in certain situations. As shown later in this paper, the set $P^0_{\hat{y}(\cdot)}$ may be very different from the true estimation $P^{\varepsilon}_{\hat{y}(\cdot)}$ or even empty for arbitrarily small ε. The reason for such an effect is the fact that the values of the measurement $\hat{y}(t)$ may happen to be away from the (equilibrium) set $K_0(x(t))$ for some solutions $(x(\cdot), \hat{y}(\cdot))$ of (1.1)–(1.2) corresponding to some $v(\cdot) \in \mathcal{V}$. This is a consequence of possible "singular" behavior of the singularly perturbed equation (1.2) which occurs when the disturbance function $v(\cdot)$ changes rapidly in time, at least as fast as the dynamics of the sensor (1.2). Such a singular behavior is related to the discontinuity of the reachable set of singularly perturbed control systems first observed in [7]. In the "regular" case, as opposed to the singular one, the relation $\hat{y}(t) \in K_0(x(t))$ is satisfied approximately, with error proportional to ε and then the sensor model (1.6) needs to be ε-modified only.

The following is a simple example illustrating singular behavior. Consider two identical systems with states x_1 and x_2 in $\mathbb{R}$, described by

$$\dot{x}_1(t) = px_1(t), \quad x_1(0) = 1,$$
$$\dot{x}_2(t) = px_2(t), \quad x_2(0) = 1.$$

Suppose that each of the states is measured by a sensor, and that the second sensor is faster than the first, namely,

$$\varepsilon\dot{y}_1(t) = -y_1(t) + x_1(t) + v(t), \quad y_1(0) = 0, \tag{1.9}$$
$$\frac{\varepsilon}{2}\dot{y}_2(t) = -y_2(t) + x_2(t) + v(t), \quad y_2(0) = 0. \tag{1.10}$$

We assume that the disturbance vector v affecting the two sensors has bounded magnitude, i.e., $|v(t)| \le 1$. Let the set Δ consist of a finite number of points $t_i = ih$, $i = 1, \dots, k$, $h = 1/k$. Suppose that the true value of the parameter is $p = 0$ (the systems are static) and that the realization of the disturbance $v(\cdot)$ has the form $v(t) = v_0(t + \alpha\varepsilon)$, where (for convenience) $\alpha = \ln 2$ and

$$v_0(t) = \begin{cases} -1 & \text{for } t \in [t_i, t_i + \frac{h}{2}], \\ 1 & \text{for } t \in (t_i + \frac{h}{2}, t_{i+1}]. \end{cases}$$

The solutions of (1.9) and (1.10) associated with $x_1(t) = x_2(t) = 0$ and the disturbance $v(\cdot)$ just defined satisfy

$$\hat{y}_1(t_i) = 1 + O(\varepsilon), \quad \hat{y}_2(t_i) = \frac{3}{2} + O(\varepsilon).$$

Neglecting the dynamics of the sensors results in two identical static sensor models,

$$y_j(t_i) = x_j(t_i) + v_i, \quad |v_i| \le 1, \ \ i = 1, \dots, k, \quad j = 1, 2. \tag{1.11}$$

Obviously, the set of parameters p that are consistent with the measurements $\hat{y}_j(t_i)$ according to the sensor model (1.11) is empty. A possible way to handle this problem is to "regularize" the static model by artificially introducing new disturbances w_1 and w_2, each bounded by a constant d. Then we obtain the static sensor model

$$y_j(t_i) = x_j(t_i) + v_i + w_i^j, \quad |v_i| \le 1, \ \ |w_i^j| \le d, \ \ i = 1, \dots, k, \ j = 1, 2. \tag{1.12}$$

Since $|\hat{y}_1(t_i) - \hat{y}_2(t_i)| = 1/2 + O(\varepsilon)$, it is clear that to ensure $p = 0 \in P^0_{\hat{y}}$ one has to take $d \ge 1/4 - O(\varepsilon)$. That is, even for arbitrarily small ε, the static model (1.11) must be significantly modified to be usable for parameter identification.

In the following section we obtain a general sufficient condition for a static sensor model of the form $y \in K(x)$ to provide correct results when used instead of the "true" model (1.2) in the parameter identification problem. In section 3 we obtain conditions for regular behavior, where a slight modification, proportional to ε, of the instantaneous response model (1.6) suffices to obtain correct results. In section 4 we give a complete answer to the question of how to define the mapping $K(\cdot)$ of the static sensor, in the case of singular behavior.

2. From the dynamic to a static sensor model. We use the following notation. The space $\mathbb{R}^m$ is endowed with any Hilbert norm $|\cdot|$ with the scalar product denoted by $\langle \cdot, \cdot \rangle$. The corresponding unit ball is denoted by $\mathcal{B}$. For a closed set $Z \subset \mathbb{R}^m$ and a point $y \in \mathbb{R}^n$ we denote $\operatorname{dist}(y, Z) \stackrel{def}{=} \min\{|y - z| \mid z \in Z\}$. $\mathcal{P}_Z(y) \stackrel{def}{=} \{z \in Z \mid |z - y| = \operatorname{dist}(y, Z)\}$ is the set of projections of y on the closed set Z. The proximal normal cone to the closed set $Y \subset \mathbb{R}^m$ at the point $y \in Y$ is defined as

$$N_Y^{\perp}(y) \stackrel{def}{=} \{l \in \mathbb{R}^m \mid y \in \mathcal{P}_Y(y + \alpha l) \text{ for some } \alpha > 0\}.$$

In this section we study the following abstract model of the static sensor:

$$y(t) \in K(x(t)) + c\varepsilon\mathcal{B}, \tag{2.1}$$

where $K : \mathbb{R}^n \Rightarrow \mathbb{R}^m$ is a set-valued map and c is a positive constant. Given the measurement $\hat{y}(\cdot)$ of the system (1.1)–(1.2) for $t \in \Delta$, the deterministic estimation set of p based on the model (2.1) is described by

$$\begin{aligned} P_{\hat{y}(\cdot)} \stackrel{def}{=} \{p \in P \mid & \text{ there exist } v(\cdot) \in \mathcal{V} \text{ and a solution } x(\cdot) \text{ of (1.1) corresponding} \\ & \text{to } \hat{y}(\cdot), v(\cdot) \text{ such that (2.1) holds for } y(t) = \hat{y}(t), \ \ t \in \Delta\}. \end{aligned} \tag{2.2}$$

We use the following assumptions.

(A) There is a compact set $S \subset \mathbb{R}^n$ such that for each $p \in P$ and every $v(\cdot) \in \mathcal{V}$, every solution of the differential equation

$$\dot{x}(t) = f(p, x(t), \mathcal{F}(\hat{y}(\cdot))(t), v(t)), \ \ x(0) = x_0,$$

has values in the interior of S for all $t \in [0, 1]$. The functions $f : P \times \mathbb{R}^n \times \mathbb{R}^m \times V \to \mathbb{R}^n$ and $g : \mathbb{R}^n \times \mathbb{R}^m \times V \to \mathbb{R}^m$ are locally Lipschitz continuous. There exists a constant M such that $|f(p, x, \mathcal{F}(\hat{y}(\cdot))(t), v)| \le M$ for all $p \in P$, $x \in S$, $t \in \Delta$, and $v \in V$.

(B) For each $x \in S$ the set $K(x)$ is nonempty and closed. There exists a constant L such that $K(x'') \subset K(x') + L|x'' - x'|\mathcal{B}$ for every $x', x'' \in S$. In addition, we assume $Y_0 \subset K(x_0)$.

(C) There exists $\lambda > 0$ such that for every $x \in S$, $y \in K(x)$, $l \in N^{\perp}_{K(x)}(y)$, and $v \in V$

$$\langle g(x, y + l, v), l\rangle \le -\lambda |l|^2.$$

We will see further that assumption C plays a crucial role for passing from the dynamic sensor model to a static one. This assumption is inspired by the recently developed proximal approach to stability and invariance; see [3, 4, 13]. Here, in the general case, its form is fairly abstract; in the following sections we show that in specific cases it reduces to a computationally tractable condition.

The following theorem is the central result of the paper.

THEOREM 2.1. *Let assumptions* A, B, *and* C *hold, let the constant* c *in* (2.1) satisfy $c \ge LM/\lambda$, and let $\varepsilon > 0$. Then

$$P^{\varepsilon}_{\hat{y}(\cdot)} \subset P_{\hat{y}(\cdot)}.$$

The meaning of this result is clear: if we apply the static sensor model (2.1) under the above assumptions, then the estimation set $P_{\hat{y}(\cdot)}$ obtained on the basis of the measured output must contain the true value of the parameter p.

In the proof of the theorem we use the notion of contingent derivative (see, e.g., Aubin and Frankowska [2]) and the following lemma. We recall that $\xi \in \mathbb{R}^m$ is an element of the contingent derivative $DK(x, z; \eta)$ of the set-valued mapping $K : \mathbb{R}^n \Rightarrow \mathbb{R}^m$ at the point (x, z) on the graph of $K(\cdot)$ in the direction η if

$$\liminf_{h\to 0+} \frac{1}{h} \operatorname{dist}(z + h\xi, K(x + h\eta)) = 0.$$

LEMMA 2.2. *Let the functions* $x : [0, 1] \to \mathbb{R}^n$ *and* $y : [0, 1] \to \mathbb{R}^m$ *be absolutely continuous and let the set-valued mapping* $K : \mathbb{R}^n \Rightarrow \mathbb{R}^m$ *satisfy assumption* B. *Then the function* $\rho(t) \stackrel{def}{=} \operatorname{dist}(y(t), K(x(t)))$ *is absolutely continuous and*

$$\dot\rho(t) \le \min_{z\in \mathcal{P}_{K(x(t))}(y(t))} \min_{\xi \in DK(x(t),z;\dot x(t))} \frac{\langle \dot y(t) - \xi, y(t) - z\rangle}{\rho(t)}$$

for a.e. t *for which* $\rho(t) > 0$.

Proof. The absolute continuity of $\rho(\cdot)$ is obvious. Let t be a point where $\rho(t) > 0$ and each of the functions $x(\cdot)$, $y(\cdot)$, and $\rho(\cdot)$ is differentiable. Let $z \in \mathcal{P}_{K(x(t))}(y(t))$ and let $\xi \in DK(x(t), z; \dot x(t))$. Then there exist sequences $h_k \to 0+$ and $\omega_k \to 0$ such that

$$z + h_k\xi + h_k\omega_k \in K(x(t) + h_k\dot x(t)) \subset K(x(t + h_k)) + o(h_k)\mathcal{B},$$

where $o(\cdot)$ is any function with $o(h)/h \to 0$ when $h \to 0$. Then $z + h_k\xi + h_k\omega'_k \in K(x(t + h_k))$ for some $\omega'_k \to 0$. Hence,

$$\rho(t + h_k) \le |y(t + h_k) - z - h_k\xi| + o(h_k) \le |y(t) - z + h_k(\dot y(t) - \xi)| + o(h_k).$$

Since $|y(t) - z| = \rho(t) > 0$, taking the directional derivative of the norm in the right-hand side we obtain

$$\rho(t + h_k) \le \rho(t) + h_k \frac{\langle \dot y(t) - \xi, y(t) - z\rangle}{|y(t) - z|} + o(h_k).$$

Rearranging the last inequality and passing to the limit with k we obtain the desired inequality. □

Proof of Theorem 2.1. Let $p \in P^{\varepsilon}_{\hat{y}(\cdot)}$ and let $v^p_\varepsilon(\cdot), x^p_\varepsilon(\cdot)$ correspond to p according to (1.4). This means that there exists a solution $y(\cdot)$ of (1.2) with $x = x^p_\varepsilon$ and $v = v^p_\varepsilon$ such that $y(t) = \hat{y}(t)$ for $t \in \Delta$. Since $P^{\varepsilon}_{\hat{y}(\cdot)}$ and $P_{\hat{y}(\cdot)}$ depend only on the values of $\hat{y}(\cdot)$, these two sets will not change if we extend the domain of $\hat{y}$ to $[0,1]$ by taking $\hat{y}(t) = y(t)$ for all $t \in [0,1]$. In this way we ensure that $\hat{y}(\cdot)$ satisfies (1.2) with $x = x^p_\varepsilon$ and $v = v^p_\varepsilon$. Then, to prove the theorem, it is enough to establish the inclusion $\hat{y}(t) \in K(x^p_\varepsilon(t)) + c\varepsilon\mathcal{B}$ with $c = ML/\lambda$ or, equivalently, the inequality $\rho(t) \stackrel{def}{=} \operatorname{dist}(\hat{y}(t), K(x^p_\varepsilon(t))) \le c\varepsilon$.

According to the last part of assumption B, $\rho(0) = 0$. Lemma 2.2 implies that $\rho(\cdot)$ is absolutely continuous and for almost every t for which $\rho(t) > 0$ and at which $\dot{x}^p_\varepsilon(t)$ and $\dot{\hat{y}}(t)$ exist and (1.1)–(1.2) are satisfied, we have

$$\dot{\rho}(t) \le \min_{z \in \mathcal{P}_{K(x^p_\varepsilon(t))}(\hat{y}(t))} \min_{\xi \in DK(x^p_\varepsilon(t), z; \dot{x}^p_\varepsilon(t))} \frac{\langle \dot{\hat{y}}(t) - \xi, \hat{y}(t) - z\rangle}{\rho(t)}. \tag{2.3}$$

The term $\langle \dot{\hat{y}}(t), \hat{y}(t) - z\rangle$ can be estimated by

$$\langle \varepsilon^{-1} g(x^p_\varepsilon(t), \hat{y}(t), v^p_\varepsilon(t)), \hat{y}(t) - z\rangle \le -\frac{\lambda}{\varepsilon}(\rho(t))^2,$$

where in the last estimation we use assumption C and the relations

$$\hat{y}(t) - z \in N^{\perp}_{K(x^p_\varepsilon(t))}(z), \quad |\hat{y}(t) - z| = \rho(t).$$

Hence,

$$\begin{aligned} \dot{\rho}(t) &\le -\frac{\lambda}{\varepsilon}(\rho(t))^2 + \min_{z \in \mathcal{P}_{K(x^p_\varepsilon(t))}(\hat{y}(t))} \min_{\xi \in DK(x^p_\varepsilon(t), z; \dot{x}^p_\varepsilon(t))} \frac{|\langle \xi, \hat{y}(t) - z\rangle|}{\rho(t)} \\ &\le -\frac{\lambda}{\varepsilon}(\rho(t))^2 + \min_{z \in \mathcal{P}_{K(x^p_\varepsilon(t))}(\hat{y}(t))} \min_{\xi \in DK(x^p_\varepsilon(t), z; \dot{x}^p_\varepsilon(t))} |\xi|. \end{aligned} \tag{2.4}$$

In order to estimate the last term we prove that assumption B implies

$$\min_{\xi \in DK(x,z;l)} |\xi| \le L|l| \tag{2.5}$$

for every $x \in S$, $z \in K(x)$, and $l \in \mathbb{R}^n$. Indeed, for every $h > 0$ there exists $z_h \in K(x+hl)$ such that $|z - z_h| \le Lh$. Thus the sequence $\xi_h = (z_h - z)/h$ has a subsequence ξ_{h_k} converging to a point ξ, and $|\xi| \le L$. Since $z + h_k\xi_{h_k} = z_{h_k} \in K(x + h_k l)$, we obtain that $\xi \in DK(x, z; l)$; hence (2.5) holds.

Taking into account assumption A and (2.5), from (2.4) we obtain

$$\dot{\rho}(t) \le -\frac{\lambda}{\varepsilon}\rho(t) + LM.$$

The above inequality need not be fulfilled for those t for which $\rho(t) = 0$, but it is sufficient (together with $\rho(0) = 0$) to verify that the desired inequality $\rho(t) \le c\varepsilon$ holds. The proof is complete. □

The two coupled equations (1.1)–(1.2) represent a singular perturbation model. In the realm of singular perturbations, one usually assumes a certain type of stability

for the fast dynamics. For our model such an assumption means that the function g describing the dynamic sensor must ensure a certain tracking property for the solution of (1.2). Here we use the following assumption.

(D) There exists a positive constant λ such that for every $x \in S$, $y_1, y_2 \in \mathbb{R}^m$, and $v \in V$,

$$\langle g(x, y_2, v) - g(x, y_1, v), y_2 - y_1 \rangle \leq -\lambda |y_1 - y_2|^2.$$

Assumption D is related to the so-called one-sided Lipschitz condition which is used in the analysis of stiff differential equations. For various versions of this condition, see [6, 14]. In the case of a function g which is invertible and differentiable in y, assumption D is implied by the (uniform) negative definiteness of the matrix $\partial g/\partial y$ with respect to the scalar product $\langle \cdot, \cdot \rangle$. Note that this scalar product was arbitrarily chosen, and therefore the familiar, in the linear case, requirement that the real parts of the eigenvalues be negative is covered.

Under assumption D, assumption C has the following equivalent form which will be used in the next section.

PROPOSITION 2.3. *If assumptions* A, B, *and* D *are satisfied, then assumption* C *is equivalent to the following:*

$$\langle g(x, y, v), l \rangle \leq 0 \quad \textit{for all } x \in S,\ y \in K(x),\ v \in V,\ l \in N^{\perp}_{K(x)}(y). \tag{2.6}$$

Proof. Suppose that assumption C is satisfied and assume that, on the contrary,

$$\langle g(x, y, v), l \rangle = \delta > 0$$

for some $x \in S$, $y \in K(x)$, $v \in V$, and $l \in N^{\perp}_{K(x)}(y)$, say, with $|l| = 1$. Then

$$\langle g(x, y + \alpha l, v), \alpha l \rangle \geq \langle g(x, y, v), \alpha l \rangle - L' \alpha^2 = \delta \alpha - L' \alpha^2 > 0$$

for all sufficiently small positive α. Here L' is the Lipschitz constant of g in a neighborhood of the point (x, y, v). This contradicts assumption C, since $\alpha l \in N^{\perp}_{K(x)}(y)$.

Now, let (2.6) be fulfilled. Then for every x, y, v, l chosen as in assumption C, we have $\langle g(x, y, v), l \rangle \leq 0$. Applying assumption D for $y_1 = y \in K(x)$ and $y_2 = y_1 + l$ we obtain

$$\langle g(x, y + l, v), l \rangle \leq \langle g(x, y + l, v), l \rangle - \langle g(x, y, v), l \rangle$$

$$= \langle g(x, y_2, v) - g(x, y_1, v), y_2 - y_1 \rangle \leq -\lambda |l|^2.$$

This completes the proof. ∎

3. The regular case. In this section we obtain conditions for regularity of the sensor model. By regularity we mean the following: there exists a small, that is, proportional to ε, modification of the static sensor model (1.5), obtained by neglecting the sensor dynamics, which provides correct results when used for deterministic parameter identification. Specifically, we answer the question under what circumstances assumptions B and C are satisfied by the equilibrium mapping $K_0(\cdot)$ defined in (1.7).

First, note that $K_0(x)$ is a closed set, provided that V is compact. Further, the Lipschitz-type assumption in B for K_0 is standard in the set-valued framework, for sufficient conditions; see [2]. From [14] it follows that if assumption D is fulfilled, then

$K_0(x)$ is nonempty for every $x \in S$. The remaining condition for the initial value of the observation is a natural requirement, meaning that at the beginning of the process the sensors are in equilibrium ($\dot{y} = 0$). An alternative condition is to suppose that some interval $[0, \delta], \delta > 0$, does not contain points from the set Δ.

Thus, the critical requirement for regularity is represented by assumption C.

In the following we suppose that assumption D holds. Then (2.6) is equivalent to C, according to Proposition 2.3. We focus on (2.6) in the special case where the function g has the form

$$g(x, y, v) = g_0(x, y) + C(x)v.$$

Here $g_0 : S \times \mathbb{R}^m \to \mathbb{R}^m$ and $C : S \to \mathbb{R}^{n\times r}$ are Lipschitz continuous functions with respect to x, uniformly in y. We suppose that for all $x \in S$ the function $g_0(x, \cdot)$ is invertible, differentiable, and with locally Lipschitz derivative, and the derivative $\partial g_0/\partial y(x, y)$ is invertible for all y. We also suppose that the set V is convex and compact.

PROPOSITION 3.1. *Under the assumptions listed in the above paragraph, the map $K_0(\cdot)$ is nonempty and compact-valued and Lipschitz continuous. Moreover, assumption* C *is equivalent to the following:*

$$-\frac{\partial g_0}{\partial y}(x, \varphi(x, v))C(x)T_V(v) \subset C(x)T_V(v) \quad \textit{for all } x \in S, \textit{ for all } v \in V, \tag{3.1}$$

where $\varphi(x, v)$ is the unique solution of the equation $0 = g_0(x, y) + C(x)v$ and $T_V(v)$ is the tangent cone to V at v.

Proof. We already know that the set $K_0(x)$ is closed and nonempty. Since $K_0(x) = g_0^{-1}(x, -C(x)V)$, where the inversion is with respect to the second argument, the first claim follows from the classical inverse function theorem.

By Proposition 2.3, assumption C is equivalent to (2.6). According to the proximal characterization of the strong invariance property with respect to a differential inclusion obtained in [9] (see also [3]) and the tangential characterization of the same property [1], the relation (2.6) (for the set $K_0(x)$) is equivalent to

$$g(x, \bar{y}, V) \subset T_{K_0(x)}(\bar{y}) \quad \text{for all } x \in S,\ \bar{y} \in K_0(x). \tag{3.2}$$

Since x is fixed, we skip the dependence of x in the rest of the proof.

Let $\bar{v} \in V$ and $\bar{y}$ be arbitrary vectors satisfying the relation $0 = g(\bar{y}, \bar{v})$, that is, $\bar{y} = \varphi(\bar{v})$. Then (3.2) can be rewritten as $C(V - \bar{v}) \subset T_{K_0(x)}(\bar{y})$ or, equivalently, as

$$CT_V(\bar{v}) \subset T_{K_0(x)}(\bar{y}) \quad \text{for all } \bar{v} \in V.$$

It remains to prove that

$$T_{K_0}(\bar{y}) = -\left[\frac{\partial g_0}{\partial y}(\bar{y})\right]^{-1} CT_V(\bar{v}). \tag{3.3}$$

The inclusion of $T_{K_0}(\bar{y})$ in the right-hand side can be verified by applying the definition of the contingent cone. To prove the inverse inclusion we first define the function

$$\omega_h(\eta) \overset{def}{=} \frac{g_0(\bar{y} + h\eta) - g_0(\bar{y})}{h} - \frac{\partial g_0}{\partial y}(\bar{y})\eta,$$

where h is a positive parameter and $\eta \in \mathbb{R}^m$. A standard estimation implies that $\omega_h(\cdot)$ is Lipschitz continuous with Lipschitz constant $L'h/2$, where L' is the Lipschitz constant of $\frac{\partial g_0}{\partial y}(\cdot)$ at $\bar{y}$. Then for every fixed $\xi \in \mathbb{R}^m$ with $|\xi| \leq 1$ and for all sufficiently small h, the operator

$$\eta \mapsto \xi - \left[\frac{\partial g_0}{\partial y}(\bar{y})\right]^{-1} \omega_h(\eta)$$

maps $2\mathcal{B}$ into $2\mathcal{B}$ and is contractive; it therefore has a fixed point $\hat{\eta}_h(\xi)$ and obviously

$$|\hat{\eta}_h(\xi) - \xi| \leq \frac{L'}{2} \left| \left[\frac{\partial g_0}{\partial y}(\bar{y})\right]^{-1} \right| h. \tag{3.4}$$

Now take an arbitrary element ξ, $|\xi| \leq 0.5$ from the right-hand side of (3.3). There exist a sequence $h_k \to 0$ and a sequence $v_k \in V$ such that

$$\xi = -\left[\frac{\partial g_0}{\partial y}(\bar{y})\right]^{-1} C \lim_k \frac{v_k - \bar{v}}{h_k}.$$

Then $\xi_k \to \xi$ for $\xi_k \stackrel{def}{=} -[\frac{\partial g_0}{\partial y}(\bar{y})]^{-1} C(v_k - \bar{v})/h_k$. Since $|\xi_k| \leq 1$ for all sufficiently large k we can define $\eta_k = \hat{\eta}_{h_k}(\xi_k)$. We have

$$h_k \frac{\partial g_0}{\partial y}(\bar{y})\xi_k = -C(v_k - \bar{v}) = -g_0(\bar{y}) - Cv_k.$$

From the definition of η_k, we obtain

$$g(\bar{y} + h_k\eta_k, v_k) = g_0(\bar{y}) + h_k \frac{\partial g_0}{\partial y}(\bar{y})\eta_k + h_k\omega_{h_k}(\eta_k) + Cv_k$$

$$= g_0(\bar{y}) + h_k \frac{\partial g_0}{\partial y}(\bar{y})\xi_k + Cv_k = 0.$$

This means that $\xi \in T_{K_0}(\bar{y})$ since $\eta_k \to \xi$ according to (3.4). The proof is now complete. □

To better understand condition (3.1) we denote $A = (\partial g_0/\partial y)(x, y)$, $C = C(x)$ and consider the case where V is a box, $V = [\alpha_1, \beta_1] \times \cdots \times [\alpha_r, \beta_r]$.

PROPOSITION 3.2. Condition (3.1) is equivalent to the following: each column of the matrix C is an eigenvector of the matrix A corresponding to an eigenvalue that is real and nonpositive.

Proof. Let (3.1) be fulfilled. We shall prove the claim for the first column of C. The case $r = 1$ is obvious; therefore we suppose that $r > 1$.

Denote by $e_i \in \mathbb{R}^r$ the vector with the ith component equal to one and all the other components equal to zero. Then $e_1 \in T_V((\alpha_1, v_2, \ldots, v_r))$ for every $v_i \in [\alpha_i, \beta_i]$. Condition (3.1) implies that $l \stackrel{def}{=} -ACe_1 \in CT_V((\alpha_1, v_2, \ldots, v_r))$. Hence, given $\sigma = (\sigma_2, \ldots, \sigma_r)$ with all $\sigma_i \in \{-1, 1\}$, by choosing appropriate $v_2, \ldots, v_r$ we conclude that l has the representation $l = Cz_\sigma$, where $\langle e_1, z_\sigma \rangle \geq 0$ and $\operatorname{sign}\langle e_i, z_\sigma \rangle = \sigma_i$ for $i = 2, \ldots, r$. Taking an arbitrary $\sigma' = (\sigma_3, \ldots, \sigma_r)$ (if $r > 2$) and a convex combination of $z_{(-1,\sigma')}$ and $z_{(1,\sigma')}$, we can represent l as $l = Cz'_{\sigma'}$, where now $\langle e_1, z'_{\sigma'} \rangle \geq 0$, $\langle e_2, z'_{\sigma'} \rangle = 0$, and $\operatorname{sign}\langle e_i, z'_{\sigma'} \rangle = \sigma'_i$ for $i = 3, \ldots, r$ (if $r > 2$). Proceeding by induction we obtain the representation $l = Cz$, where $\langle e_1, z \rangle \geq 0$ and $\langle e_i, z \rangle = 0$ for

$i = 2, \dots, r$. That is, $l = -AC_1 = \gamma C_1$, where C_1 is the first column of C and $\gamma \geq 0$. This completes the proof of the necessity. The proof of the sufficiency is straightforward. □

Let us consider again the example in the introduction. Here $r = 1$ and

$$A = \begin{pmatrix} -1 & 0 \\ 0 & -2 \end{pmatrix}, \quad C = \begin{pmatrix} 1 \\ 2 \end{pmatrix}.$$

The vector C is not an eigenvector; therefore, as was argued in the introduction, the dynamic sensor model (1.9)–(1.10) is not regular. The regularity condition would be fulfilled, however, if the second sensor (1.10) were identical to the first one.

Let us consider the same example, but for a moment forget that the disturbance $v \in [-1, 1]$ is the same for the two sensors. That is, we pass to the case $r = 2$ with

$$C = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}.$$

Here the two columns of C are obviously eigenvectors of A corresponding to the eigenvalues -1 and -2, respectively; therefore the use of the static sensor model

$$y_1 = x_1 + v_1, \quad y_2 = x_2 + v_2, \quad v_1, v_2 \in [-1 - c\varepsilon, 1 + c\varepsilon]$$

is justified. This model, however, is not minimal; it is "too pessimistic." In the next section we show a way to find a minimal static model providing correct results for the parameter identification problem.

4. The singular case. In the preceding section we showed that the static sensor model (1.6) obtained by simply neglecting the sensor dynamics can be applied for deterministic estimation of the parameter p in very special cases only. Specifically, for a linear time-invariant system, the condition described in Proposition 3.2 is not generic. In this section we show how to construct a static sensor model, represented by a set $K(x)$, larger than $K_0(x)$, which satisfies the requirements of Theorem 2.1.

First we recall some notions from [1]. A set $Y \subset \mathbb{R}^m$ is *strongly invariant* (merely "invariant" in the terminology in [1]) with respect to the differential inclusion $\dot{y} \in G(y)$ if every trajectory $y(\cdot)$ of this differential inclusion starting from a point of Y never leaves Y. For any set Y and for a mapping G that is Lipschitz continuous, there exists a unique minimal closed set—the so-called *invariance envelope* of Y (denoted $\mathrm{Inv}_G(Y)$) that contains Y and is strongly invariant with respect to G.

Going back to the identification problem, let us suppose that the measurement data $\hat{y}(t)$, $t \in \Delta$ are given, that assumptions A and D from section 2 are fulfilled, and that the equilibrium mapping $K_0(\cdot)$ satisfies assumption B. Denote $\bar{K}(x) \stackrel{def}{=} \mathrm{Inv}_{G(x,\cdot)}(K_0(x))$, where $G(x, y) = g(x, y, V)$. We also suppose that the function g has the following Lipschitz property with respect to x: there is a constant L_x such that

$$|g(x', y, v) - g(x'', y, v)| \leq L_x |x' - x''| \quad \text{for all } x', x'' \in S \text{ for all } y \in \bar{K}(x').$$

THEOREM 4.1. *Let the conditions listed in the last paragraph hold. Then $\bar{K}$ is the unique minimal (with respect to pointwise inclusion) mapping from S to the subsets of $\mathbb{R}^m$ satisfying assumptions* B *and* C *such that $K_0(x) \subset \bar{K}(x)$ for all $x \in S$.*

Proof. For $x \in S$ the set $\bar{K}(x)$ is closed by definition and nonempty, since $K_0(x) \subset \bar{K}(x)$ is nonempty according to [14]. Let us prove the Lipschitz property.

Let $x', x'' \in S$, $y'' \in \bar{K}(x'')$. We prove that

$$\operatorname{dist}(y'', \bar{K}(x')) \le L + \frac{L_x}{\lambda}. \tag{4.1}$$

The invariance envelope $\operatorname{Inv}_{G(x,\cdot)}(K_0(x))$ is the closure of the set of all points $y(t)$, $t \ge 0$, where $y(\cdot)$ is a trajectory of $\dot{y} \in G(x, y)$ starting from a point of $K_0(x)$. Then for an arbitrary $\delta > 0$ there exist $y_0'' \in K_0(x'')$, $T > 0$, and a measurable $v(\cdot) : [0, T] \mapsto V$ such that the (unique) solution y_2 of the equation

$$\dot{y}(t) = g(x'', y(t), v(t)), \quad y(0) = y_0'', \tag{4.2}$$

satisfies $|y'' - y_2(T)| \le \delta$. There is $y_0' \in K_0(x')$ such that $|y_0' - y_0''| \le L|x' - x''|$. Denote by $y_1(\cdot)$ the solution of (4.2) with x', y_0' instead of x'', y_0''. Then $y_1(T) \in \bar{K}(x')$, hence $\operatorname{dist}(y'', \bar{K}(x')) \le |y_1(T) - y_2(T)| + \delta$. Denote $d(t) = |y_1(t) - y_2(t)|$. Whenever differentiable and nonzero, $d(\cdot)$ satisfies

$$\dot{d}(t) = \frac{\langle \dot{y}_1(t) - \dot{y}_2(t), y_1(t) - y_2(t) \rangle}{d(t)}$$

$$= \frac{\langle g(x', y_1(t), v(t)) - g(x'', y_2(t), v(t)), y_1(t) - y_2(t) \rangle}{d(t)} \le L_x|x' - x''| - \lambda d(t).$$

Here we used the Lipschitz property of g and assumption D. From here we conclude that $d(t) \le (L + L_x/\lambda)|x' - x''|$ which implies (4.1) since δ was arbitrarily chosen.

The condition $\hat{y}(0) \in \bar{K}(x_0)$ is fulfilled since it is assumed for $K_0(x_0)$. It remains to show that assumption C holds. Under D, assumption C is equivalent to (2.6), according to Proposition 2.3. From [3, 9], the latter is equivalent to the strong invariance of $\bar{K}(x)$. In addition, $\bar{K}(x)$ is the smallest strongly invariant set containing $K_0(x)$. This completes the proof. □

Since the set $K_0(x)$ consists only of equilibrium points of the mapping $G(x, \cdot)$, its invariant envelope can be described as the limit (in the sense of Painlevé–Kuratowski)

$$\bar{K}(x) = \lim_{T \to +\infty} R_x(T),$$

where $R_x(T)$ is the reachable set at T of the system

$$\dot{y}(t) = g(x, y(t), v(t)), \quad y(0) \in K_0(x), \quad v(t) \in V.$$

The reachable set can be analytically found only in exceptional cases (like in the example below), but there are efficient methods for its enclosure and approximation; see, e.g., the survey [11].

Let us compute the set $\bar{K}(x)$ for the example considered in the introduction and in section 3. Easy calculations give us

$$R_x(t) = e^{\begin{pmatrix} -t & 0 \\ 0 & -2t \end{pmatrix}} K_0(x) + \int_0^t e^{\begin{pmatrix} -t+s & 0 \\ 0 & -2t+2s \end{pmatrix}} \left(\begin{pmatrix} x_1 \\ 2x_2 \end{pmatrix} + \begin{pmatrix} 1 \\ 2 \end{pmatrix} [-1, 1] \right) ds.$$

Integrating and taking the limit for $t \to +\infty$ we get

$$\bar{K}(x) = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \int_0^{+\infty} \begin{pmatrix} e^{-s} & 0 \\ 0 & e^{-2s} \end{pmatrix} \begin{pmatrix} 1 \\ 2 \end{pmatrix} [-1, 1]\, ds.$$

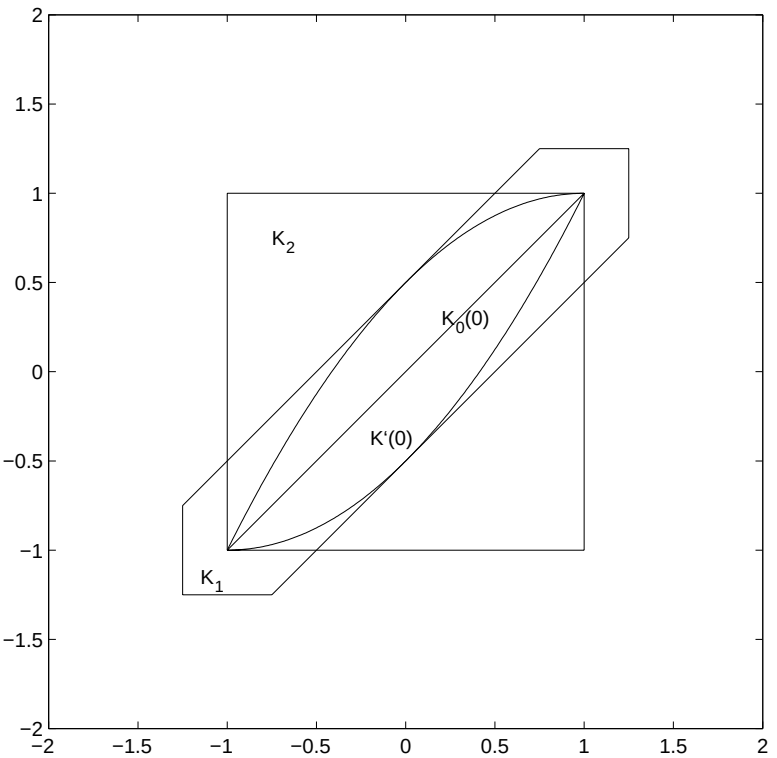

FIG. 1. *Various models of the static sensor.*

The last integral of a set-valued mapping is in the sense of Aumann; see, e.g., [2]. Its calculation gives the set $R = \{(y_1, y_2) \in \mathbb{R}^2 |\ 0.5y_1^2 + y_1 - 0.5 \le y_2 \le -0.5y_1^2 + y_1 + 0.5\}$. Finally we have

$$\bar{K}(x) = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + R.$$

The set $\bar{K}(x)$ is given on Figure 1 for $x = 0$. Note the difference with the formally obtained static model $K_0(0)$ as well as with the two regularizations, K_1 as discussed in the introduction and K_2 in section 3.

ADMISSIBILITY OF CONTROL OPERATORS FOR SOLUTION FAMILIES TO VOLTERRA INTEGRAL EQUATIONS*

MICHAEL JUNG†

Abstract. We reduce the admissibility of finite-dimensional control operators for an evolution system (satisfying certain mild regularity conditions) to that for a semigroup control system, for which there are plenty of results available in the literature. One such necessary and sufficient condition is the Carleson measure criterion. We prove this condition explicitly for evolution systems without the regularity assumption mentioned above. We also look at some examples which show that our respective hypotheses are necessary.

Key words. admissibility, evolutionary equations, control theory, Carleson measure, completely positive

1. Introduction. This paper deals with control theory for nonautonomous, infinite-dimensional dynamical systems which arise from Volterra integral equations. Classical theory for C_0-semigroups considers the (autonomous) system

$$\begin{aligned} x'(t) &= Ax(t) + Bu(t), \qquad t \geq 0, \\ x(0) &= x_0, \end{aligned} \tag{1}$$

where x is a function with values in the state space X, u is a function with values in the control space, and B is the control operator. In order that the uncontrolled system has a solution, we assume that A is the generator of a C_0-semigroup $T(\cdot)$ in X. Particularly in boundary control problems unbounded control operators arise. A detailed example is given in [6].

We will be interested in the case where the control space is one-dimensional. Any finite-dimensional control operator can be obtained as a sum of one-dimensional operators. Consequently, the solution to (1) will be obtained as a sum if the individual solutions exist. We will write b instead of B, where b is a nonzero element of the range space of B.

This equation was studied in [7] and [10] and later generalized to B of higher rank in [4]. Interesting cases arise when B is unbounded, in other words, when B cannot be identified by an element b of its range space in X, but only in a larger space; see also [2]. This paper also deals with the preliminary question of which operators B are admissible, and not which operators B make the system controllable [3]. Necessary and sufficient criteria were established for admissibility of the control element b in the C_0-semigroup case in the aforementioned papers.

We are interested in a generalized version of this setting, namely, the generalized (Volterra) system:

$$\begin{aligned} x'(t) &= (da * Ax)(t) + bu(t), \\ x(0) &= x_0 \end{aligned}$$

for a a scalar-valued function of bounded variation. Integrating these equations with respect to time, we are thus led to consider the following problem:

$$x(t) = x_0 + (a * Ax)(t) + (1 * bu)(t), \qquad t \geq 0. \tag{2}$$

We wrote the equation in a derivative-free way. This will be of convenience later on and indeed is slightly more general with the appropriate requirement on a than had we chosen to write it in its original setting (1).

It is the purpose of this paper to determine necessary and sufficient conditions under which b will be a suitable control element for (2) in an L^2-setting. In section 3 we will reduce the admissibility for an evolution system to that for a semigroup system under certain regularity conditions. This, in particular, extends the known Carleson measure criterion. In section 2 we will prove this with less regularity needed. These will depend on A and a, of course. The corresponding problem for semigroups was considered in [7] and [10]. We will see that the semigroup conditions remain valid if a is completely positive. Completely positive functions were studied intensively in [9]. Consequently, many control operators known for semigroups can also be used in the Volterra integral equation case.

Let us start by presenting the terminology used in this setting: $\mathbb{R}_+ = (0, \infty)$ and $\mathbb{C}_+ = \{\lambda \in \mathbb{C} : \Re(\lambda) > 0\}$. Assume that X is the (Banach) state space and $u \in L^2(\mathbb{R}_+)$. We have a complete solution theory for the uncontrolled equation in the case that A is a closed operator, a is of subexponential growth, and some compatibility conditions are met (see [9, section 1]). For the time being, we assume these conditions are met. If $S(\cdot)$ is the solution family to the uncontrolled equation (mapping x_0 onto the solution), the (mild) solution to (2) is formally obtained via the variation of constants formula and can be expressed as

$$x(t) = \frac{d}{dt}(S * (x_0 + 1 * bu))(t) = S(t)x_0 + (S * bu)(t), \qquad t \geq 0.$$

We therefore call b admissible if the above equation can be made rigorous. (We understand that to mean that b is an admissible control element.) Let X^{-1} be the completion of X with the norm $\|(\lambda I - A)^{-1} \cdot\|$, where λ is in the resolvent set $\rho(A)$; different values of $\lambda \in \rho(A)$ yield equivalent norms. S extends to a solution family in that space. We assume in the present paper that $b \in X^{-1}$. In the semigroup case it was proven (see [11]) that this has to be the case if b is to be admissible.

DEFINITION 1.1. *If there exist a $t_0 > 0$ and $c > 0$, such that $\|(S*bu)(t_0)\| \leq c\|u\|_2$ for all $u \in L_2([0, t_0])$, then b is called* admissible *(for time $t_0 > 0$).*

This is a direct generalization of the standard definition, e.g., given in [11]. Note that if this definition is true for $t_0 > 0$, then it is also true for all $0 < t < t_0$, while it need not be true for $t > t_0$ (in contrast to the semigroup case). This definition is unaffected by a reflection of u about the ordinate, so we may integrate over the product Sbu where convenient, instead of calculating the convolution. The set X^S denotes the set of admissible vectors that are admissible for all times.

We make some notational conventions. Functions defined on some subset of the real axis are trivially extended without stating this fact each time. For functions $f \in L^p(\mathbb{R})$ and $g \in BV(\mathbb{R})$, we have for their convolution $f * dg \in L^p(\mathbb{R})$. A complex-valued measure $\mu \in \mathcal{M}(\mathbb{R}_+)$ is called *Laplace transformable* if

$$\int_0^\infty e^{-\epsilon t} |d\mu(t)| < \infty$$

for some $\epsilon > 0$. We define the Laplace transform $\mathcal{L}$ for all Laplace transformable measures

$$\mathcal{L}(d\mu)(z) = \int_0^\infty e^{-zt} d\mu(t), \qquad \Re(z) > \epsilon. \tag{3}$$

We extend the transform of a function analytically in the component of $\mathbb{C}$ which contains (ϵ, ∞) and denote this extension with the same symbol. The Laplace transform $\mathcal{L}$ and the Fourier transform $\mathcal{F}$ are related via $\mathcal{L}(d\mu)(iz) = \mathcal{F}(d\mu)(z)$ for appropriate transformable measures $\mu \in \mathcal{M}(\mathbb{R}_+)$ and $z \in \mathbb{R}$. Let

$$e_0(t) = \begin{cases} 1 & \text{for } t > 0, \\ 0 & \text{for } t \leq 0, \end{cases}$$

the Heaviside function.

We recall a definition from [1]. A function $a \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ is called *completely positive* if there exists a nonnegative, nondecreasing, and concave function $k : \mathbb{R}_+ \to \mathbb{R}$ such that

$$z\mathcal{L}(a)(z)\mathcal{L}(dk)(z) = 1, \qquad z \geq 0. \tag{4}$$

A measure $\mu \in \mathcal{M}(\mathbb{R}_+)$ is called completely positive if it is Laplace transformable and $z\mathcal{L}(d\mu)(z)\mathcal{L}(dk)(z) = 1$, accordingly. The function k can be decomposed as

$$k(t) = k_0 + k_\infty t + \int_0^t k_1(\tau) d\tau, \qquad t > 0, \tag{5}$$

with k_1 nonnegative, nonincreasing, and $k_1(\infty) = 0$. See section 4 in [9] for more details on completely positive functions.

A family S is called *solution family* to (2) if it is strongly continuous on X and on $X_1 := (D(A), \|\cdot\| + \|A\cdot\|)$, $S(0) = I$ and satisfies $S(t)x = x + A(a * S)(t)x$ for $x \in X$; in particular, $(a * S)(t)x \in X_1$.

2. Admissibility for diagonal operators. We restrict ourselves to let a be a completely positive, Laplace transformable function and A be a diagonal operator in this section. More specifically, let $X = l^2(\mathbb{N})$ and $Ae_n = \lambda_n e_n$ for e_n the nth unit vector. We also assume, without loss of generality, that $\sigma := \sup_{n\in\mathbb{N}} \Re(\lambda_n) < 0$. There are no requirements with regard to accumulation points. Many operators can be represented in this way; the most important class is normal generators with a compact resolvent in a Hilbert space. Then (2) has a unique strongly continuous diagonal solution family $S(t)e_n = s_{-\lambda_n}(t)e_n$ (see [9, section 4]). The scalar function s_λ satisfies the equation

$$s_\lambda(t) = 1 + \lambda(a * s_\lambda)(t), \qquad t \geq 0.$$

We now introduce the notion of a Carleson measure (see [8, chapter 8], [7]). Note, that the element b can be interpreted as a vector $(b_n)_n$, although generally not in $l^2(\mathbb{N})$. The vector b has an associated measure μ_b, where $\mu_b(M) = \sum_{-\lambda_n \in M} |b_n|^2$, which depends on $(\lambda_n)_n$; we will also denote that measure with b, in the hope of not having introduced too much ambiguity.

Definition 2.1. *Let $R(h,k) = \{z \in \mathbb{C}_+ : 0 < \Re(z) < h, |\Im(z) - k| < h\}$. Then b is called a* Carleson measure*, if there exists a $M > 0$, such that for all $h > 0$ and $k \in \mathbb{R}$: $\sum_{-\lambda_n \in R(h,k)} |b_n|^2 \leq Mh$.*

We may now formulate and prove the main theorem of this section, giving a necessary condition for admissibility of (2) in the sense of Definition 1.1. A sufficient condition is given in the next section (Theorem 3.2). The condition here is essentially the same—the Carleson measure criterion—as in the semigroup case. It has been proved that the Carleson measure criterion is equivalent to admissibility for diagonal, analytic, and invertible semigroups (see, e.g., [11]). The new results encompass the semigroup case, but the theorem below yields the criterion's necessity without the restrictions given in the next section for general operators (Theorem 3.3), whereas it is sufficient for admissibility, as we shall also see in the next section. Why the restrictions $\kappa > 0$ and $\alpha < \infty$ (see below) are required will be seen from the examples; what proved to be a necessary and sufficient criterion in the semigroup case cannot be applied without precaution in the Volterra integral equation case.

We assume the same properties on A and a as before. We define three characteristic values for a. Let $k : \mathbb{R}_+ \to \mathbb{R}$ be the function related with a as in (4). Then

$$\begin{aligned}\kappa &:= \lim_{t\to 0} k(t) = k_0,\\ \omega &:= \lim_{t\to\infty} k(t)/t = k_\infty,\\ \alpha &:= \lim_{t\to 0} k'(t) = k_1(0+) + k_\infty.\end{aligned}$$

Note that all these values are nonnegative but α may be infinite. The limit (of the increasing sequence) for α need not exist.

We use the subordination principle to represent s_λ: there exists a function $w : \mathbb{R}_+^2 \to \mathbb{R}_+$, such that

$$\begin{aligned}s_\lambda(t) &= -\int_0^\infty e^{\lambda s} d_s w(t,s)\\ &= -\mathcal{L}(d_\cdot w(t,\cdot))(-\lambda), \qquad t \geq 0,\ \Re(\lambda) < 0.\end{aligned}$$

(See [9, Theorem 4.1 and Corollary 4.5].) The function w has certain properties we will now exploit.

We set $w_0(t,s) = w(t,s) - e_0(t - \kappa s)$, $t, s \geq 0$. We state the following lemma without proof. It is not hard to check, given the properties of w listed in [9, section 4].

LEMMA 2.2. *If $\alpha < \infty$, then $\lim_{(t,s)\to 0} w_0(t,s) = w_0(0,0) = 0$ and for each $\epsilon > 0$ there exists $t_0 > 0$, such that for all $0 < t \leq t_0$ holds $\|w_0(t,\cdot)\|_{BV[0,t_0]} < \epsilon$.*

THEOREM 2.3. *Let $\kappa > 0, \alpha < \infty$. If b is admissible for $T > 0$, then b is a Carleson measure.*

Proof. We have already stated that admissibility holds for all $0 < t_0 \leq T$. We shall prove that there exists $t_0 > 0$ and $m > 0$, such that for all $h > 0$ and $k \in \mathbb{R}$ there exists $u \in L^2[0,t_0]$ with $\|u\|_2 = 1$, such that

$$\left|\int_0^{t_0} s_\lambda(t)u(t)dt\right| = \left|\int_0^{t_0}\int_0^\infty e^{\lambda s} d_s w(t,s)u(t)dt\right| \geq m\, h^{-1/2}$$

for $-\lambda \in R(h,k) \cap \sigma(-A)$. This is sufficient to prove the claim, because

$$\sum_{-\lambda_n \in R(h,k)} |b_n|^2 \leq \sum_{-\lambda_n \in R(h,k)} \left|b_n \int_0^{t_0} s_{\lambda_n}(t)u(t)dt\right|^2 / (m^2 h^{-1})$$

$$\begin{aligned}
&\le m^{-2}h\sum_{n\in\mathbb{N}}\left|b_n\int_0^{t_0}s_{\lambda_n}(t)u(t)dt\right|^2\\
&\le m^{-2}h\left\|\int_0^{t_0}S(t)bu(t)dt\right\|^2\\
&\le cm^{-2}\,h.
\end{aligned}$$

Therefore let $\epsilon=\inf_{z\in R(0,1)}|z^{-1}(1-e^{-z})|$ and choose $0<t_0\le T$, such that

$$\sup_{t\in[0,t_0]}\|w_0(t,\cdot)\|_{BV[0,t_0]}<\epsilon/2.$$

Then let $\widetilde{u}(t)=e_0(\kappa/h-t)e^{ikt/\kappa}$ and $u(t)=\widetilde{u}(t)/\|\widetilde{u}\|_2=h^{-1/2}\kappa^{1/2}\widetilde{u}(t)$. We then obtain with $w_0(t,s)=w(t,s)-e_0(t-\kappa s)$, $t,s\ge 0$, from Lemma 2.2

$$\begin{aligned}
\left|\int_0^{t_0}s_\lambda(t)\widetilde{u}(t)dt\right|&=\left|\int_0^{t_0}\int_0^{\infty}e^{\lambda s}d_sw(t,s)\widetilde{u}(t)dt\right|\\
&\ge\left|\int_0^{t_0}e^{\lambda t/\kappa}\widetilde{u}(t)dt\right|-\frac{\epsilon}{2}\int_0^{t_0}|\widetilde{u}(t)|dt\\
&\ge\left|\int_0^{\kappa/h}e^{(\lambda+ik)t/\kappa}dt\right|-\frac{\epsilon}{2}\int_0^{\kappa/h}dt\\
&=\left|\kappa\frac{1-e^{(\lambda+ik)/h}}{\lambda+ik}\right|-\frac{\epsilon\kappa}{2h}\\
&\ge\frac{\epsilon\kappa}{2h}.
\end{aligned}$$

We have silently assumed $\kappa/h\le t_0$. If this does not hold, the corresponding claim holds with t_0 replacing κ/h. Since all λ_n fulfill $\Re(\lambda_n)>-\sigma$, we can safely assume $h\ge\sigma$ and there exists a constant $c>0$, such that $\kappa/h\le ct_0$. We find

$$\left|\int_0^{t_0}s_\lambda(t)u(t)dt\right|\ge\min(c,1)\frac{\epsilon\kappa}{2h\|\widetilde{u}\|_2}\ge\min(c,1)\frac{\epsilon\kappa^{1/2}}{2}h^{-1/2}.$$

This finishes the proof. □

A converse of this theorem is shown in the next section (Theorem 3.2).

We now take a look at the situation in which $\kappa=0$. Then, if $\alpha<\infty$, we find by [9, p. 95, case 2] that $a(t)dt$ has a jump at zero. But this implies that a is not absolutely continuous. Consequently, a cannot be completely positive in that case. We are thus not able to use the subordination principle as we did in the theorems above. A minor extension is possible however. Although the sufficiency theorem, Theorem 2.3, can be proved, if a is just a (completely positive) measure, necessity is not true; the following provides a counterexample if $\kappa=0$.

Example 2.4. Let $Ae_n=(-1+in^{5/3})e_n$ and let $b\in X^{-1}$. Choose $a(t)=\delta_0$; then $a(t)dt$ is completely positive. (The corresponding k of (4) equals $k(t)=t$.) We have $w(t,s)=e^{-s}$ and $s_\lambda(t)=(1-\lambda)^{-1}$. Regarding admissibility, we obtain from (2) $x(t)=Ax(t)+(1*bu)(t)$, which yields $(S*bu)(t)=(I-A)^{-1}b(1*u)(t)$, which satisfies Definition 1.1 obviously (for $u\in L_2([0,T])$). Thus all b are admissible. But let $b_n=n\in\mathbb{N}$, for instance; then $(b_n)_n\in X^{-1}$. We have for $h=n^{5/3}>1$

$$h^{-1}\sum_{-\lambda_n\in R(h,\omega)}|b_n|^2=n^{-5/3}\sum_{j=0}^{n}j=n^{-5/3}(n^2-n)/2,$$

which is obviously not bounded, i.e., b is not a Carleson measure.

The next example shows that $\kappa > 0$ and $\alpha < \infty$ are a necessary requirement in Theorem 2.3.

Example 2.5. Let $Ae_n = -ne_n$ and let $b_n = n^\gamma$ for $n \in \mathbb{N}$ with $0 < \gamma < 1/2$. Choose $a(t) = (\pi t)^{-1/2}$ (the corresponding k of (4) equals $k(t) = 2(t/\pi)^{1/2}$); then we infer from [9, section 4] that

$$s_n(t) = \frac{2}{\sqrt{\pi}} e^{n^2 t} \int_{n\sqrt{t}}^{\infty} e^{-r^2} dr.$$

Let $0 < \beta < 1$. First we estimate the $L^2([0,T])$-norm of s_n:

$$\begin{aligned}
\|s_n\|_2^2 &= \frac{4}{\pi} \int_0^T \left(e^{n^2 t} \int_{n\sqrt{t}}^{\infty} e^{-r^2} dr \right)^2 dt \\
&\le \frac{4}{\pi} \int_0^T \left(e^{n^2 t} \int_{n\sqrt{t}}^{\infty} e^{-rn\sqrt{t}} dr \right)^{2\beta} \left(\int_{n\sqrt{t}}^{\infty} e^{n^2 t - r^2} dr \right)^{2-2\beta} dt \\
&\le \frac{4}{\pi} \int_0^T \left(\frac{1}{n^2 t} \right)^{\beta} \left(\int_0^{\infty} e^{-r^2} dr \right)^{2-2\beta} dt \\
&= C(T, \gamma, \beta) n^{-2\beta}.
\end{aligned}$$

Now we show that b is indeed admissible:

$$\begin{aligned}
\sum_{n=0}^{\infty} |b_n|^2 \left| \int_0^T s_{-n}(t) u(t) dt \right| &\le \sum_{n=0}^{\infty} |b_n|^2 \|s_{-n}\|_2^2 \|u\|_2^2 \\
&\le C(T, \gamma, \beta) \|u\|_2^2 \sum_{n=0}^{\infty} n^{2(\gamma - \beta)},
\end{aligned}$$

which is bounded if $\beta - \gamma > 1/2$. But b is not a Carleson measure

$$h^{-1} \sum_{-\lambda_n \in R(h,\omega)} |b_n|^2 = (1/n) \sum_{k=0}^{n} k^{2\gamma} = O(n^{2\gamma}), \quad n \to \infty,$$

for $h = n\,(n \in \mathbb{N})$. Moreover, by choosing γ, β appropriately, it is easy to see that b may lie outside any fractional power space between X and X^{-1}.

Moreover, we can improve the above example, if we choose $a(t) = t^\delta$ with $\delta < -1/2$. Since $S(\cdot)$ is analytic and $\|AS(\cdot)\| \in L_2(\mathbb{R}_+)$, we have $S * bu = AS * A^{-1}u \in C(\mathbb{R}_+, X)$ (see [9, Example 2.1 and Theorem 2.2]). Again, all $b \in X^{-1}$ are admissible.

We can improve the example in another direction and show that $\alpha < \infty$ is necessary. Choose $k(t) = 1 + 2(t/\pi)^{1/2}$, the corresponding a; then $\kappa > 0$ but $\alpha < \infty$. A similar but more lengthy calculation yields the same result as above. Note that

$$s_n(t) = n\pi^{-1} \int_0^{\infty} e^{-rt} r^{-1/2} (r + (r-n)^2)^{-1} dr$$

in this case.

3. Admissibility for general operators. For nondiagonal operators some significant results are available with respect to admissibility. In fact, admissibility is equivalent to $\|(\lambda - A)^{-1} b\|^2 \le K/|\Re(\lambda)|$ for some $K > 0$ in some right half-plane

in the case of normal or left-invertible semigroups (see [4]). For more results in that line, see [5]. However, a general criterion for admissibility seems not to be known even in the autonomous case. We will therefore try to relate the Volterra integral equation to the underlying Cauchy problem, thereby reducing the question to that problem. We again assume A is the generator of a C_0-semigroup in a Banach space X. Then it is known (for the semigroup case) that any admissible b is a vector in X^{-1} (see [11]). X^{-1} can also be viewed as the "smallest" space Y containing X, such that $A : D(A) \subset X \to Y$ has a continuous extension. Again we assume a is completely positive. Then the solution family to (2) for $b = 0$ can be represented similarly as in the section before as

$$S(t) = \int_0^\infty T(s) d_s w(t,s), \qquad t \geq 0, \tag{6}$$

where T is the semigroup generated by A.

The space of admissible vectors X^T for the semigroup case is continuously embedded in X^{-1}. If we can present $S(t)$ as a perturbation of $T(t)$ with the perturbing part mapping X^{-1} into X, we have equality for the space of admissible vectors, $X^T = X^S$. This idea is inspired by the fact that $S(t)$ is an integral of $T(\cdot)$ for $t \geq 0$ and integrals have smoothing properties. For this to work we need regularity of the involved integral kernels as we will see.

We thus need to decompose w in (6) into regular and singular parts. An informal calculation yields

$$S(t) = \int_0^\infty T(s) w_r(t,s) ds + \sum w_s^j(t) T(t_j),$$

where w_s^j gives the level of the jumps of $w(t,\cdot)$ at t_j. This is made precise in the following lemma.

LEMMA 3.1. *The function w can be decomposed as*

$$w(t,s) = e^{-\omega s} w_0(t - \kappa s, s) + e^{-\alpha s} e_0(t - \kappa s)$$

for $t, s > 0$. (a) *Let k_1 be the nonnegative, nonincreasing function given in* (5). *w_0 is nonnegative, $w_0(\cdot, s)$ is nondecreasing, $w_0(t,\cdot)$ is nonincreasing, and $w_0(0+, s) = 0$. If $k_1 \in W^{1,2}_{\mathrm{loc}}([0,\infty))$, then $w_0 \in W^{1,2}_{\mathrm{loc}}([0,\infty)^2)$.* (b) *If $k_1 \in W^{2,2}_{\mathrm{loc}}([0,\infty))$, then also $w_0 \in W^{2,2}_{\mathrm{loc}}([0,\infty)^2)$.*

Proof. Let $T > 0$; we will calculate all L^2-norms on $[0,T]$. From [9, Proposition 4.10] we infer that $w_0 \in W^{1,1}_{\mathrm{loc}}(\mathbb{R}^2_+)$. Note that we may set $\kappa = \omega = 0$, since this will not change the regularity. Moreover, let $l(t) = -\int_0^t s dk_1(s)$. Then $l'(t) = t k_1{}'(t)$ and

$$\partial_t w_0(t,s) = s t^{-1} \int_0^t l'(t-r) d_r w(r,s) + t^{-1} \lim_{h \to 0} h^{-1} \int_t^{t+h} l(t+h-r) d_r w(r,s).$$

To estimate the L^2-norm of the first term we use a simple convolution estimate and $|r/t| \leq 1$ for $r \in [0,t]$. But for the second term we get, using the fact that k_1 is nonincreasing, the following estimate:

$$\begin{aligned} &\left| \lim_{h \to 0} h^{-1} \int_t^{t+h} l(t+h-r) d_r w(r,s) \right| \\ &\leq \lim_{h \to 0} h^{-1} \int_0^h \int_0^{h-r} u |dk_1(u)| \, |d_r w(t+r,s)| \end{aligned}$$

$$\leq \lim_{h\to 0} \int_0^h |k_1(h-r) - k_1(0)|\, |d_r w(t+r,s)|$$
$$\leq \lim_{h\to 0} \sup_{s\in[0,h]} |k_1(s) - k_1(0)|.\|w(\cdot,s)\|_{BV} \;=\; 0.$$

On the other hand, we have

$$-\partial_s w_0(t,s) = (k_1 * \partial_t w_0)(t,s) + e^{-\alpha s}(k_1(t) - \alpha)$$

for almost all $t, s > 0$. We thus get for calculating the norm of w_0 in $W^{1,2}([0,T]^2)$

$$\|\partial_t w_0(\cdot,s)\|_2 \leq s\|{k_1}'\|_2 \|w(\cdot,s)\|_{BV} \leq s\|{k_1}'\|_2,$$
$$\|\partial_s w_0(\cdot,s)\|_2 \leq T^{1/2}\|k_1\|_2 \|\partial_t w_0(\cdot,s)\|_2 + e^{-\alpha s}\|k_1\|_2 + T^{1/2}\alpha e^{-\alpha s}$$

from which follows the claim.

We now calculate the second derivatives in case (b) for $t > 0$. First we get

$$s^{-1}\partial_t^2 w_0(t,s) = t^{-1}\int_0^t ({k_1}'(r) - rt^{-1}{k_1}'(r)) d_r w(t-r,s) \tag{7}$$
$$+ t^{-1}\int_0^t r{k_1}''(r) d_r w(t-r,s) \tag{8}$$
$$+ \lim_{h\to 0} h^{-1}\int_t^{t+h} l'(t+h-r) d_r w(r,s). \tag{9}$$

Note that from the first part of the proof we may infer with $k_1 \in W^{2,2}([0,T])$ we have

$$\|\partial_t w_0(\cdot,s)\|_\infty \leq s\|{k_1}'\|_\infty \|w(\cdot,s)\|_{BV} \leq s\|{k_1}'\|_\infty < \infty.$$

We estimate the second part of the right side of (7) (the first part is clearly bounded) and obtain

$$\int_0^T \left| \int_0^t rt^{-2}{k_1}'(t-r) d_r w(r,s) \right|^2 dt$$
$$= \int_0^T \left| \int_0^t rt^{-2}{k_1}'(t-r)\partial_r w_0(r,s) dr \right|^2 dt$$
$$\leq \int_0^T t^{-2} \int_0^t |{k_1}'(t-r)|^2 dr \int_0^t |\partial_r w_0(r,s)|^2 dr\, dt$$
$$< C\|k_1\|_{W^{2,2}}$$

(uniformly in $s \in [0,T]$). Now we calculate the desired bound for (8) using a standard estimate for convolutions.

$$\int_0^T \left| \int_0^t rt^{-1}{k_1}''(r) d_r w(t-r,s) \right|^2 dt$$
$$= \int_0^T \int_0^t |{k_1}''(r)|^2 d_r w(t-r,s) dt$$
$$\leq C\|{k_1}''\|_2.$$

We estimate (9) using the fact that $w(\cdot, s)$ is differentiable with bounded derivative for $t > 0$.

$$\lim_{h\to 0}\left|h^{-1}\int_t^{t+h}(t+h-r)k_1{}'(t+h-r)d_r w(r,s)\right| \le \lim_{h\to 0}\int_0^h |k_1{}'(h-r)||d_r w(t+r,s)| \;=\; 0.$$

Thus $\|\partial_t^2 w_0(\cdot,s)\|_2 \le 3Cs\|k_1\|_{W^{2,2}}$, which concludes the proof for $\partial_t^2 w_0$. We have for the remaining derivatives for almost all $t, s > 0$

$$-\partial_t\partial_s w_0(t,s) = (k_1 * \partial_t^2 w_0)(t,s) + e^{-\alpha s}k_1{}'(t) + \partial_t w_0(0,s)k_1(t),$$
$$-\partial_s^2 w_0(t,s) = (k_1 * \partial_s\partial_t w_0)(t,s) - \alpha e^{-\alpha s}(k_1(t) - \alpha).$$

Consequently,

$$\|\partial_t\partial_s w_0(\cdot,s)\|_2 \le \|k_1\|_1\|\partial_t^2 w_0(\cdot,s)\|_2 + e^{-\alpha s}\|k_1{}'\|_2 + \partial_t w_0(0,s)\|k_1\|_2,$$
$$\|\partial_s^2 w_0(\cdot,s)\|_2 \le \|k_1\|_1\|\partial_s\partial_t w_0(\cdot,s)\|_2 + \alpha e^{-\alpha s}(\|k_1\|_1 + \alpha T^{1/2}),$$

which concludes the proof for the remaining derivatives.

Note that we have omitted the proof of the measurability for the derivatives in question. This can be proven by standard mollifier arguments. □

We are now in a position to prove some relationships that hold between the spaces of admissible vectors X^T and X^S.

THEOREM 3.2. *Suppose that $a \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ is a completely positive function with $\kappa > 0$ and let $k_1 \in W^{1,2}_{\mathrm{loc}}([0,\infty))$. Then b is admissible for the Volterra case (i.e., (2)) if it is admissible for the autonomous case (i.e., (1)).*

Proof. $w(t,\cdot)$ can be decomposed according to Lemma 3.1 into a regular part with density $w_r(t,\cdot) \in L^2([0,t/\kappa])$ and a singular part $w_s(t,\cdot)$ with a jump at t/κ of level $e^{-\alpha t/\kappa}$. We thus may estimate two terms in the admissibility equation which correspond to the regular and singular parts, respectively. For the first we get (using $C_{T/\kappa}$ as the $L_2([0,T/\kappa])$-norm of $T(\cdot)b$)

$$\begin{aligned}
&\left\|\int_0^T\int_0^\infty T(s)bu(t)w_r(t,s)ds\,dt\right\| \\
&= \left\|\int_0^T\int_0^{t/\kappa} T(s)bu(t)w_r(t,s)ds\,dt\right\| \\
&= \left\|\int_0^{T/\kappa} T(s)b\int_{\kappa s}^T u(t)\,w_r(t,s)dt\,ds\right\| \\
&\le C_{T/\kappa}\left\|\int_{\kappa(\cdot)}^T u(t)w_r(t,\cdot)dt\right\|_2 \\
&\le C_{T/\kappa}\left(\int_0^T\left\|\int_{\kappa s}^T u(t)w_r(t,s)dt\right\|^2 ds\right)^{1/2} \\
&\le C_{T/\kappa}\left(\|u\|_2^2\int_0^T\|w_r(\cdot,s)\|_2 ds\right)^{1/2} \\
&\le C_{T/\kappa}\|w_r\|_2\|u\|_2.
\end{aligned}$$

For the singular part we have

$$\begin{aligned}&\left\|\int_0^T\int_0^\infty T(s)bu(t)dw_s(t,s)\,dt\right\|\\&=\left\|\int_0^T e^{-\alpha t/\kappa}T(t/\kappa)bu(t)dt\right\|\\&\le C_{T/\kappa}\kappa\|e^{-\alpha(\cdot)}u(\kappa\cdot)\|_2\le C_{T/\kappa}\|u\|_2.\qquad\square\end{aligned}$$

Note that we have proven a partial converse of Theorem 2.3 in view of the results from [11].

This theorem can be generalized in that one may consider control operators with a range space of higher dimension. Moreover, functions w with more jumps than just at zero can be dealt with on the same basis of proof, but giving a priori conditions on a is more difficult. We thus have $X^T\subset X^S$. Be reminded that Theorem 2.3 does not require $\kappa>0$ for the same result in the diagonal case.

As to the necessity of the condition on k_1, we observe Example 2.5 again. There, we found b that was not admissible for the semigroup generated by A, but admissible for the equation

$$x(t)=x_0+(a*Ax)(t)+(1*bu)(t).$$

In that case $k(t)=2\sqrt{t/\pi}$ and thus $k_1(t)=1/\sqrt{t\pi}$. But $k_1\notin W^{1,2}_{\mathrm{loc}}([0,\infty))$.

Assume that the hypothesis of Theorem 3.2 holds, except that $\kappa=0$. Then the decomposition of w into a regular part with density w_r and a singular part yields a trivial singular part and $w_r(t,\cdot)\in L^2([0,T])$. Now assume $w_r(t,\cdot)\in W^{1,2}([0,T])$. Thus

$$\|(S*bu(T-\cdot))(T)\|=\left\|\int_0^T\int_0^\infty T(s)bu(t)w_r(t,s)ds\,dt\right\|.$$

We remark that $\int_0^t v(s)T(s)x\,ds\in D(A)$ for all $x\in X$, if $v\in W^{1,1}([0,t])$, which is easy to prove. (Use $AT(\cdot)=T'(\cdot)$ and partial integration.) We then need to see that

$$v(\cdot)=\int_0^T u(t)w_r(t,\cdot)dt\in W^{1,1}([0,T]).$$

But this is true, since $w_r(t,\cdot)\in W^{1,2}([0,T])\subset W^{1,1}([0,T])$. Therefore any $b\in X^{-1}$ is admissible in this situation ($\kappa=0$).

THEOREM 3.3. *Suppose that $a\in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ is a completely positive function with $\kappa>0$ and let $k_1\in W^{2,2}_{\mathrm{loc}}([0,\infty))$. Then b is admissible for the Volterra case (i.e., (2)) if and only if it is admissible for the autonomous case (i.e., (1)).*

Proof. By Lemma 3.1, $S(t)$ can be expressed as

$$S(t)=e^{-\alpha t/\kappa}T(t/\kappa)+\int_0^{t/\kappa}T(s)w_r(t,s)ds,\tag{10}$$

where $w_r\in W^{1,1}_{\mathrm{loc}}([0,\infty)^2)$. Now let $\kappa>0$. Since $X^T\subset X^{-1}$, for a given $t>0$,

$$b\mapsto\int_0^\infty w_r(\cdot,s)T(s)b\,ds$$

maps X^T into $L^2([0,t],X)$. Observe that the integral vanishes outside of a compact interval. □

Thus $X^S = X^T$ if we require more regularity on k_1. The representation (10) is however interesting in its own right. The subordinated solution family under this condition is an additive perturbation of the (shifted and rescaled) semigroup with a very "smooth" operator. The perturbation maps not only X^{-1} into X and, similarly, X into X^1 but also is uniformly continuous (cf. [9, section 4]).

In closing we would like to remark that extensions of the presented results to infinite-dimensional control operators are possible. In particular, Theorems 3.2 and 3.3 remain valid even for infinite-dimensional B. An eigenvector expansion in a Hilbert space is also possible for certain constellations. A full-fledged analysis of the infinite-dimensional case is however beyond the scope of this paper; we refer to [12] and [5] for operator generalizations of the Carleson measure criterion in the autonomous case.

Acknowledgment. I would like to thank an unnamed referee for some invaluable suggestions, improving, in particular, the examples.

ABSTRACT OPTIMAL LINEAR FILTERING*

VLADIMIR N. FOMIN† AND MICHAEL V. RUZHANSKY‡

Abstract. The linear optimal filtering problems in infinite dimensional Hilbert spaces and their extensions are investigated. The quality functional is allowed to be a general quadratic functional defined by a possibly degenerate operator. We describe the solution of the stable and the causal filtering problems. In the case of causal filtering, we establish the relation with a relaxed causal filtering problem in the extended space. We solve the last problem in continuous and discrete cases and give the necessary and sufficient conditions for the solvability of the original causal problem as well as the conditions for the analogue of the Bode–Shannon formula to define an optimal filter.

Key words. linear filtering, stable filtering, causal filtering, optimal filter, Bode–Shannon formula

1. Introduction.

We consider the linear optimal filtering problems in infinite dimensional Hilbert spaces and their extensions. Briefly, the problem is as follows. Let H', H'' be Hilbert spaces and $z = \left[\begin{smallmatrix} x \\ y \end{smallmatrix}\right]$ a random element in $H = H' \times H''$, where x and y are unobservable and observable components of z in H' and H'', respectively. The correlation operator of z is assumed to be bounded in H and we denote by $\mathbb{H}$ a subset of all linear operators $h : H'' \to H'$. The $\mathbb{H}$-optimal linear filtering problem is a problem of the estimations of the unobservable component x based on the realizations of the observable component y in the form

$$\hat{x} = hy \tag{1.1}$$

solving the minimization problem in $\mathbb{H}$

$$J(h) \to \inf_{h \in \mathbb{H}}, \tag{1.2}$$

where the quality functional J is defined by

$$J(h) = E||D(x - \hat{x})||^2 \tag{1.3}$$

with a suitable norm in (1.3) and a linear operator $D : H' \to H'$. The operator D here is an arbitrary operator in general. In that which follows we will sometimes assume that it has an adjoint D^* and that it is continuous if the other operators in the problem are continuous. The choice of operator D allows us to perform the minimization of the quality functional $J(h)$ with respect to some of the variables. In this case D is not bijective and its choice is dictated by the problem at hand. If D is bijective, then, as we shall see, the minimization in (1.2) is performed with respect to *all* variables with certain weights assigned. This leads to the linear transformation of

the solution for $D = I$, I being the identity operator. If D is degenerate, the solution of (1.2) is not unique and we will provide formulas for it.

If $\mathbb{H}$ consists of all continuous linear operators h, the problem (1.1), (1.2), (1.3) is called *stable*. If H' and H'' are Hilbert resolution spaces, one has a time structure in H and in its terms defines an "independent of the future" class of the causal continuous operators $\mathbb{H}$. In this case the problem is called *causal*.

If H' and H'' are finite dimensional (the time set $\mathbb{T}$ is discrete and finite), the problem (1.1), (1.2), (1.3) is quite trivial: the causal operators become the lower triangular matrices in a natural basis. In the case of the nondegenerate correlation matrix R_y of the random vector y and the identity matrix D, the problem (1.2) is solvable in the class of the causal weight operators, the solution is unique, and it can be effectively expressed in the terms of the Holetsky factorization [2] of R_y. This result finds various applications [11], [9].

In the case of the discrete time $\mathbb{T} = \mathbb{Z}$ and a stationary partially observable process (time series) z, the problem (1.2) was first treated by Kolmogorov [8]. In the case of the continuous time its solution was first obtained by Wiener [11], who also developed a method for the synthesis of the transfer function of the optimal filter. The Wiener–Kolmogorov optimal filtering theory of the stationary processes was universally accepted partly due to the interpretation of the optimal filter given by Bode and Shannon [1], where the signal y is being "prewhitened" first and the result is optimally processed. The solution representation for optimization problem (1.2), allowing the mentioned interpretation, bears the name of the Bode–Shannon formula.

However, in many applications one estimates only the specific components of x or their combination, which is represented by the degenerate matrix D in the quality functional (1.3) and the solutions of the generalized finite dimensional problems can be found in [10]. In this case the solution need not be unique and there are conditions on the degeneracy of D for which the Bode–Shannon formula still defines an optimal filter.

On the other hand, the infinite dimensional applications required the development of the filtering theory in Hilbert [3] and sometimes Banach spaces [4], [7]. The unobservable component of a process can be formed by the infinite dimensional filter. For example, it can be given by several differential equations with delay or by differential integral equations. In this case it is not possible to use the methods developed for the finite dimensional state space. The method discussed in the paper allows us to formulate such infinite dimensional problems and provides techniques for their solutions. For the applications of this theory to the problem of the linear estimation of the parameters of a signal based on the observations of its realizations see, for example, [4]. In this paper the stable filtering problem will be solved for the general quadratic quality functional (1.3). The solution of the causal filtering problem need not exist in general. We will establish necessary and sufficient conditions of solvability by relaxing the problem, thus allowing a slightly general class of the weight operators in (1.2). The relaxed problem can be solved and the analysis of its solution can be used for the construction of minimizing sequences. The solutions will be given for continuous and discrete resolutions. The conditions for the analogue of the Bode–Shannon formula of [4] to define an optimal filter will also be given.

Some of the literature we are referring to is in Russian, and for the sake of completeness, the results of [4] needed in this paper will be briefly reviewed. We will not give the complete proofs of them in order to avoid technicalities which are unimportant to the nature of the results of this paper. One can consult [5] for some of

the details. A preliminary version of this paper appeared as a preprint [6] while the second author worked at Utrecht University.

In section 2 we fix the notation related to the concept of the extended Hilbert space and random elements in it. In section 3 we formulate and give the solution of the general linear filtering problem in extended Hilbert spaces in Theorem 3.1. The stable linear filtering problem is solved in section 4 (Theorem 4.1). Section 5 is devoted to the causal filtering problem. In subsections 5.1 and 5.2 we discuss Hilbert resolution spaces, their extensions, and linear operators in extended spaces. In subsection 5.3 we formulate the problem. The corresponding relaxed problem is solved in subsection 5.4 (Theorem 5.8). In subsection 5.5 we treat the case of the discrete resolution of the identity (Theorem 5.11) and give necessary and sufficient conditions of the solvability of the original problem (Theorem 5.12). In section 6 the concept of the spectral factorization will be discussed, and the conditions for the Bode–Shannon formula to define an optimal filter will be given in Theorem 6.4.

2. Preliminaries. In this section we will briefly introduce several constructions, which will be used throughout this paper.

2.1. Extended Hilbert spaces and linear operators. Here we will briefly review a concept of the extended Hilbert space (see also [5]). Let H be a complex Hilbert space with an inner product $\langle\cdot,\cdot\rangle$ and let $F \subset H$ be a linear dense subset of H. We will need the notion of F-weak convergence in H.

DEFINITION 2.1. *A sequence $\psi_l \in H$ is called an* F-weakly Cauchy sequence *if*

$$\lim_{l,m\to\infty} \langle \psi_l - \psi_m, \phi\rangle = 0 \text{ for all } \phi \in F.$$

Let Ψ be a set of all F-weakly Cauchy sequences $\psi = \{\psi_l\}$, $\psi_l \in H$, $l \in \mathbb{N}$. Let $\overset{F}{\cong}$ be an equivalence relation in Ψ: $\psi \overset{F}{\cong} \xi$ if $\lim_{m\to\infty}\langle \psi_m - \xi_m, \phi\rangle = 0$ for all $\phi \in F$. Then it is not difficult to check that the quotient space $H_F \equiv \Psi/\overset{F}{\cong}$ of Ψ with respect to the equivalence relation $\overset{F}{\cong}$ is a linear Hausdorff topological space.

Every element $\bar\psi \in H_F$ defines a functional $\bar\psi^* : F \to \mathbb{C}$ by $\bar\psi^*(\phi) = \lim_{l\to\infty}\langle \psi_l, \phi\rangle$, where $\{\psi_l\}$ is a sequence from $\bar\psi$. This duality is an extension of the inner product in H and we will denote this also by $\bar\psi^*(\phi) = \langle \bar\psi, \phi\rangle$. The following relation is obvious.

PROPOSITION 2.1. *H_F is complete in F-weak topology and $F \subset H \subset H_F$.*

The pair (F, H_F) is called an equipment of H, and H with such an equipment is called an equipped Hilbert space. We will also use a construction which gives a space equivalent to H_F.

DEFINITION 2.2. *The space F^* is a space of all the elements f for which there exists a sequence $f_l \in H^*$ such that $f(\phi) = \lim_{l\to\infty} f_l(\phi)$ for all $\phi \in F$.*

Obviously, F^* is complete with respect to the topology of componentwise convergence on F. This implies the completeness of H_F in view of the following.

PROPOSITION 2.2.

(i) *F^* is isomorphic to H_F.*

(ii) *Let $\bar\psi \in H_F$. Define for the corresponding $\bar\psi^* \in F^*$ a "norm" $|\bar\psi^*|_{F^*} = \sup_{\phi\in F} \frac{|\langle\bar\psi,\phi\rangle|}{|\phi|_H}$. Then $\bar\psi \in H$ if and only if $|\bar\psi^*|_{F^*} < \infty$. In this case $|\bar\psi^*|_{F^*} = |\bar\psi|_H$.*

The proof easily follows from the definitions above. Let $A : H \to H$ be a linear operator defined in a dense subspace $D(A)$ of H. Recall the following.

DEFINITION 2.3. *Let $D_* \subset H$ be a space of all elements $\phi \in H$ for which there exist $f(\phi) \in H$ such that $\langle A\psi, \phi\rangle = \langle \psi, f(\phi)\rangle$ for all $\psi \in D(A)$. The operator adjoint to A is defined as $A^* : D_* \to H$, such that $A^*\phi = f(\phi)$.*

One then has $D_* = D(A^*)$. An operator A is called *symmetric* if $D(A) \subset D(A^*)$ and for every $\phi, \psi \in D(A)$ holds $\langle A\psi, \phi\rangle = \langle \psi, A\phi\rangle$. A symmetric operator A is called *self-adjoint* if $D(A) = D(A^*)$.

Let $\bar{A} : D(\bar{A}) \to H_F$ be an extension of A. Assume $F \cap D(\bar{A})$ to be dense in H. Similar to the definition above, define D_* as a space of all $\phi \in F$ for which there exist $f(\phi) \in F$ such that $\langle \bar{A}\bar{\psi}, \phi\rangle = \langle \bar{\psi}, f(\phi)\rangle$ for all $\bar{\psi} \in D(\bar{A})$. Let $\bar{A}^* : D_* \to H_F$ be an operator defined by $\langle \bar{A}\bar{\psi}, \phi\rangle = \langle \bar{\psi}, \bar{A}^*\phi\rangle$ for all $\bar{\psi} \in D(\bar{A})$, $\phi \in D_*$. The F-weak closure of $\bar{A}^*$ is called *the adjoint* to $\bar{A}$ in H_F and will be also denoted by $\bar{A}^*$. As above, $\bar{A}$ is called *symmetric* if $D(\bar{A}) \subset D(\bar{A}^*)$ and A is symmetric. A symmetric operator $\bar{A}$ is called *self-adjoint* if $D(\bar{A}) = D(\bar{A}^*)$.

Example 2.1. Let M be a smooth manifold and let $H = L^2(M)$ with respect to some positive smooth density on M. Let F_k be a space of k-times continuously differentiable compactly supported functions in M. Then the F_k-weak completion of H is a space of distributions of order k in M.

Example 2.2. Let $H = l^2(\mathbb{N})$ with its standard inner product and let $A : l^2 \to l^2$ be defined by $(A\phi)_n = \sum_{k=1}^{\infty} A_{nk}\phi_k$ with suitable conditions on A_{nk}. Let $F \subset H$ be a set of all the sequences consisting of a finite number of nonzero elements. Then F is dense in H and $F \subset D(A) \subset H$. For the extension of H with respect to F one has $H_F = \mathbb{R}^{\mathbb{N}}$, the space of all the sequences with values in $\mathbb{R}$. One readily checks that the above extension of A yields a linear operator $\bar{A}$ in $\bar{l^2} = H_F$ defined by a matrix A_{nk} with $D(\bar{A}) = \{\phi : \sum_{k=1}^{\infty} |A_{nk}\phi_k|^2 < \infty, n \in \mathbb{N}\}$. An important particular case of this example is the following.

Example 2.3. Let $\mathbb{T} = (t_{\mathrm{s}}, t_{\mathrm{f}})$ be a subinterval of $\mathbb{R}$ and let $H = L^2(\mathbb{T})$ be equipped with the standard inner product. Let F be the space of L^2-integrable continuously differentiable functions on $\mathbb{T}$. Then H_F contains not only functions $f \in L^2(\mathbb{T})$ but their generalized derivatives Df as well. In the filtering problems of time series, one normally encounters a discrete set $\mathbf{t} \subset \mathbb{T}$ without accumulation points (with the possible exception of its endpoints). There is a natural correspondence between this set and the Hilbert space $l^2(\mathbf{t})$ over it. The space $L^2(\mathbb{T})$ is infinite dimensional while $l^2(\mathbf{t})$ is infinite dimensional only if $\mathbf{t}$ is infinite. If $\mathbf{t}$ is finite, the space $l^2(\mathbf{t})$ is a standard Euclidean space.

Example 2.4. In this example D denotes the generalized derivative as in Example 2.3 (no relation with the operator D in (1.3)). Let the partially observable element $z = \binom{x}{\mathrm{D}y}$ satisfy $Ez = 0$. Let $x = x(\cdot) \in \mathbb{R}^n$ be a L^2-continuous random process with realizations $x \in L^2(\mathbb{T})$. Let $\mathrm{D}y$ be a scalar random process related to x by a linear "observation scheme":

$$\mathrm{d}y(t) = C^*(t)x(t)\mathrm{d}t + \mathrm{d}w(t), \tag{2.1}$$

where $w(\cdot) \in L_2(\mathbf{T})$ is a standard Gaussian–Wiener process ($Ew(t) = 0$, $w(t_{\mathrm{s}}) = 0$, $Ew(t)w(t') = \min\{t, t'\}$), independent of x, and $C : \mathbb{T} \to \mathbb{R}^n$ is a given continuous function. The correlation operator $R_x = Exx^*$ of a random element x is an integral operator in $L_2(\mathbb{T})$,

$$(R_x\phi)(t) = \int_{t'=t_{\mathrm{s}}}^{t_{\mathrm{f}}} R_x(t, t')\phi(t')\mathrm{d}t', \tag{2.2}$$

where $R_x(\cdot,\cdot) = Ex(t)x^*(t')$ is the correlation matrix of the random process $x = \{x(t),\ t \in \mathbb{T}\}$. This matrix is continuous on $\mathbb{T}\times\mathbb{T}$ because x is L^2-continuous. The random element (process) y is now a generalized element with realizations in $L^2(\mathbb{T})_F$ (see Example 2.3). Its correlation operator $R_{\mathrm{D}}y = E\mathrm{D}y(\mathrm{D}y)^*$ is given by

$$R_{\mathrm{D}y} = C^* R_x C + I, \tag{2.3}$$

where the operator $C : L_2(\mathbb{T}) \to L_2(\mathbb{T})$ is determined by $(C\psi)(t) = C(t)\psi(t)$, $\psi(\cdot) \in L_2(\mathbb{T})$, and I is the identity operator in $L^2(\mathbb{T})$. Formula (2.3) defines the bounded operator $R_y : L^2(\mathbb{T}) \to L^2(\mathbb{T})$ which can be viewed as a singular integral operator with the kernel

$$\begin{aligned} R_{\mathrm{D}y}(t,t') &= C^*(t)R_x(t,t')C(t) + \delta(t-t') \\ &= K(t,t') + \delta(t-t'). \end{aligned} \tag{2.4}$$

The correlation operator between x and $\mathrm{D}y$ is given by

$$R_{x\mathrm{D}y} = R_x C. \tag{2.5}$$

Formulas (2.3), (2.5) allow us to represent the full correlation operator $R_z = Ezz^*$ of the partially observable element z as

$$R_z = \begin{Vmatrix} R_x & R_{x\mathrm{D}y} \\ R^*_{x\mathrm{D}y} & R_{\mathrm{D}y} \end{Vmatrix} = \begin{Vmatrix} R_x & R_x C \\ C^* R_x & C^* R_x C + I \end{Vmatrix}. \tag{2.6}$$

2.2. Generalized random elements. Let F, H, H_F be as above and let $(\Omega, \mathcal{A}, P)$ be a probability space, where P is a complete measure.

Definition 2.4. *A mapping $z : \Omega \to H_F$ is called a* random H_F-element *if for every $\phi \in F$ the following hold:*

(i) *$z^*\phi = \langle z, \phi\rangle : \Omega \to \mathbb{C}$ is a random variable.*

(ii) *$E(z^*\phi) = (Ez)^*\phi$ for some $Ez \in H_F$.*

(iii) *There exists c such that $E|(z - Ez)^*\phi|^2 \le c|\phi|^2_H$ for all $\phi \in F$.*

Without loss of generality, we will consider the centralized elements, $Ez^*\phi = 0$ for all $\phi \in F$. Then $E\overline{z^*\phi}z^*\phi = E|z^*\phi|^2 = \langle \phi, R_z\phi\rangle$ is a quadratic form in F. A linear operator R_z is called the *correlation operator* of z. Property (iii) of the definition implies that R_z is a continuous operator on F and, therefore, it can be extended to a continuous self-adjoint operator in H, $R_z \in \mathcal{L}(H)$. Thus, we have proved the following.

Proposition 2.3. *$R_z \in \mathcal{L}(H)$, $R_z^* = R_z$, and $R_z \ge 0$ in the sense of quadratic forms.*

In analogy with the classical case we will write $R_z = Ezz^*$. Note that Definition 2.4 is equivalent to the condition that $z : \Omega \to H_F$ is measurable, centralized, and has the continuous correlation operator, where Ω and H_F are equipped with σ-algebras $\mathcal{A}$ and one generated by the open sets of F-weak topology in H_F, respectively.

Example 2.5. The random processes can be interpreted as random generalized elements of a Hilbert space. Let $T > 0$ and $H = L^2(m,T)$ be a Hilbert space of m-vector functions on $[0,T]$ equipped with the standard inner product. Let $w = \{w(t), 0 \le t \le T\}$ be a Gauss process, such that almost all realizations of w are elements of $L^2(m,T)$ and $E\int_0^T |w(t)|^2 dt < \infty$. Then R_w is a nuclear operator. If $T = +\infty$, then almost all realizations of $w \notin L^2(m,T)$, but for $F = \mathcal{C}_{\mathrm{comp}}([0,T])$ the realizations of w are elements of $L^2(m,T)_F$.

Example 2.6. Now we return to Example 2.3 and assume that $\mathbb{T} = \mathbb{R}$, ($t_s = -\infty$, $t_f = \infty$). Assume that the partially observable process z is stationary. A stationary linear filter takes the form

$$\hat{x}(t) = \int_{-\infty}^{\infty} h(t - t')\mathrm{d}y(t'), \qquad t \in R. \tag{2.7}$$

Suppose that the optimal filter must minimize the quality functional given by

$$J(h) = E|x(t) - \hat{x}(t)|^2, \tag{2.8}$$

where we can observe that because we assume that the process is stationary, the quality functional $J(h)$ does not depend on t. Let $G_z(\omega)$, $\omega \in \mathbb{R}$, denote the symbol of the correlation operator R_z. Recall that the symbol is just the Fourier transform of the correlation matrix $R_z(\cdot)$. The matrix $G_z(\cdot)$ is also called the *spectral density* of the stationary process z. Then in view of (2.7) the symbol $H_{opt}(\cdot)$ of the transfer operator h_{opt} (the symbol is called the *transfer function* of the optimal filter and is equal to the Fourier transform of the weight function $h(\cdot)$) is given by

$$H_{opt}(\omega) = G_x(\omega)C[C^*G_x(\omega)C + 1]^{-1}, \tag{2.9}$$

where $C \in \mathbb{R}^n$ is the vector from (2.1). This vector C does not depend on t since z is stationary. If instead of (2.8) we take the quality functional

$$J(h) = E|D(x(t) - \hat{x}(t))|^2 \tag{2.10}$$

with a degenerate matrix D, then the transfer function of an optimal filter is not unique; see Theorem 3.1.

3. Linear filtering. Let $H = H' \times H''$, where H' and H'' are Hilbert spaces with inner products $\langle \cdot, \cdot \rangle_{H'}$ and $\langle \cdot, \cdot \rangle_{H''}$, respectively. Let $F' \subset H'$ and $F'' \subset H''$ be linear dense subsets. The elements $\phi \in H$ can be interpreted as $\phi = \left[\begin{smallmatrix} \phi' \\ \phi'' \end{smallmatrix}\right]$ with $\phi' \in H'$, $\phi'' \in H''$. Let $F = F' \times F''$. We will consider random H_F elements $z = [\begin{smallmatrix} x \\ y \end{smallmatrix}]$, with x and y random ${H'}_{F'}$- and ${H''}_{F''}$-elements, respectively. The correlation operator R_z will be assumed continuous on H, which is natural in view of Proposition 2.3, and will have the following block form:

$$R_z = \begin{bmatrix} R_x & R_{xy} \\ R_{yx} & R_y \end{bmatrix},$$

where we write $R_x = Exx^*$, $R_y = Eyy^*$, $R_{xy} = R_{yx}^* = Exy^*$.

Let $h : {H''}_{F''} \to {H'}_{F'}$ be linear. We assume now that there exists an operator $h^* : {H'}_{F'} \to {H''}_{F''}$ defined on the whole of ${H'}_{F'}$, such that for every $\phi' \in F'$, $\phi'' \in F''$ one has

$$(h\phi'')^*\phi' = (\phi'')^*(h^*\phi'). \tag{3.1}$$

Relation (3.1) defines h^* uniquely and h^* is the adjoint to the operator h.

Let x and y be the unobservable and observable components of z, respectively. We define the random ${H'}_{F'}$-element $\hat{x}$ by

$$\hat{x} = hy. \tag{3.2}$$

One readily checks that $\hat{x}$ is a random element in the sense of Definition 2.4 in view of our assumptions on h. Then $R_{\hat{x}} = hR_y h^* : H' \to H'$ is involutive in H' as the correlation operator of a random element $\hat{x}$. The element $\hat{x}$ is interpreted as a linear estimate of the nonobservable component x of a random H_F element z, based on the realizations of its observable component y. The relation (3.2) is called *a linear filter with weight operator* h.

Let a linear operator $D : {H'}_{F'} \to {H'}_{F'}$ have an adjoint D^*. We define *the quality functional* as

$$J_{\phi'}(h) = E|\langle \phi', D(x - \hat{x})\rangle|^2,\ \phi' \in F'. \tag{3.3}$$

Let $\mathbb{H}$ be a given subset of linear operators $h : {H''}_{F''} \to {H'}_{F'}$. Then the $\mathbb{H}$-*optimal filtering problem* is defined as a problem of the minimization of the functionals

$$J_{\phi'}(h) \to \inf_{h\in\mathbb{H}}, \tag{3.4}$$

defined by (3.3), (3.2) for every $\phi' \in F'$.

We will need a notion of the pseudo inversion of an operator. Let $A : H \to H$ be a Hermitian linear operator in a Hilbert space H. Let Q_A be an orthogonal projection on the image of A, $Q_A : H \to \mathrm{Im}A$. The space $Q_A H$ is invariant for A and we write $A^{-1}Q_A$ for the inverse of A in $Q_A H$. The operator

$$A^+ = Q_A \circ A^{-1}Q_A \circ Q_A$$

is called the *pseudo inverse of* A. It follows that

$$A^+A = AA^+ = Q_A. \tag{3.5}$$

One readily checks that (3.5) determines A^+ uniquely and thus we have the following.

Proposition 3.1. *Let A be a Hermitian operator. The solution of*

$$\langle Ag - f, Ag - f\rangle \to \inf_{g\in H},\ f \in H,$$

with minimal norm defines a linear functional of f which is given by $g = A^+ f$.

We will not prove this fact here since we will not use it explicitly. Assume that $\mathbb{H}$ is a space of all linear operators $h : {H''}_{F''} \to {H'}_{F'}$. Then the solution of the $\mathbb{H}$-optimal filtering problem is given by the following.

Theorem 3.1. *Let the correlation operator R_z of a random H element z be continuous in H and let R_y^+ denote the pseudo inverse operator for the correlation operator R_y of y in H''. Then the minimization problem* (3.4) *in the class $\mathbb{H}$ of all weight operators $h : {H''}_{F''} \to {H'}_{F'}$ is solvable and any solution is of the form*

$$h_{\mathrm{opt}} = R_{xy}R_y^+ + Q, \tag{3.6}$$

where $Q : {H''}_{F''} \to {H'}_{F'}$ is any linear operator satisfying $DQQ_{R_y} = 0$ and Q_{R_y} is the kernel of R_y. Moreover, one has

$$\inf_{h\in\mathbb{H}} J_{\phi'}(h) = J_{\phi'}(h_{\mathrm{opt}}) = \langle \phi', D[R_x - R_{xy}R_y^+ R_{xy}^*]D^*\phi'\rangle.$$

The proof follows the lines of the proof of Theorem 4.1, which is given in the next section. The existence of D^* ensures the decomposition (4.3), from which the statement of Theorem 3.1 follows.

4. Linear stable filtering. If $\mathbb{H}$ is a space of all *continuous* linear operators from H'' to H', then the linear filters of the form (3.2) with weight operator in $\mathbb{H}$ are called *stable* and the $\mathbb{H}$-optimal filtering problem is called the *stable filtering problem*. In this case one allows $\phi' \in H'$ in (3.3) and the minimization problem can be reformulated for scalar functionals

$$J(h) = \sup_{\phi' \in H'} \frac{E|\langle \phi', D(x - \hat{x})\rangle|^2}{|\phi'|^2_{H'}}. \tag{4.1}$$

Now we are ready to describe the solution of the linear stable filtering problem. Let us assume that R_y is continuously invertible in its image $R_y H''$, which means that there exists a neighborhood U of zero such that $\sigma(R_y) \cap U = \{0\}$, $\sigma(R_y)$ being the spectrum of R_y. We will also assume that the operator D in the quality functional (3.3) is continuous in H' and has an adjoint D^*.

THEOREM 4.1. *Let the correlation operator R_z of a random H element z be continuous in H and assume that the correlation operator R_y of y has the continuous pseudo inverse operator R_y^+ in H''. Then the minimization problem* (3.4) *in the class $\mathbb{H}$ of all continuous weight operators $h : H'' \to H'$ is solvable and any solution is of the form*

$$h_{\text{opt}} = R_{xy} R_y^+ + Q, \tag{4.2}$$

where $Q : H'' \to H'$ is any linear continuous operator satisfying $DQQ_{R_y} = 0$. Moreover, one has

$$\inf_{h \in \mathbb{H}} J_{\phi'}(h) = J_{\phi'}(h_{\text{opt}}) = \langle \phi', D[R_x - R_{xy} R_y^+ R_{xy}^*] D^* \phi' \rangle_{H'}.$$

The operators (4.2) *are also optimal in the problem with quality functional* (4.1) *and*

$$\inf_{h \in \mathbb{H}} J(h) = J(h_{\text{opt}}) = |D[R_x - R_{xy} R_y^+ R_{xy}^*] D^*|_{H'}.$$

Proof. First we rewrite the quality functionals (3.3) as

$$J_{\phi'}(h) = \langle \phi', R_{D(x - hy)} \phi' \rangle,$$

where $R_{D(x-hy)}$ is the correlation operator of $D(x - hy)$, and using the existence of D^* and h^* we have

$$\begin{aligned} R_{D(x-hy)} &= E[D(x - hy)][D(x - hy)]^* = DE(x - hy)(x - hy)D^* \\ &= D[R_x - R_{xy} h^* - h R_{yx} + h R_y h^*] D^*. \end{aligned}$$

This means

$$\begin{aligned} J_{\phi'}(h) &= \langle \phi', D[R_x - R_{xy} h^* - h R_{yx} + h R_y h^*] D^* \phi' \rangle \\ &= \langle \phi', D[R_x - R_{xy} R_y^+ R_{xy}^*] D^* \phi' \rangle \\ &+ \langle \phi', D(h - R_{xy} R_y^+) R_y (h - R_{xy} R_y^+)^* D^* \phi' \rangle. \end{aligned} \tag{4.3}$$

Here only the second term depends on h and it is a nonnegative quadratic form attaining its minimum if and only if $D(h - R_{xy} R_y^+) Q_{R_y} = 0$ in view of Proposition 2.3. The set of all continuous h satisfying this equation is precisely the set of h_{opt} in (4.2) for all linear continuous $Q : H'' \to H'$ satisfying $DQ_{R_y} = 0$. For such h_{opt} the second term in (4.3) is zero, implying the second statement of the theorem. It follows from

(4.3) that functionals (4.2) are also optimal for the problem (4.1) and one readily verifies the last statement of the theorem. The proof is complete. □

REMARK 4.1. *If the kernel of R_y is nontrivial ($Q_{R_y} \neq I_{H''}$), then one has $h = h_{\rm opt} + \tilde{h}(I_{H''} - Q_{R_y})$, where Q_{R_y} is the orthogonal projection on the image of R_y, and $J_{\phi'}(h) = J_{\phi'}(h_{\rm opt})$ for every linear continuous operator $\tilde{h} : H'' \to H'$. If R_y is bijective ($Q_{R_y} = I_{H''}$), then $R_y^+ = R_y^{-1}$ and $h_{\rm opt} = R_{xy}R_y^{-1} + Q$, $DQ = 0$. If D is bijective, then the only solution of* (3.4) *is $h_{\rm opt} = R_{xy}R_y^+$.*

REMARK 4.2. *These methods can be applied for the problems of linear estimation of the parameters of a signal based on the observations of its realizations.*

We will not discuss it here, but the reader can consult [4] and [5] for the detailed applications.

5. Linear causal filtering. In this section we will give the solution of the generalized linear causal filtering problem. However, we need some preliminary notions and results first.

5.1. Hilbert resolution spaces and causal operators. Let H be a Hilbert space, let $\mathbb{T} = (t_s, t_f)$, $-\infty \le t_s < t_f \le +\infty$, and let $\mathbb{P}_T = \{P_t, t \in \mathbb{T}\}$ be a family of commutative projectors $P_t : H \to H$, $P_t^2 = P_t$, $P_tP_s = P_sP_t$, $t, s \in \mathbb{T}$. Let $\mathbb{P}_T$ satisfy the following two properties:

(i) *Monotonicity*: $P_tP_s = P_s$ for $t \ge s$, $t, s \in \mathbb{T}$.

(ii) *Completeness*: $\lim_{t\to t_s} P_t = 0_H$, $\lim_{t\to t_f} P_t = I_H$, where the limits are taken in the strong operator topology.

Note, that condition (i) is equivalent to the fact that $P_sH \subset P_tH$, $t \ge s$. We assume the family $\mathbb{P}_T$ to be bounded uniformly in t: $\sup_{t\in\mathbb{T}} |P_t| < \infty$ and strongly continuous from the left: $\lim_{\epsilon\to 0+} P_{t-\epsilon}\phi = P_t\phi$ for every $\phi \in H$. Such family $\mathbb{P}_T$ is called a *resolution of the identity of* H and $(H, \mathbb{P}_T)$ is called a *Hilbert resolution space*. If $\mathbb{P}_T$ consists of the orthogonal projectors $P_t = P_t^*$, then it is called a *Hermitian resolution of the identity*. In this case the condition of the uniform boundedness in t is automatically satisfied since $|P_t| \le 1$.

Let $H = H' \times H''$, where $(H', \mathbb{P}'_T)$, $(H'', \mathbb{P}''_T)$ are Hilbert resolution spaces. Then H may be equipped with the canonical resolution of the identity

$$P_t = \begin{bmatrix} P'_t & 0_{12} \\ 0_{21} & P''_t \end{bmatrix}, \ t \in \mathbb{T}, \tag{5.1}$$

where $0_{12} : H'' \to H'$, $0_{21} : H' \to H''$ are zero operators.

DEFINITION 5.1. *Let $A : D(A) \to H$ be a linear densely defined operator. A is called* finite from above *if there exists a measurable, essentially bounded function $\tau : \mathbb{T} \to \mathbb{T}$, such that for almost all $t \in \mathbb{T}$ the operator P_tA is bounded in H and if $t - \tau(t) \in \mathbb{T}$, then*

$$P_tA = P_tAP_{t-\tau(t)} \tag{5.2}$$

on $D(A) \cap P_{t-\tau(t)}D(A)$. The function $\tau = \tau_+(\cdot)$ is called the upper characteristic *of A. A finite from above operator A with characteristic $\tau_+(\cdot)$ is called* τ-causal *or* τ_+-finite.

The space of all τ_+-finite operators will be denoted by $\mathbb{A}^\tau$ and $\mathbb{A}^0 = \cup_\tau \mathbb{A}^\tau$. 0-causal operators are called *causal*. For $\phi \in H$ one can consider a trajectory $\{P_t\phi, \ t \in \mathbb{T}\}$ connecting ϕ and zero in H. Then (5.2) means that a τ-causal operator A considered as a shift operator along these trajectories does not depend on a

future with respect to the resolution; namely, it follows from the completeness of $\mathbb{P}_T$ that $P_t A\phi$ is independent of $P_s\phi$ for $s > t - \tau(t)$. One also has a notion of finiteness from below, given in the following.

DEFINITION 5.2. *Let $A : D(A) \to H$ be a linear densely defined operator. A is called* finite from below *if there exists a measurable, essentially bounded function $\tau : \mathbb{T} \to \mathbb{T}$, such that for almost all $t \in \mathbb{T}$ the operator $(I_H - P_t)A$ is defined in $D(A)$ and if $t - \tau(t) \in \mathbb{T}$, then*

$$(I_H - P_t)A = (I_H - P_t)A(I_H - P_{t-\tau(t)}) \tag{5.3}$$

on $D(A) \cap (I_H - P_{t-\tau(t)})D(A)$. The function $\tau = \tau_-(\cdot)$ is called the lower characteristic *of A. A finite from below operator A with characteristic $\tau_-(\cdot)$ is called* τ-anticausal.

DEFINITION 5.3. *Let $A : D(A) \to H$ be a linear densely defined operator. A is called* finite *if it is finite from above and below.*

Note that for the Hermitian resolution of the identity, A is finite from below if and only if A^* is finite from above and in this case $\tau_-(A) = \tau_+(A^*)$. 0-anticausal operators are called *anticausal* and one writes $\mathbb{A}_\tau$ for all $\tau = \tau_-$-anticausal operators, $\mathbb{A}_0 = \cup_\tau \mathbb{A}_\tau$. If $A \in \mathbb{A}^0 \cap \mathbb{A}_0$ and $\tau_+ = \tau_- = \tau$, then A is called τ-*local*. 0-local operator is called *local*. Every operator commuting with $\mathbb{P}_T$ is local. We will need the following property.

LEMMA 5.4 (see [4]). *Let $A \in \mathbb{A}^\tau$ (resp., $\mathbb{A}_\tau$), $A' \in \mathbb{A}^{\tau'}$ (resp., $\mathbb{A}_{\tau'}$). Then $B = AA'$ (if the composition exists) is finite from above (resp., below) with characteristic $\beta(t) = \tau(t) + \tau'(t - \tau(t))$.*

Example 5.1. Let $H = L^2(\mathbb{R})$ and $(h\phi)(t) = \int_{-\infty}^{+\infty} h(t,s)\phi(s)ds$. Hilbert space L^2 becomes a resolution space when equipped with a family $\mathbb{P}_T$ defined by

$$P_t\phi(s) = \begin{cases} \phi(s) & \text{if } s \le t, \\ 0 & \text{if } s > t. \end{cases}$$

One readily sees that h is τ-causal (anticausal) if and only if $h(t,s) = 0$ for $s > \min(t, t - \tau(t))$, $(s < \max(t, t - \tau(t)))$. In particular, h is local if and only if $h = 0$.

5.2. Extended Hilbert resolution spaces. Assume now that H is infinite dimensional and $t_f = +\infty$. An element $\phi \in H$ is called *finite* if there exist $t_*(\phi) \in \mathbb{T}$, $t_* < \infty$, such that $P_t\phi = \phi$ for all $t \ge t_*$. Let F be a space of all finite elements of H. Then F is dense in H and $\bar{H} = H_F$ is called the t-*extension* or t-*completion* of H. We write $t - \lim_{n\to\infty} \phi_n = \phi$ if for every $t \in \mathbb{T}$ one has $\lim_{n\to\infty} P_t\phi_n = P_t\phi$; $\phi_n, \phi \in H$. This defines t-*convergence* in H and the associated Hausdorff topology is weaker than the canonical inner product topology of H. Note that H is not complete with respect to t-convergence. One readily checks the following simple proposition.

PROPOSITION 5.1. *The completion of H with respect to t-topology is isomorphic to H_F, the F-weak completion of H.*

A densely defined operator A in H is called t-*continuous* if for every sequence $\phi_n \in D(A)$ with $t - \lim_{n\to\infty} \phi_n = 0$ one has $t - \lim_{n\to\infty} A\phi_n = 0$. Note that a general continuous operator in H need not be t-continuous. Now we collect the further properties following [4] (see also [5], [3]).

LEMMA 5.5. *The following hold:*

(i) *Operator A is t-continuous if and only if it is finite.*

(ii) *If A is t-continuous, then by Proposition* 5.1 *it allows an extension to an operator $\bar{A}$ in $\bar{H}$: $\bar{A}|_H = A$. In particular, every $P_t \in \mathbb{P}_T$, being a local*

operator, allows an extension to $\bar{P}_t$ in $\bar{H}$. The family $\overline{\mathbb{P}_T}$ is a resolution of the identity in $\bar{H}$. One can generalize the notions of causality for $\bar{H}$, in particular, $\bar{P}_t$ are local in $\bar{H}$.

(iii) *For every $t \in \mathbb{T}$ and $\bar{\phi} \in \bar{H}$ holds $\bar{P}_t\bar{\phi} \in P_tH$.*

(iv) *A restriction of τ-causal operator $\bar{A}$ in $\bar{H}$ to H defines a τ-causal operator A in H.*

(v) *If $|\bar{\phi}|_{\bar{H}} = \sup_{t\in\mathbb{T}} |\bar{P}_t\bar{\phi}|_H$, then $|\bar{\phi}|_{\bar{H}} < \infty$ if and only if $\bar{\phi} \in H$. In this case $|\bar{\phi}|_{\bar{H}} = |\bar{\phi}|_H$.*

(vi) *Let $\bar{A} : \bar{H} \to \bar{H}$ be linear τ-causal. Then there exists an operator $\bar{A}^* : \bar{H} \to \bar{H}$ uniquely defined by*

$$(\bar{P}_t\bar{A}\bar{P}_{t-\tau(t)}\bar{\phi})^*\psi = (\bar{P}_{t-\tau(t)}\bar{\phi})^*\bar{A}^*\bar{P}_t\psi$$

for every $\psi \in F$, $\bar{\phi} \in \bar{H}$, $t \in \mathbb{T}$. The operator $\bar{A}^*$ is the adjoint to $\bar{A}$ and is $(-\tau)$-anticausal.

DEFINITION 5.6. *An operator $\bar{A} : \bar{H} \to \bar{H}$ is called* τ-bounded *for a measurable function $\tau : \mathbb{T} \to \mathbb{T}$ if*

$$\sup_{\bar{\phi}\in\bar{H}} \sup_{t\in\mathbb{T}} \frac{|\bar{P}_t\bar{A}\bar{\phi}|_H}{|\bar{P}_{t-\tau(t)}\bar{\phi}|_H} < \infty.$$

0*-bounded operators are called* stable [3].

We collect the properties of τ-bounded operators in the following.

LEMMA 5.7. *The following hold:*

(i) *Let $\bar{A} : \bar{H} \to \bar{H}$ be τ-bounded. Then H is an invariant subspace for $\bar{A}$ and the restriction $\bar{A}|_H$ is continuous.*

(ii) *Let $\bar{A} : \bar{H} \to \bar{H}$ be τ-bounded for $\tau \geq 0$. Then $\bar{A}$ is τ-causal with respect to $\overline{\mathbb{P}_T}$.*

(iii) *An operator $\bar{A} : \bar{H} \to \bar{H}$ is stable if and only if*
   (a) *$\bar{A}$ is causal,*
   (b) *H is an invariant subspace of $\bar{A}$,*
   (c) *the restriction $\bar{A}|_H$ is continuous in H.*

5.3. Linear causal filtering problem. Let $(H', \mathbb{P}'_T)$, $(H'', \mathbb{P}''_T)$ be Hermitian resolution spaces. Let $H = H' \times H''$ be equipped with the resolution defined by (5.1). We denote by $\mathbb{H}^\tau$ the space of all linear continuous τ-causal operators $h : H'' \to H'$. Let $D : H' \to H'$ be continuous with the adjoint $D^* : H' \to H'$. Then *the optimal linear causal filtering problem* is the minimization problem

$$J_{\phi'}(h) \to \inf_{h\in\mathbb{H}^\tau} \tag{5.4}$$

for every $\phi' \in H'$, where $J_{\phi'}(h)$ is defined by

$$J_{\phi'}(h) = E|\langle \phi', D(x - hy)\rangle|^2,\ h \in \mathbb{H}^\tau. \tag{5.5}$$

It turns out that the condition of the continuity of weight operators is very restrictive for the solution of the problem (5.4). In general, the optimal filtering problem in the class of continuous weight operators can be unsolvable or can be very complicated. At the same time, if we drop the continuity condition the problem can be solved. It is relatively simple to check whether the weight operator of the determined optimal filter is continuous. In this way one can obtain solutions for the original continuous problem. We will apply the methods presented in [4]; namely, first we relax the problem (5.4) allowing h to be unbounded. Analyzing the solution of the relaxed problem we derive the conditions for the solvability of (5.4).

5.4. Generalized linear causal filtering problem. Let $\bar{H}'$, $\bar{H}''$ be the t-completions of H' and H'', respectively. Let $\bar{\mathbb{H}}^\tau$ be the space of all linear τ-causal operators $\bar{h} : \bar{H}'' \to \bar{H}'$, such that for every $t \in \mathbb{T}$ the operators $\bar{P}'_t \bar{h} \bar{h}^* \bar{P}'_t : P'_t H' \to P'_t H'$ are continuous. Assume z to be a random $\bar{H}$ element, and, therefore, $R_z = Ezz^*$, $z = \left[\begin{smallmatrix} x \\ y \end{smallmatrix}\right]$, is bounded on the space F of finite elements in H and can then be continuously extended to the whole of H. The problem is to find linear estimates of a random H' element x based on the realizations of a random H'' element y of the form

$$\hat{x} = \bar{h}y, \tag{5.6}$$

minimizing for every $t \in \mathbb{T}$ the functional

$$J^{(t)}(\bar{h}) = E|D\bar{P}_t(x - \hat{x})|^2_{H'}. \tag{5.7}$$

Note that $J^{(t)}(\bar{h})$ is finite for $\bar{h} \in \bar{\mathbb{H}}^\tau$, $t \in \mathbb{T}$; therefore the problem of the minimization

$$J^{(t)}(\bar{h}) \to \inf_{\bar{h} \in \bar{\mathbb{H}}^\tau} \tag{5.8}$$

for every $t \in \mathbb{T}$ is correctly posed. Let us reformulate the problem (5.8) now. For $\phi' \in H'$ we define

$$\begin{aligned} J^{(t)}_{\phi'}(\bar{h}) &= E|\langle \phi', DP'_t(x - \hat{x})\rangle_{H'}|^2 = E|\langle \phi', DP'_t(x - \bar{h}x)\rangle_{H'}|^2 \\ &= \langle \phi', DP'_t[R_x - R_{xy}\bar{h}^* - \bar{h}R_{yx} + \bar{h}R_y\bar{h}^*]P'_t D^*\phi'\rangle_{H'}. \end{aligned} \tag{5.9}$$

Now, the problem (5.8) is equivalent to the problem

$$J^{(t)}_{\phi'}(\bar{h}) \to \inf_{\bar{h} \in \bar{\mathbb{H}}^\tau} \tag{5.10}$$

for every $\phi' \in H'$.

THEOREM 5.8. *Let $R_z = Ezz^*$ satisfy the following:*

(i) *The operators $R_z^{(t,t)} = \bar{P}_t R_z \bar{P}_t : P_t H \to P_t H$ are continuous for every $t \in \mathbb{T}$.*

(ii) *The operators $P''_t R_y P''_t : H'' \to H''$ are positive in the invariant subspace $P''_t H''$ for every $t \in \mathbb{T}$.*

Then for every $t \in \mathbb{T}$ there exist $\hat{x}_t \in P'_t H'$ such that for every $\phi \in H'$ one has

$$E|\langle \phi', D(x - \hat{x}_t)\rangle_{H'}|^2 = \inf_{h \in \bar{\mathbb{H}}^\tau} E|\langle \phi', D(x - P'_t hy)\rangle_{H'}|^2.$$

The estimates $\hat{x}_t$ are given by

$$\hat{x}_t = R_{xy}^{(t,t-\tau(t))}(R_y^{(t-\tau(t),t-\tau(t))})^{-1} P''_{t-\tau(t)} y + Q_t P''_{t-\tau(t)} y, \tag{5.11}$$

where $R_{xy}^{(t,t-\tau(t))} = P'_t R_{xy} P''_{t-\tau(t)}$, $R_y^{(t,t)} = P''_t R_y P''_t$, $(R_y^{(t,t)})^{-1}$ means the inverse of $R_y^{(t,t)}$ in the invariant subspace $P''_{t-\tau(t)} H''$, and any $Q_t : H'' \to H'$ such that $DQ_t Q_{R_y} = 0$. Moreover,

$$\begin{aligned} E|\langle \phi', D(x - \hat{x}_t)\rangle_{H'}|^2 = \langle \phi', D[&P'_t R_x P'_t \\ &- R_{xy}^{(t,t-\tau(t))}(R_y^{(t-\tau(t),t-\tau(t))})^{-1} R_{yx}^{(t-\tau(t),t)}]D^*\phi'\rangle_{H'}. \end{aligned}$$

Proof. In view of (5.11) we rewrite (5.9) as

$$J^{(t)}_{\phi'}(\bar{h}) = \langle \phi', D[P'_t R_x P'_t - R^{(t,t-\tau(t))}_{xy}\bar{h}^* - \bar{h}R^{(t-\tau(t),t)}_{yx} + \bar{h}R^{(t-\tau(t),t-\tau(t))}_{y}\bar{h}^*]D^*\phi'\rangle_{H'}. \tag{5.12}$$

The minimization problem (5.10) is now the same as the minimization of the functionals (5.12) in the invariant for $R^{(t-\tau(t),t-\tau(t))}_y$ subspace $H''_{t-\tau(t)} = P''_{t-\tau(t)}H''$. This is the minimization problem (3.4) for $H' = P'_t H'$ and $H'' = H''_{t-\tau(t)}$. Theorem 4.1 together with the invertibility of $R^{(t-\tau(t),t-\tau(t))}_y$ by the assumption (ii) of Theorem 5.8 imply the solution of the problem in the form given by (5.11) and the last formula of the theorem. □

REMARK 5.1. *In view of the discussion above it is easy to see that problem* (5.4) *is solvable if and only if the solution of* (5.8) *is a continuous* τ*-causal operator. In this case the restriction of this operator to* H'' *gives a solution to* (5.4).

The detailed discussion and the solutions of these problems for $D = I_{H'}$ can be found in [4], [5], [7]. We will treat further the spaces with the discrete resolution of the identity. In general, the problems described above can be reduced to the discrete case by a suitable approximation of $\mathbb{P}_T$ by discrete resolutions of the identity; see [4] for the details.

5.5. Discrete resolutions of the identity. We assume now that $\mathbb{P}_T$ is a piecewise constant operator valued functional on $\mathbb{T}$ with at most a countable number of discontinuity points without accumulations in $\mathbb{T}$. Let $\mathbf{t} = \{t_k, k \in \mathbb{K}\}$ be a finite or a countable ordered subset of $\mathbb{T}$ without accumulation points, $\mathbb{K} = \mathbb{Z} \cap (0, K)$, $t_0 = t_s$, $t_K = t_f$, K finite or $K = +\infty$. The *discrete resolution of the identity in* H *corresponding to* $\mathbf{t} \subset \mathbb{T}$ is the set $\mathbb{P}_{\mathbf{t}} = \{P_t, t \in \mathbf{t}\}$. The family of the orthogonal projectors $Q_k = P_{t_k} - P_{t_{k-1}}$, $k \in \mathbb{K}$, determines the resolution $\mathbb{P}_{\mathbf{t}}$ uniquely due to the relation $P_t = \sum_{k:t_k \le t} Q_k$. These projectors are mutually orthogonal: $Q_k Q_l = Q_l Q_k = 0_H$ for $k \ne l$.

DEFINITION 5.9. *A family* $\mathbb{Q}_K$ *of the mutually orthogonal projectors* Q_k *is called* the orthogonal resolution of the identity *if* $\mathbb{Q}_K$ *is complete in a sense that* $Q_k \to O_H$ *for* $k \to k_s$ *and* $\sum_{l \le k} Q_l \to I_H$ *for* $k \to k_f$. *The pair* $(H, \mathbb{Q}_K)$ *is called the* discrete resolution space.

Every linear operator $R : H \to H$ can be decomposed with respect to $\mathbb{Q}_K$ into blocks $R_{kl} = Q_k R Q_l$ and $R = \sum_{k,l \in \mathbb{K}} R_{kl}$. The definitions of finiteness, causality, and anticausality can be reformulated in terms of the discrete structure $\mathbb{Q}_K$. The function τ in Definitions 5.1, 5.2 is replaced by $\tau : \mathbf{t} \to \mathbf{t}$ with a property that $\tau(t_k) = t_l$, $k, l \in \mathbb{K}$, and the latter corresponds to a function $\kappa : \mathbb{K} \to \mathbb{K}$ such that $\tau(t_k) = t_{\kappa(k)}$. In analogy to the continuous case one has the following.

DEFINITION 5.10. *A linear operator* $R : H \to H$ *is called* κ-causal (strictly κ-causal, κ-anticausal) *if* $R_{kl} = 0_H$ *for* $l > k - \kappa(k)$ ($l \ge k - \kappa(k)$, $l < k - \kappa(k)$), *respectively. It is called* neutral *if it is causal and anticausal.*

For a linear operator $R : H \to H$ we denote its κ-causal, anticausal, and neutral components by $R_{[\kappa]} = \sum_{l \le k - \kappa(k)} R_{kl}$, $R^{[\kappa]} = \sum_{l \ge k - \kappa(k)} R_{kl}$, $R_{[[\kappa]]} = \sum_{l = k - \kappa(k)} R_{kl}$, respectively.

Now we are ready to formulate the optimal causal filtering problem for the discrete resolution space $H = H' \times H''$, H', H'' equipped with the orthogonal resolutions of the identity $\mathbb{Q}'_K$ and $\mathbb{Q}''_K$, respectively. Let $\mathbb{H}^\kappa$ denote the space of all κ-causal continuous operators $h : H'' \to H'$ and $\hat{x}_k = Q'_k \hat{x}$, $y_k = Q''_k y$, $h_{kl} = Q'_k h Q''_l$. Then the problem

is the linear estimation

$$\hat{x}_k = \sum_{l \le k-\kappa(k)} h_{kl} y_l \tag{5.13}$$

minimizing the functionals

$$J_{\phi'}(h) = E|\langle \phi', D(x - hy)\rangle|^2 \to \inf_{h \in \mathbb{H}^\kappa} \tag{5.14}$$

for every $\phi \in H'$. Note that this is the same as the minimization of

$$J_k(h) = E|D(x_k - \hat{x}_k)|^2 \to \inf_{h \in \mathbb{H}^\kappa} \tag{5.15}$$

for every $k \in \mathbb{K}$, where $x_k = Q_k' x$.

In analogy with the continuous case we will treat the relaxed problem first, replacing the condition of the continuity of h by the continuity of $h_k = Q_k' h = \sum_{l \in \mathbb{K}} h_{kl} : H'' \to H'$ for every $k \in \mathbb{K}$. The space of all linear κ-causal operators for which all the correspondent operators h_k are continuous will be denoted by $\bar{\mathbb{H}}^\kappa$. Note that because J_k are finite when R_z is bounded, the problem

$$J_k(h) = E|D(x_k - \hat{x}_k)|^2 \to \inf_{h \in \bar{\mathbb{H}}^\kappa},\ k \in \mathbb{K}, \tag{5.16}$$

is correctly posed. Note that if $\bar{H}', \bar{H}''$ are the completions of H', H'' in t-topology, then the space $\bar{\mathbb{H}}^\kappa$ is isomorphic to the space of all κ-causal operators from $\bar{H}''$ to $\bar{H}'$. The problem now becomes

$$J_k(h) = E|DQ_k'(x - \bar{h}y)|^2 \to \inf_{\bar{h} \in \bar{\mathbb{H}}^\kappa},\ k \in \mathbb{K}. \tag{5.17}$$

In analogy to Theorem 5.8 and Theorem 2.3 in [4] we have the following.

THEOREM 5.11. *Let $R_z = Ezz^*$ be continuous and R_y satisfy $P_{t_k} R_y P_{t_k} \ge \epsilon P_{t_k}$ for some $\epsilon > 0$ and for every $k \in \mathbb{K}$. Then all the solutions $\bar{h}_{\text{opt}} : \bar{H}'' \to \bar{H}'$ of the problem* (5.17) *are given by*

$$\bar{h}_{\text{opt}} = \sum_{k \in \mathbb{K}} Q_k' R_{xy} P''_{t_{k-\kappa(k)}} (P''_{t_{k-\kappa(k)}} R_y P''_{t_{k-\kappa(k)}})^{-1} P''_{t_{k-\kappa(k)}} + Q, \tag{5.18}$$

where $Q \in \bar{\mathbb{H}}^\kappa$ satisfies $DQ_k'Q = 0$. One has

$$\inf_{h \in \bar{\mathbb{H}}^\kappa} J_k(\bar{h}) = J_k(\bar{h}_{\text{opt}})$$
$$= |DP'_{t_k}[R_x - R_{xy} P''_{t_{k-\kappa(k)}} (P''_{t_{k-\kappa(k)}} R_y P''_{t_{k-\kappa(k)}})^{-1} P''_{t_{k-\kappa(k)}} R_{yx}] P'_{t_k} D^*|.$$

The proof is similar to the proof of Theorem 5.8 and is based on the calculations of $\hat{x}_k$ as an optimal estimate in the subspace of H'' spanned by $y_l' = Q_k' y$, $l \le k - \kappa(k)$. Similar to [4, Theorem 2.4] for the solution of the original problem (5.15) we have the following.

THEOREM 5.12. *Let the assumptions of Theorem* 5.11 *be satisfied. Then the problem* (5.15) *is solvable if and only if the solution $\bar{h} : \bar{H}'' \to \bar{H}'$ of* (5.17) *is κ-bounded. In this case the image of H'' under $\bar{h}$ is contained in H' and the restriction $\bar{h}|_{H''}$ is the solution of* (5.15).

Proof. Under the assumptions of Theorem 5.12, formula (5.18) defines the optimal linear filters for (5.17). If $\bar{h}_{\text{opt}}$ is κ-finite, the operator $\bar{h}_{\text{opt}}|_{H''}$ is continuous and

defines the weight operators for the solutions of (5.15). If $\bar{h}_{\rm opt}$ is not κ-bounded, the converse is also obvious from Lemma 5.7. □

Note that by taking finite partial sums in (5.18) one obtains minimizing sequences for the problem. These minimizing sequences are also available in the case when $\bar{h}$ is not κ-bounded and the problem (5.15) is not solvable in $\mathbb{H}^\kappa$.

6. Bode–Shannon representation of optimal filters. First we will briefly review the results on the spectral factorization of the operators which we need in order to discuss the application of Bode–Shannon theory (cf. [1], [4], [9], [10]) in our setting. Detailed discussion on various types of spectral factorization and separation of the operators can be found in [4].

Let $\mathbb{P}_T$ be a Hermitian resolution of the identity in H. As in the previous section we denote by $\bar{H}$ a t-completion of H and by $\mathbf{t}$ a discrete linearly ordered subset of $\mathbb{T}$. Let $\mathbb{G}_{\mathbf{t}}$ be a space of all bijective operators $\bar{G}:\bar{H}\to\bar{H}$ such that $\bar{P}_t\bar{G}\bar{P}_t$ and $\bar{P}_t\bar{G}^{-1}\bar{P}_t$ are continuous as operators from P_tH to P_tH for every $t\in\mathbf{t}$. Note that $\mathbb{G}_{\mathbf{t}}$ contains the space of all causal, causally invertible operators in H.

DEFINITION 6.1. *An operator $\bar{G}\in\mathbb{G}_{\mathbf{t}}$ is called* spectrally factorizable *if there exists a causal with respect to $\mathbb{P}_T$ operator $\bar{U}:\bar{H}\to\bar{H}$, such that the inverse of $\bar{U}$ exists and is causal in $\bar{H}$ and $\bar{G}=\bar{U}\bar{U}^*$, where $\bar{U}^*$ is the adjoint of $\bar{U}$.*

Let $\bar{G}=\bar{U}\bar{U}^*$ be a spectral factorization of $\bar{G}$. If $\bar{U},\bar{U}^{-1}$ are stable (Definition 5.6), the restrictions $\bar{U}|_H,\bar{U}^{-1}|_H$ are causal and continuous in H in view of Lemma 5.7. This implies that the restriction $G=\bar{G}|_H$ is continuous in H and we can summarize it in the following.

DEFINITION 6.2. *A continuous operator $G:H\to H$ is called* strongly spectrally factorizable *if there exists a continuous causal operator $U:H\to H$ with continuous and causal inverse, such that $G=UU^*$, where U^* is the adjoint of U.*

We call operator $\bar{G}\in\mathbb{G}_{\mathbf{t}}$ *positive* if the operators $\bar{P}_t\bar{G}\bar{P}_t$, $\bar{P}_t\bar{G}^{-1}\bar{P}_t:P_tH\to P_tH$ are nonnegative for every $t\in\mathbf{t}$. The following are Theorems 2.5 and 2.6 in [4] (see also [7], [3]).

THEOREM 6.3.

(i) *Every positive operator $\bar{G}\in\mathbb{G}_{\mathbf{t}}$ is spectrally factorizable. A causal with respect to the discrete resolution $\bar{P}_{\mathbf{t}}$ operator $\bar{U}$ factorizing $\bar{G}$ is unique up to the multiplication from the right by a neutral unitary in $\bar{H}$ operator.*

(ii) *Let $\bar{G}\in\mathbb{G}_{\mathbf{t}}$ and assume that the restriction $G=\bar{G}|_H$ is positive and continuous in H. Then G is strongly spectrally factorizable. A causal with respect to the discrete resolution $\mathbb{Q}_K$ operator U factorizing G is unique up to the multiplication from the right by a neutral unitary in H operator.*

It is convenient in the discrete case $(H,\mathbb{Q}_K)$ to denote by $\mathbb{G}_K$ the space of all bijective operators $\bar{G}:\bar{H}\to\bar{H}$ such that for every $k\in\mathbb{K}$ the operators

$$\sum_{l=0}^{k}\sum_{m=0}^{k}\bar{Q}_l\bar{G}\bar{Q}_m,\quad \sum_{l=0}^{k}\sum_{m=0}^{k}\bar{Q}_l\bar{G}^{-1}\bar{Q}_m$$

are continuous from $H^k=\bigoplus_{l=0}^{k}\bar{Q}_lH$ to H^k. $\bar{G}\in\mathbb{G}_K$ is called *positive* if the operators in the definition of $\mathbb{G}_K$ are nonnegative for every $k\in\mathbb{K}$.

Let $H=H'\times H''$ be equipped with the orthogonal resolution of the identity given by $Q_k=\left[\begin{smallmatrix}Q'_k & 0\\ 0 & Q''_k\end{smallmatrix}\right]$, $Q'_k\in\mathbb{Q}'_K$, $Q''_k\in\mathbb{Q}''_K$. The κ-causal filters are given by

$$\hat{x}_k=\sum_{l=0}^{k-\kappa(k)}h_{kl}y_l,$$

where $h_{kl} : Q_l'' H'' \to Q_k' H'$ are linear continuous. The corresponding filter $\bar{h} : \bar{H''} \to \bar{H'}$ is defined by having its blocks equal to h_{kl}.

THEOREM 6.4. *Assume that $R_z \in \mathbb{G}_K$, that $R_y : H'' \to H''$ is positive and $\kappa \geq 0$. Then all optimal linear filters for the discrete generalized linear causal filtering problem* (5.17) *are of the form*

$$\bar{h}_{\mathrm{opt}} = [R_{xy}(U^{-1})^*]_{[\kappa]} U^{-1} + Q, \tag{6.1}$$

where U is a causal operator strongly factorizing R_y, $[R_{xy}(U^{-1})^*]_{[\kappa]}$ is the κ-causal component of $R_{xy}(U^{-1})^* : \bar{H''} \to \bar{H'}$, and any $Q \in \bar{\mathbb{H}}^\kappa$ such that $DQ = 0$. One has

$$\inf_{\bar{h} \in \bar{\mathbb{H}}^\kappa} J_k(\bar{h}) = J_k(\bar{h}_{\mathrm{opt}})$$
$$= |DQ_k[R_x - R_{xy}R_y^{-1}R_{yx} + [R_{xy}(U^{-1})^*]_{[\bar{\kappa}]}([R_{xy}(U^{-1})^*]_{[\bar{\kappa}]})^*]Q_k D^*|.$$

Proof. Let $L = R_{xy}(U^{-1})^* - [R_{xy}(U^{-1})^*]_{[\kappa]}$ denote the strictly anticausal component of $R_{xy}(U^{-1})^*$. Rewriting $J_k(\bar{h})$ in analogy with (4.3) we have

$$\begin{aligned} E|\langle \phi', DQ_k'(x - \bar{h}y)\rangle|^2 &= \langle \phi', DQ_k'[R_x - R_{xy}\bar{h}^* - \bar{h}R_{yx} + \bar{h}R_y\bar{h}^*]Q_k'D^*\phi'\rangle \\ &= \langle \phi', DQ_k'[R_x - R_{xy}R_y^{-1}R_{yx}]Q_k'D^*\phi'\rangle \\ &+ \langle \phi', DQ_k'(\bar{h}U - M - L)(\bar{h}U - M - L)^*Q_k'D^*\phi'\rangle \\ &= \langle \phi', DQ_k'[R_x - R_{xy}R_y^{-1}R_{yx}]Q_k'D^*\phi'\rangle \\ &+ \langle \phi', DQ_k'(\bar{h}U - M)(\bar{h}U - M)^*Q_k'D^*\phi'\rangle \\ &+ \langle \phi', DQ_k'[(\bar{h}U - M)L^* - L(\bar{h}U - M)^*]Q_k'D^*\phi'\rangle, \end{aligned} \tag{6.2}$$

where M denotes $[R_{xy}(U^{-1})^*]_{[\kappa]}$, $R_{xy}(U^{-1})^* = L + M$. Note that in the last equality in (6.2) the first term is constant in h, the second one is quadratic in $\bar{h}U - M$, and the third is linear. Now, an application of Lemma 5.4 yields the κ-causality of $\bar{h}U - M$, and in view of strict causality of L^* again by Lemma 5.4, the operator $(\bar{h}U - M)L^*$ is strictly κ-causal. It follows that $Q_k'(\bar{h}U - M)L^*Q_k' = 0$ if $\kappa \geq 0$. This means that the linear term in (6.2) vanishes and the minimum is attained if and only if the quadratic term in (6.2) is zero. This is the case of $\bar{h}U - M = S$ for any $S \in \bar{\mathbb{H}}^\kappa$ such that $DS = 0$. Multiplication by 0-causal operators U, U^{-1} does not change κ-causality in view of Lemma 5.4 and we obtain formula (6.1) with $Q = SU^{-1}$. The last formula of the theorem follows from the substitution of $\bar{h}_{\mathrm{opt}}$ into the last expression of (6.2). □

COROLLARY 6.5. *For $D = I_{H'}$ the only operator in* (6.1) *is obtained by taking $Q = 0$. This operator is called the* Bode–Shannon weight operator *and the filter* (5.13) *is called the* Bode–Shannon filter.

COROLLARY 6.6. *If R_z is stable, R_y^{-1} exists and is continuous in H, and stable operator $R_{xy}(U^{-1})^*$ has the stable κ-causal component, then the original linear optimal causal filtering problem* (5.15) *is solvable and all optimal weight operators are the restrictions of $\bar{h}_{\mathrm{opt}}$ in* (6.1) *to H''.*

The proof is similar to the proof of Theorem 5.12 and is left as an exercise. The reader can consult [4] for the application to the finite dimensional stationary processes, where the conditions of Corollary 6.6 are reduced to the conditions in terms of analytic functions.

REMARK 6.1. *If the operator D^*D in* (1.3) *allows a spectral factorization*

$$D^*D = \tilde{D}^*\tilde{D}$$

with a causal operator $\tilde{D}$, and in addition R_y is positive and the problem (1.2) *is solvable, then an optimal weight operator must solve the equation*

$$\tilde{D}h = (\tilde{D}R_{xy}(U^{-1})^*)_{[\kappa]}U^{-1}.$$

Although in this paper we prove the Bode–Shannon formula for the optimal filtering problem with the discrete time only, its analogue is valid for the continuous time as well. We use this opportunity to demonstrate it. We return to Example 2.3.

Example 6.1. Assume that the filter takes the form

$$\hat{x}(t) = \int_0^{t-\tau} h(t,t')\,\mathrm{d}y(t'), \qquad t_\mathrm{s} \le t-\tau \le t_\mathrm{f}, \tag{6.3}$$

where $\tau \in \mathbb{R}$ is given. In this case the causality of the filter (6.3) is determined by the family P_t, $t \in (t_\mathrm{s}, t_\mathrm{f})$, of projections from Example 5.1. The quality functional is

$$J_t(h) = E|x(t) - \hat{x}(t)|^2, \qquad t_\mathrm{s} \le t-\tau \le t_\mathrm{f}. \tag{6.4}$$

The Bode–Shannon formula for the optimal τ-causal filter is (cf. Theorem 6.4 and (2.5))

$$h_{opt} = [R_x C(U^{-1})^*]^{(\tau)}U^{-1}, \tag{6.5}$$

where $I+U$ is the spectral factor for $R_{\mathrm{D}y}$. It means that $C^*R_xC+I = (I+U)(I+U)^*$ with the causal and causally invertible operator $I+U$. $[\cdot]^{(\tau)}$ stands for the τ-separation of the corresponding operator. We will not analyze formula (6.5) in detail here, but note that in the nonoperator terms it has the form

$$\hat{x}(t) = \int_{t_\mathrm{s}}^{t-\tau} g(t,t')\,\mathrm{d}v(t'), \tag{6.6}$$

where

$$g(t,t') = R_x(t,t')C(t') - \int_{t_\mathrm{s}}^{t'} R_x(t,t')C(t'')Q(t',t'')\,\mathrm{d}t'',$$

$$\mathrm{d}v(t) = \mathrm{d}y(t) - \left[\int_{t_\mathrm{s}}^{t} Q(t,t')\mathrm{d}y(t')\right]\mathrm{d}t, \tag{6.7}$$

and function $Q(\cdot,\cdot)$ solves the equation

$$Q(t,t') + \int_{t_\mathrm{s}}^{t} Q(t,t'')K(t'',t')\mathrm{d}t'' = K(t,t'), \qquad Q(t,t') = 0, \;\; t' > t, \tag{6.8}$$

and $K(\cdot,\cdot)$ is the function from (2.4). Note that $g(t,t') = 0$ when $t' > t-\tau$. See Theorem 2.1 in [5] for the details. (6.8) is a special case of the Hopf–Wiener equation.

Example 6.2. Formulas (6.6)–(6.8) for the optimal filter simplify considerably in the stationary case (see Example 2.6). The reason is that it is possible to reformulate the problem in frequency terms. Instead of the noncausal filter (2.7) the estimation is performed now with the causal filter

$$\hat{x}(t) = \int_{-\infty}^{t-\tau} h(t-t')\mathrm{d}y(t'), \qquad t \in \mathbb{R}. \tag{6.9}$$

In terms of the symbols of the involved operators, the Bode–Shannon formula (6.5) acquires the form

$$H_{opt}(\omega) = [G_{x\mathrm{D}y}(\omega)[1 + U(-\omega)]^{-1}]^{(\tau)}[1 + U(\omega)]^{-1}, \tag{6.10}$$

where $U(\cdot)$ is analytic in the lower half space and can be found from the factorization condition

$$C^* G_y(\omega) C + 1 = [1 + U(\omega)][1 + U(-\omega)] \tag{6.11}$$

(see Theorem 2.4 in [5]). τ-separation $[\cdot]^{(\tau)}$ in this case is determined by

$$\tilde{L}(\omega) = \int_{-\infty}^{\infty} e^{-i\omega t} L(t)\mathrm{d}t \to [\tilde{L}(\omega)]^{(\tau)} = \int_{\tau}^{\infty} e^{-i\omega t} L(t)\mathrm{d}t. \tag{6.12}$$

There are effective algorithms for the factorization and τ-separation in this case [5].

Example 6.3. Let us discuss finally a relation with the Kalman–Bucy filter. In many applications it is often assumed that the nonobservable component x of the partially observable process satisfies the stochastic equation

$$\mathrm{d}x(t) = A(t)x(t)\mathrm{d}t + B(t)\mathrm{d}w'(t), \tag{6.13}$$

where $A(\cdot)$, $B(\cdot)$ are continuous and bounded on $\mathbb{T}$ matrix valued functions, $w'(\cdot)$ is the standard Gaussian–Wiener process independent of the observation error $w(\cdot)$ in (2.1). If the initial state $x(0)$ is given, formulas (2.1), (6.13) uniquely define the correlation operator of the partially observable process $z = \binom{x}{\mathrm{D}y}$ (D is the generalized derivative here). This provides a principal possibility to construct the optimal τ-causal filter. However, it is sometimes problematic to use equations (6.6)–(6.8) not only because it is complicated to calculate the weight function $g(\cdot,\cdot)$, but also because one is required to store all the previously calculated values of the process. At the same time, the recursive approach of (2.1), (6.13) allows us to derive recursive formulas for the optimal filters. Such formulas do not require us the computationally complicated factorization procedure. They also do not require us to store the whole "history" of the process for further calculations. In the case of classical filtration ($\tau = 0$) these equations are the well-known Kalman–Bucy filter. We will not give these equations here since they can be found in almost any book on recursive filtering; see, for example, [5]. In the problems with $\tau \neq 0$ such formulas can also be derived and they can be viewed as a generalization of the Kalman–Bucy filter. However, this is a large independent topic and we will not pursue it here. We only note that in the derivation of such formulas the Bode–Shannon representation (6.5) of the optimal filter turns out to be very useful.

H_2 AND H_∞ ROBUST FILTERING FOR DISCRETE-TIME LINEAR SYSTEMS*

JOSÉ C. GEROMEL†, JACQUES BERNUSSOU‡, GERMAIN GARCIA‡, AND MAURÍCIO C. DE OLIVEIRA†

Abstract. This paper investigates robust filtering design problems in H_2 and H_∞ spaces for discrete-time systems subjected to parameter uncertainty which is assumed to belong to a convex bounded polyhedral domain. It is shown that, by a suitable change of variables, both design problems can be converted into convex programming problems written in terms of linear matrix inequalities (LMI). The results generalize the ones available in the literature to date in several directions. First, all system matrices can be corrupted by parameter uncertainty and the admissible uncertainty may be structured. Then, assuming the order of the uncertain system is known, the optimal guaranteed performance H_2 and H_∞ filters are proven to be of the same order as the order of the system. Comparisons with robust filters for systems subjected to norm-bounded uncertainty are provided in both theoretical and practical settings. In particular, it is shown that under the same assumptions the results here are generally better as far as the minimization of a guaranteed cost expressed in terms of H_2 or H_∞ norms is considered. Some numerical examples illustrate the theoretical results.

1. Introduction.

State estimation has been one of the fundamental issues in the control area and there have been a lot of works following those of Kalman (in the stochastic framework [1]) and Luenberger (in the deterministic one [3, 12]). For control purpose, the will to estimate an unmeasurable linear combination of the state variables is clearly justified, for instance, by the *separation principle* well known in the case of models without uncertainty. For systems subjected to parameter uncertainty no such principle has been stated; however, there has been an increasing interest in the robust H_∞ literature and, aside from the robust control area, a large number of papers have addressed the dual problem of robust state estimation. A special issue of the Journal of Nonlinear and Robust Control was devoted to this problem in 1996 ([10]; see also [13] and the references therein).

In the late contributions to robust filtering, the problem is formulated in a Kalman stochastic-like context where the state estimation of uncertain dynamic systems in the presence of process noise is based upon noisy measurements. The filter determination is carried out by defining a suitable performance index in terms of the state estimation error variance. Fundamentally, two kinds of performance indexes have been considered according to the a priori assumptions on the input noise. In the classical H_2 filtering approach the noise characteristics are known leading to the minimization of the H_2 norm of the transfer function from the process noise to the estimation error.

For uncertain systems, an upper bound on the previous performance index is established in terms of a single quadratic Lyapunov function, which naturally motivates the denomination of quadratic guaranteed cost state estimation [9, 13, 19]. More recently, the H_∞ filtering approach has been developed from the loose assumption of boundedness of the noise variance. In this case, the performance index to be minimized being the worst case H_∞ norm from the process noise to the estimation error [11, 16, 18]. All contributions cited rely on a particular uncertainty representation, namely, *norm-bounded uncertainty*. In this case, the mathematical model of the uncertain system exhibits explicitly a nominal model located at the center of the hyper ellipsoid of uncertainty in the parameter space. The results developed for the filtering problem are quite close to the ones derived in the robust control area due to the dual relationship of both problems. In this sense, one can classify the results and solvability conditions according to the Riccati-type equations as in [3, 20] or the linear matrix inequalities (LMI) as in [4]. Some comments concerning the two problems can be made for the mixed H_2/H_∞ filtering approach [8, 10].

Taking into account convex polytopic type uncertainty, [7] raises some difficulties linked to the fact that we are faced to structured uncertainty and the system representation does not explicitly exhibit any particular nominal model. For instance, the necessary and sufficient stabilizability conditions for dynamic output feedback control have only recently received some answer in terms of nonlinear matrix inequalities [5].

In this paper, we solve the state estimation problem for an uncertain discrete-time system under convex polytopic uncertainty addressing the H_2 as well as the H_∞ settings. It is shown that by restricting our attention to the class of linear and time-invariant filters, the filtering problem can be solved using the now classical LMI machinery [2]. Although a great effort has been made toward the synthesis of robust control for convex bounded uncertain systems [7, 5, 14, 15], in the literature to date there is no available result for linear filtering design of systems subjected to this class of parameter uncertainty. The lack of results on the robust filtering problem for convex polytopic uncertain systems appears to be due to the fact that the estimation error cannot be bounded by means of the solution of a Riccati-like equation. Here, it is considered that all matrices, namely, the state, input, and output matrices, are uncertain parameter dependent and also that structured uncertainties are allowed. A very interesting case of this new potentiality is the design of decentralized filters [6, 17]. Moreover, our approach allows to prove that even under parametric uncertainty the optimal filter order equals the order of the system supposed to be known. To ease the presentation only the stationary case is treated in detail, although the same lines can be used to deal with the nonstationary case.

The notation used throughout is as follows. Capital letters denote matrices and small letters denote vectors. For scalars we use small Greek letters. For matrices or vectors $(')$ indicates transpose. For symmetric matrices $X > 0$ (≥ 0) indicates that X is positive definite (nonnegative definite). Finally, for square matrices trace$[X]$ denotes the trace function of X being equal to the sum of its eigenvalues. For a transfer function $T(\zeta)$ analytic outside the unit circle, $\|T(\zeta)\|_2$ and $\|T(\zeta)\|_\infty$ denote the standard H_2 and H_∞ norms, respectively. Furthermore, for the sake of easing the notation of partitioned symmetric matrices the symbol $(\bullet)'$ denotes generically each of its symmetric blocks.

2. Problem statement. Let us consider the following linear time-invariant system

$$x(k+1) = Ax(k) + Bw(k), \tag{2.1}$$

$$y(k) = Cx(k) + Dw(k), \tag{2.2}$$

$$z(k) = Lx(k), \tag{2.3}$$

where $x \in R^n$ is the state, $w \in R^m$ is the zero mean, white noise input with identity power spectrum density matrix, $y \in R^r$ is the measured output, and $z \in R^s$ is the vector to be estimated. It is assumed that

1. All matrix dimensions are known.
2. Matrix $M \in R^{(n+r)\times(n+m)}$ defined as

$$M := \begin{bmatrix} A & B \\ C & D \end{bmatrix} \tag{2.4}$$

is unknown but it belongs to a given convex bounded polyhedral domain $\mathcal{D}_c$. Hence, from [7] each uncertain matrix of this set can be written as an unknown convex combination of N given extreme matrices $M_1, M_2, \ldots, M_N$, that is, $M \in \mathcal{D}_c$ if and only if

$$M = \sum_{i=1}^{N} \lambda_i M_i \tag{2.5}$$

holds for some $\lambda_1 \geq 0, \lambda_2 \geq 0, \ldots, \lambda_N \geq 0$ such that $\lambda_1 + \cdots + \lambda_N = 1$.

3. Matrix L is known.

It is important to make clear that the mathematical description of the convex polytopic domain $\mathcal{D}_c$ is sufficiently general to include, as a particular case, many uncertain systems with practical appealing. For instance, only some elements of M may be unknown and several elements of M may depend on the same unknown parameter. These two situations can easily be accommodated by a proper choice of the set of extreme matrices.

At this point, it is important to compare the above uncertainty description characterized by the convex set $\mathcal{D}_c$ with norm-bounded uncertainty as considered in [13, 18]. A system subjected to norm-bounded parameter uncertainty is such that matrix M belongs to the set $\mathcal{D}_n$ and each matrix is written in the form

$$M = M_0 + H\Omega E \tag{2.6}$$

for some matrix $\Omega \in R^{p\times q}$ such that $\Omega'\Omega \leq I$, where M_0 defines the nominal system and $H \in R^{(n+r)\times p}$ and $E \in R^{q\times(n+m)}$ are known matrices. From the Schur complement formula [2], it is seen that

$$\Omega'\Omega \leq I \Longleftrightarrow \begin{bmatrix} I & \Omega \\ (\bullet)' & I \end{bmatrix} \geq 0, \tag{2.7}$$

which makes clear that the uncertainty represented by matrix Ω belongs to a convex set and the same is true for M since it depends affinely on the matrix Ω. The conclusion is that the set $\mathcal{D}_n$ is convex but not necessarily a polyhedral set. In some important cases (see the examples in section 6) $\mathcal{D}_n$ is also polyhedral. This occurs when the uncertain matrix presents some a priori known structure, as, for instance, $\Omega'\Omega$ diagonal. In these situations it is always possible to determine a finite number of extreme matrices M_i, $i = 1, \ldots, N$ such that $\mathcal{D}_n = \mathcal{D}_c$. In the general case this equality does not hold. However, $\mathcal{D}_n$ being convex, it is again possible to determine N matrices Ω_i, $i = 1, \ldots, N$, on the boundary of the LMI (2.7) such that with $M_i = M_0 + H\Omega_i E$, $i = 1, \ldots, N$, there holds

$$\mathcal{D}_c \subset \mathcal{D}_n, \tag{2.8}$$

and $\mathcal{D}_c$ tends toward $\mathcal{D}_n$ as the number of extreme matrices N increases. It is clear that the contrary also holds since due to convexity it is always possible to determine N matrices Ω_i, $i = 1, \ldots, N$, not on the boundary of the LMI (2.7) such that $\mathcal{D}_n \subset \mathcal{D}_c$ and $\mathcal{D}_c$ tend toward $\mathcal{D}_n$ as the number of extreme matrices N increases. Hence, for N sufficiently large, the set $\mathcal{D}_n$ may be replaced by $\mathcal{D}_c$ within any desired precision. Of course, the main advantage in doing this is that $\mathcal{D}_c$ can accommodate many particular structures of the uncertain matrix which cannot be directly exploited, without introducing conservatism, with $\mathcal{D}_n$. However, it is important to point out that by adopting this approximation, the number of LMI to be handled may be very large.

To make this point clear let us consider the uncertain system of [18] which is more general than the one considered in [13]. We have $A = A_0 + H_1\Omega E$, $B = B_0$, $C = C_0 + H_2\Omega E$, and $D = D_0$ which can be written in the form (2.6), that is,

$$M = \begin{bmatrix} A_0 & B_0 \\ C_0 & D_0 \end{bmatrix} + \begin{bmatrix} H_1 \\ H_2 \end{bmatrix} \Omega \begin{bmatrix} E & 0 \end{bmatrix}. \tag{2.9}$$

However, if we want to consider a more general uncertain model defined by $A = A_0 + \bar{H}_1\Omega_1\bar{E}_1$, $B = B_0$, $C = C_0 + \bar{H}_2\Omega_2\bar{E}_2$, and $D = D_0$, then we now must write

$$M = \begin{bmatrix} A_0 & B_0 \\ C_0 & D_0 \end{bmatrix} + \begin{bmatrix} \bar{H}_1 & 0 \\ 0 & \bar{H}_2 \end{bmatrix} \begin{bmatrix} \Omega_1 & 0 \\ 0 & \Omega_2 \end{bmatrix} \begin{bmatrix} \bar{E}_1 & 0 \\ \bar{E}_2 & 0 \end{bmatrix}, \tag{2.10}$$

putting in evidence that (2.10) can be written as (2.9) with $H_1 := [\bar{H}_1\ 0]$, $H_2 := [0\ \bar{H}_2]$, and $E' := [\bar{E}_1'\ \bar{E}_2']$. However, the uncertain matrix Ω must be constrained to present the block diagonal structure

$$\Omega = \begin{bmatrix} \Omega_1 & 0 \\ 0 & \Omega_2 \end{bmatrix}. \tag{2.11}$$

As discussed before, this structure can approximately be treated with $\mathcal{D}_c$ and N sufficiently large. On the contrary, to apply directly the results of [13, 18] the a priori structure of Ω cannot be taken into account and consequently some conservatism on the robust filter design is necessarily introduced.

The problems to be dealt with in this paper are now formulated. We restrict ourselves to design an estimate $\hat{z}$ of z given by $\hat{z} = \mathcal{F} \cdot y$, where $\mathcal{F}$ is a linear, finite dimensional, and time-invariant operator producing at any time the estimation error $e := z - \hat{z}$. Defining $T_M(\zeta)$ the transfer function from the noise input w to the estimation error e, our goals are to solve the following design problems.

- H_2 *filtering problem:* Find a guaranteed estimation performance index $\rho_2(\cdot)$ such that

$$\sup_{M \in \mathcal{D}_c} \|T_M(\zeta)\|_2^2 \leq \rho_2(\mathcal{F}) \tag{2.12}$$

  and given $\mu > 0$ find all filters $\mathcal{F} \in \mathcal{C}$ such that (2.12) holds for $\rho_2(\mathcal{F}) = \mu$. Among all feasible filters, find the optimal one that minimizes $\rho_2(\mathcal{F})$ over $\mathcal{C}$.
- H_∞ *filtering problem:* Find a guaranteed estimation performance index $\rho_\infty(\cdot)$ such that

$$\sup_{M \in \mathcal{D}_c} \|T_M(\zeta)\|_\infty^2 \leq \rho_\infty(\mathcal{F}) \tag{2.13}$$

  and given $\mu > 0$ find all filters $\mathcal{F} \in \mathcal{C}$ such that (2.13) holds for $\rho_\infty(\mathcal{F}) = \mu$. Among all feasible filters, find the optimal one that minimizes $\rho_\infty(\mathcal{F})$ over $\mathcal{C}$.

In the above problems, the feasible set $\mathcal{C}$ is used to impose a particular class of linear, finite dimensional, and causal operators. In the present case, we consider $\mathcal{C}$ as the set of all linear time-invariant operators with state space realization of the form

$$\hat{x}(k+1) = A_f\hat{x}(k) + B_f y(k), \tag{2.14}$$

$$\hat{z}(k) = C_f\hat{x}(k), \tag{2.15}$$

where the matrices $A_f \in R^{n_f\times n_f}$, $B_f \in R^{n_f\times r}$, and $C_f \in R^{s\times n_f}$ and the scalar $n_f > 0$ are to be determined. In other words $\mathcal{C}$ is taken as the set of all linear time-invariant operators of any order and with strictly proper transfer functions. Moreover, it is considered that the initial condition of system (2.1) as well as the initial condition of the filter (2.14) are both zero. Connecting the filter to the system (2.1)−(2.3) we can write the transfer function $T_M(\zeta)$ as

$$T_M(\zeta) := \tilde{C}(\zeta I - \tilde{A})^{-1}\tilde{B}, \tag{2.16}$$

where matrices $\tilde{A}$, $\tilde{B}$, and $\tilde{C}$ of compatible dimensions are given by

$$\tilde{A} := \begin{bmatrix} A & 0 \\ B_fC & A_f \end{bmatrix},\ \tilde{B} := \begin{bmatrix} B \\ B_fD \end{bmatrix},\ \tilde{C} := \begin{bmatrix} L & -C_f \end{bmatrix}. \tag{2.17}$$

Some well-known results extensively used in this paper, namely, the Schur complement and partitioned LMI, can be found in [2, 14].

3. H_2 filtering. This section is devoted to H_2 filter design, as stated before. First we analyze the classical situation where all system parameters are precisely known, that is, matrix $M \in \mathcal{D}_c$ is arbitrary but fixed and $n_f = n$. In that which follows the optimal robust H_2 filter is obtained. Its dimension is proved to be equal to that of the uncertain system and a comparison with the results available in the literature to date is provided.

It is well known that for $\mu > 0$ the inequality $\|T_M(\zeta)\|_2^2 < \mu$ holds if and only if there exist symmetric matrices $\tilde{P}$ and W such that

$$\text{trace}[W] < \mu,\ \begin{bmatrix} \tilde{P} & \tilde{P}\tilde{C}' \\ (\bullet)' & W \end{bmatrix} > 0,\ \begin{bmatrix} \tilde{P} & \tilde{A}\tilde{P} & \tilde{B} \\ (\bullet)' & \tilde{P} & 0 \\ (\bullet)' & (\bullet)' & I \end{bmatrix} > 0, \tag{3.1}$$

where it is important to notice that in the above problem all constraints are taken strictly (see [3]). Hence, the minimum value of μ in (3.1) gives $\|T_M(\zeta)\|_2^2 = \mu+\epsilon$, where $\epsilon > 0$ is an amount arbitrarily small defined by the designer during the optimization process.

Our main purpose is, if possible, to convert the nonlinear matrix inequality appearing in (3.1) into LMI. If this goal is accomplished, the H_2 filter design problem turns out to be a convex programming problem which can be solved by very efficient numerical methods. To this end, let us partition $\tilde{P}$ and its inverse as

$$\tilde{P} := \begin{bmatrix} X & U \\ (\bullet)' & \hat{X} \end{bmatrix},\ \tilde{P}^{-1} := \begin{bmatrix} Y & V \\ (\bullet)' & \hat{Y} \end{bmatrix}, \tag{3.2}$$

where $X, Y \in R^{n\times n}$ and $\hat{X}, \hat{Y} \in R^{n_f\times n_f}$ are all symmetric and positive definite matrices. Multiplying the first row of $\tilde{P}$ by the first column of $\tilde{P}^{-1}$ reveals that $XY + UV' = I$, and taking into account the partition of $\tilde{P}$ and that of its inverse we

get $Y^{-1} = X - U\hat{X}^{-1}U'$. The key observation is that for any given symmetric and positive definite matrices such that $X > Y^{-1}$ and U square ($n_f = n$) and nonsingular, then from the first equality above we have V also nonsingular. Consequently, due to the second equality it is always possible to find $\hat{X} > 0$ ensuring that $\tilde{P} > 0$. From this partition of matrix $\tilde{P}$ let us introduce the following one-to-one change of variables:

$$\begin{bmatrix} A_f & B_f \\ C_f & 0 \end{bmatrix} := \begin{bmatrix} V & 0 \\ 0 & I \end{bmatrix}^{-1} \begin{bmatrix} Q & F \\ G & 0 \end{bmatrix} \begin{bmatrix} U'X^{-1} & 0 \\ 0 & I \end{bmatrix}^{-1}, \tag{3.3}$$

where the indicated inverses exist due to the fact that X is symmetric and positive definite and matrices V and U are both nonsingular. It is interesting to observe that in the above parameterization, one of matrices V or U can be freely defined by the designer without any loss of generality. This claim is easily seen from the filter transfer function

$$\begin{aligned} F_f(\zeta) &:= C_f \left(\zeta I - A_f\right)^{-1} B_f \\ &= GX \left(\zeta VU' - QX\right)^{-1} F, \end{aligned} \tag{3.4}$$

which depends only on the product of matrices V and U' being given by $VU' = I - YX$. The importance of this fact is that by choosing one of these matrices, we can get a filter with a particular state space realization. This point will be addressed in more detail in that which follows. Denoting $Z := X^{-1}$, the next theorem gives a partial solution, expressed in terms of LMI, to the H_2 filtering problem stated in the previous section for $M \in \mathcal{D}_c$ fixed and $n = n_f$.

THEOREM 1. *Let $M \in \mathcal{D}_c$ be given. All filters $\mathcal{F} \in \mathcal{C}$ such that $n = n_f$ and $\|T_M(\zeta)\|_2^2 < \mu$ are given by* (3.3)*, where U and V are full rank matrices such that $UV' = I - Z^{-1}Y$. Moreover, the scalar μ, matrices Q, G, F, and the symmetric matrices Y, Z, W satisfy the LMI*

$$\text{trace}[W] < \mu, \tag{3.5}$$

$$\begin{bmatrix} Z & Z & L' - G' \\ (\bullet)' & Y & L' \\ (\bullet)' & (\bullet)' & W \end{bmatrix} > 0, \tag{3.6}$$

$$\begin{bmatrix} Z & Z & ZA & ZA & ZB \\ (\bullet)' & Y & YA + FC + Q & YA + FC & YB + FD \\ (\bullet)' & (\bullet)' & Z & Z & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & Y & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & I \end{bmatrix} > 0. \tag{3.7}$$

Proof. From the fact that $n_f = n$ and matrices U and V are nonsingular the relation (3.3) is a one-to-one transformation. Defining the square and full rank matrix

$$\tilde{J} := \begin{bmatrix} X^{-1} & Y \\ 0 & V' \end{bmatrix} \tag{3.8}$$

it can be verified that the second inequality in (3.1) multiplied to the left by the full rank matrix $J' := \text{diag}[\tilde{J}', I]$ and to the right by J provides the LMI (3.6). Furthermore, doing the same to the third inequality in (3.1) with matrix $J := \text{diag}[\tilde{J}, \tilde{J}, I]$ we get the LMI (3.7), which together with (3.5) proves the proposed theorem. ∎

Notice that as in [7, 6] the main idea to get the above result stems from the definition of the new set of variables (3.3) which converts the problem under consideration to a convex feasibility problem expressed in terms of LMI only. If the LMI given in Theorem 1 are feasible, then a particular filter state space realization is readily obtained. For instance, the choice $V = V' = -Y$ leads to $U'Z = I - Y^{-1}Z$ in which case (3.3) provides the feasible filter

$$C_f = G\left(I - Y^{-1}Z\right)^{-1},\ A_f = -Y^{-1}Q\left(I - Y^{-1}Z\right)^{-1},\ B_f = -Y^{-1}F. \tag{3.9}$$

It is interesting to observe that the classical H_2 optimal filter can be recovered from the LMI (3.5)−(3.7) if we replace these inequalities by nonstrict ones and restrict our attention to the filters generated from $Z \to 0$. Doing so, to keep feasibility we must impose

$$G = L,\ Q = -YA - FC, \tag{3.10}$$

which together with the choice $W = LY^{-1}L'$ enables us to write

$$\operatorname{trace}[LY^{-1}L'] < \mu,\ \begin{bmatrix} Y & YA + FC & YB + FD \\ (\bullet)' & Y & 0 \\ (\bullet)' & (\bullet)' & I \end{bmatrix} > 0. \tag{3.11}$$

Considering for simplicity that $BD' = 0$ and $DD' = I$, defining $P := Y^{-1}$, and choosing $F = -YAPC'(CPC' + I)^{-1}$ we have

$$\begin{aligned} &\min_{P>0} \operatorname{trace}[LPL'], \\ &APA' - P - APC'(CPC' + I)^{-1}CPA' + BB' < 0, \end{aligned} \tag{3.12}$$

which comes from the Schur complement of inequality (3.11). From the well-known results on the monotonicity of the Riccati equation, it is clear that the optimal solution to problem (3.12) is arbitrarily close to the symmetric and nonnegative definite solution of the algebraic discrete Riccati equation

$$APA' - P - APC'(CPC' + I)^{-1}CPA' + BB' = 0. \tag{3.13}$$

In addition, from (3.9) the optimal filter state space realization is given by matrices $C_f = L$, $A_f = -Y^{-1}Q = A - B_fC$ and $B_f = -Y^{-1}F = APC'(CPC' + I)^{-1}$ which we recognize as being the Kalman filter. The above manipulations prove that the Kalman filter is on the boundary of the LMI (3.5)−(3.7) and hence is close (within any prespecified precision) to the optimal solution of the convex problem consisting of the minimization of μ under the LMI constraints provided in Theorem 1. Of course the main goal of Theorem 1 is to treat not precisely known systems but systems subjected to parameter uncertainty as will become clear in that which follows.

Referring back to the result of Theorem 1, it is interesting to notice that it is always possible to eliminate the matrix variable G since it appears only in the LMI (3.6). In fact, permuting the second and third columns and rows we get an equivalent LMI

$$\begin{bmatrix} Z & L' - G' & Z \\ (\bullet)' & W & L \\ (\bullet)' & (\bullet)' & Y \end{bmatrix} > 0, \tag{3.14}$$

which using the Schur complement can be rewritten in the equivalent form

$$\begin{bmatrix} Z - ZY^{-1}Z & L' - G' - ZY^{-1}L' \\ (\bullet)' & W - LY^{-1}L' \end{bmatrix} > 0, \tag{3.15}$$

and from [14] we are able to say that the LMI (3.6) can be replaced by

$$\begin{bmatrix} Y & L' \\ (\bullet)' & W \end{bmatrix} > 0, \quad \begin{bmatrix} Z & Z \\ (\bullet)' & Y \end{bmatrix} > 0 \tag{3.16}$$

together with $G = L(I - Y^{-1}Z)$. This is important because the number of free variables in problem (3.5)−(3.7) becomes smaller and we are sure that no conservatism is introduced. Moreover, this formula for G enables us to impose, with no loss of generality, that $C_f = L$ as already considered in [18] and the references therein. Indeed, this occurs if we set $U = U' = Z^{-1} - Y^{-1}$ since

$$\begin{aligned} C_f &= G(U'Z)^{-1} \\ &= L(I - Y^{-1}Z)Z^{-1}\left(Z^{-1} - Y^{-1}\right)^{-1} \\ &= L, \end{aligned} \tag{3.17}$$

and solving the equation $XY + UV' = I$ we get $V = V' = -Y$. These two matrices are of full rank as required to generate the optimal filter matrices from Theorem 1 variables. Hence, we have proven the following result.

THEOREM 2. *Let $M \in \mathcal{D}_c$ be given. All filters $\mathcal{F} \in \mathcal{C}$ such that $n = n_f$ and $\|T_M(\zeta)\|_2^2 < \mu$ are given by matrices*

$$C_f = L, \ A_f = -Y^{-1}Q\left(I - Y^{-1}Z\right)^{-1}, \ B_f = -Y^{-1}F, \tag{3.18}$$

where the scalar μ, matrices Q, F, and the symmetric matrices Y, Z, W satisfy the LMI (3.7) *and*

$$\text{trace}[W] < \mu, \quad \begin{bmatrix} Y & L' \\ (\bullet)' & W \end{bmatrix} > 0. \tag{3.19}$$

From the previous results it is not difficult to verify that there is no hope to determine a filter of dimension $n_f \neq n$ with smaller value of $\|T_M(\zeta)\|_2$ than those provided by Theorem 2. In fact, taking $n_f < n$, matrix $\tilde{J}$ in (3.8) is no longer square but still exhibits full row rank. From this, relaxing the strict character of the basic inequalities (3.6) and (3.7) and performing the same calculations as before we see that (3.6) and (3.7) still hold. However, it is no longer possible to solve $Y^{-1} = X - U\hat{X}^{-1}U'$ unless Y and X are such that $\text{rank}(X - Y^{-1}) = n_f$. This constraint is not convex and so convexity of the associated feasibility problem is lost. More important is the fact that if it exists the feasible reduced order filter will produce a greater or at most equal value of $\|T_M(\zeta)\|_2$. On the other hand, taking $n_f > n$ then matrix $\tilde{J}$ in (3.8) is not square but presents full column rank. So, to adopt the same reasoning as before, we need to replace it by the square and nonsingular matrix

$$\tilde{J} = \begin{bmatrix} X^{-1} & Y & 0 \\ 0 & V' & S \end{bmatrix}, \tag{3.20}$$

where S of compatible dimensions spans the null space of U. Adopting the same steps as before, we see that both inequalities (3.6) and (3.7) must hold once again,

and in the affirmative case, it is possible to construct a feasible filter which produces the same value of $\|T_M(\zeta)\|_2$ as the full order filter with $n = n_f$. Let us now turn our attention to the robust H_2 filter design. To this end we need the following result.

LEMMA 1. *Assume $\mathcal{F} \in \mathcal{C}$ is a given filter and consider the problem*

(3.21)
$$\rho_2(\mathcal{F}) := \min_{\tilde{P}} \left\{ \text{trace}[\tilde{C}\tilde{P}\tilde{C}'] \ : \ \begin{bmatrix} \tilde{P} & \tilde{A}_i\tilde{P} & \tilde{B}_i \\ (\bullet)' & \tilde{P} & 0 \\ (\bullet)' & (\bullet)' & I \end{bmatrix} > 0 \ , i = 1, 2, \ldots, N \right\},$$

where matrices $\tilde{A}_i$ and $\tilde{B}_i$ are the same as $\tilde{A}$ and $\tilde{B}$ with the submatrices A, B, C, and D of M, replaced by those of the extreme matrices

$$M_i := \begin{bmatrix} A_i & B_i \\ C_i & D_i \end{bmatrix}, \ i = 1, 2, \ldots, N. \tag{3.22}$$

If problem (3.21) *is feasible, then $\rho_2(\mathcal{F})$ is a valid upper bound to $\|T_M(\zeta)\|_2^2$ for all $M \in \mathcal{D}_c$, that is, it satisfies inequality* (2.12).

Proof. Consider that for some $\mathcal{F} \in \mathcal{C}$, problem (3.21) has been solved providing $\tilde{P} > 0$. For any $M \in \mathcal{D}_c$, there exists a convex combination such that

$$M = \sum_{i=1}^{N} \lambda_i \begin{bmatrix} A_i & B_i \\ C_i & D_i \end{bmatrix}. \tag{3.23}$$

Hence, keeping in mind the structures of matrices $\tilde{A}$ and $\tilde{B}$ given in (2.17) we get

$$\begin{bmatrix} \tilde{P} & \tilde{A}\tilde{P} & \tilde{B} \\ (\bullet)' & \tilde{P} & 0 \\ (\bullet)' & (\bullet)' & I \end{bmatrix} = \sum_{i=1}^{N} \lambda_i \begin{bmatrix} \tilde{P} & \tilde{A}_i\tilde{P} & \tilde{B}_i \\ (\bullet)' & \tilde{P} & 0 \\ (\bullet)' & (\bullet)' & I \end{bmatrix} > 0. \tag{3.24}$$

Applying to the above inequality the Schur complement formula together with (3.21), we have the upper bound to the H_2 norm of the transfer function $T_M(\zeta)$

$$\begin{aligned} \|T_M(\zeta)\|_2^2 &= \text{trace}\left[\sum_{k=0}^{\infty} \tilde{C}\tilde{A}^k\tilde{B}\tilde{B}'\tilde{A}'^k\tilde{C}'\right] \\ &< \text{trace}[\tilde{C}\tilde{P}\tilde{C}'] \\ &< \rho_2(\mathcal{F}) \ \text{ for all } \ M \in \mathcal{D}_c, \end{aligned} \tag{3.25}$$

which is the desired result. □

The upper bound to the H_2 norm of $T_M(\zeta)$ provided by Lemma 1 deserves some comments. In the case of precisely known parameters it coincides with the true value of $\|T_M(\zeta)\|_2^2$ and so does not introduce any conservatism. This case is obtained for $N = 1$ and the filter synthesis procedure of Theorem 2 is valid. For convex polytopic systems it suffices to include as many LMI as the number of extreme matrices needed to define $\mathcal{D}_c$. The other matrices in the interior of $\mathcal{D}_c$ are automatically considered. In this sense we can say that the worst situation certainly occurs in an extreme point of the uncertain domain. Finally, adopting the same reasoning as before, the following result is proven.

THEOREM 3. *The optimal H_2 robust filter which minimizes $\rho_2(\mathcal{F})$ for all $\mathcal{F} \in \mathcal{C}$ is a filter with dimension $n_f = n$ given by* (3.18)*, where matrices Q, F and the symmetric matrices Z, Y, W minimize μ under the constraints* (3.19) *and*

$$\begin{bmatrix} Z & Z & ZA_i & ZA_i & ZB_i \\ (\bullet)' & Y & YA_i + FC_i + Q & YA_i + FC_i & YB_i + FD_i \\ (\bullet)' & (\bullet)' & Z & Z & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & Y & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & I \end{bmatrix} > 0 \tag{3.26}$$

for all $i = 1, 2, \ldots, N$. Furthermore, the minimum H_2 guaranteed performance cost satisfying (2.12) *is given by $\rho_2(\mathcal{F}) = \text{trace}[W]$.*

Notice that the proof of Theorem 3 follows the same pattern as before. The structure of the constraint in (3.21) is identical to (3.1), where each submatrix of M is replaced by the corresponding submatrix of M_i, $i = 1, 2, \ldots, N$. At this point it is important to stress that the parameter uncertainty we can handle with Theorem 3 is more general than the very recent results of [13, 18].

Our purpose now is to compare the previous results of this section with the best ones available in the literature to date [13]. Given a domain $\mathcal{D}_n$ we assume the scalar N (possibly infinite) and the extreme matrices M_i, $i = 1, 2, \ldots, N$, are determined such that $\mathcal{D}_c = \mathcal{D}_n$.

The key observation is that the full order, i.e., $n_f = n$, robust filter matrices $(\bar{A}_f, \bar{B}_f, \bar{C}_f)$ provided in those references are given from the symmetric and nonnegative solutions of two algebraic discrete Riccati equations depending on the nominal model and on matrices H_1, H_2, and E in (2.9). Moreover, these solutions depend on a parameter $\varepsilon > 0$ which is optimized to get the best guaranteed performance. Hence, with the optimal value $\varepsilon^\star > 0$ a symmetric and nonnegative definite matrix $\bar{P}$ is determined such that

$$\|T_M(\zeta)\|_2^2 \le \text{trace}[\tilde{C}\bar{P}\tilde{C}'],\ \tilde{A}\bar{P}\tilde{A}' - \bar{P} + \tilde{B}\tilde{B}' \le 0 \ \text{ for all } \ M \in \mathcal{D}_n. \tag{3.27}$$

This solution presents two important properties. As expected $\bar{C}_f = L$ and $\bar{P}$ can be partitioned as

$$\bar{P} = \begin{bmatrix} P_1 & P_2 \\ P_2 & P_2 \end{bmatrix} \ge 0, \tag{3.28}$$

where P_1 and P_2 are symmetric and nonnegative definite matrices. Perturbing slightly matrices P_1 and P_2 if necessary in order that these matrices become positive definite and the inequalities in (3.27) and (3.28) become strict, choosing $M_i \in \mathcal{D}_n$ for $i = 1, 2, \ldots, N$ so as to produce $\mathcal{D}_c = \mathcal{D}_n$, and taking into account (3.27), we conclude that with

$$Z := P_1^{-1},\ U := P_2,\ Y = -V := (P_1 - P_2)^{-1} \tag{3.29}$$

there exist matrices Q and F easily determined from $(\bar{A}_f, \bar{B}_f)$ and (3.3) such that all LMI in (3.26) are feasible. In addition to $P_1 > P_2$ in (3.28), choosing $W > L(P_1 - P_2)L'$ the corresponding cost is given by

$$\text{Trace}[W] = \text{trace}[L(P_1 - P_2)L'] + \epsilon, \tag{3.30}$$

which differs from the minimum upper bound of (3.27) by an amount of order $\epsilon > 0$ which once again can be taken arbitrarily small. This proves that Theorem 3 generally

provides a robust filter with better or at least equal performance than [13]. Moreover, Theorem 3 applies to more general models subjected to parametric uncertainties and no unidimensional search (with respect to the parameter ε) is needed. These aspects will be illustrated by means of numerical examples.

4. H_∞ filtering. In this section the problem of H_∞ filtering design is addressed. The same main lines adopted to deal with H_2 filters are again used. First the classical H_∞ filter is analyzed for $M \in \mathcal{D}_c$ fixed and $n = n_f$. In that which follows the optimal guaranteed robust H_∞ filter is determined, and it is proven that it exhibits the same dimension of the uncertain plant. Finally a comparison with the very recent results of [18] is provided.

It is well known that the transfer function from the input noise to the estimation error satisfies the inequality $\|T_M(\zeta)\|_\infty^2 < \mu$ for $\mu > 0$ if and only if there exists a symmetric matrix $\tilde{P}$ such that

$$\begin{bmatrix} \tilde{P} & \tilde{A}\tilde{P} & \tilde{B} & 0 \\ (\bullet)' & \tilde{P} & 0 & \tilde{P}\tilde{C}' \\ (\bullet)' & (\bullet)' & I & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & \mu I \end{bmatrix} > 0. \tag{4.1}$$

In order to convert this nonlinear matrix inequality into an LMI we proceed by partitioning the matrix variable $\tilde{P}$ and its inverse as indicated in (3.2). Introducing again the matrix variable $Z := X^{-1}$ we have the following result.

THEOREM 4. *Let $M \in \mathcal{D}_c$ be given. All filters $\mathcal{F} \in \mathcal{C}$ such that $n = n_f$ and $\|T_M(\zeta)\|_\infty^2 < \mu$ are given by* (3.3) *where U and V are full rank matrices such that $UV' = I - Z^{-1}Y$. Moreover, the scalar μ, the matrices Q, G, F, and the symmetric matrices Y, Z satisfy the LMI*

$$\begin{bmatrix} Z & Z & ZA & ZA & ZB & 0 \\ (\bullet)' & Y & YA + FC + Q & YA + FC & YB + FD & 0 \\ (\bullet)' & (\bullet)' & Z & Z & 0 & L' - G' \\ (\bullet)' & (\bullet)' & (\bullet)' & Y & 0 & L' \\ (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & I & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & \mu I \end{bmatrix} > 0. \tag{4.2}$$

Proof. From the fact that $n_f = n$ and matrices U and V are nonsingular the relation (3.3) is a one-to-one transformation. Defining the square and full rank matrix $\tilde{J}$ as indicated in (3.8), the multiplication of (4.1) to the left by $J' := \mathrm{diag}[\tilde{J}', \tilde{J}', I, I]$ and to the right by J provides the LMI (4.2). □

Choosing $V = V' = -Y$ we get $U'Z = I - Y^{-1}Z$ and (3.3) provides once again the filter state space realization

$$C_f = G\left(I - Y^{-1}Z\right)^{-1},\ A_f = -Y^{-1}Q\left(I - Y^{-1}Z\right)^{-1},\ B_f = -Y^{-1}F, \tag{4.3}$$

from which it is interesting to observe that the H_∞ filter design problem differs from the H_2 one in the following relevant aspect concerning matrix G. In the previous design it could be eliminated from the associated LMI constraint by applying the Schur complement together with the result of [14]. If we do the same to (4.2) it is again possible to split that inequality into two LMI. However, the value of matrix G will depend on the system matrices M and L. This solution is not valid for robust filter design since by assumption matrix M is not known.

As for H_2 filters, it is possible to recover the H_∞ central filter by allowing $Z \to 0$. Considering for ease that $BD' = 0$, $DD' = I$, and (4.2) with nonstrict inequality, the possible choice of $Z \to 0$ leads necessarily to $G = L$ and $Q = -YA - FC$. In this case the remaining variables have to satisfy the LMI

$$\begin{bmatrix} Y & YA+FC & YB+FD & 0 \\ (\bullet)' & Y & 0 & L' \\ (\bullet)' & (\bullet)' & I & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & \mu I \end{bmatrix} > 0. \tag{4.4}$$

To get the central H_∞ filter we define the new variable $P := (Y - \mu^{-1}L'L)^{-1}$ and impose $F = -YAPC'(CPC' + I)^{-1}$. Performing the Schur complement to inequality (4.4) we have

$$APA' - \left(P^{-1} + \mu^{-1}L'L\right)^{-1} - APC'(CPC' + I)^{-1}CPA' + BB' < 0. \tag{4.5}$$

Consequently, under the assumption that (4.2) is feasible, that is, it admits an interior point, there always exits a feasible solution arbitrarily close to the symmetric and positive definite solution of the algebraic discrete Riccati equation

$$APA' - \left(P^{-1} + \mu^{-1}L'L\right)^{-1} - APC'(CPC' + I)^{-1}CPA' + BB' = 0, \tag{4.6}$$

in which case the state space representation of the associated filter is given by matrices $C_f = L$, $A_f = A - B_f C$, and $B_f = APC'(CPC' + I)^{-1}$ being the central H_∞ filter which clearly satisfies $\|T_M(\zeta)\|_\infty^2 < \mu$. Furthermore, the minimum value of μ such that a solution $P > 0$ to (4.6) exists provides a central filter with optimal H_∞ performance.

Referring back to the general problem, it is important to stress that nothing is gained in terms of the performance index under consideration if we consider $n_f \neq n$. Indeed, for $n_f < n$, besides (4.2), a supplementary nonconvex constraint must be added which may cause performance deterioration. On the other hand for $n_f > n$ the same LMI (4.2) still must hold and so it is always possible to reduce the filter order to $n_f = n$ keeping the same performance level. We are now in position to analyze the robust H_∞ filter.

LEMMA 2. *Assume $\mathcal{F} \in \mathcal{C}$ is a given filter and consider the problem*

$$\rho_\infty(\mathcal{F}) := \min_{\tilde{P},\mu} \left\{ \mu \ : \ \begin{bmatrix} \tilde{P} & \tilde{A}_i\tilde{P} & \tilde{B}_i & 0 \\ (\bullet)' & \tilde{P} & 0 & \tilde{P}\tilde{C}' \\ (\bullet)' & (\bullet)' & I & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & \mu I \end{bmatrix} > 0 \ , i = 1, 2, \ldots, N \right\}, \tag{4.7}$$

where matrices $\tilde{A}_i$ and $\tilde{B}_i$ are the same as $\tilde{A}$ and $\tilde{B}$ with the submatrices A, B, C, and D of M, replaced by those of the extreme matrices $M_1, M_2, \ldots, M_N$. If problem (4.7) *is feasible, then $\rho_\infty(\mathcal{F})$ is a valid upper bound to $\|T_M(\zeta)\|_\infty^2$ for all $M \in \mathcal{D}_c$, that is, it satisfies inequality* (2.13).

The proof of Lemma 2 follows the same lines of that for Lemma 1 and is thus omitted. Notice that the index $i = 1, 2, \ldots, N$ does not appear in matrix $\tilde{C}$ due to our assumption that matrix L is fixed and known. For $N = 1$ the upper bound provided by Lemma 2 matches with $\|T_M(\zeta)\|_\infty^2$ which means that no conservatism is introduced. The next theorem is the main result of this section and states that the optimal H_∞ robust filter can be determined from a convex programming problem.

THEOREM 5. *The optimal H_∞ robust filter which minimizes $\rho_\infty(\mathcal{F})$ for all $\mathcal{F} \in \mathcal{C}$ is a filter with dimension $n_f = n$ and state space realization given by* (4.3) *where matrices Q, G, F and the symmetric matrices Z, Y minimize μ under the constraint*

$$\begin{bmatrix} Z & Z & ZA_i & ZA_i & ZB_i & 0 \\ (\bullet)' & Y & YA_i + FC_i + Q & YA_i + FC_i & YB_i + FD_i & 0 \\ (\bullet)' & (\bullet)' & Z & Z & 0 & L' - G' \\ (\bullet)' & (\bullet)' & (\bullet)' & Y & 0 & L' \\ (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & I & 0 \\ (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & (\bullet)' & \mu I \end{bmatrix} > 0 \tag{4.8}$$

for all $i = 1, 2, \ldots, N$. Furthermore, the minimum H_∞ guaranteed performance cost satisfying (2.13) *is given by $\rho_\infty(\mathcal{F}) = \mu$.*

Paper [18] proposes the most general method for H_∞ filter design dealing with norm-bounded uncertainty acting on matrices A and C of model (2.1)−(2.3). The procedure depends on the existence of a parameter $\varepsilon > 0$ such that two algebraic Riccati equations admit symmetric, nonnegative, and stabilizing solutions. In the affirmative case, a full order H_∞ filter defined by the triplet of matrices $(\bar{A}_f, \bar{B}_f, \bar{C}_f)$ with $\bar{C}_f = L$ is determined such that

$$\|T_M(\zeta)\|_\infty^2 < \mu,\ \tilde{A}\bar{P}\tilde{A}' - \left(\bar{P}^{-1} + \mu^{-1}\tilde{C}'\tilde{C}\right)^{-1} + \tilde{B}\tilde{B}' \leq 0 \ \text{ for all } \ M \in \mathcal{D}_n \tag{4.9}$$

hold for some matrix $\bar{P}$ exhibiting the partitioned structure (3.28) where P_1 and P_2 are symmetric and nonnegative definite matrices. Perturbing slightly matrices P_1 and P_2 if necessary and assuming that N extreme matrices M_i for all $i = 1, 2, \ldots, N$ have been determined such that $\mathcal{D}_c = \mathcal{D}_n$ then we can say that with (4.9) there exist matrices Q, G, and F easily determined from $(\bar{A}_f, \bar{B}_f, \bar{C}_f)$ and (3.3) such that all LMI in (4.8) are feasible. This means that the filter of [18] is always feasible for Theorem 5 but the contrary, of course, is not always true unless $\mathcal{D}_n$ is defined by a one-block uncertain matrix.

5. H_2 and H_∞ decentralized filtering. Another important point of the design procedure provided in the present paper concerns the H_2 and H_∞ filter structures. In signal and systems estimation when the overall system is described by a number of units coupled together by means of an interconnection network, it is of interest to know whether it is possible to connect local filters in order to estimate the local state variables [6, 17]. Assuming no parameter uncertainty exists, the model is given by (2.1)−(2.3), where B, C, D, and L but not A are block diagonal matrices. The goal is to determine a filter as (2.14)−(2.15) with A_f, B_f, and C_f block diagonal matrices of compatible dimensions. In this case the filter can be split into a set of local filters acting on each subsystem level. Recalling that the inverse of a block diagonal matrix is also a block diagonal matrix and that the product of block diagonal matrices is a block diagonal matrix, then (3.18) or more generally (4.3) reveals that our goal is accomplished provided we include in the H_2 and H_∞ filtering design problems these additional constraints: *matrices Z, Y, Q, G, and F are block diagonal.* Fortunately this corresponds to constrain to zero some entries of those matrices and convexity is preserved. Of course the same reasoning can be drawn for the design of robust filters.

6. Illustrative examples. In this section we solve the H_2 filter design problem for several systems of the form (2.1)−(2.3) to illustrate the most important aspects of the theory introduced so far. In all examples the uncertainty acts on matrix A

only but is of unstructured and structured types. The procedure given in [13], which is based on a necessary and sufficient condition for guaranteed cost state estimation, has been implemented and it is used for comparison purposes.

Consider a linear discrete-time system with

$$B = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \; C = \begin{bmatrix} 1 & 0 \end{bmatrix}, \; D = \begin{bmatrix} 0 & 0 & \sqrt{2} \end{bmatrix}, \; L = \begin{bmatrix} 1 & 1 \end{bmatrix}. \tag{6.1}$$

Optimal H_2 filter: The nominal matrix $A = A_0$ is given by

$$A_0 = \begin{bmatrix} 0.9 & 0.1 \\ 0.01 & 0.9 \end{bmatrix}. \tag{6.2}$$

For $N = 1$ corresponding to the nominal system, Theorem 3 provides the Kalman optimal H_2 filter $\mathcal{F}_{kal}$ with the associated minimum cost $\rho_2(\mathcal{F}_{kal}) = 8.0759$ and state space realization

$$A_{kal} = \begin{bmatrix} 0.4427 & 0.1000 \\ -0.1615 & 0.9000 \end{bmatrix}, \; B_{kal} = \begin{bmatrix} 0.4573 \\ 0.1715 \end{bmatrix}, \; C_{kal} = \begin{bmatrix} 1 & 1 \end{bmatrix}. \tag{6.3}$$

Robust H_2 filter: Consider an uncertain system with $A = A_0 + \Delta A$ where A_0 is given by (6.2) and

$$\Delta A = \begin{bmatrix} 0 & 0.06\alpha \\ 0.05\beta & 0 \end{bmatrix} = \begin{bmatrix} 0.06 & 0 \\ 0 & 0.05 \end{bmatrix} \begin{bmatrix} \alpha & 0 \\ 0 & \beta \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \tag{6.4}$$

where $|\alpha| \leq 1$ and $|\beta| \leq 1$. This is a two-block uncertainty which can be exactly described by the set $\mathcal{D}_c$ but not by the set $\mathcal{D}_n$ unless the uncertain matrix is taken as diagonal, that is, $\Omega := \text{diag}[\alpha, \beta]$. However, the results available in the literature to date [13, 18] cannot be directly applied unless the block diagonal structure of Ω is not imposed, in which case some conservatism is necessarily introduced. The design procedure of [13] with the best value for the parameter $\varepsilon = 1.5264e - 04$ provides a suboptimal guaranteed cost H_2 filter $\mathcal{F}_{sub}$ with state space realization

$$A_{sub} = \begin{bmatrix} 0.0335 & 0.1014 \\ -0.2551 & 0.9117 \end{bmatrix}, \; B_{sub} = \begin{bmatrix} 0.8667 \\ 0.2652 \end{bmatrix}, \; C_{sub} = \begin{bmatrix} 1 & 1 \end{bmatrix}. \tag{6.5}$$

On the other hand, applying Theorem 3 with $N = 4$ matrices corresponding to the extreme points of the uncertain domain we get the optimal guaranteed cost H_2 filter $\mathcal{F}_{opt}$ given by

$$A_{opt} = \begin{bmatrix} 0.0383 & 0.0982 \\ -0.3681 & 0.8986 \end{bmatrix}, \; B_{opt} = \begin{bmatrix} 0.8490 \\ 0.3779 \end{bmatrix}, \; C_{opt} = \begin{bmatrix} 1 & 1 \end{bmatrix}. \tag{6.6}$$

Table 6.1 shows, for each filter, the value of the guaranteed H_2 cost $\rho_2(\mathcal{F})$ as well as the maximum value of $\|T_M(\zeta)\|_2^2$ with respect to the matrix M which depends through (6.4) on the uncertain parameters α and β. As expected, the Kalman filter, which is optimal for the nominal system, is the worst under parametric uncertainty. The filter of [13] is suboptimal with respect to the guaranteed cost because, as we have said before, the two-block structure of the uncertainty matrix Ω cannot be considered in the design procedure proposed. It is interesting to observe that the filter determined from Theorem 3 is the better one with respect to guaranteed H_2 cost as well as the true worst case value of the H_2 estimation cost.

TABLE 6.1
H_2 filter performance: multiblock uncertainty.

Filter	$\mathcal{F}_{kal}$	$\mathcal{F}_{sub}$	$\mathcal{F}_{opt}$
$\rho_2(\mathcal{F})$	–	129.7915	100.0278
$\sup_{M\in\mathcal{D}_c}\|T_M(\zeta)\|_2^2$	49.4994	38.2183	30.0664

TABLE 6.2
H_2 filter performance: one-block uncertainty.

Filter	$\mathcal{F}_{kal}$	$N=2$	$N=4$	$N=8$	$\mathcal{F}_{opt}$
$\rho_2(\mathcal{F})$	–	9.6796	13.0219	13.0446	13.0446
$\sup_{M\in\mathcal{D}_n}\|T_M(\zeta)\|_2^2$	12.9427	–	–	11.8646	11.8646

Robust H_2 filter: Consider now an uncertain system with $A = A_0 + \Delta A$ where A_0 is given by (6.2) and

$$\Delta A = \begin{bmatrix} 0 & 0.06\alpha \\ 0 & 0.05\beta \end{bmatrix} = \begin{bmatrix} 0.06 & 0 \\ 0 & 0.05 \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \end{bmatrix} \begin{bmatrix} 0 & 1 \end{bmatrix}, \tag{6.7}$$

where the uncertain parameters are such that $\alpha^2+\beta^2 \le 1$. This case of only one-block uncertainty is exactly described by the domain $\mathcal{D}_n$ with $\Omega' = [\alpha\ \beta]'$. Using [13] the following optimal guaranteed H_2 cost filter is obtained:

$$A_{opt} = \begin{bmatrix} 0.3521 & 0.1069 \\ -0.2211 & 0.9400 \end{bmatrix},\ B_{opt} = \begin{bmatrix} 0.5479 \\ 0.2311 \end{bmatrix},\ C_{opt} = \begin{bmatrix} 1 & 1 \end{bmatrix}. \tag{6.8}$$

In this case, the uncertainty domain cannot be exactly represented by the polytopic domain $\mathcal{D}_c$. However, Table 6.2 shows that with the extreme matrices calculated from

$$\begin{bmatrix} \alpha_i \\ \beta_i \end{bmatrix} = \begin{bmatrix} \cos(2\pi i/N) \\ \sin(2\pi i/N) \end{bmatrix},\ i = 1, 2, \ldots, N, \tag{6.9}$$

for $N = 8$ the problem given in Theorem 3 provides the same guaranteed cost optimal robust filter which, in addition, performs better that the nominal Kalman filter.

7. Conclusion. The robust filtering problem has been addressed in this paper in the case when convex polytopic uncertainty is present on the dynamic, input, and output matrices. Unlike Kalman-type approaches using Riccati equations that generally deal with unstructured (one-block) norm-bounded uncertainty, the uncertain type handled here may be highly structured and then encompasses most of the results available in the literature to date. The filtering problem has been solved using H_2 and H_∞ optimization formulations, both with LMI machinery. Indeed, the proposed filter parameterization enables us to define parametric optimization problems in terms of linear matrix inequalities, a feature which is now known to be very fortunate since it allows the use of very efficient numerical solvers. Some illustrative numerical examples have been developed to show the usefulness of the proposed approach and its superiority for dealing with structured (multiblock) uncertainty. The LMI tool can be exploited to solve efficiently complex problems with structured uncertainty (interval

as well as norm-bounded type) in the presence of convex constraints expressed in terms of LMI as, for instance, structural and integral quadratic constraints.

SECOND ORDER SUFFICIENT OPTIMALITY CONDITIONS FOR SOME STATE-CONSTRAINED CONTROL PROBLEMS OF SEMILINEAR ELLIPTIC EQUATIONS*

EDUARDO CASAS†, FREDI TRÖLTZSCH‡, AND ANDREAS UNGER‡

Abstract. This paper deals with a class of optimal control problems governed by elliptic equations with nonlinear boundary condition. The case of boundary control is studied. Pointwise constraints on the control and certain equality and set-constraints on the state are considered. Second order sufficient conditions for local optimality of controls are established.

Key words. boundary control, semilinear elliptic equations, sufficient optimality conditions, state constraints

1. Introduction.

In contrast to the optimal control of linear systems with a convex objective, where first order necessary optimality conditions are already sufficient for optimality, higher order conditions such as second order sufficient optimality conditions (SSC) should be employed to verify optimality for nonlinear systems. Second order sufficient optimality conditions have also proved to be useful for showing important properties of optimal control problems such as local uniqueness of optimal controls and their stability with respect to certain perturbations. Moreover, they may serve as an assumption to guarantee the convergence of numerical methods in optimal control. In this respect, we refer to the general expositions by Maurer and Zowe [15] and Maurer [14] for different aspects of second order sufficient optimality conditions. The approximation of programming problems in Banach spaces is discussed in Alt [2]. Moreover, Alt [3], [4] has established a general convergence analysis for Lagrange–Newton methods in Banach spaces.

Meanwhile, an extensive number of publications have been devoted to different aspects of second order sufficient optimality conditions for control problems governed by ordinary differential equations. The well-known *two-norm discrepancy* has in particular received a good deal of attention. We refer, for instance, to Ioffe [13] and Maurer [14].

First investigations of second order sufficient optimality conditions for control problems governed by partial differential equations have been published by Goldberg and Tröltzsch [11], [12] for the boundary control of parabolic equations with nonlinear boundary conditions. In [9], Casas, Tröltzsch, and Unger have extended these ideas to elliptic boundary control problems with pointwise constraints on the control. Moreover, they tightened the gap between second order necessary and sufficient

optimality conditions. This was done by the consideration of sets of strongly active constraints according to Dontchev et al. [10]. This technique is also related to first order sufficient optimality conditions introduced by Maurer and Zowe [15]. It should be mentioned that as many as four norms have to be used in this case (L^∞-norm for differentiation, L^2-norm to formulate second order sufficient optimality conditions, L^1-norm for the first order sufficient optimality condition, and certain L^p-norms to obtain optimal regularity results).

Bonnans [5] has shown that a very weak form of second order sufficient conditions can be used to verify local optimality for a particular class of semilinear elliptic control problems with constraints on the control: If the second order derivative of the Lagrange function is a Legendre form, then it suffices to have its positivity in all critical directions.

In our paper, the results of [9] will be extended to additional constraints on the state. In this way, we are continuing the investigations by Casas and Tröltzsch [8] on second order *necessary conditions*. We also rely on general ideas of Maurer and Zowe [15], combining their approach with a detailed splitting technique.

At the beginning, we aimed to establish second order sufficient optimality conditions for boundary control problems governed by semilinear elliptic equations in domains of arbitrary dimension with general pointwise constraints on the control and the state. However, we soon recognized that *pointwise* state-constraints lead to essential and somewhat surprising difficulties. To establish second order sufficient optimality conditions for problems with pointwise state-constraints given on the whole domain, we had to restrict ourselves to two-dimensional domains with controls appearing linearly in the boundary condition. These obstacles might indicate some limits for the "traditional" type of second order sufficient optimality conditions for control problems governed by PDEs.

If pointwise state-constraints are imposed on compact subsets of the domain, while the other quantities are sufficiently smooth, then arbitrary dimensions can be treated without restrictions on the nonlinearities. In this case the adjoint state belongs to $L^\infty(\Gamma)$. Moreover, we are able to avoid the assumption of linearity of the boundary condition with respect to the control by introducing some extended form of second order optimality conditions.

2. The optimal control problem. We consider the problem: *Minimize* the functional

$$F_0(y,u) = \int_\Omega f(x,y(x))\,dx + \int_\Gamma g(x,y(x),u(x))\,dS(x) \tag{2.1}$$

subject to the *equation of state*

$$\begin{cases} -\Delta y(x) + y(x) = 0 & \text{in } \Omega, \\ \partial_\nu y(x) = b(x,y(x),u(x)) & \text{on } \Gamma, \end{cases} \tag{2.2}$$

to the constraints on the *state* y

$$F_i(y) = 0, \quad i = 1,\dots,m, \tag{2.3}$$

$$E(y) \in K, \tag{2.4}$$

and to the constraints on the *control* u

$$u_a(x) \le u(x) \le u_b(x) \quad \text{almost everywhere (a.e.) on } \Gamma. \tag{2.5}$$

In this setting, $\Omega \subset \mathbb{R}^n$ is a bounded domain with a Lipschitz boundary Γ according to the definition by Nečas [17]. Moreover, sufficiently smooth functions $f : \Omega \times \mathbb{R} \to \mathbb{R}$ and $g, b : \Gamma \times \mathbb{R}^2 \to \mathbb{R}$ are given. The symbol ∂_ν is used for the derivative in the direction of the unit outward normal ν on Γ. The functionals $F_i : C(\overline{\Omega}) \to \mathbb{R}$, $i = 1, \dots, m$, are supposed to be twice continuously Fréchet differentiable, that is, to be of class C^2. By E we denote a mapping of class C^2 from $C(\overline{\Omega})$ into a real Banach space Z. $K \subset Z$ is a nonempty convex closed set, and u_a, $u_b : \Gamma \to \mathbb{R}$ are functions of $L^\infty(\Gamma)$ satisfying $u_a(x) \le u_b(x)$ on Γ.

The *control* u is looked for in the control space $\mathcal{U} = L^\infty(\Gamma)$, while the *state* y is defined as *a weak solution* of (2.2) in the state space $C(\overline{\Omega}) \cap H^1(\Omega) = Y$, that is,

$$\int_\Omega (\nabla y \nabla v + yv)\, dx = \int_\Gamma b(\cdot, y, u) v \, dS \quad \forall v \in H^1(\Omega). \tag{2.6}$$

We endow Y with the norm $\|y\|_Y = \|y\|_{C(\overline{\Omega})} + \|y\|_{H^1(\Omega)}$. The following assumptions are imposed on the given quantities.

(A1) For each fixed $x \in \Omega$ or Γ, respectively, the functions $f = f(x, y)$, $g = g(x, y, u)$, and $b = b(x, y, u)$ are of class C^2 with respect to (y, u). For fixed (y, u), they are Lebesgue measurable with respect to $x \in \Omega$ or $x \in \Gamma$, respectively.

Throughout the paper, partial derivatives are indicated by associated subscripts. For instance, b_{yu} stands for $\partial^2 b / \partial y \partial u$. By $b'(x, y, u)$ and $b''(x, y, u)$ we denote the gradient and the Hessian matrix of b with respect to (y, u):

$$b'(x, y, u) = \begin{pmatrix} b_y(x, y, u) \\ b_u(x, y, u) \end{pmatrix}, \quad b''(x, y, u) = \begin{pmatrix} b_{yy}(x, y, u) & b_{yu}(x, y, u) \\ b_{uy}(x, y, u) & b_{uu}(x, y, u) \end{pmatrix};$$

$|b'|$ and $|b''|$ are defined by adding the absolute values of all entries.

In the next assumption, fixed parameters $p > n - 1$ and s, r are used, which depend on n. For the possible (minimal) choice of s and r we refer to the discussion of regularity in (3.13). Roughly speaking, we have $y|_\Gamma \in L^s(\Gamma)$ and $y \in L^r(\Omega)$ in the linearized system (2.2) if $u \in L^2(\Gamma)$. As usual, s' and r' denote conjugate numbers. For instance, s' is defined by $1/s' + 1/s = 1$.

(A2) For all $M > 0$ there are constants $C_M > 0$, functions $\Psi_f^M \in L^{(r/2)'}(\Omega)$, $\Psi_g^{M,1} \in L^{(s/2)'}(\Gamma)$, $\Psi_g^{M,2} \in L^{2(s/2)'}(\Gamma)$, $\Psi_g^{M,3} \in L^\infty(\Gamma)$, and a continuous, monotone increasing function $\eta \in C(\mathbb{R}^+ \cup \{0\})$ with $\eta(0) = 0$ such that

(i)

$$b_y(x, y, u) \le 0 \qquad \text{a.e. } x \in \Gamma, \ \forall (y, u) \in \mathbb{R}^2, \tag{2.7}$$

$b(\cdot, 0, 0) \in L^p(\Gamma)$, for a $p > n - 1$,
$|b'(x, y, u)| + |b''(x, y, u)| \le C_M$,
$|b''(x, y_1, u_1) - b''(x, y_2, u_2)| \le C_M \, \eta(|y_1 - y_2| + |u_1 - u_2|)$
for almost all $x \in \Gamma$ and all $|y|, |u|, |y_i|, |u_i| \le M$, $i = 1, 2$;

(ii) $f(\cdot, 0) \in L^1(\Omega)$, $f_y(\cdot, 0) \in L^{r'}(\Omega)$, $f_{yy}(\cdot, 0) \in L^{(r/2)'}(\Omega)$
$|f_{yy}(x, y_1) - f_{yy}(x, y_2)| \le \Psi_f^M(x) \, \eta(|y_1 - y_2|)$
$\forall \, x \in \Omega$, $|y_i| \le M$, $i = 1, 2$;

(iii) $g(\cdot,0,0) \in L^1(\Gamma)$, $g_y(\cdot,0,0) \in L^{s'}(\Gamma)$, $g_u(\cdot,0,0) \in L^2(\Gamma)$,
$g_{yy}(\cdot,0,0) \in L^{(s/2)'}(\Gamma)$, $g_{yu}(\cdot,0,0) \in L^{2(s/2)'}(\Gamma)$, $g_{uu}(\cdot,0,0) \in L^\infty(\Gamma)$
(here, $\cdot$ stands for x)

$$|g_{yy}(x,y_1,u_1) - g_{yy}(x,y_2,u_2)| \le \Psi_g^{M,1}(x)\eta(|y_1-y_2|+|u_1-u_2|),$$
$$|g_{yu}(x,y_1,u_1) - g_{yu}(x,y_2,u_2)| \le \Psi_g^{M,2}(x)\eta(|y_1-y_2|+|u_1-u_2|),$$
$$|g_{uu}(x,y_1,u_1) - g_{uu}(x,y_2,u_2)| \le \Psi_g^{M,3}(x)\eta(|y_1-y_2|+|u_1-u_2|),$$
for almost all $x \in \Gamma$ and all $|y_i| \le M$, $|u_i| \le M$.

REMARK 2.1. *Notice that the estimates in* (i)–(iii) *imply boundedness and Lipschitz properties of* b, f, g, b', f', g' *in several L-spaces. We omit them, because they follow from the mean value theorem.*

(A3) (i) Let us define the norm

$$\|y\|_2 = \|y\|_{C(A)} + \|y\|_{L^r(\Omega)} + \|y\|_{L^s(\Gamma)}$$

for $y \in C(\overline{\Omega})$, where $A \subset \overline{\Omega}$ is a certain measurable compact subset. Here A stands for a set, where we know $y \in C(A)$ for Neumann boundary data given in $L^2(\Gamma)$. In the case $n = 2$ we may take $A = \overline{\Omega}$, while $A \subset \Omega$ is needed for $n > 2$. For $A = \emptyset$ we put $\|y\|_{C(A)} = 0$.
We assume at a fixed reference state $\overline{y} \in C(\overline{\Omega})$ that

$$|F_i'(\overline{y})y| \le C_F\|y\|_2 \quad \forall y \in C(\overline{\Omega}),$$
$$|F_i''(\overline{y})[y_1,y_2]| \le C_F\|y_1\|_2\|y_2\|_2 \quad \forall y_1, y_2 \in C(\overline{\Omega})$$

holds with some $C_F > 0$. Moreover, we require with a $C_M > 0$

$$|F_i'(y_1)y - F_i'(y_2)y| \le C_M\|y_1-y_2\|_2\|y\|_2,$$
$$|(F_i''(y_1) - F_i''(y_2))[y,v]| \le C_M\,\eta(\|y_1-y_2\|_{C(\overline{\Omega})})\|y\|_2\|v\|_2$$

$\forall\, y_j$ with $\|y_j\|_{C(\overline{\Omega})} \le M$, $j = 1,2$, $\forall\, y$, v from $C(\overline{\Omega})$, and $\forall\, i = 1,\dots,m$.

(ii) Analogous assumptions are imposed on $E : C(\overline{\Omega}) \to Z$, where $\|\cdot\|_Z$ is to be substituted for $|\cdot|$. For instance,

$$\|E'(\overline{y})y\|_Z \le C_E\|y\|_2 \quad \forall y \in C(\overline{\Omega})$$

is supposed.

We shall explain the main constructions of our paper by the following canonical example (P) that fits in the general setting.

Example (P). Minimize

$$\frac{1}{2}\int_\Omega (y-y_d)^2dx + \frac{\alpha}{2}\int_\Gamma u^2dS$$

subject to

$$\begin{aligned} -\triangle y + y &= 0 && \text{in } \Omega,\\ \partial_\nu y &= u - y^3 && \text{on } \Gamma, \end{aligned}$$

and

$$|u| \le 1, \qquad y(0) \le y_0$$

in the open unit ball $\Omega \subset \mathbb{R}^3$ around zero, where $\alpha > 0$, $y_0 \in \mathbb{R}$, and $y_d \in L^\infty(\Omega)$ are given. Here, we have $Z = \mathbb{R}$, $K = \mathbb{R}^-$, $A = \{0\}$, $E(y) = y(0) - y_0$, and we need $y \in C(\Omega)$ to make E well defined.

3. The state equation and first order necessary optimality conditions. It can be shown that the equation (2.2) admits for each $u \in \mathcal{U}^{ad}$ a unique weak solution $y = y(u) \in Y$, where $\mathcal{U}^{ad} = \{u \in L^\infty(\Gamma) \,|\, u_a(x) \le u(x) \le u_b(x) \text{ a.e. on } \Gamma\}$. Moreover, there is a constant M such that

$$\|y(u)\|_Y \le M \quad \forall u \in \mathcal{U}^{ad}. \tag{3.1}$$

In particular, it holds that $\|y\|_{C(\overline{\Omega})} \le M$. Casas and Tröltzsch [8] have proved that the mapping $u \mapsto y(u)$ from $L^\infty(\Gamma)$ into Y is of class C^2. Furthermore, the Lipschitz property

$$\|y(u_1) - y(u_2)\|_2 \le C_2 \|u_1 - u_2\|_{L^2(\Gamma)}$$

holds for all u_1, $u_2 \in \mathcal{U}^{ad}$, where C_2 is a positive constant and $\|\cdot\|_2$ is defined in (A3). For fixed $u \in \mathcal{U}^{ad}$ we have $b(\cdot, y, u) \in L^p(\Gamma)$, hence the weak solution $y \in Y$ of (2.2) belongs to the space

$$Y_{q,p} = \{y \in H^1(\Omega) \,|\, -\Delta y + y \in L^q(\Omega), \partial_\nu y \in L^p(\Gamma)\},$$

which is known to be continuously embedded into $Y = C(\overline{\Omega}) \cap H^1(\Omega)$ for each $q > n/2$ and each $p > n - 1$.

In all of what follows we assume that a *reference pair* $(\overline{y}, \overline{u}) \in Y \times \mathcal{U}^{ad}$ is given, satisfying, together with an associated *adjoint state* $\overline{\varphi} \in W^{1,\sigma}(\Omega)$ $\forall \sigma < n/(n-1)$, and with *Lagrange multipliers*

$$\overline{\lambda} = (\overline{\lambda}_1, \dots, \overline{\lambda}_m)^T \in \mathbb{R}^m, \qquad \overline{z}^* \in Z^*,$$

the associated standard *first order necessary optimality conditions*. We will just assume them. They can be proved following Casas [7], Bonnans and Casas [6], or Zowe and Kurcyusz [23]. The first order optimality system to be satisfied by $(\overline{y}, \overline{u})$ consists of the state equations (2.2), the constraint $\overline{u} \in \mathcal{U}^{ad}$, the *adjoint equations*

$$-\Delta\overline{\varphi} + \overline{\varphi} = f_y(\cdot, \overline{y}) + \sum_{i=1}^m \overline{\lambda}_i F_i'(\overline{y})|_\Omega + (E'\overline{y})^* \overline{z}^*|_\Omega \qquad \text{in } \Omega, \tag{3.2}$$

$$\partial_\nu \overline{\varphi} = b_y(\cdot, \overline{y}, \overline{u})\overline{\varphi} + g_y(\cdot, \overline{y}, \overline{u}) + \sum_{i=1}^m \overline{\lambda}_i F_i'(\overline{y})|_\Gamma + (E'\overline{y})^* \overline{z}^*|_\Gamma \quad \text{on } \Gamma \tag{3.3}$$

for the adjoint state $\overline{\varphi}$, the *complementary slackness condition*

$$\langle \overline{z}^*, \kappa - E(\overline{y}) \rangle \le 0 \quad \forall \kappa \in K, \tag{3.4}$$

and the *variational inequality*

$$\int_\Gamma (g_u(x, \overline{y}(x), \overline{u}(x)) + \overline{\varphi}(x) b_u(x, \overline{y}(x), \overline{u}(x)))(u(x) - \overline{u}(x))\, dS(x) \ge 0 \tag{3.5}$$

$\forall\, u \in \mathcal{U}^{ad}$. We have $F_i'(\overline{y}) \in C(\overline{\Omega})^*$, $i = 1, \dots, m$, and $E'(\overline{y})^* \overline{z}^* \in C(\overline{\Omega})^*$; hence these quantities can be identified with real Borel measures on $\overline{\Omega}$. Let a nonnegative function $\beta \in L^\infty(\Gamma)$ and real Borel measures μ_Ω and μ_Γ concentrated on Ω and Γ, respectively, be given. Then the problem

$$\begin{cases} -\Delta\varphi + \varphi = \mu_\Omega & \text{in } \Omega, \\ \partial_\nu \varphi + \beta\varphi = \mu_\Gamma & \text{on } \Gamma \end{cases} \tag{3.6}$$

admits a unique solution $\varphi \in W^{1,\sigma}(\Omega)\ \forall\ \sigma < n/(n-1)$ (see Casas [7]; the reader is also referred to Stampacchia [20] for the Dirichlet case). In view of this, we may write

$$\overline{\varphi} = \varphi_0 + \sum_{i=1}^{m} \lambda_i \varphi_i + \varphi_E,$$

where φ_0, φ_i, and φ_E solve (3.6) for $\mu_\Omega = f_y$, $F_i'(\overline{y})|_\Omega$, $E'(\overline{y})^*\overline{z}^*|_\Omega$, and $\mu_\Gamma = g_y$, $F_i'(\overline{y})|_\Gamma$, $E'(\overline{y})^*\overline{z}^*|_\Gamma$, respectively. We have at least φ_0, φ_i, and φ_E in $W^{1,\sigma}(\Omega)$. Moreover, $\overline{\varphi}$ satisfies the formula of integration by parts

$$\int_\Omega (-\Delta y + y)\varphi\, dx + \int_\Gamma (\partial_\nu y + \beta y)\varphi\, dS(x) = \int_\Omega y\, d\mu_\Omega + \int_\Gamma y\, d\mu_\Gamma \tag{3.7}$$

$\forall\ y \in Y_{q,p}$, where $q > n/2$, $p > n-1$. It is easy to verify that the optimality conditions can be expressed by the *Lagrange function*

$$\begin{aligned}\mathcal{L}(y,u,\varphi,\lambda,z^*) = F_0(y,u) - \int_\Omega (-\Delta y + y)\,\varphi\, dx - \int_\Gamma (\partial_\nu y - b(\cdot,y,u))\varphi\, dS \\ + \sum_{j=1}^{m} \lambda_j F_j(y) + \langle z^*, E(y)\rangle,\end{aligned} \tag{3.8}$$

$\mathcal{L} : Y_{q,p} \times \mathcal{U} \times W^{1,\sigma}(\Omega) \times \mathbb{R}^m \times Z^* \to \mathbb{R}$. The regularity of y and φ fits together, as $\varphi \in W^{1,\sigma}(\Omega)\ \forall\ \sigma < n/(n-1)$ ensures $\varphi \in L^s(\Omega)\ \forall\ s < n/(n-2)$ (Nečas [17, Thm. 3.4, p. 69]), and $\varphi|_\Gamma \in L^r(\Gamma)$ holds $\forall\ r < 1 + 1/(n-2)$ [17, Thm. 4.2, p. 84]). Therefore, this definition makes sense. In (3.8), $\langle\cdot,\cdot\rangle$ denotes the duality pairing between Z and its dual space Z^*. The Lagrange function $\mathcal{L}$ is of class C^2 with respect to (y,u) for fixed φ, λ, and z^*.

Thanks to (3.7), the optimality system can be rewritten in terms of $\mathcal{L}$. Then it is expressed by (2.6), the constraints on the state (2.3), (2.4), the constraints on the control $u \in \mathcal{U}^{ad}$, and

$$\mathcal{L}_y(\overline{y},\overline{u},\overline{\varphi},\overline{\lambda},\overline{z}^*)y = 0 \quad \forall y \in Y, \tag{3.9}$$

$$\mathcal{L}_u(\overline{y},\overline{u},\overline{\varphi},\overline{\lambda},\overline{z}^*)(u-\overline{u}) \geq 0 \quad \forall u \in \mathcal{U}^{ad}, \tag{3.10}$$

$$\langle \overline{z}^*, \kappa - E(\overline{y})\rangle \leq 0 \quad \forall \kappa \in K. \tag{3.11}$$

This form is more convenient for our later evaluations.

Example. In (P), adjoint equation and variational inequality are given by

$$\begin{aligned} -\triangle\overline{\varphi} + \overline{\varphi} = \overline{y} - y_d + \overline{z}^* \circ \delta(0), \qquad & \partial_\nu\overline{\varphi} + 3\,\overline{y}^2\overline{\varphi} = 0, \\ \int_\Gamma (\alpha\overline{u} + \overline{\varphi})(u-\overline{u})dS \geq 0 \qquad & \forall |u| \leq 1, \end{aligned}$$

where $\delta(0)$ is the Dirac measure.

To shorten our notation, derivatives taken at $(\overline{y},\overline{u},\overline{\varphi},\overline{\lambda},\overline{z}^*)$ will be indicated by a bar. For instance, $\overline{\mathcal{L}}_y y$, $\overline{\mathcal{L}}_u(u-\overline{u})$ stand for the derivatives in (3.9) and (3.10), respectively. $\overline{\mathcal{L}}_{yy}[y_1,y_2]$ denotes the second order derivative of $\mathcal{L}$ in the directions y_1, y_2 taken at $(\overline{y},\overline{u},\overline{\varphi},\overline{\lambda},\overline{z}^*)$. Moreover, $\overline{\mathcal{L}}_{ww}[w_1,w_2]$ is the second order derivative of $\mathcal{L}$ in the directions $w_1 = (y_1,u_1)$, $w_2 = (y_2,u_2)$. If $w_1 = w_2 = w$, then we write for short $\overline{\mathcal{L}}_{ww}[w,w] = \overline{\mathcal{L}}_{ww}[w]^2$.

Next we provide some useful results on linearized versions of the state equation. Regard first the linear system

$$\begin{cases} -\Delta y + y = f & \text{in } \Omega, \\ \partial_\nu y + \beta y = g & \text{on } \Gamma, \end{cases} \tag{3.12}$$

where $\beta \in L^\infty(\Gamma)$ is nonnegative. For each pair $(f,g) \in L^1(\Omega) \times L^1(\Gamma)$, this system admits a unique solution $y \in W^{1,\sigma}(\Omega)$, where $\sigma < n/(n-1)$; see Casas [7]. (Notice that a function of L^1 can be considered as a Borel measure.) On the other hand, the solution y of (3.12) belongs to $H^1(\Omega) \cap C(\overline{\Omega})$ if $(f,g) \in L^q(\Omega) \times L^p(\Gamma)$. This regularity result is well known for domains with C^1-boundary. Moreover, it remains true for domains with Lipschitz boundary in the sense of Nečas [17] (see Stampacchia [19] and Murthy and Stampacchia [16]). On account of this, the mapping $D : (f,g) \mapsto (y, y|_\Gamma)$ is continuous from $L^1(\Omega) \times L^1(\Gamma)$ into $L^s(\Omega) \times L^t(\Gamma)$ for $s < n/(n-2)$ and $t < (n-1)/(n-2)$. D is continuous also from $L^q(\Omega) \times L^p(\Gamma)$ into $L^\infty(\Omega) \times L^\infty(\Gamma)$. We obtain these spaces by embedding results for $W^{1,\sigma}(\Omega)$ [1], [17], [20]. In both cases, this mapping is linear and continuous. Interpolation theory applies to show the following results for D considered as a mapping defined on $L^2(\Omega) \times L^2(\Gamma)$:

$$y \in \begin{cases} C(\overline{\Omega}), & n = 2, \\ L^r(\Omega)\ \forall r < \infty, & n = 3, \\ L^r(\Omega)\ \forall r < \dfrac{2n}{n-3}, & n \geq 4, \end{cases} \quad y|_\Gamma \in \begin{cases} C(\Gamma), & n = 2, \\ L^s(\Gamma)\ \forall s < \infty, & n = 3, \\ L^s(\Gamma)\ \forall s < \dfrac{2(n-1)}{n-3}, & n \geq 4. \end{cases} \tag{3.13}$$

4. Regularity condition and linearization theorem. Let us recall that we consider a fixed reference pair $(\overline{y}, \overline{u})$ satisfying, together with $(\overline{\varphi}, \overline{\lambda}, \overline{z}^*)$, the first order necessary conditions (3.9)–(3.11).

The *linearized cone* of $\mathcal{U}^{ad}$ at $\overline{u}$ is the set $\mathcal{C}(\overline{u}) = \{v \in L^\infty(\Gamma) \,|\, v = \varrho(u - \overline{u}),\ \varrho \geq 0,\ u \in \mathcal{U}^{ad}\}$. Let $F = F(y)$ denote the mapping $y \mapsto (F_1(y), \dots, F_m(y))^T$ from Y to $\mathbb{R}^m$. For convenience, we introduce the set of all feasible pairs

$$\mathcal{M} = \{w = (y,u) \in Y \times \mathcal{U}^{ad} \,|\, y = G(u) \text{ and } y \text{ satisfies the state-constraints}\}$$

(notice that G is the nonlinear control-state-mapping). Following Maurer and Zowe [15], the *linearized cone* $L(\mathcal{M}, \overline{w})$ at $\overline{w} = (\overline{y}, \overline{u})$ is defined by

$$L(\mathcal{M}, \overline{w}) = \{w \,|\, w = (y,u),\ u \in \mathcal{C}(\overline{u}) \text{ and } (y,u) \text{ satisfies (4.1)–(4.3)}\},$$

where

$$\begin{cases} -\Delta y + y &= 0 & \text{in } \Omega, \\ \partial_\nu y &= b_y(\cdot, \overline{y}, \overline{u})y + b_u(\cdot, \overline{y}, \overline{u})u & \text{on } \Gamma, \end{cases} \tag{4.1}$$

$$F'(\overline{y})y = 0, \tag{4.2}$$

$$E'(\overline{y})y \in K(E(\overline{y})). \tag{4.3}$$

Here, $K(E(\overline{y})) = \{z \in Z \mid z = \varrho(\kappa - E(\overline{y})),\ \varrho \geq 0,\ \kappa \in K\}$ is the conical hull of $K - E(\overline{y})$.

REMARK 4.1. *The choice* $Z = \mathbb{R}^k$, $E(y) = (E_1(y), \dots, E_k(y))^T$, $K = (\mathbb{R}^k)^-$ *for* $E : Y \to Z$ *is of particular interest. Then* (4.3) *reduces to*

$$E_i'(\overline{y})y \leq 0$$

for all active $i \in \{1, \dots, k\}$, *that is for all* i, *where* $E_i(\overline{y}) = 0$ *holds.*

Example. The linearized cone for (P) is the set of the following pairs (y,u): They satisfy $u \in \mathcal{C}(\overline{u})$ and

$$-\triangle y + y = 0, \qquad \partial_\nu y + 3\overline{y}^2 y = u, \tag{4.4}$$

$$y(0) \le 0, \tag{4.5}$$

if $\overline{y}(0) = y_0$ (active state constraint). If the state constraint is not active, then (4.5) disappears.

The following *regularity assumption* (R) is basic for our further analysis: To formulate (R) we combine the two state constraints to one general constraint. We therefore take $\boldsymbol{Z} = \mathbb{R}^m \times Z$, $\boldsymbol{K} = \{0\} \times K$, define $T : Y \to \boldsymbol{Z}$ by $T(y) = (F(y), E(y))$, and put $\boldsymbol{K}(T(\overline{y})) = \{0\} \times K(E(\overline{y}))$. The regularity condition was introduced by Zowe and Kurcyusz [23] and requires

$$T'(\overline{y})G'(\overline{u})\mathcal{C}(\overline{u}) - \boldsymbol{K}(T(\overline{y})) = \boldsymbol{Z}. \tag{R}$$

This condition is sufficient for the existence of a (nondegenerate) Lagrange multiplier associated to the state-constraint $E(y) \in K$; see [23]. We should emphasize that (R) does not rely on the condition $\operatorname{int} K \neq \emptyset$. In Appendix 7.1 we shall present some sufficient conditions for (R) which, however, require $\operatorname{int} K \neq \emptyset$. (R) is discussed for the canonical example (P) there. For $Z = \mathbb{R}^k$, $K = (\mathbb{R}^k)^-$, the condition (R) is equivalent to the well-known *Mangasarian–Fromowitz condition.*

THEOREM 4.2. *Suppose that (R) is satisfied. Then for all pairs $(\hat{y},\hat{u}) \in \mathcal{M}$ there is a pair $(y,u) \in L(\mathcal{M},\overline{w})$ such that the difference $r = (r^y, r^u) = (\hat{y},\hat{u}) - (\overline{y},\overline{u}) - (y,u)$ can be estimated by*

$$\|r\|_{Y\times L^\infty(\Gamma)} \le C_{L,p}\|\hat{u}-\overline{u}\|_{L^\infty(\Gamma)}\|\hat{u}-\overline{u}\|_{L^p(\Gamma)} \quad \forall p > n-1, \tag{4.6}$$

$$\|r\| \le C_{L,2}\|\hat{u}-\overline{u}\|_{L^\infty(\Gamma)}\|\hat{u}-\overline{u}\|_{L^2(\Gamma)}, \tag{4.7}$$

where $\|r\| = \|r^y\|_2 + \|r^u\|_{L^2(\Gamma)}$. In the particular case $b(x,y,u) = b_1(x,y) + b_2(x)u$ we have

$$\|r\|_{Y\times L^\infty(\Gamma)} \le C_{L,p}\|\hat{u}-\overline{u}\|^2_{L^p(\Gamma)} \quad \forall p > n-1. \tag{4.8}$$

This theorem is proved in Appendix 7.2. Let us conclude this section by considering some useful estimates for $\mathcal{L}''$ and for certain remainder terms. First, we evaluate

$$\overline{\mathcal{L}}''[(y_1,u_1),(y_2,u_2)] = \mathcal{L}''(\overline{y},\overline{u},\overline{\varphi},\overline{\lambda},\overline{z}^*)[(y_1,u_1),(y_2,u_2)],$$

where $\mathcal{L}''$ denotes the second order derivative of $\mathcal{L}$ with respect to (y,u). We have

$$\begin{aligned}\overline{\mathcal{L}}''[(y_1,u_1),(y_2,u_2)] &= \int_\Omega f_{yy}(\cdot,\overline{y})y_1y_2\,dx + \int_\Gamma (y_1,u_1)g''(\cdot,\overline{y},\overline{u})(y_2,u_2)^T\,dS \\ &\quad + \int_\Gamma \overline{\varphi}\cdot(y_1,u_1)b''(\cdot,\overline{y},\overline{u})(y_2,u_2)^T\,dS \\ &\quad + \sum_{i=1}^m \overline{\lambda}_i F_i''(\overline{y})[y_1,y_2] + \langle \overline{z}^*, E''(\overline{y})[y_1,y_2]\rangle.\end{aligned} \tag{4.9}$$

Example. In the case of **(P)**, $\overline{\mathcal{L}}''$ admits the form

$$\overline{\mathcal{L}}''[(y_1,u_1),(y_2,u_2)] = \int_\Omega y_1y_2dx + \int_\Gamma (6\overline{\varphi}\,\overline{y}\,y_1y_2 + \alpha u_1u_2)dS.$$

The term connected with $\overline{\varphi}$ causes trouble, more precisely,

$$I = \int_\Gamma \overline{\varphi}\,(b_{yy}(\cdot,\overline{y},\overline{u})y_1y_2 + b_{yu}(\cdot,\overline{y},\overline{u})(y_1u_2+y_2u_1) + b_{uu}(\cdot,\overline{y},\overline{u})u_1u_2)\,dS. \tag{4.10}$$

An estimate of I is needed with respect to the norm $\|y\|_2 + \|u\|_{L^2(\Gamma)}$ (cf. (4.19)). We therefore have to require at least $\overline{\varphi} \in L^2(\Gamma)$ in the second item and $\overline{\varphi} \in L^\infty(\Gamma)$ in the third one. On the other hand, only $\overline{\varphi} \in L^r(\Gamma)$ follows from $\overline{\varphi} \in W^{1,\sigma}(\Omega)$ for $r < (n-1)/(n-2)$; see Nečas [17, p. 84]. For $n = 2$ we obtain $\overline{\varphi} \in L^r(\Gamma)$ for all $r < \infty$, while $n = 3$ yields the regularity $\overline{\varphi} \in L^r(\Gamma)$ for all $r < 2$. On account of this, the following additional assumption is crucial for our analysis.

(A4) Let one of the following statements be true:
- (i) $\overline{\varphi} \in L^\infty(\Gamma)$.
- (ii) $b_{uu}(x,y,u) = 0$ on $\Gamma \times \mathbb{R}^2$ and, if $n \geq 3$, then $\overline{\varphi} \in L^r(\Gamma)$ for some $r > n-1$.
- (iii) $b_{uu}(x,y,u) = b_{yu}(x,y,u) = 0$ on $\Gamma \times \mathbb{R}^2$ and, if $n \geq 4$, then $\overline{\varphi} \in L^r(\Gamma)$ for some $r > (n-1)/2$.
- (iv) $b''(\cdot,y,u) = 0$.

We briefly comment on the consequences of these assumptions: (i) is true if $\overline{f}_y \in L^q(\Omega)$, $\overline{g}_y \in L^p(\Gamma)$ and if the restrictions of F_i', $i = 1,\dots,m$, and $E'(\overline{y})^*\overline{z}^*$ to Ω and Γ, respectively, belong to $L^q(\Omega)$, $L^p(\Gamma)$, as well. Moreover, (i) holds for functionals F_i', $i = 1,\dots,m$, and $E'(\overline{y})^*\overline{z}^*$ of $C(\overline{\Omega})^*$, where the associated real Borel measures are concentrated on the set $A \subset \Omega$.

In addition to some assumptions on the regularity of $\overline{\varphi}$ for $n \geq 3,4$, (ii) requires linearity of b with respect to u, that is $b(x,y,u) = b_0(x,y) + b_1(x,y)u$, (iii) means that $b(x,y,u) = b_1(x,y) + b_2(x)u$, while (iv) is true only for an affine-linear boundary condition (but yet also true for a nonlinear functional F_0).

(A4) is obviously satisfied in the example (P).

As a consequence of (A3) and (A4), *pointwise state-constraints* on the whole set $\overline{\Omega}$ can only be handled by the standard part of our theory if u appears linearly in the boundary condition and $n = 2$. In the considerations below, we denote by r_i^T the remainder terms associated with the ith order Taylor expansion of a mapping T. For instance, the following first and second order expansions of $b(x,y,u)$ are used at triplets (x,y,u) and $(x,\overline{y},\overline{u}) \in \mathbb{R}^{n+2}$:

$$b(x,y,u) - b(x,\overline{y},\overline{u}) = b'(x,\overline{y},\overline{u})(y-\overline{y},u-\overline{u}) + r_1^b, \tag{4.11}$$

where

$$r_1^b = (b_y^\vartheta - \overline{b}_y)(y-\overline{y}) + (b_u^\vartheta - \overline{b}_u)(u-\overline{u}) \tag{4.12}$$

and $b_y^\vartheta, b_u^\vartheta, \overline{b}_y, \overline{b}_u$ denote b_y, b_u taken at $(x,\overline{y}+\vartheta(y-\overline{y}),\overline{u}+\vartheta(u-\overline{u}))$ and $(x,\overline{y},\overline{u})$, respectively, with some $\vartheta \in (0,1)$. Expanding the same expression up to the order two, we have

$$\begin{aligned} b(x,y,u) - b(x,\overline{y},\overline{u}) &= b'(x,\overline{y},\overline{u})(y-\overline{y},u-\overline{u}) \\ &\quad + \frac{1}{2}(y-\overline{y},u-\overline{u})b''(x,\overline{y},\overline{u})\begin{pmatrix} y-\overline{y} \\ u-\overline{u}\end{pmatrix} + r_2^b, \end{aligned} \tag{4.13}$$

with the second order remainder term

$$r_2^b = \frac{1}{2}(y-\overline{y}, u-\overline{u})[b''^{,\vartheta} - \overline{b}''](y-\overline{y}, u-\overline{u})^T. \tag{4.14}$$

Here, $b''^{,\vartheta}$, $\overline{b}''$ denote the Hessian matrix of b with respect to (y,u) taken at the same triplets as above. Due to our assumptions on b' and b'', the estimates

$$|r_1^b| \le C_M(|y-\overline{y}|^2 + |u-\overline{u}|^2), \tag{4.15}$$

$$|r_2^b| \le C_M\,\eta(|y-\overline{y}| + |u-\overline{u}|)(|y-\overline{y}|^2 + |u-\overline{u}|^2) \tag{4.16}$$

are valid $\forall\ |y|, |\overline{y}|, |u|, |\overline{u}| \le M$. We continue with the discussion of the remainders $r_1^{\mathcal{L}}$ and $r_2^{\mathcal{L}}$. A Taylor expansion of $\mathcal{L}$ gives

$$\begin{aligned}
&\mathcal{L}(y,u,\overline{\varphi},\overline{\lambda},\overline{z}^*) - \mathcal{L}(\overline{y},\overline{u},\overline{\varphi},\overline{\lambda},\overline{z}^*)\\
&= \overline{\mathcal{L}}_y(y-\overline{y}) + \overline{\mathcal{L}}_u(u-\overline{u}) + r_1^{\mathcal{L}}\\
&= \overline{\mathcal{L}}_y(y-\overline{y}) + \overline{\mathcal{L}}_u(u-\overline{u}) + \frac{1}{2}\left(\overline{\mathcal{L}}_{yy}[y-\overline{y}]^2 + 2\overline{\mathcal{L}}_{yu}[y-\overline{y}, u-\overline{u}] + \overline{\mathcal{L}}_{uu}[u-\overline{u}]^2\right) + r_2^{\mathcal{L}},
\end{aligned}$$

where $\overline{\mathcal{L}}$ indicates that $\mathcal{L}$ and its derivatives are taken at $(\overline{y},\overline{u},\overline{\varphi},\overline{\lambda},\overline{z}^*)$. We have

$$\begin{aligned}
r_1^{\mathcal{L}} &= (\mathcal{L}_y^\vartheta - \overline{\mathcal{L}}_y)(y-\overline{y}) + (\mathcal{L}_u^\vartheta - \overline{\mathcal{L}}_u)(u-\overline{u})\\
r_2^{\mathcal{L}} &= \frac{1}{2}\big((\mathcal{L}_{yy}^\vartheta - \overline{\mathcal{L}}_{yy})[y-\overline{y}]^2 + 2(\mathcal{L}_{yu}^\vartheta - \overline{\mathcal{L}}_{yu})[y-\overline{y}, u-\overline{u}] + (\mathcal{L}_{uu}^\vartheta - \overline{\mathcal{L}}_{uu})[u-\overline{u}]^2\big).
\end{aligned}$$

$\mathcal{L}^\vartheta$ indicates that $(\overline{y}+\vartheta(y-\overline{y}), \overline{u}+\vartheta(u-\overline{u}), \overline{\varphi}, \overline{\lambda}, \overline{z}^*)$ is substituted for $(y,u,\overline{\varphi},\overline{\lambda},\overline{z}^*)$ in $\mathcal{L}'$ and $\mathcal{L}''$ with some $\vartheta \in (0,1)$. On account of the assumptions (A1)–(A4), we are able to verify

$$|r_1^{\mathcal{L}}| \le C_{\mathcal{L}}(\|y-\overline{y}\|_2^2 + \|u-\overline{u}\|_{L^2(\Gamma)}^2), \tag{4.17}$$

$$|r_2^{\mathcal{L}}| \le C_{\mathcal{L}}\,\eta(\|y-\overline{y}\|_{C(\overline{\Omega})} + \|u-\overline{u}\|_{L^\infty(\Gamma)})\cdot(\|y-\overline{y}\|_2^2 + \|u-\overline{u}\|_{L^2(\Gamma)}^2), \tag{4.18}$$

and

$$|\overline{\mathcal{L}}''[(y_1,u_1),(y_2,u_2)]| \le C_{\mathcal{L}}(\|y_1\|_2 + \|u_1\|_{L^2(\Gamma)})(\|y_2\|_2 + \|u_2\|_{L^2(\Gamma)}). \tag{4.19}$$

The constant $C_{\mathcal{L}} > 0$ depends in particular on $\overline{\varphi}$. For the definition of η we refer to the assumption (A2). The analysis of (4.17)–(4.19) is performed in Appendix 7.3.

5. Standard second order sufficient optimality condition. Our main aim is to establish sufficient optimality conditions close to the necessary ones derived in Casas and Tröltzsch [8]. Therefore, we include also certain *first order sufficient optimality conditions*. We shall combine an approach going back to Zowe and Maurer [15] with a splitting technique introduced by Dontchev et al. [10]. The method of [10] was focused on the optimal control of ordinary differential equations. It was extended later by the authors in [9] to the case of elliptic equations without state-constraints.

In [15], Maurer and Zowe introduced first order sufficient optimality conditions for differentiable optimization problems subject to a general constraint $g(w) \le 0$. For our problem, the application of their approach in its full generality is rather technical. Therefore, in an initial step we incorporate the first order sufficient optimality condition only for the constraints on the control. Later, we shall deal in the same way with additional state-constraints.

The role of first order sufficient conditions can be explained most easily by the minimization problem $\{\min f(x) \,|\, x_a \le x \le x_b\}$, where $f : \mathbb{R}^n \to \mathbb{R}$ is of class C^2. Let $\bar{x}$ satisfy the first order necessary conditions (variational inequality). If $n = 1$, then $f'(\bar{x}) \neq 0$ implies that $\bar{x}$ is a local minimizer (even for concave f). Therefore, the second order sufficient optimality condition $f''(\bar{x}) > 0$ is needed only in the case $f'(\bar{x}) = 0$, where the first order necessary condition is not sufficient. The situation is similar for $n > 1$: The positive definiteness of $f''(\bar{x})$ has to be required only on the subspace $\{x \in \mathbb{R}^n \,|\, x^i = 0 \text{ if } D^i f(\bar{x}) \neq 0\}$.

Define for fixed $\tau > 0$ (arbitrarily small) the set

$$\Gamma_\tau = \{x \in \Gamma \,|\, |g_u(x, \overline{y}(x), \overline{u}(x)) + \overline{\varphi}(x) b_u(x, \overline{y}(x), \overline{u}(x))| \ge \tau\}.$$

Γ_τ is a subset of "strongly active" control constraints (cf. (3.5)). In other words, $\Gamma_\tau = \{x \in \Gamma| \quad |\mathcal{L}_u(\bar{y}, \bar{u}, \bar{\varphi}, \bar{\lambda}, \bar{z}^*)(x)| \ge \tau\}$ is the set, where the gradient of the objective (expressed as a function of the control) is sufficiently steep. In the example above, τ can be chosen as the minimal value of all nonvanishing $|D^i f(\bar{x})|$.

We mention at this point the relation

$$\langle \overline{z}^*, E'(\overline{y}) y \rangle \le 0 \tag{5.1}$$

$\forall\ (y, u) \in L(\mathcal{M}, \overline{w})$, which follows from $\langle \overline{z}^*, E'(\overline{y}) y \rangle = \varrho \langle \overline{z}^*, \kappa - E(\overline{y}) \rangle \le 0$ in view of (3.4).

Let $\mathcal{P}_\tau : L^\infty(\Gamma) \to L^\infty(\Gamma)$ denote the projection operator $u \mapsto \chi_{\Gamma \setminus \Gamma_\tau} u = \mathcal{P}_\tau u$. In other words, $(\mathcal{P}_\tau u)(x) = u(x)$ holds on $\Gamma \setminus \Gamma_\tau$, while $(\mathcal{P}_\tau u)(x) = 0$ holds on Γ_τ. We begin with our first and at the same time simplest *second order sufficient optimality condition*.

(SSC) There exist positive numbers τ and δ such that

$$\mathcal{L}''(\overline{y}, \overline{u}, \overline{\varphi}, \overline{\lambda}, \overline{z}^*)[w_2, w_2] \ge \delta \|u_2\|^2_{L^2(\Gamma)} \tag{5.2}$$

holds for all pairs $w_2 = (y_2, u_2)$ constructed in the following way: For every $w = (y, u) \in L(\mathcal{M}, \overline{w})$, we split up the control part u in $u_1 = (u - \mathcal{P}_\tau u)$ and $u_2 = \mathcal{P}_\tau u$. The solutions of the linearized state equation

$$\begin{cases} -\Delta y_i + y_i = 0 & \text{in } \Omega, \\ \partial_\nu y_i = b_y(\cdot, \overline{y}, \overline{u}) y_i + b_u(\cdot, \overline{y}, \overline{u}) u_i & \text{on } \Gamma \end{cases} \tag{5.3}$$

associated with u_i are denoted by y_i, $i = 1, 2$. By this construction, we get the representation $w = w_1 + w_2 = (y_1, u_1) + (y_2, u_2)$.

REMARK 5.1. *The coercitivity condition* (5.2) *of* (SSC) *is required on the whole set* $L(\mathcal{M}, \overline{w})$ *if* Γ_τ *is empty. This rather strong second order condition is obtained by the formal setting* $\tau = \infty$.

THEOREM 5.2. *Let the feasible pair* $\overline{w} = (\overline{y}, \overline{u})$ *satisfy the regularity condition* (R)*, the first order necessary optimality conditions* (3.9)–(3.11)*, and the second order sufficient optimality condition* (SSC)*. Suppose further that the general assumptions* (A1)–(A4) *are satisfied. Then there are constants* $\varrho > 0$ *and* $\delta' > 0$ *such that*

$$F_0(\hat{y}, \hat{u}) \ge F_0(\overline{y}, \overline{u}) + \delta' \|\hat{u} - \overline{u}\|^2_{L^2(\Gamma)} \tag{5.4}$$

holds for all feasible pairs $\hat{w} = (\hat{y}, \hat{u})$ *such that*

$$\|\hat{u} - \overline{u}\|_{L^\infty(\Gamma)} < \varrho. \tag{5.5}$$

Proof. We denote by $\bar l = (\overline{\varphi}, \overline{\lambda}, \overline{z}^*)$ the triplet of Lagrange multipliers appearing in the first order necessary optimality conditions. Let an arbitrary feasible pair $\hat w = (\hat y, \hat u)$ be given. Then

$$F_0(\hat w) - F_0(\overline{w}) = \mathcal{L}(\hat w, \bar l) - \mathcal{L}(\overline{w}, \bar l) - \langle \overline{z}^*, E(\hat y) - E(\bar y)\rangle \tag{5.6}$$

follows from $F(\hat w) = F(\overline{w}) = 0$. The complementary slackness condition implies

$$-\langle \overline{z}^*, E(\hat y) - E(\bar y))\rangle \geq 0.$$

Hence we can neglect this term, and a second order Taylor expansion yields

$$\begin{aligned} F_0(\hat w) - F_0(\overline{w}) &\geq \mathcal{L}(\hat w, \bar l) - \mathcal{L}(\overline{w}, \bar l) \\ &\geq \int_\Gamma l_u\,(\hat u - \overline{u})\,dS + \frac{1}{2}\mathcal{L}''(\overline{w}, \bar l)[\hat w - \overline{w}]^2 + r_2^{\mathcal{L}}(\overline{w}, \hat w - \overline{w}), \end{aligned}$$

where $l_u(x) = g_u(x, \overline{y}(x), \overline{u}(x)) + \overline{\varphi}(x) b_u(x, \overline{y}(x), \overline{u}(x))$. Using the variational inequality, we find

$$F_0(\hat w) - F(\overline{w}) \geq \tau \int_{\Gamma_\tau} |\hat u - \overline{u}|\,dS + \frac{1}{2}\mathcal{L}''(\overline{w}, \bar l)[\hat w - \overline{w}]^2 + r_2^{\mathcal{L}}(\overline{w}, \hat w - \overline{w}). \tag{5.7}$$

Let us introduce for convenience the bilinear form $B = \mathcal{L}''(\overline{w}, \bar l)$. Next we approximate $\hat w - \overline{w}$ by $w = (y, u) \in L(\mathcal{M}, \overline{w})$, according to Theorem 4.2. In this way we get a remainder $r = (r^y, r^u) = \hat w - \overline{w} - w$ satisfying the estimate

$$\|r\| \leq C_L \|\hat u - \overline{u}\|_{L^\infty(\Gamma)} \|\hat u - \overline{u}\|_{L^2(\Gamma)}. \tag{5.8}$$

It follows that $B[\hat w - \overline{w}]^2 = B[w]^2 + 2B[r, w] + B[r]^2$. We have $w \in L(\mathcal{M}, \overline{w})$; hence (SSC) applies to $B[w]^2$. Now we substitute in $B[w]^2$ the representation $w = w_1 + w_2$ described in (SSC) and deduce

$$\begin{aligned} B[w]^2 &= B[w_2]^2 + 2B[w_1, w_2] + B[w_1]^2 \\ &\geq \delta \|u_2\|^2_{L^2(\Gamma)} - 2C_{\mathcal{L}}(\|y_1\|_2 + \|u_1\|_{L^2(\Gamma)})(\|y_2\|_2 + \|u_2\|_{L^2(\Gamma)}) \\ &\quad - C_{\mathcal{L}}(\|y_1\|_2 + \|u_1\|_{L^2(\Gamma)})^2 \end{aligned}$$

from (SSC) and (4.19). In the following, c will denote a generic constant. Suppose that $\varrho < 1$ is given and assume $\|\hat u - \overline{u}\|_{L^\infty(\Gamma)} < \varrho$. Then $\|y_i\|_2 \leq c\|u_i\|_{L^2(\Gamma)}$ and Young's inequality together yield

$$\begin{aligned} B[w]^2 &\geq \delta \|u_2\|^2_{L^2(\Gamma)} - \frac{\delta}{2}\|u_2\|^2_{L^2(\Gamma)} - c\|u_1\|^2_{L^2(\Gamma)} \\ &\geq \frac{\delta}{2}\int_{\Gamma\setminus\Gamma_\tau} u^2\,dS - c\int_{\Gamma_\tau} u^2\,dS \\ &\geq \frac{\delta}{2}\int_{\Gamma\setminus\Gamma_\tau} |\hat u - \overline{u}|^2\,dS - c\int_{\Gamma\setminus\Gamma_\tau} |\hat u - \overline{u}|\,|r^u|\,dS - c\int_{\Gamma_\tau} |\hat u - \overline{u}|^2\,dS \\ &\quad - c\int_{\Gamma_\tau} |\hat u - \overline{u}|\,|r^u|\,dS - c\int_{\Gamma_\tau} |r^u|^2\,dS. \end{aligned} \tag{5.9}$$

The expression under the third integral is estimated by $\|\hat u - \overline{u}\|_{L^\infty(\Gamma)}|\hat u - \overline{u}|$. In the other integrals (except the first) we insert (5.8) and derive

$$B[w]^2 \geq \frac{\delta}{2}\int_{\Gamma\setminus\Gamma_\tau} |\hat u - \overline{u}|^2\,dS - c\varrho\int_{\Gamma_\tau} |\hat u - \overline{u}|\,dS - c\varrho\|\hat u - \overline{u}\|^2_{L^2(\Gamma)}. \tag{5.10}$$

The treatment of $B[r,w]$ and $B[r]^2$ is simpler. We find

$$\begin{aligned}|B[r,w]| &\le c\|r\|\|u\|_{L^2(\Gamma)} = c\|r\|\|\hat u-\overline u+r^u\|_{L^2(\Gamma)}\\ &\le c\varrho\|\hat u-\overline u\|^2_{L^2(\Gamma)}.\end{aligned}$$

The same type of estimate applies to $B[r]^2$. Altogether,

$$B[\hat w-\overline w]^2 \ge \frac{\delta}{2}\int_{\Gamma\setminus\Gamma_\tau}|\hat u-\overline u|^2\,dS - c\varrho\int_{\Gamma_\tau}|\hat u-\overline u|\,dS - c\varrho\|\hat u-\overline u\|^2_{L^2(\Gamma)} \tag{5.11}$$

is obtained. By substituting (5.11) in (5.7), we get

$$\begin{aligned}F_0(\hat w)-F_0(\overline w) &\ge (\tau-c\varrho)\int_{\Gamma_\tau}|\hat u-\overline u|\,dS+\frac{\delta}{2}\int_{\Gamma\setminus\Gamma_\tau}|\hat u-\overline u|^2\,dS - c\varrho\|\hat u-\overline u\|^2_{L^2(\Gamma)}\\ &\quad -|r_2^{\mathcal L}(\overline w,\hat w-\overline w)|\\ &\ge \frac{\tau}{2}\int_{\Gamma_\tau}|\hat u-\overline u|\,dS+\frac{\delta}{2}\int_{\Gamma\setminus\Gamma_\tau}|\hat u-\overline u|^2\,dS - c\varrho\|\hat u-\overline u\|^2_{L^2(\Gamma)}\\ &\quad -|r_2^{\mathcal L}(\overline w,\hat w-\overline w)|.\end{aligned}$$

Since $\|\hat u-\overline u\|_{L^\infty(\Gamma)}\le 1$ was assumed, $|\hat u-\overline u|\ge|\hat u-\overline u|^2$ holds a.e. Using this in the first integral, setting $\delta'=\min\{\tau/2,\delta/2\}$, and substituting the estimate (4.18) for $r_2^{\mathcal L}$, we complete our estimation by

$$\begin{aligned}F_0(\hat w)-F_0(\overline w) &\ge \|\hat u-\overline u\|^2_{L^2(\Gamma)}(\delta'-c\varrho-\eta(c\|\hat u-\overline u\|_{L^\infty(\Gamma)}))\\ &\ge \frac{\delta'}{2}\|\hat u-\overline u\|^2_{L^2(\Gamma)}\end{aligned}$$

for sufficiently small $\varrho>0$. □

Our condition (SSC) does not have the form expected from a comparison with second order conditions in finite dimensional spaces. In particular, the pair (y_2,u_2) constructed in (SSC) does not in general belong to $L(\mathcal M,\overline w)$. To overcome this difficulty, we introduce another regularity condition $(\mathrm R)_\tau$ that is stronger than (R). This new constraint qualification is similar to that one used in Casas and Tröltzsch [8] to derive second order *necessary* conditions.

Let $\mathcal C_\tau(\overline u)$ denote the set of controls $u\in\mathcal C(\overline u)$ having the property $u(x)=0$ if $x\in\Gamma_\tau$. We strengthen (R) to

$$T'(\overline y)G'(\overline u)\mathcal C_\tau(\overline u)-\boldsymbol K(T(\overline y))=\boldsymbol Z. \tag{$\mathrm R)_\tau$}$$

On using $(\mathrm R)_\tau$, we are able to show that the following *second order sufficient optimality condition* implies (5.4) as well.

$(\mathrm{SSC})_\tau$ There exist positive numbers τ and δ such that

$$\mathcal L''(\overline y,\overline u,\overline\varphi,\overline\lambda,\overline z^*)[w,w]\ge\delta\|u\|^2_{L^2(\Gamma)} \tag{5.12}$$

holds for all pairs $w=(y,u)$ of $L(\mathcal M,\overline w)$ with the property $u(x)=0$ for almost every $x\in\Gamma_\tau$.

THEOREM 5.3. *Let the assumptions of Theorem* 5.2 *be fulfilled, where* (R) *and* (SSC) *are replaced by* $(\mathrm R)_\tau$ *and* $(\mathrm{SSC})_\tau$. *Then the assertion of Theorem* 5.2 *remains true.*

Proof. The proof is almost identical to that of Theorem 5.2. The only difference consists in a more detailed splitting. In the first part of the proof we repeat the steps up to the splitting $w = w_1 + w_2$ after (5.8). Define $\Phi = T \circ G$. Then we have

$$\Phi'(\overline{u})(u_1 + u_2) \in K(\Phi(\overline{u})),$$

as $w_1 + w_2 \in L(\mathcal{M}, \overline{w})$. Therefore,

$$\Phi'(\overline{u})u_2 \in K(\Phi(\overline{u})) - \Phi'(\overline{u})u_1$$

holds so that $w_2 = (y_2, u_2)$ does not in general belong to the linearized cone. Thanks to the regularity condition $(\mathrm{R})_\tau$, the linear version of the Robinson–Ursescu theorem (see Robinson [18]) implies the existence of u_H in $\mathcal{C}_\tau(\overline{u})$ with the following properties: The inclusion

$$\Phi'(\overline{u})u_H \in K(\Phi(\overline{u}))$$

holds, and

$$\|u_2 - u_H\|_{L^2(\Gamma)} \le c\|u_1\|_{L^2(\Gamma)} \tag{5.13}$$

is satisfied (see the proof of Theorem 4.2 in the appendix). In other words, we find a pair $w_H = (y_H, u_H)$ in $L(\mathcal{M}, \overline{w})$ with $u_H = 0$ on Γ_τ. Hence, (SSC) applies to $B[w_H]^2$. Moreover, the control u_H is sufficiently close to u_2.

Now we define $\tilde{u}_2 = u_H$ and $\tilde{u}_1 = u_1 + (u_2 - u_H)$. Further, let $\tilde{y}_i = G'(\overline{u})\tilde{u}_i$ denote the corresponding solution of the linearized state equation. Then $\tilde{w}_i = (\tilde{y}_i, \tilde{u}_i)$ is substituted for $w_i = (y_i, u_i)$, $i = 1, 2$. The only difference between the proofs of Theorem 5.2 and 5.3 appears between the formulas and (5.8) and (5.9): We use the splitting $w = \tilde{w}_1 + \tilde{w}_2$ instead of $w = w_1 + w_2$. Moreover, the first line of the estimate (5.9) is changed as follows:

$$\begin{aligned} B[w]^2 &\ge \delta \|\tilde{u}_2\|^2_{L^2(\Gamma)} - \frac{\delta}{4}\|\tilde{u}_2\|^2_{L^2(\Gamma)} - c\,\|\tilde{u}_1\|^2_{L^2(\Gamma)} \\ &\ge \frac{3\delta}{4}\,\|u_2 + (u_H - u_2)\|^2_{L^2(\Gamma)} - c\,\|u_1 + (u_2 - u_H)\|^2_{L^2(\Gamma)} \\ &\ge \frac{\delta}{2}\,\|u_2\|^2_{L^2(\Gamma)} - c\,\|u_1\|^2_{L^2(\Gamma)}, \end{aligned}$$

where we have used the estimate (5.13). Then we proceed word for word as in the proof of Theorem 5.2. □

Example. Let us briefly comment on (SSC) in the case of (P) for an active state constraint $\overline{y}(0) = y_0$. Then $L(\mathcal{M}, \overline{w})$ is expressed through (4.4), (4.5), and a quite strong second order condition is formulated by

$$\overline{\mathcal{L}}''(\overline{y}, \overline{u}, \overline{\varphi}, \overline{z}^*)[w, w] \ge \delta\|u\|^2_{L^2(\Gamma)} \tag{5.14}$$

for *all* $w = (y, u) \in L(\mathcal{M}, \overline{w})$. In this way, we would not take advantage of strongly active control constraints. These constraints appear on $\Gamma_\tau = \{x \in \Gamma \,|\, |\alpha\overline{u}(x) + \overline{\varphi}(x)| \ge \tau|\}$. We split $(y, u) = (y_1, u_1) + (y_2, u_2)$, where $u_2 = 0$ on Γ_τ and $u_1 = 0$ on $\Gamma \setminus \Gamma_\tau$. (SSC) requires the coercitivity condition (5.14) only for (y_2, u_2), while (y_1, u_1) is handled by first order sufficient optimality conditions. Notice that y_2 might violate the state-constraint $y(x_0) \le 0$. We avoid this by $(\mathrm{SSC})_\tau$: It requires the coercitivity

condition for the following $u \in \mathcal{C}(\overline{u})$: They vanish on Γ_τ and satisfy together with the associated solution y of the linearized partial differential equation the state-constraint $y(x_0) \le 0$.

The paper [15] shows that "strongly active" state-constraints may also contribute terms to the first order sufficient optimality conditions. However, this leads to a rather technical construction and more restrictive assumptions. We have to suppose that the function b is linear with respect to the control u and $n = 2$. The corresponding theorem is stated below. Define for fixed $\beta > 0$ and $\tau > 0$ the following subset of $L(\mathcal{M}, \overline{w})$:

$$L_{\beta,\tau}(\mathcal{M}, \overline{w}) = \{w \,|\, w = (y, u) \in L(\mathcal{M}, \overline{w}) \text{ and } w \text{ satisfies (5.15) below}\}.$$

The decisive inequality characterizing $L_{\beta,\tau}$ is

$$\langle \overline{z}^*, E'(\overline{y})y\rangle \ge -\beta \int_{\Gamma\setminus\Gamma_\tau} |u(x)|\, dS(x). \tag{5.15}$$

$L_{\beta,\tau}(\mathcal{M}, \overline{w})$ is the subset of $L(\mathcal{M}, \overline{w})$, where the term $\langle \overline{z}^*, E(y)\rangle$ does not much contribute to the first order sufficient optimality condition. It is only this set $L_{\beta,\tau}(\mathcal{M}, \bar{w})$ where we have to require second order conditions, namely, the following condition.

(SSC′) There exist positive numbers β, τ, and δ such that

$$\mathcal{L}''(\overline{y}, \overline{u}, \overline{\varphi}, \overline{\lambda}, \overline{z}^*)[w_2, w_2] \ge \delta \|u_2\|^2_{L^2(\Gamma)} \tag{5.16}$$

holds for all $w_2 = (y_2, u_2)$ obtained in the same way introduced in (SSC) by elements w taken from the smaller set $L_{\beta,\tau}(\mathcal{M}, \overline{w})$.

Using this condition, we formulate the following.

THEOREM 5.4. *Let the feasible pair $\overline{w} = (\overline{y}, \overline{u})$ satisfy the regularity condition* (R)*, the first order necessary optimality conditions* (3.9)–(3.11)*, and the second order sufficient optimality condition* (SSC′)*. Suppose further that the general assumptions* (A1)–(A4) *are satisfied. Moreover, assume that $n = 2$ and $b(x, y, u) = b_1(x, y) + b_2(x)u$. Then there are constants $\varrho > 0$ and $\delta' > 0$ such that*

$$F_0(\hat{y}, \hat{u}) \ge F_0(\overline{y}, \overline{u}) + \delta' \|\hat{u} - \overline{u}\|^2_{L^2(\Gamma)} \tag{5.17}$$

holds for all feasible pairs $\hat{w} = (\hat{y}, \hat{u})$ satisfying

$$\|\hat{u} - \overline{u}\|_{L^\infty(\Gamma)} < \varrho. \tag{5.18}$$

Proof. We begin in the way we have shown Theorem 5.2 by

$$F_0(\hat{w}) - F_0(\overline{w}) = \mathcal{L}(\hat{w}, \bar{l}) - \mathcal{L}(\overline{w}, \bar{l}) - \langle \overline{z}^*, E(\hat{y}) - E(\bar{y})\rangle. \tag{5.19}$$

Once again, the representation $\hat{w} - \overline{w} = w + r$ is obtained. Now we distinguish between two cases.

Case I: $w = (y, u) \in L(\mathcal{M}, \overline{w})\setminus L_{\beta,\tau}(\mathcal{M}, \overline{w})$. This is the case where we deduce (5.17) from first order sufficiency. Here, the inequality

$$-\langle \overline{z}^*, E'(\overline{y})y\rangle > \beta \int_{\Gamma\setminus\Gamma_\tau} |u(x)|\, dS(x) \tag{5.20}$$

is fulfilled. We transform (5.19) as follows:

$$\begin{aligned} F_0(\hat w) - F_0(\overline w) &= \mathcal{L}'(\overline w, \bar l)(\hat w - \overline w) + r_1^{\mathcal{L}}(\overline w, \hat w - \overline w) - \langle \overline z^*, E(\hat y) - E(\overline y)\rangle \\ &= \mathcal{L}_y(\overline w, \bar l)(\hat y - \overline y) + \mathcal{L}_u(\overline w, \bar l)(\hat u - \overline u) - \langle \overline z^*, E'(\overline y)(\hat y - \overline y)\rangle \\ &\quad + r_1^{\mathcal{L}}(\overline w, \hat w - \overline w) - \langle \overline z^*, r_1^E(\overline y, \hat y - \overline y)\rangle \\ &= 0 + \int_\Gamma l_u(x)(\hat u(x) - \overline u(x))\, dS(x) - \langle \overline z^*, E'(\overline y) y\rangle \\ &\quad + r_1^{\mathcal{L}}(\overline w, \hat w - \overline w) - \langle \overline z^*, E'(\overline y) r^y + r_1^E(\overline y, \hat y - \overline y)\rangle, \end{aligned} \tag{5.21}$$

where $l_u(x)$ stands for $g_u(x, \overline y(x), \overline u(x)) + \overline\varphi(x) b_u(x, \overline y(x), \overline u(x))$.

Owing to $n = 2$ and $b(x, y, u) = b_1(x, y) + b_2(x)u$, we are able to apply the strong estimate (4.8) with $p = 2$. This yields

$$\|r\|_{Y \times L^\infty(\Gamma)} \le C_{L,2} \|\hat u - \overline u\|^2_{L^2(\Gamma)}. \tag{5.22}$$

By Theorem 4.2, (5.22), (4.17), and (A3 (ii)) we have

$$\max\{\|r^y\|_2, |r_1^{\mathcal{L}}|, \|r_1^E\|_Z\} \le c(\|\hat y - \overline y\|_2^2 + \|\hat u - \overline u\|^2_{L^2(\Gamma)}).$$

Now the Lipschitz property of the mapping $u \mapsto y(u) = G(u)$ from $L^2(\Gamma)$ into $C(\overline\Omega)$ (note that $n = 2$) permits us to estimate the last three items of (5.21) by $c\,\|\hat u - \overline u\|^2_{L^2(\Gamma)}$. (5.20) is applied to the second one, while the first one is treated by Γ_τ: We know that

$$l_u(x)(\hat u(x) - \overline u(x)) \ge 0 \quad \text{a.e. on } \Gamma;$$

hence

$$\int_\Gamma l_u\, (\hat u - \overline u)\, dS \ge \int_{\Gamma_\tau} l_u(\hat u - \overline u)\, dS = \int_{\Gamma_\tau} |l_u|\, |\hat u - \overline u|\, dS \ge \tau \int_{\Gamma_\tau} |\hat u - \overline u|\, dS.$$

Inserting this in (5.21) we continue with

$$\begin{aligned} F_0(\hat w) - F_0(\overline w) &\ge \tau \int_{\Gamma_\tau} |\hat u - \overline u|\, dS + \beta \int_{\Gamma \setminus \Gamma_\tau} |u|\, dS - c\|\hat u - \overline u\|^2_{L^2(\Gamma)} \\ &\ge \tau \int_{\Gamma_\tau} |\hat u - \overline u|\, dS + \beta \int_{\Gamma \setminus \Gamma_\tau} |\hat u - \overline u|\, dS - c\|\hat u - \overline u\|^2_{L^2(\Gamma)} \end{aligned}$$

in view of $\|r^u\|_{L^\infty(\Gamma)} \le c\|\hat u - \overline u\|^2_{L^2(\Gamma)}$. Proceeding with the estimation, we deduce

$$\begin{aligned} F_0(\hat w) - F_0(\overline w) &\ge \min\{\beta, \tau\} \|\hat u - \overline u\|_{L^1(\Gamma)} - c\varrho \|\hat u - \overline u\|_{L^1(\Gamma)} \\ &\ge \beta' \|\hat u - \overline u\|_{L^1(\Gamma)} \end{aligned}$$

with some $\beta' > 0$, provided that $\|\hat u - \overline u\|_{L^\infty(\Gamma)} \le \varrho \le \varrho_1$ is fulfilled and ϱ_1 is sufficiently small. Assume additionally that $\varrho_1 \le 1$. Then $|\hat u - \overline u|^2 \le |\hat u - \overline u|$ holds a.e.; hence

$$F_0(\hat w) - F_0(\overline w) \ge \beta' \|\hat u - \overline u\|^2_{L^2(\Gamma)} \tag{5.23}$$

follows for $\|\hat u - \overline u\|_{L^\infty(\Gamma)} \le \varrho_1$.

Case II: $w \in L_{\beta,\tau}(\mathcal{M}, \overline w)$ (partial use of first order sufficient optimality conditions). Here, we neglect the term $\langle \overline z^*, E(\hat y) - E(\overline y)\rangle$ and proceed word for word as in the proof of Theorem 5.2, using $L_{\beta,\tau}$ instead of L. ∎

REMARK 5.5. *Unfortunately, the definition of* $L_{\beta,\tau}(\mathcal{M},\overline{w})$ *is not constructive. It is difficult to describe in an explicit way which* $(y,u)\in L(\mathcal{M},\overline{w})$ *belong to the different cases* I *or* II. *Therefore, this type of first order sufficient condition is only of limited value (see, for instance, the next example).*

Example. To illustrate (SSC′) for (P) in comparison with (SSC), let us assume for simplicity $\overline{u}\in \operatorname{int}\mathcal{U}^{ad}$, hence $\Gamma_\tau=\emptyset$. Then (SSC) requires the coercitivity condition (5.14) on the whole set $L(\mathcal{M},\overline{w})$. If $\overline{y}(0)=y_0$ and $\overline{z}^*>0$ (strong complementarity), then (SSC′) is weaker than (SSC): (5.14) is not needed for all $(y,u)\in L(\mathcal{M},\overline{w})$ satisfying

$$-\overline{z}^*y(0)\ge\beta\int_\Gamma|u(x)|dS. \tag{5.24}$$

Assume that y can be represented by a positive Green's function $G=G(x,\xi)$,

$$y(0)=\int_\Gamma G(0,\xi)u(\xi)dS(\xi),$$

such that $G(0,\xi)\ge\gamma>0$ on Γ. Then (5.24) is fulfilled with $\beta=\overline{z}^*\gamma\ \forall\ u\le 0$. Moreover, all $u\ge 0$, $u\ne 0$ do not contribute to $L(\mathcal{M},\overline{w})$. Therefore, the coercitivity condition (5.14) is needed only for all u having positive and negative parts U_+ and U_-, where U_+ dominates U_-. However, this information does not essentially improve (SSC).

REMARK 5.6. *Theorem* 5.2 *follows from Theorem* 5.4 *by setting* $\beta=0$, *where we can avoid the restrictions* $n=2$ *and* $b(x,y,u)=b_1(x,y)+b_2(x)u$.

The cone $\mathcal{C}(\overline{u})$ *is defined by* $\mathcal{C}(\overline{u})=\{\rho(u-\overline{u})\,|\,u\in\mathcal{U}^{ad},\rho\ge 0\}$. *Its closure in* $L^2(\Gamma)$ *is*

$$\operatorname{cl}\mathcal{C}(\overline{u})=\{v\in L^2(\Gamma)\,|\,v(x)\le 0\ \textit{if}\ \overline{u}(x)=u_b(x),\ v(x)\ge 0,\ \textit{if}\ \overline{u}(x)=u_a(x)\}.$$

Let us redefine $L(\mathcal{M},\overline{w})$ *by substituting* $\operatorname{cl}\mathcal{C}(\overline{u})$ *for* $\mathcal{C}(\overline{u})$ *and require* (SSC) *in this form. Then* (SSC) *appears to be stronger, and Theorem* 5.2 *holds as well, since* $\operatorname{cl}\mathcal{C}(\overline{u})\supset\mathcal{C}(\overline{u})$. *However, it can be proved by* (R) *and the generalized open mapping theorem that* (SSC) *based on* $\operatorname{cl}\mathcal{C}(\overline{u})$ *is in fact equivalent to* (SSC) *established with* $\mathcal{C}(\overline{u})$. *This follows by continuity arguments.*

6. Extended second order conditions. A study of the preceding sections reveals that (SSC) is sufficient for local optimality in any dimension of Ω without restrictions on the form of the nonlinear function b, whenever (A3) is satisfied and $\overline{\varphi}\in L^\infty(\Gamma)$. $\overline{\varphi}$ is bounded and measurable if pointwise state-constraints are given only in compact subsets of Ω with the other quantities being sufficiently smooth. In two-dimensional domains, pointwise state-constraints can be imposed on $\bar\Omega$, if $b(x,y,u)$ is linear with respect to u. An extension to $\overline{\varphi}\in L^r(\Gamma)$ requires stronger assumptions on b. However, we shall briefly sketch in this section that some extended form of (SSC) may partially improve the results for $n\le 3$.

Let us assume $\overline{\varphi}\notin L^\infty(\Gamma)$. Then it seems to be natural to introduce in $L^\infty(\Gamma)$ another norm

$$\|u\|_\varphi=\left(\int_\Gamma(1+|\overline{\varphi}(x)|)u^2(x)\,dS(x)\right)^{1/2}.$$

This definition is justified, as $u\in L^\infty(\Gamma)$ and $y\in C(\overline{\Omega})$ holds in all parts of our paper. For $\overline{\varphi}\in L^\infty(\Gamma)$, the new norm is equivalent to $\|u\|_{L^2(\Gamma)}$. To get rid of the restrictions

imposed on b in (A4) we redefine the set of strongly active control constraints Γ_τ by

$$\Gamma_{\tau,\varphi} = \{x \in \Gamma \,|\, |g_u(x,\overline{y}(x),\overline{u}(x)) + \overline{\varphi}(x) b_u(x,\overline{y}(x),\overline{u}(x))| \geq \tau(1+|\overline{\varphi}(x)|)\}. \tag{6.1}$$

Moreover, we substitute the condition

$$\mathcal{L}''(\overline{y},\overline{u},\overline{\varphi},\overline{\lambda},\overline{z}^*)[w_2,w_2] \geq \delta \|u_2\|_\varphi^2 \tag{6.2}$$

for (5.2). If $\overline{\varphi} \notin L^\infty(\Gamma)$, then (6.2) is stronger than (5.2). On the other hand, the term $\int_\Gamma \overline{\varphi} b_{uu} u_2^2 dS$ contributes to $\mathcal{L}''$. (SSC) implies (at least) the nonnegativity of $\overline{\varphi} b_{uu}$; hence

$$\int_\Gamma \overline{\varphi} b_{uu} u_2^2 dS = \int_\Gamma |\overline{\varphi}|\, |b_{uu}| u_2^2 dS \geq \kappa \int_\Gamma |\overline{\varphi}| u_2^2 dS$$

holds, provided that $|b_{uu}| \geq \kappa$. In view of this, (6.2) appears quite natural.

Now Theorem 5.2 *remains true for* $n \leq 3$ *without assumption* (A4).

This statement is easy to verify. Apart from the estimates (4.17)–(4.19), our theory is not influenced by introducing $\|u\|_\varphi$. The discussion of (4.17)–(4.19) is the decisive point. We are able to replace $\|\cdot\|_{L^2(\Gamma)}$ by $\|\cdot\|_\varphi$ there, as the basic inequalities (7.14)–(7.16) (Appendix 7.3) can be slightly reformulated: (7.14) is nothing more than

$$\int_\Gamma |\overline{\varphi}| u^2 dS \leq \|u\|_\varphi^2, \tag{6.3}$$

while (7.16) remains unchanged ($n = 2, 3$). Only (7.15) has to be substituted by

$$\begin{aligned} \int_\Gamma |\overline{\varphi}|\, |y|\, |u|\, dS &= \int_\Gamma |\overline{\varphi}|^{1/2} |y|\, |\overline{\varphi}|^{1/2} |u|\, dS \leq \|u\|_\varphi \left(\int_\Gamma |\overline{\varphi}| y^2 dS \right)^{1/2} \\ &\leq \|\overline{\varphi}\|^{1/2}_{L^{s/(s-2)}(\Gamma)} \|y\|_{L^s(\Gamma)} \|u\|_\varphi. \end{aligned} \tag{6.4}$$

Here we have invoked (7.15) for sufficiently large s ($n = 2, 3$). Now a careful study of the proof of Theorem 5.2 shows that (A4) can be removed on using (6.3) and (6.4). Assuming (6.2), we arrive at the estimate (5.4) with $\|\hat{u} - \overline{u}\|_\varphi^2$ instead of $\|\hat{u} - \overline{u}\|_{L^2(\Gamma)}^2$. Then (5.4) follows from $\|u\|_\varphi \geq \|u\|_{L^2(\Gamma)}$. The same arguments apply to the first order sufficient conditions in Theorem 5.4 for $n = 2$ if we redefine $L_{\beta,\tau}(\mathcal{M},\overline{w})$ by substituting for (5.15) the inequality

$$\langle \overline{z}^*, E'(\overline{y}) y \rangle \geq -\beta \int_{\Gamma \setminus \Gamma_\tau} (1 + |\overline{\varphi}|) |u|\, dS. \tag{6.5}$$

7. Appendix.

7.1. On the regularity condition. Regard the state equation (4.1) linearized at $(\overline{y},\overline{u})$. Let $\hat{Y} \subset H^1(\Omega)$ be the set of all solutions of this equation associated to $u \in L^\infty(\Gamma)$. In other words, we have $\hat{Y} = G'(\overline{u}) L^\infty(\Gamma)$. (R) is satisfied in the following particular cases.

(a) $K = Z$ (no inequality constraints). Then (R) means $F'(\overline{y}) G'(\overline{u}) \mathcal{C}(\overline{u}) = \mathbb{R}^m$. This condition is satisfied if, in addition to the surjectivity property $F'(\overline{y})\hat{Y} = \mathbb{R}^m$, the following holds: There is a $\tilde{u} \in \operatorname{int}_{L^\infty(\Gamma)} \mathcal{U}^{ad}$ with $F'(\overline{y})\tilde{y} = 0$. Here, $\tilde{y}$ denotes the solution of the linearized state equation (4.1) associated with $\tilde{u} - \overline{u}$, that is,

$\tilde{y} = G'(\overline{u})(\tilde{u} - \overline{u})$. The proof follows from [22, Lemma 1.2.2].

(b) $F = 0$ (no equality constraints). In this case, (R) is read as $E'(\overline{y})G'(\overline{u})\mathcal{C}(\overline{u}) - K(E(\overline{u})) = Z$. Once again, (R) is implied by two separate conditions: We assume $E'(\overline{y})\hat{Y} - K(E(\overline{y})) = Z$ and require the existence of an $\tilde{u} \in \operatorname{int}_{L^\infty(\Gamma)} \mathcal{U}^{ad}$ with the property that $E'(\overline{y})\tilde{y} \in K(E(\overline{y}))$ holds at $\tilde{y} = G'(\overline{u})(\tilde{u} - \overline{u})$ [22, Lemma 1.2.2]. It should be mentioned that case (a) follows from (b).

Example. (P) is worth discussing in this context. If the state constraint $y(0) \le y_0$ is not active at $\overline{y}$, then (R) is obviously satisfied. Therefore, we assume $\overline{y}(0) = y_0$ and get $K(E(\overline{y})) = \{z \in \mathbb{R} \,|\, z \le 0\} = \mathbb{R}^-$. Then $E'(\overline{y})\hat{Y} - K(E(\overline{y})) = Z$ reduces to the following requirement: For every $z \in \mathbb{R}^-$ there exists a function $u \in L^\infty(\Gamma)$ such that the equation $y(0) = z$ is satisfied by the corresponding solution y of the linearized equation (4.4). This property is fulfilled, since we may find at least one $u \in L^\infty(\Gamma)$ such that $y(0) \ne 0$. Hence, (R) is implied by the following conditions: There are $\tilde{u} \in L^\infty(\Gamma)$ and $\varepsilon > 0$ such that $|\tilde{u}| \le 1 - \varepsilon$ holds and that the solution $\tilde{y}$ of (4.4) corresponding to $\tilde{u} - \overline{u}$ satisfies $\tilde{y}(0) \le 0$.

(c) General case. Let us assume $\operatorname{int}_Z K \ne \emptyset$ and $\operatorname{int}_{L^\infty(\Gamma)} \mathcal{U}^{ad} \ne \emptyset$. We require the surjectivity property

$$F'(\overline{y})\hat{Y} = \mathbb{R}^m. \tag{7.1}$$

Moreover, assume the existence of a $\tilde{u} \in \operatorname{int}_{L^\infty(\Gamma)} \mathcal{U}^{ad}$ such that

$$E(\overline{y}) + E'(\overline{y})\tilde{y} \in \operatorname{int}_Z K, \tag{7.2}$$

$$F'(\overline{y})\tilde{y} = 0 \tag{7.3}$$

holds for $\tilde{y} = G'(\overline{u})(\tilde{u} - \overline{u})$. Then (R) is fulfilled. To show this, we first mention the simple fact that $\tilde{z} \in \operatorname{int}_Z K$ implies $\tilde{z} + z/\varrho \in K$ for arbitrary $z \in Z$ if ϱ is sufficiently large. We have to verify that the system

$$F'(\overline{y})y = z_1, \tag{7.4}$$

$$E'(\overline{y})y - \varrho(k - E(\overline{y})) = z_2 \tag{7.5}$$

is solvable $\forall\ z_1 \in \mathbb{R}^m$, $z_2 \in Z$ by some $y \in G'(\overline{u})\mathcal{C}(\overline{u})$, $k \in K$, and $\varrho \ge 0$: From (7.1) we find $u_1 \in L^\infty(\Gamma)$ such that $y_1 = G'(\overline{u})u_1$ solves the equation

$$F'(\overline{y})y_1 = z_1.$$

Now we add to y_1 a multiple of $\tilde{y}$. Then

$$F'(\overline{y})(y_1 + \varrho\tilde{y}) = F'(\overline{y})y_1 = z_1$$

is obtained from (7.3). Consequently, (7.4) holds for $y = y_1 + \varrho\tilde{y}$. Moreover, we deduce from (7.2) for sufficiently large ϱ that

$$E(\overline{y}) + E'(\overline{y})\tilde{y} - \frac{1}{\varrho}(z_2 - E'(\overline{y})y_1) = k \in K.$$

This relation is equivalent to

$$E'(\overline{y})(y_1 + \varrho\tilde{y}) - \varrho(k - E(\overline{y})) = z_2.$$

Therefore, (7.5) is satisfied by $y = y_1 + \varrho\tilde{y}$. Furthermore, $u_1 + \varrho(\tilde{u} - \overline{u}) = \varrho(\tilde{u} + (1/\varrho)u_1 - \overline{u}) \in \mathcal{C}(\overline{u})$ holds for sufficiently large ϱ. This is true, since $\tilde{u} + (1/\varrho)u_1 \in \mathcal{U}^{ad}$ for ϱ large enough (notice that $\tilde{u} \in \operatorname{int}_{L^\infty(\Gamma)} \mathcal{U}^{ad}$). Thus we have also shown $y \in G'(\overline{u})\mathcal{C}(\overline{u})$.

7.2. Proof of the linearization theorem. To prove Theorem 4.2 we need the following auxiliary result.

LEMMA 7.1. *Let $\overline{u}, \hat{u} \in \mathcal{U}^{ad}$ be given with associated states $\overline{y}, \hat{y}$ defined by* (2.2). *Introduce $y \in Y$ as the solution of the linearized state equation*

$$\begin{cases} -\Delta y + y = 0 & \text{in } \Omega, \\ \partial_\nu y = b_y(\cdot, \overline{y}, \overline{u})y + b_u(\cdot, \overline{y}, \overline{u})(\hat{u} - \overline{u}) & \text{on } \Gamma. \end{cases} \tag{7.6}$$

Then the estimates

$$\|\hat{y} - \overline{y} - y\|_Y \le C_p \|\hat{u} - \overline{u}\|_{L^\infty(\Gamma)} \|\hat{u} - \overline{u}\|_{L^p(\Gamma)} \quad \forall p > n - 1, \tag{7.7}$$

$$\|\hat{y} - \overline{y} - y\|_2 \le C_2 \|\hat{u} - \overline{u}\|_{L^\infty(\Gamma)} \|\hat{u} - \overline{u}\|_{L^2(\Gamma)} \tag{7.8}$$

are satisfied with certain constants C_p, C_2. If $b_u(x, y, u)$ does not depend on y and u, then we have

$$\|\hat{y} - \overline{y} - y\|_Y \le C_p \|\hat{u} - \overline{u}\|^2_{L^p(\Gamma)} \quad \forall p > n - 1. \tag{7.9}$$

Proof. We use the first order expansion of b at $(x, \overline{y}, \overline{u})$ and obtain from (2.2), (7.6), and (4.11) the system

$$\begin{aligned} -\Delta(\hat{y} - \overline{y} - y) + (\hat{y} - \overline{y} - y) &= 0 \quad \text{in } \Omega, \\ \partial_\nu(\hat{y} - \overline{y} - y) - b_y(\cdot, \overline{y}, \overline{u})(\hat{y} - \overline{y} - y) &= r_1^b \quad \text{on } \Gamma, \end{aligned}$$

where

$$|r_1^b(x)| \le C_M(|\hat{y}(x) - \overline{y}(x)|^2 + |\hat{u}(x) - \overline{u}(x)|^2)$$

and M depends on $\mathcal{U}^{ad}$ (notice that the boundedness of $\mathcal{U}^{ad}$ implies a uniform bound on all admissible states). Therefore, the discussion of (3.12) yields for $p > n - 1$

$$\begin{aligned} \|\hat{y} - \overline{y} - y\|_Y &\le c\|r_1^b\|_{L^p(\Gamma)} \\ &\le c\left(\left(\int_\Gamma |\hat{y} - \overline{y}|^{2p} dS\right)^{\frac{1}{p}} + \left(\int_\Gamma |\hat{u} - \overline{u}|^{2p} dS\right)^{\frac{1}{p}}\right). \end{aligned}$$

The mapping $u \mapsto y = G(u)$ is Lipschitz from $L^p(\Gamma)$ to $C(\overline{\Omega})$ for $p > n - 1$. If $p = 2$, then the Lipschitz property holds in the norm $\|y\|_2$ for y. For $p > n - 1$, we continue by

$$\|\hat{y} - \overline{y} - y\|_Y \le c\left(\|\hat{u} - \overline{u}\|^2_{L^p(\Gamma)} + \|\hat{u} - \overline{u}\|_{L^\infty(\Gamma)} \|\hat{u} - \overline{u}\|_{L^p(\Gamma)}\right),$$

while $p = 2$ yields only

$$\|\hat{y} - \overline{y} - y\|_2 \le c\|\hat{u} - \overline{u}\|_{L^\infty(\Gamma)} \|\hat{u} - \overline{u}\|_{L^2(\Gamma)}.$$

We have shown (7.7) and (7.8). If b_u does not depend on (y, u), then $b_u(\cdot, \overline{y} + \vartheta(\hat{y} - \overline{y}), \overline{u} + \vartheta(\hat{u} - \overline{u})) = b_u(\cdot, \overline{y}, \overline{u})$; hence

$$|r_1^b| = |(b_y^\vartheta - \bar{b}_y)(\hat{y} - \overline{y})| \le c|\hat{y} - \overline{y}|^2.$$

This yields

$$\|r_1^b\|_{L^p(\Gamma)} \le c\left(\|\hat{y} - \overline{y}\|_{C(\Gamma)} \|\hat{y} - \overline{y}\|_{L^p(\Gamma)}\right) \le c\|\hat{u} - \overline{u}\|^2_{L^p(\Gamma)},$$

that is, (7.9). □

Proof of Theorem 4.2. Define $v = \hat{u} - \overline{u}$ and let $\tilde{y}$ denote the solution of the linear system (4.1) associated to $u := v$. We have $\tilde{y} = G'(\overline{u})v$, where $G : L^\infty(\Gamma) \to Y$ is the control-state mapping $u \mapsto y = G(u)$ for the nonlinear system (2.2). By Lemma 7.1,

$$\|\hat{y} - \overline{y} - \tilde{y}\|_Y \le e(v), \tag{7.10}$$

where $e(v)$ denotes the right-hand side of the estimates (7.7) and (7.9), respectively, depending on the assumptions on b. Let us introduce the mapping $\Phi(u) = T(G(u))$. Its derivative is $\Phi'(\overline{u})v = T'(\overline{y})G'(\overline{u})v$, and the regularity condition (R) can be rewritten as

$$\Phi'(\overline{u})\mathcal{C}(\overline{u}) - \boldsymbol{K}(\Phi(\overline{u})) = \boldsymbol{Z}.$$

We know that $\Phi(\hat{u}) \in K$, hence a Taylor expansion yields

$$\Phi(\hat{u}) = \Phi(\overline{u}) + \Phi'(\overline{u})(\hat{u} - \overline{u}) + r_1^\Phi, \tag{7.11}$$

where the norm of r_1^Φ can be estimated by

$$\|r_1^\Phi\|_Z \le c\, e(v). \tag{7.12}$$

Since $\Phi(\hat{u})$ and $k = \Phi(\overline{u})$ belong to K, (7.11) implies $\Phi'(\overline{u})(\hat{u} - \overline{u}) + k + r_1^\Phi \in K$; thus also

$$\Phi'(\overline{u})(\hat{u} - \overline{u}) \in -r_1^\Phi + K(\Phi(\overline{u})). \tag{7.13}$$

In other words, we have $\hat{u} - \overline{u} \in \mathcal{C}(\overline{u})$ and $\Phi'(\overline{u})(\hat{u} - \overline{u}) \le_{K(\Phi(\overline{u}))} -r_1^\Phi$, where $z \ge_{K(\Phi(\overline{u}))} 0$ is defined by $z \in K(\Phi(\overline{u}))$. Owing to (R), this inequality is regular in the sense of Robinson [18]. Therefore, we are able to apply the linear version of the Robinson–Ursescu theorem (see [18]): It implies the existence of a constant $C_R > 0$ and a $u \in \mathcal{C}(\overline{u})$ satisfying $\|u - (\hat{u} - \overline{u})\|_{L^\infty(\Gamma)} \le C_R \|r_1^\Phi\|_Z$ together with

$$\Phi'(\overline{u})u \in K(\Phi(\overline{u})).$$

Consequently, for $y = G'(\overline{u})u$, we have $(y, u) \in L(\mathcal{M}, \overline{w})$ and

$$\|u - (\hat{u} - \overline{u})\|_{L^\infty(\Gamma)} \le \tilde{c} e(v).$$

The estimates stated in (4.6) and (4.8) follow immediately.

(4.7) is proved completely analogous. Here, $e(v)$ is defined by (7.8), $\|\cdot\|_Y$ is to be replaced by $\|\cdot\|_2$, and $\|\cdot\|_{L^2(\Gamma)}$ is to be substituted for $\|\cdot\|_{L^\infty(\Gamma)}$. We rely on the continuity of $\Phi'(\overline{y})$ in the L^2-norm. □

7.3. Estimates of the Lagrange function. In this subsection we derive the estimates (4.17)–(4.19) for $r_1^{\mathcal{L}}$, $r_2^{\mathcal{L}}$, and $\mathcal{L}''$. They depend mainly on the estimation of I defined in (4.10), which is performed by the discussion of the following integrals:

$$\int_\Gamma |\overline{\varphi}|\, u^2\, dS \le c\|u\|^2_{L^2(\Gamma)}, \tag{7.14}$$

provided that assumption (A4 (i)) is fulfilled, and

$$\int_\Gamma |\overline{\varphi}|\,|y|\,|u|\,dS \le c\|\overline{\varphi}y\|_{L^2(\Gamma)}\|u\|_{L^2(\Gamma)} \le c\|\overline{\varphi}^2\|^{1/2}_{L^{(s/2)'}(\Gamma)}\|y^2\|^{1/2}_{L^{s/2}(\Gamma)}\|u\|_{L^2(\Gamma)}$$
$$\le c\|\overline{\varphi}\|_{L^{2s/(s-2)}(\Gamma)}\|y\|_{L^s(\Gamma)}\|u\|_{L^2(\Gamma)}. \tag{7.15}$$

These estimates are justified by (A4 (ii)): For $n = 2$ we know $y \in C(\Gamma)$ and $\varphi \in L^r(\Gamma)$ $\forall r < \infty$. If $n \ge 3$, then $y \in L^s(\Gamma)$ holds $\forall\ s < 2(n-1)/(n-3)$ (including $s < \infty$ for $n = 3$). The function $2s/(s-2) = 2/(1-1/s)$ is monotone decreasing. Therefore, $s \uparrow 2(n-1)/(n-3)$ implies $2s/(s-2) \downarrow n-1$, so that $\overline{\varphi} \in L^r(\Gamma)$ for some $r > n-1$ justifies (7.15) with a sufficiently large s. Finally,

$$\int_\Gamma |\overline{\varphi}|y^2\,dS \le \|\overline{\varphi}\|_{L^{(s/2)'}(\Gamma)}\|y^2\|_{L^{s/2}(\Gamma)} = \|\overline{\varphi}\|_{L^{s/(s-2)}(\Gamma)}\|y\|^2_{L^s(\Gamma)} \tag{7.16}$$

is estimated by (A4 (iii)): In the case $n = 2$ we can take $s = \infty$, as $y \in C(\Gamma)$ and $\varphi \in L^1(\Gamma)$ is true without any additional assumption. For $n = 3$ we know $y \in L^s(\Gamma)\ \forall\ s < \infty$. If $s \uparrow \infty$, then $s/(s-2) \downarrow 1 < n/(n-1)$. Since $\varphi \in L^r(\Gamma)$ holds $\forall\ r < n/(n-1)$, (7.16) is true for sufficiently large s. In the case $n \ge 4$ we repeat the analysis of the case $n \ge 3$. This leads to the additional assumption $\overline{\varphi} \in L^r(\Gamma)$ for some $r > \frac{n-1}{2}$. Now it is easy to derive the estimates (4.17)–(4.19) for $\mathcal{L}''$, $r_1^{\mathcal{L}}$, and $r_2^{\mathcal{L}}$: For instance, I in (4.10) is handled by (7.14)–(7.16), and

$$|I| \le \int_\Gamma |\overline{\varphi}|(|\overline{b}_{yy}|\,|y_1y_2| + |\overline{b}_{yu}|(|y_1u_2| + |y_2u_1|) + |\overline{b}_{uu}|\,|u_1u_2|\,dS$$
$$\le c(\|y_1\|_2 + \|u_1\|_{L^2(\Gamma)})(\|y_2\|_2 + \|u_2\|_{L^2(\Gamma)}),$$

as $\overline{b}_{yy}$, $\overline{b}_{yu}$, and $\overline{b}_{uu}$ belong to $L^\infty(\Gamma)$. The other parts of $\mathcal{L}''$ are discussed by means of (A1)–(A3). This yields (4.19) after easy evaluations. In the same way, the remainder terms are investigated. Here, the quantities in I are the most difficult ones again. For instance, (7.14)–(7.16) applies to discussing

$$|r_2^I| = \int_\Gamma |\overline{\varphi}|\ \big\{|b^\vartheta_{yy} - \overline{b}_{yy}|\,|y-\overline{y}|^2 + 2|b^\vartheta_{yu} - \overline{b}_{yu}|\,|y-\overline{y}|\,|u-\overline{u}|$$
$$+ |b^\vartheta_{uu} - \overline{b}_{uu}|\,|u-\overline{u}|^2\big\}\,dS$$
$$\le c\eta(\|y-\overline{y}\|_{C(\Gamma)} + \|u-\overline{u}\|_{L^\infty(\Gamma)})(\|y-\overline{y}\|_2^2 + \|u-\overline{u}\|^2_{L^2(\Gamma)}),$$

which contributes to $r_2^{\mathcal{L}}$. The other terms of $r_2^{\mathcal{L}}$ are handled by the estimates for second order derivatives in (A1)–(A3) in a direct way. Simple evaluations of this type verify (4.17)–(4.18). We leave the details to the reader.

RELATIONSHIP BETWEEN BACKWARD STOCHASTIC DIFFERENTIAL EQUATIONS AND STOCHASTIC CONTROLS: A LINEAR-QUADRATIC APPROACH*

MICHAEL KOHLMANN† AND XUN YU ZHOU‡

Abstract. It is well known that backward stochastic differential equations (BSDEs) stem from the study on the Pontryagin type maximum principle for optimal stochastic controls. A solution of a BSDE hits a given *terminal* value (which is a random variable) by virtue of an *additional* martingale term and an *indefinite* initial state. This paper attempts to explore the relationship between BSDEs and stochastic controls by interpreting BSDEs as some stochastic optimal control problems. More specifically, associated with a BSDE, a new stochastic control problem is introduced with the *same* dynamics but a *definite* given initial state. The martingale term in the original BSDE is regarded as the control, and the objective is to minimize the second moment of the difference between the terminal state and the terminal value given in the BSDE. This problem is solved in a closed form by the stochastic linear-quadratic (LQ) theory developed recently. The general result is then applied to the Black–Scholes model, where an optimal mean-variance hedging portfolio is obtained explicitly in terms of the option price. Finally, a modified model is investigated, where the difference between the state and the expectation of the given terminal value at *any* time is taken into account.

Key words. BSDE, stochastic control, LQ control, stochastic Riccati equation (SRE), Black–Scholes model

1. Introduction.

Backward stochastic differential equation (BSDE) theory and applications have remained very active in recent years. Consider the linear BSDE

$$\begin{cases} dp(t) = [A(t)p(t) + B(t)q(t) + f(t)]dt + q(t)dW(t), \\ p(T) = \xi, \end{cases} \tag{1.1}$$

where ξ is a random variable that will become certain only at the terminal time T. As is well known the equation was initially introduced by Bismut [2, 3] when he was studying the adjoint (dual) equations associated with a stochastic maximum principle for stochastic optimal controls. Basically, (1.1) tells how to price the *marginal value* of the resource represented by the state variable in a random environment. The solution of (1.1) has two components, $p(\cdot)$ and $q(\cdot)$, the former being the price while the latter signifies the uncertainty between the present and terminal times. The linear BSDEs were later extended to nonlinear ones by Pardoux and Peng [21], motivated by stochastic control problems, and independently by Duffie and Epstein [6] in their study of recursive utility in finance. The BSDE theory has found wide applications

in partial differential equations, stochastic controls, and, especially, mathematical finance. For the most updated accounts of the BSDE theory and applications see the books by Yong and Zhou [24, Chapter 7] and Ma and Yong [19].

While BSDEs originally arise from stochastic control problems, the purpose of this paper is to further investigate the relationship between BSDEs and stochastic controls from a different angle by interpreting a BSDE as a stochastic linear-quadratic (LQ) control problem (so it is a reverse of the original "birth process" of BSDEs!) which can be solved explicitly. To be precise, note that in (1.1) the terminal value is specified while the initial value is left open. But if the equation has a solution, then the initial value cannot be chosen arbitrarily; rather it is uniquely determined by the solution and is hence *part* of the solution. Therefore, solving (1.1) amounts to the following statement: start with a *proper* initial condition and choose an *appropriate* diffusion term to hit the given value ξ at the terminal.

Then it will be very natural to modify the above statement and consider the following stochastic optimal control problem. For the *same* dynamics of (1.1), starting with a *given* initial state x, choose a control $q(\cdot)$ so that the terminal state $p(T)$ stays as *close* to the given terminal value ξ as possible. Note that since now the initial value x is given a priori, one in general cannot expect that $p(T)$ will hit ξ exactly by choosing certain $q(\cdot)$. Hence it is reasonable to require that the *difference* between the two is minimized. Here, the "difference" may be measured by, say, the second moment of the algebraic difference between the two random variables. More interestingly, if we regard the initial state also as a decision variable, then the optimal state-control pair of the problem $(p(\cdot), q(\cdot))$ is exactly the solution of the original BSDE!

It turns out that the control problem formulated above is a stochastic optimal LQ problem that can be solved *analytically* via a stochastic Riccati equation (SRE), employing the similar technique as developed recently in [4, 5].

We then apply the general results obtained to the Black–Scholes model. Taking advantage of the fact that in this particular case the state (wealth) is a scalar, one can solve the SRE explicitly and hence the corresponding optimal mean-variance hedging problem. It turns out that an optimal portfolio consists of the replicating strategy for the claim and the Merton portfolio for a quadratic terminal utility.

Finally we consider a modified model where the difference between the state and the expected terminal value must be kept small at *any* time. Again explicit optimal control is derived via an SRE which is shown to be always solvable. The result is then applied to the Black–Scholes model which gives rise to an auxiliary process that dynamically corrects any large deviation of the price from the expected value of the claim.

It should be noted that the idea of regarding the martingale term $q(t)$ as a control variable was first employed by Ma and Yong [17, 18] to prove the solvability of certain class of nonlinear forward-backward stochastic differential equations (FBSDEs). Moreover, Yong [23], using the so-called four-step-scheme developed by Ma, Protter, and Yong [16], discussed the solvability of a linear FBSDE from a stochastic controllability point of view. This paper, however, concentrates on the *relation* between the BSDEs and stochastic controls instead of the solvability of BSDEs, as we believe that this relation is a fundamental issue in BSDE and control theory. To elaborate, a linear BSDE can be interpreted as a dual of the stochastic control problem, where the martingale term $q(t)$ is exactly the dual variable corresponding to the controlled diffusion term. Now, it turns out that this dual variable can also be regarded as a control variable by which the BSDE naturally leads to a stochastic control problem.

This reveals a certain "symmetric" duality relation between BSDEs and stochastic control problems.

The rest of the paper is organized as follows. In section 2 we formulate the model. Section 3 presents the optimal solution to the problem. Section 4 is concerned with the solvability of the SRE necessary for the optimal control derived in section 3. In section 5 we have a special case, namely, the Black–Scholes model is considered and an optimal hedging portfolio is derived explicitly based on the results of the previous sections. Section 6 is devoted to a modified model. Finally, section 7 concludes the paper.

2. Problem formulation. Throughout this paper $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}_{t\geq 0})$ is a fixed filtered complete probability space on which is defined a standard $\mathcal{F}_t$-adapted m-dimensional Brownian motion $W(t) \equiv (W^1(t), \dots, W^m(t))'$ with $W(0) = 0$. It is assumed that $\mathcal{F}_t = \sigma\{W(s) : s \leq t\}$. We denote by $L^2_{\mathcal{F}}(0, T; R^d)$ the set of all R^d-valued, measurable stochastic processes $\psi(t)$ adapted to $\mathcal{F}_t$, such that $E\int_0^T |\psi(t)|^2 dt < +\infty$.

Notation. We make the following additional notation.

M' : the transpose of any vector or matrix M;

$|M| := \sqrt{\sum_{i,j} m_{ij}^2}$ for any matrix or vector $M = (m_{ij})$;

S^n : the space of all $n \times n$ symmetric matrices;

S^n_+ : the subspace of all nonnegative definite matrices of S^n;

$\hat{S}^n_+$: the subspace of all positive definite matrices of S^n;

$C([0, T]; X)$: the Banach space of X-valued continuous functions on $[0, T]$ endowed with the maximum norm $\|\cdot\|$ for a given Hilbert space X;

$L^2(0, T; X)$: the Hilbert space of X-valued integrable functions on $[0, T]$ endowed with the norm $\left(\int_0^T \| f(t) \|_X^2 \, dt\right)^{\frac{1}{2}}$ for a given Hilbert space X;

$L^\infty(0, T; X)$: the Banach space of X-valued essentially bounded functions on $[0, T]$ endowed with the norm $\sup_{0\leq t\leq T} \| f(t) \|_X$ for a given Hilbert space X.

Consider the controlled system

$$\begin{cases} dx(t) = \Big[A(t)x(t) + \sum_{j=1}^m B_j(t)u_j(t) + f(t)\Big] dt \\ \qquad\qquad + \sum_{j=1}^m u_j(t) dW^j(t), \ t \in [0, T], \\ x(0) = x, \end{cases} \tag{2.1}$$

where $x(t), x, u_j(t), f(t) \in R^n$, and $A(t), B_j(t) \in R^{n\times n}$. Throughout this paper we assume that $A(t), B_j(t)$ are bounded deterministic functions and $f \in L^2_{\mathcal{F}}(0, T; R^n)$. For a given $\mathcal{F}_T$-measurable square integrable random variable ξ (i.e., $E|\xi|^2 < +\infty$), the problem is to select an ($\mathcal{F}_t$-adapted) control process $u(\cdot) \equiv (u_1(\cdot), \dots, u_m(\cdot)) \in L^2_{\mathcal{F}}(0, T; R^{mn})$ so as to minimize the cost functional

$$J(x, u(\cdot)) = E\frac{1}{2}|x(T) - \xi|^2. \tag{2.2}$$

To simplify the cost functional, it is natural to define

$$y(t) = x(t) - E(\xi|\mathcal{F}_t). \tag{2.3}$$

Since $E(\xi|\mathcal{F}_t)$ is an $\mathcal{F}_t$-martingale and $\mathcal{F}_t$ is generated by the standard Brownian motion $W(t)$, by the martingale representation theorem ([14]) there is $z(\cdot) \equiv (z_1(\cdot), \dots, z_m(\cdot)) \in L^2_{\mathcal{F}}(0,T;R^{mn})$ so that

$$E(\xi|\mathcal{F}_t) = E\xi + \sum_{j=1}^{m} \int_0^t z_j(s) dW^j(s). \tag{2.4}$$

By (2.1), (2.3), and (2.4), with the new state variable $y(\cdot)$ the controlled system becomes

$$\begin{cases} dy(t) = \Big[A(t)y(t) + \sum_{j=1}^m B_j(t)u_j(t) + g(t)\Big]\, dt \\ \qquad\quad + \sum_{j=1}^m [u_j(t) - z_j(t)] dW^j(t),\ t \in [0,T], \\ y(0) = x - E\xi \equiv y, \end{cases} \tag{2.5}$$

where

$$g(t) = f(t) + A(t)E(\xi|\mathcal{F}_t), \tag{2.6}$$

and the cost functional reduces to

$$J(y, u(\cdot)) = E\frac{1}{2}|y(T)|^2. \tag{2.7}$$

Notice that the above problem is a stochastic LQ control problem with *random* nonhomogeneous terms in both drift and diffusion coefficients.

3. Solutions. In this section we solve the problem (2.1)–(2.2) or (2.5)–(2.7) by LQ techniques. The main idea is simply the *completion of squares*. It should be noted that the problem under consideration is a *singular* LQ problem in that the running cost is identically zero and therefore it cannot be solved by the conventional approach as developed by Wonham [22] and others. Indeed, study on the general (possibly singular) stochastic LQ problem is interesting in its own right and has recently been developed extensively (see [4, 5]). For a systematic treatment of stochastic LQ problems, see also [24, Chapter 6].

In the rest of this paper, we may write X for a (deterministic or stochastic) process $X(t)$, omitting the variable t, whenever no confusion arises. Under this convention, when $X \in C([0,T];S^n)$, $X \geq (>)0$ means $X(t) \geq (>)0,\ \forall t \in [0,T]$.

We introduce the following SRE

$$\begin{cases} \dot{P} + PA + A'P - \sum_{j=1}^m PB_jP^{-1}B_j'P = 0, \\ P(T) = I, \\ P(t) > 0 \quad \forall\, t \in [0,T], \end{cases} \tag{3.1}$$

along with a BSDE

$$\begin{cases} d\phi(t) = & -\Big[(A' - \sum_{j=1}^m PB_jP^{-1}B_j')\phi - \sum_{j=1}^m PB_jP^{-1}\beta_j \\ & +P(g + \sum_{j=1}^m B_jz_j)\Big] \\ & \quad (t)dt + \sum_{j=1}^m \beta_j(t)dW^j(t), \\ \phi(T) = & 0. \end{cases} \tag{3.2}$$

Note that the SRE (3.1) is fundamentally different from the *conventional* Riccati equation[1] in that (3.1) involves the *inverse* of the unknown. In addition, the third constraint of (3.1) must also be satisfied by any solution. In general, such an equation does *not* automatically admit a solution. (The solvability of this equation is interesting on its own; see section 4 below.) On the other hand, if (3.1) has a solution $P(\cdot) \in C([0,T]; R^{n\times n})$, then (3.2) must admit an $\mathcal{F}_t$-adapted solution $(\phi(\cdot), \beta_j(\cdot), j = 1,\dots,m)$ as (3.2) is a linear BSDE with bounded coefficients and square integrable nonhomogeneous terms; see [2, 3, 7, 21, 19] or [24, Chapter 7] for more details about BSDEs.

THEOREM 3.1. *If* (3.1) *and* (3.2) *admit solutions* $P \in C([0,T]; \hat{S}^n_+)$ *and* $(\phi(\cdot), \beta_j(\cdot), j = 1,\dots,m) \in L^2_{\mathcal{F}}(0,T;R^n) \times L^2_{\mathcal{F}}(0,T;R^{nm})$, *respectively, then the problem* (2.5)–(2.7) *has an optimal feedback control* $u^*(\cdot) \equiv (u_1^*(\cdot),\dots,u_m^*(\cdot))$, *where*

$$u_j^*(t) = -P(t)^{-1}B_j(t)'\big[P(t)y^*(t) + \phi(t)\big] - P(t)^{-1}\beta_j(t) + z_j(t),\ j = 1,\dots,m. \tag{3.3}$$

Moreover, the optimal cost value under the above control is

$$\begin{aligned} J^*(y) = {} & \tfrac{1}{2}y'P(0)y + y'\phi(0) + \tfrac{1}{2}E\int_0^T \Big[2\phi' g - 2\textstyle\sum_{j=1}^m \beta_j z_j + \sum_{j=1}^m z_j' P z_j \\ & - \textstyle\sum_{j=1}^m (P^{-1}B_j'\phi + P^{-1}\beta_j - z_j)'P(P^{-1}B_j'\phi + P^{-1}\beta_j - z_j)\Big](t)dt. \end{aligned} \tag{3.4}$$

Proof. For any control $u(\cdot)$ and the corresponding state trajectory $y(\cdot)$, applying Ito's formula, we get

$$\begin{aligned} \tfrac{1}{2}d[y(t)'P(t)y(t)] = {} & \tfrac{1}{2}\Big[\textstyle\sum_{j=1}^m (u_j - z_j)'P(u_j - z_j) + 2y'Pg \\ & + \textstyle\sum_{j=1}^m (y'PB_jP^{-1}B_j'Py + 2u_j'B_j'Py)\Big](t)dt + \tfrac{1}{2}\{\cdots\}dW(t), \end{aligned} \tag{3.5}$$

and

$$\begin{aligned} d[\phi(t)'y(t)] = {} & \Big[-\phi'(A - \textstyle\sum_{j=1}^m B_jP^{-1}B_j'P)y + \sum_{j=1}^m \beta_j'P^{-1}B_j'Py \\ & - \Big(g' + \textstyle\sum_{j=1}^m z_j'B_j'\Big)Py + \phi'\Big(Ay + \sum_{j=1}^m B_ju_j + g\Big) \\ & + \textstyle\sum_{j=1}^m \beta_j'(u_j - z_j)\Big](t)dt + \{\cdots\}dW(t). \end{aligned} \tag{3.6}$$

Then we integrate both (3.5) and (3.6) from 0 to T, take expectations, and add them together. Trying to complete a square and going through a fairly tedious manipulation, we end up with

$$\begin{aligned} & J(y,u(\cdot)) \\ & = \tfrac{1}{2}E\int_0^T \Big[2\phi' g - 2\textstyle\sum_{j=1}^m \beta_j z_j + \sum_{j=1}^m z_j' P z_j \\ & + \textstyle\sum_{j=1}^m (u_j + P^{-1}B_j'Py + P^{-1}B_j'\phi + P^{-1}\beta_j - z_j)'P(u_j + P^{-1}B_j'Py \\ & \qquad + P^{-1}B_j'\phi + P^{-1}\beta_j - z_j) \\ & - \textstyle\sum_{j=1}^m (P^{-1}B_j'\phi + P^{-1}\beta_j - z_j)'P(P^{-1}B_j'\phi + P^{-1}\beta_j - z_j)\Big](t)dt \\ & + \tfrac{1}{2}y'P(0)y + y'\phi(0). \end{aligned} \tag{3.7}$$

It follows immediately that the optimal feedback control is given by (3.3) and the optimal value is given by (3.4) *provided* that the corresponding equation (2.5) under (3.3) has a solution. But under the linear feedback (3.3), the system (2.5) is a

[1]By a conventional Riccati equation we mean one associated with the *deterministic* LQ problem (see [1]) as opposed to that associated with the *stochastic* LQ problem (see [22, 4]).

nonhomogeneous linear SDE with bounded coefficients and square integrable nonhomogeneous terms. Hence it must admit one and only one solution by standard SDE theory. This completes the proof. □

Now we would like to derive the optimal feedback control in terms of the original variable $x(t)$. Interestingly, the optimal control can be obtained via the original BSDE that motivated the optimal control problem (2.1)–(2.2).

THEOREM 3.2. *Under the same assumptions of Theorem* 3.1, *the control problem* (2.1)–(2.2) *has an optimal feedback control* $u^*(\cdot) \equiv (u_1^*(\cdot), \dots, u_m^*(\cdot))$, *where*

$$u_j^*(t) = -P(t)^{-1}B_j(t)'P(t)\big[x^*(t) - p(t)\big] + q_j(t),\ j = 1, \dots, m, \tag{3.8}$$

where $(p(\cdot), q_j(\cdot), j = 1, \dots, m) \in L^2_{\mathcal{F}}(0,T;R^n) \times L^2_{\mathcal{F}}(0,T;R^{nm})$ *is the unique* $\mathcal{F}_t$*-adapted solution of the following BSDE:*

$$\begin{cases} dp(t) = \Big[A(t)p(t) + \sum_{j=1}^m B_j(t)q_j(t) + f(t)\Big]\,dt \\ \qquad\quad + \sum_{j=1}^m q_j(t)dW^j(t),\ t \in [0,T], \\ p(T) = \xi. \end{cases} \tag{3.9}$$

Proof. First of all, consider the matrix-valued ODE

$$\begin{cases} \dot{Q} - AQ - QA' + \sum_{j=1}^m B_jQB_j' = 0, \\ Q(T) = I, \end{cases} \tag{3.10}$$

which must admit a unique solution $Q(\cdot)$ since it is linear with bounded coefficients. Denote $S = PQ$, and then by the differential chain rule it is easy to verify that S satisfies

$$\begin{cases} \dot{S} = SA' - A'S + \sum_{j=1}^m PB_jP^{-1}B_j'S - \sum_{j=1}^m PB_jP^{-1}SB_j', \\ S(T) = I. \end{cases} \tag{3.11}$$

This is a linear equation, and hence it has a unique solution $S \equiv I$. It leads to $Q(t) = P(t)^{-1}$.

Now, noting (2.3), the feedback control (3.3) can be written as

$$\begin{aligned} u_j^*(t) = \quad & -P(t)^{-1}B_j(t)'\big[P(t)x^*(t) - P(t)E(\xi|\mathcal{F}_t) + \phi(t)\big] \\ & -P(t)^{-1}\beta_j(t) + z_j(t), \quad j = 1, \dots, m. \end{aligned} \tag{3.12}$$

Denote

$$\begin{aligned} &p(t) = E(\xi|\mathcal{F}_t) - P(t)^{-1}\phi(t) \equiv E(\xi|\mathcal{F}_t) - Q(t)\phi(t), \\ &q_j(t) = z_j(t) - P(t)^{-1}\beta_j(t) \equiv z_j(t) - Q(t)\beta_j(t),\ j = 1, \dots, m. \end{aligned} \tag{3.13}$$

Since $Q(t)$ is bounded and $(p(\cdot), q_j(\cdot), j = 1, \dots, m) \in L^2_{\mathcal{F}}(0,T;R^n) \times L^2_{\mathcal{F}}(0,T;R^{nm})$, applying Ito's formula to (2.4), (3.10), and (3.2), we can verify that $(p(\cdot), q_j(\cdot), j = 1, \dots, m)$ satisfies the BSDE (3.9). Therefore the desired result follows by virtue of the uniqueness of solutions to (3.9). □

Remark 3.1. Equation (3.4) also gives the optimal cost functional value as a function of the initial value $y \equiv x - E\xi$, which turns out to be quadratic. If the controller has the choice of selecting the initial value y so as to minimize $J^*(y)$, then

the "best" initial value would be obtained by setting $\frac{d}{dy}J^*(y)|_{y=y^*} = 0$. This yields $y^* = -P(0)^{-1}\phi(0)$. Returning to the original variable x, we get that the best initial value for $x(\cdot)$ will be

$$x^* = y^* + E\xi = -P(0)^{-1}\phi(0) + E\xi = p(0), \tag{3.14}$$

where the last equality is due to (3.13). This certainly makes perfect sense, as it implies that one should choose the initial value $p(0)$ so as to minimize the difference between the terminal state value and the given value ξ. (Of course, in this case the minimum difference is zero since starting with $p(0)$ one can hit ξ *exactly* at the end, by the BSDE theory.) Therefore, the solution pair $(p(\cdot), q(\cdot))$ of the BSDE (3.9) may be regarded as the optimal state-control pair of minimizing $J(x, u(\cdot))$ (as given by (2.2)) over $(x, u(\cdot))$ subject to the dynamics of (2.1). This gives an interpretation of $(p(\cdot), q(\cdot))$ via a stochastic control problem. In this perspective, if a BSDE does not have an adapted solution (e.g., when the underlying filtration is *not* generated by the Brownian motion involved), we may still define a "pseudosolution" via the corresponding stochastic control problem.

Remark 3.2. Under the optimal feedback (3.8), the optimal trajectory $x^*(\cdot)$ evolves as

$$\begin{cases} dx^*(t) = & \left\{ \left[A - \sum_{j=1}^m B_j P^{-1} B_j' P\right] x^* + \sum_{j=1}^m B_j P^{-1} B_j' P p + f \right. \\ & \left. + \sum_{j=1}^m B_j q_j \right\}(t)dt \\ & + \sum_{j=1}^m [-P^{-1} B_j' P x^* + P^{-1} B_j' P p + q_j](t) dW^j(t), \\ x^*(0) = & x. \end{cases} \tag{3.15}$$

Moreover, the difference $\Delta(t) = x^*(t) - p(t)$ satisfies

$$\begin{cases} d\Delta(t) = & \left[A - \sum_{j=1}^m B_j P^{-1} B_j' P\right](t)\Delta(t)dt \\ & - \sum_{j=1}^m [P^{-1} B_j' P](t)\Delta(t) dW^j(t), \\ \Delta(0) = & x - p(0). \end{cases} \tag{3.16}$$

Notice that $\Delta(\cdot)$ satisfies a homogeneous linear SDE, and hence must be identically zero if the initial is zero, namely, if $x = p(0)$. In this case, by (3.8), the optimal control is $u_j^*(t) = q_j(t)$. This is exactly in line with the observation in Remark 3.1.

Remark 3.3. Applying Ito's formula, we can show that $\Lambda(t) \equiv \Delta(t)\Delta(t)'$ satisfies

$$\begin{cases} d\Lambda(t) = & \left[\left(A - \sum_{j=1}^m B_j P^{-1} B_j' P\right)\Lambda + \Lambda\left(A - \sum_{j=1}^m B_j P^{-1} B_j' P\right)'\right](t)dt \\ & + \sum_{j=1}^m [P^{-1} B_j' P \Lambda P B_j P^{-1}](t)dt + \sum_{j=1}^m \{\cdots\} dW^j(t), \\ \Lambda(0) = & (x - p(0))(x - p(0))'. \end{cases}$$

Taking expectations, we conclude that $\Gamma(t) \equiv E[\Delta(t)\Delta(t)']$ follows

$$\begin{cases} \dot{\Gamma} - \bar{A}\Gamma - \Gamma\bar{A}' - \sum_{j=1}^m P^{-1} B_j' P \Gamma P B_j P^{-1} = 0, \\ \Gamma(0) = (x - p(0))(x - p(0))', \end{cases} \tag{3.17}$$

where $\bar{A} = A - \sum_{j=1}^m B_j P^{-1} B_j' P$. This is a linear ODE. Solving it gives the optimal cost functional value to be $\frac{1}{2}\mathrm{tr}\,\Gamma(T)$.

Remark 3.4. The results obtained above are based on the LQ approach. LQ models constitute an extremely important class of optimal control problems and their optimal solutions can be obtained explicitly via the Riccati equations, due to the nice underlying structures (see [1, 4, 5, 10, 12, 22, 24]). The general SRE is introduced in [4] as a BSDE of the Pardoux–Peng type ([21]) for the case where all the coefficients are *random*. It reduces to (3.1) for the present case. Consequently, the results in this section can be extended to the case where the coefficients A, B_j are adapted random processes.

4. Solvability of SRE. In the previous section we derived explicitly an optimal control (in a feedback form) of the problem. However, there is one gap remaining, namely the results depend on the SRE (3.1) being solvable. The solvability of the SRE is by no means trivial and is interesting in its own right. In [4], a necessary and sufficient condition for the solvability of SREs more general than (3.1) is derived. However the condition there is rather implicit. This section gives an explicit condition which ensures that (3.1) admits a unique solution.

To this end, we first consider a *conventional* Riccati equation

$$\begin{cases} \dot{P} + PA + A'P - \sum_{j=1}^{m} PB_j K^{-1} B_j' P = 0, \\ P(T) = I, \end{cases} \tag{4.1}$$

where $K > 0$ is given a priori (compare (4.1) and (3.1)). Note that the above equation is a bit different from the standard one arising from *deterministic* control problems (see [1]) where $m = 1$. But the case $m > 1$ can be treated in the same way without any difficulty. In particular, (4.1) is associated with the deterministic LQ problem

$$\text{Minimize} \quad J(s, y; u(\cdot)) = \int_s^T \frac{1}{2} \sum_{j=1}^{m} u_j(t)' K(t) u_j(t) dt + \frac{1}{2} |x(T)|^2,$$

$$\text{Subject to} \quad \begin{cases} \dot{x}(t) = A(t)x(t) + \sum_{j=1}^{m} B_j(t) u_j(t), \\ x(s) = y, \end{cases}$$

where $(s, y) \in [0, T] \times R^n$. Namely, the value function of the above LQ problem is $\frac{1}{2} y' P(s) y$, where P is the solution to (4.1). Denote $\mathcal{K} = \{K \in L^\infty(0, T; \hat{S}_+^m) \mid K^{-1} \in L^\infty(0, T; \hat{S}_+^m)\}$. It can be checked that $C([0, T]; \hat{S}_+^m) \subset \mathcal{K}$. For each $K \in \mathcal{K}$, we know from the classical Riccati theory (as well as the remark above) that (4.1) admits a unique solution $P \in C([0, T]; S_+^n)$. Thus we can define a mapping $\Psi : \mathcal{K} \to C([0, T]; S^n)$ as $\Psi(K) = P$.

THEOREM 4.1. *The SRE* (3.1) *admits a unique solution if and only if there exists* $K \in C([0, T]; \hat{S}_+^m)$ *such that*

$$\Psi(K) \geq K. \tag{4.2}$$

Proof. This is a special case of [4, Theorem 4.2]. □

THEOREM 4.2. *If*

$$A(t) + A(t)' \geq \sum_{j=1}^{m} B_j(t) B_j(t)', \tag{4.3}$$

then the SRE (3.1) *admits a unique solution.*

Proof. We will show that (4.2) holds for $K = \varepsilon I$ with some $\varepsilon > 0$. To this end, for $\varepsilon > 0$ set $P_\varepsilon = \Psi(\varepsilon I) - \varepsilon I$. Then P_ε satisfies

$$\begin{cases} \dot{P}_\varepsilon + P_\varepsilon \left(A - \sum_{j=1}^m B_j B_j' \right) + \left(A - \sum_{j=1}^m B_j B_j' \right)' P_\varepsilon - \varepsilon^{-1} \sum_{j=1}^m P_\varepsilon B_j B_j' P_\varepsilon \\ \quad + \varepsilon \left(A + A' - \sum_{j=1}^m B_j B_j' \right) = 0, \\ P_\varepsilon(T) = I - \varepsilon I. \end{cases} \tag{4.4}$$

Therefore, under the assumption (4.3) and when $0 < \varepsilon < 1$, the above is a standard conventional Riccati equation which admits a unique solution $P_\varepsilon \geq 0$. This implies that (4.2) holds with $K = \varepsilon I$. The result follows then from Theorem 4.1. □

Remark 4.1. In [4], an algorithm of computing the solution to the SREs is given. Boiling down to the special SRE (3.1), the algorithm stipulates that one starts with $K = \varepsilon I$ (with $0 < \varepsilon < 1$) and solves the conventional Riccati equation (4.1) recursively. The resulting sequence of solutions will monotonically converge to the solution of SRE (3.1).

It should be noted that (4.3) only gives an (easily verifiable) *sufficient* condition for the solvability of SRE (3.1). In other special cases (see section 5 below), solvability of the SRE can also be shown without (4.3).

5. Black–Scholes model. We now apply the general results obtained in the previous sections to a contingent claim problem with the Black–Scholes setup. Suppose there is a market in which $m + 1$ assets (or securities) are traded continuously. One of the assets is the *bond* whose price process $P_0(t)$ is subject to the following (deterministic) ODE:

$$\begin{cases} dP_0(t) = r(t)P_0(t)dt, \quad t \in [0, T], \\ P_0(0) = p_0 > 0. \end{cases} \tag{5.1}$$

The other m assets are *stocks* whose price processes $P_1(t), \ldots, P_m(t)$ satisfy the following SDE:

$$\begin{cases} dP_i(t) = P_i(t) \left[b_i(t)dt + \sum_{j=1}^m \sigma_{ij}(t) dW^j(t) \right], \quad t \in [0, T], \\ P_i(0) = p_i > 0. \end{cases} \tag{5.2}$$

Define the *covariance matrix*

$$\sigma(t) = \begin{pmatrix} \sigma_1(t) \\ \vdots \\ \sigma_m(t) \end{pmatrix} \equiv (\sigma_{ij}(t))_{m \times m}. \tag{5.3}$$

The basic assumption throughout this section is

$$\sum(t) \equiv \sigma(t)\sigma(t)' \geq \delta I \quad \forall\, t \in [0, T] \tag{5.4}$$

for some $\delta > 0$. We also assume that all the given functions are measurable and uniformly bounded in t.

Consider an agent whose total wealth at time $t \geq 0$ is denoted by $x(t)$. Assume that the trading of shares takes place continuously and transaction cost and consump-

tions are not considered. Then $x(\cdot)$ satisfies (see, e.g., Karatzas and Shreve [13] and Elliott and Kopp [9])

$$\begin{cases} dx(t) &= \Big\{r(t)x(t) + \sum_{i=1}^m \big[b_i(t) - r(t)\big]\pi_i(t)\Big\}dt \\ &\quad + \sum_{j=1}^m \sum_{i=1}^m \sigma_{ij}(t)\pi_i(t)dW^j(t), \\ x(0) &= x > 0, \end{cases} \tag{5.5}$$

where $\pi_i(t)$, $i = 0, 1, 2 \ldots, m$, denotes the total market value of the agent's wealth in the ith bond/stock. We call $\pi(t) \equiv (\pi_1(t), \ldots, \pi_m(t))'$ a *portfolio* of the agent. Set

$$u(t) \equiv (u_1(t), \ldots, u_m(t))' = \sigma(t)'\pi(t), \text{ or } \pi(t) = \textstyle\sum(t)^{-1}\sigma(t)u(t). \tag{5.6}$$

On the other hand, due to (5.4), the model is *arbitrage free*, namely, there exists a *risk premium process* $\theta(\cdot)$ satisfying

$$\theta(t)\sigma(t)' = (b_1(t) - r(t), \ldots, b_m(t) - r(t)). \tag{5.7}$$

With the above notation (5.5) becomes

$$\begin{cases} dx(t) = \Big[r(t)x(t) + \sum_{j=1}^m \theta_j(t)u_j(t)\Big]\, dt + \sum_{j=1}^m u_j(t)dW^j(t), \\ x(0) = x. \end{cases} \tag{5.8}$$

The objective is, for each given initial wealth x and a contingent claim ξ (which is an $\mathcal{F}_T$-measurable square integrable random variable), to choose a (*mean-variance*) *hedging portfolio* $\pi(\cdot)$ (or, equivalently, a control $u(\cdot)$) so as to minimize

$$J(x, u(\cdot)) = \frac{1}{2}E|x(T) - \xi|^2. \tag{5.9}$$

Remark 5.1. Although the classical hedging problem is to make the difference on the right-hand side of (5.9) to be zero, it has become familiar to also call problem (5.9) a (mean-variance) hedging problem. The reason is at least two-fold. On the one hand, one may decompose the classical hedging problem into several problems of the type (5.9) with different initial conditions in order to characterize the price as well as the hedging portfolio for the original problem. This decomposition can be carried out based on an "extended asset method" recently introduced by Gourerioux, Laurent, and Pham [11] and extended by Laurent and Pham [15]. On the other hand, there is a growing interest in measuring risk when it is a priori known that with the initial capital x the contingent claim cannot be reached. In this case, the criterion (5.9) seems to be a viable alternative.

The problem (5.8)–(5.9) is a special case of the general model studied in section 4, so we can apply the results there. Interestingly, in this case the corresponding SRE is explicitly solvable due to the specific structure that the state variable is a *scalar* (and hence so is the solution to the SRE).

THEOREM 5.1. *The optimal portfolio of the hedging problem consisting of* (5.8) *and* (5.9) *is*

$$\pi^*(t) = -\textstyle\sum(t)^{-1}(b_1(t) - r(t), \ldots, b_m(t) - r(t))'[x^*(t) - p(t)] + \sum(t)^{-1}\sigma(t)q(t), \tag{5.10}$$

where $(p(\cdot), q(\cdot)) \equiv (p(\cdot), q_j(\cdot), j = 1, \ldots, m) \in L^2_{\mathcal{F}}(0, T; R^n) \times L^2_{\mathcal{F}}(0, T; R^{nm})$ *is the unique* $\mathcal{F}_t$*-adapted solution of the BSDE*

$$\begin{cases} dp(t) = \Big[r(t)p(t) + \sum_{j=1}^m \theta_j(t)q_j(t)\Big]\, dt + \sum_{j=1}^m q_j(t)dW^j(t), \\ p(T) = \xi. \end{cases} \tag{5.11}$$

Proof. The SRE (3.1) in the present case reduces to (noting that the unknown $P(t)$ of the equation is a scalar)

$$\begin{cases} \dot{P}(t) + 2r(t)P(t) - \sum_{j=1}^m \theta_j(t)^2 P(t) = 0, \\ P(T) = 1, \\ P(t) > 0, \ t \in [0,T]. \end{cases} \tag{5.12}$$

Denote $\rho(t) = \sum_{j=1}^m \theta_j(t)^2$. Then the above equation has a unique solution $P(t) = e^{-\int_t^T (\rho(s)-2r(s))ds}$. Note that the third inequality constraint in (5.12) is automatically satisfied by this solution. On the other hand, the associated equation (3.2) reads

$$\begin{cases} d\phi(t) = & -\Big\{[r(t)-\rho(t)]\phi(t) - \sum_{j=1}^m \theta_j(t)\beta_j(t) \\ & \quad + P(t)\left[g(t) + \sum_{j=1}^m \theta_j(t) z_j(t)\right]\Big\}dt \\ & \quad + \sum_{j=1}^m \beta_j(t) dW^j(t), \\ \phi(T) = & 0. \end{cases} \tag{5.13}$$

Applying Theorem 3.2 and noticing that $P(t)$ is now a scalar, we obtain

$$u_j^*(t) = -\theta_j(t)[x^*(t) - p(t)] + q_j(t). \tag{5.14}$$

Appealing to (5.6) and writing in a vector form, we obtain the desired result (5.10). □

Remark 5.2. The formula (5.10) has a straightforward interpretation in financial terms. Indeed, it is well known that the second term on the right-hand side of (5.10) is the *replicating portfolio* for the claim ξ when the initial wealth is the initial option price $p(0)$. The other term is exactly the *Merton portfolio* for a terminal utility function $c(x) = x^2$ (Merton [20]). Therefore, our optimal hedging policy (5.10) for our problem is the sum of the replicator for the claim and the Merton portfolio. Consequently, if the initial endowment x is different from the fair initial price $p(0)$ necessary to replicate the contingent claim ξ, then the difference $x - p(0)$ should be invested according to the Merton strategy.

Remark 5.3. In the Black–Scholes model, (3.17) reduces to

$$\begin{cases} \dot{\Gamma}(t) - 2r(t)\Gamma(t) + \sum_{j=1}^m \theta_j(t)^2 \Gamma(t) = 0, \\ \Gamma(0) = (x - p(0))^2. \end{cases} \tag{5.15}$$

This gives $\Gamma(t) = (x-p(0))^2 e^{-\int_0^t (\rho(s)-2r(s))ds}$. Hence the optimal value of (5.12) is $\frac{1}{2}\Gamma(T) = \frac{1}{2}P(0)(x-p(0))^2$.

Remark 5.4. By the explicit form of $P(\cdot)$, the solution to the SRE, as obtained in the proof of Theorem 5.1, we may understand $P(t)$ to be a sort of *normalizing* factor with respect to the "least-square" criterion in (5.9) as well as the discounting process in time. Moreover, by the first equality of (3.13), $\phi(t)$ is nothing but the *normalized* difference between the present expected value of the claim ξ and its present fair price.

6. A modified model. In the previous sections we investigated a model where only the terminal variance is to be minimized. It is more in line with the *European option* in the context of option theory where only the terminal situation is of interest.

To motivate the modified model we are going to formulate in this section let us consider the pricing problem of an American contingent claim ξ where the holder has the right to exercise the option at any time $\tau \in [0,T]$. This claim cannot be hedged by a self-financing portfolio, and it is necessary to introduce a (nondecreasing) consumption process $C(\cdot)$ in the price process

$$\begin{cases} dp(t) = \left[r(t)p(t) + \sum_{j=1}^m \theta_j(t)q_j(t)\right]dt + \sum_{j=1}^m q_j(t)dW^j(t) - dC(t), \\ p(T) = \xi \end{cases} \tag{6.1}$$

in order to push upwards the process $p(t)$ to keep it above the expected value of the claim $E(\xi|\mathcal{F}_t)$ at *any* time, while the amount of pushing should be minimal in the sense that

$$\int_0^T [p(t) - E(\xi|\mathcal{F}_t)]dC(t) = 0. \tag{6.2}$$

Pricing an American claim as a stopping time problem is extensively described in the literature (see, e.g., Karatzas and Shreve [13] and Elliott and Kopp [9]). Its equivalence to the existence problem of a solution $C(\cdot)$ to (6.1) can be found in El Karoui and Quenez [8].

In the modified mean-variance hedging problem below, the wealth $x(t)$ is to be kept near the expected value of the claim $E(\xi|\mathcal{F}_t)$ at *any* time $t \geq 0$ (rather than just at the terminal time). Whereas the solution to this modified problem does not really provide a solution to the original American contingent claim problem, in view of the formal analogies of the results below to those in pricing problems, we shall discuss in Remark 6.2 a possible interpretation of the modified model.

Motivated by the above, let us consider a modification of the model (2.1)–(2.2). Instead of cost functional (2.2), we consider

$$\tilde{J}(x,u(\cdot)) = \frac{1}{2}E\left[\int_0^T |x(t) - E(\xi|\mathcal{F}_t)|^2 dt + |x(T) - \xi|^2\right] \tag{6.3}$$

while keeping the same dynamics as in (2.1). (One can also put different weights on the running cost and the terminal cost, but we will not bother to do it here.)

Employing the same change of variable (2.3), we get the state equation (2.5) with the new cost functional

$$\tilde{J}(y,u(\cdot)) = \frac{1}{2}E\left[\int_0^T |y(t)|^2 dt + |y(T)|^2\right]. \tag{6.4}$$

To solve this problem, we only need to slightly modify the argument in section 3. Specifically, the SRE (3.1), for the present case, is changed to

$$\begin{cases} \dot{P} + PA + A'P - \sum_{j=1}^m PB_jP^{-1}B_j'P + I = 0, \\ P(T) = I, \\ P(t) > 0 \quad \forall\, t \in [0,T]. \end{cases} \tag{6.5}$$

The form of the associated equation (3.2) remains unchanged (but with the *new* $P(\cdot)$ in it as determined by (6.5)).

THEOREM 6.1. *If* (6.5) *and* (3.2) *admit solutions* $P \in C([0,T];\hat{S}^n_+)$ *and* $(\phi(\cdot),\beta_j(\cdot), j=1,\dots,m) \in L^2_{\mathcal{F}}(0,T;R^n)\times L^2_{\mathcal{F}}(0,T;R^{nm})$, *respectively, then the optimal control problem consisting of* (2.1) *and* (6.3) *has an optimal feedback control* $u^*(\cdot) \equiv (u_1^*(\cdot),\dots,u_m^*(\cdot))$, *where*

$$u_j^*(t) = -P(t)^{-1}B_j(t)'P(t)\big[x^*(t)-p(t)\big] + q_j(t),\ j=1,\dots,m, \tag{6.6}$$

where $(p(\cdot),q_j(\cdot),j=1,\dots,m) \in L^2_{\mathcal{F}}(0,T;R^n)\times L^2_{\mathcal{F}}(0,T;R^{nm})$ *is the unique* $\mathcal{F}_t$*-adapted solution of the BSDE*

$$\begin{cases} dp(t) = \Big[A(t)p(t) + \sum_{j=1}^m B_j(t)q_j(t) + f(t) - P(t)^{-2}\phi(t)\Big]\,dt \\ \qquad\quad + \sum_{j=1}^m q_j(t)dW^j(t),\ t\in[0,T], \\ p(T) = \xi, \end{cases} \tag{6.7}$$

or, equivalently,

$$\begin{cases} dp(t) = & \Big\{[A(t)+P(t)^{-1}]p(t) + \sum_{j=1}^m B_j(t)q_j(t) + f(t) \\ & -P(t)^{-1}E(\xi|\mathcal{F}_t)\Big\}dt \\ & + \sum_{j=1}^m q_j(t)dW^j(t),\ t\in[0,T], \\ p(T) = & \xi. \end{cases} \tag{6.8}$$

Proof. Consider the matrix-valued ODE

$$\begin{cases} \dot{Q} - AQ - QA' + \sum_{j=1}^m B_jQB_j' - Q^2 = 0, \\ Q(T) = I, \end{cases} \tag{6.9}$$

which is a conventional Riccati equation. Hence it admits a unique solution $Q(\cdot)$. Denote $S = PQ$, and then S satisfies

$$\begin{cases} \dot{S} = SA' - A'S + SQ - Q + \sum_{j=1}^m PB_jP^{-1}B_j'S - \sum_{j=1}^m PB_jP^{-1}SB_j', \\ S(T) = I. \end{cases} \tag{6.10}$$

This equation has the only solution $S\equiv I$, implying $Q(t) = P(t)^{-1}$. Now, performing the same change of variables in (3.13), we get that $(p(\cdot),q_j(\cdot),j=1,\dots,m)$ satisfies (6.7). Equation (6.8) is equivalent to (6.7) due to the fact that $P(t)^{-2}\phi(t) = P(t)^{-1}[E(\xi|\mathcal{F}_t) - p(t)]$ (see (3.13)). □

Remark 6.1. We note that in this case $(p(\cdot),q_j(\cdot),j=1,\dots,m)$ no longer satisfies the *original* BSDE (5.11) which is the starting point of the control problem under consideration in this paper. The reason is that the BSDE (5.11) only concerns the terminal situation but not any time between the present and the terminal times. Therefore a large deviation of $p(t)$ from the expected terminal value $E(\xi|\mathcal{F}_t)$ is allowed in the setup of (5.11). However, in our modified model, it is required that this deviation cannot be too large (which will be realized by the optimal control); therefore, in the optimal feedback control, one no longer compares against the original BSDE (5.11).

It is interesting that in this case the SRE (6.5) *automatically* admits a solution.

THEOREM 6.2. *The SRE* (6.5) *admits a unique solution.*

Proof. Employing the same argument as that in the proof of Theorem 4.2, set $P_\varepsilon = \Psi(\varepsilon I) - \varepsilon I$. Then P_ε satisfies

$$\begin{cases} \dot{P}_\varepsilon + P_\varepsilon \left(A - \sum_{j=1}^m B_j B_j'\right) + \left(A - \sum_{j=1}^m B_j B_j'\right)' P_\varepsilon \\ \quad -\varepsilon^{-1} \sum_{j=1}^m P_\varepsilon B_j B_j' P_\varepsilon \\ \quad +\varepsilon \left(A + A' - \sum_{j=1}^m B_j B_j'\right) + I = 0, \\ P_\varepsilon(T) = I - \varepsilon I. \end{cases} \tag{6.11}$$

When $\varepsilon > 0$ is small enough, $\varepsilon(A + A' - \sum_{j=1}^m B_j B_j') + I > 0$, hence the solution of the above equation (which is a conventional Riccati equation), $P_\varepsilon \geq 0$. This implies that (4.2) holds with $K = \varepsilon I$ for a sufficiently small $\varepsilon > 0$. The result follows then from Theorem 4.1. □

Now let us consider the corresponding Black–Scholes model. The SRE (5.12) is modified to

$$\begin{cases} \dot{P}(t) + 2r(t)P(t) - \sum_{j=1}^m \theta_j(t)^2 P(t) + 1 = 0, \\ P(T) = 1, \\ P(t) > 0,\ t \in [0, T]. \end{cases} \tag{6.12}$$

This equation has an explicit solution

$$P(t) = e^{-\int_t^T (\rho(s) - 2r(s))ds} + \int_t^T e^{-\int_t^s (\rho(\tau) - 2r(\tau))d\tau} ds > 0.$$

(The existence of solutions can also be concluded from Theorem 6.2.)

THEOREM 6.3. *The optimal (feedback) hedging portfolio for the modified Black–Scholes model is*

$$\pi^*(t) = -\sum(t)^{-1}(b_1(t) - r(t), \ldots, b_m(t) - r(t))'[x^*(t) - p(t)] + \sum(t)^{-1}\sigma(t)q(t), \tag{6.13}$$

where $(p(\cdot), q(\cdot)) \equiv (p(\cdot), q_j(\cdot), j = 1, \ldots, m) \in L^2_{\mathcal{F}}(0, T; R^n) \times L^2_{\mathcal{F}}(0, T; R^{nm})$ *is the unique* $\mathcal{F}_t$*-adapted solution of the following BSDE:*

$$\begin{cases} dp(t) = \left[r(t)p(t) + \sum_{j=1}^m \theta_j(t) q_j(t) + \frac{p(t) - E(\xi|\mathcal{F}_t)}{P(t)}\right] dt + \sum_{j=1}^m q_j(t) dW^j(t), \\ p(T) = \xi. \end{cases} \tag{6.14}$$

Proof. This follows immediately from Theorem 6.1 along with (5.6). □

Remark 6.2. Equation (6.14) is exactly in the same form as (6.1) with

$$C(t) = -\int_0^t \frac{p(s) - E(\xi|\mathcal{F}_s)}{P(s)} ds. \tag{6.15}$$

This process, $C(\cdot)$, plays a similar role to the cumulative consumption process in the original American contingent claim problem. It is no longer a nondecreasing process due to the underlying mean-variance criterion; however, the function of it is to correct any large deviation of the price $p(t)$ from the expected value of the claim $E(\xi|\mathcal{F}_t)$ at any time t. On the other hand, since in our model the price $p(t)$ is allowed to go

either above or under $E(\xi|\mathcal{F}_t)$, we do not have (6.2). Nevertheless, we do have the analogous relations

$$(6.16)\quad \int_0^T [p(t) - E(\xi|\mathcal{F}_t)]^+ [dC(t)]^- = 0, \quad \text{and} \quad \int_0^T [p(t) - E(\xi|\mathcal{F}_t)]^- [dC(t)]^+ = 0,$$

where $a^+ = \max\{a, 0\}$ and $a^- = \max\{-a, 0\}$. Therefore, the interpretation of the portfolio (6.13) is that one should hedge (in the mean-variance sense) the claim using the auxiliary process $C(\cdot)$ and invest the rest of the wealth according to the Merton portfolio.

7. Concluding remarks. In this paper we studied the relationship between BSDEs and stochastic control problems. We introduced a stochastic LQ model associated with a BSDE and solved the problem in a closed form by virtue of the stochastic LQ theory developed recently. The results were then applied to solve an optimal mean-variance hedging problem associated with a Black–Scholes contingent claim model. Our study suggested that the solution pair of a BSDE can be interpreted as the state-control pair of a stochastic control problem. This finding is expected to lead insights into the nature of the BSDEs as well as their applications in finance problems.

Acknowledgment. The authors would like to thank the two referees for their constructive comments that led to an improved version of the paper.

SIMULTANEOUS EXACT CONTROLLABILITY AND SOME APPLICATIONS*

MARIUS TUCSNAK† AND GEORGE WEISS‡

Abstract. We study the exact controllability of two systems by means of a common finite-dimensional input function, a property called simultaneous exact controllability. Most of the time we consider one system to be infinite-dimensional and the other finite-dimensional. In this case we show that if both systems are exactly controllable in time T_0 and the generators have no common eigenvalues, then they are simultaneously exactly controllable in any time $T > T_0$. Moreover, we show that similar results hold for approximate controllability. For exactly controllable systems we characterize the reachable subspaces corresponding to input functions of class H^1 and H^2. We apply our results to prove the exact controllability of a coupled system composed of a string with a mass at one end. Finally, we consider an example of two infinite-dimensional systems: we characterize the simultaneously reachable subspace for two strings controlled from a common end. The result is obtained using a recent generalization of a classical inequality of Ingham.

Key words. linear system, operator semigroup, admissible control operator, Gramian, exact controllability, exact observability, simultaneous controllability, wave equation, boundary control, coupled system

1. Introduction.

We consider two control systems (possibly infinite-dimensional), with the states denoted by z_1, z_2, described by the equations

$$\begin{cases} \dot{z}_1(t) = A_1 z_1(t) + B_1 u(t), & z_1(0) = 0, \\ \dot{z}_2(t) = A_2 z_2(t) + B_2 u(t), & z_2(0) = 0. \end{cases} \tag{1.1}$$

Here, a dot denotes differentiation with respect to the time t, A_1, A_2 are generators of strongly continuous operator semigroups on the corresponding state spaces, and B_1, B_2 are admissible control operators for these semigroups. Note that the two systems receive the same input function u. These systems are called *simultaneously exactly controllable in time* T (where $T > 0$), if for any states f_1 and f_2, an L^2-function u can be found such that $z_1(T) = f_1$ and $z_2(T) = f_2$.

Simultaneous exact controllability was first considered by Russell in [22] and it is the subject of Chapter 5 in Lions [20]. The simultaneous controllability of two Riesz spectral systems (one hyperbolic and one parabolic) was studied in section 4 of Hansen [10] (see also Hansen and Zhang [12]). We were led to investigate simultaneous exact controllability in our study of coupled systems (sometimes called hybrid systems), such as a string with a mass at one end, or the SCOLE model of a beam clamped at one end and with a rigid body at the other end.

Our main result (proved in section 3) concerns the situation where one system is finite-dimensional. We show that, in this case, if A_1 and A_2 have no common eigenvalues and if both are exactly controllable in time T_0, then they are simultaneously

exactly controllable in any time $T > T_0$. For $T = T_0$ this is not always true, as we show in an example (see section 4).

The concept of simultaneous approximate controllability of two systems in time T is similar to the controllability concept defined earlier, but now the reachable pairs of states (f_1, f_2) must be dense in the product of the respective state spaces. Considering again one system to be finite-dimensional, we have a result that resembles our main result, but now we have no information on the time T needed for simultaneous approximate controllability: we only know that some $T > 0$ will work. Other results in section 3 concern the characterization of the reachable subspace of an exactly controllable system, when the input function u is constrained to be in the Sobolev space H^1 (or H^2) with $u(0) = 0$ (or with $u(0) = \dot{u}(0) = 0$).

In section 4 we give two applications to systems governed by partial differential equations (PDEs), both based on the (nonhomogeneous) one-dimensional wave equation. These two interdependent examples illustrate how simultaneous controllability results can be applied in the analysis of coupled systems. In section 5 we characterize the simultaneously reachable subspace of two systems describing vibrating strings. The results here are based on recent generalizations of an inequality of Ingham.

2. Some background on infinite-dimensional systems. In this section we gather, for easy reference, some basic facts about admissible control and observation operators, controllability, and observability. Some results here are new, but most are well known. For the latter, we do not give proofs; we only refer to the relevant literature.

We assume that X is a Hilbert space and $A : \mathcal{D}(A) \to X$ is the generator of a strongly continuous semigroup $\mathbb{T}$ on X. We define the Hilbert space X_1 as $\mathcal{D}(A)$ with the norm $\|z\|_1 = \|(\beta I - A)z\|$, where $\beta \in \rho(A)$ is fixed (this norm is equivalent to the graph norm). The Hilbert space X_{-1} is the completion of X with respect to the norm $\|z\|_{-1} = \|(\beta I - A)^{-1}z\|$. This space is isomorphic to $\mathcal{D}(A^*)^*$, and we have

$$X_1 \subset X \subset X_{-1}, \tag{2.1}$$

densely and with continuous embeddings. $\mathbb{T}$ extends to a semigroup on X_{-1}, denoted by the same symbol. The generator of this extended semigroup is an extension of A, whose domain is X, so that $A : X \to X_{-1}$.

We assume that U is a Hilbert space and $B \in \mathcal{L}(U, X_{-1})$ is an *admissible control operator* for $\mathbb{T}$, defined as in Weiss [24]. This means that if z is the solution of

$$\dot{z}(t) = Az(t) + Bu(t) \tag{2.2}$$

(an equation in X_{-1}), with $z(0) = z_0 \in X$ and $u \in L^2([0, \infty), U)$, then $z(t) \in X$ $\forall t \geq 0$. In this case, z is a continuous X-valued function of t. We have

$$z(t) = \mathbb{T}_t z_0 + \Phi_t u, \tag{2.3}$$

where $\Phi_t \in \mathcal{L}(L^2([0, \infty), U), X)$ is defined by

$$\Phi_t u = \int_0^t \mathbb{T}_{t-\sigma} B u(\sigma) d\sigma. \tag{2.4}$$

The above integration is done in X_{-1}, but the result is in X. The Laplace transform of z is

$$\hat{z}(s) = (sI - A)^{-1} \left[z_0 + B\hat{u}(s) \right].$$

B is called *bounded* if $B \in \mathcal{L}(U, X)$ (and unbounded otherwise).

We assume that Y is another Hilbert space and $C \in \mathcal{L}(X_1, Y)$ is an *admissible observation operator* for $\mathbb{T}$, defined as in Weiss [25]. This means that for every $T > 0$ there exists a $K_T \geq 0$ such that

$$\int_0^T \|C\mathbb{T}_t z_0\|^2 dt \leq K_T^2 \|z_0\|^2 \qquad \forall z_0 \in \mathcal{D}(A). \tag{2.5}$$

C is called *bounded* if it can be extended such that $C \in \mathcal{L}(X, Y)$.

We regard $L^2_{loc}([0,\infty), Y)$ as a Fréchet space with the seminorms being the L^2 norms on the intervals $[0, n]$, $n \in \mathbb{N}$. Then the admissibility of C means that there is a continuous operator $\Psi : X \to L^2_{loc}([0,\infty), Y)$ such that

$$(\Psi z_0)(t) = C\mathbb{T}_t z_0 \qquad \forall z_0 \in \mathcal{D}(A). \tag{2.6}$$

The operator Ψ is completely determined by (2.6), because $\mathcal{D}(A)$ is dense in X. We introduce the Λ-*extension* of C, denoted C_Λ, by

$$C_\Lambda z_0 = \lim_{\lambda \to +\infty} C\lambda(\lambda I - A)^{-1} z_0, \tag{2.7}$$

whose domain $\mathcal{D}(C_\Lambda)$ consists of all $z_0 \in X$ for which the limit exists. If we replace C by C_Λ, formula (2.6) becomes true $\forall z_0 \in X$ and for almost every $t \geq 0$. For $z_0 \in \mathcal{D}(A)$, Ψz_0 is almost everywhere (a.e.) differentiable and

$$\frac{d}{dt}\left(C\mathbb{T}_t z_0\right) = C_\Lambda \mathbb{T}_t A z_0 \qquad \text{for almost every } t \geq 0. \tag{2.8}$$

If $y = \Psi z_0$, then its Laplace transform is

$$\hat{y}(s) = C(sI - A)^{-1} z_0. \tag{2.9}$$

If $\mathbb{T}$ is exponentially stable, then $\Psi \in \mathcal{L}(X, L^2([0,\infty), Y))$.

The following duality result holds: if $\mathbb{T}$ is a semigroup on X with generator A, then $B \in \mathcal{L}(U, X_{-1})$ is an admissible control operator for $\mathbb{T}$ if and only if $B^* : \mathcal{D}(A^*) \to U$ is an admissible observation operator for the dual semigroup $\mathbb{T}^*$. Moreover, the adjoint of Φ_T from (2.4) is given by

$$(\Phi_T^* z_0)(t) = B_\Lambda^* \mathbb{T}_{T-t}^* z_0 \tag{2.10}$$

for almost every $t \in [0, T]$, where $B_\Lambda^* z = \lim_{\lambda \to +\infty} \lambda B^*(\lambda I - A^*)^{-1} z$, as in (2.7). For all the facts listed so far in this section, we refer to [24], [25], and [26].

For $C, \mathbb{T}$ as in (2.5) and for every $T > 0$, we introduce the bounded operator $\Psi_T : X \to L^2([0, T], Y)$ by truncating Ψ to $[0, T]$, i.e., $\forall t \in [0, T]$,

$$\left(\Psi_T z_0\right)(t) = C\mathbb{T}_t z_0 \qquad \forall z_0 \in \mathcal{D}(A). \tag{2.11}$$

The *observability Gramians* of (A, C) are the operators

$$P_T = \Psi_T^* \Psi_T \qquad \forall T \geq 0.$$

Thus, for $z_0 \in \mathcal{D}(A)$,

$$P_T z_0 = \int_0^T \mathbb{T}_t^* C^* C \mathbb{T}_t z_0 dt,$$

and, to get an expression valid $\forall z_o \in X$, we may replace C by C_Λ in the above formula. If $\mathbb{T}$ is exponentially stable, then we may also take $T = \infty$, defining the Gramian $P = \Psi^*\Psi$, which satisfies $A^*P + PA = -C^*C$. For more on Gramians we refer to Hansen and Weiss [11] or Russell and Weiss [23].

DEFINITION 2.1. *With the notation as in* (2.11) *the pair* (A, C) *is exactly observable in time* T *if* Ψ_T *is bounded from below, i.e., there exists* $k_T > 0$ *such that*

$$\int_0^T \|C\mathbb{T}_t z_0\|_Y^2 dt \geq k_T^2 \|z_0\|_X^2 \qquad \forall z_0 \in \mathcal{D}(A). \tag{2.12}$$

The pair (A, C) *is approximately observable in time* T *if* $\operatorname{Ker} \Psi_T = \{0\}$.

As is well known, for finite-dimensional systems the properties in Definition 2.1 are equivalent and independent of T, and if they hold, then we say that (A, C) is *observable*. We remark that $\int_0^T \|C\mathbb{T}_t z_0\|_Y^2 > 0$ $\forall z_0 \in \mathcal{D}(A)$ is not sufficient for approximate observability in time T.

Clearly, the following assertions hold true.

PROPOSITION 2.2. *The pair* (A, C) *is exactly observable in time* T *if and only if* P_T *is invertible. Similarly,* (A, C) *is approximately observable in time* T *if and only if* P_T *is one-to-one. If* $T > \tau$, *then* $P_T \geq P_\tau$.

With the notation from (2.11) it is easy to see that if $z_0 \in \mathcal{D}(A)$, then $\Psi_T z_0 \in H^1(0, T; Y)$. The following partial converse will be needed in section 3.

PROPOSITION 2.3. *With the notation as in* (2.11), *suppose that* (A, C) *is exactly observable in time* T_0. *If* $z_0 \in X$ *and* $T > T_0$ *are such that* $\Psi_T z_0 \in H^1(0, T; Y)$, *then* $z_0 \in \mathcal{D}(A)$. *For* $T = T_0$, *the implication is not true in general.*

Proof. Denote $y = \Psi_T z_0$, so that $y \in H^1(0, T; Y)$. Using, for example, Proposition VIII.3 (p. 124) in Brezis [6], we obtain

$$\sup_{\varepsilon \in (0, T-T_0)} \int_0^{T_0} \left\| \frac{y(t+\varepsilon) - y(t)}{\varepsilon} \right\|_Y^2 dt < \infty.$$

Since, for almost every $t \in [0, T_0]$, $y(t+\varepsilon) - y(t) = C_\Lambda \mathbb{T}_t (\mathbb{T}_\varepsilon - I) z_0$, it follows that

$$\sup_{\varepsilon \in (0, T-T_0)} \left\| \Psi_{T_0} \frac{\mathbb{T}_\varepsilon - I}{\varepsilon} z_0 \right\|_{L^2([0,T_0],Y)} < \infty.$$

Because of the exact observability estimate (2.12), this implies

$$\sup_{\varepsilon \in (0, T-T_0)} \left\| \frac{\mathbb{T}_\varepsilon - I}{\varepsilon} z_0 \right\|_X < \infty.$$

By a simple result on operator semigroups, see for instance Theorem 2.12 (p. 88) in Butzer and Berens [7], it follows that $z_0 \in \mathcal{D}(A)$. To see that for $T = T_0$ the implication is false, consider the left-shift semigroup $\mathbb{T}$ on $X = L^2[0, 1]$ with point observation at the left end. Thus $A = \frac{d}{d\xi}$, $\mathcal{D}(A) = \{x \in H^1(0,1) | x(1) = 0\}$, and $Cx = x(0)$. This system is exactly observable in time $T_0 = 1$. However, if $z_0(\xi) = 1$ $\forall \xi \in (0, 1)$, then $\Psi_1 z_0 \in H^1(0, 1)$, but $z_0 \notin \mathcal{D}(A)$. □

DEFINITION 2.4. *Let* A *be the generator of a strongly continuous semigroup* $\mathbb{T}$ *on* X *and let* $B \in \mathcal{L}(U, X_{-1})$ *be an admissible control operator for* $\mathbb{T}$. *The pair* (A, B) *is exactly controllable in time* $T > 0$, *if for every* $f_0 \in X$ *there exists a* $u \in L^2([0, T], U)$ *such that*

$$\int_0^T \mathbb{T}_{T-\sigma} B u(\sigma) d\sigma = f_0.$$

(A, B) is approximately controllable in time T if the set of those f_0 for which the above property holds is dense.

In other words, we say that (A, B) is exactly controllable in time T if Φ_T is onto, i.e., Ran $\Phi_T = X$, and (A, B) is approximately controllable in time T if Ran Φ_T is dense in X. For finite-dimensional systems the above properties are equivalent and independent of T, and if they hold we say that (A, B) is *controllable*.

PROPOSITION 2.5. *We assume that A is the generator of a semigroup $\mathbb{T}$ on X and $B \in \mathcal{L}(U, X_{-1})$ is an admissible control operator for $\mathbb{T}$. Then (A, B) is exactly controllable in time T if and only if (A^*, B^*) is exactly observable in time T. Similarly, (A, B) is approximately controllable in time T if and only if (A^*, B^*) is approximately observable in time T.*

This proposition is an easy consequence of (2.10). It is used frequently in the literature on control of systems governed by PDEs (see, e.g., the HUM method of Lions [20]). For more details on exact controllability (observability) in a functional-analytic setting we refer to Avdonin and Ivanov [2] or [23] and the references therein. In the PDE's-setting, the relevant literature is overwhelming, and we mention the books of Lions [20], Lagnese and Lions [16], and Komornik [21] and the paper of Bardos, Lebeau, and Rauch [5].

3. Main results. First we give the definition of the simultaneous controllability concepts used.

DEFINITION 3.1. *For $j \in \{1, 2\}$, let A_j be the generators of the strongly continuous semigroups $\mathbb{T}^j$ acting on the Hilbert spaces X^j. Let U be a Hilbert space and let $B_j \in \mathcal{L}(U, X^j_{-1})$ be admissible control operators for $\mathbb{T}^j$.*

The pairs (A_j, B_j) are called simultaneously exactly controllable in time $T > 0$ if for every state $f_j \in X^j$ there exists a function $u \in L^2([0, T], U)$ such that

$$\int_0^T \mathbb{T}^j_{T-\sigma} B_j u(\sigma) d\sigma = f_j.$$

The same pairs are called simultaneously approximately controllable in time $T > 0$ if the property described above holds for (f_1, f_2) in a dense subspace of $X^1 \times X^2$.

It is clear that the concepts introduced in the last definition are equivalent to the exact (approximate) controllability in time T of the pair

$$A = \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix}, \qquad B = \begin{bmatrix} B_1 \\ B_2 \end{bmatrix}.$$

Using Proposition 2.5, the above concepts can be characterized by duality.

PROPOSITION 3.2. *With the notation of Definition 3.1, we have:*

1. *The pairs (A_1, B_1) and (A_2, B_2) are simulteanously exactly controllable in time T if and only if there exists $k_T > 0$ such that $\forall (z_0^1, z_0^2) \in \mathcal{D}(A_1^*) \times \mathcal{D}(A_2^*)$ we have*

$$\int_0^T \|B_1^* \mathbb{T}_t^{1*} z_0^1 + B_2^* \mathbb{T}_t^{2*} z_0^2\|_U^2 \geq k_T^2 \left(\|z_0^1\|_{X^1}^2 + \|z_0^2\|_{X^2}^2 \right). \tag{3.1}$$

2. *The pairs (A_1, B_1) and (A_2, B_2) are simultaneously approximately controllable in time T if and only if the following statement holds.*
   If $(z_0^1, z_0^2) \in X^1 \times X^2$ are such that

$$B_{1\Lambda}^* \mathbb{T}_t^{1*} z_0^1 + B_{2\Lambda}^* \mathbb{T}_t^{2*} z_0^2 = 0 \qquad \text{for almost every } t \in [0, T], \tag{3.2}$$

then $(z_0^1, z_0^2) = (0, 0)$.

We mention that in (3.2) we must use the Λ-extensions as in (2.10). The reason is that it is not possible to use only $(z_0^1, z_0^2) \in \mathcal{D}(A_1^*) \times \mathcal{D}(A_2^*)$ (this follows from the comments after Definition 2.1).

The main result of this section is the following theorem.

THEOREM 3.3. *Let A be the generator of the strongly continuous semigroup $\mathbb{T}$ acting on the Hilbert space X. Let $B \in \mathcal{L}(\mathbb{C}^m, X)$ be an admissible control operator for $\mathbb{T}$ and assume that (A, B) is exactly controllable in time T_0. Let $a \in \mathbb{C}^{n\times n}$ and $b \in \mathbb{C}^{n\times m}$ be matrices such that (a, b) is controllable. Assume that A and a have no common eigenvalues. Then the pairs (A, B) and (a, b) are simultaneously exactly controllable in any time $T > T_0$.*

First we prove the following approximate controllability result.

LEMMA 3.4. *Suppose that $T > T_0$ and that (A, B), (a, b) satisfy the assumptions of Theorem* 3.3. *Then these two pairs are simultaneously approximately controllable in time T for every $T > T_0$.*

Proof. Let $T > T_0$ be fixed. Denote by V the set of all $v_0 \in \mathbb{C}^n$ such that there exists a $z_0 \in X$ with

$$B_\Lambda^* \mathbb{T}_t^* z_0 + b^* e^{a^* t} v_0 = 0 \qquad \text{for almost every } t \in [0, T]. \tag{3.3}$$

Using the approximate controllability of (A, B) in time T_0 and Proposition 2.5, we see that the function $t \to B_\Lambda^* \mathbb{T}_t^* z_0$, $t \in [0, T]$, determines z_0. By (3.3), this function is determined by v_0. Thus, if $v_0 \in V$, then z_0 satisfying (3.3) is unique and depends linearly on v_0: $z_0 = Qv_0$. Since the function $t \to b^* e^{a^* t} v_0$ is smooth, by Proposition 2.3 we have that

$$Qv_0 \in \mathcal{D}(A^*) \qquad \forall v_0 \in V.$$

Now we show that $\forall v_0 \in V$, we have

$$Qa^* v_0 = A^* Q v_0. \tag{3.4}$$

Indeed, by differentiating (3.3) with respect to time and using (2.8), we obtain that

$$B_\Lambda^* \mathbb{T}_t^* A^* Q v_0 + b^* e^{a^* t} a^* v_0 = 0 \tag{3.5}$$

for almost every $t \in [0, T]$, which shows that $a^* v_0 \in V$ and (3.4) holds.

Let $\widetilde{a}$ denote the restriction of a^* to its invariant subspace V. If $V \neq \{0\}$, then $\widetilde{a}$ must have an eigenvalue $\lambda \in \sigma(a^*)$ and a corresponding eigenvector $\widetilde{v}$. Formula (3.4) implies that $A^* Q\widetilde{v} = \lambda Q\widetilde{v}$. Since Q is one-to-one, we have that $Q\widetilde{v} \neq 0$, so that λ is an eigenvalue of A^*. This is in contradiction to the assumption in Theorem 3.3, and hence we must have $V = \{0\}$. Thus, (3.3) implies that $(z_0, v_0) = (0, 0)$ and we can apply the second part of Proposition 3.2. ∎

Proof of Theorem 3.3. Let $T > T_0$ be fixed. According to Proposition 2.5 it suffices to show that the pair

$$\mathcal{A}^* = \begin{bmatrix} A^* & 0 \\ 0 & a^* \end{bmatrix}, \qquad \mathcal{B}^* = \begin{bmatrix} B^* & b^* \end{bmatrix} \tag{3.6}$$

is exactly observable in time T. We already know from Lemma 3.4 and Proposition 2.5 that $(\mathcal{A}^*, \mathcal{B}^*)$ is approximately observable in time T. Let $\mathcal{P}_T$ denote the observability

Gramian of $(\mathcal{A}^*, \mathcal{B}^*)$, so that $\mathcal{P}_T > 0$. We partition $\mathcal{P}_T$ in a natural way, according to the product space $X \times \mathbb{C}^n$:

$$\mathcal{P}_T = \begin{bmatrix} P_T & L \\ L^* & p_T \end{bmatrix}.$$

We want to show that $\mathcal{P}_T$ is invertible (i.e., bounded from below). It is not difficult to see that P_T is the observability Gramian of (A^*, B^*) and p_T is the observability Gramian of (a^*, b^*). As (A^*, B^*) and (a^*, b^*) are exactly observable in time T, by Proposition 2.2, both P_T and p_T are positive and boundedly invertible. We bring in the Schur-type factorization

$$\begin{bmatrix} P_T & L \\ L^* & p_T \end{bmatrix} = \begin{bmatrix} P_T & 0 \\ L^* & I \end{bmatrix} \begin{bmatrix} P_T^{-1} & 0 \\ 0 & \Delta \end{bmatrix} \begin{bmatrix} P_T & L \\ 0 & I \end{bmatrix},$$

where $\Delta = p_T - L^* P_T^{-1} L$ (this is checked by multiplying out). Notice that the first factor is the adjoint of the last, and they are invertible. Therefore, $\mathcal{P}_T$ is invertible if and only if the middle factor is invertible. Since P_T^{-1} is obviously bounded from below, we see that $\mathcal{P}_T$ is bounded from below if and only if Δ is bounded from below. Since $\mathcal{P}_T > 0$, from the factorization we see that $\Delta > 0$. But Δ is a matrix, so that $\Delta > 0$ implies that Δ is invertible. Thus we have proved that $\mathcal{P}_T$ is invertible. By Proposition 2.2, $(\mathcal{A}^*, \mathcal{B}^*)$ is exactly observable in time T. □

Remark 3.5. Under the assumptions of Theorem 3.3, in general, the two systems will not be simultaneously exactly controllable in time T_0. An example to illustrate this will be given in section 4.

In the rest of this section we shall investigate simultaneous approximate controllability. With the assumptions of Theorem 3.3 we obviously obtain simultaneous approximate controllability, but the result is not sharp as it asks for exact controllability of each component. We give below a simultaneous approximate controllability result by supposing only approximate controllability of each component.

At this point we introduce some notation. Let A be the generator of a strongly continuous semigroup. Then the resolvent set $\rho(A)$ contains a right half-plane. The resolvent set is not necessarily connected, and we denote by $\rho_\infty(A)$ the connected component of $\rho(A)$ which contains some right half-plane. (Obviously, there is only one such component.) In particular, if $\sigma(A)$ is countable, as is often the case in applications, then $\rho_\infty(A) = \rho(A)$.

PROPOSITION 3.6. *Let A be the generator of the strongly continuous semigroup $\mathbb{T}$ acting on the Hilbert space X. Let $B \in \mathcal{L}(\mathbb{C}^m, X_{-1})$ be an admissible control operator for $\mathbb{T}$ and assume that (A, B) is approximately controllable in time T_0. Let $a \in \mathbb{C}^{n\times n}$ and $b \in \mathbb{C}^{n\times m}$ be matrices such that (a, b) is controllable. Further, assume that*

$$\sigma(a) \subset \rho_\infty(A). \tag{3.7}$$

Then there exists $T > 0$ such that the pairs (A, B) and (a, b) are simultaneously approximately controllable in time T.

Proof. To arrive at a contradiction, we assume that the opposite holds: $(\mathcal{A}, \mathcal{B})$ from (3.6) is not approximately controllable in any time. Then it follows from Proposition 3.2 that for every $k \in \mathbb{N}$ there exists a $z_k \in X$ and a $v_k \in \mathbb{C}^n$ such that $(z_k, v_k) \neq (0, 0)$ and

$$B_\Lambda^* \mathbb{T}_t^* z_k + b^* e^{a^* t} v_k = 0 \qquad \forall\, t \in [0, k]. \tag{3.8}$$

It follows from the approximate observability in time T_0 of (A^*, B^*) that $\forall k > T_0$ we must have $v_k \neq 0$. Hence we may assume without loss of generality that $\|v_k\|_{\mathbb{C}^n} = 1$. By the compactness of the unit ball in $\mathbb{C}^n$, we may assume further that the sequence (v_k) is convergent: $\lim v_k = v_0$. Then it follows that if we define the functions $y_k \in L^2_{loc}([0,\infty), \mathbb{C}^m)$ by

$$y_k(t) = b^* e^{a^* t} v_k \qquad \text{for } k \in \{0, 1, 2, \dots\},$$

then $\lim y_k = y_0$ (in L^2_{loc}). Let Ψ_{T_0} be the operator defined by

$$\Psi_{T_0} z_0 = B^*_\Lambda \mathbb{T}^*_t z_0 \qquad \forall t \in [0, T_0],$$

and let Π_{T_0} denote the truncation of a function defined on $[0,\infty)$ to $[0, T_0]$. Then (3.8) implies that

$$\Psi_{T_0} z_k + \Pi_{T_0} y_k = 0 \qquad \forall k \geq T_0.$$

Since Ker $\Psi_{T_0} = \{0\}$, the above equation shows that z_k is uniquely determined by y_k, which in turn is obtained from v_k. All these dependencies are linear, so that there is an operator $R : \mathbb{C}^n \to X$ (possibly nonunique, depending on the span of all v_k) such that $z_k = Rv_k \ \forall k \in \mathbb{N}$. Hence, the sequence (z_k) is convergent, and we put $z_0 = \lim z_k = Rv_0$. Now it is easy to conclude from (3.8) that

$$(\Psi z_0)(t) + b^* e^{a^* t} v_0 = 0 \qquad \text{for almost every } \ t \geq 0.$$

Taking Laplace transforms, we obtain from the last formula that for some $\alpha \in \mathbb{R}$ and every $s \in \mathbb{C}$ with Re $s > \alpha$,

$$B^*(sI - A^*)^{-1} z_0 + b^*(sI - a^*)^{-1} v_0 = 0. \tag{3.9}$$

By analytic continuation, this formula remains valid on $\rho_\infty(A^*) \setminus \sigma(a^*)$. (On the other connected components of $\rho(A^*)$ we have no such information.) Since $v_0 \neq 0$ (actually, its norm is 1) and (a^*, b^*) is observable, the rational function $b^*(sI - a^*)^{-1} v_0$ is not zero. Therefore it has poles at a nonempty subset of $\sigma(a^*)$, which by (3.7) is contained in $\rho_\infty(A^*)$. The first term in (3.9) being analytic around $\sigma(a^*)$, it follows that the left-hand side of (3.9) has poles, which is absurd. Thus we have proved that $(\mathcal{A}, \mathcal{B})$ must be approximately controllable in some time T. □

Note that the lemma says nothing about the time T in which $(\mathcal{A}, \mathcal{B})$ is approximately controllable. If T_0 is minimal for (A, B), then of course $T \geq T_0$.

In the last part of this section we characterize the reachable subspaces of an exactly controllable system, when the input function is restricted to Sobolev type spaces strictly included in L^2.

Let A be the generator of a strongly continuous semigroup $\mathbb{T}$ on X and let $B \in \mathcal{L}(U, X_{-1})$ be an admissible control operator for $\mathbb{T}$. Suppose that the pair (A, B) is *exactly controllable* in time T, in the sense of Definition 2.4. This means that the range of the operator Φ_T defined by (2.4) is equal to X. A natural question is the characterization of the states which can be reached by more regular inputs. Define

$$H^1_L(0, T; U) = \{\psi \in H^1(0, T; U) \mid \psi(0) = 0\}.$$

The existence and uniqueness result below shows that the space reachable by means of controls in $H^1_L(0, T; U)$ cannot be larger than the space Z defined by

$$Z = X_1 + (\beta I - A)^{-1} BU = (\beta I - A)^{-1}(X + BU), \tag{3.10}$$

where $\beta \in \rho(A)$ (Z does not depend on the choice of β). The norm on Z is defined by

$$\|z\|_Z^2 = \inf\left\{\|x\|^2 + \|u\|^2 \mid x \in X,\, u \in U,\, z = (\beta I - A)^{-1}(x + Bu)\right\}.$$

LEMMA 3.7. *For any $u \in H^1_L(0,T;U)$, the solution z of (2.2) with $z(0) = 0$ is such that*

$$z \in C(0,T;Z) \cap C^1(0,T,X).$$

Proof. Let $u \in H^1_L(0,T;U)$ and denote by w the solution of

$$\dot{w} = Aw + B\dot{u}, \qquad w(0) = 0.$$

As B is an admissible control operator we have that $w \in C([0,T];X)$. Moreover it is easily checked that the function $t \to \int_0^T w(s)ds$ satisfies (2.2). Since the solution of (2.2) with $z(0) = 0$ is unique, we obtain

$$z(t) = \int_0^T w(s)ds,$$

which obviously yields that

$$z \in C^1([0,T],X). \tag{3.11}$$

On the other hand (2.2) gives

$$(\beta I - A)z(t) = \beta z(t) - \dot{z}(t) + Bu(t) \qquad \forall t \in [0,T]. \tag{3.12}$$

Since $\beta z - \dot{z} + Bu \in C([0,T], X + BU)$, relation (3.12) with $\beta \in \rho(A)$ implies

$$z \in C([0,T],Z). \tag{3.13}$$

From (3.11) and (3.13) we clearly obtain the conclusion of the lemma. □

We can now characterize the states which are reachable by means of input functions in $H^1_L(0,T;U)$ as follows.

PROPOSITION 3.8. *Suppose that the pair (A,B) is exactly controllable in time T_0. Then $\forall T > T_0$, the reachable space by means of input functions $u \in H^1_L(0,T;U)$ is the space Z from* (3.10).

Proof. We know from Lemma 3.7 that the reachable space is included in Z. To show that Z is contained in the reachable space, take $\beta \in \rho(A)$ and consider two systems with states w and v and input u_1, described by

$$\dot{w} = (A - \beta I)w + Bu_1, \tag{3.14}$$

$$\dot{v} = u_1. \tag{3.15}$$

For an arbitrary $z^0 \in Z$ choose $w^0 \in X,\ v^0 \in U$ such that

$$z^0 = (\beta I - A)^{-1}[w^0 - Bv^0]. \tag{3.16}$$

Since 0 is not an eigenvalue of $A - \beta I$, by Theorem 3.3 the systems (3.14) and (3.15) are simultaneously exactly controllable in any time $T > T_0$. Hence we can find $u_1 \in L^2([0,T];U)$ such that the solutions $w,\ v$ of (3.14) and (3.15) satisfy

$$w(0) = 0, \qquad w(T) = e^{-\beta T}w^0, \qquad v(0) = 0, \qquad v(T) = e^{-\beta T}v^0. \tag{3.17}$$

We define the function z_1 by

$$z_1(t) = (\beta I - A)^{-1}(w(t) - Bv(t)) \qquad \forall t \in [0,T].$$

Then it is easy to see that

$$z_1(0) = 0, \qquad z_1(T) = e^{-\beta T} z^0. \tag{3.18}$$

Moreover, after a simple calculation, (3.14) and (3.15) imply that

$$\dot{z}_1(T) = -w(t) = (A - \beta I) z_1(t) - Bv(t) \qquad \forall t \in (0,T). \tag{3.19}$$

If we define now

$$z(t) = e^{\beta t} z_1(t), \qquad u(t) = e^{\beta t} v(t),$$

relations (3.18) and (3.19) imply that z and u satisfy (2.2) together with $z(0) = 0$ and $z(T) = z^0$. This means that Z is included in the space reachable by means of input functions $u \in H^1_L(0,T;U)$, as claimed. □

4. Applications.

4.1. Applications to the equation of a vibrating string. In this subsection we apply the results obtained in previous sections to the equation of a nonhomogeneous vibrating string. First we show that, with suitably chosen spaces, the system corresponding to the string equation and an integrator are simultaneously exactly controllable. In the case of a homogeneous string we show that the simultaneous exact controllability time is strictly larger than the exact controllability time for the string alone, i.e., we give the counterexample announced in Remark 3.5. In the second part of this subsection we characterize the space of the states which are reachable by means of an H^1 or H^2 input function u with $u(0) = 0$ and, in the case $u \in H^2$, also $\dot{u}(0) = 0$.

Let us consider the initial and boundary value problem

$$\begin{cases} \ddot{w}(x,t) = [m(x) w_x(x,t)]_x, & 0 < x < 1, \\ w(0,t) = 0, & w(1,t) = u(t), \\ w(x,0) = 0, & \dot{w}(x,0) = 0 \end{cases} \tag{4.1}$$

with

$$m \in W^{1,\infty}(0,1), \qquad m(x) \geq m_0 > 0 \qquad \forall x \in (0,1). \tag{4.2}$$

The equations above represent the simplest model of a nonhomogeneous elastic string. Following well-known ideas (see for instance Lasiecka and Triggiani [18], [19]) the system (4.1) can be written in the abstract form (2.2), provided we use the notation

$$z = \begin{bmatrix} w \\ \dot{w} \end{bmatrix}, \qquad X = L^2[0,1] \times H^{-1}(0,1), \qquad U = \mathbb{C},$$

$$A = \begin{bmatrix} 0 & I \\ A_0 & 0 \end{bmatrix}, \qquad B = \begin{bmatrix} 0 \\ -A_0 D \end{bmatrix}, \tag{4.3}$$

where

$$\mathcal{D}(A_0) = H_0^1(0,1), \qquad A_0 : \mathcal{D}(A_0) \to H^{-1}(0,1), \qquad A_0 h = (m(x)h_x)_x,$$

so that $A_0 < 0$, and the Dirichlet map $D : \mathbb{C} \to L^2[0,1]$ is defined by

$$D\alpha = y \Longleftrightarrow \{(m(x)y_x)_x = 0 \text{ in } (0,1),\ y(0) = 0,\ y(1) = \alpha\}$$

(see also [1]). From the above it clearly follows that $A : \mathcal{D}(A) \to X$, with

$$\mathcal{D}(A) = H_0^1(0,1) \times L^2[0,1],$$

and that A is skew-adjoint: $A^* = -A$. Note that $B^* = \begin{bmatrix} 0 & D^* \end{bmatrix}$ and, for every $h \in H^2(0,1) \cap H_0^1(0,1)$, $D^* A_0 h = m(1)h_x(1)$. We denote by $\mathbb{T}$ the semigroup generated by A. Well-known computations, using the above expressions for A^* and B^* (see again [18], [19]) give that

$$B^* \mathbb{T}_t^* \begin{bmatrix} z^0 \\ z^1 \end{bmatrix} = m(1)\phi_x(1,t) \qquad \forall \begin{bmatrix} z^0 \\ z^1 \end{bmatrix} \in \mathcal{D}(A), \tag{4.4}$$

where ϕ solves the corresponding homogeneous problem

$$\ddot{\phi}(x,t) = (m(x)\phi_x(x,t))_x, \qquad 0 < x < 1,\ t \in (0,T), \tag{4.5}$$

$$\phi(0,t) = \phi(1,t) = 0, \qquad t \in [0,T], \tag{4.6}$$

$$\phi(\cdot,0) = \phi^0 = A_0^{-1} z^1 \in H^2(0,1) \cap H_0^1(0,1), \tag{4.7}$$

$$\dot{\phi}(\cdot,0) = \phi^1 = z^0 \in H_0^1(0,1). \tag{4.8}$$

It is by now well known that B is an admissible control operator and the couple (A,B) is exactly controllable in any time $T > T_0$, where $T_0 = \frac{2}{\sqrt{m_0}}$ (see for instance Zuazua [27]). Moreover, if $m = 1$, then the system (A,B) is exactly controllable in time 2 (see for instance Haraux [15]).

Consider now the following system of two scalar differential equations with the same input u:

$$\begin{cases} \dot{v} = u, \\ \dot{w} = w + u. \end{cases} \tag{4.9}$$

The result below, concerning the simultaneous exact controllability of (4.1) and (4.9), gives, in particular, the counterexample announced in Remark 3.5.

PROPOSITION 4.1. *The systems* (4.1) *and* (4.9) *are simultaneously exactly controllable in any time $T > T_0$, where $T_0 = \frac{2}{\sqrt{m_0}}$. However, if $m = 1$, then the systems* (4.1) *and* (4.9) *are not simultaneously approximately controllable in time $T_0 = 2$.*

Proof. We can write the system (4.9) in the form $\dot{q} = aq + bu$, where

$$q = \begin{bmatrix} v \\ w \end{bmatrix}, \qquad a = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}, \qquad b = \begin{bmatrix} 1 \\ 1 \end{bmatrix}, \tag{4.10}$$

and it is clear that (a, b) is controllable. The eigenvalues of A from (4.3) are on the imaginary axis and nonzero. The simultaneous exact controllability in any time $T > T_0$ follows from the exact controllability of the system in (4.1) in any time $T > T_0$, by applying Theorem 3.3.

We still have to prove the lack of simultaneous approximate controllability in time 2, in the case of a homogeneous string with $m = 1$. Choose $w_0 \in \mathbb{R}$, $w_0 \neq 0$. As the family formed by $(\sin(n\pi t)_{n\geq 1}, \cos(n\pi t)_{n\geq 1})$ together with the constant function $1/\sqrt{2}$ is an orthonormal basis in $L^2(0,2)$, we can find sequences $(a_n)_{n\geq 1}$ and $(b_n)_{n\geq 1}$ in l^2 and $v_0 \in \mathbb{R}$ such that

$$\sum_{n=1}^{\infty}(-1)^n[a_n \cos(n\pi t) + b_n \sin(n\pi t)] + v_0 + e^t w_0 = 0 \qquad \text{for a.e. } t \in [0,2]. \tag{4.11}$$

Note that the functions $\sin(n\pi x)$ $(x \in (0,1))$ are eigenvectors of A_0. If we denote

$$z^0(x) = \pi \sum_{n=1}^{\infty} b_n \sin(n\pi x), \qquad z^1(x) = \pi^2 \sum_{n=1}^{\infty} n a_n \sin(n\pi x),$$

then $z^0 \in L^2[0,1]$ and $z^1 \in H^{-1}(0,1)$. Now using (4.4) and (4.10), relation (4.11) can be written as

$$B_\Lambda^* \mathbb{T}_t^* \begin{bmatrix} z^0 \\ z^1 \end{bmatrix} + b^* e^{a^* t} \begin{bmatrix} v_0 \\ w_0 \end{bmatrix} = 0 \qquad \text{for almost every } t \in [0,2].$$

Since $w_0 \neq 0$, this relation with Proposition 3.2 implies that the systems (4.1) and (4.9) are not simultaneously approximately controllable in time $T_0 = 2$. □

For $l > 0$ we define the space

$$H_L^2(0,l) = \{u \in H^2(0,l) \mid u(0) = \dot{u}(0) = 0\}.$$

The states of the system (4.1) which can be reached by means of H_L^1 and H_L^2 input functions can be characterized as follows.

PROPOSITION 4.2. *Suppose that $m(x)$ satisfies (4.2) and $T > T_0 = \frac{2}{\sqrt{m_0}}$. Then the space of all states $(w(T), \dot{w}(T))$ which can be reached in time T by means of input functions $u \in H_L^1(0,T)$ is $Z = H_L^1(0,1) \times L^2[0,1]$.*

Moreover, the space of all states $(w(T), \dot{w}(T))$ which can be reached in time T by means of input functions $u \in H_L^2(0,T)$ is $Z_1 = [H_L^1(0,1) \cap H^2(0,1)] \times H_L^1(0,1)$.

Proof. For $u \in H_L^1(0,T)$ it suffices to apply Proposition 3.8 and to notice that, with the notation (4.3), the space Z defined by (3.10) is $H_L^1(0,1) \times L^2[0,1]$. For $u \in H_L^2(0,T)$ we consider the new input $\widetilde{u} = \dot{u}$, a new state space equal to $H_L^1(0,1) \times L^2[0,1]$, and we apply again Proposition 3.8. □

4.2. Controllability of a coupled system. Consider a vertical string whose horizontal displacement in a given plane is described by the wave equation on the spatial domain $(0,1)$. The upper end (corresponding to $x = 0$) is kept fixed and an object of mass M is attached at the lower end (corresponding to $x = 1$). The external input is a horizontal force v acting on the object, and it is contained in the plane mentioned earlier. We neglect the moment of inertia of the object (i.e., we imagine the object to be very small). From simple physical considerations, and taking a certain constant to be one, we obtain that this system is described by the following equations,

valid $\forall x \in (0,1)$ and $\forall t \in (0,\infty)$:

$$\begin{cases} \ddot{w}(x,t) = [m(x)w_x]_x(x,t), w(0,t) = 0, \\ M\ddot{w}(1,t) - w_x(1,t) = v(t), \\ w(x,0) = \dot{w}(x,0) = 0, \ x \in (0,1). \end{cases} \tag{4.12}$$

Here, w is the controlled wave (horizontal displacement) and $\dot{w}$ is the horizontal velocity. The appropriate spaces for all these functions will be specified later. The point $x = 0$ is just reflecting waves, while the active end $x = 1$ is where both the observation and the control take place. We shall often write $w(t)$ to denote a function of x, meaning that $w(t)(x) = w(x,t)$, and similarly for other functions.

A direct analysis of the well-posedness, controllability, and observability of this system is not trivial, in spite of the simplicity of the system. We will show below that we can obtain a sharp result by simply applying Proposition 4.2. We begin by identifying the natural state space of (4.12).

PROPOSITION 4.3. *Suppose that $m(\cdot)$ satisfies* (4.2) *and that $v \in L^2[0,T]$. Then the initial and boundary value problem* (4.12) *admits a unique solution*

$$w \in C(0,T; H^1_L(0,1) \cap H^2(0,1)) \cap C^1(0,T; H^1_L(0,1)). \tag{4.13}$$

Proof. Using semigroups or a standard Galerkin method, it is easy to prove that $\forall v \in L^2[0,T]$, the problem (4.12) admits a unique solution

$$w \in C(0,T; H^1_L(0,1)) \cap C^1(0,T; L^2[0,1]), \tag{4.14}$$

which satisfies the first equation from (4.12) in $\mathcal{D}'((0,1)\times(0,T))$ and the second in $\mathcal{D}'(0,T)$ (notice that $w_x(1,\cdot)$ makes sense in $H^{-2}(0,T)$). Consider a sequence (v_n) in $\mathcal{D}(0,T)$ such that $v_n \to v$ in $L^2[0,T]$. If we denote by (w_n) the corresponding sequence of smooth solutions of (4.12), it is clear that

$$w_n \to w \ \text{ in } L^\infty(0,T; H^1_L(0,1)) \cap W^{1,\infty}(0,T; L^2[0,1]), \tag{4.15}$$

$$w_n(1,t) = \dot{w}_n(1,t) = 0 \qquad \forall n \geq 1. \tag{4.16}$$

Moreover, by multiplying the equation

$$(\ddot{w}_m - \ddot{w}_n)(x,t) = [m(x)(w_m - w_n)_x]_x(x,t)$$

by $x\frac{\partial}{\partial x}(w_m - w_n)(x,t)$ and by integrating over $[0,1]\times[0,T]$, we obtain, after well-known calculations, the existence of a constant $C > 0$ such that

$$\int_0^T |(w_m - w_n)_x(1,t)|^2 \, dt$$

$$\leq C\left(\|w_n - w_m\|_{L^\infty(0,T;H^1(0,1))} + \|\dot{w}_n - \dot{w}_m\|_{L^\infty(0,T;L^2[0,1])}\right). \tag{4.17}$$

Since

$$M\ddot{w}_n(1,t) - (w_n)_x(1,t) = v_n(t),$$

relation (4.17) implies that $\ddot{w}_n(1,\cdot)$ is a Cauchy sequence in $L^2[0,T]$. By using (4.15) and (4.16), we obtain that $w(1,\cdot) \in H_L^2(0,T)$. The regularity (4.13) follows now from Proposition 4.2. □

PROPOSITION 4.4. *Suppose that m satisfies* (4.2) *and $T > T_0 = \frac{2}{\sqrt{m_0}}$. Then the system* (4.12) *is well posed and exactly controllable in time T in the space $X = [H_L^1(0,1) \cap H^2(0,1)] \times H_L^1(0,1)$. In other words, $(w^0, w^1) \in [H_L^1(0,1) \cap H^2(0,1)] \times H_L^1(0,1)$ if and only if there exists $v \in L^2[0,T]$ such that the solution of* (4.12) *satisfies*

$$w(T) = w^0, \qquad \dot{w}(T) = w^1. \tag{4.18}$$

Proof. By Proposition 4.2, for any $(w^0, w^1) \in [H_L^1(0,1) \cap H^2(0,1)] \times H_L^1(0,1)$ there exist

$$w \in C(0,T; H^2(0,1)), \qquad u \in H_L^2(0,T) \tag{4.19}$$

satisfying (4.1) and (4.18). From (4.19) it obviously follows that if we define

$$v(t) = m\ddot{u}(t) - w_x(1,t),$$

then $v \in L^2[0,T]$ and w, v satisfy (4.12) and (4.18). □

5. The simultaneously reachable subspace of two infinite-dimensional systems. In this section we study an example showing that for certain pairs of infinite-dimensional systems it is still possible to derive results similar to those obtained in the previous section. However, the reachable space and the reachability time are more difficult to characterize. The problem we tackle is the one-dimensional version of an open question raised in Lions [20]. We give here only the results which are simple consequences of recent work on nonharmonic Fourier series. A detailed study of this problem requires new techniques and is the subject of the forthcoming paper by Avdonin and Tucsnak [3].

For $\xi \in (0,1)$ we consider the problems

$$\begin{cases} \ddot{w}_1(x,t) - (w_1(x,t))_{xx} = 0 \quad \forall x \in (0,\xi), \quad \forall t \in (0,\infty), \\ w_1(0,t) = 0, \ w_1(\xi,t) = u(t) \quad \forall t \in (0,\infty), \\ w_1(x,0) = 0, \ \dot{w}_1(x,0) = 0 \quad \forall x \in (0,\xi) \end{cases} \tag{5.1}$$

and

$$\begin{cases} \ddot{w}_2(x,t) - (w_2(x,t))_{xx} = 0 \quad \forall x \in (\xi,1), \quad \forall t \in (0,\infty), \\ w_2(1,t) = 0, \ w_2(\xi,t) = u(t) \quad \forall t \in (0,\infty), \\ w_2(x,0) = 0, \ \dot{w}_2(x,0) = 0 \quad \forall x \in (\xi,1). \end{cases} \tag{5.2}$$

The systems above model the vibrations of two strings joined at a common end at $x = \xi$, the input being the displacement of this common point.

By using notation similar to the one used in (4.3), we can easily define the operators (A_i, B_i), $i = 1, 2$ such that the equations (5.1), (5.2) can be written as in (1.1), with state spaces $X^1 = L^2[0,\xi] \times H^{-1}(0,\xi)$ and $X^2 = L^2[\xi,1] \times H^{-1}(\xi,1)$. According to classical results, B_1 (resp., B_2) is an admissible control operator and the system (A_1, B_1) (resp., (A_2, B_2)) is exactly controllable in time 2ξ (resp., $2(1-\xi)$). The aim of this section is to describe, to some extent, the space of the states in $X^1 \times X^2$ which are reachable by means of an input function $u \in L^2[0,T]$, with sufficiently large T.

We cannot give a precise characterization of this reachable space but we give sharp embedding results in appropriate Sobolev spaces.

For $s > -\frac{1}{2}$, we introduce the space $\mathcal{W}_s \subset X^1 \times X^2$ of quadruples of functions $(w_1^0, w_1^1, w_2^0, w_2^1)$ satisfying

$$(w_1^0, w_1^1, w_2^0, w_2^1) \in H^{s+1}(0,\xi) \times H^s(0,\xi) \times H^{s+1}(\xi,1) \times H^s(\xi,1),$$

$$w_1^0(0) = 0, \qquad w_2^0(1) = 0, \qquad w_1^0(\xi) = w_2^0(\xi).$$

Denote by $\mathbb{Q}$ the set of rational numbers. We denote by $\mathcal{S}$ the set of all numbers $\rho \in (0,1)$ such that $\rho \notin \mathbb{Q}$ and if $[0, a_1, \dots, a_n, \dots]$ is the expansion of ρ as a continuous fraction, then (a_n) is bounded. Note that $\mathcal{S}$ is uncountable and, by classical results on diophantine approximation (cf. [8, p. 120]), its Lebesgue measure is zero. Roughly speaking, the set $\mathcal{S}$ contains the irrationals which are "badly" approximable by rational numbers. In particular, by the Euler–Lagrange theorem (cf. [17, p. 57]) $\mathcal{S}$ contains all $\xi \in (0,1)$ such that ξ is an irrational quadratic number (i.e., satisfying a second degree equation with rational coefficients). According to a classical result (see, for instance, [17]), if $\xi \in \mathcal{S}$, then there exists a constant $C_\xi > 0$ such that

$$\left|\xi - \frac{p}{q}\right| \geq \frac{C_\xi}{q^2} \qquad \forall p, q \in \mathbb{N}. \tag{5.3}$$

We can now state our main result concerning the lack of simultaneous exact controllability of the two strings, which also gives some information on the simultaneously reachable space as a function of ξ.

THEOREM 5.1. *Suppose that $T > \max\{4\xi, 4(1-\xi)\}$. Then the following holds.*

(a) *For any $\xi \in \mathcal{S}$, all the elements of $\mathcal{W}_0$ can be reached in time T by means of an input $u \in L^2[0,T]$.*

(b) *For almost all $\xi \in [0,1]$ and $\forall s > 0$, all the states in $\mathcal{W}_s$ can be reached in time T by means of an input $u \in L^2[0,T]$.*

(c) *The results above are sharp in the sense that, for any $\xi \in (0,1)$ and $s \in (-\frac{1}{2}, 0)$, we can find a state in $\mathcal{W}_s$ which is not reachable by means of an input $u \in L^2[0,T]$. In particular, for any $T > 0$, the systems (5.1), (5.2) are not simultaneously exactly controllable in time T (in the natural energy space $X^1 \times X^2$).*

As a tool in our proof, $\forall s > -\frac{1}{2}$ we introduce the space

$$\mathcal{V}_s = H_0^{s+1}(0,\xi) \times H^s(0,\xi) \times H_0^{s+1}(\xi,1) \times H^s(\xi,1).$$

It is clear that $\mathcal{V}_s$ is a subspace of W_s (with finite codimension). In order to prove Theorem 5.1, we notice first that for $s < \frac{1}{2}$, the reachability of $\mathcal{W}_s$ is equivalent to the reachability of its subspace $\mathcal{V}_s$. More precisely, we have the following lemma.

LEMMA 5.2. *Let $s \in (-\frac{1}{2}, \frac{1}{2})$. Then all the elements of $\mathcal{W}_s$ can be reached in time T by means of an input $u \in L^2[0,T]$ if and only if the same property holds for $\mathcal{V}_s$.*

Proof. One of the implications is trivial. Take $(w_1^0, w_1^1, w_2^0, w_2^1) \in \mathcal{W}_s$ for some fixed $s \in (-\frac{1}{2}, \frac{1}{2})$ and denote $\alpha = w_1^0(\xi) = w_2^0(\xi)$. Let $\psi_1(x,t)$, $\psi_2(x,t)$ be the solutions of (5.1), (5.2) with $u = u_\psi$, where

$$u_\psi(t) = \frac{\alpha}{T^2} t^2.$$

It can be checked, arguing similarly as in the proof of Lemma 3.7, but differentiating twice, that

$$(\psi_1, \dot\psi_1, \psi_2, \dot\psi_2) \in C([0,T]; \mathcal{W}_1).$$

In particular, this implies that the above statement is true with $\mathcal{W}_s$ in place of $\mathcal{W}_1$. Moreover, we have

$$\psi_1(0,T) = \psi_2(1,T) = 0, \qquad \psi_1(\xi,T) = \psi_2(\xi,T) = \alpha.$$

The above equalities (together with $s < \frac{1}{2}$) imply that

$$(w_1^0 - \psi_1(\cdot,T), w_1^1 - \dot\psi_1(\cdot,T), w_2^0 - \psi_2(\cdot,T), w_2^1 - \dot\psi_2(\cdot,T)) \in \mathcal{V}_s.$$

Suppose now that all the elements of $\mathcal{V}_s$ can be reached in time T by means of an input in $L^2[0,T]$. It follows that there exists an input $u_\varphi \in L^2[0,T]$ such that the solutions φ_1, φ_2 of (5.1) and (5.2) with $u = u_\varphi$ satisfy the conditions

$$\varphi_1(x,T) = w_1^0(x) - \psi_1(x,T),\ \dot\varphi_1(x,T) = w_1^1(x) - \dot\psi_1(x,T), \quad \text{in } L^2[0,\xi], \tag{5.4}$$

$$\varphi_2(x,T) = w_2^0(x) - \psi_2(x,T),\ \dot\varphi_2(x,T) = w_2^1(x) - \dot\psi_2(x,T), \quad \text{in } L^2[\xi,1]. \tag{5.5}$$

If we define the input $u \in L^2[0,T]$ by $u = u_\psi + u_\varphi$, then the corresponding solutions w_1 and w_2 of (5.1), (5.2) satisfy

$$w_1(x,T) = w_1^0(x),\ \dot w_1(x,T) = w_1^1(x),\ w_2(x,T) = w_2^0(x),\ \dot w_2(x,T) = w_2^1(x).$$

Thus, the elements of $\mathcal{W}_s$ can be reached in time T by an input $u \in L^2[0,T]$. □

The main tool used in the proof of Theorem 5.1 is a recent generalization of a classical inequality of Ingham. This result was first proved in Jaffard, Tucsnak, and Zuazua [14] for $T > \frac{12\sqrt{6}}{\delta}$ and then improved in Baiochi, Komornik, and Loreti [4] for $T > \frac{4\pi}{\delta}$. Its statement (following [4]) is the following theorem.

THEOREM 5.3. *Let $M > 0$ and let (λ_n) be a strictly increasing real sequence over $\mathbb{Z}$ satisfying*

$$\lambda_{n+2} - \lambda_n \geq \delta > 0 \qquad \forall n \in \mathbb{Z} \ \text{ with } \ |n| \geq M. \tag{5.6}$$

Then $\forall T > \dfrac{4\pi}{\delta}$ there exist constants $C_1, C_2 > 0$ such that

$$C_1 \sum \left[\left(|a_n|^2 + |a_{n+1}|^2\right) |\lambda_{n+1} - \lambda_n|^2 + |a_n + a_{n+1}|^2 \right] \leq \int_0^T \left| \sum a_n e^{i\lambda_n t} \right|^2 dt$$

$$\leq C_2 \sum \left[\left(|a_n|^2 + |a_{n+1}|^2\right) |\lambda_{n+1} - \lambda_n|^2 + |a_n + a_{n+1}|^2 \right] \quad \forall (a_n) \in l^2.$$

Let us now consider the initial and boundary value problems

$$\ddot\phi_1(x,t) - \frac{\partial^2 \phi_1}{\partial x^2}(x,t) = 0 \qquad \forall x \in (0,\xi) \qquad \forall t \in (0,\infty), \tag{5.7}$$

$$\phi_1(0,t)=\phi_1(\xi,t)=0 \qquad \forall t\in(0,\infty), \tag{5.8}$$

$$\phi_1(x,0)=\phi_1^0(x), \qquad \dot\phi_1(x,0)=\phi_1^1(x) \qquad \forall x\in(0,\xi), \tag{5.9}$$

and

$$\ddot\phi_2(x,t)-\frac{\partial^2\phi_2}{\partial x^2}(x,t)=0 \qquad \forall x\in(\xi,1) \qquad \forall t\in(0,\infty), \tag{5.10}$$

$$\phi_2(1,t)=\phi_2(\xi,t)=0 \qquad \forall t\in(0,\infty), \tag{5.11}$$

$$\phi_2(x,0)=\phi_2^0(x), \quad \dot\phi_2(x,0)=\phi_2^1(x) \qquad \forall x\in(\xi,1). \tag{5.12}$$

We will use the following duality result, which is related to Proposition 3.2. This result follows from Theorem 2.1 in Dolecki and Russell [9] or from the HUM method of Lions (see [20]).

LEMMA 5.4. *The space of the states of* (5.1), (5.2) *which can be reached by means of the same input* $u\in L^2[0,T]$ *contains the space* $\mathcal{V}_s$, $s\in(-\frac12,\frac12)$ *if and only if there exist* $C,T>0$ *such that the solutions* ϕ_1,ϕ_2 *of* (5.7)–(5.12) *satisfy*

$$\int_0^T\left|\frac{\partial\phi_2}{\partial x}(\xi,t)-\frac{\partial\phi_1}{\partial x}(\xi,t)\right|^2dt$$

$$\geq\left(\|\phi_1^0\|^2_{H^{-s}(0,\xi)}+\|\phi_1^1\|^2_{H^{-1-s}(0,\xi)}+\|\phi_2^0\|^2_{H^{-s}(\xi,1)}+\|\phi_2^1\|^2_{H^{-1-s}(0,\xi)}\right)$$

$$\forall(\phi_1^0,\phi_1^1,\phi_2^0,\phi_2^1)\in\big(H^2(0,\xi)\cap H_0^1(0,\xi)\big)\times H_0^1(0,\xi)\times\big(H^2(\xi,1)\cap H_0^1(\xi,1)\big)\times H_0^1(\xi,1).$$

Proof of Theorem 5.1. If $\phi_1^0\in H^2(0,\xi)\cap H_0^1(0,\xi)$, $\phi_1^1\in H_0^1(0,\xi)$, $\phi_2^0\in H^2(\xi,1)\cap H_0^1(\xi,1)$, $\phi_2^1\in H_0^1(\xi,1)$, it is known that we have the expansions

$$\left.\begin{array}{ll}\phi_1^0(x)= & \sum_{n\geq1}c_n\sin\left(\frac{n\pi x}{\xi}\right)\\ \phi_1^1(x)= & \frac{\pi}{\xi}\sum_{n\geq1}nd_n\sin\left(\frac{n\pi x}{\xi}\right)\end{array}\right\}\ x\in(0,\xi),$$

$$\left.\begin{array}{ll}\phi_2^0(x)= & \sum_{n\geq1}e_n\sin\left(\frac{n\pi(1-x)}{1-\xi}\right)\\ \phi_2^1(x)= & \frac{\pi}{1-\xi}\sum_{n\geq1}nf_n\sin\left(\frac{n\pi(1-x)}{1-\xi}\right)\end{array}\right\}\ x\in(\xi,1),$$

where the sequences (n^2c_n), (n^2d_n), (n^2e_n), and (n^2f_n) are in l^2. A standard calculation shows that the solutions ϕ_1,ϕ_2 of (5.7)–(5.12) are given by

$$\phi_1(x,t)=\sum_{n\in\mathbb{Z}}a_ne^{i\frac{n\pi}{\xi}t}\sin\left(\frac{n\pi x}{\xi}\right), \qquad x\in(0,\xi), \tag{5.13}$$

$$\phi_2(x,t)=\sum_{n\in\mathbb{Z}}b_ne^{i\frac{n\pi}{1-\xi}t}\sin\left(\frac{n\pi(1-x)}{1-\xi}\right), \qquad x\in(\xi,1), \tag{5.14}$$

where

$$a_n = \begin{cases} \frac{c_n - id_n}{2} & \text{for } n \geq 1, \\ \frac{c_{-n} + id_{-n}}{2} & \text{for } n \leq -1, \\ 0 & \text{for } n = 0, \end{cases} \tag{5.15}$$

$$b_n = \begin{cases} \frac{e_n - if_n}{2} & \text{for } n \geq 1, \\ \frac{e_{-n} + if_{-n}}{2} & \text{for } n \leq -1, \\ 0 & \text{for } n = 0. \end{cases} \tag{5.16}$$

If we denote by $(\lambda_n)_{n\in\mathbb{Z}}$ the strictly increasing sequence formed by the elements of the set

$$\Lambda = \left[\cup_{n\in\mathbb{Z}} \left\{\frac{n\pi}{\xi}\right\}\right] \bigcup \left[\cup_{n\in\mathbb{Z}} \left\{\frac{n\pi}{1-\xi}\right\}\right],$$

we can easily check that

$$\lambda_{n+2} - \lambda_n \geq in\left\{\frac{\pi}{\xi}, \frac{\pi}{1-\xi}\right\} \qquad \forall n \in \mathbb{Z}. \tag{5.17}$$

On the other hand, from (5.3) it easily follows (see [13] for details) that, $\forall \xi \in \mathcal{S}$, there exists a constant $C_\xi > 0$ with

$$\lambda_{n+1} - \lambda_n \geq \frac{C_\xi}{|\lambda_n|} \qquad \forall n \in \mathbb{Z}^*, \tag{5.18}$$

where $\mathbb{Z}^* = \mathbb{Z} \setminus \{0\}$. Moreover (5.13), (5.14) imply

$$\frac{\partial \phi_2}{\partial x}(\xi, t) - \frac{\partial \phi_1}{\partial x}(\xi, t) = \sum_{n\in\mathbb{Z}^*} (-1)^{n+1} n\pi \left(\frac{a_n}{\xi} e^{i\frac{n\pi t}{\xi}} + \frac{b_n}{1-\xi} e^{i\frac{n\pi t}{1-\xi}}\right), \tag{5.19}$$

which yields

$$\frac{\partial \phi_2}{\partial x}(\xi, t) - \frac{\partial \phi_1}{\partial x}(\xi, t) = \sum_{n\in\mathbb{Z}^*} k_n \lambda_n e^{i\lambda_n t}, \tag{5.20}$$

with the sequence (k_n) satisfying

$$\sum_{n\in\mathbb{Z}^*} |k_n|^2 = \sum_{n\in\mathbb{Z}^*} (|a_n|^2 + |b_n|^2). \tag{5.21}$$

Relations (5.18), (5.20), (5.21), and Theorem 5.3 imply that there exists a constant $K_\xi > 0$ such that

$$\int_0^T \left|\frac{\partial \phi_2}{\partial x}(\xi, t) - \frac{\partial \phi_1}{\partial x}(\xi, t)\right|^2 dt \geq K_\xi \sum_{n\in\mathbb{Z}} \left(|a_n|^2 + |b_n|^2\right) \tag{5.22}$$

$\forall \xi \in \mathcal{S}$ and $\forall T > \max\{4\xi, 4(1-\xi)\}$. Inequality (5.22) combined with Lemma 5.4 implies that the elements in $\mathcal{V}_0$ are reachable by means of an input in $L^2[0, T]$. By using Lemma 5.2 we obtain assertion (a) of Theorem 5.1.

According to Lemma 7.3 in [13], $\forall \varepsilon > 0$ there exists a set $B_\varepsilon \subset (0,1)$, of Lebesgue measure 1, such that $\forall \xi \in B_\varepsilon$, there exists a constant $C_\xi > 0$ with

$$\lambda_{n+1} - \lambda_n \geq \frac{C_\xi}{|\lambda_n|^{1+\varepsilon}} \qquad \forall n \in \mathbb{Z}^*. \tag{5.23}$$

Relations (5.20), (5.21), (5.23), and Theorem 5.3 imply that there exists a constant $K_\xi > 0$ such that

$$\int_0^T \left| \frac{\partial \phi_2}{\partial x}(\xi, t) - \frac{\partial \phi_1}{\partial x}(\xi, t) \right|^2 dt \geq K_\xi \sum_{n \in \mathbb{Z}} \left(\frac{|a_n|^2 + |b_n|^2}{|\lambda_n|^{2\varepsilon}} \right) \tag{5.24}$$

$\forall \xi \in B_\varepsilon$ and $\forall T > \max\{4\xi, 4(1-\xi)\}$. Lemma 5.4 combined with (5.24) implies that $\forall s \in (0, \frac{1}{2})$, the elements in $\mathcal{V}_s$ are reachable by an input in $L^2[0,T]$. By applying again Lemma 5.2 we get assertion (b) of Theorem 5.1 for $s < \frac{1}{2}$. For $s \geq \frac{1}{2}$ the assertion remains true because $\mathcal{W}_s \subset \mathcal{W}_r$ for $s > r$.

In order to prove assertion (c) we notice that, $\forall \xi \in (0,1)$, we can use the continuous fractions expansion of $\frac{1-\xi}{\xi}$ to construct a sequence $(p(n))$ with values in $\mathbb{N}$, with $\lim_{n \to \infty} p(n) = \infty$, such that

$$\lambda_{p(n)+1} - \lambda_{p(n)} \leq \frac{C}{p(n)} \qquad \forall n \in \mathbb{N}. \tag{5.25}$$

If we denote by (ϕ_{1n}) (resp., by (ϕ_{2n})) the sequence of solutions of (5.7)–(5.9) (resp., of (5.10)–(5.12)) having initial data $(\sin(\frac{p(n)\pi}{\xi}), 0)$ (resp., $(\sin(\frac{(p(n)+1)\pi}{1-\xi}), 0)$, relations (5.13), (5.14), and (5.25) imply that

$$\lim_{n \to \infty} \frac{\displaystyle\int_0^T \left| \frac{\partial \phi_{2n}}{\partial x}(\xi, t) - \frac{\partial \phi_{1n}}{\partial x}(\xi, t) \right|^2 dt}{\|\phi_{1n}(0)\|^2_{H^s(0,\xi)} + \|\phi_{2n}(0)\|^2_{H^s(\xi,1)}} = 0$$

$\forall s < 0$. Using again Lemma 5.4 we conclude that (c) also holds. □

Remark 5.5. The fact that (5.24) holds for any $T > \max\{4\xi, 4(1-\xi)\}$ was proved in [4]. Earlier versions of this inequality (corresponding to larger values of T) were given in [13] and [14]. Notice that (5.24) and the standard duality argument imply only reachability of elements in $\mathcal{V}_s$. In order to get the reachability of elements in $\mathcal{W}_s$ we need a different argument, namely Lemma 5.2.

Remark 5.6. Intuitively it does not seem reasonable to have a minimal simultaneous reachability time depending on ξ. This question and other related issues (simultaneous approximate controllability, simultaneous spectral controllability) are tackled in [3]. In this work it is shown that the minimal time for these various types of controllability is $T = 2$.

Acknowledgments. The authors wish to thank Enrique Zuazua for suggesting a method to obtain the optimal approximate controllability time in Lemma 3.4. We are grateful to Sergei Avdonin, Francis Conrad, Scott Hansen, and Olof Staffans for helpful discussions and references.

BIFURCATION CONTROL VIA STATE FEEDBACK FOR SYSTEMS WITH A SINGLE UNCONTROLLABLE MODE*

WEI KANG†

Abstract. The state feedback control of bifurcations with quadratic or cubic degeneracy is addressed for systems with a single uncontrollable mode. Based on normal forms and invariants, the classification of bifurcations for systems with a single uncontrollable mode is obtained (Table 1). Using invariants, stability characterizations are derived for a family of bifurcations, including saddle-node bifurcations, transcritical bifurcations, pitchfork bifurcations, and bifurcations with a cusp or hysteresis phenomenon. Bifurcations in systems under perturbed feedbacks are also addressed. In the case of a saddle-node bifurcation, continuous but not differentiable feedbacks are introduced to locally remove the bifurcation and to achieve the stability.

Key words. bifurcation, invariants, normal form, feedback control

1. Introduction.

Nonlinear dynamical systems exhibit complicated performance around bifurcation points. As the parameter of a system is varied, changes may occur in the qualitative structure of its solutions around a point of bifurcation. Using a feedback to stabilize a system with bifurcations has been studied by many authors (see, for instance, [1], [5], [8], [11], [20], and [25]). Many engineering applications of bifurcation control can be found in the literature (e.g., control of surge and rotating stall in engine compressors, flight control under high angle-of-attack). Quadratic and cubic feedbacks were introduced in [1] for the stabilization of bifurcated equilibria. It was proved in [1] that the periodic solution of a Hopf bifurcation can be stabilized by using state feedbacks. For the period doubling bifurcation, the method of harmonic balance was introduced in [8]. A feedback design method for delaying and stabilizing period doubling bifurcations was obtained. In [25], control laws were designed for the suppression of chaos in a thermal convection system model. A review of bifurcation and chaos in control systems can be found in [5]. More references on related topics can be found in [4], a bibliography of publications on bifurcation and chaos in control systems.

The main goal of this paper is to develop a framework for the analysis and control of bifurcations. Stability characterizations are obtained for control systems around bifurcations with quadratic or cubic degeneracy. Several well-known static bifurcations are addressed in this paper in a unified approach. This is made possible by using normal forms. The main results in sections 4 and 5 are summarized in Table 1, which is a complete classification of bifurcations with quadratic or cubic degeneracy for systems having a single uncontrollable mode. Because the system has only one uncontrollable mode, it does not have the Hopf bifurcation if the feedback stabilizes the controllable part. The Hopf bifurcation occurs for normal forms with two uncontrollable modes (see [7]).

What makes this paper unique is the approach based on the normal form and the

TABLE 1

The bifurcations under state feedbacks. In the table, Q_1 is defined by (3.5), $\bar{Q}$ is defined by (4.1), D is defined by (4.23), and $\tilde{Q}$ is a function defined by $\tilde{Q}(a,b,c) = [a_1 \ -a_z \ 0]\ Q\ [a\ b\ c]^T$.

System	Condition		Bifurcation	Stability
System (2.2)	$Q_1(a_1,-a_z) \neq 0$	$\det(\bar{Q}) > 0$	The origin is an insolated equilibrium point	The system is unstable
		$\det(\bar{Q}) < 0$	Transcritical bifurcation	The system is stable at (z,x,μ) if $\hat{Q}(z,x_1,\mu) > 0$
				The system is unstable at (z,x,μ) if $\hat{Q}(z,x_1,\mu) < 0$
	$Q_1(a_1,-a_z) = 0$	$D \neq 0$ $\tilde{Q}(0,-a_\mu,a_1) \neq 0$	Pitchfork bifurcation	Supercritical if $D < 0$
				Subcritical if $D > 0$
System (2.3)	$Q_1(a_1,-a_z) \neq 0$		Saddle-node bifurcation	The system is stable at (z,x,μ) if $Q_1(z,x_1)z < 0$
				The system is unstable at (z,x,μ) if $Q_1(z,x_1)z > 0$
	$Q_1(a_1,-a_z) = 0$	$D \neq 0$	No bifurcation, there exists a unique equilibrium point for every fixed value of μ	All equilibrium points are stable if $D < 0$
				All equilibrium points are unstable if $D > 0$

invariants of nonlinear control systems. The two successful methods in the classical bifurcation theory are the normal form method and the projection method. They have been applied to control systems [1], [2], [21], [22]. The control system normal form adopted in the present paper is different from those used in the literature of nonlinear dynamical systems without control inputs. Why is it necessary to introduce the control system normal form instead of adopting the Poincaré normal form of vector fields? In fact, even for a linear control system $\dot{x} = Ax + Bu$, the controller normal form is more useful than the diagonal form of A in the feedback design. The normal form of nonlinear control systems generalizes the linear controller form. An affine control system $\dot{x} = f(x) + g(x)u$ has two vector fields $f(x)$ and $g(x)$. Therefore, the normal form of a control system requires the simplification of both f and g simultaneously. The simplification of f does not necessarily result in a simple form for g. Furthermore, the transformation group of control systems consists of changes of coordinates and feedbacks. This is different from the normal form theory of dynamical systems where feedbacks are not considered. The resonant terms defined for the control system normal form characterize the nature of a control system because they are invariant under both changes of coordinates and state feedbacks. The results obtained in this paper are intrinsic. They link the qualitative properties such as the bifurcation of control systems and its stability with their invariants.

An advantage of using the control system normal form is that the stability around bifurcations for a family of control systems is equivalent to the stability of their normal forms. This equivalence relation significantly simplifies the problem. It enables us to study a family of control systems with various bifurcations in a unified approach. The results proved in this paper provide a complete classification of bifurcations with quadratic or cubic degeneracy for systems having a single uncontrollable mode (Table 1).

Another advantage of the normal form approach is that the set of all equilibria of a control system (without feedback) in normal form can be found, and it is ap-

proximately a quadratic surface. Based on the geometric interpretation of equilibrium sets, we can describe how feedbacks change the distribution of the equilibrium points in the closed-loop system. This is important because the graph of the equilibrium points determines the type of the bifurcation. For certain systems, the position of an equilibrium point determines its stability as well. Furthermore, understanding the geometry of equilibrium sets enables us to characterize bifurcations under feedbacks which are not zero at the critical point.

The paper is organized as follows. Two bifurcation problems are formulated in section 2. Normal forms and invariants, the foundation of the framework, are introduced in section 3. The bifurcation control for systems with a single zero uncontrollable mode are studied in section 4 and section 5. In section 6, general feedbacks which are not zero at the critical point are studied. The classification of bifurcations are summarized in Table 1.

2. The problem formulation. Consider the following control system with a parameter

$$\dot{x} = f(x,\mu) + g(x,\mu)u, \qquad f(0,0) = 0, \tag{2.1}$$

where $x \in \mathbb{R}^n$ is the state variable, $u \in \mathbb{R}^m$ is the control input, and μ is the parameter. We assume that the rank of $g(x)$ is m at the point of interest. Unless it is otherwise specified, all vector fields and state feedbacks in this paper are C^k for some $k > 0$ sufficiently large. System (2.1) is said to be *linearly controllable* at $(x,\mu) = (0,0)$ if its linearization (A,B),

$$A = \frac{\partial f}{\partial x}(0,0), \qquad B = g(0,0)$$

is controllable. The origin $(x,\mu) = (0,0)$ is called an equilibrium or equilibrium point of (2.1) because $x(t) = 0$ is a constant solution if $\mu = 0$ and $u = 0$. Constant solutions may exist for other values of (x,μ,u). The *equilibrium set* is defined by

$$E = \{(x,\mu) | \text{ there exists } u_0 \in \mathbb{R} \text{ such that } f(x,\mu) + g(x,\mu)u_0 = 0\}.$$

A point in E is called an *equilibrium* or *equilibrium point*. Feedbacks are not involved in this definition. If the control input u is substituted by a feedback $u = u(x)$, a *closed-loop equilibrium*, (x_0,μ_0), is defined by $f(x_0,\mu_0) + g(x_0,\mu_0)u(x_0) = 0$. The set of all closed-loop equilibria is

$$E_c = \{(x,\mu) | f(x,\mu) + g(x,\mu)u(x) = 0\}.$$

The concept of an equilibrium set plays an important role in this paper. It is known that the closed-loop equilibrium set E_c, in general, is changed if the feedback is varied. However, the set E_c under any state feedback must be a subset of E. So, E consists of all possible closed-loop equilibria. The topology of E_c is induced from E.

The classical bifurcation theory studies the change of qualitative properties of dynamical systems as the parameters are varied. Qualitative properties include the topology of the equilibrium set, the stability, the existence of periodic solutions, etc. Control systems have two types of qualitative properties, which are those invariant under regular feedbacks (for example, the controllability, the stabilizability, and the topology of E) and those determined by the closed-loop system (for example, the closed-loop equilibria and the stability under a state feedback). Studying how these

properties are changed with parameters leads to the following two bifurcation problems for control systems.

PROBLEM 2.1. *Bifurcation of control systems. The problem focuses on the change of qualitative properties of control systems (such as controllability and stabilizability).*

PROBLEM 2.2. *Bifurcation control by using feedbacks. The problem focuses on the feedback design to achieve the stability around a critical point, or to achieve the desired performance by qualitatively changing a bifurcation.*

Problem 2.1 was addressed in [14] and [15] for systems with a single uncontrollable mode. In the present paper, we focus on Problem 2.2. It is proved that the same control system may exhibit several different kinds of bifurcations under different feedbacks. Instead of focusing on a single bifurcation, we ask the following questions. What kinds of bifurcations can occur in a control system, and what is the relationship between bifurcations and control laws? It is a different viewpoint from the existing bifurcation control approaches. It is known that local bifurcations at a linearly controllable point can be either removed or delayed by pole placement. In this paper, we study systems which are not linearly controllable. The work is motivated by engineering problems such as engine compressors and submersible vehicles [23], [20], [17]. In addition to the engineering applications, our research on uncontrollable systems is also motivated by the fact that qualitative properties such as controllability and stabilizability of control systems are generic (they are not changed by a small variation of parameters) at a linearly controllable point. If a system is not linearly controllable at a point, nonlinear phenomena such as bifurcations are expected around the critical point.

It is assumed throughout this paper that there exists a single uncontrollable mode (denoted by λ) in the linearization. The dimension of the state space is at least two ($n \geq 2$). If $\lambda \neq 0$, the sign of λ determines the stabilizability of the uncontrollable dynamics. Therefore, the variation of μ does not change the stability, i.e., there is no stationary bifurcation at $\mu = 0$. If $\lambda = 0$, the stability of the system depends on the value of the parameter. Different kinds of bifurcations occur in the performance. So, we focus on systems with $\lambda = 0$ in the following sections. Under a suitable linear change of coordinates and linear feedback, a system with a single uncontrollable mode $\lambda = 0$ can be transformed into one of the following forms (see [15] or [16]).

$$\begin{aligned} \dot{z} &= f_1(z, x, \mu) + g_1(z, x, \mu)u, \\ \dot{x} &= A_2 x + B_2 u + f_2(z, x, \mu) + g_2(z, x, \mu)u \end{aligned} \tag{2.2}$$

or

$$\begin{aligned} \dot{z} &= \mu + f_1(z, x, \mu) + g_1(z, x, \mu)u, \\ \dot{x} &= A_2 x + B_2 u + f_2(z, x, \mu) + g_2(z, x, \mu)u, \end{aligned} \tag{2.3}$$

where f_1, f_2, and their first derivatives equal zero at the origin $(z, x, \mu) = (0, 0, 0)$, g_1 and g_2 equal zero at the origin. The pair (A_2, B_2) is in the following Brunovsky form:

$$A_2 = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & 0 & \cdots & 1 \\ 0 & 0 & 0 & \cdots & 0 \end{bmatrix}_{(n-1)\times(n-1)}, \quad B_2 = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 1 \end{bmatrix}. \tag{2.4}$$

A feedback

$$u = \alpha(z, x, \mu) \tag{2.5}$$

for bifurcation control is a smooth function of (z, x, μ) such that $\alpha(0, 0, 0) = 0$. The linearization of a feedback is in the following form:

$$\alpha(z, x, \mu) = a_z z + \sum_{i=1}^{n-1} a_i x_i + a_\mu \mu + O(z, x, \mu)^2. \tag{2.6}$$

Notice that the value of μ is not always available. The function $\alpha(z, x, \mu)$ involves the parameter μ for two reasons. (1) Introducing μ in $\alpha(z, x, \mu)$ makes the theory more general. Feedbacks independent of μ form a subset of the feedbacks defined by (2.5). (2) By transforming the original system into it normal form, the linearization of the last equations in (2.2) and (2.3) has only one term which is the input u. However, the original system may have the terms with μ in the last equation. In this case, the term μ is absorbed in (2.5). So, a_μ in (2.6) comes from the original model. It is not necessarily zero.

In this paper, a system is said to be *stable* at a given equilibrium point if it is locally asymptotically stable at this point. To achieve stability, feedbacks in this paper are assumed to satisfy the following assumption.

ASSUMPTION 2.3. *The state feedback* (2.6) *places the controllable poles in the left half plane, i.e., the eigenvalues of the matrix* $A_2 + B_2 \begin{bmatrix} a_1 & a_2 & \cdots & a_{n-1} \end{bmatrix}$ *are all in the left half plane.*

It is known that $(-1)^n a_1$ equals the multiplication of all eigenvalues of the matrix

$$A_2 + B_2 \begin{bmatrix} a_1 & a_2 \cdots a_{n-1} \end{bmatrix}.$$

From Assumption 2.3, these eigenvalues are on the left half plane. So we have the following lemma.

LEMMA 2.4. *If a feedback* (2.6) *satisfies Assumption* 2.3*, then* $a_1 < 0$.

3. Normal forms and invariants. In this section, nonlinear invariants are defined by the coefficients of resonant terms. Then quadratic normal forms in [14] and [15] are introduced without proof.

3.1. Resonant terms and invariants. In the classical theory of dynamical systems, a set of resonant terms was found for the homogeneous parts of nonlinear systems. The coefficients of resonant terms are invariant under homogeneous transformations. For systems with the Hopf bifurcation, the values of invariants determine the stability of the periodic solutions. For control systems, the invariants were introduced in [12] for linearly controllable systems. In this section, a set of invariants is found for systems which are not linearly controllable. It plays a key role in the stability analysis for control systems with bifurcations.

The quadratic and cubic terms in the Taylor expansion of vector fields are used in the proofs of many results. The homogeneous parts of degree d for f_i and g_i in (2.2) and (2.3) are denoted by $f_i^{[d]}$ and $g_i^{[d]}$. For instance, the quadratic terms in the Taylor expansion of $f_1 + g_1 u$ have the form $f_1^{[2]}(z, x, \mu) + g_1^{[1]}(z, x, \mu)u$. The components of $f_i^{[d]}$ and $g_1^{[d-1]}$ are homogeneous polynomials of degree d and $d-1$, respectively. A homogeneous transformation of degree d for control systems consists of the change of coordinates and state feedbacks in the form

$$\begin{aligned} &z = \bar{z} + \phi_1^{[d]}(\bar{z}, \bar{x}, \mu), \qquad x = \bar{x} + \phi_2^{[d]}(\bar{z}, \bar{x}, \mu), \\ &u = \bar{u} + \alpha^{[d]}(\bar{z}, \bar{x}, \mu) + \beta^{[d-1]}(\bar{z}, \bar{x}, \mu)\bar{u}, \end{aligned} \tag{3.1}$$

where $\bar{z}$ and $\bar{x}$ are the new coordinates and $\bar{u}$ is the new control input introduced by the regular feedback. A transformation of degree d does not change the terms of degree less than d in a control system. If $d = 2$, (3.1) is called a quadratic transformation. If $d = 3$, it is called a cubic transformation.

DEFINITION 3.1. *Consider* (2.2) *or* (2.3). *A homogeneous term in* $f_i^{[d]}(z, x, \mu)$ *or* $g_i^{[d-1]}(z, x, \mu)u$, *is called a resonant term if transformations of the form* (3.1) *leave the coefficient of the term invariant. The coefficient of a resonant term is called an invariant.*

For instance, if (3.1) is applied to (2.2), it can be proved that the term $\bar{z}^2$ in $\bar{f}_1^{[2]}$ of the resulting system has the same coefficient as the term z^2 in $f_1^{[2]}$ of (2.2). So z^2 in $f_1^{[2]}$ is resonant. Notice that the resonant terms of control systems are different from the resonant terms in the classical theory of dynamical systems. A resonant term in Definition 3.1 is invariant under both changes of coordinates and state feedbacks. However, the classical dynamic systems theory does not deal with any feedback. In the next theorem, resonant terms are found for (2.2) and (2.3). Define

$$\begin{aligned} &R^{[d]}(z, x_1, \mu) = f_1^{[d]}(z, x, \mu)|_{x_2=x_3=\cdots=x_{n-1}=0}, \\ &R_1^{[d]}(z, x_1) = R(z, x_1, 0), \end{aligned} \tag{3.2}$$

where $f_1^{[d]}(z, x, \mu)$ is the homogeneous vector field of degree d from the Taylor expansion of $f_1(z, x, \mu)$ in (2.2) and (2.3).

THEOREM 3.2. *In* (2.2), *all terms of* $R^{[d]}(z, x_1, \mu)$ *are resonant. In* (2.3), *all terms of* $R_1^{[d]}(z, x_1)$ *are resonant.*

Proof. Consider the system (2.2). Suppose that (2.2) is transformed into the following system by (3.1):

$$\begin{aligned} \dot{\bar{z}} &= \bar{f}_1(\bar{z}, \bar{x}, \mu) + \bar{g}_1(\bar{z}, \bar{x}, \mu)\bar{u}, \\ \dot{\bar{x}} &= A_2\bar{x} + B_2\bar{u} + \bar{f}_2(\bar{z}, \bar{x}, \mu) + \bar{g}_2(\bar{z}, \bar{x}, \mu)\bar{u}. \end{aligned}$$

It was proved in [13] that the homogeneous parts of f_1 and $\bar{f}_1$ satisfy the homological equation

$$\frac{\partial \phi_1^{[d]}(z, x, \mu)}{\partial x} A_2 x = f_1^{[d]}(z, x, \mu) - \bar{f}_1^{[d]}(z, x, \mu).$$

However,

$$\frac{\partial \phi_1^{[d]}}{\partial x} A_2 x = \frac{\partial \phi_1^{[d]}}{\partial x_1} x_2 + \cdots + \frac{\partial \phi_1^{[d]}}{\partial x_{n-2}} x_{n-1}. \tag{3.3}$$

Therefore, every term of $f_1^{[d]} - \bar{f}_1^{[d]}$ has at least one of the variables $x_2, \ldots, x_{n-1}$. The terms in $R(z, x_1, \mu)$ do not appear in $f_1^{[d]} - \bar{f}_1^{[d]}$. This implies that the function $R^{[d]}(z, x_1, \mu)$ in $f_1^{[d]}$ is invariant under (3.1).

Now consider the system (2.3). The homological equation for $f_1^{[d]}$ is

$$\frac{\partial \phi_1^{[d]}(z, x, \mu)}{\partial z} \mu + \frac{\partial \phi_1^{[d]}(z, x, \mu)}{\partial x} A_2 x = f_1^{[d]}(z, x, \mu) - \bar{f}_1^{[d]}(z, x, \mu).$$

From (3.3), every nonzero term in $f_1^{[d]} - \bar{f}_1^{[d]}$ has at least one of the variables μ, $x_2, \ldots, x_{n-1}$. This implies that the coefficients in $R_1^{[2]}(z, x_1)$ are not changed by (3.1). ∎

In the following, the coefficients of resonant terms are denoted by γ with corresponding subindices. For example, the coefficient of z^2 in $R_1^{[2]}(z,x_1)$ or $R^{[2]}(z,x_1,\mu)$ is γ_{zz}, the coefficient of $zx_1\mu$ is $\gamma_{zx_1\mu}$, etc. Based on this theorem, the coefficients γ_{zz}, γ_{zx_1}, $\gamma_{z\mu}$, $\gamma_{x_1x_1}$, $\gamma_{x_1\mu}$, $\gamma_{\mu\mu}$ in (2.2) and the coefficients γ_{zz}, γ_{zx_1}, $\gamma_{x_1x_1}$ in (2.3) are called (quadratic) invariants. They are part of the quadratic invariants introduced in [12] and [15] using Lie brackets. The quadratic functions of resonant terms $R^{[2]}(z,x_1,\mu)$ and $R_1^{[2]}(z,x_1)$ determine two symmetric matrices,

$$Q=\begin{bmatrix} \gamma_{zz} & \frac{\gamma_{zx_1}}{2} & \frac{\gamma_{z\mu}}{2} \\ \frac{\gamma_{zx_1}}{2} & \gamma_{x_1x_1} & \frac{\gamma_{x_1\mu}}{2} \\ \frac{\gamma_{z\mu}}{2} & \frac{\gamma_{x_1\mu}}{2} & \gamma_{\mu\mu} \end{bmatrix}, \qquad Q_1=\begin{bmatrix} \gamma_{zz} & \frac{\gamma_{zx_1}}{2} \\ \frac{\gamma_{zx_1}}{2} & \gamma_{x_1x_1} \end{bmatrix}. \tag{3.4}$$

In this paper, the quadratic function defined by Q (or Q_1) is also denoted by $Q(x,y,z)$ (or $Q_1(x,y)$), i.e.,

$$Q(x,y,z)=\begin{bmatrix} x & y & z \end{bmatrix} Q \begin{bmatrix} x & y & z \end{bmatrix}^T, \quad Q_1(x,y)=\begin{bmatrix} x & y \end{bmatrix} Q_1 \begin{bmatrix} x & y \end{bmatrix}^T. \tag{3.5}$$

Equivalently,

$$Q(z,x_1,\mu)=R^{[2]}(z,x_1,\mu), \quad Q_1(z,x_1)=R_1^{[2]}(z,x_1).$$

3.2. Quadratic normal forms. Since systems with the same normal form have equivalent bifurcations, most proofs in this paper are given for quadratic normal forms. From [15] and [16], (2.2) and (2.3) can be transformed into a unique system in normal form by a suitable quadratic transformation of the form (3.1) with $d=2$.

For (2.2), the normal form is

$$\begin{aligned} \dot z &= \sum_{i=2}^{n-1}\gamma_{x_ix_i}x_i^2+Q(z,x_1,\mu)+O(z,x,\mu,u)^3, \\ \dot x &= A_2x+B_2u+\tilde f_2^{[2]}(x)+O(z,x,\mu,u)^3. \end{aligned} \tag{3.6}$$

For (2.3), the normal form is

$$\begin{aligned} \dot z &= \mu+\sum_{i=2}^{n-1}\gamma_{x_ix_i}x_i^2+\gamma_{x_1\mu}x_1\mu+Q_1(z,x_1)+O(z,x,\mu,u)^3, \\ \dot x &= A_2x+B_2u+\tilde f_2^{[2]}(x)+O(z,x,\mu,u)^3, \end{aligned} \tag{3.7}$$

where $\tilde f_2^{[2]}(x)$ is in the extended controller form of [12]. Details are omitted since it is not used in this paper. Before the end of this section, we introduce the following well-known result on stationary bifurcations (see [9]).

THEOREM 3.3. *Consider the following one-dimensional dynamical system with a parameter μ.*

$$\dot x=f(x,\mu), \qquad f(0,0)=0, \qquad x\in\mathbb{R}. \tag{3.8}$$

(i) *It has a saddle-node bifurcation at the origin if*

$$f_x(0,0)=0, \qquad f_\mu(0,0)\neq 0, \qquad f_{xx}(0,0)\neq 0. \tag{3.9}$$

(ii) *It has a transcritical bifurcation at the origin if*

$$\begin{aligned} &f_x(0,0)=0, \qquad f_\mu(0,0)=0,\\ &f_{xx}(0,0)\neq 0, \qquad f_{x\mu}^2(0,0)-f_{xx}(0,0)f_{\mu\mu}(0,0)>0. \end{aligned} \tag{3.10}$$

(iii) *It has a pitchfork bifurcation at the origin if*

$$f_x(0,0)=0, \quad f_\mu(0,0)=0, \quad f_{xx}(0,0)=0, \quad f_{x\mu}(0,0)\neq 0, \quad f_{xxx}(0,0)\neq 0. \tag{3.11}$$

If $f_{xxx}(0,0)<0$, *the pitchfork bifurcation is supercritical. If* $f_{xxx}(0,0)>0$, *it is subcritical.*

4. Bifurcations of system (2.2). In this section, all bifurcations of (2.2) with both quadratic and cubic degeneracies are addressed. An example is given to illustrate the feedback design technique of this section. In the example, the model of engine compressors with the transcritical bifurcation is studied. Feedbacks are designed to stabilize the equilibria on the positive side of the uncontrollable variable R.

Define a matrix $\bar{Q}$ from the linearization of a feedback and the quadratic invariants of (2.2)

$$\bar{Q}=\begin{bmatrix} a_1 & -a_z & 0\\ 0 & -a_\mu & a_1 \end{bmatrix} Q \begin{bmatrix} a_1 & 0\\ -a_z & -a_\mu\\ 0 & a_1 \end{bmatrix}, \tag{4.1}$$

where Q is defined by (3.4). The matrix $\bar{Q}$ is used in the next theorem to characterize the bifurcation. Following the notation introduced in section 2, E_c represents the set of closed-loop equilibrium points, i.e.,

$$E_c=\{(x,\mu)|f(x,\mu)+g(x,\mu)\alpha(x,\mu)=0\}. \tag{4.2}$$

THEOREM 4.1. *Consider a closed-loop system* (2.2)–(2.6) *satisfying Assumption* 2.3. *Suppose*

$$Q_1(a_1,-a_z)\neq 0. \tag{4.3}$$

(i) *If* $\bar{Q}$ *is sign definite, then* $(z,x,\mu)=(0,0,0)$ *is an isolated equilibrium point of the closed-loop system. It is unstable.*

(ii) *If* $\bar{Q}$ *is indefinite with full rank, then the closed-loop system has a transcritical bifurcation around the origin.*

(iii) *Assume that the feedback satisfies the condition in* (ii). *Given any* $(z,x,\mu)\in E_c$ *in a neighborhood of the origin, it is locally asymptotically stable if*

$$\begin{bmatrix} a_1 & -a_z & 0 \end{bmatrix} Q \begin{bmatrix} z & x_1 & \mu \end{bmatrix}^T>0. \tag{4.4}$$

The system is unstable if

$$\begin{bmatrix} a_1 & -a_z & 0 \end{bmatrix} Q \begin{bmatrix} z & x_1 & \mu \end{bmatrix}^T<0. \tag{4.5}$$

Remark. In $zx_1\mu$-space, the open loop equilibrium set E of (3.6) is approximately a cone

$$\begin{aligned} &Q(z,x_1,\mu)=0,\\ &x_i=0 \qquad \text{for } i=2,3,\dots,n-1, \end{aligned} \tag{4.6}$$

provided that Q is indefinite with full rank (see [15]). The third and higher degree terms are omitted in the approximation. Under the feedback

$$\alpha(z,x,\mu)=\sum a_i x_i + a_z z + a_\mu \mu + O(z,x,\mu)^2,$$

the closed-loop equilibrium set E_c is the intersection between E and the surface $\alpha(z,x,\mu)=0$. Therefore, E_c is approximated by the intersection between the plane $a_z z + a_1 x_1 + a_\mu \mu = 0$ and the cone (4.6). The geometry of E_c has two generic cases, which are (1) it has a unique point, and (2) the intersection consists of two lines. The first case is characterized by (i) of Theorem 4.1. The graph of E_c in the second case indicates a transcritical bifurcation, which is proved by (ii) of Theorem 4.1. □

Since (2.2) is equivalent to its normal form (3.6), it is important to find a center manifold and the reduced system on it for the normal form (3.6). This is obtained in the following lemma.

LEMMA 4.2. *Consider the quadratic normal form* (3.6). *Under the state feedback* (2.6), *the center manifold of the closed-loop system satisfies*

$$x_1 = -\frac{a_z}{a_1} z - \frac{a_\mu}{a_1}\mu + O(z,\mu)^2, \qquad x_i = O(z,\mu)^2 \quad for \;\; i = 2,\dots,n-1. \tag{4.7}$$

The reduced system on the center manifold satisfies

$$\dot z = \frac{1}{a_1^2} \begin{bmatrix} z & \mu \end{bmatrix} \bar Q \begin{bmatrix} z & \mu \end{bmatrix}^T + O(z,\mu)^2. \tag{4.8}$$

Proof. From [3], the center manifold is determined by a function $x=\pi(z,\mu)$, where $\pi(z,\mu)$ can be approximated by polynomials. The function $\pi(z,\mu)$ satisfies an equation of the following form:

$$A\pi(z,\mu) + Bu(z,\pi,\mu) + O(z,\pi,\mu)^2 = \frac{\partial \pi}{\partial z} O(z,\pi,\mu)^2.$$

Denote the linear part of $\pi(z,\mu)$ by $\pi^{[1]}(z,\mu)$. The linearization of this equation is

$$\pi_2^{[1]} = 0, \quad \pi_3^{[2]} = 0, \dots, \quad a_z z + a_1 \pi_1^{[1]}(z,\mu) + a_\mu \mu = 0. \tag{4.9}$$

It is easy to check that the linear part of (4.7) satisfies (4.9). The functions in (4.7) are equivalent to

$$\begin{bmatrix} z \\ x_1 \\ \mu \end{bmatrix} = \frac{1}{a_1} \begin{bmatrix} a_1 & 0 \\ -a_z & -a_\mu \\ 0 & a_1 \end{bmatrix} \begin{bmatrix} z \\ \mu \end{bmatrix} + O(z,\mu)^2, \quad x_i = O(z,\mu)^2 \;\text{ for }\; 2 \le i \le n-1.$$

Substituting this relation into the z dynamical equation in (3.6), we obtain (4.8) as the reduced system on the center manifold. □

The proof of Theorem 4.1. Since (2.2) can be transformed into its normal form (3.6) by a quadratic transformation, and since the conditions in the theorem are invariant under quadratic transformations, it is enough to prove the result for the quadratic normal form (3.6).

(i) The closed-loop system is equivalent to its reduced system (4.8) on the center manifold. Denote the right side of (4.8) by $f_c(z,\mu)$. If $\bar Q$ is sign definite, then $(z,\mu) = (0,0)$ is the unique local solution of $f_c(z,\mu)=0$. Therefore, the origin is an isolated equilibrium point. In this case, the reduced system (4.8) at $\mu = 0$ is

$$\dot z = \frac{1}{a_1^2} Q_1(a_1, -a_z) z^2 + O(z)^3.$$

Since $\det(\bar{Q}) > 0$ and since $Q_1(a_1, -a_z)$ is the first diagonal entry in $\bar{Q}$, we know that $Q_1(a_1, -a_z) \neq 0$. The system is unstable. Part (i) is proved.

(ii) Now, assume that $\det(\bar{Q}) < 0$. It is obvious that

$$\frac{\partial f_c}{\partial z}(0,0) = 0, \qquad \frac{\partial f_c}{\partial \mu}(0,0) = 0. \tag{4.10}$$

It is easy to check that

$$\frac{\partial^2 f_c}{\partial z^2}(0,0) = \frac{1}{a_1^2} Q_1(a_1, -a_z) \neq 0. \tag{4.11}$$

$$\frac{\partial^2 f_c}{\partial z^2}(0,0)\frac{\partial^2 f_c}{\partial \mu^2}(0,0) - \left(\frac{\partial^2 f_c}{\partial z \mu}(0,0)\right)^2 = 4\det(\bar{Q}) < 0. \tag{4.12}$$

Therefore, the conditions in (ii) of Theorem 3.3 are satisfied. This implies that the closed-loop system has a transcritical bifurcation.

(iii) The stability of the closed-loop system agrees with the reduced system on the center manifold. It is easy to check that

$$\frac{\partial f_c}{\partial z} = \frac{2}{a_1^2} \begin{bmatrix} 1 & 0 \end{bmatrix} \bar{Q} \begin{bmatrix} z & \mu \end{bmatrix}^T + O(z,\mu)^2. \tag{4.13}$$

If (z, x, μ) is in E_c, then (z, μ) is an equilibrium point on the center manifold,

$$\begin{bmatrix} z & \mu \end{bmatrix} \bar{Q} \begin{bmatrix} z & \mu \end{bmatrix}^T + O(z,\mu)^3 = 0, \qquad x_1 = -\frac{a_z}{a_1} z - \frac{a_\mu}{a_1}\mu + O(z,\mu)^2. \tag{4.14}$$

Therefore,

$$\begin{bmatrix} z & \mu \end{bmatrix} = \begin{bmatrix} z_0 & \mu_0 \end{bmatrix} t + O(t)^2, \qquad x_1 = \left(-\frac{a_z}{a_1} z_0 - \frac{a_\mu}{a_1}\mu_0\right) t + O(t)^2, \tag{4.15}$$

where $t \in \mathbb{R}$ and $(z_0, \mu_0) \neq (0,0)$ satisfies

$$\begin{bmatrix} z_0 & \mu_0 \end{bmatrix} \bar{Q} \begin{bmatrix} z_0 & \mu_0 \end{bmatrix}^T = 0. \tag{4.16}$$

From (4.1) and (4.15), we have

$$\frac{1}{a_1} \begin{bmatrix} a_1 & -a_z & 0 \end{bmatrix} Q \begin{bmatrix} z & x_1 & \mu \end{bmatrix}^T = \frac{1}{a_1^2} \begin{bmatrix} 1 & 0 \end{bmatrix} \bar{Q} \begin{bmatrix} z_0 & \mu_0 \end{bmatrix}^T t + O(t)^2. \tag{4.17}$$

If we can prove that

$$\begin{bmatrix} 1 & 0 \end{bmatrix} \bar{Q} \begin{bmatrix} z_0 & \mu_0 \end{bmatrix}^T \neq 0, \tag{4.18}$$

then the sign of $\frac{1}{a_1^2} \begin{bmatrix} 1 & 0 \end{bmatrix} \bar{Q} \begin{bmatrix} z_0 & \mu_0 \end{bmatrix}^T t$, which agrees with that of $\frac{\partial f_c}{\partial z}$, is opposite to the sign of the number given by

$$\begin{bmatrix} a_1 & -a_z & 0 \end{bmatrix} Q \begin{bmatrix} z & x_1 & \mu \end{bmatrix}^T,$$

because $a_1 < 0$. Therefore, (4.4) implies that $\frac{\partial f_c}{\partial z} < 0$ at the point in E_c around zero. The closed-loop system is locally asymptotically stable. Similarly, (4.5) implies that the system is unstable.

Now we prove (4.18) by contradiction. Suppose

$$\begin{bmatrix} 1 & 0 \end{bmatrix} \bar{Q} \begin{bmatrix} z_0 & \mu_0 \end{bmatrix}^T = 0. \tag{4.19}$$

Because $\det(\bar{Q}) \neq 0$, and because $(z_0, \mu_0) \neq (0,0)$, we have that $\bar{Q} \begin{bmatrix} z_0 & \mu_0 \end{bmatrix}^T \neq 0$. Equation (4.16) implies that $\begin{bmatrix} z_0 & \mu_0 \end{bmatrix} \bar{Q} \begin{bmatrix} z_0 & \mu_0 \end{bmatrix}^T = 0$. Comparing this equation with (4.19), we have that $\mu_0 = 0$ and $z_0 \neq 0$. Therefore, (4.19) implies $q_{1\,1} = 0$, where $q_{1\,1}$ is the entry in $\bar{Q}$ at the upper-left corner. However, $q_{1\,1} = Q(a_1, -a_z)$. It contradicts (4.3). Therefore, (4.18) is true.

Remark. From (4.13), it is obvious that the system is locally asymptotically stable at $(z, x, \mu) \in E_c$ if $\begin{bmatrix} 1 & 0 \end{bmatrix} \bar{Q} \begin{bmatrix} z & \mu \end{bmatrix} < 0$. This is another method of stability testing.

Theorem 4.1 deals with bifurcation control under the assumption $Q_1(a_1, -a_z) \neq 0$. In the following, we study the case where $Q_1(a_1, -a_z) = 0$. For this purpose, we need cubic invariants. The function of cubic resonant terms, $R^{[3]}(z, x_1)$, of the normal form (3.6) is denoted by $C(z, x_1)$, which is

$$C(z, x_1) = R_1^{[3]}(z, x_1) = f_1^{[3]}(z, x, \mu)|_{x_2 = x_3 = \cdots = x_{n-1} = \mu = 0}, \tag{4.20}$$

where $f_1^{[3]}$ represents the cubic part in the first equation of (3.6). The state feedback for bifurcation control is

$$\begin{aligned} &u = \alpha(z, x, \mu), \\ &\alpha(z, x, \mu) = a_z z + a_1 x_1 + \cdots + a_{n-1} x_{n-1} + a_\mu x_\mu + \alpha^{[2]}(z, x, \mu) + O(z, x, \mu)^3, \end{aligned} \tag{4.21}$$

where $\alpha^{[2]}$ is a quadratic homogeneous polynomial. The coefficients in $\alpha^{[2]}$ are denoted by a_{zz}, $a_{z\mu}$, $a_{x_1 x_1}$, $a_{x_1 \mu}$, etc. The following quadratic function from $\alpha^{[2]}$ is useful:

$$\alpha_{z x_1}^{[2]}(z, x_1) = a_{zz} z^2 + a_{z x_1} z x_1 + a_{x_1 x_1} x_1^2, \tag{4.22}$$

i.e., $\alpha_{z x_1}^{[2]}$ is the restriction of $\alpha^{[2]}$ to the $z x_1$-plane. To simplify the notation, we define

$$D = a_1 C(a_1, -a_z) + (2 a_z \gamma_{x_1 x_1} - a_1 \gamma_{z x_1}) \alpha_{z x_1}^{[2]}(a_1, -a_z), \tag{4.23}$$

where $\gamma_{x_1 x_1}$ and $\gamma_{z x_1}$ are quadratic invariants in (3.4).

THEOREM 4.3. *Consider a closed-loop system* (3.6)–(4.21) *satisfying Assumption* 2.3.

(i) *Suppose*

$$Q_1(a_1, -a_z) = 0. \tag{4.24}$$

Then the closed-loop system has a pitchfork bifurcation at the origin provided

$$\begin{aligned} &D \neq 0, \\ &\begin{bmatrix} a_1 & -a_z & 0 \end{bmatrix} Q \begin{bmatrix} 0 & -a_\mu & a_1 \end{bmatrix}^T \neq 0. \end{aligned} \tag{4.25}$$

(ii) *The pitchfork bifurcation is supercritical if $D < 0$. It is subcritical if $D > 0$.*

Proof. The center manifold of (3.6)–(4.21) is the graph of $x = \pi(z, \mu)$, which satisfies

$$\frac{\partial \pi}{\partial z} \left(\sum_{i=2}^{n-1} \gamma_{x_i x_i} \pi_i^2 + Q(z, \pi_1, \mu) \right) = A_2 \pi + B_2 \alpha(z, \pi, \mu) + \tilde{f}_2^{[2]}(\pi) + O(z, \pi, \mu)^3. \tag{4.26}$$

The Taylor expansion of $\pi(z,\mu)$ is $\pi(z,\mu)=\pi^{[1]}(z,\mu)+\pi^{[2]}(z,\mu)+\cdots$. Solving (4.26) to the second degree, we have

$$
\begin{aligned}
&\pi_1^{[1]}(z,x)=-\frac{a_z}{a_1}z-\frac{a_\mu}{a_1}\mu, \qquad \pi_i^{[1]}(z,\mu)=0 \ \text{ for } \ i=2,\dots,n-1,\\
&\pi_1^{[2]}(z,\mu)=-\frac{1}{a_1}\begin{bmatrix} z & \pi_1^{[1]} & \mu \end{bmatrix}\Big(-\frac{a_z a_2}{a_1}Q+Q_{fb}\Big)\begin{bmatrix} z & \pi_1^{[1]} & \mu \end{bmatrix}^T,\\
&\pi_2^{[2]}(z,\mu)=-\frac{a_z}{a_1}Q(z,\pi_1^{[1]},\mu),
\end{aligned}
\tag{4.27}
$$

where Q_{fb} represents the matrix of the quadratic function of z, x_1, and μ in the feedback (4.21). More specifically,

$$
Q_{fb}=\begin{bmatrix} a_{zz} & \dfrac{a_{zx_1}}{2} & \dfrac{a_{z\mu}}{2}\\ \dfrac{a_{zx_1}}{2} & a_{x_1x_1} & \dfrac{a_{x_1\mu}}{2}\\ \dfrac{a_{z\mu}}{2} & \dfrac{a_{x_1\mu}}{2} & a_{\mu\mu} \end{bmatrix}.
$$

The closed-loop system has the same bifurcation as its reduced system on the center manifold. The reduced system is $\dot z=f_c(z,\mu)$, where $f_c(z,\mu)$ is obtained by substituting $x=\pi(z,\mu)$ into the z dynamical equation in (3.6)–(4.21). It has the following approximation:

$$
f_c(z,\pi,\mu)=\begin{bmatrix} z & \pi_1 & \mu \end{bmatrix}Q\begin{bmatrix} z & \pi_1 & \mu \end{bmatrix}^T+f_1^{[3]}(z,\pi^{[1]},\mu)+O(z,\mu)^4. \tag{4.28}
$$

From (4.27), we have

$$
\begin{bmatrix} z & \pi_1^{[1]} & \mu \end{bmatrix}Q\begin{bmatrix} z & \pi_1^{[1]} & \mu \end{bmatrix}^T=\frac{1}{a_1^2}\begin{bmatrix} z & \mu \end{bmatrix}\bar Q\begin{bmatrix} z & \mu \end{bmatrix}^T. \tag{4.29}
$$

Therefore,

$$
\begin{aligned}
&\frac{\partial f_c}{\partial z}(0,0)=0, \quad \frac{\partial f_c}{\partial \mu}(0,0)=0,\\
&\frac{\partial^2 f_c}{\partial z^2}(0,0)=\frac{2}{a_1^2}Q_1(a_1,-a_z),\\
&\frac{\partial^2 f_c}{\partial z\mu}(0,0)=\frac{1}{a_1^2}\begin{bmatrix} a_1 & -a_z & 0 \end{bmatrix}Q\begin{bmatrix} 0 & -a_\mu & a_1 \end{bmatrix}^T.
\end{aligned}
\tag{4.30}
$$

From (4.27) and (4.24), we have

$$
\begin{bmatrix} z & \pi_1^{[1]}(z,0) & 0 \end{bmatrix}Q_{fb}\begin{bmatrix} z & \pi_1^{[1]}(z,0) & 0 \end{bmatrix}^T=\alpha_{zx_1}^{[2]}\Big(z,-\frac{a_z}{a_1}z\Big)=\frac{1}{a_1^2}\alpha_{zx_1}^{[2]}(a_1,-a_z)z^2,
$$

$$
\begin{bmatrix} z & \pi_1^{[1]}(z,0) & 0 \end{bmatrix}Q\begin{bmatrix} z & \pi_1^{[1]}(z,0) & 0 \end{bmatrix}^T=Q_1\Big(z,-\frac{a_z}{a_1}z\Big)=\frac{1}{a_1^2}Q_1(a_1,-a_z)z^2=0,
$$

$$
f_1^{[3]}(z,\pi^{[1]}(z,0),0)=C\Big(z,-\frac{a_z}{a_1}z\Big)=\frac{1}{a_1^3}C(a_1,-a_z)z^3. \tag{4.31}
$$

Equations (4.31) and (4.27) imply

$$
\pi_1(z,0)=-\frac{a_z}{a_1}z-\frac{1}{a_1^3}\alpha_{zx_1}^{[2]}(a_1,-a_z)z^2. \tag{4.32}
$$

In order to find the coefficient of z^3 in $f_c(z, \pi(z,0),0)$, we substitute the formulae of $f_1^{[3]}(z, \pi^{[1]}(z,0),0)$ and $\pi_1(z,0)$ in (4.31) and (4.32) into (4.28). The substitution yields

$$\frac{\partial^3 f_c}{\partial z^3}(0,0) = \frac{6}{a_1^4}\Big(a_1 C(a_1,-a_z) + (2a_z\gamma_{x_1x_1} - a_1\gamma_{zx_1})\alpha^{[2]}_{zx_1}(a_1,-a_z)\Big) = \frac{6}{a_1^4}D. \tag{4.33}$$

From (4.30), (4.33), (4.24), and (4.25), we have

$$\frac{\partial^2 f_c}{\partial z^2}(0,0) = 0, \qquad \frac{\partial^2 f_c}{\partial z\mu}(0,0) \neq 0, \qquad \frac{\partial^3 f_c}{\partial z^3}(0,0) \neq 0. \tag{4.34}$$

Equations (4.34) and (4.30) imply that the reduced dynamical system on the center manifold satisfies (3.11). Therefore, the system has a pitchfork bifurcation. Furthermore, the bifurcation is supercritical if $D < 0$, and it is subcritical if $D > 0$. □

Since $\alpha^{[2]}_{zx_1}$ is in the feedback, its coefficients are adjustable. There always exist suitable quadratic functions $\alpha^{[2]}_{zx_1}$ which render the pitchfork bifurcation supercritical, provided

$$2a_z\gamma_{x_1x_1} - a_1\gamma_{zx_1} \neq 0. \tag{4.35}$$

This condition is related to the rank of Q_1. From $Q_1(a_1,-a_z) = 0$, we have

$$\begin{bmatrix} a_1, -a_z \end{bmatrix} \begin{bmatrix} \gamma_{zz}a_1 - \frac{\gamma_{zx_1}}{2}a_z & \frac{\gamma_{zx_1}}{2}a_1 - \gamma_{x_1x_1}a_z \end{bmatrix}^T = 0. \tag{4.36}$$

Therefore, if $2a_z\gamma_{x_1x_1} - a_1\gamma_{zx_1} = 0$, (4.36) implies $a_1(\gamma_{zz}a_1 - \frac{\gamma_{zx_1}}{2}a_z) = 0$. Since $a_1 \neq 0$, we have $Q_1 \begin{bmatrix} a_1 & -a_z \end{bmatrix}^T = \begin{bmatrix} 0 & 0 \end{bmatrix}^T$. So, $\operatorname{rank}(Q_1) < 2$. This is equivalent to saying that $\operatorname{rank}(Q_1) = 2$ implies (4.35). Therefore, we have the following.

COROLLARY 4.4. *Suppose that* (3.6)–(4.21) *satisfies* (4.24) *and* (4.25). *If* Q_1 *has full rank, then there exists a quadratic function* $\alpha^{[2]}_{zx_1}(z,x_1)$ *for the nonlinear feedback such that the closed-loop system has a supercritical pitchfork bifurcation.*

Remark. If $C(a_1,-a_z) > 0$, then $\alpha^{[2]}_{zx_1}(z,x_1) = 0$ implies $D < 0$. In this case, a linear feedback renders the pitchfork bifurcation supercritical.

Now we introduce the following model of engine compressors as an example of Theorem 4.1. The system exhibits various bifurcation phenomena (see, for instance, [23], [20], [18], and [6]). The compressor control has been studied by many authors ([19], [20], and [18]). The example introduced here is not for the purpose of proving new results for compressor control. We use the model to illustrate some ideas of feedback design based on the results of this section. In the following, the results obtained in [18] are proved using Theorem 4.1. The simplest model that describes the system is a three-state ODE in Moore and Greitzer [24],

$$\begin{aligned} \dot{R} &= \sigma R(-2\phi - \phi^2 - R), \\ \dot{\phi} &= -\psi - \frac{3}{2}\phi^2 - \frac{1}{2}\phi^3 - 3R\phi - 3R, \\ \dot{\psi} &= \phi - \sqrt{\psi+\psi_0}\Big(\frac{2}{\sqrt{\psi_0}} + \mu + u\Big) + 2, \end{aligned} \tag{4.37}$$

where $R \geq 0$ is the normalized stall cell squared amplitude, ϕ is the mass flow, ψ is the pressure rise, and ψ_0 and σ are constant positive numbers. The control input u can be changed by varying the throttle opening. The system has an uncertain parameter

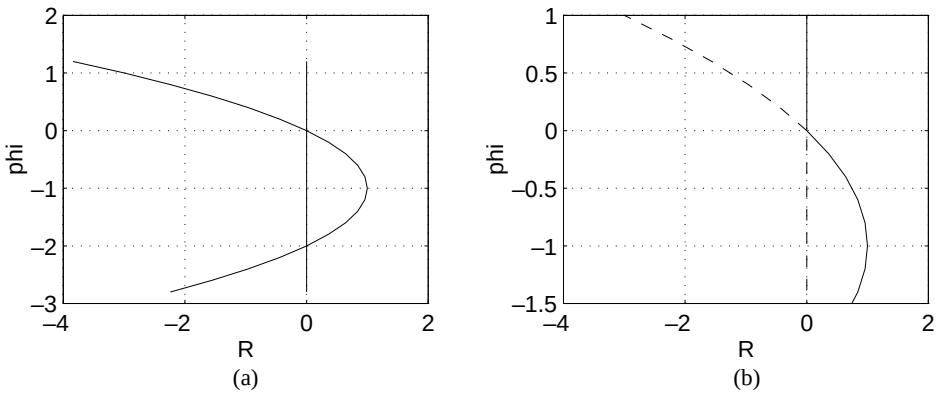

FIG. 4.1. *The equilibrium set of* (4.38).

μ. The values of ϕ, ψ, and u are shifted by a constant [19] so that the origin is the focal bifurcation point. A simple linear change of coordinates $z = R$, $x_1 = \phi$, and $x_2 = -\psi - 3R$ transforms the dynamics into the following system in the form of (2.3).

$$\begin{aligned} \dot{z} &= -2\sigma z x_1 - \sigma z^2 - \sigma z x_1^2, \\ \dot{x}_1 &= x_2 - \frac{3}{2}x_1^2 - \frac{1}{2}x_1^3 - 3zx_1, \\ \dot{x}_2 &= -\frac{3}{\psi_0}z - x_1 - \frac{1}{\psi_0}x_2 + \sqrt{\psi_0}(\mu + u) + O(z, x_1, x_2, \mu, u)^2. \end{aligned} \tag{4.38}$$

Although the quadratic part of the system is not in normal form, the invariant matrices Q and Q_1 are found from the resonant terms

$$Q = \begin{bmatrix} Q_1 & 0 \\ 0 & 0 \end{bmatrix}, \qquad Q_1 = \begin{bmatrix} -\sigma & -\sigma \\ -\sigma & 0 \end{bmatrix}.$$

So Q_1 is indefinite. In zx_1-plane (or equivalently $R\phi$-plane), the graph of the equilibrium set E is shown in Figure 4.1a. The state of the real system always stays in the region $R \geq 0$. Therefore, it is desired to find state feedbacks which render the system asymptotically stable at equilibrium points with $R > 0$. The equilibrium points with $R < 0$ are meaningless. Consider a state feedback

$$u = k_1 R + k_2 \phi + k_3 \psi + O(R, \phi, \psi)^2. \tag{4.39}$$

In the coordinates (z, x_1, x_2), (4.39) is

$$u = (k_1 - 3k_3)z + k_2 x_1 - k_3 x_2 + O(z, x_1, x_2)^2. \tag{4.40}$$

Substituting (4.40) into (4.38), the closed-loop system satisfies

$$a_z = -\frac{3}{\psi_0} + \sqrt{\psi_0}(k_1 - 3k_3), \quad a_1 = -1 + \sqrt{\psi_0}k_2, \quad a_2 = -\frac{1}{\psi_0} - \sqrt{\psi_0}k_3, \quad a_\mu = \sqrt{\psi_0}. \tag{4.41}$$

It is easy to check that

$$Q_1(a_1, -a_z) = -\sigma a_1(a_1 - 2a_z), \qquad \bar{Q} = \sigma \begin{bmatrix} a_1(a_1 - 2a_z) & -a_1 a_\mu \\ -a_1 a_\mu & 0 \end{bmatrix}. \tag{4.42}$$

Equations in (4.42) imply that the conditions in (ii) of Theorem 4.1 are satisfied if $a_1 \neq 2a_z$. Therefore, the bifurcation is transcritical. In the following, we use the result (iii) of Theorem 4.1 to find all feedbacks which stabilize the system at the equilibrium points with $R > 0$. From (4.38), the equilibrium points with $z > 0$ satisfy $z = -(2x_1 + x_1^2)$, and

$$\begin{bmatrix} a_1 & -a_z \end{bmatrix} Q_1 \begin{bmatrix} z & x_1 \end{bmatrix}^T = \sigma\left((a_1 - 2a_z)x_1 + (a_1 - a_z)x_1^2\right), \qquad x_1 < 0. \tag{4.43}$$

So (4.43) and Theorem 4.1 imply that, to guarantee the stability of the system at the equilibrium points with $z > 0$, we need $a_z > \dfrac{a_1}{2}$. Substituting (4.40) into this inequality, we have

$$2k_1 - k_2 - 6k_3 > (6 - \psi_0)/\psi_0^{\frac{3}{2}}. \tag{4.44}$$

Another branch of equilibrium points satisfies $z = 0$, so $\begin{bmatrix} a_1 & -a_z \end{bmatrix} Q_1 \begin{bmatrix} z & x_1 \end{bmatrix}^T = -\sigma a_1 x_1$. On this curve, the closed-loop system is locally asymptotically stable if $x_1 > 0$. In summary, if the feedback (4.39) satisfies Assumption 2.3 and (4.44), then the closed-loop system has a transcritical bifurcation. It is locally asymptotically stable at the equilibrium points where $R > 0$ or $R = 0$ and $\phi > 0$. The closed-loop equilibrium points are shown in Figure 4.1b. The system is locally stable on the solid curve, and unstable on the dotted curve.

If the scaled amplitude of the rotating stall cell is adopted as a state to replace R, the system model has a pitchfork bifurcation at the critical point. Its normal form and invariants satisfy the conditions in Corollary 4.4. Stabilization feedbacks obtained in [20] and [18] for the pitchfork bifurcation can be derived based on the invariants and Corollary 4.4. Details are omitted for the reason of space.

5. Bifurcations of system (2.3). In this section, bifurcations of (2.3) with both quadratic and cubic degeneracy are addressed. The results are summarized in Table 1. The bifurcations are classified based on the number $Q_1(a_1, -a_z)$. It was proved in [15] that the equilibrium set E of (2.3) is approximately a paraboloid or a saddle defined by

$$\mu + Q_1(z, x_1) = 0. \tag{5.1}$$

The set of closed-loop equilibrium points, E_c, is approximately the intersection between (5.1) and the plane

$$a_z z + a_1 x_1 + a_\mu \mu = 0, \tag{5.2}$$

where a_z, a_1, and a_μ are the coefficients in (2.6). Therefore, E_c is a quadratic curve. The following theorem proves that the closed-loop system has a saddle-node bifurcation. The stability of the system is characterized by the location of the closed-loop equilibrium points. Define two subsets, E_- and E_+, of the open loop equilibrium set E by

$$E_- = \{(z, x, \mu) \in E | Q_1(z, x_1)z < 0\}, \qquad E_+ = \{(z, x, \mu) \in E | Q_1(z, x_1)z > 0\}. \tag{5.3}$$

The following theorem proves that $E_c \cap E_-$ consists of stable equilibrium points and $E_c \cap E_+$ consists of unstable equilibrium points. The origin is the border between the two parts.

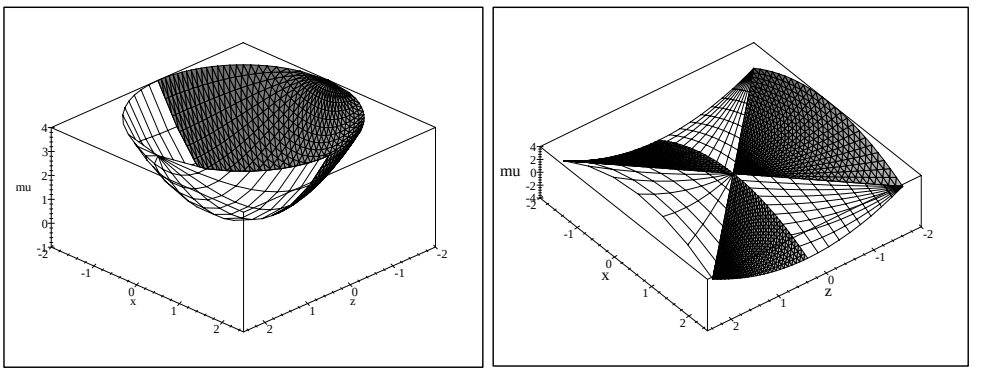

FIG. 5.1. *The gridded area is E_-. The shaded area is E_+.*

THEOREM 5.1. *Consider a closed-loop system* (2.3)–(2.6) *satisfying Assumption* 2.3. *Suppose*

$$Q_1(a_1, -a_z) \neq 0. \tag{5.4}$$

(i) *The system has a saddle-node bifurcation at the origin. The set E_c satisfies*

$$\begin{aligned} x_1 &= -\frac{a_z}{a_1} z + O(z)^2, \qquad & \mu &= -\frac{1}{a_1^2} Q(a_1, -a_z) z^2 + O(z)^3, \\ x_i &= O(z)^2, & i &= 2, \ldots, n-1. \end{aligned} \tag{5.5}$$

(ii) *The closed-loop system is locally asymptotically stable at the points in $E_c \cap E_-$ and the system is unstable at the points in $E_c \cap E_+$. In a neighborhood of the origin,*

$$E_c = (E_c \cap E_-) \cup (E_c \cap E_+) \cup \{(z, x, \mu) = (0, 0, 0)\}. \tag{5.6}$$

Condition (5.4) is always true if Q_1 is sign definite. If Q_1 is indefinite, E is approximately a saddle. Condition (5.4) implies that the plane (5.2) does not meet (5.1) on a line in the zx_1-plane. If (5.4) is false, E_c is not a quadratic curve of μ. This case is addressed later in this section.

Remark. Geometrically, the sets E_- and E_+ are simple. In [15] and [16], it was proved that the open loop equilibrium set E is approximately either a paraboloid or a saddle given by (5.1). In the case of a paraboloid, Q_1 is sign definite. So E_- and E_+ are simply the half paraboloid given by $z > 0$ and $z < 0$ (Figure 5.1a). In the case of a saddle, the set $Q_1(z, x)z = 0$ consists of three planes in $zx_1\mu$-space given by $Q_1(z, x) = 0$ and $z = 0$. They divide E into six parts. Three of them form E_- and the others form E_+. A point is in $E_c \cap E_-$ (or $E_c \cap E_+$) if and only if $\mu z > 0$ (or $\mu z < 0$) (Figure 5.1b).

LEMMA 5.2. *If $n \geq 3$, the center manifold of a system* (3.7)–(2.6) *has the form*

$$x_1 = -\frac{a_z}{a_1} z - \frac{1}{a_1}\left(a_\mu - \frac{a_2 a_z}{a_1}\right)\mu + O(z, \mu)^2, \qquad x_2 = -\frac{a_z}{a_1}\mu + O(z, \mu)^2, \tag{5.7}$$

and $x_i = O(z, \mu)^2$ for $i \geq 3$. The reduced system on center manifold is defined by

$$\begin{aligned} f_c(z, \mu) = \mu &+ Q_1\left(z, -\frac{a_z}{a_1} z - \frac{1}{a_1}\left(a_\mu - \frac{a_2 a_z}{a_1}\right)\mu\right) \\ &+ \gamma_{x_2 x_2} \frac{a_z^2}{a_1^2}\mu^2 + \gamma_{x_1 \mu}\left(-\frac{a_z}{a_1} z - \frac{1}{a_1}\left(a_\mu - \frac{a_2 a_z}{a_1}\right)\mu\right)\mu + O(z, \mu)^3. \end{aligned} \tag{5.8}$$

Proof. The center manifold $x = \pi(z, \mu)$ satisfies the equation

$$A\pi(z,\mu) + Bu(z,\pi,\mu) + O(z,\pi,\mu)^2 = \frac{\partial \pi}{\partial z}(\mu + O(z,\pi,\mu)^2).$$

Formula (5.7) is obtained by solving the linearization of this equation. The reduced dynamical system on the center manifold is derived by substituting (5.7) into the z dynamical equation in (3.7). □

Proof. The proof of Theorem 5.1. (i) Since (5.4) and (5.5) are invariant under (3.1), we prove Theorem 5.1 for systems in the normal form (3.7). To find E_c, we set the dynamics in the closed-loop system to be zero. Solving the linear and quadratic parts of the equations yields

$$x_1 = -\frac{a_z}{a_1} z - \frac{a_\mu}{a_1}\mu + O(z,\mu)^2, \qquad x_i = O(z,\mu)^2, \;\; i = 2, \ldots, n-1, \tag{5.9}$$

where a_1 is not zero (Lemma 2.4). Substitute this into the following equation:

$$\mu + \sum_{i=2}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{x_1 \mu} x_1 \mu + Q_1(z, x_1) + O(z, x, \mu, u)^3 = 0.$$

Therefore, $\mu = -\dfrac{1}{a_1^2} Q_1(a_1, -a_z) z^2 + O(z)^3$. This relation and (5.9) imply the condition (5.5).

To study the bifurcation, we focus on the center manifold. From (5.8), the following relation can be derived.

$$\frac{\partial f_c}{\partial z}(0,0) = 0, \qquad \frac{\partial f_c}{\partial \mu}(0,0) = 1 \neq 0, \qquad \frac{\partial^2 f_c}{\partial z^2}(0,0) = \frac{2}{a_1^2} Q(a_1, -a_z) \neq 0. \tag{5.10}$$

From (ii) of Theorem 3.3, the closed-loop system has a saddle-node bifurcation.

(ii) We prove (5.6) first. It is known that the points in E_c satisfy (5.5). Substituting (5.5) into $Q_1(z, x_1)z$, we have

$$Q_1(z, x_1) z = \frac{1}{a_1^2} Q_1(a_1, -a_z) z^3 + O(z)^4. \tag{5.11}$$

Notice that $Q_1(a_1, -a_z) \neq 0$. This implies that locally the points in E_c satisfy $Q_1(z, x_1)z \neq 0$ if $z \neq 0$. Therefore, (5.6) holds. To prove the stability properties claimed in Theorem 5.1, it is enough to show that (5.8) is locally stable at points in $E_c \cap E_-$ and unstable in $E_c \cap E_+$. From (5.5) and (5.8), it can be proved that at a point in E_c,

$$\frac{\partial f_c}{\partial z} = \frac{2}{a_1^2} Q_1(a_1, -a_z) z + O(z)^2. \tag{5.12}$$

Therefore, (5.8) is locally asymptotically stable when $Q_1(a_1, -a_z)z < 0$. From (5.11), the sign of $Q_1(a_1, -a_z)z$ is the same as the sign of $Q_1(z, x_1)z$ for points in E_c. Therefore, (5.8) is locally stable at any point in $E_c \cap E_-$. Similarly, (5.8) is unstable at any point in $E_c \cap E_+$. □

Remark. From (5.12), it is obvious that the closed-loop system is asymptotically stable at $(z, x, \mu) \in E_c$ if $Q_1(a_1, -a_z)$ and z have opposite sign. This is another way to test the stability.

The feedback in Theorem 5.1 is smooth. A saddle-node bifurcation occurs. The system has unstable equilibrium points around the origin. Furthermore, there is no closed-loop equilibrium point for either $\mu > 0$ or $\mu < 0$. In the following, C^0 feedbacks are employed under which the closed-loop system has a unique equilibrium point for any value of μ, no matter if μ is positive or negative. And the C^0 feedback renders the system locally stable at all the equilibrium points. In fact, a continuous (but not differentiable at $z = 0$) feedback can place all the closed-loop equilibrium points around the origin inside E_-. The C^0 feedback is

$$\alpha(z, x, \mu) = a_z|z| + a_1x_1 + \cdots + a_{n-1}x_{n-1} + a_\mu x_\mu + O(z, x, \mu)^2, \tag{5.13}$$

where $|z|$ is not differentiable, and the rest of the function is C^k for some $k \geq 1$.

THEOREM 5.3. *Consider* (2.3)–(5.13) *satisfying Assumption* 2.3. *Suppose* a_z *satisfies*

$$Q_1(a_1, -a_z) < 0, \quad Q_1(a_1, a_z) > 0. \tag{5.14}$$

Then, in a neighborhood of $(z, x, \mu) = (0, 0, 0)$, (2.3)–(5.13) *has a unique equilibrium point for every value of* μ. *The equilibrium point is stable if* $\mu \neq 0$.

The quadratic form $Q_1(x, y)$ has both positive and negative values if it is indefinite. The region in the xy-plane defined by $Q_1(x, y) > 0$ has two connected pieces. If the region is not symmetric with respect to the x-axis, there always exists an a_z satisfying (5.14). If $Q_1(x, y)$ is positive or negative definite, E is a paraboloid (Figure 5.1a). It is impossible to obtain equilibrium points in E_c for both $\mu < 0$ and $\mu > 0$, no matter what kind of feedback is used.

Remark. The theorem does not claim the stability at $\mu = 0$. In fact, the unique equilibrium at $\mu = 0$ is $(z, x) = (0, 0)$. However, the system is not smooth at $z = 0$. Therefore, the theory of center manifold is not applicable. The justification of the stability at $\mu = 0$ requires tools of nonsmooth vector fields. For some special cases, the stability at $\mu = 0$ is obvious. For example, if $f_1(z, x, \mu) = 0$ and $g_1(z, x, \mu) = 0$ at all the points $(z, x, \mu) = (0, x, 0)$, then the subspace $z = 0$ is an invariant submanifold. It follows a standard argument that, on each side of $z = 0$, the performance of the system is equivalent to a smooth vector field. The stability is guaranteed by the center manifold theory.

Proof. The feedback is equivalent to

$$\alpha(z, x, \mu) = \begin{cases} a_z z + a_1x_1 + \cdots + a_{n-1}x_{n-1} + a_\mu x_\mu + O(z, x, \mu)^2 & \text{if } z \geq 0, \\ -a_z z + a_1x_1 + \cdots + a_{n-1}x_{n-1} + a_\mu x_\mu + O(z, x, \mu)^2 & \text{if } z < 0. \end{cases}$$

From (5.5), the closed-loop equilibrium points are

$$\begin{aligned} \mu &= \begin{cases} -\dfrac{1}{a_1^2}Q(a_1, -a_z)z^2 + O(z)^3 & \text{if } z \geq 0, \\ -\dfrac{1}{a_1^2}Q(a_1, a_z)z^2 + O(z)^3 & \text{if } z < 0, \end{cases} \\ x_1 &= -\frac{a_z}{a_1}|z| + O(z)^2, \quad x_i = O(z)^2, \ \ i = 2, \ldots, n-1. \end{aligned} \tag{5.15}$$

The condition (5.14) and the first equation of (5.15) imply that the sign of μ at any equilibrium point is the same as the sign of z. Therefore, there exist equilibrium points on both sides of $\mu = 0$. Since the first equation of (5.15) is locally a one-to-one correspondence, (2.3)–(5.13) has a unique equilibrium point for every value of μ.

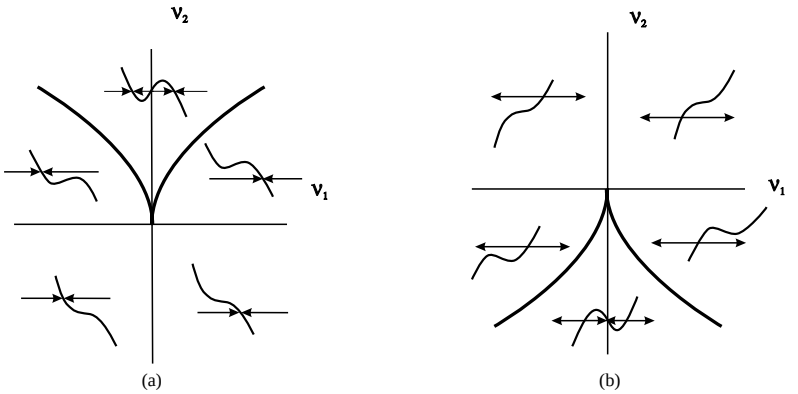

FIG. 5.2. *A cusp and some phase portraits of* $f(z, \nu_1, \nu_2)$. $D_3(0) < 0$ *in* (a); $D_3(0) > 0$ *in* (b).

To study the stability, the reduced system on the center manifold $\dot{z} = f_c(z, \mu)$ is used, where $f_c(z, \mu)$ is defined by (5.8). From (5.12), we have

$$\frac{\partial f_c}{\partial z}(z, \mu) = \begin{cases} \dfrac{2}{a_1^2} Q_1(a_1, -a_z) z + O(z)^2, & z > 0, \\ \dfrac{2}{a_1^2} Q_1(a_1, a_z) z + O(z)^2, & z < 0. \end{cases}$$

This relation and the condition (5.14) imply that $\dfrac{\partial f_c}{\partial z}(z, \mu) < 0$ at every closed-loop equilibrium point with $\mu \neq 0$. So the system is stable at equilibrium points with $\mu \neq 0$. □

The feedback in Theorems 5.1 and 5.3 satisfies $Q_1(a_1, -a_z) \neq 0$. If it does not hold, the quadratic part of a vector field is degenerate. We focus on this case in the rest of this section. Before the next theorem is introduced, it is necessary to review the bifurcation with a cusp equilibrium set. Consider a one-dimensional system with two parameters ν_1 and ν_2:

$$\begin{aligned} &\dot{z} = f(z, \nu_1, \nu_2) = \nu_1 + \nu_2 z + D_2(\nu_1, \nu_2) z^2 + D_3(\nu_1, \nu_2) z^3 + O(z)^4, \\ &D_2(0, 0) = 0, \qquad D_3(0, 0) \neq 0. \end{aligned} \tag{5.16}$$

The system has cubic degeneracy. Following [10], the set of degenerate equilibrium points is defined by $f(z, \nu_1, \nu_2) = 0$ and $\dfrac{\partial f}{\partial z}(z, \nu_1, \nu_2) = 0$. It is a cusp approximated by

$$\nu_2^3 = -27 D_3(0, 0) \nu_1^2 / 4. \tag{5.17}$$

Following [10], the stability around the cusp is illustrated in Figure 5.2. The solid cusp represents (5.17). The cubic curves in Figure 5.2 represent the graphs of $y = f(z, \nu_1, \nu_2)$ for a pair of fixed values (ν_1, ν_2) in different regions. In Figure 5.2a, $D_3(0, 0)$ is less than zero. In Figure 5.2b, $D_3(0, 0)$ is positive. A system with $D_3(0, 0) < 0$ performs more stably than otherwise.

Now let's consider (3.7) with the feedback (4.21). It is proved that the system has a saddle-node bifurcation if $Q_1(a_1, -a_z) \neq 0$. If $Q_1(a_1, -a_z) = 0$, the center manifold

of the closed-loop system is $x_i = \pi_i(z,\mu)$ for $i = 1,\dots,n-1$. Its linear and quadratic parts are

$$\pi_1^{[1]}(z,\mu) = -\frac{a_z}{a_1}z - \frac{1}{a_1}\left(a_\mu - \frac{a_2 a_z}{a_1}\right)\mu, \pi_2^{[1]}(z,\mu) = -\frac{a_z}{a_1}\mu, \quad \pi_i^{[1]}(z,\mu) = 0 \text{ for } i \geq 3,$$

$$\pi_1^{[2]}(z,0) = -\frac{1}{a_1^3}\alpha_{zx_1}^{[2]}(a_1,-a_z)z^2, \qquad \pi_2^{[2]}(z,0) = 0,\dots,\pi_{n-1}^{[2]}(z,0) = 0, \tag{5.18}$$

in which $\alpha_{zx_1}^{[2]}$ is defined by (4.21) and (4.22). We only consider the case $n \geq 3$, which is slightly different from $n = 2$. The argument for $n = 2$ is similar. Substituting $x = \pi(z,\mu)$ into the uncontrollable part in (3.7)–(4.21), the reduced system on the center manifold is

$$\begin{aligned} \dot{z} &= f_c(z,\mu), \\ f_c(z,\mu) &= \mu + \sum_{i=2}^{n-1}\gamma_{x_i x_i}\pi_i^2 + \gamma_{x_1\mu}\pi_1\mu + Q_1(z,\pi_1) \\ &\quad + f_1^{[3]}(z,\pi,\mu) + g_1^{[2]}(z,\pi,\mu)\alpha(z,\pi,\mu) + O(z,\pi,\mu)^3. \end{aligned} \tag{5.19}$$

Substitute (5.18) into f_c. The expansion of f_c in z is

$$f_c(z,\mu) = D_0(\mu) + D_1(\mu)z + D_2(\mu)z^2 + D_3(\mu)z^3 + \cdots, \tag{5.20}$$

$$D_0(\mu) = \mu + O(\mu)^2, \ \ D_1(\mu) = O(\mu), \ \ D_2(\mu) = \frac{1}{a_1^2}Q_1(a_1,-a_z) + O(\mu) = O(\mu), \tag{5.21}$$

$$D_3(0) = \frac{1}{a_1^3}C(a_1,-a_z) + \frac{1}{a_1^4}(2a_z\gamma_{x_1x_1} - a_1\gamma_{zx_1})\alpha_{zx_1}^{[2]}(a_1,-a_z) = D, \tag{5.22}$$

where $C(a_1,-a_z)$ is defined by (4.20). The notation D is introduced in (4.23). In the following, we introduce the unfolding of (5.20). Let ν_1 and ν_2 be the parameters which replace the coefficients of lower degree terms in (5.20). The unfolding system is

$$\dot{z} = \tilde{f}_c(z,\nu_1,\nu_2) = \nu_1 + \nu_2 z + \tilde{D}_2(\nu_1)z^2 + \tilde{D}_3(\nu_1)z^3 + \cdots, \tag{5.23}$$

$$\nu_1 = D_0(\mu), \quad \nu_2 = D_1(\mu). \tag{5.24}$$

where $\tilde{D}_2(\nu_1) = D_2(D_0^{-1}(\nu_1))$ and $\tilde{D}_3(\nu_1) = D_3(D_0^{-1}(\nu_1))$. This system is in the form of (5.16). Its bifurcation diagram is illustrated in Figure 5.2. From (5.21), we have $\nu_2 = O(\nu_1)$. Therefore, the curve (5.24) and the cusp intersect at the origin. The curve (5.24) is transversal to the ν_2-axis. Therefore, the curve does not get inside the cusp area because both curves of the cusp are tangent to the ν_2-axis (see Figure 5.3). Around the origin, (5.19) has a unique equilibrium point for every value of μ. From (5.22), the system is always stable if $D < 0$.

THEOREM 5.4. *Consider* (3.7)–(4.21) *satisfying Assumption* 2.3. *Suppose*

$$\begin{aligned} &Q_1(a_1,-a_z) = 0, \\ &D \neq 0. \end{aligned} \tag{5.25}$$

(i) *The system has no bifurcation. There exists a neighborhood of* $(z,x,\mu) = (0,0,0)$ *in which* (3.7)–(4.21) *has a unique closed-loop equilibrium point for any value of* μ.

(ii) *The system* (3.7)–(4.21) *is stable if* $D < 0$. *It is unstable if* $D > 0$.

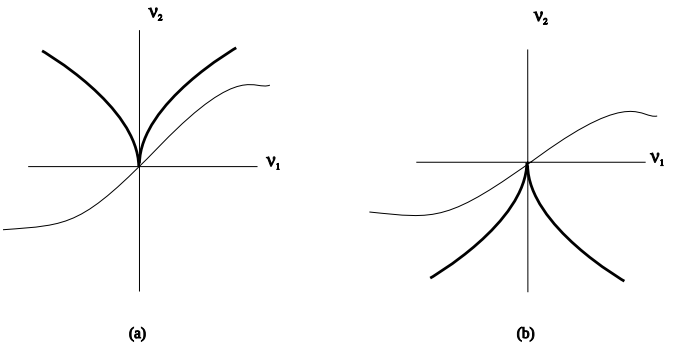

FIG. 5.3. *The picture of the cusp* (5.17) *and the curve* (5.25).

Remark. Notice that the inequality $D < 0$ is also a condition in Theorem 4.3. From the proof of Corollary 4.4, stabilizing feedbacks can be found for the system (3.7)–(4.21) around the cusp, provided that Q_1 has full rank.

The result in Theorem 5.4 can be proved without embedding it into the cusp bifurcation. However, the embedding becomes critical when more complicated cases are considered. For example, if the control $\alpha(z, x, \mu)$ is not zero at the origin, a two-dimensional diagram is required for the analysis as shown in the next section.

6. Closed-loop system with a perturbed feedback. In the previous sections, all feedbacks are assumed to be zero at the origin. However, bifurcations can be qualitatively changed if the feedback does not vanish at the origin. A feedback which is not zero at the origin is treated as a perturbed feedback,

$$u = \alpha(z, x, \mu) + \nu, \tag{6.1}$$

where $\alpha(z, x, \mu)$ satisfies $\alpha(0, 0, 0) = 0$ and Assumption 2.3. The parameter ν is a perturbation.

6.1. System (2.3). It is proved in section 4 that (2.2)–(6.1) has a transcritical bifurcation at $\nu = 0$ if $\det(\bar{Q}) < 0$. From the imperfection theory, two saddle-node bifurcations are generated at the critical point if the symmetry in the system is broken.

THEOREM 6.1. *Consider a control system* (2.2) *with* $\det(Q) \neq 0$. *Suppose that* $\alpha(z, x, \mu)$ *satisfies* (ii) *of Theorem* 4.1. *For any fixed value of* ν *around* $\nu = 0$, (2.2)–(6.1) *is a system with a single parameter* μ. *It has two saddle-node bifurcations around the origin if* $\nu \neq 0$. *The bifurcation diagram of* (2.2)–(6.1) *in* $z\mu$*-plane is shown in Figure* 6.1.

Proof. Given the normal form (3.6) with the feedback (6.1), its center manifold satisfies

$$x_1 = -\frac{a_z}{a_1} z - \frac{a_\mu}{a_1}\mu - \frac{1}{a_1}\nu + O(z, \mu, \nu)^2, \qquad x_i = O(z, \mu, \nu)^2 \quad \text{for } i \geq 2. \tag{6.2}$$

Denote

$$P = \begin{bmatrix} 1 & 0 & 0 \\ -a_z/a_1 & -a_\mu/a_1 & 1/a_1 \\ 0 & 1 & 0 \end{bmatrix}, \qquad P^T Q P = \begin{bmatrix} \bar{Q} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix},$$

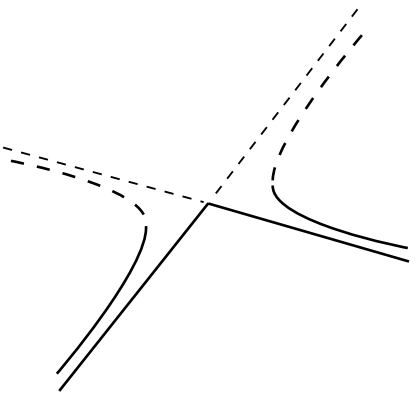

FIG. 6.1. *The bifurcation diagram of the closed-loop system for a fixed value of ν. At $\nu = 0$, it is a transcritical bifurcation. At $\nu \neq 0$, it consists of two saddle-node bifurcations.*

where $\bar{Q}$ is defined by (4.1), $Q_{12}^T = Q_{21}$, and the reduced system on the center manifold is

$$\dot{z} = \begin{bmatrix} z & \mu & \nu \end{bmatrix} P^T Q P \begin{bmatrix} z & \mu & \nu \end{bmatrix}^T + O(z,\mu,\nu)^3. \tag{6.3}$$

Define $\begin{bmatrix} \bar{z} & \bar{\mu} \end{bmatrix} = \begin{bmatrix} z & \mu \end{bmatrix} + Q_{21}\bar{Q}^{-1}\nu$; then

$$\dot{\bar{z}} = (Q_{22} - Q_{21}\bar{Q}^{-1}Q_{12})\nu^2 + \begin{bmatrix} \bar{z} & \bar{\mu} \end{bmatrix} \bar{Q} \begin{bmatrix} \bar{z} & \bar{\mu} \end{bmatrix}^T + O(\bar{z},\bar{\mu},\bar{\nu})^3. \tag{6.4}$$

Since Q has full rank, it is easy to check that $Q_{22} - Q_{21}\bar{Q}^{-1}Q_{12} \neq 0$. The bifurcation of (6.4) at $\nu \neq 0$ is the ν perturbation of a transcritical bifurcation. In the imperfection theory (see, for instance, [26] or [9]), it was proved that two saddle-node bifurcations are generated around the critical point (Figure 6.1). □

6.2. System (3.7). Consider (3.7). If the invariant quadratic form $Q_1(z, x_1)$ is positive or negative definite, the equilibrium set of (3.7) is a paraboloid. Its intersection with the surface $\nu + \alpha(z, x, \mu) = 0$ is the set of closed-loop equilibrium points. It is approximately a quadratic curve for any value of ν around zero. Furthermore, the closed-loop system has a saddle-node bifurcation for small values of μ. Therefore, the perturbation does not qualitatively change the bifurcation. Another case is more interesting in which $Q_1(z, x_1)$ is not sign definite and $Q_1(a_1, -a_z) = 0$. In this case, it is proved in the following that the system's performance can be dramatically changed by the perturbation. On one side of $\nu = 0$, the system has no bifurcation. And on the other side, the system exhibits the hysteresis phenomenon. Since the case for $n = 2$ is similar to the case $n \geq 3$, we only prove the result for $n \geq 3$. The center manifold of (3.7)–(6.1) and the reduced system satisfy

$$\begin{aligned} x_1 &= -\frac{a_z}{a_1} z - \frac{a_1 a_\mu - a_2 a_z}{a_1^2}\mu - \frac{1}{a_1}\nu + O(z,\mu)^2, \\ x_2 &= -\frac{a_z}{a_1}\mu + O(z,\mu)^2,\ x_i = O(z,\mu)^2 \text{ for } i \geq 3, \\ \dot{z} &= f_c(z,\mu,\nu) = \nu_1 + \nu_2 z + D_2(\mu,\nu)z^2 + Dz^3 + \cdots, \end{aligned}$$

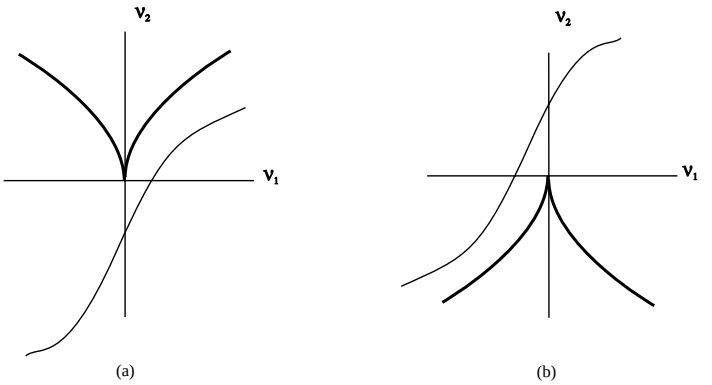

FIG. 6.2. *The figure of* $(\nu_1, \nu_2) = (D_1(\mu, \nu), D_2(\mu, \nu))$ *for a fixed value of* ν.

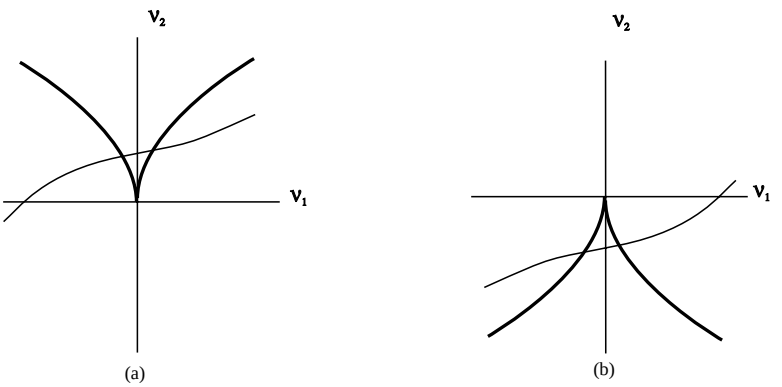

FIG. 6.3. *The figure of* $(\nu_1, \nu_2) = (D_1(\mu, \nu), D_2(\mu, \nu))$ *for a fixed value of* ν.

where D is defined by (4.23), and

$$
\begin{aligned}
\nu_1 &= \mu + O(\mu, \nu)^2, \\
\nu_2 &= \left(\frac{2\gamma_{x_1x_1} a_z - \gamma_{zx_1} a_1}{a_1^2} \left(a_\mu - \frac{a_2 a_z}{a_1} \right) - \frac{\gamma_{x_1\mu} a_z}{a_1} \right) \mu \\
&\quad + \frac{2a_z \gamma_{x_1x_1} - a_1 \gamma_{zx_1}}{a_1^2} \nu + \cdots.
\end{aligned} \tag{6.5}
$$

For any fixed value of ν, (6.5) represents a curve in the $\nu_1\nu_2$-plane. The bifurcation of (3.7)–(6.1) is determined by this curve and the cusp (5.17). If $(2a_z\gamma_{x_1x_1} - a_1\gamma_{zx_1})\nu$ and D have the same signs, then (6.5) and (5.17) have no intersection around the origin (see Figure 6.2). From the cusp bifurcation diagram (Figure 5.2), we know that no bifurcation occurs around the origin. If $(2a_z\gamma_{x_1x_1} - a_1\gamma_{zx_1})\nu$ and D have opposite sign, then the curve (6.5) meets with (5.17) at two different points (see Figure 6.3). Suppose that (6.5) intersects (5.17) at $\mu_1 < 0$ and $\mu_2 > 0$. Then the system has one equilibrium point for $\mu < \mu_1$ or $\mu > \mu_2$. There exist three equilibrium points if $\mu_1 < \mu < \mu_2$. The bifurcation diagram is shown in Figure 6.4, which is called a hysteresis [26]. We summarize the results in the following theorem.

THEOREM 6.2. *Consider* (3.7)–(6.1) *in which* $\alpha(z, x, \mu)$ *satisfies Assumption* 2.3 *and* (5.25). *Fix any value for* ν *around* $\nu = 0$, *and* (3.7)–(6.1) *has the following*

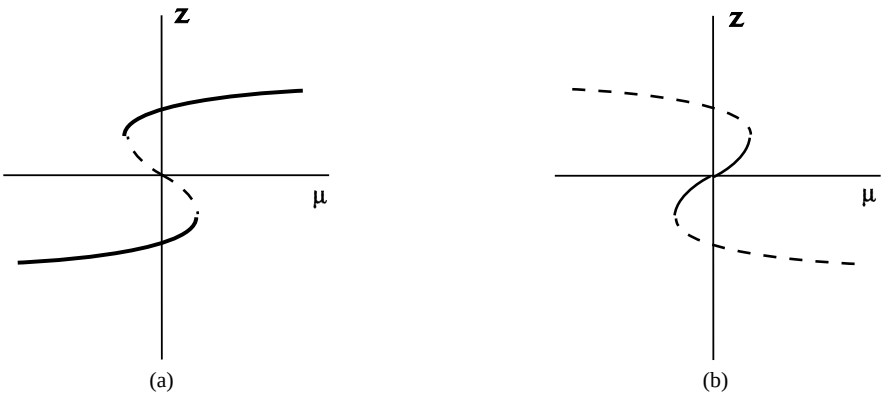

FIG. 6.4. *The hysteresis. In* (a), $D < 0$. *In* (b), $D > 0$.

properties.

(i) *If* $(2a_z\gamma_{x_1x_1} - a_1\gamma_{zx_1})D\nu > 0$, (3.7)–(4.21) *has no bifurcation around the origin and* $\mu = 0$. *There exists a neighborhood of* $(z, x, \mu) = (0, 0, 0)$ *in which the system has a unique closed-loop equilibrium point for every value of* μ. *Furthermore, the system is stable if* $D < 0$, *and the system is unstable if* $D > 0$.

(ii) *If* $(2a_z\gamma_{x_1x_1} - a_1\gamma_{zx_1})D\nu < 0$, *the system exhibits hysteresis. Its stability is determined by the value of* D *as shown in Figure* 6.4.

7. Conclusion. In this paper, the problem of bifurcation control by nonlinear state feedbacks is studied thoroughly. Based on normal forms and invariants, all bifurcations exhibited in the performance of nonlinear control systems with a zero uncontrollable mode are studied. Feedbacks can be designed based on the results to achieve the stability or to achieve the desired bifurcation pattern. It is proved in section 4 that systems having the normal form (3.6) exhibit a transcritical bifurcation or a pitchfork bifurcation. The transcritical bifurcation can be converted into a supercritical pitchfork bifurcation by using state feedbacks. In section 5, it is proved that systems with the normal form (3.7) have a saddle-node bifurcation. It can be locally removed by a C^0 state feedback, provided that the equilibrium set is a saddle. If the closed-loop system satisfies the cubic degeneracy condition $(Q_1(a_1, -a_z) = 0, D \neq 0)$, the saddle-node bifurcation is also locally removable by feedbacks. Its closed-loop equilibrium set can be embedded into the diagram of a cusp. Under feedbacks which are not zero at the critical point, it is shown in section 6 that a transcritical bifurcation of (3.6) is bifurcated into two saddle-node bifurcations. For the system (3.7) with cubic degeneracy, it has either a hysteresis or no bifurcation, depending on the value of the feedback at the critical point. All the conditions on bifurcations and their stability are characterized by invariants and the coefficients in the feedback. The results obtained in sections 4 and 5 draw a complete picture of bifurcations under smooth feedbacks which are zero at the critical point. This is summarized in Table 1.

The approach based on control system normal forms can certainly be used for the study of other bifurcations which are not addressed here. For instance, the normal form of control systems with a pair of imaginary uncontrollable modes or with a double zero uncontrollable mode are available [7]. The control of the Hopf bifurcation and the double zero bifurcation based normal form is part of our future research.

SPECTRAL ANALYSIS OF FOKKER–PLANCK AND RELATED OPERATORS ARISING FROM LINEAR STOCHASTIC DIFFERENTIAL EQUATIONS*

DANIEL LIBERZON† AND ROGER W. BROCKETT‡

Abstract. We study spectral properties of certain families of linear second-order differential operators arising from linear stochastic differential equations. We construct a basis in the Hilbert space of square-integrable functions using modified Hermite polynomials, and obtain a representation for these operators from which their eigenvalues and eigenfunctions can be computed. In particular, we completely describe the spectrum of the Fokker–Planck operator on an appropriate invariant subspace of rapidly decaying functions. The eigenvalues of the Fokker–Planck operator provide information about the speed of convergence of the corresponding probability distribution to steady state, which is important for stochastic estimation and control applications. We show that the operator families under consideration can be realized as solutions of differential equations in the double bracket form on an operator Lie algebra, which leads to a simple expression for the flow of their eigenfunctions.

Key words. modified Hermite polynomials, linear stochastic differential equation, Fokker–Planck operator, double bracket equation

1. Introduction.

Given a system of stochastic differential equations, one can associate with it a (deterministic) partial differential equation which describes the evolution of the probability density with time. This so-called *Fokker–Planck equation* takes the form

$$\frac{\partial \rho}{\partial t} = L\rho, \tag{1}$$

where L is a second-order linear differential operator known as the *Fokker–Planck operator*. If $g_0, g_1, g_2, \ldots$ are the eigenfunctions of L corresponding to distinct eigenvalues $\lambda_0, \lambda_1, \lambda_2, \ldots$, then the solution of (1) with initial condition

$$\rho(0,x) = \sum_{i=0}^{\infty} \alpha_i g_i(x), \qquad \alpha_i \in \mathbb{R},$$

is given by

$$\rho(t,x) = \sum_{i=0}^{\infty} \alpha_i e^{\lambda_i t} g_i(x).$$

Thus the eigenvalues of the Fokker–Planck operator L, particularly the one with the smallest magnitude, provide information about the speed of convergence of the probability distribution to steady state (when one exists), which is important in stochastic filtering and control applications. For a discussion along these lines and examples, see [3].

In the paper by Holley, Kusuoka, and Stroock [14], and more recently in [7], [8], [9], spectral properties of Fokker–Planck operators associated with certain types of nonlinear stochastic systems were investigated with the view towards applications to function minimization procedures. In this paper we confine our attention to Fokker–Planck operators that correspond to *linear* stochastic differential equations. An understanding of their spectral properties, besides being of interest in its own right, under certain circumstances helps shed some light on the nonlinear case (see [16, p. 88]). As in [14], we consider these operators as acting on a dense subspace of $L^2(\mathbb{R}^n)$ (rather than $L^1(\mathbb{R}^n)$ which might seem more natural from the probabilistic point of view). We apply a standard gauge transformation technique to convert them to self-adjoint operators, which greatly facilitates the analysis.

The paper starts with the one-dimensional case. Motivated by the explicit form of the steady-state probability density, we modify the classical Hermite polynomials by introducing one additional parameter σ (in our context, σ corresponds to the steady-state variance). This construction leads to an orthonormal basis for $L^2(\mathbb{R})$ with respect to which the operators under consideration take a particularly transparent form. The representation thus obtained allows us to compute their eigenvalues and eigenfunctions directly. As a result, we are able to provide a complete description of the spectrum of the Fokker–Planck operator on an appropriate invariant subspace of rapidly decaying functions. We then show that the essential features of this analysis carry over to the multidimensional case and enable us to obtain information about eigenvalues of Fokker–Planck operators in a more general setting.

Moreover, we observe that the operator families parameterized by σ can be described by differential equations on an operator Lie algebra which take the so-called *double bracket* form $\frac{dL}{d\sigma} = [L,[L,M]]$. This leads to a simple expression for the flow of the corresponding eigenfunctions. The study of differential equations in the double bracket form on finite-dimensional Lie algebras was initiated in [2] and [6] in connection with integrable gradient flows and numerical algorithms. It was shown, in particular, that such equations give rise to isospectral flows. In this paper we present what seems to be a new framework in which double bracket equations appear. The corresponding flows on an operator Lie algebra preserve the eigenvalues (actually, the entire spectrum in the self-adjoint case). This property is supported by probabilistic intuition.

The paper is organized as follows. In section 2 we construct an orthonormal basis in $L^2(\mathbb{R})$ using modified Hermite polynomials. In section 3 we study second-order differential operators arising from scalar linear stochastic differential equations. In section 4 we treat the multidimensional case, giving generalizations of the previous results. In section 5 we discuss double bracket differential equations on an operator Lie algebra and indicate connections with some known results on completely integrable gradient flows.

2. Orthonormal bases in $L^2(\mathbb{R})$. It is well known (see, e.g., [15, p. 121]) that the *Hermite functions*

$$u_k(x) = h_k(x)e^{-x^2/2}, \qquad k = 0, 1, \ldots, \tag{2}$$

where $h_k(x) = \frac{1}{\pi^{1/4}\sqrt{2^k k!}}\, e^{x^2}\, \frac{d^k e^{-x^2}}{dx^k}$ are the *Hermite polynomials*, form an orthonormal basis for $L^2(\mathbb{R})$. We consider here the *modified Hermite polynomials*

$$h_k(x,\sigma) := \frac{\sqrt{\sigma^k}}{(\sigma\pi)^{1/4}\sqrt{2^k k!}} e^{x^2/\sigma} \frac{d^k e^{-x^2/\sigma}}{dx^k}\,, \qquad k = 0, 1, \ldots,$$

where $\sigma > 0$ is a real parameter, and introduce the *modified Hermite functions*

$$u_k(x,\sigma) := h_k(x,\sigma) e^{-x^2/2\sigma} = c_k(\sigma) e^{x^2/2\sigma} \frac{d^k e^{-x^2/\sigma}}{dx^k} \tag{3}$$

with constants $c_k(\sigma)$ given by the relations

$$c_k(\sigma) = \frac{\sqrt{\sigma^k}}{(\sigma\pi)^{1/4}\sqrt{2^k k!}}. \tag{4}$$

The functions (3) reduce to those given by (2) for $\sigma = 1$. Various modifications of the classical Hermite polynomials, analogous to (and more general than) the one considered here, can be found in the literature [10], [13].

LEMMA 1. *For any $\sigma > 0$, the functions* (3) *form an orthonormal basis for $L^2(\mathbb{R})$.*

Proof. We have

$$\begin{aligned}\langle u_k(x,\sigma), u_l(x,\sigma)\rangle &= c_k(\sigma)c_l(\sigma) \int_{-\infty}^{\infty} e^{x^2/\sigma} \frac{d^k e^{-x^2/\sigma}}{dx^k} \frac{d^l e^{-x^2/\sigma}}{dx^l} dx \\ &= c_k(1)c_l(1) \int_{-\infty}^{\infty} e^{y^2} \frac{d^k e^{-y^2}}{dy^k} \frac{d^l e^{-y^2}}{dy^l} dy,\end{aligned}$$

where we have made the change of variable $x = \sqrt{\sigma}\, y$. The statement of the lemma follows from the fact that the Hermite functions (2) form an orthonormal basis for $L^2(\mathbb{R})$. □

3. Fokker–Planck operators in $L^2(\mathbb{R})$. Let us consider the linear stochastic differential equation in the Itô sense

$$dx = -ax\, dt + b\, dw, \qquad a > 0, \tag{5}$$

where $x \in \mathbb{R}$ and w is a standard Wiener process. The reader may consult [11] for basic concepts of the theory of stochastic differential equations. The equation for the steady-state probability density that corresponds to (5) is $L(a,b)\rho(x) = 0$, where

$$L(a,b)\rho := \frac{b^2}{2}\rho_{xx} + ax\rho_x + a\rho \tag{6}$$

and ρ_x and ρ_{xx} denote the first and the second derivatives of ρ, respectively. The operator $L(a,b)$ is the *Fokker–Planck operator* associated with (5). Define

$$\sigma = \frac{b^2}{2a}. \tag{7}$$

The steady-state probability density is then given by $\bar{\rho}(x) = Ne^{-x^2/2\sigma}$, where $N > 0$ is a normalization constant. Dividing the Fokker–Planck operator $L(a,b)$ by a, we are led to studying a one-parameter family of differential operators, L_σ, defined by

$$L_\sigma\rho := \frac{1}{a} L(a, \sqrt{2a\sigma})\rho = \sigma\rho_{xx} + x\rho_x + \rho\,, \qquad \sigma > 0. \tag{8}$$

Before proceeding, we need to specify the domain of the above operators. It is easy to see that $L_\sigma u_k(x,\sigma) \in L^2(\mathbb{R})$ for each k, and L_σ is well defined by the formula (8) on the dense subspace U of $L^2(\mathbb{R})$ consisting of finite linear combinations of the functions $u_k(x,\sigma)$. We then define L_σ to be the minimal closed linear operator in $L^2(\mathbb{R})$ such that $L_\sigma\rho$ is given by (8) whenever $\rho \in C^2(\mathbb{R}) \cap L^2(\mathbb{R})$ and $\sigma\rho_{xx} + x\rho_x + \rho \in L^2(\mathbb{R})$. We thus obtain an operator $L_\sigma : \mathcal{D}_{L_\sigma} \to L^2(\mathbb{R})$, where $\mathcal{D}_{L_\sigma}$ is a dense subspace of $L^2(\mathbb{R})$ that contains U. Throughout the paper, unless specified otherwise, all differential operators are to be interpreted in the above sense.[1] For details on defining differential operators in this way, see [12].

The analysis of the operators L_σ is complicated by the fact that they are not self-adjoint. There is a standard technique which allows one to convert these operators to self-adjoint ones (this is sometimes referred to as *gauge*, or *ground state, transformation*). In our case, write $\rho = vf$, where the function v is to be fixed. We have

$$L_\sigma(vf) = \sigma v_{xx} f + 2\sigma v_x f_x + \sigma v f_{xx} + x v_x f + x v f_x + v f.$$

We see that in order for the first-order derivatives to disappear, v must satisfy the equation $v_x = -\dfrac{x}{2\sigma} v$. Letting

$$v = e^{-x^2/4\sigma} \tag{9}$$

we obtain $v^{-1} L_\sigma(vf) = \sigma f_{xx} + (\frac{1}{2} - \frac{x^2}{4\sigma}) f$.

Motivated by the above discussion, we define a new operator family, T_σ, by the formula

$$T_\sigma \rho := \sigma\rho_{xx} + \Big(\frac{1}{2} - \frac{x^2}{4\sigma}\Big)\rho, \qquad \sigma > 0. \tag{10}$$

For any positive σ, the operator T_σ is closed and self-adjoint, its domain being a dense subspace $\mathcal{D}_{T_\sigma}$ of $L^2(\mathbb{R})$ (defined as explained before).

We know that $L_\sigma u_0(x,\sigma) = L_\sigma c_0 e^{-x^2/2\sigma} = 0$, i.e., $e^{-x^2/2\sigma}$ is an eigenfunction with the eigenvalue zero. To investigate the spectral properties of the operators L_σ and T_σ, it seems natural to use the basis given by the modified Hermite functions (3) (with the same value of σ). We first carry out direct calculations for the family L_σ, setting the stage for the multidimensional case. We will then see that the analysis of the self-adjoint operators T_σ is more straightforward and allows one to obtain precise information about the spectrum of the original Fokker–Planck operator on an appropriate space of rapidly decaying functions.

PROPOSITION 2. *The spectrum of the operator $L_\sigma : \mathcal{D}_{L_\sigma} \to L^2(\mathbb{R})$ is independent of σ. For any $\sigma > 0$, the eigenvalues of L_σ are all numbers in the half-plane $\{\lambda \in \mathbb{C} : \operatorname{Re}\lambda < 1/2\}$.*

[1] Alternatively, $C^2(\mathbb{R})$ here could be replaced by the space of functions $\rho : \mathbb{R} \to \mathbb{R}$ such that ρ_x exists and is absolutely continuous, i.e., the space of twice weakly differentiable functions for which the differential expression (8) is defined almost everywhere.

Proof.[2] Straightforward computations give

$$L_\sigma u_k(x,\sigma) = c_k(\sigma)\left[\left(2+\frac{2x^2}{\sigma}\right)e^{x^2/2\sigma}\frac{d^k e^{-x^2/\sigma}}{dx^k} + 3xe^{x^2/2\sigma}\frac{d^{k+1}e^{-x^2/\sigma}}{dx^{k+1}} + \sigma e^{x^2/2\sigma}\frac{d^{k+2}e^{-x^2/\sigma}}{dx^{k+2}}\right]. \tag{11}$$

We introduce the notation $d_k(x,\sigma) = e^{x^2/2\sigma}\dfrac{d^k e^{-x^2/\sigma}}{dx^k}$, so that (11) becomes

$$L_\sigma u_k = c_k\left(\left(2+\frac{2x^2}{\sigma}\right)d_k + 3xd_{k+1} + \sigma d_{k+2}\right). \tag{12}$$

To obtain recurrence relations on d_k, notice that by Newton's binomial formula we have

$$d_{k+1} = e^{x^2/2\sigma}\left(-\frac{2x}{\sigma}\frac{d^k e^{-x^2/\sigma}}{dx^k} - \frac{2k}{\sigma}\frac{d^{k-1}e^{-x^2/\sigma}}{dx^{k-1}}\right)$$

which in the new notation becomes

$$d_{k+1} = -\frac{2x}{\sigma}d_k - \frac{2k}{\sigma}d_{k-1}\,. \tag{13}$$

From (13) we obtain

$$xd_k = -\frac{\sigma}{2}d_{k+1} - kd_{k-1}, \qquad k = 1,2,\ldots, \tag{14}$$

and also (multiplying both sides of (13) by x and then using (14))

$$\frac{2x^2}{\sigma}d_k = (2k+1)d_k + \frac{\sigma}{2}d_{k+2} + \frac{2k(k-1)}{\sigma}d_{k-2}. \tag{15}$$

Combining (12)–(15) gives

$$L_\sigma u_k = c_k\left(-kd_k + \frac{2k(k-1)}{\sigma}d_{k-2}\right) \tag{16}$$

and we see that the terms containing d_{k+2} disappear. Moreover, notice that we have

$$\frac{2k(k-1)}{\sigma}\,c_k = \sqrt{k(k-1)}\,c_{k-2}. \tag{17}$$

The formulas (16) and (17) imply that with respect to the basis (3) the operator L_σ takes the upper triangular form as given by

$$L_\sigma u_k(x,\sigma) = -ku_k(x,\sigma) + \sqrt{k(k-1)}u_{k-2}(x,\sigma). \tag{18}$$

From (18) it immediately follows that the spectrum of L_σ is independent of σ. Moreover, it is easy to see that the nonpositive integers are eigenvalues of L_σ. The

[2]The proofs in this section are given in sketched form; full details can be found in [16].

corresponding eigenfunctions are finite linear combinations of the basis elements u_k and thus belong to $C^\infty(\mathbb{R}) \cap L^2(\mathbb{R})$. They do not, however, form a complete set of eigenfunctions. The formula (18) implies that the existence of an eigenfunction of L_σ with an eigenvalue λ is equivalent to the convergence of at least one of the series

$$\sum_{n=1}^{\infty} \frac{\lambda^2(\lambda+2)^2 \cdots (\lambda+2n-2)^2}{(2n)!}$$

and

$$\sum_{n=1}^{\infty} \frac{(\lambda+1)^2(\lambda+3)^2 \cdots (\lambda+2n-1)^2}{(2n+1)!}.$$

Using Gauss' test for convergence (see, e.g., [18]), one can show in a straightforward manner that each series converges if $\mathrm{Re}\lambda < 1/2$ and diverges if $\mathrm{Re}\lambda \geq 1/2$. □

We can gain more insight into the spectral properties of the operator L_σ from its probabilistic interpretation. Recall that L_σ was defined in terms of the Fokker–Planck operator $L(a,b)$ via the formula (8). It follows from Proposition 2 that the eigenvalues of $L(a,b)$ are all numbers in the half-plane $\{\lambda \in \mathbb{C} : \mathrm{Re}\,\lambda < a/2\}$. (However, it can be deduced from (1) that any eigenfunction of $L(a,b)$ that is nonnegative and belongs to $L^1(\mathbb{R})$ must be proportional to the steady-state probability density, which corresponds to the eigenvalue zero.) The fact that the spectrum of $L(a,b)$ does not depend on the noise coefficient b should not be surprising if we notice that we can change b by simply rescaling x; i.e., substituting $y = px$ in (5) for an arbitrary $p \in \mathbb{R}$ gives $\dot{y} = -ay + pb\dot{w}$. It is easy to check that the spectrum of the Fokker–Planck operator associated with (5) is not affected by such changes of variable.

We now turn our attention to the family of self-adjoint operators T_σ defined by (10). It is well known that Hermite polynomials appear frequently in expressions for eigenfunctions of self-adjoint linear second-order differential operators. The next proposition shows that the eigenfunctions of T_σ are given by the modified Hermite functions (3) and is to be considered as a preparation for a more general result to be presented in the next section. For $\sigma = 1/2$, the statement reduces to a standard result involving the classical Hermite functions (see, e.g., [1, p. 256]).

PROPOSITION 3. *For any $\sigma > 0$, the spectrum of the operator $T_\sigma : \mathcal{D}_{T_\sigma} \to L^2(\mathbb{R})$ consists of the nonpositive integers, all of which are eigenvalues. The corresponding eigenfunctions are the functions $u_k(x, 2\sigma)$, i.e., $T_\sigma u_k(x, 2\sigma) = -k\, u_k(x, 2\sigma)$.*

Proof. For $\rho = e^{x^2/4\sigma} \frac{d^k e^{-x^2/2\sigma}}{dx^k}$ one can verify that

$$T_\sigma \rho = e^{x^2/4\sigma} \frac{d^k e^{-x^2/2\sigma}}{dx^k} + x e^{x^2/4\sigma} \frac{d^{k+1} e^{-x^2/2\sigma}}{dx^{k+1}} + \sigma e^{x^2/4\sigma} \frac{d^{k+2} e^{-x^2/2\sigma}}{dx^{k+2}}$$

which in our previous notation becomes

$$T_\sigma d_k(x, 2\sigma) = d_k(x, 2\sigma) + x d_{k+1}(x, 2\sigma) + \sigma d_{k+2}(x, 2\sigma). \tag{19}$$

Replacing σ by 2σ in (14) and substituting into (19), we arrive at

$$T_\sigma d_k(x, 2\sigma) = -k\, d_k(x, 2\sigma).$$

This immediately implies the second part of the statement. The first part of the statement follows from this, since we have found an orthonormal basis in $L^2(\mathbb{R})$ consisting of eigenfunctions of T_σ. □

As a consequence, the eigenvalues of the original operator L_σ restricted to the space of functions of the form $\rho = vf$, where v is given by (9) and $f \in \mathcal{D}_{T_\sigma}$, are the nonpositive integers. The eigenfunction that corresponds to the eigenvalue $-k$ is given by $e^{-x^2/4\sigma}u_k(x, 2\sigma) = c_k(2\sigma)\frac{d^k e^{-x^2/2\sigma}}{dx^k}$. This leads us to a complete characterization of the spectrum of the Fokker–Planck operator $L(a, b)$ restricted to an appropriate space of rapidly decaying functions. Namely, let us denote by $\mathcal{L}_\sigma$ the space of functions that can be represented by finite linear combinations of the form $\sum_{k=1}^m \alpha_k \frac{d^k e^{-x^2/2\sigma}}{dx^k}$, $\alpha_k \in \mathbb{R}$. From the definitions of L_σ and T_σ and from Proposition 3 we immediately obtain the following result.

COROLLARY 4. *The space $\mathcal{L}_\sigma$ is invariant with respect to the Fokker–Planck operator $L(a, b)$ associated with* (5). *The spectrum of the restriction of $L(a, b)$ to $\mathcal{L}_\sigma$ consists of the numbers* 0, $-a$, $-2a$, $-3a$, $\ldots$, *all of which are eigenvalues.*

Remark 1. The eigenfunctions of L_σ on $\mathcal{L}_\sigma$ found above form an orthonormal basis for the space $L^2(\mathbb{R}, e^{x^2/2\sigma}dx)$, on which the operator L_σ can be shown to be self-adjoint. If instead of $\mathcal{L}_\sigma$ we consider a dense subspace of $L^2(\mathbb{R}, e^{x^2/2\sigma}dx)$ containing $\mathcal{L}_\sigma$, which can be constructed as explained at the beginning of the section, the statement about the spectrum still applies. Clearly, this larger subspace is no longer invariant under the action of $L(a, b)$. The operator T_σ is convenient because it is self-adjoint with respect to the standard inner product on $L^2(\mathbb{R})$.

We see in view of (7) that as the value of a increases while the noise coefficient b stays constant, the rate of decay of functions in $\mathcal{L}_\sigma$ becomes more rapid and so does the convergence to steady state. If we fix one member of the family $\{T_\sigma : \sigma > 0\}$, say, $T_{1/2}$, then for any value of σ the operator T_σ can be expressed as $T_\sigma = \Theta_\sigma^{-1} T_{1/2} \Theta_\sigma$, where Θ_σ is the unitary operator defined by $\Theta_\sigma u_k(x, 2\sigma) = u_k(x, 1) = u_k(x)$. We will use this observation in section 5.

4. Fokker–Planck operators in $L^2(\mathbb{R}^n)$. Consider the system of linear stochastic differential equations

$$dx = Ax\,dt + B\,dw\,, \qquad x \in \mathbb{R}^n, \tag{20}$$

where w is a standard m-dimensional Wiener process and A and B are matrices of suitable dimensions. Recall that *separable functions*, i.e., functions that can be expressed as products $\rho_1(x_1)\cdots\rho_n(x_n)$, span a dense subspace of $L^2(\mathbb{R}^n)$. Thus we can construct an orthonormal basis for $L^2(\mathbb{R}^n)$ by taking products of the modified Hermite functions (3) for each variable. The analysis of the previous section now directly generalizes to those linear stochastic systems in $\mathbb{R}^n$ whose equations are completely decoupled. In this case, the Fokker–Planck operator decomposes into a sum of Fokker–Planck operators of the kind considered above for each variable. Our earlier results then imply, in particular, that the sums of the eigenvalues of the matrix A are eigenvalues of the corresponding Fokker–Planck operator, and that the corresponding eigenfunctions belong to the space $C^\infty(\mathbb{R}^n) \cap L^2(\mathbb{R}^n)$ and can be explicitly constructed.

Although the analysis for the general multidimensional system (20) is more complicated than in the scalar case, results that parallel most of our earlier developments can be obtained. Let us denote the Fokker–Planck operator associated with (20) by L_n and consider it as being a closed operator defined on a dense subspace $\mathcal{D}_{L_n}$ of

$L^2(\mathbb{R}^n)$ (cf. section 3). We have the following expression for L_n:

$$L_n\rho = \frac{1}{2}\sum_{i,j=1}^{n}(BB^T)_{ij}\,\rho_{x_ix_j} - \sum_{i,j=1}^{n}A_{ij}x_j\rho_{x_i} - \mathrm{tr}A\cdot\rho. \tag{21}$$

From this point on, let us make the following two assumptions with regard to the system (20):

(a) The eigenvalues of A have negative real parts.

(b) (A,B) is a controllable pair (i.e., $\mathrm{rank}(B, AB, \ldots, A^{n-1}B) = n$).

Under these assumptions, the steady-state variance equation

$$AQ + QA^T + BB^T = 0 \tag{22}$$

associated with (20) has a positive definite symmetric solution Q. After an appropriate change of coordinates in $\mathbb{R}^n$ we can have $Q = \frac{1}{2}I$, so that $A = \Omega - BB^T$ with Ω skew-symmetric. Such a coordinate transformation does not change the eigenvalues of the Fokker–Planck operator L_n. The steady-state probability density then becomes $\bar\rho(x) = Ne^{-x^Tx}$, $N > 0$, and this is an eigenfunction that corresponds to the eigenvalue zero of the Fokker–Planck operator.

Next let us determine all eigenfunctions of L_n that take the form

$$\rho(x) = (h_1x_1 + \cdots + h_nx_n)\bar\rho(x) = h^Tx\bar\rho(x), \qquad h \in \mathbb{R}^n. \tag{23}$$

LEMMA 5. *Suppose that $A = \Omega - BB^T$, where $\Omega = -\Omega^T$. Then the function (23) is an eigenfunction of the operator L_n with eigenvalue λ if and only if h is an eigenvector of the matrix A with the same eigenvalue λ.*

Proof. Let ρ be of the form (23). Taking into account that $L_n\bar\rho = 0$, we have

$$\begin{aligned} L_n\rho &= \sum_{i,j=1}^{n}(BB^T)_{ij}(h)_i(-2x_j)\bar\rho - \sum_{i,j}A_{ij}x_j(h)_i\bar\rho \\ &= -\bar\rho\sum_{i,j=1}^{n}(A_{ji} + 2(BB^T)_{ji})(h)_jx_i \\ &= \bar\rho\sum_{i,j=1}^{n}(\Omega_{ij} - (BB^T)_{ij})(h)_jx_i = \sum_{i=1}^{n}(Ah)_ix_i\bar\rho \end{aligned}$$

and this obviously equals $\lambda\rho = \lambda\sum_i h_ix_i\bar\rho$ if and only if $Ah = \lambda h$. ∎

Denote by $h_1, \ldots, h_k$ the eigenvectors of A and by $\lambda_1, \ldots, \lambda_k$ the corresponding eigenvalues ($k \le n$). Now let us see how L_n acts on functions of the form

$$\rho(x) = \bar\rho(x)\prod_{m\in J}h_m^Tx, \tag{24}$$

where the product is taken over some index set J whose elements are (not necessarily distinct) positive integers no greater than n. Using Lemma 5 and the fact that

$L_n\bar\rho = 0$, we have

$$\begin{aligned} L_n(\bar\rho \textstyle\prod_{m\in J} h_m^T x) &= \sum_{i,j=1}^{n} \sum_{m,l\in J} (BB^T)_{ij}(h_m)_i(h_l)_j \bar\rho \prod_{p\in J\setminus\{m,l\}} h_p^T x \\ &\quad + \sum_{i,j=1}^{n} \sum_{m\in J} (BB^T)_{ij}(h_m)_i \bar\rho_{x_j} \prod_{p\in J\setminus\{m\}} h_p^T x \\ &\quad - \sum_{i,j=1}^{n} \sum_{m\in J} A_{ij}x_j(h_m)_i \bar\rho \prod_{p\in J\setminus\{m\}} h_p^T x \\ &= \sum_{i,j=1}^{n} \sum_{m,l\in J} (BB^T)_{ij}(h_m)_i(h_l)_j \bar\rho \prod_{p\in J\setminus\{m,l\}} h_p^T x + \Big(\sum_{m\in J} \lambda_m\Big)\bar\rho \prod_{m\in J} h_m^T x. \end{aligned}$$

Thus functions of the form (24) for various index sets J form an invariant subspace under the action of L_n. It is not hard to see that $\sum_{m\in J}\lambda_m$ are eigenvalues of L_n. The corresponding eigenfunctions are finite linear combinations of functions of the form (24). Summarizing, we have the following theorem.

THEOREM 6. *The sums of the eigenvalues of the matrix A are eigenvalues of the Fokker–Planck operator $L_n : \mathcal{D}_{L_n} \to L^2(\mathbb{R}^n)$.*

Theorem 6 can probably be best appreciated in the following context. It is well known and easy to show that there are $N_n^p = \binom{n+p-1}{p}$ linearly independent monomials of degree p in n variables of the form $x_1^{p_1}\dots x_n^{p_n}$, where $\sum_{i=1}^n p_i = p$ and $p_i \ge 0$. The linear differential equation

$$\dot x = Ax, \qquad x \in \mathbb{R}^n,$$

gives rise to the equation

$$\frac{d}{dt}x^{[p]} = A_{[p]}x^{[p]}, \qquad x^{[p]} \in \mathbb{R}^{N_n^p}.$$

One of the basic properties of the matrix $A_{[p]}$ defined in this way is that its eigenvalues are the p-term sums of the eigenvalues of A. As is shown in [4], the matrices $A_{[p]}$ are directly related to the pth moment equations for the system (20).

Theorem 6 shows that the situation in the infinite-dimensional case is consistent with the one described in the previous paragraph in the following sense. Associated with the system (20) we have the Fokker–Planck equation for the probability density

$$\frac{\partial\rho(t,x)}{\partial t} = L_n\rho(t,x).$$

The operator L_n is well defined on a dense subspace of $L^2(\mathbb{R}^n)$. We know that the basis elements in $L^2(\mathbb{R}^n)$ can be taken to be polynomials of an arbitrary degree multiplied by Gaussians, and we have shown that the sums (with an arbitrary number of terms) of the eigenvalues of A are eigenvalues of the operator L_n.

In view of the results of section 3, it would be interesting to obtain conditions under which it is possible to convert the Fokker–Planck operator L_n to a self-adjoint operator by means of an appropriate gauge transformation. The following result provides such conditions, as well as an explicit formula for the function v to be used.

PROPOSITION 7. *Suppose that the matrix B is nondegenerate and that we have*

$$ABB^T = BB^TA^T. \tag{25}$$

If the function v is defined by the formula

$$v = e^{x^T (BB^T)^{-1} Ax/2}, \tag{26}$$

then the operator T_n given by

$$T_n \rho = v^{-1} L_n (v\rho)$$

is self-adjoint.

Proof. The first-order terms in the expression for T_n are

$$\frac{1}{2} \sum_{j,k=1}^{n} (BB^T)_{jk} \left(v_{x_j} \frac{\partial}{\partial x_k} + v_{x_k} \frac{\partial}{\partial x_j} \right) - \sum_{i,j=1}^{n} A_{ij} x_j v \frac{\partial}{\partial x_i}.$$

We see that the coefficient of $\dfrac{\partial}{\partial x_i}$ is

$$\sum_{j=1}^{n} (BB^T)_{ij} v_{x_j} - \sum_{j=1}^{n} A_{ij} x_j v$$

and we need this to be zero for each i. This is equivalent to having

$$(BB^T) \operatorname{grad} v = Ax\, v$$

or

$$\operatorname{grad} v = (BB^T)^{-1} Ax\, v. \tag{27}$$

Therefore, we must have

$$\begin{aligned} v_{x_i x_j} &= \frac{\partial}{\partial x_i} \left[\sum_{k=1}^{n} ((BB^T)^{-1} A)_{jk} x_k\, v \right] \\ &= ((BB^T)^{-1} A)_{ji}\, v + \sum_{k=1}^{n} ((BB^T)^{-1} A)_{jk} x_k\, v_{x_i} \\ &= ((BB^T)^{-1} A)_{ji}\, v + \sum_{k=1}^{n} ((BB^T)^{-1} A)_{jk} x_k \sum_{l=1}^{n} ((BB^T)^{-1} A)_{il} x_l\, v. \end{aligned}$$

The compatibility conditions $v_{x_i x_j} = v_{x_j x_i}$ now imply that the matrix $(BB^T)^{-1} A$ has to be symmetric:

$$(BB^T)^{-1} A = A^T (BB^T)^{-1}.$$

Multiplying both sides of this formula by BB^T, we arrive at (25). It is straightforward to show that the function given by (26) satisfies (27). ∎

Let us switch to coordinates in which $Q = \sigma I$ for some $\sigma > 0$ (in the language of statistical thermodynamics, these are coordinates in which the *equipartition of energy* property holds, and σ is the steady-state *temperature* of the system). Then $(A + A^T)\sigma = -BB^T$, and (25) can be rewritten as $A^2 = (A^T)^2$. This last condition is satisfied, for example, if A is symmetric. In this case (26) becomes

$$v = e^{-x^T x/4\sigma} \tag{28}$$

which is a constant multiple of the square root of the steady-state probability density. This is in accordance with our earlier results for the one-dimensional case.

Denote by ∇ the gradient with respect to the metric on $\mathbb{R}^n$ given by $G = (BB^T)^{-1}$. In other words, given a function $\phi : \mathbb{R}^n \to \mathbb{R}$, we define the vector $\nabla\phi$ by $(\nabla\phi)_i = \sum_{j=1}^n (BB^T)_{ij}\phi_{x_j}$. Assume that $A = A^T$ and that the positive definite solution of (22) is $Q = \sigma I$. Let $\phi(x) = \frac{1}{4\sigma}x^T x$. Then we have

$$(\nabla\phi)_i = 2\sigma \sum_{j=1}^n A_{ij}\phi_{x_j} = \sum_{j=1}^n A_{ij}x_j$$

so that the system (20) can be rewritten as

$$dx = -\nabla\phi(x)\,dt + B\,dw. \tag{29}$$

Systems of the general form (29) and the corresponding steady-state probability densities were studied in [8].

Under the present assumptions, the Fokker–Planck operator takes the form

$$L_{n,\sigma}\rho = -\sigma \sum_{i,j=1}^n A_{ij}\rho_{x_i x_j} - \sum_{i,j=1}^n A_{ij}x_j\rho_{x_i} - \operatorname{tr}A \cdot \rho.$$

Using Proposition 7, we can also construct a self-adjoint operator which in this case is given by

$$T_{n,\sigma}\rho = -\sigma \sum_{i,j=1}^n A_{ij}\rho_{x_i x_j} - \left(\frac{1}{2}\operatorname{tr}A - \frac{1}{4\sigma}\sum_{i,j=1}^n A_{ij}x_i x_j\right)\rho.$$

As we have done throughout the paper, we consider the above expression as defining a closed operator acting on a dense subspace of $L^2(\mathbb{R}^n)$ which we denote by $\mathcal{D}_{T_{n,\sigma}}$. The following result is to be viewed as a generalization of Proposition 3 to the case of the multidimensional system (20) written in equipartition coordinates as explained earlier ($Q = \sigma I$), under the assumption that in these coordinates the nonrandom part of the system is symmetric ($A = A^T$). As shown above, this system is of the gradient form (29) for an appropriate quadratic function ϕ and a suitable constant metric.

THEOREM 8. *For any $\sigma > 0$, the spectrum of the operator $T_{n,\sigma} : \mathcal{D}_{T_{n,\sigma}} \to L^2(\mathbb{R}^n)$ consists of eigenvalues which are the sums of the eigenvalues of the matrix A.*

Proof. The matrix A has n real negative eigenvalues $\lambda_1, \dots, \lambda_n$. There exists an orthogonal matrix R such that $RAR^T = D$, where $D = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$. Making the change of variables $y = Rx$, we obtain an operator $\overline{T}_{n,\sigma}$ given by

$$\overline{T}_{n,\sigma}\rho = -\sigma\sum_{i=1}^n \lambda_i\rho_{y_i y_i} - \left(\frac{1}{2}\sum_{i=1}^n \lambda_i - \frac{1}{4\sigma}\sum_{i=1}^n \lambda_i y_i^2\right)\rho.$$

The spectrum of $\overline{T}_{n,\sigma}$ is the same as that of $T_{n,\sigma}$. We have $\overline{T}_{n,\sigma} = -\sum_{i=1}^n \lambda_i T_{\sigma,y_i}$, where T_{σ,y_i} are the operators considered in section 3 for each variable (cf. remarks made at the beginning of this section). To complete the proof, recall that by Proposition 3 the eigenvalues of T_{σ,y_i} are the nonpositive integers. The eigenfunctions of $\overline{T}_{n,\sigma}$ are given by the products of the functions $u_k(y_i, 2\sigma)$ for each variable; they form an orthonormal basis for $L^2(\mathbb{R}^n)$. ∎

As before, we conclude that the eigenvalues of the original operator $L_{n,\sigma}$ restricted to the space of functions of the form $\rho = vf$, where v is given by (28) and $f \in \mathcal{D}_{T_{n,\sigma}}$, are the sums of the eigenvalues of A. The corresponding eigenfunctions take the form $vg_k(x,\sigma)$, where $g_k(x,\sigma)$, $k = 0, 1, \dots$ are the eigenfunctions of $T_{n,\sigma}$ described in the proof of Theorem 8. Let $\mathcal{L}_{n,\sigma}$ denote the space of functions $\{\rho : v^{-1}\rho = \sum_{k=1}^{m} \alpha_k g_k(x,\sigma)\}$, $\alpha_k \in \mathbb{R}$. As a generalization of Corollary 4 we have the following statement.

COROLLARY 9. *The space $\mathcal{L}_{n,\sigma}$ is invariant with respect to the Fokker–Planck operator $L_{n,\sigma}$ associated with* (29)*. The spectrum of the restriction of $L_{n,\sigma}$ to $\mathcal{L}_{n,\sigma}$ consists of eigenvalues which are the sums of the eigenvalues of the matrix A.*

Remark 2. Under the change of variables described in the proof of Theorem 8 the operator $L_{n,\sigma}$ becomes a Fokker–Planck operator associated with a decoupled system. This makes the statement of Corollary 9 obvious in view of Corollary 4 and the discussion at the beginning of this section. In the case when A is a scalar multiple of the identity matrix, the spectrum (but not the eigenfunctions) of the operator $L_{n,\sigma}$ on $\mathcal{L}_{n,\sigma}$ can be obtained from the analysis of its adjoint presented in [19, section 7.5]. The eigenfunctions of $L_{n,\sigma}$ on $\mathcal{L}_{n,\sigma}$ found above form an orthonormal basis for the space $L^2(\mathbb{R}^n, e^{x^T x/4\sigma}dx)$. We could also consider $L_{n,\sigma}$ as acting on a larger dense subspace of $L^2(\mathbb{R}^n, e^{x^T x/4\sigma}dx)$, which would not change the spectrum—cf. Remark 1 in section 3.

It is interesting to notice that, given the original system (20), we can always find a basis in which $Q = \sigma I$ satisfies (22) and $A = A^T$ if A is allowed to depend on time. First, switch to an equipartition basis in which we have $Q = \sigma I$. Note that the last equality is preserved under orthogonal coordinate transformations. Let $\Omega = \frac{1}{2}(A - A^T)$. Making the change of variable $y = e^{-\Omega t}x$ in (20), we obtain

$$dy = \frac{1}{2}e^{-\Omega t}(A + A^T)e^{\Omega t}y\,dt + e^{-\Omega t}B\,dw \tag{30}$$

and the first term features a symmetric matrix as needed.

5. Double bracket equations. Consider the operators P_1, P_2, P_3, and P_4 acting on the space

$$\mathcal{D} = \{\rho \in C^2(\mathbb{R}) \cap L^2(\mathbb{R}) : \rho_{xx}, x\rho_x, x^2\rho \in L^2(\mathbb{R})\}$$

that are defined as follows:

$$P_1\rho = \rho_{xx}, \qquad P_2\rho = x\rho_x, \qquad P_3\rho = x^2\rho, \qquad P_4\rho = \rho.$$

It is easy to verify that the linear span of the above operators is closed under commutation with respect to the usual Lie bracket $[P_i, P_j] = P_iP_j - P_jP_i$. We will let $\mathfrak{g}$ denote the operator Lie algebra spanned by P_i, $i = 1, 2, 3, 4$. Such Lie algebras and their representations have been studied in the context of quantum mechanics and, more recently, estimation theory [5].

Observe that L_σ and T_σ can be realized as operators in $\mathfrak{g}$ because $\mathcal{D} \subset \mathcal{D}_{L_\sigma}$ for each $\sigma > 0$. More precisely, let us denote by $L(\sigma)$ and $T(\sigma)$ the restrictions of L_σ and T_σ to $\mathcal{D}$. Proposition 3 implies that $T(\sigma)$, $0 < \sigma < \infty$, is an isospectral family of operators in $\mathfrak{g}$. In fact, for any $\sigma > 0$ the spectrum of $T(\sigma)$ consists of eigenvalues which are the nonpositive integers. As we know from Proposition 2, the nonpositive integers are also eigenvalues of $L(\sigma)$ for each $\sigma > 0$ (because the corresponding eigenfunctions of L_σ belong to $\mathcal{D}$).

In this section we show that the families of operators $L(\sigma)$ and $T(\sigma)$ correspond to integral curves of differential equations in the double bracket form on $\mathfrak{g}$. We also obtain the corresponding dynamical representation for the family of modified Hermite functions defined by (3). The proofs are completely straightforward calculations and will not be given.

PROPOSITION 10. *Let M be an operator in $\mathfrak{g}$ defined by $M\rho = \frac{1}{4}\rho_{xx}$. Then $L(\sigma)$, $0 < \sigma < \infty$, is a solution of the differential equation*

$$\frac{dL}{d\sigma} = [L, [L, M]]. \tag{31}$$

The Fokker–Planck operator associated with (5) is uniquely determined by two parameters: σ, which corresponds to the steady-state variance, and a, which describes the speed of convergence to steady state. In making the transition to the operators L_σ we factored out the dependence on a. Thus the flow (31) can be thought of as evolving on the "slice" of Fokker–Planck operators with the same spectral properties but different steady states. As we will see, in the multidimensional case σ corresponds to the steady-state temperature of the system (defined in section 4).

To each of the operators $L(\sigma)$ there corresponds the steady-state probability density ρ_σ which satisfies the equation $L(\sigma)\rho_\sigma(x) = 0$. The flow (31) on the operator Lie algebra $\mathfrak{g}$ thus induces a flow on the manifold of Gaussian probability densities. For example, making the change of variable $\sigma = e^t$, we obtain a particular case of the gradient flow of Gaussians described by Nakamura in [17].

PROPOSITION 11. *Let N be an operator in $\mathfrak{g}$ defined by $N\rho = \frac{1}{2}\rho_{xx}$. Then $T(\sigma)$, $0 < \sigma < \infty$, is a solution of the differential equation*

$$\frac{dT}{d\sigma} = [T, [T, N]]. \tag{32}$$

In view of the remarks made at the end of section 3, we can write $T(\sigma) = \Theta^{-1}(\sigma)T(1/2)\Theta(\sigma)$, with the domain of $\Theta(\sigma)$ properly defined. Using the fact that for all $\sigma > 0$ the operator $\Theta(\sigma)$ is unitary and the operators $T(\sigma)$ and $N(\sigma)$ are self-adjoint, we arrive at the equation

$$\frac{d\Theta}{d\sigma} = T(1/2)\Theta N - \Theta N\Theta^{-1}T(1/2)\Theta = \Theta[T, N] \tag{33}$$

which describes the evolution of the eigenbasis for $T(\sigma)$ induced by the flow (32). This is the same equation as the one obtained in [6] for the finite-dimensional case.

We point out an interesting analogy between the results of Propositions 10 and 11 and the sorting algorithms described in [6]. If N is a real diagonal matrix with unrepeated eigenvalues, and if $H(0)$ is a suitably chosen symmetric matrix, then the solution of the double bracket equation $\dot{H} = [H, [H, N]]$ approaches a diagonal matrix $H(\infty)$ such that the diagonal elements of $H(\infty)$ and N are similarly ordered; since $H(\infty)$ is diagonal, it commutes with N. For large positive values of σ, the "principal term" of the operators $L(\sigma)$ and $T(\sigma)$ is $\sigma\frac{d^2}{dx^2}$, which is proportional to both M and N and thus commutes with them. Thus the double bracket equations (31) and (32) can be thought of as performing a task of "operator sorting."

We would like to generalize the above results to the multidimensional case. Consider the operators $P_{1,i,j}$, $P_{2,i,j}$, $P_{3,i,j}$, and P_4 acting on the space

$$\mathcal{D}_n = \{\rho \in C^2(\mathbb{R}^n) \cap L^2(\mathbb{R}^n) : \rho_{x_ix_j}, x_i\rho_{x_j}, x_ix_j\rho \in L^2(\mathbb{R}^n)\ \forall i, j = 1, 2, \ldots, n\}$$

that are defined as follows:

$$P_{1,i,j}\rho = \rho_{x_i x_j}, \qquad P_{2,i,j}\rho = x_i \rho_{x_j}, \qquad P_{3,i,j}\rho = x_i x_j \rho, \qquad P_4 \rho = \rho.$$

These operators span a Lie algebra which we denote by $\mathfrak{g}_n$. For each $\sigma > 0$, let $L_n(\sigma)$ and $T_n(\sigma)$ denote the restrictions of $L_{n,\sigma}$ and $T_{n,\sigma}$ to $\mathcal{D}_n$. Theorem 8 implies that $T_n(\sigma)$, $0 < \sigma < \infty$, is an isospectral family of operators in $\mathfrak{g}_n$.

PROPOSITION 12. *Let M be an operator in $\mathfrak{g}_n$ defined by*

$$M\rho = -\frac{1}{4} \sum_{i,j=1}^{n} (A^{-1})_{ij} \rho_{x_i x_j}.$$

Then $L_n(\sigma)$, $0 < \sigma < \infty$, is a solution of the differential equation

$$\frac{dL}{d\sigma} = [L, [L, M]].$$

PROPOSITION 13. *Let N be an operator in $\mathfrak{g}_n$ defined by*

$$N\rho = -\frac{1}{2} \sum_{i,j=1}^{n} (A^{-1})_{ij} \rho_{x_i x_j}.$$

Then $T_n(\sigma)$, $0 < \sigma < \infty$, is a solution of the differential equation

$$\frac{dT}{d\sigma} = [T, [T, N]].$$

As in the scalar case, we can define a unitary operator Θ_σ by $\Theta_\sigma g_k(x, \sigma) = g_k(x, 1)$, where $g_k(x, \sigma)$ are the eigenfunctions of $T_n(\sigma)$. This operator will then satisfy (33), which describes the flow of these eigenfunctions. Finally, note that Propositions 12 and 13 apply to the system (30) without any changes (except that now $T_n(\sigma)$ will also depend on t).

Acknowledgments. The first author would like to thank Mark Adler for helpful discussions and Daniel Stroock for calling his attention to the book [19].

STABILIZATION OF LINEAR DIFFERENTIAL SYSTEMS VIA HYBRID FEEDBACK CONTROLS*

ELENA LITSYN†, YURII V. NEPOMNYASHCHIKH‡, AND ARCADY PONOSOV§

Abstract. We study so-called "hybrid feedback stabilizers" for an arbitrarily general system of linear differential equations. We prove that under assumptions of controllability and observability there exists a hybrid feedback output control which makes the system asymptotically stable. The control is designed by making use of a discrete automaton implanted into the system's dynamics. In general, the automaton has infinitely many locations, but it gives rise to a "uniform" (in some sense) feedback control. The approach we propose goes back to classical feedback control techniques combined with some ideas used in stability theory for equations with time-delay.

Key words. stabilization, hybrid feedback control, functional differential equations

AMS subject classification. 93D15

1. Introduction.

Hybrid systems are those that combine both discrete and continuous dynamics. Many examples of hybrid systems can be found in manufacturing systems, intelligent vehicle highway systems, and various chemical plants. Hybrid systems also arise when there is a necessity to combine logical decision with the generation of continuous control laws. See also the "biological" Example 1.2 below.

We are interested in the question of how to stabilize a continuous control plant through its interaction with a discrete time controller (an automaton). Such a feedback complements the output feedback within the plant when the latter fails to stabilize the system or fails to give smooth stabilization. This, for example, may be the case if no complete information on the plant's dynamics is available.

The framework we use follows developments in hybrid systems, as described in Nerode and Kohn [12]. The stability and stabilization notions we use are classical (see, for example, [11], [14], [16], [17], where some relevant results can be found). Some results on stabilization of hybrid systems are available in the literature [1], [5], [9], [13]. In this paper we exploit ideas proposed by Artstein [2], who studied a possibility of stabilization by hybrid feedback controls via examples. The point of view given in [2] is that one has an underlying continuous plant, and the challenge is to stabilize it efficiently with a hybrid device.

Let us now consider some examples that give a partial motivation for our study. More examples can be found in [15].

Example 1.1 (the harmonic oscillator). A rather simple example of a linear system

which cannot be stabilized by an ordinary output feedback is two-dimensional:

$$\frac{d\xi}{dt} = \eta, \qquad \frac{d\eta}{dt} = -\xi + u, \qquad y = \xi. \tag{1.1}$$

This is the harmonic oscillator where the control is an external force and the only measured quantity (output) is the position variable ξ.

Although this system is both controllable and observable, it cannot be stabilized by (even discontinuous and nonlinear) output feedback (see, e.g., [2]) since any control $u = f(\xi)$ makes curves of the form $\xi^2 + \eta^2 + 2\int_0^\xi f(\rho)d\rho = c$ invariant under the flow.

However, it was shown in [2] that there exists a *hybrid feedback control* under which system (1.1) becomes asymptotically stable.

Example 1.2 (predator–prey interactions). Our second example gives a "biological" motivation for studying hybrid feedback controls. Consider the well-known predator–prey model

$$\frac{x'}{x} = -b_1 + a_1 y, \qquad \frac{y'}{y} = b_2 - a_2 x, \tag{1.2}$$

where a_i, b_i are positive; $x(t)$ describes a population at time t of a species called *the predator* (fish, animals, insects, etc.); and $y(t)$ describes a population at time t of another species called *the prey*.

The *predator* lives on the *prey*; $\frac{x'}{x}$ and $\frac{y'}{y}$ mean the growth rates of the populations.

The linearization about the equilibrium state (e_1, e_2) gives the following linear system:

$$\dot{X} = e_1 a_1 Y, \qquad \dot{Y} = -e_2 a_2 X, \tag{1.3}$$

that is, the harmonic oscillator which is asymptotically *unstable*. Any attempt to stabilize (1.3) (i.e., (1.2) locally) by inserting a certain control into the right-hand side of (1.3) fails. Such a control, usually called a "harvesting strategy," would give

$$\frac{x'}{x} = -b_1 - u + a_1 y, \qquad \frac{y'}{y} = b_2 - v - a_2 x. \tag{1.4}$$

The linearization of (1.4) about the new equilibrium (e_1^v, e_2^u) state will again give an asymptotically unstable system

$$\dot{X} = e_1^v a_1 Y \equiv e_1 a_1 Y - \frac{v a_1}{a_2} Y, \qquad \dot{Y} = -e_2^u a_2 X \equiv -e_2 a_2 X - \frac{u a_2}{a_1} X.$$

The problem becomes more complicated if it is not allowed to harvest the prey. Then $v = 0$, and we obtain nothing but the controlled oscillator (1.1) up to a change of variables.

We also remark that (1.2) describes one of the simplest models of biological interactions. If we take more species and more complicated interactions, then we shall arrive at more general control problems.

The goal of the paper. We look at a general linear system of differential equations which is asymptotically unstable. We also assume that no complete information about solutions is available and that we cannot continuously influence the solutions. Nevertheless, we ask whether it is still possible to stabilize the system.

In Artstein [2] two conjectures have been mentioned: (1) whether there exists a kind of elementary hybrid stabilizer $u(\cdot)$ driven by an automaton with finitely many locations and (2) whether there is a possibility for expediency by using more general hybrid stabilizers.

In the present paper, we give a partial affirmative answer to Artstein's questions. Namely, we describe here how one can explicitly design a hybrid feedback stabilizer for a general linear system. To do so, we introduce a new class of hybrid feedback control strategies and automata with infinitely many locations, this being a natural generalization of the elementary hybrids used in [2]. Our approach is based on the classical stabilization technique as well as on some recent results in the theory of *functional differential equations* [3], [4], [7].

2. Formulation of the main result. The following system of linear differential equations

$$\begin{aligned} \dot{x} &= Ax + Bu, \\ y &= Cx \end{aligned} \tag{2.1}$$

is under consideration. Here $x \in \mathbf{R}^n$ is a physical state of the system, $y \in \mathbf{R}^m$ is the output, and the control u is an element of $\mathbf{R}^\ell$. A, B, C are given real matrices of the sizes $n \times n$, $n \times \ell$, $m \times n$, respectively. *The control $u(\cdot)$ is assumed to depend on the output $y(\cdot)$ only.* The nature of this dependence is specified below.

The following problem is being studied: find (if there is a possibility) a (hybrid feedback) control u under which system (2.1) becomes asymptotically stable.

To specify our setup, we need some definitions and auxiliary results (see also [6], [8], [14], [16]).

DEFINITION 2.1. *Denoting by Z the set of all admissible controls, we say that the system* (2.1) *is Z-stabilizable if there exists a control $u \in Z$ under which* (2.1) *is u-stabilizable.*

The following technical theorem will be used.

THEOREM 2.2. *The pair (A, B) is controllable if and only if for any set Λ of n complex numbers which is symmetric with respect to the real axis, there exists a real $\ell \times n$-matrix G such that $\sigma(A + BG) = \Lambda$.*

In that which follows, for the sake of simplicity we will write $[A]_B$ instead of the $n \times \ell n$-matrix $[B\ AB\ \dots\ A^{n-1}B]$ and ${}_C[A]$ instead of the $mn \times n$-matrix $([A^\top]_{C^\top})^\top$.

The next statement is well known.

THEOREM 2.3 (Kalman's criterion). 1. *The pair (A, B) is controllable if and only if* $\operatorname{rank}([A]_B) = n$. 2. *The pair (A, C) is observable if and only if* $\operatorname{rank}({}_C[A]) = n$.

We will always assume in this paper that the pair (A, B) is controllable, and the pair (A, C) is observable.

Denote by $\mathcal{L}_0$ the class of controls $u = Gy$, where G is a constant $\ell \times m$-matrix. The following statement is of wide use in control theory.

LEMMA 2.4. *If* $\operatorname{rank} C = n$ *then the system* (2.1) *is $\mathcal{L}_0$-stabilizable.*

Proof. According to Theorem 2.2 there exists a real $\ell \times n$-matrix G_0 such that the matrix $A + BG_0$ is stable. Since $\operatorname{rank} C = n \le m$, there exists the left inverse matrix C_l^{-1}. The matrix $G = G_0 C_l^{-1}$ then provides a control which stabilizes the system (2.1). □

If $\operatorname{rank} C < n$, then this may imply an absence of a stabilizer in the class $\mathcal{L}_0$. If in addition one assumes that it may be desirable in applications to have discrete stabilizers, one immediately arrives at the concept of a *hybrid system* consisting of a discrete automaton coupled with a system to be stabilized (a plant).

Below we describe the concept of an automaton, basically following the approach presented in [2]. Our setup is a bit more general, however, since we also admit automata with infinitely many locations, so that our definitions differ from those in [2]. We have in mind a typical automaton, described by a triple $\mathcal{A} = (Q, I, M)$, where

(i) Q is a set of all possible automaton states (locations);

(ii) the set I contains the input alphabet;

(iii) the transition map $M : Q \times I \to Q$ indicates the location after a transition time, based on the previous location q and input i at the time of transition.

We also let our automaton follow solutions of the system (2.1). This can be done by assuming there is one more triplet $\mathcal{B} = (T, i, q_0)$. Here

(iv) $T : Q \to (0, \infty)$ is a mapping which sets a period $T(q)$ between transition times;

(v) $i : \mathbf{R}^m \to I$ is a function providing the element $i(y)$ of the alphabet I for any output y of the system (2.1);

(vi) and $q_0 = q(\tau_0)$ is a state of the automaton at the initial time τ_0.

We will later assume, without loss of generality, that $\tau_0 = 0$.

DEFINITION 2.5. *By an automaton we mean a* 6*-tuple* $\Delta = (Q, I, M, T, i, q_0)$.

For arbitrary sets X, Y (topological spaces X, Y) we denote by $\mathbf{P}(X, Y)$ (resp., $\mathbf{C}(X, Y)$) the set of all functions (resp., continuous functions) from X to Y.

Now, for any automaton Δ satisfying (i)–(vi) we define by induction a Volterra operator $F_\Delta : \mathbf{C}([0, \infty), \mathbf{R}^m) \to \mathbf{P}([0, \infty), Q)$. For each $y \in \mathbf{C}([0, \infty), \mathbf{R}^n)$, F_Δ is given by the following:

1. $(F_\Delta y)(0) = q(0); \quad \tau_1 = T(q(0)); \quad (F_\Delta y)(t) \equiv q(0), \quad t \in [0, \tau_1)$.
2. $(F_\Delta y)(\tau_1) = M(q(0), i(y(\tau_1))) := q(\tau_1); \quad \tau_2 = \tau_1 + T(q(\tau_1))$;
   $(F_\Delta y)(t) = q(\tau_1), \quad t \in [\tau_1, \tau_2)$.

3. If $\tau_0, \tau_1, \ldots, \tau_k$ and the values $(F_\Delta y)(t)$ for $t \in [0, \tau_k)$ are already known, then τ_{k+1} and $(F_\Delta y)(t)$ for $t \in [\tau_k, \tau_{k+1})$ are defined by the equalities

$$(F_\Delta y)(\tau_k) = M(q(\tau_{k-1}), i(y(\tau_k))) := q(\tau_k); \quad \tau_{k+1} = \tau_k + T(q(\tau_k));$$
$$(F_\Delta y)(t) \equiv q(\tau_k), \quad t \in [\tau_k, \tau_{k+1}).$$

DEFINITION 2.6. *A control* $u(\cdot)$ *of the type*

$$u(t) = \varphi(y(t), (F_\Delta y)(t)), \tag{2.2}$$

where $\varphi : \mathbf{R}^m \times Q \to \mathbf{R}^\ell$ *is a certain function, will be addressed as a* hybrid feedback control (HFC).

Denote by $\tilde{\mathcal{H}}$ a class of all HFC in the sense of Definition 2.6.

Let ω be finite or infinite cardinal. A class of HFC (2.2) generated by an automaton $\Delta = (Q, I, M, T, i, q_0)$, where $\operatorname{card} Q \le w$, $\operatorname{card} I \le w$ ($\operatorname{card} \mathcal{D}$ stands for the cardinality of a set $\mathcal{D}$), will be denoted by $\mathcal{H}_\omega$.

DEFINITION 2.7. *A hybrid feedback control* $u(\cdot)$ *belonging to the class* $\mathcal{H}_\omega$ *will be called* ω*-HFC.*

Some examples. 1. The class $\mathcal{H}_0$ consists of ordinary (nonlinear) feedback controls which are of the type $u = f(y)$ for some function $f : \mathbf{R}^m \to \mathbf{R}^\ell$. Clearly, $\mathcal{L}_0 \subset \mathcal{H}_0$ ($\mathcal{L}_0$ was introduced before Lemma 2.4, above).

2. It is also evident that $\mathcal{H}_1 = \mathcal{H}_0$, i.e., in case Q degenerates into a singleton, any HFC is given by a feedback control of the type $u = f(y)$ for a function $f : \mathbf{R}^m \to \mathbf{R}^\ell$.

3. An elementary hybrid system is that with a finite number of locations $Q = \{q_1, \ldots, q_n\}$ (see [2]). An elementary hybrid system gives rise to an elementary HFC.

In our notation, an elementary HFC is nothing but an n-HFC (or HFC of the class $\mathcal{H}_n$) for some natural number n. A typical elementary (or, more generally, discrete) hybrid system's dynamic is continuous, and the solution satisfies (2.1) with $u = \varphi(y, q_i)$ on the time intervals $(\tau_i, \tau_{i+1}]$ which cover $\mathbf{R}_+$. More specific examples of 2- and 3-HFCs are presented in [2].

The class $\cup_{n=1}^{\infty}\mathcal{H}_n$ of all elementary hybrids will hereafter be denoted by $\mathcal{H}_e$.

Let σ and ω_1 be the cardinalities of a countable set and a continuum set, respectively. Then

$$\mathcal{H}_0 = \mathcal{H}_1 \subset \mathcal{H}_2 \subset \cdots \subset \bigcup_{n=1}^{\infty} \mathcal{H}_n = \mathcal{H}_e \subset \mathcal{H}_\sigma \subset \mathcal{H}_{\omega_1} \subset \cdots \subset \tilde{\mathcal{H}}.$$

For systems in finite-dimensional spaces (when $y \in \mathbf{R}^m$) we always have $\mathcal{H}_{\omega_1} = \tilde{\mathcal{H}}$. The classes $\mathcal{H}_\omega$ for $\omega > \omega_1$ can be useful for more general dynamical systems, for example, those in abstract metric spaces or other topological spaces (some examples can be found in [12]).

Now we are able to define the class of HFCs which we will use to find a stabilizer to a system (2.1).

DEFINITION 2.8. *An HFC $u(\cdot)$ given by* (2.2) *is called* uniform *if*

(1) *T is a constant function;*

(2) *the function φ does not depend on the first argument, i.e., $u(t) = \varphi((F_\Delta y)(t))$.*

The set of all uniform HFCs will hereafter be denoted by $\mathcal{H}$. Clearly, $\mathcal{H} \subset \mathcal{H}_\sigma$.

The main result of our paper follows.

THEOREM 2.9. *The system* (2.1) *is $\mathcal{H}$-stabilizable under assumptions of controllability of (A, B) and observability of (A, C).*

3. The proof of the main result. We find it convenient to use the following notation:

– $\mathcal{M}_{j,k}$ is the set of all real $j \times k$-matrices;
– $\mathcal{M}_k = \mathcal{M}_{k,k}$ is the set of all real $k \times k$-matrices;
– $\mathcal{L}(\mathbf{R}^j, \mathbf{R}^k)$ is the set of all linear operators from $\mathbf{R}^j$ to $\mathbf{R}^k$;
– $\mathcal{L}(\mathbf{R}^k) = \mathcal{L}(\mathbf{R}^k, \mathbf{R}^k)$ is the set of all linear operators in the space $\mathbf{R}^k$;
– $|\cdot|$ is the Euclidean norm in the spaces $\mathbf{R}^k$ (for any k);
– $\|\cdot\|$ is the corresponding operator-norm in the spaces $\mathcal{L}(\mathbf{R}^j, \mathbf{R}^k)$;
– I_k is the identity $k \times k$-matrix;
– χ_E is the characteristic function of a set E;
– $\mathbf{C}$ is the space of all continuous functions from $[0, \infty)$ to $\mathbf{R}^n$;
– $\mathbf{L}_0$ is the space of all Lebesgue measurable functions from $[0, \infty)$ to $\mathbf{R}^n$.

We need two lemmas to prove Theorem 2.9.

LEMMA 3.1. *There exists an $(\ell \times n)$-matrix G such that the matrix $A + BG$ is stable and the matrix pair $(A + BG, C)$ is observable.*

Proof. According to Theorem 2.2 we choose a matrix $G_0 \in \mathcal{M}_{\ell,n}$, for which $A + BG_0$ is stable. Clearly, there exists $\varepsilon > 0$ such that for any $t \in (1 - \varepsilon, 1 + \varepsilon)$ a matrix $A + tBG_0$ is stable. Consider a function $\psi : \mathbf{R} \to \mathbf{R}$, which to each t associates the sum of squares of all nth order minors of the matrix ${}_C[A + tBG_0]$.

Due to Kalman's criterion $\mathcal{P} := \{\, t \in \mathbf{R} \mid (A + tBG, C) \text{ is observable} \,\} = \psi^{-1}(\mathbf{R} \setminus \{0\})$. Evidently, ψ is a polynomial, and moreover, $\psi \not\equiv 0$. The last inequality follows immediately from the observability of the pair (A, C), which implies $\psi(0) \neq 0$. Thus ψ has a finite number of zeros and, therefore there exists $t^* \in \mathcal{P} \bigcap (1 - \varepsilon, 1 + \varepsilon)$. Hence, the matrix $G = t^* G_0$ satisfies the required conditions. ∎

Our next lemma is a version of the Lyapunov stability theorem for a class of *functional differential equations*. Some similar, but not exactly similar, results are available in the literature (see, e.g., [3], [7], and references therein).

The Cauchy formula we will use is classical (see, e.g., [3] or [4]):

$$x(t) = \mathcal{X}(t)x(0) + \int_0^t \mathcal{C}(t,s)f(s)ds, \qquad t \geq 0. \tag{3.1}$$

Here $\mathcal{C}(t,s)$ is the Cauchy matrix of the equation

$$Lx \equiv \dot{x}(t) - \sum_{k=1}^{n} \tilde{a}_k(t)x[h_k(t)] = f(t), \qquad t > 0, \tag{3.2}$$

and $\mathcal{X}(t)$ is the fundamental matrix of the corresponding homogeneous equation.

LEMMA 3.2. *Let $\tilde{a}_k : [0,\infty) \to \mathcal{L}(\mathbf{R}^n)$ be locally Lebesgue-integrable and $h_k : [0,\infty) \to \mathbf{R}$ Lebesgue measurable functions. Assume that there exist $N, \beta, \tau > 0$ such that $\zeta(t) \leq h_k(t) \leq t$, $t \in [0,\infty)$, $k = 1, \dots, n$, where $\zeta(t) = \max\{0, t-\tau\}$ and*

$$\|\mathcal{C}(t,s)\| \leq Ne^{-\beta(t-s)}. \tag{3.3}$$

Then there exists $\varepsilon > 0$ such that for any operator $V : \mathbf{C} \to \mathbf{L}_0$ satisfying

$$|(Vx)(t)| \leq \varepsilon \max_{\zeta(t)\leq s\leq t} |x(s)|, \qquad t \in [0,\infty), \quad x \in \mathbf{C}, \tag{3.4}$$

the zero solution of the perturbed equation

$$Lx = Vx \tag{3.5}$$

is globally exponentially stable:

$$|x(t)| \leq N_0 e^{-\beta_0 t}|x(0)|, \qquad t \geq 0, \tag{3.6}$$

for any solution $x(t)$ of (3.6) and for some positive constants N_0, β_0 independent of $x(t)$.

Proof. From the Cauchy formula (3.1) as well as from (3.3) and (3.4) it immediately follows that

$$|x(t)| \leq Ne^{-\beta t}|x(0)| + N\varepsilon \int_0^t e^{-\beta(t-s)} \max_{\zeta(s)\leq\xi\leq s} |x(\xi)|ds, \qquad t \geq 0.$$

Putting $z(t) := \max_{\zeta(t)\leq s\leq t}|x(t)|e^{\beta t}$ we obtain the estimate

$$z(t) \leq N_0|x(0)| + N_0\varepsilon \int_0^t z(s)ds, \qquad t \geq 0,$$

with $N_0 = Ne^{\beta\tau}$.

By the Gronwall–Bellman inequality, $z(t) \leq N_0|x(0)|e^{N_0\varepsilon}$, $t \geq 0$, so that $|x(t)| \leq N_0 e^{(N_0\varepsilon-\beta)t}|x(0)|$, $t \geq 0$. Then for any $\varepsilon < \beta/N_0$ we obtain the estimate (3.6). ∎

Now we are ready to start proving our central result.

I. By Lemma 3.1, we find a matrix $G \in \mathcal{M}_{m,n}$ such that the matrix $A + BG$ is stable and the pair $(A + BG, C)$ is observable.

Let us fix an arbitrary $\tau > 0$ and put

$$A(t) = \chi_{[0,\tau]}A_0 + \chi_{[\tau,\infty)}A_1, \qquad \tau \in [0,\infty),$$

where $A_0 = A, \quad A_1 = A + BG$.

Denote by $X(t,s)$ the Cauchy matrix of the ordinary differential equation $\dot{x} = A(t)x$. We do not assume in that which follows that $t \geq s$ (defining $X(s,t) = X^{-1}(t,s)$ if necessary). Evidently,

$$\begin{array}{ll} X(t,s) = e^{A_1(t-s)}, & t \geq \tau, \quad s \geq \tau, \\ X(t,s) = X(t,\tau-0)X(\tau,s) = e^{A_0(t-\tau)}e^{A_1(\tau-s)}, & 0 \leq t \leq \tau \leq s. \end{array} \tag{3.7}$$

We do not describe all possible cases here, restricting ourselves to those formulae which we are going to use in the course of the proof.

II. Consider the following equation for the unknown matrix-valued function $X(t) := [X_1(t), \ldots, X_n(t)] \in \mathcal{M}_{n,mn}$ with $X_k : [\tau, \infty) \to \mathcal{M}_{n,m}$:

$$\sum_{k=1}^{n} X_k(t) C X(p\tau + kh, t) = I_n, \quad t \in [(p+1)\tau, (p+2)\tau) := E_p. \tag{3.8}$$

Here $h = \tau/n$ and $p = 0, 1, 2, \ldots$. Our next aim is to prove existence of a solution $X(t)$ to this equation.

(a) Let us first assume that $t \in E_0$. Then $0 \leq kh \leq \tau \leq t, \quad k = 1, \ldots, n$, and due to (3.7)

$$X(kh, t) = e^{A_0(kh-\tau)}e^{A_1(\tau-t)} = T_0^{k-1}U_0, \quad k = 1, \ldots, n, \tag{3.9}$$

where $T_0 = e^{A_0 h}, \quad U_0 = e^{A_0(h-\tau)}e^{A_1(\tau-t)}$.

(b) Let t belong to $E_p, \quad p = 1, 2, \ldots$. Then $0 < \tau \leq p\tau + kh \leq t, \quad k = 1, \ldots, n$, and according to (3.7)

$$X(p\tau + kh, t) = T_1^{k-1}U_p, \quad k = 1, \ldots, n, \tag{3.10}$$

where $T_1 = e^{A_1 h}, \quad U_p = e^{A_1(p\tau+h-t)}$. Notice that from the observability of the pairs (A_i, C) and Kalman's criterion it follows that $\operatorname{rank}({}_C[A_i]) = n$, $i = 0, 1$. Hence, for generic h (see, e.g., [10]),

$$\operatorname{rank}({}_C[T_i]) = n \tag{3.11}$$

as well. In what follows we shall always assume, without loss of generality, that our h satisfies conditions (3.11).

For an arbitrary ordered n-tuple $\mathcal{K} = \{k_1, \ldots k_n\} \subset \{1, 2, \ldots, mn\}$ ($k_j < k_{j+1}$, $j = 1, \ldots, n-1$) we now define two operators $R_{\mathcal{K}} : \mathcal{M}_{mn,n} \to \mathcal{M}_n$, $S_{\mathcal{K}} : \mathcal{M}_n \to \mathcal{M}_{mn,n}$ in the following manner:

– jth row in the matrix $R_{\mathcal{K}}Z$ coincides with k_jth row of the matrix Z;

– k_jth column of the matrix $S_{\mathcal{K}}Z$ coincides with jth column of the matrix Z;

– the columns with numbers $k \notin \mathcal{K}$ of the matrix $S_{\mathcal{K}}Z$ are all null-columns.

From (3.11) it follows that for some ordered n-tuples $\mathcal{K}_i \subset \{1, 2, \ldots, mn\}$ the matrices $R_{\mathcal{K}_i}({}_C[T_i])$ $(i = 1, 2)$ are nonsingular. Due to (3.9), (3.10), it is straightforward that the matrix $X(t)$, defined by

$$X(t) = S_{\mathcal{K}_i}\left(U_p^{-1}\left(R_{\mathcal{K}_i}({}_C[T_i])^{-1}\right)\right), \tag{3.12}$$

satisfies (3.9), where it is assumed that $i = p = 0$ for $t \in E_0$ and $i = 1$ for $t \in E_p$, $p = 1, 2, \ldots$.

III. Put

$$u_1(t) = \begin{cases} 0, & 0 \le t < \tau, \\ G\left(\sum_{k=1}^{n} X_k(t) y(p\tau + kh)\right), & t \in E_p, \quad p = 0, 1, 2, \dots, \end{cases} \tag{3.13}$$

where $y = Cx$ and $X(t) := [X_1(t), \dots, X_n(t)]$ is defined by (3.12). Due to (3.8),

$$u_1(t) = G\left(\sum_{k=1}^{n} X_k(t) C x(p\tau + kh)\right)$$
$$= G\left(\sum_{k=1}^{n} X_k(t) C X(p\tau + kh, t) x(t)\right) = Gx(t),$$
$$t \in E_p, \quad p = 0, 1, 2, \dots.$$

Hence, (2.1) coincides with the exponentially stable linear equation $\dot{x} = A_1 x$ in the interval $t \in [\tau, \infty)$. Therefore, the system (2.1) is u_1-stabilizable.

But u_1 is not yet a hybrid feedback control in the sense of Definition 2.8.

According to the formula (2.2) we now need to find suitable discrete approximations for $A_i(t)$ and $Cx(\tau h + kh)$. To do so, we will use a technique based on the preservation of the asymptotic stability for functional differential equations with respect to small perturbations both in coefficients and time-delays [4].

IV. Let us first rewrite the system (2.1) involving the control u_1 in the form of the following delay-equation:

$$\dot{x}(t) - \sum_{k=0}^{n} a_k(t) x[h_k(t)] = 0, \quad t \in [0, \infty). \tag{3.14}$$

Here

$$a_0(t) = \chi_{[0,\tau)}(t) A, \qquad a_k(t) = \chi_{[\tau,\infty)}(t) BGX_k(t) C, \quad k = 1, \dots, n,$$
$$h_0(t) = t, \qquad h_k(t) = \sum_{p=0}^{\infty} \chi_{E_p}(t)(p\tau + kh), \quad k = 1, \dots, n.$$

As shown in III, (3.14) is exponentially stable. From (3.12), it also follows that

$$a_k(t) = BG\, S_{\mathcal{K}_i}\left(U_p^{-1}\left(R_{\mathcal{K}_i}\,({}_C[T_i])^{-1}\right)\right) \Lambda_k C, \tag{3.15}$$
$$k = 1, \dots, n, \quad t \in E_p, \quad p = 0, 1, 2, \dots,$$

where the block matrices $\Lambda_k \in \mathcal{M}_{mn,n}$ are defined by

$$\Lambda_k = (\underbrace{\theta \dots \theta}_{m(k-1)}\ I_m \underbrace{\theta \dots \theta}_{m(n-k)})^{\top}, \qquad k = 1, \dots, n$$

(θ is an m-dimensional zero vector-column), and $i = 0$ for $p = 0$, $i = 1$ for $p > 0$.

The representation (3.15) implies that each of the functions $a_k : [0, \infty) \to \mathcal{L}(\mathbf{R}^n)$ is piecewise continuous with possible jumps at the points $p\tau$, $p = 1, 2, \dots$, only.

Since

$$\|a_k(t)\| \le \max\left\{\|A\|, \|BG\| \cdot \|C\| \cdot \max_{i=1,2}\left\|(S_{\mathcal{K}_i}({}_C[T_i]))^{-1}\right\|\right.$$
$$\left.\times \max(1, \|e^{-A_0\tau}\|) \cdot \|e^{A_1\tau}\|\right\} < \infty, \qquad t \in [\tau, \infty),$$

the functions a_k are bounded. Then, according to Corollary 2 in [4, p. 173], there exists $\sigma > 0$ such that for all locally Lebesgue-integrable functions $\tilde{a}_k : [0,\infty) \to \mathcal{L}(\mathbf{R}^n)$, satisfying

$$\max_k \limsup_{t\to\infty} \|a_k(t) - \tilde{a}_k(t)\| < \sigma, \tag{3.16}$$

the Cauchy matrix $\mathcal{C}(t,s)$ of (3.2) has the exponential estimate (3.3).

Equalities (3.15) and (3.10) imply a periodicity of a_k with the period τ for $t \geq 2\tau$. Now let us approximate $X(t)$ by a step function on $[2\tau, 3\tau]$. For the sake of convenience, we may assume that the points $2\tau + kh$ are included in the set of possible jump-points of the step function. Then we extend this function τ-periodically to the interval $[3\tau,\infty)$. Finally, we approximate $X(t)$ on $[\tau, 2\tau]$ by a suitable step function. Let us notice that such approximations can be found with a prescribed accuracy. Our output will be a function $\tilde{X}(t) = [\tilde{X}_1(t), \dots, \tilde{X}_n(t)]$ of the form

$$\tilde{X}_k(t) = \sum_{j=0}^{J-1} \chi_{E_{1j}}(t)\tilde{c}_{kj} + \sum_{p=1}^{\infty}\sum_{j=0}^{J-1} \chi_{E_{pj}}(t)c_{kj}, \quad t \in E_{pj}, \tag{3.17}$$

where J is a natural constant, $\delta = \tau/J$, $E_{pj} = [(p+1)\tau + j\delta, (p+1)\tau + (j+1)\delta)$, and $\tilde{c}_{kj}, c_{kj} \in \mathcal{M}_{n,m}$ are some matrices as well. Here $k = 1, \dots, n$, $j = 0, 1, \dots, J-1$, and $p = 0, 1, \dots$. By construction, $\|\tilde{X}_k(t) - X_k(t)\| < \sigma \cdot (\|BG\| \cdot \|C\|)^{-1}$.

We now set $a_0(t) \equiv A$, $\tilde{a}_k(t) = BG\tilde{X}_k(t)C$, $k = 1, \dots, n$. Then

$$\max_k \sup_{t\in[0,\infty)} \|\tilde{a}_k(t) - a_k(t)\| < \sigma,$$

so that (3.16) holds.

Consequently, we obtain that the Cauchy matrix of (3.2) admits the exponential estimate (3.3).

V. According to Lemma 3.2 one can choose a positive ε such that for any (as general as necessary) nonlinear operator $V : \mathbf{C} \to \mathbf{L}_0$ satisfying the condition (3.4) every solution x of the perturbed equation (3.5) has the exponential estimate (3.6) with certain positive constants N_0, β_0 (independent of x).

By (3.17), $\varepsilon_1 := \varepsilon[\,\|BG\| \cdot \|C\| \cdot \sup_{t\in[0,\infty)} \sum_{k=1}^n \|\tilde{X}_k(t)\|\,]^{-1} > 0$. A multivalued function $\Phi : \mathbf{R}^m \to 2^{\mathbf{Q}^m}$ ($\mathbf{Q}$ is the set of rational numbers) defined by

$$\Phi(v) = \{r \in \mathbf{Q}^m \,|\, |v - r| \leq \varepsilon_1 |v|\}$$

then has nonempty images: $\Phi(v) \neq \emptyset$, $v \in \mathbf{R}^m$. We take an arbitrary selector ϱ of the multivalued function Φ and define V as follows:

$$(Vx)(t) = \sum_{k=1}^n BG\tilde{X}_k(t)\left(\varrho(Cx[h_k(t)]) - Cx[h_k(t)]\right). \tag{3.18}$$

It is easy to check that V acts from $\mathbf{C}$ to $\mathbf{L}_0$ and satisfies the inequality (3.4). Hence (3.5) with the operator V just defined becomes asymptotically stable, and the stability is uniform with respect to compact subsets.

By construction, (3.5) has the form

$$\dot{x}(t) = Ax(t) + \sum_{k=1}^n BG\tilde{X}_k(t)\varrho(Cx[h_k(t)]).$$

This equation is, in turn, equivalent to the original system (2.1), where the corresponding control u is defined by

$$(3.19)\quad u(t)=\begin{cases} 0, & t\in[0,\tau),\\ G\left(\sum\limits_{k=1}^{n}\tilde{c}_{kj}\varrho(y(kh))\right), & t\in E_{0j},\quad j=0,1,\dots,J-1,\\ G\left(\sum\limits_{k=1}^{n}c_{kj}\varrho(y(p\tau+kh))\right), & t\in E_{pj},\quad j=0,1,\dots,J-1,\\ & \qquad\quad p=1,2,\dots. \end{cases}$$

Recall that $y=Cx$ is the output.

The system (2.1) controlled by u from (3.19) is therefore asymptotically stable, and the stability is uniform with respect to any compact subset of $\mathbf{R}^n$.

VI. We have not yet shown that $u\in\mathcal{H}$.

Put $N_J=\{0,1,\dots,J-1\}$ and denote by Ω a subset of $\mathcal{M}_{\ell,mn}$ consisting of the block matrices

$$\tilde{c}_j=(G\tilde{c}_{1j},\dots,G\tilde{c}_{nj}),\quad c_j=(Gc_{1j},\dots,Gc_{nj}),\quad \bar{z}=(z,\dots,z),\quad j=1,\dots,J-1,$$

where $z\in\mathcal{M}_{\ell,mn}\setminus\{G\tilde{c}_{kj},Gc_{kj}\mid k=1,\dots,n,\quad j=1,\dots,J-1\}$ is arbitrary. Put $\mathcal{Y}\subset\Omega\times N_J$. The elements of $\mathcal{Y}$ are $(\bar{z},j)$, $(\tilde{c}_j,j)$, and (c_j,j). Let us define a mapping $M_0:\mathcal{Y}\to\mathcal{Y}$ by

$$\begin{aligned} &M_0(\bar{z},j)=(\bar{z},j+1), && j=1,\dots,J-2, && M_0(z,J-1)=(\tilde{c}_0,0),\\ &M_0(\tilde{c}_j,j)=(\tilde{c}_{j+1},j+1), && j=0,1,\dots,J-2, && M_0(\tilde{c}_{J-1},J-1)=(c_0,0),\\ &M_0(c_j,j)=(c_{j+1},j+1), && j=0,1,\dots,J-2, && M_0(c_{J-1},J-1)=(c_0,0). \end{aligned}$$

Let P be the set of all row-vectors of the form $q=(q_1,\dots,q_n)$, where $q_k\in\mathbf{Q}^m$. We extend now M_0 to the set $\Omega\times N_J$ and define two mappings $M_-:P\times N_J\times P\to P$ and $M_+:P\times P\times N_J\to P$ as follows:

$$M_-(q,j,i)=\begin{cases} q & \text{if } j\neq J-1,\ j\neq\frac{kJ}{n},\ k=1,\dots,n-1,\\ (q_1,\dots,q_{k-1},i,q_{k+1},\dots,q_n) & \text{if } j=\frac{kJ}{n},\ k=1,\dots,n-1,\\ (q_1,\dots,q_{n-1},i) & \text{if } j=J-1, \end{cases}$$

where $q=(q_1,\dots,q_n)$,

$$M_+(q^+,q^-,j)=\begin{cases} q^+ & \text{if}\quad j\neq 0,\\ q^- & \text{if}\quad j=0. \end{cases}$$

We first describe an automaton $\Delta=(Q,I,M,T,i,q_0)$. Let the (countable) set $Q=P\times P\times(\Omega\times N_J)$ contain 4-tuples $(q^+,q^-,(c,j))$ and the (countable) alphabet I be equal to $\mathbf{Q}^m$. The mapping $M:Q\times I\to Q$ is then defined by

$$M(q^+,q^-,(c,j),i)=(M_+(q^+,M_-(q^-,j,i),j),M_-(q^-,j,i),M_0(c,j)).$$

Assume that $T\equiv\delta$ and define $i:\mathbf{R}^m\to I$ and q_0 by

$$i(s)=\varrho(s),\qquad q_0=(\Theta,\Theta,(\bar{z},0)),$$

where Θ is zero in P.

Finally, we choose a function $\varphi : Q \to \mathbf{R}^\ell$ as follows:

$$\varphi((q_1, \dots, q_n), q^-, ((d_1, \dots, d_n), j)) = \begin{cases} 0 & \text{if} \quad (d_1, \dots, d_n) = \bar{z}, \\ \sum\limits_{k=1}^{n} d_k q_k & \text{if} \quad (d_1, \dots, d_n) \neq \bar{z}. \end{cases}$$

By construction, the control u given by (3.19) is of the form $u(\cdot) = \varphi((F_\Delta y)(\cdot))$ and belongs to the class $\mathcal{H}$. The control u is therefore a uniform HFC in the sense of Definition 2.8. Moreover according to part V of the proof, the control u stabilizes the system (2.1). The proof of Theorem 2.9 is completed.

4. An example. Here we show how the proposed algorithm can be used to design an explicit hybrid strategy to stabilize particular systems.

Example 4.1. Consider the linear control system

$$\dot{\xi} = \eta + u, \qquad \dot{\eta} = \xi, \qquad u(t) = \varphi(\xi(t), (F_\Delta \xi)(t)). \tag{4.1}$$

This system has the following two properties:

1. There is no linear HFC stabilizing the system (4.1).

2. The pair (A, B) is controllable, the pair (A, C) is observable, so that according to Theorem 2.9 the system (4.1) is $\mathcal{H}$-stabilizable. The corresponding hybrid control strategy can be written explicitly.

To prove 1, one may observe that for an arbitrary $\eta_0 > 0$ the set $(\xi(t), \eta(t)) \in [0, \infty) \times [\eta_0, \infty) := \mathcal{D}$ is flow-invariant for any linear control strategy. This excludes asymptotic stability.

Now, in order to design an *explicit* HFC $u \in \mathcal{H}$ stabilizing the system (4.1) one should follow the algorithm from Theorem 2.9. For instance, if we take $G = [\,-2, \, -3\,]$, then the eigenvalues of the matrix $A + BG$ will be $-1 \pm i$, so that $A + BG$ is stable, and G can be used to construct an HFC. We put also $h = \frac{\pi}{2}$. Evidently,

$$e^{A_0 t} = \begin{bmatrix} \cosh t & \sinh t \\ \sinh t & \cosh t \end{bmatrix}, \qquad e^{A_1 t} = e^{-t} \cdot \begin{bmatrix} \cos t - \sin t & -2 \sin t \\ \sin t & \cos t + \sin t \end{bmatrix}. \tag{4.2}$$

The fundamental matrix defined in (3.7) satisfies

$$\|X(t, s)\| \leq \sqrt{7}\, e^{2\pi - t + s}, \qquad t \geq s \geq 0.$$

Now, from this and from simple estimates on $\|BG\|$, $\|C\|$ we can deduce that any piecewise approximation $\tilde{X}(t)$ of the matrix function $X(t)$ satisfying

$$\|\tilde{X}_k(t) - X_k(t)\| < \frac{e^{-4\pi}}{8\sqrt{7}}, \qquad k = 1, 2, \quad t \in [\pi, \infty), \tag{4.3}$$

will stabilize the system (4.1).

To obtain this estimate one can, e.g., define $\tilde{X}_k(t)$, $k = 1, 2$, by putting

$$\tilde{X}_k(t) = \sum_{p=0}^{\infty} \sum_{j=0}^{J-1} \chi_{E_{pj}}(t) X_k(2\pi(p+1) + \pi(2j+1)/(2J)), \quad t \in E_{pj}, \tag{4.4}$$

where $J = 5 \times 10^7$, $E_{pj} = [2\pi(p+1) + \pi j/J, 2\pi(p+1) + \pi(j+1)/J)$, $j = 0, 1, \dots, J-1$, and $p = 0, 1, \dots$.

Finally, for some $\varepsilon_1 \in (0, \frac{e^{-4\pi}}{40\sqrt{7}})$ we define a function $\varrho : \mathbf{R} \to \mathbf{Q}$ by $\varrho(v) = \big[10^K v\big] \cdot 10^{-K}$, where $K = \max\{1,\ 1 + [\lg \frac{2}{\varepsilon|v|}]\}$, $[w]$ being the integral part of $w \in \mathbf{R}$.

The resulting hybrid strategy will be as follows.

We set $u(t) = 0$ when $t \in [0, 2\pi)$ and define

$$\begin{aligned} u(t) = &-2X_{11}(2\pi(p+1) + \pi(2j+1)/(2J)) \cdot \varrho(\xi(\pi p + \pi/2)) \\ &-3X_{21}(2\pi(p+1) + \pi(2j+1)/(2J)) \cdot \varrho(\xi(\pi p + \pi/2)) \\ &-2X_{12}(2\pi(p+1) + \pi(2j+1)/(2J)) \cdot \varrho(\xi(\pi p + \pi)) \\ &-3X_{22}(2\pi(p+1) + \pi(2j+1)/(2J)) \cdot \varrho(\xi(\pi p + \pi)) \end{aligned}$$

when $t \in E_{pj},\ \ j = 0, 1, \ldots, J-1,\ \ p = 0, 1, \ldots$.

Remark. All the estimates in this example are rather rough. Using mathematical software will give more suitable constants if required.

5. Conclusion. We do not have answers to the following questions.

(1) Is an arbitrary system (2.1) $\mathcal{H}_e$-stabilizable under assumptions of (A, B)-controllability and (A, C)-observability? In other words, it is not clear to what extent one may use HFCs with finitely many locations in order to stabilize (2.1).

(2) Examples show that the assumptions of (A, B)-controllability and (A, C)-observability are not necessary for the hybrid feedback stabilization (just take a trivial example of an exponentially stable linear system with $B = C = 0$). The second open problem is to find better conditions for the hybrid feedback stabilization in terms of matrices A, B, C.

Acknowledgments. We would like to thank Professor Zvi Artstein for introducing us to the problem and for his very helpful comments. We are also grateful to the anonymous referee who carefully read the manuscript and suggested a number of improvements.

MINIMAX CONTROLS FOR UNCERTAIN PARABOLIC SYSTEMS*

NADIR ARADA†, MAÏTINE BERGOUNIOUX‡, AND JEAN-PIERRE RAYMOND§

Abstract. We consider systems governed by a nonlinear parabolic equation with a distributed control and a disturbance in the initial condition. We prove the existence of solutions to a corresponding minimax problem, and we obtain necessary optimality conditions in the form of Pontryagin's principles.

Key words. uncertain systems, minimax, semilinear parabolic equations, existence of optimal solutions, necessary optimality conditions, Pontryagin's principle

1. Introduction.

In this paper we consider an uncertain system described by the parabolic equation

$$\frac{\partial y}{\partial t} + Ay + \Phi(x,t,y) = u \text{ in } Q, \qquad y = \psi \text{ on } \Sigma, \tag{1.1}$$
$$y(x,0) = y_o(x) + g(x) \text{ in } \Omega,$$

where $Q = \Omega\times]0,T[$, Ω is a bounded domain in $\mathbb{R}^N$, $\Sigma = \Gamma\times]0,T[$, Γ is the boundary of Ω, and A is a second-order elliptic operator, $\psi \in L^\infty(\Sigma)$. The function u is a control variable; the initial condition is not completely known. We only suppose that g belongs to G_{ad}, where G_{ad} is a closed convex subset of $L^\infty(\Omega)$ (not necessarily reduced to a unique element). For this reason, system (1.1) is called an "uncertain system." Many physical systems may be described by equations involving disturbances, noises, or uncertainties. Here we suppose that the disturbance only appears through the initial condition, but the results of this paper may be extended to other classical situations. We can, for example, consider systems with a disturbance or a control in the boundary condition (see [2, 3]). Let us denote by $y(u,g)$ the solution of (1.1) corresponding to (u,g), and for a given $g \in G_{ad}$, consider the problem

$$(\mathcal{P}_g) \qquad \inf \{ \mathcal{I}(y(u,g),u,g) \mid u \in U_{ad} \},$$

where U_{ad} is a given control set, and $\mathcal{I}$ is a cost functional that we make explicit hereafter. We denote by $\text{Argmin}(\mathcal{P}_g)$ the set of solutions to $(\mathcal{P}_g)$, and we set $J(u,g) = \mathcal{I}(y(u,g),u,g)$. The control problem that we consider is the following.

$$(\mathcal{P}) \qquad \begin{cases} \text{Find } \bar{u} \in U_{ad} \text{ such that } \bar{u} \in \text{Argmin } (\mathcal{P}_{\bar{g}}) \text{ for some } \bar{g} \in G_{ad}, \text{ and} \\ J(u_g,g) \le J(\bar{u},\bar{g}) \text{ for all } g \in G_{ad} \text{ and all } u_g \in \text{ Argmin } (\mathcal{P}_g). \end{cases}$$

§UMR-CNRS 5640, UFR MIG, Université Paul Sabatier, 31062 Toulouse Cedex 4, France (raymond@mip.ups-tlse.fr).

This problem may be expressed in an equivalent form as

$$\begin{cases} \text{Find } \bar{g} \in G_{ad} \text{ and } u_{\bar{g}} \in \text{ Argmin } (\mathcal{P}_{\bar{g}}) \text{ such that} \\ J(u_g, g) \leq J(u_{\bar{g}}, \bar{g}) \text{ for all } g \in G_{ad} \text{ and all } u_g \in \text{ Argmin } (\mathcal{P}_g), \end{cases}$$

or

$$\max_{g \in G_{ad}} \min_{u \in U_{ad}} J(u, g) \ .$$

The cost functional that we consider is defined as follows:

$$\mathcal{I}(y, u, g) = \int_Q (F(x, t, y) + H(x, t, u)) \, dx \, dt + \int_\Omega (\ell(x, y(T)) + L(x, g)) \, dx,$$

where H is convex with respect to u, and L is concave with respect to g. We prove the existence of optimal solutions to $(\mathcal{P})$ (Theorem 4.3), and we establish optimality conditions in the form of Pontryagin's principles (Theorems 2.1 and 2.2). The proof of Pontryagin's principle for an optimal solution $\bar{g}$ is derived via Taylor's expansions of the state variable and the cost functional for diffuse perturbations of $\bar{g}$ (see Theorem 5.2). This is the main part of the paper. When the state equation is linear and when F and ℓ are convex, the proof is much simpler (see Theorem 2.3 and its proof in section 6.3).

We may relate this kind of problem to the concept of robustness, since considering a min-max problem is equivalent to finding the best control which takes into account the "worst" disturbance in the initial value. For linear equations, such problems have been studied by Lions [11]. The notion of "least regret controls" in [11] corresponds to our definition of robust controls.

Problem (P) is also connected to H_∞-control problems. Indeed for a quadratic functional of the form

$$\mathcal{I}(y, u, g) = \int_Q |y - y_d|^2 \, dx \, dt + \int_Q u^2 \, dx \, dt - \gamma \int_\Omega g^2 \, dx \qquad (\gamma > 0),$$

for linear equations ($\Phi \equiv 0$), and for the control sets $U_{ad} = L^2(Q)$, $G_{ad} = L^2(\Omega)$, robust controls that we consider are suboptimal solutions to some H_∞-control problems (see [5, p. 218]). However the terminology of "robust control" is not adapted here since we always deal with open-loop systems.

A series of papers has been widely devoted to uncertain systems [14], [1]. To analyze the different original contributions and to compare our results with the previous ones, we must distinguish the nature of the system under consideration (i.e., the state equation) and the definition of optimal solutions. First examine the second point. Ahmed and Xiang [1] and Mordukhovitch and Zhang [12] establish optimality conditions for saddle points, that is optimal strategies $(\bar{u}, \bar{g})$ satisfying

$$\sup_{g \in G_{ad}} \inf_{u \in U_{ad}} J(u, g) = \inf_{g \in G_{ad}} \sup_{u \in U_{ad}} J(u, g) = J(\bar{u}, \bar{g}).$$

The inequality

$$\sup_{g \in G_{ad}} \inf_{u \in U_{ad}} J(u, g) \leq \inf_{g \in G_{ad}} \sup_{u \in U_{ad}} J(u, g)$$

is always satisfied, and it is well known that for linear equations and convex cost functionals, the equality holds [6]. For nonlinear equations, the results presented here

are new to our knowledge. Thus our optimal solutions are different from the ones of Ahmed and Xiang. Indeed, for a saddle point strategy, that is for $(\bar{u}, \bar{g}) \in U_{ad} \times G_{ad}$ satisfying

$$J(\bar{u}, g) \leq J(\bar{u}, \bar{g}) \leq J(u, \bar{g}) \qquad \text{for all } u \in U_{ad}, \text{ all } g \in G_{ad},$$

optimality conditions for $\bar{u}$ and $\bar{g}$ can be obtained by separately considering two optimization problems [1]. Such an approach is not applicable for the problem that we consider. Mordukhovitch and Zhang [12] study minimax problems in the presence of pointwise state constraints. Optimality conditions are established for saddle point solutions satisfying the state constraints. Taking advantage of the linear structure of the state equation, the saddle point problem is split into two optimization problems. Still in this case, optimality conditions for $\bar{u}$ and $\bar{g}$ can be obtained separately. To our knowledge, the optimality conditions established in Theorem 2.2 for a minimax problem of the form

$$\sup_{g \in G_{ad}} \inf_{u \in U_{ad}} J(u, g)$$

are a completely new result. Papageorgiou [14] and Ahmed and Xiang [1] consider uncertain systems where the noise is modeled by parametrized measures. These authors consider a control problem where the uncertain term appears as a *distributed* measure. Our purpose is to consider an initial perturbation because in many situations, for example, in data assimilation, the initial condition is not well known. In this case, the disturbance can be considered as an impulsive disturbance, and the analysis is more complicated (see the Taylor's expansions stated in Theorem 5.2 and the role played by the parameter τ_ρ).

The systems considered in [1] are more general than the one considered here, but the results in [1] cannot be applied to problems with uncertain initial conditions. Since the case of convection-diffusion equations considered in section 5 in [1] is interesting from the point of view of applications, we explain in section 7 how to extend our results to these kinds of equations.

Finally, we mention that the existence of solutions for minimax control problems governed by variational inequalities is proven in [14].

The paper is organized as follows. After setting the problem, we present the main assumptions and results in section 2. Section 3 is devoted to the study of solutions for the state and adjoint equations. We prove existence results for the control problems in section 4. In section 5, we establish some Taylor expansions that are used to perform the proofs of the main results in section 6. Extensions to convection-diffusion equations are stated in section 7.

2. Assumptions and main results.

2.1. Assumptions. Throughout the paper, Ω is a bounded open and connected subset in $\mathbb{R}^N (N \geq 2)$ of class $C^{2+\bar{\gamma}}$ for some $0 < \bar{\gamma} \leq 1$, and q is a positive constant satisfying $q > \frac{N}{2} + 1$. The operator A is of the form $Ay(x) = -\sum_{i,j=1}^{N} D_i(a_{ij}(x) D_j y(x))$, where D_i denotes the partial derivative with respect to x_i. The coefficients a_{ij} of A belong to $\mathcal{C}^{1+\bar{\gamma}}(\overline{\Omega})$ and satisfy the condition

$$a_{ij}(x) = a_{ji}(x) \ \text{ for all } i, j \in \{1, \ldots, N\}, \quad m_o |\xi|^2 \leq \sum_{i,j=1}^{N} a_{ij}(x) \xi_i \xi_j$$

for every $\xi \in \mathbb{R}^N$ and every $x \in \overline{\Omega}$, with $m_o > 0$.

Let us define the notation.

- The conormal derivative of y with respect to A is denoted by $\dfrac{\partial y}{\partial n_A}$; that is

$$\frac{\partial y}{\partial n_A}(s,t) = \sum_{i,j} a_{ij}(s) D_j y(s,t) n_i(s),$$

  where $n = (n_1, \ldots, n_N)$ is the unit normal to Γ outward Ω.
- $\overline{\Omega}_o = \overline{\Omega} \times \{0\}$, $\overline{\Omega}_T = \overline{\Omega} \times \{T\}$. For any $\tau > 0$, we set $Q_{\tau T} = \Omega \times]\tau, T[$, $\Omega_\tau = \{ x \in \Omega \mid d(x, \Gamma) > \tau \}$, $Q^\tau = \Omega_\tau \times]\tau, T[$ (d is the Euclidean distance).
- For every $1 \le d \le \infty$, the usual norms in the spaces $L^d(\Omega)$, $L^d(Q)$, $L^d(\Sigma)$ will be denoted by $\|\cdot\|_{d,\Omega}$, $\|\cdot\|_{d,Q}$, $\|\cdot\|_{d,\Sigma}$.
- If $\mathcal{O}$ is a locally compact subset of $\mathbb{R}^{N+1}$, $\mathcal{C}_b(\mathcal{O})$ denotes the space of bounded continuous functions on $\mathcal{O}$, and $\mathcal{C}_o(\mathcal{O})$ the space of all continuous functions from $\mathcal{O}$ into $\mathbb{R}$ vanishing at infinity. The dual space of $\mathcal{C}_o(\mathcal{O})$ is denoted by $\mathcal{M}_b(\mathcal{O})$ (it is the space of bounded Radon measures on $\mathcal{O}$).

Now let us set the assumptions.

(A1) The control set is defined as

$$U_{ad} = \{ u \in L^q(Q) \mid u(x,t) \in K_U(x,t) \text{ for almost all } (x,t) \in Q \},$$

where $K_U(\cdot)$ is a measurable multivalued mapping with nonempty, convex, and closed values in $\mathcal{P}(\mathbb{R})$. The set of constraints on g is defined by

$$G_{ad} = \{ g \in L^\infty(\Omega) \mid g(x) \in K_G(x) \subset G \text{ for almost all } x \in \Omega \},$$

where $K_G(\cdot)$ is a measurable multivalued mapping with nonempty, convex, and closed values in $\mathcal{P}(\mathbb{R})$, and G is a compact subset of $\mathbb{R}$. We suppose that U_{ad} and G_{ad} are nonempty.

REMARK 2.1. *Observe that U_{ad} is a closed, convex subset of $L^q(Q)$. Similarly, G_{ad} is convex and bounded in $L^\infty(\Omega)$ and closed in $L^s(\Omega)$ for all $1 \le s \le +\infty$.*

(A2) Φ is a Carathéodory function from $Q \times \mathbb{R}$ into $\mathbb{R}$. For almost every $(x,t) \in Q$, $\Phi(x,t,\cdot)$ is of class $\mathcal{C}^1$. Moreover, the following estimates hold.

$$|\Phi(x,t,0)| \le \Phi_1(x,t), \ 0 \le \Phi'_y(x,t,y) \le \Phi_1(x,t)\, \eta(|y|),$$

where $\Phi_1 \in L^q(Q)$, and η is a nondecreasing function from $\mathbb{R}^+$ to $\mathbb{R}^+$.

(A3) F and H are Carathéodory functions from $Q \times \mathbb{R}$ to $\mathbb{R}$. For almost all $(x,t) \in Q$, $F(x,t,\cdot)$ is of class $\mathcal{C}^1$ and $H(x,t,\cdot)$ is convex. Moreover, the following estimates hold.

$$-C_1|y|^\sigma \le F(x,t,y) \le F_1(x,t)\, \eta(|y|), \quad |F'_y(x,t,y)| \le F_2(x,t)\, \eta(|y|),$$

$$C_1|u|^q \le H(x,t,u) \le H_1(x,t) + C_2\, |u|^q,$$

where $C_1 > 0$, $C_2 > 0$, $1 \le \sigma < q$, $F_1 \in L^1(Q)$, $H_1 \in L^1(Q)$, $F_2 \in L^m(Q)$ with $m > 1$, and η is defined as in (A2) .

(A4) ℓ and L are Carathéodory functions from $\Omega \times \mathbb{R}$ into $\mathbb{R}$. For almost all $x \in \Omega$, $\ell(x,\cdot)$ is $\mathcal{C}^1$, $L(x,\cdot)$ is concave, and the following estimates hold.

$$-C_1|y|^\sigma \le \ell(x,y) \le \ell_1(x)\, \eta(|y|), \ |\ell'_y(x,y)| \le \ell_2(x)\, \eta(|y|), \ |L(x,g)| \le L_1(x)\, \eta(|g|),$$

where $\ell_1 \in L^1(\Omega)$, $L_1 \in L^1(\Omega)$, $\ell_2 \in L^m(\Omega)$; $m > 1$ and σ are the same exponents as in (A3), and η is as in (A2).

2.2. Statement of the main results. Let us define the Hamiltonian functions:

$$\mathcal{H}_Q(x,t,u,p) = H(x,t,u) - pu \qquad \text{for all } (x,t,u,p) \in Q \times \mathbb{R}^2,$$

$$\mathcal{H}_\Omega(x,y,w,p) = L(x,w) - pw \qquad \text{for all } (x,w,p) \in \Omega \times \mathbb{R}^2.$$

The following result provides necessary optimality conditions (as a Pontryagin's principle) for solutions to $(\mathcal{P}_g)$, where $g \in G_{ad}$ is fixed.

THEOREM 2.1. *Suppose that* (A1)–(A4) *are fulfilled. For any $g \in G_{ad}$, let u_g be a solution of $(\mathcal{P}_g)$. Then there exists $p_g \in L^1(0,T;W_o^{1,1}(\Omega))$, such that*

$$\begin{cases} -\dfrac{\partial p_g}{\partial t} + A\,p_g + \Phi'_y(x,t,y(u_g,g))\,p_g + F'_y(x,t,y(u_g,g)) = 0 & \text{in } Q, \\ \\ p_g(x,T) + \ell'_y(x,y(u_g,g)(T)) = 0 & \text{in } \Omega, \end{cases} \tag{2.1}$$

and

$$\mathcal{H}_Q(x,t,u_g(x,t),p_g(x,t)) = \min_{u \in K_U(x,t)} \mathcal{H}_Q(x,t,u,p_g(x,t)) \quad \text{for almost every } (x,t) \in Q. \tag{2.2}$$

Next we are concerned with necessary optimality conditions for solutions to problem $(\mathcal{P})$.

THEOREM 2.2. *Assume* (A1)–(A4). *Then $(\mathcal{P})$ admits at least a solution $\bar g$. In addition, there exists a solution $\bar u$ to $(\mathcal{P}_{\bar g})$, and $\bar p \in L^1(0,T;W_o^{1,1}(\Omega))$, such that*

$$\begin{cases} -\dfrac{\partial \bar p}{\partial t} + A\bar p + \Phi'_y(x,t,y(\bar u,\bar g))\,\bar p + F'_y(x,t,y(\bar u,\bar g)) = 0 & \text{in } Q, \\ \\ \bar p(x,T) + \ell'_y(x,y(\bar u,\bar g)(T)) = 0 & \text{in } \Omega, \end{cases} \tag{2.3}$$

and

$$\mathcal{H}_Q(x,t,\bar u(x,t),\bar p(x,t)) = \min_{u \in K_U(x,t)} \mathcal{H}_Q(x,t,u,\bar p(x,t)) \quad \text{for a.e. } (x,t) \in Q, \tag{2.4}$$

$$\mathcal{H}_\Omega(x,\bar g(x),\bar p(x,0)) = \max_{g \in K_G(x)} \mathcal{H}_\Omega(x,g,\bar p(x,0)) \quad \text{for a.e. } x \in \Omega. \tag{2.5}$$

In the case of linear equations, and when the cost functional is convex with respect to the state variable, a more accurate statement is given below.

THEOREM 2.3. *Suppose that* (A1)–(A4) *are fulfilled. Suppose in addition that Φ is of the form $\Phi(\cdot,y) = a(\cdot)y + b(\cdot)$ (with $a \in L^q(Q)$, $a \ge 0$, $b \in L^q(Q)$), and that $F(x,t,\cdot)$ and $\ell(x,\cdot)$ are convex. Let $\bar g$ be a solution of (P) and let $u_{\bar g}$ be in $Arg\inf(P_{\bar g})$. Then there exists $\bar p \in L^1(0,T;W_0^{1,1}(\Omega))$ satisfying the equation*

$$\begin{cases} -\dfrac{\partial \bar p}{\partial t} + A\bar p + \Phi'_y(x,t,y(u_{\bar g},\bar g))\,\bar p + F'_y(x,t,y(u_{\bar g},\bar g)) = 0 & \text{in } Q, \\ \\ \bar p(x,T) + \ell'_y(x,y(u_{\bar g},\bar g)(T)) = 0 & \text{in } \Omega, \end{cases} \tag{2.6}$$

and such that

$$\mathcal{H}_Q(x,t,u_{\bar g}(x,t),\bar p(x,t)) = \min_{u \in K_U(x,t)} \mathcal{H}_Q(x,t,u,\bar p(x,t)) \text{ for a.e. } (x,t) \in Q, \tag{2.7}$$

$$\mathcal{H}_\Omega(x,\bar g(x),\bar p(x,0)) = \max_{g \in K_G(x)} \mathcal{H}_\Omega(x,g,\bar p(x,0)) \text{ for a.e. } x \in \Omega. \tag{2.8}$$

3. State equation. Adjoint equation.

3.1. Existence and regularity for the solution of state equation. Let a be a nonnegative function in $L^q(Q)$, let ϕ be in $L^q(Q)$, let f be in $L^\infty(\Sigma)$, and let w be in $L^\infty(\Omega)$. Consider the following equation.

$$\frac{\partial y}{\partial t} + Ay + ay = \phi \ \text{ in } Q, \qquad y = f \ \text{ on } \Sigma, \qquad y(0) = w \ \text{ in } \Omega. \tag{3.1}$$

DEFINITION 3.1. *A function $y \in L^1(Q)$ is a weak solution of* (3.1) *if and only if $a\,y \in L^1(Q)$ and*

$$\int_Q y \left(-\frac{\partial z}{\partial t} + A\,z + a\,z\right) dx\,dt = \int_Q \phi\,z\,dx\,dt + \int_\Omega w\,z(0)\,dx - \int_\Sigma f\,\frac{\partial z}{\partial n_A} ds\,dt$$

for all $z \in \mathcal{C}^2(\overline{Q})$ such that $z(T) = 0$ and $z_{|\Sigma} = 0$.

PROPOSITION 3.1 (see [2, Proposition 3.6]). *Equation* (3.1) *admits a unique weak solution $y \in L^1(Q)$. This solution belongs to $\mathcal{C}_b(Q \cup \Omega_T)$ and satisfies*

$$\|y\|_{\infty,Q} \le C(\|\phi\|_{q,Q} + \|f\|_{\infty,\Sigma} + \|w\|_{\infty,\Omega}),$$

where $C \equiv C(T, \Omega, N, q)$ does not depend on a.

PROPOSITION 3.2 (see [2, Proposition 3.7]). *Let a be a nonnegative function in $L^q(Q)$ such that $\|a\|_{q,Q} \le M$. For every $\tau > 0$, the weak solution y of* (3.1) *is Hölder continuous on $\overline{Q^\tau}$ and satisfies*

$$\|y\|_{\mathcal{C}^{\nu,\nu/2}(\overline{Q^\tau})} \le C(\tau)(\|\phi\|_{q,Q} + \|f\|_{\infty,\Sigma} + \|w\|_{\infty,\Omega}) \quad \text{for some } 0 < \nu < 1,$$

where $C(\tau) \equiv C(T, \Omega, N, M, q, \tau)$.

Now we recall some results for the (nonlinear) state equation.

DEFINITION 3.2. *A function $y \in L^1(Q)$ is a weak solution of* (1.1) *if and only if $\Phi(\cdot, y(\cdot)) \in L^1(Q)$ and*

$$\int_Q y \left(-\frac{\partial z}{\partial t} + A\,z\right) dx\,dt + \int_Q (\Phi(x,t,y) - u)\,z\,dx\,dt = -\int_\Sigma \psi \frac{\partial z}{\partial n_A} ds\,dt + \int_\Omega (y_o + g)\,z(0)\,dx$$

for all $z \in \mathcal{C}^2(\overline{Q})$ satisfying $z(T) = 0$ and $z_{|\Sigma} = 0$.

THEOREM 3.1 (see [2, Theorem 3.9]). *Let u be in $L^q(Q)$, let g be in $L^\infty(\Omega)$, and let y_o be in $L^\infty(\Omega)$. Equation* (1.1) *admits a unique weak solution $y(u,g)$. This solution belongs to $\mathcal{C}_b(Q \cup \Omega_T)$ and satisfies*

$$\|y(u,g)\|_{\infty,Q} \le C(\|u\|_{q,Q} + \|\psi\|_{\infty,\Sigma} + \|g\|_{\infty,\Omega} + \|y_o\|_{\infty,\Omega} + 1), \tag{3.2}$$

where $C = C(T, \Omega, N, q)$.

THEOREM 3.2 (see [2, Theorem 3.10]). *For every $M > 0$ and every $\tau > 0$, there exists a positive constant $C(\tau) \equiv C(T, \Omega, N, q, \tau, M)$ and $\nu > 0$ such that, for every $(u,g) \in L^q(Q) \times L^\infty(\Omega)$ satisfying $\|u\|_{q,Q} + \|g\|_{\infty,\Omega} \le M$, the weak solution $y(u,g)$ of* (1.1) *corresponding to (u,g) is Hölder continuous on $\overline{Q^\tau}$ and satisfies*

$$\|y(u,g)\|_{C^{\nu,\nu/2}(\overline{Q^\tau})} \le C(\tau).$$

3.2. Adjoint equation. Consider the following terminal boundary value problem.

$$-\frac{\partial p}{\partial t} + A\,p + a\,p = \phi \ \text{ in } Q, \qquad p = 0 \text{ on } \Sigma, \qquad p(T) = w \ \text{ in } \Omega_T, \tag{3.3}$$

where a is a nonnegative function in $L^q(Q)$, $\phi \in L^1(Q)$, and $w \in L^1(\Omega)$.

DEFINITION 3.3. *A function $p \in L^1(0,T;W_o^{1,1}(\Omega))$ is a weak solution of* (3.3) *if and only if $a\,p \in L^1(Q)$ and*

$$\int_Q \left(p\,\frac{\partial z}{\partial t} + \sum_{i,j=1}^{N} a_{ij} D_j p\, D_i z + a\,z\,p \right) dx\,dt = \int_Q \phi z\,dx\,dt + \int_\Omega w z(T)\,dx$$

for all $z \in \mathcal{C}^1(\overline{Q}) \cap \mathcal{C}_o(Q \cup \Omega_T)$.

THEOREM 3.3. (see [2, Theorem 4.2]) *Let $\phi \in L^1(Q)$, $w \in L^1(\Omega)$, and let a be a nonnegative function in $L^q(Q)$ satisfying $\|a\|_{q,Q} \le M$. Then* (3.3) *admits a unique weak solution p in $L^1(0,T;W_o^{1,1}(\Omega))$. This solution belongs to $L^\delta(0,T;W_o^{1,d}(\Omega))$ for all (δ,d) satisfying $\delta > 1$, $d > 1$, $\frac{N}{2d} + \frac{1}{\delta} > \frac{N+1}{2}$. Moreover, there exists a function in $L^1(\Sigma)$, denoted by $\frac{\partial p}{\partial n_A}$, and a function in $L^1(\Omega)$, denoted by $p(0)$, such that*

$$\int_Q \left(\frac{\partial z}{\partial t} + A\,z + a\,z\right) p\,dx\,dt - \int_\Sigma z\,\frac{\partial p}{\partial n_A} ds\,dt + \int_\Omega z(0)\,p(0)\,dx = \int_Q \phi z\,dx\,dt + \int_\Omega w z(T)\,dx$$

for all $z \in \left\{ \ y \in \mathcal{C}_b(Q \cup \Omega_T) | \frac{\partial y}{\partial t} + A\,y \in L^q(Q),\ y_{|\Sigma} \in L^\infty(\Sigma),\ y(0) \in L^\infty(\Omega) \ \right\}$.

4. Existence results for min and max problems. Before dealing with existence results for the different problems, we have to establish some lower semicontinuity properties for the cost functional. As the state variable is implicitly involved in the cost functional, the following result is crucial for what follows.

THEOREM 4.1. *For every $\tau \in]0,T[$, the mapping $(u,g) \mapsto y(u,g)$ is sequentially continuous from $U_{ad} \times G_{ad}$, endowed with its weak-$L^q(Q)\times$ weak-star-$L^\infty(\Omega)$ topology, into $\mathcal{C}(\overline{Q^\tau})$.*

Proof. Let $(u_n, g_n)_n$ be a sequence converging to $(\tilde{u}, \tilde{g})$ for the weak-$L^q(Q)\times$ weak-star-$L^\infty(\Omega)$ topology. Let y_n be the solution of (1.1), corresponding to (u_n, g_n). Due to (3.2), the sequence $(y_n)_n$ is bounded in $L^\infty(Q)$. Then there exists a subsequence, still indexed by n, and $\tilde{y} \in L^\infty(Q)$ such that $(y_n)_n$ converges to $\tilde{y}$ for the weak-star topology of $L^\infty(Q)$. Moreover, from Theorem 3.2, the sequence $(y_n)_n$ is bounded in $\mathcal{C}^{\nu,\nu/2}(\overline{Q^\tau})$ for some $\nu > 0$ and for all $\tau \in]0,T[$. Since the imbedding from $\mathcal{C}^{\nu,\nu/2}(\overline{Q^\tau})$ into $\mathcal{C}(\overline{Q^\tau})$ is compact, $(y_n)_n$ converges to $\tilde{y}$ uniformly on $\overline{Q^\tau}$ for all $\tau > 0$. On the other hand, observe that y_n satisfies

$$\begin{aligned}\int_Q y_n \left(-\frac{\partial z}{\partial t} + A\,z\right) dx\,dt + \int_Q (\Phi(x,t,y_n) - u_n)\ z\,dx\,dt \\ = -\int_\Sigma \psi \frac{\partial z}{\partial n_A}\,ds\,dt + \int_\Omega (y_o + g_n)\,z(0)\,dx\end{aligned}$$

for all $z \in \mathcal{C}^2(\overline{Q})$ satisfying $z(T) = 0$ and $z_{|\Sigma} = 0$. With (A2) on Φ and Lebesgue's theorem, we can pass to the limit when n tends to infinity, and we obtain

$$\int_Q \tilde{y} \left(-\frac{\partial z}{\partial t} + A\,z\right) dx\,dt + \int_Q (\Phi(x,t,\tilde{y}) - \tilde{u})\ z\,dx\,dt$$

$$= - \int_\Sigma \psi \frac{\partial z}{\partial n_A} ds\, dt + \int_\Omega (y_o + \tilde{g})\, z(0)\, dx$$

for all $z \in \mathcal{C}^2(\overline{Q})$ satisfying $z(T) = 0$ and $z_{|\Sigma} = 0$. Therefore, $\tilde{y}$ is the solution of (1.1) corresponding to $(\tilde{u}, \tilde{g})$. ∎

COROLLARY 4.1. *For all $g \in G_{ad}$, the mapping $u \mapsto J(u, g)$ is sequentially lower semicontinuous on U_{ad}, endowed with the weak-topology of $L^q(Q)$.*

Proof. Let g be in G_{ad}, and let $(u_n)_n$ be a sequence converging to some $\tilde{u}$ for the weak topology of $L^q(Q)$. Let $y_n = y(u_n, g)$ and $\tilde{y} = y(\tilde{u}, g)$ be the associated solutions of (1.1). We observe that

$$\begin{aligned} &J(\tilde{u}, g) - J(u_n, g) \\ &= \int_Q F_n(x,t)(\tilde{y} - y_n)\, dx\, dt + \int_\Omega \ell_n\, (\tilde{y} - y_n)\, (T)\, dx + \int_Q (H(x,t,\tilde{u}) - H(x,t,u_n))\, dx\, dt, \end{aligned}$$

where

$$\begin{aligned} F_n(x,t) &= \int_0^1 F'_y\, (x, t, (1-\theta)\, y_n + \theta \tilde{y})\ d\theta \\ \text{and } \ell_n(x) &= \int_0^1 \ell'_y\, (x, (1-\theta) y_n(T) + \theta\, \tilde{y}(T))\ d\theta. \end{aligned}$$

Due to Theorem 4.1, the sequence $(y_n)_n$ converges to $\tilde{y}$ uniformly on $\overline{Q^\tau}$ for all $\tau > 0$. With assumptions on F and ℓ and Lebesgue's theorem, we obtain

$$\lim_{n \to +\infty} \int_Q F_n(x,t)\, (\tilde{y} - y_n)\, dx\, dt = \lim_{n \to +\infty} \int_\Omega \ell_n(x)\, (\tilde{y} - y_n)(T)\, dx = 0\,. \tag{4.1}$$

On the other hand, from [9, Theorem 2.1, Chapter 8], we deduce that

$$\int_Q H(x,t,\tilde{u})\, dx\, dt \leq \liminf_{n \to +\infty} \int_Q H(x,t,u_n)\, dx\, dt\,. \tag{4.2}$$

The sequential lower semicontinuity of $J(\cdot, g)$ follows from (4.1) and (4.2). ∎

Now we are able to give an existence result of solutions to problem $(\mathcal{P}_g)$.

THEOREM 4.2. *Let g be in G_{ad}. If* (A1)–(A4) *are fulfilled, then problem $(\mathcal{P}_g)$ admits at least one solution.*

Proof. Let g be in G_{ad}, and let u be in U_{ad}. From (A3)–(A4) and Theorem 3.1, it follows that

$$\begin{aligned} J(u,g) \geq\ & C_1 ||u||^q_{q,Q} - C(||u||^\sigma_{q,Q} + ||\Psi||^\sigma_{\infty,\Sigma} + ||y_0||^\sigma_{\infty,\Omega} + ||g||^\sigma_{\infty,\Omega} + 1) \\ & - ||L_1||_{1,\Omega}\ ||\eta(g + y_0)||_{\infty,\Omega}. \end{aligned} \tag{4.3}$$

With Young's inequality we can prove that the infimum of $(\mathcal{P}_g)$ belongs to $\mathbb{R}$. Let $(u_n)_n$ be a minimizing sequence for $(\mathcal{P}_g)$. Due to (4.3), the sequence $(u_n)_n$ is bounded in $L^q(Q)$. Then there exist a subsequence, still indexed by n, and $u \in U_{ad}$, such that $(u_n)_n$ converges to u for the weak topology of $L^q(Q)$. Due to Corollary 4.1, we have

$$J(u,g) \leq \liminf_n J(u_n, g) \leq \inf(\mathcal{P}_g),$$

and the proof is complete. ∎

To study the existence of solutions to problem $(\mathcal{P})$, we have to set some continuity results.

PROPOSITION 4.1. *Let $(g_n)_n \subset G_{ad}$ be a sequence converging to some $g \in G_{ad}$ for the weak-star topology of $L^\infty(\Omega)$. Let u_{g_n} be an element in Argmin$(\mathcal{P}_{g_n})$. Then there exists $u_g \in$ Argmin$(\mathcal{P}_g)$ such that the following conditions hold.*

- *$(u_{g_n})_n$ converges (up to a subsequence) to u_g for the weak topology of $L^q(Q)$.*
- *$(y(u_{g_n}, g_n))_n$ converges (up to a subsequence) to $y(u_g, g)$ in $\mathcal{C}(\overline{Q^\tau})$ for all $\tau > 0$.*

Proof. Due to (4.3), since $(g_n)_n$ is bounded in $L^\infty(\Omega)$, and since $J(u_{g_n}, g_n) \leq J(u_o, g_n) \leq M$ (for some u_o fixed in U_{ad}), the sequence $(u_{g_n})_n$ is bounded in U_{ad}. Then there exists a subsequence, still indexed by n, and $\tilde{u}$, such that $(u_{g_n})_n$ converges to $\tilde{u}$ for the weak topology of $L^q(Q)$. Since U_{ad} is closed and convex in $L^q(Q)$, it is also weakly closed and $\tilde{u} \in U_{ad}$. Due to Theorem 4.1, the sequence $(y(u_{g_n}, g_n))_n$ converges to $y(\tilde{u}, g)$ in $\mathcal{C}(\overline{Q^\tau})$ for all $\tau > 0$. Let us prove that $\tilde{u}$ belongs to Argmin $(\mathcal{P}_g)$. By definition, u_{g_n} satisfies

$$J(u_{g_n}, g_n) \leq J(u, g_n) \qquad \text{for all } u \in U_{ad}. \tag{4.4}$$

With arguments similar to those used in Corollary 4.1, we can prove that

$$\lim_{n\to+\infty} \int_Q F(x,t,y(u_{g_n}, g_n))\,dx\,dt = \int_Q F(x,t,y(\tilde{u}, g))\,dx\,dt, \tag{4.5}$$

$$\lim_{n\to+\infty} \int_Q F(x,t,y(u, g_n))\,dx\,dt = \int_Q F(x,t,y(u, g))\,dx\,dt\,, \tag{4.6}$$

$$\lim_{n\to+\infty} \int_\Omega \ell(x,y(u_{g_n}, g_n)(T))\,dx = \int_\Omega \ell(x,y(\tilde{u}, g)(T))\,dx\,, \tag{4.7}$$

$$\lim_{n\to+\infty} \int_\Omega \ell(x,t,y(u, g_n)(T))\,dx = \int_\Omega \ell(x,y(u, g)(T))\,dx\,, \tag{4.8}$$

$$\int_Q H(x,t,\tilde{u})\,dx\,dt \leq \liminf_{n\to+\infty} \int_Q H(x,t,u_{g_n})\,dx\,dt\,. \tag{4.9}$$

From (4.5)–(4.9) and passing to the limit when n tends to infinity in (4.4), we obtain

$$J(\tilde{u}, g) \leq J(u, g) \qquad \text{for all } u \in U_{ad}.$$

Therefore, $\tilde{u}$ belongs to Argmin $(\mathcal{P}_g)$, and we set $\tilde{u} \equiv u_g$. The second assertion follows from Corollary 4.1. ∎

THEOREM 4.3. *Assume* (A1)–(A4) *are fulfilled; then the minimax problem $(\mathcal{P})$ admits at least one solution $\bar{g}$.*

Proof. First we observe that problem $(\mathcal{P})$ is equivalent to

$$\max\ \{J(u_g, g) \mid u_g \in \text{Argmin}\,(\mathcal{P}_g)\ g \in G_{ad}\}.$$

Let $(g_n)_n$ be a maximizing sequence for $(\mathcal{P})$. Since G_{ad} is bounded in $L^\infty(\Omega)$, there exist a subsequence, still indexed by n, and $\tilde{g}$, such that $(g_n)_n$ converges to $\tilde{g}$ for the

weak-star topology of $L^\infty(\Omega)$. In addition, $\tilde{g}$ is also the weak limit of g_n in $L^s(\Omega)$ for all $s \geq 1$. Since G_{ad} is convex and closed in $L^s(\Omega)$, it is also weakly closed and $\tilde{g} \in G_{ad}$. From assumption (A4) on L, we deduce that

$$\limsup_{n\to+\infty} \int_\Omega (L(x, g_n) - L(x, \tilde{g}))\, dx \leq 0. \tag{4.10}$$

On the other hand, with Proposition 4.1, we know that $(u_{g_n})_n$ (where $u_{g_n} \in \text{Argmin } (\mathcal{P}_{g_n})$) converges (up to a subsequence) to some $u_{\tilde{g}} \in \text{Argmin } (\mathcal{P}_{\tilde{g}})$ for the weak topology of $L^q(Q)$, and $(y(u_{g_n}, g_n))_n$ converges (up to a subsequence) to $y(u_{\tilde{g}}, \tilde{g})$ in $\mathcal{C}(\overline{Q^\tau})$ for all $\tau > 0$. Therefore,

$$\begin{aligned} J(u_{g_n}, g_n) - J(u_{\tilde{g}}, \tilde{g}) &= (J(u_{g_n}, g_n) - J(u_{\tilde{g}}, g_n)) + (J(u_{\tilde{g}}, g_n) - J(u_{\tilde{g}}, \tilde{g})) \\ &\leq J(u_{\tilde{g}}, g_n) - J(u_{\tilde{g}}, \tilde{g}) \\ &= \int_Q (F(x, t, y(u_{\tilde{g}}, g_n)) - F(x, t, y(u_{\tilde{g}}, \tilde{g})))\, dx\, dt \\ &\quad + \int_\Omega (\ell(x, y(u_{\tilde{g}}, g_n)(T)) - \ell(x, y(u_{\tilde{g}}, \tilde{g})(T)))\, dx \\ &\quad + \int_\Omega (L(x, g_n) - L(x, \tilde{g}))\, dx\ . \end{aligned} \tag{4.11}$$

As in the proof of Proposition 4.1, we have

$$\lim_{n\to+\infty} \int_Q (F(x, t, y(u_{\tilde{g}}, g_n)) - F(x, t, y(u_{\tilde{g}}, \tilde{g})))\, dx\, dt = 0, \tag{4.12}$$

$$\lim_{n\to+\infty} \int_\Omega (\ell(x, y(u_{\tilde{g}}, g_n)(T)) - \ell(x, y(u_{\tilde{g}}, \tilde{g})(T)))\, dx = 0. \tag{4.13}$$

Consequently, with (4.11), (4.10), (4.12), and (4.13), it follows that

$$\begin{aligned} \sup_{g\in G_{ad}} \{J(u_g, g) \mid u_g \in \text{Arg inf}(P_g)\} &= \lim_{n\to+\infty} J(u_{g_n}, g_n) \\ &= \limsup_{n\to+\infty} J(u_{g_n}, g_n) \leq J(u_{\tilde{g}}, \tilde{g}). \end{aligned}$$

Since $\tilde{g}$ belongs to G_{ad} and $u_{\tilde{g}}$ belongs to $\text{Arg inf}(P_{\tilde{g}})$, $\tilde{g}$ is a solution to $(\mathcal{P})$. ∎

5. Taylor expansions. In order to give optimality conditions we need some Taylor expansions. In what follows, $\mathcal{L}^{N+1}$ denotes the $(N+1)$-dimensional Lebesgue measure.

THEOREM 5.1 (Taylor expansion of y with respect to u). *Let ρ be in $]0, 1[$. For every u_1, $u_2 \in U_{ad}$, and every $g \in G_{ad}$, there exist measurable subsets $Q_\rho \subset Q$ such that*

$$\mathcal{L}^{N+1}(Q_\rho) = \rho \mathcal{L}^{N+1}(Q),$$

$$\int_{Q_\rho} (H(x, t, u_2) - H(x, t, u_1))\, dx\, dt = \rho \int_Q (H(x, t, u_2) - H(x, t, u_1))\, dx\, dt,$$

$$y_\rho = y_1 + \rho z + r_\rho, \quad \textit{with} \quad \lim_{\rho\to 0} \frac{1}{\rho} ||r_\rho||_{\mathcal{C}(\overline{Q})} = 0,$$

$$J(u_\rho, g) = J(u_1, g) + \rho \left(J'_y(u_1, g_1)z + \int_Q (H(x,t,u_2) - H(x,t,u_1))\, dx\, dt \right) + o(\rho),$$

where

$$u_\rho(x,t) = \begin{cases} u_1(x,t) & \text{in } Q \setminus Q_\rho, \\ \\ u_2(x,t) & \text{in } Q_\rho, \end{cases}$$

y_ρ and y_1 are the solutions of (1.1) *corresponding to (u_ρ, g) and (u_1, g), and z is the solution of*

$$\frac{\partial z}{\partial t} + Az + \Phi'_y(\cdot, y_1)z = u_2 - u_1 \text{ in } Q, \qquad z = 0 \text{ on } \Sigma, \qquad z(0) = 0 \text{ in } \Omega.$$

Proof. See [16, Theorem 4.1] or [15]. □

THEOREM 5.2 (Taylor expansion of y with respect to g). *Let ρ be in $]0,1[$, and set $\tau_\rho = \rho^{m' + \frac{q\bar{q}}{q-\bar{q}}}$, where $q > \bar{q} > \frac{N}{2} + 1$ ($m > 1$ is the exponent in* (A4)*, and m' is the conjugate exponent to m). For every g_1, $g_2 \in G_{ad}$, there exist measurable subsets $\Omega_\rho \subset \Omega$, and there exists $u_{g_1} \in Arg\inf\ (P_{g_1})$, such that the following hold.*

$$\mathcal{L}^N(\Omega_\rho) = \rho \mathcal{L}^N(\Omega),$$

$$\int_{\Omega_\rho} (L(x,g_2) - L(x,g_1))\, dx = \rho \int_\Omega (L(x,g_2) - L(x,g_1))\, dx, \tag{5.1}$$

$$y(u_{g_\rho}, g_\rho) = y(u_{g_\rho}, g_1) + \rho z_1 + r_\rho, \text{ with } \lim_{\rho \to 0} \frac{1}{\rho} ||r_\rho||_{\mathcal{C}(\overline{Q}_{\tau_\rho T})} = 0, \tag{5.2}$$

$$J(u_{g_\rho}, g_\rho) = J(u_{g_\rho}, g_1) + \rho \left(J'_y(u_{g_1}, g_1)z_1 + \int_\Omega (L(x,g_2) - L(x,g_1))\, dx \right) + o(\rho), \tag{5.3}$$

where

$$g_\rho(x) = \begin{cases} g_1(x) & \text{on } \Omega \setminus \Omega_\rho, \\ \\ g_2(x) & \text{on } \Omega_\rho, \end{cases} \qquad u_{g_\rho} \in Arg\inf\ (P_{g_\rho}),$$

$y(u_{g_\rho}, g_\rho)$ and $y(u_{g_\rho}, g_1)$ are the solutions of (1.1) *corresponding to (u_ρ, g_ρ) and (u_ρ, g_1), and z_1 is the solution of*

$$\frac{\partial z}{\partial t} + Az + \Phi'_y(x, t, y(u_{g_1}, g_1))\, z = 0 \text{ in } Q, \qquad z = 0 \text{ on } \Sigma, \qquad z(0) = g_2 - g_1 \text{ in } \Omega.$$

The proof is based on the following lemmas.

LEMMA 5.1. (see [16, Lemma 4.1]) *Let g_1, g_2 be in $L^\infty(\Omega)$. For every $\rho \in]0,1[$, there exists a sequence of measurable subsets $(\Omega_\rho^n)_n$ in Ω, such that*

$$\mathcal{L}^N(\Omega_\rho^n) = \rho \mathcal{L}^N(\Omega),$$

$$\int_{\Omega_\rho^n} (L(x,g_2) - L(x,g_1))dx = \rho \int_\Omega (L(x,g_2) - L(x,g_1))dx,$$

$$\left(\frac{\chi_{\Omega_\rho^n}}{\rho}\right)_n \text{ converges to } 1 \text{ for the weak-star topology of } L^\infty(\Omega),$$

where $\chi_{\Omega_\rho^n}$ *denotes the characteristic function of* Ω_ρ^n.

LEMMA 5.2. *Let be* $\rho \in]0,1[$, *and let* $(\Omega_\rho^n)_n$ *be the sequence of measurable subsets defined in Lemma* 5.1. *Set*

$$g_\rho^n(x) = \begin{cases} g_1(x) & \text{on } \Omega \setminus \Omega_\rho^n, \\ g_2(x) & \text{on } \Omega_\rho^n. \end{cases}$$

Then the sequence $(g_\rho^n)_n$ *converges to* $\rho g_2 + (1-\rho)g_1$ *for the weak-star topology of* $L^\infty(\Omega)$.

Proof. Let be $\varphi \in L^1(\Omega)$. We have

$$\left| \int_\Omega g_\rho^n \, \varphi \, dx - \int_\Omega (\rho g_2 + (1-\rho)g_1) \, \varphi \, dx \right| = \left| \int_\Omega (g_\rho^n - \rho g_2 - (1-\rho)g_1) \, \varphi \, dx \right|$$

$$= \rho \left| \int_\Omega \left(\frac{\chi_{\Omega_\rho^n}}{\rho} - 1 \right) (g_2 - g_1) \, \varphi \, dx \right| \to 0 \quad \text{as } n \to \infty. \qquad \square$$

Proof of Theorem 5.2. Let $u_{g_\rho^n}$ be in Argmin $(\mathcal{P}_{g_\rho^n})$. With Lemma 5.2 and Proposition 4.1, we can prove that $(u_{g_\rho^n})_n$ (or at least a subsequence) weakly converges to some $u_\rho \in L^q(Q)$, $u_\rho \in$ Argmin $\left(\mathcal{P}_{(\rho g_2 + (1-\rho)g_1)}\right)$, and

$$\lim_{n\to\infty} \left\| y(u_{g_\rho^n}, g_\rho^n) - y\left(u_\rho, \rho g_2 + (1-\rho)g_1\right) \right\|_{\mathcal{C}(\bar{Q}^\tau)} = 0 \qquad \text{for all } \tau > 0. \tag{5.4}$$

With similar arguments we prove that $(u_\rho)_\rho$ weakly converges to some $u_{g_1} \in$Argmin$(\mathcal{P}_{g_1})$, and

$$\lim_{\rho\to 0} \left\| y(u_{g_1}, g_1) - y\left(u_\rho, \rho g_2 + (1-\rho)g_1\right) \right\|_{\mathcal{C}(\bar{Q}^\tau)} = 0 \qquad \text{for all } \tau > 0. \tag{5.5}$$

Step 1. We first establish (5.2). The function $\zeta_\rho^n = \frac{1}{\rho}\big(y(u_{g_\rho^n}, g_\rho^n) - y(u_{g_\rho^n}, g_1)\big) - z_1$ belongs to$C_b(Q \cup \Omega_T)$, and it is the solution of

$$\frac{\partial \zeta}{\partial t} + A\zeta + \beta_\rho^n \zeta = h_\rho^n \text{ in } Q, \quad \zeta = 0 \text{ on } \Sigma, \quad \zeta(0) = f_\rho^n \text{ in } \Omega,$$

where

$$\beta_\rho^n = \int_0^1 \Phi_y' \left(\cdot, \theta \; y(u_{g_\rho^n}, g_\rho^n) + (1-\theta) \; y(u_{g_\rho^n}, g_1) \right) d\,\theta,$$

$$h_\rho^n = \left(\Phi_y'(\cdot, y(u_{g_1}, g_1)) - \beta_\rho^n\right) z_1, \; f_\rho^n = \left(1 - \frac{1}{\rho}\chi_{\Omega_\rho^n}\right)(g_1 - g_2).$$

We look for $n \in \mathbb{N}^*$ as a function of ρ, say $n(\rho)$, such that

$$\lim_{\rho \searrow 0} \left\| \zeta_\rho^{n(\rho)} \right\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})} = 0. \tag{5.6}$$

Set $\zeta_\rho^n = \zeta_\rho^{n,1} + \zeta_\rho^{n,2}$, where $\zeta_\rho^{n,1} \in \mathcal{C}(\overline{Q})$ is the solution of

$$\frac{\partial \zeta}{\partial t} + A\zeta + \beta_\rho^n \zeta = h_\rho^n \text{ in } Q, \quad \zeta = 0 \text{ on } \Sigma, \quad \zeta(0) = 0 \text{ in } \Omega,$$

and $\zeta_\rho^{n,2} \in C_b(Q \cup \Omega_T)$ is the solution of

$$\frac{\partial \zeta}{\partial t} + A\zeta + \beta_\rho^n \zeta = 0 \text{ in } Q, \quad \zeta = 0 \text{ on } \Sigma, \quad \zeta(0) = f_\rho^n \text{ in } \Omega.$$

Let $\eta_\rho^n \in C_b(Q \cup \Omega_T)$ be the solution of

$$\frac{\partial \eta}{\partial t} + A\eta + \beta\eta = 0 \text{ in } Q, \quad \eta = 0 \text{ on } \Sigma, \quad \eta(0) = f_\rho^n \text{ in } \Omega,$$

where $\beta(\cdot) = \Phi'_y(\cdot, y(u_{g_1}, g_1))$. The operator $\mathcal{T}$ which associates ζ, the solution of

$$\frac{\partial \zeta}{\partial t} + A\zeta + \beta\zeta = 0 \text{ in } Q, \quad \zeta = 0 \text{ on } \Sigma, \quad \zeta(0) = w \text{ in } \Omega,$$

with $w \in L^\infty(\Omega)$, is continuous from $L^\infty(\Omega)$ into $C^{\nu,\nu/2}(\overline{Q}_{\tau_\rho T})$ for some $0 < \nu < 1$ (see Proposition 3.2). Since the imbedding from $C^{\nu,\nu/2}(\overline{Q}_{\tau_\rho T})$ into $\mathcal{C}(\overline{Q}_{\tau_\rho T})$ is compact, $\mathcal{T}$ can be considered as a compact operator from $L^\infty(\Omega)$ into $\mathcal{C}(\overline{Q}_{\tau_\rho T})$. Since the sequence $(f_\rho^n)_n$ converges to 0 for the weak-star topology of $L^\infty(\Omega)$, we obtain

$$\lim_{n \to \infty} ||\eta_\rho^n||_{\mathcal{C}(\overline{Q}_{\tau_\rho T})} = 0. \tag{5.7}$$

From (5.4) and (5.7), we deduce the existence of some integer $n(\rho)$ such that

$$\left\| y\left(u_{g_\rho^{n(\rho)}}, g_\rho^{n(\rho)}\right) - y\left(u_\rho, \rho g_2 + (1-\rho) g_1\right) \right\|_{\mathcal{C}(\bar{Q}^{\tau_\rho})} + \|\eta_\rho^{n(\rho)}\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})} \leq \rho. \tag{5.8}$$

On the other hand, the function $\zeta_\rho^{n(\rho),2} - \eta_\rho^{n(\rho)}$ belongs to $\mathcal{C}(\overline{Q})$ and satisfies

$$\frac{\partial \zeta}{\partial t} + A\zeta + \beta_\rho^{n(\rho)} \zeta = (\beta - \beta_\rho^{n(\rho)}) \eta_\rho^{n(\rho)} \text{ in } Q, \quad \zeta = 0 \text{ on } \Sigma, \quad \zeta(0) = 0 \text{ in } \Omega.$$

There exists $C \equiv C(T, \Omega, q, N) > 0$, independent of ρ, such that

$$\|\zeta_\rho^{n(\rho),1}\|_{\mathcal{C}(\overline{Q})} \leq C \|h_\rho^{n(\rho)}\|_{q,Q},$$

$$\|\zeta_\rho^{n(\rho),2} - \eta_\rho^{n(\rho)}\|_{\mathcal{C}(\overline{Q})} \leq C \|(\beta - \beta_\rho^{n(\rho)}) \eta_\rho^{n(\rho)}\|_{\bar{q},Q} \leq C \|\beta - \beta_\rho^{n(\rho)}\|_{q,Q} \, \|\eta_\rho^{n(\rho)}\|_{r,Q},$$

where $\frac{1}{r} = \frac{1}{\bar{q}} - \frac{1}{q}$ ($\bar{q}$ obeys $q > \bar{q} > \frac{N}{2} + 1$; see assumptions). It follows that

$$\begin{aligned} \|\zeta_\rho^{n(\rho),2} - \eta_\rho^{n(\rho)}\|_{\mathcal{C}(\overline{Q})} \\ \leq C \|\beta - \beta_\rho^{n(\rho)}\|_{q,Q} \left(\|\eta_\rho^{n(\rho)}\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})} + (\mathcal{L}^{N+1}(Q \setminus Q_{\tau_\rho T}))^{\frac{1}{r}} \|\eta_\rho^{n(\rho)}\|_{\infty,Q} \right) \end{aligned}$$

$$\begin{aligned}
&\leq C\|\beta-\beta_\rho^{n(\rho)}\|_{q,Q}\left(\|\eta_\rho^{n(\rho)}\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})}+\tau_\rho^{\frac{1}{r}}\|f_\rho^{n(\rho)}\|_{\infty,\Omega}\right)\\
&\leq C\|\beta-\beta_\rho^{n(\rho)}\|_{q,Q}\left(\|\eta_\rho^{n(\rho)}\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})}+\tau_\rho^{\frac{1}{r}}\,\rho^{-1}\|g_1-g_2\|_{\infty,\Omega}\right)\\
&\leq C\|\beta-\beta_\rho^{n(\rho)}\|_{q,Q}\left(\|\eta_\rho^{n(\rho)}\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})}+\rho^{m'\frac{q-\bar q}{q\bar q}}\right)\\
&\leq C\|\beta-\beta_\rho^{n(\rho)}\|_{q,Q}\left(\ \rho+\rho^{m'\frac{q-\bar q}{q\bar q}}\right).
\end{aligned}$$

Therefore,

$$\begin{aligned}
\|\zeta_\rho^{n(\rho)}\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})} \leq\ & \|\zeta_\rho^{n(\rho),1}\|_{\mathcal{C}(\overline{Q})}+\|\zeta_\rho^{n(\rho),2}-\eta_\rho^{n(\rho,\tau)}\|_{\mathcal{C}(\overline{Q})}+\|\eta_\rho^{n(\rho)}\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})}\\
\leq\ & C\left(\|h_\rho^{n(\rho)}\|_{q,Q}+\|\beta-\beta_\rho^{n(\rho)}\|_{q,Q}(\rho+\rho^{m'\frac{q-\bar q}{q\bar q}})+\rho\right).
\end{aligned}$$

With assumption (A2) and with Lebesgue's theorem of dominated convergence, we can prove that $\left(h_\rho^{n(\rho)}\right)_\rho$ converges to 0 in $L^q(Q)$. Thus (5.6) follows from the last inequality. Let us set $\Omega_\rho=\Omega_\rho^{n(\rho)}$ and $g_\rho=g_\rho^{n(\rho)}$. We have $y(u_{g_\rho},g_\rho)=y\big(u_{g_\rho^{n(\rho)}},g_\rho^{n(\rho)}\big)$, $y(u_{g_\rho},g_1)=y\big(u_{g_\rho^{n(\rho)}},g_1\big)$, $\frac{r_\rho}{\rho}=\zeta_\rho^{n(\rho)}$, and (5.2) is proved.

Step 2. Now we establish (5.3). First observe that, with (5.8), we have

$$\begin{aligned}
c\|y(u_{g_\rho,g_\rho})-\ y\ (u_{g_1},g_1)\|_{\mathcal{C}(\overline{Q^\tau})} \leq\ & \|y(u_{g_\rho},g_\rho)-y\left(u_\rho,\rho g_2+(1-\rho)g_1\right)\|_{\mathcal{C}(\overline{Q^\tau})}\\
&+\|y(u_{g_1},g_1)-y\left(u_\rho,\rho g_2+(1-\rho)g_1\right)\|_{\mathcal{C}(\overline{Q^\tau})}\\
\leq\ & \rho+\|y(u_{g_1},g_1)-y\left(u_\rho,\rho g_2+(1-\rho)g_1\right)\|_{\mathcal{C}(\overline{Q^\tau})}\ \text{for all } \tau>0.
\end{aligned}$$

Therefore, from (5.5) it follows that

$$\lim_{\rho\to 0}\|y(u_{g_\rho},g_\rho)-y(u_{g_1},g_1)\|_{\mathcal{C}(\overline{Q^\tau})}=0 \text{ for all } \tau>0. \tag{5.9}$$

On the other hand,

$$\left|\frac{J(u_{g_\rho},g_\rho)-J(u_{g_\rho},g_1)}{\rho}-\Delta J\right|$$

$$\leq\left|\int_Q\left(\frac{F(x,t,y(u_{g_\rho},g_\rho))-F(x,t,y(u_{g_1},g_1))}{\rho}-F'_y(x,t,y(u_{g_1},g_1))z_1(x,t)\right)dx\,dt\right|$$

$$+\left|\int_\Omega\left(\frac{\ell(x,y(u_{g_\rho},g_\rho)(T))-\ell(x,y(u_{g_1},g_1)(T))}{\rho}-\ell'_y(x,y(u_{g_1},g_1)(T))\,z_1(x,T)\right)dx\right|$$

$$=I_\rho^1+I_\rho^2.$$

(Due to (5.1), the integrand L does not appear in the above estimate.) From the equation satisfied by $\dfrac{r_\rho}{\rho}=\zeta_\rho^{n(\rho)}$, we deduce that

$$\left\|\frac{r_\rho}{\rho}\right\|_{\infty,Q}\leq C\left(\|h_\rho^{n(\rho)}\|_{q,Q}+\|f_\rho^{n(\rho)}\|_{\infty,\Omega}\right)\leq C\left(\|h_\rho^{n(\rho)}\|_{q,Q}+\frac{1}{\rho}\right).$$

With (A3), we obtain

$$\begin{aligned}
I_\rho^1 \leq\ & \left\| F_\rho \frac{r_\rho}{\rho} \right\|_{1,Q} + \| \left(F_\rho - F'_y(\cdot, y(u_{g_1}, g_1)) \right) z_1 \|_{1,Q} \\
\leq\ & C \left(\|F_\rho\|_{m,Q} \left\| \frac{r_\rho}{\rho} \right\|_{m',Q} + \|F_\rho - F'_y(\cdot, y(u_{g_1}, g_1))\|_{1,Q} \right) \\
\leq\ & C \left(\left\| \frac{r_\rho}{\rho} \right\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})} + \left[\mathcal{L}^{N+1}(Q \setminus Q_{\tau_\rho T}) \right]^{\frac{1}{m'}} \left\| \frac{r_\rho}{\rho} \right\|_{\infty,Q} + \|F_\rho - F'_y(\cdot, y(u_{g_1}, g_1))\|_{1,Q} \right) \\
\leq\ & C \left(\left\| \frac{r_\rho}{\rho} \right\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})} + (\tau_\rho)^{\frac{1}{m'}} \left[\|h_\rho^{n(\rho)}\|_{q,Q} + \frac{1}{\rho} \right] + \|F_\rho - F'_y(\cdot, y(u_{g_1}, g_1))\|_{1,Q} \right) \\
\leq\ & C \left(\rho + (\tau_\rho)^{\frac{1}{m'}} \|h_\rho^{n(\rho)}\|_{q,Q} + \rho^{\frac{q\bar{q}}{m'(q-\bar{q})}} + \|F_\rho - F'_y(\cdot, y(u_{g_1}, g_1))\|_{1,Q} \right),
\end{aligned}$$

where

$$F_\rho = \int_0^1 F'_y(\cdot, (1-\theta) y(u_{g_1}, g_1) + \theta y(u_{g_\rho}, g_\rho))\, d\theta,$$

and C is a positive constant independent of ρ. Similarly to the calculus of I_ρ^1, and due to (A4), we prove that

$$I_\rho^2 \leq C \left(\rho + (\tau_\rho)^{\frac{1}{m'}} \|h_\rho^{n(\rho)}\|_{q,Q} + \rho^{\frac{q\bar{q}}{m'(q-\bar{q})}} + \|\ell_\rho(\cdot) - \ell'_y(\cdot, y(u_{g_1}, g_1)(T))\|_{1,\Omega} \right),$$

where

$$\ell_\rho(\cdot) = \int_0^1 \ell'_y(\cdot, (1-\theta) y(u_{g_1}, g_1)(T) + \theta y(u_{g_\rho}, g_\rho)(T))\, d\theta,$$

and where C is a positive constant independent of ρ. Due to (5.9), by assumptions on F and ℓ, and Lebesgue's theorem of dominated convergence, we have

$$\lim_{\rho \to 0} \|F_\rho - F'_y(\cdot, y(u_{g_1}, g_1))\|_{1,Q} = 0 \quad \text{and} \quad \lim_{\rho \to 0} \|L_\rho(T) - L'_y(\cdot, y(u_{g_1}, g_1)(T))\|_{1,\Omega} = 0.$$

Thus $\lim_{\rho \to 0} I_\rho^1 = \lim_{\rho \to 0} I_\rho^2 = 0$, and the proof is complete. ∎

6. Proof of the optimality conditions.

6.1. Proof of Theorem 2.1: Optimality conditions for $(\mathcal{P}_g)$. The proof is similar to the one given in [2, Theorem 2.1]. We rewrite it for the convenience of the reader. Let ρ be in $]0,1[$. Let g be in G_{ad}, u_g in Argmin $(\mathcal{P}_g)$, and u in U_{ad}. Due to Theorem 5.1, there exists a measurable subset Q_ρ such that $\mathcal{L}^{N+1}(Q_\rho) = \rho \mathcal{L}^{N+1}(Q)$, and

$$y(u_\rho(g), g) = y(u_g, g) + \rho z_g + r_\rho, \quad \text{with } \lim_{\rho \to 0} \frac{1}{\rho} \|r_\rho\|_{\mathcal{C}(\overline{Q})} = 0,$$

$$J(u_\rho(g), g) = J(u_g, g) + \rho \Delta J + o(\rho),$$

where $u_\rho(g)$ is defined by

$$u_\rho(g)(x,t) = \begin{cases} u_g(x,t) & \text{in } Q \setminus Q_\rho, \\ u(x,t) & \text{in } Q_\rho, \end{cases}$$

$y(u_\rho(g),g)$ is the solution to (1.1) corresponding to $(u_\rho(g),g)$, z_g is the weak solution of

$$\frac{\partial z}{\partial t} + A\,z + \Phi'_y(x,t,y(u_g,g))\,z = u - u_g \text{ in } Q, \qquad z = 0 \text{ on } \Sigma, \qquad z(0) = 0 \text{ in } \Omega,$$

and

$$\Delta J = \int_Q \left(F'_y(x,t,y(u_g,g))z_g + (H(x,t,u) - H(x,t,u_g))\right)\,dx\,dt + \int_\Omega \ell'_y(x,y(u_g,g))\,z_g(T)\,dx.$$

Since $(u_\rho(g),g)$ is admissible for $(\mathcal{P}_g)$, it follows that $J(u_g,g) \le J(u_\rho(g),g)$ and

$$-\Delta J \le \lim_{\rho\to 0} \frac{J(u_g,g) - J(u_\rho(g),g)}{\rho} \le 0\ . \tag{6.1}$$

Let p_g be the weak solution of (2.1). Using the Green formula of Theorem 3.3, we obtain

$$-\int_Q F'_y(x,t,y(u_g,g))z_g\,dx\,dt - \int_\Omega \ell'_y(x,y(u_g,g)(T))\,z_g(T)\,dx$$

$$= \int_Q p_g\left(\frac{\partial z_g}{\partial t} + A\,z_g + \Phi'_y(x,t,y(u_g,g))\,z_g\right)\,dx\,dt = \int_Q p_g\,(u-u_g)\,dx\,dt.$$

Taking the definition of ΔJ into account, we have

$$\Delta J = \int_Q H(x,t,u) - H(x,t,u_g)\,dx\,dt - \int_Q p_g(x,t)(u(x,t) - u_g(x,t)\,dx\,dt. \tag{6.2}$$

From (6.1) and (6.2), we finally obtain

$$\int_Q \mathcal{H}_Q(x,t,\bar u_g,p_g)\,dx\,dt \le \int_Q \mathcal{H}_Q(x,t,u,p_g)\,dx\,dt \quad \text{for all } u \in U_{ad}.$$

The pointwise Pontryagin's principle (2.2) is next obtained by the method developed in [16, section 5.2]. □

6.2. Proof of Theorem 2.2: Optimality conditions for $(\mathcal{P})$. Let ρ be in $]0,1[$, let τ_ρ be as in Theorem 5.2, and let $g \in G_{ad}$. We recall that $\bar g$ is the optimal solution to $(\mathcal{P})$ that we want to characterize. Due to Theorem 5.2, there exist $\bar u \in$ Argmin $(\mathcal{P}_{\bar g})$ and measurable subsets Ω_ρ such that

$$\mathcal{L}^N(\Omega_\rho) = \rho\mathcal{L}^N(\Omega),$$

$$y(u_{g_\rho}, g_\rho) = y(u_{g_\rho}, \bar{g}) + \rho \bar{z} + \tilde{r}_\rho, \quad \text{with } \lim_{\rho \to 0} \frac{1}{\rho} \|\tilde{r}_\rho\|_{\mathcal{C}(\overline{Q}_{\tau_\rho T})} = 0,$$

$$J(u_{g_\rho}, g_\rho) = J(u_{g_\rho}, \bar{g}) + \rho \left(J'_y(\bar{u}, \bar{g})\bar{z} + \int_\Omega (L(x, g) - L(x, \bar{g}))dx \right) + o(\rho), \tag{6.3}$$

where

$$g_\rho(x) = \begin{cases} \bar{g}(x) & \text{in } \Omega \setminus \Omega_\rho, \\ g(x) & \text{in } \Omega_\rho, \end{cases} \qquad u_{g_\rho} \in \text{ Argmin } (\mathcal{P}_{g_\rho}),$$

and $\bar{z}$ is the solution of the equation

$$\frac{\partial z}{\partial t} + A\, z + \Phi'_y(\cdot, y(\bar{u}, \bar{g}))\, z = 0 \ \text{ in } Q, \ z = 0 \text{ on } \Sigma, \ z(0) = g - \bar{g} \ \text{ in } \Omega\ .$$

Since $\bar{g}$ is a solution to $(\mathcal{P})$ and $\bar{u} \in \text{Argmin}(\mathcal{P}_{\bar{g}})$, we see that

$$0 \le \frac{J(\bar{u}, \bar{g}) - J(u_{g_\rho}, g_\rho)}{\rho} \le \frac{J(u_{g_\rho}, \bar{g}) - J(u_{g_\rho}, g_\rho)}{\rho}.$$

With (6.3), we obtain

$$0 \le \lim_{\rho \to 0} \frac{J(u_{g_\rho}, \bar{g}) - J(u_{g_\rho}, g_\rho)}{\rho}$$

$$= -\int_Q F'_y(x, t, y(\bar{u}, \bar{g}))\, \bar{z}\, dx\, dt - \int_\Omega \ell'_y(x, y(\bar{u}, \bar{g})(T))\, \bar{z}(T)\, dx - \int_\Omega (L(x, g) - L(x, \bar{g}))\, dx\ .$$

Using the Green formula of Theorem 3.3, we have

$$-\int_Q F'_y(x, t, y(\bar{u}, \bar{g}))\, \bar{z}\, dx\, dt - \int_\Omega \ell'_y(x, y(\bar{u}, \bar{g})(T))\, \bar{z}(T)\, dx = \int_\Omega \bar{p}(x, 0)\, (g - \bar{g})(x)\, dx\ .$$

Therefore,

$$\int_\Omega \mathcal{H}_\Omega(x, g, \bar{p}(x, 0))\, dx \le \int_\Omega \mathcal{H}_\Omega(x, \bar{g}, \bar{p}(x, 0))\, dx \text{ for all } g \in G_{ad}.$$

The pointwise Pontryagin's principle (2.5) is obtained by the method developed in [16, section 5.2]. Finally, since $\bar{u}$ belongs to Argmin $(\mathcal{P}_{\bar{g}})$, (2.4) follows from Theorem 2.1. □

6.3. Proof of Theorem 2.3. The optimality condition for $u_{\bar{g}}$ is a direct consequence of Theorem 2.1. Let us prove optimality conditions for $\bar{g}$. Let g be in G_{ad} and u_g be an element of Arg inf(P_g). For ρ in $]0, 1[$, set $y_\rho = (1 - \rho)\ y(u_{\bar{g}}, \bar{g}) + \rho\ y(u_g, g)$. Since Φ is affine with respect to y, y_ρ is the solution of (1.1) corresponding to $((1 - \rho)\ u_{\bar{g}} + \rho\ u_g, (1 - \rho)\ \bar{g} + \rho\ g)$. Due to the convexity of F and ℓ, we have

$$\begin{aligned} \int_Q F(x, t, y_\rho)\, dx\, dt + \int_\Omega \ell(x, y_\rho(T))\, dx & \\ \le\ (1 - \rho) \left(\int_Q F(x, t, y(u_{\bar{g}}, \bar{g}))\, dx\, dt + \int_\Omega \ell(x, y(u_{\bar{g}}, \bar{g})(T))\, dx \right) & \\ +\ \rho \left(\int_Q F(x, t, y(u_g, g))\, dx\, dt + \int_\Omega \ell(x, y(u_g, g)(T))\, dx \right). & \end{aligned}$$

Set

$$J_\rho = \int_Q F(x,t,y_\rho)\,dx\,dt + \int_\Omega \ell(x,y_\rho(T))\,dx + (1-\rho)\left(\int_Q H(x,t,u_{\bar g})\,dx\,dt + \int_\Omega L(x,\bar g)dx\right) + \rho\left(\int_Q H(x,t,u_g)\,dx\,dt + \int_\Omega L(x,g)\,dx\right).$$

With the previous inequality, we obtain

$$J_\rho \le (1-\rho)J(u_{\bar g},\bar g) + \rho J(u_g,g).$$

From the optimality of $\bar g$, we have $J(u_g,g) \le J(u_{\bar g},\bar g)$, and thus

$$J_\rho \le (1-\rho)J(u_{\bar g},\bar g) + \rho J(u_g,g) \le J(u_{\bar g},\bar g).$$

It follows that

$$\begin{aligned} 0 \le \lim_{\rho\to 0}\frac{J(u_{\bar g},\bar g)-J_\rho}{\rho} = {} & \int_Q F'_y(x,t,y(u_{\bar g},\bar g))\ (y(u_{\bar g},\bar g)-y(u_g,g))\ dx\,dt \\ & + \int_\Omega \ell'_y(x,y(u_{\bar g},\bar g)(T)),\ (y(u_{\bar g},\bar g)-y(u_g,g)(T))\ dx \\ & + \int_Q (H(x,t,u_{\bar g})-H(x,t,u_g))\,dx\,dt \\ & + \textstyle\int_\Omega (L(x,\bar g)-L(x,g))\,dx. \end{aligned} \tag{6.4}$$

From (6.4), by using the Green formula of Theorem 3.3 (with $z = y(u_{\bar g},\bar g) - y(u_g,g)$), we obtain

$$\int_Q \bar p(u_{\bar g}-u_g)\,dx\,dt + \int_\Omega \bar p(0)(\bar g - g)\,dx$$

$$\le \int_Q (H(x,t,u_{\bar g})-H(x,t,u_g))\,dx\,dt + \int_\Omega (L(x,\bar g)-L(x,g))\,dx.$$

Recalling (2.7), we deduce that

$$\int_\Omega (L(x,g)-\bar p(0)g)\,dx - \int_\Omega (L(x,\bar g)-\bar p(0)\bar g)\,dx$$

$$\le \int_Q (H(x,t,u_{\bar g})-\bar p u_{\bar g})dx\,dt - \int_Q (H(x,t,u_g)-\bar p u_g)\,dx\,dt \le 0.$$

The proof is complete. □

7. Some extensions. We can also consider models which take into account the first order derivatives of the state variable both in the equation and the cost functional. For example, consider the parabolic equation

$$\begin{aligned} \frac{\partial y}{\partial t} + Ay + \overrightarrow{V}\cdot\nabla y + \Phi(x,t,y) = u \text{ in } Q,\ y = 0 \ \text{ on } \Sigma, \\ y(x,0) = y_o(x) + g(x) \ \text{ in } \Omega, \end{aligned} \tag{7.1}$$

where A, Φ, and u satisfy the assumptions of section 2, $\overrightarrow{V}$ belongs to $L^\infty(0,T;(L^\infty(\Omega))^N)$, and the cost functional is defined by

$$\mathcal{I}(y,u,g) = \int_Q \left(F(\cdot,y) + G(\cdot,\nabla y) + H(\cdot,u)\right)\, dx\, dt + \int_\Omega \left(\ell(\cdot,y(T)) + L(\cdot,g)\right)\, dx. \tag{7.2}$$

The regularity results used in the proof of Theorem 5.2 are still true for the above equation [10], [8]. The adjoint equation corresponding to a solution $\bar{y}$ of (7.1) is

$$\begin{cases} -\dfrac{\partial p}{\partial t} + Ap - \overrightarrow{V}\cdot\nabla p + \Phi'_y(\cdot,\bar{y})\, p + F'_y(\cdot,\bar{y}) - \operatorname{div}\left(G'_z(\cdot,\nabla\bar{y})\right) = 0 & \text{in } Q, \\ \\ p(\cdot,T) + \ell'_y(\cdot,\bar{y}(T)) = 0 & \text{in } \Omega, \end{cases} \tag{7.3}$$

where G'_z denotes the derivative of G with respect to ∇y. If $G'_z(\cdot,\nabla\bar{y})$ belongs to $L^r(Q)$ with $r > 1$, then (7.3) admits a unique solution in $L^1(0,T;W_0^{1,1}(\Omega))$. The condition $G'_z(\cdot,\nabla\bar{y}) \in L^r(Q)$ can be easily checked if G'_z satisfies a suitable growth condition. For $\overrightarrow{V} \equiv 0$ and $\Phi'_y \equiv 0$, the existence to (7.3) can be deduced from [17]. For the general case, that is if $\overrightarrow{V} \not\equiv 0$ and $\Phi'_y \not\equiv 0$, the existence can be shown by using a fixed point technique as in [13]. Therefore, Theorem 2.2 may be extended (with obvious modifications) to problem (P) corresponding to (7.1) and the functional (7.2). Notice that we have considered homogeneous boundary conditions, as in the example of convection-diffusion systems studied in [1]. The analysis corresponding to nonhomogeneous boundary conditions of the form $y = \psi \in L^\infty(\Sigma)$ is more delicate since we only know that ∇y belongs to $L^1_{loc}(Q)$.

For a state equation with a nonlinear term depending on the gradient ∇y, the analysis is more complicated and some additional material is needed (see for example [7, Chapter 4]). The results presented in our paper do not recover this case, and the extension to such models requires another lengthy study of the state equation which cannot be included here.

INVARIANT SOLUTIONS OF DIFFERENTIAL GAMES AND HAMILTON–JACOBI–ISAACS EQUATIONS FOR TIME-MEASURABLE HAMILTONIANS*

PIERRE CARDALIAGUET† AND SŁAWOMIR PLASKACZ‡

Abstract. We characterize invariance of time-varying domains with respect to differential games with time-measurable dynamics. We deduce from this result a new definition of viscosity solutions to some first order Hamilton–Jacobi equations with time-measurable Hamiltonians.

Key words. differential games, Hamilton–Jacobi–Isaacs equation, viscosity solutions, time-measurable Hamiltonians

1. Introduction. We study, on one hand, invariance of time-varying domains with respect to differential games with time-measurable dynamics (sections 2 and 3) and, on the other hand, first order Hamilton–Jacobi equations with time-measurable Hamiltonians (section 4).

We consider a differential game

$$\begin{cases} x'(t) = f(t, x(t), y(t), z(t)), \\ x(0) = x_0, \end{cases}$$

where f is only measurable with respect to the time. A time-varying domain $t \rightsquigarrow P(t) \subset R^N$ (a tube) is a set-valued map with nonempty closed values. The paper is mainly concerned with the following problem: Under which condition can one of the players prevent the state $x(t)$ of the system from leaving $P(t)$ under any action of the other player? The problem was considered by Cardaliaguet in [7] and by Cardaliaguet–Plaskacz in [8] for differential games with a more regular right-hand side. The time-measurable case was studied by Frankowska–Plaskacz–Rzeżuchowski in [15] and by Frankowska–Plaskacz in [14] for differential inclusions (see also [1], [2]).

In the second part we consider Hamilton–Jacobi–Isaacs equations

$$\frac{\partial V}{\partial t} + H\left(t, x, \frac{\partial V}{\partial x}\right) = 0$$

with a time-measurable Hamiltonian H given by

$$H(t, x, p) = \inf_z \sup_y \langle f(t, x, y, z), p \rangle.$$

We generalize a definition of viscosity solutions and obtain the uniqueness and the existence of such solutions. Our approach to the definition of a solution and our

methods of the proof are similar to the ones used by Frankowska for the first time in [12], and later by Frankowska–Plaskacz–Rzezuchowski in [15].

Hamilton–Jacobi equations with time-measurable Hamiltonians were considered also by Ishii in [17], by Lions–Perthame in [18] and by Barron–Jensen in [5]. Our definition of a generalized viscosity solution seems to be more elementary than others collected in [18]. It is difficult to compare them directly. The equivalence of different definitions follows from the uniqueness results which hold true in all cases.

Let us consider a tube $P : [0,T] \rightsquigarrow R^N$ and a dynamic f as previously. As usual in two players differential games, we are interested in the following problems:

The first problem. For any initial position $x_0 \in P(t_0)$, does there exist a nonanticipative strategy[1] α of the first player such that, for any time-measurable control $z(\cdot)$ chosen by the second player, the solution to

$$\begin{cases} x'(t) = f(t, x(t), \alpha(z(\cdot))(t), z(t)), \\ x(t_0) = x_0 \end{cases} \tag{1.1}$$

satisfies

$$x(t) \in P(t) \qquad \forall t \in [t_0, T]?$$

In Theorem 2.2 we show that a left absolutely continuous tube P enjoys the above stated property if and only if it is a discriminating tube, i.e., there exists a set $C \subset [0,T]$ of full measure such that, for any $t \in C$ and any $x \in P(t)$,

$$\forall (n_t, n_x) \in N^0_{\mathrm{Graph}(P)}(t,x), \sup_z \inf_y \langle (n_t, n_x), (1, f(t,x,y,z)) \rangle \leq 0.$$

The second problem. For any initial position $x_0 \in P(t_0)$, for any $\epsilon > 0$ and any nonanticipative strategy α of the first player, does there exist a time-measurable control $z(\cdot)$ of the second player, such that the solution $x(\cdot)$ to (1.1) satisfies

$$x(t) \in P(t) + B(0,\epsilon) \qquad \forall t \in [t_0, T]?$$

In Theorem 3.2 we show that a left absolutely continuous tube P enjoys this property if and only if it is a leadership tube, i.e., there exists a set $C \subset [0,T]$ of full measure such that, for any $t \in C$ and for any $x \in P(x)$,

$$\forall (n_t, n_x) \in N^0_{\mathrm{Graph}(P)}(t,x), \inf_z \sup_y \langle (n_t, n_x), (1, f(t,x,y,z)) \rangle \leq 0.$$

In the second part of the paper we use the above results to prove that the value function of the differential game is the unique solution of the appropriate Hamilton–Jacobi–Isaacs equations. We use and generalize some results of Evans–Souganidis [11]. In [11] it was proved that the value function is a viscosity solution of a Hamilton–Jacobi–Isaacs equation. We prove that the value function is a generalized viscosity solution and also we give an elementary proof (using Theorems 2.2 and 3.2) that a generalized solution of a Hamilton–Jacobi–Isaacs equation is equal to the value function. In this way we prove uniqueness of solution for some Hamilton–Jacobi equations with time-measurable Hamiltonians.

[1] These strategies are also often called Elliot–Kalton's strategies. The definition is recalled below.

2. Discriminating domains. We consider a differential game with dynamics given by $x'(t) = f(t, x(t), y, z)$. By $x(\cdot; t_0, x_0, y(\cdot), z(\cdot))$ we denote the solution of the Cauchy problem

$$\begin{cases} x'(t) = f(t, x(t), y(t), z(t)) \ \text{ for a.e. } \ t \in [0, T], \\ x(t_0) \ = \ x_0, \end{cases}$$

where $y : [0, T] \to Y$, $z : [0, T] \to Z$ are measurable controls (open loops) of player I and II, respectively, and Y, Z are compact metric spaces. We further introduce a set-valued map $P : [0, T] \rightsquigarrow R^n$, i.e., $P(t) \subset R^n$ and $P(t) \neq \emptyset$ for every $t \in [0, T]$, regarded as a time-dependent constraints set or a tube of constraints. A tube P is called left absolutely continuous if there exists an integrable function $\mu : [0, T] \to [0, +\infty)$ such that for every $t_1 < t_2$ we have

$$P(t_1) \subset P(t_2) + B\left(0, \int_{t_1}^{t_2} \mu(s)\, \mathrm{ds}\right),$$

where $B(x_0, r)$ denotes the ball in R^n centered at x_0 with radius r and $A + D = \{a + d \ : \ a \in A \& d \in D\}$ for A, $D \subset R^n$. Given a closed subset K of Euclidean space E, the Bouligand contingent cone $T_K(x)$ to K at $x \in K$ is defined by

$$T_K(x) = \left\{ e \in E \ : \ \liminf_{h \to 0^+} \frac{\text{dist } (x + he, K)}{h} = 0 \right\}.$$

For $T \subset E$ we let $T^\perp$ for the polar cone to T,

$$T^\perp = \{w \in E \ \ \langle w, v \rangle \leq 0, \ \text{for every } v \in T\}.$$

We set

$$N_K^0(x) = T_K^\perp(x)$$

and say that $N_K^0(x)$ is the normal cone to K at $x \in K$.

Let $M_t = \{y : [t, T] \to Y \ \ : \ \ y \text{ is measurable}\}$ and $N_t = \{z : [t, T] \to Z \ \ : \ z \text{ is measurable}\}$. We say that a map $\alpha : N_t \to M_t$ is a nonanticipative strategy if for every controls z_1, $z_2 \in N_t$ such that

$$z_1(s) = z_2(s) \text{ for almost all } s \in [t, \tau]$$

we have

$$\alpha(z_1)(s) = \alpha(z_2)(s) \text{ for almost all } s \in [t, \tau].$$

Let Γ_t denote the set of all nonanticipative strategies $\alpha : N_t \to M_t$.

Definition 2.1 (discriminating tube). *A tube $P : [0, T] \rightsquigarrow R^n$ is a discriminating tube for $f : [0, T] \times R^n \times Y \times Z \to R^n$ if there exists a full measure set $C \subset [0, T]$ such that for every $t \in C$ and every $x \in P(t)$ we have*

$$\begin{gathered} \forall (n_t, n_x) \in N^0_{Graph(P)}(t, x), \ \forall z \in Z, \ \exists y \in Y, \\ \langle (n_t, n_x), (1, f(t, x, y, z)) \rangle \leq 0. \end{gathered} \tag{2.1}$$

THEOREM 2.2. *We assume that a tube $P : [0,T] \rightsquigarrow R^n$ is left absolutely continuous and that a right-hand side $f : [0,T] \times R^n \times Y \times Z \to R^n$ satisfies the following conditions:*

$$f(\cdot, x, y, z) \text{ is measurable for every } x, y, z; \tag{2.2}$$

$$\begin{gathered}\exists l \in L^1(0,T),\ \forall x_1,\ x_2,\ \forall y \in Y,\ \forall z \in Z,\\ \|f(t,x_1,y,z) - f(t,x_2,y,z)\| \le l(t)\|x_1 - x_2\| \quad \text{for a.a. } t \in [0,T];\end{gathered} \tag{2.3}$$

$$f(t,x,\cdot,\cdot) \text{ is continuous for every } t, x; \tag{2.4}$$

$$\exists\, \mu \in L^1(0,T),\ \forall t,x,y,z,\ \ \|f(t,x,y,z)\| \le \mu(t); \tag{2.5}$$

$$\forall (t,x,z) \in [0,T] \times R^n \times Z,\ \ \{f(t,x,y,z) \,:\, y \in Y\} \text{ is convex}. \tag{2.6}$$

If P is a discriminating tube for f, then for each $t_0 \in [0,T]$ and $x_0 \in P(t_0)$

$$\exists \alpha \in \Gamma_{t_0},\ \forall z(\cdot) \in N_{t_0},\ \forall t \in [t_0,T],\ x(t;t_0,x_0,\alpha(z),z) \in P(t). \tag{2.7}$$

Conversely, if for each $t_0 \in [0,T]$ and $x_0 \in P(t_0)$

$$\begin{gathered}\forall \varepsilon > 0,\ \exists \alpha \in \Gamma_{t_0},\ \forall z(\cdot) \in N_{t_0},\ \forall t \in [t_0,T],\\ x(t;t_0,x_0,\alpha(z),z) \in P(t) + B(0,\varepsilon),\end{gathered} \tag{2.8}$$

then P is a discriminating tube for f.

The proof of Theorem 2.2 makes use of a viability result for differential inclusions and a nonexpansive selection theorem in ultrametric spaces. First, we recall a viability result in an appropriate version.

DEFINITION 2.3 (viability tube). *A tube $P : [0,T] \rightsquigarrow R^n$ is a viability tube for $F : [0,T] \times R^n \rightsquigarrow R^n$ if there exists a full measure set $C \subset [0,T]$ such that for every $t \in C$ and every $x \in P(t)$ we have*

$$(\{1\} \times F(t,x)) \cap \overline{co}\left(T_{Graph(P)}(t,x)\right) \neq \emptyset. \tag{2.9}$$

THEOREM 2.4. *Assume that a nonempty closed valued tube $P : [0,T] \rightsquigarrow R^n$ is left absolutely continuous and that a set valued-map $F : [0,T] \times R^n \rightsquigarrow R^n$ satisfies the following conditions:*

$$F(t,x) \text{ is nonempty closed convex;} \tag{2.10}$$

$$d_H(F(t,x_1),F(t,x_2)) \le l(t)|x_1 - x_2| \text{ a.e. in } [0,T],\ l(\cdot) \in L^1[0,T]; \tag{2.11}$$

$$F(\cdot,x) \text{ is measurable;} \tag{2.12}$$

$$\|F(t,x)\| \le \mu(t) \text{ a.e. in } [0,T],\ \ \mu \in L^1(0,T). \tag{2.13}$$

Then the tube P is a viability tube for F if and only if $\forall\ t_0 \in [0,T)$, $x_0 \in P(t_0)$ there exists an absolutely continuous solution $x : [t_0,T] \to R^n$ of

$$\begin{cases} x'(t) \in F(t,x(t)) \ \ \textit{a.e. in } [t_0,T], \\ x(t_0) = x_0, \\ x(t) \in P(t) \ \ \forall t \in [t_0,T]. \end{cases} \tag{2.14}$$

Proof. Fix $t_0 \in [0,T)$, $x_0 \in P(t_0)$. Define

$$g(t) = \inf\{\operatorname{dist}(x(t),P(t)) \ : \ x \in \operatorname{Sol}_F(t_0,x_0)\},$$

where $\operatorname{Sol}_F(t_0,x_0)$ denotes the set of solutions of Cauchy problem

$$\begin{cases} x' \in F(t,x), \\ x(t_0) = x_0. \end{cases}$$

By Lemma 4.8 in [16], if the tube P is absolutely continuous, then the function g is absolutely continuous. Assuming that P is only left absolutely continuous, we obtain that g has bounded variation and Gronwall inequality holds true for g. Namely, we have the following lemma.

LEMMA 2.5. *If P is left absolutely continuous, then*

(a) $g(t_2) \le g(t_1) + 2\int_{t_1}^{t_2} \mu(s)\,ds$, *for* $t_0 \le t_1 < t_2 \le T$;

(b) *g has bounded variation, in particular g is differentiable a.e. in $[t_0,T]$;*

(c) *if there exists $c \in L^1(t_0,T)$ such that $g'(t) \le c(t)g(t)$, a.e. in $[t_0,T]$, then $g \equiv 0$.*

Proof. Fix $t_1 < t_2$. Since $\operatorname{Sol}_F(t_0,x_0)$ is compact, there exists $x \in \operatorname{Sol}_F(t_0,x_0)$ such that $g(t_1) = \operatorname{dist}(x(t_1),P(t_1))$. We have

$$\begin{gathered} g(t_2) \le \operatorname{dist}(x(t_2),P(t_2)) \\ \le \|x(t_2) - x(t_1)\| + \operatorname{dist}(x(t_1),P(t_1)) + \sup\{\operatorname{dist}(y,P(t_2)) \ : \ y \in P(t_1)\} \\ \le \int_{t_1}^{t_2} \mu(s)\,ds + g(t_1) + \int_{t_1}^{t_2} \mu(s), \end{gathered}$$

which is our assertion (a).

To estimate the variation of g on $[t_0,T]$, we take a partition $t_0 < t_1 < \cdots < t_k = T$. Let $S = \{i \in \{1,2,\dots,k\} \ : \ g(t_i) - g(t_{i-1}) \ge 0\}$ and $S' = \{1,2,\dots,k\} \setminus S$. We have

$$g(t_k) - g(t_0) = \sum_{i=1}^{k} g(t_i) - g(t_{i-1}) = \sum_{i\in S} |g(t_i) - g(t_{i-1})| - \sum_{i\in S'} |g(t_i) - g(t_{i-1})|.$$

Thus

$$\sum_{i=1}^{k} |g(t_i) - g(t_{i-1})| = 2\sum_{i\in S} |g(t_i) - g(t_{i-1})| + g(t_k) - g(t_0) \le 6\int_{t_0}^{T} \mu(s)\,ds,$$

which gives us (b).

We set $h(t) = \sup\{g(s) \ : \ s \in [t_0,t]\}$. The function h is nonnegative, nondecreasing, $g(t) \le h(t)$ for $t \in [t_0,T]$, and

$$h(t_2) - h(t_1) \le 2\int_{t_1}^{t_2} \mu(s)\,ds$$

for $t_1 < t_2$. Hence h is absolutely continuous. Moreover, we have

$$\limsup_{\tau\to 0^+} \frac{h(t+\tau)-h(t)}{\tau} \le \max\left(\limsup_{\tau\to 0^+} \frac{g(t+\tau)-g(t)}{\tau}, 0\right).$$

Thus, for almost all $t \in [t_0, T]$, we have $h'(t) \le c(t)\, h(t)$. Gronwall inequality now yields $h \equiv 0$, which completes the proof of Lemma 2.5. □

The proof of Theorem 2.4 runs as the proof of Theorem 4.7 in [16] with the difference that we use our Lemma 2.5 instead of Lemma 4.8 in [16]. □

A metric ρ in a space M is an ultrametric if it satisfies strong triangle inequality

$$\rho(x,z) \le \max(\rho(x,y), \rho(y,z)).$$

We say that a subset K of an ultrametric space M is (*)-closed if for every sequence $\{y_n\} \subset K$ and every sequence $\{c_n\}$ ($c_n \ge c_{n+1} \ge 0$) such that $\rho(y_n, y_{n+1}) \le c_n$, there is $\bar{y} \in K$ such that $\rho(\bar{y}, y_n) \le c_n$, for every n.

REMARK 2.6. *If D_1, D_2 are nonempty (*)-closed subsets of an ultrametric space M, then the Hausdorff distance $d_H(D_1, D_2) \le r$ if and only if for every $d_1 \in D_1$ there is $d_2 \in D_2$ such that $\rho(d_1, d_2) \le r$ and for every $d_2 \in D_2$ there is $d_1 \in D_1$ such that $\rho(d_1, d_2) \le r$.*

We say that a set-valued map $A : N \rightsquigarrow M$ is nonexpansive set-valued map from an ultrametric space (N, ρ_N) into another ultrametric space (M, ρ_M) if A satisfies

$$\begin{aligned}
&\forall (n_1, n_2) \in N \times N,\\
&\text{(a)}\ \ \forall m_1 \in A(n_1),\ \exists m_2 \in A(n_2),\ \rho_M(m_1, m_2) \le \rho_N(n_1, n_2),\\
&\text{(b)}\ \ \forall m_2 \in A(n_2),\ \exists m_1 \in A(n_1),\ \rho_M(m_1, m_2) \le \rho_N(n_1, n_2).
\end{aligned}$$

LEMMA 2.7 (nonexpansive selection). *If $A : N \rightsquigarrow M$ is a nonexpansive set-valued map from an ultrametric space (N, ρ_N) into an ultrametric space (M, ρ_M) with nonempty (*)-closed values, then there exists a nonexpansive selection $\alpha : N \mapsto M$ of A.*

The proof of Lemma 2.7 is given in the appendix.

REMARK 2.8. *Given $y_1, y_2 \in M_{t_0}$ we define*

$$\rho(y_1, y_2) = T - \sup\{t \in [t_0, T] \,:\, y_1(s) = y_2(s) \text{ for a.a. } t \in [t_0, t]\}.$$

It is easy to see that (M_{t_0}, ρ) is an ultrametric space. Moreover, a strategy $\alpha : N_{t_0} \to M_{t_0}$ is nothing but a nonexpansive map in the meaning of the ultrametric ρ.

Proof of Theorem 2.2. Fix $t_0 \in [0, T]$, $x_0 \in P(t_0)$, and $\tilde{z}(\cdot) \in N_{t_0}$.

We define a set-valued map $F_{\tilde{z}(\,\cdot\,)}(t,x) = \{f(t,x,y,\tilde{z}(t)) \,:\, y \in Y\}$. By the regularity of f: (2.2), (2.3), (2.4), (2.5), and (2.6), the set-valued map $F_{\tilde{z}(\,\cdot\,)}$ satisfies (2.10), (2.11), (2.12), (2.13). By the separation theorem and (2.2), we have for every $t \in C$ and $x \in P(t)$

$$\forall z \in Z,\ \exists y \in Y,\ (1, f(t,x,y,z)) \in \overline{co}\left(T_{\mathrm{Graph}(P)}(t,x)\right). \tag{2.15}$$

Thus $F_{\tilde{z}(\,\cdot\,)}$ satisfies condition (2.9). Therefore there exists an absolutely continuous solution $\tilde{x} : [t_0, T] \to R^n$ of the differential inclusion $\tilde{x}'(t) \in F_{\tilde{z}(\,\cdot\,)}(t, \tilde{x}(t))$ such that $\tilde{x}(t_0) = x_0$ and $\tilde{x}(t) \in P(t)$ for every $t \in [t_0, T]$. By measurable selection Theorem 8.2.10 in [3], there exists a measurable map $\tilde{y} : [t_0, T] \to Y$ such that $x(t; t_0, x_0, \tilde{y}(\,\cdot\,), \tilde{z}(\,\cdot\,)) = \tilde{x}(t)$ for $t \in [t_0, T]$.

We define a set-valued map $A : N_{t_0} \rightsquigarrow M_{t_0}$ by

$$A(z(\cdot)) = \{y(\cdot) \in M_{t_0} \,:\, x(t; t_0, x_0, y(\cdot), z(\cdot)) \in P(t) \text{ for } t \in [t_0, T]\}.$$

We have shown that the values of the map A are nonempty. Now we verify that the map A satisfies the remaining assumptions of Lemma 2.7.

Let $z_1, z_2 \in N_{t_0}$ and $y_1 \in A(z_1)$. We set $t_1 = T - \rho(z_1, z_2)$ and $x_1 = x(t_1\,;, t_0, x_0, y_1, z_1)$. We have $x_1 \in P(t_1)$. By (2.15) and Theorem 2.4, there exists a solution $\hat{x} : [t_1, T] \to R^n$ of a differential inclusion $\hat{x}'(t) \in F_{z_2}(t, \hat{x}(t))$ such that $\hat{x}(t_1) = x_1$ and $\hat{x}(t) \in P(t)$ for $t \in [t_1, T]$, where $F_{z_2}(t, x) = \{f(t, x, y, z_2(t)) \,:\, y \in Y\}$. By Theorem 8.2.10 in [3], there exists a measurable map $y_3 : [t_1, T] \to Y$ such that $x(t; t_1, x_1, y_3, z_2) = \hat{x}(t)$ for $t \in [t_1, T]$. Setting

$$y_2(t) = \begin{cases} y_1(t) & \text{for} \quad t \in [t_0, t_1), \\ y_3(t) & \text{for} \quad t \in [t_1, T], \end{cases}$$

we get $y_2 \in A(z_2)$ such that $\rho(y_1, y_2) \le \rho(z_1, z_2)$, which means that the map A is nonexpansive.

Now, we show that the set $A(z)$ is $(*)$-closed for every $z \in N_{t_0}$. Let $0 \le \cdots \le c_{k+1} \le c_k \le \cdots \le c_1 \le T - t_0$, $c = \lim_{k\to\infty} c_k$ and $y_k \in A(z)$ satisfy $\rho(y_k, y_{k+1}) \le c_k$. We set $t_k = T - c_k$. Obviously, we have $x(t; t_0, x_0, y_k, z) = x(t; t_0, x_0, y_{k+1}, z)$ for $t \in [t_0, t_k]$. We define a map $y_\infty : [t_0, T - c[\to Y$ by

$$y_\infty(t) = \begin{cases} y_1(t) & \text{for} \quad t \in [t_0, t_1), \\ y_k(t) & \text{for} \quad t \in [t_{k-1}, t_k) \text{ and } k = 2, 3, \ldots . \end{cases}$$

We set $x_\infty = \lim_{t\to(T-c)^-} x(t, t_0, x_0, y_\infty, z)$. It is easy to check that $x_\infty \in P(T - c)$. By (2.15) and Theorem 2.4, there exists a solution $\bar{x} : [T - c, T] \to R^n$ of a differential inclusion $\bar{x}'(t) \in F_z(t, \bar{x}(t))$ such that $\bar{x}(T - c) = x_\infty$ and $\bar{x}(t) \in P(t)$ for $t \in [T - c, T]$. By Theorem 8.2.10 in [3], there exists a measurable map $\bar{y} : [T - c, T] \to Y$ such that $x(t; T - c, x_\infty, \bar{y}, z) = \bar{x}(t)$ for $t \in [T - c, T]$. Setting

$$y(t) = \begin{cases} y_\infty(t) & \text{for} \quad t \in [t_0, T - c), \\ \bar{y}(t) & \text{for} \quad t \in [T - c, T], \end{cases}$$

we get $y \in A(z)$ such that $\rho(y_k, y) \le c_k$, which means that the set $A(z)$ is $(*)$-closed.

Finally, by Lemma 2.7, there exists a nonexpansive selection $\alpha : N_{t_0} \to M_{t_0}$ of A, which is the desired strategy.

For the converse, we set $F_z(t, x) = \{f(t, x, y, z) \,:\, y \in Y\}$. By Lemma 2.6 in [16], there is a full measure set $C \in [0, T]$ such that

$$\forall\, (t_0, x_0, z) \in C \times R^d \times Z,\ \forall\, \varepsilon > 0,\ \exists\, \delta > 0,\ \forall\, x(\cdot) \in \mathrm{Sol}_{F_z}(t_0, x_0),$$

$$\forall\, 0 < |h| < \delta,\ \frac{1}{h}(x(t_0 + h) - x_0) \in F_z(t_0, x_0) + B(0, \varepsilon).$$

Fix $t_0 \in C$, $x_0 \in P(t_0)$, $z_0 \in Z$. Applying (2.7) we obtain an $\alpha_n \in \Gamma_{t_0}$ such that $x_n(t) := x(t, t_0, x_0, \alpha_n(z), z) \in P(t) + B(0, 1/n)$, for $t \in [t_0, T]$, where $z(\cdot)$ is a constant control on $[t_0, T]$ equal to z_0. For fixed $h > 0$ let $x(t_0 + h)$ be a condensing point of the

sequence $(x_n(t_0+h))$. Obviously, we have $x(t_0+h) \in P(t_0+h)$ and for sufficiently small h

$$\frac{x(t_0+h)-x(t_0)}{h} \in F_{z_0}(t_0,x_0) + B(0,\varepsilon).$$

There is a sequence $h_n > 0$ tending to zero such that $v := \lim_{n\to\infty} \frac{x(t_0+h_n)-x(t_0)}{h_n} \in F_{z_0}(t_0,x_0)$. We find $y_0 \in Y$ such that $v = f(t_0,x_0,y_0,z_0)$. We have $(1,v) \in T_{\mathrm{Graph}(P)}(t_0,x_0)$, which yields

$$\langle (n_t,n_x), (1, f(t_0,x_0,y_0,z_0))\rangle \le 0$$

for every $(n_t,n_x) \in N^0_{\mathrm{Graph}(P)}(t_0,x_0)$. ∎

3. Leadership domains.

DEFINITION 3.1 (leadership tube). *The tube $P(\cdot)$ is a leadership tube for f if there exists a set C of full measure in $[0,T]$ such that for every $t \in C$ and $x \in P(t)$*

$$\begin{gathered} \forall (n_t,n_x) \in N^0_{Graph(P)}(t,x),\ \exists z \in Z,\ \forall y \in Y, \\ \langle (n_t,n_x), (1, f(t,x,y,z))\rangle \le 0. \end{gathered} \tag{3.1}$$

THEOREM 3.2. *We assume that a tube $P : [0,T] \rightsquigarrow R^n$ is left absolutely continuous and that the right-hand side $f : [0,T] \times R^n \times Y \times Z \to R^n$ satisfies* (2.2), (2.3), (2.4), and (2.5). *Then $P(\cdot)$ is a leadership tube for f if and only if for any $t_0 \in [0,T]$ and $x_0 \in P(t_0)$*

$$\begin{gathered} \forall \varepsilon > 0,\ \forall \alpha \in \Gamma_{t_0},\ \exists z(\cdot) \in N_{t_0},\ \forall t \in [t_0,T], \\ x(t;t_0,x_0,\alpha(z),z) \in P(t) + B(0,\varepsilon). \end{gathered} \tag{3.2}$$

The proof is based on the following lemma.

LEMMA 3.3. *Let f and $P(\cdot)$ be as in Theorem* 3.2. *The following assertions are equivalent:*

(i) *$P(\cdot)$ is a leadership tube for f.*

(ii) *From any initial condition (t_0,z_0) belonging to Graph(P), and for any measurable map $a : [0,T] \times Z \to Y$, there is at least one solution to the differential inclusion:*

$$\begin{cases} v'(t) \in \overline{co} \bigcup_z f(t,v(t),a(t,z),z) \ \ a.e.\ in\ [t_0,T], \\ v(t_0) = v_0 \end{cases} \tag{3.3}$$

with $v(t) \in P(t)$ for every $t \in [t_0,T]$.

Proof. Assume that $P(\cdot)$ is a leadership tube. There exists a set C of full measure in $[t_0,T]$ such that $\forall t \in C$, $x \in P(t)$, $(n_t,n_x) \in N^0_{\mathrm{Graph}(P)}(t,x)$,

$$\inf_z \sup_y \langle f(t,x,y,z), n_x\rangle + n_t \le 0.$$

For any measurable map $a : [t_0,T] \times Z \to Y$, the set-valued map F_a, defined by

$$F_a(t,x) := \overline{co} \bigcup_z f(t,x,a(t,z),z),$$

is measurable, bounded by $\mu(\cdot)$, has convex compact values, and, for almost every $t \in [t_0,T]$, $x \rightsquigarrow F_a(t,x)$, is $l(t)-$Lipschitz.

Let us now prove that the tube $P(\cdot)$ is viable for F_a. Let $t \in C$, $x \in P(t)$, $(n_t, n_x) \in N^0_{\mathrm{Graph}(P)}(t,x)$. Then

$$\begin{array}{rcl} \inf_{w \in F_a(t,x)} \langle w, n_x \rangle + n_t & = & \inf_z \langle f(t,x,a(t,z),z), n_x \rangle + n_t \\ & \leq & \inf_z \sup_y \langle f(t,x,y,z), n_x \rangle + n_t \ \leq \ 0. \end{array}$$

So $P(\cdot)$ is a viability tube for F_a and Theorem 2.4 states that (ii) holds true.

Conversely, assume that the tube $P(\cdot)$ enjoys property (ii). Fix $n_x \in R^n$, $x_0 \in R^n$ and define

$$Y_{n_x,x_0}(t,z) := \left\{ \bar{y} \in Y \mid \langle f(t,x_0,\bar{y},z), n_x \rangle = \sup_y \langle f(t,x_0,y,z), n_x \rangle \right\}$$

and

$$G_{n_x,x_0}(t,x) := \overline{co} \left\{ f(t,x,y,z) \mid y \in Y_{n_x,x_0}(t,z) \ \& \ z \in Z \right\}.$$

First we prove that the tube $P(\cdot)$ is viable for the set-valued map G_{n_x,x_0} for any n_x and x_0. The set-valued map $Y_{n_x,x_0}(\cdot,\cdot)$ is measurable, so it enjoys a measurable selection $a_{n_x,x_0}(\cdot,\cdot)$. Note that

$$F_{a_{n_x,x_0}}(t,x) = \overline{co} \bigcup_z f(t,x,a_{n_x,x_0}(t,z),z) \ \subset G_{n_x,x_0}(t,x)$$

for almost all $t \in [t_0,T]$ and for all x. Thus, from (ii), there is a solution to the differential inclusion for G_{n_x,x_0} which remains in the tube $P(\cdot)$.

Let us point out that G_{n_x,x_0} is measurable and bounded. Moreover, G_{n_x,x_0} is upper semicontinuous with respect to (n_x,x_0,x) and has convex compact values for almost every $t \in [t_0,T]$. Thus Lemma 2.6 of [16] yields the existence of a set C of full measure in $[t_0,T]$ such that $\forall (\tau, x_\tau, n_x, x_0) \in C \times R^n \times R^n \times R^n$, $\forall \epsilon > 0$, $\exists \delta > 0$ such that, for any solution $x(\cdot)$ to the differential inclusion for G_{n_x,x_0} starting at x_τ at time τ, one has

$$\forall 0 < |h| < \delta, \ \ \frac{1}{h}(x(\tau+h) - x_\tau) \in G_{n_x,x_0}(\tau,x_\tau) + \epsilon B. \tag{3.4}$$

Let $\tau \in C$, $x_\tau \in P(\tau)$, and $(n_t,n_x) \in N^0_{Graph(P(\cdot))}(\tau,x_\tau)$. We have already proved that there is a solution $x(\cdot)$ of the differential inclusion for G_{n_x,x_τ} starting from x_τ at time τ which remains in the tube $P(\cdot)$ on $[\tau,T]$. From (3.4), for any $h \in]0,\delta[$, there is some $w_h \in G_{n_x,x_\tau}(\tau,x_\tau)$ such that

$$\frac{1}{h}(x(\tau+h) - x_\tau) \in w_h + \epsilon B.$$

Since $G_{n_x,x_\tau}(\tau,x_\tau)$ is compact, w_h converges, up to a subsequence, to some $w \in G_{n_x,x_\tau}(\tau,x_\tau)$. Thus, $(1,w)$ belongs to $T_{Graph(P(\cdot))}(\tau,x_\tau)$, and $\langle n_x, w \rangle + n_t \leq 0$. From the very definition of $G_{n_x,x_\tau}(\tau,x_\tau)$, one has

$$\begin{array}{rcl} 0 \ \geq \ \langle n_x, w \rangle + n_t & \geq & \inf_{v \in G_{n_x,x_\tau}(\tau,x_\tau)} \langle v, n_x \rangle + n_t \\ & = & \inf_z \inf_{y \in Y_{n_x,x_\tau}(\tau,z)} \langle f(\tau,x_\tau,y,z), n_x \rangle + n_t \\ & = & \inf_z \sup_y \langle f(\tau,x_\tau,y,z), n_x \rangle + n_t. \end{array}$$

So we have finally proved that, for any $\tau \in C$, for any $x_\tau \in P(\tau)$, and for any $(n_t,n_x) \in N^0_{Graph(P(\cdot))}(\tau,x_\tau)$,

$$\inf_y \sup_z \langle f(\tau,x_\tau,y,z), n_x \rangle + n_t \leq 0,$$

i.e., $P(\cdot)$ is a leadership tube. □

Proof of Theorem 3.2. Assume that $P(\cdot)$ enjoys the property described in Theorem 3.2, and let us prove that $P(\cdot)$ is a leadership tube. Let $a(\cdot,\cdot) : [0,T] \times Z \to Y$, and define the nonanticipative strategy α in the following way:

$$\forall z(\cdot) \in N, \ \ \alpha(z(\cdot))(t) := a(t, z(t)).$$

For any initial position (t_0, z_0) belonging to the graph of $P(\cdot)$, for any $\epsilon > 0$, there is a control $z_\epsilon(\cdot)$ such that the solution $x_\epsilon(\cdot) := x(t_0, x_0, \alpha(z_\epsilon(\cdot)), z_\epsilon(\cdot))$ satisfies

$$\forall t \in [t_0, T], \ \ d_{P(t)}(x_\epsilon(t)) \leq \epsilon.$$

Note that the $x_\epsilon(\cdot)$ are solutions of the differential inclusion (3.3). Since the set of solutions of this differential inclusion is compact, there exists a subsequence of the $x_\epsilon(\cdot)$ convergent to a solution $x(\cdot)$ of (3.3) satisfying $x(t) \in P(t)$ for any $t \in [t_0, T]$. Then Lemma 3.3 states that the tube $P(\cdot)$ is a leadership tube.

Conversely, assume now that $P(\cdot)$ is a leadership tube and fix any $\epsilon > 0$. The idea of the proof consists in constructing the desired control $z(\cdot)$ step by step, on intervals $[n\tau, (n+1)\tau)$, where $\tau > 0$ is fixed and shall be chosen later in function of ϵ.

For that purpose, we need the following estimation.

LEMMA 3.4. *Let f and $P(\cdot)$ be as in Theorem* 3.2, *$t_0 \in [0,T)$, and $x_0 \notin P(t_0)$. Assume that $P(\cdot)$ is a leadership tube. For any nonanticipative strategy α, there is a control $z(\cdot)$ such that, if we set $x(\cdot) := x(t_0, x_0, \alpha(z(\cdot)), z(\cdot))$, then for every $t \in [t_0, T]$,*

$$\begin{array}{rl} d^2_{P(t)}(x(t)) \leq & \left(1 + 2\int_{t_0}^t l(s)ds\right) d^2_{P(t_0)}(x_0) + 4\left(\int_{t_0}^t \mu(s)ds\right)^2 \\ & +2d_{P(t_0)}(x_0) \int_{t_0}^t l(s) \int_{t_0}^s \mu(\sigma)\, d\sigma ds. \end{array}$$

Proof of Lemma 3.4. The proof is based on Lemma 3.3. Let v_0 belong to the proximal projection of x_0 onto $P(t_0)$. Set $\nu := x_0 - v_0$. Consider the following set-valued map:

$$(s,z) \rightsquigarrow \left\{ \bar{y} \in Y \mid \langle f(s, v_0, \bar{y}, z), \nu \rangle = \max_y \langle f(s, v_0, y, z), \nu \rangle \right\}.$$

This set-valued map is measurable and, so, enjoys a measurable selection $a(\cdot,\cdot)$. In the same way, the set-valued map

$$s \rightsquigarrow \left\{ \bar{z} \in Z \mid \max_y \langle f(s, v_0, y, \bar{z}), \nu \rangle = \min_z \max_y \langle f(s, v_0, y, z), \nu \rangle \right\}$$

is measurable and enjoys a measurable selection $z(\cdot) \in N_{t_0}$.

Let us denote now $x(\cdot) := x(t_0, x_0, \alpha(z(\cdot)), z(\cdot))$ and let $v(\cdot)$ be a solution to

$$\begin{cases} v'(t) \in \overline{co} \bigcup_z f(t, v(t), a(t,z), z) \ \text{ f.a.e. } t \in [t_0, T], \\ v(t_0) = v_0, \end{cases}$$

which remains in the tube on $[t_0, T]$ (Lemma 3.3). Then

$$\begin{array}{rcl} d^2_{P(t)}(x(t)) & \leq & \|x(t) - v(t)\|^2 \\ & = & \|(x(t) - x_0) + (\nu) + (v_0 - v(t))\|^2 \\ & = & \|x(t) - x_0\|^2 + \|\nu\|^2 + \|v_0 - v(t)\|^2 + 2\langle x(t) - x_0, \nu \rangle \\ & + & 2\langle x(t) - x_0, v_0 - v(t) \rangle + 2\langle \nu, v_0 - v(t) \rangle. \end{array}$$

Note that $\|x(t)-x_0\|^2$, $\|v_0-v(t)\|^2$, and $\langle x(t)-x_0, v_0-v(t)\rangle$ are bounded by $(\int_{t_0}^t \mu(s)ds)^2$. Note also that $\|\nu\|^2 = d^2_{P(t_0)}(x(t_0))$.

Let us now estimate $\langle x(t)-x_0,\nu\rangle$:

$$\begin{array}{rcl}\langle x(t)-x_0,\nu\rangle &=& \int_{t_0}^t \langle f(s,x(s),\alpha(z(\cdot))(s),z(s)),\nu\rangle ds\\ &\le& \int_{t_0}^t \langle f(s,v_0,\alpha(z(\cdot))(s),z(s)),\nu\rangle ds\\ &+& \|\nu\|\int_{t_0}^t l(s)\|x(s)-v_0\|ds.\end{array}$$

For almost every s,

$$\begin{array}{l}\langle f(s,v_0,\alpha(z(\cdot))(s),z(s)),\nu\rangle\\ \quad\le \langle f(s,v_0,a(s,z(s)),z(s)),\nu\rangle\\ \quad= \min_z\langle f(s,v_0,a(s,z),z),\nu\rangle\\ \quad= \min_{w\in\overline{co}\bigcup_z f(s,v_0,a(s,z),z)}\langle w,\nu\rangle\\ \quad\le \langle v'(s),\nu\rangle + l(s)\|\nu\|\|v(s)-v_0\|\end{array}$$

from the very definition of $a(\cdot,\cdot)$ and of $z(\cdot)$ and because $x\rightsquigarrow \overline{co}\bigcup_z f(s,v,a(s,z),z)$ is $l(s)-$Lipschitz for almost all s. So, we have finally

$$\begin{array}{rl}\langle x(t)-x_0,\nu\rangle &\le \langle v(t)-v(0),\nu\rangle\\ &\quad+\|\nu\|\int_{t_0}^t l(s)(\|x(s)-v_0\|+\|v(s)-v_0\|)ds.\end{array}$$

Since f is bounded by $\mu(\cdot)$,

$$\|x(s)-v_0\|\le\int_{t_0}^s \mu(\sigma)\,d\sigma+\|\nu\| \text{ and } \|v(s)-v_0\|\le\int_{t_0}^s\mu(\sigma)\,d\sigma,$$

so that

$$\langle x(t)-x_0,\nu\rangle+\langle\nu,v_0-v(t)\rangle\le\|\nu\|\int_{t_0}^t l(s)\left(\|\nu\|+2\int_{t_0}^s\mu(\sigma)\,d\sigma\right)ds.$$

In conclusion,

$$\begin{array}{rl}d^2_{P(t)}(x(t))\le & \|\nu\|^2+4\left(\int_{t_0}^t\mu(s)ds\right)^2\\ &+2\|\nu\|\int_{t_0}^t l(s)\left(\|\nu\|+2\int_{t_0}^s\mu(\sigma)\,d\sigma\right)ds.\end{array}$$

□

Construction of $z(\cdot)$. We construct $z(\cdot)$ step by step, on intervals of the form $[n\tau,(n+1)\tau)$, where $\tau>0$ is fixed and shall be chosen below (τ depends mainly on ϵ).

Assume that we have already defined $z(\cdot)$ on $[0,n\tau]$. Then set $x_n := x(n\tau;t_0,x_0,\alpha(z(\cdot)),z(\cdot))$ (Note that x_n is well defined because α is nonanticipative.)

• If x_n belongs to $P(n\tau)$, then choose any $z\in Z$ and set $z(\cdot):=z$ on $[n\tau,(n+1)\tau)$.

• Otherwise, let $z_1(\cdot)$ be the control defined in Lemma 3.4 for $(t_0,x_0):=(n\tau,x_n)$. Then we set $z(\cdot):=z_1(\cdot)$ on $[n\tau,(n+1)\tau)$.

Note that the distance between $x(t):=x(t;t_0,x_0,\alpha(z(\cdot)),z(\cdot))$ and $P(t)$ ($t\in[t_0,T]$) is maximal if $x_n\notin P(n\tau)$ for any $n>0$. In that case, this distance satisfies $\forall t\in[n\tau,(n+1)\tau)$,

$$\begin{array}{rl}d^2_{P(t)}(x(t))\le & \left(1+2\int_{n\tau}^t l(s)ds\right)d^2_{P(n\tau)}(x_n)+4\left(\int_{n\tau}^t\mu(s)ds\right)^2\\ &+2d_{P(n\tau)}(x_n)\int_{n\tau}^t l(s)\int_{n\tau}^s\mu(\sigma)\,d\sigma\,ds\end{array}$$

from Lemma 3.4. In particular,

$$\forall t \in [n\tau, (n+1)\tau),\ d^2_{P(t)}(x(t)) \le d_{n+1}(\tau),$$

where $d_n(\tau)$ is the sequence defined by $d_0(\tau) = 0$ and

$$d_{n+1}(\tau) = (1 + \alpha_n(\tau))\, d_n(\tau) + \beta_n(\tau),$$

where $\alpha_n(\tau) := 2\int_{n\tau}^{(n+1)\tau} l(s)ds$,

$$\beta := \max\left\{4; 2 \sup_{z(\cdot)\in N_{t_0}} \sup_{t\in[t_0,T]} d_{P(t)}(x(t; t_0, x_0, \alpha(z(\cdot)), z(\cdot)))\right\}$$

(note that $\beta < +\infty$ because f is bounded and $P(\cdot)$ is absolutely continuous), and

$$\beta_n(\tau) := \beta\left[\left(\int_{n\tau}^{(n+1)\tau} \mu(s)ds\right)^2 + \int_{n\tau}^{(n+1)\tau} l(s)\int_{n\tau}^{s} \mu(\sigma)\, d\sigma ds\right].$$

To prove that the sequence constructed step by step satisfies the conclusion of Theorem 3.2, it is sufficient to apply the following lemma.

LEMMA 3.5. *Let d_n be the sequence defined previously. For any $\epsilon > 0$, there is $\tau_0 > 0$ such that, if $0 < \tau < \tau_0$, then*

$$\forall n \le \frac{T+\tau}{\tau},\ \ d_n(\tau) \le \epsilon.$$

Proof. Fix $\epsilon > 0$. To simplify the notations, we shall write d_i instead of $d_i(\tau)$, α_i instead of $\alpha_i(\tau)$, and so on.

It is easy to prove by induction that

$$d_{n+1} = \sum_{i=0}^{n}\left(\prod_{j=i}^{n-1}(1+\alpha_j)\right)\beta_i$$

(where, by convention, $\prod_{j=n}^{n-1}(1+\alpha_j) = 1$). Note that

$$\left(\prod_{j=0}^{n}(1+\alpha_j)\right) = \exp\left[\sum_{j=0}^{n}\ln(1+\alpha_j)\right] \le \exp\left[\sum_{j=0}^{n}\alpha_j\right] \le \exp\left[2\|l(\cdot)\|_1\right]$$

from the very definition of α_i. So,

$$d_{n+1} \le \exp\left[2\|l(\cdot)\|_1\right]\sum_{i=0}^{n}\beta_i.$$

Set $\epsilon_0 := \epsilon/(\beta e^{2\|l\|_1}\|l+\mu\|_1)$. Now choose τ small enough (say, $\tau < \tau_0$) in such a way that $\int_{i\tau}^{(i+1)\tau} l(s)ds \le \epsilon_0$ and $\int_{i\tau}^{(i+1)\tau}\mu(s)ds \le \epsilon_0$ for any i such that $i\tau \le T$.

Then, for any $n \le \frac{T}{\tau}$,

$$\sum_{i=0}^{n}\beta_i \le \beta\epsilon_0\sum_{i=0}^{n}\int_{i\tau}^{(i+1)\tau}(\mu(s)+l(s))ds \le \beta\epsilon_0\|\mu+l\|_1$$

so that

$$d_{n+1} \le \beta\epsilon_0\|\mu + l\|_1 e^{2\|l\|_1} \le \epsilon. \qquad \square$$

REMARK 3.6. *If $Z = \{z_0\}$, then the differential game reduces to the control system with dynamics given by $\hat{f}(t,x,y) = f(t,x,y,z_0)$. Assume, moreover, that $\{f(t,x,y,z_0) : y \in Y\}$ is convex for every t and x. Then leadership tube condition* (3.1) *implies that*

$$\forall y \in Y,\ (1, f(t,x,y,z_0)) \in \overline{co}\left(T_{Graph(P)}(t,x)\right)$$

and discriminating tube condition (2.1) *implies that*

$$\exists y \in Y,\ (1, f(t,x,y,z_0)) \in \overline{co}\left(T_{Graph(P)}(t,x)\right).$$

4. Value function and Hamilton–Jacobi–Isaacs equations. We mostly adopt here the notation of Evans–Souganidis [11].

Dynamic of a differential game is given by $f : [0,T] \times R^n \times Y \times Z \to R^n$. We assume that f satisfies (2.2), (2.3), (2.4), and (2.5). We shall consider a terminal time payoff functional

$$Q(y,z) = Q_{t_0x_0}(y,z) = g(x(T,\, t_0, x_0, y, z)),$$

where $g : R^n \to R$ is a continuous function, $y \in M_{t_0}$, $z \in N_{t_0}$.

We define

$$U(t_0,x_0) = \sup_{\alpha\in\Gamma_{t_0}} \inf_{z\in N_{t_0}} Q_{t_0x_0}(\alpha(z),z),$$
$$H(t,x,p) = \min_{z\in Z} \max_{y\in Y} \langle f(t,x,y,z), p\rangle.$$

We call $U : [0,T] \times R^n \to R$ the value function of the differential game and $H : [0,T] \times R^n \times R^n \to R$ the Hamiltonian. In [11], U and H are called the upper value function and the upper Hamiltonian. Besides these, a lower value function and a lower Hamiltonian are considered there. We formulate all results only for the upper value function. Following [11], we can reformulate them for the lower value function. If the value function U is differentiable in its domain, then it satisfies the Isaacs (Hamilton–Jacobi–Isaacs) equation:

$$U_t + H(t,x,U_x) = 0.$$

Evans and Souganidis in [11] proved that if g is Lipschitz continuous and f is continuous and Lipschitz continuous with respect to x, then U is a viscosity solution of Isaacs equation, i.e., for every $t \in (0,T)$ and $x \in R^n$

$$(h_1) \quad \forall(-p_t,-p_x,1) \in N^0_{\mathrm{Hyp}(U)}(t,x,U(t,x)),\ \ p_t + H(t,x,p_x) \ge 0$$

and

$$(h_2) \quad \forall(p_t,p_x,-1) \in N^0_{\mathrm{Epi}(U)}(t,x,U(t,x)),\ \ p_t + H(t,x,p_x) \le 0,$$

where $\mathrm{Hyp}(U) = \{(t,x,u) \in [0,T] \times R^n \times R : u \le U(t,x)\}$ and $\mathrm{Epi}(U) = \{(t,x,u) \in [0,T] \times R^n \times R : u \ge U(t,x)\}$.

We start with some properties of value function.

THEOREM 4.1 (Theorem 3.1 in [11]). *For each $0 \le t < t+h \le T$ and $x \in R^n$,*

$$U(t,x) = \sup_{\alpha\in\Gamma_t} \inf_{z\in N_t} U(t+h, x(t+h,\, t, x, \alpha(z), z)).$$

This is the dynamic programming optimality condition.

Next we examine regularity of the value function. We recall that the modulus of continuity $m_{f,A}(\delta)$ of a function $f : X \to Y$ (X, Y are metric spaces) on a subset $A \subset X$ is given by

$$m_{f,A}(\delta) = \sup\{d(f(x_1), f(x_2)) \,:\, x_1, x_2 \in A,\ d(x_1,x_2) \le \delta\}$$

for $\delta > 0$. It is easy to check that f is uniformly continuous on A if and only if $\lim_{\delta\to 0^+} m_{f,A}(\delta) = 0$. Moreover, $m_{f,A}(\cdot)$ is nondecreasing and if $A \subset B \subset X$, then $m_{f,A}(\delta) \le m_{f,B}(\delta)$.

PROPOSITION 4.2. *If f satisfies* (2.2), (2.3), (2.4), (2.5) *and $g : R^n \to R$ is continuous, then we have*

$$m_{U(t_0,\,\cdot\,),\, B(0,R)}(\delta) \le m_{g,\, B(0,R+\int_{t_0}^T \mu(s)\,ds)}\left(\delta \exp\left(\int_{t_0}^T l(s)\,ds\right)\right).$$

Proof. Fix $t_0 \in [0,T]$, α and z. By (2.3) and the Gronwall inequality, we have

$$\|x(T,\, t_0, x_1, \alpha(z), z) - x(T,\, t_0, x_2, \alpha(z), z)\| \le \exp\left(\int_{t_0}^T l(s)\,ds\right)\|x_1 - x_2\|.$$

By (2.5), we obtain

$$\|x(T,\, t_0, x_0, \alpha(z), z) - x_0\| \le \int_{t_0}^T \mu(s)\,ds.$$

If we use the above estimations, the proof is straightforward. □

COROLLARY 4.3. *The function $U(t_0,\,\cdot\,)$ is continuous for every $t_0 \in [0,T]$.*

We define the tubes $E,\ H : [0,T] \rightsquigarrow R^n$ by $E(t) = \{(x,u) \,:\, u \ge U(t,x)\}$, $H(t) = \{(x,u) \,:\, u \le U(t,x)\}$. We call E the epitube and H the hypotube generated by value function U. Obviously $\mathrm{Graph}(H) = \mathrm{Hyp}(U)$ and $\mathrm{Graph}(E) = \mathrm{Epi}(U)$.

PROPOSITION 4.4. *If f satisfies* (2.5)*, then the epitube E and the hypotube H generated by the value function U are left absolutely continuous, namely,*

$$E(t_1) \subset E(t_2) + \left(\int_{t_1}^{t_2} \mu(s)\right) B\,ds,$$

$$H(t_1) \subset H(t_2) + \left(\int_{t_1}^{t_2} \mu(s)\right) B\,ds$$

for $t_1 < t_2$.

Proof. Fix $x \in R^n$, $0 \le t_1 < t_2 \le T$. By Theorem 4.1,

$$U(t_1,x) = \sup_{\alpha\in\Gamma_{t_1}} \inf_{z\in N_{t_1}} U(t_2, x(t_2,\, t_1, x, \alpha(z), z)).$$

Take $\varepsilon > 0$. There is $\alpha_0 \in \Gamma_{t_1}$ such that

$$U(t_1, x) - \varepsilon < \inf_{z \in N_{t_1}} U(t_2, x(t_2,\, t_1, x, \alpha_0(z), z)) \le U(t_1, x).$$

Next, there is $z_0 \in N_{t_1}$ such that

$$U(t_1, x) - \varepsilon < U(t_2, x(t_2,\, t_1, x, \alpha_0(z_0), z_0)) < U(t_1, x) + \varepsilon. \tag{4.1}$$

We set $x(\cdot) = x(\cdot\,,\, t_1, x, \alpha_0(z_0), z_0)$. If $u \ge U(t_1, x)$, then $U(t_2, x(t_2)) < u + \varepsilon$. Thus $(x(t_2), u + \varepsilon) \in E(t_2)$. Therefore,

$$\operatorname{dist}((x, u), E(t_2)) \le (\|x(t_2) - x\|^2 + \varepsilon^2)^{1/2}.$$

Hence,

$$E(t_1) \subset E(t_2) + B\bigg(\int_{t_1}^{t_2} \mu(s)\, ds\bigg).$$

Now, let $(x, u) \in H(t_1)$. By (4.1), $u - \varepsilon < U(t_2, x(t_2))$. Thus $(x(t_2), u - \varepsilon) \in H(t_2)$. Therefore,

$$\operatorname{dist}((x, u), H(t_2)) \le (\|x(t_2) - x\|^2 + \varepsilon^2)^{1/2},$$

which completes the proof. □

PROPOSITION 4.5. *If $U : [0, T] \times R^n \to R$ is a value function, then for each $t_0 \in [0, T]$ and $x_0 \in R^n$*

$$\begin{gathered} \forall \varepsilon > 0,\ \exists \alpha \in \Gamma_{t_0},\ \forall z \in N_{t_0},\ \forall t \in [t_0, T], \\ U(t_0, x_0) \le U(t, x(t; t_0, x_0, \alpha(z), z)) + \varepsilon, \end{gathered} \tag{4.2}$$

$$\begin{gathered} \forall \varepsilon > 0,\ \forall \alpha \in \Gamma_{t_0},\ \exists z \in N_{t_0},\ \forall t \in [t_0, T], \\ U(t_0, x_0) \ge U(t, x(t; t_0, x_0, \alpha(z), z)) - \varepsilon. \end{gathered} \tag{4.3}$$

Proof. Fix $t_0 \in [0, T]$, $x_0 \in R^n$, and $\varepsilon > 0$.

First we prove that if U is the value function, then (4.2) holds true. By the definition of the value function, there exists an $\alpha_\varepsilon \in \Gamma_{t_0}$ such that

$$U(t_0, x_0) \le \inf_{z \in N_{t_0}} g(x(T; t_0, x_0, \alpha(z), z)) + \varepsilon/2.$$

We show that (4.2) holds true for α_ε. To the contrary, assume that there are $z_0 \in N_{t_0}$ and $t_1 \in [0, T]$ such that

$$U(t_0, x_0) > U(t_1, x_1) + \varepsilon,$$

where $x_1 = x(t_1; t_0, x_0, \alpha_\varepsilon(z_0), z_0)$. Given $z_1 \in N_{t_1}$, we set

$$(z_0, z_1)(s) = \begin{cases} z_0(s) & \text{for} \quad s \in [t_0, t_1), \\ z_1(s) & \text{for} \quad s \in [t_1, T]. \end{cases}$$

Let $\alpha_1 \in \Gamma_{t_1}$ be given by

$$\alpha_1(z_1)(s) = \alpha_\varepsilon(z_0, z_1)(s) \tag{4.4}$$

for $s \in [t_1, T]$. Obviously, $U(t_1, x_1) \geq \inf_{z_1 \in N_{t_1}} g(x(T; t_1, x_1, \alpha_1(z_1), z_1)$ and hence there is $z_1 \in N_{t_1}$ such that

$$\inf_{z \in N_{t_1}} g(x(T; t_1, x_1, \alpha_1(z), z)) > g(x(T; t_1, x_1, \alpha_1(z_1), z_1)) - \varepsilon/2.$$

Setting $\tilde{z} = (z_0, z_1)$ we have

$$x(T; t_0, x_0, \alpha_\varepsilon(\tilde{z}), \tilde{z}) = x(T; t_1, x_1, \alpha_1(z_1), z_1).$$

Thus

$$U(t_0, x_0) > U(t_1, x_1) + \varepsilon > g(x(T; t_0, x_0, \alpha_\varepsilon(\tilde{z}), \tilde{z})) - \frac{\varepsilon}{2} + \varepsilon,$$

which is the desired contradiction.

Fix $\alpha \in \Gamma_{t_0}$. We divide the proof of (4.3) into two steps.

Step 1. We fix a division $t_0 < t_1 < \cdots < t_k = T$ of the interval $[t_0, T]$. By the dynamic programming optimality condition (Theorem 4.1), there is $z_0 \in N_{t_0}$ such that

$$U(t_0, x_0) > U(t_1, x_1) - \frac{\varepsilon}{2k},$$

where $x_1 = x(t_1; t_0, x_0, \alpha(z_0), z_0)$. Taking $\alpha_0 = \alpha$ in (4.4) we obtain an $\alpha_1 \in \Gamma_{t_1}$. By the dynamic programming optimality condition again, we obtain $z_1 \in N_{t_1}$ such that

$$U(t_1, x_1) > U(t_2, x_2) - \frac{\varepsilon}{2k},$$

where $x_1 = x(t_2; t_1, x_1, \alpha_1(z_1), z_1)$.

We proceed by induction getting a sequence $z_2 \in N_{t_2}, \ldots, z_{k-1} \in N_{t_{k-1}}$. Setting $\tilde{z}(s) = z_i(s)$, for $s \in [t_{i-1}, t_i)$, we obtain

$$U(t_0, x_0) \geq U(t_i, x(t_i; t_0, x_0, \alpha(\tilde{z}), \tilde{z})) - \frac{i\varepsilon}{2k}.$$

Step 2. We set $R = \|x_0\| + 1$ and find $\delta > 0$ such that

$$m_{g, B(R + \int_{t_0}^T \mu(s)ds)} \left(\delta \int_{t_0}^T l(s)ds \right) < \frac{\varepsilon}{2}.$$

Next we choose a division $t_0 < t_1 < \cdots < t_k = T$ of the interval $[t_0, T]$ such that $\int_{t_{i-1}}^{t_i} \mu(s)ds < \frac{\delta}{2}$, for $i = 1, 2, \ldots, k$. By Step 1, we find $\tilde{z} \in N_{t_0}$ such that $U(t_0, x_0) > U(t_i, \tilde{x}(t_i)) - \frac{\varepsilon}{2}$, where $\tilde{x}(t) = x(t; t_0, x_0, \alpha(\tilde{z}), \tilde{z})$. Fix $t \in [t_{i-1}, t_i]$. By the dynamic programming optimality condition $U(t, \tilde{x}(t)) \in [\inf\{U(t_i, y) \ : \ \|y - \tilde{x}(t)\| \leq \int_t^{t_i} \mu(s)ds\}, \sup\{U(t_i, y) \ : \ \|y - \tilde{x}(t)\| \leq \int_t^{t_i} \mu(s)ds\}] (:= J)$. Since $\|\tilde{x}(t_i - \tilde{x}(t)\| \leq \int_t^{t_i} \mu(s)ds$ then also $U(t_i, \tilde{x}(t_i)) \in J$. Thus $\|U(t, \tilde{x}(t)) - U(t_i, \tilde{x}(t_i)\| \leq \sup\{\|U(t_1, y_1) - U(t_1, y_2)\| \ : \ y_1, y_2 \in B(\tilde{x}(t_0), \int_t^{t_i} \mu(s)ds)\} \leq \varepsilon/2$, which completes the proof. □

THEOREM 4.6. *Suppose that $g : R^n \to R$ is continuous and $f : [0, T] \times R^n \times Y \times Z \to R^n$ satisfies* (2.2), (2.3), (2.4), (2.5), *and* (2.6). *Let the Hamiltonian $H : [0, T] \times R^n \times R^n \to R$ and the value function $U : [0, T] \times R^n \to R$ be generated by f, g. Then a function $W : [0, T] \times R^n \to R$ is the value function, i.e., $W = U$, if and only if W satisfies the following conditions:*

(a) $W(T, \cdot) = g(\cdot)$;

(b) $W(t,\cdot)$ *is continuous function, for every* $t \in [0,T]$*;*

(c) *the epitube* E_W *and the hypotube* H_W *are left absolutely continuous, where* $E_W(t) = \{(x,w) \in R^n \times R : w \geq W(t,x)\}$ *and* $H_W(t) = \{(x,w) \in R^n \times R : w \leq W(t,x)\}$*;*

(d) *there exists a full measure set* $C \subset [0,T]$ *such that for every* $t \in C$ *and* $x \in R^n$

$$\forall (n_t, n_x, n_u) \in N^0_{Graph(H_W)}(t,x,W(t,x)), \quad -n_t + H(t,x,-n_x) \geq 0 \tag{4.5}$$

$$\forall (n_t, n_x, n_u) \in N^0_{Graph(E_W)}(t,x,W(t,x)), \quad n_t + H(t,x,n_x) \leq 0. \tag{4.6}$$

REMARK 4.7. *Note that, if* $W = U$ *is smooth, then* (4.5) *and* (4.6) *mean nothing but that* W *satisfies the Hamilton–Jacobi–Isaacs equation:*

$$\frac{\partial W}{\partial t}(t,x) + H\left(t,x,\frac{\partial W}{\partial x}(t,x)\right) = 0.$$

Proof. Suppose that $W = U$. Corollary 4.3 and Proposition 4.4 yield (b) and (c). Let $\tilde{f}(t,x,u,y,z) = (f(t,x,y,z),0)$, $u \in R$. The function $(x(t),u(t)) = (x(t;t_0,x_0,\alpha(z),z),U(t_0,x_0))$ is the solution of the Cauchy problem

$$\begin{cases} (x'(t),u'(t)) = \tilde{f}(t,x(t),u(t),\alpha(z),z), \\ (x(t_0),u(t_0)) = (x_0,U(t_0,x_0)). \end{cases}$$

From (4.2) it follows that (2.8) holds true for $P = H_W$ and $f = \tilde{f}$. By Theorem 2.2, the hypotube H_W is a discriminating tube for $\tilde{f}$. From this we conclude (4.5). From (4.3) it follows that (3.2) holds true for $P = E_W$ and $f = \tilde{f}$. By Theorem 3.2, the epitube E_W is a leadership tube for $\tilde{f}$. From this we conclude (4.6).

Now, suppose that a function W satisfies (a), (b), (c), and (d). From (4.5) it follows that the hypotube H_W is a discriminating tube for $\tilde{f}$. Fix t_0 and x_0. By Theorem 2.2, there is $\alpha \in \Gamma_{t_0}$ such that for every $z \in N_{t_0}$

$$(x(T;t_0,x_0,\alpha(z),z),W(t_0,x_0)) \in H_W(T).$$

Hence

$$\forall \alpha, \ \exists z, \quad W(t_0,x_0) \leq W(T,x(T;t_0,x_0,\alpha(z),z)).$$

Thus

$$W(t_0,x_0) \leq \sup_\alpha \inf_z g(x(T;t_0,x_0,\alpha(z),z)).$$

From (4.6) it follows that the epitube E_W is a leadership tube for $\tilde{f}$. Fix t_0, x_0. By Theorem 3.2, for every $\varepsilon > 0$ and every $\alpha \in \Gamma_{t_0}$, there is $z \in N_{t_0}$

$$(x(T;t_0,x_0,\alpha(z),z),W(t_0,x_0)) \in E_W(T) + B(0,\varepsilon).$$

Since g is uniformly continuous on $B(x_0, \int_{t_0}^T \mu(s)ds)$, we have

$$W(t_0,x_0) \geq \sup_\alpha \inf_z g(x(T;t_0,x_0,\alpha(z),z)),$$

which completes the proof. □

5. Appendix. The aim of the appendix is to prove Lemma 2.7. Lemma 2.7 has been announced in [8]. We proceed the proof with some elementary properties of ultrametric spaces.

PROPOSITION 5.1. *If $y_1, y_2, y_3 \in M$ and $\rho(y_1, y_2) < \rho(y_2, y_3)$, then $\rho(y_1, y_3) = \rho(y_2, y_3)$.*

Proof. We have $\rho(y_2, y_3) \leq \max(\rho(y_1, y_2), \rho(y_1, y_3))$. Thus $\rho(y_2, y_3) \leq \rho(y_1, y_3)$. Moreover, $\rho(y_1, y_3) \leq \max(\rho(y_1, y_3), \rho(y_2, y_3)) = \rho(y_2, y_3)$. □

Let K be a nonempty subset of M. We denote by Q_K the family of nonempty subsets of K of the form

$$\{y \in K \,:\, \rho(y, y_0) \leq c\},$$

where $y_0 \in K$ and $c \geq 0$.

PROPOSITION 5.2. *If $D \in Q_K$ and $\bar{y} \in D$, then $D = \{y \in K \,:\, \rho(y, \bar{y}) \leq diam\, D\}$.*

Proof. Fix $y_0 \in K$, $c \geq 0$ and define $D = \{y \in K \,:\, \rho(y, y_0) \leq c\}$. Let $\bar{y} \in D$. Obviously, we have $D \subset \{y \in K \,:\, \rho(y, \bar{y}) \leq \mathrm{diam} D\}$. If $y \in K$ and $\rho(y, \bar{y}) \leq \mathrm{diam} D$, then $\rho(y, y_0) \leq \max(\rho(y, \bar{y}), \rho(\bar{y}, y_0)) \leq \max(\mathrm{diam} D, c) = c$. □

PROPOSITION 5.3. *If $D \in Q_K$, $y_1 \in M$, $c \geq 0$ are such that $D_1 = \{y \in D \,:\, \rho(y, y_1) \leq c\}$ is a nonempty set, then $D_1 \in Q_K$.*

Proof. Fix $\bar{y} \in D_1$. By Proposition 5.2, we have $D = \{y \in K \,:\, \rho(y, \bar{y}) \leq \mathrm{diam}\, D\}$.

Case 1. If $\mathrm{diam}\, D \leq c$, then $D_1 = D$.

Indeed, for any $y \in D$, we have $\rho(y, y_1) \leq \max(\rho(y, \bar{y}), \rho(\bar{y}, y_1)) \leq \max(\mathrm{diam}\, D, c) = c$.

Case 2. If $\mathrm{diam}\, D > c$, then $D_1 = \{y \in K \,:\, \rho(y, \bar{y}) \leq c\}$.

If $y \in D_1$, then $\rho(y, \bar{y}) \leq \max(\rho(y, y_1), \rho(y_1, \bar{y})) \leq c$. Thus $D_1 \subset \{y \in K \,:\, \rho(y, \bar{y}) \leq c\}$. If $y \in K$ and $\rho(y, \bar{y}) \leq c$, then $y \in D$ and $\rho(y, y_1) \leq \max(\rho(y, \bar{y}), \rho(\bar{y}, y_1)) \leq c$. □

PROPOSITION 5.4. *If $D_1, D_2 \in Q_K$, $D_1 \subset D_2$, and $D_1 \neq D_2$, then $diam D_1 < diam D_2$.*

Proof. Suppose that $\mathrm{diam}\, D_1 = \mathrm{diam}\, D_2 = d$ and $D_1 \subset D_2$. If $y_1 \in D_1$ and $y_2 \in D_2$, then $D_1 = \{y \in K \,:\, \rho(y, y_1) \leq d\}$ and $D_2 = \{y \in K \,:\, \rho(y, y_2) \leq d\}$. We have $\rho(y_1, y_2) \leq d$. If $y \in D_2$, then $\rho(y, y_1) \leq \max(\rho(y, y_2), \rho(y_2, y_1)) \leq d$, which involves that $y \in D_1$. □

PROPOSITION 5.5. *Suppose that K is a nonempty $(^*)$-closed subset of M, and a family $\{D_\omega \in Q_K \,:\, \omega \in \Omega\}$ satisfies the following condition:*

$$\forall \omega_1, \omega_2 \in \Omega,\ D_{\omega_1} \subset D\omega_2 \text{ or } D_{\omega_2} \subset D\omega_1.$$

Then

(1) $\forall \omega_1, \omega_2 \in \Omega,\ (diam\, D_{\omega_1} \leq diam\, D_{\omega_2} \Longrightarrow D_{\omega_1} \subset D_{\omega_2})$.

(2) *If a sequence $\{\omega_n\} \subset \Omega$ satisfies the conditions*
- *$diam\, D_{\omega_{n+1}} \leq diam\, D_{\omega_n}$ $(:= d_n)$,*
- *$\lim_{n\to\infty} d_n = \inf_{\omega\in\Omega} diam\, D_\omega$ $(:= d)$,*

then for every sequence $y_n \in D_{\omega_n}$ there is $\bar{y} \in K$ such that $\rho(\bar{y}, y_n) \leq d_n$ and

$$\bigcap_{\omega\in\Omega} D_\omega = \{y \in K \,:\, \rho(y, \bar{y}) \leq d\}. \tag{5.1}$$

(3) *The set $D = \bigcap_{\omega\in\Omega} D_\omega$ belongs to Q_K.*

Proof. Assertion (1) is an immediate consequence of Proposition 5.4.
By Proposition 5.2,

$$D_{\omega_n} = \{y \in K \,:\, \rho(y, y_n) \le d_n\}.$$

According to assertion (1), $D_{\omega_{n+1}} \subset D_{\omega_n}$ for every n. Therefore, $\rho(y_{n+1}, y_n) \le d_n$. Since K is (*)-closed, there is $\bar{y} \in K$ such that $\rho(\bar{y}, y_n) \le d_n$.

If $y \in D_{\omega_n}$, then $\rho(y, \bar{y}) \le \max(\rho(y, y_n), \rho(y_n, \bar{y})) \le d_n$.

Let us choose $y \in K$ such that $\rho(y, \bar{y}) \le d$ and pick some $\omega \in \Omega$. There is ω_n such that $d_n \le \operatorname{diam} D_\omega$. By the assertion (a), we have $D_{\omega_n} \subset D_\omega$. Moreover, $\rho(y, y_n) \le \max(\rho(y, \bar{y}), \rho(\bar{y}, y_n)) \le \max(d, d_n) = d_n$. Hence $y \in D_{\omega_n}$.

By (5.1), we obtain statement (3). □

Proof of Lemma 2.7. First we define a partial order $(\mathcal{P}, \le)$. The family $\mathcal{P}$ consists of all nonempty valued nonexpansive maps $C : N \rightsquigarrow M$ such that $C(z) \in Q_{A(z)}$ for every $z \in N$. Since $A \in \mathcal{P}$, then the family $\mathcal{P}$ is nonempty. We say that $C_1 \le C_2$ if $C_1(z) \subset C_2(z)$ for every $z \in N$.

Step 1. Let $\{C_\omega\}_{\omega\in\Omega} \subset \mathcal{P}$ be a chain. Define a set-valued map $C : N \rightsquigarrow M$ by $C(z) = \bigcap_{\omega\in\Omega} C_\omega(z)$. By Proposition 5.5(3), we have $C(z) \in Q_{A(z)}$ for every $z \in N$. Now, we show that C is a nonexpansive map. Let us take $z_1, z_2 \in N$ and $\bar{y_1} \in C(z_1)$.

Case 1. $\rho(z_1, z_2) \ge \inf_{\omega\in\Omega} \operatorname{diam} C_\omega(z_2)$. We choose a sequence $\{\omega_n\} \subset \Omega$ such that $d_{n+1} \le d_n \,(:= \operatorname{diam} C_{\omega_n}(z_2))$ and $\lim_{n\to\infty} d_n = \inf_{\omega\in\Omega} \operatorname{diam} C_\omega(z_2)$. Since C_{ω_n} is a nonexpansive map, then there is $y_n \in C_{\omega_n}(z_2)$ such that $\rho(\bar{y_1}, y_n) \le \rho(z_1, z_2)$. By Proposition 5.5(2), there is $\bar{y} \in C(z_2)$ such that $\rho(y_n, \bar{y}) \le d_n$. Therefore $\rho(\bar{y_1}, \bar{y}) \le \max(\rho(\bar{y_1}, y_n), \rho(y_n, \bar{y})) \le \max(\rho(z_1, z_2), d_n)$.

Case 2. $\rho(z_1, z_2) < \inf_{\omega\in\Omega} \operatorname{diam} C_\omega(z_2)$. Let us fix $\omega_0 \in \Omega$ and choose $y_0 \in C_{\omega_0}(z_2)$ such that $\rho(\bar{y_1}, y_0) \le \rho(z_1, z_2)$. We claim that $y_0 \in C(z_2)$. We pick some $\omega \in \Omega$ and choose $y_\omega \in C_\omega(z_2)$ such that $\rho(\bar{y_1}, y_\omega) \le \rho(z_1, z_2)$. Thus $\rho(y_0, y_\omega) \le \max(\rho(y_0, y_1), \rho(y_1, y_\omega)) \le \rho(z_1, z_2)$. By Proposition 5.2, we have $C_\omega(z_2) = \{y \in A(z_2) \,:\, \rho(y, y_\omega) \le \operatorname{diam} C_\omega(z_2)\}$. Therefore $y_0 \in C_\omega(z_2)$.

Step 2. Suppose that $C \in \mathcal{P}$ and there is $z_0 \in N$ such that $\operatorname{diam} C(z_0) > 0$, i.e., C is not a single-valued map. We define a map $\tilde{C} : N \rightsquigarrow M$ by

$$\tilde{C}(z) = \begin{cases} C(z) & \text{if} \quad \rho(z, z_0) \ge d, \\ \{y \in C(z) \,:\, \rho(y, y_0) \le \rho(z, z_0)\} & \text{if} \quad \rho(z, z_0) < d, \end{cases}$$

where $d = \operatorname{diam} C(z_0)$ and y_0 is a fixed element of $C(z_0)$. Obviously, $\tilde{C}(z_0) = \{y_0\} \ne C(z_0)$. Since C is a nonexpansive map, then $\tilde{C}(z) \ne \emptyset$ for every $z \in N$. By Proposition 5.3, we have $\tilde{C}(z) \in Q_{A(z)}$ for every $z \in N$. Now, we show that $\tilde{C}$ is a nonexpansive map. Let us take $z_1, z_2 \in N$ and $y_1 \in \tilde{C}(z_1)$.

Case 1. $\rho(z_1, z_0) \ge d$ and $\rho(z_2, z_0) < d$. Let us take an arbitrary $y_2 \in \tilde{C}(z_2)$. By Proposition 5.1, we have $\rho(z_1, z_2) = \rho(z_1, z_0)$. Since C is a nonexpansive map, then there is $\bar{y_0} \in C(z_0)$ such that $\rho(y_1, \bar{y_0}) \le \rho(z_1, z_0)$. Therefore $\rho(y_1, y_2) \le \max(\rho(y_1, \bar{y_0}), \rho(\bar{y_0}, y_0), \rho(y_0, y_2)) \le \max(\rho(z_0, z_2), d) \le \rho(z_1, z_2)$.

Case 2. $\rho(z_1, z_0) < d$ and $\rho(z_2, z_0) < d$.

- $\rho(z_1, z_0) \le \rho(z_2, z_0)$. By Proposition 5.1, we have $\rho(z_1, z_2) = \rho(z_2, z_0)$. For any $y_2 \in \tilde{C}(z_2)$ we have $\rho(y_1, y_2) \le \max(\rho(y_1, y_0), \rho(y_0, y_2)) \le \max(\rho(z_1, z_0), \rho(z_0, z_2)) = \rho(z_1, z_2)$.
- $\rho(z_1, z_0) > \rho(z_2, z_0)$. By Proposition 5.1, we have $\rho(z_1, z_2) = \rho(z_1, z_0)$. Let y_2 be an arbitrary element of $\tilde{C}(z_2)$. Therefore, $\rho(y_1, y_2) \le \max(\rho(y_1, y_0), \rho(y_0, y_2)) \le \max(\rho(z_1, z_0), \rho(z_0, z_2)) = \rho(z_1, z_2)$.

- $\rho(z_1, z_0) = \rho(z_2, z_0)$. Since C is a nonexpansive map, then there is $y_2 \in C(z_2)$ such that $\rho(y_1, y_2) \leq \rho(z_1, z_2)$. Observe that $\rho(z_1, z_2) \leq \max(\rho(z_1, z_0), \rho(z_0, z_2)) = \rho(z_1, z_0)$. So $\rho(y_2, y_0) \leq \max(\rho(y_2, y_1), \rho(y_1, y_0)) \leq \max(\rho(z_2, z_1, \rho(z_1, z_0)) = \rho(z_1, z_0) = \rho(z_2, z_0)$. Therefore, $y_2 \in \tilde{C}(z_2)$.

By Step 1 and Step 2 together and Kuratowski–Zorn's lemma, we obtain the existence of a nonexpansive (single-valued) selection $\alpha : N \mapsto M$ of the set-valued map $A : N \rightsquigarrow M$. □

ON SOME NECESSARY CONDITIONS OF OPTIMALITY FOR A NONLOCAL VARIATIONAL PRINCIPLE*

JULIO MUÑOZ†

Abstract. The aim of this work is to deduce optimality conditions for a nonlocal variational principle in the one-dimensional scalar case. We consider the relaxation of the problem in terms of Young measures. This relaxation is a new problem where we perform variations to derive optimality conditions, and those conditions yield explicit information about minimizers in the homogeneous case. It also provides a method capable of finding minimizers for some specific problems.

Key words. optimization, nonlocality, optimality conditions, relaxation

1. Introduction. This paper is devoted to the obtainment of generalized equilibrium conditions for the one-dimensional scalar variational principle

$$\inf \{J(u) : u \in \mathcal{A}\}, \tag{1.1}$$

where

$$J(u) = \int_{I\times I} W\left(u'(x_1), u'(x_2)\right) dx_1 dx_2, \tag{1.2}$$

$$\mathcal{A} = \left\{ u \in W^{1,p}(I) : u - u_0 \in W_0^{1,p}(I) \right\}, \tag{1.3}$$

I is an open interval in $\mathbf{R}$, and $u_0 \in W^{1,p}(I)$ such that $J(u_0) < \infty$.

It is well known that the existence of solutions is strongly related to the weak lower semicontinuity of the functional (1.2). For the problem above this property is equivalent to a sort of inequality of nonlocal nature: the energy density W must satisfy

$$\sum_{i,j=1}^{2n} W(\lambda_i, \lambda_j) \geq 4 \sum_{i,j=1}^{n} W\left(\frac{\lambda_{2i-1}+\lambda_{2i}}{2}, \frac{\lambda_{2j-1}+\lambda_{2j}}{2}\right) \tag{1.4}$$

for any $n \in \mathbf{N}$ and any choice $\lambda_1, \lambda_2, \ldots, \lambda_{2n} \in \mathbf{R}$ (see [22]).

Unfortunately inequalities like (1.4) are complicated to check and that makes the analysis of existence too difficult. Moreover, this kind of problem is different if we compare it to the relaxation of nonconvex classical variational problems where we can substitute the original problem with its convexified version. The nonlocal nature of problems like (1.1)–(1.3) seems to block this approach because an equivalent convexification does not make sense, or at least it is not so clear in this situation. We shall deal with this question later.

Notice we restrict our attention to the homogenous problem, $W = W(u'(x_1), u'(x_2))$. The general case $W = W(x_1, x_2, u'(x_1), u'(x_2))$ is briefly discussed in section 6.

Our approach to the problem is not new (cf. Young [31], [32], McShane [18], Warga [28]). In order to study the original problem (1.1)–(1.3) we shall consider its relaxation in terms of the Young measures, generated by sequences of gradients of admissible functions. We shall call it the *generalized problem* (see (2.6)–(2.8)). Its analysis on problems without the weak lower semicontinuity property can be used to anticipate the oscillatory behavior of minimizing sequences. Also, the existence of solutions to the original problem (1.1)–(1.3) can be dealt with once the generalized problem is solved.

The contribution of this work is to provide a tool to study the generalized problem. We mainly concentrate on the obtainment of necessary conditions of optimality for this principle. We get generalized equilibrium conditions (Theorems 3.1 and 3.2). They are established by making variations on the Young measures and are only useful when we are dealing with the homogeneous problem (i.e., when W depends only on the gradients). In that case they enable us to solve and describe the optimal structure in some examples. It also helps us to understand the appearance of microstructure and its dependence on the imposed boundary conditions.

Some basic references on optimization and relaxation are [2], [7], [8], [10], [13], [15], [17], [23], [26], [28], and [33]. About variational calculus using Young measures, [9], [16], [19], [20], [21], [22], [23], [24], [29], and [33] can be looked at. The analysis of principles similar to (1.1)–(1.3) can be found in [1], [11], [12], [22], and [25].

The paper is organized as follows. In section 2 we revise some preliminaries and tools. Section 3 is devoted to the variational analysis and the equilibrium conditions. In section 4 we apply those conditions exploring one example, already proposed in [22]. In section 5 we propose a relaxation through what we shall call the nonlocal convex envelope. In the final section we talk about the limitations of our method for the nonhomogeneous problem.

2. Some preliminaries and tools. Consider the optimization problem (1.1)–(1.3). We assume the density energy

$$W : \mathbf{R} \times \mathbf{R} \to \mathbf{R} \tag{2.1}$$

is smooth and satisfies the bounds

$$c\left(|A_1|^p + |A_2|^p - 1\right) \le W(A_1, A_2) \le C\left(|A_1|^p + |A_2|^p + 1\right), \tag{2.2}$$

$$\left|\frac{\partial W}{\partial A_i}(A_1, A_2)\right| \le C\left(|A_1|^{p-1} + |A_2|^{p-1} + 1\right), \tag{2.3}$$

$$\left|\frac{\partial^2 W}{\partial A_i^2}(A_1, A_2)\right| \le C\left(|A_1|^{p-2} + |A_2|^{p-2} + 1\right), \tag{2.4}$$

$i = 1, 2$, $2 < p < \infty$, $0 < c < C$. For simplicity we assume $I = (0, 1)$ and $u_0(x) = \gamma x$, $\gamma \in \mathbf{R}$, so that (1.1)–(1.3) can be written in a simpler way:

$$\inf\left\{\int_0^1 \int_0^1 W(u'(x_1), u'(x_2))\, dx_1 dx_2 : u \in W^{1,p}(I), \right. \\ \left. \text{with } u(0) = 0 \text{ and } u(1) = \gamma\right\}. \tag{2.5}$$

As we have mentioned, the lack of the weak lower semicontinuity property or the difficulties to check it induces us to consider the following problem:

$$\inf\left\{\overline{J}(\nu) : \nu \in \overline{\mathcal{A}}\right\}, \tag{2.6}$$

where

$$\overline{J}(\nu) = \int_{I\times I}\int_{\mathbf{R}\times\mathbf{R}} W(\lambda_1,\lambda_2)\, d\nu_{x_1}(\lambda_1)\, d\nu_{x_2}(\lambda_2)\, dx_1 dx_2 \tag{2.7}$$

and $\overline{\mathcal{A}}$ is the set of Young measures $\nu = \{\nu_x\}_{x\in I}$ such that

$$\int_I\int_{\mathbf{R}} |\lambda|^p\, d\nu_x(\lambda)\, dx < \infty, \quad \int_I\int_{\mathbf{R}} \lambda d\nu_x(\lambda)\, dx = \gamma. \tag{2.8}$$

Here, we follow [22] from which we stress the following results. First, Theorem 2.1 characterizes the Young measures generated by weakly convergent sequences of the form $\{(u'(x_1), u'(x_2))\}$. (This result can also be directly deduced using denseness results of Dirac Young measures (cf. [29], [3]).) By using Theorem 2.1 we can easily prove the second result, Theorem 2.2, which guarantees that under the preceding hypotheses, (2.6)–(2.8) is a generalized version of (2.5).

THEOREM 2.1. *$\Lambda_{(x_1,x_2)}$ is the Young measure generated by $\left\{\left(u_j'(x_1), u_j'(x_2)\right)\right\}$, $\{u_j(x)\}$ a bounded sequence in $W^{1,p}(I)$, if and only if*

$$\Lambda_{(x_1,x_2)} = \nu_{x_1}\otimes\nu_{x_2}$$

and

$$\int_I\int_{\mathbf{R}} |\lambda|^p\, d\nu_x(\lambda)\, dx < \infty,$$

where $\nu = \{\nu_x\}_{x\in I}$ is the Young measure generated by $\left\{u_j'(x)\right\}$.

THEOREM 2.2. *Under (2.2) there exists $\upsilon \in \overline{\mathcal{A}}$ such that*

$$m = \overline{J}(\upsilon) = \inf\left\{\overline{J}(\nu) : \nu \in \overline{\mathcal{A}}\right\}, \tag{2.9}$$

where m is the infimum given in (1.1).

Regarding Theorem 2.1 and the fundamental theorem of Young measures [5], [23], [26], we have the representation

$$\lim_{j\to\infty}\int_{I\times I} \psi\left(u_j'(x_1), u_j'(x_2)\right) dx_1 dx_2$$
$$= \int_{I\times I}\int_{\mathbf{R}\times\mathbf{R}} \psi(\lambda_1,\lambda_2)\, d\nu_{x_1}(\lambda_1)\, d\nu_{x_2}(\lambda_2)\, dx_1 dx_2,$$

where $\nu = \left\{\nu_{(x_1,x_2)}\right\}_{(x_1,x_2)\in I\times I}$ is the Young measure generated by the sequence of pairs $\left\{\left(u_j'(x_1), u_j'(x_2)\right)\right\}$, provided ψ is continuous and $\left\{\psi\left(u_j'(x_1), u_j'(x_2)\right)\right\}$ converges weakly in $L^1(I\times I)$. Besides, Theorem 2.2 guarantees at least the existence of a minimizer $\upsilon \in \overline{\mathcal{A}}$ for the generalized functional $\overline{J}$. Thus, for any minimizing sequence $\{w_j\} \subset \mathcal{A}$ there is a Young measure $\upsilon \in \overline{\mathcal{A}}$ such that $m = \overline{J}(\upsilon) = \lim_{i\to\infty} J(w_j)$.

Let us now consider the following: ν, a homogeneous Young measure in $\overline{\mathcal{A}}$; $\{u_j(x)\}$, a sequence in $\mathcal{A}$ such that $\left\{u_j'(x)\right\}$ generates ν; and $\{\psi_j(x)\}$, a bounded

sequence in $W_0^{1,p}(I)$ generating a homogeneous Young measure. Let $\mu = \{\mu_x\}_{x\in I}$ be the Young measure generated by the sequence of pairs $\left\{\left(u_j'(x), \psi_j'(x)\right)\right\}$. Notice that $\left\{\left(u_j'(x), \psi_j'(x)\right)\right\}$ does not necessarily generate a homogeneous Young measure even if each one of its components does.

THEOREM 2.3 (see [14], [27]). *Under the above circumstances, for any $x \in I$ and any $(\lambda_1, \lambda_2) \in \operatorname{supp} \mu_x$,*

$$\mu_x(\lambda_1, \lambda_2) = \mu_x(\lambda_2|\lambda_1) \otimes \nu(\lambda_1), \tag{2.10}$$

where $\mu_x(\cdot|\lambda_1)$ is a probability measure for any $\lambda_1 \in \operatorname{supp}\nu$ and the map

$$\lambda_1 \to \int_{\mathbf{R}} f(\lambda_1, \lambda_2)\, d\mu_x(\lambda_2|\lambda_1)$$

is ν-measurable, provided f is integrable with respect to μ_x.

The decomposition (2.10)[1] implies

$$\int_{\mathbf{R}\times\mathbf{R}} f(\lambda_1, \lambda_2)\, d\mu_x(\lambda_1, \lambda_2) = \int_{\mathbf{R}} \left(\int_{\mathbf{R}} f(\lambda_1, \lambda_2)\, d\mu_x(\lambda_2|\lambda_1) \right) d\nu(\lambda_1).$$

We also need the following result.

PROPOSITION 2.4 (see [24]).

(i) *If H is continuous and is assumed to verify $|H(\lambda)| \le C\left(|\lambda|^{p-1} + 1\right)$, $p > 1$, $C > 0$, and*

$$\int_{\mathbf{R}} H(\lambda)\, \Upsilon(\lambda)\, d\nu(\lambda_1) = 0$$

for any ν-measurable function Υ such that

$$\int_{\mathbf{R}} \Upsilon(\lambda)\, d\nu(\lambda) = 0 \quad \text{and} \quad \int_{\mathbf{R}} |\Upsilon(\lambda)|^p\, d\nu(\lambda) < \infty, \tag{2.11}$$

then

$$H(\lambda) = \int_{\mathbf{R}} H(\lambda)\, d\nu(\lambda)$$

for any $\lambda \in \operatorname{supp}\nu$.

(ii) *If G is continuous and verifies $|G(\lambda)| \le C\left(|\lambda|^{p-2} + 1\right)$, $p > 2$, $C > 0$, and*

$$\int_{\mathbf{R}} G(\lambda)\, \Gamma(\lambda)\, d\nu(\lambda) \ge 0$$

for any ν-measurable and positive function Γ such that

$$\int_{\mathbf{R}} (\Gamma(\lambda))^{p/2}\, d\nu(\lambda) < \infty, \tag{2.12}$$

then

$$G(\lambda) \ge 0$$

for any $\lambda \in \operatorname{supp}\nu$.

[1] In Young measure theory this is usually written as $\mu_x(d\lambda_1, d\lambda_2) = \mu_x(d\lambda_2|\lambda_1) \otimes \nu(d\lambda_1)$, which distinguishes parameters from the integration variable.

3. Generalized equilibrium conditions. We study the generalized version of the optimization principle (2.5) under the hypotheses (2.2)–(2.4). The generalized version of (2.5) is the minimization of the functional

$$\overline{J}(\nu) = \int_{I\times I}\int_{\mathbf{R}\times\mathbf{R}} W(\lambda_1,\lambda_2)\, d\nu_{x_1}(\lambda_1)\, d\nu_{x_2}(\lambda_2)\, dx_1 dx_2, \tag{3.1}$$

with $\overline{\mathcal{A}}$ as the set of admissibility. The independence on the x_i permits us to simplify the problem. We can restrict $\overline{\mathcal{A}}$ to the subset composed by its homogeneous members. To be more precise, given $\nu = \{\nu_x\}_{x\in I} \in \overline{\mathcal{A}}$, we can consider its homogenization $\overline{\nu}$, also a probability measure in $\overline{\mathcal{A}}$, such that $\overline{J}(\nu) = \overline{J}(\overline{\nu})$. The proof of this statement is easy: recall that $\overline{\nu}$ is defined via the formula

$$\langle \overline{\nu}, \chi\rangle = \fint_I \int_{\mathbf{R}} \chi(\lambda)\, d\nu_x(\lambda)\, dx$$

for any continuous function χ,[2] and consequently

$$\int_{\mathbf{R}} \lambda d\overline{\nu}(\lambda) = \gamma. \tag{3.2}$$

Then

$$\overline{J}(\nu) = \int_0^1 \int_{\mathbf{R}} L(\lambda_2)\, d\nu_{x_2}(\lambda_2)\, dx_2,$$

where

$$\begin{aligned} L(\lambda_2) &= \int_0^1 \left[\int_{\mathbf{R}} W(\lambda_1,\lambda_2)\, d\nu_{x_1}(\lambda_1)\right] dx_1 \\ &= \int_0^1 (\overline{\nu}, W(\cdot,\lambda_2))\, dx_1 \\ &= \int_0^1 \int_{\mathbf{R}} W(\lambda_1,\lambda_2)\, d\overline{\nu}(\lambda_1)\, dx_1. \end{aligned}$$

In the same way we have

$$\begin{aligned} \overline{J}(\nu) &= \int_0^1 \int_{\mathbf{R}} L(\lambda_2)\, d\nu_{x_2}(\lambda_2)\, dx_2 \\ &= \int_0^1 \int_{\mathbf{R}} L(\lambda_2)\, d\overline{\nu}(\lambda_2)\, dx_2 \\ &= \int_0^1 \int_0^1 \left[\int_{\mathbf{R}}\int_{\mathbf{R}} W(\lambda_1,\lambda_2)\, d\overline{\nu}(\lambda_1)\, d\overline{\nu}(\lambda_2)\right] dx_1 dx_2 \\ &= \overline{J}(\overline{\nu}). \end{aligned}$$

We analyze (3.1) assuming that the elements competing in the principle are only the homogeneous Young measures ν of $\overline{\mathcal{A}}$ such that $\int_{\mathbf{R}} \lambda d\nu(\lambda) = \gamma$. We denote this set

[2]That is the definition for the homogenization of a Young measure; however, the average does not affect the integral because $|I| = 1$.

of admissibility by $\overline{\mathcal{A}}_h^{\gamma}$. Let the framework be the one introduced before Theorem 2.3. We consider the gradients $w_j'(x) = u_j'(x) + t\psi_j'(x)$, where $\{u_j'(x)\}$ generates the homogeneous Young measure ν, a minimizer of the general principle (3.1). If we take $\{w_j'\}$ and consider μ^t, its homogeneous Young measure in $\overline{\mathcal{A}}_h^{\gamma}$, we set the function

$$h(t) \doteq \overline{J}(\mu^t) = \int_{\mathbf{R}} \int_{\mathbf{R}} W(\alpha_1, \alpha_2)\, d\mu^t(\alpha_1)\, d\mu^t(\alpha_2), \quad t \in \mathbf{R}.$$

Consequently,

$$h(t) = \int_0^1 \int_0^1 \int_{\mathbf{R}^2} \int_{\mathbf{R}^2} W(\lambda_1 + t\delta_1, \lambda_2 + t\delta_2)\, d(\gamma_{x_1}(\lambda_1, \delta_1) \otimes \gamma_{x_2}(\lambda_2, \delta_2))\, dx_1 dx_2,$$

where $\gamma = \{\gamma_{x_i}(\lambda_i, \delta_i)\}_{x_i \in I}$ is the Young measure generated by the sequences of pairs $\{(u_j'(x_i), \psi_j'(x_i))\}$, $i = 1, 2$.

The function h has a minimum for $t = 0$. By the smoothness assumptions on W we have the classical equilibrium conditions $h'(0) = 0$ and $h''(0) \geq 0$. Henceforth the point is to express these conditions in a more transparent way.

By Theorem 2.3 we have the decomposition

$$\gamma_{x_i}(\lambda_i, \delta_i) = \gamma_{x_i}(\delta_i | \lambda_i) \otimes \nu(\lambda_i). \tag{3.3}$$

We define the homogenized Young measure of γ by

$$\langle \overline{\gamma}, \chi(\lambda_i, \delta_i) \rangle = \fint_0^1 \int_{\mathbf{R}^2} \chi(\lambda_i, \delta_i)\, d\gamma_{x_i}(\lambda_i, \delta_i)\, dx_i.$$

Then

$$\langle \overline{\gamma}, \chi(\cdot) \rangle = \int_{\mathbf{R}} \chi(\lambda_i)\, d\nu(\lambda_i) = \langle \nu, \chi(\cdot) \rangle,$$

which implies that ν is the canonical projection onto $\mathbf{R}$ of $\overline{\gamma}$ ($\nu(E) = \overline{\gamma}(E \times \mathbf{R})$). Now, defining $\overline{\gamma}(\delta_i | \lambda_i)$ via the formula

$$\langle \overline{\gamma}(\delta_i | \lambda_i), \chi(\cdot) \rangle = \fint_0^1 \int_{\mathbf{R}} \chi(\delta_i)\, \gamma_{x_i}(\delta_i | \lambda_i)\, dx_i$$

(χ continuous) and using (3.3) we see

$$\begin{aligned} \langle \overline{\gamma}, \chi(\lambda_i, \delta_i) \rangle &= \int_{\mathbf{R}} \left[\fint_0^1 \int_{\mathbf{R}} \chi(\lambda_i, \delta_i)\, d\gamma_{x_i}(\delta_i | \lambda_i)\, dx_i \right] d\nu(\lambda_i) \\ &= \int_{\mathbf{R}^2} \chi(\lambda_i, \delta_i)\, d(\overline{\gamma}(\delta_i | \lambda_i) \otimes \nu(\lambda_i)). \end{aligned}$$

Therefore,

$$\overline{\gamma}(\lambda_i, \delta_i) = \overline{\gamma}(\delta_i | \lambda_i) \otimes \nu(\lambda_i), \tag{3.4}$$

and consequently h can be read as

$$h(t) = \int_{\mathbf{R}^2} \int_{\mathbf{R}^2} W(\lambda_1 + t\delta_1, \lambda_2 + t\delta_2)\, d(\overline{\gamma}(\lambda_1, \delta_1) \otimes \overline{\gamma}(\lambda_2, \delta_2)).$$

We should only take into account that $h'(t) = 0$ ((2.3) and (2.4) permit us the interchange of derivation and integration; see [6, p. 215]) to arrive at

$$0 = \int_{\mathbf{R}^2} \int_{\mathbf{R}^2} \left\{ \frac{d}{dt} W(\lambda_1 + t\delta_1, \lambda_2 + t\delta_2) \Big|_{t=0} \right\} d(\overline{\gamma}(\lambda_1, \delta_1) \otimes \overline{\gamma}(\lambda_2, \delta_2)),$$

which means

$$0 = \int_{\mathbf{R}^2} \int_{\mathbf{R}^2} \left\{ \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_1} \delta_1 + \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_2} \delta_2 \right\} d(\overline{\gamma}(\lambda_1, \delta_1) \otimes \overline{\gamma}(\lambda_2, \delta_2)),$$

so that by (3.4) we can write

$$\begin{aligned} 0 &= \int_{\mathbf{R}^2 \times \mathbf{R}^2} \left\{ \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_1} \delta_1 + \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_2} \delta_2 \right\} d(\overline{\gamma}(\delta_1 | \lambda_1) \otimes \nu(\lambda_1)) \, d(\overline{\gamma}(\delta_2 | \lambda_2) \otimes \nu(\lambda_2)) \\ &= \int_{\mathbf{R}^2} \left\{ \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_1} \int_{\mathbf{R}} \delta_1 d\overline{\gamma}(\delta_1 | \lambda_1) + \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_2} \int_{\mathbf{R}} \delta_2 d\overline{\gamma}(\delta_2 | \lambda_2) \right\} d\nu(\lambda_1) \, d\nu(\lambda_2). \end{aligned}$$

If we denote $\Upsilon(\lambda_j) \doteq \int_{\mathbf{R}} \delta_j d\overline{\gamma}(\delta_j | \lambda_j)$, $j = 1, 2$, the above equilibrium conditions read as

$$0 = \int_{\mathbf{R}^2} \left\{ \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_1} \Upsilon(\lambda_1) + \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_2} \Upsilon(\lambda_2) \right\} d\nu(\lambda_1) \, d\nu(\lambda_2),$$

and by change of variables we have

$$\begin{aligned} 0 &= \int_{\mathbf{R}^2} \left\{ \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_1} + \frac{\partial W(\lambda_2, \lambda_1)}{\partial A_2} \right\} \Upsilon(\lambda_1) \, d\nu(\lambda_1) \, d\nu(\lambda_2) \\ &= \int_{\mathbf{R}} \left\{ \int_{\mathbf{R}} \left\{ \frac{\partial W(\lambda_1, \lambda_2)}{\partial A_1} + \frac{\partial W(\lambda_2, \lambda_1)}{\partial A_2} \right\} d\nu(\lambda_2) \right\} \Upsilon(\lambda_1) \, d\nu(\lambda_1) \\ &= \int_{\mathbf{R}} H(\lambda_1) \Upsilon(\lambda_1) \, d\nu(\lambda_1), \end{aligned}$$

where

$$H(\lambda_1) \doteq \int_{\mathbf{R}} \left\{ \frac{\partial W}{\partial A_1}(\lambda_1, \lambda_2) + \frac{\partial W}{\partial A_2}(\lambda_2, \lambda_1) \right\} d\nu(\lambda_2).$$

We observe

$$\begin{aligned} \int_{\mathbf{R}} \Upsilon(\lambda_j) \, d\nu(\lambda_j) &= \int_{\mathbf{R}^2} \int_0^1 \delta_j d\gamma_x(\delta_j | \lambda_j) \, dx d\nu(\lambda_j) \\ &= \int_0^1 \int_{\mathbf{R}^2} \delta_j d\gamma_x(\delta_j | \lambda_j) \, d\nu(\lambda_j) \\ &= \int_0^1 \int_{\mathbf{R}^2} \delta_j d\gamma_x(\lambda_j, \delta_j) \, dx = 0, \end{aligned}$$

and by Jensen's inequality

$$\begin{aligned} \int_{\mathbf{R}} |\Upsilon(\lambda_j)|^p \, d\nu(\lambda_j) &= \int_{\mathbf{R}} \left| \int_{\mathbf{R}} \delta_j d\overline{\gamma}(\delta_j | \lambda_j) \right|^p d\nu(\lambda_j) \\ &\leq \int_{\mathbf{R}} \int_{\mathbf{R}} |\delta_j|^p \, d\overline{\gamma}(\delta_j | \lambda_j) \, d\nu(\lambda_j) \\ &= \int_0^1 \int_{\mathbf{R}^2} |\delta_j|^p \, d\gamma_x(\lambda_j, \delta_j) \, dx < \infty. \end{aligned}$$

Reciprocally, for any field Υ fulfilling (2.11), we can find a sequence $\left\{\left(u_j'\left(x_i\right),\psi_j'\left(x_i\right)\right)\right\}$, where $\left\{u_j'\left(x\right)\right\}$generates ν and $\left\{\psi_j\left(x\right)\right\}$ is a bounded sequence in $W_0^{1,p}\left(I\right)$ such that its Young measure can be written as

$$\mu\left(\lambda,\delta\right)=\mu\left(\delta|\,\lambda\right)\otimes\nu\left(\lambda\right)$$

and $\int_{\mathbf{R}}\delta d\mu\left(\delta|\,\lambda\right)=\Upsilon$ (see [22] and [23] for a complete discussion). Therefore, we can now use Proposition 2.4(i) to state the following result.

THEOREM 3.1. *Under the above circumstances*

$$\operatorname{supp}\nu\subset\left\{\lambda\in\mathbf{R}:H\left(\lambda\right)=\int_{\mathbf{R}}H\left(\lambda_1\right)d\nu\left(\lambda_1\right)\right\}.$$

Now, our investigation is concerned with the condition $h''(0)\geq 0$. According to this inequality and by some simple computations we have

$$\begin{aligned}0\leq&\int_{\mathbf{R}^2}\left\{\frac{\partial^2W}{\partial A_1^2}\left(\lambda_1,\lambda_2\right)\int_{\mathbf{R}}\delta_1^2d\overline{\gamma}\left(\delta_1|\,\lambda_1\right)+\frac{\partial^2W}{\partial A_2^2}\left(\lambda_1,\lambda_2\right)\int_{\mathbf{R}}\delta_2^2d\overline{\gamma}\left(\delta_2|\,\lambda_2\right)\right.\\&\left.+2\frac{\partial^2W}{\partial A_1\partial A_2}\left(\lambda_1,\lambda_2\right)\int_{\mathbf{R}}\delta_1d\overline{\gamma}\left(\delta_1|\,\lambda_1\right)\int_{\mathbf{R}}\delta_2d\overline{\gamma}\left(\delta_2|\,\lambda_2\right)\right\}d\nu\left(\lambda_1\right)d\nu\left(\lambda_2\right)\\=&\int_{\mathbf{R}^2}\left\{\frac{\partial^2W}{\partial A_1^2}\left(\lambda_1,\lambda_2\right)\Gamma\left(\lambda_1\right)+\frac{\partial^2W}{\partial A_2^2}\left(\lambda_1,\lambda_2\right)\Gamma\left(\lambda_2\right)\right.\\&\left.+2\frac{\partial^2W}{\partial A_1\partial A_2}\left(\lambda_1,\lambda_2\right)\Upsilon\left(\lambda_1\right)\Upsilon\left(\lambda_2\right)\right\}d\nu\left(\lambda_1\right)d\nu\left(\lambda_2\right),\end{aligned}$$

where

$$\Gamma\left(\lambda_i\right)=\int_{\mathbf{R}}\delta_i^2d\overline{\gamma}\left(\delta_i|\,\lambda_i\right).$$

By Jensen's inequality, if

$$2\Upsilon\left(\lambda_1\right)\Upsilon\left(\lambda_2\right)\leq\Upsilon\left(\lambda_1\right)^2+\Upsilon\left(\lambda_2\right)^2\leq\Gamma\left(\lambda_1\right)+\Gamma\left(\lambda_2\right),$$

then

$$\begin{aligned}0\leq&\int_{\mathbf{R}^2}\left\{\frac{\partial^2W}{\partial A_1^2}\left(\lambda_1,\lambda_2\right)\Gamma\left(\lambda_1\right)+\frac{\partial^2W}{\partial A_2^2}\left(\lambda_1,\lambda_2\right)\Gamma\left(\lambda_2\right)\right.\\&\left.+\frac{\partial^2W}{\partial A_1\partial A_2}\left(\lambda_1,\lambda_2\right)\Gamma\left(\lambda_1\right)+\frac{\partial^2W}{\partial A_1\partial A_2}\left(\lambda_1,\lambda_2\right)\Gamma\left(\lambda_2\right)\right\}d\nu\left(\lambda_1\right)d\nu\left(\lambda_2\right),\end{aligned}$$

and by changing the variables we have

$$\begin{aligned}0\leq&\int_{\mathbf{R}}\left\{\int_{\mathbf{R}}\left\{\frac{\partial^2W}{\partial A_1^2}\left(\lambda_1,\lambda_2\right)+\frac{\partial^2W}{\partial A_2^2}\left(\lambda_2,\lambda_1\right)\right.\right.\\&\left.\left.+\frac{\partial^2W}{\partial A_1\partial A_2}\left(\lambda_1,\lambda_2\right)+\frac{\partial^2W}{\partial A_1\partial A_2}\left(\lambda_2,\lambda_1\right)\right\}d\nu\left(\lambda_2\right)\right\}\Gamma\left(\lambda_1\right)d\nu\left(\lambda_1\right).\end{aligned}$$

Obviously $\Gamma\left(\lambda_i\right)\geq 0$, and again by Jensen's inequality ($p\geq 2$),

$$\begin{aligned}\int_{\mathbf{R}}\left|\Gamma\left(\lambda_i\right)\right|^{p/2}d\nu\left(\lambda_i\right)&=\int_{\mathbf{R}}\left|\int_{\mathbf{R}}\delta_i^2d\overline{\gamma}\left(\delta_i|\,\lambda_i\right)\right|^{p/2}d\nu\left(\lambda_i\right)\\&\leq\int_{\mathbf{R}}\int_{\mathbf{R}}\left|\delta_i\right|^p d\overline{\gamma}\left(\delta_i|\,\lambda_i\right)d\nu\left(\lambda_i\right)\\&=\int_0^1\int_{\mathbf{R}^2}\left|\delta_i\right|^p d\gamma_x\left(\lambda_i,\delta_i\right)<\infty.\end{aligned}$$

As before, given any positive Γ verifying (2.12), we can build a sequence of pairs whose Young measure is written in the form $\mu(\lambda,\delta)=\mu(\delta|\lambda)\otimes\nu(\lambda)$ and such that the second moment $\int_{\mathbf{R}}\delta^2 d\mu(\delta|\lambda)$ coincides with Γ. So, by Proposition 2.4(ii)

$$G(\lambda_1)\geq 0$$

for any $\lambda_1\in\operatorname{supp}\nu$, where

$$G(\lambda_1)\doteq\int_{\mathbf{R}}\left\{\frac{\partial^2 W}{\partial A_1^2}(\lambda_1,\lambda_2)+\frac{\partial^2 W}{\partial A_2^2}(\lambda_2,\lambda_1)+\frac{\partial^2 W}{\partial A_1\partial A_2}(\lambda_1,\lambda_2)+\frac{\partial^2 W}{\partial A_1\partial A_2}(\lambda_2,\lambda_1)\right\}d\nu(\lambda_2).$$

THEOREM 3.2.

$$\operatorname{supp}\nu\subset\{\lambda\in\mathbf{R}:G(\lambda)\geq 0\}.$$

4. One example. We show how Theorems 3.1 and 3.2 may be applied to solve the generalized problem and to decide about the existence of solutions to the original problem (2.5), in some simple situations.

Let us take

$$W(\lambda_1,\lambda_2)=\left(\lambda_1^2+\lambda_2^2-1\right)^2$$

and suppose ν is a minimizer for (3.1). The equilibrium condition of Theorem 3.1 gives in this case the identity

$$\int_{\mathbf{R}}\int_{\mathbf{R}}\left\{8\lambda_1\left(\lambda_1^2+\lambda_2^2-1\right)\right\}d\nu(\lambda_2)\,d\nu(\lambda_1)=\int_{\mathbf{R}}\left\{8\lambda_1\left(\lambda_1^2+\lambda_2^2-1\right)\right\}d\nu(\lambda_2)$$

for any $\lambda_1\in\operatorname{supp}\nu$. That is,

$$\begin{aligned}\int_{\mathbf{R}}\lambda_1^3 d\nu(\lambda_1)+\int_{\mathbf{R}}\lambda_1 d\nu(\lambda_1)\int_{\mathbf{R}}\lambda_2^2 d\nu(\lambda_2)-\int_{\mathbf{R}}\lambda_1 d\nu(\lambda_1)\\ =\lambda_1^3+\lambda_1\int_{\mathbf{R}}\lambda_2^2 d\nu(\lambda_2)-\lambda_1.\end{aligned}\tag{4.1}$$

This fact shows that at most there exist three different mass points for ν; let us denote them by γ_1,γ_2, and γ_3, and suppose $\nu=\alpha_1\delta_{\gamma_1}+\alpha_2\delta_{\gamma_2}+\alpha_3\delta_{\gamma_3}$, where $\alpha_i\in[0,1]$, $\sum_{i=1}^3\alpha_i=1$. If we write (4.1) in terms of the moments for ν, we obtain

$$\gamma_j^3+(m_2-1)\gamma_j=m_3+m_1(m_2-1),$$

where $m_k=\sum_{j=1}^3\alpha_j\gamma_j^k$, $k=1,2,3$. We supply the above identity with the constraint $u(x)=\gamma\cdot x$ on $\partial(0,1)$ (see (3.2)), thus $m_1=\gamma$; and finally, we arrive at the system of equations

$$\gamma_j^3+\left(\sum_{j=1}^3\alpha_j\gamma_j^2-1\right)\gamma_j=\left(\sum_{j=1}^3\alpha_j\gamma_j^3\right)+\left(\sum_{j=1}^3\alpha_j\gamma_j^2-1\right)\gamma,\tag{4.2}$$

$$\sum_{j=1}^3\alpha_j\gamma_j=\gamma,\tag{4.3}$$

whose unknowns are γ_1, γ_2, γ_3, α_1, and α_2. Moreover, by Theorem 3.2 we have for any γ_j, $j = 1, 2, 3$, the constraints

$$\Upsilon(\gamma_j) = 3\gamma_j^2 + 2m_1\gamma_j + m_2 - 1 \geq 0. \tag{4.4}$$

Notice that the information about minimizing measures has been reduced to the study of the nonlinear system (4.2)–(4.3) with the constraints (4.4). In general the resulting system has a family of solutions. Once these solutions are found and substituted in (3.1), we would have reduced the difficulties in the task of finding minimizers.

In the present example we get the following solutions to (4.2)–(4.3).

R-1. If $\gamma \in [-\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}]$, we obtain
(i) $\nu = \delta_c$, with $c \in [-\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}]$,
(ii) $\nu = d\delta_{\frac{\sqrt{2}}{2}} + (1-d)\delta_{-\frac{\sqrt{2}}{2}}$, and
(iii) $\nu = d\delta_{\frac{-1}{2}} + (1-d)\delta_{\frac{1}{2}}$.

R-2. If $\gamma > \frac{\sqrt{2}}{2}$ or $\gamma < -\frac{\sqrt{2}}{2}$, we have $\nu = \delta_c$, where $c > \frac{\sqrt{2}}{2}$ or $c < -\frac{\sqrt{2}}{2}$, respectively.

In the range R-1 the unique solution is $\nu = \frac{1+\gamma\sqrt{2}}{2}\delta_{\frac{\sqrt{2}}{2}} + \frac{1-\gamma\sqrt{2}}{2}\delta_{-\frac{\sqrt{2}}{2}}$. We discard $\nu = d\delta_{-\frac{1}{2}} + (1-d)\delta_{\frac{1}{2}}$ because by using (4.4) we necessarily get that $d = \frac{1}{2}$ and $\overline{J}(\frac{1}{2}\delta_{-\frac{1}{2}} + \frac{1}{2}\delta_{\frac{1}{2}}) > 0$. In R-2 there exists only one solution, $\nu = \delta_\gamma$. Consequently we can write the infimum of the problem as a function of γ:

$$\overline{J}_W(\gamma) = \begin{cases} 0 & \text{if } -\frac{\sqrt{2}}{2} \leq \gamma \leq \frac{\sqrt{2}}{2}, \\ \left(2\gamma^2 - 1\right)^2 & \text{otherwise.} \end{cases}$$

There are some other examples for which the optimality conditions can be applied. For instance, we can take

$$W(\lambda_1, \lambda_2) = ((\lambda_1 + \lambda_2)^2 - 1)^2 + (\lambda_1 - \lambda_2)\arctan(\lambda_1 + \lambda_2)^2$$

or

$$W(\lambda_1, \lambda_2) = (\lambda_1^2 + \lambda_2^2 - 1)^2 + \arctan\lambda_1^2 + \arctan\lambda_2^2.$$

5. Relaxation. The purpose of this section is to suggest a new relaxation of the homogeneous problem

$$\inf\left\{\int_{I\times I} W(u'(x), u'(y))\,dxdy : u \in W_0^{1,p}(I) + \gamma.x\right\}. \tag{5.1}$$

The idea is to maintain the density energy in all regions where the infimum of the principle (3.1) is attained by a Dirac delta. In those regions where the solutions give rise to oscillations we consider a new density energy whose definition is similar to the traditional convexification. Specifically, for every function W satisfying the conditions (2.2) we define its *nonlocal convexification* as

$$\widetilde{C}W = \sup\left\{S : S \leq W,\ \overline{J}_S(\gamma) = S(\gamma,\gamma) = \overline{J}_W(\gamma) \qquad \text{for any } \gamma \in \mathbf{R}\right\},$$

where

$$\overline{J}_G(\gamma) \doteq \inf\left\{\int_{\mathbf{R}\times\mathbf{R}} G(\lambda_1, \lambda_2)\,d\mu(\lambda_1)\,d\mu(\lambda_2) : \mu \in \overline{\mathcal{A}}_h^\gamma\right\}.$$

The leading idea is to find a new variational principle whose infimum is attained and coincides with m_γ, the infimum of the original problem (5.1). To achieve this we use the variational principle associated with the nonlocal convexification (see (5.2) below).

Unfortunately we cannot ensure that

$$\mathcal{S} \doteq \left\{S : S \leq W,\ \overline{J}_S(\gamma) = S(\gamma,\gamma) = \overline{J}_W(\gamma) \qquad \text{for any } \gamma \in \mathbf{R}\right\}$$

is a nonempty set. Even though we can consider separately the convex functions S such that $S \leq W$ and $\overline{J}_S(\gamma) = S(\gamma,\gamma)$,[3] we will not be able to state $S(\gamma,\gamma) = \overline{J}_W(\gamma)$ for any $\gamma \in \mathbf{R}$. If we suppose this obstacle has been overcome and we can get the corresponding generalized formulation for the principle

$$\inf\left\{\int_{I\times I} \widetilde{C}W(u'(x),u'(y))\,dxdy : u \in W_0^{1,p}(I) + \gamma.x\right\}, \tag{5.2}$$

then we would have that for any $\gamma \in \mathbf{R}$, $m_\gamma = \widetilde{m}_\gamma$ and there would exist $v \in W_0^{1,p}(I) + \gamma.x$ such that $\int_{I\times I} \widetilde{C}W(v'(x),v'(y))\,dxdy = \widetilde{m}_\gamma$, where $\widetilde{m}_\gamma$ is the infimum of (5.2). The proof is straightforward.

Notice that for the obtainment of the nonlocal convexification we have to find $\overline{J}_W(\gamma)$ for any γ and after getting that, we must investigate the kind of Young measures which are solutions to this principle, making the emphasis on when they are Dirac deltas. In spite of the fact that this process could be carried out, we shall not be able to define $\widetilde{C}W$ in all $\mathbf{R}^2$. That reduces the significance of the nonlocal convex envelope. We illustrate this by examining the example dealt in section 4: we know that $\nu = \frac{1+\gamma\sqrt{2}}{2}\delta_{\frac{\sqrt{2}}{2}} + \frac{1-\gamma\sqrt{2}}{2}\delta_{\frac{-\sqrt{2}}{2}}$ is the minimizer if $\gamma \in [\frac{-1}{\sqrt{2}}, \frac{1}{\sqrt{2}}]$ such that $\overline{J}_W(\gamma) = 0$. If the Young measure is a delta, $\overline{J}_W(\gamma) = W(\gamma,\gamma) = \left(2\gamma^2 - 1\right)^2$, $\gamma \notin [\frac{-1}{\sqrt{2}}, \frac{1}{\sqrt{2}}]$. Those facts induce us to define $\widetilde{C}W$, only in a subset of $\mathbf{R}^2$, as

$$\widetilde{C}W(\lambda_1,\lambda_2) = \begin{cases} W(\lambda_1,\lambda_2) & \text{if } |\lambda_1|, |\lambda_2| \geq \frac{\sqrt{2}}{2}, \\ 0 & \text{if } |\lambda_1|, |\lambda_2| < \frac{\sqrt{2}}{2}. \end{cases} \tag{5.3}$$

To find a complete definition of $\widetilde{C}W$ in $\mathbf{R}^2$ remains an open question. The difficulties are obvious. We observe that basically the obstacle is the nonemptiness of $\mathcal{S}$. Somehow, this task involves a nonlocal problem which clearly turns up when we try to define the convexification out of the diagonal $\{\lambda_1 = \lambda_2\}$. In any case, further work must be done in order to establish rigorously any kind of relaxation, perhaps like (5.2), which could be used successfully in some examples.

6. Final remarks. The analysis exhibited in sections 2 and 3 can be carried out if W depends on $(u'(x_1), \ldots, u'(x_n))$. Nevertheless, when $W = W(x_1, \ldots, x_n, u(x_1), \ldots, u(x_2), u'(x_1), \ldots, u'(x_n))$ this sort of analysis is not useful to derive necessary conditions. In this case a possible variational analysis can be performed taking Young measures generated by sequences of the type $\left\{u_j'(x_1) + t\psi'(x_1)\right\}$, where $\psi \in W_0^{1,p}(0,1)$ and $\left\{u_j'(x_1)\right\}$ is any sequence generating a minimizer (see [20]). If $\nu = \{\nu_x\}_{x\in(0,1)}$ is any minimizer of (2.6)–(2.8) with $W = W(x_1,x_2,\lambda_1,\lambda_2)$, then

$$\frac{\partial}{\partial x_1}\left\{\int_0^1 \left[A(x_1,x_2) + B(x_2,x_1)\right] dx_2\right\} = 0 \tag{6.1}$$

[3]Recall that separated convexity is a sufficient condition for the weak lower semicontinuity (cf. [22]).

in a weak sense, and

$$\int_0^1 C(x_1,x_2)\,dx_2 \geq 0 \quad \text{almost everywhere } x_1 \in (0,1), \tag{6.2}$$

where

$$A(x_1,x_2) = \int_{\mathbf{R}^2} \frac{\partial W}{\partial A_1}(x_1,x_2,\lambda_1,\lambda_2)\,d\nu_{x_1}(\lambda_1)\,d\nu_{x_2}(\lambda_2),$$
$$B(x_1,x_2) = \int_{\mathbf{R}^2} \frac{\partial W}{\partial A_2}(x_1,x_2,\lambda_1,\lambda_2)\,d\nu_{x_1}(\lambda_1)\,d\nu_{x_2}(\lambda_2),$$

and

$$C(x_1,x_2) = \int_{\mathbf{R}^2} \left\{ \frac{\partial^2 W}{\partial A_1^2}(x_1,x_2,\lambda_1,\lambda_2) + \frac{\partial^2 W}{\partial A_1 \partial A_2}(x_1,x_2,\lambda_1,\lambda_2) + \frac{\partial^2 W}{\partial A_1 \partial A_2}(x_2,x_1,\lambda_2,\lambda_1) + \frac{\partial^2 W}{\partial A_2^2}(x_2,x_1,\lambda_2,\lambda_1) \right\} d\nu_{x_1}(\lambda_1)\,d\nu_{x_2}(\lambda_2).$$

Clearly, the equilibrium conditions (6.1) and (6.2) do not seem to be the appropriate way to detect generalized minimizers. Even for the homogeneous case, the equilibrium conditions (Theorems 3.1 and 3.2) could be imprecise or not explicit enough to obtain solutions. In either case, it seems to be necessary to implement some additional information: for instance, we might, in some problems, complete the obtained necessary conditions with some sort of result limiting the number of Dirac deltas appearing (as a convex combination) in the representation of the solution. This approach has been used in Balder [4] within the frame of nonconvex optimal control problems, Winkler [30] for the minimization of affine functionals defined on moments sets, and also Bonnetier and Conca [7], [8] for a problem in optimal design.

Finally, we want to point out that the analysis of section 3 in higher dimensions becomes tremendously difficult. The crucial point is that we have to consider Young measures $\mu(\lambda_1,\lambda_2)$ coming from sequences of gradients of $\{(u_j(x),\psi_j(x))\}$, $x \in \Omega$, which are vector valued functions. This fact implies profound restrictions on the measure μ, and therefore on the fields Γ and Υ. The difficulties we have to face require a deeper analysis than the one performed here.

Acknowledgments. The author would like to thank Pablo Pedregal for several useful discussions on various issues related to this paper and would also like to acknowledge the referees for their careful reading of the original manuscript and their valuable suggestions and criticism.

THEORETICAL AND NUMERICAL ANALYSIS OF AN OPTIMAL CONTROL PROBLEM RELATED TO WASTEWATER TREATMENT*

A. MARTÍNEZ†, C. RODRÍGUEZ‡, AND M. E. VÁZQUEZ-MÉNDEZ‡

Abstract. In this work we deal with the design and management of wastewater treatment systems, mainly the disposal of sea outfalls discharging polluting effluent from a sewerage system. This problem is formulated as a pointwise optimal control problem with state and control constraints. The main difficulties arise from the lack of regularity of the second member in the state system and from the pointwise constraints on the state variables. We develop the theoretical analysis of the problem, we propose an algorithm for its numerical resolution, and finally, we give results for a realistic problem posed in the *ría* of Vigo, Spain.

Key words. pointwise control, pointwise state constraints, wastewater treatment, constrained optimization

1. Introduction: The physical problem.

We consider a domain Ω with boundary Γ occupied by shallow water (as can be the case of a *ría*, an estuary, or a lake), where polluting wastewater is discharged through N_E outfalls, each one corresponding to a depuration plant. We also assume that inside the domain Ω there exist several zones ($A_i \subset \Omega,\ i = 1, \ldots, N_Z$) of bath, marine cultures, and so on, where it is necessary to ensure the water quality with pollution concentrations lower than an allowed maximum level.

In order to control the marine pollution some parameters are used that indicate the quality level of liquid media and its capacity to hold the aquatic life. Among these indicators we mention dissolved oxygen, temperature, and pH.

Oxygen is used by bacteria to decompose the organic matter. This process can be measured in terms of the need of oxygen, the so-called *biological oxygen demand* (BOD). If the pollution level is not too high this need can be satisfied by the *dissolved oxygen* (DO). If the quantity of organic matter increases beyond a maximum value the DO is not enough to decompose it, leading to important modifications (anaerobic processes) in the ecosystem. This fact means that in each protected area $A_i, i = 1, \ldots, N_Z$, a threshold value σ_i of BOD must not be exceeded and a minimum level of DO ζ_i must be guaranteed. To ensure this, one has to depure wastewater by chemical or biological treatments before discharging it into the sea.

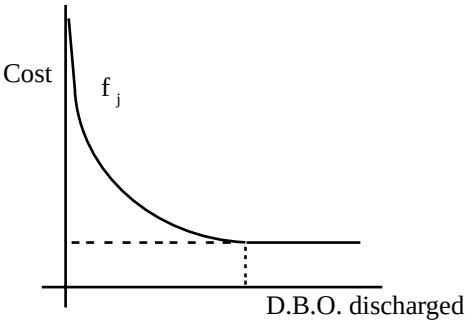

FIG. 1.1. *Standard function* $f_j(m)$.

The cost of the depuration in the jth plant, $j = 1, \ldots, N_E$, can be assumed to depend on the BOD in such a way that a lower level of BOD leads to a more intensive depuration and, consequently, to a higher cost. Taking in mind that absolute depuration is not feasible and that there exists a minimum cost, even in the case where no treatment is developed, the cost function f_j takes a form similar to the one shown in Figure 1.1.

The problem is then to determine the level of discharges in order to minimize the global depuration cost and to guarantee the above-mentioned constraints on the water quality in protected areas. Mathematically, this is a parabolic optimal control problem with pointwise state constraints and with pointwise control.

In recent years, several authors have studied parabolic optimal control problems with pointwise state constraints (see, for instance, Casas [4], Fattorini and Sritharan [8], Hu and Yong [12], Raymond and Zidani [18]). Lions [13], Saguez [19], Simon [20], and others have dealt with optimal control problems of parabolic type with pointwise control, but they did not include state constraints. Bermúdez, Martínez, and Rodríguez [2] studied a related stationary problem with pointwise state constraints and considered a control on the location. However, the dynamic problem with pointwise control and pointwise state constraints has not yet been, as far as we know, reported in the open literature.

From the theoretical point of view the main difficulties of the problem are due to the fact that the second member of the state system includes radon measures and to the presence of pointwise state constraints, which lead us to work in regular functional spaces in order to obtain the adjoint state.

Numerically, difficulties arise from the high number of constraints related to the time and space discretizations and to the demands imposed on the levels of BOD and DO.

2. Mathematical modeling. Let us suppose that the outfalls are located in the points $P_j \in \Omega,\ j = 1, \ldots, N_E$, and denote by $m_j(t),\ j = 1, \ldots, N_E$, the discharge of BOD in the point P_j at the time t. The evolution of the BOD and the DO in the domain $\Omega \subset R^2$ is governed, according to the distributed version of the model of Streter–Phelps, by the following partial differential equations system (cf. [1] and [16]), whose numerical resolution has been carried out in [21]. In this way, the concentrations

of BOD and DO in a point $x \in \Omega$ and a time $t \in (0,T)$, denoted $\rho_1(x,t)$ and $\rho_2(x,t)$, respectively, can be obtained as the solution of the boundary value problem

$$
\begin{aligned}
\frac{\partial \rho_1}{\partial t} + \vec{u}\nabla\rho_1 - \beta_1\Delta\rho_1 &= -\kappa_1\rho_1 + \frac{1}{h}\sum_{j=1}^{N_E} m_j\delta(x-P_j) && \text{in } \Omega\times(0,T),\\
\frac{\partial \rho_1}{\partial n} &= 0 && \text{on } \Gamma\times(0,T),\\
\rho_1(x,0) &= 0 && \text{in } \Omega,\\
\frac{\partial \rho_2}{\partial t} + \vec{u}\nabla\rho_2 - \beta_2\Delta\rho_2 &= -\kappa_1\rho_1 + \frac{1}{h}\kappa_2(d_s-\rho_2) && \text{in } \Omega\times(0,T),\\
\frac{\partial \rho_2}{\partial n} &= 0 && \text{on } \Gamma\times(0,T),\\
\rho_2(x,0) &= \rho_{20}(x) && \text{in } \Omega,
\end{aligned}
\tag{2.1}
$$

where $h(x,t)$ and $\vec{u}(x,t)$ denote, respectively, the height and the mean horizontal velocity of the fluid layer, obtained as a solution of the Saint-Venant equations (see [3]), $\delta(x-P_j)$ represents the Dirac measure in the point P_j, and parameters $\beta_1 > 0,\ \beta_2 > 0$ (horizontal viscosity coefficients involving dispersion and turbulence effects), $\kappa_1 > 0,\ \kappa_2 > 0$ (kinetic coefficients related to temperature and transference of oxygen through the surface), and d_s (oxygen saturation density) can be obtained from experimental measurements.

If we assume now that inside the domain Ω there are N_Z protected zones A_i, where a maximum level of BOD and a minimum level of DO must be ensured, that is,

$$
\rho_{1|A_i\times(0,T)} \le \sigma_i, \quad i = 1,\dots,N_Z, \tag{2.2}
$$

$$
\rho_{2|A_i\times(0,T)} \ge \zeta_i, \quad i = 1,\dots,N_Z, \tag{2.3}
$$

and we know the convex functions $f_j \in C^2(0,\infty)$ (the treatment cost of the discharge in the point $P_j,\ j = 1,\dots,N_E$) and, consequently, the global cost of the depuration system in a time interval $[0,T]$, which is given by

$$
J(m) = \sum_{j=1}^{N_E}\int_0^T f_j\left(m_j(t)\right)dt, \tag{2.4}
$$

then the problem $(\mathcal{P})$ of the optimal management of the depuration systems consists of finding the values of BOD $m_j(t) > 0,\ j = 1,\dots,N_E$, throughout the time interval in such a way that they satisfy the state system (2.1) and the constraints (2.2) and (2.3) and they minimize the cost function (2.4).

3. Analysis of the state system. Let $\Omega \subset R^2$ be a bounded domain with boundary Γ smooth enough. We make the following assumptions on the problem data:

$$
h \in C(\bar{\Omega}\times[0,T]) \quad h(x,t) \ge \alpha > 0 \quad \forall (x,t) \in \bar{\Omega}\times[0,T],
$$

$$
\vec{u} \in [L^\infty(\Omega\times(0,T))]^2, \quad \rho_{20} \in C^2(\bar{\Omega}), \quad m = (m_j)_{j=1}^{N_E} \in U_{ad},
$$

where

$$U_{ad} = \{m \in (L^\infty(0,T))^{N_E} \ : \ 0 < \underline{m}_j \le m_j(t) \le \overline{m}_j \text{ almost everywhere (a.e.) in } (0,T), \\ j = 1, \dots, N_E\}.$$

The weak solution of the system (2.1) can be defined by transposition techniques (see Lions and Magenes [14], Casas [4]) in the following way.

DEFINITION 3.1. *Given* $r, s \in [1,2), \frac{2}{r} + \frac{2}{s} > 3$, *we say that* $\rho = (\rho_1, \rho_2) \in [L^r(0,T; W^{1,s}(\Omega))]^2$ *is a solution of the system* (2.1) *if* $\forall\ \Phi = (\Phi_1, \Phi_2) \in [L^2(0,T; H^2(\Omega)) \cap H^1(0,T; L^2(\Omega))]^2 \cap [C^1(\bar{\Omega} \times [0,T])]^2$ *such that* $\Phi(.,T) = 0$, *it is verified that*

$$\begin{aligned} \int_0^T \int_\Omega \Big\{ & - \frac{\partial \Phi_1}{\partial t}\rho_1 - \frac{\partial \Phi_2}{\partial t}\rho_2 + \beta_1 \nabla\Phi_1 \nabla\rho_1 + \beta_2 \nabla\Phi_2 \nabla\rho_2 + \vec{u}\Phi_1 \nabla\rho_1 \\ & + \vec{u}\Phi_2 \nabla\rho_2 + \kappa_1 \Phi_1 \rho_1 + \kappa_1 \Phi_2 \rho_1 + \frac{1}{h(x,t)} \kappa_2 \Phi_2 \rho_2) \Big\} \, dx \, dt \\ & = \sum_{j=1}^{N_E} \int_0^T \frac{1}{h(P_j,t)} \Phi_1(P_j,t) m_j(t) \, dt \\ & + \int_0^T \int_\Omega \frac{1}{h(x,t)} \kappa_2 d_s \Phi_2(x,t) \, dx \, dt + \int_\Omega \Phi_2(x,0) \rho_{20}(x) \, dx. \end{aligned} \tag{3.1}$$

Let $\mathcal{A}$ be the operator defined by

$$\begin{aligned} \langle \mathcal{A}(w_1,w_2), (z_1,z_2) \rangle = \int_\Omega \Big(& - \beta_1 \Delta w_1 z_1 - \beta_2 \Delta w_2 z_2 \\ & + \vec{u} \cdot \nabla w_1 z_1 + \vec{u} \cdot \nabla w_2 z_2 + \kappa_1 w_1 z_1 + \kappa_1 w_1 z_2 + \frac{1}{h} \kappa_2 w_2 z_2 \Big) \, dx \end{aligned}$$

for $(w_1, w_2), (z_1, z_2)$ such that the previous expression makes sense. Then we have the following result.

THEOREM 3.2. *There exists a unique pair*

$$\rho = (\rho_1, \rho_2) \in [L^r(0,T; W^{1,s}(\Omega))]^2 \cap [L^2(0,T; L^2(\Omega))]^2$$

with

$$\frac{\partial \rho}{\partial t} = \left(\frac{\partial \rho_1}{\partial t}, \frac{\partial \rho_2}{\partial t} \right) \in [L^r(0,T; (W^{1,s'}(\Omega))')]^2$$

$\forall\ r, s \in [1,2), \frac{2}{r} + \frac{2}{s} > 3$, *such that* ρ *is the solution of* (2.1) *and satisfies*

$$\begin{aligned} \int_0^T \left\langle -\frac{\partial \Phi}{\partial t} + \mathcal{A}^*(\Phi), \rho \right\rangle dt = & \sum_{j=1}^{N_E} \int_0^T \frac{1}{h(P_j,t)} \Phi_1(P_j,t) m_j(t) \, dt \\ & + \int_0^T \int_\Omega \frac{1}{h(x,t)} \kappa_2 d_s \Phi_2(x,t) \, dx \, dt + \int_\Omega \Phi_2(x,0) \rho_{20}(x) \, dx \end{aligned} \tag{3.2}$$

$\forall\ \Phi = (\Phi_1, \Phi_2) \in \mathcal{B}$, *where*

$$\begin{aligned} \mathcal{B} = \Big\{ & \Phi = (\Phi_1, \Phi_2) \in [L^2(0,T; H^2(\Omega)) \cap H^1(0,T; L^2(\Omega))]^2 \ : \\ & - \frac{\partial \Phi}{\partial t} + \mathcal{A}^*(\Phi) \in [L^2(0,T; L^2(\Omega))]^2, \quad \frac{\partial \Phi}{\partial n_{\mathcal{A}^*}}_{|\Gamma \times (0,T)} = 0, \quad \Phi(.,T) = 0 \Big\}. \end{aligned}$$

Besides, there exist constants $C_k,\ k = 1, \dots, 6$, *only depending on data, such that*

$$\|\rho\|_{[L^r(0,T;W^{1,s}(\Omega))]^2} \le C_1 \sum_{i=1}^{N_E} \|m_i\|_{L^\infty(0,T)} + C_2 \|\rho_{20}\|_{C(\bar\Omega)} + C_3\, d_s \tag{3.3}$$

and

$$\|\rho\|_{[L^2(0,T;L^2(\Omega))]^2} \le C_4 \sum_{i=1}^{N_E} \|m_i\|_{L^\infty(0,T)} + C_5 \|\rho_{20}\|_{C(\bar\Omega)} + C_6\, d_s. \tag{3.4}$$

Proof. In the proof of this result we will adapt the one of Casas [4, Theorem 6.3] in order to obtain the new L^2-estimate (3.4) which is possible in this case due to the fact that the second member takes the form $\sum_{j=1}^{N_E} m_j(t)\delta(x - P_j)$.

Thus, let $\{f_j^k\}_{k\in N} \subset C(\bar\Omega),\ j = 1, \dots, N_E$, be weak* convergent sequences to $\delta(x - P_j)$ in the measures space $M(\bar\Omega) = C(\bar\Omega)'$, verifying $\|f_j^k\|_{L^1(\Omega)} \le 1$.

Let us consider $\rho^k = (\rho_1^k, \rho_2^k)$ the solution of system

$$\begin{aligned}
\frac{\partial \rho_1^k}{\partial t} + \vec u \nabla \rho_1^k - \beta_1 \Delta \rho_1^k + \kappa_1 \rho_1^k &= \frac{1}{h} \sum_{j=1}^{N_E} m_j f_j^k && \text{in } \Omega \times (0,T),\\
\frac{\partial \rho_1^k}{\partial n} &= 0 && \text{on } \Gamma \times (0,T),\\
\rho_1^k(x,0) &= 0 && \text{in } \Omega,\\
\frac{\partial \rho_2^k}{\partial t} + \vec u \nabla \rho_2^k - \beta_2 \Delta \rho_2^k + \kappa_1 \rho_1^k + \frac{1}{h}\kappa_2 \rho_2^k &= \frac{1}{h}\kappa_2 d_s && \text{in } \Omega \times (0,T),\\
\frac{\partial \rho_2^k}{\partial n} &= 0 && \text{on } \Gamma \times (0,T),\\
\rho_2^k(x,0) &= \rho_{20}(x) && \text{in } \Omega.
\end{aligned} \tag{3.5}$$

For all $\Psi = (\Psi^0, \Psi^1, \Psi^2) \in [\{\mathcal{D}(\Omega \times (0,T))\}^2]^3$ we denote by y^Ψ the solution of the system

$$\begin{aligned}
-\frac{\partial y_1}{\partial t} - \nabla.(\vec u y_1) - \beta_1 \Delta y_1 + \kappa_1 (y_1 + y_2) &= \Psi_1^0 - \frac{\partial \Psi_1^1}{\partial x_1} - \frac{\partial \Psi_1^2}{\partial x_2} && \text{in } \Omega \times (0,T),\\
\beta_1 \frac{\partial y_1}{\partial n} + \vec u.\vec n\, y_1 &= 0 && \text{on } \Gamma \times (0,T),\\
y_1(x,T) &= 0 && \text{in } \Omega,\\
-\frac{\partial y_2}{\partial t} - \nabla.(\vec u y_2) - \beta_2 \Delta y_2 + \frac{1}{h}\kappa_2 y_2 &= \Psi_2^0 - \frac{\partial \Psi_2^1}{\partial x_1} - \frac{\partial \Psi_2^2}{\partial x_2} && \text{in } \Omega \times (0,T),\\
\beta_2 \frac{\partial y_2}{\partial n} + \vec u.\vec n\, y_2 &= 0 && \text{on } \Gamma \times (0,T),\\
y_2(x,T) &= 0 && \text{in } \Omega.
\end{aligned}$$

Then we have

$$\begin{aligned}
&\int_0^T \int_\Omega \left\{ \sum_{i=1}^2 \Psi_i^0 \rho_i^k + \sum_{i,j=1}^2 \Psi_i^j \frac{\partial \rho_i^k}{\partial x_j} \right\} dx\, dt \int_0^T \left\langle -\frac{\partial y^\Psi}{\partial t} + \mathcal{A}^*(y^\Psi), \rho^k \right\rangle dt \\
&\quad = \int_0^T \left\langle \frac{\partial \rho^k}{\partial t} + \mathcal{A}(\rho^k), y^\Psi \right\rangle dt + \int_\Omega y_2^\Psi(x,0) \rho_{20}(x)\, dx
\end{aligned}$$

$$= \sum_{j=1}^{N_E} \int_0^T \int_\Omega \frac{1}{h(x,t)} f_j^k(x) m_j(t) y_1^\Psi(x,t)\, dx\, dt$$
$$+ \int_0^T \int_\Omega \frac{1}{h(x,t)} \kappa_2 d_s y_2^\Psi(x,t)\, dx\, dt + \int_\Omega y_2^\Psi(x,0)\rho_{20}(x)\, dx.$$

From this we deduce

$$\int_0^T \int_\Omega \left\{ \sum_{i=1}^2 \Psi_i^0 \rho_i^k + \sum_{i,j=1}^2 \Psi_i^j \frac{\partial \rho_i^k}{\partial x_j} \right\} dx\, dt$$
$$\le \frac{1}{\alpha} \sum_{i=1}^{N_E} \|m_i\|_{L^\infty(0,T)} \sum_{j=1}^{N_E} \int_0^T \int_\Omega |f_j^k(x) y_1^\Psi(x,t)|\, dx\, dt$$
$$+ \frac{1}{\alpha} \kappa_2 d_s \int_0^T \int_\Omega |y_2^\Psi(x,t)|\, dx\, dt + \int_\Omega |y_2^\Psi(x,0)\rho_{20}(x)|\, dx$$
$$\le \left\{ \tilde{C}_1 \sum_{i=1}^{N_E} \|m_i\|_{L^\infty(0,T)} + \tilde{C}_2 \|\rho_{20}\|_{C(\bar{\Omega})} + \tilde{C}_3\, d_s \right\} \|y^\Psi\|_{[C(\bar{\Omega}\times[0,T])]^2}.$$

On the other hand, from Ladyzhenskaja, Solonnikov, and Uraltseva [15] and Di Benedetto [6] we get

$$\int_0^T \int_\Omega \left\{ \sum_{i=1}^2 \Psi_i^0 \rho_i^k + \sum_{i,j=1}^2 \Psi_i^j \frac{\partial \rho_i^k}{\partial x_j} \right\} dx\, dt$$
$$\le \left\{ \tilde{C}_4 \sum_{i=1}^{N_E} \|m_i\|_{L^\infty(0,T)} + \tilde{C}_5 \|\rho_{20}\|_{C(\bar{\Omega})} + \tilde{C}_6\, d_s \right\} \sum_{j=0}^2 \|\Psi^j\|_{[L^{r'}(0,T;L^{s'}(\Omega))]^2}.$$

Due to the density of the space $\{\Psi^0 - \frac{\partial \Psi^1}{\partial x_1} - \frac{\partial \Psi^2}{\partial x_2} : \Psi \in [\{\mathcal{D}(\Omega \times (0,T))\}^2]^3\}$ in $[L^{r'}(0,T;(W^{1,s}(\Omega))')]^2$ we deduce the boundedness of $\{\rho^k\}$ in $[L^r(0,T;W^{1,s}(\Omega))]^2$.

Thus, taking a subsequence if necessary, we obtain that $\{\rho^k\}$ weakly converges to ρ in $[L^r(0,T;W^{1,s}(\Omega))]^2$ and that the limit satisfies the estimate (3.3). Moreover, ρ is independent on r and s (cf. Casas [4]). Finally, since $W^{1,s}(\Omega) \subset M(\bar{\Omega}) \subset (W^{1,s'}(\Omega))'$, we have that

$$\frac{\partial \rho}{\partial t} \in [L^r(0,T;(W^{1,s'}(\Omega))')]^2.$$

On the other hand, if we choose $\Psi = (\Psi^0, 0, 0)$ and argue as before, we obtain

$$\int_0^T \int_\Omega \sum_{i=1}^2 \Psi_i^0 \rho_i^k\, dx\, dt \le \left\{ \tilde{C}_7 \sum_{i=1}^{N_E} \|m_i\|_{L^\infty(0,T)} \right.$$
$$\left. + \tilde{C}_8 \|\rho_{20}\|_{C(\bar{\Omega})} + \tilde{C}_9\, d_s \right\} \|y^\Psi\|_{[L^2(0,T;H^2(\Omega))\cap H^1(0,T;L^2(\Omega))]^2}.$$

By the estimates of Ladyzhenskaja, Solonnikov, and Uraltseva [15] we know that

$$\|y^\Psi\|_{[L^2(0,T;H^2(\Omega))\cap H^1(0,T;L^2(\Omega))]^2} \le \tilde{C}_{10} \|\Psi^0\|_{[L^2(0,T;L^2(\Omega))]^2}$$

and we obtain the boundedness of $\{\rho^k\}$ in $[L^2(0,T;L^2(\Omega))]^2$, from which we can deduce that the solution ρ belongs to the space $[L^2(0,T;L^2(\Omega))]^2$ and satisfies the estimate (3.4).

Given $\Phi=(\Phi_1,\Phi_2)\in[L^2(0,T;H^2(\Omega))\cap H^1(0,T;L^2(\Omega))]^2\cap[C^1(\bar\Omega\times[0,T])]^2$ with $\Phi(.,T)=0$, multiplying (3.5) by Φ, and integrating by parts we have

$$\begin{aligned}\int_0^T\int_\Omega\Big\{&-\frac{\partial\Phi_1}{\partial t}\rho_1^k-\frac{\partial\Phi_2}{\partial t}\rho_2^k+\beta_1\nabla\Phi_1\nabla\rho_1^k+\beta_2\nabla\Phi_2\nabla\rho_2^k+\vec u\Phi_1\nabla\rho_1^k\\&+\vec u\Phi_2\nabla\rho_2^k+\kappa_1\Phi_1\rho_1^k+\kappa_1\Phi_2\rho_1^k+\frac{1}{h(x,t)}\kappa_2\Phi_2\rho_2^k)\Big\}\,dx\,dt\\&=\sum_{j=1}^{N_E}\int_0^T\int_\Omega\frac{1}{h(x,t)}\Phi_1(x,t)m_j(t)f_j^k(x)\,dx\,dt\\&+\int_0^T\int_\Omega\frac{1}{h(x,t)}\kappa_2 d_s\Phi_2(x,t)\,dx\,dt+\int_\Omega\Phi_2(x,0)\rho_{20}(x)\,dx.\end{aligned}$$

Passing to the limit we deduce (3.1) and, consequently, ρ is a solution of (2.1).

In order to prove (3.2), given $\Phi=(\Phi_1,\Phi_2)\in\mathcal{B}$, by multiplying (3.5) by Φ and integrating by parts we deduce

$$\begin{aligned}\int_0^T\Big\langle-\frac{\partial\Phi}{\partial t}+\mathcal{A}^*(\Phi),\rho^k\Big\rangle\,dt&=\sum_{j=1}^{N_E}\int_0^T\int_\Omega\frac{1}{h(x,t)}\Phi_1(x,t)m_j(t)f_j^k(x)\,dx\,dt\\&+\int_0^T\int_\Omega\frac{1}{h(x,t)}\kappa_2 d_s\Phi_2(x,t)\,dx\,dt+\int_\Omega\Phi_2(x,0)\rho_{20}(x)\,dx,\end{aligned}$$

and (3.2) is obtained by passing to the limit. The uniqueness of solution can be ensured from (3.2) (see Casas [4]). □

LEMMA 3.3. *Functions ρ_1 and ρ_2 are continuous in $\bar A_i\times[0,T]\ \forall\, i=1,\dots,N_Z$.*

Proof. Let $E\subset\Omega$ be a closed subset smooth enough such that

$$\begin{aligned}&P_j\in E\quad\forall j=1,\dots,N_E,\\&\cup_{i=1}^{N_Z}\bar A_i\subset\subset\Omega\backslash E.\end{aligned}$$

From the weak formulation (3.2) we deduce that

$$\begin{aligned}&\int_0^T\int_{\Omega\backslash E}\left(-\frac{\partial\Phi}{\partial t}+\mathcal{A}^*(\Phi)\right)\rho\,dx\,dt\\&\quad=\int_0^T\int_\Omega\left(-\frac{\partial\Phi}{\partial t}+\mathcal{A}^*(\Phi)\right)\rho\,dx\,dt=\sum_{j=1}^{N_E}\int_0^T\frac{1}{h(P_j,t)}\Phi_1(P_j,t)m_j(t)\,dt\\&\quad+\int_0^T\int_\Omega\frac{1}{h(x,t)}\kappa_2 d_s\Phi_2(x,t)\,dx\,dt+\int_\Omega\Phi_2(x,0)\rho_{20}(x)\,dx\\&\quad=\int_0^T\int_{\Omega\backslash E}\frac{1}{h(x,t)}\kappa_2 d_s\Phi_2(x,t)\,dx\,dt\quad\forall\Phi\in[\mathcal{D}((\Omega\backslash E)\times(0,T))]^2;\end{aligned}$$

that is, ρ satisfies

$$\int_0^T \int_{\Omega\backslash E} \left(-\frac{\partial \Phi}{\partial t} + \mathcal{A}^*(\Phi) \right) \rho \, dx \, dt$$
$$= \int_0^T \int_{\Omega\backslash E} \frac{1}{h(x,t)} \kappa_2 d_s \Phi_2(x,t) \, dx \, dt \quad \forall \Phi \in [\mathcal{D}((\Omega\backslash E) \times (0,T))]^2$$

with initial data $\rho_1(x,0) = 0$ and $\rho_2(x,0) = \rho_{20}$.

Thus, $\rho = (\rho_1, \rho_2) \in [L^2(0,T; H^1_{loc}(\Omega\backslash E))]^2 \cap [C(0,T; L^2_{loc}(\Omega\backslash E))]^2$ is a local solution of the problem

$$\begin{aligned}
\frac{\partial \rho_1}{\partial t} + \vec{u}\nabla\rho_1 - \beta_1 \Delta \rho_1 &= -\kappa_1 \rho_1 && \text{in } (\Omega\backslash E) \times (0,T), \\
\frac{\partial \rho_2}{\partial t} + \vec{u}\nabla\rho_2 - \beta_2 \Delta \rho_2 &= -\kappa_1 \rho_1 + \frac{1}{h}\kappa_2 (d_s - \rho_2) && \text{in } (\Omega\backslash E) \times (0,T), \\
\rho_1(x,0) &= 0 && \text{in } \Omega\backslash E, \\
\rho_2(x,0) &= \rho_{20} && \text{in } \Omega\backslash E.
\end{aligned} \tag{3.6}$$

From this we can obtain (see Ladyzhenskaja, Solonnikov, and Uraltseva [15, Chapter III, Theorem 10.1]) that ρ is continuous in the compact subsets of $(\Omega\backslash E) \times [0,T]$.

Particularly,

$$\rho \in [C(\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T])]^2. \qquad \square$$

In order to obtain optimality conditions for the control problem it will be necessary to obtain the Gateaux derivative of the mappings:

$$F_1 : m \in (L^\infty(0,T))^{N_E} \longrightarrow F_1(m) = \rho_{1|\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T]} \in C(\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T]),$$
$$F_2 : m \in (L^\infty(0,T))^{N_E} \longrightarrow F_2(m) = \rho_{2|\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T]} \in C(\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T]).$$

First, we obtain the following continuity result.

LEMMA 3.4. *There exist constants $\hat{C}_1, \hat{C}_2, \hat{C}_3$ such that*

$$\|\rho\|_{[C(\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T])]^2} \le \hat{C}_1 \sum_{i=1}^{N_E} \|m_i\|_{L^\infty(0,T)} + \hat{C}_2 \|\rho_{20}\|_{C(\bar{\Omega})} + \hat{C}_3 \, d_s.$$

Proof. As a consequence of Lemma 3.3 and the estimates for $\max|\rho(x,t)|$ in $(\Omega\backslash E) \times [0,T]$ (see Ladyzhenskaja, Solonnikov, and Uraltseva [15, Chapter III, Theorem 8.1 and Chapter II, Theorem 6.2]) we have

$$\begin{aligned}
\|\rho\|_{[C(\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T])]^2} &= \|\hat{\rho}\|_{[C(\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T])]^2} \\
&\le \bar{C}_1 \|\hat{\rho}\|_{[L^2(0,\hat{T}; L^2(\Omega\backslash E))]^2} + \bar{C}_2 \|\rho_{20}\|_{C(\overline{\Omega\backslash E})} + \bar{C}_3 \, d_s,
\end{aligned}$$

where $\hat{\rho}$ is the solution of the following boundary value problem:

$$
\begin{aligned}
\frac{\partial \hat{\rho}_1}{\partial t} + \vec{u}\nabla\hat{\rho}_1 - \beta_1\Delta\rho_1 = -\kappa_1\hat{\rho}_1 + \frac{1}{h}\chi_{[0,T]}\sum_{j=1}^{N_E} m_j\delta(x-P_j) \qquad & \text{in } \Omega\times(0,\hat{T}),\\
\frac{\partial \hat{\rho}_1}{\partial n} = 0 \qquad & \text{on } \Gamma\times(0,\hat{T}),\\
\hat{\rho}_1(x,0) = 0 \qquad & \text{in } \Omega,\\
\frac{\partial \hat{\rho}_2}{\partial t} + \vec{u}\nabla\hat{\rho}_2 - \beta_2\Delta\hat{\rho}_2 = -\kappa_1\hat{\rho}_1 + \frac{1}{h}\kappa_2(d_s-\hat{\rho}_2) \qquad & \text{in } \Omega\times(0,\hat{T}),\\
\frac{\partial \hat{\rho}_2}{\partial n} = 0 \qquad & \text{on } \Gamma\times(0,\hat{T}),\\
\hat{\rho}_2(x,0) = \rho_{20}(x) \qquad & \text{in } \Omega
\end{aligned}
\tag{3.7}
$$

for $\hat{T} > T$ and $\chi_{[0,T]}$ the characteristic function of $[0,T]$. Thus, by estimate (3.4) of Theorem 3.2 we deduce

$$
\|\rho\|_{[C(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T])]^2} \le \hat{C}_1\sum_{i=1}^{N_E}\|m_i\|_{L^\infty(0,T)} + \hat{C}_2\,\|\rho_{20}\|_{C(\bar{\Omega})} + \hat{C}_3\,d_s. \qquad \square
$$

Now, we can deduce the Gateaux differentiability.

LEMMA 3.5. *The mappings F_1 and F_2 are Gateaux differentiable. Moreover,*

$$
\begin{aligned}
DF_1(m)(n) &= \omega_{1\,|\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]},\\
DF_2(m)(n) &= \omega_{2\,|\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]},
\end{aligned}
$$

where ω_1 and ω_2 are the solutions of the linearized system:

$$
\begin{aligned}
\frac{\partial \omega_1}{\partial t} + \vec{u}\nabla\omega_1 - \beta_1\Delta\omega_1 = -\kappa_1\omega_1 + \frac{1}{h}\sum_{j=1}^{N_E} n_j\delta(x-P_j) \qquad & \text{in } \Omega\times(0,T),\\
\frac{\partial \omega_1}{\partial n} = 0 \qquad & \text{on } \Gamma\times(0,T),\\
\omega_1(x,0) = 0 \qquad & \text{in } \Omega,\\
\frac{\partial \omega_2}{\partial t} + \vec{u}\nabla\omega_2 - \beta_2\Delta\omega_2 = -\kappa_1\omega_1 - \frac{1}{h}\kappa_2\omega_2 \qquad & \text{in } \Omega\times(0,T),\\
\frac{\partial \omega_2}{\partial n} = 0 \qquad & \text{on } \Gamma\times(0,T),\\
\omega_2(x,0) = 0 \qquad & \text{in } \Omega.
\end{aligned}
\tag{3.8}
$$

Proof. Let (ω_1,ω_2) be the solution of system (3.8). Arguing as in Lemma 3.3 we can prove that

$$
\begin{aligned}
\omega_{1\,|\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]} &\in C(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]),\\
\omega_{2\,|\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]} &\in C(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]).
\end{aligned}
$$

Let us denote by $\rho(m)$ the solution of the state system (2.1) corresponding to a second member m. Thus, for $m,n\in L^\infty(0,T)$ and $\alpha\in(0,1)$ given, since ρ_1 is affine, it satisfies

$$
\rho_1(m+\alpha n)(x,t) - \rho_1(m)(x,t) = \alpha\omega_1(x,t) \quad \forall (x,t)\in\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T].
$$

Then,

$$\lim_{\alpha\to 0}\frac{\rho_1(m+\alpha n)-\rho_1(m)}{\alpha}=\omega_1$$

in $C(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T])$. As a consequence of Lemma 3.4, the mapping taking n into ω_1 is linear and continuous. Thus,

$$DF_1(m)(n)=\omega_{1\,|\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]}.$$

Arguing in the same way with ρ_2 we also obtain that

$$DF_2(m)(n)=\omega_{2\,|\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]}. \qquad \square$$

4. Existence of a solution of the optimal control problem. We have the following theorem.

THEOREM 4.1. *If there exists a feasible control $\tilde{m}\in U_{ad}$ such that*

$$\tilde{\rho_1}_{|A_i\times(0,T)}\le\sigma_i,\quad i=1,\dots,N_Z,$$
$$\tilde{\rho_2}_{|A_i\times(0,T)}\ge\zeta_i,\quad i=1,\dots,N_Z,$$

then the optimal control problem has, at least, a solution.

Proof. Let $\{m^k\}_{n\in N}\in U_{ad}$ be a minimizing sequence. From the boundedness of the sequence we can deduce the existence of a subsequence (still denoted in the same way) that converges weakly in $(L^2(0,T))^{N_E}$ to an element $m\in U_{ad}$. From Theorem 3.2 we deduce that the sequence $\rho^k=(\rho_1^k,\rho_2^k)=(\rho_1(m^k),\rho_2(m^k))$ is bounded in $[L^r(0,T;W^{1,s}(\Omega))]^2$. Thus, for $r,s>1$, we have

$$\rho^k\longrightarrow\rho\quad\text{ weakly in }[L^r(0,T;W^{1,s}(\Omega))]^2.$$

So, passing to the limit, we obtain that ρ satisfies (3.1) and, consequently, $\rho=\rho(m)$.

Arguing as in Lemma 3.4 and taking into account the boundedness of m^k in $L^\infty(0,T)$, we obtain that the sequences ρ_j^k, $j=1,2$, are bounded, for some $\alpha\in(0,1)$, in $C^{\alpha,\alpha/2}(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T])$ (cf. [15, Chapter III, Theorem 10.1]). Then, using the compact imbedding of $C^{\alpha,\alpha/2}(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T])$ in $C(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T])$, we obtain the existence of subsequences, still denoted ρ_j^k, uniformly converging to ρ_j. Thus, from the direct pointwise convergence, we deduce

$$\rho_{1\,|A_i\times(0,T)}\le\sigma_i\quad\forall i=1,\dots,N_Z, \tag{4.1}$$
$$\rho_{2\,|A_i\times(0,T)}\ge\zeta_i\quad\forall i=1,\dots,N_Z. \tag{4.2}$$

Finally, since J is weakly lower semicontinuous (because of continuity and convexity of J), we have

$$J(m)\le\liminf J(m^k)$$

from which we deduce that m is a solution of the optimal control problem. $\square$

5. Optimality conditions. In this section we will obtain a first order optimality system satisfied by every solution of the optimal control problem. In order to express the optimality conditions in a simpler way we introduce functions p_1,p_2 as the solution (in the sense of Definition 5.1 below) of the following boundary value problem:

$$
\begin{aligned}
-\frac{\partial p_1}{\partial t} - \nabla.(\vec{u}p_1) - \beta_1\Delta p_1 + \kappa_1(p_1+p_2) &= \mu_{1|\Omega\times(0,T)} && \text{in } \Omega\times(0,T),\\
\beta_1\frac{\partial p_1}{\partial n} + \vec{u}.\vec{n}\,p_1 &= 0 && \text{on } \Gamma\times(0,T),\\
p_1(x,T) &= \mu_{1|\Omega\times\{T\}} && \text{in } \Omega,\\
-\frac{\partial p_2}{\partial t} - \nabla.(\vec{u}p_2) - \beta_2\Delta p_2 + \frac{1}{h}\kappa_2 p_2 &= \mu_{2|\Omega\times(0,T)} && \text{in } \Omega\times(0,T),\\
\beta_2\frac{\partial p_2}{\partial n} + \vec{u}.\vec{n}\,p_2 &= 0 && \text{on } \Gamma\times(0,T),\\
p_2(x,T) &= \mu_{2|\Omega\times\{T\}} && \text{in } \Omega,
\end{aligned}
\tag{5.1}
$$

where μ_1, μ_2 are regular Borel measures in $\bar{\Omega}\times[0,T]$. The weak solution of the system (5.1) can be defined by transposition techniques (Casas [4]) in the following way.

DEFINITION 5.1. *Given r, $s \in [1,2)$, $\frac{2}{r}+\frac{2}{s} > 3$, we say that $p = (p_1,p_2) \in [L^r(0,T;W^{1,s}(\Omega))]^2$ is a solution of the system (5.1) if $\forall\ z = (z_1,z_2) \in [L^2(0,T;H^1(\Omega)) \cap C^1(\bar{\Omega}\times[0,T])]^2$ such that $z(.,0) = 0$, it is verified that*

$$
\begin{aligned}
\int_0^T\int_\Omega \Big\{ &\frac{\partial z_1}{\partial t}p_1 + \frac{\partial z_2}{\partial t}p_2 + \rho_1\nabla z_1\nabla p_1 + \rho_2\nabla z_2\nabla p_2 + \vec{u}\nabla z_1 p_1 + \vec{u}\nabla z_2 p_2\\
&+\kappa_1 z_1 p_1 + \kappa_1 z_1 p_2 + \frac{1}{h(x,t)}\kappa_2 z_2 p_2\Big\}\,dx\,dt = \int_0^T\int_\Omega z_1 d\mu_1(x,t)\\
&+\int_0^T\int_\Omega z_1 d\mu_1(x,t) + \int_\Omega z_1(x,T)d\mu_{1T}(x) + \int_\Omega z_2(x,T)d\mu_{2T}(x).
\end{aligned}
$$

We denote by I_C the indicator function of a set C and by ∂f the subdifferential of a convex function f (see Ekeland and Temam [7]). If we define the sets S_1 and S_2 by

$$
\begin{aligned}
S_1 &= \{y \in C(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]):\ y(x,t) \le \sigma_j \quad \forall (x,t)\in \overline{A}_j\times[0,T],\ j=1,\dots,N_Z\},\\
S_2 &= \{\omega \in C(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]):\ \omega(x,t) \ge \zeta_j \quad \forall (x,t)\in \overline{A}_j\times[0,T],\ j=1,\dots,N_Z\},
\end{aligned}
$$

we have the following result.

THEOREM 5.2. *Let $m \in U_{ad}$ be an optimal control. Then, there exist two functions $\rho_1,\ \rho_2 \in L^r(0,T;W^{1,s}(\Omega)) \cap L^2(0,T;L^2(\Omega))\ \forall\ r,\ s \in [1,2),\ \frac{2}{r}+\frac{2}{s} > 3$, solving (2.1) and two functions $p_1,\ p_2 \in L^r(0,T;W^{1,s}(\Omega))$ solving (5.1), where $\mu_1,\ \mu_2$ are two Borel measures, with support in $\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]$, such that*

$$
\mu_{i_{|\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]}} \in \partial I_{S_i}(F_i(m)), \quad i=1,2, \tag{5.2}
$$

and the following relation is satisfied:

$$
\begin{aligned}
&\sum_{j=1}^{N_E}\Big\{\int_0^T f_j{}'(m_j(t))(n_j(t)-m_j(t))\,dt\\
&+\int_0^T \frac{1}{h(P_j,t)}p_1(P_j,t)(n_j(t)-m_j(t))\,dt\Big\} \ge 0 \quad \forall n \in U_{ad}.
\end{aligned}
\tag{5.3}
$$

Proof. Let m be a solution of the minimization problem:

$$\min_{n\in U_{ad}} J(n) + I_{S_1}(F_1(n)) + I_{S_2}(F_2(n)).$$

Since $U_{ad} \subset L^\infty(0,T)$ is a convex set and the functions F_1 and F_2 are affine and differentiable in m we obtain (see Ekeland and Temam [7]) the existence of two measures $\tilde{\mu}_1$, $\tilde{\mu}_2$, satisfying (5.2), such that

$$\begin{aligned} DJ(m)(n-m) + \langle (DF_1(m))^*(\tilde{\mu}_1), n-m\rangle \\ +\langle (DF_2(m))^*(\tilde{\mu}_2), n-m\rangle \geq 0 \quad \forall n \in U_{ad}, \end{aligned}$$

where

$$\begin{aligned} DJ(m)(n-m) &= \sum_{j=1}^{N_E} \int_0^T f_j{}'(m_j(t))(n_j(t)-m_j(t))\,dt, \\ \langle (DF_1(m))^*(\tilde{\mu}_1), n-m\rangle &= \langle \tilde{\mu}_1, DF_1(m)(n-m)\rangle, \\ \langle (DF_2(m))^*(\tilde{\mu}_2), n-m\rangle &= \langle \tilde{\mu}_2, DF_2(m)(n-m)\rangle. \end{aligned}$$

Then, we define $\mu_j = \tilde{\mu}_j\, \chi_{\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T]}$, $j = 1,2$. We also introduce $p = (p_1, p_2) \in [L^r(0,T; W^{1,s}(\Omega))]^2$ for r, $s \in [1,2)$ with $\frac{2}{r} + \frac{2}{s} > 3$ such that it is solution of (5.1) and satisfies (cf. Casas [4])

$$\begin{aligned} &\int_0^T \left\langle p, \frac{\partial z}{\partial t} + \mathcal{A}(z) \right\rangle dt \\ &\quad = \int_{\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T]} z_1\, d\mu_1(x,t) + \int_{\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T]} z_2\, d\mu_2(x,t) \quad \forall z \in \mathcal{R}, \end{aligned}$$

where

$$\begin{aligned} \mathcal{R} = \Bigg\{ & z = (z_1, z_2) \in [L^2(0,T; H^1(\Omega)) \cap C(\bar{\Omega} \times [0,T])]^2 \ : \\ & \frac{\partial z}{\partial t} + \mathcal{A}(z) \in L^\infty(\Omega \times (0,T)),\ \frac{\partial z}{\partial n_{\mathcal{A}}}_{|\Gamma \times (0,T)} = 0,\ z(.,0) = 0 \Bigg\}. \end{aligned}$$

Finally, it can be shown that

$$\begin{aligned} &\langle \mu_1, DF_1(m)(n-m)\rangle + \langle \mu_2, DF_2(m)(n-m)\rangle \\ &\quad = \sum_{j=1}^{N_E} \int_0^T \frac{1}{h(P_j,t)} p_1(P_j,t)(n_j(t)-m_j(t))\,dt. \end{aligned}$$

In effect, let $\omega = (\omega_1, \omega_2)$ be the solution of the linearized problem (3.8). Then, as was shown in Lemma 3.5,

$$\begin{aligned} DF_1(m)(n-m) &= \omega_{1\,|\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T]}, \\ DF_2(m)(n-m) &= \omega_{2\,|\cup_{i=1}^{N_Z} \bar{A}_i \times [0,T]}. \end{aligned}$$

Let $\{\theta^k\}$ be a mollifier sequence for the Dirac measure $\delta(x-0)$ with support in $B(0,\frac{1}{k})$ and let $\omega^k=(\omega_1^k,\omega_2^k)$ be the solution of the system

$$\begin{aligned}
\frac{\partial\omega_1^k}{\partial t}+\vec{u}\nabla\omega_1^k-\beta_1\Delta\omega_1^k=-\kappa_1\omega_1^k+\frac{1}{h}\sum_{j=1}^{N_E}(n_j-m_j)\theta^k(x-P_j) \qquad & \text{in } \Omega\times(0,T),\\
\frac{\partial\omega_1^k}{\partial n}=0 \qquad & \text{on } \Gamma\times(0,T),\\
\omega_1^k(x,0)=0 \qquad & \text{in } \Omega,
\end{aligned}$$

$$\begin{aligned}
\frac{\partial\omega_2^k}{\partial t}+\vec{u}\nabla\omega_2^k-\beta_2\Delta\omega_2^k=-\kappa_1\omega_1^k-\frac{1}{h}\kappa_2\omega_2^k \qquad & \text{in } \Omega\times(0,T),\\
\frac{\partial\omega_2^k}{\partial n}=0 \qquad & \text{on } \Gamma\times(0,T),\\
\omega_2^k(x,0)=0 \qquad & \text{in } \Omega.
\end{aligned}$$

From $\|\theta^k\|_{L^1(\Omega)}=1$ we obtain (see Theorem 3.2) that ω_1^k and ω_2^k are bounded in $L^r(0,T;W^{1,s}(\Omega))$ and $L^2(0,T;L^2(\Omega))$. Consequently,

$$\begin{aligned}
\omega_1^k &\longrightarrow \eta_1 \qquad \text{weakly in } L^r(0,T;W^{1,s}(\Omega)),\\
\omega_2^k &\longrightarrow \eta_2 \qquad \text{weakly in } L^r(0,T;W^{1,s}(\Omega)),
\end{aligned}$$

and, since θ^k is weak* convergent to $\delta(x-0)$, we deduce

$$\eta_1=\omega_1, \qquad \eta_2=\omega_2.$$

Due to the boundedness of ω_j^k, $j=1,2$, in $L^2(0,T;L^2(\Omega))$, we deduce that the sequences $\omega_{j\,|\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]}^k$, are bounded in $C^{\alpha,\alpha/2}(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T])$, for some $\alpha\in(0,1)$. Then, by the compact imbedding in $C(\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T])$, we obtain the existence of subsequences uniformly converging to ω_j.

By the definition of p we have that

$$\begin{aligned}
&\int_0^T\left\langle p,\frac{\partial\omega^k}{\partial t}+\mathcal{A}(\omega^k)\right\rangle dt\\
&\quad=\int_{\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]}\omega_1^k\,d\mu_1(x,t)+\int_{\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]}\omega_2^k\,d\mu_2(x,t)\\
&\quad=\langle\mu_1,\omega_1^k\rangle+\langle\mu_2,\omega_2^k\rangle.
\end{aligned}$$

Thus, by the characterization of ω^k:

$$\begin{aligned}
&\langle\mu_1,\omega_1^k\rangle+\langle\mu_2,\omega_2^k\rangle\\
&\quad=\sum_{j=1}^{N_E}\int_0^T\int_\Omega\frac{1}{h(x,t)}p_1(x,t)(n_j(t)-m_j(t))\theta^k(x-P_j)\,dx\,dt\\
&\quad=\sum_{j=1}^{N_E}\int_0^T\int_{B(P_j,\frac{1}{k})}\frac{1}{h(x,t)}p_1(x,t)(n_j(t)-m_j(t))\theta^k(x-P_j)\,dx\,dt.
\end{aligned}$$

So, if we pass to the limit, taking into account that ω^k is smooth inside $\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]$ and that p_1 is smooth outside $\cup_{i=1}^{N_Z}\bar{A}_i\times[0,T]$, we obtain that

$$\langle\mu_1,\omega_1\rangle+\langle\mu_2,\omega_2\rangle=\sum_{j=1}^{N_E}\int_0^T\frac{1}{h(P_j,t)}p_1(P_j,t)(n_j(t)-m_j(t))\,dt,$$

which concludes the proof. ∎

6. The discretized problem. The first step in the numerical resolution of the problem is solving the state system. In order to do it, we carry out a time discretization, treating the convective term with a method of characteristics. For the time interval $[0,T]$ we choose an integer number N and we define $\Delta t = \frac{T}{N} > 0$ and $t_n = n\Delta t \ \forall n = 0,\dots,N$. Then, for the semidiscretized problem, we consider a variational formulation and approximate it by a space discretization with finite elements. We approximate Ω by the polygonal set Ω_h and choose an admissible triangulation τ_h of it (see [5]) with triangles of diameter $\le h$ and such that the vertices on the boundary of Ω_h also lie on the boundary of Ω. We define V_h as the following finite element space:

$$V_h = \left\{ v_h \in C^0(\bar{\Omega}),\ v_{h|K} \in P_1,\ K \in \tau_h \right\}.$$

The velocity and height fields, necessary for the discretized problem, are obtained by solving the Saint-Venant equations [3]. So, the resultant discretized problem is equivalent to the linear system

$$\left\{ \begin{array}{ll} M_{1h}\rho_{1h}^{n+1} = b_{1h}^n & \\ & \forall\ n = 0,\dots,N-1, \\ M_{2h}\rho_{2h}^{n+1} = b_{2h}^n & \end{array} \right. \tag{6.1}$$

for ρ_{1h}^0 and ρ_{2h}^0 given, and with

- $\rho_{1h}^{n+1} = \left(\rho_{1h}^{n+1}(x_1),\dots,\rho_{1h}^{n+1}(x_{N_v})\right)^t$,
- $(M_{1h})_{ij} = \beta_1 \int_\Omega \nabla\tilde{v}_i \nabla\tilde{v}_j dx + \left(\frac{1}{\Delta t} + \kappa_1\right)\int_\Omega \tilde{v}_i\tilde{v}_j dx$,
- $(b_{1h}^n)_l = \frac{1}{\Delta t}\int_\Omega (\rho_{1h}^n\ X_h^n)\tilde{v}_l dx + \int_\Omega \frac{1}{h^n}\sum_{j=1}^{N_E} m_j(t_n)\delta(x-P_j)\tilde{v}_l dx$,
- $\rho_{2h}^{n+1} = \left(\rho_{2h}^{n+1}(x_1),\dots,\rho_{2h}^{n+1}(x_{N_v})\right)^t$,
- $(M_{2h})_{ij} = \beta_2 \int_\Omega \nabla\tilde{v}_i \nabla\tilde{v}_j dx + \frac{1}{\Delta t}\int_\Omega \tilde{v}_i\tilde{v}_j dx$,
- $(b_{2h}^n)_l = -\kappa_2 \int_\Omega \frac{1}{h^n}\rho_{2h}^n\tilde{v}_l dx + \frac{1}{\Delta t}\int_\Omega (\rho_{2h}^n\ X_h^n)\tilde{v}_l dx - \kappa_1\int_\Omega \rho_{1h}^{n+1}\tilde{v}_l dx + \kappa_2\int_\Omega \frac{1}{h^n} d_s\tilde{v}_l dx$,

where $\{\tilde{v}_1,\tilde{v}_2,\dots,\tilde{v}_{N_v}\}$ is a basis of V_h such that $\tilde{v}_i(x_j) = \delta_{ij}$, $h^n(x) = h(x,t_n)$, and $X^n(x)$ is the position at instant t_n of the particle that will be at point x in the instant t_{n+1} (see [21] for further details).

The discretized cost $\hat{J}$ and the discretized constraints g are given by

$$\begin{array}{rccl} \hat{J}: & R^{N\times N_E} & \longrightarrow & R, \\ & m & \longrightarrow & \hat{J}(m) = \Delta t \displaystyle\sum_{j=1}^{N_E}\sum_{n=0}^{N-1} C_{jn} f_j(m_{jn}), \end{array}$$

$$\begin{array}{rccl} g: & R^{N\times N_E} & \longrightarrow & R^{N\times N_{VZ}} \times R^{N\times N_{VZ}} \times R^{N\times N_E}, \\ & m & \longrightarrow & g(m) = (\underbrace{\tilde{\rho}_{1h} - \sigma,\ \zeta - \tilde{\rho}_{2h}}_{= g_1(m)},\ \underbrace{\underline{m} - m}_{= g_2(m)})^t, \end{array}$$

where

- m is the vector consisting of all of the discharges at all times,
- m_{jn} is the amount of BOD discharged in P_j at time t_n,
- C_{jn} are the weights of the quadrature formula,
- N_{VZ} is the number of vertices in the protected areas,
- $\tilde{\rho}_{ih}$ is a vector of values of ρ_{ih} at each vertex included in the protected areas and for all times.

We remark that the function g can be decomposed into g_1, which is putting together the constraints about the water quality, and g_2, which collects the control constraints.

Then, the optimal control problem is approached by the following discretized problem:

$$(\mathcal{P}_{\mathcal{F}}) \quad \begin{cases} \min\limits_{m \in R^{N \times N_E}} & \hat{J}(m) \\ \text{such that} & g(m) \leq 0. \end{cases}$$

If the constraints set is nonempty, then this problem has a solution because this set is compact and the cost function is convex.

7. Numerical resolution by a feasible points algorithm. We solve the discretized control problem $(\mathcal{P}_{\mathcal{F}})$ by using a feasible points method which is based on a globally convergent algorithm introduced by Herskovits [9, 10] and Panier, Tits, and Herskovits [17].

We use the following notation:

- p is the dimension of the control and q is the number of the constraints on the state,
- (λ, θ) is the vector of the dual variables,
- $L(m, \lambda, \theta)$ is the Lagrangian,
- $H(m, \lambda, \theta)$ is the Hessian.

So, the first order Karush–Kuhn–Tucker optimality conditions for the discretized problem can be written as follows:

$$\nabla \hat{J}(m) + \nabla g_1 \lambda - I\theta = 0, \tag{7.1}$$

$$G_1(m)\lambda = 0, \qquad G_2(m)\theta = 0, \tag{7.2}$$

$$\lambda \geq 0, \qquad \theta \geq 0, \tag{7.3}$$

$$g_1(m) \leq 0, \qquad g_2(m) \leq 0, \tag{7.4}$$

where $G_1(m)$ and $G_2(m)$ are diagonal matrices, of order q and p, respectively, and with diagonal elements being the values of the corresponding functions $g_i(m)$.

The basic idea of the feasible points algorithm consists of solving the system of (7.1)–(7.2) in (m, λ, θ) by using a fixed point method, in such a way that the conditions (7.3)–(7.4) hold at each iteration.

Thus, for a given point $(m^k, \lambda^k, \theta^k)^t$, the Newton's method applied to the previous system computes the next iteration $(m_0^{k+1}, \lambda_0^{k+1}, \theta_0^{k+1})^t$ by solving

$$\begin{pmatrix} m_0^{k+1} \\ \lambda_0^{k+1} \\ \theta_0^{k+1} \end{pmatrix} = \begin{pmatrix} m^k \\ \lambda^k \\ \theta^k \end{pmatrix} - \begin{pmatrix} H(m^k, \lambda^k, \theta^k) & \nabla g_1 & -I \\ \Lambda^k (\nabla g_1)^t & G_1^k & 0 \\ -\Theta^k & 0 & G_2^k \end{pmatrix}^{-1} \begin{pmatrix} \nabla \hat{J}(m^k) + \nabla g_1 \lambda^k - I\theta^k \\ G_1^k \lambda^k \\ G_2^k \theta^k \end{pmatrix},$$

where Λ^k and Θ^k are diagonal matrices whose elements are the coordinates of λ^k and θ^k, respectively.

Obviously, conditions (7.3) and (7.4) do not usually hold at this new point $(m_0^{k+1}, \lambda_0^{k+1}, \theta_0^{k+1})^t$. Then, we define d^k as a search direction in m and rewrite the previous equality by computing $(d^k, \lambda_0^{k+1}, \theta_0^{k+1})^t$ as the solution of the following linear system:

$$\begin{pmatrix} H(m^k, \lambda^k, \theta^k) & \nabla g_1 & -I \\ \Lambda^k(\nabla g_1)^t & G_1^k & 0 \\ -\Theta^k & 0 & G_2^k \end{pmatrix} \begin{pmatrix} d^k \\ \lambda_0^{k+1} \\ \theta_0^{k+1} \end{pmatrix} = \begin{pmatrix} -\nabla \hat{J}(m^k) \\ 0 \\ 0 \end{pmatrix}. \tag{7.5}$$

Now, in order to determine the new primal point m^{k+1}, we perform a line search along d^k (by using an extension of Armijo's rule [11]) for obtaining a step t^k which leads us to a new point where the cost reduction is satisfactory.

Finally, the new value of the dual variable $(\lambda^{k+1}, \theta^{k+1})^t$ can be computed by several updating methods. We use the following one, based upon an idea from Herskovits [9]:

(1) We choose positive numbers ξ_1, ξ_2, μ_1, μ_2, λ^I, θ^I.

(2) For $i = 1, \ldots, q$, and for $j = 1, \ldots, p$, we define

$$(\lambda^{k+1})_i = \sup\{(\lambda_0^{k+1})_i, \xi_1 \|d^k\|^2\},$$

$$(\theta^{k+1})_j = \sup\{(\theta_0^{k+1})_j, \xi_2 \|d^k\|^2\}.$$

(3) If $\left(g_1(m^{k+1})\right)_i \geq -\mu_1$ and $(\lambda^{k+1})_i < \lambda^I$, then $(\lambda^{k+1})_i = \lambda^I$.

(4) If $\left(g_2(m^{k+1})\right)_j \geq -\mu_2$ and $(\theta^{k+1})_j < \theta^I$, then $(\theta^{k+1})_j = \theta^I$.

In this algorithm the role played by the resolution of the linear system (7.5) must be noted. Since all the constraints are linear we have $H^k = H(m^k, \lambda^k, \theta^k) = \nabla^2 \hat{J}(m^k)$, which, due to the particular form of $\hat{J}$, is diagonal and easy to compute. On the other hand, the convexity of f_j, $j = 1, \ldots, N_E$, ensures that H^k is positive definite and, consequently (see [17]), the matrix of the linear system is nonsingular if the components of λ^k and θ^k related to active constraints are strictly positive.

Thus, the nonsingular matrix, of order $(2p + q)$, has diagonal blocks, except $\nabla g_1 \in \mathcal{M}_{p \times q}$ and $\Lambda^k(\nabla g_1)^t \in \mathcal{M}_{q \times p}$. If the values of p and q are not too large, the system (7.5) can be easily solved, for instance, by a preconditioned biconjugate method.

However, in a realistic problem where p and q are very large, the need of preconditioning each iteration causes this method to become very slow. In this case the followed strategy consists of solving the linear system by blocks, locating previously the active constraints in order to avoid ill-conditioning. The resultant system is full and nonsymmetric, but only of order ($p +$ number of active constraints), and can be then solved, for instance, by the QR method.

8. Numerical results. Multiple tests have been developed, solving the previous problem for several *rías* in Galicia, Spain, with different initial values in the optimization algorithm, and the achieved results have always been satisfactory.

In this section we present the numerical results obtained when solving the problem on a realistic situation: We have taken a two-dimensional mesh of the *ría* of Vigo as

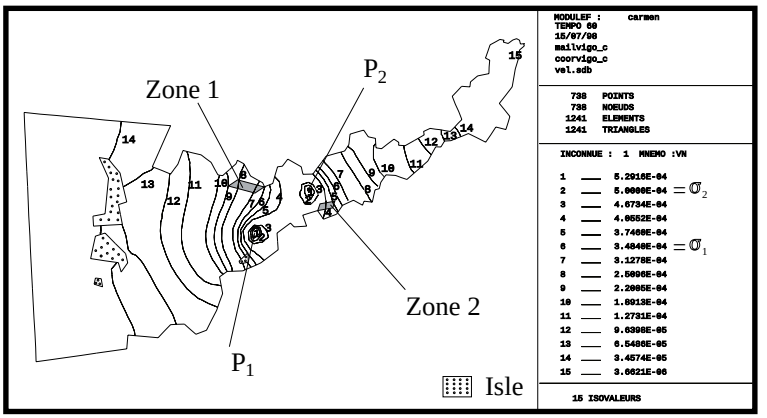

FIG. 8.1. *BOD concentration at high tide.*

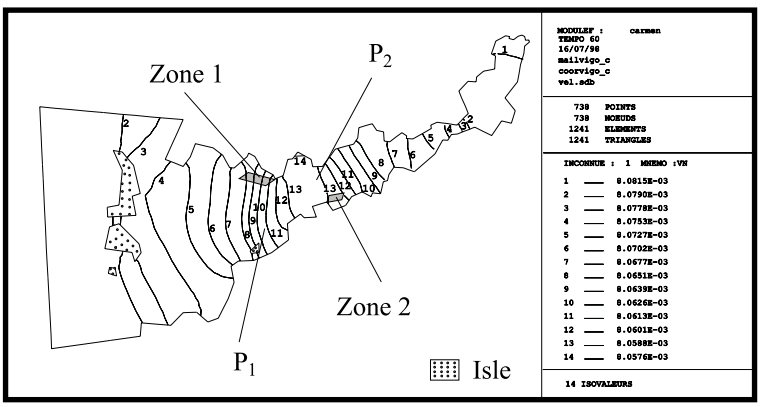

FIG. 8.2. *DO concentration at high tide.*

domain Ω, where we have considered two protected areas and two points of discharge (see Figures 8.1 and 8.2). We have also supposed that it is necessary to guarantee lower levels of pollution in zone 1 than in zone 2. (The values of the parameters can be seen in Table 8.1.)

The cost function is given in Figure 8.3: If we assume pollutant concentration of the sewage arriving to the sewage farm is 150 $\mathrm{Kg/m^3}$, then the depuration cost above this value is constant. The velocity and the height of the water have been obtained to solve the Saint-Venant equations on this domain. The numerical resolution of the Saint-Venant equations has been carried out in [3].

Figures 8.1 and 8.4 show the BOD concentration at high tide and at low tide, respectively. The constraints occur everywhere in the protected areas; at high tide, they saturate at one of the vertices in zone 1, but at low tide, after a tidal cycle, the saturation takes place at one of the vertices in zone 2.

The values of the optimal discharges, which produce this situation, can be seen in Figure 8.5. The discharge rate is greater during rising tide at point 2 than at point 1. However, during ebb tide (after $t = 60$) the flow rate decreases at P_2 and increases

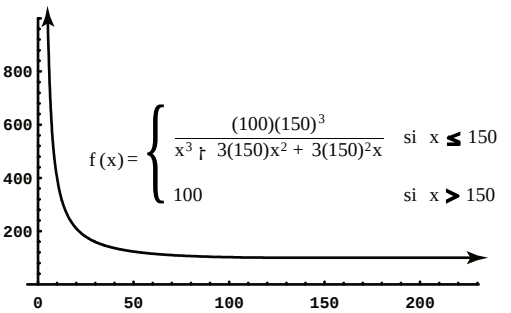

FIG. 8.3. *Cost function.*

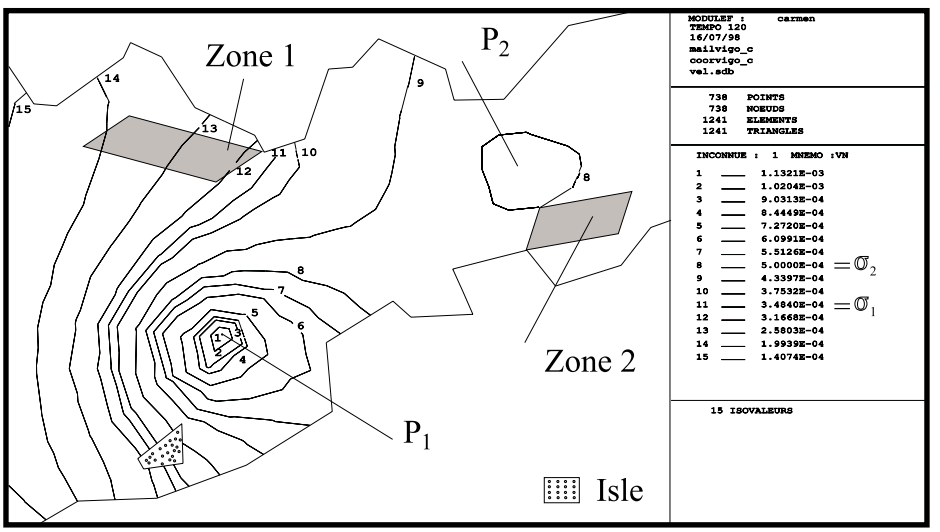

FIG. 8.4. *BOD concentration at low tide.*

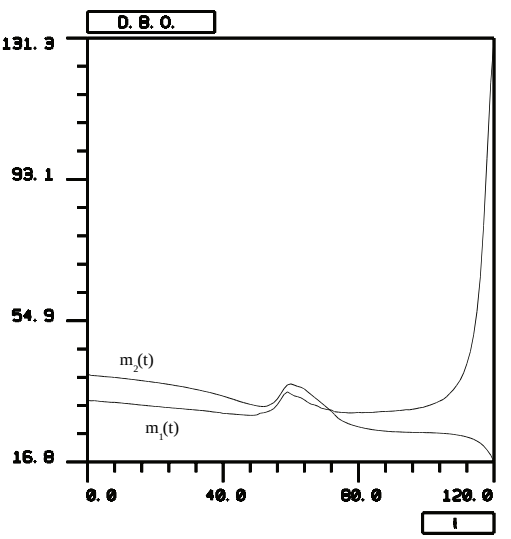

FIG. 8.5. *Optimal discharges during a tidal cycle.*

TABLE 8.1
Parameters for solving the problem ($\mathcal{P}_\mathcal{F}$) on the ría of Vigo.

Saint-Venant parameters	Empiric coefficients	Adimensional constants
Tidal cycle: T=12.4 h	$\beta_1 = \beta_2 = 2000$ m^2/s	$N = 120$
Tidal run: 2.8 m	$\kappa_1 = 1.15\,10^{-5}$ s^{-1}	$\xi_1 = 10^{-8}$
Water density: 1000 Kg/m^3	$\kappa_2 = 9\,10^{-12}$ s^{-1}	$\xi_2 = 10^{-8}$
Air density: 1.28 Kg/m^3	$d_s = 8.98\,10^{-3}$ Kg/m^3	$\mu_1 = 10^{-5}$
North latitude: 0.7326 rad	$\rho_{20} = 8.082\,10^{-3}$ Kg/m^3	$\mu_2 = 10^{-5}$
Wind direction: 3.9269 rad	$\sigma_1 = 3.48398\,10^{-4}$ Kg/m^3	$\lambda^I = 1$
Wind velocity: 10 Km/h	$\sigma_2 = 5\,10^{-4}$ Kg/m^3	$\theta^I = 1$
Angular velocity of Earth:	$\zeta_1 = 8.05255\,10^{-3}$ Kg/m^3	
7.92 10^{-5} rad/s	$\zeta_2 = 8.03218\,10^{-3}$ Kg/m^3	
	$\underline{m} = 0$ Kg/m^3	
	$\overline{m} = 150$ Kg/m^3	

at P_1. This is an obvious consequence of the outfalls position. In fact, during rising tide, P_2 is *better* than P_1, but during ebb tide P_1 is *the best* of them.

This work is being developed in the framework of a project sponsored by the government of Galicia, Spain, the final aim of which is the salubrity of the ecosystem formed by Galician *rías*. This is a very important purpose, from both an ecological and an economical point of view, because of its influence on shellfish production and touristic resources, and the local administration will provide data for validation of the models and optimization methods presented here.

BASIC CONTROL FOR THE VISCOUS MOORE–GREITZER PARTIAL DIFFERENTIAL EQUATION*

BJÖRN BIRNIR† AND HÖSKULDUR ARI HAUKSSON†

Abstract. The notions of basic controllability and basic control are defined. A quadratic optimal control of the linearized viscous Moore–Greitzer equation is presented, and it is confirmed that stall is uncontrollable in this model. A basic control is constructed for the nonlinear viscous Moore–Greitzer equation which can control both surge and stall. Some extensions of this construction are discussed. Numerical simulations of the basic control are presented, and its performance is compared to the performance of a backstepping control constructed by Banaszuk, Hauksson, and Mezić [*SIAM J. Control Optim.*, 37 (1999), pp. 1503–1537]. It is shown that the viscous Moore–Greizer equation with throttle control is not basically controllable, but under certain conditions, adding air injection control will make the equation basically controllable.

Key words. optimal control of PDE, Moore–Greitzer equation, basic control, basic attractor, global attractor

1. Introduction.

In recent years a lot of attention has been devoted to the study of air flow through turbomachines. The main reason for this interest is that when a turbomachine, such as a jet engine, operates close to its optimal operating parameter values, the flow can become unstable. These instabilities put a large stress on the engine, and in some cases the engine needs to be turned off in order to recover original operation. For this reason jet engines are currently operated away from their optimal operating parameter values.

A jet engine can be thought of as a compressor, where the incoming air is compressed by alternating rings of rotating blades and stationary blades. The mixture of fuel and compressed air is then ignited, and the resulting combustion generates thrust that propels the aircraft. There are primarily two types of instabilities that occur in the flow through the compressor. They are called *surge* and *stall*. Surge is characterized by large oscillations of the mean mass flow through the engine. During part of the cycle, the mean mass flow may become reversed, thrusting air out the front end of the engine. This puts a large stress on the components of the engine and seriously impairs its performance. When stall occurs, there are regions of relatively low air flow that form at isolated locations around the rim of the compressor. Here too, the phenomenon can be so pronounced that the flow in these isolated regions is reversed. Again, this causes a large stress on the components of the engine and reduces its performance.

Moore and Greitzer published in 1986 a PDE model for turbomachines which has been very successful [26]. A substantial amount of work has been done on finite Galerkin approximations of that model since (see, e.g., [23], [20], and references

†Department of Mathematics, University of California Santa Barbara, Santa Barbara, CA 93106 and Science Institute, University of Iceland, 3 Dunhaga, IS-107 Reykjavik, Iceland (birnir@math.ucsb.edu, URL: www.math.ucsb/~birnir, hauksson@math.ucsb.edu).

therein). Banaszuk, Hauksson, and Mezić [2] considered the full PDE model of Moore and Greitzer.

Currently Mezić [24] has derived a model of the three dimensional flow in jet engine compressors. His model reduces to that presented in [6] when one assumes that the dependence of the flow on the radial direction is negligible. The viscous term in that equation, first introduced by Adomaitis and Abed [1], has, however, a new and better interpretation in Mezić's treatment. The term is not due to the viscosity of the air, but rather, it is a diffusion term due to the inviscid process of turbulent momentum transport via Reynolds stresses. The difference is several orders of magnitude of the constant ν, which now represents the eddy viscosity. It is this model with the additional assumption that the flow is independent of the radial coordinate that we use here. In this form the model is known as the viscous Moore–Greitzer equation (vMG equation).

Birnir and Hauksson [6] proved that the vMG equation is well posed in the Hilbert space $X = \bar{H}^1 \times \mathbf{R}^2$, where $\bar{H}^1$ denotes the Sobolev space with index one of functions on the unit circle with square integrable first derivative and zero mean. This solution is smooth in space and time variables, and this dynamical system has a global attractor with finite Hausdorff and fractal dimensions. In [7] the authors analyzed the basic attractor and found explicit solutions for stall for certain parameter values and showed that they are stable and persist under small perturbations of the parameters. Stall is a solitary wave that rotates around the annulus at half the rotor speed of the engine. They conclude that the basic attractor consists of design flow, surge, and one or more stall solutions. The analysis of the basic attractor (see subsection 1.1) was extended for all parameter values in [8], and there and in Hauksson [16] they derived a reduced order model that captures the dynamics of the vMG equation quantitatively as well as qualitatively. These results are in good agreement with experimental [12] and numerical results [14].

There have been numerous control related results reported for Galerkin truncations of the Moore–Greitzer equation. The first control result for the full system, and to our knowledge the only one until now, was presented by Banaszuk, Hauksson, and Mezić [2]. They constructed a feedback throttle control which made design flow attract all of the state space for the inviscid Moore–Greitzer equation. This equation is a hyperbolic equation and the nature of its solutions are quite different than that for the vMG equation. Current results by Mezić [24] indicate that the latter is a better physical model for the flow through the jet engine compression system. The controller obtained by Banaszuk, Hauksson, and Mezić is not very cost effective. In particular, it over-reacts to small-amplitude high-frequency disturbances which are naturally damped in the viscous model.

The backstepping control given by Banaszuk, Hauksson, and Mezić shows that one can eliminate stall and surge by using throttle control. The question we want to answer in this paper is how simple can we make the control design, and how efficient can the control be? The control philosophy we want to adopt is to construct a control strategy that can recover design flow operation after large disturbances, but this strategy is not necessarily good for regulating the design flow. For that a different strategy would be used.

This paper is arranged as follows. In the immediate subsection we present the equations of motion and assumptions. This section also explains the dynamics of the model briefly. Section 3 defines basic controllability and attractor controllability. Section 4 considers the simplest possibility, which is to linearize the system about the design flow and then apply the standard optimal control theory to obtain an

optimal control subject to quadratic cost. Here we confirm that stall is uncontrollable in the linearized model. Section 5 considers first the case when the throttle is moved adiabatically. We then use our knowledge of the basic attractor of the system to construct a basic control which recovers design flow operation from stall or surge. Numerical simulations are presented in section 6. Here we compare the basic control with the backstepping control. In section 7 we prove that the vMG equation with throttle control is not basically controllable. Moreover, if one in addition has air injection at one's disposal, the vMG equation is basically controllable.

1.1. The equation of motion and assumptions. Currently Mezić [24] has derived a model of the three dimensional flow through the compression system in jet engines. When one assumes that the flow does not depend on the radial direction, the equations reduce to the following:

$$\frac{\partial}{\partial t}\varphi = \nu\frac{\partial^2\varphi}{\partial\theta^2} - \frac{1}{2}\frac{\partial\varphi}{\partial\theta} + \psi_c(\Phi+\varphi) - \overline{\psi_c}, \quad \theta\in[0,2\pi], \tag{1.1}$$

$$\dot{\Phi} = \frac{1}{l_c}(\overline{\psi_c} - \Psi), \tag{1.2}$$

$$\dot{\Psi} = \frac{1}{4l_cB^2}(\Phi - \gamma F_T^{-1}(\Psi)), \tag{1.3}$$

where

$$\overline{\psi_c} := \frac{1}{2\pi}\int_0^{2\pi}\psi_c(\Phi(t)+\varphi(t,\theta))d\theta. \tag{1.4}$$

In this guise the equations are a special case of the original equations presented by Moore and Greitzer [26], except for an additional term due to the eddy viscosity. This term was first suggested by Adomaitis and Abed [1], but without the justification later provided by Mezić. The equation is known as the vMG equation. Here the dot represents the total derivative with respect to time.

The characteristic ψ_c is a cubic polynomial with a negative leading coefficient, and F_T^{-1} is a smooth function which is equal to $F_T^{-1}(\Psi) = \Psi|\Psi|^{-1/2}$ outside a small neighborhood of the origin.

In what follows, we will allow γ to depend on the state, but we will assume that it does so in a smooth way and that there exists a constant $\tilde{\gamma}$ such that

$$\gamma(\Phi,\Psi,\varphi) \geq \tilde{\gamma} > 0.$$

With these restrictions on γ, the results on existence of unique solutions and their regularity [6] still hold. In addition, the system will again have a global attractor whose fractal and Hausdorff dimensions can be bounded by the same bounds as in [6] with γ replaced by $\tilde{\gamma}$.

2. The basic attractor. Once the existence of a global attractor has been established, the natural question arises: How can one construct the global attractor, and can one obtain a system of ODEs that describe the evolution on the attractor? There are, for the most part, two main approaches that researchers have taken here.

The first one, and the more popular one, is to think of the attractor as a set embedded in a larger manifold, often called an inertial manifold (see, e.g., [11] and [13]). The problem of finding ODEs that describe the flow on this manifold or an approximate manifold is then solved by using a Galerkin projection onto a basis (see,

e.g., [27] and [21]). The number of basis vectors needed is often quite large. This can be due to either the fact that the bounds on the dimension of the attractors found by current methods tend to be rather conservative, or that the asymptotic dynamics of the system in question are in fact high dimensional. Hence the system of ODEs is not tractable for analytical analysis but lends itself better to numerical work.

The second approach is to consider only the core of the attractor called the basic attractor (see below). Here one constructs the particular solutions in the attractor which attract "almost all" of the phase space. For some systems, the asymptotic dynamics in this "almost every" sense are low dimensional, and one can completely determine the flow on the basic attractor *analytically*.

Here we adopt the second approach, but before we go further, let us clarify what we mean by the basic attractor and by "almost every."

2.1. Prevalence and basic attractors. We need to extend the measure theoretic terms measure zero and almost every to infinite dimensional Banach spaces. Furthermore, we want to do it in such a way that these definitions behave well under the operations of the vector space. It turns out that it suffices that they behave well under translations of the set. The problem here lies in that there do not exist any nontrivial translation invariant measures in infinite dimensional spaces. If a subset $U \subset X$ in an infinite dimensional Banach space is nonempty and μ is a translation invariant measure on X, then either $\mu(U) = 0$ or $\mu(U) = \infty$. Following Hunt, Sauer, and Yorke [17], the ideas of measure zero and almost every can be replaced by shy and prevalent.

DEFINITION 2.1. *Let X denote a separable Banach space. We denote by $S + v$ the translate of the set $S \subset X$ by a vector v. A measure μ is said to be* transverse *to a Borel set $S \subset X$ if the following two conditions hold.*

- *There exists a compact set $U \subset X$ for which $0 < \mu(U) < \infty$.*
- *$\mu(S + v) = 0$ for every $v \in X$.*

A Borel set $S \subset X$ is called shy *if there exists a compactly supported measure transverse to S. More generally, a subset of X is called shy if it is contained in a shy Borel set. The complement of a shy set is said to be a* prevalent *set.*

The basic attractor should be the smallest part of the global attractor $\mathcal{A}$ which attracts a prevalent set. Let us make this more precise.

DEFINITION 2.2. *An attractor $\mathcal{B}$ is a* basic attractor *if it satisfies the following two conditions.*

1. *The basin of attraction of $\mathcal{B}$ is prevalent.*
2. *$\mathcal{B}$ is minimal with respect to property* (1)*, i.e., there exists no strictly smaller $\mathcal{B}' \subset \mathcal{B}$ with* $\text{basin}(\mathcal{B}) \subset \text{basin}(\mathcal{B}')$*, up to shy sets.*

This means that every point of $\mathcal{B}$ is essential; no point can be removed without removing a portion of the basin that is not shy. In numerical simulations or in physical experiments one would therefore only expect to observe the basic attractor after a long-enough settling period.

In general, the basic attractor will be disconnected although the global attractor is connected. We can therefore speak of components of the basic attractor.

The following theorem, which is an extension of a finite dimensional version by Milnor [25], was proven in Birnir [4].

THEOREM 2.3. *Let $\mathcal{A}$ be the compact attractor of a continuous map $T(t)$ on a separable Banach space X. Then $\mathcal{A}$ can be decomposed into a basic attractor $\mathcal{B}$ and a remainder $\mathcal{C}$,*

$$\mathcal{A} = \mathcal{B} \cup \mathcal{C},$$

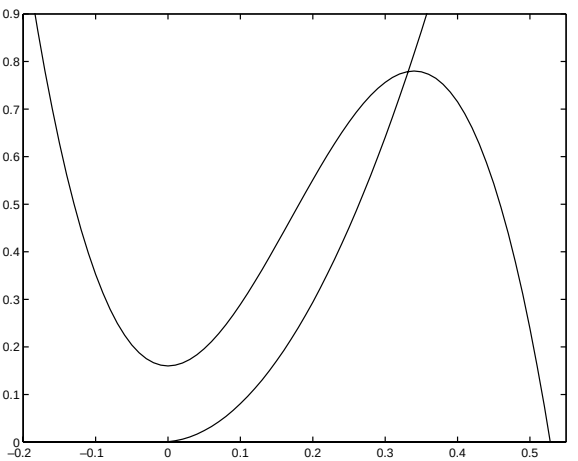

FIG. 2.1. *Two characteristics: the cubic compressor characteristic and the parabolic throttle characteristic. The intersection of these curves is a stationary solution for* $\varphi = 0$. *They are stable to the right of the peak.*

such that basin$(\mathcal{B})$ *is prevalent and basin*$(\mathcal{C})\backslash$*basin*$(\mathcal{B})$ *is shy.*

The basic attractor $\mathcal{B}$ for the vMG equation depends on the parameters in the equation; in particular, it depends on the throttle parameter $\mathcal{B} = \mathcal{B}(\gamma)$. It will prove useful later to have the following definition. Let $\tilde{\gamma} > 0$. The *basic union attractor* is the union of basic attractors

$$\cup_{\gamma \geq \tilde{\gamma}} \mathcal{B}(\gamma).$$

A complete description of the basic union attractor for the vMG equation has been given in [7] and [8]. It turns out that in the cases where an explicit description of $\mathcal{B}$ has been given (see also [5] and [9]), the dimension of $\mathcal{B}$ is small, whereas the dimension of $\mathcal{C}$ can be quite large.

2.2. The geometry of the basic attractor. Experimental and numerical evidence indicate that the basic attractor in axial compression systems is low dimensional [12], [14], [15], [30]. It can consist of a combination of axisymmetric design flow, surge, and stall. The design flow is a stationary solution, and surge is a periodic cycle which has been well studied (see [26] and [23]). It only involves the two ODEs in the system (1.1)–(1.3). Stall has been studied in low-order Galerkin truncations of the Moore–Greitzer equations [23], [20].

2.2.1. Design flow. Under normal conditions the engine operates in design flow. There the flow through the compressor is uniform in space and time and the pressure rise is relatively high. In particular, $\varphi = 0$, and Φ and Ψ are constant.

Figure 2.1 shows the (Φ, Ψ) plane. The parabola starting at the origin represents all stationary solutions for (1.3) and is called the throttle characteristic. The cubic curve represents all stationary solutions for (1.2), given that $\varphi = 0$, and is called the compressor characteristic. Since $\varphi = 0$ is a stationary solution for (1.1), we can conclude that the intersection of the two curves in Figure 2.1 is a stationary solution for the full system (1.1)–(1.3). This stationary solution is called design flow.

To analyze the stability of design flow $(0, \Phi_0, \Psi_0)$, we linearize the system about the design flow solution. Let us define the variable $y = (y_1, y_2, y_3) = (\varphi, \Phi - \Phi_0, \Psi -$

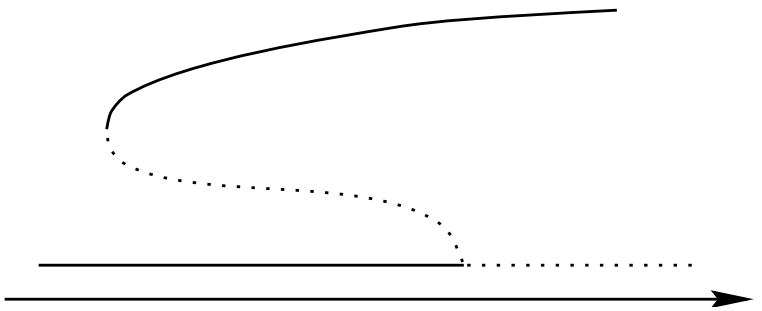

FIG. 2.2. *The design flow undergoes a series of subcritical Hopf bifurcation to surge and stall. The amplitude of the periodic orbits is plotted as a function of the bifurcation parameter.*

Ψ_0). The linearized system is

$$\dot{y} = Ay,$$

where

$$A = \begin{bmatrix} \nu\partial_\theta^2 + \psi_c'(\Phi_0) & 0 & 0 \\ 0 & \frac{1}{l_c}\psi'(\Phi_0) & -\frac{1}{l_c} \\ 0 & \frac{1}{4l_cB^2} & \frac{-\gamma}{4l_cB^2}(F_T^{-1})'(\Psi_0) \end{bmatrix}.$$

This is a block diagonal system, and its stability and bifurcations have been analyzed completely (see [23] and [10]). When the throttle parameter γ is decreased, the average flow Φ decreases as well and the design flow undergoes a series of subcritical Hopf bifurcations. If the parameter B is large enough, there will be one Hopf bifurcation originating from the two dimensional block related to the two ODEs (1.2)–(1.3). This bifurcation gives rise to surge. Furthermore, when $\psi_c'(\Phi) = \nu n^2$, then the nth Fourier harmonic will become unstable and another subcritical Hopf bifurcation occurs. The number of these Hopf bifurcations, which give rise to stall, is bounded by

$$n_{max} \leq \sqrt{\frac{1}{\nu}\max_{\Phi}\psi_c'(\Phi)}. \tag{2.1}$$

Figure 2.2 shows how the amplitude of the periodic orbits originating from the subcritical Hopf bifurcations varies with the bifurcation parameter.

Design flow is stable to the right of the peak of the compressor characteristic. It is desirable to operate the engine on the right side of the peak with as high a pressure rise as possible without risking the system being thrown over to the unstable side by disturbances.

2.2.2. Surge. Surge is a limit cycle in the two ODEs (1.2)–(1.3), where the nonaxisymmetric disturbance is zero, $\varphi = 0$. It has been studied by many authors, among them Greitzer [15] and McCaughan [22], [23]. It arises as a subcritical Hopf bifurcation in the system

$$\dot{\Phi} = \frac{1}{l_c}(\psi_c(\Phi) - \Psi),$$
$$\dot{\Psi} = \frac{1}{4B^2l_c}(\Phi - \gamma F_T^{-1}(\Psi)),$$

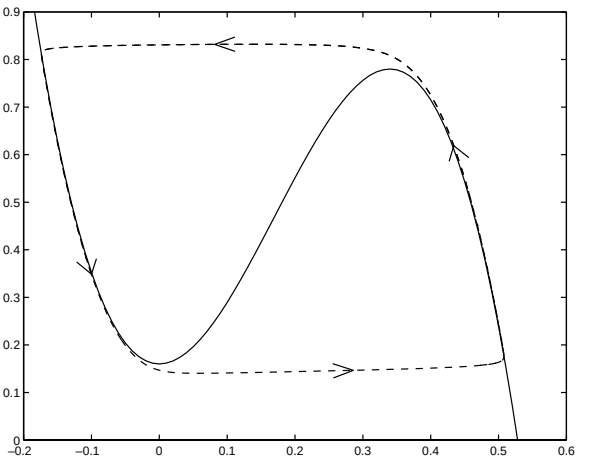

FIG. 2.3. *The surge limit cycle in the* (Φ, Ψ) *plane where* $\varphi = 0$.

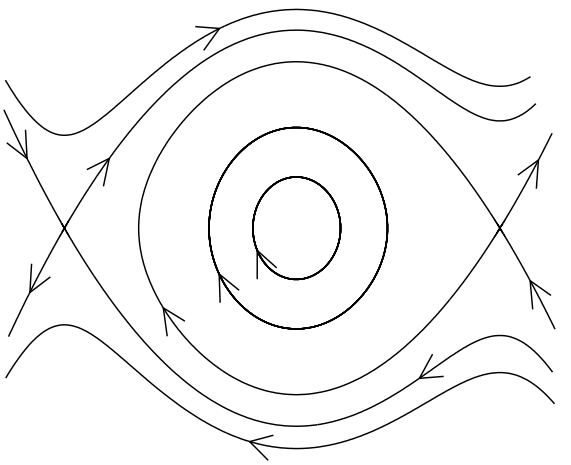

FIG. 2.4. *The phase portrait for Duffing's equation in the general case when* $\gamma \neq \gamma_*$.

which occurs for a large enough B when the throttle parameter γ is decreased. Since the bifurcation is subcritical, we have a one-parameter family of unstable surge cycles that originates from the bifurcation point. This branch bends on itself, and the cycles become stable [23], [10]. These stable cycles are fairly large, and a simulation of one is shown in Figure 2.3.

The solution spends most of its time on the two vertical sides of the cycle. There the slope of the compressor characteristic is negative, so all nonaxisymmetric disturbances are damped.

2.2.3. Stall. Stall is a solitary wave solution. The wave rotates around the unit circle, and the average flow Φ and pressure rise Ψ are constant. When one looks for traveling wave solutions of the vMG equation, the problem can be reduced to finding periodic solutions of Duffing's equation with the correct periods [7], [8]. These periodic solutions lie inside a homoclinic (or heteroclinic) orbit (see Figure 2.4), and since the compressor characteristic is a cubic polynomial, these solutions can be found explicitly

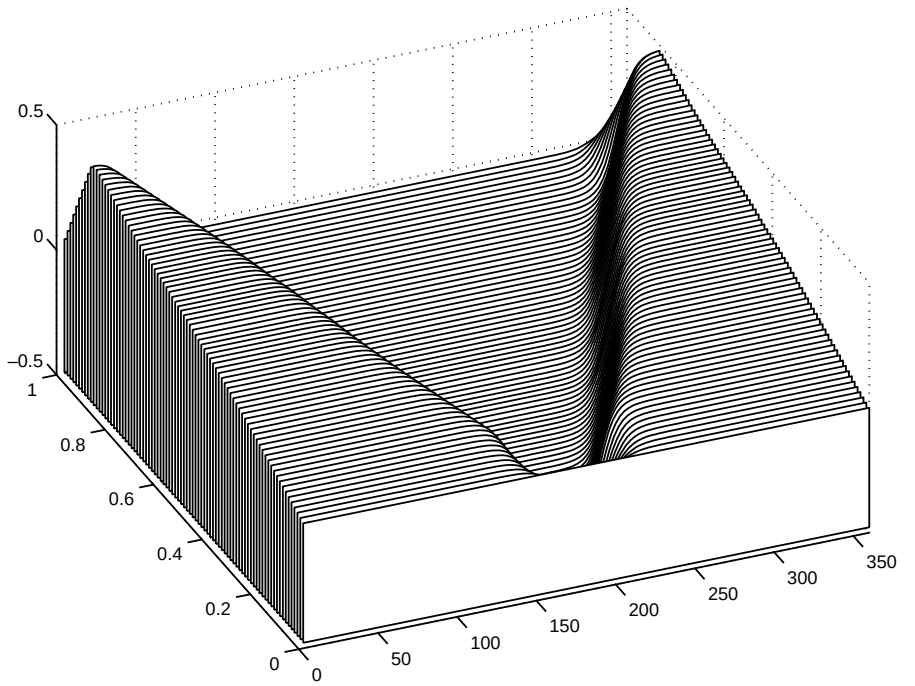

FIG. 2.5. *The one-parameter family of stall cells. As the parameter β varies from zero to one, the stall cell grows from a constant zero solution to a narrow stall cell that slowly widens until it fills out the annulus and the stall disturbance becomes zero again.*

with quadratures. They can be expressed as rational functions of the Jacobi elliptic function ns [29].

$$\varphi(\eta) = \frac{p - q\sqrt{\frac{-B_2}{A_2}}ns\left(\eta(p-q)\sqrt{-B_1A_2} + i\hat{\omega}_2, \sqrt{\frac{B_2A_1}{B_1A_2}}\right)}{1 - \sqrt{\frac{-B_2}{A_2}}ns\left(\eta(p-q)\sqrt{-B_1A_2} + i\hat{\omega}_2, \sqrt{\frac{B_2A_1}{B_1A_2}}\right)}.$$

Here $\hat{\omega}_2$ is half the imaginary period of ns and p, q, A_1, A_2, B_1, B_2 are constants.

The shape of the solitary wave depends on the parameters in the equation; in particular, the shape depends on γ. By varying the parameters we can in fact construct a one-parameter family of stall solutions. The one-parameter family for the one-pulse solitary waves is shown in Figure 2.5.

It can be shown that for a large parameter range (see [7]), the stall solutions in the one-parameter family are asymptotically stable and hence belong to the basic union attractor.

3. Basic controllability. Let us consider now the issue of controllability. In finite dimensional control theory, a system is said to be controllable if for every two points $x_0, x_1 \in X$ and every two real numbers $t_0 < t_1$, there exists a control function u such that the unique solution of the equation

$$\dot{x} = F(x,u), \qquad x(t_0) = x_0 \tag{3.1}$$

satisfies $x(t_1) = x_1$.

In infinite dimensional spaces this notion of controllability is too restrictive. For practical control applications one can never have more than finitely many control parameters, if for no other reason than the fundamentals of computing require computer outputs to be finite. There is therefore no hope that nonlinear evolution equations in infinite dimensional spaces will be controllable in this strict sense in practical applications.

If an evolution equation has an attractor and a basic attractor, its solutions will converge asymptotically to the attractor for all initial conditions and to the basic attractor for almost all initial conditions. The simplest thing one could ask of the control is that it make all or almost all initial conditions give rise to solutions that converge to a given component in the basic attractor. A more stringent requirement on the control would be that it make all or a prevalent set of (almost all) initial conditions give rise to solutions that converge to a given component in the global attractor. This requires one to have enough control authority over the local unstable manifolds of the hyperbolic trajectories in the attractor to make them attractive. Consider the following definitions.

DEFINITION 3.1. (3.1) *is* basically controllable *if for all bounded sets* M, *all* $x_o \in M$, *every minimal component of the basic attractor* $\mathcal{B}_j$, *and all* $\epsilon > 0$, *there exists a finite time* $T(M)$ *and a control function* $u(t)$, *such that the solution* $x(t)$ *with initial data* $x_o \in M$ *satisfies*

$$\|x(t) - \mathcal{B}_j\| < \epsilon$$

for all $t > T(M)$.

This definition says that given an initial point one can steer to any component of the basic attractor in finite time. It is hopeless to get a finite T for x_o lying in a prevalent (full measure) set in the infinite dimensional space, for the reason discussed above. It is not wise to attempt to control every solution in the $\mathcal{A}$-attractor, because in general it ($\mathcal{C}$) contains many hyperbolic solutions and their heteroclinic connections.

DEFINITION 3.2. (3.1) *is* attractively controllable *if for all bounded sets* M, *all* $x_o \in M$, *every trajectory* z *in the attractor* $\mathcal{A}$, *and all* $\epsilon > 0$, *there exists a finite time* $T(M)$ *and a control function* $u(t)$, *such that the solution* $x(t)$ *with initial data* $x_o \in M$ *satisfies*

$$\|x(t) - \omega(z)\| < \epsilon$$

for all $t > T(M)$.

This definition says that given an initial point one can steer to the ω limit set of any trajectory in the $\mathcal{A}$-attractor in finite time.

We will in what follows, for the sake of brevity, also speak of basic controllability as b-controllability and attractive controllability as a-controllability. Clearly a-controllability implies b-controllability. Not surprisingly, the control construction relies heavily on the geometry of the basic attractor. Consequently it is referred to as *basic control*. The remainder $\mathcal{C} = \mathcal{A} \backslash \mathcal{B}$ from section 2.1 plays a large role in basic control. In general one would like to use its heteroclinic connections to move efficiently from one minimal basic attractor to another.

To get stronger results than a-controllability or b-controllability of the form that one could get from an arbitrary initial condition to a point in the attractor in a short time is, in general, hopeless. Since one's control only actuates finitely many dimensions, one would need to wait an arbitrarily long time (determined by the dissipation rate) for the part of the solution which, in some sense, is perpendicular to the control action to settle onto the desired point.

4. Basic control for design flow of the linearized equation. The most important component of the basic attractor of the vMG equation is the design flow component. The goal is to construct a basic control that makes all solutions converge to the design flow. The simplest approach one could take would be to linearize the system about design flow, $(\Phi_0, \Psi_0, 0)$, corresponding to a throttle parameter γ_0, and apply the classical optimal control theory. We define the control parameter $u = \gamma - \gamma_0$, and we make a change of coordinates $(t, \eta) = (t, \theta - \frac{1}{2}t)$ to simplify the equations. Furthermore, we define the variable $y = (y_1, y_2, y_3) = (\varphi, \Phi - \Phi_0, \Psi - \Psi_0)$. The linearized equations can now be written as

$$\dot{y} = Ay + Bu, \tag{4.1}$$

where

$$A = \begin{bmatrix} \nu\partial_\theta^2 + \psi_c'(\Phi_0) & 0 & 0 \\ 0 & \frac{1}{l_c}\psi'(\Phi_0) & -\frac{1}{l_c} \\ 0 & \frac{1}{4l_cB^2} & \frac{-\gamma_0}{4l_cB^2}(F_T^{-1})'(\Psi_0) \end{bmatrix} \tag{4.2}$$

and

$$B = \begin{bmatrix} 0 \\ 0 \\ \frac{1}{4l_cB^2}(F_T^{-1})'(\Psi_0) \end{bmatrix}. \tag{4.3}$$

Since the operator A is sectorial, it generates an analytic semigroup in X. We denote by $T(t)$ the semigroup operator on X, and the norm and inner product will be denoted by $\|\cdot\|$ and $\langle\cdot,\cdot\rangle$, respectively. In this form the equations can be tackled using the standard optimal control theory in Hilbert spaces (see Lions [19] and Banks [3]).

Observe first that this system is block diagonal. It can be split into two parts: a two dimensional part that describes the evolution of the average flow and the pressure rise, and a part of codimension 2 which describes the evolution of stall. This second part does not depend on the control parameter γ and can therefore be integrated separately. In other words, stall does not depend on the control parameter and is therefore uncontrollable. The problem is now reduced to a two dimensional problem.

We seek a feedback control that will minimize the cost functional

$$J(y) = \frac{1}{2}(y_1^2(t_f) + y_2^2(t_f)) + \frac{1}{2}\int_0^{t_f} S(y_1^2(t) + y_2^2(t)) + Ru^2 dt.$$

It is a well-known result [3] that the optimal feedback control is given by

$$u = -\frac{1}{R}B^T Q(t) y(t),$$

where the symmetric matrix $Q(t)$ satisfies the matrix Riccati equation

$$\dot{Q}(t) = -Q(t)A - AQ(t) + \frac{1}{R}Q(t)BB^TQ(t) - SI, \qquad Q(t_f) = I.$$

Here I is the identity matrix and S and R are positive constants. Solving the Riccati equation is equivalent to solving the three ODEs

$$\begin{aligned} \dot{q}_{11} &= (\tfrac{1}{4l_cB^2}(F_T^{-1})'(\Psi_0))^2 q_{12}^2 - S - 2(a_{11}q_{11} + a_{21}q_{12}), \\ \dot{q}_{12} &= (\tfrac{1}{4l_cB^2}(F_T^{-1})'(\Psi_0))^2 q_{12}q_{22} - a_{12}q_{11} - (a_{11} + a_{22})q_{12} - a_{21}q_{22}, \\ \dot{q}_{22} &= (\tfrac{1}{4l_cB^2}(F_T^{-1})'(\Psi_0))^2 q_{22}^2 - S - 2(a_{12}q_{12} + a_{22}q_{22}), \\ q_{ij}(t_f) &= \delta_{ij}, \end{aligned} \tag{4.4}$$

where δ_{ij} is the Kronecker delta. This system can be solved backwards in time numerically. The optimal feedback control is now given by

$$u = \frac{1}{4l_c B^2}(F_T^{-1})'(\Psi_0)((\Phi - \Phi_0)q_{12}(t) + (\Psi - \Psi_0)q_{22}(t)).$$

Design flow solutions that sit to the right of the peak on the compressor characteristic (see Figure 2.1) have the property that all the uncontrollable modes are stable, so in this case the design flow is b-controllable and, in fact, a-controllable. However, the fact that stall is uncontrollable in the linear system renders this control of limited use. It is well known that in the nonlinear system for design flow solutions close to the peak of the characteristic, small nonaxisymmetric disturbances can cause the system to go into stall. On the other hand, the result by Banaszuk, Hauksson, and Mezić [2] proves that design flow can be globally stabilized by using only throttle control. Their control is, however, not optimal in any sense of the word, and it reacts very violently to high frequency disturbances which are damped in the viscous model. The question that now arises is whether there is something in between these two control constructions, i.e., does there exist a control which globally stabilizes the design flow but does not require as much control effort as the control constructed by Banaszuk, Hauksson, and Mezić? We tackle this problem in the next section.

5. Basic control of design flow for the nonlinear equation. The basic attractor for constant throttle functions has been analyzed completely [7], [8], and one would like to use this knowledge of the asymptotic dynamics when constructing a control law. However, when γ is no longer constant but a function of the state variables, the components of the basic attractor may change, altering the asymptotic dynamics.

Let us assume for now that we only consider control strategies that move the throttle in an adiabatic fashion. Restricting the control to this class guarantees that the basic attractor is unchanged. The best one can hope to do here is to slide the solution along the basic attractor until it reaches the desired operation point. If stall occurs, then one slides the system along the branch of stable stall cells by increasing γ until the saddle-node bifurcation point is reached, stall ceases to exist, and the flow converges to design flow. This design flow is achieved at a very low pressure rise. In order to increase the pressure rise we decrease γ again until the desired operation point is reached. Figure 5.1 shows the bifurcation diagram for the first stall solution.

Within the class of adiabatic controls, this is the optimal control. When one considers the larger class of controls that are not necessarily adiabatic, this control strategy is no longer optimal. It has, however, been shown that a reduced order model, which reduces the flow to the basic attractor, captures the dynamics of the full model not only qualitatively but also quantitatively [8]. Transient behavior, while the flow is going from one component of the basic attractor to another, is also well captured. With this in mind it makes sense to modify the adiabatic control construction by tracking trajectories on the basic attractor. If the tracking is done in an optimal fashion, one would hope that the resulting control strategy is close to an optimal strategy with respect to some cost function. We claim that our basic control strategy is in this sense near optimal.

Let $\xi(t)$ be a parameterization of a family of stationary solutions in the basic union attractor $\cup_\gamma \mathcal{B}$. Note that since we are working in a rotating frame of reference, (η, t), stall solutions will be stationary solutions. Then, corresponding to $\xi(t)$, we can find $\bar{\gamma}(t)$ such that for $\gamma = \bar{\gamma}(t)$, $\xi(t)$ is a stationary solution of (1.1)–(1.3). We

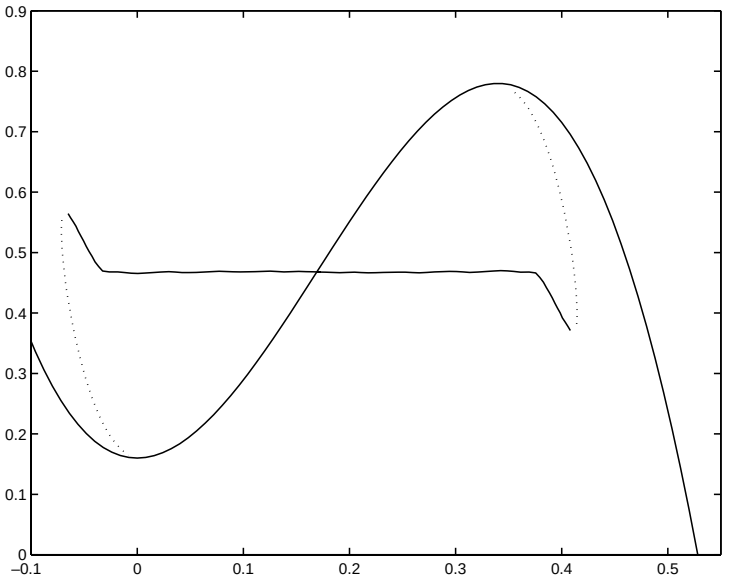

FIG. 5.1. *This figure shows the bifurcation diagram for the first stall solution in the* (Φ, Ψ)*-plane. The flat solid curve represents the stable branch, and the dotted curves represent the unstable branches of stall cells.*

denote the solution of the system (1.1)–(1.3) as $x(t) = (\Phi, \Psi, \varphi)(t) = \xi(t) + y(t)$ and the control parameter $\gamma = \bar{\gamma}(t) + u(t)$. Let us now linearize this system about the trajectory $\xi(t)$ and write it as

$$\dot{y} = A(t)y + B(t)u - \dot{\xi}(t). \tag{5.1}$$

Here $A(t)$ and $B(t)$ depend on time through the trajectory $\xi(t)$. Our goal is to make y as small as possible with very little control effort. In other words, we want to find a regulator for (5.1) which is optimal with respect to the cost function

$$J(u) = \frac{1}{2}\|S_f y(t_f)\|^2 + \frac{1}{2}\int_0^{t_f} \|Sy(t)\|^2 + Ru^2(t)dt,$$

where R is a constant and S_f and S are symmetric positive definite linear operators.

This is a well-known problem, and it can be solved exactly (see Sage and White [28] or Banks [3]). The optimal feedback control is given by

$$u(t) = -\frac{1}{R}B^T(t)(Q(t)y(t) - \zeta(t)),$$

where the symmetric operator $Q(t)$ satisfies the equation

$$\dot{Q}(t) = -Q(t)A(t) - A(t)Q(t) + \frac{1}{R}Q(t)B(t)B^T(t)Q(t) - S, \qquad Q(t_f) = S_f, \tag{5.2}$$

and the function $\zeta(t)$ satisfies

$$\dot{\zeta}(t) = -\left(A(t) - \frac{1}{R}B(t)B^T(t)Q(t)\right)^T \zeta(t) - Q(t)\dot{\xi}(t), \qquad \zeta(t_f) = 0. \tag{5.3}$$

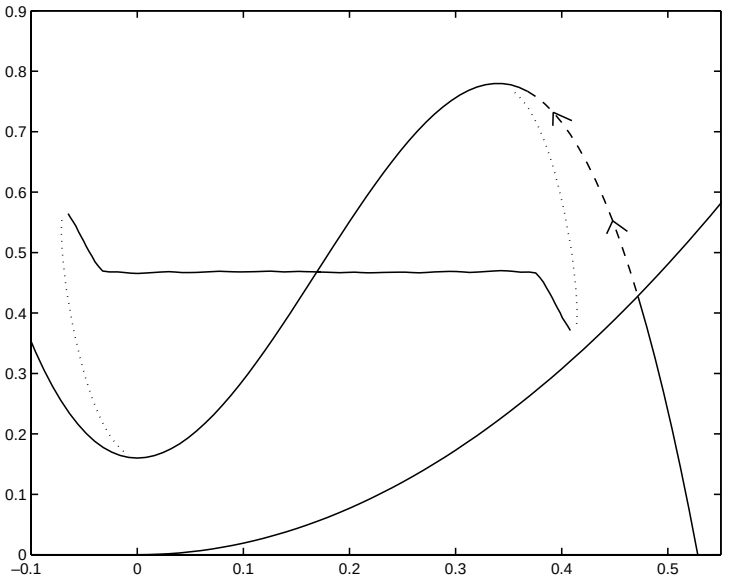

FIG. 5.2. *This figure shows the throttle setting $\gamma = \gamma_1$ that defines the start of the trajectory ξ_1, which is shown as a dashed line.*

These equations can be solved backwards in time to yield the optimal control u.

It turns out that when one linearizes the system about a trajectory on the basic attractor, then all but finitely many directions in state space will be uncontrollable. The uncontrolled dynamics are stable, and, as a result, (5.2) and (5.3) will reduce to finitely many ODEs.

5.1. Construction of the controller. To make the construction of the controller as simple and intuitive as possible, we proceed in the following way. When a disturbance occurs in the system that is large enough so that the system cannot recover without intervention, we change the control parameter to a setting where the only component in the basic attractor is the design flow. This consists of increasing γ to a level γ_1 so that the throttle characteristic no longer intersects the branch of stall cells. We then wait until the flow is in a small-enough neighborhood U of the design flow. This design flow setting is, however, at a low pressure rise level, so to increase the pressure rise we now track a trajectory ξ_1 to the desired design flow setting (see Figure 5.2). As we will prove later, if the state is close enough to the starting point of ξ_1 and the cost on the control small enough, this strategy will work for all initial disturbances.

This control construction will still be very close to the original one as the system will settle into stall or surge very fast and then traverse near the basic attractor towards the design flow corresponding to the throttle setting γ_1.

The linearization of the system about the trajectory ξ_1 is exactly that given by (4.2) and (4.3), except for that now these operators are time-dependent, i.e., instead of (Φ_0, Ψ_0) we have $(\Phi, \Psi)_{\bar{\gamma}(t)}$. Just like before, there is an uncontrollable subspace of codimension 2, but since we are on the right side of the peak of the characteristic, this space is stable and small disturbances will decay in time. We therefore only need to consider the first two modes which describe the flow in the (Φ, Ψ)-plane, and it

suffices to know q_{11}, q_{12}, q_{22}, ζ_1, and ζ_2. The equations for these coefficients are

$$\begin{aligned}
\dot{q}_{11} &= (\tfrac{1}{4l_cB^2}(F_T^{-1})'(\Psi_{\bar{\gamma}(t)}))^2\tfrac{q_{12}^2}{R} - s_{11} - 2(a_{11}(t)q_{11} + a_{21}(t)q_{12}),\\
\dot{q}_{12} &= (\tfrac{1}{4l_cB^2}(F_T^{-1})'(\Psi_{\bar{\gamma}(t)}))^2\tfrac{q_{12}q_{22}}{R} - s_{12} - a_{12}(t)q_{11}\\
&\quad -(a_{11}(t) + a_{22}(t))q_{12} - a_{21}(t)q_{22},\\
\dot{q}_{22} &= (\tfrac{1}{4l_cB^2}(F_T^{-1})'(\Psi_{\bar{\gamma}(t)}))^2\tfrac{q_{22}^2}{R} - s_{22} - 2(a_{12}(t)q_{12} + a_{22}(t)q_{22}),\\
q(t_f)_{ij} &= s_{fij}
\end{aligned} \tag{5.4}$$

and

$$\begin{aligned}
\dot{\zeta}_1 &= -a_{11}(t)\zeta_1 - (a_{21}(t) - (\tfrac{1}{4l_cB^2}(F_T^{-1})'(\Psi_{\bar{\gamma}(t)}))^2\tfrac{q_{21}}{R})\zeta_2 - q_{11}\dot{\xi}_1 - q_{12}\dot{\xi}_1,\\
\dot{\zeta}_2 &= -a_{12}(t)\zeta_1 - (a_{22}(t) - (\tfrac{1}{4l_cB^2}(F_T^{-1})'(\Psi_{\bar{\gamma}(t)}))^2\tfrac{q_{22}}{R})\zeta_2 - q_{12}\dot{\xi}_1 - q_{22}\dot{\xi}_1,\\
\zeta(t_f) &= 0.
\end{aligned} \tag{5.5}$$

The basic feedback control is now given by

$$u(t) = \gamma_1 \tag{5.6}$$

if $x(t)$ has not reached the neighborhood U and

$$u(t) = \frac{1}{4l_cB^2R}(F_T^{-1})'(\Psi_{\bar{\gamma}(t)})[(\Phi - \Phi_{\bar{\gamma}(t)})q_{12}(t) + (\Psi - \Psi_{\bar{\gamma}(t)})q_{22}(t) + \zeta_2] \tag{5.7}$$

otherwise.

THEOREM 5.1. *There exists an open set U around $\xi_1(0) = (\varphi_1, \Phi_1, \Psi_1)$, a constant R, and a prevalent set $Y \subset X$ such that the control strategy given by* (5.6) *and* (5.7) *make all solutions of the vMG equation, with initial conditions in Y, converge to the desired stable design flow.*

Proof. For $u = \gamma_1$, the only component in the basic attractor is the design flow at the starting point of $\xi_1 = \xi_1(0)$. Hence there exists a prevalent set $Y \subset X$ such that for all initial conditions in Y the solution will converge to $\xi_1(0)$. Let $U \subset X$ be an open neighborhood of $\xi_1(0)$. By making U smaller, we can make sure that the stall disturbance is as small as we please and that (φ, Φ, Ψ) is as close to the starting point of the trajectory ξ_1 as we please before we start tracking the trajectory.

On the other hand, if there is no stall disturbance, i.e., if $\varphi = 0$, then by decreasing R we can track the trajectory ξ_1 as closely as we want. The feedback control is robust with respect to small disturbances, so as long as the stall disturbance stays small we can guarantee that we stay within a small neighborhood of the trajectory. It therefore remains only to show that small stall disturbances will remain small.

The energy method for (1.1) gives us that

$$\begin{aligned}
\tfrac{1}{2}\tfrac{d}{dt}\|\varphi\|_1^2 &\le -\nu\|\varphi_\eta\|_1^2 + \tfrac{1}{2\pi}\int_0^{2\pi}\psi_c'(\Phi + \varphi)\varphi_\eta^2 d\theta\\
&\le (-\nu + \tfrac{1}{2\pi}\max_\theta \psi_c'(\Phi + \varphi))\|\varphi\|_1^2.
\end{aligned}$$

Here $\|\cdot\|_1$ is the Sobolev norm in $\bar{H}^1$. The trajectory ξ_1 lies to the right of the peak of the compressor characteristic, and on that side the derivative of the characteristic is negative. By making Φ stay close enough to the trajectory and the L^∞ norm of φ small enough, we can guarantee that the second term will be less than or equal to

zero. The L^∞ norm is bounded by the $\bar{H}^1$ norm, and as a result if (φ, Φ, Ψ) stays close to the trajectory, then small stall disturbances will decay. □

One can clearly construct the trajectory so that the point being tracked by the control will be moving in a smooth fashion. Furthermore, parameterizing the trajectory in a very slow manner approaches the adiabatic control construction which will guarantee that γ will be positive and bounded away from zero. This then guarantees that the control given will be a smooth function, and the existence and regularity results mentioned in the introduction still hold.

5.2. Modifications of control construction. The control construction given here above is but one of many possible constructions. It could be beneficial to construct a regulator for the starting point of ξ_1 instead of just setting $u = \gamma_1$, or one could track a trajectory along the stall branch. The first extension is very simple, but the other one is not as trivial and we outline an approach to it here. The hard part lies in linearizing the system in the correct basis so that the problem reduces to a finite dimensional problem.

In [7] we proved that for specific parameter values when one linearizes the system about a stall solution there is a subspace of codimension 3 which is uncontrollable but stable for a large parameter range. The three dimensional subspace which can be influenced by the throttle parameter is spanned by the average flow, the pressure rise, and one more vector. This vector corresponds to the internal degree of freedom that widens and shrinks the stall cell, and is given by $(\varphi^2 - \overline{\varphi^2}, 0, 0)$, where φ is the stall solution and $\overline{\varphi^2}$ represents the average of φ^2. One of the key elements of that proof was that a part of the linearized operator, the Lamé operator, given by

$$L = \nu\partial_{\eta\eta} + \psi_c'(\Phi + \varphi),$$

had two eigenvectors given by $\varphi^2 + a_1$ and $\varphi^2 + a_2$, and those two combined to give the vector that interacted with pressure rise and average flow.

Now let (φ, Φ, Ψ) be a general stall solution. Then the corresponding operator L will have one zero eigenvalue corresponding to translations of the solution.

THEOREM 5.2. *Assume that the self-adjoint operator L has two eigenvectors of the form $\chi^+ = \varphi^2 + k_1^+\varphi + k_2^+$ and $\chi^- = \varphi^2 + k_1^-\varphi + k_2^-$ corresponding to distinct eigenvalues, each with one dimensional eigenspace. Assume also that the spectrum has a simple zero eigenvalue and the rest of the spectrum is negative.*

Then the vMG equation linearized about the stall solution has an uncontrollable subspace $\mathcal{Q}$ of codimension 3 which is stable, and $\mathcal{Q}^\perp$ is the span of $\{(\chi^+ - \overline{\chi^+}, 0, 0), (0, 1, 0), (0, 0, 1)\}$.

Here the overline represents the angular average as before.

Proof. We know from [7] that the spectrum of the Lamé potential consists of five single eigenvalues and the rest of the spectrum is negative and double and converges to infinity. Varying the Fréchet derivative ψ_c' by a small amount will be a relatively compact perturbation which will perturb the spectrum only slightly [18]. In particular, we can assume that the spectrum of L converges to $-\infty$.

Because (φ, Φ, Ψ) is a traveling wave solution of (1.1)–(1.3) and since the characteristic is a cubic polynomial, we know that

$$\varphi_{\eta\eta} = a\varphi^3 + b\varphi^2 + c\varphi + d$$

for some constants a, b, c, d which depend on Φ. By completing the quadratures, one can also show that φ satisfies the equation

$$\frac{1}{2}(\varphi_\eta)^2 = \frac{1}{4}a\varphi^4 + \frac{1}{3}b\varphi^3 + \frac{1}{2}c\varphi^2 + d\varphi + e$$

for some constant e. Using these two equations, one can show that the two eigenvalues λ^+ and λ^- corresponding to the two eigenvectors χ^+ and χ^- are the real roots of

$$(c - \nu\lambda)\left(\frac{\nu\lambda}{3a} + \frac{c}{a} - \frac{2b^2}{9a^2}\right) - \frac{2bd}{3a} - 4e = 0,$$

and we have

$$\begin{aligned} k_1^+ &= \tfrac{2b}{3a} = k_1^- \\ k_2^+ &= \tfrac{1}{c-\nu\lambda^+}\left(\tfrac{2bd}{3a} + 4e\right) \\ k_2^- &= \tfrac{1}{c-\nu\lambda^-}\left(\tfrac{2bd}{3a} + 4e\right). \end{aligned}$$

Notice that

$$\psi_c'(\Phi + \varphi) = \chi^+ + C = \chi^- + C'$$

for some constants C and C'.

Let $\phi \in H^1 \backslash \mathrm{span}\{\chi^+, \chi^-\}$, and define $\chi = \chi^+ - \overline{\chi^+} = \chi^- - \overline{\chi^-}$. Since eigenspaces corresponding to different eigenvalues are orthogonal and $\mathrm{span}\{\chi^+, \chi^-\} = \mathrm{span}\{\chi, 1\}$, we know that $\langle \phi, 1\rangle = 0$ and thus $\phi \in \bar{H}^1$. Furthermore, since $\psi_c' \in \mathrm{span}\{\chi^+, \chi^-\}$, we have $\overline{\psi_c'}\phi = \langle \psi_c', \phi\rangle = 0$. We can now conclude that if ϕ lies in an eigenspace of L corresponding to the eigenvalue λ, then $(\phi, 0, 0)$ lies in an eigenspace of A corresponding to the same eigenvalue. Let $\mathcal{Q}$ be the subspace spanned by all such functions, and notice that we have $A\mathcal{Q} \subset \mathcal{Q}$.

For any $\phi \in H^1 \backslash \mathrm{span}\{\chi^+, \chi^-\} \subset \bar{H}^1$, we have $(\phi, 0, 0) \in \mathcal{Q}$, and we can conclude that $\mathrm{codim}(\mathcal{Q})$ in $H^1 \times \mathbf{R}^2$ is 4. Since $\mathcal{Q} \subset \bar{H}^1 \times \mathbf{R}^2$, we can also conclude that $\mathrm{codim}(\mathcal{Q})$ in $\bar{H}^1 \times \mathbf{R}^2$ is 3. The orthogonal complement of $\mathcal{Q}$ is $\mathcal{Q}^\perp = \mathrm{span}\{(\chi^+ - \overline{\chi^+}, 0, 0), (0, 1, 0), (0, 0, 1)\}$ and one quickly verifies that $A\mathcal{Q}^\perp \subset \mathcal{Q}^\perp$. From all of the above we conclude that the spectrum of A is

$$\sigma(A) = \sigma(A|_{\mathcal{Q}}) \cup \sigma(A|_{\mathcal{Q}^\perp})$$

and that A is block diagonal with two blocks. The block corresponding to $\mathcal{Q}$ is orthogonal to the control action and is therefore uncontrollable. We know that $\mathcal{Q}$ contains a one dimensional center subspace corresponding to direction of propagation of the stall solution, and the rest of $\mathcal{Q}$ belongs to the stable subspace of A. ∎

As a result of the above theorem, when one wants to track a trajectory along stall solutions, one only has to consider the projection of the linearized system onto the three dimensional space $\mathcal{Q}^\perp$. One therefore only needs to consider a 3×3 projection of $Q(t)$.

Remark 5.3. Theorem 5.2 has some implications for nonaxisymmetric control actuation. If we assume control actuation that does not destroy this spectral structure of the equation, then the theorem would indicate that the nonaxisymmetric component of the control action should be shaped like the vector $\chi = \chi^+ - \overline{\chi^+}$. This would move the state along the one-parameter family of stall cells as opposed to trying to push off this strongly attracting surface.

Figure 5.3 shows the stall cell and the vector χ for two different parameter settings: on the left for the specific parameter values chosen in [7] and on the right for a general parameter setting. This figure shows that the general characteristics of the vector χ are the same.

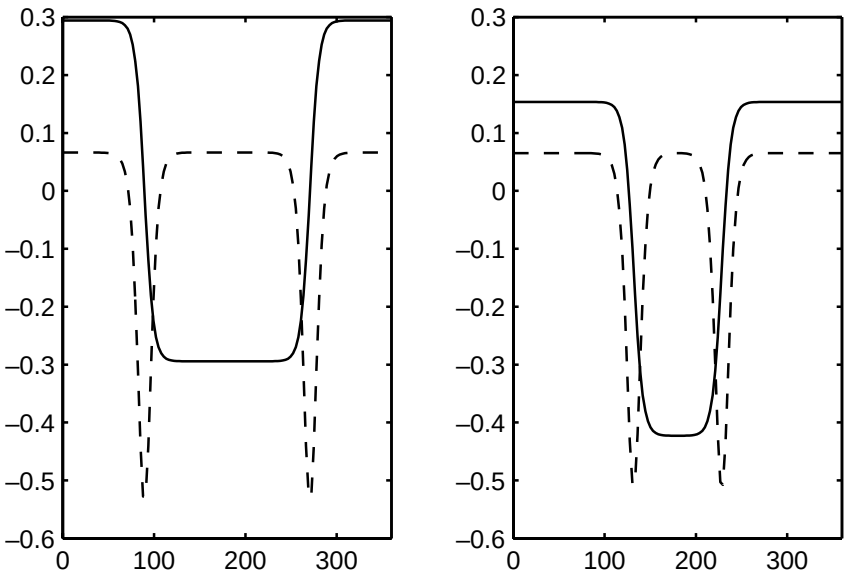

FIG. 5.3. *This figure shows stall cells and the vector χ for the specific parameter settings given in* [7] *on the left and a general parameter setting on the right. The stall cell is given by a solid line and χ by a dashed line.*

6. Numerical simulations. Here we present some numerical simultions that display how our control (5.6)–(5.7) performs, and its performance is compared with that of the backstepping control given by Banaszuk, Hauksson, and Mezić [2]. For all of the simulations the initial condition is a small disturbance in the average flow and pressure rise but a large disturbance in the stall direction. The two ODEs (1.2) and (1.3) are solved by a Runge–Kutta routine, which is coupled together with a Lax–Wendroff scheme, which solves (1.1).

The backstepping control is a much more forceful control that uses more control effort, as can be seen in Figure 6.1. It does, however, kill the disturbance faster, as seen in Figures 6.2, 6.3, and 6.4. The state has a much smaller excursion in the (Φ, Ψ)-plane with the basic control, and in particular the pressure rise never drops completely (see Figures 6.5, 6.6, and 6.4).

It should be clear from these simulations that the backstepping control reacts too strongly to stall disturbances. One could argue that the gain chosen for the stall component in the control construction should be decreased, but here we have set it at its smallest allowed level, or equal to $\sqrt{\pi/6}$ [2].

Surge is in general harder to control than stall. It requires more control effort and is a more violent instability. We present here some simulations which show how the two controls handle a surging compressor. As can be seen in Figure 6.7, both controls are saturated. The control strategy with the least effort that could recover design flow from surge would probably just involve increasing γ slightly and then waiting for the system to complete a single surge oscillation. Figures 6.8 and 6.9 show the (Φ, Ψ) phase planes during the transient, and Figures 6.10 and 6.11 show how the stall transient behaves. The backstepping control does a better job at recovering design flow quickly, but at a greater cost, as can be seen in Figure 6.7. The pressure rise in the compressor is shown as a function of time in Figure 6.12.

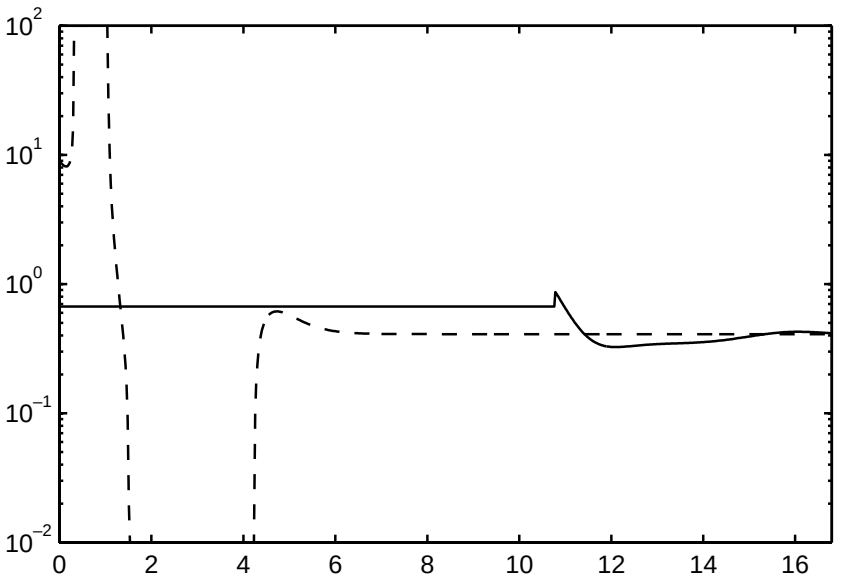

FIG. 6.1. *Here we compare on a logarithmic scale the control effort by the two strategies. The backstepping control result is shown in a dashed line and the basic control in a solid line. The backstepping control kills the disturbance in half the time it takes our control to do so, but at the cost of using extreme control effort.*

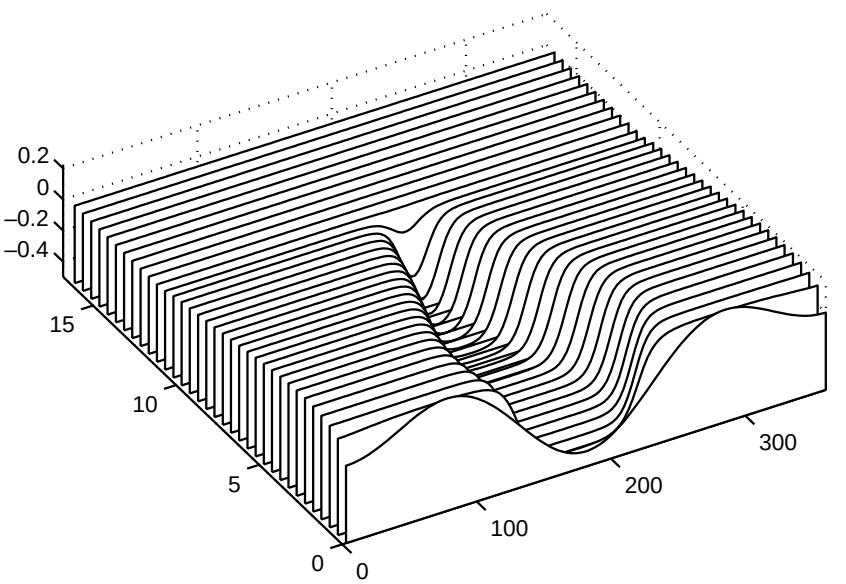

FIG. 6.2. *The evolution of the stall disturbance under the basic control. The system goes into a fully blown stall which then slowly narrows until it vanishes.*

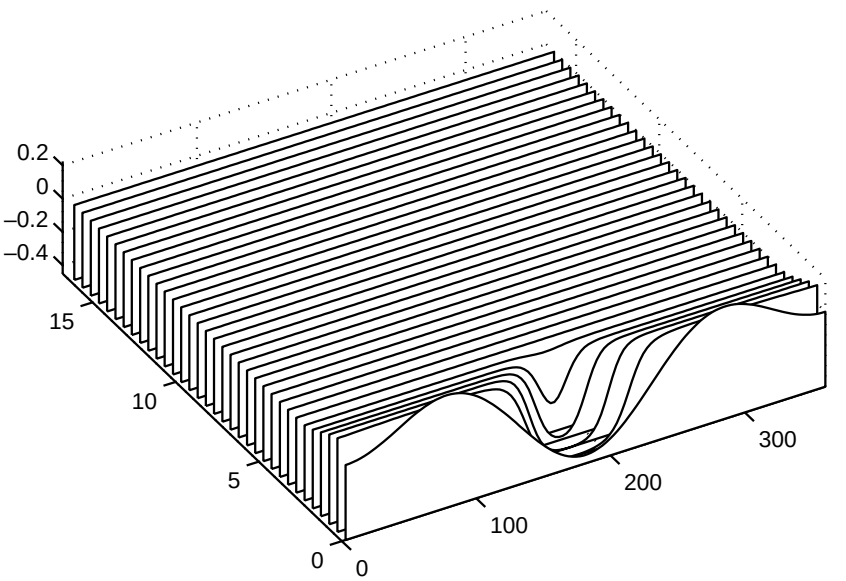

FIG. 6.3. *The evolution of the stall disturbance under the backstepping control. Here the system never reaches a fully blown stall because the control reacts very strongly to stall disturbances.*

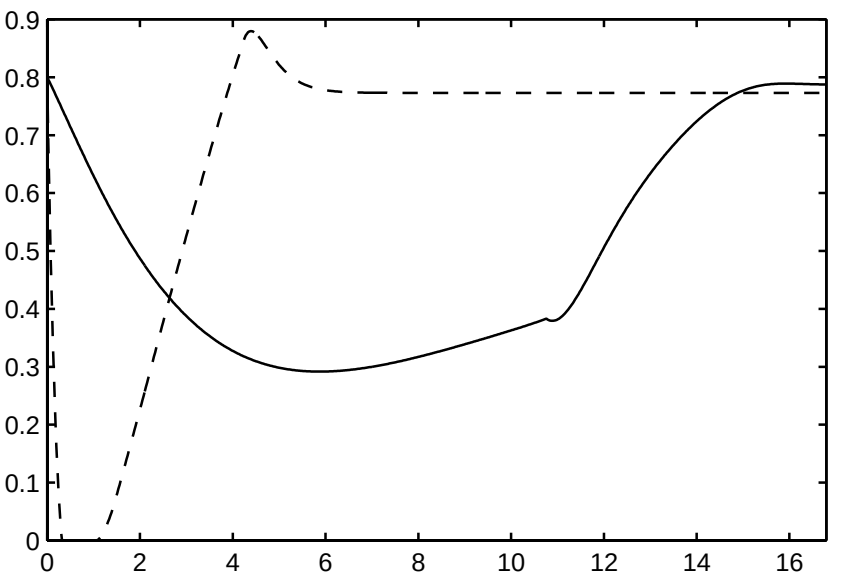

FIG. 6.4. *Here we compare the pressure rise delivered by the compressor under the two strategies. The backstepping control result is shown in a dashed line and the basic control in a solid line. The backstepping control kills the disturbance in half the time it takes our control to do so. However, the pressure rise drops considerably more for the backstepping control.*

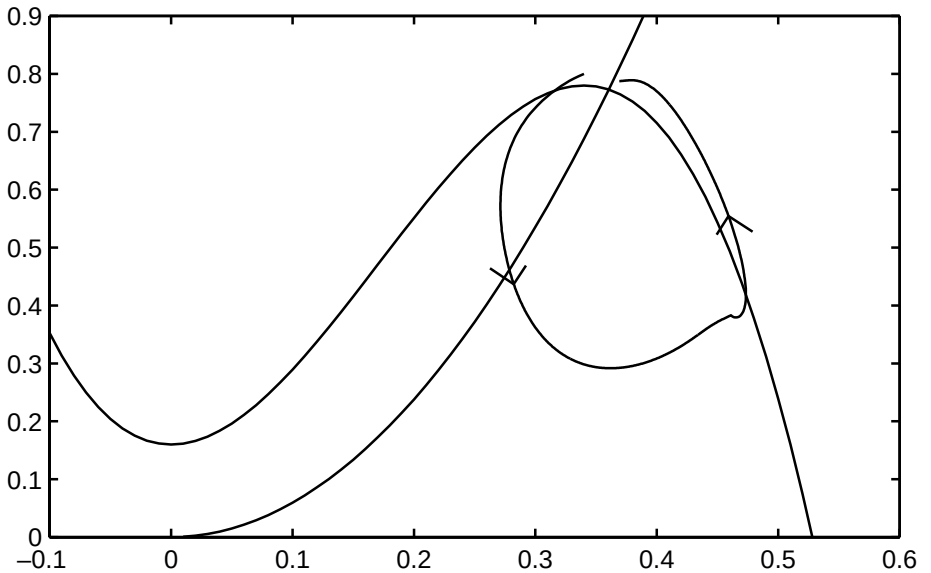

FIG. 6.5. *The* (Φ, Ψ)*-phase plane for the basic control. The large disturbance grows into stall, but design flow is then recovered.*

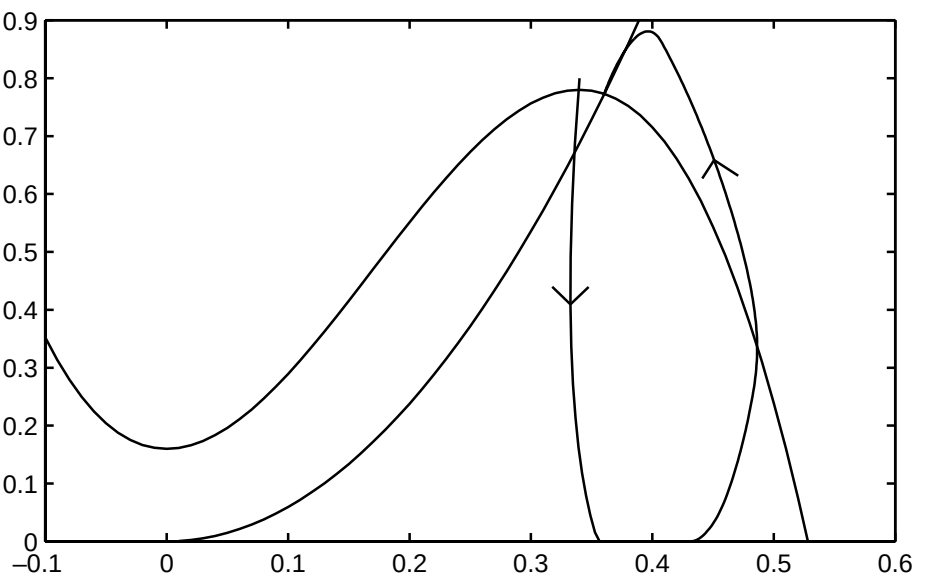

FIG. 6.6. *The* (Φ, Ψ)*-phase plane for the backstepping control. The large disturbance grows into stall, and here the excursion in this phase plane is much larger than before. There is a complete loss of pressure rise over a certain time interval. Design flow, however, is recovered.*

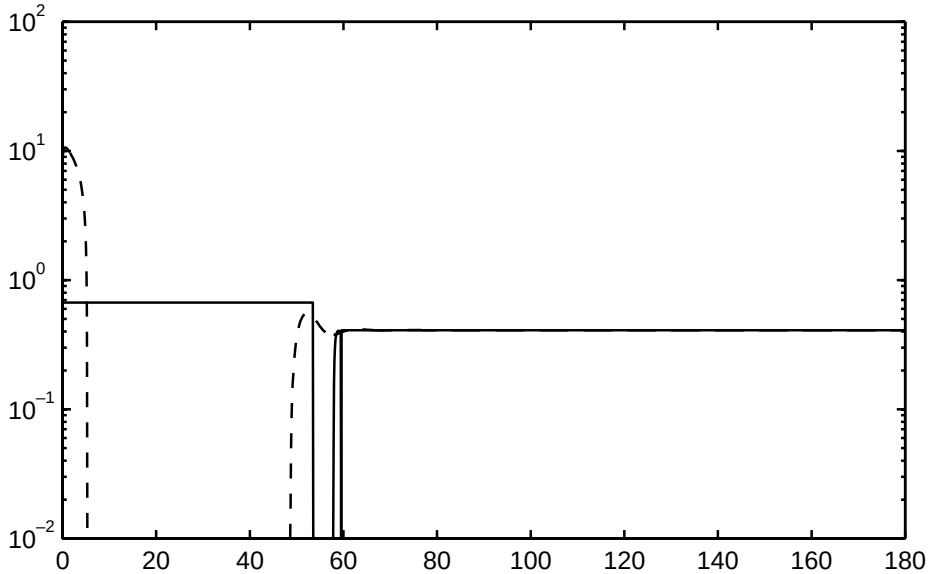

FIG. 6.7. *Here we compare on a logarithmic scale the control effort by the two strategies. The backstepping control result is shown in a dashed line and our control in a solid line. The backstepping control recovers design flow considerably faster than the basic control. Both control strategies saturate which indicates how hard it is to control surge.*

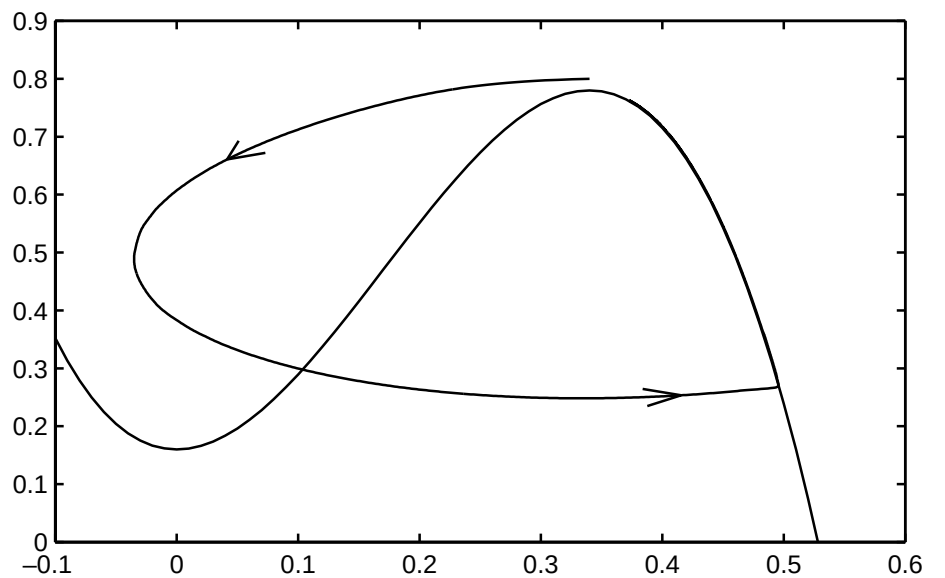

FIG. 6.8. *The* (Φ, Ψ)*-plane when controlling a surging compressor with the basic control.*

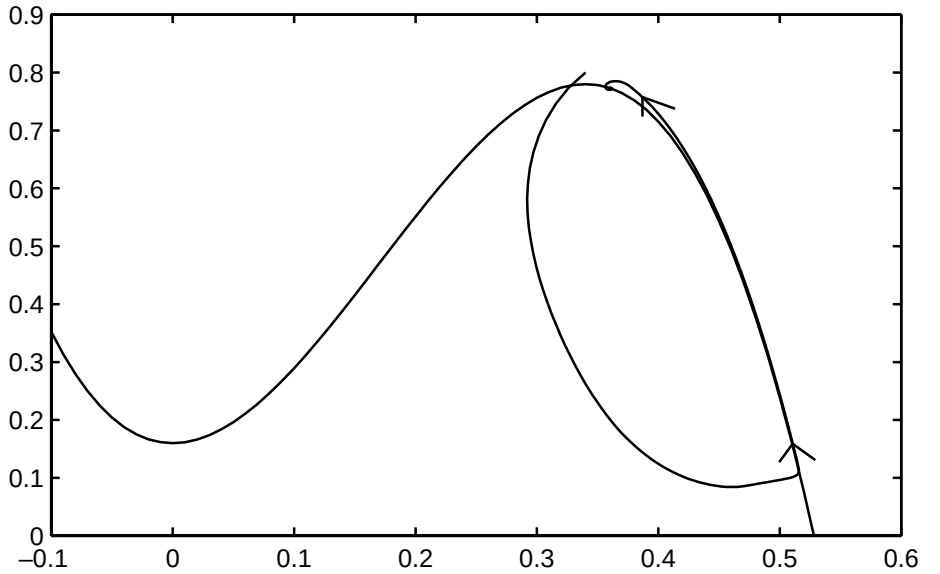

FIG. 6.9. *The* (Φ, Ψ)*-plane when controlling a surging compressor with the backstepping control.*

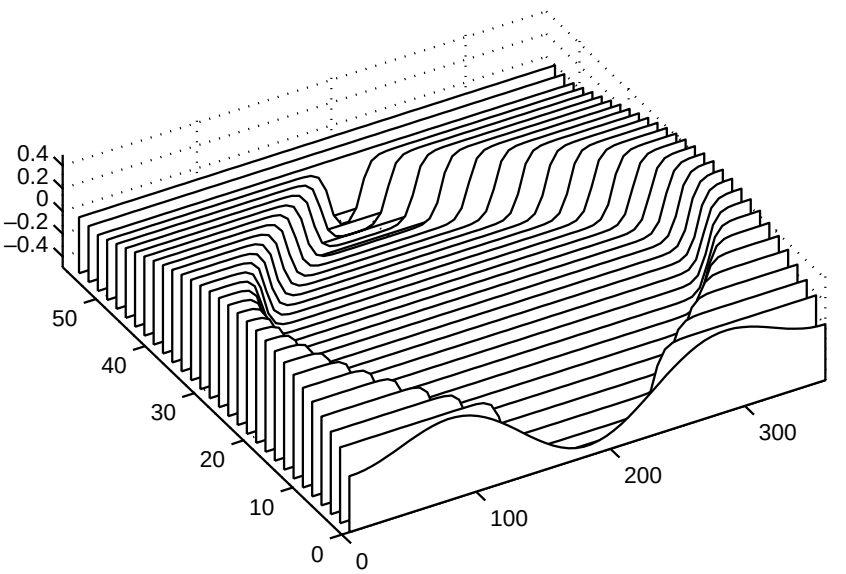

FIG. 6.10. *The transient behavior in* φ *as the basic controller recovers design flow.*

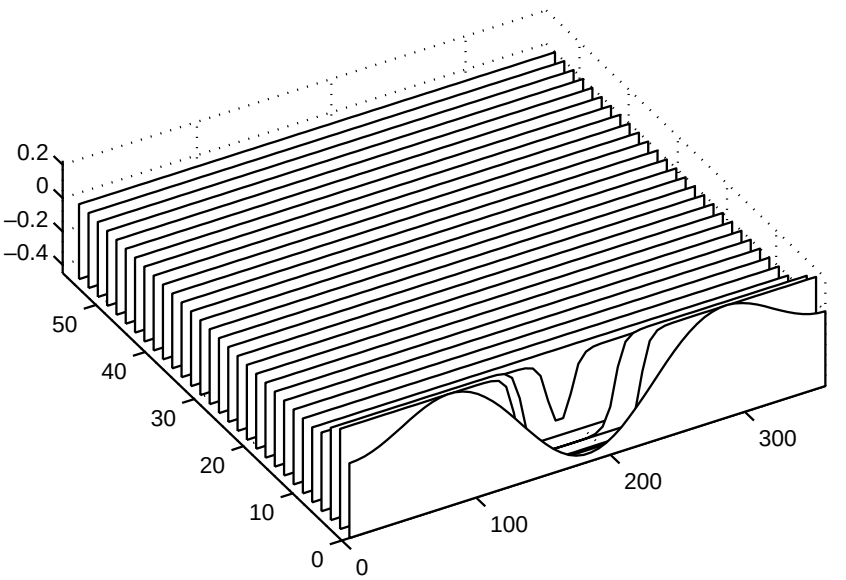

FIG. 6.11. *The transient behavior in φ as the backstepping controller recovers design flow.*

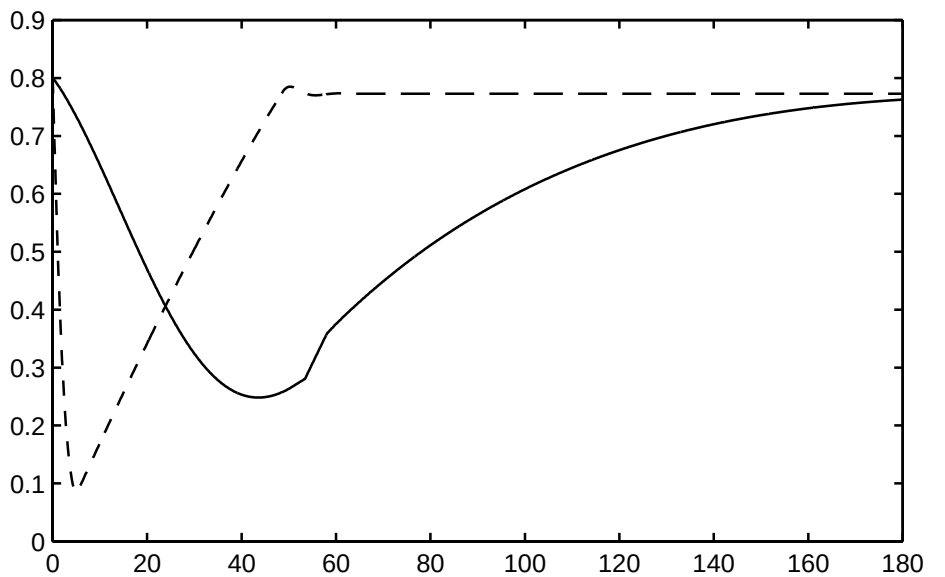

FIG. 6.12. *Here we compare the pressure rise delivered by the compressor under the two strategies during surge instability. The backstepping control result is shown in a dashed line and the basic control in a solid line. The backstepping control kills the disturbance in a shorter time than it takes the basic control to do so.*

7. Basic controllability of the vMG equation. We consider here the problem of when the vMG equation is b-controllable. Although this problem is not of great practical importance, it is more important theoretically to show that there exists at least one example of a system which is b-controllable.

Here above we have constructed a basic feedback control for design flow. In order to have b-controllability, it suffices to show that we can get from any trajectory of the attractor $\mathcal{A}$ to any component in the basic attractor. However, the next theorem says that this is impossible with only throttle control.

THEOREM 7.1. *If the global attractor of the vMG equation contains more than one stall component, then the vMG equation with throttle control only is not b-controllable.*

Proof. The only way we can influence the stall part of the equation, with only throttle control at our disposal, is through Φ (see (1.1)). Consider now a solution of the vMG equation such that $\varphi(0,\theta) = k\sin\theta$ for some nonzero constant k. If we consider only (1.1), then this is a time dependent parabolic equation for which it is well known that the number of local maxima and local minima is nonincreasing in time. It is therefore not possible to start with this initial condition and use throttle control to get to a stall component which has more than one local maximum and one local minimum. In fact, one can show that this is true for all initial conditions close enough to the one chosen here, so the vMG equation is not b-controllable with throttle control. □

Assume now that the parameter B is small enough that there is no surge component in the basic attractor [7], and further assume that we can influence the flow in a nonaxisymmetric way by air injection or bleeding in addition to throttle control. We will avoid the difficult issue of exactly how to model the air injection but will instead make the following simple hypothesis.

Hypothesis 1. If the flow at time t is axisymmetric, i.e., $\varphi(t,\cdot) = 0$, then by use of air injectors or bleeding we can modify the flow so that for $j = 1,\dots,n$ and some small $\epsilon > 0$, $\varphi(t+\epsilon,\cdot)$ will be small but nonzero, $2\pi/j$ periodic, and will have exactly j local maxima and minima.

We have already proven in Theorem 5.1 that there exists a basic feedback control, which uses only throttle, that makes all initial conditions converge asymptotically to the stable design flow component $\mathcal{B}_0$. To prove b-controllability, it therefore suffices to construct a set of controls that take us from the design flow to any one of the stall components $\mathcal{B}_1,\dots,\mathcal{B}_n$. Recall that if the basic attractor has n stall components, then as one decreases the throttle γ the design flow undergoes n supercritical Hopf bifurcations which give rise to the stall solutions [7], [8], [23].

THEOREM 7.2. *Let the basic attractor of the Moore–Greitzer equation consist of design flow and n stall solutions $\mathcal{B}_1,\dots,\mathcal{B}_n$. Assume* Hypothesis 1 *and that we have throttle control. Then the vMG equation is b-controllable.*

Proof. We start with the stable design flow $\mathcal{B}_0$. By Theorem 5.1 there exists a throttle control strategy that makes all solutions in a bounded set $M \subset X$ converge to $\mathcal{B}_0$. Now we slowly decrease the throttle setting to $\gamma = \gamma_*$. By decreasing the throttle γ beyond the point where the design flow undergoes the jth Hopf bifurcation, the jth harmonic becomes unstable. For this throttle setting, design flow is unstable and hence not in the basic attractor, and the system must go into stall. In other words, the component $\mathcal{B}_0$ of the basic attractor has bifurcated to the unstable component $\mathcal{C}_0$ of the reminder (see Theorem 2.3). The basic attractor itself now consists of the stable stall cells $\mathcal{B}_i$ (see [8]). The same theorem says that all the minimal basic attractors

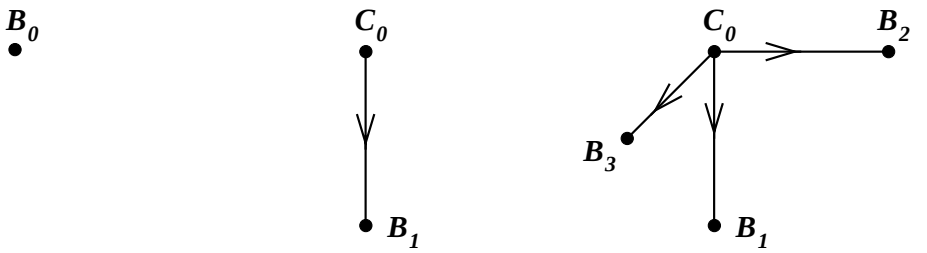

FIG. 7.1. *The global attractor for small B and $\gamma = \gamma_*$. ν decreases from left to right.*

$\mathcal{B}_i$ are connected to the unstable manifolds W_i^u of the unstable design flow $\mathcal{C}_0$ (see Figure 7.1). Now start with design flow $\mathcal{C}_0$, and consider the initial conditions for the deviation $\varphi(0, x)$ from design flow. By using the air injectors or bleeding we can, by Hypothesis 1, make the solution at time ϵ be $2\pi/j$ periodic with exactly j local maxima and j local minima. The rest of the argument concludes that this initial data lie in the jth unstable manifold W_j^u of design flow $\mathcal{C}_0$ and must follow it to the jth stable stall component B_j. Namely, the unstable manifold to the ith stall solution is $2\pi/i$ periodic. Our solution, which is $2\pi/j$ periodic, must settle onto the global attractor, and it can only settle onto the design flow or a stall solution which is $2\pi/k$ periodic, where $k = jm$ for some integer m. However, the number of maxima and minima of $\varphi(t, \cdot)$ is nonincreasing in time (see the proof of Theorem 7.1) and thus m cannot be greater than one. Furthermore, the design flow is unstable with respect to $2\pi/j$ periodic disturbances so the solution cannot settle onto design flow. The only possibility remaining is that the solution settle onto the jth stall solution $\mathcal{B}_j$.

We have now constructed a control which takes the stable design flow $\mathcal{B}_0$ to $\mathcal{B}_j$; in particular, it takes the stable design flow to an open set U in the basin of attraction of $\mathcal{B}_j$. By continuity this control will take a small neighborhood V of the stable design flow into U. We have already constructed in Theorem 5.1 a throttle control which guarantees that for any initial condition we can get from any bounded set $M \subset X$ into V in finite time. We can thus get into U in finite time, and the proof is complete. □

8. Conclusion. We defined b-controllability and a-controllability and presented arguments why these would be meaningful definitions of controllability for infinite dimensional nonlinear dynamical systems. We proved that the vMG equation with throttle control is not b-controllable, and we showed how the control can be modified, by including air injection or bleeding, to make the vMG equation b-controllable.

The backstepping control presented by Banaszuk, Hauksson, and Mezić was the first attempt at constructing a control strategy for the Moore–Greitzer PDE. The vMG equation, which is a better physical model for the airflow through the compression system, has different asymptotic dynamics than the Moore–Greitzer equation, and these asymptotic dynamics have been analyzed by the authors in [7], [6], and [8]. Here we go one step further and use the knowledge of the asymptotic dynamics to construct a control strategy that utilizes the dynamics and hence needs considerably less control effort.

Given a good knowledge of the asymptotic dynamics, one could create a host of different control strategies that would recover design flow operation from stall and surge. By using the dynamics one can considerably reduce the control effort, and it is in this sense that we say that our control construction is near optimal. In fact,

one could use this knowledge to modify the backstepping controller by Banaszuk, Hauksson, and Mezić in that it does not need to react to stall in such a forceful manner.

We have shown here that the basic control does a good job of recovering design flow from stall disturbances. It does not do it as quickly as the backstepping control but with a much smaller control effort, and in this sense the basic control is a much more realistic strategy. Neither of the controls does a good job of recovering design flow from surge disturbances. This is due to the fact that surge disturbances are of a more violent nature and are harder to control. Both controls saturate in this case.

Recall that the control constructed here is mainly intended for recovering design flow operation after large disturbances have occurred. Ideally it would be coupled together with a regulator that would keep the state near design flow during normal operation, and then when large disturbances occur the near optimal control would take over. It is also important to mention that we do not consider the control constructed here as the best possible control. We would however argue that a good knowledge of the basic attractor of the equation is essential to construct a good control strategy. Furthermore, we believe that this approach of analyzing the basic attractor and using the knowledge of the asymptotic dynamics to construct basic control strategies for b-controllable systems can offer a viable alternative to linearizing high dimensional systems and applying linear optimal control theory to the linearized system.

Acknowledgments. We would like to thank Petar Kokotović, Bassam Bamieh, Dan Fontain, Igor Mezić, and Andrzej Banaszuk for fruitful discussions.

ASYMPTOTIC STABILITY AND ENERGY DECAY RATES FOR SOLUTIONS OF THE WAVE EQUATION WITH MEMORY IN A STAR-SHAPED DOMAIN*

M. AASSILA†, M. M. CAVALCANTI‡, AND J. A. SORIANO‡

Abstract. We study the asymptotic stability and give the energy decay rates for solutions of the wave equation with boundary dissipation of the memory type.

Key words. wave equation, boundary condition of memory type

AMS subject classifications. 35L05, 35L20, 35B37

1. Introduction.

A basic linear model for the evolution of sound in a compressible fluid is the system of partial differential equations

$$\rho v_t(t,x) + \operatorname{grad} p(x,t) = 0, \tag{1.1}$$

$$\alpha p_t(t,x) + \operatorname{div} v(t,x) = 0, \quad t > 0, \ \ x \in \mathbf{R}^n, \tag{1.2}$$

where p denotes acoustic pressure and v the velocity field; cf., e.g., Leis [9]. In what follows the equilibrium density ρ and the compressibility α will be assumed to be constant and then without loss of generality to be equal to 1. Eliminating v from this system one obtains a wave equation for the pressure p:

$$p_{tt}(t,x) = \Delta p(t,x), \quad t > 0, \ \ x \in \mathbf{R}^n. \tag{1.3}$$

When the fluid is enclosed in a region $\Omega \subset \mathbf{R}^n$, (1.3) has to be supplemented by conditions at $\partial\Omega$, the boundary of Ω. The following three dissipative boundary conditions are discussed in the mathematical literature on time domain models for acoustics.

First, equating the acoustic impedance $\xi(x) \in \mathbf{C}$ of the boundary surface at x with the ratio between the fluid's pressure and its velocity normal to the surface results in

$$\frac{\partial p}{\partial \nu}(t,x) + \xi(x) p_t(t,x) = 0, \quad t > 0, \ \ x \in \partial\Omega, \tag{1.4}$$

where $\frac{\partial}{\partial \nu}$ denotes the derivative in the direction of the outer normal of $\partial\Omega$. The well-posedness of the equation with boundary conditions (1.4) and the asymptotic behavior of its solutions has been investigated in [3], [4], [15].

Second, adding a friction term $\beta(x)p_t(t,x)$, $\beta > 0$, to the classic Robin condition yields

$$\frac{\partial p}{\partial \nu}(t,x) + \beta(x) p_t(t,x) + \alpha(x) p(x,t) = 0, \quad t > 0, \ \ x \in \partial\Omega. \tag{1.5}$$

‡Departamento de Matemática, Universidade Estadual de Maringá, 87020-900 Maringá, PR, Brasil (marcelo@gauss.dma.uem.br, soriano@gauss.dma.uem.br).

This condition has been studied, e.g., in [8].

Third, modeling the boundary surface as independent oscillations and equating the velocity δ_t of the impenetrable surface with the normal velocity of the fluid at boundary points leads to

$$n(x)\delta_{tt}(t,x) + d(x)\delta_t(t,x) + k(x)\delta(t,x) = -p(t,x),$$

$$\frac{\partial p}{\partial \nu}(t,x) + \delta_{tt}(t,x) = 0, \quad t > 0, \ \ x \in \partial\Omega. \tag{1.6}$$

In [2], where this boundary model is formulated for the velocity potential, spectral properties of the generator of the solution semigroup are given.

Looking for more general results, we find in [11, Equation (6.3.11)] that the pressure of the combination of a wave $F(T_i)$, $T_i = t - (x_1 \sin\theta - x_2 \cos\theta)$, that is incident at angle θ onto the surface $x_2 = 0$, with the reflected wave in direction $T_r - t = -(x_1 \cos\theta + x_2 \cos\theta)$, is of the form

$$p(t,x) = F(T_i) + F(T_r) + \int_{-\infty}^{+\infty} F(\tau) W(T_r - \tau)\, d\tau. \tag{1.7}$$

Here W represents the modification of the reflected wave that is caused by the motion of the surface. This means that a general linear reflection process is to be modeled by convolution of the acoustic wave with a function that characterizes the boundary material. In order to cast (1.4)–(1.6) into a common form, we write

$$\frac{\partial p}{\partial \nu}(t,x) + dk * p_t(t,x) = 0, \quad t > 0, \ \ x \in \partial\Omega, \tag{1.8}$$

where $dk * p_t(t,x) = \int_0^t dk(\tau,x) p_t(t-\tau,x)$.

Another approach that also leads to convolution boundary conditions of the form (1.8) is the modeling of the boundary as the surface of a viscoelastic material.

In this paper, we are concerned more precisely with the asymptotic behavior of solutions to the following problem:

$$u'' - \Delta u = 0 \quad \text{in } \Omega \times \mathbf{R}_+, \tag{1.9}$$

$$u = 0 \quad \text{on } \Gamma_0 \times \mathbf{R}_+, \tag{1.10}$$

$$\frac{\partial u}{\partial \nu} + \int_0^t k(t-s,x) u'(s)\, ds + a(x) g(u') = 0 \quad \text{on } \Gamma_1 \times \mathbf{R}_+, \tag{1.11}$$

$$u(x,0) = u_0(x), \quad u'(x,0) = u_1(x), \quad x \in \Omega, \tag{1.12}$$

where $\Omega \subset \mathbf{R}^n$ is an open bounded domain with boundary $\Gamma = \Gamma_0 \cup \Gamma_1$ of class C^2, $a : \Gamma_1 \to \mathbf{R}_+ \in L^\infty(\Gamma_1)$ is such that $a(x) \geq a_0 > 0$, $k : \mathbf{R}_+ \times \Gamma_1 \to \mathbf{R}_+ \in C^2(\mathbf{R}_+, L^\infty(\Gamma_1))$, and $g : \mathbf{R} \to \mathbf{R}$ is a continuous nondecreasing function such that $g(0) = 0$ and $|g(x)| \leq 1 + C|x|$, $C > 0$.

Problems related to (1.9)–(1.12) were studied by many authors, e.g., Muñoz Rivera [12], Tadayuki and Rinko [17], Prüss [14], Dix and Torrejon [5], Guesmia [6], Propst and Prüss [13], Renardy, Hrusa, and Nohel [16], and the references therein.

Our paper is organized as follows. In section 2, we state our main results. In section 3 we give the proofs, and in section 4 we study the strong asymptotic stability under weak assumptions on Ω and g.

2. Main results. The following hypotheses are made on Ω and on the functions k and g:

$$\Gamma_0 \neq \emptyset \quad \text{or} \quad \inf_{\Gamma_1 \times \mathbf{R}_+} k \neq 0, \tag{2.1}$$

$$m \cdot \nu \geq \delta > 0 \quad \text{on } \Gamma_1, \quad m \cdot \nu \leq 0 \quad \text{on } \Gamma_0, \quad m(x) = x - x^0 (x^0 \in \mathbf{R}^n), \tag{2.2}$$

$$k \geq 0 \quad \text{on } \Gamma_1 \times \mathbf{R}_+, \tag{2.3}$$

$$k' \leq 0 \quad \text{on } \Gamma_1 \times \mathbf{R}_+, \tag{2.4}$$

$$\exists \alpha > 0, \quad k'' \geq -\alpha k' \quad \text{on } \Gamma_1 \times \mathbf{R}_+, \tag{2.5}$$

$$C_1 |x|^p \leq |g(x)| \leq C_2 |x|^{1/p} \quad \text{if } |x| \leq 1, \tag{2.6}$$

$$C_3 |x| \leq |g(x)| \leq C_4 |x| \quad \text{if } |x| \geq 1, \tag{2.7}$$

where $p \geq 1$ and $C_i \, (1 \leq i \leq 4)$ are four positive constants.

Remark 2.1. (1) An example of function k satisfying (2.3)–(2.5) is

$$k(t,x) = f(x)\, e^{-\alpha t} + g(x) \quad \text{on } \Gamma_1 \times \mathbf{R}_+,$$

where $f, g \in L^\infty(\Gamma_1, \mathbf{R}_+)$.

(2) The condition (2.1) implies that the formula $\int_\Omega |\nabla u|^2 \, dx + \int_{\Gamma_1} k \, |u|^2 \, d\Gamma$ defines a norm on $H^1(\Omega)$ equivalent to the usual one.

(3) The condition (2.2) implies that $\overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset$, and Ω is star-shaped with respect to x^0. It could be weakened, as was done in [8].

For the sake of completeness, we give a brief outline of the well-posedness of problem (1.9)–(1.12). This problem could be rewritten in the following form:

$$\langle u'', v \rangle + \int_0^t d\beta \, (t - \tau, u'(\tau), v) + \alpha(u, v) + \int_{\Gamma_1} a(x) g(u') v \, d\Gamma = 0, \tag{2.8}$$

$$u(0) = u_0, \quad u'(0) = u_1, \tag{2.9}$$

where

$$\beta(t, u, v) = \int_\Gamma k(t,x) u(x) v(x) \, d\Gamma, \quad \beta(0, u, v) = 0, \quad t > 0, \quad u, v \in H^1_{\Gamma_0}(\Omega),$$

$$H^1_{\Gamma_0}(\Omega) = \left\{ u \in H^1(\Omega); \ \ u = 0 \quad \text{on } \Gamma_0 \right\},$$

$$\alpha(u, v) = \int_\Omega \nabla u \cdot \nabla v \, dx, \quad u, v \in H^1_{\Gamma_0}(\Omega).$$

The problem (2.8)–(2.9) could be reformulated as an evolutionary integral equation of variational type, and thanks to the monotonicity and to the growth condition $|g(x)| \leq 1 + C|x|$ assumed on the function g, we can have access to the results and methods developed in section 6 of Prüss [14] to obtain the following theorem.

THEOREM 2.1. *For all given initial data* $(u_0, u_1) \in H^1_{\Gamma_0}(\Omega) \times L^2(\Omega)$, *problem* (1.9)–(1.12) *admits a unique global weak solution*

$$u \in C\left(\mathbf{R}_+, H^1_{\Gamma_0}(\Omega)\right) \cap C^1\left(\mathbf{R}_+, L^2(\Omega)\right). \tag{2.10}$$

Furthermore, if $(u_0, u_1) \in \left(H^2(\Omega) \cap H^1_{\Gamma_0}(\Omega)\right) \times H^1_{\Gamma_0}(\Omega)$ *and* g *is globally Lipschitz continuous, then the solution has the following regularity:*

$$u \in C\left(\mathbf{R}_+, H^2(\Omega)\right) \cap C^1\left(\mathbf{R}_+, H^1_{\Gamma_0}(\Omega)\right) \cap C^2\left(\mathbf{R}_+, L^2(\Omega)\right). \tag{2.11}$$

We define the energy of the solution given by (2.10) by the following formula:

$$E(t) := \frac{1}{2}\int_\Omega \left(|u'(t,x)|^2 + |\nabla u(t,x)|^2\right) dx + \frac{1}{2}\int_{\Gamma_1} k(t,x)\,|u(t,x) - u_0(x)|^2\, d\Gamma \tag{2.12}$$

$$-\frac{1}{2}\int_{\Gamma_1}\int_0^t k'(t-s,x)\,|u(t,x) - u(s,x)|^2\, ds\, d\Gamma.$$

Our main results are the following.

THEOREM 2.2. *Assume that hypotheses* (2.1)–(2.7) *hold and that*

$$\alpha \inf_{\Gamma_1} k(0) > -2 \inf_{\Gamma_1} k'(0). \tag{2.13}$$

Then we have

$$E(t) \leq CE(0)e^{-\omega t} \quad if \;\; p = 1, \;\; C > 0, \;\; \omega > 0, \;\; t \geq 0, \tag{2.14}$$

$$E(t) \leq \frac{CE(0)}{(1+t)^{2/(p-1)}} \quad if \;\; p > 1, \;\; C > 0, \;\; t \geq 0 \tag{2.15}$$

for every weak solution to (1.9)–(1.12) *and initial data* $(u_0, u_1) \in H^1_0(\Omega) \times L^2(\Omega)$.

Remark 2.2. Theorem 2.2 has a serious drawback: it never can be applied for bounded functions g (because of $C_3 > 0$ in (2.7)). The purpose of the following theorem is to obtain a variant of Theorem 2.2 for bounded feedback functions.

THEOREM 2.3. *Assume* (2.1)–(2.5) *and assume that the function* g *is bounded and globally Lipschitz continuous and that the inequalities* (2.6) *are satisfied with some positive constants* C_1, C_2 *and with a number* p *satisfying*

$$p \geq n - 1. \tag{2.16}$$

Then for every strong solution u *to* (1.9)–(1.12) *we have*

$$E(t) \leq \frac{CE(0)}{(1+t)^{2/(p-1)}}, \quad C > 0, \;\; t \geq 0. \tag{2.17}$$

To end this section, we recall the following useful lemma.

LEMMA 2.4 (see [7, Lemma 9.1]). *Let $E : \mathbf{R}_+ \to \mathbf{R}_+$ be a nonincreasing function and assume that there exist two constants $\alpha > 0$ and $T > 0$ such that*

$$\int_t^{+\infty} E^{\alpha+1}(s)\,ds \le TE(0)^{\alpha}E(t) \quad for\ all\ \ t \in \mathbf{R}_+. \tag{2.18}$$

Then we have

$$E(t) \le E(0)\left(\frac{T+\alpha t}{T+\alpha T}\right)^{-1/\alpha} \quad for\ all\ \ t \ge T. \tag{2.19}$$

3. Proofs. To justify all the computations that follow, we will assume that u is a strong solution and that by a classical density argument the results of Theorem 2.2 still hold for the weak solution.

To simplify the computations and without lost of generality, we will transform the boundary condition (1.11) in another more practical one considering $u_0 = 0$ on Γ_1.

A simple integration by parts yields

$$\int_0^t k(t-s,x)u'(s,x)\,ds$$

$$= [k(t-s,x)u(s,x)]_0^t + \int_0^t k'(t-s,x)u(s,x)\,ds$$

$$= \int_0^t k'(t-s,x)u(s,x)\,ds + k(0,x)u(t,x).$$

Hence, the problem (1.9)–(1.12) is now transformed into

$$u'' - \Delta u = 0 \quad \text{in } \Omega \times \mathbf{R}_+, \tag{3.1}$$

$$u = 0 \quad \text{on } \Gamma_0 \times \mathbf{R}_+, \tag{3.2}$$

$$\frac{\partial u}{\partial \nu} + \int_0^t k'(t-s,x)u(s,x)\,ds + k(0)u + a(x)g(u') = 0 \quad \text{on } \Gamma_1 \times \mathbf{R}_+, \tag{3.3}$$

$$u(x,0) = u_0(x), \quad u'(x,0) = u_1(x) \quad \text{in } \Omega. \tag{3.4}$$

LEMMA 3.1. *The energy defined by* (2.12) *is nonincreasing and it holds that*

$$\frac{1}{2}\int_S^T \int_{\Gamma_1} \int_0^t k''(t-s)\left(u(t)-u(s)\right)^2 ds\,d\Gamma\,dt + \int_S^T \int_{\Gamma_1} a(x)g(u')u'\,d\Gamma\,dt$$

$$-\frac{1}{2}\int_S^T \int_{\Gamma_1} k'\,|u|^2\,d\Gamma\,dt = E(S) - E(T) \le E(S)$$

for every $0 \le S < T < +\infty$. In particular, $\int g(u')u' \le c|E'(0)|$ for a suitable constant c.

Proof.

$$E(T) - E(S) = \int_S^T E'(t)\,dt$$

$$= \int_S^T \int_\Omega (u'u'' + \nabla u \cdot \nabla u')\,dx\,dt + \int_S^T \int_{\Gamma_1} kuu'\,d\Gamma\,dt + \frac{1}{2}\int_S^T \int_{\Gamma_1} k' |u|^2\,d\Gamma\,dt$$

$$- \int_S^T \int_{\Gamma_1} \int_0^t k'(t-s)\,(u(t) - u(s))\,u'(t)\,ds\,d\Gamma\,dt$$

$$-\frac{1}{2}\int_S^T \int_{\Gamma_1} \int_0^t k''(t-s)\,(u(t) - u(s))^2\,ds\,d\Gamma\,dt.$$

Using (3.1)–(3.3) and the Green formula, we obtain

$$E(T) - E(S) = -\int_S^T \int_{\Gamma_1} a(x) g(u') u'\,d\Gamma\,dt + \frac{1}{2}\int_S^T \int_{\Gamma_1} k' |u|^2\,d\Gamma\,dt$$

$$-\frac{1}{2}\int_S^T \int_{\Gamma_1} \int_0^t k''(t-s)\,(u(t) - u(s))^2\,ds\,d\Gamma\,dt$$

$$+ \int_S^T \int_{\Gamma_1} uu' \left(k - k(0) - \int_0^t k'(t-s)ds\right) d\Gamma\,dt.$$

Hence

$$E(S) - E(T)$$

$$= \int_S^T \int_{\Gamma_1} a(x) g(u') u'\,d\Gamma\,dt + \frac{1}{2}\int_S^T \int_{\Gamma_1} \int_0^t k''(t-s)\,(u(t) - u(s))^2\,ds\,d\Gamma\,dt$$

$$-\frac{1}{2}\int_S^T \int_{\Gamma_1} k' |u|^2\,d\Gamma\,dt. \qquad \square$$

LEMMA 3.2. *Setting*

$$Mu := 2(m \cdot \nabla u) + (n-1)u,$$

it holds that

$$\int_S^T E^{\frac{p-1}{2}} \int_\Omega \left(|u'|^2 + |\nabla u|^2\right) dx\,dt$$

$$= -\left[E^{\frac{p-1}{2}} \int_\Omega u'(Mu)\,dx\right]_S^T + \frac{p-1}{2}\int_S^T E^{\frac{p-3}{2}} E' \int_\Omega u'(Mu)\,dx\,dt$$

$$+ \int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_0} (m \cdot \nu) |\nabla u|^2\,d\Gamma\,dt + \int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} (m \cdot \nu) \left(|u'|^2 - |\nabla u|^2\right) d\Gamma\,dt$$

$$+ \int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} (Mu) \frac{\partial u}{\partial \nu}\,d\Gamma\,dt.$$

Proof. We have

$$0 = \int_S^T E^{\frac{p-1}{2}} \int_\Omega (Mu)\,(u'' - \Delta u)\; dx\, dt$$

$$= \left[E^{\frac{p-1}{2}} \int_\Omega u'(Mu)\, dx\right]_S^T - \frac{p-1}{2} \int_S^T E^{\frac{p-3}{2}} E' \int_\Omega u'(Mu) dx\, dt$$

$$- \int_S^T E^{\frac{p-1}{2}} \int_\Omega (u'(Mu') + (Mu)\Delta u)\, dx\, dt,$$

and

$$\int_\Omega (u'(Mu') + (Mu)\Delta u)\, dx$$

$$= \int_\Omega \left(m \cdot \nabla (u')^2 + (n-1)\,|u'|^2 - \nabla u \cdot \nabla (Mu)\right) dx + \int_\Gamma (Mu) \frac{\partial u}{\partial \nu} d\Gamma$$

$$= \int_\Omega \left(m \cdot \nabla (u')^2 + (n-1)\,|u'|^2 - 2\,|\nabla u|^2 - m \cdot \nabla\,|\nabla u|^2 - (n-1)\,|\nabla u|^2\right) dx$$

$$+ \int_\Gamma (Mu) \frac{\partial u}{\partial \nu} d\Gamma$$

$$= - \int_\Omega \left(|u'|^2 + |\nabla u|^2\right) dx + \int_\Gamma \left((m \cdot \nu)\left(|u'|^2 - |\nabla u|^2\right) + (Mu)\frac{\partial u}{\partial \nu}\right) d\Gamma$$

$$= - \int_\Omega \left(|u'|^2 + |\nabla u|^2\right) dx + \int_{\Gamma_0} \left(-(m \cdot \nu)\,|\nabla u|^2 + (2m \cdot \nabla u)\frac{\partial u}{\partial \nu}\right) d\Gamma$$

$$+ \int_{\Gamma_1} (m \cdot \nu) \left((|u'|^2 - |\nabla u|^2) + (Mu)\frac{\partial u}{\partial \nu}\right) d\Gamma\,.$$

Since (3.2) implies that $\nabla u = \frac{\partial u}{\partial \nu}\nu$ on Γ_0, we obtain the desired result. ∎

LEMMA 3.3. *It holds that*

$$\int_S^T E^{\frac{p-1}{2}} \int_\Omega \left(|u'|^2 + |\nabla u|^2\right) dx\, dt \le C(\varepsilon)E(S) + \varepsilon \int_S^T E^{\frac{p+1}{2}}(t)\, dt + C(\varepsilon)E(S)$$

$$+(n-1) \int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} u \frac{\partial u}{\partial \nu} d\Gamma\, dt + \frac{R^2}{\delta} \int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} \left(\frac{\partial u}{\partial \nu}\right)^2 d\Gamma\, dt,$$

where $0 \le S < T < +\infty$, $R = ||m||_{L^\infty(\Omega)}$, C *is a positive constant,* ε *is an arbitrary small real number, and* δ *comes from* (2.2).

Proof. Here and in what follows C will denote various positive constants which may be different at different occurences.

From the nonincreasingness of the energy, we deduce that

$$\left| E^{\frac{p-1}{2}} \int_\Omega u' M(u)\, dx \right| \le CE,$$

$$\left| E^{\frac{p-3}{2}} E' \int_\Omega u'(Mu)\, dx \right| \le -CE^{\frac{p-1}{2}} E' \le -C\left(E^{\frac{p+1}{2}}\right)',$$

and

$$\int_S^T E^{\frac{p-3}{2}} E' \int_\Omega u'(Mu) dx\, dt \le CE(S).$$

Thanks to the Young inequality, we have

$$2\int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} \frac{\partial u}{\partial \nu}\,(m\cdot\nabla u)\, d\Gamma\, dt$$

$$\le \delta \int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} |\nabla u|^2\, d\Gamma\, dt + \frac{R^2}{\delta} \int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} \left(\frac{\partial u}{\partial \nu}\right)^2 d\Gamma\, dt,$$

and by the relations (2.6)–(2.7), we obtain

$$\int_{|u'|\le 1} (m\cdot\nu)\,|u'|^2\, d\Gamma \le C \int_{|u'|\le 1} (m\cdot\nu)\,(u'g(u'))^{\frac{2}{p+1}}\, d\Gamma$$

$$\le C\left(\int_{\Gamma_1} (m\cdot\nu)\, u' g(u')\, d\Gamma\right)^{\frac{2}{p+1}} \le C\,(-E')^{\frac{2}{p+1}}$$

and

$$\int_{|u'|\ge 1} (m\cdot\nu)\,|u'|^2\, d\Gamma \le \int_{|u'|\ge 1} (m\cdot\nu)\, u' g(u') d\Gamma \le -CE'.$$

Hence

$$\int_S^T E^{\frac{p-1}{2}} \int_{|u'|\le 1} (m\cdot\nu)\,|u'|^2\, d\Gamma\, dt \le C\int_S^T E^{\frac{p-1}{2}}\,(-E')^{\frac{2}{p+1}}\, dt$$

$$\le \int_S^T \left(\varepsilon E^{\frac{p+1}{2}} - C(\varepsilon)E'\right) dt$$

$$\le \varepsilon \int_S^T E^{\frac{p+1}{2}}(t)\, dt + C(\varepsilon)E(S), \tag{3.5}$$

and

$$\int_S^T E^{\frac{p-1}{2}} \int_{|u'|\ge 1} (m\cdot\nu)\,|u'|^2\, d\Gamma dt \le CE(S). \tag{3.6}$$

From this, it follows that

$$\int_S^T E^{\frac{p-1}{2}} \int_\Omega \left(|u'|^2 + |\nabla u|^2\right) dx\, dt \le CE(S) + \varepsilon \int_S^T E^{\frac{p+1}{2}}(t)\, dt$$

$$+C(\varepsilon)E(S) + (n-1)\int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} u\frac{\partial u}{\partial \nu} d\Gamma\, dt$$

$$+\delta \int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} |\nabla u|^2\, d\Gamma\, dt + \frac{R^2}{\delta}\int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} \left(\frac{\partial u}{\partial \nu}\right)^2 d\Gamma\, dt$$

$$-\int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} (m\cdot\nu)\, |\nabla u|^2\, d\Gamma\, dt,$$

and then we deduce the result by $m \cdot \nu \ge \delta > 0$ on Γ_1.

LEMMA 3.4. *It holds that*

$$-\int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} u\frac{\partial u}{\partial \nu} d\Gamma\, dt$$

$$\le CE(S) + \varepsilon \int_S^T E^{\frac{p-1}{2}} \int_\Omega |u'|^2\, dx\, dt + \varepsilon \int_S^T E^{\frac{p+1}{2}}(t) dt + C(\varepsilon)E(S)$$

for every $\varepsilon > 0$, $0 \le S < T < \infty$.

Proof. We will use the idea introduced by Conrad and Rao [4]. Let φ be a solution of

$$-\Delta\varphi = 0 \quad \text{in } \Omega, \qquad \varphi = u \quad \text{on } \Gamma.$$

By the classical results of elliptic partial differential equations theory we have

$$\int_\Omega \nabla\varphi \cdot \nabla u\, dx = \int_\Omega |\nabla\varphi|^2\, dx,$$

$$\int_\Omega |\varphi|^2\, dx \le C\int_\Gamma |u|^2\, d\Gamma,$$

$$\int_\Omega |\varphi'|^2\, dx \le C\int_\Gamma |u'|^2\, d\Gamma.$$

Multiplying (3.1) with $E^{\frac{p-1}{2}}\varphi$ we obtain

$$-\int_S^T E^{\frac{p-1}{2}} \int_\Gamma \varphi\frac{\partial u}{\partial \nu} d\Gamma\, dt = -\left[E^{\frac{p-1}{2}} \int_\Omega u'\varphi\, dx\right]_S^T + \frac{p-1}{2}\int_S^T E^{\frac{p-3}{2}}E' \int_\Omega u'\varphi dx\, dt$$

$$+\int_S^T E^{\frac{p-1}{2}} \int_\Omega u'\varphi' dx\, dt - \int_S^T E^{\frac{p-1}{2}} \int_\Omega \nabla u\cdot\nabla\varphi dx\, dt.$$

It follows that

$$\left[E^{\frac{p-1}{2}}\int_\Omega u'\varphi\,dx\right]_S^T \le CE(S),$$

$$\int_S^T E^{\frac{p-3}{2}}E'\int_\Omega u'\varphi dx\,dt \le CE(S),$$

$$\int_S^T E^{\frac{p-1}{2}}\int_\Omega u'\varphi' dx\,dt$$

$$\le \varepsilon\int_S^T E^{\frac{p-1}{2}}\int_\Omega |u'|^2\,dx\,dt + C(\varepsilon)\int_S^T E^{\frac{p-1}{2}}\int_\Omega |\varphi'|^2\,dx\,dt$$

$$\le \varepsilon\int_S^T E^{\frac{p-1}{2}}\int_\Omega |u'|^2\,dx\,dt + C(\varepsilon)\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1} |u'|^2\,d\Gamma\,dt$$

$$\le \varepsilon\int_S^T E^{\frac{p-1}{2}}\int_\Omega |u'|^2\,dx\,dt + C(\varepsilon)E(S) + \varepsilon\int_S^T E^{\frac{p+1}{2}}(t)dt. \qquad \square$$

LEMMA 3.5. *Define*

$$\gamma := \gamma(x) = \frac{\lambda}{k(0)} \quad with \quad \lambda > \max\left\{\frac{n-1}{2}, \frac{R^2}{\delta}\,||k(0)||_{L^\infty(\Gamma_1)}\right\}.$$

Then it holds that

$$\int_S^T E^{\frac{p+1}{2}}(t)\,dt \le CE(S) + (1-\lambda)\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1} k(0)\,|u|^2\,d\Gamma\,dt$$

$$+2\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\gamma\left(\int_0^t k'(t-s)u(s)\,ds\right)^2 d\Gamma\,dt.$$

Proof. Thanks to (3.3) and to the Young inequality we have

$$\frac{R^2}{\delta}\left(\frac{\partial u}{\partial\nu}\right)^2 + (n-1)u\frac{\partial u}{\partial\nu}$$

$$\le \gamma\left(\left(\frac{\partial u}{\partial\nu} + k(0)u\right)^2 - k^2(0)\,|u|^2\right) + (n-1-2\gamma k(0))\,u\frac{\partial u}{\partial\nu}$$

$$\le \gamma\left(a(x)g(u') + \int_0^t k'(t-s)u(s)\,ds\right)^2 - \lambda k(0)\,|u|^2$$

$$+(n-1-2\lambda)u\frac{\partial u}{\partial\nu}$$

$$\le 2\gamma a^2(x)g(u')^2 + 2\gamma\left(\int_0^t k'(t-s)u(s)\,ds\right)^2 - \lambda k(0)\,|u|^2$$

$$+(n-1-2\lambda)u\frac{\partial u}{\partial\nu}.$$

By (2.1)–(2.7) we obtain

$$2\int_{|u'|\le 1}\gamma a^2(x)g(u')^2d\Gamma \le C\int_{|u'|\le 1}(u'g(u'))^{\frac{2}{p+1}}\,d\Gamma$$

$$\le C\left(\int_{\Gamma_1}u'g(u')d\Gamma\right)^{\frac{2}{p+1}} \le C\,(-E')^{\frac{2}{p+1}}$$

and

$$2\int_{|u'|\ge 1}\gamma a^2(x)g(u')^2d\Gamma \le C\int_{|u'|\ge 1}u'g(u')\,d\Gamma \le CE'. \tag{3.7}$$

Hence

$$2\int_S^T E^{\frac{p-1}{2}}\int_{|u'|\le 1}\gamma a^2(x)g(u')^2d\Gamma\,dt \le \varepsilon\int_S^T E^{\frac{p+1}{2}}(t)dt + C(\varepsilon)E(S)$$

and

$$2\int_S^T E^{\frac{p-1}{2}}\int_{|u'|\ge 1}\gamma a^2(x)g(u')^2d\Gamma\,dt \le CE(S).$$

Consequently

$$\int_S^T E^{\frac{p-1}{2}}\int_\Omega\left(|u'|^2+|\nabla u|^2\right)dx\,dt$$

$$\le CE(S)+\varepsilon\int_S^T E^{\frac{p+1}{2}}(t)\,dt + C(\varepsilon)E(S) - \lambda\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}k(0)\,|u|^2\,d\Gamma\,dt$$

$$+2\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\gamma\left(\int_0^t k'(t-s)u(s)\,ds\right)^2 d\Gamma\,dt$$

$$+(n-1-2\lambda)\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}u\frac{\partial u}{\partial\nu}d\Gamma\,dt.$$

On the other hand, from (2.5) it holds that

$$-\frac{1}{2}\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\int_0^t k'(t-s)\,(u(t)-u(s))^2\,ds\,d\Gamma\,dt$$

$$\le \frac{1}{2\alpha}\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\int_0^t k''(t-s)\,(u(t)-u(s))^2\,ds\,d\Gamma\,dt$$

$$\le C\int_S^T E^{\frac{p-1}{2}}E'dt \le CE(S)$$

and

$$\frac{1}{2}\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1} k\,|u|^2\,d\Gamma\,dt \le \frac{1}{2}\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1} k(0)\,|u|^2\,d\Gamma\,dt.$$

Thus from (2.12) and taking the inequalities above into account we deduce

$$2\int_S^T E^{\frac{p+1}{2}}(t)\,dt \le (1-\lambda)\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1} k(0)\,|u|^2\,d\Gamma\,dt$$

$$+CE(S)+C(\varepsilon)E(S)+\varepsilon\int_S^T E^{\frac{p+1}{2}}(t)\,dt$$

$$+2\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\gamma\left(\int_0^t k'(t-s)u(s)\,ds\right)^2 d\Gamma\,dt$$

$$-(2\lambda+1-n)\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1} u\frac{\partial u}{\partial\nu}d\Gamma\,dt.$$

From Lemma 3.4 , the last inequality yields

$$\int_S^T E^{\frac{p+1}{2}}(t)\,dt \le C(\varepsilon)E(S)+\frac{(1-\lambda)}{1-\varepsilon(2\lambda+2-n)}\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1} k(0)\,|u|^2\,d\Gamma\,dt$$

$$+\frac{2}{1-\varepsilon(2\lambda+2-n)}\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\gamma\left(\int_0^t k'(t-s)u(s)\,ds\right)^2 d\Gamma\,dt. \qquad \square$$

LEMMA 3.6. *Let $\varepsilon>0$ be such that*

$$\varepsilon\inf_{\Gamma_1} k'(0)+1>0. \tag{3.8}$$

Then, for any $0\le S<T<\infty$ we have

$$\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\gamma\left(\int_0^t k'(t-s,x)u(s)\,ds\right)^2 d\Gamma dt$$

$$\le CE(S)+\frac{\lambda}{\varepsilon\alpha}\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}|u|^2\,d\Gamma dt.$$

Proof. Let $\varepsilon>0$ be such that (3.8) holds and we define

$$h:=h(x)=\frac{k(0)}{\alpha\,(1+\varepsilon k'(0))}\quad \text{on } \Gamma_1, \tag{3.9}$$

$$I:=\left(\int_0^t k'(t-s,x)u(s)\,ds\right)^2-h\int_0^t k''(s)\,(u(t)-u(s))^2\,ds+hk'u^2.$$

By (3.8) it holds that $h \geq 0$ and $h \in L^\infty(\Gamma_1)$. On the other hand we have

$$I \leq \left(\int_0^t -k'(t-s,x)\,ds\right)\left(\int_0^t -k'(t-s,x)u^2(s)\,ds\right) - h\int_0^t k''(t-s,x)u^2(s)\,ds$$

$$+2hu\int_0^t k''(t-s,x)u(s)\,ds + hk'(0)u^2 - hk'u^2 + hk'u^2$$

$$\leq (k-k(0))\int_0^t k'(t-s,x)u^2(s)\,ds - h\int_0^t k''(t-s,x)u^2(s)\,ds$$

$$+h\left(k'(0)+\frac{1}{\varepsilon}\right)u^2 + \varepsilon h\left(\int_0^t k''(t-s,x)u(s)\,ds\right)^2.$$

Applying the Hölder inequality to the last integral in the above inequality and using the fact that

$$\int_0^t k'(t-s,x)u^2(s)\,ds \leq 0 \quad \text{and} \quad \varepsilon hk'\int_0^t k''(t-s,x)u^2(s)\,ds \leq 0,$$

we obtain

$$I \leq \left[\frac{1}{\alpha}k(0) - h\left(1+\varepsilon k'(0)\right)\right]\int_0^t k''(t-s,x)u^2(s)\,ds + h\left(k'(0)+\frac{1}{\varepsilon}\right)|u|^2,$$

and hence by (3.9) we have

$$I \leq \frac{1}{\varepsilon\alpha}k(0)\,|u|^2.$$

As $h \in L^\infty(\Gamma_1)$, it holds that

$$\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\gamma I\,d\Gamma dt \leq \int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\frac{\lambda}{\varepsilon\alpha}k(0)\,|u|^2\,d\Gamma\,dt,$$

$$\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\left\{\gamma\left(\int_0^t k'(t-s,x)u(s)\,ds\right)^2\right.$$

$$\left.-h\int_0^t k''(s)\left(u(t)-u(s)\right)^2 ds + hk'\,|u|^2\right\}d\Gamma dt$$

$$\leq \int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\frac{1}{\varepsilon\alpha}k(0)\,|u|^2\,d\Gamma\,dt,$$

and by Lemma 3.1 it follows that

$$\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}\gamma\left(\int_0^t k'(t-s,x)u(s)\,ds\right)^2 d\Gamma dt$$

$$\leq CE(S) + \frac{\lambda}{\varepsilon\alpha}\int_S^T E^{\frac{p-1}{2}}\int_{\Gamma_1}|u|^2\,d\Gamma dt. \qquad \square$$

Hence we deduce from Lemma 3.5 that

$$\int_S^T E^{\frac{p+1}{2}}(t)dt \leq CE(S) + \int_S^T E^{\frac{p-1}{2}} \int_{\Gamma_1} \left((1-\lambda)\, k(0) + \frac{2\lambda}{\varepsilon\alpha} \right) |u|^2 \, d\Gamma dt.$$

We would like to make a choice of λ such that

$$(1-\lambda)\, k(0) + \frac{2\lambda}{\varepsilon\alpha} \leq 0,$$

and then by Lemma 2.4 we deduce the desired decay rates.

The condition

$$\alpha \inf_{\Gamma_1} k(0) > -2 \inf_{\Gamma_1} k'(0)$$

implies that

$$\exists \varepsilon' > 0 \ \text{ such that } \quad \alpha \inf_{\Gamma_1} k(0) > -(2+\varepsilon') \inf_{\Gamma_1} k'(0).$$

We choose $\varepsilon > 0$ such that

$$-\varepsilon \inf_{\Gamma_1} k'(0) = \frac{\varepsilon' + 4}{2(\varepsilon' + 2)} \quad (\text{we always have} \quad \varepsilon \inf_{\Gamma_1} k'(0) + 1 > 0).$$

Then, we have

$$(1-\lambda)k(0) + \frac{2\lambda}{\varepsilon\alpha} = \frac{\lambda}{\varepsilon\alpha}\left(2 - \varepsilon\alpha k(0)\right) + k(0)$$

$$\leq \frac{\lambda}{\varepsilon\alpha}\Big(2 + \varepsilon(2+\varepsilon') \inf_{\Gamma_1} k'(0)\Big) + k(0)$$

$$= \frac{-\varepsilon'}{2\varepsilon\alpha}\lambda + k(0).$$

Hence, if we choose

$$\lambda = \max\left\{ n-1, \left(\frac{R^2}{\delta} + \frac{2\varepsilon\alpha}{\varepsilon'} \right) ||k(0)||_{L^\infty(\Gamma_1)} \right\}$$

(note that $\lambda > \max\{\frac{n-1}{2}, \frac{R^2}{\delta}\, ||k(0)||_{L^\infty(\Gamma_1)}\}$ still holds), we obtain

$$(1-\lambda)k(0) + \frac{2\lambda}{\varepsilon} \leq 0. \qquad \square$$

Proof of Theorem 2.3. Repeating the same arguments as in Theorem 2.2, except the part where the first inequality of (2.7) involving C_3 is applied (cf. (3.5)–(3.7)), it remains to establish the estimate

$$E^{\frac{p-1}{2}} \int_{\Gamma_1} |u'|^2 \, d\Gamma \leq \varepsilon E^{\frac{p+1}{2}} - C(\varepsilon)E' \tag{3.10}$$

for every $\varepsilon > 0$. Then the theorem will follow by applying Lemma 2.4.

For brevity we shall denote the norm of $L^\beta(\Gamma)$ by $||\cdot||_\beta$. Set

$$s := \frac{2}{p+1} \quad \text{and} \quad \alpha := \frac{2-s}{1-s}.$$

We have $0 < s < 1$ and $\alpha := \frac{2p}{p-1} > 2$. We establish for every $\varepsilon > 0$ the inequality

$$E^{\frac{p-1}{2}} \int_{\Gamma_1, |u'| \geq 1} |u'|^2 \, d\Gamma \leq \varepsilon E^{\frac{p+1}{2}} ||u'||_\alpha^\alpha - C(\varepsilon) E'. \tag{3.11}$$

Indeed, we deduce

$$E^{\frac{p-1}{2}} \int_{\Gamma_1, |u'| \geq 1} |u'|^2 \, d\Gamma \leq C E^{\frac{p-1}{2}} \int_{\Gamma_1, |u'| \geq 1} |u'|^{2-s} \left(u' g(u')\right)^s d\Gamma$$

$$\leq C E^{\frac{p-1}{2}} \left|\left||u'|^{2-s}\right|\right|_{\frac{1}{1-s}} \left|\left|\left(u' g(u')\right)^s\right|\right|_{\frac{1}{s}}$$

$$\leq C E^{\frac{p-1}{2}} ||u'||_\alpha^{(1-s)\alpha} ||u' g(u')||_1^s$$

$$\leq C E^{\frac{p-1}{2}} ||u'||_\alpha^{(1-s)\alpha} (-E')^s$$

$$\leq \varepsilon E^{\frac{p-1}{2(1-s)}} ||u'||_\alpha^\alpha - C(\varepsilon) E'$$

$$= \varepsilon E^{\frac{p+1}{2}} ||u'||_\alpha^\alpha - C(\varepsilon) E'.$$

Using the trace theorem

$$H^1(\Omega) \hookrightarrow L^{\frac{2p}{p-1}}(\Gamma) = L^\alpha(\Gamma),$$

which follows from (2.16), we have from (3.8) that

$$E^{\frac{p-1}{2}} \int_{\Gamma_1} |u'|^2 \, d\Gamma \leq C \varepsilon E^{\frac{p+1}{2}} - C(\varepsilon) E'.$$

Hence, (3.10) follows with another ε. □

4. Strong asymptotic stability. In this section we are interested in the following nonlinear damped wave equation with a memory term:

$$u'' - \Delta u + g(u') + \int_0^t h(t-\tau) \Delta u(\tau) \, d\tau = 0 \quad \text{in} \quad \Omega \times \mathbf{R}_+, \tag{4.1}$$

$$u = 0 \quad \text{on} \quad \Gamma \times \mathbf{R}_+, \tag{4.2}$$

$$u(x,0) = u_0(x), \;\; u'(x,0) = u_1(x) \quad \text{in} \quad \Omega. \tag{4.3}$$

It is easy to verify that all the results of section 2 still hold for (4.1)–(4.3). However, Theorems 2.2 and 2.3 are marked by the following features:

(a) the domain Ω is bounded;

(b) the dissipative term g is of a preassigned polynomial growth at the origin.

These assumptions are critically invoked in the proofs in the following ways:

(a) the boundedness of Ω allows the use of some compact imbedding theorems (and LaSalle's invariance principle can then be used to prove the strong asymptotic stability);

(b) the polynomial growth at the origin of the dissipative term g allows the construction of a standard Lyapunov function or the use of some specific integral inequalities, which are then used to yield the desired decay rates.

Our goal in this section is to weaken considerably the above assumptions (a)–(b). Indeed, in our formulation Ω is not necessarily bounded, and no growth assumption at the origin is imposed on g. This results in major difficulties, which require the development of a new approach in successfully solving the problem of strong asymptotic stability. This approach was introduced by the first author in [1]. More precisely the following assumptions are made on Ω, g and h:

(A1) Assumptions on Ω:

$$\Omega \text{ is of finite measure.}$$

(A2) Assumptions on g:

$$g : \mathbf{R} \to \mathbf{R} \quad \text{is locally Lipschitz continuous;}$$

$$g(x)x > 0 \quad \text{for all} \quad x \neq 0, \quad g(0) = 0;$$

there exists $q \geq 2$ satisfying $(n-2)q \leq 2n$ and $c_1, c_2 >$ such that

$$c_1|x| \leq |g(x)| \leq c_2|x|^q \quad \text{for all} \quad |x| \geq 1.$$

(A3) Assumptions on the kernel h:

$$h : \mathbf{R}_+ \to \mathbf{R}_+ \text{ is a bounded } C^2 \text{ function;}$$

there exists $l > 0$ such that

$$1 - \int_0^\infty h(x)\,dx = l > 0,$$

and there exists a positive constant η such that

$$h'(t) \leq -\eta h(t) \quad \text{for all} \quad t \geq 0.$$

We define the energy of a solution

$$u \in C(\mathbf{R}_+, H_0^1(\Omega)) \cap C^1(\mathbf{R}_+, L^2(\Omega)) \tag{4.4}$$

by the following formula:

$$E(t) := \frac{1}{2}|u'(t)|^2 + \frac{1}{2}|\nabla u(t)|^2.$$

Our main result in this section is the following theorem.

THEOREM 4.1. *It holds that*

$$E(t) \to 0 \quad as \quad t \to +\infty$$

for every weak solution to (4.1)–(4.3) *given by* (4.4).

In a first step we will assume that we have a strong solution to justify all the computations that follow, and by a classical density argument, the result of Theorem 4.1 still holds for weak solutions. The well-posedness can be derived from the same arguments as in [14].

A simple computation shows that

$$E'(t) = -(g(u'), u') + \int_0^t h(t-\tau)(\nabla u(\tau), \nabla u'(t))\, d\tau.$$

Let

$$(h\square\nabla u)(t) := \int_0^t h(t-\tau)|\nabla u(t) - \nabla u(\tau)|^2\, d\tau; \tag{4.5}$$

hence it is not difficult to see, after integrating by parts, that

$$\int_0^t h(t-\tau)(\nabla u(\tau), \nabla u'(t))\, d\tau = -\frac{1}{2}(h\square\nabla u)'(t) + \frac{1}{2}(h'\square\nabla u)(t)$$

$$+ \frac{1}{2}\frac{d}{dt}\left\{\left(\int_0^t h(s)\, ds\right)|\nabla u(t)|^2\right\} - \frac{1}{2}h(t)|\nabla u(t)|^2. \tag{4.6}$$

From (4.6) and the value of $E'(t)$ we deduce that

$$\frac{d}{dt}\left\{\frac{1}{2}|u'(t)|^2 + \frac{1}{2}|\nabla u(t)|^2 + \frac{1}{2}(h\square\nabla u)(t) - \frac{1}{2}\left(\int_0^t h(s)\, ds\right)|\nabla u(t)|^2\right\}$$

$$= -(g(u'), u') + \frac{1}{2}(h'\square\nabla u)(t) - \frac{1}{2}h(t)|\nabla u(t)|^2. \tag{4.7}$$

Then, defining the modified energy $e(t)$ by

$$e(t) := \frac{1}{2}|u'(t)|^2 + \frac{1}{2}\left(1 - \int_0^t h(s)\, ds\right)|\nabla u(t)|^2 + \frac{1}{2}(h\square\nabla u)(t) \tag{4.8}$$

from (4.7) one has

$$e'(t) = -(g(u'), u') + \frac{1}{2}(h'\square\nabla u)(t) - \frac{1}{2}h(t)|\nabla u(t)|^2. \tag{4.9}$$

Taking (4.8) into account we infer that

$$E(t) \le Me(t) \quad \text{for all} \quad t \ge 0, \tag{4.10}$$

where $M = \max\{l^{-1}, 1\}$.

Our aim is to show that

$$E(t) \to 0 \quad \text{as} \quad t \to +\infty,$$

but in view of (4.10) it is enough to prove that

$$e(t) \to 0 \quad \text{as} \quad t \to +\infty. \tag{4.11}$$

Let us note that by the assumptions assumed on h we have

$$e'(t) \leq 0 \quad \text{for all} \quad t \geq 0. \tag{4.12}$$

In order to prove (4.11), we need the three following lemmas.

LEMMA 4.2. *It holds that*

$$\int_0^t \int_\Omega |ug(u')|\, dxds = o(t), \quad t \to +\infty.$$

LEMMA 4.3. *It holds that*

$$\int_0^t \int_\Omega |u'|^2\, dxds = o(t), \quad t \to +\infty.$$

LEMMA 4.4. *It holds that*

$$\int_0^t J(s)\, ds = o(t), \quad t \to +\infty,$$

where

$$J(t) = -\left(\int_0^t h(s)\, ds\right) |\nabla u(t)|^2 + (h\square\nabla u)(t)$$

$$+ \int_0^t h(t-\tau)(\nabla u(\tau), \nabla u(t))\, d\tau. \tag{4.13}$$

Proof of Lemma 4.2. As g is locally Lipschitz continuous we have

$$\int_{|u'|\leq 1} |ug(u')|\, dx \leq c \int_\Omega (|u'|\, |g(u')|)^{\frac{1}{2}}\, |u|\, dx \leq c \left(\int_\Omega u' g(u')\, dx\right)^{\frac{1}{2}} \|u\|_{L^2(\Omega)}.$$

Similarly, by (A2) we have

$$\int_{|u'|>1} |ug(u')|\, dx \leq c \left(\int_\Omega u' g(u')\, dx\right)^{\frac{q}{q+1}} \|u\|_{L^{q+1}(\Omega)}.$$

Then from Hölder's inequality we obtain

$$\int_0^t \int_\Omega |ug(u')|\, dxds \leq c \left(\int_0^t \int_\Omega u' g(u')\, dxds\right)^{\frac{1}{2}} \sqrt{t} \sup_{[0,t]} \|u(s)\|_{L^2(\Omega)}$$

$$+ ct^{\frac{1}{q+1}} \left(\int_0^t \int_\Omega u' g(u')\, dxds\right)^{\frac{q}{q+1}} \sup_{[0,t]} \|u(s)\|_{L^{q+1}(\Omega)}.$$

Using the Hölder, Sobolev, and Poincaré inequalities we have

$$\|u(s)\|_{L^2(\Omega)} \leq c\, \|u(s)\|_{L^{q+1}(\Omega)} \leq c\, E(s)^{\frac{1}{2}} \leq c\, e(0)^{\frac{1}{2}} \quad \text{for all} \quad s \geq 0.$$

From these estimates it follows that

$$\int_0^t \int_\Omega |ug(u')|\,dxds \le c\sqrt{t} + ct^{\frac{1}{q+1}} = o(t), \quad t \to +\infty.$$

Proof of Lemma 4.3. Let $\varepsilon > 0$ be an arbitrarily small real and set

$$M(\varepsilon) = \sup\left\{ \frac{x}{g(x)}; \quad |x| \ge \sqrt{\frac{\varepsilon}{|\Omega|}} \right\};$$

by hypotheses (A2), we have $M(\varepsilon) < +\infty$. Clearly,

$$\int_{|u'|<\sqrt{\frac{\varepsilon}{|\Omega|}}} |u'|^2\,dx \le \varepsilon.$$

On the other hand

$$\int_{|u'|\ge\sqrt{\frac{\varepsilon}{|\Omega|}}} |u'|^2\,dx = \int_{|u'|\ge\sqrt{\frac{\varepsilon}{|\Omega|}}} \frac{|u'|}{g(u')}\,u'g(u')\,dx \le M(\varepsilon)\int_\Omega u'g(u')\,dx.$$

As

$$\int_{|u'|\ge\sqrt{\frac{\varepsilon}{|\Omega|}}} |u'|^2\,dx \le c\sqrt{2e(0)}\,\left(\int_{|u'|\ge\sqrt{\frac{\varepsilon}{|\Omega|}}} |u'|^2\,dx\right)^{\frac{1}{2}},$$

we deduce that

$$\int_\Omega |u'|^2\,dx \le \varepsilon + c\sqrt{2e(0)M(\varepsilon)}\,\left(\int_\Omega u'g(u')\,dx\right)^{\frac{1}{2}},$$

and then by the Hölder inequality

$$\int_0^t \int_\Omega |u'|^2\,dxds \le \varepsilon t + c\sqrt{2e(0)M(\varepsilon)}\,\sqrt{t}\,\left(\int_0^t \int_\Omega u'g(u')\,dxds\right)^{\frac{1}{2}}$$

$$\le \varepsilon t + ce(0)\sqrt{2M(\varepsilon)}\,\sqrt{t} = o(t), \quad t \to +\infty,$$

by Lemma 4.2.

Proof of Lemma 4.4. Define

$$I_1 := \int_0^t h(t-\tau)(\nabla u(\tau), \nabla u(t))\,d\tau.$$

We have

$$|I_1| = \left| \int_0^t h(t-\tau)(\nabla u(\tau) - \nabla u(t), \nabla u(t))\, d\tau + \int_0^t h(t-\tau)|\nabla u(t)|^2\, d\tau \right|$$

$$\leq |\nabla u(t)| \int_0^t h(t-\tau)|\nabla u(\tau) - \nabla u(t)|\, d\tau + \left(\int_0^t h(s)\, ds \right) |\nabla u(t)|^2$$

$$\leq \left(\operatorname{esssup}_{t\geq 0} |\nabla u(t)| \right) \left(\int_0^t h(s)\, ds \right)^{1/2} \left(\int_0^t h(t-\tau)|\nabla u(t) - \nabla u(\tau)|^2\, d\tau \right)^{1/2}$$

$$+ \left(\int_0^t h(s)\, ds \right) |\nabla u(t)|^2;$$

that is,

$$|I_1| \leq \left(\operatorname{esssup}_{t\geq 0} |\nabla u(t)| \right) \|h\|_{L^1(0,\infty)}^{1/2} \left[(h \square \nabla u)(t) \right]^{1/2} + \left(\int_0^t h(s)\, ds \right) |\nabla u(t)|^2. \tag{4.14}$$

Define

$$I_2 := (h \square \nabla u)(t);$$

then we have

$$|I_2| = \int_0^t h(t-\tau)|\nabla u(t) - \nabla u(\tau)|^2\, d\tau$$

$$\leq \int_0^t h(t-\tau) \left(|\nabla u(t)| + |\nabla u(\tau)| \right) |\nabla u(t) - \nabla u(\tau)|\, d\tau$$

$$\leq \left(2 \operatorname{esssup}_{\zeta\geq 0} |\nabla u(\zeta)| \right) \int_0^t h(t-\tau)|\nabla u(t) - \nabla u(\tau)|\, d\tau$$

$$\leq \left(2 \operatorname{esssup}_{\zeta\geq 0} |\nabla u(\zeta)| \right) \left(\int_0^t h(s)\, ds \right)^{1/2} \left(\int_0^t h(t-\tau)|\nabla u(t) - \nabla u(\tau)|^2\, d\tau \right)^{1/2};$$

that is,

$$|I_2| \leq \left(2 \operatorname{esssup}_{\zeta\geq 0} |\nabla u(\zeta)| \right) \|h\|_{L^1(0,\infty)}^{1/2} (h \square \nabla u)^{1/2}(t). \tag{4.15}$$

Combining (4.13), (4.14), and (4.15) we deduce that

$$J(t) \leq \left(3 \operatorname{esssup}_{\zeta\geq 0} |\nabla u(\zeta)| \right) \|h\|_{L^1(0,\infty)}^{1/2} \left[(h \square \nabla u)(t) \right]^{1/2}. \tag{4.16}$$

Thanks to the above inequality and to the hypotheses on h one has

$$J(t) \le \big(3\mathrm{esssup}_{\zeta\ge 0}|\nabla u(\zeta)|\big)\,\|h\|^{1/2}_{L^1(0,\infty)}\left(-\frac{1}{\eta}(h'\Box\nabla u)(t)\right)^{1/2}$$

$$\le 3\sqrt{2}\big(E(0)\big)^{1/2}\|h\|^{1/2}_{L^1(0,\infty)}\left(-\frac{1}{\eta}(h'\Box\nabla u)(t)\right)^{1/2} \tag{4.17}$$

$$= c\left(-\frac{1}{\eta}(h'\Box\nabla u)(t)\right)^{1/2}.$$

Integrating (4.17) over $(0,t)$, we obtain from (4.9) that

$$\int_0^t J(s)\,ds \le c\int_0^t 1\cdot\left(-\frac{1}{\eta}(h'\Box\nabla u)(s)\right)^{1/2} ds$$

$$\le c\left(\int_0^t 1\,ds\right)^{1/2}\left(\int_0^t -\frac{1}{\eta}(h'\Box\nabla u)(s)\,ds\right)^{1/2}$$

$$= c\sqrt{t}\int_0^t\left(-\frac{1}{\eta}(h'\Box\nabla u)(s)\right)ds \le \frac{2c}{\eta}e(0)\sqrt{t} = o(t),\quad t\to+\infty.$$

Proof of Theorem 4.1. Put

$$\phi(t) := (u(t), u'(t));$$

then we have

$$\phi'(t) = -|\nabla u(t)|^2 - (g(u'),u) + \int_0^t h(t-\tau)(\nabla u(\tau),\nabla u(t))\,d\tau + |u'(t)|^2. \tag{4.18}$$

Adding and subtracting appropriate terms in (4.18) it follows that

$$\phi'(t) = -2e(t) + 2|u'(t)|^2 - (g(u'),u)$$

$$-\left(\int_0^t h(s)\,ds\right)|\nabla u(t)|^2 + (h\Box\nabla u)(t) + \int_0^t h(t-\tau)(\nabla u(\tau),\nabla u(t))\,d\tau. \tag{4.19}$$

That is,

$$\phi'(t) = -2e(t) + 2|u'(t)|^2 - (g(u'),u) + J(t).$$

Then, it follows that

$$\phi(t) - \phi(0) = \int_0^t \big\{2|u'(t)|^2 - 2e(t) - (g(u'),u) + J(s)\big\}\,ds.$$

Assume that, contrary to our claim, $l := \lim_{t\to\infty} e(t) > 0$. Then by Lemmas 4.2–4.4, we have

$$\phi(t) - \phi(0) \le -2lt + o(t),\quad t\to+\infty.$$

It follows that $\phi(t) \to -\infty$ as $t \to +\infty$. But this is impossible because

$$\left| \int_\Omega uu' \, dx \right| \leq c \int_\Omega (|\nabla u|^2 + u'^2) \, dx \leq ce(0).$$

We conclude that $\lim_{t\to+\infty} E(t) = 0$.

Remark 4.1. If g was linear or superlinear near zero, then it is sufficient to assume that Ω is an open set in which the Poincaré inequality holds. If we, furthermore, add the term u to (4.1), then we can assume that $\Omega = \mathbf{R}^n$.

OPTIMAL POLICIES FOR n-DIMENSIONAL SINGULAR STOCHASTIC CONTROL PROBLEMS PART I: THE SKOROKHOD PROBLEM*

LUKASZ KRUK†

Abstract. An n-dimensional Brownian motion is controlled by adding a process of locally bounded variation to it so as to minimize an expected infinite-horizon discounted cost. We show, by direct probabilistic techniques, that the optimal control is a solution of a (generalized) Skorokhod problem.

Key words. singular stochastic control, optimal policy, the Skorokhod problem

AMS subject classification. 93E20

PII. S0363012998347535

1. Introduction.

Singular stochastic control of Markov processes is a class of problems in which we are allowed to alter the drift of a process (usually the Brownian motion) at a price proportional to the variation of the control used. Admissible controls may not be absolutely continuous and may have jumps. The corresponding Bellman equation for such a problem is a pair of differential inequalities, one of second, the other of first order. The latter one determines the nonaction region $\mathcal{C}$. It was shown that in many cases the optimal control makes the underlying Markov process a diffusion reflected at the boundary of $\mathcal{C}$ with an initial jump to its boundary if it starts outside $\mathcal{C}$. The first papers in which a problem of this type was considered are, to our knowledge, [1, 2].

One of the problems that attracted the attention of researchers in this field was to minimize

$$u_M(x) = E^x \int_0^\infty e^{-t}[h(X_t)dt + d\xi_t], \tag{1}$$

where $x \in R^n$ is fixed, h is a nonnegative, convex function (usually smooth),

$$X_t = x + \sqrt{2}W_t + M_t \tag{2}$$

with W_t an n-dimensional Brownian motion, M_t any adapted process of bounded variation over finite time-intervals, and ξ_t the variation of M up to time t. Variations of this problem in one dimension were considered in [3, 4, 11, 12, 13, 16, 17, 19, 20, 24] and other papers (see, e.g., [25] or [9] for more complete references). It was shown that the corresponding value function u is twice continuously differentiable (smooth fit), and the optimal policy is the Brownian motion reflected at the endpoints of the interval in which the absolute value of the derivative of u is less than 1. Simplified treatment of the one-dimensional case was later given in [6, 7].

*Received by the editors November 12, 1998; accepted for publication (in revised form) November 24, 1999; published electronically May 26, 2000. This work is a part of the author's Ph.D. thesis at the Courant Institute of Mathematical Sciences, New York University.

Generalization of these results to higher dimensions, however, is not straightforward. Some regularity of both the domain and the vector field determining the reflection direction is necessary to define the Brownian motion reflected at the boundary of such a domain (see, e.g., [14, 23, 30, 33]). In the two-dimensional case, $C^{2,\alpha}$ regularity was obtained for both the value function and the boundary of the nonaction region by PDE methods: elliptic regularity and regularity for free-boundary problems [29]. In dimensions greater than two only partial results are known: the value function is $W^{2,\infty}_{loc}$; the optimal policy exists and is unique [26, 31], keeps the controlled process in some compact set $\tilde{D}$ containing $\overline{\mathcal{C}}$, and does not act in $\mathcal{C}$ [25]. Regularity of the free boundary away from some corner points for a similar n-dimensional problem was shown in [34].

Let us also mention that this class of stochastic control problems is closely related to the target zone models of the foreign exchange rates (see, e.g., [21]). In fact, our initial motivation for considering it was to use it in multilateral target zone modeling.

In this article we prove, by a direct probabilistic argument, that in any dimension the optimal policy minimizing (1) is a solution to the Skorokhod problem (in a slightly generalized sense, to be defined later). This approach, however, leaves the question of smooth fit in higher dimensions unanswered. The second part examines the case of a radially symmetric running cost h and considers a similar problem with ergodic (instead of exponential) discounting in which we limit the admissible controlled processes to Brownian motions reflected normally at the boundary of some domain.

2. The optimal policy as a solution to the Skorokhod problem.

2.1. Definitions and assumptions. Let $(W_t, \mathcal{F}_t, t \geq 0)$ be a standard n-dimensional Brownian motion defined on a complete probability space $(\Omega, \mathcal{F}, P)$. Let $\{\mathcal{F}_t\}$ be the augmentation of the filtration generated by W (see [18, p. 89]). Let, for a given $x \in R^n$, a process X_t be defined by (2), where M_t is a left-continuous process adapted to $\mathcal{F}_t$ such that (s.t.), for all $T > 0$, P almost surely (a.s.), the variation of $M_\cdot(\omega)$ on the interval $[0, T]$ is finite. As is customary in singular stochastic control theory, we write

$$M_t = \int_0^t N_s d\xi_s, \tag{3}$$

where $|N_t| = 1$ for every $t \geq 0$ a.s. and ξ is nondecreasing and left-continuous. In other words, $\xi_t(\omega)$ is the total variation of $M_\cdot(\omega)$ on the interval $[0, t]$, $N_t(\omega)$ is the Radon–Nikodym derivative of the measure induced on $[0, \infty)$ by $M_\cdot(\omega)$ with respect to its total variation $\xi_\cdot(\omega)$. In what follows, we shall always describe M_t as (N_t, ξ_t).

Let $h : R^n \to R$ be a strictly convex function satisfying, for appropriate positive constants C_0, c_0, and $q > 1$, the following conditions:

$$h \in C^{2,1}(R^n), \tag{4}$$

$$0 \leq h(x) \leq C_0(1 + |x|^q), \tag{5}$$

$$|h(x) - h(x + x')| \leq C_0(1 + h(x) + h(x + x'))^{1-1/q}|x'|, \tag{6}$$

$$h(x + \lambda x') + h(x - \lambda x') - 2h(x) \leq C_0\lambda^2(1 + h(x))^r, \qquad r = \left(1 - \frac{2}{q}\right)^+, \tag{7}$$

$$c_0|y|^2 \leq D^2h(x)y \cdot y \tag{8}$$

for all $x, x' \in R^n$, $|x'| \le 1$, $0 \le \lambda \le 1$. These conditions are similar to those in [26]. (As the authors of that paper expressed it, (5), (6), (7) say that "h is roughly speaking of polynomial growth.") In particular, (6) yields

$$|\nabla h(x)| \le \tilde{C}_0(1 + h(x)) \tag{9}$$

and (7) yields

$$D^2h(x)y \cdot y \le C_0(1 + h(x))|y|^2, \tag{10}$$

so the assumptions of [29] are also satisfied. We need them because we want to use the results from both these papers. It may be a good idea to see how (5)–(8) work for a quadratic function (Ax, x) with a symmetric positive definite matrix A in order to get used to them.

For convenience, we assume that $\inf_{x \in R^n} h(x) = h(0) = 0$.

For a given control process (N, ξ), we define the corresponding cost by

$$V_{(N,\xi)}(x) = E^x \int_0^\infty e^{-t}[h(X_t)dt + d\xi_t]. \tag{11}$$

The task is to minimize $V_{(N,\xi)}(x)$ in the class of all admissible controls, i.e., to find

$$u(x) = \inf_{N,\xi} V_{(N,\xi)}(x), \tag{12}$$

where (N_t, ξ_t) are as described above. If this minimum is attained for some $(\tilde{N}, \tilde{\xi})$, we say that

$$\nu_t = \int_0^t \tilde{N}_s d\tilde{\xi}_s \tag{13}$$

is an optimal policy (for x).

DEFINITION 2.1. *If, for a sequence (N_n, ξ_n) of controls,*

$$u(x) = \lim_{n \to \infty} V_{(N_n,\xi_n)}(x), \tag{14}$$

we say that (N_n, ξ_n) is a sequence of ϵ-optimal policies (for x).

To avoid unnecessary complications in the exposition of the proofs, we will use this definition rather than (as is done usually) check that for a given control (N, ξ) $u(x) \ge V_{(N,\xi)}(x) - \epsilon$.

LEMMA 2.2. *The optimal policy (if it exists) is unique.*

LEMMA 2.3. *For every $x \in R^n$ there exists a unique optimal policy ν^*. Moreover, if (N_n, ξ_n) is a sequence of ϵ-optimal policies for x, then we can extract from it a subsequence $n_k \to \infty$ s.t.*

$$\nu_t^{n_k} = \int_0^t N_s^{n_k} d\xi_s^{n_k} \to \nu_t^* \tag{15}$$

for $L_{eb} \times P$ almost all (t, ω), where L_{eb} is the Lebesgue measure on $[0, \infty)$.

These lemmas are essentially proved in [26]. It can be shown, by a direct control-theoretic approach given in [26], that the value function $u \in W^{2,\infty}_{loc}$ and, moreover, it satisfies the Bellman equation

$$\max(u - \triangle u - h, |\nabla u|^2 - 1) = 0 \tag{16}$$

in R^n (see the appendix at the end of this paper (section 3) for further discussion).

It can also be proven by PDE methods that (16) admits a unique nonnegative, convex $W^{2,\infty}_{loc}$ solution (see [8, 15, 29]). Nonnegativity and convexity of the value function are easy consequences of its definition (see [9, Lemma VIII.3.2]), so the value function u is a unique nonnegative, convex $W^{2,\infty}_{loc}$ solution of the Bellman equation (16).

In what follows, let us denote the total variation of a function $f(s)$ on an interval $[0,t]$ by $\bigvee_{[0,t]} f$.

As we have mentioned before, for $n = 1$ or 2 it is known that $u \in C^{2,\alpha}$ for every $\alpha \in (0,1)$. In both cases, the optimal policy makes X_t a Brownian motion reflected at $\partial\mathcal{C}$ at the direction of $-\nabla u$, where

$$\mathcal{C} = \{x \in R^n : |\nabla u(x)| < 1\}. \tag{17}$$

More precisely, the optimally controlled process X_t solves the following problem (with $G := \mathcal{C}$, $v := -\nabla u$).

DEFINITION 2.4. *Let G be an open domain in R^n, $S = \partial G$. Let $x_0 \in G$ and let v be an unit vector field defined on S, i.e., for each $x \in S$, $|v(x)| = 1$, pointing inside G (in particular, nontangential to S). We say that a continuous process*

$$\nu_t = \int_0^t N_s d\xi_s, \tag{18}$$

where $\xi_t = \bigvee_{[0,t]} \nu$, is a solution to a Skorokhod problem for reflected Brownian motion in $\overline{G}$ starting at x_0 with reflection direction v along S if

(a) *$|N_t| \equiv 1$, ξ_t is continuous and nondecreasing;*

(b) *the process X_t defined by*

$$X_t = x_0 + \sqrt{2}W_t + \int_0^t N_s d\xi_s \tag{19}$$

satisfies

$$X_t \in \overline{G}, \quad 0 \le t < \infty, \ \text{a.s.}; \tag{20}$$

(c) *for every $0 \le t < \infty$*

$$\xi_t = \int_0^t I_{[X_s \in \partial G, N_s = v(X_s)]} d\xi_s. \tag{21}$$

This is what is customarily called a solution to the Skorokhod problem for W_t, G, v (see, e.g., [23]).

Now we shall give a slightly modified definition of a solution to the Skorokhod problem.

DEFINITION 2.5. *Let G be an open domain in R^n, $S = \partial G$. Let $x_0 \in G$ and let v be a continuous unit vector field defined on S, i.e., for each $x \in S$ $|v(x)| = 1$. We say that a left-continuous process*

$$\nu_t = \int_0^t N_s d\xi_s, \tag{22}$$

where $|N_t| = 1$, $\xi_t = \bigvee_{[0,t]} \nu$, is a solution to the modified Skorokhod problem for reflected Brownian motion in $\overline{G}$ starting at x_0 with reflection direction v along S if

(a) *with probability* 1*, every possible jump of the process*

$$X_t = x_0 + \sqrt{2}W_t + \nu_t \tag{23}$$

occurs on some interval I *contained in* S *and parallel to the vector field* v *on* I*, i.e., such that for all* $\tilde{x} \in I$*,* $v(\tilde{x})$ *is parallel to* I*. If* X_t *encounters such an interval* I*, it instantaneously jumps to its endpoint in the direction of* v *on* I*.*

Stating this condition more formally, (a.s. $\omega \in \Omega$ *for all* $t \geq 0$*), the following statement is true:* $\xi_{t^+}(\omega) > \xi_t(\omega)$ *(i.e., the trajectory* $X_\cdot(\omega)$ *has a jump at* t*) iff there exists a closed interval*

$$I = \{z_0 + tv(x) : t \in [0, c]\} \subseteq S, \tag{24}$$

where $z_0 \in R^n$*,* $c > 0$*,* $x = X_t(\omega)$*, s.t.* $x \in I$ *and* $v(\tilde{x})$ *is parallel to* I *for every* $\tilde{x} \in I$*. Also, if we assume that* I *is a maximal interval with such properties (i.e., there is no* $\tilde{I}$ *enjoying the same properties and s.t.* I *is properly contained in* $\tilde{I}$*), then* $X_{t+}(\omega) = z_0 + cv(x)$*, and* (b), (c) *are as in the previous definition.*

In particular, if intervals of the type described in (a) do not exist (e.g., v is never tangential to S or G is strictly convex), then ξ_t is continuous in $[0, \infty)$ a.s. ω, and this definition reduces to the previous one.

The goal of this paper is to prove the following theorem in any dimension n.

THEOREM 2.6. *For every* $x \in \overline{\mathcal{C}}$ *the optimal policy* $\nu_t = \int_0^t N_s d\xi_s$ *is a solution to the modified Skorokhod problem for* W_t*,* $\mathcal{C}$*,* $-\nabla u$*.*

Intuitively, such a theorem should be true because for the optimally controlled process X_t all the inequalities in the corresponding verification theorem (see, e.g., Theorem VIII.4.1 in [9]) must, in fact, be equalities. We actually use this idea in one of the stages of our proof.

The rest of this paper is entirely devoted to the proof of Theorem 2.6. The proof is long and proceeds in several steps. In subsection 2.2 we construct a sequence of ϵ-optimal policies which are used in subsection 2.3 to prove the condition (b) from Definition 2.5. Subsection 2.4 contains the proof of (c). To prove (a), we need one of the consequences of the Bellman principle and the strong Markov property of the optimally controlled process. We show them in subsection 2.5; the following subsection provides the proof of (a). The concluding subsection 2.7 contains further discussion of some details of the proof.

2.2. Some ϵ-optimal policies. Let, for every $\epsilon > 0$,

$$\mathcal{C}_\epsilon = \{|\nabla u|^2 < 1 - \epsilon\}, \qquad S_\epsilon = \partial \mathcal{C}_\epsilon. \tag{25}$$

In the set $\mathcal{C}$ (defined by (17)), $u \in C^{4,\alpha}$ for every $\alpha \in (0, 1)$.

Indeed, let B be any open ball such that $\overline{B} \subseteq \mathcal{C}$. By Theorem 6.13 of [10], the Dirichlet problem

$$\tilde{u} - \triangle \tilde{u} = h$$

in B,

$$\tilde{u} = u \tag{26}$$

on ∂B, has a solution $\tilde{u} \in C^0(\overline{B}) \cap C^{2,\alpha}(B)$. In particular, $\tilde{u} - u \in W^{2,\infty}(B)$, so, by (26), $\tilde{u} - u \in W_0^{1,2}(B)$ (see [10, p. 154]). By Theorem 8.9 of [10], $u \equiv \tilde{u}$ in B, so

$u \in C^{2,\alpha}(B)$. By Theorem 6.17 of [10], $u \in C^{4,\alpha}(B)$ (and thus $u \in C^{4,\alpha}(\mathcal{C})$) for all $\alpha \in (0,1)$.

Also, u is strictly convex in $\mathcal{C}$ (see (4.10) of [29]). Thus in $\overline{\mathcal{C}}_{\frac{\epsilon}{2}}$, by compactness,

$$\inf_{x \in \overline{\mathcal{C}}_{\frac{\epsilon}{2}}} \inf_{\nu \in R^n, |\nu|=1} (D^2 u)\nu \cdot \nu \geq c_\epsilon > 0. \tag{27}$$

In particular, if $w = |\nabla u|^2$,

$$\nabla w(x) \neq 0 \ \text{ for all } \ x \in S_\epsilon, \tag{28}$$

because for $\nu = \frac{\nabla u}{|\nabla u|}$, $x \in S_\epsilon$,

$$w(x) = 1 - \epsilon, \qquad w(x) = \left| \frac{\partial u}{\partial \nu} \right|^2, \tag{29}$$

$$\frac{\partial^2 u}{\partial \nu^2} \geq c_\epsilon \ \text{ near } \ S_\epsilon, \tag{30}$$

so

$$\sqrt{w(x+\lambda\nu)} \geq \frac{\partial u}{\partial \nu}(x+\lambda\nu) \tag{31}$$

$$\geq \frac{\partial u}{\partial \nu}(x) + \frac{c_\epsilon}{2}\lambda \tag{32}$$

$$= \sqrt{w(x)} + \frac{c_\epsilon}{2}\lambda \tag{33}$$

for λ small enough, so

$$\frac{\partial \sqrt{w(x)}}{\partial \nu} \geq \frac{c_\epsilon}{2} \tag{34}$$

on S_ϵ, which clearly implies $\frac{\partial w(x)}{\partial \nu} \neq 0$ on S_ϵ. Thus, by the implicit function theorem, S_ϵ is a $C^{3,\alpha}$ hypersurface for every $\alpha \in (0,1)$. Of course, the vector field

$$v(x) = -\frac{\nabla u(x)}{|\nabla u(x)|} \tag{35}$$

is also $C^{3,\alpha}$ in the neighborhood of S_ϵ.

LEMMA 2.7. *$v(x)$ is not tangential to S_ϵ.*

Proof. Suppose that, at $x \in S_\epsilon$, $\nabla u(x)$ is tangential to S_ϵ. Then, by (33) and $v(x) = -\nu(x)$,

$$\sqrt{w(x - \lambda v(x))} \geq \sqrt{w(x)} + \frac{c_\epsilon}{2}\lambda = \sqrt{1-\epsilon} + \frac{c_\epsilon}{2}\lambda \tag{36}$$

for small $\lambda > 0$. But, on the other hand, $v(x)$ is tangential to $S_\epsilon = \{w(x) = 1 - \epsilon\}$, so

$$w(x - \lambda v(x)) = w(x) + O(\lambda^2) = 1 - \epsilon + O(\lambda^2), \tag{37}$$

a contradiction.

One can also see that ∇u points outside (not inside) $\mathcal{C}_\epsilon$ (actually, it is proven in [29] that $|\nabla u|$ increases in the direction of ∇u), so it is possible to define an

instantaneous reflection at S_ϵ in the direction $v(x)$, i.e., the solution to the Skorokhod problem for W_t, $\mathcal{C}_\epsilon$, $v(x)$ (see [23]). We shall denote it by

$$\nu_t^\epsilon = \int_0^t N_s^\epsilon d\xi_s^\epsilon. \tag{38}$$

LEMMA 2.8. *ν_t^ϵ are ϵ-optimal policies for our control problem.*

Proof. The value function u satisfies

$$\triangle u - u + h = 0 \text{ in } \mathcal{C}_\epsilon \tag{39}$$

and

$$\frac{\partial u}{\partial v} = -\sqrt{w(x)} = -\sqrt{1-\epsilon} \text{ on } \partial\mathcal{C}_\epsilon. \tag{40}$$

(Recall that v is the direction of $-\nabla u$, so $\sqrt{w(x)} = |\frac{\partial u}{\partial v}| = -\frac{\partial u}{\partial v}$.)

Thus, by Itô's rule for continuous semimartingales (see, e.g., [18, Theorem 3.3.6]) applied to $e^{-t}u(X_t^\epsilon)$, where

$$X_t^\epsilon = x + \sqrt{2}W_t + \nu_t^\epsilon, \tag{41}$$

taking into account the fact that $\mathcal{C}$ is bounded [29, Lemma 4.4], we get

$$\begin{aligned} u(x) &= E^x \int_0^\infty e^{-t}[h(X_t^\epsilon)dt + \sqrt{w(X_t^\epsilon)}d\xi_t^\epsilon] \\ &= E^x \int_0^\infty e^{-t}[h(X_t^\epsilon)dt + \sqrt{1-\epsilon}d\xi_t^\epsilon] \\ &\geq \sqrt{1-\epsilon}\, E^x \int_0^\infty e^{-t}[h(X_t^\epsilon)dt + d\xi_t^\epsilon] \\ &= \sqrt{1-\epsilon}\, J_x(\nu^\epsilon), \end{aligned} \tag{42}$$

where $J_x(\tilde{\nu})$ denotes the cost associated with choosing the policy

$$\tilde{\nu_t} = \int_0^t \tilde{N}_s d\tilde{\xi}_s, \tag{43}$$

i.e.,

$$J_x(\tilde{\nu}) = E^x \int_0^\infty e^{-t}[h(\tilde{X}_t)dt + d\tilde{\xi}_t], \tag{44}$$

and

$$\tilde{X}_t = x + \sqrt{2}W_t + \tilde{\nu}_t. \tag{45}$$

(The inequality in (42) is true because $h \geq 0$.)

This proves ϵ-optimality of ν^ϵ.

2.3. The optimal policy keeps the process in $\overline{\mathcal{C}}$. By Lemmas 2.3 and 2.8 we see that, for any fixed $x \in \mathcal{C}$, there exists a sequence $\epsilon_k \downarrow 0$ s.t.

$$\nu^{\epsilon_k} \to \nu \text{ almost everywhere (a.e.) } L_{eb} \times P \text{ on } [0,\infty) \times \Omega, \tag{46}$$

where ν^{ϵ_k} are defined by (38) and

$$\nu_t = \int_0^t N_s d\xi_s \tag{47}$$

is the unique optimal policy. Let

$$X_t = x + \sqrt{2}W_t + \nu_t \tag{48}$$

be the optimally controlled process.

LEMMA 2.9. *$X_t \in \overline{\mathcal{C}}$ for all $0 \le t < \infty$ a.s. if $x \in \mathcal{C}$.*

Proof. Let

$$A = \{\omega : (X_t^{\epsilon_k})(\omega) \in \overline{\mathcal{C}}_{\epsilon_k} \text{ for all } 0 \le t < \infty \text{ and all } k \ge 0\}. \tag{49}$$

From the definition of ν_t^ϵ (see the paragraph preceding (38)) and (41) we know that $P(A) = 1$. $\overline{\mathcal{C}}_{\epsilon_k} \subseteq \mathcal{C}$ for all $\epsilon > 0$, so for $\omega \in A$ and every $t \ge 0$, $X_t^{\epsilon_k}(\omega) \in \overline{\mathcal{C}}$. Also let

$$B = \{\omega : X^{\epsilon_k}(\omega) \to X(\omega) \text{ a.e. } L_{eb} \text{ on } [0,\infty)\}. \tag{50}$$

By (46) $P(B) = 1$. For all $\omega \in A \cap B$, $X_t(\omega) \in \overline{\mathcal{C}}$ L_{eb} a.e. on $[0,\infty)$, because $\overline{\mathcal{C}}$ is closed. But ν is left-continuous, so $\nu_t(\omega) \in \overline{\mathcal{C}}$ for all $0 \le t < \infty$ and $\omega \in A \cap B$ (for $t = 0$ it is true because $X(0) = x \in \mathcal{C}$). The proof is complete.

Remark. The statement of the last lemma is also true for $x \in \partial\mathcal{C}$. Indeed, in this case let $x_n \in \mathcal{C}$ be s.t. $x_n \to x$ and suppose we want to control the process starting at x. Policies

$$\tilde{\nu}^{x^n} = \nu^{x^n} + x_n - x \tag{51}$$

jump at time 0 from the starting point x to x_n and then follow ν^{x_n}, the optimal policy for the process starting at x_n. Because $x_n \to x$ and u is continuous, it is easy to see that $\tilde{\nu}^{x^n}$ is a sequence of ϵ-optimal policies for x and, by the last lemma,

$$X_t^n = x + \sqrt{2}W_t + \tilde{\nu}^{x^n} = x_n + \sqrt{2}W_t + \nu^{x^n} \in \overline{\mathcal{C}} \tag{52}$$

for all $0 \le t < \infty$ a.s. Repeating the proof of the last lemma we see that also the optimally controlled process

$$X_t = x + \sqrt{2}W_t + \nu_t^x \in \overline{\mathcal{C}} \text{ for all } 0 \le t < \infty \text{ a.s.} \tag{53}$$

2.4. The optimal policy acts only on $\partial\mathcal{C}$, and its push direction is $-\nabla u$. To prove (c) from Definition 2.5 (with $G = \mathcal{C}$, $v = -\nabla u$), we would like to use Meyer's version of Itô's rule for semimartingales to $e^{-t}u(X_t)$ and proceed similarly as in the proof of Theorem 3.1 in [29]. The problem is that we cannot assume $u \in C^2$, only $u \in W^{2,\infty}_{loc}$. A standard way to overcome this difficulty is to use a regularization of u by convolutions (see, e.g., [9, proof of Theorem VII.4.1]). Another regularization, perhaps more natural in this context, will be discussed in remark (2) in section 2.7. (Alternatively, we can apply Itô's formula directly to our case, without going through the regularization, if we use the results from [32].)

Let $\phi \in C^\infty$, $\phi \geq 0$, supp $\phi \subseteq B_1 = \{x : |x| \leq 1\}$, $\int_{R^n} \phi = 1$. Let $\phi_\epsilon = \frac{\phi(\frac{x}{\epsilon})}{\epsilon^n}$ and let

$$\tilde{u}_\epsilon(x) = (u * \phi_\epsilon)(x) = \int_{R^n} u(y)\phi(x-y)dy, \tag{54}$$

$\tilde{u}_\epsilon \in C^\infty$. Let $h^\epsilon = h * \phi_\epsilon$.

From (16)

$$u - \triangle u \leq h, \qquad |\nabla u| \leq 1, \tag{55}$$

so

$$\tilde{u}_\epsilon - \triangle \tilde{u}_\epsilon \leq h^\epsilon, \qquad |\nabla \tilde{u}_\epsilon| \leq 1 \text{ in } R^n. \tag{56}$$

Let $T > 0$. Using Meyer's version of Itô's rule for semimartingales [27, pp. 278, 301], we get

$$\begin{aligned} E^x(e^{-T}\tilde{u}_\epsilon(X_T)) = \tilde{u}_\epsilon(x) &\\ + E^x \int_0^T e^{-t}(\triangle \tilde{u}_\epsilon - \tilde{u}_\epsilon)(X_t)dt &\\ + E^x \int_0^T e^{-t}\nabla \tilde{u}_\epsilon(X_t)N_t d\xi_t &\\ + E^x \left\{ \sum_{0 \leq t < T} e^{-t}(\tilde{u}_\epsilon(X_{t+}) - \tilde{u}_\epsilon(X_t) - \nabla \tilde{u}_\epsilon(X_t)N_t(\xi_{t+} - \xi_t)) \right\}. & \end{aligned}$$

(The last term keeps account of jumps of X_t.)

By (56), we get

$$\begin{aligned} E^x(e^{-T}\tilde{u}_\epsilon(X_T)) + E^x \int_0^T e^{-t}h^\epsilon(X_t)dt - E^x \int_0^T e^{-t}\nabla \tilde{u}_\epsilon(X_t)N_t d\xi_t &\\ + E^x \left\{ \sum_{0 \leq t < T} e^{-t}(\tilde{u}_\epsilon(X_t) - \tilde{u}_\epsilon(X_{t+}) + \nabla \tilde{u}_\epsilon(X_t)N_t(\xi_{t+} - \xi_t)) \right\} &\\ \geq \tilde{u}_\epsilon(x). & \end{aligned} \tag{57}$$

Now, $X_t \in \overline{\mathcal{C}}$ for all $t \geq 0$ a.s. and, by Lemma 4.4 from [29], $\mathcal{C}$ is bounded. Because u, ∇u, $D^2 u$ are bounded on $B_R = \{x : |x| \leq R\}$, where $\overline{\mathcal{C}} \subseteq B_{R-1}$, we infer that h^ϵ, $\tilde{u}_\epsilon$, $\epsilon < 1$ are bounded uniformly on $\overline{\mathcal{C}}$ and

$$\tilde{u}_\epsilon \to u, \quad \nabla \tilde{u}_\epsilon \to \nabla u, \quad h^\epsilon \to h \quad \text{uniformly in } \overline{\mathcal{C}}. \tag{58}$$

On the other hand,

$$u(x) = E^x \int_0^\infty e^{-t}[h(X_t)dt + d\xi_t] \tag{59}$$

because ν is the optimal policy. In particular,

$$E^x \int_0^\infty e^{-t}d\xi_t < \infty, \tag{60}$$

so

$$E^x \int_0^T e^{-t} d\xi_t < \infty. \tag{61}$$

Thus, using the bounded convergence theorem, we get from (57)

$$\begin{aligned} &E^x(e^{-T}u(X_T)) + E^x \int_0^T e^{-t} h(X_t)dt - E^x \int_0^T e^{-t} \nabla u(X_t) N_t d\xi_t \\ &+E^x \left\{ \sum_{0 \le t < T} e^{-t}(u(X_t) - u(X_{t+}) + \nabla u(X_t) N_t(\xi_{t+} - \xi_t)) \right\} \\ &\qquad \ge u(x). \end{aligned} \tag{62}$$

The last term on the left-hand side is nonpositive because of convexity of u (recall that, by (48) and (47), $N_t(\xi_{t+} - \xi_t) = X_{t+} - X_t$), so we arrive at

$$E^x(e^{-T}u(X_T)) + E^x \int_0^T e^{-t} h(X_t)dt - E^x \int_0^T e^{-t} \nabla u(X_t) N_t d\xi_t \ge u(x). \tag{63}$$

Letting T go to infinity we get, because of boundedness of X_t, $|\nabla u| \le 1$, $|N_t| = 1$, and (60),

$$E^x \int_0^\infty e^{-t} h(X_t)dt - E^x \int_0^\infty e^{-t} \nabla u(X_t) N_t d\xi_t \ge u(x). \tag{64}$$

Using this inequality and (59) we arrive at

$$E^x \int_0^\infty e^{-t}(-\nabla u(X_t)) N_t d\xi_t \ge E^x \int_0^\infty e^{-t} d\xi_t, \tag{65}$$

i.e.,

$$E^x \int_0^\infty e^{-t}(1 + \nabla u(X_t) N_t) d\xi_t \le 0. \tag{66}$$

But $|\nabla u(X_t) N_t| \le 1$ by $|N_t| = 1$, $|\nabla u| \le 1$, so (66) gives

$$-\nabla u(X_t) N_t = 1, \quad d\xi \text{ a.e. on } [0, \infty), \quad P \text{ a.s.} \tag{67}$$

In particular, because $|\nabla u| < 1$ in $\mathcal{C}$,

$$X_t \in R^n - \mathcal{C}, \quad d\xi \text{ a.e. on } [0, \infty), \quad P \text{ a.s.}, \tag{68}$$

so

$$X_t \in \partial\mathcal{C}, \quad d\xi \text{ a.e. on } [0, \infty), \quad P \text{ a.s.} \tag{69}$$

But if $X_t \in \partial\mathcal{C}$, $|\nabla u(X_t)| = 1$, so (67) can hold only if

$$N_t = -\nabla u(X_t), \quad d\xi \text{ a.e. on } [0, \infty), \quad P \text{ a.s.} \tag{70}$$

Statements (69) and (70) prove the condition (c) from Definition 2.5.

2.5. The optimally controlled Brownian motion is a Markov process. Let V be the set of admissible policies (described in subsection 2.1). It is known that for singular stochastic control problems the Bellman principle holds; i.e., for every stopping time T of the filtration $(\mathcal{F}_t)$ and every $x \in R^n$

$$u(x) = \inf_{\tilde{\nu}} \left\{ E^x \int_0^T e^{-t}[h(\tilde{X}_t)dt + d\tilde{\xi}_t] + E^x(e^{-T}u(\tilde{X}_T)) \right\}, \tag{71}$$

where $\tilde{X}_t$, $\tilde{\nu}_t$, $\tilde{\xi}_t$ are as in (45), (43) (see [9, section VIII.5]). We want to prove that this infimum is actually attained for the optimal policy.

LEMMA 2.10. *Let $\nu_t = \int_0^t N_s d\xi_s$ be the optimal policy for x and let the process X_t defined by* (48) *be the optimally controlled Brownian motion starting at x. Then*

$$u(x) = E^x \int_0^T e^{-t}[h(X_t)dt + d\xi_t] + E^x e^{-T}u(X_T). \tag{72}$$

Proof. Let

$$V_\epsilon = \left\{ \nu_t \in V : \ \nu_t = \int_0^t \dot{\nu}_s ds : |\dot{\nu}_s| \le \frac{1}{\epsilon} \ \text{ for all } \ s \ge 0 \right\} \tag{73}$$

be a subclass of controls allowed in our problem. The value function

$$u^\epsilon(x) = \inf_{\tilde{\nu} \in V_\epsilon} \left\{ E^x \int_0^\infty e^{-t}[h(\tilde{X}_t)dt + d\tilde{\xi}_t] \right\} \tag{74}$$

converges to u uniformly on compact sets as $\epsilon \to 0$ [26] (see also the appendix). By the classical control theory for diffusion processes, a unique optimal policy $\tilde{\nu}_t^\epsilon = \int_0^t \tilde{N}_s^\epsilon d\tilde{\xi}_s^\epsilon$ for the problem (74) exists and

$$u^\epsilon(x) = E^x \int_0^T e^{-t}[h(\tilde{X}_t^\epsilon)dt + d\tilde{\xi}_t^\epsilon] + E^x e^{-T}u(\tilde{X}_T^\epsilon), \tag{75}$$

where

$$\tilde{X}_t^\epsilon = x + \sqrt{2}W_t + \tilde{\nu}_t^\epsilon. \tag{76}$$

The proof of (75) can be obtained, for example, by a suitable modification of the argument proving Lemma IV.3.1 in [9].

$u^\epsilon(x) \to u(x)$, so $\tilde{\nu}_t^\epsilon$ are ϵ-optimal policies for the problem (11)–(12) and the point x. By Lemma 2.3, there exists a sequence $\epsilon_k \downarrow 0$ s.t.

$$\nu_t^{\epsilon_k} \to \nu_t \tag{77}$$

for $L_{eb} \times P$ almost all (t, ω).

Assume, for simplicity, that

$$X_T^{\epsilon_k} \to X_T \tag{78}$$

a.s. and that the stopping time T is finite a.s. (We shall remove these assumptions later.) Then, by (77) and (78), letting $k \to \infty$ in (75) for $\epsilon = \epsilon_k$, we get, by Fatou's lemma,

$$\begin{aligned} u(x) &= \liminf_{k\to\infty} u^{\epsilon_k}(x) \\ &= \liminf_{k\to\infty} \left(E^x \int_0^T e^{-t}[h(\tilde{X}_t^\epsilon)dt + d\tilde{\xi}_t^\epsilon] + E^x e^{-T} u(\tilde{X}_T^\epsilon) \right) \\ &\geq E^x \liminf_{k\to\infty} \left(\int_0^T e^{-t}[h(\tilde{X}_t^\epsilon)dt + d\tilde{\xi}_t^\epsilon] + e^{-T} u(\tilde{X}_T^\epsilon) \right) \\ &= E^x \int_0^T e^{-t}[h(X_t)dt + d\xi_t] + E^x e^{-T} u(X_T). \end{aligned} \tag{79}$$

(A similar argument was used in the proof of Theorem 8 in [26].)

This, together with (71), yields (72) for a finite T under the assumption (78). Now suppose that (78) does not hold. However, by (77), there exists $\epsilon_k \downarrow 0$ s.t. (78) holds for $T + \epsilon_k$ instead of T. Using (72) for $T + \epsilon_k$ and letting $k \to \infty$ we get, again by Fatou,

$$\begin{aligned} u(x) &\geq E^x \int_0^{T+} e^{-t}[h(X_t)dt + d\xi_t] + E^x e^{-T} u(X_{T+}) \\ &= E^x \int_0^T e^{-t}[h(X_t)dt + d\xi_t] \\ &\quad + E^x e^{-T}(|X_{T+} - X_T| + (u(X_{T+}) - u(X_T)) + u(X_T)) \\ &\geq E^x \int_0^T e^{-t}[h(X_t)dt + d\xi_t] + E^x(e^{-T} u(X_T)) \end{aligned} \tag{80}$$

because $|\nabla u| \leq 1$; so, by (71) and (80), (72) holds for a finite T. The latter assumption may now be removed by considering (72) for $T \wedge n$ and another limiting procedure. Let us remark that if $P[T = \infty] > 0$, we do not have a problem with the interpretation of (72), because u is bounded in $\overline{\mathcal{C}}$, in which X_t takes its values a.s. In this case we can either regard $e^{-T}u(X_T)$ on $[T = \infty]$ as 0 or replace the last term in (72) by $E^x[I_{[t<\infty]} e^{-T} u(X_T)]$. The proof of Lemma 2.10 is complete.

In fact, (63) (the argument used to prove it goes through for a stopping time T also) and the above considerations yield another proof of (71) (for the problem considered here).

To proceed further, we need the following lemma.

LEMMA 2.11. *Let $T > 0$ be a constant. For PX_T^{-1} a.e. $\tilde{x} \in \overline{\mathcal{C}}$ the following statement is true:*

$$\vartheta_t^{\tilde{x}} := \nu_{t-T} - \nu_T \tag{81}$$

is the optimal policy controlling $\tilde{x} + \sqrt{2}\tilde{W}_t$, where $\tilde{W}_t = W_{t-T} - W_T$ is a Brownian motion starting from $\tilde{x}$ under the measure $\tilde{P}^{\tilde{x}} = P(\cdot | X_T = \tilde{x})$ (by this we mean the value of the regular conditional probability distribution of $(W_t, \nu_t, t \geq 0)$ given the σ-field $\sigma(X_T)$ on the event $X_T = \tilde{x}$).

Proof. We have

$$u(x) = E^x \int_0^T e^{-t}[h(X_t)dt + d\xi_t] + E^x \left(e^{-T} E^{X_T} \int_T^\infty e^{-(t-T)}[h(X_t)dt + d\xi_t] \right), \tag{82}$$

where $E^{X_T} = E(.|X_T)$ is the conditional expectation operator. For simplicity, assume that ν_t (ξ_t) is left-continuous for *all* $\omega \in \Omega$. This can be achieved by modifying ν on a set of measure zero, which clearly does not lead to any difficulty. Let

$$Y = \int_0^\infty e^{-t}[h(X_{t+T})dt + d\xi_{t+T}]. \tag{83}$$

Y is a $\sigma(W_t, \nu_t, t \geq 0)$-measurable random variable. As is well known (see, e.g., [28, Theorem 3, p. 174], which is stated in the one-dimensional case, but whose proof goes through also in n dimensions), for some Borel function $f : \mathcal{R}^n \to \mathcal{R}$

$$E^{X_T} Y = f(X_T) \tag{84}$$

$(PX_T^{-1}$ a.e.), i.e. for PX_T^{-1} a.e. $\tilde{x} \in \overline{\mathcal{C}}$,

$$f(\tilde{x}) = \tilde{E}^{\tilde{x}} \int_0^\infty e^{-t}[h(X_{t+T})dt + d\xi_{t+T}], \tag{85}$$

where the last expectation is the value of $E^{X_T} Y$ on $[X_T = \tilde{x}]$. Equation (82) combined with (83) and (84) yields

$$u(x) = E^x \int_0^T e^{-t}[h(X_t)dt + d\xi_t] + E^x(e^{-T} f(X_T)). \tag{86}$$

We want to prove that $f(\tilde{x}) = u(\tilde{x})$, PX_T^{-1} a.e., on $\overline{\mathcal{C}}$. $\tilde{W}_t$ is a Brownian motion independent on $\mathcal{F}_t$ (in particular on X_T), so it may be seen that $f(\tilde{x})$ is a payoff of the form (11) for the Brownian motion $\tilde{W}_t$ on $(\Omega, \mathcal{F}_t, \tilde{P}^{\tilde{x}})$ (starting at $\tilde{x}$). Indeed, $\tilde{E}^{\tilde{x}} \int_0^\infty e^{-t}[h(X_{t+T})dt + d\xi_{t+T}]$ defined as above is $(PX_T^{-1}$ a.e.) the expectation of Y under $\tilde{P}^{\tilde{x}}$. This can be seen by approximating Y by suitable finite sums, as in the definition of an integral, evaluating their expectations under $\tilde{P}^{\tilde{x}}$, and then going to the limit, using the bounded and monotone convergence theorems. Also, $\xi_\cdot(\omega)$ is left-continuous for all $\omega \in \Omega$ by assumption. Moreover, the value function for the latter control problem is again u. (The same argument as that for W_t shows that it is a nonnegative, convex $W_{loc}^{2,\infty}$ solution to (16), which is unique by Theorem 4.5 of [29].)

The above considerations lead to

$$u \leq f \tag{87}$$

$(PX_T^{-1}$ a.e.) on $\overline{\mathcal{C}}$.

We want to show that, in fact, equality holds in (87). Suppose it is not true, i.e.,

$$PX_T^{-1}(A) > 0, \tag{88}$$

where

$$A = \{\tilde{x} \in \overline{\mathcal{C}} : u(\tilde{x}) < f(\tilde{x})\}. \tag{89}$$

Of course, (87), (88), and (89) yield

$$E^x e^{-T} u(X_T) < E^x e^{-T} f(X_T). \tag{90}$$

Then, by (72), (90), and (86),

$$u(x) < E^x \int_0^T e^{-t}[h(X_t)dt + d\xi_t] + E^x(e^{-T} f(X_T)) = u(x), \tag{91}$$

a contradiction.

Thus, $u(\tilde{x}) = f(\tilde{x})$ for PX_T^{-1} a.e. $\tilde{x} \in \overline{\mathcal{C}}$. But, by the definitions of u and f, this means exactly that, for PX_T^{-1} a.e. $\tilde{x} \in \overline{\mathcal{C}}$, $\vartheta_t^{\tilde{x}}$ defined by (81) is indeed the optimal policy for $\tilde{W}_t$ under $\tilde{P}^{\tilde{x}}$. The proof is complete.

One can see that in Lemma 2.11, T can be any stopping time of the filtration $\{\mathcal{F}_t\}$. We must modify the above argument (and the statement of Lemma 2.11) suitably, replacing $\sigma(X_T)$ by $\sigma(T, X_T)$, PX_T^{-1} by $P[T, X_T]^{-1}$, $\tilde{P}^{\tilde{x}}$ by $\tilde{P}^{\tilde{x},t}$ (the value of the regular conditional probability distribution of $(T, W_t, \nu_t, t \geq 0)$ given $\sigma(T, X_T)$ on $[X_T = \tilde{x}, T = t]$), and using the strong Markov property of a Brownian motion.

As a by-product of the above reasoning, in particular of Lemma 2.11 for a stopping time T, we get that the optimally controlled process X_t is a strong Markov process with respect to the filtration $\{\mathcal{F}_t,\ t \geq 0\}$. Indeed, for any $t > 0$

$$X_{T+t} - X_T = (W_{T+t} - W_T) + (\nu_{T+t} - \nu_T),$$

the Brownian increment is independent on $\mathcal{F}_T$, and all the relevant information about the increment of ν that can be found in $\mathcal{F}_T$ is, as we have just seen, the value of X_T. Thus, all the information about

$$X_{T+t} = (X_{T+t} - X_T) + X_T$$

that can be found in $\mathcal{F}_T$ is actually the value of X_T.

2.6. Possible jumps of the optimal policy. Suppose that $x \in \partial\mathcal{C}$ has the following property.

There exists an interval $I \subseteq \partial\mathcal{C}$ such that

$$I = \{a + t\eta : t \in [0, c]\} \tag{92}$$

for some $\eta \in R^n$, $|\eta| = 1$, $a \in R^n$, $c > 0$, $\nabla u \equiv \eta$ on I, and $x \in I - \{a\}$.

We shall denote the set of all such x by D. We assume that I in the above definition is maximal, i.e., is the sum of all the intervals with such property. Then

$$u(a + \eta t) = u(a) + t, \qquad t \in [0, c], \tag{93}$$

because

$$\frac{\partial u}{\partial \eta} = \nabla u \cdot \eta = |\nabla u|^2 = 1 \ \text{ on } \ I. \tag{94}$$

Analytically, D can be defined by

$$D = \bigcup_{i=1}^{\infty} \left\{ x \in \partial\mathcal{C} :\ u(x) - u\left(x - \frac{1}{i}\nabla u(x)\right) = \frac{1}{i} \right\}, \tag{95}$$

so D is a countable sum of closed sets, in particular a Borel measurable set.

Let ν^x be the optimal policy for the process starting from $x \in D$ and let $x = a + t\eta$, a, t, and η as above. Then

$$\nu_t^x = \begin{cases} 0 & \text{if } t = 0, \\ a - x + \nu_t^a & \text{if } t > 0; \end{cases} \tag{96}$$

i.e., the optimal policy first jumps from x to a and proceeds optimally thereafter.

Indeed, if we define ν^x by (96), then, by (93),

$$J_x(\nu^x) = |a - x| + u(a) = t + u(a) = u(x). \tag{97}$$

Now we shall analyze the jumps of the optimal policy ν^x for an arbitrary $x \in \overline{\mathcal{C}}$.

LEMMA 2.12. *For every starting state $x \in \overline{\mathcal{C}}$ a.s. $\omega \in \Omega$ the only discontinuities of $X_\cdot(\nu^x_\cdot)$ are possibly jumps of the type described in Definition* 2.5(a) *(for $G = \mathcal{C}$, $v = -\nabla u$) at $X_t \in D$.*

Proof. First we want to prove that, a.s., X_t jumps only when $X_t \in D$. Suppose it is not true. Because ν^x is left-continuous, the only possible discontinuities of ν^x are jumps. Suppose ν^x does have jumps and let

$$T^\epsilon(\omega) = \inf\{t \geq 0 : X_t(\omega) \notin D, |X_t(\omega) - X_{t+}(\omega)| \geq \epsilon\}; \tag{98}$$

i.e., T^ϵ is the first time the process X_t undergoes a jump of magnitude at least ϵ starting outside D. Suppose ϵ is so small that $P[T^\epsilon < \infty] > 0$. By a theorem in [5, p. 84] (see also [18, p. 10]), there is a sequence $T_1, T_2, \ldots$ of stopping times exhausting the jumps of X_t (ν_t), i.e.,

$$\{(t,\omega) \in [0,\infty) \times \Omega : X_t(\omega) \neq X_{t+}(\omega)\} \in \sum_{i=1}^{\infty} \{(t,\omega) \in [0,\infty) \times \Omega : T_i(\omega) = t\}. \tag{99}$$

(This is slightly different than the original theorem in [5], which dealt with right-continuous, instead of left-continuous, processes, but it is easy to see that if the filtration itself is right-continuous, our version follows from the original one in a straightforward way.) Thus,

$$T^\epsilon(\omega) = \inf\{T_i(\omega) : X_{T_i(\omega)} \notin D, |X_{T_i(\omega)}(\omega) - X_{T_i(\omega)+}(\omega)| \geq \epsilon\}. \tag{100}$$

ν^x_t is a process of bounded variation on each finite interval (a.s.), so, a.s., on each interval $[0,T]$ there can be only finitely many jumps of magnitude at least ϵ, so in (100) we can use min instead of inf. Thus, T^ϵ is a stopping time. (It was not entirely obvious from the very beginning, because D does not have to be open or closed.)

On $[T^\epsilon < \infty]$ $X_{T^\epsilon} \in \overline{\mathcal{C}} - D$, $X_{T^\epsilon +} \in \overline{\mathcal{C}}$, so, by $|\nabla u| \leq 1$,

$$u(X_{T^\epsilon(\omega)+}(\omega)) + |X_{T^\epsilon(\omega)+}(\omega) - X_{T^\epsilon(\omega)}(\omega)| > u(X_{T^\epsilon(\omega)}(\omega)) \tag{101}$$

because ∇u is not identically equal to -1 on the interval joining $X_{T^\epsilon(\omega)}(\omega)$ to $X_{T^\epsilon(\omega)+}(\omega)$.

Using (72) for $T^\epsilon + \frac{1}{n}$, then letting $n \to \infty$ and using the bounded convergence theorem as in (80), we get

$$\begin{aligned} u(x) &= E^x \int_0^{T^\epsilon(\omega)} e^{-t}[h(X_t)dt + d\xi_t] \\ &\quad + E^x(e^{-T^\epsilon(\omega)}|X_{T^\epsilon(\omega)+}(\omega) - X_{T^\epsilon(\omega)}(\omega)|I_{[T^\epsilon<\infty)}) \\ &\quad + E^x(I_{[T^\epsilon<\infty)}e^{-T^\epsilon(\omega)}u(X_{T^\epsilon(\omega)+})) \\ &> E^x \int_0^{T^\epsilon(\omega)} e^{-t}[h(X_t)dt + d\xi_t] \\ &\quad + E^x(I_{[T^\epsilon<\infty)}e^{-T^\epsilon(\omega)}u(X_{T^\epsilon(\omega)})) \\ &= u(x); \end{aligned} \tag{102}$$

the inequality follows from (101), and the last equality follows from (72). But (102) is a clear contradiction. Thus, a.s., X_t jumps only when $X_t \in D$.

The fact that for $X_t \in D$ the optimally controlled process X_t a.s. jumps to the endpoint of the interval I from the Definition 2.5(a), where $X_t \in I$, follows from (96) and Lemma 2.11 combined with the fact that there are at most countably many jumps of X_t (see (99)). The lemma is proved.

This ends the proof of Theorem 2.6.

COROLLARY 2.13. *If $D = \emptyset$, then X_t, ξ_t, ν_t are continuous.*

COROLLARY 2.14. *Let $x \in D$. Then there exists an interval I as in* (92) *such that $x = a + t\eta$, $t > 0$. Then ν^a is continuous at* 0, *because $a \notin D$. Thus, by* (96), *the optimal policy ν^x starting from x jumps immediately to a and $\lim_{t\downarrow 0} \nu_t^x = a$.*

2.7. Remarks and supplements. (1) Using Lemma 2.9, the remark following it, the boundedness of $\mathcal{C}$, (70), and letting $T \to \infty$ in (62) we get

$$\begin{aligned} E^x \int_0^\infty & e^{-t}[h(X_t)dt + d\xi_t] \\ & + E^x \left\{ \sum_{0 \le t < \infty} e^{-t}(u(X_t) - u(X_{t+}) + \nabla u(X_t) N_t(\xi_{t+} - \xi_t)) \right\} \\ & \ge u(x). \end{aligned}$$

But, by (59), it means that the second expectation is 0, so all the terms

$$u(X_t) - u(X_{t+}) + \nabla u(X_t) N_t(\xi_{t+} - \xi_t) = 0, \tag{103}$$

P a.s. (because, as we have explained in the justification of (63), these terms are all nonpositive). But $N_t = -\nabla u(X_t)$ and $|\nabla u| \le 1$, so, by $\xi_{t+} - \xi_t = |X_{t+} - X_t|$, we have

$$\frac{\partial u}{\partial v} \equiv 1 \ \text{ if } \ v = \frac{X_{t+} - X_t}{|X_{t+} - X_t|} \tag{104}$$

on the whole interval joining X_t to X_{t+}. Thus, because $X_t \in \overline{\mathcal{C}}$ for every $t \ge 0$ a.s., we conclude that, for a.e. $\omega \in \Omega$ and all $t \ge 0$ s.t. $X_t \ne X_{t+}$, $[X_t, X_{t+}]$ is contained in some interval I of the form given in (a) of the Definition 2.5. However, this method does not ensure that X_{t+} is actually the endpoint of such I, and neither does it ensure that X_t *must* jump at points of D. This is the reason why we need an argument like that given in sections 2.5–2.6.

(2) Another way of regularizing the value function u in the proof given in subsection 2.4 is to use, instead of $\tilde{u}_\epsilon$, the function u^ϵ defined by (74), which is the value function for an approximating control problem (see the appendix; compare also [35, proof of Theorem 4.3]). u^ϵ satisfies

$$u^\epsilon - \triangle u^\epsilon + \frac{1}{\epsilon} \max(|\nabla u^\epsilon| - 1, 0) = h \ \text{ in } \ R^n. \tag{105}$$

Now we cannot claim that $|\nabla u^\epsilon| \le 1$, but from the estimates in [26] we know that u^ϵ, ∇u^ϵ, $D^2 u^\epsilon$ are bounded uniformly on B_R ($\overline{\mathcal{C}} \subseteq B_{R-1}$) for $\epsilon > 0$. Moreover, for a subsequence (still denoted by u^ϵ) $u_\epsilon \to u$, $\nabla u_\epsilon \to \nabla u$ uniformly in B_R and, from (105), $u^\epsilon - \triangle u^\epsilon \le h$, so we can repeat the proof of subsection 2.4 with u^ϵ instead of $\tilde{u}_\epsilon$ and h instead of h^ϵ.

(3) Let the starting point $x \in R^n - \overline{\mathcal{C}}$. By a modification of the argument given in [29] we can show that in this case the optimal policy jumps immediately to some point $\hat{x} \in \partial\mathcal{C}$ and then follows the optimal policy $\nu^{\hat{x}}$. We provide the details for the sake of completeness.

Let us introduce, following [29], the following change of coordinates. Let y_0 be a point at which the minimum of u in R^n is attained. By Lemma 4.4 in [29], it is unique and belongs to $\mathcal{C}$. Choose $\delta > 0$, $\mu > 0$ s.t.

$$B_{2\delta}(y_0) \subseteq \mathcal{C}, \tag{106}$$

$$D^2u(\tilde{x})y \cdot y \geq \mu|y|^2 \tag{107}$$

for all $\tilde{x} \in B_{2\delta}(y_0)$ (recall that u is strictly convex in $\mathcal{C}$ by (4.10) of [29]),

$$\mu \leq |\nabla u(\tilde{x})|^2 \leq \frac{1}{2} \tag{108}$$

for all $\tilde{x} \in \partial B_\delta(y_0)$, and

$$\nabla u(y_0 + \delta\theta) \cdot \theta \geq \mu \tag{109}$$

for all $\theta \in S_1$, where S_1 is the unit sphere. For $\theta \in S_1$, we define the gradient flow $\psi(t, \theta)$ by

$$\frac{d}{dt}\psi(t, \theta) = \nabla u(\psi(t, \theta)) \tag{110}$$

for all $t \geq 0$ and

$$\psi(0, \theta) = y_0 + \delta\theta. \tag{111}$$

Let $x \in R^n - B_\delta(y_0)$, $x = \psi(t, \theta)$. We assign to x the coordinates (t, θ). It was shown in [29] that this change of variables is a homeomorphism between $R^n - B_\delta(y_0)$ and $[0, \infty) \times S_1$. (This part of the argument given there goes through in n dimensions; compare remarks on p. 332 of [9].) Now suppose that x, the starting point of the process (2), belongs to $R^n - \overline{\mathcal{C}}$. Let θ_0 be s.t. $x = \psi(t_0, \theta_0)$ for some $t_0 > 0$ and let

$$t_1 = \inf\{t \leq t_0 : \psi(t, \theta_0) \in \partial\mathcal{C}\}.$$

(This set is nonempty because of (106), (111), and the fact that, by assumption, x does not belong to $\overline{\mathcal{C}}$.) Let $\hat{x} = \psi(t_1, \theta_0)$. Then $\hat{x} \in \partial\mathcal{C}$, so the vector $v := \nabla u(\hat{x})$ has the norm 1. Let

$$L = \{\hat{x} + tv : t \geq 0\}.$$

Then, by $|v| = 1$, convexity of u, and the fact that $|\nabla u| \leq 1$, we have $u(\hat{x} + tv) = u(\hat{x}) + t$ for $t \geq 0$, in particular, $\nabla u(\hat{x} + tv) = v$, $t \geq 0$. But this means that, by the definition of the gradient flow ψ, for $t \geq t_1$,

$$\psi(t, \theta_0) = \hat{x} + (t - t_1)v; \tag{112}$$

so, in particular, $x = \hat{x} + (t_0 - t_1)v$ (put $t = t_0$ in (112)) and $\nabla u \equiv v$ on L. Thus,

$$u(x) = u(\hat{x}) + (t_0 - t_1)$$

and

$$|x - \hat{x}| = t_0 - t_1;$$

so, by an argument analogous to that given at the beginning of subsection 2.6,

$$\nu_t^x = \hat{x} - x + \nu_t^{\hat{x}}$$

for every $t > 0$ P-a.s.

(4) It is clear that any process that solves the Skorokhod problem for W_t, $\mathcal{C}$, $-\nabla u$ in the sense of Definition 2.5 is an optimal policy for our problem (compare, e.g., the verification Theorem VIII.4.1 from [9]). Thus, uniqueness of the optimal policy implies uniqueness of a solution to the modified Skorokhod problem for W_t, $\mathcal{C}$, $-\nabla u$.

Usually, some assumptions about regularity of the boundary of a region are necessary to prove existence and uniqueness of a solution to the Skorokhod problem. Here, all such assumptions are hidden in the very nature of the stochastic control problem and, if $n \geq 3$ we do not know what they are, i.e., how regular $\partial\mathcal{C}$ really is. The conjecture is that for higher dimensions "smooth fit" holds also, $\partial\mathcal{C}$ is smooth, say $C^{2,\alpha}$, and ∇u is nontangential to $\partial\mathcal{C}$, so the optimal policy is a solution to the Skorokhod problem in the usual sense, as in the two-dimensional case.

3. Appendix. In this paper, we have used some results from [26], where a problem slightly different from minimizing (11) was considered. However, it is easy to establish analogous results in our case by essentially the same techniques. The aim of this appendix is to provide a concise discussion of some minor adjustments which make the proofs from [26] work in the case of (11) and (12) and to sketch the main idea of the $W_{loc}^{2,\infty}$ regularity result contained in [26]. Compare also [31], where the results from [26] are used for the problem (11)–(12) with no additional comments.

We make all the assumptions of section 2.1. For the proof of Lemma 2.2 in section 2 of this paper, first let us remark that, by strict convexity of h,

$$\triangle_2 h(x,y) = \frac{h(x) + h(y)}{2} - h\left(\frac{x+y}{2}\right) > 0 \tag{113}$$

for all $x, y \in R^n$, $x \neq y$, so the proof of Theorem 7 in [26] also goes through in our case. Indeed, if we have two optimal policies

$$\nu_t^1 = \int_0^t N_s d\zeta_s, \tag{114}$$

$$\nu_t^2 = \int_0^t M_s d\eta_s, \tag{115}$$

take

$$\nu_t = \frac{\nu_t^1 + \nu_t^2}{2} = \int_0^t \tilde{N}_s d\tilde{\xi}_s. \tag{116}$$

We have

$$\xi_t = \bigvee_{[0,t]} \left[\frac{\nu_s^1 + \nu_s^2}{2}\right] \leq \frac{1}{2}\left[\bigvee_{[0,t]} \nu_s^1 + \bigvee_{[0,t]} \nu_s^2\right] = \frac{\zeta_t + \eta_t}{2}, \tag{117}$$

which allows us to use the proof in [26]. Also, we can mimic the proof of Theorem 8 from that paper and the corollary following it to get the proof of our Lemma 2.3.

The argument proving that the value function u defined by (12) is in $W^{2,\infty}_{loc}$ and (16) holds is essentially like that given in [26]. Its main idea is easy to understand: we begin with an approximating problem of controlling (11) in the class V_ϵ defined by (73), which is a subclass of controls allowed in our problem. Then a standard argument (see, e.g., [22, Theorem 5, p. 289]) shows that the value function u^ϵ defined by (74) belongs to $W^{2,\infty}_{loc}$ and satisfies the Bellman equation (105), so in fact, by elliptic regularity, $u^\epsilon \in C^{2,\alpha}$ for every $\alpha \in (0,1)$. One gets, by a direct probabilistic approach, a priori estimates for u^ϵ, ∇u^ϵ, and D^2u^ϵ independent of ϵ by estimating appropriate difference quotients. Then, using $u^\epsilon \to u$, we have the same estimates for u, and an easy additional argument using (105) convinces us that (16) holds. In fact, convergence of u^ϵ to u, although intuitively obvious (every function of bounded variation on finite intervals can be easily approximated by elements of V_ϵ as $\epsilon \to 0$), is surprisingly technical to prove (see [26]).

For another, PDE-based proof of existence of a $W^{2,\infty}_{loc}$ solution to the Bellman equation (16) see [8, 15, 29].

Acknowledgments. I want to express my deep gratitude to my advisor, Professor Marco Avellaneda, for many helpful discussions. I also thank the referees for their valuable suggestions.

A GENERALIZED MATHEMATICAL PROGRAM WITH EQUILIBRIUM CONSTRAINTS*

J. V. OUTRATA†

Abstract. The paper concerns an optimization problem with a generalized equation among the constraints. This model includes standard mathematical programs with parameter-dependent variational inequalities or complementarity problems as side constraints. Using Mordukhovich's generalized differential calculus, we derive necessary optimality conditions and apply them to problems, where the equilibria are governed by implicit complementarity problems and by hemivariational inequalities.

Key words. generalized equation, coderivative, subdifferential, constraint qualification

1. Introduction. According to [10], by *mathematical program with equilibrium constraints* (MPEC) one understands an optimization problem where, among the constraints, the following *variational inequality* (VI) arises:

$$\begin{aligned} &\text{for a given } x \in \mathbb{R}^n, \text{ find } y \in \Gamma(x) \text{ such that} \\ &\langle F(x,y), v-y\rangle \geq 0 \quad \text{for all } v \in \Gamma(x), \end{aligned} \tag{1.1}$$

where F maps $\mathbb{R}^n \times \mathbb{R}^m$ into $\mathbb{R}^m$ and Γ is a closed- and convex-valued multifunction mapping $\mathbb{R}^n$ into subsets of $\mathbb{R}^m$. If $\Gamma(x) = \mathbb{R}^m_+$ for all $x \in \mathbb{R}^n$, (1.1) reduces to a *nonlinear complementarity problem* (NCP). In what follows x is called the *control* or *decision parameter* and y the *state variable*. Both these variables arise generally in the objective and are possibly subject to other constraints.

Not all equilibria, however, can be modeled in the form (1.1). In continuum mechanics [3], for instance, we find the so-called VIs of second kind, which, after an appropriate discretization, attain the following form:

$$\begin{aligned} &\text{for a given } x \in \mathbb{R}^n, \text{ find } y \in \Xi \text{ such that} \\ &\langle F(x,y), v-y\rangle + J(v) - J(y) \geq 0 \quad \text{for all } v \in \Xi, \end{aligned} \tag{1.2}$$

where F is the same function as in (1.1), $J[\mathbb{R}^m \to \mathbb{R}]$ is a convex continuous function, and Ξ is a nonempty closed convex subset of $\mathbb{R}^m$. Since J is not differentiable at all points of Ξ, the VI (1.2) cannot be converted to the form (1.1).

Remark. (1.2) describes, e.g., a discretized contact problem with *given* friction; cf. [5]. The state variable corresponds then to the (vector-valued) displacement at the nodes of discretization and x to the body forces and surface tractions.

Further, when modeling the behavior of bodies made from composites (fiberglass or sandwich constructions), one arrives at so-called hemivariational inequalities; cf. [17]. After a discretization, they lead to models which cannot be converted to the form (1.1) either.

*Received by the editors March 3, 1999; accepted for publication (in revised form) December 3, 1999; published electronically May 26, 2000. This research was supported by grant A 1075707 of the Czech Academy of Sciences.

†Institute of Information Theory and Automation, Academy of Sciences of the Czech Republic, Pod vodárenskou věží 4, 182 08 Prague, Czech Republic (outrata@utia.cas.cz).

Both the VI (1.2) as well as a discretized hemivariational inequality can be, however, rewritten into the form of the *generalized equation* (GE):

$$0 \in F_1(x,y) + Q(F_2(x,y)), \tag{1.3}$$

where F_1, F_2 map $\mathbb{R}^n \times \mathbb{R}^m$ into $\mathbb{R}^m$, $\mathbb{R}^\ell$, respectively, and $Q[\mathbb{R}^\ell \rightsquigarrow \mathbb{R}^m]$ is a multifunction with the closed graph. In the case of the VI (1.2) we put $F_1 := F,\ F_2(x,y) := y$, and

$$Q(y) := \partial J(y) + N_\Xi(y), \tag{1.4}$$

where $\partial J(y)$ is the standard subdifferential of J at y (in the sense of convex analysis), and

$$N_\Xi(y) := \begin{cases} \text{the standard normal cone to } \Xi \text{ at } y & \text{provided } y \in \Xi, \\ \emptyset & \text{otherwise.} \end{cases}$$

In the case of an NCP one has $F_1 := F,\ F_2(x,y) := y$,

$$Q(y) := N_{\mathbb{R}^m_+}(y),$$

and also the VI (1.1) can mostly be converted to the form (1.3), e.g., when Γ is given by means of (control-dependent) equalities and inequalities; cf. [16].

On the basis of these considerations we define the (generalized) MPEC as the optimization problem:

$$\begin{array}{ll} \text{minimize} & f(x,y) \\ \text{subject to} & \\ & 0 \in F_1(x,y) + Q(F_2(x,y)), \\ & (x,y) \in \omega, \end{array} \tag{1.5}$$

where $f[\mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}]$ is an objective and $\omega \subset \mathbb{R}^n \times \mathbb{R}^m$ is the set of *admissible control (decision)-state pairs*. The GE (1.3) models the *equilibrium constraint*.

The aim of this paper is

(i) to derive first-order necessary optimality conditions for (1.5);

(ii) to apply these conditions to two distinguished classes of (1.5) with equilibria governed by implicit complementarity problems and by hemivariational inequalities.

In these investigations our basic tool is the "nonconvex" generalized differential calculus of Mordukhovich [11], [12], [13]. The applied approach utilizes the idea of exact penalization of the equilibrium constraint used already in [22] (in case of equilibria given by (lower-level) optimization problems). Instead of penalizing $\|v\|$ for

$$v \in F_1(x,y) + Q(F_2(x,y)),$$

which would correspond to the approach in [21], our "equilibrium constraint violation" is given by

$$v \in \begin{bmatrix} -F_2(x,y) \\ F_1(x,y) \end{bmatrix} + \operatorname{Gph} Q, \tag{1.6}$$

where $\operatorname{Gph} Q$ denotes the graph of multifunction Q. This enables one to respect easily joint constraints in both variables x and y. Furthermore, it is advantageous when applying a penalty approach to the numerical solution of (1.5).

The paper is organized as follows. The next section is devoted to a general mathematical program, to which form problem (1.5) can be converted. In section 3 the optimality conditions for (1.5) are established. Attention is paid also to the polyhedral case, where the constraint qualification can be omitted. Section 4 deals with the application of the obtained conditions to MPECs with equilibria described by implicit complementarity problems and by hemivariational inequalities.

The following notation is employed: x^i is the ith component of a vector $x \in \mathbb{R}^n$, $\overline{\mathbb{R}}$ is the extended real line, and $\mathbb{R}^n_+$ denotes the nonnegative orthant of $\mathbb{R}^n$. E is the unit matrix. For an $[m \times n]$ matrix A and an index set $I \subset \{1, 2, \ldots, m\}$, A_I is the submatrix of A with rows specified by I. Similarly, for a vector $d \in \mathbb{R}^n$, d_I is the subvector composed from the components d^i, $i \in I$. Furthermore, $epi\, f$ is the epigraph of a function f and $\partial^c f(x)$ is the Clarke's subdifferential of f at x. For a multifunction $Q[\mathbb{R}^n \rightsquigarrow \mathbb{R}^m]$, $\mathrm{Ker} Q := \{x \in \mathbb{R}^n \,|\, 0 \in Q(x)\}$. If D is a cone with vertex at the origin, then D^0 is its negative polar cone. For x, $y \in \mathbb{R}^n$ the inequalities $x \geq y$, $x > y$ mean $x^i \geq y^i$ and $x^i > y^i$ for all i, respectively. $\mathbb{B}$ is the unit ball, $cl\,\Omega$ denotes the closure of a set Ω, and $\mathrm{dist}_\Omega(x)$ is the distance of x to Ω.

For the reader's convenience, we close this section with three fundamental definitions from Mordukhovich's generalized differential calculus used throughout the paper.

Consider a set $\Pi \subset \mathbb{R}^p$.

DEFINITION 1.1. *Let $a \in \mathrm{cl}\,\Pi$. The nonempty cone*

$$T_\Pi(a) := \limsup_{t \downarrow 0} \frac{\Pi - a}{t}$$

is called the contingent cone *to Π at a.*[1] *The* generalized normal cone *to Π at a, denoted $N_\Pi(a)$, is defined by*

$$N_\Pi(a) = \limsup_{a' \overset{cl\ \Pi}{\longrightarrow} a} T^0_\Pi(a').$$

If Π is convex, $N_\Pi(a)$ amounts to the standard normal cone to Π at a in the sense of convex analysis. The cone $N_\Pi(a)$ is generally nonconvex, but the multifunction $N_\Pi(\cdot)$ is upper semicontinuous at each point of $cl\Pi$ (with respect to $cl\Pi$), which is essential in the calculus of Mordukhovich's subdifferentials and coderivatives introduced below.

DEFINITION 1.2. *Let $\varphi[\mathbb{R}^p \to \overline{\mathbb{R}}]$ be an arbitrary extended real-valued function and $a \in dom\,\varphi$. The set*

$$\partial^- \varphi(a) := \{a^* \in \mathbb{R}^p | (a^*, -1) \in N_{epi\,\varphi}(a, \varphi(a))\}$$

is called Mordukhovich's subdifferential *of φ at a.*

DEFINITION 1.3. *Let $\Phi[\mathbb{R}^p \rightsquigarrow \mathbb{R}^q]$ be an arbitrary multifunction and $(a, b) \in cl\,\mathrm{Gph}\,\Phi$. The multifunction $D^*\Phi(a, b)\,[\mathbb{R}^q \to \mathbb{R}^p]$ defined by*

$$D^*\Phi(a, b)\,(b^*) := \{a^* \in \mathbb{R}^p | (a^*, -b^*) \in N_{Gph\,\Phi}(a, b)\}, \quad b^* \in \mathbb{R}^q,$$

is called the coderivative *of Φ at (a, b).*

Besides these notions we also will need several results of Mordukhovich from [11], [12], and [13]; for the reader's convenience three of them are stated in the appendix. For a thorough study of Mordukhovich's theory the reader is referred to [11].

[1] The "lim sup" in the definitions of $T_\Pi(a)$ and $N_\Pi(a)$ is the upper limit of multifunctions in the sense of Kuratowski–Painlevé; cf. [1].

2. Auxiliary results. Consider first a general mathematical program

$$\begin{array}{ll} \text{minimize} & \varphi(u) \\ \text{subject to} & \\ & u \in \Pi, \end{array} \tag{2.1}$$

where $\varphi[\mathbb{R}^p \to \mathbb{R}]$ is locally Lipschitz and Π is a nonempty and closed subset of $\mathbb{R}^p$. For such programs, first-order necessary optimality conditions attain the following form; cf. [11, Theorem 7.1].

PROPOSITION 2.1. *Let $\hat{u}$ be a (local) solution of* (2.1). *Then one has*

$$0 \in \partial^- \varphi(\hat{u}) + N_\Pi(\hat{u}). \tag{2.2}$$

Assume now that

$$\Pi = \{u \in \Theta \mid -F(u) \in \Lambda\}, \tag{2.3}$$

where $F[\mathbb{R}^p \to \mathbb{R}^q]$ is continuously differentiable and Θ, Λ are closed subsets of $\mathbb{R}^p$ and $\mathbb{R}^q$, respectively. By Φ we denote the multifunction defined by

$$\Phi(u) := F(u) + \Lambda.$$

Our next aim is to derive optimality conditions for problem (2.1) with Π given by (2.3). In this case, unfortunately, the direct computation of $N_\Pi(\hat{u})$ can be quite complicated and so we apply the mentioned penalization approach of [22], [21] and employ the following important concept.

DEFINITION 2.1. *A multifunction $\Psi[\mathbb{R}^q \rightsquigarrow \mathbb{R}^p]$ is said to be* pseudo–upper-Lipschitz *continuous at $(\overline{v}, \overline{u}) \in \operatorname{Gph} \Psi$ with modulus $L \geq 0$, provided there exists a neighborhood $\mathcal{V}$ of $\overline{v}$ and a neighborhood $\mathcal{U}$ of $\overline{u}$ such that*

$$\Psi(v) \cap \mathcal{U} \subset \Psi(\overline{v}) + L\|v - \overline{v}\| \, \mathbb{B} \quad \textit{for all } v \in \mathcal{V}.$$

This concept has been introduced in [7] and entitled pseudo–upper-Lipschitz continuity in [21]. If in the above definition one can put $\mathcal{U} = \mathbb{R}^p$, then Ψ is in fact *(locally) upper-Lipschitz* at $\overline{v}$ with modulus L; cf. [19].

In the further development we make use of the two lemmas given below. The first one comes from [21] and is actually valid without any structural assumptions on Φ.

LEMMA 2.2. *Assume that $\hat{u}$ is a (local) solution of* (2.1) *with Π given by* (2.3). *Further suppose that the multifunction $\Phi^{-1}(\cdot) \cap \Theta$ is pseudo–upper-Lipschitz continuous at $(0, \hat{u})$ with modulus L. Then there exist a neighborhood $\mathcal{V}$ of $0 \in \mathbb{R}^q$ and a neighborhood $\mathcal{U}$ of $\hat{u}$ such that $(v, u) = (0, \hat{u})$ solves the penalized program*

$$\begin{array}{ll} \textit{minimize} & \varphi(u) + r\|v\| \\ \textit{subject to} & \\ & v \in \Phi(u) \cap \mathcal{V}, \\ & u \in \Theta \cap \mathcal{U}, \end{array} \tag{2.4}$$

provided $r \geq L\lambda$, where $\lambda \geq 0$ is the Lipschitz modulus of φ near $\hat{u}$.

The next result is an easy consequence of Theorem A.2 from the appendix.

LEMMA 2.3. *Under the imposed assumptions for each $(u, v) \in \operatorname{Gph} \Phi$ one has*

$$D^*\Phi(u, v)\,(v^*) = \begin{cases} (\nabla F(u))^{\mathrm{T}} v^* & \textit{provided } v^* \in -N_\Lambda(v - F(u)), \\ \emptyset & \textit{otherwise.} \end{cases}$$

Proof. The set Λ can be viewed as the value of a constant multifunction defined on $\mathbb{R}^p$ with the graph $\mathbb{R}^p \times \Lambda$ so that for $\xi \in \Lambda$

$$N_{\operatorname{Gph}\Lambda}(u,\xi) = 0 \times N_\Lambda(\xi);$$

cf. [11, Proposition 1.6]. Hence, for $\xi \in \Lambda$ one has

$$D^*\Lambda(u,\xi)\,(v^*) = \begin{cases} 0 & \text{provided } -v^* \in N_\Lambda(\xi), \\ \emptyset & \text{otherwise,} \end{cases}$$

and the result follows directly from Theorem A.2. ∎

On the basis of the preceding two lemmas we can now state the next result, which is a specialization of [21, Theorem 3.1] to our structure of multifunction Φ.

THEOREM 2.4. *Assume that $\hat{u}$ is a (local) solution of* (2.1) *with* Π *given by* (2.3). *Further suppose that the multifunction $\Phi^{-1}(\cdot) \cap \Theta$ is pseudo–upper-Lipschitz continuous at $(0,\hat{u})$. Then there exists a* Karush–Kuhn–Tucker *(KKT) vector $\hat{v}^* \in N_\Lambda(-F(\hat{u}))$ such that*

$$0 \in \partial^- \varphi(\hat{u}) - (\nabla F(\hat{u}))^{\mathrm{T}} \hat{v}^* + N_\Theta(\hat{u}). \tag{2.5}$$

Proof. By Lemma 2.2 we can apply Proposition 2.1 to program (2.4), provided r is sufficiently large. This yields

$$\begin{bmatrix} 0 \\ 0 \end{bmatrix} \in \begin{bmatrix} \partial^- \varphi(\hat{u}) \\ r\mathbb{B} \end{bmatrix} + N_{\operatorname{Gph}\Phi \cap (\mathcal{U}\times\mathcal{V}) \cap (\Theta \times \mathbb{R}^q)}(\hat{u},0). \tag{2.6}$$

By Definition 1.3 one has

$$N_{\operatorname{Gph}\Phi\cap(\mathcal{U}\times\mathcal{V})}(\hat{u},0) = \{(u^*,w^*) \in \mathbb{R}^p \times \mathbb{R}^q \,|\, u^* \in D^*\Phi(\hat{u},0)\,(-w^*)\}$$

and thus, in virtue of Lemma 2.3,

$$N_{\operatorname{Gph}\Phi\cap(\mathcal{U}\times\mathcal{V})}(\hat{u},0) = \left\{(u^*,w^*) \in \mathbb{R}^p \times \mathbb{R}^q \,|\, u^* = -(\nabla F(\hat{u}))^{\mathrm{T}} w^*,\ w^* \in N_\Lambda(-F(\hat{u}))\right\}.$$

By [11, Proposition 1.6],

$$N_{\Theta\times\mathbb{R}^\ell}(\hat{u},0) = N_\Theta(\hat{u}) \times \{0\}.$$

Hence one has

$$N_{\operatorname{Gph}\Phi\cap(\mathcal{U}\times\mathcal{V})}(\hat{u},0) \cap (-N_{\Theta\times\mathbb{R}^q}(\hat{u},0)) = \{0\}. \tag{2.7}$$

By invoking Theorem A.3, relation (2.6) thus implies that

$$\begin{bmatrix} 0 \\ 0 \end{bmatrix} \in \begin{bmatrix} \partial^- \varphi(\hat{u}) \\ r\mathbb{B} \end{bmatrix} + \begin{bmatrix} -(\nabla F(\hat{u}))^{\mathrm{T}} \hat{v}^* \\ \hat{v}^* \end{bmatrix} + \begin{bmatrix} N_\Theta(\hat{u}) \\ 0 \end{bmatrix}$$

for some $\hat{v}^* \in N_\Lambda(-F(\hat{u}))$. In this way relation (2.5) has been established. ∎

Remark. Statements of the above type can be found in many works on mathematical programming with various subdifferentials and normal cones and even for nonsmooth maps F [20], [6]. In [21] conditions of this type have been derived for the program

$$\begin{array}{ll} \text{minimize} & \varphi(u) \\ \text{subject to} & \\ & 0 \in \Phi(u), \\ & u \in \Theta \end{array}$$

under no structural assumptions on Φ. Then, however, one needs an additional requirement to ensure the validity of the appropriate counterpart to (2.5).

3. Optimality conditions. We return now to problem

$$\begin{array}{ll} \text{minimize} & f(x,y) \\ \text{subject to} & \\ & 0 \in F_1(x,y) + Q(F_2(x,y)), \\ & (x,y) \in \omega, \end{array} \tag{3.1}$$

and pose the following additional assumptions:

(A1) f is locally Lipschitz on $\mathbb{R}^n \times \mathbb{R}^m$;

(A2) F_1, F_2 are continuously differentiable;

(A3) $\omega \subset \mathbb{R}^n \times \mathbb{R}^m$ is nonempty and closed.

To convert (3.1) to the form (2.1) with Π given by (2.3) it suffices to put $u := (x,y) \in \mathbb{R}^n \times \mathbb{R}^m$, $F(u) := \left[\begin{smallmatrix} -F_2(x,y) \\ F_1(x,y) \end{smallmatrix}\right]$, $\Theta := \omega$, and $\Lambda := \operatorname{Gph} Q$. Indeed, the equilibrium constraint can equivalently be written in the form

$$\left[\begin{array}{c} F_2(x,y) \\ -F_1(x,y) \end{array} \right] \in \operatorname{Gph} Q,$$

and so, consequently, the respective multifunction $\Phi[\mathbb{R}^n \times \mathbb{R}^m \rightsquigarrow \mathbb{R}^\ell \times \mathbb{R}^m]$ is defined by

$$\Phi(x,y) := \left[\begin{array}{c} -F_2(x,y) \\ F_1(x,y) \end{array} \right] + \operatorname{Gph} Q. \tag{3.2}$$

The pseudo–upper-Lipschitz continuity of a multifunction is implied by both the pseudo-Lipschitz as well as the upper-Lipschitz continuity [1], [19]. Let us consider first the case where the multifunction $\Phi^{-1}(\cdot) \cap \omega$ is pseudo-Lipschitz around $(0,\hat{x},\hat{y})$. On the basis of Theorem 2.4 and Theorem A.1 from the appendix we obtain directly the following optimality conditions.

THEOREM 3.1. *Let assumptions* (A1)–(A3) *be fulfilled and let* $(\hat{x},\hat{y})$ *be a (local) solution of* (3.1). *Assume further that the constraint qualification*

(CQ)

$$\left.\begin{array}{l} \left[\begin{array}{cc} (\nabla_x F_2(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_x F_1(\hat{x},\hat{y}))^{\mathrm{T}} \\ (\nabla_y F_2(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_y F_1(\hat{x},\hat{y}))^{\mathrm{T}} \end{array} \right] \left[\begin{array}{c} w \\ z \end{array} \right] \in -N_\omega(\hat{x},\hat{y}) \\ (w,z) \in N_{\operatorname{Gph} Q}(F_2(\hat{x},\hat{y}), -F_1(\hat{x},\hat{y})) \end{array}\right\} \text{ implies } \left\{ \begin{array}{l} w = 0, \\ z = 0 \end{array} \right.$$

holds true. Then there exist a pair $(\xi,\eta) \in \partial^- f(\hat{x},\hat{y})$, *a pair* $(\gamma,\delta) \in N_\omega(\hat{x},\hat{y})$, *and a KKT pair* $(\hat{w},\hat{z}) \in N_{\operatorname{Gph} Q}(F_2(\hat{x},\hat{y}), -F_1(\hat{x},\hat{y}))$ *such that*

$$\begin{aligned} 0 &= \xi + (\nabla_x F_2(\hat{x},\hat{y}))^{\mathrm{T}} \hat{w} - (\nabla_x F_1(\hat{x},\hat{y}))^{\mathrm{T}} \hat{z} + \gamma, \\ 0 &= \eta + (\nabla_y F_2(\hat{x},\hat{y}))^{\mathrm{T}} \hat{w} - (\nabla_y F_1(\hat{x},\hat{y}))^{\mathrm{T}} \hat{z} + \delta. \end{aligned} \tag{3.3}$$

Proof. Let us denote by Ψ the map $\Phi^{-1}(\cdot) \cap \omega$, i. e., for $v = (v_1,v_2) \in \mathbb{R}^\ell \times \mathbb{R}^m$,

$$\Psi(v) := \left\{ (x,y) \in \omega \,\middle|\, \left[\begin{array}{c} v_1 + F_2(x,y) \\ v_2 - F_1(x,y) \end{array} \right] \in \operatorname{Gph} Q \right\}.$$

By [13, Theorem 3.2] we know that Ψ is pseudo-Lipschitz around $(0,\hat{x},\hat{y})$ if and only if $D^*\Psi(0,\hat{x},\hat{y})\,(0) = \{0\}$. Map Ψ has exactly the structure of multifunction $\sum$ analyzed in Theorem A.1 with

$$H(v_1,v_2,x,y) = \left[\begin{array}{c} v_1 + F_2(x,y) \\ v_2 - F_1(x,y) \end{array} \right], \ \Omega = \mathbb{R}^\ell \times \mathbb{R}^m \times \omega \text{ and } \Lambda = \operatorname{Gph} Q.$$

Due to the specific structure of the Jacobian $\nabla H(0,0,\hat{x},\hat{y})$ one easily verifies that both qualification conditions of Theorem A.1 are fulfilled. Hence,

$$D^*\Psi(0,0,\hat{x},\hat{y})\,(x^*,y^*) \subset \left\{ \left(v_1^*, v_2^*\right) \in \mathbb{R}^\ell \times \mathbb{R}^m \Big| \right.$$

$$\left[\begin{array}{c} v_1^* \\ v_2^* \\ -x^* \\ -y^* \end{array} \right] = \left[\begin{array}{cc} E & 0 \\ 0 & E \\ (\nabla_x F_2(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_x F_1(\hat{x},\hat{y}))^{\mathrm{T}} \\ (\nabla_y F_2(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_y F_1(\hat{x},\hat{y}))^{\mathrm{T}} \end{array} \right] \left[\begin{array}{c} w \\ z \end{array} \right] + \{0\} \times \{0\} \times N_\omega(\hat{x},\hat{y}),$$

$$\left. (w,z) \in N_{\mathrm{Gph}\,Q}(F_2(\hat{x},\hat{y}), -F_1(\hat{x},\hat{y})) \right\}$$

and

$$D^*\Psi(0,0,\hat{x},\hat{y})\,(0,0) = \left\{ (w,z) \in N_{\mathrm{Gph}\,Q}(F_2(\hat{x},\hat{y}), -F_1(\hat{x},\hat{y})) \right|$$

$$\left. \left[\begin{array}{cc} (\nabla_x F_2(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_x F_1(\hat{x},\hat{y}))^{\mathrm{T}} \\ (\nabla_y F_2(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_y F_1(\hat{x},\hat{y}))^{\mathrm{T}} \end{array} \right] \left[\begin{array}{c} w \\ z \end{array} \right] \in -N_\omega(\hat{x},\hat{y}) \right\}.$$

We observe that (CQ) ensures the pseudo-Lipschitz continuity of $\Phi^{-1}(\cdot) \cap \omega$ at $(0,\hat{x},\hat{y})$. The rest follows readily from Theorem 2.4. □

Observe that, expectantly, x and y enter (3.3) in a fully symmetric way. Only a specific structure of F_1, F_2 causes possibly different roles of the control and the state variable known from standard MPECs.

Condition (CQ) amounts to the standard Mangasarian–Fromowitz constraint qualification for the constraint set

$$\left\{ (x,y) \in \omega \,\middle|\, \left[\begin{array}{c} F_2(x,y) \\ -F_1(x,y) \end{array} \right] \in \mathrm{Gph}\, Q \right\}$$

at $(\hat{x},\hat{y})$ in the so-called dual form. It prevents the existence of (abnormal) nonzero multipliers $(w,z) \in N_{\mathrm{Gph}\,Q}(F_2(\hat{x},\hat{y}), -F_1(\hat{x},\hat{y}))$ such that

$$0 \in \left[\begin{array}{cc} (\nabla_x F_2(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_x F_1(\hat{x},\hat{y}))^{\mathrm{T}} \\ (\nabla_y F_2(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_y F_1(\hat{x},\hat{y}))^{\mathrm{T}} \end{array} \right] \left[\begin{array}{c} w \\ z \end{array} \right] + N_\omega(\hat{x},\hat{y}).$$

Using a particular structure of Q and ω it is sometimes possible to derive also a primal version of (CQ); cf. [15].

The statement of Theorem 3.1 reduces to [21, Theorem 3.2 (c,d)] provided $F_2(x,y) = y$, $Q(\cdot) = N_\Xi(\cdot)$ with a closed convex set $\Xi \subset \mathbb{R}^m$, and the state variable is not subject to any constraints. To verify (CQ) and to be able to apply the derived optimality conditions, we need, however, some structural assumptions on Q (and ω). In [15] the constraint qualification as well as the optimality conditions have been converted to a workable form in the case of equilibria governed by nonlinear complementarity problems and for ω given by smooth inequalities. We return to this subject in the next section, where we analyze two special classes of (3.1).

Let $\tilde{\omega}$ be a closed subset of $\mathbb{R}^n$. For a problem of the type

$$\begin{array}{ll} \text{minimize} & f(x,y) \\ \text{subject to} & \\ & 0 \in F_1(x,y) + Q(y), \\ & x \in \tilde{\omega}, \end{array} \tag{3.4}$$

there is a possibility to ensure the validity of (CQ) via the strong regularity (cf. [18]) of the GE

$$0 \in F_1(\hat{x},y) + Q(y) \tag{3.5}$$

at $\hat{y}$.

PROPOSITION 3.2. *Let* (A1)–(A3) *(with* $\omega = \tilde{\omega} \times \mathbb{R}^m$*) be fulfilled and let* $(\hat{x},\hat{y})$ *be a (local) solution of* (3.4)*. Further assume that the GE* (3.5) *is strongly regular at* $\hat{y}$*, i.e., that the map*

$$\Delta : \eta \mapsto \{y \in \mathbb{R}^m \,|\, \eta \in F_1(\hat{x},\hat{y}) + \nabla_y F_1(\hat{x},\hat{y})\,(y-\hat{y}) + Q(y)\} \tag{3.6}$$

is locally single-valued and Lipschitz around $(0,\hat{y})$*. Then* (CQ) *is fulfilled.*

Proof. By the assumptions, Δ is pseudo-Lipschitz around $(0,\hat{y})$. Hence, again by invoking [13, Theorem 3.2], we have

$$D^*\Delta(0,\hat{y})\,(0) = \{0\}. \tag{3.7}$$

Since (cf. [13])

$$y^* \in D^*\Delta^{-1}(\hat{y},0)\,(\eta^*) \Leftrightarrow -\eta^* \in D^*\Delta(0,\hat{y})\,(-y^*),$$

relation (3.7) amounts to

$$\operatorname{Ker} D^*\Delta^{-1}(\hat{y},0) = \{0\}. \tag{3.8}$$

By Theorem A.3

$$D^*\Delta^{-1}(\hat{y},0)\,(\eta^*) = (\nabla_y F_1(\hat{x},\hat{y}))^{\mathrm{T}}\eta^* + D^*Q(\hat{y},-F_1(\hat{x},\hat{y}))\,(\eta^*).$$

Putting $z := -\eta^*$, condition (3.8) can thus be written in the form

$$\left.\begin{array}{l} w - (\nabla_y F_1(\hat{x},\hat{y}))^{\mathrm{T}} z = 0 \\ (w,z) \in N_{\operatorname{Gph} Q}(\hat{y},-F_1(\hat{x},\hat{y})) \end{array}\right\} \text{ implies } z = 0. \tag{3.9}$$

Since $z = 0$ implies $w = 0$ and

$$N_\omega(\hat{x},\hat{y}) = N_{\tilde{\omega}}(\hat{x}) \times \{0\},$$

condition (3.9) ensures the satisfaction of (CQ). □

The pseudo–upper-Lipschitz continuity of $\Phi^{-1}(\cdot) \cap \omega$ is also implied by the (locally) upper-Lipschitz continuity of this map. To simplify the corresponding statement, we will assume the following.

(A4) With a given $[s \times n]$ matrix C, a given $[s \times m]$ matrix D, and a given vector $c \in \mathbb{R}^s$,

$$\omega := \{(x,y) \in \mathbb{R}^n \times \mathbb{R}^m \,|\, Cx + Dy + c \le 0\}. \tag{3.10}$$

For a fixed $(\overline{x}, \overline{y}) \in \omega$ let

$$M(\overline{x}, \overline{y}) := \left\{ i \in \{1, 2, \ldots, s\} \,|\, (C\overline{x})^i + (D\overline{y})^i + c^i = 0 \right\}.$$

Consider now the optimization problem

$$\begin{array}{ll} \text{minimize} & f(x,y) \\ \text{subject to} & \\ & 0 \in A_1 x + B_1 y + a_1 + Q(A_2 x + B_2 y + a_2), \\ & (x,y) \in \omega, \end{array} \tag{3.11}$$

where A_1, A_2, B_1, B_2, a_1, and a_2 are given matrices and vectors of appropriate dimensions, and ω is given by (3.10).

THEOREM 3.3. *Let $(\hat{x}, \hat{y})$ be a (local) solution of problem* (3.11). *Suppose that Q is polyhedral (i.e.,* $\operatorname{Gph} Q$ *is a union of finitely many convex polyhedral sets), and* (A1), (A4) *are fulfilled. Then there exist a pair $(\xi, \eta) \in \partial^- f(\hat{x}, \hat{y})$, a KKT pair $(\hat{w}, \hat{z}) \in N_{\operatorname{Gph} Q}(A_2\hat{x} + B_2\hat{y} + a_2,\ -A_1\hat{x} - B_1\hat{y} - a_1)$, and a multiplier $\hat{\mu} \in \mathbb{R}^s_+$ such that*

$$\begin{aligned} 0 &= \xi + A_2^{\mathrm{T}}\hat{w} - A_1^{\mathrm{T}}\hat{z} + C^{\mathrm{T}}\hat{\mu}, \\ 0 &= \eta + B_2^{\mathrm{T}}\hat{w} - B_1^{\mathrm{T}}\hat{z} + D^{\mathrm{T}}\hat{\mu}, \\ \hat{\mu}^i &= 0 \quad \textit{for all } i \notin M(\hat{x}, \hat{y}). \end{aligned} \tag{3.12}$$

Proof. By the imposed assumptions, $\operatorname{Gph}\Phi$ is a union of finitely many convex polyhedral sets and ω is convex polyhedral. This implies in virtue of [19] that $\Phi^{-1}(\cdot) \cap \omega$ is (locally) upper-Lipschitz at 0, and hence the conditions of Theorem 2.4 are fulfilled. It remains to express relation (3.3) in terms of our problem data. By the convexity and polyhedrality of ω one has

$$N_\omega(\hat{x}, \hat{y}) = \left\{ \begin{bmatrix} C^{\mathrm{T}} \\ D^{\mathrm{T}} \end{bmatrix} \mu \,\middle|\, \mu \in \mathbb{R}^s_+,\ \mu^i = 0 \quad \text{for } i \notin M(\hat{x}, \hat{y}) \right\}. \tag{3.13}$$

Hence, it suffices to insert (3.13) into (3.3) and take into account the specific structure of functions F_1, F_2. ∎

We conclude this section with a simple academic example illustrating the optimality conditions of Theorem 3.3. Consider the MPEC

$$\begin{array}{ll} \text{minimize} & \dfrac{1}{2}x - y \\ \text{subject to} & \\ & 0 \in y - x + \partial|y|, \\ & x \in [-2, 0]. \end{array} \tag{3.14}$$

In this one-dimensional MPEC it is easy to construct the map S assigning x those y's which are feasible with respect to the equilibrium constraint; this map is depicted in Figure 1. Hence the unique global solution of (3.14) is the point $(\hat{x}, \hat{y}) = (-1, 0)$. One has $F_1(x,y) = y - x$, $F_2(x,y) = y$ and $Q(\cdot) = \partial|\cdot|$. Since $\operatorname{Gph} Q$ is polyhedral (cf. Figure 2), all assumptions of Theorem 3.3 are fulfilled. On the basis of Definition 1.1 and Figure 2 one easily deduces that

$$N_{\operatorname{Gph}\partial|\cdot|}(\hat{y}, \hat{x} - \hat{y}) = N_{\operatorname{Gph}\partial|\cdot|}(0, -1) = \{(w,z) \,|\, \text{either } wz = 0 \text{ or } w > 0 \text{ and } z < 0\}.$$

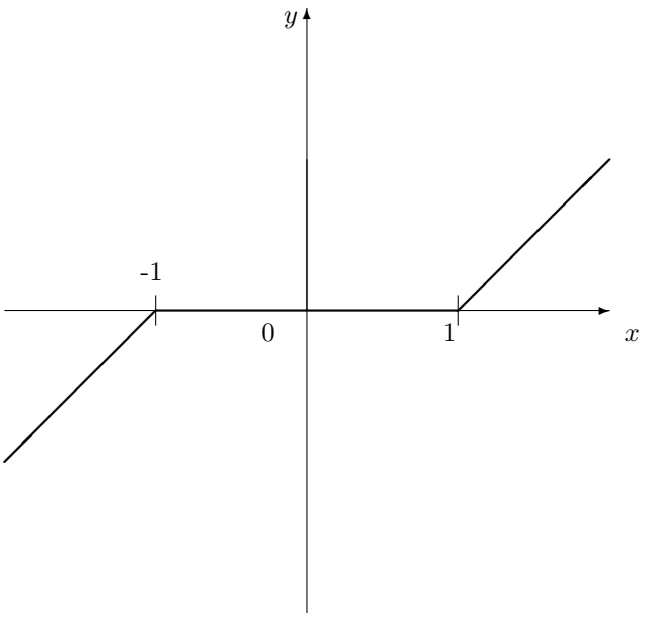

FIG. 1. Gph S.

Conditions (3.12) attain the form

$$0 = \frac{1}{2} + z,$$
$$0 = -1 + w - z,$$

and we observe that they are fulfilled with

$$(\hat{w}, \hat{z}) = \left(\frac{1}{2}, -\frac{1}{2}\right) \in N_{\operatorname{Gph} \partial|\cdot|}(0, -1).$$

The next section is devoted to two important classes of MPECs, where the optimality conditions of Theorems 3.1 and 3.3 can be converted to a workable form.

4. Applications. Assume that we are given two continuously differentiable functions F, $G[\mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^m]$ and consider equlibria governed by the parameter-dependent *implicit complementarity problem* (ICP):

for a given $x \in \mathbb{R}^n$, find $y \in \mathbb{R}^m$ such that

$$F(x,y) \geq 0,\ y \geq G(x,y) \quad \text{and} \quad \langle y - G(x,y), F(x,y)\rangle = 0.$$

If $G \equiv 0$, the ICP reduces to the standard nonlinear complementarity problem. As an ICP one can model, e.g., (discretized) obstacle problems with compliant obstacles [8] or filtration through porous media [14]. In [16] optimality conditions have been derived for MPECs with such equilibria under the strong regularity assumption. Here we remove this assumption and strengthen the conditions from [16] using the approach of the preceding section.

It is well known that an ICP can equivalently be formulated as the GE of the type (1.3):

$$0 \in F(x,y) + N_{\mathbb{R}^m_+}(y - G(x,y)). \tag{4.1}$$

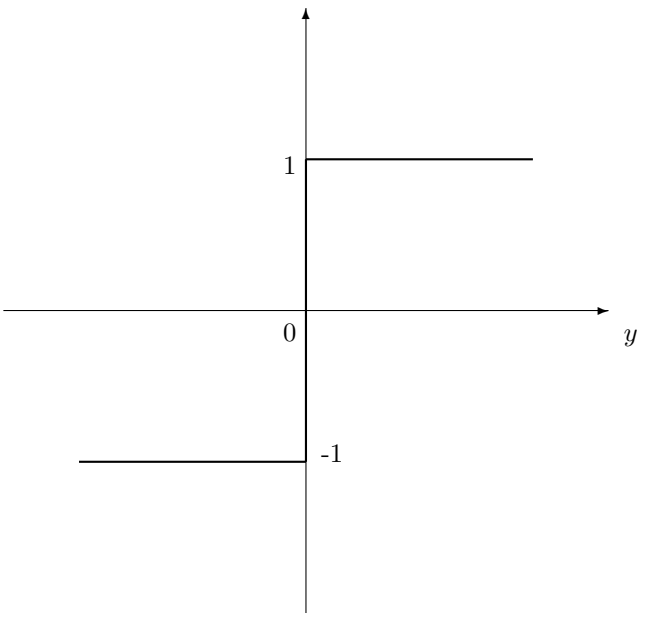

FIG. 2. Gph $\partial|y|$.

Analogously to [15] we associate with a pair (x, y), feasible with respect to (4.1), the index sets

$$\begin{aligned} L(x,y) &:= \left\{ i \in \{1,2,\ldots,m\} \,|\, y^i > G^i(x,y) \right\}, \\ I(x,y) &:= \left\{ i \in \{1,2,\ldots,m\} \,|\, y^i = G^i(x,y) \right\}, \\ I_+(x,y) &:= \left\{ i \in I(x,y) \,|\, F^i(x,y) > 0 \right\}, \\ I_0(x,y) &:= \left\{ i \in I(x,y) \,|\, F^i(x,y) = 0 \right\}. \end{aligned}$$

Evidently, $L(x,y) \cup I_+(x,y) \cup I_0(x,y) = \{1,2,\ldots,m\}$. Since we will associate these index sets only with a (locally) optimal pair $(\hat{x}, \hat{y})$, their arguments are dropped whenever they occur as subscripts.

On the basis of Theorem 3.1 we can now state the optimality conditions for the problem

$$\begin{array}{ll} \text{minimize} & f(x,y) \\ \text{subject to} & \\ & 0 \in F(x,y) + N_{\mathbb{R}^m_+}(y - G(x,y)), \\ & (x,y) \in \omega. \end{array} \tag{4.2}$$

THEOREM 4.1. *Let $(\hat{x}, \hat{y})$ be a (local) solution of problem* (4.2) *and let the assumptions* (A1), (A3) *be fulfilled. Further suppose that the constraint qualification*

(CQ*)

$$\left.\begin{array}{l} \left[\begin{array}{cc} -(\nabla_x G_I(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_x F_{L\cup I_0}(\hat{x},\hat{y}))^{\mathrm{T}} \\ (E_I)^{\mathrm{T}} - (\nabla_y G_I(\hat{x},\hat{y}))^{\mathrm{T}} & -(\nabla_y F_{L\cup I_0}(\hat{x},\hat{y}))^{\mathrm{T}} \end{array}\right] \left[\begin{array}{c} w_I \\ z_{L\cup I_0} \end{array}\right] \in -N_\omega(\hat{x},\hat{y}) \\ \text{for } i \in I_0(\hat{x},\hat{y}), \text{ either } w^i z^i = 0 \text{ or } w^i < 0 \text{ and } z^i > 0 \end{array}\right\} \text{implies } w_I = 0, z_{L\cup I_0} = 0$$

holds true. Then there exist a pair $(\xi,\eta)\in\partial^- f(\hat x,\hat y)$*, a pair* $(\gamma,\delta)\in N_\omega(\hat x,\hat y)$*, and a KKT pair* $(\hat w,\hat z)\in\mathbb{R}^m\times\mathbb{R}^m$ *such that* $\hat w_L=0,\hat z_{I_+}=0$*,*

$$\begin{aligned}0 &= \xi-(\nabla_x G_I(\hat x,\hat y))^{\mathrm T}\hat w_I-(\nabla_x F_{L\cup I_0}(\hat x,\hat y))^{\mathrm T}\hat z_{L\cup I_0}+\gamma,\\ 0 &= \eta+\hat w-(\nabla_y G_I(\hat x,\hat y))^{\mathrm T}\hat w_I-(\nabla_y F_{L\cup I_0}(\hat x,\hat y))^{\mathrm T}\hat z_{L\cup I_0}+\delta,\end{aligned}\tag{4.3}$$

and for $i\in I_0(\hat x,\hat y)$*, either* $\hat w^i\hat z^i=0$ *or* $\hat w^i<0$ *and* $\hat z^i>0$*.*

Proof. Evidently, the GE (4.1) is a special case of the GE (1.3) with

$$F_1(x,y)=F(x,y),\quad F_2(x,y)=y-G(x,y),\quad\text{and}\quad Q(\cdot)=N_{\mathbb{R}^m_+}(\cdot).$$

In virtue of [15, Lemma 2.2] we readily infer that

$$\begin{aligned}N_{\operatorname{Gph}N_{\mathbb{R}^m_+}}(\hat y-G(\hat x,\hat y),-F(\hat x,\hat y)) = \{(w,z)\in\mathbb{R}^m\times\mathbb{R}^m \mid w_L=0,\ z_{I_+}=0\\ \text{and for } i\in I_0(\hat x,\hat y) \text{ either } w^iz^i=0 \text{ or } w^i<0 \text{ and } z^i>0\}.\end{aligned}\tag{4.4}$$

Consequently, it suffices to apply Theorem 3.1 and realize that (CQ) becomes (CQ*) and conditions (3.3) attain the form (4.3). □

Remark. If $G\equiv 0$ and the state variable is not subject to any constraints, Theorem 4.1 reduces to the optimality conditions derived in [15]. Indeed, since $\hat w_{I_+}$ is arbitrary and the third term at the right-hand side of the second equation in (4.3) disappears, we can neglect all equations

$$0=\eta^i+\hat w^i-\big((\nabla_y F_{L\cup I_0}(\hat x,\hat y))^{\mathrm T}z_{L\cup I_0}\big)^i+\delta^i$$

for $i\in I_+(\hat x,\hat y)$. In the case of genuine ICPs this is, however, not possible.

For the mathematical description of the behavior of some modern materials like fiberglass or sandwich composites a theory has been developed in [17], leading to so-called hemivariational inequalities. After a suitable discretization, some of them attain the form of the GE

$$0\in A(x)\,y+b(x)+Q(y),\tag{4.5}$$

where the maps $A[\mathbb{R}^n\to\mathbb{R}^m\times\mathbb{R}^m]$ and $b[\mathbb{R}^n\to\mathbb{R}^m]$ are continuously differentiable and

$$Q(y)=\mathop{\mathrm{X}}_{i=1}^m Q_i(y^i),\quad Q_i(y^i)=\begin{cases}\partial^c J(y^i) & \text{for}\quad i\in I_1,\\ 0 & \text{for}\quad i\in\{1,2,\dots,m\}\setminus I_1\end{cases}\tag{4.6}$$

with a locally Lipschitz function $J[\mathbb{R}\to\mathbb{R}]$ and a given index set $I_1\subset\{1,2,\dots,m\}$. In (4.5) y corresponds, e.g., to displacement or stresses at single nodes of discretization and x describes, e.g., the shape of the body in question; cf. [9]. Since J is a function of one variable, in most cases the set $\operatorname{Gph}\partial^c J\subset\mathbb{R}^2$ can easily be constructed. Moreover, if J is a piecewise smooth function, then also the generalized normal cone can readily be computed at each point of $\operatorname{Gph}\partial^c J$.

Consider now the problem

$$\begin{aligned}&\text{minimize} && f(x,y)\\ &\text{subject to}\\ &&& (x,y) \text{ is feasible with respect to the GE (4.5)},\\ &&& (x,y)\in\omega.\end{aligned}\tag{4.7}$$

THEOREM 4.2. *Let $(\hat{x}, \hat{y})$ be a (local) solution of problem* (4.7) *and let the assumptions* (A1), (A3) *be fulfilled. Further suppose that the constraint qualification*

$$\left.\begin{array}{l}(\mathrm{CQ}^+)\\ \left[\begin{array}{cc} 0 & -(\nabla_x(A(\hat{x})\,\hat{y}+b(\hat{x})))^{\mathrm{T}} \\ (E_{I_1})^{\mathrm{T}} & -(A(\hat{x}))^{\mathrm{T}} \end{array}\right]\left[\begin{array}{c} w_{I_1} \\ z \end{array}\right] \in -N_\omega(\hat{x},\hat{y})\\ \text{for } i\in I_1 \text{ one has } (w^i,z^i)\in N_{\mathrm{Gph}\,\partial^c J}(\hat{y}^i,-(A(\hat{x})\,\hat{y}+b(\hat{x}))^i)\end{array}\right\} \text{implies} \left\{\begin{array}{l} w_{I_1}=0,\\ z=0\end{array}\right.$$

holds true. Then there exist a pair $(\xi,\eta)\in\partial^- f(\hat{x},\hat{y})$, a pair $(\gamma,\delta)\in N_\omega(\hat{x},\hat{y})$, and a KKT pair $(\hat{w},\hat{z})\in\mathbb{R}^m\times\mathbb{R}^m$ such that

$$\begin{aligned} \hat{w}^i &= 0 \quad \text{for } i\notin I_1,\\ 0 &= \xi-(\nabla_x(A(\hat{x})\,\hat{y}+b(\hat{x})))^{\mathrm{T}}\hat{z}+\gamma,\\ 0 &= \eta+\hat{w}-(A(\hat{x}))^{\mathrm{T}}\hat{z}+\delta, \end{aligned} \tag{4.8}$$

and for $i\in I_1$ one has $(\hat{w}^i,\hat{z}^i)\in N_{\mathrm{Gph}\,\partial^c J}(\hat{y}^i,-(A(\hat{x})\,\hat{y}+b(\hat{x}))^i)$.

Proof. It suffices to apply Theorem 3.1 with $F_1(x,y):=A(x)\,y+b(x)$, $F_2(x,y):=y$, and Q given by (4.6). If $i\notin I_1$, then clearly

$$N_{\mathrm{Gph}\,Q_i}(\hat{y}^i,0)=\left\{(w^i,z^i)\in\mathbb{R}\times\mathbb{R}\,|\,w^i=0\right\}. \qquad \square$$

We illustrate now the application of the above statement by a simple academic example. Consider the MPEC

$$\begin{array}{ll} \text{minimize} & -2xy-x\\ \text{subject to} & \\ & 0\in 2xy+x+\partial^c J(y),\\ & x\in[-2,2], \end{array} \tag{4.9}$$

where

$$J(y):=\begin{cases} 0 & \text{for} \quad |y|\geq 1,\\ \frac{1}{2}y^2+y+\frac{1}{2} & \text{for} \quad y\in(-1,0],\\ \frac{1}{2}y^2-y+\frac{1}{2} & \text{for} \quad y\in(0,1). \end{cases}$$

The set $\mathrm{Gph}\,\partial^c J$ is depicted in Figure 3. Due to the relation between our hemivariational inequality and the objective in (4.9), we deduce that $(\hat{x},\hat{y})=(1,0)$ is the (global) solution of (4.9). Condition $(\mathrm{CQ})^+$ is fulfilled because $N_\omega(\hat{x},\hat{y})=(0,0)$ and

$$\left[\begin{array}{cc} 0 & -1\\ 1 & -2 \end{array}\right]\left[\begin{array}{c} w\\ z \end{array}\right]=\left[\begin{array}{c} 0\\ 0 \end{array}\right] \text{ implies } w=z=0.$$

System (4.8) attains the form

$$\begin{aligned} 0&=-1-z,\\ 0&=-2+w-2z, \end{aligned}$$

and possesses the unique solution $(\hat{w},\hat{z})=(0,-1)$. Since $(0,-1)$ evidently belongs to $N_{\mathrm{Gph}\,\partial^c J}(0,-1)$, the optimality conditions of Theorem 4.2 are satisfied.

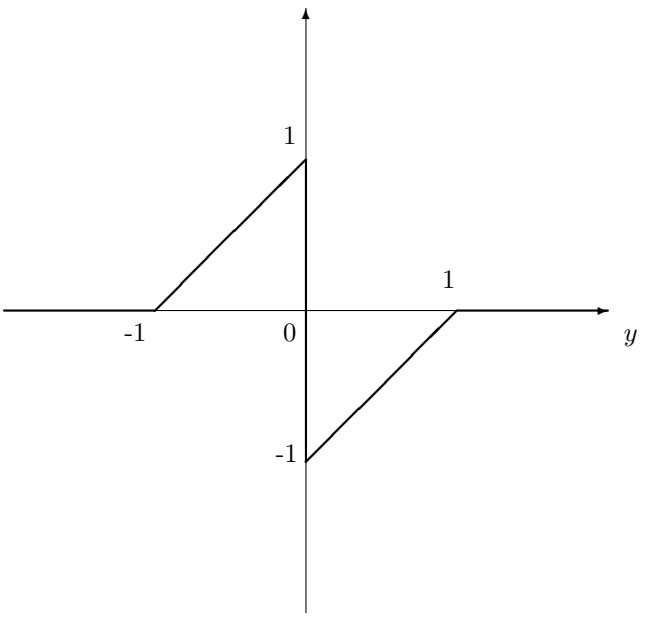

FIG. 3. $\operatorname{Gph} \partial^c J$.

5. Concluding remarks. The derived optimality conditions can well be used in testing of optimality (stationarity) of approximate solutions to problems of the type (1.5) computed by various available numerical methods.

The computation of the generalized normal cone to the graph of Q is substantially facilitated provided Q is polyhedral. Then, for a pair $(u, v) \in \operatorname{Gph} Q$, one has

$$N_{\operatorname{Gph} Q}(u, v) = \left\{ \bigcup T^0_{\operatorname{Gph} Q}(u', v') \,|\, (u', v') \in \mathcal{O} \cap \operatorname{Gph} Q \right\},$$

where $\mathcal{O}$ is any sufficiently small neighborhood of (u, v); cf. [2]. The situation is particularly simple provided

$$Q(y) = \bigtimes_{i=1}^{m} Q_i(y^i),$$

as in the case of both equilibria considered in the previous section. A different discretization of hemivariational inequalities leads, however, to a different situation, where

$$Q(y) = \bigtimes_{j=1}^{m} Q_j(y_j)$$

with the subvectors y_j of y having a "low" dimension. Nevertheless, even in such a situation the computation of $N_{\operatorname{Gph} Q}$ is still realistic.

In this paper the desired pseudo–upper-Lipschitz continuity of $\Phi^{-1}(\cdot) \cap \omega$ (with Φ given by (3.2)) is in the nonpolyhedral case ensured via condition (CQ) implying in fact the (more restrictive) pseudo-Lipschitz continuity. It seems that under some additional assumptions on Q and ω it is possible to guarantee this property by a weaker condition than (CQ) [4]. This issue is, however, rather complicated and deserves a separate study.

The last remark concerns the numerical solution of (1.5). From the above theory it is clear that under the assumptions of Theorem 3.1 or Theorem 3.3 the function

$$P : (x, y) \longmapsto \operatorname{dist}_{\operatorname{Gph} Q} \left(\begin{bmatrix} F_2(x, y) \\ -F_1(x, y) \end{bmatrix} \right) \tag{5.1}$$

is a Lipschitzian error bound of $\Phi^{-1}(0) \cap \omega$ with respect to test vectors from $\omega \cap \tilde{\mathcal{O}}$, where $\tilde{\mathcal{O}}$ is a neighborhood of $(\hat{x}, \hat{y})$. If we succeed to assign the graph of Q a suitable metric in $\mathbb{R}^\ell \times \mathbb{R}^m$ for which the values of P can easily be computed, we could try to solve (1.5) via the penalized problem

$$\begin{array}{ll} \text{minimize} & f(x, y) + \rho P(x, y) \\ \text{subject to} & \\ & (x, y) \in \omega \end{array} \tag{5.2}$$

with a suitably chosen penalty parameter $\rho \geq 0$.

Appendix. The generalized normal cones and the coderivatives of closed-graph multifunctions admit a rich calculus which is based mainly on the so-called extremal principle; cf. [11], [12]. Next we give three statements of this calculus which have been applied in sections 2 and 3. The first one concerns the multifunction

$$\Sigma(v) := \{u \in \mathbb{R}^p \mid H(v, u) \in \Lambda,\ (v, u) \in \Omega\}, \tag{A.1}$$

where $v \in \mathbb{R}^q$, H maps $\mathbb{R}^q \times \mathbb{R}^p$ into $\mathbb{R}^s$, $\Lambda \subset \mathbb{R}^s$, and $\Omega \subset \mathbb{R}^q \times \mathbb{R}^p$.

THEOREM A.1 (see [12, Theorem 6.10]). *Let Λ and Ω be closed and let H be continuously differentiable. For a pair $(v, u) \in \mathbb{R}^q \times \mathbb{R}^p$ assume that $(v, u) \in \Omega$, $H(v, u) \in \Lambda$, and the qualification conditions*

$$N_\Lambda(H(v, u)) \cap \operatorname{Ker}(\nabla H(v, u))^{\mathrm{T}} = \{0\},$$
$$(\nabla H(v, u))^{\mathrm{T}} N_\Lambda(H(v, u)) \cap (-N_\Omega(v, u)) = \{0\}$$

are fulfilled. Then for all $u^* \in \mathbb{R}^p$ one has the inclusion

$$D^*\Sigma(v, u)(u^*) \subset \left\{v^* \in \mathbb{R}^q \mid (v^*, -u^*) \in (\nabla H(v, u))^{\mathrm{T}} N_\Lambda(H(v, u)) + N_\Omega(v, u)\right\}. \tag{A.2}$$

The second statement concerns the sum of a function $\Phi_1[\mathbb{R}^p \to \mathbb{R}^\ell]$ and a multifunction $\Phi_2[\mathbb{R}^p \rightsquigarrow \mathbb{R}^\ell]$.

THEOREM A.2 (see [12, Corollary 4.4]). *Let Φ_1 be continuously differentiable on a neighborhood of $u \in \mathbb{R}^p$ and let Φ_2 have the closed graph. Then for each $v \in \Phi_1(u) + \Phi_2(u)$ and $v^* \in \mathbb{R}^\ell$ one has*

$$D^*(\Phi_1 + \Phi_2)(u, v)(v^*) = (\nabla \Phi_1(u))^{\mathrm{T}} v^* + D^*\Phi_2(u, v - \Phi_1(u))(v^*). \tag{A.3}$$

In some situations we would like to compute the generalized normal cone to an intersection of sets. The respective fundamental result from [11] can be, in the case of only two sets, simplified to the following form.

THEOREM A.3. *Consider two sets $\Omega_1, \Omega_2 \subset \mathbb{R}^s$ and a point $z \in cl\Omega_1 \cap cl\Omega_2$. Assume that*

$$N_{\Omega_1}(z) \cap (-N_{\Omega_2}(z)) = \{0\}.$$

Then one has the inclusion

$$N_{\Omega_1 \cap \Omega_2}(z) \subset N_{\Omega_1}(z) + N_{\Omega_2}(z).$$

Acknowledgments. The author would like to express his gratitude to B. Mordukhovich and D. Ralph for many helpful discussions on the subject of the paper. He is also deeply indebted to both referees for a number of constructive and helpful suggestions.

OPTIMAL CONTROL OF PARABOLIC DIFFERENTIAL EQUATIONS WITH TWO POINT BOUNDARY STATE CONSTRAINTS*

GENGSHENG WANG†

Abstract. This paper deals with the necessary conditions of optimality for some optimal control problems governed by some parabolic differential equations involving monotone graphs. The two point boundary (time variable) state constraints are discussed. Some analyses on the state equations are given.

Key words. variational inequality, optimal control, state constraint, maximum principle

AMS subject classifications. 49K20, 35J65

1. Introduction.

Let $H = L^2(\Omega)$, where $\Omega \subset R^N$ is a bounded domain with smooth boundary, $Q = \Omega \times (0,T)$.

We shall study the optimal control problems governed by nonlinear parabolic equations of the form

$$y' + Ay + \beta(y) \ni Bu \quad \text{almost everywhere (a.e.) in } Q, \tag{1.1}$$

with the state constraint

$$(y(0), y(T)) \in S \subset H \times H. \tag{1.2}$$

The pay-off functional is given by

$$L(y,u) = \int_0^T [g(t, y(t)) + h(u(t))]dt. \tag{1.3}$$

Note that y' in (1.1) is the strong derivative with respect to t of the function $y : Q \to R$ as a function of t from $[0,T]$ to $L^2(\Omega)$.

For the data in (1.1)–(1.3), we have the following assumptions.

(H_1) Let $V \subset H$ be a real Hilbert space such that V is dense in H and $V \subset H \subset V'$ algebraically and topologically, where V' is the dual of V. Further, the injection of V into H is compact.

$A : V \to V'$ is a linear continuous and symmetric operator from V to V' satisfying the coercivity condition

$$\langle Ay, y\rangle \geq w\|y\|_V^2 - \alpha\|y\|_H^2 \quad \text{for all } y \in V, \tag{1.4}$$

where $w > 0$ and $\alpha \in R$.

(H_2) β is a maximal monotone graph in $R \times R$ with $0 \in D(\beta)$. Moreover, there exists a constant C independent of ε such that

$$\langle Ay, \beta_\varepsilon(y)\rangle \geq -C(1 + \|\beta_\varepsilon(y)\|_H)(1 + \|y\|_H) \tag{1.5}$$

*Received by the editors May 1, 1998; accepted for publication (in revised form) May 28, 1999; published electronically May 26, 2000. This research was partially supported by the HuaCheng Foundation of China.

†Mathematics Department, Huazhong Normal University, Wuhan 430079, P.R. of China (kyc@ccnu.edu.cn).

for all

$$y \in D(A_H) \equiv \{y \in V; Ay \in H\},$$

where $\beta_\varepsilon(r) = \varepsilon^{-1}(r - (1+\varepsilon\beta)^{-1}r)$ for all $\varepsilon > 0,\ r \in R$.

Let $\phi : H \to \overline{R} = (-\infty, +\infty]$ be the lower semicontinuous convex function defined by

$$\phi(y) = \int_\Omega j(y(x))dx,$$

where $j : R \to \overline{R}$ is such that $\beta = \partial j$.

Then $\partial\phi(y) = \{w \in H : w(x) \in \beta(y(x))$ a.e. $x \in \Omega\}$ (cf. [1] or [6]), where $\partial\phi$ denotes the subdifferential of ϕ.

Suppose

$$\overline{D(\phi)} = H, \tag{1.6}$$

where $D(\phi)$ denotes the effective domain of ϕ.

(H_3) $S \subset D(\phi) \times H \subset H \times H$ is a convex closed subset with finite codimensionality (cf. [3]).

(H_4) B is a linear continuous operator from a real Hilbert space U to H.

(H_5) The functional $h : U \to \overline{R}$ is convex and lower semicontinuous (l.s.c.). Moreover, there exist $c_1 > 0$ and $c_2 \in R$ such that $h(u) \geq c_1\|u\|_U^2 + c_2$ for all $u \in U$.

(H_6) $g : [0,T] \times H \to R^+$ is measurable in t, and for every $r > 0$, there exists $L_r > 0$ independent of t such that $g(t,0) \in L^\infty(0,T)$ and

$$|g(t,y) - g(t,z)| \leq L_r\|y - z\|_H$$

for all $t \in [0,T]$, $\|y\|_H + \|z\|_H \leq r$.

Note that, by (H_2), the state equation (1.1) is equivalent to

$$y'(t) + Ay(t) + \partial\phi(y(t)) \ni Bu(t) \text{ a.e. } t \in (0,T). \tag{1.7}$$

As we know (cf. [1]), for any $u \in L^2(0,T;U), y_0 \in D(\phi) \cap V$, (1.7) with the initial condition

$$y(0) = y_0 \tag{1.8}$$

has a unique solution

$$y \equiv y(t, y_0, u) \in W^{1.2}([0,T];H) \cap C([0,T];H) \cap L^2(0,T;D(A_H)).$$

If $y_0 \in H(= \overline{D(\phi)}$, by (1.6)), then (1.7) with (1.8) has a unique solution in $C([0,T];H)$ with $t^{1/2}y' \in L^2(0,T;H), t^{1/2}y \in L^2(0,T;D(A_H))$.

Now we formulate the optimal control problems as follows.

Let $A_{ad} = \{(y,u) \in W^{1,2}([0,T];H) \cap C([0,T;H) \cap L^2(0,T;D(A_H)) \times L^2(0,T;U) \mid y$ is the solution of (1.7) with (1.8) corresponding to $u, (y(0), y(T)) \in S\}$.

We are asked to find

(P) Min $L(y,u)$ over $(y,u) \in A_{ad}$.

Recently, many mathematicians have discussed the optimal control problems governed by linear and nonlinear parabolic differential equations. Barbu made many contributions in this field (cf. [1]). Li and Yong studied the maximal principle for optimal control governed by some nonlinear parabolic equations with two point boundary (time variable) state constraints (cf. [3], [4]). Pavel also discussed the necessary conditions for optimal control governed by linear parabolic equations with two-point boundary constraints (cf. [6]). However, there are some stronger restrictions on the nonlinear terms on the case studied by Li and Yong so that the state equation and its variational equation can be studied by linear semigroup. In Barbu's works, the two point boundary state constraints were considered less for the nonlinear state equation.

The present work in this paper is concerned with the optimal control problem governed by the state equation which is the same as what Barbu discussed in [1] and much more general than those in Li and Yong's case [3]. However, the problem studied in [1] does not involve state constraints.

Because of the involvement of the state constraint, we construct a new kind of penalty functional for the pay-off function. The idea is based on those in [1]. Also, some analyses for the state equation, like the sensitivity of the state with respect to the control, are discussed.

Due to the involvement of monotone graphs in the state equation, we need some restrictions on the initial data for the state equation, so we assume $S \subset D(\phi) \times H$ instead of $S \subset H \times H$ (Li and Yong's case). Also, the variational equations now involve measure, so the methods used in Li and Yong's case do not work here.

The plan of this paper is as follows. Section 2 gives an approximating control process. In section 3, we state and prove the necessary conditions on optimality for the problem (P). In section 4, some remarks are given.

2. The approximating control process. Let (y^*, u^*) be optimal for the problem (P). Then

$$y^{*\prime}(t) + Ay^*(t) + \beta(y^*(t)) \ni Bu^*(t), \qquad \text{a.e. } t \in (0,T), \qquad (y^*(0), y^*(T)) \in S$$

and

$$L(y^*, u^*) = \operatorname{Inf} L(y,u) \text{ over } (y,u) \in A_{ad}.$$

In order to introduce the approximating control process, we need the approximations β_ε and β^ε for β and related results. For the details we refer readers to [1].

Set $\beta_\varepsilon = \varepsilon^{-1}(1 - (1+\varepsilon\beta)^{-1})$ and

$$\beta^\varepsilon(r) = \int_{-\infty}^{+\infty} [\beta_\varepsilon(r - \varepsilon^2\theta) - \beta_\varepsilon(-\varepsilon^2\theta)]\rho(\theta)d\theta + \beta_\varepsilon(0), \tag{2.1}$$

where ρ is a C_0^∞-mollifier on R, i.e., $\rho \in C_0^\infty(R)$, $\rho(0) = 0$ for $|r| > 1, \rho(r) = \rho(-r)$, and $\int_{-\infty}^{\infty} \rho(r)dr = 1$.

Then β^ε is infinitely differentiable and Lipschitzian with Lipschitz constant ε^{-1}, and

$$\dot\beta^\varepsilon(r) \geq 0 \quad \text{for all } r \in R, \tag{2.2}$$

$$|\beta^\varepsilon(r) - \beta_\varepsilon(r)| \leq 2\varepsilon \quad \text{for all } r \in R. \tag{2.3}$$

Let $\phi^\varepsilon : H \to R$ be given by

$$\phi^\varepsilon(y) = \int_\Omega j^\varepsilon(y(x))dx \quad \text{for all } y \in H, \tag{2.4}$$

where $j^\varepsilon(r) = \int_0^r \beta^\varepsilon(s)ds$ for all $r \in R$.

Then ϕ^ε is Frechet differentiable on H and

$$\nabla\phi^\varepsilon(y(x)) = \beta^\varepsilon(y(x)) \text{ a.e. } x \in \Omega \quad \text{for all } y \in H. \tag{2.5}$$

Let $\phi_\varepsilon : H \to R$ be defined by

$$\phi_\varepsilon(y) = \operatorname{Inf}\left\{ \frac{\|y-z\|_H^2}{2\varepsilon} + \phi(z); \quad z \in H \right\}.$$

Then $\nabla\phi_\varepsilon(y(x)) = \beta_\varepsilon(y(x))$ a.e. $x \in \Omega$.

We also have

$$\|\nabla\phi_\varepsilon(y) - \nabla\phi^\varepsilon(y)\|_H \le 2\varepsilon \quad \text{for all } y \in H \text{ and } \varepsilon > 0, \tag{2.6}$$

and

$$\|\phi_\varepsilon(y) - \phi^\varepsilon(y)\|_H \le C_\varepsilon\|y\|_H \quad \text{for all } y \in H \text{ and } \varepsilon > 0. \tag{2.7}$$

Now consider the following approximating equations:

$$\begin{cases} y' + Ay + \beta^\varepsilon(y) = Bu, \\ y(0) = y_0. \end{cases} \tag{2.8}$$

As we know, for any $y_0 \in H, u \in L^2(0,T;U)$, (2.8) has a unique solution in $W^{1,2}((0,T];H) \cap C([0,T];H) \cap L^2(0,T;V)$ (cf. [1]).

We also have the following result on (2.8).

LEMMA 2.1. *For $\varepsilon > 0$ given, let $u_1, u_2 \in L^2(0,T;U)$ and $y_{1,0}$, $y_{2,0} \in H$. Suppose that y_1 and y_2 are the solutions of* (2.8) *corresponding to u_1, $y_{1,0}$ and $u_2, y_{2,0}$, respectively. Then*

$$\|y_1 - y_2\|_{C([0,T];H)} \le C[\ \|y_{1,0} - y_{2,0}\|_H + \|u_1 - u_2\|_{L^2(0,T;U)}\ ]$$

for some constant C independent of ε for $1 \ge \varepsilon > 0$.

Proof. Note that (2.8) is equivalent to

$$\begin{cases} y' + Ay + \nabla\phi_\varepsilon(y) = \nabla\phi_\varepsilon(y) - \nabla\phi^\varepsilon(y) + Bu, \\ y(0) = y_0. \end{cases} \tag{2.9}$$

We have

$$\begin{aligned} &(y_1 - y_2)' + A(y_1 - y_2) + \nabla\phi_\varepsilon(y_1) - \nabla\phi_\varepsilon(y_2) \\ &= \nabla\phi_\varepsilon(y_1) - \nabla\phi^\varepsilon(y_1) - [\nabla\phi_\varepsilon(y_2) - \nabla\phi^\varepsilon(y_2)] + B(u_1 - u_2). \end{aligned} \tag{2.10}$$

Multiplying (2.10) by $(y_1 - y_2)$ and integrating over $(0,t)$, by (H_1) and (2.6), one obtains

$$\begin{aligned} &\|(y_1 - y_2)(t)\|_H^2 + 2w\int_0^t \|y_1 - y_2\|_V^2 ds \\ &\le \|y_1(0) - y_2(0)\|_H^2 + 2\alpha\int_0^t \|y_1 - y_2\|_H^2 ds \\ &+ \int_0^t 4\varepsilon\|y_1 - y_2\|_H + C_\delta\int_0^t \|u_1 - u_2\|_V^2 + \delta\int_0^t \|y_1 - y_2\|_H^2 ds \end{aligned} \tag{2.11}$$

for any $\delta > 0$ and some constant C_δ depending on δ.

Applying Gronwall's inequality to (2.11), we get

$$\|(y_1 - y_2)(t)\|_{C([0,T];H)} \le C[\|y_{1,0} - y_{2,0}\|_H + \|u_1 - u_2\|_{L^2(0,T;U)}]$$

for some constant C independent of ε for $0 < \varepsilon \le 1$. This completes the proof.

Next, we recall the approximation g_ε of g and h_ε of h as follows. For the details, we refer readers to [1].

$g_\varepsilon : [0,T] \times H \to R$ is defined by

$$g_\varepsilon(t,y) = \int_{R^n} g(t, p_n y - \varepsilon \wedge_n \tau)\rho_n(\tau)d\tau, \tag{2.12}$$

where $n = [\varepsilon^{-1}]$, ρ_n is a mollifier in R^n, $p_n : H \to X_n$ is the projection of H on X_n which is the finite dimensional space generated by $\{e_i\}_{i=1}^n$, where $\{e_i\}_{i=1}^\infty$ is an orthonormal basis in H. $\wedge_n : R^n \to X_n$ is the operator defined by $\wedge_n(\tau) = \Sigma_{i=1}^n \tau_i e_i$, $\tau = (\tau_1, \dots, \tau_n)$.

$h_\varepsilon : H \to \overline{R}$ is defined by

$$h_\varepsilon(y) = \text{ Inf } \{\|y - x\|_H^2/(2\varepsilon) + h(x); x \in H\}. \tag{2.13}$$

Now we define the penalty $L_\varepsilon : H \times L^2(0,T;U) \to R$ by

$$\begin{aligned} L_\varepsilon(y_0,u) &= \int_0^T [g_\varepsilon(t,y_\varepsilon) + h_\varepsilon(u)]dt + \frac{1}{2}\|y_0 - y^*(0)\|_H^2 \\ &+ \tfrac{1}{2}\|u - u^*\|^2_{L^2(0,T;U)} + \tfrac{1}{2\varepsilon^{1/2}}[d_S(y_\varepsilon(0), y_\varepsilon(T)) + \varepsilon^{1/2}]^2, \end{aligned} \tag{2.14}$$

where y_ε is the solution of (2.8) and $h_\varepsilon, g_\varepsilon$ are given by (2.13) and (2.12), respectively. $d_S(y_\varepsilon(0), y_\varepsilon(T))$ denotes the distance of $(y_\varepsilon(0), y_\varepsilon(T))$ to S.

The approximating optimal control problems are as follows:

$$(\mathrm{P}^\varepsilon) \qquad \text{Minimize } L_\varepsilon(y_0,u) \quad \text{ over } (y_0,u) \in H \times L^2(0,T;U).$$

First of all, we show the existence of the optimalities for (P^ε).

THEOREM 2.2. (P^ε) *has at least one optimal solution.*

Proof. Let $\varepsilon > 0$ be fixed. It is clear that $\mathrm{Inf} L_\varepsilon(y_0,u) > -\infty$.

Let $d = \text{ Inf } L_\varepsilon(y_0,u), (y_0,u) \in H \times L^2(0,T;U)$ and $\{y_{0,n}, u_n\}$ be a minimizing sequence such that

$$d \le L_\varepsilon(y_{0,n}, u_n) \le d + n^{-1}. \tag{2.15}$$

By (H_5), (H_6), and (2.15), $\{u_n\}$ and $\{y_{0,n}\}$ are bounded in $L^2(0,T;U)$ and H, respectively. Without loss of generality, we may assume that $u_n \to \tilde{u}$ weakly in $L^2(0,T;U)$, and $y_{0,n} \to \tilde{y_0}^*$ weakly in H (relabeling if necessary).

By Lemma 2.1, it is clear that L_ε is continuous in $y_{0,n}$ in H and so by (1.6), for each $n \in N$. We may choose $\tilde{y}_{0,n} \in D(\phi) \cap V$ such that

$$\|y_{0,n} - \tilde{y}_{0,n}\|_H < 1/n \quad \text{and} \quad |L_\varepsilon(y_{0,n}, u_n) - L_\varepsilon(\tilde{y}_{0,n}, u_n)| < 1/n. \tag{2.16}$$

Let $\tilde{y}_{\varepsilon,n}$ be the solution of (2.9) corresponding to u_n and $\tilde{y}_{0,n}$, i.e., $\tilde{y}_{\varepsilon,n} \in W^{1,2}([0,T];H) \cap C([[0,T];H) \cap L^2(0,T;V)$ and satisfy

$$\begin{cases} \tilde{y}'_{\varepsilon,n} + A\tilde{y}_{\varepsilon,n} + \nabla\phi_\varepsilon(\tilde{y}_{\varepsilon,n}) = \nabla\phi_\varepsilon(\tilde{y}_{\varepsilon,n}) - \nabla\phi^\varepsilon(\tilde{y}_{\varepsilon,n}) + Bu_n, \\ \tilde{y}_{\varepsilon,n}(0) = \tilde{y}_{0,n}. \end{cases} \tag{2.17}$$

Multiplying (2.17) by $\tilde{y}_{\varepsilon,n}$ and integrating over $(0,t)$, by (H_1), we have

$$\|\tilde{y}_{\varepsilon,n}(t)\|_H^2 + 2w\int_0^t \|\tilde{y}_{\varepsilon,n}(s)\|_V^2 ds + 2\int_0^t \langle \nabla\phi_\varepsilon(\tilde{y}_{\varepsilon,n}), \tilde{y}_{\varepsilon,n}\rangle ds$$
$$\le \|y_{0,n}\|_H^2 + \int_0^t \langle Bu_n, \tilde{y}_{\varepsilon,n}\rangle ds + \alpha\int_0^t \|\tilde{y}_{\varepsilon,n}\|_H^2 ds + \int_0^t \langle \nabla\phi_\varepsilon(\tilde{y}_{\varepsilon,n}) - \nabla\phi^\varepsilon(\tilde{y}_{\varepsilon,n}), \tilde{y}_{\varepsilon,n}\rangle ds.$$

This implies by Gronwall's inequality and (2.6) that

$$\|\tilde{y}_{\varepsilon,n}\|_{C([0,T];H)} + \|\tilde{y}_{\varepsilon,n}\|_{L^2(0,T;V)} + \int_0^t \langle \nabla\phi_\varepsilon(\tilde{y}_{\varepsilon,n}), \tilde{y}_{\varepsilon,n}\rangle ds \le C, \tag{2.18}$$

where C is a constant independent of ε and n (cf. [1]).

Multiplying (2.17) by $\tilde{y}'_{\varepsilon,n}$ and integrating from 0 to t, we have

$$\begin{aligned}&\int_0^t \|\tilde{y}'_{\varepsilon,n}(s)\|_H^2 + \int_0^t \langle A\tilde{y}_{\varepsilon,n}, \tilde{y}_{\varepsilon,n}\rangle + \int_0^t \langle \nabla\phi_\varepsilon(\tilde{y}_{\varepsilon,n}), \tilde{y}'_{\varepsilon,n}\rangle \\ &= \int_0^t \langle Bu_n, \tilde{y}_{\varepsilon,n}\rangle + \int_0^t \langle \nabla\phi_\varepsilon(\tilde{y}_{\varepsilon,n}) - \nabla\phi^\varepsilon(\tilde{y}_{\varepsilon,n}), \tilde{y}'_{\varepsilon,n}\rangle.\end{aligned} \tag{2.19}$$

Note that

$$\begin{aligned}&\int_0^t \langle A\tilde{y}_{\varepsilon,n}, y'_{\varepsilon,n}\rangle ds = \frac{1}{2}\int_0^t \frac{d}{ds}\langle A\tilde{y}_{\varepsilon,n}, \tilde{y}_{\varepsilon,n}\rangle ds \\ &= \tfrac{1}{2}[\langle A\tilde{y}_{\varepsilon,n}(t), \tilde{y}_{\varepsilon,n}(t)\rangle - \langle A\tilde{y}_{0,n}, \tilde{y}_{0,n}\rangle].\end{aligned} \tag{2.20}$$

Since $\{\tilde{y}_{0,n}\} \subset V \cap D(\phi)$ is bounded, we have that $\langle A\tilde{y}_{0,n}, \tilde{y}_{0,n}\rangle$ is bounded.

$$\int_0^t \langle \nabla\phi_\varepsilon(\tilde{y}_{\varepsilon,n}), \tilde{y}'_{\varepsilon,n}\rangle ds = \int_0^t \frac{d}{ds}\phi_\varepsilon(\tilde{y}_{\varepsilon,n}(s)) ds = \phi_\varepsilon(\tilde{y}_{\varepsilon,n}(t)) - \phi_\varepsilon(\tilde{y}_{0,n}). \tag{2.21}$$

Since ϕ_ε is convex and continuously Frechet differentiable and $\{\tilde{y}_{0,n}\}$ is bounded, $\{\phi_\varepsilon(\tilde{y}_{0,n})\}$ is bounded. By (2.18)–(2.21), we obtain

$$\|\tilde{y}'_{\varepsilon,n}\|_{L^2(0,T;H)}^2 + \|\tilde{y}_{\varepsilon,n}\|_{L^2(0,T;V)}^2 + \|\tilde{y}_{\varepsilon,n}\|_{C([0,T];H)}^2 + \phi_\varepsilon(\tilde{y}_{\varepsilon,n}(t)) \le C, \tag{2.22}$$

where C is a constant independent of n and may be different from the constant in (2.18).

The convexity and continuity of ϕ_ε imply that ϕ_ε is bounded below by an affine functional in H. Thus (2.22) shows that

$$\|\tilde{y}'_{\varepsilon,n}\|_{L^2(0,T;H)} + \|\tilde{y}_{\varepsilon,n}\|_{L^2(0,T;V)} + \|\tilde{y}_{\varepsilon,n}\|_{C([0,T];H)} \le C. \tag{2.23}$$

Multiplying (2.17) by $A\tilde{y}_{\varepsilon,n}$ and integrating over $(0,t)$, by (2.18)–(2.23), (H_1), and (1.5) of (H_2), we may obtain

$$\|Ay_{\varepsilon,n}\|_{L^2(0,T;H)}^2 \le C. \tag{2.24}$$

Now by (2.18), (2.23), and (2.24), using the Arzela–Ascoli theorem, we obtain (cf. Lemma 5.1 of [1]) that there exist subsequences of $\{\tilde{y}_{\varepsilon,n}\}$ and $\{u_n\}$, still denoted by them, such that

$\tilde{y}_{\varepsilon,n} \to \tilde{y}_\varepsilon^*$ strongly in $C([0,T];H) \cap L^2(0,T;V)$ as $n \to \infty$,

$A\tilde{y}_{\varepsilon,n} \to A\tilde{y}_\varepsilon^*$ weakly in $L^2(0,T;H)$ as $n \to \infty$, and

$\tilde{y}'_{\varepsilon,n} \to \tilde{y}^*_\varepsilon$ weakly in $L^2(0,T;H)$ as $n \to \infty$.
Thus $\nabla\phi^\varepsilon(\tilde{y}_{\varepsilon,n}) \to \nabla\phi^\varepsilon(\tilde{y}^*_{\varepsilon,n})$ in $L^2(0,T;H)$.
So by taking the limit for $n \to \infty$ in (2.17), we have

$$\begin{cases} (\tilde{y}^*_\varepsilon)' + A\tilde{y}^*_\varepsilon + \nabla\phi^\varepsilon(\tilde{y}^*_\varepsilon) = B\tilde{u}^*, \\ \tilde{y}^*_\varepsilon(0) = \tilde{y}^*_0. \end{cases}$$

Since $d \le L_\varepsilon(y_{0,n}, u_n) \le d + 1/n$, by (2.16) we have

$$d \le L_\varepsilon(\tilde{y}_{0,n}, u_n) \le d + 2/n. \tag{2.25}$$

Since $\tilde{y}_{\varepsilon,n} \to \tilde{y}^*_\varepsilon$ strongly in $C([0,T];H)$, we obtain (note that h_ε is convex)

$$\int_0^T g_\varepsilon(t, \tilde{y}_{\varepsilon,n})dt \to \int_0^T g_\varepsilon(t, \tilde{y}^*_\varepsilon) \text{as } n \to \infty \quad \text{and} \quad \underline{\lim}_{n\to\infty} \int_0^T h_\varepsilon(u_\varepsilon) \ge \int_0^T h_\varepsilon(u^*).$$

This with (2.25) implies

$$L_\varepsilon(\tilde{y}^*_0, u^*) = d.$$

This completes the proof.

The following results are useful in discussing the approximating control problems.

LEMMA 2.3. *Let $u^\varepsilon \in L^2(0,T;U)$ and y^ε_0 be such that $u^\varepsilon \to \overline{u}$ weakly in $L^2(0,T;U)$ and $y^\varepsilon_0 \to \overline{y}_0$ weakly in H as $\varepsilon \to 0$. Let y^ε be the solution of (2.8) corresponding to u^ε and y^ε_0. Then $y^{\varepsilon_n} \to \overline{y}$ strongly in $L^2(0,T;H)$, $y^{\varepsilon_n}(t) \to \overline{y}(t)$ weakly in H for every $t \in [0,T]$ on a subsequence $\{\varepsilon_n\}$, where $\overline{y} \in W^{1,2}((0,T];H) \cap C([0,T];H)$ is the solution of the problem*

$$\begin{cases} \overline{y}' + A\overline{y} + \beta(\overline{y}) \ni B\overline{u} \quad \text{a.e.} \quad t \in (0,T), \\ \overline{y}(0) = \overline{y}_0. \end{cases}$$

Proof. We have

$$\begin{cases} (y^\varepsilon)' + Ay^\varepsilon + \nabla\phi_\varepsilon(y^\varepsilon) = \nabla\phi_\varepsilon(y^\varepsilon) - \nabla\phi^\varepsilon(y^\varepsilon) + Bu^\varepsilon, \\ y^\varepsilon(0) = y^\varepsilon_0. \end{cases} \tag{2.26}$$

Multiplying (2.26) by y^ε and integrating over $(0,t)$, by (H_1) and (2.6), we obtain

$$\|y^\varepsilon(t)\|^2_H + \int_0^T \|y^\varepsilon\|^2_V + \int_0^t \phi_\varepsilon(y^\varepsilon)ds \le C \tag{2.27}$$

for any $t \in (0,T)$.

Multiplying (2.26) by $s.(y^\varepsilon(s))'$ and integrating over $(0,t)$ by (2.6), we get

$$\begin{aligned} &\int_0^t s\|(y^\varepsilon)'(s)\|^2_H - \int_0^t s\langle Ay^\varepsilon, y^\varepsilon\rangle ds \\ &+t\langle Ay^\varepsilon(t), y^\varepsilon(t)\rangle - \int_0^t \phi_\varepsilon(y^\varepsilon)ds + t\phi_\varepsilon(y^\varepsilon(t)) \\ &\le \int_0^t \langle Bu^\varepsilon, s(y^\varepsilon)'\rangle + t\int_0^t 2\varepsilon\|(y^\varepsilon)'\|_H ds. \end{aligned}$$

By (2.27) and the boundedness of

$$\int_0^t \langle Ay^\varepsilon, y^\varepsilon\rangle,$$

which is from (H_1) and (2.27), we obtain

$$\int_0^t s\|(y^\varepsilon)'(s)\|_H^2 ds + t\langle Ay^\varepsilon(t), y^\varepsilon(t)\rangle + t\phi_\varepsilon(y^\varepsilon(t)) \le C \tag{2.28}$$

for each $t \in [0,T]$, where C is a constant independent of ε and $t \in [0,T]$.

Multiplying (2.26) by $t\phi_\varepsilon(y^\varepsilon(t))$ and integrating from 0 to t, by (2.27), (2.28), (H_1), and (1.5) of (H_2), we obtain

$$\int_0^t s\|\phi_\varepsilon(y^\varepsilon(t))\|_H^2 \le C. \tag{2.29}$$

Multiplying (2.26) by $sAy^\varepsilon(s)$ and integrating over $(0,t)$, by (2.6), using the same arguments as above, we obtain

$$\int_0^t s\|Ay^\varepsilon(s)\|_H^2 \le C. \tag{2.30}$$

Now by (2.27)–(2.30), using the Arzela–Ascoli theorem, there exists a $\overline{y} \in W^{1,2}((0,T];H) \cap L^2(0,T;V) \cap C([0,T];H)$ such that (cf. [1])

$y^{\varepsilon_n} \to \overline{y}$ weakly in $L^2(0,T;V)$ and strongly in $L^2(\delta,T;H)$ for each $\delta > 0$,

$Ay^{\varepsilon_n} \to A\overline{y}$ weakly in every $L^2(\delta,T;H)$,

$(y^{\varepsilon_n})' \to \overline{y}'$ weakly in every $L^2(\delta,T;H)$, and

$\nabla\phi_{\varepsilon_n}(y^{\varepsilon_n}) \to \xi$ weakly in every $L^2(\delta,T;H)$.

It follows that (cf. [1], [5]) $y^{\varepsilon_n} \to \overline{y}$ strongly in $L^2(0,T;H)$ and $\nabla\phi_{\varepsilon_n}(y^{\varepsilon_n}) \to \xi \in \partial\phi(\overline{y})$ weakly in every $L^2(\delta,T;H)$ on a subsequence $\{\varepsilon_n\}$. Also, $\overline{y}$ satisfies

$$\begin{cases} \overline{y}' + A\overline{y} + \beta(\overline{y}) \ni B\overline{u}, \\ \overline{y}(0) = \overline{y}_0. \end{cases}$$

Now by (2.27)–(2.30), using the same arguments as those in [1], (cf. Lemma 5.2 of [1]), we get $y^{\varepsilon_n}(t) \to \overline{y}(t)$ weakly in H for each $t \in [0,T]$.

This completes the proof.

LEMMA 2.4. *Let $y_0 \in D(\phi) \cap V$, $u \in L^2(0,T;U)$, and y^ε be the solution of the problem* (2.8). *Then $y^\varepsilon \to y$ in $C([0,T];H) \cap L^2(0,T;V)$, where $y \in W^{1,2}([0,T];H) \cap C([0,T];H)$ is the solution of the problem* (1.1) *with the initial condition $y(0) = y_0$. Moreover,*

$$\|y^\varepsilon - y\|_{C([0,T];H)} \le C\varepsilon^{1/2}, \tag{2.31}$$

where C is a constant independent of ε.

This result is due to Barbu (cf. Lemma 5.1 of [1]).

LEMMA 2.5. *Let $(y_{\varepsilon,0}, u_\varepsilon)$ be optimal for the problem (P^ε) and y_ε be the solution corresponding to u_ε and $y_{\varepsilon,0}$. Then $y_{\varepsilon_n} \to y^*$ in $C([0,T];H)$ and $u_{\varepsilon_n} \to u^*$ in $L^2(0,T;U)$ strongly as $\varepsilon_n \to 0$ on some subsequence $\{\varepsilon_n\}$.*

Proof. For each $\varepsilon > 0$, let y^ε be the solution of (2.8) corresponding to $y^*(0)$ and u^*. By Lemma 2.4, $y^\varepsilon \to y^*$ in $C([0,T];H)$. We have (cf. [1], [5])

$$g_\varepsilon(t, y^\varepsilon(t)) \to g(t, y^*(t)) \quad \text{for all } t \in [0,T], \quad h_\varepsilon(u^*(t)) \to h(u^*(t)) \text{ a.e. } t \in (0,T).$$

So

$$\lim_{\varepsilon\to 0} \int_0^t g_\varepsilon(t, y^\varepsilon(t)) = \int_0^t g(t, y^*(t))dt, \ \lim_{\varepsilon\to 0} \int_0^t h_\varepsilon(u^*(t)) = \int_0^t h(u^*(t)). \tag{2.32}$$

Since $(y_{\varepsilon,0}, u_\varepsilon)$ is optimal for the problem (P_ε), we have

$$\begin{aligned} &L_\varepsilon(y_{\varepsilon,0}, u_\varepsilon) \le L_\varepsilon(y^*(0), u^*) \\ &= \int_0^T [g_\varepsilon(t, y^\varepsilon) + h_\varepsilon(u^*)]dt + \frac{1}{2\varepsilon^{1/2}}[d_S(y^\varepsilon(0), y^\varepsilon(t)) + \varepsilon^{1/2}]^2. \end{aligned}$$

By (2.31), we get

$$\begin{aligned} &\tfrac{[ds(y^\varepsilon(0), y^\varepsilon(T)) + \varepsilon^{1/2}]^2}{2\varepsilon^{1/2}} \\ &\le \tfrac{\{[\|y^\varepsilon(0) - y^*(0)\|_H^2 + \|y^\varepsilon(T) - y^*(T)\|_H^2]^{1/2} + \varepsilon^{1/2}\}^2}{2\varepsilon^{1/2}} \\ &\le C\varepsilon^{1/2} \to 0 \ \text{ as } \ \varepsilon \to 0. \end{aligned} \tag{2.33}$$

By (2.32) and (2.33), we yield

$$\overline{\lim}_{\varepsilon\to 0} L_\varepsilon(y_{\varepsilon,0}, u_\varepsilon) \le L(y^*, u^*). \tag{2.34}$$

On the other hand, one can easily verify that $\{u_\varepsilon\}$ and $\{y_{\varepsilon,0}\}$ are bounded in $L^2(0,T;U)$ and H, respectively.

Without loss of generality, we may assume that $u_\varepsilon \to u_1^*$, $y_{\varepsilon,0} \to y_{1,0}^*$ weakly in $L^2(0,T;U)$ and H, respectively.

Let $y_1^*(t)$ be the solution of (2.8) corresponding to $y_{1,0}^*$ and u_1^*.

By Lemma 2.3, $y_\varepsilon \to y_1^*$ strongly in $L^2(0,T;H)$.

Consider $\underline{\lim}_{\varepsilon\to 0} L_\varepsilon(y_{\varepsilon,0}, u_\varepsilon)$.

By the arguments in [1],

$$\underline{\lim}_{\varepsilon\to 0} \int_0^T h_\varepsilon(u_\varepsilon) \ge \int_0^T h(u_1^*),\ \lim_{\varepsilon\to 0} \int_0^T g_\varepsilon(t, y_\varepsilon) = \int_0^T g(t, y_1^*).$$

Thus

$$\underline{\lim}_{\varepsilon\to 0} \int_0^T L_\varepsilon(y_{\varepsilon,0}, u_\varepsilon) \ge \int_0^T [g(t, y_1^*) + h(u_1^*)]. \tag{2.35}$$

By (2.14) and (2.34), one can check easily that

$$\frac{1}{2\varepsilon^{1/2}}[d_S(y_\varepsilon(0), y_\varepsilon(T)) + \varepsilon^{1/2}]^2 \le C.$$

Thus $d_S(y_\varepsilon(0), y_\varepsilon(T)) \to 0$ as $\varepsilon \to 0$.

By Lemma 2.3, there exists a subsequence of $\{\varepsilon\}_{\varepsilon>0}$, still denoted by itself, such that $y_\varepsilon(T) \to y_1^*(T)$ weakly in H.

Since S is convex and closed in $H \times H$, we have

$$(y_{1,0}^*, y_1^*(T)) \in S. \tag{2.36}$$

Indeed, suppose that (2.36) did not hold.

By the Hahn–Banach theorem, there exist $f \in H \times H$ and $\alpha \in R$ such that

$$f(y_{1,0}^*, y_1^*(T)) > \alpha \quad \text{and} \quad f(y_0, y_1) < \alpha \quad \text{for all } (y_0, y_1) \in S. \tag{2.37}$$

Choose $\gamma > 0$ such that

$$f(y_{1,0}^*, y_1^*(T)) > \alpha + \gamma. \tag{2.38}$$

Since $d_S(y_\varepsilon(0), y_\varepsilon(T)) \to 0$, there exists $(y'_\varepsilon(0), y'_\varepsilon(T)) \in S$ such that

$$\|y'_\varepsilon(0) - y_\varepsilon(0)\|_H + \|y'_\varepsilon(T) - y_\varepsilon(T)\|_H < \varepsilon.$$

It is clear that $(y'_\varepsilon(0), y'_\varepsilon(T)) \to (y^*_{1,0}, y^*_1(T))$ weakly in $H \times H$. Thus

$$f(y'_\varepsilon(0), y'_\varepsilon(T)) \to f(y^*_{1,0}, y^*_1(T)) \quad \text{as} \quad \varepsilon \to 0. \tag{2.39}$$

By (2.37)–(2.39), we obtain

$$\alpha \geq \overline{\lim}_{\varepsilon \to 0} f(y'_\varepsilon(0), y'_\varepsilon(T)) = f(y^*_{1,0}, y^*_1(T)) > \alpha + \gamma.$$

This contradiction shows (2.36).

Now (2.36) yields (y^*_1, u^*_1) is admissible, i.e., $(y^*_1, u^*_1) \in A_{ad}$ and

$$L(y^*_1, u^*_1) \geq L(y^*, u^*). \tag{2.40}$$

Thus by (2.34), (2.35), and (2.40), we imply

$$\lim_{\varepsilon \to 0} L_\varepsilon(y_{\varepsilon,0}, u_\varepsilon) = L(y^*, u^*).$$

By (2.14), we obtain

$$u_\varepsilon \to u^* \quad \text{strongly in } L^2(0,T;U) \quad \text{and} \quad y_{\varepsilon,0} \to y^*(0) \quad \text{strongly in } H. \tag{2.41}$$

Now we prove $y_\varepsilon \to y^*$ strongly in $C([0,T];H)$.

Since $y^*(0) \in D(\phi) \cap V$, by Lemma 2.1, we may assume without loss of generality that $y_{\varepsilon,0} \in D(\phi) \cap V$ (since $\overline{D(\phi) \cap V} = H$ by the assumption (1.6)).

Multiply the equation

$$\begin{cases} y'_\varepsilon + Ay_\varepsilon + \nabla\phi_\varepsilon(y_\varepsilon) = \nabla\phi_\varepsilon(y_\varepsilon) - \nabla\phi^\varepsilon(y_\varepsilon) + Bu_\varepsilon, \\ y_\varepsilon(0) = y_{\varepsilon,0} \qquad \text{a.e.} \quad t \in (0,T) \end{cases} \tag{2.42}$$

by y_ε, y'_ε and $\nabla\phi_\varepsilon(y_\varepsilon)$, respectively. Using the similar arguments in the proof of Lemma 2.3 and noting (2.41) and the fact that $y_{\varepsilon,0}$ and $y^*(0) \in D(\phi) \cap V$, we obtain after some manipulation

$$\|y_\varepsilon(t)\|^2_H + \int_0^T [\|y_\varepsilon(t)\|^2_V + \|y'_\varepsilon(t)\|^2_H + \|\nabla\phi_\varepsilon(y_\varepsilon(t))\|^2_H]dt \leq C \quad \text{for } t \in [0,T],\ \varepsilon > 0. \tag{2.43}$$

On the other hand, by (2.42) we have

$$\begin{cases} (y_\varepsilon - y_\lambda)' + A(y_\varepsilon - y_\lambda) + \nabla\phi_\varepsilon(y_\varepsilon) - \nabla\phi_\lambda(y_\lambda) \\ \quad = \nabla\phi_\varepsilon(y_\varepsilon) - \nabla\phi^\varepsilon(y_\varepsilon) + \nabla\phi^\lambda(y_\lambda) - \nabla\phi_\lambda(y_\lambda) + B(u_\varepsilon - u_\lambda), \\ y_\varepsilon - y_\lambda(0) = y_{\varepsilon,0} - y_{\lambda,0}. \end{cases} \tag{2.44}$$

Multiplying (2.44) by $(y_\varepsilon - y_\lambda)$ and using assumption (H_1) and (2.6), we obtain

$$\begin{aligned} &\tfrac{1}{2}\tfrac{d}{dt}\|y_\varepsilon(t) - y_\lambda(t)\|^2 + w\|y_\varepsilon(t) - y_\lambda(t)\|^2 \\ &+\langle \nabla\phi_\varepsilon(y_\varepsilon(t)) - \nabla\phi_\lambda(y_\lambda(t)), y_\varepsilon(t) - y_\lambda(t)\rangle \\ &\leq (1+\alpha)\|y_\varepsilon(t) - y_\lambda(t)\|^2_H + (\varepsilon + \lambda) \\ &+\langle B(u_\varepsilon - u_\lambda), y_\varepsilon - y_\lambda\rangle + \tfrac{1}{2}\|y_{\varepsilon,0} - y_{\lambda,0}\|^2_H. \end{aligned} \tag{2.45}$$

Recall (cf. [5]) that

$$\nabla\phi_\varepsilon(y_\varepsilon) = \varepsilon^{-1}(y_\varepsilon - (I+\varepsilon\partial\phi)^{-1}y_\varepsilon) \in \partial\phi((I+\varepsilon\partial\phi)^{-1}y_\varepsilon).$$

Since by (2.43) $\{\nabla\phi_\varepsilon(y_\varepsilon)\}$ is bounded in $L^2(0,T;H)$, we have by integrating (2.45) over $(0,t)$ that

$$\begin{aligned}
&\tfrac{1}{2}\|y_\varepsilon(t)-y_\lambda(t)\|_H^2 + w\int_0^t \|y_\varepsilon(s)-y_\lambda(s)\|_V^2 ds \\
&\le \tilde{\alpha}\int_0^t \|y_\varepsilon(s)-y_\lambda(s)\|_H^2 ds + \int_0^T \|B(u_\varepsilon-u_\lambda)\|_H^2 + \tfrac{1}{2}\|y_{\varepsilon,0}-y_{\lambda,0}\|_H^2 \\
&+\int_0^t \langle \nabla\phi_\varepsilon(y_\varepsilon(s)) - \nabla\phi_\lambda(y_\lambda(s)), \varepsilon\nabla\phi_\varepsilon(y_\varepsilon(s)) - \lambda\nabla\phi_\lambda(y_\lambda(s))ds\rangle + (\varepsilon+\lambda) \\
&\le \tilde{\alpha}\int_0^t \|y_\varepsilon(s)-y_\lambda(s)\|_H^2 ds + C(\varepsilon+\lambda) \\
&+\tfrac{1}{2}\|y_{\varepsilon,0}-y_{\lambda,0}\|_H^2 + \|B(u_\varepsilon-u_\lambda)\|^2_{L^2(0,T;H)}.
\end{aligned}$$

By Gronwall's inequality,

$$\begin{aligned}
&\|y_\varepsilon(t)-y_\lambda(t)\|_H^2 + \int_0^T \|y_\varepsilon(t)-y_\lambda(t)\|_V^2 dt \\
&\le C(\varepsilon+\lambda) + \|y_{\varepsilon,0}-y_{\lambda,0}\|_H^2 + \|B(u_\varepsilon-u_\lambda)\|^2_{L^2(0,T;H)}.
\end{aligned} \tag{2.46}$$

By (2.41), (2.43), and (2.46), using the same arguments in [1] (cf. Theorem 4.5 of [1]), we obtain

$$y_\varepsilon \to y^* \text{ in } C([0,T];H)\cap L^2(0,T;V).$$

This completes the proof.

3. Necessary conditions on optimality. Let ∂g be the generalized gradient of $y \to g(t,y)$ and ∂h be the subdifferential of h (cf. [2]).

Let $Y^* = (H^s(\Omega))' + V'$ which is the dual of $Y = H^s(\Omega)\cap V$ with $s > N/2$. We state the main results of the necessary conditions on optimality as follows.

THEOREM 3.1. *Let (y^*,u^*) be an optimal pair of problem* (P). *Suppose that* (H_1)–(H_6) *hold. Then there exist the function $p \in L^\infty(0,T;H)\cap L^2(0,T;V)\cap BV([0,T];Y^*)$, the measure $\mu \in (L^\infty(Q))^*$, and $\lambda_0 \in R$ with $\lambda_0 \ge 0$ satisfying*

$$\begin{gathered}
p' - Ap - \mu \in L^\infty(0,T;H), \\
p'(t) - Ap(t) - \mu \in \lambda_0\partial g(t,y^*(t)) \quad a.e. \quad in\ (0,T), \\
\langle\, p(0), x_0 - y^*(0)\,\rangle - \langle\, p(T), x_1 - y^*(T)\,\rangle \le 0
\end{gathered}$$

for all $(x_0,x_1) \in S$ (transversality condition).

$$B^*p(t) \in \lambda_0\partial h(u^*(t)) \quad a.e.\ t \in (0,T),$$

and $(\lambda_0,p) \ne 0$.

Proof. Let $(y_{\varepsilon,0},u_\varepsilon)$ be optimal for the problem (P^ε) and y_ε be the solution of (2.8) corresponding to $(y_{\varepsilon,0},u_\varepsilon)$.

For any $v \in L^2(0,T;U), \eta \in H$ given, let $u_\varepsilon^\lambda = u_\varepsilon + \lambda v$, $y_{\varepsilon,0}^\lambda = y_{\varepsilon,0} + \lambda\eta$, $\lambda > 0$, and let y_ε^λ be the solution of the problem (2.8) corresponding to $y_{\varepsilon,0}^\lambda$ and u_ε^λ.

By Lemma 2.1, $y_\varepsilon^\lambda \to y_\varepsilon$ strongly in $C([0,T];H)$ as $\lambda \to 0$.

Since $(y_{\varepsilon,0}, u_\varepsilon)$ is optimal, we have $L_\varepsilon(y_{\varepsilon,0}^\lambda, u_\varepsilon^\lambda) \geq L_\varepsilon(y_{\varepsilon,0}, u_\varepsilon)$ for any $\lambda > 0$, $v \in L^2(0,T;U)$, and $\eta \in H$.

Thus

$$\frac{L_\varepsilon(y_{\varepsilon,0}^\lambda, u_\varepsilon^\lambda) - L_\varepsilon(y_{\varepsilon,0}, u_\varepsilon)}{\lambda} \geq 0. \tag{3.1}$$

Let $\nabla g_\varepsilon(t, y_\varepsilon)$ be the gradient of g_ε to the second variable at y_ε, and let $\nabla h_\varepsilon(u_\varepsilon)$ be the gradient of h_ε at u_ε. After some simple calculations, we obtain

$$\lim_{\lambda\to 0} \int_0^T \frac{g_\varepsilon(t, y_\varepsilon^\lambda) - g_\varepsilon(t, y_\varepsilon)}{\lambda} = \int_0^T \langle \nabla g^\varepsilon(t, y_\varepsilon), z_\varepsilon \rangle \tag{3.2}$$

with $z_\varepsilon \in C([0,T];H) \cap W^{1,2}([0,T];H)$ satisfying

$$\begin{cases} z_\varepsilon' + Az_\varepsilon + \dot{\beta}^\varepsilon(y_\varepsilon) z_\varepsilon = Bv, \\ z_\varepsilon(0) = \eta, \end{cases} \tag{3.3}$$

$$\lim_{\lambda\to 0} \int_0^T \frac{h_\varepsilon(u_\varepsilon^\lambda) - h_\varepsilon(u_\varepsilon)}{\lambda} dt = \int_0^T \langle \nabla h_\varepsilon(u_\varepsilon), v \rangle dt, \tag{3.4}$$

$$\begin{aligned} &\lim_{\lambda\to 0} \tfrac{1}{2} \Big[\tfrac{\|u_\varepsilon^\lambda - u^*\|_H^2 - \|u_\varepsilon - u^*\|_H^2}{\lambda} + \tfrac{\|y_{\varepsilon,0}^\lambda - y^*(0)\|_H^2 - \|y_{\varepsilon,0} - y^*(0)\|_H^2}{\lambda} \Big] \\ &= \int_0^T \langle u_\varepsilon - u^*, v \rangle dt + \langle y_{\varepsilon,0} - y^*(0), \eta \rangle, \end{aligned} \tag{3.5}$$

and

$$\begin{aligned} &\lim_{\lambda\to 0} \tfrac{1}{2\varepsilon^{1/2}} \left\{ \tfrac{[d_S(y_\varepsilon^\lambda(0), y_\varepsilon^\lambda(T)) + \varepsilon^{1/2}]^2 - [d_S(y_\varepsilon(0), y_\varepsilon(T)) + \varepsilon^{1/2}]^2}{\lambda} \right\} \\ &= \tfrac{1}{\varepsilon^{1/2}} [\, d_S(y_\varepsilon(0), y_\varepsilon(T)) + \varepsilon^{1/2} \,] \, [\, \langle a_\varepsilon \, , \, \eta \rangle + \langle b_\varepsilon \, , \, z^\varepsilon(T) \rangle \,], \end{aligned} \tag{3.6}$$

where $(a_\varepsilon, b_\varepsilon) \in \partial d_S(y_\varepsilon(0), y_\varepsilon(T))$, the subdifferential of d_S at $(y_\varepsilon(0), y_\varepsilon(T))$.

Since S is convex and closed,

$$\partial ds(y_\varepsilon(0), y_\varepsilon(T)) = \begin{cases} \nabla ds(y_\varepsilon(0), y_\varepsilon(T)) & \text{if } (y_\varepsilon(0), y_\varepsilon(T)) \notin S, \\ 0 & \text{if } (y_\varepsilon(0), y_\varepsilon(T)) \in S \end{cases}$$

and

$$\|a_\varepsilon\|_H^2 + \|b_\varepsilon\|_H^2 = 1 \quad \text{if } (y_\varepsilon(0), y_\varepsilon(T)) \notin S. \tag{3.7}$$

Let

$$\lambda_\varepsilon = \frac{\varepsilon^{1/2}}{ds(y_\varepsilon(0), y_\varepsilon(T)) + \varepsilon^{1/2}}. \tag{3.8}$$

By (3.7) and (3.8)

$$2 \geq |\lambda_\varepsilon|^2 + \|a_\varepsilon\|_H^2 + \|b_\varepsilon\|_H^2 \geq 1. \tag{3.9}$$

By (3.1)–(3.6), we yield

$$\begin{aligned}(3.10)\quad &\lambda_\varepsilon\left[\int_0^T \langle \nabla g_\varepsilon(t,y_\varepsilon), z_\varepsilon\rangle dt + \int_0^T \langle \nabla h_\varepsilon(u_\varepsilon), v\rangle dt\right] + [\langle a_\varepsilon, \eta\rangle + \langle b_\varepsilon, z^\varepsilon(T)\rangle] \\ &\geq \int_0^T \langle u^* - u_\varepsilon\ ,\ v\rangle dt + \langle y^*(0) - y_{\varepsilon,0}\ ,\ \eta\rangle \equiv q(\varepsilon, v, \eta).\end{aligned}$$

By (3.9), we may assume that (relabeling if necessary)

$$(3.11)\qquad \lambda_\varepsilon \to \lambda_0 \quad \text{and} \quad a_\varepsilon \to a, b_\varepsilon \to b \text{ weakly in } H.$$

It follows by Theorem 1.14 of [1] that the boundary value problem

$$(3.12)\qquad \begin{cases} p_\varepsilon' - Ap_\varepsilon - \dot\beta^\varepsilon(y_\varepsilon)p_\varepsilon = \lambda_\varepsilon \nabla g_\varepsilon(t, y_\varepsilon) & \text{in } Q, \\ p_\varepsilon(T) = -b_\varepsilon & \text{in } \Omega \end{cases}$$

has a unique solution $p_\varepsilon \in L^2(0,T;V) \cap C([0,T];H)$ with $p_\varepsilon' \in L^2(0,T;V')$.

Since $y_\varepsilon \to y^*$ strongly in $C([0,T];H) \cap L^2(0,T;V)$ from Lemma 2.5, by the same arguments as those in [1] (cf. Lemma 5.3 of [1]), there exists $p \in BV([0,T];Y^*) \cap L^2(0,T;V) \cap L^\infty(0,T;H)$ and $\mu \in (L^\infty(Q))^*$ such that on some subsequence $\{\varepsilon_n\}$,

$$(3.13)\qquad p_{\varepsilon_n} \to p \quad \text{in } L^2(0,T;H), \qquad \text{weakly in } L^2(0,T;V), \quad \text{weak star in } L^\infty(0,T;H),$$

where $Y^* = (H^s(\Omega))' \cap V'$ with $s > N/2$ which is the dual of $Y = H^s(\Omega) \cap V$, and

$$(3.14)\qquad p_{\varepsilon_n}(t) \to p(t) \quad \text{strongly in } Y^* \text{ and weakly in } H \text{ for every } t \in [0,T],$$

$$(3.15)\qquad \dot\beta^{\varepsilon_n}(y_{\varepsilon_n})p_{\varepsilon_n} \to \mu \quad \text{weak star in } (L^\infty(Q))^*,$$

$$(3.16)\qquad \begin{aligned} &\nabla g_{\varepsilon_n}(t, y_{\varepsilon_n}) \to \xi_1 \text{ weak star in } L^\infty(0,T;H) \\ &\quad \text{with } \xi_1(t) \in \partial g(t, y^*(t)) \quad \text{a.e. } t \in (0,T), \end{aligned}$$

where $\partial g(t,y)$ is the generalized gradient of $y \to g(t,y)$.

Now letting $\varepsilon_n \to 0$ in (3.12), it follows by (3.11) and (3.13)–(3.16) that p satisfies the equations

$$(3.17)\qquad \begin{cases} p' - Ap - \mu \in \lambda_0 \partial g(t, y^*) & \text{a.e. in } (0,T), \\ p(T) = -b \end{cases}$$

and

$$(3.18)\qquad p' - Ap - \mu \in L^\infty(0,T;H),$$

where p' is the derivative in the sense of V'-valued distribution.

It follows from (3.3), (3.10), and (3.12) that

$$(3.19)\qquad -\int_0^T \langle B^* p_\varepsilon, v\rangle + \lambda_\varepsilon \int_0^T \langle \nabla h_\varepsilon(u_\varepsilon), v\rangle + \langle a_\varepsilon, \eta\rangle - \langle p_\varepsilon(0), \eta\rangle \geq q(\varepsilon, v, \eta)$$

for all $v \in L^2(0,T;U)$ and $\eta \in H$.

Since $u_\varepsilon \to u^*$ in $L^2(0,T;U)$, by a standard argument (cf. [1], [5]), we have

$$\int_0^T \langle \nabla h_\varepsilon(u_\varepsilon), v\rangle \to \int_0^T \langle \xi(t), v\rangle \text{ with } \xi(t) \in \partial h(u^*(t)) \quad \text{a.e. } t \in (0,T) \tag{3.20}$$

for all $v \in L^2(0,T;U)$, where ∂h denotes the subdifferential of h.

Letting $\varepsilon \to 0$ in (3.19), it follows from (3.13) and (3.20) that

$$-\int_0^T \langle B^*p, v\rangle + \lambda_0 \int_0^T \langle \xi(t), v\rangle + \langle a, \eta\rangle - \langle p(0), \eta\rangle \geq 0 \tag{3.21}$$

for all $v \in L^2(0,T;U)$ and $\eta \in H$.

Since $(a_\varepsilon, b_\varepsilon) \in d_S(y_{\varepsilon,0}, y_\varepsilon(T))$, we have

$$\langle a_\varepsilon, x_0 - y_{0,\varepsilon}\rangle + \langle b_\varepsilon, x_1 - y_\varepsilon(T)\rangle \leq 0 \text{ for all } (x_0, x_1) \in S.$$

Thus

$$\begin{aligned} &\langle a_\varepsilon, x_0 - y^*(0)\rangle + \langle b_\varepsilon, x_1 - y^*(T)\rangle \\ &\leq \langle a_\varepsilon, y_{\varepsilon,0} - y^*(0)\rangle + \langle b_\varepsilon, y_\varepsilon(T) - y^*(T)\rangle \\ &\equiv q_1(\varepsilon) \end{aligned} \tag{3.22}$$

for all $(x_0, x_1) \in S$.

By Lemma 2.5 and (3.9), $q_1(\varepsilon) \to 0$ as $\varepsilon \to 0$. We claim $(\lambda_0, a, b) \neq 0$. Indeed, if $\lambda_0 = 0$, by (3.9), $\|a_\varepsilon\|_H^2 + \|b_\varepsilon\|_H^2 \geq \delta > 0$.

Since S is finite codimensional (by (H_3)), so is $S - (y^*(0), y^*(T))$ (cf. Proposition 3.4 of [3]).

Thus by (3.22), we yield $(a, b) \neq 0$ and

$$\langle a, x_0 - y^*(0)\rangle + \langle b, x_1 - y^*(T)\rangle \leq 0 \tag{3.23}$$

for all $(x_0, x_1) \in S$ (cf. Lemma 3.6 [3]).

Now by (3.21) we have $(\lambda_0, p) \neq 0$. Indeed, if $\lambda_0 = 0$, then $(a, b) \neq 0$. By (3.17), $p \neq 0$ if $\mu \neq 0$ or $b \neq 0$ If $\mu = 0$ and $b = 0$, we have $p(0) = 0$. Then (3.21) makes $\langle a, \eta\rangle \geq 0$ for all $\eta \in H$. So $a = 0$. This contradiction implies that $p \neq 0$. Next we prove the transversality condition.

For any $(x_0, x_1) \in S$, let $v = 0, \eta = x_0 - y^*(0)$ in (3.21), which yields

$$\langle p(0) - a, x_0 - y^*(0)\rangle \leq 0. \tag{3.24}$$

By (3.23) and (3.24) and noting that $p(T) = -b$, we obtain

$$\langle p(0), x_0 - y^*(0)\rangle - \langle p(T), x_1 - y^*(T)\rangle \leq 0 \tag{3.25}$$

for all $(x_0, x_1) \in S$.

Finally in (3.21), by letting $\eta = 0$ and using a standard argument in [1], it follows from (3.20) that

$$B^*p \in \lambda_0 \partial h(u^*(t)) \quad \text{a.e.} \quad t \in (0,T). \tag{3.26}$$

Thus (3.17), together with (3.18), (3.25), and (3.26) completes the proof.

4. Some remarks.

Remark 4.1. Let $S = Q_1 \times Q_2$, where $Q_1 \subset D(\phi) \cap V \subset H$, $Q_2 \subset H$ are convex and closed sets. Suppose that either Q_1 or Q_2 is finite codimensional. Then all results in Theorem 3.1 remain true without assumption (H_3). (Note that one of Q_1 and Q_2 has finite codimensionality which cannot imply that S does.)

Indeed, we need only to show that $(\lambda_0, a, b) \neq 0$ in (3.11).

Suppose that $\lambda_0 = 0$ and $a = 0$. Then by (3.9) we have $\|b_\varepsilon\|_H^2 \geq \delta > 0$ for constant δ. Now by (3.22), we have $\langle b_\varepsilon, x_1 - y^*(T)\rangle \leq \tilde{q}_1(\varepsilon)$ for all $x_1 \in Q_2$. $\tilde{q}_1(\varepsilon) \to 0$ as $\varepsilon \to 0$.

Since Q_2 is finite codimensional, so is $Q_2 - y^*(T)$ (cf. [3]). By the same arguments in the proof of Theorem 3.1, one obtains $b_\varepsilon \to b \neq 0$.

Remark 4.2. Let β be locally Lipschitz continuous, monotone on R, and satisfying the growth condition

$$0 \leq \beta'(r) \leq c(|\beta(r)| + |r| + 1) \quad \text{a.e. } r \in R. \tag{4.1}$$

Then $D(\phi)$ is dense in H (cf. section 5.3 of [1]). Thus, the results of Theorem 3.1 remain true.

Moreover, $p \in AC([0,T], Y^*) \cap C_w([0,T]; H)$ and $\mu \in L^1(Q)$, where $C_w([0,T]; H)$ denotes the space of all weakly continuous functions from $[0,T]$ to H.

Remark 4.3. Let β be globally Lipschitz and monotone. Then $\{\dot{\beta}^\varepsilon\}$ is uniformly bounded on R (cf. Proposition 5.3 of [1]) and $\overline{D(\phi)} = H$. In this case, we may weaken the assumption (H_3) on S.

Start from the variational equation (3.3):

$$\begin{cases} z_\varepsilon' + Az_\varepsilon + \dot{\beta}^\varepsilon(y_\varepsilon) z_\varepsilon = Bv, \\ z_\varepsilon(0) = \eta. \end{cases} \tag{4.2}$$

Multiplying (4.2) by $z_\varepsilon, z_\varepsilon', Az_\varepsilon$ and integrating over $(0,t)$, by the uniform boundedness of $\{\dot{\beta}^\varepsilon\}$, we may have

$$\|z_\varepsilon\|_{C([0,T];H)} + \|z_\varepsilon'\|_{L^2(0,T;H)} + \|Az_\varepsilon\|_{L^2(0,T;H)} \leq C. \tag{4.3}$$

On the other hand, $\dot{\beta}^\varepsilon(y_\varepsilon) z_\varepsilon$ is weakly compact in $L^2(Q)$, so $\dot{\beta}(y_\varepsilon) z_\varepsilon \to \tilde{\mu}$ weakly in $L^2(Q)$.

Thus by (4.2) and (4.3), using the Arzela–Ascoli theorem, on some subsequence ε_n, we have

$$\begin{aligned} &z_{\varepsilon_n} \to z \text{ in } C([0,T]; H) \text{ strongly}, \\ &Az_{\varepsilon_n} \to Az \text{ weakly in } L^2(0,T;H), \\ &z_{\varepsilon_n}' \to z_{\varepsilon_n}' \text{ weakly in } L^2(0,T;H). \end{aligned}$$

So $z \in C([0,T]; H) \cap W^{1,2}([0,T]; H)$ and satisfies

$$\begin{cases} z' + Az + \mu = Bv, \\ z(0) = \eta. \end{cases} \tag{4.4}$$

Let

$$\tilde{R}_r = \big\{(\eta, z(T)) : \ \eta \in B_1(0), \text{ where } z \text{ is the solution of (4.3) with } v \in \tilde{B}_r(0)\big\},$$

where $B_1(0)$ is the unit ball of H, and where $\tilde{B}_r(0)$ is the ball in $L^2(0,T;U)$ with radius r, center 0.

Instead of (H_3), we may assume

$(\tilde{H}_3)$ $S \subset (D(\phi) \cap V) \times H \subset H \times H$ is closed and convex. $\tilde{R} - S$ has finite codimensionality.

The results of Theorem 3.1 remain true if we use $(\tilde{H}_3)$ instead of (H_3).

Indeed, by (3.10) and (3.22), we have

$$\begin{aligned}&\lambda_\varepsilon \left[\int_0^T \langle \Delta g_\varepsilon(t, y_\varepsilon), z_\varepsilon\rangle dt + \int_0^T \langle \Delta h_\varepsilon(u_\varepsilon), v\rangle dt\right]\\ &+\langle a_\varepsilon, \eta - x_0 + y^*(0)\rangle + \langle b_\varepsilon, z^\varepsilon(T) - x_1 + y^*(T)\rangle\\ &\geq q_2(\varepsilon, v, \eta),\end{aligned}$$

where $q_2(\varepsilon, v, \eta) = q(\varepsilon, v, \eta) - q_1(\varepsilon)$.

Thus

$$\begin{aligned}&\lambda_\varepsilon \left[\int_0^T \langle \Delta g_\varepsilon(t, y_\varepsilon), z_\varepsilon\rangle + \int_0^T \langle \Delta h_\varepsilon(u_\varepsilon), v\rangle dt\right]\\ &+\langle a_\varepsilon, \eta - x_0 + y^*(0)\rangle + \langle b_\varepsilon, z(T) - x_1 + y^*(T)\rangle\\ &\geq q_2(\varepsilon, v, \eta) + \langle b_\varepsilon, z(T) - z^\varepsilon(T)\rangle\\ &\equiv \tilde{q}(\varepsilon, v, \eta),\end{aligned}$$

where $\tilde{q}(\varepsilon, v, \eta) \to 0$ uniformly in $\eta \in B_1(0), v \in \tilde{B}_r(0)$, as $\varepsilon \to 0$.

Then $(\tilde{H}_3)$ guarantees $(\lambda_0, a, b) \neq 0$ (cf. [4]).

At last, we give an example as follows.

Example 1. Let β be a locally Lipschitz continuous monotone graph on R and satisfy the growth condition (4.1), $A = -\Delta$, $V = H_0^1(\Omega)$, and $S = \{y_0\} \times Q_2$ with $y_0 \in H_0^1(\Omega)$, and $Q_2 \subset H$ has finite codimension.

Then problem (P) reduces to the problem as follows:

(P_1) Min $L(y, u)$
subject to all
$(y, u) \in W^{1,2}([0, T]; H) \cap C([0, T]; H) \cap L^2(0, T; D(A_H)) \times L^2(0, T; U)$
satisfying the parabolic equation

$$\begin{cases} y_t - \Delta y + \beta(y) = Bu & \text{a.e. } Q,\\ y(x, t) = 0 & \text{in } \partial\Omega,\\ y(x, 0) = y_0(x), y(x, T) \in Q_2. \end{cases}$$

By Remark 4.1 and Remark 4.2, we may apply the theorem to problem (P_1) to get the necessary conditions of the pair for the problem (P_1).

DELAY SENSITIVITY OF QUADRATIC CONTROLLERS: A SINGULAR PERTURBATION APPROACH*

PAPA MOMAR NDIAYE† AND MICHEL SORINE†

Abstract. We study the variations of the quadratic performance associated to a linear differential system of retarded type for small values of the delays. From an interpretation of delays as singular perturbations of abstract evolution operators, we revisit the usual theory of representation and optimal control of retarded systems. This leads to a new parameterization of associated Riccati operators for which insight is gained in the dependence on the delays. This explicit parameterization of Riccati operators by the delays enables us to prove differentiability at zero for performance viewed as a function of the delays, in the LQ-optimal or $\mathcal{H}_\infty$ suboptimal control. In each case, the gradient is explicitly computed in terms of the nonnegative solution of the finite dimensional Riccati equation associated to the nondelay control problem. A thorough treatment is stated for the linear quadratic optimal case, and the $\mathcal{H}_\infty$ suboptimal control is presented as an application.

Key words. optimal control, delay, sensitivity, singular perturbation, robust control

1. Introduction.

Small time delay often appears as a side effect of network control of physical systems. In the specific case where the sensors, actuators, and processors share a single channel, the true open loop system has delayed inputs and outputs and possibly state delays resulting from delayed output feedback. In view of real time control, such delays are small but strongly dependent on ordering decisions, and it would be desirable for a given control law to be able to have an a priori estimate of the sensitivity of the performance of the controlled system to small delays.

This paper mainly addresses the issue of the variations of the optimal value of a quadratic cost associated to a linear system perturbed by small delays in its inputs and state. Therefore, given some delay-vectors $\vec{k} = (k_1, \dots, k_I)$, $\vec{h} = (h_1, \dots, h_J)$ with $(k_i, h_j) \in [0, K] \times [0, H]$ for K, $H > 0$, we consider the following equation:

$$\text{(1.1)} \qquad \begin{cases} \dot{x}(t) = A_0 x(t) + \displaystyle\sum_{i=1}^{I} A_i x(t-k_i) + B_0 u(t) + \sum_{j=1}^{J} B_j u(t-h_j) \\ \text{almost everywhere (a.e.) } t \in [0,T], \\ x(0) = x_{00} \in \mathbb{R}^n, \quad x = x_0 \text{ a.e. } t \in [-K, 0], \quad x_0 \in L^2(-K, 0; \mathbb{R}^m), \\ u \in L^2(-H, T; \mathbb{R}^m), \quad u = u_0 \text{ a.e. } t \in [-H, 0], \end{cases}$$

where $A_i \in \mathcal{L}(\mathbb{R}^n)$ and $B_j \in \mathcal{L}(\mathbb{R}^m, \mathbb{R}^n)$ for $i \in \{0, \dots, I\}$ and $j \in \{0, \dots, J\}$. Also, to the solution $x(.) = x(.; \vec{k}; \vec{h}; u)$ of (1.1), we associate the following quadratic cost:

$$\text{(1.2)} \qquad J_T(x) = \frac{1}{2}\langle x(T), G(T)x(T)\rangle_{\mathbb{R}^n} + \frac{1}{2}\int_0^T \{\|Cx\|^2_{\mathbb{R}^p} + \langle u, Ru\rangle_{\mathbb{R}^m}\}dt,$$

where $G(T) \in \mathcal{L}(\mathbb{R}^n)$ is nonnegative for $T \in \mathbb{R}_+$ and $G(\infty) = 0$; $C \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^p)$; R

positive. Moreover, by $\widehat{J}_T(\vec{k},\vec{h})$ we denote the infimum

$$\min_{u\in L^2(0,T;\mathbb{R}^m)} J_T(x(.;\vec{k};\vec{h};u))$$

for $T \in \mathbb{R}_+ \cup \{+\infty\}$. Then the central problem of interest is the computation of the gradient of the function $(\vec{k},\vec{h}) \longrightarrow \widehat{J}_T(\vec{k},\vec{h})$ at the point $(\vec{k},\vec{h}) = (0,0)$.

We recall that, in a more general framework of systems of evolution with small changes in some parameter, Pritchard [20] has shown that there exists some constant $0 < c < 1$, depending on the nondelay optimal feedback and such that $c\widehat{J}_T(0,0) \leq \widehat{J}_T(\vec{k},0)$, whereas Dontchev [13, 14, 15], with singular perturbation techniques, computes $|\widehat{J}_T(\vec{k},0) - \widehat{J}_T(0,0)|$ in terms of the multipliers occurring in the optimality condition. More recently, for a single state delay case, Clarke and Wolenski [3, Theorem 3.2] prove the differentiability of the optimum of some associated performance and provide a characterization of the derivative in the multipliers occurring in the optimality condition. In this paper, we propose a simplification of these results in the case of quadratic minimization, and extend them to the optimum of the min-max problem associated to $\mathcal{H}_\infty$ disturbance attenuation via state feedback controller. We prove the existence of the partial derivative at zero under weaker conditions than those of Clarke and Wolenski [3]. Moreover, and this is our major contribution, we provide an explicit gradient formula for the quadratic optimal cost with partial derivatives at zero, simply expressed in terms of the solution of the finite dimensional Riccati equation solving the nondelay optimal control problem, for both finite and infinite horizons. We also state a similar result for the $\mathcal{H}_\infty$ robust performance.

The keynote of this paper is an interpretation of the delays as singular perturbations of some evolution operators that leads to an unusual variant of classical state space representations via semigroup techniques. For the representation of solutions, we refer to Ichikawa [16], Delfour and Karrakchou [9, 10], and Delfour [8]. Then using a well-known compensation trick—see, e.g., Kokotović and Yackel [18] for the finite dimensional case—we parameterize Riccati operators with the delays when revisiting optimal control of delay systems in the Pritchard and Salamon class [4, 21, 22]. In view of that parameterization, the problem of the sensitivity analysis of the optimal performance becomes a study, in the neighborhood of zero, of continuity of the components of some four-block decomposition associated to Riccati operators.

Section 3 introduces the proposed state space representation and defines the framework in which the control problem will be solved. Next, linear quadratic optimal control theory for retarded equations is revisited in section 4. New regularity theorems for Riccati operators—some weak differentiability-like results—are presented in section 5. We believe that these are of independent interest, so we state them as separate theorems. They make the proof of sensitivity results given in section 6 rather elementary. Finally, in section 7 we present the $\mathcal{H}_\infty$ case.

2. Main results.

THEOREM 2.1. *Let us assume $T < \infty$. Then*

(i) *with u_0 continuous on the left side of 0, we have*

$$\frac{\partial \widehat{J_T}}{\partial h_j}(0,0) = \langle x_{00},\ \Delta_j(P_T)x_{00}\rangle_{\mathbb{R}^n}, \tag{2.1}$$

where $\Delta_j(P_T) = P_T(0)B_jR^{-1}B^TP_T(0)$ for P_T, the nonnegative symmetric

solution of the Riccati equation

$$\frac{dP_T}{dt} + A^T P_T + P_T A - P_T B R^{-1} B^T P_T + C^T C = 0 \text{ in } C(0,T;\mathcal{L}(\mathbb{R}^n)),$$
$$P_T(T) = G(T). \tag{2.2}$$

(ii) *With x_0 continuous on the left side of 0, we have*

$$\frac{\partial \widehat{J_T}}{\partial k_i}(0,0) = -\langle P_T x_{00},\ A_i x_{00}\rangle_{\mathbb{R}^n}. \tag{2.3}$$ □

THEOREM 2.2. *Assume the triple (A,B,C) stabilizable and detectable. Then*

(i) *with u_0 continuous on the left side of 0, we have*

$$\frac{\partial \widehat{J_\infty}}{\partial h_j}(0,0) = \langle x_{00},\ \Delta_j(P_\infty) x_{00}\rangle_{\mathbb{R}^n}, \tag{2.4}$$

where $\Delta_j(P_\infty) = P B_j R^{-1} B^T P_\infty$ for P_∞, the nonnegative symmetric solution of the Riccati equation

$$A^T P_\infty + P_\infty A - P_\infty B R^{-1} B^T P_\infty + C^T C = 0 \text{ in } \mathcal{L}(\mathbb{R}^n). \tag{2.5}$$

(ii) *with x_0 continuous on the left side of 0, we have*

$$\frac{\partial \widehat{J_\infty}}{\partial k_i}(0,0) = -\langle P_\infty x_{00},\ A_i x_{00}\rangle_{\mathbb{R}^n}. \tag{2.6}$$ □

Remark 2.1. For the existence of partial derivatives with respect to state delays, we need only continuity of x_0 on the left side of 0, a condition which is weaker than the existence of $\|\dot{x}_0\|_\infty$ as required in Clarke and Wolenski [3, Theorem 3.2]. □

Example 2.1. *Sensitivity to small input delay.* If we take $J = 1$ and assume $B_0 = 0$, then $\Delta_1(P_\infty) = P_\infty B_1 R^{-1} B_1^T P_\infty = K_{opt} R K_{opt} \geq 0$ where the matrix $K_{opt} = -R^{-1} B_1^T P_\infty$ is the optimal gain for $h = 0$. Therefore formula (2.4) becomes

$$\frac{\partial \widehat{J_\infty}}{\partial h}(0,0) = \langle K_{opt} x_{00},\ R K_{opt} x_{00}\rangle_{\mathbb{R}^n} \geq 0, \tag{2.7}$$

from which we have $\widehat{J_T}(0,0) \leq \widehat{J_T}(0,h)$ for a sufficiently small h. Moreover, we see that the degradation of the optimal performance increases with the optimal gain. □

3. Singular perturbations and product-space approach for representation of solutions. First of all, we point out that for computation of the partial derivatives at the point $(k,h) = (0,0)$, we need only to compare optimal cost with solely one state or input delay to nondelay optimal cost. So it is sufficient to restrict further analysis to the cases $(I = 0; J = 1)$ and $(I = 1; J = 0)$ which in fact will be studied separately. By doing so, we do not lose any generality while we simplify statements of intermediate steps and proofs. Henceforth, we are justified in assuming that the system of interest is

$$\begin{cases} \dot{x}(t) = A_0 x(t) + A_1 x(t-k) + B_0 u(t) + B_1 u(t-h) \text{ a.e. } t \in [0,T], \\ x(0) = x_{00} \in \mathbb{R}^n,\ x = x_0 \text{ a.e. } t \in [-k,0], \quad x_0 \in L^2(-k,0;\mathbb{R}^n), \\ u \in L^2(-h,T;\mathbb{R}^m), \quad u = u_0 \text{ a.e. } t \in [-h,0]. \end{cases} \tag{3.1}$$

So, in the following, with $A = A_0 + A_1$ and $B = B_0 + B_1$, we shall look separately for state space representations when $(k = 0,\ h > 0)$ and when $(k > 0,\ h = 0)$. These situations will be referred to as the retarded input system and retarded state system, respectively. We start with the retarded input case, since it is enough to provide a comprehensive statement of the approaches that will be taken in this paper.

3.1. Retarded input system: $(k = 0,\ h > 0)$. First recall that in this case, the solution of (3.1) is given in the space $H^1_{loc}(0,\infty;\mathbb{R}^n)$ by the variation of the constants formula

$$x(t) = e^{At}x_{00} + \int_0^t e^{A(t-s)}\{B_0u(s) + B_1u(s-h)\}ds. \tag{3.2}$$

But for controller synthesis, it is more convenient to have a description of this solution with a variation of the constants formula associated to a nondelay evolution system. A common way is to follow the choice originated by Ichikawa [16] which consists in choosing, as a support for description, the extended state defined by the pair $(x(t), v(t,.))' \in \mathcal{H}^m_h = \mathbb{R}^n \times L^2(-h,0;\mathbb{R}^m)$ with the segment function v given by $v(t,\theta) = u(t+\theta)$ for a.e. $t \in [0,T]$ and $\theta \in [-h,0]$. Such a choice leads to an equivalent linear system of evolution in $\mathcal{H}^m_h$ with unbounded input but bounded solutions as explained in [16] (see also Bensoussan et al. [1]). That line is well known to provide both optimal feedback and cost.

Now we point out that it is nothing but the presence of the delay that has brought the system from finite to infinite dimensions, so the delay may be interpreted as a singular perturbation in a convenient framework. Moreover, in view of sensitivity analysis, it is desirable for simplicity to have a non-delay-dependent state space. A natural way to do this is to rescale the variable θ, in order to choose $\mathcal{H}^m_1 = \mathbb{R}^n \times L^2(-1,0;\mathbb{R}^m)$ as state space. The proposed rescaling will transform our problem with varying space to one with evolution operators singularly parameterized by the delay.

Introduce the scaled functions u^h and φ^h, defined in $L^2(0,T;L^2(-1,0;\mathbb{R}^m))$ and $L^2(-1,0;\mathbb{R}^m)$, respectively, by $u^h(t,\sigma) = v(t,\sigma h)$ and $\varphi^h(\sigma) = u_0(\sigma h)$ for a.e. $t \in [0,T]$ and $\sigma \in [-1,0]$. Then observing that $h\frac{\partial u^h}{\partial t} = \frac{\partial u^h}{\partial \sigma}$ in $L^2(0,T;L^2(-1,0;\mathbb{R}^m))$ with $u^h(0,.) = \varphi^h \in L^2(-1,0;\mathbb{R}^m)$ and $u^h(.,0) = u \in L^2(0,T;\mathbb{R}^m)$, the use of standard transposition techniques yields

$$\left\{\begin{array}{lcl} h\dfrac{\partial u^h}{\partial t} & = & Du^h + \delta^*_{\sigma=0}u \quad \text{in } L^2(0,T;H^1(-1,0;\mathbb{R}^m)') \\ u^h(0,.) & = & \varphi^h(.) \in L^2(-1,0;\mathbb{R}^m), \end{array}\right. \tag{3.3}$$

where $D = \frac{\partial}{\partial\sigma}$ with domain $\mathcal{D}(D) = \{u \in H^1(-1,0;\mathbb{R}^m),\ u(0) = 0\}$.

Then, using the shorthand $\mathcal{H}^m = \mathcal{H}^m_1$, setting $X_h(t,.) = \binom{x(t)}{u^h(t,.)} \in \mathcal{H}^m$, and $\mathcal{W} = \mathbb{R}^n \times H^1(-1,0;\mathbb{R}^m)$, we get, for any $h > 0$, the following equation of evolution:

$$\left\{\begin{array}{lcl} \dfrac{\partial X_h}{\partial t} & = & \mathcal{A}_hX_h + \mathcal{B}_hu \quad \text{in } L^2(0,T;\mathcal{W}^{m'}), \\ X_h(0,.) & = & \begin{pmatrix} x_{00} \\ \varphi^h \end{pmatrix} \in \mathcal{H}^m, \end{array}\right. \tag{3.4}$$

where

$$\mathcal{A}_h = \begin{pmatrix} A & B_1\delta_{\sigma=-1} \\ 0 & \dfrac{1}{h}D \end{pmatrix}, \quad \mathcal{D}(\mathcal{A}_h) = \mathbb{R}^n \times \mathcal{D}(D), \quad \mathcal{B}_h = \begin{pmatrix} B_0 \\ \dfrac{1}{h}\delta^*_{\sigma=0} \end{pmatrix} \in \mathcal{L}(\mathbb{R}^m, \mathcal{W}^{m'}).$$

Note that if we have chosen $\mathcal{H}_H^m$ with $H \geq h$ as initial state space as it is done sometimes in the literature, then the rescaling will lead to $\mathcal{H}_{\frac{H}{h}}^m$ instead of $\mathcal{H}_1^m$.

Now it clear that $h = 0$ is a singularity of operators $\mathcal{A}_h$ and $\mathcal{B}_h$. The next step is the well-posedness of that equation. At this stage, observe that if—by construction—the extended state space is $\mathcal{H}^m$, then the input operator $\mathcal{B}_h$ is unbounded in $\mathcal{H}^m$. Further insight into the characteristics of the operator $\mathcal{A}_h$ will show that despite that unboundedness, the solution of (3.4) will remain inside $\mathcal{H}^m$.

PROPOSITION 3.1. *Henceforth let the space $\mathcal{H}^m$ be identified with its dual and take it as a pivot space. Then we have the following:*

(i) *$\mathcal{A}_h$ is the infinitesimal generator of a C_0-semigroup $\mathcal{S}_h(t)$ on $\mathcal{H}^m$. In addition, the $\mathcal{H}^m$-adjoint of the operator $\mathcal{A}_h$ is given with $\mathcal{D}(\mathcal{A}_h^*) = \{\binom{y}{w} \in \mathcal{W}^m,\ w(-1) = hB_1^T y\}$ by*

$$\mathcal{A}_h^* \begin{pmatrix} y \\ w \end{pmatrix} = \begin{pmatrix} A_0^T y \\ -\dfrac{1}{h} Dw \end{pmatrix}.$$

(ii) *Furthermore, for $t \geq 0$, the restriction to $\mathcal{D}(\mathcal{A}_h^*)$ of $\mathcal{S}_h^*$, the adjoint of the semigroup $\mathcal{S}_h$, defines a C_0-semigroup on $\mathcal{H}^m$ and then $\mathcal{S}_h(t)$ may be extended to a C_0-semigroup on the Hilbert space $\mathcal{D}(\mathcal{A}_h^*)'$.* □

That means that the operator $\mathcal{A}_h$ is the infinitesimal generator of a C_0-semigroup $\mathcal{S}_h(t)$ on Hilbert spaces ordered by dense and continuous injections, namely $\mathcal{D}(\mathcal{A}_h) \hookrightarrow \mathcal{H}^m \hookrightarrow \mathcal{D}(\mathcal{A}_h^*)'$. Therefore the weak solution of (3.4) may be defined by the variation of the constants formula

$$X_h(t,.) = \mathcal{S}_h(t) \begin{pmatrix} x_{00} \\ \varphi^h(.) \end{pmatrix} + \int_0^t \mathcal{S}_h(t-s)\mathcal{B}_h u(s) ds, \tag{3.5}$$

where, at first sight, it seems that we only have $X_h \in C(0,T;\mathcal{D}(\mathcal{A}_h^*)')$. But in fact, due to the structure of the semigroup $\mathcal{S}_h$, we have additional regularity in view of the following property of the convolution term.

LEMMA 3.2. *The operator $u \longmapsto \{t \to \int_0^t \mathcal{S}_h(t-s)\mathcal{B}_h u(s) ds\}$ is linear and continuous from $L^2(0,T;\mathbb{R}^m)$ to $C(0,T;\mathcal{H}^m)$.* □

The proofs of Proposition 3.1 and Lemma 3.2 are given in the appendix. Their combination is useful towards a complete characterization of the introduced infinite dimensional state representation which ultimately satisfies the following.

THEOREM 3.3.

(i) *The function X_h given by formula* (3.5) *is the unique solution in*

$$\left\{ X \in C(0,T;\mathcal{H}^m) \ :\ \frac{dX}{dt} \in L^2(0,T;\mathcal{D}(\mathcal{A}_h^*)') \right\} \tag{3.6}$$

of the weak equation

$$\begin{cases} \dfrac{dX}{dt} &= \mathcal{A}_h X + \mathcal{B}_h u \quad \text{in } L^2(0,T;\mathcal{D}(\mathcal{A}_h^*)'), \\ X(0) &= \begin{pmatrix} x_{00} \\ \varphi^h \end{pmatrix} \in \mathcal{H}^m. \end{cases} \tag{3.7}$$

In addition, there exists a constant $c > 0$ such that

$$\|X_h\|_{C(0,T;\mathcal{H}^m)} + \left\| \frac{\partial X_h}{\partial t} \right\|_{L^2(0,T;\mathcal{D}(\mathcal{A}_h^*)')} \leq c \left[\left\| \begin{pmatrix} x_{00} \\ \varphi^h \end{pmatrix} \right\|_{\mathcal{H}^m} + \|u\|_{L^2(0,T;\mathbb{R}^m)} \right]. \tag{3.8}$$

(ii) *Moreover, the first component of this weak solution X_h is equal to x, given by the formula* (3.2)*, which is the unique solution of the retarded equation* (3.1). □

The derivation of this theorem is immediate. The first item comes from the lemma, when using, e.g., the reference [1, Theorem 3.1, p. 173]. The second one is the outcome of a detailed rewriting of formula (3.5).

Remark 3.1. It is worth recalling that the property $X_h \in C(0,T;\mathcal{H}^m)$ follows easily from continuity of the translation in L^2 combined with the estimation

$$\|x\|_{W^{1,2}(0,T;\mathbb{R}^n)} \leq C\left[|x_{00}|_{\mathbb{R}^n} + \|x_0\|_{L^2(-K,0;\mathbb{R}^n)} + \|u\|_{L^p(-H,T;\mathbb{R}^m)}\right] \tag{3.9}$$

which can be found, e.g., in [1]. So the interest of the relation $\frac{\partial X_h}{\partial t} \in L^2(0,T;\mathcal{D}(\mathcal{A}_h^*)')$ is in additional information on the segment function u^h, which satisfies equation $\frac{\partial u^h}{\partial t} = h\frac{\partial u^h}{\partial \sigma}$ with $u^h(t,0) = u(t)$, and belongs to $L^2(0,T;H^1(-1,0;\mathbb{R}^m)')$. □

3.2. Retarded state system: ($k > 0$, $h = 0$). In this case the solution is given in $H^1_{loc}(0,\infty;\mathbb{R}^n)$ by the variation of the constants formula

$$x(t) = e^{A_0 t}x_{00} + \int_0^t e^{A_0(t-s)}A_1 x(s-k)ds + \int_0^t e^{A_0(t-s)}Bu(s)ds. \tag{3.10}$$

It is well known that this solution may be described in a product-space framework by means of the pair $(x(t), z(t,.))'$ with $z(t,\theta) = x(t+\theta)$, $t \geq 0$, $\theta \in [-k,0]$. Moreover, when considering only the homogeneous part of the retarded equation, this pair is generated by a C_0-semigroup acting on the extended initial condtion $(x_{00}, x_0)'$. See, e.g., Delfour [8] or Staffans [25, 26] for further details.

To emphasize the singular perturbation effect of the delay, we rescale the segment function z before following the product-space lines for state representation. To this end, we introduce the functions defined by $x^k(t,\sigma) = x(t+\sigma k)$ for $t \geq 0$ and $\sigma \in [-1,0]$, and $\psi^k(\sigma) = x_0(\sigma k)$. Then the solution of the homogeneous part of the retarded equation may be described from $(x_{00}, \psi^k)'$ with some linear operator given in $\mathcal{H}^n = \mathbb{R}^n \times L^2(-1,0;\mathbb{R}^n)$ by

$$\mathcal{S}_k(t)\begin{pmatrix} x_{00} \\ \psi^k(.) \end{pmatrix} = \begin{pmatrix} x(t) \\ x^k(t,.) \end{pmatrix} \ \forall\ t \geq 0 \ \text{ and } \ \begin{pmatrix} x_{00} \\ \psi^k \end{pmatrix} \in \mathcal{H}^n. \tag{3.11}$$

This next statement is a characterization of $\mathcal{S}_k$ that comes from the usual properties of the extended C_0-semigroup associated to a delay equation of retarded type [1, p. 61].

PROPOSITION 3.4. *$\mathcal{S}_k$ is a C_0-semigroup on $\mathcal{H}^n$ which is generated by the operator defined on $\mathcal{H}^n$ with domain $\mathcal{D}(\mathcal{A}_k) = \{\binom{x}{y} \in \mathcal{W}^n = \mathbb{R}^n \times H^1(-1,0;\mathbb{R}^n),\ y(0) = x\}$ as*

$$\mathcal{A}_k = \begin{pmatrix} A_0 & A_1\delta_{\sigma=-1} \\ 0 & \dfrac{1}{k}\dfrac{\partial}{\partial\sigma} \end{pmatrix}. \qquad \square$$

Thus setting $X_k = \binom{x(t)}{x^k(t,.)}$ and $\mathcal{B}_k = \binom{B}{0} \in \mathcal{L}(\mathbb{R}^m, \mathcal{H}^n)$, we have the following evolution equation

$$\begin{cases} \dfrac{\partial X_k}{\partial t} &= \mathcal{A}_k X_k + \mathcal{B}_k u \quad \text{in } L^2(0,T;\mathcal{H}^n), \\ X_k(0,.) &= \begin{pmatrix} x_{00} \\ \psi^k(.) \end{pmatrix} \in \mathcal{H}^n. \end{cases} \tag{3.12}$$

Now we have a bounded equation of evolution in the state space $\mathcal{H}^n$. It is obvious that for any initial condition in $\mathcal{H}^n$, its solution satisfies $X_k \in C(0,T;\mathcal{H}^n)$. Moreover, (3.12) may be extended by means of the method of transposition. In addition, easy computations lead to the following characterization of the adjoint of $\mathcal{A}_k$ that will be useful here.

LEMMA 3.5. *The $\mathcal{H}^n$-adjoint of the operator $\mathcal{A}_k$ is given with domain $\mathcal{D}(\mathcal{A}_k^*) = \{\binom{v}{w} \in \mathcal{W}^n,\ w(-1) = kA_1^T v\}$ as*

$$\mathcal{A}_k^* \begin{pmatrix} v \\ w \end{pmatrix} = \begin{pmatrix} A_0^T v + \dfrac{1}{k}\delta_{\sigma=0} w \\ -\dfrac{1}{k}\dfrac{\partial}{\partial \sigma} w \end{pmatrix}. \qquad \square$$

Then we have the following theorem.

THEOREM 3.6. *Given any $t \in [0,T]$, $X_0 \in \mathcal{H}^n$, and $u \in L^2(0,T;\mathbb{R}^m)$,*

$$X(t) = \mathcal{S}_k(t)X_0 + \int_0^t \mathcal{S}_k(t-s)\mathcal{B}_k u(s)ds \ \in \mathcal{H}^n \tag{3.13}$$

is the unique solution in the space

$$\left\{ X \in C(0,T;\mathcal{H}^n) : \frac{dX}{dt} \in L^2(0,T;\mathcal{D}(\mathcal{A}_k^*)') \right\} \tag{3.14}$$

of the transposed adjoint equation

$$\begin{cases} \dfrac{dX}{dt} &= \widetilde{\mathcal{A}}_k X + \mathcal{B}_k u \quad \text{in } L^2(0,T;\mathcal{D}(\mathcal{A}_k^*)'), \\ X(0) &= X_0 \in \mathcal{H}^n, \end{cases} \tag{3.15}$$

where

$$\widetilde{\mathcal{A}}_k \in \mathcal{L}(\mathcal{D}(\mathcal{A}_k),\mathcal{H}^n) \ \cap \ \mathcal{L}(\mathcal{W}^n,\mathcal{W}^{n'}) \ \cap \ \mathcal{L}(\mathcal{H}^n,\mathcal{D}(\mathcal{A}_k^*)') \tag{3.16}$$

is the extension of $\mathcal{A}_k$ given on $\mathcal{W}^n$ by

$$\widetilde{\mathcal{A}}_k = \begin{pmatrix} A_0 & A_1\delta_{\sigma=-1} \\ \dfrac{1}{k}\delta^*_{\sigma=0} & \dfrac{1}{k}D \end{pmatrix}. \tag{3.17}$$

Extension $\widetilde{\mathcal{A}}_k$ generates $\mathcal{S}_k$, henceforth considered as a C_0-semigroup on any of the three spaces $\mathcal{D}(\mathcal{A}_k) \hookrightarrow \mathcal{H}^n \hookrightarrow \mathcal{D}(\mathcal{A}_k^*)'$ which are ordered by continuous and dense injections. Specifically, for $X_0 = \binom{x_{00}}{\psi^k}$, X coincides with the augmented state given from x by $\binom{x}{x^k}$. $\square$

Proof. Theorem 3.6 is given in Appendix A.3.

Remark 3.2. Since $\mathcal{B}_k u \in L^2(0,T;\mathcal{H}^n) \Longrightarrow \{t \to \int_0^t \mathcal{S}_k(t-s)\mathcal{B}_k u(s)ds\} \in L^2(0,T;\mathcal{D}(\mathcal{A}_k))$ and in view of [1, Proposition 3.2], the different concepts of solution (strong, mild, and weak) coincide for the equation of evolution (3.12), so we just say "the solution." Furthermore, we may notice that

$$X_0 \in \mathcal{D}(\mathcal{A}_k) \Longrightarrow X_k \in L^2(0,T;\mathcal{D}(\mathcal{A}_k)), \tag{3.18}$$

$$X_0 \in \mathcal{W}^n \Longrightarrow X_k \in L^2(0,T;\mathcal{W}^n). \qquad \square \tag{3.19}$$

4. Linear quadratic optimal control revisited. To begin with, we state in the first subsection the solution of the linear quadratic minimization problem as a special case of the general result for systems belonging to the abstract class of Pritchard and Salamon [21]. The interest in such a setting is that it notably simplifies the form of well-known associated Riccati equations that can be found in many places in the literature. Without attempting to give a complete overview of references on existence and representation of the solution of the Riccati equation for delay systems, we mention the works of Bensoussan et al. [1], Delfour and Karrakchou [9, 10], Pritchard and Salamon [21, 22], Salamon [23, 24], Staffans [27], and Vinter and Kwong [30]. The second subsection introduces, for these infinite dimensional Riccati operators, a parameterization by the delays which corresponds to a singular perturbation analysis as proposed by Kokotović and Yackel [18] in finite dimensions. Thanks to such a parameterization, the question of the dependance of the solution of the Riccati equation with respect to the delays just turns to a problem of existence of weak limits for some appropriate operators.

Before going further, we recall that the Pritchard and Salamon class is a class of systems satisfying the regularity conditions stated in the following definition [4].

DEFINITION 4.1. *Consider W, V, U, and K four real and separable Hilbert spaces such that $W \hookrightarrow V$, and consider $\mathcal{S}(t)$ a C_0-semigroup on V and W. Then the linear system $(\mathcal{S},\mathcal{B},\mathcal{C})$*

$$\left\{\begin{array}{rcl} x(t) &=& \mathcal{S}(t)x_0 + \displaystyle\int_0^t \mathcal{S}(t-s)\mathcal{B}u(s)ds, \quad t \geq 0, \\ y(t) &=& \mathcal{C}x(t), \quad (x_0,u) \in V \times L^2_{loc}(0,\infty;U) \end{array}\right. \tag{4.1}$$

is said to belong to the abstract Pritchard and *Salamon class for W and V with respect to $\mathcal{S}$—in short $(\mathcal{S},\mathcal{B},\mathcal{C}) \in \mathcal{C}_{PS}(W,V,U,K)$—if we have the following.*

(1) *$\mathcal{B} \in \mathcal{L}(U,V)$ is such that there exists t and $b > 0$ satisfying*

$$\int_0^t \mathcal{S}(t-s)\mathcal{B}u(s)ds \in W \quad \text{and} \quad \| \int_0^t \mathcal{S}_h(t-s)\mathcal{B}u(s)ds\|_W \leq b\|u\|_{L^2(0,t;U)}.$$

(2) *$\mathcal{C} \in \mathcal{L}(W,K)$ is such that there exists t and $c > 0$ satisfying*

$$\|\mathcal{C}\mathcal{S}(.)x\|_{L^2(0,t;K)} \leq c\|x\|_V \quad \forall x \in W.$$

If, moreover, $\mathcal{D}_V(\mathcal{A}) \hookrightarrow W$, then $(\mathcal{S},\mathcal{B},\mathcal{C})$ is said to be regular. ∎

4.1. Solution of the control problem. We have the following.

PROPOSITION 4.2.

(i) *Denote the operator $(C,0) \in \mathcal{L}(\mathcal{H}^m,\mathbb{R}^p)$ as $\mathcal{C}_h$ and assume $h > 0$. Then the triple $(\mathcal{S}_h,\mathcal{B}_h,\mathcal{C}_h) \in \mathcal{C}_{PS}(\mathcal{H}^m,\mathcal{D}(\mathcal{A}_h^*)',\mathbb{R}^m,\mathbb{R}^p)$ and is regular.*

(ii) *Denote the operator $(C,0) \in \mathcal{L}(\mathcal{H}^n,\mathbb{R}^p)$ as $\mathcal{C}_k$ and assume $k > 0$. Then the triple $(\mathcal{S}_k,\mathcal{B}_k,\mathcal{C}_k) \in \mathcal{C}_{PS}(\mathcal{H}^n,\mathcal{D}(\mathcal{A}_k^*)',\mathbb{R}^n,\mathbb{R}^p)$ and is regular.*

Then, with the notation

$$\sigma_s^+[V] = \{P \in \mathcal{L}_s(V,V'),\ \langle P\phi,\phi\rangle_{V,V'} \geq 0\ \forall \phi \in V\}, \tag{4.2}$$

we can state the next theorem as the particular case of [21, Proposition 2.8].

THEOREM 4.3 (Finite horizon control: $\boldsymbol{T < \infty}$).

(i) *Assume $h > 0$ and denote $\left(\begin{smallmatrix} G(T) & 0 \\ 0 & 0 \end{smallmatrix}\right) \in \mathcal{L}(\mathcal{H}^m)$ as $\mathcal{G}_h(T)$. Then there exists a unique operator $\mathcal{P}_{T,h}$ such that*

$$\widehat{J_T}(0,h) = \frac{1}{2}\left\langle X_h(0,.), \mathcal{P}_{T,h}(0)X_h(0,.)\right\rangle_{\mathcal{H}^m}, \tag{4.3}$$

and the optimal control is $u_{opt}(t) = -R^{-1}\mathcal{B}_h^*\mathcal{P}_{T,h}(t)X_h(t,.)$, with X_h given by Theorem 3.3. That operator $\mathcal{P}_{T,h} \in C^1(0,T,\mathcal{L}_s(\mathcal{H}^m)) \cap C(0,T,\sigma_s^+[\mathcal{D}(\mathcal{A}_h^*)'])$ is the unique nonnegative self-adjoint solution of the Riccati equation

$$\begin{aligned} &\frac{\partial \mathcal{P}_{T,h}}{\partial t} + \mathcal{A}_h^*\mathcal{P}_{T,h} + \mathcal{P}_{T,h}\mathcal{A}_h - \mathcal{P}_{T,h}\mathcal{B}_h R^{-1}\mathcal{B}_h^*\mathcal{P}_{T,h} + \mathcal{C}_h^*\mathcal{C}_h = 0, \\ &\mathcal{P}_{T,h}(T) = \mathcal{G}_h(T). \end{aligned} \tag{4.4}$$

(ii) *Assume $k > 0$ and denote $\left(\begin{smallmatrix} G(T) & 0 \\ 0 & 0 \end{smallmatrix}\right) \in \mathcal{L}(\mathcal{H}^n)$ as $\mathcal{G}_k(T)$. Then there exists a unique operator $\mathcal{Q}_{T,k}$ such that*

$$\widehat{J_T}(k,0) = \frac{1}{2}\left\langle X_k(0,.), \mathcal{Q}_{T,k}(0)X_k(0,.)\right\rangle_{\mathcal{H}^n}, \tag{4.5}$$

and the optimal control is $u_{opt}(t) = -R^{-1}\mathcal{B}_k^*\mathcal{Q}_{T,k}(t)X_k(t,.)$, where X_k is given by Theorem 3.6. $\mathcal{Q}_{T,k} \in C^1(0,T,\mathcal{L}_s(\mathcal{H}^n)) \cap C(0,T,\sigma_s^+[\mathcal{D}(\mathcal{A}_k^*)'])$ is the unique nonnegative self-adjoint solution of the Riccati equation

$$\begin{aligned} &\frac{\partial \mathcal{Q}_{T,k}}{\partial t} + \widetilde{\mathcal{A}}_k^*\mathcal{Q}_{T,k} + \mathcal{Q}_{T,k}\widetilde{\mathcal{A}}_k - \mathcal{Q}_{T,k}(t)\mathcal{B}_k R^{-1}\mathcal{B}_k^*\mathcal{Q}_{T,k} + \mathcal{C}_k^*\mathcal{C}_k = 0, \\ &\mathcal{Q}_{T,k}(T) = \mathcal{G}_k(T). \end{aligned} \tag{4.6}$$

∎

Below, we recall the weak stabilizability and detectability assumptions required to state the infinite horizon case as an application of [21, Theorem 3.4].

DEFINITION 4.4. *Set $J_\infty(u,x,y) = \|y\|^2_{L^2(0,\infty,K)} + \|\mathcal{R}^{\frac{1}{2}}u\|^2_{L^2(0,\infty,K)}$ for some $\mathcal{R}$ positive in U and (x,u,y) satisfying (4.1). $(\mathcal{S},\mathcal{B},\mathcal{C}) \in \mathcal{C}_{PS}(W,V,U,K)$ is said to be*

(1) stabilizable *if $\forall x_0 \in V, \exists u_{x_0} \in L^2(0,\infty;\mathbb{R}^m)$ such that $J_\infty(u_{x_0},x,y) < \infty$;*
(2) detectable *if $\forall \left(\begin{smallmatrix} x_0 \\ u \end{smallmatrix}\right) \in V \times L^2(0,\infty;\mathbb{R}^m)$ such that $J_\infty(u,x,y) < \infty$, we have $x \in L^2(0,\infty;V)$).*

THEOREM 4.5 (Infinite horizon control).

(i) *Assume that $(\mathcal{S}_h,\mathcal{B}_h,\mathcal{C}_h)$ is stabilizable and detectable in the sense of Definition 4.4. Then there exists a unique operator $\mathcal{P}_{\infty,h}$ such that*

$$\widehat{J_\infty}(0,h) = \frac{1}{2}\left\langle X_h(0,.), \mathcal{P}_{\infty,h}X_h(0,.)\right\rangle_{\mathcal{H}^m} \tag{4.7}$$

and the optimal control is $u_{opt}(t) = -R^{-1}\mathcal{B}_h^*\mathcal{P}_{\infty,h}X_h(t,.)$. That $\mathcal{P}_{\infty,h} \in \sigma_s^+[\mathcal{D}(\mathcal{A}_h^*)']$ is the unique nonnegative self-adjoint solution of the Riccati equation (in $\mathcal{H}^m$)

$$\mathcal{A}_h^*\mathcal{P}_{\infty,h} + \mathcal{P}_{\infty,h}\mathcal{A}_h - \mathcal{P}_{\infty,h}\mathcal{B}_h R^{-1}\mathcal{B}_h^*\mathcal{P}_{\infty,h} + \mathcal{C}_h^*\mathcal{C}_h = 0. \tag{4.8}$$

(ii) *Assume that $(\mathcal{S}_k,\mathcal{B}_k,\mathcal{C}_k)$ is stabilizable and detectable in the sense of Definition 4.4. Then there exists a unique operator $\mathcal{Q}_{\infty,k}$ such that*

$$\widehat{J_\infty}(k,0) = \frac{1}{2}\left\langle X_k(0,.), \mathcal{Q}_{\infty,k}X_k(0,.)\right\rangle_{\mathcal{H}^n}, \tag{4.9}$$

and the optimal control is $u_{opt}(t) = -R^{-1}\mathcal{B}_k^*\mathcal{Q}_{\infty,k}X_k(t,.)$. *That* $\mathcal{Q}_{\infty,k} \in \sigma^+[\mathcal{D}(\mathcal{A}_k^*)']$ *is the unique nonnegative self-adjoint solution of the Riccati equation (in* $\mathcal{H}^n$*)*

$$\widetilde{\mathcal{A}}_k^*\mathcal{Q}_{\infty,k} + \mathcal{Q}_{\infty,k}\widetilde{\mathcal{A}}_k - \mathcal{Q}_{\infty,k}\mathcal{B}_k R^{-1}\mathcal{B}_k^*\mathcal{Q}_{\infty,k} + \mathcal{C}_k^*\mathcal{C}_k = 0. \qquad \square \tag{4.10}$$

Remark 4.1. If we define the functions $\mathcal{N}_h$ and Δ_k by $\mathcal{N}_h(\lambda) = B_0 + B_1e^{-\lambda h}$ and $\Delta_k(\lambda) = \lambda I_d - A_0 - A_1e^{\lambda k}$ for $k,\ h \geq 0$, and $\lambda \in \mathbb{C}$, then using, e.g., [22, Theorem 3.5], stabilizability and detectability in Theorem 4.5 can be reformulated as more usual rank tests for $[\Delta_\bullet(\lambda),\ \mathcal{N}_\bullet(\lambda)]$ and $[{}^{\Delta_\bullet(\lambda)}_{C}]$. Moreover, for the input delay case, a simpler test is given by Chyung [2]: Rank $\left[D\ AD\ A^2D \dots A^{n-1}D\right] = n$, with $D = B_0 + e^{-Ah}B_1$.

4.2. Parameterization and decomposition of Riccati operators. In this subsection, we propose for the previously given Riccati operators a four-block decomposition combined with a parameterization by the delays h or k. This type of parameterization was introduced by Kokotović and Yackel [18] for the Riccati matrix solving the LQ control problem of singular perturbed finite dimensional systems. Here, it makes available some regularity results on Riccati operators and this leads to a decomposition of Riccati equations which will be useful for sensitivity analysis. We restrict detailed computations and proofs to the finite horizon input delay case. The state delay and stationary cases may be derived in a similar way. Input delay results are stated in Propositions 4.7 and 4.8 and the state delay results are in Propositions 4.9 and 4.6.

PROPOSITION 4.6. *For any* $h > 0$, $t \in [0,T]$, *and* $T < \infty$, *the Riccati operator* $\mathcal{P}_{T,h}(t)$ *has in* $\mathcal{L}_s(\mathcal{H}^m)$ *the decomposition*

$$\mathcal{P}_{T,h}(t) = \begin{pmatrix} \mathcal{P}^1_{T,h}(t) & h\mathcal{P}^2_{T,h}(t) \\ h\mathcal{P}^{2*}_{T,h}(t) & h\mathcal{P}^3_{T,h}(t) \end{pmatrix} \tag{4.11}$$

with $\mathcal{P}^1_{T,h} \in C^1(0,T;\mathcal{L}_s(\mathbb{R}^n))$*; and operators* $\mathcal{P}^2_{T,h} \in C^1(0,T;\mathcal{L}_s(L^2(-1,0;\mathbb{R}^m),\mathbb{R}^n))$ *and* $\mathcal{P}^3_{T,h} \in C^1(0,T;\mathcal{L}_s(L^2(-1,0;\mathbb{R}^m))$ *having representations*

$$[\mathcal{P}^{2*}_{T,h}(t)x](\sigma) = \mathcal{P}^{2*}_{T,h}(t,\sigma)x \quad \forall (x,\sigma) \in \mathbb{R}^n \times [-1,0], \tag{4.12}$$

$$[\mathcal{P}^3_{T,h}(t)y](\sigma) = \int_{-1}^{0} \mathcal{P}^3_{T,h}(t,\sigma,r)y(r)dr \quad \forall y \in L^2(-1,0;\mathbb{R}^m) \tag{4.13}$$

that satisfy, for t *and* $r \in [0,T]$,

$$\mathcal{P}^{2*}_{T,h}(t,.) \in H^1(-1,0;\mathcal{L}(\mathbb{R}^n,\mathbb{R}^m)), \tag{4.14}$$

$$\mathcal{P}^3_{T,h}(t,.,r) \in H^1([-1,0];\mathcal{L}(\mathbb{R}^m)). \tag{4.15}$$

Moreover, $\mathcal{P}^3_{T,h}(t)$ *maps* $L^2(-1,0;\mathbb{R}^m)$ *to* $H^1(-1,0;\mathbb{R}^m)$ *and the following limiting conditions hold:*

$$\mathcal{P}^{2*}_{T,h}(t,-1) = B_1^T\mathcal{P}^1_{T,h}(t), \tag{4.16}$$

$$[\mathcal{P}^3_{T,h}(t)y](-1) = hB_1^T\mathcal{P}^2_{T,h}(t)y \quad \forall y \in L^2(-1,0;\mathbb{R}^m). \qquad \square \tag{4.17}$$

Proof. First, we point out that the existence of a four-block decomposition is a consequence of linearity of $\mathcal{P}_{T,h}(t)$ and the product-space structure of $\mathcal{H}^m = \mathbb{R}^n \times$

$L^2(-1,0,\mathbb{R}^m)$. We impose the presence of the factor h in this decomposition with the aim of simplifying the singularity which appears in $\mathcal{B}_h$ for small values of h. Then the representations of the blocks with the kernels of some continuous operator is a classical trick (see, e.g., Ichikawa [16], Delfour, McCalla, and Mitter [11], or Delfour and Mitter [12]). The only remaining point is in regard to regularity results and limiting conditions. For that, we may remember that the integral form of the Riccati operator arising in the solution of the control problem is obtained via a quasi-evolution operator (see, e.g., Curtain and Pritchard [5, 6], Pritchard and Salamon [21]) in such a way that the desired result will follow from a decomposition of the integral Riccati equation.

The quasi-evolution operator $U_h \in \mathcal{L}(\mathcal{H}^m)$ we mention is linked to $\mathcal{P}_h$ in the following way:

$$U_h(t,s)X = \mathcal{S}_h(t-s)X - \int_s^t \mathcal{S}_h(t-r)\mathcal{B}_h R^{-1}\mathcal{B}_{\vec{h}}^* \mathcal{P}_{T,h} U_{\vec{h}}(r,s)X\,dr, \tag{4.18}$$

$$\mathcal{P}_{T,h}(t)X = \mathcal{S}_h^*(T-t)\mathcal{G}_h(T)U_h(T,t)X + \int_t^T \mathcal{S}_h^*(r-t)\mathcal{C}_h^*\mathcal{C}_h U_h(r,t)X\,dr, \tag{4.19}$$

$$for\ X \in \mathcal{H}^m\ and\ 0 \le s \le t \le T.$$

Now let us decompose U_h as $U_h = \left(\begin{smallmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{smallmatrix}\right)$ and set $X = \left(\begin{smallmatrix} x \\ y \end{smallmatrix}\right) \in \mathcal{H}^m$. Then, since $\mathcal{G}_h = \left(\begin{smallmatrix} G & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $\mathcal{C}_h = (C,0)$, when writing $\mathcal{S}_h = \left(\begin{smallmatrix} \mathcal{S}_{11} & \mathcal{S}_{12} \\ 0 & \mathcal{S}_{22} \end{smallmatrix}\right)$, we get

$$\mathcal{S}_h^*(T-t)\mathcal{G}_h U_h(T,t)\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \mathcal{S}_{11}^*(T-t)G\,[\,U_{11}(T,t)x + U_{12}(T,t)y\,] \\ \mathcal{S}_{12}^*(T-t)G\,[\,U_{11}(T,t)x + U_{12}(T,t)y\,] \end{pmatrix}.$$

Therefore the decomposition of $\mathcal{P}_{T,h}$ produces the relations

$$\mathcal{P}_{T,h}^1(t)x = \mathcal{S}_{11}^*(T-t)GU_{11}(T,t)x + \int_t^T \mathcal{S}_{11}^*(r-t)C^*CU_{11}(r,t)x\,dr, \tag{4.20}$$

$$h\mathcal{P}_{T,h}^2(t)y = \mathcal{S}_{11}^*(T-t)GU_{12}(T,t)y + \int_t^T \mathcal{S}_{11}^*(r-t)C^*CU_{12}(r,t)y\,dr; \tag{4.21}$$

and, for $\sigma \in [-1,0]$,

$$h\mathcal{P}_{T,h}^{2*}(t,\sigma)x = \mathcal{S}_{12}^*(T-t)(\sigma)GU_{11}(T,t)x + \int_t^T \mathcal{S}_{12}^*(r-t)(\sigma)C^*CU_{11}(r,t)x\,dr, \tag{4.22}$$

$$h\mathcal{P}_{T,h}^3(t)y(\sigma) = \mathcal{S}_{12}^*(T-t)(\sigma)GU_{12}(T,t)y + \int_t^T \mathcal{S}_{12}^*(r-t)(\sigma)C^*CU_{12}(r,t)y\,dr. \tag{4.23}$$

But for $y \in \mathbb{R}^n$, we have $\mathcal{S}_{11}^*(t) = e^{A^T t}$ and $\mathcal{S}_{12}^*(t)y(\sigma) = h\chi_{\{t-h_j \ge 0\}} e^{-h(\sigma+1)} B_1 \mathcal{S}_{11}^*(t)y$. Then the regularities of $\mathcal{P}_{T,h}^{2*}$ and $\mathcal{P}_{T,h}^3$ as well as the limiting conditions follow from the property: $\sigma \longrightarrow \mathcal{S}_{11}^*(t-h(\sigma+1)) \in H^1(-1,0;\mathbb{R}^n)$. □

As a consequence of the Proposition 4.6, we may decompose the Riccati differential equation (4.4) in order to identify the components $\mathcal{P}_{T,h}^1$, $\mathcal{P}_{T,h}^2$ and $\mathcal{P}_{T,h}^3$. Then we get (we set $H^1 = H^1(-1,0;\mathbb{R}^m)$ and $L^2 = L^2(-1,0;\mathbb{R}^m)$)

$$\left\{\begin{array}{lcl} \langle \dot{\mathcal{P}}_{T,h}^1(t)x_1, x_2\rangle_{\mathbb{R}^n} & = & -\langle (A - B_0R^{-1}\delta_{\sigma=0}\mathcal{P}_{T,h}^{2*}(t,\sigma))x_1, \mathcal{P}_{T,h}^1(t)x_2\rangle_{\mathbb{R}^n} \\ & & -\langle \mathcal{P}_{T,h}^1(t)x_1, (A - B_0R^{-1}\delta_{\sigma=0}\mathcal{P}_{T,h}^{2*}(t,\sigma))x_2\rangle_{\mathbb{R}^n} \\ & & +\langle B_0^T\mathcal{P}_{T,h}^1(t)x_1, R^{-1}B_0^T\mathcal{P}_{T,h}^1(t)x_2\rangle_{\mathbb{R}^n} \\ & & +\langle \delta_{\sigma=0}\mathcal{P}_{T,h}^{2*}(t,\sigma)x_1, R^{-1}\delta_{\sigma=0}\mathcal{P}_{T,h}^{2*}(t,\sigma)x_2\rangle_{\mathbb{R}^m} \\ & & -\langle Cx_1, Cx_2\rangle_{\mathbb{R}^p}, \\ \mathcal{P}_{T,h}^1(T)x_1 & = & G(T)x_1 \quad \forall x_1, x_2 \in \mathbb{R}^n; \end{array}\right. \tag{4.24}$$

$$
(4.25)\quad \begin{cases} h\langle \dot{\mathcal{P}}^2_{T,h}(t)y,x\rangle_{\mathbb{R}^n} &= -\langle \mathcal{P}^1_{T,h}(t)B_1\delta_{\sigma=-1}y,x\rangle_{\mathbb{R}^n} \\ &\quad +\langle \mathcal{P}^1_{T,h}(t)B_0R^{-1}\delta_{\sigma=0}\mathcal{P}^3_{T,h}(t)y,x\rangle_{\mathbb{R}^n} \\ &\quad +\langle \delta_{\sigma=0}\mathcal{P}^3_{T,h}(t)y,R^{-1}\delta_{\sigma=0}\mathcal{P}^{2*}_{T,h}(t,\sigma)x\rangle_{\mathbb{R}^m} \\ &\quad -\langle Dy,\mathcal{P}^{2*}_{T,h}(t,.)x\rangle_{L^2}+\ h\{\langle \mathcal{P}^2_{T,h}(t)y,Ax\rangle_{\mathbb{R}^n} \\ &\quad -\langle B_0^T\mathcal{P}^2_{T,h}(t)y,R^{-1}B_0^T\mathcal{P}^1_{T,h}(t)x\rangle_{\mathbb{R}^n} \\ &\quad -\langle B_0^T\mathcal{P}^2_{T,h}(t)y,R^{-1}\delta_{\sigma=0}\mathcal{P}^{2*}_{T,h}(t,\sigma)x\rangle_{\mathbb{R}^m}\}, \\ \mathcal{P}^{2*}_{T,h}(t,-1)x &= B_1^T\mathcal{P}^1_{T,h}(t)x \quad \forall x\in\mathbb{R}^n\ \forall y\in H^1; \end{cases}
$$

$$
(4.26)\quad \begin{cases} h\langle \dot{\mathcal{P}}^3_{T,h}(t)y,z\rangle_{L^2} &= -\langle Dy,\mathcal{P}^3_{T,h}(t)z\rangle_{L^2}-\langle \mathcal{P}^3_{T,h}(t)y,Dz\rangle_{L^2} \\ &\quad +\langle \delta_{\sigma=0}\mathcal{P}^3_{T,h}(t)y,R^{-1}\delta_{\sigma=0}\mathcal{P}^3_{T,h}(t)z\rangle_{\mathbb{R}^m} \\ &\quad +h\{\langle B_0^T\mathcal{P}^2_{T,h}(t)y,R^{-1}\delta_{\sigma=0}\mathcal{P}^3_{T,h}(t)z\rangle_{\mathbb{R}^m} \\ &\quad +\langle B_0^T\mathcal{P}^2_{T,h}(t)z,R^{-1}\delta_{\sigma=0}\mathcal{P}^3_{T,h}(t)y\rangle_{\mathbb{R}^m} \\ &\quad -\langle B_1\delta_{\sigma=-1}y,\mathcal{P}^2_{T,h}(t)z\rangle_{\mathbb{R}^n} \\ &\quad -\langle \mathcal{P}^2_{T,h}(t)y,B_1\delta_{\sigma=-1}z\rangle_{\mathbb{R}^n}\} \\ &\quad +h^2\langle B_0^T\mathcal{P}^2_{T,h}(t)z,R^{-1}B_0^T\mathcal{P}^2_{T,h}(t)y\rangle_{\mathbb{R}^m}, \\ \mathcal{P}^3_{T,h}(t)y(-1) &= hB_1^T\mathcal{P}^2_{T,h}(t)y \quad \forall y,z\in H^1. \end{cases}
$$

For infinite horizon, we can derive the associated decomposition in a similar way.

PROPOSITION 4.7. *For any $h>0$, $\mathcal{P}_{\infty,h}$ may be written in $\mathcal{L}(\mathcal{H}^m)$ as*

$$
(4.27)\qquad \mathcal{P}_{\infty,h}=\begin{pmatrix} \mathcal{P}^1_{\infty,h} & h\mathcal{P}^2_{\infty,h} \\ h\mathcal{P}^{2*}_{\infty,h} & h\mathcal{P}^3_{\infty,h}\end{pmatrix},
$$

where $\mathcal{P}^1_{\infty,h}\in\mathcal{L}(\mathbb{R}^n)$; $\mathcal{P}^3_{\infty,h}\in\mathcal{L}(L^2(-1,0;\mathbb{R}^m)$ with range $H^1(-1,0;\mathbb{R}^m)$ satisfies

$$
(4.28)\qquad [\mathcal{P}^3_{\infty,h}y](-1)=hB_1^T\ \mathcal{P}^2_{\infty,h}\ y\quad \forall y\in L^2(-1,0;\mathbb{R}^m)
$$

and $\mathcal{P}^2_{\infty,h}\in\mathcal{L}(L^2(-1,0;\mathbb{R}^m),\mathbb{R}^n)$ has the following representation:

$$
(4.29)\qquad \forall(x,\sigma)\in\mathbb{R}^n\times[-1,0]\ :\ [\mathcal{P}^{2*}_{\infty,h}x](\sigma)=\mathcal{P}^{2*}_{\infty,h}(\sigma)x,
$$

with $\mathcal{P}^{2*}_{\infty,h}\in H^1(-1,0;\mathcal{L}(\mathbb{R}^n,\mathbb{R}^m))$ satisfying the limiting condition

$$
(4.30)\qquad \mathcal{P}^{2*}_{\infty,h}(-1)=B_1^T\mathcal{P}^1_{\infty,h}.\qquad \square
$$

For the state delay, we have analogues of Proposition 4.6 and 4.7.

PROPOSITION 4.8. *For any $k>0$, $t\in[0,T]$, and $T<\infty$, the Riccati operator $\mathcal{Q}_{T,k}(t)$ has in $\mathcal{L}_s(\mathcal{H}^n)$ the following decomposition:*

$$
(4.31)\qquad \mathcal{Q}_{T,k}(t)=\begin{pmatrix} \mathcal{Q}^1_{T,k}(t) & k\mathcal{Q}^2_{T,k}(t) \\ k\mathcal{Q}^{2*}_{T,k}(t) & k\mathcal{Q}^3_{T,k}(t)\end{pmatrix},
$$

with $\mathcal{Q}^1_{T,k}\in C^1(0,T;\mathcal{L}_s(\mathbb{R}^n))$ and operators $\mathcal{Q}^2_{T,k}\in C^1(0,T;\mathcal{L}_s(L^2(-1,0;\mathbb{R}^m),\mathbb{R}^n))$ and $\mathcal{Q}^3_{T,k}\in C^1(0,T;\mathcal{L}_s(L^2(-1,0;\mathbb{R}^n))$ having representations

$$
(4.32)\qquad [\mathcal{Q}^{2*}_{T,k}(t)x](\sigma)=\mathcal{Q}^{2*}_{T,k}(t,\sigma)x\quad\forall(x,\sigma)\in\mathbb{R}^n\times[-1,0],
$$

$$
(4.33)\qquad [\mathcal{Q}^3_{T,k}(t)y](\sigma)=\int_{-1}^0\mathcal{Q}^3_{T,k}(t,\sigma,r)y(r)dr\quad\forall y\in L^2(-1,0;\mathbb{R}^n)
$$

that satisfy, for t *and* $r \in [0,T]$,

$$\mathcal{Q}^{2*}_{T,k}(t,.) \in H^1(-1,0;\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)), \tag{4.34}$$

$$\mathcal{Q}^{3}_{T,k}(t,.,r) \in H^1([-1,0];\mathcal{L}(\mathbb{R}^n)). \tag{4.35}$$

Moreover, $\mathcal{Q}^3_{T,k}(t)$ *maps* $L^2(-1,0;\mathbb{R}^n)$ *to* $H^1(-1,0;\mathbb{R}^n)$ *and we also have*

$$\mathcal{Q}^{2*}_{T,k}(t,-1) = A_1^T \mathcal{Q}^1_{T,k}(t), \tag{4.36}$$

$$[\mathcal{Q}^3_{T,k}(t)y](-1) = kA_1^T \mathcal{Q}^2_{T,k}(t)y \quad \forall y \in L^2(-1,0;\mathbb{R}^n). \qquad \square \tag{4.37}$$

PROPOSITION 4.9. *For any* $k>0$, *the Riccati operator* $\mathcal{Q}_{\infty,k}$ *may be written in* $\mathcal{L}(\mathcal{H}^n)$ *in the following way:*

$$\mathcal{Q}_{\infty,k} = \begin{pmatrix} \mathcal{Q}^1_{\infty,k} & k\mathcal{Q}^2_{\infty,k} \\ k\mathcal{Q}^{2*}_{\infty,k} & k\mathcal{Q}^3_{\infty,k} \end{pmatrix}, \tag{4.38}$$

where $\mathcal{Q}^1_{\infty,k} \in \mathcal{L}(\mathbb{R}^n)$, *and* $\mathcal{Q}^3_{\infty,k} \in \mathcal{L}(L^2(-1,0;\mathbb{R}^n)$ *with range* $H^1(-1,0;\mathbb{R}^n)$ *satisfies*

$$[\mathcal{Q}^3_{\infty,k}y](-1) = kA_1^T\ \mathcal{Q}^2_{\infty,k}\ y \quad \forall y \in L^2(-1,0;\mathbb{R}^n); \tag{4.39}$$

and $\mathcal{Q}^2_{\infty,k} \in \mathcal{L}(L^2(-1,0;\mathbb{R}^n),\mathbb{R}^n)$ *has the following representation:*

$$\forall (x,\sigma) \in \mathbb{R}^n \times [-1,0]\ :\ [\mathcal{Q}^{2*}_{\infty,k}x](\sigma) = \mathcal{Q}^{2*}_{\infty,k}(\sigma)x \tag{4.40}$$

with $\mathcal{Q}^{2*}_{\infty,k} \in H^1(-1,0;\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n))$ *satisfying the limiting condition*

$$\mathcal{Q}^{2*}_{\infty,k}(-1) = {A_1}^T \mathcal{Q}^1_{\infty,k}. \qquad \square \tag{4.41}$$

Then we may decompose the Riccati equation (4.6) in the following way (we set $H^1 = H^1(-1,0;\mathbb{R}^n)$ and $L^2 = L^2(-1,0;\mathbb{R}^n)$):

$$\left\{\begin{array}{lcl} \forall\ x_1,x_2 \in \mathbb{R}^n\ : & & \\ \langle \dot{\mathcal{Q}}^1_k(t)x_1,x_2\rangle_{\mathbb{R}^n} &=& -\langle A_0x_1, \mathcal{Q}^1_{T,k}(t)x_2\rangle_{\mathbb{R}^n} - \langle \mathcal{Q}^1_{T,k}(t)x_1, A_0x_2\rangle_{\mathbb{R}^n} \\ & & -\langle x_1, R^{-1}\delta_{\sigma=0}\mathcal{Q}^{2*}_{T,k}(t,\sigma)x_2\rangle_{\mathbb{R}^n} \\ & & -\langle R^{-1}\delta_{\sigma=0}\mathcal{Q}^{2*}_{T,k}(t,\sigma)x_1,x_2\rangle_{\mathbb{R}^n} \\ & & +\langle B^T\mathcal{Q}^1_{T,k}(t)x_1, B^T\mathcal{Q}^1_{T,k}(t)x_2\rangle_{\mathbb{R}^n} \\ & & -\langle Cx_1,Cx_2\rangle_{\mathbb{R}^p}, \\ \mathcal{Q}^1_{T,k}(T)x_1 &=& G(T)x_1, \end{array}\right. \tag{4.42}$$

$$\left\{\begin{array}{lcl} \forall x \in \mathbb{R}^n, \forall y \in H^1\ : & & \\ k\langle \dot{\mathcal{Q}}^2_{T,k}(t)y,x\rangle_{\mathbb{R}^n} &=& -\langle \mathcal{Q}^1_{T,k}(t)A_1\delta_{\sigma=-1}y,x\rangle_{\mathbb{R}^n} \\ & & +\langle R^{-1}\delta_{\sigma=0}\mathcal{Q}^3_{T,k}(t)y,x\rangle_{\mathbb{R}^n} - \langle Dy, \mathcal{Q}^{2*}_{T,k}(t,.)x\rangle_{L^2} \\ & & +k\langle B^T\mathcal{Q}^2_{T,k}(t)y, B^T\mathcal{Q}^1_{T,k}(t)x\rangle_{\mathbb{R}^m} \\ & & +k\langle \mathcal{Q}^2_{T,k}(t)y, A_0x\rangle_{\mathbb{R}^n}, \\ \mathcal{Q}^{2*}_k(t,-1)x &=& A_1^T\mathcal{Q}^1_{T,k}(t)x, \end{array}\right. \tag{4.43}$$

$$\left\{\begin{array}{lcl} \forall y \in H^1, \forall z \in H^1\ : & & \\ \langle k\dot{\mathcal{Q}}^3_{T,k}(t)y,z\rangle_{L^2} &=& -\langle Dy, \mathcal{Q}^3_{T,k}(t)z\rangle_{L^2} - \langle \mathcal{Q}^3_{T,k}(t)y, Dz\rangle_{L^2} \\ & & +k\{\langle A_1\delta_{\sigma=-1}y, \mathcal{Q}^2_{T,k}(t)z\rangle_{\mathbb{R}^n} \\ & & -\langle \mathcal{Q}^2_{T,k}(t)y, A_1\delta_{\sigma=-1}z\rangle_{\mathbb{R}^n}\} \\ & & +k^2\langle B^T\mathcal{Q}^2_{T,k}(t)y, B^T\mathcal{Q}^2_{T,k}(t)z\rangle_{\mathbb{R}^m} \\ \mathcal{Q}^3_{T,k}(t)y(-1) &=& kA_1^T\mathcal{Q}^2_{T,k}(t)y. \end{array}\right. \tag{4.44}$$

Some closing remarks follow.

Remark 4.2. In view of Proposition 4.9, we may derive the equations satisfied by the components $\mathcal{Q}^i_{\infty,k}$, for $i \in \{1,2,3\}$, from (4.42), (4.43), (4.44). Obviously it is sufficient to take 0 as a substitute for their right-hand side and the ordered triple $(\mathcal{Q}^1_{\infty,k}, \mathcal{Q}^2_{\infty,k}, \mathcal{Q}^3_{\infty,k})$ for $(\mathcal{Q}^1_{T,k}, \mathcal{Q}^2_{T,k}, \mathcal{Q}^3_{T,k})$. □

Remark 4.3. A similar remark holds for the triples $(\mathcal{P}^1_{\infty,h}, \mathcal{P}^2_{\infty,h}, \mathcal{P}^3_{\infty,h})$ and $(\mathcal{P}^1_{T,h}, \mathcal{P}^2_{T,h}, \mathcal{P}^3_{T,h})$ when recalling that the triple $(\mathcal{P}^1_{T,h}, \mathcal{P}^2_{T,h}, \mathcal{P}^3_{T,h})$ satisfies the system of equations (4.24), (4.25), (4.26). □

5. Differentiability results for Riccati operators. For regularity results on Riccati operators $\mathcal{P}_{\bullet,k}$ and $\mathcal{Q}_{\bullet,k}$, we shall use the shorthand

$$\mathcal{E}_q = \mathcal{L}(\mathcal{H}^q) \times \mathcal{L}(L^2(-1,0;\mathbb{R}^q),\mathbb{R}^n) \times \mathcal{L}(L^2(-1,0;\mathbb{R}^q)) \quad \text{for} \quad q \in \{m,n\} \tag{5.1}$$

$$\text{and } \mathcal{I}_m \text{ defined as } \mathcal{I}_m(y) = -\int_{-1}^{0} y(\sigma)d\sigma \text{ for } y \in \mathbb{R}^m. \tag{5.2}$$

The first theorem is on the sensitivity of the Riccati operator solving the input delay case.

THEOREM 5.1. *We have the following items.*

(i) *For $T < \infty$ and $t \in [0,T]$, the mapping*

$$\Phi : \begin{array}{ccc} \mathbb{R}^*_+ & \longrightarrow & \mathcal{L}(\mathcal{H}^m) \times \mathcal{E}_m, \\ h & \longmapsto & \left(\dfrac{d\mathcal{P}^1_{T,h}}{dt}(t),\ \mathcal{P}^1_{T,h}(t),\ \mathcal{P}^2_{T,h}(t),\ \mathcal{P}^3_{T,h}(t) \right) \end{array} \tag{5.3}$$

satisfies

$$w - \lim_{h\to 0} \Phi(h) = \left(\frac{dP_T}{dt}(t),\ P_T(t),\ P_T(t)B_1\,\mathcal{I}_m,\ 0 \right), \tag{5.4}$$

where $P_T \in \mathcal{L}(\mathbb{R}^n)$ is the nonnegative symmetric solution of the Riccati equation

$$\begin{aligned} &\frac{dP_T}{dt} + A^T P_T + P_T A - P_T B R^{-1} B^T P_T + C^T C = 0 \text{ in } C(0,T;\mathcal{L}(\mathbb{R}^n)), \\ &P_T(T) = G(T). \end{aligned} \tag{5.5}$$

Moreover $\mathcal{P}^1_{T,h}$, the finite dimensional 1-1*-block of $\mathcal{P}_{T,h}$, satisfies*

$$\left(\frac{d\mathcal{P}^1_{T,h}}{dt},\ \mathcal{P}^1_{T,h} \right) = \left(\frac{dP_T}{dt},\ P_T \right) + o(h) \text{ on } [0,T]. \tag{5.6}$$

(ii) *For $T = \infty$, the mapping*

$$\overline{\Phi} : \begin{array}{ccc} \mathbb{R}^*_+ & \longrightarrow & \mathcal{E}_m, \\ h & \longmapsto & (\mathcal{P}^1_{\infty,h},\ \mathcal{P}^2_{\infty,h},\ \mathcal{P}^3_{\infty,h}) \end{array} \tag{5.7}$$

satisfies

$$w - \lim_{h\to 0} \overline{\Phi}(h) = (P_\infty,\ P_\infty B_1\,\mathcal{I}_m,\ 0), \tag{5.8}$$

where $P_\infty \in \mathcal{L}(\mathbb{R}^n)$ is the nonnegative symmetric solution of the equation

$$A^*P_\infty + P_\infty A - P_\infty B R^{-1} B^* P_\infty + C^*C = 0. \tag{5.9}$$

Moreover $\mathcal{P}^1_{\infty,h}$, the finite dimensional 1-1*-block of $\mathcal{P}_{\infty,h}$, satisfies*

$$\mathcal{P}^1_{\infty,h} = P_\infty + o(h). \qquad \square \tag{5.10}$$

Note first that Theorem 5.1 implies that for any $T \in \mathbb{R} \cup \{+\infty\}$:

$$w - \lim_{h\to 0} \mathcal{P}_{T,h} = \begin{pmatrix} P_T & 0 \\ 0 & 0 \end{pmatrix} \quad \text{in} \quad \mathcal{H}^m, \tag{5.11}$$

which is a classical result from Delfour [8]. So by continuity, we can give a meaning to the number $\mathcal{P}_{T,0}$ by setting $\mathcal{P}_{T,0} = w - \lim_{h\to 0}\mathcal{P}_{T,h}$. The novelty is that this theorem may be interpreted as a weak differentiability result for Riccati operators $\mathcal{P}_{T,h}$, for any $T \in \mathbb{R} \cup \{+\infty\}$. Indeed, we can evaluate the limiting value of the ratio

$$V_T(h) = \frac{\mathcal{P}_{T,h} - \mathcal{P}_{T,0}}{h}, \tag{5.12}$$

since Theorem 5.1 simply says that in $\mathcal{H}^m = \mathbb{R}^n \times L^2(0,T;\mathbb{R}^m)$,

$$w - \lim_{h\to 0} V_T(h) = \begin{pmatrix} 0 & P_T B_1 \mathcal{I}_m \\ -B_1^T P_T & 0 \end{pmatrix} \quad \text{for any} \quad T \in \mathbb{R} \cup \{+\infty\}. \tag{5.13}$$

Likewise for the state delay case, we have the following.

THEOREM 5.2. *We have the following items.*

(i) *For $T < \infty$ and $t \in [0,T]$, the mapping*

$$\Psi : \begin{array}{ccc} \mathbb{R}^*_+ & \longrightarrow & \mathcal{L}(\mathcal{H}^n) \times \mathcal{E}_n, \\ k & \longmapsto & \left(\dfrac{d\mathcal{Q}^1_{T,k}}{dt}(t),\ \mathcal{Q}^1_{T,k}(t),\ \mathcal{Q}^2_{T,k}(t),\ \mathcal{Q}^3_{T,k}(t) \right) \end{array} \tag{5.14}$$

satisfies

$$w - \lim_{k\to 0} \Psi(k) = \left(\frac{dP_T}{dt}(t),\ P_T(t),\ P_T(t)A_1 \mathcal{I}_n,\ 0 \right), \tag{5.15}$$

where $P_T \in \mathcal{L}(\mathbb{R}^n)$ is the nonnegative symmetric solution of the Riccati equation (5.5)*. Moreover, $\mathcal{Q}^1_{T,k}$, the finite dimensional* 1-1*-block of $\mathcal{Q}_{T,k}$, satisfies*

$$\left(\frac{d\mathcal{Q}^1_{T,k}}{dt},\ \mathcal{Q}^1_{T,k} \right) = \left(\frac{dP_T}{dt},\ P_T \right) + o(k) \text{ on } [0,T]. \tag{5.16}$$

(ii) *For $T = \infty$, the mapping*

$$\overline{\Psi} : \begin{array}{ccc} \mathbb{R}^*_+ & \longrightarrow & \mathcal{E}_n, \\ k & \longmapsto & (\mathcal{Q}^1_{\infty,k},\ \mathcal{Q}^2_{\infty,k},\ \mathcal{Q}^3_{\infty,k}) \end{array} \tag{5.17}$$

satisfies

$$w - \lim_{k\to 0} \overline{\Psi}(k) = (P_\infty,\ P_\infty A_1 \mathcal{I}_n,\ 0), \tag{5.18}$$

where $P_\infty \in \mathcal{L}(\mathbb{R}^n)$ is the nonnegative symmetric solution of the Riccati equation (5.9)*. Moreover, $\mathcal{Q}^1_{\infty,k}$, the finite dimensional* 1-1*-block of $\mathcal{Q}_{\infty,k}$, satisfies*

$$\mathcal{Q}^1_{\infty,k} = P_\infty + o(k). \qquad \square \tag{5.19}$$

Obviously, we have $w-\lim_{k\to 0}\mathcal{Q}_{T,k}=\left(\begin{smallmatrix}P_T & 0\\ 0 & 0\end{smallmatrix}\right)$ in $\mathcal{H}^n$. Then setting $\mathcal{Q}_{T,0}=P_T$ and $W_T(k)=\frac{\mathcal{Q}_{T,k}-\mathcal{Q}_{T,0}}{k}$, it results from Theorem 5.2 that we have, in $\mathcal{H}^n=\mathbb{R}^n\times L^2(0,T;\mathbb{R}^n)$,

$$w-\lim_{h\to 0}W_T(k)=\begin{pmatrix}0 & P_TA_1\mathcal{I}_n\\ -A_1^TP_T & 0\end{pmatrix}\quad\text{for any } T\in\mathbb{R}\cup\{+\infty\}. \tag{5.20}$$

The proofs of Theorems 5.1 and 5.2 are identical. We restrict ourselves to the first one.

Proof of Theorem 5.1. Proof of (i). Denote

$$(\mathcal{P}_0^1(t),\ \dot{\mathcal{P}}_0^1(t),\ \mathcal{P}_0^2(t),\ \mathcal{P}_0^3(t))=w-\lim_{h\to 0}\Phi(h). \tag{5.21}$$

Because $\forall h>0,\ \forall t\in[0,T]\ :\ \dot{\mathcal{P}}_h(t)\in\mathcal{L}(\mathcal{H}^m)$, there exists some $M>0$ such that $\|\dot{\mathcal{P}}_h(t)\|\le M$. Using the shorthand $H^1=H^1(-1,0;\mathbb{R}^m)$ and $L^2=L^2(-1,0;\mathbb{R}^m)$, we get

$$\forall x\in\mathbb{R}^n,\ \forall y\in H^1:\lim_{h\to 0}h\langle\dot{\mathcal{P}}_h^2(t)y,x\rangle_{\mathbb{R}^n}=0, \tag{5.22}$$

$$\forall y,z\in H^1:\lim_{h\to 0}h\langle\dot{\mathcal{P}}_h^3(t)y,z\rangle_{L^2}=0. \tag{5.23}$$

Thus it follows from (4.24) to (4.26) that $(\mathcal{P}_0^1(t),\ \dot{\mathcal{P}}_0^1(t),\ \mathcal{P}_0^2(t),\ \mathcal{P}_0^3(t))$ satisfies the following:

$$\begin{cases}\langle\dot{\mathcal{P}}_0^1(t)x_1,x_2\rangle_{\mathbb{R}^n} &= -\langle(A-B_0R^{-1}\delta_{\sigma=0}\mathcal{P}_0^{2*}(t,\sigma))x_1,\mathcal{P}_0^1(t)x_2\rangle_{\mathbb{R}^n}\\ &\quad -\langle\mathcal{P}_0^1(t)x_1,(A-B_0R^{-1}\delta_{\sigma=0}\mathcal{P}_0^{2*}(t,\sigma))x_2\rangle_{\mathbb{R}^n}\\ &\quad +\langle B_0^T\mathcal{P}_0^1(t)x_1,R^{-1}B_0^T\mathcal{P}_0^1(t)x_2\rangle_{\mathbb{R}^n}\\ &\quad +\langle\delta_{\sigma=0}\mathcal{P}_0^{2*}(t,\sigma)x_1,R^{-1}\delta_{\sigma=0}\mathcal{P}_0^{2*}(t,\sigma)x_2\rangle_{\mathbb{R}^m}\\ &\quad -\langle Cx_1,Cx_2\rangle_{\mathbb{R}^p},\\ \mathcal{P}_0^1(T)x_1 &= G(T)x_1\quad\forall x_1,x_2\in\mathbb{R}^n;\end{cases} \tag{5.24}$$

$$\begin{cases}0=-\langle\mathcal{P}_0^1(t)B_1\delta_{\sigma=-1}y,x\rangle_{\mathbb{R}^n}+\langle\mathcal{P}_0^1(t)B_0R^{-1}\delta_{\sigma=0}\mathcal{P}_0^3(t)y,x\rangle_{\mathbb{R}^n}\\ \qquad+\langle\delta_{\sigma=0}\mathcal{P}_0^3(t)y,R^{-1}\delta_{\sigma=0}\mathcal{P}_0^{2*}(t,\sigma)x\rangle_{\mathbb{R}^m}-\langle Dy,\mathcal{P}_0^{2*}(t,.)x\rangle_{L^2},\\ \mathcal{P}_0^{2*}(t,-1)x=B_1^T\mathcal{P}_0^1(t)x\quad\forall x\in\mathbb{R}^n,\forall y\in H^1;\end{cases} \tag{5.25}$$

$$\begin{cases}0=-\langle Dy,\mathcal{P}_0^3(t)z\rangle_{L^2}-\langle\mathcal{P}_0^3(t)y,Dz\rangle_{L^2}+\langle\delta_{\sigma=0}\mathcal{P}_0^3(t)y,R^{-1}\delta_{\sigma=0}\mathcal{P}_0^3(t)z\rangle_{\mathbb{R}^m}\\ \mathcal{P}_0^3(t)y(-1)=0\quad\forall y,z\in H^1.\end{cases} \tag{5.26}$$

This last equation may be viewed as the stationary Riccati equation associated to the control problem

$$\begin{cases}\dfrac{\partial Y}{\partial t}(t,\sigma)=DY(t,\sigma)+\delta_{\sigma=0}^*u(t),\ \text{a.e. } t\ge 0\\ u\in L^2(0,\infty;\mathbb{R}^m),\ Y(0,\sigma)\in L^2(-1,0;\mathbb{R}^m),\\ \min\limits_{u\in L^2(0,\infty;\mathbb{R}^m)}J(Y,u)=\displaystyle\int_0^\infty\frac{1}{2}\langle u,Ru(t)\rangle_{\mathbb{R}^m}dt.\end{cases} \tag{5.27}$$

Now we point out that this function Y we wish to control satisfies the equation of transport associated to a unit delay ($h=1$). That is, Y is given by

$$Y(t,\sigma)=u(t+\sigma h)_{|_{h=1}}=u(t+\sigma),\quad -1\le\sigma\le 0. \tag{5.28}$$

Therefore the optimal command for the quadratic control problem (5.27) is the input $u \equiv 0$ in $L^2(-1,0;\mathbb{R}^m)$, which implies that the solution of (5.26) is

$$\mathcal{P}_0^3(t) \equiv 0 \text{ in } L^2(-1,0;\mathbb{R}^m), \tag{5.29}$$

which agrees with the limiting condition $[\mathcal{P}_0^3(t)y](-1) = 0$.

Now let us clarify the relationship between $\mathcal{P}_0^2$ and $\mathcal{P}_0^1$, which satisfy the system

$$\left\{ \begin{array}{l} 0 = \langle \mathcal{P}_0^1(t) B_1 \delta_{\sigma=-1} y, x\rangle_{\mathbb{R}^n} + \langle Dy, \mathcal{P}_0^{2*}(t,.)x\rangle_{L^2}, \\ \mathcal{P}_0^{2*}(t,-1)x = B_1^T \mathcal{P}_0^1(t)x \quad \forall x \in \mathbb{R}^n,\ \forall y \in H^1. \end{array} \right. \tag{5.30}$$

By transposition, we get $\mathcal{P}_0^2(t,.)D = -\mathcal{P}_0^1(t)B_1\delta_{\sigma=-1}$ so that multiplying on the right side with the inverse of the operator $D = \frac{\partial}{\partial\sigma}$ yields

$$\begin{array}{rcl} \mathcal{P}_0^2(t)y & = & -\mathcal{P}_0^1(t)B_1\delta_{\sigma=-1}\displaystyle\int_\sigma^0 y(s)ds \\ & = & -\mathcal{P}_0^1(t)B_1\displaystyle\int_{-1}^0 y(s)ds = -\mathcal{P}_0^1(t)B_1\mathcal{I}_m y \quad \forall y \in L^2(-1,0;\mathbb{R}^m). \end{array} \tag{5.31}$$

There remains the computation of $\mathcal{P}_0^1$. For this we need further insight in the expression $\mathcal{P}_0^{2*}(t,0)$, so we shall apply the integration by parts formula to the factor $\langle Dy, \mathcal{P}_0^{2*}(t,.)x\rangle_{L^2}$. Taking $y \in \mathcal{D}(D) = \{y \in H^1(-1,0;\mathbb{R}^m,\ y(0) = 0\}$, we get

$$\langle Dy, \mathcal{P}_0^{2*}(t,.)x\rangle_{L^2} = -\langle y, D\mathcal{P}_0^{2*}(t,.)x\rangle_{L^2} - \langle \varphi(-1), \mathcal{P}_0^{2*}(t,-1)x\rangle_{\mathbb{R}^m}, \tag{5.32}$$

so (5.30) becomes

$$\left\{ \begin{array}{l} 0 = \langle y, D\mathcal{P}_0^{2*}(t,.)x\rangle_{L^2}\ \forall \begin{pmatrix} x \\ y \end{pmatrix} \in \mathbb{R}^n \times \mathcal{D}(D), \\ \mathcal{P}_0^{2*}(t,-1)x = B_1^T\mathcal{P}_0^1(t)x. \end{array} \right. \tag{5.33}$$

With a density argument, we deduce that the linear form

$$y \to \langle y(\sigma), D\mathcal{P}_0^{2*}(t,\sigma)x\rangle_{L^2} = \int_{-1}^0 \langle y(\sigma), \frac{\partial}{\partial\sigma}\mathcal{P}_0^{2*}(t,\sigma)x\rangle_{\mathbb{R}^m} d\sigma$$

is identically equal to zero on $H^1(-1,0;\mathbb{R}^m)$, and then $\int_{-1}^0 \frac{\partial}{\partial\sigma}\mathcal{P}_0^{2*}(t,\sigma)x d\sigma = 0$. So finally we have

$$\mathcal{P}_0^{2*}(t,0)x = \mathcal{P}_0^{2*}(t,-1)x = B_1^T\mathcal{P}_0^1(t)x \quad \forall x \in \mathbb{R}^n. \tag{5.34}$$

Because $\forall x \in \mathbb{R}^n$, we have $\delta_{\sigma=0}\mathcal{P}_0^{2*}(t,\sigma)x = B_1^T\mathcal{P}_0^1(t)x$, we see that $\mathcal{P}_0^1$ satisfies

$$\left\{ \begin{array}{lcl} \langle \dot{\mathcal{P}}_0^1(t)x_1, x_2\rangle_{\mathbb{R}^n} & = & -\langle (A - B_0R^{-1}B_1^T\mathcal{P}_0^1(t))x_1, \mathcal{P}_0^1(t)x_2\rangle_{\mathbb{R}^n} \\ & & -\langle \mathcal{P}_0^1(t)x_1, (A - B_0R^{-1}B_1^T\mathcal{P}_0^1(t)x_2\rangle_{\mathbb{R}^n} \\ & & +\langle B_0^T\mathcal{P}_0^1(t)x_1, R^{-1}B_0^T\mathcal{P}_0^1(t)x_2\rangle_{\mathbb{R}^n} \\ & & +\langle B_1^T\mathcal{P}_0^1(t)x_1, R^{-1}B_1^T\mathcal{P}_0^1(t)x_2\rangle_{\mathbb{R}^m} - \langle Cx_1, Cx_2\rangle_{\mathbb{R}^p}, \\ \mathcal{P}_0^1(T)x_1 & = & G(T)x_1 \quad \forall\, x_1, x_2 \in \mathbb{R}^n. \end{array} \right. \tag{5.35}$$

Thus, recalling that $B = B_0 + B_1$, we may write

$$\left\{ \begin{array}{lcl} \langle \dot{\mathcal{P}}_0^1(t)x_1, x_2\rangle_{\mathbb{R}^n} & = & -\langle \mathcal{P}_0^1(t)x_1, Ax_2\rangle_{\mathbb{R}^n} - \langle \mathcal{P}_0^1(t)x_1, A\mathcal{P}_0^1(t)x_2\rangle_{\mathbb{R}^n} \\ & & +\langle B^T\mathcal{P}_0^1(t)x_1, R^{-1}B^T\mathcal{P}_0^1(t)x_2\rangle_{\mathbb{R}^n} - \langle Cx_1, Cx_2\rangle_{\mathbb{R}^p}, \\ \mathcal{P}_0^1(T)x_1 & = & Gx_1 \quad \forall\, x_1, x_2 \in \mathbb{R}^n, \end{array} \right. \tag{5.36}$$

which means that $\mathcal{P}_0^1 = P_T$, the unique solution of (5.5), thus completing the proof of formula (5.4).

For approximation of the 1-1-block of $\mathcal{P}_{T,h}$ (equation (5.6)) let us assume that

$$\mathcal{P}_h^1(t) = [\mathcal{P}_0^1 + h\mathcal{P}_h^{1,r}](t), \quad t \in [0,T].$$

Then we have

$$(5.37)\begin{cases} \langle \dot{\mathcal{P}}_h^{1,r}(t)x_1, x_2\rangle_{\mathbb{R}^n} &= -\langle (A - B_0R^{-1}\delta_{\sigma=0}\mathcal{P}_h^{2*}(t,\sigma))x_1, \mathcal{P}_h^{1,r}(t)x_2\rangle_{\mathbb{R}^n} \\ & \quad -\langle \mathcal{P}_h^{1,r}(t)x_1, (A - B_0R^{-1}\delta_{\sigma=0}\mathcal{P}_h^{2*}(t,\sigma))x_2\rangle_{\mathbb{R}^n} \\ & \quad +\langle B_0^T\mathcal{P}_h^1(t)x_1, R^{-1}B_0^T\mathcal{P}_h^{1,r}(t)x_2\rangle_{\mathbb{R}^n} \\ & \quad +\langle B_0^T\mathcal{P}_h^{1,r}(t)x_1, R^{-1}B_0^T\mathcal{P}_h^{1,r}(t)x_2\rangle_{\mathbb{R}^n} \\ & \quad +h\,\langle B_0^T\mathcal{P}_h^{1,r}(t)x_1, R^{-1}B_0^T\mathcal{P}_0^1(t)x_2\rangle_{\mathbb{R}^n}, \\ \mathcal{P}_h^{1,r}(T)x_1 &= 0 \quad \forall\, x_1, x_2 \in \mathbb{R}^n, \end{cases}$$

and passing to the limit with $(\mathcal{P}_0^{1,r}(t),\ \dot{\mathcal{P}}_0^{1,r}(t)) = w - \lim_{h\to 0}(\mathcal{P}_h^{1,r}(t),\ \dot{\mathcal{P}}_h^{1,r}(t))$, and recalling that $\mathcal{P}_0^{2*}(t,0) = B_1^T\mathcal{P}_0^1(t)$, we get

$$(5.38)\quad \begin{cases} \langle \dot{\mathcal{P}}_0^{1,r}(t)x_1, x_2\rangle_{\mathbb{R}^n} &= -\langle (A - BR^{-1}B^T\mathcal{P}_0^1(t))x_1, \mathcal{P}_0^{1,r}(t)x_2\rangle_{\mathbb{R}^n} \\ & \quad -\langle \mathcal{P}_0^{1,r}(t)x_1, (A - BR^{-1}B^T\mathcal{P}_0^1(t))x_2\rangle_{\mathbb{R}^n}, \\ \mathcal{P}_0^{1,r}(T)x_1 &= 0\ \forall\, x_1, x_2 \in \mathbb{R}^n, \end{cases}$$

so that $(\frac{d\mathcal{P}_{T,h}^1}{dt}(t),\ \mathcal{P}_0^{1,r}(t)) \equiv (0,0)$. This implies

$$(5.39)\qquad \left(\frac{d\mathcal{P}_{T,h}^1}{dt}(t),\ \mathcal{P}_{T,h}^1(t)\right) = \left(\frac{dP_T}{dt}(t),\ P_T(t)\right) + o(h) \ \text{ for } \ t \in [0,T],$$

which ends the proof of item (i).

Finally, we observe that item (ii) can be derived in a similar way, thus completing the proof. □

6. Proof of main results. The proofs of Theorems 2.1 and 2.2, identical in principle, are based on Theorems 5.1 and 5.2, respectively. We restrict ourselves to the first one.

Proof of Theorem 2.1. As pointed out in section 3, we may also restrict ourselves to $I = J = 1$.

Proof of (i). Recall that $\widehat{J_T}(0,0) = \frac{1}{2}\langle x_{00}, P_T(0)x_{00}\rangle_{\mathbb{R}^n}$ and that we also have

$$(6.1)\ \widehat{J_T}(0,h) = \frac{1}{2}\langle x_{00}, \mathcal{P}_h^1(0)x_{00}\rangle_{\mathbb{R}^n} + \frac{h}{2}[2\langle x_{00}, \mathcal{P}_h^2(0)\varphi^h\rangle_{L^2} + \langle \varphi^h, \mathcal{P}_h^3(0)\varphi^h\rangle_{L^2}].$$

Now, in view of Theorem 5.1(i), which ensures that $\mathcal{P}_h^1(0) = P_T(0) + o(h)$, we have

$$(6.2)\qquad \widehat{J_T}(0,0) = \frac{1}{2}\left\langle x_{00},\ \mathcal{P}_h^1(0)x_{00}\right\rangle_{\mathbb{R}^n} + o(h)\langle x_{00},\ x_{00}\rangle_{\mathbb{R}^n}.$$

Moreover, from Theorem 5.1, we also have

$$(6.3)\qquad \lim_{h\to 0}\langle y, \mathcal{P}_h^3(0)y\rangle_{L^2} = 0\ \forall y \in L^2$$

so that

$$\lim_{h\to 0}\frac{\widehat{J_T}(0,h)-\widehat{J_T}(0,0)}{h}=\lim_{h\to 0}\langle x_{00},\ \mathcal{P}_h^2(0)\varphi^h\rangle_{L^2} \tag{6.4}$$

$$=-\left\langle B_1^TP_T(0)x_{00},\ \lim_{h\to 0}\int_{-1}^0 u(\sigma h)d\sigma\right\rangle_{\mathbb{R}^m} \tag{6.5}$$

(recall that $\varphi^h(\sigma)=u(\sigma h)$)

$$=-\left\langle B_1^TP_T(0)x_{00},\ \lim_{h\to 0}\frac{1}{h}\int_{-h}^0 u(\theta)d\theta\right\rangle_{\mathbb{R}^m}. \tag{6.6}$$

The continuity of u on the left side of 0 allows us to write

$$\lim_{h\to 0}\frac{1}{h}\int_{-h}^0 u(\theta)d\theta=u(0)=-R^{-1}B^TP_T(0)x_{00}. \tag{6.7}$$

Therefore we have

$$\lim_{h\to 0}\frac{\widehat{J_T}(0,h)-\widehat{J_T}(0,0)}{h}=\langle x_{00},\Delta_1(P_T)x_{00}\rangle_{\mathbb{R}^n} \tag{6.8}$$

with $\Delta_1(P_T)=P(0)B_1R^{-1}B^TP_T(0)$, which we wished to prove.

Proof of (ii) Clearly, in view of Theorem 5.2(i), we have

$$\lim_{k\to 0}\frac{\widehat{J_T}(k,0)-\widehat{J_T}(0,0)}{k}=\lim_{k\to 0}\left\langle x_{00},\ \mathcal{Q}_k^2(0)\psi^k\right\rangle_{L^2}, \tag{6.9}$$

and this readily turns into

$$\lim_{k\to 0}\frac{\widehat{J_T}(k,0)-\widehat{J_T}(0,0)}{k}=-\langle A_1^TP_T(0)x_{00},\ \lim_{k\to 0}\int_{-1}^0\psi^k(\sigma)d\sigma\rangle_{\mathbb{R}^n} \tag{6.10}$$

$$=-\langle A_1^TP_T(0)x_{00},\ \lim_{k\to 0}\int_{-1}^0 x_0(\sigma k)d\sigma\rangle_{\mathbb{R}^n}. \tag{6.11}$$

From continuity of x at 0, we get

$$\lim_{k\to 0}\int_{-1}^0 x_0(\sigma k)d\sigma=\lim_{k\to 0}\frac{1}{k}\int_{-k}^0 x_0(\theta)d\theta\rangle_{\mathbb{R}^n}=x_0(0)=x_{00}, \tag{6.12}$$

and then

$$\lim_{k\to 0}\frac{\widehat{J_T}(k,0)-\widehat{J_T}(0,0)}{k}=-\langle A_1x_{00},\ P(0)x_{00}\rangle_{\mathbb{R}^n}, \tag{6.13}$$

which ends this proof. □

7. Application to sensitivity of $\mathcal{H}_\infty$ robust performance. As a typical example of $\mathcal{H}_\infty$ suboptimal control we consider the system

$$\begin{cases}\dot{x}(t)=Ax(t-k)+B_0u(t)+B_1u(t-h)+B_dw(t)\quad \text{a.e. } t\geq 0,\\ z(t)=Cx(t)+Du(t),\\ x(0)=x_{00}\in\mathbb{R}^n,\quad x=x_0 \text{ a.e. } t\in[-k,0],\quad u=u_0 \text{ a.e. } t\in[-h,0],\\ x_0\in L^2(-k,0;\mathbb{R}^n),\quad u\in L^2(-h,\infty;\mathbb{R}^m),\quad w\in L^2(0,\infty;\mathbb{R}^q),\end{cases} \tag{7.1}$$

where $(A, B_d, B_1) \in \mathcal{L}(\mathbb{R}^n \times \mathbb{R}^q \times \mathbb{R}^m, \mathbb{R}^n)$ and $(C, D) \in \mathcal{L}(\mathbb{R}^n \times \mathbb{R}^m, \mathbb{R}^p)$, with the objective of ensuring a given level of disturbance attenuation. We recall (see Tadmor [28]) that for $\gamma > 0$, the inequality $\|z\|_{L^2(0,\infty;\mathbb{R}^p)} < \gamma^2 \|w\|_{L^2(0,\infty;\mathbb{R}^q)}$ is achievable if and only if there exists a control $u_\gamma \in L^2(0,\infty;\mathbb{R}^m)$ that realizes

$$\widehat{J}_\gamma(k,h) = \sup_{w \in L^2(0,\infty;\mathbb{R}^q)} \inf_{u \in L^2(0,\infty;\mathbb{R}^m)} \frac{1}{2} \{\|z\|_{L^2(0,\infty;Z)} - \gamma^2 \|w\|_{L^2(0,\infty;\mathbb{R}^q)}\}. \tag{7.2}$$

Assume that the initial conditions u_0 and x_0 are continuous on the left side of 0, the triple (A, B_1, C) is controllable and observable, $D^T[C\ D] = [0\ R]$ with R positive definite, and moreover there exists some $\varepsilon > 0$ such that $\forall\ (\omega, x, u) \in \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m$ satisfying $j\omega x = Ax + Bu$ we have $\|Cx + Du\|_{\mathbb{R}^p} \geq \varepsilon \|x\|_{\mathbb{R}^n}$. Then it is known from Glover and Doyle [17] that $\widehat{J}_\gamma(0,0)$ exists if and only if there exists a nonnegative solution to the Riccati equation

$$A^T P_\gamma + P_\gamma A + P_\gamma(\gamma^{-2} B_d B_d^T - B R^{-1} B^T) P_\gamma + C^T C = 0, \tag{7.3}$$

where $B = B_0 + B_1$. Then we have the following statement.

THEOREM 7.1. *Take a $\gamma > 0$ such that there exists a nonnegative solution to the Riccati equation* (7.3). *Assume that there exists some neighborhood of* $(0,0)$ *where* $(k,h) \longrightarrow J^\gamma(k,h)$ *is well defined. Then, with* x_0 *continuous on the left side of* 0, *we have*

$$\frac{\partial \widehat{J}_\gamma(0,0)}{\partial k} = \langle P_\gamma x_{00}, A x_{00} \rangle_{\mathbb{R}^n}, \tag{7.4}$$

$$\frac{\partial \widehat{J}_\gamma(0,0)}{\partial h} = -\langle P_\gamma x_{00}, B_1 R^{-1} B^T P_\gamma x_{00} \rangle_{\mathbb{R}^n}. \qquad \square \tag{7.5}$$

For instance, this theorem says that if $B_0 = 0$ and h is sufficiently small, then we have: $\frac{\partial \widehat{J}_\gamma(0,0)}{\partial h} = -\langle x_{00}, K_\gamma R K_\gamma x_{00} \rangle_{\mathbb{R}^n} \leq 0$, where $K_\gamma = -R^{-1} B_1^T P_\gamma$ is the nondelay $\mathcal{H}_\infty$ suboptimal gain, so that $\widehat{J}_\gamma(0,h) \leq \widehat{J}_\gamma(0,0) \leq 0$. This means that *even if there exists a γ-admissible feedback for a small $h > 0$*, the corresponding closed loop system is less robust than the closed loop system, ensuring the disturbance attenuation at the same level without delay. Moreover, for a given γ, the degradation of the robust performance due to the presence of a small input delay is proportional to the square of the nondelay $\mathcal{H}_\infty$ suboptimal gain.

Sketch of the proof. Briefly, we only recast the problem of sensitivity analysis in the framework previously introduced for the LQ optimal case and use a Riccati-type result given by Van Keulen [29] for $\mathcal{H}_\infty$ control in the Pritchard and Salamon class. Then we have analogues of Propositions 4.8 and 4.6 (likewise for Theorems 5.1(ii) and 5.2(ii)). In the following, we survey the main lines of the retarded input case.

First, we observe that with $\mathcal{B}_d = \binom{B_d}{0} \in \mathcal{L}(\mathbb{R}^q, \mathcal{H}^m)$, a product-space description of (7.1) is obtained in $\mathcal{H}^m$ by adding the input $\mathcal{B}_d w$ to the equation of evolution (3.4). That is, the solution x is the first component of

$$Y_h(t,\sigma) = \mathcal{S}_h(t) \begin{pmatrix} x_{00} \\ \varphi_h(\sigma) \end{pmatrix} + \int_0^t \mathcal{S}_h(t-s)\{\mathcal{B}_d w(s) + \mathcal{B}_h u(s)\} ds, \tag{7.6}$$

and setting $\mathcal{C}_h = (\,C \quad 0\,) \in \mathcal{L}(\mathcal{H}^m, \mathbb{R}^q)$ gives

$$z(t) = \mathcal{C}_h Y_h(t,\sigma) + Du(t), \tag{7.7}$$

with $(\mathcal{S}_h, \mathcal{B}_h, \mathcal{C}_h) \in \mathcal{C}_{PS}(\mathcal{H}^m, \mathcal{D}(\mathcal{A}_h^*)', \mathbb{R}^m, \mathbb{R}^p)$ (see Proposition 4.2(i)). Now we remark that if there exists some feedback $F \in \mathcal{L}(\mathcal{H}^m, \mathbb{R}^m)$ (an admissible output operator) such that the semigroup

$$\mathcal{S}_{\mathcal{B}_{h^F}}(t)x = \mathcal{S}_h(t)x + \int_0^t \mathcal{S}_h(t-s)\mathcal{B}_h F\, \mathcal{S}_{\mathcal{B}_{h^F}}(s)x ds, \quad t \geq 0, \quad x \in \mathcal{H}^m, \tag{7.8}$$

is exponentially stable on $\mathcal{D}(\mathcal{A}_h^*)'$, then with [29, Lemma 2.14], we get

$$\begin{cases} Y_h(t,\sigma) &= \mathcal{S}_{\mathcal{B}_{h^F}}(t)\begin{pmatrix} x_{00} \\ \varphi_h(\sigma)\end{pmatrix} + \displaystyle\int_0^t \mathcal{S}_{\mathcal{B}_{h^F}}(t-s)\mathcal{B}_d w(s) ds, \\ z(t) &= (\mathcal{C}_h + DF)Y_h(t,\sigma). \end{cases} \tag{7.9}$$

Moreover, we then have regular $(\mathcal{S}_{\mathcal{B}_{h^F}}, \mathcal{B}_d, (\mathcal{C}_h + DF)) \in \mathcal{C}_{PS}(\mathcal{H}^m, \mathcal{D}(\mathcal{A}_h^*)', \mathbb{R}^m, \mathbb{R}^p)$, and it follows from [29, Lemma 3.2] that the linear operator $G_{\mathcal{B}_{h^F}}$ defined by

$$G_{\mathcal{B}_{h^F}} w(t) = (\mathcal{C}_h + DF)\int_0^t \mathcal{S}_{\mathcal{B}_{h^F}}(t-s)\mathcal{B}_d w(s) ds \tag{7.10}$$

satisfies

$$G_{\mathcal{B}_{h^F}} \in \mathcal{L}(L^2(0,\infty;\mathbb{R}^q), L^2(0,\infty;\mathbb{R}^p)). \tag{7.11}$$

The feedback $F \in \mathcal{L}(\mathcal{H}^m, \mathbb{R}^m)$ will be said to be γ-admissible for system (7.6)–(7.7) if it is an admissible output operator for $\mathcal{H}^m$ and $\mathcal{D}(\mathcal{A}_h^*)'$ with respect to $\mathcal{S}_h$, such that the semigroup $\mathcal{S}_{\mathcal{B}_{h^F}}$ is exponentially stable on $\mathcal{D}(\mathcal{A}_h^*)'$ and $G_{\mathcal{B}_{h^F}}$ satisfies $\|G_{\mathcal{B}_{h^F}}\| \leq \gamma$.

Then the solution of problem (7.2) comes from Van Keulen [29, Theorem 4.4]. That is, assuming that there exists $\varepsilon > 0$ such that $\forall(\omega, X, u) \in \mathbb{R} \times \mathcal{D}(\mathcal{A}_h) \times \mathbb{R}^m$ satisfying $j\omega X = \mathcal{A}_h X + \mathcal{B}_h u$, we have $\|\mathcal{C}_h X + Du\|_{\mathbb{R}^p} \geq \varepsilon \|X\|_{\mathcal{H}^m}$ and that $D^T[C\ D] = [0\ R]$ with R positive; the two following items are equivalent.

(1) There exists a γ-admissible feedback for the system (7.6)–(7.7).

(2) There exists a unique operator $\mathcal{P}_{\gamma,h} \in \sigma^+[\mathcal{D}(\mathcal{A}_h^*)']$ solution of the Riccati equation (in $\mathcal{H}^m$)

$$\mathcal{A}_h^* \mathcal{P}_{\gamma,h} + \mathcal{P}_{\gamma,h}\mathcal{A}_h + \mathcal{P}_{\gamma,h}(\gamma^{-2}\mathcal{B}_d\mathcal{B}_d^* - \mathcal{B}_h R^{-1}\mathcal{B}_h^*)\mathcal{P}_{\gamma,h} + \mathcal{C}_h^*\mathcal{C}_h = 0. \tag{7.12}$$

Moreover, the feedback $F_\gamma = -R^{-1}\mathcal{B}_h^*\mathcal{P}_{\gamma,h}$ is γ-admissible and the input $u_\gamma(t,h) = F_\gamma Y_h(t,.)$ achieves

$$\widehat{J}_\gamma(0,h) = -\frac{1}{2}\langle Y_h(0,.), \mathcal{P}_{\gamma,h} Y_h(0,.)\rangle_{\mathcal{H}^m}. \tag{7.13}$$

The rest of the proof is easy. Observing that Proposition 4.8 still holds when taking $\mathcal{P}_{\gamma,h}$ as a substitute for $\mathcal{P}_h$, and setting

$$\mathcal{P}_{\gamma,h} = \begin{pmatrix} \mathcal{P}^1_{\gamma,h} & h\mathcal{P}^2_{\gamma,h} \\ h\mathcal{P}^{2*}_{\gamma,h} & h\mathcal{P}^3_{\gamma,h} \end{pmatrix}$$

in $\mathcal{L}(\mathcal{H}^m)$, we get the following equations:

$$\begin{cases} \forall x_1, x_2 \in \mathbb{R}^n & : \\ 0 &= -\langle (A - B_0 R^{-1}\delta_{\sigma=0}\mathcal{P}^{2*}_{\gamma,h})x_1, \mathcal{P}^1_{\gamma,h}x_2\rangle_{\mathbb{R}^n} \\ & \quad -\langle \mathcal{P}^1_{\gamma,h}(t)x_1, (A - B_0 R^{-1}\delta_{\sigma=0}\mathcal{P}^{2*}_{\gamma,h})x_2\rangle_{\mathbb{R}^n} \\ & \quad +\langle B_0^T\mathcal{P}^1_{\gamma,h}x_1, R^{-1}B_0^T\mathcal{P}^1_{\gamma,h}x_2\rangle_{\mathbb{R}^n} \\ & \quad +\gamma^{-2}\langle B_d^T\mathcal{P}^1_{\gamma,h}x_1, B_d^T\mathcal{P}^1_{\gamma,h}x_2\rangle_{\mathbb{R}^n} \\ & \quad +\langle \delta_{\sigma=0}\mathcal{P}^{2*}_{\gamma,h}x_1, R^{-1}\delta_{\sigma=0}\mathcal{P}^{2*}_{\gamma,h}x_2\rangle_{\mathbb{R}^m} + \langle Cx_1, Cx_2\rangle_{\mathbb{R}^p}, \end{cases} \tag{7.14}$$

$$
(7.15)\quad \left\{\begin{array}{lcl}
\forall x\in\mathbb{R}^n, & & \forall y\in H^1:\\
0 & = & -\langle \mathcal{P}^1_{\gamma,h}B_1\delta_{\sigma=-1}y,x\rangle_{\mathbb{R}^n}+\langle \mathcal{P}^1_{\gamma,h}B_0R^{-1}\delta_{\sigma=0}\mathcal{P}^3_{\gamma,h}y,x\rangle_{\mathbb{R}^n}\\
& & +\langle \delta_{\sigma=0}\mathcal{P}^3_{\gamma,h}y,R^{-1}\delta_{\sigma=0}\mathcal{P}^{2*}_{\gamma,h}x\rangle_{\mathbb{R}^m}-\langle Dy,\mathcal{P}^{2*}_{\gamma,h}x\rangle_{L^2}\\
& & +h\{\langle \mathcal{P}^2_{\gamma,h}y,Ax\rangle_{\mathbb{R}^n}-\langle B_0^T\mathcal{P}^2_h y,R^{-1}B_0^T\mathcal{P}^1_{\gamma,h}x\rangle_{\mathbb{R}^n}\\
& & -\langle B_0^T\mathcal{P}^2_{\gamma,h}y,R^{-1}\delta_{\sigma=0}\mathcal{P}^{2*}_{\gamma,h}x\rangle_{\mathbb{R}^m}\},\\
\mathcal{P}^{2*}_{\gamma,h}(-1) & = & B_1^T\mathcal{P}^1_{\gamma,h},
\end{array}\right.
$$

and

$$
(7.16)\quad \left\{\begin{array}{lcl}
\forall y\in H^1, & & \forall z\in H^1:\\
0 & = & -\langle Dy,\mathcal{P}^3_h(t)z\rangle_{L^2}-\langle \mathcal{P}^3_{\gamma,h}y,Dz\rangle_{L^2}\\
& & +\langle \delta_{\sigma=0}\mathcal{P}^3_h y,R^{-1}\delta_{\sigma=0}\mathcal{P}^3_{\gamma,h}z\rangle_{\mathbb{R}^m}\\
& & +h\{\langle B_0^T\mathcal{P}^2_{\gamma,h}y,R^{-1}\delta_{\sigma=0}\mathcal{P}^3_{\gamma,h}z\rangle_{\mathbb{R}^m}\\
& & +\langle B_0^T\mathcal{P}^2_{\gamma,h}z,R^{-1}\delta_{\sigma=0}\mathcal{P}^3_{\gamma,h}y\rangle_{\mathbb{R}^m}\\
& & -\langle B_1\delta_{\sigma=-1}y,\mathcal{P}^2_{\gamma,h}z\rangle_{\mathbb{R}^n}-\langle \mathcal{P}^2_{\gamma,h}y,B_1\delta_{\sigma=-1}z\rangle_{\mathbb{R}^n}\}\\
& & +h^2\langle B_0^T\mathcal{P}^2_{\gamma,h}z,R^{-1}B_0^T\mathcal{P}^2_{\gamma,h}y\rangle_{\mathbb{R}^m},\\
\mathcal{P}^3_{\gamma,h}y(-1) & = & hB_1^T\mathcal{P}^2_{\gamma,h}y.
\end{array}\right.
$$

Remark 7.1. Except for the term $\gamma^{-2}B_dB_d^T$ in (7.21), we have to deal with the set of equations satisfied by the components of the decomposition of $\mathcal{P}_h$ (cf. (4.24) to (4.26) and Remark 4.3). Therefore Theorem 5.1(i) remains true when setting $\mathcal{P}_{\gamma,h}$ as a substitute for $\mathcal{P}_h$ and P_γ for $\mathcal{P}_\infty$. Thus, in particular, we have

$$
(7.17)\qquad \mathcal{P}^1_{\gamma,h}=P_\gamma+o(h),\quad w-\lim_{h\to0}\mathcal{P}^3_{\gamma,h}=0,
$$

$$
(7.18)\qquad w-\lim_{h\to0}\mathcal{P}^2_{\gamma,h}y=-P_\gamma B_1\int_{-1}^0 y(\sigma)d\sigma\quad\forall y\in L^2(-1,0;\mathbb{R}^m).\qquad\square
$$

Therefore we get

$$
\lim_{h\to0}\frac{\widehat{J}_\gamma(0,h)-\widehat{J}_\gamma(0,0)}{h}=-\lim_{h\to0}\langle x_{00},\,\mathcal{P}^2_{\gamma,h}\varphi^h\rangle_{L^2}=\langle B_1^T\mathcal{P}_\gamma x_{00},\,\lim_{h\to0}\int_{-1}^0\varphi^h(\sigma)d\sigma\rangle_{L^2}.
$$

But $\varphi^h(\sigma)=u_0(\sigma h)$ so that $\int_{-1}^0\varphi^h(\sigma)d\sigma=\frac{1}{h}\int_{-h}^0 u_0(\theta)d\theta$ and then with continuity of u on the left side of 0 we have

$$
\lim_{h\to0}\int_{-1}^0\varphi^h(\sigma)d\sigma=\lim_{h\to0}\frac{1}{h}\int_{-h}^0 u_0(\theta)d\theta=u_\gamma(0)=-R^{-1}B^TP_\gamma x_{00}.
$$

So finally we get

$$
\lim_{h\to0}\frac{\widehat{J}_\gamma(0,h)-\widehat{J}_\gamma(0,0)}{h}=-\langle x_{00},P_\gamma B_1R^{-1}B^TP_\gamma x_{00}\rangle_{\mathbb{R}^n},
$$

which we aimed to prove. $\square$

8. Conclusion. In this paper, we have considered the sensitivity of the optimal cost for linear time invariant systems with respect to small delays. We have given a new approach to solving this problem and provided new results. Related topics of interest, such as providing a measure of degradation for when the delay free optimal feedback is implemented on the delayed model, are under investigation.

Appendix.

A.1. Proof of Proposition 3.1. Part (i). The characterization of the C_0-semigroup $\mathcal{S}_h$ and $\mathcal{A}_h$ and Part (i) follows easily from a rescaling in the standard form of the solution semigroup for the delay equation (see, e.g., [16]). This semigroup is given as $\mathcal{S}_h(t) = \left(\begin{smallmatrix} \mathcal{S}_{11}(t) & \mathcal{S}_{12}(t) \\ 0 & \mathcal{S}_{22}(t) \end{smallmatrix}\right)$, where $\mathcal{S}_{11}(t) \in \mathcal{L}(\mathbb{R}^n)$, $\mathcal{S}_{12}(t) \in \mathcal{L}((L^2(-1,0;\mathbb{R}^m),\mathbb{R}^n)$ and $\mathcal{S}_{22}(t) \in \mathcal{L}(L^2(-1,0;\mathbb{R}^m))$ are given by

$$\begin{array}{rcl} \mathcal{S}_{11}(t) & = & e^{At}, \quad \mathcal{S}_{12}(t)z = h\displaystyle\int_0^{\frac{t}{h}} e^{A(t-\sigma h)} B_1 z(\sigma-1)d\sigma, \\ \mathcal{S}_{22}(t) & = & T\left(\dfrac{t}{h}\right), \text{ with } T(t) \text{ semigroup of translation in } L^2(-1,0;\mathbb{R}^m). \end{array} \tag{A.1}$$

Now let us characterize the adjoint of $\mathcal{A}_h$. For this, taking some $\left(\begin{smallmatrix} x \\ z \end{smallmatrix}\right) \in \mathcal{D}(\mathcal{A}_h)$, consider $\left(\begin{smallmatrix} v \\ w \end{smallmatrix}\right) \in \mathcal{D}(\mathcal{A}_h^*)$ and $\left(\begin{smallmatrix} f \\ g \end{smallmatrix}\right) \in \mathcal{H}^m$ such that

$$\begin{aligned} \left\langle \mathcal{A}_h \begin{pmatrix} x \\ z \end{pmatrix}, \begin{pmatrix} v \\ w \end{pmatrix} \right\rangle_{\mathcal{H}} &= \langle Ax + B_1 z(-1), v\rangle_{\mathbb{R}^n} + \frac{1}{h}\int_{-1}^0 \langle Dz, w\rangle_{\mathbb{R}^m} d\sigma \\ &= \langle x, f\rangle_{\mathbb{R}^n} + \int_{-1}^0 \langle z, g\rangle_{\mathbb{R}^m} d\sigma. \end{aligned}$$

So choosing $z = 0$, we get $\langle Ax, v\rangle_{\mathbb{R}^n} = \langle x, f\rangle_{\mathbb{R}^n}$. So $v \in \mathbb{R}^n$ and $A^T v = f$.

Moreover, since $\int_{-1}^0 \langle z, g\rangle_{\mathbb{R}^m} d\sigma = -\int_{-1}^0 \langle Dz, \int_{-1}^\sigma g(s)ds\rangle_{\mathbb{R}^m} d\sigma$, we have $\int_{-1}^0 \langle Dz, \frac{1}{h}w - B_1^T v + \int_{-1}^\sigma g(s)ds\rangle_{\mathbb{R}^m} d\sigma = 0$. Therefore $w = h(B_1^T v - \int_{-1}^\sigma g(s)ds)$, which implies $w(-1) = hB_1^T v$ and $Dw = -hg$. So finally we get

$$\mathcal{A}_h^* \begin{pmatrix} y \\ w \end{pmatrix} = \begin{pmatrix} A^T y \\ -\dfrac{1}{h} Dw \end{pmatrix} \quad \text{and} \quad \mathcal{D}(\mathcal{A}_h^*) = \left\{ \begin{pmatrix} y \\ w \end{pmatrix} \in \mathcal{W}^m,\ w(-1) = hB_1^T y \right\},$$

which we intended to prove.

Part (ii). Now the semigroup $\{\mathcal{S}_h(t)\}_{t\geq 0}$ may be extended by transposition and duality as a semigroup on $\mathcal{D}(\mathcal{A}_h^*)'$ (see, e.g., [19]) as soon as we prove that $\{\mathcal{S}_h^*(t)\}_{t\geq 0}$ is a C_0-semigroup on $\mathcal{D}(\mathcal{A}_h^*)$. The adjoint semigroup $\mathcal{S}_h^*$ may be computed as $\mathcal{S}_h^*(t) = \left(\begin{smallmatrix} \mathcal{S}_{11}^*(t) & 0 \\ \mathcal{S}_{12}^*(t) & \mathcal{S}_{22}^*(t) \end{smallmatrix}\right) \in \mathcal{L}(\mathcal{H})$, where

$$\begin{aligned} \mathcal{S}_{11}^*(t) &= e^{A^T t},\ t \geq 0, \\ \mathcal{S}_{12}^*(t)v(\sigma) &= hB_1^T\, \overline{\mathcal{S}_{11}^*}(t - h(\sigma+1))v \ \text{ with } \ \overline{\mathcal{S}_{11}^*}(t) = \mathcal{S}_{11}^*(t)\chi_{\{t\geq 0\}}, \\ \mathcal{S}_{22}^*(t)z(\sigma) &= \begin{cases} z\left(\sigma - \dfrac{t}{h}\right) & \text{if } \ t - h < \sigma h \leq 0, \\ 0 \text{ if } \ -h \leq \sigma h \leq t - h. \end{cases} \end{aligned}$$

Then for the rest of the proof, it will be sufficient to check that the space $\mathcal{D}(\mathcal{A}_h^*)$ is stable by $\mathcal{S}_h^*(t)$. For that, take $\left(\begin{smallmatrix} v \\ w \end{smallmatrix}\right) \in \mathcal{D}(\mathcal{A}_h^*)$ and denote $\psi(\sigma)$ the second component of $\mathcal{S}_h^*(t)\left(\begin{smallmatrix} v \\ w \end{smallmatrix}\right)$. Then $\psi(\sigma) = hB_1^T\, \overline{\mathcal{S}}_{11}^*(t - h(\sigma+1))v + w(\sigma - \frac{t}{h})$, which implies :$\psi(-1) = hB_1^T\, \overline{\mathcal{S}_{11}^*}(t)v$.

Moreover,

$$\begin{cases} \sigma \leq \dfrac{t-h}{h} \Longrightarrow \psi(\sigma) = hB_1^T\, \mathcal{S}_{11}^*(t - h(\sigma+1))v, \\ \sigma > \dfrac{t-h}{h} \Longrightarrow \psi(\sigma) = w\left(\sigma - \dfrac{t}{h}\right), \end{cases}$$

with $\lim_{\sigma\to\frac{t-h}{h}} w(\sigma-\frac{t}{h}) = w(-1) = hB_1^T v = \psi(\frac{t-h}{h})$. Therefore, in order to prove that $D\psi \in L^2(-1,0;\mathbb{R}^m)$, it is enough to prove that $hB_1^T\ \mathcal{S}_{11}^*(t-h(.+1))v \in H^1(-1,\frac{t-h}{h};\mathbb{R}^m)\ \forall v\in\mathbb{R}^n$. But we may point out that $\{t\to\mathcal{S}_{11}^*(t)=e^{A^Tt}\}\in H^1(0,T;\mathcal{L}(\mathbb{R}^n))$, so when introducing F defined from $[-1,0]$ to $\mathbb{R}^n$ as $F(\sigma)=\mathcal{S}_{11}^*(t-h(\sigma+1))v$, we have the following smoothness property:

$$F\in H^1\left(\frac{t-T-h}{h},\frac{t-h}{h};\mathbb{R}^n\right)\subset H^1\left(-1,\frac{t-h}{h};\mathbb{R}^n\right)\quad\forall h>0.$$

So the final conclusion follows from the remark:

$$B_1^T\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^m)\implies hB_1^T\mathcal{S}_{11}^*(t-h(.+1))v=hB_1^TF(.)\in H^1\left(-1,\frac{t-h}{h};\mathbb{R}^m\right).\qquad\square$$

A.2. Proof of Lemma 3.2. In view of [1, Proposition 3.1, p. 172], this is equivalent to proving that there exists some $b>0$ such that $\forall\ t\in[0,T]$ and $u\in L^2(0,t\ ;\ \mathbb{R}^m)$, we get

$$\int_0^t\mathcal{S}_h(t-s)\mathcal{B}_hu(s)ds\in\mathcal{H}^m\ \text{ and }\ \|\int_0^t\mathcal{S}_h(t-s)\mathcal{B}_hu(s)ds\|_{\mathcal{H}^m}\le b\|u\|_{L^2(0,t;\mathbb{R}^m)}.$$

To this end, it will be sufficient to prove that $y\longrightarrow\langle\int_0^t\mathcal{S}_h(t-s)\mathcal{B}_hu(s)ds,y\rangle_{\mathcal{H}^m}$ defines a continuous linear form for the normed space topology of $\mathcal{H}^m$.

For this, let us take $z=\binom{y}{w}\in\mathcal{D}(\mathcal{A}_h^*)=\{\binom{y}{w}\in\mathcal{W}^m,\ w(-1)=hB_1^Ty\}$. Then

$$\left\langle\int_0^t\mathcal{S}_h(t-s)\mathcal{B}_hu(s)ds,z\right\rangle_{\mathcal{H}^m}=\int_0^t\langle\underbrace{\mathcal{B}_hu(s)}_{\in\mathcal{W}^{m\prime}},\ \underbrace{\mathcal{S}_h^*(t-s)z}_{\in\mathcal{D}(\mathcal{A}_h^*)\subset\mathcal{W}^m}\rangle_{\mathcal{H}^m}ds.$$

So denoting ψ the second component of $\mathcal{S}_h^*(t-s)z$, we get, with Appendix A.1,

$$\psi(\sigma)=hB_1^Te^{A^T(t-s-h(\sigma+1))}y\chi_{\{\sigma\le\frac{t-s-h}{h}\}}+w\left(\sigma-\frac{t-s}{h}\right)\chi_{\{\sigma\ge\frac{t-s-h}{h}\}}$$

in such a way that ψ defines a continuous function (see the end of the proof of Proposition 3.1 in appendix A.1 for details). Then applying the Dirac distribution $\delta_{\theta=0}$ to ψ, we get

$$\begin{aligned}\int_0^t\langle\mathcal{B}_hu(s),\mathcal{S}_h^*(t-s)z\rangle_{\mathcal{H}^m}ds&=\int_0^t\langle u(s),B_0e^{A^T(t-\sigma h)}y+{B_1}^Te^{A^T(t-h-s)}y\chi_{\{s\le t-h\}}\\&\qquad+\frac{1}{h}w\left(\frac{t-s}{h}\right)\chi_{\{s>t-h\}}\rangle_{\mathcal{H}_h^m}ds\\&=\left\langle\int_0^te^{A(t-s)}B_0u(s)ds+\int_0^te^{A(t-s)}B_1u(s-h)ds,y\right\rangle_{\mathbb{R}^n}\\&\qquad+\int_{-h}^0\langle u(s(h+1)+t),w(s)\rangle_{\mathbb{R}^m}ds,\end{aligned}$$

which proves the continuity of $z\to\langle\int_0^t\mathcal{S}_h(t-s)\mathcal{B}_hu(s)ds,z\rangle_{\mathcal{H}^m}$ in $\mathcal{D}(\mathcal{A}_h^*)$ endowed with the normed space topology of $\mathcal{H}^m$. By density argument, we conclude that this continuity result remains true in the normed space $\mathcal{H}_h^m$. $\square$

A.3. Proof of Theorem 3.6. In view of Remark 3.2 about identifying strong and weak solutions, we just need to prove that $\tilde{\mathcal{A}}_k$ defined by (3.17) coincides on $\mathcal{W}^n$ with $(\mathcal{A}_k^*)^*$, the transposed adjoint of $\mathcal{A}_k$. To this end, we shall use the method of transposition which simply reduces to a double integration by parts. Starting with the equation

$$\text{(A.2)} \qquad \left\{ \begin{array}{l} \begin{pmatrix} x(t) \\ y(t,.) \end{pmatrix} = \begin{pmatrix} A_0 & A_1\delta_{\sigma=-1} \\ 0 & \dfrac{1}{k}\dfrac{\partial}{\partial\sigma} \end{pmatrix} \begin{pmatrix} x(t) \\ y(t,.) \end{pmatrix} \\ \begin{pmatrix} x(0) \\ y(0,.) \end{pmatrix} = \begin{pmatrix} x_{00} \\ \psi^k(.) \end{pmatrix} \end{array} \right. \qquad \text{in} \quad \mathcal{H}^m,$$

we observe that any $\binom{x(t)}{y(t,.)} \in \mathcal{D}(\mathcal{A}_k)$ satisfies

$$\text{(A.3)} \qquad \left\{ \begin{array}{l} y(t,.) \in H^1(-1,0;\mathbb{R}^n) \ \text{ a.e. } t \in [0,T], \\ y(t,0) = x(t) \in L^2(0,T;\mathbb{R}^n), \end{array} \right.$$

and also that such a y is the solution to the equation of transport:

$$\text{(A.4)} \qquad \left\{ \begin{array}{l} k\dfrac{\partial y}{\partial t} = \dfrac{\partial y}{\partial \sigma} \\ y(0,.) = \psi^k(.) \in L^2(-1,0;\mathbb{R}^n) \\ y(t,0) = x(t) \ \in L^2(0,T,\mathbb{R}^n) \end{array} \right. \qquad \text{in } L^2(0,T;L^2(-1,0;\mathbb{R}^n)).$$

Now let us apply the method of transposition to the previous equation. Take $\varphi \in L^2(0,T;L^2(-1,0;\mathbb{R}^n)) = L^2(0,T;\mathbb{R}^n) \times L^2(-1,0;\mathbb{R}^n)$. Then (A.4) implies

$$\text{(A.5)} \quad k\int_{t=0}^{t=T}\int_{\sigma=-1}^{\sigma=0} \frac{\partial y}{\partial t}(t,\sigma)\varphi(t,\sigma)dtd\sigma = \int_{t=0}^{t=T}\int_{\sigma=-1}^{\sigma=0} \frac{\partial y}{\partial \sigma}(t,\sigma)\varphi(t,\sigma)dtd\sigma.$$

From an integration by parts, it follows that

$$\text{(A.6)} \quad k\int_{\sigma=-1}^{\sigma=0}\left(y\varphi|_{t=0}^{t=T} - \int_{t=0}^{t=T} y\frac{\partial\varphi}{\partial t}\right)d\sigma = \int_{t=0}^{t=T}\left(y\varphi|_{\sigma=-1}^{\sigma=0} - \int_{\sigma=-1}^{\sigma=0} y\frac{\partial\varphi}{\partial\sigma}d\sigma\right)dt.$$

Now, let us make the following assumptions on the test-functions:

$$\varphi(t,-1) = 0 \ \text{ a.e. } t \in [0,T] \quad \text{and} \quad \varphi(T,\sigma) = 0 \ \text{ a.e. } \sigma \in [-1,0].$$

Then in view of the initial and limiting conditions given in (A.4), (A.6) becomes

$$\text{(A.7)} \qquad k\int_{\sigma=-1}^{\sigma=0}\psi^k(\sigma)\varphi(0,\sigma)d\sigma - \int_{t=0}^{t=T}\int_{\sigma=-1}^{\sigma=0} y\left(k\frac{\partial\varphi}{\partial t} - \frac{\partial\varphi}{\partial\sigma}d\sigma\right)dt = \int_{t=0}^{t=T} x(t)\varphi(t,\sigma)dt.$$

Since a necessary condition to make such an equation meaningful is

$$k\frac{\partial\varphi}{\partial t} - \frac{\partial\varphi}{\partial\sigma} \in L^2(0,T;\mathbb{R}^n) \times L^2(-1,0;\mathbb{R}^n),$$

we choose the space

$$\mathcal{E}_{test} = \left\{ \varphi \in L^2(0,T;L^2(-1,0;\mathbb{R}^n)), \quad \left| \begin{array}{l} k\dfrac{\partial\varphi}{\partial t} - \dfrac{\partial\varphi}{\partial\sigma} \in L^2(0,T;L^2(-1,0;\mathbb{R}^n)), \\ \varphi(T,.) = 0, \quad \varphi(.,-1) = 0, \end{array} \right. \right\}$$

as a set of test-functions. From

$$\frac{\partial}{\partial t}^{*} = -\frac{\partial}{\partial t},\ \mathcal{D}\left(\frac{\partial}{\partial t}^{*}\right) = \{y \in H^1(0,T;\mathbb{R}^n),\ y(T) = 0\}$$

and

$$\frac{\partial}{\partial \sigma}^{*} = -\frac{\partial}{\partial \sigma},\ \mathcal{D}\left(\frac{\partial}{\partial \sigma}^{*}\right) = \{y \in H^1(-1,0;\mathbb{R}^n),\ y(-1) = 0\},$$

we see that the space $\mathcal{E}_{test}$ is a subset of the set of strong solutions of the adjoint equation of (A.4) and that

$$\varphi \in \mathcal{E}_{test} \quad \Leftrightarrow \quad \varphi(.,\sigma) \in H^1\left(0,T;\mathcal{D}\left(\frac{\partial}{\partial \sigma}^{*}\right)\right) \text{ and } \varphi(t,.) \in H^1\left(-1,0;\mathcal{D}\left(\frac{\partial}{\partial t}^{*}\right)\right).$$

Now for $\varphi \in \mathcal{E}_{test}$, we may write, with $L^2 \times L^2 = L^2(0,T;\mathbb{R}^n) \times L^2(-1,0;\mathbb{R}^n)$,

$$k\langle \psi^k, \delta_{t=0}\varphi\rangle_{L^2(-1,0;\mathbb{R}^q)} - \left\langle y, \left(k\frac{\partial}{\partial t} - \frac{\partial \varphi}{\partial \sigma}\right)\varphi\right\rangle_{L^2\times L^2} = \langle \delta^*_{\sigma=0}x(t), \varphi\rangle_{L^2\times L^2}. \tag{A.8}$$

Then with the operator $\frac{\partial}{\partial t} - \frac{\partial \varphi}{\partial \sigma}$, the formal adjoint of the operator $-(\frac{\partial}{\partial t} - \frac{\partial \varphi}{\partial \sigma})$, we get

$$k\langle \psi^k, \delta_{t=0}\varphi\rangle_{L^2(-1,0;\mathbb{R}^n)} + \left\langle \left(k\frac{\partial}{\partial t} - \frac{\partial \varphi}{\partial \sigma}\right)y, \varphi\right\rangle_{L^2\times L^2} = \langle \delta^*_{\sigma=0}x(t), \varphi\rangle_{L^2\times L^2}. \tag{A.9}$$

Hence

$$\left\{\begin{array}{lcll} k\dfrac{\partial y}{\partial t}(t,.) & = & \dfrac{\partial y}{\partial \sigma}(t,.) + \delta^*_{\sigma=0}x(t) & \\ & = & Dy(t,.) + \delta^*_{\sigma=0}x(t) & \text{in } H^1(-1,0;\mathbb{R}^n)', \\ y(0,.) & = & \psi^k(.) \in L^2(-1,0;\mathbb{R}^n) & \end{array}\right. \tag{A.10}$$

where $D = \frac{\partial}{\partial \sigma}$ with $\mathcal{D}(\frac{\partial}{\partial \sigma}) = \{y \in H^1(-1,0;\mathbb{R}^n),\ y(0) = 0\}$.

We may observe that the linear operator $(\frac{\partial}{\partial \sigma}^{*})^* \in \mathcal{L}(L^2(-1,0;\mathbb{R}^n), \mathcal{D}(\frac{\partial}{\partial \sigma}^{*})')$ has been constructed en route as a continuous extension of $D \in \mathcal{L}(\mathcal{D}(D), L^2(-1,0;\mathbb{R}^n))$. Hence D may be seen as an element of

$$\mathcal{L}(H^1(-1,0;\mathbb{R}^n), H^1(-1,0;\mathbb{R}^n)') \cap \mathcal{L}\left(L^2(-1,0;\mathbb{R}^n), \mathcal{D}\left(\frac{\partial}{\partial \sigma}^{*}\right)'\right).$$

Now (A.2) becomes

$$\left\{\begin{array}{l} \begin{pmatrix}\dot{x}\\ \dot{y}\end{pmatrix} = \widetilde{\mathcal{A}}_k \begin{pmatrix}x\\ y\end{pmatrix} \\ \begin{pmatrix}x(0)\\ y(0,.)\end{pmatrix} = \begin{pmatrix}x_{00}\\ \psi^k(.)\end{pmatrix} \in \mathcal{H}^n \end{array}\right. \text{ in } L^2(0,T,\mathcal{D}(\mathcal{A}^*_k)'), \tag{A.11}$$

where $\widetilde{\mathcal{A}}_k$ is the extension by transposition of $\mathcal{A}_k$, given on $\mathcal{W}^n$ by

$$\widetilde{\mathcal{A}}_k = \begin{pmatrix} A_0 & A_1\delta_{\sigma=-1} \\ \dfrac{1}{k}\delta^*_{\sigma=0} & \dfrac{1}{k}D \end{pmatrix}$$

and satisfies $\widetilde{\mathcal{A}}_k \in \mathcal{L}(\mathcal{D}(\mathcal{A}_k), \mathcal{H}^n) \cap \mathcal{L}(\mathcal{W}^n, \mathcal{W}^{n'}) \cap \mathcal{L}(\mathcal{H}^n, \mathcal{D}(\mathcal{A}^*_k)')$, which is what we wanted to prove. □

ADAPTIVE CONTROL FOR SEMILINEAR STOCHASTIC SYSTEMS*

T. E. DUNCAN†, B. MASLOWSKI‡, AND B. PASIK-DUNCAN†

Abstract. An adaptive, ergodic cost stochastic control problem for a partially known, semilinear, stochastic system in an infinite dimensional space is formulated and solved. The solutions of the Hamilton–Jacobi–Bellman equations for the discounted cost and the ergodic cost stochastic control problems require some special interpretations because they do not typically exist in the usual sense. The solutions of the parameter dependent ergodic Hamilton–Jacobi–Bellman equations are obtained from some corresponding discounted cost control problems as the discount rate tends to zero. The solutions of the ergodic Hamilton–Jacobi–Bellman equations are shown to depend continuously on the parameter. A certainty equivalence adaptive control is given that is based on the optimal controls from the solutions of the ergodic Hamilton–Jacobi–Bellman equations and a strongly consistent family of estimates of the unknown parameter. This adaptive control is shown to achieve the optimal ergodic cost for the known system.

Key words. stochastic adaptive control, ergodic control, stochastic semilinear systems, stochastic optimal control, distributed parameter systems

1. Introduction.

Ergodic cost stochastic control problems for finite dimensional, nonlinear stochastic systems have been investigated for more than two decades (e.g., [2], [9], [25], and [1], [28], and the references therein). There has been some work on the corresponding adaptive control problem for these partially known stochastic systems. In [3], [4], [5] some properties of the solution of the Hamilton–Jacobi–Bellman (HJB) equation of optimal control are used to verify self-optimality of an adaptive control using a strongly consistent family of estimates of the unknown parameters. In [17] an almost optimal adaptive control is constructed for a partially known nonlinear stochastic system. To obtain an optimal feedback control in an explicit form, the associated HJB equation must be solved, and for an adaptive control problem, a continuous dependence of the solution of the HJB equation must be verified. Some results for an infinite time horizon discounted cost control problem for a semilinear stochastic system in an infinite dimensional state space are given in [22], where the HJB equation is considered in the mild form, and in [23], where a viscosity solution of the HJB equation is used. Some results for an ergodic cost control problem for a semilinear stochastic system in an infinite dimensional state space are given in [20], where the HJB equation is solved. This is apparently the only result for ergodic cost control for semilinear stochastic systems using the HJB equation. Some other approaches and results for ergodic cost control are given in [16], [18]. For adaptive control, there are results for linear stochastic systems with an ergodic quadratic cost in [13], [14], [15]. Since the results for the discounted cost and the ergodic cost stochastic control problems for known semilinear stochastic systems are relatively recent, it appears that this is the first work on adaptive control for stochastic semilinear systems.

In this paper an adaptive, ergodic cost control problem is solved for a semilinear stochastic system in an infinite dimensional state space using a solution of the HJB equation. An adaptive control is obtained from the certainty equivalence principle and the optimal control from the solution of the HJB equation. Continuity of the optimal cost with respect to the parameter is shown and the adaptive control is verified to be self-optimal.

A brief outline of the paper is given now. In section 2, the adaptive control problem is formulated and the assumptions are described. An example of a controlled stochastic parabolic partial differential equation is given for which the assumptions are satisfied. Some preparatory results for the analysis of the adaptive control problem are given. For example, the tightness of the probability laws of the solutions of the controlled semilinear systems and a uniform boundedness of their moments are verified. Some uniform bounds on the derivatives of the Markov transition semigroup for the uncontrolled system are also verified. In section 3, the parameter estimation problem is considered. In this section it is assumed that the unknown parameter appears affinely in the stochastic system. With an identifiability condition, it is shown that a family of least squares estimates is strongly consistent. In section 4, the self-optimality of an adaptive control is verified. Initially the parameter dependent, infinite dimensional HJB equations for the ergodic and discounted costs control problems are formally introduced. Their solutions are defined by the generator of an Ornstein–Uhlenbeck semigroup. A family of suitably normalized solutions of the HJB equations for the discounted costs are shown to be relatively compact for arbitrarily small discount rates and all values of the parameter in the Sobolev space $W^{1,2}(H,\mu)$, where H is the Hilbert space that is the state space for the system and μ is a limiting Gaussian measure for the solution of the associated uncontrolled linear system (Ornstein–Uhlenbeck process). This relative compactness property provides the ergodic control result as a suitable limit of the discounted control results as the discount rate tends to zero. The proof of the relative compactness uses a method in [20] for known systems in a space of continuous, polynomially bounded functions where an upper bound on the norm of the controls is required. The existence and the uniqueness of the solution of the ergodic HJB equation and its relation to an optimal control and the optimal cost are given. While the existence of the solution follows from a result in [20], the uniqueness of the solution in $W^{1,2}(H,\mu)$ is new. The continuous dependence of the solutions of the ergodic HJB equations on the parameter in the $W^{1,2}(H,\mu)$ is verified. A certainty equivalence adaptive control is defined that is based on the optimal controls from the solutions of the ergodic HJB equations and a strongly consistent family of estimates of the unknown parameter. The main results of section 4, Theorem 4.1 and Corollary 4.2, state the self-optimality of this adaptive control, that is, this adaptive control achieves the optimal ergodic cost for the true system.

2. Preliminaries. Let $(X(t),\, t \geq 0)$ be an H-valued, parameter dependent, controlled process that satisfies the stochastic differential equation

$$\begin{aligned} dX(t) &= (AX(t) + f(\alpha, X(t)) - u(t))dt + Q^{1/2}dW(t), \\ X(0) &= x, \end{aligned} \tag{2.1}$$

where H is a real, separable Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and norm $|\cdot|$, $A : \mathrm{Dom}(A) \to H$ is a densely defined, unbounded linear operator on H, $f(\alpha, \cdot) : H \to H$ for each $\alpha \in \mathcal{A} \subset \mathbb{R}^q$ that is a compact set of parameters, $(W(t),\, t \geq 0)$ is a

standard, cylindrical H-valued Wiener process defined on a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P})$ and $Q^{1/2} \in \mathcal{L}(H)$. The family of admissible controls is

$$\mathcal{U} = \{u : \mathbb{R}_+ \times \Omega \to B_R \mid u \text{ is measurable and } (\mathcal{F}_t) \text{ adapted}\}, \tag{2.2}$$

where $B_R = \{y \in H \mid |y| \le R\}$ and $R > 0$ is fixed. A family of Markov controls, e.g., $u(t) = \tilde{u}(X(t))$, is also considered where $\tilde{u} \in \tilde{\mathcal{U}}$ and

$$\tilde{\mathcal{U}} = \{\tilde{u} : H \to B_R \mid \tilde{u} \text{ is Borel measurable}\}. \tag{2.3}$$

The cost functionals $J(x, \lambda, u)$ and $\tilde{J}(x, u)$ are given as

$$J(x, \lambda, u) = \mathbb{E}_{x,u} \int_0^\infty e^{-\lambda t}(\psi(X(t)) + h(u(t)))dt \tag{2.4}$$

and

$$\tilde{J}(x, u) = \liminf_{T\to\infty} \mathbb{E}_{x,u} \frac{1}{T} \int_0^T (\psi(X(t)) + h(u(t)))dt, \tag{2.5}$$

where $\lambda > 0$, $h : B_R \to \mathbb{R}_+$, and $\psi : H \to \mathbb{R}$, that describe a discounted and an ergodic control problem, respectively.

The adaptive control problem is to find a family of strongly consistent estimates of the unknown parameter α and to determine an adaptive control from the family of admissible controls such that the optimal ergodic cost, $\inf_{u\in\mathcal{U}} \tilde{J}(x, u)$, is achieved.

The following assumptions are selectively used in the paper.

(A1) The linear operator $Q = Q^{1/2^*}Q^{1/2}$ is invertible, $Q^{-1} \in \mathcal{L}(H)$ and $(S(t), t \ge 0)$, where $S(t) = e^{tA}$, is an exponentially stable semigroup of contractions, that is,

$$\|S(t)\|_{\mathcal{L}(H)} \le e^{-\omega t}$$

for all $t \ge 0$ and some $\omega > 0$. Furthermore, the semigroup is Hilbert–Schmidt and there is a $\gamma > 0$ such that

$$\int_0^T t^{-\gamma} \|S(t)\|^2_{\mathrm{HS}} dt < \infty$$

for some $T > 0$, where $\|\cdot\|_{\mathrm{HS}}$ is the Hilbert–Schmidt norm.

(A2) The function $f(\alpha, \cdot) : H \to H$ is Lipschitz continuous and Gâteaux differentiable. The Gâteaux derivative $Df(\alpha, \cdot)h$ is continuous on H for each $h \in H$ and $\alpha \in \mathcal{A}$ and there is a $\beta \in \mathbb{R}$ such that

$$\langle Df(\alpha, x)h, h\rangle \le \beta|h|^2$$

for all $x \in H$, $h \in H$, and $\alpha \in \mathcal{A}$.

(A3) The function $f(\cdot, x) : \mathcal{A} \to H$ is continuous for each $x \in H$ and there are constants $p > 0$ and $C > 0$ such that

$$|f(\alpha, x)| \le C(1 + |x|^p)$$

for each $x \in H$ and $\alpha \in \mathcal{A}$.

(A4) $\psi \in C_b(H)$.

(A5) The function $h : H \to \mathbb{R}$ is convex and bounded on bounded sets and continuous. The function $\tilde{H} : H \to \mathbb{R}$ given by $\tilde{H}(x) = \sup_{|y|\le R}[\langle y, x\rangle - h(y)]$ is continuously Fréchet differentiable.

Some implications of the assumptions (A1)–(A5) are described now. Consider the linear stochastic differential equation obtained from (2.1) by choosing $f \equiv 0$ and $u \equiv 0$, that is,

$$dZ(t) = AZ(t)dt + Q^{1/2}dW(t), \quad Z(0) = x. \tag{2.6}$$

It is well known (e.g., [11]) that if (A1) is satisfied then (2.6) has a unique mild solution

$$Z(t) = S(t)x + \int_0^t S(t-r)Q^{1/2}dW(r) \tag{2.7}$$

which is an H-valued process with continuous sample paths, is ergodic, and has a unique invariant probability measure

$$\mu = N(0, Q_\infty), \tag{2.8}$$

where

$$Q_\infty = \int_0^\infty S(r)QS^*(r)dr$$

is a trace class operator on H. If (A2) is satisfied, then (2.1) has a unique mild solution

$$X(t) = S(t)x + \int_0^t S(t-r)(f(\alpha, X(r)) - u(r))dr + \int_0^t S(t-r)Q^{1/2}dW(r) \tag{2.9}$$

for each $u \in \mathcal{U}$ and $\alpha \in \mathcal{A}$. If the control in (2.1) has the feedback form $u(t) = \tilde{u}(X(t))$, where $\tilde{u} \in \tilde{\mathcal{U}}$, then the solution of (2.1) is obtained by an absolute continuity of measures as a weak solution in the probabilistic sense. More specifically, if $\mathbb{P}$ is the probability measure for the solution of (2.1) with $u \equiv 0$, then the probability measure $\mathbb{P}_{\tilde{u}}$ for the solution of

$$dX(t) = (AX(t) + f(\alpha, X(t)) - \tilde{u}(X(t)))dt + Q^{1/2}dW(t), \quad X(0) = x \tag{2.10}$$

is induced from $\mathbb{P}$ by the Radon–Nikodým derivative

$$\frac{d\mathbb{P}_{\tilde{u}}}{d\mathbb{P}} = \exp\left[-\int_0^T \langle Q^{-1/2}\tilde{u}(X(s)), dW(s)\rangle - \frac{1}{2}\int_0^T |Q^{-1/2}\tilde{u}(X(s))|^2 ds\right]. \tag{2.11}$$

The assumption (A3) is used to verify a suitable continuous dependence of the solutions of the ergodic HJB equations on the parameter which is important to verify the self-optimality of a certainty equivalence adaptive control. The assumptions (A4) and (A5) are standard conditions on a cost functional in the stochastic control of semilinear systems (e.g., [20], [22]). Note that (A5) is satisfied in the case where $h(x) = |x|^2$ so that $\tilde{H}(x) = \hat{H}(|x|)$, where

$$\hat{H}(r) = \begin{cases} \frac{r^2}{4} & \text{if } |r| \le 2R, \\ R|r| - R^2 & \text{if } |r| > 2R. \end{cases}$$

To provide some additional perspective for the adaptive control problem, an example of a stochastic partial differential equation that satisfies the assumptions is given. Consider the stochastic partial differential equation

$$\frac{\partial y}{\partial t}(t,\xi) = \frac{\partial^2 y}{\partial \xi^2}(t,\xi) + F(\alpha, y(t,\xi)) - u(t,\xi) + \eta(t,\xi) \tag{2.12}$$

for $(t,\xi) \in \mathbb{R}_+ \times (0,1)$ with the initial condition $y(0,\xi) = y_0(\xi)$, $\xi \in (0,1)$ and the Dirichlet boundary conditions

$$y(t,0) = y(t,1) = 0$$

for $t \geq 0$. The function $F : \mathcal{A} \times \mathbb{R} \to \mathbb{R}$ satisfies the following: $F(\cdot, y)$ is continuous for each $y \in \mathbb{R}$, $F(\alpha, \cdot)$ is (globally) Lipschitz continuous for each $\alpha \in \mathcal{A}$, $|F(\alpha, y)| \leq C(1 + |y|)$ for some $C > 0$ and all $\alpha \in \mathcal{A}$ and $y \in \mathbb{R}$, and $F'(\alpha, y) \leq \beta$ for some $\beta \in \mathbb{R}$, and the term η formally denotes a space time white noise. The control $(u(t),\, t \geq 0)$ is assumed to be adapted to the noise process and to take values in a ball, B_R, in $L^2(0,1)$. The formal equation (2.12) can be rigorously described in a standard way as an equation of the form (2.1) in the Hilbert space $H = L^2(0,1)$, $A = \partial^2/\partial\xi^2$, $\mathrm{Dom}(A) = \{\varphi \in L^2(0,1) \mid \varphi, \varphi' \text{ are absolutely continuous, } \varphi'' \in L^2(0,1), \varphi(0) = \varphi(1) = 0\}$, $f(\alpha, x)(\xi) = F(\alpha, x(\xi))$ for $x \in H$, $\alpha \in \mathcal{A}$, $\xi \in (0,1)$ and a cylindrical Wiener process with $Q = \delta I$ where $\delta > 0$ is a constant and I is the identity on I. For ψ and h in the cost functionals (2.4), (2.5) arbitrary $\psi \in C_b(L^2(0,1))$ and $h : L^2(0,1) \to \mathbb{R}_+$ satisfying (A5) can be chosen, e.g., $h(u) = |u|^2$. It is well known that all of the assumptions (A1)–(A5) are satisfied where $\gamma \in (0, 1/4)$ in (A1).

It is convenient to denote by $\mathbb{P}^\alpha_{x,u}$ the probability measure on Ω for the solution of (2.1) with $X(0) = x$, a control $u \in \mathcal{U}$, and a parameter $\alpha \in \mathcal{A}$. Let $\mathbb{E}^\alpha_{x,u}$ be the expectation for the probability $\mathbb{P}^\alpha_{x,u}$.

In the following proposition some stability, boundedness, and tightness properties are given.

PROPOSITION 2.1. *If* (A1) *and* (A2) *are satisfied, where* $\omega - \beta > 0$, *then the following apply.*

(i) *For each* $p' > 0$ *and* $T > 0$ *the following inequalities are satisfied:*

$$\sup_{\alpha \in \mathcal{A}} \sup_{u \in \mathcal{U}} \mathbb{E}^\alpha_{x,u} \left[\sup_{0 \leq t \leq T} |X(t)|^{2p'} \right] \leq C_T |x|^{2p'} + \tilde{C}_T \tag{2.13}$$

and

$$\sup_{t \in \mathbb{R}_+} \sup_{\alpha \in \mathcal{A}} \sup_{u \in \mathcal{U}} \mathbb{E}^\alpha_{x,u} [|X(t)|^{2p'}] \leq C_1 |x|^{2p'} + C_2. \tag{2.14}$$

(ii) *For each* $x \in H$, $\alpha \in \mathcal{A}$, *and* $u \in \mathcal{U}$ *the following inequality is satisfied:*

$$\limsup_{t \to \infty} \frac{1}{t} \int_0^t |X(s)|^2 ds < \infty \qquad \textit{almost surely (a.s.)} \ \mathbb{P}^\alpha_{x,u}. \tag{2.15}$$

(iii) *For each* $x \in H$, $\alpha \in \mathcal{A}$, *and* $u \in \mathcal{U}$ *there is a sequence* $(K_n,\, n \in \mathbb{N})$ *of compact sets in* H *such that*

$$\lim_{n \to \infty} \sup_{t \geq 1} \mathbb{P}^\alpha_{x,u}(X(t) \in H \setminus K_n) = 0, \tag{2.16}$$

so the family of measures $(\mu_{X(t)},\, t \geq 1)$ *is tight where* $\mu_{X(t)}$ *is the probability law for* $X(t)$.

Proof. To verify (i) the solution of (2.1) can be expressed as

$$X(t) = \mu(t, \tilde{Z}) + \tilde{Z}(t),$$

where

$$\tilde{Z}(t) = -\int_0^t S(t-r)u(r)dr + \int_0^t S(t-r)Q^{1/2}dW(r)$$

and $\mu(t,\varphi)$ is the solution of the deterministic integral equation

$$\mu(t,\varphi) = S(t)x + \int_0^t S(t-r)f(\alpha, \mu(r,\varphi)) + \varphi(r))dr,$$

where $\varphi \in C(\mathbb{R}_+, H)$ and $\varphi(0) = 0$. Since the semigroup $(S(t),\, t \geq 0)$ is exponentially stable, it easily follows that

$$\sup_{t\in\mathbb{R}_+} \mathbb{E}|\tilde{Z}(t)|^m < \infty \tag{2.17}$$

for each $m > 0$. Thus to verify (2.14), it suffices to show that

$$\sup \mathbb{E}^{\alpha}_{x,u}[|\mu(t,\tilde{Z})|^{2p'}] \leq C(1 + |x|^{2p'}) \tag{2.18}$$

for some constant C and the supremum is taken over all $t \in \mathbb{R}_+$, $u \in \mathcal{U}$, and $\alpha \in \mathcal{A}$. It can be assumed in (A2) that $\beta \leq 0$, for otherwise βI can be subtracted from f and added to A. Using the standard approximation of f by the sequence $(f_n,\, n \in \mathbb{N})$, where $f_n = (1/n)[(I - nf)^{-1} - I]$, and using the Gronwall lemma it follows that

$$|\mu(t,\varphi)|^{2p'} \leq e^{-2p'\omega t}|x|^{2p'} + 2p\int_0^t e^{-2p'\omega(t-s)}|f(\alpha,\varphi(s))|\ |\mu(s,\varphi)|^{2p'-1}ds \tag{2.19}$$

(cf. [20, Lemma 2.2] or [12] for a similar verification). By (A3) it follows that

$$|f(\alpha,x)| \leq \tilde{C}(1 + |x|^p) \tag{2.20}$$

for all $x \in H$ and $\alpha \in \mathcal{A}$ and some constant $\tilde{C}$. If $p' = 1/2$, then (2.17) and (2.19) imply (2.18). Otherwise a verification by induction is made as follows. Assume that

$$\sup_{t\in\mathbb{R}_+,\ \alpha\in\mathcal{A},\ u\in\mathcal{U}} \mathbb{E}^{\alpha}_{x,u}[|\mu(t,\tilde{Z})|^{2p'-(1/2)}] \leq C_3|x|^{2p'-(1/2)} + C_4$$

for all $x \in H$ and some constants C_3 and C_4. Using (2.19) and the Hölder inequality with exponents $q = [2p' - (1/2)]/(2p' - 1)$ and $q' = q/(q-1)$ it follows that

$$\begin{aligned}\mathbb{E}^{\alpha}_{x,u}[|\mu(t,\tilde{Z})|^{2p'}] &\leq e^{-2p'\omega t}|x|^{2p'} + C_5\int_0^t e^{-2p'\omega(t-s)}(\mathbb{E}^{\alpha}_{x,u}|f(\alpha,\tilde{Z}(s))|^{q'})^{1/q'}ds \\ &\qquad \cdot (\mathbb{E}^{\alpha}_{x,u}|\mu(t,\tilde{Z})|^{2p'-(1/2)})^{1/q} \\ &\leq C_6|x|^{2p'} + C_7\end{aligned}$$

for all $x \in H$ and some constants C_6 and C_7. This completes the verification of (2.14). It has been shown [30] that

$$\mathbb{E}\left[\sup_{0\leq t\leq T}|\tilde{Z}(t)|^q\right] < \infty$$

for each $q > 0$. Thus the inequality (2.13) follows from (2.19) in a similar way.

To verify (ii) the inequalities (2.19) and (2.20) imply that

$$\frac{1}{t}\int_0^t |\mu(r,\varphi)|^2 dr \le \frac{C_8(x)}{t} + C_9 \frac{1}{t}\int_0^t |\varphi(s)|^{2p} ds$$

for some $C_8(x)$ depending on $x \in H$ and constant C_9. Thus

$$\begin{aligned} \frac{1}{t}\int_0^t |X(s)|^2 ds &\le \frac{2}{t}\int_0^t |\mu(s,\tilde{Z})|^2 ds + \frac{2}{t}\int_0^t |\tilde{Z}(s)|^2 ds \\ &\le \frac{2C_8(x)}{t} + \frac{2C_9}{t}\int_0^t |\tilde{Z}(s)|^{2p} ds + \frac{2}{t}\int_0^t |\tilde{Z}(s)|^2 ds. \end{aligned} \tag{2.21}$$

Note that

$$\frac{1}{t}\int_0^t \left|\int_0^s S(s-r)u(r)dr\right|^{2q} ds \le \frac{1}{t}\int_o^t \left(\frac{R}{\omega}\right)^{2q} ds \le \left(\frac{R}{\omega}\right)^{2q} \tag{2.22}$$

and

$$\lim_{t\to\infty} \frac{1}{t}\int_0^t \left|\int_0^s S(s-r)Q^{1/2} dW(r)\right|^{2q} ds = C(q)(\operatorname{Tr} Q_\infty)^q \qquad \text{a.s. } \mathbb{P}^\alpha_{x,u} \tag{2.23}$$

for any $q \in \mathbb{N}$, and $C(q)$ depends only on q. This equality follows because the Ornstein–Uhlenbeck process $(\int_0^t S(t-r)dW(r),\ t \ge 0)$ is ergodic and by the strong law of large numbers (cf. [27]) the family of time averages in (2.23) converge almost surely to the $2q$th moment of the invariant measure, $\mu = N(0, Q_\infty)$. The inequalities (2.21) and (2.22) and the equality (2.23) verify the inequality (2.15) in (ii).

To verify (iii) the solution $(X(t),\ t \ge 0)$ of (2.1) is expressed as

$$\begin{aligned} X(t+1) &= S(1)X(t) + \int_t^{t+1} S(t+1-r)(f(\alpha, X(r)) - u(r))dr \\ &\quad + \int_t^{t+1} S(t+1-r)Q^{1/2} dW(r) \\ &= S(1)X(t) + \int_0^1 S(1-r)\lambda(\alpha, r+t)dr + \int_0^1 S(1-r)Q^{1/2} d\tilde{W}(r), \end{aligned} \tag{2.24}$$

where $\tilde{W}(r) = W(r+t)$ and

$$\lambda(\alpha, s) = f(\alpha, X(s)) - u(s).$$

Since it can be assumed that $\gamma \in (0,1)$ in (A1), let $q = 1/\gamma$ and $v \in (1/q, 1]$. Define the linear operator $J_v : L^2(0,1;H) \to H$ as

$$J_v h = \int_0^1 (1-s)^{v-1} S(1-s)h(s)ds.$$

It is well known (e.g., [11]) that J_v is a compact operator and

$$\int_0^1 S(1-r)Q^{1/2} dW(r) = \frac{\sin\frac{1}{2}\pi\gamma}{\pi} J_{\gamma/2}(Y),$$

where

$$Y(s) = \int_0^s (s-u)^{-\gamma/2} S(s-u) Q^{1/2} dW(u).$$

Thus (2.24) can be rewritten as

$$X(t+1) = S(1)X(t) + J_1\lambda(\alpha, \cdot + t) + \frac{\sin \frac{1}{2}\pi\gamma}{\pi} J_{\gamma/2}(Y)$$

for $t \geq 0$. Let $|\cdot|_q$ be the norm in $L^q(0,1;H)$. By (2.20) and (i) it follows that

$$\mathbb{E}^\alpha_{x,u} |\lambda(\alpha, \cdot + t)|_q^q \leq \mathbb{E}^\alpha_{x,u} k_1 \left(R^q + k_2 \int_0^1 |X(r+t)|^{qp} dt \right) \leq k_3 \tag{2.25}$$

and (A1) implies that

$$\mathbb{E}^\alpha_{x,u} \int_0^1 |Y(s)|^2 ds \leq k_4 \int_0^1 \left(\int_0^s (s-u)^{-\gamma} |S(s-u)|^2_{\mathrm{HS}} du \right)^2 ds \leq k_5 \tag{2.26}$$

for some constants $k_1 - k_5$ that do not depend on $t \in \mathbb{R}_+$, $\alpha \in \mathcal{A}$, and $u \in \mathcal{U}$. Define a sequence of compact sets $(K_n,\, n \in \mathbb{N})$ as

$$K_n = \{y \in H \mid y \in S(1)x + J_1 h + J_{\gamma/2} g,\ |x|^2 + |h|_q^q + |g|_q^q \leq n\}.$$

By the Chebyshev inequality it follows that

$$\mathbb{P}^\alpha_{x,u}(X(t+1) \notin K_n) \leq \frac{1}{n} \left[\mathbb{E}^\alpha_{x,u} \left(|X(t)|^2 + |\lambda(\alpha, \cdot + t)|_q^q + \left(\frac{\sin \frac{1}{2}\pi\gamma}{\pi} \right)^q |Y|_q^q \right) \right]$$

so that

$$\lim_{n\to\infty} \sup_{t \geq 1} \mathbb{P}^\alpha_{x,u}(X(t) \in H \setminus K_n) = 0$$

by (2.25), (2.26), and (i). □

In what follows let $(P_t^\alpha,\, t \geq 0)$ be the Markov transition semigroup induced by the solution of (2.1) with $u \equiv 0$. It is clear that for each $\alpha \in \mathcal{A}$, $(P_t^\alpha,\, t \geq 0)$ is a semigroup of bounded, linear operators on $C_b(H)$.

This section is concluded with some bounds on the Fréchet derivative of $P_t^\alpha \varphi$ for $t \geq 0$. For a bounded, Borel measurable function $\phi : H \to \mathbb{R}$, let $\|\phi\| = \sup_{x \in H} |\phi(x)|$ be the essential supremum.

PROPOSITION 2.2. *If* (A1) *and* (A2) *are satisfied with* $\omega - \beta > 0$, *then for each* $t > 0$, $\alpha \in \mathcal{A}$, *and* $\varphi \in C_b(H)$ *the function* $P_t^\alpha \varphi : H \to C_b(H)$ *is Fréchet differentiable and its Fréchet derivative* $DP_t^\alpha \varphi$ *satisfies the following inequalities:*

$$\|DP_t^\alpha \varphi\| \leq |Q^{-1/2}|_{\mathcal{L}(H)} t^{-1/2} \|\varphi\|, \qquad t > 0, \tag{2.27}$$

and

$$\|DP_t^\alpha \varphi\| \leq |Q^{-1/2}|_{\mathcal{L}(H)} e^{-(\omega-\beta)(t-1)} \|\varphi\|, \qquad t > 1, \tag{2.28}$$

where $\|\cdot\| = \sup_{x \in H} |\cdot|$. *From* (2.27) *and* (2.28) *the following inequality is satisfied:*

$$\|DP_t^\alpha \varphi\| \leq k(\omega_1) |Q^{-1/2}|_{\mathcal{L}(H)} t^{-1/2} e^{-\omega_1 t} \|\varphi\| \tag{2.29}$$

for $t > 0$ and each $\omega_1 \in (0, \omega - \beta)$ for a constant $k(\omega_1)$ that depends only on ω_1, ω, and β.

Proof. Let $(X^{\alpha,x}(t), t \geq 0)$ be the solution of (2.1) with $u \equiv 0$. By Proposition 7 in [10] it follows that the map $x \mapsto X^{\alpha,x}(t)$ is Gâteaux differentiable in the mean square for each $t \in \mathbb{R}_+$ and its directional derivative at x in the direction $h \in H$, $Y_h^{\alpha,x}(t)$, is a mild solution of the random linear differential equation

$$\frac{d}{dt}Y_h^{\alpha,x}(t) = (A + Df(\alpha, X^{\alpha,x}(t)))Y_h^{\alpha,x}(t),$$

$$Y_h^{\alpha,x}(0) = h.$$

Let $g_n(\alpha, x) = n(nI - A)^{-1}Df(\alpha, x)$ for $n \in \mathbb{N}$ and let $(y_n(t), t \geq 0)$ be the strong solution of the random linear differential equation

$$\frac{d}{dt}y_n(t) = (A + g_n(\alpha, X^{\alpha,x}(t)))y_n(t),$$
$$y_n(0) = n(nI - A)^{-1}h = h_n.$$

By (A1) it follows that

$$\begin{aligned}\frac{d}{dt}|y_n(t)|^2 &= 2\langle (A + g_n(\alpha, X^{\alpha,x}(t)))y_n(t), y_n(t)\rangle \\ &\leq -2\omega|y_n(t)|^2 + 2\langle g_n(\alpha, X^{\alpha,x}(t))y_n(t), y_n(t)\rangle\end{aligned}$$

so that

$$|y_n(t)|^2 \leq |h_n|^2 - 2\omega\int_0^t |y_n(s)|^2 ds + 2\int_0^t \langle g_n(\alpha, X^{\alpha,x}(s))y_n(s), y_n(s)\rangle ds.$$

Letting $n \to \infty$ and using standard properties of the Yoshida approximations and (A2) it follows that

$$|Y_k^{\alpha,x}(t)| \leq |h|^2 - 2(\omega - \beta)\int_0^t |Y_h^{\alpha,x}(s)|^2 ds$$

and

$$|Y_h^{\alpha,x}(t)|^2 \leq |h|^2 e^{-2(\omega-\beta)t}. \tag{2.30}$$

By Theorem 4.1 in [12] it follows that $DP_t^\alpha \varphi \in C_b(H)$ for $t > 0$ and

$$\langle DP_t^\alpha \varphi(x), h\rangle = \frac{1}{t}\mathbb{E}\varphi(X^{\alpha,x}(t))\int_0^t \langle Q^{-1/2}Y_h^{\alpha,x}(s), dW(s)\rangle$$

for $t > 0$ is satisfied for each $h \in H$, so by (2.30) it follows that

$$\|DP_t^\alpha \varphi\| \leq |Q^{-1/2}|_{\mathcal{L}(H)} t^{-1/2}\|\varphi\| \tag{2.31}$$

for $t > 0$ and (2.27) is verified. Furthermore, setting $\varphi_1^\alpha = P_1^\alpha \varphi$ and using the semigroup property of P_t^α it follows that

$$\begin{aligned}\langle DP_t^\alpha \varphi(x), h\rangle &= \langle DP_{t-1}^\alpha \varphi_1^\alpha(x), h\rangle \\ &= \langle D(\mathbb{E}\varphi_1^\alpha(X^{\alpha,x}(t-1)), h\rangle \\ &= \mathbb{E}\langle D\varphi_1^\alpha(X^{\alpha,u}(t-1), Y_h^{\alpha,x}(t-1)\rangle\end{aligned}$$

for $t > 1$, $h \in H$, and $x \in H$. Now using (2.30) and (2.31) with $t = 1$ it follows that

$$\|DP_t^\alpha \varphi\| \leq |Q^{-1/2}|_{\mathcal{L}(H)}\|\varphi\| e^{-(\omega-\beta)(t-1)}$$

for $t \geq 1$. ∎

3. Parameter estimation. In this section the estimation of the unknown parameter is considered where the parameter appears affinely in f, that is,

$$f(\alpha, x) = f_o(x) + \sum_{i=1}^{q} \alpha^i f_i(x), \tag{3.1}$$

where $\alpha = (\alpha^1, \dots, \alpha^q)^{\mathrm{T}}$. It is assumed that $f_0, f_1, \dots, f_q$ satisfy the relevant conditions on f in (A2) and (A3).

Let $(u(t),\, t \geq 0)$ be an admissible control and let $(X(t),\, t \geq 0)$ be the associated solution of (2.1). For notational simplicity, the dependence of X on u is suppressed. Let

$$\mathcal{A}(t) = (a_{ij}(t)) \tag{3.2}$$

and

$$\tilde{\mathcal{A}}(t) = (\tilde{a}_{ij}(t)) \tag{3.3}$$

for $t \geq 0$ be two $\mathcal{L}(\mathbb{R}^q, \mathbb{R}^q)$-valued processes, where

$$a_{ij}(t) = \int_0^t \langle Pf_i(X(s)), Pf_j(X(s))\rangle ds$$

and

$$\tilde{a}_{ij}(t) = \frac{a_{ij}(t)}{a_{ii}(t)},$$

and $P : H \to P(H)$ is a fixed finite dimensional projection on H with range in $\mathrm{Dom}(A^*)$ that is chosen to satisfy the subsequent assumptions (A6) and (A7).

For the verification of the strong consistency (e.g., [26]) of a family of least squares estimates of the unknown parameter vector, the following two assumptions are used.

(A6) For each admissible control law, the $\mathcal{L}(\mathbb{R}^q, \mathbb{R}^q)$-valued process $(\hat{\mathcal{A}}(t),\, t \geq 0)$ satisfies

$$\liminf_{t\to\infty} |\det \tilde{\mathcal{A}}(t)| > 0 \qquad \text{a.s.}$$

and

(A7) there is a $c > 0$ such that $|Pf_i(x)|^2 > c$ for $i \in \{1, \dots, q\}$ and all $x \in H$.

It is elementary to give examples where (A6) and (A7) are satisfied. For example, (A6) and (A7) are trivially satisfied if $(Pf_1, Pf_2, \dots, Pf_q)$ are nonzero, orthogonal elements for each $x \in H$ and their norms are uniformly bounded away from zero.

The estimate of the unknown parameter vector at time t, $\hat{\alpha}(t)$, is the minimizer of the quadratic functional of α, $L(t;\alpha)$, given by

$$\begin{aligned} L(t;\alpha) = &- \int_0^t \sum_{i=1}^{q} \langle P\alpha^i f_i(X(s)), dPX(s)\rangle \\ &+ \frac{1}{2}\int_0^t \sum_{i=1}^{q} |P\alpha^i f_i(X(s))|^2 ds. \end{aligned} \tag{3.4}$$

The minimizer of (3.4) is the solution of the family of linear equations

$$\mathcal{A}(t)\hat{\alpha}(t) = \mathcal{A}(t)\alpha_0 + b(t) \tag{3.5}$$

or equivalently

$$\tilde{\mathcal{A}}(t)\hat{\alpha}(t) = \tilde{\mathcal{A}}(t)\alpha_0 + \tilde{b}(t), \tag{3.6}$$

where $\mathcal{A}(t)$ and $\tilde{\mathcal{A}}(t)$ are given by (3.2) and (3.3), respectively, $b(t) = (b_1(t), \dots, b_q(t))^{\mathrm{T}}$, $\tilde{b}(t) = (\tilde{b}_1(t), \dots, \tilde{b}_q(t))^{\mathrm{T}}$,

$$b_j(t) = \int_0^t \langle Pf_i(X(s)), dPQ^{1/2}W(t)\rangle$$

and

$$\tilde{b}_j(t) = \frac{b_j(t)}{a_{jj}(t)}$$

for $j = \{1, \dots, q\}$, and α_0 is the true parameter vector.

The family of estimates $(\hat{\alpha}(t),\, t \geq 0)$ is strongly consistent as described in the following result.

THEOREM 3.1. *Let* $(u(t),\, t \geq 0)$ *be an admissible control law. If* (A1)–(A4) *and* (A6)–(A7) *are satisfied, then the family of least squares estimates* $(\hat{\alpha}(t),\, t \geq 0)$*, where* $\hat{\alpha}(t)$ *is the solution of* (3.6)*, is strongly consistent, that is,*

$$\lim_{t\to\infty} \hat{\alpha}(t) = \alpha_0 \qquad a.s., \tag{3.7}$$

where α_0 *is the true parameter vector.*

Proof. By (A7), a time change in the stochastic integrals in the components of $b(t)$, and the law of large numbers for Brownian motion, it follows that

$$\lim_{t\to\infty} \tilde{b}(t) = 0 \qquad \text{a.s.} \tag{3.8}$$

The assumption (A6) ensures that for $t \gg 0$ $\tilde{\mathcal{A}}^{-1}(t,\omega)$ exists and is bounded for almost all ω, so the equality (3.8) implies that $\hat{\alpha}(t) \to \alpha_0$ a.s. as $t \to \infty$. □

In [21], the parameter estimation of α in (2.1) is considered where f depends on α not necessarily affinely. With an identifiability condition and some other conditions, it is shown that a family of maximum likelihood estimates of α is strongly consistent. This result is a generalization of [5] to some infinite dimensional systems. The infinite dimensional setting presents some significant difficulties that either do not occur or are relatively easily overcome in finite dimensions, e.g., the application of an Itô formula without strong solutions, the tightness of a family of empirical measures, and some properties of Markov semigroups.

4. Adaptive control. In this section an adaptive control is constructed using a solution to the infinite dimensional HJB equation. This control is shown to be self-optimizing for a strongly consistent family of estimates of the unknown parameter. To verify the self-optimality property, a continuous dependence of the solutions of the HJB equations with respect to the parameter in a suitable function space is an important tool. Initially the HJB equations are introduced corresponding to the discounted and the ergodic cost functionals (2.4) and (2.5) and a summary and some modifications of some known results on these control problems are given.

The formal HJB equations corresponding to the control problems (2.1), (2.4) and (2.1), (2.5) are, respectively,

$$\begin{aligned}\frac{1}{2}\operatorname{Tr} QD^2 v_\alpha^\lambda(x) + \langle Ax, Dv_\alpha^\lambda(x)\rangle + \langle f(\alpha,x), Dv_\alpha^\lambda(x)\rangle \\ - \tilde{H}(Dv_\alpha^\lambda(x)) + \psi(x) = \lambda v_\alpha^\lambda(x),\end{aligned} \tag{4.1}$$

$$\begin{aligned}\frac{1}{2}\operatorname{Tr} QD^2 v_\alpha(x) + \langle Ax, Dv_\alpha(x)\rangle + \langle f(\alpha,x), Dv_\alpha(x)\rangle \\ - \tilde{H}(Dv_\alpha(x)) + \psi(x) = \rho(\alpha).\end{aligned} \tag{4.2}$$

In (4.2) it is necessary to solve for the pair $(v_\alpha, \rho(\alpha))$, $\rho(\alpha) \in \mathbb{R}$ for each $\alpha \in \mathcal{A}$.

The existence of strong solutions to (4.1) and (4.2) is unlikely because of the first two terms on the left-hand side of these equations, specifically because Q is not trace class and A is only densely defined in H. The approach in [20] is to replace the first two terms in (4.1) and (4.2) by the generator of an Ornstein–Uhlenbeck semigroup in a suitable function space. The results of [20], [22] are used but for simplicity the solutions of (4.1) and (4.2) are defined in a weaker sense which is suitable for the applications to adaptive control.

Let $\mu = N(0, Q_\infty)$ be the invariant measure and

$$(R_t\varphi)(x) = \mathbb{E}_x\varphi(Z(t))$$

be the Markov transition semigroup for the Ornstein–Uhlenbeck process $(Z(t),\, t \geq 0)$ that is the solution of (2.6). It is well known that $(R_t,\, t \geq 0)$ is a strongly continuous semigroup on the Hilbert space

$$\mathcal{H} = L^2(H, \mu).$$

Let $\mathcal{L}$ be the infinitesimal generator of the semigroup $(R_t,\, t \geq 0)$ in $\mathcal{H}$. Furthermore, let $\mathcal{L}_0$ be given by

$$\mathcal{L}_0\varphi(x) = \frac{1}{2}\operatorname{Tr} QD^2\varphi(x) + \langle x, A^*D\varphi(x)\rangle \tag{4.3}$$

for $x \in H$ and $\varphi \in \operatorname{Dom}(\mathcal{L}_0)$, where $\operatorname{Dom}(\mathcal{L}_0) = \{\varphi \in C_b^2(H) \mid (1/2)\operatorname{Tr} QD^2\varphi(\cdot) \in C_b(H),\ \langle \cdot, A^*D\varphi(\cdot)\rangle \in C_b(H)\}$.

Let $\varphi \in \operatorname{Dom}(\mathcal{L}_0)$ and use the Itô formula to obtain

$$\begin{aligned}(\mathcal{L}\varphi)(x) &= \lim_{t\downarrow 0}\frac{1}{t}(R_t\varphi(x) - \varphi(x)) \\ &= \lim_{t\downarrow 0}\frac{1}{t}(\mathbb{E}_x\varphi(Z(t)) - \varphi(x)) \\ &= (\mathcal{L}_0\varphi)(x)\end{aligned}$$

so $\mathcal{L}$ is a closed extension of the operator $\mathcal{L}_0$. This equality motivates the following definition of solution of (4.1) and (4.2).

DEFINITION 4.1. *A function $v_\alpha^\lambda \in \operatorname{Dom}(\mathcal{L})$ and a pair $(v_\alpha, \rho(\alpha)) \in \operatorname{Dom}(\mathcal{L}) \times \mathbb{R}$ are solutions to* (4.1) *and* (4.2)*, respectively, if*

$$\mathcal{L}v_\alpha^\lambda + \langle f(\alpha,\cdot), Dv_\alpha^\lambda\rangle - \tilde{H}(Dv_\alpha^\lambda) + \psi = \lambda v_\alpha^\lambda \tag{4.4}$$

and

$$\mathcal{L}v_\alpha + \langle f(\alpha,\cdot), Dv_\alpha\rangle - \tilde{H}(Dv_\alpha) + \psi = \rho(\alpha) \tag{4.5}$$

are satisfied.

This definition of solutions to (4.1) and (4.2) requires only that the solutions be in $\mathrm{Dom}(\mathcal{L}) \subset L^2(H,\mu)$ so (4.4) and (4.5) are understood in an $L^2(H,\mu)$ sense. This relatively weak notion of solution is used to avoid some technical complications. Some results on the solutions to (4.1) and (4.2) are given in [20] and [22]. It is shown that the solutions are more regular than that required in Definition 4.1. For the following two propositions the parameter $\alpha \in \mathcal{A}$ is fixed.

PROPOSITION 4.1. *If* (A1), (A2), (A4), *and* (A5) *are satisfied, then* (4.1) *has one and only one solution* v_α^λ *in* $\mathrm{Dom}(\mathcal{L}) \cap C_b^1(H)$. *Furthermore,*

$$v_\alpha^\lambda(x) = \inf_{u\in\mathcal{U}} J(x,\lambda,u) \tag{4.6}$$

so that v_α^λ *gives the optimal cost and an optimal control in feedback form is* $\hat{u}_\alpha^\lambda(x) = D\tilde{H}(Dv_\alpha^\lambda(x))$ *for the discounted cost control problem* (2.1), (2.4).

This proposition has been basically proven by Gozzi and Rouy [22] when $f(\alpha,\cdot)$ is bounded. The generalization in Proposition 4.2 has been done by Goldys and Maslowski [20].

The ergodic control problem is usually considered to be more difficult than the discounted control problem because the HJB equation (4.2) has an intrinsic degeneracy; that is, there is no uniqueness of the solution to (4.2) because if $(v_\alpha,\ \rho(\alpha))$ is a solution of (4.2), then $(v_\alpha + c,\ \rho(\alpha))$ for $c \in \mathbb{R}$ is also a solution. The following proposition describes results in [20] for a slightly more general problem.

PROPOSITION 4.2. *If* (A1), (A2), (A4), *and* (A5) *are satisfied, where* $\omega - \beta > 0$ *and*

$$R < \frac{\sqrt{\omega_1}}{|Q^{-1/2}|_{\mathcal{L}(H)} k(\omega_1)\sqrt{\pi}}, \tag{4.7}$$

where $\omega_1 \in (0, \omega-\beta)$ *and* $k(\omega_1) > 0$ *is the constant given in* (2.29), *then there is a unique solution* $(v_\alpha, \rho(\alpha)) \in \mathrm{Dom}(\mathcal{L}) \times \mathbb{R}_+$ *such that* $v_\alpha \in C^1(H)$, $Dv_\alpha \in C_b(H)$, *and* $v_\alpha(0) = 0$. *Furthermore,*

$$\rho(\alpha) = \inf_{u\in\mathcal{U}} \tilde{J}(x,u) \tag{4.8}$$

so that $\rho(\alpha)$ *is the optimal cost and an optimal control in feedback form is* $\hat{u}_\alpha(x) = D\tilde{H}(Dv_\alpha(x))$ *for the ergodic control problem* (2.1), (2.5)

The following result provides a relative compactness of some translates of (v_α^λ) that allows the ergodic solution v_α to be obtained as a "limit" of the discounted control problems.

PROPOSITION 4.3. *If* (A1), (A2), (A4), *and* (A5) *are satisfied, where* $\omega - \beta > 0$ *and the inequality* (4.7) *are satisfied, then the family of functions* $(\bar{v}_\alpha^\lambda;\ \alpha \in \mathcal{A},\ \lambda \in (0,1])$ *is relatively compact in the Sobolev space* $W^{1,2}(H,\mu)$, *where* $\bar{v}_\alpha^\lambda = v_\alpha^\lambda - c(\alpha,\lambda)$ *and*

$$c(\alpha,\lambda) = \frac{1}{\lambda}\int_H (\langle f(\alpha,x), Dv_\alpha^\lambda(x)\rangle - \tilde{H}(Dv_\alpha^\lambda(x)) + \psi(x))\mu(dx).$$

Proof. Let $\hat{P}_t^{\alpha,\lambda} : C_b(H) \to C_b(H)$ be the Markov transition semigroup corresponding to the solution of (2.1) using the optimal control $\hat{u}_\alpha^\lambda$, that is, $\hat{P}_t^{\alpha,\lambda}\varphi(x) = \mathbb{E}\varphi(X^{x,\alpha,\lambda}(t))$, where $(X^{x,\alpha,\lambda}(t),\, t \geq 0)$ satisfies

$$dX^{x,\alpha,\lambda}(t) = (AX^{x,\alpha,\lambda}(t) + f(\alpha, X^{x,\alpha,\lambda}(t)) - \hat{u}_\alpha^\lambda(X^{x,\alpha,\lambda}(t)))dt + Q^{1/2}dW(t),$$
$$X^{x,\alpha,\lambda}(0) = x.$$

Initially it is verified that there is a function $\gamma \in L^1(0,\infty)$ that does not depend on α or λ such that

$$\|D\hat{P}_t^{\alpha,\lambda}\varphi\| \leq \gamma(t)\|\varphi\| \tag{4.9}$$

for each $\varphi \in C_b(H)$. It is known that the function $\xi(t,x) = \hat{P}_t^{\alpha,\lambda}\varphi(x)$ is a solution to the backward Kolmogorov equation, which is defined as a mild solution, that is, $\xi(t,\cdot) \in C_b^1(H)$ for each $t > 0$ and it satisfies the integral equation

$$\xi(t,x) = P_t^\alpha\varphi(x) + \int_0^t P_{t-s}^\alpha\langle -\hat{u}_\alpha^\lambda(\cdot), D\xi(s,\cdot)\rangle(x)ds \tag{4.10}$$

for $t > 0$, where $(P_t^\alpha,\, t \geq 0)$ is the Markov transition semigroup of the solution of (2.1) with $u \equiv 0$. Using the differentiability of (4.10) in x and Proposition 2.2, it follows that

$$\begin{aligned}\|D\hat{P}_t^{\alpha,\lambda}\varphi\| &\leq k(\omega_1)|Q^{-1/2}|_{\mathcal{L}(H)}t^{-1/2}e^{-\omega_1 t}\|\varphi\| \\ &\quad + \int_0^t k(\omega_1)|Q^{-1/2}|_{\mathcal{L}(H)}(t-s)^{-1/2}e^{-\omega_1(t-s)}R\|D\hat{P}_s^{\alpha,\lambda}\varphi\|ds\end{aligned} \tag{4.11}$$

for $t > 0$, where $\omega_1 \in (0, \omega - \beta)$ and $k(\omega_1)$ is given in (2.29). Let $c = k(\omega_1)|Q^{-1/2}|_{\mathcal{L}(H)}\|\varphi\|$ and $C = k(\omega_1)|Q^{-1/2}|_{\mathcal{L}(H)}R$ so (4.11) can be written as

$$\|D\hat{P}_t^{\alpha,\lambda}\varphi\| \leq ct^{-1/2}e^{-\omega_1 t} + C\int_0^t (t-s)^{-1/2}e^{-\omega_1(t-s)}\|D\hat{P}_t^{\alpha,\lambda}\varphi\|ds.$$

By the generalized Gronwall lemma (Lemma 7.11 in [24]), if

$$\left(C\Gamma\left(\frac{1}{2}\right)\right)^2 < \theta < \omega_1, \tag{4.12}$$

where $\Gamma(\cdot)$ is the gamma function, then there is a universal constant $k > 0$ such that

$$\|D\hat{P}_t^{\alpha,\lambda}\varphi\| \leq \gamma(t)\|\varphi\|$$

for $t > 0$, where

$$\begin{aligned}\gamma(t) &= k(\omega_1)|Q^{-1/2}|_{\mathcal{L}(H)} \\ &\quad \times \left(e^{-\omega_1 t}t^{-1/2} + k\int_0^t e^{(\theta-\omega_1)(t-s)}(t-s)^{-1/2}e^{-\omega_1 s}s^{-1/2}ds\right)\end{aligned}$$

and $\gamma \in L^1(0,\infty)$ by a property of convolution from Young's inequality. The inequality (4.7) guarantees that (4.12) is satisfied for some θ so the inequality (4.9) is satisfied.

Next it is shown that there is a constant C_1 that does not depend on α or λ such that

$$\|D\bar{v}_\alpha^\lambda\| \le C_1$$

for $\lambda \in (0,1]$ and $\alpha \in \mathcal{A}$. Since v_α^λ is the optimal cost and $\hat{u}_\alpha^\lambda$ is the optimal control for the discounted control problem (2.1), (2.4) from Proposition 2.2, it follows that

$$v_\alpha^\lambda(x) = \int_0^\infty e^{-\lambda t}\hat{P}_t^{\alpha,\lambda}(\psi + h(\hat{u}_\lambda^\alpha))(x)dt$$

for each $x \in H$, $\lambda \in (0,1]$, and $\alpha \in \mathcal{A}$. Since v_α^λ and $\bar{v}_\alpha^\lambda$ differ only by a constant, it follows from (4.9) that

$$\begin{aligned}\|D\bar{v}_\alpha^\lambda\| &\le \int_0^\infty \|D\hat{P}_t^{\alpha,\lambda}(\psi + h(\hat{u}_\lambda^\alpha))\|dt \\ &\le \left(\|\varphi\| + \sup_{|y|\le R}|h(y)|\right)\int_0^\infty \gamma(t)dt := C_1. \end{aligned} \tag{4.13}$$

Let $Q_t = \int_0^t S(r)QS^*(r)dr$. Clearly Q_t is the covariance operator of the (Gaussian) probability law of $Z(t)$, where $(Z(t),\, t \ge 0)$ is the Ornstein–Uhlenbeck process that satisfies (2.6). It is known that $(Z(t),\, t \ge 0)$ is strongly Feller, that is, $\text{Range}(S(t)) \subset \text{Range}(Q_t^{1/2})$ for $t > 0$ so the operator $\Gamma(t) = Q_t^{-1/2}S(t) \in \mathcal{L}(H)$ [11]. Furthermore, it follows from [8] and [20] that

$$\int_0^\infty |\Gamma(t)|_{\mathcal{L}(H)}dt < \infty. \tag{4.14}$$

The resolvent of the infinitesimal generator $\mathcal{L}$ can be expressed as

$$(\lambda I - \mathcal{L})^{-1}\varphi = \int_0^\infty e^{-\lambda t}R_t\varphi dt$$

for $\varphi \in \mathcal{H}$ so the solution v_α^λ of (4.4) satisfies the integral equation

$$v_\alpha^\lambda = \int_0^\infty e^{-\lambda t}R_t(\langle f(\alpha,\cdot), Dv_\alpha^\lambda\rangle - \tilde{H}(Dv_\alpha^\lambda) + \psi)dt.$$

Since the inequality

$$|DR_t\varphi|_{L^2(H,\mu;H)} \le |\Gamma(t)|_{\mathcal{L}(H)}|\varphi|_{\mathcal{H}} \tag{4.15}$$

is satisfied for $t > 0$, by the Cameron–Martin formula (Lemma 3 in [7]) the integral operators

$$T_\lambda = \int_0^\infty e^{-\lambda t}DR_t dt$$

for $\lambda \in [0,1]$ converge in the $\mathcal{L}(\mathcal{H}, L^2(H,\mu;H))$ norm. Since for each $t > 0$ the linear operator $DR_t : \mathcal{H} \to L^2(H,\mu;H)$ is compact [7], the operators T_λ are also compact. Thus

$$D\bar{v}_\alpha^\lambda = Dv_\alpha^\lambda = T_\lambda\xi_\alpha^\lambda,$$

where $T_\cdot : [0,1] \to \mathcal{L}(\mathcal{H}, L^2(H,\mu;H))$ is continuous and

$$\xi_\alpha^\lambda := \langle f(\alpha,\cdot), Dv_\alpha^\lambda\rangle - \tilde{H}(Dv_\alpha^\lambda) + \psi$$

for $\alpha \in \mathcal{A}$ and $\lambda \in (0,1]$ are uniformly bounded in $\mathcal{H}$ by (4.13). It follows that the family $(D\bar{v}_\alpha^\lambda,\ \alpha \in \mathcal{A},\ \lambda \in (0,1])$ is relatively compact in $L^2(H,\mu;H)$. Note that

$$\bar{v}_\alpha^\lambda = \int_0^\infty e^{-\lambda t} R_t(\xi_\alpha^\lambda - \lambda c(\lambda,\alpha))dt, \tag{4.16}$$

where

$$\int_H (\xi_\alpha^\lambda - \lambda c(\lambda,\alpha))d\mu = 0. \tag{4.17}$$

Furthermore, by [7] the semigroup is compact in $\mathcal{H}$ and there is a $\lambda_1 > 0$ such that $|R_t\varphi|_{\mathcal{H}} \le e^{-\lambda_1 t}|\varphi|_{\mathcal{H}}$ for each $\varphi \in \mathcal{H}$ satisfying $\int \varphi d\mu = 0$. Using (4.16) and (4.17), v_α^λ can replace $D\bar{v}_\alpha^\lambda$ above to verify that $(v_\alpha^\lambda,\ \alpha \in \mathcal{A},\ \lambda \in (0,1])$ is relatively compact in $\mathcal{H}$. □

A result on the approximation of functions in $\mathrm{Dom}(\mathcal{L})$ by functions in $\mathrm{Dom}(\mathcal{L}_0)$ is given. Similar results in different spaces have been given (e.g., [6], [20], [22]). Let $\mathcal{W} \subset W^{1,2}(H,\mu)$ be given by

$$\begin{aligned}\mathcal{W} = \{\varphi \in W^{1,2}(H,\mu)\ |\varphi \in \mathrm{Dom}(\mathcal{L}),\ \|D\varphi\| < \infty,\\ |\varphi(x)| + |\mathcal{L}\varphi(x)| \le k(1+|x|^q) \text{ for all } x \in H\\ \text{and some real numbers } k \text{ and } q\}.\end{aligned}$$

LEMMA 4.1. *If $\varphi \in \mathcal{W}$, then there is a sequence $(\varphi_n, n \in \mathbb{N})$ such that $\varphi_n \in \mathrm{Dom}(\mathcal{L}_0)$, $\varphi_n \in \mathcal{W}$ for fixed k and q defining $\mathcal{W}$ for all $n \in \mathbb{N}$, $\sup_n \|D\varphi_n\| < \infty$, and*

$$\lim_{n\to\infty} |\varphi_n - \varphi|_{\mathcal{H}} = 0, \tag{4.18}$$

$$\lim_{n\to\infty} |\mathcal{L}_0\varphi_n - \mathcal{L}\varphi|_{\mathcal{H}} = 0, \tag{4.19}$$

$$\lim_{n\to\infty} |D\varphi_n - D\varphi|_{L^2(H,\mu;H)} = 0. \tag{4.20}$$

Proof. Choose $\lambda > 0$ and fix it. Let $\xi = \lambda\varphi - \mathcal{L}\varphi$. Since the inequality

$$|\xi(x)| \le k(1+|x|^q) \tag{4.21}$$

for all $x \in H$ is satisfied, there is a sequence $(\xi_n, n \in \mathbb{N})$ such that $\xi_n \in \mathrm{Dom}(\mathcal{L}_0)$ and ξ_n satisfies (4.21) for all $n \in \mathbb{N}$, $\xi_n \to \xi$ in $\mathcal{H}$ as $n \to \infty$, and $\sup_n \|D\xi_n\| < \infty$. A similar construction is given in Lemma 4.5 in [20]. Now let

$$\varphi_n = \int_0^\infty e^{-\lambda t} R_t\xi_n dt. \tag{4.22}$$

Since $(\lambda I - \mathcal{L})^{-1} : \mathrm{Dom}(\mathcal{L}_0) \to \mathrm{Dom}(\mathcal{L}_0)$ and $\varphi_n = (\lambda I - \mathcal{L})^{-1}\xi_n$, it follows that $\varphi_n \in \mathrm{Dom}(\mathcal{L}_0)$. Furthermore,

$$|\varphi_n - \varphi|_{\mathcal{H}} \le \int_0^\infty e^{-\lambda t}|R_t(\xi_n - \xi)|_{\mathcal{H}} dt \le |\xi_n - \xi|_{\mathcal{H}} \int_0^\infty e^{-\lambda t} dt$$

and

$$|D\varphi_n - D\varphi|_{L^2(H,\mu;H)} \le \int_0^\infty e^{-\lambda t}|DR_t(\xi_n - \xi)|_{L^2(H,\mu;H)}dt$$
$$\le |\xi_n - \xi|_{\mathcal{H}} \int_0^\infty e^{-\lambda t}|\Gamma(t)|_{\mathcal{L}(H)}dt.$$

This latter inequality follows from (4.15) and the convergence of the right-hand side to zero as $n \to \infty$ follows from (4.14) and the definition of $(\xi_n,\, n \in \mathbb{N})$. It can be verified directly that

$$\|DR_t\xi_n\| = \left\|D\mathbb{E}\xi_n\left(S(t)x + \int_0^t S(t-r)Q^{1/2}dW(r)\right)\right\| \le \|D\xi_n\|$$

for $t > 0$ so that

$$\sup_n \|D\varphi_n\| \le \frac{1}{\lambda}\sup_n \|D\xi_n\| < \infty.$$

Since $\mathcal{L}_0\varphi_n = \lambda\varphi_n - \xi_n$ it follows that $\mathcal{L}_0\varphi_n = \mathcal{L}\varphi_n \to y$ on $\mathcal{H}$ as $n \to \infty$ for some $y \in \mathcal{H}$ because $\mathcal{L}$ is a closed operator. Thus, $y = \mathcal{L}\varphi$. The uniform polynomial bounds on φ_n and thereby on $\mathcal{L}_0\varphi_n$ follow from the same bounds on ξ_n and (4.22). □

The following proposition is a "$W^{1,2}(H,\mu)$-version" of a result in [20] on the existence and the uniqueness of a solution to the ergodic HJB equation which is described in Proposition 4.2. While the existence result is weaker than the one in Proposition 4.2, the family of solutions for uniqueness is enlarged. The parameter $\alpha \in \mathcal{A}$ in the following proposition is fixed.

PROPOSITION 4.4. *If* (A1), (A2), (A4), (A5) *with* $\omega - \beta > 0$, *and* (4.7) *are satisfied, then there is a unique solution* $(v_\alpha, \rho(\alpha)) \in (\mathcal{W} \cap C(H)) \times \mathbb{R}$ *of* (4.2) *such that* $v_\alpha(0) = 0$. *Furthermore, the equality* (4.8) *is satisfied and an optimal control in feedback form is* $\hat{u}_\alpha(x) = D\tilde{H}(Dv_\alpha(x))$ *for the ergodic control problem* (2.1), (2.5).

Proof. The existence of the solution $(v_\alpha, \rho(\alpha))$ with the required properties including (4.8) and an optimal feedback control follow from a result in [20] that is given here as Proposition 4.2. However, it should be noted that the existence of a solution is a simple consequence of Proposition 4.3. Since $(|\lambda c(\alpha,\lambda)|,\, \lambda \in (0,1])$ is uniformly bounded, there is a sequence $(\lambda_n,\, n \in \mathbb{N})$ such that $\lambda_n \downarrow 0$ and $(\bar{v}_\alpha^{\lambda_n}, \lambda_n c(\alpha,\lambda_n)) \to (\bar{v}_\alpha, \delta)$ in $W^{1,2}(H,\mu) \times \mathbb{R}$ for some $(\bar{v}_\alpha, \delta) \in W^{1,2}(H,\mu) \times \mathbb{R}$. Letting $\lambda_n \downarrow 0$ in (4.1) and using the closedness of $\mathcal{L}$ in $\mathcal{H}$ it follows that $\bar{v}_\alpha \in \mathrm{Dom}(\mathcal{L})$ and

$$\mathcal{L}\bar{v}_\alpha + \langle f(\alpha,\cdot), D\bar{v}_\alpha\rangle - \tilde{H}(D\bar{v}_\alpha) + \psi = \delta$$

is satisfied.

Now let $(\bar{v}, \bar{\delta}) \in (\mathcal{W} \cap C(H)) \times \mathbb{R}$ be a solution of (4.2) satisfying $\bar{v}(0) = 0$. To verify uniqueness, it suffices to show that $(\bar{v}, \bar{\delta}) = (v_\alpha, \rho(\alpha))$, where $(v_\alpha, \rho(\alpha))$ is the solution of (4.2) whose existence is given by Proposition 4.2.

Initially it is shown that

$$\bar{\delta} = \rho(\alpha). \tag{4.23}$$

This verification is analogous to the corresponding part of the proof of Proposition 4.2 that is given in [20]. Let $(\bar{v}_n,\, n \in \mathbb{N})$ be a sequence such that $\bar{v}_n \in \mathrm{Dom}(\mathcal{L}_0)$ for each $n \in \mathbb{N}$ and

$$\bar{v}_n \to \bar{v}, \quad \mathcal{L}_0\bar{v}_n \to \mathcal{L}\bar{v} \qquad \text{in } \mathcal{H}, \tag{4.24}$$

$$\sup_n \|D\bar{v}_n\| < \infty, \quad D\bar{v}_n \to D\bar{v} \qquad \text{in } L^2(H,\mu;H), \tag{4.25}$$

and $\bar{v}_n$ and $\mathcal{L}_0\bar{v}_n$ are uniformly, polynomially bounded (cf. Lemma 4.1). Clearly, the pair $(\bar{v}_n, \bar{\delta})$ satisfies the equation

$$\mathcal{L}_0\bar{v}_n + \langle f(\alpha,\cdot), D\bar{v}_n\rangle - \tilde{H}(D\bar{v}_n) + \psi_n = \bar{\delta},$$

where

$$\psi_n = \bar{\delta} + \tilde{H}(D\bar{v}_n) - \langle f(\alpha,\cdot), D\bar{v}_n\rangle - \mathcal{L}_0\bar{v}_n.$$

Apply the Itô formula using the function $-\bar{\delta}t + \bar{v}_n(x)$ and the process that is the solution of (2.1) with the control $D\tilde{H}(D\bar{v}_n)$ to show that $\bar{\delta}$ is the optimal cost for the control problem (2.1) and (2.5), where ψ is replaced by ψ_n in (2.5). Since $\psi_n \to \psi$ (at least) pointwise by (4.24) and (4.25) and the sequence $(\psi_n,\, n \in \mathbb{N})$ is uniformly polynomially bounded, the limit as $n \to \infty$ can be taken to show that $\bar{\delta}$ is the optimal cost for the control problem (2.1) and (2.5) so that (4.14) is verified.

It remains to show that $\bar{v} = v_\alpha$. Let $(v_n,\, n \in \mathbb{N})$ be a sequence such that

$$v_n \to v_\alpha, \quad \mathcal{L}_0 v_n \to \mathcal{L} v_\alpha \qquad \text{in } \mathcal{H}, \tag{4.26}$$

$$\sup_n \|Dv_n\| < \infty. \quad Dv_n \to Dv_\alpha \qquad \text{in } L^2(H,\mu;H), \tag{4.27}$$

and v_n and $\mathcal{L}_0 v_n$ are uniformly, polynomially bounded using the notation of Lemma 4.1. Recall that $\alpha \in \mathcal{A}$ is fixed so the dependence of v_n on α is suppressed. Let $\bar{u}_n = D\tilde{H}(Dv_n)$ and $\bar{u} = D\tilde{H}(Dv_\alpha)$ be controls. For an arbitrary $\Phi \in C([0,T],H)$ it easily follows from (4.27) that

$$\begin{aligned}
&|\mathbb{E}_{\tau,x,\bar{u}_n}\Phi(X(\cdot)) - \mathbb{E}_{\tau,x,\bar{u}}\Phi(X(\cdot))| \\
&\quad \le \mathbb{E}_{\tau,x}\Phi(X(\cdot))\left|\exp\left(-\int_0^T \langle Q^{-1/2}\bar{u}_n(X(s)), dW(s)\rangle \right.\right. \\
&\qquad\qquad \left. - \frac{1}{2}\int_0^T |Q^{-1/2}\bar{u}_n(X(s))|^2 ds\right) \\
&\qquad \left. - \exp\left(-\int_0^T \langle Q^{-1/2}\bar{u}(X(s)), dW(s)\rangle - \frac{1}{2}\int_0^T |Q^{-1/2}\bar{u}(X(s))|^2 ds\right)\right| \\
&\quad \to 0 \qquad \text{as } n \to \infty
\end{aligned}$$

for $\tau \in [0,T)$, where $\mathbb{E}_{\tau,x,u}$ and $\mathbb{E}_{\tau,x}$ denote the expectations associated with the initial condition $X(\tau) = x$ and $(X(t),\, t \ge \tau)$ is the solution to (2.1) with $X(\tau) = x$ and $u \in \mathcal{U}$ and $u \equiv 0$, respectively. By the Skorokhod theorem there is a probability space $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$ and stochastic processes $(X_n(t), t \ge \tau)$ for $n \in \mathbb{N}$ and $(X_0(t),\, t \ge \tau)$ such that $X_n(\cdot)$ and $X_0(\cdot)$ have the probability laws on $C([\tau,\infty);H)$ that are identical with the solutions of (2.1) with the feedback controls $\bar{u}_n(X_n)$ and $\bar{u}(X_0)$, respectively, and

$$\lim_{n\to\infty} \sup_{s\in[\tau,T]} |X_n(s) - X_0(s)| = 0 \qquad \text{a.s. } \tilde{\mathbb{P}}$$

for each $T > \tau$. By the definition of $\tilde{H}$ in (A5) it follows that

$$\begin{aligned} 0 &= \tilde{H}(Dv_\alpha(x)) + h(\bar{u}(x)) - \langle \bar{u}(x), Dv_\alpha(x)\rangle \\ &\le \tilde{H}(D\bar{v}(x)) + h(\bar{u}(x)) - \langle \bar{u}(x), D\bar{v}(x)\rangle \end{aligned}$$

so that

$$\begin{aligned} &\mathcal{L}v_\alpha(x) + \langle f(\alpha,x), Dv_\alpha(x)\rangle - \langle \bar{u}(x), Dv_\alpha(x)\rangle \\ &\quad \le \mathcal{L}\bar{v}(x) + \langle f(\alpha,x), D\bar{v}(x)\rangle - \langle \bar{u}(x), D\bar{v}(x)\rangle, \end{aligned}$$

and therefore

$$\begin{aligned} &\mathcal{L}v_n(x) + \langle f(\alpha,x), Dv_n(x)\rangle - \langle \bar{u}_n(x), Dv_n(x)\rangle \\ &\quad \le \mathcal{L}_0\bar{v}_n(x) + \langle f(\alpha,x), D\bar{v}_n(x)\rangle - \langle \bar{u}_n(x), D\bar{v}_n(x)\rangle + \delta_n(x) \end{aligned}$$

for all $x \in H$, where $\delta_n : H \to \mathbb{R}$ converges to 0 as $n \to \infty$ in $L^2(H,\mu)$ and $(\delta_n,\ n \in \mathbb{N})$ is uniformly, polynomially bounded. Using the Itô formula it follows that the processes

$$\Psi_n(t) = v_n(X_n(t)) - \bar{v}_n(X_n(t)) - \int_\tau^t \delta_n(X_n(s))ds$$

for $t \ge \tau$ satisfy the inequality

$$\tilde{\mathbb{E}}\Psi_n(t) \le \Psi_n(\tau) = v_n(x) - \bar{v}_n(x),$$

where $\tilde{\mathbb{E}}$ is the expectation in $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$. Note that the probability laws for $X_n(s)$ for each $s \in \mathbb{R}_+$ and $n \in \mathbb{N} \cup \{0\}$ are mutually absolutely continuous with μ because by the Girsanov theorem any of these measures is equivalent to the Gaussian measure $N(S(t)x, Q_t)$ (the law for $Z(t)$ from the solution of (2.6)) and $N(S(t)x, Q_t)$ is equivalent to μ from the strong Feller property for each $t > 0$ and $x \in H$ (e.g., [27]). It follows that

$$\lim_{n\to\infty} \tilde{\mathbb{E}}\Psi_n(t) = \tilde{\mathbb{E}}(v_\alpha(X_0(t)) - \bar{v}(X_0(t)))$$

and thus

$$\mathbb{E}_{\tau,x,\bar{u}}(v_\alpha(X(t)) - \bar{v}(X(t))) \le v_\alpha(x) - \bar{v}(x)$$

for $t \ge \tau$ and $x \in H$. Since $\tau \in [0,t]$ and $x \in H$ are arbitrary, it follows that the process $(v_\alpha(X(t)) - \bar{v}(X(t)),\ t \ge 0)$, where $(X(t),\ t \ge 0)$ satisfies (2.1) with $u(t) = \bar{u}(X(t))$, is a supermartingale.

Furthermore,

$$\sup_{t\ge 0} \mathbb{E}_{x,\bar{u}} |v_\alpha(X(t)) - \bar{v}(X(t))| \le k \sup_{t\ge 0} \mathbb{E}(1 + |X(t)|^q) < \infty$$

for some positive constants k and q by Proposition 2.1 (i). Thus, there is a limit of $(v_\alpha(X(t)) - \bar{v}(X(t)),\ t \ge 0)$ a.s. $\mathbb{P}^\alpha_{x,\bar{u}}$ as $t \to \infty$. Since the solution of (2.1) is ergodic for these feedback controls, for each ball B in H there is a sequence of random times $(\sigma_n,\ n \in \mathbb{N})$ that increase to infinity such that $X(\sigma_n) \in B$ (cf. [29]). Since $v_\alpha(0) - \bar{v}(0) = 0$ and $v_\alpha - \bar{v} : H \to \mathbb{R}$ is a continuous function, letting $B = B_{1/n}$ for $n \in \mathbb{N}$ it follows that

$$\liminf_{t\to\infty} (v_\alpha(X(t)) - \bar{v}(X(t))) = 0 \qquad \text{a.s. } \mathbb{P}^\alpha_{x,\bar{u}}$$

so that

$$\lim_{t\to\infty}(v_\alpha(X(t)) - \bar{v}(X(t))) = 0 \qquad \text{a.s. } \mathbb{P}^\alpha_{x,\bar{u}}. \tag{4.28}$$

If there is a $y \in H$ such that $v_\alpha(y) - \bar{v}(y) > 0$, then $v_\alpha - \bar{v} > \Delta > 0$ in an open ball B_y centered at y. Choosing $B = B_y$ above gives a contradiction to (4.28) so that $v_\alpha \equiv \bar{v}$. □

COROLLARY 4.1. *If* (A1)–(A5) *where* $\omega - \beta > 0$ *are satisfied and* (4.7) *is satisfied, then the function* $v_\cdot : \mathcal{A} \to W^{1,2}(H,\mu)$ *given by* $\alpha \mapsto v_\alpha$ *is continuous and*

$$\|Dv_\alpha\| < C_1 \tag{4.29}$$

for all $\alpha \in \mathcal{A}$ *and some constant* $C_1 > 0$ *that does not depend on* $\alpha \in \mathcal{A}$ *where* v_α *is the unique solution of the ergodic HJB equation given in Proposition* 4.4.

Proof. Let $\bar{v}_\alpha$ be the first component of the solution of the ergodic HJB which is given in the proof of Proposition 4.4 as a limit of $\bar{v}^\lambda_\alpha$ in $W^{1,2}(H,\mu)$ as $\lambda \downarrow 0$. By (4.13) it follows that

$$\|Dv_\alpha\| = \|D\bar{v}_\alpha\| \le C_1$$

because by the uniqueness part of Proposition 4.4 v_α and $\bar{v}_\alpha$ differ only by a constant. Clearly the family $(\bar{v}_\alpha,\ \alpha \in \mathcal{A})$ is relatively compact in $W^{1,2}(H,\mu)$ by Proposition 4.3. Using this relative compactness and the closedness of the derivative operator for any sequence $(\bar{v}_{\alpha_n},\ n \in \mathbb{N})$ such that $\alpha_n \to \alpha_0$ as $n \to \infty$ there is a subsequence again denoted $(\bar{v}_{\alpha_n},\ n \in \mathbb{N})$ such that $\bar{v}_{\alpha_n} \to \tilde{v}$ and $D\bar{v}_{\alpha_n} \to D\tilde{v}$ a.e. μ for some $\tilde{v}$. Furthermore, the sequence $(\rho(\alpha_n),\ n \in \mathbb{N})$ is uniformly bounded by (4.13) and Proposition 4.4 and there is a subsequence again denoted by $(\rho(\alpha_n),\ n \in \mathbb{N})$ such that $\rho(\alpha_n) \to \tilde{\rho}$ for some $\tilde{\rho} \in \mathbb{R}$. Since $\mathcal{L}\bar{v}_{\alpha_n} + \langle f(\alpha_n,\cdot), D\bar{v}_n\rangle - \tilde{H}(D\bar{v}_{\alpha_n}) + \psi = \rho(\alpha_n)$ and the operator $\mathcal{L}$ is closed in $\mathcal{H}$, it follows by (A3) that the limit as $n \to \infty$ is

$$\mathcal{L}\tilde{v} + \langle f(\alpha,\cdot), D\tilde{v}\rangle - \tilde{H}(D\tilde{v}) + \psi = \rho \qquad \text{a.e. } \mu.$$

By (4.29), $\tilde{v}$ is continuous and $D\tilde{v}$ is bounded so that $\tilde{v} \in \mathcal{W}$. By the uniqueness part of Proposition 4.4 it follows that $\tilde{v} - \tilde{v}(0) = v_{\alpha_0}$. By (4.28) and the (μ) almost sure convergence $\bar{v}_{\alpha_n} \to \tilde{v}$ as $n \to \infty$ it follows that $\bar{v}_{\alpha_n}(0) \to \tilde{v}(0)$. Therefore, $v_{\alpha_n} = \bar{v}_{\alpha_n} - \tilde{v}_{\alpha_n}(0) \to \tilde{v} - \tilde{v}(0) = v_{\alpha_0}$ as $n \to \infty$. □

For a certainty equivalence adaptive control and a consistent family of estimators of the unknown parameter vector, it is shown that this control is self optimizing. Consider (2.1) with the true parameter value $\alpha_0 \in \mathcal{A}$, that is,

$$\begin{aligned} dX(t) &= (AX(t) + f(\alpha_0, X(t)) - \tilde{u}(t))dt + Q^{1/2}dW(t), \\ X(0) &= x, \end{aligned}$$

where

$$\tilde{u}(t) = D\tilde{H}(Dv_{\alpha(t)}(X(t))), \tag{4.30}$$

where $(\alpha(t),\ t \ge 0)$ is an adapted, measurable, $\mathcal{A}$-valued process satisfying

$$\lim_{t\to\infty}\alpha(t) = \alpha_0 \tag{4.31}$$

in probability $\mathbb{P}$ and v_α is given in Proposition 4.4.

The following theorem and its corollary provide solutions to an adaptive control problem described by (2.1) and (2.5).

THEOREM 4.1. *Given the adaptive control problem described by* (2.1) *and* (2.5), *where* $\alpha_0 \in \mathcal{A}$ *is the true parameter vector, if* (A1)–(A5) *are satisfied,* $\omega - \beta > 0$, *the inequality* (4.7), *is satisfied, and the* $\mathcal{A}$*-valued family of estimates of* α_0 $(\alpha(t),\, t \geq 0)$, *satisfies* (4.31), *then*

$$\tilde{J}(x, \tilde{u}) = \rho(\alpha_0) \tag{4.32}$$

for each $x \in H$, *where* $\tilde{u}$ *is the adaptive control given by* (4.30).

Proof. For notational simplicity, let $v = v_{\alpha_0}$ and $\rho = \rho(\alpha_0)$. Let $v_n \in \mathrm{Dom}(\mathcal{L}_0)$ for $n \in \mathbb{N}$ be a sequence that converges to v as in (4.26), (4.27). The Itô formula applied to $(v_n(X(t)) - \rho t,\, t \geq 0)$ yields the equation

$$\begin{aligned} &- \rho t + \mathbb{E}_{x,\tilde{u}} v_n(X(t)) \\ &\quad = v_n(x) + \mathbb{E}_{x,\tilde{u}} \int_0^t [-\rho + \mathcal{L}_0 v_n(X(s)) + \langle f(\alpha_0, X(s)), Dv_n(X(s))\rangle \\ &\qquad\qquad - \langle \tilde{u}(s), Dv_n(X(s))\rangle] ds. \end{aligned}$$

Since v_n satisfies

$$\mathcal{L}_0 v_n + \langle f(\alpha_0, \cdot), Dv_n\rangle - \tilde{H}(Dv_n) + \psi_n = \rho,$$

where

$$\psi_n = \rho + \tilde{H}(Dv_n) - \langle f(\alpha_0, \cdot), Dv_n\rangle - \mathcal{L}_0 v_n,$$

it follows that

$$\begin{aligned} &- \rho t + \mathbb{E}_{x,\tilde{u}} v_n(X(t)) \\ &\quad = v_n(x) + \mathbb{E}_{x,\tilde{u}} \int_0^t [-\psi_n(X(s)) + \tilde{H}(Dv_n(X(s))) - \langle \tilde{u}(s), Dv_n(X(s))\rangle] ds. \end{aligned}$$

By the definition of $\tilde{H}$ in (A5) it follows that

$$-\tilde{H}(Dv_n(X(s))) - h(\tilde{u}(X(s))) + \langle \tilde{u}_n(X(s)), Dv_n(X(s))\rangle = 0,$$

where

$$\tilde{u}_n(x) = D\tilde{H}(Dv_n(x)).$$

Therefore,

$$\begin{aligned} \rho t &= \mathbb{E}_{x,\tilde{u}} v_n(X(t)) - v_n(x) \\ &\quad + \mathbb{E}_{x,\tilde{u}} \int_0^t [\psi_n(X(s)) + h(\tilde{u}_n(X(s))) + \langle \tilde{u}(s) - \tilde{u}_n(X(s)), Dv_n(X(s))\rangle] ds. \end{aligned}$$

Using the properties of convergence $v_n \to v$ in (4.26), (4.27), the uniform polynomial bound on the sequence $(v_n,\, n \in \mathbb{N})$ and Proposition 2.1 (i), the passage to the limit $(n \to \infty)$ yields the equation

$$\begin{aligned} \rho t &= \mathbb{E}_{x,\tilde{u}} v(X(t)) - v(x) \\ &\quad + \mathbb{E}_{x,\tilde{u}} \int_0^t [\psi(X(s)) + h(\tilde{u}_0(X(s))) + \langle \tilde{u}(s) - \tilde{u}_0(X(s)), Dv(X(s))\rangle] ds, \end{aligned} \tag{4.33}$$

where $\tilde{u}_0(x) = D\tilde{H}(Dv(x))$. By Proposition 2.1 (i) it follows that

$$\lim_{t\to\infty} \frac{1}{t}\mathbb{E}_{x,\tilde{u}} v(X(t)) = 0$$

for each $x \in H$. By an interpolation result (Lemma 4.6 in [22]) it follows that

$$\|Dv_\alpha^\lambda\|_{r,\theta} \le c_1 + c_2\|Dv_\alpha^\lambda\| + c_3 \sup_{x\in B_r} |f(\alpha,x)|\|Dv_\alpha^\lambda\| \tag{4.34}$$

for some universal constants c_1, c_2, c_3 and a suitable constant $\theta > 0$, where $\|\cdot\|_{r,\theta}$ denotes the norm of Hölder continuous functions with exponent θ on the ball B_r. The result in [22] is stated for $r = \infty$ and f bounded but (4.34) follows directly if f is truncated outside of B_r and using the fact that $\mathcal{L}$ is a local operator so the truncation does not affect the solution v_α^λ in B_r. By (A3) and (4.13) it follows that $\|Dv_\alpha^\lambda\|_{r,\theta} \le c_3(1 + r^p)$ for some constant c_3 that does not depend on α or λ. Thus by the proof of Corollary 4.1 it follows that

$$\lim_{\alpha\to\alpha_0} Dv_\alpha = Dv_{\alpha_0} \tag{4.35}$$

uniformly on compact sets. For a compact set $K \subset H$ if follows that

$$\begin{aligned}
&\mathbb{E}_{x,\tilde{u}}|D\tilde{H}(Dv_{\alpha_0}(X(s))) - D\tilde{H}(Dv_{\alpha(t)}(X(s)))| \\
&\quad = \mathbb{E}_{x,\tilde{u}}|D\tilde{H}(Dv_{\alpha_0}(X(s))) - D\tilde{H}(Dv_{\alpha(t)}(X(s)))|1_{\{X(s)\in K\}} \\
&\quad\quad + \mathbb{E}_{x,\tilde{u}}|D\tilde{H}(Dv_{\alpha_0}(X(s))) - D\tilde{H}(Dv_{\alpha(t)}(X(s)))|1_{\{X(s)\notin K\}}.
\end{aligned} \tag{4.36}$$

The second term on the right-hand side of (4.36) is bounded above by

$$2R\mathbb{P}_{x,\tilde{u}}(X(s) \in H \setminus K)$$

which can be made arbitrarily small for a compact set K sufficiently large by Proposition 2.1 (iii) for $s \ge 1$ and R is given in (2.2). The first term on the right-hand side of (4.36) tends to zero as $s \to \infty$ by the locally uniform convergence in (4.35). These two facts imply that

$$\lim_{s\to\infty} \mathbb{E}_{x,\tilde{u}}|D\tilde{H}(Dv_{\alpha_0}(X(s))) - D\tilde{H}(Dv_{\alpha(s)}(X(s)))| = 0. \tag{4.37}$$

By a similar argument it follows that

$$\lim_{s\to\infty} \mathbb{E}_{x,\tilde{u}}|h(D\tilde{H}(Dv_{\alpha_0}(X(s)))) - h(D\tilde{H}(Dv_{\alpha(s)}(X(s))))| = 0. \tag{4.38}$$

Dividing (4.33) by t and letting $t \to \infty$, the equality (4.32) follows by (4.37) and (4.38). This completes the proof. □

COROLLARY 4.2. *Given the adaptive control problem described by* (2.1) *and* (2.5), *where* $\alpha_0 \in \mathcal{A}^0$, *is the true parameter vector and* f *satisfies* (3.1). *Let* $(\alpha(t), t \ge 0)$ *be the family of estimates of* α_0 *given by*

$$\alpha(t) = 1_{\{\hat{\alpha}(t)\in\mathcal{A}\}}\hat{\alpha}(t) + 1_{\{\hat{\alpha}(t)\notin\mathcal{A}\}}\alpha^*,$$

where $\hat{\alpha}(t)$ *is the solution of* (3.5) *and* α^* *is a fixed element of* $\mathcal{A}$. *If* (A1)–(A7) *are*

satisfied, $\omega - \beta > 0$*, and the inequality* (4.7) *is satisfied, then*

$$\tilde{J}(x, \tilde{u}) = \rho(\alpha_0)$$

for each $x \in H$*, where* $\tilde{u}$ *is the adaptive control given by* (4.30)*.*

MOMENT APPROACH TO NONLINEAR TIME OPTIMALITY*

G. M. SKLYAR† AND S. YU. IGNATOVICH‡

Abstract. The time-optimal control problem to a stationary point for an affine analytic nonlinear system is considered as a certain nonlinear power Markov moment min-problem. Conditions for a solution to be asymptotically close to a solution of a linear time-optimal control problem are obtained in terms of Lie brackets of the vector fields appearing in the system.

Key words. time-optimal control problem, Markov moment min-problem, series of nonlinear power moments, local equivalence

1. Introduction and the main result. In the mathematical theory of linear control problems a remarkable place is occupied by the moment method. This method allows us to consider a number of such problems as problems from functional analysis. That gives a deep and well-developed technique for investigation.

The initial idea of the approach relies on the interpretation of the transfer conditions given by the Cauchy formula as moment equalities with respect to the control function. More specifically, let a linear system of the form

$$\dot{x} = A(t)x + B(t)u \tag{1.1}$$

be given, $x \in \mathbb{R}^n$, $u \in \mathbb{R}^1$, and the control $u(t)$, $t \in [0,T]$ transfers the system from an initial state $x(0) = x^0$ to the final state $x(T) = 0$. Then the function $u(t)$ satisfies the moment equalities

$$x_k^0 = \langle g_k, u \rangle = \int_0^T g_k(t)u(t)dt, \qquad k = 1, \dots, n, \tag{1.2}$$

where $g_k(t) = -\phi^{-1}(t)B(t)$ and $\phi(t)$ is the fundamental matrix of the system $\dot{x} = A(t)x$ such that $\phi(0) = I$.

If admissible controls are taken from a ball in a certain functional space H, then the control problem becomes the abstract Krein moment problem [15] in H and the controllability conditions are interpreted as conditions for solvability of the moment problem.

One of the most important and natural statements of a control problem is the problem with geometric restrictions on control. In this case $H = L_\infty[0,T]$, and we obtain the famous $(-1,1)$-Markov moment problem [17],

$$s_k = \int_0^T g_k(t)u(t)dt, \qquad k = 1, \dots, n, \qquad -1 \le u(t) \le 1. \tag{1.3}$$

This problem has *a unique* solution if and only if s is such that $[0,T]$ is *the smallest* interval for which (1.3) holds. Moreover, if the functions $g_1(t),\dots,g_n(t)$ form a Tchebycheff system on $(0,T)$, then in the mentioned case $u(t)$ equals ± 1 and has no more than $n-1$ points of discontinuity.

That leads to the following statement of the moment problem (Markov moment problem on the smallest possible interval or min-problem [11]): for a given sequence of functions $\{g_k(t)\}_{k=1}^n$, $t\in[0,T]$, and a vector s, find the smallest possible interval $[0,\theta_s]\subset[0,T]$ such that for $\theta=\theta_s$ the following representation holds:

$$s_k=\int_0^\theta g_k(t)u(t)dt,\qquad k=1,\dots,n,\qquad |u(t)|\le 1; \tag{1.4}$$

and construct the function $u(t)=u_s(t)$ corresponding to this representation. The pair $(\theta_s,u_s(t))$ is called the solution of the min-problem. It follows from the above that the function $u_s(t)$ is unique, equals ± 1 on $(0,\theta_s)$, and has no more than $n-1$ points of discontinuity.

From the point of view of the optimal control, the Markov moment min-problem (1.4) is equivalent to the time-optimal control problem for linear system (1.1). In this relation note that the uniqueness and cited properties of the function $u_s(t)$ (which is interpreted as the time-optimal control) are well known in optimal control theory.

Nevertheless, the statement of the Markov min-problem gives a new, more precise tool for investigation of time optimality. On the one hand, it allows us to obtain an analytic solution of the time-optimal control problem in a number of important special cases [12, 13, 14] by employing deep techniques from classical moment theory. On the other hand, it suggests an approach to study the optimal solutions $(\theta_s,u_s(t))$, in particular, their behavior depending on the sequence $\{g_k(t)\}_{k=1}^n$ defined, in turn, by the system parameters.

Suppose the functions $g_1(t),\dots,g_n(t)$ are real analytic in $t\in[0,T]$. Then we represent the moment equalities (1.4) in the following form:

$$s_k=\sum_{i=0}^{\infty}\frac{1}{i!}g_k^{(i)}(0)\int_0^\theta t^i u(t)dt,\qquad k=1,\dots,n. \tag{1.5}$$

Let the functions $g_1(t),\dots,g_n(t)$ be linearly independent, as corresponds to the condition of null-controllability of (1.1). Let $\ell_1<\dots<\ell_n$ be indices of the first n linearly independent vectors from the sequence $\{g^{(j)}(0)\}_{j=0}^\infty$, and $G=(\frac{1}{\ell_1!}g^{(\ell_1)}(0),\dots,\frac{1}{\ell_n!}g^{(\ell_n)}(0))^{-1}$. Then (1.5) leads to

$$\tilde{s}_k=(Gs)_k=\int_0^\theta t^{\ell_k}u(t)dt+\sum_{j=\ell_k+1}^{\infty}r_{kj}\int_0^\theta t^j u(t)dt,\qquad k=1,\dots,n.$$

Note that in the right-hand side of the equalities the second term has a higher order of smallness than the first one as $\theta\to 0$. So, these equalities suggest asymptotic closeness of the solution of the min-problem (1.4) and the solution of the power min-problem with gaps [14]

$$\tilde{s}_k=\int_0^\theta t^{\ell_k}u(t)dt,\qquad k=1,\dots,n,\qquad |u(t)|\le 1, \tag{1.6}$$

as θ is small. Define this closeness more precisely following [18] as follows.

DEFINITION 1.1. *Two moment min-problems of the form* (1.4) *(with respect to sequences* $\{g_k(t)\}_{k=1}^n$ *and* $\{\tilde{g}_k(t)\}_{k=1}^n$ *of linearly independent functions), with solutions* $(\theta_s, u_s(t))$ *and* $(\tilde{\theta}_s, \tilde{u}_s(t))$*, respectively, are called locally equivalent to each other in a neighborhood of the origin if there exists a linear nonsingular operator* $L : \mathbb{R}^n \to \mathbb{R}^n$ *such that*

$$\frac{\tilde{\theta}_{Ls}}{\theta_s} \to 1, \qquad \frac{1}{\theta}\int_0^{\theta} |\tilde{u}_{Ls}(t) - u_s(t)|dt \to 0 \quad \text{as} \quad s \to 0,$$

where $\theta = \min\{\tilde{\theta}_{Ls}, \theta_s\}$.

Two time-optimal control problems (for controllable systems $\dot{x} = A(t)x + B(t)u$ *and* $\dot{x} = \tilde{A}(t)x + \tilde{B}(t)u$*) are called locally equivalent to each other in a neighborhood of the origin if the corresponding moment min-problems are locally equivalent.*

This approach allows us to construct a complete local classification of moment min-problems of the form (1.4) with real analytic functions $g_k(t)$ (and time-optimal control problems for systems of the form (1.1) with real analytic coefficients). This classification given in [18] is based on the following theorem.

THEOREM 1.2 (on local equivalence of linear problems). *Two time-optimal control problems (for controllable systems* $\dot{x} = A(t)x + B(t)u$ *and* $\dot{x} = \tilde{A}(t)x + \tilde{B}(t)u$ *with real analytic coefficients) are locally equivalent in a neighborhood of the origin if and only if the indices of the first n linearly independent vectors from the sequences* $\{(-A(t) + d/dt)^i B(t)\big|_{t=0}\}_{i=0}^{\infty}$ *and* $\{(-\tilde{A}(t) + d/dt)^i \tilde{B}(t)\big|_{t=0}\}_{i=0}^{\infty}$ *coincide.*

This fact means in essence that every min-problem (1.4) is locally equivalent to a certain power min-problem with gaps (1.6). Thus, in the sense of asymptotic behavior of solutions, the set of Markov moment min-problems of the form (1.4) splits into equivalence classes, and power min-problems with gaps (1.6) are representatives of these classes.

In the present work we intend to develop the moment approach to nonlinear systems of the form

$$\dot{x} = a(t,x) + b(t,x)u, \qquad a(t,0) \equiv 0, \tag{1.7}$$

in order to study the asymptotic behavior of solutions of the nonlinear time-optimal control problem to the stationary point $x = 0$ in a sense close to Definition 1.1. Namely, we are interested in the special subclass of such systems which are "close" to linear ones in the sense of the following definition.

DEFINITION 1.3. *Consider two time-optimal control problems*

$$\dot{x} = a(t,x) + b(t,x)u(t), \quad |u(t)| \le 1, \quad x(0) = x^0, \quad x(\theta) = 0, \quad \theta \to \min, \tag{1.8}$$

and

$$\dot{x} = A(t)x + B(t)u(t), \quad |u(t)| \le 1, \quad x(0) = x^0, \quad x(\theta) = 0, \quad \theta \to \min, \tag{1.9}$$

in a neighborhood of the origin. Suppose $a(t,0) \equiv 0$ *and both of systems are null-controllable. Denote by* $(\theta_{x^0}^{Lin}, u_{x^0}^{Lin}(t))$ *the solution of linear problem* (1.9) *and by* $\{(\theta_{x^0}, \tilde{u}(t)) : \tilde{u}(t) \in U_{x^0}\}$ *the set of solutions of nonlinear problem* (1.8) *(it is nonempty due to null-controllability of the system; see* [3]*).*

The nonlinear time-optimal control problem (1.8) *is said to be locally equivalent to the linear problem* (1.9) *if there exists a nonsingular transformation* Φ *of a neighborhood of the origin in* $\mathbb{R}^n$, $\Phi(0) = 0$, *such that*

$$\frac{\theta_{\Phi(x^0)}}{\theta_{x^0}^{Lin}} \to 1, \qquad \sup_{\tilde{u}(t) \in U_{\Phi(x^0)}} \frac{1}{\theta}\int_0^{\theta} |u_{x^0}^{Lin}(t) - \tilde{u}(t)|dt \to 0 \quad \text{as} \quad x^0 \to 0, \tag{1.10}$$

where $\theta = \min\{\theta_{\Phi(x^0)}, \theta_{x^0}^{Lin}\}$.

In other words, the local equivalence means that there exists such a change of variables $z = \Phi^{-1}(x)$ in the nonlinear system that solutions $\{(\theta_{x^0}^z, \tilde{u}(t)) : \tilde{u}(t) \in U_{x^0}^z\}$ of the time-optimal control problem for the system in the new variables z are "asymptotically close" to the solution of the linear problem, i.e.,

$$\frac{\theta_{x^0}^z}{\theta_{x^0}^{Lin}} \to 1, \qquad \sup_{\tilde{u}(t)\in U_{x^0}^z} \frac{1}{\theta}\int_0^\theta |u_{x^0}^{Lin}(t) - \tilde{u}(t)|dt \to 0 \quad \text{as} \quad x^0 \to 0; \quad \theta = \min\{\theta_{x^0}^z, \theta_{x^0}^{Lin}\}.$$

In order to formulate the main result we introduce mappings R_a, R_b (corresponding to $a(t,x)$, $b(t,x)$) acting on a real analytic vector function $d(t,x)$ by the rule

$$R_a d(t,x) = d_t(t,x) + d_x(t,x)\cdot a(t,x),$$
$$R_b d(t,x) = d_x(t,x)\cdot b(t,x).$$

Here $d_t(t,x) = \partial d(t,x)/\partial t$, and $d_x(t,x)$ is the matrix $\{\partial d_i(t,x)/\partial x_j\}_{i=1,\dots,n}^{j=1,\dots,n}$. Further, let $[R_a, R_b]$ denote the operator commutator, $[R_a, R_b] = R_a \circ R_b - R_b \circ R_a$, and $\operatorname{ad}_{R_a}^0 R_b = R_b$, $\operatorname{ad}_{R_a}^{m+1} R_b = [R_a, \operatorname{ad}_{R_a}^m R_b]$, $m \ge 0$. Let also $E(x) \equiv x$. Note that the condition $a(t,0) \equiv 0$ implies

$$\operatorname{ad}_{R_a}^i R_b E(x)\Big|_{\substack{t=0\\x=0}} = (-a_x(t,0) + d/dt)^i b(t,0)\Big|_{t=0}, \qquad i \ge 0. \tag{1.11}$$

The main result of the paper is the following theorem.

THEOREM 1.4 (on local equivalence of nonlinear problems to linear ones). *Consider a time-optimal control problem for control affine real analytic system* (1.7). *Let its linearization* $\dot{x} = a_x(t,0)x + b(t,0)u$ *be controllable.*

The original nonlinear time-optimal control problem is locally equivalent to the problem for a certain linear system (and then, in particular, for its own linearization) in the sense of Definition 1.3 *if and only if the system satisfies condition* (E),

$$\text{(E)}\quad \left[\operatorname{ad}_{R_a}^{m_1} R_b, \cdots \left[\operatorname{ad}_{R_a}^{m_{k-1}} R_b, \operatorname{ad}_{R_a}^{m_k} R_b\right]\cdots\right] E(x)\Big|_{\substack{t=0\\x=0}} \in \operatorname{Lin}\left\{\operatorname{ad}_{R_a}^i R_b E(x)\Big|_{\substack{t=0\\x=0}}\right\}_{i=0}^{m-2},$$

where $m = m_1 + \cdots + m_k + k$ *for all* $k \ge 2$, $m_1, \dots, m_k \ge 0$.

In its turn the time-optimal control problem for the linearization is reduced to the Markov moment min-problem which is equivalent to the power moment min-problem with gaps in the sense of Definition 1.1. *The solution of this latter problem (which can be computed analytically in a number of cases) may serve as an approximation of the optimal time and control for the original problem in a neighborhood of the origin (after a change of variables* $z = L\Phi^{-1}(x)$, *where* Φ *is from Definition* 1.3 *and* L *is a certain matrix). Moreover, this change of variables may be chosen in polynomial form.*

REMARK 1.5. *If* $\operatorname{rank}\{\operatorname{ad}_{R_a}^i R_b E(x)_{|\,\substack{t=0\\x=0}}\}_{i=0}^N = n$, *then condition* (E) *is substantial for* $k \ge 2$ *and* $m_1, \dots, m_k \ge 0$ *such that* $m = m_1 + \cdots + m_k + k \le N + 1$ *only. That means that only a finite number of relations determines the property of local equivalence to a linear time-optimal control problem.*

REMARK 1.6. *The proof of the sufficiency of the theorem is constructive, namely, we explicitly build a polynomial change of variables* $z = \Phi^{-1}(x)$ (*section* 5).

In order to prove Theorem 1.4, we propose a development of the moment approach to the nonlinear case. We suggest considering the following:

(i) series of nonlinear power moments instead of systems of the form (1.7);

(ii) transformations of such series instead of changes of variables in systems;

(iii) nonlinear moment min-problems instead of time-optimal control problems.

In this way the local equivalence of time-optimal control problems turns into the local equivalence of moment min-problems.

Elements of the moment approach are given in sections 2–5.

In Theorem 2.1 the representation of systems of the form (1.7) as series of nonlinear power moments is given. In essence, we transform M. Fliess' series representation of trajectories of system (1.7) to the case when the final point is fixed.

The concept of a nonlinear power Markov moment min-problem is introduced in section 3 as well as the definition of local equivalence of nonlinear and linear problems.

The basic tool in our approach is the concept of an essentially linearizable (ess-linearizable) series of nonlinear power moments given in section 4. Two substantial steps of the proof of Theorem 1.4 are presented in Theorems 4.2 and 5.1. Theorem 4.2 shows that a nonlinear time-optimal control problem is locally equivalent to a linear one if and only if its series is ess-linearizable. On the other hand, Theorem 5.1 states that the series is ess-linearizable if and only if the system satisfies condition (E).

As a result, the proof of Theorem 1.4 following from Theorems 4.2 and 5.1 can be found in section 6 as well as a number of special classes of systems satisfying the conditions of the theorem.

Section 7 contains a description of some results developing the moment approach and announces some future results.

2. Series of nonlinear power moments. The basic point for the present section is conditions which the control function $u(t)$ transferring the initial state to the origin by virtue of system (1.7) satisfies.

For systems of the form (1.7), it is natural to consider the Volterra series expansion of a solution [1, 2, 8, 9, 16], as an analogue of the Cauchy formula for the linear case. Taking into account that the final point $x(\theta) = 0$ is stationary for system (1.7) ($a(t, 0) \equiv 0$), one can obtain the transform conditions in the following form:

$$x_q^0 = \sum_{k=1}^{\infty} \int_0^{\theta} \int_0^{\tau_1} \dots \int_0^{\tau_{k-1}} w_q(\tau_1, \dots, \tau_k) u(\tau_1) \cdots u(\tau_k) d\tau_k \cdots d\tau_2 d\tau_1, \tag{2.1}$$

$q = 1, \dots, n$, where the kernels $w_q(\tau_1, \dots, \tau_k)$ depend on system parameters and the control $u(t)$ transfers system (1.7) from x^0 to the origin in time θ. Equalities (2.1) are supposed to be considered as a generalization of moment equalities (1.2).

In order to generalize the representation (1.5), it seems to be natural to pass in (2.1) to the expansion of kernels $w_q(\tau_1, \dots, \tau_k)$ into Taylor series. Note, however, that the series we obtain does not possess an important property: its remainder is not of higher order of smallness than the partial sum as $\theta \to 0$. To satisfy this condition one has to change the manner of summation of the series. This leads us to the necessity of finding another form of transfer conditions called *a series of nonlinear power moments.*

THEOREM 2.1. *Let functions $a(t, x)$, $b(t, x)$ be analytic on a neighborhood of the origin in $\mathbb{R}^{n+1}$. Denote by $U_{x^0}(\theta)$ the set of all controls $u(t) \in L_\infty[0, \theta]$, $\|u\| \le 1$, transferring x^0 to the origin in time θ by virtue of system* (1.7).

Then there exists a number $T_0 > 0$ such that for any $\theta \in [0, T_0]$ a point x^0 satisfying the condition $U_{x^0}(\theta) \neq \emptyset$ admits the representation in the form of a series

of nonlinear power moments,

$$x^0 = \sum_{m=1}^{\infty} \sum_{\substack{m_1+\dots+m_k+k=m \\ k\geq 1, m_j\geq 0}} v_{m_1\dots m_k}\xi_{m_1\dots m_k}(\theta,u), \qquad u(t)\in U_{x^0}(\theta), \tag{2.2}$$

where $\xi_{m_1\dots m_k}(\theta,u)$ *denote nonlinear power moments of the function* $u(t)$,

$$\xi_{m_1\dots m_k}(\theta,u) = \int_0^\theta \int_0^{\tau_1} \dots \int_0^{\tau_{k-1}} \tau_1^{m_1}\tau_2^{m_2}\dots\tau_k^{m_k} \prod_{j=1}^{k} u(\tau_j)d\tau_k\dots d\tau_2 d\tau_1, \tag{2.3}$$

and constant vector coefficients $v_{m_1\dots m_k}$ *are of the form*

$$v_{m_1\dots m_k} = \frac{(-1)^k}{m_1!\dots m_k!} \operatorname{ad}_{R_a}^{m_1} R_b \circ \dots \circ \operatorname{ad}_{R_a}^{m_k} R_b E(x)\Big|_{\substack{t=0\\x=0}}. \tag{2.4}$$

Moreover, there exists a constant $K>0$ *such that for any* $\theta\in[0,T_0]$ *and* $u(t)\in L_\infty[0,\theta]$, $\|u\|\leq 1$, *the following estimate holds:*

$$\sum_{m=1}^{\infty} \left\| \sum_{\substack{m_1+\dots+m_k+k=m \\ k\geq 1, m_j\geq 0}} v_{m_1\dots m_k}\xi_{m_1\dots m_k}(\theta,u) \right\| < K. \tag{2.5}$$

Let us explain the place which this result occupies with respect to Fleiss' well-known expansion of a solution of the Cauchy problem for system (1.7) into a series of iterated integrals [4, 5, 6, 7]. Suppose $u(t)\in U_{x^0}(\theta)$ and consider the trajectory $x(t)$ of (1.7). Then the vector function $y(t)=x(\theta-t)$ is a solution of the Cauchy problem

$$\dot y = -\hat a(t,y) - \hat b(t,y)\hat u(t), \qquad y(0)=0,$$

where $\hat u(t)=u(\theta-t)$, $\hat a(t,y)=a(\theta-t,y)$, and $\hat b(t,y)=b(\theta-t,y)$, and satisfies the end condition $y(\theta)=x^0$. Applying Fliess' expansion to $y(t)$, we obtain

$$\begin{aligned} y(t) = y(0) + \sum_{m=1}^{\infty} \sum_{M\subset\{1,\dots,m\}} (-1)^m R_{\hat c_m}\circ R_{\hat c_{m-1}}\circ\dots \\ \circ R_{\hat c_1}E(y)\Big|_{\substack{t=0\\y=0}} \int_0^t \int_0^{\tau_1} \dots \int_0^{\tau_{m-1}} \prod_{j\in M} u(\theta-\tau_j)d\tau_m\dots d\tau_2 d\tau_1, \end{aligned}$$

where $\hat c_j(t,y)=\hat b(t,y)$ if $j\in M$, and $\hat c_j(t,y)=\hat a(t,y)$ otherwise; $E(y)\equiv y$. Obviously, this representation implies

$$\begin{aligned} x(\theta-t) = \sum_{m=1}^{\infty} \sum_{M\subset\{1,\dots,m\}} (-1)^m R_{c_m}\circ R_{c_{m-1}}\circ\dots \\ \circ R_{c_1}E(x)\Big|_{\substack{t=\theta\\x=0}} \int_{\theta-t}^{\theta} \int_{\theta-t}^{\tau_1} \dots \int_{\theta-t}^{\tau_{m-1}} \prod_{j\in M} u(\tau_{m+1-j})d\tau_m\dots d\tau_2 d\tau_1, \end{aligned} \tag{2.6}$$

where $c_j(t,x)=b(t,x)$ if $j\in M$, and $c_j(t,x)=a(t,x)$ otherwise. One can show that there exists $T_0>0$ such that (2.6) holds for $t=\theta\in[0,T_0]$.

It is easy to see that in the case of an autonomous system ($a(t,x) \equiv a(x)$, $b(t,x) \equiv b(x)$), coefficients of the expansion do not depend on θ. So, taking into account the condition $a(0) \equiv 0$ which implies $R_a^m d(0) = 0$, $m \geq 1$, we obtain representation (2.2)–(2.4) directly by simplification of integrals

$$\int_0^\theta \int_0^{\tau_1} \cdots \int_0^{\tau_{m-1}} \prod_{j \in M} u(\tau_{m+1-j}) d\tau_m \dots d\tau_2 d\tau_1,$$

which leads to nonlinear power moments.

However, in the nonautonomous case the coefficients of integrals in (2.6) are functions on θ. Hence, to obtain representation (2.2)–(2.4) from (2.6), one has to transform the sum expanding each coefficient into the Taylor series at $t = 0$. This shows a difference between the expansion of the Cauchy problem solution and transfer conditions which coefficients are calculated at the final point with respect to the state ($x = 0$) and at the "initial point" with respect to the time ($t = 0$). Therefore, the direct reduction of a nonautonomous case to an autonomous one which is generally accepted for the Cauchy problem is impossible for the transfer problem. This fact explains the meaning of Theorem 2.1.

We emphasize especially that representation (2.2)–(2.4) holds only if $x = 0$ is a stationary point for the system.

DEFINITION 2.2. *We say that a series S of the form*

$$S = \sum_{m=1}^{\infty} \sum_{\substack{m_1+\dots+m_k+k=m \\ k \geq 1, m_j \geq 0}} v_{m_1 \dots m_k} \xi_{m_1 \dots m_k}, \tag{2.7}$$

$v_{m_1 \dots m_k} \in \mathbb{R}^n$, represents a system of the form (1.7) *if there exist two real analytic vector functions $a(t,x)$, $b(t,x)$ such that coefficients $v_{m_1 \dots m_k}$ satisfy* (2.4).

Note that each such series represents not one system but a family of systems (connected by certain time-dependent changes of variables).

An essential advantage of representation (2.2)–(2.4) is a possibility to study analytic transformations of system (1.7) as analytic transformations over its series of nonlinear power moments and, therefore, as certain transformations over the vector coefficients $v_{m_1 \dots m_k}$. The following lemma states the exact expression for coefficients of the transformed series.

LEMMA 2.3. *Let a series S represent a system of the form* (1.7)*, and let F be an analytic transformation of a neighborhood of the origin in $\mathbb{R}^n$, $F(0) = 0$. Then the series $\tilde{S} = F(S)$ represents the system $\dot{z} = \tilde{a}(t,z) + \tilde{b}(t,z)u$, where $z = F(x)$ and the coefficients $\tilde{v}_{m_1 \dots m_k}$ of $\tilde{S}$ can be found by the following formulas:*

$$\tilde{v}_{m_1 \dots m_k} = \sum_{r=1}^{k} \frac{1}{r!} D^{(r)} F(0) \sum{}' v_{m_{i_{11}} \dots m_{i_{1\ell_1}}} \cdots v_{m_{i_{r1}} \dots m_{i_{r\ell_r}}}, \tag{2.8}$$

where $D^{(r)}$ is the rth derivative operator and the sum $\sum'$ is taken on all collections of nonempty nonintersecting sets $\{i_{j1}, \dots, i_{j\ell_j}\}$, $j = 1, \dots, r$, such that $i_{j1} < \dots < i_{j\ell_j}$ and $\cup_{j=1}^{r} \{i_{j1}, \dots, i_{j\ell_j}\} = \{1, \dots, k\}$.

Further, we use the following definition.

DEFINITION 2.4. *For given $v_{m_1 \dots m_k}$, we refer to the number $m = m_1 + \dots + m_k + k$ as the order of $v_{m_1 \dots m_k}$ and to the number k as its multiplicity.*

REMARK 2.5. *As follows from Lemma* 2.3*, all terms of multiplicity k in the series $\tilde{S} = F(S)$ are completely determined by the first k derivatives of the transformation F.*

3. Nonlinear moment min-problem. In [11, 12], the new approach to a time-optimal control problem has been introduced on the base of the concept of a Markov moment min-problem to which the time-optimal control problem can be reduced. Developing this idea, we formulate *the nonlinear Markov moment problem on the smallest possible interval (nonlinear moment min-problem)* for a series S of the form (2.7) representing a system as follows.

For any vector $s \in \mathbb{R}^n$, indicate (if possible) the minimal number $\theta_s \geq 0$ for which there exists a function $u_s(t) \in L_\infty[0, \theta_s]$ such that $\|u_s\| \leq 1$ and the following equality holds:

$$s = \sum_{m=1}^{\infty} \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\geq 1, m_j \geq 0}} v_{m_1 \ldots m_k} \xi_{m_1 \ldots m_k}(\theta, u), \tag{3.1}$$

as $\theta = \theta_s$ and $u(t) = u_s(t)$. If such a pair $(\theta_s, u_s(t))$ exists, then it is called *a solution* of the min-problem.

Note that the nonlinear Markov moment min-problem is naturally interpreted as the time-optimal control problem for system (1.7) (from the point $x(0) = s$). Moreover, if the system is locally null-controllable, then a solution of the time-optimal control problem exists for any initial point from a neighborhood of the origin due to [3].

In [11, 18] the question on local equivalence of linear moment min-problems was considered. It proved to be that power moment min-problems with gaps [14] play the main role in this investigation. Now we introduce the concept of local equivalence of a nonlinear moment min-problem and a linear power moment min-problem.

DEFINITION 3.1. *Let the nonlinear Markov moment min-problem* (3.1) *have a solution for any s from a neighborhood of the origin. Denote by $\{(\theta_s, \tilde{u}(t)) \colon \tilde{u}(t) \in U_s\}$ the set of all its solutions.*

This problem is called locally equivalent to the power moment min-problem with gaps

$$s_q = \int_0^\theta t^{\ell_q} u(t) dt, \qquad q = 1, \ldots, n, \qquad 0 \leq \ell_1 < \cdots < \ell_n, \tag{3.2}$$

if there exists a nonsingular analytic transformation Φ of a neighborhood of the origin, $\Phi(0) = 0$, such that

$$\frac{\theta_{\Phi(s)}}{\theta_s^{Lin}} \to 1, \tag{3.3}$$

$$\sup_{\tilde{u}(t) \in U_{\Phi(s)}} \frac{1}{\theta} \int_0^\theta |u_s^{Lin}(t) - \tilde{u}(t)| dt \to 0, \tag{3.4}$$

as $s \to 0$, where $\theta = \min\{\theta_{\Phi(s)}, \theta_s^{Lin}\}$ and $(\theta_s^{Lin}, u_s^{Lin}(t))$ is a solution of (3.2).

Note that this definition in essence coincides with the definition of local equivalence between nonlinear and linear time-optimal control problems (Definition 1.3).

4. Essentially linearizable series and local equivalence. Within our approach, we introduce the following definition.

DEFINITION 4.1. *A series S of the form* (2.7) *is called linearly nonsingular if* $\operatorname{rank}\{v_i\}_{i=0}^{\infty} = n$.

A series S of the form (2.7) *is called essentially linear (ess-linear) if it is linearly nonsingular and*

$$v_{m_1\dots m_k} \in \operatorname{Lin}\{v_i\}_{i=0}^{m-2}, \qquad \text{where} \quad m = m_1 + \cdots + m_k + k$$

for any $k \geq 2$, $m_1, \dots, m_k \geq 0$. We denote by $\mathcal{L}_e$ the set of all ess-linear series.

A series S is called ess-linearizable if there exists an analytic transformation (ess-linearizing transformation) F of a neighborhood of the origin, $F(0) = 0$, such that $F(S) \in \mathcal{L}_e$.

In other words, a linearly nonsingular series is ess-linear if and only if each coefficient of multiplicity greater than 1 is included in the linear span of coefficients of *smaller order* and multiplicity 1.

The following theorem shows the significance of this concept.

THEOREM 4.2. *Consider a time-optimal control problem for control affine real analytic system* (1.7). *Let its linearization at the origin be controllable.*

The original nonlinear time-optimal control problem is locally equivalent to the problem for a certain linear system in the sense of Definition 1.3 *if and only if the series S representing the system* (1.7) *is ess-linearizable.*

Proof of sufficiency. Suppose the ess-linearizable series S of the form (2.7) represents the system (1.7). Let F be such a transformation that $\tilde{S} = F(S) \in \mathcal{L}_e$. Without loss of generality, we may assume that $\tilde{S}$ is of the form $\tilde{S} = \Xi + \tilde{\rho}$, where

$$\Xi = (\xi_{\ell_1}, \dots, \xi_{\ell_n}), \qquad \tilde{\rho}_q = \sum_{m=\ell_q+2}^{\infty} \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\geq 1, m_j \geq 0}} (\tilde{v}_{m_1\dots m_k})_q \xi_{m_1\dots m_k}, \qquad q = 1, \dots, n,$$

where coefficients $\tilde{v}_{m_1\dots m_k}$ and $v_{m_1\dots m_k}$ are connected by equalities (2.8).

We prove that nonlinear Markov moment min-problem (3.1) for the series S is locally equivalent to linear problem (3.2) in the sense of Definition 3.1 with transformation $\Phi = F^{-1}$; therefore, the original nonlinear time-optimal control problem is locally equivalent to the problem for a certain linear system in the sense of Definition 1.3.

Put $\Phi = F^{-1}$; then the set of solutions $\{(\theta_{\Phi(s)}, \tilde{u}(t)) : \tilde{u}(t) \in U_{\Phi(s)}\}$ of the problem (3.1) coincides with the set of solutions of the problem

$$s = \Xi(\theta, u) + \tilde{\rho}(\theta, u); \tag{4.1}$$

that is,

$$s = \Xi(\theta_{\Phi(s)}, \tilde{u}) + \tilde{\rho}(\theta_{\Phi(s)}, \tilde{u}) \quad \text{for any} \quad \tilde{u}(t) \in U_{\Phi(s)}.$$

Denote by $(\theta_s^{Lin}, u_s^{Lin}(t))$ the solution of the linear problem (3.2). Then

$$\theta_{s^0}^{Lin} \leq \theta_{\Phi(s)}, \qquad s^0 = s - \tilde{\rho}(\theta_{\Phi(s)}, \tilde{u}), \qquad \tilde{u}(t) \in U_{\Phi(s)}. \tag{4.2}$$

Estimate $\theta_{\Phi(s)}$ from above. Following [11] we introduce the operator $D : \mathbb{R}^n \to \mathbb{R} \times L_\infty[0, \infty]$, associating a pair $(\theta_x^{Lin}, u_x^{Lin}(t))$ to a vector x. Obviously, the operator $G_s(x) = s - \tilde{\rho}(D(x))$ is defined in a neighborhood of the origin. Next we show that the operator G_s has a stationary point in a certain subneighborhood of the origin.

Since $\xi_{m_1\dots m_k}(\theta, u) = \theta^m \xi_{m_1\dots m_k}(1, \hat{u})$, where $m = m_1 + \cdots + m_k + k$, $\hat{u}(t) = u(t\theta)$, $t \in [0, 1]$, we have from (2.5)

$$\left\| \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\geq 1, m_j \geq 0}} \tilde{v}_{m_1\dots m_k} \xi_{m_1\dots m_k}(\theta, u) \right\| \leq (K_1\theta)^m, \qquad m \geq 1,$$

where the constant K_1 does not depend on θ and $u(t) \in L_\infty[0,\theta]$, $\|u\| \le 1$. Hence, for $\theta \to 0$,

$$|\tilde\rho_q(\theta,u)| \le \sum_{m=\ell_q+2}^{\infty} (K_1\theta)^m \le K_2\theta^{\ell_q+2}, \qquad q=1,\dots,n. \tag{4.3}$$

Consider now the closed neighborhood of the origin $V_\varepsilon = \{x : |x_q| \le \varepsilon^{\ell_q+1}, q = 1,\dots,n\}$, $\varepsilon > 0$, and note that $\theta_x^{Lin} \le C_1\varepsilon$ for any $x \in V_\varepsilon$, where $C_1 = \max\{\theta_x^{Lin}, x \in V_1\} \ge 1$. Put $\varepsilon(s) = \max_{1\le q\le n}\{(2|s_q|)^{\frac{1}{\ell_q+1}}\}$. It is easy to see that if $\varepsilon(s) \le (2K_2C_1^{\ell_n+2})^{-1}$, then the operator G_s maps the closed set $V_{\varepsilon(s)}$ to itself. At the same time, G_s is continuous, and hence it has a stationary point $s^1 \in V_{\varepsilon(s)}$, $G_s(s^1) = s^1$, that is,

$$s = \Xi(\theta_{s^1}^{Lin}, u_{s^1}^{Lin}) + \tilde\rho(\theta_{s^1}^{Lin}, u_{s^1}^{Lin}).$$

Hence

$$\theta_{\Phi(s)} \le \theta_{s^1}^{Lin}, \qquad s^1 = s - \tilde\rho(\theta_{s^1}^{Lin}, u_{s^1}^{Lin}) \to 0 \quad \text{as} \quad s \to 0. \tag{4.4}$$

Thus from (4.2)–(4.4), we have

$$\theta_{s^0}^{Lin} \le \theta_{\Phi(s)} \le \theta_{s^1}^{Lin}, \tag{4.5}$$

$$\left|\left(s^1 - s^0\right)_q\right| \le 2K_2(\theta_{s^1}^{Lin})^{\ell_q+2}, \qquad \left|\left(s - s^1\right)_q\right| \le K_2(\theta_{s^1}^{Lin})^{\ell_q+2}, \qquad q=1,\dots,n.$$

Following [18], we introduce an operator $H_\delta : \mathbb{R}^n \to \mathbb{R}^n$ acting by the rule

$$H_\delta(x) = \left(\frac{x_1}{\delta^{\ell_1+1}}, \dots, \frac{x_n}{\delta^{\ell_n+1}}\right),$$

and we note that

$$\theta_x^{Lin} = \delta\theta_{H_\delta(x)}^{Lin}, \qquad u_x^{Lin}(t) = u_{H_\delta(x)}^{Lin}(t/\delta), \qquad t \in [0, \theta_x^{Lin}].$$

Putting $\delta = \theta_{s^1}^{Lin}$, we obtain

$$\theta_{H_\delta(s^1)}^{Lin} = 1, \qquad \left\|H_\delta(s^1 - s^0)\right\| \le 2K_2\delta, \qquad \left\|H_\delta(s - s^1)\right\| \le K_2\delta,$$

so $\operatorname{dist}(H_\delta(s^0), \{x : \theta_x^{Lin} = 1\}) \le 2K_2\delta$, $\operatorname{dist}(H_\delta(s), \{x : \theta_x^{Lin} = 1\}) \le K_2\delta$. Since θ_x^{Lin} is uniformly continuous as a function of x and $\delta = \theta_{s^1}^{Lin} \to 0$ as $s \to 0$, we have

$$\frac{\theta_s^{Lin}}{\theta_{s^1}^{Lin}} = \frac{\theta_{H_\delta(s)}^{Lin}}{\theta_{H_\delta(s^1)}^{Lin}} = \theta_{H_\delta(s)}^{Lin} \to 1, \qquad \frac{\theta_{s^0}^{Lin}}{\theta_{s^1}^{Lin}} = \frac{\theta_{H_\delta(s^0)}^{Lin}}{\theta_{H_\delta(s^1)}^{Lin}} = \theta_{H_\delta(s^0)}^{Lin} \to 1 \qquad \text{as} \quad s \to 0,$$

which proves (3.3) due to (4.5).

In order to prove (3.4), let us make use of the fact that the function $u_s^{Lin}(t)$ is piecewise constant, $|u_s^{Lin}(t)| = 1$, and has no more than $n-1$ points of discontinuity on the interval $(0, \theta_s^{Lin})$. For any s consider the polynomial $p_s(t) = \sum_{q=1}^n \alpha_q^{(s)} t^{\ell_q}$, $t \in [0,1]$, $\max_{1\le q\le n} |\alpha_q^{(s)}| = 1$, which has its roots in the points of discontinuity

of $u_s^{Lin}(t\theta_s^{Lin})$ and $\operatorname{sign} p_s(t) = u_s^{Lin}(t\theta_s^{Lin})$ as $u_s^{Lin}(t\theta_s^{Lin}) \neq 0$. Let us consider any $\tilde{u}(t) \in U_{\Phi(s)}$ and put $\tilde{u}(t) = 0$ as $t > \theta_{\Phi(s)}$. We have

$$\int_0^{\theta_s^{Lin}} p_s(t/\theta_s^{Lin}) u_s^{Lin}(t)dt - \int_0^{\theta_{\Phi(s)}} p_s(t/\theta_s^{Lin})\tilde{u}(t)dt$$

$$= \sum_{q=1}^{n} \alpha_q^{(s)} \frac{\xi_{\ell_q}(\theta_s^{Lin}, u_s^{Lin}) - \xi_{\ell_q}(\theta_{\Phi(s)}, \tilde{u})}{(\theta_s^{Lin})^{\ell_q}} = \sum_{q=1}^{n} \frac{\alpha_q^{(s)}}{(\theta_s^{Lin})^{\ell_q}} \tilde{\rho}_q(\theta_{\Phi(s)}, \tilde{u}),$$

which yields

$$\left| \int_0^{\theta_s^{Lin}} p_s(t/\theta_s^{Lin}) u_s^{Lin}(t)dt - \int_0^{\theta_{\Phi(s)}} p_s(t/\theta_s^{Lin})\tilde{u}(t)dt \right| \leq \sum_{q=1}^{n} \frac{K_2 \theta_{\Phi(s)}^{\ell_q+2}}{(\theta_s^{Lin})^{\ell_q}}.$$

On the other hand,

$$\int_0^{\theta_s^{Lin}} p_s(t/\theta_s^{Lin}) u_s^{Lin}(t)dt - \int_0^{\theta_{\Phi(s)}} p_s(t/\theta_s^{Lin})\tilde{u}(t)dt$$

$$= \int_0^{\theta_s^{Lin}} p_s(t/\theta_s^{Lin}) \left(u_s^{Lin}(t) - \tilde{u}(t)\right) dt + \int_{\theta_{\Phi(s)}}^{\theta_s^{Lin}} p_s(t/\theta_s^{Lin})\tilde{u}(t)dt.$$

Thus we get

$$\frac{1}{\theta_s^{Lin}} \int_0^{\theta_s^{Lin}} \left|p_s(t/\theta_s^{Lin})\right| \left|u_s^{Lin}(t) - \tilde{u}(t)\right| dt = \frac{1}{\theta_s^{Lin}} \left| \int_0^{\theta_s^{Lin}} p_s(t/\theta_s^{Lin}) \left(u_s^{Lin}(t) - \tilde{u}(t)\right) dt \right|$$

$$\leq \theta_{\Phi(s)} \sum_{q=1}^{n} K_2 \left(\frac{\theta_{\Phi(s)}}{\theta_s^{Lin}}\right)^{\ell_q+1} + \sum_{q=1}^{n} \frac{1}{\ell_q + 1} \left| 1 - \left(\frac{\theta_{\Phi(s)}}{\theta_s^{Lin}}\right)^{\ell_q+1} \right|$$

for any $\tilde{u}(t) \in U_{\Phi(s)}$. The latter relation and (3.3) yield

$$\sup_{\tilde{u}(t)\in U_{\Phi(s)}} \frac{1}{\theta_s^{Lin}} \int_0^{\theta_s^{Lin}} \left|p_s(t/\theta_s^{Lin})\right| \left|u_s^{Lin}(t) - \tilde{u}(t)\right| dt \to 0 \quad \text{as} \quad s \to 0. \tag{4.6}$$

Now we prove that (4.6) implies (3.4). Consider any sequence $\{s_k\}_{k=1}^{\infty}$, $s_k \to 0$ as $k \to \infty$, and any $\tilde{u}_k(t) \in U_{\Phi(s_k)}$. Without loss of generality, we assume that $p_{s_k}(t) \to p(t)$ as $k \to \infty$ pointwise, where $p(t) = \sum_{q=1}^{n} \alpha_q t^{\ell_q}$, $t \in [0,1]$, $\max_{1\leq q\leq n} |\alpha_q| = 1$. Further, for any $\varepsilon > 0$, we put $F_\varepsilon = \{t \in [0,1] : |p(t)| \geq \varepsilon\}$. Note that $\mu F_\varepsilon \to 1$ as $\varepsilon \to 0$. Then we get

$$\int_0^1 \left|u_{s_k}^{Lin}(t\theta_{s_k}^{Lin}) - \tilde{u}_k(t\theta_{s_k}^{Lin})\right| dt \leq \frac{1}{\varepsilon} \int_{F_\varepsilon} |p(t)| \left|u_{s_k}^{Lin}(t\theta_{s_k}^{Lin}) - \tilde{u}_k(t\theta_{s_k}^{Lin})\right| dt + 2(1 - \mu F_\varepsilon)$$

$$\leq \frac{2}{\varepsilon} \int_0^1 |p(t) - p_{s_k}(t)|dt + \frac{1}{\varepsilon} \int_0^1 |p_{s_k}(t)| \left|u_{s_k}^{Lin}(t\theta_{s_k}^{Lin}) - \tilde{u}_k(t\theta_{s_k}^{Lin})\right| dt + 2(1 - \mu F_\varepsilon).$$

Using the arbitrariness of ε, we obtain from this relation and (4.6)

$$\lim_{k\to\infty} \sup_{\tilde{u}_k(t)\in U_{\Phi(s_k)}} \int_0^1 \left|u_{s_k}^{Lin}(t\theta_{s_k}^{Lin}) - \tilde{u}_k(t\theta_{s_k}^{Lin})\right| dt = 0,$$

and, therefore, (3.4) is valid due to (3.3). Sufficiency is proved.

Necessity is based essentially on Lemma 8.3.

Let the original nonlinear time-optimal control problem be locally equivalent to the problem for the linear system $\dot{x} = A(t)x + B(t)u$, and let $\ell_1 < \cdots < \ell_n$ be indices of the first n linearly independent vectors from the sequence $\{(-A(t) + d/dt)^j B(t)|_{t=0}\}_{j=0}^{\infty}$. Then the corresponding linear moment min-problem is locally equivalent to the power moment min-problem with gaps (3.2) [18]. Hence, under the conditions of the theorem, nonlinear moment min-problem (3.1) for a series S representing the system is locally equivalent to the power moment min-problem with gaps (3.2) as well. Without loss of generality, we may assume that the transformation Φ satysfying (3.3), (3.4) is the identity one. Our aim is to show that S is ess-linear and $\{v_{\ell_i}\}_{i=1}^n$ are the first n linearly independent elements from the sequence $\{v_j\}_{j=0}^{\infty}$.

Let $(\theta_s, u_s(t))$ and $(\theta_s^{Lin}, u_s^{Lin}(t))$ be solutions of min-problems (3.1) and (3.2), respectively. Then for any s from a neighborhood of the origin we have

$$s = \sum_{i=1}^{n} e_i \xi_{\ell_i}(\theta_s^{Lin}, u_s^{Lin}) = \sum_{m=1}^{\infty} \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\ge 1, m_j\ge 0}} v_{m_1\ldots m_k} \xi_{m_1\ldots m_k}(\theta_s, u_s), \tag{4.7}$$

where $e_i = (0, \ldots, 1, \ldots, 0)$ with 1 on the ith place. Further, (3.3), (3.4) give

$$\xi_{m_1\ldots m_k}(\theta_s, u_s) - \xi_{m_1\ldots m_k}(\theta_s^{Lin}, u_s^{Lin}) = \bar{o}((\theta_s^{Lin})^m) \quad \text{as} \quad s \to 0, \tag{4.8}$$

$m = m_1 + \cdots + m_k + k$. Besides, since $\xi_{m_1\ldots m_k}(\theta, u) = \theta^m \xi_{m_1\ldots m_k}(1, \hat{u})$, where $\hat{u}(t) = u(t\theta)$, $t \in [0, 1]$, then estimate (2.5) for the series S implies

$$\left\| \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\ge 1, m_j\ge 0}} v_{m_1\ldots m_k} \xi_{m_1\ldots m_k}(\theta_s, u_s) \right\| \le (K_1\theta_s)^m \tag{4.9}$$

as $\theta_s \in [0, T_0)$, $T_0 > 0$, where the constant K_1 does not depend on s.

Denote by U^j, $j \ge 0$, the set of all functions $u_j(t) \in L_\infty[0, 1]$, $\|u_j\| = 1$, having no more than j points of discontinuity. When s runs through the domain $\{s \in \mathbb{R}^n : \theta_s^{Lin} < T_0\}$, the function $u_s^{Lin}(t\theta_s^{Lin})$ runs through the set U^{n-1}. Hence, we infer from (4.7)–(4.9)

$$\begin{aligned} \sum_{m=1}^{\ell_n+1} \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\ge 1, m_j\ge 0}} \theta^m v_{m_1\ldots m_k} \left(\xi_{m_1\ldots m_k}(1, u_{n-1}) + \bar{o}(1)\right) + \bar{o}(\theta^{\ell_n+1}) \\ = \sum_{i=1}^{n} \theta^{\ell_i+1} e_i \xi_{\ell_i}(1, u_{n-1}) \end{aligned} \tag{4.10}$$

as $\theta \to 0$, which is valid for any function $u_{n-1}(t) \in U^{n-1}$.

Further, we prove that $S \in \mathcal{L}_e$ by induction on *the order* of $v_{m_1\ldots m_k}$ using the following notation.

Notation. We say that two vectors $z_1, z_2 \in \mathbb{R}^n$ are equivalent up to terms of order $m \geq 1$ with respect to the series S and write $z_1 \overset{m,S}{\cong} z_2$ if $z_1 - z_2 \in \operatorname{Lin}\{v_i\}_{i=0}^{m-2}$ as $m \geq 2$ and $z_1 = z_2$ as $m = 1$.

Now let $q = 1$ or $q \geq 2$, $\operatorname{rank}\{v_j\}_{j=0}^{q-2} = r$, $\{v_{\ell_i}\}_{i=1}^{r}$ be the first r linearly independent vectors from the sequence $\{v_j\}_{j=0}^{q-2}$ (if $r > 0$), and

$$v_{\ell_i} \overset{\ell_i+1,S}{\cong} e_i, \quad i = 1, \dots, r, \quad v_{m_1 \dots m_k} \overset{m,S}{\cong} 0, \quad k \geq 2, \quad m_1 + \dots + m_k + k = m \leq q-1.$$

Then (4.10) implies in particular

$$(v_{q-1} - w)\xi_{q-1}(1, u_r) + \sum_{\substack{m_1+\dots+m_k+k=q \\ k \geq 2, m_j \geq 0}} v_{m_1 \dots m_k} \xi_{m_1 \dots m_k}(1, u_r) \overset{q,S}{\cong} 0$$

for any $u_r(t) \in U^r$, where $w = e_{r+1}$ as $q = \ell_{r+1} + 1$ and $w = 0$ otherwise. Due to Lemma 8.3, we get $v_{m_1 \dots m_k} \overset{q,S}{\cong} 0$ for any $k \geq 2$, $m_1 + \dots + m_k + k = q$ and $v_{q-1} \overset{q,S}{\cong} e_{r+1}$ if $q = \ell_{r+1} + 1$. The induction arguments complete the proof. □

REMARK 4.3. *As follows from the proof of Theorem* 4.2*, one can simplify Definition* 3.1*. Namely, in* (3.4) *it is sufficient to require the existence of a function* $u_{\Phi(s)}(t) \in U_{\Phi(s)}$ *such that* $\frac{1}{\theta} \int_0^\theta |u_{\Phi(s)}(t) - u_s^{Lin}(t)| dt \to 0$.

5. Essentially linearizable series and condition (E). The result of this section is the following theorem.

THEOREM 5.1. *A series* S *representing a system of the form* (1.7) *is ess-linearizable if and only if this system is null-controllable with respect to the first approximation and satisfies condition* (E).

Proof of necessity. Let a series representing a systems of the form (1.7) be ess-linearizable. Then, in particular, it is linearly nonsingular, and hence, due to (1.11) the system is null-controllable with respect to the first approximation.

Note that condition (E) is satisfied for systems represented by ess-linear series. On the other hand, the property of a system to satisfy condition (E) is invariant with respect to nonsingular analytic substitutions of variables. In fact, if F is an analytic transformation and the system (1.7) in the new variables $z = F(x)$ takes the form $\dot{z} = \tilde{a}(t, z) + \tilde{b}(t, z)u$, then

$$\operatorname{ad}^m_{R_{\tilde{a}}} R_{\tilde{b}} E(z)\Big|_{\substack{t=0 \\ z=0}} = D^{(1)}F(0) \operatorname{ad}^m_{R_a} R_b E(x)\Big|_{\substack{t=0 \\ x=0}}, \qquad m \geq 0,$$

$$\begin{aligned} &\left[\operatorname{ad}^{m_1}_{R_{\tilde{a}}} R_{\tilde{b}}, \dots, \left[\operatorname{ad}^{m_{k-1}}_{R_{\tilde{a}}} R_{\tilde{b}}, \operatorname{ad}^{m_k}_{R_{\tilde{a}}} R_{\tilde{b}}\right] \cdots\right] E(z)\Big|_{\substack{t=0 \\ z=0}} \\ &= D^{(1)}F(0)\left[\operatorname{ad}^{m_1}_{R_a} R_b, \cdots \left[\operatorname{ad}^{m_{k-1}}_{R_a} R_b, \operatorname{ad}^{m_k}_{R_a} R_b\right] \cdots\right] E(x)\Big|_{\substack{t=0 \\ x=0}} \end{aligned}$$

for any $k \geq 2$, $m_1, \dots, m_k \geq 0$. Hence condition (E) is satisfied for systems represented by ess-linearizable series as well.

To prove sufficiency we need the following notation.

Notation. We say that a linearly nonsingular series $S^{(p)}$ with coefficients $v^{(p)}_{m_1 \dots m_k}$ is partially ess-linear up to terms of multiplicity p and write $S^{(p)} \in \mathcal{L}^p_e$ if $p = 1$ or $v^{(p)}_{m_1 \dots m_k} \overset{m,S^{(p)}}{\cong} 0$ for k such that $2 \leq k \leq p$, where $m = m_1 + \dots + m_k + k$ (in terms of the notation introduced in the proof of Theorem 4.2).

Sufficiency. Let a series S represent a system of the form (1.7) which is null-controllable with respect to the first approximation and satisfies condition (E). Then S is linearly nonsingular. Let $\{v_{\ell_1},\dots,v_{\ell_n}\}$, $\ell_1<\dots<\ell_n$, be the first n linearly independent vectors from the sequence $\{v_i\}_{i=0}^{\infty}$. Due to Remark 2.5, one can find an ess-linearizing transformation in the form of a polynomial of power ℓ_n+1. We describe such a transformation in the form of *the ess-linearizing algorithm for the series* S.

The 1*st step.* The linear transformation $F_1=(v_{\ell_1},\dots,v_{\ell_n})^{-1}$ maps S to the series $S^{(1)}=F_1(S)=\sum v^{(1)}_{m_1\dots m_k}\xi_{m_1\dots m_k}\in\mathcal{L}_e^1$ such that $v^{(1)}_{\ell_q}=e_q$, $q=1,\dots,n$.

The $(p+1)$*th step.* Assume that after p steps the series S is transformed to the series $S^{(p)}\in\mathcal{L}_e^p$ of the form

$$\begin{aligned}S^{(p)}_q&=\xi_{\ell_q}+\sum_{m=\ell_q+2}^{\ell_n+1}\sum_{k=1}^{\min\{m,p\}}\sum_{m_1+\dots+m_k+k=m}(v^{(p)}_{m_1\dots m_k})_q\xi_{m_1\dots m_k}\\&\quad+\sum_{m=p+1}^{\ell_n+1}\sum_{k=p+1}^{m}\sum_{m_1+\dots+m_k+k=m}(v^{(p)}_{m_1\dots m_k})_q\xi_{m_1\dots m_k}+\rho^{(p)}_q,\end{aligned}\tag{5.1}$$

where $v^{(p)}_{\ell_r}=e_r$, $r=1,\dots,n$, and $\rho^{(p)}_q$ contain terms of order greater than ℓ_n+1,

$$\rho^{(p)}_q=\sum_{m=\ell_n+2}^{\infty}\sum_{m_1+\dots+m_k+k=m}(v^{(p)}_{m_1\dots m_k})_q\xi_{m_1\dots m_k},\qquad q=1,\dots,n.$$

Then the series $S^{(p)}$ represents a system $\dot x=a^{(p)}(t,x)+b^{(p)}(t,x)u$, and this system satisfies condition (E).

Introduce the polynomial transformation F_{p+1} defined as

$$\begin{aligned}&D^{(1)}F_{p+1}(0)=I,\qquad D^{(k)}F_{p+1}(0)=0,\qquad k\ne1,\qquad k\ne p+1,\\&\big(D^{(p+1)}F_{p+1}(0)e_{r_1}\cdots e_{r_{p+1}}\big)_q\\&\qquad=\begin{cases}0 & \text{as}\ \ \ell_q+1<\ell_{r_1}+\dots+\ell_{r_{p+1}}+p+1,\\ -\big(v^{(p)}_{\ell_{r_1}\dots\ell_{r_{p+1}}}\big)_q & \text{as}\ \ \ell_q+1\ge\ell_{r_1}+\dots+\ell_{r_{p+1}}+p+1\end{cases}\\&\quad\text{for}\quad q=1,\dots,n,\qquad 1\le r_1\le\dots\le r_{p+1}\le n,\end{aligned}\tag{5.2}$$

and consider the series $S^{(p+1)}=F_{p+1}(S^{(p)})$. Due to Lemmas 8.4 and 8.5 we get $S^{(p+1)}\in\mathcal{L}_e^{p+1}$.

In other words, for any $q=1,\dots,n$ we subtract the product of the lines of (5.1) with the indices $r_1,\dots,r_{p+1}$ multiplied by $(v^{(p)}_{\ell_{r_1}\dots\ell_{r_{p+1}}})_q$ from the qth line if and only if $\ell_q+1\ge\ell_{r_1}+\dots+\ell_{r_{p+1}}+p+1$, $1\le r_1\le\dots\le r_{p+1}\le n$, $q=1,\dots,n$. As $v^{(p)}_{\ell_r}=e_r$, $r=1,\dots,n$; then this allows us to exclude from the qth equality of (5.1) the moments $\xi_{\ell_{r_1}\dots\ell_{r_{p+1}}}$ such that $1\le r_1\le\dots\le r_{p+1}\le n$, where $\ell_q+1\ge\ell_{r_1}+\dots+\ell_{r_{p+1}}+p+1$, $q=1,\dots,n$. Conditions (i) and (ii) of Lemma 8.4 (satisfied due to Lemma 8.5) obviously yield that all moments of the form $\xi_{m_1\dots m_{p+1}}$ such that $m_1+\dots+m_{p+1}+p+1\le\ell_q+1$, $m_1,\dots,m_{p+1}\ge0$, become excluded from the qth equality too; therefore, $S^{(p+1)}\in\mathcal{L}_e^{p+1}$.

After ℓ_n+1 *steps* of the algorithm, one obtains the ess-linearizing transformation $F=F_{\ell_n+1}\circ\dots\circ F_1$ since $S^{(\ell_n+1)}\in\mathcal{L}_e$, and, therefore, S is ess-linearizable. □

6. Proof of Theorem 1.4 and examples. The proof of Theorem 1.4 follows from Theorems 4.2 and 5.1 immediately. Really, let a system of the form (1.7) be null-controllable with respect to the first approximation. Due to Theorem 4.2, the nonlinear time-optimal control problem for this system is equivalent to a certain linear problem if and only if the series representing the system is ess-linearizable. At the same time, Theorem 5.1 yields that this series is ess-linearizable if and only if the system satisfies condition (E). The construction of the polynomial transformation $F = \Phi^{-1}$ may be found in the proof of Theorem 5.1.

Moreover, as follows from the proof of Theorem 4.2, the equivalent linear time-optimal control problem corresponds to the moment min-problem (3.2), where $\ell_1, \dots, \ell_n$ are indices of the first n linearly independent vectors from the sequence $\{v_i\}_{i=0}^{\infty}$. Taking into account (1.11), we get that the time-optimal control problem for the linearization corresponds to the moment min-problem which is equivalent to (3.2) as well. Hence, if the nonlinear time-optimal control problem is equivalent to a certain linear problem, then it is equivalent to the problem for the linearization as well.

The fact that the solution of the problem (3.2) may serve as an approximation of the optimal time and control for the original time-optimal control problem in a neighborhood of the origin (after the change of variables) immediately follows now from Definitions 1.1 and 1.3 and Theorem 1.2. □

Consider now special classes of systems satisfying conditions of Theorem 1.4.

(i) Consider a system of the form

$$\dot{x} = A(t)x + f(t)(u + g(t,x)), \qquad g(t,0) \equiv 0, \tag{6.1}$$

where $x \in \mathbb{R}^n$, $u \in \mathbb{R}^1$, $A(t)$, $f(t)$, and $g(t,x)$ are a matrix, an n-dimensional vector, and a function real analytic in neighborhoods of the origin in $\mathbb{R}^1$ and $\mathbb{R}^{n+1}$, respectively. The system (6.1) is of the form (1.7) where $a(t,x) = A(t)x + f(t)g(t,x)$, $b(t,x) = f(t)$. Obviously,

$$\operatorname{ad}_{R_a} R_b E(x) = \mu_1^1(t,x)\Delta f(t) + \mu_0^1(t,x) f(t),$$

where $\Delta = \frac{d}{dt} - A(t)$, $\mu_1^1(t,x) \equiv 1$, $\mu_0^1(t,x) = -\sum_{i=1}^{n} \frac{\partial}{\partial x_i} g(t,x) f_i(t)$. It is easy to see that for any $m \geq 0$,

$$\operatorname{ad}_{R_a}^m R_b E(x) = \sum_{j=0}^{m} \mu_j^m(t,x)\Delta^j f(t),$$

where $\mu_m^m(t,x) \equiv 1$ and $\mu_j^m(t,x)$ are real analytic functions, $j = 0, \dots, m-1$.

Suppose the system $\dot{x} = A(t)x + f(t)u$ is locally controllable, which yields $\operatorname{rank}\{\Delta^m f(0)\}_{m=0}^{\infty} = n$. Then $\operatorname{rank}\{\operatorname{ad}_{R_a}^m R_b E(x)_{|\substack{t=0\\x=0}}\}_{m=0}^{\infty} = n$, so the series of nonlinear power moments representing system (6.1) is linearly nonsingular. Further,

$$\left[\operatorname{ad}_{R_a}^{m_1} R_b, \cdots \left[\operatorname{ad}_{R_a}^{m_{k-1}} R_b, \operatorname{ad}_{R_a}^{m_k} R_b\right] \cdots\right] E(x) = \sum_{j=0}^{M} \mu_j^{m_1 \dots m_k}(t,x)\Delta^j f(t),$$

where $M = \max\{m_1, \dots, m_k\} \leq m_1 + \cdots + m_k + k - 2$ as $k \geq 2$ and $\mu_j^{m_1 \dots m_k}(t,x)$ are real analytic functions, $j = 0, \dots, M$, $k \geq 2$, $m_1, \dots, m_k \geq 0$. Hence condition (E) is satisfied and the time-optimal control problem for system (6.1) is locally equivalent to the linear time-optimal problem for the system $\dot{x} = A(t)x + f(t)u$.

(ii) Consider an autonomous "shifted" bilinear system of the form

$$\dot{x} = Ax + (Bx + f)u, \tag{6.2}$$

where $x \in \mathbb{R}^n$, $u \in \mathbb{R}^1$, $f \in \mathbb{R}^n$. We have $a(x) = Ax$, $b(x) = Bx + f$. Denote by $[A, B]$ the matrix commutator, $[A, B] = B \cdot A - A \cdot B$, and let $\operatorname{ad}_A^0 B = B$, $\operatorname{ad}_A^{m+1} B = [A, \operatorname{ad}_A^m B]$, $m \geq 1$. Then

$$\operatorname{ad}_{R_a}^m R_b E(x) = \operatorname{ad}_A^m Bx + (-1)^m A^m f, \qquad m \geq 0,$$

$$\left[\operatorname{ad}_{R_a}^{m_1} R_b, \cdots \left[\operatorname{ad}_{R_a}^{m_{k-1}} R_b, \operatorname{ad}_{R_a}^{m_k} R_b\right] \cdots\right] E(x)$$

$$= \left[\operatorname{ad}_A^{m_1} B, \cdots \left[\operatorname{ad}_A^{m_{k-1}} B, \operatorname{ad}_A^{m_k} B\right] \cdots\right] x + \sum_{(p_1,\ldots,p_k)\in Z} \mu^{p_1\cdots p_k} \operatorname{ad}_A^{p_1} B \cdots \operatorname{ad}_A^{p_{k-1}} B \cdot A^{p_k} f,$$

where Z denotes the set of all permutations of numbers $m_1, \ldots, m_k$ and $\mu^{p_1\cdots p_k} \in \mathbb{R}$, $k \geq 2$, $m_1, \ldots, m_k \geq 0$.

Now let the system (6.2) be of the form

$$\begin{aligned} \dot{x}_1 &= u(1 + B_{11}x_1 + \cdots + B_{1n}x_n), \\ \dot{x}_q &= x_{q-1} + u(B_{qq}x_q + \cdots + B_{qn}x_n), \qquad 2 \leq q \leq n. \end{aligned} \tag{6.3}$$

Then $\operatorname{ad}_{R_a}^i R_b E(0) = (-1)^i e_{i+1}$, $i = 0, \ldots, n-1$. Further, elements of matrices $\operatorname{ad}_A^p B$, $p \geq 0$, satisfy the condition $(\operatorname{ad}_A^p B)_{ij} = 0$ as $i > j + p$, $1 \leq i, j \leq n$. Hence $\operatorname{ad}_A^p B e_q \in \operatorname{Lin}\{e_j\}_{j=1}^{q+p}$, $q = 1, \ldots, n-p$, $0 \leq p \leq n-1$, and therefore

$$\operatorname{ad}_A^{p_1} B \cdots \operatorname{ad}_A^{p_{k-1}} B \cdot A^{p_k} f \in \operatorname{Lin}\{\operatorname{ad}_{R_a}^i R_b E(0)\}_{i=0}^M,$$

where $M = p_1 + \cdots + p_k = m_1 + \cdots + m_k \leq m_1 + \cdots + m_k + k - 2$ as $k \geq 2$, which proves (E). Thus the time-optimal control problem for system (6.3) is locally equivalent to the linear problem for the system $\dot{x}_1 = u$, $\dot{x}_q = x_{q-1}$, $q = 2, \ldots, n$.

(iii) Consider the nonlinear triangular system

$$\begin{aligned} \dot{x}_q &= \varphi_q(t, x_1, \ldots, x_{q+1}), \qquad 1 \leq q \leq n-1, \\ \dot{x}_n &= \varphi_n(t, x) + \psi(t, x)u, \end{aligned} \tag{6.4}$$

where $\varphi_q(t, x_1, \ldots, x_{q+1})$, $q = 1, \ldots, n-1$, $\varphi_n(t, x)$, and $\psi(t, x)$ are real analytic functions in neighborhoods of the origin in $\mathbb{R}^{q+2}$ and $\mathbb{R}^{n+1}$, respectively, $\varphi_q(t, 0) \equiv 0$, $q = 1, \ldots, n$. Suppose also $\frac{\partial}{\partial x_{q+1}}\varphi_q(0, 0) \neq 0$, $q = 1, \ldots, n-1$, $\psi(0, 0) \neq 0$. Under these conditions there exists a nonsingular transformation which reduces system (6.4) to the system $\dot{x}_q = x_{q+1}$, $q = 1, \ldots, n-1$, $\dot{x}_n = \alpha(t, x) + \beta(t, x)u$; $\alpha(t, 0) \equiv 0$, $\beta(0, 0) \neq 0$, and can be found constructively [10]. Let us prove that the time-optimal control problem for system (6.4) is locally equivalent to the problem for the system $\dot{x}_q = x_{q+1}$, $q = 1, \ldots, n-1$, $\dot{x}_n = u$.

We have $a(t, x) = (\varphi_1(t, x_1, x_2), \ldots, \varphi_n(t, x))$; hence

$$a_x(t, x) = \begin{pmatrix} * & \frac{\partial\varphi_1(t,x)}{\partial x_2} & 0 & \ldots & 0 \\ * & * & \frac{\partial\varphi_2(t,x)}{\partial x_3} & \ldots & 0 \\ \ldots & \ldots & \ldots & \ldots & \ldots \\ * & * & * & \ldots & \frac{\partial\varphi_{n-1}(t,x)}{\partial x_n} \\ * & * & * & \ldots & \frac{\partial\varphi_n(t,x)}{\partial x_n} \end{pmatrix},$$

and therefore $\mathrm{ad}_{R_a} R_b E(x) = \frac{\partial \varphi_{n-1}(t,x)}{\partial x_n}\psi(t,x)e_{n-1} + \mu_n^1(t,x)e_n$. One easily proves that

$$\mathrm{ad}_{R_a}^m R_b E(x) = \prod_{j=n-m}^{n-1} \frac{\partial \varphi_j(t,x)}{\partial x_{j+1}}\psi(t,x)e_{n-m} + \sum_{j=1}^{m} \mu_{n+1-j}^m(t,x)e_{n+1-j}, \quad 1 \le m \le n-1.$$

Thus, $\mathrm{rank}\{\mathrm{ad}_{R_a}^m R_b E(x)_{|\substack{t=0\\x=0}}\}_{m=0}^{n-1} = n$ and $\mathrm{Lin}\{\mathrm{ad}_{R_a}^m R_b E(x)_{|\substack{t=0\\x=0}}\}_{m=0}^{M} = \mathrm{Lin}\{e_j\}_{j=n-M}^{n}$, $0 \le M \le n-1$. Further,

$$\left[\mathrm{ad}_{R_a}^{m_1} R_b, \cdots \left[\mathrm{ad}_{R_a}^{m_{k-1}} R_b, \mathrm{ad}_{R_a}^{m_k} R_b\right] \cdots\right] E(x) = \sum_{j=0}^{\min\{M,n-1\}} \mu_{n-j}^{m_1 \ldots m_k}(t,x)e_{n-j},$$

where $M = \max\{m_1, \ldots, m_k\} \le m_1 + \cdots + m_k + k - 2$ as $k \ge 2$, which proves the validity of (E) and, therefore, the desired result.

7. Some ways of generalization and arising problems.

(A) Within the moment approach, the further step which seems to be natural is to consider series of nonlinear power moments, transformations of series, and nonlinear moment min-problems irrespective to systems and the time-optimal control problem, as it has been done for the linear case [11]. In this way a natural object is a series of the form (2.7) with *arbitrary* constant vector coefficients $v_{m_1 \ldots m_k}$ satisfying the requirement (2.5) (which implies the convergence) and the Markov moment min-problem (3.1) for this series. In this relation it is extremely important to emphasize that, in contrast to the linear case, not every such series represents a system of the form (1.7). The first difficulty to emerge is the question on the existence of a solution of the min-problem. To avoid it one can modify the definition of the local equivalence of the nonlinear moment min-problem to a linear one. We require:

(i) the "local controllability" property: for any s from a neighborhood of the origin there exists θ such that the set $U_s(\theta)$ of all $u(t) \in L_\infty[0,\theta]$, $\|u\| \le 1$, satisfying (3.1) is not empty;

(ii) the existence of an approximation $\tilde{\theta}_{\Phi(s)}$ of $\theta_{\Phi(s)}^{inf} = \inf\{\theta : U_{\Phi(s)}(\theta) \ne \emptyset\}$ such that $U_{\Phi(s)}(\tilde{\theta}_{\Phi(s)}) \ne \emptyset$ and

$$\frac{\theta_s^{Lin}}{\tilde{\theta}_{\Phi(s)}} \to 1, \qquad \frac{\tilde{\theta}_{\Phi(s)}}{\theta_{\Phi(s)}^{inf}} \to 1, \qquad \sup_{\tilde{u}(t) \in U_{\Phi(s)}(\tilde{\theta}_{\Phi(s)})} \frac{1}{\theta}\int_0^\theta \left|u_s^{Lin}(t) - \tilde{u}(t)\right| dt \to 0 \quad \text{as} \quad s \to 0,$$

where $\theta = \min\{\theta_s^{Lin}, \theta_{\Phi(s)}^{inf}\}$.

With this definition the sufficiency in Theorem 4.2 remains true:

(i) If the series S is ess-linearizable (Definition 4.1) and $\{v_{\ell_i}\}_{i=1}^n$ are the first n linearly independent vectors from the sequence $\{v_i\}_{i=0}^\infty$, then the nonlinear moment min-problem is locally equivalent to the linear one of the form (3.2). The necessity in Theorem 4.2 can be proved in the following particular case.

(ii) If the nonlinear moment min-problem is locally equivalent to the linear min-problem of the form

$$s_q = \int_0^\theta t^{q-1}u(t)dt, \qquad q = 1, \ldots, n,$$

then the series S is ess-linearizable and $\mathrm{rank}\{v_i\}_{i=0}^{n-1} = n$.

However, in the general case the necessity in Theorem 4.2 is false. For example, the one-dimensional moment min-problems $s = \xi_{000} + \xi_2$ and $s = \xi_2$ are equivalent although the series $S = \xi_{000} + \xi_2$ is not ess-linearizable.

(B) The representation of systems in the form of series of nonlinear power moments is easily extended to the case of multi-input systems,

$$\dot{x} = a(t,x) + \sum_{i=1}^{h} b_i(t,x)u_i. \tag{7.1}$$

For such systems a representation of the form (2.2) becomes an expansion with respect to nonlinear power "multimoments,"

$$\xi^{i_1\ \dots\ i_k}_{m_1 \dots m_k} = \int_0^\theta \int_0^{\tau_1} \dots \int_0^{\tau_{k-1}} \tau_1^{m_1}\tau_2^{m_2}\dots\tau_k^{m_k} \prod_{j=1}^{k} u_{i_j}(\tau_j)\,d\tau_k \dots d\tau_2 d\tau_1,$$

with coefficients analogous to (2.4) but including $\operatorname{ad}^m_{R_a} R_{b_i}$, $m \geq 0$, $i = 1, \dots, h$. Condition (E) is generalized in a natural way as well.

Finally, one may consider series of nonlinear power "multimoments" with arbitrary constant coefficients satisfying an estimate analogous to (2.5). We call the series ess-linearizable if it can be transformed to the form

$$F(S)_q = \xi^{i_q}_{\ell_q} + \sum_{j=i_q+1}^{h} \alpha_{qj}\xi^{j}_{\ell_q} + \rho_q, \qquad q = 1, \dots, n,$$

where ρ_q includes terms of order greater than $\ell_q + 1$. Here $\ell_q \geq 0$, $i_q \in \{1, \dots, h\}$, and $(\ell_1, i_1) < \dots < (\ell_n, i_n)$ in the lexicographic sense.

For systems of the form (7.1), the result analogous to Theorem 5.1 is valid.

(i) A series of nonlinear power "multi-input" moments representing a system of the form (7.1) is ess-linearizable if and only if the system satisfies condition (E).

For series with arbitrary coefficients, we have the following assertions.

(ii) For a linearly nonsingular series of nonlinear power "multi-input" moments with arbitrary coefficients, the ess-linearizing algorithm can be applied; it gives an ess-linear series after a finite number of steps if and only if the series is ess-linearizable.

(iii) The series S is ess-linearizable if and only if each series $S^{(p)} \in \mathcal{L}^p_e$, $p \geq 1$, constructed by the ess-linearizing algorithm satisfies the conditions of Lemma 8.4 and, therefore, can be transformed to $S^{(p+1)} \in \mathcal{L}^{p+1}_e$ using a transformation analogous to (5.2).

(C) One of our main ideas is to interpret "the closeness" of a given nonlinear system to a linear one in terms of the reducibility of its series to the form $S = \Xi + R$, where Ξ is a vector of linear moments and $R_q/\Xi_q \to 0$ as $\theta \to 0$, $\|u\| \leq 1$. This suggests considering the much more general problem on classification of systems of the form (7.1). Namely, one can regard two systems as equivalent if their series are reducible to the same "canonical form" $S = C + R$ with the "principal part" C, where the components C_q are linear combinations of certain moments and $R_q/C_q \to 0$ as $\theta \to 0$, $\|u\| \leq 1$. The question is how to choose "principal parts" which represent classes of equivalence and systems corresponding to them. In the forthcoming paper, we give such a classification in terms of some structures induced by systems in *the algebra of nonlinear power "multimoments."*

Another important question is to investigate the realizability of series of nonlinear power "multimoments" as systems of the form (7.1):

(i) under what conditions on coefficients of the series there exist such vector functions $a(t,x), b_1(t,x), \dots, b_h(t,x)$ that the series represents (7.1);

(ii) under what conditions these vector functions are time-independent.

This question will be a subject of a forthcoming paper as well.

8. Auxiliary results. This section contains the technical results used in sections 4 and 5.

Denote by U^j, $j \geq 0$, the set of all functions $u_j(t) \in L_\infty[0,1]$, $\|u_j\| = 1$, having no more than j points of discontinuity.

LEMMA 8.1. *Let $r \geq 2$, $0 = \alpha_0 < \alpha_1 < \alpha_2 \leq \cdots \leq \alpha_{r-1} \leq \alpha_r = 1$, and*

$$u_r^1(t) = \sigma(-1)^{j-1}, \qquad t \in [\alpha_{j-1}, \alpha_j), \qquad j = 1, \dots, r, \qquad \sigma = \pm 1$$

(that is the function u_r^1 has at least one point of discontinuity). Then any moment $\xi_{m_1 \dots m_k}(1, u_r^1)$, $k \geq 2$, can be represented as $\xi_{m_1 \dots m_k}(1, u_r^1) = \sum_{j=0}^{m} \alpha_1^j \varphi_j(\alpha_2, \dots, \alpha_{r-1})$, $m = m_1 + \cdots + m_k + k$, where, in particular,

$$\varphi_j(\alpha_2, \dots, \alpha_{r-1}) = \begin{cases} 0 & \text{as } 0 < j \leq m_k, \\ \frac{2\sigma}{m_k+1} \xi_{m_1 \dots m_{k-1}}(1, u_{r-1}) & \text{as } j = m_k + 1, \end{cases}$$

and the function $u_{r-1}(t) \in U^{r-1}$ is defined as follows:

$$u_{r-1}(t) = -\sigma, \quad t \in [0, \alpha_1), \quad u_{r-1}(t) = \sigma(-1)^{j-1}, \quad t \in [\alpha_{j-1}, \alpha_j), \quad j = 2, \dots, r.$$

To formulate the following lemma, we introduce the notations

$$\begin{aligned} \prod_{j=\ell}^{k} \operatorname{ad}_{R_a}^{m_j} R_b &= \operatorname{ad}_{R_a}^{m_\ell} R_b \circ \cdots \circ \operatorname{ad}_{R_a}^{m_k} R_b, \ 1 \leq \ell \leq k, \\ \left[\operatorname{ad}_{R_a}^{m_j} R_b\right]_{j=\ell}^{k} &= [\operatorname{ad}_{R_a}^{m_\ell} R_b, \cdots [\operatorname{ad}_{R_a}^{m_{k-1}} R_b, \operatorname{ad}_{R_a}^{m_k} R_b] \cdots], \qquad 1 \leq \ell \leq k-1. \end{aligned} \tag{8.1}$$

LEMMA 8.2. *Suppose that a series S of the form (2.7) represents a system of the form (1.7), $q \geq 2$, $\operatorname{rank}\{v_i\}_{i=0}^{q-2} = r$, and $\ell_1 < \cdots < \ell_r$ are indices of the first r linearly independent vectors from the sequence $\{v_i\}_{i=0}^{q-2}$. Let also*

$$v_{m_1 \dots m_k} \overset{m,S}{\cong} 0$$

for any $k \geq 2$, $m_1, \dots, m_k \geq 0$ such that $m_1 + \cdots + m_k + k = m \leq q-1$. Then

$$\prod_{j=1}^{i-1} \operatorname{ad}_{R_a}^{m_j} R_b \circ \left[\operatorname{ad}_{R_a}^{m_j} R_b\right]_{j=i}^{p-1} \circ \prod_{j=p}^{k} \operatorname{ad}_{R_a}^{m_j} R_b E(x)\Big|_{\substack{t=0 \\ x=0}} \overset{q,S}{\cong} 0$$

for any $k \geq 3$, $m_1, \dots, m_k \geq 0$ such that $m_1 + \cdots + m_k + k = q$ and any $p = 3, \dots, k$, $i = 1, \dots, p-2$. As a consequence,

(i) *for any $k \geq 3$, $m_1, \dots, m_k \geq 0$ such that $m_1 + \cdots + m_k + k = q$, and any permutation $Z(1, \dots, k-1)$ of numbers $\{1, \dots, k-1\}$ we have*

$$v_{m_1 \dots m_k} - v_{Z(m_1, \dots, m_{k-1}) m_k} \overset{q,S}{\cong} 0;$$

(ii) *for any* $k \geq 2$, $m_1, \dots, m_k \geq 0$ *such that* $m_1 + \dots + m_k + k = q$ *and* $\{m_1, \dots, m_{k-1}\} \not\subset \{\ell_1, \dots, \ell_r\}$, *we have* $v_{m_1 \dots m_k} \overset{q,S}{\cong} 0$.

LEMMA 8.3 (on equivalence of series having the same values on bang-bang controls). *Let a series* S *of the form* (2.7) *represent a system of the form* (1.7). *Let* $q \geq 2$ *be such a number that*

$$v_{m_1 \dots m_k} \overset{m,S}{\cong} 0$$

for any $k \geq 2$, $m_1, \dots, m_k \geq 0$ *such that* $m = m_1 + \dots + m_k + k \leq q - 1$. *Put* $r = \operatorname{rank}\{v_j\}_{j=0}^{q-2}$, *and suppose*

$$(v_{q-1} - w)\xi_{q-1}(1, u_r) + \sum_{\substack{m_1 + \dots + m_k + k = q \\ k \geq 2, m_j \geq 0}} v_{m_1 \dots m_k} \xi_{m_1 \dots m_k}(1, u_r) \overset{q,S}{\cong} 0 \tag{8.2}$$

for any $u_r(t) \in U^r$, *where* $w \in \mathbb{R}^n$. *Then*

$$v_{q-1} \overset{q,S}{\cong} w, \qquad v_{m_1 \dots m_k} \overset{q,S}{\cong} 0 \tag{8.3}$$

for any $k \geq 2$, $m_1, \dots, m_k \geq 0$ *such that* $m_1 + \dots + m_k + k = q$.

Proof. Suppose $r = 0$; then $v_j = 0$ as $j \leq q - 2$ and $v_{m_1 \dots m_k} = 0$ as $k \geq 2$, $m_1 + \dots + m_k + k = q$ due to assertion (ii) of Lemma 8.2. Then (8.2) implies $v_{q-1} = w$, which proves (8.3).

Now let $r \geq 1$. We proceed by induction *on the last index* m_k. Suppose $p = 0$ or $1 \leq p \leq q - 1$ and the second relation of (8.3) holds for any set of indices $m_1, \dots, m_k$ such that $k \geq 2$, $0 \leq m_k \leq p - 1$, $m_1, \dots, m_{k-1} \geq 0$, $m_1 + \dots + m_k + k = q$. Our aim is to show that (8.3) is valid for any $m_1, \dots, m_k$ such that $m_k = p$, $m_1, \dots, m_{k-1} \geq 0$, $m_1 + \dots + m_{k-1} + p + k = q$. We have from (8.2) and the induction supposition that for any $u_r(t) \in U^r$,

$$(v_{q-1} - w)\xi_{q-1}(1, u_r) + \sum_{\substack{m_1 + \dots + m_k + k = q \\ k \geq 2,\ m_1, \dots, m_{k-1} \geq 0, m_k \geq p}} v_{m_1 \dots m_k} \xi_{m_1 \dots m_k}(1, u_r) \overset{q,S}{\cong} 0.$$

Let $u_r(t)$ have at least one point of discontinuity $\alpha_1 \in (0, 1)$. Then, using Lemma 8.1 and the equality $\xi_{q-1}(1, u_r) = \pm\frac{1}{q}(2\sum_{j=1}^{r}(-1)^{j-1}\alpha_j^q + (-1)^r)$, we obtain $v_{q-1} \overset{q,S}{\cong} w$ if $p = q - 1$ (the first of relations (8.3)) and

$$\sum_{\substack{m_1 + \dots + m_{k-1} + p + k = q \\ k \geq 2, m_j \geq 0}} v_{m_1 \dots m_{k-1} p}\ \xi_{m_1 \dots m_{k-1}}(1, u_{r-1}) \overset{q,S}{\cong} 0 \quad \text{for any} \quad u_{r-1}(t) \in U^{r-1} \tag{8.4}$$

if $p \leq q - 2$.

Let $\ell_1 < \dots < \ell_r$ be indices of the first r linearly independent vectors from the sequence $\{v_j\}_{j=0}^{q-2}$. Due to assertion (ii) of Lemma 8.2, (8.4) reads

$$\sum_{\substack{m_1 + \dots + m_{k-1} + p + k = q \\ k \geq 2, m_j \geq 0 \\ m_1, \dots, m_{k-1} \in \{\ell_1, \dots, \ell_r\}}} v_{m_1 \dots m_{k-1} p}\ \xi_{m_1 \dots m_{k-1}}(1, u_{r-1}) \overset{q,S}{\cong} 0. \tag{8.5}$$

Let Z denote the set of all distinct permutations of numbers $m_1, \dots, m_{k-1}$, and N denotes the number of such permutations. Since

$$\sum_{(q_1,\dots,q_{k-1})\in Z} v_{q_1\dots q_{k-1}p}\,\xi_{q_1\dots q_{k-1}} = v_{m_1\dots m_{k-1}p} \sum_{(q_1,\dots,q_{k-1})\in Z} \xi_{q_1\dots q_{k-1}} + \sum_{(q_1,\dots,q_{k-1})\neq(m_1,\dots,m_{k-1})} (v_{q_1\dots q_{k-1}p} - v_{m_1\dots m_{k-1}p})\xi_{q_1\dots q_{k-1}},$$

and

$$\sum_{(q_1,\dots,q_{k-1})\in Z} \xi_{q_1\dots q_{k-1}} = \frac{N}{(k-1)!}\prod_{i=1}^{k-1}\xi_{m_i},$$

we get from (8.5) and assertion (i) of Lemma 8.2 that

$$\sum_{\substack{m_1+\dots+m_{k-1}+p+k=q\\ k\geq 2, m_j\geq 0\\ m_1\leq\dots\leq m_{k-1}\in\{\ell_1,\dots,\ell_r\}}} v_{m_1\dots m_{k-1}p}\frac{N}{(k-1)!}\prod_{i=1}^{k-1}\xi_{m_i}(\theta,\bar u_{r-1}) \overset{q,S}{\cong} 0 \tag{8.6}$$

for any $\theta\geq 0$ and control $\bar u_{r-1}(t) = u_{r-1}(t/\theta)$, $t\in[0,\theta]$, where $u_{r-1}(t)$ runs through the set U^{r-1}. Since $\{\xi_{\ell_j}(\theta,\bar u_{r-1})\}_{j=1}^r$ are independent as polynomials of r variables (points of discontinuity of $\bar u_{r-1}(t)$ and θ), we have from (8.6) that $v_{m_1\dots m_{k-1}p} \overset{q,S}{\cong} 0$ if $m_1\leq\dots\leq m_{k-1}$ and $m_1,\dots,m_{k-1}\in\{\ell_1,\dots,\ell_r\}$. Finally, Lemma 8.2 yields that (8.3) holds for any $m_1,\dots,m_k$ such that $m_k = p$, $m_1,\dots,m_{k-1}\geq 0$, $m_1+\dots+m_{k-1}+p+k=q$. □

LEMMA 8.4. *Let $S^{(p)}\in\mathcal{L}_e^p$, $p\geq 1$. Denote $S^{(p+1)} = F_{p+1}(S^{(p)})$, where F_{p+1} is defined by* (5.2). *Then $S^{(p+1)}\in\mathcal{L}_e^{p+1}$ under the two following conditions satisfied for any $m_1,\dots,m_{p+1}\geq 0$.*

(i) *For an arbitrary permutation $Z(1,\dots,p+1)$ of numbers $\{1,\dots,p+1\}$*

$$v^{(p)}_{m_1\dots m_{p+1}} \overset{m,S^{(p)}}{\cong} v^{(p)}_{Z(m_1,\dots,m_{p+1})},\quad m = m_1+\dots+m_{p+1}+p+1.$$

(ii) *If $v^{(p)}_{m_1} \overset{m,S^{(p)}}{\cong} \sum_{\ell=1}^{n_1}\alpha_\ell v^{(p)}_{q_\ell}$, then $v^{(p)}_{m_1\dots m_{p+1}} \overset{m,S^{(p)}}{\cong} \sum_{\ell=1}^{n_1}\alpha_\ell v^{(p)}_{q_\ell m_2\dots m_{p+1}}$, where $m = m_1+\dots+m_{p+1}+p+1$, $\alpha_\ell\in\mathbb{R}$.*

LEMMA 8.5. *Let $S^{(p)}\in\mathcal{L}_e^p$ represent a control system $\dot x = a^{(p)}(t,x)+b^{(p)}(t,x)u$, which satisfies condition* (E). *Then (under the notations analogous to* (8.1)*) the following equalities hold:*

$$\prod_{j=1}^{\ell}\mathrm{ad}^{m_j}_{R_{a^{(p)}}}R_{b^{(p)}}\circ\Big[\mathrm{ad}^{m_j}_{R_{a^{(p)}}}R_{b^{(p)}}\Big]^q_{j=l+1}\circ\prod_{j=q+1}^{p+1}\mathrm{ad}^{m_j}_{R_{a^{(p)}}}R_{b^{(p)}}E(x)\Big|_{\substack{t=0\\ x=0}} \overset{m,S^{(p)}}{\cong} 0$$

for any $q=2,\dots,p+1$, $\ell=0,\dots,q-2$; $m_1,\dots,m_{p+1}\geq 0$, where $m = m_1+\dots+m_{p+1}+p$ as $q<p+1$ and $m_1+\dots+m_{p+1}+p+1$ as $q=p+1$. As a consequence, conditions (i) *and* (ii) *of Lemma* 8.4 *are satisfied.*

OBSERVABILITY INEQUALITIES FOR SHALLOW SHELLS*

PENG-FEI YAO†

Abstract. We consider some observability inequalities from boundary for a general shallow shell with a middle surface of any shape. At first, an estimate is established by the geometric multiplier method in the case that no boundary conditions are imposed under some checkable geometric conditions. Then our results yield continuous observability estimates for two kinds of boundary conditions which have a physical meaning with an explicit observability time and hence, by duality, exact controllability results.

Key words. shallow shell, Bochner's technique, observability inequality

1. Introduction: Statement of main results.

The purpose of this paper is to establish some observability estimates for the shallow shell from which some boundary exact controllability results can be derived. This problem has been well understood in the case of wave equations and plates and, in particular, in the constant coefficient case; see Komornik [19], Lagnese and Lions [21]. It is, in general, hard to handle the variable coefficient case in which some special tools are often needed in addition to the classical multiplier method, for instance, the microlocal analysis method of Bardos, Lebeau, and Rauch [1], the pseudodifferential method of Tataru [28], [29], [30], and the geometric method of Yao [36]. In the case of thin shells with a middle surface of any shape, very little is apparently known in the context of control/stabilization theory, partly because thin shell problems are always of variable coefficient (at least about space variables). Generally, direct adaptation of the techniques, traditionally developed in assuming that the middle surface is defined by one coordinate, would not be fully adequate when dealing with some observability estimates since the presence of the Christoffel symbols Γ_{jk}^{k} can often make computing too complicated.

First, we shall briefly introduce the classical shallow model in a version produced by Yao [37], in which the middle surface is viewed as a Riemann manifold with the induced metric in $\mathbb{R}^3$. One of the advantages in doing this is to build a bridge to modern geometry. For instance, the Bochner technique, which cannot be applied once fixed in one coordinate, is the key ingredient used throughout this paper to overcome the complexity of computation when we deal with all the estimates. This technique, which describes a method initiated by Bochner some fifty years ago for proving some identities of geometric interest, is not so easily described, but it offers the greatest computational simplification on some variable coefficient problems. For details, we refer to Wu [35].

Next, we set up an assumption (H2) on the middle surface under which an estimate for the shallow model is established in the case that no boundary conditions are imposed (Theorem 1.1). In fact, this assumption also works for some observability inequalities of Naghdi's models; see Yao [40]. In subsection 2.1 we shall show that

*Received by the editors May 19, 1999; accepted for publication (in revised form) November 15, 1999; published electronically June 15, 2000. This work was supported by the National Natural Science Foundation of China and the National Key Project of China.

†Institute of Systems Science, Academy of Mathematics and Systems Science, Chinese Academy of Science, Beijing 100080, P. R. China (pfyao@iss03.iss.ac.cn).

the main assumption (H2) always holds locally for the middle surface of any shape (Proposition 2.2) and how to find a vector field to meet it when the middle surface of the shallow shell is of constant curvature or revolution (Propositions 2.3 and 2.4). In particular, several examples of the middle surface that verify the main assumption (H2) are presented in subsection 1.4.

Finally, the estimates in Theorem 1.1 will produce continuous observability inequalities in both Dirichlet and Neumann cases (Theorems 1.2 and 1.3), respectively, by a compactness/uniqueness argument to absorb the lower order terms as in Bardos, Lebeau, and Rauch [1] or in Zuazua [41]. Fortunately, all the uniqueness results we need here can, in both cases, be derived from certain old uniqueness issues (Proposition 2.13), i.e., Hörmander [16], or Shirota [27].

In addition, regularities of solutions to all the shallow equations needed here should be an intrinsic issue. Since we are mainly concerned with estimates of inequalities, it is assumed that all the regularities of solutions we need hold in this paper.

We mention that some works have been done on control problems of some special shallow shells, for example, Chen, Coleman, and Liu [8] for circular cylindrical shells, Lasiecka, Triggiani, and Valente [23], Triggiani [32] for spherical shells, and Geymont, Loreti, and Valente [12].

1.1. Some notation. We introduce some notation in preparation for shallow shell equations and the observability inequalities. It is mentioned that all definitions and notation in this subsection are standard and classical in the literature.

Denote the usual inner product in $\mathbb{R}^3$ by $\langle\cdot,\cdot\rangle$, i.e., the dot product. Let M be a surface in $\mathbb{R}^3$. For simplicity, M is assumed to be smooth. Surface M produces a natural Riemannian manifold of dimension 2 with the induced metric in $\mathbb{R}^3$. We denote this induced metric on surface M by g or by $\langle\cdot,\cdot\rangle$, as convenient. For each $x \in M$, M_x is the tangential space of M at x. It is assumed that surface M is orientable with the unit normal field N on M. Denote the set of all vector fields on M by $\mathcal{X}(M)$. Denote the set of all k-order tensor fields and the set of all k-forms on M by $T^k(M)$ and $\Lambda^k(M)$, respectively, where k is a nonnegative integer. Then

$$\Lambda^k(M) \subset T^k(M). \tag{1.1}$$

In particular, $\Lambda^0(M) = T^0(M) = C^\infty(M)$ is the set of all C^∞ functions on M and

$$T^1(M) = T(M) = \Lambda(M) = \mathcal{X}(M), \tag{1.2}$$

where $\Lambda(M) = \mathcal{X}(M)$ is in the following isomorphism: for $X \in \mathcal{X}(M)$ given,

$$U(Y) = \langle Y, X\rangle \quad \forall\, Y \in \mathcal{X}(M) \tag{1.3}$$

determines a unique $U \in \Lambda(M)$.

It is well known that, for each $x \in M$, k-order tensor space T^k_x on M_x is an inner product space defined as follows. Let e_1, e_2 be an orthonormal basis of M_x. For any α, $\beta \in T^k_x$, $x \in M$, the inner product is given by

$$\langle \alpha, \beta\rangle_{T^k_x} = \sum_{i_1,\dots,i_k=1}^{2} \alpha(e_{i_1},\dots,e_{i_k})\beta(e_{i_1},\dots,e_{i_k}) \quad \text{at } x. \tag{1.4}$$

In particular, for $k = 1$ definition (1.4) becomes

$$g(\alpha,\beta) = \langle \alpha, \beta\rangle_{T_x} = \langle \alpha, \beta\rangle \quad \forall\, \alpha,\, \beta \in M_x, \tag{1.5}$$

that is, the induced inner product of M_x in $\mathbb{R}^3$.

Let Ω be a bounded region of surface M with a regular boundary Γ or without boundary (when Γ is empty). From (1.4), $T^k(\Omega)$ are then inner product spaces in the following sense:

$$(T_1, T_2)_{T^k(\Omega)} = \int_\Omega \langle T_1, T_2 \rangle_{T_x^k}\, dx, \quad T_1,\, T_2 \in T^k(\Omega), \tag{1.6}$$

where dx is the volume element of surface M in its Riemannian metric g.

The completions of $T^k(\Omega)$ in inner products (1.6) are denoted by $L^2(\Omega, T^k)$. In particular, $L^2(\Omega, \Lambda) = L^2(\Omega, T)$. $L^2(\Omega)$ is the completion of $C^\infty(\Omega)$ in the following inner product:

$$(f, h)_{L^2(\Omega)} = \int_\Omega f(x)h(x)\, dx, \quad f,\, h \in C^\infty(\Omega). \tag{1.7}$$

Let D be the Levi–Civita connection on M in the induced metric g of surface M. For $U \in \mathcal{X}(M)$, DU is the covariant differential of U which is a 2-order covariant tensor field in the following sense:

$$DU(X, Y) = D_Y U(X) = \langle D_Y U,\, X \rangle \quad \forall\, X,\, Y \in M_x,\, x \in M. \tag{1.8}$$

We also define $D^*U \in T^2(M)$ by

$$D^*U(X, Y) = DU(Y, X) \quad \forall\, X,\, Y \in M_x,\, x \in M, \tag{1.9}$$

that is, $D^*U \in T^2(M)$ is the transpose of DU. For any $T \in T^2(M)$, the trace of T at $x \in M$ is defined by

$$\mathrm{tr}T = \sum_{i=1}^{2} T(e_i, e_i) \tag{1.10}$$

where e_1, e_2 is an orthonormal basis of M_x. It is obvious that $\mathrm{tr}T \in C^\infty(M)$ if $T \in T^2(M)$.

For $T \in T^k(M)$ and $X \in \mathcal{X}(M)$, we define $l_X T \in T^{k-1}(M)$ by

$$l_X T(X_1, \ldots, X_{k-1}) = T(X, X_1, \ldots, X_{k-1}) \quad \forall\, X_1, \ldots, X_{k-1} \in \mathcal{X}(M). \tag{1.11}$$

For X, $Y \in \mathcal{X}(M)$, the curvature operator $R_{XY}\colon \mathcal{X}(M) \to \mathcal{X}(M)$ is defined by

$$R_{XY} = -D_X D_Y + D_Y D_X + D_{[X,Y]}, \tag{1.12}$$

where $[X, Y]$ is the Lie product of vector fields X and Y. We have the following identity (see Wu [33, section 2, Lem. 4]):

$$D^2T(\ldots, X, Y) = D^2T(\ldots, Y, X) + (R_{XY}T)(\ldots), \tag{1.13}$$

for $T \in T^k(M)$, $\ldots$, X, $Y \in \mathcal{X}(M)$.

The curvature tensor R of the Levi–Civita connection is given by

$$R(X, Y, Z, W) = \langle R_{XY}Z,\, W \rangle, \quad X,\, Y,\, Z,\, W \in M_x,\, x \in M, \tag{1.14}$$

which is a 4-order tensor field on M.

The Sobolev space $H^k(\Omega)$ is the completion of $C^\infty(\Omega)$ with respect to the norm

$$\|f\|^2_{H^k(\Omega)} = \sum_{i=1}^{k} \|D^k f\|^2_{L^2(\Omega,T^k)} + \|f\|^2_{L^2(\Omega)}, \quad f \in C^\infty(\Omega), \tag{1.15}$$

where $D^k f$ is the kth covariant differential of f in the induced metric g of M, which is a k-order tensor field on Ω, and $\|\cdot\|_{L^2(\Omega,T^k)}$ and $\|\cdot\|_{L^2(\Omega)}$ are the induced norms in inner products (1.6)–(1.7), respectively. For details on Sobolev spaces on Riemannian manifolds, we refer to Hebey [15] or Taylor [31].

Another important Sobolev space for us is $H^k(\Omega,\Lambda)$, defined by

$$H^k(\Omega,\Lambda) = \{U \,|\, U \in L^2(\Omega,\Lambda),\ D^i U \in L^2(\Omega,T^{i+1}),\ 1 \le i \le k\} \tag{1.16}$$

with inner product

$$(U,V)_{H^k(\Omega,\Lambda)} = \sum_{i=0}^{k} (D^i U, D^i V)_{L^2(\Omega,T^{i+1})} \quad \forall\ U,\ V \in H^k(\Omega,\Lambda) \tag{1.17}$$

(for example, see Wu [34]). In particular, $H^0(\Omega,\Lambda) = L^2(\Omega,\Lambda)$.

For $\hat{\Gamma} \subset \Gamma$, set

$$H^1_{\hat{\Gamma}}(\Omega,\Lambda) = \{W \,|\, W \in H^1(\Omega,\Lambda),\ W|_{\hat{\Gamma}} = 0\}; \tag{1.18}$$

$$H^2_{\hat{\Gamma}}(\Omega) = \left\{ w \,|\, w \in H^2(\Omega),\ w|_{\hat{\Gamma}} = \frac{\partial w}{\partial n}|_{\hat{\Gamma}} = 0 \right\}. \tag{1.19}$$

In particular, $H^1_0(\Omega,\Lambda) = H^1_\Gamma(\Omega,\Lambda)$ and $H^2_0(\Omega) = H^2_\Gamma(\Omega)$.

1.2. Model. Let us assume that the middle surface of the shell occupies a bounded region Ω of surface M in $\mathbb{R}^3$. The shell, a body in $\mathbb{R}^3$, is defined by

$$\mathcal{S} = \{\, p \,|\, p = x + zN(x),\ x \in \Omega,\ -h/2 < z < h/2 \,\}, \tag{1.20}$$

where h is the thickness of the shell, i.e., "small"; see Ciarlet and Paumier [9].

Denote by $\zeta(x)$ the displacement vector of point x of the middle surface. We decompose displacement vector ζ into sums:

$$\zeta(x) = W(x) + w(x)N(x), \quad x \in \Omega,\ W(x) \in M_x, \tag{1.21}$$

i.e., W and w are components of ζ on the tangent plane and on the normal of the undeformed middle surface Ω, respectively. The linearized strain tensor and the change of curvature tensor of the middle surface Ω are given by

$$\Upsilon(\zeta) = \frac{1}{2}(DW + D^*W) + w\Pi \tag{1.22}$$

and

$$\rho(\zeta) = -D^2 w \tag{1.23}$$

in a coordinate-free form, respectively, where Π is the second fundamental form of surface M and $D^2 w$ the Hessian of w, which are justified for a shallow shell. For (1.22) and (1.23), we refer to Niordson [25, p. 355] or to Koiter [17, p. 27].

The shell strain energy associated to a displacement field ζ of the middle surface Ω can be written as

$$\mathcal{B}_1(\zeta,\zeta) = \frac{Eh}{1-\mu^2}\int_\Omega B(\zeta,\zeta)\,dx, \tag{1.24}$$

where

$$B(\zeta,\zeta) = a(\Upsilon(\zeta),\Upsilon(\zeta)) + \gamma a(\rho(\zeta),\rho(\zeta)), \quad \gamma = h^2/12, \tag{1.25}$$

$$a(\Upsilon(\zeta),\Upsilon(\zeta)) = (1-\mu)\langle\Upsilon(\zeta),\Upsilon(\zeta)\rangle_{T_x^2} + \mu(\mathrm{tr}\Upsilon(\zeta))^2, \tag{1.26}$$

for $x\in\Omega$, where E, μ denote, respectively, Young's modulus and Poison's coefficient of the material. For (1.24), we refer to Bernadou and Boisserie [3, p. 15].

Thus, with expression (1.24), we are able to associate the following symmetric bilinear form, directly defined on the middle surface Ω:

$$\mathcal{B}(\zeta,\eta) = \int_\Omega B(\zeta,\eta)\,dx, \tag{1.27}$$

where ζ is given in (1.21) and

$$\eta = U + uN, \quad U(x)\in M_x,\ x\in\Omega. \tag{1.28}$$

Denote by H and by k the mean curvature and the Gauss curvature of surface M, respectively. From Yao [37], we have the following Green formula for a shallow shell.

Formula I. Let bilinear form $\mathcal{B}(\cdot,\cdot)$ be given in (1.27). For $\zeta=(W,w)$, $\eta=(U,u)\in H^1(\Omega,\Lambda)\times H^2(\Omega)$, we have

$$\mathcal{B}(\zeta,\eta) = (\mathcal{A}\zeta,\eta)_{L^2(\Omega,\Lambda)\times L^2(\Omega)} + \int_\Gamma \partial(\mathcal{A}\zeta,\eta)\,d\Gamma, \tag{1.29}$$

where

$$\begin{aligned}\partial(\mathcal{A}\zeta,\eta) &= B_1(W,w)\langle U,n\rangle + B_2(W,w)\langle U,\tau\rangle\\ &+\gamma\left[(\Delta w + (1-\mu)B_3 w)\frac{\partial u}{\partial n} - \left(\frac{\partial\Delta w}{\partial n} + (1-\mu)B_4 w\right)u\right];\end{aligned} \tag{1.30}$$

n, τ are the normal and the tangential along curve Γ, respectively;

$$\mathcal{A}\zeta = \begin{pmatrix} -\boldsymbol{\Delta}_\mu W - (1-\mu)kW - \mathcal{F}(w)\\ \gamma[\Delta^2 w - (1-\mu)\delta(kdw)] + (H^2 - 2(1-\mu)k)w + \mathcal{G}(W)\end{pmatrix}, \tag{1.31}$$

$\boldsymbol{\Delta}_\mu$ is of the Hodge–Laplacian type, applied to 1-forms (or equivalently, vector fields), defined by

$$\boldsymbol{\Delta}_\mu = -\left(\frac{1-\mu}{2}\delta d + d\delta\right), \tag{1.32}$$

where d is the exterior differential, δ the formal adjoint of d, Δ the Laplacian on manifold M,

$$\begin{cases}\mathcal{F}(w) = (1-\mu)l_{dw}\Pi + \mu H dw + w dH,\\ \mathcal{G}(W) = (1-\mu)\langle DW,\Pi\rangle_{T_x^2} - \mu H\delta W,\end{cases} \tag{1.33}$$

and

$$\begin{cases} B_1(W,w) = (1-\mu)\Upsilon(\zeta)(n,n) + \mu(wH - \delta W), \\ B_2(W,w) = (1-\mu)\Upsilon(\zeta)(n,\tau), \\ B_3 w = -D^2 w(\tau,\tau), \\ B_4 w = \dfrac{\partial}{\partial\tau}(D^2 w(\tau,n)) + k(x)\dfrac{\partial w}{\partial n}. \end{cases} \tag{1.34}$$

By the "principle of virtual work" and Formula I, we obtain the following displacement equations for a shallow shell (see Yao [37]) after changing t to t/λ with $\lambda^2 E/(1-\mu^2) = 1$.

Formula II. We assume that there are no external loads on the shell and that the shell is clamped along a portion Γ_0 of Γ and is free on Γ_1, where $\Gamma_0 \cup \Gamma_1 = \Gamma$ and $\Gamma_0 \cap \Gamma_1 = \emptyset$. Then the displacement vector $\zeta = (W,w)$ satisfies the following boundary value problem:

$$\left.\begin{aligned} &W_{tt} - [\boldsymbol{\Delta}_\mu W + (1-\mu)kW + F(w)] = 0 \\ &w_{tt} - \gamma\Delta w_{tt} + \gamma\left(\Delta^2 w - (1-\mu)\delta(kdw)\right) \\ &\qquad\qquad +(H^2 - 2(1-\mu)k)w + \mathcal{G}(W)] = 0 \\ &\zeta(0) = \zeta_0, \quad \zeta_t(0) = \zeta_1 \end{aligned}\right\} \quad \text{in } Q_\infty, \tag{1.35}$$

$$\left.\begin{aligned} &W = 0 \\ &w = \frac{\partial w}{\partial n} = 0 \end{aligned}\right\} \quad \text{on } \Sigma_{0\infty}, \tag{1.36}$$

$$\left.\begin{aligned} &B_1(W,w) = B_2(W,w) = 0 \\ &\Delta w + (1-\mu)B_3 w = 0 \\ &\frac{\partial \Delta w}{\partial n} + (1-\mu)B_4 w - \frac{\partial w_{tt}}{\partial n} = 0 \end{aligned}\right\} \quad \text{on } \Sigma_{1\infty}, \tag{1.37}$$

where

$$Q_\infty = \Omega \times (0,\infty), \quad \Sigma_{0\infty} = \Gamma_0 \times (0,\infty), \quad \Sigma_{1\infty} = \Gamma_1 \times (0,\infty). \tag{1.38}$$

Remark 1.1. In the literature, for some special cases the displacement equations are expressed in terms of three displacement components of the shell and their derivatives such as spherical shells (Lasiecka, Trigginia, and Valente [23]) and circular cylindrical ones (Chen, Coleman, and Liu [8]). For a shell with a general middle surface of any shape, this method may not be possible (see some comments by Koiter [18, p. 33]) and we have to draw support from Formula II.

Remark 1.2. If the shell is flat, a plate, (1.35) is uncoupled. The equation on component w is the same as in Lagnese [20, pp. 15–16], a Kirchhoff plate (see Yao [37]).

1.3. Observability inequalities. In obtaining observability inequalities, the ellipticity of the shell strain energy is necessary, which is assumed throughout; that is, there is constant $\lambda_0 \geq 1$ such that (H.1)

$$\lambda_0 \mathcal{B}(\zeta,\zeta) \geq \|DW\|^2_{L^2(\Omega,T^2)} + \gamma\|D^2 w\|^2_{L^2(\Omega,T^2)} \tag{1.39}$$

for $\zeta = (W, w) \in H^1(\Omega, \Lambda) \times H^2(\Omega)$. The above inequality is established if Π and $D\Pi$ are small enough (see Bernadou and Oden [5]) and proved if there is some information on the curvature of the middle surface (Yao [37]).

Main Assumption (H.2). Suppose that there is a vector field $V \in \mathcal{X}(M)$ such that

$$DV(X, X) = b(x)|X|^2, \quad X \in M_x,\ x \in \overline{\Omega}, \tag{1.40}$$

where b is a function on Ω. Set

$$a(x) = \frac{1}{2}\langle DV, \mathcal{E}\rangle_{T_x^2}, \quad x \in \overline{\Omega}, \tag{1.41}$$

where $\mathcal{E}$ is the volume element of M. Moreover, suppose that b and a meet inequality

$$2 \min_{x\in\overline{\Omega}} b(x) > \lambda_0(1+\mu) \max_{x\in\overline{\Omega}} |a(x)|. \tag{1.42}$$

We say that middle surface Ω satisfies assumption (H2) if there is a vector field V such that conditions (1.40) and (1.42) hold.

Set

$$\sigma_0 = \max_{x\in\Omega} |V|; \quad \sigma_1 = \min_{x\in\Omega} b(x) - \frac{\lambda_0(1+\mu)}{2} \max_{x\in\Omega} |a(x)|; \tag{1.43}$$

$$Q = \Omega \times (0, T); \quad \Sigma_0 = \Gamma_0 \times (0, T); \quad \Sigma_1 = \Gamma_1 \times (0, T). \tag{1.44}$$

Remark 1.3. Geometric condition (1.40) is used in Yao [38] for some observability inequalities of the Euler–Bernoulli equation with variable coefficients. If the shell is flat, a plate, then $M = \mathbb{R}^2$. For any $x^0 \in \mathbb{R}^2$, set $V = x - x^0$. It is easily checked that

$$DV = g, \quad x \in \mathbb{R}^2,$$

where g is the dot product in R^2, with $b = 1$ and $a = 0$. For any M, we will show that there always exists a vector field to meet condition (1.40) on Ω (Proposition 2.2 of subsection 2.1). In addition, relations (2.8) in Proposition 2.2 mean that Assumption (H2) always holds locally. Indeed, for any $x_0 \in M$ fixed, by relations (2.8) there are a vector field V, defined by (2.7), and $\epsilon > 0$ such that

$$2 \min_{x\in B(\epsilon)} b(x) > \lambda_0(1+\mu) \max_{x\in B(\epsilon)} |a(x)|,$$

where $B(\epsilon)$ is the geodesic ball with radius ϵ and centered at x_0. The above inequality means that Assumption (H2) is true if middle surface $\Omega \subset B(\epsilon)$.

Let surface M be of constant curvature or revolution. Propositions 2.3 and 2.4 in subsection 2.1 will show that there exists a vector field V such that relation (1.40) holds on the whole surface M with $a(x) = 0\,\forall\, x \in M$. So if middle surface $\Omega \subset M$ such that $b(x) \neq 0\,\forall\, x \in \overline{\Omega}$, then Assumption (H2) holds for Ω.

The total energy of the shell is to be defined by

$$E(t) = \frac{1}{2}[\|W_t\|^2_{L^2(\Omega,\Lambda)} + \|w_t\|^2_{L^2(\Omega)} + \gamma\|Dw_t\|^2_{L^2(\Omega,\Lambda)} + \mathcal{B}(\eta, \eta)]. \tag{1.45}$$

For $\eta = (W, w)$, we set

$$\eta_1 = (W, 0); \quad \eta_2 = (0, w); \tag{1.46}$$

$$L(t) = \|W(t)\|^2_{L^2(\Omega,\Lambda)} + \|w(t)\|^2_{L^2(\Omega)} + \gamma\|w_t(t)\|^2_{L^2(\Omega)} + \|Dw(t)\|^2_{L^2(\Omega,\Lambda)}. \tag{1.47}$$

THEOREM 1.1. *Let Assumptions* (H.1) *and* (H.2) *hold. Let* $\eta = (W, w)$ *solve the problem*

$$\eta_{tt} - \gamma(0, \Delta w_{tt}) + \mathcal{A}\eta = 0 \tag{1.48}$$

such that all the terms on the left-hand side of inequality (1.49) *below are well defined.*

Given $T > 0$*, then for any* $\epsilon > 0$*, there is* $C_\epsilon > 0$*, independent of* η*, such that*

$$SB|_\Sigma + C_\epsilon \left[L(0) + L(T) + \int_0^T L(t)dt \right] + (\sigma_0\lambda_0 + \epsilon)[E(0) + E(T)] \geq \sigma_1 \int_0^T E(t)dt, \tag{1.49}$$

where

$$\begin{aligned} SB|_\Sigma &= \frac{1}{2}\int_\Sigma [|\eta_t|^2 + \gamma|Dw_t|^2 - B(\eta,\eta)]\langle V, n\rangle \, d\Sigma \\ &+ \int_\Sigma \left[\partial\left(\mathcal{A}\eta,\, m(\eta) - \frac{1}{2}b\eta_2 + \frac{1}{2}h\eta_1\right) + \gamma\left(V(w) - \frac{1}{2}bw\right)\frac{\partial w_{tt}}{\partial n} \right] d\Sigma; \end{aligned} \tag{1.50}$$

$$m(\eta) = (D_V W, V(w)); \quad h = 2b - \sigma_1. \tag{1.51}$$

Dirichlet control. First, we consider the Dirichlet mixed problem in unknown $\zeta = (\Phi, \phi)$:

$$\begin{cases} \zeta_{tt} - \gamma(0, \Delta\phi_{tt}) + \mathcal{A}\zeta = 0 \quad \text{in} \quad \Omega \times (0,T), \\ \zeta(0) = \zeta^0, \quad \zeta_t(0) = \zeta^1 \quad \text{on} \quad \Omega, \\ \Phi|_{\Gamma_1} = 0, \quad \Phi|_{\Gamma_0} = U, \quad 0 < t < T, \\ \phi|_{\Gamma_1} = \dfrac{\partial\phi}{\partial n}|_{\Gamma_1} = 0, \quad 0 < t < T, \\ \phi|_{\Gamma_0} = u, \quad \dfrac{\partial\phi}{\partial n}|_{\Gamma_0} = v, \quad 0 < t < T, \end{cases} \tag{1.52}$$

with control functions U, u, and v. Its dual version in $\eta = (W, w)$ follows:

$$\begin{cases} \eta_{tt} - \gamma(0, \Delta w_{tt}) + \mathcal{A}\eta = 0 \quad \text{in} \quad Q, \\ \eta(0) = \eta^0, \quad \eta_t(0) = \eta^1 \quad \text{on} \quad \Omega, \\ W = 0 \quad \text{on} \quad \Sigma, \\ w = \dfrac{\partial w}{\partial n} = 0 \quad \text{on} \quad \Sigma. \end{cases} \tag{1.53}$$

Remark 1.4. In the flat case, for the normal component, one control function $\frac{\partial\phi}{\partial n}|_{\Gamma_0} = v$ is enough; see Lagnese and Lions [21]. We here add another control function $\phi|_{\Gamma_0} = u$ for problem (1.52) in order to avoid the following uniqueness assumption: the problem

$$\begin{cases} \lambda^2\eta - \lambda^2\gamma(0, \Delta w) + \mathcal{A}\eta = 0 \quad \text{on} \quad \Omega, \\ W = 0 \quad \text{on} \quad \Gamma, \\ w = \dfrac{\partial w}{\partial n} = 0 \quad \text{on} \quad \Gamma, \\ D_n W = \Delta w = 0 \quad \text{on} \quad \Gamma_0 \end{cases} \tag{1.54}$$

admits the unique zero solution. The above uniqueness result does not fall into a class of systems to which the Holmgren theorem may be applied even if the coefficients are

analytic since it is not the Cauchy problem for component w(it does for component W). For the flat case, it has been proved in Lagnese and Lions [21].

Continuous observability inequality in the Dirichlet case. From Proposition 2.12 of subsection 2.2, it is easily checked that if $\eta = (W, w)$ solves problem (1.53), then

$$SB|_{\Sigma} = \frac{1}{2}\int_{\Sigma} B(\eta,\eta)\langle V, n\rangle \, d\Sigma. \tag{1.55}$$

The exact controllability of problem (1.52) then leads to the following observability inequality: to seek constant $T_0 > 0$ such that, for any $T > T_0$, there is $c > 0$ satisfying

$$\int_{\Sigma_0} \left[B(\eta,\eta) + \gamma \left(\frac{\partial \Delta w}{\partial n} \right)^2 \right] d\Sigma \geq cE(0), \tag{1.56}$$

where $\eta = (W, w)$ is a solution to problem (1.53) with the initial data $(\eta^0, \eta^1) \in \big(L^2(\Omega,\Lambda) \times H_0^1(\Omega)\big) \times \big(H^{-1}(\Omega,\Lambda) \times L^2(\Omega)\big)$, and

$$\int_{\Sigma_0} B(\eta,\eta)\, d\Sigma = \gamma \int_{\Sigma_0} (\Delta w)^2 \, d\Sigma + \int_{\Sigma_0} \left[(DW(n,n))^2 + \frac{1-\mu}{2} \left(DW(\tau,n)\right)^2 \right] d\Sigma. \tag{1.57}$$

We have the following theorem.

THEOREM 1.2 (Dirichlet case). *Let Assumptions* (H.1) *and* (H.2) *hold. Then for any $T > T_0$, there exists $c > 0$ such that observability inequality* (1.56) *holds, where*

$$T_0 = 2\lambda_0 \sigma_0 / \sigma_1; \tag{1.58}$$

$$\Gamma_0 = \{x \,|\, x \in \Gamma,\, V(x) \cdot n(x) > 0\}. \tag{1.59}$$

Neumann control. Here we let $\overline{\Gamma_1} \neq \emptyset$, $\overline{\Gamma_0} \cap \overline{\Gamma_1} = \emptyset$ and consider problem $\zeta = (\Phi, \phi)$:

$$\begin{cases} \zeta_{tt} - \gamma(0, \Delta\phi_{tt}) + \mathcal{A}\zeta = 0 \quad \text{in} \quad Q, \\ \zeta(0) = \zeta^0, \quad \zeta_t(0) = \zeta^1 \quad \text{on} \quad \Omega. \end{cases} \tag{1.60}$$

We can act on $\Sigma_1 = \Gamma_1 \times (0,T)$ by

$$\begin{cases} \Phi = 0 \quad \text{on} \quad \Sigma_1, \\ \phi = \dfrac{\partial \phi}{\partial n} = 0 \quad \text{on} \quad \Sigma_1, \end{cases} \tag{1.61}$$

and we can act on Σ_0 by

$$\begin{cases} B_1(\Phi,\phi) = u_1 \quad B_2(\Phi,\phi) = u_2 \quad \text{on} \quad \Sigma_0, \\ \Delta\phi + (1-\mu)B_3\phi = v_1 \quad \text{on} \quad \Sigma_0, \\ \dfrac{\partial \Delta\phi}{\partial n} + (1-\mu)B_4\phi - \dfrac{\partial \phi_{tt}}{\partial n} = v_2 \quad \text{on} \quad \Sigma_0. \end{cases} \tag{1.62}$$

The dual problem for the above is the following in $\eta = (W, w)$:

$$\begin{cases} \eta_{tt} - \gamma(0, \Delta w_{tt}) + \mathcal{A}\eta = 0 \quad \text{in} \quad Q, \\ \eta(0) = \eta^0, \quad \eta_t(0) = \eta^1 \quad \text{on} \quad \Omega, \end{cases} \tag{1.63}$$

subject to the boundary condition

$$\begin{cases} W = 0 \quad \text{on} \quad \Sigma_1, \\ w = \dfrac{\partial w}{\partial n} = 0 \quad \text{on} \quad \Sigma_1, \end{cases} \tag{1.64}$$

$$\begin{cases} B_1(W,w) = B_2(W,w) = 0 \quad \text{on} \quad \Sigma_0, \\ \Delta w + (1-\mu)B_3 w = 0 \quad \text{on} \quad \Sigma_0, \\ \dfrac{\partial \Delta w}{\partial n} + (1-\mu)B_4 w - \dfrac{\partial w_{tt}}{\partial n} = 0 \quad \text{on} \quad \Sigma_0. \end{cases} \tag{1.65}$$

Continuous observability inequality in the Neumann case. Let $\eta = (W, w)$ solve problem (1.63)–(1.65). It is easy to check from Proposition 2.12 of subsection 2.2 and boundary conditions (1.64) and (1.65) that

$$SB|_\Sigma = \frac{1}{2}\int_{\Sigma_0} [|\eta_t|^2 + \gamma|Dw_t|^2 - B(\eta,\eta)]\langle V, n\rangle \, d\Sigma + \frac{1}{2}\int_{\Sigma_1} B(\eta,\eta)\langle V, n\rangle \, d\Sigma. \tag{1.66}$$

It follows from (1.66) that to obtain the observability inequality is to seek $T_0 > 0$ such that for any $T > T_0$, there is $c > 0$ satisfying

$$\int_{\Sigma_0} [|\eta_t|^2 + \gamma|Dw_t|^2] \, d\Sigma \geq cE(0) \tag{1.67}$$

for all initial data $(\eta^0, \eta^1) \in \left(H^1_{\Gamma_1}(\Omega,\Lambda) \times H^2_{\Gamma_1}(\Omega)\right) \times \left(L^2(\Omega,\Lambda) \times L^2(\Omega)\right)$ for which the left-hand side of (1.67) is finite.

We have the following theorem.

THEOREM 1.3 (Neumann case). *Let Assumptions* (H.1) *and* (H.2) *hold. Then for any $T > T_0$, there is $c > 0$ such that inequality* (1.67) *holds, where T_0 and Γ_0 are defined by* (1.58) *and* (1.59)*, respectively.*

Remark 1.5. Exact controllability results (in suitable function spaces) for $T > T_0$ follow from (1.56) and (1.67) and duality.

Remark 1.6. Let the shell be flat, that is, $M = \mathbb{R}^2$. Then system (1.35) becomes two systems, where one is a wave equation on component W and the other is a plate on component w. We may take $\lambda_0 = 1$. If we set $V = x - x_0$, x_0 a fixed point in $\mathbb{R}^2$, then inequalities (1.56) and (1.67) on component w are exactly the same as in Lagnese and Lions [21]. In this case, $\sigma_1 = 1$. It follows that $T_0 = 2diameter(\Omega)$, which is the best for wave component W; see Komornik [19]. In this sense, T_0 in (1.58) is the best.

1.4. Some examples. We give here some examples that verify Assumption (H2).

Example 1.1. Let middle surface Ω be of constant curvature. Suppose that the curvature of manifold (M, g) is constant k. Given $x_0 \in M$, let ρ be the distance function from $x \in M$ to x_0 on (M, g), i.e., $\rho(x) = dis(x_0, x)$. Set $V = h(\rho)D\rho$, where $h(\rho)$ is defined by

$$h(\rho) = \begin{cases} \sin(\sqrt{k}\rho(x)), & k > 0, \\ \rho(x), & k = 0, \\ \sinh(\sqrt{-k}\rho(x)), & k < 0. \end{cases} \tag{1.68}$$

By Proposition 2.3 of subsection 2.1, we have

$$DV = b(x)g \quad \text{and} \quad a(x) = 0, \tag{1.69}$$

where

$$b(x) = \begin{cases} \sqrt{k}\cos\left(\sqrt{k}\rho(x)\right), & k > 0, \\ 1, \quad k = 0, \\ \sqrt{-k}\cosh\left(\sqrt{-k}\rho(x)\right), & k < 0. \end{cases} \tag{1.70}$$

It follows that Assumption (H2) holds with vector field V if and only if $\min_{x\in\Omega} b(x) > 0$. By expression (1.70), we have the following conclusions:

(a) If $k > 0$, Assumption (H2) holds when $\overline{\Omega}$ is contained by a geodesic ball with radius $\pi/(2\sqrt{k})$;

(b) If $k \le 0$, Assumption (H2) holds for any $\Omega \subset M$. □

Example 1.2. Let middle surface Ω be a portion of surface M of revolution, where

$$M = \{(x, y, z) \,|\, (x, y) \in \mathbb{R}^2,\ z = \log(1 + x^2 + y^2)\}. \tag{1.71}$$

Set $f(r) = \log(1 + r^2)$. It is easy to check that the curvature is

$$k(p) = -\frac{2(1 + r^2)}{[1 + (1 + r^2)^2]^2} < 0, \tag{1.72}$$

where $p = (x, y, f(r))$ and $r = \sqrt{x^2 + y^2}$ so that inequality (2.25) in Proposition 2.4 holds. By applying Proposition 2.4 of subsection 2.1 to this case, there are a vector field V on M and a function $b(p) > 0$ on M such that

$$DV = b(p)g \quad \text{and} \quad a(p) = 0 \quad \forall p \in M, \tag{1.73}$$

where g is the induced metric of M in $\mathbb{R}^3$ and $a(p) = \frac{1}{2}\langle DV, \mathcal{E}\rangle_{T_p^2}$ is defined by (1.41), that is, Assumption (H2) holds for any $\Omega \subset M$. □

Finally, we give an example with Assumption (H2) holding but $a(x) = \frac{1}{2}\langle DV, \mathcal{E}\rangle_{T_x^2} \neq 0$.

Example 1.3. Consider a helicoid, defined by

$$M = \{\alpha(t, s) \,|\, (t, s) \in \mathbb{R}^2,\ t > 0\}, \tag{1.74}$$

where

$$\alpha(t, s) = (t\cos s, t\sin s, c_0 s), \quad c_0 > 0. \tag{1.75}$$

The Gauss curvature is $-c_0^2/(t^2 + c_0^2)^2$.

We set

$$E_1 = \alpha_t = (\cos s, \sin s, 0); \tag{1.76}$$

$$E_2 = \frac{1}{\sqrt{t^2 + c_0^2}}\alpha_s = \frac{1}{\sqrt{t^2 + c_0^2}}(-t\sin s, t\cos s, c_0). \tag{1.77}$$

Then E_1, E_2 makes up a frame field on the whole surface M. We may obtain

$$D_{E_1}E_1 = 0; \quad D_{E_2}E_1 = \frac{t}{t^2 + c_0^2}E_2; \tag{1.78}$$

$$D_{E_1}E_2 = 0; \quad D_{E_2}E_2 = \frac{-t}{t^2 + c_0^2}E_1, \tag{1.79}$$

where D is the Levi–Civita connection of surface M.

For any $c > 0$, we set

$$V_c = f_c E_1 + hE_2, \tag{1.80}$$

where

$$f_c = \sqrt{t^2 + c_0^2}\left(\int_0^t \frac{dt}{\sqrt{t^2 + c_0^2}} + c\right); \quad h = \sqrt{t^2 + c_0^2}s. \tag{1.81}$$

We then have

$$DV_c = b_c g + a\mathcal{E} \quad \text{for} \quad c > 0, \tag{1.82}$$

where g is the induced metric of M in $\mathbb{R}^3$, $\mathcal{E}$ is the volume element of M, and

$$b_c = 1 + \frac{t}{t^2 + c_0^2} f_c; \quad a = -\frac{st}{\sqrt{t^2 + c_0^2}}. \tag{1.83}$$

It is clear that, for any $\Omega \subset M$ bounded with $\overline{\Omega} \subset M$ and for any constant $c_1 > 0$, there is $c > 0$ large enough such that

$$\min_{x\in\Omega} b_c \geq c_1 \max_{x\in\Omega} |a|; \tag{1.84}$$

that is, for any $\Omega \subset M$, we can find a vector field V_c ($c > 0$ large enough), defined by (1.80), to meet geometric conditions (1.40) and (1.42). □

Remark 1.7. It is easy to check by the curvature information and Yao [37] that Examples 1.1–1.3 satisfy Assumption (H1), too.

2. Geometric conditions; proofs of main results.

2.1. On geometric conditions. We give some information on how to find a vector field to meet conditions (1.40) and (1.42).

PROPOSITION 2.1. *Let vector field V be given such that* (1.40) *holds. If $T \in T^2(M)$ is a symmetric,* 2*-order tensor field, then*

$$\langle T, T(\cdot, D.V)\rangle_{T_x^2} = b|T|^2_{T_x^2} \quad \text{at } x \in M; \tag{2.1}$$

$$\mathrm{tr}T\mathrm{tr}T(\cdot, D.V) = b(\mathrm{tr}T)^2 \quad \text{at } x \in M, \tag{2.2}$$

where "·" denotes the position of the variable.

Proof. Let $T \in T^2(M)$ be symmetric. Given $x \in M$, there is an orthonormal basis e_1, e_2 of M_x such that

$$T(e_1, e_2) = 0, \quad \text{at } x, \tag{2.3}$$

since $T(\cdot, \cdot)$ is a symmetric, bilinear form on $M_x \times M_x$. Conditions (1.40) and (2.3) yield

$$\begin{aligned} T(e_i, D_{e_i}V) &= T(e_i,\ DV(e_i, e_i)e_i + DV(e_j, e_i)e_j) \\ &= bT(e_i, e_i) + DV(e_j, e_i)T(e_i, e_j) = bT(e_i, e_i) \end{aligned} \tag{2.4}$$

for $j \neq i,\ i = 1, 2$. By (2.3) and (2.4), we obtain

$$\langle T, T(\cdot, D.V)\rangle_{T_x^2} = \sum_{ij=1}^{2} T(e_i, e_j)T(e_i, D_{e_j}V) = \sum_{i=1}^{2} T(e_i, e_i)T(e_i, D_{e_i}V)$$
$$= b\sum_{i=1}^{2}(T(e_i, e_i))^2 = b\sum_{ij=1}^{2}(T(e_i, e_j))^2 = b|T|^2_{T_x^2} \quad \text{at } x$$

and

$$\mathrm{tr}T(\cdot, D.V) = \sum_{i=1}^{2} T(e_i, D_{e_i}V) = b\sum_{i=1}^{2} T(e_i, e_i) = b\mathrm{tr}T \quad \text{at } x. \qquad \square$$

Consider a set Θ which consists of all the C^∞ functions q such that there is a region $\aleph \subset M$ satisfying $\overline{\Omega} \subset \aleph$ and

$$\Delta q = k(x) \quad \forall\ x \in \aleph, \tag{2.5}$$

where k is the Gaussian curvature function of M. It is easily checked that Θ is nonempty by an elliptic boundary value problem for the Laplacian since $\Omega \subset M$ is a bounded region with a nonempty boundary Γ. For a given $q \in \Theta$, consider a metric on $\aleph$ given by

$$\hat{g} = e^{2q}g, \tag{2.6}$$

where g is the induced metric of M in $\mathbb{R}^3$. Denote by $(\aleph, \hat{g})$ the Riemannian manifold with metric (2.6) and by $\hat{\rho}(x)$ the distance function on $(\aleph, \hat{g})$ from $x^0 \in \aleph$ to $x \in \aleph$, respectively. Let $\hat{D}$ be the covariant differential of $(\aleph, \hat{g})$ in metric $\hat{g}$.

PROPOSITION 2.2. *Given $q \in \Theta$ and $x^0 \in \aleph$, set*

$$V(x) = \hat{\rho}(x)\hat{D}\hat{\rho}(x), \quad x \in \aleph. \tag{2.7}$$

Then vector field V on $\aleph$ (so that on Ω) meets condition (1.40) *where $b = 1 - V(q)$ and $a = \langle Dq \otimes V, \mathcal{E}\rangle_{T_x^2}$ such that*

$$\lim_{x\to x_0} b(x) = 1 \quad \textit{and} \quad \lim_{x\to x_0} a(x) = 0, \tag{2.8}$$

that is, conditions (1.40) *and* (1.42) *hold locally.*

Proof. We do a computation in a coordinate. Let (x_1, x_2) be a coordinate on $\aleph$. Set

$$g_{ij} = \left\langle \frac{\partial}{\partial x_i}, \frac{\partial}{\partial x_j} \right\rangle \quad \text{and} \quad \hat{g}_{ij} = \hat{g}\left(\frac{\partial}{\partial x_i}, \frac{\partial}{\partial x_j}\right) \tag{2.9}$$

for $1 \leq i, j \leq 2$. It follows from (2.6) and (2.9) that $\hat{g}_{ij} = e^{2q}g_{ij}$.

Denote the coefficients of connections D and $\hat{D}$ by Γ_{ij}^k and by $\hat{\Gamma}_{ij}^k$, respectively. From Schoen and Yau [26, Chapter 5], we have formulae

$$\Gamma_{ij}^k = \hat{\Gamma}_{ij}^k - \delta_{ik}\frac{\partial q}{\partial x_j} - \delta_{jk}\frac{\partial q}{\partial x_i} + g_{ij}\sum_{l=1}^{2} g^{kl}\frac{\partial q}{\partial x_l} \tag{2.10}$$

and

$$\Delta q - k + \hat{k}e^{2q} = 0 \quad \text{in} \quad \aleph, \tag{2.11}$$

where $\hat{k}$ is the Gaussian curvature function of $(\aleph, \hat{g})$ in metric $\hat{g}$ and $(g^{ij}) = (g_{ij})^{-1}$. Relations (2.5) and (2.11) yield

$$\hat{k} = 0 \quad \text{in} \quad \aleph, \tag{2.12}$$

i.e., $(\aleph, \hat{g})$ is of zero curvature. It is well known that

$$\hat{D}V = \frac{1}{2}\hat{D}^2\hat{\rho}^2 = \hat{g} \quad \text{in} \quad \aleph \tag{2.13}$$

because of (2.12).

Let $V = h_1\dfrac{\partial}{\partial x_1} + h_2\dfrac{\partial}{\partial x_2}$. For any vector field $X = X_1\dfrac{\partial}{\partial x_1} + X_2\dfrac{\partial}{\partial x_2}$, it follows from (2.10) that

$$\begin{aligned} D_X V &= \sum_{j=1}^{2} X(h_j)\frac{\partial}{\partial x_j} + \sum_{ij=1}^{2} X_i h_j D_{\frac{\partial}{\partial x_i}}\frac{\partial}{\partial x_j} = \sum_{j=1}^{2} X(h_j)\frac{\partial}{\partial x_j} + \sum_{k=1}^{2}\sum_{ij=1}^{2} X_i h_j \Gamma_{ij}^{k}\frac{\partial}{\partial x_k} \\ &= \hat{D}_X V - V(q)X - X(q)V + \langle X, V\rangle Dq. \end{aligned} \tag{2.14}$$

By (2.14), (2.6), and (2.13), we obtain

$$\begin{aligned} DV(X,X) &= \langle \hat{D}_X V, X\rangle - V(q)|X|^2 = e^{-2q}\hat{D}V(X,X) - V(q)|X|^2 \\ &= e^{-2q}\hat{g}(X,X) - V(q)|X|^2 = (1 - V(q))|X|^2 \end{aligned} \tag{2.15}$$

$\forall\ X \in M_x,\ x \in \aleph$, and

$$\begin{aligned} a(x) &= \frac{1}{2}\langle DV, \mathcal{E}\rangle = \frac{1}{2}[DV(e_1,e_2) - DV(e_2,e_1)] \\ &= \langle e_1, V\rangle e_2(q) - \langle e_2, V\rangle e_1(q) = \langle Dq \otimes V, \mathcal{E}\rangle_{T_x^2}, \end{aligned} \tag{2.16}$$

where e_1, e_2 is an orthonormal basis of M_x with the positive orientation. Since $e^q|\hat{D}\hat{\rho}| = 1$ we then obtain $|V| = \hat{\rho}(x)e^{-q}$ so that (2.8) follows from (2.16) and $b = 1 - V(q)$. □

Given $x^0 \in M$. Let r: $(0,\infty) \to \mathbb{R}^n$ be a geodesic with $r(0) = x^0$ parameterized by arc length in Riemannian metric g. Denote the distance on (M, g) by dis. For sufficiently small $t > 0$ we know that $dis(r(t), x^0) = t$, since the exponential map $\exp_{x^0}$: $M_{x^0} \to M$ is injective on a sufficiently small ball in (M, g). We recall that $r(t_0)$ is called the cut point of r with respect to x^0, if $t_0 > 0$ is such that $d_g(r(t), x^0) = t$, $0 \le t < t_0$, and $d_g(r(t), x^0) < t\ \forall\ t > t_0$; see Cheeger and Ebin [6]. The union of all cut points is called the cut locus of x^0 and denoted by $cut(x^0)$. For any $X \in M_{x^0}$, $|X| = 1$, there is at most one cut point on the geodesic $\exp_{x^0} tX$ $(t \ge 0)$. Thus $cut(x^0)$ is the image of the exponential map on some closed subset of S^{n-1} and the n-dimensional measure of $cut(x^0)$ is zero. Set $\mu(X) = d_g(x^0, r(t_0))$, if $r(t_0)$ is the cut point of x^0 along $r(t) = \exp_{x^0} tX$; $\mu(X) = \infty$, when there is no cut point of x^0 along r, where $X \in S^{n-1} \subset M_{x^0}$. We define

$$E(x_0) = \left\{ tX \,|\, 0 \le t < \mu(X),\ X \in S^{n-1} \subset M_{x^0} \right\}.$$

Then $\exp_{x^0}\colon E(x_0) \to \exp_{x^0} E(x_0)$ is a diffeomorphism. It is obvious that $\exp_{x^0} E(x_0)$ is a star domain and

$$M = \exp_{x^0}(E) \cup cut(x^0).$$

PROPOSITION 2.3. *Let M be of constant curvature k. Given $x_0 \in M$, let ρ be the distance function from $x \in M$ to x_0 on (M, g), i.e., $\rho(x) = dis(x_0, x)$. Set $V = h(\rho)D\rho$, where $h(\rho)$ is defined by*

$$h(\rho) = \begin{cases} \sin(\sqrt{k}\rho(x)), & k > 0, \\ \rho(x), & k = 0, \\ \sinh(\sqrt{-k}\rho(x)), & k < 0, \end{cases} \tag{2.17}$$

for $x \in \exp_{x_0} E(x_0)$. Then

$$DV = b(x)g \quad \text{and} \quad a(x) = 0, \quad x \in \exp_{x_0} E(x_0), \tag{2.18}$$

where

$$b(x) = \begin{cases} \sqrt{k}\cos(\sqrt{k}\rho(x)), & k > 0, \\ 1, & k = 0, \\ \sqrt{-k}\cosh(\sqrt{-k}\rho(x)), & k < 0. \end{cases} \tag{2.19}$$

Proof. It is well known that

$$D^2\rho(\tau, \tau) = \begin{cases} \sqrt{k}\cot(\sqrt{k}\rho(x)), & k > 0, \\ \dfrac{1}{\rho(x)}, & k = 0, \\ \sqrt{-k}\coth(\sqrt{-k}\rho(x)), & k < 0, \end{cases} \qquad x \in \exp_{x_0} E(x_0), \tag{2.20}$$

where $\tau \in M_x$ such that $D\rho$, τ is an orthonormal basis of M_x and $D^2\rho$ is the Hessian of distance function ρ at x. Since $D^2\rho(D\rho, X) = 0$ for any $X \in M_x$, it follows from (2.20) that

$$DV(X, Y) = h'(\rho)\langle D\rho, X\rangle\langle D\rho, Y\rangle + h(\rho)D^2\rho(X, Y) = b(x)\langle X, Y\rangle, \tag{2.21}$$

for any $X, Y \in M_x$. Since DV is symmetric, $a(x) = 0$. ∎

PROPOSITION 2.4. *Let f be a function on the zy-plane, $z = f(y)$ for $y > 0$. Consider a surface, given by*

$$M = \left\{(x, y, z) \,|\, z = f(r), r = \sqrt{x^2 + y^2}, (x, y) \in \mathbb{R}^2\right\}. \tag{2.22}$$

The curvature is

$$k(p) = \frac{f'(r)f''(r)}{r(1 + f'^2)^2}, \quad p = (x, y, z) \in M. \tag{2.23}$$

Then there exist a vector field V and a function b such that

$$DV = b(p)g \quad \text{and} \quad a(p) = 0, \quad p \in M, \tag{2.24}$$

where g is the induced metric of M in $\mathbb{R}^3$. Furthermore, if

$$\int_{k(t)>0} tk(t)dt \le 1, \tag{2.25}$$

then

$$b(p) > 0 \quad \forall p \in M, \tag{2.26}$$

where

$$k(t) = \frac{f'(r(t))f''(r(t))}{r(t)(1+f'^2(r(t)))^2}, \quad t > 0, \tag{2.27}$$

and $r(t)$ is defined by equation

$$t = \int_0^{r(t)} \sqrt{1+f'^2(s)}ds, \tag{2.28}$$

for $t \geq 0$.

Proof. Denote $p_0 = (0, 0, f(0))$. Let $\rho(p) = dis(p_0, p)$ be the distance function from $p \in M$ to p_0 on (M, g). Set $V = \varphi(\rho)D\rho$, where φ is the solution to the problem

$$\begin{cases} \varphi''(t) + k(t)\varphi(t) = 0, \quad t > 0, \\ \varphi(0) = 0, \quad \varphi'(0) = 1. \end{cases} \tag{2.29}$$

We will show that $DV = \varphi'(\rho(p))g$ for any $p \in M$.

Let $p = (x, y, f(r)) \in M$ with $r = \sqrt{x^2+y^2}$. Since M is of revolution, it is easily checked that curve σ: $[0, \rho(p)] \to M$, given by

$$\sigma(t) = \left(r(t)\frac{x}{r},\, r(t)\frac{y}{r},\, f(r(t))\right),$$

is the unique minimizing geodesic, parameterized by arc length, which joins p_0 to p. Since $k(\sigma(t)) = k(t)$ for $0 \leq t \leq \rho(p)$, it is well known that

$$D^2\rho(\tau, \tau) = \frac{\varphi'(\rho)}{\varphi(\rho)}, \tag{2.30}$$

where $\tau \in M_p$ such that $D\rho$, τ is an orthonormal basis of M_p. It follows from (2.30) that

$$\begin{aligned} DV(X,Y) &= \langle D_Y V, X\rangle = \varphi'(\rho)\langle D\rho, X\rangle\langle D\rho, Y\rangle + \varphi(\rho)D^2\rho(X,Y) \\ &= \varphi'(\rho)\langle D\rho, X\rangle\langle D\rho, Y\rangle + \varphi'(\rho)\langle X, \tau\rangle\langle Y, \tau\rangle = \varphi'(\rho)\langle X, Y\rangle, \end{aligned} \tag{2.31}$$

for any $X, Y \in M_p$.

Let inequality (2.25) hold. We next prove $\varphi'(t) > 0$ for $t \geq 0$.

Set $\widetilde{k}(t) = \max(k, 0)$. Let ϕ be the solution to the problem

$$\begin{cases} \phi''(t) + \widetilde{k}(t)\phi = 0, \quad t > 0, \\ \phi(0) = 0, \quad \phi'(0) = 1. \end{cases} \tag{2.32}$$

Inequality (2.25) means that

$$\int_0^\infty t\widetilde{k}(t)\, dt \leq 1. \tag{2.33}$$

By Proposition 4.2 of Green and Wu [13], it follows from (2.32) and (2.33) that

$$\phi > 0 \quad \text{and} \quad \phi' > 0 \quad \text{on} \quad (0, \infty). \tag{2.34}$$

In addition, Sturm's theorem gives

$$\varphi \geq \phi > 0 \quad \text{on} \quad (0,\infty) \tag{2.35}$$

since $\widetilde{k}(t) \geq k(t)$ for $t \geq 0$. To complete our proof, by (2.34) it will suffice to prove $\varphi' \geq \phi'$ on $(0,\infty)$. Set $u(t) = \varphi'\phi - \varphi\phi'$. By (2.29), (2.32), and (2.35), we obtain

$$u'(t) = \varphi''\phi - \varphi\phi'' = (\widetilde{k} - k)\varphi\phi \geq 0 \tag{2.36}$$

on $(0,\infty)$. It follows from (2.36) and $u(0) = 0$ that $u(t) \geq 0$ on $(0,\infty)$. We then have, from (2.34) and (2.35),

$$\left(\frac{\varphi'}{\phi'}\right)' = \frac{1}{\phi'^2}[(\widetilde{k} - k)\varphi\phi' + \widetilde{k}u(t)] \geq 0 \tag{2.37}$$

on $(0,\infty)$. Inequality (2.37) gives $\varphi' \geq \phi'$ on $(0,\infty)$ since $\varphi'(0) = \phi'(0) = 1$.

2.2. Some multiplier identities.. To estimate inequality (1.49), we need some multiplier identities which have been built for the classical wave equations; see Lions [24], Lasiecka and Triggiani [22], and Chen [7]; for the Kirchhoff plates, see Lagnese and Lions [21]; and for variably coefficient wave equations and Euler–Bernoulli equations see Yao [36], [38]. We now consider their generalizations for the shallow shell.

In the following, let vector field V be such that condition (1.40) holds. Denote by $lot(\eta)$ the lower order term with respect to the energy level, that is, for any $\epsilon > 0$ there is $c_\epsilon > 0$ such that

$$|lot(\eta)| \leq \epsilon \int_0^T E(t)dt + c_\epsilon \left[L(0) + L(T) + \int_0^T L(t)dt \right], \tag{2.38}$$

where $E(t)$ and $L(t)$ are defined in (1.45) and (1.47), respectively.

PROPOSITION 2.5. *Let $\eta = (W, w)$ solve problem* (1.48) *such that all the terms in* (2.39) *and* (2.40) *below are well defined. Let f be a function on Ω. Then*

$$\int_Q f[|W_t|^2 - B(\eta,\eta_1)]\, dQ = -\int_\Sigma \partial(\mathcal{A}\eta, f\eta_1)\, d\Sigma + lot(\eta); \tag{2.39}$$

$$\int_Q f[w_t^2 + \gamma|Dw_t|^2 - B(\eta,\eta_2)]\, dQ = -\int_\Sigma \left[\partial(\mathcal{A}\eta, f\eta_2) + \gamma f w \frac{\partial w_{tt}}{\partial n}\right] d\Sigma + lot(\eta), \tag{2.40}$$

where η_1, η_2 are given by (1.46).

Proof. We multiply (1.48) by $f\eta_2$. Then

$$\begin{aligned}(w_t, fw)_{L^2(\Omega)}|_0^T - \int_Q f w_t^2 dQ - \gamma \int_0^T (\Delta w_{tt}, fw)_{L^2(\Omega)} dt \\ + \int_0^T (\mathcal{A}\eta, f\eta_2)_{L^2(\Omega,\Lambda)\times L^2(\Omega)} dt = 0.\end{aligned} \tag{2.41}$$

The third term equals

$$\begin{aligned}
&-\gamma(\Delta w_t, fw)_{L^2(\Omega)}|_0^T + \gamma\int_0^T (\Delta w_t, fw_t)_{L^2(\Omega)}dt\\
&\qquad = \gamma(Dw_t, D(fw))_{L^2(\Omega,\Lambda)}|_0^T - \gamma\int_Q \langle Dw_t, D(fw_t)\rangle dQ\\
&\qquad\quad -\gamma\int_\Gamma fw\frac{\partial w_t}{\partial n}d\Gamma|_0^T + \gamma\int_\Sigma fw_t\frac{\partial w_t}{\partial n}d\Sigma\\
&\qquad = -\gamma\int_Q f|Dw_t|^2dQ - \gamma\int_\Sigma fw\frac{\partial w_{tt}}{\partial n}d\Sigma + lot(\eta). \qquad (2.42)
\end{aligned}$$

The fourth term equals (using formula (1.29))

$$\int_Q fB(\eta,\eta_2)dQ - \int_\Sigma \partial(\mathcal{A}\eta, f\eta_2)d\Sigma + lot(\eta), \qquad (2.43)$$

since we have

$$D^2(fw) = fD^2w + Df\otimes Dw + Dw\otimes Df + wD^2f, \qquad (2.44)$$

where " $\otimes$ " is the tensor product, and

$$\int_Q B(\eta, f\eta_2)dQ = \gamma\int_Q a(\rho(\eta),\rho(f\eta_2))\,dQ = \int_Q fB(\eta,\eta_2)\,dQ + lot(\eta). \qquad (2.45)$$

Inserting (2.42) and (2.43) into (2.41), we obtain identity (2.40).

We multiply (1.48) by $f\eta_1$ and obtain identity (2.39) through a similar computation. □

LEMMA 2.6. *For any W, $V\in\mathcal{X}(M)$, we have*

$$D(D_VW) = D_V(DW) + R(V,\cdot,W,\cdot) + DW(\cdot, D_\cdot V), \qquad (2.46)$$

where $R(\cdot,\cdot,\cdot,\cdot)$ is the tensor of curvature, given in (1.14)*, and "$\cdot$" denotes the position of variable.*

Proof. Given $x\in M$, let E_1, E_2 be a frame field normal at x. We then have, from (1.14) and (1.13),

$$\begin{aligned}
&D(D_VW)(E_i,E_j) = E_j(D_VW(E_i)) = E_j(DW(E_i,V))\\
&= D^2W(E_i,V,E_j) + DW(E_i, D_{E_j}V)\\
&= D^2W(E_i,E_j,V) + R_{VE_j}W(E_i) + DW(E_i, D_{E_j}V)\\
&= D_V(DW)(E_i,E_j) + R(V,E_j,W,E_i) + DW(E_i, D_{E_j}V), \quad \text{at } x, \qquad (2.47)
\end{aligned}$$

since $(D_{E_j}E_i)(x) = 0$ and $(D_VE_i)(x) = \sum_{k=1}^2\langle V,E_k\rangle(D_{E_k}E_i)(x) = 0$ for $1\le i, j\le 2$.

Identity (2.46) follows from (2.47). □

LEMMA 2.7. *Let $V\in\mathcal{X}(\Omega)$ be given. Set*

$$G(V,\eta)(X,Y) = \frac{1}{2}[DW(X,D_YV) + DW(Y,D_XV)], \quad X, Y\in M_x,\ x\in M. \qquad (2.48)$$

Then

$$\Upsilon(m(\eta)) = D_V\Upsilon(\eta) + G(V,\eta) + l(\eta); \qquad (2.49)$$

$$\rho(m(\eta)) = D_V\rho(\eta) + \rho(\eta)(\cdot, D.V) + \rho(\eta)(D.V, \cdot) + l(\eta), \tag{2.50}$$

where $l(\eta)$ *denote all the terms such that* $\int_0^T |l(\eta)|dt = lot(\eta)$.

Proof. First, by (1.22) and (2.46), we have

$$\begin{aligned} D_V\Upsilon(\eta) &= \frac{1}{2}[D_V(DW) + D_V(D^*W)] + V(w)\Pi + wD_V\Pi \\ &= \frac{1}{2}[D(D_VW) + (D(D_VW))^* - R(V,\cdot,W,\cdot) - R(W,\cdot,V,\cdot)] \\ &\quad -G(V,\eta) + V(w)\Pi + wD_V\Pi = \Upsilon(m(\eta)) - G(V,\eta) - l(\eta), \end{aligned} \tag{2.51}$$

that is, identity (2.49), where

$$l(\eta) = \frac{1}{2}[R(V,\cdot,W,\cdot) + R(W,\cdot,V,\cdot)] - wD_V\Pi. \tag{2.52}$$

Given $x \in \Omega$, let E_1, E_2 be a frame field normal at x. By (1.13), we then have

$$\begin{aligned} D^2(V(w))(E_i,E_j) &= E_jE_i(Dw(V)) = E_j(D^2w(E_i,V) + Dw(D_{E_i}V)) \\ &= D^3w(E_i,W,E_j) + D^2w(E_i,D_{E_j}V) + E_j\langle Dw, D_{E_i}V\rangle \\ &= D_V(D^2w)(E_i,E_j) + R(Dw,E_i,W,E_j) \\ &\quad +D^2w(E_i,D_{E_j}V) + E_j\langle Dw, D_{E_i}V\rangle \quad \text{at } x, \end{aligned} \tag{2.53}$$

since $(D_{E_i}E_j)(x) = 0$ for $1 \le i, j \le 2$. The last term in (2.53) can be computed as follows:

$$\begin{aligned} E_j(DV(Dw,E_i)) &= D^2V(Dw,E_i,E_j) + DV(D_{E_j}Dw,E_i) \\ &= l_{Dw}D^2V(E_i,E_j) + D^2w(D_{E_i}V,E_j), \quad \text{at } x. \end{aligned} \tag{2.54}$$

Inserting (2.54) into (2.53) yields

$$D^2(V(w)) = D_V(D^2w) + D^2w(\cdot, D.V) + D^2w(D.V,\cdot) - l(\eta), \tag{2.55}$$

where

$$l(\eta) = -R(Dw,\cdot,V,\cdot) - l_{Dw}D^2V, \tag{2.56}$$

that is, identity (2.50) since $\rho(\eta) = -D^2w$. □

LEMMA 2.8. *Let* $V \in \mathcal{X}(\Omega)$ *be such that* (1.40) *holds. Then*

$$\begin{aligned} \mathcal{B}(\eta, m(\eta)) &= \frac{1}{2}\int_\Gamma B(\eta,\eta)\langle V,n\rangle\, d\Gamma + \int_\Omega a(\Upsilon(\eta), G(V,\eta))\, dx \\ &\quad + \int_\Omega b[B(\eta,\eta_2) - B(\eta,\eta_1)]\, dx + l(\eta). \end{aligned} \tag{2.57}$$

Proof. First, we compute $\int_\Omega a(\Upsilon(\eta), \Upsilon(m(\eta))dx$.

By (2.49), we obtain

$$\langle \Upsilon(\eta), \Upsilon(m(\eta))\rangle_{T_x^2} = \frac{1}{2}V(|\Upsilon(\eta)|^2_{T_x^2}) + \langle \Upsilon(\eta), G(V,\eta)\rangle_{T_x^2} + \langle \Upsilon(\eta), l(\eta)\rangle_{T_x^2} \tag{2.58}$$

for $x \in \Omega$. It follows from (2.58) and by divergence formula that

$$\begin{aligned}\int_\Omega \langle \Upsilon(\eta), \Upsilon(m(\eta))\rangle_{T_x^2}\, dx =& \frac{1}{2}\int_\Gamma |\Upsilon(\eta)|^2_{T_x^2}\langle V, n\rangle\, d\Gamma - \int_\Omega b|\Upsilon(\eta)|^2_{T_x^2}\, dx \\ &+ \int_\Omega \langle \Upsilon(\eta), G(V,\eta)\rangle_{T_x^2}\, dx + l(\eta),\end{aligned} \tag{2.59}$$

since $\mathrm{div} V = 2b$.

Given $x \in \Omega$. Let E_1, E_2 be a frame field normal at x. We then have

$$V(\mathrm{tr}\Upsilon(\eta)) = \sum_{i=1}^{2} D_V \Upsilon(\eta)(E_i, E_i) = \mathrm{tr} D_V \Upsilon(\eta) \quad \text{at } x, \tag{2.60}$$

since $(D_V E_i)(x) = 0$ for $i = 1, 2$. From (2.49) and (2.60), an argument similar to (2.59) gives

$$\begin{aligned}\int_\Omega \mathrm{tr}\Upsilon(\eta)\mathrm{tr}\Upsilon(m(\eta))\, dx =& \frac{1}{2}\int_\Gamma (\mathrm{tr}\Upsilon(\eta))^2\langle V, n\rangle\, d\Gamma - \int_\Omega b(\mathrm{tr}\Upsilon(\eta))^2\, dx \\ &+ \int_\Omega \mathrm{tr}\Upsilon(\eta)\mathrm{tr}G(V,\eta)\, dx + l(\eta).\end{aligned} \tag{2.61}$$

Using (2.59), (2.61), and (1.26), we obtain the following identity:

$$\begin{aligned}\int_\Omega a(\Upsilon(\eta), \Upsilon(m(\eta)))\, dx =& \frac{1}{2}\int_\Gamma a(\Upsilon(\eta), \Upsilon(\eta))\langle V, n\rangle\, d\Gamma - \int_\Omega bB(\eta,\eta_1)\, dx \\ &+ \int_\Omega a(\Upsilon(\eta), G(V,\eta))\, dx + l(\eta),\end{aligned} \tag{2.62}$$

since $B(\eta, \eta_1) = a(\Upsilon(\eta), \Upsilon(\eta)) + l(\eta)$.

We now compute $\int_\Omega \gamma a(\rho(\eta), \rho(m(\eta)))dx$.

Since $\rho(\eta)$ is symmetric, we have by properties (2.1), (2.2), and identity (2.50)

$$\langle \rho(\eta), \rho(m(\eta))\rangle_{T_x^2} = \frac{1}{2}V(|\rho(\eta)|^2_{T_x^2}) + 2b|\rho(\eta)|^2 + l(\eta); \tag{2.63}$$

$$\mathrm{tr}\rho(\eta)\mathrm{tr}\rho(m(\eta)) = \frac{1}{2}V((\mathrm{tr}\rho(\eta))^2) + 2b(\mathrm{tr}\rho(\eta))^2 + l(\eta). \tag{2.64}$$

Combining (2.63) with (2.64) we obtain the following identity by divergence formula:

$$\begin{aligned}\int_\Omega \gamma a(\rho(\eta), \rho(m(\eta)))\, dx =& \frac{1}{2}\int_\Gamma \gamma a(\rho(\eta), \rho(\eta))\langle V, n\rangle\, d\Gamma \\ &+ \int_\Omega bB(\eta,\eta_2)\, dx + l(\eta).\end{aligned} \tag{2.65}$$

Adding up (2.62) and (2.65), we obtain identity (2.57). □

PROPOSITION 2.9. *Let $\eta = (W, w)$ solve problem (1.48). Then*

$$\begin{aligned}&\frac{1}{2}\int_\Sigma [|\eta_t|^2 + \gamma|Dw_t|^2 - B(\eta,\eta)]\langle V, n\rangle\, d\Sigma \\ &+ \int_\Sigma \left[\partial(\mathcal{A}\eta, m(\eta)) + \gamma V(w)\frac{\partial w_{tt}}{\partial n}\right] d\Sigma \\ &= Z|_0^T + \int_Q b[|\eta_t|^2 + B(\eta,\eta_2) - B(\eta,\eta_1)]\, dQ \\ &+ \int_Q a(\Upsilon(\eta), G(V,\eta))\, dQ + lot(\eta),\end{aligned} \tag{2.66}$$

where

$$Z = (\eta_t, m(\eta))_{L^2(\Omega,\Lambda)\times L^2(\Omega)} + \gamma(Dw_t, D(V(w)))_{L^2(\Omega)}. \tag{2.67}$$

Proof. We multiply (1.48) by $m(\eta)$. Then

$$\begin{aligned}&(\eta_t, m(\eta))_{L^2(\Omega,\Lambda)\times L^2(\Omega)}|_0^T - \int_0^T (\eta_t, m(\eta_t))_{L^2(\Omega,\Lambda)\times L^2(\Omega)}\, dt\\ &-\gamma\int_0^T (\Delta w_{tt}, V(w))_{L^2(\Omega)}dt + \int_0^T (\mathcal{A}\eta, m(\eta))_{L^2(\Omega,\Lambda)\times L^2(\Omega)}\, dt = 0.\end{aligned} \tag{2.68}$$

Let us compute each term in (2.68) separately.

By the divergence formula

$$\text{second term} = -\frac{1}{2}\int_Q V(|\eta_t|^2)dQ = -\frac{1}{2}\int_\Sigma |\eta_t|^2\langle V, n\rangle d\Sigma + \int_Q b|\eta_t|^2 dQ. \tag{2.69}$$

By Yao [36, Lemma 2.1] and (1.40), we have

$$\begin{aligned}\langle Dw_t, D(V(w_t))\rangle &= DV(Dw_t, Dw_t) + \frac{1}{2}\mathrm{div}(|Dw_t|^2V) - \frac{1}{2}|Dw_t|^2\mathrm{div}V\\ &= \frac{1}{2}\mathrm{div}(|Dw_t|^2V)\end{aligned} \tag{2.70}$$

since $\mathrm{div}V = 2b$. It follows from (2.70) and Green's formula that

$$-(\Delta w_t, V(w_t))_{L^2(\Omega)} = \frac{1}{2}\int_\Gamma |Dw_t|^2\langle V, n\rangle\, d\Gamma - \int_\Gamma V(w_t)\frac{\partial w_t}{\partial n}\, d\Gamma. \tag{2.71}$$

By (2.71), we obtain

$$\begin{aligned}\text{third term} &= -\gamma(\Delta w_t, V(w))_{L^2(\Omega)}|_0^T + \gamma\int_0^T (\Delta w_t, V(w_t))_{L^2(\Omega)}dt\\ &= \gamma(Dw_t, D(V(w)))_{L^2(\Omega,\Lambda)}|_0^T - \frac{\gamma}{2}\int_\Sigma |Dw_t|^2\langle V, n\rangle d\Sigma\\ &\quad -\gamma\int_\Sigma V(w)\frac{\partial w_{tt}}{\partial n}\, d\Sigma.\end{aligned} \tag{2.72}$$

By formulae (1.29) and (2.57), we have

$$\begin{aligned}\text{third term} &= \int_0^T \mathcal{B}(\eta, m(\eta))\, dt - \int_\Sigma \partial(\mathcal{A}\eta, m(\eta))\, d\Sigma\\ &= \frac{1}{2}\int_\Sigma B(\eta,\eta)\langle V, n\rangle\, d\Sigma - \int_\Sigma \partial(\mathcal{A}\eta, m(\eta))\, d\Sigma + lot(\eta)\\ &\quad + \int_Q b[B(\eta,\eta_2) - B(\eta,\eta_1)]\, dQ + \int_Q a(\Upsilon(\eta), G(V,\eta))\, dQ.\end{aligned} \tag{2.73}$$

Adding up all the terms, we obtain identity (2.66). ∎

LEMMA 2.10. *Let Z be given in* (2.67). *Then, for any $\epsilon > 0$, there is $c_\epsilon > 0$, independent of η, such that*

$$|Z(t)| \le (\lambda_0\sigma_0 + \epsilon)E(t) + c_\epsilon L(t), \tag{2.74}$$

where λ_0 and σ_0 are defined in (1.39) *and* (1.43)*, respectively.*

Proof. Given $\epsilon > 0$, it is easily checked that there is $c_\epsilon > 0$ such that

$$|(w_t, V(w))_{L^2(\Omega)} + \gamma(Dw, D_{Dw_t}V)_{L^2(\Omega,\Lambda)}| \le \epsilon E(t) + c_\epsilon L(t). \tag{2.75}$$

Therefore by formula $D(V(w)) = Dw(D.V) + l_V D^2 w$ and (2.75), we obtain the following estimate:

$$\begin{aligned} |Z| &= |(W_t, D_V W)_{L^2(\Omega,\Lambda)} + \gamma(Dw_t, l_V D^2 w)_{L^2(\Omega,\Lambda)} \\ &\quad + (w_t, V(w))_{L^2(\Omega)} + \gamma(Dw, D_{Dw_t}V)_{L^2(\Omega,\Lambda)}| \\ &\le \sigma_0[\|W_t\|_{L^2(\Omega,\Lambda)}\|DW\|_{L^2(\Omega,T^2)} + \gamma\|Dw_t\|_{L^2(\Omega,\Lambda)}\|D^2 w\|_{L^2(\Omega,T^2)}] \\ &\quad + \epsilon E(t) + c_\epsilon L(t) \\ &\le (\sigma_0\lambda_0 + \epsilon)E(t) + c_\epsilon L(t). \qquad \square \end{aligned} \tag{2.76}$$

LEMMA 2.11. *Let $V \in \mathcal{X}(\Omega)$ be such that conditions* (1.40) *and* (1.42) *hold. Then*

$$\int_\Omega a(\Upsilon(\eta_1), G(V, \eta_1))\, dx \ge \sigma_1 \int_\Omega B(\eta_1, \eta_1)\, dx. \tag{2.77}$$

Proof. It is easily checked that condition (1.40) implies

$$DV = bg + a\mathcal{E}, \quad x \in \Omega, \tag{2.78}$$

where g is the induced metric of M in $\mathbb{R}^3$ and $\mathcal{E}$ the volume element of M.

Given $x \in \Omega$, since $\Upsilon(\eta_1)$ is symmetric, we may take e_1, e_2, as an orthonormal basis of M_x, with the positive orientation such that

$$DW(e_1, e_2) + DW(e_2, e_1) = 0 \quad \text{at } x. \tag{2.79}$$

Formula (2.78) implies

$$D_{e_1}V = be_1 - ae_2, \quad D_{e_2}V = ae_1 + be_2 \quad \text{at } x. \tag{2.80}$$

Denote $W_{ij} = DW(e_i, e_j)$ for $1 \le i, j \le 2$. Then formulae (2.80) and (2.48) yield

$$G(V, \eta_1)(e_1, e_1) = DW(e_1, D_{e_1}V) = bW_{11} - aW_{12}; \tag{2.81}$$

$$G(V, \eta_1)(e_2, e_2) = DW(e_2, D_{e_2}V) = aW_{21} + bW_{22} \quad \text{at } x. \tag{2.82}$$

It follows from (2.81), (2.82), and (2.79) that

$$\langle \Upsilon(\eta_1), G(V, \eta_1)\rangle_{T_x^2} = b(W_{11}^2 + W_{22}^2) + aW_{21}(W_{11} + W_{22}). \tag{2.83}$$

Similarly, we may obtain

$$\mathrm{tr}\Upsilon(\eta_1)\mathrm{tr}G(V, \eta_1) = b(W_{11} + W_{22})^2 + 2aW_{21}(W_{11} + W_{22}) \quad \text{at } x. \tag{2.84}$$

Thus relations (2.83) and (2.84) yield

$$\begin{aligned} a(\Upsilon(\eta_1), G(V, \eta_1)) &= ba(\Upsilon(\eta_1), \Upsilon(\eta_1)) + (1 + \mu)aW_{21}(W_{11} + W_{22}) \\ &\ge ba(\Upsilon(\eta_1), \Upsilon(\eta_1)) - \frac{1 + \mu}{2}|a||DW|_{T_x^2}^2. \end{aligned} \tag{2.85}$$

By inequality (1.39) and (2.85), we obtain inequality (2.77). □

PROPOSITION 2.12. *Let* $\eta = (W, w) \in H^1(\Omega, \Lambda) \times H^2(\Omega)$ *and* $\hat{\Gamma} \subset \Gamma$ *be relatively open such that*

$$W|_{\hat{\Gamma}} = 0, \quad w|_{\hat{\Gamma}} = \frac{\partial w}{\partial n}|_{\hat{\Gamma}} = 0. \tag{2.86}$$

Then

$$\text{(i)} \quad B(\eta, \eta) = \gamma(\Delta w)^2 + (DW(n,n))^2 + \frac{1-\mu}{2}(DW(\tau, n))^2 \quad \text{on} \quad \hat{\Gamma}; \tag{2.87}$$

$$\text{(ii)} \quad \partial(\mathcal{A}\eta, m(\eta)) = B(\eta, \eta)\langle V, n\rangle \quad \text{on} \quad \hat{\Gamma}. \tag{2.88}$$

Proof. Given $x \in \hat{\Gamma}$, conditions $W|_{\hat{\Gamma}} = w|_{\hat{\Gamma}} = 0$ imply

$$D_\tau W = 0; \tag{2.89}$$

$$\Upsilon(\eta)(\tau, \tau) = DW(\tau, \tau) = \langle D_\tau W, \tau\rangle = 0; \tag{2.90}$$

$$\Upsilon(\eta)(n, \tau) = \frac{1}{2}[DW(\tau, n) + \langle D_\tau W, n\rangle] = \frac{1}{2}DW(\tau, n); \tag{2.91}$$

$$\Upsilon(\eta)(n, n) = DW(n, n). \tag{2.92}$$

It follows from (2.89)–(2.92) that

$$|\Upsilon(\eta)|^2_{T^2_x} = (DW(n,n))^2 + \frac{1}{2}(DW(\tau, n))^2; \quad (\text{tr}\Upsilon(\eta))^2 = (DW(n,n))^2, \tag{2.93}$$

so that we obtain

$$a(\Upsilon(\eta), \Upsilon(\eta)) = (DW(n,n))^2 + \frac{1-\mu}{2}(DW(\tau, n))^2 \quad \text{at } x. \tag{2.94}$$

A similar computation yields

$$a(\rho(\eta), \rho(\eta)) = (\Delta w)^2 \quad \text{at } x. \tag{2.95}$$

Inserting (2.94) and (2.95) into (1.25), we obtain (2.87).

By Yao [38, Lemma 2.5] and (2.86), we have

$$\frac{\partial(V(w))}{\partial n} = \langle V, n\rangle \Delta w \quad \text{and} \quad V(w) = \langle Dw, V\rangle = 0 \quad \text{on} \quad \hat{\Gamma}. \tag{2.96}$$

Since $D_V W = \langle V, n\rangle D_n W + \langle V, \tau\rangle D_\tau W = \langle V, n\rangle D_n W$, we obtain

$$\langle D_V W, n\rangle = \langle V, n\rangle DW(n,n) \quad \text{and} \quad \langle D_V W, \tau\rangle = \langle V, n\rangle DW(\tau, n) \quad \text{on} \quad \hat{\Gamma}. \tag{2.97}$$

In addition, condition (2.86) implies

$$B_1(W, w) = (1-\mu)DW(n,n) + \mu DW(n,n) + \mu\langle D_\tau W, \tau\rangle = DW(n,n); \tag{2.98}$$

$$B_2(W, w) = \frac{1-\mu}{2}[DW(\tau, n) + \langle D_\tau W, n\rangle] = \frac{1-\mu}{2}DW(\tau, n); \tag{2.99}$$

$$B_3 w = -D^2 w(\tau, \tau) = -\langle D_\tau(Dw), \tau\rangle = 0; \tag{2.100}$$

$$B_4 w = \frac{\partial}{\partial \tau}\left(D^2 w(\tau, n)\right) = \frac{\partial}{\partial \tau}\left(D^2 w(n, \tau)\right) = \frac{\partial}{\partial \tau}\left(\langle D_\tau(Dw), n\rangle\right) = 0. \tag{2.101}$$

Inserting (2.96)–(2.101) into (1.30), we obtain (2.88) by (i). □

PROPOSITION 2.13. *Let λ be a complex number and $\hat{\Gamma} \subset \Gamma$ be relatively open. Let $\eta = (W, w)$ solve the problem*

$$\lambda^2 \eta - \lambda^2 \gamma(0, \Delta w) + \mathcal{A}\eta = 0 \quad on \quad \Omega \tag{2.102}$$

subject to boundary conditions

$$\begin{cases} W = DW = 0 \quad on \quad \hat{\Gamma}, \\ w = \dfrac{\partial w}{\partial n} = \Delta w = \dfrac{\partial \Delta w}{\partial n} = 0 \quad on \quad \hat{\Gamma}. \end{cases} \tag{2.103}$$

Then

$$W = w = 0 \quad on \quad \Omega. \tag{2.104}$$

Proof. It will suffice to show that this uniqueness result is the Cauchy problem consisting of a system of three equations of the fourth order with the same principal part Δ^2, where Δ is the Laplacian on manifold M. Therefore, this proposition is covered by Shirota [27] .

Denote by $LF(\eta)$ some terms for which there is constant C such that

$$|LF(\eta)|^2 \le C \sum_{i=0}^{3} (|D^i W|^2 + |D^i w|^2) \quad \text{on} \quad \Omega. \tag{2.105}$$

It is easily checked from (2.102) and (1.31) that we have the following equation on component W:

$$\frac{1-\mu}{2} \delta d W + d\delta W = (k - \mu k - \lambda^2) W + \mathcal{F}(w). \tag{2.106}$$

Applying $d\delta$ to both sides of equation (2.106), we obtain

$$d\delta d\delta W = d\delta[(k - \mu k - \lambda^2) W + \mathcal{F}(w)], \tag{2.107}$$

since $\delta^2 = 0$. Similarly, it follows that

$$\delta d \delta d W = \frac{2}{1-\mu} \delta d[(k - \mu k - \lambda^2) W + \mathcal{F}(w)]. \tag{2.108}$$

Relations (2.107) and (2.108) yield

$$\boldsymbol{\Delta}^2 W = LF(\eta), \tag{2.109}$$

where $\boldsymbol{\Delta}$ is the Hodge–Laplacian, defined by $\boldsymbol{\Delta} = \delta d + d\delta$.

Let (x_1, x_2) be a coordinate and $W = (w_1, w_2)$ in this coordinate. It is easy to check that

$$\boldsymbol{\Delta}^2 W = (\Delta^2 w_1, \Delta^2 w_2) + LF(w_1, w_2). \tag{2.110}$$

By (2.109) and (2.110), system (2.102) is equivalent to the following

$$\begin{cases} \Delta^2 w_1 = LF(w_1, w_2, w), \\ \Delta^2 w_2 = LF(w_1, w_2, w), \\ \Delta^2 w = LF(w_1, w_2, w). \end{cases} \tag{2.111}$$

To complete the proof, we have to show that there are the Cauchy data on $\hat{\Gamma}$ enough for problem (2.111). For this purpose, by boundary conditions (2.103), it will suffice to show

$$D^2 W|_{\hat{\Gamma}} = D^3 W|_{\hat{\Gamma}} = 0. \tag{2.112}$$

Given $x \in \hat{\Gamma}$, let E_1, E_2 be a frame field normal at x such that $E_1(x) = n$ and $E_2(x) = \tau$. By (2.103), we obtain at x

$$D^2 W(E_i, E_j, \tau) = \tau(DW(E_i, E_j)) - DW(D_\tau E_i, E_j) - DW(E_i, D_\tau E_j) = 0, \tag{2.113}$$

for $1 \le i, j \le 2$. It follows from (1.13), (2.103), and (2.113) that at x

$$D^2 W(E_i, \tau, E_j) = D^2 W(E_i, E_j, \tau) + R(\tau, E_j, W, E_i) = 0, \tag{2.114}$$

for $1 \le i, j \le 2$.

By Wu [35, pp. 305–306] and (2.113–2.114), we have at x

$$\begin{aligned} \delta dW &= -\sum_{i=1}^{2} D_{E_i} D_{E_i} W + \sum_{ij=1}^{2} \langle D_{E_j} D_{E_i} W, E_j \rangle E_i \\ &= -\sum_{i=1}^{2} [D^2 W(n, E_i, E_i) n + D^2 W(\tau, E_i, E_i)\tau] + \sum_{i=1}^{2} \left[\sum_{j=1}^{2} D^2 W(E_j, E_i, E_j) \right] E_i \\ &= -D^2 W(\tau, n, n)\tau; \end{aligned} \tag{2.115}$$

$$d\delta W = -\sum_{i=1}^{2} \left[\sum_{j=1}^{2} D^2 W(E_j, E_j, E_i) \right] E_i = -D^2 W(n, n, n) n. \tag{2.116}$$

After inserting (2.115) and (2.116) into (2.106), we obtain by (2.103)

$$-D^2 W(n, n, n) n - \frac{(1-\mu) D^2 W(\tau, n, n)}{2} \tau = (k - \mu k - \lambda^2) W + \mathcal{F}(w) = 0 \tag{2.117}$$

at x, that is, $D^2 W(n, n, n) = D^2 W(\tau, n, n) = 0$, which implies

$$D^2 W = 0 \quad \text{at } x. \tag{2.118}$$

Similarly, we may obtain $D^3 W|_{\hat{\Gamma}} = 0$. □

2.3. Proofs of main results.

Proof of Theorem 1.1. Since $\Upsilon(\eta) = \Upsilon(\eta_1) + l(\eta)$ and $G(V,\eta) = G(V,\eta_1)$, inequality (2.77) yields

$$\int_\Omega a(\Upsilon(\eta), G(V,\eta))\,dx \geq \sigma_1 \int_\Omega B(\eta,\eta_1)\,dx + l(\eta). \tag{2.119}$$

In addition, it is easily checked that $B(\eta_1,\eta_2) = l(\eta)$ so that we have

$$B(\eta,\eta_2) = B(\eta_2,\eta_2) + l(\eta). \tag{2.120}$$

We now are ready to establish inequality (1.49).

By (1.50), (2.66), and (2.119), we obtain the following:

$$\begin{aligned} SB|_\Sigma = {} & Z|_0^T + \int_Q b[|\eta_t|^2 + B(\eta,\eta_2) - B(\eta,\eta_1)]\,dQ \\ & + \int_Q a(\Upsilon(\eta), G(V,\eta))\,dQ + lot(\eta) \\ & + \frac{1}{2}\int_\Sigma \left[\partial(\mathcal{A}\eta, -b\eta_2 + h\eta_1) - \gamma b w \frac{\partial w_{tt}}{\partial n}\right] d\Sigma \\ \geq {} & Z|_0^T + \int_Q b(|W_t|^2 + w_t^2)\,dQ \\ & + \int_Q bB(\eta,\eta_2)\,dQ + \int_Q (\sigma_1 - b)B(\eta,\eta_1)\,dQ + lot(\eta) \\ & + \frac{1}{2}\int_\Sigma \left[\partial(\mathcal{A}\eta, -b\eta_2 + h\eta_1) - \gamma b w \frac{\partial w_{tt}}{\partial n}\right] d\Sigma. \end{aligned} \tag{2.121}$$

Now rewrite the sum of the second, the third, and the fourth terms in the right-hand side of inequality (2.121), as follows in terms of identities (2.39) and (2.40):

$$\begin{aligned} & \int_Q b(|W_t|^2 + w_t^2)\,dQ + \int_Q bB(\eta,\eta_2)\,dQ + \int_Q (\sigma_1 - b)B(\eta,\eta_1)\,dQ \\ & = \sigma_1 \int_0^T E(t)dt + \frac{1}{2}\int_Q (b - \sigma_1)[w_t^2 + \gamma|Dw_t|^2 + B(\eta_2,\eta_2)]\,dQ + \int_Q b w_t^2\,dQ \end{aligned} \tag{2.122}$$

$$\begin{aligned} & + \frac{1}{2}\int_Q (2b - \sigma_1)[|W_t|^2 - B(\eta,\eta_1)]\,dQ + \frac{1}{2}\int_Q b[B(\eta,\eta_2) - w_t^2 - \gamma|Dw_t|^2]\,dQ + lot(\eta) \\ & \geq \sigma_1 \int_0^T E(t)dt + \frac{1}{2}\int_\Sigma \left[\partial(\mathcal{A}\eta, b\eta_2 - h\eta_1) + \gamma b w \frac{\partial w_{tt}}{\partial n}\right] d\Sigma + lot(\eta), \end{aligned} \tag{2.123}$$

where $h = 2b - \sigma_1$. Inserting (2.123) into (2.121), we obtain the desired inequality (1.49) by means of inequality (2.74).

Proofs of Theorems 1.2 *and* 1.3. By a compactness/uniqueness argument as in Bardos, Lebeau, and Rauch [1] or in Zuazua [41], the lower order terms in estimate (1.49) can be absorbed and we obtain both inequalities (1.56) and (1.67), since in both cases the uniqueness we need is covered by Proposition 2.13. It is mentioned that in both cases we also have $E(t) = E(0)$. □

Acknowledgments. Some results of this paper were obtained when the author was visiting the Institute of Applied Mathematics and Mechanics, University of Virginia. The author would like to thank Professors I. Lasiecka and R. Triggiani for bringing this topic to him and for their hospitality.

STABILITY RADIUS AND INTERNAL VERSUS EXTERNAL STABILITY IN BANACH SPACES: AN EVOLUTION SEMIGROUP APPROACH*

STEPHEN CLARK†, YURI LATUSHKIN‡, STEPHEN MONTGOMERY-SMITH‡, AND TIMOTHY RANDOLPH†

Abstract. In this paper the theory of evolution semigroups is developed and used to provide a framework to study the stability of general linear control systems. These include autonomous and nonautonomous systems modeled with unbounded state-space operators acting on Banach spaces. This approach allows one to apply the classical theory of strongly continuous semigroups to time-varying systems. In particular, the complex stability radius may be expressed explicitly in terms of the generator of an (evolution) semigroup. Examples are given to show that classical formulas for the stability radius of an autonomous Hilbert-space system fail in more general settings. Upper and lower bounds on the stability radius are proven for Banach-space systems. In addition, it is shown that the theory of evolution semigroups allows for a straightforward operator-theoretic analysis of internal stability as determined by classical frequency-domain and input-output operators, even for nonautonomous Banach-space systems. In particular, for the nonautonomous setting, internal stability is shown to be equivalent to input-output stability for stabilizable and detectable systems. For the autonomous setting, an explicit formula for the norm of input-output operator is given.

Key words. evolution semigroups, stability radius, exponential stability, external stability, spectral mapping theorem, transfer function

1. Introduction.

Presented here is a study of stability of infinite-dimensional linear control systems which is based on the relatively recent development of the theory of evolution semigroups. These semigroups have been used in the study of exponential dichotomy of time-varying differential equations and more general hyperbolic dynamical systems; see [7, 23, 24, 27, 29, 34, 43] and the bibliographies therein. The intent of this paper is to show how the theory of evolution semigroups can be used to provide a clarifying perspective, and prove new results, on the uniform exponential stability for general linear control systems, $\dot{x}(t) = A(t)x(t) + B(t)u(t)$, $y(t) = C(t)x(t)$, $t \geq 0$. The operators $A(t)$ are generally unbounded operators on a Banach space X, while the operators $B(t)$ and $C(t)$ may act on Banach spaces U and Y, respectively. In addressing the general settings, difficulties arise both from the time-varying aspect and from a loss of Hilbert-space properties. This presentation, however, provides some relatively simple operator-theoretic arguments for properties that extend classical theorems of autonomous systems in finite dimensions. The topics

covered here include characterizing internal stability of the nominal system in terms of appropriate input-state-output operators and, subsequently, using these properties to obtain new explicit formulas for bounds on the stability radius. Nonautonomous systems are generally considered, but some results apply only to autonomous ones, such as the upper bound for the stability radius (section 4.3), the formula for the norm of the input-output operator in Banach spaces (section 4.4), and a characterization of stability that is related to this formula (section 5.2).

Although practical considerations usually dictate that U and Y are Hilbert spaces (indeed, finite dimensional), the Banach-space setting addressed here may be motivated by the problem of determining optimal sensor (or actuator) location. For this, it may be natural to consider $U = X$ and $B = I_X$ (or $Y = X$ and $C = I_X$) [5]; if the natural state space X is a Banach space, then, as will be shown in this paper, Hilbert-space characterizations of internal stability or its robustness do not apply. We also show that even in the case of Hilbert spaces U and Y, known formulas for the stability radius involving the spaces $L^2(\mathbb{R}_+, U)$ and $L^2(\mathbb{R}_+, Y)$ do not apply if the L^2 norm is replaced by, say, the L^1 norm—see the examples in subsection 4.5. In addition to the general setting of nonautonomous systems on Banach spaces, autonomous and Hilbert-space systems are considered.

For the autonomous case, the primary observation we make about general Banach-space settings versus the classical L^2 and Hilbert-space setting can be explained using the notion of L^p–Fourier multipliers. For this, let $H(s) = C(A - is)^{-1}B$, $s \in \mathbb{R}$, denote the transfer function, and let $\mathbf{F}$ denote the Fourier transform. The transfer function H is said to be an *L^p–Fourier multiplier* if the operator $u \mapsto \mathbf{F}^{-1}H(\cdot)\mathbf{F}u$ can be extended from the Schwartz class of rapidly decaying U-valued functions to a bounded operator from $L^p(\mathbb{R}; U)$ to $L^p(\mathbb{R}; Y)$; see, e.g., [1] for the definitions. As shown in Theorem 4.11, the norm of this operator is equal to the norm of the input-output operator. If U and Y are Hilbert spaces and $p = 2$, then H is an L^2–Fourier multiplier if and only if $\|H(\cdot)\|$ is bounded on $\mathbb{R}$; see formula (4.20). For Banach spaces and/or $p \neq 2$, this latter condition is necessary but *not sufficient* for H to be an L^p–Fourier multiplier. As a result, our formula (4.18) for the norm of the input-output operator is more involved.

To motivate the methods, recall Lyapunov's stability theorem which says that if A is a bounded linear operator on X and if the spectrum of A is contained in the open left half of the complex plane, then the solution of the autonomous differential equation $\dot{x}(t) = Ax(t)$ on X is uniformly exponentially stable; equivalently, the spectrum $\sigma(e^{tA})$ is contained in the open unit disk $\{z \in \mathbb{C} : |z| < 1\}$ for $t > 0$. This is a consequence of the fact that when A is a bounded operator, then the spectral mapping theorem holds: $\sigma(e^{tA}) \setminus \{0\} = e^{t\sigma(A)}$, $t \neq 0$. Difficulties with Lyapunov's theorem arise when the operators A are allowed to be unbounded. In particular, it is well known that there exist strongly continuous semigroups $\{e^{tA}\}_{t\geq 0}$ that are *not* uniformly exponentially stable even though $\mathrm{Re}\lambda \leq \omega < 0$ for all $\lambda \in \sigma(A)$; see, e.g., [2, 29, 41]. For nonautonomous equations the situation is worse. Indeed, even for finite-dimensional X it is possible for the spectra of $A(t)$ to be the same for all $t > 0$ *and* contained in the open left half-plane, yet the corresponding solutions to $\dot{x}(t) = A(t)x(t)$ are not uniformly exponentially stable (see [15, Ex. 7.1] for a classical example). In the development that follows we plan to show how these difficulties can be overcome by the construction of an "evolution semigroup." This is a family of operators defined on a superspace of functions from $\mathbb{R}$ into X, such as $L^p(\mathbb{R}, X)$, $1 \leq p < \infty$, or $C_0(\mathbb{R}, X)$.

Section 2 sets up the notation and provides background information. Section 3 presents the basic properties of the evolution semigroups. Included here is the property that the spectral mapping theorem always holds for these semigroups when they are defined on X-valued functions on the *half-line*, such as $L^p(\mathbb{R}_+, X)$. A consequence of this is a characterization of exponential stability for nonautonomous systems in terms of the invertibility of the generator Γ of the evolution semigroup. This operator and its role in determining exponential stability is the basis for many of the subsequent developments. In particular, the semigroup $\{e^{tA}\}_{t\geq 0}$ *is* uniformly exponentially stable provided $\operatorname{Re}\lambda < 0$ for all $\lambda \in \sigma(\Gamma)$.

Section 4 addresses the topic of the (complex) stability radius; that is, the size of the smallest disturbance, $\Delta(\cdot)$, under which the perturbation, $\dot{x}(t) = (A(t)+\Delta(t))x(t)$, of an exponentially stable system, $\dot{x}(t) = A(t)x(t)$, loses exponential stability. Results address structured and unstructured perturbations of autonomous and nonautonomous systems in both Banach- and Hilbert-space settings. Examples are given which highlight some important differences between these settings. Also included in this section is a discussion about the transfer function for infinite-dimensional *time-varying* systems. This concept arises naturally in the context of evolution semigroups.

In section 5 the explicit relationship between internal and external stability is studied for general linear systems. This material expands on the ideas begun in [37]. A classical result for autonomous systems in Hilbert space is the fact that exponential stability of the nominal system (internal stability) is, under the hypotheses of stabilizability and detectability, equivalent to the boundedness of the transfer function in the right half-plane (external stability). Such a result does not apply to nonautonomous systems, and a counterexample shows that this property fails to hold for Banach-space systems. Properties from section 4 provide a natural Banach-space extension of this result: the role of transfer function is replaced by the input-output operator. Moreover, for autonomous systems we provide an explicit formula relating the norm of this input-output operator to that of the transfer function. Finally, we prove two theorems—one for nonautonomous and one for autonomous systems—which characterize internal stability in terms of the various input-state-output operators.

This introduction concludes with a brief synopsis of the main results. The characterization of uniform exponential stability in terms of an evolution semigroup and its generator is given in Theorem 3.2, Theorem 3.5, and Corollary 3.6. Although these results are essentially known, the proofs are approached in a new way. In particular, Theorem 3.5 identifies the operator $\mathbb{G} = -\Gamma^{-1}$ used to determine stability throughout the paper. Theorem 4.2 records the main observation that the input-output operator, $\mathbb{L} = \mathcal{C}\mathbb{G}\mathcal{B}$, for a general nonautonomous system is related to the inverse of the generator of the evolution semigroup. A very short proof of the known fact that the stability radius for such a system is bounded from below by $\|\mathbb{L}\|^{-1}$ is also provided here. The upper bound for the stability radius, being given in terms of the transfer function, applies only to autonomous systems and is proven in subsection 4.3. The upper bound, as identified here for Banach spaces, seems to be new although our proof is based on the idea of the Hilbert-space result of [18, Thm. 3.5]. In subsection 4.3 we also introduce the pointwise stability radius and dichotomy radius. Estimates for the former are provided by Theorems 4.3 and 4.4 while the latter is addressed in Lemma 4.5. Examples 4.13 and 4.15 show that, for autonomous Banach-space systems, both inequalities for the upper and lower bounds on the stability radius (see Theorem 4.1) can be strict. In view of the possibility of the strict inequality $\|\mathbb{L}\| > \sup_{s\in\mathbb{R}} \|C(A-is)^{-1}B\|$, Theorem 4.11 provides a new Banach-space formula for $\|\mathbb{L}\|$ in terms of A, B, and C. In

section 5 this expression for $\|L\|$ is used to relate state-space versus frequency-domain stability—concepts which are *not* equivalent for Banach-space systems. A special case of this expression gives a new formula for the growth bound of a semigroup on a Banach space; see Theorem 5.4 and the subsequent paragraph. Finally, Theorem 5.3 extends a classical characterization of stability for stabilizable and detectable control systems as it applies to nonautonomous Banach-space settings.

2. Notation and preliminaries. Throughout the paper, $\mathcal{L}(X,Y)$ will denote the set of bounded linear operators between complex Banach spaces X and Y. If A is a linear operator on X, $\sigma(A)$ will denote the spectrum of A, $\rho(A)$ will denote the resolvent set of A relative to $\mathcal{L}(X) = \mathcal{L}(X,X)$, and $\|A\|_\bullet = \|A\|_{\bullet,X} := \inf\{\|Ax\| : x \in \mathrm{Dom}(A), \|x\| = 1\}$. In particular, if A is invertible in $\mathcal{L}(X)$, $\|A\|_\bullet = 1/\|A^{-1}\|_{\mathcal{L}(X)}$. Also, let $\mathbb{C}_+ = \{\lambda \in \mathbb{C} : \mathrm{Re}\ \lambda > 0\}$.

If A generates a strongly continuous (or C_0) semigroup $\{e^{tA}\}_{t\geq 0}$ on a Banach space X, the following notation will be used: $s(A) = \sup\{\mathrm{Re}\lambda : \lambda \in \sigma(A)\}$ denotes the spectral bound; $s_0(A) = \inf\{\omega \in \mathbb{R} : \ \{\lambda : \mathrm{Re}\lambda > \omega\} \subset \rho(A) \quad \text{and} \quad \sup_{\mathrm{Re}\lambda>\omega} \|(A - \lambda)^{-1}\| < \infty\}$ is the abscissa of uniform boundedness of the resolvent; and $\omega_0(e^{tA}) = \inf\{\omega \in \mathbb{R} : \ \|e^{tA}\| \leq Me^{t\omega} \quad \text{for some} \quad M \geq 0 \quad \text{and all} \quad t \geq 0\}$ denotes the growth bound of the semigroup. In general, $s(A) \leq s_0(A) \leq \omega_0(e^{tA})$ (see, e.g., [29]) with *strict* inequalities possible; see [2, 29, 41] for examples. However, when X is a Hilbert space, the following spectral mapping theorem of Gearhart holds (see, e.g., [2, p. 95] or [29, 33]).

THEOREM 2.1. *If A generates a strongly continuous semigroup $\{e^{tA}\}_{t\geq 0}$ on a Hilbert space, then $s_0(A) = \omega_0(e^{tA})$. Moreover, $1 \in \rho(e^{2\pi A})$ if and only if $i\mathbb{Z} \subset \rho(A)$ and $\sup_{k\in\mathbb{Z}} \|(A - ik)^{-1}\| < \infty$.*

In particular, this result shows that on a Hilbert space X the semigroup $\{e^{tA}\}_{t\geq 0}$ is uniformly exponentially stable if and only if $\sup_{\lambda\in\mathbb{C}_+} \|(A - \lambda)^{-1}\| < \infty$ [19].

Now consider operators $A(t)$, $t \geq 0$, with domain $\mathrm{Dom}(A(t))$ in a Banach space X. If the abstract Cauchy problem

$$\dot{x}(t) = A(t)x(t), \quad x(\tau) \in \mathrm{Dom}(A(\tau)), \qquad t \geq \tau \geq 0, \tag{2.1}$$

is well-posed in the sense that there exists an evolution (solving) family of operators $\mathcal{U} = \{U(t,\tau)\}_{t\geq\tau}$ on X which gives a differentiable solution, then $x(\cdot) : t \mapsto U(t,\tau)x(\tau)$, $t \geq \tau$, in $\mathbb{R}$ is differentiable, $x(t)$ is in $\mathrm{Dom}(A(t))$ for $t \geq 0$, and (2.1) holds. The precise meaning of the term evolution family used here is as follows.

DEFINITION 2.2. *A family of bounded operators $\{U(t,\tau)\}_{t\geq\tau}$ on X is called an* evolution family *if*

(i) *$U(t,\tau) = U(t,s)U(s,\tau)$ and $U(t,t) = I$ for all $t \geq s \geq \tau$;*

(ii) *for each $x \in X$ the function $(t,\tau) \mapsto U(t,\tau)x$ is continuous for $t \geq \tau$.*

An evolution family $\{U(t,\tau)\}_{t\geq\tau}$ is called exponentially bounded *if, in addition,*

(iii) *there exist constants $M \geq 1$, $\omega \in \mathbb{R}$ such that*

$$\|U(t,\tau)\| \leq Me^{\omega(t-\tau)}, \quad t \geq \tau.$$

Remarks 2.3.

(a) An evolution family $\{U(t,\tau)\}_{t\geq\tau}$ is called *uniformly exponentially stable* if in part (iii), ω can be taken to be strictly less than zero.

(b) Evolution families appear as solutions for abstract Cauchy problems (2.1). Since the definition requires that $(t,\tau) \mapsto U(t,\tau)$ is merely strongly continuous, the operators $A(t)$ in (2.1) can be unbounded.

(c) In the autonomous case where $A(t) \equiv A$ is the infinitesimal generator of a strongly continuous semigroup $\{e^{tA}\}_{t\geq 0}$ on X, then $U(t,\tau) = e^{(t-\tau)A}$ for $t \geq \tau$ is a strongly continuous exponentially bounded evolution family.

(d) The existence of a *differentiable* solution to (2.1) plays little role in this paper, so the starting point will usually not be (2.1), but rather the existence of an exponentially bounded evolution family.

In the next section we will define the evolution semigroup relevant to our interests for the nonautonomous Cauchy problem (2.1) on the half-line $\mathbb{R}_+ = [0,\infty)$. For now, we begin by considering the autonomous equation $\dot{x}(t) = Ax(t)$, $t \in \mathbb{R}$, where A is the generator of a strongly continuous semigroup $\{e^{tA}\}_{t\geq 0}$ on X. If $\mathcal{F}_{\mathbb{R}}$ is a space of X-valued functions, $f : \mathbb{R} \to X$, define

$$(E^t_{\mathbb{R}} f)(\tau) = e^{tA} f(\tau - t) \quad \text{for } f \in \mathcal{F}_{\mathbb{R}}. \tag{2.2}$$

If $\mathcal{F}_{\mathbb{R}} = L^p(\mathbb{R}, X)$, $1 \leq p < \infty$, or $\mathcal{F}_{\mathbb{R}} = C_0(\mathbb{R}, X)$, the space of continuous functions vanishing at infinities (or another Banach function space as in [34]) this defines a strongly continuous semigroup of operators $\{E^t_{\mathbb{R}}\}_{t\geq 0}$ whose generator will be denoted by $\Gamma_{\mathbb{R}}$. In the case $\mathcal{F}_{\mathbb{R}} = L^p(\mathbb{R}, X)$, $\Gamma_{\mathbb{R}}$ is the closure (in $L^p(\mathbb{R}, X)$) of the operator $-d/dt + \mathcal{A}$, where $(\mathcal{A}f)(t) = Af(t)$ and

$$\begin{aligned}\operatorname{Dom}(-d/dt + \mathcal{A}) &= \operatorname{Dom}(-d/dt) \cap \operatorname{Dom}(\mathcal{A}) \\ &= \{v \in L^p(\mathbb{R}, X) : v \in AC(\mathbb{R}, X),\ v' \in L^p(\mathbb{R}, X), \\ &\qquad v(s) \in \operatorname{Dom}(\mathcal{A}) \text{ for almost every } s, \text{ and } -v' + Av \in L^p(\mathbb{R}, X)\}.\end{aligned}$$

The important properties of this "evolution semigroup" are summarized in the following remarks; see [23] and also further developments in [29, 34, 43]. The unit circle in $\mathbb{C}$ is denoted here by $\mathbb{T} = \{z \in \mathbb{C} : |z| = 1\}$.

Remarks 2.4. The spectrum $\sigma(E^t_{\mathbb{R}})$ for $t > 0$ is invariant with respect to rotations centered at the origin, and $\sigma(\Gamma_{\mathbb{R}})$ is invariant with respect to translations along $i\mathbb{R}$. Moreover, the following are equivalent.

(i) $\sigma(e^{tA}) \cap \mathbb{T} = \emptyset$ on X.

(ii) $\sigma(E^t_{\mathbb{R}}) \cap \mathbb{T} = \emptyset$ on $\mathcal{F}_{\mathbb{R}}$.

(iii) $0 \in \rho(\Gamma_{\mathbb{R}})$ on $\mathcal{F}_{\mathbb{R}}$. As a consequence,

$$\sigma(E^t_{\mathbb{R}}) \setminus \{0\} = e^{t\sigma(\Gamma_{\mathbb{R}})}, \quad t > 0. \tag{2.3}$$

Note that $\{E^t_{\mathbb{R}}\}_{t\geq 0}$ has the spectral mapping property (2.3) on $\mathcal{F}_{\mathbb{R}}$ even if the underlying semigroup $\{e^{tA}\}_{t\geq 0}$ does not have the spectral mapping property on X. In the latter case, it may be that the exponential stability of the solutions to $\dot{x} = Ax$ on $\mathbb{R}$ are not determined by the spectrum of A. However, such stability *is determined* by the spectrum of $\Gamma_{\mathbb{R}}$. This is made explicit by the following corollary of Remarks 2.4. The spectral bound $s(\Gamma_{\mathbb{R}})$ and the growth bound $\omega_0(E^t_{\mathbb{R}})$ for the evolution semigroup coincide and are equal to the growth bound of $\{e^{tA}\}_{t\geq 0}$:

$$s(\Gamma_{\mathbb{R}}) = \omega_0(E^t_{\mathbb{R}}) = \omega_0(e^{tA}).$$

One of the difficulties related to nonautonomous problems is that their associated evolution families are two-parameter families of operators. From this point of view, it would be of interest to define a *one-parameter* semigroup that is associated to the solutions of the nonautonomous Cauchy problem (2.1). For such a semigroup to be useful, its properties should be closely connected to the asymptotic behavior of

the original nonautonomous problem. Ideally, this semigroup would have a generator that plays the same significant role in determining the stability of the solutions as the operator A played in Lyapunov's classical stability theorem for finite-dimensional autonomous systems $\dot{x} = Ax$. This can, in fact, be done, and the operator of interest is the generator of the following *evolution semigroup* that is induced by the two-parameter evolution family: if $\mathcal{U} = \{U(t,\tau)\}_{t\geq\tau}$ is an evolution family, define operators $E^t_{\mathbb{R}}$, $t \geq 0$, on $\mathcal{F}_{\mathbb{R}} = L^p(\mathbb{R}, X)$ or $\mathcal{F}_{\mathbb{R}} = C_0(\mathbb{R}, X)$ by

$$(E^t_{\mathbb{R}} f)(\tau) = U(\tau, \tau - t) f(\tau - t), \quad \tau \in \mathbb{R}, \quad t \geq 0. \tag{2.4}$$

When $\mathcal{U}$ is exponentially bounded, this defines a strongly continuous evolution semigroup on $\mathcal{F}_{\mathbb{R}}$ whose generator will be denoted by $\Gamma_{\mathbb{R}}$. As shown in [23] and [34], the spectral mapping theorem (2.3) holds for this semigroup. Moreover, the existence of an exponential dichotomy for solutions to $\dot{x}(t) = A(t)x(t)$, $t \in \mathbb{R}$, is characterized by the condition that $\Gamma_{\mathbb{R}}$ is invertible on $\mathcal{F}_{\mathbb{R}}$. Note that in the autonomous case where $U(t,\tau) = e^{(t-\tau)A}$, this is the evolution semigroup defined in (2.2). In the nonautonomous case, the construction of an evolution semigroup is a way to "autonomize" a time-varying Cauchy problem by replacing the time-dependent differential equation $\dot{x} = A(t)x$ on X by an autonomous differential equation $\dot{f} = \Gamma f$ on a superspace of X-valued functions.

3. Evolution semigroups and Cauchy problems. In order to tackle the problem of characterizing the exponential stability of solutions to the nonautonomous Cauchy problem (2.1) on the half-line $\mathbb{R}_+$, the following variant of the above evolution semigroup is needed. As before, let $\{U(t,\tau)\}_{t\geq\tau}$ be an exponentially bounded evolution family, and define operators E^t, $t \geq 0$, on functions $f : \mathbb{R}_+ \to X$ by

$$(E^t f)(\tau) = \begin{cases} U(\tau, \tau - t) f(\tau - t), & 0 \leq t \leq \tau, \\ 0, & 0 \leq \tau < t. \end{cases} \tag{3.1}$$

This defines a strongly continuous semigroup of operators on the space of functions $\mathcal{F} = L^p(\mathbb{R}_+, X)$, and the generator of this *evolution semigroup* will be denoted by Γ. This also defines a strongly continuous semigroup on $C_{00}(\mathbb{R}_+, X) = \{f \in C_0(\mathbb{R}_+, X) : f(0) = 0\}$. For more information on evolution semigroups on the half-line, see also [27, 28, 29, 43].

3.1. Stability. The primary goal of this subsection is to identify the useful properties of the semigroup of operators defined in (3.1) which will be used in the subsequent sections. In particular, the following spectral mapping theorem will allow this semigroup to be used in characterizing the exponential stability of solutions to (2.1) on $\mathbb{R}_+$. See also [34, 43] for different proofs. The spectral symmetry portion of this theorem is due to Rau [38].

THEOREM 3.1. *Let $\mathcal{F}$ denote $C_{00}(\mathbb{R}_+, X)$ or $L^p(\mathbb{R}_+, X)$. The spectrum $\sigma(\Gamma)$ is a half-plane, the spectrum $\sigma(E^t)$ is a disk centered at the origin, and*

$$e^{t\sigma(\Gamma)} = \sigma(E^t) \setminus \{0\}, \quad t > 0. \tag{3.2}$$

Proof. The arguments for the two cases $\mathcal{F} = C_{00}(\mathbb{R}_+, X)$ and $\mathcal{F} = L^p(\mathbb{R}_+, X)$ are similar, so only the first one is considered here.

We first note that $\sigma(\Gamma)$ is invariant under translations along $i\mathbb{R}$, and $\sigma(E^t)$ is invariant under rotations about zero. This spectral symmetry is a consequence of the

fact that for $\xi \in \mathbb{R}$,

$$E^t e^{i\xi\cdot} f = e^{i\xi\cdot} e^{-i\xi t} E^t f, \quad \text{and} \quad \Gamma e^{i\xi\cdot} = e^{i\xi\cdot}(\Gamma - i\xi). \tag{3.3}$$

The inclusion $e^{t\sigma(\Gamma)} \subseteq \sigma(E^t) \setminus \{0\}$ follows from the standard spectral inclusion for strongly continuous semigroups [2]. In view of the spectral symmetry, it suffices to show that $\sigma(E^t) \cap \mathbb{T} = \emptyset$ whenever $0 \in \rho(\Gamma)$. To this end, we replace the Banach space X in Remarks 2.4 by $C_{00}(\mathbb{R}_+, X)$ and consider two semigroups $\{\tilde{E}^t\}_{t\geq 0}$ and $\{\mathcal{E}^t\}_{t\geq 0}$ with generators $\tilde{\Gamma}$ and $\mathcal{G}$, respectively, acting on the space $C_0(\mathbb{R}, C_{00}(\mathbb{R}_+, X))$. These semigroups are defined by

$$(\tilde{E}^t h)(\tau,\theta) = \begin{cases} U(\theta, \theta - t)h(\tau - t, \theta - t) & \text{for} \quad \theta \geq t, \\ 0 & \text{for} \quad 0 \leq \theta < t, \end{cases}$$

$$(\mathcal{E}^t h)(\tau,\theta) = \begin{cases} U(\theta, \theta - t)h(\tau, \theta - t) & \text{for} \quad \theta \geq t, \\ 0 & \text{for} \quad 0 \leq \theta \leq t, \end{cases}$$

where $\tau \in \mathbb{R}$ and $h(\tau, \cdot) \in C_{00}(\mathbb{R}_+, X)$. Note that if $H \in C_0(\mathbb{R}, C_{00}(\mathbb{R}_+, X))$, then $h(\tau, \cdot) := H(\tau) \in C_{00}(\mathbb{R}_+, X)$ and we recognize $\{\tilde{E}^t\}_{t\geq 0}$ as the evolution semigroup induced by $\{E^t\}_{t\geq 0}$, as in (2.2):

$$(\tilde{E}^t H)(\tau) = E^t H(\tau - t).$$

Also, the semigroup $\{\mathcal{E}^t\}_{t\geq 0}$ is the family of multiplication operators given by

$$(\mathcal{E}^t H)(\tau) = E^t H(\tau).$$

The generator $\mathcal{G}$ of this semigroup is the operator of multiplication by Γ: $(\mathcal{G}H)(\tau) = \Gamma(H(\tau))$, where $H(\tau) \in \mathrm{Dom}(\Gamma)$ for $\tau \in \mathbb{R}$. In particular, if $0 \in \rho(\Gamma)$ on $\mathcal{F}$, then $(\mathcal{G}^{-1}H)(\tau) = \Gamma^{-1}(H(\tau))$, and so $0 \in \rho(\mathcal{G})$.

Let J denote the isometry on $C_0(\mathbb{R}, C_{00}(\mathbb{R}_+, X))$ given by $(Jh)(\tau,\theta) = h(\tau+\theta, \theta)$ for $\tau \in \mathbb{R}$, $\theta \in \mathbb{R}_+$. Then J satisfies the identity

$$(\mathcal{E}^t J h)(\tau,\theta) = (J\tilde{E}^t h)(\tau,\theta), \quad \tau \in \mathbb{R}, \quad \theta \in \mathbb{R}_+.$$

It follows that $\mathcal{G}JH = J\tilde{\Gamma}H$ for $H \in \mathrm{Dom}(\tilde{\Gamma})$, and $J^{-1}\mathcal{G}H = \tilde{\Gamma}J^{-1}H$ for $H \in \mathrm{Dom}(\mathcal{G})$. Consequently, $\sigma(\mathcal{G}) = \sigma(\tilde{\Gamma})$ on $C_0(\mathbb{R}, C_{00}(\mathbb{R}_+, X))$. In particular, $0 \in \rho(\tilde{\Gamma})$. Therefore, $\sigma(E^t) \cap \mathbb{T} = \emptyset$ follows from Remarks 2.4 applied to the semigroup $\{E^t\}_{t\geq 0}$ on $\mathcal{F}$ in place of $\{e^{tA}\}_{t\geq 0}$ on X.

The facts that $\sigma(\Gamma)$ is a half-plane and $\sigma(E^t)$ is a disk follow from the spectral mapping property (3.2) and [38, Prop. 2]. □

An important consequence of this theorem is the property that the growth bound $\omega_0(E^t)$ equals the spectral bound $s(\Gamma)$. This leads to the following simple result on stability.

THEOREM 3.2. *Let $\mathcal{F}$ denote $C_{00}(\mathbb{R}_+, X)$ or $L^p(\mathbb{R}_+, X)$. An exponentially bounded evolution family $\{U(t,\tau)\}_{t\geq\tau}$ is exponentially stable if and only if the growth bound $\omega_0(E^t)$ of the induced evolution semigroup on $\mathcal{F}$ is negative.*

Proof. Let $\mathcal{F} = C_{00}(\mathbb{R}_+, X)$. If $\{U(t,\tau)\}_{t\geq\tau}$ is exponentially stable, then there exist $M > 1$, $\beta > 0$ such that $\|U(t,\tau)\|_{\mathcal{L}(X)} \leq Me^{-\beta(t-\tau)}$, $t \geq \tau$. For $\tau \geq 0$ and $f \in C_{00}(\mathbb{R}_+, X)$,

$$\begin{aligned} \|E^\tau f\|_{C_{00}(\mathbb{R}_+,X)} = \sup_{t>0} \|E^\tau f(t)\|_X &= \sup_{t>\tau} \|U(t, t-\tau) f(t-\tau)\|_X \\ &\leq \sup_{t>\tau} \|U(t, t-\tau)\|_{\mathcal{L}(X)} \|f(t-\tau)\|_X \\ &\leq Me^{-\beta\tau} \|f\|_{C_{00}(\mathbb{R}_+,X)}. \end{aligned}$$

Conversely, assume there exist $M > 1$, $\alpha > 0$ such that $\|E^t\| \le Me^{-\alpha t}$, $t \ge 0$. Let $x \in X$, $\|x\| = 1$. For fixed $t > \tau > 0$, choose $f \in C_{00}(\mathbb{R}_+, X)$ such that $\|f\|_{C_{00}(\mathbb{R}_+,X)} = 1$ and $f(\tau) = x$. Then,

$$\begin{aligned}\|U(t,\tau)x\|_X = \|U(t,\tau)f(\tau)\|_X &= \|E^{(t-\tau)}f(t)\|_X \\ &\le \sup_{\theta>0} \|E^{(t-\tau)}f(\theta)\|_X \\ &= \|E^{(t-\tau)}f\|_{C_{00}(\mathbb{R}_+,X)} \\ &\le Me^{-\alpha(t-\tau)}.\end{aligned}$$

A similar argument works for $\mathcal{F} = L^p(\mathbb{R}_+, X)$. □

The remainder of this subsection focuses on the operator used for determining exponential stability. In fact, stability is characterized by the boundedness of this operator which, as seen below, is equivalent to the invertibility of Γ, the generator of the evolution semigroup. We begin with the autonomous case.

Datko and van Neerven have characterized the exponential stability of solutions for autonomous equations $\dot{x} = Ax$, $t \ge 0$, in terms of a convolution operator $\mathbb{G}$ induced by $\{e^{tA}\}_{t\ge0}$. In this autonomous setting,

$$(E^t f)(\tau) = \begin{cases} e^{tA}f(\tau - t), & 0 \le t \le \tau, \\ 0, & 0 \le \tau < t, \end{cases} \tag{3.4}$$

and the convolution operator takes the following form: for $f \in L^1_{loc}(\mathbb{R}_+, X)$,

$$(\mathbb{G}f)(t) := \int_0^t e^{\tau A}f(t-\tau)\,d\tau = \int_0^\infty (E^\tau f)(t)\,d\tau, \quad t \ge 0. \tag{3.5}$$

For the reader's convenience, we cite Theorem 1.3 of [28] (see also [13]) in the following remarks.

Remarks 3.3. If $\{e^{tA}\}_{t\ge0}$ is a strongly continuous semigroup on X, and $1 \le p < \infty$, then the following are equivalent.

(i) $\omega_0(e^{tA}) < 0$.

(ii) $\mathbb{G}f \in L^p(\mathbb{R}_+, X)$ for all $f \in L^p(\mathbb{R}_+, X)$.

(iii) $\mathbb{G}f \in C_0(\mathbb{R}_+, X)$ for all $f \in C_0(\mathbb{R}_+, X)$.

Remarks 3.4.

(a) Note that condition (ii) is equivalent to the boundedness of $\mathbb{G}$ on $L^p(\mathbb{R}_+, X)$. To see this, it suffices to show that the map $f \mapsto \mathbb{G}f$ is a closed operator on $L^p(\mathbb{R}_+, X)$ and then to apply the closed graph theorem. For this, let $f_n \to f$ and $\mathbb{G}f_n \to g$ in $L^p(\mathbb{R}_+, X)$. Then $(\mathbb{G}f_n)(t) \to (\mathbb{G}f)(t)$ for each $t \in \mathbb{R}$. Also, every norm-convergent sequence in $L^p(\mathbb{R}_+, X)$ contains a subsequence that converges pointwise almost everywhere. Thus $(\mathbb{G}f_{n_k})(t) \to g(t)$ for almost all t. This implies that $\mathbb{G}f = g$, as claimed.

(b) Also, condition (iii) is equivalent to the boundedness of $\mathbb{G}$ on $C_0(\mathbb{R}_+, X)$. This follows from the uniform boundedness principle applied to the operators $\mathbb{G}_t : f \mapsto \int_0^t e^{\tau A}f(t-\tau)\,d\tau$.

We now extend this result so that it may be used to describe exponential stability for a nonautonomous equation. For this define an operator $\mathbb{G}$ in an analogous way: let $\{U(t,\tau)\}_{t\ge\tau}$ be an evolution family and $\{E^t\}_{t\ge0}$ the evolution semigroup in (3.1).

Then define $\mathbb{G}$ for $f \in L^1_{loc}(\mathbb{R}_+, X)$ as

$$(\mathbb{G}f)(t) := \int_0^\infty (E^\tau f)(t)\,d\tau = \int_0^t U(t, t-\tau)f(t-\tau)\,d\tau = \int_0^t U(t,\tau)f(\tau)\,d\tau, \qquad t \geq 0. \tag{3.6}$$

For $\mathbb{G}$ acting on $\mathcal{F} = C_{00}(\mathbb{R}_+, X)$ or $L^p(\mathbb{R}_+, X)$, standard semigroup properties show that $\mathbb{G}$ equals $-\Gamma^{-1}$ provided the semigroup $\{E^t\}_{t\geq 0}$ or the evolution family is uniformly exponentially stable. Parts (i) $\Leftrightarrow$ (ii) of Remarks 3.3 and the nonautonomous version below are the classical results by Datko [13]. Our proof uses the evolution semigroup and creates a formally autonomous problem so that Remarks 3.3 can be applied.

THEOREM 3.5. *The following are equivalent for the evolution family of operators* $\{U(t,\tau)\}_{t\geq\tau}$ *on* X.

(i) $\{U(t,\tau)\}_{t\geq\tau}$ *is exponentially stable.*

(ii) $\mathbb{G}$ *is a bounded operator on* $L^p(\mathbb{R}_+, X)$.

(iii) $\mathbb{G}$ *is a bounded operator on* $C_0(\mathbb{R}_+, X)$.

Before proceeding with the proof, note that statement (ii) is equivalent to the statement: $\mathbb{G}f \in L^p(\mathbb{R}_+, X)$ for each $f \in L^p(\mathbb{R}_+, X)$. This is seen as in Remark 3.4. See also [6] for similar facts.

Proof. By Theorem 3.2, (i) implies that $\{E^t\}_{t\geq 0}$ is exponentially stable, and formula (3.6) implies (ii) and (iii). The implication (ii)$\Rightarrow$(i) will be proved here; the argument for (iii)$\Rightarrow$(i) is similar. The main idea is again to use the "change-of-variables" technique, as in the proof of Theorem 3.1.

Consider the operator $\tilde{\mathbb{G}}$ on $L^p(\mathbb{R}, L^p(\mathbb{R}_+, X)) = L^p(\mathbb{R}\times\mathbb{R}_+, X)$ defined as multiplication by $\mathbb{G}$. More precisely, for $h \in L^p(\mathbb{R}\times\mathbb{R}_+, X)$ with $\mathbf{h}(\theta) := h(\theta, \cdot) \in L^p(\mathbb{R}_+, X)$, define

$$(\tilde{\mathbb{G}}h)(\theta, t) = \mathbb{G}(\mathbf{h}(\theta))(t) = \int_0^t U(t, t-\tau)h(\theta, t-\tau)\,d\tau, \quad t \in \mathbb{R}_+, \quad \theta \in \mathbb{R}.$$

In view of statement (ii), this operator is bounded. For the isometry J defined on the space $L^p(\mathbb{R}, L^p(\mathbb{R}_+, X))$ by $(Jh)(\theta, t) = h(\theta + t, t)$, we have

$$(J^{-1}\tilde{\mathbb{G}}Jh)(\theta, t) = \int_0^t U(t, t-\tau)h(\theta-\tau, t-\tau)\,d\tau. \tag{3.7}$$

Next, let $\{E^t\}_{t\geq 0}$ be the evolution semigroup (3.1) induced by $\{U(t,\tau)\}_{t\geq\tau}$, and define $\mathbb{G}_*$ to be the operator of convolution with this semigroup as in (3.5); that is,

$$(\mathbb{G}_*\mathbf{h})(\theta) = \int_0^\infty E^\tau \mathbf{h}(\theta-\tau)\,d\tau, \quad \mathbf{h} \in L^p(\mathbb{R}, L^p(\mathbb{R}_+, X)). \tag{3.8}$$

If $h(\theta, \cdot) = \mathbf{h}(\theta) \in L^p(\mathbb{R}_+, X)$, then by definition (3.1), evaluating (3.8) at t gives

$$[(\mathbb{G}_*\mathbf{h})(\theta)](t) = (\mathbb{G}_*h)(\theta, t) = \int_0^t U(t, t-\tau)h(\theta-\tau, t-\tau)\,d\tau, \quad t \in \mathbb{R}_+,\ \theta \in \mathbb{R}. \tag{3.9}$$

From (3.7) it follows that $\mathbb{G}_* = J^{-1}\tilde{\mathbb{G}}J$ is a bounded operator on $L^p(\mathbb{R}, L^p(\mathbb{R}_+, X))$.

Now, each function $\mathbf{h}_+ \in L^p(\mathbb{R}_+, L^p(\mathbb{R}_+, X))$ is an $L^p(\mathbb{R}_+, X)$-valued function on the half-line $\mathbb{R}_+$. We extend each such $\mathbf{h}_+$ to a function $\mathbf{h} \in L^p(\mathbb{R}, L^p(\mathbb{R}_+, X))$ by setting $\mathbf{h}(\theta) = \mathbf{h}_+(\theta)$ for $\theta \geq 0$ and $\mathbf{h}(\theta) = 0$ for $\theta < 0$. Note that $\mathbb{G}_*\mathbf{h} \in L^p(\mathbb{R}, L^p(\mathbb{R}_+, X))$ because $\mathbb{G}_*$ is bounded on $L^p(\mathbb{R}, L^p(\mathbb{R}_+, X))$. Consider the function $\mathbf{f}_+ : \mathbb{R}_+ \to L^p(\mathbb{R}_+, X)$ defined by

$$\mathbf{f}_+(t) = \int_0^t E^\tau \mathbf{h}_+(t-\tau)\, d\tau = \int_0^\infty E^\tau \mathbf{h}(t-\tau)\, d\tau, \quad t \in \mathbb{R}_+.$$

To complete the proof of the theorem, it suffices to prove the following claim:

$$\mathbf{f}_+ \in L^p(\mathbb{R}_+, L^p(\mathbb{R}_+, X)).$$

Indeed, the operator $\mathbf{h}_+ \mapsto \mathbf{f}_+$ is the convolution operator as in (3.5) defined by the semigroup operators E^t instead of e^{tA}. An application of Remarks 3.3 to E^t on $L^p(\mathbb{R}_+, X)$ (in place of e^{tA} on X) shows that the semigroup $\{E^t\}_{t\geq 0}$ is exponentially stable on $L^p(\mathbb{R}_+, X)$ provided that

$$\mathbf{f}_+ \in L^p(\mathbb{R}_+, L^p(\mathbb{R}_+, X)) \quad \text{for each } \mathbf{h}_+ \in L^p(\mathbb{R}_+, L^p(\mathbb{R}_+, X)).$$

But if $\{E^t\}_{t\geq 0}$ is exponentially stable, the evolution family $\{U(t,\tau)\}_{t\geq\tau}$ is exponentially stable by Theorem 3.2.

To prove the claim, apply formula (3.9) for $h(\theta, t) = h_+(\theta, t)$, $\theta \geq 0$, and $h(\theta, t) = 0$, $\theta < 0$, $t \in \mathbb{R}_+$, where $\mathbf{h}_+(\theta) = h_+(\theta, \cdot)$. This gives

$$(\mathbb{G}_* h)(\theta, t) = \begin{cases} \displaystyle\int_0^{\min\{\theta,t\}} U(t, t-\tau) h_+(\theta-\tau, t-\tau)\, d\tau & \text{for} \quad \theta \geq 0,\ t \in \mathbb{R}_+, \\ (\mathbb{G}_* h)(\theta, t) = 0 & \text{for} \quad \theta < 0,\ t \in \mathbb{R}_+. \end{cases}$$

Thus the function

$$\theta \mapsto (\mathbb{G}_* h)(\theta, \cdot) = (\mathbb{G}_* \mathbf{h})(\theta) \in L^p(\mathbb{R}_+, X)$$

is in the space $L^p(\mathbb{R}_+, L^p(\mathbb{R}_+, X))$. On the other hand, denoting $f_+(\theta, \cdot) := \mathbf{f}_+(\theta) \in L^p(\mathbb{R}_+, X)$, we have that

$$f_+(\theta, t) = \int_0^{\min\{\theta,t\}} U(t, t-\tau) h_+(\theta-\tau, t-\tau)\, d\tau, \quad \theta, t \in \mathbb{R}_+.$$

Thus $\theta \mapsto f_+(\theta, \cdot) = (\mathbb{G}_* h)(\theta, \cdot)$ is a function in $L^p(\mathbb{R}_+, L^p(\mathbb{R}_+, X))$, and the claim is proved. □

This theorem makes explicit, in the case of the half-line $\mathbb{R}_+$, the relationship between the stability of an evolution family $\{U(t,\tau)\}_{t\geq\tau}$ and the generator Γ of the corresponding evolution semigroup (3.1). Indeed, as shown above, stability is equivalent to the boundedness of $\mathbb{G}$, in which case $\mathbb{G} = -\Gamma^{-1}$. Combining Theorems 3.1, 3.2, and 3.5 yields the following corollary.

COROLLARY 3.6. *Let $\{U(t,\tau)\}_{t\geq\tau}$ be an exponentially bounded evolution family and let Γ denote the generator of the induced evolution semigroup on $L^p(\mathbb{R}_+, X)$, $1 \leq p < \infty$, or $C_{00}(\mathbb{R}_+, X)$. The following are equivalent.*

(i) *$\{U(t,\tau)\}_{t\geq\tau}$ is exponentially stable.*

(ii) *Γ is invertible with $\Gamma^{-1} = -\mathbb{G}$.*

(iii) *$s(\Gamma) < 0$.*

For more information on stability and dichotomy of evolution families on the semiaxis see [27].

3.2. Perturbations and robust stability. This subsection briefly considers perturbations of (2.1) of the form

$$\dot{x}(t) = (A(t) + D(t))x(t), \quad t \geq 0. \tag{3.10}$$

It will not, however, be assumed that (3.10) has a differentiable solution. For example, let $\{e^{tA_0}\}_{t\geq 0}$ be a strongly continuous semigroup generated by A_0, let $A_1(t) \in \mathcal{L}(X)$ for $t \geq 0$, and define $A(t) = A_0 + A_1(t)$. Then even if $t \mapsto A_1(t)$ is continuous, the Cauchy problem (2.1) may not have a differentiable solution for all initial conditions $x(0) = x \in \mathrm{Dom}(A) = \mathrm{Dom}(A_0)$ (see, e.g., [31]). Therefore we will want our development to allow for equations with solutions that exist only in the following mild sense.

Let $\{U(t,\tau)\}_{t\geq\tau}$ be an evolution family of operators corresponding to a solution of (2.1), and consider the nonautonomous inhomogeneous equation

$$\dot{x}(t) = A(t)x(t) + f(t), \qquad t \geq 0, \tag{3.11}$$

where f is a locally integrable X-valued function on $\mathbb{R}_+$. A function $x(\cdot)$ is a mild solution of (3.11) with initial value $x(\theta) = x_\theta \in \mathrm{Dom}(A(\theta))$ if

$$x(t) = U(t,\theta)x_\theta + \int_\theta^t U(t,\tau)f(\tau)\,d\tau, \quad t \geq \theta.$$

Given operators $D(t)$, the existence of mild solutions to an additively perturbed (3.10) corresponds to the existence of an evolution family $\{U_1(t,\tau)\}_{t\geq\tau}$ satisfying

$$U_1(t,\theta)x = U(t,\theta)x + \int_\theta^t U(t,\tau)D(\tau)U_1(\tau,\theta)x\,d\tau \tag{3.12}$$

for all $x \in X$. It will be assumed that the perturbation operators $D(t)$ are strongly measurable and essentially bounded functions of t. In view of this, we use the notation $\mathcal{L}_s(X)$ to denote the set $\mathcal{L}(X)$ endowed with the strong operator topology, and we use $L^\infty(\mathbb{R}_+, \mathcal{L}_s(X))$ to denote the set of bounded, strongly measurable $\mathcal{L}(X)$-valued functions on $\mathbb{R}_+$. A function $D(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(X))$ induces a multiplication operator $\mathcal{D}$ defined by $\mathcal{D}x(t) = D(t)x(t)$ for $x(\cdot) \in L^p(\mathbb{R}_+, X)$. In fact, $\mathcal{D}$ is a bounded operator on $L^p(\mathbb{R}_+, X)$ with $\|\mathcal{D}\| \leq \|D(\cdot)\|_\infty := \operatorname{ess\,sup}_{t\in\mathbb{R}_+} \|D(t)\|$.

Evolution semigroups induced by an evolution family as in (3.1) have been studied by several authors who have characterized such semigroups in terms of their generators on general Banach function spaces of X-valued functions (see [36, 43] and the bibliographies therein). The sets $\mathcal{F} = L^p(\mathbb{R}_+, X)$ or $\mathcal{F} = C_{00}(\mathbb{R}_+, X)$ considered here are examples of more general "Banach function spaces." In the development that follows we use a theorem of Schnaubelt [43] (see also Räbiger et al. [35, 36]) which shows exactly when a strongly continuous semigroup on $\mathcal{F}$ arises from a strongly continuous evolution family on X. We state a version of this result which will be used below; a more general version is proven in [36]. The set $C_c^1(\mathbb{R}_+)$ consists of differentiable functions on $\mathbb{R}_+$ that have compact support.

THEOREM 3.7. *Let $\{T^t\}_{t\geq 0}$ be a strongly continuous semigroup generated by Γ on $\mathcal{F}$. The following are equivalent.*

(i) *$\{T^t\}_{t\geq 0}$ is an evolution semigroup; i.e., there exists an exponentially bounded evolution family so that T^t is defined as in* (3.1).

(ii) *There exists a core, $\mathcal{C}$, of Γ such that for all $\varphi \in C_c^1(\mathbb{R}_+)$ and $f \in \mathcal{C}$, it follows that $\varphi f \in \mathrm{Dom}(\Gamma)$ and $\Gamma(\varphi f) = -\varphi' f + \varphi\Gamma f$. Moreover, there exists $\lambda \in \rho(\Gamma)$ such that $R(\lambda,\Gamma) : \mathcal{F} \to C_{00}(\mathbb{R}_+, X)$ is continuous with dense range.*

Now let $\{U(t,\tau)\}_{t\geq\tau}$ be an evolution family on X, and let Γ be the generator of the corresponding evolution semigroup, $\{E^t\}_{t\geq 0}$, as in (3.1). If $D(\cdot)\in L^\infty(\mathbb{R}_+,\mathcal{L}_s(X))$, then the multiplication operator $\mathcal{D}$ is a bounded operator on $\mathcal{F}=L^p(\mathbb{R}_+,X)$. Since a bounded perturbation of a generator of a strongly continuous semigroup is itself such a generator, the operator $\Gamma_1=\Gamma+\mathcal{D}$ generates a strongly continuous semigroup, $\{E_1^t\}_{t\geq 0}$ on $\mathcal{F}$ (see, e.g., [30]). In fact, Γ_1 generates an *evolution* semigroup; see [35, 43].

PROPOSITION 3.8. *Let $D(\cdot)\in L^\infty(\mathbb{R}_+,\mathcal{L}_s(X))$, and let $\{U(t,\tau)\}_{t\geq\tau}$ be an exponentially bounded evolution family. Then there exists a unique evolution family $\mathcal{U}_1=\{U_1(t,\tau)\}_{t\geq\tau}$ which solves the integral equation* (3.12)*. Moreover, $\mathcal{U}_1$ is exponentially stable if and only if $\Gamma+\mathcal{D}$ is invertible.*

Proof. As already observed, $\Gamma_1=\Gamma+\mathcal{D}$ generates a strongly continuous semigroup, $\{E_1^t\}_{t\geq 0}$ on $\mathcal{F}$. To see that this is in fact an evolution semigroup, note that for $\lambda\in\rho(\Gamma)\cap\rho(\Gamma_1)$,

$$\mathrm{Range}(R(\lambda,\Gamma))=\mathrm{Dom}(\Gamma)=\mathrm{Dom}(\Gamma+\mathcal{D})=\mathrm{Range}(R(\lambda,\Gamma_1))$$

is dense in $C_{00}(\mathbb{R}_+,X)$. Also, if $\mathcal{C}$ is a core for Γ, then it is a core for Γ_1, and so for $\varphi\in C_c^1(\mathbb{R})$, $f\in\mathcal{C}$,

$$\Gamma_1(\varphi f)=\Gamma(\varphi f)+\mathcal{D}(\varphi f)=-\varphi' f+\varphi\Gamma f+\varphi\mathcal{D}f=-\varphi' f+\varphi(\Gamma+\mathcal{D})f.$$

Consequently, Theorem 3.7 shows that $\{E_1^t\}_{t\geq 0}$ corresponds to an evolutionary family, $\{U_1(t,\tau)\}_{t\geq\tau}$. Moreover, $x(t)=U_1(t,\tau)x(\tau)$ is seen to define a mild solution to (3.10). Indeed,

$$E_1^t f=E^t f+\int_0^t E^{(t-\tau)}\mathcal{D}E_1^\tau f\,d\tau \tag{3.13}$$

holds for all $f\in F$. In particular, for $x\in X$ and any $\varphi\in C_c^1(\mathbb{R})$, setting $f=\varphi\otimes x$ in (3.13), where $\varphi\otimes x(t)=\varphi(t)x$, and using a change of variables leads to

$$\varphi(\theta)U_1(t,\theta)x=\varphi(\theta)U(t,\theta)x+\varphi(\theta)\int_\theta^t U(t,\tau)D(\tau)U_1(\tau,\theta)x\,d\tau.$$

Therefore, (3.12) holds for all $x\in X$.

Finally, Corollary 3.6 shows that $\mathcal{U}_1$ is exponentially stable if and only if Γ_1 is invertible. ∎

The existence of mild solutions under bounded perturbations of this type is well known (see, e.g., [10]), but an immediate consequence of the approach given here is the property of robustness for the stability of $\{U(t,\tau)\}_{t\geq\tau}$. Indeed, by continuity properties of the spectrum of an operator Γ, there exists $\epsilon>0$ such that Γ_1 is invertible whenever $\|\Gamma_1-\Gamma\|<\epsilon$; that is, $\{U_1(t,\tau)\}_{t\geq\tau}$ is exponentially stable whenever $\|D(\cdot)\|_\infty<\epsilon$. Also, the type of proof presented here can be extended to address the case of unbounded perturbations. For an example of this, we refer to [36]. Finally, and most important to the present paper, is the fact that this approach provides insight into the concept of the stability radius. This topic is studied next.

4. Stability radius. The goal of this section is to use the previous development to study the (complex) stability radius of an exponentially stable system. Loosely speaking, this is a measurement on the size of the smallest operator under which the additively perturbed system loses exponential stability. This is an important concept

for linear systems theory and was introduced by Hinrichsen and Pritchard as the basis for a state-space approach to studying robustness of linear time-invariant [17] and time-varying systems [16, 18, 32]. A systematic study of various stability radii in the spirit of the current paper has recently be given by Fischer and van Neerven [14].

4.1. General estimates. In this subsection we give estimates for the stability radius of general nonautonomous systems on Banach spaces. The perturbations considered here are additive "structured" perturbations of output feedback type. That is, let U and Y be Banach spaces, and let $\Delta(t) : Y \to U$ denote an unknown disturbance operator. The operators $B(t) : U \to X$ and $C(t) : X \to Y$ describe the structure of the perturbation in the following (formal) sense: if $u(t) = \Delta(t)y(t)$ is viewed as a feedback for the system

$$\begin{aligned} &\dot{x}(t) = A(t)x(t) + B(t)u(t), \qquad x(s) = x_s \in \mathrm{Dom}(A(s)),\\ &y(t) = C(t)x(t), \quad t \geq s \geq 0, \end{aligned} \tag{4.1}$$

then the nominal system $\dot{x}(t) = A(t)x(t)$ is subject to the structured perturbation

$$\dot{x}(t) = (A(t) + B(t)\Delta(t)C(t))x(t), \quad t \geq 0. \tag{4.2}$$

In this section B and C do not represent input and output operators; rather, they describe the structure of the uncertainty of the system. Also, systems considered throughout this paper are not assumed to have differentiable solutions, and so (4.2) is to be interpreted in the mild sense as described in (3.12), where $D(t) = B(t)\Delta(t)C(t)$. Similarly, (4.1) is interpreted in the mild sense; that is, there exists a strongly continuous exponentially bounded evolution family $\{U(t,\tau)\}_{t\geq\tau}$ on a Banach space X which satisfies

$$\begin{aligned} &x(t) = U(t,s)x(s) + \int_s^t U(t,\tau)B(\tau)u(\tau)\,d\tau,\\ &y(t) = C(t)x(t), \qquad t \geq s \geq 0. \end{aligned} \tag{4.3}$$

In the case of time-invariant systems, (4.3) takes the form

$$\begin{aligned} &x(t) = e^{tA}x_0 + \int_0^t e^{(t-\tau)A}Bu(\tau)\,d\tau,\\ &y(t) = Cx(t), \qquad t \geq 0, \end{aligned} \tag{4.4}$$

where $\{e^{tA}\}_{t\geq 0}$ is a strongly continuous semigroup on X generated by A, $x(0) = x_0 \in \mathrm{Dom}(A)$.

It should be emphasized that we will not address questions concerning the existence of solutions for a perturbed system (4.2) beyond the point already discussed in Proposition 3.8. In view of that proposition, we make the following assumptions: B, C, and Δ are strongly measurable and essentially bounded functions of t; i.e., $B(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(U,X))$, $C(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(X,Y))$, and $\Delta(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(Y,U))$. As such, they induce bounded multiplication operators, $\mathcal{B}$, $\mathcal{C}$, and $\tilde{\Delta}$ acting on the spaces $L^p(\mathbb{R}_+, U)$, $L^p(\mathbb{R}_+, X)$, and $L^p(\mathbb{R}_+, Y)$, respectively.

Next, for an exponentially bounded evolution family $\{U(t,\tau)\}_{t\geq\tau}$, define the "input-output" operator $\mathbb{L}$ on functions $u : \mathbb{R}_+ \to U$ by the rule

$$(\mathbb{L}u)(t) = C(t)\int_0^t U(t,\tau)B(\tau)u(\tau)\,d\tau.$$

Using the above notation, note that $\mathbb{L} = \mathcal{C}\mathbb{G}\mathcal{B}$. Much of the stability analysis that follows is based on this observation in combination with Theorem 3.5 which shows that the operator $\mathbb{G}$ completely characterizes stability of the corresponding evolution family.

We now turn to the definition of the stability radius. For this let $\mathcal{U} = \{U(t,\tau)\}_{t\geq\tau}$ be an exponentially stable evolution family on X. Set $\mathcal{D} = \mathcal{B}\tilde{\Delta}\mathcal{C}$, and let $\mathcal{U}_\Delta = \{U_\Delta(t,\tau)\}_{t\geq\tau}$ denote the evolution family corresponding to solutions of the perturbed equation (3.10). That is, $\mathcal{U}_\Delta$ satisfies

$$U_\Delta(t,s)x = U(t,s)x + \int_s^t U(t,\tau)B(\tau)\Delta(\tau)C(\tau)U_\Delta(\tau,s)x\,d\tau, \qquad x \in X.$$

Define the (complex) *stability radius* for $\mathcal{U}$ with respect to the perturbation structure $(B(\cdot), C(\cdot))$ as the quantity

$$r_{stab}(\mathcal{U}, B, C) = \sup\{r \geq 0 : \|\Delta(\cdot)\|_\infty \leq r \Rightarrow \mathcal{U}_\Delta \text{ is exponentially stable}\}.$$

This definition applies to both nonautonomous and autonomous systems, though in the latter case the notation $r_{stab}(\{e^{tA}\}, B, C))$ will be used to distinguish the case where all the operators except $\Delta(t)$ are independent of t. We will have occasion to consider the *constant stability radius* which is defined for the case in which $\Delta(t) \equiv \Delta$ is constant; this will be denoted by $rc_{stab}(\{e^{tA}\}, B, C))$ or $rc_{stab}(\mathcal{U}, B, C))$, depending on the context. The above remarks concerning $\Gamma + \mathcal{D}$ (see Proposition 3.8), when combined with Theorem 3.2, make it clear that

$$r_{stab}(\mathcal{U}, B, C) = \sup\{r \geq 0 : \|\Delta(\cdot)\|_\infty \leq r \Rightarrow \Gamma + \mathcal{B}\tilde{\Delta}\mathcal{C} \text{ is invertible}\}. \tag{4.5}$$

It is well known that for autonomous systems in which U and Y are Hilbert spaces and $p = 2$, the stability radius may be expressed in terms of the norm of the input-output operator or the transfer function

$$\frac{1}{\|\mathbb{L}\|_{\mathcal{L}(L^2)}} = r_{stab}(\{e^{tA}\}, B, C) = \frac{1}{\sup_{s\in\mathbb{R}} \|C(A - is)^{-1}B\|}; \tag{4.6}$$

see, e.g., [18, Thm. 3.5]. For nonautonomous equations, a scalar example given in Example 4.4 of [16] shows that, in general, a strict inequality $1/\|\mathbb{L}\| < r_{stab}(\mathcal{U}, B, C)$ may hold. Moreover, even for autonomous systems, when Banach spaces are allowed or when $p \neq 2$, Example 4.13 and Example 4.15 below will show that neither of the equalities in (4.6) necessarily hold. Subsection 4.3 focuses on autonomous equations, and a primary objective there is to prove the following result.

THEOREM 4.1. *For the general autonomous systems,*

$$\frac{1}{\|\mathbb{L}\|_{\mathcal{L}(L^p)}} \leq r_{stab}(\{e^{tA}\}, B, C) \leq \frac{1}{\sup_{s\in\mathbb{R}} \|C(A - is)^{-1}B\|}, \quad 1 \leq p < \infty. \tag{4.7}$$

As seen next, the lower bound here holds for general nonautonomous systems and may be proven in a very direct way using the make-up of the operator $\mathbb{L} = \mathcal{C}\mathbb{G}\mathcal{B}$. This lower bound is also proven in [18, Thm. 3.2] using a completely different approach.

THEOREM 4.2. *Assume $\mathcal{U}$ is an exponentially stable evolution family, and let Γ denote the generator of the corresponding evolution semigroup. If*

$$B(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(U, X)) \quad \textit{and} \quad C(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(X, Y)),$$

then $\mathbb{L}$ is a bounded operator from $L^p(\mathbb{R}_+, U)$ to $L^p(\mathbb{R}_+, Y)$, $1 \le p < \infty$, the formula

$$\mathbb{L} = \mathcal{C}\mathbb{G}\mathcal{B} = -\mathcal{C}\Gamma^{-1}\mathcal{B}$$

holds, and

$$\frac{1}{\|\mathbb{L}\|} \le r_{stab}(\mathcal{U}, B, C). \tag{4.8}$$

In the "unstructured" case, where $U = Y = X$ and $B = C = I$, one has

$$\mathbb{L} = -\Gamma^{-1}, \quad \text{and} \quad \frac{1}{\|\Gamma^{-1}\|} \le r_{stab}(\mathcal{U}, I, I) \le \frac{1}{r(\Gamma^{-1})},$$

where $r(\cdot)$ denotes the spectral radius.

Proof. Since $\mathcal{U}$ is exponentially stable, Γ is invertible and $\Gamma^{-1} = -\mathbb{G}$. The required formula for $\mathbb{L}$ follows from (3.6).

Set $\mathcal{H} := \Gamma^{-1}\mathcal{B}\tilde{\Delta}$. To prove (4.8), let $\Delta(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(Y, U))$ and suppose that $\|\Delta(\cdot)\|_\infty < 1/\|\mathbb{L}\|$. Then $\|\mathbb{L}\tilde{\Delta}\| < 1$, and hence $I - \mathbb{L}\tilde{\Delta} = I + \mathcal{C}\Gamma^{-1}\mathcal{B}\tilde{\Delta}$ is invertible on $L^p(\mathbb{R}_+, Y)$. That is, $I + \mathcal{C}\mathcal{H}$ is invertible on $L^p(\mathbb{R}_+, Y)$, and hence $I + \mathcal{H}\mathcal{C}$ is invertible on $L^p(\mathbb{R}_+, X)$ (with inverse $(I - \mathcal{H}(I + \mathcal{C}\mathcal{H})^{-1}\mathcal{C})$). Now

$$\Gamma + \mathcal{B}\tilde{\Delta}\mathcal{C} = \Gamma(I + \Gamma^{-1}\mathcal{B}\tilde{\Delta}\mathcal{C}) = \Gamma(I + \mathcal{H}\mathcal{C}),$$

and so $\Gamma + \mathcal{B}\tilde{\Delta}\mathcal{C}$ is invertible. It follows from the expression (4.5) that $1/\|\mathbb{L}\| \le r_{stab}(\mathcal{U}, B, C)$.

For the last assertion, suppose that $r_{stab}(\mathcal{U}, I, I) > 1/r(\Gamma^{-1})$. Then there exists λ such that $|\lambda| = r(\Gamma^{-1})$ and $\lambda + \Gamma^{-1}$ is not invertible. But then setting $\tilde{\Delta} \equiv \frac{1}{\lambda}$ gives $\|\tilde{\Delta}\| = \frac{1}{|\lambda|} < r_{stab}(\mathcal{U}, I, I)$, and so $\Gamma + \tilde{\Delta} = \tilde{\Delta}(\lambda + \Gamma^{-1})\Gamma$ is invertible, which is a contradiction. ∎

4.2. The transfer function for nonautonomous systems. In this subsection we consider a time-varying version of (4.6) and then observe that the concept of a transfer function, or frequency-response function, arises naturally from these ideas. For this we assume in this subsection that X, U, and Y are Hilbert spaces and $p = 2$.

Let $\{U(t, \tau)\}_{t \ge \tau}$ be a uniformly exponentially stable evolution family, and let $\{E^t\}_{t \ge 0}$ be the induced evolution semigroup with generator Γ on $L^2(\mathbb{R}_+, X)$. Recall that $\mathcal{B}$ and $\mathcal{C}$ denote multiplication operators, with respective multipliers $B(\cdot)$ and $C(\cdot)$, that act on the spaces $L^2(\mathbb{R}_+, U)$ and $L^2(\mathbb{R}_+, X)$, respectively. Let $\tilde{\mathcal{B}}$ and $\tilde{\mathcal{C}}$ denote operators of multiplication induced by $\mathcal{B}$ and $\mathcal{C}$, respectively; e.g., $(\tilde{\mathcal{B}}\mathbf{u})(t) = \mathcal{B}(\mathbf{u}(t))$ for $\mathbf{u} : \mathbb{R}_+ \to L^2(\mathbb{R}_+, U)$. Now consider the operator $\mathbb{G}_*$ as defined in (3.8) and note that operator $\mathbb{L}_* := \tilde{\mathcal{C}}\mathbb{G}_*\tilde{\mathcal{B}}$ may be viewed (formally) as an input-output operator for the "autonomized" system $\dot{f} = \Gamma f + \mathcal{B}u, \ \ g = \mathcal{C}f,$ where the state space is $L^2(\mathbb{R}_+, X)$. It follows from the known Hilbert-space equalities in (4.6) that

$$\frac{1}{\|\mathbb{L}_*\|} = r_{stab}(\{E^t\}, \mathcal{B}, \mathcal{C}) = \frac{1}{\sup_{s \in \mathbb{R}} \|\mathcal{C}(\Gamma - is)^{-1}\mathcal{B}\|}.$$

Note, however, that the rescaling identities (3.3) for Γ imply that

$$\|\mathbb{L}_*\| = \|\mathcal{C}(\Gamma - is)^{-1}\mathcal{B}\| = \|\mathcal{C}\Gamma^{-1}\mathcal{B}\| = \|\mathbb{L}\|,$$

and so the stability radius for the evolution semigroup is also $1/\|\mathbb{L}\|$. In view of the above-mentioned nonautonomous scalar example for which $1/\|\mathbb{L}\| < r_{stab}(\mathcal{U}, B, C)$, we

see that even though the evolution semigroup (or its generator) completely determines the exponential stability of a system, it does not provide a formula for the stability radius.

However, the operator $\mathcal{C}(\Gamma - is)^{-1}\mathcal{B}$ appearing above suggests that the transfer function for time-varying systems arises naturally when viewed in the context of evolution semigroups. Several authors have considered the concept of a transfer function for nonautonomous systems, but the work of Ball, Gohberg, and Kaashoek [4] seems to be the most comprehensive in providing a system-theoretic input-output interpretation for the value of such a transfer function at a point. Their interpretation justifies the term *frequency-response* function for time-varying finite-dimensional systems with "time-varying complex exponential inputs." Our remarks concerning the frequency response for time-varying infinite-dimensional systems will be restricted to inputs of the form $u(t) = u_0 e^{\lambda t}$.

For motivation, consider the input-output operator $\mathbb{L}$ associated with an autonomous system (4.4) where the nominal system is exponentially stable. The *transfer function* of $\mathbb{L}$ is the unique bounded analytic $\mathcal{L}(U, Y)$-valued function H, defined on $\mathbb{C}_+ = \{\lambda \in \mathbb{C} : \operatorname{Re} \lambda > 0\}$ such that for any $u \in L^2(\mathbb{R}_+, U)$,

$$(\widehat{\mathbb{L}u})(\lambda) = H(\lambda)\hat{u}(\lambda), \qquad \lambda \in \mathbb{C}_+,$$

where $\widehat{\ }$ denotes the Laplace transform (see, e.g., [44]). In this autonomous setting, A generates a uniformly exponentially stable strongly continuous semigroup, and $\mathbb{L} = \mathcal{C}\mathbb{G}\mathcal{B}$, where $\mathbb{G}$ is the operator of convolution with the semigroup operators e^{tA} (see (3.5)). Standard arguments show that $(\widehat{\mathbb{L}u})(\lambda) = C(\lambda - A)^{-1}B\hat{u}(\lambda)$; that is, $H(\lambda) = C(\lambda - A)^{-1}B$.

Now let $\mathbb{L}$ be the input-output operator for the nonautonomous system (4.3). We wish to identify the transfer function of $\mathbb{L}$ as the Laplace transform of the appropriate operator. We are guided by the fact that, just as $(\lambda - A)^{-1}$ may be expressed as the Laplace transform of the semigroup generated by A, the operator $(\lambda - \Gamma)^{-1}$ is the Laplace transform of the evolution semigroup. For nonautonomous systems, $\mathbb{L}$ is again given by $\mathcal{C}\mathbb{G}\mathcal{B}$, although now $\mathbb{G}$ from (3.6) is not, generally, a convolution operator. So instead recall the operator $\mathbb{G}_*$ from (3.8) which *is* the operator of convolution with the evolution semigroup $\{E^t\}_{t\geq 0}$. As noted above, the operator $\mathbb{L}_* := \tilde{\mathcal{C}}\mathbb{G}_*\tilde{\mathcal{B}}$ may be viewed as an input-output operator for an autonomous system (where the state space is $L^2(\mathbb{R}_+, X)$). Therefore, the autonomous theory applies directly to show that, for $\mathbf{u} \in L^2(\mathbb{R}_+, L^2(\mathbb{R}_+, U))$,

$$(\widehat{\mathbb{L}_*\mathbf{u}})(\lambda) = \mathcal{C}(\lambda - \Gamma)^{-1}\mathcal{B}\hat{\mathbf{u}}(\lambda). \tag{4.9}$$

In other words, the transfer function for $\mathbb{L}_*$ is $\mathcal{C}(\lambda - \Gamma)^{-1}\mathcal{B}$, where

$$\mathcal{C}(\lambda - \Gamma)^{-1}\mathcal{B}u = \mathcal{C}\int_0^\infty e^{-\lambda\tau}E^\tau\mathcal{B}u\,d\tau, \qquad u \in L^2(\mathbb{R}_+, U).$$

Evaluating these expressions at $t \in \mathbb{R}_+$ gives

$$[\mathcal{C}(\lambda - \Gamma)^{-1}\mathcal{B}u](t) = \int_0^t C(t)U(t,\tau)B(\tau)u(\tau)e^{-\lambda(t-\tau)}\,d\tau. \tag{4.10}$$

It is natural to call $\mathcal{C}(\lambda - \Gamma)^{-1}\mathcal{B}$ the transfer function for the nonautonomous system. Moreover, the following remarks show that, by looking at the right-hand side of

(4.10), this gives a natural frequency-response function for nonautonomous systems. To see this, we first consider autonomous systems and note that the definition of the transfer function for an autonomous system can be extended to allow for a class of "Laplace transformable" functions that are in $L^2_{loc}(\mathbb{R}_+, U)$ (see, e.g., [44]). This class includes constant functions of the form $v_0(t) = u_0$, $t \geq 0$, for a given $u_0 \in U$. If a periodic input signal of the form $u(t) = u_0 e^{i\omega t}$, $t \geq 0$, (for some $u_0 \in U$ and $\omega \in \mathbb{R}$) is fed into an autonomous system with initial condition $x(0) = x_0$, then, by definition of the input-output operator, we have

$$(\mathbb{L}u)(t) = C(i\omega - A)^{-1}Bu_0 \cdot e^{i\omega t} - Ce^{tA}x_0, \quad (\mathbb{L}u)(t) = C\int_0^t e^{(t-s)A}Bu(s)\,ds.$$

Thus the output

$$y(t; u(\cdot), x_0) = (\mathbb{L}u)(t) + Ce^{tA}x_0 = C(i\omega - A)^{-1}Bu_0 \cdot e^{i\omega t}$$

has the same frequency as the input. In view of this, the function $C(i\omega - A)^{-1}B$ is sometimes called the frequency-response function. Now recall that the semigroup $\{e^{tA}\}_{t\geq 0}$ is stable and so $\lim_{t\to\infty} \|Ce^{tA}x_0\| = 0$. On the other hand, consider $v(t) = u_0$ and (formally) apply $\mathcal{C}(i\omega - \Gamma)^{-1}\mathcal{B}$ to this v. For $x_0 = (i\omega - A)^{-1}Bu_0$, a calculation based on the Laplace transform formula for the resolvent of the generator (applied to the evolution semigroup $\{E^t\}_{t\geq 0}$) yields the identity

$$\left[\mathcal{C}(i\omega - \Gamma)^{-1}\mathcal{B}u_0\right](t) = C(i\omega - A)^{-1}Bu_0 - Ce^{tA}x_0 \cdot e^{-i\omega t}.$$

Let us consider this expression $[\mathcal{C}(i\omega - \Gamma)^{-1}\mathcal{B}u_0](t)$ in the nonautonomous case. By (4.10), this coincides with the frequency-response function for time-varying systems which is defined in [4, Cor. 3.2] by the formula

$$\int_0^t C(t)U(t,\tau)B(\tau)u_0 e^{i\omega(\tau - t)}\,d\tau.$$

Also, as noted in this reference, the result of our derivation agrees with the Arveson frequency-response function as it appears in [42]. We recover it here explicitly as the Laplace transform of an input-output operator (see (4.9)).

4.3. Autonomous systems. In this subsection we give the proof of (4.7) when X, U, and Y are Banach spaces. In the process, however, we also consider two other "stability radii": a pointwise stability radius and a dichotomy radius.

First, we give a generalization to Banach spaces of Theorem 2.1 (cf. [23]). Here, $\mathcal{F}_{per}$ denotes the Banach space $L^p([0, 2\pi], X)$, $1 \leq p < \infty$. If $\{e^{tA}\}_{t\geq 0}$ is a strongly continuous semigroup on X, $\{E^t_{per}\}_{t\geq 0}$ will denote the evolution semigroup defined on $\mathcal{F}_{per}$ by the rule $E^t_{per}f(s) = e^{tA}f([s - t](\mathrm{mod}\, 2\pi))$; its generator will be denoted by Γ_{per}. The symbol Λ will be used to denote the set of all finite sequences $\{v_k\}_{k=-N}^N$ in X or $\mathcal{D}(A)$, or $\{u_k\}_{k=-N}^N$ in U.

THEOREM 4.3. *Let A generate a C_0 semigroup $\{e^{tA}\}_{t\geq 0}$ on X. Let B and C be as above, and $\Delta \in (Y, U)$. Let $\{e^{t(A+B\Delta C)}\}_{t\geq 0}$ be the strongly continuous semigroup generated by $A + B\Delta C$. Then the following are equivalent.*

(i) $1 \in \rho(e^{2\pi(A+B\Delta C)})$.

(ii) $i\mathbb{Z} \subset \rho(A + B\Delta C)$ *and*

$$\sup_{\{v_k\}\in\Lambda} \frac{\|\sum_k (A - ik + B\Delta C)^{-1}v_k e^{ik(\cdot)}\|_{\mathcal{F}_{per}}}{\|\sum_k v_k e^{ik(\cdot)}\|_{\mathcal{F}_{per}}} < \infty.$$

(iii) $i\mathbb{Z} \subset \rho(A + B\Delta C)$ *and*

$$\inf_{\{v_k\}\in\Lambda} \frac{\|\sum_k (A - ik + B\Delta C)v_k e^{ik(\cdot)}\|_{\mathcal{F}_{per}}}{\|\sum_k v_k e^{ik(\cdot)}\|_{\mathcal{F}_{per}}} > 0.$$

Further, if Γ_{per} *denotes the generator of the evolution semigroup on* $\mathcal{F}_{per}$*, as above, and if* $1 \in \rho(e^{2\pi A})$*, then* Γ_{per} *is invertible and*

$$\|\mathcal{C}\Gamma_{per}^{-1}\mathcal{B}\| = \sup_{\{u_k\}\in\Lambda} \frac{\|\sum_k C(A - ik)^{-1}Bu_k e^{ik(\cdot)}\|_{L^p([0,2\pi],Y)}}{\|\sum_k u_k e^{ik(\cdot)}\|_{L^p([0,2\pi],U)}}, \tag{4.11}$$

where $\mathcal{C}\Gamma_{per}^{-1}\mathcal{B} \in \mathcal{L}(L^p([0,2\pi],U), L^p([0,2\pi],Y))$.

Proof. The equivalence of (i)–(iii) follows as in Theorem 2.3 of [23]. For the last statement, let $\{u_k\}$ be a finite set in U, and consider functions f and g of the form

$$f(s) = \sum_k (A - ik)^{-1}Bu_k e^{iks} \quad \text{and} \quad g(s) = \sum_k Bu_k e^{iks}.$$

Then $f = \Gamma_{per}^{-1}g$. For,

$$\begin{aligned}(\Gamma_{per}f)(s) &= \frac{d}{dt}\Big|_{t=0} e^{tA}f([s-t]\mathrm{mod}2\pi)\\ &= \sum_k [A(A - ik)^{-1}Bu_k e^{iks} - ik(A - ik)^{-1}Bu_k e^{iks}] = g(s).\end{aligned}$$

For functions of the form $h(s) = \sum_k u_k e^{iks}$, where $\{u_k\}_k$ is a finite set in U, we have $\mathcal{C}\Gamma^{-1}\mathcal{B}h = \sum_k C(A - ik)^{-1}Bu_k e^{ik(\cdot)}$. Taking the supremum over all such functions gives

$$\begin{aligned}\|\mathcal{C}\Gamma_{per}^{-1}\mathcal{B}\| &= \sup_h \frac{\|\mathcal{C}\Gamma_{per}^{-1}\mathcal{B}h\|}{\|h\|}\\ &= \sup_{\{u_k\}\in\Lambda} \frac{\|\sum_k C(A - ik)^{-1}Bu_k e^{ik(\cdot)}\|_{L^p([0,2\pi],Y)}}{\|\sum_k u_k e^{ik(\cdot)}\|_{L^p([0,2\pi],U)}}.\end{aligned}$$

□

In view of these facts we introduce a "pointwise" variant of the constant stability radius: for $t_0 > 0$ and $\lambda \in \rho(e^{t_0 A})$, define the *pointwise stability radius*

$$rc_{stab}^{\lambda}(e^{t_0 A}, B, C) := \sup\{r > 0 : \|\Delta\|_{\mathcal{L}(Y,U)} \le r \Rightarrow \lambda \in \rho(e^{t_0(A+B\Delta C)})\}.$$

By rescaling, the study of this quantity can be reduced to the case of $\lambda = 1$ and $t_0 = 2\pi$. Indeed,

$$rc_{stab}^{\lambda}(e^{t_0 A}, B, C) = \frac{2\pi}{t_0} rc_{stab}^{\lambda}(e^{2\pi A'}, B, C) \quad \text{where} \quad A' = \frac{t_0}{2\pi}A.$$

Also, after writing $\lambda = |\lambda|e^{i\theta}$ $(\theta \in \mathbb{R})$, note that

$$rc_{stab}^{\lambda}(e^{2\pi A}, B, C) = rc_{stab}^{1}(e^{2\pi A''}, B, C) \quad \text{for} \quad A'' = A - \frac{1}{2\pi}(\ln|\lambda| + i\theta).$$

Therefore,

$$rc_{stab}^{\lambda}(e^{t_0 A}, B, C) = \frac{2\pi}{t_0} rc_{stab}^{1}(e^{2\pi A'''}, B, C)$$

for

$$A''' = \frac{1}{2\pi}(t_0 A - \ln|\lambda| - i\theta).$$

In the following theorem we estimate $rc^1_{stab}(e^{2\pi A}, B, C)$. The idea for the proof goes back to [18]. See also further developments in [14].

THEOREM 4.4. *Let $\{e^{tA}\}_{t\geq 0}$ be a strongly continuous semigroup generated by A on X, and assume $1 \in \rho(e^{2\pi A})$. Let Γ_{per} denote the generator of the induced evolution semigroup on $\mathcal{F}_{per}$. Let $B \in \mathcal{L}(U, X)$ and $C \in \mathcal{L}(X, Y)$. Then*

$$\frac{1}{\|\mathcal{C}\Gamma^{-1}_{per}\mathcal{B}\|} \leq rc^1_{stab}(e^{2\pi A}, B, C) \leq \frac{1}{\sup_{k\in\mathbb{Z}} \|C(A-ik)^{-1}B\|}. \tag{4.12}$$

If U and Y are Hilbert spaces and $p = 2$, then equalities hold in (4.12).

Proof. The first inequality follows from an argument as in Theorem 4.2. For the second inequality, let $\epsilon > 0$, and choose $\bar{u} \in U$ with $\|\bar{u}\| = 1$ and $k_0 \in \mathbb{Z}$ such that

$$\|C(A - ik_0)^{-1}B\bar{u}\|_Y \geq \sup_{k\in\mathbb{Z}} \|C(A-ik)^{-1}B\| - \epsilon > 0.$$

Using the Hahn–Banach theorem, choose $y^* \in Y^*$ with $\|y^*\| \leq 1$ such that

$$\left\langle y^*, \frac{C(A-ik_0)^{-1}B\bar{u}}{\|C(A-ik_0)^{-1}B\bar{u}\|_Y} \right\rangle = 1.$$

Define $\Delta \in \mathcal{L}(Y, U)$ by

$$\Delta y = -\frac{\langle y^*, y\rangle}{\|C(A-ik_0)^{-1}B\bar{u}\|_Y}\bar{u}, \quad y \in Y.$$

We note that

$$\Delta C(A-ik_0)^{-1}B\bar{u} = -\frac{\langle y^*, C(A-ik_0)^{-1}B\bar{u}\rangle}{\|C(A-ik_0)^{-1}B\bar{u}\|_Y}\bar{u} = -\bar{u}, \tag{4.13}$$

and

$$\|\Delta\| \leq \frac{1}{\|C(A-ik_0)^{-1}B\bar{u}\|_Y} \leq \frac{1}{\sup_{k\in\mathbb{Z}} \|C(A-ik_0)^{-1}B\bar{u}\|_Y - \epsilon}. \tag{4.14}$$

Now set $\bar{v} := (A - ik_0)^{-1}B\bar{u}$ in X. By (4.13), $\Delta C\bar{v} = -\bar{u}$, and so

$$(A - ik_0 + B\Delta C)\bar{v} = (A-ik_0)\bar{v} + B\Delta C\bar{v} = B\bar{u} - B\bar{u} = 0.$$

Therefore,

$$\inf_{\{v_k\}\in\Lambda} \frac{\|\sum_k (A - ik + B\Delta C)v_k e^{ik(\cdot)}\|_{\mathcal{F}_{per}}}{\|\sum_k u_k e^{ik(\cdot)}\|_{\mathcal{F}_{per}}} \leq \frac{\|(A-ik_0+B\Delta C)\bar{v}e^{ik_0(\cdot)}\|_{\mathcal{F}_{per}}}{\|\bar{v}e^{ik_0(\cdot)}\|_{\mathcal{F}_{per}}} = 0.$$

By Theorem 4.3, $1 \notin \rho(e^{2\pi(A+B\Delta C)})$. This shows that $rc^1_{stab}(e^{2\pi A}, B, C) \leq \|\Delta\|$.

To finish the proof, suppose that $rc^1_{stab}(e^{2\pi A}, B, C) > (\sup_{k\in\mathbb{Z}} \|C(A-ik)^{-1}B\|)^{-1}$. Then with $r := (\sup_{k\in\mathbb{Z}} \|C(A-ik)^{-1}B\bar{u}\|_Y - \epsilon)^{-1}$, and $\epsilon > 0$ chosen to be sufficiently small, one has

$$\frac{1}{\sup_{k\in\mathbb{Z}} \|C(A-ik)^{-1}B\bar{u}\|_Y} < r < rc^1_{stab}(e^{2\pi A}, B, C).$$

But then by (4.14), $\|\Delta\| \le r < rc^1_{stab}(e^{2\pi A}, B, C)$, which is a contradiction.

For the last statement of the theorem, note that Parseval's formula applied to (4.11) gives

$$\|\mathcal{C}\Gamma^{-1}_{per}\mathcal{B}\| = \sup_{\{u_k\}\in\Lambda} \frac{\left(\sum_k \|C(A-ik)^{-1}Bu_k\|^2_Y\right)^{1/2}}{\left(\sum_k \|u_k\|^2_U\right)^{1/2}} \le \sup_{k\in\mathbb{Z}} \|C(A-ik)^{-1}B\|. \tag{4.15}$$

Therefore,

$$\frac{1}{\|\mathcal{C}\Gamma^{-1}_{per}\mathcal{B}\|} \ge \frac{1}{\sup_{k\in\mathbb{Z}} \|C(A-ik)^{-1}B\|},$$

and hence equalities hold in (4.12). ∎

Next we consider the following "hyperbolic" variant of the constant stability radius. Recall that a strongly continuous semigroup $\{e^{tA}\}_{t\ge 0}$ on X is called *hyperbolic* if

$$\sigma(e^{tA}) \cap \mathbb{T} = \emptyset, \quad \text{where } \mathbb{T} = \{z \in \mathbb{C} : |z| = 1\}$$

for some (and, hence, for all) $t > 0$ (see, e.g., [29]). The hyperbolic semigroups are those for which the differential equation $\dot{x} = Ax$ has exponential dichotomy (see, e.g., [12]) with the dichotomy projection P being the Riesz projection corresponding to the part of spectrum of e^A that lies in the open unit disc.

For a given hyperbolic semigroup $\{e^{tA}\}_{t\ge 0}$ and operators B, C we define the *constant dichotomy radius* as

$$\begin{aligned} rc_{dich}(\{e^{tA}\}, B, C) := \sup\{r \ge 0 : \|\Delta\|_{\mathcal{L}(Y,U)} \le r \text{ implies} \\ \sigma(e^{t(A+B\Delta C)}) \cap \mathbb{T} = \emptyset \text{ for all } t > 0\}. \end{aligned}$$

The dichotomy radius measures the size of the smallest $\Delta \in \mathcal{L}(Y, U)$ for which the perturbed equation $\dot{x} = [A + B\Delta C]x$ loses the exponential dichotomy.

Now for any $\xi \in [0, 1]$, consider the rescaled semigroup generated by $A_\xi := A - i\xi$ consisting of operators $e^{tA_\xi} = e^{-i\xi t}e^{tA}$, $t \ge 0$. The pointwise stability radius can be related to the dichotomy radius as follows.

LEMMA 4.5. *Let $\{e^{tA}\}_{t\ge 0}$ be a hyperbolic semigroup. Then*

$$rc_{dich}(\{e^{tA}\}, B, C) = \inf_{\xi\in[0,1]} rc^1_{stab}(e^{2\pi A_\xi}, B, C).$$

Proof. Denote the left-hand side by α and the right-hand side by β. First fix $r < \beta$. Let $\xi \in [0, 1]$. If $\|\Delta\| \le r$, then $1 \in \rho(e^{2\pi(A_\xi + B\Delta C)})$ and so $e^{i\xi 2\pi} \in \rho(e^{2\pi(A+B\Delta C)})$ for all $\xi \in [0, 1]$. That is, $e^{is} \in \rho(e^{2\pi(A+B\Delta C)})$ for all $s \in \mathbb{R}$, and so $\sigma(e^{2\pi(A+B\Delta C)}) \cap \mathbb{T} = \emptyset$. This shows that $r \le \alpha$, and so $\beta \le \alpha$.

Now suppose $r < \alpha$. If $\|\Delta\| \le r$, then $\sigma(\{e^{t(A+B\Delta C)}\}) \cap \mathbb{T} = \emptyset$, and so $e^{i\xi t} \in \rho(e^{t(A+B\Delta C)})$ for all $\xi \in [0, 1], t \in \mathbb{R}$. That is, $1 \in \rho(e^{t(A_\xi + B\Delta C)})$. This says $r \le \beta$ and so $\alpha \le \beta$. ∎

Under the additional assumption that the semigroup $\{e^{tA}\}_{t\ge 0}$ is exponentially stable (that is, hyperbolic with a trivial dichotomy projection $P = I$), Lemma 4.5 gives, in fact, a formula for the constant *stability* radius. Indeed, the following simple proposition holds.

PROPOSITION 4.6. *Let $\{e^{tA}\}_{t\ge 0}$ be an exponentially stable semigroup. Then*

$$rc_{dich}(\{e^{tA}\}, B, C) = rc_{stab}(\{e^{tA}\}, B, C).$$

Proof. Denote the left-hand side by α and the right-hand side by β. Take $r < \beta$ and any Δ with $\|\Delta\| \le r$. By definition of the constant stability radius, $\omega_0(\{e^{t(A+B\Delta C)}\}) < 0$. In particular, $\sigma(e^{t(A+B\Delta C)}) \cap \mathbb{T} = \emptyset$, and $r \le \alpha$ shows that $\beta \le \alpha$.

Suppose that $\beta < r < \alpha$ for some r. By the definition of the stability radius β, there exists a Δ with $\|\Delta\| \in (\beta, r)$ such that the semigroup $\{e^{t(A+B\Delta C)}\}_{t\ge 0}$ is not stable.

For any $\tau \in [0,1]$ one has $\|\tau\Delta\| \le r < \alpha$. By the definition of the dichotomy radius α it follows that the semigroup $\{e^{t(A+\tau B\Delta C)}\}_{t\ge 0}$ is hyperbolic for each $\tau \in [0,1]$. Now consider its dichotomy projection

$$P(\tau) = (2\pi i)^{-1} \int_{\mathbb{T}} \left(\lambda - e^{A+\tau B\Delta C}\right)^{-1} d\lambda,$$

which is the Riesz projection corresponding to the part of $\sigma(e^{A+\tau B\Delta C})$ located inside of the open unit disk. The function $\tau \mapsto P(\tau)$ is norm continuous. Indeed, since the bounded perturbation $\tau B\Delta C$ of the generator A is continuous in τ, the operators $e^{t(A+\tau B\Delta C)}$, $t \ge 0$, depend on τ continuously (see, e.g., [30, Cor. 3.1.3]); this implies the continuity of $P(\cdot)$ (see, e.g., [12, Thm. I.2.2]).

By assumption $\{e^{tA}\}_{t\ge 0}$ is exponentially stable, so $P(0) = I$. Also, $P(1) \ne I$ since the semigroup $\{e^{t(A+B\Delta C)}\}_{t\ge 0}$ with $\|\Delta\| \le r < \alpha$ is hyperbolic but not stable. Since either $\|I - P(\tau)\| = 0$ or $\|I - P(\tau)\| \ge 1$, this contradicts the continuity of $\|P(\cdot)\|$. ∎

A review of the above development shows that the inequality claimed in (4.7) of Theorem 4.1 can now be proved.

Proof of Theorem 4.1. Indeed, $r_{stab}(\{e^{tA}\}, B, C) \le rc_{stab}(\{e^{tA}\}, B, C)$, and so

$$\begin{aligned}
\frac{1}{\|\mathbb{L}\|} \le r_{stab}(\{e^{tA}\}, B, C) &\le rc_{stab}(\{e^{tA}\}, B, C) && \text{(Theorem 4.2)}\\
&\le rc_{dich}(\{e^{tA}\}, B, C) && \text{(Proposition 4.6)}\\
&\le \inf_{\xi\in[0,1]} rc^1_{stab}(e^{2\pi A_\xi}, B, C) && \text{(Lemma 4.5)}\\
&\le \inf_{\xi\in[0,1]} \frac{1}{\sup_{k\in\mathbb{Z}} \|C(A_\xi - ik)^{-1}B\|} && \text{(Theorem 4.4)}\\
&= \frac{1}{\sup_{s\in\mathbb{R}} \|C(A - is)^{-1}B\|}. && \blacksquare
\end{aligned}$$

We will need below the following simple corollary that holds for *bounded* generators A. (In fact, as shown in [14, Cor. 2.5], formula (4.16) below holds provided A generates a semigroup $\{e^{tA}\}_{t\ge 0}$ that is *uniformly* continuous just for $t > 0$.)

COROLLARY 4.7. *Assume $A \in \mathcal{L}(X)$ generates a (uniformly continuous) stable semigroup on a Banach space X. Then*

$$rc_{stab}(\{e^{tA}\}, B, C) = \frac{1}{\sup_{s\in\mathbb{R}} \|C(A - is)^{-1}B\|}. \tag{4.16}$$

Proof. By Theorem 4.1, it remains to prove only the inequality "$\ge$." Fix Δ with $\|\Delta\|$ strictly less than the right-hand side of (4.16). Since $A + B\Delta C \in \mathcal{L}(X)$, it suffices to show that $A + B\Delta C - \lambda = (A - \lambda)(I + (A - \lambda)^{-1}B\Delta C)$ is invertible for

each λ with $\operatorname{Re}\lambda \geq 0$. By the analyticity of resolvent, $\sup_{\operatorname{Re}\lambda\geq 0}\|C(A-\lambda)^{-1}B\| \leq \sup_{s\in\mathbb{R}}\|C(A-is)^{-1}B\|$. Thus

$$\begin{aligned}\|\Delta\| &< \frac{1}{\sup_{s\in\mathbb{R}}\|C(A-is)^{-1}B\|}\\ &\leq \frac{1}{\sup_{\operatorname{Re}\lambda\geq 0}\|C(A-\lambda)^{-1}B\|} \leq \frac{1}{\|C(A-\lambda)^{-1}B\|}, \quad \operatorname{Re}\lambda \geq 0,\end{aligned}$$

implies that $I+C(A-\lambda)^{-1}B\Delta$ is invertible. Therefore (cf. the proof of Theorem 4.2), $I+(A-\lambda)^{-1}B\Delta C$ is invertible. ∎

4.4. The norm of the input-output operator. Since the lower bound on the stability radius is given by the norm of the input-output operator, which is defined by way of the solution operators, it is of interest to express this quantity in terms of the operators A, B, and C. In this subsection it is shown that for autonomous systems this quantity can, in fact, be expressed explicitly in terms of the transfer function

$$\|\mathbb{L}\| = \sup_{u\in\mathcal{S}(\mathbb{R},U)} \frac{\|\int_{\mathbb{R}} C(A-is)^{-1}Bu(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},Y)}}{\|\int_{\mathbb{R}} u(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},U)}}. \tag{4.17}$$

Here we use $\mathcal{S}(\mathbb{R},X)$ to denote the Schwartz class of rapidly decreasing X-valued functions defined on $\mathbb{R}$: $\{v:\mathbb{R}\to X \,\big|\, \sup_{s\in\mathbb{R}}\|s^m v^{(n)}(s)\|<\infty; n,m\in\mathbb{N}\}$. As noted in (4.6), $\|\mathbb{L}\|$ equals $\sup_{s\in\mathbb{R}}\|C(A-is)^{-1}B\|$ if U and Y are Hilbert spaces and $p=2$. The section concludes by providing a similar expression, involving sums, which serves as a lower bound for the constant stability radius.

The current focus is on autonomous systems, so let $\{e^{tA}\}_{t\geq 0}$ be a strongly continuous semigroup generated by A and consider the evolution semigroups $\{E^t_{\mathbb{R}}\}_{t\geq 0}$ defined on functions on the entire real line as in (2.2), and $\{E^t\}_{t\geq 0}$ defined for functions on the half-line as in (3.4). As before, $\Gamma_{\mathbb{R}}$ and Γ will denote the generators of these semigroups on $L^p(\mathbb{R},X)$ and $L^p(\mathbb{R}_+,X)$, respectively. Both semigroups will be used as we first show that $\|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\|$ equals the expression in (4.17) and then check that $\|\mathbb{L}\| \equiv \|\mathcal{C}\Gamma^{-1}\mathcal{B}\| = \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\|$.

Given $v\in\mathcal{S}(\mathbb{R},X)$, let g_v denote the function

$$g_v(\tau) = \frac{1}{2\pi}\int_{\mathbb{R}} v(s)e^{i\tau s}\,ds, \quad \tau\in\mathbb{R},$$

and set $\mathfrak{G} = \{g_v : v\in\mathcal{S}(\mathbb{R},X)\}$. Assuming $\sup_{s\in\mathbb{R}}\|(A-is)^{-1}\|<\infty$, define, for a given $v\in\mathcal{S}(\mathbb{R},X)$, the function

$$f_v(\tau) = \frac{1}{2\pi}\int_{\mathbb{R}} (A-is)^{-1}v(s)e^{i\tau s}\,ds, \quad \tau\in\mathbb{R},$$

and set $\mathfrak{F} = \{f_v : v\in\mathcal{S}(\mathbb{R},X)\}$.

PROPOSITION 4.8. *Assume* $\sup_{s\in\mathbb{R}}\|(A-is)^{-1}\|<\infty$. *Then*

(i) $\mathfrak{G}$ *consists of differentiable functions, and is dense in* $L^p(\mathbb{R},X)$;

(ii) $\mathfrak{F}$ *is dense in* $\operatorname{Dom}(\Gamma_{\mathbb{R}})$;

(iii) *if* $v\in\mathcal{S}(\mathbb{R},X)$, *then* $\Gamma_{\mathbb{R}}f_v = g_v$.

Proof. For $g\in L^1(\mathbb{R},X)$, denote the Fourier transform by

$$\hat{g}(\tau) = \frac{1}{2\pi}\int_{\mathbb{R}} e^{-is\tau}g(s)\,ds.$$

Note that $\mathfrak{G} = \{g : \mathbb{R} \to X : \exists\ v \in \mathcal{S}(\mathbb{R}, X) \text{ so that } \hat{g} = v\}$, and so $\mathfrak{G}$ contains the set $\{g \in L^1(\mathbb{R}, X) : \hat{g} \in \mathcal{S}(\mathbb{R}, X)\}$. Since the latter set is dense in $L^p(\mathbb{R}, X)$, property (i) follows.

$\mathfrak{G}$ consists of differentiable functions since for $v \in \mathcal{S}(\mathbb{R}, X)$, the integral defining g_v converges absolutely. Moreover, for $v \in \mathcal{S}(\mathbb{R}, X)$, the function $w(s) = (A - is)^{-1}v(s)$, $s \in \mathbb{R}$, is also in $\mathcal{S}(\mathbb{R}, X)$, since $\sup_{s\in\mathbb{R}} \|(A - is)^{-1}\| < \infty$. Hence f_v is differentiable with derivative

$$f_v'(\tau) = \frac{1}{2\pi}\int_{\mathbb{R}} is(A - is)^{-1}v(s)e^{i\tau s}\,ds = \frac{1}{2\pi}\int_{\mathbb{R}} isw(s)e^{i\tau s}\,ds.$$

So $f_v' \in L^p(\mathbb{R}, X)$, and hence $\mathfrak{F}$ is dense in $\mathrm{Dom}(-d/dt + \mathcal{A})$.

Property (iii) follows from the following calculation:

$$\begin{aligned}(\Gamma f_v)(\tau) &= \frac{1}{2\pi}\int_{\mathbb{R}} [-is(A - is)^{-1}v(s)e^{is\tau} + A(A - is)^{-1}v(s)e^{is\tau}]\,ds \\ &= \frac{1}{2\pi}\int_{\mathbb{R}} (A - is)(A - is)^{-1}v(s)e^{is\tau}\,ds = g_v(\tau). \qquad \square\end{aligned}$$

Set $\Lambda_{\mathcal{S}} = \{v \in \mathcal{S}(\mathbb{R}, X) : v(s) \in \mathrm{Dom}(A) \text{ for } s \in \mathbb{R},\ Av \in \mathcal{S}(\mathbb{R}, X)\}$.

PROPOSITION 4.9. *Let $\{e^{tA}\}_{t\geq 0}$ be a strongly continuous semigroup generated by A. Let Γ and $\Gamma_{\mathbb{R}}$ be the generators of the evolution semigroups on $L^p(\mathbb{R}_+, X)$ and $L^p(\mathbb{R}, X)$, as defined in (3.4) and (2.2), respectively. Then the following assertions hold.*

(i) *If $\sigma(A) \cap i\mathbb{R} = \emptyset$ and $\sup_{s\in\mathbb{R}} \|(A - is)^{-1}\| < \infty$, then*

$$\|\Gamma_{\mathbb{R}}\|_{\bullet, L^p(\mathbb{R},X)} = \inf_{v\in\Lambda_{\mathcal{S}}} \frac{\|\int_{\mathbb{R}}(A - is)v(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},X)}}{\|\int_{\mathbb{R}} v(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},X)}}.$$

(ii) *If $\Gamma_{\mathbb{R}}$ is invertible on $L^p(\mathbb{R}, X)$, then $\{e^{tA}\}_{t\geq 0}$ is hyperbolic and*

$$\|\Gamma_{\mathbb{R}}^{-1}\|_{\mathcal{L}(L^p(\mathbb{R},X))} = \sup_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|\int_{\mathbb{R}}(A - is)^{-1}v(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},X)}}{\|\int_{\mathbb{R}} v(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},X)}}.$$

(iii) *If Γ is invertible on $L^p(\mathbb{R}_+, X)$, then $\{e^{tA}\}_{t\geq 0}$ is exponentially stable and*

$$\|\Gamma^{-1}\|_{\mathcal{L}(L^p(\mathbb{R}_+,X))} = \|\Gamma_{\mathbb{R}}^{-1}\|_{\mathcal{L}(L^p(\mathbb{R},X))}.$$

Proof. To show (i), let $v \in \mathcal{S}(\mathbb{R}, X)$. Since $\sup_{s\in\mathbb{R}} \|(A - is)^{-1}\| < \infty$, the formula $w(s) = (A - is)^{-1}v(s)$, $s \in \mathbb{R}$, defines a function w in $\Lambda_{\mathcal{S}}$. Now

$$g_v(\tau) = \frac{1}{2\pi}\int_{\mathbb{R}}(A - is)(A - is)^{-1}v(s)e^{is\tau}\,ds = \frac{1}{2\pi}\int_{\mathbb{R}}(A - is)w(s)e^{is\tau}\,ds$$

and

$$f_v(\tau) = \frac{1}{2\pi}\int_{\mathbb{R}} w(s)e^{is\tau}\,ds.$$

However, from Proposition 4.8,

$$\|\Gamma_{\mathbb{R}}\|_{\bullet} = \inf_{f_v\in\mathfrak{F}} \frac{\|\Gamma_{\mathbb{R}} f_v\|}{\|f_v\|} = \inf_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|g_v\|}{\|f_v\|} = \inf_{w\in\Lambda_{\mathcal{S}}} \frac{\|\int_{\mathbb{R}}(A - is)w(s)e^{is(\cdot)}\,ds\|}{\|\int_{\mathbb{R}} w(s)e^{is(\cdot)}\,ds\|}.$$

To see (ii), note that

$$\|\Gamma_{\mathbb{R}}^{-1}\| = \|\Gamma_{\mathbb{R}}\|_\bullet^{-1} = \left[\inf_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|\Gamma_{\mathbb{R}} f_v\|}{\|f_v\|}\right]^{-1} = \sup_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|f_v\|}{\|g_v\|}.$$

For (iii) note that $\|\Gamma_{\mathbb{R}}\|_{\bullet,L^p(\mathbb{R},X)} \le \|\Gamma\|_{\bullet,L^p(\mathbb{R}_+,X)}$. Indeed, let $f \in L^p(\mathbb{R},X)$ with $\operatorname{supp} f \subseteq \mathbb{R}_+$. If $f \in \operatorname{Dom}(-d/dt+\mathcal{A})$, then $\operatorname{supp}\Gamma_{\mathbb{R}} f \subseteq \mathbb{R}_+$ and $\|\Gamma_{\mathbb{R}} f\|_{L^p(\mathbb{R},X)} = \|\Gamma f\|_{L^p(\mathbb{R}_+,X)}$. To see that $\|\Gamma_{\mathbb{R}}\|_\bullet \ge \|\Gamma\|_\bullet$, let $\epsilon > 0$ and choose $f \in \operatorname{Dom}(-d/dt+\mathcal{A})$ with compact support such that $\|f\|_{L^p(\mathbb{R},X)} = 1$ and $\|\Gamma_{\mathbb{R}}\|_\bullet \ge \|\Gamma_{\mathbb{R}} f\| - \epsilon$. Now choose $\tau \in \mathbb{R}$ such that $f_\tau(s) := f(s-\tau)$, $s \in \mathbb{R}$, defines a function, $f_\tau \in L^p(\mathbb{R},X)$, with $\operatorname{supp} f_\tau \subseteq \mathbb{R}_+$. Let $\bar{f}_\tau$ denote the element of $L^p(\mathbb{R}_+,X)$ which coincides with f_τ on $\mathbb{R}_+$. Then $\|f_\tau\| = \|\bar{f}_\tau\|$ and $\Gamma\bar{f}_\tau = -d/dt\, f(\cdot-\tau) + Af(\cdot-\tau) = (\Gamma_{\mathbb{R}} f)_\tau$. Therefore, $\|\Gamma_{\mathbb{R}}\|_\bullet \ge \|\Gamma_{\mathbb{R}} f\| - \epsilon = \|(\Gamma_{\mathbb{R}} f)_\tau\| - \epsilon = \|\Gamma_{\mathbb{R}}\bar{f}_\tau\| - \epsilon \ge \|\Gamma\|_\bullet - \epsilon$. ∎

PROPOSITION 4.10. *The set* $\mathfrak{G}_U = \{g_u : u \in \mathcal{S}(\mathbb{R},U)\}$ *is dense in* $L^p(\mathbb{R},U)$. *If* $u \in \mathcal{S}(\mathbb{R},U)$ *and* $B \in \mathcal{L}(U,X)$, *then* $Bu \in \mathcal{S}(\mathbb{R},X)$ *and* $\Gamma_{\mathbb{R}} f_{Bu} = \mathcal{B} g_u$.

Proof. The first statement is clear, as in Proposition 4.8. The second follows from the properties of Schwartz functions, and from the calculation

$$\Gamma_{\mathbb{R}} f_{Bu} = g_{Bu}(\tau) = \frac{1}{2\pi}\int_{\mathbb{R}} Bu(s)e^{is\tau}\,ds = B\frac{1}{2\pi}\int_{\mathbb{R}} u(s)e^{is\tau}\,ds. \qquad ∎$$

Recall (see Remarks 2.4 and Theorem 3.2) that $\{e^{tA}\}_{t\ge0}$ is hyperbolic (respectively, stable) if and only if $\Gamma_{\mathbb{R}}$ (respectively, Γ) is invertible on $L^p(\mathbb{R},X)$ (respectively, $L^p(\mathbb{R}_+,X)$).

THEOREM 4.11. *If* $\Gamma_{\mathbb{R}}$ *is invertible on* $L^p(\mathbb{R},X)$, *then*

$$\|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\| = \sup_{u\in\mathcal{S}(\mathbb{R},U)} \frac{\|\int_{\mathbb{R}} C(A-is)^{-1}Bu(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},Y)}}{\|\int_{\mathbb{R}} u(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},U)}}. \tag{4.18}$$

If Γ *is invertible on* $L^p(\mathbb{R}_+,X)$, *then the norm of* $\mathbb{L} = \mathcal{C}\Gamma^{-1}\mathcal{B}$, *as an operator from* $L^p(\mathbb{R}_+,U)$ *to* $L^p(\mathbb{R}_+,Y)$, *is given by the above formula:*

$$\|\mathbb{L}\| = \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\|. \tag{4.19}$$

If, in addition, U *and* Y *are Hilbert spaces and* $p = 2$, *then*

$$\|\mathbb{L}\| = \sup_{s\in\mathbb{R}} \|C(A-is)^{-1}B\|_{\mathcal{L}(U,Y)}. \tag{4.20}$$

Proof. For $u \in \mathcal{S}(\mathbb{R},U)$, consider functions f_{Bu} and g_u. Proposition 4.10 gives $f_{Bu} = \Gamma_{\mathbb{R}}^{-1}\mathcal{B} g_u$ and

$$\begin{aligned}\|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\| &= \sup_{g_u\in\mathfrak{G}_U} \frac{\|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B} g_u\|_{L^p(\mathbb{R},Y)}}{\|g_u\|_{L^p(\mathbb{R},U)}} = \sup_{g_u\in\mathfrak{G}_U} \frac{\|\mathcal{C} f_{Bu}\|}{\|g_u\|} \\ &= \sup_{u\in\mathcal{S}(\mathbb{R},U)} \frac{\|\int_{\mathbb{R}} C(A-is)^{-1}Bu(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},Y)}}{\|\int_{\mathbb{R}} u(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},U)}},\end{aligned}$$

which proves (4.18).

Now if Γ is invertible on $L^p(\mathbb{R}_+,X)$, then $\{e^{tA}\}_{t\ge0}$ is exponentially stable by Corollary 3.6. Hence $\Gamma_{\mathbb{R}}$ is invertible on $L^p(\mathbb{R},X)$. Moreover, for the case of the *stable* semigroup $\{e^{tA}\}_{t\ge0}$, the formula for $\Gamma_{\mathbb{R}}^{-1}$ (see, e.g., [25]) takes the form

$$(\Gamma_{\mathbb{R}}^{-1} f)(t) = \int_0^\infty e^{sA} f(t-s)\,ds = \int_{-\infty}^t e^{(t-s)A} f(s)\,ds.$$

If $\operatorname{supp} f \subseteq (0,\infty)$, then

$$(\Gamma_{\mathbb{R}}^{-1} f)(t) = \int_{-\infty}^{t} e^{(t-s)A} f(s)\, ds = \int_{0}^{t} e^{(t-s)A} f(s)\, ds. \tag{4.21}$$

For a function $h \in L^p(\mathbb{R}_+, X)$, define an extension $\tilde{h} \in L^p(\mathbb{R}, X)$ by $\tilde{h}(t) = h(t)$ for $t \geq 0$ and $\tilde{h}(t) = 0$ for $t < 0$. Then (4.21) shows that $\Gamma_{\mathbb{R}}^{-1}\tilde{h} = (\Gamma^{-1}h)^{\sim}$. In particular, for $u \in L^p(\mathbb{R}_+, U)$, $\widetilde{\mathbb{L}u} = \widetilde{\mathcal{C}\Gamma^{-1}\mathcal{B}u} = \mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\tilde{u}$. Therefore,

$$\begin{aligned}\|\mathbb{L}u\|_{L^p(\mathbb{R}_+,Y)} &= \|\widetilde{\mathbb{L}u}\|_{L^p(\mathbb{R},Y)} = \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\tilde{u}\|_{L^p(\mathbb{R},Y)} \\ &\leq \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\| \cdot \|\tilde{u}\|_{L^p(\mathbb{R},U)} = \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\| \cdot \|u\|_{L^p(\mathbb{R}_+,U)}.\end{aligned}$$

This shows that $\|\mathbb{L}\| \leq \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\|$.

To prove that equality holds in (4.19), let $\epsilon > 0$ and choose $u \in L^p(\mathbb{R}, U)$, $\|u\| = 1$, such that $\|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}u\|_{L^p(\mathbb{R},Y)} \geq \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\| - \epsilon$. Without loss of generality, u may be assumed to have compact support. Now choose r such that $\operatorname{supp} u(\cdot - r) \subseteq (0,\infty)$ and set $w(\cdot) := u(\cdot - r)$. Then $w \in L^p(\mathbb{R}, U)$ with $\operatorname{supp} w \subseteq (0,\infty)$. Let $\bar{w}$ denote the element of $L^p(\mathbb{R}_+, U)$ that coincides with w on $\mathbb{R}_+$. As in (4.21) we have

$$\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}w(t) = C\int_{0}^{t} e^{(t-s)A}Bw(s)\, ds = C\int_{-\infty}^{t} e^{(t-s)A}Bw(s)\, ds.$$

Since $\|\bar{w}\|_{L^p(\mathbb{R}_+,U)} = \|w\|_{L^p(\mathbb{R},U)} = \|u\|_{L^p(\mathbb{R},U)} = 1$, it follows that

$$\begin{aligned}\|\mathbb{L}\| &\geq \|\mathbb{L}\bar{w}\|_{L^p(\mathbb{R}_+,Y)} = \|\widetilde{\mathbb{L}\bar{w}}\|_{L^p(\mathbb{R},Y)} \\ &= \|\mathbb{L}\tilde{w}\|_{L^p(\mathbb{R},Y)} = \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}w\|_{L^p(\mathbb{R},Y)} \\ &= \|C\int_{-\infty}^{\cdot} e^{(\cdot-\tau)A}Bu(\tau)\, d\tau\|_{L^p(\mathbb{R},Y)} \\ &= \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}u\|_{L^p(\mathbb{R},Y)} \geq \|\mathcal{C}\Gamma_{\mathbb{R}}^{-1}\mathcal{B}\| - \epsilon.\end{aligned}$$

This confirms (4.19). Parseval's formula and (4.7) give (4.20). □

If $\{e^{tA}\}_{t\geq 0}$ is exponentially stable, then the inequalities in (4.7) give lower and upper bounds on the stability radius in terms of $\mathbb{L}$ and $C(A - is)^{-1}B$, respectively. The previous theorem shows that $\|\mathbb{L}\|$ can be explicitly expressed in terms of an integral involving $C(A - is)^{-1}B$. We conclude by observing that a lower bound for the constant stability radius can be expressed by a similar formula involving a sum. For this, let $\xi \in [0,1]$ and set

$$S_\xi := \sup_{\{u_k\}\in\Lambda} \frac{\|\sum_k C(A - i\xi - ik)^{-1}Bu_k e^{ik(\cdot)}\|_{L^p([0,2\pi],Y)}}{\|\sum_k u_k e^{ik(\cdot)}\|_{L^p([0,2\pi],U)}}.$$

We note that S_ξ is computed as in (4.11) with A replaced by $A_\xi = A - i\xi$.

COROLLARY 4.12. *Let $\{e^{tA}\}_{t\geq 0}$ be an exponentially stable semigroup generated by A. Then*

$$\frac{1}{\sup_{\xi\in[0,1]} S_\xi} \leq rc_{stab}(\{e^{tA}\}, B, C) \leq \frac{1}{\sup_{s\in\mathbb{R}} \|C(A - is)^{-1}B\|}.$$

Proof. Fix $\xi \in [0,1]$, and let $\Gamma_{per,\xi}$ denote the generator on $L^p([0,2\pi],X)$ of the evolution semigroup induced by $\{e^{tA_\xi}\}_{t\geq 0}$. By Theorem 4.3, $\|\mathcal{C}\Gamma_{per,\xi}^{-1}\mathcal{B}\| = S_\xi$, and so by Theorem 4.4,

$$\frac{1}{S_\xi} \leq rc^1_{stab}(e^{2\pi A_\xi}, B, C) \leq \frac{1}{\sup_{k\in\mathbb{Z}} \|C(A_\xi - ik)^{-1}B\|}.$$

By Proposition 4.6, taking the infimum over $\xi \in [0,1]$ gives

$$\begin{aligned}\frac{1}{\sup_{\xi\in[0,1]} S_\xi} &\leq \inf_{\xi\in[0,1]} rc^1_{stab}(e^{2\pi A_\xi}, B, C) = rc_{stab}(\{e^{tA}\}, B, C)\\ &\leq \inf_{\xi\in[0,1]} \frac{1}{\sup_{k\in\mathbb{Z}} \|C(A_\xi - ik)^{-1}B\|}\\ &= \frac{1}{\sup_{s\in\mathbb{R}} \|C(A - is)^{-1}B\|}. \qquad \square\end{aligned}$$

4.5. Two counterexamples. In contrast to the Hilbert-space setting, the following Banach-space examples show that either inequality in (4.7) may be strict. We start with the example where the second inequality in (4.7) is strict.

Example 4.13. An example due to Arendt (see, e.g., [29], Ex. 1.4.5) exhibits a (positive) strongly continuous semigroup $\{e^{tA}\}_{t\geq 0}$ on a Banach space X with the property that $s_0(A) < \omega_0(A) < 0$ for the abscissa of uniform boundedness of the resolvent and the growth bound. Now, for α such that $0 \leq \alpha \leq -\omega_0(A)$, consider a rescaled semigroup generated by $A + \alpha$, and denote by $\Gamma_{A+\alpha}$ the generator of the induced evolution semigroup on $L^p(\mathbb{R}_+, X)$. The following relationships hold:

$$\text{for } 0 \leq \alpha < -\omega_0(A), \quad s_0(A+\alpha) = s_0(A) + \alpha < \omega_0(A) + \alpha = \omega_0(A+\alpha) < 0;$$

$$\text{for } \alpha_0 := -\omega_0(A), \quad s_0(A+\alpha_0) < \omega_0(A+\alpha_0) = 0.$$

This says that $s_0(A+\alpha) < 0$ for all $\alpha \in [0,\alpha_0]$ and hence

$$M := \sup_{\alpha\in[0,\alpha_0]} \sup_{s\in\mathbb{R}} \|(A + \alpha - is)^{-1}\| < \infty.$$

Now note (see Corollary 3.6) that $\omega_0(A+\alpha) < 0$ if and only if $\|\Gamma^{-1}_{A+\alpha}\| < \infty$. Since $\omega_0(A+\alpha) \to 0$ as $\alpha \to \alpha_0$, we conclude that $\|\Gamma^{-1}_{A+\alpha}\| \to \infty$ as $\alpha \to \alpha_0$. Since $\alpha \mapsto \|\Gamma^{-1}_{A+\alpha}\|$ is a continuous function of α on $[0,\alpha_0)$, there exists $\alpha_1 \in [0,\alpha_0)$ such that $\|\Gamma^{-1}_{A+\alpha_1}\| > M$, and so the following inequality is strict:

$$\frac{1}{\|\Gamma^{-1}_{A+\alpha_1}\|} < \frac{1}{\sup_{s\in\mathbb{R}} \|(A + \alpha_1 - is)^{-1}\|}.$$

Also, we claim that there exists $\alpha_2 \in [0,\alpha_0)$ such that the following inequality is strict:

$$rc_{stab}(\{e^{t(A+\alpha_2)}\}, I, I) < \frac{1}{\sup_{s\in\mathbb{R}} \|(A + \alpha_2 - is)^{-1}\|}.$$

To see this, let us suppose that for each $\alpha \in [0,\alpha_0)$ one has $rc_{stab}(\{e^{t(A+\alpha)}\}, I, I) \geq 1/(2M)$. Again, using that $\omega_0(A+\alpha) \to 0$ as $\alpha \to \alpha_0$, find $\alpha \in [0,\alpha_0)$ such that

$|\omega_0(A+\alpha)| < 1/(2M)$. Let $\Delta = \omega_0(A+\alpha)I$. Since $\|\Delta\| = |\omega_0(A+\alpha)|$, by the definition of stability radius one has

$$0 > \omega_0(A+\alpha+\Delta) = \omega_0(A+\alpha) - \omega_0(A+\alpha) = 0,$$

which is a contradiction. Thus there exists $\alpha_2 \in [0, \alpha_0)$ such that

$$rc_{stab}(\{e^{t(A+\alpha_2)}\}, I, I) \le \frac{1}{2M} < \frac{1}{M} \le \frac{1}{\sup_{s\in\mathbb{R}} \|(A+\alpha_2 - is)^{-1}\|},$$

as claimed. ∎

This example shows that the second inequality in (4.7) can be strict due to the Banach-space pathologies related to the failure of Gearhart's Theorem 2.1. Another example, given below, shows that the first inequality in (4.7) could be strict due to the lack of Parseval's formula (see (4.15) in the proof of Theorem 4.4). That is, the choice of $p = 2$ in (4.6) is as important as the fact that X in (4.6) is a *Hilbert* space. First, we need a formula for the norm of the input-output operator on $L^1(\mathbb{R}_+, X)$.

PROPOSITION 4.14. *Assume $\{e^{tA}\}_{t\ge 0}$ is an exponentially stable C_0 semigroup on a Banach space X. The norm of the operator $\mathbb{L} = \Gamma^{-1}$ on $L^1(\mathbb{R}_+, X)$ is*

$$\|\Gamma^{-1}\|_{\mathcal{L}(L^1(\mathbb{R}_+,X))} = \sup_{\|x\|=1} \int_0^\infty \|e^{tA}x\|\, dt. \tag{4.22}$$

Proof. Recall (see (3.5)) that

$$\Gamma^{-1} f(t) = -\int_0^t e^{\tau A} f(t-\tau)\, d\tau \quad t \in \mathbb{R}_+, \quad f \in L^1(\mathbb{R}_+, X)$$

is the convolution operator. Choose positive $\delta_n \in L^1(\mathbb{R}_+, \mathbb{R})$ with $\|\delta_n\|_{L^1} = 1$ such that

$$\|g * \delta_n - g\|_{L^1(\mathbb{R}_+,X)} \to 0 \quad \text{as} \quad n \to \infty \quad \text{for each} \quad g \in L^1(\mathbb{R}_+, X).$$

Fix $x \in X$, $\|x\| = 1$, let $f = \delta_n x \in L^1(\mathbb{R}_+, X)$, and note that

$$\Gamma^{-1} f(t) = -\int_0^t e^{\tau A} x\, \delta_n(t-\tau)\, d\tau = -(g * \delta_n)(t) \quad \text{for} \quad g(t) = e^{tA}x, \quad t \in \mathbb{R}_+.$$

This implies "$\ge$" in (4.22). To see "$\le$," take $f = \sum_{i=1}^N \alpha_i x_i$ with $\alpha_i \in L^1(\mathbb{R}_+, \mathbb{R})$ having disjoint supports and $\|x_i\| = 1$, $i = 1, \dots, N$. Now $\|f\|_{L^1(\mathbb{R}_+,X)} = \sum_i \|\alpha_i\|_{L^1}$, and for $f_i(t) = e^{tA}x_i$ one has

$$\Gamma^{-1} f(t) = -\int_0^t \sum_i e^{\tau A} x_i \alpha_i(t-\tau)\, d\tau = -\sum_i (f_i * \alpha_i)(t).$$

Using Young's inequality,

$$\begin{aligned}\|\Gamma^{-1} f\|_{L^1(\mathbb{R}_+,X)} &\le \sum_i \|f_i * \alpha_i\|_{L^1(\mathbb{R}_+,X)} \\ &\le \sum_i \|f_i\|_{L^1(\mathbb{R}_+,X)} \|\alpha_i\|_{L^1} \le \sup_{\|x\|=1} \int_0^\infty \|e^{tA}x\|\, dt \sum_i \|\alpha_i\|_{L^1}. \qquad \blacksquare\end{aligned}$$

Example 4.15. Take $X = \mathbb{C}^2$ with the ℓ_1 norm. Let

$$A = \begin{pmatrix} -1 & 1 \\ -1 & -1 \end{pmatrix} \quad \text{so that} \quad e^{tA} = \begin{pmatrix} e^{-t}\cos(t) & e^{-t}\sin(t) \\ -e^{-t}\sin(t) & e^{-t}\cos(t) \end{pmatrix},$$

and

$$(A - is)^{-1} = \frac{1}{(1+is)^2 + 1} \begin{pmatrix} -1 - is & -1 \\ 1 & -1 - is \end{pmatrix}.$$

Since the extreme points of X are $e^{i\theta}e_1$ and $e^{i\theta}e_2$ ($\theta \in \mathbb{R}$), where e_1 and e_2 are the unit vectors of $\mathbb{C}^2$, we see that

$$\|(A - is)^{-1}\| = \frac{|1 + is| + 1}{|(1+is)^2 + 1|}.$$

It may be numerically established that

$$\sup_{s \in \mathbb{R}} \|(A - isI)^{-1}\| \approx 1.087494476.$$

By Corollary 4.7, the reciprocal to the last expression is equal to $rc_{stab}(\{e^{tA}\}, I, I)$. On the other hand, using Proposition 4.14,

$$\begin{aligned} \|\mathbb{L}\| = \|\Gamma_A^{-1}\| &= \sup_{\|x\|=1} \int_0^\infty \|e^{tA}x\|\, dt \\ &= \int_0^\infty |e^{-t}\cos(t)| + |e^{-t}\sin(t)|\, dt \approx 1.262434309. \end{aligned}$$

Therefore, the first inequality in (4.7) may be strict. □

The following example shows that the norm of the input-output operator depends on p.

Example 4.16. Let

$$A = \begin{pmatrix} 9/2 & -5/2 \\ 25/2 & -13/2 \end{pmatrix},$$

acting on $\mathbb{C}^2$ with the Euclidean norm. Thus

$$e^{tA} = e^{-t} \begin{pmatrix} \cos t + (11/2)\sin t & -(5/2)\sin t \\ (25/2)\sin t & \cos t - (11/2)\sin t \end{pmatrix}.$$

Then

$$\|\Gamma^{-1}\|_{L_1 \to L_1} \geq \int_0^\infty \|e^{tA}e_1\|\, dt \approx 7.748310791,$$

whereas

$$\|\Gamma^{-1}\|_{L_2 \to L_2} = \sup_{s \in R} \|(A - is)^{-1}\| \approx 2.732492852. \qquad \square$$

5. Internal and external stability. Work aimed at properties of stability and robustness of linear time-invariant systems is often based on transform techniques. More specifically, if the transfer function $H(\lambda) = C(A-\lambda)^{-1}B$ is a bounded analytic function of λ in the right half-plane $\mathbb{C}_+ = \{\lambda \in \mathbb{C} : \mathrm{Re}\lambda > 0\}$, then the autonomous system (4.4) is said to be *externally stable*. This property is often used to deduce *internal stability* of the system, i.e., the uniform exponential stability of the nominal system $\dot{x} = Ax$. The relationship between internal and external stability has been studied extensively; see, e.g., [3, 9, 8, 21, 26, 39, 40] and the references therein. In this section we examine the extent to which these techniques apply to Banach-space settings and time-varying systems. For this, *input-output stability* of the system (4.3) will refer to the property that the input-output operator $\mathbb{L}$ is bounded from $L^p(\mathbb{R}_+, U)$ to $L^p(\mathbb{R}_+, Y)$. If internal stability is assumed initially, then the inequalities in (4.7) exhibit a relationship between these concepts of stability. The next two theorems look at these relationships more closely and show, in particular, when internal stability may be deduced from one of the "external" stability conditions. Therefore, throughout this section $\{U(t,\tau)\}_{t\geq\tau}$ will denote a strongly continuous exponentially bounded evolution family that is *not* assumed to be exponentially stable.

5.1. The nonautonomous case. In this subsection we give a very short proof of the fact that for general nonautonomous systems on Banach spaces, internal stability is equivalent to stabilizability, detectability, and input-output stability. Before proceeding, it is worth reviewing some properties of time-invariant systems. For this, let $\{e^{tA}\}_{t\geq 0}$ be a strongly continuous semigroup generated by A on X, and let $H_+^\infty(\mathcal{L}(X))$ denote the space of operator-valued functions $G : \mathbb{C} \to \mathcal{L}(X)$ which are analytic on $\mathbb{C}_+$ and $\sup_{\lambda\in\mathbb{C}_+} \|G(\lambda)\| < \infty$. If X is a Hilbert space, it is well known that $\{e^{tA}\}_{t\geq 0}$ is exponentially stable if and only if $\lambda \mapsto (\lambda - A)^{-1}$ is an element of $H_+^\infty(\mathcal{L}(X))$; see, e.g., [11, Thm. 5.1.5]. This is a consequence of the fact that when X is a Hilbert space, $s_0(A) = \omega_0(e^{tA})$ (see [29] or Theorem 2.1). If X is a Banach space, then strict inequality $s_0(A) < \omega_0(e^{tA})$ can hold, and so exponential stability is no longer determined by the operator $G(\lambda) = (\lambda - A)^{-1}$. Extending these ideas to address systems (4.4), one considers $H(\lambda) = C(\lambda - A)^{-1}B$: it can be shown that if U and Y are Hilbert spaces, then (4.4) *is internally stable if and only if it is stabilizable, detectable, and externally stable* (i.e., $H(\cdot) \in H_+^\infty(\mathcal{L}(U,Y))$). See Rebarber [39] for a general result of this type. It should be pointed out that this work of Rebarber and others more recently allows for a certain degree of unboundedness of the operators B and C. Such "regular" systems (see [44]) and their time-varying generalizations might be addressed by combining the techniques of the present paper (including the characterization of generation of evolution semigroups as found in [36]) along with those of [18] and [20]. This will not be done here.

If one allows for Banach spaces, the conditions of stabilizability and detectability are *not* sufficient to ensure that external stability implies internal stability. Indeed, let A generate a semigroup for which $s_0(A) < \omega_0(e^{tA}) = 0$ (see Example 4.13). Then the system (4.4) with $B = I$ and $C = I$ is trivially stabilizable, detectable, and externally stable. But since $\omega_0(e^{tA}) = 0$, it is not internally stable.

Since the above italicized statement concerning external stability fails for Banach-space systems (4.4) and does not apply to time-varying systems (4.3), we aim to prove the following extension of this.

THEOREM 5.1. *The system* (4.3) *is internally stable if and only if it is stabilizable, detectable, and input-output stable.*

This theorem appears as part of Theorem 5.3. A version of it for finite-dimensional

time-varying systems was proven by Anderson in [3]. The fact that Theorem 5.1 actually *extends* the Hilbert-space statement above follows from the fact that the Banach-space inequality $\sup_{\lambda\in\mathbb{C}_+}\|H(\lambda)\|\le\|\mathbb{L}\|$ (see [45]) which relates the operators that define external and input-output stability is actually an *equality* for Hilbert-space systems (see also [44]).

In Theorems 5.1 and 5.3 the following definitions are used.

DEFINITION 5.2. *The nonautonomous system* (4.3) *is said to be*

(a) stabilizable *if there exists* $F(\cdot)\in L^\infty(\mathbb{R}_+,\mathcal{L}_s(X,U))$ *and a corresponding exponentially stable evolution family* $\{U_{BF}(t,\tau)\}_{t\ge\tau}$ *such that, for* $t\ge s$ *and* $x\in X$, *one has*

$$U_{BF}(t,s)x=U(t,s)x+\int_s^t U(t,\tau)B(\tau)F(\tau)U_{BF}(\tau,s)x\,d\tau; \tag{5.1}$$

(b) detectable *if there exists* $K(\cdot)\in L^\infty(\mathbb{R}_+,\mathcal{L}_s(Y,X))$ *and a corresponding exponentially stable evolution family* $\{U_{KC}(t,\tau)\}_{t\ge\tau}$ *such that, for* $t\ge s$ *and* $x\in X$, *one has*

$$U_{KC}(t,s)x=U(t,s)x+\int_s^t U_{KC}(t,\tau)K(\tau)C(\tau)U(\tau,s)x\,d\tau. \tag{5.2}$$

An autonomous control system is called stabilizable *if there is an operator* $F\in\mathcal{L}(X,U)$ *such that* $A+BF$ *generates a uniformly exponentially stable semigroup; that is,* $\omega_0(A+BF)<0$. *Such a system is* detectable *if there is an operator* $K\in\mathcal{L}(Y,X)$ *such that* $A+KC$ *generates a uniformly exponentially stable semigroup.*

Using Theorem 3.5 to characterize exponential stability in terms of the operator $\mathbb{G}$ as in (3.6) makes the proof of the following theorem a straightforward manipulation of the appropriate operators.

THEOREM 5.3. *The following are equivalent for a strongly continuous exponentially bounded evolution family of operators* $\mathcal{U}=\{U(t,\tau)\}_{t\ge\tau}$ *on a Banach space* X.

(i) $\mathcal{U}$ *is exponentially stable on* X.
(ii) $\mathbb{G}$ *is a bounded operator on* $L^p(\mathbb{R}_+,X)$.
(iii) *System* (4.3) *is stabilizable and* $\mathbb{G}\mathcal{B}$ *is a bounded operator from* $L^p(\mathbb{R}_+,U)$ *to* $L^p(\mathbb{R}_+,X)$.
(iv) *System* (4.3) *is detectable and* $\mathcal{C}\mathbb{G}$ *is a bounded operator from* $L^p(\mathbb{R}_+,X)$ *to* $L^p(\mathbb{R}_+,Y)$.
(v) *System* (4.3) *is stabilizable and detectable and* $\mathbb{L}=\mathcal{C}\mathbb{G}\mathcal{B}$ *is a bounded operator from* $L^p(\mathbb{R}_+,U)$ *to* $L^p(\mathbb{R}_+,Y)$.

Proof. The equivalence of (i) and (ii) is the equivalence of (i) and (ii) in Theorem 3.5.

To see that (ii) implies (iii), (iv), and (v), note that $\mathcal{B}$ and $\mathcal{C}$ are bounded, and thus $\mathbb{L}$ is bounded when $\mathbb{G}$ is bounded. So when (ii) holds, the exponential stability of $\mathcal{U}$ together with the boundedness of $B(\cdot)$, $C(\cdot)$, $F(\cdot)$, and $K(\cdot)$ assure the existence of the evolution families $\{U_{BF}(t,\tau)\}_{t\ge\tau}$ and $\{U_{KC}(t,\tau)\}_{t\ge\tau}$ as solutions of the integral equations in Definition 5.2, thereby showing that (iii), (iv), and (v) hold.

To see that (iii) $\Rightarrow$ (ii), first note that the assumption of stabilizability assures the existence of an exponentially stable evolution family $\mathcal{U}_{BF}=\{U_{BF}(t,\tau)\}_{t\ge\tau}$ satisfying (5.1) for some $F(\cdot)\in L^\infty(\mathbb{R}_+,\mathcal{L}_s(X,U))$. Given this exponentially stable family, we define the operator $\mathbb{G}_{BF}$ by

$$\mathbb{G}_{BF}f(s):=\int_0^s U_{BF}(s,\tau)f(\tau)\,d\tau=\int_0^\infty (E^\tau_{BF}f)(s)\,d\tau, \tag{5.3}$$

where $\{E^\tau_{BF} f\}_{t\geq 0}$ is the semigroup induced by the evolution family $\mathcal{U}_{BF}$ as described in (3.1). $\mathbb{G}_{BF}$ is a bounded operator on $L^p(\mathbb{R}_+, X)$ by the equivalence of (i) and (ii).

For $f(\cdot) \in L^p(\mathbb{R}_+, X)$ and $s \in \mathbb{R}_+$, take $x = f(s)$ in (5.1). Then let $\xi = \tau - s$ to obtain

$$U_{BF}(t,s)f(s) = U(t,s)f(s) + \int_0^{t-s} U(t,\xi+s)B(\xi+s)F(\xi+s)U_{BF}(\xi+s,s)f(s)\,d\xi.$$

From this equation and from the definition of the semigroups $\{E^t\}_{t\geq 0}$ and $\{E^t_{BF}\}_{t\geq 0}$ we obtain

$$(E^{t-s}_{BF} f)(t) = (E^{t-s} f)(t) + \int_0^{t-s} (E^{t-s-\xi}\mathcal{B}\mathcal{F}E^\xi_{BF} f)(t)\,d\xi$$

and hence for $0 \leq r$ and $0 \leq \sigma$ that

$$(E^r_{BF} f)(\sigma) = (E^r f)(\sigma) + \int_0^r (E^{r-\xi}\mathcal{B}\mathcal{F}E^\xi_{BF} f)(\sigma)\,d\xi.$$

Integrate from 0 to ∞ to obtain

$$(\mathbb{G}_{BF} f)(\sigma) = (\mathbb{G} f)(\sigma) + \int_0^\infty \int_0^r (E^{r-\xi}\mathcal{B}\mathcal{F}E^\xi_{BF} f)(\sigma)\,d\xi\,dr.$$

Let $r = \zeta + \eta$ and $\xi = \eta$ to obtain

$$\begin{aligned}(\mathbb{G}_{BF} f)(\sigma) &= (\mathbb{G} f)(\sigma) + \int_0^\infty \int_0^\infty (E^\zeta \mathcal{B}\mathcal{F}E^\eta_{BF} f)(\sigma)\,d\eta\,d\zeta \\ &= (\mathbb{G} f)(\sigma) + (\mathbb{G}\mathcal{B}\mathcal{F}\mathbb{G}_{BF} f)(\sigma).\end{aligned} \tag{5.4}$$

That $\mathbb{G}$ is bounded now follows from (5.4), the boundedness of $\mathbb{G}\mathcal{B}$, and the boundedness of $\mathbb{G}_{BF}$ and $\mathcal{F}$.

To see that (iv) $\Rightarrow$ (ii), first note that the assumption of detectability assures the existence of an exponentially stable evolution family $\mathcal{U}_{KC} = \{U_{KC}(t,\tau)\}_{t\geq\tau}$ satisfying (5.2) for some $K(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(Y,X))$. Given this exponentially stable family, the operator $\mathbb{G}_{KC}$, defined in a manner analogous to $\mathbb{G}_{BF}$ in (5.3), is a bounded operator on $L^p(\mathbb{R}_+, X)$. A derivation beginning with (5.2) and similar to that which gave (5.4) now gives $\mathbb{G}_{KC} = \mathbb{G} + \mathbb{G}_{KC}\mathcal{K}\mathcal{C}\mathbb{G}$. This equation, together with the assumed boundedness of $\mathbb{G}_{KC}$, $\mathcal{K}$, and $\mathcal{C}\mathbb{G}$, gives the boundedness of $\mathbb{G}$.

Finally, to see that (v) $\Rightarrow$ (ii), again note that the assumption of detectability yields an exponentially stable evolution family $\mathcal{U}_{KC}$ and an associated bounded operator $\mathbb{G}_{KC}$. For $u(\cdot) \in L^p(\mathbb{R}_+, U)$ and $s \in \mathbb{R}_+$ take $x = B(s)u(s)$ in (5.2). A calculation similar to that which gave (5.4) now gives $\mathbb{G}_{KC}\mathcal{B} = \mathbb{G}\mathcal{B} + \mathbb{G}_{KC}\mathcal{K}\mathcal{C}\mathbb{G}\mathcal{B}$. The assumed boundedness of $\mathbb{L} = \mathcal{C}\mathbb{G}\mathcal{B}$, $\mathcal{K}$, and $\mathbb{G}_{KC}$ now yields the boundedness of $\mathbb{G}\mathcal{B}$. The boundedness of $\mathbb{G}\mathcal{B}$ together with the assumption of stabilizability implies that $\mathbb{G}$ is bounded by the equivalence of (iii) and (ii). □

5.2. The autonomous case. The main result of this subsection is Theorem 5.4 which builds on Theorem 4.11 and parallels Theorem 5.3 for autonomous systems of the form (4.4). The main point is to provide explicit conditions, in terms of the operators A, B, and C, which imply internal stability.

Let $A_\alpha := A - \alpha I$ denote the generator of the rescaled semigroup $\{e^{-\alpha t}e^{tA}\}_{t\geq 0}$.

THEOREM 5.4. *Let $\{e^{tA}\}_{t\geq 0}$ be a strongly continuous semigroup on a Banach space X generated by A. Let U and Y be Banach spaces and assume $B \in \mathcal{L}(U,X)$ and $C \in \mathcal{L}(X,Y)$. Then the following are equivalent.*

(i) *$\{e^{tA}\}_{t\geq 0}$ is exponentially stable.*

(ii) *$\mathbb{G}$ is a bounded operator on $L^p(\mathbb{R}_+,X)$.*

(iii) *$\sigma(A)\cap\overline{\mathbb{C}}_+ = \emptyset$ and $\displaystyle\sup_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|\int_{\mathbb{R}}(A_\alpha - is)^{-1}v(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},X)}}{\|\int_{\mathbb{R}} v(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},X)}} < \infty$ for all $\alpha \geq 0$.*

(iv) *$\sigma(A)\cap\overline{\mathbb{C}}_+ = \emptyset$ and $\displaystyle\sup_{u\in\mathcal{S}(\mathbb{R},U)} \frac{\|\int_{\mathbb{R}}(A_\alpha - is)^{-1}Bu(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},X)}}{\|\int_{\mathbb{R}} u(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},U)}} < \infty$ for all $\alpha \geq 0$, and (4.4) is stabilizable.*

(v) *$\sigma(A)\cap\overline{\mathbb{C}}_+ = \emptyset$ and $\displaystyle\sup_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|\int_{\mathbb{R}} C(A_\alpha - is)^{-1}v(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},Y)}}{\|\int_{\mathbb{R}} v(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},X)}} < \infty$ for all $\alpha \geq 0$, and (4.4) is detectable.*

(vi) *$\sigma(A)\cap\overline{\mathbb{C}}_+ = \emptyset$ and $\displaystyle\sup_{u\in\mathcal{S}(\mathbb{R},U)} \frac{\|\int_{\mathbb{R}} C(A_\alpha - is)^{-1}Bu(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},Y)}}{\|\int_{\mathbb{R}} u(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},U)}} < \infty$ for all $\alpha \geq 0$, and (4.4) is both stabilizable and detectable.*

Moreover, if $\{e^{tA}\}_{t\geq 0}$ is exponentially stable, then the norm of the input-output operator $\mathbb{L} = \mathcal{C}\mathbb{G}\mathcal{B}$ is equal to

$$\sup_{u\in\mathcal{S}(\mathbb{R},U)} \frac{\|\int_{\mathbb{R}} C(A - is)^{-1}Bu(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},Y)}}{\|\int_{\mathbb{R}} u(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R},U)}}.$$

Proof. First note that the equivalence of statements (i) and (ii) follows from Remarks 3.3. Also, the implication (i)⇒(vi), as well as the last statement of the theorem, follow from Theorem 4.11. The exponential stability of $\{e^{tA}\}_{t\geq 0}$ is equivalent to the invertibility of $\Gamma_{\mathbb{R}}$ (Corollary 3.6), and so (iii) follows from (i) by Proposition 4.9.

To see that (iii) implies (i), begin by setting $\alpha = 0$. We wish to use properties of $\mathfrak{F}$ as in Proposition 4.8. We begin by observing that if the expression in (iii) is finite, then $\sup_{s\in\mathbb{R}}\|(A - is)^{-1}\| < \infty$. Indeed, if this were not the case, then there would exist $s_n \in \mathbb{R}$ and $x_n \in \mathrm{Dom}(A)$ with $\|x_n\| = 1$ such that $\|(A - is_n)x_n\| \to 0$ as $n \to \infty$. Choose functions $\beta_n \in \mathcal{S}(\mathbb{R})$ with the property that

$$\lim_{n\to\infty} \frac{\|\int_{\mathbb{R}} \beta_n(s)(is_n - is)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R})}}{\|\int_{\mathbb{R}} \beta_n(s)e^{is(\cdot)}\,ds\|_{L^p(\mathbb{R})}} = 0. \tag{5.5}$$

Note: to construct such a sequence of functions β_n, one takes, without loss of generality, $s_n = 0$ in (5.5) and chooses a "bump" function $\beta_0(s)$ where $\beta_0(0) = 1$ and β_0 has support in $(-1,1)$. Then set $\beta_n(s) = n\beta_0(ns)$. If $\check{}$ denotes the inverse Fourier transform, then $\check{\beta}_n(\tau) = \check{\beta}_0(\tau/n)$. Also, for $\alpha_n(s) = s\beta_n(s)$, one has $\check{\alpha}_n(\tau) = \frac{1}{n}\check{\alpha}_0(\tau/n)$, and so

$$\frac{\|\int_{\mathbb{R}} \beta_n(s)se^{is(\cdot)}\,ds\|^p_{L^p(\mathbb{R})}}{\|\int_{\mathbb{R}} \beta_n(s)e^{is(\cdot)}\,ds\|^p_{L^p(\mathbb{R})}} = \frac{\|\check{\alpha}_n\|^p}{\|\check{\beta}_n\|^p} = \frac{\left(\frac{1}{n}\right)^p\|\check{\alpha}_0\|^p}{\|\check{\beta}_0\|^p} \to 0 \quad \text{as } n \to \infty.$$

Now, setting $v_n(s) := \beta_n(s)(A - is)x_n$ gives a function v_n in $\mathcal{S}(\mathbb{R}, X)$ with the properties that $(A - is)^{-1}v_n(s) = \beta_n(s)x_n$. Thus

$$\begin{aligned}
\frac{\| \int_{\mathbb{R}} (A - is)^{-1} v_n(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} v_n(s) e^{is(\cdot)}\, ds\|} &= \frac{\| \int_{\mathbb{R}} \beta_n(s) x_n e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} \beta_n(s)(A - is)x_n e^{is(\cdot)}\, ds\|} \\
&= \frac{\| \int_{\mathbb{R}} \beta_n(s) x_n e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} \beta_n(s)(A - is_n)x_n e^{is(\cdot)}\, ds + \beta_n(s)(is_n - is)x_n e^{is(\cdot)}\, ds\|} \\
&\geq \frac{\| \int_{\mathbb{R}} \beta_n(s) x_n e^{is(\cdot)}\, ds\|}{\|(A - is_n)x_n\| \, \| \int_{\mathbb{R}} \beta_n(s) e^{is(\cdot)}\, ds\| + \| \int_{\mathbb{R}} \beta_n(s)(is_n - is)x_n e^{is(\cdot)}\, ds\|} \\
&= \left(\|(A - is_n)x_n\| + \frac{\| \int_{\mathbb{R}} \beta_n(s)(is_n - is) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} \beta_n(s) e^{is(\cdot)}\, ds\|} \right)^{-1}.
\end{aligned}$$

By the choice of s_n, x_n, and β_n, this last expression goes to ∞ as $n \to \infty$, contradicting (iii). Hence if the expression in (iii) is finite for $\alpha = 0$, then $\sup_{s\in\mathbb{R}} \|(A - is)^{-1}\| < \infty$.

Now we may apply Proposition 4.8(ii) and Proposition 4.9 to obtain

$$\|\Gamma_{\mathbb{R}}\|_\bullet = \inf_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|\Gamma_{\mathbb{R}} f_v\|}{\|f_v\|} = \inf_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|g_v\|}{\|f_v\|} = \left(\sup_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|f_v\|}{\|g_v\|} \right)^{-1} > 0.$$

This shows that $0 \notin \sigma_{ap}(\Gamma_{\mathbb{R}})$ and so, by [23], it follows that $\sigma_{ap}(e^{tA}) \cap \mathbb{T} = \emptyset$. On the other hand, since $\sigma(A) \cap i\mathbb{R} = \emptyset$, it follows from the spectral mapping theorem for the residual spectrum $\sigma_r(e^{tA})$ that

$$\sigma(e^{tA}) \cap \mathbb{T} = \big[\sigma_{ap}(e^{tA}) \cup \sigma_r(e^{tA})\big] \cap \mathbb{T} = \emptyset.$$

The same argument holds for any $\alpha \geq 0$. As a result, $\{e^{tA_\alpha}\}_{t\geq 0}$ is hyperbolic for each $\alpha \geq 0$, and thus $\{e^{tA}\}_{t\geq 0}$ is exponentially stable.

So far it has been shown that the statements (i)–(iii) are equivalent, and that statement (i) implies (vi). By showing that (vi)⇒(iv)⇒(iii) and (vi)⇒(v)⇒(iii), we complete the proof.

To see that (vi) implies (iv), begin by setting $\alpha = 0$. Since (4.4) is detectable, there exists $K \in \mathcal{L}(Y, X)$ such that $A + KC$ generates an exponentially stable semigroup. By the implication (i)⇒(iii) for the semigroup $\{e^{t(A+KC)}\}$, it follows that

$$M_1 := \sup_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\| \int_{\mathbb{R}} (A + KC - is)^{-1} v(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} v(s) e^{is(\cdot)}\, ds\|}$$

is finite. So

(5.6)

$$\sup_{u\in\mathcal{S}(\mathbb{R},U)} \frac{\| \int_{\mathbb{R}} (A + KC - is)^{-1} B u(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} u(s) e^{is(\cdot)}\, ds\|}$$

$$= \sup_{u\in\mathcal{S}(\mathbb{R},U)} \frac{\| \int_{\mathbb{R}} (A + KC - is)^{-1} B u(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} B u(s) e^{is(\cdot)}\, ds\|} \cdot \frac{\|B \int_{\mathbb{R}} u(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} u(s) e^{is(\cdot)}\, ds\|} \leq M_1 \|B\|.$$

By hypothesis in (vi),

$$M_2 := \sup_{u\in\mathcal{S}(\mathbb{R},U)} \frac{\| \int_{\mathbb{R}} C(A - is)^{-1} B u(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} u(s) e^{is(\cdot)}\, ds\|}$$

is finite. For $u \in \mathcal{S}(\mathbb{R}, U)$, let $w(s) = KC(A - is)^{-1}Bu(s),\ s \in \mathbb{R}$. Then

$$\frac{\| \int_{\mathbb{R}} (A + KC - is)^{-1} KC(A - is)^{-1} Bu(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} u(s) e^{is(\cdot)}\, ds\|} \tag{5.7}$$

$$= \frac{\| \int_{\mathbb{R}} (A + KC - is)^{-1} w(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} w(s) e^{is(\cdot)}\, ds\|} \cdot \frac{\|K \int_{\mathbb{R}} C(A - is)^{-1} Bu(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} u(s) e^{is(\cdot)}\, ds\|}$$

$$\leq M_1 \|K\| M_2.$$

Finally, since

$$(A - is)^{-1} B = (A + KC - is)^{-1} B + (A + KC - is)^{-1} KC(A - is)^{-1} B,$$

it follows from (5.6) and (5.7) that

$$\sup_{u \in \mathcal{S}(\mathbb{R}, U)} \frac{\| \int_{\mathbb{R}} (A - is)^{-1} Bu(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} u(s) e^{is(\cdot)}\, ds\|} \leq M_1 \|B\| + M_1 \|K\| M_2.$$

This argument holds for all $\alpha \geq 0$, so the implication (vi)⇒(iv) follows.

To see that (iv) implies (iii), we again argue only in the case $\alpha = 0$. Since (4.4) is stabilizable, there exists $F \in B(X, U)$ such that $A + BF$ generates an exponentially stable semigroup. By the implication (i)⇒(iii) for the semigroup $\{e^{t(A+BF)}\}$, it follows that

$$M_3 := \sup_{v \in \mathcal{S}(\mathbb{R}, X)} \frac{\| \int_{\mathbb{R}} (A + BF - is)^{-1} v(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} v(s) e^{is(\cdot)}\, ds\|}$$

is finite. By the hypotheses in (iv),

$$M_4 := \sup_{u \in \mathcal{S}(\mathbb{R}, U)} \frac{\| \int_{\mathbb{R}} (A - is)^{-1} Bu(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} u(s) e^{is(\cdot)}\, ds\|}$$

is finite. For $v \in \mathcal{S}(\mathbb{R}, X)$, set $w(s) = F(A + BF - is)^{-1} v(s),\ s \in \mathbb{R}$. Then

$$\sup_{v \in \mathcal{S}(\mathbb{R}, X)} \frac{\| \int_{\mathbb{R}} (A - is)^{-1} BF(A + BF - is)^{-1} v(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} v(s) e^{is(\cdot)}\, ds\|} \tag{5.8}$$

$$= \frac{\| \int_{\mathbb{R}} (A - is)^{-1} Bw(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} w(s) e^{is(\cdot)}\, ds\|} \cdot \frac{\|F \int_{\mathbb{R}} (A + BF - is)^{-1} v(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} v(s) e^{is(\cdot)}\, ds\|}$$

$$\leq M_4 \|F\| M_3.$$

Since

$$(A - is)^{-1} = (A + BF - is)^{-1} + (A - is)^{-1} BF(A + BF - is)^{-1},$$

it follows from (5.8) that

$$\sup_{v \in \mathcal{S}(\mathbb{R}, X)} \frac{\| \int_{\mathbb{R}} (A - is)^{-1} v(s) e^{is(\cdot)}\, ds\|}{\| \int_{\mathbb{R}} v(s) e^{is(\cdot)}\, ds\|} \leq M_3 + M_4 \|F\| M_3.$$

Thus (iii) follows from (iv). Similar arguments show that (vi)⇒(v) and that (v)⇒(iii). □

From the equivalence of statements (i) and (iii), it follows that the growth bound of a semigroup on a Banach space is given by

$$\omega_0(e^{tA}) = \inf\left\{\alpha \in \mathbb{R} : \sup_{v\in\mathcal{S}(\mathbb{R},X)} \frac{\|\int_{\mathbb{R}}(A_\alpha - is)^{-1}v(s)e^{is(\cdot)}\,ds\|}{\|\int_{\mathbb{R}} v(s)e^{is(\cdot)}\,ds\|} < \infty\right\}.$$

This is a natural generalization of the formula for the growth bound for a semigroup on a Hilbert space as provided by Gearhart's theorem (see [19, 2, 29, 33] and cf. Theorem 2.1):

$$\omega_0(e^{tA}) = s_0(A) = \inf\left\{\alpha \in \mathbb{R} : \sup_{\mathrm{Re}\lambda\geq\alpha} \|(A-\lambda)^{-1}\| < \infty\right\}.$$

THEOREM 5.5. *Let $\{e^{tA}\}_{t\geq 0}$ be a strongly continuous semigroup on a Banach space X with the property that $s_0(A) = \omega_0(e^{tA})$. Assume (4.4) is stabilizable and detectable. If $\overline{\mathbb{C}}_+ \subset \rho(A)$ and $M := \sup_{s\in\mathbb{R}} \|C(A-is)^{-1}B\| < \infty$, then $\{e^{tA}\}_{t\geq 0}$ is exponentially stable.*

Proof. Choose operators $F \in \mathcal{L}(X,U)$ and $K \in \mathcal{L}(Y,X)$ such that the semigroups generated by $A+BF$ and $A+KC$ are exponentially stable. Then $s_0(A+BF) < 0$ and $s_0(A+KC) < 0$, and so

$$M_1 := \sup_{s\in\mathbb{R}} \|(A+BF-is)^{-1}\| \quad \text{and} \quad M_2 := \sup_{s\in\mathbb{R}} \|(A+KC-is)^{-1}\|$$

are both finite. Since

$$(A-is)^{-1}B = (A+KC-is)^{-1}B + (A+KC-is)^{-1}KC(A-is)^{-1}B,$$

it follows that

$$M_3 := \sup_{s\in\mathbb{R}} \|(A-is)^{-1}B\| \leq M_2\|B\| + M_2\|K\|M.$$

Also,

$$(A-is)^{-1} = (A+BF-is)^{-1} + (A-is)^{-1}BF(A+BF-is)^{-1},$$

and so

$$\sup_{s\in\mathbb{R}} \|(A-is)^{-1}\| \leq M_1 + M_3\|F\|M_1.$$

Therefore, $\omega_0(e^{tA}) = s_0(A) < 0$. □

The following result, based on [22], describes a particular situation in which $s_0(A) = \omega_0(e^{tA})$.

COROLLARY 5.6. *Assume that for the generator A of a strongly continuous semigroup $\{e^{tA}\}_{t\geq 0}$ on a Banach space X there exists an $\omega > \omega_0(e^{tA})$ such that*

$$\int_{-\infty}^{\infty} \|(\omega + i\tau - A)^{-1}x\|_X^2\,d\tau < \infty \quad \textit{for all} \quad x \in X, \tag{5.9}$$

and

$$\int_{-\infty}^{\infty} \|(\omega + i\tau - A^*)^{-1} x^*\|_{X^*}^2 \, d\tau < \infty \quad \textit{for all} \quad x^* \in X^*, \tag{5.10}$$

where X^* is the adjoint space. Then system (4.4) *is internally stable if and only if it is stabilizable, detectable, and externally stable.*

Proof. According to [22] (see also [29, Cor. 4.6.12]), conditions (5.9)–(5.10) imply $s_0(A) = \omega_0(e^{tA})$. Now Theorem 5.5 gives the result. ∎

SOLVABLE STATES IN n-PLAYER STOCHASTIC GAMES*

NICOLAS VIEILLE†

Abstract. We prove that, in every stochastic game with finitely many states and actions, there exists at least one state, starting from which an equilibrium payoff exists. This is achieved by proving that there exists a solvable set. This generalizes to an arbitrary number of players a result due to Thuijsman and Vrieze in the case of two players.

Key words. stochastic games, nonzero-sum games, equilibrium payoff

1. Introduction.

We prove that, in every stochastic game with finitely many states and actions, there exists at least one state, starting from which an equilibrium payoff exists. An associated ϵ-equilibrium profile consists of playing essentially like some stationary profile x, sustained by appropriate threats. More precisely, the players cycle periodically over some ergodic sets of the Markov chain induced by x and travel between these sets by using small perturbations of x.

This result is a generalization to an arbitrary number of players of a result due to Thuijsman and Vrieze [6] (see also [8]) in the case of two players. For two players, the analog result turned out to be the first step in the proof of existence of equilibrium payoffs for general two-player games (cf. [9]).

The proof is much more involved than for two players. Usually, states are compared by means of the (undiscounted) min max values. This is not enough here. We order the states lexicographically, using *discounted* min max values. We argue that the set of states with highest min max values contains a solvable set. As far as I know, this is the first result on nonzero-sum games for which this refined comparison between states turns out to be important (a similar comparison was used by Tijs and Vrieze [7] for two-player, zero-sum games).

This has the consequence that in every stochastic game, there exists at least one initial state for which an equilibrium payoff does exist.

Section 2 is devoted to the model and the statement of the result. Section 3 contains some additional definitions and a refined statement of the result. The existence of a solvable set is established in section 5.

2. Model and results.

2.1. Rules of the games.

For every finite set S, $\Delta(S)$ is the simplex of probability distributions over S; for $\mu \in \Delta(S)$ and $s \in S$, the probability of s is $\mu(s)$. The set of players is $\mathcal{I} = \{1, \dots, I\}$, with $I \in \mathbf{N}$.

A stochastic game is described by a finite set of states K, the finite set A^i of actions available to player $i \in \mathcal{I}$ in each state k, a transition function $\mathbf{q} : K \times A \to \Delta(K)$, with $A = \prod_i A^i$, which describes the evolution of the state of the game, and a function $g : K \times A \to \mathbf{R}^I$ which describes the payoff received by the players in any stage.

†Ecole Polytechnique, Laboratoire D'Économétrie, 1 rue Descartes, 75005 Paris, France (vieille@poly.polytechnique.fr).

The game is played as follows. The set of stages is the set $\mathbf{N}^*$ of positive integers. The initial state k_1 is given. In stage n, the current state k_n is announced to the players. Each player i chooses an action $a_n^i \in A^i$; the action combination $a_n = (a_n^i)_{i\in\mathcal{I}}$ is publicly announced, k_{n+1} is drawn according to $\mathbf{q}(\cdot|k_n, a_n)$, and the game proceeds to stage $n+1$.

We denote by $H_\infty = (K \times A)^{\mathbf{N}}$ the set of plays and by $H_n = (K \times A)^{n-1} \times K$ the set of histories up to stage n. A *strategy* of player i is a sequence $\sigma^i = (\sigma_n^i)_{n\in\mathbf{N}^*}$, where $\sigma_n^i : H_n \to \Delta(A^i)$ describes the behavior of player i in stage n. The set of strategies of player i is denoted by Σ^i, and we set $\Sigma = \prod_{i\in\mathcal{I}} \Sigma^i$.

We denote by $\mathcal{H}_n$ the algebra of cylinder sets over H_∞, induced by H_n, and we set $\mathcal{H}_\infty = \sigma(\mathcal{H}_n, n \in \mathbf{N}^*)$.

We denote by $\mathbf{P}_{k,\sigma}$ the probability distribution over $(H_\infty, \mathcal{H}_\infty)$, when the initial state is k, and the players use the strategies σ. Expectations with respect to $\mathbf{P}_{k,\sigma}$ are denoted by $\mathbf{E}_{k,\sigma}$.

The mixed extension of $\mathbf{q}$ to $K \times \prod_i \Delta(A^i)$ is still denoted by $\mathbf{q}$. We will follow standard use and denote by $-i$ the *coalition* of players other than i: we set $A^{-i} = \prod_{j\neq i} A^j$, $\Sigma^{-i} = \prod_{j\neq i} \Sigma^i$, and we use similar shortcuts whenever needed.

All norms used in the paper are *supremum* norms. We assume for simplicity that $\|g\| \leq 1$. The cardinality of a finite set A is denoted by $|A|$. Finally, for $P \in \Delta(K)$ and $f : K \to \mathbf{R}$, we denote either by Pf or $P[f]$ the expectation of f under P.

2.2. min max and equilibrium payoffs. We denote by $g_n = g(k_n, a_n) \in \mathbf{R}^I$ the payoff in stage n and by

$$\gamma_n(k, \sigma) = \mathbf{E}_{k,\sigma}\left[\frac{1}{n}\sum_{p=1}^{n} g_p\right]$$

the expected average payoff up to stage n, when the initial state is k, and the players use $\sigma \in \Sigma$. We set $\gamma_n(\sigma) = (\gamma_n(k, \sigma))_{k\in K}$, and we will use similar vector notations whenever convenient.

As often happens in stochastic games, punishment strategies will play an important role. Recall that $v^i \in \mathbf{R}^K$ is the min max for player i if (see [3]) the following hold.

1. Players $-i$ can guarantee v^i: for every $\epsilon > 0$, there exists $\sigma_\epsilon^{-i} \in \Sigma^{-i}$ and a stage $N_0 \in \mathbf{N}$, such that
$$\forall \sigma^i \in \Sigma^i, n \geq N_0, \gamma_n^i(\sigma^i, \sigma_\epsilon^{-i}) \leq v^i + \epsilon.$$
2. Player i can defend v^i: for every $\epsilon > 0$, there exists a stage $N_0 \in \mathbf{N}$, such that for every $\sigma^{-i} \in \Sigma^{-i}$,
$$\exists \sigma^i \in \Sigma^i, \text{ such that } \forall n \geq N_0, \gamma_n^i(\sigma^i, \sigma^{-i}) \geq v^i - \epsilon.$$

The first condition says that, by playing (σ_ϵ^{-i}), players other than i ensure that player i's average payoffs will not exceed v^i. The second says that player i always has a reply which keeps his average payoff above v^i. Therefore, $v^i(k)$ is the punishment level that players $-i$ may inflict on player i, starting from k.

The existence of the min max in this framework has been proven by Neyman [4], extending the proof of Mertens and Neyman [2].

As usual, we say that $\sigma_* \in \Sigma$ is an ϵ-equilibrium profile in the n-stage game if for every $k \in K$, $i \in \mathcal{I}$, and $\sigma^i \in \Sigma^i$,

$$\gamma_n^i(k, \sigma^i, \sigma_*^{-i}) \leq \gamma_n^i(k, \sigma_*) + \epsilon.$$

We say that σ_* is an ϵ-equilibrium profile if it is an ϵ-equilibrium profile in the n-stage game for every n large enough.

Finally, we define equilibrium payoffs.

DEFINITION 1. *Let $d \in (\boldsymbol{R}^I)^K$. d is an equilibrium payoff if, for every $\varepsilon > 0$, there exists an ε-equilibrium profile σ^* and an integer N_0 such that*

$$||d - \gamma_n(\sigma^*)|| < \varepsilon \quad \forall n \geq N_0.$$

The set of equilibrium payoffs of Γ is denoted by $E(\Gamma)$. It is clear how to specialize the above definitions to a *given* initial state. We denote $E_k(\Gamma)$ the set of equilibrium payoffs of the game Γ, with initial state k. Notice that $E_k(\Gamma) \subset \mathbf{R}^I$ and that $E(\Gamma) = \prod_{k\in K} E_k(\Gamma)$.

Our basic result is the following.

THEOREM 2. *There exists $k \in K$, with $E_k(\Gamma) \neq \emptyset$.*

We actually prove a more precise result, stated below (Proposition 9).

3. Preliminaries. In this section, we define solvable states and give in Proposition 7 an improved statement of Theorem 2.

3.1. Stationary strategies and communication. A strategy of player i is *stationary* if the behavior of player i depends only upon the *current* state. Thus a stationary strategy can be identified to a vector $x^i = (x^i_k)$, where $x^i_k \in \Delta(A^i)$ is the lottery used by player i whenever the current state is k. We denote by $\mathcal{S}^i (= \Delta(A^i)^K)$ the set of stationary strategies of player i and set $\mathcal{S} = \prod_i \mathcal{S}^i$.

For $x^i_k \in \Delta(A^i)$, $\mathrm{supp}(x^i_k) = \{a^i \in A^i, x^i_k(a^i) > 0\}$ is the support of x^i_k. For $x^i = (x^i_k)_{k\in K} \in \mathcal{S}^i$, we set $\mathrm{supp}(x^i) = \prod_k \mathrm{supp}(x^i_k)$.

For every $x \in \mathcal{S}$, the sequence $(k_n)_{n\in\mathbf{N}^*}$ is a Markov chain under $\mathbf{P}_{k,x}$. Hence $\gamma(x) = \lim_{n\to\infty} \gamma_n(x)$ exists. For simplicity, we shall speak of ergodic sets for x, instead of ergodic sets for the Markov chain induced by x, and we shall use similar shortcuts whenever convenient. If R is an ergodic set for x, then $\gamma(k, x)$ is independent of $k \in R$. We simply write $\gamma_R(x)$.

We define now *communicating* sets, which generalize *ergodic* sets. A *perturbation* of $x \in \mathcal{S}$ is a profile $\tilde{x} \in \mathcal{S}$ such that $\mathrm{supp}(x) \subseteq \mathrm{supp}(\tilde{x})$.

Let $x \in \mathcal{S}$, and let $k, k' \in K$. A finite sequence $(k_0 = k, k_1, \ldots, k_N = k')$ in K is a path from k to k' under x if, for any $n \in \{0, \ldots, N-1\}$, $\mathbf{q}(k_{n+1}|k_n, x_{k_n}) > 0$. k *leads to* k' under x if there exists a path from k to k'.

A subset E of K is closed under x if $\mathbf{q}(E|k, x_k) = 1$ for every $k \in E$.

DEFINITION 3. *Let $x \in \mathcal{S}$, $E \subseteq K$. E is a communicating set for x if, for any $k, k' \in E$, there exists a perturbation $\tilde{x}$ of x such that, under $\tilde{x}$, E is closed and k leads to k'.*

This captures the idea that the players are able to visit an infinite number of times any given state in E, without leaving E.

DEFINITION 4. *$\mathcal{C}(x)$ is the set of communicating sets for x.*

Remark. Of course, any set which is ergodic for x is a communicating set for x. More generally, let $x, x' \in \mathcal{S}$ be such that $\mathrm{supp}(x) \subseteq \mathrm{supp}(x')$. Every ergodic set for x' is a communicating set for x.

3.2. Solvable sets. Let $x \in \mathcal{S}$, and let $E \in \mathcal{C}(x)$. We denote by $\mathcal{R}_E(x)$ the set of subsets of E which are ergodic for x. Since a communicating set for x is closed under x, $\mathcal{R}_E(x) \neq \emptyset$.

DEFINITION 5. *Let $x \in \mathcal{S}$, $E \in \mathcal{C}(x)$, and $\mu \in \Delta(\mathcal{R}_E(x))$. The 3-tuple (E, x, μ) is solvable if for every $k \in E, i \in \mathcal{I}, a^i \in A^i$, one has*

$$\mathbf{q}(\cdot|k, a^i, x_k^{-i})v^i \leq \sum_{R \in \mathcal{R}_E(x)} \mu(R)\gamma_R^i(x).$$

It is convenient to say simply that E is solvable. We refer to the quantity

$$\sum_{R \in \mathcal{R}_E(x)} \mu(R)\gamma_R^i(x)$$

as the solvable payoff of E. It follows from the definition that the solvable payoff is at least $\max_{k \in E} v(k)$. We shall prove Propositions 6 and 7, stated below. They obviously imply Theorem 2.

PROPOSITION 6. *Let (E, x, μ) be a solvable set. For $k \in E, \sum_R \mu(R)\gamma_R(x) \in E_k(\Gamma)$.*

PROPOSITION 7. *There exists a solvable set.*

The notion of solvable sets that is used here for n-player games is the generalization of the one that proved most useful in the analysis of two-player games (see [9]). It turns out that the proof of Proposition 7 we give below establishes the existence of *easy initial sets.*

DEFINITION 8. *Let $E \subseteq K$. The set E is an easy initial set if, for every $\varepsilon > 0$, there exists a stationary profile x such that E is an ergodic set for x and, for every $k \in E, i \in \mathcal{I}, a^i \in A^i$, one has*

$$\mathbf{q}(\cdot|k, a^i, x_k^{-i})v^i - \varepsilon \leq \gamma_E^i(x).$$

This notion is due to Thuijsman and Vrieze [6]. It is not difficult to check that easy initial sets are solvable. Therefore, the existence of easy initial sets is a stronger result than the existence of solvable sets. Also, replacing solvable sets by easy initial sets in the statement of Proposition 6 (and modifying the rest of the statement accordingly) would allow for a slightly easier proof. We nevertheless deal here with the notion of solvable sets, since this notion is slightly easier to use in two-player games. This hints that it might also be the case for n-player games.

3.3. Reminder on discounted games. We recall here some known facts about discounted games. For $\lambda \in (0, 1], \sigma \in \Sigma$, and $k \in K$, we denote by

$$\gamma_\lambda(k, \sigma) = E_{k,\sigma}\left[\lambda \sum_{n=1}^{\infty} (1-\lambda)^{n-1} g_n\right]$$

the discounted payoff induced by σ, when the initial state is k.

For $i \in \mathcal{I}$, we also denote by $v_\lambda^i(k) = \min_{\Sigma^{-i}} \max_{\Sigma^i} \gamma_\lambda^i(k, \sigma^{-i}, \sigma^i)$ the discounted min max value for player i.

For $\lambda \in (0, 1]$, $i \in \mathcal{I}$, and $x \in \mathcal{S}$, we define an operator $U_{\lambda,x}^i$ over functions $u : K \to \mathbf{R}$ by

$$U_{\lambda,x}^i u(k) = \lambda g^i(k, x_k) + (1-\lambda)\mathbf{q}(\cdot|k, x_k)u.$$

Let $e \in \mathbf{R}^K$ be the vector $(1, 1, \ldots, 1)$. The following two facts are well known.

Fact 1. For $u : K \to \mathbf{R}, c \in \mathbf{R}, x \in \mathcal{S}$, and $\lambda \in (0, 1]$,

$$U_{\lambda,x}^i u \geq u - c \cdot e \Rightarrow \gamma_\lambda^i(x) \geq u - \frac{c}{\lambda}.$$

Indeed, $U^i_{\lambda,x}u \geq u - c\cdot e$ yields inductively $(U^i_{\lambda,x})^n u \geq u - c(\frac{1-(1-\lambda)^n}{\lambda})\cdot e$. The right-hand side property follows, since $\gamma^i_\lambda(x) = \lim_{n\to\infty}(U^i_{\lambda,x})^n u$.

Fact 2 (see Shapley [5]). For every $x^{-i} \in \mathcal{S}^{-i}$, there exists $x^i \in \mathcal{S}^i$, such that

$$U^i_{\lambda,(x^{-i},x^i)} v^i_\lambda \geq v^i_\lambda.$$

It is known (cf. Bewley and Kohlberg [1] and Neyman [4]) that $v^i = \min_{\lambda\to 0} v^i_\lambda$ and that, for each $i \in \mathcal{I}$ and $k \in K$, the function $\lambda \mapsto v^i_\lambda(k)$ has a Puiseux expansion in a neighborhood of 0: there exists $\lambda_0 > 0, M \in \mathbf{N}, N \in \mathbf{Z}$, and a sequence of real numbers $a^i_p(k)$, $p \in \mathbf{Z}$, such that

$$\forall \lambda < \lambda_0,\ v^i_\lambda(k) = \sum_{p=N}^{+\infty} a^i_p(k)\lambda^{\frac{p}{M}}.$$

Since payoffs are bounded, $a^i_p(k) = 0$ for $p < 0$.

4. Solvable payoffs are equilibrium payoffs. This lemma is proven in Vieille [9] in the case of two players. We briefly sketch the extension to an arbitrary number of players.

We describe ϵ-equilibrium profiles associated to $\sum_R \mu(R)\gamma_R(x)$. The players visit cyclically the elements of $\mathcal{R}_E(x)$ in a fixed order $R_1, \ldots, R_L$, without ever leaving E. In each visit to R_l, they stick to x during N_l stages. Going from one element R_l to the following one R_{l+1} is feasible using small perturbations of x, since E is a communicating set for x. For each l, we choose a stationary profile $x(l)$, such that E is closed under $x(l)$, and R_{l+1} is the only subset of E which is ergodic for $x(l)$. Moreover, we require that $x(l)$ be close to x. The length N_l of the visits to R_l is chosen to be proportional to $\mu(R_l)$ and sufficiently large so that (i) the payoff during one visit to R_l is close to $\gamma_{R_l}(x)$, and (ii) the expected time between two visits is small compared to the length of the visits.

This behavior is supported by tests, designed as follows. Players need to enforce not only that each player i plays roughly according to x^i during the visits to the different sets, but also that player i indeed plays $x^i(l)$ when the profile asks for going from one ergodic set R_l to the following one R_{l+1}. On the equilibrium path, there will be infinitely many cycles and hence infinitely many excursions from R_l to R_{l+1}. Denote by F_l the smallest subset of E, which contains R_l and is closed for $x(l)$. On the equilibrium path, only states in F_l can be reached during an excursion from R_l to R_{l+1}. Moreover, each of the states in F_l will be visited infinitely many times during these excursions. These observations allow for standard statistical checking of the play of each player, based on the empirical distribution of moves. Details are standard.

As soon as one of the statistical tests is failed by some player, say by player i, the others switch to a *punishment profile* which brings player i's future payoffs down to v^i.

Remark. If one did replace min max values by max min values in the definition of a solvable set, the proof of existence would be much simpler than the one below. However, the above scenario does not work, since there is no punishment profile which brings player i's payoffs down to the max min.

Remark. In the two-player case, simpler ε-equilibrium profiles can be designed. Checking of the opponent's play can be reduced to checking that its average payoff remains (after sufficiently many stages) close to its theoretical payoff. This is not true for more than two-player games, since it might then be in player i's interest to deviate

in such a way as to increase player j's payoff ($j \neq i$), in order to benefit from the punishment of player j.[1]

Remark. In the case of two players, Proposition 6 can be extended. Assume that perfect monitoring does not hold, and that, prior to playing in stage n, each player is only told the current state k_n and the payoff vector obtained in the previous stage g_{n-1}. There might exist profitable deviations from the above scenario. However, this is not the case (hence the scenario describes an ϵ-equilibrium profile) if the following additional assumptions are satisfied.

1. v is constant over E.
2. For each $R \in \mathcal{R}_E(x)$, the perturbation $\tilde{x}$ of x which is used to reach R can be chosen in such a way that for every $k \in E, i \in \mathcal{I}$, and $a^i \in A^i$,

$$\mathbf{q}(\cdot|k, a^i, \tilde{x}_k^{-i})v^i \leq \sum_{R \in \mathcal{R}_E(x)} \mu(R)\gamma_R^i(x).$$

(The first test in the scenario can no longer be performed; it has to be replaced by: check that the current state is in E.) The solvable sets which we define below will enjoy these additional properties by construction. Therefore, Theorem 2 still holds.

5. Existence of a solvable set.

5.1. Preliminary discussion. A few preliminary explanations are in order at this point. We prove below the existence of a solvable set within the set of states with *highest* min max value (ranked according to some lexicographic order).

The basic idea is the following. Intuitively, each player i might prevent the play from leaving the states with highest min max value: otherwise, players $-i$ could bring players i's average payoffs below this highest value (simply by playing in such a way that the play reaches a set with lower min max values, and by playing optimally from then on). The obvious idea is then to order the states lexicographically, according to their min max values, to consider the set F of states with maximal min max values, and to find a stationary equilibrium in the discounted constrained game, in which each player is restricted to the actions that prevent the play from leaving F (this is a bit loose, since the corresponding sets of actions have to be defined iteratively; precise statements will follow). One then would prove that the payoff induced by this constrained equilibrium is individually rational, and one would deduce that some ergodic set for this equilibrium is solvable.

There are difficulties in implementing this program. If one deals with the *undiscounted* min max value, it is not true that constrained discounted equilibria yield individually rational payoffs (even approximately), as is shown by the two-player, zero-sum example below.

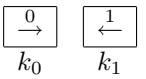
$$\begin{matrix} 0 & 1^* \\ 1^* & 0^* \end{matrix}$$

This game has one nonabsorbing state k, which is described by the previous matrix, and two absorbing states k_0 and k_1, with payoffs 0 and 1. As usual, the meaning of a starred entry is that, if the entry is played in state k, the play moves to the absorbing state with the corresponding payoff. Since an absorbing state is always solvable, the existence of solvable sets is here trivial. However, observe that the undiscounted value in the nonabsorbing state is 1 (the stationary strategy which puts a weight of ε to the

[1] I wish to thank a referee for pointing this out.

bottom row guarantees $1-\varepsilon$). The states with maximal undiscounted value to player 1 are therefore k and k_1. Set $F=\{k,k_1\}$. In the nonabsorbing state, the only action of player 1 that prevents the play from leaving F is the top row. Given that player 1 is playing the top row, both actions of player 2 prevent the play from leaving F. In the constrained game, where player 1 is restricted to the top row, the unique discounted equilibrium is clearly obtained when player 2 plays the left row, which results in a payoff of zero, which is not individually rational. Thus the above program fails (of course, one might argue that, for every player, there is always one initial state such that the corresponding payoff is individually rational; the fact that we deal with more than two players would lead to substantial difficulties).

Therefore, some care is needed in the comparison of states. We instead deal with the *discounted* min max value. But it is not true that a player can prevent the play from leaving the set of states with highest discounted min max value, as is shown by the next trivial one-player game.



This game has two states: the player has only one action in each state, and the play bounces back and forth between k_0 and k_1 (arrays indicate transitions, and numbers indicate current payoffs). The discounted payoff starting from k_1 is $\frac{1}{2-\lambda}$, which is higher than the payoff $\frac{1-\lambda}{2-\lambda}$ starting from k_0. Notice that the spread $\frac{\lambda}{2-\lambda}$ is some $O(\lambda)$. This is why the correct notion of comparison will allow for this $O(\lambda)$.

5.2. States with high discounted min max value. Let $f:(0,1]\to\mathbf{R}$ be a function with a Puiseux expansion $f(\lambda)=\sum_{p=0}^{\infty}a_p\lambda^{\frac{p}{M}}$ in the neighborhood of 0. We use the Landau notation and write $f=O(\lambda)$ if the function $\lambda\mapsto\frac{f(\lambda)}{\lambda}$ is bounded in a neighborhood of 0. This amounts to $\frac{1}{M}\inf\{p\in\mathbf{N},a_p\neq 0\}\geq 1$.

Let $F\subseteq K$. Since F is finite, it is clear that $\lambda\mapsto\max_F v^i_\lambda$ has a Puiseux expansion in the neighborhood of 0. We set

$$B_i(F)=\{k\in F,\ \max_F v^i_\lambda - v^i_\lambda(k)=O(\lambda)\}:$$

this is the (nonempty) subset of states of (almost) highest value for player i.

For $k\in B_i(F)$, there exist $c_0\geq 0$ and $\lambda_0>0$ such that

$$\forall\lambda<\lambda_0,\ \max_F v^i_\lambda - v^i_\lambda(k)\leq c_0\lambda. \tag{1}$$

For $k\notin B_i(F)$, there exists $c_1>0$, $\lambda_0>0$, and $\beta<1$, such that

$$\forall\lambda<\lambda_0,\ \max_F v^i_\lambda - v^i_\lambda(k)>c_1\lambda^\beta. \tag{2}$$

Since K and $\mathcal{I}$ are finite, we may choose c_0,c_1,λ_0, and β independently of F,k, and i.

Set then $F_0=K$ and, for $i=1,\dots,I$, $F_i=B_i(F_{i-1})$, and $F=F_I$. We shall prove the following improvement of Proposition 7.

PROPOSITION 9. *There exists a solvable set (E,x,μ), with $E\subseteq F$.*

Remark. The order $1,\dots,I$ on the players is obviously arbitrary: if one constructs the sets (F_i) using any other order on the players, the conclusion of Proposition 9 still holds.

For $k \in F$, we define inductively subsets $\tilde{A}_k^i$ of A^i for $i = 1, \dots, I$. The definitions of $\tilde{A}_k^1$ and of $\tilde{A}_k^i$ are similar. We give only the latter. For $k \in K$, set $B_k^j = \tilde{A}_k^j$ if $j < i$ and $B_k^j = A_k^j$ if $j > i$.

For $k \in F_i$, we set

$$\tilde{A}_k^i = \{a^i \in A^i \ \forall a^{-i} \in B_k^{-i},\ \mathbf{q}(F_i|k, a^i, a^{-i}) = 1\} :$$

this set contains the actions of player i that prevent the play from leaving F_i, if players $-i$ play actions in B_k^{-i}. For $k \notin F_i$, we set $\tilde{A}_k^i = A^i$.

Leaving aside for a moment the issue of nonemptiness of $\tilde{A}_k^i$, we briefly explain the motivation and the agenda.

By induction, given that players $-i$ use only actions with B_k^{-i}, the play, once in F_{i-1}, stays in F_{i-1}. F_i is to be thought of as those states in F_{i-1} with maximal min max value to player i. For $k \in F_i$, $\tilde{A}_k^i$ is the set of actions which force the play to remain within F_i. We shall consider discounted games in which each player i is restricted to actions in $\tilde{A}_k^i$. These games do have a stationary equilibrium x_λ (standard proof). We shall prove that any subset E of F which is ergodic for some x_λ is solvable, with payoff $\lim_{\lambda \to 0} \gamma_\lambda(k, x_\lambda)$, where $k \in E$. In order to establish this fact, we need to prove three kinds of results.

- A communication property: it will be trivial, given the construction of the set.
- No unilateral deviation of a player i can increase the current min max level: $\forall a^i, \mathbf{q}(\cdot|k, a^i, x_k^{-i})v^i \le v^i(k)$. This will be straightforward, given the definitions of the sets (F_i) and $(\tilde{A}^i)$.
- Somewhat surprisingly, the only nontrivial issue is that of individual rationality: is it true that $\lim_{\lambda \to 0} \gamma_\lambda^i(k, x_\lambda) \ge v^i(k)$? The positive answer will be deduced from Lemma 12.

5.3. Properties of $\tilde{A}_k^i$. For $k \in F_i$ and $\lambda < \lambda_0$, the following hold by definition:

1. For each $a^i \in A^i$ and $a^{-i} \in B_k^{-i}$, one has $\mathbf{q}(F_{i-1}|k, a^i, a^{-i}) = 1$; hence, using (1),

$$\mathbf{q}(\cdot|k, a^i, a^{-i})v_\lambda^i \le v_\lambda^i(k) + c_0\lambda;$$

therefore,

$$U_{\lambda, a^i, a^{-i}}^i v_\lambda^i(k) \le v_\lambda^i(k) + C_0\lambda \tag{3}$$

for some C_0 which depends only upon the data of the game.

2. For each $a^i \notin \tilde{A}_k^i$, there exists $a^{-i} \in B_k^{-i}$, such that $\mathbf{q}(F_i|k, a^i, a^{-i}) < 1$. Since $\mathbf{q}(F_i|k, a^i, a^{-i}) = 1$, this implies, using (2), that

$$\mathbf{q}(\cdot|k, a^i, a^{-i})v_\lambda^i < v_\lambda^i(k) - \eta c_1 \lambda^\beta + c_0\lambda,$$

where $\eta > 0$ depends only upon $\mathbf{q}$. Therefore, there exists $\lambda_1 < \lambda_0$ such that

$$\forall \lambda < \lambda_1, U_{\lambda, a^i, a^{-i}}^i v_\lambda^i(k) < v_\lambda^i(k) - c_2\lambda^\beta \tag{4}$$

for some $c_2 > 0$ which depends upon the data of the game.

LEMMA 10. $\tilde{A}^i_k \neq \emptyset \ \forall i,\ k \in F_i$.

Proof. We proceed by induction over i. Fix x^{-i} with $\mathrm{supp}(x^{-i}) = B^{-i}$. For each $\lambda > 0$, there exists $a^i = (a^i_k) \in (A^i)^K$ such that $U^i_{\lambda,(a^i,x^{-i})} v^i_\lambda \geq v^i_\lambda$ (Fact 2). Since $(A^i)^K$ is finite, there exist $a^i \in (A^i)^K$ and a sequence (λ_n) decreasing to 0, such that

$$U^i_{\lambda_n,a^i,x^{-i}} v^i_{\lambda_n} \geq v^i_{\lambda_n} \text{for every } n.$$

From (1) and (2), one deduces that $a^i_k \in \tilde{A}^i_k$ for every k. □

We shall need the following property.

LEMMA 11. *Let Ω be a finite set, $P_1, P_2 \in \Delta(\Omega)$, $u : \Omega \to \mathbf{R}$. Then*

$$|P_1 u - P_2 u| \leq \|P_1 - P_2\| \max_{k,k' \in \Omega} |u(k) - u(k')|.$$

Proof. Clearly, $|P_1 u - P_2 u|$ is unchanged when a constant is added to u. Replace u by $u - \min_\Omega u$, so that $\max_{k,k' \in \Omega} |u(k) - u(k')| = \max_\Omega u$. Then

$$|P_1 u - P_2 u| \leq \sum_{k \in \Omega} |P_1(k) - P_2(k)| u(k) \leq \|P_1 - P_2\| \max_\Omega u. \qquad \square$$

The next lemma essentially entails that provided players $-i$ use some profile x^{-i} with $\mathrm{supp}(x^{-i}) \subseteq B^{-i}$, there is a reply x^i of player i with $\mathrm{supp}(x^i) \subseteq \tilde{A}^i$, such that $\gamma^i_\lambda(x^{-i}, x^i) \geq v^i_\lambda - o(1)$.

Choose a real number $\gamma > 0$, such that $\beta + \gamma < 1$.

LEMMA 12. *Let $\lambda < \min\{\lambda_1, (\frac{c_2}{C_0})^{\frac{1}{1-\beta-\gamma}}\}$, and let $x^{-i} \in \mathcal{S}^{-i}$. If $\mathrm{supp}(x^{-i}) \subseteq B^{-i}$, there exists $a^i \in \tilde{A}^i$, such that*

$$U^i_{\lambda,a^i,x^{-i}} v^i_\lambda \geq v^i_\lambda - c_3 \lambda^{1+\gamma},$$

with $c_3 = |A^{-i}|(1 + 2C_0)$.

Proof. Choose $\tilde{x}^{-i}$, such that

$$\begin{cases} \mathrm{supp}(\tilde{x}^{-i}) = B^{-i}, \\ \|\tilde{x}^{-i} - x^{-i}\| \leq |A^{-i}| \lambda^\gamma, \\ \tilde{x}^j_k(a^j_k) \geq \lambda^\gamma \ \forall k, j, a^j_k \in \tilde{A}^j_k. \end{cases}$$

($\tilde{x}^{-i}$ is to be interpreted as a λ^γ-perturbation of x^{-i}.)

Choose $a^i = (a^i_k) \in (A^i)^K$, such that $U^i_{\lambda,a^i,\tilde{x}^{-i}} v^i_\lambda \geq v^i_\lambda$. We argue now that $a^i_k \in \tilde{A}^i_k$ for every k. Since $\tilde{A}^i_k = A^i$ for $k \notin F_i$, this may only fail for some $k \in F_i$. In that case, one would have

$$U^i_{\lambda,a^i,a^{-i}} v^i_\lambda(k) \leq v^i_\lambda(k) + C_0 \lambda$$

for each $a^{-i}_k \in B^{-i}_k$, and

$$U^i_{\lambda,a^i,a^{-i}} v^i_\lambda(k) < v^i_\lambda(k) - c_2 \lambda^\beta$$

for at least one $a^{-i}_k \in B^{-i}_k$. By summation, one would get

$$U^i_{\lambda,a^i,\tilde{x}^{-i}} v^i_\lambda(k) < v^i_\lambda(k) - c_2 \lambda^{\beta+\gamma} + C_0 \lambda,$$

which would contradict the choice of a^i. Hence $a^i_k \in \tilde{A}^i_k$ for every $k \in K$.

Apply now Lemma 11, with $P_1 = \mathbf{q}(\cdot|k, a_k^i, x_k^{-i})$, $P_2 = \mathbf{q}(\cdot|k, a_k^i, \tilde{x}_k^{-i})$, and $u = v_\lambda^i$. This yields

$$\begin{aligned}|U^i_{\lambda,a^i,\tilde{x}^i} v^i_\lambda(k) - U^i_{\lambda,a^i,x^{-i}} v^i_\lambda(k)| &\le \lambda \|\tilde{x}_k^i - x_k^i\| \max|g^i| \\ &\quad + \|\tilde{x}_k^i - x_k^i\| \max_{k_1,k_2\in F} |v_\lambda^i(k_1) - v_\lambda^i(k_2)| \\ &\le |A^{-i}|\lambda^{1+\gamma}(1 + 2C_0).\end{aligned}$$

The result follows. □

5.4. Constrained games and solvable sets. Let $\tilde{\mathcal{S}}^i = \{x^i \in \mathcal{S}^i, \mathrm{supp}(x^i) \subseteq \tilde{A}^i\}$, and set $\tilde{\mathcal{S}} = \prod_i \tilde{\mathcal{S}}^i$. Let $\lambda > 0$. We define a best-reply map $\mathbf{B}_\lambda : \tilde{\mathcal{S}} \to \tilde{\mathcal{S}}$. For $i \in I, x \in \tilde{\mathcal{S}}$, and $k \in K$, set

$$\mathbf{B}^i_{\lambda,k}(x^{-i}) = \mathrm{argmax}_{\Delta(\tilde{A}^i_k)} U^i_{\lambda,.,x^{-i}} v^i_\lambda(k),$$

and

$$\mathbf{B}^i_\lambda(x^{-i}) = \prod_k \mathbf{B}^i_{\lambda,k}(x^{-i}).$$

Finally, we set $\mathbf{B}_\lambda(x) = \prod_i \mathbf{B}^i_\lambda(x^{-i})$.

Clearly, $\mathbf{B}_\lambda$ is upperhemicontinuous and convex-valued. Therefore, by Kakutani's theorem, it has a fixed point x_λ. By compactness, there exists a sequence $(\lambda_n)_n$ decreasing to 0, such that $\overline{x} = \lim_{n\to\infty} x_{\lambda_n}$ and $\gamma = \lim_{n\to\infty} \gamma_{\lambda_n}(x_{\lambda_n})$ exist.

Let $x \in \tilde{\mathcal{S}}$ such that $\mathrm{supp}(x) = \tilde{A}$. By construction, F is stable under x. Choose a set $E \subseteq F$, ergodic for x.

LEMMA 13. *There exists a distribution μ over $\mathcal{R}_E(\overline{x})$ such that $(E, \overline{x}, \mu)$ is solvable.*

Proof. To avoid cumbersome notations, we write λ instead of λ_n. All limits below are taken along the sequence (λ_n).

First, notice that $\mathrm{supp}(\overline{x}) \subseteq \mathrm{supp}(x)$; since E is ergodic for x, $E \in \mathcal{C}(\overline{x})$. Also, since $\mathrm{supp}(x_\lambda) \subseteq \mathrm{supp}(x)$, E is stable under x_λ.

Using Lemma 12 and the fixed-point property of x_λ, one has

$$U^i_{\lambda,x_\lambda} v^i_\lambda \ge v^i_\lambda - c_3\lambda^{1+\gamma}$$

for each player i. Hence $\gamma^i_\lambda(x_\lambda) \ge v^i_\lambda - c_3\lambda^\gamma$, by Fact 1.

For $k_0 \in E$, it is well known (see Thuijsman and Vrieze [6]) that $\lim_{\lambda\to 0} \gamma_\lambda(k_0, x_\lambda)$ belongs to the convex hull of $\{\gamma_R(\overline{x}), R \in \mathcal{R}_E(\overline{x})\}$. Hence there exists a distribution μ over $\mathcal{R}_E(\overline{x})$, such that

$$\lim_{\lambda\to 0} \gamma_\lambda(k_0, x_\lambda) = \sum_{R\in\mathcal{R}_E(\overline{x})} \mu(R)\gamma_R(\overline{x}) \ge v(k_0).$$

To complete the proof, we prove that

$$\mathbf{q}(\cdot|k, a^i, \overline{x}_k^{-i}) v^i \le \max_E v^i \tag{5}$$

for each i, $k \in E$, and $a^i \in A^i$.

By construction, $v^i(k) = \max_{F_{i-1}} v^i$ for every player i and $k \in E$. In particular, v is constant over E.

Since $\mathrm{supp}(\overline{x}^j_k) \subseteq B^j_k$ for each $j \ne i$, one has $\mathbf{q}(F_{i-1}|k, a^i, \overline{x}_k^{-i}) = 1$. This implies (5). □

MAXIMALLY ROBUST CONTROLLERS FOR MULTIVARIABLE SYSTEMS*

S. K. GUNGAH†, G. D. HALIKIAS‡, AND I. M. JAIMOUKHA§

Abstract. The set of all optimal controllers which maximize a robust stability radius for unstructured additive perturbations may be obtained using standard Hankel-norm approximation methods. These controllers guarantee robust stability for *all* perturbations which lie inside an open ball in the uncertainty space (say, of radius r_1). Necessary and sufficient conditions are obtained for a perturbation lying on the boundary of this ball to be destabilizing for *all* maximally robust controllers. It is thus shown that a "worst-case direction" exists along which all boundary perturbations are destabilizing. By imposing a parametric constraint such that the permissible perturbations cannot have a "projection" of magnitude larger than $(1-\delta)r_1$, $0 < \delta \leq 1$, in the most critical direction, the uncertainty region guaranteed to be stabilized by a *subset* of all maximally robust controllers can be *extended* beyond the ball of radius r_1. The choice of the *"best"* maximally robust controller—in the sense that the uncertainty region guaranteed to be stabilized becomes as large as possible—is associated with the solution of a superoptimal approximation problem. Expressions for the improved stability radius are obtained and some interesting links with μ-analysis are pursued.

Key words. robust control, μ-analysis, stability radius, superoptimization, Nehari problem

1. Notation. $\mathcal{R}, \mathcal{R}_+$, and $\mathcal{C}$ denote the sets of real, nonnegative, and complex numbers, respectively. $\mathcal{C}_+$ ($\bar{\mathcal{C}}_+$), $\mathcal{C}_-$ ($\bar{\mathcal{C}}_-$) denote the open (closed) right half-plane and the open (closed) left half-plane, respectively. For a complex matrix A, A^T denotes the transpose while A' denotes the complex-conjugate transpose. $\sigma_i(A)$ denotes the ith largest singular value. The smallest singular value is denoted by $\underline{\sigma}(A)$ and the largest singular value is denoted by $\bar{\sigma}(A)$. The norm of A is defined as $\|A\| = \bar{\sigma}(A)$. For a square A, $\lambda(A)$ is the spectrum of A and $\lambda_{\max}(A)$ is the largest eigenvalue.

$\mathcal{L}_\infty^{p\times m}$ denotes the space of all $p \times m$ matrix functions with entries uniformly bounded on the $j\omega$-axis. $\mathcal{H}_\infty^{p\times m}$ and $\mathcal{H}_\infty^{-p\times m}$ denote the subspaces of $\mathcal{L}_\infty^{p\times m}$ consisting of all matrix functions whose elements are analytic in $\bar{\mathcal{C}}_+$ and $\bar{\mathcal{C}}_-$, respectively. $\|.\|_\infty$ denotes the $\mathcal{L}_\infty$ norm of matrices in $\mathcal{L}_\infty$ or the $\mathcal{H}_\infty$ norm of matrices in $\mathcal{H}_\infty$, depending on context. $\gamma\mathcal{B}\mathcal{H}_\infty^{p\times m} = \{G \in \mathcal{H}_\infty^{p\times m} : \|G\|_\infty \leq \gamma\}$ is the γ ball of $\mathcal{H}_\infty^{p\times m}$. The prefix $\mathcal{R}$ before a set symbol means that the elements of the set are restricted to be real-rational. Matrix dimensions of spaces will be occasionally suppressed.

$G(s)^\sim := G'(-\bar{s})$ denotes the *para-hermitian conjugate* of $G(s)$. $G(s)^{-\sim}$ stands for $(G(s)^\sim)^{-1}$. The *Hankel operator* with symbol $G \in \mathcal{H}_\infty$ is denoted by Γ_G while $\sigma_i(\Gamma_G)$ denotes the ith largest Hankel singular value of G. The Hankel norm of G, $\sigma_1(\Gamma_G)$, is also written as $\|\Gamma_G\|$ and the smallest Hankel singular value as $\underline{\sigma}(\Gamma_G)$.

A real-rational function $G(s)$ is called *stable* if it has no poles in $\bar{\mathcal{C}}_+$. If $G(s)$ has no poles in $\bar{\mathcal{C}}_-$, it is called *antistable*. Matrix (scalar and vector) transfer functions will

be represented by uppercase (lowercase) boldface letters and with the dependence on s mostly suppressed. If $\boldsymbol{G}^{-1} = \gamma^{-2}\boldsymbol{G}^{\sim}$, then $\boldsymbol{G}$ is called γ-*allpass* (or simply *allpass* if $\gamma = 1$) and satisfies $\boldsymbol{G}\boldsymbol{G}^{\sim} = \boldsymbol{G}^{\sim}\boldsymbol{G} = \gamma^2 I$. A matrix function $\boldsymbol{G} \in \mathcal{RH}_\infty$ which satisfies $\boldsymbol{G}^{\sim}\boldsymbol{G} = I$ is called *inner*. A matrix function $\boldsymbol{G}(s) \in \mathcal{RH}_\infty$ which has full column rank for all $s \in \bar{\mathcal{C}}_+$ is called *outer*. If $\boldsymbol{U} \in \mathcal{L}_\infty^{l\times q}$ and

$$\boldsymbol{H} = \begin{bmatrix} \boldsymbol{H}_{11} & \boldsymbol{H}_{12} \\ \boldsymbol{H}_{21} & \boldsymbol{H}_{22} \end{bmatrix} \in \mathcal{L}_\infty^{(p+q)\times(m+l)}$$

with $\boldsymbol{H}_{11} \in \mathcal{L}_\infty^{p\times m}$, we define the lower linear fractional map $\mathcal{F}_l(\boldsymbol{H},\boldsymbol{U}) = \boldsymbol{H}_{11} + \boldsymbol{H}_{12}\boldsymbol{U}(I - \boldsymbol{H}_{22}\boldsymbol{U})^{-1}\boldsymbol{H}_{21}$, provided that $I - \boldsymbol{H}_{22}(\infty)\boldsymbol{U}(\infty)$ is invertible. If $\boldsymbol{U} \in \mathcal{L}_\infty^{m\times p}$, we define the upper linear fractional map $\mathcal{F}_u(\boldsymbol{H},\boldsymbol{U}) = \boldsymbol{H}_{22} + \boldsymbol{H}_{21}\boldsymbol{U}(I - \boldsymbol{H}_{11}\boldsymbol{U})^{-1}\boldsymbol{H}_{12}$, provided that $I - \boldsymbol{H}_{11}(\infty)\boldsymbol{U}(\infty)$ is invertible. If $\mathcal{U}$ is a set, then $\mathcal{F}_l(\boldsymbol{H},\mathcal{U})$ denotes the set $\{\mathcal{F}_l(\boldsymbol{H},\boldsymbol{U}) : \boldsymbol{U} \in \mathcal{U}\}$ and if $\boldsymbol{G}_1, \boldsymbol{G}_2, \boldsymbol{G}_3 \in \mathcal{L}_\infty$ have appropriate dimensions, then $\boldsymbol{G}_1 + \boldsymbol{G}_2\mathcal{U}\boldsymbol{G}_3$ denotes the set $\{\boldsymbol{G}_1 + \boldsymbol{G}_2\boldsymbol{U}\boldsymbol{G}_3 \ : \ \boldsymbol{U} \in \mathcal{U}\}$.

If $\boldsymbol{G} \in \mathcal{L}_\infty$, we define, for each i, $s_i^\infty(\boldsymbol{G}) = \sup_{\omega\in\mathcal{R}} \sigma_i(\boldsymbol{G}(j\omega))$. Clearly, $s_1^\infty(\boldsymbol{G}) = \|\boldsymbol{G}\|_\infty$. Suppose that $\mathcal{T}$ is a set of matrix functions. $\boldsymbol{T} \in \mathcal{T}$ is called a kth level *superoptimal* function if it minimizes the sequence $\{s_1^\infty(\boldsymbol{T}), s_2^\infty(\boldsymbol{T}), \ldots, s_k^\infty(\boldsymbol{T})\}$ with respect to lexicographic ordering among all $\boldsymbol{T} \in \mathcal{T}$. The minimized sequence is denoted by $\{s_1(\mathcal{T}), \ldots, s_k(\mathcal{T})\}$, and the $s_i(\mathcal{T})$s are called the superoptimal levels of $\mathcal{T}$.

2. Introduction. The work presented in this paper is related to the problem of maximizing the robust stability radius for systems subject to unstructured additive perturbations [25], [6], [23], [24]. In [6] it was shown that this problem is equivalent to a Nehari approximation. Moreover, an explicit state-space parametrization was obtained for all controllers which guarantee a robust stabilization radius $r < r_1$. A parametrization of all maximally robust controllers ($r = r_1$) is implicit in [6] and may be obtained from [4], [5]. The theory of optimal interpolation is used in [23] to give a solution for single input/single output systems.

In the multi-input/single output or single input/multi-output case, the optimal controller is unique. In the matrix case, however, a continuum of optimal controllers typically exists. It is therefore natural to ask whether a subset of these controllers offers improved robust stability properties, in the sense that it guarantees closed-loop stability for a larger class of uncertainties, compared to those offered by the optimal solution set considered in total. More specifically, we seek to identify the set of all controllers which guarantees robust stability for the largest possible region of the uncertainty space containing the open ball of radius r_1 as a subset. Clearly, this can only be achieved by imposing a structure on the set of admissible uncertainties.

Our approach is as follows: From the work in [25], [24], and [6] the maximum robust stability radius r_1 is the inverse of the smallest achievable $\mathcal{H}_\infty$ norm among all interpolating functions $\mathcal{T} = \{\boldsymbol{K}(I - \boldsymbol{G}\boldsymbol{K})^{-1}\}$, as $\boldsymbol{K}$ varies over the set of all internally stabilizing compensators of $\boldsymbol{G}$. Using an allpass dilation technique, the set of all optimal interpolating functions $\mathcal{T}_1 = \{\boldsymbol{T} \in \mathcal{T} : \|\boldsymbol{T}\|_\infty = r_1^{-1}\} \subseteq \mathcal{T}$ has the form $\mathcal{T}_1 = \boldsymbol{Y}\mathrm{diag}(r_1^{-1}\boldsymbol{a}, \hat{\boldsymbol{R}} + \mathcal{Q})\boldsymbol{X}$, where $\hat{\boldsymbol{R}} \in \mathcal{RH}_\infty^-$, $\boldsymbol{X}$ and $\boldsymbol{Y}$ are square inner matrices, $\boldsymbol{a}$ is a scalar allpass function, and $\mathcal{Q}$ is the set of all r_1^{-1} suboptimal Nehari extensions of $\hat{\boldsymbol{R}}$, i.e., $\mathcal{Q} = \{\boldsymbol{Q} \in \mathcal{H}_\infty : \|\hat{\boldsymbol{R}} + \boldsymbol{Q}\|_\infty \le r_1^{-1}\}$.

Every optimal controller corresponding to an interpolating function in $\mathcal{T}_1$ stabilizes *all* perturbations which lie inside the open ball $\mathcal{D}_{r_1} = \{\boldsymbol{\Delta} \in \mathcal{L}_\infty : \|\boldsymbol{\Delta}\|_\infty < r_1, \eta(\boldsymbol{G} + \boldsymbol{\Delta}) = \eta(\boldsymbol{G})\}$, where $\eta(\cdot)$ denotes number of poles in $\mathcal{C}_+$. Next, we consider perturbations $\boldsymbol{\Delta}$ which lie on the boundary of $\mathcal{D}_{r_1}$. It is shown that such boundary

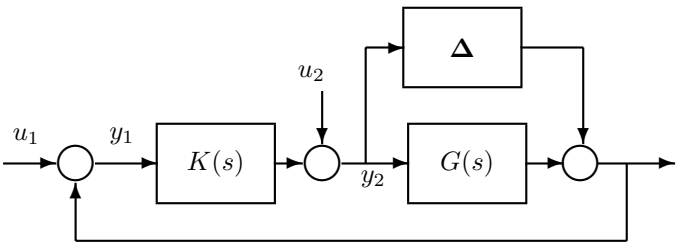

FIG. 1. *Closed-loop system.*

perturbations are *uniformly* destabilizing (i.e., they destabilize the closed-loop system for every optimal controller) if and only if $|\boldsymbol{x}^T(j\omega)\boldsymbol{\Delta}(j\omega)\boldsymbol{y}(j\omega)| = r_1$ for some frequency ω, and where $\boldsymbol{x}^T$ and $\boldsymbol{y}$ are the first row and column of $\boldsymbol{X}$ and $\boldsymbol{Y}$, respectively. Moreover, all frequencies ω are equally critical, in the sense that destabilizing boundary perturbations can be constructed for every $\omega \in \mathcal{R}$. This shows that it is futile to attempt to extend the uncertainty set guaranteed to be stabilized by a subset of all optimal controllers in the (frequency-dependent) direction defined by vectors $\boldsymbol{x}^T$ and $\boldsymbol{y}$. By imposing a parametric constraint (uniform in ω) such that the permissible perturbations cannot have a "projection" of magnitude larger than $(1-\delta)r_1$ $(0 < \delta \leq 1)$ in this direction, the uncertainty region guaranteed to be stabilized by a subset of all optimal controllers can be extended beyond $\mathcal{D}_{r_1}$. Using a result in [15], it is shown that for each $\delta \in (0, 1]$ the corresponding constrained robust stability radius is maximized by the set of controllers which minimize the first two superoptimal levels of $\mathcal{T}$. A closed-form expression of the improved stability radius is also obtained which involves δ and the first two superoptimal levels of $\mathcal{T}$. This work is related to the results presented in [18] which also uses superoptimization concepts to give an extension of the allowable perturbation set.

An alternative interpretation of our results leads to interesting connections with the problem of robust stabilization of systems subject to structured perturbations and μ-synthesis in general [19]. By suitably defining δ, robust stabilization problems for a number of uncertainty structures can be formulated in our setting, and bounds on the achievable robust-stability radius can be obtained. An upper bound on μ for the constant complex case is derived in the last section.

The layout of the paper is as follows: Section 3 outlines a number of known results in the area of robust stabilization of systems subject to unstructured additive perturbations. The maximum robust stability radius is obtained by solving a Nehari approximation problem [6] and leads to a parametrization of all optimal interpolating functions, using the results of [4], [5]. An alternative parametrization of this set is obtained in section 4, using an allpass dilation technique [7], [5]. A recursive application of this method leads to the solution of the superoptimal approximation problem [26], [22], [16], [13], [14], [12], [20], [21]. In our context, this parametrization of the set of all optimal interpolating functions is used to characterize all uniformly destabilizing boundary perturbations. This analysis is carried out in section 4, which also includes our main result (Theorem 4.8) whose proof is based on a result from [15] (see Theorems 4.6 and 4.7). In section 5 a new (upper) bound on the structured singular value μ is obtained (for the constant problem). Finally, section 6 contains the conclusions.

3. Robust stabilization for unstructured additive perturbations. Let $\boldsymbol{G} \in \mathcal{RL}_\infty$. When $\boldsymbol{\Delta} = 0$, the closed-loop system in Figure 1 is internally stable

if and only if it is well-posed, i.e., $\det(I - \boldsymbol{G}(\infty)\boldsymbol{K}(\infty)) \neq 0$ and the four transfer functions $(u_1, u_2) \to (y_1, y_2)$ are in $\mathcal{H}_\infty$. In this case, we write $(\boldsymbol{G}, \boldsymbol{K}) \in \mathcal{S}$ and $\boldsymbol{K} \in \mathcal{K}$. Consider the set of additively perturbed systems $\boldsymbol{G} + \boldsymbol{\Delta}, \boldsymbol{\Delta} \in \mathcal{D}_r(\boldsymbol{G}, \boldsymbol{w})$, where $\boldsymbol{w}$ is a scalar outer $\mathcal{RH}_\infty$ (weighting) function and

$$\mathcal{D}_r(\boldsymbol{G}, \boldsymbol{w}) = \left\{ \boldsymbol{\Delta} \in \mathcal{L}_\infty : \|\boldsymbol{w}^{-1}\boldsymbol{\Delta}\|_\infty < r, \eta(\boldsymbol{G}) = \eta(\boldsymbol{G} + \boldsymbol{\Delta}) \right\},$$

in which $\eta(\cdot)$ denotes the number of poles in $\mathcal{C}_+$, counted in a MacMillan degree sense. The system $(\boldsymbol{G}, \boldsymbol{K})$ is said to be $(r, \boldsymbol{w})$ robustly stable if $(\boldsymbol{G} + \boldsymbol{\Delta}, \boldsymbol{K}) \in \mathcal{S}$ for all $\boldsymbol{\Delta} \in \mathcal{D}_r(\boldsymbol{G}, \boldsymbol{w})$. $(\boldsymbol{G}, \boldsymbol{K})$ is said to be maximally robustly stable if (i) $(\boldsymbol{G}, \boldsymbol{K})$ is $(r_1, \boldsymbol{w})$ robustly stable and (ii) there exists $\boldsymbol{\Delta} \in \partial\mathcal{D}_{r_1}(\boldsymbol{G}, \boldsymbol{w}) = \{\boldsymbol{\Delta} \in \mathcal{L}_\infty : \|\boldsymbol{w}^{-1}\boldsymbol{\Delta}\|_\infty = r_1, \eta(\boldsymbol{G}) = \eta(\boldsymbol{G} + \boldsymbol{\Delta})\}$, such that $(\boldsymbol{G} + \boldsymbol{\Delta}, \boldsymbol{K}) \notin \mathcal{S}$. The following theorem [25] gives necessary and sufficient conditions for robust stabilization in the presence of additive unstructured perturbations.

THEOREM 3.1 (see [25], [6], [24]). *Let $\boldsymbol{G} \in \mathcal{RL}_\infty$ and suppose that $(\boldsymbol{G}, \boldsymbol{K}) \in \mathcal{S}$. Then $(\boldsymbol{G}, \boldsymbol{K})$ is $(r, \boldsymbol{w})$ robustly stable if and only if $\|\boldsymbol{w}\boldsymbol{K}(I - \boldsymbol{G}\boldsymbol{K})^{-1}\|_\infty \leq r^{-1}$.*

The following result [6], [1] shows that, without loss of generality, $\boldsymbol{G}$ can be assumed to be antistable and $\boldsymbol{w}$ can be taken to be equal to one.

THEOREM 3.2 (see [6], [1]). *Let $\boldsymbol{w}^{-1}\boldsymbol{G}$ have a decomposition $\boldsymbol{w}^{-1}\boldsymbol{G} = \boldsymbol{G}_1 + \boldsymbol{G}_2$ with $\boldsymbol{G}_1^\sim, \boldsymbol{G}_2 \in \mathcal{RH}_\infty$, and $\boldsymbol{G}_1(\infty) = 0$. Then there exists a $\boldsymbol{K} \in \mathcal{L}_\infty$ such that $(\boldsymbol{G}, \boldsymbol{K})$ is $(r, \boldsymbol{w})$ robustly stable if and only if $\boldsymbol{K} = \boldsymbol{w}^{-1}\boldsymbol{K}_1(I + \boldsymbol{G}_2\boldsymbol{K}_1)^{-1}$ for some $\boldsymbol{K}_1$ such that $(\boldsymbol{G}_1, \boldsymbol{K}_1)$ is $(r, 1)$ robustly stable and $\det\{(I + \boldsymbol{G}_2\boldsymbol{K}_1)(\infty)\} \neq 0$.*

Remark 3.1. We assume for simplicity that $\boldsymbol{G}^\sim \in \mathcal{RH}_\infty$, $\boldsymbol{G}(\infty) = 0$, and $\boldsymbol{w} = 1$. We also use the simplified notation

$$\mathcal{D}_r(\boldsymbol{G}) := \mathcal{D}_r(\boldsymbol{G}, 1) = \{\boldsymbol{\Delta} \in \mathcal{L}_\infty : \|\boldsymbol{\Delta}\|_\infty < r, \eta(\boldsymbol{G}) = \eta(\boldsymbol{G} + \boldsymbol{\Delta})\}, \tag{1}$$

$$\partial\mathcal{D}_r(\boldsymbol{G}) := \partial\mathcal{D}_r(\boldsymbol{G}, 1) = \{\boldsymbol{\Delta} \in \mathcal{L}_\infty : \|\boldsymbol{\Delta}\|_\infty = r, \eta(\boldsymbol{G}) = \eta(\boldsymbol{G} + \boldsymbol{\Delta})\}. \tag{2}$$

Let $\boldsymbol{G}$ have left and right coprime factorizations $\boldsymbol{G} = \boldsymbol{N}\boldsymbol{M}^{-1} = \tilde{\boldsymbol{M}}^{-1}\tilde{\boldsymbol{N}}$, respectively, with $\boldsymbol{N}, \boldsymbol{M}, \tilde{\boldsymbol{N}}, \tilde{\boldsymbol{M}} \in \mathcal{RH}_\infty$ and let $\boldsymbol{U}, \boldsymbol{V}, \tilde{\boldsymbol{U}}, \tilde{\boldsymbol{V}} \in \mathcal{RH}_\infty$ satisfy the Bezout identities $\tilde{\boldsymbol{V}}\boldsymbol{M} - \tilde{\boldsymbol{U}}\boldsymbol{N} = I$ and $\tilde{\boldsymbol{M}}\boldsymbol{V} - \tilde{\boldsymbol{N}}\boldsymbol{U} = I$. Then the set of all stabilizing controllers of $\boldsymbol{G}$ is

$$\mathcal{K} = \{(\boldsymbol{U} + \boldsymbol{M}\boldsymbol{Q})(\boldsymbol{V} + \boldsymbol{N}\boldsymbol{Q})^{-1} : \boldsymbol{Q} \in \mathcal{H}_\infty\}. \tag{3}$$

Let $\mathcal{T} = \{\boldsymbol{K}(I - \boldsymbol{G}\boldsymbol{K})^{-1} : \boldsymbol{K} \in \mathcal{K}\}$. We refer to $\mathcal{T}$ as the set of all *interpolating functions*. Using the parametrization of $\mathcal{K}$ in (3) gives the alternative characterization of $\mathcal{T}$ as

$$\mathcal{T} = \{(\boldsymbol{U} + \boldsymbol{M}\boldsymbol{Q})\tilde{\boldsymbol{M}} \ : \ \boldsymbol{Q} \in \mathcal{H}_\infty\}. \tag{4}$$

Let $\boldsymbol{G}$ have a minimal balanced realization $\boldsymbol{G}(s) = C(sI - A)^{-1}B + D$, such that $Re\ \lambda_i(A) > 0$ for all i and with $A\Sigma + \Sigma A' = BB'$, $A'\Sigma + \Sigma A = C'C$, $\Sigma = \operatorname{diag}(\sigma_1, \sigma_2, \ldots, \sigma_n)$, $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_n > 0$. Let $F = B'\Sigma^{-1}$ and $H = \Sigma^{-1}C'$. The coprime factors $\boldsymbol{N}, \boldsymbol{M}, \tilde{\boldsymbol{N}}, \tilde{\boldsymbol{M}}$ can now be defined (together with $\boldsymbol{U}, \boldsymbol{V}, \tilde{\boldsymbol{U}}, \tilde{\boldsymbol{V}}$) as

$$\begin{bmatrix} \boldsymbol{M}(s) & \boldsymbol{U}(s) \\ \boldsymbol{N}(s) & \boldsymbol{V}(s) \end{bmatrix} = \begin{bmatrix} -F \\ C \end{bmatrix} (sI - A + BF)^{-1} \begin{bmatrix} B & H \end{bmatrix} + \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix},$$

$$\begin{bmatrix} \tilde{\boldsymbol{V}}(s) & -\tilde{\boldsymbol{U}}(s) \\ -\tilde{\boldsymbol{N}}(s) & \tilde{\boldsymbol{M}}(s) \end{bmatrix} = \begin{bmatrix} F \\ -C \end{bmatrix} (sI - A + HC)^{-1} \begin{bmatrix} B & H \end{bmatrix} + \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix},$$

with $\boldsymbol{M}$ and $\tilde{\boldsymbol{M}}$ inner [3]. The next result shows that the maximal robust stability radius is equal to the smallest Hankel singular value of $\boldsymbol{G}(-s)$.

THEOREM 3.3 (see [6], [24]). *Let $\boldsymbol{G}^{\sim} \in \mathcal{RH}_\infty, \boldsymbol{G}(\infty) = 0$. Then the maximum stability radius r_1 for which $(\boldsymbol{G}, \boldsymbol{K})$ is $(r_1, 1)$ robustly stable for some $\boldsymbol{K} \in \mathcal{K}$ is given by $r_1 = \underline{\sigma}(\Gamma_{\boldsymbol{G}(-s)})$.*

Proof. From Theorem 3.1 $(\boldsymbol{G}, \boldsymbol{K})$ is $(r, 1)$ robustly stable if (i) $\boldsymbol{K}$ stabilizes $\boldsymbol{G}$ internally, and (ii) $\|\boldsymbol{K}(I - \boldsymbol{G}\boldsymbol{K})^{-1}\|_\infty \leq r^{-1}$. Hence,

$$r_1^{-1} = \inf \ \{\|\boldsymbol{K}(I - \boldsymbol{G}\boldsymbol{K})^{-1}\|_\infty : \boldsymbol{K} \in \mathcal{K}\},$$

where $\mathcal{K}$ is the set of all internally stabilizing controllers of $\boldsymbol{G}$. From (4),

$$r_1^{-1} = \inf \ \{\|(\boldsymbol{U} + \boldsymbol{M}\boldsymbol{Q})\tilde{\boldsymbol{M}}\|_\infty : \boldsymbol{Q} \in \mathcal{H}_\infty\} = \inf \ \{\|\boldsymbol{M}^{\sim}\boldsymbol{U} + \boldsymbol{Q}\|_\infty : \mathbf{Q} \in \mathcal{H}_\infty\} \tag{5}$$

since $\boldsymbol{M}, \tilde{\boldsymbol{M}}$ are inner. A straightforward state-space calculation shows that

$$\boldsymbol{M}^{\sim}\boldsymbol{U}(s) = -B'\Sigma^{-1}(sI - A)^{-1}\Sigma^{-1}C' \in \mathcal{RH}_\infty^- \tag{6}$$

in previously defined notation. From Nehari's theorem the infimum in (5) is attained and is given by the Hankel norm of $\boldsymbol{M}^{\sim}\boldsymbol{U}(-s)$. It is also straightforward to verify that the realization in (6) is balanced with grammians equal to $-\Sigma^{-1}$. Thus, the realization in (6) is minimal, and

$$r_1^{-2} = \|\Gamma_{\boldsymbol{M}^{\sim}\boldsymbol{U}(-s)}\|^2 = \lambda_{\max}(\Sigma^{-2}) = \underline{\sigma}^{-2}(\Gamma_{\boldsymbol{G}(-s)})$$

from which it follows that $r_1 = \underline{\sigma}(\Gamma_{\boldsymbol{G}(-s)})$, as required. ∎

Remark 3.2. Let $\boldsymbol{G}$ satisfy the assumptions of Theorem 3.3 and assume that the MacMillan degree of $\boldsymbol{G}$ is n. Let the Hankel singular values of $\boldsymbol{G}(-s)$ and $\boldsymbol{M}^{\sim}\boldsymbol{U}(-s)$ be $\{\sigma_i(\Gamma_{\boldsymbol{G}(-s)})\}$ and $\{\sigma_i(\Gamma_{\boldsymbol{M}^{\sim}\boldsymbol{U}(-s)})\}$, respectively, ordered in nonincreasing order of magnitude. Then $\sigma_n(\Gamma_{\boldsymbol{G}(-s)}) > 0$. Further, a slight adaptation of Theorem 3.3 shows that $\sigma_i(\Gamma_{\boldsymbol{G}(-s)}) = \sigma_{n-i+1}^{-1}(\Gamma_{\boldsymbol{M}^{\sim}\boldsymbol{U}(-s)})$ for each $i = 1, 2, \ldots, n$.

4. Main results. The set of all maximally robust controllers may be characterized in terms of the set of all optimal Nehari extensions of $\boldsymbol{M}^{\sim}\boldsymbol{U}$, i.e., the set of all $\boldsymbol{Q} \in \mathcal{H}_\infty$ which achieve

$$\|\boldsymbol{M}^{\sim}\boldsymbol{U} + \boldsymbol{Q}\|_\infty = r_1^{-1}. \tag{7}$$

This set can be parametrized as a linear fractional map of the set of all r_1 stable contractions [4], [5]. This parametrization is outlined next.

Remark 4.1. To avoid a messy indexing system we assume hereafter that the largest Hankel singular values of $\boldsymbol{R}(-s)$ and $\hat{\boldsymbol{R}}(-s)$ defined below in Theorems 4.1 and 4.2, respectively, are nonrepeated. These conditions are equivalent to the assumption that the first two superoptimal levels $s_1(\mathcal{T})$ and $s_2(\mathcal{T})$ are nonrepeated.

THEOREM 4.1 (see [14], [5], [7]). *Let $\boldsymbol{R} = \boldsymbol{M}^{\sim}\boldsymbol{U} \in \mathcal{RH}_\infty^{-p\times m}$ and define $r_1 = \bar{\sigma}^{-1}(\Gamma_{\boldsymbol{R}(-s)})$ (see Theorem 3.3). Then there exists an embedding of $\boldsymbol{R}$ of the form*

$$\boldsymbol{H} = \begin{bmatrix} \boldsymbol{H}_{11} & \boldsymbol{H}_{12} \\ \boldsymbol{H}_{21} & \boldsymbol{H}_{22} \end{bmatrix} = \begin{bmatrix} \boldsymbol{R} + \boldsymbol{Q}_{11} & \boldsymbol{Q}_{12} \\ \boldsymbol{Q}_{21} & \boldsymbol{Q}_{22} \end{bmatrix}$$

$$:= \begin{bmatrix} \boldsymbol{R} & 0 \\ 0 & 0 \end{bmatrix} + \boldsymbol{Q}_a \in \mathcal{RL}_\infty^{(p+m-1)\times(m+p-1)}$$

with $\boldsymbol{Q}_a \in \mathcal{RH}_\infty$*, such that* $\boldsymbol{H}\boldsymbol{H}^\sim = \boldsymbol{H}^\sim\boldsymbol{H} = r_1^{-2} I_{p+m-1}$ *and* $\|\boldsymbol{H}_{22}\|_\infty = \|\boldsymbol{Q}_{22}\|_\infty < r_1^{-1}$*. Further, the set of all (optimal)* $\boldsymbol{Q} \in \mathcal{H}_\infty^{p\times m}$ *such that* $\|\boldsymbol{R}+\boldsymbol{Q}\|_\infty = r_1^{-1}$ *is given by*

$$\mathcal{S}_1 = \mathcal{F}_l(\boldsymbol{Q}_a, r_1\mathcal{BH}_\infty^{(p-1)\times(m-1)}). \tag{8}$$

Let $\mathcal{K}_1$ denote the set of all maximally robust (r_1-robust) controllers of $\boldsymbol{G}$, and let $\mathcal{T}_1 = \{\boldsymbol{K}(I-\boldsymbol{G}\boldsymbol{K})^{-1} : \boldsymbol{K} \in \mathcal{K}_1\} \subseteq \mathcal{T}$ denote the set of all optimal interpolating functions. In view of (3) and (4), together with Theorems 3.3 and 4.1, these sets may be parametrized as $\mathcal{K}_1 = \{(\boldsymbol{U}+\boldsymbol{M}\boldsymbol{Q})(\boldsymbol{V}+\boldsymbol{N}\boldsymbol{Q})^{-1} : \boldsymbol{Q} \in \mathcal{F}_l(\boldsymbol{Q}_a, r_1\mathcal{BH}_\infty^{(p-1)\times(m-1)})\}$ and

$$\mathcal{T}_1 = \{(\boldsymbol{U}+\boldsymbol{M}\boldsymbol{Q})\tilde{\boldsymbol{M}} : \boldsymbol{Q} \in \mathcal{F}_l(\boldsymbol{Q}_a, r_1\mathcal{BH}_\infty^{(p-1)\times(m-1)})\}, \tag{9}$$

respectively. The next theorem gives an alternative parametrization of the set of all optimal solutions of (7), and therefore of $\mathcal{T}_1$ in (9). The result shows that $\mathcal{T}_1$ can be diagonalized by rational allpass transformations and is used extensively in this work.

THEOREM 4.2 (see [10]). *Let all variables be as defined in Theorem* 4.1*. Then, the following hold:*

1. *There exists an* r_1^{-1}*-allpass completion of* $\boldsymbol{H}_{22} = \boldsymbol{Q}_{22}$ *of the form*

$$\bar{\boldsymbol{H}} = \begin{bmatrix} \bar{\boldsymbol{H}}_{11} & \bar{\boldsymbol{H}}_{12} \\ \bar{\boldsymbol{H}}_{21} & \boldsymbol{H}_{22} \end{bmatrix} = \begin{bmatrix} \hat{\boldsymbol{R}}+\bar{\boldsymbol{Q}}_{11} & \bar{\boldsymbol{Q}}_{12} \\ \bar{\boldsymbol{Q}}_{21} & \boldsymbol{Q}_{22} \end{bmatrix} := \begin{bmatrix} \hat{\boldsymbol{R}} & 0 \\ 0 & 0 \end{bmatrix} + \bar{\boldsymbol{Q}}_a$$

   with $\bar{\boldsymbol{Q}}_a \in \mathcal{RH}_\infty$ *such that* $\bar{\boldsymbol{H}}\bar{\boldsymbol{H}}^\sim = \bar{\boldsymbol{H}}^\sim\bar{\boldsymbol{H}} = r_1^{-2} I_{p+m-2}$, $\hat{\boldsymbol{R}} \in \mathcal{RH}_\infty^{-(p-1)\times(m-1)}$ *and* $\bar{\boldsymbol{Q}}_{12}^{-1}, \bar{\boldsymbol{Q}}_{21}^{-1} \in \mathcal{RH}_\infty$.
2. *The set of all* $\bar{\boldsymbol{Q}} \in \mathcal{H}_\infty^{(p-1)\times(m-1)}$ *such that* $\|\hat{\boldsymbol{R}}+\bar{\boldsymbol{Q}}\|_\infty \le r_1^{-1}$ *is given by*

$$\bar{\mathcal{S}}_1 = \mathcal{F}_l(\bar{\boldsymbol{Q}}_a, r_1\mathcal{BH}_\infty^{(p-1)\times(m-1)}).$$

3. *There exist inner matrices* $\boldsymbol{X}$ *and* $\boldsymbol{Y}$ *and a scalar allpass function* $\boldsymbol{a}$ *such that*

$$\mathcal{T}_1 = \boldsymbol{Y}\ \mathrm{diag}(r_1^{-1}\boldsymbol{a}, \mathcal{F}_l(\bar{\boldsymbol{H}}, r_1\mathcal{BH}_\infty^{(p-1)\times(m-1)}))\boldsymbol{X}. \tag{10}$$

   Further,

$$\mathcal{F}_l(\bar{\boldsymbol{H}}, r_1\mathcal{BH}_\infty^{(p-1)\times(m-1)}) = \{\hat{\boldsymbol{R}}+\bar{\boldsymbol{Q}} : \bar{\boldsymbol{Q}} \in \mathcal{H}_\infty^{(p-1)\times(m-1)}, \|\hat{\boldsymbol{R}}+\bar{\boldsymbol{Q}}\|_\infty \le r_1^{-1}\}. \tag{11}$$

Proof.

1. The construction of the r_1^{-1}-allpass completion $\bar{\boldsymbol{H}}$ is an exercise in standard factorization theory which can be performed using either transfer function or state-space techniques [3]. The details can be found in [14], [11], [12], [10].
2. The fact that r_1^{-1} is a suboptimal level of $\hat{\boldsymbol{R}}$ follows from part 1 since $\bar{\boldsymbol{Q}}_{11} \in \mathcal{RH}_\infty$ and $\|\hat{\boldsymbol{R}}+\bar{\boldsymbol{Q}}_{11}\|_\infty \le \|\bar{\boldsymbol{H}}\|_\infty = r_1^{-1}$. Part 2 now follows from part 1 and [5, Theorem 3.2] since $\bar{\boldsymbol{Q}}_a, \bar{\boldsymbol{Q}}_{12}^{-1}, \bar{\boldsymbol{Q}}_{21}^{-1}, \hat{\boldsymbol{R}}^\sim \in \mathcal{RH}_\infty$ by construction.
3. Define $\boldsymbol{V}_\perp = \boldsymbol{H}_{12}\bar{\boldsymbol{H}}_{12}^{-1} \in \mathcal{RH}_\infty$ and $\boldsymbol{W}_\perp = \boldsymbol{H}_{21}^\sim\bar{\boldsymbol{H}}_{21}^{-\sim} \in \mathcal{RH}_\infty^-$. Since $r_1\boldsymbol{H}$ and $r_1\bar{\boldsymbol{H}}$ are allpass, a manipulation will verify that $\boldsymbol{V}_\perp^\sim\boldsymbol{H}_{11}\boldsymbol{W}_\perp = \bar{\boldsymbol{H}}_{11}$ and

$$\bar{\boldsymbol{H}}_{21}\bar{\boldsymbol{H}}_{21}^\sim = r_1^{-2} I_{m-1} - \boldsymbol{H}_{22}\boldsymbol{H}_{22}^\sim = \boldsymbol{H}_{21}\boldsymbol{H}_{21}^\sim \implies \boldsymbol{W}_\perp^\sim\boldsymbol{W}_\perp = I_{m-1}.$$

Similarly,

$$\bar{\boldsymbol{H}}_{12}^{\sim}\bar{\boldsymbol{H}}_{12} = r_1^{-2} I_{p-1} - \boldsymbol{H}_{22}^{\sim}\boldsymbol{H}_{22} = \boldsymbol{H}_{12}^{\sim}\boldsymbol{H}_{12} \quad \Longrightarrow \quad \boldsymbol{V}_{\perp}^{\sim}\boldsymbol{V}_{\perp} = I_{p-1}.$$

Hence there exist $\boldsymbol{v} \in \mathcal{RH}_{\infty}^{p\times 1}$, $\boldsymbol{w}^{\sim} \in \mathcal{RH}_{\infty}^{1\times m}$ such that

$$\boldsymbol{V} = \begin{bmatrix} \boldsymbol{v} & \boldsymbol{V}_{\perp} \end{bmatrix}, \qquad \boldsymbol{W} = \begin{bmatrix} \boldsymbol{w} & \boldsymbol{W}_{\perp} \end{bmatrix} \tag{12}$$

are square inner. Now consider the product

$$\begin{aligned} \begin{bmatrix} \boldsymbol{V}^{\sim} & 0 \\ 0 & I \end{bmatrix} \boldsymbol{H} \begin{bmatrix} \boldsymbol{W} & 0 \\ 0 & I \end{bmatrix} &= \begin{bmatrix} \boldsymbol{v}^{\sim}\boldsymbol{H}_{11}\boldsymbol{w} & \boldsymbol{v}^{\sim}\boldsymbol{H}_{11}\boldsymbol{W}_{\perp} & \boldsymbol{v}^{\sim}\boldsymbol{H}_{12} \\ \boldsymbol{V}_{\perp}^{\sim}\boldsymbol{H}_{11}\boldsymbol{w} & \boldsymbol{V}_{\perp}^{\sim}\boldsymbol{H}_{11}\boldsymbol{W}_{\perp} & \boldsymbol{V}_{\perp}^{\sim}\boldsymbol{H}_{12} \\ \boldsymbol{H}_{21}\boldsymbol{w} & \boldsymbol{H}_{21}\boldsymbol{W}_{\perp} & \boldsymbol{H}_{22} \end{bmatrix} \\ &= \begin{bmatrix} \boldsymbol{v}^{\sim}\boldsymbol{H}_{11}\boldsymbol{w} & \boldsymbol{Y}_{12} & \boldsymbol{Y}_{13} \\ \boldsymbol{Y}_{21} & \bar{\boldsymbol{H}}_{11} & \bar{\boldsymbol{H}}_{12} \\ \boldsymbol{Y}_{31} & \bar{\boldsymbol{H}}_{21} & \boldsymbol{H}_{22} \end{bmatrix}. \end{aligned} \tag{13}$$

Since $\boldsymbol{V}, \boldsymbol{W}, r_1\boldsymbol{H}$, and $r_1\bar{\boldsymbol{H}}$ are allpass, all $\boldsymbol{Y}_{ij}$ terms in (13) are equal to zero, and $\boldsymbol{v}^{\sim}\boldsymbol{H}_{11}\boldsymbol{w}$ is r_1^{-1}-allpass, i.e., $\boldsymbol{v}^{\sim}\boldsymbol{H}_{11}\boldsymbol{w} = r_1^{-1}\boldsymbol{a}$ for some scalar allpass rational function $\boldsymbol{a}$. A simple manipulation using (13) verifies that

$$\mathcal{F}_l(\boldsymbol{H}, r_1\mathcal{BH}_{\infty}^{(p-1)\times(m-1)}) = \boldsymbol{V}\ \mathrm{diag}(r_1^{-1}\boldsymbol{a}, \mathcal{F}_l(\bar{\boldsymbol{H}}, r_1\mathcal{BH}_{\infty}^{(p-1)\times(m-1)}))\boldsymbol{W}^{\sim}. \tag{14}$$

Since

$$\mathcal{F}_l(\boldsymbol{H}, r_1\mathcal{BH}_{\infty}^{(p-1)\times(m-1)}) = \{\boldsymbol{R} + \boldsymbol{Q} : \boldsymbol{Q} \in \mathcal{H}_{\infty},\ \|\boldsymbol{R} + \boldsymbol{Q}\|_{\infty} = r_1^{-1}\}$$

we may write from (8), (9), and (14)

$$\begin{aligned} \mathcal{T}_1 &= (\boldsymbol{U} + \boldsymbol{M}\mathcal{F}_l(\boldsymbol{Q}_a, r_1\mathcal{BH}_{\infty}^{(p-1)\times(m-1)}))\tilde{\boldsymbol{M}} \\ &= \boldsymbol{M}(\boldsymbol{M}^{\sim}\boldsymbol{U} + \mathcal{F}_l(\boldsymbol{Q}_a, r_1\mathcal{BH}_{\infty}^{(p-1)\times(m-1)}))\tilde{\boldsymbol{M}} \\ &= \boldsymbol{M}\mathcal{F}_l(\boldsymbol{H}, r_1\mathcal{BH}_{\infty}^{(p-1)\times(m-1)})\tilde{\boldsymbol{M}} \\ &= \boldsymbol{Y}\ \mathrm{diag}(r_1^{-1}\boldsymbol{a}, \mathcal{F}_l(\bar{\boldsymbol{H}}, r_1\mathcal{BH}_{\infty}^{(p-1)\times(m-1)}))\boldsymbol{X} \end{aligned}$$

as required, with $\boldsymbol{Y} := \boldsymbol{MV}$ and $\boldsymbol{X} := \boldsymbol{W}^{\sim}\tilde{\boldsymbol{M}}$ square inner. This proves the theorem. □

Remark 4.2. The theorem shows that every optimal interpolating function $\boldsymbol{T} \in \mathcal{T}_1$ has a partial pseudosingular value decomposition with largest "singular value" r_1^{-1} and corresponding left and right "singular vectors" $\boldsymbol{Mv}$ and $\boldsymbol{w}^{\sim}\tilde{\boldsymbol{M}}$, respectively. The two "singular vectors" corresponding to the largest "singular value" are real-rational.

In what follows we develop improved robust stability properties for the set of controllers which minimize the pair $\{s_1(\mathcal{T}), s_2(\mathcal{T})\}$ with respect to lexicographic ordering. We denote the set of interpolating functions with this property by $\mathcal{T}_2$ and the corresponding set of controllers by $\mathcal{K}_2$. Clearly, $\mathcal{T}_2 \subseteq \mathcal{T}_1 \subseteq \mathcal{T}$ and $\mathcal{K}_2 \subseteq \mathcal{K}_1 \subseteq \mathcal{K}$. We refer to $\mathcal{T}_2$ ($\mathcal{K}_2$) as the superoptimal set of interpolating functions (controllers) with respect to the first two levels. The following lemma gives a parametrization of the set $\mathcal{T}_2$.

LEMMA 4.3. *$\mathcal{T}_2$ may be parametrized as*

$$\mathcal{T}_2 = \boldsymbol{Y}_1\ \mathrm{diag}(s_1\boldsymbol{a}, s_2\boldsymbol{b}, \check{\boldsymbol{R}} + \mathcal{S}_2)\boldsymbol{X}_1 \tag{15}$$

in which s_1 and s_2 denote the first two superoptimal levels of $\mathcal{T}$ with $s_1 = r_1^{-1}$, $\boldsymbol{Y}_1$ and $\boldsymbol{X}_1$ are square inner matrices, $\boldsymbol{a}$ and $\boldsymbol{b}$ are scalar rational allpass functions, $\check{\boldsymbol{R}} \in \mathcal{RH}_\infty^{-(p-2)\times(m-2)}$, and $\mathcal{S}_2 = \{\check{\boldsymbol{Q}} \in \mathcal{H}_\infty : \|\check{\boldsymbol{R}} + \check{\boldsymbol{Q}}\|_\infty \le s_2\}$. Further, the first column (row) of $\boldsymbol{Y}_1$ ($\boldsymbol{X}_1$) is identical to the first column (row) of $\boldsymbol{Y}$ ($\boldsymbol{X}$) defined in Theorem 4.2.

Proof. From (10), since $\boldsymbol{X}$ and $\boldsymbol{Y}$ are square inner and $\boldsymbol{a}$ is allpass, we have

$$s_2 = \inf \ \{ \ \|\mathcal{F}_l(\bar{\boldsymbol{H}}, \boldsymbol{U})\|_\infty : \boldsymbol{U} \in r_1 \mathcal{BH}_\infty^{(p-1)\times(m-1)}\}.$$

Using (11) this is equivalent to

$$s_2 = \inf \ \{\|\hat{\boldsymbol{R}} + \hat{\boldsymbol{Q}}\|_\infty : \hat{\boldsymbol{Q}} \in \mathcal{H}_\infty^{(p-1)\times(m-1)}\} = \|\Gamma_{\hat{\boldsymbol{R}}(-s)}\|,$$

where the second equality follows from Nehari's theorem. Clearly, $\mathcal{T}_2$ may be obtained by replacing $\mathcal{F}_l(\bar{\boldsymbol{H}}, r_1 \mathcal{BH}_\infty^{(p-1)\times(m-1)})$ by the set

$$\{\hat{\boldsymbol{R}} + \hat{\boldsymbol{Q}} : \hat{\boldsymbol{Q}} \in \mathcal{H}_\infty^{(p-1)\times(m-1)} \ , \ \ \|\hat{\boldsymbol{R}} + \hat{\boldsymbol{Q}}\|_\infty = s_2\}, \tag{16}$$

which reveals the recursive character of the problem. Since $\hat{\boldsymbol{R}} \in \mathcal{RH}_\infty^{-(p-1)\times(m-1)}$, a parametrization of (16) may be obtained from Theorem 4.1 with $\boldsymbol{R}$ replaced by $\hat{\boldsymbol{R}}$ and s_1 replaced by s_2. That is, Theorem 4.1 guarantees that there exists an s_2-allpass embedding of $\hat{\boldsymbol{R}}$ of the form

$$\hat{\boldsymbol{H}} = \begin{bmatrix} \hat{\boldsymbol{H}}_{11} & \hat{\boldsymbol{H}}_{12} \\ \hat{\boldsymbol{H}}_{21} & \hat{\boldsymbol{H}}_{22} \end{bmatrix} := \begin{bmatrix} \hat{\boldsymbol{R}} + \hat{\boldsymbol{Q}}_{11} & \hat{\boldsymbol{Q}}_{12} \\ \hat{\boldsymbol{Q}}_{21} & \hat{\boldsymbol{Q}}_{22} \end{bmatrix} = \begin{bmatrix} \hat{\boldsymbol{R}} & 0 \\ 0 & 0 \end{bmatrix} + \hat{\boldsymbol{Q}}_a$$

in which $\hat{\boldsymbol{Q}}_{11} \in \mathcal{RH}_\infty^{(p-1)\times(m-1)}$, $\hat{\boldsymbol{Q}}_{12} \in \mathcal{RH}_\infty^{(p-1)\times(p-2)}$, $\hat{\boldsymbol{Q}}_{21} \in \mathcal{RH}_\infty^{(m-2)\times(m-1)}$, and $\hat{\boldsymbol{Q}}_{22} \in \mathcal{RH}_\infty^{(m-2)\times(p-2)}$ and such that $\hat{\boldsymbol{H}}\hat{\boldsymbol{H}}^\sim = \hat{\boldsymbol{H}}^\sim \hat{\boldsymbol{H}} = s_2^2 I_{p+m-3}$ and $\|\hat{\boldsymbol{H}}_{22}\|_\infty = \|\hat{\boldsymbol{Q}}_{22}\|_\infty < s_2$. Moreover, the set of all $\hat{\boldsymbol{Q}}$ in (16) is generated by $\mathcal{F}_l(\hat{\boldsymbol{Q}}_a, s_2^{-1}\mathcal{BH}_\infty^{(p-2)\times(m-2)})$. Next, we apply Theorem 4.2 to obtain an s_2-allpass embedding of $\hat{\boldsymbol{H}}_{22} = \hat{\boldsymbol{Q}}_{22}$ of the form

$$\check{\boldsymbol{H}} = \begin{bmatrix} \check{\boldsymbol{H}}_{11} & \check{\boldsymbol{H}}_{12} \\ \check{\boldsymbol{H}}_{21} & \hat{\boldsymbol{H}}_{22} \end{bmatrix} = \begin{bmatrix} \check{\boldsymbol{R}} + \check{\boldsymbol{Q}}_{11} & \check{\boldsymbol{Q}}_{12} \\ \check{\boldsymbol{Q}}_{21} & \hat{\boldsymbol{Q}}_{22} \end{bmatrix} = \begin{bmatrix} \check{\boldsymbol{R}} & 0 \\ 0 & 0 \end{bmatrix} + \check{\boldsymbol{Q}}_a$$

with $\check{\boldsymbol{Q}}_{11} \in \mathcal{RH}_\infty^{(p-2)\times(m-2)}$, $\check{\boldsymbol{Q}}_{12} \in \mathcal{RH}_\infty^{(p-2)\times(p-2)}$, and $\check{\boldsymbol{Q}}_{21} \in \mathcal{RH}_\infty^{(m-2)\times(m-2)}$. Also, $\check{\boldsymbol{R}} \in \mathcal{RH}_\infty^{-(p-2)\times(m-2)}$, $\check{\boldsymbol{Q}}_{12}^{-1}, \check{\boldsymbol{Q}}_{21}^{-1} \in \mathcal{RH}_\infty$, and $\check{\boldsymbol{H}}\check{\boldsymbol{H}}^\sim = \check{\boldsymbol{H}}^\sim \check{\boldsymbol{H}} = s_2^2 I_{p+m-4}$. Further, Theorem 4.2 shows that the set of all $\check{\boldsymbol{Q}} \in \mathcal{H}_\infty$ such that $\|\check{\boldsymbol{R}} + \check{\boldsymbol{Q}}\|_\infty \le s_2$ is given by $\mathcal{S}_2 = \mathcal{F}_l(\check{\boldsymbol{Q}}_a, s_2^{-1}\mathcal{BH}_\infty^{(p-2)\times(m-2)})$. The proof of Theorem 4.2(3) may now be repeated step by step to show that there exist square inner matrices $\boldsymbol{V}_1$ and $\boldsymbol{W}_1^\sim$ and a scalar rational allpass function $\boldsymbol{b}$ such that

$$\mathcal{F}_l(\hat{\boldsymbol{H}}, s_2^{-1}\mathcal{BH}_\infty^{(p-2)\times(m-2)}) = \boldsymbol{V}_1 \ \mathrm{diag}(s_2\boldsymbol{b}, \mathcal{F}_l(\check{\boldsymbol{H}}, s_2^{-1}\mathcal{BH}_\infty^{(p-2)\times(m-2)}))\boldsymbol{W}_1^\sim.$$

Hence from (10), $\mathcal{T}_2 = \boldsymbol{Y}_1 \ \mathrm{diag}(s_1\boldsymbol{a}, s_2\boldsymbol{b}, \mathcal{F}_l(\check{\boldsymbol{H}}, s_2^{-1}\mathcal{BH}_\infty^{(p-2)\times(m-2)}))\boldsymbol{X}_1$, where we have defined the square inner matrix functions

$$\boldsymbol{Y}_1 = \boldsymbol{Y} \ \mathrm{diag}(1, \boldsymbol{V}_1), \qquad \boldsymbol{X}_1 = \ \mathrm{diag}(1, \boldsymbol{W}_1^\sim)\boldsymbol{X}.$$

Equation (10) agrees with the parametrization in (15). Note further that the first column (row) of $\boldsymbol{Y}_1$ ($\boldsymbol{X}_1$) is identical with the first column (row) of $\boldsymbol{Y}$ ($\boldsymbol{X}$) and that for every $\check{\boldsymbol{Q}} \in \mathcal{S}_2$, $\|\check{\boldsymbol{R}} + \check{\boldsymbol{Q}}\|_\infty \le s_2$, as required. ∎

In the next part of the section we identify the set of all $\boldsymbol{\Delta} \in \partial\mathcal{D}_{r_1}(\boldsymbol{G})$ which destabilize $(\boldsymbol{G}, \boldsymbol{K})$ for *every* $\boldsymbol{K} \in \mathcal{K}_1$. We refer to such $\boldsymbol{\Delta}$'s as *uniformly destabilizing.*

LEMMA 4.4. *There exists* $\boldsymbol{\Delta} \in \partial\mathcal{D}_{r_1}(\boldsymbol{G})$ *such that* $(\boldsymbol{G}+\boldsymbol{\Delta}, \boldsymbol{K}) \notin \mathcal{S}$ *for every* $\boldsymbol{K} \in \mathcal{K}_1$. *Furthermore,* $\boldsymbol{\Delta}$ *can be chosen to be a stable real-rational matrix function.*

Proof. Pick any $\omega_o \in \mathcal{R}$ and define

$$\Delta_o = \boldsymbol{X}^{\sim}(j\omega_o)\ \mathrm{diag}(r_1/\boldsymbol{a}(j\omega_o), 0)\boldsymbol{Y}^{\sim}(j\omega_o) \in \mathcal{C}^{m\times p}.$$

Then $\eta(\boldsymbol{G}) = \eta(\boldsymbol{G}+\Delta_o)$, $\|\Delta_o\|_\infty = r_1$ and so $\Delta_o \in \partial\mathcal{D}_{r_1}(\boldsymbol{G})$. Let $\boldsymbol{T} \in \mathcal{T}_1$ be any optimal interpolating function so that $\boldsymbol{T} = \boldsymbol{Y}\ \mathrm{diag}(r_1^{-1}\boldsymbol{a}, \boldsymbol{\Phi})\boldsymbol{X}$, where $\boldsymbol{\Phi} = \mathcal{F}_l(\bar{\boldsymbol{H}}, r_1\boldsymbol{\Psi})$ for some $\boldsymbol{\Psi} \in \mathcal{BH}_\infty^{(p-1)\times(m-1)}$ from Theorem 4.2. Then it is simple to show that $\det\ [I - \Delta_o\boldsymbol{T}(j\omega_o)] = 0$ for any $\boldsymbol{\Psi}$ and so $\det\ [I - \Delta_o\boldsymbol{T}(j\omega_o)] = 0$ for all $\boldsymbol{T} \in \mathcal{T}_1$. Since

$$\det\{I - (\boldsymbol{G}+\Delta_o)\boldsymbol{K}(j\omega_o)\} = \det\{I - \boldsymbol{G}\boldsymbol{K}(j\omega_o)\}\det\{I - \Delta_o\boldsymbol{T}(j\omega_o)\} = 0,$$

$(\boldsymbol{G}+\Delta_o, \boldsymbol{K}) \notin \mathcal{S}$ for every $\boldsymbol{K} \in \mathcal{K}_1$ by the generalized Nyquist theorem [25].

In the final part of the proof, we construct a stable real-rational $\boldsymbol{\Delta}$ such that $\boldsymbol{\Delta} \in \partial\mathcal{D}_{r_1}(\boldsymbol{G})$ and $\boldsymbol{\Delta}(j\omega_o) = \Delta_o$. Define the unit vectors

$$y_1 = \boldsymbol{a}(-j\omega_o)\boldsymbol{v}'(j\omega_o)\boldsymbol{M}'(j\omega_o) \in \mathcal{C}^{1\times p}, \qquad x_1 = \tilde{\boldsymbol{M}}'(j\omega_o)\boldsymbol{w}(j\omega_o) \in \mathcal{C}^{m\times 1}$$

so that x_1 is the first column of $\boldsymbol{X}^{\sim}(j\omega_o)$ and $y_1/\boldsymbol{a}(-j\omega_o)$ is the first row of $\boldsymbol{Y}^{\sim}(j\omega_o)$. Next, express each component of x_1 and y_1 as

$$(x_1)_i = \hat{x}_i e^{j\phi_i}, \ \ (y_1)_i = \hat{y}_i e^{j\theta_i},$$

where $\hat{y}_i, \hat{x}_i \in \mathcal{R}$ and $\phi_i, \theta_i \in [0, \pi)$. (This fixes the signs of $\hat{y}_i, \hat{x}_i$.) Define the inner vector functions

$$\hat{\boldsymbol{y}}(s) = \begin{bmatrix} \hat{y}_1\frac{s-\alpha_1}{s+\alpha_1} \\ \vdots \\ \hat{y}_p\frac{s-\alpha_p}{s+\alpha_p} \end{bmatrix}, \qquad \hat{\boldsymbol{x}}(s) = \begin{bmatrix} \hat{x}_1\frac{s-\beta_1}{s+\beta_1} \\ \vdots \\ \hat{x}_m\frac{s-\beta_m}{s+\beta_m} \end{bmatrix}$$

so that

$$\arg\left\{\frac{j\omega_o - \alpha_i}{j\omega_o + \alpha_i}\right\} = \theta_i\ ,\ i = 1, 2, \ldots, p, \ \ \arg\left\{\frac{j\omega_o - \beta_i}{j\omega_o + \beta_i}\right\} = \phi_i,\ i = 1, 2, \ldots, m,$$

with $\alpha_i, \beta_i \in \mathcal{R}_+$ for all i. (If $\theta_i = 0$ or $\phi_i = 0$, we simply replace the ith entry of $\hat{\boldsymbol{y}}$ or $\hat{\boldsymbol{x}}$ by $\hat{x}_i$ or $\hat{y}_i$, respectively.) Next, define the $\mathcal{RH}_\infty$ function $\boldsymbol{\Delta} = r_1\hat{\boldsymbol{x}}\hat{\boldsymbol{y}}^T \in \mathcal{RH}_\infty^{m\times p}$ and note that $\boldsymbol{\Delta}(j\omega_o) = \Delta_o = r_1 x_1 y_1^T$ by construction. Since $\boldsymbol{\Delta} \in \mathcal{RH}_\infty$, $\eta(\boldsymbol{G}) = \eta(\boldsymbol{G}+\boldsymbol{\Delta})$. Finally, note that $\|\boldsymbol{\Delta}\|_\infty = r_1$, which implies that $\boldsymbol{\Delta} \in \partial\mathcal{D}_{r_1}(\boldsymbol{G})$. ∎

Remark 4.3. The proof is an adaptation of a result in [25]. Indeed, it is not surprising that (real-rational) destabilizing perturbations exist on $\partial\mathcal{D}_{r_1}(\boldsymbol{G})$. The new information supplied by Lemma 4.4 is that (real-rational) boundary perturbations exist which are destabilizing for *every* maximally robust controller $\boldsymbol{K} \in \mathcal{K}_1$.

Denote by $\boldsymbol{x}^T$ and $\boldsymbol{y}$ the first row and column of $\boldsymbol{X}$ and $\boldsymbol{Y}$, respectively, defined in Theorem 4.2. Then, all uniformly destabilizing perturbations constructed in Lemma 4.4 have the property that $|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}(j\omega)| = r_1$ for some $\omega \in \mathcal{R}$. Moreover, such perturbations can be constructed for *every* $\omega \in \mathcal{R}$. The next result shows that

condition $|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}(j\omega)| = r_1$ is necessary for a $\boldsymbol{\Delta} \in \partial\mathcal{D}_{r_1}(\boldsymbol{G})$ to be destabilizing for every $\boldsymbol{K} \in \mathcal{K}_1$.

LEMMA 4.5. *Let $\boldsymbol{\Delta} \in \partial\mathcal{D}_{r_1}(\boldsymbol{G})$ be a destabilizing perturbation of $\boldsymbol{G}$ for every $\boldsymbol{K} \in \mathcal{K}_1$. Then there exists an $\omega \in \mathcal{R}$, such that*

$$|\boldsymbol{x}^T(j\omega)\boldsymbol{\Delta}(j\omega)\boldsymbol{y}(j\omega)| = r_1. \tag{17}$$

Proof. The set $\mathcal{T}_1$ is given by (10). Pick any $\boldsymbol{\Psi} \in r_1\mathcal{BH}_\infty^{(p-1)\times(m-1)}$ so that $\|\boldsymbol{\Psi}\|_\infty < r_1$. Since $\bar{\boldsymbol{H}}$ is r_1^{-1}-allpass, $\boldsymbol{\Phi} = \mathcal{F}_l(\bar{\boldsymbol{H}}, \boldsymbol{\Psi})$ satisfies $\|\boldsymbol{\Phi}\|_\infty < r_1^{-1}$. Since $\boldsymbol{\Delta}$ destabilizes $\boldsymbol{G}$ for every $\boldsymbol{K} \in \mathcal{K}_1$, it is also destabilizing for

$$\boldsymbol{K} = (\boldsymbol{U} + \boldsymbol{M}\mathcal{F}_l(\boldsymbol{Q}_a, \boldsymbol{\Psi}))(\boldsymbol{V} + \boldsymbol{N}\mathcal{F}_l(\boldsymbol{Q}_a, \boldsymbol{\Psi}))^{-1} \in \mathcal{K}_1,$$

corresponding to the interpolation function $\boldsymbol{T} = \boldsymbol{Y}\ \mathrm{diag}(r_1^{-1}\boldsymbol{a}, \boldsymbol{\Phi})\boldsymbol{X}$. Since $\alpha\boldsymbol{\Delta}$ is a stabilizing perturbation of $\boldsymbol{G}$ for every $\alpha \in [0, 1)$, there exists $\omega_o \in \mathcal{R}$ such that $\det\{I_m - \boldsymbol{\Delta}(j\omega_o)\boldsymbol{T}(j\omega_o)\} = 0$ or equivalently that

$$\det\left\{I_m - \boldsymbol{\Delta}(j\omega_o)\boldsymbol{Y}(j\omega_o)\begin{bmatrix} r_1^{-1}\boldsymbol{a}(j\omega_o) & 0 \\ 0 & \boldsymbol{\Phi}(j\omega_o)\end{bmatrix}\boldsymbol{X}(j\omega_o)\right\} = 0,$$

which implies that

$$\det\left\{I_m - \boldsymbol{X}(j\omega_o)\boldsymbol{\Delta}(j\omega_o)\boldsymbol{Y}(j\omega_o)\begin{bmatrix} r_1^{-1}\boldsymbol{a}(j\omega_o) & 0 \\ 0 & \boldsymbol{\Phi}(j\omega_o)\end{bmatrix}\right\} = 0. \tag{18}$$

Define

$$\begin{bmatrix} x_1^T \\ X_\perp^T \end{bmatrix} = \boldsymbol{X}(j\omega_o),$$

$\begin{bmatrix} y_1 & Y_\perp \end{bmatrix} = \boldsymbol{Y}(j\omega_o)$, and

$$\tilde{\Delta} = \begin{bmatrix} \tilde{\delta}_{11} & \tilde{\Delta}_{12} \\ \tilde{\Delta}_{21} & \tilde{\Delta}_{22}\end{bmatrix} = \begin{bmatrix} x_1^T \\ X_\perp^T \end{bmatrix}\boldsymbol{\Delta}(j\omega_o)\begin{bmatrix} y_1 & \boldsymbol{a}(j\omega_o) & Y_\perp \end{bmatrix}.$$

Then (18) may be written as

$$\det\begin{bmatrix} 1 - r_1^{-1}\tilde{\delta}_{11} & -\tilde{\Delta}_{12}\boldsymbol{\Phi}(j\omega_o) \\ -r_1^{-1}\tilde{\Delta}_{21} & I_{m-1} - \tilde{\Delta}_{22}\boldsymbol{\Phi}(j\omega_o)\end{bmatrix} = 0. \tag{19}$$

Next, we show that $\tilde{\delta}_{11} = r_1$. Suppose for contradiction that

$$1 - r_1^{-1}\tilde{\delta}_{11} \neq 0. \tag{20}$$

Then (19) implies that

$$\begin{aligned} & (1 - r_1^{-1}\tilde{\delta}_{11})\ \det\left\{I_{m-1} - \tilde{\Delta}_{22}\boldsymbol{\Phi} - r_1^{-1}\tilde{\Delta}_{21}\left(1 - r_1^{-1}\tilde{\delta}_{11}\right)^{-1}\tilde{\Delta}_{12}\boldsymbol{\Phi}(j\omega_o)\right\} = 0, \\ \Rightarrow\quad & \det\left\{I_{m-1} - \left(\tilde{\Delta}_{22} + r_1^{-1}\tilde{\Delta}_{21}\left(1 - r_1^{-1}\tilde{\delta}_{11}\right)^{-1}\tilde{\Delta}_{12}\right)\boldsymbol{\Phi}(j\omega_o)\right\} = 0, \\ \Rightarrow\quad & \det\left\{I_{m-1} - \mathcal{F}_u(\tilde{\Delta}, r_1^{-1})\boldsymbol{\Phi}(j\omega_o)\right\} = 0. \end{aligned}$$

Since $1 - r_1^{-1}\tilde{\delta}_{11} \neq 0$ by assumption, the upper linear fractional map is well-posed; moreover, $\bar{\sigma}(\tilde{\Delta}) = r_1$ which implies that $\bar{\sigma}(\mathcal{F}_u(\tilde{\Delta}, r_1^{-1})) \leq r_1$ [5]. Also, since $\bar{\sigma}(\boldsymbol{\Phi}(j\omega_o)) < r_1^{-1}$, we have that $\bar{\sigma}(\mathcal{F}_u(\tilde{\Delta}, r_1^{-1})\boldsymbol{\Phi}(j\omega_o)) < 1$. Hence,

$$\underline{\sigma}\left(I - \mathcal{F}_u(\tilde{\Delta}, r_1^{-1})\boldsymbol{\Phi}(j\omega_o)\right) \geq 1 - \bar{\sigma}\left(\mathcal{F}_u(\tilde{\Delta}, r_1^{-1})\boldsymbol{\Phi}(j\omega_o)\right) > 0,$$

and thus $\det\{I - \mathcal{F}_u(\tilde{\Delta}, r_1^{-1})\boldsymbol{\Phi}(j\omega_o)\} \neq 0$, contradicting (20). Hence,

$$\tilde{\delta}_{11} = r_1 \Rightarrow | \boldsymbol{x}^T(j\omega_o)\boldsymbol{\Delta}(j\omega_o)\boldsymbol{y}(j\omega_o) | = r_1$$

since $|\boldsymbol{a}(j\omega_o)| = 1$. □

Remark 4.4. Lemma 4.5 above shows that every $\boldsymbol{\Delta} \in \partial\mathcal{D}_{r_1}(\boldsymbol{G})$ which is destabilizing for all $\boldsymbol{K} \in \mathcal{K}_1$ satisfies $|\boldsymbol{x}^T(j\omega_o)\boldsymbol{\Delta}(j\omega_o)\boldsymbol{y}(j\omega_o)| = r_1$ for some $\omega_o \in \mathcal{R}$. Define the inner product of two matrices of compatible dimensions A and B as $\langle A, B\rangle = \text{trace}(A'B)$. Then, (17) says that every $\boldsymbol{\Delta} \in \partial\mathcal{D}_{r_1}(\boldsymbol{G})$ which is destabilizing for all $\boldsymbol{K} \in \mathcal{K}_1$ satisfies $|\langle \boldsymbol{y}(j\omega_o)\boldsymbol{x}^T(j\omega_o), \boldsymbol{\Delta}(j\omega_o)\rangle| = r_1$, i.e., that it has projection of magnitude r_1 in the "most critical direction" $\boldsymbol{y}(j\omega_o)\boldsymbol{x}^T(j\omega_o)$ for some $\omega_o \in \mathcal{R}$. Moreover, the proof of Lemma 4.4 shows that all frequencies $\omega \in \mathcal{R}$ are "equally critical," in the sense that the generalized Nyquist criterion can be violated at *any* $\omega \in \mathcal{R}$. This implies that it is futile to attempt to extend the uncertainty set guaranteed to be stabilized by a subset of $\mathcal{K}_1$ in the (frequency-dependent) direction $\boldsymbol{y}(j\omega)\boldsymbol{x}^T(j\omega)$, $\omega \in \mathcal{R}$. Suppose now that we impose a "structure" on the perturbation set of the form

$$| \boldsymbol{x}^T(j\omega)\boldsymbol{\Delta}(j\omega)\boldsymbol{y}(j\omega) | \leq r_1(1-\delta) \quad \text{for all } \omega \in \mathcal{R}$$

for some (fixed) $\delta \in [0, 1)$. Note in view of Lemmas 4.4 and 4.5 that this bound is assumed to be uniform in ω. In other words, we constrain the perturbation set so that $\boldsymbol{\Delta}$ cannot have a projection of magnitude larger that $r_1(1-\delta)$ in the most critical direction for all $\omega \in \mathcal{R}$. Formally, define the set

$$\mathcal{E}(\delta, \mu) = \{\boldsymbol{\Delta} \in \mathcal{D}_\mu(\boldsymbol{G}) : \|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}\|_\infty \leq r_1(1-\delta)\}, \tag{21}$$

where $\mathcal{D}_\mu(\boldsymbol{G})$ is defined in (1). Then, for each $\delta \in (0, 1]$ we want to find the set of controllers $\mathcal{K}_\delta \subseteq \mathcal{K}_1$ which maximize $\mu = \mu(\delta)$ under the constraint that $\boldsymbol{G} + \boldsymbol{\Delta}$ is stable for all $\boldsymbol{\Delta} \in \mathcal{D}_{r_1}(\boldsymbol{G}) \cup \mathcal{E}(\delta, \mu)$. Suppose that the maximum μ is attained and is given by $\mu^*(\delta)$. It is clear that $\mu^*(\delta)$ is a nondecreasing function of $\delta \in (0, 1]$. It is shown below that the sets $\mathcal{K}_\delta$ are identical for every $\delta \in (0, 1]$ and equal to $\mathcal{K}_2$. A closed-form expression of $\mu^*(\delta)$ is also obtained which involves the first two superoptimal levels of $\mathcal{T}$.

The problem formulation in the above remark is motivated by a related problem in [15]: Suppose that $A \in \mathcal{C}^{n\times n}$ is nonsingular. We know that if $\bar{\sigma}(E) = \underline{\sigma}(A)$, then $A - E$ is singular if and only if $\langle u_n v_n', E\rangle = u_n' E v_n = \underline{\sigma}(A)$, where u_n and v_n denote the singular vectors of A corresponding to $\underline{\sigma}(A)$. Also, if $\bar{\sigma}(E) < \underline{\sigma}(A)$, then $A - E$ is nonsingular. Suppose that $\bar{\sigma}(E) = \underline{\sigma}(A)$ and E is constrained to have a projection of magnitude (strictly) less than $\underline{\sigma}(A)$ in the direction $u_n v_n'$. This means that $A - E$ cannot become singular, and therefore, $\bar{\sigma}(E)$ must increase for $A - E$ to lose rank. To find how much $\bar{\sigma}(E)$ can increase before singularity occurs, we formulate the problem

$$d(\phi) = \min \{\|E\| : \det(A - E) = 0, |\langle u_n v_n', E\rangle| \leq \phi\} \tag{22}$$

for $\phi < \underline{\sigma}(A) := \sigma_n(A)$. The solution to this problem is provided by the next theorem.

THEOREM 4.6. *Let A be a square nonsingular complex matrix which has a singular value decomposition $A = U\Sigma V'$, where $\Sigma = \operatorname{diag}(\sigma_1, \ldots, \sigma_{n-1}, \sigma_n)$ with $\sigma_1 \geq \cdots \geq \sigma_{n-2} \geq \sigma_{n-1} > \sigma_n > 0$ and denote by u_n and v_n the last columns of U and V, respectively. Then all E which minimize* (22) *are given by*

$$E = U \begin{bmatrix} P_s & 0 & 0 \\ 0 & -\phi & \nu \\ 0 & \nu' & \phi \end{bmatrix} V',$$

where P_s is arbitrary except for the constraint

$$\|P_s\| \leq \sqrt{\sigma_n \sigma_{n-1} + \phi(\sigma_n - \sigma_{n-1})} \tag{23}$$

and ν is given by

$$\nu = \sqrt{(\phi + \sigma_{n-1})(\sigma_n - \phi)} e^{j\theta},\ \theta \in [0, 2\pi).$$

The minimum value of $d(\phi)$ in (22) *is given by the right-hand side (RHS) of* (23).

Proof. See [15]. In the original statement of the theorem [15], all singular values of A are assumed to be distinct. This assumption can be relaxed to the condition $\sigma_n \geq \cdots \geq \sigma_{n-2} \geq \sigma_{n-1} > \sigma_n > 0$ used here. □

Remark 4.5. Theorem 4.6 says that, provided $|\langle u_n v_n', E\rangle| \leq \phi < \sigma_n$, $\|E\|$ can increase from σ_n to $d(\phi) = \sqrt{\sigma_n \sigma_{n-1} + \phi(\sigma_n - \sigma_{n-1})}$ before $A - E$ becomes singular. In [15] this is exploited to derive robust-stability bounds for a class of additive, multiplicative, and inverse-multiplicative perturbations. Note that these results are a posteriori, i.e., they can be applied to assess the robust stability of a design only *after* a compensator has been designed. In our case, the results in [15] can be applied a priori in the sense that they can be used to characterize directly the subset of all maximally robust controllers which maximize the "radius" $\mu(\delta)$ of the uncertainty set $\mathcal{E}(\mu, \delta)$ defined in (21). The a priori character of these results in our case is a consequence of the alternative parametrization of the set of all optimal interpolation functions given in Theorem 3.2, which shows that there exists a (frequency-dependent) worst-case direction (defined by the vectors $\boldsymbol{y} = \boldsymbol{M}\boldsymbol{v}$ and $\boldsymbol{x}^T = \boldsymbol{w}^{\sim}\tilde{\boldsymbol{M}}$ in (12)) which is *identical* for *all* maximally robust controllers $\boldsymbol{K} \in \mathcal{K}_1$. The vectors $\boldsymbol{v}$ and $\boldsymbol{w}$ are associated with the maximal Schmidt pair of the Hankel operator $\Gamma_{\boldsymbol{R}(-s)}$ (see [16] for details).

In what follows, we use Theorem 4.6 to characterize the subset of all optimal controllers $\mathcal{K}_1$ which maximize $\mu^*(\delta)$. We first need a slightly different version of Theorem 4.6 which also allows us to treat the nonsquare and the singular cases.

THEOREM 4.7. *Suppose that $T \in \mathcal{C}^{p\times m}$ has a singular value decomposition, $T = U\ \operatorname{diag}(\Sigma, 0)V'$, with $\Sigma = \operatorname{diag}(\sigma_1, \sigma_2, \ldots, \sigma_t)$, $\sigma_1 > \sigma_2 \geq \sigma_3 \geq \cdots \geq \sigma_t > 0$. Let v and u be the first columns of V and U, respectively, and let $\phi < \sigma_1^{-1}$ be given. Define*

$$\mathcal{B}_d^{m\times p} = \{E \in \mathcal{C}^{m\times p}\ :\ \|E\| < d\},$$

$$\mathcal{P}(\phi) = \{E \in \mathcal{C}^{m\times p} : |v'Eu| \leq \phi\}, \tag{24}$$

and

$$d(\phi) = \sup\ \{d\ :\ \det(I_m - ET) \neq 0 \text{ for all } E \in \mathcal{B}_d^{m\times p} \cap \mathcal{P}(\phi)\}. \tag{25}$$

Then

1. *$d(\phi)$ is given by*

$$d(\phi) = \sqrt{\frac{1}{\sigma_1\sigma_2} - \phi\left(\frac{1}{\sigma_2} - \frac{1}{\sigma_1}\right)}; \tag{26}$$

2. *all $E \in \mathcal{P}(\phi)$ such that $\det(I_m - ET) = 0$ and $\|E\| = d(\phi)$ are given by*

$$E = V\begin{bmatrix} \phi & \nu & 0 \\ \nu' & -\phi & 0 \\ 0 & 0 & P_s \end{bmatrix} U', \qquad \nu = e^{j\theta}\sqrt{\left(\frac{1}{\sigma_2} + \phi\right)\left(\frac{1}{\sigma_1} - \phi\right)}, \tag{27}$$

where $\theta \in [0, 2\pi)$ and P_s is arbitrary except from the constraint $\|P_s\| \le d(\phi)$.

Proof. Introduce the partitions $U = [U_1 \;\; U_2]$ and $V = [V_1 \;\; V_2]$, where $U_1 \in \mathcal{C}^{p\times t}$ and $V_1' \in \mathcal{C}^{t\times m}$. For $E \in \mathcal{C}^{m\times p}$,

$$\det(I_m - ET) \neq 0 \Leftrightarrow \det\left(I_m - V'EU\ \operatorname{diag}(\Sigma, 0)\right) \neq 0$$

which is also equivalent to

$$\det\begin{bmatrix} I_t - V_1'EU_1\Sigma & 0 \\ -V_2'EU_1\Sigma & I_{m-t} \end{bmatrix} \neq 0 \Leftrightarrow \det(\Sigma^{-1} - V_1'EU_1) \neq 0.$$

Let $r = \sigma_1^{-1}$. The transformation

$$\mathcal{C}^{m\times p} \to \mathcal{C}^{t\times t} \;\; : \;\; E \to \tilde{E} = V_1'EU_1 \tag{28}$$

maps $\mathcal{B}_r^{m\times p}$ onto $V_1'\mathcal{B}_r^{m\times p}U_1 = \mathcal{B}_r^{t\times t}$: Clearly, for any $E \in \mathcal{B}_r^{m\times p}$, $\|\tilde{E}\| \le \|E\|$ and hence $\tilde{E} \in \mathcal{B}_r^{t\times t}$. Conversely, since all solutions to the equation $\tilde{E} = V_1'EU_1$ are given by

$$E = \begin{bmatrix} V_1 & V_2 \end{bmatrix}\begin{bmatrix} \tilde{E} & \tilde{E}_{12} \\ \tilde{E}_{21} & \tilde{E}_{22} \end{bmatrix}\begin{bmatrix} U_1' \\ U_2' \end{bmatrix}, \tag{29}$$

where $\tilde{E}_{21} \in \mathcal{C}^{(m-t)\times t}$, $\tilde{E}_{12} \in \mathcal{C}^{t\times(p-t)}$, and $\tilde{E}_{22} \in \mathcal{C}^{(m-t)\times(p-t)}$ are arbitrary matrices of the specified dimensions, every $\tilde{E} \in \mathcal{B}_r^{t\times t}$ is the image of the set

$$\left\{E = \begin{bmatrix} V_1 & V_2 \end{bmatrix}\begin{bmatrix} \tilde{E} & \tilde{E}_{12} \\ \tilde{E}_{21} & \tilde{E}_{22} \end{bmatrix}\begin{bmatrix} U_1' \\ U_2' \end{bmatrix} \;:\; \left\|\begin{bmatrix} \tilde{E} & \tilde{E}_{12} \\ \tilde{E}_{21} & \tilde{E}_{22} \end{bmatrix}\right\| < d\right\} \subseteq \mathcal{B}_r^{m\times p}$$

under (28). Moreover, since $|v_1'Eu_1| \le \phi \Leftrightarrow |\tilde{E}_{11}| \le \phi$, (25) is equivalent to

$$d(\phi) = \sup\ \{d \;:\; \det(\Sigma^{-1} - \tilde{E}) \neq 0 \text{ for all } \tilde{E} \in \{\tilde{E} \in \mathcal{B}_r^{t\times t} \;:\; |\tilde{E}_{11}| < \phi\}\},$$

where $\tilde{E}_{11}$ denotes the (1,1) element of $\tilde{E}$. By introducing suitable permutations, $d(\phi)$ may obtained by applying Theorem 4.6 and is given by the RHS of (26) which proves part 1. The set of all $\tilde{E}$ with $\|\tilde{E}\| = d(\phi)$ such that $\det(\Sigma^{-1} - \tilde{E}) = 0$ under the constraint $|\tilde{E}_{11}| \le \phi < \sigma_1^{-1}$ is given via a slight adaptation of Theorem 4.6 as

$$\tilde{E} = \begin{bmatrix} \phi & \nu & 0 \\ \nu' & -\phi & 0 \\ 0 & 0 & \tilde{P}_s \end{bmatrix}, \tag{30}$$

in which ν is defined in (27) and $\tilde{P}_s \in \mathcal{C}^{(t-2)\times(t-2)}$ is arbitrary except from the constraint $\|\tilde{P}_s\| \leq d(\phi)$. It then follows from (29) and the properties of (28) that all $E \in \mathcal{P}(\phi, d)$ such that $\det(I_m - ET) = 0$ and $\|E\| = d(\phi)$ are of the form given in (29) with $\tilde{E}$ given by (30) subject to the constraint $\|E\| \leq d(\phi)$, Thus all such E's are of the form

$$E = V \begin{bmatrix} \phi & \nu & 0 & E_{14} \\ \nu' & -\phi & 0 & E_{24} \\ 0 & 0 & \tilde{P}_s & E_{34} \\ E_{41} & E_{42} & E_{43} & E_{44} \end{bmatrix} U' \tag{31}$$

subject to the constraint $\|E\| \leq d(\phi)$. Since

$$\begin{bmatrix} \phi & \nu \\ \nu' & -\phi \end{bmatrix} \begin{bmatrix} \phi & \nu \\ \nu' & -\phi \end{bmatrix} = d(\phi)^2 I_2$$

we have that $E_{14} = 0, E_{24} = 0, E_{41} = 0, E_{42} = 0$, and

$$\left\| \begin{bmatrix} \tilde{P}_s & E_{34} \\ E_{43} & E_{44} \end{bmatrix} \right\| \leq d(\phi).$$

Thus (31) agrees with the parametrization of part 2. ∎

Remark 4.6. Note that $d(\phi)$ depends only on the two largest singular values of T, σ_1 and σ_2, and on ϕ (and hence on u and v, the left and right singular vectors corresponding to σ_1). Note also that $d(\phi)$ is a decreasing function of σ_2. Since all optimal interpolating functions have the same largest singular value s_1 (for all frequencies), and furthermore, share the same left and right singular vectors corresponding to s_1, Theorem 4.7 suggests a link between the maximization of $\mu^*(\delta)$ and the minimization of the second largest singular value of the elements of $\mathcal{T}_1$.

The next theorem, which is our main result, shows that $\mu^*(\delta)$ is maximized uniquely by the set of all superoptimal controllers with respect to the first two levels.

THEOREM 4.8. *Let $\mathcal{T}_1 \subseteq \mathcal{H}_\infty^{p\times m}$ be as defined in* (10). *Let $\boldsymbol{x}^T$ and $\boldsymbol{y}$ be the first row and column of $\boldsymbol{X}$ and $\boldsymbol{Y}$, respectively, and define $\mathcal{D}_r(\boldsymbol{G})$ and $\mathcal{E}(\delta, \mu)$ as in* (1) *and* (21), *respectively, for some (fixed) $\delta \in [0, 1]$. Let $\mu^*(\delta)$ be the supremum of μ such that there exists a $\boldsymbol{K}$ for which $(\boldsymbol{G}+\boldsymbol{\Delta}, \boldsymbol{K}) \in \mathcal{S}$ for every $\boldsymbol{\Delta} \in \mathcal{D}_{r_1}(\boldsymbol{G}) \cup \mathcal{E}(\delta, \mu)$. Then the following hold:*

1. *For each δ,*

$$\mu^*(\delta) = \sqrt{\frac{1}{s_1}\left(\frac{\delta}{s_2} + \frac{1-\delta}{s_1}\right)} \geq r_1,$$

   where s_1 and s_2 are the two superoptimal levels of $\mathcal{T}$ with $s_1 = r_1^{-1}$.
2. *For each $0 < \delta \leq 1$ the following two statements are equivalent:*
   (a) $(\boldsymbol{G} + \boldsymbol{\Delta}, \boldsymbol{K}) \in \mathcal{S}$ *for every* $\boldsymbol{\Delta} \in \mathcal{D}_{r_1}(\boldsymbol{G}) \cup \mathcal{E}(\delta, \mu^*(\delta))$,
   (b) $\boldsymbol{K} \in \mathcal{K}_2$.
3. (a) $\mathcal{E}(0, \mu^*(0)) = \mathcal{D}_{r_1}(\boldsymbol{G})$,
   (b) *for each* $\boldsymbol{K} \in \mathcal{K}_2$, $(\boldsymbol{G} + \boldsymbol{\Delta}, \boldsymbol{K}) \in \mathcal{S}$ *for every* $\boldsymbol{\Delta} \in \bigcup_{\delta\in[0,1]} \mathcal{E}(\delta, \mu^*(\delta))$.
4. *Let σ_n and σ_{n-1} denote the two smallest Hankel singular values of $\boldsymbol{G}(-s)$ with $\sigma_{n-1} > \sigma_n$. Then,*

$$\mu^*(\delta) \geq \sqrt{\delta\sigma_n\sigma_{n-1} + (1-\delta)\sigma_n^2}.$$

Proof. Let $\boldsymbol{K} \in \mathcal{K}_2$ and define $\boldsymbol{T} = \boldsymbol{K}(I - \boldsymbol{G}\boldsymbol{K})^{-1} \in \mathcal{H}_\infty$. Fix $\delta \in (0,1]$ and define

$$\mu_1^*(\delta, \boldsymbol{K}) = \sup \{ \mu : (\boldsymbol{G} + \boldsymbol{\Delta}, \boldsymbol{K}) \in \mathcal{S} \text{ for all } \boldsymbol{\Delta} \in \mathcal{D}_{r_1}(\boldsymbol{G}) \cup \mathcal{E}(\delta, \mu)\}$$

and $\mu_1^*(\delta) = \sup \{\mu_1^*(\delta, \boldsymbol{K}) : \boldsymbol{K} \in \mathcal{K}_2\}$. Clearly $\mu_1^*(\delta, \boldsymbol{K}) \le \mu_1^*(\delta) \le \mu^*(\delta)$. We show that

$$r_1 \ge \mu_1^*(\delta, \boldsymbol{K}) \ge \sqrt{\frac{1}{s_1}\left(\frac{\delta}{s_2} + \frac{1-\delta}{s_1}\right)}. \tag{32}$$

Since the largest Hankel singular value of $\boldsymbol{R}(-s)$ is assumed to be simple, we have from [16] that $s_2 \le \sigma_2(\Gamma_{\boldsymbol{R}(-s)}) < \sigma_1(\Gamma_{\boldsymbol{R}(-s)}) = s_1$. Set μ_1 equal to the RHS of (32) and suppose for contradiction that there exists a $\boldsymbol{\Delta} \in \mathcal{D}_{r_1}(\boldsymbol{G}) \cup \mathcal{E}(\delta, \mu_1)$ such that $(\boldsymbol{G} + \boldsymbol{\Delta}, \boldsymbol{K}) \notin \mathcal{S}$. Clearly, if $\boldsymbol{\Delta} \in \mathcal{D}_{r_1}(\boldsymbol{G})$ it cannot be destabilizing and hence $\boldsymbol{\Delta} \in \mathcal{E}(\delta, \mu_1) \backslash \mathcal{D}_{r_1}(\boldsymbol{G})$. Thus $r_1 \le \|\boldsymbol{\Delta}\|_\infty < \mu_1$ and $\|\boldsymbol{x}^T \boldsymbol{\Delta} \boldsymbol{y}\|_\infty \le r_1(1-\delta)$. Since $\boldsymbol{K}$ stabilizes $\boldsymbol{G}$, it follows from the generalized Nyquist theorem that

$$\det(I - \boldsymbol{G}\boldsymbol{K}(j\omega)) \ne 0 \text{ for all } \omega \in \mathcal{R}. \tag{33}$$

Now, let ξ vary continuously in the interval $[0,1]$ and consider the resulting deformation of the Nyquist plot of $\det(I - (\boldsymbol{G} + \xi\boldsymbol{\Delta})\boldsymbol{K}(j\omega))$. Since $\boldsymbol{\Delta}$ is destabilizing, there exist an $\omega_o \in \mathcal{R}$ and a $\xi_o \in (0,1]$ such that

$$\det(I - (\boldsymbol{G}(j\omega_o) + \xi_o \boldsymbol{\Delta}(j\omega_o))\boldsymbol{K}(j\omega_o)) = 0$$

which implies that

$$\det(I - \boldsymbol{G}(j\omega_o)\boldsymbol{K}(j\omega_o)) \det(I - \xi_o \boldsymbol{\Delta}(j\omega_o)\boldsymbol{T}(j\omega_o)) = 0$$

or equivalently that

$$\det(I - \xi_o \boldsymbol{\Delta}(j\omega_o)\boldsymbol{T}(j\omega_o)) = 0 \tag{34}$$

from (33). Now $\|\boldsymbol{x}^T \boldsymbol{\Delta} \boldsymbol{y}\|_\infty \le r_1(1-\delta)$ implies that

$$\xi_o |\boldsymbol{x}^T(j\omega_o)\boldsymbol{\Delta}(j\omega_o)\boldsymbol{y}(j\omega_o)| \le \frac{1-\delta}{s_1} := \phi \tag{35}$$

since $0 < \xi_o \le 1$. Since the two largest singular values of $\boldsymbol{T}(j\omega_o)$ are s_1 and s_2, respectively, Theorem 4.7 guarantees that $\det(I - \xi_o E \boldsymbol{T}(j\omega_o)) \ne 0$ for all E such that

$$\|E\| < \frac{1}{\xi_o}\sqrt{\frac{1}{s_1 s_2} - \phi\left(\frac{1}{s_2} - \frac{1}{s_1}\right)} = \frac{1}{\xi_o}\sqrt{\frac{1}{s_1}\left(\frac{\delta}{s_2} + \frac{1-\delta}{s_2}\right)} = \frac{\mu_1}{\xi_o} \tag{36}$$

provided that

$$\xi_o |\boldsymbol{x}^T(j\omega_o) E \boldsymbol{y}(j\omega_o)| \le \frac{1-\delta}{s_1} = \phi. \tag{37}$$

Thus, Theorem 4.7 also guarantees the nonsingularity of $I - \xi_o \boldsymbol{\Delta}(j\omega_o)\boldsymbol{T}(j\omega_o)$ from (35), (36), and the fact that $\|\boldsymbol{\Delta}(j\omega_o)\| \le \|\boldsymbol{\Delta}\|_\infty < \mu_1 \le \mu_1 \xi_o^{-1}$. This contradicts (34) and hence shows that

$$\mu^*(\delta) \ge \mu_1^*(\delta) \ge \mu_1^*(\delta, \boldsymbol{K}) \ge \sqrt{\frac{1}{s_1}\left(\frac{\delta}{s_2} + \frac{1-\delta}{s_1}\right)}. \tag{38}$$

Next, it is shown that the second and third inequalities in (38) are in fact equalities. To establish this fact, it suffices to construct a $\boldsymbol{\Delta} \in \mathcal{RH}_\infty$ ($\Rightarrow \eta(\boldsymbol{G}) = \eta(\boldsymbol{G}+\boldsymbol{\Delta})$) such that (i) $\|\boldsymbol{\Delta}\|_\infty$ is equal to the RHS of (38), (ii) $\|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}\|_\infty \leq r_1(1-\delta)$, and (iii) $(\boldsymbol{G}+\boldsymbol{\Delta}, \boldsymbol{K})$ is unstable for every $\boldsymbol{K} \in \mathcal{K}_2$.

Using Lemma 4.3 the interpolating function $\boldsymbol{T} \in \mathcal{T}_2$ corresponding to any $\boldsymbol{K} \in \mathcal{K}_2$ can be written in the form

$$\boldsymbol{T} = \boldsymbol{Y}_1 \operatorname{diag}(s_1\boldsymbol{a}, s_2\boldsymbol{b}, \check{\boldsymbol{R}} + \check{\boldsymbol{Q}})\boldsymbol{X}_1,$$

in which $\boldsymbol{Y}_1$ and $\boldsymbol{X}_1$ are square inner matrices, $\boldsymbol{a}$ and $\boldsymbol{b}$ are scalar allpass functions, and $\|\check{\boldsymbol{R}} + \check{\boldsymbol{Q}}\|_\infty \leq s_2$. In addition, also from Lemma 4.3, the first column (row) of $\boldsymbol{Y}_1$ ($\boldsymbol{X}_1$) is identical to the first column (row) of $\boldsymbol{Y}$ ($\boldsymbol{X}$); these are denoted by $\boldsymbol{y}$ and $\boldsymbol{x}^T$, respectively. Define the allpass matrix function $\boldsymbol{Y}_2 = \boldsymbol{Y}_1 \operatorname{diag}(\boldsymbol{a}, \boldsymbol{b}, I_{p-2})$. Then $\boldsymbol{T} = \boldsymbol{Y}_2 \operatorname{diag}(s_1, s_2, \check{\boldsymbol{R}}+\check{\boldsymbol{Q}})\boldsymbol{X}_1$. Factor $\boldsymbol{X}_1^\sim$ and $\boldsymbol{Y}_2^\sim$ as $\boldsymbol{X}_1^\sim = \boldsymbol{N}_1 \operatorname{diag}(\boldsymbol{d}_1, \boldsymbol{d}_2, \ldots, \boldsymbol{d}_m)$ and $\boldsymbol{Y}_2^\sim = \operatorname{diag}(\tilde{\boldsymbol{d}}_1, \tilde{\boldsymbol{d}}_2, \ldots, \tilde{\boldsymbol{d}}_p)\boldsymbol{N}_2$ where the functions $\boldsymbol{N}_1, \boldsymbol{N}_2, \boldsymbol{d}_i^{-1}, \tilde{\boldsymbol{d}}_i^{-1}$ are in $\mathcal{RH}_\infty$, $\boldsymbol{N}_1, \boldsymbol{N}_2$ are square inner, and the $\boldsymbol{d}_i$'s, $\tilde{\boldsymbol{d}}_i$'s are scalar allpass functions; these are left and right coprime factorizations of the columns of $\boldsymbol{X}_1^\sim$ and the rows of $\boldsymbol{Y}_2^\sim$ with inner denominators. Next pick any $\omega_o \in \mathcal{R}$, and write for each $i = 1, 2$, $\boldsymbol{d}_i(j\omega_o) = \exp(j\phi_i)$, $\tilde{\boldsymbol{d}}_i(j\omega_o) = \exp(j\tilde{\phi}_i)$, where $-\pi \leq \phi_i, \tilde{\phi}_i < \pi$. Define two diagonal inner matrices $\boldsymbol{A}_1 = \operatorname{diag}(\boldsymbol{\alpha}_1, \boldsymbol{\alpha}_2)$ and $\boldsymbol{A}_2 = \operatorname{diag}(\tilde{\boldsymbol{\alpha}}_1, \tilde{\boldsymbol{\alpha}}_2)$ as follows: For each $i \in \{1, 2\}$, if $0 < \phi_i < \pi$ ($0 < \tilde{\phi}_i < \pi$), set $\boldsymbol{\alpha}_i(s) = (s-\beta_i)(s+\beta_i)^{-1}$ ($\tilde{\boldsymbol{\alpha}}_i(s) = (s-\tilde{\beta}_i)(s+\tilde{\beta}_i)^{-1}$), where $\arg(j\omega_o - \beta_i)(j\omega_o + \beta_i)^{-1} = \phi_i > 0$ ($\arg(j\omega_o - \tilde{\beta}_i)(j\omega_o + \tilde{\beta}_i)^{-1} = \tilde{\phi}_i > 0$). In the case that $-\pi < \phi_i < 0$, set $\boldsymbol{\alpha}_i(s) = -(s-\beta_i)(s+\beta_i)^{-1}$ ($\tilde{\boldsymbol{\alpha}}_i(s) = -(s-\tilde{\beta}_i)(s+\tilde{\beta}_i)^{-1}$), where $\arg(j\omega_o - \beta_i)(j\omega_o + \beta_i)^{-1} = \pi + \phi_i > 0$ ($\arg(j\omega_o - \tilde{\beta}_i)(j\omega_o + \tilde{\beta}_i)^{-1} = \pi + \tilde{\phi}_i > 0$). Finally, if $\phi_i = 0$ ($\tilde{\phi}_i = 0$) or $\phi_i = -\pi$ ($\tilde{\phi}_i = -\pi$), set $\boldsymbol{\alpha}_i$ ($\tilde{\boldsymbol{\alpha}}_i$) to 1 or -1, respectively.

Next, let $\boldsymbol{N}_{11}$ ($\boldsymbol{N}_{21}$) denote the matrix consisting of the first two columns (rows) of $\boldsymbol{N}_1$ ($\boldsymbol{N}_2$), and define $\boldsymbol{\Delta} \in \mathcal{RH}_\infty$ as

$$\boldsymbol{\Delta} = \boldsymbol{N}_{11}\boldsymbol{A}_1 \begin{bmatrix} \phi & \nu_o \\ \nu_o & -\phi \end{bmatrix} \boldsymbol{A}_2\boldsymbol{N}_{21},$$

where ϕ is defined in (35) and

$$\nu_o = \sqrt{\left(\frac{1}{s_2} + \phi\right)\left(\frac{1}{s_1} - \phi\right)} = \sqrt{\frac{\delta}{s_1}\left(\frac{1}{s_2} + \frac{1-\delta}{s_1}\right)}, \tag{39}$$

where the second equality in (39) follows by using the definition of ϕ in (35). Since $\boldsymbol{N}_{11}$, $\boldsymbol{N}_{21}^T$, $\boldsymbol{A}_1$, and $\boldsymbol{A}_2$ are inner matrices,

$$\|\boldsymbol{\Delta}\|_\infty = \left\| \begin{bmatrix} \phi & \nu_o \\ \nu_o & -\phi \end{bmatrix} \right\| = \sqrt{\phi^2 + \nu_o^2},$$

which is equal to the RHS of (38) after some simple algebra.

Since, $\boldsymbol{X}_1\boldsymbol{X}_1^\sim = I_m$ and $\boldsymbol{X}$ and $\boldsymbol{X}_1$ have the same first row ($\boldsymbol{x}^T$), we have

$$\boldsymbol{x}^T\boldsymbol{X}_1^\sim = [1\ 0\ \ldots\ 0] \ \Rightarrow\ \boldsymbol{x}^T\boldsymbol{N}_1 \operatorname{diag}(\boldsymbol{d}_1, \boldsymbol{d}_2, \ldots, \boldsymbol{d}_m) = [1\ 0\ \ldots\ 0],$$

and hence

$$\boldsymbol{x}^T\boldsymbol{N}_{11} = [\ \boldsymbol{d}_1^{-1}\ \ 0\ ]. \tag{40}$$

Similarly, since $\boldsymbol{Y}_1^{\sim}\boldsymbol{Y}_1 = I_p$ and matrices $\boldsymbol{Y}$ and $\boldsymbol{Y}_1$ share their first column ($\boldsymbol{y}$),

$$\boldsymbol{Y}_1^{\sim}\boldsymbol{y} = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \Rightarrow \begin{bmatrix} \boldsymbol{a} & 0 & 0 \\ 0 & \boldsymbol{b} & 0 \\ 0 & 0 & I_{p-2} \end{bmatrix} \boldsymbol{Y}_2^{\sim}\boldsymbol{y} = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

or, equivalently, that

$$\boldsymbol{N}_2\boldsymbol{y} = \begin{bmatrix} \tilde{\boldsymbol{d}}_1^{-1}\boldsymbol{a}^{-1} \\ 0 \\ \vdots \\ 0 \end{bmatrix} \Rightarrow \boldsymbol{N}_{21}\boldsymbol{y} = \begin{bmatrix} \tilde{\boldsymbol{d}}_1^{-1}\boldsymbol{a}^{-1} \\ 0 \end{bmatrix}. \tag{41}$$

Using (40) and (41) we conclude that

$$\|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}\|_\infty = \left\| \boldsymbol{x}^T\boldsymbol{N}_{11}\boldsymbol{A}_1 \begin{bmatrix} \phi & \nu_o \\ \nu_o & -\phi \end{bmatrix} \boldsymbol{A}_2\boldsymbol{N}_{21}\boldsymbol{y} \right\|_\infty = \|\phi\boldsymbol{a}^{-1}\boldsymbol{d}_1^{-1}\tilde{\boldsymbol{d}}_1^{-1}\boldsymbol{\alpha}_1\tilde{\boldsymbol{\alpha}}_1\|_\infty = \phi,$$

using (37) and the fact that $\boldsymbol{a}, \boldsymbol{d}_1, \boldsymbol{d}_3, \boldsymbol{\alpha}_1$, and $\tilde{\boldsymbol{\alpha}}_1$ are all scalar allpass.

Using the identity $\det(I - AB) = \det(I - BA)$, $\det(I_m - \boldsymbol{\Delta}(j\omega_o)\boldsymbol{T}(j\omega_o))$ can be written as

$$\det\left\{ I - \boldsymbol{X}_1(j\omega_o)\boldsymbol{N}_{11}(j\omega_o)\boldsymbol{A}_1(j\omega_o) \begin{bmatrix} \phi & \nu_o \\ \nu_o & -\phi \end{bmatrix} \boldsymbol{A}_2(j\omega_o)\boldsymbol{N}_{21}(j\omega_o)\boldsymbol{Y}_2(j\omega_o)\Pi \right\},$$

where we have defined $\Pi = \operatorname{diag}(s_1, s_2, \check{\boldsymbol{R}}(j\omega_o) + \check{\boldsymbol{Q}}(j\omega_o))$. It is now easy to verify from the construction of $\boldsymbol{A}_1$ and $\boldsymbol{A}_2$ above that

$$\boldsymbol{X}_1(j\omega_o)\boldsymbol{N}_{11}(j\omega_o)\boldsymbol{A}_1(j\omega_o) = \begin{bmatrix} I_2 \\ 0_{m-2,2} \end{bmatrix}, \ \boldsymbol{A}_2(j\omega_o)\boldsymbol{N}_{21}(j\omega_o)\boldsymbol{Y}_2(j\omega_o) = [I_2 \ 0_{2,p-2}],$$

and hence

$$\det(I_m - \boldsymbol{\Delta}(j\omega_o)\boldsymbol{T}(j\omega_o)) = \det \begin{bmatrix} 1 - \phi s_1 & -\nu_o s_2 & 0 \\ -\nu_o s_1 & 1 + \phi s_2 & 0 \\ 0 & 0 & I_{m-2} \end{bmatrix}$$

or

$$\det(I_m - \boldsymbol{\Delta}(j\omega_o)\boldsymbol{T}(j\omega_o)) = (1 - \phi s_1)(1 + \phi s_2) - \nu_o^2 s_1 s_2 = 0,$$

after some simple algebra using (39). This implies that

$$\det(I_m - (\boldsymbol{G}(j\omega_o) + \boldsymbol{\Delta}(j\omega_o))\boldsymbol{K}(j\omega_o)) = 0,$$

and hence $\boldsymbol{\Delta}$ is destabilizing from the generalized Nyquist theorem [25]. This shows that the third inequality in (38) is indeed an equality as claimed. Since $\boldsymbol{\Delta}$ is destabilizing for every $\boldsymbol{K} \in \mathcal{K}_2$, the second equality in (38) also follows.

To establish that the first inequality in (38) is an equality it suffices to construct for each $\boldsymbol{K} \in \mathcal{K}_1 \backslash \mathcal{K}_2$ a $\boldsymbol{\Delta} \in \mathcal{RH}_\infty^{m\times p}$ such that (i) $\|\boldsymbol{\Delta}\|_\infty$ is (strictly) less than the RHS of (38), (ii) $\|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}\|_\infty \le r_1(1-\delta)$, and (iii) $(\boldsymbol{G} + \boldsymbol{\Delta}, \boldsymbol{K}) \notin \mathcal{S}$. Take any $\boldsymbol{K} \in \mathcal{K}_1$, $\boldsymbol{K} \notin \mathcal{K}_2$ and let $\boldsymbol{T} = \boldsymbol{K}(I - \boldsymbol{G}\boldsymbol{K})^{-1}$. From Theorem 4.2, $\boldsymbol{T} \in \mathcal{T}_1$ has the form

$\boldsymbol{T} = \boldsymbol{Y}\ \mathrm{diag}(s_1\boldsymbol{a}, \hat{\boldsymbol{R}} + \bar{\boldsymbol{Q}})\boldsymbol{X}$, where $\|\hat{\boldsymbol{R}} + \bar{\boldsymbol{Q}}\|_\infty \leq s_1$. Since $\boldsymbol{T} \notin \mathcal{T}_2$, there exists an $\omega_o \in \mathcal{R}_+$ such that

$$s_2 < \overline{\sigma}\left(\hat{\boldsymbol{R}}(j\omega_o) + \bar{\boldsymbol{Q}}(j\omega_o)\right) \leq s_1.$$

Let $\hat{\boldsymbol{R}}(j\omega_o) + \bar{\boldsymbol{Q}}(j\omega_o)$ have a singular value decomposition

$$\hat{\boldsymbol{R}}(j\omega_o) + \bar{\boldsymbol{Q}}(j\omega_o) = U\ \mathrm{diag}(\Sigma, 0_{p-t-1,m-t-1})V',$$

where $\Sigma = \mathrm{diag}(\sigma_1, \sigma_2, \ldots, \sigma_t)$ with $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_t > 0$. Then, $s_2 < \sigma_1 \leq s_1$. Denote by $u = [u_1\ u_2\ \ldots\ u_{p-1}]^T$ and $v = [v_1\ v_2\ \ldots\ v_{m-1}]^T$ the first column of U and V, respectively. Define an inner vector $\boldsymbol{\psi} = [\boldsymbol{\psi}_1\ \boldsymbol{\psi}_2\ \ldots\ \boldsymbol{\psi}_{p-1}]^T \in \mathcal{RH}_\infty^{(p-1)\times 1}$ as follows: Write $u_i = \rho_i \exp(j\theta_i)$ for each $i = 1, 2, \ldots, p$, where the ρ_i's are real and $0 \leq \theta_i < \pi$; if $\theta_i \neq 0$, set $\boldsymbol{\psi}_i(s) = \rho_i(s - \beta_i)(s + \beta_i)^{-1}$, where $\beta_i > 0$ and is such that $\arg((j\omega_o - \beta_i)(j\omega_o + \beta_i)^{-1}) = \theta_i$; if $\theta_i = 0$, set $\boldsymbol{\psi}_i = \rho_i$. Clearly, $\boldsymbol{\psi} \in \mathcal{RH}_\infty^{(p-1)\times 1}$, $\boldsymbol{\psi}^\sim\boldsymbol{\psi} = 1$, and $\boldsymbol{\psi}(j\omega_o) = u$. In a similar way, construct an $\mathcal{RH}_\infty^{(m-1)\times 1}$ inner vector $\boldsymbol{\xi}$ which "interpolates" v at $s = j\omega_o$, i.e., $\boldsymbol{\xi}(j\omega_o) = v$.

Define $\hat{\boldsymbol{X}}_1 = \mathrm{diag}(1, \boldsymbol{\xi}^\sim) \in \mathcal{RL}_\infty^{2\times m}$ and $\hat{\boldsymbol{Y}}_1 = \boldsymbol{Y}\ \mathrm{diag}(\boldsymbol{a}, \boldsymbol{\psi}) \in \mathcal{RL}_\infty^{p\times 2}$. Clearly, $\hat{\boldsymbol{X}}_1\hat{\boldsymbol{X}}_1^\sim = \hat{\boldsymbol{Y}}_1^\sim\hat{\boldsymbol{Y}}_1 = I_2$. Define factorizations of the columns (rows) of $\hat{\boldsymbol{X}}_1^\sim$ ($\hat{\boldsymbol{Y}}_1^\sim$) of the form $\hat{\boldsymbol{X}}_1^\sim = \hat{\boldsymbol{N}}_1\mathrm{diag}(\boldsymbol{d}_1, \boldsymbol{d}_2)$ and $\hat{\boldsymbol{Y}}_1^\sim = \mathrm{diag}(\tilde{\boldsymbol{d}}_1, \tilde{\boldsymbol{d}}_2)\hat{\boldsymbol{N}}_2$ such that $\hat{\boldsymbol{N}}_1$ and $\hat{\boldsymbol{N}}_2^T$ are inner and $\boldsymbol{d}_1, \boldsymbol{d}_2, \tilde{\boldsymbol{d}}_1, \tilde{\boldsymbol{d}}_2$ are scalar allpass. Similar to a previous part of the proof, define 2×2 inner matrices $\boldsymbol{A}_1 = \mathrm{diag}(\boldsymbol{\alpha}_1, \boldsymbol{\alpha}_2)$ and $\boldsymbol{A}_2 = \mathrm{diag}(\tilde{\boldsymbol{\alpha}}_1, \tilde{\boldsymbol{\alpha}}_2)$ such that $\boldsymbol{d}_1(j\omega_o)\boldsymbol{\alpha}_1(j\omega_o) = 1$, $\boldsymbol{d}_2(j\omega_o)\boldsymbol{\alpha}_2(j\omega_o) = 1$, $\tilde{\boldsymbol{d}}_1(j\omega_o)\tilde{\boldsymbol{\alpha}}_1(j\omega_o) = 1$, and $\tilde{\boldsymbol{d}}_2(j\omega_o)\tilde{\boldsymbol{\alpha}}_2(j\omega_o) = 1$.

Define $\boldsymbol{\Delta} \in \mathcal{RH}_\infty^{m\times p}$ as

$$\boldsymbol{\Delta} = \hat{\boldsymbol{N}}_1\boldsymbol{A}_1\begin{bmatrix} \phi & \nu_1 \\ \nu_1 & -\phi \end{bmatrix}\boldsymbol{A}_2\hat{\boldsymbol{N}}_2, \qquad \nu_1 = \sqrt{\left(\frac{1}{\sigma_1} + \phi\right)\left(\frac{1}{s_1} - \phi\right)}.$$

The inner character of $\hat{\boldsymbol{N}}_1, \hat{\boldsymbol{N}}_2^T, \boldsymbol{A}_1$, and $\boldsymbol{A}_2$ implies that $\|\boldsymbol{\Delta}\|_\infty = \sqrt{\phi^2 + \nu_1^2} < \sqrt{\phi^2 + \nu_o^2}$ since $s_2 < \sigma_1$. Thus, $\|\boldsymbol{\Delta}\|_\infty$ is strictly less than the RHS of (38). Moreover, it can be easily verified that $\|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}\|_\infty = \phi$. Finally, using the identity $\det(I - AB) = \det(I - BA)$ we can write

$$\det(I_m - \boldsymbol{\Delta}(j\omega_o)\boldsymbol{T}(j\omega_o)) = \det\left(I_m - Z_1\begin{bmatrix} \phi & \nu_1 \\ \nu_1 & -\phi \end{bmatrix}Z_2\begin{bmatrix} s_1 & 0 & 0 \\ 0 & \sigma_1 & 0 \\ 0 & 0 & * \end{bmatrix}\right),$$

where

$$\begin{aligned} Z_1 &= \mathrm{diag}(1, V')\boldsymbol{X}(j\omega_o)\boldsymbol{N}_1(j\omega_o)\boldsymbol{A}_1(j\omega_o), \\ Z_2 &= \boldsymbol{A}_2(j\omega_o)\boldsymbol{N}_2(j\omega_o)\boldsymbol{Y}(j\omega_o)\ \mathrm{diag}(\boldsymbol{a}(j\omega_o), U), \end{aligned}$$

and * denotes a matrix not relevant for our present purposes. It can be easily verified from the above construction that $Z_1^T = [I_2\ \ 0_{2,m-1}]$ and $Z_2 = [I_2\ \ 0_{2,p-1}]$, and hence

$$\det(I_m - \boldsymbol{\Delta}(j\omega_o)\boldsymbol{T}(j\omega_o)) = \det\begin{bmatrix} 1 - \phi s_1 & -\nu_1\sigma_1 & 0 \\ -\nu_1 s_1 & 1 + \phi\sigma_1 & 0 \\ 0 & 0 & I_{m-2} \end{bmatrix} = 0,$$

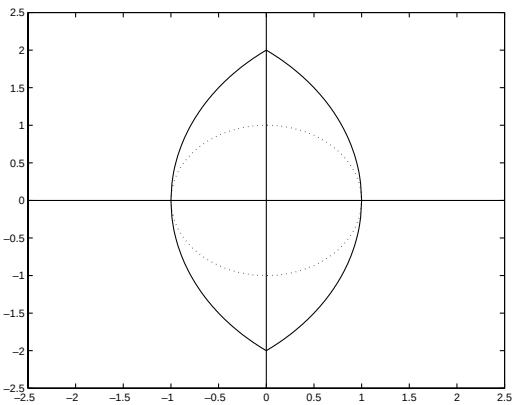

FIG. 2. *Extended permissible uncertainty set.*

which implies that $(\boldsymbol{G}+\boldsymbol{\Delta},\boldsymbol{K})$ is unstable from the generalized Nyquist theorem. Since such destabilizing $\boldsymbol{\Delta}$'s with $\|\boldsymbol{\Delta}\|_\infty < \mu_1^*(\delta)$ and $\|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}\|_\infty = r_1(1-\delta)$ can be constructed for any $\boldsymbol{K}\in\mathcal{K}_1\backslash\mathcal{K}_2$, we conclude that $\mu^*(\delta)=\mu_1^*(\delta)$ and part 1 is proved. It is also clear that $\mathcal{K}_2$ is the set of all controllers $\boldsymbol{K}$ such that $(\boldsymbol{G}+\boldsymbol{\Delta},\boldsymbol{K})\in\mathcal{S}$ for every $\boldsymbol{\Delta}\in\mathcal{D}_{r_1}(\boldsymbol{G})\cup\mathcal{E}(\delta,\mu^*(\delta))$ and part 2 follows.

To prove part 3, note that setting $\delta=0$ in (21) gives

$$\mathcal{E}(0,\mu)=\{\boldsymbol{\Delta}\in\mathcal{L}_\infty : \|\boldsymbol{\Delta}\|_\infty<\mu,\ \|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}\|_\infty\le r_1, \eta(\boldsymbol{G})=\eta(\boldsymbol{G}+\boldsymbol{\Delta})\}.$$

Since from Lemma 4.4 there exist uniformly destabilizing perturbations of $\boldsymbol{G}$ in $\partial\mathcal{D}(\boldsymbol{G})$, we have that $\mu^*(0)\le r_1$. Now,

$$\mathcal{E}(0,r_1)=\{\boldsymbol{\Delta}\in\mathcal{L}_\infty\ :\ \|\boldsymbol{\Delta}\|_\infty<r_1,\ \|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}\|_\infty\le r_1, \eta(\boldsymbol{G})=\eta(\boldsymbol{G}+\boldsymbol{\Delta})\}. \tag{42}$$

In view of the condition $\|\boldsymbol{\Delta}\|_\infty < r_1$ in (42) and the fact that $\|\boldsymbol{x}\|_\infty=\|\boldsymbol{y}\|_\infty=1$, condition $\|\boldsymbol{x}^T\boldsymbol{\Delta}\boldsymbol{y}\|_\infty\le r_1$ in the characterization of $\mathcal{E}(0,r_1)$ in (42) is superfluous and thus $\mathcal{E}(0,r_1)=\mathcal{D}_{r_1}(\boldsymbol{G})$. Hence, $\mu^*(0)=r_1$ and the set of all $\boldsymbol{K}$ such that $(\boldsymbol{G}+\boldsymbol{\Delta},\boldsymbol{K})\in\mathcal{S}$ for every $\boldsymbol{\Delta}\in\mathcal{D}_{r_1}(\boldsymbol{G})\cup\mathcal{E}(0,\mu^*(0))=\mathcal{D}_{r_1}(\boldsymbol{G})$ is clearly $\mathcal{K}_1$. Since $\mathcal{K}_2\subseteq\mathcal{K}_1$, part 3 follows immediately from part 2. Finally, part 4 follows from the relations $s_1=\sigma_1(\Gamma_{\boldsymbol{R}(-s)})=\sigma_n^{-1}$, $\sigma_2(\Gamma_{\boldsymbol{R}(-s)})=\sigma_{n-1}^{-1}$ (see Theorem 3.3 and the subsequent remark), and the inequality $s_2\le\sigma_2(\Gamma_{\boldsymbol{R}(-s)})$ (see [16]). □

Remark 4.7. Figure 2 is an illustration of the set $\bigcup_{\delta\in[0,1]}\mathcal{E}(\delta,\mu^*(\delta))$ in the two-dimensional case. Here, $s_1=1$ and $s_2=0.25$. The "worst direction" is assumed to be the horizontal axis. The (open) disc of radius one represents the set of uncertainties guaranteed to be stabilized by optimal controllers. The area bounded by the solid curve represents the set of uncertainties guaranteed to be stabilized by (second-level) superoptimal controllers. Note the increase in the stability radius in all directions other than the worst direction.

5. An upper bound on the structured-singular value. So far, our results have been restricted to the unstructured uncertainty case. Our overall aim has been to use the degrees of freedom in the set of all optimal ("maximally robust") controllers $\mathcal{K}_1$ in order to extend as far as possible the region of the uncertainty space guaranteed to be stabilized by a subset of $\mathcal{K}_1$. The optimal subset of $\mathcal{K}_1$ has been identified as the set of superoptimal controllers with respect to the first two levels, $\mathcal{K}_2$.

A different interpretation of our method allows us to apply our results to structured uncertainty models as well. The crucial point is that the region of the uncertainty space which is nondestabilizing can be extended beyond $\mathcal{D}_{r_1}$ only *by imposing a structure* on the admissible set of uncertainties; this structure, in our case, is of the form of a projection (uniform in frequency) in the "worst-case direction" $\langle \boldsymbol{y}\boldsymbol{x}^T, . \rangle$, along which all uniformly destabilizing perturbations in $\partial\mathcal{D}_{r_1}(\boldsymbol{G})$ have been shown to lie. Suppose that the uncertainty is known to have a (block) diagonal structure, $\boldsymbol{\Delta}$, say. The following general procedure can be used in principle to obtain a lower bound on $r_{\boldsymbol{\Delta}}$, the robust stability radius with respect to structure $\boldsymbol{\Delta}$.

- Maximize the robust stability radius for a class of unstructured perturbations; let the maximum (unstructured) robust stability radius be r_1 and the corresponding worst-case direction be $\langle \boldsymbol{y}\boldsymbol{x}^T, . \rangle$.
- Given a specific uncertainty structure $\boldsymbol{\Delta}$, find the largest $\delta^* \in (0, 1]$ compatible with $\boldsymbol{\Delta}$, i.e., the maximum $\delta^* \in (0, 1]$ such that $|\langle \boldsymbol{y}\boldsymbol{x}^T, \Delta \rangle| \leq r_1(1 - \delta^*)$, uniformly in ω *for every* $\Delta \in \boldsymbol{\Delta}$.
- Then $\mu^*(\delta^*)$ is a guaranteed lower bound of the robust stability radius of the system with respect to uncertainty structure $\boldsymbol{\Delta}$.

This general method for calculating bounds for the structured robust-stability radius, $r_{\boldsymbol{\Delta}}$ (equivalently the structured singular value $\mu_{\boldsymbol{\Delta}}$), will be developed in future work. In this section we present preliminary results for the constant μ problem and a simple example illustrating our method. A more complete development is given in [9].

We use the definitions and notation of [19]. Let $T \in \mathcal{C}^{n\times n}$ have a singular value decomposition

$$T = U\Sigma V', \quad \Sigma = \operatorname{diag}(\sigma_1, \sigma_2, \ldots, \sigma_n), \quad U, V \in \mathcal{C}^{n\times n}, \quad U'U = V'V = I_n \tag{43}$$

and assume that

$$\sigma_1 > \sigma_2 \geq \sigma_3 \geq \cdots \geq \sigma_n > 0. \tag{44}$$

Define the structured uncertainty set

$$\boldsymbol{\Delta} = \{\operatorname{diag}(\delta_1 I_{r_1}, \ldots, \delta_S I_{r_S}, \Delta_1, \ldots, \Delta_F) : \delta_1, \ldots, \delta_S \in \mathcal{C}, \Delta_j \in \mathcal{C}^{m_j \times m_j}, j = 1, \ldots, F\}$$

with $\sum_{i=1}^{S} r_i + \sum_{j=1}^{F} m_j = n$ and let $\mathbf{B}_{\boldsymbol{\Delta}} = \{\Delta \in \boldsymbol{\Delta} : \|\Delta\| \leq 1\}$. Then the structured singular value of T is defined as

$$\mu_{\boldsymbol{\Delta}}(T)^{-1} = \min_{\substack{\Delta\in\boldsymbol{\Delta} \\ \det(I-\Delta T)=0}} \|\Delta\| = \min_{\substack{\Delta\in\boldsymbol{\Delta} \\ \det(\Sigma^{-1}-V'\Delta U)=0}} \|\Delta\|$$

(if there exists no $\Delta \in \boldsymbol{\Delta}$ such that $\det(I - \Delta T) = 0$, we define $\mu_{\boldsymbol{\Delta}}(T) = 0$). Let $u, v \in \mathcal{C}^{n\times 1}$ be the first columns of U and V, respectively. Partition u and v compatibly with $\boldsymbol{\Delta}$ as follows:

$$u = \begin{bmatrix} u_1 \\ \vdots \\ u_S \\ u_{S+1} \\ \vdots \\ u_{S+F} \end{bmatrix}, \quad v = \begin{bmatrix} v_1 \\ \vdots \\ v_S \\ v_{S+1} \\ \vdots \\ v_{S+F} \end{bmatrix}, \quad u_i, v_i \in \mathcal{C}^{r_i}, \quad u_{S+j}, v_{S+j} \in \mathcal{C}^{m_j} \tag{45}$$

for $i = 1, \ldots, S$ and $j = 1, \ldots, F$. Then it is straightforward to verify that

$$\alpha_0 := \max_{\Delta \in \mathbf{B}_{\mathbf{\Delta}}} |v'\Delta u| = \sum_{i=1}^{S} |v_i' u_i| + \sum_{j=1}^{F} \|v_{S+j}\| \|u_{S+j}\| \leq 1. \tag{46}$$

Define the set $\mathbf{\Delta}_{\alpha_0} := \{\Delta \in \mathcal{C}^{n\times n} : |v'\Delta u| \leq \alpha_0 \|\Delta\|\}$. Clearly $\mathbf{\Delta} \subseteq \mathbf{\Delta}_{\alpha_0}$. It follows that

$$\mu_{\mathbf{\Delta}}(T)^{-1} = \min_{\substack{\Delta \in \mathbf{\Delta} \\ \det(\Sigma^{-1} - V'\Delta U) = 0}} \|\Delta\| \geq \min_{\substack{\Delta \in \mathbf{\Delta}_{\alpha_0} \\ \det(\Sigma^{-1} - V'\Delta U) = 0}} \|\Delta\| =: \bar{\mu}_{\mathbf{\Delta}}(T)^{-1}.$$

Thus $\bar{\mu}_{\mathbf{\Delta}}(T)$ is an upper bound on $\mu_{\mathbf{\Delta}}(T)$. The evaluation of $\bar{\mu}_{\mathbf{\Delta}}(T)$ is related to the results of [15] (see Theorem 4.7). The next result uses Theorem 4.7 to give an expression for $\bar{\mu}_{\mathbf{\Delta}}(T)$ that involves only σ_1, σ_2, u, v, and the uncertainty set $\mathbf{\Delta}$ and shows that $\bar{\mu}_{\mathbf{\Delta}}(T)$ is increasing in σ_2.

THEOREM 5.1. *Let $T \in \mathcal{C}^{n\times n}$ have a singular value decomposition as in* (43) *and assume that* (44) *is satisfied. Let u and v and the first columns of U and V, respectively, be partitioned as in* (45) *and define α_0 as in* (46).

1. *Let*

$$d = (\sigma_1 - \sigma_2)\alpha_0/2 + \sqrt{[(\sigma_1 - \sigma_2)\alpha_0/2]^2 + \sigma_1\sigma_2}. \tag{47}$$

Then

$$\bar{\mu}_{\mathbf{\Delta}}(T) := \left(\min_{\substack{\det(\Sigma^{-1} - V'\Delta U) = 0 \\ |v'\Delta u| \leq \alpha_0 \|\Delta\|}} \|\Delta\| \right)^{-1} = d. \tag{48}$$

2. *For all $\alpha_0 \in [0, 1]$ we have*

$$\mu_{\mathbf{\Delta}}(T) \leq \bar{\mu}_{\mathbf{\Delta}}(T) \leq \sigma_1. \tag{49}$$

3. *If $\alpha_0 = 1$, then*

$$\mu_{\mathbf{\Delta}}(T) = \bar{\mu}_{\mathbf{\Delta}}(T) = \sigma_1. \tag{50}$$

4. *If $\alpha_0 < 1$, then*

$$\mu_{\mathbf{\Delta}}(T) \leq \bar{\mu}_{\mathbf{\Delta}}(T) < \sigma_1 \tag{51}$$

with $\mu_{\mathbf{\Delta}}(T) = \bar{\mu}_{\mathbf{\Delta}}(T)$ if and only if there exists $\Delta \in \mathbf{\Delta}$ such that

$$V'\Delta U = d^{-1} \begin{bmatrix} \alpha_0 & e^{j\theta}\sqrt{1-\alpha_0^2} & 0 \\ e^{-j\theta}\sqrt{1-\alpha_0^2} & -\alpha_0 & 0 \\ 0 & 0 & \Delta_{22} \end{bmatrix} \tag{52}$$

for arbitrary θ and any $\Delta_{22} \in \mathcal{C}^{(n-2)\times(n-2)}$ satisfying $\|\Delta_{22}\| \leq 1$.

Proof.

1. We first show that

$$\bar{\mu}_{\mathbf{\Delta}}(T)^{-1} \leq d^{-1}. \tag{53}$$

Let

$$\Delta = d^{-1}V \begin{bmatrix} \alpha_0 & \sqrt{1-\alpha_0^2} & 0 \\ \sqrt{1-\alpha_0^2} & -\alpha_0 & 0 \\ 0 & 0 & 0_{(n-2)\times(n-2)} \end{bmatrix} U'.$$

Then it is easy to verify that $\|\Delta\| = d^{-1},\ |v'\Delta u| = \alpha_0 d^{-1} \le \alpha_0\|\Delta\|$, and

$$\det(\Sigma^{-1} - V'\Delta U) = \sigma_1^{-1}\sigma_2^{-1} - \alpha_0 d^{-1}(\sigma_2^{-1} - \sigma_1^{-1}) - \alpha_0^2 d^{-2} = 0$$

after some manipulation, and this proves (53). Thus we can restrict our search in (48) to the set

$$\{\Delta \in \mathcal{C}^{n\times n} : \|\Delta\| \le d^{-1},\ |v'\Delta u| \le \alpha_0 d^{-1}\}$$

and so

$$\begin{aligned} \bar{\mu}_{\mathbf{\Delta}}(T)^{-1} &= \min_{\substack{\det(\Sigma^{-1}-V'\Delta U)=0 \\ |v'\Delta u|\le\alpha_0 d^{-1} \\ \|\Delta\|\le d^{-1}}} \|\Delta\| \\ &= \sqrt{\sigma_1^{-1}\sigma_2^{-1} - \alpha_0 d^{-1}(\sigma_2^{-1} - \sigma_1^{-1})} = d^{-1}, \end{aligned} \tag{54}$$

where the first equality in (54) follows from Theorem 4.7 and the second equality follows from a straightforward calculation using the definition of d (in fact, d is defined so that d^{-1} is the positive solution of (54)).

2. It is straightforward to verify that $d \le \sigma_1$. The first inequality follows from the definitions of $\bar{\mu}_{\mathbf{\Delta}}(T)$ and $\mu_{\mathbf{\Delta}}(T)$.
3. Suppose that $\alpha_0 = 1$. Then a simple calculation verifies that $d = \sigma_1$ which proves the second equality in (50). To prove the first equality, define

$$\Delta = \sigma_1^{-1}\mathrm{diag}(\delta_1 I_{r_1}, \ldots, \delta_S I_{r_S}, \Delta_1, \ldots, \Delta_F) \in \mathbf{\Delta},$$

where

$$\begin{aligned} \delta_i &= \frac{|v_i'u_i|}{v_i'u_i} \in \mathcal{C} \quad (\delta_i = 0 \text{ if } v_i'u_i = 0), \quad i = 1, \ldots, S, \\ \Delta_j &= \frac{v_j u_j'}{\|v_j\|\|u_j\|} \in \mathcal{C}^{m_j\times m_j} \quad (\Delta_j = 0 \text{ if } \|v_j\|\|u_j\| = 0), \quad j = 1, \ldots, F, \end{aligned}$$

where u_i, v_i are defined in (45). Then $\|\Delta\| = \sigma_1^{-1}$ and $v'\Delta u = \sigma_1^{-1}$. This implies that $V'\Delta U = \mathrm{diag}(\sigma_1^{-1}, \Delta_{22})$ for some Δ_{22} with $\|\Delta_{22}\| \le \sigma_1^{-1}$. It is easy to verify that $\det(\Sigma^{-1} - V'\Delta U) = 0$ and so $\mu_{\mathbf{\Delta}}(T) = \sigma_1$ and the first equality in (50) is proved.
4. Suppose that $\alpha_0 < 1$. Then a simple verification shows that $d < \sigma_1$ and establishes the second inequality in (51). Part 2 of Theorem 4.7 gives all Δ such that $\|\Delta\| = d^{-1},\ \det(\Sigma^{-1} - V'\Delta U) = 0$, and $|v'\Delta u| \le \alpha_0 d^{-1}$ as in (52). Hence $\mu_{\mathbf{\Delta}}(T) = \bar{\mu}_{\mathbf{\Delta}}(T)$ if and only if there exists such a $\Delta \in \mathbf{\Delta}$.

This completes the proof. □

Remark 5.1. Note that $\bar{\mu}_{\mathbf{\Delta}}(T)$ depends only on σ_1, σ_2, and α_0 (see (47) and (48)), and α_0 in turn depends only on u, v, and the structured uncertainty set $\mathbf{\Delta}$ (see (46)). In the context of the robust stabilization of systems with unstructured additive

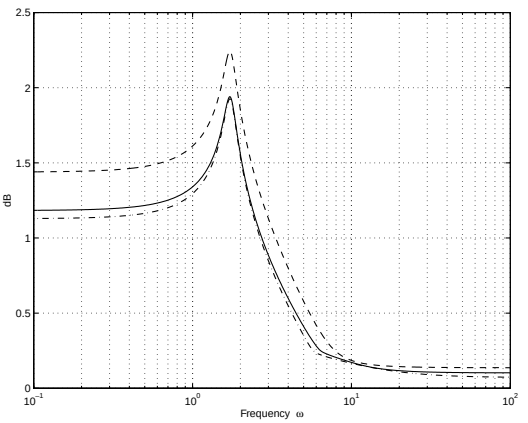

FIG. 3. $\sigma_1(\boldsymbol{T})$ *(dashed), D-iteration upper bound (dash-dot), and upper bound* $\bar{\mu}_{\boldsymbol{\Delta}}(\boldsymbol{T})$ *(solid).*

perturbations, all optimal interpolating functions share the same largest singular value s_1 at all frequencies. They also share the same (frequency-dependent) singular vectors corresponding to s_1 (the inner vectors $\boldsymbol{x}$ and $\boldsymbol{y}$). Thus the only free parameter that can be used to minimize $\bar{\mu}_{\boldsymbol{\Delta}}(\cdot)$ within the set $\mathcal{T}_1$ is the second largest singular value. Noting that $\bar{\mu}_{\boldsymbol{\Delta}}(\cdot)$ is a nonincreasing function of σ_2 (see (47)) suggests that within $\mathcal{T}_1$, $\bar{\mu}_{\boldsymbol{\Delta}}(\cdot)$ is minimized by $\mathcal{T}_2$. This will be elaborated in a future work.

Remark 5.2. The bound $\bar{\mu}_{\boldsymbol{\Delta}}$, although in general tighter than σ_1, is less tight than the upper bound of the D-iteration [19]. In fact, it is shown in [19] that at the end of the D-iteration, either

1. $\sigma_1(T) = \sigma_2(T)$, in which case our results are not applicable (see (44)), or
2. $\sigma_1(T) > \sigma_2(T)$, in which case $\mu_{\boldsymbol{\Delta}}(T) = \sigma_1(T)$. It can be shown that this corresponds to $\alpha_0 = 1$.

The main purpose in this work is to illustrate the improved robustness properties of superoptimal controllers, rather than attempting to improve the D-iteration bound.

Example 5.1. This example illustrates the upper bound $\bar{\mu}_{\boldsymbol{\Delta}}(\boldsymbol{T})$, where

$$\boldsymbol{T} \stackrel{s}{=} \left[\begin{array}{cc} A & B \\ C & D \end{array}\right] = \left[\begin{array}{ccc|cccc} -5.91 & -11.49 & 6.03 & -0.59 & -1.90 & 0.19 & 1.35 \\ -1.85 & -5.62 & 1.63 & -0.31 & 1.11 & 0.63 & 0.12 \\ -7.71 & -17.40 & 7.07 & 0.97 & 0.72 & -0.35 & -0.58 \\ \hline -0.37 & 0.49 & 0.52 & 0.01 & 0.22 & 0.71 & 0.97 \\ 1.43 & -0.09 & 1.36 & 0.60 & 0.70 & 0.23 & 0.36 \\ 0.07 & 0.37 & -0.41 & 0.82 & 0.52 & 0.45 & 0.05 \\ -0.23 & -0.15 & 0.66 & 0.98 & 0.93 & 0.17 & 0.76 \end{array}\right]$$

is chosen as random with A stable. The computation is carried out pointwise across the frequency grid, i.e., for each ω, $\sigma_1(\boldsymbol{T}(j\omega))$ and $\bar{\mu}_{\boldsymbol{\Delta}}(\boldsymbol{T}(j\omega))$ are computed and compared with the D-iteration upper bound. The uncertainty structure $\boldsymbol{\Delta}$ is taken to be diagonal, i.e., $S = 0, F = 4, m_j = 1$ for $j = 1, \ldots, 4$. The plots are shown in Figure 3.

6. Conclusions. By way of conclusion, we summarize our contribution.

- We have analyzed in detail the maximum robust stabilization problem subject to unstructured additive perturbations. We have shown that a critical direction exists in the uncertainty space, along which all maximum-norm boundary

perturbations are destabilizing for every optimal controller.

- We have shown that by imposing a parametric constraint in the most critical direction, the set of uncertainties guaranteed to be stabilized by a subset of all optimal controllers can be further extended. We have shown that the optimal solution to this problem is associated with the set of superoptimal controllers with respect to the first two levels, and we have obtained a closed-form expression for the improved robust stability radius which involves the first two superoptimal levels.
- By adapting out results to the structured uncertainty case, we have obtained an easily computable upper bound on the structured-singular value (which is tighter than the largest singular value), without the need to carry out a D-iteration. We have further shown that the minimization of this bound is equivalent to the minimization of the second largest singular value, which again motivates superoptimization.

There are a number of related research directions which we intend to pursue.

- For purposes of clarity, our technique has been restricted to unstructured additive uncertainty models. There is no conceptual difficulty, however, in extending our method to other types of unstructured uncertainty (multiplicative, inverse-multiplicative, coprime) or to include frequency weightings. Rather than analyzing each case individually, we intend to address the general problem involving linear fractional transformation uncertainty models [17]. This is likely to involve a general-distance superoptimal approximation problem, the solution of which is already in place [26], [8], [16], [13], [14], [12].
- Our method relies on Theorem 4.7 which generalizes a result in [15]. Section 5 suggests that generalizing this theorem should be useful in robust stability analysis of systems subject to structured uncertainty. We have derived some results in this direction which will be reported in a future publication.
- We intend to investigate the possibility of applying our method as an alternative to current μ-synthesis techniques. The main potential advantage of our approach is the possibility of avoiding the calculation of the optimal scaling "D-matrix" in the $D - K$ iteration [2] (currently carried out pointwise over a discretized frequency grid) by using instead the directionality information provided by the two Schmidt vectors, which define the worst-case direction in our setting. The success of such an approach will ultimately rest on how tightly we can overbound the structured singular value. Although our computational experience so far is promising, this remains an open question.

DISTURBANCE DECOUPLING FOR DESCRIPTOR SYSTEMS BY STATE FEEDBACK*

DELIN CHU† AND VOLKER MEHRMANN‡

Abstract. We study the disturbance decoupling problem for linear time invariant descriptor systems. We give necessary and sufficient conditions for the existence of a solution to the disturbance decoupling problem with or without stability via a proportional and/or derivative feedback that also makes the resulting closed-loop system regular and/or of index at most one. All results are proved constructively based on condensed forms that can be computed using orthogonal matrix transformations, i.e., transformations that can be implemented in a numerically stable way.

Key words. descriptor system, state feedback, disturbance decoupling, stability, orthogonal matrix transformation

1. Introduction.

We consider linear and time-invariant continuous descriptor systems of the form

$$\begin{aligned} E\dot{x}(t) &= Ax(t) + Bu(t) + Gq(t), \qquad x(t_0) = x_0,\ t \geq t_0, \\ y(t) &= Cx(t), \end{aligned} \tag{1}$$

where E, $A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$, $G \in \mathbf{R}^{n\times p}$, $C \in \mathbf{R}^{q\times n}$, and $\dot{x} = dx/dt$. The term $q(t), t \geq 0$, represents a disturbance, which may represent modeling or measuring errors, noise, or higher order terms in linearization. We study the problem of constructing feedbacks that suppress this disturbance in the sense that $q(t)$ does not affect the input-output behavior of the system. In this paper, we study only square systems (E, A are square). This seems to be a restriction, since in general models that arise from automatic modeling or from heterogeneous systems are often rectangular, e.g., [16]. In [7], however, it was shown that for every rectangular system there exists an underlying square system that can be obtained via a numerically backward stable procedure by removing redundancies and higher index uncontrollable and unobservable parts in the system. It is possible to formulate all the results in this paper also for rectangular systems, by incorporating the transformations performed in [7] into the methods and the theorems. But this would make the paper, which is quite technical already, even longer and more technical. For this reason we restrict ourselves to the square case. Similarly, we also assume without loss of generality (w.l.o.g.) that B, G are full column rank and C is full row rank, i.e., $\operatorname{rank}(B) = m$, $\operatorname{rank}(G) = p$, $\operatorname{rank}(C) = q$. If this is not the case, then this can be easily achieved, via a numerically stable procedure, by removing the nullspaces and appropriate renaming of variables.

The theory for (1) is well established from the analytical, geometric, and numerical points of view; see, e.g., [11, 17, 22, 30]. Existence and uniqueness of (classical) solutions to (1) for sufficiently smooth input functions and consistent initial values are guaranteed if (E, A) is *regular*, i.e., if $\det(\alpha E - \beta A) \neq 0$ for some $(\alpha, \beta) \in \mathbf{C}^2$. This means in particular that the system has to be square. The system (1) is said to have *index at most one* if the dimension of the largest nilpotent block in the Kronecker canonical form of (E, A) is at most one [14, 4]. It is well known that systems that are regular and of index at most one can be separated into purely dynamical and purely algebraic parts (fast and slow modes), and in theory the algebraic part can be eliminated to give a reduced-order standard system. The reduction process, however, may be ill-conditioned with respect to numerical computation. For this reason it is preferable to use descriptor system models rather than turning the problem into a standard system. Nonetheless most numerical simulation methods work well for systems of index at most one (see [4]) and the usual class of piecewise continuous input functions can be used. Also classical techniques for important control applications like stabilization, pole assignment, or linear quadratic control can be applied; see, e.g., [22, 5, 6].

If the index is larger than one, however, then impulses arise in the response of the system if the control is not sufficiently smooth [5, 11]. This restricts the set of admissable input functions and impulses can also arise due to the presence of modeling, measurement, linearization, and roundoff errors in the real system. Furthermore, the use of numerical integration methods is restricted; see [4].

There are essentially two possibilities to deal with higher index systems in the context of control systems. Either an index reduction is performed (see, e.g., [7, 18]) to obtain an equivalent system of index at most one, or an appropriate feedback control is chosen to ensure that the closed-loop system is regular and of index at most one. Techniques for the construction of such feedbacks were developed in [5, 6, 8] based on transformations to condensed forms via orthogonal matrix transformations, which can be implemented as numerically stable algorithms. This paper, which is strongly inspired by the work of [5, 6, 8], extends these techniques to the solution of the disturbance decoupling problem.

The *disturbance decoupling problem* for descriptor systems (1) can be stated as follows: *Find necessary and sufficient conditions under which there exists a proportional and derivative feedback of the form* $u(t) = Fx(t) - K\dot{x}(t)$, *such that matrix pencil* $(E + BK, A + BF)$ *is regular and of index at most one and* $C(s(E + BK) - (A + BF))^{-1}G = 0$, *where* $C(s(E + BK) - (A + BF))^{-1}G$ *is the transfer-function matrix of the closed-loop system*

$$(E + BK)\dot{x}(t) = (A + BF)x(t) + Gq(t), \quad y(t) = Cx(t). \tag{2}$$

For standard systems ($E = I$) this problem is well studied (see [23, 24, 25, 26, 27, 29, 30]). Our attention, however, will focus on the case that E is singular. Let us briefly summarize some previous results. The disturbance decoupling problem for continuous-time descriptor systems was first formulated in [21] and the problem was solved under the assumption, among other conditions, that the output is independent of the input disturbance in the sense that there is a set of admissible initial conditions such that the response of the system is zero. But, since the disturbance input is usually unknown, it is not clear how, and if at all, a given initial state x_0 can be qualified as an admissible initial condition. In [3] the problem was solved from the geometric point of view, using the concepts of sliding and coasting subspaces by means

of a set of necessary and sufficient conditions for obtaining disturbance decoupling in implicit discrete systems. These results are not constructive and numerically stable methods cannot be based on this approach. Furthermore the index of the system is not considered. In [19, 20] again the discrete time disturbance decoupling problem is discussed and structurally equivalent characterizations are presented for the solvability of the disturbance decoupling problems for implicit discrete-time systems.

In [1] the standard disturbance decoupling problem for continuous-time descriptor systems was considered as formulated in the standard state-space system theory [30], i.e., given the system (1), find (if possible) a proportional state feedback such that, regardless of the initial value of x_0, the disturbance input has no influence on the output of the systems for $t \geq 0$, and yet the uniqueness of solutions for the closed-loop system is ensured. Also in [1] necessary and sufficient conditions were given for solvability of the disturbance decoupling problem under the assumptions $\operatorname{rank}\begin{bmatrix} E & G \end{bmatrix} = n$ and $\operatorname{rank}\begin{bmatrix} E & B & G \end{bmatrix} = n$. But the obtained conditions are rather cumbersome and are only partly given in terms of the original data (E, A, B, C, G). Moreover, combined derivative and proportional state feedback, the index and stability of the system, and also numerical aspects of the algorithms have not been considered in the literature so far.

To demonstrate the great flexibility of our matrix pencil approach, we also discuss the extra requirement that the closed-loop system be stable, i.e., that all the finite generalized eigenvalues of $s(E + BK) - (A + BF)$ are in the open left half-plane. Furthermore a similar approach yields also the solution for partly measurable disturbances, i.e., we also study the use of a proportional and derivative feedback of the form $u(t) = Fx(t) - K\dot{x}(t) + Hq(t)$, such that the matrix pencil $(E + BK, A + BF)$ is regular, of index at most one, and

$$C(s(E + BK) - (A + BF))^{-1}(G + BH) = 0.$$

Again, we also include the stability of the closed-loop system as an extra requirement.

All our results are proved constructively, based on condensed forms under orthogonal matrix transformations which can be directly implemented as numerically stable algorithms.

The paper is organized as follows. In section 2 we introduce some notation and give some preliminary results. In sections 3 and 4 we solve the disturbance decoupling problems without and with stability, respectively. We discuss separately the case that the system is only regularized and that it also has index at most one. It should be noted that several more results on this topic could have been included but are omitted for lack of space. See the technical reports [9, 10].

2. Preliminaries. In this section we introduce the notation and give some preliminary results. We denote by $\deg(p)$ the degree of a polynomial p and by $\operatorname{rank}_g[M(s)]$ the generic rank of a rational matrix valued function $M(s)$ and by $\bar{\mathbf{C}}^+$ the closed right half-plane. Let the orthogonal complement of the space spanned by the columns of a matrix M be denoted by $M^\perp$. A matrix with orthogonal columns spanning the right nullspace of a matrix M is denoted by $S_\infty(M)$ and a matrix with orthogonal columns spanning the right nullspace of M^T by $T_\infty(M)$. For convenience of notation we identify a subspace and a matrix whose columns form an orthonormal basis of this subspace. These orthonormal bases will be available from the condensed forms that we determine.

In principle the complete analysis of descriptor systems could be based on the Kronecker canonical forms of the associated matrix pencils [14, 13], but it is in general

impossible to compute the Kronecker canonical form with a finite precision numerical algorithm, since small changes in the data can drastically change the canonical form. Instead one can obtain a condensed form under orthogonal equivalence transformations. This form, the generalized upper triangular (GUPTRI) form, is well analyzed [12, 13], and numerically stable algorithms are available and have been implemented in LAPACK [2]. The GUPTRI form displays all the invariants, in particular, the left and right Kronecker indices, but it is not the complete canonical form.

LEMMA 2.1 (see [12]). *Given a matrix pencil (E, A), $E, A \in \mathbf{R}^{n\times l}$, there exist orthogonal matrices $P \in \mathbf{R}^{n\times n}$, $Q \in \mathbf{R}^{l\times l}$ such that (PEQ, PAQ) are in the following GUPTRI form:*

$$(3)\quad P(sE-A)Q = \begin{array}{c} \\ n_1 \\ n_2 \\ n_3 \\ n_4 \end{array} \begin{array}{c} \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \end{array} \\ \begin{bmatrix} sE_{11}-A_{11} & sE_{12}-A_{12} & sE_{13}-A_{13} & sE_{14}-A_{14} \\ 0 & sE_{22}-A_{22} & sE_{23}-A_{23} & sE_{24}-A_{24} \\ 0 & 0 & sE_{33}-A_{33} & sE_{34}-A_{34} \\ 0 & 0 & 0 & sE_{44}-A_{44} \end{bmatrix} \end{array}.$$

Here $n_2 = l_2, n_3 = l_3$, $sE_{11} - A_{11}$, and $sE_{44} - A_{44}$ contain all left and right singular Kronecker blocks of $sE - A$, respectively. Furthermore, $sE_{22} - A_{22}$ and $sE_{33} - A_{33}$ are regular and contain the regular finite and infinite structure of $sE - A$, respectively.

Based on the form (3), we introduce the following spaces which we will use to describe a geometric, coordinate-free, characterization of the solution to the disturbance decoupling problem.

DEFINITION 2.2 (see [12]). *Given a matrix pencil (E, A), $E, A \in \mathbf{R}^{n\times l}$, and orthogonal matrices P, Q such that $P(sE - A)Q$ is of the form* (3). *Then*

1. *The minimal left reducing subspace $V_{m-l}[E, A]$ of (E, A) is the space spanned by the leading n_1 columns of P^T.*
2. *The minimal right reducing subspace $V_{m-r}[E, A]$ of (E, A) is the space spanned by the leading l_1 columns of Q.*
3. *The left reducing subspace corresponding to the finite spectrum of (E, A), denoted by $V_{f-l}[E, A]$, is the space spanned by the leading $n_1 + n_2$ columns of P^T.*
4. *The right reducing subspace corresponding to the finite spectrum of (E, A), denoted by $V_{f-r}[E, A]$, is the space spanned by the leading $l_1 + l_2$ columns of Q.*

The problem of constructing feedbacks such that the closed-loop system is regular, of index at most one, and stable has already been studied in detail in the literature. We summarize some of the relevant results in the following lemmas.

LEMMA 2.3 (see [5, 11, 28]). *Given $E, A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$.*

(i) *There exists $F \in \mathbf{R}^{m\times n}$ such that $(E, A + BF)$ is regular if and only if*

$$(4)\qquad \operatorname{rank}_g \begin{bmatrix} sE - A & B \end{bmatrix} = n.$$

(ii) *There exists $F \in \mathbf{R}^{m\times n}$ such that $(E, A + BF)$ is regular and of index at most one if and only if*

$$(5)\qquad \operatorname{rank} \begin{bmatrix} E & AS_\infty(E) & B \end{bmatrix} = n.$$

(iii) *There exist $F, K \in \mathbf{R}^{m\times n}$ such that $(E+BK, A+BF)$ is regular and of index at most one if and only if*

$$(6)\qquad \operatorname{rank} \begin{bmatrix} E & AS_\infty(T_\infty^T(B)E) & B \end{bmatrix} = n.$$

(iv) *There exists a matrix* $F \in \mathbf{R}^{m\times n}$ *such that* $(E, A+BF)$ *is regular and stable if and only if*

$$\operatorname{rank}\begin{bmatrix} sE-A & B \end{bmatrix} = n \quad \forall s \in \mathbf{C}^{+}. \tag{7}$$

(v) *There exists a matrix* $F \in \mathbf{R}^{m\times n}$ *such that* $(E, A+BF)$ *is regular, stable, and of index at most one if and only if conditions* (5) *and* (7) *hold.*

(vi) *There exist matrices* $F, G \in \mathbf{R}^{m\times n}$ *such that* $(E+BG, A+BF)$ *is regular and stable if and only if condition* (7) *holds.*

(vii) *There exist matrices* $F, G \in \mathbf{R}^{m\times n}$ *such that* $(E+BG, A+BF)$ *is regular, stable, and of index at most one if and only if conditions* (6) *and* (7) *hold.*

Remark 2.1. Condition (5) is often called *controllability at infinity*, since if it holds, then the Jordan structure of the spectrum at infinity can be modified arbitrarily. This condition is not invariant under derivative feedback (see [5]), hence condition (6) is needed when combined state and derivative is used. Condition (4) is sometimes called *regularizability* [7]. If a system satisfies both (5) and (7), then it is called *strongly stabilizable*; see [22, p. 14].

The spaces occurring in Lemma 2.3 can be easily computed via numerically stable procedures, like singular value decomposition or rank revealing QR-decompositions [15, 2]. Thus, they can be checked numerically within the limitations of numerical rank decisions and nullspace computations in finite arithmetic.

For the disturbance decoupling problem, we need the following lemma.

LEMMA 2.4. *Consider a system of the form* (1). *If* (E, A) *is regular, then* $C(sE-A)^{-1}G = 0$ *if and only if*

$$\operatorname{rank}_g \begin{bmatrix} sE-A & G \\ C & 0 \end{bmatrix} = n.$$

Proof. The proof follows directly from the fact that for any $s \in \mathbf{C}$ with $\det(sE-A) \neq 0$ we have

$$\operatorname{rank}(C(sE-A)^{-1}G) = \operatorname{rank}\begin{bmatrix} sE-A & G \\ C & 0 \end{bmatrix} - \operatorname{rank}(sE-A). \qquad \square$$

We close this section with a technical lemma that we will use frequently in subsequent sections.

LEMMA 2.5. *Consider matrices* E, A, B *such that*

$$sE-A := \begin{matrix} \\ l_1 \\ l_2 \end{matrix}\begin{matrix} \begin{matrix} t \end{matrix} \\ \begin{bmatrix} sE_1-A_1 \\ -A_2 \end{bmatrix} \end{matrix}, \quad B := \begin{matrix} \\ l_1 \\ l_2 \end{matrix}\begin{matrix} \begin{matrix} r \end{matrix} \\ \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} \end{matrix}$$

with $l_1 \leq t$ *and* B_2 *of full row rank.*

(i) *If*

$$\operatorname{rank}_g \begin{bmatrix} sE_1-A_1 & B_1 \\ -A_2 & B_2 \end{bmatrix} = l_1 + l_2, \tag{8}$$

then there exist a matrix $F \in \mathbf{R}^{r\times t}$ *and a nonsingular matrix* $Z \in \mathbf{R}^{t\times t}$ *such that*

$$(sE-A-BF)Z = \begin{matrix} \\ l_1 \\ l_2 \end{matrix}\begin{matrix} \begin{matrix} l_1 & t-l_1 \end{matrix} \\ \begin{bmatrix} s\Theta_1-\Phi_1 & -\Phi_2 \\ 0 & 0 \end{bmatrix} \end{matrix} \tag{9}$$

with (Θ_1, Φ_1) *regular.*

(ii) *If* (8) *holds and furthermore*

$$\operatorname{rank}\begin{bmatrix} E_1 & A_1S_\infty(E_1) & B_1 \\ 0 & A_2S_\infty(E_1) & B_2 \end{bmatrix} = l_1 + l_2, \tag{10}$$

then there exist a matrix $F \in \mathbf{R}^{r\times t}$ *and a nonsingular matrix* $Z \in \mathbf{R}^{t\times t}$ *such that* $(sE - A - BF)Z$ *has partitioning* (9) *with* (Θ_1, Φ_1) *regular and of index at most one.*

Proof. Let $W \in \mathbf{R}^{t\times t}$ and $Q \in \mathbf{R}^{r\times r}$ be orthogonal matrices such that

$$(sE-A)W = \begin{matrix} \\ l_1 \\ l_2 \end{matrix}\begin{matrix} \begin{matrix} l_1 & t-l_1 \end{matrix} \\ \begin{bmatrix} sE_{11}-A_{11} & -A_{12} \\ -A_{21} & -A_{22} \end{bmatrix} \end{matrix}, \quad \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} Q = \begin{matrix} l_1 \\ l_2 \end{matrix}\begin{matrix} \begin{matrix} l_2 & r-l_2 \end{matrix} \\ \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & 0 \end{bmatrix} \end{matrix}$$

with B_{21} nonsingular (note that B_2 has full row rank).

(i) Condition (8) is equivalent to

$$\operatorname{rank}_g \begin{bmatrix} sE_{11}-A_{11} & A_{12} & B_{11} & B_{12} \\ -A_{21} & A_{22} & B_{21} & 0 \end{bmatrix} = l_1 + l_2.$$

Since B_{21} is nonsingular, using Schur complements, this is equivalent to

$$\operatorname{rank}_g \begin{bmatrix} sE_{11} - (A_{11} - B_{11}B_{21}^{-1}A_{21}) & A_{12} - B_{11}B_{21}^{-1}A_{22} & B_{12} \end{bmatrix} = l_1.$$

Then, applying Lemma 2.3(iii) immediately gives the existence of a regularizing feedback.

(ii) Analogously, (10) is equivalent to

$$\operatorname{rank}\begin{bmatrix} E_{11} & A_{11}S_\infty(E_{11}) & A_{12} & B_{11} & B_{12} \\ 0 & A_{21}S_\infty(E_{11}) & A_{22} & B_{21} & 0 \end{bmatrix} = l_1 + l_2,$$

which is equivalent to

$$\operatorname{rank}\begin{bmatrix} E_{11} & (A_{11} - B_{11}B_{21}^{-1}A_{21})S_\infty(E_{11}) & (A_{12} - B_{11}B_{21}^{-1}A_{22}) & B_{12} \end{bmatrix} = l_1.$$

Lemma 2.3(i) then gives the existence of a feedback that makes the system regular and of index at most one.

Actually the feedbacks in both cases can be constructed explicitly as follows. Let

$$Z := W\begin{bmatrix} I & 0 \\ \tilde{Z} & I \end{bmatrix}, \quad F := Q\begin{bmatrix} F_{11} & F_{12} \\ F_{21} & 0 \end{bmatrix} W^T,$$

where F_{11} and F_{12} are constructed from

$$B_{21}\begin{bmatrix} F_{11} & F_{12} \end{bmatrix} = -\begin{bmatrix} A_{21} & A_{22} \end{bmatrix} \tag{11}$$

and $\tilde{Z}$ and F_{21} are constructed via the algorithm given in the appendix of [5]. ∎

Remark 2.2. The construction of the feedback in the proof of Lemma 2.5 needs the solution of a linear system in (11). This system may be very ill-conditioned and hence a numerical solution of this system may create large errors. A different approach to constructing the desired feedback is the following.

Using a rank revealing QR-decomposition, construct an orthogonal matrix P such that

$$P \begin{bmatrix} B_{11} \\ B_{21} \end{bmatrix} =: \begin{bmatrix} 0 \\ \tilde{B}_{21} \end{bmatrix}$$

with $\tilde{B}_{21}$ nonsingular. Set, with compatible partitioning,

$$P \begin{bmatrix} sE_{11} - A_{11} & A_{12} \\ -A_{21} & A_{22} \end{bmatrix} =: \begin{bmatrix} s\tilde{E}_{11} - \tilde{A}_{11} & \tilde{A}_{12} \\ s\tilde{E}_{21} - \tilde{A}_{21} & \tilde{A}_{22} \end{bmatrix}, \quad P \begin{bmatrix} B_{12} \\ 0 \end{bmatrix} =: \begin{bmatrix} \tilde{B}_{12} \\ \tilde{B}_{22} \end{bmatrix}.$$

Then apply the algorithm in the appendix of [5] to compute $\tilde{Z}$ and F_{21} such that $(\tilde{E}_{11}, \tilde{A}_{11} + \tilde{A}_{12}X + \tilde{B}_{12}F_{21})$ is regular and of index at most one.

After having introduced the preliminaries, in the next sections we discuss the disturbance decoupling problem.

3. The disturbance decoupling problem. In this section, we first establish a condensed form for matrix quintuples (E, A, B, C, G) under orthogonal equivalence transformations and then solve the disturbance decoupling problem without the stability requirement.

The general philosophy is to generate an equivalent representation of the original system that displays the system properties and can be used to construct the desired feedbacks in the solution of the disturbance decoupling problem. The main feature of the new condensed form is that it is (in contrast to canonical forms that are used in previous work on this subject, like, e.g., [1]) based on orthogonal matrix transformations which can be implemented as numerically stable algorithms, thus guaranteeing robust computation of the desired quantities, if this is possible. The spaces that we will need for the solution are the following (with the notation introduced in section 2).

$$\Pi := T_\infty \left(\begin{bmatrix} B & G \\ 0 & 0 \end{bmatrix} \right), \quad \Psi := T_\infty(G), \quad \Lambda_r := V_{f-r} \left[\Pi^T \begin{bmatrix} E \\ 0 \end{bmatrix}, \Pi^T \begin{bmatrix} A \\ C \end{bmatrix} \right],$$

$$\Lambda_l := V_{f-l} \left[\Pi^T \begin{bmatrix} E \\ 0 \end{bmatrix}, \Pi^T \begin{bmatrix} A \\ C \end{bmatrix} \right], \quad \Lambda_t := \begin{bmatrix} \Pi^\perp & \Pi \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & \Lambda_l \end{bmatrix}. \tag{12}$$

With the abbreviations $\Gamma_1 := \left[\begin{smallmatrix} 0 & \Psi^T E \\ 0 & 0 \end{smallmatrix}\right]$ and $\Gamma_2 := \left[\begin{smallmatrix} \Psi^T B & \Psi^T A \\ 0 & 0 \end{smallmatrix}\right]$ we further introduce the spaces

$$\begin{aligned} &\Lambda_1 := \Lambda_t^T \begin{bmatrix} E \\ 0 \end{bmatrix} \Lambda_r, \quad \Lambda_2 := \Lambda_t^T \begin{bmatrix} A \\ C \end{bmatrix} \Lambda_r, \\ &\Lambda_3 := \Lambda_t^T \begin{bmatrix} B \\ 0 \end{bmatrix}, \quad \Lambda_4 := (V_{f-l}^\perp[\Gamma_1, \Gamma_2])^T \, \Gamma_1 V_{f-r}^\perp[\Gamma_1, \Gamma_2]. \end{aligned} \tag{13}$$

These spaces can be easily obtained from the following condensed form under orthogonal transformations.

THEOREM 3.1. *Consider a system of the form* (1) *with* $E, A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$, $G \in \mathbf{R}^{n\times p}$, $C \in \mathbf{R}^{q\times n}$. *Then there exist orthogonal matrices* $U, V \in \mathbf{R}^{n\times n}$ *such that*

$$UEV = \begin{array}{c} \\ p \\ \tilde{n}_2 \\ \tilde{n}_3 \\ \tilde{n}_4 \\ \tilde{n}_5 \end{array} \begin{array}{c} \begin{array}{ccc} n_1 & n_2 & n_3 \end{array} \\ \begin{bmatrix} E_{11} & E_{12} & E_{13} \\ E_{21} & E_{22} & E_{23} \\ 0 & E_{32} & E_{33} \\ 0 & E_{42} & E_{43} \\ 0 & 0 & E_{53} \end{bmatrix} \end{array}, \quad UAV = \begin{array}{c} \\ p \\ \tilde{n}_2 \\ \tilde{n}_3 \\ \tilde{n}_4 \\ \tilde{n}_5 \end{array} \begin{array}{c} \begin{array}{ccc} n_1 & n_2 & n_3 \end{array} \\ \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \\ 0 & A_{42} & A_{43} \\ 0 & 0 & A_{53} \end{bmatrix} \end{array},$$

$$UB = \begin{array}{c} \\ p \\ \tilde{n}_2 \\ \tilde{n}_3 \\ \tilde{n}_4 \\ \tilde{n}_5 \end{array} \begin{bmatrix} B_1 \\ B_2 \\ B_3 \\ 0 \\ 0 \end{bmatrix}, \quad UG = \begin{array}{c} \\ p \\ \tilde{n}_2 \\ \tilde{n}_3 \\ \tilde{n}_4 \\ \tilde{n}_5 \end{array} \begin{bmatrix} G_1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \quad CV = \begin{array}{c} \begin{array}{ccc} n_1 & n_2 & n_3 \end{array} \\ \begin{bmatrix} 0 & C_2 & C_3 \end{bmatrix} \end{array}, \tag{14}$$

where G_1, E_{21}, B_3, *and* E_{42} *are of full row rank and furthermore*

$$\operatorname{rank}(sE_{53} - A_{53}) = n_3, \quad \operatorname{rank} \begin{bmatrix} sE_{42} - A_{42} & sE_{43} - A_{43} \\ 0 & sE_{53} - A_{53} \\ C_2 & C_3 \end{bmatrix} = n_2 + n_3 \qquad \forall s \in \mathbf{C}.$$

Proof. The proof is given constructively via Algorithm 1 in Appendix A. ∎

Using condensed form (14) we can determine directly the following important spaces and their dimensions.

LEMMA 3.2. *Let* E, A, B, C, G *be in the condensed form* (14).

(i) *We have*

$$\begin{aligned} \tau &:= \dim\left(V_{f-l}\left[\begin{bmatrix} 0 & \Psi^T E \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} \Psi^T B & \Psi^T A \\ 0 & C \end{bmatrix}\right]\right) = \tilde{n}_2, \\ \mu &:= \dim\left(V_{f-r}^{\perp}\left[\begin{bmatrix} \Psi^T B & \Psi^T E \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & \Psi^T A \\ 0 & C \end{bmatrix}\right]\right) = n_2 + n_3, \\ \eta &:= \dim\left(V_{f-l}\left[\begin{bmatrix} \Psi^T B & \Psi^T E \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & \Psi^T A \\ 0 & C \end{bmatrix}\right]\right) - \tau = \tilde{n}_3. \end{aligned} \tag{15}$$

(ii) *Let* $S := S_\infty\left(\begin{bmatrix} E_{11} \\ E_{21} \end{bmatrix}\right)$; *then*

$$\operatorname{rank} \begin{bmatrix} E_{11} & A_{11}S & B_1 \\ E_{21} & A_{21}S & B_2 \\ 0 & A_{31}S & B_3 \end{bmatrix} = \operatorname{rank} \begin{bmatrix} \Lambda_1 & \Lambda_2 S_\infty(\Lambda_1) & \Lambda_3 \end{bmatrix}, \text{ with}$$

$$\operatorname{rank} \begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} = \operatorname{rank}(\Lambda_1), \quad \operatorname{rank} \begin{bmatrix} E_{32} & E_{33} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix} = \operatorname{rank}(\Lambda_4). \tag{16}$$

(iii) *The matrix*

$$T_\infty^T\left(\begin{bmatrix} E_{11} & B_1 \\ E_{21} & B_2 \\ 0 & B_3 \end{bmatrix}\right) \begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} S_\infty\left(T_\infty^T\left(\begin{bmatrix} B_1 \\ B_2 \\ B_3 \end{bmatrix}\right) \begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix}\right)$$

has full row rank if and only if $T_\infty^T(\begin{bmatrix} \Lambda_1 & \Lambda_3 \end{bmatrix})\Lambda_2 S_\infty(T_\infty^T(\Lambda_3)\Lambda_1)$ *is of full row rank.*

Proof. The proof is given in Appendix B. ∎

Based on the condensed form (14) and Lemma 2.3 we obtain the following necessary conditions for the existence of feedbacks that make the system regular and of index at most one.

LEMMA 3.3. *Given system* (1) *in condensed form* (14)*, we have the following.*

(i) *If there exists a feedback* $F \in \mathbf{R}^{m\times n}$ *such that* $(E, A+BF)$ *is regular and of index at most one, i.e., if condition* (5) *holds, then* $\tilde{n}_5 = n_3$, $E_{53} = 0$, A_{53} *is nonsingular, and furthermore,*

$$\operatorname{rank}\begin{bmatrix} E_{32} \\ E_{42} \end{bmatrix} = \operatorname{rank}\begin{bmatrix} E_{32} & E_{33} \\ E_{42} & E_{43} \end{bmatrix}. \tag{17}$$

(ii) *If there exist* $F, K \in \mathbf{R}^{m\times n}$ *such that* $(E+BK, A+BF)$ *is regular and of index at most one, i.e., if condition* (6) *holds, then* $\tilde{n}_5 = n_3$, $E_{53} = 0$, A_{53} *is nonsingular and*

$$\operatorname{rank}\begin{bmatrix} E_{11} & E_{12} & E_{13} & B_1 \\ E_{21} & E_{22} & E_{23} & B_2 \\ 0 & E_{32} & E_{33} & B_3 \\ 0 & E_{42} & E_{43} & 0 \end{bmatrix} = \operatorname{rank}\begin{bmatrix} E_{11} & E_{12} & B_1 \\ E_{21} & E_{22} & B_2 \\ 0 & E_{32} & B_3 \\ 0 & E_{42} & 0 \end{bmatrix}. \tag{18}$$

Proof. Let the system be given in the condensed form (14).

(i) If there exists $F := \begin{bmatrix} F_1 & F_2 & F_3 \end{bmatrix}$, partitioned conformly to (14), such that $(E, A+BF)$ is regular and of index at most one, then the last block row in (14), which cannot be modified by proportional feedback, must satisfy $\operatorname{rank}_g(sE_{53} - A_{53}) = \tilde{n}_5$. But $sE_{53} - A_{53}$ is of full column rank for any $s \in C$ and thus $n_3 = \tilde{n}_5$ and $\det(sE_{53} - A_{53}) = \det(-A_{53})$. Therefore, the nonsingularity of A_{53} follows directly from the regularity of $(E, A+BF)$. Moreover,

$$\begin{aligned}
\operatorname{rank}(E) &= \deg(\det(sE - A - BF)) \\
&= \deg\left(\det\left(\begin{bmatrix} sE_{11} - A_{11} - B_1F_1 & sE_{12} - A_{12} - B_1F_2 \\ sE_{21} - A_{21} - B_2F_1 & sE_{22} - A_{22} - B_2F_2 \\ -A_{31} - B_3F_1 & sE_{32} - A_{32} - B_3F_2 \\ 0 & sE_{42} - A_{42} \end{bmatrix}\right)\right) \\
&\quad + \deg(\det(sE_{53} - A_{53})) \\
&= \deg\left(\det\left(\begin{bmatrix} sE_{11} - A_{11} - B_1F_1 & sE_{12} - A_{12} - B_1F_2 \\ sE_{21} - A_{21} - B_2F_1 & sE_{22} - A_{22} - B_2F_2 \\ -A_{31} - B_3F_1 & sE_{32} - A_{32} - B_3F_2 \\ 0 & sE_{42} - A_{42} \end{bmatrix}\right)\right) \\
&\leq \operatorname{rank}\left(\begin{bmatrix} E_{11} & E_{12} \\ E_{21} & E_{22} \\ 0 & E_{32} \\ 0 & E_{42} \end{bmatrix}\right).
\end{aligned}$$

But, we have

$$\operatorname{rank}(E) \geq \operatorname{rank}\left(\begin{bmatrix} E_{11} & E_{12} \\ E_{21} & E_{22} \\ 0 & E_{32} \\ 0 & E_{42} \end{bmatrix}\right) + \operatorname{rank}(E_{53}),$$

and hence $E_{53} = 0$. We also have

$$\operatorname{rank}\begin{bmatrix} E_{11} & E_{12} & E_{13} \\ E_{21} & E_{22} & E_{23} \\ 0 & E_{32} & E_{33} \\ 0 & E_{42} & E_{43} \end{bmatrix} = \operatorname{rank}(E) = \operatorname{rank}\begin{bmatrix} E_{11} & E_{12} \\ E_{21} & E_{22} \\ 0 & E_{32} \\ 0 & E_{42} \end{bmatrix},$$

which implies (17).

(ii) If there exist $F := \begin{bmatrix} F_1 & F_2 & F_3 \end{bmatrix}$ and $K := \begin{bmatrix} K_1 & K_2 & K_3 \end{bmatrix}$ such that $(E + BK, A + BF)$ is regular and of index at most one, then, since E_{53}, A_{53} are not affected by these feedbacks, it follows from part (i) that $\tilde{n}_5 = n_3$, $E_{53} = 0$, and A_{53} is nonsingular. Similarly to part (i), we get that

$$\operatorname{rank}(E + BK) = \operatorname{rank}\left(\begin{bmatrix} E_{11} + B_1K_1 & E_{12} + B_1K_2 \\ E_{21} + B_2K_1 & E_{22} + B_2K_2 \\ B_3K_1 & E_{32} + B_3K_2 \\ 0 & E_{42} \end{bmatrix}\right).$$

However, since $E_{53} = 0$, we also have

$$\operatorname{rank}(E + BK) = \operatorname{rank}\left(\begin{bmatrix} E_{11} + B_1K_1 & E_{12} + B_1K_2 & E_{13} + B_1K_3 \\ E_{21} + B_2K_1 & E_{22} + B_2K_2 & E_{23} + B_2K_3 \\ B_3K_1 & E_{32} + B_3K_2 & E_{33} + B_3K_3 \\ 0 & E_{42} & E_{43} \end{bmatrix}\right),$$

and hence

$$\begin{aligned} &\operatorname{rank}\left(\begin{bmatrix} E_{11} + B_1K_1 & E_{12} + B_1K_2 & E_{13} + B_1K_3 \\ E_{21} + B_2K_1 & E_{22} + B_2K_2 & E_{23} + B_2K_3 \\ B_3K_1 & E_{32} + B_3K_2 & E_{33} + B_3K_3 \\ 0 & E_{42} & E_{43} \end{bmatrix}\right) \\ &= \operatorname{rank}\left(\begin{bmatrix} E_{11} + B_1K_1 & E_{12} + B_1K_2 \\ E_{21} + B_2K_1 & E_{22} + B_2K_2 \\ B_3K_1 & E_{32} + B_3K_2 \\ 0 & E_{42} \end{bmatrix}\right), \end{aligned}$$

which implies (18). □

We will now apply these results to solve the disturbance decoupling problem.

We present the results in a coordinate free way, but note that all the quantities are available via numerically stable procedures from the results presented before.

THEOREM 3.4. *Consider a system of the form* (1) *and let the spaces* Λ_i *be as in* (13) *and* τ, η, *and* μ *as in* (15).

(a) *There exists a feedback matrix* $F \in \mathbf{R}^{m\times n}$ *such that the pencil* $(E, A + BF)$ *is regular, of index at most one, and* $C(sE - (A + BF))^{-1}G = 0$ *if and only if condition* (5) *and furthermore the following three conditions hold:*

$$\tau + \mu \le n - p; \tag{19}$$

$$\operatorname{rank}(\Lambda_1) + \operatorname{rank}(\Lambda_4) = \operatorname{rank}(E); \tag{20}$$

$$\operatorname{rank}\begin{bmatrix} \Lambda_1 & \Lambda_2 S_\infty(\Lambda_1) & \Lambda_3 \end{bmatrix} = p + \tau + \eta. \tag{21}$$

(b) *There exist feedback matrices* $F, K \in \mathbf{R}^{m\times n}$*, such that the pencil* $(E+BK, A+BF)$ *is regular of index at most one and* $C(s(E+BK)-(A+BF))^{-1}G = 0$ *if and only if condition* (6) *holds,*

$$\text{(22)}\quad \operatorname{rank}_g \begin{bmatrix} T_\infty^T(G)(sE-A) & T_\infty^T(G)B \\ C & 0 \end{bmatrix} - \operatorname{rank} \begin{bmatrix} T_\infty^T(G)B \\ 0 \end{bmatrix} \le n-p,$$

and $W_1 := T_\infty^T(\begin{bmatrix} \Lambda_1 & \Lambda_3 \end{bmatrix})\Lambda_2 S_\infty(T_\infty^T(\Lambda_3)\Lambda_1)$ *has full row rank.*

Proof. By Theorem 3.1 there exist orthogonal matrices that transform the system to the form (14). Thus, for the proof we may assume, w.l.o.g., that the system is already in form (14).

(a) *Necessity.* Let $F \in \mathbf{R}^{m\times n}$ be such that $(E, A+BF)$ is regular, of index at most one, and $C(sE-(A+BF))^{-1}G = 0$. Partition $F =: \begin{bmatrix} F_1 & F_2 & F_3 \end{bmatrix}$ compatibly with (E, A, B). Then (5) follows directly from Lemma 2.3(ii). Furthermore, by Lemma 2.4 we have that $\operatorname{rank}_g \begin{bmatrix} sE_{21}-A_{21}-B_2F_1 \\ -A_{32}-B_3F_1 \end{bmatrix} = n-p-n_2-n_3$. Hence, we obtain

$$n-p-n_2-n_3 \ge \operatorname{rank}_g \begin{bmatrix} sE_{21}-A_{21}-B_2F_1 \end{bmatrix} \ge \operatorname{rank}(E_{21}) = \tilde{n}_2,$$

i.e., by (15), condition (19) holds.

To prove conditions (20)–(21), observe from Lemma 3.3, and since $(E, A+BF)$ is regular and of index at most one, we have

$$\begin{aligned} \operatorname{rank}(E) &= \deg(\det(sE-A-BF)) = \deg(\det(sE_{53}-A_{53})) \\ &\quad + \deg\left(\det\begin{bmatrix} sE_{11}-A_{11}-B_1F_1 & sE_{12}-A_{12}-B_1F_2 \\ sE_{21}-A_{21}-B_2F_1 & sE_{22}-A_{22}-B_2F_2 \\ -A_{31}-B_3F_1 & sE_{32}-A_{32}-B_3F_3 \\ 0 & sE_{42}-A_{42} \end{bmatrix}\right) \\ &= \deg\left(\det\begin{bmatrix} sE_{11}-A_{11}-B_1F_1 & sE_{12}-A_{12}-B_1F_2 \\ sE_{21}-A_{21}-B_2F_1 & sE_{22}-A_{22}-B_2F_2 \\ -A_{31}-B_3F_1 & sE_{32}-A_{32}-B_3F_3 \\ 0 & sE_{42}-A_{42} \end{bmatrix}\right). \end{aligned} \tag{23}$$

Hence, from (23) it follows that

$$\begin{aligned} \operatorname{rank}(E) &= \operatorname{rank}\begin{bmatrix} E_{11} & E_{12} \\ E_{21} & E_{22} \\ 0 & E_{32} \\ 0 & E_{42} \end{bmatrix} \\ &= \deg\left(\det\begin{bmatrix} sE_{11}-A_{11}-B_1F_1 & sE_{12}-A_{12}-B_1F_2 \\ sE_{21}-A_{21}-B_2F_1 & sE_{22}-A_{22}-B_2F_2 \\ -A_{31}-B_3F_1 & sE_{32}-A_{32}-B_3F_2 \\ 0 & sE_{42}-A_{42} \end{bmatrix}\right). \end{aligned} \tag{24}$$

Using that E_{21}, E_{42} are of full row rank, we may assume, w.l.o.g. (by performing appropriate equivalence transformations), that

$$E_{11} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \Sigma_{11} & 0 \end{bmatrix}, \quad E_{21} = \begin{bmatrix} \Sigma_{21} & 0 & 0 \end{bmatrix}, \quad E_{32} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \Theta_{32} & 0 \end{bmatrix},$$
$$E_{42} = \begin{bmatrix} 0 & 0 & \Sigma_{42} \end{bmatrix}, \quad E_{12} = \begin{bmatrix} \tilde{E}_{12} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad E_{22} = 0,$$

where $\Sigma_{11} \in \mathbf{R}^{p_1\times p_1}, \Sigma_{21} \in \mathbf{R}^{\tilde{n}_2\times\tilde{n}_2}, \Sigma_{42} \in \mathbf{R}^{\tilde{n}_4\times\tilde{n}_4}$ are nonsingular and $\Theta_{32} \in \mathbf{R}^{(n_2-\tilde{n}_4)\times t}$ is of full column rank. Partition accordingly, $A_{42} = \begin{bmatrix} \Phi_{64} & \Phi_{65} & \Phi_{66} \end{bmatrix}$, and

$$A_{11}+B_1F_1 = \begin{bmatrix} \Phi_{11} & \Phi_{12} & \Phi_{13} \\ \Phi_{21} & \Phi_{22} & \Phi_{23} \end{bmatrix}, \quad A_{12}+B_1F_2 = \begin{bmatrix} \Phi_{14} & \Phi_{15} & \Phi_{16} \\ \Phi_{24} & \Phi_{25} & \Phi_{26} \end{bmatrix},$$
$$A_{21}+B_2F_1 = \begin{bmatrix} \Phi_{31} & \Phi_{32} & \Phi_{33} \end{bmatrix}, \quad A_{22}+B_2F_2 = \begin{bmatrix} \Phi_{34} & \Phi_{35} & \Phi_{36} \end{bmatrix},$$
$$A_{31}+B_3F_1 = \begin{bmatrix} \Phi_{41} & \Phi_{42} & \Phi_{43} \\ \Phi_{51} & \Phi_{52} & \Phi_{53} \end{bmatrix}, \quad A_{32}+B_3F_2 = \begin{bmatrix} \Phi_{44} & \Phi_{45} & \Phi_{46} \\ \Phi_{54} & \Phi_{55} & \Phi_{56} \end{bmatrix}.$$

Then (24) yields that

$$\begin{bmatrix} T_\infty^T(\tilde{E}_{12})\Phi_{13} & T_\infty^T(\tilde{E}_{12})\Phi_{14}S_\infty(\tilde{E}_{12}) \\ \Phi_{43} & \Phi_{44}S_\infty(\tilde{E}_{12}) \\ T_\infty^T(\Theta_{32})\Phi_{53} & T_\infty^T(\Theta_{32})\Phi_{54}S_\infty(\tilde{E}_{12}) \end{bmatrix}$$

is nonsingular.
Hence, we obtain that

$$\operatorname{rank}\begin{bmatrix} T_\infty^T(\tilde{E}_{12})\Phi_{13} \\ \Phi_{43} \\ T_\infty^T(\Theta_{32})\Phi_{53} \end{bmatrix} = n_1 - p_1 - \tilde{n}_2. \tag{25}$$

But, from Lemma 2.4 we have

$$\operatorname{rank}_g \begin{bmatrix} s\Sigma_{21}-\Phi_{31} & -\Phi_{32} & -\Phi_{33} \\ -\Phi_{41} & -\Phi_{42} & -\Phi_{43} \\ -\Phi_{51} & -\Phi_{52} & -\Phi_{53} \end{bmatrix} = n-p-n_2-n_3 = n_1-p,$$

and hence

$$\operatorname{rank}\begin{bmatrix} \Phi_{43} \\ T_\infty^T(\Theta_{32})\Phi_{53} \end{bmatrix} \le \operatorname{rank}\begin{bmatrix} \Phi_{43} \\ \Phi_{53} \end{bmatrix} \le n_1-p-\tilde{n}_2. \tag{26}$$

Thus, by (25), we have

$$\operatorname{rank}(T_\infty^T(\tilde{E}_{12})\Phi_{13}) \ge p-p_1, \tag{27}$$

where $p-p_1$ is the number of rows of Φ_{13}. This implies that $\tilde{E}_{12}=0$, and hence (24) implies that

$$\operatorname{rank}(E) = \operatorname{rank}\begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} + \operatorname{rank}\begin{bmatrix} E_{32} \\ E_{42} \end{bmatrix},$$

and thus, Lemma 3.3(i) yields that

$$\operatorname{rank}(E) = \operatorname{rank}\begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} + \operatorname{rank}\begin{bmatrix} E_{32} & E_{33} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix}.$$

Then, Lemma 3.2(ii) gives (20). Furthermore, using (26) and (27) we have that

$$\operatorname{rank}(\Phi_{13}) = p-p_1, \qquad \operatorname{rank}\begin{bmatrix} \Phi_{43} \\ \Phi_{53} \end{bmatrix} = \operatorname{rank}\begin{bmatrix} \Phi_{43} \\ T_\infty^T(\Theta_{32})\Phi_{53} \end{bmatrix} = n_1-p-\tilde{n}_2,$$

and thus with $S := S_\infty([\begin{smallmatrix} E_{11} \\ E_{21} \end{smallmatrix}])$, we obtain

$$\operatorname{rank} \begin{bmatrix} E_{11} & A_{11}S & B_1 \\ E_{21} & A_{21}S & B_2 \\ 0 & A_{31}S & B_3 \end{bmatrix} = p + \tilde{n}_2 + \tilde{n}_3. \tag{28}$$

Then (21) follows directly from Lemma 3.2(ii).

Sufficiency. Using conditions (19) and (21) and Lemmas 2.3(ii) and (2.5)(ii), there exist $\tilde{F}_1 \in \mathbf{R}^{m\times n_1}$ and a nonsingular matrix $Z \in \mathbf{R}^{n_1\times n_1}$ such that

$$\begin{bmatrix} sE_{11} - A_{11} - B_1\tilde{F}_1 \\ sE_{21} - A_{21} - B_2\tilde{F}_1 \\ -A_{31} - B_3\tilde{F}_1 \end{bmatrix} Z$$

$$= \begin{array}{c} \\ p \\ \tilde{n}_2 \\ \tilde{n}_3 \end{array} \begin{array}{c} \begin{array}{cc} p+\tilde{n}_2 & n_1-p-\tilde{n}_2 \end{array} \\ \begin{bmatrix} s\Theta_{11} - \Phi_{11} & -\Phi_{12} \\ s\Theta_{21} - \Phi_{21} & -\Phi_{22} \\ 0 & 0 \end{bmatrix} \end{array}$$

with $([\begin{smallmatrix} \Theta_{11} \\ \Theta_{21} \end{smallmatrix}], [\begin{smallmatrix} \Phi_{11} \\ \Phi_{21} \end{smallmatrix}])$ regular and of index at most one.

By (5) and (20) and Lemma 3.3 it follows that $\tilde{n}_5 = n_3$, $E_{53} = 0$, A_{53} is nonsingular, and furthermore,

$$\operatorname{rank}(E) = \operatorname{rank} \begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} + \operatorname{rank} \begin{bmatrix} E_{32} \\ E_{42} \end{bmatrix}. \tag{29}$$

Note that B_3 and E_{42} are of full row rank, so by Lemma 2.3(ii) there exist matrices $\hat{F}_1 \in \mathbf{R}^{m\times(n_1-p-\tilde{n}_2)}$ and $F_2 \in \mathbf{R}^{m\times n_2}$ such that

$$\left(\begin{bmatrix} 0 & E_{32} \\ 0 & E_{42} \end{bmatrix}, \begin{bmatrix} B_3\hat{F}_1 & A_{32} + B_3F_2 \\ 0 & A_{42} \end{bmatrix} \right)$$

is regular and of index at most one. Taking $F_1 := \tilde{F}_1 + \begin{bmatrix} 0 & \hat{F}_1 \end{bmatrix} Z^{-1}$, $F := \begin{bmatrix} F_1 & F_2 & F_3 \end{bmatrix}$ with F_3 arbitrary, it is easy to see that $(E, A + BF)$ is regular, of index at most one, and $C(sE - A - BF)^{-1}G = 0$.

(b) *Necessity.* Let $F, K \in \mathbf{R}^{m\times n}$ be such that $(E + BK, A + BF)$ is regular, of index at most one, and $C(s(E+BK)-(A+BF))^{-1}G = 0$. Then condition (6) follows directly from Lemma 2.3(iii). As in (a), by Lemma 2.4 we have that

$$\operatorname{rank}_g \begin{bmatrix} s(E_{21} + B_2K_1) - (A_{21} + B_2F_1) \\ sB_3K_1 - (A_{31} + B_3F_1) \end{bmatrix} = n - p - n_2 - n_3,$$

which implies that

$$\begin{aligned} &\operatorname{rank}_g \begin{bmatrix} sE_{21} - A_{21} & B_2 \\ -A_{31} & B_3 \end{bmatrix} - \operatorname{rank} \begin{bmatrix} B_2 \\ B_3 \end{bmatrix} \\ &= \operatorname{rank}_g \begin{bmatrix} s(E_{21} + B_2K_1) - (A_{21} + B_2F_1) & B_2 \\ sB_3K_1 - (A_{31} + B_3F_1) & B_3 \end{bmatrix} - \operatorname{rank} \begin{bmatrix} B_2 \\ B_3 \end{bmatrix} \\ &\le \operatorname{rank}_g \begin{bmatrix} s(E_{21} + B_2K_1) - (A_{21} + B_2F_1) \\ sB_3K_1 - (A_{31} + B_3F_1) \end{bmatrix} = n - p - n_2 - n_3. \end{aligned}$$

Thus,

$$n-p \geq n_2+n_3+\operatorname{rank}_g \begin{bmatrix} sE_{21}-A_{21} & B_2 \\ -A_{31} & B_3 \end{bmatrix} - \operatorname{rank} \begin{bmatrix} B_2 \\ B_3 \end{bmatrix}$$
$$= \operatorname{rank}_g \begin{bmatrix} T_\infty^T(G)(sE-A) & T_\infty^T(G)B \\ C & 0 \end{bmatrix} - \operatorname{rank} \begin{bmatrix} T_\infty^T(G)B \\ 0 \end{bmatrix},$$

i.e., (22) holds.

Since $\left[\begin{smallmatrix} E_{21}+B_2K_1 & B_2 \\ B_3K_1 & B_3 \end{smallmatrix}\right]$ is of full row rank, from (28) we have that

$$\begin{bmatrix} E_{11}+B_1K_1 & (A_{11}+B_1F_1)\tilde{S} & B_1 \\ E_{21}+B_2K_1 & (A_{21}+B_2F_1)\tilde{S} & B_2 \\ B_3K_1 & (A_{31}+B_3F_1)\tilde{S} & B_3 \end{bmatrix}$$

is of full row rank, where

$$\tilde{S} := S_\infty \left(\begin{bmatrix} E_{11}+B_1K_1 \\ E_{21}+B_2K_1 \\ B_3K_1 \end{bmatrix} \right).$$

Equivalently, we obtain that

$$\begin{bmatrix} E_{11} & A_{11}\tilde{S}_\infty & B_1 \\ E_{21} & A_{21}\tilde{S}_\infty & B_2 \\ 0 & A_{31}\tilde{S}_\infty & B_3 \end{bmatrix}$$

is of full row rank. Thus, using the relation between

$$S_\infty \left(T_\infty^T \left(\begin{bmatrix} B_1 \\ B_2 \\ B_3 \end{bmatrix} \right) \begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} \right)$$

and $\tilde{S}_\infty$, we have that

$$T_\infty^T \left(\begin{bmatrix} E_{11} & B_1 \\ E_{21} & B_2 \\ 0 & B_3 \end{bmatrix} \right) \begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} S_\infty \left(T_\infty^T \left(\begin{bmatrix} B_1 \\ B_2 \\ B_3 \end{bmatrix} \right) \begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} \right)$$

is of full row rank and using Lemma 3.2(iii) so is W_1.

Sufficiency. Since E_{21}, B_3 are of full row rank, using Lemma 2.1, we can determine orthogonal matrices $P_1 \in \mathbf{R}^{p\times p}$, $P_2 \in \mathbf{R}^{(\tilde{n}_2+\tilde{n}_3)\times(\tilde{n}_2+\tilde{n}_3)}$, and $W \in \mathbf{R}^{m\times m}$ such that

$$\begin{bmatrix} P_1 & \\ & P_2 \end{bmatrix} \begin{bmatrix} sE_{11}-A_{11} & sE_{12}-A_{12} & sE_{13}-A_{13} \\ sE_{21}-A_{21} & sE_{22}-A_{22} & sE_{23}-A_{23} \\ -A_{31} & sE_{32}-A_{32} & sE_{33}-A_{33} \end{bmatrix}$$
$$= \begin{array}{c} \\ l_1 \\ p-l_1 \\ l_2 \\ \tilde{n}_2+\tilde{n}_3-l_2 \end{array} \begin{array}{c} \begin{array}{ccc} n_1 & n_2 & n_3 \end{array} \\ \begin{bmatrix} s\Theta_{11}-\Phi_{11} & s\Theta_{12}-\Phi_{12} & s\Theta_{13}-\Phi_{13} \\ s\Theta_{21}-\Phi_{21} & s\Theta_{22}-\Phi_{12} & s\Theta_{23}-\Phi_{13} \\ s\Theta_{31}-\Phi_{21} & s\Theta_{32}-\Phi_{32} & s\Theta_{33}-\Phi_{33} \\ s\Theta_{41}-\Phi_{41} & s\Theta_{42}-\Theta_{42} & s\Theta_{43}-\Phi_{43} \end{bmatrix} \end{array},$$

$$\begin{bmatrix} P_1 & \\ & P_2 \end{bmatrix} \begin{bmatrix} B_1 \\ B_2 \\ B_3 \end{bmatrix} W = \begin{array}{c} \\ l_1 \\ p-l_1 \\ l_2 \\ \tilde{n}_2+\tilde{n}_3-l_2 \end{array} \begin{bmatrix} \tilde{B}_{11} & 0 \\ \tilde{B}_{21} & \tilde{B}_{22} \\ 0 & 0 \\ \tilde{B}_{41} & 0 \end{bmatrix}$$

with $\tilde{B}_{22}, \Theta_{31}$ of full row rank and $\tilde{B}_{41}$ nonsingular. Now determine K_{11}, K_{21} from

$$\begin{bmatrix} \tilde{B}_{21} & \tilde{B}_{22} \\ \tilde{B}_{41} & 0 \end{bmatrix} W \begin{bmatrix} K_{11} \\ K_{21} \end{bmatrix} = - \begin{bmatrix} \Theta_{21} \\ \Theta_{41} \end{bmatrix}.$$

The last two conditions imply that $p + l_2 \le n_1$ and

$$\operatorname{rank} \begin{bmatrix} \Theta_{11} + \tilde{B}_{11}K_{11} & \Phi_{11}\tilde{S} & \tilde{B}_{11} & 0 \\ 0 & \Phi_{21}\tilde{S} & \tilde{B}_{21} & \tilde{B}_{22} \\ \Theta_{31} & \Phi_{31}\tilde{S} & 0 & 0 \\ 0 & \Phi_{41}\tilde{S} & \tilde{B}_{41} & 0 \end{bmatrix} = p + \tilde{n}_2 + \tilde{n}_3,$$

where $\tilde{S} = S_\infty([\begin{smallmatrix} \Theta_{11}+\tilde{B}_{11}K_{11} \\ \Theta_{31} \end{smallmatrix}])$. By Lemma 2.5 there exist F_{11}, F_{21}, and a nonsingular matrix Z satisfying

$$\begin{bmatrix} s(\Theta_{11} + \tilde{B}_{11}K_{11}) - \Phi_{11} - \tilde{B}_{11}F_{11} \\ -\Phi_{21} - \tilde{B}_{21}F_{11} - \tilde{B}_{22}F_{21} \\ s\Theta_{31} \\ -\Phi_{41} - \tilde{B}_{41}F_{11} \end{bmatrix} Z$$

$$= \begin{array}{c} \\ l_1 \\ p - l_1 \\ l_2 \\ \tilde{n}_2 + \tilde{n}_3 - l_2 \end{array} \begin{array}{c} \begin{array}{cc} p + l_2 & n_1 - p - l_2 \end{array} \\ \begin{bmatrix} s\tilde{\Theta}_{11} - \tilde{\Phi}_{11} & -\tilde{\Phi}_{12} \\ -\tilde{\Phi}_{21} & -\tilde{\Phi}_{22} \\ s\tilde{\Theta}_{31} - \tilde{\Phi}_{31} & -\tilde{\Phi}_{32} \\ 0 & 0 \end{bmatrix} \end{array}$$

with

$$\left(\begin{bmatrix} \tilde{\Theta}_{11} \\ 0 \\ \tilde{\Theta}_{31} \end{bmatrix}, \begin{bmatrix} \tilde{\Phi}_{11} \\ \tilde{\Phi}_{21} \\ \tilde{\Phi}_{31} \end{bmatrix} \right)$$

regular and of index at most one. Using condition (6) and Lemma 3.3(ii), we obtain that $\tilde{n}_5 = n_3$. Hence, we can determine $\hat{K}_{11}, \hat{K}_{21}, K_{12}, K_{22}$ such that

$$\begin{bmatrix} \tilde{B}_{21} & \tilde{B}_{22} \end{bmatrix} \begin{bmatrix} \hat{K}_{11} & K_{12} \\ \hat{K}_{21} & K_{22} \end{bmatrix} = - \begin{bmatrix} 0 & \Theta_{22} \end{bmatrix},$$

and $\begin{bmatrix} \tilde{B}_{41}\hat{K}_{11} & \Theta_{42} + \tilde{B}_{41}K_{12} \\ 0 & E_{42} \end{bmatrix}$ is nonsingular. Let

$$K_1 := \begin{bmatrix} K_{11} \\ K_{21} \end{bmatrix} + \begin{bmatrix} 0 & \hat{K}_{11} \\ 0 & \hat{K}_{21} \end{bmatrix} Z^{-1}, \quad K_2 := \begin{bmatrix} K_{12} \\ K_{22} \end{bmatrix}, \quad K_3 := \begin{bmatrix} K_{13} \\ K_{23} \end{bmatrix},$$

and

$$F_1 := \begin{bmatrix} F_{11} \\ F_{21} \end{bmatrix},$$

where K_{13}, K_{23} will be determined later, and set $K := W \begin{bmatrix} K_1 & K_2 & K_3 \end{bmatrix}$ and $F := W \begin{bmatrix} F_1 & 0 & 0 \end{bmatrix}$. Then we have

$$\begin{bmatrix} P_1 & & \\ & P_2 & \\ & & I \end{bmatrix} (s(E+BK)-(A+BF)) \begin{bmatrix} Z & & \\ & I & \end{bmatrix}$$

$$= \begin{bmatrix} s\tilde{\Theta}_{11}-\tilde{\Phi}_{11} & s\tilde{B}_{11}\hat{K}_{11}-\tilde{\Phi}_{12} & s(\Theta_{12}+\tilde{B}_{11}K_{12})-\Phi_{12} & s(\Theta_{13}+\tilde{B}_{11}K_{13})-\Phi_{13} \\ -\tilde{\Phi}_{21} & -\tilde{\Phi}_{12} & -\Phi_{22} & s(\Theta_{23}+\tilde{B}_{21}K_{13}+\tilde{B}_{22}K_{23})-\Phi_{23} \\ s\tilde{\Theta}_{31}-\tilde{\Phi}_{31} & -\tilde{\Phi}_{32} & s\Theta_{32}-\Phi_{32} & s\Theta_{33}-\Phi_{33} \\ 0 & s(\tilde{B}_{41}\hat{K}_{11}) & s(\Theta_{42}+\tilde{B}_{41}K_{12})-\Phi_{42} & s(\Theta_{43}+\tilde{B}_{41}K_{13})-\Phi_{43} \\ 0 & 0 & sE_{42}-A_{42} & sE_{43}-A_{43} \\ 0 & 0 & 0 & sE_{53}-A_{53} \end{bmatrix}.$$

By (18), and since $\begin{bmatrix} \tilde{B}_{41}\hat{K}_{11} & \Theta_{42}+\tilde{B}_{41}K_{12} \\ 0 & E_{42} \end{bmatrix}$ is nonsingular, we have that

$$\operatorname{rank} \begin{bmatrix} \tilde{\Theta}_{11} & \Theta_{12} & \Theta_{13} & \tilde{B}_{11} \\ \tilde{\Theta}_{31} & \Theta_{32} & \Theta_{33} & 0 \\ 0 & \Theta_{42} & \Theta_{43} & \tilde{B}_{41} \\ 0 & E_{42} & E_{43} & 0 \end{bmatrix} = \operatorname{rank} \begin{bmatrix} \tilde{\Theta}_{11} & \Theta_{12} & \tilde{B}_{11} \\ \tilde{\Theta}_{31} & \Theta_{32} & 0 \\ 0 & \Theta_{42} & \tilde{B}_{41} \\ 0 & E_{42} & 0 \end{bmatrix}.$$

Therefore, there exists K_{13} such that

$$\operatorname{rank} \begin{bmatrix} \tilde{\Theta}_{11} & \Theta_{12}+\tilde{B}_{11}K_{12} & \Theta_{13}+\tilde{B}_{11}K_{13} \\ \tilde{\Theta}_{31} & \Theta_{32} & \Theta_{33} \\ 0 & \Theta_{42}+\tilde{B}_{41}K_{12} & \Theta_{43}+\tilde{B}_{41}K_{13} \\ 0 & E_{42} & E_{43} \end{bmatrix} = \operatorname{rank} \begin{bmatrix} \tilde{\Theta}_{11} & \Theta_{12}+\tilde{B}_{11}K_{12} \\ \tilde{\Theta}_{31} & \Theta_{32} \\ 0 & \Theta_{42}+\tilde{B}_{41}K_{12} \\ 0 & E_{42} \end{bmatrix}.$$

Finally, we determine K_{23} from

$$\tilde{B}_{22}K_{23} = -(\Theta_{23}+\tilde{B}_{21}K_{13}).$$

We have from Lemma 3.3 that $E_{53}=0$ and that A_{53} is nonsingular. Thus, for F, K determined by the described procedure, $(E+BK, A+BF)$ is regular and of index at most one. It is also easy to see that $C(s(E+BK)-(A+BF))^{-1}G = 0$. □

Remark 3.1. If the index one condition is not required, then in case (a) necessary and sufficient conditions are given by (4), (19), and

$$\operatorname{rank}_g \begin{bmatrix} sE-A & B \\ C & 0 \end{bmatrix} = \operatorname{rank}_g \begin{bmatrix} sE-A & B & G \\ C & 0 & 0 \end{bmatrix} \tag{30}$$

and in case (b) by (4), (22), and (30). The proof of the necessary and sufficient conditions and the construction of feedbacks that regularize the system without achieving index at most one are discussed in detail in [9].

Remark 3.2. The previous results can also be modified to the case when only derivative feedback is used. Since the results are essentially dual results to the ones for state feedback by exchanging the roles of E and A, we omit them. Details are given in the reports [9, 10].

4. The disturbance decoupling problem with stability. In this section we study the case where the extra requirement that the closed-loop system be stable is added. Similarly to section 3, first we prove a condensed form for matrix quintuples (E, A, B, C, G) under orthogonal equivalence transformations and determine different left and right reducing subspaces that are needed for the solution of the disturbance decoupling problem with stability.

THEOREM 4.1. *Given a system of the form* (1)*, there exist orthogonal matrices* $U, V \in \mathbf{R}^{n\times n}$ *such that*

$$U(sE-A)V = \begin{array}{c} \\ \tilde{n}_1 \\ \tilde{n}_2 \\ \tilde{n}_3 \\ \tilde{n}_4 \\ \tilde{n}_5 \\ \tilde{n}_6 \end{array} \begin{array}{c} \begin{array}{cccc} n_1 & n_2 & n_3 & n_4 \end{array} \\ \begin{bmatrix} sE_{11}-A_{11} & sE_{12}-A_{12} & sE_{13}-A_{13} & sE_{14}-A_{14} \\ -A_{21} & sE_{22}-A_{22} & sE_{23}-A_{23} & sE_{24}-A_{24} \\ -A_{31} & sE_{32}-A_{32} & sE_{33}-A_{33} & sE_{34}-A_{34} \\ 0 & sE_{42}-A_{42} & sE_{43}-A_{43} & sE_{44}-A_{44} \\ 0 & 0 & sE_{53}-A_{53} & sE_{54}-A_{54} \\ 0 & 0 & 0 & sE_{64}-A_{64} \end{bmatrix} \end{array},$$

$$UB = \begin{array}{c} \\ \tilde{n}_1 \\ \tilde{n}_2 \\ \tilde{n}_3 \\ \tilde{n}_4 \\ \tilde{n}_5 \\ \tilde{n}_6 \end{array} \begin{bmatrix} B_1 \\ 0 \\ B_3 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \quad UG = \begin{array}{c} \\ \tilde{n}_1 \\ \tilde{n}_2 \\ \tilde{n}_3 \\ \tilde{n}_4 \\ \tilde{n}_5 \\ \tilde{n}_6 \end{array} \begin{bmatrix} G_1 \\ G_2 \\ G_3 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \quad CV = \begin{array}{c} \begin{array}{cccc} n_1 & n_2 & n_3 & n_4 \end{array} \\ \begin{bmatrix} 0 & 0 & C_3 & C_4 \end{bmatrix} \end{array}, \tag{31}$$

where E_{11}*,* G_2*,* B_3*, and* E_{53} *are of full row rank,* E_{42} *is square and nonsingular (i.e.,* $n_2 = \tilde{n}_4$*,), and furthermore* $\forall s \in \mathbf{C}$

$$\operatorname{rank}(sE_{64}-A_{64}) = n_4, \quad \operatorname{rank}\begin{bmatrix} sE_{53}-A_{53} \\ C_3 \end{bmatrix} = n_3,$$
$$\operatorname{rank}\begin{bmatrix} sE_{11}-A_{11} & B_1 & G_1 \\ -A_{21} & 0 & G_2 \\ -A_{31} & B_3 & G_3 \end{bmatrix} = \tilde{n}_1 + \tilde{n}_2 + \tilde{n}_3.$$

Proof. The proof is constructive and can be obtained by an algorithm similar to Algorithm 1. A detailed description of the method can be found in [10]. ∎

Similarly to the proof of Lemma 3.2, using the condensed form (31) we can characterize the following spaces:

$$\begin{aligned} &\Delta_r := V_{m-r}\left[\Pi^T\begin{bmatrix} E \\ 0 \end{bmatrix}, \Pi^T\begin{bmatrix} A \\ C \end{bmatrix}\right], \quad \Delta_l := V_{m-l}\left[\Pi^T\begin{bmatrix} E \\ 0 \end{bmatrix}, \Pi^T\begin{bmatrix} A \\ C \end{bmatrix}\right], \\ &\Delta_t := \begin{bmatrix} \Pi^{\perp} & \Pi \end{bmatrix}\begin{bmatrix} I & 0 \\ 0 & \Delta_l \end{bmatrix}, \\ &\Delta_1 := \Delta_t^T\begin{bmatrix} E \\ 0 \end{bmatrix}\Delta_r, \qquad \Delta_2 := \Delta_t^T\begin{bmatrix} A \\ C \end{bmatrix}\Delta_r, \\ &\Delta_3 := \Delta_t^T\begin{bmatrix} B \\ 0 \end{bmatrix}, \qquad \Delta_4 := \Delta_t^T\begin{bmatrix} G \\ 0 \end{bmatrix}, \end{aligned} \tag{32}$$

where Π is as in (12). We introduce furthermore the following indices which are determined by the condensed form of Theorem 4.1:

$$\begin{aligned}\nu &:= \operatorname{rank}\begin{bmatrix} B & G \end{bmatrix} + \operatorname{rank}(\Delta_l), \quad \xi := \operatorname{rank}(\Delta_r),\\ \chi &:= \dim\left(V_{m-l}\left[\begin{bmatrix} E & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} A & B & G \\ C & 0 & 0 \end{bmatrix}\right]\right)\\ &\quad + \dim\left(V_{f-l}\left[\begin{bmatrix} E & B & G \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} A & 0 & 0 \\ C & 0 & 0 \end{bmatrix}\right]\right)\\ &\quad - \dim\left(V_{f-l}\left[\begin{bmatrix} E & B & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} A & 0 & G \\ C & 0 & 0 \end{bmatrix}\right]\right). \end{aligned} \tag{33}$$

From the form (31) we then immediately obtain that

$$\xi = n_1, \qquad \chi = \tilde{n}_1 + \tilde{n}_2, \qquad \nu = \tilde{n}_1 + \tilde{n}_2 + \tilde{n}_3.$$

THEOREM 4.2. *Consider a system of the form* (1)*, spaces* Δ_i *as in* (32)*, and indices* χ*,* ξ*, and* ν *as in* (33)*.*

(a) *There exist feedback matrices* $F \in \mathbf{R}^{m\times n}$ *and* $H \in \mathbf{R}^{m\times d}$ *such that* $(E, A + BF)$ *is regular, of index at most one, stable, and* $C(sE - (A + BF))^{-1}(G + BH) = 0$ *if and only if conditions* (5) *and* (7) *and the following three conditions hold:*

$$\operatorname{rank}\begin{bmatrix} s\Delta_1 - \Delta_2 & \Delta_3 \end{bmatrix} = \nu \quad \forall s \in \mathbf{C}^+, \tag{34}$$

$$\operatorname{rank}\begin{bmatrix} \Delta_1 & \Delta_2 S_\infty(\Delta_1) & \Delta_3 \end{bmatrix} = \nu, \tag{35}$$

$$\chi \le \xi. \tag{36}$$

(b) *There exist feedback matrices* $F, K \in \mathbf{R}^{m\times n}$*, and* $H \in \mathbf{R}^{m\times d}$ *such that* $(E + BK, A + BF)$ *is regular, of index at most one, stable, and* $C(s(E + BK) - (A + BF))^{-1}(G + BH) = 0$ *if and only if conditions* (6)*,* (7)*, and* (34)*, as well as*

$$\operatorname{rank}_g \begin{bmatrix} T_\infty^T(B)(sE - A) & T_\infty^T(B)G \\ C & 0 \end{bmatrix} \le n, \tag{37}$$

hold and furthermore $W_2 := T_\infty^T(\begin{bmatrix} \Delta_1 & \Delta_3 \end{bmatrix})\Delta_2 S_\infty(T_\infty^T(\Delta_3)\Delta_1)$ *is of full row rank.*

Proof. Let $U, V \in \mathbf{R}^{n\times n}$ be orthogonal matrices such that $U(sE - A)V$, UB, CV, and UG are in the form (31). Then condition (34) translates to

$$\operatorname{rank}\begin{bmatrix} sE_{11} - A_{11} & B_1 \\ -A_{21} & 0 \\ -A_{31} & B_3 \end{bmatrix} = \tilde{n}_1 + \tilde{n}_2 + \tilde{n}_3 \quad \forall s \in \mathbf{C}^+$$

and (36) means that $\tilde{n}_1 + \tilde{n}_2 \le n_1$. Condition (35) translates to

$$\operatorname{rank}\begin{bmatrix} E_{11} & A_{11}S_\infty(E_{11}) & B_1 \\ 0 & A_{21}S_\infty(E_{11}) & 0 \\ 0 & A_{31}S_\infty(E_{11}) & B_3 \end{bmatrix} = \tilde{n}_1 + \tilde{n}_2 + \tilde{n}_3$$

and W_2 has full rank if and only if

$$T_\infty^T\left(\begin{bmatrix} E_{11} & B_1 \\ 0 & 0 \\ 0 & B_3 \end{bmatrix}\right) \begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} S_\infty\left(T_\infty^T\left(\begin{bmatrix} B_1 \\ 0 \\ B_3 \end{bmatrix}\right)\begin{bmatrix} E_{11} \\ 0 \\ 0 \end{bmatrix}\right)$$

has full row rank.

(a) *Necessity.* Let $F \in \mathbf{R}^{m\times n}$ and $H \in \mathbf{R}^{m\times d}$ be such that $(E, A+BF)$ is regular, of index at most one, and stable and $C(sE-(A+BF))^{-1}(G+BH)=0$. Conditions (5) and (7) follow directly by Lemma 2.3(v). If we partition

$$FV = \begin{matrix} \\ \end{matrix}\begin{matrix} n_1 & n_2 & n_3 & n_4 \end{matrix}$$
$$\begin{bmatrix} F_1 & F_2 & F_3 & F_4 \end{bmatrix},$$

then by Lemma 2.4 we have that

$$\sum_{i=1}^{4} n_i = n = \operatorname{rank}_g \begin{bmatrix} sE-(A+BF) & G+BH \\ C & 0 \end{bmatrix}$$
$$= n_2+n_3+n_4+\operatorname{rank}_g \begin{bmatrix} sE_{11}-(A_{11}+B_1F_1) & G_1+B_1H \\ -A_{21} & G_2 \\ -(A_{31}+B_3F_1) & G_3+B_3H \end{bmatrix}.$$

Hence,

$$\operatorname{rank}_g \begin{bmatrix} sE_{11}-(A_{11}+B_1F_1) & G_1+B_1K \\ -A_{21} & G_2 \\ -(A_{31}+B_3F_1) & G_3+B_3K \end{bmatrix} = n_1, \tag{38}$$

which implies condition (36), since

$$\tilde{n}_1+\tilde{n}_2 = \operatorname{rank}_g \begin{bmatrix} sE_{11}-(A_{11}+B_1F_1) & G_1+B_1H \\ -A_{21} & G_2 \end{bmatrix} \le n_1.$$

To show (34) let P_1 be an orthogonal matrix such that

$$P_1^T \begin{bmatrix} G_1+B_1H \\ G_2 \\ G_3+B_3H \end{bmatrix} = \begin{matrix} t_1 \\ \tilde{t}_2 \end{matrix} \begin{bmatrix} \tilde{G}_1 \\ 0 \end{bmatrix} \tag{39}$$

with $\tilde{G}_1$ of full row rank. Set

$$\begin{matrix} t_1 \\ \tilde{t}_2 \end{matrix} \begin{bmatrix} s\tilde{E}_{11}-\tilde{A}_{11} \\ s\tilde{E}_{21}-\tilde{A}_{21} \end{bmatrix} := P_1^T \begin{bmatrix} sE_{11}-(A_{11}+B_1F_1) \\ -A_{21} \\ -(A_{31}+B_3F_1) \end{bmatrix} \tag{40}$$

and compute the GUPTRI form of $(\tilde{E}_{21}, \tilde{A}_{21})$

$$\hat{P}_1^T(s\tilde{E}_{21}-\tilde{A}_{21})Q_1 = \begin{matrix} \\ t_2 \\ t_3 \end{matrix} \begin{matrix} r_1 & r_2 \end{matrix} \begin{bmatrix} s\Theta_{21}-\Phi_{21} & s\Theta_{22}-\Phi_{22} \\ 0 & s\Theta_{32}-\Phi_{32} \end{bmatrix} \tag{41}$$

with Θ_{21} of full row rank and $s\Theta_{32}-\Phi_{32}$ of full column rank $\forall s \in \mathbf{C}$. Set

$$\begin{matrix} r_1 & r_2 \end{matrix}$$
$$\begin{bmatrix} s\Theta_{11}-\Phi_{11} & s\Theta_{12}-\Phi_{12} \end{bmatrix}$$

$$:= (s\tilde{E}_{11}-\tilde{A}_{11})Q_1, \quad \begin{matrix} t_1 \\ t_2 \\ t_3 \end{matrix} \begin{bmatrix} \Psi_1 \\ \Psi_2 \\ \Psi_3 \end{bmatrix} := \begin{bmatrix} I & \\ & \hat{P}_1^T \end{bmatrix} P_1^T \begin{bmatrix} B_1 \\ 0 \\ B_3 \end{bmatrix}. \tag{42}$$

Since

$$\operatorname{rank}\begin{bmatrix} sE_{11}-A_{11} & B_1 & G_1 \\ -A_{21} & 0 & G_2 \\ -A_{31} & B_3 & G_3 \end{bmatrix} = \operatorname{rank}\begin{bmatrix} s\Theta_{11}-\Phi_{11} & s\Theta_{12}-\Phi_{12} & \Psi_1 & \tilde{G}_1 \\ s\Theta_{21}-\Phi_{21} & s\Theta_{22}-\Phi_{22} & \Psi_2 & 0 \\ 0 & s\Theta_{32}-\Phi_{32} & \Psi_3 & 0 \end{bmatrix}$$
$$= \tilde{n}_1+\tilde{n}_2+\tilde{n}_3 = t_1+t_2+t_3$$

$\forall s \in \mathbf{C}$, it follows that $\operatorname{rank}\begin{bmatrix} s\Theta_{32}-\Phi_{32} & \Psi_3 \end{bmatrix} = t_3 \ \forall s \in \mathbf{C}$. By (38) we also have that $t_1+t_2+r_2 = t_1+\operatorname{rank}_g(s\Theta_{21}-\Phi_{21})+r_2 = n_1 = r_1+r_2$, or equivalently we have that

$$t_1+t_2 = r_1 \text{ and } \begin{bmatrix} s\Theta_{11}-\Phi_{11} \\ s\Theta_{21}-\Phi_{21} \end{bmatrix} \text{ is square.} \tag{43}$$

We know that $(E, A+BF)$ is regular and stable, so we have that $([\begin{smallmatrix}\Theta_{11}\\ \Theta_{21}\end{smallmatrix}], [\begin{smallmatrix}\Phi_{11}\\ \Phi_{21}\end{smallmatrix}])$ is regular and stable. Therefore, we have $\forall s \in \mathbf{C}^+$ that

$$\operatorname{rank}\begin{bmatrix} sE_{11}-A_{11} & B_1 \\ -A_{21} & 0 \\ -A_{31} & B_3 \end{bmatrix} = \operatorname{rank}\begin{bmatrix} sE_{11}-(A_{11}+B_1F_1) & B_1 \\ -A_{21} & 0 \\ -(A_{31}+B_3F_1) & B_3 \end{bmatrix}$$
$$= \operatorname{rank}\begin{bmatrix} s\Theta_{11}-\Phi_{11} & s\Theta_{12}-\Phi_{12} & \Psi_1 \\ s\Theta_{21}-\Phi_{21} & s\Theta_{22}-\Phi_{22} & \Psi_2 \\ 0 & s\Theta_{32}-\Phi_{32} & \Psi_3 \end{bmatrix}$$
$$= t_1+t_2+\operatorname{rank}\begin{bmatrix} s\Theta_{32}-\Phi_{32} & \Psi_3 \end{bmatrix} = t_1+t_2+t_3 = \tilde{n}_1+\tilde{n}_2+\tilde{n}_3,$$

which gives condition (34).

We have that E_{11}, G_2, and B_3 are of full row rank, so that $\begin{bmatrix} \Theta_{32} & \Psi_3 \end{bmatrix}$ is also of full row rank. Since $(E, A+BF)$ is regular and of index at most one, we have that $([\begin{smallmatrix}\Theta_{11}\\ \Theta_{21}\end{smallmatrix}], [\begin{smallmatrix}\Phi_{11}\\ \Phi_{21}\end{smallmatrix}])$ is also regular and of index at most one. Then, using the standard characterization of pencils that are regular and of index at most one, e.g., [5], we obtain that $\operatorname{rank}[\begin{smallmatrix}\Theta_{11} & \Phi_{11}\hat{S}\\ \Theta_{21} & \Phi_{21}\hat{S}\end{smallmatrix}] = t_1+t_2$ with $\hat{S} = S_\infty([\begin{smallmatrix}\Theta_{11}\\ \Theta_{21}\end{smallmatrix}])$. Therefore, we have

$$\tilde{n}_1+\tilde{n}_2+\tilde{n}_3 = t_1+t_2+t_3 \geq \operatorname{rank}\begin{bmatrix} E_{11} & A_{11}S_\infty(E_{11}) & B_1 \\ 0 & A_{21}S_\infty(E_{11}) & 0 \\ 0 & A_{31}S_\infty(E_{11}) & B_3 \end{bmatrix}$$
$$= \operatorname{rank}\begin{bmatrix} E_{11} & (A_{11}+B_1F_1)S_\infty(E_{11}) & B_1 \\ 0 & A_{21}S_\infty(E_{11}) & 0 \\ 0 & (A_{31}+B_3F_1)S_\infty(E_{11}) & B_3 \end{bmatrix}$$
$$= \operatorname{rank}\begin{bmatrix} \Theta_{11} & \Theta_{12} & \tilde{\Phi}_1\tilde{S} & \Psi_1 \\ \Theta_{21} & \Theta_{22} & \tilde{\Phi}_2\tilde{S} & \Psi_3 \\ 0 & \Theta_{32} & \tilde{\Phi}_3\tilde{S} & \Psi_3 \end{bmatrix}$$
$$\geq \operatorname{rank}\begin{bmatrix} \Theta_{11} & \Theta_{12} & \Phi_{11}\hat{S} & \Psi_1 \\ \Theta_{21} & \Theta_{22} & \Phi_{21}\hat{S} & \Psi_2 \\ 0 & \Theta_{32} & 0 & \Psi_3 \end{bmatrix} = t_1+t_2+t_3,$$

where

$$\begin{bmatrix} \tilde{\Phi}_1 \\ \tilde{\Phi}_2 \\ \tilde{\Phi}_3 \end{bmatrix} = \begin{bmatrix} \Phi_{11} & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \\ 0 & \Phi_{32} \end{bmatrix}, \quad \tilde{S} = S_\infty\left(\begin{bmatrix} \Theta_{11} & \Theta_{12} \\ \Theta_{21} & \Theta_{22} \\ 0 & \Theta_{32} \end{bmatrix}\right).$$

Hence, (35) follows.

Sufficiency. Since conditions (7) and (5) hold, similarly to Lemma 3.3, we have

(44)
$$\operatorname{rank}(E) = \operatorname{rank}(E_{11}) + \operatorname{rank}\begin{bmatrix} E_{22} & E_{23} \\ E_{32} & E_{33} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix}, \quad \tilde{n}_6 = n_4,\ E_{64} = 0,\ \det(A_{64}) \neq 0.$$

Hence, by condition (36), we have that $n_2 + n_3 \leq \tilde{n}_3 + n_2 + \tilde{n}_5$, and therefore, as in Theorem 2.4 of [8], we can compute a matrix $X \in \mathbf{R}^{\tilde{n}_3 \times n_2}$ such that

$$\operatorname{rank}\begin{bmatrix} E_{32} + XE_{22} & E_{33} + XE_{23} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix} = \operatorname{rank}\begin{bmatrix} E_{22} & E_{23} \\ E_{32} & E_{33} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix}.$$

As a consequence, we obtain

$$\operatorname{rank}(E) = \operatorname{rank}(E_{11}) + \operatorname{rank}\begin{bmatrix} E_{32} + XE_{22} & E_{33} + XE_{23} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix}. \tag{45}$$

Since conditions (34), (36), and (35) hold, by a slight modification of Lemma 2.5, there exist $\tilde{F}_1 \in \mathbf{R}^{m \times n_1}$ and a nonsingular matrix Z such that

$$\begin{bmatrix} sE_{11} - (A_{11} + B_1\tilde{F}_1) \\ -A_{21} \\ -(A_{31} + XA_{21} + B_3\tilde{F}_1) \end{bmatrix} Z$$
$$= \begin{array}{c} \\ \tilde{n}_1 \\ \tilde{n}_2 \\ \tilde{n}_3 \end{array} \begin{array}{c} \begin{array}{cc} \tilde{n}_1 + \tilde{n}_2 & n_1 - (\tilde{n}_1 + \tilde{n}_2) \end{array} \\ \begin{bmatrix} s\Theta_{11} - \Phi_{11} & -\Phi_{12} \\ s\Theta_{21} - \Phi_{21} & -\Phi_{22} \\ 0 & 0 \end{bmatrix} \end{array}$$

with $([\begin{smallmatrix}\Theta_{11}\\ \Theta_{21}\end{smallmatrix}], [\begin{smallmatrix}\Phi_{11}\\ \Phi_{21}\end{smallmatrix}])$ regular, of index at most one, and stable. By condition (7), we obtain $\forall\ s \in \mathbf{C}^+$

$$\operatorname{rank}\begin{bmatrix} s\tilde{E}_{32} - \tilde{A}_{32} & s\tilde{E}_{33} - \tilde{A}_{33} & s\tilde{E}_{34} - \tilde{A}_{34} & B_3 \\ sE_{42} - A_{42} & sE_{43} - A_{43} & sE_{44} - A_{44} & 0 \\ 0 & sE_{53} - A_{53} & sE_{54} - A_{54} & 0 \\ 0 & 0 & sE_{64} - A_{64} & 0 \end{bmatrix} = n - (\tilde{n}_1 + \tilde{n}_2),$$

where

$$\tilde{E}_{32} = E_{32} + XE_{22}, \quad \tilde{A}_{32} = A_{32} + XA_{22}, \quad \tilde{E}_{33} = E_{33} + XE_{23},$$
$$\tilde{A}_{33} = A_{33} + XA_{23}, \quad \tilde{E}_{34} = E_{34} + XE_{24}, \quad \tilde{A}_{34} = A_{34} + XA_{24}.$$

We also have that B_3, E_{53} are of full row rank, E_{42} and A_{64} are nonsingular, and $E_{64} = 0$. Moreover, condition (45) obviously says that

$$\operatorname{rank}\begin{bmatrix} E_{32} + XE_{22} & E_{33} + XE_{23} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix}$$
$$= \operatorname{rank}\begin{bmatrix} E_{32} + XE_{22} & E_{33} + XE_{23} & E_{34} + XE_{24} \\ E_{42} & E_{43} & E_{44} \\ 0 & E_{53} & E_{54} \end{bmatrix}.$$

Thus, by Lemma 2.3(iv), there exists a matrix

$$\begin{matrix} n_1-(\tilde{n}_1+\tilde{n}_2) & n_2 & n_3 & n_4 \end{matrix}$$
$$\begin{bmatrix} \hat{F}_1 & F_2 & F_3 & F_4 \end{bmatrix}$$

such that

$$\left(\begin{bmatrix} 0 & \tilde{E}_{32} & \tilde{E}_{33} & \tilde{E}_{34} \\ 0 & E_{42} & E_{43} & E_{44} \\ 0 & 0 & E_{53} & E_{54} \\ 0 & 0 & 0 & E_{64} \end{bmatrix}, \begin{bmatrix} B_3\hat{F}_1 & \tilde{A}_{32}+B_3F_2 & \tilde{A}_{33}+B_3F_3 & \tilde{A}_{34}+B_3F_4 \\ 0 & A_{42} & A_{43} & A_{44} \\ 0 & 0 & A_{53} & A_{54} \\ 0 & 0 & 0 & A_{64} \end{bmatrix} \right)$$

is regular, of index at most one, and stable.

Let

$$F_1 := \tilde{F}_1 + \begin{bmatrix} 0 & \hat{F}_1 \end{bmatrix} Z^{-1}, \quad F := \begin{bmatrix} F_1 & F_2 & F_3 & F_4 \end{bmatrix} V^T;$$

we have that $(E, A+BF)$ is regular, of index at most one, and stable. Furthermore, if we compute H from $(G_3+XG_2)+B_3H=0$, then we also have disturbance decoupling.

(b) *Necessity.* Let $F, K \in \mathbf{R}^{m\times n}$, and $H \in \mathbf{R}^{m\times d}$ be such that $(E+BK, A+BF)$ is regular, of index at most one, and stable and the disturbances are decoupled. Then conditions (6)–(7) and (37) follow directly Lemma 2.3(vii), Lemma 2.4, and the inequality

$$\operatorname{rank}_g \begin{bmatrix} T_\infty^T(B)(sE-A) & T_\infty^T(B)G \\ C & 0 \end{bmatrix} \le \operatorname{rank}_g \begin{bmatrix} sE-(A+BF) & G+BH \\ C & 0 \end{bmatrix} = n.$$

Partition

$$\begin{matrix} & n_1 & n_2 & n_3 & n_4 \end{matrix} \qquad \begin{matrix} & n_1 & n_2 & n_3 & n_4 \end{matrix}$$
$$FV =: \begin{bmatrix} F_1 & F_2 & F_3 & F_4 \end{bmatrix}, \quad KV =: \begin{bmatrix} K_1 & K_2 & K_3 & K_4 \end{bmatrix}.$$

To prove (34), note that E_{11}, G_2, and B_3 are of full row rank, so there exists an orthogonal matrix $\hat{P}_1$ such that in

$$\begin{matrix} \hat{t}_1 \\ \hat{t}_2 \\ \hat{t}_3 \end{matrix} \begin{bmatrix} s\hat{E}_{11}-\hat{A}_{11} \\ -\hat{A}_{21} \\ -\hat{A}_{31} \end{bmatrix} := \hat{P}_1^T \begin{bmatrix} s(E_{11}+B_1K_1)-A_{11} \\ -A_{21} \\ s(B_3K_1)-A_{31} \end{bmatrix},$$

$$\begin{matrix} \hat{t}_1 \\ \hat{t}_2 \\ \hat{t}_3 \end{matrix} \begin{bmatrix} \hat{B}_1 \\ 0 \\ \hat{B}_3 \end{bmatrix} := \hat{P}_1^T \begin{bmatrix} B_1 \\ 0 \\ B_3 \end{bmatrix}, \quad \begin{matrix} \hat{t}_1 \\ \hat{t}_2 \\ \hat{t}_3 \end{matrix} \begin{bmatrix} \hat{G}_1 \\ \hat{G}_2 \\ \hat{G}_3 \end{bmatrix} := \hat{P}_1^T \begin{bmatrix} G_1 \\ G_2 \\ G_3 \end{bmatrix},$$

$\hat{E}_{11}$, $\hat{G}_2$, and $\hat{B}_3$ have full row rank.

If we set $\hat{P} := \begin{bmatrix} \hat{P}_1 & \\ & I \end{bmatrix} \in \mathbf{R}^{n\times n}$, then we obtain that $\hat{P}^TU(s(E+BK)-A)V$, $\hat{P}^TUB$, $\hat{P}^TUG$, CV are in the condensed form (31). Since there exist $F \in \mathbf{R}^{m\times n}$ and $K \in \mathbf{R}^{m\times p}$ such that $(E+BK, A+BF)$ is regular and stable and the disturbances are decoupled, it follows from part (a) that

$$\operatorname{rank} \begin{bmatrix} sE_{11}-A_{11} & B_1 \\ -A_{21} & 0 \\ -A_{31} & B_3 \end{bmatrix} = \operatorname{rank} \begin{bmatrix} s\hat{E}_{11}-\hat{A}_{11} & \hat{B}_1 \\ -\hat{A}_{21} & 0 \\ -\hat{A}_{31} & \hat{B}_3 \end{bmatrix} = \hat{t}_1+\hat{t}_2+\hat{t}_3 = \tilde{n}_1+\tilde{n}_2+\tilde{n}_3$$

$\forall s \in \mathbf{C}^+$, which is condition (34). Moreover, by part (a) we also have

$$\begin{aligned}\operatorname{rank}\begin{bmatrix} E_{11}+B_1K_1 & A_{11}\hat{S} & B_1 \\ 0 & A_{21}\hat{S} & 0 \\ B_3K_1 & A_{31}\hat{S} & B_3 \end{bmatrix} &= \operatorname{rank}\begin{bmatrix} \hat{E}_{11} & \hat{A}_{11}S_\infty(\hat{E}_{11}) & \hat{B}_1 \\ 0 & \hat{A}_{21}S_\infty(\hat{E}_{11}) & 0 \\ 0 & \hat{A}_{31}S_\infty(\hat{E}_{11}) & \hat{B}_3 \end{bmatrix} \\ &= \hat{t}_1+\hat{t}_2+\hat{t}_3 \\ &= \tilde{n}_1+\tilde{n}_2+\tilde{n}_3\end{aligned}$$

with

$$\hat{S} = S_\infty\left(\begin{bmatrix} E_{11}+B_1K_1 \\ 0 \\ B_3K_1 \end{bmatrix}\right).$$

Thus we have that

$$T_\infty^T\left(\begin{bmatrix} E_{11} & B_1 \\ 0 & 0 \\ 0 & B_3 \end{bmatrix}\right)\begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix}\hat{S}$$

is of full row rank and hence W_2 is also.

Sufficiency. Since (6) and (7) hold, it follows by Lemma 2.3(vii) that there exist F_0, K_0 such that $(E+BK_0, A+BF_0)$ is regular and of index at most one. Hence

$$\begin{aligned}\det(U(s(E+BK_0)-(A+BF_0))V) &\neq 0, \\ \deg(\det(U(s(E+BK_0)-(A+BF_0))V)) &= \operatorname{rank}(U(E+BK_0)).\end{aligned}$$

Similarly to Lemma 3.3, a direct calculation yields that

$$\operatorname{rank}\begin{bmatrix} E_{22} & E_{23} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix} = \operatorname{rank}\begin{bmatrix} E_{22} & E_{23} & E_{24} \\ E_{42} & E_{43} & E_{44} \\ 0 & E_{53} & E_{54} \end{bmatrix}, \quad \tilde{n}_6 = n_4, \quad E_{64} = 0,$$

$$A_{64} \text{ is nonsingular.} \tag{46}$$

Note that since E_{11}, G_2, and B_3 are of full row rank, there exists an orthogonal matrix $P_1 \in \mathbf{R}^{\nu\times\nu}$ such that

$$\begin{aligned} & P_1^T\begin{bmatrix} sE_{11}-A_{11} & sE_{12}-A_{12} & sE_{13}-A_{13} & sE_{14}-A_{14} & B_1 & G_1 \\ -A_{21} & sE_{22}-A_{22} & sE_{23}-A_{23} & sE_{24}-A_{24} & 0 & G_2 \\ -A_{31} & sE_{32}-A_{32} & sE_{33}-A_{33} & sE_{34}-A_{34} & B_3 & G_3 \end{bmatrix} \\ & \begin{matrix} \\ t_1 \\ = \tilde{n}_2 \\ t_3 \end{matrix}\begin{matrix} \begin{matrix} n_1 & n_2 & n_3 & n_4 & m & d \end{matrix} \\ \begin{bmatrix} s\tilde{E}_{11}-\tilde{A}_{11} & s\tilde{E}_{12}-\tilde{A}_{12} & s\tilde{E}_{13}-\tilde{A}_{13} & s\tilde{E}_{14}-\tilde{A}_{14} & 0 & \tilde{G}_1 \\ A_{21} & sE_{22}-A_{22} & sE_{23}-A_{23} & sE_{24}-A_{24} & 0 & G_2 \\ s\tilde{E}_{31}-\tilde{A}_{31} & s\tilde{E}_{32}-\tilde{A}_{32} & s\tilde{E}_{33}-\tilde{A}_{33} & s\tilde{E}_{34}-\tilde{A}_{34} & \tilde{B}_3 & \tilde{G}_3 \end{bmatrix} \end{matrix},\end{aligned} \tag{47}$$

with $\tilde{E}_{11}$, and $\tilde{B}_3$ full row rank. Then (37) implies that $t_1+\tilde{n}_2 \le n_1$. Furthermore, by (46) we have $n_2+n_3 \le t_3+n_2+\tilde{n}_5$. Note that E_{42} is nonsingular and E_{53} is full row rank; thus, as in the construction given Theorem 2.4 of [8], there exists a matrix $X \in \mathbf{R}^{t_3\times\tilde{n}_2}$ such that

$$\operatorname{rank}\begin{bmatrix} XE_{22} & XE_{23} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix} = \operatorname{rank}\begin{bmatrix} E_{22} & E_{23} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix}. \tag{48}$$

With this X, by (46) and (48) we have

$$\text{(49)}\quad \operatorname{rank}\begin{bmatrix} \tilde{E}_{11} & \tilde{E}_{12} & \tilde{E}_{13} & \tilde{E}_{14} \\ 0 & E_{22} & E_{23} & E_{24} \\ 0 & XE_{22} & XE_{23} & XE_{24} \\ 0 & E_{42} & E_{43} & E_{44} \\ 0 & 0 & E_{53} & E_{54} \end{bmatrix} = \operatorname{rank}(\tilde{E}_{11}) + \operatorname{rank}\begin{bmatrix} XE_{22} & XE_{23} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix}.$$

Determine

$$K := \begin{matrix} n_1 & n_2 & n_3 & n_4 \end{matrix} \\ \begin{bmatrix} K_1 & K_2 & K_3 & K_4 \end{bmatrix}$$

from

$$\tilde{B}_3 \begin{bmatrix} K_1 & K_2 & K_3 & K_4 \end{bmatrix} + \begin{bmatrix} \tilde{E}_{31} & \tilde{E}_{32} & \tilde{E}_{33} & \tilde{E}_{34} \end{bmatrix} = 0;$$

then, since W_2 has full rank if and only if $\operatorname{rank}(\tilde{A}_{11} S_\infty(\tilde{E}_{11})) = \tilde{n}_2$, and since we have already shown that (46) and (49) hold, similarly to the sufficiency in part (a), we obtain the desired feedback matrices F and H. See [10] for details. □

Remark 4.1. If the index one condition is not required, then in (a) necessary and sufficient conditions are given by (7), (34), and (36) and in (b) by (7), (34), and (37). The proof of these conditions and the construction of feedbacks that regularize the system without achieving index at most one are discussed in detail in [10].

Remark 4.2. We can extend these results to systems that include a feedthrough term, which arises frequently in H_∞ and LQG control (see [26]), i.e., systems of the form

$$\begin{aligned} E\dot{x}(t) &= Ax(t) + Bu(t) + Gq(t);\ x(t_0) = x_0, \qquad t \geq t_0, \\ y(t) &= Cx(t) + Du(t), \end{aligned} \tag{50}$$

where E, A, B, G, C are as in (1) and $D \in \mathbf{R}^{p\times m}$.

Using the singular value decomposition of D, e.g., [15],

$$P^T D W = \begin{matrix} r_d \\ q - r_d \end{matrix} \begin{matrix} \begin{matrix} r_d & m - r_d \end{matrix} \\ \begin{bmatrix} D_1 & 0 \\ 0 & 0 \end{bmatrix} \end{matrix}, \tag{51}$$

with P, W orthogonal and D_1 of size $r_d \times r_d$ and nonsingular, we can set

$$\begin{aligned} BW =: & \begin{matrix} r_d & m - r_d \end{matrix} \\ & \begin{bmatrix} B_1 & B_2 \end{bmatrix}, \quad P^T C =: \begin{matrix} r_d \\ q - r_d \end{matrix} \begin{bmatrix} C_1 \\ C_2 \end{bmatrix}, \\ W^T u =: & \begin{bmatrix} u_1 \\ u_2 \end{bmatrix}, \quad P^T y =: \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \end{aligned} \tag{52}$$

and furthermore for $F \in \mathbf{R}^{m\times n}$

$$\begin{bmatrix} F_1 \\ F_2 \end{bmatrix} := W^T F - \begin{bmatrix} D_1^{-1} C_1 \\ 0 \end{bmatrix}. \tag{53}$$

Then for the solution of the disturbance decoupling problem it suffices to perform the analysis of the augmented system

$$\begin{aligned} \hat{E}\dot{\hat{x}} &= \hat{A}\hat{x} + \hat{B}\hat{u} + \hat{G}q, \\ \hat{y} &= \hat{C}\hat{x}, \end{aligned} \tag{54}$$

where

$$\hat{E} := \begin{bmatrix} E & 0 \\ 0 & 0 \end{bmatrix}, \quad \hat{A} := \begin{bmatrix} A & B_1 \\ C_1 & D_1 \end{bmatrix} \in \mathbf{R}^{\hat{n}\times\hat{n}},$$
$$\hat{B} := \begin{bmatrix} B_2 \\ 0 \end{bmatrix} \in \mathbf{R}^{\hat{n}\times\hat{m}}, \quad \hat{C} := \begin{bmatrix} C_2 & 0 \end{bmatrix} \in \mathbf{R}^{\hat{p}\times\hat{n}}, \quad \hat{G} := \begin{bmatrix} G \\ 0 \end{bmatrix} \in \mathbf{R}^{\hat{n}\times\hat{d}},$$

and $\hat{n} := n+r_d$, $\hat{m} := m-r_d$, $\hat{p} := p-r_d$. For this system the results from the previous section apply, and hence the case of systems with feedthrough can be reduced to the previous results. See [10] for more details.

5. Conclusions. In this paper we have studied the disturbance decoupling problem with or without stability for descriptor systems. We have given necessary and sufficient conditions for solving this problem and at the same time ensuring that the resulting closed-loop system is regular and has index at most one. The proofs are constructive, based on condensed forms that can be computed via orthogonal matrix transformations and can be implemented as numerically stable procedures.

Appendix A.

Constructive proof of Theorem 3.1. In the following algorithm we need row compressions, column compressions, or simultaneous row and column compressions of matrices. Such compressions can be obtained in the usual way via QR-factorizations, rank revealing QR-factorizations, URV-decompositions, or singular value decompositions; see [15, 2].

We also need the computation of GUPTRI forms which can be obtained via the LAPACK routine DGGBAK from LAPACK [2].

ALGORITHM 1.

Input: Matrices E, $A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$, $G \in \mathbf{R}^{n\times p}$, $C \in \mathbf{R}^{q\times n}$.

Output: Orthogonal matrices U, V, P, W, and the condensed form (14).

Step 1. Perform a row compression and a column compression such that

$$UB =: \begin{bmatrix} B_1 \\ B_2 \\ 0 \end{bmatrix}, \quad UG =: \begin{bmatrix} G_1 \\ 0 \\ 0 \end{bmatrix}, \quad CV =: \begin{bmatrix} 0 & C_3 \end{bmatrix}$$

with G_1, B_2 of full row rank and C_3 of full column rank. Set

$$U(sE-A)V =: \begin{bmatrix} sE_{11}-A_{11} & sE_{13}-A_{13} \\ sE_{21}-A_{21} & sE_{23}-A_{23} \\ sE_{31}-A_{31} & sE_{33}-A_{33} \end{bmatrix}.$$

Step 2. Compute the GUPTRI form of (E_{31}, A_{31}),

$$U_2(sE_{31}-A_{31})V_2 =: \begin{bmatrix} sE_{31}-A_{31} & sE_{32}-A_{32} \\ 0 & sE_{42}-A_{42} \end{bmatrix}$$

with E_{31} of full row rank and $sE_{42} - A_{42}$ of full column rank for any $s \in \mathbf{C}$. Set

$$\begin{bmatrix} sE_{11} - A_{11} \\ sE_{21} - A_{21} \end{bmatrix} V_2 =: \begin{bmatrix} sE_{11} - A_{11} & sE_{12} - A_{12} \\ sE_{21} - A_{21} & sE_{22} - A_{22} \end{bmatrix},$$
$$U_2(sE_{33} - A_{33}) =: \begin{bmatrix} sE_{33} - A_{33} \\ sE_{43} - A_{43} \end{bmatrix}.$$

Step 3. Compute the GUPTRI form of $(\begin{bmatrix} E_{42} & E_{43} \end{bmatrix}, \begin{bmatrix} A_{42} & A_{43} \end{bmatrix})$,

$$U_3 \begin{bmatrix} sE_{42} - A_{42} & sE_{43} - A_{43} \end{bmatrix} V_3 =: \begin{bmatrix} sE_{42} - A_{42} & sE_{43} - A_{43} \\ 0 & sE_{53} - A_{53} \end{bmatrix}$$

with E_{42} of full row rank and $sE_{53} - A_{53}$ of full column rank for any $s \in \mathbf{C}$. Set

$$\begin{bmatrix} sE_{12} - A_{12} & sE_{13} - A_{13} \\ sE_{22} - A_{22} & sE_{23} - A_{23} \\ sE_{32} - A_{32} & sE_{33} - A_{33} \end{bmatrix} := \begin{bmatrix} sE_{12} - A_{12} & sE_{13} - A_{13} \\ sE_{22} - A_{22} & sE_{23} - A_{23} \\ sE_{32} - A_{32} & sE_{33} - A_{33} \end{bmatrix} V_3$$

and $\begin{bmatrix} C_2 & C_3 \end{bmatrix} := \begin{bmatrix} 0 & C_3 \end{bmatrix} V_3$.

Step 4. Perform a row compression

$$U_4 \begin{bmatrix} sE_{21} - A_{21} \\ sE_{31} - A_{31} \end{bmatrix} =: \begin{bmatrix} sE_{21} - A_{21} \\ -A_{31} \end{bmatrix}$$

with E_{21} of full row rank. Set

$$\begin{bmatrix} sE_{22} - A_{22} & sE_{23} - A_{23} \\ sE_{32} - A_{32} & sE_{33} - A_{33} \end{bmatrix} := U_4 \begin{bmatrix} sE_{22} - A_{22} & sE_{23} - A_{23} \\ sE_{32} - A_{32} & sE_{33} - A_{33} \end{bmatrix},$$
$$\begin{bmatrix} B_2 \\ B_3 \end{bmatrix} := U_4 \begin{bmatrix} B_2 \\ 0 \end{bmatrix},$$

and

$$U := \begin{bmatrix} I & & \\ & U_4 & \\ & & I \end{bmatrix} \begin{bmatrix} I & \\ & U_3 \end{bmatrix} \begin{bmatrix} I & \\ & U_2 \end{bmatrix} U_1, \quad V := V_1 \begin{bmatrix} V_2 & \\ & I \end{bmatrix} \begin{bmatrix} I & \\ & V_3 \end{bmatrix}.$$

Appendix B.

Proof of Lemma 3.2. Let $\tilde{U}$ be an orthogonal matrix such that

$$\tilde{U} \begin{bmatrix} B_2 \\ B_3 \end{bmatrix} = \begin{matrix} l_2 \\ \tilde{n}_2 + \tilde{n}_3 - l_2 \end{matrix} \begin{bmatrix} \tilde{B}_2 \\ 0 \end{bmatrix}$$

with $\tilde{B}_2$ of full row rank. Set

$$\tilde{U} \begin{bmatrix} sE_{21} - A_{21} & sE_{22} - A_{22} & sE_{23} - A_{23} \\ -A_{31} & sE_{32} - A_{32} & sE_{33} - A_{33} \end{bmatrix}$$
$$=: \begin{matrix} l_2 \\ \tilde{n}_2 + \tilde{n}_3 - l_2 \end{matrix} \begin{matrix} \begin{matrix} n_1 & \quad n_2 & \quad n_3 \end{matrix} \\ \begin{bmatrix} s\tilde{E}_{21} - \tilde{A}_{21} & s\tilde{E}_{22} - \tilde{A}_{22} & s\tilde{E}_{23} - \tilde{A}_{23} \\ s\tilde{E}_{31} - \tilde{A}_{31} & s\tilde{E}_{32} - \tilde{A}_{32} & s\tilde{E}_{33} - \tilde{A}_{33} \end{bmatrix} \end{matrix}$$

and partition $\tilde{U} = \begin{smallmatrix} l_2 \\ \tilde{n}_2+\tilde{n}_3-l_2 \end{smallmatrix} [\begin{smallmatrix} \tilde{U}_2 \\ \tilde{U}_3 \end{smallmatrix}]$. Then since

$$\begin{bmatrix} sE_{42}-A_{42} & sE_{43}-A_{43} \\ 0 & sE_{53}-A_{53} \\ C_2 & C_3 \end{bmatrix}$$

is of full column rank and G_1, E_{21}, and B_3 are of full row rank $\forall s \in \mathbf{C}$, we have that $\tilde{E}_{31}$ is also of full row rank, and

$$\Pi = \begin{bmatrix} 0 & 0 \\ \tilde{U}_3^T & 0 \\ 0 & I_{\tilde{n}_4+\tilde{n}_5+q} \end{bmatrix} \in \mathbf{R}^{(n+q)\times(n+q-p-l_2)},$$

$$\begin{bmatrix} \Pi^\perp & \Pi \end{bmatrix} = \begin{bmatrix} W_\pi^T & \\ & I_{\tilde{n}_4+\tilde{n}_5+q} \end{bmatrix} \in \mathbf{R}^{(n+q)\times(n+q)},$$

$$\Lambda_r = \begin{bmatrix} I_{n_1} \\ 0 \end{bmatrix} W_r \in \mathbf{R}^{n\times n_1}, \quad \Lambda_l = \begin{bmatrix} I_{\tilde{n}_2+\tilde{n}_3-l_2} \\ 0 \end{bmatrix} \tilde{W}_l^T \in \mathbf{R}^{(n+q-p-l_2)\times(\tilde{n}_2+\tilde{n}_3-l_2)},$$

$$\Lambda_t = \begin{bmatrix} W_\pi^T & \\ & I_{\tilde{n}_4+\tilde{n}_5+q} \end{bmatrix} \begin{bmatrix} I_{p+\tilde{n}_2+\tilde{n}_3} \\ 0 \end{bmatrix} \begin{bmatrix} I_{p+l_2} & \\ & \tilde{W}_l^T \end{bmatrix},$$

where $W_\pi, W_r, \tilde{W}_l$ are orthogonal. If we set $W_l = [\begin{smallmatrix} I_{p+l_2} & \\ & \tilde{W}_l \end{smallmatrix}] W_\pi$, then we obtain

$$\Lambda_1 = W_l \begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} W_r, \qquad \Lambda_2 = W_l \begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} W_r, \qquad \Lambda_3 = W_l \begin{bmatrix} B_1 \\ B_2 \\ B_3 \end{bmatrix}.$$

Note that

$$\begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} W_r S_\infty \left(\begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} W_r \right) = \begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} S_\infty \left(\begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} \right),$$

$$T_\infty^T \left(W_l \begin{bmatrix} E_{11}W_r & B_1 \\ E_{21}W_r & B_2 \\ 0 & B_3 \end{bmatrix} \right) W_l \begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} W_r = T_\infty^T \left(\begin{bmatrix} E_{11} & B_1 \\ E_{21} & B_2 \\ 0 & B_3 \end{bmatrix} \right) \begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} W_r,$$

$$S_\infty \left(T_\infty^T \left(W_l \begin{bmatrix} B_1 \\ B_2 \\ B_3 \end{bmatrix} \right) W_l \begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} W_r \right) = W_r^T S_\infty \left(T_\infty^T \left(\begin{bmatrix} B_1 \\ B_2 \\ B_3 \end{bmatrix} \right) \begin{bmatrix} E_{11} \\ E_{21} \\ 0 \end{bmatrix} \right).$$

Since B_3 is of full row rank, there exists an orthogonal matrix $\tilde{V}$ such that $\begin{bmatrix} B_3 & A_{31} \end{bmatrix} \tilde{V} = \begin{bmatrix} 0 & \Phi_{32} \end{bmatrix}$ with Φ_{32} nonsingular. Set (with conformal partitioning) $\begin{bmatrix} B_2 & A_{21} \end{bmatrix} \tilde{V} = \begin{bmatrix} \Phi_{21} & \Phi_{22} \end{bmatrix}$, $\begin{bmatrix} 0 & E_{21} \end{bmatrix} \tilde{V} = \begin{bmatrix} \Theta_{21} & \Theta_{22} \end{bmatrix}$, and $\hat{V} := [\begin{smallmatrix} \tilde{V} & \\ & I \end{smallmatrix}] \in \mathbf{R}^{(n+m)\times(n+m)}$. Then, we obtain that

$$\begin{bmatrix} -\Psi B & \Psi(sE-A) \\ 0 & C \end{bmatrix} \hat{V}$$

$$= \begin{bmatrix} s\Theta_{21}-\Phi_{21} & s\Theta_{22}-\Phi_{22} & sE_{22}-A_{22} & sE_{23}-A_{23} \\ 0 & -\Phi_{32} & sE_{32}-A_{32} & sE_{33}-A_{33} \\ 0 & 0 & sE_{42}-A_{42} & sE_{43}-A_{43} \\ 0 & 0 & 0 & sE_{53}-A_{53} \\ 0 & 0 & C_2 & C_3 \end{bmatrix}.$$

Since E_{21}, B_2 are of full row rank and Φ_{32} is nonsingular, it follows that Θ_{21} is also of full row rank. Note that

$$\begin{bmatrix} -\Phi_{32} & sE_{42} - A_{42} & sE_{43} - A_{43} \\ 0 & 0 & sE_{53} - A_{53} \\ 0 & C_2 & C_3 \end{bmatrix}$$

is of full column rank $\forall\ s \in \mathbf{C}$. Hence,

$$\operatorname{rank}(\Lambda_4) = \operatorname{rank} \begin{bmatrix} 0 & E_{32} & E_{33} \\ 0 & E_{42} & E_{43} \\ 0 & 0 & E_{53} \\ 0 & 0 & 0 \end{bmatrix} = \operatorname{rank} \begin{bmatrix} E_{32} & E_{33} \\ E_{42} & E_{43} \\ 0 & E_{53} \end{bmatrix}.$$

Since

$$\begin{bmatrix} \Psi(sB) & \Psi(sE - A) \\ 0 & -C \end{bmatrix} = \begin{bmatrix} sB_2 & sE_{21} - A_{21} & sE_{22} - A_{22} & sE_{23} - A_{23} \\ sB_3 & -A_{31} & sE_{32} - A_{32} & sE_{33} - A_{33} \\ 0 & 0 & sE_{42} - A_{42} & sE_{43} - A_{43} \\ 0 & 0 & 0 & sE_{53} - A_{53} \\ 0 & 0 & -C_2 & -C_3 \end{bmatrix},$$

$\left[\begin{smallmatrix} B_2 & E_{21} \\ B_3 & 0 \end{smallmatrix}\right]$ are of full row rank and

$$\begin{bmatrix} sE_{42} - A_{42} & sE_{43} - A_{43} \\ 0 & sE_{53} - A_{53} \\ -C_2 & -C_3 \end{bmatrix}$$

is of full column rank $\forall s \in \mathbf{C}$. □

(C, A)-INVARIANCE OF MODULES OVER PRINCIPAL IDEAL DOMAINS*

NAOHARU ITO†, WILAND SCHMALE‡, AND HARALD K. WIMMER§

Abstract. For discrete-time linear systems over a principal ideal domain, three types of (C, A)-invariance can be distinguished. Connections between these notions are investigated. For pure submodules, necessary and sufficient conditions for dynamic (C, A)-injection invariance are given. Sufficient conditions are obtained in the general case.

Key words. systems over rings, (C, A)-invariance, injection-invariance, (A, B)-invariance, feedback invariance, pure submodules, closure of submodules

1. Introduction.

Consider a real n-dimensional linear system

$$x(t+1) = Ax(t) + Bu(t),\ y(t) = Cx(t), \tag{1.1}$$

with a dynamical observer of the form

$$z(t+1) = Az(t) + Bu(t) - K[y(t) - Cz(t)].$$

The error $e(t) = x(t) - z(t)$ satisfies $e(t+1) = (A+KC)e(t)$. Hence, if ϕ is a subspace of $\mathbb{R}^n$ which is invariant under $A + KC$, then the error $e(t)$ will remain in ϕ provided that the initial error $e(0)$ is in ϕ. Such (C, A)-invariant subspaces, which are basic tools for the construction of observers, have been studied in [3], [28], [25], [8], [11]. The differentiable structure of sets of (C, A)-invariant subspaces was investigated in [10]. Classification and parametrization results were obtained in [16]. Applications to disturbance decoupling by observation feedback and disturbance decoupled estimation can be found in [25].

If (1.1) is a system over a field, then the following important fact is well known. Given ϕ, there exists a K such that $(A + KC)\phi \subseteq \phi$ if and only if

$$A(\phi \cap \operatorname{Ker} C) \subseteq \phi. \tag{1.2}$$

For systems over rings, Example 1.2 below shows that the equivalence between $(A + KC)$-invariance and the geometric property (1.2) is not valid in general, which gives rise to distinct notions of (C, A)-invariance. It is indispensable for prospective applications of systems over rings to clarify the interdependence of those invariance concepts. If a real linear system depends polynomially on a parameter or if it has

commensurable delays, then it can be viewed as a system over the ring $\mathbb{R}[s]$ or more generally as a system over a principal ideal domain (PID) (see, e.g., [26], [23], [12]). Accordingly in this paper the underlying ring R will be a PID. We refer to [7] for linear systems over PIDs and to [9], [17], [2] for applications. In a subsequent paper [19] we apply our present results to disturbance decoupling by dynamic measurement feedback. An example of an engineering application is the decoupling control of a ship propelled by a pitch propeller. The problem was studied by Kono et al. [21]. It was solved in [17] by applying results on diagonal decoupling to delay systems.

Let (C, A) and (A, B) be pairs of matrices with $A \in R^{n\times n}$, $C \in R^{l\times n}$, $B \in R^{n\times m}$. In this paper, ϕ will always be a submodule of R^n with $\operatorname{rank}\phi = r$ and $\operatorname{rank}(\phi \cap \operatorname{Ker} C) = k$.

DEFINITION 1.1.

(i) *A submodule ϕ is called (C, A)-invariant if*

$$A(\phi \cap \operatorname{Ker} C) \subseteq \phi.$$

(ii) *We say ϕ is (C, A)-injection-invariant if there exists a matrix $K \in R^{n\times l}$ such that*

$$(A + KC)\phi \subseteq \phi. \tag{1.3}$$

It is well known that (1.3) implies (1.2). If R is not a field, then the converse need not be true. The following example can be found in [8].

Example 1.2. Take $R = \mathbb{Q}[\tau]$, $n = 2$, and define

$$A = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}, \quad C = (\tau \quad 0), \quad \phi = \operatorname{Im}\begin{pmatrix} 1 \\ 0 \end{pmatrix}. \tag{1.4}$$

Clearly ϕ is (C, A)-invariant because of $\phi \cap \operatorname{Ker} C = 0$. If $K = (\alpha\ \beta)^T$ is a matrix such that (1.3) holds, then $1 + \beta\tau = 0$, which is possible for $\beta \in R[1/\tau]$ but not for $\beta \in R$. We point out that the submodule $C\phi = \tau R$ does not satisfy $(\phi^\perp)^\perp = \phi$ such that the example later will confirm Corollary 5.2.

The next example shows that injection-invariance can be achieved by extending the data A, C, ϕ in a way which corresponds to dynamic feedback.

Example 1.3. Define A, C, ϕ as in (1.4). Set

$$A^e = \left(\begin{array}{cc|c} 1 & 0 & 0 \\ 1 & 1 & 0 \\ \hline 0 & 0 & 0 \end{array}\right), \quad C^e = \left(\begin{array}{cc|c} \tau & 0 & 0 \\ \hline 0 & 0 & 1 \end{array}\right), \quad \phi^e = \operatorname{Im} M^e, \quad M^e = \left(\begin{array}{c|c} 1 & 0 \\ 0 & 1 \\ \hline 0 & \tau \end{array}\right).$$

Define

$$K^e = \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 1 & 1 \end{pmatrix}.$$

Then

$$(A^e + K^eC^e)M^e = M^e \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix},$$

i.e., $(A^e + K^eC^e)\phi^e \subseteq \phi^e$, and ϕ^e extends ϕ in the sense of $\phi^e \cap (R^2 \oplus 0) = \phi \oplus 0$.

With regard to the preceding example and in particular motivated by a dual concept in the theory of (A, B)-invariant submodules (to be discussed in section 2) we introduce another invariance notion. Let q be a nonnegative integer, and let 0^q be the zero submodule of R^q. We consider extensions of order q of A and C of the form

$$A_q^e = \begin{pmatrix} A & 0 \\ 0 & 0_{q\times q} \end{pmatrix}, \quad C_q^e = \begin{pmatrix} C & 0 \\ 0 & I_q \end{pmatrix}. \tag{1.5}$$

To a submodule ϕ we associate the sets

$$E(\phi, q) = \{\psi \mid \psi \text{ submodule of } R^{n+q},\ \psi \cap (R^n \oplus 0^q) = \phi \oplus 0^q\},$$

and

$$E(\phi) = \cup\{E(\phi, q),\ q \geq 0\}.$$

This type of module extensions appears already in [25].

DEFINITION 1.4. *We call ϕ dynamically (C, A)-injection-invariant of order $q \geq 0$ if there exist a matrix $K^e \in R^{(n+q)\times(l+q)}$ and a submodule $\phi^e \in E(\phi, q)$ such that*

$$(A_q^e + K^e C_q^e)\phi^e \subseteq \phi^e. \tag{1.6}$$

For a pair (C, A) and a submodule ϕ we now have three notions of invariance. It is the purpose of this paper to study the relations between those three concepts. In section 5 we shall prove the following result.

PROPOSITION 1.5. *If ϕ is dynamically (C, A)-injection-invariant, then ϕ is (C, A)-invariant.*

The theory of (A, B)-invariant submodules in section 2 might suggest that a converse of Proposition 1.5 should be true, at least for those submodules ϕ that are pure, i.e., which are direct summands of R^n, or equivalently, which satisfy $(\phi^\perp)^\perp = \phi$. As usual we define $\phi^\perp = \{x \in R^n \mid x^T y = 0 \text{ for all } y \in R^n\}$, and we call $\mathcal{S}\phi = (\phi^\perp)^\perp$ the closure of ϕ. Because of $\mathcal{S}\phi = \phi$, or equivalent closure properties, it has also been common (see, e.g., [9], [22]) to speak of closed instead of pure submodules. Basic properties of the closure operator $\mathcal{S}$ and of pure submodules will be reviewed in the appendix. For our purposes it is important to know that (dynamic) (C, A)-injection-invariance of ϕ is inherited by $\mathcal{S}\phi$. Our main result for pure submodules is the following.

THEOREM 1.6. *Let ϕ be a pure submodule of R^n of rank r. Then ϕ is dynamically (C, A)-injection-invariant if and only if $\phi^\perp$ contains a submodule ψ satisfying*

(i) $\operatorname{rank} \psi = n - r$,

(ii) $A^T\psi \subseteq \psi + \operatorname{Im}(C^T)$.

Note that condition (ii) means that ψ is (A^T, C^T)-invariant according to Definition 2.1 below. Hence the two conditions (i) and (ii) hold if and only if the unique maximal (A^T, C^T)-invariant submodule of $\phi^\perp$ has rank $n - r$.

Having Theorem 1.6 at our disposal we claim that (C, A)-invariance is not sufficient for dynamical (C, A)-injection-invariance.

Example 1.7. Take $R = \mathbb{Q}[\tau]$, $n = 2$, $r = 1$, and

$$A = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad C = (\tau \quad 1), \quad \phi = \operatorname{Im} \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

Again we have $\phi \cap \operatorname{Ker} C = 0$. Hence ϕ is (C, A)-invariant. It requires a considerable effort to verify directly that there does not exist an extension $\phi^e \in E(\phi)$ and a matrix

K^e such that $(A^e + K^e C^e)\phi^e \subseteq \phi^e$. On the other hand, it follows immediately from Theorem 1.6 that ϕ cannot be dynamically (C, A)-injection-invariant, since in $\phi^\perp = \mathrm{Im}(0, 1)^T$ only the zero submodule is (A^T, C^T)-invariant.

We continue our paper as follows. In section 2 we review types of (A, B)-invariance that correspond to the notions in Definitions 1.1 and 1.4. It will become evident that our results with respect to (C, A) are not dual ones of (A, B)-invariance results. In section 3 we give the proof of Theorem 1.6 and obtain further criteria for pure submodules. In section 4 we work with bases of submodules and develop matrix representations which will then be exploited in section 5 to derive sufficient conditions for (dynamic) (C, A)-injection-invariance in the general nonpure case.

2. (A, B)-invariance. If R is a field, then the (C, A)-invariance condition (1.2) is equivalent to a dual (A^T, C^T)-invariance condition for $\phi^\perp$. That is, we have

$$A(\phi \cap \ker C) \subseteq \phi \iff A^T \phi^\perp \subseteq \phi^\perp + \mathrm{Im}\, C^T. \tag{2.1}$$

Over a PID, (2.1) in general is no longer true. We have only

$$A\,\mathcal{S}(\phi \cap \ker C) \subseteq \mathcal{S}\,\phi \iff A^T \phi^\perp \subseteq \mathcal{S}\left[\phi^\perp + \mathcal{S}(\mathrm{Im}\, C^T)\right]. \tag{2.2}$$

Therefore, in general, results on (A, B)-invariance cannot be carried over to dual ones on (C, A)-invariance. In the special case where ϕ, $\mathrm{Im}\, C^T$, and $\phi^\perp + \mathrm{Im}\, C^T$ are pure submodules the equivalence (2.2) implies (2.1).

For systems over rings dualization, in particular duality between controllability (or reachability) and observability has been a fundamental issue (see, e.g., [5], [6], and [15]). It is known [15] that among PIDs only fields have the property that controllability of (A, B) is always equivalent to observability of the corresponding transposed system. In general, controlled and observed invariance are intrinsically different concepts. Note that (A, B)-invariance (2.3) is preserved under homomorphisms. On the other hand consider Example 1.7 where the homomorphism induced by $\tau \mapsto 0$ destroys (C, A)-invariance.

Let us briefly review some facts and definitions on (A, B)-invariance, for which we refer to [14], [8], and [18]. In accordance with Definition 1.1 we have two concepts, a geometric and a feedback characterization.

DEFINITION 2.1.

(i) *A submodule ψ of R^n is called (A, B)-invariant if*

$$A\psi \subseteq \psi + \mathrm{Im}\, B. \tag{2.3}$$

(ii) *We say ψ is (A, B)-feedback-invariant if there exists a matrix $F \in R^{m\times n}$ such that*

$$(A + BF)\psi \subseteq \psi. \tag{2.4}$$

The notion of dynamic (A, B)-feedback-invariance was introduced in [9] and then also studied in [17] and [18]. For $q \geq 0$ let A_q^e be given as in (1.5). Define

$$B_q^e = \begin{pmatrix} B & 0 \\ 0 & I_q \end{pmatrix}$$

correspondingly. Let $\mathcal{P}$ be the projection of $R^n \oplus R^q$ onto R^n. To a submodule $\psi \subseteq R^n$ we associate the sets

$$G(\psi, q) = \{\mu \mid \mu \,\text{submodule of}\, R^n \oplus R^q \,\text{with}\, \mathcal{P}\mu = \psi\}$$

and $G(\psi) = \cup\{G(\psi, q),\, q \geq 0\}$.

DEFINITION 2.2. *A submodule ψ of R^n is called dynamically (A, B)-feedback-invariant of order q if there exists a $\psi^b \in G(\psi, q)$ and a matrix $F^b \in R^{(n+q)\times(m+q)}$ such that*

$$(A_q^e + B_q^e F^b)\psi^b \subseteq \psi^b.$$

We note that for pure submodules and pure extensions, Definition 1.4 and Definition 2.2 are related by duality. Namely, if $(\phi^\perp)^\perp = \phi$ and $\phi^e \in E(\phi, q)$, then (by Lemma 3.1 below) we have $\mathcal{P}[(\phi^e)^\perp] = \phi^\perp$. Hence $(\phi^e)^\perp \in G(\phi^\perp, q)$. Similarly, if $\psi^b \in G(\psi, q)$, then

$$(\psi^b)^\perp \cap (R^n \oplus 0^q) = \psi^\perp$$

and $(\psi^b)^\perp \in E(\psi^\perp, q)$.

The interdependence between the preceding three types of invariance with respect to (A, B) is well understood. It is clear that over a commutative ring (2.4) implies (2.3). The following example from [14] shows that the converse need not be true.

Example 2.3. Consider $R = \mathbb{Q}[\tau]$, $n = 2$, and

$$A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \; B = \begin{pmatrix} \tau & 0 \\ 0 & 1 \end{pmatrix}, \; \psi = \operatorname{Im} \begin{pmatrix} 0 \\ \tau \end{pmatrix}.$$

The submodule ψ is (A, B)-invariant but not (A, B)-feedback-invariant.

For pure submodules the two notions of Definition 2.1 coincide.

PROPOSITION 2.4 (see [14]). *A pure submodule of R^n is (A, B)-invariant if and only if it is (A, B)-feedback-invariant.*

For the next result, which is in contrast to Proposition 1.5 and Example 1.7, we refer to [17], [18], and also to [9].

THEOREM 2.5.

(i) *A submodule ψ of R^n is dynamically (A, B)-feedback-invariant if and only if it is (A, B)-invariant.*

(ii) *If ψ is (A, B)-invariant and $\psi = \operatorname{Im} N$, $N \in R^{n\times t}$, $\operatorname{rank} \psi = t$, then there exists an*

$$F^b = \begin{pmatrix} 0_{n\times n} & F_{12} \\ 0_{t\times n} & F_{22} \end{pmatrix} \in R^{(n+t)\times(n+t)}$$

such that

$$(A_t^e + B_t^e F^b) \operatorname{Im} \begin{pmatrix} N \\ I_t \end{pmatrix} \subseteq \operatorname{Im} \begin{pmatrix} N \\ I_t \end{pmatrix}. \tag{2.5}$$

Proof. We include a proof of (ii), since for Theorem 1.6 we shall need a submodule of the form $\psi^b = \operatorname{Im} \binom{N}{I_t}$. Note that (2.5) holds if

$$\begin{pmatrix} AN + BF_{12} \\ F_{22} \end{pmatrix} = \begin{pmatrix} N \\ I_t \end{pmatrix} T \tag{2.6}$$

for some T. Now (2.3) is equivalent to

$$AN = NS_1 + BS_2 \tag{2.7}$$

for some matrices S_1, S_2, over R. Hence we can take $F_{12} = -S_2$ and $F_{22} = S_1$, and (2.7) yields (2.6) with $T = S_1$. ∎

We have indicated before that (C, A)-invariance is preserved under the closure operation $\mathcal{S}$. In general, a corresponding result is not true for (A, B)-invariance, not even for reachable pairs (A, B).

Example 2.6. Take $R = \mathbb{Z}$. If

$$A = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, B = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}, \phi = \operatorname{Im} \begin{pmatrix} 2 \\ 4 \end{pmatrix},$$

then ϕ is (A, B)-invariant but $\mathcal{S}\,\phi$ is not.

Hautus [13] has characterized (A, B)-invariance by a frequency domain condition, which remains valid over commutative rings. For a submodule μ of R^n let

$$\mu[[s^{-1}]] = \left\{ \sum_{j=0}^{\infty} v_j s^{-j}, \quad v_j \in \mu \right\}$$

be the set of formal power series in s^{-1} over μ.

PROPOSITION 2.7. *A submodule ϕ of R^n is (A, B)-invariant if and only if for each $x \in \phi$ there exists a $\xi(s) \in s^{-1}\phi[[s^{-1}]]$ and a $w(s) \in s^{-1}R^m[[s^{-1}]]$ such that*

$$x = (sI - A)\xi(s) - Bw(s). \tag{2.8}$$

Proof. "⇒" Set $\xi_1 = x$. Then we have $A\xi_1 = \xi_2 - Bw_1$ for some $\xi_2 \in \phi$ and $w_1 \in R^m$ and we can define recursively sequences (ξ_j) and (w_j) such that $\xi_j \in \phi$ and $\xi_{j+1} = A\xi_j + Bw_j$, $j \geq 1$. If we set

$$\xi(s) = \xi_1 s^{-1} + \xi_2 s^{-2} + \cdots \quad \text{and} \quad w(s) = w_1 s^{-1} + w_2 s^{-2} + \cdots, \tag{2.9}$$

we obtain (2.8).

"⇐" Now assume (2.8) and (2.9). Then $x = \xi_1$ and $0 = -A\xi_1 + \xi_2 - Bw_1$ yield $Ax \in \phi + \operatorname{Im} B$. ∎

It would be of interest to know whether (C, A)-invariance can be characterized in a similar way. Based on the matrix

$$\begin{pmatrix} sI - A \\ C \end{pmatrix}$$

such a frequency domain description could lead to a computable criterion for (C, A)-invariance.

3. Criteria for pure submodules. Our main objective in this section is the proof of Theorem 1.6. We begin with a technical result.

LEMMA 3.1. *If $\phi^e \in E(\phi)$, then*

$$\mathcal{S}\,\mathcal{P}\big[(\phi^e)^\perp\big] = \phi^\perp. \tag{3.1}$$

Proof. Because of (6.1) we have

$$\mathcal{S}\big[(\phi^e)^\perp + (R^n \oplus 0)^\perp\big] = \big(\phi^e \cap (R^n \oplus 0)\big)^\perp = \phi^\perp \oplus R^q,$$

and we obtain

$$\mathcal{S}\,\mathcal{P}\big[(\phi^e)^\perp\big] = \mathcal{S}\,\mathcal{P}\big[(\phi^e)^\perp + (R^n \oplus 0)^\perp\big] = \mathcal{S}\,\mathcal{P}\big[\mathcal{S}\big((\phi^e)^\perp + (R^n \oplus 0)^\perp\big)\big] = \phi^\perp. \qquad ∎$$

Proof of Theorem 1.6. First assume that ϕ is dynamically (C, A)-injection-invariant. Let $\phi^e \in E(\phi, q)$ and K^e be such that

$$(A^e + K^e C^e)\phi^e \subseteq \phi^e. \tag{3.2}$$

Then $(A^{eT} + C^{eT} K^{eT})\phi^{e\perp} \subseteq \phi^{e\perp}$ implies

$$A^T \mathcal{P}(\phi^{e\perp}) \subseteq \mathcal{P}(\phi^{e\perp}) + \operatorname{Im} C^T.$$

Hence the submodule $\mathcal{P}(\phi^{e\perp})$ is (A^T, C^T)-invariant and because of (3.1) it is of rank $n - r$.

To prove the converse we have a submodule $\hat{\phi}$ of $\phi^\perp$ at our disposal that is (A^T, C^T)-invariant and has rank $n - r$. Then $\hat{\phi} = \operatorname{Im} N$ with $N \in R^{n\times(n-r)}$ and $\operatorname{Ker} N = 0$. Define $\hat{\phi}^b = \operatorname{Im} \binom{N}{I_{n-r}}$ and $\phi^e = (\hat{\phi}^b)^\perp$. Then

$$\phi^e = \operatorname{Im} \begin{pmatrix} I_n \\ -N^T \end{pmatrix} \in E(\phi, n - r).$$

Take $q = n - r$ in (1.5). From Theorem 2.5(ii) we know that there exists a matrix K^b such that

$$(A^{eT} + C^{eT} K^{bT})\hat{\phi}^b \subseteq \hat{\phi}^b.$$

Hence

$$(A^e + K^b C^e)\phi^e \subseteq \phi^e, \quad \phi^e \in E(\phi),$$

which shows that ϕ is dynamically (C, A)-injection-invariant. □

Corollary 3.2. *Let ϕ be a pure submodule of R^n. If*

$$A^T \phi^\perp \subseteq \phi^\perp + \mathcal{S}(\operatorname{Im} C^T), \tag{3.3}$$

or if

$$A \operatorname{Ker} C \subseteq \phi, \tag{3.4}$$

then ϕ is dynamically (C, A)-injection-invariant.

Proof. Let $\lambda \in R$, $\lambda \neq 0$, be such that $\lambda \mathcal{S}(\operatorname{Im} C^T) \subseteq \operatorname{Im} C^T$. Then $\operatorname{rank} \lambda\phi^\perp = n - r$ and (3.3) implies that $\lambda\phi^\perp$ is (A^T, C^T)-invariant. Note that $(\operatorname{Ker} C)^\perp = \mathcal{S}(\operatorname{Im} C^T)$. Hence (3.4) yields $A^T \phi^\perp \subseteq \mathcal{S}(\operatorname{Im} C^T)$, which is a special case of (3.3). □

The following example shows that condition (3.3) is sufficient but not necessary for dynamic (C, A)-injection-invariance.

Example 3.3. Consider $R = \mathbb{Q}[\tau]$ and

$$A = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, C = \begin{pmatrix} \tau & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \phi = \operatorname{Im} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}.$$

Take $q = 2$ and $\phi^e = \operatorname{Im} M^e$, where

$$M^e = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & \tau & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Then $\phi^e \in E(\phi, 2)$. For

$$K^e = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

we obtain

$$\operatorname{Im}(A^e + K^e C^e) M^e = \operatorname{Im} \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 & 0 \\ \tau & 1 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix} M^e = \operatorname{Im} \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \\ \tau & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \subseteq \operatorname{Im} M^e.$$

Hence ϕ is dynamically (C, A)-injection-invariant. As far as condition (3.3) is concerned we note that

$$\phi^\perp = \operatorname{Im} \begin{pmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{pmatrix} = \operatorname{Im}(e_2,\, e_3).$$

Now $A^T e_3 = (1, 0, 0)^T \in \phi^\perp + \mathcal{S}(\operatorname{Im} C^T)$ would mean

$$\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 & \tau & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \\ a_3 \\ a_4 \end{pmatrix}$$

for some $a_j \in R = \mathbb{Q}[\tau]$. But $\tau a_3 = 1$ is impossible in R. Hence ϕ is a submodule which does not satisfy (3.3).

4. Bases and matrices. A nonsingular matrix $U \in R^{n\times n}$ is called unimodular if $U^{-1} \in R^{n\times n}$. Let us say that there exists a basis of $R^{n\times n}$ such that $\phi = \operatorname{Im} M$ if there exists a unimodular U such that $U \operatorname{Im} M = \phi$. We first describe transformations of A, C, ϕ that preserve the three types of (C, A)-invariance.

LEMMA 4.1. *Let $U \in R^{n\times n}$ and $V \in R^{l\times l}$ be unimodular. Set*

$$\tilde{A} = U^{-1} A U,\ \tilde{C} = VCU,\ \tilde{\phi} = U^{-1}\phi. \tag{4.1}$$

The submodule ϕ is dynamically (C, A)-injection-invariant of order q if and only if $\tilde{\phi}$ is dynamically $(\tilde{C}, \tilde{A})$-injection-invariant of the same order.

Proof. Assume $\phi = \operatorname{Im} M$, $M \in R^{n\times r}$, and set $\tilde{M} = U^{-1}M$. Then $\tilde{\phi} = \operatorname{Im} \tilde{M}$. Let $K^e \in R^{(n+q)\times(l+q)}$ and

$$M^e = \begin{pmatrix} M_1^e \\ M_2^e \end{pmatrix} \in R^{(n+q)\times r}$$

be such that $\operatorname{Im}(A^e + K^e C^e) M^e \subseteq \operatorname{Im} M^e$ and $\operatorname{Im} M^e \in E(\phi, q)$, i.e., $\operatorname{Im} M = M_1^e \operatorname{Ker}(M_2^e)$. Now define

$$\tilde{K}^e = \begin{pmatrix} U^{-1} & 0 \\ 0 & I_q \end{pmatrix} K^e \begin{pmatrix} V^{-1} & 0 \\ 0 & I_q \end{pmatrix}$$

and

$$\tilde{M}^e = \begin{pmatrix} \tilde{M}_1^e \\ \tilde{M}_2^e \end{pmatrix} = \begin{pmatrix} U^{-1} & 0 \\ 0 & I_q \end{pmatrix} M^e.$$

Then $\operatorname{Im}(\tilde{A}^e + \tilde{K}^e\tilde{C}^e)\tilde{M}^e \subseteq \operatorname{Im} \tilde{M}^e$ and $\operatorname{Im} \tilde{M} = \tilde{M}_1^e \operatorname{Ker}(\tilde{M}_2^e)$. □

It is obvious that a corresponding statement is true for (C, A)-invariance. It will be convenient to choose a suitable basis of R^n such that conditon (1.2) can be expressed in terms of blocks of a corresponding matrix representation of A and C.

LEMMA 4.2. *There exists a basis of R^n such that*

$$\phi \cap \operatorname{Ker} C = \operatorname{Im} \begin{pmatrix} D_1 \\ 0_{(r-k)\times k} \\ 0_{(n-r)\times k} \end{pmatrix}, \quad D_1 \in R^{k\times k}, \det D_1 \neq 0, \tag{4.2}$$

and

$$\phi = \operatorname{Im} \begin{pmatrix} D_1 & D_{12} \\ 0 & D_2 \\ 0 & 0 \end{pmatrix}, \quad D_2 \in R^{(r-k)\times(r-k)}, \det D_2 \neq 0. \tag{4.3}$$

If C is partitionend according to (4.3), *then*

$$C = (0 \quad C_2 \quad C_3), \quad C_2 \in R^{l\times(r-k)}, \quad \operatorname{Ker} C_2 = 0, \tag{4.4}$$

and

$$VC_2 = \begin{pmatrix} \tilde{C}_2 \\ 0 \end{pmatrix}, \ \tilde{C}_2 \in R^{(r-k)\times(r-k)}, \ \det \tilde{C}_2 \neq 0 \tag{4.5}$$

for some unimodular V.

A basis of R^n can be chosen in such a way that

$$\mathcal{S}\,\phi = \operatorname{Im} \begin{pmatrix} I_k & 0 \\ 0 & I_{r-k} \\ 0 & 0 \end{pmatrix}, \tag{4.6}$$

and

$$\mathcal{S}\,\phi \cap \operatorname{Ker} C = \operatorname{Im} \begin{pmatrix} I_k \\ 0 \\ 0 \end{pmatrix}. \tag{4.7}$$

If $A(\phi \cap \operatorname{Ker} C) \subseteq \phi$, then

$$A = \begin{pmatrix} A_{11} & A_{12} & A_{13} \\ 0 & A_{22} & A_{23} \end{pmatrix}, \ A_{11} \in R^{r\times k}, \tag{4.8}$$

and

$$\operatorname{Im} A_{11}D_1 \subseteq \operatorname{Im} \begin{pmatrix} D_1 & D_{12} \\ 0 & D_2 \end{pmatrix}. \tag{4.9}$$

If $\phi = \mathcal{S}\,\phi$, then (4.9) *is trivially satisfied.*

Proof. Since $\mathrm{Ker}C$ is a pure submodule there is a basis of R^n such that $\mathrm{Ker}C = \mathrm{Im}\binom{I_p}{0}$. We can modify this basis in such a way that $\phi = \mathrm{Im}\, M$ with

$$M = \begin{pmatrix} M_1 \\ M_2 \\ 0 \end{pmatrix} \in R^{n\times r},\ M_1 \in R^{p\times r},\ M_2 \in R^{t\times r},$$

where M_2 has full row rank. In particular, we can choose M_2 such that $M_2 = (0 \quad M_{22})$, $M_{22} \in R^{t\times t}$, $\det M_{22} \neq 0$. Hence

$$M = \begin{pmatrix} M_{11} & M_{12} \\ 0 & M_{22} \\ 0 & 0 \end{pmatrix},$$

and we obtain

$$\phi \cap \mathrm{Ker}C = \left\{ M\begin{pmatrix} x \\ y \end{pmatrix},\ M_{22}y = 0 \right\} = \left\{ M\begin{pmatrix} x \\ y \end{pmatrix},\ y = 0 \right\} = \mathrm{Im} \begin{pmatrix} M_{11} \\ 0 \\ 0 \end{pmatrix}.$$

Since M_{11} has full column rank we have

$$\text{column rank}(M_{11}) = k = \mathrm{rank}(\phi \cap \mathrm{Ker}C).$$

A suitable change of basis of R^n yields $M_{11} = \binom{D_1}{0}$ with D_1 as in (4.2), which implies (4.3). The remaining parts of the lemma are easy to verify. □

We now characterize extensions of submodules in terms of matrices. Let $\phi \subseteq R^n$ be given as

$$\phi = \mathrm{Im}\, M,\ M = \begin{pmatrix} D \\ 0 \end{pmatrix},\ D \in R^{r\times r},\ \det D \neq 0.$$

Consider $\phi^e \in E(\phi, q)$ with

$$\phi^e = \mathrm{Im}\, M^e = \mathrm{Im} \left(\begin{array}{c} M_1 \\ M_2 \\ \hline M_3 \end{array}\right) \in R^{[r+(n-r)+q]\times t}$$

and

$$\mathrm{Ker}\, M^e = 0. \tag{4.10}$$

Then $\phi^e \in E(\phi, q)$ is equivalent to

$$\mathrm{Im} \begin{pmatrix} D \\ 0 \end{pmatrix} = \begin{pmatrix} M_1 \\ M_2 \end{pmatrix} \mathrm{Ker}\, M_3. \tag{4.11}$$

We can assume $M_3 = (0_{\rho\times\rho}, M_{32})$, $\mathrm{Ker}\, M_{32} = 0$. Then (4.11) yields $M_2 = (0_{(n-r)\times\rho}, M_{22})$. If $M_1 = (M_{11}\, M_{12})$ is partitioned accordingly, then (4.11) is equivalent to $\mathrm{Im}\, D = \mathrm{Im}\, M_{11}$. Hence we have $\rho \geq r$. Now $M_{11} \in R^{r\times\rho}$ and (4.10) imply $\rho = r$. We can take $M_{11} = D$ and conclude that $\phi^e \in E(\phi)$ if and only if $\phi^e = \mathrm{Im}\, M^e$ for some M^e of the form

$$M^e = \left(\begin{array}{cc} D & N \\ 0 & P \\ \hline 0 & Q \end{array}\right),\ \mathrm{Ker}\, Q = 0. \tag{4.12}$$

If $\phi = \mathcal{S}\,\phi$, then $M = \binom{I_r}{0}$ and we can choose $N = 0$ in (4.12) such that

$$M^e = \left(\begin{array}{cc} I_r & 0 \\ 0 & P \\ \hline 0 & Q \end{array}\right). \tag{4.13}$$

5. Criteria for nonpure submodules. In this section we shall first give a proof of Proposition 1.5 and then present results on submodules that are not pure.

Proof of Proposition 1.5. Assume $A^e + K^e C^e \in R^{(n+q)\times(n+q)}$ and

$$\operatorname{Im}(A^e + K^e C^e) M^e \subseteq \operatorname{Im} M^e \tag{5.1}$$

for some

$$K^e = \begin{pmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{pmatrix} \in R^{(n+q)\times(l+q)},$$

and $M^e = \binom{P}{Q}$, $Q \in R^{q\times r}$, with $\operatorname{Im} M^e \in E(\phi, q)$. From (5.1) follows

$$(A + K_{11}C)P + K_{12}Q = PT, \tag{5.2}$$

$$K_{21}CP + K_{22}Q = QT \tag{5.3}$$

for some $T \in R^{r\times r}$. We have to show that $y \in \phi \cap \operatorname{Ker} C$ implies $Ay \in \phi$. Because of $\operatorname{Im}\binom{P}{Q} \in E(\phi, q)$ we have $y = Pw$ for some w with $Qw = 0$. Then (5.2), (5.3), and $Cy = 0$ yield $APw = PTw$, $QTw = 0$. Hence $Ay = PTw \in \phi$. □

Examining the preceding proof we find that a slightly more general result is true. Namely, if K^e is a matrix over $R[1/d]$ for some $d \in R$, $d \neq 0$, and if the elements of $A^e + K^e C^e$ are in R, then (1.6) implies (C, A)-invariance of ϕ. We also note that in Example 1.2 a weaker form of injection-invariance can be achieved with an observer matrix K over the ring $\mathbb{Q}[\tau, 1/\tau]$. It can be an advantage to embed R into a larger ring $R[1/d]$, e.g., in order to solve coefficient assignment problems [1]. We shall use that approach below. The following definition will be needed. For a submodule η of R^l with $\operatorname{rank}\eta = t$ and invariant factors $f_t \mid \cdots \mid f_1$, define $\Delta(\eta) = f_1$. Note that the submodule η is pure if and only if $\Delta(\eta) = 1$.

PROPOSITION 5.1. *Set $d = \Delta(C\phi)$. The submodule ϕ is (C, A)-invariant if and only if there exists a matrix $K \in R[1/d]^{n\times l}$ such that $A + KC \in R^{n\times n}$ and $(A + KC)\phi \subseteq \phi$.*

Proof. For the "if" part we refer to the remark on the proof of Proposition 1.5. For the "only if" part, assume ϕ as in Lemma 4.2 such that

$$C = \begin{pmatrix} 0 & \tilde{C}_2 & * \\ 0 & 0 & * \end{pmatrix}, \quad \tilde{C}_2 \in R^{(r-k)\times(r-k)},\ \det \tilde{C}_2 \neq 0.$$

We know that $A(\phi \cap \operatorname{Ker} C) \subseteq \phi$ implies

$$A = \begin{pmatrix} A_{11} & A_{12} & * \\ 0 & A_{22} & * \end{pmatrix}$$

and (4.9). Then

$$C\phi = \operatorname{Im}\begin{pmatrix} \tilde{C}_2 D_2 \\ 0 \end{pmatrix}.$$

Using the Smith form it is easy to see that the elements of $(\tilde{C}_2 D_2)^{-1}$ are in $R[1/d]$. Therefore, it is possible to choose

$$K = \begin{pmatrix} K_{11} & * \\ K_{21} & * \end{pmatrix} \in R[1/d]^{r+(n-r)\times(k+(l-k))}$$

in such a way that

$$A_{11}D_{12} + (A_{12} + K_{11}\tilde{C}_2)D_2 = 0 \quad \text{and} \quad (A_{22} + K_{21}\tilde{C}_2)D_2 = 0.$$

Hence K has the desired properties. □

We know from Proposition 2.4 that for pure submodules (A, B)-invariance is equivalent to (A, B)-feedback invariance. The corresponding result for (C, A)-invariance involves the submodule $C\phi$.

COROLLARY 5.2. *If $C\phi$ is a pure submodule, then ϕ is (C, A)-invariant if and only if ϕ is (C, A)-injection-invariant.*

The next proposition again deals with (C, A)-injection-invariance.

PROPOSITION 5.3. *Let ϕ be a (C, A)-invariant submodule that satisfies*

$$C\,\mathcal{S}(\phi) = \mathcal{S}(C\phi). \tag{5.4}$$

If

$$\phi = (\phi \cap \operatorname{Ker} C) + (\phi \cap \operatorname{Im} C^T), \tag{5.5}$$

in particular if $\phi = \mathcal{S}\,\phi$, then ϕ is (C, A)-injection-invariant.

Proof. Let ϕ, $\mathcal{S}\,\phi$ and C be given by (4.3), (4.6), and (4.4). Because of $C\,\mathcal{S}(\phi) = \operatorname{Im} C_2$ and (5.4) we can assume

$$C_2 = (I_{r-k}\ 0)^T \tag{5.6}$$

in $C = (0\ C_2\ C_3)$. Then

$$\operatorname{Im} C^T = \operatorname{Im} \begin{pmatrix} 0 \\ I_{r-k} & 0 \\ C_3^T \end{pmatrix}$$

and (5.5) imply $\phi = \operatorname{Im} M$ with

$$M = \begin{pmatrix} D_1 & 0 \\ 0 & D_2 \\ 0 & 0 \end{pmatrix}. \tag{5.7}$$

Recall that in the given setting (C, A)-invariance of ϕ is equivalent to (4.8) and (4.9). Because of (5.7) we have (4.9) in the form

$$\operatorname{Im} A_{11}D_1 \subseteq \operatorname{Im} \begin{pmatrix} D_1 & 0 \\ 0 & D_2 \end{pmatrix}. \tag{5.8}$$

Let

$$K = \begin{pmatrix} K_1 \\ K_2 \end{pmatrix}$$

be partitioned conforming to A in (4.8). Then

$$(A + KC)M = \begin{pmatrix} A_{11} & A_{12} + K_1C_2 \\ 0 & A_{22} + K_2C_2 \end{pmatrix} \begin{pmatrix} D_1 & 0 \\ 0 & D_2 \end{pmatrix}.$$

Because of (5.6) we can choose K_1 and K_2 in such a way that $A_{i2} + K_iC_2 = 0$, $i = 1, 2$. Then (5.8) implies $\operatorname{Im}(A + KC)M \subseteq \operatorname{Im} M$, which proves (C, A)-injection-invariance. □

We now extend Theorem 1.6 to submodules ϕ where all invariant factors are equal.

THEOREM 5.4. *Let $\phi \subseteq R^n$ be a submodule of rank r that is isomorphic to $dR \oplus \cdots \oplus dR$. Then ϕ is dynamically (C, A)-injection-invariant if and only if $\phi^\perp$ contains an (A^T, C^T)-invariant submodule of rank $n - r$.*

Proof. "⇐" We can assume

$$\phi = \operatorname{Im} \begin{pmatrix} dI_r \\ 0 \end{pmatrix}.$$

Then $\mathcal{S}\,\phi = \binom{I_r}{0}$. Because of $(\mathcal{S}\,\phi)^\perp = (\phi)^\perp$ we see from Theorem 1.6 that $\mathcal{S}\,\phi$ is dynamically (C, A)-injection-invariant. Let $(\mathcal{S}\,\phi)^e \in E(\phi, q)$ and K^e be such that

$$(A^e + K^eC^e)(\mathcal{S}\,\phi)^e \subseteq (\mathcal{S}\,\phi)^e.$$

By (4.13) we have

$$(\mathcal{S}\,\phi)^e = \operatorname{Im} \begin{pmatrix} I_r & 0 \\ 0 & P \\ 0 & Q \end{pmatrix}, \ \operatorname{Ker} Q = 0,$$

for some P and Q. Hence $\phi^e = d(\mathcal{S}\,\phi)^e \in E(\phi, q)$ and $(A^e + K^eC^e)\phi^e \subseteq \phi^e$.

"⇒" Since $\mathcal{S}\,\phi$ together with ϕ is dynamically (C, A)-injection-invariant we can use Theorem 1.6 again and complete the proof. □

6. Appendix on pure submodules and closure. According to Kaplanski [20] the concept of pure submodules can be attributed to Prüfer (1923). It has been introduced in systems theory by Conte and Perdon [7]. In this section we collect some basic facts on pure submodules and a related closure operator, for which we refer to [4], [27], [7], [22], [24]. The terminology is not uniform. Sometimes pure submodules are called saturated, e.g., in [27] and [24], or closed, e.g., in [9] and [22]. As before we are dealing with a PID R and submodules of $V := R^n$. Let $L(V)$ be the lattice of submodules of V.

DEFINITION 6.1. *For $\phi \in L(V)$ set*

$$\mathcal{S}\,\phi = (\phi^\perp)^\perp.$$

The submodule ϕ is called pure if $\phi = \mathcal{S}\,\phi$.

The mapping $\phi \mapsto \mathcal{S}\,\phi$ is a closure operator on $L(V)$ such that (i) $\phi \subseteq \psi$ implies $\mathcal{S}\,\phi \subseteq \mathcal{S}\,\psi$, (ii) $\phi \subseteq \mathcal{S}\,\phi$, and (iii) $S(S\phi) = S\phi$.

LEMMA 6.2.

(i) *The closure $\mathcal{S}\,\phi$ is the smallest pure submodule of V containing ϕ. We have*

$$\mathcal{S}\,\phi = \{x \in V \mid \alpha x \in \phi \text{ for some } \alpha \in R,\ \alpha \neq 0\}.$$

(ii) *Let the columns of $M \in R^{n\times r}$ be a basis of ϕ. Let $f_r \mid \cdots \mid f_1$ be the invariant factors of ϕ such that*

$$\Sigma = \begin{pmatrix} \operatorname{diag}(f_r, \dots, f_1) \\ 0 \end{pmatrix}$$

is the Smith form of M. If U and W are unimodular and $M = U\Sigma W$, then $\phi = \operatorname{Im} U\Sigma$ and $\mathcal{S}\,\phi = \operatorname{Im} U(I_r\ 0)^T$.

(iii) $\operatorname{rank} \mathcal{S}\,\phi = \operatorname{rank} \phi$.

(iv) $\mathcal{S}(\phi^\perp) = \phi^\perp$.

We include a proof of the identity (6.1) below.

LEMMA 6.3. *For submodules μ and θ we have*

$$\mathcal{S}(\mu) \cap \mathcal{S}(\theta) = \mathcal{S}(\mu \cap \theta).$$

The intersection of pure submodules is pure. Furthermore,

$$\mathcal{S}(\mu^\perp + \theta^\perp) = (\mu \cap \theta)^\perp. \tag{6.1}$$

Proof. For $\pi, \rho \in L(V)$ we have

$$(\pi + \rho)^\perp = \pi^\perp \cap \rho^\perp.$$

Taking $\pi = \mu^\perp$ and $\rho = \theta^\perp$ we obtain

$$(\mu^\perp + \theta^\perp)^\perp = \mathcal{S}(\mu) \cap \mathcal{S}(\theta),$$

which implies

$$\mathcal{S}(\mu^\perp + \theta^\perp) = [\mathcal{S}(\mu) \cap \mathcal{S}(\theta)]^\perp = [\mathcal{S}(\mu \cap \theta)]^\perp = (\mu \cap \theta)^\perp. \qquad \square$$

Over PIDs several different ways to characterize pure submodules are known.

LEMMA 6.4. *For $\phi \in L(V)$ the following statements are equivalent.*

(i) *ϕ is a pure submodule.*

(ii) *ϕ is a direct summand of V.*

(iii) *$\phi \cap \alpha V = \alpha\phi$ for all $\alpha \in R$.*

(iv) *All invariant factors of ϕ are 1.*

(v) *V/ϕ is torsion-free.*

Acknowledgment. We would like to thank D. Flockerzi for a valuable comment.

APPROXIMATION AND LIMIT RESULTS FOR NONLINEAR FILTERS OVER AN INFINITE TIME INTERVAL: PART II, RANDOM SAMPLING ALGORITHMS*

AMARJIT BUDHIRAJA† AND HAROLD J. KUSHNER‡

Abstract. The paper is concerned with approximations to nonlinear filtering problems that are of interest over a very long time interval. Since the optimal filter can rarely be constructed, one needs to compute with numerically feasible approximations. The signal model can be a jump-diffusion, reflected or not. The observations can be taken either in discrete or continuous time. The cost of interest is the pathwise error per unit time over a long time interval. In a previous paper of the authors [A. Budhiraja and H.J. Kushner, *SIAM J. Control Optim.*, 37 (1999), pp. 1946–1979], it was shown, under quite reasonable conditions on the approximating filter and on the signal and noise processes that as time, bandwidth, process and filter approximation, etc. go to their limit in any way at all, the limit of the pathwise average costs per unit time is just what one would get if the approximating processes were replaced by their ideal values and the optimal filter was used. When suitable approximating filters cannot be readily constructed due to excessive computational requirements or to problems associated with a high signal dimension, approximations based on random sampling methods (or, perhaps, combinations of sampling and analytical methods) become attractive, and are the subject of a great deal of attention. The work of the previous paper is extended to a wide class of such algorithms. Under quite broad conditions, covering virtually all the cases considered to date, it is shown that the pathwise average errors converge to the same limit that would be obtained if the optimal filter was used, as time goes to infinity and the approximation parameter goes to its limit in any way at all. All the extensions (e.g., wide bandwidth observation or system driving noise) in [A. Budhiraja and H.J. Kushner, *SIAM J. Control Optim.*, 37 (1999), pp. 1946–1979] hold for our random sampling algorithms as well.

Key words. nonlinear filters, numerical approximations to nonlinear filters, robustness of filters, infinite time filtering, occupation measures, pathwise average errors, random sampling algorithms

1. Introduction.

This paper is an extension of the work in [3], which was concerned with the performance of a wide variety of approximations to optimal nonlinear filters over very long time intervals, where *pathwise average* errors are of interest. Let us first briefly review the motivation for that paper. Suppose that the underlying signal model is a diffusion or jump-diffusion $X(\cdot)$ (reflected or not), or a discrete time Markov chain, with white noise corrupted observations, and the dynamics and/or the observation function are nonlinear. Then, except for some few examples, one cannot construct "finite" or computable optimal filters, and some type of approximation must be used.

A very common approximation method starts by approximating the process $X(\cdot)$ by a simpler process $\tilde{X}^h(\cdot)$ for which the optimal nonlinear filter can be constructed, and then uses that filter but with the observations being those on the actual physical process $X(\cdot)$. For example, $\tilde{X}^h(\cdot)$ might be a discretized (in state and/or in time)

form of $X(\cdot)$. It is such that, as $h \to 0$, $\tilde{X}^h(\cdot)$ converges weakly to $X(\cdot)$. Let $\Pi^h(\cdot)$ denote the actual approximating filter. For each h, it is a measure valued process, and $\Pi^h(\cdot)$ converges weakly to the true conditional distribution process as $h \to 0$, i.e., the computed expectations of any bounded and continuous function converge to the true conditional expectation [25, 23]. However, if the filter is to be used over a very long interval $[0, T]$, the most appropriate errors are often the *pathwise average* (rather than the mathematical expectation) errors per unit time, for whatever definition of "error" that is appropriate. This is the case since we work with only one long path, and the mathematical expectation over all paths might not be a useful indicator of the quality of the approximation. For specificity in this introduction, let us define the average pathwise cost or error on $[0, T]$ to be

$$G^{h,T}(\phi) = \frac{1}{T}\int_0^T f(\phi(X(t)) - \langle \Pi^h(t), \phi\rangle)dt, \tag{1.1}$$

where $\phi(\cdot)$ is a bounded and continuous function and $f(\cdot)$ is an arbitrary continuous function. Our results cover much more general forms of the cost or error function.

Now there are two parameters h and T. The convergence of the filter process $\Pi^h(\cdot)$ over any fixed finite interval says nothing about the behavior of the pathwise average errors as $h \to 0$ and $T \to \infty$ arbitrarily. Under reasonable conditions, it was shown in [3] that the pathwise errors converge in probability to an optimal deterministic limit, and this limit is exactly what one would get for the limit of the mathematical expectation $EG^{h,T}(\phi)$ if the *true optimal filter* was used instead of $\Pi^h(t)$. This is an ideal result. The convergence is independent of how $h \to 0$ or $T \to \infty$. For applications, it is important that h and T be allowed to go to their limits in an arbitrary way.

The reference [3] actually dealt with a much more general setup. The signal process was allowed to be not necessarily a diffusion but a process (possibly driven by wide bandwidth noise), which converges weakly to a diffusion as some parameter converges to its limit (e.g., the noise bandwidth goes to infinity). Wide bandwidth observation noise was also allowed. The case where the observations are taken in discrete time was also covered.

We also note the reference [25], where the pathwise average error was replaced by the expectation of the pathwise average error. In [18], the asymptotics of the filter alone were dealt with, and it was presumed that the filter was the true optimal filter, not an approximation.

We now turn to the description of this paper. In [3], the approximate filter was that for an approximating process $\tilde{X}^h(\cdot)$ but with the actual physical observations on $X(\cdot)$ used. One common and convenient example is the Markov chain approximation method, where the approximating process $\tilde{X}^h(\cdot)$ is a continuous time interpolation of a Markov chain [24, 23]. When the dimension is larger than three or four, such methods can have excessively high computational requirements. Alternatives based on random sampling or Monte Carlo then become attractive, analogous to the case of classical multidimensional integration. The topic is of considerable current interest, e.g., [5, 6, 7, 12, 13, 15, 16, 27, 28, 29]. Such methods are also of interest when the transition probabilities are very hard to compute, e.g., in discrete time problems, where the signal is the output of a system with very complex dynamics, but which can be conveniently simulated. All of the issues in [3] (which were mentioned above) arise here as well, in addition to the potentially serious errors due to the random sampling and the very large time intervals. Owing to the sampling errors as well as to the other (computational and modeling) approximations that are made in the filter

and signal processes, it is conceivable that the long term pathwise average errors per unit time will be large, even with approximations that would perform well over some bounded time interval.

This paper extends the results in [3] to such sampling based algorithms. To distinguish the algorithms in [3] from those of this paper, we refer to the former as *integration* algorithms, since the conditional distributions are computed using integrations or summations over the distributions of the approximating processes. One must keep in mind that random sampling based filters usually require a large number of samples if they are to work well.

Appropriate analogues of the occupation measure methods in [3] are employed for the proofs. Section 2 provides the standard background for the filtering problem in continuous time. Section 3 discusses the formulation of the limit problem for the continuous time case in terms of occupation measures and states a main result from [3] which will be used. Section 4 repeats this for the discrete time problem. In order to effectively exploit the past results, the problem is set up in such a way that the proofs are close to those for the "integration" algorithms of [3]. Thus only the differences in the proofs will be presented. In preparation for this, the structure of the proof in [3] is briefly outlined, and the points where there will be a difference are noted. A fundamental assumption in [3] is the *consistency* assumption which quantifies the convergence of the computational approximating process $\tilde{X}^h(\cdot)$ to $X(\cdot)$ as $h \to 0$. This is A4.1 here. It will be weakened in several ways, depending on the form of the random sampling algorithm.

Section 5 concerns a variety of forms of the sampling algorithms in discrete time. The simplest form is based on a pure random sampling of an approximating process $\tilde{X}^h(\cdot)$. The part of the convergence proof which differs from that in [3] is given. The basic scheme can be generalized in many ways. The standard variance reduction methods such as antithetic variables and stratified sampling can be used. Combinations of integration and sampling methods are often of great use, since it might be most convenient to simulate some parts of the problem but to use "integrations" over distributions of approximating processes in others. See Examples 5.6 and 5.7 in section 5. In order to cover all of the above cases, we reformulate the consistency condition so that it holds for all the above examples and in fact covers quite general algorithms. Section 6 concerns the use of importance sampling methods for the discrete time problem [5, 10, 29]. The standard form is discussed. But the most interesting form is where the measure change depends on the next observation, which is thus used to guide the simulation on the current time interval. Some such algorithms were used in [5, 29], as well as by the authors. The proofs for all of these cases differ only slightly from that given for the basic example in section 5, and thus only the differences are discussed. Finally, in section 7 we study the continuous time analogues of the various random sampling and combined random sampling-integration algorithms studied in sections 5 and 6. We begin by indicating the form of the approximating filter for the case where the random samples are mutually independent and identically distributed (i.i.d.). We then consider a general form of the approximating filter which covers not only the case of such i.i.d. samples but also various variance reduction schemes and importance sampling algorithms of the type studied for discrete time problems in sections 5 and 6.

2. Background: The optimal filter and numerical approximations: Continuous time. The optimal filter is in continuous time. For simplicity and specificity

and until further notice, suppose that the signal process is the $\mathbb{R}^r$ valued diffusion

$$dX = p(X)dt + \sigma(X)dW, \tag{2.1}$$

where $W(\cdot)$ is a standard vector-valued Wiener process and $p(\cdot)$ and $\sigma(\cdot)$ are continuous. We suppose that the solution is unique in the weak sense for each initial condition. Furthermore, suppose throughout that there is a compact set G such that $X(t) \in G$ for all t if $X(0) \in G$, and we always let $X(0) \in G$. All probability measures (random or not) on $\mathbb{R}^r$ considered hereafter will be assumed to have their support contained in G. The observation process is

$$Y(t) = \int_0^t g(X(s))ds + B(t), \tag{2.2}$$

where $g(\cdot)$ is a continuous vector-valued function and $B(\cdot)$ is a standard vector-valued Wiener process, independent of $W(\cdot)$ and $X(0)$.

As pointed out in [3], the approximation and limit results proved there continue to hold, with minor changes in the proofs, for the case where the signal process is a jump-diffusion or is a reflecting diffusion with appropriate conditions on the reflection direction. However, for the sake of simplicity, we confine our work to the model (2.1).

Let $\tilde{X}(\cdot)$ be a process satisfying (2.1), and which (loosely speaking) is conditionally independent of $(X(\cdot), W(\cdot), B(\cdot))$ given its initial condition: We formalize this as follows. $\tilde{X}(\cdot)$ is a process satisfying (2.1) (with $W(\cdot)$ replaced by some other Brownian motion) such that there exists a (possibly random) probability measure Π^* on $\mathbb{R}^r$ with the properties that are conditioned on Π^*, $\tilde{X}(\cdot)$ is independent of $(X(\cdot), W(\cdot), B(\cdot))$, and the conditional distribution of $\tilde{X}(0)$ given Π^* is Π^*. We will call Π^* the "random initial distribution" of $\tilde{X}(\cdot)$ (i.e., the distribution of $\tilde{X}(0)$). It will vary depending on the need and will be specified when needed.

For any process $U(\cdot)$, let $U_{a,b}$, $a \le b$, denote the set $\{U(s), a \le s \le b\}$. Let $E_Z f$ denote the expectation of a function f given the data (or σ-algebra) Z. Until further notice, let $\Pi(0)$ denote the distribution of $X(0)$ and $\Pi(t)$ the distribution of $X(t)$ given the data $Y_{0,t}$ and $\Pi(0)$. Define

$$R(\tilde{X}_{0,t}, Y_{0,t}) = \exp\left[\int_0^t g'(\tilde{X}(s))dY(s) - \frac{1}{2}\int_0^t |g(\tilde{X}(s))|^2 ds\right]. \tag{2.3}$$

Using the representation of the optimal filter $\Pi(\cdot)$ as it was originally developed in [20], for each bounded and measurable real-valued function $\phi(\cdot)$, we can define the evolution of the optimal filter by

$$\int \phi(x)\Pi(t)(dx) \equiv \langle \Pi(t), \phi\rangle = \frac{E_{\{\Pi(0), Y_{0,t}\}}[\phi(\tilde{X}(t))R(\tilde{X}_{0,t}, Y_{0,t})]}{E_{\{\Pi(0), Y_{0,t}\}}R(\tilde{X}_{0,t}, Y_{0,t})}. \tag{2.4}$$

The notation $E_{\{\Pi(0), Y_{0,t}\}}$ denotes the expectation conditioned on the data $Y_{0,t}$ and on $\Pi(0)$ being the initial distribution of $\tilde{X}(\cdot)$ (i.e., $\Pi(0)$ is the current value of what we generically called Π^* above). This representation is convenient for our purposes and is equivalent to the forms used subsequently which were based on measure transformations, as in [8, 14, 26].

The Markov property of $X(\cdot)$ implies that the filter defined by (2.4) satisfies the semigroup relation

$$\langle \Pi(t), \phi\rangle = \frac{E_{\{\Pi(t-s), Y_{t-s,t}\}}[\phi(\tilde{X}(s))R(\tilde{X}_{0,s}, Y_{t-s,t})]}{E_{\{\Pi(t-s), Y_{t-s,t}\}}R(\tilde{X}_{0,s}, Y_{t-s,t})},\ 0 < s \le t. \tag{2.5}$$

In (2.5), $\Pi(t-s)$ is the random initial distribution of $\tilde{X}(\cdot)$. Throughout the paper, we use the notation $E_{\{\Pi(a),Y_{a,b}\}}F(\tilde{X}_{0,s},Y_{a,b})$ for the conditional expectation, given the data $\{Y_{a,b},\Pi(a)\}$ and where the random initial distribution for $\tilde{X}(\cdot)$ is $\Pi(a)$. The analogous notation will be used when approximations to $\tilde{X}(\cdot)$ are used.

An approximating filter. Except for some special cases, $\Pi(t)$ is very hard to compute for nonlinear problems, and thus one must use some type of approximation. Perhaps the most common method of approximation is to approximate the signal process by a simpler form for which a convenient filter can be constructed. Then the approximate filter is obtained by constructing the filter for that approximating signal process, but using the actual physical observations. For example, the approximating filter might be that for a time and space discretization of the process (2.1). The key mathematical ideas behind such approximations and their convergence properties (over finite time intervals) are in [24], in connection with the Markov chain approximation method, a canonical form of this idea.

Let us formalize the above canonical approximation. Let $\tilde{X}^h(\cdot)$ denote the approximating process, which is used to construct the approximating filter, i.e., the approximating filter is constructed as though the true process was $\tilde{X}^h(\cdot)$, but in this filter, we use the actual physical observations defined by (2.2).

Let $\Pi^h(0)$ be an approximation to the true initial distribution of $X(0)$. The $\tilde{X}^h(\cdot)$ might be a Markov process, e.g., a continuous time Markov chain on a finite state space. More commonly, it is an interpolation of a discrete parameter process: i.e., there is $\delta_h > 0$ which goes to zero as $h \to 0$ such that $\tilde{X}^h(\cdot)$ is constant on the intervals $[n\delta_h, n\delta_h + \delta_h)$ and $\tilde{X}^h(n\delta_h), n = 0, \ldots,$ is Markov. When the signal process is defined in continuous time, we always assume that $\tilde{X}^h(\cdot)$ is of one of these two forms. Furthermore, we always suppose (without loss of generality) that $\tilde{X}^h(t)$ takes values in G.

Define

$$R(\tilde{X}^h_{0,t},Y_{0,t}) = \exp\left[\int_0^t g'(\tilde{X}^h(s))dY(s) - \frac{1}{2}\int_0^t |g(\tilde{X}^h(s))|^2 ds\right]. \tag{2.6}$$

For Markov $\tilde{X}^h(\cdot)$, the approximating filter $\Pi^h(\cdot)$ is defined by

$$\langle \Pi^h(t),\phi\rangle = \frac{E_{\{\Pi^h(0),Y_{0,t}\}}[\phi(\tilde{X}^h(t))R(\tilde{X}^h_{0,t},Y_{0,t})]}{E_{\{\Pi^h(0),Y_{0,t}\}}R(\tilde{X}^h_{0,t},Y_{0,t})}, \tag{2.7}$$

and $\Pi^h(\cdot)$ satisfies the semigroup equation

$$\langle \Pi^h(t+s),\phi\rangle = \frac{E_{\{\Pi^h(t),Y_{t,t+s}\}}[\phi(\tilde{X}^h(s))R(\tilde{X}^h_{0,s},Y_{t,t+s})]}{E_{\{\Pi^h(t),Y_{t,t+s}\}}R(\tilde{X}^h_{0,s},Y_{t,t+s})},\ s>0,\ t\geq 0. \tag{2.8}$$

According to our standard notation, the initial distribution of $\tilde{X}^h(\cdot)$ in (2.6) is $\Pi^h(0)$, and it is $\Pi^h(t)$ in (2.8).

When $\tilde{X}^h(\cdot)$ is piecewise constant with $\tilde{X}^h(n\delta)$ being Markov, then the approximating filter is defined by (2.7) and (2.8), but where t and s are integral multiples of δ, and $\Pi^h(\cdot)$ is constant on the intervals $[n\delta, n\delta+\delta)$. Thus the evolution of $\Pi^h(\cdot)$ can be written in recursive form in general. We see that, by Bayes' rule, (2.7) and (2.8) are filters for the $\tilde{X}^h(\cdot)$ process, but with the actual observations $Y_{n\delta,n\delta+\delta}$ used at step n. The conditions for convergence of this Markov chain approximation method are in [21, 24]. The following is the essential condition.

A2.1. *A consistency assumption.* We assume that for any sequence $\{\Pi^h\}$ of probability measures converging weakly to some probability measure Π, $\tilde{X}^h(\cdot)$ with the initial distribution Π^h converges weakly to $\tilde{X}(\cdot)$ with the initial distribution Π.

By the fact that $X(\cdot)$ is a Feller process, A2.1 is equivalent to the following: For any sequence Π^h and any $q(\cdot)$ which is a bounded, continuous, and real-valued function on the Skorohod space $D[G;0,\infty)$ (the space of G-valued functions which are right continuous and have left-hand limits and with the Skorohod topology),

$$E_{\Pi^h} q(\tilde{X}^h(\cdot)) - E_{\Pi^h} q(\tilde{X}(\cdot)) \to 0, \tag{2.9}$$

as $h \to 0$.

3. Occupation measures: Continuous time. We now provide the definitions which are needed for the formulation of the limit and robustness results. The methods are based on occupation measure arguments.

Assumptions and definitions. The measure valued process $\Pi(\cdot)$ is well defined by (2.4) no matter what the initial condition $\Pi(0)$ is, even if it is *not* the distribution of $X(0)$, or if it is random but *independent* of $(W(\cdot), B(\cdot))$. Thus we can speak of the pair $(X(\cdot), \Pi(\cdot))$ as having an arbitrary initial condition. We say that the process $(X(\cdot), \Pi(\cdot))$ is stationary if the distribution of $(X(t+\cdot), \Pi(t+\cdot))$ does not depend on t. From the Feller–Markov property of $X(\cdot)$ and the semigroup relation (2.5), it is easy to show that $(X(\cdot), \Pi(\cdot))$ is a Feller–Markov process. Since G is compact, $\mathcal{M}(G)$ is compact, and so $(X(\cdot), \Pi(\cdot))$ takes values in a compact state space. Thus there exists at least one stationary process. Let $\bar{Q}(\cdot)$ denote the measure of the *joint* process $\Psi(\cdot) = (X(\cdot), \Pi(\cdot), Y(\cdot), B(\cdot), W(\cdot))$, where $(X(\cdot), \Pi(\cdot))$ is stationary. Let $\bar{Q}_f(\cdot)$ denote the measure of the stationary joint process $(X(\cdot), \Pi(\cdot))$.

We make the following key assumption throughout.

A3.1. *A uniqueness assumption.* The process $(X(\cdot), \Pi(\cdot))$ has a unique stationary measure.

The importance of the uniqueness of the stationary joint process was shown in [25]. Some discussion of the uniqueness of $\bar{Q}_f(\cdot)$ is in [3, section 7], where there is also a discussion of the filtering interpretation of the stationary process. See also [1] for other sufficient conditions for A3.1. For each $t \geq 0$, define the shifted process $\Psi_f^h(t,\cdot) = (X(t+\cdot), \Pi^h(t+\cdot))$ and the centered and/or shifted processes

$$\Psi^h(t,\cdot) = (\Psi_f^h(t,\cdot), Y(t+\cdot) - Y(t), B(t+\cdot) - B(t), W(t+\cdot) - W(t)).$$

The path spaces. The vector-valued processes such as $X(\cdot), Y(\cdot), B(\cdot), \tilde{X}(\cdot)$, and so forth will take values in the path space $D[\mathbb{R}^k;0,\infty)$, i.e., in the space of $\mathbb{R}^k$-valued functions which are right continuous and have left-hand limits, with the Skorohod topology [2, 9] for the appropriate value of k.

Let $\mathcal{M}(G)$ denote the space of measures on G with the weak topology. The optimal filter $\Pi(t)$ and its approximations $\Pi^h(t)$ at each time t take values in $\mathcal{M}(G)$. The process $\Pi(\cdot)$ and its approximations will take values in the space $D[\mathcal{M}(G);0,\infty)$, also with the Skorohod topology used.

For a random variable Z and set A, let $I_A(Z)$ denote the indicator function of the event that $Z \in A$. Let C be a measurable set in the product path space of $\Psi^h(t,\cdot)$. Define the *occupation measure* $Q^{h,T}(\cdot)$ by

$$Q^{h,T}(C) = \frac{1}{T}\int_0^T I_C(\Psi^h(t,\cdot))dt. \tag{3.1}$$

In what follows, lower case letters $x(\cdot), \pi(\cdot)$, etc. are used for the canonical sample paths. Letters such as $x, y, \ldots$, are used to denote vectors such as $x(t), y(t)$, etc. Define $\psi_f(\cdot) = (x(\cdot), \pi(\cdot))$, $\Psi_f(\cdot) = (X(\cdot), \Pi(\cdot))$, and $\psi(\cdot) = (x(\cdot), \pi(\cdot), y(\cdot), b(\cdot), w(\cdot))$.

The random measures $Q^{h,T}(\cdot)$ defined by (3.1) take values in the space of measures on the product path space

$$\mathcal{M}(D[\mathbb{R}^k; 0, \infty) \times D[\mathcal{M}(G); 0, \infty))$$

for the appropriate value of k (which is the sum of the dimensions of x, y, b, w).

An error or cost function. Let $F(\cdot)$ be a real-valued function on $D[G; 0, \infty) \times D[\mathcal{M}(G); 0, \infty)$ which is measurable and continuous (with probability 1 (w.p.1)) with respect to the measure $\bar{Q}_f(\cdot)$). Owing to the compactness of G, we can suppose that $F(\cdot)$ is bounded. As in [3], we are concerned with the asymptotic (pathwise) behavior of the sample averages $\int_0^T F(\Psi_f^h(t, \cdot))dt/T$ as $h \to 0$ and $T \to \infty$. Let $Q_f^{h,T}(\cdot)$ denote the $(X(\cdot), \Pi^h(\cdot))-$marginal of $Q^{h,T}(\cdot)$, i.e., for arbitrary measurable set C' in the product path space of $\Psi_f^h(t, \cdot)$,

$$Q_f^{h,T}(C') = \frac{1}{T} \int_0^T I_{C'}(\Psi_f^h(t, \cdot))dt.$$

By the definition of the occupation measure, we can write

$$\frac{1}{T} \int_0^T F(\Psi_f^h(t, \cdot))dt = \int F(\psi_f(\cdot))Q_f^{h,T}(d\psi_f(\cdot)). \tag{3.2}$$

The representation (3.2) shows that the asymptotic values of the left-hand side can be obtained from the limits of the set of occupation measures $Q_f^{h,T}$, as $T \to \infty$ and $h \to 0$.

It was shown in [3] that for a broad class of approximate filters

$$\frac{1}{T} \int_0^T F(\Psi_f^h(t, \cdot))dt \to \int F(\psi_f(\cdot))\bar{Q}_f(d\psi_f(\cdot)) \tag{3.3}$$

in probability as $T \to \infty$ and $h \to 0$ in any way at all. As pointed out in [3], the arbitrariness of the way that $T \to \infty$ and $h \to 0$ is crucial in applications. It was also shown that

$$\frac{1}{T} \int_0^T F(\Psi_f^h(t, \cdot))dt \to \int F(\psi_f(\cdot))\bar{Q}_f(d\psi_f(\cdot)), \tag{3.3$'$}$$

where $\Pi(\cdot)$ in (3.3$'$) is the true optimal filter. Note that via an application of the dominated convergence theorem, we can replace the expressions on the left sides of (3.3) and (3.3$'$) by their expected values.

Let $\phi(\cdot)$ be a bounded, continuous, and real-valued function. A special case of (3.3) is the convergence of the mean square error

$$\begin{aligned} G^{h,T}(\phi) &\equiv \frac{1}{T} \int_0^T [\langle \Pi^h(t), \phi \rangle - \phi(X(t))]^2 dt \\ &\to \int [\langle \pi(0), \phi \rangle - \phi(x(0))]^2 \bar{Q}_f(d\psi_f(\cdot)) \end{aligned} \tag{3.4}$$

in the sense of probability as $h \to 0$ and $T \to \infty$ in any way at all. The right side of (3.4) is what one would also get as the limit if the true optimal filter was used

(and even with an expectation of the pathwise average used) [3]. In this sense, there is pathwise asymptotic optimality of the approximating filter over the infinite time interval.

The following is the main background theorem from [3].

THEOREM 3.1. *Let the filtering model be as in section* 2. *Assume the uniqueness condition* A3.1. *Define the approximate filter* $\Pi^h(\cdot)$ *via* (2.7) *where* $\tilde{X}^h(\cdot)$ *satisfies the consistency condition* A2.1. *Then, for every sequence* $\{h_k, T_k\}_{k\geq 1}$ *such that* $h_k \to 0$ *and* $T_k \to \infty$ *as* $k \to \infty$, *the family* $\{Q^{h_k,T_k}(\cdot); k \geq 1\}$ *is tight. Extract a weakly convergent subsequence with weak sense limit denoted by* $Q(\cdot)$, *a measure-valued random variable. Let* $Q^\omega(\cdot)$ *denote the sample values of* $Q(\cdot)$. $Q^\omega(\cdot)$ *induces a process, denoted by*

$$\Psi^\omega(\cdot) = \{X^\omega(\cdot), \Pi^\omega(\cdot), Y^\omega(\cdot), B^\omega(\cdot), W^\omega(\cdot)\}.$$

Here, the ω *indexes the process, not the sample paths of the process. For almost all* ω *the following hold. The processes* $(B^\omega(\cdot), W^\omega(\cdot))$ *are independent standard Wiener, with respect to which* $\{X^\omega(\cdot), \Pi^\omega(\cdot), Y^\omega(\cdot)\}$ *are nonanticipative.*

$$dY^\omega = g(X^\omega)dt + dB^\omega, \tag{3.5}$$

$$dX^\omega = p(X^\omega)dt + \sigma(X^\omega)dW^\omega. \tag{3.6}$$

For each bounded and measurable real-valued function $\phi(\cdot)$,

$$\langle \Pi^\omega(t), \phi\rangle = \frac{E_{\{\Pi^\omega(0), Y^\omega_{0,t}\}}[\phi(\tilde{X}(t))R(\tilde{X}_{0,t}, Y^\omega_{0,t})]}{E_{\{\Pi^\omega(0), Y^\omega_{0,t}\}}R(\tilde{X}_{0,t}, Y^\omega_{0,t})}. \tag{3.7}$$

Equivalently, for all t, s,

$$\langle \Pi^\omega(t+s), \phi\rangle = \frac{E_{\{\Pi^\omega(t), Y^\omega_{t,t+s}\}}[\phi(\tilde{X}(t+s))R(\tilde{X}_{0,s}, Y^\omega_{t,t+s})]}{E_{\{\Pi^\omega(t), Y^\omega_{t,t+s}\}}R(\tilde{X}_{0,s}, Y^\omega_{t,t+s})}. \tag{3.8}$$

$(X^\omega(\cdot), \Pi^\omega(\cdot))$ *is the unique stationary process, and hence its distribution does not depend on* ω *or on the chosen convergent subsequence. Finally,* (3.3) *holds in probability as* $h \to 0$ *and* $T \to \infty$ *in any way at all for any bounded and measurable real-valued function* $F(\cdot)$ *which is continuous almost everywhere with respect to* $\bar{Q}_f(\cdot)$.

4. The discrete time problem. Now we review the discrete time form of the results in the previous section. Let all processes be defined in discrete time. The signal process $X(\cdot) = \{X(n), n < \infty\}$ is assumed to be Feller–Markov and takes values in the compact set G. The observations are defined by $Y(0) = 0$ and

$$\delta Y_n \equiv Y(n) - Y(n-1) = g(X(n)) + \xi(n),\ n = 1, \ldots, \tag{4.1}$$

where $\{\xi(n)\}$ are mutually independent $(0, I)$-Gaussian random variables which are independent of $X(\cdot)$, and $g(\cdot)$ is continuous.

The Bayes' rule formula for the true conditional distribution of $X(n)$ given $Y_{0,n}$ can be represented in terms of an auxiliary process $\tilde{X}(\cdot)$ as for the continuous time case in section 2, where $\tilde{X}(\cdot)$ has the same evolution law as that of $X(\cdot)$ but (conditioned

on its possibly random initial distribution) is independent of all the other processes. Define

$$R(\tilde{X}_{0,n}, Y_{0,n}) = \exp\left[\sum_{i=1}^{n} g'(\tilde{X}(i))\delta Y_i - \frac{1}{2}\sum_{i=1}^{n} |g(\tilde{X}(i))|^2\right].$$

Then the optimal filter $\Pi(\cdot)$ can be defined by its moments

$$\langle \Pi(n), \phi\rangle = \frac{E_{\{\Pi(0), Y_{0,n}\}}[\phi(\tilde{X}(n))R(\tilde{X}_{0,n}, Y_{0,n})]}{E_{\{\Pi(0), Y_{0,n}\}}R(\tilde{X}_{0,n}, Y_{0,n})},$$

where $\Pi(0)$ is the distribution of $X(0)$ and $\tilde{X}(0)$. Alternatively,

$$\langle \Pi(n), \phi\rangle = \frac{E_{\{\Pi(n-1), \delta Y_n\}}[\phi(\tilde{X}(1))R(\tilde{X}(1), \delta Y_n)]}{E_{\{\Pi(n-1), \delta Y_n\}}R(\tilde{X}(1), \delta Y_n)}, \tag{4.2}$$

where with an abuse of notation we have defined

$$R(x, y) = \exp[g(x)'y - |g(x)|^2/2].$$

Analogously to the continuous time observation case, except in some special cases, one cannot evaluate (4.2), and it is generally necessary to approximate it in some way. The approximation problems and methods are similar to those in section 3 (see [3] for details). Namely, build a filter for a simpler Markov process $\tilde{X}^h(\cdot)$ (in discrete time here), which has values in the compact set G and which approximates $X(\cdot)$, but use the actual physical observations.

This procedure is formalized as follows. For $n = 1, \ldots,$ define

$$R(\tilde{X}^h_{0,n}, Y_{0,n}) = \exp\left[\sum_{i=1}^{n} g'(\tilde{X}^h(i))\delta Y_i - \frac{1}{2}\sum_{i=1}^{n} |g(\tilde{X}^h(i))|^2\right].$$

Now define the approximating filter $\Pi^h(\cdot)$ by its moments:

$$\langle \Pi^h(n), \phi\rangle = \frac{E_{\{\Pi^h(0), Y_{0,n}\}}[\phi(\tilde{X}^h(n))R(\tilde{X}^h_{0,n}, Y_{0,n})]}{E_{\{\Pi^h(0), Y_{0,n}\}}R(\tilde{X}^h_{0,n}, Y_{0,n})}. \tag{4.3}$$

Then, one has the following recursive representation for $\Pi^h(\cdot)$.

$$\langle \Pi^h(n), \phi\rangle = \frac{E_{\{\Pi^h(n-1), \delta Y_n\}}[\phi(\tilde{X}^h(1))R(\tilde{X}^h(1), \delta Y_n)]}{E_{\{\Pi^h(n-1), \delta Y_n\}}R(\tilde{X}^h(1), \delta Y_n)}. \tag{4.4}$$

Equations (4.3) and (4.4) correspond to the filter which models the signal process via $\tilde{X}^h(\cdot)$ but uses the actual observations $\delta Y_n = Y(n) - Y(n-1)$.

The process $\tilde{X}^h(\cdot)$ in (4.4) is assumed to be independent of the other processes, given its initial distribution. We also use the following analogue of the basic consistency assumption A2.1, which is the sense of approximation of $X(\cdot)$ by $\tilde{X}^h(\cdot)$.

A4.1. *A consistency assumption.* For any sequence $\{\Pi^h\}$ of probability measures converging weakly to some probability measure Π, $(\tilde{X}^h(0), \tilde{X}^h(1))$ with the initial distribution Π^h converges weakly to $(\tilde{X}(0), \tilde{X}(1))$ with the initial distribution Π.

Analogously to the situation in section 3, (4.2) is well defined even if $\Pi(0)$ is not the initial distribution of $X(\cdot)$. Allowing the initial condition $(X(0), \Pi(0))$ to be arbitrary, the discrete time process $\Psi_f(\cdot) = (X(\cdot), \Pi(\cdot))$ is Feller–Markov. We now write the discrete time analogue of the key uniqueness assumption.

A4.2. *A uniqueness assumption.* There is a unique stationary process $\Psi_f(\cdot) = (X(\cdot), \Pi(\cdot))$. Denote its measure by $\bar{Q}_f(\cdot)$.

The occupation measure. For each n, define $B(n) = \sum_{i=1}^{n} \xi^i$, and define the analogue of $\Psi^h(t, \cdot)$, namely,

$$\Psi^h(n, \cdot) = \{X(n + \cdot), \Pi^h(n + \cdot), Y(n + \cdot) - Y(n), B(n + \cdot) - B(n)\},$$

$$\Psi^h_f(n, \cdot) = \{X(n + \cdot), \Pi^h(n + \cdot)\}.$$

Define the canonical elements of the path spaces $\psi(\cdot)$ and $\psi_f(\cdot)$ analogously, as done in section 3.

The Skorohod topology is replaced by a "sequence" topology, as in [3]. The $\Pi^h(n)$ still takes values in $\mathcal{M}(G)$, and the weak topology is still used on this space. Define the occupation measure $Q^{h,N}(\cdot)$ as follows. For a Borel set C in the product sequence space

$$Q^{h,N}(C) = \frac{1}{N} \sum_{n=1}^{N} I_C(\Psi^h(n, \cdot)). \tag{4.6}$$

Analogously to the definitions in section 3, define $\Psi(\cdot) = (X(\cdot), \Pi(\cdot), Y(\cdot), B(\cdot))$. Let $F(\cdot)$ be a real-valued bounded and continuous (w.p.1 with respect to $\bar{Q}_f(\cdot)$) function of $\psi_f(\cdot)$. Then, the following discrete time analogue of Theorem 3.1 is proved in [3].

THEOREM 4.1. *Let the filtering model be as above. Assume that* A4.2 *holds. Define the approximate filter via* (4.3)*, where we assume that the auxiliary process* $\tilde{X}^h(\cdot)$ *satisfies* A4.1*. Then* $\{Q^{h,N}(\cdot); h > 0, N \geq 0\}$ *is tight. Let* $Q(\cdot)$ *denote a weak sense limit, always as* $h \to 0$ *and* $N \to \infty$*. Let* ω *be the canonical variable on the probability space on which* $Q(\cdot)$ *is defined, and denote the sample values by* $Q^\omega(\cdot)$*. Then, for each* ω*,* $Q^\omega(\cdot)$ *is a measure on the product path (sequence) space. It induces a process*

$$\Psi^\omega(\cdot) = (X^\omega(\cdot), \Pi^\omega(\cdot), Y^\omega(\cdot), B^\omega(\cdot)). \tag{4.7}$$

For almost all ω *the following hold.* $(X^\omega(\cdot), \Pi^\omega(\cdot))$ *is stationary.* $B^\omega(\cdot)$ *is the sum of mutually independent* $N(0, I)$ *random variables* $\{\xi^\omega(n)\}$ *which are independent of* $X^\omega(\cdot)$*. Also*

$$\delta Y^\omega_n \equiv Y^\omega(n) - Y^\omega(n-1) = g(X^\omega(n)) + \xi^\omega(n), \tag{4.8}$$

and $X^\omega(\cdot)$ *has the transition function of* $X(\cdot)$*. For each integer* n *and each bounded and measurable real-valued function* $\phi(\cdot)$*,*

$$\langle \Pi^\omega(n), \phi \rangle = \frac{E_{\{\Pi^\omega(0), Y^\omega_{0,n}\}}[\phi(\tilde{X}(n)) R(\tilde{X}_{0,n}, Y^\omega_{0,n})]}{E_{\{\Pi^\omega(0), Y^\omega_{0,n}\}} R(\tilde{X}_{0,n}, Y^\omega_{0,n})}. \tag{4.9}$$

Finally,

$$\frac{1}{N} \sum_{n=1}^{N} F(\Psi^h_f(n + \cdot)) = \int F(\psi_f(\cdot)) \bar{Q}^{h,N}_f(d\psi_f(\cdot)) \to \int F(\psi_f(\cdot)) \bar{Q}_f(d\psi_f(\cdot)) \tag{4.10}$$

in probability, where $h \to 0$ and $N \to \infty$ in any way at all.

Discussion of the proof. In the problems of this paper, the approximating filter will be constructed using random sampling methods or combinations of random sampling and integration methods. Since many arguments in the proofs are similar to those used in [3], in what follows we will try to use as much of the proof in [3] as possible and to concentrate on the differences. In view of that we now highlight the chief features of the proof in [3]. We comment on the discrete parameter case, but analogous remarks hold for the continuous parameter model. Further details are in the reference. In [3] (see (4.6)), the measure valued random variable $Q^{h,N}(\cdot)$ was obtained as an occupation measure connected with the processes $X(\cdot), \Pi^h(\cdot), B(\cdot), Y(\cdot)$, and the same definition will be used in what follows, but with the new definitions of $\Pi^h(\cdot)$ of this paper used.

The first step in the proof of Theorem 4.1 is to show that the sequence $\{Q^{h,N}(\cdot); h, N\}$ of measure-valued random variables is tight. For that, it suffices to show that the sequence of its expectations is tight [22, Chapter 1.6]. In order to show that, it is enough to show that the families $\{X(n+\cdot); n \geq 0\}$, $\{B(n+\cdot) - B(n); n \geq 0\}$, $\{Y(n+\cdot) - Y(n); n \geq 0\}$, and $\{\Pi^h(n+\cdot); h > 0, n \geq 0\}$ are tight. However, showing that is trivial in view of the compactness of the state space. We note that in the continuous time case the proof of tightness of these processes involves a little more work.

By the first equality in (4.10), the limit is determined by the weak sense limits of the occupation measures, as $N \to \infty$, and $h \to 0$. Thus we need to determine the sample values $Q^\omega(\cdot)$ of any weak sense limit $Q(\cdot)$. Equivalently, we need to characterize the set of processes induced by $Q^\omega(\cdot)$. The proof of the stationarity of $(X^\omega(\cdot), \Pi^\omega(\cdot))$ in [3] will work without any change for the problems of this paper. Furthermore the proofs of the representation (4.8) and that $X^\omega(\cdot)$ has the law of evolution of $X(\cdot)$ for almost all ω will be no different than the analogous arguments in [3], and similarly for the continuous parameter case. Thus, establishing the representation (4.9) becomes the only step in the proof that will be different from that in [3]. Once this step is established, (4.10) follows readily from the uniqueness assumption on the invariant measure of the joint signal and filter process.

The proof of the representation for $\Pi^\omega(\cdot)$ will differ, depending on the choice of $\Pi^h(\cdot)$. The following comments concerning a key detail in the proof of the representation (4.9) in [3] will be useful in providing a guide to the proofs for the cases of this paper.

For arbitrary $\psi(\cdot) = (x(\cdot), \pi(\cdot), y(\cdot), b(\cdot))$, and integer m define the function $A(\cdot)$ by

$$A(\psi(m)) = \langle \pi(m), \phi \rangle - \frac{E_{\{\pi(m-1), y(m)\}}[\phi(\tilde{X}(1)) R(\tilde{X}(1), y(m))]}{E_{\{\pi(m-1), y(m)\}} R(\tilde{X}(1), y(m))}. \tag{4.11}$$

The aim of the proof in [3] was to show that, for almost all ω and all m,

$$A(\Psi^\omega(m)) = 0, \qquad \text{w.p.1}, \tag{4.12}$$

which implies (4.9). This was done by showing that

$$0 = E \int Q^\omega(d\psi) \, [A(\psi(m))]_1^2, \tag{4.13}$$

where we define

$$[A]_1^2 = \min\{|A|^2, 1\}. \tag{4.14}$$

The prelimit form of the right side of (4.13) is

$$E\int Q^{h,N}(d\psi)\,[A(\psi(m))]_1^2\,, \tag{4.15}$$

which, by the definition of $Q^{h,N}(\cdot)$, equals

$$\frac{1}{N}E\sum_{n=1}^{N}[A(\Psi^h(m+n))]_1^2, \tag{4.16}$$

where

$$A(\Psi^h(n)) = \langle \Pi^h(n), \phi\rangle - \frac{E_{\{\Pi^h(n-1),\delta Y_n\}}[\phi(\tilde{X}(1))R(\tilde{X}(1),\delta Y_n)]}{E_{\{\Pi^h(n-1),\delta Y_n\}}R(\tilde{X}(1),\delta Y_n)}. \tag{4.17}$$

In order to show (4.13), it suffices to show

$$E[A(\Psi^h(n))]_1^2 \to 0$$

uniformly in n as $h \to 0$. Finally, to show the above, it suffices, in view of tightness of the families $\{\Pi^h(n); h>0, n>0\}$, $\{\delta Y_n; n>0\}$, and the consistency assumption A4.1, to show that

$$E\left[\langle \Pi^h(n), \phi\rangle - \frac{E_{\{\Pi^h(n-1),\delta Y_n\}}[\phi(\tilde{X}^h(1))R(\tilde{X}^h(1),\delta Y_n)]}{E_{\{\Pi^h(n-1),\delta Y_n\}}R(\tilde{X}^h(1),\delta Y_n)}\right]_1^2 \tag{4.18}$$

converges to 0 uniformly in n as $h \to 0$.

However, in view of the definition of $\Pi^h(n)$ via (4.4), the above expression is identically zero, which implies that (4.13) holds for any weak sense limit. An analogue of this argument will be used in the next section.

5. Some approximating filters of interest: Discrete time. In [3], the approximate filter $\Pi^h(\cdot)$ was defined by the analytical formula (4.4) for the discrete time problem, and by (2.7) for the continuous time problem. One example is the Markov chain approximation method, where the auxiliary process $\tilde{X}^h(\cdot)$ is a Markov chain approximation to $\tilde{X}(\cdot)$. When the dimension is high, such methods can have excessively high computational requirements. Alternatives, based on random sampling or Monte Carlo then become attractive, analogous to the case of classical multidimensional integration [5, 6, 7, 12, 13, 15, 16, 27, 28, 29]. In this section, several forms of this approach will be discussed. We start with the simplest form, which uses unsophisticated random sampling to evaluate the right-hand side of (4.4). The problem is set up so that much of the proof of [3, Theorem 5.1] (this is Theorem 4.1 above) can be used. After treating this simple (but canonical) case, we then move on to more general approximations, pointing out at each instance the crucial condition required for the analogue of Theorem 4.1 to hold.

EXAMPLE 5.1 (the basic "sampling" filter). *Let v^h be a sequence of integers which goes to infinity as $h \to 0$. Let $\Pi^h(n-1)$ denote the estimate of the conditional distribution of $X(n-1)$, given $Y_{0,n-1}$. Given $\Pi^h(n-1)$, we now construct $\Pi^h(n)$ based on "random sampling." Let $\{\tilde{X}^{h,l,n}(\cdot), l \le v^h\}$ be i.i.d. samples (which are independent of δY_n, conditioned on $\Pi^h(n-1)$) from $\tilde{X}^h(\cdot)$, where $\tilde{X}^h(\cdot)$ satisfies the consistency condition* A4.1 *and has the initial distribution $\Pi^h(n-1)$. One need only*

simulate samples of $\tilde{X}^h(0), \tilde{X}^h(1)$.

The filter $\Pi^h(n)$ *is defined by the sample average:*

$$\langle \Pi^h(n), \phi \rangle = \frac{\sum_{l=1}^{v^h} \phi(\tilde{X}^{h,l,n}(1)) R(\tilde{X}^{h,l,n}(1), \delta Y_n)/v^h}{\sum_{l=1}^{v^h} R(\tilde{X}^{h,l,n}(1), \delta Y_n)/v^h}, \tag{5.1}$$

which yields our estimate $\Pi^h(n)$ *of the conditional distribution of* $X(n)$, *given* $Y_{0,n}$.

THEOREM 5.2. *Under* A4.1 *and* A4.2 *and the above construction of* $\Pi^h(\cdot)$, *the conclusions of Theorem* 4.1 *hold.*

Proof. The basic steps in the proof of Theorem 4.1 were outlined after the statement of that theorem. The proof of the current theorem is similar, and we will only concern ourselves with the differences.

The set $\{Q^{h,N}(\cdot); h > 0, T < \infty\}$ is obviously tight since each of the families $\{X(n+\cdot); n \geq 0\}$,$\{B(n+\cdot) - B(n); n \geq 0\}$, $\{Y(n+\cdot) - Y(n); n \geq 0\}$, and $\{\Pi^h(n+\cdot); h > 0, n \geq 0\}$ is tight. Let $Q(\cdot) = \{Q(n), n = 0, 1, \ldots\}$ denote the limit of a weakly convergent subsequence, and denote the samples by $Q^\omega(\cdot)$. Then $Q^\omega(\cdot)$ induces a process $\Psi^\omega(\cdot)$ as in (4.7), and we need to identify the components. The stationarity of $(X^\omega(\cdot), \Pi^\omega(\cdot))$ is proved as in [3], with no change. Similarly, the characterization (4.8), the properties of $B^\omega(\cdot)$, and the fact that $X^\omega(\cdot)$ has the transition function of $X(\cdot)$ is done exactly as in [3].

The main difference is in the proof of (4.9). Proceeding as illustrated for Theorem 4.1, to identify $\Pi^\omega(\cdot)$ we need only to show (4.13). Analogously to the procedure in section 4, this is done by showing that the expression in (4.18) converges to 0 uniformly in n as $h \to 0$. By using the definition of $\Pi^h(n)$, (4.18) can be rewritten as

$$E\left[\frac{\sum_{l=1}^{v^h} \phi(\tilde{X}^{h,l,n}(1)) R(\tilde{X}^{h,l,n}(1), \delta Y_n)/v^h}{\sum_{l=1}^{v^h} R(\tilde{X}^{h,l,n}(1), \delta Y_n)/v^h} - \frac{E_{\{\Pi^h(n-1), \delta Y_n\}}[\phi(\tilde{X}^h(1)) R(\tilde{X}^h(1), \delta Y_n)]}{E_{\{\Pi^h(n-1), \delta Y_n\}} R(\tilde{X}^h(1), \delta Y_n)}\right]_1^2. \tag{5.2}$$

Owing to the properties of the $[\cdot]_1^2$ metric defined by (4.14), we can work with the numerators and denominators separately, and it is only necessary to show that, for arbitrary bounded and continuous $\phi(\cdot)$,

$$E\left[\frac{1}{v^h}\sum_{l=1}^{v^h} \phi(\tilde{X}^{h,l,n}(1)) R(\tilde{X}^{h,l,n}(1), \delta Y_n) - E_{\{\Pi^h(n-1), \delta Y_n\}} \phi(\tilde{X}^h(1)) R(\tilde{X}^h(1), \delta Y_n)\right]_1^2 \tag{5.3}$$

goes to zero uniformly in n, as $h \to 0$. But this clearly holds since for each h and n, $\{\tilde{X}^{h,l,n}(\cdot), l\}$ are mutually i.i.d. and independent of δY_n (conditioned on $\Pi^h(n-1)$), and the mean square value (conditional on $\{\Pi^h(n-1), \delta Y_n\}$) of the functional

$$\phi(\tilde{X}^{h,l,n}(1)) R(\tilde{X}^{h,l,n}(1), \delta Y_n) - E_{\{\Pi^h(n-1), \delta Y_n\}} \phi(\tilde{X}^{h,l,n}(1)) R(\tilde{X}^{h,l,n}(1), \delta Y_n)$$

has uniformly (in h, l, n) bounded expectation. □

We remark that in the above proof we found it convenient to work with the expression in (5.3), however in view of the consistency condition A4.1 on $\tilde{X}^h(\cdot)$, showing that the expression in (5.3) goes to zero, uniformly in n, as $h \to 0$ is equivalent to showing the same for the expression in (5.3′) below.

$$E\left[\frac{1}{v^h}\sum_{l=1}^{v^h}\phi(\tilde{X}^{h,l,n}(1))R(\tilde{X}^{h,l,n}(1),\delta Y_n) - E_{\{\Pi^h(n-1),\delta Y_n\}}\phi(\tilde{X}(1))R(\tilde{X}(1),\delta Y_n)\right]_1^2. \tag{5.3′}$$

EXAMPLE 5.3 (some generalizations of the filter in Example 5.1). As can be observed from the proof of Theorem 5.1, the crucial step is the establishing of convergence of the expression in (4.18) or, equivalently, of (5.3′), the form that we will use. This convergence is essentially the consequence of the consistency condition A4.1. However, as we will indicate in the following discussion, this consistency condition can be weakened considerably. This leads to many useful extensions of the basic form of the "sampling" algorithm of Example 5.1.

A weaker form of the consistency assumption A4.1. We retain the assumption of mutual independence (conditional on $\Pi^h(n-1),\delta Y_n$) of the $\{\tilde{X}^{h,l,n}(\cdot), l \le v^h\}$ for each h,n, and that the probability law of $\{\tilde{X}^{h,l,n}(0)\}$ is $\Pi^h(n-1)$, but we allow more flexibility in the choice of the individual $\tilde{X}^{h,l,n}(\cdot)$. Namely, in the construction of $\Pi^h(n)$ in (5.1), the Markov family from which $\tilde{X}^{h,l,n}(\cdot)$ is sampled may differ for different l,n. However, the initial conditions $\tilde{X}^{h,l,n}(0)$ still form an i.i.d. sample from $\Pi^h(n-1)$. To see the possibilities, write the expression in the brackets in (5.2) as the sum of the two terms:

$$\frac{\sum_{l=1}^{v^h}\phi(\tilde{X}^{h,l,n}(1))R(\tilde{X}^{h,l,n}(1),\delta Y_n)/v^h}{\sum_{l=1}^{v^h}R(\tilde{X}^{h,l,n}(1),\delta Y_n)/v^h} - \frac{E_{\{\Pi^h(n-1),\delta Y_n\}}\sum_{l=1}^{v^h}\phi(\tilde{X}^{h,l,n}(1))R(\tilde{X}^{h,l,n}(1),\delta Y_n)/v^h}{E_{\{\Pi^h(n-1),\delta Y_n\}}\sum_{l=1}^{v^h}R(\tilde{X}^{h,l,n}(1),\delta Y_n)/v^h}, \tag{5.4}$$

and

$$\frac{E_{\{\Pi^h(n-1),\delta Y_n\}}\sum_{l=1}^{v^h}\phi(\tilde{X}^{h,l,n}(1))R(\tilde{X}^{h,l,n}(1),\delta Y_n)/v^h}{E_{\{\Pi^h(n-1),\delta Y_n\}}\sum_{l=1}^{v^h}R(\tilde{X}^{h,l,n}(1),\delta Y_n)/v^h} - \frac{E_{\{\Pi^h(n-1),\delta Y_n\}}[\phi(\tilde{X}(1))R(\tilde{X}^h(1),\delta Y_n)]}{E_{\{\Pi^h(n-1),\delta Y_n\}}R(\tilde{X}(1),\delta Y_n)}. \tag{5.5}$$

Owing to the use of the $[\cdot]_1^2$ metric defined by (4.14), it is enough to work separately with the differences of the numerators and of the denominators in each of (5.4) and (5.5). Then, to handle (5.4), use the mutual independence and the uniform bounds on the expectations of the conditional variances. To handle (5.5), we will use a revised form of the consistency assumption A4.1, which is the following.

A5.1. For each (n,h), the set $\{\tilde{X}^{h,l,n}(\cdot), l\}$ is mutually independent and independent of δY_n, conditioned on $\Pi^h(n-1)$. Suppose that an arbitrary Π^h replaces

$\Pi^h(n-1)$ in the construction of the $\{\tilde{X}^{h,l,n}(0), l\}$. Then, as $h \to 0$, for any such sequence and for each bounded, continuous, and real-valued function $\Phi(\cdot)$,

$$E_{\Pi^h}\Phi(\tilde{X}^{h,l,n}(1)) - E_{\Pi^h}\Phi(\tilde{X}(1)) \to 0 \tag{5.6}$$

uniformly in n and l.

This assumption, when used for $\Phi(x) \equiv \Phi_y(x) = \phi(x)R(x,y)$ for each fixed y, leads to the desired convergence for the expression in (5.6). Observe that even though $R(\cdot)$ is not bounded, we can, without loss of generality, assume so since the family $\{\delta Y_n; n \geq 1\}$ is tight. For this reason and the fact that we use the metric (4.14), we do not need the convergence in A5.1 for $\Phi(\cdot) = \Phi_y(\cdot)$ to hold uniformly in y.

Note that we are no longer assuming that the $\tilde{X}^{h,l,n}(\cdot)$ are all samples of the same $\tilde{X}^h(\cdot)$ process. The second part of A5.1 will hold iff for all Π and any sequence $\{h_k, l_k, n_k\}_{k\geq 1}$ for which ($\mathcal{L}(X)$ denotes the probability law of X)

$$\mathcal{L}(\tilde{X}^{h_k,l_k,n_k}(0)) \Rightarrow \Pi$$

as $k \to \infty$, we have that

$$\mathcal{L}(\tilde{X}^{h_k,l_k,n_k}(0), \tilde{X}^{h_k,l_k,n_k}(1)) \Rightarrow \mathcal{L}(\tilde{X}(0), \tilde{X}(1)) \text{ as } k \to \infty,$$

where $\tilde{X}(0)$ has the law Π.

Dropping the mutual conditional independence. Return to the expression (5.2). Let $\Phi(\cdot)$ be bounded and continuous. Then the convergence in (5.2) is implied by the following even weaker consistency assumption, which can replace A4.1 and the mutual independence in Theorem 5.1.

A5.2. For each (h,n), $\{\tilde{X}^{h,l,n}(\cdot), l\}$ is independent of δY_n, conditioned on $\Pi^h(n-1)$, but they might not be independent in l. They are constructed subject to the following rule. Suppose that an arbitrary measure $\Pi^{h,n}$ (on G) takes the role of $\Pi^h(n-1)$ in the construction of the $\{\tilde{X}^{h,l,n}(\cdot), l\}$. Then the associated process $\{\tilde{X}^{h,l,n}(\cdot), l\}$ is constructed such that as $h \to 0$ for any bounded, continuous, and real-valued function $\Phi(\cdot)$,

$$\frac{1}{v^h}\sum_{l=1}^{v^h} \Phi(\tilde{X}^{h,l,n}(1)) - E_{\{\Pi^{h,n}\}}\Phi(\tilde{X}(1)) \to 0, \tag{5.7}$$

in probability, uniformly in n.

It is clear that this condition (instead of A4.1 and mutual independence of samples) suffices for Theorem 5.2 to hold for the corresponding $\{\Pi^h(n)\}$. The usefulness of this condition lies in the cases where the samples $\{\tilde{X}^{h,l,n}(\cdot), l \leq v^h\}$ for fixed h,n are not mutually independent. It is of particular value when the random sampling incorporates some variance reduction method where the samples are not mutually independent, e.g., antithetic variables or stratified sampling such as discussed next.

Variance reduction methods. The standard methods for variance reduction in Monte Carlo, such as stratified sampling and antithetic variables, can all be used here and in the subsequent algorithms and examples. We comment on one form of stratified sampling. Let $\Pi^h(n-1)$ be concentrated on points $\{x^{h,l,n}; l = 1, \ldots, v^h\}$, and let $\Pi^h_l(n-1)$ denote the weight that $\Pi^h(n-1)$ puts on $x^{h,l,n}$.

In this example, we only use variance reduction to get the samples of the initial values $\tilde{X}^{h,l,n}(0)$. Once these are given, the sample values of $\tilde{X}^{h,l,n}(1)$ are obtained by

sampling independently, using the transition probability of the approximating Markov process $\tilde{X}^{h,n}(\cdot)$. So we concentrate on the initial values for fixed n.

If the $v^h\Pi_l^h(n-1)$ were all integers, then the best sampling of the values of the $\tilde{X}^{h,l,n}(0)$ would be to take the initial point $x^{h,l,n}$ exactly $v^h\Pi_l^h(n-1)$ times, since then the variance of the sampling error of the *initial condition* would be zero. Clearly all the $v^h\Pi_l^h(n-1)$ would not usually be integers, but one tries to approximate the ideal as well as possible. One common approach is the following. First take the point $x^{h,l,n}$ exactly $[v^h\Pi_l^h(n-1)]$ (the integer part) times. After this step, the "residual" number of points remaining to be chosen is

$$\delta v^{h,n} = \sum_l \delta v_l^{h,n},$$

where

$$\delta v_l^{h,n} = (v^h\Pi_l^h(n-1) - [v^h\Pi_l^h(n-1)]).$$

The "residual frequency" of point $x^{h,l,n}$ is $\delta v_l^{h,n}/\delta v^{h,n}$. Now divide the set $\{x^{h,l,n}, l\}$ into disjoint subsets $S_i^{h,n}, i = 1, \ldots$. The set $S_i^{h,n}$ has $\delta v^{h,n,i}$ points where

$$\delta v^{h,n,i} = \sum_{l \in S_i^{h,n}} \delta v_l^{h,n}.$$

Allocate $[\delta v^{h,n,i}]$ initial points to subset i, and then select these points randomly (with replacement) from $S_i^{h,n}$, where the point $x^{h,l,n} \in S_i^{h,n}$ is given the weight $\delta v_l^{h,n}/\delta v^{h,n,i}$. Since

$$\bar{v}^{h,n} \equiv \delta v^{h,n} - \sum_i [\delta v^{h,n,i}] \geq 0,$$

we still need to allocate $\bar{v}^{h,n}$ points, if this is positive. Generally, if the division into subgroups is done properly, $\bar{v}^{h,n}/v^h$ will be either zero or small. If it is positive, either repeat the above procedure to allocate the remaining $\bar{v}^{h,n}$ points, or just select $\bar{v}^{h,n}$ points randomly from the original v^h points with appropriately modified weights.

It is easy to see that the above construction can be put in the framework of Example 5.3, and condition A5.2 holds.

The grouping into subsets might be done by dividing the points according to their "geographic location," if this is meaningful.

EXAMPLE 5.4. We would like to treat algorithms that use combinations of random sampling and integration methods in a general way. This will require an alteration in the consistency condition A5.1 or A5.2. In order to motivate the form which it will take, we first consider an example for which A5.2 is satisfied. Let $\tilde{X}^{h,n}(\cdot)$ be processes satisfying A5.1. Having defined the approximate filter $\Pi^h(j)$ for $j = 1, 2, \ldots, n-1$ suppose that $\{\tilde{X}^{h,l,n}(\cdot), l \leq v^h\}$ are samples of $\tilde{X}^{h,n}(\cdot)$ and that they are conditionally independent of δY_n given $\Pi^h(n-1)$. Define $\Pi^h(n)$ via (5.1). If the samples are mutually independent (conditioned on $\Pi^h(n-1)$) and $\tilde{X}^{h,n}(0)$ has distribution $\Pi^h(n-1)$, then condition A5.1 (and thus A5.2) is satisfied. Theorem 5.2 can be proved under weaker consistency conditions than A5.1 or A5.2, which allow great and useful flexibility in constructing the filter. To motivate a useful general form, let us first rewrite Example 5.3 in the following suggestive way.

For each h and n, define a measure (on the sample space $G \times G$) valued random variable $P^{h,n}_{\Pi^{h,n-1}}$ as follows. Let $P^{h,n}_{\Pi^h(n-1)}(A)$ be the fraction of the samples $\{\tilde{X}^{h,l,n}(\cdot), l \le v^h\}$ that are in the Borel set $A \subset G \times G$. In particular, $P^{h,n}_{\Pi^h(n-1)}\{B \times G\}$ is the fraction of the samples $\tilde{X}^{h,l,n}(0)$ which are in the set B. Since this $P^{h,n}_{\Pi^h(n-1)}$ is just the "sampling occupation measure," condition A5.2 is equivalent to

$$E\left[\int \Phi(x(1))dP^{h,n}_{\Pi^h(n-1)}(x(\cdot)) - E_{\{\Pi^h(n-1)\}}\Phi(\tilde{X}(1))\right]^2_1 \to 0 \tag{5.8}$$

uniformly in n as $h \to 0$.

Thus the crucial condition becomes the convergence of the expression in (5.8). The advantage of writing the condition in the form (5.8) is that, being written in terms of a random measure $P^{h,n}_{\Pi^h(n-1)}$, it suggests other choices of approximate filters that need not be based exclusively on Monte Carlo or random sampling. For example, as seen in Example 5.5 below, $P^{h,n}_{\Pi^h(n-1)}$ might be determined partly by random sampling and partly analytically.

A generalization of $P^{h,n}_{\Pi^h(n-1)}$ *and the approximating filter.* Motivated by the suggestiveness of (5.8), we now consider the following general form of the approximate filter and the consistency condition. Let $\{\Pi^h(n); n \ge 1\}$ be defined recursively as follows. Having defined $\Pi^h(n-1)$, let $P^{h,n}_{\Pi^h(n-1)}$ be a measure-valued random variable on the sample space $G \times G$, which is conditionally independent of δY_n given $\Pi^h(n-1)$. Define $\Pi^h(n)$ by

$$\langle \Pi^h(n), \phi\rangle = \frac{\int \phi(x(1))R(x(1), \delta Y_n)dP^{h,n}_{\Pi^h(n-1)}(x(\cdot))}{\int R(x(1), \delta Y_n)dP^{h,n}_{\Pi^h(n-1)}(x(\cdot))}. \tag{5.9}$$

We will need the following consistency condition.

A5.3. For each bounded, continuous, and real-valued function $\Phi(\cdot)$, as $h \to 0$,

$$\int \Phi(x(1))dP^{h,n}_{\Pi^h(n-1)}(x(\cdot)) - E_{\{\Pi^h(n-1)\}}\Phi(\tilde{X}(1)) \to 0, \tag{5.10}$$

in probability, uniformly in n.

We now have the following useful result whose proof follows from the above comments.

THEOREM 5.5. *Theorem* 5.2 *holds for the above constructed* $\Pi^h(\cdot)$ *if in the assumptions of that theorem the consistency condition* A5.3 *replaces* A4.1 *and the mutual independence of the samples.*

Remarks. Although not needed, it will often be the case that

$$E_{\Pi^h(n-1)}P^{h,n}_{\Pi^h(n-1)}\{B \times G\} = \Pi^h(n-1)(B). \tag{5.11}$$

The advantage of A5.3 is that it can be used for a large variety of approximation methods. For example, in the form (4.4), $P^{h.n}_{\Pi^h(n-1)}$ would be the measure of $(\tilde{X}^h(0), \tilde{X}^h(1))$ with $\tilde{X}^h(0)$ having the (random) distribution $\Pi^h(n-1)$. The conditions for the convergence for the classical Markov chain approximation, the random sampling method above, and various combinations of them, either in the same or in different time frames, can all be put into the form of (5.10) for appropriate choices

of $P^{h,n}_{\Pi^h(n-1)}$. Importance sampling methods can also be fit into the same scheme and used to improve the performance of the filter, as shown in the next section.

EXAMPLE 5.6 (an application of A5.3). A combination of random sampling and integration algorithms will be considered in this example. Consider the following commonly used model. Let $X(n) = b(X(n-1), \zeta(n-1))$, where $b(\cdot)$ is bounded and continuous and the $\{\zeta(n)\}$ are mutually i.i.d. (with distribution function P_ζ, with compact support), and independent of $X(0)$. First, suppose that $\Pi(n-1)$ is the actual conditional distribution of $X(n-1)$, given $Y_{0,n-1}$. Then the optimal $\Pi(n)$ is defined by (4.2). If the computation on the right side of (4.2) is not possible, as is usually the case, it would be approximated in some way. The difficulties in evaluating the right side might be due to the problem of computing the one step transition probability of the Markov process $\{X(n)\}$, or to the actual integrations over a possibly continuous state space that are required to evaluate (4.2). As usual, let h denote the approximation parameter for the actual practical filter, and let $\Pi^h(n)$ denote the estimate of the conditional distribution given $Y_{0,n}$.

Let $\Pi^h(n-1)$ be given. We wish to compute $\Pi^h(n)$. This can be done by a direct simulation as in Example 5.1, by combined "simulation-integration," or perhaps even by a pure "integration," method. These possibilities will be illustrated. Suppose that we approximate P_ζ by P^h_ζ, which might have a (computationally) more convenient support and is such that $P^h_\zeta \Rightarrow P_\zeta$. In addition, approximate $b(\cdot)$ by a measurable function $b_h(\cdot)$ such that

$$\lim_{h\to 0} \sup_{x,\zeta} |b(x,\zeta) - b_h(x,\zeta)| = 0.$$

If the associated integrations are convenient to carry out, one can use (4.3) to define $\Pi^h(n)$, where we define

$$\tilde{X}^h(1) = b_h(\tilde{X}^h(0), \zeta^h). \tag{5.12a}$$

In (5.12a), $\tilde{X}^h(0)$ has distribution $\Pi^h(n-1)$ and ζ^h has distribution P^h_ζ. If the support of P^h_ζ is finite and $b_h(\cdot)$ takes only finitely many values, then the integrations reduce to summations. The $\tilde{X}^h(\cdot)$ process thus defined satisfies the consistency condition A4.1. Hence Theorem 4.1 holds for $\Pi^h(\cdot)$ if A4.2 holds.

Alternatively, one can simply use Monte Carlo as in Example 5.1. All sampling below is "conditionally independent" of the past, given $\Pi^h(n-1)$. Take v^h independent samples from $\Pi^h(n-1)$ and from P^h_ζ and call them $\tilde{X}^{h,n,l}(0)$ and $\zeta^{h,n,l}$, $l \le v^h$, resp. Then use the formula

$$\tilde{X}^{h,n,l}(1) = b_h(\tilde{X}^{h,n,l}(0), \zeta^{h,n,l}) \tag{5.12b}$$

and (5.1) to get $\Pi^h(n)$.

Combinations of the above two approaches might be worthwhile also. For example, if the support of the P^h_ζ is a (not too big) finite set, then one can sample from $\Pi^h(n-1)$, but "integrate" over the noise for each sample of the initial condition by doing the necessary summations. One would normally try to choose the support of P^h_ζ such that the integrals are well approximated for an appropriate set of functions $\phi(\cdot)$. On the other hand, one might discretize the state space such that the support of the $\tilde{X}^h(0)$ (i.e., of each of the $\Pi^h(n)$) is confined to a finite set G_h, and integrate with respect to the "initial" measure $\Pi^h(n-1)$, but simulate the noise. For each of these combinations, there is a $P^{h,n}_{\Pi^h(n-1)}$ such that A5.3 holds, provided that the

discretization of the space converges to the whole space in an appropriate manner and, for the part of the computation which involves random sampling, the number of samples goes to infinity as $h \to 0$. The construction of $P^{h,n}_{\Pi^h(n-1)}$ is not hard and the details are omitted.

EXAMPLE 5.7 (a Markov chain approximation method). In this example, by considering a sampled diffusion model, we illustrate a potentially useful combination of integration and simulation. Suppose that the signal process $X(n)$ is a sample from a diffusion process $X(\cdot)$ at discrete time n. Suppose that $X(\cdot)$ solves an Itô equation with a unique weak sense solution for each initial condition and has continuous drift and diffusion coefficients. Then the exact filter (4.2) involves getting the probability distribution of $\tilde{X}(1)$ (which solves the same Itô equation) with the correct initial distribution $\Pi(n-1), n = 1, \ldots$. One could try to solve the Fokker–Planck equation by some numerical method. This is not easy when there are degeneracies. The Markov chain approximation method [24] is a general and powerful approach which converges under the specified conditions, even with quite weak (reflecting) boundary reflections and jumps added. The following discussion uses the idea of the Markov chain approximation without going into excessive details.

For each h, let $\{X^h_n\}$ be a discrete parameter Markov chain on a finite state space $G_h \subset G$, and let $p^h(x,z)$ denote the one step transition probabilities. For $\delta_h > 0$, define the continuous time interpolation $\tilde{X}^h(\cdot)$ by $\tilde{X}^h(t) = X^h_n$ on the interval $[n\delta_h, n\delta_h + \delta_h)$. Suppose, without loss of generality, that $1/\delta_h$ is an integer, and assume that $\tilde{X}^h(\cdot)$ satisfies the consistency assumption A4.1. The use of such chains in the construction of approximate filters is now quite common. See [21, 24, 23]. The references [21, 24] give straightforward and automatic ways of constructing such chains.

In [21, 24] and in current usage in applications, the process $\tilde{X}^h(\cdot)$ is used as in the algorithm (4.4). But it can also be used as the basic simulated process in (5.1). In order to demonstrate the possibilities, we now illustrate an interesting combination of these two schemes which is rather different from the combinations illustrated by Example 5.6. We work with a single observation interval at a time, and for concreteness we discuss the method for the time interval $[0,1]$. Let $\Pi^h = \Pi^h(0)$ denote the approximation to the distribution of $X(0)$. We need to approximate the distribution of $\tilde{X}(1)$. This is done by either computing or estimating the distribution of X^h_{1/δ_h}, where X^h_0 has the distribution Π^h.

To estimate or compute the distribution of X^h_{1/δ_h}, we recursively estimate or compute the distribution of the X^h_m for $m = 1, 2, \ldots, 1/\delta_h$. The motivation behind the combined integration/Monte Carlo procedure to be described is that in some regions of the state space, it might be easier to use one method and in other regions the other method. For illustrative purposes, we suppose that G is divided into disjoint subsets G_1 and G_2 and define $G_{h,i} = G_h \cap G_i$. Suppose that it is easy to compute the transition probabilities $p^h(x,z)$ for $x \in$ some neighborhood of G_1, but harder for x outside of that neighborhood. We suppose that it is feasible to run simulations of the process for any selected initial condition. For example, $p^h(x,z)$ might be given implicitly as the output of a complicated physical mechanism for which the transition probability is hard to compute when x is in G_2 but which can be simulated. We try to exploit this situation by simulating where convenient and integrating where that is convenient. The division into subsets G_i and the associated "difficulty" of some procedure in G_i is meant to be suggestive. We will sometimes be "integrating" when in G_2 and sometimes simulating when in G_1. But the major part of each type of computation will be done in the region where it is advantageous.

Let us divide the unit interval into n_h (an integer) subintervals, with $\epsilon = \delta_h k_h$. Thus $1/\delta_h = k_h n_h$. For notational simplicity, we work with the interval $[0,1]$, but the method is identical for all the intervals $[n, n+1]$. Let μ_m^h denote the estimate of the distribution of $X_{mk_h}^h$ with values $\mu_m^h(x), x \in G_h$, where we start with $\mu_0^h = \Pi^h$. The time interval ϵ should be small enough such that the paths starting in $G_{h,i}$ stay close to it with a high probability on that interval. One needs to be careful if ϵ is allowed to go to zero as $h \to 0$ (which we do not do), since it is well known from simulations that the procedure can degenerate unless v^h goes to infinity fast enough (and at a rate which depends on how fast $\epsilon \to 0$). In fact, there is little loss of generality or practicality in fixing ϵ to be a small constant.

Suppose that μ_m^h is given. Then μ_{m+1}^h is computed as follows. First, do the analytic computation using $p^h(x,z)$ to get the part of $\mu_{m+1}^h(z)$ which is due to the initial states in $G_{h,1}$. Namely, compute

$$\sum_{x \in G_{h,1}} P\{X_{(m+1)k_h}^h = z \big| X_{mk_h}^h = x\} \mu_m^h(x). \tag{5.13a}$$

The part of $\mu_{m+1}^h(z)$ which is due to initial states in $G_{h,2}$ is obtained by simulation. To simulate, we sample a total of v^h points (where $v^h \to \infty$) in $G_{h,2}$ with relative probabilities $\{\mu_m^h(x), x \in G_{h,2}\}$. Denote the samples by $\{X_0^{h,l,m}, l \le v^h\}$. The sampling of the $\{X_0^{h,l,m}, l \le v^h\}$ can be done either with replacement or, preferably, using a variance reduction method such as the one based on stratified sampling which was described at the end of Example 5.3. For each of these "initial values" $X_0^{h,l,m}, l \le v^h$, simulate at random a path of the chain for k_h steps. Let $\{X_k^{h,l,m}, k \le k_0\}$ denote the sample values.

Then the part of the estimate of $\mu_{m+1}^h(z)$ which is due to initial states in $G_{h,2}$ is

$$\left[\sum_{x \in G_{h,2}} \mu_m^h(x) \right] \frac{1}{v^h} \sum_{l=1}^{v_h} I_{\{X_{k_h}^{h,l,m} = z\}}. \tag{5.13b}$$

The sum of (5.13a) and (5.13b) is $\mu_{m+1}^h(z)$. If $h \to 0$ and Π^h converges weakly to, say, Π, it follows from the consistency condition A4.1 for the $\tilde{X}^h(\cdot)$ process that $\mu_{n_h}^h(\cdot)$ converges weakly to the distribution of $\tilde{X}(1)$, which corresponds to $\tilde{X}(0)$ having distribution Π.

To identify the measure $P_{\Pi^h(n-1)}^{h,n}$ in A5.3 (for our example $n = 1$) note the following. It is the measure on $G_h \times G_h$, with initial distribution given by our combination of $\mu_0^h(x)$ for $x \in G_{h,1}$ and the sampling distribution for $x \in G_{h,2}$. The distribution of the terminal value, conditioned on the initial distribution, is computed by repeating the updating procedure outlined above $1/\epsilon$ times.

We note that variance reduction methods can be employed in the sampling of the random paths themselves.

6. More examples: Importance sampling methods for discrete time models. Importance sampling methods are in common use to improve the performance of Monte Carlo algorithms (see, for example, [10, 11]). The basic idea can be seen from the following simple example. Suppose that we wish to estimate $Ef(X)$ via Monte Carlo, where $f(\cdot)$ is bounded and continuous and X has distribution P. The simplest estimate has the form $\sum_{i=1}^n f(X_i)/n$, where $\{X_i\}$ are mutually independent and chosen at random from P. Suppose that we know that values of X in a set A have

the dominant effect on $Ef(X)$, where A has small probability. Then large n would be needed to get a good estimate. Let Q be mutually absolutely continuous with respect to P, and where $Q(A)$ has a "moderate" value. Then for appropriate choice of Q, the unbiased estimate $\sum_{i=1}^{n} f(X_i)[dP/dQ](X_i)/n$ has a much smaller variance than the original estimate, where now the X_i are drawn at random and independently from Q [10, 11]. Importance sampling attempts to sample more (using Q) in the regions which prior information suggests are more important, and corrects for this bias via the weighing with the Radon–Nikodym derivative.

Importance sampling has also been used to improve the quality of nonlinear filtering algorithms that use random sampling [5, 29]. When used over an infinite time interval, the robustness and convergence questions raised earlier in the paper remain important. In the next example, we discuss the general idea of importance sampling and show how the associated proof of convergence is covered by what has already been done for setups such as that in Example 5.1 of section 5. In this next example, we describe the importance sampling on a typical interval $[n-1, n]$, and it does not use the next observation δY_n. This next observation can provide useful information to guide the sampling. There are many intriguing possibilities, and one form of such a use is discussed in Example 6.4. We only illustrate some possibilities. There are numerous possible variations, and the choice of the better ones is still a matter of research. With all of the variations, variance reduction methods can be used, as can combined sampling-integration methods.

EXAMPLE 6.1 (the basic idea of importance sampling in Monte Carlo filtering). Return to the setup used in Example 5.1 of section 5. Let P^h_{n-1} denote the probability law of $\tilde{X}^h(\cdot) = (\tilde{X}^h(0), \tilde{X}^h(1))$ when $\Pi^h(n-1)$ is the measure of $\tilde{X}^h(0)$. For each h and n, let $M^{h,n}$ denote a random measure which is almost surely (a.s.) mutually absolutely continuous (i.e., measure equivalent) with respect to P^h_{n-1}. For each h and n, let $\{\tilde{X}^{h,l,n}(\cdot), l \le v^h\}$ be mutually conditionally independent, conditioned on $\delta Y_n, P^h_{n-1}, M^{h,n}$, and with the distribution $M^{h,n}$. Define the likelihood ratio (the Radon–Nikodym derivative) and its value on the random path $\tilde{X}^{h,k,n}(\cdot)$ by

$$L^{h,n} = \frac{dP^h_{n-1}}{dM^{h,n}}, \qquad L^{h,k,n} = \frac{dP^h_{n-1}}{dM^{h,n}}(\tilde{X}^{h,k,n}(\cdot)). \tag{6.1}$$

We introduce the following assumption.

A6.1.

$$\sup_{h,n} E\frac{dP^h_{n-1}}{dM^{h,n}}(\tilde{X}^h(0), \tilde{X}^h(1))R^2(\tilde{X}^h(1), \delta Y_n) < \infty, \tag{6.2}$$

where $\tilde{X}^h(\cdot)$ in (6.2) has the distribution P^h_{n-1} (conditioned on $\delta Y_n, P^h_{n-1}, M^{h,n}$).

Define the approximate filter $\Pi^h(\cdot)$ to be:

$$\langle \Pi^h(n), \phi\rangle = \frac{\sum_{l=1}^{v^h} L^{h,k,n}\phi(\tilde{X}^{h,l,n}(1))R(\tilde{X}^{h,l,n}(1), \delta Y_n)/v^h}{\sum_{l=1}^{v^h} L^{h,k,n}R(\tilde{X}^{h,l,n}(1), \delta Y_n)/v^h}. \tag{6.3}$$

THEOREM 6.2. *Assume* A4.1, A4.2, A6.1, *and the filter form* (6.3). *Then Theorem* 5.1 *holds.*

Proof. To prove the theorem, it suffices to show that

$$E\left[\frac{1}{v^h}\sum_{k=1}^{v_h}(L^{h,k,n}\Phi(\tilde{X}^{h,k,n}(1), \delta Y_n) - E_{\Pi^h(n-1),\delta Y_n}\Phi(\tilde{X}^h(1), \delta Y_n))\right]^2 \tag{6.4}$$

converges to 0 uniformly in n as $h \to 0$, where $\Phi(x,y) = \phi(x)R(x,y)$ and $\phi(\cdot)$ is any bounded and continuous real-valued function.

We can write

$$\begin{aligned} &E_{M^{h,n},P^h_{n-1},\delta Y_n} L^{h,k,n}\Phi(\tilde{X}^{h,k,n}(1),\delta Y_n) \\ &= E_{M^{h,n},P^h_{n-1},\delta Y_n}\Phi(\tilde{X}^h(1),\delta Y_n) = E_{\Pi^h(n-1),\delta Y_n}\Phi(\tilde{X}^h(1),\delta Y_n), \end{aligned} \tag{6.5}$$

where as before the subscript in the expectation is the conditioning data and $\tilde{X}^h(\cdot)$ in the second and the third expression has the law (conditioned on $M^{h,n}, P^h_{n-1}, \delta Y_n$) P^h_{n-1}. The first equality follows by the definition of the Radon–Nikodym derivative. The second equality is simply a statement of the fact that all we need to know about $\tilde{X}^h(\cdot)$ to compute the expectation is its initial distribution and the one step law of evolution.

Under $M^{h,n}$, the samples are mutually independent, conditioned on $\delta Y_n, P^h_{n-1}, M^{h,n}$. By the above facts, (6.4) can be rewritten as

$$\begin{aligned} &EE_{M^{h,n},P^h_{n-1},\delta Y_n}\left[\frac{1}{v^h}\sum_{k=1}^{v_h}(L^{h,k,n}\Phi(\tilde{X}^{h,k,n}(1),\delta Y_n) - E_{\Pi^h(n-1),\delta Y_n}\Phi(\tilde{X}^h(1),\delta Y_n))\right] \\ &= \frac{1}{(v^h)^2}EE_{M^{h,n},P^h_{n-1},\delta Y_n}\sum_{k=1}^{v_h}[L^{h,k,n}\Phi(\tilde{X}^{h,k,n}(1),\delta Y_n) - E_{\Pi^h(n-1),\delta Y_n}\Phi(\tilde{X}^h(1),\delta Y_n)]^2. \end{aligned} \tag{6.6}$$

The right-hand side of (6.6) is

$$O(1)\frac{1}{v^h}EE_{M^{h,n},P^h_{n-1},\delta Y_n}[L^{h,n}R^2(\tilde{X}^h(1),\delta Y_n)].$$

The last term, in turn, can be bounded by

$$O(1)\frac{1}{v^h}\left(E\left[\frac{dP^h_{n-1}}{dM^{h,n}}(\tilde{X}^h(0),\tilde{X}^h(1))R^2(\tilde{X}^h(1),\delta Y_n)\right] + ER^2(\tilde{X}^h(1),\delta Y_n)\right),$$

where $\tilde{X}^h(\cdot)$ is as in A6.1. The above expression is easily seen to be $O(1/v^h)$ by (6.2). □

An extension: Dropping the mutual independence. As in Example 5.3 of section 5, where we relaxed the condition on mutual independence of samples by instead assuming A5.2, we can formulate a similar condition here which can be used to incorporate variance reduction methods along with importance sampling. More precisely, let $M^{h,n}$ be as before. Also let $\{\tilde{X}^{h,l,n}(\cdot); l \le v^h\}$ be as before, except that they need not be (conditionally) mutually independent. Instead of assuming A6.1, assume A6.2 below.

A6.2. Let $\Phi(x,y) = \phi(x)R(x,y)$, where $\phi(\cdot)$ is a bounded and continuous real-valued function. Then

$$E\left[\frac{1}{v^h}\sum_{k=1}^{v_h}(L^{h,k,n}\Phi(\tilde{X}^{h,k,n}(1),\delta Y_n) - E_{\Pi^h(n-1),\delta Y_n}\Phi(\tilde{X}^h(1),\delta Y_n))\right]_1^2$$

converges to 0 uniformly in n as $h \to 0$.

The following extension of Theorem 6.2 can now be stated.

THEOREM 6.3. *Theorem* 5.2 *holds for the filter defined by* (6.3) *under* A4.1, A4.2, *and* A6.2.

Remark on A6.1 *and* A6.2. Assumptions A6.1 and A6.2 are seen to hold for many examples of interest. Perhaps most commonly, the desired change of measure is such that

$$\sup_{h,n} \sup_{x,y \in G} \frac{dP^h_{n-1}}{dM^{h,n}}(x,y) < \infty.$$

In such a case A6.1 is clearly satisfied. Typically the importance sampling is with respect to initial condition only, and Π^h_{n-1} is a discrete probability measure (see Example 6.4). In such situations a natural choice of $M^{h,n}$ is the measure obtained by multiplying the probabilities of the points by appropriate weights which are uniformly bounded in h and n. An important case where the uniform boundedness does not hold, but where A6.1 can be verified, is described in Example 6.4. Note that if the measure $M^{h,n}$ only depends upon $\{\delta Y_j; j \le n-1\}$, then A6.1 can be simplified to

$$\sup_{h,n} E \frac{dP^h_{n-1}}{dM^{h,n}}(\tilde{X}^h(0), \tilde{X}^h(1)) < \infty.$$

Furthermore, for all these situations, if the sampling is done from $M^{h,n}$, using some variance reduction scheme of the types illustrated in section 5 rather than in a purely i.i.d. manner, then A6.2 holds.

As stated above, of special interest is the case where the importance sampling is with respect to the initial condition only. To illustrate this case, we consider the special case of Example 5.6 of section 5, where the sampling filter without importance sampling is given by (5.1) with $\tilde{X}^{h,n,l}(\cdot)$ defined via (5.12b). Then P^h_{n-1} can be identified with the measure $\Pi^h(n-1) \times P^h_\zeta$ in that this measure determines that of $(\tilde{X}^h(0), \tilde{X}^h(1))$. Now, let us write $M^{h,n}$ in a similar manner; namely, $M^{h,n} = M^{h,n}_0 \times P^h_\zeta$, where $M^{h,n}_0$ is a random measure on G. In this case, the measure transformation is over the initial condition only and we have

$$L^{h,n} = \frac{d\Pi^h(n-1)}{dM^{h,n}_0} \quad \text{and} \quad L^{h,k,n} = \frac{d\Pi^h(n-1)}{dM^{h,n}_0}(\tilde{X}^{h,k,n}(0)).$$

In the next example, we see that the idea of applying importance sampling to the initial condition can be enhanced by the use of the next observation δY_n, to determine the $M^{h,n}_0$.

Example 6.4 (observation dependent importance sampling). Appropriate measure transformations $M^{h,n}$ (or $M^{h,n}_0$ as defined at the end of the above example) can improve the estimates quite a bit [5, 29]. Better $M^{h,n}$ will depend on the next observation δY_n, and we will illustrate the point via the signal model of Example 5.6 of section 5, where $\tilde{X}^h(\cdot)$ is defined by (5.12). Data and examples of such a procedure can be found in [29]. Again, A6.1 and the mutual absolute continuity are the only conditions (in addition to A4.1 and A4.2) that need to be verified for Theorem 5.1 to hold for the $\Pi^h(\cdot)$ defined in this example. Keep in mind that we are illustrating only one type of procedure, and even that has many variations. Consider the following procedure.

Suppose that $\Pi^h(n-1)$ is concentrated on the v^h points $\{x^{h,l,n}, l \le v^h\}$, with the lth point having probability $\Pi^h_l(n-1)$. The paths emanating from some of the $x^{h,l,n}$ might be "poor" predictors of the observation δY_n in the sense that the conditional density

$$p\{\delta Y_n | X(n) = b_h(x^{h,l,n}, \xi^h)\}$$

is very small with a high probability. For some other points $x^{h,l,n}$, this value might be high with a reasonable probability. It seems reasonable to explore the paths emanating from the more promising initial points more fully, if this can be done without (asymptotically) biasing the procedure. The main problem is that we do not know (apart from the values of $\Pi^h(n-1)$) which are the more promising points and how much more promising they are. The "weights" for the importance sampling are to be determined by an exploratory sampling procedure, after which the sampling to get the next estimate $\Pi^h(n)$ will be done. This "double" sampling explains the complexity of the following algorithm. Nevertheless, such algorithms are sometimes useful [29] in that the total computation for a filter with comparable accuracy can be less than what is needed for a direct method such as that in Example 5.1.

The procedure starts by getting a "typical" value of $b_h(x^{h,l,n}, \xi^h)$. The word "typical" is used loosely here. The aim is to get some preliminary approximation to the "predictive values" of the trajectories emanating from the point, given the next observation. This "typical value" might be an estimate of the mean value, or it might be a simple sample value or an average of several sample values. We call these the "indicator" values and denote them by $\hat{X}^{h,l,n}(1), l \le v^h$. Then the "predictive power" of this indicator value is computed, and the associated weights used to get the importance sampling measure for the final computation of $\Pi^h(n)$. The details follow in algorithmic form.

(1) Let $\hat{X}^{h,l,n}(1)$ $(l \le v^h)$ denote an "indicator" quantity, which (hopefully) is highly correlated with the "value" of sampling with initial condition $x^{h,l,n}$. (The points for which we get such an "indicator" quantity might also be chosen by some sampling procedure.)

(2) Compute the conditional Gaussian density $p(\delta Y_n | X(n) = \hat{X}^{h,l,n}(1))$, and define the "conditional likelihood" of the observation

$$p^{h,l,n} = \frac{p(\delta Y_n | X(n) = \hat{X}^{h,l,n}(1))}{\sum_k \Pi_k^h(n-1) p(\delta Y_n | X(n) = \hat{X}^{h,k,n}(1))}, \qquad l \le v_h. \tag{6.7}$$

The numerator of $p^{h,l,n}$ up to a normalizing factor is $R(\hat{X}^{h,l,n}(1), \delta Y_n)$. Note that $p^{h,l,n}$ is not a probability. If the numerator in (6.7) is the same for all points, then $p^{h,l,n} = 1$ for all l.

(3) Sample $m^{h,n} \ge v^h$ times (with replacement) from the set

$$\{x^{h,l,n}, l \le v^h\}$$

with weights proportional to the $p^{h,l,n}\Pi_l^h(n-1)$. Note that $\sum_l p^{h,l,n}\Pi_l^h(n-1) = 1$. This yields a set which we denote by

$$\{\overline{x}^{h,l,n}, l \le m^{h,n}\}.$$

It is found in practice that the performance is often better if $m^{h,n}$ is several times v^h. This tends to assure a better spread for the support of the conditional distribution.

(4) Sample $\{\zeta^{h,k,n}, k \le m^{h,n}\}$ from P_ζ^h and compute

$$\overline{X}^{h,l,n}(1) = b_h(\overline{x}^{h,l,n}, \zeta^{h,k,n}), \qquad k \le m^{h,n}. \tag{6.8}$$

(5) If $v^h = m^{h,n}$, then set $\tilde{X}^{h,l,n}(1) = \overline{X}^{h,l,n}(1) = x^{h,l,n+1}$. If $v^h < m^{h,n}$, then resample at random (with replacement) v^h times from $\{\overline{X}^{h,l,n}(1), l \le m^{h,n}\}$ to get the set $\{\tilde{X}^{h,k,n}(1), k \le v^h\}$, and set $x^{h,k,n+1} = \tilde{X}^{h,k,n}(1)$.

In this procedure, the measure $M^{h,n}$ was defined by defining $M_0^{h,n}$ via the weight

$$M_{0,k}^{h,n} = p^{h,k,n}\Pi_l^h(n-1) \tag{6.9}$$

that it puts on the initial point $x^{h,l,n}$. Finally, we use the filter defined by (6.3) with

$$L^{h,l,n} = \frac{1}{p^{h,l,n}}. \tag{6.10}$$

The set of likelihood functions clearly satisfy A6.1, and the corresponding measures satisfy the mutual absolute continuity requirement.

Note on numerical data. Various forms of the suggested algorithmic forms have been simulated on the four-dimensional problem of [4]. The model represented a ship moving in a region limited by a shoreline, and this led to the nonlinearities. The observations were angle only, and there was little data in each observation. We tried to make comparisons with essentially the same program time used for the various cases. While no effort was made to optimize the performance of any algorithm, certain conclusions can be drawn. Wherever possible, use an "integration" method. They were more efficient with "moderately" limited computation time and generally performed well. Depending on the parameters, the Monte Carlo methods might be close. Variance reduction methods definitely help. The observation dependent importance sampling methods of the type of Example 6.4 further reduced the error variances by about 10%. Now, drop the equal time constraints. There were lower bounds to the (experimental) error variances for the integration algorithm, as its "order" increased. These bounds are usually larger than the true variances and were larger than error variances for the Monte Carlo methods for large numbers of samples. Owing to the large number of samples (hence pseudorandom numbers) needed for the Monte Carlo, a considerable effort needs to be put into the coding to achieve realistic execution times. Owing to the several layers of sampling used in the observation dependent importance sampling method, combinations of Monte Carlo and integration methods often improved on the purely Monte Carlo, but there is no room for the many details here.

7. The continuous time problem. In this section we will study the continuous time analogues of the various random sampling and combined random sampling-integration algorithms studied in sections 5 and 6. Our basic filtering model will be that in section 2. To fix ideas, we will begin by indicating the form of the approximating filter for the case where the random samples are mutually independent and identically distributed, analogously to what was done in (5.1). We will then consider a general form of the approximating filter which would cover not only the case of such i.i.d. samples but also various variance reduction schemes and importance sampling algorithms of the type studied in Examples 5.3, 6.1, and 6.4.

7.1. Example and motivation. In typical uses of the approximation (2.7), the approximating signal process $\tilde{X}^h(\cdot)$ is a piecewise constant interpolation of a discrete time process. One good example is the Markov chain approximation such as used in Example 5.7. Most current applications seem to use such Markov chain based approximations, whether they are of the explicit forms discussed in [24] or other forms which satisfy the required local consistency property, e.g., based on approximate solutions to the Fokker–Planck equation over small intervals.

Following the idea and terminology of Example 5.7, let X_n^h denote the underlying Markov chain, and let $\tilde{X}^h(\cdot)$ denote its piecewise constant interpolation, with

interpolation interval δ_h. Then one can use the approximating filter (2.7). Since the approximating process $\tilde{X}^h(\cdot)$ is piecewise constant, $R(\tilde{X}^h_{0,t}, Y_{0,t})$ equals

$$\begin{aligned}(7.1)\qquad &\exp\sum_{k=0}^{[t/\delta_h]-1}\left[g'(X^h_k)\left[Y(k\delta_h+\delta_h)-Y(k\delta_h)\right]-\frac{\delta_h}{2}\left|g(X^h_k)\right|^2\right]\\ &\times\exp\left[g'(X^h_{[t/\delta_h]})\left[Y(t)-Y([t/\delta_h]\delta_h)\right]-\tfrac{t-[t/\delta_h]\delta_h}{2}|g(X^h_{[t/\delta_h]})|^2\right].\end{aligned}$$

However, in practice observations cannot truly be taken continuously, and one would incorporate the observation into the filter at the discrete time instants $n\delta_h$ only. In fact, for such nonlinear problems the notion of continuous updating seems to be a mathematical fiction, although the times between updating might be very small. Thus one would approximate $R(\tilde{X}^h_{0,t}, Y_{0,t})$ by $R^h(\tilde{X}^h_{0,t}, Y_{0,t})$ which is defined by the following (piecewise constant) expression

$$(7.2)\qquad \exp\sum_{k=0}^{[t/\delta_h]-1}\left[g'(X^h_k)\left[Y(k\delta_h+\delta_h)-Y(k\delta_h)\right]-\frac{\delta_h}{2}\left|g(X^h_k)\right|^2\right].$$

Whatever the form of $\tilde{X}^h(\cdot)$, whether it is obtained explicitly as an interpolation of a discrete time chain X^h_n or not, the samples $\tilde{X}^h(n\delta_h)$ are always a Markov chain. For notational simplicity, we always write $\tilde{X}^h(n\delta_h) = X^h_n$.

A random sampling algorithm. The above paragraph argues that it is not a restriction to require the approximating filter process to be piecewise constant. This logic also holds for algorithms based on random sampling. It holds even if some higher-order interpolation method (say that of Milstein or other types used in [17]) is used, since even then we would use the interpolation to get a better approximation to the signal process at discrete time instants $n\delta_h$. Thus, in the approximate filters that are considered here, we approximate the conditional distribution at the instants $n\delta_h$, and we suppose that the filter is constant on $[n\delta_h, n\delta_h+\delta_h)$.

Since the estimate of the conditional distribution will be updated at each $n\delta_h$, we could try to duplicate the various methods in Examples 5.1 to 6.4, with the basic interval being δ_h, and then prove convergence as $\delta_h \to 0$. The resampling at the beginning of each interval in the various examples exploited the updated information to get more sample trajectories from the points which seemed to be more likely, in view of the information in the observations. But random sampling also loses information. There is always a chance that the better points will not be sampled. This chance is reduced as v^h increases. When resampling occurs very frequently, say at each time instant $n\delta_h$, the procedure can degenerate very fast as $\delta_h \to 0$, unless v^h increases fast enough as $\delta_h \to 0$. One can quantify such a statement. But it is also a common observation in simulations, including the ones that we have carried out. Reference [6] resamples at each discrete interval, in a "minimum variance" way, but v^h must grow as $1/\delta_h$. Such a rapid increase in v^h is an inefficient use of the computational resources, especially in view of the fact that the estimates of the conditional distribution do not change much in small intervals.

Owing to the above observations, we take the following "practical" approach. Divide time into subunits of (small, but fixed—they do not go to zero) length ϵ, and suppose that $\epsilon/\delta_h = n_h$ is always an integer. We resimulate the $\tilde{X}^h(\cdot)$ each ϵ units of time, although the observations are incorporated at the instants $n\delta$.

The general model given below is motivated by the ideas of Examples 5.4 to 6.4, and we give an analogue of condition A5.3 (namely, conditions A7.1, A7.2) which

covers many cases of interest. But, for specificity, let us first consider the case where the process $\tilde{X}^h(\cdot)$ satisfies the consistency assumption A2.1 and the samples taken on $[n\epsilon, n\epsilon+\epsilon)$ are mutually independent and independent of $Y(\cdot)$ given their initial distribution $\Pi^h(n\epsilon)$. Denote these samples by $\{\tilde{X}^{h,l,n}(\cdot), l \le v^h\}$. Define

$$R^h(\tilde{X}_{0,s}, Y_{n\epsilon,n\epsilon+s}) \tag{7.3}$$
$$= \exp \sum_{k=0}^{[s/\delta_h]-1} \left[g'(X_k^h)\left[Y(n\epsilon+k\delta_h+\delta_h) - Y(n\epsilon+k\delta_h)\right] - \frac{\delta_h}{2}\left|g(X_k^h)\right|^2 \right].$$

Thus $R^h(x_{0,s}, Y_{a,b})$ differs from $R(x_{0,s}, Y_{a,b})$ only in that in the former the function $x(\cdot)$ is replaced by the piecewise constant function with value $x(k\delta_h)$ on $[k\delta_h, k\delta_h+\delta_h)$. The basic approximating filter based on random sampling for $s = q\delta_h < \epsilon$ where q is an integer is

$$\langle \Pi^h(n\epsilon+s), \phi\rangle = \frac{\sum_{l=1}^{v^h} \phi(\tilde{X}^{h,l,n}(s)) R^h(\tilde{X}_{0,s}^{h,l,n}, Y_{n\epsilon,n\epsilon+s})/v^h}{\sum_{l=1}^{v^h} R^h(\tilde{X}_{0,s}^{h,l,n}, Y_{n\epsilon,n\epsilon+s})/v^h}. \tag{7.4}$$

This is just the "continuous time" analogue of (5.1).

As stated earlier, we will suppose that $\Pi^h(\cdot)$ is constant on the intervals $[q\delta_h, q\delta_h+\delta_h)$. Alternatively, if desired, we can interpolate, and one natural interpolation would use the form (7.4), but with the term

$$g'(X^h_{[s/\delta_h]})\left[Y(n\epsilon+s) - Y(n\epsilon+[s/\delta_h]\delta_h)\right] - \frac{s-[s/\delta_h]\delta_h}{2}|g(X^h_{[s/\delta_h]})|^2 \tag{7.5}$$

added to the sum in (7.3). The treatment of both forms is nearly identical.

As in the discrete time case, we are interested in random sampling and random sampling-integration algorithms which are more general than (7.4), with (conditional) i.i.d. samples. We would like to allow the possibility of incorporating variance reduction methods as in Example 5.3, or perhaps the sampling can be guided using some importance sampling scheme as in Examples 6.1 and 6.4. We might even be interested in algorithms which are part integration and part random sampling, say of the form discussed in Examples 5.6 and 5.7. In view of this, we work with the following general form of the approximate filter, which is our continuous time analogue of the discrete time filter defined via (5.10). The chosen general structure is motivated by the same considerations which led to (5.10) and A5.11, the desire to include many types of approximations of interest under one roof, with a general assumption which can be verified in particular cases of interest, analogously to what was done for the discrete time case. The conditions A7.1 and A7.2 hold for the independent samples case under A2.1.

Let δ_h, ϵ, n_h be as above. Define the approximating filter $\Pi^h(\cdot)$ as follows. Having defined $\Pi^h(t)$ for $0 \le t \le n\epsilon$, let $P^{h,n}_{\Pi^h(n\epsilon)}$ be conditionally independent of $\{Y_t - Y_{n\epsilon}; t \ge n\epsilon\}$ given $\Pi^h(n\epsilon)$. Define, for $1 \le j \le n_h$,

$$\langle \Pi^h(n\epsilon+j\delta_h), \phi\rangle = \frac{\int \phi(x(j\delta_h)) R^h(x_{0,j\delta_h}, Y_{n\epsilon,n\epsilon+j\delta_h}) dP^{h,n}_{\Pi^h(n\epsilon)}(x(\cdot))}{\int R^h(x_{0,j\delta_h}, Y_{n\epsilon,n\epsilon+j\delta_h}) dP^{h,n}_{\Pi^h(n\epsilon)}(x(\cdot))}. \tag{7.6}$$

For points in $[n\epsilon, (n+1)\epsilon)$ not of the form $n\epsilon + j\delta_h$, the filter is defined via the piecewise constant and right continuous interpolation. In the independent sample

case (7.4), $P^{h,n}_{\Pi^h(n\epsilon)}$ is the occupation measure defined analogously to the way it was defined above (5.9) for the discrete time case. We assume that the family $\{P^{h,n}_{\Pi^h(n\epsilon)}\}$ satisfies A7.1 and A7.2 below. Given the very general structure allowed for the filter, some condition such as A7.2 is needed for the continuous time problem in order to avoid simulated processes that are "wild." Under A2.1, condition A7.2 holds for the i.i.d. case illustrated in (7.4), since there each $\tilde{X}^{h,l,n}(\cdot)$ is a replica of the $\tilde{X}^h(\cdot)$ of A2.1 with initial conditions in the compact set G.

A7.1. For every bounded and continuous real valued function $\Phi(\cdot)$ of $x(\cdot)$ on the interval $[0,\epsilon]$ and which depends on $x(\cdot)$ only at a finite number of points,

$$\lim_{h\to 0}\sup_n E\left[\int \Phi(x(\cdot))dP^{h,n}_{\Pi^h(n\epsilon)}(x(\cdot)) - E_{\Pi^h(n\epsilon)}\Phi(\tilde{X}(\cdot))\right]^2_1 = 0.$$

We will impose another condition on the $P^{h,n}_{\Pi^h(n\epsilon)}$. For motivation, consider the case of independent samples discussed above. For $\mu > 0, \delta > 0$, define the set of paths

$$C^\delta_\mu = \left\{x(\cdot) : \sup_{s\le\delta, t+s\le\epsilon, t\le\epsilon} |x(t+s) - x(t)| \ge \mu\right\}.$$

Then our second condition is the following.

A7.2.

$$\lim_{\delta\to 0}\limsup_h \sup_n EP^{h,n}_{\Pi^h(n\epsilon)}(C^\delta_\mu) = 0 \quad \text{for each} \quad \mu > 0. \tag{7.7}$$

Remark on A7.1 *and* A7.2. The assumption A7.1 is similar to the assumption (A5.3) made for the discrete time problem. For the cases where $P^{h,n}_{\Pi^h(n\epsilon)}$ is constructed via i.i.d. sampling or some variance reduction scheme, it is verified as easily as in the discrete time case. Also, if this measure is constructed via a combination of sampling and integration in manner similar to Example 5.7, where the observations are incorporated at each time $n\delta_h$, one can again verify A7.1 by using the consistency condition A2.1. The assumption A7.1 continues to hold if the samplings of the initial conditions $\tilde{X}^{h,l,n}(0)$ are determined by importance sampling as in Example 6.4. Assumption A7.2 simply states that for small h, the sampled paths don't change much in the mean over small intervals, uniformly in n. For all the above examples this assumption can be verified by using the consistency condition A2.1 on the $\tilde{X}^h(\cdot)$ process.

The following lemma will be used in some of the tightness arguments used below.

LEMMA 7.1 [19, Theorem 2.7b]. *Let $\{Z_n(\cdot), n\}$ be a family of processes with paths in the Skorohod space $D[S_0; 0, \infty)$, where S_0 is a complete and separable metric space with metric $\gamma(\cdot)$. For each $\delta > 0$ and each t in a dense set, let there be a compact set $S_{\delta,t} \subset S_0$ such that*

$$\sup_n P\{Z_n(t) \notin S_{\delta,t}\} \le \delta.$$

Let $\mathbb{F}^n_t$ denote the minimal σ-algebra which measures $\{Z_n(u), u \le t\}$, and let $\mathcal{T}_n(T)$ denote the set of $\mathbb{F}^n_t$-stopping times which are less than $T > 0$. Suppose that for each T

$$\lim_{\delta\to 0}\limsup_n \sup_{\tau\in\mathcal{T}_n(T)} E\left[\gamma\left(Z_n(\tau+\delta), Z_n(\tau)\right) \wedge 1\right] = 0.$$

Then $\{Z^n(\cdot)\}$ is tight.

THEOREM 7.2. *Let* $(X(\cdot), Y(\cdot))$ *be as in section* 2. *Assume* A3.1, A7.1, *and* A7.2. *Then the conclusions of Theorem* 3.1 *hold for the approximate filter* $\Pi^h(\cdot)$ *defined as above.*

Proof. Many of the details of the proof are the same as in the proof of Theorem 3.1 and its variations used in the proof of Theorem 5.2 and its successors for the discrete time case. The key differences are in the proof of tightness of $\{Q^{h_k,T_k}(\cdot); k \geq 1\}$ for any sequences $h_k \to 0, T_k \to \infty$, and the proof of the representation (3.8), and we concentrate on these points. In the discrete time theorems, the tightness of $\{Q^{h_k,T_k}(\cdot); k \geq 1\}$ was essentially obvious due to the compactness of G. There was no issue of "path properties," in showing the tightness due to the discrete time parameter. In the current continuous time case, we need to deal with the path properties. Owing to the use of the weak topology, it is enough to prove the tightness of the set

$$\{\langle \Pi^{h_k}(t_k + \cdot), \phi\rangle; h_k, T_k\}$$

for each bounded and continuous real-valued function $\phi(\cdot)$ on G.

In proving the tightness of the above family, we use the criterion in the lemma. The main step is establishing that for each $\phi(\cdot)$, as above,

$$\lim_{\delta\to 0} \limsup_{h\to 0} \sup_t \sup_{\tau\in\mathcal{T}^{h,t}(\rho)} E\left|\langle \Pi^h(t+\tau+\delta), \phi\rangle - \langle \Pi^h(t+\tau), \phi\rangle\right|_1^2 = 0, \tag{7.8}$$

where $\mathcal{T}^{h,t}(\rho)$ denotes the set of stopping times bounded by ρ for the process $\Pi^h(t+\cdot)$. We can assume without loss of generality that δ in the above expression is less than ϵ. Thus $t+\tau$ and $t+\tau+\delta$ are either in the same interval of the form $[j\epsilon, (j+1)\epsilon)$ or they are in adjacent such intervals. This observation along with an application of a triangle inequality shows that, in order to prove (7.8), it suffices to prove that

$$\limsup_{h\to 0} \sup_j \sup_{0\leq K_1\leq K_2\leq n_h, |K_1-K_2|\delta_h\leq\delta} E\left|\langle \Pi^h(j\epsilon + K_1\delta_h), \phi\rangle - \langle \Pi^h(j\epsilon + K_2\delta_h), \phi\rangle\right|_1^2 \tag{7.9}$$

converges to 0 as $\delta \to 0$. Note that $j\epsilon + K_1\delta_h$ and $j\epsilon + K_2\delta_h$ are both in the interval $[j\epsilon, j\epsilon + \epsilon]$.

Now we bound the above expectation by the sum of the following three terms. The first two terms are, for $i = 1, 2$,

$$\limsup_{h\to 0} \sup_j \sup_{0\leq K_i\delta_h\leq\epsilon} F_1(j, h, K_i\delta_h), \tag{7.10}$$

where

$$F_1(j,h,K_i\delta_h) = E\left[\langle \Pi^h(j\epsilon + K_i\delta_h), \phi\rangle - \frac{E_{\Pi^h(j\epsilon), Y_{j\epsilon, j\epsilon+K_i\delta_h}} \phi(\tilde{X}(K_i\delta_h)) R^h(\tilde{X}_{0,K_i\delta_h}, Y_{j\epsilon,j\epsilon+K_i\delta_h})}{E_{\Pi^h(j\epsilon), Y_{j\epsilon,j\epsilon+K_i\delta_h}} R^h(\tilde{X}_{0,K_i\delta_h}, Y_{j\epsilon,j\epsilon+K_i\delta_h})}\right]_1^2.$$

The third term is

$$\limsup_{h\to 0} \sup_j \sup_{0\leq K_1\delta_h\leq K_2\delta_h\leq\epsilon, |K_1-K_2|\delta_h\leq\delta} F_2(j, h, K_1\delta_h, K_1\delta_h), \tag{7.11}$$

where

$$F_2(j,h,K_1\delta_h,K_1\delta_h) = E\left[\frac{E_{\Pi^h(j\epsilon),Y_{j\epsilon,j\epsilon+K_1\delta_h}}\phi(\tilde{X}(K_1\delta_h))R^h(\tilde{X}_{0,K_1\delta_h},Y_{j\epsilon,j\epsilon+K_1\delta_h})}{E_{\Pi^h(j\epsilon),Y_{j\epsilon,j\epsilon+K_1\delta_h}}R^h(\tilde{X}_{0,K_1\delta_h},Y_{j\epsilon,j\epsilon+K_1\delta_h})} - \frac{E_{\Pi^h(j\epsilon),Y_{j\epsilon,j\epsilon+K_2\delta_h}}\phi(\tilde{X}(K_2\delta_h))R^h(\tilde{X}_{0,K_2\delta_h},Y_{j\epsilon,j\epsilon+K_2\delta_h})}{E_{\Pi^h(j\epsilon),Y_{j\epsilon,j\epsilon+K_2\delta_h}}R^h(\tilde{X}_{0,K_2\delta_h},Y_{j\epsilon,j\epsilon+K_2\delta_h})}\right]_1^2.$$

In dealing with (7.11), owing to the properties of the $|\cdot|_1^2$ metric defined by (4.14), we need only work with the differences of the numerators and denominators separately. Then, (7.11) is easily dealt with using the continuity property of $\tilde{X}(\cdot)$. In particular, it follows from the fact that for any bounded and continuous function $\phi(\cdot)$

$$\lim_{\delta\to 0}\sup_{|K_1-K_2|\delta_h\le\delta}\sup_{\pi} E\Big[E_{\pi,Y_{j\epsilon,j\epsilon+K_1\delta_h}}\phi(\tilde{X}(K_1\delta_h))R^h(\tilde{X}_{0,K_1\delta_h},Y_{j\epsilon,j\epsilon+K_1\delta_h}) - E_{\pi,Y_{j\epsilon,j\epsilon+K_2\delta_h}}\phi(\tilde{X}(K_2\delta_h))R^h(\tilde{X}_{0,K_2\delta_h},Y_{j\epsilon,j\epsilon+K_2\delta_h})\Big]_1^2 = 0, \tag{7.12}$$

where $K_i\delta_h \le \epsilon$.

Now we consider (7.10). By the definition of $\Pi^h(j\epsilon)$ in terms of $P^{h,j}_{\Pi^h(j\epsilon)}$ in (7.6), the first term inside the bars in (7.10) equals

$$\frac{\int \phi(x(K_i\delta_h))R^h(x_{0,K_i\delta_h},Y_{j\epsilon,j\epsilon+K_i\delta_h})dP^{h,j}_{\Pi^h(j\epsilon)}(x(\cdot))}{\int R^h(x_{0,K_i\delta_h},Y_{j\epsilon,j\epsilon+K_i\delta_h})dP^{h,j}_{\Pi^h(j\epsilon)}(x(\cdot))}. \tag{7.13}$$

Again, we need only work with the differences of the numerators of the right-hand term inside the bars in (7.10) and that in (7.13) for arbitrary bounded and continuous $\phi(\cdot)$.

The proof that the limit of (7.10) as $\delta \to 0$ is zero will use an approximation method. For small $\Delta > 0$, with ϵ an integral multiple of Δ, define $R^\Delta(x_{0,s},Y_{a,a+s})$ by

$$\exp\left\{\sum_{i:i\Delta<s} g'(x(i\Delta))\left[Y(a+i\Delta+\Delta)-Y(a+i\Delta)\right] - \frac{\Delta}{2}\sum_{i:i\Delta<s}|g(x(i\Delta))|^2\right\}.$$

For each h, define

$$A^{h,\Delta} = \sup_{K_i\delta_h\le\epsilon}\sup_j\sup_\pi E_\pi[R^h(\tilde{X}_{0,K_i\delta_h},Y_{j\epsilon,j\epsilon+K_i\delta_h}) - R^\Delta(\tilde{X}_{0,K_i\delta_h},Y_{j\epsilon,j\epsilon+K_i\delta_h})]_1^2.$$

For each $\rho > 0$, there is $\Delta_0 > 0$ such that for $\Delta < \Delta_0$ and small $h > 0$ we have $A^{h,\Delta} \le \rho$. Define

$$B^{h,\Delta} = \sup_{K_i\delta_h\le\epsilon}\sup_j E\int\left[R^h(x_{0,K_i\delta_h},Y_{j\epsilon,j\epsilon+K_i\delta_h}) - R^\Delta(x_{0,K_i\delta_h},Y_{j\epsilon,j\epsilon+K_i\delta_h})\right]_1^2 dP^{h,j}_{\Pi^h(j\epsilon)}(x(\cdot)). \tag{7.14}$$

By A7.2, for each $\rho > 0$ there is $\Delta_0 > 0$ such that for $\Delta < \Delta_0$, and small $h > 0$, $B^{h,\Delta} \le \rho$. This assertion is proved as follows. Define $x^\Delta(t) = x(i\Delta)$ for $t \in [i\Delta, i\Delta+\Delta)$. To

prove the assertion, it is sufficient to show that

$$\limsup_h \sup_j \sup_{K_i \le n_h} \int \left[\sum_{l=0}^{K_i} \left[g(x(l\delta_h)) - g(x^\Delta(l\delta_h)) \right]' \left[Y(l\delta_h + \delta_h) - Y(l\delta_h) \right] \right]^2 d[EP^{h,j}_{\Pi^h(j\epsilon)}(x(\cdot))] \tag{7.15}$$

is arbitrarily small if Δ is small enough. By A7.2, we can suppose that the difference of the $g-$terms in the bracket in (7.15) is as small as we wish, and this implies the assertion.

Thus, to show that the limit of (7.10) is zero as $\delta \to 0$, it is sufficient to show that

$$\begin{aligned} &\lim_{\Delta\to 0} \limsup_{h\to 0} \sup_j \sup_{0\le K_i\delta_h \le \epsilon} \\ &\quad E \Bigg| \int \phi(x(K_i\delta_h)) R^\Delta(x_{0,K_i\delta_h}, Y_{j\epsilon, j\epsilon + K_i\delta_h}) dP^{h,j}_{\Pi^h(j\epsilon)}(x(\cdot)) \\ &\qquad - E_{\Pi^h(j\epsilon), Y_{j\epsilon, j\epsilon+K_i\delta_h}} \phi(\tilde{X}(K_i\delta_h)) R^\Delta(\tilde{X}_{0,K_i\delta_h}, Y_{j\epsilon, j\epsilon+K_i\delta_h}) \Bigg|_1^2 = 0. \end{aligned} \tag{7.16}$$

By A7.2, it is sufficient to show (7.16) if the $K_i\delta_h$ in the $\phi(x(K_i\delta_h))$ and $\phi(\tilde{X}(K_i\delta_h))$ are replaced by the closest integral multiple of Δ for small Δ. Now, all the $K_i\delta_h$ in (7.16) are integral multiples of Δ for some fixed Δ. Hence, the $\sup_{0\le K_i\delta_h\le\epsilon}$ in (7.16) is redundant and can be dropped. We would like to use A7.1 at this point. But A7.1 holds only for each function $\Phi(\cdot)$. In (7.16), Δ is fixed, and we can suppose without loss of generality that $\epsilon = k_0\Delta$ for some integer k_0. Given any small $\rho > 0$, there is a bounded set B_ρ such that the values of $\{Y(j\epsilon + t) - Y(j\epsilon), t \le \epsilon\}$ are confined to B_ρ with at least probability $1 - \rho$ for all j. Because of this and the continuity of $R^\Delta(\cdot)$, we need only verify (7.16) for some finite set of values of the $Y-$variables. Due to this and to the fact that $k_0 < \infty$, we need only evaluate (7.16) for each $Y(\cdot)$ and $K_i\delta_h \le \epsilon$ being some arbitrary multiple of Δ. Then A7.1 can be used and guarantees (7.16). This completes the proof of tightness of $\{Q^{h_k,T_k}(\cdot), k \ge 1\}$.

We now prove the representation in (3.8). The general scheme used in Theorem 5.2 for this characterization will be followed. Let $\psi(\cdot) = (x(\cdot), \pi(\cdot), y(\cdot), b(\cdot))$ denote the canonical paths of the signal process, the conditional probability process, the observation process, and the observation noise process. They are connected by $y(t) = \int_0^t g'(x(s))ds + b(t)$. For arbitrary bounded and continuous $\phi(\cdot)$, arbitrary $\psi(\cdot)$, and times t, s, define the function $A(\psi(\cdot); t, s))$ by

$$A(\psi(\cdot); t, s) = \langle \pi(t+s), \phi \rangle - \frac{E_{\{\pi(t), y_{t,t+s}\}}[\phi(\tilde{X}_{0,s}) R(\tilde{X}_{0,s}, y_{t,t+s})]}{E_{\{\pi(t), y_{t,t+s}\}} R(\tilde{X}_{0,s}, y_{t,t+s})}. \tag{7.17}$$

Recall the definition of $\Psi^\omega(\cdot)$ from Theorem 3.1. We will also use other notations from section 3. The aim of the proof of Theorem 3.2 in [3], which is our Theorem 3.1, was to show that, for almost all ω and all t, s,

$$A(\Psi^\omega(\cdot); t, s) = 0, \qquad \text{w.p.1}, \tag{7.18}$$

which implies (3.8). In fact it suffices to consider $s \le \epsilon$. Hereafter we will consider only such values of s without any further comment.

The statement in (7.18) will be proved by showing that

$$0 = E \int Q^{\omega}(d\psi)\,[A(\psi(\cdot);t,s)]_1^2\,. \tag{7.19}$$

The prelimit form of the right side of (7.19) is

$$E \int Q^{h,T}(d\psi)\,[A(\psi(\cdot);t,s)]_1^2\,,$$

which, by the definition of $Q^{h,T}(\cdot)$, equals

$$\frac{1}{T}\int_0^T E\left[A(\Psi^h(\cdot);u+t,s)\right]_1^2 du, \tag{7.20}$$

where

$$A(\Psi^h(\cdot);t,s) = \langle \Pi^h(t+s),\phi\rangle - \frac{E_{\{\Pi^h(t),Y_{t,t+s}\}}[\phi(\tilde{X}(s))R(\tilde{X}_{0,s},Y_{t,t+s})]}{E_{\{\Pi^h(t),Y_{t,t+s}\}}R(\tilde{X}_{0,s},Y_{t,t+s})}. \tag{7.21}$$

In order to show (7.19), it suffices to show that

$$\lim_h \sup_t E[A(\Psi^h(\cdot);t,s)]_1^2 \to 0. \tag{7.22}$$

Furthermore, in view of the properties of the $\tilde{X}(\cdot)$ process and the tightness of the set $\{\Pi^h(t);h,t\}$, to prove (7.22) it is clearly sufficient to show that

$$\sup_t E\left[\langle \Pi^h(t+s),\phi\rangle - \frac{E_{\{\Pi^h(t),Y_{t,t+s}\}}[\phi(\tilde{X}(s))R^h(\tilde{X}_{0,s},Y_{t,t+s})]}{E_{\{\Pi^h(t),Y_{t,t+s}\}}R^h(\tilde{X}_{0,s},Y_{t,t+s})}\right]_1^2 \to 0 \tag{7.23}$$

as $h \to 0$.

Since $s < \epsilon$, the points t and $t+s$ are either in the same subinterval of the form $[j\epsilon,(j+1)\epsilon]$ or are in adjacent intervals of this form. We consider below the case of adjacent intervals. The arguments required for the same interval case are simpler versions of the former case and thus are omitted. Let now $t \in [j\epsilon + i\delta_h, j\epsilon + i\delta_h + \delta_h)$ and $t+s \in [(j+1)\epsilon + i'\delta_h, (j+1)\epsilon + i'\delta_h + \delta_h)$. Showing (7.23) is equivalent to proving that, for each s,

$$E\left[\langle \Pi^h(t+s),\phi\rangle - \frac{E_{\{\Pi^h(j\epsilon+i\delta_h),Y_{j\epsilon+i\delta_h,t+s}\}}\left[\phi(\tilde{X}(\alpha\delta_h))R^h(\tilde{X}_{0,\alpha\delta_h},Y_{j\epsilon+i\delta_h,(j+1)\epsilon+i'\delta_h})\right]}{E_{\{\Pi^h(j\epsilon+i\delta_h),Y_{j\epsilon+i\delta_h,t+s}\}}R^h(\tilde{X}_{0,\alpha\delta_h},Y_{j\epsilon+i\delta_h,(j+1)\epsilon+i'\delta_h})}\right]_1^2 \tag{7.24}$$

converges to 0 as $h \to 0$, uniformly in t, where $\alpha = n_h + i' - i$. Thus, $|\alpha\delta_h - s| \le \delta_h$.

The expectation in (7.24) can be bounded above by the sum of

$$E\left[\langle \Pi^h(t+s),\phi\rangle - \frac{E_{\{\Pi^h((j+1)\epsilon),Y_{(j+1)\epsilon,t+s}\}}\left[\phi(\tilde{X}(i'\delta_h))R^h(\tilde{X}_{0,i'\delta_h},Y_{(j+1)\epsilon,(j+1)\epsilon+i'\delta_h})\right]}{E_{\{\Pi^h((j+1)\epsilon),Y_{(j+1)\epsilon,t+s}\}}R^h(\tilde{X}_{0,i'\delta_h},Y_{(j+1)\epsilon,(j+1)\epsilon+i'\delta_h})}\right]_1^2 \tag{7.25}$$

and

$$E\left[\frac{E_{\{\Pi^h((j+1)\epsilon),Y_{(j+1)\epsilon,t+s}\}}[\phi(\tilde{X}(i'\delta_h))R^h(\tilde{X}_{0,i'\delta_h},Y_{(j+1)\epsilon,(j+1)\epsilon+i'\delta_h})]}{E_{\{\Pi^h((j+1)\epsilon),Y_{(j+1)\epsilon,t+s}\}}R^h(\tilde{X}_{0,i'\delta_h},Y_{(j+1)\epsilon,(j+1)\epsilon+i'\delta_h})} - \frac{E_{\{\Pi^h(j\epsilon+i\delta_h),Y_{j\epsilon+i\delta_h,t+s}\}}[\phi(\tilde{X}(\alpha\delta_h))R^h(\tilde{X}_{0,\alpha\delta_h},Y_{j\epsilon+i\delta_h,(j+1)\epsilon+i'\delta_h})]}{E_{\{\Pi^h(j\epsilon+i\delta_h),Y_{j\epsilon+i\delta_h,t+s}\}}R^h(\tilde{X}_{0,\alpha\delta_h},Y_{j\epsilon+i\delta_h,(j+1)\epsilon+i'\delta_h})}\right]_1^2. \tag{7.26}$$

Using the definition from (7.6) of $\Pi^h(t+s)$ in terms of $P^{h,j+1}_{\Pi^h((j+1)\epsilon)}$ in (7.25) and working with numerators and denominators separately, as we may, it follows that showing the convergence to zero of the $\sup_t$ of (7.25) as $h \to 0$ to zero is equivalent to showing the same for

$$E\Bigg[\int \phi(x(i'\delta_h))R^h(x_{0,i'\delta_h}, Y_{(j+1)\epsilon,(j+1)\epsilon+i'\delta_h})dP^{h,j+1}_{\Pi^h((j+1)\epsilon)}(x(\cdot)) - E_{\{\Pi^h((j+1)\epsilon),Y_{(j+1)\epsilon,t+s}\}}[\phi(\tilde{X}(i'\delta_h))R^h(\tilde{X}_{0,i'\delta_h}, Y_{(j+1)\epsilon,(j+1)\epsilon+i'\delta_h})]\Bigg]^2_1. \tag{7.27}$$

Let $\Delta > 0$ be small. Now, repeat the logic which led to (7.16). By A7.2 and the continuity properties of $\tilde{X}(\cdot)$, it is sufficient to prove the result if both of the $R^h(\cdot)$ in (7.27) are replaced by $R^\Delta(\cdot)$, and the $i'\delta_h$ in $\tilde{X}(i'\delta_h)$ and $x(i'\delta_h)$ are replaced by the nearest integral multiple of Δ. Then A7.1 yields the desired convergence. This takes care of (7.25).

We now turn to (7.26). This time we do not work with the numerators and denominators separately. For motivation, note that if $\Pi^h(\cdot)$ were the true conditional distribution for the discrete time signal process $X(n\delta_h)$, then (7.26) is identically zero. Let $\Delta > 0$ be small, and let ϵ be an integral multiple of Δ. Owing to the properties of $\tilde{X}(\cdot)$ and the tightness of the set $\{\Pi^h(t+\cdot); h, t\}$, it is sufficient to show that the $\lim_h \sup_t$ of (7.26) is zero if $R^h(\cdot)$ were replaced by $R^\Delta(\cdot)$ and the $i\delta_h$ and $i'\delta_h$ were integral multiples of Δ. Thus we can write $t = j\epsilon + k_1\Delta$ and $t+s = (j+1)\Delta + k_2\Delta$, where $k_i\Delta \le \epsilon$. Using the fact that the k_i have only finitely many values, it is sufficient to show that

$$\lim_h \sup_j E\Bigg[\frac{E_{\{\Pi^h((j+1)\epsilon),Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta}\}}[\phi(\tilde{X}(k_2\Delta))R^\Delta(\tilde{X}_{0,k_2\Delta}, Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta})]}{E_{\{\Pi^h((j+1)\epsilon),Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta}\}}[R^\Delta(\tilde{X}_{0,k_2\Delta}, Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta})]} - \frac{E_{\{\Pi^h(j\epsilon+k_1\Delta),Y_{j\epsilon+k_1\Delta,(j+1)\epsilon+k_2\Delta}\}}[\phi(\tilde{X}(\epsilon-k_1\Delta+k_2\Delta))R^\Delta(\tilde{X}_{0,\epsilon-k_1\Delta+k_2\Delta}, Y_{j\epsilon+k_1\Delta,(j+1)\epsilon+k_2\Delta})]}{E_{\{\Pi^h(j\epsilon+k_1\Delta),Y_{j\epsilon+k_1\Delta,(j+1)\epsilon+k_2\Delta}\}}[R^\Delta(\tilde{X}_{0,\epsilon-k_1\Delta+k_2\Delta}, Y_{j\epsilon+k_1\Delta,(j+1)\epsilon+k_2\Delta})]}\Bigg]^2_1 = 0. \tag{7.28}$$

The difficulty in treating this term is that the initial times are different, being $(j+1)\epsilon$ in the first term and $j\epsilon + i\delta_h$ in the second. Because of this, we need to represent both initial measures in terms of the same quantity, namely, in terms of $P^{h,j}_{\Pi^h(j\epsilon)}$, and the details will now be given. Define the function

$$\Theta\left(\phi, k_2\Delta, Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta}, x\right) = E\left[\phi(\tilde{X}(k_2\Delta))R^\Delta(\tilde{X}_{0,k_2\Delta}, Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta})\middle|\tilde{X}(0) = x, Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta}\right]. \tag{7.29}$$

If $\phi(\cdot)$ is equal to the constant function with value unity, we simply write 1 for ϕ in (7.29). Then, using the definition (7.6) of $\Pi^h((j+1)\epsilon)$ in terms of $P^{h,j}_{\Pi^h(j\epsilon)}$, the numerator of the first term inside the bars in (7.28) can be rewritten as

$$\frac{\int \Theta\left(\phi, k_2\Delta, Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta}, x(\epsilon)\right) R^\Delta(x_{0,\epsilon}, Y_{j\epsilon,(j+1)\epsilon})dP^{h,j}_{\Pi^h(j\epsilon)}(x(\cdot))}{\int R^\Delta(x_{0,\epsilon}, Y_{j\epsilon,(j+1)\epsilon})dP^{h,j}_{\Pi^h(j\epsilon)}(x(\cdot))}. \tag{7.30}$$

The denominator of the left-hand term inside the bars in (7.28) has the same representation, but with 1 replacing ϕ. Thus, that left-hand term can be written as

$$\frac{\int \Theta\left(\phi, k_2\Delta, Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta}, x(\epsilon)\right) R^\Delta(x_{0,\epsilon}, Y_{j\epsilon,(j+1)\epsilon})dP^{h,j}_{\Pi^h(j\epsilon)}x(\cdot))}{\int \Theta\left(1, k_2\Delta, Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta}, x(\epsilon)\right) R^\Delta(x_{0,\epsilon}, Y_{j\epsilon,(j+1)\epsilon})dP^{h,j}_{\Pi^h(j\epsilon)}(x(\cdot))}. \tag{7.31}$$

By A7.1, without changing the limits in (7.28), this fraction can be replaced by

$$\frac{E_{\{\Pi^h(j\epsilon),Y_{j\epsilon,(j+1\epsilon)+k_2\Delta}\}}\Theta\left(\phi,k_2\Delta,Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta},x(\epsilon)\right)R^{\Delta}(x_{0,\epsilon},Y_{j\epsilon,(j+1)\epsilon})}{E_{\{\Pi^h(j\epsilon),Y_{j\epsilon,(j+1\epsilon)+k_2\Delta}\}}\Theta\left(1,k_2\Delta,Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta},x(\epsilon)\right)R^{\Delta}(x_{0,\epsilon},Y_{j\epsilon,(j+1)\epsilon})}. \tag{7.32}$$

In turn, using the Markov property of $\tilde{X}(\cdot)$, the definition of $\Theta(\cdot)$ as a conditional expectation, and the fact that $R^{\Delta}(\cdot)$ is the exponential of a sum, this equals

$$\frac{E_{\{\Pi^h(j\epsilon),Y_{j\epsilon,(j+1)\epsilon)+k_2\Delta}\}}\phi(\tilde{X}(\epsilon+k_2\Delta))R^{\Delta}(\tilde{X}_{0,\epsilon+k_2\Delta},Y_{j\epsilon,(j+1)\epsilon+k_2\Delta})}{E_{\{\Pi^h(j\epsilon),Y_{j\epsilon,(j+1)\epsilon)+k_2\Delta}\}}R^{\Delta}(\tilde{X}_{0,\epsilon+k_2\Delta},Y_{j\epsilon,(j+1)\epsilon+k_2\Delta})}. \tag{7.33}$$

Now we turn our attention to the second term inside the bars in (7.28). This is treated in essentially the same way as was the first term. Consider the numerator of that term. The expectation, conditioned on

$$\{\tilde{X}(\epsilon-k_1\Delta)=x,\tilde{X}_{0,\epsilon-k_1\Delta},Y_{j\epsilon+k_1\Delta,(j+1)\epsilon+k_2\Delta}\},$$

is just

$$\Theta(\phi,k_2\Delta,Y_{(j+1)\epsilon,(j+1)\epsilon+k_2\Delta},x)R^{\Delta}(X_{0,\epsilon-k_1\Delta},Y_{j\epsilon+k_1\Delta,(j+1)\epsilon}).$$

We proceed as we did above with the first term. Using the definition (7.6) yields an expression analogous to (7.29). Then applying first A7.1 and then the Markov property of $\tilde{X}(\cdot)$ to that expression yields that we can replace the second term in (7.28) by (7.33) as well without changing the limit. We omit the details, which are nearly the same as for the first term. Thus the term in the bars in (7.28) can be replaced by zero without changing the limit.

The proof of (7.22) is now complete. □

AN APPROXIMATION THEORY FOR STRONGLY STABILIZING SOLUTIONS TO THE OPERATOR LQ RICCATI EQUATION*

J. C. OOSTVEEN†, R. F. CURTAIN†, AND K. ITO‡

Abstract. The linear-quadratic (LQ) control problem is considered for a class of infinite-dimensional systems with bounded input and output operators, that are not exponentially stabilizable, but only strongly stabilizable. A sufficient condition for the existence of a minimizing control and of a stabilizing solution to the associated LQ Riccati equation is given. The main contribution of this paper is the convergence of the stabilizing solutions of a sequence of finite-dimensional Riccati equations to the strongly stabilizing solution of the infinite-dimensional Riccati equation. The result is applied to a model of propagation of sound waves in a one-dimensional wave-guide.

Key words. linear quadratic control problem, algebraic Riccati equation on Hilbert space, dissipative systems, collocated actuators and sensors

1. Introduction.

Controllers designed on the basis of an infinite-dimensional model of the plant are very often infinite-dimensional as well. In particular, this is the case for LQ-, LQG-, and H_∞-controllers. Of course, when one wants to actually compute or even implement such a controller, one has to approximate it by a finite-dimensional controller. Therefore, over the years much research has been directed towards developing approximation schemes for these controllers and, in particular, approximation schemes for numerical solutions of algebraic Riccati equations. Many of the papers use an approach based on approximation results for C_0-semigroups, i.e., they use a version of the Trotter–Kato theorem in the proof of convergence of the solution of the Riccati equation (see, for instance, Banks and Burns [1], Gibson [9], Ito [11], Kappel and Salamon [14], and the references therein).

In all previous papers it was assumed that A generates an exponentially stable semigroup or that (A, B) is exponentially stabilizable. This is not always the case. In the literature, there are many examples of systems with dissipative generators that cannot be exponentially stabilized by a compact feedback operator (see Gibson [8]). In this paper, we consider the linear-quadratic (LQ) Riccati equation for systems $\Sigma(A, B, C)$ with bounded input and output operator, but we assume that $\Sigma(A, B, C)$ is strongly stabilizable and not exponentially stabilizable. Such systems occur often as models of flexible structures and in problems of wave propagation and scattering. The lack of exponential stability makes the analysis more difficult and our main contribution is the development of an approximation theory for stabilizing solutions of the LQ Riccati equation under the relaxed stabilizability assumption of strong stabilizability. Our present contribution is motivated by recent results on the existence

of stabilizing solutions to Riccati equations for strongly stabilizable systems with bounded inputs and outputs (see Oostveen and Curtain [20]).

In section 2, we introduce some of the basic notions and we derive sufficient conditions for the existence and uniqueness of a strongly stabilizing solution to the LQ Riccati equation for systems that are strongly stabilizable and detectable. Existence results for (strongly) stabilizing solutions of more general Riccati equations can be found in Staffans [23] and Mikkola [18]. We prove a sharper existence result, but more importantly, our approximation results depend on the construction in our proof. Section 3 contains results about the convergence of finite-dimensional approximations of an infinite-dimensional system. The approximation result for the strongly stabilizing solution of the algebraic Riccati equation then follows in section 4. This result is specialized to dissipative systems with collocated actuators and sensors in section 5. These systems have a state-space description $\Sigma(A, B, B^*)$, where A generates a contraction semigroup (i.e., A is a dissipative operator). The terminology "collocated" for the condition $C = B^*$ comes from the fact that this condition arises when actuators and sensors are implemented at the same location. Although mathematically very special, this class is very important from an applications point of view. They are the typical example of systems that are strongly stabilizable, but not exponentially stabilizable. Finally, in section 6, we illustrate the approximation result with an example of LQ control for an acoustical problem. The model for this example was described in Morse and Ingard [19] and Beale [2], and the approximation of the system was taken from Ito and Propst [12].

2. The standard LQ Riccati equation for strongly stabilizable systems. Consider the system

$$\begin{aligned} \dot{z}(t) &= Az(t) + Bu(t), \quad z(0) = z_0, \\ y(t) &= Cz(t), \end{aligned} \tag{2.1}$$

where A is the infinitesimal generator of a C_0-semigroup $T(t)$ on the separable Hilbert space Z, $B \in \mathcal{L}(U, Z)$, $C \in \mathcal{L}(Z, Y)$, where U and Y are separable Hilbert spaces as well. In what follows we denote this system by $\Sigma(A, B, C)$. We want to find $\overline{u} \in \mathbf{L}_2(0, \infty; U)$ that minimizes the quadratic cost criterion

$$\mathcal{J}(u, z_0) = \int_0^\infty (\|y(t)\|^2 + \|u(t)\|^2)dt. \tag{2.2}$$

Before we give conditions for the existence of a solution for this problem, we give a number of definitions related to the stability of systems $\Sigma(A, B, C, D)$ (i.e., systems as in (2.1) where the second equation is replaced by $y(t) = Cz(t) + Du(t)$ and $D \in \mathcal{L}(U, Y)$). The following concept of a system was introduced in Weiss [24] in the more general context of well-posed linear systems.

DEFINITION 2.1. *Consider the system $\Sigma(A, B, C, D)$. We introduce the following maps for this system.*

- *The* input map $\Phi_t : \mathbf{L}_2(0, t; U) \to Z$ *is given by*

$$\Phi_t u = \int_0^t T(s)Bu(s)ds.$$

If for all u $\lim_{t\to\infty} \Phi_t u$ exists, then we define the extended input map Φ *by*

$$\Phi u = \lim_{t\to\infty} \Phi_t u.$$

- *The* output map $\Psi_t : Z \to \mathbf{L}_2(0,t;Y)$ *defined by*

$$(\Psi_t z)(\cdot) = CT(\cdot)z.$$

This map has a limit for $t \to \infty$ *as an operator from* Z *to* $\mathbf{L}_2^{loc}(0,\infty;Y)$. *If the limit exists as an operator from* Z *to* $\mathbf{L}_2(0,\infty;Y)$, *then it is called the* extended output map *and denoted by* Ψ. *It is then given by*

$$(\Psi z)(\cdot) = CT(\cdot)z.$$

- *The* extended input-output map $\mathbb{F} : \mathbf{L}_2(0,\infty;U) \to \mathbf{L}_2(0,\infty;Y)$ *is given by*

$$(\mathbb{F}u)(\cdot) = Du(\cdot) + C\int_0^\infty T(\cdot - s)Bu(s)ds.$$

It is defined via a similar limiting procedure as the extended output map.

- *For* $\alpha \in \mathbb{R}$, *let* $\mathbb{C}_\alpha^+ = \{s \in \mathbb{C} | \mathrm{Re}(s) > \alpha\}$. *The* transfer function $G(s) : \mathbb{C}_\alpha^+ \to \mathcal{L}(U,Y)$ *is given by*

$$G(s) = D + C(sI - A)^{-1}B.$$

We remark that if $T(t)$ is exponentially stable, then the extended input, output, and input-output maps are well defined and $G \in \mathbf{H}_\infty$. For our applications exponential stability is too strong and so we introduce the following weaker notions.

DEFINITION 2.2. *Consider the system* $\Sigma(A,B,C,D)$ *and the associated operators defined above.*

- $T(t)$ *is a* strongly stable C_0-semigroup *if* $\lim_{t\to\infty} T(t)z = 0$ *for all* $z \in Z$;
- $\Sigma(A,B,C,D)$ *is* input stable *if* $\Phi \in \mathcal{L}(\mathbf{L}_2(0,\infty;U),Z)$;
- $\Sigma(A,B,C,D)$ *is* output stable *if* $\Psi \in \mathcal{L}(Z,\mathbf{L}_2(0,\infty;Y))$;
- $\Sigma(A,B,C,D)$ *is* input-output stable *if* $\mathbb{F} \in \mathcal{L}(\mathbf{L}_2(0,\infty;U),\mathbf{L}_2(0,\infty;Y))$.

If $\Sigma(A,B,C,D)$ *satisfies all the above notions, then we call it a* strongly stable system.

These stability notions could have been defined in a different way. For instance, output stability is known to be equivalent to the condition $C(sI-A)^{-1}z \in \mathbf{H}_2(Y)$ for all $z \in Z$. It is also equivalent to C being an *infinite-time admissible observation operator* for $T(t)$. Input stability is equivalent to the condition that $B^*(sI-A^*)^{-1}z \in \mathbf{H}_2(U)$ for all $z \in Z$ and to B being an *infinite-time admissible control operator* for $T(t)$ (see, for instance, Hansen and Weiss [10]). Finally, input-output stability is equivalent to $G(s) \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$.

The intuition behind these definitions is that a system is input stable if every $\mathbf{L}_2$-input results in a bounded state, a system is output stable if every initial condition results in an $\mathbf{L}_2$-output and a system is input-output stable if an $\mathbf{L}_2$-input results in an $\mathbf{L}_2$-output. A class of examples of strongly stable systems can be found in section 5.

Next we prove a result on the existence of a unique solution to the LQ control problem.

THEOREM 2.3. *Consider the system* $\Sigma(A,B,C)$ *with cost criterion* (2.2).

a. *Suppose that there exists an operator* $F \in \mathcal{L}(Z,U)$ *such that* $A+BF$ *generates a strongly stable semigroup* $T_F(t)$ *and* $\Sigma(A+BF,B,\left[\begin{smallmatrix}F\\C\end{smallmatrix}\right])$ *is output stable. Then there exists a minimizing control* $\overline{u}$ *which is given by* $\overline{u}(t) = -B^*X_0z(t)$, *where* X_0 *is the minimal self-adjoint nonnegative solution to the algebraic Riccati equation*

$$A^*Xz + XAz - XBB^*Xz + C^*Cz = 0 \tag{2.3}$$

for all $z \in D(A)$. Moreover, the corresponding minimal cost is given by

$$\mathcal{J}(\overline{u}, z_0) = \langle X_0 z_0, z_0 \rangle.$$

b. *If, in addition, there exists an operator $L \in \mathcal{L}(Y, Z)$ such that $A + LC$ generates a strongly stable C_0-semigroup $T_L(t)$ and $\Sigma(A + LC, \begin{bmatrix} L & B \end{bmatrix}, C)$ is input stable, then X_0 is the unique self-adjoint nonnegative solution to* (2.3). *Moreover, $A - BB^*X_0$ generates a strongly stable semigroup.*

Proof. a. Choosing $u = Fz$, we obtain

$$\begin{aligned}\mathcal{J}(Fz, z_0) &= \int_0^\infty (\|CT_F(t)z_0\|^2 + \|FT_F(t)z_0\|^2)dt \\ &\leq \text{const.}\|z_0\|^2,\end{aligned}$$

since $\Sigma(A + BF, B, \begin{bmatrix} F \\ C \end{bmatrix})$ is output stable. So the system satisfies the conditions of Theorem 6.2.4 in Curtain and Zwart [5] and there exists a minimal self-adjoint nonnegative solution X_0 of (2.3), such that the minimal cost is $\mathcal{J}(\overline{u}, z_0) = \langle X_0 z_0, z_0 \rangle$. From this we immediately obtain the following estimates, which we will use in the proof of part b.

$$\int_0^\infty \|B^*X_0 T_{X_0}(t)z_0\|^2 dt \leq \|X_0\|\|z_0\|^2 \tag{2.4}$$

and

$$\int_0^\infty \|CT_{X_0}(t)z_0\|^2 dt \leq \|X_0\|\|z_0\|^2, \tag{2.5}$$

where $T_{X_0}(t)$ is the semigroup generated by $A - BB^*X_0$.

b. We show that (2.4) and (2.5) hold if X_0 is any nonnegative solution of the Riccati equation (2.3). For clarity we write Π for an arbitrary nonnegative solution and reformulate (2.3) as

$$A_\Pi^*\Pi z + \Pi A_\Pi z + \Pi BB^*\Pi z + C^*Cz = 0, \tag{2.6}$$

where $A_\Pi = A - BB^*\Pi$ generates the semigroup $T_\Pi(t)$. Let $z = T_\Pi(t)z_0$ for $z_0 \in D(A)$ and take the inner product with $T_\Pi(t)z_0$ to obtain

$$\langle \Pi T_\Pi(t)z_0, A_\Pi T_\Pi(t)z_0 \rangle + \langle \Pi A_\Pi T_\Pi(t)z_0, T_\Pi(t)z_0 \rangle + \|B^*\Pi T_\Pi(t)z_0\|^2 + \|CT_\Pi(t)z_0\|^2 = 0.$$

Integrating with respect to t gives

$$\langle \Pi T_\Pi(t)z_0, T_\Pi(t)z_0 \rangle + \int_0^t \|B^*\Pi T_\Pi(s)z_0\|^2 + \int_0^t \|CT_\Pi(s)z_0\|^2 = \langle \Pi z_0, z_0 \rangle, \tag{2.7}$$

and this proves the claim.

c. We generalize Lemma 6.2.6 of Curtain and Zwart [5] to the strongly stable case. Let Π be a nonnegative solution to (2.3) such that $T_\Pi(t)$ is strongly stable. Define the following subset of controls:

$$\begin{aligned}U_{stab}(z_0) = \Big\{ & u \in \mathbf{L}_2(0, \infty; U) | \\ & z(t) = T(t)z_0 + \int_0^t T(t-s)Bu(s)ds \text{ and } z(t) \to 0 \text{ as } t \to \infty \Big\}.\end{aligned}$$

This set is nonempty, since $\overline{u}(t) = -B^*\Pi T_\Pi(t)z_0$ is in $U_{stab}(z_0)$; the closed-loop system has the state $z(t) = T_\Pi(t)z_0$ and $\overline{u} \in \mathbf{L}_2(0,\infty;U)$ follows from part b, above. Let $\tilde{\Pi}$ be any other nonnegative self-adjoint solution to (2.3). As in Lemma 6.2.6, it is easily shown that for any $u \in U_{stab}$ the cost on the finite-interval $[0,t_e]$ satisfies

$$\begin{aligned}\int_0^{t_e} (\|y(t)\|^2 + \|u(t)\|^2)dt &= \langle z_0, \tilde{\Pi}z_0\rangle - \langle z(t_e), \tilde{\Pi}z(t_e)\rangle \\ &\quad + \int_0^{t_e} \langle (u(s) + B^*\tilde{\Pi}z(s)), (u(s) + B^*\tilde{\Pi}z(s))\rangle ds \\ &\geq \langle z_0, \tilde{\Pi}z_0\rangle - \langle z(t_e), \tilde{\Pi}z(t_e)\rangle.\end{aligned}$$

Since $\tilde{\Pi} \geq 0$ and $z(t_e) \to 0$ as $t_e \to \infty$, we arrive at

$$\begin{aligned}\langle z_0, \tilde{\Pi}z_0\rangle &\leq \int_0^\infty (\|y(t)\|^2 + \|u(t)\|^2)dt \\ &= \mathcal{J}(u, z_0)\end{aligned}$$

for all $u \in U_{stab}$. Now $\overline{u} = -B^*\Pi T_\Pi(\cdot)z_0 \in U_{stab}$ and so

$$\langle z_0, \tilde{\Pi}z_0\rangle \leq \mathcal{J}(\overline{u}, z_0) = \langle z_0, \Pi z_0\rangle,$$

where we have used (2.7) and the fact that T_Π is strongly stable. Thus, Π is the maximal self-adjoint solution of (2.3).

d. We see that it remains to prove that $A - BB^*X_0$ generates a strongly stable C_0-semigroup. To do this, we write

$$\begin{aligned}\dot{z} &= (A - BB^*X_0)z \\ &= (A + LC)z + (-LC - BB^*X_0)z\end{aligned}$$

and so

$$z(t) = T_L(t)z_0 - \int_0^t T_L(t-s) \begin{bmatrix} L & B \end{bmatrix} \begin{bmatrix} Cz(s) \\ B^*X_0z(s) \end{bmatrix} ds.$$

Now, by the strong stability of $T_L(t)$, $T_L(t)z_0 \to 0$ as $t \to \infty$. Furthermore, $u_1(t) = Cz(t) \in \mathbf{L}_2(0,\infty;Y)$ by (2.5) and $u_2(t) = B^*X_0z(t) \in \mathbf{L}_2(0,\infty;U)$ by (2.4). So Lemma 12 in Oostveen and Curtain [20] applies to show that the integral term tends to zero as t tends to infinity. So, we obtain that $z(t)$ tends to zero as t goes to infinity, and $T_{X_0}(t)$ is strongly stable. □

We remark that a slightly less general version of this theorem was proven in Oostveen and Curtain [20], in which it was assumed that one could take $F = KC$ and $L = BK$ for some $K \in \mathcal{L}(Y,U)$. In Staffans [23] and Mikkola [18] abstract results on more general Riccati equations are proven. However, Mikkola proved the existence of a unique stabilizing solution, whereas we prove that the solution is unique in the class of self-adjoint nonnegative operators. For interpretations of Theorem 2.3 in terms of strong stabilizability and strong detectability, we refer to Curtain and Oostveen [4].

Next, we show how to reformulate the problem as an equivalent one for a strongly stable system. This was also done in Oostveen and Curtain [20] under the assumption that $F = KC$ and $L = BK$. Our assumptions in this paper are weaker.

THEOREM 2.4. *Consider the problem of minimizing the cost functional* (2.2) *subject to* $\Sigma(A,B,C)$ *under the assumption that there exist* $F \in \mathcal{L}(Z,U)$ *and* $L \in \mathcal{L}(Y,Z)$ *such that*

A1. *$A+BF$ and $A+LC$ generate strongly stable C_0-semigroups $T_F(t)$ and $T_L(t)$, respectively;*
A2. *$\Sigma(A+BF, B, \left[\begin{smallmatrix} F \\ C \end{smallmatrix}\right])$ is input-output stable and output stable;*
A3. *$\Sigma(A+LC, \left[\begin{smallmatrix} L & B \end{smallmatrix}\right], F)$ is input stable, output stable, and input-output stable.*

Then this problem is equivalent to that of minimizing the cost functional

$$\mathcal{J}_F(v, z_0) = \int_0^\infty (\|v(t) + Fz(t)\|^2 + \|y(t)\|^2)dt \tag{2.8}$$

subject to

$$\begin{aligned} \dot{z}(t) &= (A + BF)z(t) + Bv(t), \quad z(0) = z_0, \\ y(t) &= Cz(t). \end{aligned} \tag{2.9}$$

The optimal control for (2.8), (2.9) *is given by*

$$\overline{v}(t) = -(\mathbb{F}_F^*\mathbb{F}_F)^{-1}\mathbb{F}_F^*\Psi_F z_0, \tag{2.10}$$

where Ψ_F and $\mathbb{F}_F$ are the extended output map and the extended input-output map, respectively, of the system $\Sigma(A + BF, B, [\begin{smallmatrix} F \\ C \end{smallmatrix}], [\begin{smallmatrix} I \\ 0 \end{smallmatrix}])$. Moreover, there exists a unique nonnegative solution to the algebraic Riccati equation (2.3), *which is given by*

$$X = \Psi_F^* \left[I - \mathbb{F}_F(\mathbb{F}_F^*\mathbb{F}_F)^{-1}\mathbb{F}_F^*\right] \Psi_F. \tag{2.11}$$

Proof. a. Note that with $u = v + Fz$, the systems (2.1) (with $D = 0$) and (2.9) have the same solution

$$z(t) = T_F(t)z_0 + \int_0^t T_F(t-s)Bv(s)ds$$

and $\mathcal{J}_F(v, z_0) = \mathcal{J}(u, z_0)$. Therefore, the two optimization problems are equivalent if $\mathcal{J}(u, z_0) < \infty$ for $u \in \mathbf{L}_2(0, \infty; U)$ if and only if $v = u - Fz \in \mathbf{L}_2(0, \infty; U)$. Suppose first that $v \in \mathbf{L}_2(0, \infty; U)$. Since $\Sigma(A + BF, B, F)$ is input-output stable, $Fz(t) - FT_F(t)z_0 \in \mathbf{L}_2(0, \infty; U)$ and since $\Sigma(A+BF, B, F)$ is output stable, $FT_F(t)z_0$ and hence $Fz(t) \in \mathbf{L}_2(0, \infty; U)$. Thus $u \in \mathbf{L}_2(0, \infty; U)$. The output stability and input-output stability of $\Sigma(A + BF, B, C)$ imply that $Cz(t) \in \mathbf{L}_2(0, \infty; Y)$ which, together with $u \in \mathbf{L}_2(0, \infty; U)$, shows that $\mathcal{J}(u, z_0) < \infty$.

Conversely, suppose that $\mathcal{J}(u, z_0) < \infty$ and write

$$z(t) = T_L(t)z_0 + \int_0^t T_L(t-s)(Bu(s) - Ly(s))ds.$$

Then $Fz(t) - FT_L(t)z_0 \in \mathbf{L}_2(0, \infty; U)$ since $\Sigma(A+LC, \left[\begin{smallmatrix} B & L \end{smallmatrix}\right], F)$ is input-output stable. Also, $FT_L(t)z_0 \in \mathbf{L}_2(0, \infty; U)$, since $\Sigma(A + LC, B, F)$ is output stable. So $Fz(t) \in \mathbf{L}_2(0, \infty; U)$ and therefore also $v = u - Fz \in \mathbf{L}_2(0, \infty; U)$.

b. We now obtain an explicit solution of the minimization of (2.8) for the stable system (2.9) in terms of the bounded maps $\mathbb{F}_F$, Ψ_F given by

$$\begin{aligned} \Psi_F z_0 &= \left[\begin{smallmatrix} F \\ C \end{smallmatrix}\right] T_F(t)z_0, \\ (\mathbb{F}_F v)(t) &= \left[\begin{smallmatrix} v(t) \\ 0 \end{smallmatrix}\right] + \left[\begin{smallmatrix} F \\ C \end{smallmatrix}\right] \int_0^t T_F(t-s)Bv(s)ds. \end{aligned}$$

Since $\mathcal{J}_F(v, z_0) < \infty$ for all $v \in \mathbf{L}_2(0,\infty;U)$ we can write (2.8) equivalently as

$$\mathcal{J}_F(v, z_0) = \|\Psi_F z_0 + \mathbb{F}_F v\|^2.$$

Next we show that the cost functional $\mathcal{J}_F$ is coercive in v. Let the operator $\mathbb{F}_{LF}$ denote the extended input-output map of the system $\Sigma(A+LC, \left[\begin{array}{cc} B & -L \end{array}\right], -F, \left[\begin{array}{cc} I & 0 \end{array}\right])$. By assumption A3, $\mathbb{F}_{LF} \in \mathcal{L}(\mathbf{L}_2(0,\infty;U\times Y), \mathbf{L}_2(0,\infty;U))$. We show that $\mathbb{F}_{LF}\mathbb{F}_F = I_{L_2(0,\infty;U)}$, using a frequency domain argument. Let $\widehat{\ }$ denote Laplace transforms and let $v \in \mathbf{L}_2(0,\infty;U)$, $y \in \mathbf{L}_2(0,\infty;Y)$. Then,

$$\begin{aligned}&\widehat{(\mathbb{F}_{LF}(v \oplus y))}(s)\\ &= \left(\left[\begin{array}{cc} I & 0 \end{array}\right] - F(sI - A - LC)^{-1}\left[\begin{array}{cc} B & -L \end{array}\right]\right)\left(\begin{array}{c} \hat{v}(s) \\ \hat{y}(s) \end{array}\right)\end{aligned}$$

and

$$\widehat{(\mathbb{F}_F v)}(s) = \left(\left[\begin{array}{c} I \\ 0 \end{array}\right] + \left[\begin{array}{c} F \\ C \end{array}\right](sI - A - BF)^{-1}B\right)\hat{v}(s).$$

Now,

$$\begin{aligned}&\widehat{(\mathbb{F}_{LF}\mathbb{F}_F v)}(s)\\ &= \left\{F(sI - A - LC)^{-1}(LC - BF)(sI - A - BF)^{-1}B\right.\\ &\qquad \left. -F(sI - A - LC)^{-1}B + F(sI - A - BF)^{-1}B + I\right\}\hat{v}(s)\\ &= F(sI - A - LC)^{-1}\left\{-sI + A + BF + sI - A - LC + LC - BF\right\}\\ &\quad \cdot(sI - A - BF)^{-1}B\hat{v}(s) + \hat{v}(s)\\ &= \hat{v}(s).\end{aligned}$$

Consequently, $(\mathbb{F}_{LF}\mathbb{F}_F v)(t) = v(t)$ for all $v \in \mathbf{L}_2(0,\infty;U)$.

We deduce

$$\begin{aligned}\|v\|^2 &= \|\mathbb{F}_{LF}\mathbb{F}_F v\|^2\\ &\le \|\mathbb{F}_{LF}\|^2\|\mathbb{F}_F v\|^2\\ &= \|\mathbb{F}_{LF}\|^2\langle \mathbb{F}_F v, \mathbb{F}_F v\rangle\\ &\le \|\mathbb{F}_{LF}\|^2\|\mathbb{F}_F^*\mathbb{F}_F v\|\|v\|.\end{aligned}$$

Note that because of the identity $\mathbb{F}_{LF}\mathbb{F}_F = I$ we cannot have $\|\mathbb{F}_{LF}\| = 0$. Thus,

$$\|\mathbb{F}_F^*\mathbb{F}_F v\| \ge \|\mathbb{F}_{LF}\|^{-2}\|v\|. \tag{2.12}$$

We can now apply the theory of paragraphs 1.1.1–1.1.3 in Lions [17] to show that there exists a unique minimizing control $\overline{v} \in \mathbf{L}_2(0,\infty;U)$ that is characterized by

$$\mathbb{F}_F^*\mathbb{F}_F\overline{v} + \mathbb{F}_F^*\Psi_F z_0 = 0. \tag{2.13}$$

Because (2.12) implies that $\mathbb{F}_F^*\mathbb{F}_F$ is boundedly invertible, we can solve (2.13) for $\overline{v}$ to obtain (2.10).

From Theorem 2.3 we know that

$$\mathcal{J}_F(\overline{v}, z_0) = \mathcal{J}(\overline{u}, z_0) = \langle X_0 z_0, z_0\rangle$$

and (2.11) follows. □

It is interesting to note that although the strategy in Oostveen and Curtain [20] is also to express the general control problem via a feedback in terms of an equivalent stable one, the feedbacks are different and the formulas for X are very different. In the stable case ($F = 0$, $L = 0$), however, the formulas for X coincide. For proving convergence results for the standard LQ Riccati equation the approach in this paper is more convenient.

It turns out that A1, A2, A3, below, are key conditions in proving our main approximation result in section 4. Consequently, we introduce the following definition.

DEFINITION 2.5. *The system* $\Sigma(A, B, C)$ *is* strongly stabilizable-detectable *if there exist* $F \in \mathcal{L}(Z, U)$ *and* $L \in \mathcal{L}(Y, Z)$ *such that*

A1. $A+BF$ *and* $A+LC$ *generate strongly stable* C_0*-semigroups* $T_F(t)$ *and* $T_L(t)$*, respectively;*

A2. $\Sigma(A+BF, B, \left[\begin{smallmatrix} F \\ C \end{smallmatrix}\right])$ *is input-output stable and output stable;*

A3. $\Sigma(A+LC, \left[\begin{smallmatrix} L & B \end{smallmatrix}\right], F)$ *is input-output stable, input stable, and output stable.*

We remark that if both $A + BF$ and $A + LC$ generate exponentially stable C_0-semigroups on Z, then the conditions A1, A2, and A3 hold automatically. For a more detailed analysis of these conditions, we refer to Curtain and Oostveen [4].

3. Approximation for strongly stable systems. Consider again the system on the Hilbert spaces Z, U, Y

$$\begin{aligned} \dot{z}(t) &= Az(t) + Bu(t), \\ y(t) &= Cz(t) \end{aligned} \tag{3.1}$$

and a sequence of approximating systems on the finite-dimensional spaces $Z^N = \mathbb{R}^{k(N)}$, $U^N = \mathbb{R}^{m(N)}$, $Y^N = \mathbb{R}^{p(N)}$,

$$\begin{aligned} \dot{z}^N(t) &= A^N z^N(t) + B^N u^N(t), \\ y^N(t) &= C^N z^N(t). \end{aligned} \tag{3.2}$$

We assume the existence of injective linear maps

$$\begin{aligned} i^N &: \mathbb{R}^{k(N)} \to Z, \\ j^N &: \mathbb{R}^{m(N)} \to U, \\ k^N &: \mathbb{R}^{p(N)} \to Y \end{aligned}$$

and surjective linear maps

$$\begin{aligned} \pi^N &: Z \to \mathbb{R}^{k(N)}, \\ \rho^N &: U \to \mathbb{R}^{m(N)}, \\ \sigma^N &: Y \to \mathbb{R}^{p(N)}, \end{aligned}$$

such that $\pi^N i^N$, $\rho^N j^N$, and $\sigma^N k^N$ are identity maps and $i^N \pi^N$, $j^N \rho^N$, and $k^N \sigma^N$ are orthogonal projections. Note that it is not necessary that $(i^N)^* = \pi^N$, $(j^N)^* = \rho^N$, or $(k^N)^* = \sigma^N$. On the spaces $\mathbb{R}^{k(N)}$, $\mathbb{R}^{m(N)}$, and $\mathbb{R}^{p(N)}$ we will always consider the induced inner products

$$\begin{aligned} \langle z_1, z_2 \rangle_{k(N)} &= \langle i^N z_1, i^N z_2 \rangle_Z, \\ \langle u_1, u_2 \rangle_{m(N)} &= \langle j^N u_1, j^N u_2 \rangle_U, \\ \langle y_1, y_2 \rangle_{p(N)} &= \langle k^N y_1, k^N y_2 \rangle_Y. \end{aligned}$$

$(A^N)^*$, $(B^N)^*$, $(C^N)^*$ will denote the adjoint matrices with respect to the induced inner products. As we use the norms corresponding to these inner products as well,

it is obvious that $\|i^N\| = \|j^N\| = \|k^N\| = \|\pi^N\| = \|\rho^N\| = \|\sigma^N\| = 1$. Define $Z^N = \text{range}(i^N\pi^N)$, $U^N = \text{range}(j^N\rho^N)$, and $Y^N = \text{range}(k^N\sigma^N)$. Then

$$\|i^N B^N \rho^N\|_{\mathcal{L}(U^N, Z^N)} = \|B^N\|_{\mathcal{L}(\mathbb{R}^{m(N)}, \mathbb{R}^{k(N)})},$$
$$\|k^N C^N \pi^N\|_{\mathcal{L}(Z^N, Y^N)} = \|C^N\|_{\mathcal{L}(\mathbb{R}^{k(N)}, \mathbb{R}^{p(N)})},$$

and similar equalities hold for all operators defined in an analogous way.

Associated with $\Sigma(A, B, C)$, we define the operators $T, \Phi, \Psi, \mathbb{F}, G(s)$ as in Definition 2.1. The operators $T^N, \Phi^N, \Psi^N, \mathbb{F}^N, G^N(s)$ are defined in the same way, based on the system $\Sigma(A^N, B^N, C^N)$. In the latter case, we are dealing with a finite-dimensional system. Hence, $T^N(t) = e^{A^N t}$ and $(\Psi^N z)(t) = C^N e^{A^N t} z$.

DEFINITION 3.1. $\Sigma(A^N, B^N, C^N)$ converges strongly *to* $\Sigma(A, B, C)$ *if for all* $z \in Z$,

$$T(t)z = \lim_{N\to\infty} i^N e^{A^N t}\pi^N z,$$
$$T^*(t)z = \lim_{N\to\infty} i^N e^{(A^N)^* t}\pi^N z$$

uniformly on compact time intervals, and for all $z \in Z$, $u \in U$, $y \in Y$,

$$Bu = \lim_{N\to\infty} i^N B^N \rho^N u,$$
$$B^* z = \lim_{N\to\infty} j^N (B^N)^* \pi^N z,$$
$$Cz = \lim_{N\to\infty} k^N C^N \pi^N z,$$
$$C^* y = \lim_{N\to\infty} i^N (C^N)^* \sigma^N y,$$
$$u = \lim_{N\to\infty} j^N \rho^N u,$$
$$y = \lim_{N\to\infty} k^N \sigma^N y.$$

Note that the convergence of the semigroup in the above definition implies, by taking $t = 0$, that for all $z \in Z$,

$$z = \lim_{N\to\infty} i^N \pi^N z. \tag{3.3}$$

In connection with the convergence of a sequence of finite-dimensional systems to an infinite-dimensional system, we introduce a notion of uniform stability of the sequence of finite-dimensional systems.

DEFINITION 3.2. $\Sigma(A^N, B^N, C^N)$ *is* uniformly output stable *if there exists* $c > 0$ *such that for all* $z \in Z$,

$$\sup_N \int_0^\infty \|k^N C^N e^{A^N t}\pi^N z\|^2 dt = \sup_N \int_0^\infty \|k^N (\Psi^N \pi^N z)(t)\|^2 dt \le c\|z\|^2.$$

$\Sigma(A^N, B^N, C^N)$ *is* uniformly input-output stable *if there exists* $c > 0$ *such that*

$$\sup_N \|k^N \mathbb{F}^N \rho^N\| = \sup_N \|k^N G^N(s)\rho^N\|_{H_\infty} = \sup_N \|k^N C^N (sI - A^N)^{-1} B^N \rho^N\|_{H_\infty} \le c.$$

In the proof of the following lemma, as well as in all other convergence proofs in this paper, we will use the fact that if the sequences of operators R^N and S^N converge strongly to R and S, respectively, then $R^N S^N$ converges strongly to RS.

LEMMA 3.3. *Suppose that $T(t)$ is strongly stable, $\Sigma(A,B,C)$ is output stable, the finite-dimensional systems $\Sigma(A^N,B^N,C^N)$ converge strongly to $\Sigma(A,B,C)$, and $\Sigma(A^N,B^N,C^N)$ is uniformly output stable. Then for all $z \in Z$,*

$$\lim_{N\to\infty} k^N \Psi^N \pi^N z = \Psi z$$

in $\mathbf{L}_2(0,\infty;Y)$ and

$$\lim_{N\to\infty} i^N (\Psi^N)^* \sigma^N y = \Psi^* y$$

in Z for all $y \in \mathbf{L}_2(0,\infty;Y)$.

Proof. For any $t_1 > 0$, we obtain

$$\begin{aligned}
&\|\Psi z - k^N \Psi^N \pi^N z\|^2_{L_2(0,\infty;Y)} \\
&= \int_0^\infty \|CT(t)z - k^N C^N e^{A^N t}\pi^N z\|^2 dt \\
&= \int_0^{t_1} \|CT(t)z - k^N C^N e^{A^N t}\pi^N z\|^2 dt \\
&\quad + \int_{t_1}^\infty \|CT(t)z - k^N C^N e^{A^N t}\pi^N z\|^2 dt \\
&= \int_0^{t_1} \|CT(t)z - k^N C^N e^{A^N t}\pi^N z\|^2 dt \\
&\quad + \int_0^\infty \|CT(t+t_1)z - k^N C^N e^{A^N (t+t_1)}\pi^N z\|^2 dt.
\end{aligned}$$

Now, the integrand of the second integral satisfies

$$\begin{aligned}
&\|CT(t+t_1)z - k^N C^N e^{A^N (t+t_1)}\pi^N z\|^2 \\
&= \|CT(t+t_1)z - (k^N C^N e^{A^N (t+t_1)}\pi^N z - k^N C^N e^{A^N t}\pi^N T(t_1)z) \\
&\quad - k^N C^N e^{A^N t}\pi^N T(t_1)z\|^2 \\
&\le (\|CT(t+t_1)z\| + \|k^N C^N e^{A^N t}\{e^{A^N (t_1)}\pi^N z - \pi^N T(t_1)z\}\| \\
&\quad + \|\|k^N C^N e^{A^N t}\pi^N T(t_1)z\|)^2 \\
&\le 3\|CT(t+t_1)z\|^2 + 3\|k^N C^N e^{A^N t}\{e^{A^N (t_1)}\pi^N z - \pi^N T(t_1)z\}\|^2 \\
&\quad + 3\|k^N C^N e^{A^N t}\pi^N T(t_1)z\|^2.
\end{aligned}$$

Hence,

$$\begin{aligned}
&\|\Psi z - k^N \Psi^N \pi^N z\|^2_{L_2(0,\infty;Y)} \\
&\le \int_0^{t_1} \|CT(t)z - k^N C^N e^{A^N t}\pi^N z\|^2 dt + 3\int_0^\infty \|CT(t+t_1)z\|^2 \\
&\quad + 3\int_0^\infty \|k^N C^N e^{A^N t}\{e^{A^N t_1}\pi^N z - \pi^N T(t_1)z\}\|^2 \\
&\quad + 3\int_0^\infty \|\|k^N C^N e^{A^N t}\pi^N T(t_1)z\|^2 \\
&=: \alpha_1 + \alpha_2 + \alpha_3 + \alpha_4.
\end{aligned}$$

Now we will derive estimates for each of the integral terms $\alpha_1, \alpha_2, \alpha_3, \alpha_4$. For α_1 we have

$$\alpha_1 \leq 2\int_0^{t_1} \|(C - k^N C^N \pi^N)T(t)z\|^2 dt + 2\sup_N \|k^N C^N \pi^N\|^2 \int_0^{t_1} \|T(t)z - i^N e^{A^N t}\pi^N z\|^2 dt.$$

The right-hand side tends to zero as N tends to infinity by the Lebesgue dominated convergence theorem because the systems $\Sigma(A^N, B^N, C^N)$ are strongly convergent to $\Sigma(A, B, C)$. α_2 satisfies

$$\alpha_2 = 2\int_0^{\infty} \|CT(t_1 + t)z\|^2 dt = 2\|\Psi T(t_1)z\| \leq 2\|\Psi\|\|T(t_1)z\|,$$

which tends to zero as t_1 tends to infinity, independently of N, because of the output stability of $\Sigma(A, B, C)$ and the strong stability of $T(t)$. Since the systems $\Sigma(A^N, B^N, C^N)$ are uniformly output stable, there exists a positive constant c, such that

$$\alpha_3 \leq 3c\|i^N e^{A^N t_1}\pi^N z - T(t_1)z\|^2.$$

The right-hand side tends to zero as N tends to infinity because $\Sigma(A^N, B^N, C^N)$ converges strongly to $\Sigma(A, B, C)$. For the same constant c, we have

$$\alpha_4 \leq 3c\|T(t_1)z\|^2,$$

the right-hand side of which tends to zero, independently of N, because $T(t)$ is strongly stable. These estimates together show that $k^N \Psi^N \pi^N z \to \Psi z$ strongly as $N \to \infty$. Because $\|i^N(\Psi^N)^*\sigma^N\| = \|\Psi^N\| \leq c$, we can use Lemma 3.5 (page 151) of Kato [15] to argue that it is sufficient for the proof of convergence of $i^N(\Psi^N)^*\sigma^N y$ to $\Psi^* y$ to consider $y \in \mathbf{L}_2(0, \infty; Y)$ with compact support (the argument being that the class $\mathbf{L}_2(0, \infty)$-functions with compact support is dense in $\mathbf{L}_2(0, \infty)$). So, let $y \in \mathbf{L}_2(0, \infty; Y)$ have support on $[0, t_1]$, $t_1 > 0$. Then

$$\begin{aligned}\|\Psi^* y - i^N(\Psi^N)^*\sigma^N y\| &\leq \int_0^{t_1} \|(T^*(t) - i^N e^{(A^N)^* t}\pi^N)C^* y(t)\| dt \\ &\quad + \int_0^{t_1} \|i^N e^{(A^N)^* t}\pi^N\|\|(C^* - i^N(C^N)^*\sigma^N)y(t)\| dt.\end{aligned}$$

Both integrals tend to zero as $N \to \infty$ because the systems $\Sigma(A^N, B^N, C^N)$ are strongly convergent to $\Sigma(A, B, C)$. □

COROLLARY 3.4. *Under the assumptions of Lemma* 3.3,

$$\lim_{N\to\infty} \|k^N C^N (sI - A^N)^{-1}\pi^N z - C(sI - A)^{-1} z\|_{H_2(Y)} = 0$$

for all $z \in Z$.

Proof. This result follows directly by taking Laplace transforms in Lemma 3.3 and applying the Paley–Wiener theorem (see, e.g., Theorem A.6.21 in Curtain and Zwart [5]). □

LEMMA 3.5. *Suppose that the assumptions of Lemma* 3.3 *hold and, in addition,* $\Sigma(A,B,C)$ *is input-output stable and* $\Sigma(A^N,B^N,C^N)$ *is uniformly input-output stable. Then, for all* $u \in \mathbf{L}_2(0,\infty;U)$,

$$\lim_{N\to\infty} k^N \mathbb{F}^N \rho^N u = \mathbb{F}u$$

in $\mathbf{L}_2(0,\infty;Y)$. *Similarly, for all* $y \in \mathbf{L}_2(0,\infty;Y)$,

$$\lim_{N\to\infty} j^N (\mathbb{F}^N)^* \sigma^N y = \mathbb{F}^* y$$

in $\mathbf{L}_2(0,\infty;U)$.

Proof. By the uniform input-output stability of the systems $\Sigma(A^N,B^N,C^N)$, the operators $k^N\mathbb{F}^N\rho^N$ are uniformly bounded in N. Therefore it is sufficient to prove the convergence $\mathbb{F}^N u \to \mathbb{F}u$ for input functions u with compact support. Let $u \in \mathbf{L}_2(0,\infty;U)$ with support in $[0,t_1]$, and let y, y^N be defined by $y = \mathbb{F}u$, $y^N = k^N\mathbb{F}^N\rho^N u$ and define $M_1 = \sup_N \sup_{t\in[0,t_1]} \|i^N e^{A^N t}\pi^N\|$. Then

$$\begin{aligned}
&\|y(t) - y^N(t)\|^2 \\
&\le 3\int_0^t \|(C - k^N C^N \pi^N) T(s) B u(t-s)\|^2 ds \\
&\quad +3 \sup_N \|k^N C^N \pi^N\| \int_0^t \|(T(s) - i^N e^{A^N s}\pi^N) B u(t-s)\|^2 ds \\
&\quad +3\, M_1 \sup_N \|k^N C^N \pi^N\| \int_0^t \|(B - i^N B^N \rho^N) u(t-s)\|^2 ds,
\end{aligned}$$

for $0 \le t \le t_1$. By the strong convergence of $\Sigma(A^N,B^N,C^N)$ to $\Sigma(A,B,C)$ and the Lebesgue dominated convergence theorem, it now follows that $\|y - y^N\|_{L_2(0,t_1;Y)} \to 0$ as $N \to \infty$. Furthermore, defining

$$\begin{aligned}
z_u &= \int_0^{t_1} T(t_1 - s) B u(s) ds, \\
z_u^N &= \int_0^{t_1} e^{A^N(t_1-s)} B^N \rho^N u(s) ds,
\end{aligned}$$

we have, since u has support in $[0,t_1]$,

$$\begin{aligned}
y(t+t_1) &= (\Psi z_u)(t), \\
y^N(t+t_1) &= k^N(\Psi^N z_u^N)(t).
\end{aligned}$$

Lemma 3.3 now applies to prove that $\|y - y^N\|_{L_2(t_1,\infty;Y)} \to 0$ as $N \to \infty$.

To prove the convergence of $(\mathbb{F}^N)^*$, note that because of the uniform boundedness of $(\mathbb{F}^N)^*$ it is again sufficient to consider only y with compact support $[0,t_1]$. The proof then proceeds completely analogously to the case above. ∎

COROLLARY 3.6. *Under the assumptions of Lemma* 3.5,

$$\lim_{N\to\infty} \|k^N G^N(s)\rho^N \hat{u}(s) - G(s)\hat{u}(s)\|_{H_2(Y)} = 0$$

for all $\hat{u}(s) \in \mathbf{H}_2(U)$. *Similarly, for all* $\hat{y}(s) \in \mathbf{H}_2(Y)$,

$$\lim_{N\to\infty} j^N (G^N(s))^* \sigma^N \hat{y}(s) - G(s)^* \hat{y}(s)\|_{\mathbf{H}_2(Y)} = 0.$$

Proof. This result follows directly by taking Laplace transforms in Lemma 3.5 and applying the Paley–Wiener theorem (see, e.g., Theorem A.6.21 in Curtain and Zwart [5]). □

We remark that the above properties even hold for $\hat{u}(s) \equiv u$, $\hat{y}(s) \equiv y$ (see Corollary 3.4). However, in general we do not have that

$$\lim_{N\to\infty} \|k^N C^N (sI - A^N)^{-1} B^N \rho^N - C(sI - A)^{-1} B\|_{H_\infty} = 0.$$

See Proposition 1 and the counterexample on page 1146 in Kappel and Salamon [14].

4. Approximation for strongly stabilizable-detectable systems. In this section we will prove our main convergence result for Riccati equations for strongly stabilizable-detectable systems. The idea will be to transform the problem to an equivalent stable problem as in Theorem 2.4, and to apply the results for stable systems from section 3 to this stable problem. Before we prove this result in Theorem 4.2, we state and prove the following lemma, which relates the strong convergence of a system to which a feedback law is applied to the strong convergence of the original system.

LEMMA 4.1. *Let the sequence of systems $\Sigma(A^N, B^N, C^N)$ converge strongly to $\Sigma(A, B, C)$ and let the sequence of matrices $F^N \in \mathbb{R}^{m(N)\times k(N)}$ be chosen such that the operator sequences $j^N F^N \pi^N \in \mathcal{L}(Z, U)$ and $i^N (F^N)^* \rho^N \in \mathcal{L}(U, Z)$ converge strongly to F and F^*, respectively. Then $\Sigma(A^N + B^N F^N, B^N, [\begin{smallmatrix} F^N \\ C^N \end{smallmatrix}])$ converges strongly to $\Sigma(A + BF, B, [\begin{smallmatrix} F \\ C \end{smallmatrix}])$ as N tends to infinity.*

Proof. The only nontrivial part of the proof is the proof of the strong convergence of the sequence $i^N e^{(A^N + B^N F^N)t} \pi^N z$ to $T_F(t)z$, uniformly on compact time intervals, as N tends to infinity. By Theorem 3.1.7 of Davies [7], this is equivalent to proving that for all $z \in D(A)$, there exists a sequence $z^N \in \mathbb{R}^{k(N)}$ such that

$$\begin{aligned} i^N z^N &\to z, \\ i^N (A^N + B^N F^N) z^N &\to (A + BF) z. \end{aligned} \tag{4.1}$$

Because $i^N e^{A^N t} \pi^N z$ converges strongly to $T(t)z$, there exists a sequence of z^N for every $z \in D(A)$ such that

$$\begin{aligned} i^N z^N &\to z, \\ i^N A^N z^N &\to Az. \end{aligned} \tag{4.2}$$

Now taking this sequence z^N, we obtain

$$i^N (A^N + B^N F^N) z^N = i^N A^N z^N + i^N B^N F^N z^N.$$

From (4.2) it follows that the first term converges to Az. For the convergence of the second term, note that the assumptions state that

$$\begin{aligned} &i^N B^N \rho^N u \to Bu \text{ for all } u \in U \text{ and} \\ &j^N F^N \pi^N z \to Fz \text{ for all } z \in Z, \end{aligned}$$

and so, $i^N B^N \rho^N j^N F^N \pi^N z = i^N B^N F^N \pi^N z \to BFz$. Now,

$$\begin{aligned} \|i^N B^N F^N z^N - BFz\| &\le \|i^N B^N F^N (z^N - \pi^N z)\| + \|i^N B^N F^N \pi^N z - BFz\| \\ &\le \|i^N B^N F^N\| \|(z^N - \pi^N z)\| + \|i^N B^N F^N \pi^N z - BFz\|. \end{aligned}$$

Evidently, the second term converges to zero. The same holds for the first term, because $\|i^N B^N F^N\|$ is uniformly bounded by the uniform boundedness theorem and

$$\begin{aligned}\|(z^N - \pi^N z)\| &= \|\pi^N i^N z^N - \pi^N i^N \pi^N z\| \\ &\le \|\pi^N\| \cdot \|i^N z^N - i^N \pi^N z\| \\ &\le \|\pi^N\| \left(\|i^N z^N - z\| + \|z - i^N \pi^N z\|\right) \\ &\to 0. \qquad \square\end{aligned}$$

Now, we can prove our main result of this section, which is the approximation of a strongly stabilizing solution of the Riccati equation by a sequence of solutions to finite-dimensional Riccati equations.

THEOREM 4.2. *Consider the algebraic Riccati equation* (2.3)*, and assume that*

1. *the system $\Sigma(A, B, C)$ is strongly stabilizable-detectable (i.e., there exist $F \in \mathcal{L}(Z, U)$ and $L \in \mathcal{L}(Y, Z)$ for which the properties* A1–A3 *in Definition* 2.5 *are satisfied);*
2. *there exists a sequence of systems $\Sigma(A^N, B^N, C^N)$ which is strongly convergent to $\Sigma(A, B, C)$;*
3. *there exists a sequence of matrices $F^N \in \mathcal{L}(\mathbb{R}^{k(N)}, \mathbb{R}^{m(N)})$ such that*
   a. *$j^N F^N \pi^N \to F$ strongly and $i^N (F^N)^* \rho^N \to F^*$ strongly, where F is the operator from part* 1*.;*
   b. *$A^N + B^N F^N$ is a stable matrix;*
   c. *$\Sigma(A^N + B^N F^N, B^N, \left[\begin{smallmatrix} F^N \\ C^N \end{smallmatrix}\right])$ is uniformly output stable;*
   d. *$\Sigma(A^N + B^N F^N, B^N, \left[\begin{smallmatrix} F^N \\ C^N \end{smallmatrix}\right])$ is uniformly input-output stable;*
4. *there exists a sequence of matrices $L^N \in \mathcal{L}(\mathbb{R}^{m(N)}, \mathbb{R}^{p(N)})$ such that*
   a. *$A^N + L^N C^N$ is a stable matrix;*
   b. *$\Sigma(A^N + L^N C^N, \left[\begin{smallmatrix} B^N & L^N \end{smallmatrix}\right], F^N)$ is uniformly input-output stable.*

Then for every $z \in Z$,

$$Xz = \lim_{N \to \infty} i^N X^N \pi^N z,$$

where $X \in \mathcal{L}(Z)$ is the unique self-adjoint nonnegative solution of the algebraic Riccati equation (2.3) *and $X^N \in \mathcal{L}(\mathbb{R}^{k(N)})$ are the unique self-adjoint nonnegative solutions of the sequence of algebraic Riccati equations*

$$(A^N)^* X^N + X^N A^N - X^N B^N (B^N)^* X^N + (C^N)^* C^N = 0. \tag{4.3}$$

Moreover, denoting $F_X = -B^* X$ and $F^N_{X^N} = -(B^N)^* X^N$, the approximating closed-loop systems

$$\Sigma\left(A^N + B^N F^N_{X^N}, B^N, \begin{bmatrix} F^N_{X^N} \\ C^N \end{bmatrix}\right)$$

converge strongly to the infinite-dimensional closed-loop system

$$\Sigma\left(A + BF_X, B, \begin{bmatrix} F_X \\ C \end{bmatrix}\right).$$

Proof. We apply Theorem 2.4 to the approximating finite-dimensional systems $\Sigma(A^N, B^N, C^N)$. Since $A^N + B^N F^N$ and $A^N + L^N C^N$ are stable matrices, all of the assumptions A1–A3 are satisfied and the solutions to (4.3) are given by

$$X^N = (\Psi^N_F)^* \left[I - \mathbb{F}^N_F ((\mathbb{F}^N_F)^* \mathbb{F}^N_F)^{-1} (\mathbb{F}^N_F)^*\right] \Psi^N_F, \tag{4.4}$$

where Ψ_F^N and $\mathbb{F}_F^N$ are the output map and extended input-output map, respectively, for the system $\Sigma(A^N + B^N F^N, B^N, \left[\begin{smallmatrix} F^N \\ C^N \end{smallmatrix}\right], \left[\begin{smallmatrix} I \\ 0 \end{smallmatrix}\right])$. We apply Lemma 3.3 to obtain

$$\lim_{N\to\infty} (j^N \oplus k^N)\Psi_F^N \pi^N z = \Psi z \text{ in } \mathbf{L}_2(0,\infty; U \oplus Y), \tag{4.5}$$

$$\lim_{N\to\infty} i^N (\Psi_F^N)^* (\rho^N \oplus \sigma^N) w = \Psi_F^* w \tag{4.6}$$

for all $z \in Z$ and $w \in \mathbf{L}_2(0,\infty; U \oplus Y)$, where $j^N \oplus k^N$ denotes the direct sum of j^N and k^N, defined by $(j^N \oplus k^N)(u^N, y^N) = (j^N u^N, k^N y^N)$.

Similarly, Lemma 3.5 yields

$$(j^N \oplus k^N)\mathbb{F}_F^N \rho^N \to \mathbb{F}_F \text{ strongly}, \tag{4.7}$$

$$j^N (\mathbb{F}_F^N)^* (\rho^N \oplus \sigma^N) \to \mathbb{F}_F^* \text{ strongly} \tag{4.8}$$

as $N \to \infty$. Analogously to the definition of $\mathbb{F}_{LF}$ in the proof of Theorem 2.4, we define $\mathbb{F}_{LF}^N$ to be the extended input-output map of the system

$$\Sigma(A^N + L^N C^N, \left[\begin{smallmatrix} B^N & -L^N \end{smallmatrix}\right], -F^N, \left[\begin{smallmatrix} I & 0 \end{smallmatrix}\right]).$$

Assumption 4a of the present theorem tells us that $\|F_{LF}^N\|$ is uniformly bounded. Now from assumption 3d, $\sup \|\mathbb{F}_F^N\| < \infty$, and from (2.12), we have

$$\|((\mathbb{F}_F^N)^* \mathbb{F}_F^N)^{-1}\| \le \|\mathbb{F}_{LF}^N\|^2.$$

This shows that $\|((\mathbb{F}_F^N)^* \mathbb{F}_F^N)^{-1}\|$ is bounded from above uniformly in N. We also deduce that $\|j^N((\mathbb{F}_F^N)^* \mathbb{F}^N)^{-1}\rho^N\|$ are uniformly bounded from above, the reason being that we use the induced inner products on $\mathbb{R}^{m(N)}$ and so $\|((\mathbb{F}_F^N)^* \mathbb{F}_F^N)^{-1}\| = \|j^N((\mathbb{F}_F^N)^* \mathbb{F}^N)^{-1}\rho^N\|$. Thus,

$$\begin{aligned}
&\|j^N((\mathbb{F}_F^N)^* \mathbb{F}_F^N)^{-1}\rho^N v - (\mathbb{F}_F^* \mathbb{F}_F)^{-1} v\| \\
&\quad \le \|j^N((\mathbb{F}_F^N)^* \mathbb{F}_F^N)^{-1}\rho^N v - j^N \rho^N (\mathbb{F}_F^* \mathbb{F}_F)^{-1} v\| \\
&\qquad + \|j^N \rho^N (\mathbb{F}_F^* \mathbb{F}_F)^{-1} v - (\mathbb{F}_F^* \mathbb{F}_F)^{-1} v\| \\
&\quad = \|j^N((\mathbb{F}_F^N)^* \mathbb{F}_F^N)^{-1}\rho^N \left\{\mathbb{F}_F^* \mathbb{F}_F - j^N (\mathbb{F}_F^N)^* \mathbb{F}_F^N \rho^N\right\} (\mathbb{F}_F^* \mathbb{F}_F)^{-1} v\| \\
&\qquad + \|(j^N \rho^N - I)(\mathbb{F}_F^* \mathbb{F}_F)^{-1} v\| \\
&\quad \to 0
\end{aligned} \tag{4.9}$$

as $N \to \infty$.

The representations (2.11) and (4.4), together with the convergence results in (4.5)–(4.9), show that $i^N X^N \pi^N \to X$ strongly as $N \to \infty$. It is an easy consequence of the strong convergence of the stabilizing solutions that the optimal feedback operator $F_{X_N}^N$ and its adjoint converge strongly to their infinite-dimensional counterparts. The convergence of the approximating closed-loop systems now follows from the remark before Theorem 4.2. □

In the above theorem we have established the strong convergence of the approximating closed-loop systems to the infinite-dimensional closed-loop system. In practice, however, one would like to apply the finite-dimensional feedback to the infinite-dimensional plant. It is easy to see that the resulting closed-loop system

$$\Sigma\left(A + Bj^N F_{X^N}^N \pi^N, B, \left[\begin{smallmatrix} F_{X^N}^N \\ C \end{smallmatrix}\right]\right)$$

does converge strongly to the infinite-dimensional closed-loop system, as N tends to infinity. However, we have not been able to show that $A + Bj^N F^N \pi^N$ generates a strongly stable semigroup. Indeed, we doubt that this is true.

5. Applications to dissipative systems with collocated actuators and sensors. The class considered in this section, although mathematically quite special, is often used to model large flexible structures with collocated sensors and actuators (see, for instance, Joshi [13]). Systems in this class are the classical examples of systems that are strongly stabilizable but not exponentially stabilizable. The main feature is that they may have infinitely many unstable poles, which means that they are not exponentially stabilizable using a finite-rank, bounded input operator: exponentially stabilizable systems with a finite-rank, bounded input operator have at most finitely many unstable poles (see Curtain and Zwart [5, Theorem 5.2.6]). The state-space description is $\Sigma(A, B, C)$, where A is a dissipative operator on the Hilbert space Z, $B \in \mathcal{L}(U, Z)$ and $B = C^*,\ D = D^* \geq 0$. The terminology "collocated" for the condition $B = C^*$ comes from the fact that the condition arises if the actuators and sensors are implemented at the same location. This class was analyzed in Curtain and van Keulen [3], where they showed that the transfer function was positive-real and that the controller $K = -I$ robustly stabilized the system with respect to coprime factor perturbations with a robustness margin of at least $1/\sqrt{2}$.

We need to define notions of approximate controllability and approximate observability. We will not give the most intuitive definitions, but instead, we give an equivalent technical condition. For a more detailed treatment, see, e.g., Curtain and Zwart [5]. The system $\Sigma(A, B, C)$ is *approximately observable* if the operator $\Psi : Z \to \mathbf{L}_2(0, \infty; Y)$, given by $(\Psi z)(\cdot) = CT(\cdot)z$, satisfies $\ker(\Psi) = \{0\}$. The system $\Sigma(A, B, C)$ is *approximately controllable* if $\Sigma(A^*, C^*, B^*)$ is approximately observable. For a finite-dimensional system, these notions coincide with the usual controllability and observability definitions.

We consider linear systems $\Sigma(A, B, B^*)$ under the following assumptions.

- H1. A generates a C_0-semigroup of contractions $T(t)$ on the separable Hilbert space Z (i.e., A is a dissipative operator: $\langle Az, z\rangle + \langle z, Az\rangle \leq 0$ for all $z \in D(A)$).
- H2. U is a separable Hilbert space and $B \in \mathcal{L}(U, Z)$.
- H3. $\Sigma(A, B, B^*)$ is approximately observable.
- H4. $\Sigma(A, B, B)$ is approximately controllable.
- H5. A has compact resolvent.

The algebraic Riccati equation associated with this system is

$$A^*Xz + XAz - XBB^*Xz + BB^*z = 0 \tag{5.1}$$

for all $z \in D(A)$. The following properties of $\Sigma(A, B, B^*)$ were proven under the assumptions H1–H5 in [3, 6, 20, 22], respectively (see Oostveen and Curtain [21] for more details).

- P1. $A - BB^*$ generates the strongly stable C_0-semigroup $T_B(t)$ and $A^* - BB^*$ generates the strongly stable C_0-semigroup $T_B^*(t)$.
- P2. $\int_0^\infty \|B^*T_B(t)z\|^2 dt \leq \frac{1}{2}\|z\|^2$.
- P3. $\int_0^\infty \|B^*T_B^*(t)z\|^2 dt \leq \frac{1}{2}\|z\|^2$.
- P4. $B^*(sI - A + BB^*)^{-1}B \in \mathbf{H}_\infty(\mathcal{L}(U))$ and $\|B^*(sI - A + BB^*)^{-1}B\|_\infty \leq 1$.
- P5. There exists a unique self-adjoint nonnegative solution X to the algebraic Riccati equation (5.1) and $\|X\| \leq 1$.

The properties P1–P4 above can be summarized by saying that, choosing $F = -B^*$, $L = -B$, the system $\Sigma(A, B, B^*)$ is strongly stabilizable-detectable, i.e., $\Sigma(A - BB^*, B, B^*)$ is input stable, output stable, and input-output stable and $A - BB^*$ generates a strongly stable semigroup.

The claims above that $\|B^*(sI - A + BB^*)^{-1}B\|_\infty \leq 1$ and $\|X\| \leq 1$ were not found in [20]. Therefore we will provide proofs for them here. First, note that for $G(s) = B^*(sI - A + BB^*)^{-1}B$

$$\begin{aligned} &G(j\omega)^*G(j\omega) + (I - G(j\omega))^*(I - G(j\omega)) \\ &= 2G(j\omega)^*G(j\omega) + I - G(j\omega)^* - G(j\omega) \\ &= I + B^*(-j\omega I - A^* + BB^*)^{-1}(A + A^*)(j\omega I - A + BB^*)^{-1}B \\ &\leq I, \end{aligned}$$

where the inequality follows from the fact that A is dissipative. Thus,

$$I - G(j\omega)^*G(j\omega) \geq (I - G(j\omega))^*(I - G(j\omega)) \geq 0.$$

So, $G(j\omega)^*G(j\omega) \leq I$, which implies that $\|G\|_\infty \leq 1$.

For the estimate of the norm of X, note that

$$\langle Xz_0, z_0\rangle \leq \mathcal{J}(-B^*z(t), z_0) = 2\int_0^\infty \|B^*T_B(t)z_0\|^2 dt \leq \|z_0\|^2,$$

which implies that $\|X\| \leq 1$.

We now suppose that U and Y are finite-dimensional, $U = Y = \mathbb{R}^m$, and that there exists a sequence of injective linear maps $i^N : \mathbb{R}^{n(N)} \to Z$ and a sequence of surjective linear maps $\pi^N : Z \to \mathbb{R}^{n(N)}$ such that $\pi^N i^N = I_{n(N)}$ and $i^N\pi^N$ is an orthogonal projection on Z. We define a sequence of approximating systems $\Sigma(A^N, B^N, C^N)$ on $\mathbb{R}^{n(N)}$, where $A^N : \mathbb{R}^{n(N)} \to \mathbb{R}^{n(N)}N$ is such that

$$A^N + (A^N)^* \leq 0 \tag{5.2}$$

and B^N, C^N are chosen such that

$$\begin{aligned} B^N &= \pi^N B, \\ C^N &= B^* i^N. \end{aligned} \tag{5.3}$$

Now, we can give sufficient conditions for $\Sigma(A^N, B^N, C^N)$ to converge strongly to $\Sigma(A, B, B^*)$.

LEMMA 5.1. *Assume that the following conditions are satisfied.*

a1. *The sequence of injective maps $i^N : \mathbb{R}^{n(N)} \to Z$ and the sequence of surjective maps $\pi^N : Z \to \mathbb{R}^{n(N)}$ satisfy $\pi^N i^N = I_{n(N)}$, $i^N\pi^N$ is an orthogonal projection on Z, and $i^N\pi^N z \to z$ as $N \to \infty$ for all $z \in Z$.*

a2. *For all $z \in D(A)$ there exists a sequence $z^N \in \mathbb{R}^{n(N)}$ such that*

$$\begin{aligned} \|i^N z^N - z\| &\to 0 \quad \textit{and} \\ \|i^N A^N z^N - Az\| &\to 0 \ \textit{as}\ N \to \infty. \end{aligned} \tag{5.4}$$

a3. *For all $z \in D(A^*)$ there exists a sequence $z^N \in \mathbb{R}^{n(N)}$ such that*

$$\begin{aligned} \|i^N z^N - z\| &\to 0 \quad \textit{and} \\ \|i^N (A^N)^* z^N - A^* z\| &\to 0 \ \textit{as}\ N \to \infty. \end{aligned} \tag{5.5}$$

Then $\Sigma(A^N, B^N, C^N)$ defined by (5.2), (5.3) *converges strongly to $\Sigma(A, B, B^*)$. Moreover, $C^N = (B^N)^*$.*

Proof. We first show that $C^N = (B^N)^*$. For $u \in \mathbb{R}^m$, $z \in \mathbb{R}^{n(N)}$,

$$\begin{aligned}
&\langle B^N u, z\rangle_{\mathbb{R}^{n(N)}} \\
&= \langle \pi^N B u, z\rangle_{\mathbb{R}^{n(N)}} \\
&= \langle i^N \pi^N B u, i^N z\rangle_Z \\
&= \langle u, B^*(i^N\pi^N)^* i^N z\rangle_{\mathbb{R}^m} \\
&= \langle u, B^* i^N \pi^N i^N z\rangle_{\mathbb{R}^m} \\
&= \langle u, B^* i^N z\rangle_{\mathbb{R}^m} \\
&= \langle u, C^N z\rangle_{\mathbb{R}^m},
\end{aligned}$$

using the facts that $i^N\pi^N$ is an orthogonal projection and that $\pi^N i^N = I_{n(N)}$.

From Theorem 3.1.7 on page 80 in Davies [7], we have that (5.4) is equivalent to

$$i^N e^{A^N t}\pi^N z \to T(t)z$$

uniformly on compact time-intervals for all $z \in Z$, and (5.5) is equivalent to

$$i^N e^{(A^N)^* t}\pi^N z \to T^*(t)z$$

uniformly on compact time intervals for all $z \in Z$. Next, $i^N B^N = i^N\pi^N B \to B$ as $N \to \infty$ and $C^N\pi^N = (B^N)^*\pi^N = B^* i^N \pi^N \to B^*$ as $N \to \infty$, which completes the proof. ∎

LEMMA 5.2. *Let $\Sigma(A^N, B^N, C^N)$ satisfy the conditions of Lemma 5.1. Then $C^N = (B^N)^*$. Moreover, $\Sigma(A^N - B^N(B^N)^*, B^N, C^N)$ is uniformly output stable and uniformly input-output stable. If $\Sigma(A^N, B^N, (B^N)^*)$ is observable, then $A^N - B^N(B^N)^*$ is a stable matrix.*

Proof. We have $(B^N)^* = C^N$ and $A^N + (A^N)^* \le 0$. Therefore, the system $\Sigma(A^N - B^N(B^N)^*, B^N, (B^N)^*)$ satisfies properties P3 and P4. Hence it is uniformly output stable and uniformly input-output stable. The stability of $A^N - B^N(B^N)^*$ follows as in the infinite-dimensional case from the observability of the pair $(A^N, (B^N)^*)$ and $A^N + (A^N)^* \le 0$. Consider solutions $z(t) \in \mathbb{R}^{n(N)}$ of

$$\dot z(t) = (A^N - B^N(B^N)^*)z(t), \quad z(0) = z_0,$$

for arbitrary $z_0 \in \mathbb{R}^{n(N)}$. We introduce as a Lyapunov function for this differential equation $V(z) = \|z\|^2$. Then, if we differentiate V along solutions of the differential equation, we obtain

$$\begin{aligned}
&\frac{d}{dt}V(z(t)) \\
&= \langle z(t), \dot z(t)\rangle + \langle \dot z(t), z(t)\rangle \\
&= \langle z(t), (A^N - B^N(B^N)^*)z(t)\rangle + \langle (A^N - B^N(B^N)^*)z(t), z(t)\rangle \\
&= \langle (A^N + (A^N)^* - 2B^N(B^N)^*)z(t), z(t)\rangle \\
&\le -2\|(B^N)^* z(t)\|^2, \qquad (5.6)
\end{aligned}$$

where the inequality follows from the dissipativity of A^N. Now by Lasalle's invariance principle (see Lasalle [16]) all solutions $z(t)$ converge to the largest $A^N - B^N(B^N)^*$-invariant subset of the set

$$\mathcal{S} = \{z \in \mathbb{R}^{n(N)} |\ \langle (A^N + (A^N)^* - 2B^N(B^N)^*)z, z\rangle = 0\}.$$

Now let $0 \neq z_0 \in \mathcal{S}$, then for all $t \geq 0$, $z(t) = e^{(A^N - B^N(B^N)^*)t} z_0 \in \mathcal{S}$. And so, by (5.6)

$$0 = \frac{d}{dt} V(z(t)) \leq -2\|(B^N)^* z(t)\|^2 = -2\|(B^N)^* e^{(A^N - B^N(B^N)^*)t} z_0\|^2.$$

Hence, for all $t \geq 0$, $(B^N)^* e^{(A^N - B^N(B^N)^*)t} z_0 = 0$, which by the observability assumption implies that $z_0 = 0$. Thus $\mathcal{S} = \{0\}$ and consequently $A^N - B^N(B^N)^*$ is stable. □

Remark 5.3. If we assume that $i^N \pi^N z \to z$ and we choose $A^N = \pi^N A i^N$, then A^N satisfies the assumptions of Lemma 5.1, i.e., $A^N + (A^N)^* \leq 0$ and for all $z \in D(A)$, there is a sequence z^N which converges to z and for which $i^N A^N z^N$ converges to Az.

Indeed, if we choose the sequence $z^N = \pi^N z$, then

$$i^N z^N = i^N \pi^N z \ \to \ z$$

and

$$i^N A^N z^N = i^N \pi^N A i^N \pi^N z \ \to \ Az,$$

because $i^N \pi^N$ converges strongly to I, as N tends to infinity.

Furthermore, for $z_1, z_2 \in \mathbb{R}^{n(N)}$,

$$\begin{aligned}
&\langle A^N z_1, z_2 \rangle_{\mathbb{R}^{n(N)}} \\
&= \langle i^N \pi^N A i^N z_1, i^N z_2 \rangle_Z \\
&= \langle A i^N z_1, i^N \pi^N i^N z_2 \rangle_Z \text{ since } i^N \pi^N \text{ is an orthogonal projection} \\
&= \langle A i^N z_1, i^N z_2 \rangle_Z \text{ since } \pi^N i^N = I_{N(n)} \\
&= \langle i^N z_1, A^* i^N z_2 \rangle_Z \\
&= \langle i^N \pi^N i^N z_1, A^* i^N z_2 \rangle_Z \text{ since } \pi^N i^N = I_{N(n)} \\
&= \langle i^N z_1, i^N \pi^N A^* i^N z_2 \rangle_Z \text{ since } i^N \pi^N \text{ is an orthogonal projection} \\
&= \langle z_1, \pi^N A^* i^N z_2 \rangle_{\mathbb{R}^{n(N)}},
\end{aligned}$$

and so $(A^N)^* = \pi^N A^* i^N$. Now,

$$\begin{aligned}
&\langle (A^N + (A^N)^*) z, z \rangle_{\mathbb{R}^{n(N)}} \\
&= \langle \pi^N (A + A^*) i^N z, z \rangle_{\mathbb{R}^{n(N)}} \\
&= \langle i^N \pi^N (A + A^*) i^N z, i^N z \rangle_Z \\
&= \langle (A + A^*) i^N z, i^N \pi^N i^N z \rangle_Z \text{ since } i^N \pi^N \text{ is an orthogonal projection} \\
&= \langle (A + A^*) i^N z, i^N z \rangle_Z \text{ since } \pi^N i^N = I_{N(n)} \\
&\leq 0 \text{ since } A \text{ is dissipative.}
\end{aligned}$$

Thus $A^N + (A^N)^* \leq 0$.

The following corollary is now a direct consequence of Theorem 4.2, Lemmas 5.1 and 5.2, Remark 5.3, and the properties of systems $\Sigma(A, B, B^*)$.

COROLLARY 5.4. *Let the system* $\Sigma(A, B, B^*)$ *satisfy the assumptions* H1–H4*, and furthermore, assume that* $U = Y = \mathbb{R}^m$*. Let the sequence of approximating systems* $\Sigma(A^N, B^N, C^N)$ *as in* (5.2) *and* (5.3) *satisfy the assumptions of Lemma* 5.2*. Then* $X^N \to X$ *strongly as* $N \to \infty$*, where* X *and* X^N *are the solutions of the Riccati equation associated with* $\Sigma(A, B, B^*)$ *and* $\Sigma(A^N, B^N, C^N)$*, respectively.*

The class of dissipative systems with collocated actuators and sensors has a very special structure. However, one can also allow hybrid systems composed of a distributed system of the structure $\Sigma(A, B, B^*)$ coupled with a finite-dimensional system $\Sigma(A_f, B_f, C_F)$. The composite system

$$\Sigma\left(\begin{bmatrix} A & 0 \\ 0 & A_f \end{bmatrix}, \begin{bmatrix} B \\ B_f \end{bmatrix}, \begin{bmatrix} B^* & C_f \end{bmatrix}\right)$$

will satisfy the assumptions of our theory, provided that $\Sigma(A^N, B^N, C^N)$ are chosen as before and $\Sigma(A_f, B_f, C_f)$ is minimal. This broadens the class of possible applications considerably.

6. A numerical example: The one-dimensional wave equation with boundary oscillators. In this section, we apply the approximation result to a model of propagation of sound in a one-dimensional wave-guide of length 1, where the ends react as linear oscillators to the acoustic pressure. Actuating and sensing take place through the two ends.

Let subscripts x and t denote partial derivatives with respect to these variables. $\Psi(x,t)$ denotes the velocity potential, so that $\Psi_x(x,t)$ is the particle velocity in the fluid and $\Psi_t(x,t)$ is the acoustic pressure. Now, Ψ satisfies the wave equation

$$\Psi_{tt}(x,t) = \Psi_{xx}(x,t), \quad x \in (0,1).$$

The displacements of the two ends $\eta_0(t)$ at $x = 0$ and $\eta_1(t)$ at $x = 1$ satisfy

$$\frac{d^2\eta_0}{dt^2}(t) + d_0\frac{d\eta_0}{dt}(t) + k_0\eta_0(t) = -\rho_0\Psi_t(0,t) + f_1(t),$$
$$\frac{d^2\eta_1}{dt^2}(t) + d_1\frac{d\eta_1}{dt}(t) + k_1\eta_1(t) = -\rho_1\Psi_t(1,t) + f_2(t),$$

where f_1 and f_2 are external forces at the ends. From continuity of velocity at the boundary, we obtain

$$\frac{d\eta_0}{dt}(t) = -\frac{\partial\Psi}{\partial x}(0,t),$$
$$\frac{d\eta_1}{dt}(t) = \frac{\partial\Psi}{\partial x}(1,t).$$

The measurements are taken to be proportional to the velocities at the endpoints

$$y_1(t) = \frac{1}{2\rho_0}\frac{d\eta_0}{dt}(t),$$
$$y_2(t) = \frac{1}{2\rho_1}\frac{d\eta_1}{dt}(t).$$

The model can be brought into first-order form straightforwardly, introducing $z = \mathrm{col}(z_1, z_2, z_3, z_4, z_5, z_6)$ as the state, where $z_1 = \Psi$, $z_2 = \Psi_t$, $z_3 = \eta_0$, $z_4 = \eta_1$, $z_5 = \dot{\eta}_0$ and $z_6 = \dot{\eta}_1$. The state-space is then endowed with the norm corresponding to the energy of the system (see Beale [2]). For the approximation that we want to perform, a different state-space realization, introduced by Ito and Propst [12], is more convenient. An important difference between the approach of Ito and Propst and the one of Beale is that the former obtain an A-operator that has compact resolvent, but Beale does

not. The approach of Ito and Propst is to decompose Ψ into a part w^+ propagating in the positive direction and a part w^- propagating in the negative direction:

$$w^+(x,t) = \frac{1}{2}(\Psi_t(x,t) - \Psi_x(x,t)),$$
$$w^-(x,t) = \frac{1}{2}(\Psi_t(x,t) + \Psi_x(x,t)).$$

Defining $\phi_0 = \eta_0$, $\phi_1 = \eta_1$, $\psi_0 = \dot{\eta_0}$, $\psi_1 = \dot{\eta_1}$, we obtain

$$\frac{d}{dt}\begin{bmatrix} w^-(x,t) \\ w^+(x,t) \\ \phi_0(t) \\ \phi_1(t) \\ \psi_0(t) \\ \psi_1(t) \end{bmatrix} = \begin{bmatrix} w_x^-(x,t) \\ -w_x^+(x,t) \\ \psi_0(t) \\ \psi_1(t) \\ -\rho_0 w^-(0,t) - \rho_0 w^+(0,t) - k_0\phi_0(t) - d_0\psi_0(t) \\ -\rho_1 w^-(1,t) - \rho_1 w^+(1,t) - k_1\phi_1(t) - d_1\psi_1(t) \end{bmatrix},$$

with boundary conditions

$$\psi_0(t) = -w^-(0,t) + w^+(0,t),$$
$$\psi_1(t) = w^-(1,t) - w^+(1,t).$$

The state-space is taken to be $Z_0 = \mathbf{L}_2(0,1)\times\mathbf{L}_2(0,1)\times\mathbb{R}^4$ with inner product (writing $z = \mathrm{col}(w^-(x), w^+(x), \phi_0, \phi_1, \psi_0, \psi_1)$)

$$\langle z, \tilde{z}\rangle = \langle w^-, \tilde{w}^-\rangle_{L_2} + \langle w^+, \tilde{w}^+\rangle_{L_2} + \frac{k_0}{2\rho_0}\phi_0\tilde{\phi_0} + \frac{k_1}{2\rho_1}\phi_1\tilde{\phi_1} + \frac{1}{2\rho_0}\psi_0\tilde{\psi_0} + \frac{1}{2\rho_1}\psi_1\tilde{\psi_1}. \tag{6.1}$$

The input and output spaces are $U = Y = \mathbb{R}^2$. Let us define the operators A_0, B_0, and C_0 as

$$D(A_0) = \{z \in Z_0 \mid w^- \in H^1(0,1),\ w^+ \in H^1(0,1), \\ \psi_0 = -w^-(0) + w^+(0),\ \psi_1 = w^-(1) - w^+(1)\}, \tag{6.2}$$

$$A_0 z = \begin{bmatrix} w_x^-(x,t) \\ -w_x^+(x,t) \\ \psi_0(t) \\ \psi_1(t) \\ -\rho_0 w^-(0,t) - \rho_0 w^+(0,t) - k_0\phi_0(t) - d_0\psi_0(t) \\ -\rho_1 w^-(1,t) - \rho_1 w^+(1,t) - k_1\phi_1(t) - d_1\psi_1(t) \end{bmatrix}, \tag{6.3}$$

$$B_0 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad C_0 = \begin{bmatrix} 0 & 0 & 0 & 0 & \frac{1}{2\rho_0} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{2\rho_1} \end{bmatrix}. \tag{6.4}$$

With these definitions, the system can be written as

$$\dot{z} = A_0 z + B_0 u,$$
$$y = C_0 z.$$

It is an easy computation to see that $C_0 = B_0^*$.

In Ito and Propst [12], it was shown that A_0 generates a C_0-semigroup of contractions $T_0(t)$ on Z_0 and A_0 has compact resolvent. Because A_0 has compact resolvent, A_0 has only point spectrum and it can be computed that $\lambda \in \sigma(A_0)$ if and only if λ satisfies

$$0 = (\lambda^2 + (d_0 + \rho_0)\lambda + k_0)(\lambda^2 + (d_1 + \rho_1)\lambda + k_1)e^{\lambda} - (\lambda^2 + (d_0 - \rho_0)\lambda + k_0)(\lambda^2 + (d_1 - \rho_1)\lambda + k_1)e^{-\lambda}. \tag{6.5}$$

Except $\lambda = 0$, all eigenvalues have negative real part and occur in complex conjugate pairs. The associated eigenvectors are given by

$$z_\lambda = \begin{bmatrix} (\lambda^2 + (d_0 + \rho_0)\lambda + k_0)(\lambda^2 + (d_1 - \rho_1)\lambda + k_1)e^{\lambda x} \\ \lambda^2 + (d_0 - \rho_0)\lambda + k_0)(\lambda^2 + (d_1 - \rho_1)\lambda + k_1)e^{-\lambda x} \\ -2\rho_0(\lambda^2 + (d_1 - \rho_1)\lambda + k_1) \\ -2\rho_1(\lambda^2 + (d_0 + \rho_0)\lambda + k_0)e^{\lambda} \\ -2\rho_0(\lambda^2 + (d_1 - \rho_1)\lambda + k_1)\lambda \\ -2\rho_1(\lambda^2 + (d_0 + \rho_0)\lambda + k_0)\lambda e^{\lambda} \end{bmatrix}.$$

The vectors $\{z_\lambda |\ \lambda \in \sigma(A)\}$ form a complete orthogonal set in Z_0, and all eigenvalues are simple.

Because in acoustics, one is interested only in variations of the pressure, we have to add an extra condition to "filter out" states that correspond to the hydrostatic pressure, i.e., the part of pressure that is constant in the spatial variable. It can be checked that this corresponds to states that are a multiple of $z_0 = \mathrm{col}(k_0k_1, k_0k_1, -2\rho_0k_1, -2\rho_1k_0, 0, 0)$. This leads to the extra condition

$$\int_0^1 w^-(x)dx + \int_0^1 w^+(x)dx - \phi_0 - \phi_1 = 0.$$

Therefore, we do not use Z_0 as our state-space, but the quotient space

$$Z = \left\{ z \in Z_0 | \int_0^1 w^-(x)dx + \int_0^1 w^+(x)dx - \phi_0 - \phi_1 = 0 \right\}.$$

Z is a closed linear subspace of Z_0 and thus a Hilbert space with the same inner product. Define $A = A_0|_Z$. A is the generator of a C_0-semigroup of contractions $T(t)$ in Z because $T_0(t)$ maps Z into Z (this follows from the fact that z_0 is an eigenvector of A and Z is the orthogonal complement of z_0 in Z_0).

A also inherits the properties that it is a Riesz-spectral operator and that it has compact resolvent from A_0. So A also has only a point spectrum and $\lambda \in \sigma(A)$ if and only if $\lambda \neq 0$ and λ satisfies (6.5). Define B and C as the restrictions of B_0 and C_0 to Z. Using the controllability and observability test in Theorem 4.2.3 of Curtain and Zwart [5], it can be computed that $\Sigma(A, B, C)$ is approximately controllable and approximately observable. We show only the controllability, as the observability is completely analogous. By Theorem 4.2.3 in Curtain and Zwart [5], $\Sigma(A, B, C)$ is controllable if for all $\lambda \in \sigma_p(A)$

$$(\langle b_1, z_\lambda \rangle, \langle b_2, z_\lambda \rangle) \neq 0,$$

where b_1, b_2 are the two columns of B. In our case,

$$(\langle b_1, z_\lambda \rangle, \langle b_2, z_\lambda \rangle) = (-2\rho_0(\lambda^2 + (d_1 - \rho_1)\lambda + k_1)\lambda,\ -2\rho_1(\lambda^2 + (d_0 + \rho_0)\lambda + k_0)\lambda e^{\lambda}).$$

As $0 \in \rho(A)$, $\langle b_1, z_\lambda \rangle = 0$ implies that $\lambda^2 + (d_1 - \rho_1)\lambda + k_1 = 0$. Similarly, $\langle b_2, z_\lambda \rangle = 0$ implies that $\lambda^2 + (d_0 + \rho_0)\lambda + k_0 = 0$. But these two conditions together imply that $z_\lambda = 0$, which contradicts the fact that λ is an eigenvalue of A.

We can summarize the previous results by saying that $C = B^*$ and the system $\Sigma(A, B, B^*)$ satisfies the assumptions H1–H5 as in section 5. In particular, $A - BB^*$ generates a strongly stable semigroup $T_B(t)$. It is interesting to note that $T_B(t)$ cannot be an exponentially stable semigroup for the following reason. Let $\tilde{A}$ denote A for the specific case that $d_0 = d_1 = 0$. This operator $\tilde{A}$ satisfies $\mathrm{Re}\langle \tilde{A}z, z \rangle = 0$ and so $\tilde{A}$ generates a unitary semigroup $\tilde{T}(t)$. Moreover,

$$A - BB^* = \tilde{A} - BB^* - \begin{bmatrix} 0 & & \\ & d_0 & 0 \\ & 0 & d_1 \end{bmatrix}.$$

So $A - BB^*$ is a compact perturbation of $\tilde{A}$ and the same holds for $A + BF$ for arbitrary bounded F. Now, because $A - BB^*$ generates a strongly stable contraction semigroup $T_B(t)$, we can apply Theorem 2 of Gibson [8] to show that the semigroup $T_F(t)$ generated by $A + BF$ is exponentially stable if and only if both $T_B(t)$ and $\tilde{T}(t)$ are exponentially stable. This is impossible, because $\tilde{T}(t)$ is unitary.

Next, we construct a sequence of approximating finite-dimensional systems, and we will show that it satisfies the conditions that guarantee convergence of the approximating solutions of the finite-dimensional LQ Riccati equations to the solution of the infinite-dimensional LQ Riccati equation. Ito and Propst proposed an approximation scheme for $\Sigma(A_0, B_0, C_0)$. We explain this scheme and then make an obvious modification of it to obtain an approximation scheme for $\Sigma(A, B, C)$. We use a spectral method based on Legendre polynomials. This method is very well suited for our problem: it is accurate and converges very fast (faster than the polynomial rate). Moreover, it is known that this scheme does not produce extraneous eigenvalues, which standard finite element and finite difference methods may do.

Let $z = \mathrm{col}(w^-(x), w^+(x), \phi_0, \phi_1, \psi_0, \psi_1) \in Z_0$. We define z_0^N by

$$z_0^N = \pi_0^N z = (w_0^-, \ldots, w_N^-, w_0^+, \ldots, w_{N-1}^+, \phi_0^N, \phi_1^N, \psi_0^N, \psi_1^N)^T \in \mathbb{R}^{2N+5},$$

where $\phi_0^N = \phi_0$, $\phi_1^N = \phi_1$, $\psi_0^N = \psi_0$, $\psi_1^N = \psi_1$, and w_k^-, w_m^+, $k = 0, \ldots, N$, $m = 0, \ldots, N-1$, are defined as follows. Let $P_k(x)$ be the Legendre polynomial of degree k. The set $\{P_k(x),\ k \in \mathbb{N}\}$ forms an orthogonal basis of $\mathbf{L}_2(-1, 1)$ and $\|P_k\|^2_{L_2(-1,1)} = 2/(2k+1)$. Hence the polynomials $p_k(x) = \sqrt{2k+1}P_k(2x-1)$ form an orthonormal basis for $\mathbf{L}_2(0, 1)$. We expand $w^-(x)$ and $w^+(x)$ with respect to the basis $\{p_k(x),\ k \in \mathbb{N}\}$ and truncate these expressions as shown below:

$$w_N^-(x) = \sum_{k=0}^{N} w_k^- p_k(x),$$

$$w_{N-1}^+(x) = \sum_{k=0}^{N-1} w_k^+ p_k(x).$$

Note the difference in notation between the approximating function $w_N^-(x)$ and the coefficient w_N^-. Let i_0^N denote the corresponding embedding which associates with a vector v in $\mathbb{R}^{2N+5}$ an element in Z_0, defined by

$$i_0^N v = \mathrm{col}\left(\sum_{k=0}^{N} v_{k+1} p_k(x), \sum_{k=0}^{N-1} v_{N+2+k} p_k(x), v_{2N+2}, v_{2N+3}, v_{2N+4}, v_{2N+5} \right).$$

Next, we introduce

$$\tilde{w}_N^-(x) = \sum_{k=0}^{N} w_k^- p_k(x) + a p_{N+1}(x),$$
$$\tilde{w}_{N-1}^+(x) = \sum_{k=0}^{N-1} w_k^+ p_k(x) + b p_N(x),$$

where a and b are chosen such that $\tilde{w}_N^-(x)$ and $\tilde{w}_{N-1}^+(x)$ satisfy the boundary conditions

$$\psi_0 = -\tilde{w}_N^-(0) + \tilde{w}_{N-1}^+(0),$$
$$\psi_1 = \tilde{w}_N^-(1) - \tilde{w}_{N-1}^+(1).$$

We will now use $\tilde{w}_N^-(x)$ and $\tilde{w}_{N-1}^+(x)$ to define the approximation A_0^N of A_0.

$$A_0^N \begin{bmatrix} w_0^- \\ \vdots \\ w_N^- \\ w_0^+ \\ \vdots \\ w_{N-1}^+ \\ \phi_0 \\ \phi_1 \\ \psi_0 \\ \psi_1 \end{bmatrix} = \begin{bmatrix} a_0^- \\ \vdots \\ a_N^- \\ a_0^+ \\ \vdots \\ a_{N-1}^+ \\ \psi_0 \\ \psi_1 \\ -k_0\phi_0 - d_0\psi_0 - \rho_0\tilde{w}_N^-(0) - \rho_0\tilde{w}_{N-1}^+(0) \\ -k_1\phi_1 - d_1\psi_1 - \rho_1\tilde{w}_N^-(1) - \rho_1\tilde{w}_{N-1}^+(1) \end{bmatrix},$$

and $a_0^-, \ldots, a_N^-, a_0^+, \ldots, a_{N-1}^+$ are defined via

$$\frac{d\tilde{w}_N^-}{dx}(x) = \sum_{k=0}^{N} a_k^- p_k(x), \quad -\frac{d\tilde{w}_{N-1}^+}{dx}(x) = \sum_{k=0}^{N-1} a_k^+ p_k(x).$$

The approximations B_0^N and C_0^N of B_0 and C_0 are given by

$$B_0^N = \begin{bmatrix} 0_{(2N+3)\times 2} \\ I_2 \end{bmatrix}, \quad C_0^N = (B^N)^*.$$

The approximating state z^N is now obtained by orthogonal projection of z_0^N on the $(2N+4)$-dimensional linear subspace of $\mathbb{R}^{2N+5}$ of vectors satisfying

$$\int_0^1 \sum_{k=0}^{N} w_k^- p_k(x)dx + \int_0^1 \sum_{k=0}^{N-1} w_k^+ p_k(x)dx - \phi_0 - \phi_1 = 0.$$

Let this orthogonal projection be denoted by χ^N and the associated embedding from $\mathbb{R}^{2N+4}$ into $\mathbb{R}^{2N+5}$ by h^N. The approximating system $\Sigma(A^N, B^N, C^N)$ is obtained by restricting A_0^N, B_0^N, and C_0^N to this $(2N+4)$-dimensional space, i.e., $A^N = \chi^N A_0^N h^N$, $B^N = \chi^N B_0^N$, $C^N = C_0^N h^N$. The projection π^N and embedding i^N for the total approximation are now given as

$$i^N : \mathbb{R}^{2N+4} \to Z, \quad i^N = i_0^N h^N,$$
$$\pi^N : Z \to \mathbb{R}^{2N+4}, \quad \pi^N = \chi^N \pi_0^N.$$

Now $\pi^N i^N$ is an orthogonal projection in Z and $i^N \pi^N = I_{2N+4}$.

TABLE 6.1
Comparison of norms of the different approximations.

N	$\|X^N\|$	$\|X^N - \pi^N i^M X^M \pi^M i^N\|$
2	0.9802	6.31e-11
4	0.9802	1.81e-10
8	0.9802	6.25e-10
16	0.9802	2.32e-9
32	0.9802	1.57e-8
64	0.9802	0

In Ito and Propst [12] it was shown that for every $z \in D(A)$ there exists a sequence $z^N \in \mathbb{R}^{2N+4}$ such that

$$\|i^N z^N - z\| \to 0 \quad \text{and}$$
$$\|i^N A^N z^N - Az\| \to 0,$$

as $N \to \infty$. Similarly, we can prove that for all $z \in D(A^*)$ there exists a sequence $z^N \in \mathbb{R}^{2N+4}$ such that

$$\|i^N z^N - z\| \to 0 \quad \text{and}$$
$$\|i^N (A^N)^* z^N - A^* z\| \to 0.$$

It is easily shown that C^N and B^N converge strongly to C and B, respectively. As in Lemma 5.1 these results imply that $\Sigma(A^N, B^N, C^N)$ converges strongly to $\Sigma(A, B, B^*)$. Hence, we can conclude from Corollary 5.4 that if $\Sigma(A^N, B^N, C^N)$ is observable for all N, then the solution X of the infinite-dimensional LQ Riccati equation associated with $\Sigma(A, B, B^*)$ can be approximated by the sequence of solutions X^N of the matrix LQ Riccati equations associated with $\Sigma(A^N, B^N, C^N)$.

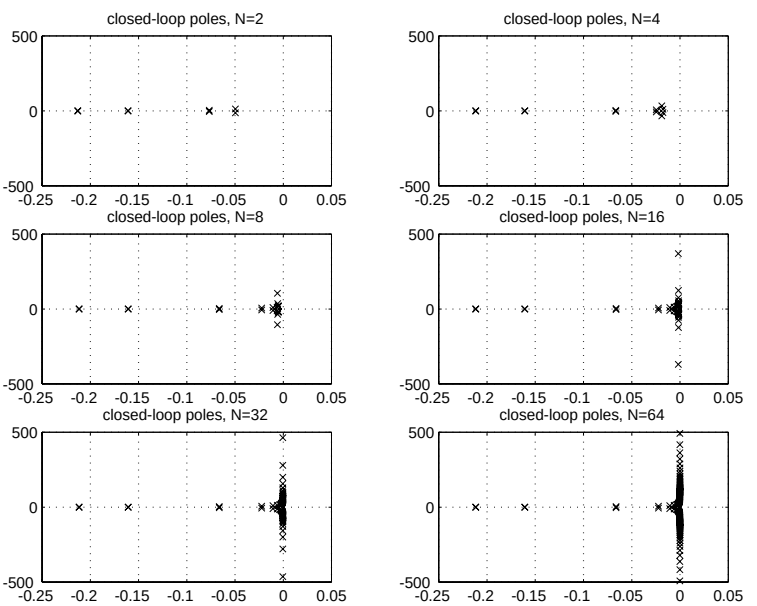

FIG. 6.1. *Closed-loop poles,* $N = 2, 4, 8, 16, 32, 64$.

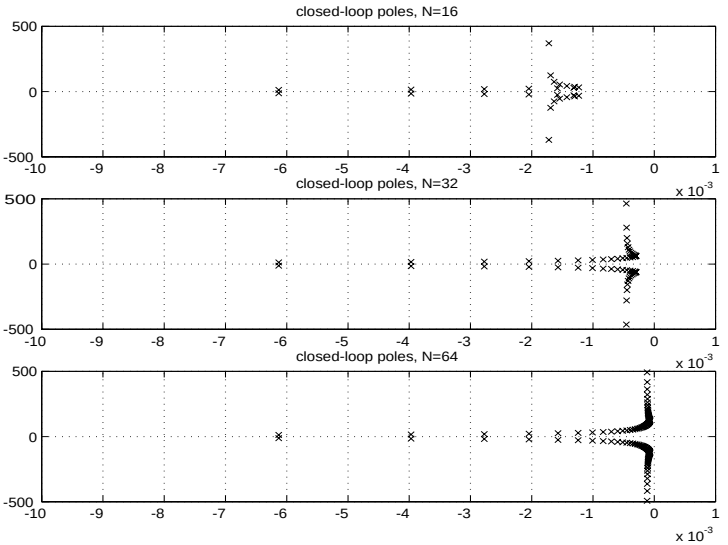

FIG. 6.2. *Closed-loop poles,* $N = 16, 32, 64$.

We implemented the approximation scheme in Matlab. The values for the parameters we used are

$$\rho_0 = \rho_1 = 1,$$
$$d_0 = d_1 = 0.01,$$
$$k_0 = k_1 = 1.$$

We computed the approximating systems for $N = 2, 4, 8, 16, 32, 64$. Then we computed the solutions to the Riccati equations corresponding to these approximations.

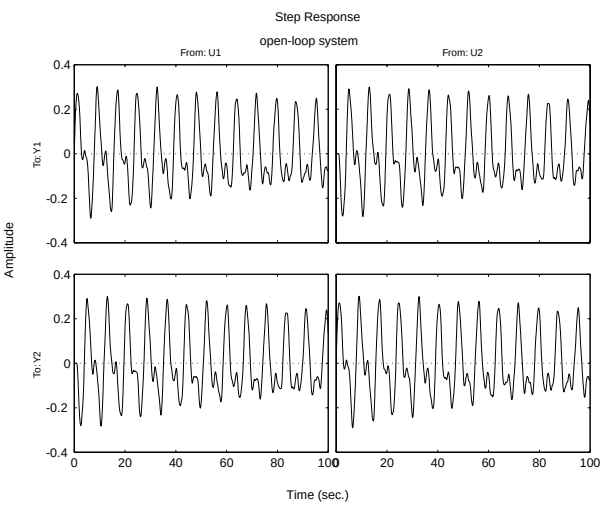

FIG. 6.3. *Open-loop step response,* $N = 16$.

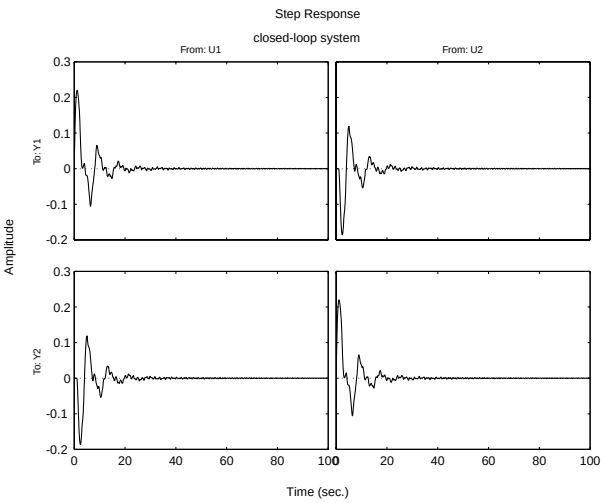

FIG. 6.4. *Closed-loop step response,* $N = 16$.

To illustrate the convergence of the solutions, we compare the solutions in a number of characteristics. First, we compute the matrix norms of the approximating solutions. Second, we restrict X^{64} to the spaces on which the lower-order approximations are defined and compute the norm of the difference: $\|X^N - \pi^N i^M X^M \pi^M i^N\|$. This norm measures to what extent the lower-order approximations matches the behavior of the higher-order one on the lower-dimensional space. These values are listed in Table 6.1, above.

Third, we give plots of the closed-loop poles. Finally, we computed the open-loop and closed-loop step responses for $N = 16$ and $N = 64$. Because these were indistinguishable for the two values of N used, we give only the plots for $N = 16$.

From these results, we observe the following. The norms of the approximations are very close to each other, and far larger than the norm of the difference between the low-order approximations and the restriction of X^{64} to the lower-order spaces.

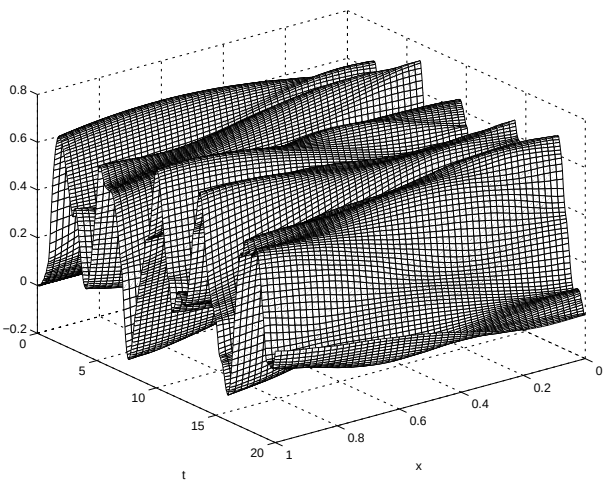

FIG. 6.5. *Open-loop step response,* $N = 16$.

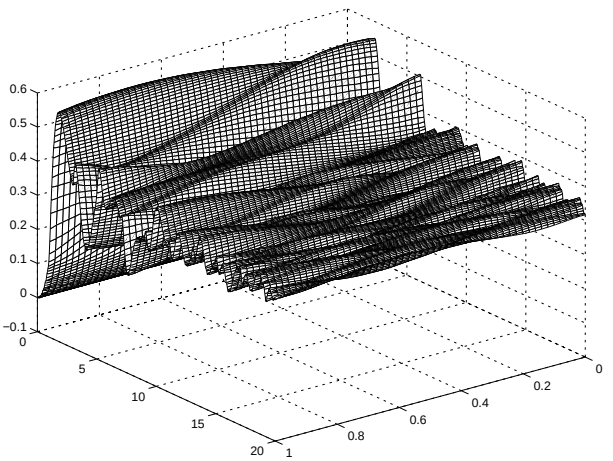

FIG. 6.6. *Closed-loop step response,* $N = 16$.

This indicates that the low-order approximations capture very well the behavior of the infinite-dimensional solution on the finite-dimensional spaces on which they are defined. The plots of the closed-loop poles in Figures 6.1 and 6.2 indicate that also the closed-loop system matrices converge as N tends to infinity. As expected, since the original system is not exponentially stabilizable, the poles are converging to the imaginary axis. The plots of the step responses are not very different for the different values of N. We plotted step responses for $N = 16$ in Figures 6.3 and 6.4. In Figures 6.5 and 6.6 we plotted the response of the velocity potential $\Psi(x,t)$ to a step input at $x = 0$, both for the open-loop and closed-loop system.

SUPERLINEAR CONVERGENCE OF AFFINE-SCALING INTERIOR-POINT NEWTON METHODS FOR INFINITE-DIMENSIONAL NONLINEAR PROBLEMS WITH POINTWISE BOUNDS*

MICHAEL ULBRICH† AND STEFAN ULBRICH†

Abstract. We develop and analyze a superlinearly convergent affine-scaling interior-point Newton method for infinite-dimensional problems with pointwise bounds in L^p-space. The problem formulation is motivated by optimal control problems with L^p-controls and pointwise control constraints. The finite-dimensional convergence theory by Coleman and Li [*SIAM J. Optim.*, 6 (1996), pp. 418–445] makes essential use of the equivalence of norms and the exact identifiability of the active constraints close to an optimizer with strict complementarity. Since these features are not available in our infinite-dimensional framework, algorithmic changes are necessary to ensure fast local convergence. The main building block is a Newton-like iteration for an affine-scaling formulation of the KKT-condition. We demonstrate in an example that a stepsize rule to obtain an interior iterate may require very small stepsizes even arbitrarily close to a nondegenerate solution. Using a pointwise projection instead we prove superlinear convergence under a weak strict complementarity condition and convergence with Q-rate >1 under a slightly stronger condition if a smoothing step is available. We discuss how the algorithm can be embedded in the class of globally convergent trust-region interior-point methods recently developed by M. Heinkenschloss and the authors. Numerical results for the control of a heating process confirm our theoretical findings.

1. Introduction.

We introduce an affine-scaling interior-point Newton method for the solution of the infinite-dimensional nonlinear optimization problem

(P)
$$\begin{aligned} &\text{minimize} && f(u) \\ &\text{subject to} && u \in \mathcal{B} \stackrel{\text{def}}{=} \{u \in L^p : a(x) \le u(x) \le b(x) \text{ almost everywhere (a.e.) on } \Omega\} \end{aligned}$$

and study its local convergence behavior in detail. Here $\Omega \subset \mathbb{R}^n$ is a domain with positive and finite Lebesgue measure $0 < \mu(\Omega) < \infty$, and

$$L^t = L^t(\Omega), \quad 1 \le t \le \infty,$$

denotes the usual Banach space of (equivalence classes of) real-valued measurable functions for which the norm

$$\|u\|_t \stackrel{\text{def}}{=} \left(\int_\Omega |u(x)|^t \, dx \right)^{1/t} \quad (t < \infty), \quad \|u\|_\infty \stackrel{\text{def}}{=} \operatorname*{ess\,sup}_{x \in \Omega} |u(x)|$$

†Lehrstuhl für Angewandte Mathematik und Mathematische Statistik, Technische Universität München, 80290 München, Germany (mulbrich@mathematik.tu-muenchen.de, sulbrich@mathematik.tu-muenchen.de).

is bounded. Let $2 \le p \le \infty$ and assume that the objective function $f : \mathcal{D} \longrightarrow \mathbb{R}$ is continuous on an open neighborhood $\mathcal{D} \subset L^p$ of $\mathcal{B}$. Additional requirements on f will be given below. The lower and upper bound functions $a, b \in L^\infty$ are assumed to have positive distance from each other, i.e.,

$$\operatorname*{ess\,inf}_{x\in\Omega} \ (b(x) - a(x)) > 0.$$

Then $\mathcal{B}$ has a nonempty L^∞-interior

$$\mathcal{B}^\circ \stackrel{\text{def}}{=} \bigcup_{\delta>0} \{u \in L^p \ : \ a(x) + \delta \le u(x) \le b(x) - \delta \ \text{ for almost all (a.a.) } \ x \in \Omega\}.$$

Problems of type (P) arise, for instance, when the black-box approach is applied to optimal control problems with bound-constrained L^p-control. See, e.g., the problems studied by Burger and Pogu [5], Kelley and Sachs [17], Sachs [24], and Tian and Dunn [25].

Our minimum assumptions on the objective function f follow.

ASSUMPTION.

(A1) *$f : \mathcal{D} \subset L^p \longrightarrow \mathbb{R}$ is twice continuously Fréchet differentiable with derivatives*

$$\begin{aligned} g \stackrel{\text{def}}{=} \nabla f &: \mathcal{D} \longrightarrow L^{p'}, \qquad && \frac{1}{p} + \frac{1}{p'} = 1. \\ \nabla^2 f &: \mathcal{D} \longrightarrow \mathcal{L}(L^p, L^{p'}), && \end{aligned}$$

Moreover, there is $C_g > 0$ such that $\|g(u)\|_\infty < C_g$ for all $u \in \mathcal{B}$.

Since $g(u)$ is an element of $L^{p'}$, the last requirement looks quite restrictive at first view. However, the boundedness of $\|g(u)\|_\infty$ is required only for $u \in \mathcal{B}$, which is a bounded subset of L^∞. This together with the fact that in many applications the gradient is defined via the solution of an adjoint differential equation can often be used to establish this assumption. For details we refer to section 11, where we apply our theory to the boundary control of a heating process.

The algorithm presented in this paper is based on the application of a Newton-like iteration to an affine-scaling formulation of the first-order necessary optimality conditions. For finite-dimensional problems this class of algorithms has been introduced and analyzed by Coleman and Li [6], [7]. Extensions to problems with additional equality constraints were studied in Dennis, Heinkenschloss, and Vicente [8], Heinkenschloss and Vicente [15], and Vicente [27], [28]. In all of the above papers except for [28], the affine-scaling Newton iteration is embedded in a trust-region interior-point algorithm to achieve global convergence. In a recent paper (Ulbrich, Ulbrich, and Heinkenschloss [26]) we extended the finite-dimensional global convergence theory of Coleman and Li [7] for trust-region interior-point algorithms to the infinite-dimensional problem class (P). The present paper continues these investigations and focuses on the local superlinear convergence of a closely related affine-scaling interior-point Newton method which plays the same important role in our setting as the ordinary Newton method does in the local analysis of trust-region algorithms for unconstrained optimization. Problem (P) is a special type of cone-constrained optimization problem in Banach space. For this very general class of problems Alt [2] developed a Lagrange–Newton-SQP method and proved quadratic convergence. A drawback of SQP-type methods lies in the fact that in each step a linearly cone-constrained quadratic problem or, equivalently, a linear generalized equation has to be solved. In our setting each SQP-subproblem would have the form (P) with the objective f replaced by a quadratic approximation. The solution of these problems is by no means trivial and

requires a multiple of the effort needed to perform a Newton-like step. Therefore, although SQP-methods are quadratically convergent, their efficiency crucially depends on the availability of fast solvers for the subproblems. The method proposed in this paper will be shown to converge with Q-order $1+\beta$, $0<\beta<1$, while, essentially, each iteration requires only the solution of a linear equation, which is usually much cheaper than solving an SQP-subproblem.

During the last fifteen years several attempts have been undertaken to develop algorithms for which each iteration is not much more expensive than an ordinary Newton step. One of these is the projected Newton method which was introduced by Bertsekas [3] for finite-dimensional bound-constrained problems. Kelley and Sachs [17] extended this method to problems of type (P) with special structure and proved local convergence with Q-rate $1+\beta$, $0<\beta<1$. The class of problems addressed in [17] is essentially the same as the one discussed in section 8 of this work. Although it is possible in the finite-dimensional case to prove quadratic convergence (see [3]), Kelley and Sachs could not establish this result in their infinite-dimensional setting. In this paper we develop local convergence results for infinite-dimensional affine-scaling interior-point Newton methods which are similar to those by Kelley and Sachs for projected Newton methods. Like Kelley and Sachs, we observe a gap between the achievable convergence rate in the finite- and infinite-dimensional settings. Our theory covers a more comprehensive problem class and requires weaker assumptions than that for projected Newton methods in [17]. The cost for one iteration of our algorithm is dominated by the solution of a linear equation and is therefore comparable to that of a projected Newton step.

The development of a local convergence theory for our infinite-dimensional setting turns out to be much more delicate than in the finite-dimensional case. First of all, strict complementarity, i.e., $g(\bar{u})(x)\neq 0$ for a.a. $x\in\Omega$ with $\bar{u}(x)\in\{a(x),b(x)\}$, at a local solution $\bar{u}\in\mathcal{B}$ of (P) does not guarantee that the absolute value of the gradient $g(\bar{u})$ is uniformly bounded away from zero on the active set. As a consequence, even for $u\in\mathcal{B}$ arbitrarily close to $\bar{u}$, the active set at $\bar{u}$ cannot be identified exactly by means of the information available at u. And, finally, since the L^t- and L^∞-norm, $1\le t<\infty$, are not equivalent, an iterate u_k may be very close to the solution $\bar{u}$ in L^t but still deviate substantially from $\bar{u}$ on a small set of nonzero measure. These are the main reasons why—in contrast to the finite-dimensional case—it seems not to be possible to achieve quadratic convergence in our general setting. They also make necessary several modifications of the original finite-dimensional algorithm investigated in [6] and [7] to establish superlinear convergence in the infinite-dimensional framework. Essentially, these modifications consist of the enforcement of strict feasibility by a modified projection instead of a stepsize rule and the introduction of a smoothing step to overcome the nonequivalence of norms. An example that proves the necessity of the first modification is given in Example 6.3.

The difficulties described and the necessity of modifications arise not only theoretically, but can also be observed in the finite-dimensional numerical practice. In Examples 6.3 and 6.5 we discuss in detail a scenario where our proof-driven modifications are shown to be necessary for mesh-independent convergence behavior. In this example, a simple problem of type (P) is investigated that meets all our assumptions. By discretizing problem (P) a finite-dimensional bound-constrained problem (PD) is obtained. To compute an approximate solution of (P) we apply a finite-dimensional analogue of our affine-scaling interior-point Newton method to the discretized problem (PD). The algorithm performs almost independently of the mesh size of the discretiza-

tion and converges locally superlinearly (very close to the solution even quadratically due to the finite-dimensionality of (PD)). This observed mesh-independent behavior can be viewed as the natural finite-dimensional counterpart to the availability of an infinite-dimensional convergence theory for this method. For comparison, we also apply to (PD) the affine-scaling interior-point Newton method without our modifications, which in finite dimensions is locally quadratically convergent [6], [7]. It turns out that the region of quadratic convergence is very small and, in addition, shrinks rapidly for increasingly fine meshes. Therefore, this original algorithm is not mesh-independent. This shows that the development of efficient algorithms for the solution of infinite-dimensional optimization problems also leads to improved finite-dimensional methods.

In the following we give a rough outline of the theory developed in this paper. As mentioned above, the heart of our algorithm is a Newton-like step applied to the affine-scaling formulation $d(u)g(u) = 0$ of the Karush–Kuhn–Tucker (KKT) conditions. Here $d(u) \in L^\infty$ denotes a suitably chosen weighting function, the affine-scaling function. In the Newton equation the generally nonexisting derivative of $u \longmapsto d(u)g(u)$ is replaced by an appropriate operator $G(u)$. If $u_k^s \in \mathcal{B}^\circ$ denotes the current (actually smoothed; see below) iterate, then the affine-scaling Newton step reads

$$G(u_k^s)(u_{k+1}^n - u_k^s) = -d(u_k^s)g(u_k^s).$$

The analysis of this iteration will be carried out under a regularity assumption on $G(u)$ and the following smoothness assumption.

ASSUMPTION.

(A2) *There are $2 \le q < r \le s \le \infty$, $s \ge p$, such that $g : \mathcal{B} \subset L^s \longrightarrow L^r$ is Lipschitz continuous with constant L_g and $g : \mathcal{B} \subset L^s \longrightarrow L^q$ is Lipschitz continuously Fréchet differentiable. We denote the Lipschitz constant of $\nabla g = \nabla^2 f$ by $L_{g'}$.*

We establish the estimate $\|u_{k+1}^n - \bar{u}\|_q = o(\|u_k^s - \bar{u}\|_s)$ if strict complementarity holds at the local solution $\bar{u}$ of (P), and $\|u_{k+1}^n - \bar{u}\|_q \le C\|u_k^s - \bar{u}\|_s^{1+\beta}$, $0 < \beta < 1$, if a slightly stronger strict complementarity condition is satisfied. This discrepancy of the norms is, among other things, caused by the fact that the complementarity can be arbitrarily weak on small sets. To overcome this difficulty we follow [17] and assume the availability of a smoothing step $u_k \in \mathcal{B}^\circ \longmapsto u_k^s = S_k^\circ(u_k) \in \mathcal{B}^\circ$ with $\|u_k^s - \bar{u}\|_s \le C_S\|u_k - \bar{u}\|_q$. Moreover, since u_{k+1}^n may lie outside of $\mathcal{B}^\circ$, we define a back-transport $u \longmapsto P[u_k^s](u) \in \mathcal{B}^\circ$ by an interior-point modification of the pointwise projection onto $\mathcal{B}$. We will see that a stepsize rule is inappropriate in our framework, although it yields quadratic convergence in the finite-dimensional case. We prove that the combination

$$u_k \rightsquigarrow u_k^s = S_k^\circ(u_k) \rightsquigarrow u_{k+1}^n \rightsquigarrow u_{k+1} = P[u_k^s](u_{k+1}^n)$$

generates sequences (u_k) and (u_k^s) that converge superlinearly to $\bar{u}$ in L^q and L^s, respectively. If the stronger strict complementarity condition holds we prove convergence with Q-rate $1 + \beta$. We apply our results to a class of problems with L^2-regularization for which a projected Newton method was analyzed in [17] and show that the assumptions therein imply ours. For this problem class a smoothing step can be derived from a fixed point formulation of the KKT-conditions. Moreover, we show that the second-order sufficiency condition of Dunn and Tian [9] implies our regularity assumption on G. Finally, we discuss how our algorithm can be embedded in the globally convergent class of trust-region interior-point methods recently introduced in

[26]. The resulting method is applied to the boundary control of a heating process which was already considered in [5], [20].

This paper is organized as follows. In section 2 we introduce some notation and put together several important estimates for L^p-spaces. Moreover, we state the first-order necessary optimality conditions for problem (P) in standard- and affine-scaling formulation. Our particular choice of the affine-scaling function and the basic affine-scaling Newton step are introduced in section 3. Here we discuss also why an iteration based on this step alone is, in general, neither well-defined nor convergent and sketch the idea of a smoothing step and a back-transport that take care of these problems. An outline of our algorithm and its convergence properties in a clearly arranged abstract setting is given in section 4. In section 5 we carry out a thorough analysis of the Newton-like step. In section 6 the affine-scaling interior-point Newton algorithm is formulated. Moreover, we introduce a back-transport based on a pointwise projection onto $\mathcal{B}$, explain why in our infinite-dimensional setting a stepsize-rule is not suitable for a back-transport, and address the smoothing step. Our convergence results are presented in section 7. In section 8 we apply our results to a class of L^2-regularized problems and show that our assumptions are weaker than those used in [17]. In section 9 we discuss the relationship between sufficient second-order conditions developed in [9] and the regularity assumptions we impose on the approximate derivative operator G. Section 10 addresses the question of how our algorithm can be used to accelerate the globally convergent class of trust-region interior-point algorithms recently proposed in [26]. Finally, we present numerical results for the boundary control of a heating process in section 11.

2. Preliminaries.

2.1. Notation. We write $B^c = \Omega \setminus B$ for the complement of a measurable set $B \subset \Omega$ and denote the characteristic function of B by χ_B, i.e., $\chi_B(x) = 1$ for $x \in B$, and $\chi_B(x) = 0$ otherwise. If $v : \Omega \longrightarrow \mathbb{R}$ is measurable, then we set $v_B \stackrel{\text{def}}{=} \chi_B v$. Moreover, we write $\|\cdot\|_{t,B}$ for $\|\chi_B \cdot\|_t$, $1 \le t \le \infty$.

$\mathcal{L}(Y, Z)$ is the space of bounded linear operators from the Banach space Y into the Banach space Z. The operator norm on $\mathcal{L}(L^{q_1}, L^{q_2})$ is denoted by $\|\cdot\|_{q_1,q_2}$. We write I for the identity operator $y \longmapsto y$. As representation of the dual space of L^t, $1 \le t < \infty$, we choose $L^{t'}$, $1/t + 1/t' = 1$, with the corresponding dual pairing $\langle v, w\rangle = \int_\Omega v(x)w(x)dx$, $v \in L^t$, $w \in L^{t'}$.

2.2. Some inequalities. For convenience, we recall a couple of well-known norm estimates for L^p-spaces.

LEMMA 2.1. *For all $1 \le q_1 \le q_2 \le \infty$ and $v \in L^{q_2}(\Omega)$ we have*

$$\|v\|_{q_1} \le m_{q_1,q_2}\|v\|_{q_2}$$

with $m_{q_1,q_2} = \mu(\Omega)^{\frac{1}{q_1}-\frac{1}{q_2}}$. Here $1/\infty$ has to be interpreted as zero.

Proof. See, e.g., [1, Thm. 2.8]. ∎

LEMMA 2.2 (interpolation inequality). *Given $1 \le q_1 \le q_2 \le \infty$ and $0 \le \theta \le 1$, let $1 \le q_0 \le \infty$ satisfy $1/q_0 = \theta/q_1 + (1-\theta)/q_2$. Then for all $v \in L^{q_2}$,*

$$\|v\|_{q_0} \le \|v\|_{q_1}^{\theta}\|v\|_{q_2}^{1-\theta}. \tag{1}$$

Proof. See [26, Lem. 5.2]. ∎

LEMMA 2.3. *Let $q_0 \in [1,\infty]$ and $q_1, q_1' \in [1,\infty]$ with $1/q_1 + 1/q_1' = 1$ be given. Then for all $u \in L^{q_0 q_1}$ and $v \in L^{q_0 q_1'}$ we have*

$$\|uv\|_{q_0} \le \|u\|_{q_0 q_1} \|v\|_{q_0 q_1'}.$$

Proof. In the nontrivial case $q_0 < \infty$, apply Hölder's inequality:

$$\|u\|_{q_0 q_1}^{q_0} \|v\|_{q_0 q_1'}^{q_0} = \||u|^{q_0}\|_{q_1} \||v|^{q_0}\|_{q_1'} \ge \||u|^{q_0}|v|^{q_0}\|_1 = \|uv\|_{q_0}^{q_0}. \qquad \square$$

LEMMA 2.4. *For $v \in L^q$, $1 \le q < \infty$, and all $\delta > 0$ holds*

$$\mu\left(\{x \in \Omega : \ |v(x)| \ge \delta\}\right) \le \delta^{-q} \|v\|_q^q.$$

Proof.

$$\|v\|_q^q = \||v|^q\|_1 \ge \|\chi_{\{|v| \ge \delta\}} |v|^q\|_1 \ge \mu(\{|v| \ge \delta\})\delta^q. \qquad \square$$

2.3. Necessary optimality conditions. The method is based on an affine-scaling formulation of the first-order necessary optimality conditions. A detailed derivation of these conditions can be found in [26]. Therein we also prove second-order necessary conditions which are not needed in our context.

THEOREM 2.5 (first-order necessary optimality conditions, KKT conditions). *Let $\bar u$ be a local minimizer of problem* (P) *and assume that f is differentiable at $\bar u$. In the case $p = \infty$ assume in addition that the gradient satisfies $g(\bar u) \in L^1$. Then*
(O1) $\bar u \in \mathcal{B}$,

$$\text{(O2)} \quad g(\bar u)(x) \begin{cases} = 0 & \text{for } x \in \Omega \text{ with } a(x) < \bar u(x) < b(x), \\ \ge 0 & \text{for } x \in \Omega \text{ with } \bar u(x) = a(x), \\ \le 0 & \text{for } x \in \Omega \text{ with } \bar u(x) = b(x) \end{cases} \qquad \text{a.e. on } \Omega,$$

are satisfied.

Proof. See [26, Thm. 3.1]. $\square$

The inequality (O2) can be converted into an equation by pointwise multiplication with an *affine-scaling* function $d(\bar u)$, where $d : \mathcal{B} \longrightarrow L^\infty$ satisfies

$$d(u)(x) \begin{cases} = 0 & \text{if } u(x) = a(x) \text{ and } g(u)(x) \ge 0, \\ = 0 & \text{if } u(x) = b(x) \text{ and } g(u)(x) \le 0, \\ > 0 & \text{else} \end{cases} \tag{2}$$

for a.a. $x \in \Omega$. For details we refer to [26]. The idea was first introduced by Coleman and Li in [7] for the finite-dimensional case.

LEMMA 2.6. *Let $f : \mathcal{D} \subset L^p \longrightarrow \mathbb{R}$ be differentiable and $\bar u \in \mathcal{B}$. In the case $p = \infty$ assume in addition that the gradient satisfies $g(u) \in L^1$, $u \in \mathcal{B}$. Then* (O2) *is equivalent to*

$$d(\bar u) g(\bar u) = 0 \tag{3}$$

for all d satisfying (2).

Proof. See [26, Lem. 3.2]. $\square$

3. A Newton-like step. As for all efficient methods, we aim to apply Newton's method to a suitable formulation of the optimality system. In our approach we take (3) which, according to Lemma 2.6, is equivalent to the first-order necessary condition (O2). We use the freedom provided by (2) to choose the affine-scaling function d in such a way that dg is as smooth as possible in a neighborhood of a KKT-point $\bar{u}$ of (P). A possible realization of (2) is the following function space analogue of the affine-scaling matrix of Coleman and Li [7]:

$$d_{\mathrm{I}}(u)(x) \stackrel{\text{def}}{=} \begin{cases} u(x) - a(x) & \text{if } g(u)(x) > 0 \text{ or} \\ & g(u)(x) = 0 \text{ and } u(x) \le (a(x) + b(x))/2, \\ b(x) - u(x) & \text{if } g(u)(x) < 0 \text{ or} \\ & g(u)(x) = 0 \text{ and } u(x) > (a(x) + b(x))/2. \end{cases} \tag{4}$$

In general, the mapping $u \in \mathcal{B} \subset L^\infty \longmapsto d_{\mathrm{I}}(u) \in L^\infty$ is discontinuous at a KKT-point $\bar{u}$ since $|d_{\mathrm{I}}(u) - d_{\mathrm{I}}(\bar{u})| = b - a - |u - \bar{u}|$ on $\{x \in \Omega : g(u)(x)g(\bar{u})(x) < 0\}$ (note that for all these x holds $g(\bar{u})(x) \neq 0$ and thus $d_{\mathrm{I}}(\bar{u})(x) = 0$, since $\bar{u}$ is a KKT-point). In comparison to our smoother choice of d given in (5) below, this would lead to additional complications in our theory. Our affine-scaling function d enjoys a nice Lipschitz continuity property (see Lemma 5.3), which is very convenient, especially for the investigations in sections 8 and 10. Nevertheless, our convergence theory in section 5 can be extended to the choice $d = d_{\mathrm{I}}$. One has to exploit the fact that the above-mentioned subset of Ω is small and that $d(u)g(u)$ is small on this set as well. We discuss this issue in Remark 5.15. Our affine-scaling function is defined as follows: Choose $\zeta \in (0, 1/2]$, $\kappa > 0$, and define

$$c : x \in \Omega \longmapsto \min\{\zeta(b(x) - a(x)), \kappa\}\ , \quad \nu \stackrel{\text{def}}{=} \operatorname*{ess\,inf}_{x \in \Omega}\ c(x).$$

Then our affine-scaling function is given by $d : \mathcal{B} \longrightarrow L^\infty$,

$$d(u)(x) = \begin{cases} \min\{|g(u)(x)|, c(x)\} & \text{if } -g(u)(x) > u(x) - a(x) \\ & \text{and } u(x) \le (a(x) + b(x))/2, \\ \min\{|g(u)(x)|, c(x)\} & \text{if } g(u)(x) > b(x) - u(x) \\ & \text{and } u(x) \ge (a(x) + b(x))/2, \\ \min\{u(x) - a(x), b(x) - u(x), c(x)\} & \text{else.} \end{cases} \tag{5}$$

Throughout the paper and without further notice we will frequently use the fact that

$$\|d(u)\|_\infty \le \kappa \quad \text{for all } u \in \mathcal{B}.$$

As we will see in Lemma 5.1, a suitable approximate derivative $G(u) \in \mathcal{L}(L^p, L^{p'})$ of $d(u)g(u)$ can be obtained by formally applying the product rule which yields

$$G(u) = d(u)\nabla^2 f(u) + d'(u)g(u)I \tag{6}$$

with $d' : \mathcal{B} \longrightarrow L^\infty$ suitably chosen. We recall that the only requirements on d' needed for the global convergence analysis in [26] are the conditions $d'(u)g(u) \ge 0$ and $\|d'(u)\|_\infty \le c_{d'}$ for all $u \in \mathcal{B}$. Our choice

$$d'(u) \stackrel{\text{def}}{=} \chi_{\{d(u) < c\}} \operatorname{sgn}(g(u)), \quad u \in \mathcal{B},$$

can be motivated as follows: Let $\bar{u}$ be a KKT-point and let u tend to $\bar{u}$ in L^p. Then the sets $\{g(u) > 0 \wedge d(u) = u - a \wedge g(\bar{u}) > 0\}$ tend to $\{g(\bar{u}) > 0\}$ in measure.

Analogously, the sets $\{g(u) < 0 \wedge d(u) = b - u \wedge g(\bar{u}) < 0\}$ tend to $\{g(\bar{u}) < 0\}$. On these sets, the choice $d'(u) = \operatorname{sgn}(g(u))$ is obtained by formal differentiation with respect to $u(x)$. Furthermore, $d'(u)g(u)$ tends to zero on the set $\{g(\bar{u}) = 0\}$ in $L^{p'}$ since $\|d'(u)\|_\infty$ is bounded. It turns out that the contribution of $d'(u)g(u)$ on this set is small enough for any uniformly bounded choice of $d'(u)$ to get a sufficiently good approximation $G(u)(u - \bar{u})$ of $d(u)g(u) - d(\bar{u})g(\bar{u})$ (cf. Lemma 5.1).

If u is an interior point of $\mathcal{B}$ with respect to the L^∞-norm, more precisely $u \in \mathcal{B}^\circ$, then the multiplication operator $d(u)I$ is an automorphism of L^t for all $1 \le t \le \infty$. Since our algorithm will rely on the bijectivity of $d(u_k)I$ at each iterate u_k, we require $u_k \in \mathcal{B}^\circ$ for all k. Given a current iterate $u^c \in \mathcal{B}^\circ$, we define a Newton-like step for the solution of the affine-scaling equation (3):

$$G(u^c)(u^n - u^c) = -d(u^c)g(u^c). \tag{7}$$

Let $\bar{u} \in \mathcal{B}$ be a KKT-point, i.e., $d(\bar{u})g(\bar{u}) = 0$. Then subtracting the trivial identity $G(u^c)(\bar{u} - \bar{u}) = -d(\bar{u})g(\bar{u})$ from (7) yields the equivalent equations

$$G(u^c)(u^n - \bar{u}) = R(u^c), \tag{8}$$

$$R(u) \stackrel{\text{def}}{=} d(\bar{u})g(\bar{u}) - d(u)g(u) - G(u)(\bar{u} - u). \tag{9}$$

For a classical analysis of the Newton-like iteration induced by (7) we would typically need that, for suitable q_1, q_2 and $u \in \mathcal{B}^\circ \subset L^{q_1}$ close to $\bar{u}$, the operator $G(u)$ is invertible in $\mathcal{L}(L^{q_1}, L^{q_2})$ and that $\|G(u)^{-1}R(u)\|_{q_1} = o(\|u - \bar{u}\|_{q_1})$. Moreover, for $u^c \in \mathcal{B}^\circ$ close to $\bar{u}$ the solution u^n of (7) is required to lie again in $\mathcal{B}^\circ$ to keep the iteration alive. $G(u)$ contains the multiplication operator $d'(u)g(u)I$ which for arbitrary $\varepsilon > 0$ is an automorphism of $L^{q_1}(\{x \in \Omega : |g(u)(x)| > \varepsilon\})$. Hence, $G(u) \in \mathcal{L}(L^{q_1}, L^{q_2})$ will, in general, hold only if $q_1 \ge q_2$. However, in Lemma 5.4 we will show that for $q_1 \ge q_2$ it is untenable to assume the uniform boundedness of $\|G(u)^{-1}\|_{q_2,q_1}$ in a neighborhood of $\bar{u}$. The following approach remedies the situation. With q and s as in (A2) we will introduce a multiplication operator $W(u) \in \mathcal{L}(L^q, L^q)$ such that the uniform boundedness of $(W(u)G(u))^{-1}$ in $\mathcal{L}(L^q, L^q)$ is a relatively weak requirement which is, e.g., implied by assumptions used for the analysis of a projected Newton method in [17]. Then, in Lemma 5.9 we will show that under suitable assumptions $\|W(u)R(u)\|_q = o(\|u - \bar{u}\|_s)$ holds. There seems to be no way to prove the more favorable estimate $\|W(u)R(u)\|_q = o(\|u - \bar{u}\|_q)$. Even the weaker estimate $\|R(u)\|_q = o(\|u - \bar{u}\|_q)$ requires at least the continuity of the gradient $g(u)$ from L^q to L^∞. For details see Lemma 5.1 and the proof of Lemma 5.5. Kelley and Sachs [17] overcame similar difficulties by introducing a smoothing step $u \in L^q \longmapsto u^s \in L^s$ with the property $\|u^s - \bar{u}\|_s \le \text{const}\|u - \bar{u}\|_q$. We take the same approach. Finally, it is very likely that the iteration eventually breaks down with an $u^n \notin \mathcal{B}^\circ$. Therefore, we must include a back-transport that takes u^n back into the interior of $\mathcal{B}$. This back-transport can be implemented as an interior-point modification of the pointwise projection $P(u) = \max\{a, \min\{b, u\}\}$ which satisfies $|P(u) - \bar{u}| \le |u - \bar{u}|$.

4. Outline of the algorithm in an abstract setting. The fundamental building blocks and convergence properties of the algorithm can be described most conveniently in the following abstract framework. Let X_0, X_1, and X_2 be Banach spaces, $\mathcal{K}^\circ \subset X_1$ be a convex nonempty set, and $X_1 \subset X_0$ be continuously embedded. Denote by $\mathcal{K}$ the closure of $\mathcal{K}^\circ$ in X_1. Given the mapping $E : \mathcal{K} \longrightarrow X_2$, we want to solve the equation

$$E(u) = 0, \quad u \in \mathcal{K}. \tag{10}$$

To this end, we define a Newton-like iteration based on the linear approximation $E(u+s) - E(u) \approx G(u)s$, $G : \mathcal{K}^\circ \longrightarrow \mathcal{L}(X_0, X_2)$. The kth Newton iteration is augmented by a *smoothing step* $u_k \longmapsto u_k^s = S_k^\circ(u_k) \in \mathcal{K}^\circ$ and a *back-transport* $P[v] : X_0 \longrightarrow \mathcal{K}^\circ$, $v \in \mathcal{K}^\circ$; see below. The index k indicates that the smoothing step S_k° can be chosen at runtime.

ALGORITHM 4.1 (abstract Newton iteration).

1. Choose $u_0 \in \mathcal{K}^\circ$.
2. For $k = 0, 1, 2, \ldots$
   - 2.1. If $E(u_k) = 0$, STOP.
   - 2.2. Select and perform a smoothing step: $u_k^s = S_k^\circ(u_k)$.
   - 2.3. Compute $u_{k+1}^n \in X_0$ from
   $$G(u_k^s)(u_{k+1}^n - u_k^s) = -E(u_k^s) \quad \text{(Newton-like step)}.$$
   - 2.4. Transport u_{k+1}^n back to $\mathcal{K}^\circ$: $u_{k+1} = P[u_k^s](u_{k+1}^n)$.

Let $\bar{u} \in \mathcal{K}$ be a solution to (10). Then we can rewrite the equation in step 2.3 as follows:

$$G(u_k^s)(u_{k+1}^n - \bar{u}) = E(\bar{u}) - E(u_k^s) - G(u_k^s)(\bar{u} - u_k^s) \stackrel{\text{def}}{=} R(u_k^s).$$

Algorithm 4.1 is locally superlinear convergent under the following general assumptions.

Abstract Assumptions. There are constants $\rho, C_S > 0$ such that the following hold:

1. If in the kth iteration of Algorithm 4.1 $\|u_k - \bar{u}\|_{X_0} < \rho$ holds, then in step 2.2 the smoothing step S_k° is chosen in such a way that
   $$\|S_k^\circ(u_k) - \bar{u}\|_{X_1} \le C_S \|u_k - \bar{u}\|_{X_0}.$$
2. There exists $C_P > 0$ and a monotone increasing function
   $$\delta_P : [0, C_S\rho) \longrightarrow [0, \infty), \quad \lim_{t \to 0^+} \delta_P(t) = 0, \tag{11}$$
   such that for all $u \in X_0$, $v \in \mathcal{K}^\circ$ with $\|v - \bar{u}\|_{X_1} < C_S\rho$ holds
   $$\|P[v](u) - \bar{u}\|_{X_0} \le C_P \|u - \bar{u}\|_{X_0} + \delta_P(\|v - \bar{u}\|_{X_1}) \|v - \bar{u}\|_{X_1}.$$
3. There are monotone increasing functions
   $$\gamma, \delta_R : [0, C_S\rho) \longrightarrow [0, \infty), \quad \lim_{t \to 0^+} \gamma(t)\delta_R(t) = 0, \tag{12}$$
   a Banach space X_3, and an operator $W : \mathcal{K}^\circ \longrightarrow \mathcal{L}(X_2, X_3)$ such that
   (a) for all $u \in \mathcal{K}^\circ$, $\|u - \bar{u}\|_{X_1} < C_S\rho$, and $r \in X_2$ there exists a unique $s \in X_1$ with
   $$G(u)s = r, \quad \|s\|_{X_0} \le \gamma(\|u - \bar{u}\|_{X_1}) \|W(u)r\|_{X_3};$$
   (b) for all $u \in \mathcal{K}^\circ$, $\|u - \bar{u}\|_{X_1} < C_S\rho$,
   $$\|W(u)R(u)\|_{X_3} \le \delta_R(\|u - \bar{u}\|_{X_1}) \|u - \bar{u}\|_{X_1}.$$

THEOREM 4.2. *Let $\bar{u} \in \mathcal{K}$ be a solution to* (10). *Assume that the above assumptions hold. Then there is $0 < \rho_0 \le \rho$ such that for all $u_0 \in \mathcal{K}^\circ$, $\|u_0 - \bar{u}\|_{X_0} < \rho_0$, Algorithm* 4.1 *is well-defined and either terminates with $u_k \in \mathcal{K}^\circ$ solving* (10) *or generates sequences $(u_k) \subset \mathcal{K}^\circ$ and $(u_k^s) \subset \mathcal{K}^\circ$ that converge superlinearly to $\bar{u}$ in X_0 and X_1, respectively.*

Proof. We introduce the abbreviations $\varepsilon_k \overset{\text{def}}{=} \|u_k - \bar{u}\|_{X_0}$ and $\varepsilon_k^s \overset{\text{def}}{=} \|u_k^s - \bar{u}\|_{X_1}$. Let $u_k \in \mathcal{K}^\circ$ satisfy $\varepsilon_k < \rho$. Then $\varepsilon_k^s < C_S\rho$ by Abstract Assumption 1, and thus, using the assumptions,

$$\begin{aligned}\varepsilon_{k+1} &= \|P[u_k^s](u_{k+1}^n) - \bar{u}\|_{X_0} \le C_P\|u_{k+1}^n - \bar{u}\|_{X_0} + \delta_P(\varepsilon_k^s)\varepsilon_k^s \\ &\le C_P\gamma(\varepsilon_k^s)\|W(u_k^s)R(u_k^s)\|_{X_3} + \delta_P(\varepsilon_k^s)\varepsilon_k^s \le (C_P\gamma(\varepsilon_k^s)\delta_R(\varepsilon_k^s) + \delta_P(\varepsilon_k^s))\varepsilon_k^s \\ &\le C_S(C_P\gamma(C_S\varepsilon_k)\delta_R(C_S\varepsilon_k) + \delta_P(C_S\varepsilon_k))\varepsilon_k.\end{aligned} \tag{13}$$

By (11) and (12), there is $0 < \rho_0 \le \rho$ such that

$$C_S(C_P\gamma(C_Sz)\delta_R(C_Sz) + \delta_P(C_Sz)) < 1 \quad \text{for all } 0 \le z < \rho_0.$$

Therefore, if $\varepsilon_0 < \rho_0 \le \rho$, we have $\varepsilon_k < \rho_0 \le \rho$ for all k. In particular, the algorithm is well-defined. Moreover,

$$\varepsilon_{k+1}^s \le C_S\varepsilon_{k+1} \le C_S(C_P\gamma(\varepsilon_k^s)\delta_R(\varepsilon_k^s) + \delta_P(\varepsilon_k^s))\varepsilon_k^s. \tag{14}$$

Now (13) yields superlinear convergence of (u_k) to $\bar{u}$ in X_0, and (14) yields superlinear convergence of (u_k^s) to $\bar{u}$ in X_1. ∎

Remark 4.3. It is easier to find a smoothing step $u_k \in \mathcal{K}^\circ \longmapsto S_k(u_k) \in X_1$ that satisfies all requirements in Abstract Assumption 1, except for the condition $S_k(u_k) \in \mathcal{K}^\circ$. If the operator $P[v]$ can be defined in such a way that, in addition to Abstract Assumption 2, for all $u \in X_1$ with $\|u - \bar{u}\|_{X_1} < C_S\rho$ and all $v \in \mathcal{K}^\circ$ with $\|v - \bar{u}\|_{X_0} < \rho$ holds

$$\|P[v](u) - \bar{u}\|_{X_1} \le \bar{C}_P\|u - \bar{u}\|_{X_1} + \bar{C}_P'\|v - \bar{u}\|_{X_0}, \tag{15}$$

then obviously $u_k \in \mathcal{K}^\circ \longmapsto S_k^\circ(u_k) \overset{\text{def}}{=} P[u_k](S_k(u_k))$ defines a smoothing step satisfying Abstract Assumption 1, with C_S replaced by $\bar{C}_PC_S + \bar{C}_P'$. For our problem (P) we will be able to define $P[v]$ in such a way that (15) holds; see Lemma 6.4. ∎

In our setting we have $\mathcal{K}^\circ = \mathcal{B}^\circ$ and, consequently, $\mathcal{K} = \mathcal{B}$. The mapping E is given by $u \longmapsto d(u)g(u)$. The crucial topics of our analysis consist in the proper choice of the spaces X_i, the weighting operator W, and the proof that under appropriate conditions the above abstract assumptions hold. A few remarks on the "nonstandard" building blocks of Algorithm 4.1 are in order. If there exists a projection $P : X_0 \longrightarrow \mathcal{K} \subset X_0$ onto $\mathcal{K}$ that is Lipschitz at $\bar{u}$, e.g., $P(u) = \min\{b, \max\{a, u\}\}$ for $X_0 = L^q$ and $\mathcal{K} = \mathcal{B}$, then the back-transport operator $P[v]$ can (and will) be implemented by an interior-point modification of P. More specifically, $P[v](u)$ will consist in the projection $P(u)$ of u onto $\mathcal{K}$ followed by a tiny step towards the point $v \in \mathcal{K}^\circ$ to achieve $P[v](u) \in \mathcal{K}^\circ$. The idea of a smoothing step was already used by Kelley and Sachs [17]. It is a tool to compensate the discrepancy of the X_0-norm on the left side and the stronger X_1-norm on the right side of the inequality

$$\|u_{k+1}^n - \bar{u}\|_{X_0} \le \gamma(\|u_k^s - \bar{u}\|_{X_1})\delta_R(\|u_k^s - \bar{u}\|_{X_1})\|u_k^s - \bar{u}\|_{X_1}$$

which is obtained by combining Abstract Assumptions 3(a) and (b).

5. Analysis of the Newton-like iteration. We return to the affine-scaling Newton iteration (8) and begin to verify the abstract assumptions of section 4. The following lemma states a pointwise estimate for the remainder term $R(u)$.

LEMMA 5.1. *Let* (A1) *hold. In addition, let* (O1) *and* (O2) *be satisfied at* $\bar{u}$. *Then for all* $u \in \mathcal{B}$ *the inequality*

$$|R(u)| \le d(u)|g(\bar{u}) - g(u) - \nabla^2 f(u)(\bar{u}-u)| + (|g(\bar{u})|d(u) + |g(u)||\bar{u}-u|) \tag{16}$$

holds on Ω *and, moreover,*

$$\begin{aligned} |R(u)| \le\ & d(u)|g(\bar{u}) - g(u) - \nabla^2 f(u)(\bar{u}-u)| \\ & + \min\{\max\{d(u), |g(u)|\}, |g(\bar{u}) - g(u)|\} \max\{|\bar{u}-u|, |g(\bar{u}) - g(u)|\} \end{aligned} \tag{17}$$

is satisfied on $J \stackrel{\text{def}}{=} \{x \in \Omega :\ |u(x) - \bar{u}(x)| < c(x)\}$.

Proof. Let $u \in \mathcal{B}$ be given and set $I = \{x \in \Omega :\ d(u)(x) < c(x)\}$. Then we get

$$\begin{aligned} & d(\bar{u})g(\bar{u}) - d(u)g(u) - G(u)(\bar{u}-u) \\ & \quad = d(\bar{u})g(\bar{u}) - d(u)g(u) - d(u)\nabla^2 f(u)(\bar{u}-u) - \chi_I |g(u)|(\bar{u}-u) \\ & \quad = d(u)(g(\bar{u}) - g(u) - \nabla^2 f(u)(\bar{u}-u)) + g(\bar{u})(d(\bar{u}) - d(u)) - \chi_I |g(u)|(\bar{u}-u). \end{aligned}$$

Since (O1) and (O2) are satisfied at $\bar{u}$ we have $d(\bar{u})g(\bar{u}) = 0$ by Lemma 2.6 and hence the first estimate is obvious. We complete the proof by verifying that for a.a. $x \in J$

$$\begin{aligned} R_1(u)(x) &\le \min\{\max\{d(u)(x), |g(u)(x)|\}, |g(\bar{u})(x) - g(u)(x)|\} \\ &\qquad \cdot \max\{|\bar{u}(x) - u(x)|, |g(\bar{u})(x) - g(u)(x)|\}, \\ R_1(u)(x) &\stackrel{\text{def}}{=} \big|g(\bar{u})(x)\big(d(\bar{u})(x) - d(u)(x)\big) - \chi_I(x)|g(u)(x)|\big(\bar{u}(x) - u(x)\big)\big|. \end{aligned} \tag{18}$$

We use again $d(\bar{u})g(\bar{u}) = 0$. On the subset of all $x \in J$ with $g(\bar{u})(x) = 0$ we get

$$R_1(u) = \chi_I |g(u)||\bar{u}-u| \le |g(u) - g(\bar{u})||\bar{u}-u|,$$

and (18) is obvious.

For all $x \in J$ with $g(\bar{u})(x) \ne 0$ we have $d(\bar{u})(x) = 0$. (O2) implies that only the cases $\bar{u}(x) = a(x)$ and $g(\bar{u})(x) > 0$ or $\bar{u}(x) = b(x)$ and $g(\bar{u})(x) < 0$ can occur.

We first look at $x \in J$ with $\bar{u}(x) = a(x)$ and $g(\bar{u})(x) > 0$. Since $\zeta \le 1/2$ and $x \in J$, we get $u(x) - a(x) < b(x) - u(x)$. Hence, we obtain (mind that $\bar{u}(x) = a(x)$)

$$d(u)(x) = \begin{cases} \min\{|g(u)(x)|, c(x)\} & \text{if } -g(u)(x) > u(x) - \bar{u}(x) \ge 0, \\ \min\{u(x) - \bar{u}(x), c(x)\} & \text{else.} \end{cases}$$

If $d(u)(x) = u(x) - \bar{u}(x) < c(x)$, then $x \in I$ and using $d(\bar{u})(x) = 0$, $g(\bar{u})(x) \ge 0$ we get for all these x

$$R_1(u) = \big||g(\bar{u})| - |g(u)|\big||\bar{u}-u| \le |g(\bar{u}) - g(u)||\bar{u}-u|.$$

If, in addition, $|g(\bar{u})(x) - g(u)(x)| \le d(u)(x)$, then (18) holds, for

$$R_1(u)(x) \le \min\{d(u)(x), |g(\bar{u})(x) - g(u)(x)|\}|\bar{u}(x) - u(x)|.$$

Otherwise, we have $|g(\bar{u})(x) - g(u)(x)| > d(u)(x) = u(x) - \bar{u}(x) = |\bar{u}(x) - u(x)|$, and therefore

$$R_1(u)(x) \le \min\{d(u)(x), |g(\bar{u})(x) - g(u)(x)|\}|g(\bar{u})(x) - g(u)(x)|,$$

which implies (18). If $d(u)(x) = |g(u)(x)| < c(x)$, then $x \in I$, $g(u)(x) \le 0 \le g(\bar{u})(x)$. Thus, we have for all such x that $\max\{|g(u)|, |g(\bar{u})|\} \le |g(\bar{u}) - g(u)|$ and

$$\begin{aligned} R_1(u) &= \big|-g(\bar{u})|g(u)| - |g(u)|(\bar{u} - u)\big| \\ &= |g(u)|\big||\bar{u} - u| - |g(\bar{u})|\big| \le |g(u)| \max\{|\bar{u} - u|, |g(\bar{u})|\} \\ &\le \min\{|g(u)|, |g(\bar{u}) - g(u)|\} \max\{|\bar{u} - u|, |g(\bar{u}) - g(u)|\}. \end{aligned}$$

It remains the case $x \in J \cap I^c$, i.e., $x \in J$ and $d(u)(x) = c(x)$. Here $u(x) - \bar{u}(x) \ge c(x) = d(u)(x)$ or $-g(u)(x) \ge c(x) = d(u)(x)$. Since $x \in J$, the first case cannot occur. Therefore, we have $g(u)(x) \le -d(u)(x) \le 0 \le g(\bar{u})(x)$ for all $x \in J \cap I^c$, and hence

$$R_1(u) = |g(\bar{u})d(u)| \le |g(\bar{u})||g(u)| \le \min\{|g(u)|, |g(\bar{u}) - g(u)|\}|g(\bar{u}) - g(u)|.$$

For $\bar{u}(x) = b(x)$ and $g(\bar{u})(x) < 0$ the same arguments can be used and the proof is complete. ∎

Let (O1) and (O2) hold for $\bar{u}$. We define the active set $\bar{A}$ and the inactive set $\bar{I}$:

$$\bar{A} = \{x \in \Omega : \bar{u}(x) \in \{a(x), b(x)\}\}, \quad \bar{I} = \bar{A}^c.$$

Furthermore, the usual strict complementarity condition shall hold at $\bar{u}$ (note that $|g(\bar{u})|$ is a Lagrange multiplier).

Assumption (strict complementarity condition).

(C) $g(\bar{u})(x) \ne 0$ *for a.a.* $x \in \bar{A}$.

In contrast to the finite-dimensional case the active set cannot, in general, be identified after a finite number of iterations under the strict complementarity condition (C), since the gradient may be arbitrarily small on the active set, especially near its boundary. But we shall use (C) to show that the residual set of "uncertainty" is small. We need the following continuity property of d.

Lemma 5.2. *Let the assumptions of Lemma* 2.6 *hold. In addition, let* (O1) *and* (O2) *be satisfied at* $\bar{u}$. *Then for all* $u \in \mathcal{B}$ *the inequality*

$$|d(u) - d(\bar{u})| \le \max\{|u - \bar{u}|, |g(u) - g(\bar{u})|\}$$

holds on $J \stackrel{\text{def}}{=} \{x \in \Omega : |u(x) - \bar{u}(x)| < (b(x) - a(x))/2\}$.

Proof. Let $x \in J$ be arbitrary. Since (O1) and (O2) hold at $\bar{u}$, the identity $d(\bar{u})g(\bar{u}) = 0$ is valid by Lemma 2.6. In addition, (O2) ensures that

$$d(\bar{u})(x) = \min\{\bar{u}(x) - a(x), b(x) - \bar{u}(x), c(x)\}.$$

By definition, we have

$$d(u)(x) = \min\{u(x) - a(x), b(x) - u(x), c(x)\} \quad \text{or} \tag{19}$$

$$d(u)(x) = \min\{|g(u)(x)|, c(x)\} \ge \min\{u(x) - a(x), b(x) - u(x), c(x)\}. \tag{20}$$

For all x from case (19) as well as all x with $d(u)(x) = \min\{|g(u)(x)|, c(x)\} \le d(\bar{u})(x)$ we get

$$|d(\bar{u}) - d(u)| \le |\min\{\bar{u} - a, b - \bar{u}, c\} - \min\{u - a, b - u, c\}| \le |u - \bar{u}|,$$

where we have used the inequality (cf. [26, Lem. 9.3])

$$|\min\{a_1, \dots, a_n\} - \min\{b_1, \dots, b_n\}| \le \max\{|a_1 - b_1|, \dots, |a_n - b_n|\}.$$

For all x with $d(u)(x) = \min\{|g(u)(x)|, c(x)\} > d(\bar{u})(x)$ we have

$$|d(u) - d(\bar{u})| \le d(u) \le |g(u)| \le |g(u) - g(\bar{u})|.$$

The last inequality is obvious if $g(\bar{u})(x) = 0$. For $g(\bar{u})(x) \neq 0$ it follows from the observation that $g(u)(x)$ and $g(\bar{u})(x)$ have different signs. In fact, by (O2) only the cases $\bar{u}(x) = a(x)$, $g(\bar{u})(x) > 0$ or $\bar{u}(x) = b(x)$, $g(\bar{u})(x) < 0$ can occur. If $\bar{u}(x) = a(x)$ and $g(\bar{u})(x) > 0$, then $u(x) - a(x) < b(x) - u(x)$ since $x \in J$. Hence, by the definition of $d(u)$, $d(u)(x) = \min\{|g(u)(x)|, c(x)\}$ is only possible for $g(u)(x) < 0$. Finally, if $\bar{u}(x) = b(x)$, $g(\bar{u})(x) < 0$, then $b(x) - u(x) < u(x) - a(x)$ and $d(u)(x) = \min\{|g(u)(x)|, c(x)\}$ requires $g(u)(x) > 0$. ∎

The pointwise estimates in Lemmas 5.1 and 5.2 can be converted into norm estimates by invoking Assumption (A2). As a consequence of Lemma 5.2 we get the Lipschitz continuity of d at $\bar{u}$.

LEMMA 5.3. *If* (O1), (O2) *hold at* $\bar{u}$ *and Assumptions* (A1) *and* (A2) *are satisfied, then for all* $u \in \mathcal{B}$

$$\|d(u) - d(\bar{u})\|_r \le \left(m_{r,s} + L_g + \frac{2\kappa m_{r,s}}{\nu}\right) \|u - \bar{u}\|_s \stackrel{\text{def}}{=} L_d \|u - \bar{u}\|_s$$

with $m_{r,s}$ *defined as in Lemma* 2.1.

Proof. On $B \stackrel{\text{def}}{=} \{x \in \Omega : |u(x) - \bar{u}(x)| < \nu/2\}$ Lemma 5.2 is applicable and yields with (A2) and Lemma 2.1

$$\|d(u) - d(\bar{u})\|_{r,B} \le \|\max\{|u - \bar{u}|, |g(u) - g(\bar{u})|\}\|_r \le (m_{r,s} + L_g)\|u - \bar{u}\|_s.$$

Since $|d(u)(x) - d(\bar{u})(x)| \le \kappa$, we get on B^c

$$\|d(u) - d(\bar{u})\|_{r,B^c} \le \|\kappa\|_{r,B^c} \le \left\|\kappa \frac{2|u - \bar{u}|}{\nu}\right\|_{r,B^c} \le \frac{2\kappa}{\nu}\|u - \bar{u}\|_r \le \frac{2\kappa m_{r,s}}{\nu}\|u - \bar{u}\|_s.$$

The triangle inequality completes the proof. ∎

In the finite-dimensional case the existence and uniform boundedness of $G(u)^{-1}$ in a neighborhood of $\bar{u}$ can be ensured if $\bar{u}$ satisfies sufficient second-order conditions with strict complementarity; see [7]. The following considerations show that the requirement of uniform boundedness of $G(u)^{-1}$ close to $\bar{u}$ is unacceptably strong in the infinite-dimensional setting. Since

$$g(\bar{u})(x) = 0 \quad \text{a.e. on } \bar{I}\,, \quad d(\bar{u})(x) = 0 \quad \text{a.e. on } \bar{A}, \tag{21}$$

and by (A2) and Lemma 5.3

$$\|d(u) - d(\bar{u})\|_r + \|g(u) - g(\bar{u})\|_r \le (L_d + L_g)\|u - \bar{u}\|_s,$$

the set

$$N_\varepsilon(u) \stackrel{\text{def}}{=} \{x \in \Omega : |g(u)(x)| + d(u)(x) \le \varepsilon\} \tag{22}$$

may have nonzero measure for arbitrarily small $\varepsilon > 0$ if $\|u - \bar{u}\|_s$ is small enough. Typically, an open neighborhood of a part of $\partial\bar{A}$ is contained in $N_\varepsilon(u)$.

Let $1 \le q_2 \le q_1 \le \infty$ and assume that $\|\nabla^2 f(u)\|_{q_1,q_2}$ is uniformly bounded on an L^s-neighborhood of $\bar{u}$. The following lemma shows that in the above scenario

$\|G(u)\|_{q_1,q_2}$ is uniformly bounded, but $\|G(u)^{-1}\|_{q_2,q_1}$ is not. This is caused by the fact that the operator

$$H(u) = W(u)G(u) \quad \text{with} \quad W(u) = \frac{1}{|g(u)| + d(u)} I \ , \quad u \in \mathcal{B}, \tag{23}$$

is still uniformly bounded in $\mathcal{L}(L^{q_1}, L^{q_2})$ although $\|W(u)\|_{q_2,q_2} \to \infty$ as $\|u - \bar{u}\|_s$ tends to zero. More precisely, we have the following lemma.

LEMMA 5.4. *Let $u \in \mathcal{B}^\circ$, $1 \le q_2 \le q_1 \le \infty$, and $\nabla^2 f(u) \in \mathcal{L}(L^{q_1}, L^{q_2})$. Then*

(i) $G(u) \in \mathcal{L}(L^{q_1}, L^{q_2})$, $\quad \|G(u)\|_{q_1,q_2} \le m_{q_2,q_1} \|g(u)\|_\infty + \kappa \|\nabla^2 f(u)\|_{q_1,q_2}$,

(ii) $H(u) \in \mathcal{L}(L^{q_1}, L^{q_2})$, $\quad \|H(u)\|_{q_1,q_2} \le m_{q_2,q_1} + \|\nabla^2 f(u)\|_{q_1,q_2}$,

(iii) *if $G(u)$ is invertible in $\mathcal{L}(L^{q_1}, L^{q_2})$, then*

$$\|G(u)^{-1}\|_{q_2,q_1} \ge \varepsilon^{-1} \|H(u)\|_{q_1,q_2}^{-1}$$

for all $\varepsilon > 0$ with $\mu(N_\varepsilon(u)) > 0$.

Here m_{q_2,q_1} is as in Lemma 2.1.

Proof. Assertion (i) follows immediately from the definition of $G(u)$. The estimate

$$\begin{aligned} \|H(u)v\|_{q_2} &\le \left\| \frac{\chi_{\{d(u)<c\}}|g(u)|}{|g(u)| + d(u)} v \right\|_{q_2} + \left\| \frac{d(u)}{|g(u)| + d(u)} \nabla^2 f(u) v \right\|_{q_2} \\ &\le m_{q_2,q_1} \|v\|_{q_1} + \|\nabla^2 f(u)\|_{q_1,q_2} \|v\|_{q_1} \end{aligned}$$

yields (ii). To prove (iii) let $G(u) \in \mathcal{L}(L^{q_1}, L^{q_2})$ be invertible and $\varepsilon > 0$ such that $\mu(N_\varepsilon(u)) > 0$. Then $\|w_\varepsilon\|_{q_2} > 0$ for $w_\varepsilon \stackrel{\text{def}}{=} \chi_{N_\varepsilon(u)}$, and, setting $v_\varepsilon = G(u)^{-1} w_\varepsilon$,

$$\|H(u)v_\varepsilon\|_{q_2} \le \|H(u)\|_{q_1,q_2} \|G(u)^{-1}\|_{q_2,q_1} \|w_\varepsilon\|_{q_2}.$$

On the other hand, the definition of $N_\varepsilon(u)$ yields

$$\|H(u)v_\varepsilon\|_{q_2} = \left\| \frac{w_\varepsilon}{|g(u)| + d(u)} \right\|_{q_2} \ge \frac{\|w_\varepsilon\|_{q_2}}{\varepsilon}.$$

Combining both estimates gives (iii). ∎

The identity

$$H(u) = \frac{\chi_{\{d(u)<c\}}|g(u)|}{|g(u)| + d(u)} I + \frac{d(u)}{|g(u)| + d(u)} \nabla^2 f(u)$$

shows that the operator $H(u)$ is "almost" a pointwise convex combination of the identity and the Hessian $\nabla^2 f(u)$. If (A2) and the strict complementarity condition (C) hold, then using (21) and Lemma 5.3, one can show with the same techniques as in the proof of Lemma 8.3 that

$$\frac{\chi_{\{d(u)<c\}}|g(u)|}{|g(u)| + d(u)} \xrightarrow{L^q} \chi_{\bar{A}} \quad \text{and} \quad \frac{d(u)}{|g(u)| + d(u)} \xrightarrow{L^q} \chi_{\bar{I}} \quad \text{a.e. as} \quad u \in \mathcal{B}^\circ \xrightarrow{L^s} \bar{u}.$$

Thus, they converge in all spaces L^t, $1 \le t < \infty$, by (A1) and the interpolation inequality of Lemma 2.2.

Hence, we impose the following assumption on $G(u)$ which, as we will see, is implied by the assumptions in the paper of Kelley and Sachs [17] on the projected Newton method (cf. Lemma 8.3) and in important cases by a sufficient second-order condition of Dunn and Tian [9] (see Theorem 9.5).

ASSUMPTION.

(A3) *There is* $0 < \rho_H \le 1$ *such that the operator* $H(u)$ *defined in* (23) *satisfies* $H(u) \in \mathcal{L}(L^q, L^q)$ *and is invertible for all* $u \in \mathcal{B}^\circ$, $\|u - \bar{u}\|_s < \rho_H$, *with uniformly bounded inverse, more precisely,* $\|H(u)^{-1}\|_{q,q} < C_H$.

We now return to the analysis of (8). Since for $u \in \mathcal{B}^\circ$ there is $\delta > 0$ with $d(u) > \delta$, the multiplication operator $W(u)$ defined in (23) is a linear continuous automorphism of L^t, $1 \le t \le \infty$. Applying $W(u^c)$ from the left to (8) yields the equivalent equation

$$H(u^c)(u^n - \bar{u}) = W(u^c)R(u^c). \tag{24}$$

Since $H(u^c) \in \mathcal{L}(L^q, L^q)$ is invertible by (A3) if $\|u^c - \bar{u}\|_s < \rho_H$, we derive an upper bound for the L^q-norm of the right-hand side, as follows.

LEMMA 5.5. *Let* (O1), (O2) *hold at* $\bar{u}$. *Moreover, let* (A1) *and* (A2) *be satisfied. Then for all* $u \in \mathcal{B}^\circ$ *holds*

$$\begin{aligned}\|W(u)R(u)\|_q \le L_{g'}\|u - \bar{u}\|_s^2 + (m_{r,s} + L_g)\|Q(u)\|_{\tilde{q}}\|u - \bar{u}\|_s \\ + \max\{\|g(\bar{u})\|_\infty, \|b - a\|_\infty\}\,\nu^{-\frac{s}{\tilde{q}}}\|u - \bar{u}\|_s^{\frac{s}{\tilde{q}}},\end{aligned} \tag{25}$$

where $\tilde{q} \overset{\text{def}}{=} \frac{qr}{r-q}$ $(= q$ *if* $r = \infty)$,

$$Q(u) = \frac{\min\{\max\{d(u), |g(u)|\}, |g(u) - g(\bar{u})|\}}{|g(u)| + d(u)}, \tag{26}$$

and the last term has to be interpreted as zero in the case $s = \infty$ *for* $\|u - \bar{u}\|_\infty < \nu$.

Proof. For $J \overset{\text{def}}{=} \{x \in \Omega : |u(x) - \bar{u}(x)| < \nu\}$ we may apply Lemma 5.1 and obtain with (26), (A2), and the mean value theorem

$$\begin{aligned}\|W(u)R(u)\|_q &\le \left\|\frac{d(u)}{|g(u)| + d(u)}\right\|_\infty \|g(\bar{u}) - g(u) - \nabla^2 f(u)(\bar{u} - u)\|_q \\ &\quad + \|Q(u)\max\{|u - \bar{u}|, |g(u) - g(\bar{u})|\}\|_{q,J} + \left\|\frac{|g(\bar{u})|d(u) + |g(u)||u - \bar{u}|}{|g(u)| + d(u)}\right\|_{q,J^c} \\ &\le \sup_{\tau\in[0,1]} \|\nabla^2 f(u + \tau(\bar{u} - u)) - \nabla^2 f(u)\|_{s,q}\|u - \bar{u}\|_s \\ &\quad + \|Q(u)\|_{\frac{qr}{r-q},J}\|\max\{|u - \bar{u}|, |g(u) - g(\bar{u})|\}\|_r \\ &\quad + \max\{\|g(\bar{u})\|_\infty, \|b - a\|_\infty\}\,\mu(J^c)^{1/q},\end{aligned} \tag{27}$$

where we have applied Lemma 2.3 with $q_0 = q$ and $q_1 = r/q$ in the last step. Now (A2) immediately yields the first two terms on the right-hand side of (25). To finish the proof, we first observe that $\mu(J^c) = 0$ for $\|u - \bar{u}\|_\infty < \nu$. Hence, we have (25) with the mentioned interpretation for $s = \infty$. If finally $s < \infty$, we have

$$\mu(J^c) = \|1\|_{s,J^c}^s \le \|(u - \bar{u})/\nu\|_{s,J^c}^s \le \nu^{-s}\|u - \bar{u}\|_s^s.$$

Using this in the last term of the above inequality, we get (25). ∎

It is important to notice that the term $Q(u)$ is crucial for our analysis since

$$|Q(u)(x)| = \left|\frac{\min\{\max\{d(u)(x), |g(u)(x)|\}, |g(u)(x) - g(\bar{u})(x)|\}}{|g(u)(x)| + d(u)(x)}\right| = O(1)$$

on $\{\max\{d(u), |g(u)|\} \le \text{const}|g(u) - g(\bar{u})|\}$. In contrast to the finite-dimensional case, these sets may have nonzero measure under any reasonable strict complementarity condition even if $\|u - \bar{u}\|_\infty$ is arbitrarily small. On the other hand, under

Assumption (A2) we get the following estimate on the complement of the set $N_\varepsilon(u)$ defined in (22):

$$|Q(u)(x)| \le \frac{|g(u)(x) - g(\bar{u})(x)|}{\varepsilon} \quad \text{for all } x \in N_\varepsilon(u)^c.$$

Remark 5.6. Since the estimate (25) is sharp and usually $\|Q(u)\|_\infty = O(1)$ for $u \in \mathcal{B}^\circ \xrightarrow{L^\infty} \bar{u}$, an estimate of the form

$$\|u^n - \bar{u}\|_\infty = o(\|u^c - \bar{u}\|_\infty) \quad (u^c \in \mathcal{B}^\circ \xrightarrow{L^\infty} \bar{u})$$

for the solution u^n of the affine-scaling Newton equation (7) does not, in general, hold even if (A2), (A3) are satisfied with $q = \infty$. □

The following lemma estimates the Lebesgue measure of the residual sets $N_\varepsilon(u)$.

LEMMA 5.7. *Let* (A1), (A2) *hold. If* $\bar{u}$ *satisfies* (O1), (O2), *and* (C), *then the following is true:*

(i) $\omega : [0,\infty) \longrightarrow [0,\infty)$, $\omega(\varepsilon) \stackrel{\text{def}}{=} \mu(N_\varepsilon(\bar{u}))$ *is monotone increasing and satisfies*

$$\lim_{\varepsilon \to 0+} \omega(\varepsilon) = \omega(0) = 0. \tag{28}$$

(ii) *For all* $u \in \mathcal{B}$ *holds*

$$\mu(N_\varepsilon(u)) \le \omega(2\varepsilon) + \varepsilon^{-r}(L_g + L_d)^r \|u - \bar{u}\|_s^r$$

with the obvious interpretation for $r = s = \infty$ *by setting* $\alpha^\infty = 0$ *for* $\alpha \in [0,1)$.

Proof. ω is nonnegative and increasing, since $N_{\tilde{\varepsilon}}(\bar{u}) \subset N_\varepsilon(\bar{u})$ for $0 < \tilde{\varepsilon} \le \varepsilon$. Hence, $\lim_{\varepsilon \to 0+} \omega(\varepsilon)$ exists and

$$\lim_{\varepsilon \to 0+} \omega(\varepsilon) = \mu\left(\bigcap_{\varepsilon > 0} N_\varepsilon(\bar{u})\right).$$

By (C) and the definition of d there is a set N of measure zero with

$$|g(\bar{u})(x)| + d(\bar{u})(x) > 0 \quad \text{for all } x \in N^c.$$

Hence, $N_0(\bar{u}) \subset N$ and thus $\omega(0) = \mu(N_0(\bar{u})) = 0$. Moreover, for all $x \in N^c$ there is $\varepsilon_0 > 0$ with $x \notin N_\varepsilon(\bar{u})$ for all $0 < \varepsilon < \varepsilon_0$. This shows

$$\bigcap_{\varepsilon > 0} N_\varepsilon(\bar{u}) \subset N,$$

which implies (28). To prove (ii), we use the triangle inequality and get

$$\begin{aligned} N_\varepsilon(u) &= \{|g(u)| + d(u) \le \varepsilon\} \\ &\subset \{|g(\bar{u})| + d(\bar{u}) \le \varepsilon + |g(u) - g(\bar{u})| + |d(u) - d(\bar{u})|\} \\ &\subset N_{2\varepsilon}(\bar{u}) \cup \{|g(u) - g(\bar{u})| + |d(u) - d(\bar{u})| \ge \varepsilon\}. \end{aligned}$$

In the case $r = \infty$, we have by (A2) and Lemma 5.3

$$\big\||g(u) - g(\bar{u})| + |d(u) - d(\bar{u})|\big\|_\infty \le (L_g + L_d)\|u - \bar{u}\|_\infty.$$

Hence, $N_\varepsilon(u) \subset N_{2\varepsilon}(\bar u)$ for $(L_g+L_d)\|u-\bar u\|_\infty < \varepsilon$, which is the obvious interpretation of (ii) for $r = s = \infty$. For $r < \infty$ we have by (A2) and Lemmas 2.4 and 5.3

$$\begin{aligned}\mu\left(\{|g(u)-g(\bar u)| + |d(u)-d(\bar u)| \ge \varepsilon\}\right) &\le \varepsilon^{-r}\big\||g(u)-g(\bar u)| + |d(u)-d(\bar u)|\big\|_r^r \\ &\le \varepsilon^{-r}(L_g+L_d)^r\|u-\bar u\|_s^r.\end{aligned}$$

This proves (ii). ∎

The following stronger strict complementarity condition will enable us to prove convergence with Q-rate > 1, since we get additional control on the growth of $\omega(\varepsilon)$.

Assumption (strong strict complementarity condition).

(CS) *There are* $\bar q > 0$, $C_C > 0$, *and* $\varepsilon_0 > 0$ *such that*

$$\omega(\varepsilon) = \mu(\{|g(\bar u)| + d(\bar u) \le \varepsilon\}) \le C_C\varepsilon^{\bar q} \quad \textit{for all} \;\; 0 < \varepsilon < \varepsilon_0.$$

Remark 5.8. It is easy to see that condition (CS) is satisfied if the following regularity assumptions on $\bar u$ and the active set $\bar A$ hold. They are relaxations of Assumption 2.4 in [17] as follows.

There is $c_0 > 0$ such that for all sufficiently small $\delta > 0$

$$\mu\left(\left\{x \in \Omega \,:\, \operatorname{dist}(x, \partial\bar A) \le \delta\right\}\right) \le c_0\delta$$

and for suitable $c_1 > 0$ the following growth estimates hold true:

$$\begin{aligned}|g(\bar u)(x)| &\ge c_1(\operatorname{dist}(x,\partial\bar A))^{1/\bar q} \quad &&\text{for all } x \in \bar A,\\ \min\{\bar u(x)-a(x), b(x)-\bar u(x)\} &\ge c_1(\operatorname{dist}(x,\partial\bar A))^{1/\bar q} \quad &&\text{for all } x \in \bar I = \bar A^c.\end{aligned}$$ ∎

The previous lemma enables us to estimate the norm of $Q(u)$. Together with Lemma 5.5 we get the following.

Lemma 5.9. *Let* (O1), (O2), *and* (C) *hold at* $\bar u$. *Assume that* (A1) *and* (A2) *are satisfied. Let* $\bar p \in (0,1)$ *and* $\rho \in (0,1]$ *be arbitrary such that* $(L_g+L_d)\rho^{1-\bar p} \le 1$. *Then there is* $C_{WR} > 0$ *depending only on* $\mu(\Omega)$, $\|b-a\|_\infty$, $\|g(\bar u)\|_\infty$, L_g, *and* $L_{g'}$ *but not on* q, r, s *such that for all* $u \in \mathcal{B}^\circ$, $\|u-\bar u\|_s < \rho$,

$$\|W(u)R(u)\|_q \le C_{WR}\Phi_{\bar p}(\|u-\bar u\|_s)\|u-\bar u\|_s\,, \tag{29}$$

$$\Phi_{\bar p}(z) = \omega(2z^{\bar p})^{1/\tilde q} + z^{(1-\bar p)\min\{1, r/\tilde q\}} + \left(\frac{z}{\nu}\right)^{\frac{s-q}{q}}, \tag{30}$$

where $\tilde q = qr/(r-q)$ *and* ω *is as in Lemma* 5.7.

Proof. Let $u \in \mathcal{B}^\circ$ be arbitrary with $\|u-\bar u\|_s < \rho$. According to Lemma 5.5 we have to estimate $\|Q(u)\|_{\tilde q}$ with $\tilde q = qr/(r-q)$ and Q given by (26). Let $\bar p \in (0,1)$ be arbitrary. We decompose Ω into the set

$$N(u) \overset{\text{def}}{=} N_{\|u-\bar u\|_s^{\bar p}}(u) = \left\{x \in \Omega \,:\, |g(u)(x)| + d(u)(x) \le \|u-\bar u\|_s^{\bar p}\right\}$$

and its complement $N(u)^c$. Assumption (A2) yields with the definition of $N(u)^c$

$$\|Q(u)\|_{r,N(u)^c} \le \left\|\frac{|g(u)-g(\bar u)|}{|g(u)|+d(u)}\right\|_{r,N(u)^c} \le \frac{\|g(u)-g(\bar u)\|_r}{\|u-\bar u\|_s^{\bar p}} \le L_g\|u-\bar u\|_s^{1-\bar p} \le 1. \tag{31}$$

If $\tilde q \le r$, i.e., $r \ge 2q$, one has

$$\|Q(u)\|_{\tilde q, N(u)^c} \le m_{\tilde q, r}\|Q(u)\|_{r,N(u)^c},$$

and for $\tilde{q} > r$, i.e., $q < r < 2q$, application of Lemma 2.2 with $q_0 = \tilde{q}$, $q_1 = r$, $q_2 = \infty$ yields by using $\|Q(u)\|_\infty \le 1$

$$\|Q(u)\|_{\tilde{q},N(u)^c} \le \|Q(u)\|_{r,N(u)^c}^{r/\tilde{q}}.$$

Combining this and (31) gives

$$\|Q(u)\|_{\tilde{q},N(u)^c} \le C_1 \|u-\bar{u}\|_s^{(1-\bar{p})\min\{1,r/\tilde{q}\}} \tag{32}$$

with $C_1 = L_g^{\min\{1,r/\tilde{q}\}} \max\{m_{\tilde{q},r}, 1\}$. Since $\|Q(u)\|_\infty \le 1$, we get, on the other hand, from Lemma 5.7 and Minkowski's inequality

$$\begin{aligned} \|Q(u)\|_{\tilde{q},N(u)} \le \mu(N(u))^{1/\tilde{q}} &\le \left(\omega(2\|u-\bar{u}\|_s^{\bar{p}}) + \left(\frac{(L_g+L_d)\|u-\bar{u}\|_s}{\|u-\bar{u}\|_s^{\bar{p}}}\right)^r\right)^{1/\tilde{q}} \\ &\le \omega(2\|u-\bar{u}\|_s^{\bar{p}})^{1/\tilde{q}} + (L_g+L_d)^{r/\tilde{q}} \|u-\bar{u}\|_s^{(1-\bar{p})r/\tilde{q}}. \end{aligned} \tag{33}$$

Combining (25), (32), (33), and $\|Q(u)\|_{\tilde{q}} \le \|Q(u)\|_{\tilde{q},N(u)^c} + \|Q(u)\|_{\tilde{q},N(u)}$ gives (29). Since $m_{q_1,q_2} \le \max\{1, \mu(\Omega)\}$, it is easy to see that C_{WR} depends only on the quantities listed above. ∎

Our first main result is the following.

THEOREM 5.10. *Let* (O1), (O2), *and* (C) *hold at* $\bar{u}$. *If Assumptions* (A1), (A2), *and* (A3) *are satisfied, then for all* $u^c \in \mathcal{B}^\circ$ *with* $\|u^c - \bar{u}\|_s < \rho_H$ (7) *has a unique solution* $u^n \in L^q$. *In addition, for every* $\bar{p} \in (0,1)$ *and* $0 < \rho \le \rho_H$ *satisfying* $(L_g + L_d)\rho^{1-\bar{p}} \le 1$ *there is* $C > 0$ *depending only on* $\mu(\Omega), \|b-a\|_\infty, \|g(\bar{u})\|_\infty, L_g, L_{g'}$, *and* C_H, *but not on* q, r, s *such that for all* $u^c \in \mathcal{B}^\circ$ *with* $\|u^c - \bar{u}\|_s < \rho$

$$\|u^n - \bar{u}\|_q \le C\Phi_{\bar{p}}(\|u^c - \bar{u}\|_s)\|u^c - \bar{u}\|_s \tag{34}$$

with $\Phi_{\bar{p}}$ *given by* (30).

Proof. For $u^c \in \mathcal{B}^\circ$, $\|u^c - \bar{u}\|_s < \rho_H$, the unique solvability of (7) is obvious by the assumptions. In addition now let $\|u^c - \bar{u}\|_s < \rho$ hold. Since $\bar{u}$ satisfies (O1), (O2), the equations (7) and (24) are equivalent. By the choice of $\rho > 0$ we may apply (A3) to obtain

$$\|u^n - \bar{u}\|_q \le \|H(u^c)^{-1}\|_{q,q} \|W(u^c)R(u^c)\|_q \le C_H \|W(u^c)R(u^c)\|_q.$$

Lemma 5.9 completes the proof with $C = C_H C_{WR}$. ∎

For the important case $r = s = \infty$ the proof of Theorem 5.10 can be obtained without the careful analysis of residual sets in Lemmas 5.3, 5.7, and 5.5 since these sets have measure zero for $\|u - \bar{u}\|_\infty$ small. We have the following corollary.

COROLLARY 5.11. *Under the additional assumptions* $r = s = \infty$ *and* $\rho \le \nu$, *Theorem* 5.10 *holds with* (34) *replaced by*

$$\|u^n - \bar{u}\|_q \le C\ (\omega(2\|u^c - \bar{u}\|_\infty^{\bar{p}})^{1/q} + \|u^c - \bar{u}\|_\infty^{1-\bar{p}})\|u^c - \bar{u}\|_\infty. \tag{35}$$

In the very likely case that in addition to the assumptions of Theorem 5.10, the strong strict complementarity condition (CS) holds, we get the following even stronger result.

COROLLARY 5.12. *In addition to the assumptions of Theorem* 5.10 *let condition* (CS) *hold. Then with the choice* $\bar{p} = \min\{r/(r+\bar{q}), \tilde{q}/(\tilde{q}+\bar{q})\}$ *the estimate* (34) *implies that for all* $u^c \in \mathcal{B}^\circ$ *with* $\|u^c - \bar{u}\|_s < \rho$

$$\|u^n - \bar{u}\|_q \le \bar{C}\left(\|u^c - \bar{u}\|_s^{\frac{\bar{q}}{\tilde{q}+\max\{1,\tilde{q}/r\}\bar{q}}} + \left(\frac{\|u^c - \bar{u}\|_s}{\nu}\right)^{\frac{s-q}{q}}\right)\|u^c - \bar{u}\|_s,$$

where $\tilde{q} = qr/(r-q)$ *and* $\bar{C}$ *depends on* $\mu(\Omega), \|b-a\|_\infty, \|g(\bar{u})\|_\infty, L_g, L_{g'}, C_H, C_C, \bar{q}$, *and* ε_0, *but not on* q, r, s. *For* $\rho \le (\varepsilon_0/2)^{1/\bar{p}}$ *the constant* $\bar{C}$ *can be chosen independently of* C_C, ε_0, *and* $\bar{q}$.

Proof. From (CS) we have $\omega(\varepsilon) \le C_C \varepsilon^{\bar{q}}$ for a fixed $\bar{q} > 0$ and all $\varepsilon \in]0, \varepsilon_0[$. Obviously, if we choose $C_C \ge \mu(\Omega)\varepsilon_0^{-\bar{q}}$ and remember $\omega(0) = 0$, the bound for $\omega(\varepsilon)$ holds for all $\varepsilon \ge 0$. We determine the optimal choice of $\bar{p}$ in (34) from

$$\frac{\bar{p}\bar{q}}{\tilde{q}} = (1-\bar{p})\min\{1, r/\tilde{q}\}.$$

If $r \le \tilde{q}$, this gives $\bar{p} = \frac{r}{r+\bar{q}} \le \frac{\tilde{q}}{\tilde{q}+\bar{q}}$ and the common exponent $\frac{\bar{p}\bar{q}}{\tilde{q}} = \frac{\bar{q}}{\tilde{q}+\bar{q}(\tilde{q}/r)}$. If $r > \tilde{q}$, we get $\bar{p} = \frac{\tilde{q}}{\tilde{q}+\bar{q}} < \frac{r}{r+\bar{q}}$ and $\frac{\bar{p}\bar{q}}{\tilde{q}} = \frac{\bar{q}}{\tilde{q}+\bar{q}}$. ∎

Remark 5.13. It is possible to prove an even higher convergence speed by splitting Ω in the proof of Lemma 5.9 not only in $N_{\|u-\bar{u}\|_s^{\bar{p}}}(u)$ and its complement but in $N^0(u), N^1(u)\setminus N^0(u), \dots, N^l(u)\setminus N^{l-1}(u), N^l(u)^c$, where $N^k(u) \stackrel{\text{def}}{=} N_{\|u-\bar{u}\|_s^{\bar{p}_k}}(u)$ and $1 > \bar{p}_0 > \bar{p}_1 > \cdots > \bar{p}_l > 0$. Now the $\bar{p}_k$ can be chosen in such a way that the smallest exponent is maximized. In favor of the clarity of the presentation we have not applied this more sophisticated technique. ∎

For $r = s = \infty$ we state the more handy result below.

COROLLARY 5.14. *If in Corollary* 5.11 *the condition* (C) *is replaced by the strong strict complementarity condition* (CS), *then for all* $u^c \in \mathcal{B}^\circ$ *with* $\|u^c - \bar{u}\|_\infty < \rho$

$$\|u^n - \bar{u}\|_q \le \bar{C}\|u^c - \bar{u}\|_\infty^{1+\bar{q}/(q+\bar{q})}.$$

Remark 5.15. The analysis can also be carried out for the Coleman–Li affine-scaling function d_{I} with $d_{\mathrm{I}}' \stackrel{\text{def}}{=} \operatorname{sgn}(g)$. Hereby one can proceed as follows:

(1) The estimate (16) holds and a simplified version of (17) can be established on $J = \{g(u)g(\bar{u}) > 0 \vee g(\bar{u}) = 0\}$.

(2) An analogue of Lemma 5.5 can be established if J is chosen as in (1). The last term in the second line of (27) can be estimated similar to the second one by

$$\|1\|_{\frac{qr}{r-q}, J^c}\||g(u) - g(\bar{u})| + |u-\bar{u}|\|_r \le (L_g + m_{r,s})\mu(J^c)^{\frac{r-q}{qr}}\|u-\bar{u}\|_s.$$

(3) Part (i) of Lemma 5.7 remains true and instead of (ii) one can prove

$$\mu(N_\varepsilon(u)\cap J) \le \omega(2\varepsilon) + \varepsilon^{-r}(L_g + m_{r,s})^r\|u-\bar{u}\|_s^r,$$

since $N_\varepsilon(u)\cap J \subset \{|g(u)| + d(\bar{u}) - |u-\bar{u}| \le \varepsilon\}$. Moreover, for all $\varepsilon > 0$ $J^c \subset N_\varepsilon(\bar{u}) \cap \{|g(u) - g(\bar{u})| > \varepsilon\}$ holds and thus $\mu(J^c) \le \omega(\varepsilon) + \varepsilon^{-r}L_g^r\|u-\bar{u}\|_s^r$, which shows that $\mu(J^c) \to 0$ as $u \to \bar{u}$ in L^s if the strict complementarity (C) holds.

(4) Now, one can proceed along the lines of Lemma 5.9. ∎

Assume for a moment that the iteration $u_0 \in \mathcal{B}^\circ$, $G(u_k)(u_{k+1}-u_k) = -d(u_k)g(u_k)$, is well-defined, i.e., $(u_k) \subset \mathcal{B}^\circ$ in particular. We have already observed that the sequence (u_k) may fail to converge superlinearly in L^∞ even if (A2), (A3) hold with $q = \infty$. As pointed out in [17] and [18] the same is true for directly applied projected Newton methods because the active set cannot be identified on a residual set of nonzero measure. In these papers a smoothing step is used to achieve fast L^∞-convergence. Theorem 5.10 will enable us to add such a modification if an appropriate smoothing step is available. The same problems arise also in the case $s < \infty$, since a result of the form (34) requires $s > q$.

Moreover, as we will see in Example 6.3, the case $u_{k+1} \notin \mathcal{B}^\circ$ occurs very likely for some k. Hence, a back-transport into $\mathcal{B}^\circ$ is necessary. Therefore, we will use the following ingredients to design a superlinearly convergent algorithm (cf. the outline in section 4).

SMOOTHING STEP: $u_k \in \mathcal{B}^\circ \longmapsto u_k^s = S_k^\circ(u_k) \in \mathcal{B}^\circ$ with $\|u_k^s - \bar{u}\|_s \le C_S \|u_k - \bar{u}\|_q$.

NEWTON STEP: $u_{k+1}^n \in L^q$ solves $G(u_k^s)(u_{k+1}^n - u_k^s) = -d(u_k^s)g(u_k^s)$.

BACK-TRANSPORT: $u_{k+1}^n \in L^q \longmapsto u_{k+1} = P[u_k^s](u_{k+1}^n) \in \mathcal{B}^\circ$
with $\|u_{k+1} - \bar{u}\|_q \le C_P \|u_{k+1}^n - \bar{u}\|_q + C_P' \|u_k^s - \bar{u}\|_s^2$.

Here C_S, C_P, and C_P' are positive constants.

5.1. An affine-scaling Newton algorithm. Provided that smoothing step and back-transport with the above properties are available, the previous considerations and the abstract convergence theory in section 4 suggest the following algorithm.

ALGORITHM 5.16 (affine-scaling interior-point Newton algorithm).

1. Choose $u_0 \in \mathcal{B}^\circ$.
2. For $k = 0, 1, 2, \ldots$
   - 2.1. If $d(u_k)g(u_k) = 0$, STOP.
   - 2.2. Select and perform a smoothing step: $u_k^s = S_k^\circ(u_k)$.
   - 2.3. Compute $u_{k+1}^n \in L^q$ from
   $$G(u_k^s)(u_{k+1}^n - u_k^s) = -d(u_k^s)g(u_k^s) \quad \text{(affine-scaling Newton step)}.$$
   - 2.4. Transport u_{k+1}^n back to $\mathcal{B}^\circ$: $u_{k+1} = P[u_k^s](u_{k+1}^n)$.

6. Back-transport and smoothing-step.

6.1. The back-transport. Since the solution u_{k+1}^n of the affine-scaling Newton equation in step 2.3 is not necessarily an interior point of $\mathcal{B}$, a back-transport into $\mathcal{B}^\circ$ is needed. In [7] a stepsize rule is used for this purpose. A reflection technique was proposed in [4] and [6]. We will see that in our function space, setting very small stepsizes σ_k may be necessary to achieve $u_k^s + \sigma_k(u_{k+1}^n - u_k^s) \in \mathcal{B}^\circ$. Thus, a stepsize rule fails to provide superlinear convergence; cf. Example 6.3. Therefore, we will propose and analyze a projection technique which is also an attractive alternative to reflection techniques in the finite-dimensional case.

6.1.1. Back-transport by projection. Since $\bar{u} \in \mathcal{B}$, the pointwise projection $P(u)$ of u onto $\mathcal{B}$ with $P : L^1 \longrightarrow \mathcal{B}$ defined by

$$P(u) = \max\{a, \min\{b, u\}\} \tag{36}$$

obviously satisfies $|P(u) - v| \leq |u - v|$ on Ω for all $v \in \mathcal{B}$. Hence,

$$\|P(u) - v\|_t \leq \|u - v\|_t \tag{37}$$

for all $t \in [1, \infty]$, $v \in \mathcal{B}$, and $u \in L^t$.

As mentioned earlier, an interior-point modification $P[v]$, $v \in \mathcal{B}^\circ$, of P can be used to obtain a back-transport satisfying the required property

$$\|P[v](u) - \bar{u}\|_q \leq C_P \|u - \bar{u}\|_q + C'_P \|v - \bar{u}\|_s^2. \tag{38}$$

In fact, for $\xi \in (0, 1)$, typically $\xi > 0.9$, and $v \in \mathcal{B}^\circ$ choose

$$P[v] : L^q \longrightarrow \mathcal{B}^\circ, \quad P[v](u) = v + \max\{\xi, 1 - \|P(u) - v\|_q\}(P(u) - v). \tag{39}$$

Then obviously

$$P[v](u) - P(u) = \min\{1 - \xi, \|P(u) - v\|_q\}(v - P(u)),$$

and hence

$$\begin{aligned} &\|P[v](u) - P(u)\|_q \leq \|P(u) - v\|_q^2, \\ &\|P[v](u) - P(u)\|_t \leq \|b - a\|_t \|P(u) - v\|_q \ , \quad 1 \leq t \leq \infty. \end{aligned} \tag{40}$$

Using this, we can derive (38).

LEMMA 6.1. *Let P and $P[v]$, $v \in \mathcal{B}^\circ$, be defined according to* (36) *and* (39). *Then condition* (38) *holds with $C_P = (2\|b - a\|_q + 1)$, $C'_P = 2m_{q,s}^2$.*

Proof. Let $v \in \mathcal{B}^\circ$ and $u \in L^q$. Using the properties of $P[v]$ yields

$$\begin{aligned} \|P[v](u) - \bar{u}\|_q &\leq \|P[v](u) - P(u)\|_q + \|P(u) - \bar{u}\|_q \leq \|P(u) - v\|_q^2 + \|u - \bar{u}\|_q \\ &\leq 2\ (\|P(u) - \bar{u}\|_q^2 + \|v - \bar{u}\|_q^2) + \|u - \bar{u}\|_q \\ &\leq (2\|b - a\|_q + 1)\|u - \bar{u}\|_q + 2\|v - \bar{u}\|_q^2 \\ &\leq (2\|b - a\|_q + 1)\|u - \bar{u}\|_q + 2m_{q,s}^2 \|v - \bar{u}\|_s^2. \end{aligned}$$

∎

6.1.2. Projection vs. stepsize rule for back-transport. The following arguments and Example 6.3 below show that even if (A2), (A3) hold for $q = \infty$ and $\|u_k^s - \bar{u}\|_\infty$ is arbitrarily small, stepsizes $\sigma_k \leq \varepsilon \ll 1$ may be necessary to ensure $u_k^s + \sigma_k(u_{k+1}^n - u_k^s) \in \mathcal{B}^\circ$. Let $u_k^s \in \mathcal{B}^\circ$ be arbitrary. From step 2.3 in Algorithm 5.16 we deduce for x with $d(u_k^s)(x) < c(x)$ and $g(u_k^s)(x) \neq 0$

$$u_k^s(x) - u_{k+1}^n(x) = \left(\operatorname{sgn}(g(u_k^s)(x)) + \frac{(\nabla^2 f(u_k^s)(u_{k+1}^n - u_k^s))(x)}{|g(u_k^s)(x)|} \right) d(u_k^s)(x). \tag{41}$$

If we look at those $x \in \Omega$ where in addition $\bar{u}(x) = a(x)$ and $|g(u_k^s)(x)|$ is small, say, $|g(u_k^s)(x)| \leq u_k^s(x) - a(x)$, then

$$d(u_k^s)(x) = u_k^s(x) - a(x).$$

Thus, we need stepsize $\sigma_k \leq \varepsilon$ if

$$\left(\nabla^2 f(u_k^s)(u_{k+1}^n - u_k^s)\right)(x) \geq \left(1 + \varepsilon^{-1}\right) |g(u_k^s)(x)|,$$

since (41), the equality for $d(u_k^s)(x)$, and the last inequality imply

$$u_k^s(x) - u_{k+1}^n(x) \geq \varepsilon^{-1}(u_k^s(x) - a(x)).$$

But even for $\|u_k^s - \bar{u}\|_\infty$ arbitrarily small the set

$$\left\{x \in \Omega : \ \bar{u}(x) = a(x), \ \left(\nabla^2 f(u_k^s)(u_{k+1}^n - u_k^s)\right)(x) \geq \left(1 + \varepsilon^{-1}\right)|g(u_k^s)(x)|\right\}$$

may have nonzero measure, because $|g(u_k^s)|$ is typically very small on a neighborhood of $\partial\bar{A}$.

Since superlinear convergence can be guaranteed only if the sequence of stepsizes converges to one, a stepsize rule for the Newton-like step is unsuitable for the infinite-dimensional case although it was proven to give quadratic convergence in the finite-dimensional case (see [7]).

Remark 6.2. In the finite-dimensional case one can easily show by using a componentwise version of (41) that $\sigma_k = 1 - O(\|u_{k+1} - u_k\|)$ if second-order sufficiency conditions with strict complementarity hold at $\bar{u}$. See [6], [7]. □

The following example illustrates that in the infinite-dimensional case the above scenario of small stepsizes can really occur.

Example 6.3. We consider problem (P) with quadratic objective function

$$f : u \in L^2([0,1]) \longmapsto \frac{1}{2}\|u\|_2^2 - \frac{1}{4}\left(\int_0^1 u(x)\,dx\right)^2$$

and feasible set $\mathcal{B} \stackrel{\text{def}}{=} \{u \in L^2([0,1]) : \ a(x) \stackrel{\text{def}}{=} x - \frac{1}{2} \leq u(x) \leq 10 \stackrel{\text{def}}{=} b(x) \text{ a.e.}\}$. f is smooth with

$$g(u) = u - \frac{1}{2}\int_0^1 u(x)\,dx\ , \quad \nabla^2 f(u)\,v = g(v),$$

and strictly convex, since by Jensen's inequality $(v, \nabla^2 f(u)v)_2 \geq \frac{1}{2}\|v\|_2^2$ for all $v \in L^2$. The unique global minimum of f on $\mathcal{B}$ is given by $\bar{u}(x) = \max\{y, a(x)\}$ with $y = 3/2 - \sqrt{2}$, because f is strictly convex, $g(\bar{u}) = \bar{u} - y = 0$ on the inactive set $\bar{I} = [0, \hat{x})$, $\hat{x} = y + 1/2$, and $g(\bar{u}) = \bar{u} - y \geq 0$ on the active set $\bar{A} = [\hat{x}, 1] = \{\bar{u} = a\}$. It is easy to check that (A1)–(A3), (C), and (CS) hold for $p = q = 2$, $r = s = \infty$. For $0 < \varepsilon < 1$ the function $u_\varepsilon \in \mathcal{B}^\circ$, $u_\varepsilon(x) \stackrel{\text{def}}{=} \bar{u}(x) + \varepsilon|x - \hat{x}| + \varepsilon^2/10$, is strictly feasible with $\|u_\varepsilon - \bar{u}\|_\infty = \hat{x}\varepsilon + \varepsilon^2/10 < \varepsilon$. Moreover, the gradient $g(u_\varepsilon)$ is negative in a neighborhood of the boundary point $\hat{x}$ of $\bar{A}$ which leads to the above scenario of small stepsizes:

$$g(u_\varepsilon)(\hat{x}) = \frac{\varepsilon}{20}\,(-45 + 30\sqrt{2} + \varepsilon) < -\frac{\varepsilon}{20}, \quad 0 < \varepsilon < 1.$$

Now we analyze what happens if we take u_ε as starting point for an affine-scaling Newton step s_ε, i.e., $G(u_\varepsilon)s_\varepsilon = -d(u_\varepsilon)g(u_\varepsilon)$, or, in detail,

$$s_\varepsilon - \frac{1}{2}\frac{d(u_\varepsilon)}{d'(u_\varepsilon)g(u_\varepsilon) + d(u_\varepsilon)}\int_0^1 1 \cdot s_\varepsilon(x)\,dx = -\frac{d(u_\varepsilon)g(u_\varepsilon)}{d'(u_\varepsilon)g(u_\varepsilon) + d(u_\varepsilon)}. \tag{42}$$

Since the operator $(d'(u_\varepsilon)g(u_\varepsilon) + d(u_\varepsilon))^{-1}G(u_\varepsilon)$ on the left (which coincides with $H(u_\varepsilon)$ for ε small enough) is a "rank-one modification" of the identity, its inverse

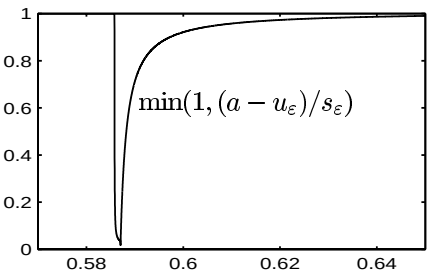

FIG. 1.

can be explicitly determined by applying the Sherman–Morrison–Woodbury lemma in $L^2([0,1])$. It is possible to derive an explicit closed formula for the function s_ε. Table 1 shows the maximum stepsize $\sigma_{\max} \stackrel{\text{def}}{=} \max\{\sigma \in [0,1] : u_\varepsilon + \sigma s_\varepsilon \in \mathcal{B}\}$ for $c \stackrel{\text{def}}{=} 2$, and the relative L^2-norm of the part of s_ε that would be cut off by a pointwise projection. All values were obtained using the closed formula for s_ε. Figure 1 depicts for $\varepsilon = 1/100$ a plot of the pointwise allowed maximum stepsize. We see that the severe restriction on the stepsize stems from points in a small neighborhood of $\hat{x} \approx 0.5857$. This neighborhood contains a zero of g_ε located in the active set which leads exactly to the scenario discussed above. Outside of the neighborhood depicted in Figure 1 the pointwise allowed maximum stepsize is ≥ 0.99.

Thus, u_ε is a sequence tending to $\bar{u}$ in L^∞ as $\varepsilon \to 0^+$ for which the corresponding maximum stepsizes $\sigma_{\max}$ tend to zero whereas the relative L^2-difference between the affine-scaling Newton step s_ε and the projected step $P(u_\varepsilon + s_\varepsilon) - u_\varepsilon$ approaches zero. □

The previous example shows that a stepsize rule may lead to arbitrarily small stepsizes for iterates that are arbitrarily close to the solution $\bar{u}$. Thus, it has to be replaced by another back-transport to achieve fast local convergence. On the other hand, the example motivates the back-transport by projection introduced in section 6.1.1, since it leads only to a tiny change of the step in the L^2-norm.

After the introduction of a smoothing step in the next section, this example will be continued in Example 6.5. There we will illustrate (among other things) that the use of a stepsize rule may lead to almost a stagnation of the iteration whereas the proposed projection technique in conjunction with a smoothing step yields fast convergence.

6.2. The smoothing step. We have already observed that a smoothing step is necessary because the strongest available estimate after one iteration of (7) is (34) with $q < s$. In the further analysis we assume that in each iteration k of Algorithm

5.16 a—possibly noninterior—smoothing step

$$u_k \in \mathcal{B} \longmapsto S_k(u_k) \in L^s \tag{43}$$

is available. Let $\bar{u} \in \mathcal{B}$ satisfy (O1) and (O2). Analogously to the Abstract Assumption 1 in section 4 we make the following assumption.

ASSUMPTION (smoothing property).

(S) *There are $\rho_S > 0$ and $L_S > 0$ such that the smoothing steps S_k defined in* (43) *possess the following property:*

$$\|S_k(u_k) - \bar{u}\|_s \le L_S \|u_k - \bar{u}\|_q \quad \text{for all } k \text{ with } \|u_k - \bar{u}\|_q < \rho_S.$$

This assumption allows us to choose $S_k(u_k) = u_k$ if $u_k \in \{u : \|u - \bar{u}\|_s \le L_S \|u - \bar{u}\|_q\}$. As already outlined in Remark 4.3, the smoothing step

$$u_k \longmapsto S_k^\circ(u_k) \stackrel{\text{def}}{=} P[u_k](S_k(u_k)) \tag{44}$$

is an interior-point modification of S_k as follows.

LEMMA 6.4. *Let $\bar{u}$ satisfy* (O1), (O2) *and let* (S) *hold. If $P[v]$ is defined by* (39), *then S_k° as defined in* (44) *satisfies $S_k^\circ(u_k) \in \mathcal{B}^\circ$. Moreover,*

$$\|S_k^\circ(u_k) - \bar{u}\|_s \le C_S \|u_k - \bar{u}\|_q$$

holds for all k with $\|u_k - \bar{u}\|_q < \rho_S$, where $C_S = (m_{q,s}\|b - a\|_s + 1)L_S + \|b - a\|_s$.

Proof. $P[u_k](S_k(u_k)) \in \mathcal{B}^\circ$ does obviously hold for all $k \ge 0$, since $u_k \in \mathcal{B}^\circ$. Now let $k \ge 0$ be arbitrary with $\|u_k - \bar{u}\|_q < \rho_S$. Using the properties (37), (40) of P and $P[u_k]$, we get

$$\begin{aligned}
\|P[u_k](S_k(u_k)) - \bar{u}\|_s &\le \|P[u_k](S_k(u_k)) - P(S_k(u_k))\|_s + \|P(S_k(u_k)) - \bar{u}\|_s \\
&\le \|b - a\|_s \|P(S_k(u_k)) - u_k\|_q + \|S_k(u_k) - \bar{u}\|_s \\
&\le \|b - a\|_s (\|P(S_k(u_k)) - \bar{u}\|_q + \|u_k - \bar{u}\|_q) + \|S_k(u_k) - \bar{u}\|_s \\
&\le (m_{q,s}\|b - a\|_s + 1)\|S_k(u_k) - \bar{u}\|_s + \|b - a\|_s \|u_k - \bar{u}\|_q \\
&\le C_S \|u_k - \bar{u}\|_q,
\end{aligned}$$

where we have used (S) in the last step. ∎

We will show in section 8 how a smoothing step can be constructed for a class of regularized problems by using a fixed point formulation of the KKT-conditions (O1), (O2).

In the following example we will demonstrate that our proof-driven modifications of the basic interior-point Newton method—to replace the stepsize rule by a projection based procedure and to augment the iteration with a smoothing step—are actually necessary to achieve mesh-independence after discretization.

Example 6.5. We return to Example 6.3 to compare the performance of three variants of the affine-scaling interior-point Newton method:

(I) Algorithm 5.16.

(II) Algorithm 5.16 with 2.4 replaced by a stepsize rule:

2.4′ Transport u_{k+1}^n back to $\mathcal{B}^\circ$ by the following stepsize rule:

$$\begin{aligned}
s_k^n &= u_{k+1}^n - u_k^s, \quad \sigma_{k,\max} = \max\{\sigma \in [0,1] : u_k^s + \sigma s_k^n \in \mathcal{B}\}, \\
u_{k+1} &= u_k^s + \max\{\xi, 1 - \|s_k^n\|_2\}\, \sigma_{k,\max} s_k^n, \quad \xi \text{ as in (39)}.
\end{aligned}$$

(III) Algorithm 5.16 without smoothing step 2.2.

In Algorithms (I) and (II) we apply smoothing to u_k only if the L^2- and L^∞-norm of $u_k - u^s_{k-1}$ differ too much:

$$S^\circ_k(u_k) \stackrel{\text{def}}{=} \begin{cases} P[u_k](u_k - g(u_k)) & \text{if } k \geq 1 \text{ and } \|u_k - u^s_{k-1}\|_\infty \geq 3\|u_k - u^s_{k-1}\|_2, \\ u_k & \text{else.} \end{cases}$$

The interior-point modification of the projected gradient step is indeed a smoothing step. This follows from Lemma 6.4 and the discussion in section 8. For the numerical realization of the methods we have discretized the problem by approximating $L^2([0,1])$ with piecewise linear functions on a uniform grid with $N+1$ points for $N = 200, 2000$, and 200000, respectively. To check the decrease properties of the new iterates, we use the fact that u^n_{k+1} solves the affine-scaling Newton equation in step 2.3 if and only if u^n_{k+1} is a stationary point of the quadratic function $\psi[u^s_k](u)$ defined by (62); cf. section 10. This function is used as quadratic model in the interior-point trust-region methods recently analyzed in [26]. Since $\psi[u^s_k]$ is strictly convex in our context, it attains its global minimum at s^n_k. We start the iterations with $u_0 = u_\varepsilon$, $\varepsilon = 0.5$, and $\xi = 0.999995$. We begin with a comparison of Algorithms (I) and (II) for $N = 200$.

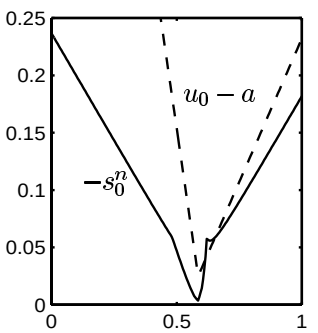

FIG. 2

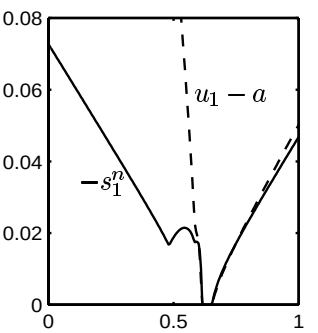

FIG. 3

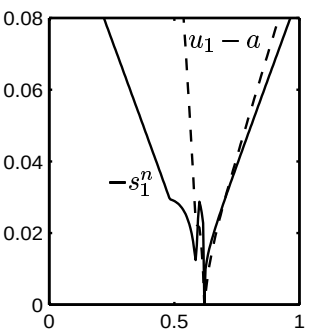

FIG. 4

The distances $\|u_{k+1} - \bar{u}\|_2$, $\|u^s_{k+1} - \bar{u}\|_\infty$ from the solution $\bar{u}$ of the discrete problem and the decrease ratio $\psi[u^s_k](u_{k+1})/\psi[u^s_k](u^n_{k+1})$ are shown in Table 2. For method (II) we have also added $\sigma_{k,\max}$. Figure 2 depicts $-s^n_0$ and the distance to the lower bound $u_0 - a$ (dashed). Figures 3 and 4 show the same quantities, i.e., $-s^n_1$ and $u_1 - a$, after one step of Algorithms (I) and (II), respectively. We see that the stepsize rule in (II) leads to an iterate u_1 and a new search direction s^n_1 that requires a very small stepsize of 0.0128 yielding almost no progress. The reason is depicted in Figure 4:

s_1^n has a small peak on the set where the distance to the lower bound is small. On the other hand, the part of $s_k^n = u_{k+1}^n - u_k^s$ that is cut off by a projection is very small. Hence, the projection leads to a nearly optimal decrease of $\psi[u_k^s]$ in every step. Figures 5 and 6 show the first iterates for both iterations. While our Algorithm (I) converges in 5 steps to high accuracy, method (II) needs 28 iterations to enter the region of quadratic convergence which exists according to the finite-dimensional theory. Then it converges in two more steps to high accuracy. Using the starting points of Example 6.3 for sufficiently fine discretizations leads to approximately the same small stepsizes as in Example 6.3. Thus, Algorithm (II) is not mesh-independent and its region of quadratic convergence shrinks with the grid-size. Since for the starting point u_ε, $\varepsilon = 0.5$, also in this example the performance of Algorithm (II) is worse for finer grids—it needs 270 iterations for $N = 2000$—we compare only the mesh-dependence of Algorithms (I) and (III). Table 3 contains the distances $\|u_{k+1} - \bar{u}\|_2$, $\|u_{k+1}^s - \bar{u}\|_\infty$ from the solution $\bar{u}$ of the discrete problems for $N = 2000$ and $N = 200000$. As indicated by our results we observe mesh-independent superlinear convergence of Algorithm (I). On the other hand, we see that Algorithm (III) is *not* mesh-independent and that the region of fast local convergence obviously shrinks. □

† $e_{k+1} = u_{k+1} - \bar{u}$, $e_{k+1}^s = u_{k+1}^s - \bar{u}$. * Smoothing occurred, i.e., $u_{k+1}^s \neq u_{k+1}$.

The above example shows that both of our algorithmic modifications, the projection as back-transport and the smoothing step, are necessary to obtain mesh-independent superlinear convergence. This demonstrates that the finite-dimensional convergence theory for Algorithm (II), which guarantees local quadratic convergence, is not sufficient to ensure mesh-independent behavior.

7. The convergence result. In the following we will always work with the smoothing steps

$$u_k \in \mathcal{B}^\circ \longmapsto S_k^\circ(u_k) \stackrel{\text{def}}{=} P[u_k](S_k(u_k)) \in \mathcal{B}^\circ, \quad S_k \text{ as in (43)}.$$

We will now prove that Algorithm 5.16 converges superlinearly (respectively, with Q-order $1 + \bar{q}/(\tilde{q} + \max\{1, \tilde{q}/r\}\,\bar{q})$) in L^s to $\bar{u}$ if $\bar{u}$ satisfies the first-order necessary conditions with strict complementarity (C) (respectively, (CS)) as well as (A3), a smoothing step exists, and $\|u_0 - \bar{u}\|_q$ is small enough. More precisely, we have the following theorem.

THEOREM 7.1. *Let $\bar{u}$ satisfy* (O1), (O2), *and* (C). *If* (A1)–(A3) *and* (S) *hold, then for $\bar{p} \in (0,1)$ there is $\rho > 0$ such that for all $u_0 \in \mathcal{B}^\circ$ with $\|u_0 - \bar{u}\|_q < \rho$ Algorithm* 5.16 *is well-defined and produces iterates with*

$$\|u_{k+1} - \bar{u}\|_q \le \bar{C}_1 \Phi_{\bar{p}}(C_S \|u_{k+1} - \bar{u}\|_q) \|u_{k+1} - \bar{u}\|_q, \tag{45}$$

$$\|u_{k+1}^s - \bar{u}\|_s \le \bar{C}_2 \Phi_{\bar{p}}(\|u_{k+1}^s - \bar{u}\|_s) \|u_{k+1}^s - \bar{u}\|_s, \tag{46}$$

where $\bar{C}_1, \bar{C}_2 > 0$ depend on $\mu(\Omega), \|b - a\|_\infty, \|g(\bar{u})\|_\infty, L_g, L_{g'}, C_H, L_S$, but not on q, r, s and $\Phi_{\bar{p}}$ is given by (30), *i.e.,*

$$\Phi_{\bar{p}}(z) = \omega(2z^{\bar{p}})^{1/\tilde{q}} + z^{(1-\bar{p})\min\{1, \frac{r}{\tilde{q}}\}} + \left(\frac{z}{\nu}\right)^{\frac{s-q}{q}}.$$

In the case $r = s = \infty$ the function $\Phi_{\bar{p}}$ simplifies to $\Phi_{\bar{p}}(z) = \omega(2z^{\bar{p}})^{1/q} + z^{1-\bar{p}}$.

Proof. Choose $0 < \rho \le \rho_S$. We will reduce ρ as the proof proceeds. From Lemma 6.4 we deduce

$$\|u_k^s - \bar{u}\|_s \le C_S \|u_k - \bar{u}\|_q. \tag{47}$$

By choosing $\rho > 0$ appropriately we can apply Theorem 5.10 with ρ replaced by $C_S\rho$ and $u^c = u_k^s$. We obtain that for all $u_k \in \mathcal{B}^\circ$, $\|u_k - \bar{u}\|_q < \rho$,

$$\|u_{k+1}^n - \bar{u}\|_q \le C\Phi_{\bar{p}}(\|u_k^s - \bar{u}\|_s)\|u_k^s - \bar{u}\|_s \le CC_S\Phi_{\bar{p}}(C_S\|u_k - \bar{u}\|_q)\|u_k - \bar{u}\|_q, \tag{48}$$

where $\Phi_{\bar{p}}$ is given by (30). Lemma 6.1 yields

$$\begin{aligned} \|u_{k+1} - \bar{u}\|_q = \|P[u_k^s](u_{k+1}^n) - \bar{u}\|_q &\le C_P\|u_{k+1}^n - \bar{u}\|_q + C_P'\|u_k^s - \bar{u}\|_s^2 \\ &\le C_S\ (CC_P\Phi_{\bar{p}}(C_S\|u_k - \bar{u}\|_q) + C_SC_P'\|u_k - \bar{u}\|_q)\ \|u_k - \bar{u}\|_q. \end{aligned} \tag{49}$$

This proves (45), since the $\Phi_{\bar{p}}$-term is of lowest order. By the properties of ω (see Lemma 5.7), $\Phi_{\bar{p}}(z)$ tends to zero as $z \to 0$. Hence, possibly after a further reduction of ρ, the algorithm is well-defined, since $u_0 \in \mathcal{B}^\circ$, $\|u_0 - \bar{u}\|_q < \rho$ implies $u_k \in \mathcal{B}^\circ$,

$\|u_k - \bar{u}\|_q < \rho$ for all k. Now (46) is obtained by combining (47) with k replaced by $k+1$, and the first inequalities in (48) and (49):

$$\begin{aligned}\|u_{k+1}^s - \bar{u}\|_s &\le C_S \|u_{k+1} - \bar{u}\|_q \\ &\le C_S (C_P \|u_{k+1}^n - \bar{u}\|_q + C_P' \|u_k^s - \bar{u}\|_s^2) \\ &\le C_S \left(C C_P \Phi_{\bar{p}}(\|u_k^s - \bar{u}\|_s) + C_P' \|u_k^s - \bar{u}\|_s\right) \|u_k^s - \bar{u}\|_s. \qquad \square\end{aligned}$$

If, in addition, (CS) holds, we get convergence with Q-order > 1 as follows.

COROLLARY 7.2. *In addition to the assumptions of Theorem* 7.1 *let condition* (CS) *hold at* $\bar{u}$. *Then with the choice* $\bar{p} = \min\{r/(r+\bar{q}), \tilde{q}/(\tilde{q}+\bar{q})\}$ *Theorem* 7.1 *yields*

$$\begin{aligned}\|u_{k+1} - \bar{u}\|_q &\le \bar{C}_1 \Phi_{CS}(C_S \|u_k - \bar{u}\|_q) \|u_k - \bar{u}\|_q, \\ \|u_{k+1}^s - \bar{u}\|_s &\le \bar{C}_2 \Phi_{CS}(\|u_k^s - \bar{u}\|_s) \|u_k^s - \bar{u}\|_s\end{aligned}$$

with $\bar{C}_1, \bar{C}_2 > 0$ *as in Theorem* 7.1, $\tilde{q} = \frac{qr}{r-q}$, *and*

$$\Phi_{CS}(z) = z^{\frac{\bar{q}}{\bar{q}+\max\{1,\tilde{q}/r\}\bar{q}}} + \left(\frac{z}{\nu}\right)^{\frac{s-q}{q}}.$$

In the case $r = s = \infty$ *the function* Φ_{CS} *assumes the simple form* $\Phi_{CS}(z) = z^{\frac{\bar{q}}{\bar{q}+\bar{q}}}$.

Proof. This follows immediately from Theorem 7.1 and Corollary 5.12. $\square$

8. Application to a class of regularized problems. In this section we apply our convergence theory to the following class of regularized problems which contains the one considered in the analysis of projected Newton methods by Kelley and Sachs [17]: We investigate problem (P) with the L^2-regularized objective function

$$f : u \in \mathcal{D} \subset L^p \longmapsto k(u) + \frac{1}{2}\|\sqrt{\alpha}(u - u^0)\|_2^2,$$

where $\alpha, u^0 \in L^\infty$ and $k : \mathcal{D} \longmapsto \mathbb{R}$ such that (A1) holds. The gradient is given by

$$g(u) = \alpha u - \alpha u^0 + \nabla k(u) \stackrel{\text{def}}{=} \alpha u + K(u).$$

We make the following assumption.

ASSUMPTION.

(A2′) *$g(u) = \alpha u + K(u)$ with $\alpha \in L^\infty$, $\alpha(x) \ge \alpha_0 > 0$ for a.a. $x \in \Omega$. Furthermore, there are $2 \le q < s \le \infty$ such that $g : \mathcal{B} \subset L^s \longrightarrow L^q$ is Lipschitz continuously Fréchet differentiable and K has the following smoothing property:*

$$K : \mathcal{B} \subset L^q \longrightarrow L^s$$

is Lipschitz continuous with Lipschitz constant L_K.

Obviously, (A2′) implies the Lipschitz continuity of $g : \mathcal{B} \subset L^s \longrightarrow L^s$ with Lipschitz constant $L_g = \|\alpha\|_\infty + m_{q,s} L_K$. Hence, (A2′) implies (A2) with $r = s$.

To perform a smoothing step we use a technique proposed in [17]. The following fixed point formulation of the optimality conditions (O1), (O2) is essential.

LEMMA 8.1. *Let* (A1) *hold. Then* (O1), (O2) *are satisfied at* $\bar{u}$ *if and only if*

$$\bar{u} = P(\bar{u} - \sigma g(\bar{u})), \tag{50}$$

where $\sigma \in L^\infty$, $\sigma > 0$ *a.e., is arbitrary.*

If in addition (A2′) *holds, then* $\bar{u}$ *satisfies* (O1), (O2) *if and only if*

$$\bar{u} = P(-\alpha^{-1}K(\bar{u})) \ (= P(\bar{u} - \alpha^{-1}g(\bar{u}))).$$

Furthermore, for all $u, v \in \mathcal{B}$ *the following holds true:*

$$\|P(-\alpha^{-1}K(u)) - P(-\alpha^{-1}K(v))\|_s \le \|\alpha^{-1}(K(u) - K(v))\|_s \le \frac{L_K}{\alpha_0}\|u - v\|_q, \tag{51}$$

i.e., the step $u_k \in \mathcal{B} \longmapsto S_k(u_k) \stackrel{\text{def}}{=} P(-\alpha^{-1}K(u_k))$ *has the smoothing property* (S) *for all* $u_k \in \mathcal{B}$.

Proof. Let $\bar{u} \in \mathcal{D}$ be arbitrary. Then (50) is satisfied if and only if (O1) holds (since the right-hand side of (50) is in $\mathcal{B}$) and

$$\sigma(x)g(\bar{u})(x) \begin{cases} \ge 0 & \text{if } \bar{u}(x) = a(x), \\ \le 0 & \text{if } \bar{u}(x) = b(x), \\ = 0 & \text{else} \end{cases} \qquad \text{a.e. on } \Omega.$$

Since $\sigma(x) > 0$ for a.a. $x \in \Omega$, this is nothing else but (O2). If in addition (A2′) holds, then $\bar{u} - \sigma g(\bar{u}) = (1 - \sigma\alpha)\bar{u} - \sigma K(\bar{u})$ and the choice $\sigma = \alpha^{-1}$ establishes the second assertion. (51) is easily obtained by using the smoothing property in (A2′) and the fact that $\|P(v) - P(w)\|_s \le \|v - w\|_s$ for all $v, w \in L^s$, since P is a pointwise projection. ∎

Remark 8.2. The smoothing step is a scaled projected gradient step obtained by making a scaled gradient step $-\alpha^{-1}g(u_k)$ and projecting the result pointwise onto $\mathcal{B}$. Moreover, $P(-\alpha^{-1}K(u_k)) - u_k$ is a descent direction for f at $u_k \in \mathcal{B}$ (cf. [13]): Since P is also the projection onto $\mathcal{B}$ in the scaled Hilbert space $(L^2, (\alpha \cdot \dots, \dots)_2)$ we get by using well-known properties of projections on closed convex sets in Hilbert space

$$0 \ge \big(\alpha(u_k - P(u_k - \alpha^{-1}g(u_k))), u_k - \alpha^{-1}g(u_k) - P(u_k - \alpha^{-1}g(u_k))\big)_2$$

and hence (note that we use the L^2 inner product as dual pairing)

$$\big\langle P(u_k - \alpha^{-1}g(u_k)) - u_k, g(u_k)\big\rangle \le -\big\|\sqrt{\alpha}(P(u_k - \alpha^{-1}g(u_k)) - u_k)\big\|_2^2. \qquad ∎$$

The preceding lemma shows that the convergence results of the previous section hold for the considered class of regularized problems if $u_k \longmapsto S_k(u_k) = P(-\alpha^{-1}K(u_k))$ is used as smoothing step.

We have already mentioned that (CS) is weaker than the corresponding assumption in [17] for the analysis of the projected Newton method. To allow a further comparison with the results in [17] we will show that (A3) is implied by Assumptions 2.1 and 2.3 in [17] which are stronger than (A2′) and the requirement that

$$\tilde{H}(u) \stackrel{\text{def}}{=} I + \alpha^{-1}\chi_{\bar{I}}K'(u)\chi_{\bar{I}}, \quad \bar{I} = \Omega \setminus \bar{A}, \tag{52}$$

has an inverse for all $u \in \mathcal{B}$, $\|u - \bar{u}\|_s < \tilde{\rho}$ with $\|\tilde{H}(u)^{-1}\|_{q,q} \le C_{\tilde{H}}$ (in [17] only $s = \infty$ is considered).

We use the following analogue of Assumption 2.2 in [17] which implies the local Lipschitz continuity of $K : \mathcal{B} \subset L^q \longrightarrow L^s$ in $\bar{u}$.

Assumption.

(A4) *There is* $\rho_K > 0$ *such that for all* $u \in \mathcal{B}$ *with* $\|u - \bar{u}\|_s < \rho_K$

$$\|K'(u)\|_{q,s} \le C_{K'}.$$

Here $K'(u) \in \mathcal{L}(L^p, L^{p'})$ *denotes the Fréchet derivative of* K *at* u.

The following lemma shows that (A3) is satisfied if (A3) holds for $\tilde{H}(u)$ defined in (52) instead of $H(u)$. Hence, (A3) is implied by Assumptions 2.2 and 2.3 in [17] for the choice $s = \infty$.

LEMMA 8.3. *Let* (O1), (O2), *and* (C) *hold at* $\bar{u}$, $\bar{A}$ *denote the active set, and* $\bar{I} = \bar{A}^c$. *If Assumptions* (A1), (A2′), *and* (A4) *are satisfied, then the following is true: If there is* $\bar{\rho} > 0$ *such that for all* $u \in \mathcal{B}$, $\|u - \bar{u}\|_s < \bar{\rho}$,

$$\bar{H}(u) \stackrel{\text{def}}{=} I + \alpha^{-1}\chi_{\bar{I}}K'(u) : L^q \longrightarrow L^q$$

is invertible with $\|\bar{H}(u)^{-1}\|_{q,q} \le C_{\bar{H}}$, *then* (A3) *holds for* $\rho_H > 0$ *sufficiently small.*

The lemma remains true if $\bar{H}(u)$ *is replaced by* $\tilde{H}(u)$ *defined in* (52) *since the uniformly bounded invertibility of* $\tilde{H}(u)$ *implies that of* $\bar{H}(u)$:

$$\bar{H}(u)^{-1} = \tilde{H}(u)^{-1} \cdot \left(I - \alpha^{-1}\chi_{\bar{I}}K'(u)\chi_{\bar{A}}I\right). \tag{53}$$

Proof. We note that $H(u)$ in Assumption (A3) can be equivalently replaced by

$$\hat{H}(u) \stackrel{\text{def}}{=} \frac{\chi_{\{d(u)<c\}}|g(u)|}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}I + \frac{d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\nabla^2 f(u)$$

if (A1) and (A2′) are satisfied. This follows from the identity

$$\hat{H}(u) = \frac{|g(u)| + d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}H(u)$$

and the fact that the first factor is continuously invertible, since

$$\frac{|g(u)| + d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)} \in \begin{cases} [\min\{\|\alpha\|_\infty^{-1}, 1\}, \max\{\alpha_0^{-1}, 1\}] & \text{on } \{d(u) < c\}, \\ [\|\alpha\|_\infty^{-1}, \alpha_0^{-1}(1 + \nu^{-1}C_g)] & \text{on } \{d(u) \ge c\}. \end{cases}$$

In particular, there exists a constant $C_{\hat{H}H}$ with

$$\|H(u)^{-1}\|_{q,q} \le C_{\hat{H}H}\|\hat{H}(u)^{-1}\|_{q,q}.$$

According to a standard result of operator theory we can establish (A3) with $C_H = 2C_{\hat{H}H}C_{\bar{H}}$ by finding $\rho_H > 0$ such that $\|\bar{H}(u) - \hat{H}(u)\|_{q,q} \le 1/(2C_{\bar{H}})$ for all $u \in \mathcal{B}^\circ$, $\|u - \bar{u}\|_s < \rho_H$. To this end, let $\rho \le \min\{1, \bar{\rho}, \rho_K\}$ and $u \in \mathcal{B}^\circ$, $\|u - \bar{u}\|_s < \rho$, be arbitrary. We will adjust ρ as the proof proceeds. We observe that

$$\bar{H}(u) - \hat{H}(u) = \left(\frac{\chi_{\bar{I}}}{\alpha} - \frac{d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\right)K'(u), \tag{54}$$

apply Lemma 2.3 with $q_0 = q$, $q_1 = s/q$, $q_1' = s/(s-q)$, use (A4), and obtain

$$\begin{aligned} \|\bar{H}(u) - \hat{H}(u)\|_{q,q} &\le \left\|\frac{\chi_{\bar{I}}}{\alpha} - \frac{d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\right\|_{\frac{qs}{s-q}} \|K'(u)\|_{q,s} \\ &\le \left\|\frac{\chi_{\bar{I}}}{\alpha} - \frac{d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\right\|_{\frac{qs}{s-q}} C_{K'}. \end{aligned}$$

We notice that $q \le \hat{q} \stackrel{\text{def}}{=} qs/(s-q) < \infty$ ($\hat{q} = q$ if $s = \infty$) and split Ω to estimate the first factor in the last expression. For

$$B(u) \stackrel{\text{def}}{=} \left\{x \in \Omega : \chi_{\{d(u)<c\}}(x)|g(u)(x)| + \alpha(x)d(u)(x) \le \sqrt{\rho}\right\}$$

and $\rho < \nu^2\alpha_0^2$ we have $B(u) \subset \{d(u) < c\}$, and thus with $\alpha_1 = \min\{\alpha_0, 1\}$

$$B(u) \subset \{x \in \Omega : \alpha_1|g(u)(x)| + \alpha_1 d(u)(x) \le \sqrt{\rho}\} = N_{\sqrt{\rho}/\alpha_1}(u).$$

Denote the complement of $B(u)$ by $B^c(u)$. The key observation is that the parenthesis in (54) is small on $B^c(u)$ and the measure of the residual set $B(u)$ is small as well. We get by Lemma 5.7 and Minkowski's inequality

$$\begin{aligned}\left\|\frac{\chi_{\bar I}}{\alpha} - \frac{d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\right\|_{\hat q, B(u)} &\le \frac{1}{\alpha_0}\mu(B(u))^{1/\hat q} \le \frac{1}{\alpha_0}\mu(N_{\sqrt{\rho}/\alpha_1}(u))^{1/\hat q}\\ &\le \frac{1}{\alpha_0}\left(\omega\left(2\frac{\sqrt{\rho}}{\alpha_1}\right) + ((L_g + L_d)\alpha_1\sqrt{\rho})^s\right)^{1/\hat q}\\ &\le \frac{1}{\alpha_0}\left(\omega\left(2\frac{\sqrt{\rho}}{\alpha_1}\right)^{1/\hat q} + ((L_g + L_d)\alpha_1\sqrt{\rho})^{s/\hat q}\right).\end{aligned}$$

Moreover, we obtain as in the proof of Theorem 5.10

$$\left\|\frac{\chi_{\bar I}}{\alpha} - \frac{d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\right\|_{\hat q, B^c(u)} \le C_1 \left\|\frac{\chi_{\bar I}}{\alpha} - \frac{d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\right\|_{s, B^c(u)}^{\min\{1, s/\hat q\}}$$

by applying Lemma 2.2 in the case $s < \hat q$ (note that the function under the norm is nonnegative and pointwise bounded by $1/\alpha_0$). We can choose $C_1 = m_{\hat q, s}$ if $\hat q \le s$ and $C_1 = \alpha_0^{-1+s/\hat q}$ if $s < \hat q$. Since $g(\bar u) = 0$ a.e. on $\bar I$ by (O2) we get with (A2)

$$\begin{aligned}\left\|\frac{\chi_{\bar I}}{\alpha} - \frac{d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\right\|_{s, B^c(u)\cap\bar I} &= \left\|\frac{\chi_{\{d(u)<c\}}|g(u) - g(\bar u)|}{\alpha\left(\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)\right)}\right\|_{s, B^c(u)\cap\bar I}\\ &\le \left\|\frac{g(u) - g(\bar u)}{\alpha_0\sqrt{\rho}}\right\|_s \le \frac{L_g}{\alpha_0}\sqrt{\rho}.\end{aligned}$$

The fact that $d(\bar u) = 0$ a.e. on $\bar A$ yields together with Lemma 5.3

$$\begin{aligned}\left\|\frac{\chi_{\bar I}}{\alpha} - \frac{d(u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\right\|_{s, B^c(u)\setminus\bar I} &= \left\|\frac{d(u) - d(\bar u)}{\chi_{\{d(u)<c\}}|g(u)| + \alpha d(u)}\right\|_{s, B^c(u)\setminus\bar I}\\ &\le \left\|\frac{d(u) - d(\bar u)}{\sqrt{\rho}}\right\|_s \le L_d\sqrt{\rho}.\end{aligned}$$

Hence, there are constants $C_1, C_2 > 0$ such that

$$\|\bar H(u) - \hat H(u)\|_{q,q} \le \left(C_1\omega\left(2\frac{\sqrt{\rho}}{\alpha_1}\right)^{1/\hat q} + C_2\sqrt{\rho}^{\min\{1, \frac{s}{\hat q}\}}\right) C_{K'}.$$

Due to Lemma 5.7, after a possible reduction of $\rho > 0$ the right-hand side is $\le 1/(2C_{\bar H})$ and the choice $\rho_H = \rho$ completes the first part of the proof.

Now assume that the assumptions hold for $\tilde H(u)$ instead of $\bar H(u)$. We only have to verify the explicit formula (53) for $\bar H(u)^{-1}$. For $v \in L^q$ we look at the equation

$$v = \bar H(u)h = \tilde H(u)h + \alpha^{-1}\chi_{\bar I}K'(u)\chi_{\bar A}h. \tag{55}$$

Premultiplication by $\chi_{\bar{A}}$ shows $h_{\bar{A}} = v_{\bar{A}}$, and hence

$$h = \tilde{H}(u)^{-1}\left(v - \alpha^{-1}\chi_{\bar{I}}K'(u)v_{\bar{A}}\right).$$

Therefore, the operator given in (53) is a left inverse of $\bar{H}(u)$. It is also a right inverse; to see this we note that $\chi_{\bar{A}}\tilde{H}(u) = \chi_{\bar{A}}I$, hence $\chi_{\bar{A}}\tilde{H}(u)^{-1} = \chi_{\bar{A}}I$, and, consequently,

$$(\tilde{H}(u) + \alpha^{-1}\chi_{\bar{I}}K'(u)\chi_{\bar{A}}I)\tilde{H}(u)^{-1}(I - \alpha^{-1}\chi_{\bar{I}}K'(u)\chi_{\bar{A}}I) = I,$$

where we have used the fact that $\chi_{\bar{A}}\alpha^{-1}\chi_{\bar{I}} = 0$. □

Remark 8.4. The results of Lemma 8.3 remain true if α also depends on u. □

9. Second-order sufficient conditions. We will now study how Algorithm 5.16 behaves in the neighborhood of a point $\bar{u}$ satisfying the second-order sufficient condition given by Dunn and Tian in [9]. We will show that it implies (A3) in the case $q = 2$ under the additional assumptions of the previous section and also for $q > 2$ if the range of $\tilde{H}(u)$ is dense in L^q. In section 10 we will use this sufficiency condition to show that the developed affine-scaling Newton method produces acceptable steps for the trust-region globalization considered in [26] if the iterates u_k are close enough to $\bar{u}$. In our notation, the second-order sufficiency conditions by Dunn and Tian [9] read as follows.

ASSUMPTION (second-order sufficient conditions by Dunn and Tian).
(OS) *Condition* (A1) *holds and there are* $t \in [1,\infty]$, $c_r > 0$ *such that*

$$|\langle v, \nabla^2 f(u)w\rangle| \le c_r\|v\|_2\|w\|_2 \quad \textit{for all } u \in \mathcal{B}, v, w \in L^\infty, \tag{56}$$

$$\lim_{\substack{u\in\mathcal{B}\\ \|u-\bar{u}\|_t\to 0}} \sup_{\substack{w\in L^\infty\\ \|w\|_2=1}} \langle w, (\nabla^2 f(u) - \nabla^2 f(\bar{u}))w\rangle = 0. \tag{57}$$

Moreover, (O1), (O2) *are satisfied at* $\bar{u}$ *and there are sets* $A \subset \bar{A}$, $I = A^c$ *and constants* $c_1, c_2 > 0$ *with*

$$g(\bar{u}) \ge c_1 \quad \textit{on } A, \quad \langle \chi_I w, \nabla^2 f(\bar{u})\chi_I w\rangle \ge c_2\|\chi_I w\|_2^2 \quad \textit{for all } w \in L^\infty. \tag{58}$$

Remark 9.1. Dunn and Tian [9] deduce (58) from the second-order necessary conditions (see also [26]), if in addition a pointwise strict complementarity condition similar to (C), the standard L^2 coercivity analogue of the necessary conditions (i.e., the second condition in (58) only for $\bar{I} = \bar{A}^c$ instead of I), and certain structure/continuity conditions hold that are typically satisfied by Bolza ODE optimal control problems. In such cases, the gap between the sufficient condition (OS) and the necessary conditions is therefore narrower than it might appear. Extensions of these results to the case of general pointwise affine constraints are established in [10], [11]. In particular, the application of the theory in [10] to nonnegativity constraints improves the sufficiency result in [9]. □

Remark 9.2. Condition (OS) is weaker (stronger) than the sufficient second-order condition of Maurer in [23] if $\|\cdot\|_2$ (respectively, $\|\cdot\|_1$) is chosen as the weak norm. Since we prefer a result of the form $f(u) - f(\bar{u}) \ge C\|u - \bar{u}\|_l^2$ for $l = 2$ rather than for $l = 1$, condition (OS) better meets our requirements. Moreover, it is obvious that in view of Lemma 2.2 the requirement $t \in [1,\infty)$ could be equivalently replaced by $t \in \{2,\infty\}$ since the relative topology of L^t on $\mathcal{B}$ is the same for all $t \in [1,\infty)$. □

9.1. L^∞-optimality. The following theorem shows that (OS) implies the L^∞-optimality of $\bar u$ for (P) (cf. [9]).

THEOREM 9.3. *Let the formal second-order sufficiency condition* (OS) *hold. Then $\bar u$ is a strict L^∞-optimizer for* (P)*, more precisely: There are $\rho > 0$ and $C > 0$ such that*

$$u \in \mathcal{B},\ \|u-\bar u\|_\infty < \rho \Longrightarrow f(u) - f(\bar u) \geq C\|u-\bar u\|_2^2.$$

Proof. The proof is a variant of the one given for Lemma 1 in [9]. Let $u \in \mathcal{B}$. With $v = u - \bar u$ we get from (OS)

$$\begin{aligned} f(u) - f(\bar u) &= \langle v, g(\bar u)\rangle + \frac{1}{2}\left(\langle v_I, \nabla^2 f(u) v_I\rangle + \langle v_A, \nabla^2 f(u)(v_A + 2v_I)\rangle\right) + o(\|v\|_2^2) \\ &\geq c_1\|v_A\|_1 + \frac{c_2}{2}\|v_I\|_2^2 - \frac{c_r}{2}\left(\|v_A\|_2^2 + 2\|v_A\|_2\|v_I\|_2\right) + o(\|v\|_2^2) \\ &\geq c_1\frac{\|v_A\|_2^2}{\|v_A\|_\infty} + \frac{c_2}{2}\|v_I\|_2^2 - \frac{c_r}{2}\left(1 + \frac{2c_r}{c_2}\right)\|v_A\|_2^2 - \frac{c_2}{4}\|v_I\|_2^2 + o(\|v\|_2^2) \\ &\geq \left(\frac{c_1}{\|v_A\|_\infty} - \frac{c_r(2c_r + c_2)}{2c_2}\right)\|v_A\|_2^2 + \frac{c_2}{4}\|v_I\|_2^2 + o(\|v\|_2^2), \end{aligned}$$

where we have used $2\alpha\beta \leq c\alpha^2 + \beta^2/c$ with $c = c_2/(2c_r)$. Note that $o(\|v\|_2^2)$ is meant for $\|v\|_\infty \to 0$. We see that the assertion follows for all $u \in \mathcal{B}$ with $\|u-\bar u\|_\infty < \rho$ if $\rho > 0$ is small enough. ∎

9.2. L^2-optimality. We make now additional assumptions on the structure of the second derivative which are met by the class of regularized problems considered in the previous section and are similar to those in [25].

ASSUMPTION.

(A5) $\nabla^2 f(u) = \beta(u)I + K'(u)$, *where $\beta : \mathcal{B} \subset L^2 \longrightarrow L^\infty$ is continuous and K' satisfies* (A4) *for suitable $2 \leq q < s \leq \infty$.*

We have the following variant of Theorem 4 in [9].

THEOREM 9.4. *Let the formal second-order sufficiency condition* (OS) *with $t < \infty$ (i.e., also for $t = 2$) and* (A5) *hold. If, in addition, $\beta(\bar u)(x) \geq \beta_0 > 0$ a.e. on Ω, then $\bar u$ is a strict L^2-optimizer (and hence L^t-optimizer, $t \in [1,\infty]$) for* (P) *in the following sense: There are $\rho > 0$ and $C > 0$ such that*

$$u \in \mathcal{B},\ \|u-\bar u\|_2 < \rho \Longrightarrow f(u) - f(\bar u) \geq C\|u-\bar u\|_2^2.$$

Proof. We compute as in the proof of Theorem 9.3

$$\begin{aligned} f(u) - f(\bar u) &\geq c_1\|v_A\|_1 + \frac{c_2}{2}\|v_I\|_2^2 + \frac{\beta_0}{2}\|v_A\|_2^2 + \frac{1}{2}\langle v_A, K'(u)(v_A + 2v_I)\rangle + o(\|v\|_2^2) \\ &\geq c_1\|v_A\|_1 + \frac{c_2}{2}\|v_I\|_2^2 + \frac{\beta_0}{2}\|v_A\|_2^2 - \|K'(u)\|_{q,s}\|v_A\|_{s'}\|v\|_q + o(\|v\|_2^2), \end{aligned}$$

where $v = u - \bar u$ and $1/s + 1/s' = 1$. Then $1 \leq s' < 2 \leq q < s$ and $1/q + 1/s' \stackrel{\text{def}}{=} 1 + \delta > 1$ because of $s > q$. Now by Lemma 2.2

$$\|v_A\|_{s'} \leq \|v_A\|_1^{1/s'}\|v_A\|_\infty^{1-1/s'}, \quad \|v\|_q \leq \|v\|_2^{2/q}\|v\|_\infty^{1-2/q}.$$

Since $\|v_A\|_\infty \leq \|v\|_\infty \leq \|b-a\|_\infty$, we find $C_1 > 0$ with

$$\|v_A\|_{s'}\|v\|_q \leq C_1\|v_A\|_1^{1/s'}\|v\|_2^{2/q} \leq C_1\left(\frac{1}{p_1'}\|v_A\|_1^{p_1'/s'} + \frac{1}{p_1}\|v\|_2^{2p_1/q}\right)$$

for all $p_1, p_1' \in (1,\infty)$, $1/p_1 + 1/p_1' = 1$, according to Young's inequality. We choose $p_1 = q(1+\varepsilon)$ and get

$$\frac{1}{p_1'} = 1 - \frac{1}{q(1+\varepsilon)} = \frac{1}{s'} + \frac{1}{q} - \frac{1}{q(1+\varepsilon)} - \delta < \frac{1}{s'(1+\varepsilon')}$$

for $\varepsilon, \varepsilon' > 0$ small enough. Hence, for $\|v\|_2$ small

$$\|K'(u)\|_{q,s}\|v_A\|_{s'}\|v\|_q \le C_K C_1(\|v_A\|_1^{1+\varepsilon'} + \|v_A\|_2^{2+2\varepsilon}),$$

which completes the proof. □

We shall now study in which cases condition (A3) is implied by the formal second-order sufficiency condition (OS). We will thereby restrict ourselves to problems which satisfy the structural assumptions of section 8.

THEOREM 9.5. *Let* (OS), (A2′) *with* $t < \infty$, *and* (A4) *hold. Then the following is true:*

(1) *If* $q = 2$, *then* (A3) *is satisfied.*

(2) *For* $q > 2$ *there are* $\rho > 0$ *and* $C_{\tilde H} > 0$ *such that for all* $u \in \mathcal{B}^\circ$, $\|u - \bar u\|_s < \rho$, *the operator* $\tilde H(u)$ *in* (52) *has the properties*

(i) $\tilde H(u) \in \mathcal{L}(L^q, L^q)$ *and* $\|\tilde H(u)v\|_q \ge C_{\tilde H}\|v\|_q$ *for all* $v \in L^q$;

(ii) *the range of* $\tilde H(u) : L^q \longrightarrow L^q$ *is closed in* L^q.

Hence, if $K' : \mathcal{B} \subset L^s \longrightarrow \mathcal{L}(L^q, L^q)$ *is continuous at* $\bar u$ *and if the range of* $\tilde H(\bar u)$ *is dense in* L^q, *then* (A3) *is satisfied.*

Proof. Let $0 < \rho \le \rho_K$ and $u \in \mathcal{B}$, $\|u - \bar u\|_s < \rho$. We will adjust ρ in what follows. By (A4) and the definition of $\tilde H(u)$ we have $\tilde H(u) \in \mathcal{L}(L^q, L^q)$ and

$$\langle \alpha v, \tilde H(u)w\rangle \le (m_{2,q}^2\|\alpha\|_\infty + m_{q',s}C_{K'})\|v\|_q\|w\|_q \quad \text{for all } v, w \in L^q. \tag{59}$$

From $t < \infty$, Lemmas 2.1 and 2.2 we deduce that $u \in \mathcal{B}$, $\|u - \bar u\|_s \to 0$ implies $\|u - \bar u\|_t \to 0$. Using $\alpha(\tilde H(u) - \tilde H(\bar u)) = \chi_{\bar I}(\nabla^2 f(u) - \nabla^2 f(\bar u))\chi_{\bar I}$ we obtain from (A2′) and (57) by a density argument in L^q

$$\lim_{\substack{u\in\mathcal{B}\\ \|u-\bar u\|_s\to 0}} \sup_{\substack{w\in L^q\\ \|w\|_2=1}} \langle w, (\tilde H(u) - \tilde H(\bar u))w\rangle = 0. \tag{60}$$

For arbitrary $w \in L^q$ we have with (OS)

$$\begin{aligned}
\langle \alpha w, \tilde H(\bar u)w\rangle &= \langle \alpha w, w\rangle + \langle \alpha w_{\bar I}, \alpha^{-1}K'(\bar u)w_{\bar I}\rangle\\
&= \langle \alpha w_{\bar A}, w_{\bar A}\rangle + \langle \alpha w_{\bar I}, w_{\bar I}\rangle + \langle w_{\bar I}, K'(\bar u)w_{\bar I}\rangle\\
&= \langle \alpha w_{\bar A}, w_{\bar A}\rangle + \langle w_{\bar I}, \nabla^2 f(\bar u)w_{\bar I}\rangle\\
&\ge \alpha_0\|w_{\bar A}\|_2^2 + c_2\|w_{\bar I}\|_2^2 \ge \min\{\alpha_0, c_2\}\,\|w\|_2^2 \stackrel{\text{def}}{=} C_1\|w\|_2^2.
\end{aligned}$$

Together with (60) this shows that for sufficiently small $\rho > 0$ we have

$$\langle \alpha w, \tilde H(u)w\rangle \ge \frac{C_1}{2}\|w\|_2^2 \quad \text{for all } w \in L^q. \tag{61}$$

Hence, in the case $q = 2$ the symmetric operator $\alpha\tilde H(u) \in \mathcal{L}(L^2, L^2)$ is bounded by (59) and positive by (61). We therefore may apply the Lax–Milgram theorem (which in our symmetric case is an immediate consequence of Riesz's representation theorem), yielding that $\tilde H(u)$ is continuously invertible in $\mathcal{L}(L^2, L^2)$ with $\|\tilde H(u)^{-1}\|_{2,2} \le 2\|\alpha\|_\infty/C_1$. By Lemma 8.3 this implies (A3) for sufficiently small $\rho_H > 0$.

Next we assume $q > 2$ and establish the second part of (2i). Let $w \in L^q$ be arbitrary. For $c > 0$ which will be adjusted later we consider two cases: If $\|w\|_2 \geq c\|w\|_q$, then by (61)

$$\frac{cC_1}{2}\|w\|_2\|w\|_q \leq \frac{C_1}{2}\|w\|_2^2 \leq \langle \alpha w, \tilde{H}(u)w\rangle \leq \|\alpha\|_\infty m_{q',2}\|w\|_2\|\tilde{H}(u)w\|_q,$$

from which

$$\|\tilde{H}(u)w\|_q \geq \frac{cC_1}{2\|\alpha\|_\infty m_{q',2}}\|w\|_q.$$

In the case $\|w\|_2 < c\|w\|_q$ we compute

$$\|\tilde{H}(u)w\|_q \geq \|w\|_q - \frac{1}{\alpha_0}\|\chi_{\bar{I}}K'(u)w_{\bar{I}}\|_q \geq \|w\|_q - \frac{1}{\alpha_0}\|K'(u)w_{\bar{I}}\|_q.$$

Applying Lemma 2.2 we obtain with (A4) and suitable $\theta \in (0,1)$

$$\|K'(u)w_{\bar{I}}\|_q \leq \|K'(u)w_{\bar{I}}\|_2^\theta \|K'(u)w_{\bar{I}}\|_s^{1-\theta} \leq \|K'(u)w_{\bar{I}}\|_2^\theta (C_{K'}\|w\|_q)^{1-\theta}.$$

Obviously, (59) also holds with the left side replaced by $|\langle v, \nabla^2 f(u)w\rangle|$. Therefore, (56) implies by a density argument together with (A2′) and (A4) that

$$\|K'(u)v\|_2 = \|\nabla^2 f(u)v - \alpha v\|_2 \leq (c_r + \|\alpha\|_\infty)\|v\|_2 \stackrel{\text{def}}{=} C_r\|v\|_2 \quad \text{for all } v \in L^q.$$

This gives

$$\|K'(u)w_{\bar{I}}\|_q \leq (C_r\|w\|_2)^\theta (C_{K'}\|w\|_q)^{1-\theta} \leq (C_r c)^\theta C_{K'}^{1-\theta}\|w\|_q,$$

and choosing $c > 0$ small enough we achieve

$$\|\tilde{H}(u)w\|_q \geq \frac{1}{2}\|w\|_q,$$

as long as $\|w\|_2 < c\|w\|_q$. Since $c > 0$ can be adjusted independently of w, (i) is shown.

To prove (ii), let $(w_k) \subset L^q$ be arbitrary. Then

$$\begin{aligned}
&\tilde{H}(u)w_k \stackrel{L^q}{\to} v \in L^q \quad (k \to \infty)\\
&\stackrel{\text{(i)}}{\Longrightarrow} \|w_k - w_l\|_q \leq C_{\tilde{H}}^{-1}\|\tilde{H}(u)w_k - \tilde{H}(u)w_l\|_q \to 0 \quad (k,l \to \infty)\\
&\Longrightarrow w_k \stackrel{L^q}{\to} w \in L^q \quad (k \to \infty) \stackrel{\text{(i)}}{\Longrightarrow} \tilde{H}(u)w_k \stackrel{L^q}{\to} \tilde{H}(u)w \quad (k \to \infty).
\end{aligned}$$

If the range of $\tilde{H}(\bar{u}) : L^q \longrightarrow L^q$ is dense, then $\tilde{H}(\bar{u})$ is injective by (i) and surjective by (ii). Thus, it has a continuous inverse by the open mapping theorem and (i) shows $\|\tilde{H}(\bar{u})^{-1}\|_{q,q} \leq C_{\tilde{H}}^{-1}$. If, in addition, $K' : \mathcal{B} \subset L^s \longrightarrow \mathcal{L}(L^q, L^q)$ is continuous at $\bar{u}$, then for $\|u - \bar{u}\|_s$ small enough $\tilde{H}(u)^{-1} \in \mathcal{L}(L^q, L^q)$ exists and (A3) is satisfied for sufficiently small $\rho_H > 0$. ∎

The previous result shows that—at least in the case $q = 2$—the application of Algorithm 5.16 to the class of problems considered in section 8 leads to superlinear convergence in a neighborhood of a point $\bar{u}$ satisfying (OS). This is especially important since formal sufficiency conditions of type (OS) are the usual starting point for proving that a rapidly convergent local method meets the trial step requirements of a globally convergent algorithm in a neighborhood of a local optimizer. Hence, it is important that the local convergence theory can be established under a sufficiency condition that is as weak as possible.

10. Trust-region globalization. The aim of this section is to show that near a local optimizer satisfying (OS) Algorithm 5.16 produces admissible trial steps for the globally convergent affine-scaling interior-point trust-region algorithm that we proposed and analyzed in [26]. The trust-region globalization extends ideas of Coleman and Li in [7] and uses the fact that $u^n \in L^q$ solves (7) for given $u^c \in \mathcal{B}^\circ$ if and only if u^n is a stationary point of the quadratic function $\psi[u^c] : L^q \longrightarrow \mathbb{R}$,

$$\psi[u^c](u) \stackrel{\text{def}}{=} \langle u - u^c, g(u^c)\rangle + \frac{1}{2}\langle u - u^c, M(u^c)(u - u^c)\rangle, \tag{62}$$
$$\text{where} \quad M(u) \stackrel{\text{def}}{=} d(u)^{-1}G(u) = \chi_{\{d(u)<c\}}|g(u)|d(u)^{-1}I + \nabla^2 f(u).$$

Here and in the following we use the standard notation s for the trial steps although it collides with the norm index occurring in (A2). There is no danger of ambiguity. As shown in [26], a globally convergent algorithm can be obtained as follows: Denote by $u_k \in \mathcal{B}^\circ$ the current iterate. We compute a trial step s_k as an approximate solution to the trust-region subproblem

$$\text{minimize } \psi[u_k](u_k + s) \text{ subject to } u_k + s \in \mathcal{B},\ \|s\|_q \le \Delta_k. \tag{63}$$

This trial step is required to satisfy the following.

Fraction of Cauchy decrease condition.

(D) $u_k + s_k \in \mathcal{B}^\circ$, $\|s_k\|_q \le \beta_0\Delta_k$, *and* $\psi[u_k](u_k + s_k) \le \beta\psi[u_k]^c$, *where*

$$\psi[u_k]^c \stackrel{\text{def}}{=} \beta \min\{\psi[u_k](u_k + s)s = -\tau d_k^\vartheta g_k,\ \tau \ge 0,\ u_k + s \in \mathcal{B},\ \|s\|_q \le \Delta_k\}$$

with fixed constants $\beta_0 > 0$, $0 < \beta < 1$, $\vartheta \ge 1$. The step s_k is accepted, i.e., $u_{k+1} = u_k + s_k$, if $r_k > \eta_1$, where $0 < \eta_1 < 1$ is fixed and the decrease ratio $r_k = r(u_k, s_k)$ is given by

$$r(u_k, s_k) \stackrel{\text{def}}{=} \frac{f(u_k + s_k) - f(u_k)}{\langle s_k, g(u_k)\rangle + \langle s_k, \nabla^2 f(u_k)s_k\rangle/2}.$$

Otherwise, i.e., if $r_k \le \eta_1$, the step is rejected: $u_{k+1} = u_k$. For our presentation it is convenient to use an update rule for the trust-region radius Δ_k that is slightly different from the one given in [26]. However, it is not hard to verify that all the convergence results stated therein remain valid. In our update rule we fix $0 < \eta_1 < \eta_2 < \eta_3 < 1$, $0 < \beta_0\gamma_0 \le \gamma_1 < 1 < \gamma_2 \le \gamma_3$, $\Delta_{\min} > 0$, and choose

$$\Delta^+ \in \begin{cases} [\gamma_0\|s_k\|_q, \gamma_1\Delta_k] & \text{if } r_k \le \eta_1, \\ [\gamma_1\Delta_k, \Delta_k] & \text{if } \eta_1 < r_k < \eta_2, \\ [\Delta_k, \gamma_2\Delta_k] & \text{if } \eta_2 < r_k < \eta_3, \\ [\gamma_2\Delta_k, \gamma_3\Delta_k] & \text{else,} \end{cases} \qquad \Delta_{k+1} := \begin{cases} \Delta^+ & \text{if } r_k \le \eta_1, \\ \max\{\Delta_{\min}, \Delta^+\} & \text{else.} \end{cases}$$

For a detailed formulation of the algorithm and its convergence properties we refer to [26]. The theory developed therein (adapted to our update rule) states that under Assumption (A1) each accumulation point of the sequence (u_k) satisfies the first-order necessary optimality conditions (O1), (O2), and, moreover, the second-order necessary condition [26, Thm. 3.3, (O3)] if (D) is replaced by a fraction of optimal decrease condition.

Keeping in mind that trust-region methods for unconstrained problems inherit their local convergence behavior from Newton's method, it is natural to try to accelerate the above trust-region method by means of Algorithm 5.16. We combine both methods as follows.

ALGORITHM 10.1 (trust-region interior-point Newton method).

1. Choose $\Delta_k \geq \Delta_{\min}$, $u_0 \in \mathcal{B}^\circ$.
2. For $k = 0, 1, 2, \ldots$
   - 2.1. If $d(u_k)g(u_k) = 0$, STOP.
   - 2.2. Select and perform a smoothing step: $u_k^s = S_k^\circ(u_k)$.
   - 2.3. Compute a trial step by Algorithm 5.16: $s_k = \min\{1, \Delta_k/\|s_k^N\|_q\}s_k^N$, where

$$s_k^N = u_{k+1}^N - u_k^s,\ u_{k+1}^N = P[u_k^s](u_{k+1}^n),\ u_{k+1}^n = u_k^s - G(u_k^s)^{-1}d(u_k^s)g(u_k^s).$$

     If s_k satisfies (D) for $\psi[u_k^s]$ then goto step 2.5.
   - 2.4. Compute a trial step that satisfies (D) for $\psi[u_k^s]$, e.g., by a descent method that starts with a line search along $-d(u_k^s)^\vartheta g(u_k^s)$.
   - 2.5. Compute the decrease ratio $r_k = r(u_k^s, s_k)$ and the new trust-region radius Δ_{k+1}. If $r_k > \eta_1$ then set $u_{k+1} = u_k^s + s_k$. Otherwise set $u_{k+1} = u_k^s$ and go to step 2.2.

Now suppose that one of the accumulation points $\bar{u} \in \mathcal{B}$ of (u_k) satisfies the second-order sufficiency condition (OS). The question is: Does this globally convergent method eventually turn into Algorithm 5.16 and thus inherit its superlinear convergence?

It is beyond the scope of this paper to answer this question in full generality, since this would require us to analyze the effect of the smoothing step on the global convergence behavior of the trust-region algorithm. We try to find a reasonable compromise by developing results that are rigorously applicable whenever the smoothing steps do not affect the global convergence. This is certainly the case if the smoothing steps decrease the objective function f; see Remark 8.2 in this context. Moreover, we require the following.

ASSUMPTION.

(A6) *$\bar{u} \in \mathcal{B}$ is an accumulation point of (u_k) at which* (OS) *holds. Moreover, condition* (A2) *is satisfied with $r = s = \infty$.*

As a first result we show that the quadratic model $\psi[u_k^s]$ has a unique minimizer if $\|u_k^s - \bar{u}\|_\infty$ is sufficiently small. To show this, we first prove the following lemma.

LEMMA 10.2. *Let* (A6) *hold. Then there are $\rho > 0$, $C_M > 0$ such that*

$$\langle v, M(u)v\rangle \geq C_M\|v\|_2^2 \quad \textit{for all } v \in L^q$$

for all $u \in \mathcal{B}^\circ$, $\|u - \bar{u}\|_\infty < \rho$.

Proof. We know that (O1), (O2) hold at $\bar{u}$. Let I and A be defined as in (OS). Since $|g(\bar{u})| \geq c_1$ a.e. on A, we get by (O2) that $d(\bar{u}) = 0$ a.e. on A and hence for sufficiently small $\rho > 0$ and all $u \in \mathcal{B}^\circ$, $\|u - \bar{u}\|_\infty < \rho$

$$|g(u)| \geq c_1/2 \quad \text{and} \quad c > d(u) \leq L_d\rho \quad \text{a.e. on } A$$

by (A2) and Lemma 5.3, respectively. (A2) yields with a density argument in L^q that (56)–(58) hold also for L^∞ replaced by L^q and thus, possibly after reducing ρ, we have

$$\langle v_I, \nabla^2 f(u)v_I\rangle \geq \frac{c_2}{2}\|v_I\|_2^2 \ \text{ for all } v \in L^q$$

as long as $u \in \mathcal{B}^\circ$, $\|u - \bar{u}\|_\infty < \rho$. Hence, for all $v \in L^q$

$$\begin{aligned}\langle v, M(u)v\rangle &= \left\langle v_A, \frac{|g(u)|}{d(u)} v_A \right\rangle + \left\langle v_I, \frac{\chi_{\{d(u)<c\}}|g(u)|}{d(u)} v_I \right\rangle \\ &\quad + \langle v_I, \nabla^2 f(u) v_I\rangle + \langle v_A, \nabla^2 f(u)(2v_I + v_A)\rangle \\ &\geq \frac{c_1}{2L_d\rho}\|v_A\|_2^2 + \frac{c_2}{2}\|v_I\|_2^2 - c_r\|v_A\|_2^2 - 2c_r\|v_A\|_2\|v_I\|_2.\end{aligned}$$

With the standard estimate

$$2c_r\|v_A\|_2\|v_I\|_2 \leq \frac{c_2}{4}\|v_I\|_2^2 + \frac{4c_r^2}{c_2}\|v_A\|_2^2$$

we arrive at

$$\langle v, M(u)v\rangle \geq \left(\frac{c_1}{2L_d\rho} - c_r - \frac{4c_r^2}{c_2}\right)\|v_A\|_2^2 + \frac{c_2}{4}\|v_I\|_2^2.$$

Now for $\rho > 0$ sufficiently small the assertion follows. ∎

THEOREM 10.3. *Let* (A3) *and* (A6) *hold and* (u_k), (u_k^s), (u_k^n), (u_k^N) *be generated by Algorithm* 10.1. *If* ρ *is sufficiently small and* $\|u_k^s - \bar{u}\|_\infty < \rho$, *then* $u_{k+1}^n \in L^q$ *is a global minimizer of* $\psi[u_k^s]$ *and*

$$\psi[u_k^s](u_{k+1}^n) = -\frac{1}{2}\langle u_{k+1}^n - u_k^s, M(u_k^s)(u_{k+1}^n - u_k^s)\rangle \leq -\frac{C_M}{2}(\|s^e\|_2^2 + \|s^i\|_2^2), \tag{64}$$

$$\psi[u_k^s](P(u_{k+1}^n)) \leq \psi[u_k^s](u_{k+1}^n) - \frac{C_M}{2}\|s^e\|_2^2 + (c_r + \nu^{-1}L_g\rho)\|s^e\|_2\|s^i\|_2 \tag{65}$$

with $s^e = u_{k+1}^n - P(u_{k+1}^n)$, $s^i = P(u_{k+1}^n) - u_k^s$. *Moreover,*

$$\psi[u_k^s](u_{k+1}^N) \leq \max\{\xi, 1 - \|s^i\|_q\}\psi[u_k^s](P(u_{k+1}^n)), \tag{66}$$

and hence

$$\frac{\psi[u_k^s](u_{k+1}^N)}{\psi[u_k^s](u_{k+1}^n)} \geq \max\{\xi, 1 - \|s^i\|_q\}\left(1 - O\left(\frac{\|s^e\|_2}{\|s^i\|_2}\right)\right). \tag{67}$$

Proof. Setting $s = u_{k+1}^n - u_k^s$ we have $s = s^e + s^i$ and $s^e s^i \geq 0$ a.e. on Ω. We use the abbreviations $d_k = d(u_k^s)$, $g_k = g(u_k^s)$, $M_k = M(u_k^s)$. According to step (3) in Algorithm 5.16, we have $M_k s = -g_k$. Hence, u_{k+1}^n is a stationary point of $\psi[u_k^s]$ and, therefore, its global minimum by Lemma 10.2. Moreover,

$$\psi[u_k^s](u_{k+1}^n) = -\frac{1}{2}\langle s, M_k s\rangle \leq -\frac{C_M}{2}\|s^e + s^i\|_2^2 \leq -\frac{C_M}{2}(\|s^e\|_2^2 + \|s^i\|_2^2).$$

To prove the second inequality we observe that for all $x \in \Omega$ with $s(x)g_k(x) < 0$ and $d_k(x) < c(x)$ we have

$$s^e(x) = 0 \quad \text{or} \quad |s^i(x)| \geq d_k(x).$$

In fact, if $s^e(x) \neq 0$, then either $s^i(x) = b(x) - u_k^s(x) > 0$ or $s^i(x) = a(x) - u_k^s(x) < 0$. In the first case we have $g_k(x) < 0$ and thus $d_k(x) = b(x) - u_k^s(x) = s^i(x)$ or $d_k(x) < c(x) < b(x) - u_k^s(x) = s^i(x)$. The second case enforces $g_k(x) > 0$ which

implies $d_k(x) = u_k^s(x) - a(x) = |s^i(x)|$ or $d_k(x) < c(x) < u_k^s(x) - a(x) = |s^i(x)|$. Hence, we get with $N = \{x \in \Omega : s(x)g_k(x) < 0\}$ and $J = \{x \in \Omega : d_k(x) < c(x)\}$

$$\left\langle s_N^e, \frac{|g_k|_J}{d_k} s^i \right\rangle \geq -\langle s_{N\cap J}^e, g_k\rangle.$$

Using this, we obtain

$$\begin{aligned}
\psi[u_k^s](u_{k+1}^n) &= \langle s^e + s^i, g_k\rangle + \frac{1}{2}\left\langle s^e + s^i, M_k(s^e + s^i)\right\rangle \\
&= \psi[u_k^s](P(u_{k+1}^n)) + \langle s_{N^c}^e, g_k\rangle + \langle s_{N\setminus J}^e, g_k\rangle + \langle s_{N\cap J}^e, g_k\rangle + \left\langle s_N^e, \frac{|g_k|_J}{d_k} s^i \right\rangle \\
&\quad + \left\langle s_{N^c}^e, \frac{|g_k|_J}{d_k} s^i \right\rangle + \frac{1}{2}\langle s^e, M_k s^e\rangle + \langle s^e, \nabla^2 f(u_k^s) s^i\rangle \\
&\geq \psi[u_k^s](P(u_{k+1}^n)) + \langle s_{N\setminus J}^e, g_k\rangle + \frac{1}{2}\langle s^e, M_k s^e\rangle + \langle s^e, \nabla^2 f(u_k^s) s^i\rangle.
\end{aligned}$$

We still need an estimate for $\langle s_{N\setminus J}^e, g_k\rangle$. To this end, we use the inclusion $N \setminus J \subset J^c$. Since $|d_k(x) - d(\bar u)(x)| \leq L_d\rho$ and $d_k(x) \geq c(x) \geq \nu$ on J^c we have $d(\bar u)(x) > 0$ a.e. on J^c for $\rho > 0$ small enough. (O2) yields $g(\bar u)(x) = 0$ on J^c and thus

$$|\langle s_{N\setminus J}^e, g_k\rangle| \leq \|s_e\|_{1,J^c}\|g_k - g(\bar u)\|_\infty \leq L_g\rho\mu(J^c)^{1/2}\|s_e\|_2.$$

Furthermore, $|g_k(x)| \leq L_g\rho < \nu$ on J_c for small ρ, which, since $d_k(x) \geq \nu$, requires

$$\nu \leq d_k(x) \leq \min\{b(x) - u_k^s(x), u_k^s(x) - a(x)\} \leq |s^i(x)|.$$

Hence, by Lemma 2.4

$$\mu(J^c) \leq \mu\{x \in \Omega : |s^i(x)| \geq \nu\} \leq \nu^{-2}\|s^i\|_2^2.$$

We conclude $|\langle s_{N\setminus J}^e, g_k\rangle| \leq \nu^{-1}L_g\rho\|s_e\|_2\|s^i\|_2$. Therefore, (65) holds. Now

$$u_{k+1}^N - u_k^s = P[u_k^s](u_{k+1}^n) - u_k^s = \max\{\xi, 1 - \|s^i\|_q\}(P(u_{k+1}^n) - u_k^s) \stackrel{\text{def}}{=} \tau(P(u_{k+1}^n) - u_k^s).$$

This implies (66), for

$$\begin{aligned}
\psi[u_k^s](P[u_k^s](u_{k+1}^n)) &= \tau\langle s^i, g_k\rangle + \frac{\tau^2}{2}\langle s^i, M_k s^i\rangle \\
&\leq \tau\left(\langle s^i, g_k\rangle + \frac{1}{2}\langle s^i, M_k s^i\rangle\right) = \tau\psi[u_k^s](P(u_{k+1}^n)),
\end{aligned}$$

where the inequality follows from $0 \leq \tau < 1$ and $\langle s^i, M_k s^i\rangle \geq 0$; see Lemma 10.2. Now (64)–(66) and a straightforward calculation give (67). ∎

Let the assumptions of Theorem 5.10 hold. Using (34) we have for $\|u_k^s - \bar u\|_\infty$ small enough

$$\begin{aligned}
\|u_{k+1}^n - u_k^s\|_q &\leq \|u_{k+1}^n - \bar u\|_q + \|u_k^s - \bar u\|_q \leq (C\Phi_{\bar p}(\|u_k^s - \bar u\|_\infty) + m_{q,\infty})\|u_k^s - \bar u\|_\infty \\
&\leq C_\Delta\|u_k^s - \bar u\|_\infty
\end{aligned}$$

with C_Δ appropriately chosen. Now

$$\|u_{k+1}^N - u_k^s\|_q = \|P[u_k^s](u_{k+1}^n) - u_k^s\|_q \leq \|P(u_{k+1}^n) - u_k^s\|_q \leq C_\Delta\|u_k^s - \bar u\|_\infty. \tag{68}$$

Hence, for $\|u_k^s - \bar{u}\|_\infty$ small enough we have (cf. (D))

$$u_{k+1}^N \in \mathcal{B}^\circ, \quad \|u_{k+1}^N - u_k^s\|_q \le \beta_0 \Delta_{\min}.$$

Using this in Theorem 10.3 we can show that if $\|s^e\|_2/\|s^i\|_2$ eventually remains small enough, then Algorithm 10.1 turns into the superlinearly convergent Algorithm 5.16. In particular, this happens if no smoothing steps are required.

THEOREM 10.4. *Let the assumptions of Theorem* 10.3 *as well as* (C) *and* (S) *hold. Then there are $\rho > 0$, $\varepsilon > 0$ such that if step $k-1$ was accepted and $\|u_k - \bar{u}\|_q < \rho$, then $s_k = s_k^N$ and step k is accepted whenever*

$$\frac{\|u_{k+1}^n - P(u_{k+1}^n)\|_2}{\|P(u_{k+1}^n) - u_k^s\|_2} < \varepsilon \tag{69}$$

holds. If there is $C_1 > 0$ with $\|u_k^s - \bar{u}\|_\infty \le C_1 \|u_k^s - \bar{u}\|_q$, then (69) *is automatically satisfied for $\|u_k - \bar{u}\|_q$ small enough.*

Proof. Assume that step $k-1$ was accepted and $\|u_k - \bar{u}\|_q < \rho$ with $\rho > 0$ sufficiently small. We use s^e and s^i as defined in Theorem 10.3. Since $\|u_k^s - \bar{u}\|_\infty \le C_S \|u_k - \bar{u}\|_q$ by (S), we get with (68)

$$\|u_{k+1}^N - u_k^s\|_q \le \|s^i\|_q \le C_\Delta C_S \|u_k - \bar{u}\|_q \le C_\Delta C_S \rho.$$

Hence, $u_{k+1}^N = u_k^s + s_{k+1}^N \in \mathcal{B}^\circ$ with $\|s_k^N\|_q \le \Delta_{\min} \le \Delta_k$ for ρ small enough. Choose $0 < \tilde{\varepsilon} < 1$ such that $(1-\tilde{\varepsilon})^2 > \beta$ with β given in (D). Possibly after reducing ρ we achieve $\|s^i\|_q \le \tilde{\varepsilon}$. For $0 < \varepsilon < 1$ sufficiently small we have by (67) and (69)

$$\frac{\psi[u_k^s](u_{k+1})}{\psi[u_k^s](u_{k+1}^n)} \ge (1-\tilde{\varepsilon})^2 > \beta.$$

Since u_{k+1}^n is the global minimizer of $\psi[u_k^s]$ by Theorem 10.3, $s_k = s_k^N$ obviously satisfies (D) for $\psi[u_k^s]$.

Now assume $\|u_k^s - \bar{u}\|_\infty \le C_1 \|u_k^s - \bar{u}\|_q$. Then Lemma 2.2 yields with $\theta = 2/q$

$$\|u_k^s - \bar{u}\|_q \le \|u_k^s - \bar{u}\|_2^\theta \|u_k^s - \bar{u}\|_\infty^{1-\theta} \le C_1^{1-\theta} \|u_k^s - \bar{u}\|_2^\theta \|u_k^s - \bar{u}\|_q^{1-\theta}$$

and thus

$$\|u_k^s - \bar{u}\|_2 \ge C_1^{1-\frac{1}{\theta}} \|u_k^s - \bar{u}\|_q \overset{\text{def}}{=} C_3 \|u_k^s - \bar{u}\|_q.$$

To show (69) for ρ small enough we use $\|u_{k+1}^n - P(u_{k+1}^n)\|_2 \le \|u_{k+1}^n - \bar{u}\|_2$ and get

$$\begin{aligned} \|P(u_{k+1}^n) - u_k^s\|_2 &\ge \|u_k^s - \bar{u}\|_2 - \|P(u_{k+1}^n) - u_{k+1}^n\|_2 - \|u_{k+1}^n - \bar{u}\|_2 \\ &\ge \|u_k^s - \bar{u}\|_2 - 2\|u_{k+1}^n - \bar{u}\|_2 \ge \frac{C_3}{C_1} \|u_k^s - \bar{u}\|_\infty - 2\|u_{k+1}^n - \bar{u}\|_2. \end{aligned}$$

Moreover, Theorem 5.10 yields

$$\|u_{k+1}^n - \bar{u}\|_2 \le m_{2,q} \|u_{k+1}^n - \bar{u}\|_q \le m_{2,q} C \Phi_{\bar{p}}(\|u_k^s - \bar{u}\|_\infty) \|u_k^s - \bar{u}\|_\infty.$$

Hence, for $\|u_k^s - \bar{u}\|_\infty$ sufficiently small we get

$$\frac{\|u_{k+1}^n - P(u_{k+1}^n)\|_2}{\|P(u_{k+1}^n) - u_k^s\|_2} \le \left(\frac{C_3 \|u_k^s - \bar{u}\|_\infty}{C_1 \|u_{k+1}^n - \bar{u}\|_2} - 2 \right)^{-1} \le \left(\frac{C_3}{C_1 m_{2,q} C \Phi_{\bar{p}}(\|u_k^s - \bar{u}\|_\infty)} - 2 \right)^{-1}$$

and the last term is $< \varepsilon$ for small ρ, since $\Phi_{\bar{p}}(\|u_k^s - \bar{u}\|_\infty) \le \Phi_{\bar{p}}(C_s \rho)$ tends to zero as $\rho \to 0$. ∎

11. Application to a control problem. In this section we present numerical results for the application of Algorithm 5.16 to a boundary control problem governed by a nonlinear heat equation which is a simplified model for the heating of a probe in a kiln. Let $Q \stackrel{\text{def}}{=} (0,1)$ denote the spatial domain with $x = 0$ at the boundary and $x = 1$ at the inside of the probe. The temperature $y(x,t)$, $(x,t) \in Q \times (0,T) \stackrel{\text{def}}{=} Q_T$ of the probe satisfies the nonlinear heat equation

$$\begin{aligned} \tau(y)y_t - (\kappa(y)y_x)_x &= h && \text{on } Q_T, \\ \kappa(y(0,t))y_x(0,t) &= \zeta(y(0,t) - u(t)), && t \in (0,T), \\ \kappa(y(1,t))y_x(1,t) &= 0, && t \in (0,T), \\ y(x,0) &= y_0(x), && x \in Q, \end{aligned} \tag{70}$$

where $y_0 : Q \longrightarrow \mathbb{R}$ is the initial temperature, $\tau, \kappa : \mathbb{R} \longrightarrow \mathbb{R}$ denote the specific heat capacity and the heat conduction, respectively, $h : Q_T \longrightarrow \mathbb{R}$ is a source term, $\zeta \in \mathbb{R}$ a given scalar, and $u : (0,T) \longrightarrow \mathbb{R}$ the control. For consistency with our notations let $\Omega \stackrel{\text{def}}{=} (0,T)$.

The control u shall be determined in such a way that the temperature $y(1,t)$ inside the probe follows a given temperature profile $y_d(t)$. Since it is well known that this nonlinear inverse heat conduction problem is ill-posed, we add a regularization in the control space and choose as objective function

$$J(y,u) = \frac{1}{2}\int_0^T \left((y(1,t) - y_d(t))^2 + \alpha\, u(t)^2\right) dt$$

with $y_d \in L^\infty((0,T))$. The problem was considered in [5]. We define the space

$$W(0,T) \stackrel{\text{def}}{=} \left\{ y \in L^2(0,T;H^1(Q)) \,:\, y_t \in L^2(0,T;H^1(Q)') \right\}$$

with norm $\|y\|_{W(0,T)} \stackrel{\text{def}}{=} \|y\|_{L^2(0,T;H^1)} + \|y_t\|_{L^2(0,T;(H^1)')}$. It is well known that $W(0,T)$ is a Hilbert space and that the embedding $W(0,T) \hookrightarrow C(0,T;L^2(Q))$ is continuous. Under the assumption that $\kappa, \tau \in C(\mathbb{R})$ with

$$0 < \kappa_1 \le \kappa(s) \le \kappa_2, \quad 0 < \tau_1 \le \tau(s) \le \tau_2 \quad \text{for all } s \in \mathbb{R}$$

it is shown in [5] that for all $h \in L^2(0,T;L^2(Q))$, $y_0 \in L^2(Q)$, and $u \in L^2(\Omega)$ there exists a solution $y \in W(0,T)$ of the state equation (70) which satisfies the stability estimate

$$\|y\|_{W(0,T)} \le C\left(\|h\|_{L^2(0,T;L^2)} + \|u\|_2 + \|y_0\|_2\right). \tag{71}$$

Uniqueness is proven under the additional assumption $y_x \in L^\infty(0,T;L^r(Q))$, $r > 2$, and $\kappa, \tau \in C^1(\mathbb{R})$. Furthermore, it was shown that for $\alpha > 0$ there exists an optimal solution $\bar{u} \in L^2(\Omega)$ of the control problem

$$\text{minimize } J(y,u) \quad \text{subject to} \quad y \in W(0,T),\ u \in L^2(\Omega) \text{ satisfy (70).} \tag{72}$$

With the lower and upper bounds $a, b \in L^\infty(\Omega)$, $b - a \ge \nu > 0$, we introduce the additional box constraints

$$u \in \mathcal{B} \stackrel{\text{def}}{=} \left\{ u \in L^2(\Omega) \,:\, a \le u \le b \right\}. \tag{73}$$

Since $\mathcal{B}$ is a closed bounded convex subset of $L^2(\Omega)$, exactly the same arguments as in [5] can be used to prove the existence of an optimal control $\bar{u} \in \mathcal{B}$ for $\alpha \ge 0$.

Assuming that for $u \in \mathcal{B}$ the solution $y = y(u)$ to (70) is unique, we can define the reduced objective function $f(u) \stackrel{\text{def}}{=} J(y(u), u)$ for which (72), (73) is equivalent to (P). This way of eliminating y is called the black-box approach.

For the rest of this paragraph assume that κ and τ are constant. Then the existence and stability result (71) is well known. As will be shown now, it implies that the affine linear mapping $u \in L^2(\Omega) \longmapsto y(1,.) \in L^q(\Omega)$ is (even completely) continuous for $2 \le q < 4$ and therefore smooth. Thus, the objective $f : L^2(\Omega) \longrightarrow \mathbb{R}$ is a well-defined and smooth quadratic function. The case $2 < q < 4$ will be used below to derive a regularity result for the gradient. In the proof of the assertion on $u \longmapsto y(1,.)$ we use the symbol "$\hookrightarrow$" for continuous and "$\hookrightarrow\hookrightarrow$" for compact embeddings. (71) shows the continuity of $u \in L^2(\Omega) \longmapsto y \in W(0,T)$. To complete the argument we show that $y \in W(0,T) \longmapsto y(1,.) \in L^q(\Omega)$ is compact for $1 \le q < 4$. Let $1/2 < \theta < \Theta < 1$. Since $H^1(Q) \hookrightarrow\hookrightarrow H^\Theta(Q) \hookrightarrow H^1(Q)'$, we have by a Lions lemma that $W(0,T) \hookrightarrow\hookrightarrow L^2(0,T;H^\Theta(Q))$ (see [21, Thm. 5.1]). Moreover, from the interpolation result $H^\theta(Q) = [L^2(Q), H^\Theta(Q)]_{\theta/\Theta}$ it can be deduced that

$$\|\cdot\|_{L^{2\Theta/\theta}(0,T;H^\theta)} \le C \, \|\cdot\|^{1-\theta/\Theta}_{L^\infty(0,T;L^2)} \|\cdot\|^{\theta/\Theta}_{L^2(0,T;H^\Theta)}.$$

Hence, $W(0,T) \hookrightarrow L^\infty(0,T;L^2(Q))$ and $W(0,T) \hookrightarrow\hookrightarrow L^2(0,T;H^\Theta(Q))$ yield the compact embedding $W(0,T) \hookrightarrow\hookrightarrow L^{2\Theta/\theta}(0,T;H^\theta(Q))$. Finally, since $H^\theta(Q) \hookrightarrow C([0,1])$, we conclude that $y \in W(0,T) \longmapsto y(1,.) \in L^{2\Theta/\theta}(\Omega)$ is compact. Now (71) shows the complete continuity of $u \in L^2(\Omega) \longmapsto y(1,.) \in L^q(\Omega)$ for $1 \le q < 4$.

In particular, the regularization in J is necessary, since (72) is ill-posed for $\alpha = 0$.

By standard results (see [22]) the gradient representation g of $u \longmapsto J(y(u), u)$ with respect to the inner product on $L^2(\Omega)$ is given by $g(u) = \alpha u + K(u)$, where $K(u) = \zeta p(0,.)$ and the *adjoint state* p satisfies

$$\begin{aligned} \tau p_t + \kappa p_{xx} &= 0, && \text{on } Q_T, \\ \kappa p_x(0,t) &= \zeta p(0,t), && t \in (0,T), \\ \kappa p_x(1,t) &= y(1,t) - y_d(t), && t \in (0,T), \\ p(x,T) &= 0, && x \in Q \end{aligned} \tag{74}$$

in the weak sense. Using Green's function, p is given by an integral equation of Volterra type with weakly singular kernel from which one can deduce that (74) defines a completely continuous affine linear mapping $y(1,.) \in L^q(\Omega) \longmapsto p \in C(Q_T)$ for all $q > 2$ (see, e.g., [24]). Combining this with the previous considerations we obtain the complete continuity of the affine linear mapping $u \in L^2(\Omega) \longmapsto K(u) = \zeta p(0,.) \in C(\Omega)$. Hence, the Fréchet-derivative K' of $K : L^2(\Omega) \longrightarrow C(\Omega)$ exists and is given by the compact linear operator $K'(u) : v \in L^2(\Omega) \longmapsto K(v) - K(0) \in C(\Omega)$. We conclude that the assumptions (A1), (A2′), and (A4) are satisfied for $q = 2$, $s = r = \infty$ and the results of section 8 can be applied.

While similar results can be shown for nonlinear boundary conditions (cf. [24], [17], [19]), a differentiability result for the nonlinear problem (72) seems not to be available. Since (72) is of importance in applications, e.g., the sterilization of canned food, we nevertheless present numerical results for the nonlinear problems and content ourselves with the complete justification of our assumptions for the case of constant κ and τ.

11.1. Discretization. As in [14], [20] we use the discretization of (72) proposed in [5]. For the space discretization we approximate $H^1(Q)$ in the variational formulation of (70) by the space $V_{\Delta x}$ of continuous functions that are piecewise linear on

the intervals $[i\Delta x, (i+1)\Delta x]$, $\Delta x \stackrel{\text{def}}{=} 1/N_x$, $i = 0, \dots, N_x - 1$. Since the time differentiation in the variational form of (70) is linear with respect to the transformed state $\phi(y) \stackrel{\text{def}}{=} \int_0^y \tau(\xi)\, d\xi$, a discontinuous Galerkin method with respect to ϕ is used where $L^2(0,T;H^1(Q))$ is approximated by the space Y_Δ of $V_{\Delta x}$-valued functions that are piecewise constant on $(k\Delta t, (k+1)\Delta t]$, $\Delta t \stackrel{\text{def}}{=} 1/N_t$, $k = 0, \dots, N_t - 1$ (the same discretization is obtained by applying a backward Euler). This leads in a natural way to the approximation of h and y_0 by their L^2-projection onto Y_Δ and $V_{\Delta x}$, respectively. The discrete control space $U_{\Delta t}$ consists of piecewise constant functions on the same partition of $(0,T]$ and y_d is approximated by its L^2 projection onto the same space. For details we refer to [5], [14], [20].

It was shown in [5] that the resulting implicit scheme admits a unique solution for $\Delta t/\Delta x^2 \le \lambda < (\tau_2/\kappa_1 - \tau_1/\kappa_2)^{-1}/6$ that converges to a solution of (70) as $\Delta t, \Delta x$ tend to zero.

11.2. Numerical tests. For the application of Algorithm 5.16 we use Example 1 of [20] (see also [14]): $T = 0.5$, $\zeta = 1$, and

$$\tau(y) = 4 + y,\ \kappa(y) = 4 - y,\ y_d(t) = 2 - e^{-t},\ y_0(x) = 2 + \cos \pi x,$$
$$h(x,t) = (-6 + 2\pi^2)\, e^{-t} \cos \pi x + \pi^2\, e^{-2t} - (1 + 2\pi^2)\, e^{-2t} \cos^2 \pi x.$$

Then the optimal control for $\alpha = 0$ without bound constraints is $u^*(t) = 2 + e^{-t}$ with associated state $y^*(x,t) = 2 + e^{-t} \cos \pi x$. The regularization parameter was set to $\alpha = 10^{-4}$. The L^2 gradient representation of $f(u) \stackrel{\text{def}}{=} J(y(u), u)$ in U_Δ was computed via the discrete adjoint equation; cf. [5]. Since—at least in the case of constant κ and τ—$\nabla^2 f(u)$ is a compact perturbation of αI, a quasi-Newton approximation of $\nabla^2 f(u)$ like BFGS or PSB is efficient also in the L^2-Hilbert space setting; see [12], [16]. Thus, we may expect that a BFGS- or PSB-approximation of the Hessian in the discrete model performs nearly independent of the discretization; cf. [16] for the mesh-independence of BFGS. For the numerical tests, Algorithm 5.16 was embedded in the trust-region framework of [26] as described in Algorithm 10.1. We took a L^2-trust-region and used an extension of the Steihaug CG-iteration in the scaled variables $\hat{s} \stackrel{\text{def}}{=} d_k^{-1} s$ to compute an approximate solution to (63) satisfying the decrease condition (D): Let u_k^s be the current iterate and B_k the approximation of $\nabla^2 f(u_k^s)$. A CG-iteration in the scaled variable $\hat{s}$ is started. If the process leaves the trust-region or $\mathcal{B}$, or if negative curvature[1] is detected, Steihaug's method yields s_k^{SH} and $s_k^1 = \sigma s_k^{SH}$ is a candidate for step 2.4 in Algorithm 10.1. Here $\sigma \in (0,1]$ is chosen maximal such that $u_k^s + 1.0005\, s_k^1 \in \mathcal{B}$. In contrast to Steihaug's algorithm we continue the CG-iteration as long as no negative curvature is detected even if it leaves the trust-region or $\mathcal{B}$ until an inexact unconstrained minimizer s_k^n of $\psi[u_k^s](u_k^s + .)$ with $\|d_k \nabla \psi[u_k^s](u_k^s + s_k^n)\|_2 \le 10^{-4} \|d_k g_k\|_2$ is found. Then $u_k^s + s_k^n$ is an approximation for u_{k+1}^n in Algorithm 10.1 with $\nabla^2 f(u_k^s)$ replaced by B_k. If the CG-iteration left the trust-region or $\mathcal{B}$, we take $s_k^2 = \min\left(\Delta_k / \|s_k^N\|_2, 1\right) s_k^N$ with the projected step $s_k^N = P[u_k^s](u_k^s + s_k^n) - u_k^s$ according to Algorithm 10.1 and $s_k^3 = \min(\Delta_k / \|s_k^S\|_2, 1) s_k^S$ with s_k^S obtained from s_k^n by the stepsize rule 2.4′ as further candidates. In (39) and 2.4′ we took $\xi = 0.99995$. Now we set $u_{k+1} = u_k^s + s_k$, where $s_k = s_k^i$, $i \in \{1,2,3\}$ is the trial step that provides the best reduction of $\psi[u_k^s]$. As the smoothing step in 2.2 of Algorithm 10.1 we use (cf. section 8)

$$S_k^\circ(u_k) \stackrel{\text{def}}{=} \begin{cases} P[u_k](u_k - \alpha^{-1} g(u_k)) & \text{if } k \ge 1 \text{ and } \|u_k - u_{k-1}^s\|_\infty \ge 3 \|u_k - u_{k-1}^s\|_2, \\ u_k & \text{else.} \end{cases}$$

[1] This does not apply to BFGS-approximations.

For our numerical results we used a BFGS-approximation of the Hessian with $B_0 = \alpha I$. In Algorithm 10.1 we set $\vartheta = 2$, $\Delta_0 = 1$, $\eta_1 = 0.1$, $\eta_2 = 0.75$, $\eta_3 = 0.9$ and $\gamma_1 = 0.5$, $\gamma_2 = \gamma_3 = 2$. The stopping criterion was $\|d(u_k^s)g(u_k^s)\|_2 \le 10^{-10}$. The upper and lower bounds for the control were $a \equiv -1000$, $b \equiv 0.8$ and we used $c \stackrel{\text{def}}{=} 0.075 \min\{b-a, 0.8\}$ in the definition of the discrete scaling function d. The optimization was started with $u_0 \equiv 0.05$.

For $N_t = 100$, $N_x = 20$ Table 4 shows the norm of the step $\|u_{k+1}^s - u_k^s\|_\infty$ and the norm $\|d(u_{k+1}^s)g(u_{k+1}^s)\|_2$ of the scaled gradient for three different algorithms. The first algorithm is as described above. It uses also the projection step s_k^2 as a candidate for the trial step and performs a smoothing step if necessary (see above). The second algorithm is the same but without smoothing. The third algorithm is the same as the second but uses only the trial steps s_k^1, s_k^3 and not the projected step s_k^2 that is suggested by our investigations.

There were no rejected trial steps in all three algorithms. Except for the first two iterations the projected step s_k^2 was chosen by the first two algorithms. Obviously the first algorithm provides the fastest convergence. But if the smoothing steps are omitted also, the usage of the projected step s_k^2 leads to a significant acceleration of the local convergence in comparison to a stepsize-based algorithm. To compare the dependence of the methods on the mesh-size, we list also the number of gradient evaluations and iterations for $(N_t, N_x) = (400, 80)$, $(3000, 200)$, and $(6000, 400)$.

The first algorithm wins on all grids and the second needs at most one additional gradient evaluation. Thus, smoothing is not very important for this example. Both

† $s_k^s = u_{k+1}^s - u_k^s$, $d_k^s = d(u_k^s)$, $g_k^s = g(u_k^s)$. * Smoothing occurred, i.e., $u_{k+1}^s \ne u_{k+1}$.

algorithms are nearly mesh-independent and need significantly less iterations than the third algorithm, which shows a weak mesh-dependence for the transition from coarse to fine grids. Note, however, that the third algorithm shows strong mesh-dependence for certain other problems; cf. Examples 6.3 and 6.5.

It is also possible to treat the state equation as an equality constraint by combining the SQP-approach with our method. For the finite-dimensional case this was proposed in [8] and [27]. The main advantage of these methods is that they only require the solution of the linearized state equation, whereas in the black-box approach the state equation has to be solved, which in the problem under consideration is about twice as expensive as the solution of the linearized equation. We believe that the extension of our theory to this class of SQP-methods is possible. For the case without box-constraints, an SQP-method for the above problem was analyzed in [20]. Also in this simpler case, an SQP-step requires the computation of the reduced gradient and the solution of the linearized state equation.

Conclusions. We have developed an affine-scaling interior-point Newton algorithm for bound-constrained minimization subject to pointwise bounds in L^p-space. The method is an extension of the algorithms by Coleman and Li [6], [7] for finite-dimensional problems. Our infinite-dimensional framework raised a couple of difficulties which are not present in the finite-dimensional case. A careful analysis led to several modifications of the original algorithm which enabled us to prove superlinear convergence for the resulting method. Under a slightly stronger strict complementarity condition we proved convergence with Q-rate >1. Our main modifications are the introduction of a smoothing step and the implementation of the back-transport by a projection instead of the usual stepsize rule. The smoothing step takes care of the fact that, in general, we can show that only for suitable $q < s$ the affine-scaling Newton step produces a point which is much closer to the solution in L^q (but not necessarily in L^s) than the current iterate was in L^s. The necessity of a smoothing step was also observed by Kelley and Sachs [17] in their study on projected Newton methods. The back-transport is required because the solution of the affine-scaling Newton equation may lie outside of the feasible set $\mathcal{B}$. In the finite-dimensional case one can prove that a stepsize rule to enforce strict feasibility generates stepsizes that converge to one. In our infinite-dimensional setting, however, this is no longer true, as we have demonstrated in Example 6.3. Therefore, we have defined a back-transport on the basis of the pointwise projection onto $\mathcal{B}$. We have discussed how smoothing steps can be obtained for a class of regularized problems. Moreover, we have shown that our theory is applicable under the assumptions used by Kelley and Sachs [17] as well as those by Dunn and Tian [9]. We have demonstrated that our algorithm can be used as an accelerator for the class of globally convergent trust-region interior-point methods introduced in [26]. The good performance of this algorithm is documented by our numerical results for the boundary control of a heating process.

Acknowledgments. The major part of this work was done while the authors were visiting the Department of Computational and Applied Mathematics and the Center for Research on Parallel Computation, Rice University. They would like to thank John Dennis, Rice University, and Klaus Ritter, Technische Universität München, for making this pleasant and fruitful visit possible.

This work was initiated and influenced by many discussions with Matthias Heinkenschloss, Rice University. His support is greatly acknowledged. The authors also are grateful to John Dennis, Rice University, and Luís Vicente, Universidade de Coimbra, for several stimulating discussions.

The authors are grateful to the referees for their insightful reading of this paper and their constructive comments.
