and $H_{n0}^1(\Gamma) = H_0^1(\Gamma \setminus \Gamma_c) \cap H_n^1(\Gamma_c)$ denote the spaces of all the functions that are compatible with the divergence free motion of the fluid. We remark that the subspaces $H_{n0}^1(\Gamma)$ and $H_n^1(\Gamma)$ are closed subspaces of $H^1(\Gamma)$ and the space $H^1(\Gamma)$ can be decomposed in $H_n^1(\Gamma) \oplus (H_n^1)^\perp(\Gamma)$. We assume no-slip boundary conditions on the rest of the boundary $\Gamma \setminus \Gamma_c$. Hence, the component of the velocity $\vec{u}^{(n)}$ on the boundary is the canonical extension of $\vec{g}^{(n)}$ from $H_n^1(\Gamma_c)$ to $H^1(\Gamma)$. We recall that this extension is a continuous map. The state variables $\vec{u}^{(n)} \in H_0^1(\Omega)$ and $p^{(n)} \in L_0^2(\Omega)$ are constrained to satisfy the semidiscrete Navier–Stokes equations

$$\begin{cases} \frac{1}{\Delta t}(\vec{u}^{(n)} - \vec{u}^{(n-1)}, \vec{v}) + \nu a(\vec{u}^{(n)}, \vec{v}) \\ \quad + c(\vec{u}^{(n)}; \vec{u}^{(n)}, \vec{v}) + b(\vec{v}, p^{(n)}) = 0 \quad \forall \, \vec{v} \in H_0^1(\Omega), \\ b(\vec{u}^{(n)}, q) = 0 \quad \forall \, q \in L_0^2(\Omega), \\ (\vec{u}^{(n)}(\vec{x}), \vec{s})_\Gamma = (\vec{g}^{(n)}(\vec{x}), \vec{s})_{\Gamma_c} \quad \forall \, \vec{s} \in H^{-1/2}(\Gamma), \end{cases} \tag{51}$$

for $n = 1, 2, \dots, N$ with $\vec{u}^{(0)} = \vec{u}_0(\vec{x}) \in curl(H^2)(\Omega)$.

Optimization is achieved by means of the minimization of the discretized functional

$$\begin{aligned} \mathcal{J}^N(\vec{\mathbf{u}}, \vec{\mathbf{g}}) = {} & \frac{\alpha}{2} \sum_{n=1}^N \|\vec{u}^{(n)} - \vec{U}^{(n)}\|^2 \Delta t \\ & + \frac{\beta}{2} \sum_{n=1}^N \left[\|\vec{g}^{(n)}\|_{\Gamma_c}^2 \Delta t + \beta_1 \|\partial_s \vec{g}^{(n)}\|_{\Gamma_c}^2 \Delta t + \beta_2 \| \, \vec{g}^{(n)} - \vec{g}^{(n-1)} \, \|_{\Gamma_c}^2 \right]. \end{aligned} \tag{52}$$

Of course, if Δt tends to zero, this functional tends to the corresponding continuous functional (4).

The *admissibility set* A_{ad} is defined by

$$\begin{aligned} A_{ad} = \{ & (\vec{\mathbf{u}}, \mathbf{p}, \vec{\mathbf{g}}) \in \mathbf{H}^1(\Omega) \times \mathbf{L}_0^2(\Omega) \times \mathbf{H}_{n0}^1(\Gamma_c) \quad \textit{such that } (\vec{\mathbf{u}}, \mathbf{p}, \vec{\mathbf{g}}) \textit{ is} \\ & \textit{solution of } (51), \ \vec{g}^{(0)} = \gamma \vec{u}_0, \textit{ and the functional in } (52) \textit{ is bounded} \}. \end{aligned}$$

The formulation of the optimal control problem in the semidiscrete approximation is given as follows:

given $\Delta t = T/N$, $\vec{u}_0 \in curl(H^2)(\Omega)$, *and* $\vec{U} \in U_{ad}$, *then* $(\vec{\mathbf{u}}, \mathbf{p}, \vec{\mathbf{g}}) \in\ A_{ad}$ *is called an optimal solution if there exists* $\epsilon > 0$ *such that*

$$\mathcal{J}^N(\vec{\mathbf{u}}, \vec{\mathbf{g}}) \le \mathcal{J}^N(\widetilde{\mathbf{u}}, \widetilde{\mathbf{h}}) \quad \forall \widetilde{h} \in \mathbf{H}^1_{n0} \tag{53}$$

whenever $\|\vec{g}^{(n)} - \widetilde{h}^{(n)}\|_{\Gamma_c} \le \epsilon$, *with* $n = 1, 2, \dots, N$.

For the semidiscrete Navier–Stokes nonhomogeneous boundary problem, one can prove the following theorem [29].

Theorem 3.1. *Let* $\Delta t = T/N$ *and* $\vec{u}_0 \in curl(H^2)(\Omega)$. *Let* $\epsilon > 0$, $\vec{\mathbf{g}} \in \mathbf{H}^1_{n0}(\Omega)$ *such that* $\sum_{i=1}^N (\|\vec{g}^{(n)}\|_1^2 \Delta t + \|\vec{g}^{(n)} - \vec{g}^{(n-1)}\|^2) \le \epsilon$, *i.e.,* $\vec{g}^N$ *and* $\vec{g}'^N$ *are uniformly bounded by* ϵ *in* $L^2((0,T); H^1(\Gamma_c))$ *and in* $L^2((0,T); L^2(\Gamma_c))$, *respectively. Then, there exists a function* $\vec{\mathbf{u}} \in \mathbf{H}^1(\Omega)$ *that is a solution of the system*

$$\begin{cases} \frac{1}{\Delta t}(\vec{u}^{(n)} - \vec{u}^{(n-1)}, \vec{v}) + \nu a(\vec{u}^{(n)}, \vec{v}) + c(\vec{u}^{(n)}; \vec{u}^{(n)}, \vec{v}) \\ \qquad + b(\vec{v}, p^{(n)}) = 0 \quad \forall \vec{v} \in H^1_0(\Omega), \quad for \quad n = 1, \dots, N, \\ b(\vec{u}^{(n)}, q) = 0 \quad \forall q \in L^2_0(\Omega), \quad for \quad n = 1, \dots, N, \\ \vec{u}^{(n)}(\vec{x}) = \vec{g}^{(n)} \quad for\ \vec{x} \in \Gamma_c, \quad for \quad n = 1, \dots, N, \\ \vec{u}^{(n)}(\vec{x}) = 0 \quad for\ \vec{x} \in \Gamma \setminus \Gamma_c, \quad for \quad n = 1, \dots, N, \\ \vec{u}^{(0)} = \vec{u}_0(\vec{x}) \in curl(H^2)(\Omega), \end{cases} \tag{54}$$

with the following estimates:

$$\|\vec{u}^{(n)}\|_1^2 \le K, \quad n = 1, 2, \dots, N, \tag{55}$$

$$\sum_{n=1}^N \|\nabla \vec{u}^{(n)}\|^2 \Delta t \le K, \tag{56}$$

$$\sum_{n=1}^N \|\vec{u}^{(n)} - \vec{u}^{(n-1)}\|^2_{H^{-1}} \le K, \tag{57}$$

where the constant K *is independent of* Δt.

If $\vec{\mathbf{g}}$ and its time derivative are uniformly bounded, then the existence of solutions of the semidiscrete-in-time optimal control problem can be proved. This fact is an easy consequence of the definition of the optimal control problem and the boundedness of the functional.

Lemma 3.2. *Let* $\Delta t = T/N$, $\vec{u}_0 \in curl(H^2)(\Omega)$, *and* $\vec{U} \in U_{ad}$. *If* $(\vec{\mathbf{u}}, \vec{\mathbf{g}})$ *is the solution of the semidiscrete optimal control problem, then for all* β_1 *and* $\beta_2 > 0$ *there exists a constant* C *independent of* Δt *such that*

$$\sum_{n=1}^N \|\vec{g}^{(n)}\|^2_{1,\Gamma} \Delta t \le C, \tag{58}$$

$$\sum_{n=1}^N \|\vec{g}^{(n)} - \vec{g}^{(n-1)}\|^2_{\Gamma} \le C, \tag{59}$$

$$\sum_{n=1}^N \|\vec{u}^{(n)}\|^2_{\Omega} \Delta t \le C. \tag{60}$$

Hence, we have that $\vec{g}^N \in L^2((0,T);H^1(\Gamma))$, $\vec{g}'^N \in L^2((0,T);L^2(\Gamma))$, *and* $\vec{u}^N \in L^2((0,T);W(\Omega))\ \forall\ N$.

The proof can be obtained by using standard techniques and can be found in [29]. We can recall that if the norm of $\vec{g}^N \in L^2((0,T);H^1(\Gamma))$ and the norm of $\vec{g}'^N \in L^2((0,T);L^2(\Gamma))$ are uniformly bounded for all N, then $\vec{g}^N$ is uniformly bounded in $L^2((0,T);L^2(\Gamma))\ \forall\ N$. Now we can state and prove the existence of solutions for the optimal control problem in an open bounded domain Ω with boundary Γ in C^2.

THEOREM 3.3. *Given* $\Delta t = T/N$, $\vec{u}_0 \in curl(H^2)(\Omega)$, *and* $\vec{U} \in U_{ad}$, *there exists a solution* $(\vec{\mathbf{u}}, \mathbf{p}, \vec{\mathbf{g}}) \in A_{ad}$ *of* (51) *such that* $\vec{\mathbf{g}}$ *minimizes the cost functional.*

Proof. The proof proceeds as in the continuous case. Let $\Delta t = T/N$ and $\{\vec{\mathbf{g}}_k\}_{k=1}^{\infty}$ be a minimizing sequence in $\mathbf{H}^1_{n0}(\Gamma_c)$. Using Theorem 3.1 and the result in (58)–(59), we find that the corresponding sequence $\vec{\mathbf{u}}_k$ is uniformly bounded in $\mathbf{H}^1(\Omega)$. Now, we can proceed with a weakly convergent subsequence and show that this subsequence converges to the solution of the optimal control problem in the semidiscrete approximation. We can write

$$\begin{aligned} \vec{g}_k^{(n)} \to \vec{g}^{(n)} &\quad \text{in} \quad H^1_0(\Gamma_c) \quad \text{weakly}, \\ \vec{u}_k^{(n)} \to \widehat{u}^{(n)} &\quad \text{in} \quad H^1(\Omega) \quad \text{weakly} \end{aligned}$$

for $n = 1, 2, \ldots, N$. By using the fact that the injection of $H^1(\Omega)$ into $L^2(\Omega)$ is compact, the subsequence converges strongly. The lower semicontinuity of the functional in (52) allows the pair $(\vec{\mathbf{u}}, \vec{\mathbf{g}})$ to minimize the functional. Since we can pass to the limit in the linear and the nonlinear terms, the pair also satisfies the semidiscrete Navier–Stokes system (51). In fact, since $\vec{\mathbf{u}}_k$ converges to $\vec{\mathbf{u}}$ strongly in $\mathbf{L}^2(\Omega)$, then for any $\vec{\mathbf{z}} \in \mathcal{V}(\Omega)$, we have

$$\lim_{k\to\infty} c(\vec{\mathbf{u}}_k; \vec{\mathbf{u}}_k, \vec{\mathbf{z}}) = c(\vec{\mathbf{u}}; \vec{\mathbf{u}}, \vec{\mathbf{z}})\,.$$

Since $\mathcal{V}(\Omega)$ is dense in $\mathbf{H}^1_0(\Omega)$, this is still true for any $\vec{\mathbf{w}}$ in $\mathbf{H}^1_0(\Omega)$ by a continuity argument. This allows us to pass to the limit in the semidiscrete equations and complete the proof. □

3.2. First-order necessary condition. In this section, we derive the first-order necessary condition in a different way. Denote by $\mathbf{B}_1, \mathbf{B}_2$ the following sets:

$$\left\{ \begin{array}{l} \mathbf{B}_1 = \mathbf{H}^1(\Omega) \times \mathbf{L}^2_0(\Omega) \times \mathbf{H}^1_{n0}(\Gamma_c), \\ \mathbf{B}_2 = \mathbf{H}^{-1}(\Omega) \times \mathbf{L}^2_0(\Omega) \times \mathbf{H}^{1/2}(\Gamma_c). \end{array} \right. \tag{61}$$

We define the nonlinear map

$$M(\vec{\mathbf{u}}, \mathbf{p}, \vec{\mathbf{g}}) : \mathbf{B}_1 \to \mathbf{B}_2$$

as $M(\vec{\mathbf{u}}, \mathbf{p}, \vec{\mathbf{g}}) = (\vec{\mathbf{f}}, \mathbf{z}, \vec{\mathbf{b}})$ if and only if

$$\left\{ \begin{array}{l} \frac{1}{\Delta t}(\vec{u}^{(n)} - \vec{u}^{(n-1)}, \vec{v}) + \nu a(\vec{u}^{(n)}, \vec{v}) + c(\vec{u}^{(n)}; \vec{u}^{(n)}, \vec{v}) \\ \qquad + b(\vec{v}, p^{(n)}) = (\vec{f}^{(n)}, \vec{v}) \quad \forall\, \vec{v} \in H^1_0(\Omega), \quad \textit{for} \quad n = 1, \ldots, N, \\ b(\vec{u}^{(n)}, q) = (z^{(n)}, q) \quad \forall\, q \in L^2_0(\Omega), \quad \textit{for} \quad n = 1, \ldots, N, \\ (\vec{u}^{(n)}, \vec{s})_\Gamma - (\vec{g}^{(n)}, \vec{s})_{\Gamma_c} = (\vec{b}^{(n)}, \vec{s})_\Gamma \quad \forall\, \vec{s} \in H^{-1/2}(\Gamma), \quad \textit{for} \quad n = 1, \ldots, N, \\ \vec{u}^{(0)} = \vec{u}_0(\vec{x}) \in curl(H^2)(\Omega). \end{array} \right. \tag{62}$$

In the same manner, let $\widehat{\mathbf{g}}$ be an optimal solution and define

$$N(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}}):\mathbf{B}_1\to\mathbb{R}\times\mathbf{B}_2$$

as $N(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})=(a,\vec{\mathbf{f}},\mathbf{z},\vec{\mathbf{b}})$ if and only if

$$\begin{pmatrix} \mathcal{J}^N(\vec{\mathbf{u}},\vec{\mathbf{g}})-\mathcal{J}^N(\widehat{\mathbf{u}},\widehat{\mathbf{g}})\\ M(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})\end{pmatrix}=\begin{pmatrix}a\\(\vec{\mathbf{f}},\mathbf{z},\vec{\mathbf{b}})\end{pmatrix}. \tag{63}$$

Thus, the constraints can be expressed as $M(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})=(0,0,0)$ and the optimal control problem can be reformulated as follows:

find $(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}})$ *and* $a\leq 0$ *such that the equation* $N(\vec{\mathbf{u}},\mathbf{p},\widehat{\mathbf{g}})=(a,0,0,0)$
is satisfied for all $\vec{\mathbf{g}}$ *such that* $\|\vec{g}^{(n)}-\widehat{g}^{(n)}\|\leq\epsilon$ *for* $n=1,2,\dots,N$
for some $\epsilon>0$.

Since we are looking for local minimum points, it is natural to define the operators $M'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})$ and $N'(\vec{\mathbf{u}},\mathbf{p},\widehat{\mathbf{g}})$. Given a $(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})$, we define the linear operator

$$M'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}}):\mathbf{B}_1\to\mathbf{B}_2$$

as $M'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})\cdot(\widetilde{\mathbf{w}},\mathbf{r},\widetilde{\mathbf{h}})=(\bar{\mathbf{f}},\bar{\mathbf{z}},\bar{\mathbf{b}})$ if and only if

$$\begin{cases} \frac{1}{\Delta t}(\widetilde{w}^{(n)}-\widetilde{w}^{(n-1)},\vec{v})+\nu a(\widetilde{w}^{(n)},\vec{v})+c(\widetilde{w}^{(n)};\vec{u}^{(n)},\vec{v})+c(\vec{u}^{(n)},\widetilde{w}^{(n)},\vec{v})\\ \quad +b(\vec{v},r^{(n)})=(\bar{f}^{(n)},\vec{v})\quad\forall\,\vec{v}\in H_0^1(\Omega),\quad \textit{for}\quad n=1,\dots,N,\\ b(\widetilde{w}^{(n)},q)=(\bar{z}^{(n)},q)\quad\forall q\in L_0^2(\Omega),\quad \textit{for}\quad n=1,\dots,N,\\ (\widetilde{w}^{(n)},\vec{s})_\Gamma-(\widetilde{h}^{(n)},\vec{s})_{\Gamma_c}=(\bar{b}^{(n)},\vec{s})_\Gamma\quad\forall\,\vec{s}\in H^{-1/2}(\Gamma),\quad \textit{for}\quad n=1,\dots,N,\\ \widetilde{w}^{(0)}=\vec{0}. \end{cases} \tag{64}$$

Let

$$N'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}}):\mathbf{B}_1\to\mathbb{R}\times\mathbf{B}_2$$

be defined as $N'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})\cdot(\widetilde{a},\widetilde{\mathbf{w}},\mathbf{r},\widetilde{\mathbf{h}})=(\bar{a},\bar{\mathbf{f}},\bar{\mathbf{z}},\bar{\mathbf{b}})$ if and only if

$$\begin{pmatrix} \mathcal{J}^{N'}(\vec{\mathbf{u}},\vec{\mathbf{g}}))\cdot(\widetilde{a},\widetilde{\mathbf{w}},\mathbf{r},\widetilde{\mathbf{h}}))\\ M'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})\cdot(\widetilde{a},\widetilde{\mathbf{w}},\mathbf{r},\widetilde{\mathbf{h}}))\end{pmatrix}=\begin{pmatrix}\bar{a}\\(\bar{\mathbf{f}},\bar{\mathbf{z}},\bar{\mathbf{b}})\end{pmatrix}. \tag{65}$$

Now we have to prove that these operators are well defined, i.e., the equations for the Gâteaux derivatives are well posed and have solutions.

LEMMA 3.4. *Given* $\Delta t=T/N$, $\vec{u}_0\in$ *curl*$(H^2)(\Omega)$, *and* $\vec{\mathbf{u}}\in\mathbf{H}^1(\Omega)$. *Then, we have*

(i) *the operator* $M'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})$ *has closed range and is onto in* $\mathbf{B}_2$;

(ii) *the operator* $N'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})$ *has closed range in* $\mathbb{R}\times\mathbf{B}_2$.

Proof. (i) We set

$$\begin{cases} \nu\widetilde{a}(\widetilde{w}^{(n)},\vec{v})=\nu a(\widetilde{w}^{(n)},\vec{v})+\frac{1}{\Delta t}(\widetilde{w}^{(n)},\vec{v})\quad\forall\vec{v}\in H_0^1(\Omega),\quad n=1,2,\dots,N,\\ (\widetilde{f}^{(n)},\vec{v})=(\vec{f}^{(n)},\vec{v})+\frac{1}{\Delta t}(\widetilde{w}^{(n-1)},\vec{v})\quad\forall\vec{v}\in H_0^1(\Omega),\quad n=1,2,\dots,N. \end{cases}$$

With this notation, the operator $M'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})$ can be written as

$$(66)\qquad \begin{cases} \nu\widetilde{a}(\widetilde{w}^{(n)},\vec{v})+c(\widetilde{w}^{(n)};\vec{u}^{\,(n)},\vec{v}) \\ \quad +\,c(\vec{u}^{\,(n)},\widetilde{w}^{(n)},\vec{v})+b(\vec{v},r^{(n)})=(\widetilde{f}^{(n)},\vec{v}) \quad \forall\,\vec{v}\in H_0^1(\Omega), \\ b(\widetilde{w}^{(n)},q)=(\bar{z}^{\,(n)},q) \quad \forall\,q\in L_0^2(\Omega), \\ (\widetilde{w}^{(n)},\vec{s})_\Gamma-(\widetilde{h}^{(n)},\vec{s})_{\Gamma_c}=(\bar{b}^{\,(n)},\vec{s})_\Gamma \quad \forall\,\vec{s}\in H^{-1/2}(\Gamma), \end{cases}$$

for $n=1,2,\dots,N$ with $\widetilde{w}^{(0)}=\vec{0}$. The function $\widetilde{f}$ is still in $H^{-1}(\Omega)$ and the range of M' is still the same if $Ran(M'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}}))=\mathbf{B}_2$. This is a steady system and one can apply the standard techniques for the stationary case; see [21]. Let S be the Stokes operator

$$S=\begin{pmatrix} A & B^* \\ B & 0 \\ \gamma_0 & 0 \end{pmatrix}.$$

By the trace theorem, using the ellipticity of A and the inf-sup property, one can see [8], [17], [18] that the Stokes operator is an isomorphism from $H^1(\Omega)\times L_0^2(\Omega)$ $\to H^{-1}(\Omega)\times L_0^2(\Omega)\times H^{-1/2}(\Gamma)$. The operator $C(\vec{w}^{\,(n)})\vec{u}^{\,(n)}$ is continuous in $\vec{w}^{\,(n)}$ from $H^{1/2}(\Gamma)$ into $H^{-1}(\Omega)$ $\forall\ \vec{u}^{\,(n)}\in H^1(\Omega)$ and $n=1,2,\dots,N$ and thus compact from $H^1(\Omega)$ into $H^{-1}(\Omega)$. The operator $C(\vec{u}^{\,(n)})\vec{w}^{\,(n)}$ is continuous $\forall\ \vec{u}\in H^1(\Omega)$ and $\forall\ n=1,2,\dots,N$ from $H^1(\Omega)$ into $H^{-1/2}(\Gamma)$ and thus compact from $H^1(\Omega)$ into $H^{-1}(\Omega)$. The perturbation operator

$$M'^{(n)}(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})=S^{(n)}+\begin{pmatrix} C(\vec{u}^{\,(n)})\vec{w}^{\,(n)}+C(\vec{w}^{\,(n)})\vec{u}^{\,(n)} \\ 0 \\ 0 \end{pmatrix}$$

is a Fredholm operator $\forall\ n=1,2,\dots,N$, i.e., it has a closed range and a finite-dimensional kernel.

(ii) The operator $M'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})$ belongs to $\mathcal{L}(\mathbf{B}_1,Ran(M'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}}))$ and therefore its kernel is a closed subspace. We recall that a linear functional $\vec{f}$ on a Banach space can have either $Ran(\vec{f})=\{0\}$ or $Ran(\vec{f})=\{\mathbb{R}\}$. Now, $N'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})$ acting on the kernel is either identically zero or onto $\mathbb{R}$. Let X,Y,Z be Banach spaces and $A:X\to Y$ and $B:X\to Z$ be linear continuous operators. If the range of B is closed in Z and the subspace $A\cdot\ker(B)$ is closed in Y, then, if we define $C:X\to Y\times Z$ by $Cx=(Ax,Bx)$, the range of C is closed in $Y\times Z$. Applying this result we prove that $Ran(N'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}}))$ is a closed set. □

The operator $N'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})$ cannot be onto. If it were, by the implicit function theorem, we would have that there exists a solution, which is different from the optimal solution, that minimizes the functional for every small neighborhood of $(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}})$. This contradicts the hypothesis that $(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}})$ is an optimal solution. Therefore the optimality condition implies the following theorem.

THEOREM 3.5. *Given $\Delta t=T/N$ and $\vec{u}_0\in curl(H^2)(\Omega)$. If $(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}})\in(\mathbf{H}^1(\Omega)\times\mathbf{L}_0^2(\Omega)\times\mathbf{H}_{n0}^1(\Gamma_c))$ is a solution of the semidiscrete optimal control problem, then the operator $N'(\vec{\mathbf{u}},\mathbf{p},\vec{\mathbf{g}})$ is not onto in $\mathbb{R}\times\mathbf{B_2}$.*

In the next theorem, we write the first-order necessary condition and characterize the optimal control solution as a solution of the corresponding Euler system of equations.

THEOREM 3.6. *Given $\Delta t = T/N$ and $\vec{u}_0 \in curl(H^2)(\Omega)$. If $(\widehat{\mathbf{u}}, \mathbf{p}, \widehat{\mathbf{g}}) \in \mathbf{H}^1(\Omega) \times \mathbf{L}_0^2(\Omega) \times \mathbf{H}_{n0}^1(\Gamma_c)$ is an optimal solution, i.e., the operator $N'(\vec{\mathbf{u}}, \mathbf{p}, \vec{\mathbf{g}})$ is not onto, then there exists a nonzero Lagrangian multiplier $\vec{\mathbf{w}}, \boldsymbol{\sigma}, \vec{\boldsymbol{\xi}} \in \mathbf{H}_0^1(\Omega) \times \mathbf{L}_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$ satisfying the Euler equations*

$$\mathcal{J}^{N'}(\widehat{\mathbf{u}}, \widehat{\mathbf{g}}) \cdot (\widetilde{\mathbf{w}}, \mathbf{r}, \widetilde{\mathbf{h}}) + \Big\langle (\vec{\mathbf{w}}, \boldsymbol{\sigma}, \vec{\boldsymbol{\xi}}), M'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}) \cdot (\widetilde{\mathbf{w}}, \mathbf{r}, \widetilde{\mathbf{h}}) \Big\rangle = 0$$
$$\forall\, (\widetilde{\mathbf{w}}, \mathbf{r}, \widetilde{\mathbf{h}}) \in \mathbf{H}^1(\Omega) \times \mathbf{L}_0^2(\Omega) \times \mathbf{H}_{n0}^1(\Gamma_c), \tag{67}$$

where $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $\mathbb{R} \times \mathbf{B}_2$ and $\mathbb{R} \times \mathbf{B}_2^*$.

Proof. From Lemma 3.4, the range of $N'(\vec{\mathbf{u}}, \mathbf{p}, \vec{\mathbf{g}})$ is a closed set and, from Theorem 3.5, this range is a closed proper subspace of $\mathbb{R} \times \mathbf{B}_2$. The Hahn–Banach theorem then implies that there exists a nonzero element of $\mathbb{R} \times \mathbf{B}_2^* = \mathbb{R} \times \mathbf{H_0^1}(\Omega) \times \mathbf{L_0^2}(\Omega) \times \mathbf{H^{1/2}}(\Gamma)$ that annihilates the range of $N'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}})$. One can find an $(\widehat{a}, \vec{\mathbf{w}}, \boldsymbol{\sigma}, \vec{\boldsymbol{\xi}}) \in \mathbb{R} \times \mathbf{B_2}^*$ such that

$$\Big\langle (\widetilde{a}, \widetilde{\mathbf{f}}, \widetilde{\mathbf{z}}, \widetilde{\mathbf{b}}), (\widehat{a}, \vec{\mathbf{w}}, \boldsymbol{\sigma}, \vec{\boldsymbol{\xi}}) \Big\rangle = 0 \quad \forall\, (\widetilde{a}, \widetilde{\mathbf{f}}, \widetilde{\mathbf{z}}, \widetilde{\mathbf{b}}) \in Ran(N'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}})),$$

where $\widehat{a}$ is different from zero as this solution is nontrivial, i.e., $M'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}})$ is onto. If we set $\widehat{a} = 1$, we have (67). □

3.3. The optimality system. From the first-order necessary condition, we can further characterize the optimal control as a solution of an differential equation.

THEOREM 3.7. *Given $\Delta t = T/N$ and $\vec{u}_0 \in curl(H^2)(\Omega)$. Let $(\vec{\mathbf{u}}, \vec{\mathbf{p}}, \vec{\mathbf{g}}) \in (\mathbf{H}^1(\Omega) \times \mathbf{L}_0^2(\Omega) \times \mathbf{H}_{n0}^1(\Gamma_c))$ denote an optimal control solution. Then, the control $\vec{g}^{\,(n)}$ satisfying the compatibility conditions*

$$\vec{g}^{\,(0)} = \gamma_0 \vec{u}_0, \qquad \int_\Gamma \vec{g}^{\,(n)} \cdot \vec{n}\; d\vec{x} = 0 \quad \textit{for}\, n = 0, 1, \ldots, N$$

is solution of the system

$$\int_{\Gamma_c} \left[\vec{g}^{\,(n)} \cdot \widetilde{h} - \frac{\beta_1}{\Delta t^2} (\vec{g}^{\,(n+1)} - 2\vec{g}^{\,(n)} + \vec{g}^{\,(n-1)}) \cdot \widetilde{h} + \beta_2 \partial_s \vec{g}^{\,(n)} \cdot \partial_s \widetilde{h} + k^{(n)} \vec{n} \cdot \widetilde{h} \right] d\vec{x}$$
$$= \frac{1}{\beta} \int_{\Gamma_c} (\vec{\xi}^{(n)} \cdot \widetilde{h})\, d\vec{x} \qquad \forall \widetilde{h} \in H_0^1(\Gamma_c),$$

for $n = 1, \ldots, N-1$ ($\vec{g}^{\,N} = \vec{g}^{\,N-1}$). The function $\vec{\xi} \in \mathbf{H}^{-1/2}(\Gamma_c)$ is defined by

$$\int_{\Gamma_c} \vec{\xi}^{(n-1)} \cdot \widetilde{v}\, d\vec{x} = \int_{\Gamma_c} (\gamma_1 \vec{w}^{\,(n-1)} - \sigma^{(n-1)} \vec{n}) \cdot \widetilde{v}\, d\vec{x} \tag{68}$$
$$= -\alpha(\vec{u}^{\,(n)} - \vec{U}^{\,(n)}, \widetilde{v}) - \frac{1}{\Delta t} (\vec{w}^{\,(n)} - \vec{w}^{\,(n-1)}, \widetilde{v})_\Omega + \nu a(\vec{w}^{\,(n-1)}, \widetilde{v})$$
$$+ c(\widetilde{v}; \vec{u}^{(n)}, \vec{w}^{\,(n-1)}) + c(\vec{u}^{\,(n)}; \widetilde{v}, \vec{w}^{\,(n-1)}) + b(\widetilde{v}, \sigma^{(n-1)})$$
$$\forall \widetilde{v} \in H^1(\Omega), \quad \textit{for} \quad n = 1, \ldots, N,$$

where $\vec{\mathbf{w}}$ *and* $\boldsymbol{\sigma}$ *satisfies*

$$
(69)\qquad
\begin{cases}
-\frac{1}{\Delta t}(\vec{w}^{\,(n)} - \vec{w}^{\,(n-1)}, \vec{v}) + \nu a(\vec{w}^{\,(n-1)}, \vec{v}) + c(\vec{w}^{\,(n-1)}; \vec{u}^{\,(n)}, \vec{v}) \\
\qquad + c(\vec{u}^{\,(n)}; \vec{w}^{\,(n-1)}, \vec{v}) + b(\vec{v}, \sigma^{(n-1)}) = \alpha(\vec{u}^{\,(n)} - \vec{U}^{\,(n)}, \vec{v}) \\
\qquad \forall\, \vec{v} \in H^1_0(\Omega), \quad \textit{for} \quad n = 1, \dots, N, \\
b(\vec{w}^{\,(n-1)}, q) = 0 \quad \forall\, q \in L^2_0(\Omega), \quad \textit{for} \quad n = 1, \dots, N, \\
(\vec{w}^{\,(n-1)}, \vec{s}\,) = 0 \quad \forall\, \vec{s} \in H^{-1/2}(\Gamma), \quad \textit{for} \quad n = 1, \dots, N, \\
\vec{w}^{\,(N)} = 0.
\end{cases}
$$

Proof. Given $\widetilde{\mathbf{h}} \in \mathbf{H}^1_{n0}(\Gamma_c)$, the first-order necessary condition (67) can be written as

$$
\begin{aligned}
&\alpha \sum_{n=1}^{N} ((\vec{u}^{\,(n)} - \vec{U}^{\,(n)})\widetilde{w}^{(n)}, 1)\Delta t \\
&+ \beta \sum_{n=1}^{N} \int_{\Gamma_c} \left[\vec{g}^{\,(n)} \cdot \widetilde{h}^{(n)} + \frac{\beta_1}{\Delta t^2}(\vec{g}^{\,(n)} - \vec{g}^{\,(n-1)})(\widetilde{h}^{(n)} - \widetilde{h}^{(n-1)}) + \beta_2 \partial_s \vec{g}^{\,(n)} \cdot \partial_s \widetilde{h}^{(n)} \right] d\vec{x}\Delta t \\
&+ \sum_{n=1}^{N} (\bar{f}^{\,(n)}, \vec{w}^{\,(n)})_\Omega \Delta t + \sum_{n=1}^{N} (\bar{z}^{\,(n)}, \sigma^{(n)})_\Omega \Delta t + \sum_{n=1}^{N} (\bar{b}^{\,(n)}, \vec{\xi}^{(n)})_\Gamma \Delta t = 0
\end{aligned}
$$

$\forall\ (\bar{\mathbf{f}}, \bar{\mathbf{z}}, \bar{\mathbf{b}}) \in \mathbf{H}^{-1}(\Omega) \times \mathbf{L}^2_0(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$. We have

$$
\begin{aligned}
&\alpha \sum_{n=1}^{N} ((\vec{u}^{\,(n)} - \vec{U}^{\,(n)})\widetilde{w}^{(n)}, 1)\Delta t \\
&+ \beta \sum_{n=1}^{N} \int_{\Gamma_c} \left[\vec{g}^{\,(n)} \cdot \widetilde{h}^{(n)} + \frac{\beta_1}{\Delta t^2}(\vec{g}^{\,(n)} - \vec{g}^{\,(n-1)})(\widetilde{h}^{(n)} - \widetilde{h}^{(n-1)}) + \beta_2 \partial_s \vec{g}^{\,(n)} \cdot \partial_s \widetilde{h}^{(n)} \right] d\vec{x}\Delta t \\
&- \sum_{n=1}^{N} \left[\frac{1}{\Delta t}(\widetilde{w}^{(n)} - \widetilde{w}^{(n-1)}, \vec{w}^{\,(n)}) + \nu a(\widetilde{w}^{(n)}, \vec{w}^{\,(n)}) + c(\widetilde{w}^{(n)}; \vec{u}^{\,(n)}, \vec{w}^{\,(n)}) \right. \\
&\qquad \left. +\ c(\vec{u}^{\,(n)}; \widetilde{w}^{(n)}, \vec{w}^{\,(n)}) + b(\vec{w}^{\,(n)}, r^{(n)}) \right] \Delta t + \sum_{n=1}^{N} b(\widetilde{w}^{(n)}, \sigma^{(n)})\Delta t \\
&+ \sum_{n=1}^{N} [(\vec{w}^{\,(n)}, \vec{\xi}^{(n)})_\Gamma - (\widetilde{h}^{(n)}, \vec{\xi}^{(n)})_{\Gamma_c}]\Delta t = 0
\end{aligned}
$$

$\forall\ (\widetilde{\mathbf{w}}, \vec{\mathbf{r}}, \widetilde{\mathbf{h}}) \in \mathbf{H}^1(\Omega) \times \mathbf{L}^2_0(\Omega) \times \mathbf{H}^1_{n0}(\Gamma)$. After integration by parts, we define the quantity $\vec{\boldsymbol{\xi}}$, as in (68), with $\vec{\mathbf{w}}$ satisfying the adjoint equations in (69). Thus, we write

$$
\begin{aligned}
&\frac{\beta_1}{\Delta t} \int_{\Gamma_c} \widetilde{h}^{(N)}(\vec{g}^{\,(N)} - \vec{g}^{\,(N-1)})\, d\vec{x}\Delta t + \sum_{n=1}^{N-1} \int_{\Gamma_c} [\vec{g}^{\,(n)} \cdot \widetilde{h}^{(n)} + \beta_2 \partial_s \vec{g}^{\,(n)} \cdot \partial_s \widetilde{h}^{(n)}]\, d\vec{x}\Delta t \\
&\qquad + \sum_{n=1}^{N-1} \int_{\Gamma_c} \left[-\frac{\beta_1}{\Delta t^2}(\vec{g}^{\,(n+1)} - 2\vec{g}^{\,(n)} + \vec{g}^{\,(n-1)}) - \frac{1}{\beta}\vec{\xi}^{(n)} \cdot \widetilde{h}^{(n)} \right] d\vec{x}\Delta t = 0.
\end{aligned}
$$

As the variation $\widetilde{h}$ is independent in the space $\mathbf{H}^1_{n0}(\Gamma_c)$, we have

$$\int_{\Gamma_c}\left[\vec{g}^{\,(n)}\cdot\widetilde{h}-\frac{\beta_1}{\Delta t^2}(\vec{g}^{\,(n+1)}-2\vec{g}^{\,(n)}+\vec{g}^{\,(n-1)})\cdot\widetilde{h}+\beta_2\partial_s\vec{g}^{\,(n)}\cdot\partial_s\widetilde{h}-\frac{1}{\beta}\vec{\xi}^{(n)}\cdot\widetilde{h}\right]d\vec{x}=0$$

$$\forall\widetilde{h}\in H^1_{n0}(\Gamma_c),\qquad n=1,\ldots,N-1, \tag{70}$$

with $\vec{g}^{\,(N)}=\vec{g}^{\,(N-1)}$. We recall that $H^1(\Gamma_c)=H^1_n(\Gamma_c)\oplus(H^1_n)^{\perp}(\Gamma_c)$ and thus

$$\widetilde{h}=\widetilde{h}_1-\vec{n}\frac{\int_{\Gamma_c}\widetilde{h}_1\cdot\vec{n}\,d\vec{x}}{\mu(\Gamma_c)},$$

where $\widetilde{h}_1\in H^1(\Gamma_c)$. We can write a weak formulation of (70) in the space $H^1_n(\Gamma_c)$ and then, by using the above decomposition, write a new formulation in $H^1(\Gamma_c)$. In this new formulation a constant vector in the normal direction appears. The weak formulation in $H^1_{n0}(\Gamma_c)$ reads

$$\begin{aligned}\int_{\Gamma_c}\Big[\vec{g}_1^{(n)}\cdot\widetilde{h}_1-\frac{\beta_1}{\Delta t^2}(\vec{g}_1^{(n+1)}-2\vec{g}_1^{(n)}+\vec{g}_1^{(n-1)})\cdot\widetilde{h}_1+\beta_2\partial_s\vec{g}_1^{(n)}\cdot\partial_s\widetilde{h}_1\\ +k^{(n)}\vec{n}\cdot\widetilde{h}_1\Big]\,d\vec{x}=\frac{1}{\beta}\int_{\Gamma_c}(\vec{\xi}^{(n)}\cdot\widetilde{h}_1)\,d\vec{x}\qquad\forall\vec{h}_1\in H^1_0(\Gamma_c),\quad \textit{for}\quad n=1,\ldots,N-1.\end{aligned}$$

The constant $k^{(n)}$ can be calculated by using the constraint

$$\int_{\Gamma}\vec{g}^{\,(n)}\cdot\vec{n}\;d\vec{x}=0.\qquad\Box$$

Now, in order to obtain the solution of the semidiscrete-in-time optimal control problem, we have to solve the semidiscrete Navier–Stokes system

$$\begin{cases}\frac{1}{\Delta t}(\vec{u}^{\,(n)}-\vec{u}^{\,(n-1)},\vec{v})+\nu a(\vec{u}^{\,(n)},\vec{v})+c(\vec{u}^{\,(n)};\vec{u}^{\,(n)},\vec{v})\\ \quad+b(\vec{v},p^{(n)})=0\quad\forall\,\vec{v}\in H^1_0(\Omega),\quad\text{for}\quad n=1,\ldots,N,\\ b(\vec{u}^{\,(n)},q)=0\quad\forall\,q\in L^2_0(\Omega),\quad\text{for}\quad n=1,\ldots,N,\\ (\vec{u}^{\,(n)},\vec{s})_{\Gamma}=(\vec{g}^{\,(n)},\vec{s})_{\Gamma_c}\quad\forall\,\vec{s}\in H^{-1/2}(\Gamma),\quad\textit{for}\quad n=1,\ldots,N,\\ \vec{w}^{\,(0)}=\vec{u}_0\in curl(H^2)(\Omega),\end{cases} \tag{71}$$

the semidiscrete adjoint system

$$\begin{cases}-\frac{1}{\Delta t}(\vec{w}^{\,(n)}-\vec{w}^{\,(n-1)},\vec{v})+\nu a(\vec{w}^{\,(n-1)},\vec{v})+c(\vec{u}^{\,(n)};\vec{v},\vec{w}^{\,(n-1)})\\ \quad+c(\vec{v};\vec{u}^{\,(n)},\vec{w}^{\,(n-1)})+b(\vec{v},\sigma^{(n-1)})=\alpha(\vec{u}^{\,(n)}-\vec{U}^{\,(n)},\vec{v})\\ \quad\forall\,\vec{v}\in H^1_0(\Omega),\quad\text{for}\quad n=1,\ldots,N,\\ b(\vec{w}^{\,(n)},q)=0\quad\forall\,q\in L^2_0(\Omega),\quad\text{for}\quad n=1,\ldots,N,\\ \vec{w}^{\,(n-1)}=0\quad\text{on}\quad\Gamma,\quad\textit{for}\quad n=1,\ldots,N,\\ \vec{w}^{\,(N)}=0\quad\text{in}\quad\Omega,\end{cases} \tag{72}$$

and the optimality condition

$$
(73)\quad \begin{cases} -\frac{\beta_1}{\Delta t^2}(\vec{g}^{\,(n+1)} - 2\vec{g}^{\,(n)} + \vec{g}^{\,(n-1)}, \widetilde{h}) + \beta_2(\partial_s \vec{g}^{\,(n)}, \partial_s \widetilde{h}) + (\vec{g}^{\,(n)}, \widetilde{h}) + k^{(n)}(\vec{n}, \widetilde{h}) \\ \quad = \frac{1}{\beta}(\gamma_1 \vec{\omega}^{\,(n)} - \vec{n}\sigma^{(n)}, \widetilde{h}) \quad \forall \widetilde{h} \in H^1_0(\Gamma_c), \quad \text{for} \quad n = 1, \dots, N-1, \\ (\vec{g}^{\,(n)}, \vec{n})_\Gamma = 0 \quad \text{for} \quad n = 1, \dots, N-1, \\ \vec{g}^{\,(n)} = 0 \quad \text{on} \quad \Gamma \setminus \Gamma_c \quad \text{for} \quad n = 1, \dots, N-1, \\ \vec{g}^{\,(0)} = \gamma_0 \vec{u}_0 \quad \text{on} \quad \Gamma_c, \\ \vec{g}^{(N)} = \vec{g}^{\,(N-1)} \quad \text{on} \quad \Gamma_c. \end{cases}
$$

4. Fully discrete space-time approximations.

4.1. Assumptions on the finite element spaces.

We consider only conforming finite element approximations. Let $X^h \subset H^1(\Omega)$ and $S^h \subset L^2(\Omega)$ be two families of finite dimensional subspaces parameterized by h that tends to zero. We also denote $X^h_0 = X^h \cap H^1_0(\Omega)$ and $S^h_0 = S^h \cap L^2_0(\Omega)$. We make the following assumptions on X^h and S^h

(a) *The approximation hypotheses:* there exists an integer l and a constant C, independent of h, $\vec{u}$, and p, such that for $1 \le k \le l$ we have

$$
(74)\qquad \inf_{\vec{u}_h \in X^h} \|\vec{u}_h - \vec{u}\|_1 \le Ch^k \|\vec{u}\|_{k+1} \quad \forall\, \vec{u} \in H^{k+1}(\Omega) \cap H^1_0(\Omega),
$$

$$
(75)\qquad \inf_{p_h \in S^h} \|p - p_h\| \le Ch^k \|p\|_k \qquad \forall\, p \in H^k(\Omega) \cap L^2_0(\Omega).
$$

(b) *The inf-sup condition or LBB condition:* there exists a constant C', independent of h, such that

$$
(76)\qquad \inf_{0 \ne q_h \in S^h} \ \sup_{0 \ne \vec{u}_h \in X^h} \frac{\int_\Omega q_h \operatorname{div} \vec{u}_h \, dx}{\|\vec{u}_h\|_1 \|q_h\|} \ge C' > 0.
$$

This condition assures the stability of the discrete Navier–Stokes solutions.

To preserve the antisymmetry of the trilinear form $c(\vec{u}; \vec{v}, \vec{w})$ on the finite element spaces, we introduce the modified trilinear form (see [32])

$$
\widetilde{c}(\vec{u}; \vec{v}, \vec{w}) = \frac{1}{2}\{c(\vec{u}; \vec{v}, \vec{w}) - c(\vec{u}; \vec{w}, \vec{v})\} \qquad \forall\, \vec{u}, \vec{v}, \vec{w} \in H^1(\Omega),
$$

from which we have

$$
(77)\qquad \begin{cases} \widetilde{c}(\vec{u}; \vec{v}, \vec{w}) = -\widetilde{c}(\vec{u}; \vec{w}, \vec{v}) \quad \forall\, \vec{u}, \vec{v}, \vec{w} \in H^1(\Omega), \\ \widetilde{c}(\vec{u}; \vec{v}, \vec{v}) = 0 \quad \forall\, \vec{u}, \vec{v}, \vec{w} \in H^1(\Omega) \end{cases}
$$

and

$$
c(\vec{u}; \vec{v}, \vec{w}) = \widetilde{c}(\vec{u}; \vec{v}, \vec{w}) \qquad \forall\, \vec{u} \in H^1_0(\Omega) \cap W(\Omega),\ \forall\, \vec{v} \in H^1(\Omega),\ \forall \vec{w} \in H^1_0(\Omega).
$$

In the framework of the conforming finite element approximation and only in the two-dimensional case (see [32]), we have

$$
(78)\qquad \begin{cases} |\widetilde{c}(\vec{u}; \vec{v}, \vec{w})| \le K_1 \|\vec{u}\|_1 \|\vec{v}\|_1 \|\vec{w}\|_1, \\ |\widetilde{c}(\vec{u}; \vec{v}, \vec{w})| \le K_2 \|\vec{u}\|^{\frac{1}{2}} \|\nabla \vec{u}\|^{\frac{1}{2}} \|\nabla \vec{v}\| \|\vec{w}\|^{\frac{1}{2}} \|\nabla \vec{w}\|^{\frac{1}{2}} \end{cases}
$$

$\forall\ \vec{u}, \vec{v}, \vec{w} \in H^1(\Omega)$.

Next, let $P^h = X^h|_\Gamma$, i.e., P_h consists of the restriction, to the boundary Γ, of functions belonging to X^h. For all choices of conforming finite element space X^h we then have that $P^h \subset H^{-1/2}(\Gamma)$. For the subspaces $P^h = X^h|_\Gamma$, we assume the approximation property: there exists an integer l and a constant C, independent of $h, \vec{s}$ such that for $1 \leq k \leq l$ we have

$$\inf_{\vec{s}_h \in p_h} \|\vec{s}_h - \vec{s}\|_{-1/2,\Gamma} \leq Ch^k \|\vec{u}\|_{k-1/2} \quad \forall \vec{s} \in H^{k-1/2}(\Gamma). \tag{79}$$

Now, let $Q^h = X^h|_{\Gamma_c}$, i.e., Q^h consists of the restriction, to the boundary segment Γ_c, of the functions belonging to X^h. For all choices of conforming finite element spaces X^h, we have that $Q^h \subset H^1(\Gamma_c)$. We define $Q_0^h = Q^h \cap H^1_{n0}(\Gamma_c)$. If the same type of polynomials are used in $Q_0^h = Q^h \cap (\Gamma_c)$ we have the following.

(c) *boundary approximating property:* there exists an integer k and a constant C, independent of $h, \vec{s}$ such that for $1 \leq m \leq k$ we have

$$\inf_{\vec{s}_h \in Q_0^h} \|\vec{s}_h - \vec{s}\|_{s,\Gamma_c} \leq Ch^{m-s+1/2} \|\vec{s}\|_{m+1/2} \quad \forall \vec{s} \in H^1_{n0}(\Gamma_c), \quad 0 \leq s \leq 1. \tag{80}$$

See [3] and [9] for details concerning the approximation on the boundary.

4.2. Formulation of the fully discrete optimal control approximation. Let $\sigma_N = \{t_n\}_{n=0}^N$ be a partition of $[0,T]$ in equal intervals $\Delta t = T/N$ with $t_0 = 0$ and $t_N = T$. For each fixed Δt (or N) and for every quantity $q(t,\vec{x})$, we associate the corresponding set $\{q_h^{(n)}\}_{n=1}^N$. We will denote the vector $(q_h^{(1)}, q_h^{(2)}, \ldots, q_h^{(N)})$ with bold-faced letter $\mathbf{q}_h$ and the space Y^N as $\mathbf{Y}$. The continuous linear function $\vec{q}_h^N(t,\vec{x})$ is defined by $\vec{q}_h^N(t_n,\vec{x}) = q_h(t_n,\vec{x})$ $\forall$ $n = 0,1,2\ldots,N$.

Given $\Delta t = T/N$, $\vec{\mathbf{g}} \in \mathbf{H}^{1/2}(\Gamma)$, and $\vec{u}_0 \in curl(H^2)(\Omega)$, then $(\vec{\mathbf{u}}_h, \mathbf{p}_h)$ is called a *generalized solution* of the fully discrete time-space approximate Navier–Stokes equations if $\vec{u}_h^{(n)} \in X^h$, $p_h^{(n)} \in S_0^h$ and $(\vec{u}_h^{(n)}, p_h^{(n)})$ satisfies the following system of equations:

$$\begin{cases} \frac{1}{\Delta t}(\vec{u}_h^{(n)} - \vec{u}_h^{(n-1)}, \vec{v}_h) + \nu a(\vec{u}_h^{(n)}, \vec{v}_h) \\ \qquad + \tilde{c}(\vec{u}_h^{(n)}; \vec{u}_h^{(n)}, \vec{v}_h) + b(\vec{v}_h, p^{(n)}) = 0 \quad \forall\, \vec{v}_h \in X_0^h, \\ b(\vec{v}_h^{(n)}, q_h) = 0 \quad \forall\, q_h \in S_0^h, \\ (\vec{u}_h^{(n)}, \vec{s})_\Gamma = (\vec{g}_h^{(n)}, \vec{s})_{\Gamma_c} \quad \forall\, \vec{s} \in Q_0^h, \end{cases} \tag{81}$$

for $n = 1, 2, \ldots, N$, with initial velocity $\vec{u}_h^{(0)} = \pi^h \vec{u}_0(\vec{x})$.

The formulation of the problem in the fully discrete approximation becomes the following:

> *given* $\Delta t = T/N$, $\vec{u}_0 \in curl(H^2)(\Omega)$, *and* $\vec{U} \in U_{ad}$, *find* $(\vec{\mathbf{u}}_h, \mathbf{p}_h, \vec{\mathbf{g}}_h)$ *in* $\mathbf{X}^h \times \mathbf{S}_0^h \times \mathbf{Q}_0^h$ *such that* $(\vec{u}_h^{(n)}, p_h^{(n)}, \vec{g}_h^{(n)})$ *is the solution of* (81) *and minimizes the cost function*

$$\begin{aligned} \mathcal{J}_h^N(\vec{\mathbf{u}}_h, \vec{\mathbf{g}}_h) &= \frac{\alpha}{2} \sum_{n=1}^N \|\vec{u}_h^{(n)} - \vec{U}^{(n)}\|^2 \Delta t \\ &+ \frac{\beta}{2} \sum_{n=1}^N [\|\vec{g}_h^{(n)}\|^2_{\Gamma_c} \Delta t + \beta_1 \|\partial_s \vec{g}_h^{(n)}\|^2_{\Gamma_c} \Delta t + \beta_2 \|(\vec{g}_h^{(n)} - \vec{g}_h^{(n-1)})\|^2_{\Gamma_c}], \end{aligned} \tag{82}$$

with $\vec g^{(0)} = \pi_h \gamma \vec u_0$.

In the above definition, the operator π_h approximates the trace of a function in the corresponding finite element space. In the framework of conforming finite elements, the existence can be proved by using the same standard techniques. We state the theorem for completeness.

THEOREM 4.1. *Given* $\Delta t = T/N$, $\vec u_0 \in curl(H^2)(\Omega)$, *and* $\vec U \in U_{ad}$, *there exists a solution* $(\vec{\mathbf{u}}_h, \mathbf{p}_h, \vec{\mathbf{g}}_h)$ *in* $\mathbf{X}^h \times \mathbf{S}_0^h \times \mathbf{Q}_0^h$ *of the fully discrete optimal control problem.*

4.3. First-order necessary condition and the optimality system. We can derive the first-order necessary condition, the Euler equation, and the final characterization for the optimal control. All these results can be obtained proceeding in a manner similar to the semidiscrete case. For conforming finite elements we can state the following theorem.

THEOREM 4.2. *Given* $\Delta t = T/N$ *and* $\vec u_0 \in curl(H^2)(\Omega)$. *Let* $(\vec{\mathbf{u}}_h, \boldsymbol{\sigma}_h, \vec{\mathbf{g}}_h) \in \mathbf{X}^h \times \mathbf{S}_0^h \times \mathbf{Q}_0^h$ *denote an optimal control solution of the discrete optimal control problem. Then, the control* $\vec{\mathbf{g}}_h$ *satisfies the following system:*

$$\int_{\Gamma_c} \Bigg[\vec g_h^{(n)} \cdot \widetilde{\vec r}_h - \frac{\beta_1}{\Delta t^2}(\vec g_h^{(n+1)} - 2\vec g_h^{(n)} + \vec g_h^{(n-1)}) \cdot \widetilde{\vec r}_h + \beta_2 \partial_s \vec g_h^{(n)} \cdot \partial_s \widetilde{\vec r}_h$$
$$+ k^{(n)} \vec n \cdot \widetilde{\vec r}_h - \frac{1}{\beta}(\vec \xi_h^{(n)} \cdot \widetilde{\vec r}_h) \Bigg] \, d\vec x dt = 0 \quad for \quad n = 1, \ldots, N-1,$$

with

$$\int_{\Gamma} \vec g_h^{(n)} \cdot \vec n \, d\vec x = 0 \quad for \quad n = 1, \ldots, N-1,$$
$$\vec g^{(0)} = \gamma_0 \vec u_0 \quad and \quad \vec g^{(N)} = \vec g^{(N-1)} \quad on \quad \Gamma_c,$$

where $\vec{\boldsymbol{\xi}}_h \in \mathbf{P}^h(\Gamma)$ *is defined by*

$$(\vec \xi_h^{(n-1)}, \widetilde{\vec v}_h)_{\Gamma_c} = \left(\frac{\partial \vec w_h^{(n-1)}}{\partial n} - \sigma_h^{(n-1)} \vec n, \widetilde{\vec v}_h \right)_{\Gamma_c}$$
$$= -\alpha(\vec u_h^{(n)} - \vec U^{(n)}, \vec v_h)_\Omega - \frac{1}{\Delta t}(\vec w_h^{(n)} - \vec w_h^{(n-1)}, \widetilde{\vec v}_h)_\Omega$$
$$+ \nu a(\vec w_h^{(n-1)}, \widetilde{\vec v}_h) + \widetilde c(\widetilde{\vec v}_h; \vec u_h^{(n)}, \vec w_h^{(n-1)}) + \widetilde c(\vec u_h^{(n)}; \widetilde{\vec v}_h, \vec w_h^{(n-1)})$$
$$+ b(\widetilde{\vec v}_h, \sigma_h^{(n-1)}) \quad \forall \widetilde{\vec v}_h \in X^h(\Omega), \quad for \quad n = 1, \ldots, N,$$

and $\vec{\mathbf{w}}_h$ *and* $\boldsymbol{\sigma}_h$ *satisfy*

$$\begin{cases} -\frac{1}{\Delta t}(\vec w_h^{(n)} - \vec w_h^{(n-1)}, \vec v_h) + \nu a(\vec w_h^{(n-1)}, \vec v_h) + \widetilde c(\vec v_h; \vec u_h^{(n)}, \vec w_h^{(n-1)}) + \widetilde c(\vec u_h^{(n)}, \vec v_h; \vec w_h^{(n-1)}) \\ \qquad + b(\vec v_h, \sigma_h^{(n-1)}) = \alpha(\vec u_h^{(n)} - \vec U^{(n)}, \vec v_h) \quad \forall \vec v_h \in X_0^h(\Omega), \quad for \quad n = 1, \ldots, N, \\ b(\vec w_h^{(n-1)}, q_h) = 0 \quad \forall q \in S_0^h(\Omega) \quad for \quad n = 1, \ldots, N, \\ \vec w_h^{(n-1)} = 0 \quad on \quad \Gamma \quad for \quad n = 1, \ldots, N, \\ \vec w_h^{(N)} = 0. \end{cases}$$

We remark that an optimal solution is a solution of the above system but among the solutions of this system there may be solutions that are not optimal.

5. Implementation of fully discrete space-time approximations. In our numerical tests we consider only tangential control. This enables us to dispense with the unknown function $k^{(n)}$ in the optimality system. The equations for tangential control consist of

(a) the Navier–Stokes system

$$(83)\qquad \begin{cases} \frac{1}{\Delta t}(\vec{u}_h^{(n)} - \vec{u}_h^{(n-1)}, \vec{v}_h) + \nu a(\vec{u}_h^{(n)}, \vec{v}_h) + \widetilde{c}(\vec{u}_h^{(n)}; \vec{u}_h^{(n)}, \vec{v}_h) \\ \qquad +b(\vec{v}_h, p_h^{(n)}) = 0 \quad \forall \vec{v}_h \in X_0^h(\Omega), \quad \text{for} \quad n = 1, \dots, N, \\ b(\vec{u}_h^{(n)}, q_h) = 0 \quad \forall q_h \in S_0^h(\Omega), \quad \text{for} \quad n = 1, \dots, N, \\ (\vec{u}_h^{(n)}, \vec{s}_h)_\Gamma = (\vec{g}_h^{(n)}, \vec{s}_h)_{\Gamma_c} \quad \forall \vec{s}_h \in P^h(\Gamma), \quad \text{for} \quad n = 1, \dots, N, \\ \vec{w}_h^{(0)} = \pi^h \vec{u}_0 \quad \text{in} \quad \Omega; \end{cases}$$

(b) the adjoint system

$$(84)\qquad \begin{cases} -\frac{1}{\Delta t}(\vec{w}_h^{(n)} - \vec{w}_h^{(n-1)}, \vec{v}_h) + \nu a(\vec{w}_h^{(n-1)}, \vec{v}_h) + \widetilde{c}(\vec{u}_h^{(n)}; \vec{v}_h, \vec{w}_h^{(n-1)}) \\ \qquad +\widetilde{c}(\vec{v}_h; \vec{u}_h^{(n)}, \vec{w}_h^{(n-1)}) + b(\vec{v}_h, \sigma_h^{(n-1)}) = \alpha(\vec{u}_h^{(n)} - \vec{U}^{(n)}, \vec{v}_h) \\ \qquad\qquad \forall \vec{v}_h \in X_0^h(\Omega), \quad \text{for} \quad n = 1, \dots, N, \\ b(\vec{w}_h^{(n-1)}, q_h) = 0 \quad \forall q_h \in S_0^h(\Omega), \quad \text{for} \quad n = 1, \dots, N, \\ \vec{w}_h^{(n-1)} = 0 \quad \text{on} \quad \Gamma, \quad \text{for} \quad n = 1, \dots, N, \\ \vec{w}_h^{(N)} = 0 \quad \text{in} \quad \Omega; \end{cases}$$

(c) the control equation

$$(85)\qquad \begin{cases} -\frac{\beta_1}{\Delta t^2}(\vec{\lambda}_h^{(n+1)} - 2\vec{\lambda}_h^{(n)} + \vec{\lambda}_h^{(n-1)}, \vec{r}_h) + \beta_2(\partial_s \vec{\lambda}_h^{(n)}, \partial_s \vec{r}_h) + (\vec{\lambda}_h^{(n)}, \vec{r}_h) \\ \qquad = \frac{1}{\beta}(\frac{\partial \vec{w}^{(n)}}{\partial n}, \vec{r}_h) \quad \forall \vec{r}_h \in Q_0^h(\Gamma_c), \quad \text{for} \quad n = 1, \dots, N-1, \\ \vec{\lambda}_h^{(n)} = 0 \quad \text{on} \quad \Gamma \setminus \Gamma_c, \quad \text{for} \quad n = 1, \dots, N-1, \\ \vec{\lambda}_h^{(0)} = \pi_h \gamma_0 \vec{u}_0 \quad \text{on} \quad \Gamma_c, \\ \vec{\lambda}_h^{(N)} = \vec{\lambda}_h^{(N-1)} \quad \text{on} \quad \Gamma_c; \end{cases}$$

(d) the compatibility boundary equation

$$(86)\qquad \vec{\lambda}^{(n)} = \vec{g}^{(n)} \quad \text{for} \quad n = 1, \dots, N,$$

where it is understood that $\vec{g}^{(n)}$ is a tangential vector.

In order to solve this numerical system, let us consider the gradient method for the optimal control problem. We have to split the system into three parts in order to apply the algorithm: the Navier–Stokes system (83), the adjoint system (84), and the control equation (85). In the gradient algorithm, we satisfy the relation in (86) only when convergence is achieved. Let $\mathcal{J}_h^N(k) = \mathcal{J}_h^N(\vec{\mathbf{u}}_h(k), \vec{\mathbf{g}}_h(k))$ and τ be the tolerance required for the convergence of the functional.

The *gradient algorithm* we study proceeds as follows:

```
(a) initialization:
    (i) given $\vec{\mathbf{g}}_h(0), \tau$, and $\epsilon = 1$;
    (ii) solve (83) with $\vec{\mathbf{g}}_h(0)$ for $\vec{\mathbf{u}}_h(0)$;
    (iii) evaluate $\mathcal{J}_h^N(0)$;
(b) main loop:
    (iv) solve (84) with $\vec{\mathbf{u}}_h(k-1)$ for $\vec{\mathbf{w}}_h(k)$;
    (v) solve (85) with $\vec{\mathbf{w}}_h(k)$ for $\vec{\boldsymbol{\lambda}}_h(k)$;
    (vi) set $\vec{g}_h^{(n)}(k) = \vec{g}_h^{(n)}(k-1) - \epsilon(\vec{g}_h^{(n)}(k-1) - \vec{\lambda}_h^{(n)}(k))$
    (vii) solve (83) for $\vec{\mathbf{u}}_h(k)$;
    (viii) evaluate $\mathcal{J}_h^N(k)$;
    (ix) if $\mathcal{J}_h^N(k) \le \mathcal{J}_h^N(k-1)$, set $\epsilon = 1.5\epsilon$ and go to (iv);
   if $\mathcal{J}_h^N(k) > \mathcal{J}_h^N(k-1)$, set $\epsilon = 0.5\epsilon$ and go to (vi).
```

The algorithm stops when $|\mathcal{J}_h^N(k) - \mathcal{J}_h^N(k-1)|/\mathcal{J}_h^N(k) \le \tau$. We can show that this gradient algorithm converges to a solution of the discrete optimality system.

THEOREM 5.1. *Let* $(\vec{\mathbf{u}}_h(k), \vec{\mathbf{w}}_h(k), \mathbf{p}_h(k), \boldsymbol{\sigma}_h(k), \vec{\mathbf{g}}_h(k))$ *be the kth iterate of the gradient algorithm and let* $(\vec{\mathbf{u}}_h, \vec{\mathbf{w}}_h, \mathbf{p}_h, \boldsymbol{\sigma}_h, \vec{\mathbf{g}}_h)$ *denote a solution of the fully discrete optimality system* (83)–(85). *Then, for* Δt *sufficiently small, there exists a ball* $\mathbf{B} \in \mathbf{Q}_0^h$*, whose radius depends on the ratio* α/β*, such that, if* $\vec{\mathbf{g}}_h(0) \in \mathbf{B}$*, the solution of the gradient algorithm converges to* $(\vec{\mathbf{u}}_h, \vec{\mathbf{w}}_h, \mathbf{p}_h, \boldsymbol{\sigma}_h, \vec{\mathbf{g}}_h)$ *as* $k \to \infty$.

Proof. The theorem follows if we make use of this classical result on the gradient algorithm. Let X be a Hilbert space with norm $\|\cdot\|$ and let $\mathcal{J}(\cdot)$ be a real-valued functional on X. Suppose that $\mathcal{J}(\cdot)$ is of class C^2; suppose that $\widehat{x}$ is a local minimizer of $\mathcal{J}(\cdot)$; suppose that there exists a ball B of X, centered at $\widehat{x}$, such that there exist two real numbers c_1 and c_2 such that $\forall\ \widetilde{g} \in B$ and $\forall\ \delta x_1, \delta x_2 \in X$

$$(87) \quad \mathcal{J}''(\widetilde{x})(\delta x_1, \delta x_2) \le c_1 \|\delta x_1\| \|\delta x_2\| \qquad \text{and} \qquad c_2 \|\delta x_1\|^2 \le \mathcal{J}''(\widetilde{x})(\delta x_1, \delta x_1),$$

where $\mathcal{J}''(\widetilde{x})(\delta x_1, \delta x_2)$ is the bilinear form associated with the second derivatives of $\mathcal{J}(\cdot)$; and suppose that ρ_k is chosen so that

$$(88) \qquad 0 < a \le \rho_k \le b < \frac{2c_2}{c_1} \qquad \forall\ k$$

for some positive numbers a and b. Then, the iterates of the gradient algorithm

$$x(k+1) = x(k) - \rho_k \nabla \mathcal{J}(x(k)), \quad k = 0, 1, 2 \ldots,$$

converge to $\widehat{x}$ for any initial iterate $x(0) \in B$. For details and proof see, e.g., [10] or [20].

In order to bound the second variation of the functional, we follows the technique used in [22, Thm. 5.21]. Here the norm $\|\vec{\mathbf{q}}_h\|_i$ is defined by $\|\vec{\mathbf{q}}_h\|_i^2 = \sum_{n=1}^N \Delta t \|\vec{q}_h^{(n)}\|_i^2$ and $\|\vec{\mathbf{q}}_h\|_{1,1,\Gamma_c}$ by $\|\vec{\mathbf{q}}_h\|_{1,1,\Gamma_c} = \|\vec{\mathbf{q}}_h\|_{1,\Gamma_c} + \sum_{n=1}^N \|\vec{q}_h^{(n)} - \vec{q}_h^{(n-1)}\|_{\Gamma_c}$. For each $\widetilde{\mathbf{g}}_h \in \mathbf{Q}_0^h$, the nonvanishing terms of the second variation of $\mathcal{J}_h^N(\widetilde{\mathbf{u}}_h(\widetilde{\mathbf{g}}_h), \widetilde{\mathbf{g}}_h)$ are given by

$$\frac{D^2 \mathcal{J}_h^N(\vec{\mathbf{u}}_h, \vec{\mathbf{g}}_h)}{D\vec{\mathbf{g}}_{1h} D\vec{\mathbf{g}}_{2h}} \cdot \delta\vec{\mathbf{g}}_{1h} \cdot \delta\vec{\mathbf{g}}_{2h}$$
$$= \alpha \sum_{n=1}^N \int_\Omega \left(\widetilde{\vec{w}}_{1h}^{(n)} \cdot \widetilde{\vec{w}}_{2h}^{(n)} + (\vec{u}_h^{(n)} - \vec{U}_h^{(n)}) \cdot \widetilde{\vec{z}}_h^{(n)} \right) d\vec{x}\, \Delta t$$

$$
\begin{aligned}
&+\beta\sum_{n=1}^{N}\int_{\Gamma_c}\Big[\vec{g}_{1h}^{(n)}\delta\vec{g}_{2h}^{(n)}+\beta_2\partial_s\delta\vec{g}_{1h}^{(n)}\partial_s\delta\vec{g}_{2h}^{(n)}\\
&\qquad+\frac{\beta_1}{\Delta t^2}(\delta\vec{g}_{1h}^{(n)}-\delta\vec{g}_{1h}^{(n-1)})(\delta\vec{g}_{2h}^{(n)}-\delta\vec{g}_{2h}^{(n-1)})\Big]d\vec{x}\,\Delta t,
\end{aligned}
$$

where the first variations $\widetilde{w}_{1h}^{(n)}\in X^h$ and $\widetilde{w}_{2h}^{(n)}\in X^h$ are solutions of $\widetilde{w}_{ih}^{(0)}=\vec{0}$ and

$$
(89)\qquad\left\{
\begin{aligned}
&\frac{1}{\Delta t}(\widetilde{w}_{ih}^{(n)}-\widetilde{w}_{ih}^{(n-1)},\vec{v}_h)+\nu a(\widetilde{w}_{ih}^{(n)},\vec{v}_h)+\widetilde{c}(\widetilde{w}_{ih}^{(n)};\vec{u}_h^{(n)},\vec{v}_h)\\
&\qquad+\widetilde{c}(\vec{u}_h^{(n)};\widetilde{w}_{ih}^{(n)},\vec{v}_h)+b(\vec{v}_h,\widetilde{r}_{ih}^{(n)})=(\delta\vec{g}_{ih}^{(n)},\vec{v}_h)\quad\forall\,\vec{v}_h\in X_0^h(\Omega),\\
&b(\widetilde{w}_{ih}^{(n)},q_h)=0\quad\forall\,q_h\in S_0^h(\Omega),\\
&(\widetilde{w}_{ih}^{(n)},\vec{s})_\Gamma=(\delta\vec{g}_{ih}^{(n)},\vec{s})_{\Gamma_c}\quad\forall\vec{s}\in H^{-1/2}(\Gamma),
\end{aligned}
\right.
$$

for $n=1,2,\ldots,N$ and for $i=1,2$, respectively, and the second variation $\widetilde{z}_h^{(n)}\in X_0^h$ is the solution of $\widetilde{z}_h^{(0)}=\vec{0}$ and

$$
(90)\left\{
\begin{aligned}
&\frac{1}{\Delta t}(\widetilde{z}_h^{(n)}-\widetilde{z}_h^{(n-1)},\vec{v}_h)+\nu a(\widetilde{z}_h^{(n)},\vec{v}_h)+\widetilde{c}(\widetilde{z}_h^{(n)};\widetilde{u}_h^{(n)},\vec{v}_h)+\widetilde{c}(\widetilde{u}_h^{(n)};\widetilde{z}_h^{(n)},\vec{v}_h)\\
&\qquad+b(\vec{v}_h,\widetilde{s}_h^{(n)})=-\widetilde{c}(\widetilde{w}_{1h}^{(n)};\widetilde{w}_{2h}^{(n)},\vec{v}_h)-\widetilde{c}(\widetilde{w}_{2h}^{(n)};\widetilde{w}_{1h}^{(n)},\vec{v}_h)\quad\forall\,\vec{v}_h\in X_0^h(\Omega),\\
&b(\widetilde{z}_h^{(n)},q_h)=0\quad\forall\,q_h\in S_0^h(\Omega),
\end{aligned}
\right.
$$

for $n=1,2,\ldots,N$.

Let $\vec{w}_h^{(n)}\in X_0^h$ be the solution of the adjoint system $\widetilde{w}_h^{(N)}=0$ and

$$
(91)\qquad\left\{
\begin{aligned}
&-\frac{1}{\Delta t}(\vec{w}_h^{(n)}-\vec{w}_h^{(n-1)},\vec{v}_h)+\nu a(\vec{v}_h,\vec{w}_h^{(n-1)})+\widetilde{c}(\vec{v}_h;\vec{u}_h^{(n)},\vec{w}_h^{(n-1)})\\
&\quad+\widetilde{c}(\vec{u}_h^{(n)};\vec{v}_h,\vec{w}_h^{(n-1)})+b(\vec{v}_h,r_h^{(n-1)})\\
&\quad=\ \alpha(\vec{u}_h^{(n)}-\vec{U}^{(n)},\vec{v}_h)\quad\forall\vec{v}_h\in X_0^h(\Omega),\\
&b(\vec{w}_h^{(n-1)},q_h)=0\quad\forall q_h\in S_0^h(\Omega),
\end{aligned}
\right.
$$

for $n=1,2,\ldots,N$.

By following arguments similar to those used in [22], we have

$$
\begin{aligned}
&\alpha\Delta t\sum_{n=1}^{N}\int_\Omega(\vec{u}^{(n)}-\vec{U}^{(n)})\cdot\widetilde{z}_h^{(n)}\\
&\qquad\qquad=\ -\Delta t\sum_{i=1}^{N}\Big(\widetilde{c}(\widetilde{w}_{1h}^{(n)};\widetilde{w}_{2h}^{(n)},\vec{w}_h^{(n-1)})+\widetilde{c}(\widetilde{w}_{2h}^{(n)};\widetilde{w}_{1h}^{(n)},\vec{w}_h^{(n-1)})\Big)
\end{aligned}
$$

and the estimates

$$\|\vec{\mathbf{w}}_h\|_1\le\alpha f_2(\|\vec{\mathbf{g}}_h-\widetilde{\mathbf{g}}_h\|_{1,\Gamma_c}),$$

$$\|\widetilde{\mathbf{w}}_h\|_1\le f_1(\|\vec{\mathbf{g}}_h-\widetilde{\mathbf{g}}_h\|_{1,\Gamma_c})\|\delta\vec{\mathbf{g}}_h\|_{1,1,\Gamma_c},$$

where $f_1(\cdot)$ and $f_1(\cdot)$ are continuous functions. Therefore, for some constants $C_1,C_2>0$, we have

$$
\begin{aligned}
&|D^2\mathcal{J}_h^N(\widetilde{\mathbf{u}}_h(\widetilde{\mathbf{g}}_h),\widetilde{\mathbf{g}}_h)(\delta\vec{\mathbf{g}}_{1h},\delta\vec{\mathbf{g}}_{2h})|\\
&\le\ \Big(3\beta\beta_{max}+\big(\alpha+\alpha C_1f_2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|_{1,\Gamma_c})\big)f_1^2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|_{1,\Gamma_c})\Big)\|\delta\vec{\mathbf{g}}_{1h}\|_{1,1,\Gamma_c}\|\delta\vec{\mathbf{g}}_{2h}\|_{1,1,\Gamma_c}
\end{aligned}
$$

and

$$
\begin{aligned}
&|D^2\mathcal{J}_h^N(\widetilde{\mathbf{u}}_h(\widetilde{\mathbf{g}}_h),\widetilde{\mathbf{g}}_h)(\delta\vec{\mathbf{g}}_{1h},\delta\vec{\mathbf{g}}_{1h})|\\
&\qquad\geq \Big(\beta\beta_{min} - C_2\alpha f_2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|_{1,\Gamma_c})f_1^2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|_{1,\Gamma_c})\Big)\|\delta\vec{\mathbf{g}}_{1h}\|^2_{1,1,\Gamma_c},
\end{aligned}
$$

where $\beta_{min}=\min\{1,\beta_1,\beta_2\}$ and $\beta_{max}=\max\{1,\beta_1,\beta_2\}$.

Now, assume that $\|\widehat{\mathbf{g}}_h-\widetilde{\mathbf{g}}_h\|_{1,\Gamma_c}\leq\xi$ so that consequently $f_1(\|\widehat{\mathbf{g}}_h-\widetilde{\mathbf{g}}_h\|_{1,\Gamma_c})\leq\xi_1$ and $\alpha f_2(\|\widehat{\mathbf{g}}_h-\widetilde{\mathbf{g}}_h\|_{1,\Gamma_c})\leq\xi_2$ for some $\xi_1,\xi_2\leq\infty$ and small β. Then, we may choose c_1 and c_2 such that

$$
c_1 = 3\beta\beta_{max} + (\alpha C_1\xi_2)\xi_1^2 \qquad\text{and}\qquad c_2=\beta\beta_{min}-\alpha C_2\xi_2\xi_1^2.
$$

It follows that, for small enough values of the ratio α/β, there exists a constant c_1 such that

$$
\frac{D^2\mathcal{J}_h^N(\vec{\mathbf{g}}_h)}{D\vec{\mathbf{g}}_{1h}D\vec{\mathbf{g}}_{2h}}\cdot\delta\vec{\mathbf{g}}_{1h}\cdot\delta\vec{\mathbf{g}}_{2h}\leq c_1\|\delta\vec{g}_{1h}^{(n)}\|^2_{1,1,\Gamma_c}\|\delta\vec{g}_{2h}^{(n)}\|^2_{1,1,\Gamma_c}
$$

and there exists a constant $c_2>0$ such that

$$
\begin{aligned}
&\frac{D^2\mathcal{J}_h^N(\vec{\mathbf{g}}_h)}{D\vec{\mathbf{g}}_{1h}D\vec{\mathbf{g}}_{2h}}\delta\vec{\mathbf{g}}_{1h}\delta\vec{\mathbf{g}}_{1h}=\alpha\sum_{n=1}^{N}\|\vec{w}_{h1}^{(n)}\|^2\Delta t\\
&+\beta\sum_{n=1}^{N}[\|\delta\vec{g}_{1h}^{(n)}\|^2\Delta t+\beta_2\|\partial_s\delta\vec{g}_{1h}^{(n)}\|^2\Delta t+\beta_1\|\vec{g}_{1h}^{(n)}-\vec{g}_{1h}^{(n-1)}\|^2]\geq c_2\|\delta\vec{\mathbf{g}}_{h2}\|^2_{1,1,\Gamma_c}. \qquad\square
\end{aligned}
$$

6. Computational examples.

6.1. Test 1. We consider a unit square domain $(0,1)\times(0,1)\subset\mathbb{R}^2$. We assume that the time interval $[0,T]$ is divided into N equal intervals ($\Delta t=T/N$). The finite element spaces are chosen to be the Taylor–Hood finite element pair with respect to a rectangular mesh, i.e., continuous piecewise biquadratic for the velocity and continuous piecewise bilinear for the pressure. The same polynomials are used for the restriction on the boundary. The mesh size is denoted by h and calculations with varying mesh sizes have been performed. In this first test, the control is the tangential velocity on the boundary and the target flow velocity is defined by

$$
\begin{aligned}
&\phi(t,z)=(1-\cos(2\pi tz))\times(1-z)^2,\\
&U(x,y)=10\frac{d}{dy}\left(\phi(.4,x)\phi(.4,y)\right),\qquad V(x,y)=-10\frac{d}{dx}\left(\phi(.4,x)\phi(.4,y)\right);
\end{aligned}
$$

note that the target velocity field vanishes on the boundary Γ.

Velocity tracking evolution. The initial velocity is chosen to be

$$
u_0(x,y)=-5U(x,y),\qquad v_0(x,y)=-5V(x,y), \tag{92}
$$

i.e., it is a high energy flow rotating in an opposite direction with respect to the target flow. Note that the initial velocity field vanishes on the boundary so that, by the compatibility condition (18), the control $\vec{g}$ vanishes at $t=0$.

In this test, $\Delta t = 0.05$, $1/\nu = 300$, α has been set to 1, β to 0.0001, and $\beta_1 = \beta_2$ to 0.1. The control is the right-side tangential boundary velocity. This evolution is described in Figure 1 with the controlled fluid depicted on the left and the desired flow on the right. All the pictures are normalized by the maximum values. At the beginning, the effect of control is felt in a very limited area near the control boundary because the high energy initial flow prevails in the central part of the domain. Then, the control gains force and progressively reaches the whole domain and finally, the controlled flow reaches the optimal approximation and keeps this stationary configuration. Figure 2 shows the error $\|\vec{u} - \vec{U}\|$ between the controlled flow $\vec{u}$ and the target flow $\vec{U}$. As we can see, the error rapidly goes to a constant value which represents the optimal steady approximation. Figures 3 and 4, respectively, show the corresponding values of the norm of the control $\vec{g}$ and its time derivative as functions of time. The control vanishes at $t = 0$ due to the compatibility condition (18), but then works hard for a short time in order to steer the controlled flow to the desired one; it then decreases and remains flat. Near $t = T$, it is not necessary to drive the flow and a decreasing boundary velocity minimizes the functional. This small change does not affect the norm error in Figure 2 due to the scale of the graph but we can see a small improvement in the match at $t = 4$. We remark that the optimal stationary controlled flow is very different from the target flow. One-sided control is not enough and the result can be considered poor. Smaller values of β cannot help and for a better control we need to extend the extent of the boundary on which control is applied.

Velocity tracking with different values of $\boldsymbol{\beta}$, $\boldsymbol{\beta_1}$, and $\boldsymbol{\beta_2}$. We want to study the effect of changing the form of the functional by changing the parameters β and β_1 ($\beta_2 = \beta_1$). The initial velocity field is set to zero.

In Figure 5, we show the error $\|\vec{u} - \vec{U}\|$ between the controlled flow $\vec{u}$ and the target flow $\vec{U}$ for different values of $\beta_1 = \beta_2$. We have $\beta_1 = \beta_2$ equal to 0.01 (a), 0.1 (b), and 1 (c). The value of β in this computation is held constant at 0.0001. The time step Δt is again 0.05 and $h = 1/16$. We note that changing β_1 has little effect on the optimal solution. Of course, the reduction in the error is a little quicker when β_1 is smaller. The norm of $\vec{g}$ and its derivative are shown in Figures 6 and 7. For low values of β_1, the control is allowed to move quicker and the sensibility of the system is greater. We note that there is a small change in control magnitude but the optimal stationary flow is still approximately the same. Differences can be noted in the nonsteady part of the evolution flow.

For different values of β we do obtain different optimal controls. In Figure 8, we see the error $\|\vec{u} - \vec{U}\|$ between the controlled flow $\vec{u}$ and the target flow $\vec{U}$ for β equal to 0.0001 (a), 0.001 (b), and 0.01 (c). For small values of β, the optimal control solution is limited by the magnitude of the control and its derivatives. For values of $\beta > 0.005$, the control is poor. Generally, a good control involves small values of β (around 0.001). In Figures 9 and 10, we show, respectively, the norm of the control $\vec{g}$ and its time derivative for the corresponding values of β. As expected, the control $\vec{g}$ approaches zero for low values of β.

Different number of controlled sides. Now we examine the effect of applying control on more sides of the flow domain. We try to repeat the evolution problem changing the number of sides. In Figures 11 to 14, we have the norm of the error, the control norm, the derivative norm in time and in space, respectively, for applying control on different numbers of sides. One-sided control is (a), two-sided control is (b), three-sided control is (c), and finally the control on the whole boundary is (d). Of course the match is improving with increasing number of controlled sides. As we can see in Figure 12, the control behaves better and the maximum strength required decreases when the number of controlled sides increases. A picture of the stationary match can be found in Figure 15. The improvement is evident. The tracking time evolution for the four-sided case is reported in Figure 16.

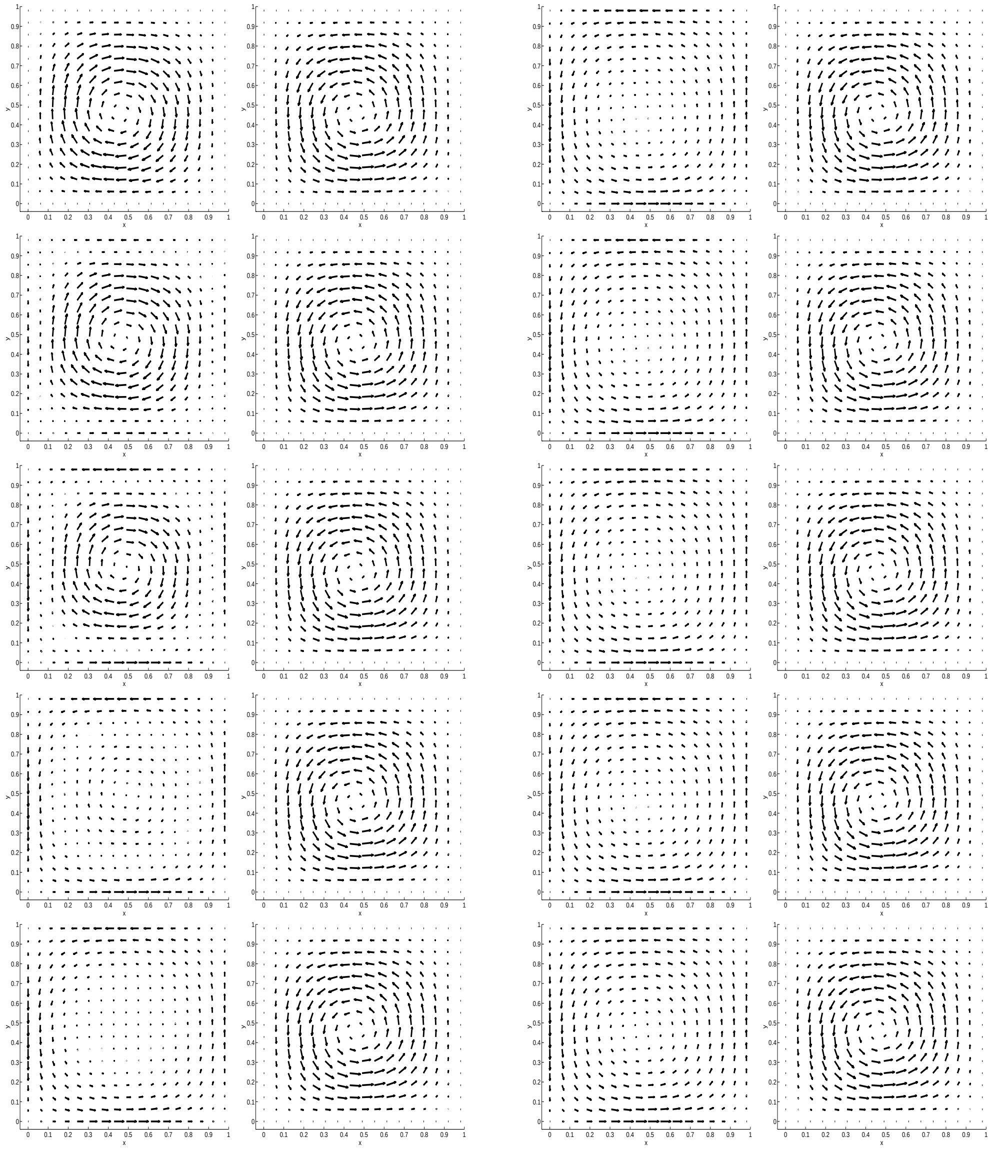

FIG. 16. *Test* 1. *Controlled (left) and target (right) flows at* $t = 0, 0.1, 0.2, 0.4, 0.6$ *(left pair of columns) and* $t = 0.8, 1, 2, 3, 4$ *(right pair of columns) for four-sided control.*

6.2. Test 2. We consider a unit square domain $(0,1) \times (0,1) \subset \mathbb{R}^2$. We assume that the time interval $[0,T]$ is divided in equal intervals of time $\Delta t = T/N$. The Taylor–Hood finite elements are used in this calculation on a rectangular mesh. We report only the final result with $h = 1/16$, but calculations with varying mesh sizes has been performed. The target velocity $\vec{U}$ for this test is time dependent and is given by

$$\phi(k,t,z) = (1 - \cos(2k\pi tz)) \times (1-z)^2 ,$$

$$a(k,t,x,y) = \frac{d}{dy}\left(\phi(k,t,x)\phi(k,t,y)\right), \qquad b(k,t,x,y) = -\frac{d}{dx}\left(\phi(k,t,x)\phi(k,t,y)\right),$$

$$U = a(.25,.4,x,y) + a(.5,t,x,y)/(4\pi t + 1),$$

$$V = b(.25,.4,x,y) + b(.5,t,x,y)/(4\pi t + 1).$$

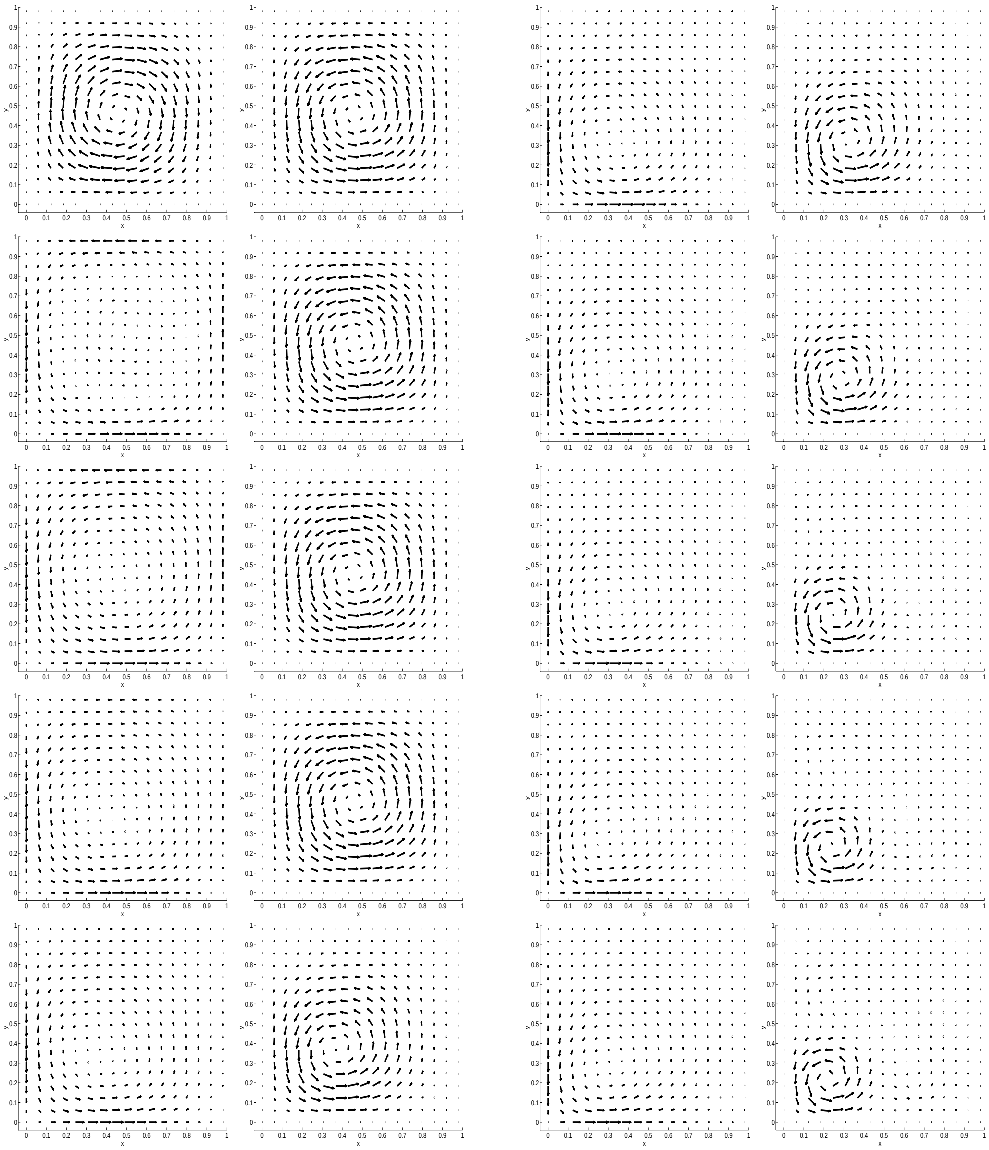

FIG. 17. *Test* 2. *Controlled (left) and target (right) flows at* $t = 0, 0.5, 1, 1.5, 2$ *(left pair of columns) and* $t = 2.5, 3, 3.5, 3.75, 4$ *(right pair of columns) for four-sided control.*

With this velocity field we have the superposition of two flows: one flow with a vortex at the center of the domain and another flow with four vortices. Each of these flows prevails at different times of the evolution. The initial velocity for the controlled flow is

$$u_0(x, y) = -5U(1, x, y), \qquad v_0(x, y) = -5V(1, x, y). \tag{93}$$

The evolution is given in Figure 17. In this computation $\alpha = 1$, $\beta = 0.001$, and $\beta_1 = \beta_2 = 0.1$, and $1/\nu = 300$. The control $\vec{g}$ is a four-sided control and that covers the whole boundary Γ. The controlled fluid is on the left, the desired flow is on the right, and all the pictures are normalized. As we can see at $t = 0.5$, the controlled flow reaches the optimal approximation and follows the motion of the target fluid.

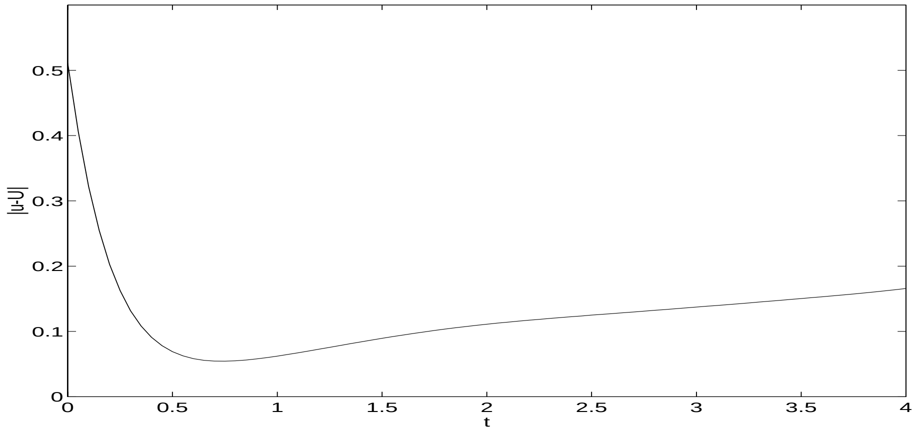

Fig. 18. *Test 2. Error* $\|\vec{u} - \vec{U}\|$.

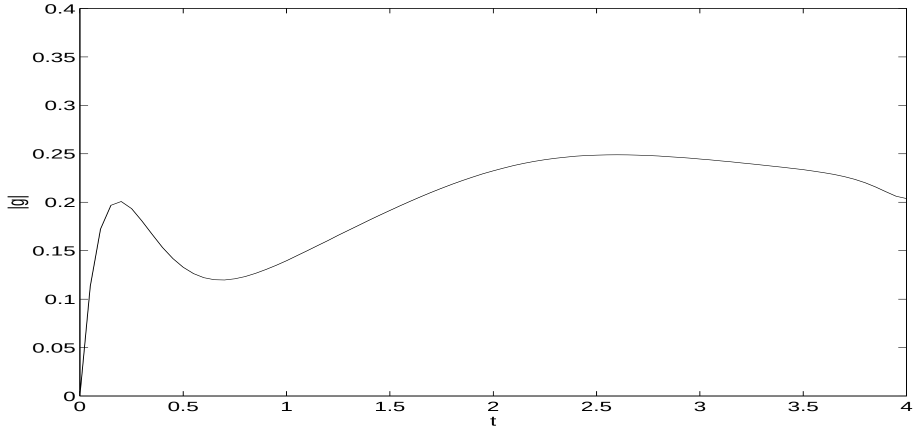

Fig. 19. *Test 2. Control norm* $\|g\|$.

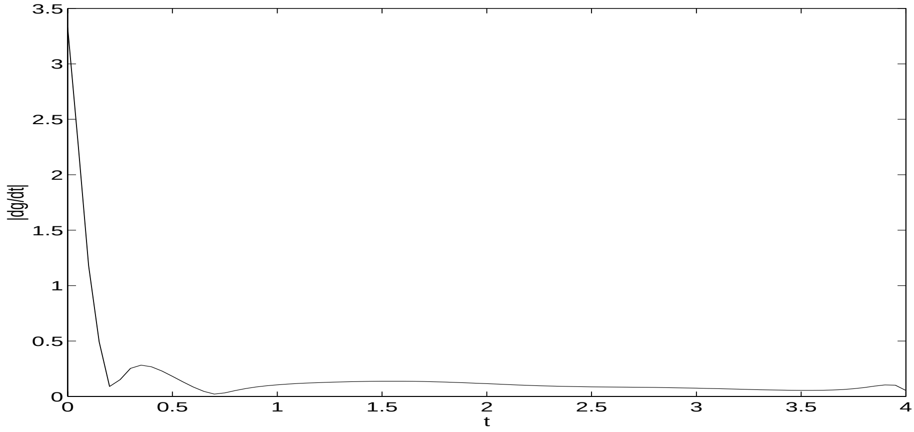

Fig. 20. *Test 2. Control norm* $\|\vec{g}_t\|$.

Figure 18 shows the error $\|\vec{u} - \vec{U}\|$ between the controlled flow $\vec{u}$ and the target flow $\vec{U}$. At the beginning the error rapidly decreases but after this initial interval of time this error increases due to changes in the desired flow. The boundary velocity cannot control the interior of the domain if the desired flow moves rapidly. However, this represents the optimum that can be achieved with the energy available. For the same flow, Figures 19 and 20, respectively, show the values of the norm of the control variable $\vec{g}$ and its time derivative.

OPTIMAL POLICIES FOR n-DIMENSIONAL SINGULAR STOCHASTIC CONTROL PROBLEMS. PART II: THE RADIALLY SYMMETRIC CASE. ERGODIC CONTROL*

LUKASZ KRUK†

Abstract. We consider a singular stochastic control problem with a radially symmetric running cost. We show that the value function is smooth, the nonaction region is a ball, and the problem has an explicit solution in terms of power series. Also, for a singular ergodic control problem with the class of admissible processes constrained to Brownian motions reflected normally at the boundary of some open, connected Caccioppoli set, we show existence, regularity, and basic properties of optimal domains using a geometric measure-theoretic approach.

Key words. singular stochastic control, radial symmetry, optimal policy, normally reflected Brownian motion, geometric measure theory

1. Introduction.

The goal of the first part of this article is to minimize

$$u_M(x) = E^x \int_0^\infty e^{-t}[h(X_t)dt + d\xi_t], \tag{1}$$

where $x \in R^n$ is fixed and h is a nonnegative, convex, radially symmetric function (suitably smooth),

$$X_t = x + \sqrt{2}W_t + M_t, \tag{2}$$

with W_t an n-dimensional Brownian motion, M_t any adapted process of bounded variation over finite time-intervals, and ξ_t the variation of M up to time t. This problem, without the assumption of radial symmetry of h, has been investigated thoroughly in the existing literature. It is known that in one (see, e.g., [6, 10, 27, 28, 29, 34, 35, 40]; consult [41] or [14] for more complete references) or two [45] dimensions the corresponding value function u is twice continuously differentiable (smooth fit) and the optimal policy is the Brownian motion reflected at the boundary of the nonaction region $\mathcal{C} = \{x \in R^n : |\nabla u(x)| < 1\}$. In higher dimensions it is only known that the value function is $W^{2,\infty}_{loc}$ and that the optimal policy exists, is unique [42, 46], and solves a generalized Skorokhod problem [36].

Under our additional assumption of radial symmetry, thanks to symmetry of the Brownian motion, the value function u itself is radially symmetric. This allows us to use one-dimensional methods, yielding a simple n-dimensional example of smooth fit and providing an explicit solution in terms of power series under an additional assumption that h is real analytic. Our work generalizes some of the recently published results of [11], where a special case of the value function $h(x) = \lambda|x|^2$ was considered.

In the second part of this article we consider a similar (not necessarily radially symmetric) problem for ergodic control in which we limit the admissible controlled processes to Brownian motions reflected normally at the boundary of some open, connected Caccioppoli set. We show existence, regularity, and some properties of optimal domains like their simple-connectedness, convexity for $n = 2$, and the mean curvature equation satisfied by their boundaries. Singular ergodic control of diffusion processes has been investigated, e.g., in [41] and the references given there. Our approach, however, differs from the results contained in those papers in both constraining the class of admissible controls and the methods used. In the context of optimizing the ergodic cost of controlling the *normally* reflected Brownian motion, regularity theory for domain-dependent functionals and the prescribed mean curvature equation seem to be convenient tools for establishing the desired properties of an optimal region.

2. The radially symmetric case.

2.1. The smooth fit. Let $(W_t, \mathcal{F}_t, t \geq 0)$ be a standard n-dimensional Brownian motion defined on a complete probability space $(\Omega, \mathcal{F}, P)$. Let $\{\mathcal{F}_t\}$ be the augmentation of the filtration generated by W (see [33]). For a given $x \in R^n$, let a process X_t be defined by (2), where M_t is a left-continuous process adapted to $\mathcal{F}_t$ such that, for all $T > 0$ P-a.s., the variation of $M_{.}(\omega)$ on the interval $[0, T]$ is finite. We write

$$M_t = \int_0^t N_s d\xi_s, \tag{3}$$

where $|N_t| = 1$ for every $t \geq 0$ almost surely (a.s.) and ξ is nondecreasing and left-continuous. In what follows, we shall always describe M_t as (N_t, ξ_t).

Let $h : R^n \to R$ be a strictly convex, radially symmetric function satisfying, for appropriate positive constants C_0, c_0, and $q > 1$, the following conditions:

$$h \in C^{2,1}(R^n), \tag{4}$$

$$0 \leq h(x) \leq C_0(1 + |x|^q), \tag{5}$$

$$|h(x) - h(x + x')| \leq C_0(1 + h(x) + h(x + x'))^{1-1/q}|x'|, \tag{6}$$

$$h(x + \lambda x') + h(x - \lambda x') - 2h(x) \leq C_0\lambda^2(1 + h(x))^r, r = \left(1 - \frac{2}{q}\right)^+, \tag{7}$$

$$c_0|y|^2 \leq D^2h(x)y \cdot y \tag{8}$$

for all $x, x' \in R^n$, $|x'| \leq 1$, and $0 \leq \lambda \leq 1$ (see [36]). We assume that $\inf_{x \in R^n} h(x) = h(0) = 0$.

For a given control process (N, ξ), we define the corresponding cost by

$$V_{(N,\xi)}(x) = E^x \int_0^\infty e^{-t}[h(X_t)dt + d\xi_t]. \tag{9}$$

The task is to minimize $V_{(N,\xi)}(x)$ in the class of all admissible controls, i.e., to find

$$u(x) = \inf_{N,\xi} V_{(N,\xi)}(x), \tag{10}$$

where (N_t, ξ_t) are as described above. If this minimum is attained for some $(\tilde{N}, \tilde{\xi})$, we say that

$$\nu_t = \int_0^t \tilde{N}_s d\tilde{\xi}_s \tag{11}$$

is an optimal policy (for x).

Recall [42, 45] that the value function u is a unique, nonnegative, convex $W^{2,\infty}_{loc}$ solution of the HJB equation

$$\max(u - \triangle u - h, |\nabla u|^2 - 1) = 0 \tag{12}$$

in R^n.

Moreover, because h is radially symmetric, the value function u also enjoys this property, thanks to the following simple lemma.

LEMMA 2.1. *Let O be any $n \times n$ orthogonal matrix (i.e., a matrix of an isometry in R^n), and let h be such that $h \circ O \equiv h$. Then $u \circ O \equiv u$.*

Proof. Let $v = u \circ O$. Then, by (12), spherical symmetry of the Laplacian, and $h \circ O \equiv h$, for any $x \in R^n$ we have

$$\begin{aligned} &\max(v(x) - \triangle v(x) - h(x), |\nabla v(x)|^2 - 1) \\ &\quad = \max(u(Ox) - \triangle u(Ox) - h(Ox), |\nabla u(Ox)|^2 - 1) = 0, \end{aligned}$$

so v also solves (12). u is a $W^{2,\infty}_{loc}$ nonnegative, convex function, so v also enjoys this property. But (12) admits a unique $W^{2,\infty}_{loc}$ nonnegative, convex solution, so $v \equiv u$ and the proof is complete.

In particular, if O is a matrix of any rotation in R^n (i.e., a rotation about some hyperplane in R^n of codimension 2 containing 0) and $h \circ O \equiv h$, then $u \circ O \equiv u$. This easily yields radial symmetry of u if h is radially symmetric. In particular, in this case $\mathcal{C}$ is radially symmetric. As was noticed in [14, pp. 332–333], the argument given in [45] shows that in any dimension $\mathcal{C}$ is connected. Also, by [45], $\mathcal{C}$ is bounded and contains the unique minimizer of u, which in our case is clearly 0 (otherwise we get a contradiction with convexity and symmetry of u). Thus, $\mathcal{C}$ is a ball $B_R(0)$ with center 0 and radius $R > 0$. Also, by spherical symmetry of u, the vector field ∇u on $\partial\mathcal{C}$ is perpendicular to $\partial\mathcal{C}$, so in $B_R(0)$ u solves

$$u - \triangle u = h \tag{13}$$

with the Neumann boundary condition

$$\frac{\partial u}{\partial \eta} = 1 \tag{14}$$

on $\partial B_R(0)$, where η denotes the outer normal to $\partial B_R(0)$, or with the Dirichlet boundary condition

$$u = c = \text{const} \tag{15}$$

on $\partial B_R(0)$, where c is the value u takes on $\partial B_R(0)$. Thus, by the well-known elliptic regularity theory (see, e.g., [22]), if $h \in C^{k,\alpha}(R^n)$ for any $\alpha \in (0,1)$, then $u \in C^{k+2,\alpha}(\overline{B}_R(0))$. Let

$$w(x) = |\nabla u(x)|^2. \tag{16}$$

Corollary 5.3 in [45] shows that $w \in C^{1,\alpha}(R^n)$ for every $\alpha \in (0,1)$. But in our case u is radially symmetric, so $w = (\frac{\partial u}{\partial r})^2$. Thus, at least away from 0, where ∇u vanishes,

$$\frac{\partial u}{\partial r} = \sqrt{w} \in C^{1,\alpha} \tag{17}$$

for $r = |x|$. In particular, u, considered as a function of r only, is $C^{2,\alpha}$ away from 0 for every $\alpha \in (0,1)$. We have arrived at the following theorem.

THEOREM 2.2. *If, in the control problem* (9)–(10)*, we assume that h is radially symmetric, then $u \in C^{2,\alpha}$ for every $\alpha \in (0,1)$ and $\mathcal{C} = B_R(0)$ for some $R > 0$. Moreover, if $h \in C^{k,\alpha}(R^n)$ for some $k \geq 2$ and $\alpha \in (0,1)$, then $u \in C^{k+2,\alpha}$ in $\overline{B}_R(0)$.*

Of course, in this case the optimal policy makes X_t a Brownian motion reflected at $\partial B_R(0)$ in the inner normal direction, with a possible initial jump to the closest point of $B_R(0)$ if the process starts outside $B_R(0)$.

2.2. The O.D.E. approach. As we have just shown, for a radially symmetric h the value function u is "essentially one-dimensional." Thus, it seems natural to solve our problem for u using the O.D.E. approach similar to that used for the 1-d control problem (see, e.g., [6], [12], [13]). Let $u(x) = v(r)$, where $r = |x|$, R as in Theorem 2.2. For $r > R$

$$\frac{dv}{dr}(r) \equiv 1 \tag{18}$$

and, by the well-known form of the Laplacian in polar coordinates (see, e.g., [31]) and the smooth fit, v satisfies

$$v(r) - \frac{d^2v}{dr^2}(r) - \frac{n-1}{r}\frac{dv}{dr}(r) - h(r) = 0 \tag{19}$$

in $(0, R)$ with boundary conditions

$$\frac{dv}{dr}(0) = 0 \tag{20}$$

(by the fact that u has a minimum at 0) and

$$\frac{dv}{dr}(R) = 1 \tag{21}$$

and the "smooth fit" condition

$$\frac{d^2v}{dr^2}(R) = 0 \tag{22}$$

resulting from (18) and the fact that u (hence v) $\in C^2$. (We are, in fact, slightly abusing the notation by using the same symbol h for the running cost, defined on R^n, and the function of one variable r equal to $h(x)$ for $|x| = r$, but it should not lead to any ambiguity.) If we know h and want to solve for v, R is also unknown, so our task is to solve (19)–(22) for both v and R. Of course, $v(r)$ defined as the value of u (the value function for our stochastic control problem) for an argument x such that $|x| = r$ solves (19)–(22), but it is not clear whether it is the *only* solution, because, as we shall soon see, (19)–(22) lead to a nonlinear equation for R. We want to show that (19)–(22) indeed admits a unique $C^2([0, R])$ solution.

From now on, we assume that v is any function satisfying (19)–(22) on some interval $[0, R]$, $R > 0$, and belonging to $C^2([0, R])$. It is easy to show, using the maximum principle, that both v_r and v_{rr} are nonnegative on $[0, R]$. Thus v is convex in $[0, R]$; in particular, v_r achieves its extreme values at the endpoints of this interval. By (20) and (21) we get

$$0 \leq \frac{dv}{dr}(r) \leq 1 \tag{23}$$

for every $r \in [0, R]$. Extending v to $[0, \infty)$ by

$$v(r) = v(R) + (r - R) \quad \text{for } r > R, \tag{24}$$

we get, by (21)–(22), a $C^2([0, \infty))$ convex function satisfying (23) on $[0, \infty)$. Now we want to show that

$$v(r) - \frac{d^2 v}{dr^2}(r) - \frac{n-1}{r}\frac{dv}{dr}(r) - h(r) \le 0 \tag{25}$$

for $r > R$. By (19),

$$v(r) - \frac{n-1}{r}\frac{dv}{dr}(r) \ge h(r) \quad \text{on } [0, R]. \tag{26}$$

Also, by (19) and (22), equality in (26) holds for $r = R$. Thus

$$\left(\frac{d}{dr}\left(v - \frac{n-1}{r}\frac{dv}{dr}\right)\right)(R) \le h_r(R), \tag{27}$$

which yields, by (21) and (22) once again,

$$1 + \frac{n-1}{R^2} \le h_r(R). \tag{28}$$

Also, by (19)–(21),

$$v(R) - \frac{n-1}{R} = h(R). \tag{29}$$

To prove (25) we need, by (24),

$$v(R) + (r - R) - \frac{n-1}{r} \le h(r), \tag{30}$$

i.e.,

$$h(R) + \frac{n-1}{R} + (r - R) - \frac{n-1}{r} \le h(r). \tag{31}$$

By convexity of h and (28) we have

$$\begin{aligned} h(r) &\ge h(R) + h_r(R)(r - R) \\ &\ge h(R) + \left(1 + \frac{n-1}{R^2}\right)(r - R). \end{aligned} \tag{32}$$

Thus, if we show

$$\frac{n-1}{R} - \frac{n-1}{r} \le \frac{n-1}{R^2}(r - R) \tag{33}$$

for $r > R$, then, by (32), (31), (so also (25)) is true. But (33) follows easily from the mean value theorem. Thus, by (19), (23), (24), and (25), if we define, for $x \in R^n$,

$$u(x) = v(|x|), \tag{34}$$

we see that u is a C^2 convex solution of (12) in R^n. Invoking uniqueness of a nonnegative, convex $W^{2,\infty}_{loc}$ solution of the HJB equation (12), once again we see that such u (thus v) is uniquely determined. We have proved the following theorem.

THEOREM 2.3. *A function $v \in C^2([0,R])$ for some $R > 0$ satisfies* (19)–(22) *iff $v(x) = u(|x|)$ for every $x \in R^n$, $|x| \leq R$, where u is the value function for the stochastic control problem* (9)–(10) *with a radially symmetric running cost function h. Moreover, extending v to $[0,\infty)$ by* (24)*, we get $v(x) \equiv u(|x|)$ in the whole R^n.*

Thus, for a solution v of the boundary value problem (19)–(21), the smooth fit condition (22) is not only necessary, but also sufficient for $v(x) \equiv u(|x|)$. An analogous result—sufficiency of (22) for describing the value function—for one-dimensional singular stochastic control problems may be found in [32] and, for more general diffusions, in [38].

It is natural to pose a similar question in dimension n. Suppose we have a bounded region G in R^n, say simply connected, and a vector field w defined on ∂G and pointing outside G. Let v be a real function defined in $\overline{G}$ such that

$$v - \triangle v = h \text{ in } G, \tag{35}$$

$$\frac{\partial v}{\partial w} = 1, \tag{36}$$

and

$$\frac{\partial^2 v}{\partial w^2} = 0 \tag{37}$$

on ∂G. Is v the restriction of the value function u for the stochastic control problem (9)–(10) to $\overline{G}$? If it does not have to be the case, is it true at least under an additional assumption that $w = \nabla u$ on ∂G ? We do not know the answer to this question and, because of the fact that the n-dimensional problem is much more complicated, it might be negative.

Now we turn to the special case of a radially symmetric real analytic running cost h satisfying the conditions given above. Then it is well known that u satisfying (13) with the boundary condition (15) is itself real analytic in $\overline{B}_R(0) = \overline{\mathcal{C}}$ and, as we have explained before, also radially symmetric. Then we can easily find u explicitly as the sum of a power series.

Let again $u(x) = v(r)$, $r = |x|$. v is real analytic on $[0,R]$, and let

$$h = \sum_{i=0}^{\infty} b_{2i}\, r^{2i} \tag{38}$$

(the odd coefficients drop out because of symmetry of h). We want to find the real analytic solution v of (19)–(22) on $[0,R]$. The corresponding homogeneous equation

$$v(r) - \frac{d^2 v}{dr^2}(r) - \frac{n-1}{r}\frac{dv}{dr}(r) = 0 \tag{39}$$

is similar to the well-known Bessel equation (see, e.g., [30]),

$$z'' + \frac{1}{x} z' + z = 0, \tag{40}$$

and can be solved in more or less the same way. Let

$$v(r) = \sum_{i=0}^{\infty} a_i r^i \tag{41}$$

be a solution of (39). Differentiating (41) term by term twice, plugging the results into (39), and equating the corresponding terms, we get

$$v_1(r) = a_0 \left(1 + \sum_{i=1}^{\infty} \frac{r^{2i}}{2 \cdot 4 \cdot \cdots \cdot (2i) \cdot n \cdot (n+2) \cdot \cdots \cdot (n+2i-2)}\right) \tag{42}$$

(we took $a_1 = 0$ to cancel the singular term $\frac{1}{r}$ in (39)). Of course, the radius of convergence of this series is ∞. As in the case of the Bessel equation, it may be shown that the second solution v_2, linearly independent on v_1, behaves at 0 similarly as the function $\log r$. Solving (19) using (38), we get

$$a_{i+2} = \frac{a_i - b_i}{(i+2)(i+n)} \tag{43}$$

for $i = 0, 2, 4, \dots$ and $a_i = 0$ for i odd. Thus, once a_0 is determined, all the remaining coefficients of the solution v can be found from (43) and, because of the singularity of v_2 at 0, all real analytic solutions of (19) in intervals containing 0 have this form. For any such solution, (20) is satisfied automatically because $a_1 = 0$. Thus, our task amounts to find constants a_0 and $R > 0$ such that the solution v of (19)–(21) on $[0, R]$ given by (41), (43) satisfies (22). By Theorem 2.3 and our previous remarks, there always exists a unique pair a_0, R ($R > 0$) satisfying this condition, and the value function $u(x)$ for the stochastic control problem (9)–(10) equals $v(|x|)$.

As an example, let us take perhaps the simplest possible running cost satisfying our assumptions, namely $h(x) = |x|^2 = r^2$. Then

$$v(r) = a_0 + \frac{a_0}{2n} r^2 + \sum_{i=2}^{\infty} \frac{a_0 - 2n}{2 \cdot 4 \cdot \cdots \cdot (2i) \cdot n \cdot (n+2) \cdot \cdots \cdot (n+2i-2)} \, r^{2i}. \tag{44}$$

Regarding R as a variable and computing a_0 in terms of R from (21), we get

$$a_0 = a_0(R) = \frac{1 + 2nS(R)}{\frac{R}{n} + S(R)}, \tag{45}$$

where

$$S(R) = \sum_{i=2}^{\infty} \frac{R^{2i-1}}{2 \cdot 4 \cdot \cdots \cdot (2i-2) \cdot n \cdot (n+2) \cdot \cdots \cdot (n+2i-2)}. \tag{46}$$

Thus, (22) gives us the following equation for R:

$$\frac{1}{n} + 2S(R) + (1 - 2R) \cdot S_1(R) = 0, \tag{47}$$

where

$$S_1(R) = \sum_{i=2}^{\infty} \frac{(2i-1)R^{2i-2}}{2 \cdot 4 \cdot \cdots \cdot (2i-2) \cdot n \cdot (n+2) \cdot \cdots \cdot (n+2i-2)}. \tag{48}$$

These equations can be solved numerically, yielding, e.g., for $n = 2$, $R = 1.4857650660\dots$, $a_0 = 1.9624905574\dots$ with accuracy to ten decimal points. See [11, Theorem 8] for a more elegant description of this solution in terms of the modified Bessel function (42).

Another simple experiment we can do is to take $h \equiv 0$ and to solve (19)–(21) in $[0, R]$, obtaining the total discounted cost of control

$$v(x) = E^x \int_0^\infty e^{-t} d\xi_t \tag{49}$$

necessary to keep the process in the ball $\overline{B}_R(0)$. The solution is of the form (42), where a_0 is chosen to match (21). We can easily check that the solution approaches ∞ as $R \to 0$. This is the reason why the optimal region $\mathcal{C}$ cannot be too small: if we try to keep the process very close to the minimum $h(0) = 0$ of the running cost, the control costs grow enormously. Thus, the optimal control can be thought of as a compromise between keeping the running cost $h(X_t)$ small and using a small amount of control.

3. Ergodic control.

3.1. Posing a problem. Now we turn to investigating the following problem. Let E be an open, connected set in R^n. To simplify the exposition, we initially assume that E is bounded and with sufficiently smooth (say C^2) boundary. (Eventually, we will remove the boundedness assumption and significantly relax the regularity requirement.) Let $x \in E$ and let $(W_t, \mathcal{F}_t, t \geq 0)$ be, as before, a standard n-dimensional Brownian motion. Finally, let X_t be defined by (2), (3), where (N_t, ξ_t) is the solution to the Skorokhod problem for the domain E and the normal reflection direction at ∂E starting at x. See, e.g., [37] for a definition and a construction of such a process. Let h be a nonnegative, Borel measurable function bounded on compact subsets of R^n with $\lim_{|x|\to\infty} h(x) = \infty$ (for some of the results to follow, the assumptions on h will be strengthened). Now let, for $T > 0$,

$$w_E(x, T) = \frac{1}{T} E^x \int_0^T [h(X_t)dt + d\xi_t], \tag{50}$$

$$u_E(x) = \lim_{T\to\infty} w_E(x, T). \tag{51}$$

By the ergodic theorem, the time-average of a quantity converges to its mean under the equilibrium measure, which is the Lebesgue measure on the domain E, properly normalized, i.e., divided by $|E|$, the Lebesgue measure of E. The limit of the expected average time spent by X_t inside E weighted by h is equal to $\frac{1}{|E|}\int_E h(x)dx$. The limit of the occupation time on the boundary for the Brownian motion $\sqrt{2}W_t$ is equal to the surface area $|\partial E|$ of E divided by its volume:

$$\lim_{T\to\infty} \frac{1}{T} E^x \int_0^T d\xi_t = \frac{|\partial E|}{|E|}. \tag{52}$$

Thus, actually, u_E does not depend on the starting point $x \in E$ (i.e., is a functional of the domain E only) and equals

$$J(E) = \frac{|\partial E|}{|E|} + \frac{1}{|E|}\int_E h(x)dx. \tag{53}$$

Our goal is to find a region E^* minimizing the ergodic value function u_E, i.e., a suitably smooth minimizer of (53).

This problem is, in a sense, a counterpart of the one with exponential discounting considered before. See [41] for an analysis of connections between singular ergodic control and singular control with exponentially discounted running cost for multidimensional Gaussian processes.

Instead of seeking an optimal control for (51) in the class of C^2 domains directly, we enlarge the domain of definition of (53) to the class of Caccioppoli sets E in R^n. Below, we recall some basic definitions; for a more complete discussion we refer to [23].

Definition 3.1 (see [23, p. 3]). *Let $G \subseteq R^n$ be an open set and let $f \in L^1(G)$. Define*

$$\begin{aligned} \int_G |Df| = \sup\{\int_G f \operatorname{div} g dx \ : \ g = (g_1, \dots, g_n) \in C_0^1(G, R^n), \\ \text{and } |g(x)| \leq 1 \text{ for all } x \in G\}, \end{aligned} \tag{54}$$

where, as usual, $\operatorname{div} g = \sum_{i=1}^n \frac{\partial g_i}{\partial x_i}$.

Definition 3.2 (see [23, p. 4]). *A function $f \in L^1(G)$ is said to have bounded variation in G if $\int_G |Df| < \infty$. We define $BV(G)$ as the space of all functions in $L^1(G)$ with bounded variation.*

It can be shown [23, Remark 1.12] that, under the norm

$$\|f\|_{BV} = \|f\|_{L^1} + \int_G |Df|, \tag{55}$$

$BV(G)$ is actually a Banach space.

In what follows, let ϕ_E denote the characteristic function (indicator) of a Borel set $E \subseteq R^n$.

Definition 3.3 (see [23, p. 5]). *Let E be a Borel set and G an open set in R^n. Define the perimeter of E in G as*

$$P(E, G) = \int_G |D\phi_E| = \sup\left\{\int_E \operatorname{div} g dx : g \in C_0^1(G, R^n),\ |g(x)| \leq 1\right\}. \tag{56}$$

If $G = R^n$, denote $P(E, R^n)$ by $|\partial E|$.

It is known that if the boundary of E is C^2, then $P(E, G) = H_{n-1}(\partial E \cap G)$, where H_{n-1} denotes the $n-1$-dimensional Hausdorff measure.

Definition 3.4 (see [23, p. 6]). *If a Borel set E has locally finite perimeter, that is, if $P(E, G) < \infty$ for every bounded open set G, then E is called a Caccioppoli set.*

Thus, we are looking for a minimizer of (53) in the class of all Caccioppoli sets, i.e., for a Caccioppoli set E^* such that

$$J(E^*) \leq J(E) \ \text{ for every Caccioppoli set } E. \tag{57}$$

For every $x \in R^n$ and $\rho > 0$, denote

$$B_\rho(x) = \{y : |x - y| < \rho\}.$$

Definition 3.5 (see [23, p. 43]). *A point x belongs to the reduced boundary, $\partial^* E$, of a set E if*

$$\int_{B_\rho(x)} |D\phi_E| > 0$$

for all $\rho > 0$, the limit $v(x) = \lim_{\rho\to 0} v_\rho(x)$ exists, where

$$v_\rho(x) = \frac{\int_{B_\rho(x)} D\phi_E}{\int_{B_\rho(x)} |D\phi_E|},$$

and $|v(x)| = 1$.

The vector $v(x)$ defined above can be regarded as the generalized unit inner normal vector to ∂E at x. Indeed, if ∂E is C^2, then $\partial^* E = \partial E$ and $v(x)$ is the unit inner normal vector to ∂E at x [23, p. 44]. Thus, $\partial^* E$ is the part of ∂E on which the generalized inner normal $v(x)$ to ∂E can be defined.

3.2. Existence of minimizers. Now we shall prove, using standard tools, that a minimizer indeed exists.

Let E_k be a minimizing sequence of Borel sets, i.e.,

$$J(E_k) \to c = \inf_E J(E). \tag{58}$$

Clearly, $c < \infty$.

Step 1. $|E_k| \le C$ for all k natural and some $C < \infty$.

Indeed, suppose $|E_k| \to \infty$, $k \to \infty$. Let $M > 0$ be an arbitrary constant. $h(x) \to \infty$ for $x \to \infty$, so the Lebesgue measure of a set $F = \{x \in R^n : h(x) \le M\}$ is finite. Let $|E_k| \ge 2|F|$. Then, by $h \ge 0$,

$$\begin{aligned}\int_{E_k} hdx &= \int_{E_k\cap F} hdx + \int_{E_k - F} hdx \\ &\ge \int_{E_k - F} hdx \\ &\ge M|E_k - F| \\ &\ge M(|E_k| - |F|) \\ &\ge \frac{M}{2}|E_k|,\end{aligned}$$

so

$$J(E_k) \ge \frac{1}{|E_k|}\int_{E_k} hdx \ge \frac{M}{2}. \tag{59}$$

Thus, $c \ge \frac{M}{2}$ for an arbitrary M, which is a clear contradiction.

Step 2. $\frac{|\partial E_k|}{|E_k|} \le C$ for all k natural and some $C < \infty$.

This follows at once from (53) and (58).

Step 3. $|\partial E_k| \le C$ for all k natural and some $C < \infty$.

This follows easily from (58) and the previous two steps.

Step 4. $|E_k| \ge c_0$ for all k and some $c_0 > 0$.

Suppose this is not true, e.g., there exists a minimizing sequence E_k such that

$$|E_k| \to 0 \text{ as } k \to \infty. \tag{60}$$

Let us recall the isoperimetric inequality [23, Corollary 1.29]: there exists a positive constant $c_1 = c_1(n)$ depending only on the dimension n such that, for every Caccioppoli set $E \subseteq R^n$, we have

$$|E|^{\frac{n-1}{n}} \le c_1(n)\, |\partial E|.$$

(Actually, as is well known, the best constant $c_1(n) = \frac{|B|^{\frac{n-1}{n}}}{|\partial B|}$, where B is an n-dimensional ball.) Using this inequality, we get

$$J(E_k) > \frac{|\partial E_k|}{|E_k|} \geq \frac{1}{c_1(n)|E|^{\frac{1}{n}}}. \tag{61}$$

But, by (60), the right-hand side of (61) diverges to ∞, and thus so does $J(E_k)$, which is a contradiction.

Step 5. We want to prove that a subsequence of E_k converges to a minimizer of (53). Say that $J(E_k) \leq c+1$, where c is given by (58). Let $M > 0$ and let $R > 0$ be large enough to assure $h \geq M$ outside $B_R(0)$. Then, for all k,

$$\begin{aligned} |E_k - B_R(0)| &\leq |E_k \cap [h \geq M]| \\ &\leq \frac{1}{M}\int_{E_k} hdx \\ &\leq \frac{|E_k|}{M}\, J(E_k) \\ &\leq \frac{C}{M}\,(c+1) \;\to\; 0 \end{aligned} \tag{62}$$

as $M \to \infty$ ($R \to \infty$) (the last inequality follows from step 1). Also, it is known that

$$|\partial(E \cap B_r)| \leq |\partial E| \tag{63}$$

for any Borel set $E \subseteq R^n$ such that $|E| < \infty$ and any ball B_r ([50]; see also [47]). Thus,

$$|\partial(E_k \cap B_R(0))| \leq |\partial E_k| < C \tag{64}$$

for every k, $R > 0$ by step 3. Thus, we see that $\phi_{E_k \cap B_R(0)}$ is a bounded subset of $BV(B_R(0))$. It is known (see Theorem 1.19 in [23]) that bounded sets in $BV(B_R)$ are relatively compact in $L^1(B_R)$, so $\phi_{E_k \cap B_R(0)}$ has a convergent subsequence in $L^1(B_R)$. But a sequence converging in L^p, $1 \leq p < \infty$, contains a subsequence converging almost everywhere (a.e.), so the limit of $\phi_{E_k \cap B_R(0)}$ in $L^1(B_R)$ must also be an indicator of some set E_R^*. By an usual diagonal argument, we can extract a subsequence, still called E_k, such that for $E^* = \bigcup_{m=1}^{\infty} E_m^*$, $\phi_{E_k \cap B_m(0)} \to \phi_{E^* \cap B_m(0)}$ in $L^1(B_m)$ for every natural m. In particular, $\phi_{E_k} \to \phi_{E^*}$ in L^1_{loc}. By semicontinuity (see Theorem 1.9 in [23])

$$|\partial E^*| \leq \lim\inf_{n\to\infty} |\partial E_k|. \tag{65}$$

By Fatou's lemma

$$\int_{E^*} hdx \leq \lim\inf_{k\to\infty} \int_{E_k} hdx. \tag{66}$$

We want to show that also $|E_k| \to |E^*|$, because this, together with step 1, (65), and (66) finishes the proof. Without any loss of generality we can, by steps 1 and 4, assume that the sequence $|E_k|$ is convergent. Define a family of Borel measures μ_k on R^n by

$$\mu_k(A) = |A \cap E_k|. \tag{67}$$

Then (62) assures that this family is tight, so there exists a measure μ on R^n such that a subsequence of μ_k converges weakly to μ (see, e.g., [7, Theorem 5.1]) and thus $\mu(R^n) = \lim_{k\to\infty}\mu_k(R^n)$. But, as we know from our previous reasoning, $\mu(A) = |A \cap E^*|$ (it is true for bounded sets by $\phi_{E_k} \to \phi_{E^*}$ in L^1_{loc}, so it is also true for all Borel sets A), so $|E_k| \to |E^*|$. Existence of minimizers for (53) is shown.

3.3. Some properties of minimizers.

3.3.1. Boundedness. For convenience, we assume that a minimizer E^* under consideration is open (Caccioppoli sets are defined only up to a set of the Lebesgue measure zero and their boundaries have measure zero). We want to prove the boundedness of E^*. Assume, to the contrary, that E^* is unbounded. Choose a large constant M and let

$$R = \sup\{x \in R^n : h(x) \le M\}. \tag{68}$$

Let $E^{**} = E^* \cap B_R(0)$ and let $\epsilon = \epsilon(M) = |E^* - E^{**}|$. By assumption, $\epsilon > 0$. By (63), $|\partial E^{**}| \le |\partial E^*|$, and thus

$$\begin{aligned} J(E^*) &= \frac{|\partial E^*|}{|E^*|} + \frac{1}{|E^*|}\int_{E^*} h(x)dx \\ &> \frac{|\partial E^{**}| + \int_{E^{**}} h(x)dx + M\epsilon}{|E^{**}| + \epsilon} \\ &> \frac{|\partial E^{**}|}{|E^{**}|} + \frac{1}{|E^{**}|}\int_{E^{**}} h(x)dx \\ &= J(E^{**}) \end{aligned}$$

if M is large enough and, consequently, if ϵ is small enough. This contradicts the fact that E^* is a minimizer of J and proves our claim.

3.3.2. Regularity. At this stage, the only thing we can guarantee is that a minimizer E^* is a bounded Caccioppoli set. In general, the boundary ∂E of a Caccioppoli set E is, up to a set of $|D\phi_E|$ (or, equivalently, the Haussdorff measure H_{n-1}) measure zero, a countable union of C^1 hypersurfaces [23, Theorem 4.4], and usually you cannot expect anything better than that. Fortunately, problems of the same nature have been studied thoroughly in variational calculus and related domains, starting from a classic theory of minimal surfaces (see, e.g., [23]), through minimizing

$$I(E) = |\partial E| + \int_E h dx \tag{69}$$

[39] until more recent developments posed in a much more abstract and general framework (see, e.g., [1, 2]). In particular, regularity of E^* can be easily deduced from known results in the following way. Define, for a Caccioppoli set E and an open, bounded set $A \subseteq R^n$,

$$\psi(E, A) = \int_A |D\phi_E| - \inf\left\{\int_A |D\phi_F| \ : \ F \triangle E \subset\subset A\right\}, \tag{70}$$

where $F \triangle E = (F - E) \cup (E - F)$ and $B \subset\subset A$ means that $\overline{B} \subseteq A$. It is known [39, 48] that if G is an open subset of R^n, $n \ge 2$, and E is a Caccioppoli set such that

$$\psi(E, B_\rho(x)) \le C\rho^n \tag{71}$$

for every $x \in G$ and every $\rho \in (0, R)$, with C and R local positive constants, then the reduced boundary $\partial^* E$ of E is a $C^{1,\frac{1}{2}}$-hypersurface in G and the Haussdorf measure

$$H_s[(\partial E - \partial^* E) \cap G] = 0 \tag{72}$$

for every $s > n - 8$. In particular, if $n \leq 7$, ∂E is $C^{1,\frac{1}{2}}$. Taking $E = E^*$, a minimizer of (53), and $G = R^n$, we show (71) using an argument similar to that given in [48] for a minimizer of (69). For completeness, we provide a sketch of the argument.

Suppose (71) is violated. Then for any $M > 0$ we can find a small ball $B_\rho(x)$ and a set $F \subset\subset B_\rho(x)$ such that

$$\int_{B_\rho(x)} |D\phi_F| \leq \int_{B_\rho(x)} |D\phi_E^*| - M\rho^n. \tag{73}$$

Then, if we take

$$E^{**} = (E^* - B_\rho(x)) \cup F,$$

we get, for M big enough,

$$J(E^{**}) < J(E^*), \tag{74}$$

because of (73) and the fact that $|E^*|$ and $\int_{E^*} h dx$ differ from $|E^{**}|$ and $\int_{E^{**}} h dx$, correspondingly, at most by $C\rho^n$ for some constant C depending on $\max_{B_\rho(x)} h$ only. However, (74) contradicts the definition of E^*.

Thus, we get $\partial^* E^* \in C^{1,\frac{1}{2}}$ and (72); in particular, for $n \leq 7$ we have $\partial E^* \in C^{1,\frac{1}{2}}$. In fact, the only assumption about h we need at this stage is $h \in L^\infty_{loc}$. Now we can improve the regularity of ∂E using the existence of multipliers in the nonparametric case (see [21, 24, 25]). Thus we have the following proposition.

PROPOSITION 3.6. *Let $h \in C^k$, $k \geq 1$, and let E^* be a minimizer of* (53). *Then $\partial^* E^*$ is a C^{k+1}- hypersurface in R^n and* (72) *holds for every $s > n - 8$. In particular, for $n \leq 7$, ∂E^* is a C^{k+1}-hypersurface in R^n.*

Let us mention that, in general, in problems of this type, smoothness of minimizers in dimensions bigger than 7 cannot be expected. A counterexample (the Simons cone) can be found in [23, Theorem 16.4].

Proposition 3.6 says that, for $n \leq 7$, the regularity of ∂E^* is precisely the same as that of a solution of the mean curvature equation (see, e.g., [22, Corollary 16.7]). We shall further discuss the reason for this in the next subsection.

An alternative way to establish an initial regularity result for ∂E^* is based on an observation that E^* also minimizes (69) under a constraint

$$|E| = \text{const} = |E^*|. \tag{75}$$

Thus, we can use known regularity results for the problem of minimizing (69) under a volume constraint in the parametric case. However, proofs of such results usually require serious work to show (71) or a similar inequality, either directly (see, e.g., [26, 49]) or by using Lagrange multipliers (see, e.g., [3]), and then use (71) in the way we have just done it, so it seems more natural to take advantage of a simple proof of (71) which can be given in the unconstrained case.

3.3.3. The mean curvature equation. Assume that $h \in C^1$. By Proposition 3.6, for $n \leq 7$, $\partial E^* \in C^2$. Thus we can obtain, from the first variation of (53), the mean curvature equation satisfied by ∂E^*. Let $x \in \partial E^*$. Let $\kappa_1, \dots, \kappa_{n-1}$ be the principal curvatures of $\partial E^* \in C^2$ at x, and let

$$H(x) = \frac{1}{n-1} \sum_{i=1}^{n-1} \kappa_i \tag{76}$$

be the mean curvature of $\partial E^* \in C^2$ at x (see, e.g., [22, section 14.6]). Then, computing the first variation of (53) at E^* under domain deformations, by the well-known fact that the first variation of the area equals $-(n-1)H$ [23, Theorem 10.4, equation (10.12), and Remark 10.6] (notice that our definition of the mean curvature differs from the one used in [22] by a normalizing factor $-(n-1)$), we get

$$H(x) = \frac{h(x) - c}{n-1}, \tag{77}$$

where c is defined by (58), because E^* is a minimizer of (53).

By Proposition 3.6, for dimensions $n \geq 8$ we have $\partial^* E^* \in C^2$. Thus, (77) holds for $x \in \partial^* E^*$, but $\partial E^* - \partial^* E^*$ may be nonempty. However, in this case we can still regard ∂E^* as a *generalized* solution to (77).

3.3.4. Connectedness and simple connectedness. From now on, in addition to $h \geq 0$ and $\lim_{|x| \to \infty} h(x) = \infty$, we assume that h is convex. We want to prove that, in any dimension n, a minimizer of (53) is simply connected in the following sense: its complement in $R^n \cup \{\infty\}$ (R^n compacted by adding a point at infinity) has only one component. Intuitively, it means that there are no holes inside a minimizer. We shall need the following lemma, which generalizes (63).

LEMMA 3.7. *Let E be a Caccioppoli set in R^n and let $C \subseteq R^n$ be convex. Then*

$$|\partial(E \cap C)| \leq |\partial E|. \tag{78}$$

This result is contained in [50, Lemma 8].

Now, let E^* be a minimizer of (53). We can, with no loss of generality, assume that E^* is open. Suppose, to the contrary, that E^* is not simply connected, i.e., its complement in $R^n \cup \{\infty\}$ has at least 2 components: A_∞ containing ∞ and a bounded component A. Choose a positive number b such that the set

$$C_b = \{x \in R^n : \ h(x) \leq b\}, \tag{79}$$

which is convex by convexity of h, contains A and $|A| > d := |E^* - C_b| > 0$. Let e be a fixed unit vector in R^n and let $\tilde{b}$ be such that

$$|A \cap H_{\tilde{b}}| = d, \tag{80}$$

where

$$H_{\tilde{b}} = \{x : \ e \cdot x \leq \tilde{b}\}. \tag{81}$$

Define

$$E^{**} = (E^* \cap C_b) \cup (A \cap H_{\tilde{b}}). \tag{82}$$

Clearly, E^{**} is a Caccioppoli set, $|E^{**}| = |E^*|$, and

$$\int_{E^{**}} hdx < \int_{E^*} hdx \tag{83}$$

by construction (h takes bigger values on $E^* - C_b$ than on $A \cap H_{\tilde{b}}$ and their measures are the same). Also, by Lemma 3.7 applied twice,

$$|\partial E^{**}| \leq |\partial(E^* \cap C_b)| \leq |\partial E^*|, \tag{84}$$

which yields

$$J(E^{**}) < J(E^*), \tag{85}$$

which is a clear contradiction.

Remark. We can always (also in the case of nonconvex h) take a *connected* minimizer E^*. Indeed, we know already that $\partial E^* \in C^2$. From now on, assume that E^* is actually open (Caccioppoli sets are defined up to a set of measure zero) and let $x \in E^*$. Let C be the component of E^* containing x. From our previous considerations it follows that the solution to the Skorokhod problem for E^* starting at x with normal reflection direction is optimal for ergodic discounting, i.e., minimizes (51). But it is clear that this solution never leaves C, so this policy also solves an analogous Skorokhod problem for C. Thus, by the ergodic theorem, C also minimizes (53).

3.3.5. Convexity in two dimensions. Let $n = 2$ and let the assumptions about h be the same as in the last subsection. We want to prove that E^*, a minimizer of (53), is convex. The proof is similar to the one we have just given. Suppose that our claim is false. Then, there exist points $x_1, x_2 \in \partial E^*$ such that

$$B \cap E^* = \emptyset, \tag{86}$$

where B is the open, nonempty set, the boundary of which consists of the interval joining x_1 to x_2 and the shorter arc joining x_1 to x_2 in ∂E^*, and moreover,

$$B \subseteq C_b \tag{87}$$

for C_b defined by (79), and b is such that

$$|E^* - C_b| = |B|. \tag{88}$$

Let

$$E^{**} = (E^* \cap C_b) \cup B. \tag{89}$$

Similarly as in the last proof, we check that $|E^{**}| = |E^*|$,

$$\int_{E^{**}} hdx < \int_{E^*} hdx, \tag{90}$$

and $|\partial(E^* \cap C_b)| \leq |\partial E^*|$. Finally, $|\partial E^{**}| < |\partial(E^* \cap C_b)|$ because the length of the interval $[x_1, x_2]$ is smaller than the length of the corresponding arc. Thus, again, (85) holds, leading to a contradiction.

Remark. This argument clearly does not go through for $n \geq 3$. In this case, a similar question, whether or not a minimizer of (69) with convex h is convex, remains open [47]. Modifications of the above argument, however, can give us partial answers to the convexity question in higher dimensions. For example, there is no point $x \in \partial^* E^*$ at which all the principal curvatures of $\partial^* E$ are strictly negative and if h (hence, by Proposition 3.8 of the next subsection, E^*) is axisymmetric, then E^* is convex.

3.3.6. Symmetry. Let $a \in R^n - \{0\}$, and let

$$N = N_a = \{x \in R^n : \ a \cdot x = 0\} \tag{91}$$

be a hyperplane in R^n. We say that a function h is symmetric with respect to N iff for every $x \in N$ and $t \in R$ we have $h(x - ta) = h(x + ta)$.

PROPOSITION 3.8. *Let the function h be nonnegative, strictly convex, and symmetric with respect to N and such that $\lim_{|x|\to\infty} h(x) = \infty$. Then, any minimizer of* (53) *is also symmetric with respect to N.*

For simplicity of the proof, assume that $a = e_n = (0, \dots, 0, 1)$, so $N = \{x : x_n = 0\}$. Let E^* be a nonsymmetric minimizer of (53). Let E^{**} be the set which results from E^* by its Steiner symmetrization with respect to the hyperplane N, i.e., for every $x = (x', 0) \in N$, $x' \in R^{n-1}$,

$$E^{**} \cap \{x + te_n : \ t \in R\} = \left\{x + te_n : \ -\frac{b}{2} \le t \le \frac{b}{2}\right\}, \tag{92}$$

where b is the one-dimensional Lebesgue measure of $E^* \cap \{x + te_n : \ t \in R\}$. By definition and Fubini's theorem, $|E^{**}| = |E^*|$. It is also well known (see, e.g., [20, 43]) that $|\partial E^{**}| \le |\partial E^*|$. Thus, if we show that

$$\int_{E^{**}} h(x)dx < \int_{E^*} h(x)dx, \tag{93}$$

we get $J(E^{**}) < J(E^*)$, which is a contradiction. (93) follows easily from a simple lemma.

LEMMA 3.9. *Let f be an even, strictly convex function on R and let $a > 0$ be a given finite number. Then, the minimum of $F(E) = \int_E f(x)dx$ over all Lebesgue measurable sets $E \subseteq R$ such that $|E| = a$ is*

$$\int_{-\frac{a}{2}}^{\frac{a}{2}} f(x)dx \tag{94}$$

and is attained iff E differs from $[-\frac{a}{2}, \frac{a}{2}]$ by a set of measure zero.

Proof. Let $E \subseteq R$ be a set such that $|E| = a$ and let $b_- = |E \cap \{x < 0\}|$, $b_+ = |E \cap \{x > 0\}|$. Obviously, by the fact that f is strictly increasing on $[0, \infty)$,

$$\int_{E\cap\{x>0\}} f(x)dx \ge \int_0^{b_+} f(x)dx, \tag{95}$$

and the equality holds iff $|E \cap \{x > 0\} \triangle [0, b_+]| = 0$. By the same reasoning applied to $E \cap \{x < 0\}$, we get that $F(E) \ge F([-b_-, b_+])$ with equality only if $E = [-b_-, b_+]$ a.e. To complete the proof, we need to show that the minimum is attained iff $b_+ = b_-$. Suppose, for example, that $b_+ > b_-$. (The argument in the opposite case is essentially the same.) Then

$$\begin{aligned}
\int_{-b_-}^{b_+} f(x)dx &= \int_{-b_-}^{b_-} f(x)dx + \int_{b_-}^{b_- + \frac{b_+ - b_-}{2}} f(x)dx + \int_{b_- + \frac{b_+ - b_-}{2}}^{b_+} f(x)dx \\
&> \int_{-b_- - \frac{b_+ - b_-}{2}}^{-b_-} f(x)dx + \int_{-b_-}^{b_-} f(x)dx + \int_{b_-}^{b_- + \frac{b_+ - b_-}{2}} f(x)dx \\
&= \int_{-b_- - \frac{b_+ - b_-}{2}}^{b_- + \frac{b_+ - b_-}{2}} f(x)dx
\end{aligned}$$

by symmetry of h and its monotonicity on $[0,\infty)$ $((-\infty,0])$ and $|[-b_-,b_+]| = |[-b_- - \frac{b_+-b_-}{2}, b_- + \frac{b_+-b_-}{2}]|$. The proof is complete.

In particular, if h is radially symmetric, then a minimizer of (53) is a ball $B_R = B_R(0)$. Putting $I(R) = J(B_R)$ and using calculus methods, we can find the radius of the optimal ball. For example, consider again the case of $n = 2$ and $h(x) = |x|^2$. We have

$$I(R) = \frac{2}{R} + \frac{\pi}{2}R^4. \tag{96}$$

This function attains its unique minimum at $R_0 = \frac{1}{\sqrt[5]{\pi}}$, so in this case $E^* = B_{\frac{1}{\sqrt[5]{\pi}}}(0)$.

3.4. A generalization. The initial assumption of smoothness and boundedness of the domains E under consideration was convenient for two reasons. First, path-by-path constructions of strong solutions to the corresponding Skorokhod problem for this case are known. Second, in this context the ergodic result

$$\lim_{T\to\infty} \frac{1}{T} E^x \int_0^T [h(X_t)dt + d\xi_t] = J(E) \tag{97}$$

for all $x \in \overline{E}$ is easy to get. In fact, we do not even need ergodic theorems here; it is enough to use the Ito's rule and the necessary and sufficient condition for solvability of the Neumann problem for the Laplace operator (see, e.g., [31, p. 95]). However, as we have already seen, it is natural to extend the class of allowed domains to Caccioppoli sets. See [9, 18, 51] for the construction of the Brownian motion reflected normally at the boundary of a bounded Caccioppoli set E; the case of an unbounded Caccioppoli domain is considered in [8, 19]. In the appendix we show that (97) actually holds for a.e. $x \in \overline{E}$ (with respect to the Lebesgue measure) if E is bounded Caccioppoli. Moreover, we have, for an arbitrary Caccioppoli set E,

$$\liminf_{T\to\infty} \frac{1}{T} E^x \int_0^T [h(X_t)dt + d\xi_t] \geq J(E) \tag{98}$$

quasi-everywhere (q.e.) in x, i.e., for all starting points $x \in \overline{E} - N$, where N is a set of the Newtonian capacity zero. $J(E)$, the right-hand side of (98), should be interpreted as $+\infty$ if $|E| = +\infty$. Both (97) and (98) follow from ergodic theorems given in [16, 17] after some technical details are taken care of. The only assumptions about h we need for (97)–(98) is that h is nonnegative, Borel measurable, and bounded on compact subsets of R^n, and $\lim_{|x|\to\infty} h(x) = \infty$. These facts, together with the arguments given in subsections 3.2-3.3, allow us to state the following theorem.

THEOREM 3.10. *Assume that $h \geq 0$ is Borel and locally bounded and $\lim_{|x|\to\infty} h(x) = \infty$. There exists an open, connected Caccioppoli set E^* such that the Brownian motion reflected normally at ∂E^* minimizes the ergodic cost*

$$\liminf_{T\to\infty} \frac{1}{T} E^x \int_0^T [h(X_t)dt + d\xi_t]$$

in the class of all Brownian motions X_t reflected normally at the boundary of some open, connected Caccioppoli set E for q.e. starting point $x \in \overline{E}$. The family of such minimizing sets E^* coincides with the family of open, connected minimizers of the functional $J(E)$ defined by (53) in the class of all Caccioppoli sets.

Recall that some properties of minimizing sets E^* were investigated in the last subsection.

Let us also remark that, in general, we cannot expect uniqueness of a minimizer E^* of J. See, e.g., [49] for related work.

3.5. Concluding remarks. Can we use analogous geometric-measure theoretic techniques in the exponentially discounted cost problem of minimizing (9)–(10)? In particular, can we establish or at least improve regularity of the free boundary $\partial\mathcal{C}$ by considerations based on regularity for the mean curvature equation? We have not found any results along this line. Admittedly, if we know from the outset that the optimal reflection direction $-\nabla u$ is *normal* to $\partial\mathcal{C}$ on the whole $\partial\mathcal{C}$, then u satisfies (13) in $\mathcal{C}$ with the Neumann boundary condition (14) and an additional free-boundary condition

$$\frac{\partial^2 u}{\partial \eta^2} = 0, \tag{99}$$

where $\eta = \nabla u$ is the outer normal at $\partial\mathcal{C}$. The last equation follows from the fact that $w = |\nabla u|^2$ is C^1,

$$\frac{\partial^2 u}{\partial \eta^2} = \frac{\partial \sqrt{w}}{\partial \eta} \tag{100}$$

on $\partial\mathcal{C}$ (compare (17)), and w attains its maximum value 1 on $\partial\mathcal{C}$. Moreover, because ∇u is perpendicular to $\partial\mathcal{C}$, we get another free-boundary condition (15). Thus, if $\partial\mathcal{C}$ is regular enough to assure that (13) holds up to the boundary (it suffices to have $\partial\mathcal{C} \in C^2$), writing (13) in the local normal-tangential system of coordinates at $x \in \partial\mathcal{C}$, we get

$$u - \triangle u = u - \frac{\partial^2 u}{\partial \eta^2} - (n-1)H\frac{\partial u}{\partial \eta} = h \tag{101}$$

on $\partial\mathcal{C}$, where H is again the mean curvature of $\partial\mathcal{C}$. Thus, by (14), (15), and (99) we get

$$H(x) = \frac{c - h(x)}{n-1} \tag{102}$$

resembling (77), with a different meaning of c of course. In fact, by Theorem 3.1 in [44], we can get both (15) and (99) under a weaker assumption that the Brownian motion reflected normally at $\partial\mathcal{C}$ minimizes (9)–(10) in the class of all solutions for the Skorokhod problem with normal reflection for C^2 domains containing x for every $x \in \mathcal{C}$. Thus, under this weaker condition (102) holds also, where, again, c is the (constant) value which the solution u of (13), (14) in $\mathcal{C}$ takes on $\partial\mathcal{C}$. Thus, one might attempt to find $\mathcal{C}$ as a *maximizer* of a (69)-type functional

$$|\partial E| + \int_E (c - h(x))dx \tag{103}$$

with a suitably chosen constant c.

As we have seen before, ∇u is normal to $\partial\mathcal{C}$ on $\partial\mathcal{C}$ if h is radially symmetric, but we are not sure whether a different example can be given. Additionally, in the radially symmetric case, $\partial\mathcal{C}$ is just a sphere, so any further considerations of its regularity are superfluous.

4. Appendix.

Let E be an open, connected Caccioppoli set in R^n and let m be the Lebesgue measure on E. Let the process X_t defined by (2), (3) be the Brownian motion reflected normally at ∂E. See [9, 18, 51] for the construction of such a process for bounded E, the case of an unbounded domain is considered in [8, 19]. The aim of this appendix is to show that (98) holds q.e. in x, i.e., for all starting points $x \in \overline{E} - N$, where N is a set of capacity zero and $J(E)$, the right-hand side of (98), is interpreted as $+\infty$ if $|E| = +\infty$. In this appendix we will use terms such as capacity, exceptional set, positive continuous additive functional, measure of finite energy integral, etc. from potential theory unified with the theory of Markov processes. Their definitions can be found, for example, in [15].

We also want to show that in the case of a bounded Caccioppoli domain E (98) can be refined to (97) for a.e. $x \in \overline{E}$.

Let $p_t = p_t(x, dy)$, $t > 0$, be the transition function of the process X_t. For a Borel function $f : R \to R$ let

$$p_t f(x) = \int_{\overline{E}} f(y) p_t(x, dy) = E^x f(X_t)$$

if the integral on the right-hand side exists.

It is clear that $\{p_t\}$ is *irreducible*; in other words, any p_t-invariant (i.e., such that $p_t f = f$ a.s. for all $t > 0$) bounded function on $\overline{E}$, integrable with respect to m, is constant a.e. in $\overline{E}$. This follows from the fact that E is open, connected, and from known averaging properties of the transition functions p_t.

First assume that E is bounded. Then h is bounded on E. Thus, by the corollary following [16, Theorem 1], we have

$$\lim_{t \to \infty} p_t h = \frac{1}{|E|} \int_E h(y) dy \tag{104}$$

for almost every $x \in \overline{E}$. In fact, this is true for q.e. $x \in \overline{E}$ by [17, Theorem 2]. This clearly implies

$$\lim_{T \to \infty} \frac{1}{T} E^x \int_0^T h(X_t) dt = \frac{1}{|E|} \int_E h(y) dy \tag{105}$$

for q.e. $x \in \overline{E}$.

Fix $s, t > 0$, and let, for $x \in \overline{E}$,

$$f(x) = E^x \xi_t. \tag{106}$$

By [18, Theorem 1.1], f is integrable with respect to m on $\overline{E}$.

We want to show that

$$E^x(\xi_{t+s} - \xi_s | X_s) = f(X_s) \tag{107}$$

P^x a.s. for q.e. $x \in \overline{E}$.

First note that, by the construction of the Brownian motion X_t reflected normally at ∂E [9, 18, 51], ξ_t is a positive continuous additive functional of X_t. Thus

$$\xi_{t+s}(\omega) - \xi_s(\omega) = \xi_t(\theta_s \omega) \tag{108}$$

for $\omega \in \Lambda$, where $P^x(\Lambda) = 1$ for all $x \in \overline{E} - N$, where N is an exceptional subset of $\overline{E}$ and $\theta_s : \Omega \to \Omega$ is the so-called *shift operator*

$$X_t \circ \theta_s(\omega) = X_{t+s}(\omega)$$

for all $\omega \in \Omega$, $t, s \geq 0$ (see, e.g., [15, p. 89], [33, p. 77]).

Fix $x \in \overline{E} - N$. It is not hard to show (107) under the assumption that ξ_t is $\mathcal{F}_t^X := \sigma\{X_u, 0 \leq u \leq t\}$-measurable. (Follow the proof below without modifying ξ_t.) However, in general we only know that ξ_t is $\{\tilde{\mathcal{F}}_t\}$-measurable, where $\{\tilde{\mathcal{F}}_t\}$ is the minimum completed admissible family for the Markov process X_t [15, pp. 89, 124], so some additional care must be taken. Using [15, Lemma 4.1.3], we can, as in the solution to [33, Problem 2.5.7], construct a $\mathcal{F}_{t+}^X$-measurable modification $\tilde{\xi}_t$ of the process ξ_t such that

$$P^y[\xi_t \neq \tilde{\xi}_t] = 0$$

for $y = x$ and for $P^x \circ X_s^{-1}$ a.e. $y \in \overline{E}$ (in [15, Lemma 4.1.3] use the measure $\mu = \frac{1}{2}(P^x \circ X_s^{-1} + \delta_x)$, where δ_x is the probability measure concentrated at the point x). To proceed further, we need to verify that

$$\xi_t \circ \theta_s = \tilde{\xi}_t \circ \theta_s \quad P^x \text{a.s.} \tag{109}$$

First, by construction,

$$P^{P^x \circ X_s^{-1}}[\xi_t \neq \tilde{\xi}_t] = 0. \tag{110}$$

Fix an $\epsilon > 0$. $[\xi_t \neq \tilde{\xi}_t] \in \mathcal{F}_{t+\epsilon}$, so, by the definition of the minimum completed admissible family for X_t, there exists a set $F \in \mathcal{B}(R^{[0,t+\epsilon]})$, the Borel σ-field on $R^{[0,t+\epsilon]}$ equipped with the product topology, such that

$$[\xi_t \neq \tilde{\xi}_t] \subseteq Z := [X. \in F],$$

where $X.$ in the above formula denotes the path of X on $[0, t+\epsilon]$, and

$$P^{P^x \circ X_s^{-1}}(Z) = 0,$$

i.e.,

$$P^y(Z) = 0 \tag{111}$$

for $P^x \circ X_s^{-1}$ a.e. y. Thus, by the Markov property of X_t,

$$\begin{aligned} P^x[\xi_t \circ \theta_s \neq \tilde{\xi}_t \circ \theta_s] &= P^x[\theta_s^{-1}[\xi_t \neq \tilde{\xi}_t]] \\ &\leq P^x[\theta_s^{-1} Z] \\ &= E^x P^x[\theta_s^{-1} Z | \mathcal{F}_s] \\ &= E^x P^{X_s}[Z] \ = \ 0, \end{aligned}$$

where the last equality follows from (111). This proves (109).

Thus, by (108), (109), and (110), we have

$$\begin{aligned} E^x(\xi_{t+s} - \xi_s | X_s) &= E^x(\xi_t \circ \theta_s | X_s) = E^x(\tilde{\xi}_t \circ \theta_s | X_s) \\ &= E^x(E^x[\tilde{\xi}_t \circ \theta_s | \mathcal{F}_s] | X_s) = E^x(E^{X_s} \tilde{\xi}_t | X_s) \\ &= E^{X_s} \tilde{\xi}_t = E^{X_s} \xi_t \\ &= f(X_s). \end{aligned}$$

The fourth inequality follows from the Markov property of X_t. (Here $E^{X_s}\tilde{\xi}_t$, $E^{X_s}\xi_t$ should be interpreted as the compositions of real functions $y \to E^y \tilde{\xi}_t$, $y \to E^y \xi_t$, and the random variable X_s.) We have shown (107).

Next, we need the fact that

$$\lim_{t\to\infty} p_t f = \frac{1}{|E|}\int_E f(y)dy \tag{112}$$

for almost every $x \in \overline{E}$. Similarly as in the proof of [16, Theorem 1], we argue that the limit $\lim_{t\to\infty} p_t f = g$ exists a.e. and in $L^1(\overline{E}, m)$ (we have $f \in L^1(\overline{E}, m)$ instead of $L^p(\overline{E}, m)$ for some $p > 1$, but the argument still goes through, because every backward martingale is convergent a.s. and in L^1). Moreover, it follows from the proof cited above that

$$E^m g = E^m f(X_0) = \int_E f(y)dy. \tag{113}$$

By [16, Corollary to Theorem 1], for any natural N we have

$$\lim_{t\to\infty} p_t(f\wedge N) = \frac{1}{|E|}\int_E (f\wedge N)(y)dy,$$

so

$$g = \lim_{t\to\infty} p_t f \geq g_0 := \frac{1}{|E|}\int_E f(y)dy.$$

But, by (113), g and g_0 have the same expectations under P^m, so they must be equal a.e. This proves (112).

Now take $t = 1$ in the definition (106) of f and denote by σ the Borel measure on R^n defined by

$$\sigma(G) = P(E, G) \tag{114}$$

for all open sets G. σ is a *smooth* measure, i.e., it charges no set of zero capacity [18]. It also follows from [18, Theorem 1.1 and Lemma 2.1] that σ is the Revuz measure corresponding to the positive continuous additive functional ξ_t in the sense of [15, Theorem 5.1.3].

We want to show that

$$\int_E f(y)dy = E^m\xi_1 = \sigma(\overline{E}) = |\partial E|. \tag{115}$$

If σ is of finite energy integral, this follows immediately from [15, Lemma 5.1.4(iii)]. In general, by [15, Theorem 3.2.3], there exists an increasing sequence $\{F_n\}$ of closed subsets of $\overline{E}$ such that

$$\sigma\left(\overline{E} - \bigcup_{n=1}^{\infty} F_n\right) = 0, \tag{116}$$

$\overline{E} - \bigcup_{n=1}^{\infty} F_n$ is an exceptional set, and the measures $I_{F_n}\cdot\sigma$, $n = 1, 2, \dots$, are of finite energy integral. By [15, Theorem 5.1.3], $I_{F_n}\cdot\sigma$ corresponds to the functional $I_{F_n}\xi$ defined by

$$(I_{F_n}\xi)_t = \int_0^t I_{F_n}(X_s)d\xi_s. \tag{117}$$

Using [15, Lemma 5.1.4(iii)] for $I_{F_n}\cdot\sigma$ and $I_{F_n}\xi$, we get

$$E^m(I_{F_n}\xi)_1 = (I_{F_n}\cdot\sigma)(\overline{E}) = \sigma(\overline{E}\cap F_n). \tag{118}$$

Letting $n\to\infty$, we get (115).

To finish the proof of (97), it suffices to show (still under the assumption that E is bounded), that

$$\lim_{T\to\infty}\frac{E^x\xi_T}{T} = \frac{|\partial E|}{|E|}$$

for a.e. $x\in\overline{E}$. Indeed, this together with (105) gives (97). To this end, let us remark that

$$\frac{E^x\xi_{[T]}}{[T]+1} \le \frac{E^x\xi_T}{T} \le \frac{E^x\xi_{[T]+1}}{[T]},$$

where $[T]$ denotes the integer part of T, so it actually suffices to show

$$\lim_{n\to\infty}\frac{E^x\xi_n}{n} = \frac{|\partial E|}{|E|} \tag{119}$$

for a.e. $x\in\overline{E}$, where the limit is taken over the integers n. We have, by (107),

$$\begin{aligned} E^x\xi_n &= E^x\left(\sum_{i=0}^{n-1}E^x(\xi_{i+1}-\xi_i|X_i)\right)\\ &= E^x\left(\sum_{i=0}^{n-1}f(X_i)\right)\\ &= \sum_{i=0}^{n-1}(p_if)(x) \end{aligned}$$

for a.e. $x\in\overline{E}$. Thus, by (112) and (115), (119) holds for a.e. $x\in\overline{E}$. This ends the proof of (97).

Now let us analyze the case of an *unbounded* Caccioppoli domain E. The construction of a normally reflected Brownian motion in E can be found in [8, 19].

Case 1. $|E|<\infty$.

Again, let σ be defined by (114). As in the previous case, σ is the Revuz measure corresponding to the positive continuous additive functional ξ_t and, by [15, Theorem 3.2.3], there exists an increasing sequence $\{F_n\}$ of closed subsets of $\overline{E}$ such that $\sigma(F_n)<\infty$ for each n, (116) holds, $\overline{E}-\bigcup_{n=1}^\infty F_n$ is an exceptional set, and the measures $I_{F_n}\cdot\sigma$, $n=1,2,\ldots$, are of finite energy integral.

Arguing as in the case of a bounded domain, but with $(I_{F_n}\xi)_t$ defined by (117) instead of ξ_t, and using (118), we get, for a.e. $x\in\overline{E}$,

$$\lim_{T\to\infty}\frac{E^x(I_{F_n}\xi)_T}{T} = \frac{E^m(I_{F_n}\xi)_1}{|E|} = \frac{\sigma(\overline{E}\cap F_n)}{|E|}.$$

Thus,

$$\liminf_{T\to\infty}\frac{E^x\xi_T}{T} \ge \frac{\sigma(\overline{E}\cap F_n)}{|E|}$$

for every $n \geq 1$, i.e.,

$$\liminf_{T\to\infty} \frac{E^x \xi_T}{T} \geq \frac{\sigma(\overline{E})}{|E|} = \frac{|\partial E|}{|E|} \tag{120}$$

for a.e. $x \in \overline{E}$.

Carefully examining this argument and using [17, Theorem 2], we can get (120) for q.e. $x \in \overline{E}$.

For any natural number N, $h \wedge N \in L^p$ for all $p \geq 1$. Thus, proceeding as in the bounded case, we get (104) and (105) with $h \wedge N$ instead of h, which yields

$$\liminf_{T\to\infty} \frac{1}{T} E^x \int_0^T h(X_t)dt \geq \frac{1}{|E|} \int_E h(y)dy \tag{121}$$

for q.e. $x \in \overline{E}$. This, together with (120), ends the proof of (98) in the case of $|E| < \infty$.

Case 2. $|E| = \infty$.

Define, for any natural number N,

$$f_N = N - (h \wedge N).$$

$f_N \in L^p$ for all $p \geq 1$, because $\lim_{|x|\to\infty} h(x) = \infty$. By [16, Corollary (ii) to Theorem 1] and [17, Theorem 2] once again, we get

$$\lim_{t\to\infty} p_t f_N = 0$$

q.e. in $\overline{E}$, so

$$\lim_{t\to\infty} p_t(h \wedge N) = N$$

q.e. in $\overline{E}$. From this we easily get

$$\liminf_{T\to\infty} \frac{1}{T} E^x \int_0^T h(X_t)dt = \infty$$

q.e. in $\overline{E}$ by the same reasoning as in the previous cases. This ends the proof of (98).

Acknowledgments. This work is a part of my Ph.D. thesis at the Courant Institute of Mathematical Sciences, New York University. I want to express my deep gratitude to my advisor, Professor Marco Avellaneda, and to Professor Robert V. Kohn for many helpful discussions. I also thank Professor Jose Luis Menaldi for his helpful comments on the first version of this paper, Professors Zhen-Qing Chen and Ruth William for references to recent papers, and the referees for their valuable suggestions.

A NONCONTROLLABILITY RESULT FOR SYSTEMS OF MIXED ORDER*

GIUSEPPE GEYMONAT† AND VANDA VALENTE‡

Abstract. In this paper we prove an abstract theorem of noncontrollability for the evolution equation associated to a Douglis–Nirenberg elliptic system of mixed order with nonempty essential spectrum. In particular, we show by Weyl's characterization of the essential spectrum that the condition of exact controllability does not hold true. We discuss examples concerning the elasticity operator in the framework of the linear membrane shell theory.

Key words. exact controllability, membrane shell theory, essential spectrum

1. Introduction.

The exact controllability of the vibrations of mixed order systems frequently arises in the control theory of distributed parameters systems and techniques of harmonic analysis, and results of spectral theory are often involved in the solution of the control problem. Excitable systems can otherwise produce vibrations which are not exactly controllable. It is the aim of our paper to describe such a situation and get an abstract noncontrollability result via spectral analysis.

In order to fix the notations we consider a system of differential equations

$$\begin{cases} \mathbf{v}_{tt} + \mathbf{A}\mathbf{v} = 0 & \text{in} \quad \Omega \times (0,T), \\ \\ \mathbf{B}\mathbf{v} = 0 & \text{on} \quad \partial\Omega \times (0,T), \end{cases} \tag{1.1}$$

where **A** is a Douglis–Nirenberg elliptic operator of mixed order and **B** is a system of normal boundary conditions. We restrict our attention to a linear selfadjoint operator associated with a sesquilinear form. Following the spectral analysis results given in [6], [7], [8], [9], we show that the exact controllability problem is strictly connected to the spectral properties of **A**; in particular, we point out that when the operator **A** has a nonempty essential spectrum, that is, the operator **A** contains a block of zero order, the system (1.1) is not exactly controllable. The proof of our main result is obtained by Weyl's characterization of the essential spectrum here recalled and reformulated. We adopt the Weyl sequences (or singular sequences) to show that the exact controllability problem cannot in general be solved.

In many physical situations the operator **A** depends on a small parameter ε and the limit as $\varepsilon \to 0$ may lead to a *singular perturbation* problem. When ε vanishes and the existence of eigenvalues which form a discrete spectrum is still ensured, the controllability problem may be solved, but if the limit problem has an essential spectrum, the system is no longer controllable; the phenomenon of the *loss of exact controllability* is therefore connected to the appearance of the *essential spectrum.*

For example, in the case of a thin shell, the perturbation parameter is represented by the shell thickness. In the spectral analysis for thin shells carried out in [5], the dependence on the thinness parameter in the formula that gives the distribution of the eigenvalues has been studied. The established result suggested, in particular, the existence of a finite accumulation point for a subsequence of eigenvalues of the limit problem. Moreover, an explicit computation of the eigenfunctions allowed us to deduce the nonexact controllability of the spherical membrane. Results of exact controllability of thin shells, including shallow shells, can be found in [4], [5], [12], [14].

This paper presents a result of independent interest which in the framework of the linear thin shell theory also generalizes the previous one and shows the phenomenology of the loss of the exact controllability in the transition shell-membrane. Although in this paper we repeatedly refer to the membrane shell operator, we insist on the interest in a criterion of noncontrollability for other applications in the control theory of distributed parameters systems. Moreover, the general formulation of our examples allows us to consider membrane shells of arbitrary shapes which can also take part in the modelling of more complex phenomena (see, for example, [11]).

2. Mixed order systems and spectral analysis.

Most of the arguments in this section have been introduced in [6], [7], [8], [9]. We consider mixed order operators which exhibit an essential spectrum.

2.1. Some assumptions.

Let $\bar{\Omega}$ be a compact d-dimensional C^∞ manifold with C^∞ boundary Γ, and let $\mathbf{A} = (A_{st})_{s,t=1,\dots,q}$ (with $q > 1$) be a selfadjoint matrix of differential operators A_{st} of order $m_s + m_t$, where

$$m_1 \geq m_2 \cdots \geq m_{q-p} > m_{q-p+1} = \cdots = m_q \geq 0 \qquad (1 \leq p < q).$$

We assume the following.

(A.I) $\mathbf{A}$ is elliptic in the sense of Douglis–Nirenberg (see [1]), i.e., the matrix of principal symbols $\sigma^0(\mathbf{A})(\mathbf{x}, \boldsymbol{\xi})$ is invertible for all $(\mathbf{x}, \boldsymbol{\xi})$ in the nonzero cotangent bundle $T^*(\bar{\Omega})\backslash 0$.

In this paper we consider operators $\mathbf{A}$ which contain a block of order 0, that is, $m_q = 0$. In this case it is useful to split $\mathbf{A}$ in blocks of positive order and zero order, respectively,

$$\mathbf{A} = \begin{pmatrix} \mathbf{A}_{NN} & \mathbf{A}_{NQ} \\ \mathbf{A}_{QN} & \mathbf{A}_{QQ} \end{pmatrix}, \tag{2.1}$$

where we have adopted the notations

$$\begin{array}{ll} N = 1, 2, \dots, q-p, & Q = q-p+1, \dots, q, \\ \mathbf{A}_{NN} = (A_{st})_{s,t \in N}, & \mathbf{A}_{NQ} = (A_{st})_{s \in N, t \in Q}, \\ \mathbf{A}_{QN} = (A_{st})_{s \in Q, t \in N}, & \mathbf{A}_{QQ} = (A_{st})_{s,t \in Q}. \end{array}$$

In (2.1) the block $\mathbf{A}_{QQ}$ is of order 0 while the other blocks are of positive order, and we assume for simplicity that the operator $\mathbf{A}_{NN}$ is elliptic.

Along with the operator $\mathbf{A}$ we consider a matrix of differential boundary operators $\mathbf{B} = (\mathbf{B}_{rs})_{r \in M, s=1,\dots q}$, where $M = \{1, 2, \dots, m\}$, $m = \sum_{s=1}^{q} m_s$. Each operator $\mathbf{B}_{rs}$ has order $\sigma_r + m_s$, where $-m_1 \leq \sigma_1 \leq \sigma_2 \cdots \leq \sigma_m \leq m_1 - 1$, and if $\sigma_r + m_s < 0$, then $\mathbf{B}_{rs} \equiv 0$. When $\sigma_r \leq -1$ for $r = 1, \dots, \ell$, then we consider the decomposition

$$\mathbf{B} = \begin{pmatrix} \mathbf{B}^0 \\ \mathbf{B}^1 \end{pmatrix}, \qquad \mathbf{B}^0 = (\mathbf{B}_{rs})_{r=1,\dots\ell;\, s=1,\dots q}. \tag{2.2}$$

(A.II) $\mathbf{B}$ defines a system of normal boundary conditions, i.e., there exists a complementary system $\mathbf{C}$ of boundary conditions such that $\{\mathbf{B},\mathbf{C}\}$ are the reduced Cauchy data of $\mathbf{A}$ (see [9]), and the following Green formula holds for smooth functions:

$$((\mathbf{A}\mathbf{v},\tilde{\mathbf{v}}))_\Omega - ((\mathbf{v},\mathbf{A}\tilde{\mathbf{v}}))_\Omega = ((\mathbf{C}\mathbf{v},\,\mathbf{B}\tilde{\mathbf{v}}))_\Gamma + ((\mathbf{B}\mathbf{v},\,\mathbf{C}\tilde{\mathbf{v}}))_\Gamma.$$

In what follows, we denote by $\mathbf{H}=\mathbf{H}^0$ the vector space $\mathbf{L}^2(\Omega)$, and we denote by $\mathbf{V}$ the vector space of functions $\mathbf{u}\in H^{m_1}(\Omega)\times H^{m_2}(\Omega)\cdots\times H^{m_q}(\Omega)$ with the boundary condition $\mathbf{B}^0\mathbf{u}=0$, equipped with the norm $\|\mathbf{u}\|_V$ induced by $\prod_{i=1}^q H^{m_i}(\Omega)$.

The realization $\mathbf{A}_B$ of $\mathbf{A}$ associated to the boundary conditions $\mathbf{B}$ is defined via the following assumption.

(A.III) $\mathbf{A}_B$ is a selfadjoint lower bounded operator in $\mathbf{H}$ associated with the sesquilinear and continuous form $a(\mathbf{u},\mathbf{v})$ on $\mathbf{V}\times\mathbf{V}$ which satisfies the inequality

$$a(\mathbf{v},\mathbf{v})+\tau\|\mathbf{v}\|_H^2 \geq c_0\,\|\mathbf{v}\|_V^2\,, \qquad c_0>0 \text{ and } \tau\in\mathbb{R}.$$

Under this assumption $\mathbf{A}_B$ is the operator in $\mathbf{H}$ with domain

$$\mathrm{D}(\mathbf{A}_B)=\left\{\mathbf{u}\in\prod_{i=1,\dots,q}H^{m_i}(\Omega);\ \mathbf{A}\mathbf{u}\in\mathbf{H},\ \mathbf{B}\mathbf{u}=0\right\}\subset\mathbf{V},$$

defined by $(\mathbf{A}_B\mathbf{u},\mathbf{v})_H=a(\mathbf{u},\mathbf{v})$ for any $\mathbf{u}\in D(\mathbf{A}_B)$ and $\mathbf{v}\in\prod_{i=1}^q H^{m_i}(\Omega)$. Realizations $\mathbf{A}_B$ verifying assumption (A.III) are determined in [9].

We can also introduce the operator $\mathbf{A}_B^{min}$ defined by $\mathbf{A}_B^{min}\mathbf{u}=\mathbf{A}\mathbf{u}$ with domain

$$\mathrm{D}(\mathbf{A}_B^{min})=\left\{\mathbf{u}\in\prod_{i=1,\dots,q}H^{m_1+m_i}(\Omega),\ \mathbf{B}\mathbf{u}=0\right\}.$$

Examples. In the linear thin shell theory we consider the *membrane approximation* of the elasticity operator. Let Ω be a bounded open set of boundary Γ of the plane $\mathbb{R}^2$; the surface S of an elastic membrane is defined by two curvilinear coordinates x_1 and x_2; it is the image in $\mathbb{R}^3$ of Ω by the map

$$\boldsymbol{\varphi}:(x_1,x_2)\in\overline{\Omega}\to\mathbb{R}^3.$$

In each point of S two tangent vectors $\mathbf{a}_\alpha=\partial\boldsymbol{\varphi}/\partial x_\alpha$ $\alpha=1,2$ and a normal vector $\mathbf{a}_3=\frac{\mathbf{a}_1\times\mathbf{a}_2}{|\mathbf{a}_1\times\mathbf{a}_2|}$ are considered.

Adopting the summation convention (Greek indices take values in the set $\{1,\,2\}$ and the Latin indices take values in the set $\{1,\,2,\,3\}$) and denoting by $f_{,\alpha}$ the partial derivative of f with respect to x_α, the *first fundamental form* $(a_{\alpha\beta})$ and the *second fundamental form* $(b_{\alpha\beta})$ are given by

$$a_{\alpha\beta}=\mathbf{a}_\alpha\cdot\mathbf{a}_\beta, \qquad \alpha,\beta=1,2,$$

$$b_{\alpha\beta}=\mathbf{a}_3\cdot\mathbf{a}_{\alpha,\beta}, \qquad \alpha,\beta=1,2;$$

moreover, if $(a^{\alpha\beta})$ denotes the inverse matrix of $(a_{\alpha\beta})$, the reciprocal basis $\mathbf{a}^\alpha$ is defined by $\mathbf{a}^\alpha=a^{\alpha\beta}\mathbf{a}_\beta$. Let $\mathbf{v}(x_1,x_2)=v_1\mathbf{a}^1+v_2\mathbf{a}^2+v_3\mathbf{a}^3=v_i\mathbf{a}^i$ be the displacement vector of S; the deformed surface is given by $\boldsymbol{\varphi}+\mathbf{v}$. In the framework of a linearized theory small displacements $\mathbf{v}$ are considered.

The energy of membrane deformation is defined by the symmetric form

$$a^m(\mathbf{v},\tilde{\mathbf{v}}) = \int_S a^{\alpha\beta\lambda\mu}\gamma_{\alpha\beta}(\mathbf{v})\gamma_{\lambda\mu}(\tilde{\mathbf{v}})\,\mathrm{d}\,S, \tag{2.3}$$

where $\mathrm{d}\,S = |\mathbf{a}_1\times\mathbf{a}_2|\,\mathrm{d}\,x_1\,\mathrm{d}\,x_2$ and

$$a^{\alpha\beta\lambda\mu} = \frac{E}{2(1+\nu)}\left[a^{\alpha\lambda}a^{\beta\mu}+a^{\alpha\mu}a^{\beta\lambda}+\frac{2\nu}{(1-\nu)}\,a^{\alpha\beta}a^{\lambda\mu}\right] \tag{2.4}$$

is the tensor of "elastic moduli," with E and ν as the Young modulus and Poisson ratio, respectively.

The *deformation tensor* of the middle surface $(\gamma_{\alpha\beta}(\mathbf{v}))$ is given by

$$\gamma_{\alpha\beta}(\mathbf{v}) = \frac{1}{2}\,(v_{\beta|\alpha}+v_{\alpha|\beta}) - b_{\alpha\beta}v_3, \tag{2.5}$$

where the bar $|$ denotes the covariant derivative defined by means of the Christoffel symbols $\Gamma^{\alpha}_{\beta\lambda} = \mathbf{a}^{\alpha}\cdot\mathbf{a}_{\beta,\lambda}$ and $\mathrm{v}_{\alpha|\beta} = \mathrm{v}_{\alpha,\beta}-\Gamma^{\lambda}_{\alpha\beta}v_{\lambda}$.

Since the component v_3 appears in (2.3) by zero order derivative, while the component v_{α} appears by first order derivatives, we have that the differential selfadjoint operator $\mathbf{A}^m$, associated to the form a^m, is a linear system of differential operators of mixed order with indices $m_1 = m_2 = 1$, $m_3 = 0$, which we can write in block decomposition as

$$\mathbf{A}^m = \begin{pmatrix} \mathbf{A}^m_{NN} & \mathbf{A}^m_{N3} \\ \mathbf{A}^m_{3N} & A^m_{33} \end{pmatrix}, \tag{2.6}$$

where $A^m_{33} = a^{\alpha\beta\lambda\mu}b_{\alpha\beta}b_{\lambda\mu}$ is a zero order operator, and $\mathbf{A}^m_{NN}$ (resp., $\mathbf{A}^m_{N3}$, $\mathbf{A}^m_{3N}$)(N=1,2) is a matrix of differential operators of order $2m_1$ (resp., m_1+m_3, m_1+m_3). Let $\mathbf{u}$ be the vector (v_1,v_2) so that $\mathbf{v} = (v_1,v_2,v_3) = (\mathbf{u},v_3)$, and let $\mathbf{V} = (H^1(\Omega))^2\times L^2(\Omega)$. We may consider three different types of boundary conditions:

(a) $\mathrm{v}_{\alpha} = 0, \quad \alpha = 1,2$ (Dirichlet conditions);

(b) $a^{\alpha\beta\sigma\mu}\gamma_{\sigma\mu}(\mathbf{v})\nu_{\beta} = 0, \quad \alpha = 1,2$ (Neumann conditions),
where $\boldsymbol{\nu}$ is the unit outward normal vector in the surface at points of ∂S;

(c) $\mathrm{v}_{\alpha}\,\nu_{\alpha} = 0, \quad a^{\alpha\beta\sigma\mu}\gamma_{\sigma\mu}(\mathbf{v})\nu_{\beta}\,\tau_{\alpha} = 0$ (intermediate conditions),
where τ_{α} denotes the components of the tangent unit vector.

We define the operator $\mathbf{A}^m_D$, $\mathbf{A}^m_N$, and $\mathbf{A}^m_I$ corresponding to the boundary conditions (a), (b), and (c), respectively. According to the mentioned boundary conditions and the position (2.2), we introduce the following vector spaces:

$\mathbf{V}^{(\mathrm{a})} = \{\mathbf{v}\in\mathbf{V},\ |\ \mathbf{B}^0\mathbf{v} = \mathbf{0}$, with $\mathbf{B}^0 = (\mathbf{B}^0_{\alpha\beta}) = \mathbf{I}\}$,
$\mathbf{V}^{(\mathrm{b})} = \mathbf{V}$,
$\mathbf{V}^{(\mathrm{c})} = \{\mathbf{v}\in\mathbf{V},\ |\ \mathbf{B}^0\mathbf{v} = \mathbf{0}$, with $\mathbf{B}^0 = (\mathbf{B}^0_{1\beta}) = \nu_{\beta}\}$.

Moreover, let $\mathbf{H}$ be the space $(L^2(\Omega))^3$ equipped with the standard scalar product

$$(\mathbf{v},\tilde{\mathbf{v}})_H = ((\mathbf{v},\tilde{\mathbf{v}})) = \int_S a^{\alpha\beta}v_{\alpha}\tilde{v}_{\beta}+v_3\tilde{v}_3dS.$$

We refer to the papers of Ciarlet and Sanchez-Palencia for ellipticity results and uniqueness and existence theorems for linear membrane shell equations (see, for instance, [2] and the references therein).

2.2. The essential spectrum. Let $\sigma_{ess}(\mathbf{A}_B)$ be the *essential spectrum* of the selfadjoint operator $\mathbf{A}_B$, and one can prove (see [7], [8]) that

$$\sigma_{ess}(\mathbf{A}_B) = \omega \cup \omega_b, \tag{2.7}$$

where ω is the closed set of $\lambda \in \mathbb{R}$ such that $\mathbf{A} - \lambda\mathbf{I}$ is not Douglis–Nirenberg elliptic, and ω_b is the closed set of $\lambda \in \mathbb{R}\backslash\omega$ for which the boundary condition does not cover $\mathbf{A} - \lambda\mathbf{I}$, i.e., does not satisfy the Shapiro–Lopatinskii condition.

We recall that the set ω is formed by the points λ such that the determinant of the principal symbol of $\mathbf{A} - \lambda\mathbf{I}$, which we denote by $\sigma^0(\mathbf{A} - \lambda\mathbf{I})(\mathbf{x}, \boldsymbol{\xi})$, vanishes for some real $\boldsymbol{\xi}$ different from zero.

Since we consider the case $m_q = 0$, $\mathbf{A} - \lambda\mathbf{I}$ is not always Douglis–Nirenberg elliptic and the set ω is *nonempty.*

The characterization of the essential spectrum is also given in terms of *singular sequences.*

PROPOSITION 2.1 (Weyl characterization of the essential spectrum [7], [16]). *Let* $\mathbf{T}$ *be a selfadjoint linear operator on a Hilbert space* $\mathbf{H}$, $\lambda^* \in \sigma_{ess}(\mathbf{T})$ *if and only if there exists a singular sequence for* $\mathbf{T} - \lambda^*\mathbf{I}$, *i.e., a sequence* $\mathbf{w}_n$ *of elements of the Hilbert space* $\mathbf{H}$ *such that*

(i_0) $\mathbf{w}_n \in D(\mathbf{T})$,

(i_1) $\|\mathbf{w}_n\|_H = 1$,

(i_2) $(\mathbf{T} - \lambda^*\mathbf{I})\mathbf{w}_n \to 0$ *in* $\mathbf{H}$ *strongly,*

(i_3) $\mathbf{w}_n$ *has no strongly convergent subsequence in* $\mathbf{H}$ *(* $\mathbf{w}_n \to 0$ *in* $\mathbf{H}$ *weakly).*

In our situation we can verify further properties.

PROPOSITION 2.2. *Under the assumptions* (A.I)-(A.III) *if* $\lambda^* = \lambda(\mathbf{x}^*, \boldsymbol{\xi}^*) \in \omega$, *then there is a singular sequence for* $\mathbf{A}_B - \lambda^*\mathbf{I}$ *such that*

(i_4) $a(\mathbf{w}_n, \mathbf{w}_n) \to \lambda^*$,

(i_5) $\mathbf{C}\mathbf{w}_n \to 0$ *in* $\mathbf{L}^2(\Gamma)$ *strongly.*

Proof. In order to prove (i_5) we recall a technique for the construction of a singular sequence. We assume by translation $\mathbf{x}^* = 0$ and take $\mathbf{w} \in C_0^\infty(\mathbb{R}^d)$ with $\|\mathbf{w}\|_H = 1$.

Now we formally write the operator $\mathbf{A}$ in the form

$$\mathbf{A} = \begin{pmatrix} \mathbf{A}_{NN} & \mathbf{0} \\ \mathbf{A}_{QN} & \mathbf{I} \end{pmatrix} \begin{pmatrix} \mathbf{I} & \mathbf{A}_{NN}^{-1}\mathbf{A}_{NQ} \\ \mathbf{0} & \mathbf{S} \end{pmatrix}, \tag{2.8}$$

where $\mathbf{S} = \mathbf{A}_{QQ} - \mathbf{A}_{QN}\mathbf{A}_{NN}^{-1}\mathbf{A}_{NQ}$. Note that we use the same symbol $\mathbf{I}$ for unit matrices of different dimension. Since $\det\sigma^0(\mathbf{A}-\lambda^*\mathbf{I}) = \det\sigma^0(\mathbf{A}_{NN})\det\sigma^0(\mathbf{S}-\lambda^*\mathbf{I})$, we have that $\det\sigma^0(\mathbf{A}_{NN}) \neq 0$ implies that $\sigma^0(\mathbf{S}) - \lambda^*\mathbf{I}$ is not bijective at $(\mathbf{0}, \boldsymbol{\xi}^*)$.

We consider the eigenvector $\boldsymbol{\vartheta}$ corresponding to the eigenvalue λ^* for $\sigma^0(\mathbf{S})$; then the sequence

$$\tilde{\mathbf{w}}_n(\mathbf{x}) = n^{d/2} e^{i(\mathbf{x}, n^2\boldsymbol{\xi}^*)} \mathbf{w}(n\mathbf{x})\, \boldsymbol{\vartheta} \tag{2.9}$$

is a singular sequence for $\mathbf{S} - \lambda^*\mathbf{I}$. The singular sequence (2.9) is often quoted in literature (see, for example [6], [7], [15]) and can be used to construct a singular sequence for $\mathbf{A} - \lambda^*\mathbf{I}$. Let $\mathbf{P}$ be a parametrix of $\mathbf{A}_{NN}$, whose kernel as an integral operator has its support close to the diagonal; the sequence

$$\mathbf{w}_n = \frac{\mathbf{w}'_n}{\|\mathbf{w}'_n\|_H}, \qquad \mathbf{w}'_n = \begin{pmatrix} -\mathbf{P}\mathbf{A}_{NQ}\tilde{\mathbf{w}}_n \\ \tilde{\mathbf{w}}_n \end{pmatrix}, \tag{2.10}$$

is a singular sequence for $\mathbf{A}-\lambda^*\mathbf{I}$ and hence for $\mathbf{A}_B-\lambda^*\mathbf{I}$ since $\lambda^*\in\omega$. Indeed, conditions (i_0) and (i_1) are verified for construction, and since

$$(2.11)\qquad (\mathbf{A}-\lambda^*\mathbf{I})\,\mathbf{w}'_n=\begin{pmatrix} (-\mathbf{A}_{NN}\mathbf{P}+\mathbf{I})\,\mathbf{A}_{NQ}\tilde{\mathbf{w}}_n+\lambda^*\,\mathbf{P}\mathbf{A}_{NQ}\tilde{\mathbf{w}}_n, \\ (\mathbf{S}-\lambda^*\mathbf{I})\tilde{\mathbf{w}}_n, \end{pmatrix},$$

we have $(\mathbf{S}-\lambda^*\mathbf{I})\tilde{\mathbf{w}}_n\to 0$ strongly in $\mathbf{H}$, and $((-\mathbf{A}_{NN}\mathbf{P}+\mathbf{I})\mathbf{A}_{NQ}+\lambda^*\mathbf{P}\mathbf{A}_{NQ})\tilde{\mathbf{w}}_n\to 0$ strongly in $\mathbf{H}$ (using that $\tilde{\mathbf{w}}_n\to 0$ weakly in $\mathbf{H}$ and that $(-\mathbf{A}_{NN}\mathbf{P}+\mathbf{I})\mathbf{A}_{NQ}+\lambda^*\mathbf{P}\mathbf{A}_{NQ}$ is a regularizing operator); then $(\mathbf{A}-\lambda^*\mathbf{I})\mathbf{w}_n\to 0$ strongly in $\mathbf{H}$. The condition (i_2) is therefore satisfied, and hence, in the hypotheses defined by the assumptions (A.I)–(A.III), we get (i_4).

Moreover, we denote by T_n the application $T_nf=n^{d/2}f(nx)$ which defines an isometry of L^2 in itself; we see that $T_n\mathbf{w}$ concentrates the support of $\tilde{\mathbf{w}}_n$ (and hence of $\mathbf{w}'_n$, since the support of $\mathbf{P}\mathbf{A}_{NQ}\tilde{\mathbf{w}}_n$ is close to $\tilde{\mathbf{w}}_n$) near the origin (i.e., $\mathbf{x}^*=0$).

It follows that for any given $\varepsilon>0$ there exists an index n_ε such that for $n>n_\varepsilon$ the function $\mathbf{w}_n$ has compact support in Ω_ε, where $\Omega_\varepsilon\subset\Omega$ and ε is the positive distance from Ω_ε to the boundary of Ω. That implies on the boundary of Ω

$$(2.12)\qquad (\mathbf{C}\mathbf{w}_n,\mathbf{C}\mathbf{w}_n)_\Gamma\to 0 \qquad \text{as} \qquad n\to\infty,$$

and hence (i_5) is verified. □

2.3. The asymptotics of the unbounded discrete spectrum. When $\mathbf{A}_B$ is selfadjoint lower bounded, the essential spectrum is bounded and there is an unbounded discrete spectrum. Following the works of Grubb and Geymonat [7], [8], we find that there exists a sequence of real eigenvalues λ_j^+ of finite multiplicity and disjoint from the essential spectrum going to $+\infty$. Let λ^o be large enough in order that $\lambda^o\notin\sigma_{ess}(\mathbf{A}_B)$; then the asymptotic behavior of λ_j^+ is given in first approximation by the asymptotic behavior of the eigenvalues of $\mathbf{A}_{NN}$. That is, there exists a constant $c(\mathbf{A}_{NN})$ such that

$$(2.13)\qquad N(\lambda,\mathbf{A})=\sum_{\lambda^o<\lambda_j^+<\lambda}1=c(\mathbf{A}_{NN})\lambda^{d/2m_{q-p}}+o(\lambda^{d/2m_{q-p}}),\quad \lambda\to\infty,$$

where

$$c(\mathbf{A}_{NN})=\frac{1}{d(2\pi)^d}\int_\Omega\int_{|\xi|=1}tr(p(\mathbf{x},\xi)^{-d/2m_{q-p}})d\sigma d\mathbf{x}$$

with

$$p(\mathbf{x},\xi)=\sigma^0(\mathbf{A}_{q-p,q-p})-\sigma^0(\mathbf{A}_{q-p,\hat{N}})\sigma^0(\mathbf{A}_{\hat{N},\hat{N}})^{-1}\sigma^0(\mathbf{A}_{\hat{N},q-p})$$

and $\hat{N}=\{1,2,\dots,q-p-1\}$. We point out that the asymptotic behavior defined by (2.13) does not depend on the choice of the boundary conditions.

Examples (continued). The eigenvalue problem for the operator $\mathbf{A}^m$ reads

$$(2.14\text{a})\qquad -a^{\alpha\beta\sigma\mu}\gamma_{\sigma\mu}(\mathbf{v})_{|\beta}-\lambda a^{\alpha\beta}v_\beta=0,\qquad \alpha=1,2,$$

$$(2.14\text{b})\qquad -a^{\alpha\beta\sigma\mu}\gamma_{\sigma\mu}(\mathbf{v})b_{\alpha\beta}-\lambda v_3=0.$$

With reference to the operators $\mathbf{A}_D^m$, $\mathbf{A}_N^m$, and $\mathbf{A}_I^m$ defined above, we may state that if λ in the system (2.14) is large enough, the asymptotic behavior of that part of the discrete spectrum, formed by eigenvalues with finite multiplicity which accumulate to $+\infty$, can be easily computed according to (2.13). In each of the above situations (examples (a), (b), and (c)), taking into account that $m_{q-p} = m_1 = m_2 = 1$, we have

$$c(\mathbf{A}^m_{NN}) = \frac{1}{2(2\pi)^2} \int_\Omega \int_{|\xi|=1} tr(\sigma^0(\mathbf{A}^m_{NN})^{-1}) d\sigma d\mathbf{x}$$

with

$$\sigma^0(\mathbf{A}^m_{NN}) = (a_{\alpha\beta})(t^{\sigma\mu})$$

and

$$t^{\sigma\mu} = a^{\sigma\gamma\mu\alpha}\xi_\alpha\xi_\gamma, \qquad \sigma, \mu = 1, 2.$$

Although the asymptotic behavior of the unbounded discrete spectrum is independent on the choice of the boundary conditions, we remark that the essential spectrum and hence the problems related to the operators $\mathbf{A}^m_D$, $\mathbf{A}^m_N$, and $\mathbf{A}^m_I$ may be very different. We recall that for the axially symmetric deformations of hemispherical membranes, as considered in [4], [5], and [17], a simple computation of the essential spectrum gives $(1-\nu^2) \in \omega$. In this situation, since we treat a one-dimensional problem, we have to restrict our attention to the boundary conditions (a) and (b). In both cases the discrete spectrum is formed by two disjoint subsequences of eigenvalues: one going to ∞ and the other one with an accumulation point $(1-\nu^2)$.

3. A noncontrollability result.

In the hypotheses assumed for the operator $\mathbf{A}$ in the previous section, we consider the following exact controllability problem.

(EC) Given $T > 0$ and an initial state $\mathbf{\Phi}^0, \mathbf{\Phi}^1$ find the control function $\mathbf{g}$ such that the unique solution $\mathbf{\Phi}$ of

$$\ddot{\mathbf{\Phi}} + \mathbf{A\Phi} = 0 \qquad \text{in } Q = \Omega \times (0,T), \tag{3.1a}$$

$$\mathbf{B\Phi} = \mathbf{g} \qquad \text{on } \Sigma = \Gamma \times (0,T), \tag{3.1b}$$

$$\mathbf{\Phi}(0) = \mathbf{\Phi}^0 \ , \quad \dot{\mathbf{\Phi}}(0) = \mathbf{\Phi}^1 \quad \text{in } \Omega \tag{3.1c}$$

satisfies the following conditions:

$$\mathbf{\Phi}(T) = 0 \ , \quad \dot{\mathbf{\Phi}}(T) = 0 \quad \text{in } \Omega. \tag{3.1d}$$

To solve the exact controllability problem, we have to look at the existence of a solution $\mathbf{g}$ of the functional equation

$$\int_\Sigma \mathbf{C}\boldsymbol{\eta}\ \mathbf{g}(s,t)\,\mathrm{d}\,s\,\mathrm{d}\,t = ((\boldsymbol{\eta}^0, \mathbf{\Phi}^1)) - ((\boldsymbol{\eta}^1, \mathbf{\Phi}^0)) \tag{3.2}$$

for all initial data $\{\boldsymbol{\eta}^0, \boldsymbol{\eta}^1\}$ of the homogeneous problem associated to (3.1a)–(3.1c) which we refer to in its variational setting.

Let $T > 0$, $\boldsymbol{\eta}^0 \in \mathbf{V}$, and $\boldsymbol{\eta}^1 \in \mathbf{H}$ be given; find a function

$$\boldsymbol{\eta}(t) \in C([0,T];\ \mathbf{V}) \cap C^1([0,T]; \mathbf{H})$$

such that for any $\tilde{\boldsymbol{\eta}} \in \mathbf{V}$

$$((\ddot{\boldsymbol{\eta}}, \tilde{\boldsymbol{\eta}}))_\Omega + a(\boldsymbol{\eta}, \tilde{\boldsymbol{\eta}}) = 0, \quad \boldsymbol{\eta}(0) = \boldsymbol{\eta}^0,\ \dot{\boldsymbol{\eta}}(0) = \boldsymbol{\eta}^1,\ \mathbf{C}\boldsymbol{\eta} \in L^2(\Sigma). \tag{3.3}$$

The existence, uniqueness, and regularity of the solution $\boldsymbol{\eta}$ of (3.3) follow from the assumptions (A.I)–(A.III) in section 2.

We have the existence of a solution $\mathbf{g}$ of (3.2) *if and only if* [3]

$$\left(\int_\Sigma (\mathbf{C}\boldsymbol{\eta})^2 \,\mathrm{d}\,s\,\mathrm{d}\,t\right)^{1/2} \geq \mathrm{const}\|\{\boldsymbol{\eta}^0, \boldsymbol{\eta}^1\}\|_{V\times H}. \tag{3.4}$$

The Hilbert uniqueness method of J. L. Lions [10], [13] gives a constructive result for exact controllability problems. If we put $\mathbf{g} = \mathbf{C}\mathbf{v}$ in (3.2), the problem is to find the initial data $\{\mathbf{v}^0, \mathbf{v}^1\}$ of the homogeneous problem which solve the functional equation

$$\int_\Sigma \mathbf{C}\boldsymbol{\eta} \quad \mathbf{C}\mathbf{v} \,\mathrm{d}\,s\,\mathrm{d}\,t = ((\boldsymbol{\eta}^0, \boldsymbol{\Phi}^1)) - ((\boldsymbol{\eta}^1, \boldsymbol{\Phi}^0)).$$

If we show that for T large enough

$$\left(\int_\Sigma (\mathbf{C}\mathbf{v})^2 \,\mathrm{d}\,s\,\mathrm{d}\,t\right)^{1/2} = \|\{\mathbf{v}^0, \mathbf{v}^1\}\|_{\mathbf{F}}$$

defines a *norm* on the set of initial data $\{\mathbf{v}^0, \mathbf{v}^1\} \in \mathbf{F} = \mathbf{V} \times \mathbf{H}$ of the homogeneous problem, then the controllability problem can be solved, and we have exact controllability for any $\{\boldsymbol{\Phi}^1, \boldsymbol{\Phi}^0\} \in \mathbf{F}'$ ($\mathbf{F}' = \mathbf{V}' \times \mathbf{H}$). Indeed, after introducing the linear operator $\Lambda : \mathbf{F} \to \mathbf{F}'$ we can solve the equation

$$\langle \Lambda\{\mathbf{v}^0, \mathbf{v}^1\}, \{\boldsymbol{\eta}^0, \boldsymbol{\eta}^1\}\rangle = ((\boldsymbol{\eta}^0, \boldsymbol{\Phi}^1)) - ((\boldsymbol{\eta}^1, \boldsymbol{\Phi}^0))$$

for any $\{\boldsymbol{\eta}^0, \boldsymbol{\eta}^1\}$ in $\mathbf{F}$ and

$$\langle \Lambda\{\mathbf{v}^0, \mathbf{v}^1\}, \{\mathbf{v}^0, \mathbf{v}^1\}\rangle = \int_\Sigma (\mathbf{C}\mathbf{v})^2 \,\mathrm{d}\,s\,\mathrm{d}\,t.$$

We are now in a position to prove the main result of this paper.

THEOREM 3.1. *We assume that the hypotheses* (A.I)–(A.III) *and the following assumption* (A.IV) *are satisfied.*

(A.IV) *There is a positive* λ^* *in the set* ω.

For each finite positive T, there exist some initial data $\{\boldsymbol{\Phi}^1, \boldsymbol{\Phi}^0\} \in \mathbf{F}' = \mathbf{V}' \times \mathbf{H}$ *such that the evolution system* (3.1a), (3.1b), (3.1c) *is not exactly controllable.*

Proof. We consider the singular sequence $\{\mathbf{w}_n\}$ for $\lambda^* \in \omega$ as we introduced in Proposition 2.2. If we choose the sequence $\{\mathbf{v}_n^0, \mathbf{v}_n^1\} \in \mathbf{V} \times \mathbf{H}$ of initial data for the homogeneous problem associated to (3.1a), (3.1b), (3.1c), with

$$\mathbf{v}_n^0 = \mathbf{w}_n\ , \qquad \mathbf{v}_n^1 = 0,$$

from (i_1) of Proposition 2.1, we have

$$\|\{\mathbf{v}_n^0, \mathbf{v}_n^1\}\|_{H\times H} = \|\mathbf{v}_n^0\|_H = 1.$$

Moreover, from assumption (A.IV),

$$\|\{\mathbf{v}_n^0, \mathbf{v}_n^1\}\|_{V\times H}^2 = \|\mathbf{v}_n^0\|_V^2 = a(\mathbf{v}_n^0, \mathbf{v}_n^0) \to \lambda^* > 0 \quad \text{as} \quad n \to \infty. \tag{3.5}$$

We denote by $\mathbf{v}_n$ the unique solution of the homogeneous problem

$$\ddot{\mathbf{v}}_n + \mathbf{A}\mathbf{v}_n = 0 \qquad \text{in } \; Q = \Omega \times (0,T), \tag{3.6}$$

$$\mathbf{B}\mathbf{v}_n = \mathbf{0} \qquad \text{on } \; \Sigma = \Gamma \times (0,T), \tag{3.7}$$

$$\mathbf{v}_n(0) = \mathbf{w}_n \;, \quad \dot{\mathbf{v}}_n(0) = \mathbf{0} \quad \text{in } \; \Omega, \tag{3.8}$$

and we introduce the function $\mathbf{f}_n = \cos(\sqrt{\lambda^*}\, t)\, \mathbf{w}_n$.

From the definition of singular sequence we have $\lambda^* \mathbf{w}_n - \mathbf{A}\mathbf{w}_n \to 0$ strongly in $\mathbf{H}$ as $n \to \infty$; moreover, we have that $\mathbf{S}_n = \ddot{\mathbf{f}}_n + \mathbf{A}\mathbf{f}_n = -\cos(\sqrt{\lambda^*}\, t)(\lambda^* \mathbf{w}_n - \mathbf{A}\mathbf{w}_n) \to 0$ strongly in $L^\infty(0,T;\mathbf{H})$ as $n \to \infty$. Now we consider the function $\mathbf{e}_n = \mathbf{v}_n - \mathbf{f}_n$ which is in $C([0,T];\mathbf{V}) \cap C^1([0,T];\mathbf{H})$ and satisfies

$$\ddot{\mathbf{e}}_n + \mathbf{A}\mathbf{e}_n = \mathbf{S}_n \qquad \text{in } \; Q = \Omega \times (0,T), \tag{3.9}$$

$$\mathbf{B}\mathbf{e}_n = \mathbf{0} \qquad \text{on } \; \Sigma = \Gamma \times (0,T), \tag{3.10}$$

$$\mathbf{e}_n(0) = \mathbf{0}, \quad \dot{\mathbf{e}}_n(0) = \mathbf{0} \quad \text{in } \; \Omega. \tag{3.11}$$

More regularity of the function $\mathbf{e}_n$ is a consequence of the compatibility condition and the regularity of the function $\mathbf{S}_n$. Indeed, we can introduce, by means of the standard technique involving the incremental quotient $(\mathbf{e}_n(t+dt) - \mathbf{e}_n(t))/dt$, the differential system in the unknown $\dot{\mathbf{e}}_n = \mathbf{k}_n$, that is,

$$\ddot{\mathbf{k}}_n + \mathbf{A}\mathbf{k}_n = \dot{\mathbf{S}}_n \qquad \text{in } \; Q = \Omega \times (0,T), \tag{3.12}$$

$$\mathbf{B}\mathbf{k}_n = \mathbf{0} \qquad \text{on } \; \Sigma = \Gamma \times (0,T), \tag{3.13}$$

$$\mathbf{k}_n(0) = \mathbf{0}, \quad \dot{\mathbf{k}}_n(0) = \mathbf{S}_n(0) - \mathbf{A}\mathbf{e}_n(0) = \mathbf{A}\mathbf{w}_n - \lambda^* \mathbf{w}_n \quad \text{in } \; \Omega. \tag{3.14}$$

Multiplying (3.12) by $\dot{k}_n$, it follows from Gronwall's inequality the energy estimate

$$E(\mathbf{k}_n(t)) = \frac{1}{2}\left\{ a(\mathbf{k}_n, \mathbf{k}_n) + \int_\Omega |\dot{\mathbf{k}}_n|^2 \right\} \le \frac{e^T}{2}\, [\|\mathbf{A}\mathbf{w}_n - \lambda^* \mathbf{w}_n\|_H^2 + T\|\dot{\mathbf{S}}_n\|^2_{L^\infty(0,T;H)}],$$

and since $\dot{\mathbf{S}}_n = \sqrt{\lambda^*}\; \sin(\sqrt{\lambda^*}\, t)(\lambda^* \mathbf{w}_n - \mathbf{A}\mathbf{w}_n)$, we obtain

$$E(\mathbf{k}_n(t)) \le C_1(T)\, \|\mathbf{A}\mathbf{w}_n - \lambda^* \mathbf{w}_n\|_H^2. \tag{3.15}$$

The previous inequality allows us to multiply (3.9) by $\mathbf{A}\dot{\mathbf{e}}_n$ and get an a priori estimate for the function $\mathbf{e}_n$. We have

$$\tilde{E}(\mathbf{e}_n(t)) = \frac{1}{2}\left\{ a(\dot{\mathbf{e}}_n, \dot{\mathbf{e}}_n) + \int_\Omega |\mathbf{A}\mathbf{e}_n|^2 \right\} = \int_Q \mathbf{S}_n\, \mathbf{A}\dot{\mathbf{e}}_n = \int_\Omega \mathbf{S}_n\, \mathbf{A}\dot{\mathbf{e}}_n - \int_0^t \int_\Omega \dot{\mathbf{S}}_n\, \mathbf{A}\mathbf{e}_n.$$

With simple algebraic manipulations, again from the Gronwall's inequality and from the definition of $\mathbf{S}_n$ and $\dot{\mathbf{S}}_n$, we get

$$\tilde{E}(\mathbf{e}_n(t)) \le C(T)\, \|\mathbf{A}\mathbf{w}_n - \lambda^* \mathbf{w}_n\|_H^2, \tag{3.16}$$

where $C(T)$ is a constant depending on T such that $\lim_{T\to\infty} C(T) = \infty$, and hence for any fixed positive T

$$\mathbf{e}_n \in L^\infty(0,T;\, D(\mathbf{A}_B^{min})), \qquad \dot{\mathbf{e}}_n \in L^\infty(0,T;\, \mathbf{V}).$$

Moreover, taking into account our assumptions, $\mathbf{A}_B^{min}$ is a maximal and monotone operator and from the Hille–Yosida theorem we have $\mathbf{e}_n \in C(0,T;D(\mathbf{A}_B^{min}))$ and $\mathbf{Ce}_n \in L^2(\Sigma)$. In these regularity hypotheses the boundary operator $\mathbf{C}$ is continuous and surjective [8], [9] and from the estimate (3.16)

$$\int_\Sigma (\mathbf{Ce}_n)^2 dsdt \to 0 \qquad \text{as } n \to \infty;$$

hence from Proposition 2.2

$$\int_\Sigma (\mathbf{Cv}_n)^2 dsdt \le 2\left\{\int_\Sigma (\mathbf{Ce}_n)^2 dsdt + \int_\Sigma (\mathbf{Cf}_n)^2 dsdt\right\} \to 0 \qquad \text{as } n \to \infty.$$

The last condition and the behavior of (3.5) are in contradiction with the necessary (and sufficient) condition for the exact controllability

$$\int_\Sigma (\mathbf{Cv}_n)^2\, dsdt \ \ge c\|\{\mathbf{v}_n^0, \mathbf{v}_n^1\}\|^2_{V\times H},$$

and that completes the proof. □

Examples (continued). The procedure proposed in the proof of the Proposition 2.2 can be applied to the operator $\mathbf{A}^m$ (see (2.6)). The vibrations of the membrane shell are described by the system

$$a^{\alpha\beta\sigma\mu}\gamma_{\sigma\mu}(\mathbf{z})_{|\beta} = a^{\alpha\beta}(z_\beta)_{tt}, \qquad \alpha = 1,2,$$

$$a^{\alpha\beta\sigma\mu}\gamma_{\sigma\mu}(\mathbf{z})b_{\alpha\beta} = (z_3)_{tt}.$$

On the boundary we assume one of these conditions:
$\mathrm{z}_\alpha = g_\alpha, \qquad \alpha = 1,2$ (the example (a));
$a^{\alpha\beta\sigma\mu}\gamma_{\sigma\mu}(\mathbf{z})\nu_\beta = g_\alpha, \qquad \alpha = 1,2$ (the example (b));
$\mathrm{z}_\alpha\, \nu_\alpha = g_1, \quad a^{\alpha\beta\sigma\mu}\gamma_{\sigma\mu}(\mathbf{z})\nu_\beta\, \tau_\alpha = g_2$ (the example (c)).
And at the initial time we prescribe

$$\mathrm{z}_\alpha(0) = \mathrm{z}_\alpha^0, \qquad (\mathrm{z}_\alpha)_t(0) = \mathrm{z}_\alpha^1.$$

The controllability problem requires us to find the control function g_α such that at a given time T

$$\mathrm{z}_\alpha(T) = 0, \qquad (\mathrm{z}_\alpha)_t(T) = 0.$$

From Theorem 3.1 it follows that the control function g_α $(\alpha = 1,2)$ does not exist for any choice of the initial data. The eigenfunctions corresponding to the eigenvalues with finite accumulation point are used to prove the lack of the exact controllability for spherical membranes (see [4] and [5]). We briefly mention that case. The axially symmetric vibrations are described by two unknowns u and w: the meridional and radial component, respectively, of the displacement vector $\mathbf{v} = (u, w)$. The equations for the hemispherical membrane vibrations take the form

$$u_{tt} = u'' + u'\mathrm{cot}\theta - u(\nu + \mathrm{cot}^2\theta) - (1+\nu)w',$$
$$w_{tt} = \frac{(1+\nu)}{\mathrm{sin}\theta}(u\mathrm{sin}\theta)' - 2(1+\nu)w,$$

where the prime stands by the derivative with respect to $\theta \in]0, \theta_0 = \frac{\pi}{2}[$. We consider the following types of homogeneous boundary conditions:

(a) $u(\theta_0, t) = 0$ (Dirichlet condition);

(b) $u' - (1+\nu)w|_{(\theta_0,t)} = 0$ (Neumann condition).

The corresponding boundary conditions in 0 are a consequence of the symmetry of the problem. The spectral analysis of these problems can be easily carried out (see [4], [5] for (a)); in particular, we recall that the related eigenfunctions are derived by the spherical functions of even order (in case (a)) and odd order (in case (b)).

The same spectral asymptotics allow us to treat the problems in an analogous way. The positive number $(1-\nu^2)$ which is in the set ω is the accumulation point of two subsequences of eigenvalues (for the eigenvalues problems defined by (a) and (b), respectively). In this particular situation a more simple proof of Theorem 3.1 can be established if we take the corresponding subsequences of eigenfunctions as initial data of the control problems. Indeed, we denote these last subsequences by $\mathbf{v}_n^{(a)}$ and $\mathbf{v}_n^{(b)}$, and we easily check as $n \to \infty$ that $(u_n^{(a)}(\theta_0))' - (1+\nu)w_n^{(a)}(\theta_0) \to 0$ and $u_n^{(b)}(\theta_0) \to 0$.

AVERAGE COST DYNAMIC PROGRAMMING EQUATIONS FOR CONTROLLED MARKOV CHAINS WITH PARTIAL OBSERVATIONS[*]

V. S. BORKAR[†]

Abstract. The value function for the average cost control of a class of partially observed Markov chains is derived as the "vanishing discount limit," in a suitable sense, of the value functions for the corresponding discounted cost problems. The limiting procedure is justified by bounds derived using a simple coupling argument.

Key words. average cost control, controlled Markov chains, partial observations, dynamic programming, vanishing discount limit

1. Introduction.

Deriving the dynamic programming equations for average cost control of partially observed Markov chains has been an elusive task. Only scattered results are available which achieve this under very restrictive conditions [5], [6], [9], [10], [11]. (See [1], section 7, for a slightly dated survey.) Our aim here is to achieve this under a fairly broad condition. This is done by first relaxing the control problem to include the class of the so-called "wide sense admissible" controls, a notion borrowed from continuous time stochastic control literature [7], and then using a simple coupling argument to get the kind of bounds we need on the discounted cost value function in order to justify the "vanishing discount" limit.

The paper is organized as follows. The next section introduces the notation and the formal statement of the average cost control problem. It also introduces the associated nonlinear filter and the class of "wide sense admissible" controls alluded to above. Section 3 contains the coupling argument leading to the key estimates on the discounted value functions. Section 4 presents the main results, viz., the derivation of the average cost dynamic programming equation as the vanishing discount limit of the dynamic programming equations for the discounted cost problem.

2. The control problem.

We consider a controlled Markov chain $\{X_n\}$ on a finite state space $S = \{1, 2, \ldots, s\}$, controlled by a control process $\{Z_n\}$ taking values in a compact metric "action space" A, and with an associated observation process $\{Y_n\}$ taking values in a finite "observation space" W with cardinality $d \geq 1$. These are realized on an underlying probability space $(\Omega, \mathcal{F}, P)$. The evolution law of (X_n, Y_n) is given by

$$P(X_{n+1} = i, Y_{n+1} = j / X_m, Y_m, Z_m, m \leq n) = p(X_n, Z_n, i, j) \tag{2.1}$$

for $i \in S, j \in W$, where $p : X \times A \times S \times W \to [0, 1]$ is a continuous function satisfying

$$\sum_{j,k} p(i, u, j, k) = 1 \ \forall i, u.$$

Call $\{Z_n\}$ strict sense admissible if it is adapted to $\sigma(Y_m, m \leq n),\ n \geq 0$. The average cost control problem under partial observations, in its original formulation, is to minimize over all such $\{Z_n\}$ the average cost

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{m=0}^{n-1} E[h(X_m, Z_m)] \tag{2.2}$$

for a prescribed "running cost" function $h \in C(S \times A)$.

We shall denote by $\mathcal{P}(S)$ the space of probability measures on S, with topology of weak convergence. Since S is finite, this is the simplex of probability vectors in R^s. Keeping in mind the larger class of $\{Z_n\}$ we introduce later, define $\mathcal{F}_n = \sigma(Y_m, Z_m, m \leq n),\ n \geq 0$, and let $\{\pi_n\}$ be the $\mathcal{P}(S)$-valued process of regular conditional laws of X_n given $\mathcal{F}_n$ for $n \geq 0$. Define $\bar{h} \in C(\mathcal{P}(S) \times A)$ by

$$\bar{h}(\nu, a) = \sum_{i\in S} \nu(i) h(i, a),$$

where we write $\nu(i)$ for $\nu(\{i\})$ by abuse of notation. The average cost control problem above can then be shown to be equivalent to the "separated" average cost control problem of controlling the $\mathcal{P}(S)$-valued controlled Markov process $\{\pi_n\}$, so as to minimize over strict sense admissible $\{Z_n\}$ the quantity

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{m=0}^{n-1} E[\bar{h}(\pi_m, Z_m)]. \tag{2.3}$$

This in fact equals (2.2), as seen by a simple conditioning argument. The dynamics of $\{\pi_n\}$ are given by the nonlinear filter (derivable by an elementary application of the Bayes rule—see, e.g., [3, Chapter VIII])

$$\pi_{n+1} = \pi_n P(Z_n, Y_{n+1})/(\pi_n P(Z_n, Y_{n+1}) 1_c),\ n \geq 0, \tag{2.4}$$

where $\{\pi_n\}$ is written as a row vector, $P(u, k)$ is the matrix $[[p(\cdot, u, \cdot, k)]]$ for $u \in A, k \in W$, and 1_c is the column vector of all l's. The initial condition π_0 is the known law of X_0.

Before we proceed, we need to exhibit $\{X_n\}$ explicitly as a noise-driven dynamical system, i.e., as

$$X_{n+1} = F(X_n, Z_n, \xi_n),\ n \geq 0, \tag{2.5}$$

where $F : S \times A \times [0, 1] \to S$ is measurable and $\{\xi_n\}$ are independently and identically distributed (i.i.d.) uniformly on [0,1]. This is possible by the stochastic realization theoretic results of [2] and may require an augmentation of the underlying probability space.

We shall now reproduce (in law) the above processes on a more convenient probability space. Let $\bar{\Omega} = [0, 1]^\infty \times A^\infty \times W^\infty \times S$, and let $\mathcal{F}$ be the corresponding product σ-field. Let (u, v, w, x) denote a typical element of $\bar{\Omega}$ with $u = [u_0, u_1, \ldots] \in [0, 1]^\infty, v = [v_0, v_1, \ldots] \in A^\infty, w = [w_0, w_1, \ldots] \in W^\infty$. Let $u^n = [u_0, u_1, \ldots, u_n]$, and define v^n, w^n accordingly for $n \geq 0$. By the definition of strict sense admissible controls, we have

$$Z_n = \psi_n(Y_0, \ldots, Y_n),\ n \geq 0, \tag{2.6}$$

for some $\psi_n : W^{n+1} \to A$. Define

$$\bar{\psi}_n(w^n) = [\psi_0(w^0), \psi_1(w^1), \dots, \psi_n(w^n)],\ n \geq 0.$$

Let l_1, l_2 denote the uniform probability measures on [0,1], W, resp. Define a probability measure P_0 on $(\bar{\Omega}, \bar{\mathcal{F}})$ by the following. If $B_1 \subset [0,1]^{n+1}$, $B_2 \subset A^{n+1}$, $B_3 \subset W^{n+1}$, and $B_4 \subset S$ are Borel, then

$$P_0\left(\Pi_{i=1}^4 B_i\right) = l_1^{n+1}(B_1) l_2^{n+1}(B_3 \cap \{w^n : \bar{\psi}_n(w^n) \in B_2\})\pi_0(B_4),$$

where l_i^n denote the appropriate product measures. Define processes $\{\xi_n\}$, $\{Z_n\}$, $\{Y_n\}$, and a random variable X_0 canonically on $(\bar{\Omega}, \bar{\mathcal{F}}, P_0)$ by

$$\begin{aligned} \xi_n(u,v,w,x) &= u_n, \\ Z_n(u,v,w,x) &= v_n, \\ Y_n(u,v,w,x) &= w_n, \\ X_0(u,v,w,x) &= x \end{aligned}$$

for $n \geq 0$. Then under P_0,

(i) $\{\xi_i\}$ are i.i.d. uniformly distributed on [0,1],
(ii) $\{Y_n\}$ are i.i.d. uniformly distributed on W,
(iii) law of X_0 is π_0,
(iv) $(\{\xi_n\}, \{Y_n\}, X_0)$ is an independent family, and,
(v) $\{Z_n\}$ is specified by (2.6).

Define $\{X_n\}$ recursively using (2.5). Then by construction, $\{X_n\}$ is a controlled Markov chain satisfying

$$P(X_{n+1} = j / X_m,\ Z_m,\ m \leq n) = \bar{p}(X_n, Z_n, j),$$

$j \in S,\ n \geq 0$, where

$$\bar{p}(i,u,j) \triangleq \sum_k p(i,u,j,k),\ i,\ j \in S,\ u \in A.$$

For $n \geq 0$, let $\mathcal{G}_n = \sigma(X_m, Y_m, \xi_m, Z_m, m \leq n)$, and let P_{0n} be the restriction of P_0 to $(\bar{\Omega}, \mathcal{G}_n)$. Define a new probability measure $\bar{P}$ on $(\bar{\Omega}, \bar{\mathcal{F}})$ as follows. If $\bar{P}_n$ denotes its restriction to $(\bar{\Omega}, \mathcal{G}_n)$, then $\bar{P}_n << P_{0n}$ $\forall n$ with

$$\Lambda_n \triangleq \frac{d\bar{P}_n}{dP_{0n}} = \prod_{m=0}^{n-1} \frac{p(X_m, Z_m, X_{m+1}, Y_{m+1})}{\bar{p}(X_m, Z_m, X_{m+1})(1/d)},\ n \geq 0.$$

It is easily verified that $(\Lambda_n, \mathcal{G}_n)$ is a nonnegative martingale with mean 1, and therefore this defines in a consistent and unique manner a probability measure $\bar{P}$ on $(\Omega, \bigvee_n \mathcal{G}_n)$. Since $\mathcal{F} = \bigvee_n \mathcal{G}_n$ by construction, we are through. Furthermore, under $\bar{P}, (X_n, Y_n, Z_n, \xi_n)$ have the same joint law as the corresponding processes on $(\Omega, \mathcal{F}, P)$ we started with, again by construction.

This construction permits us to define wide sense admissible controls along the lines of [7]: $\{Z_n\}$ is said to be wide sense admissible if for each n, Z_n is independent of $(\{\xi_m\}, X_0, \{Y_i, i > n\})$ under P_0. Note that this includes strict sense admissible controls. (Intuitively, this relaxation allows for extraneous randomization of controls that does not use any information that it shouldn't.) Our "relaxed" partially observed separated control problem then is to minimize (2.3) over all wide sense admissible $\{Z_n\}$.

This is to be interpreted in the following sense. Under P_0, the laws of $\{Y_n\}, \{\xi_n\}, X_0$ are fixed and $\{X_n\}$ is specified once $\{Z_n\}$ is. Thus the above framework is specified "in law" by specifying the conditional law of $\{Z_n\}$ given $\{Y_n\}$ or, equivalently, the joint law of $\{Y_n\}, \{Z_n\}$ (where the marginal corresponding to the law of $\{Y_n\}$ is fixed). Thus it makes sense to refer to either of these as *the* wide sense admissible control. We denote by Φ the set of wide sense admissible controls, and, by a slight abuse of notation, we denote by $\{Z_n\}$ a typical element thereof.

3. The discounted value function. In anticipation of the "vanishing discount" argument to be used later, we consider here the family of value functions associated with the discounted cost problem, indexed by the discount factor $\alpha > 0$. Recall that the discounted cost under a wide sense admissible control $\{Z_n\} \in \Phi$ and initial law π is

$$J_\alpha(\{Z_n\}, \pi) \triangleq E\left[\sum_{m=0}^{\infty} \alpha^m h(X_m, Z_m)/\pi_0 = \pi\right]$$

$$\triangleq E\left[\sum_{m=0}^{\infty} \alpha^m \bar{h}(\pi_m, Z_m)/\pi_0 = \pi\right].$$

The associated value function

$$V_\alpha(\pi) = \inf_\Phi J_\alpha(\{Z_n\}, \pi)$$

then satisfies the dynamic programming equation

$$V_\alpha(\pi) = \min_u(\bar{h}(\pi, u) + \alpha \int \eta(\pi, u, d\pi')V_\alpha(\pi')), \ \pi \in \mathcal{P}(S), \tag{3.1}$$

where $(\pi, u) \in \mathcal{P}(S) \times A \to \eta(\pi, u, d\pi') \in \mathcal{P}(\mathcal{P}(S))$ is the controlled transition kernel of the $\mathcal{P}(S)$-valued controlled Markov process $\{\pi_n\}$. From (2.4) and conditions on $p(\cdot,\cdot,\cdot,\cdot)$, one easily verifies that $\eta(\cdot,\cdot,d\pi')$ is a continuous map. (See [3, Chapter VIII] for a detailed treatment of the separated discounted cost problem.)

We shall need to compare $V_\alpha(\cdot)$ for two different values of its argument. With this in view, we construct on a common probability space two controlled Markov chains satisfying (2.1) with a "common" $\{Z_n\} \in \Phi$, but different initial laws, say $\tilde{\pi}$ and $\hat{\pi}$. This is done by a small modification of the construction of the preceding section. Note that specification of $\{Z_n\} \in \Phi$ for initial law $\tilde{\pi}$ entails specification of its joint law with $\{Y_n\}$ under P_0, assumed to satisfy the independence/conditional independence constraints in the definition of wide sense admissible controls. Denote this joint law by $\phi(dy^\infty, dz^\infty) \in \mathcal{P}(W^\infty \times A^\infty)$. Define

$$\hat{\Omega} = ([0,1]^\infty \times S) \times ([0,1]^\infty \times S) \times A^\infty \times W^\infty \times W^\infty$$

with $\hat{\mathcal{F}} =$ the corresponding product σ-field and $\hat{P}_0$ the probability measure on $(\hat{\Omega}, \hat{\mathcal{F}})$ defined by

$$\begin{aligned}&\hat{P}_0((d\tilde{u}^\infty \times d\tilde{x}) \times (d\hat{u}^\infty \times d\hat{x}) \times dz^\infty \times d\tilde{y}^\infty \times d\hat{y}^\infty)\\ &\qquad = \ell_1^\infty(d\tilde{u}^\infty)\tilde{\pi}(d\tilde{x})\ell_1^\infty(d\hat{u}^\infty)\hat{\pi}(d\hat{x})\phi(d\tilde{y}^\infty, dz^\infty)\ell_2^\infty(d\hat{y}^\infty).\end{aligned}$$

On $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P}_0)$, define processes $\{\tilde{\xi}_n\}$, $\{\hat{\xi}_n\}$, $\{Z_n\}$, $\{\tilde{Y}_n\}$, $\{\hat{Y}_n\}$, and random variables $\tilde{X}_0, \hat{X}_0$ canonically as follows: For $\omega = (\tilde{u}^\infty, \tilde{x}, \hat{u}^\infty, \hat{x}, z^\infty, \tilde{y}^\infty, \hat{y}^\infty)$, let $\tilde{\xi}_n(\omega) =$

$\tilde{u}_n,\ \hat{\xi}_n(\omega) = \hat{u}_n,\ \tilde{X}_0 = \tilde{x},\ \hat{X}_0 = \hat{x},\ Z_n = z_n,\ \tilde{Y}_n = \tilde{y}_n,\ \hat{Y}_n = \hat{y}_n,\ n \geq 0$. Define $\{\tilde{X}_n\}$, $\{\hat{X}_n\}$ recursively by

$$\begin{aligned} \tilde{X}_{n+1} &= F(\tilde{X}_n, Z_n, \tilde{\xi}_n), \\ \hat{X}_{n+1} &= F(\hat{X}_n, Z_n, \hat{\xi}_n), \end{aligned}$$

$n \geq 0$. For $n \geq 0$, let $\Gamma_n = \sigma(\hat{X}_m, \tilde{X}_m, \hat{\xi}_m, \tilde{\xi}_m, \hat{Y}_m, \tilde{Y}_m, Z_m,\ m \leq n)$. Then $\hat{\mathcal{F}} = \bigvee_n \Gamma_n$. Define a new probability measure $\hat{P}$ on $(\hat{\Omega}, \hat{\mathcal{F}})$ by the following. If $\hat{P}_n, \hat{P}_{0n}$ are restrictions of $\hat{P}, \hat{P}_0$, resp. to $(\hat{\Omega}, \Gamma_n)$, then

$$\hat{\Lambda}_n \triangleq \frac{d\hat{P}_n}{d\hat{P}_{0n}} = \prod_{m=0}^{n-1} \left(\frac{p(\tilde{X}_m, Z_m, \tilde{X}_{m+1}, \tilde{Y}_{m+1})}{\bar{p}(\tilde{X}_m, Z_m, \tilde{X}_{m+1})(1/d)} \right) \left(\frac{p(\hat{X}_m, Z_m, \hat{X}_{m+1}, \hat{Y}_{m+1})}{\bar{p}(\hat{X}_m, Z_m, \hat{X}_{m+1})(1/d)} \right),$$

$n \geq 0$. Then the controlled Markov chains $\{\tilde{X}_n\}$, $\{\hat{X}_n\}$ defined on $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$ form the desired pair in so far as their initial laws are $\tilde{\pi}, \hat{\pi}$, resp., and they are governed by a "common" $\{Z_n\} \in \Phi$, as argued below.

LEMMA 3.1. $\{\tilde{X}_n\}$ *(resp.,* $\{\hat{X}_n\}$*) is a controlled Markov chain on* $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$ *with associated observation process* $\{\tilde{Y}_n\}$ *(resp.,* $\{\hat{Y}_n\}$*) and wide sense admissible control* $\{Z_n\}$, *with its evolution governed by* (2.1).

Proof. It suffices to observe that if we consider the probability measure

$$P_1(d\tilde{u}^\infty \times d\tilde{x} \times dz^\infty \times d\tilde{y}^\infty) = \hat{P}(d\tilde{u}^\infty \times d\tilde{x} \times [0,1]^\infty \times S \times dz^\infty \times d\tilde{y}^\infty \times W^\infty)$$

on $[0,1]^\infty \times S \times A^\infty \times W^\infty$, it is precisely a special case of the construction in the preceding section of $(\bar{\Omega}, \bar{\mathcal{F}}, \bar{P})$. Thus $(\{\tilde{X}_n\}, \{\tilde{Y}_n\}, \{Z_n\})$ obey (2.1) with $\{Z_n\}$ wide sense admissible and the law of $\tilde{X}_0 = \tilde{\pi}_0$. Likewise, consider the probability measure

$$P_2(d\hat{u}^\infty \times d\hat{x} \times dz^\infty \times d\hat{y}^\infty) = \hat{P}([0,1]^\infty \times S \times d\hat{u}^\infty \times d\hat{x} \times dz^\infty \times W^\infty \times d\hat{y}^\infty)$$

on $[0,1]^\infty \times S \times A^\infty \times W^\infty$ to draw a similar conclusion about $(\{\hat{X}_n\}, \{\hat{Y}_n\}, \{Z_n\})$. □

What this construction achieves is to identify each wide sense admissible control $\{Z_n\}$ for $\tilde{\pi}$ with one wide sense admissible control for $\hat{\pi}$. (This identification can be many-one.) By a symmetric argument that interchanges the role of $\tilde{\pi}, \hat{\pi}$, one may identify every wide sense admissible control for $\hat{\pi}$ with one for $\tilde{\pi}$. Suppose $V_\alpha(\tilde{\pi}) \leq V_\alpha(\hat{\pi})$. Then for a wide sense $\{\tilde{Z}_n\}$ that is optimal for $\tilde{\pi}$,

$$\begin{aligned} |V_\alpha(\tilde{\pi}) - V_\alpha(\hat{\pi})| &= V_\alpha(\hat{\pi}) - V_\alpha(\tilde{\pi}) \\ &\leq J_\alpha(\{\tilde{Z}_n\}, \hat{\pi}) - J_\alpha(\{\tilde{Z}_n\}, \tilde{\pi}) \\ &\leq \sup_\Phi |J_\alpha(\{Z_n\}, \hat{\pi}) - J_\alpha(\{Z_n\}, \tilde{\pi}))|, \end{aligned}$$

where the above identification is used to derive the first and the second inequalities. If $V_\alpha(\tilde{\pi}) > V_\alpha(\hat{\pi})$, a symmetric argument works, interchanging the roles of $\tilde{\pi}, \hat{\pi}$. Thus

$$|V_\alpha(\tilde{\pi}) - V_\alpha(\hat{\pi})| \leq \sup_\Phi |J_\alpha(\{Z_n\}, \tilde{\pi}) - J_\alpha(\{Z_n\}, \hat{\pi})|,$$

a fact we use in Lemma 3.2 below.

The stage is now set for stating our key assumption in this paper. Let $\tau = \min\{n \geq 0 : \tilde{X}_n = \hat{X}_n\}(= \infty$ if the set in question is empty).

Assumption A. There exist $K_0 > 0, \delta \in (0, 1)$ such that

$$\sup_{i,j} \sup_{\Phi} P(\tau > n/\hat{X}_0 = i, \tilde{X}_0 = j) \leq K_0\delta^n, n \geq 0. \tag{3.2}$$

Note that for an uncontrolled chain, (3.2) would follow from irreducibility and aperiodicity. The latter, in fact, are necessary. In our case, however, we need a statement over all wide sense admissible controls, which is what (3.2) does. Simpler sufficient conditions imposing restrictions on the graph of the Markov chain can be given (see Appendix), but these would be much more restrictive. Note also that the above conditional probability summed over n gives the corresponding conditional expectation, which will then be bounded by $\frac{K_0}{1-\delta}$. As our proofs will show, the weaker hypothesis that

$$\sup_{i,j} \sup_{\Phi} E[\tau/\hat{X}_0 = i, \tilde{X}_0 = j] \leq K_0$$

will in fact suffice. However, in most interesting cases where this is available, so is (3.2).

Note also that $\tau = 0$ almost surely (a.s.) on $\{\hat{X}_0 = \tilde{X}_0\}$. Using this, we shall cast (3.2) in a more convenient form. View $S = \{1, 2, \ldots, s\} \subset R$, allowing S to inherit the Euclidean metric from R. Then for $i \neq j$ in $S, |i - j| \geq 1$. Thus without any loss of generality, we may rewrite (3.2) as

$$\sup_{\Phi} P(\tau > n/\hat{X}_0 = i, \tilde{X}_0 = j) \leq K_0\delta^n|i - j|, \; n \geq 0, i, \; j \in S. \tag{3.3}$$

The last bit of technicality we need is the metric $\rho(\cdot, \cdot)$ on $\mathcal{P}(S)$ defined by

$$\rho(\mu_1, \mu_2) = \inf E[|X_1 - X_2|],$$

where the infimum is over all pairs (X_1, X_2) of S-valued random variables such that the law of X_i is μ_i for $i = 1, 2$. This metric is equivalent to the Prohorov metric [4, p. 29] and thus metrizes the Prohorov topology which, because S is finite, is the same as the total variation norm topology, which in turn coincides with the Euclidean topology of $\mathcal{R}^s$ relativized to $\mathcal{P}(S)$. Note also that as $\mathcal{P}(S)$ is compact, every compatible metric on it, in particular ρ, is complete. The main result of this section is the following lemma.

LEMMA 3.2. *There exists a* $K_1 > 0$ *such that*

$$|V_\alpha(\mu_1) - V_\alpha(\mu_2)| \leq K_1\rho(\mu_1, \mu_2) \; \forall \mu_1, \mu_2 \in \mathcal{P}(S), \; \alpha > 0. \tag{3.4}$$

Proof. Consider the above construction with $\hat{\pi} = \mu_1, \tilde{\pi} = \mu_2$. Define an S-valued process $\bar{X}_m, m \geq 0$, and a W-valued process $\bar{Y}_m, m \geq 0$, by

$$\bar{X}_m = \hat{X}_m, \bar{Y}_m = \hat{Y}_m \quad \text{for} \quad m < \tau,$$

$$\bar{X}_m = \tilde{X}_m, \bar{Y}_m = \tilde{Y}_m \quad \text{for} \quad m \geq \tau.$$

That is $(\bar{X}_m, \bar{Y}_m)$ is obtained from $(\hat{X}_m, \hat{Y}_m)$ by "gluing" it to $(\tilde{X}_m, \tilde{Y}_m)$ from τ on, a standard construction in coupling arguments. We claim that $\{\bar{X}_m\}$ is a controlled Markov chain as in (2.1) with $\{\bar{Y}_m\}$ the associated observation process, with initial law $\hat{\pi} = \mu_1$ and the same control process $\{Z_n\} \in \Phi$ as before. To see this, observe first that the claim (except for the wide sense admissibility of $\{Z_n\}$) is equivalent to the statement that for $i \in S$, $j \in W$, $\sum_{m=1}^{n}(I\{\bar{X}_m = i, \bar{Y}_m = j\} - p(\bar{X}_{m-1}, Z_{m-1}, i, j))$, $n \geq 1$, is a $\{\Gamma_n\}$-martingale. The corresponding statements for $(\{\tilde{X}_n\}, \{\tilde{Y}_n\})$ and $(\{\hat{X}_n\}, \{\hat{Y}_n\})$ are immediate. Thus

$$E[(I\{\tilde{X}_n = i, \tilde{Y}_n = j\} - p(\tilde{X}_{n-1}, Z_{n-1}, i, j))/\Gamma_{n-1}] = 0$$

and

$$E[(I\{\hat{X}_n = i, \hat{Y}_n = j\} - p(\hat{X}_{n-1}, Z_{n-1}, i, j))/\Gamma_{n-1}] = 0,$$

whereas we need to prove

$$E[(I\{\bar{X}_n = i, \bar{Y}_n = j\} - p(\bar{X}_{n-1}, Z_{n-1}, i, j))/\Gamma_{n-1}] = 0.$$

But the left-hand side equals

$$\begin{aligned}
&E[(I\{\tilde{X}_n = i, \tilde{Y}_n = j\} - p(\tilde{X}_{n-1}, Z_{n-1}, i, j))I\{\tau \geq n\} \\
&\quad + (I\{\hat{X}_n = i, \hat{Y}_n = j\} - p(\hat{X}_{n-1}, Z_{n-1}, i, j))I\{\tau < n\}/\Gamma_{n-1}] \\
= \quad &E[(I\{\tilde{X}_n = i, \tilde{Y}_n = j\} - p(\tilde{X}_{n-1}, Z_{n-1}, i, j)/\Gamma_{n-1}]I\{\tau \geq n\} \\
&\quad + E[(I\{\hat{X}_n = i, \hat{Y}_n = j\} - p(\hat{X}_{n-1}, Z_{n-1}, i, j))/\Gamma_{n-1}]I\{\tau < n\} \\
= 0,&
\end{aligned}$$

proving the claim. The wide sense admissibility of $\{Z_n\}$ for $(\{\bar{X}_n\}, \{\bar{Y}_n\})$ can be verified easily by reference to the probability measure $\hat{P}_0$ above. Under $\hat{P}_0$, $\tilde{Y}_n$ and $\hat{Y}_n$ are both independent of $\Gamma_{n-1} \bigvee \sigma(\tilde{\xi}_m, \hat{\xi}_m, m \geq 0)$ and are identically distributed, therefore so will be $\theta\tilde{Y}_n + (1-\theta)\hat{Y}_n$ for any Γ_{n-1}-measurable $\{0, 1\}$-valued random variable θ. $\bar{Y}_n$ is a special case of this. Now let $\{\bar{\pi}_n\}$ denote the corresponding process of conditional laws. Now,

$$\begin{aligned}
|V_\alpha(\mu_1) - V_\alpha(\mu_2)| &\leq \sup_{\{Z_n\}\in\Phi} |J_\alpha(\{Z_n\}, \mu_1) - J_\alpha(\{Z_n\}, \mu_2)| \\
&\leq \sup_{\Phi} \sum_{m=0}^{\infty} \alpha^m E[|h(\bar{X}_m, Z_m) - h(\tilde{X}_m, Z_m)|] \\
&= \sup_{\Phi} \sum_{m=0}^{\infty} \alpha^m E[|h(\bar{X}_m, Z_m) - h(\tilde{X}_m, Z_m)|I\{\tau > m\}] \\
&\leq 2K_2 \sup_{\Phi} \sum_{m=0}^{\infty} \alpha^m P(\tau > m) \\
&\leq 2K_2 K_0 \sum_{m=0}^{\infty} \alpha^m \delta^m E[|\bar{X}_0 - \tilde{X}_0|],
\end{aligned}$$

where K_2 is a bound on $|h(\cdot,\cdot)|$. Let $\epsilon > 0$. By a judicious choice of the joint law of $(\bar{X}_0, \tilde{X}_0)$, this can be made

$$\begin{aligned}
&\leq \frac{2K_2K_0}{1-\alpha\delta}(\rho(\mu_1, \mu_2) + \epsilon) \\
&\leq \frac{2K_2K_0}{1-\delta}(\rho(\mu_1, \mu_2) + \epsilon).
\end{aligned}$$

Since $\epsilon > 0$ was arbitrary, the claim follows. □

4. The dynamic programming equations. Fix a $\mu^* \in \mathcal{P}(S)$ and set $\bar{V}_\alpha(\mu) = V_\alpha(\mu) - V_\alpha(\mu^*)$ for $\mu \in \mathcal{P}(S), \alpha \in (0,1)$. By Lemma 3.2, $\{\bar{V}_\alpha(\cdot), \alpha \in (0,1)\}$ is bounded equicontinuous. Letting $\alpha \to 1$, we conclude from the Arzela–Ascoli theorem that $\bar{V}_\alpha(\cdot)$ converges in $C(\mathcal{P}(S))$ to some $V(\cdot)$ along a subsequence $\{\alpha(n)\}, \alpha(n) \to 1$. By dropping to a further subsequence if necessary, we may also suppose that $\{(1-\alpha(n))V_{\alpha(n)}(\mu^*)\}$, which is clearly bounded, converges to some $\Delta \in R$ as $n \to \infty$.

Before stating our main theorem, recall that for a separated control problem, a control policy is said to be stationary if $Z_n = v(\pi_n)\ \forall n$ and some measurable $v : \mathcal{P}(S) \to A$, and stationary randomized if for all n, Z_n is conditionally independent of $X_0,\ \xi_m,\ \pi_m,\ Z_{m-1},\ Y_m,\ m \le n$, given π_n and the regular conditional law thereof given the latter is $\varphi(\pi_n)$ for some measurable $\varphi : \mathcal{P}(S) \to \mathcal{P}(A)$ ([3, Chapter VIII]). It is also easy to verify that these are wide sense admissible. By abuse of terminology, we refer to the map $v(\cdot)$ (resp., $\varphi(\cdot)$) itself as the stationary (resp., stationary randomized) policy.

THEOREM 4.1. (i) $(V(\cdot), \Delta)$ *solve the dynamic programming equation for the average cost control problem*

$$V(\pi) = \min_u \left(\bar{h}(\pi, \mu) + \int \eta(\pi, u, d\pi')V(\pi') - \Delta \right). \tag{4.1}$$

(ii) Δ *is the optimal cost, independent of the initial condition. Furthermore, a stationary policy* $v(\cdot)$ *(resp., a stationary randomized policy* $\varphi(\cdot)$*) is optimal for any initial condition if*

$$v(\pi) \in \text{(resp., support}(\varphi(\pi)) \subset) \text{ Argmin} \left(\bar{h}(\pi, \cdot) + \int \eta(\pi, \cdot, d\pi')V(\pi') \right).$$

In particular, an optimal stationary policy exists.

Proof. (i) Rewrite (3.1) as

$$\bar{V}_\alpha(\pi) = \min_u \left(\bar{h}(\pi, u) + \alpha \int \eta(\pi, u, d\pi')\bar{V}_\alpha(\pi') - (1-\alpha)V_\alpha(\mu^*) \right).$$

Letting $\alpha \to 1$ along an appropriate subsequence, we get (4.1).

(ii) The first two statements follow by a standard argument which may be found, e.g., in [8, Theorem 5.2.4, pp. 80–81]. The last claim follows from a standard measurable selection theorem—see, e.g., [12]. □

THEOREM 4.2. *If* φ *is an optimal stationary policy and* γ *is a corresponding ergodic probability measure, then, for* $\varphi(\pi, du) \stackrel{\Delta}{=} \varphi(\pi)(du)$,

$$V(\pi) = \int \bar{h}(\pi, u)\varphi(\pi, du) + \int\int \varphi(\pi, du)\eta(\pi, u, d\pi')V(\pi') - \Delta \tag{4.2}$$

for γ*—a.s.* π*. (In particular, if* v *is an optimal stationary policy, then* (4.2) *holds for* γ*—a.s.* π *for every ergodic probability measure* γ *under* v*).*

Proof. Clearly, (4.3) always holds with "$\le$" replacing "=." If the claim were false, we can integrate both sides of this inequality with respect to $\gamma(d\pi)$ to obtain

$$\Delta < \int\int \bar{h}(\pi, \cdot)d\varphi(\pi)\gamma(d\pi),$$

a contradiction to the optimality of φ. The claim follows. □

COROLLARY 4.3. *If V, V' are two bounded measurable solutions to* (4.1), $V(\pi) - V'(\pi)$ *is a constant a.s. with respect to any ergodic probability measure under any optimal stationary randomized policy.*

Proof. Let φ, γ be as in Theorem 4.2, and let $\{\pi_n\}$ be the corresponding ergodic process of conditional laws, with law of $\pi_n = \gamma \ \forall n$. By Theorem 4.2,

$$V(\pi_n) - V'(\pi_n),\ n \geq 0,$$

is a bounded martingale with respect to the natural filtration of $\{\pi_n\}$ and therefore converges a.s. But since it is also a stationary process, this is possible only if the claim holds. □

Appendix. Here is a simple sufficient condition for (3.2) to hold. Suppose that there exist $i_0 \in S,\ \eta > 0$, and $N \geq 1$ such that

$$\inf_{i,j} \inf_{\Phi} P(\hat{X}_N = \tilde{X}_N = i_0 / \hat{X}_0 = i, \tilde{X}_0 = j) \geq \eta.$$

That is, there is a path of length N from any $i \in S$ to i_0 with a minimum probability of η. (For uncontrolled chains, aperiodicity would ensure this condition for all N sufficiently large. Thus we need aperiodicity that is in some sense uniform in Φ.) Now,

$$P(\tau > N / \hat{X}_0 = i, \tilde{X}_0 = j) \leq 1 - \eta.$$

Also, by a simple conditioning argument, for $m \geq 1$,

$$\begin{aligned} P(\tau > mN/\hat{X}_0 = i, \tilde{X}_0 = j) &= E[P(\tau > mN/\Gamma_{(m-1)N}) I\{\tau > (m-1)N\}/\hat{X}_0 = i, \tilde{X}_0 = j] \\ &\leq (1-\eta) P(\tau > (m-1)N/\hat{X}_0 = i, \tilde{X}_0 = j). \end{aligned}$$

Iterating, $P(\tau > mN/\hat{X}_0 = i, \tilde{X}_0 = j) \leq (1-\eta)^m,\ m \geq 1$, from which (3.2) follows.

GLOBAL STABILIZATION OF NONLINEAR SYSTEMS WITH INPUTS SUBJECT TO MAGNITUDE AND RATE BOUNDS: A PARAMETRIC OPTIMIZATION APPROACH*

JULIO SOLÍS-DAUN†, RODOLFO SUÁREZ†, AND JOSÉ ÁLVAREZ-RAMÍREZ†

Abstract. A bounded feedback control design approach is proposed for the global asymptotic stabilization of a class of nonlinear systems with stable free dynamics. The control inputs and their derivatives are constrained to take values on sets defined by a Cartesian product of η-dimensional closed balls $\mathcal{B}_{\mathbf{r}}^{\eta}(p)$, which are defined by means of a p-norm and a radius vector parameter $\mathbf{r}$. In order to derive the bounded control stabilizer, the resulting procedure implies that gains (as state-functions) are obtained from the solution to a set of c-parameterized nonlinear programming problems. In general, the resulting closed-loop system could be *implicitly defined*, i.e., consisting of a system of differential equations plus a set of nonlinear algebraic equations (required to compute the control). Special interest is focused on an important class of homogeneous systems that includes a class of globally asymptotically stabilizable systems by linear feedback and bilinear systems. For those systems, the problem of inputs subject to *globally bounded rates* is also addressed.

1. Introduction.

Consider the multiple input continuous-time affine system

$$\dot{x} = f(x) + \sum_{j=1}^{m} u_j\, g_j(x), \tag{1.1}$$

where $x \in \mathbb{R}^n$ and $f, g_j : \mathbb{R}^n \to \mathbb{R}^n$, for $j = 1, \ldots, m$, are smooth functions. Without loss of generality, we shall assume that the origin is an equilibrium point of the associated free dynamics of (1.1), i.e., $f(0) = 0$.

Define the η-dimensional $p, \mathbf{r}$-normed closed ball by

$$\mathcal{B}_{\mathbf{r}}^{\eta}(p) := \left\{ v \in \mathbb{R}^{\eta} : \|v\|_{p,\mathbf{r}} \le 1 \right\}, \text{ where } \|v\|_{p,\mathbf{r}} := \left[\left(\tfrac{v_1}{r_1}\right)^p + \cdots + \left(\tfrac{v_\eta}{r_\eta}\right)^p \right]^{1/p}, \tag{1.2}$$

for $\mathbf{r}$ a radius vector parameter $\mathbf{r} := (r_1, \ldots, r_\eta)^\top, r_i > 0$, for $i = 1, \ldots, \eta$, and $p := s/d > 1$, with s even and d odd positive numbers. We will say that $\|v\|_{p,\mathbf{r}}$ is the $\mathbf{r}$-weighed p-norm. Observe that the *usual* p-norm $\|\cdot\|_p$ is simply the $p, \mathbf{r}$-norm when $\mathbf{r} = (1, \ldots, 1)$. We assume that, by renaming the control input entries (if necessary), the control input is given by $u = (\mathbf{u}_1, \ldots, \mathbf{u}_\mu)^\top$ with *control blocks* $\mathbf{u}_i$ taking values in different $p, \mathbf{r}$-normed balls. Thus, the *control-value set* consists on a Cartesian product of $p, \mathbf{r}$-normed closed balls,

$$U = \prod_{i=1}^{\mu} \mathcal{B}_{\mathbf{r}_i}^{m_i}(p_i) := \mathcal{B}_{\mathbf{r}_1}^{m_1}(p_1) \times \cdots \times \mathcal{B}_{\mathbf{r}_\mu}^{m_\mu}(p_\mu) \tag{1.3}$$

for $1 \leq \mu \leq m$ and $m_1 + \cdots + m_\mu = m$. We have, for instance, the following examples: (a) if $p = 2$, then $\mathcal{B}^m_{\mathbf{r}}(2)$ is an ellipsoid in $\mathbb{R}^m$ with r_j the length of its jth-semiaxe; (b) if $r_1 = \cdots = r_m = \overline{r} > 0$, then $\mathcal{B}^m_{\overline{\mathbf{r}}}(p) = \{v \in \mathbb{R}^m : \|v\|_p \leq \overline{r}\}$ is a p-normed (Minkowski) ball of radius $\overline{r}$ in $\mathbb{R}^m$; (c) if $m = m_1 + m_2 = 3$, then $\mathcal{B}^1_{r_1}(\infty) \times \mathcal{B}^2_{\overline{\mathbf{r}}_2}(p)$ is a "cylinder" with its base being a p-normed ball of radius $\overline{r} > 0$; and (d) if $\mu = m$, then (1.3) is an m-dimensional $\mathbf{r}$-hyperbox $\mathcal{B}^m_{\mathbf{r}}(\infty) = [-r_1, r_1] \times \cdots \times [-r_m, r_m]$.

By an *admissible* input u, it is meant a C^α_L *function* (i.e., a C^α ($\alpha \geq 1$) function with the possible exception of $x = 0$, and everywhere Lipschitz continuous) that takes values in a (*prescribed*) Cartesian product of $p, \mathbf{r}$-normed closed balls, that is, the set of admissible controls is given by

$$(1.4) \qquad \mathcal{U} = C^\alpha_L(\mathbb{R}^n, U) := \left\{ u : \mathbb{R}^n \to \prod_{i=1}^{\mu} \mathcal{B}^{m_i}_{\mathbf{r}_i}(p_i) : u(\cdot) \text{ is a } C^\alpha_L \text{ function} \right\}.$$

In this paper, we first address the problem of *global asymptotic stabilization* (GAS) of the system (1.1) by means of a *bounded feedback control* (BFC) function $u = u(x)$, admissible in the aforementioned sense. As a second aim, we will study the GAS problem when further subject to input derivatives restricted to lie in *prescribed* constraint sets (1.3). Throughout this paper, stabilization will always be understood as stabilization at the origin.

In the last years, there has been a growing interest concerning the GAS problem of systems by means of BFC functions. The characterization of a class of linear systems for which it can be solved led to the concept of *asymptotic null controllability with bounded controls* (ANCBC). It is well known that a linear system is ANCBC iff it is *stabilizable by arbitrarily small controllers* (SASC) (cf. Sontag [24] and references therein). Different methodologies have been proposed for GAS of linear systems via BFC functions. See, for instance, Gavrilyako, Korobov, and Sklyar [10], Sussmann, Sontag, and Yang [27] and Suárez, Álvarez-Ramírez, and Solís-Daun [26]. When further assuming the problem of *rate-limited actuators*, see Lin [16] and Solís-Daun, Álvarez-Ramírez, and Suárez [23] for *semiglobal* results, and Shewchun and Feron [22] for a *global* solution. In contrast to the case of linear control systems, the characterization of the class of nonlinear systems which have the SASC property remains as an open problem.

Lyapunov analysis is a tool usually employed for the stabilization of nonlinear systems. Indeed, many systems admit a variational approach for deriving their dynamical equations and, in that framework, the energy function provides typically a positive-definite and proper function, such that it is nonincreasing along the solution of the uncontrolled system. This idea was the subject of many works on feedback stabilization, see, for instance, [11, 13, 4, 14] and references therein. For that aim, Jurdjevic and Quinn (J–Q) [13] developed a successful approach, based on a controllability-like rank condition defined in terms of Lie derivatives: the *ad-condition.* In [4], Byrnes, Isidori and Willems introduced the concept of *zero state detectability* (ZSD) in order to address the GAS problem for the important class of *passive* (and *feedback passive*) nonlinear systems by means of smooth (generally unbounded) feedback control functions. Further, they presented a criterion (an *ad*-like condition) for testing ZSD. Recently, Coron [5] and Lin [14] obtained GAS of passive systems by using arbitrarily small stabilizers. Those results can be thought of as a first attempt towards the characterization of the class of nonlinear systems sharing the SASC property. Lin also provided a criterion for testing ZSD that generalized previously reported results.

Different methods of the J–Q approach for the stabilization of nonlinear systems by means of bounded controls have been proposed. Mazenc and Praly [20] have given sufficient conditions under which GAS of a certain subsystem by saturated control implies GAS of the overall system; further, their method served to solve the stabilization problem of feedforward systems. Teel [28] presented a small gain theorem that was used for analyzing control system design: e.g., a stabilizing algorithm for feedforward systems was obtained, which in turn was applied to the control of stabilizable linear systems with input magnitude and rate saturation. Freeman and Praly [6] presented a backstepping procedure for the design of global feedback stabilizers which are bounded both in magnitude and rate (though the achieved bounds do not satisfy prescribed constraints). Finally, Sontag and coworkers have proposed *explicit formulae* for almost smooth BFC laws that stabilize a general system (1.1), under the assumption that an appropriate *control-Lyapunov function* (CLF) (see [1]) is known. Such formulae were designed to guarantee CLF stabilization under specific control-value sets U: the Euclidean open unit ball in [15] and a family of Minkowski open unit balls (with $1 < p \leq 2$) in [19].

On the other hand, it is important to note that depending on some applications, e.g., robot manipulators, chemical control processes, etc., unlimited feedback control rate can be conceived as a disadvantage of most of the existing methods for designing bounded stabilizers. In the case of polynomial systems, the designed control often resembles a *bang-bang control*, especially when states are far from the origin. That behavior precludes their use in the mentioned applications, due to the natural responses (e.g., controller inertia) of those systems to external stimuli. Hitherto, a general methodology for the GAS problem of nonlinear systems subject to prescribed input magnitude and rate bounds is still lacking.

Taking into account the above problems, in this paper we propose a design approach that allows the GAS of a class of nonlinear systems with stable free dynamics, using BFC functions with bounded derivatives. Following the basic ideas introduced in [26], the (high-gain) control law proposed in this work increases the feedback "gain" as the controlled trajectory converges towards the origin, guaranteeing that input bounds will not be exceeded. In the general nonlinear systems case with control-value set given by a $p, \mathbf{r}$-normed ball, the proposed procedure implies that: (a) in order to derive the bounded stabilizer, the "gains" (as state-functions) are obtained from the solution of a *c-parameterized nonlinear programming* problem; and (b) the resulting closed-loop system could be *implicitly defined*, in the sense that it consists of a system of differential equations plus a nonlinear algebraic equation (required to compute the control). With respect to existing results available in the literature [5, 6, 14, 20, 28], in this work we make the following contributions.

(a) We extend Lyapunov-based designs to account for more general control-value sets.
(b) We address the problem of both magnitude and rate constraints in the control input.
(c) We introduce a state-dependent control gain to achieve a suboptimal stability margin.

The paper is organized as follows. In section 2 we present some definitions, review some previous work, and state the problem. In section 3, a stabilizing BFC function is designed in the case when the control-value set is given by an m-dimensional $p, \mathbf{r}$-normed ball. In section 4, we show that the proposed control is suboptimal. In section 5, the result is extended to the case when the control-value set is a Cartesian product of $p, \mathbf{r}$-normed balls. In section 6, we study an important class of homogeneous systems (that includes those GAS systems via linear feedback and bilinear systems), for which the constructed control law is *explicitly defined*, so that the problem of inputs subject to prescribed *globally bounded rates* can be addressed. Finally, in section 7, we present some concluding remarks.

2. Preliminaries and statement of the problem. Recall that a function $V : \mathbb{R}^n \to \mathbb{R}$ is said to be *proper* iff, for any $c \in \mathbb{R}$, the set $V^{-1}(c) = \{x \in \mathbb{R}^n : V(x) = c\}$ is compact, and it is *positive-definite* iff $V(0) = 0$ and $V(x) > 0$ for all $x \neq 0$. In general, $L_{g_j}V(x)$ denotes a Lie derivative of function $V(x)$ in the direction of function $g_j(x)$. If g denotes the matrix $g(x) = (g_1(x), \dots, g_m(x))$, $g_j : \mathbb{R}^n \to \mathbb{R}^n$, $j = 1, \dots, m$, then we define $L_gV(x) := (L_{g_1}V(x), \dots, L_{g_m}V(x))$.

In this work, we assume the following.

Hypothesis H1. *Suppose there exists a C^α ($\alpha \geq 2$) function $V : \mathbb{R}^n \to \mathbb{R}$ that is positive-definite and proper on $\mathbb{R}^n$, such that the uncontrolled system $\dot{x} = f(x)$ ((1.1) with $u = 0$) satisfies*

$$L_fV(x) \leq 0. \tag{2.1}$$

In particular, it is Lyapunov stable.

Choose a dummy output $y := (L_gV(x))^\top$ for the system (1.1). Then, the input-output system (1.1) with dummy output

$$h(x) := (L_gV(x))^\top \tag{2.2}$$

is *passive* [4, 14] with *storage function* $V(x)$.

In addition to Hypothesis H1, system (1.1) is assumed to satisfy the following.

Hypothesis H2. *The input-output system* (1.1)–(2.2) *is zero state detectable (ZSD). That is, for all $x \in \mathbb{R}^n$,*

$$\textit{if } \forall t \geq 0,\ h\left(x(t, x_0; 0)\right)|_{u=0} = 0, \quad \textit{then } \lim_{t\to\infty} x(t, x_0; 0) = 0, \tag{2.3}$$

where $x(t, x_0; u)$ is a trajectory of (1.1) *with initial condition $x(0) = x_0$.*

We will need the following simple extension of a result presented in [4].

Proposition 2.1. *Assume that system* (1.1) *satisfies Hypotheses* H1–H2. *Then, any C_L^α feedback control function*

$$u(x) = \rho\, v(x), \tag{2.4}$$

with $\rho > 0$, satisfying that

$$\begin{array}{l}\text{(i) } v(0) = 0, \quad \text{(ii) } L_gV(x)\, v(x) \leq 0, \ \textit{and} \\ \text{(iii) } L_gV(x)\, v(x) = 0 \ \textit{only if} \ L_gV(x) = 0\end{array} \tag{2.5}$$

achieves GAS of the system (1.1). *In particular, any control $v(x)$ such that $v(0) = 0$ and* $\operatorname{sign} v_j(x) = -\operatorname{sign} h_j(x)$ *for $j = 1, \dots, m$ satisfies conditions* (2.5).

Hitherto, the control given in (2.4) is not necessarily bounded. Nevertheless, in the case of passive systems, Coron and Lin, independently, provided the following SASC result.

Theorem 2.2 (see [5, 14]). *Assume that Hypotheses* H1–H2 *hold. Then GAS of system* (1.1) *is achieved by means of arbitrarily small smooth feedbacks.*

Although one can use a *smooth boundedness* technique to obtain a globally defined BFC function that globally asymptotically stabilizes the system, low-gain control designing should usually be avoided, because it can result in sluggish responses and poor performance for all initial conditions. One way to obtain a high-gain controller is to define the parameter $\rho = \rho(x)$ in (2.4) as a positive function that increases as the distance to the origin is reduced, in such a way that the controller uses the maximum input amplitude without violating the input constraint. Indeed, it is not difficult to design such a function $\rho(x)$. For instance, consider the scalar feedback control given by

$$u_\sigma(x) := \begin{cases} 0 & \text{if } h(x) = 0, \\ -\rho(x)\, h(x) = -\frac{r\,\sigma(|h(x)|)}{|h(x)|}\, h(x) & \text{otherwise,} \end{cases} \tag{2.6}$$

where $\sigma(s) \leq 1$ for all $s \geq 0$, $\sigma(s) > 0$ for $s > 0$, and σ is as smooth as desired. Clearly, this feedback control is bounded: $|u_\sigma(x)| \leq r$ for all $x \in \mathbb{R}^n$, and it can be considered as a smooth approximation to the singular bang-bang control $\vartheta(x) = -r\,\mathrm{sign}(h(x))$. However, the problem is if the obtained controller has a globally bounded input rate. Indeed, control (2.6) does not have a bounded derivative, even in the linear case. In fact, suppose that the linear system with scalar control input $\dot{x}= Ax + b\,u$, (A is an $n \times n$ matrix and $b \in \mathbb{R}^n$) satisfies Hypotheses H1–H2. In this case, $h(x) = b^\top Px$, where P is a positive-definite symmetric matrix. Consider only the case when $h(x) > 0$, so that $u_\sigma(x) = -r\,\sigma(h(x)) < 0$. The analysis of the case $h(x) < 0$ is analogous. Thus,

$$\dot{u}_\sigma= -r\ \dot{\sigma}= -r\,\nabla\sigma\ \dot{h}= -r\,\nabla\sigma(h(x))\ \left(b^\top PAx + (b^\top Pb)\,u_\sigma(x)\right). \tag{2.7}$$

Let $U(\overline{h}) := \{x \in \mathbb{R}^n : h(x) = b^\top Px = \overline{h}$, with fixed $\overline{h} > 0\}$. Then,

$$\dot{u}_\sigma|_{U(\overline{h})}= -r\,\nabla\sigma(\overline{h})\ \left(b^\top PAx + (b^\top Pb)\,\overline{u}_\sigma\right)|_{U(\overline{h})}, \tag{2.8}$$

where $u_\sigma\ |_{h=\overline{h}}= \overline{u}_\sigma$, is an *unbounded function* (unless $A = \lambda\, I_{n\times n}$, with $\lambda \leq 0$ and $I_{n\times n}$ is the $n\times n$ identity matrix). Observe that for all $x \in U(\overline{h})$, we have that $\rho(x) = \overline{\rho} = r\,\sigma(\overline{h})/\overline{h} > 0$. Then, in virtue that the set $U(\overline{h})$ ($\subseteq L(\overline{\rho}) = \{x \in \mathbb{R}^n : \rho(x) = \overline{\rho}$, $\overline{\rho} > 0\}$) is unbounded, we have that $|du_\sigma/dt|$ cannot be globally bounded.

The difference between control functions like (2.6) and the control function to be proposed in the next section is that $\rho(x)$ will be constant along the boundary of the level sets of certain proper function $E(x)$, i.e., $\rho(x)$ will be constant on compact sets. Based on this idea, we obtain control functions with derivatives restricted to lie in *prescribed* constraint sets.

3. Control design when $U = \mathcal{B}^m_{\mathrm{r}}(p)$. In general, $V(x)$ (the Lyapunov function considered in Hypothesis H1) does not necessarily satisfy the condition that its level sets are simply connected—a sufficient condition in the control function design presented in this section. One case where that condition is satisfied, is the important class of homogeneous systems studied in section 6. Thus, we assume the following definition.

DEFINITION 3.1. *Suppose that $E : \mathbb{R}^n \to \mathbb{R}$ is a smooth, proper, and positive-definite function satisfying that, for any $c > 0$, its c-level sets*

$$\mathcal{E}(c) := \{x \in \mathbb{R}^n : E(x) \leq c\} \tag{3.1}$$

are simply connected, with $0 \in \operatorname{int} \mathcal{E}(c)$*. Then, we will say that* E *is an* $\mathcal{E}$*-function.*

Suppose that the control-value set U is an m-dimensional $p, \mathbf{r}$-normed closed ball, $\mathcal{B}^m_{\mathbf{r}}(p)$, with $\mathbf{r}$ a radius vector parameter $\mathbf{r} := (r_1, \ldots, r_m)^\top$, and $p \in \mathbb{Q}^*_{>1}$, with

$$\mathbb{Q}^*_{>1} := \left\{ p \in \mathbb{Q} : p = \frac{s}{d} > 1, \text{ with } s, d \in \mathbb{N}\backslash\{0\}, \text{ even and odd numbers} \right\}, \tag{3.2}$$

which is a *dense subset* of the open interval $(1, \infty) \subset \mathbb{R}$.

In this work, the proposed control function shall depend on the *dual value* $q > 1$, related to the given $p, \mathbf{r}$-norm, defined by

$$\frac{1}{p} + \frac{1}{q} = 1. \tag{3.3}$$

From this formula, we have that $p \in \mathbb{Q}^*_{>1}$ iff $q \in \mathbb{Q}^*_{>1}$. Consider the associated *dual* $q, 1/\mathbf{r}$*-norm* given by

$$\|v\|_{q,1/\mathbf{r}} := \left[\sum_{j=1}^{m} (r_j \, v_j)^q \right]^{1/q}. \tag{3.4}$$

The $p, \mathbf{r}$ and $q, 1/\mathbf{r}$ norms have the following properties. (1) Let $R = \operatorname{diag}(r_1, \ldots, r_m)$; then $\|Rv\|_q = \|v\|_{q,1/\mathbf{r}}$ and $\|R^{-1}v\|_p = \|v\|_{p,\mathbf{r}}$. (2) *Hölder inequality*: for all $u, w \in \mathbb{R}^m$, $|u^\top w| \leq \|u\|_{q,1/\mathbf{r}} \, \|w\|_{p,\mathbf{r}}$.

In what follows, we shall propose a control design methodology for GAS of system (1.1) with smooth BFC functions. In addition, this technique will allow us to address the problem of globally bounded input rates. To this aim, we define a smooth function $\tau(x)$ that superestimates $\|v(x)\|_{q,1/\mathbf{r}}$, and it is constant along the boundary of the c-level sets of the proper function $E(x)$.

Choose an arbitrary $0 \neq x_0 \in \mathbb{R}^n$ and set $c = E(x_0)$ (> 0). Therefore, we pose the optimization problem

$$\begin{aligned} \tau(x_0) = \ & \max\nolimits_x \|v(x)\|_{q,1/\mathbf{r}} \text{ subject to (s.t.)} \\ & x \in \partial\mathcal{E}(c), \quad \text{with } c = E(x_0), \end{aligned} \tag{3.5}$$

where $v(x)$ was defined in Proposition 2.1 and ∂ denotes the boundary of a given set. Optimization problem (3.5) is a one-parameter $(c \geq 0)$ family of programs with a varying equality constraint [7, 12] such that its objective function $\|v(x)\|_{q,1/\mathbf{r}}$ does not depend on c. In particular, since $E(x)$ is proper, the family of programs given above is proper [7]. A proper program (as (3.5)) has at least one global solution, since the set $\partial\mathcal{E}(c)$ is compact. In order to exclude the case that $\partial\mathcal{E}(c)$ be a discrete set for all $c > 0$, we should restrict the problem by taking $n \geq 2$ (i.e., one-dimensional systems will not be considered).

Remark 1. Note that $E(x)$ must be an $\mathcal{E}$-function because, otherwise, if for some $c > 0$ the set $\mathcal{E}(c)$ (3.1) would not be *simply* (not even) *connected*, then it would lead to hard troubles for implementation of program (3.5).

A solution $\tau = \tau(x)$ to the optimization problem (3.5) will be called *admissible* iff it is positive-definite. Hereafter, unless otherwise specified, $\tau(x)$ will be assumed admissible. Then, for $q \geq 2$ (more specifically, $q \in \mathbb{Q}^*_{>1} \cap [2, \infty) \subset \mathbb{R}$), we define the τ-dependent control function as

$$u_\tau(x) := \frac{1}{\tau^{q-1}(x)} \left(r_1 \, (r_1 v_1(x))^{q-1}, \ldots, r_m \, (r_m v_m(x))^{q-1} \right)^\top. \tag{3.6}$$

On the other hand, from (3.3) and the definition of p, it follows that $q := s/(s-d)$, so that $q-1 = d/(s-d)$, with both d and $s-d > 0$ being odd numbers. Thus, the exponent $q-1$ in (3.6) preserves the sign of each control component v_j for $j = 1, \dots, m$; and hence, based on Proposition 2.1, global stabilization using that control is guaranteed provided that $v(x)$ is a global stabilizer. Nevertheless, observe that for $p \geq 2$ we have $q-1 < 1$, and vice versa. Thus, for $q \in \mathbb{Q}^*_{>1} \cap (1,2)$, the proposed control given by (3.6) could be nonsmooth (even non-Lipschitz) whenever $v_j(x) = 0$ for some j, because all terms in (3.6) involve potential functions with exponent $0 < \underline{q-1} < 1$. To overcome this difficulty, one can apply the following smooth approximation ("regularization") to odd root-like functions.

First of all, denote $z_j = \xi_j^{q-1}$, where $\xi_j = r_j v_j/\tau$, for $j = 1, \dots, m$, so that control (3.6) becomes

$$u_\tau(x) = \left(r_1\, z_1(x), \dots, r_m\, z_m(x)\right)^\top . \tag{3.7}$$

Then, replace each function z_j with a new function $\widehat{z}_j$ being implicitly defined from the relation: $\xi_j = (2-q)\, \widehat{z}_j^{1/(q-1)} + (q-1)\, \widehat{z}_j = ((p-2)\, \widehat{z}_j^{p-1} + \widehat{z}_j)/(p-1)$, for $j = 1, \dots, m$. Function $\widehat{z}_j(\xi_j)$ subestimates $z_j(\xi_j)$ (i.e., $|\widehat{z}_j| \leq |z_j|$ for all $|\xi_j| \leq 1$) and $\widehat{z}_j = z_j$ iff $\xi_j = -1, 0$ or 1. Further, $\widehat{z}_j(\xi_j)$ is an everywhere differentiable and bijective function in the variable ξ_j

$$\widehat{z}'_j(\xi_j) = \frac{p-1}{\Big((p-1)(p-2)\, \widehat{z}_j^{p-2}(\xi_j) + 1\Big)} > 0 \quad \forall\, |\xi_j| \leq 1. \tag{3.8}$$

Observe that $\widehat{z}'_j(0) = p-1$, so that the slope at $\xi_j = 0$ increases as $p \to \infty$. Therefore, the proposed control function when $q \in \mathbb{Q}^*_{>1} \cap (1,2)$, is the following:

$$u_\tau(x) := \left(r_1\, \widehat{z}_1(x), \dots, r_m\, \widehat{z}_m(x)\right)^\top . \tag{3.9}$$

It should be pointed out that both controllers (3.6) and (3.9) are not defined at the origin. Hence, the origin is rather a *singularity* instead of an equilibrium point of the corresponding closed-loop system. That means that the resulting system can be non-Lipschitz at the origin (uniqueness of the solutions with respect to initial conditions is not guaranteed), so that all trajectories could converge to $x = 0$ in *finite-time.* In view that for a wide range of applications, this is an undesirable feature (e.g., causing the so-called *chattering* of the controller), those controllers are redesigned by introducing a tuning parameter $\varepsilon > 0$, which can be taken as small as desired. Denote

$$v_\varepsilon(x) := \frac{1}{\varepsilon + \tau(x)}\, \left(r_1\, v_1(x), \dots, r_m\, v_m(x)\right)^\top = \frac{1}{\varepsilon + \tau(x)}\, R\, v(x), \tag{3.10}$$

where $R = \operatorname{diag}(r_1, \dots, r_m)$. Consequently, the proposed BFC function is defined as

$$u_\theta(x) := \left(r_1\, \zeta_1\left(v_{\varepsilon_1}\right), \dots, r_m\, \zeta_m\left(v_{\varepsilon_m}\right)\right)^\top , \tag{3.11}$$

where the functions ζ_j , for $j = 1, \dots, m$, are defined

$$\begin{cases} \text{explicitly}: \quad \zeta_j = (\theta v_{\varepsilon_j})^{1/(p-1)} & \text{if } p \in \mathbb{Q}^*_{>1} \cap (1,2], \\ \text{implicitly}: \quad (p-2)\zeta_j^{p-1} + \zeta_j = (p-1)\, \theta v_{\varepsilon_j} & \text{if } p \in \mathbb{Q}^*_{>1} \cap [2,\infty), \end{cases} \tag{3.12}$$

with θ a parameter close to (and less than) 1, $0 < \theta \approx 1$ (needed for proving Proposition 3.3). In the implicit case, we have that $\zeta_j'(0) = p - 1$, so that the value of the slope of functions $\zeta_j(v_{\varepsilon_j})$ at $v_{\varepsilon_j} = 0$ increases as p does. Observe that if $p = 2$, both explicit and implicit functions ζ_j coincide, so that $\zeta_j = v_{\varepsilon_j}$.

Control (3.11) fulfills the following important items. (1) It is bounded in the $p, \mathbf{r}$-normed ball $\mathcal{B}_{\mathbf{r}}^m(p)$, and (2) it achieves GAS of the system (1.1) under the hypotheses of Proposition 2.1. These facts are proved in the following proposition.

PROPOSITION 3.2. *On the basis of the hypotheses of Proposition* 2.1, *if* $\tau(x)$ *is an admissible solution to* (3.5), *then for any* $\varepsilon > 0$, *the control* $u_\theta(x)$ *given by* (3.11) *satisfies* $\|u_\theta(x)\|_{p,\mathbf{r}} < 1$ *and the closed-loop system* (1.1)–(3.11) *is GAS.*

Proof. First of all, we show that control $u_\theta(x)$ is bounded in the $p, \mathbf{r}$-norm. In fact, departing from the fact that $\tau(x) \geq \|v(x)\|_{q,1/\mathbf{r}}$ for all $x \in \mathbb{R}^n$, it follows that

$$(3.13) \qquad r_j \left(\frac{r_j\,|v_j|}{\tau} \right)^{q-1} \leq r_j \left(\frac{r_j\,|v_j|}{\|v\|_{q,1/\mathbf{r}}} \right)^{q-1} \qquad \text{for } j = 1, \dots, m, \text{ and } x \neq 0.$$

Hence, the proposed control (3.11) subestimates the *singular control*

$$(3.14) \qquad \omega_p(x) := -\Big(r_1\, \xi_1^{q-1}(x), \dots, r_m\, \xi_m^{q-1}(x) \Big)^{\top}, \quad \text{where } \xi_j = \frac{r_j\, v_j}{\|v\|_{q,1/\mathbf{r}}},$$

for $j = 1, \dots, m$, that lies precisely on the boundary of the associated closed ball $\mathcal{B}_{\mathbf{r}}^m(p)$. Then, control $u_\theta(x)$ (3.11) takes values in the *open ball* $\operatorname{int} \mathcal{B}_{\mathbf{r}}^m(p)$ ($\|u_\theta\|_{p,\mathbf{r}} < 1$), for given p and vector parameter $\mathbf{r}$. That means, control (3.11) *never saturates.*

Finally, assume that control $v(x)$ fulfills the hypotheses of Proposition 2.1 and $\tau(x)$ is admissible. Then, GAS of the closed-loop system (1.1)–(3.11) is achieved observing that the control $u_\theta(x)$ satisfies the required conditions on $v(x)$, and further, $\operatorname{sign} v(x) = \operatorname{sign} u_\theta(x)$ for all $x \in \mathbb{R}^n$. □

Clearly, if $\tau(x)$ is replaced with $\|v(x)\|_{q,1/\mathbf{r}}$ in (3.11), the resulting function has the same features, but it would be a nonsmooth control: the problem of input rate bounds is nonsense. As mentioned above, for $p = 2$ we have that $\zeta_j = v_{\varepsilon_j}$, and if, further, $r_1 = \cdots = r_m = r$, then $u_\theta(x) = \rho(x)\, v(x)$, with $\rho(x) = r^2/(\varepsilon + \tau(x))$ being constant along $\partial\mathcal{E}(c)$—a condition for input rate boundedness that smooth estimates to $\|v(x)\|_{q,1/\mathbf{r}}$ might not satisfy.

We now state that the τ-based control design is globally rate-limited. Assuming a stabilization problem with control-value sets given by $p, \mathbf{r}$-normed balls might be conceived of only mathematical interest per se. Nevertheless, we will obtain an interpretation of control rate bounds in terms of the associated ball. In fact, formula (3.11) for u_θ entails a relation between expressions $u_\theta(x)$ and $v_\varepsilon(x)$ (3.10), in such a manner that du_θ/dt can satisfy any prescribed constraint (defined as a p, κ-normed ball), whenever dv_ε/dt is proven bounded for some system. Thus, the following result, based on the assumption that dv_ε/dt is bounded, is more subtle than one could determine at first sight. The problem of *bounded input rates* is solved in the following sense. Fix the control bound parameter $\mathbf{r}$, and consider that inputs are constrained to take values in the control-value set $\mathcal{B}_{\mathbf{r}}^m(\infty) := [-r_1, r_1] \times \cdots \times [-r_m, r_m] \subset \mathbb{R}^m$, with $r_j > 0$, for $j = 1, \dots, m$. Then, given an a priori control rate bound $\kappa = (\kappa_1, \dots, \kappa_m)$, with $\kappa_j > 0$, for $j = 1, \dots, m$, there is a $p, \mathbf{r}$-normed ball $\mathcal{B}_{\mathbf{r}}^m(p)$ ($\subset \mathcal{B}_{\mathbf{r}}^m(\infty)$) and a p, κ-normed ball $\mathcal{B}_{\kappa}^m(p)$, such that control function $u_\theta(x)$ and its derivative $du_\theta(x)/dt$ are bounded in the $p, \mathbf{r}$-norm and p, κ-norm, respectively.

PROPOSITION 3.3. *For a fixed control bound* $\mathbf{r}$, *assume that* $\tau(x)$ *is a* C^α *function and* $dv_\varepsilon(x)/dt$ *has a global bound, where* $v_\varepsilon(x)$ *is given in* (3.10). *Then, for any* $\kappa =$

$(\kappa_1, \dots, \kappa_m)^\top \in \mathbb{R}^m_{>0}$, *there exists a rational number* $q \in \mathbb{Q}^*_{>1}$ *(depending on* κ*), such that control* $u_\theta(x)$ (3.11) *satisfies* $\|u_\theta(x)\|_{p,\mathbf{r}} < 1$ *and its derivative* $\|du_\theta(x)/dt\|_{p,\kappa} < 1$ *for all* $x \in \mathbb{R}^n$*, where* $p \in \mathbb{Q}^*_{>1}$ *is obtained from* (3.3).

Proof. First of all, we have to consider two cases, depending on the value of q.

1. If $q \geq 2$, from (3.11) we obtain

$$\frac{du_{\theta_j}}{dt} = r_j \theta\, z_j'(\upsilon_{\varepsilon_j}) \left(\frac{d\upsilon_{\varepsilon_j}}{dt}\right) = r_j \theta\, (q-1)\, \left(\theta \upsilon_{\varepsilon_j}\right)^{q-2} \left(\frac{d\upsilon_{\varepsilon_j}}{dt}\right) \tag{3.15}$$

for $j = 1, \dots, m$. Observe that, since for all $x \in \mathbb{R}^n$, $|\theta \upsilon_{\varepsilon_j}(x)| < 1$, then $z_j'(\upsilon_{\varepsilon_j}(x))$ is globally bounded for fixed q, and $\lim_{q\to\infty} z_j'(\upsilon_{\varepsilon_j}) \leq \lim_{q\to\infty}(q-1)\theta^{q-2} = 0$.

2. If $1 < q < 2$, from (3.11), we obtain

$$\frac{du_{\theta_j}}{dt} = r_j \theta\, \widehat{z}_j'(\upsilon_{\varepsilon_j}) \left(\frac{d\upsilon_{\varepsilon_j}}{dt}\right) = \frac{r_j \theta\, (q-1)^3}{\left((2-q)\, \widehat{z}_j^{(2-q)/(q-1)}(\upsilon_{\varepsilon_j}) + (q-1)^4\right)} \left(\frac{d\upsilon_{\varepsilon_j}}{dt}\right) \tag{3.16}$$

for $j = 1, \dots, m$. From this, it follows that $\lim_{q\to 1} \max_{\upsilon_{\varepsilon_j}} \widehat{z}_j'(\upsilon_{\varepsilon_j}) = \lim_{q \to 1} \widehat{z}_j'(0) = \infty$. Moreover, $\widehat{z}_j'(\upsilon_{\varepsilon_j}(x))$ is globally bounded for fixed q.

Then, from the previous two items, we have that each function $du_{\theta_j}(x)/dt$ will have an a priori global bound value whenever $d\upsilon_{\varepsilon_j}(x)/dt$ is globally bounded for $j = 1, \dots, m$. Therefore,

$$\left\|\frac{du_\theta}{dt}\right\|_{p,\kappa} = \left(\sum_{j=1}^m \frac{1}{\kappa_j^p} \left(\frac{du_{\theta_j}}{dt}\right)^p\right)^{1/p} = \theta \left(\sum_{j=1}^m \left(\frac{r_j}{\kappa_j} \frac{d\zeta_j}{d\xi_j}(\upsilon_{\varepsilon_j})\right)^p \left(\frac{d\upsilon_{\varepsilon_j}}{dt}\right)^p\right)^{1/p}$$

$$\leq \theta \left\|\frac{d\upsilon_\varepsilon}{dt}\right\|_p \left(\sum_{j=1}^m \left(\frac{r_j}{\kappa_j} \frac{d\zeta_j}{d\xi_j}(\upsilon_{\varepsilon_j})\right)^p\right)^{1/p} \leq \theta \left\|\frac{d\upsilon_\varepsilon}{dt}\right\|_1 \left\|RK^{-1}\, D_\xi \zeta(\upsilon_{\varepsilon_j})\right\|_1 = (\triangle),$$

where $R = \operatorname{diag}(r_1, \dots, r_m)$, $K = \operatorname{diag}(\kappa_1, \dots, \kappa_m)$, and $\|\cdot\|_1$ denotes the usual 1-norm. Since by assumption $\|d\upsilon_\varepsilon/dt\|_1 \leq \widehat{\kappa} - \lambda$ globally bounded in any norm (equivalence of norms in $\mathbb{R}^n$), from (3.15) and (3.16) we obtain

$$(\triangle) \leq \varphi(q) := \begin{cases} \theta \widehat{\kappa}\, \left\|RK^{-1}\right\|_1 (q-1)^{-1} & \text{if } q \in \mathbb{Q}^*_{>1} \cap (1, 2], \\ \theta \widehat{\kappa}\, \left\|RK^{-1}\right\|_1 (q-1)\, \theta^{q-2} & \text{if } q \in \mathbb{Q}^*_{>1} \cap [2, \infty). \end{cases} \tag{3.17}$$

Denote by $\overline{\varphi}(q)$ the extension of $\varphi(q)$ to the open interval $(1, \infty) \subset \mathbb{R}$. Observe that $\overline{\varphi} : (1, \infty) \to (0, \infty)$ is well defined. Further, it is a continuous and (via a continuity argument) *surjective* function *onto* $(0, \infty)$. Given any $\xi \in (0, \infty)$, there exists $\overline{q} \in (1, \infty)$ such that $\overline{\varphi}(\overline{q}) = \xi$. Hence, recalling that set $\mathbb{Q}^*_{>1}$ is dense in $(1, \infty)$, there exists a $q^* \in \mathbb{Q}^*_{>1}$ which can be taken as closely as desired to $\overline{q}$ such that $\varphi(q^*) < \xi$. Therefore, we have that there exists $q^* \in \mathbb{Q}^*_{>1}$ such that $\varphi(q^*) < 1$.

Consequently, given any $\kappa = (\kappa_1, \dots, \kappa_m)$ with $\kappa_j > 0$ for $j = 1, \dots, m$, there is a rational number $q \in \mathbb{Q}^*_{>1}$ such that $\|du_\theta(x)/dt\|_{p,\kappa} < 1$ for all $x \in \mathbb{R}^n$, where $p \in \mathbb{Q}^*_{>1}$ is obtained from (3.3). □

Remark 2. On the basis of the above theorem, for fixed magnitude control bound $\mathbf{r}$, the $q, 1/\mathbf{r}$-norm measures the maximal rate bounds that control $u_\theta(x)$ is allowed to have, assigning the corresponding control-value sets $\mathcal{B}^m_{\mathbf{r}}(p) \subset \mathcal{B}^m_{\mathbf{r}}(\infty)$. Hence, it shows how close control $u_\theta(x)$ is to the singular control $\omega_\infty(x) = \operatorname{sign} v(x) \in \partial\mathcal{B}^m_{\mathbf{r}}(\infty)$.

In fact, for q close to 1 (i.e., p is large enough), $\mathcal{B}_{\mathbf{r}}^m(p) \nearrow \mathcal{B}_{\mathbf{r}}^m(\infty)$, the maximum value of rate bound κ is achieved, and $u_\theta(x) \to \omega_\infty(x)$; whereas for a larger q (i.e., p tends to 1), $\mathcal{B}_{\mathbf{r}}^m(p) \searrow \mathcal{B}_{\mathbf{r}}^m(1)$, the value of κ is minimized, and $u_\theta(x)$ is farther from $\omega_\infty(x)$.

In particular, if the Lyapunov function $V(x)$ (considered in Hypothesis H1) is an $\mathcal{E}$-function, the BFC function can be redefined to take values on the *closed* ball $\mathcal{B}_{\mathbf{r}}^m(p)$. First of all, we have that the equality $S_{\tau^*} = \{x \in \mathbb{R}^n : \tau(x) \leq \tau^*\} = \mathcal{E}(c(\tau^*))$ is fulfilled for any $\tau^* > 0$, so that S_{τ^*} is an *invariant set* under all the trajectories of the closed-loop system (1.1) with control $u_\tau(x)$ given by either (3.6) or (3.9). As mentioned above, both controls $u_\tau(x)$ are smooth except at the origin, where they are *singular*. Nevertheless, a redefinition yields the BFC function

$$u^\times(x) = \begin{cases} u_\tau(x) & \text{if } x \in \mathbb{R}^n \backslash \mathcal{E}(\tau^\times), \\ \\ u_{\tau^\times}(x) & \text{if } x \in \mathcal{E}(\tau^\times), \end{cases} \tag{3.18}$$

where $u_{\tau^\times}(x) := u_\tau(x)\mid_{\tau=\tau^\times}$ and $\tau^\times > 0$ is small enough. Observe that this controller is C_L^α in $\mathbb{R}^n \backslash \partial\mathcal{E}(\tau^\times)$ (whenever $\tau(x)$ is) and it is everywhere Lipschitz continuous (a C_L^α-like function).

Remark 3. Due to the fact that $v(0) = 0$, there exists a small enough $\overline{\tau} > 0$ (in a neighborhood of 0, $\|v(x)\|_{q,1/\mathbf{r}}$ is a monotonic increasing function, so that $\tau(x)$ is also an increasing function) such that for any $\tau^\times \in (0, \overline{\tau}]$, we have $u_{\tau^\times} : \mathcal{E}(\tau^\times) \to \mathcal{B}_{\mathbf{r}}^m(p)$, i.e., for all $x \in \mathcal{E}(\tau^\times)$, control $u_{\tau^\times}(x)$ is bounded in the $p, \mathbf{r}$-norm.

Remark 4. In the case of those systems for which $\tau^\times > 0$ can be taken as arbitrary, the proper function $E(x)$ should be chosen as the associated Lyapunov function $V(x)$ in the above control design, because the neighborhood $\mathcal{E}(\tau^\times)$ must be an invariant set. Otherwise, there could be many excursions of a closed-loop trajectory outside $\mathcal{E}(\tau^\times)$, so that the feedback control (3.18) will lose smoothness any time a trajectory crosses $\partial\mathcal{E}(\tau^\times)$. Moreover, the optimization process to maintain the control's boundedness would be "*set on*" any time such a trajectory leaves that neighborhood.

PROPOSITION 3.4. *On the basis of the hypotheses of Proposition* 2.1, *if* $\tau(x)$ *is an admissible solution to the optimization problem* (3.5), *there exists a* $\overline{\tau} > 0$ *such that for any* $\tau^\times \in (0, \overline{\tau}]$, *the control* (3.18) *satisfies* $\|u^\times(x)\|_{p,\mathbf{r}} \leq 1$ *and the closed-loop system* (1.1)–(3.18) *is GAS.*

Finally, if the Lyapunov function $V(x)$ is an $\mathcal{E}$-function, a combination of the proposed control designs $u_\theta(x)$ given in (3.11) and $u^\times(x)$ given in (3.18) yields the following BFC function. Given $\tau^\times > 0$ and $\varepsilon > 0$, small enough parameters, we define the BFC function

$$u_\theta^\times(x) := \left(r_1\, \zeta_1^\times\left(v_{\varepsilon_1}(x)\right), \ldots, r_m\, \zeta_m^\times\left(v_{\varepsilon_m}(x)\right)\right)^\top, \tag{3.19}$$

with

$$\zeta_j^\times(v_{\varepsilon_j}(x)) = \begin{cases} \zeta_j(v_{\varepsilon_j}(x)) & \text{if } x \in \mathbb{R}^n \backslash \mathcal{E}(\tau^\times), \\ \\ \zeta_j(v_{\varepsilon_j}^\times(x)) & \text{if } x \in \mathcal{E}(\tau^\times), \end{cases} \tag{3.20}$$

where $\zeta_j(v_{\varepsilon_j})$ is given in (3.12) and $v_{\varepsilon_j}^\times(x) := v_{\varepsilon_j}(x)\mid_{\tau=\tau^\times}$, for $j = 1, \ldots, m$.

Even though control $u_\theta(x)$ (3.11) is smooth (whenever $\tau(x)$ is), it has the disadvantage that the optimization process (3.5) to calculate $\tau(x)$ might be carried out indefinitely, unless an explicit solution to it can be found. Besides, using $u_\theta^\times(x)$ (3.19), the "smoothness" (C^α) requirement on $\tau(x)$ from Proposition 3.3 can be relaxed to be a C_L^α function, as will be asked for in section 6. Thus, control $u_\theta^\times(x)$ (3.19) has an advantage over control design based on $u_\theta(x)$ (3.11).

For the remainder of this section, we shall focus on the *properties of the function* $\tau(x)$. First of all, it is obvious that (i) $\tau(x)$ is well defined on $\mathbb{R}^n$ since (3.5) is proper; and (ii) $\tau(x) \geq 0$.

It should be pointed out that, as stated, the optimization problem (3.5) could be nonsmooth over the set $N = \{x \in \mathbb{R}^n : v(x) = 0\}$. That trouble is overcome if $\|v(x)\|_{q,1/\mathbf{r}}^q$ is used instead as an objective function. On the other hand, control (3.19) is smooth whenever the function $\tau(x)$ is. Thus, smoothness of $\tau(x)$ is an important property that is guaranteed if the following two items hold:

1. smoothness of $\tau^q(x)$, defined as the solution to (3.5) with $\|v(x)\|_{q,1/\mathbf{r}}^q$ used as objective function, and

2. positive definiteness of $\tau(x)$.

For the *general* optimization problem, smoothness results for a function as $\tau^q(x)$ are of *generic* nature (see [7, 8]). Besides its obvious relevance on precluding *singularities* (aside from $x = 0$) on the controllers $u_\tau(x)$ and the stability results from Propositions 3.2 and 3.4, the second item entails the importance of requiring positive definiteness of τ. Thereby, in view of its own importance, we will focus on the latter problem, and further, we shall consider that the Lyapunov function $V(x)$ is an $\mathcal{E}$-function and control $v(x)$ is defined as $v(x) = -h(x) = -(L_gV(x))^\top$.

Remark 5. Positive semidefiniteness of $\tau(x)$ can be reduced to the following equivalences: $\tau(x) = 0 \Longleftrightarrow \|h(x^*)\|_{q,1/\mathbf{r}} = 0$, where x^* is an optimal point of (3.5) $\Longleftrightarrow$ for all $x \in \partial\mathcal{E}(c)$, where $c = V(x^*) \geq 0$, we have $\|h(x)\|_{q,1/\mathbf{r}} = 0$ (since $\|h(x)\|_{q,1/\mathbf{r}} \leq \|h(x^*)\|_{q,1/\mathbf{r}} = 0$) $\Longleftrightarrow$ for all $x \in \partial\mathcal{E}(c)$, $h(x) = (L_gV(x))^\top = 0 \Longleftrightarrow$ the set of vector fields $\{g_1(x), \ldots, g_m(x)\}$ is *tangential* to the whole compact set $\partial\mathcal{E}(c)$.

Hereafter, in view of the previous remark, we will assume the following.

HYPOTHESIS H3. *Assume that* $n > 1$ *and, further,* $L_gV(x)$ *does not vanish on a whole boundary level set* $\partial\mathcal{E}(c)$ *(*$c = 0$ *being the only exception), i.e., no* $c > 0$ *exists such that for all* $x \in \partial\mathcal{E}(c)$*,* $L_gV(x) = 0$.

The above hypothesis is not too restrictive, since the set of vector fields that are *transversal* to a fixed proper function ($V(x)$ in this case) is dense and open (with respect to the *Whitney topology*) in the set of all vector fields defined on $\mathbb{R}^n$. This statement follows from the results presented in [29] for general *k-jets*. Consequently, $\tau(x)$ is positive-definite, and hence an admissible function, in a *generic sense*.

Finally, we have that the function $\tau(x)$ is proved admissible in the following particular, though important, cases. Recall that a function $f : \mathbb{R}^n \to \mathbb{R}^m$ is said to be *homogeneous of degree* β iff for any $\lambda \in \mathbb{R}$, $f(\lambda x) = \lambda^\beta f(x)$; and it is said to be an *odd (even) function* iff for all $x \in \mathbb{R}^n$, $f(-x) = -f(x)$ $(= f(x))$.

PROPOSITION 3.5. *Consider system* (1.1) *and* $n > 1$. *Then,* $\tau(x)$ *is an admissible function in the following special cases:*

(a) *if* $g(x) = B = (b_j)$*—a constant* $n \times m$ *matrix;*

(b) *if* $g_j(x)$ *for* $j = 1, \ldots, m$*, and the associated Lyapunov function* $V(x)$ *are homogeneous;*

(c) *if* $g(x) = d(x) + b$*, where* $0 \neq b \in \mathbb{R}^n$ *is a constant and* $d_j(x)$ *are odd functions for* $j = 1, \ldots, m$*, and the uncontrolled system has an even Lyapunov function* $V(x)$.

Proof. The three items can be proved by reductio ad absurdum: assume that there exists $c > 0$ such that $\tau(x)|_{\partial\mathcal{E}(c)} \equiv 0$.

Case (a). In this case, the systems $\dot{x}= g_j(x) = b_j$, $j = 1, \ldots, m$, have parallel solutions, and thus $\Delta = \bigcap_{j=1}^m \ker b_j$ is a linear subspace with $\dim \Delta < n$. On the other hand, for each $c > 0$, the level set $\mathcal{E}(c)$ satisfies $\operatorname{int}\mathcal{E}(c) \neq \emptyset$ (due to continuity of $V(x)$), and the (boundary) level set $\partial\mathcal{E}(c)$ is compact (due to properness of $V(x)$). Therefore, the set of vector fields $\{b_1, \dots, b_m\}$ cannot be tangential to a whole compact set $\partial\mathcal{E}(c)$, unless $\partial\mathcal{E}(c) \subset \Delta$, but this is a contradiction.

Case (b). In view that $V(x)$ is positive-definite and $c > 0$, then $0 \in \operatorname{int}\mathcal{E}(c) \neq \emptyset$. Due to compactness of $\mathcal{E}(c)$, a continuity argument shows that given any $y \in \mathbb{R}^n$, there exist $x \in \partial\mathcal{E}(c)$ and $\eta > 0$ such that $y = \eta x$. Therefore, since $g_1(x), \dots, g_m(x)$ and $V(x)$ are homogeneous functions of degrees γ_j and β, respectively, we should obtain that for all $y \in \mathbb{R}^n$, $-h_j(y) = -L_{g_j}V(y) = -\eta^{\gamma_j+\beta-1}L_{g_j}V(x) = 0$, $j = 1, \dots, m$. Consequently, if we assume that $\tau(x)$ vanishes in a whole boundary level set $\partial\mathcal{E}(c)$, then either $g(x) \equiv 0$ or $V(x) \equiv 0$ in the whole space $\mathbb{R}^n$.

Case (c). In this case, the set of vector fields $g_j(x) = d_j(x) + b_j$, $j = 1, \dots, m$, should be tangential to the whole symmetric set $\partial\mathcal{E}(c) = \{x \in \mathbb{R}^n : V(x) = c\}$. In fact, suppose that for all $x \in \partial\mathcal{E}(c)$, $-h_j(x) = -L_{g_j}V(x) = -\nabla V(x)(d_j(x) + b_j) = 0$, $j = 1, \dots, m$. However, by symmetry, $-x \in \partial\mathcal{E}(c)$, and thus, $-h_j(-x) = -L_{g_j}V(-x) = -2\nabla V(x)\, b_j = 0$, $j = 1, \dots, m$, but this contradicts case (a). □

4. Suboptimal properties.

In this section we identify a control problem that involves a notion of optimality related to the associated Lyapunov function. Then, we will show that the proposed control $u_\theta(x)$ given in (3.11) is a suboptimal solution to that problem.

Assume that the control-value set $U \subset \mathbb{R}^m$ is compact and $0 \in U$, and denote by $\mathcal{U}^*$ the set of all U-valued piecewise continuous functions defined on $\mathbb{R}$. Although the Lyapunov approach based on Hypotheses H1–H2 suffices to analyze global stability, the fact that $V(x)$ is not strictly decreasing along the closed-loop solutions does not give a “margin” that can be exploited for robustness analysis or achieving certain performance. An approach based on the existence of a Lyapunov function for the closed-loop system could be more convenient (see [1, 15, 3]). A C^α ($\alpha \geq 1$) function $V : \mathbb{R}^n \to \mathbb{R}$ is a Lyapunov function for system (1.1) iff it is positive definite, proper, and $L_{f+\Sigma_{j=1}^m g_j u_j}V(x(t)) < 0$, where $x(t)$ is a solution to (1.1) with $u(t) \in \mathcal{U}^*$. Since $dV/dt = L_{f+\Sigma_{j=1}^m g_j u_j}V(x(t))$ represents the decay rate of $V(x(t))$, a reasonable criterion for choosing $u(t)$ is to minimize dV/dt subject to $u \in \mathcal{U}^*$. The resulting minimal control can be represented as a feedback control: for each value $x(t)$ denote by $\omega(x(t))$ the minimal value of $u \in \mathcal{U}^*$.

Definition 4.1. *Let $V : \mathbb{R}^n \to \mathbb{R}$ be a C^α ($\alpha \geq 1$) positive-definite function. We say that $\omega : \mathbb{R}^n \to U$ is optimal with respect to $V(x)$ iff for all $x \in \mathbb{R}^n$ and all $u \in \mathcal{U}^*$*

$$L_{f+\Sigma_{j=1}^m g_j \omega_j}V(x) \leq L_{f+\Sigma_{j=1}^m g_j u_j}V(x). \tag{4.1}$$

If, further, $V(x)$ satisfies that for all $x \neq 0$, $L_{f+\Sigma_{j=1}^m g_j \omega_j}V(x) < 0$, then $V(x)$ is a Lyapunov function for the closed-loop system $\dot{x} = f(x(t)) + \sum_{j=1}^m g_j(x(t))\, \omega_j(x(t))$.

In [3], the problem of finding an optimal $\omega(x)$ has been illustrated by considering special cases of set U: the Euclidean ball of radius r, $\mathcal{B}_{\mathbf{r}}^m(\infty)$ and $\mathcal{B}_{\mathbf{r}}^m(1)$. Observe that inequality (4.1) is equivalent to

$$\min_{u \in \mathcal{U}^*} \{L_g V(x)\, u\}\,. \tag{4.2}$$

For control-value set $U = \mathcal{B}_{\mathbf{r}}^m(p)$ for $1 < p < \infty$, it can be proven (via the Hölder inequality) that the minimal value is given by $-\|h(x)\|_{q,1/\mathbf{r}}$ and it is accomplished by the BFC function $\omega_p(x)$ given in (3.14) with $v(x) = -h(x)$. Control $\omega_p(x)$ lies on $\partial\mathcal{B}_{\mathbf{r}}^m(p)$

and is the unique *optimal* BFC function related to the $p, \mathbf{r}$-norm, in the sense that it is a solution to the equation $\min_{u \in \mathcal{U}^*}\{\sum_{j=1}^m L_{g_j}V(x)\, u_j\} = \sum_{j=1}^m L_{g_j}V(x)\, \omega_{p_j}(x)$. Uniqueness follows from the strict convexity of $U = \mathcal{B}_{\mathbf{r}}^m(p)$, but it is understood modulo the set $N = \{x \in \mathbb{R}^n : L_gV(x) = 0\}$ because $\omega_p(x)|_N$ is arbitrary (a *singular control*). Hence, control $\omega_p(x)$ is *not an admissible input* with respect to the set $\mathcal{U}$ given in (1.4). Thereby, given a Lyapunov function, $\omega_p(x)$ is optimal in the sense that it maximizes the *robustness stability margin* against bounded uncertainties (see [21]).

The aforementioned optimal problem is also the basis of the CLF approach for feedback stabilization. Indeed, Artstein's theorem [1] expresses that the existence of a smooth CLF is equivalent to the existence of a continuous feedback control that renders the GAS of the resulting closed-loop system. Moreover, Artstein's theorem holds for general *convex* (possibly constrained) control-value sets. However, in view that control design derived from the proof in [1] is nonconstructive (based on partitions of unity), Sontag and coworkers have proposed *explicit "universal" formulae* for *almost smooth* feedback control laws that stabilize the system (1.1), provided an appropriate CLF is known. In the bounded control case, such formulae were obtained to fullfil specific control-value sets U: the Euclidean open unit ball in [15] and Minkowski open unit balls (with $1 < p \leq 2$) in [19]. Along this line of thought, and possibly conceived as a pure mathematical problem *per se*, in [25], Sontag presented the following as an important *open* problem: *Find universal formulas for CLF stabilization for general (convex) control-value sets U.*

Remark 6. It should be noted that feedback control $u_\theta(x)$ given in (3.11) shares a similar structure to the formula (3.14) for $\omega_p(x)$ and, from the proof of Proposition 3.2, also subestimates it. Hence, if V is also a Lyapunov function for system (1.1), $u_\theta(x)$ is a smooth approximation to the optimal control $\omega_p(x)$.

Summarizing, if Hypothesis H1 holds and V is a Lyapunov function for system (1.1), the special control $u_\theta(x)$ (3.11) is threefold: (1) it is an arbitrarily small control (i.e., lies in arbitrary $p, \mathbf{r}$-normed balls) that stabilizes system (1.1); (2) it is a smooth *suboptimal robust control*; and (3) it allows us to address the problem of input *rates* constrained to lie in prescribed sets, in the context of CLF stabilization.

5. Control design when $U = \prod_{i=1}^{\mu} \mathcal{B}_{\mathbf{r}_i}^{m_i}(p_i)$. In this section we introduce a natural extension of the control design method developed in section 3 that allows us to consider all permutations of the m control input entries arbitrarily taking values in possibly different $p, \mathbf{r}$-normed balls. Without loss of generality, this condition is accomplished by renaming the control input entries (if necessary) so that u is partitioned as $u = (\mathbf{u}_1, \ldots, \mathbf{u}_\mu)^\top$, with each *control block* $\mathbf{u}_i$ taking values in a different $p_i, \mathbf{r}_i$-normed ball. For this aim, let v be the global stabilizer considered in Proposition 2.1, and take the partition $v = (\mathbf{v}_1, \ldots, \mathbf{v}_\mu)$. Denote $\mathbf{p} = (p_1, \ldots, p_\mu)$ with $p_i \in \mathbb{Q}^*_{>1}$, and define the vector parameter $\mathbf{q} = (q_1, \ldots, q_\mu)$ in such a way that p_i and q_i satisfy (3.3). Hence, each expression $(q_i - 1)$ is a quotient of two odd numbers, so that the proposed control (see below in (5.3)) will preserve the sign of the original control block $\mathbf{v}_i(x)$. (This condition is needed for the stabilization result from Proposition 2.1.)

Assume that the control-value set is given by the following Cartesian product of $p, \mathbf{r}$-normed balls:

$$U = \mathcal{B}_{\mathbf{r}_1}^{m_1}(p_1) \times \cdots \times \mathcal{B}_{\mathbf{r}_\mu}^{m_\mu}(p_\mu) \tag{5.1}$$

for $1 \leq \mu \leq m$ and $m_1 + \cdots + m_\mu = m$.

Choose an arbitrary $0 \neq x_0 \in \mathbb{R}^n$ and set $c = E(x_0)$ (> 0). In order to obtain the stabilizing BFC function, we require the solution to the following μ parametric optimization problems:

$$\begin{gathered} \tau_i(x_0) := \max_{x\in\partial\mathcal{E}(c)} \|\mathbf{v}_i(x)\|_{q_i,1/\mathbf{r}_i}\,, \\ \text{s.t.} \\ \partial\mathcal{E}(c) := \{x \in \mathbb{R}^n : E(x) = c = E(x_0)\}\,. \end{gathered} \tag{5.2}$$

A vector of solutions $\tau(x) = (\tau_1(x), \dots, \tau_\mu(x))$ to the set of optimization problems (5.2) will be called *admissible* iff each $\tau_i(x)$ is a positive definite function.

Then, for admissible $\tau(x)$, the BFC function relative to U given in (5.1) is $u_\theta = (\mathbf{u}_{\theta_1}, \dots, \mathbf{u}_{\theta_\mu})^\top$, where formulae for $\mathbf{u}_{\theta_i}$ are analogous to (3.11), i.e.,

$$\mathbf{u}_{\theta_i} := \big(\overset{[i]}{r}_1\, \overset{[i]}{\zeta}_1\big(\overset{[i]}{v}_{\varepsilon_1}\big), \dots, \overset{[i]}{r}_{m_i}\, \overset{[i]}{\zeta}_{m_i}\big(\overset{[i]}{v}_{\varepsilon_{m_i}}\big)\big)^\top, \ \text{with} \quad \overset{[i]}{v}_{\varepsilon_j}(x) := \frac{\overset{[i]}{r}_j\, \overset{[i]}{v}_j(x)}{\varepsilon_i + \tau_i(x)}\,, \tag{5.3}$$

for $j = 1, \dots, m_i$, $\varepsilon_i > 0$, are tuning parameters for $i = [i] = 1, \dots, \mu$, and the state-functions $\overset{[i]}{\zeta}_j$ are defined

$$\begin{cases} \text{explicitly}: \quad \overset{[i]}{\zeta}_j = (\theta \overset{[i]}{v}_{\varepsilon_j})^{1/(p_i-1)} & \text{if } p_i \in \mathbb{Q}^*_{>1} \cap (1,2], \\ \\ \text{implicitly}: \quad (p_i-2)(\overset{[i]}{\zeta}_j)^{p_i-1} + \overset{[i]}{\zeta}_j = (p_i-1)\theta \overset{[i]}{v}_{\varepsilon_j} & \text{if } p_i \in \mathbb{Q}^*_{>1} \cap [2,\infty), \end{cases} \tag{5.4}$$

with $0 < \theta \approx 1$ (needed in Proposition 5.2). In the implicit case, we have that $(\overset{[i]}{\zeta}_j)'(0) = p_i - 1$.

The following result follows along the line of the proof of Proposition 3.2.

PROPOSITION 5.1. *On the basis of the hypotheses of Proposition* 2.1, *if* $\tau(x)$ *is an admissible solution to the set of optimization problems* (5.2), *then for any* $\varepsilon = (\varepsilon_1, \dots \varepsilon_\mu)$, *with* $\varepsilon_i > 0$, *the control* $u_\theta(x)$ *given in* (5.3) *satisfies* $\|\mathbf{u}_{\theta_i}(x)\|_{p_i,\mathbf{r}_i} < 1$ *for* $i = 1, \dots, \mu$, *and the closed-loop system* (1.1)–(5.3) *is GAS.*

Moreover, the proposed control design (5.3) leads also to address the problem of *globally rate-limited* actuators. Fix the control bound parameter $\mathbf{r}$, and consider that inputs are constrained to take values in the m-dimensional $\mathbf{r}$-hyperbox, $\mathcal{B}^m_{\mathbf{r}}(\infty)$. Then, given an a priori control rate bound $\kappa = (\kappa_1, \dots, \kappa_\mu)$, with $\kappa_i = (\overset{[i]}{\kappa}_1, \dots, \overset{[i]}{\kappa}_{m_i})^\top \in \mathbb{R}^{m_i}_{>0}$, there is a vector of rational numbers $\mathbf{q} = (q_1, \dots, q_\mu)$, with $q_i \in \mathbb{Q}^*_{>1}$ for $i = 1, \dots, \mu$, such that control block $\mathbf{u}_{\theta_i}$ takes values in $\mathcal{B}^{m_i}_{\mathbf{r}_i}(p_i)$ and $d\mathbf{u}_{\theta_i}/dt$ takes values in $\mathcal{B}^{m_i}_{\kappa_i}(p_i)$, with p_i and q_i satisfying (3.3).

The following result follows along the lines of the proof of Proposition 3.3.

PROPOSITION 5.2. *Consider a fixed control bound* $\mathbf{r}$ *and assume that* $d\overset{[i]}{v}_{\varepsilon_j}(x)/dt$ *have global bounds for* $j = 1, \dots, m_i$ *and* $i = 1, \dots, \mu$, *where* $\overset{[i]}{v}_{\varepsilon_j}(x)$ *is given in* (5.3). *Then, for any* $\kappa = (\kappa_1, \dots, \kappa_\mu)^\top \in \mathbb{R}^m_{>0}$, *there is a* $\mathbf{q} = (q_1, \dots, q_\mu)^\top \in (\mathbb{Q}^*_{>1})^\mu$ *(depending on* κ*), such that each control block* (5.3) *satisfies* $\|\mathbf{u}_{\theta_i}\|_{p_i,\mathbf{r}_i} < 1$ *and* $\|d\mathbf{u}_{\theta_i}/dt\|_{p_i,\kappa_i} < 1$, *with* p_i *and* q_i *satisfying* (3.3) *for* $i = 1, \dots, \mu$.

Analogously to the case of control given in (3.19), if the associated Lyapunov function $V(x)$ (from Hypothesis H1) is an $\mathcal{E}$-function, a combined control design $u_\theta(x)$ with $u^\times(x)$ given in (3.18) can be proposed. Hence, given a set of small enough parameters $\tau_i^\times > 0$, and tuning parameters $\varepsilon_i > 0$, $i = 1, \dots, \mu$, we define the BFC function $u_\theta^\times = (\mathbf{u}^\times_{\theta_1}, \dots, \mathbf{u}^\times_{\theta_\mu})^\top$ with

$$\mathbf{u}^\times_{\theta_i} := \big(\overset{[i]}{r}_1\, \overset{[i]}{\zeta}{}^\times_1\big(\overset{[i]}{v}_{\varepsilon_1}\big), \dots, \overset{[i]}{r}_{m_i}\, \overset{[i]}{\zeta}{}^\times_{m_i}\big(\overset{[i]}{v}_{\varepsilon_{m_i}}\big)\big)^\top \ \text{and} \tag{5.5}$$

$$\zeta_j^{[i]\times}(v_{\varepsilon_j}^{[i]}(x)) = \begin{cases} \zeta_j^{[i]}(v_{\varepsilon_j}^{[i]}(x)) & \text{if } x \in \mathbb{R}^n \backslash \mathcal{E}(\tau_i^{\times}), \\ \zeta_j^{[i]}(v_{\varepsilon_j}^{[i]\times}(x)) & \text{if } x \in \mathcal{E}(\tau_i^{\times}), \end{cases} \tag{5.6}$$

where $\zeta_j^{[i]}(v_{\varepsilon_j}^{[i]})$ is given in (5.4) and $v_{\varepsilon_j}^{[i]\times}(x) := v_{\varepsilon_j}^{[i]}(x) \mid_{\tau_i=\tau_i^{\times}}$ for $i = 1, \ldots, \mu$.

5.1. Control design in the m-dimensional r-hyperbox. Assuming that $\mu = m$, the control-value set $U = \mathcal{B}_{\mathbf{r}}^m(\infty) := [-r_1, r_1] \times \cdots \times [-r_m, r_m] \subset \mathbb{R}^m$ is obtained. This special constraint set is important for two main reasons: (i) among all norm-based sets and fixed $\mathbf{r}$, it is the maximal set (under $\subseteq$), so that more control magnitude is available in this way; and (ii) inputs are actually independent of each other, in the sense that any input can take values without being acquainted with magnitudes taken by the remaining inputs. In this case, formula (5.3) consists of scalar control blocks $u_\theta := (r_1\, \zeta_1^{[1]}(v_{\varepsilon_1}^{[1]}), \ldots, r_m\, \zeta_m^{[m]}(v_{\varepsilon_m}^{[m]}))^\top$, with $v_{\varepsilon_j}^{[j]}(x) = (r_j\, v_j(x))/(\varepsilon_j + \tau_j(x))$, $j = 1, \ldots, m$; and expressions $\zeta_j^{[j]}(v_{\varepsilon_j}^{[j]})$ are given in (5.4), but parameters q_j do not depend on dual formula (3.3). This control design requires us to find the solution to m parametric optimization problems (5.2) corresponding to the m scalar control blocks. Thus, a closer look to the optimization problem (3.5) in the scalar input case is crucial. The optimization problem (3.5) for scalar input is equivalent to solving the two programs

$$\tau(x_0) = \max_x |v(x)| = \max\left\{\max_x v(x), -\min_x v(x)\right\}, \tag{5.7}$$

subject to $x \in \partial\mathcal{E}(c)$, where $c = E(x_0)$. This problem can be reduced to only one optimization problem if the maximum is attained always at just one program. A sufficient condition for this to hold proceeds as follows. Suppose that there exists $x_0 \in \partial\mathcal{E}(c)$ such that $\tau(x_0) = \max_x v(x) = -\min_x v(x)$ for $x \in \partial\mathcal{E}(c)$. Then, there exist x_1^*, $x_2^* \in \partial\mathcal{E}(c)$ such that $v(x_1^*) + v(x_2^*) = 0$, where x_1^* and x_2^* are optimal points of the programs $x_1^* = \arg\max_x v(x)$ and $x_2^* = -\arg\min_x v(x)$, respectively. On the basis that $\tau(x)$ is positive-definite, it follows that $x_1^* \neq x_2^*$. Then, there might exist an open interval $I = (-\delta + c, c + \delta)$, with $\delta > 0$, such that if Σ_I denotes the associated set of optimal solutions to (5.7), then Σ_I should be contained in the corresponding set of critical points of the above programs. If this is the case, Σ_I could be a disjoint union of piecewise smooth curves (cf. [12]). Henceforth, from the perspective of implementing a program, in order to avoid undesirable "jumps" between those curves, we can assume that the function $\psi : \mathbb{R} \to \mathbb{R}$, defined by

$$\psi(c) := \max_x v(x) + \min_x v(x) \quad \text{s.t.} \quad x \in \partial\mathcal{E}(c), \tag{5.8}$$

is either nonnegative or nonpositive for all $c > 0$.

Assuming that function ψ defined by (5.8) is nonnegative, the optimization problem (5.7) reduces to solve

$$\tau(x_0) = \max_{x \in \partial\mathcal{E}(c)} v(x) \geq 0, \quad \text{where } c = E(x_0). \tag{5.9}$$

Expressing the above program in terms of the first-order necessary condition for an extremum, we have that there exists $(x^*, \lambda^*) \in \mathbb{R}^n \times \mathbb{R}$, where x^* is a regular point of the constraint and $\lambda^* \in \mathbb{R}$ is a Lagrange multiplier, such that the Lagrangian

$$L_{\lambda^*}(x^*) = v(x^*) - \lambda^*(E(x) - c) \tag{5.10}$$

for fixed $c > 0$ satisfies

$$\nabla_x L_{\lambda^*}(x^*) = \nabla_x v(x^*) - \lambda^* \nabla_x E(x^*) = 0. \tag{5.11}$$

When ψ (5.8) is nonpositive, the negative version of (5.9) ($\tau(x_0) = \max_x(-v(x)) \geq 0$) must be considered. The procedure developed here will be illustrated in section 6.2.

6. A class of homogeneous systems.

In order to guarantee a constructive solution to (3.5), a sufficient condition could be that there exists a homogeneous Lyapunov function $V(x)$ associated to system (1.1) and that functions $g_j(x)$, $j = 1, \ldots, m$, are also homogeneous. If this is the case, the optimization problem is not only feasible, but the computational burden involved in solving it for each value of the parameter c is drastically reduced. The problem is solved just once.

THEOREM 6.1. *Consider the one-parameter family of optimization problems* (3.5). *Assume that* (1.1) *admits an homogeneous Lyapunov function* $V(x)$ *of even degree* $\beta \geq 2$, *and* $g_1(x), \ldots, g_m(x)$ *are homogeneous functions of degrees all equal to* γ. *Denote by* ν $(= \beta + \gamma - 1)$ *the degree of* $h_j(x) = L_{g_j} V(x)$, $j = 1, \ldots, m$, *and set* $\varsigma := \beta/\nu$. *Further assume that* $x^* \in \mathbb{R}^n$ *is an optimal point of* (3.5) *satisfying, without loss of generality,* $V(x^*) = 1/\varsigma$, *such that it is a regular point of the constraint and both* $g(x^*)$ *and* $Dh(x^*)g(x^*)$ *have full rank. Then, for any* $x \in \mathbb{R}^n$, *we have*

$$\tau(x) = \sigma\, V^{1/\varsigma}(x), \quad \text{where } \sigma = \varsigma^{1/\varsigma}\, \|h^\top(x^*)\,(Dh(x^*)\,g(x^*))^{-1}\,\|_{p,\mathbf{r}}^{-1}. \tag{6.1}$$

Proof. Choose $0 \neq x_0 \in \mathbb{R}^n$, set $c = V(x_0)$ (> 0) and let $x^* \in \mathbb{R}^n$ be an optimal point of the proper program (3.5). Then, by hypothesis and based on the Lagrange multiplier method, we have that x^* is a regular point of the constraint and that there exists $\lambda^* \in \mathbb{R}$ such that the Lagrangian

$$L^{\varsigma}_{\lambda^*}(x^*) = \|h(x^*)\|^{\varsigma}_{q,1/\mathbf{r}} - \lambda^*(V(x^*) - c) \tag{6.2}$$

for fixed $c > 0$ satisfies

$$\nabla_x L^{\varsigma}_{\lambda^*}(x^*) = \frac{\varsigma\, \tau^{\varsigma}}{q\|y^*\|^q_{q,1/\mathbf{r}}} \nabla_x(\|y^*\|^q_{q,1/\mathbf{r}}) - \lambda^* \nabla_x V(x^*) = 0, \tag{6.3}$$

where $y^* = h(x^*)$. Obviously, $\|y\|^q_{q,1/\mathbf{r}}$ is a positive-definite, convex, and homogeneous function of degree q (in the variable y). Moreover, $\|h(x^*)\|^q_{q,1/\mathbf{r}} \neq 0$, since $\tau(x^*) > 0$ (Proposition 3.5 (b)). Then, by homogeneity of $V(x)$ and $h(x)$, $\nabla_x L^{\varsigma}_{\lambda^*}(x)$ is a homogeneous function of degree $\beta - 1$. By assumption, $g(x^*)$ has full rank. Thus, postmultiply both sides of (6.3) by $g(x^*)$ to obtain

$$\nabla_x L^{\varsigma}_{\lambda^*}\, g = \frac{\varsigma\, \tau^{\varsigma}}{\tau^q} \left((r_1 h_1)^{q-1}, \ldots, (r_m h_m)^{q-1}\right) R\, Dh\, g - \lambda^* h^\top = 0, \tag{6.4}$$

where $R := \operatorname{diag}(r_1, \ldots, r_m)$. Then, in virtue that $Dh\, g$ is nonsingular at x^*, postmultiplying both sides of (6.4) by $(Dh\, g)^{-1}$ yields

$$\varsigma\, \tau^{\varsigma - 1} u_\tau^\top = \lambda^* h^\top\, (Dh\, g)^{-1}. \tag{6.5}$$

On the other hand, control function $u_\tau(x)$ given in (3.6) satisfies $\|u_\tau(x^*)\|_{p,\mathbf{r}} = 1$ for any $q > 1$. Thus, using that fact and expression (6.5), we have

$$\lambda^* = \varsigma\, \tau^{\varsigma-1}\, \|h^\top\, (Dh\, g)^{-1}\, \|^{-1}_{p,\mathbf{r}}. \tag{6.6}$$

Consider again (6.3) and postmultiply both sides by x^* to obtain

$$\nabla_x L^{\varsigma}_{\lambda^*} x^* = \frac{\varsigma}{q}\tau^{\varsigma-q}\,\nabla_x(\|y^*\|^q_{q,1/\mathbf{r}})\,x^* - \lambda^*\nabla V(x^*)\,x^* = 0. \tag{6.7}$$

Observe that $V(x)$ and $\|h(x)\|^q_{q,1/\mathbf{r}}$ are homogeneous functions of degrees β and $q\nu$, respectively. Then, by (Euler's formula) homogeneity, we have that $\nabla_x V(x)\,x = \beta\,V(x)$ and $\nabla_x(\|h(x)\|^q_{q,1/\mathbf{r}})\,x = q\nu\,\|h(x)\|^q_{q,1/\mathbf{r}}$. Then, from (6.7) and due to Proposition 3.5(b) ($\|y^*\|^q_{q,1/\mathbf{r}} \neq 0$), we obtain

$$\nabla_x L^{\varsigma}_{\lambda^*} x^* = \frac{\varsigma}{q}\tau^{\varsigma-q}\,(q\nu\;\|y^*\|^q_{q,1/\mathbf{r}}) - \beta\,\lambda^* V(x^*) = \beta\;(\tau^{\varsigma} - \lambda^* V(x^*)) = 0. \tag{6.8}$$

Thereby, we have

$$\tau^{\varsigma}(x) = \lambda^* V(x) \quad \text{for any } x \in \partial\mathcal{E}(c). \tag{6.9}$$

On the other hand, using homogeneity, we have that $\Sigma = \{x \in \mathbb{R}^n : x = \eta\,x^*,\ \eta > 0\}$ is a line of critical points of $L^{\varsigma}_{\lambda^*}$ and also a set of regular points of the constraint and $g\mid_{\Sigma}$ has full rank. Moreover, based on the proof of Proposition 3.5 (b), it follows that Σ is also a set of maximal points for the optimization program (3.5). Hence any optimal point x^* can be represented as $x^* = \eta\,x^*_0$, where, without loss of generality, x^*_0 denotes an optimal point subject to $V(x^*_0) = 1/\varsigma$. Therefore, in order to define $\tau(x)$ given in (6.9) on the whole $\mathbb{R}^n$, we proceed as follows. Given an arbitrary x_0, set $c = V(x_0)$ and let $x^* \in \partial\mathcal{E}(c)$ be the corresponding optimal point. In view that $x^* = \eta\,x^*_0$, we have that $c = V(x^*) = \eta^{\beta}/\varsigma$, and substituting this expression into (6.9) yields η as a function of τ: $\eta^{\beta}(\tau) = \varsigma\;\tau^{\varsigma}/\lambda^*$. Thus,

$$x^*(\tau) = \left(\frac{\varsigma}{\lambda^*}\,\tau^{\varsigma}\right)^{1/\beta} x^*_0. \tag{6.10}$$

Rename x^*_0 as x^*. Then, replacing x^* with $x^*(\tau)$ in (6.6), taking into account the homogeneity of the functions, and after some straightforward algebraic calculations, we obtain

$$\lambda^* = \varsigma\,\|h^{\top}(x^*)\,(Dh(x^*)\,g(x^*))^{-1}\,\|^{-\varsigma}_{p,\mathbf{r}}. \tag{6.11}$$

Finally, substituting the above expression into (6.9) yields (6.1), which is defined in $\mathbb{R}^n$. □

Remark 7. It should be worth mentioning that $\tau(x)$ given in (6.1) is also a proper Lyapunov function (i.e., it is positive-definite and radially unbounded, and $d\tau/dt < 0$ for all $x \in \mathbb{R}^n \setminus \{0\}$), provided that Hypothesis H2 holds, and it is a homogeneous function of degree ν.

THEOREM 6.2. *Consider the affine system* (1.1) *for which Hypotheses* H1–H2 *hold. Under the additional hypotheses of the above theorem, we have that the control* $u^{\times}_{\theta}(x)$ (3.19), *where* $\upsilon_{\varepsilon} = (\upsilon_{\varepsilon_1}, \ldots, \upsilon_{\varepsilon_m})^{\top}$ *given by*

$$\upsilon_{\varepsilon_j}(x) = -\frac{r_j}{\varepsilon + \sigma\,V^{1/\varsigma}(x)}\,h_j(x), \quad j = 1, \ldots, m, \tag{6.12}$$

satisfies $\|u^{\times}_{\theta}(x)\|_{p,\mathbf{r}} < 1$ *for arbitrary* $\tau^{\times} > 0$ *and* $\varepsilon > 0$, *and renders the GAS of the closed-loop system* (1.1)–(3.19), *where* σ *is given in* (6.1) *and* x^* *is an optimal point such that* $V(x^*) = 1/\varsigma$ *(without loss of generality). Furthermore, we have an a priori* *global bounded rate on the input, i.e., given any $\kappa = (\kappa_1, \dots, \kappa_m)^\top \in \mathbb{R}^m_{>0}$, there is a $q \in \mathbb{Q}^*_{>1}$ (depending on κ), such that $\|du^\times_\theta/dt\|_{p,\kappa} < 1$, with $p \in \mathbb{Q}^*_{>1}$, for any $x \in \mathbb{R}^n$, whenever $L_fV(x) \in \mathcal{O}(\|x\|^\beta_p)$, $\|Dh(x)f(x)\|_{p,1/\mathbf{r}} \in \mathcal{O}(\|x\|^\nu_p)$ and either $g(x) = B$, an $n \times m$ constant matrix, or $g_j(x) = D_jx$, with D_j being $n \times n$ constant matrices, $j = 1, \dots, m$. The value of parameter q depends on the associated order-constants, rate bound κ, control bound $\mathbf{r}$, parameter value $\tau^\times > 0$, and tuning parameter $\varepsilon > 0$.*

Proof. The stabilization result follows from Proposition 3.2 and the above theorem. Only the last assertion on the boundedness of $\|du^\times_\theta/dt\|_{p,\mathbf{r}}$ must be proved. Departing from Proposition 3.3, it turns out that du_θ/dt has an a priori global bound, whenever $d\upsilon_\varepsilon/dt$ is globally bounded. Then, from $\upsilon_\varepsilon(x)$ (6.12) and some calculations, we obtain

$$\frac{d\upsilon_\varepsilon}{dt} = (\varepsilon+\tau)^{-2}\,\nabla_x\tau\;\dot{x}\;Rh - \frac{1}{\varepsilon+\tau}\,R\,Dh\;\dot{x}$$

$$= \frac{1}{\varepsilon+\tau}\left(\frac{\sigma}{\varsigma(\varepsilon+\tau)}\,V^{\frac{1-\varsigma}{\varsigma}}\,\nabla_xV\;\dot{x}\;Rh - R\,Dh\;\dot{x}\right)$$

$$= \frac{1}{\varepsilon+\tau}\left(\frac{\sigma^\varsigma}{(\varepsilon+\tau)\,\varsigma\tau^{\varsigma-1}}\,(L_fV + L_gV\,u_\theta)\,Rh - R\,Dh\,(f + g\,u_\theta)\right),$$

where $R = \operatorname{diag}(r_1, \dots, r_m)$. Due to the fact that for all $x \in \mathbb{R}^n$, $|\upsilon_{\varepsilon_j}(x)| < 1$, $j = 1, \dots, m$, it follows that $\|\upsilon_\varepsilon\|_p < m^{1/p}$, in any p-norm. Moreover, for any $a, b \in \mathbb{R}^m$, we have (1) $\|R^{-1}a\|_{q,1/\mathbf{r}} = \|a\|_q$ and $\|R\,a\|_p = \|a\|_{p,1/\mathbf{r}}$, and (2) $|a^\top b| \le \|a\|_{q,1/\mathbf{r}}\,\|b\|_{p,\mathbf{r}}$ (Hölder inequality). Recalling that $\|u_\theta\|_{p,\mathbf{r}} < 1$, then $\|u_\theta\|_p = \varrho\|u_\theta\|_{p,\mathbf{r}} < \varrho$, with ϱ depending on $\mathbf{r}$. Hence, from the above expression and some calculations, we obtain

$$\begin{aligned}\left\|\frac{d\upsilon_\varepsilon}{dt}\right\|_p &\le \frac{\sigma^\varsigma}{(\varepsilon+\tau)\,\varsigma\tau^{\varsigma-1}}\,(-L_fV + |L_gV\,u_\theta|)\,\|\upsilon_\varepsilon\|_p + \frac{1}{(\varepsilon+\tau)}\,\|R\,Dh\,(f+g\,u_\theta)\|_p \\ &\le \frac{\sigma^\varsigma\,m^{1/p}}{\varsigma\tau^{\varsigma-1}}\left(-\frac{1}{(\varepsilon+\tau)}\,L_fV + \|R^{-1}\upsilon_\varepsilon\|_{q,1/\mathbf{r}}\,\|u_\theta\|_{p,\mathbf{r}}\right) \\ &\quad + \frac{1}{(\varepsilon+\tau)}\,\|Dh\,(f+g\,u_\theta)\|_{p,1/\mathbf{r}}\,.\end{aligned}$$

Finally,

$$\left\|\frac{d\upsilon_\varepsilon}{dt}\right\|_p \le \frac{\sigma^\varsigma m}{\varsigma\tau^{\varsigma-1}} - \frac{\sigma^\varsigma\,m^{1/p}\,L_fV}{\varsigma\tau^{\varsigma-1}(\varepsilon+\tau)} + \frac{1}{(\varepsilon+\tau)}\,\|Dh\,f\|_{p,1/\mathbf{r}} + \frac{\varrho}{(\varepsilon+\tau)}\,\|Dh\,g\|_{p,1/\mathbf{r}}\,. \tag{6.13}$$

In virtue that by assumption $\tau(x)$ is a proper function, we have that the right-hand side of the above expression is bounded in $\mathbb{R}^n\backslash\mathcal{E}(\tau^\times)$ for arbitrary $\tau^\times > 0$, if in the latter three terms, the orders of the denominators (as functions of τ) are greater than or equal to the corresponding ones of the numerators. Thus, observing that $\tau(x)$ has (degree) order ν $(= \beta + \gamma - 1)$, we obtain that $L_fV(x) \in \mathcal{O}(\|x\|^\beta_p)$ and $\|Dh(x)\;f(x)\|_{p,1/\mathbf{r}} \in \mathcal{O}(\|x\|^\nu_p)$ are boundedness conditions for the second and third terms of (6.13). Finally, the last term contains an x-dependent induced p-norm applied to an $m \times m$ matrix with homogeneous entries of even degree equal to $\beta + 2\gamma - 2$. Thereby, we must have $\beta + \gamma - 1 \ge \beta + 2\gamma - 2$, i.e., $\gamma \le 1$, to obtain the desired result.

However, smoothness on $g(x)$ over $\mathbb{R}^n$ (specifically at $x = 0$) restricts the values of γ to be 0 or 1, and, further, $g(x)$ admits only two possibilities. Either $g(x) = B$, an $n \times m$ constant matrix, or $g_j(x) = D_j x$, where D_j are $n \times n$ constant matrices, $j = 1, \dots, m$. On the other hand, in $\mathcal{E}(\tau^\times)$, the right-hand side of (6.13) is obviously bounded. Therefore, the right-hand side of (6.13) is globally bounded, with bound depending on the associated order-constants, p norm parameter, control bound $\mathbf{r}$, parameter value $\tau^\times > 0$, and tuning parameter $\varepsilon > 0$. □

Remark 8. From (6.13), it should be noted that if $\varsigma = 1$ (e.g., as in the case of bilinear systems), then control $u_\theta(x)$ can be used instead of $u_\theta^\times(x)$.

The class of homogeneous systems considered above includes those systems with $g(x) = B$ that can be globally asymptotically stabilized using a quadratic Lyapunov function (linear systems included) and homogeneous bilinear systems. In particular, for linear and bilinear systems, since their free dynamics are linear (i.e., $f(x) = Ax$), the result on inputs subject to global bounded rate is guaranteed on the basis of the above theorem. This fact will be explicitly shown below in Propositions 6.3 and 6.5.

6.1. Globally asymptotically stabilizable systems by linear feedback. Assume that the $n \times m$ constant matrix B has full rank, and consider the class of affine systems

$$\dot{x} = f(x) + Bu. \tag{6.14}$$

The proposed method is particularly well suited for any system (6.14) that can be globally asymptotically stabilized by means of linear feedback $v(x) = -(L_B V(x))^\top = -Kx$ and quadratic Lyapunov function $V(x) = \frac{1}{2}\, x^\top P x$, where P is an $n \times n$ positive-definite symmetric matrix. For such a system the optimization problem is easily implemented, and assuming that Hypotheses H1–H2 hold, a globally stabilizing BFC function is designed. Sufficient conditions for the existence of linear controllers are available in the literature (cf. [2, 17]).

As has been pointed out above, the control constraint problem $\|u(x)\|_{p,\mathbf{r}} \leq 1$ can be solved by means of the Lagrange multiplier method. In the present case, it reduces to finding a function $c = c(\tau)$ as solution of the ellipsoidal boundary (a relation)

$$\partial\mathcal{E}(\tau) = \left\{ x \in \mathbb{R}^n : V(x) = \frac{1}{2}\, x^\top P x = c(\tau) \right\}, \tag{6.15}$$

where $P = P^\top > 0$, s.t. $\|u(x)\|_{p,\mathbf{r}} \leq 1$.

PROPOSITION 6.3. *Consider the affine system* (6.14) *for which Hypothesis* H1 *holds with a quadratic Lyapunov function $V(x)$ given in* (6.15) *and further assume, without loss of generality, that B has full rank. Furthermore, if Hypothesis* H2 *holds, then control $u_\theta^\times(x)$ given in* (3.19)*, where $v_\varepsilon(x)$ is given by*

$$v_\varepsilon(x) = -\frac{1}{\varepsilon + \sigma\sqrt{x^\top P x}}\, R\, B^\top P x, \tag{6.16}$$

with $R = \operatorname{diag}(r_1, \dots, r_m)$, satisfies $\|u_\theta^\times(x)\|_{p,\mathbf{r}} < 1$ for any $\tau^\times > 0$ and $\varepsilon > 0$ and globally asymptotically stabilizes the closed-loop system (6.14)–(3.19)*, where $\sigma = 2^{1/2}/\|(x^{*\top} PB)\ (B^\top PB)^{-1}\|_{p,\mathbf{r}}$ and x^* is an optimal point satisfying $x^{*\top} P x^* = 1$. Furthermore, if $f(x)$ is a globally Lipschitz function at the origin (i.e., there exists $L > 0$ such that for all $x \in \mathbb{R}^n$, $\|f(x)\|_2 \leq L\|x\|_2$), then given any $\kappa = (\kappa_1, \dots, \kappa_m)^\top \in \mathbb{R}^m_{>0}$, there is a $q \in \mathbb{Q}^*_{>1}$ (depending on κ), such that $\|du_\theta^\times/dt\|_{p,\kappa} < 1$, with $p \in \mathbb{Q}^*_{>1}$,* *for all $x \in \mathbb{R}^n$, where q is defined in terms of matrices B and P, Lipschitz constant L, rate bound κ, control bound* $\mathbf{r}$, *and parameter value $\tau^\times$.*

Proof. First of all, since $g(x) = B$ has full rank, it follows that $B^\top PB$ is nonsingular (indeed, it is a positive-definite matrix). Moreover, any extremum x^* is a regular point of the constraint ($\nabla_x V(x) \neq 0$ for all $x \neq 0$). In view that $\beta = 2$ and $\nu = 1$, we have $\varsigma = 2$. Thus, $\tau(x)$ is given by (6.1), that is, $\tau(x) = \sigma\sqrt{x^\top Px}$, so that it is admissible. Then, based on Theorem 6.2, the global stabilization result follows.

On the other hand, from $\upsilon_\varepsilon(x)$ (6.16) and some algebraic calculations, we obtain $\frac{d\upsilon_\varepsilon}{dt} = \frac{1}{\varepsilon+\tau}\big(\frac{\sigma^2}{2(\varepsilon+\tau)\,\tau}(x^\top Pf(x) + x^\top PB\,u_\theta)RB^\top Px - RB^\top Pf(x) + R(B^\top PB)\,u_\theta\big)$.

Hence, working along the line of the proof of Theorem 6.2, we obtain

$$\left\|\frac{d\upsilon_\varepsilon}{dt}\right\|_p = \frac{\sigma^2}{2\tau}\left(\left\|R^{-1}\upsilon_\varepsilon\right\|_{q,1/\mathbf{r}}\|u_\theta\|_{p,\mathbf{r}} - \left(\frac{1}{\varepsilon+\tau}\right)x^\top P\,f(x)\right)\|\upsilon_\varepsilon\|_p$$

$$-\frac{1}{\varepsilon+\tau}\big(\left\|RB^\top P\,f(x)\right\|_p + \left\|RB^\top PB\right\|_p\|u_\theta\|_p\big).$$

From the fact that $|\upsilon_{\varepsilon_j}| < 1$, $j = 1, \ldots, m$, we have that $\|\upsilon_\varepsilon(x)\|_p < m^{1/p}$ for any p-norm. Moreover, recalling that $\|u_\theta\|_{p,\mathbf{r}} < 1$, then $\|u_\theta\|_p = \varrho\|u_\theta\|_{p,\mathbf{r}} < \varrho$, with ϱ depending on $\mathbf{r}$. Then, from the above expression, we have

$$\left\|\tfrac{d\upsilon_\varepsilon}{dt}\right\|_p \leq \tfrac{\sigma^2 m}{2\tau}\underbrace{-\frac{\sigma^2 m^{1/p}}{2\tau(\varepsilon+\tau)}(x^\top Pf(x))}_{(a)} + \underbrace{\frac{\left\|RB^\top Pf(x)\right\|_p}{(\varepsilon+\tau)}}_{(b)} + \tfrac{\varrho\left\|RB^\top PB\right\|_p}{(\varepsilon+\tau)}. \tag{6.17}$$

The expressions (a) and (b) from (6.17) admit the following bounds.

For (a) and recalling that for all $x \in \mathbb{R}^n$, $\|f(x)\|_2 \leq L\|x\|_2$, we have

$$-\frac{\sigma^2\,m^{1/p}}{2\tau(\varepsilon+\tau)}\big(x^\top P\,f(x)\big) < \frac{m^{1/p}}{2(x^\top Px)}\,\|Px\|_2\,\|f(x)\|_2 \leq \frac{L\,m^{1/p}}{2\left\|P^{1/2}x\right\|_2^2}\,\|Px\|_2\,\|x\|_2$$

$$\leq \frac{L\,m^{1/p}}{2}\left\|P^{1/2}\right\|_2\left\|P^{-1/2}\right\|_2;$$

whereas, for (b), we obtain $\frac{1}{(\varepsilon+\tau)}\|RB^\top P\,f(x)\|_p < \frac{1}{\sigma\|P^{1/2}x\|_2}\|RB^\top P\|_p\|f(x)\|_p \leq \frac{L\,\mu}{\sigma\,\lambda_{\min}(P^{1/2})}\|B^\top P\|_{p,1/\mathbf{r}}$, where $\mu > 0$ is an appropriate constant (entailed from the equivalence of norms).

Then, from the previous expressions and (6.17) and after some algebraic calculations, we finally obtain

$$\left\|\frac{d\upsilon_\varepsilon^\times}{dt}\right\|_p \leq \flat := L\left(\tfrac{m^{1/p}\lambda_{\max}(P^{1/2})}{2\lambda_{\min}(P^{1/2})} + \tfrac{\mu\,\|B^\top P\|_{p,1/\mathbf{r}}}{\sigma\lambda_{\min}(P^{1/2})}\right) + \left(\tfrac{\sigma^2 m}{2\tau^\times} + \tfrac{\varrho\left\|B^\top PB\right\|_{p,1/\mathbf{r}}}{\varepsilon+\tau^\times}\right) \tag{6.18}$$

for all $x \in \mathbb{R}^n$. □

Remark 9. The bound $\flat$ (right-hand side of (6.18)) admits a geometrical meaning in terms of the curvature of the ellipsoid $\mathcal{E}(\tau)$ (6.15). In fact, from (6.18) observe that

$$\lambda_{\max}(P^{1/2})/\lambda_{\min}(P^{1/2}) = \chi_{\max}/\chi_{\min}, \tag{6.19}$$

where $\chi_{\min}$ and $\chi_{\max}$ are the minimal and the maximal lengths of the semiaxes of the ellipsoid $\mathcal{E}(\tau)\;|_{c=1/2}$ (6.15), respectively. Hence, the more that ellipsoid resembles a ball, the smaller the attained bound value $\flat$ becomes.

Consider the particular case when system (6.14) is linear, i.e., $f(x) = Ax$, where A is an $n \times n$ matrix satisfying Hypothesis H1 and B is an $n \times m$ matrix. In this case, Hypothesis H1 can be rephrased in terms of quadratic Lyapunov functions.

HYPOTHESIS H1′. *Suppose there exists a positive-definite symmetric matrix* P $(P = P^\top > 0)$, *solution of the Lyapunov equation*

$$A^\top P + PA = -Q, \tag{6.20}$$

where Q *is a positive semidefinite matrix* $(Q \geq 0)$. *Then, the quadratic function*

$$V(x) = \frac{1}{2}\, x^\top P x \tag{6.21}$$

defines a Lyapunov function for the open-loop system (6.14).

From Theorem 6.2, if, in addition, Hypothesis H2 holds, GAS of that system with bounded control is guaranteed.

COROLLARY 6.4. *Consider the linear system case of* (6.14) *for which Hypotheses* H1′–H2 *hold and further assume, without loss of generality, that* B *has full rank. Then, the control function* $u_\theta^\times(x)$ (3.19), *where* $\upsilon_\varepsilon(x)$, *given in* (6.16), *satisfies* $\|u_\theta^\times(x)\|_{p,\mathbf{r}} < 1$ *and renders the GAS of the closed-loop system* (6.14)–(3.19). *Further, given* $\kappa \in \mathbb{R}^m_{>0}$, *there is* $q \in \mathbb{Q}^*_{>1}$ *such that* $\|du_\theta^\times/dt\|_{p,\kappa} < 1$ *for all* $x \in \mathbb{R}^n$.

Remark 10. Another approach to the problem presented in this subsection can be found in [23]. In that paper, the control-value set was given by an S-Euclidean normed ball, $\mathcal{B}^m_S = \{u \in \mathbb{R}^m : \|u\|_S := \sqrt{u^\top S\, u} \leq 1\}$, where S is an $m \times m$ positive-definite symmetric matrix. Additional features developed in [23] were (i) addressing globally bounded rates on inputs: $\|du/dt\|_S \leq \kappa$, and (ii) the semiglobal stabilization of ANCBC linear systems via feedback control laws with magnitude and rate bounds.

6.2. Homogeneous bilinear systems. Consider the class of homogeneous bilinear systems

$$\dot{x} = Ax + \sum_{j=1}^{m} u_j D_j x, \tag{6.22}$$

where A is an $n \times n$ matrix satisfying Hypothesis H1′ and D_j are $n \times n$ constant matrices, $j = 1, \ldots, m$. In this case, from Remark 8, we have $\varsigma = 1$ $(= \beta/\nu = 2/2)$, so that $u_\theta(x)$, given in (3.11), will be used instead of $u_\theta^\times(x)$ given in (3.19).

Based on Theorem 6.2, if a quadratic Lyapunov function $V(x)$, given by (6.21), exists, then a globally bounded smooth stabilizer is designed for system (6.22).

PROPOSITION 6.5. *Consider the homogeneous bilinear system* (6.22) *for which Hypothesis* H1′ *holds with a quadratic Lyapunov function* $V(x)$ *given in* (6.21). *If Hypothesis* H2 *also holds, then control* $u_\theta(x)$, *given in* (3.11), *where* $\upsilon_\varepsilon = (\upsilon_{\varepsilon_1}, \ldots, \upsilon_{\varepsilon_m})^\top$ *is given by*

$$\upsilon_{\varepsilon_j}(x) = -\frac{r_j}{2\,(\varepsilon + \sigma\, x^\top P x)}\, x^\top (PD_j + D_j^\top P)x, \quad j = 1, \ldots, m, \tag{6.23}$$

satisfies $\|u_\theta(x)\|_{p,\mathbf{r}} < 1$ *for arbitrary* $\varepsilon > 0$, *and globally asymptotically stabilizes the closed-loop system* (6.22)–(3.11), *where* $\sigma = \|h^\top(x^*)\,(Dh(x^*)\,g(x^*))^{-1}\|^{-1}_{p,\mathbf{r}}$, x^* *is an* *optimal point such that* $x^{*\top} P x^* = 2$ *and the set* $\{D_1 x^*, \ldots, D_m x^*\}$ *is linearly independent. Moreover, given any* $\kappa \in \mathbb{R}^m_{>0}$*, there is a* $q \in \mathbb{Q}^*_{>1}$ *such that* $\|du_\theta/dt\|_{p,\kappa} < 1$ *for all* $x \in \mathbb{R}^n$*.*

Proof. First of all, in view that the set $\{D_1 x^*, \ldots, D_m x^*\}$ is linearly independent, it follows that $Dh_j(x^*)\, g_j(x^*) = x^{*\top}(D_j^\top P D_j + P D_j^\top D_j) x^*$ for $j = 1, \ldots, m$, are also linearly independent (so that $Dh(x^*)\, g(x^*)$ is nonsingular). Moreover, since $\nabla_x V(x) \neq 0$ for all $x \neq 0$, any extremum x^* is a regular point of the constraint. Set $\varsigma = 1$, since $\beta = 2$ and $\nu = 2$. Then, based on Theorem 6.1, $\tau(x) = \sigma\, x^\top P x$ and it is (obviously) admissible, and from Theorem 6.2, the global stabilization result follows.

On the other hand, due to the fact that $|\upsilon_{\varepsilon_j}| < 1$, $j = 1, \ldots, m$, it follows that $\|\upsilon_\varepsilon\|_p < m^{1/p}$ for any p-norm. Moreover, $\|u_\theta\|_p \leq \varrho\, \|u_\theta\|_{p,\mathbf{r}} < \varrho$, where ϱ depends on $\mathbf{r}$. Then, from $\upsilon_\varepsilon(x)$ (6.23) and (6.20), the corresponding expression (6.13) becomes

$$\left\| \frac{d\upsilon_\varepsilon}{dt} \right\|_p \leq \sigma\, m + \frac{1}{\varepsilon + \tau} \left(\frac{\sigma\, m^{1/p}}{2}\, (x^\top Q x) + \|Dh\, Ax\|_{p,1/\mathbf{r}} + \varrho\, \|Dh\, g\|_{p,1/\mathbf{r}} \right), \tag{6.24}$$

where $Dh = g^\top P + x^\top P D g^\top$. The result follows from Theorem 6.2 observing that the right-hand side of the above expression is bounded for all $x \in \mathbb{R}^n$ and $\varepsilon > 0$. □

For the remainder of this section, we will address the control design in $\mathcal{B}^m_{\mathbf{r}}(\infty)$. As pointed out in section 5.1, the solution to the associated optimization problem for the control design in $\mathcal{B}^m_{\mathbf{r}}(\infty)$ is achieved by solving an optimization problem with scalar control constraint (5.7). Thereby, in the case of homogeneous bilinear systems, the solution to (5.11) is reduced to finding a root of the polynomial

$$p(\lambda) = \det H_\lambda, \quad \text{where } H_\lambda := (PD + D^\top P) - \lambda P. \tag{6.25}$$

If $\lambda = \lambda^*$ is the required root, considering (5.11) and (5.7), it follows that $c(\tau) = \tau/|\lambda^*|$ and $\tau(x) = \frac{1}{2}\, |\lambda^*|\, x^\top P x$. Henceforth, the BFC function $u_\theta(x)$ is defined in (5.3), where the components $\overset{[j]}{\upsilon}_{\varepsilon_j}$ are given by

$$\overset{[j]}{\upsilon}_{\varepsilon_j}(x) = -\frac{r_j}{\varepsilon_j + |\lambda_j^*|\, (x^\top P x)}\, x^\top (P D_j + D_j^\top P) x, \quad j = 1, \ldots, m. \tag{6.26}$$

The following theorem leads to the solution of convex and nonconvex optimization problems (5.7) associated to the BFC problem for homogeneous bilinear systems with *scalar control*. Depending on the definiteness of the function ψ (5.8), the sufficient conditions are expressed in terms of λ^* and the remaining roots of the polynomial $p(\lambda)$ (6.25). It should be noted that, from homogeneity, if $\psi(c) > 0$ (or < 0) for some $c > 0$, then ψ is positive- (or negative-) definite.

THEOREM 6.6. *Assume that Hypotheses* H1′–H2 *hold. Set* $\lambda^* = \max_\lambda \arg\{p(\lambda) = 0\}$*. Then:* (i) *if the optimization problem* (5.9) *holds,* λ^* *is the unique positive root of the polynomial* $p(\lambda)$*; or* (ii) *if the negative version of* (5.9) *holds, then all roots of the polynomial* $p(\lambda)$ *are negative. In either case, GAS of the system* (6.22) *is obtained by means of the control* $u_\theta(x)$ *given in* (5.3) *with components* $\overset{[j]}{\upsilon}_{\varepsilon_j}$ *given by* (6.26).

Proof. Case (i). As is well known [18], a (second-order) sufficient condition for x^* to be a maximum of the optimization problem (5.9) consists of

(a) the necessary condition: there exists $\lambda^* \in \mathbb{R}$ such that

$$x^{*\top} H_{\lambda^*} = x^{*\top}((PD + D^\top P) - \lambda^* P) = 0, \text{ and} \tag{6.27}$$

(b) the negative semidefiniteness of the Hessian matrix H_{λ^*} (*regular pencil* of matrices (6.25)) on

$$M = \left\{z \in \mathbb{R}^n : x^{*\top} P z = 0\right\} := \ker(x^{*\top} P). \tag{6.28}$$

Then, considering (6.27) and positive definiteness of $\tau(x)$ (5.9), it follows that $\lambda^* > 0$.

The following two results, specialized to the present problem, are required (cf. [9]).

(A) There exist n real characteristic values of H_λ, which can be assumed ordered: $\lambda_1 \le \cdots \le \lambda_n$. Moreover, for every k ($1 \le k \le n$), the kth characteristic value λ_k is given as the minimum ratio of the bilinear forms

$$\lambda_k = \min_x \frac{x^\top (PD + D^\top P) x}{x^\top P x}\,, \tag{6.29}$$

provided that the variable vector x is subject to $k-1$ linear relations: there exist $k-1$ (P-)orthonormal vectors z_i ($1 \le i \le k-1$), i.e., $z_i^\top P z_j = \delta_{ij}$ ($= \{1$, if $i = j$; or 0, if $i \ne j\}$), which are (P-)orthogonal to x, that is

$$x^\top P z_1 = 0,\ x^\top P z_2 = 0, \ldots, x^\top P z_{k-1} = 0. \tag{6.30}$$

(B) There is a nonsingular transformation, $x = T\xi$, which reduces the bilinear forms $x^\top(PD + D^\top P)x$ and $x^\top P x$ simultaneously to a sum of squares

$$\xi^\top \operatorname{diag}(\lambda_1, \ldots, \lambda_n)\xi \quad \text{and} \quad \xi^\top \xi. \tag{6.31}$$

Then, λ is a characteristic value of the pencil H_λ iff it is a root of the polynomial $p(\lambda) = \det H_\lambda$.

We claim that the negative semidefiniteness sufficient condition on H_{λ^*} holds if λ^* is the unique positive root of $p(\lambda)$. In fact, since $\dim M = \dim \ker(x^{*\top} P) = n-1$, from (A), it follows that $k = n$. Based on this, taking into account (B) and recalling that, by hypothesis, $\lambda_1, \ldots, \lambda_{n-1}$ are nonpositive roots of $p(\lambda)$, we obtain that matrix H_{λ^*} (6.25) is negative semidefinite on M. Moreover, $\lambda^* = \lambda_n > 0$—the Lagrange multiplier associated to x^*—is a root of the polynomial $p(\lambda)$. Therefore, $\lambda_1 \le \cdots \le \lambda_{n-1} \le 0$ and $\lambda_n > 0$ are all the characteristic values of H_λ.

Case (ii). If ψ (5.8) is nonpositive, the negative version of (5.9) holds. Then we obtain the following necessary condition for an extremum:

$$x^{*\top} H_{\nu^*} = 0, \tag{6.32}$$

where $H_{\nu^*} = (PD + D^\top P) + \nu^* P$. From this and positive definiteness of $\tau(x)$, it follows that $\nu^* > 0$. Denoting $\lambda^* := -\nu^*$, we obtain that $\lambda^* < 0$. Then, considering $p(\lambda) = \det H_\lambda$ (6.25) and reasoning analogously to case (i) yields that all roots of $p(\lambda)$ must be negative, λ^* being the greater one. □

7. Concluding remarks. In this work, we addressed the GAS problem of a class of nonlinear systems with stable free dynamics subject to both input magnitude and rate bounds. In general, in order to derive the bounded stabilizer, the resulting procedure implies that "gains," as state-functions, are the solution to a c-parameterized nonlinear programming. On broad lines, the procedure consists of defining a function $\tau(x)$, such that it is constant along the boundary of the c-level (compact) sets of certain functions. Then, taking a sequence of those c-level sets in decreasing size (converging to the origin), it is assigned to each set the corresponding possible highest "gain" (via τ), while keeping the control bounded. For general nonlinear systems, the resulting closed-loop system could be implicitly defined in the sense that the control law is obtained from the solution to a nonlinear algebraic equation. Furthermore, we show that the proposed control is suboptimal. For an important class of homogeneous nonlinear systems (including a class of GAS systems by linear feedback and bilinear systems), it is shown that the resulting programming problem can be explicitly solved, and, further, the problem of inputs subject to global bounded rates is addressed. In many applications, the control-value set is defined as the m-dimensional $\mathbf{r}$-hyperbox $\mathcal{B}^m_{\mathbf{r}}(\infty) = \{u \in \mathbb{R}^m : |u_j| \leq r_j,\, r_j > 0,\, j = 1, \ldots, m\}$. Thereby, we presented a design approach for control laws considering more general control-value sets: Cartesian products of $p, \mathbf{r}$-normed balls.

Acknowledgment. The authors are grateful to Dr. Carlos Ibarra for his helpful suggestions that improved the original version of this paper.

NONLINEAR ADAPTIVE TRACKING USING KERNEL ESTIMATORS: ESTIMATION AND TEST FOR LINEARITY*

JEAN-MICHEL POGGI† AND BRUNO PORTIER†

Abstract. We present some statistical results on nonlinear adaptive control using kernel estimators. We are concerned with a nonlinear autoregressive model of the form

$$X_{n+1} = f(X_n) + U_n + \xi_{n+1}, \qquad n \in \mathbb{N},$$

controlled using a nonparametric estimator of the unknown function f and derived from a tracking control policy. We prove an almost sure convergence result for the noise density estimator, a pointwise central limit theorem for f, and a test for linearity of the driving function f.

Key words. adaptive control, central limit theorem, discrete-time stochastic nonlinear system, kernel estimation, test for linearity

1. Introduction.

In a previous paper [14], the problem of adaptive control of nonlinear systems of the form

$$X_{n+1} = f(X_n) + U_n + \xi_{n+1}, \qquad n \in \mathbb{N}, \tag{1.1}$$

is considered, where X_n, U_n, and ξ_n are the output, input, and noise of the system, respectively. State X_n is observed, ξ_n is an unobservable noise, and control U_n is to be chosen. Initial conditions X_0 and U_0 are arbitrarily chosen. The main results of [14] deal with the almost sure convergence over dilating sets of a nonparametric estimator (based on a kernel method) of the unknown function f as well as the construction of an optimal adaptive tracking control law.

In this paper, we propose some new statistical results in this context. First, we propose a kernel method-based estimator of the probability density function (p.d.f.) of ξ_n, and we prove a uniform almost sure convergence result. Next, we establish a pointwise central limit theorem for the kernel estimator of function f as well as the associated joint asymptotic normality. Finally, we derive a test for linearity of f which can be used for identification purposes.

From a statistical viewpoint, the estimation of the regression function using the kernel method is widely investigated in the uncontrolled case ($U_n \equiv 0$ in model (1.1)). See Härdle [10] for a comprehensive survey, Robinson [18], Truong and Stone [26] under mixing assumptions (see Doukhan [4] for a full study of mixing notions), and Duflo [5] and Yakowitz [27] under Markov chains framework. Nonparametric statistical methods have been already used for the identification of nonlinear dynamical systems. See Greblicki and Pawlak [8], Greblicki [7], Krzyzak [13], Georgiev [6], and Hilgert, Senoussi, and Vila [11].

Let us now make some remarks about the existing literature on the different topics related to the main results of the paper.

Many authors have studied the pointwise asymptotic normality of the kernel estimator in uncontrolled frameworks. For the regression model, Schuster [20] establishes the joint asymptotic normality of $(\widehat{f}_n(x_1), \ldots, \widehat{f}_n(x_q))$, where $x_1, \ldots, x_q$ are q distinct points. In a mixing framework, Robinson [18] gives a multivariate central limit theorem. More recently, Roussas and Tran [19] give a central limit theorem for a recursive version of the kernel estimator of the regression function of an α-mixing process. For nonlinear autoregressive models, Duflo [5] obtains the same results.

Tests of linearity of such models have been developed by several authors in the uncontrolled case. See Tong [24], Hjellvik and Tjøstheim [12], Tjøstheim [23], and Poggi and Portier [15] for reviews. A recent paper of Poggi and Portier [16] applies the ideas previously developed for time series to control system area in a nonadaptive framework.

For a practical use of the test, the estimation of the p.d.f. of the unobservable noise ξ_n is required. Up to now, the available results deal with the uncontrolled case. For a regression model, Ahmad [1] proposes a kernel estimator of the p.d.f. of the residuals of the model. A result of almost sure convergence and a central limit theorem in the scalar case are established. For model (1.1) with $U_n \equiv 0$, Senoussi [21] builds a kernel estimator of the p.d.f. of ξ_n and proves the almost sure convergence on compact sets of its estimator.

The paper is organized as follows. In section 2, we present the model and the control law. Section 3 then develops two asymptotic results (the proofs are postponed to the appendices). These results are then used in section 4 for testing the linearity of the leading function f. Finally, section 5 contains some simulation experiments. Our simulations carried out for a simple model indicate that our asymptotic results give a good approximation for moderate sample sizes. This study by simulations concerns mainly three topics: the illustration of the behavior of the adaptive control, the estimation of the noise p.d.f., and the test for linearity of the function f.

2. Framework and assumptions. Let us now further describe the model assumptions and the control law. We assume the following properties on function f, noise ξ_n, and the initial conditions of model (1.1).

Assumption [A1].

(i) Function f is Lipschitz with Lipschitz constant r_f.

(ii) $\xi = (\xi_n)_{n \geq 1}$ is a sequence of independent and identically distributed random vectors with mean 0 and unknown invertible covariance matrix Γ.

(iii) ξ_n has a finite moment of order $m > 2$ and its distribution is absolutely continuous with respect to the Lebesgue measure. Its unknown p.d.f. denoted by p is supposed to be C^1-class; $p > 0$ and p and its gradient are bounded.

(iv) X_0 has a finite moment of order m.

In order to estimate unknown function f, we use a recursive version of the classical kernel estimator of the regression function. Then, for $x \in \mathbb{R}^d$, we estimate $f(x)$ by

$$\widehat{f}_n(x) = \frac{\sum_{i=0}^{n-1} i^{\alpha d} K\left(i^{\alpha}(X_i - x)\right)(X_{i+1} - U_i)}{\sum_{i=0}^{n-1} i^{\alpha d} K\left(i^{\alpha}(X_i - x)\right)}, \tag{2.1}$$

where K is a kernel and α is a real number in $]0,\ 1/d[$, called the bandwidth parameter. We shall call a kernel a Lipschitz positive bounded function $N : \mathbb{R}^d \to \mathbb{R}_+$ satisfying $\int N(t)\,dt = 1$ and $\int \|t\|\, N(t)\,dt < \infty$, where $\|.\|$ denotes the usual norm on $\mathbb{R}^d$.

Let us give some heuristics about the control law proposed in [14] and that we use in this paper to control model (1.1). Since the control law is designed in order to track a given reference trajectory denoted by $(X_n^*)_{n\geq 1}$, an "ideal" candidate for the control is

$$U_n = -f(X_n) + X_{n+1}^*. \tag{2.2}$$

Since f is unknown, $f(X_n)$ can be replaced by its estimate $\widehat{f}_n(X_n)$, leading to the self-tuning control, which is a second "ideal" candidate,

$$U_n = -\widehat{f}_n(X_n) + X_{n+1}^*. \tag{2.3}$$

The nonparametric estimation of function f in controlled models of the form (1.1) using a kernel method involves some kind of stability of the controlled process X_n. The tracking control law (2.3) uses a local estimation feedback and that creates new problems for the analysis of the closed-loop behavior. Portier and Oulidi [14] have investigated this question and have proposed to introduce some a priori knowledge on the function to be estimated. (This kind of approach has been first experimentally used in [17].) More precisely, this a priori knowledge about function f is modelled by a function $\widetilde{f}$, supposed to be known and which satisfies the following assumption.

Assumption [A2]. Function $\widetilde{f}$ is continuous and

$$\exists\ a_f \in \left[0,\ 1/2\right[\ \exists\ A_f \in \left]0,\ \infty\right[\ \forall\ x \in \mathbb{R}^d, \quad \left\| f(x) - \widetilde{f}(x) \right\| \leq a_f \left\| x \right\| + A_f.$$

Let $(X_n^*)_{n\geq 1}$ be a given bounded deterministic tracking trajectory such that $X_n^* \underset{n\to\infty}{\longrightarrow} x^*$ with $\|x^*\| < \infty$. The adaptive tracking control with a priori knowledge is at time n defined by

$$U_n = X_{n+1}^* - \widehat{f}_n(X_n)\mathbf{1}_{E_n}(X_n) - \widetilde{f}(X_n)\mathbf{1}_{\overline{E}_n}(X_n), \tag{2.4}$$

where $\overline{E}_n$ denotes the complementary set of E_n. The set E_n, defined by

$$E_n = \{x \in \mathbb{R}^d;\ \|\widehat{f}_n(x) - \widetilde{f}(x)\| \leq b_f \left\| x \right\| + B_f\} \tag{2.5}$$

with $b_f \in \left]a_f,\ 1-a_f\right[$ and $B_f \in \left]A_f,\ \infty\right[$, is introduced to ensure the closed-loop stability of the system. Function $\widetilde{f}$ allows us to compensate for the possible lack of observations which disrupts the local estimator $\widehat{f}_n$. Under this kind of hypothesis, both stability and convergence results are obtained and the optimality of the tracking is proved. To make the paper self-contained, let us recall some previous results of [14], useful for what follows and summarized in the following theorem.

THEOREM 2.1. *Assume that* [A1] *and* [A2] *hold.*

1. *Then, for any initial law (the law of X_0),*

$$\sup_{k\leq n} \|X_k\| = o(n^{1/m}) \ \textit{and}\ \sup_n \mathbb{E}\left[\|X_n\|^m\right] < \infty.$$

2. *Let $(v_n)_{n\geq 1}$ be a sequence of positive real numbers increasing to infinity such that $v_n = O\left(n^\nu\right)$ with $\nu > 0$. Then, for a compactly supported kernel K and for a bandwidth parameter $\alpha \in \left]0,\ 1/2d\right[$, we have for any $s \in \left]1/2 + \alpha d,\ 1\right[$,*

$$\sup_{\|x\|\leq v_n} \|\widehat{f}_n(x) - f(x)\| = o\left(\frac{n^{s-1}}{m_n}\right) + O\left(\frac{n^{-\alpha}}{m_n}\right) \quad \textit{almost surely (a.s.)}, \tag{2.6}$$

where $m_n = \inf\{p(z);\ \|z\| \leq v_n + R\}$ for some constant $R < \infty$.

In addition, if $m_n^{-1} = \inf\left(o\left(n^{\alpha}\right), O\left(n^{1-s}\right)\right)$*, then we have*

$$\sum_{k=0}^{n-1} \|\pi_k\|^2 = o(n) \quad a.s., \tag{2.7}$$

$$\widehat{\Gamma}_n = \frac{1}{n}\sum_{k=1}^{n} \left(X_k - X_k^*\right)\left(X_k - X_k^*\right)^T \xrightarrow[n\to\infty]{\text{a.s.}} \Gamma, \tag{2.8}$$

where $\pi_k = f(X_k) + U_k - X_{k+1}^* = (f - \widehat{f}_k)(X_k)\,\mathbf{1}_{E_k}(X_k) + (f - \widetilde{f})(X_k)\,\mathbf{1}_{\overline{E}_k}(X_k)$*.*

Result (2.7) is the key point used to establish convergence results of an estimator of the p.d.f. p as well as a pointwise central limit theorem for $\widehat{f}_n$. Let us also mention that the results, obtained in the next sections, hold for any control law $(U_n)_{n\geq 0}$ for which it is possible to prove that

$$\sum_{k=0}^{n-1} \left\|f(X_k) + U_k - X_{k+1}^*\right\|^2 = o(n) \quad \text{a.s.} \tag{2.9}$$

For more clarity, let us introduce the following hypothesis coming from part 2 of Theorem 2.1.

Assumption [A3]. There is a sequence of positive real numbers $(v_n)_{n\geq 1}$ increasing to infinity such that $v_n = O\left(n^{\nu}\right)$ with $\nu > 0$ and

$$\left(\inf\{p(z); \|z\| \leq v_n + R\}\right)^{-1} = \inf\{o\left(n^{\alpha}\right), O\left(n^{1-s}\right)\}$$

with $s \in]1/2 + \alpha d,\ 1[$, $\alpha \in]0,\ 1/2d[$ and for some constant $R < \infty$.

For example, when ξ_n is Gaussian (a widely used noise model), this assumption is fulfilled with $v_n = C\left(\log\log n\right)^{1/2}$, where C is any positive finite constant. In addition, taking $\alpha = 1/2(d+1)$, we obtain

$$\sup_{\|x\|\leq C(\text{loglog}\, n)^{1/2}} \left\|\widehat{f}_n(x) - f(x)\right\| = O\left(n^{-\lambda}\right) \quad \text{a.s.}$$

for any $\lambda \in]0,\ 1/2(d+1)[$.

3. Main results. The first result states both the almost sure and almost sure uniform convergence of the kernel estimator of the noise p.d.f. p. Let us remark that if the tracking objective is fulfilled, then $(X_n - X_n^*)$ is close in distribution to ξ_n, leading to a natural kernel estimator of the noise p.d.f. p denoted by $\widehat{p}_n$ and defined for all $e \in \mathbb{R}^d$ by

$$\widehat{p}_n(e) = \frac{1}{n}\sum_{i=1}^{n} i^{\beta d}\, G\left(i^{\beta}(X_i - X_i^* - e)\right), \tag{3.1}$$

where G is a kernel and β is a real number in $]0,\ 1/d[$.

THEOREM 3.1. *Assume that* [A1]–[A3] *hold.*

(1) *Then, for any* $e \in \mathbb{R}^d$, $\widehat{p}_n(e) \xrightarrow[n\to\infty]{\text{a.s.}} p(e)$.

(2) *Moreover, if* $G(x) = O(\|x\|^{-\delta})$ *with* $\delta > \frac{m\,\beta\,d}{\beta\,m+1}$*, then*

$$\sup_{e\in\mathbb{R}^d} |\widehat{p}_n(e) - p(e)| \xrightarrow[n\to\infty]{\text{a.s.}} 0.$$

Proof. The proof is straightforward using Corollary A.2 (see Appendix A) with $\varphi = G$, $\lambda = \beta d$, and $\gamma = \beta$. □

Remark. For the ARX model of the form

$$X_{n+1} = \theta^T \Psi_n + U_n + \varepsilon_{n+1}$$

with $\Psi_n = (X_n, \dots, X_{n-p+1})^T$ and $U_n = -\widehat{\theta}_n^T \Psi_n + X_{n+1}^*$, where $\widehat{\theta}_n$ is either the least or the weighted least square estimator of θ, Bercu [2] (see also Guo [9]) shows that (2.7) is fulfilled with $\pi_k = (\theta - \widehat{\theta}_k)^T \Psi_k$. Therefore, in this context, the previously defined $\widehat{p}_n$ is also a kernel estimator of the p.d.f. of ε_n and the results of Theorem 3.1 hold.

We present in the next theorem a pointwise central limit theorem and a result of joint asymptotic normality for two slightly different estimators of function f whose status will appear more clearly after the theorem. The first estimator is given by (2.1) where K is a compactly supported kernel and the second one, denoted by $\widehat{F}_n$, is given by

$$\widehat{F}_n(x) = \frac{\sum_{i=0}^{n-1} i^{\beta d} G\left(i^{\beta}(X_i - x)\right)(X_{i+1} - U_i)}{\sum_{i=0}^{n-1} i^{\beta d} G\left(i^{\beta}(X_i - x)\right)}, \tag{3.2}$$

where G is a kernel and β is a real number in $]0, 1/d[$.

THEOREM 3.2. *Assume that* [A1]–[A3] *hold, that function f is $\mathcal{C}^2$-class with bounded derivatives of order* 2 *and that kernels K and G satisfy $\int \|t\|^2 N(t)\,dt < \infty$ and for $j = 1, \dots, d$, $\int t_j\, N(t)\,dt = 0$, where t_j is the jth component of t and where N stands for K and for G.*

1) *For $\alpha \in\,]1/(d+4), 1/2d[$ and $x \in \mathbb{R}^d$,*

$$Z_n^{K,\alpha}(x) = n^{(1-\alpha d)/2}(\widehat{f}_n(x) - f(x)) \xrightarrow[n\to\infty]{\mathcal{L}} \mathcal{N}\left(0,\ \frac{\|K\|_2^2}{(1+\alpha\, d)p(x - x^*)}\,\Gamma\right) = Z^{K,\alpha}(x).$$

2) *For $\beta \in\,]1/(d+4), 1/d[$ and $x \in \mathbb{R}^d$,*

$$Z_n^{G,\beta}(x) = n^{(1-\beta d)/2}(\widehat{F}_n(x) - f(x)) \xrightarrow[n\to\infty]{\mathcal{L}} \mathcal{N}\left(0,\ \frac{\|G\|_2^2}{(1+\beta\, d)p(x - x^*)}\,\Gamma\right) = Z^{G,\beta}(x).$$

3) *Besides, for $x_1, \dots, x_q$, q distinct points of $\mathbb{R}^d$,*

$$(Z_n(x_1), \dots, Z_n(x_q)) \xrightarrow[n\to\infty]{\mathcal{L}} (Z(x_1), \dots, Z(x_q)),$$

where $Z(x_1), \dots, Z(x_q)$ are independent and where Z_n (respectively, Z) stands for $Z_n^{K,\alpha}$ or $Z_n^{G,\beta}$ (respectively, $Z^{K,\alpha}$ or $Z^{G,\beta}$), with the associated constraints on α and β.

Proof. The proof is given in Appendix B. □

Remark 3.3. In part 1 of Theorem 3.2, the range of admissible values for α comes from two sources. First, $\alpha \in\,]0, 1/2d[$ coming from Theorem 2.1 and ensuring that the key property $\sum_{k=0}^{n-1} \|\pi_k\|^2 = o(n)$ holds; second, $\alpha \in\,]1/(d+4), 1/d[$ coming from the proof of the central limit theorem (see Appendix B). So, these conditions on α imply that $d \leq 3$. To obtain a central limit theorem for an estimator of f when $d \geq 4$, we consider two different estimators of f. The first one is $\widehat{f}_n$, designed with respect to the control objective and defined using the compactly supported kernel K and the bandwidth parameter α within $]0,\, 1/2d[$. The second one is $\widehat{F}_n$, designed for statistical purposes. It is defined using the kernel G and the bandwidth parameter β within $]1/(d+4),\, 1/d[$. The parameters α and β have only to match their own constraints, leading to a general central limit theorem with respect to the state-space dimension (part 2 of Theorem 3.2).

4. Application to testing for linearity. In this section, we are concerned with a test for linearity of function f. Let us consider within model (1.1) the following hypotheses.

H_0 : $\ll f$ is linear of the form $f(x) = A_\ell^T\, x + B_\ell \gg$.
H_1 : $\ll f$ is nonlinear $\gg$.

The idea of the test statistic introduced by Poggi and Portier [15] in a slightly different framework is to compare two distinct estimators of function f. The first one is well suited under H_1 and the second one is convenient for the linear case. More precisely, this statistic of nonlinearity captures the quadratic deviations between the nonparametric estimator $\widehat{f}_n(x)$ and the least squares estimator $(\widehat{A}_n^T\, x + \widehat{B}_n)$ over q points, weighted by the estimated density at these points. The least squares estimators (LSE) $\widehat{A}_n$ and $\widehat{B}_n$ are defined by

$$\widehat{A}_n = S_{n-1}^{-1} \left(\sum_{k=0}^{n-1} X_k\, Y_k^T - \frac{1}{n} \left(\sum_{k=0}^{n-1} X_k \right) \left(\sum_{k=0}^{n-1} Y_k \right)^T \right), \tag{4.1}$$

$$S_{n-1} = \sum_{k=0}^{n-1} X_k\, X_k^T - \frac{1}{n} \left(\sum_{k=0}^{n-1} X_k \right) \left(\sum_{k=0}^{n-1} X_k \right)^T + \lambda\, I_d, \tag{4.2}$$

$$\widehat{B}_n = \frac{1}{n} \sum_{k=0}^{n-1} \left(Y_k - \widehat{A}_n^T\, X_k \right), \tag{4.3}$$

where $Y_k = X_{k+1} - U_k$, the real number λ is > 0, and I_d denotes the identity matrix of order d. The additional term $\lambda\, I_d$, which plays no role in the asymptotics, ensures that matrix S_n is always invertible.

We introduce the test statistic $T_q(n)$ defined by

$$T_q(n) = \frac{(1+\alpha d)\, n^{1-\alpha d}}{\|K\|_2^2} \sum_{j=1}^{q} \widehat{p}_n(x_j - x^*) \left\| \widehat{f}_n(x_j) - \widehat{A}_n^T\, x_j - \widehat{B}_n \right\|_{\widehat{\Gamma}_n^{-1}}^2, \tag{4.4}$$

where $x_1, \dots, x_q$ are q distinct points of $\mathbb{R}^d$, $\widehat{p}_n$ and $\widehat{\Gamma}_n$ are the estimators of p and Γ, respectively, and $\|y\|_{\widehat{\Gamma}_n^{-1}}^2 = y^T\, (\widehat{\Gamma}_n)^{-1}\, y$ for $y \in \mathbb{R}^d$.

For more clarity, we have used the nonparametric estimator $\widehat{f}_n$ in the construction of the test statistic $T_q(n)$. This choice leads to the constraint $d \leq 3$ (see Remark 3.3). However, the results on the test statistic (see Theorem 4.2) also hold true when we use $\widehat{F}_n(x)$ instead of $\widehat{f}_n(x)$, replacing K by G and α by β, with the associated constraints.

First let us state some convergence results for $\widehat{A}_n$ and $\widehat{B}_n$.

THEOREM 4.1. *Assume that* [A1]–[A3] *hold and assume that* $m > 4$.

(1) *Then,*

$$\widehat{A}_n \xrightarrow[n\to\infty]{\text{a.s.}} A = \Gamma^{-1}\, \mathbb{E}\left(\xi_1\, f(\xi_1 + x^*)^T \right),$$
$$\widehat{B}_n \xrightarrow[n\to\infty]{\text{a.s.}} B = \mathbb{E}\left(f(\xi_1 + x^*) \right) - A^T\, x^*.$$

(2) *Under* H_0*,* $A = A_\ell$*,* $B = B_\ell$*, and we have*

$$\left\|\widehat{A}_n - A\right\| = O\left(\frac{\log\log n}{n}\right)^{1/2} \quad a.s.,$$
$$\left\|\widehat{B}_n - B\right\| = O\left(\frac{\log\log n}{n}\right)^{1/2} \quad a.s.$$

Part 1 of Theorem 4.1 shows that the LSE always converge to finite limits even if the true model is nonlinear. Part 2 indicates that, when the true model is linear, despite the fact that the control law uses a nonparametric estimator, the convergence rates of the LSE are the same as those obtained with the standard linear state feedback control law with appropriate excitation (see Bercu [2] and Guo [9]).

Proof. (1) Using (1.1), let us rewrite (4.1) and (4.3) under the form

$$\begin{aligned}\frac{1}{n} S_{n-1}\widehat{A}_n = {} & \frac{1}{n}\sum_{k=0}^{n-1} X_k\, f(X_k)^T + \frac{1}{n}\sum_{k=0}^{n-1} X_k\, \xi_{k+1}^T \\ & - \left(\frac{1}{n}\sum_{k=0}^{n-1} X_k\right)\left(\frac{1}{n}\sum_{k=0}^{n-1} f(X_k) + \frac{1}{n}\sum_{k=0}^{n-1}\xi_{k+1}\right)^T,\end{aligned} \tag{4.5}$$

$$\widehat{B}_n = \frac{1}{n}\sum_{k=0}^{n-1} f(X_k) + \frac{1}{n}\sum_{k=0}^{n-1}\xi_{k+1} - \frac{1}{n}\sum_{k=0}^{n-1}\widehat{A}_n^T X_k. \tag{4.6}$$

First, let us study the convergence of S_n. Let $u \in \mathbb{R}^d$. Lemma A.3 gives

$$\frac{1}{n}\sum_{k=0}^{n-1} u^T X_k \xrightarrow[n\to\infty]{\text{a.s.}} u^T\mathbb{E}\left(\xi_1 + x^*\right) = u^T x^*, \tag{4.7}$$

and

$$\frac{1}{n}\sum_{k=0}^{n-1} u^T X_k\, X_k^T u \xrightarrow[n\to\infty]{\text{a.s.}} u^T\left(\Gamma + x^*(x^*)^T\right)u. \tag{4.8}$$

Therefore, combining these two results, we derive that

$$\frac{1}{n}\, u^T S_{n-1}\, u \xrightarrow[n\to\infty]{\text{a.s.}} u^T\Gamma\, u. \tag{4.9}$$

This result holds for any $u \in \mathbb{R}^d$. So we have, for any initial law,

$$\frac{1}{n}\, S_{n-1} \xrightarrow[n\to\infty]{\text{a.s.}} \Gamma, \tag{4.10}$$

and since Γ is supposed to be invertible,

$$\lim_{n\to\infty}\frac{\lambda_{\min}(S_{n-1})}{n} = \lambda_{\min}(\Gamma) > 0 \ \text{ a.s.}, \tag{4.11}$$

where $\lambda_{\min}(M)$ denotes the minimum eigenvalue of the matrix M.

Since $m > 2$, we have

$$\left\|\frac{1}{n}\sum_{k=0}^{n-1}\xi_{k+1}\right\| = O\left(\frac{\text{loglog } n}{n}\right)^{1/2} \quad \text{a.s.} \tag{4.12}$$

Since $\sup_n \mathbb{E}\left[\|X_n\|^m\right] < \infty$ (part 1 of Theorem 2.1), for any $n \geq 1$, $\sum_{k=0}^{n-1} X_k\, \xi_{k+1}^T$ is a square integrable martingale. In addition, since $\frac{1}{n}\sum_{k=0}^{n-1} X_k X_k^T \xrightarrow[n\to\infty]{\text{a.s.}} \Gamma + x^*(x^*)^T$ and $\sum_{n=1}^{\infty}(\frac{\|X_n\|}{\sqrt{n}})^\gamma < \infty$ for $\gamma \in]2,\, m]$, we obtain using a law of the iterated logarithm for the martingales (cf. Bercu [2] adapting an original result of Stout [22]; see also Touati [25]), that

$$\left\|\sum_{k=0}^{n-1} X_k\, \xi_{k+1}^T\right\| = O\left(n\ \text{loglog}\, n\right)^{1/2} \quad \text{a.s.} \tag{4.13}$$

Let $u \in \mathbb{R}^d$ and $v \in \mathbb{R}^d$. Using once again Lemma A.3, we deduce that

$$\frac{1}{n}\sum_{k=0}^{n-1} u^T X_k\, f(X_k)^T v \xrightarrow[n\to\infty]{\text{a.s.}} u^T\mathbb{E}\left((\xi_1 + x^*)\, f(\xi_1 + x^*)^T\right) v, \tag{4.14}$$

$$\frac{1}{n}\sum_{k=0}^{n-1} u^T f(X_k) \xrightarrow[n\to\infty]{\text{a.s.}} u^T\mathbb{E}\left(f(\xi_1 + x^*)\right). \tag{4.15}$$

These results hold for all $u \in \mathbb{R}^d$ and $v \in \mathbb{R}^d$. Hence, combining (4.10) and (4.12) to (4.15), we prove that $\widehat{A}_n \xrightarrow[n\to\infty]{\text{a.s.}} A$, and, therefore, $\widehat{B}_n \xrightarrow[n\to\infty]{\text{a.s.}} B$.

(2) Under H_0, we have, for any $x \in \mathbb{R}^d$, $f(x) = A^T x + B$, and thus, rewriting (4.5) and (4.6), we derive that

$$\begin{aligned}\|\widehat{A}_n - A\| = O\Bigg(\left(\frac{\lambda_{\min}(S_{n-1})}{n}\right)^{-1}\Bigg(\frac{\lambda}{n}\|A\| + \left\|\frac{1}{n}\sum_{k=0}^{n-1} X_k\, \xi_{k+1}^T\right\| \\ + \left\|\frac{1}{n}\sum_{k=0}^{n-1} X_k\right\| \left\|\frac{1}{n}\sum_{k=0}^{n-1}\xi_{k+1}\right\|\Bigg)\Bigg),\end{aligned} \tag{4.16}$$

$$\|\widehat{B}_n - B\| = O\left(\left\|\frac{1}{n}\sum_{k=0}^{n-1}\xi_{k+1}\right\| + \|\widehat{A}_n - A\|\left\|\frac{1}{n}\sum_{k=0}^{n-1} X_k\right\|\right). \tag{4.17}$$

Then, part 2 of Theorem 4.1 is easily obtained using (4.7) and (4.11)–(4.13). □

Now, collecting results of Theorems 3.1, 3.2, and 4.1, we derive the following theorem leading to an asymptotic test for linearity of f.

THEOREM 4.2. *Assume that hypotheses of Theorem* 3.2 *are fulfilled and that* $m > 4$. *Then, for* $\alpha \in]1/(d+4),\, 1/2d[$ *and for* q *distinct points* $x_1, x_2, \ldots, x_q$ *of* $\mathbb{R}^d$, *we have the following.*

(1) *Under* H_0, $T_q(n) \xrightarrow[n\to\infty]{\mathcal{L}} \chi^2(dq)$.

(2) *Under* H_1 *and if there is* $x \in \{x_1, x_2, \ldots, x_q\}$ *such that* $f(x) \neq A^T x + B$, *then*

$$\liminf_{n\to\infty} n^{-1+\alpha d}\, T_q(n) > 0, \ \textit{a.s.}$$

Proof. For any $x \in \mathbb{R}^d$, we have the following decomposition:

$$\begin{aligned}\widehat{f}_n(x) - \widehat{A}_n^T x - \widehat{B}_n = (\widehat{f}_n(x) - f(x)) + \left(f(x) - A^T x - B\right) \\ -(\widehat{A}_n - A)^T x - (\widehat{B}_n - B).\end{aligned} \tag{4.18}$$

From Theorem 3.1, part 2 of Theorem 3.2, and the consistency of $\widehat{\Gamma}_n$, we show that

$$\frac{n^{(1-\alpha d)/2}\sqrt{1+\alpha d}}{\|K\|_2}\left(\sqrt{\widehat{p}_n(x_j-x^*)}\;\widehat{\Gamma}_n^{-1/2}(\widehat{f}_n(x_j)-f(x_j))\right)_{1\leq j\leq q}\xrightarrow[n\to\infty]{\mathcal{L}}\mathcal{N}\,(0,\,I_{dq})\,.$$

Under H_0, $\|\widehat{A}_n-A\|+\|\widehat{B}_n-B\|\overset{\text{a.s.}}{=}O(\frac{\log\log n}{n})^{1/2}$ (see Theorem 4.1). Thus, it turns out that these linear terms are not contributing to the asymptotics. Therefore, we derive that under H_0,

$$\frac{n^{(1-\alpha d)/2}\sqrt{1+\alpha d}}{\|K\|_2}\left(\sqrt{\widehat{p}_n(x_j-x^*)}\,\widehat{\Gamma}_n^{-1/2}(\widehat{f}_n(x_j)-\widehat{A}_n^T\,x_j-\widehat{B}_n)\right)_{1\leq j\leq q}\xrightarrow[n\to\infty]{\mathcal{L}}\mathcal{N}\,(0,\,I_{dq})\,,$$

and then taking the square norm of this vector, we obtain the $\chi^2(dq)$ limiting distribution.

In addition, using the results of pointwise almost sure convergence of $\widehat{p}_n$ and $\widehat{f}_n$, the consistency of the LSE $\widehat{A}_n$ and $\widehat{B}_n$, and the almost sure limit of $\widehat{\Gamma}_n$, we easily derive that

$$\frac{n^{\alpha d-1}\,\|K\|_2^2}{1+\alpha d}\,T_q(n)\xrightarrow[n\to\infty]{\text{a.s.}}\sum_{j=1}^{q}p(x_j-x^*)\,\big\|f(x_j)-A^T\,x_j-B\big\|_{\Gamma^{-1}}^2\,,$$

and under H_1, the limit is strictly positive if there is $x\in\{x_1,\cdots,x_q\}$ such that $f(x)\neq A^T\,x+B$, which closes the proof of part 2.

If $\widehat{F}_n(x)$ is used in the definition of the test statistic $T_q(n)$ instead of $\widehat{f}_n(x)$, we proceed similarly using Theorem 3.2 and Remark B.1 of Appendix B to justify the different needed convergences of $\widehat{F}_n(x)$. □

These asymptotic results make it possible to construct a test of linearity for function f. Part 1 of Theorem 4.2 gives the null distribution, and part 2 guarantees that the asymptotic power of the test is equal to 1 since the test statistic explodes a.s.

5. Simulation study. Since only asymptotic results are available, this section is devoted to the following three main topics: the illustration of the behavior of the adaptive tracking control, the estimation of the noise p.d.f. and the results of the test of linearity for moderate sample size realizations.

In addition, since the control strategy can be used to focus around a special state-space location or, equivalently, to explore different operating points of the process, we deeply examine the real-valued simulated nonlinear unstable open-loop model defined by

$$X_{n+1}=\big(1.4+0.5\sin(X_n/3)\exp\big(-(X_n-118)^2/50\big)\big)\,X_n+U_n+\xi_{n+1},$$

where $\xi_n\sim\mathcal{N}(0,\,(1.2)^2)$, $X_0=5$, and $U_0=0$.

Let us denote by f the function defined by

$$f(x)=\big(1.4+0.5\sin(x/3)\exp\big(-(x-118)^2/50\big)\big)\,x.$$

The graph of f is given by the dotted line on Figure 5.3. This function is linear for large x and highly nonlinear for small x, and hence fits the theory maximally well. It also shows how the test for linearity can work in spite of "almost linearity" or "almost nonlinearity."

For the estimation of f, we take the bandwidth parameter $\alpha = 1/2$ and we use the Gaussian kernel with the usual normalization σ_K equal to the empirical standard deviation based on the last observations $X_{n-51}, \ldots, X_n$. The tracking trajectory is defined as follows:

$$X_n^* = x^* - (x^* - X_0^*) \exp(-\tau\, n) \quad \text{with } \tau = -(1/100) * \log(0.05).$$

This kind of tracking trajectory is usual and is such that the deviation between X_n^* and x^* is of 5% when $n = 100$. We choose the control law

$$U_n = -\widehat{f}_n(X_n)\mathbf{1}_{E_n}(X_n) - \widetilde{f}(X_n)\mathbf{1}_{\overline{E}_n}(X_n) + X_{n+1}^*,$$

where $\widetilde{f}(x) = x$ and $E_n = \{x \in \mathbb{R}^d;\ \|\widehat{f}_n(x) - \widetilde{f}(x)\| \leq 0.4\|x\| + 300\}$.

The first topic is the behavior of the adaptive control law as well as the closed-loop tracking performance.

5.1. Study of the adaptive control law. We study two typical situations depending on the value of x^*. With the first value of $x^* = 113$ (see Figures 5.1 to 5.4), the controlled process mainly explores the nonlinear part of the function f. On the other hand, with the second one, $x^* = 170$ (see Figures 5.5 to 5.8), the linear part of function f captures the data essentially.

Let us examine the "nonlinear" situation. In Figure 5.1, we can see the controlled process X_n superimposed with the tracking trajectory. We distinguish two periods: the transient part on the time interval [0, 200] and the near stationary part after time 200. The transient part can be divided again in two distinct periods: the starting period on the time interval [0, 100] and the overshoot period [100, 200]. During the starting period the closed-loop system is close to an unstable AR(1) process with coefficient 1.4. Since X_n^* goes sufficiently slowly towards its limit, the value of X_{n+1} is always in a small neighborhood of the last state-space locations leading to a local nonparametric estimator of good quality. On the other hand, during the overshoot period, the open-loop system is highly unstable and X_{n+1} is often far from the previous observations of the process, and therefore the local nonparametric estimator explores the nonlinear domain of the function f with only a few observations leading to a crude estimation. Nevertheless, the number of observations around x^* increases, and, therefore, the estimation of the function f becomes better and better and U_n matches the control objective.

In Figure 5.2, we see that the control effort is moderate on the time interval [0, 100] since the open-loop system is close to a linear system that is easy to be controlled. The control effort is very high afterward, since the open-loop system is locally highly unstable leading to the control burden (large slope). Nevertheless, this behavior is expected.

On Figures 5.3 and 5.4, one can appreciate the quality of the functional estimation of f explaining the good quality of the tracking performance after the learning period ending at time 200. The lack of proper fit in Figure 5.3 is a consequence of "lack of excitation" which is well known in a control context when tracking is the goal (see [3]).

Let us now examine the same plots but for $x^* = 170$. In contrast to the previous situation, the control effort is more regular since the local slope of function f is always the same, except for the nonlinear part corresponding to the process values within the time interval [100, 130]. As can be seen in Figure 5.5 and 5.6, both overshoots

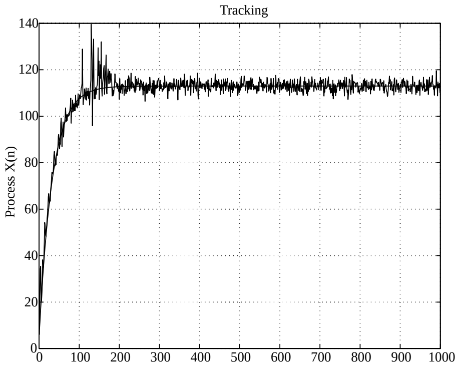

FIG. 5.1. *The process X_n superimposed with the tracking trajectory for $x^* = 113$.*

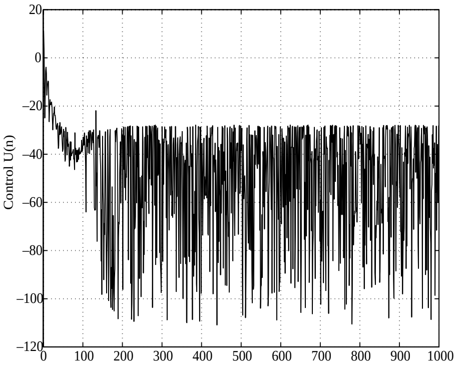

FIG. 5.2. *The corresponding adaptive control U_n.*

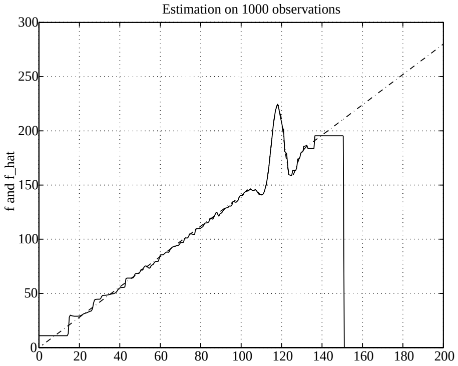

FIG. 5.3. *The true function (dashed line) superimposed with its nonparametric estimator. $x^* = 113$.*

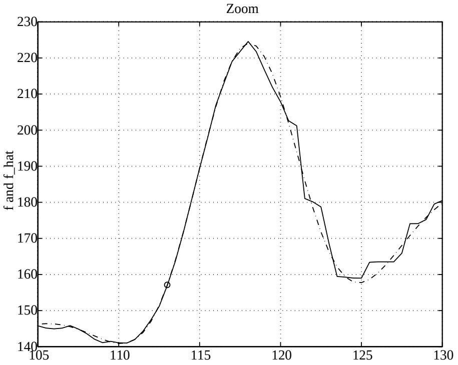

FIG. 5.4. *Zoom in Figure 5.3 showing the nonlinear part around the working point $x^* = 113$.*

for X_n and large values for U_n occur only when the data lie in this nonlinear part of function f. As in the above case, the nonparametric estimator behaves well.

A natural measure of the tracking performance is given by $\widehat{\Gamma}_n$. The result of Portier and Oulidi [14, Theorem 4.2], states that asymptotically, $\widehat{\Gamma}_n$ is equal to the noise variance Γ. Let us evaluate the quantity $(1/750)\sum_{k=251}^{1000}(X_k - X_k^*)^2$, which gives a good idea of Γ. For $x^* = 113$ and $x^* = 170$, we find 1.45 and 1.51, respectively, to be compared to the noise variance equal to 1.44.

Another way to illustrate the satisfactory behavior of the functional estimate of function f is to examine the estimation of the noise p.d.f. One can find in Figures 5.9 and 5.10 the estimates of $p(x - x^*)$ for $x^* = 113$ and $x^* = 170$, respectively, to compare with the p.d.f. of $\mathcal{N}(x^*, (1.2)^2)$. In both cases, these estimations are of good quality.

5.2. Test results for simulated data. The test defined in the previous section is global since H_0 assumes the function to be globally linear. Nevertheless, since n is finite and small, the noise ξ_n can be considered as bounded, and since the tracking objective is to put the process X_n near x^*, we can consider that we test the local linearity of the function f only on a neighborhood of x^* which contains almost all the values of the controlled process X_n. Then, we investigate various values of x^* in

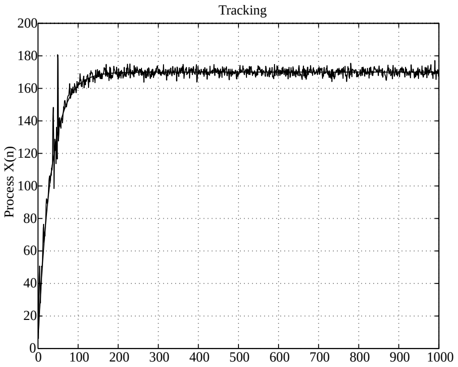

FIG. 5.5. *The process X_n superimposed with the tracking trajectory for $x^* = 170$.*

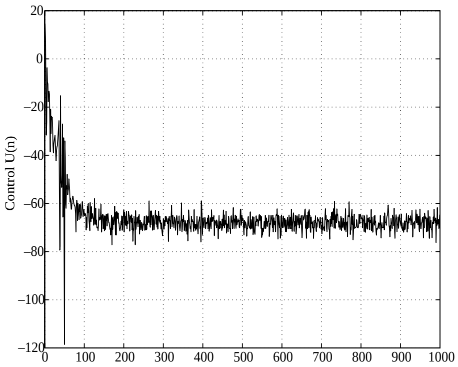

FIG. 5.6. *The corresponding adaptive control U_n.*

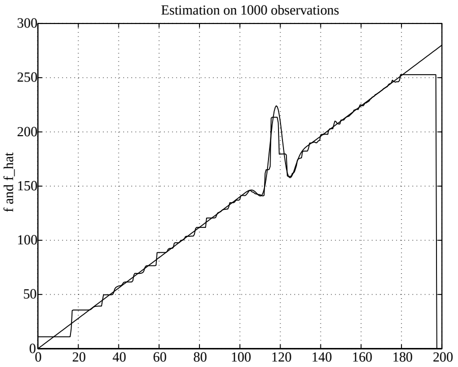

FIG. 5.7. *The true function (dashed line) superimposed with its nonparametric estimator. $x^* = 170$.*

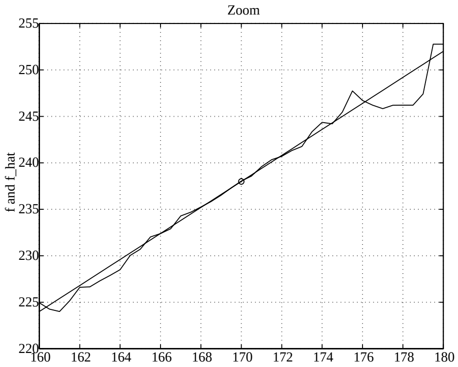

FIG. 5.8. *Zoom in Figure* 5.7 *showing the nonlinear part around the working point $x^* = 170$.*

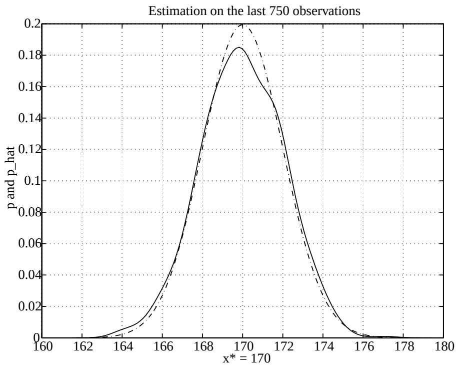

FIG. 5.10. *The true Gaussian density (dashed line) superimposed with its nonparametric estimator (dotted line). $x^* = 170$.*

order to illustrate the behavior of the test both under H_0 and under H_1. For $x^* = 70$ and $x^* = 170$, the actual system is close to a linear one, and for $x^* \in [100, 130]$, the actual system is nonlinear. One can find the selected working points in Figure 5.11.

Table 5.1
Test results under H_0. Level 5%. Percentage of rejections.

Working point	n	200	500	1000
$x^* = 70$	*Reject (%)*	2%	3.5%	3%
$t_{learn} = 200$	K.S	0.083	0.083	0.056
$x^* = 170$	*Reject (%)*	2%	4%	4%
$t_{learn} = 200$	K.S	0.087	0.086	0.088

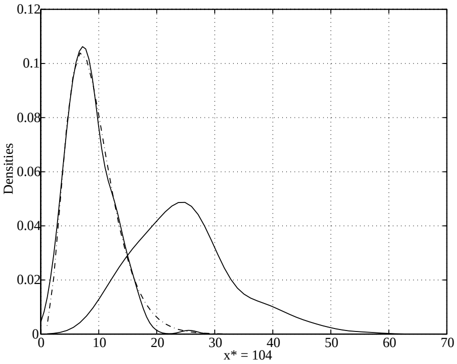

Fig. 5.12. *On the left, densities of $\sum_{i=1}^{10} Z_f^2(x_i)$ and $\chi^2(10)$, and on the right, density of $T_{10}(500)$.*

For each model, $m = 200$ independent realizations of length $n = 200, 500$, and 1000 are generated. We are interested in the empirical level under H_0 and the empirical power under H_1 as well as in the closeness between the simulated distribution of the test statistic and the corresponding theoretical distribution. We use the design points selection rule proposed in [15]. We take $q = 7$, 10, and 14 for $n = 200$, 500, and 1000, respectively.

Let us first examine the "linear" case. One can find in Table 5.1 the results obtained for $x^* = 70$ and $x^* = 170$. The closeness between the simulated distribution of the test statistic and the theoretical distribution is given by the Kolmogorow–Smirnoff (K.S.) statistic and is underlined if the test is rejected at the 5% level (the critical value is equal to 0.096). Only the data X_n obtained after time $n > t_{learn}$ are used for the test. The time t_{learn} corresponds to the end of the learning period needed to stabilize both X_n and $\widehat{f}_n$.

The empirical levels are close to the 5% theoretical level, and the simulated distribution of $T_q(n)$ is close to the $\chi^2(q)$ distribution even for moderate sample sizes.

Let us now examine the "nonlinear" case. Two problems are considered: the empirical power and the convergence in distribution under the alternative hypothesis.

In order to examine the last point, it is useful to check empirical power validity by measuring the closeness between the simulated distribution of $\sum_{i=1}^{q} Z_f^2(x_i)$ (since function f is known in the simulation case), and the $\chi^2(q)$ distribution, according to the following convergence result: $\sum_{i=1}^{q} Z_f^2(x_i) \underset{n\to\infty}{\xrightarrow{\mathcal{L}}} \chi^2(q)$, where

$$Z_f(x) = \sqrt{\frac{n^{1-\alpha}(1+\alpha)}{\|K\|_2^2\,\widehat{\Gamma}_n}}\sqrt{\widehat{p}_n(x-x^*)}\left(\widehat{f}_n(x) - f(x)\right). \tag{5.1}$$

TABLE 5.2

Working point	n	200	500	1000
$x^* = 110$	*Reject (%)*	99.5%	99%	99%
	K.S	0.082	0.033	0.090
$x^* = 118$	*Reject (%)*	100%	100%	100%
	K.S	0.034	0.033	0.092

The closeness between the two distributions is quantified by the classical K.S. statistic underlined in Table 5.2 if rejected at the 5% level.

For $x^* = 104$ and $n = 500$, these two densities (both centered at 10), and the density distribution of the test statistic $T_{10}(500)$ are shown in Figure 5.12, illustrating both reasonable convergence and the power of the test in this special case.

For various working points (see Figure 5.11), one can find in Table 5.2 the percentages of correct decisions obtained using a short learning period defined by $t_{learn} = 200$. The convergence results are quite satisfactory for $x^* = 104$, 107, 113, and 122 (see the K.S. statistic which is less than or near to the critical value) but remain unstable due to this too short learning period. For $x^* = 104$ and $x^* = 107$, the percentage of correct decisions is small for short sample sizes since the nonlinearity of function f is hard to detect. Nevertheless, this percentage increases with n and is close to 100% when $n = 1000$. So the test behaves well.

For the other working points $x^* = 110$ and 118, the learning period is too short in order to consider that the stationarity of the closed-loop model is sufficiently accurate. In Table 5.3, for a larger learning period of length $t_{learn} = 500$, the K.S. statistics become correct and the percentages of rejections are about 100%.

Appendix A. We give in this first appendix two useful results and their proofs. In what follows, the notation *cte* denotes any positive constant and $\mathcal{F} = (\mathcal{F}_n)_{n\geq 1}$ with $\mathcal{F}_n = \sigma(X_0, U_0, \xi_1, \ldots, \xi_n)$.

LEMMA A.1. *Assume that assumptions* [A1]–[A3] *hold. Let $\varphi : \mathbb{R}^d \to \mathbb{R}$ be a positive, Lipschitz, bounded function satisfying $\int \varphi(t)\,dt < \infty$, $\int \|t\|\,\varphi(t)\,dt < \infty$, and let γ and λ be two positive real numbers such that $\gamma \in\,]0,\, 1/d[$ and $\lambda \geq \gamma d$.*

Let us denote $L_n(x) = \sum_{i=1}^{n} i^{\lambda}\,\varphi\left(i^{\gamma}(X_i - x)\right)$, $\lambda' = \lambda - \gamma d + 1$, and $\overline{\varphi} = \int \varphi(t)\,dt$.

(1) *Then, for any $x \in \mathbb{R}^d$, $\lambda' n^{-\lambda'} L_n(x) \underset{n\to\infty}{\xrightarrow{\text{a.s.}}} \overline{\varphi}\, p(x - x^*)$.*

(2) *In addition, if* $\varphi(x) = O(\|x^{-\delta}\|)$ *with* $\delta > \frac{m\,\gamma\,d}{\gamma\,m+1}$, *then*

$$\sup_{x\in\mathbb{R}^d} \left|\lambda'\, n^{-\lambda'}\, L_n(x) - \overline{\varphi}\; p(x-x^*)\right| \;\xrightarrow[n\to\infty]{\text{a.s.}}\; 0.$$

Proof. Let us rewrite

$$L_n(x) - n^{\lambda'}\,\frac{\overline{\varphi}}{\lambda'}\,p(x-x^*) = M_n^L(x) + (L_n^c(x) - J_n(x)) + R_n(x), \tag{A.1}$$

where

$$M_n^L(x) = L_n(x) - L_n^c(x), \tag{A.2}$$

$$\begin{aligned} L_n^c(x) &= \sum_{i=1}^{n} i^{\lambda}\,\mathbb{E}\left[\varphi\left(i^{\gamma}(X_i - x)\right)\,/\,\mathcal{F}_{i-1}\right] \\ &= \sum_{i=1}^{n} \int i^{\lambda-\gamma d}\,\varphi(t)\,p\left(i^{-\gamma}t - \pi_{i-1} + x - X_i^*\right)\,dt, \end{aligned} \tag{A.3}$$

$$J_n(x) = \overline{\varphi}\;\sum_{i=1}^{n} i^{\lambda-\gamma d}\,p\left(x - \pi_{i-1} - X_i^*\right), \tag{A.4}$$

$$R_n(x) = J_n(x) - n^{\lambda'}\,\frac{\overline{\varphi}}{\lambda'}\,p(x-x^*). \tag{A.5}$$

Since $\lambda'\,n^{-\lambda'}\sum_{i=1}^{n}\; i^{\lambda-\gamma d} \xrightarrow[n\to\infty]{} 1$, $\overline{\varphi} < \infty$, $\int \|t\|\,\varphi(t)\,dt < \infty$, and $\|Dp\|_\infty < \infty$, where Dp denotes the gradient of p,

$$|R_n(x)| \le \overline{\varphi}\;\|Dp\|_\infty \sum_{i=0}^{n-1} i^{\lambda-\gamma d}\,\left(\|\pi_i\| + \|X_i^* - x^*\|\right) \tag{A.6}$$

$$\left|L_n^c(x) - J_n(x)\right| \le \|Dp\|_\infty \left(\int \|t\|\,\varphi(t)\,dt\right) \sum_{i=1}^{n}\; i^{\lambda-\gamma-\gamma d}. \tag{A.7}$$

Therefore, since $X_n^* \xrightarrow[n\to\infty]{} x^*$, $\sum_{k=0}^{n-1}\|\pi_k\|^2 \overset{\text{a.s.}}{=} o(n)$, and $\gamma > 0$, we derive that

$$\sup_{x\in\mathbb{R}^d} \left|\lambda' n^{-\lambda'}\; L_n^c(x) - \overline{\varphi}\; p(x-x^*)\right| \xrightarrow[n\to\infty]{\text{a.s.}} 0. \tag{A.8}$$

Now, let us study $M_n^L(x)$. For any $x \in \mathbb{R}^d$ and any $n \ge 1$, $M_n^L(x)$ is a square integrable martingale adapted to $\mathcal{F}$ for which we have, if we set $M_0^L(x) = 0$ and $\Delta_i(x) = M_i^L(x) - M_{i-1}^L(x)$,

$$\begin{aligned} \langle M^L(x)\rangle_n &= \sum_{i=1}^{n}\; \mathbb{E}\left[\Delta_i(x)^2/\mathcal{F}_{i-1}\right] \\ &\le \|p\|_\infty \left(\int \varphi^2(t)\,dt\right) \sum_{i=1}^{n} i^{2\lambda-\gamma d} = O\left(n^{1+2\lambda-\gamma d}\right). \end{aligned} \tag{A.9}$$

Then, from a strong law of large numbers for the martingales (for example, Duflo [5, Theorem 1.3.17, p. 21]), we obtain that for any $x \in \mathbb{R}^d$,

$$n^{-\lambda'}\; M_n^L(x) \xrightarrow[n\to\infty]{\text{a.s.}} 0. \tag{A.10}$$

Combining (A.8) and (A.10) gives part 1 of Lemma A.1.

To prove part 2, let us first establish the uniform almost sure convergence over dilating sets of $M_n^L(x)$. From (A.9), we have

$$\langle M(0)\rangle_n \leq \text{cte } n^{1+2\lambda-\gamma d}, \tag{A.11}$$

and since φ is supposed to be bounded,

$$|\Delta_n(0)| \leq \text{cte } n^{\lambda}. \tag{A.12}$$

In addition, since φ is supposed to be Lipschitz, we have for any $x, y \in \mathbb{R}^d$ and for any $\eta \in]0,\, 1[$,

$$\begin{aligned} \text{(A.13)}\ |\Delta_n(x) - \Delta_n(y)| &\leq \text{cte } n^{\lambda(1-\eta/2)}\, |\Delta_n(x) - \Delta_n(y)|^{\eta/2} \\ &\leq \text{cte } \|x-y\|^{\eta/2}\ n^{\lambda+\gamma\eta/2}, \\ \langle M^L(x) - M^L(y)\rangle_n &\leq \sum_{i=1}^n i^{2\lambda}\, \mathbb{E}\left[\left(\varphi\left(i^\gamma(X_i - x)\right) - \varphi\left(i^\gamma(X_i - y)\right)\right)^2/\mathcal{F}_{i-1}\right] \\ \text{(A.14)}\qquad &\leq \|p\|_\infty \sum_{i=1}^n i^{2\lambda-\gamma d} \int \left(\varphi(t) - \varphi(t + i^\gamma(x-y))\right)^{(2-\eta)+\eta}\, dt \\ &\leq \text{cte } \|x-y\|^\eta\ n^{1+2\lambda-\gamma d+\gamma\eta}. \end{aligned}$$

Then, with (A.11)–(A.14), the assumptions of Theorem 6.4.34 of Duflo [5] are fulfilled, and we derive that for any $A < \infty$, $\nu > 0$, and $t > \lambda - \frac{\gamma d}{2} + \frac{1}{2}$,

$$\sup_{\|\,x\,\| \leq A\, n^\nu} \left|M_n^L(x)\right| = o(n^t), \quad \text{a.s.,} \tag{A.15}$$

and, in particular, since $\gamma \in]0,\, 1/d[$, we can choose $t = \lambda'$. Then, combining (A.8) and (A.15), we obtain that for any $A < \infty$ and $\nu > 0$

$$\sup_{\|\,x\,\| \leq A\, n^\nu} \left|\lambda'\, n^{-\lambda'}\, L_n(x) - \overline{\varphi}\, p(x - x^*)\right| \xrightarrow[n\to\infty]{\text{a.s.}} 0. \tag{A.16}$$

Besides, since $\varphi(t) = O(\|t\|^{-\delta})$, then $L_n(x) \overset{\text{a.s.}}{=} O(\sum_{i=1}^n i^{\lambda-\gamma\delta}\, \|X_i - x\|^{-\delta})$.

Since $\sup_{k\leq n} \|X_k\| = o\left(n^{1/m}\right)$ a.s., there is an integer n^* such that for $n \geq n^*$, we have $\|X_n\| < n^{1/m}$. Hence, for x such that $\|x\| > 2\, n^{1/m}$, we have $\|X_n - x\| > n^{1/m}$ and

$$\sup_{\|x\| > 2\, n^{1/m}} n^{-\lambda'}\, L_n(x) = O(n^{\gamma d - \gamma\delta - \delta/m}) \ \text{ a.s.} \tag{A.17}$$

In addition, since $p > 0$ and $m > 2$, there is $\tau > 0$ such that $p(x) = o(\|x\|^{-\tau})$ and

$$\sup_{\|x\| > 2\, n^{1/m}} p(x - x^*) = o(n^{-\tau/m}), \tag{A.18}$$

and therefore, since $\tau > 0$ and $\delta > \frac{m\gamma d}{\gamma m + 1}$, we derive from (A.17) and (A.18) that

$$\sup_{\|x\| > 2\, n^{1/m}} \left|\lambda'\, n^{-\lambda'}\, L_n(x) - \overline{\varphi}\, p(x - x^*)\right| \xrightarrow[n\to\infty]{\text{a.s.}} 0, \tag{A.19}$$

and we close the proof of Lemma A.1 combining (A.19) and (A.16) with $A = 2$ and $\nu = 1/m$. □

Corollary A.2. *If we set* $L_n(x) = \sum_{i=1}^n i^\lambda \, \varphi\left(i^\gamma (X_i - X_i^* - x)\right)$, *then we obtain the results of Lemma* A.1 *with* $p(x)$ *instead of* $p(x - x^*)$.

Now we give a result of a strong law of large numbers for the process $(X_n)_{n\geq 1}$.

Lemma A.3. *Assume that* [A1]–[A3] *hold and that* $m > 4$. *Let* $g : \mathbb{R}^d \to \mathbb{R}$ *be a function such that*

$$|g(x) - g(y)| \leq \text{cte } \|x - y\| \left(1 + \|x\| + \|y\|\right). \tag{A.20}$$

Then, $\frac{1}{n} \sum_{k=1}^n g(X_k) \underset{n\to\infty}{\xrightarrow{\text{a.s.}}} \mathbb{E}\left(g(\xi_1 + x^*)\right)$.

Proof. Let us rewrite $\sum_{k=1}^n g(X_k) = M_n + \sum_{k=1}^n \mathbb{E}\left[g(X_k) \,/\, \mathcal{F}_{k-1}\right]$, where

$$M_n = \sum_{k=1}^n \left(g(X_k) - \mathbb{E}\left[g(X_k) \,/\, \mathcal{F}_{k-1}\right]\right).$$

Since

$$\mathbb{E}\left[g(X_k) \,/\, \mathcal{F}_{k-1}\right] - \mathbb{E}\left(g(\xi_1 + x^*)\right) = \int \left(g\left(u + \pi_{k-1} + X_k^*\right) - g(u + x^*)\right) p(u)\, du,$$

$$\begin{aligned}&\left|g\left(u + \pi_{k-1} + X_k^*\right) - g(u + x^*)\right| \\ &\quad \leq \text{cte } \|\pi_{k-1} + (X_k^* - x^*)\| \left(1 + \|u\| + \|\pi_{k-1}\| + \|X_k^* - x^*\|\right),\end{aligned}$$

and $\int \|u\| \; p(u)\, du < \infty$, we derive that

$$\left|\frac{1}{n}\sum_{k=1}^n \mathbb{E}\left[g(X_k) \,/\, \mathcal{F}_{k-1}\right] - \mathbb{E}\left(g(\xi_1 + x^*)\right)\right| = O\left(\frac{1}{n}\sum_{k=1}^n \left(\|\pi_{k-1}\|^2 + \|X_k^* - x^*\|^2\right)\right).$$

Therefore, since $X_n^* \underset{n\to\infty}{\longrightarrow} x^*$ and $\sum_{k=1}^n \|\pi_{k-1}\|^2 = o(n)$, a.s., then

$$\frac{1}{n}\sum_{k=1}^n \mathbb{E}\left[g(X_k) \,/\, \mathcal{F}_{k-1}\right] \underset{n\to\infty}{\xrightarrow{\text{a.s.}}} \mathbb{E}\left(g(\xi_1 + x^*)\right). \tag{A.21}$$

In addition, since $\sup_n \mathbb{E}\left[\|X_n\|^m\right] < \infty$ with $m > 4$, for any $n \geq 1$, M_n is a square integrable martingale adapted to $\mathcal{F}$ for which we have, if we set $M_0 = 0$,

$$\begin{aligned}\langle M\rangle_n &= \sum_{k=1}^n \mathbb{E}\left[\left(M_k - M_{k-1}\right)^2 /\mathcal{F}_{k-1}\right] \leq \sum_{k=1}^n \mathbb{E}\left[g^2(X_k)/\mathcal{F}_{k-1}\right]. \\ &= O\left(\sum_{k=1}^n \mathbb{E}\left[\left(1 + \|X_k\|^4\right)/\mathcal{F}_{k-1}\right]\right).\end{aligned} \tag{A.22}$$

Besides, since $\|X_k\|^4 = O(1 + \|\pi_{k-1}\|^4 + \|\xi_k\|^4)$ and $\mathbb{E}(\|\xi_1\|^4) < \infty$, we obtain that

$$\langle M\rangle_n = O\left(\sum_{k=1}^n (1 + \|\pi_{k-1}\|^4)\right) \;=\; o(n^{1+2/m}) \text{ a.s.} \tag{A.23}$$

Finally, since $m > 2$, we deduce from a strong law of large numbers for martingales that $n^{-1} M_n \underset{n\to\infty}{\xrightarrow{\text{a.s.}}} 0$. Lemma A.3 is established by combining this last result with (A.21). □

Appendix B. This appendix is concerned with the proof of Theorem 3.2. Without any restriction, we focus our attention on $\widehat{F}_n$, since the proofs of the results concerning $\widehat{F}_n$ and $\widehat{f}_n$ are the same. Indeed, in both cases, as mentioned in Remark 3.3, $\widehat{f}_n$ is used for the control law to ensure that the key property $\sum_{k=0}^{n-1} \|\pi_k\|^2 = o(n)$ holds.

For $x \in \mathbb{R}^d$, we can write

$$\text{(B.1)}\quad n^{(1-\beta d)/2}\left(\widehat{F}_n(x) - f(x)\right) = \frac{n}{H_{n-1}(x)}\left(n^{-(1+\beta d)/2}(R_{n-1}(x) + M_n(x))\right),$$

where

$$\text{(B.2)}\qquad H_{n-1}(x) = \sum_{i=0}^{n-1} i^{\beta d} G\left(i^{\beta}(X_i - x)\right),$$

$$\text{(B.3)}\qquad R_{n-1}(x) = \sum_{i=0}^{n-1} i^{\beta d} G\left(i^{\beta}(X_i - x)\right)(f(X_i) - f(x)),$$

$$\text{(B.4)}\qquad M_n(x) = \sum_{i=0}^{n-1} i^{\beta d} G\left(i^{\beta}(X_i - x)\right)\xi_{i+1}.$$

Let us study the convergence of the three terms $n^{-1}H_{n-1}(x)$, $n^{-(1+\beta d)/2}R_{n-1}(x)$, and $n^{-(1+\beta d)/2}M_n(x)$, respectively.

Applying Lemma A.1 with $\varphi = G$, $\lambda = \beta d$, and $\gamma = \beta$ gives for $\beta \in \,]0, 1/d[$

$$\text{(B.5)}\qquad \frac{1}{n} H_{n-1}(x) \underset{n\to\infty}{\overset{\text{a.s.}}{\longrightarrow}} p(x - x^*).$$

For $x \in \mathbb{R}^d$, $M_n(x)$ is a square integrable martingale adapted to $\mathcal{F}$ for which we have

$$\text{(B.6)}\qquad \begin{aligned}\langle M(x)\rangle_n &= \sum_{i=1}^{n} \mathbb{E}\left[(M_i(x) - M_{i-1}(x))(M_i(x) - M_{i-1}(x))^T \;/\mathcal{F}_{i-1}\right]\\ &= \left(\sum_{i=0}^{n-1} i^{2\beta d}\, G^2\left(i^{\beta}(X_i - x)\right)\right)\Gamma.\end{aligned}$$

Since G is Lipschitz and bounded, G^2 is also Lipschitz and bounded. Then, by Lemma A.1 used with $\varphi = G^2$, $\lambda = 2\beta d$, and $\gamma = \beta$,

$$\text{(B.7)}\qquad n^{-(1+\beta d)}\langle M(x)\rangle_n \underset{n\to\infty}{\overset{\text{a.s.}}{\longrightarrow}} \frac{\|G\|_2^2}{1+\beta d}\, p(x - x^*)\,\Gamma.$$

Now to apply the central limit theorem for the martingales to $n^{-(1+\beta d)/2}M_n(x)$ (see, for example, Duflo [5, Theorem 2.1.9, p. 46]), Lindeberg's condition remains to be proved. Let us denote $\tau_i = i^{\beta d}G(i^{\beta}\,(X_i - x))\xi_{i+1}$ and $\Phi(c) = \mathbb{E}[\|\xi_1\|^2\, \mathbf{1}_{\{\|\,\xi_1\,\| \,\geq\, c\}}]$.

For $\varepsilon > 0$, we have

$$\text{(B.8)}\qquad \begin{aligned}\rho_n(\varepsilon) &= n^{-(1+\beta d)} \sum_{i=0}^{n-1} \mathbb{E}\left[\|\tau_i\|^2\, \mathbf{1}_{\left\{\|\tau_i\| \geq n^{(1+\beta d)/2}\varepsilon\right\}}/\mathcal{F}_i\right]\\ &\leq n^{-(1+\beta d)}\; \Phi\left(\frac{n^{(1-\beta d)/2}\varepsilon}{\|G\|_\infty}\right)\sum_{i=0}^{n-1} i^{2\beta d}G^2\left(i^{\beta}(X_i - x)\right).\end{aligned}$$

Besides, for $i \geq 1$,

$$\mathbb{E}\left[i^{2\beta d} G^2\left(i^\beta (X_i - x)\right) / \mathcal{F}_{i-1}\right] \leq i^{\beta d} \|p\|_\infty \|G\|_2^2, \tag{B.9}$$

and thus,

$$\mathbb{E}\left(\rho_n(\varepsilon)\right) \leq \text{cte}\left(n^{-(1+\beta d)} \sum_{i=0}^{n-1} i^{\beta d}\right) \Phi\left(\frac{n^{(1-\beta d)/2}\varepsilon}{\|G\|_\infty}\right). \tag{B.10}$$

Since $n^{-(1+\beta d)} \sum_{i=0}^{n-1} i^{\beta d}$ has a finite limit and since $\lim_{c\to\infty} \Phi(c) = 0$ (since ξ has a finite moment of order $m > 2$), we derive that for $\beta \in]0,\, 1/d[$,

$$\forall \varepsilon > 0, \quad \rho_n(\varepsilon) \xrightarrow[n\to\infty]{\mathrm{P}} 0, \tag{B.11}$$

and Lindeberg's condition is fulfilled. Therefore, for $x \in \mathbb{R}^d$ and $\beta \in]0,\, 1/d[$,

$$n^{-(1+\beta d)/2} M_n(x) \xrightarrow[n\to\infty]{\mathcal{L}} \mathcal{N}\left(0,\, \frac{\|G\|_2^2}{(1+\beta d)}\, p(x - x^*)\, \Gamma\right). \tag{B.12}$$

Now, let us show that for $x \in \mathbb{R}^d$ and $\beta > 1/(d+4)$,

$$n^{-(1+\beta d)/2}\, R_{n-1}(x) \xrightarrow[n\to\infty]{\text{a.s.}} 0. \tag{B.13}$$

First, let us rewrite $R_n(x)$ under the form

$$R_n(x) = \left(R_n(x) - R_n^c(x)\right) + \left(R_n^c(x) - Q_n(x)\right) + Q_n(x), \tag{B.14}$$

where

$$\begin{aligned} R_n^c(x) &= \sum_{i=1}^n i^{\beta d} \mathbb{E}\left[G\left(i^\beta (X_i - x)\right) \left(f(X_i) - f(x)\right) / \mathcal{F}_{i-1}\right] \\ &= \sum_{i=1}^n \int G(t) \left(f(i^{-\beta} t + x) - f(x)\right) p\left(i^{-\beta} t + x - f(X_{i-1}) - U_{i-1}\right) dt, \\ Q_n(x) &= \sum_{i=1}^n p\left(x - f(X_{i-1}) - U_{i-1}\right) \int G(t)\, \left(f(i^{-\beta} t + x) - f(x)\right) dt. \end{aligned}$$

Since f is Lipschitz, $\|Dp\|_\infty < \infty$, and $\int \|t\|^2 G(t)\, dt < \infty$, we easily show that

$$\sup_{x\in\mathbb{R}^d} \|R_n^c(x) - Q_n(x)\| = O\left(n^{1-2\beta}\right) \quad \text{a.s.} \tag{B.15}$$

Let us denote f_ℓ the ℓth component of f. Since f is supposed to be $\mathcal{C}^2$−class, for $1 \leq \ell \leq d$, we have the expansion

$$f_\ell(i^{-\beta} t + x) - f_\ell(x) = \sum_{j=1}^d i^{-\beta}\, t_j\, \frac{\partial f_\ell}{\partial x_j}(x) + \frac{1}{2} \sum_{j=1}^d \sum_{k=1}^d i^{-2\beta}\, t_j\, t_k\, \frac{\partial^2 f_\ell}{\partial x_j \partial x_k}(z)$$

with $z \in \left[x,\, x + i^{-\beta} t\right]$. Thus, since $\int t_j G(t)\, dt = 0$ for any $j = 1, \ldots, d$, we derive that

$$\left\| \int G(t)\, \left(f(i^{-\beta} t + x) - f(x)\right) dt \right\| = O\left(i^{-2\beta}\right), \tag{B.16}$$

and since p is bounded, then we have

$$\sup_{x\in\mathbb{R}^d} \|Q_n(x)\| = O\left(n^{1-2\beta}\right) \quad \text{a.s.} \tag{B.17}$$

For $x \in \mathbb{R}^d$, $M_n^R(x) = R_n(x) - R_n^c(x)$ is a square integrable martingale adapted to $\mathcal{F}$ for which we have

$$\sum_{i=1}^{n} \mathbb{E}\left[\left\|M_i^R(x) - M_{i-1}^R(x)\right\|^2 / \mathcal{F}_{i-1}\right] = O\left(\sum_{i=1}^{n} i^{\beta d - 2\beta}\right) \quad \text{a.s.,} \tag{B.18}$$

since f is Lipschitz, G is bounded, $\|p\|_\infty < \infty$, and $\int \|t\|^2 G(t)\, dt < \infty$. Therefore, using a result of a strong law of large numbers for the martingales, we obtain that for $\delta > 0$,

$$M_n^R(x) = o(n^{(1+\beta d)/2-\beta} (\log n)^{(1+\delta)/2}) \quad \text{a.s.} \tag{B.19}$$

Then, using results (B.15), (B.17), and (B.19), we prove (B.13) as soon as $\beta > 1/(d+4)$. Finally, combining (B.5), (B.12), and (B.13), we obtain that for $x \in \mathbb{R}^d$, $\beta < 1/d$, and $\beta > 1/(d+4)$,

$$n^{(1-\beta d)/2}(\widehat{F}_n(x) - f(x)) \xrightarrow[n\to\infty]{\mathcal{L}} \mathcal{N}\left(0, \frac{\|G\|_2^2}{(1+\beta d)\, p(x-x^*)}\, \Gamma\right). \tag{B.20}$$

Now following Duflo [5], let us study the joint asymptotic normality. Taking the previous results into account, it suffices to prove that for q distinct points of $\mathbb{R}^d$, denoted $x_1, \ldots, x_q$, the vector $n^{-(1+\beta d)/2} (M_n(x_1), \ldots, M_n(x_q))$ converges in distribution to a centered Gaussian vector with independent components. We easily verify this by remarking that for $x \neq y$,

$$n^{-(1+\beta d)} \sum_{i=1}^{n-1} i^{2\beta d}\, G\left(i^\beta(X_i - x)\right)\, G\left(i^\beta(X_i - y)\right) \xrightarrow[n\to\infty]{\text{a.s.}} 0.$$

This completes the proof of Theorem 3.2.

Remark B.1. From (B.6) it follows easily that

$$\mathbb{E}\left[\|\langle M(x)\rangle_n\|\right] = O\left(n^{1+\beta d}\right). \tag{B.21}$$

Then, from a strong law of large numbers, we derive that $n^{-1} M_n(x) \xrightarrow[n\to\infty]{\text{a.s.}} 0$ for all $\beta \in]0,\, 1/d[$, and combining this result with (B.5), (B.15), (B.17), and (B.19) gives

$$\widehat{F}_n(x) \xrightarrow[n\to\infty]{\text{a.s.}} f(x). \tag{B.22}$$

This result is useful to prove part 2 of Theorem 4.2 when $\widehat{F}_n(x)$ is used in the construction of the test statistic $T_q(n)$ instead of $\widehat{f}_n(x)$.

CONTROLLABILITY OF SYSTEMS DESCRIBED BY CONVOLUTIONAL OR DELAY-DIFFERENTIAL EQUATIONS*

P. VETTORI† AND S. ZAMPIERI†

Abstract. In this paper, infinite dimensional systems described by convolutional equations and, in particular, by delay-differential equations are considered. Different controllability notions for this class of linear time-invariant systems are discussed and compared. A characterization of spectral controllability for a system whose trajectories satisfy a homogeneous system of independent convolutional equations is given. This result extends an analogous result which was known to hold for difference or differential equations. Finally, for a particular class of systems, including systems in the state space form, it is shown that a well-known theorem, which states the equivalence of spectral controllability and the existence of an image representation, holds true. An example is presented showing that this result is false for generic delay-differential systems as soon as there are two noncommensurate delays.

Key words. convolutional equations, delay-differential systems, linear systems, behavioral approach, functional equations, distributed delays, controllability

1. Introduction.

In solving control and optimization problems, the analysis of system controllability is always an important preliminary step. Differently from what happens for linear finite dimensional systems, for linear infinite dimensional systems controllability can be defined in various ways, and, moreover, its characterization is often a difficult task. For the class of infinite dimensional systems described by linear differential equations with delays, something more can be said, in particular, when the delays are commensurate, i.e., when they are multiples of a single delay. In [7] various definitions of controllability are proposed and compared for this class of systems.

The notion of controllability that has been analyzed in more detail in literature is the so-called spectral controllability, because it plays an important role in the spectrum assignment problem. For systems with commensurate delays, this controllability notion has been interpreted in terms of trajectories steering in [9, 23]. The use of the behavioral approach and, in particular, the notion of behavioral controllability which arises in this framework has been essential for obtaining these results.

For this reason, in this paper we will follow this approach in the analysis of controllability of delay systems and we will try to extend the results in [9, 23] to systems with noncommensurate delays and, more in general, to systems described by convolutional equations.

Now we briefly recall the notion of a dynamical system in the behavioral approach and the definition of controllability. According to this approach a dynamical system is defined as a triple

$$\Sigma = (T, W, \mathcal{B}),$$

where T denotes the time set, W denotes the system alphabet, and $\mathcal{B}$, which is a subset of the set W^T of all the trajectories, represents the set of trajectories which

†Dipartimento di Elettronica e Informatica, Università di Padova, via Gradenigo 6/a, 35131 Padova, Italy (p.vettori@dei.unipd.it, zampi@dei.unipd.it).

are allowed by the dynamical constraints imposed by the system. This is called the behavior of the system.

In this paper we will consider only systems with time set $T = \mathbb{R}$ and with time invariant behavior $\mathcal{B}$, i.e., such that for any $w \in \mathcal{B}$ we have $\sigma_\tau w \in \mathcal{B}$ for every $\tau \in \mathbb{R}$. (σ_τ is the forward shift operator which will be defined in section 2.1.) These systems will be called continuous time-invariant systems.

Differently from what happens in the classical systems theory, controllability is defined as an intrinsic property of the system rather than a property of a state space representation of the system.

Definition 1.1. *A continuous time-invariant system $\Sigma = (\mathbb{R}, W, \mathcal{B})$ is controllable if for every $w_1, w_2 \in \mathcal{B}$ there exists a trajectory $\bar{w} \in \mathcal{B}$ and a $T > 0$ such that*

$$\bar{w}(t) = \begin{cases} w_1(t) & \textit{if } t \le 0, \\ w_2(t-T) & \textit{if } t \ge T. \end{cases} \tag{1}$$

Loosely speaking, given two trajectories of a controllable behavior, there exists a trajectory in the behavior that shares the “past” with the first one and the “future” with the second one.

In the first papers devoted to the behavioral approach [22, 27], a rather complete theory for systems described by linear differential equations has been developed. Moreover, a complete characterization of controllability has been proposed. More specifically, the class of continuous systems that has been analyzed in [22] has time set $T = \mathbb{R}$, system alphabet $W = \mathbb{R}^q$, and behavior

$$\mathcal{B} = \ker R\left(\tfrac{d}{dt}\right) \triangleq \{w \in C^\infty(\mathbb{R}, \mathbb{R}^q) \text{ such that } R\left(\tfrac{d}{dt}\right) w = 0\},$$

where $R\left(\frac{d}{dt}\right) \in \mathbb{R}\left[\frac{d}{dt}\right]^{p\times q}$ is a polynomial differential operator acting from $C^\infty(\mathbb{R}, \mathbb{R}^q)$ to $C^\infty(\mathbb{R}, \mathbb{R}^p)$. The polynomial matrix provides a so-called kernel representation of the system behavior $\mathcal{B}$. It may happen that the behavior $\mathcal{B}$ also admits an image representation. This means that there exists a polynomial matrix $M\left(\frac{d}{dt}\right) \in \mathbb{R}\left[\frac{d}{dt}\right]^{q\times d}$ such that

$$\mathcal{B} = \operatorname{im} M\left(\tfrac{d}{dt}\right) \triangleq \{w = M\left(\tfrac{d}{dt}\right) v \in C^\infty(\mathbb{R}, \mathbb{R}^q) \text{ with } v \in C^\infty(\mathbb{R}, \mathbb{R}^d)\}.$$

One of the main results shown in [22] is that the existence of an image representation is equivalent to the controllability of the system. More precisely, we have the following theorem [22, Thm. 5.2.5, 6.6.1].

Theorem 1.2. *Given the matrix $R\left(\frac{d}{dt}\right) \in \mathbb{R}\left[\frac{d}{dt}\right]^{p\times q}$ and the behavior $\mathcal{B} = \ker R\left(\frac{d}{dt}\right)$, the following conditions are equivalent.*

1. *$R(\lambda)$ has constant rank for all $\lambda \in \mathbb{C}$.*
2. *$\mathcal{B}$ is controllable.*
3. *$\mathcal{B}$ admits an image representation: $\mathcal{B} = \operatorname{im} M\left(\frac{d}{dt}\right)$, where $M\left(\frac{d}{dt}\right) \in \mathbb{R}\left[\frac{d}{dt}\right]^{q\times d}$.*

Condition 1 corresponds to a generalized Popov–Belevitch–Hautus (PBH) test condition, which is also called spectral controllability.

In the discrete case [27, Thm. V.2, V.3], a similar result holds true. Actually, all the conditions in the previous theorem are shown [26, Prop. 4.3] to be equivalent to the fact that

$$\mathcal{B} = \overline{\mathcal{B}_{\text{cs}}},$$

where $\mathcal{B}_{\mathrm{cs}}$ means the subset of $\mathcal{B}$ constituted of trajectories which have compact support and where $\bar{\cdot}$ means closure with respect to the pointwise convergence topology in the space of all sequences. It can be shown that a similar equivalence holds true also in the continuous time case if we take on $C^\infty(\mathbb{R}, \mathbb{R}^q)$ the standard Fréchet topology of the uniform convergence of derivatives of any order on compacts.

Consider now the situation in which we take behaviors that are kernel of polynomial matrices in the derivative and in one delay operator. More precisely, consider continuous time systems whose behaviors satisfy the relation

$$\mathcal{B} = \{w \in C^\infty(\mathbb{R}, \mathbb{R}^q) \ : \ R\left(\tfrac{d}{dt}, \sigma\right) w = 0\} = \ker R\left(\tfrac{d}{dt}, \sigma\right),$$

where σ is the unitary shift operator $(\sigma f)(t) = f(t-1)$, and where $R\left(\frac{d}{dt}, \sigma\right) \in \mathbb{R}\left[\frac{d}{dt}, \sigma\right]^{p \times q}$ is a polynomial matrix in two variables.

These systems are called differential systems with one delay or with commensurate delays. They have been analyzed in [9, 23], in which the following result has been shown.

THEOREM 1.3. *Given the matrix* $R\left(\frac{d}{dt}, \sigma\right) \in \mathbb{R}\left[\frac{d}{dt}, \sigma\right]^{p \times q}$ *and the behavior* $\mathcal{B} = \ker R\left(\frac{d}{dt}, \sigma\right)$*, the following conditions are equivalent.*

1. $R(\lambda, e^{-\lambda})$ *has constant rank for all* $\lambda \in \mathbb{C}$.
2. $\mathcal{B}$ *is controllable.*
3. $\mathcal{B}$ *admits an image representation* $\mathcal{B} = \operatorname{im} M\left(\frac{d}{dt}, \sigma\right)$*, where* $M\left(\frac{d}{dt}, \sigma\right) \in \mathbb{R}\left[\frac{d}{dt}, \sigma\right]^{q \times d}$.

The above result is similar to Theorem 1.2. Condition 1 is the generalization of spectral controllability for delay-differential systems. It is possible to prove that condition $\mathcal{B} = \overline{\mathcal{B}_{\mathrm{cs}}}$ is equivalent to controllability even in this case. This is a direct consequence of the results we present in this contribution (see Remark 4.8).

In this paper we will present some results on controllability for linear continuous time systems with several noncommensurate delays. We will show to what extent the results presented in [22, 26, 27] and extended in the one-delay case in [9, 23] continue to hold true also in the multidelay case.

More specifically, in this paper we will prove that Theorem 1.3 can be extended to the multidelay case as well as to more generic convolutional operators only partially. We will present a theorem showing what extension is possible in general and a counterexample showing that a complete extension does not hold. Finally, we will specify an interesting subclass of systems for which a complete extension is possible.

Our interest in studying differential systems with several noncommensurate delays is not only of theoretical nature. It is quite clear that a family of noncommensurate delays can be approximated arbitrarily well by a family of delays which are multiples of a single delay. Therefore, one could argue that any differential system with several noncommensurate delays can be approximated by a differential system with only one delay. This is correct in principle. However, we must pay attention to a delicate point: the analysis of systems with noncommensurate delays is important just because sometimes the approximating differential system with one delay may have different structural properties with respect to the original system to be approximated. Example 3.4 describes a differential system with two delays: the system is spectrally controllable if and only if the delays are noncommensurate. However, it admits an image representation only if the ratio of the delays is not a Liouville irrational number (see Proposition 2.6).

Furthermore, observe that even if an approximation would make sense, the better the approximation is, the higher the degrees of the delay-differential operators describing the approximating system have to be, thus giving rise to computational complexity problems.

2. Notation and preliminaries.

In this section we introduce the notation which will be used in this paper. We recall the most important properties of the function spaces and operator algebras which will be considered in the following sections.

2.1. Function spaces and functionals.

We will consider only behaviors that are subsets of smooth functions. More precisely, if we denote by $\mathcal{E}$ the set of infinitely differentiable functions $C^\infty(\mathbb{R},\mathbb{R})$ equipped with the standard Fréchet topology (uniform convergence of derivatives of any order on compacts), then behaviors considered in this paper are always subspaces of $\mathcal{E}^q$ for some positive $q \in \mathbb{N}$.

The subspace of smooth functions having compact support (test functions) is denoted by $\mathcal{D}$, and the set of holomorphic functions on $\mathbb{C}$ is denoted by $\mathcal{O}$.

These spaces have topological duals, i.e., the sets of continuous linear functionals. It is well known that the topological dual $\mathcal{D}'$ of $\mathcal{D}$ coincides with the space of Schwartz distributions, while the topological dual $\mathcal{E}'$ of $\mathcal{E}$ consists in that subset of $\mathcal{D}'$ constituted by compact support distributions [24, Thm. 24.2].

The value of $\alpha \in \mathcal{E}'$ at $w \in \mathcal{E}$ is denoted by $\langle \alpha, w \rangle \in \mathbb{R}$. The shift operator σ_τ, with delay $\tau \in \mathbb{R}$, is defined for every $w \in \mathcal{E}$ as $(\sigma_\tau w)(t) \triangleq w(t-\tau)$. This operator can be used to show how every distribution $\alpha \in \mathcal{E}'$ acts on $\mathcal{E}$ by mapping $w \in \mathcal{E}$ into the convolution $(\alpha \star w)(t) \triangleq \langle \alpha, \sigma_t w \rangle$. It can be shown that convolutions are still in $\mathcal{E}$ and that in this way $\mathcal{E}'$ is isomorphic to the set of continuous linear operators on $\mathcal{E}$ that commute with σ_τ for every $\tau \in \mathbb{R}$ (see [25, Thm. 2.16]).

2.2. Paley–Wiener functions.

It is possible to define the Laplace transforms of distributions in $\mathcal{E}'$ [24, Exercise 25.20]. The Laplace transform maps a distribution with compact support $\alpha \in \mathcal{E}'$ into $\hat{\alpha}(s) \triangleq \langle \alpha, e^{-st} \rangle$, where α acts on e^{-st}, regarded as a function of t with parameter $s \in \mathbb{C}$. It can be seen that $\hat{\alpha}(s)$ is always a holomorphic function [24, Prop. 29.1].

If $a(s) \in \mathcal{O}$ is the Laplace transform of $\alpha \in \mathcal{E}'$ and $w \in \mathcal{E}$ is a smooth function, convolutions will be denoted also as

$$a(s)w \triangleq \alpha \star w \in \mathcal{E}.$$

It can be seen that, given $\alpha, \beta \in \mathcal{E}'$, there is a unique distribution denoted by $\alpha \star \beta \in \mathcal{E}'$, called the convolution of α and β, such that $\alpha \star (\beta \star w) = (\alpha \star \beta) \star w$ for every $w \in \mathcal{E}$; moreover, the Laplace transform of a convolution is the product of the transforms $\widehat{\alpha \star \beta}(s) = \hat{\alpha}(s)\hat{\beta}(s)$. Actually this is a classical and fundamental result. The Paley–Wiener theorem [2, p. 27–28] states that the convolutional algebra of distributions with compact support is isomorphic, via Laplace transform, to the multiplicative algebra of Paley–Wiener functions so defined:

$$(2) \qquad \mathcal{A} \triangleq \{a(s) \in \mathcal{O} \text{ such that } \exists A, B, C > 0,\ |a(s)| \le A(1+|s|)^B e^{C|\operatorname{Re} s|}\ \forall s \in \mathbb{C}\}.$$

In this context, every matrix $M(s) = [m_{ij}(s)] \in \mathcal{A}^{p \times q}$ represents two distinct operators. On one hand, it acts as a convolutional operator on (column) vectors with entries in $\mathcal{E}$, i.e.,

$$M(s) : \mathcal{E}^q \to \mathcal{E}^p,\ w \mapsto v = M(s)w, \text{ i.e., } v_i = \sum_{j=1}^{q} m_{ij}(s) w_j.$$

On the other hand, it can be seen as a linear transformation on (row) vectors with entries in $\mathcal{A}$. To distinguish the different meanings of the same matrix, we use in this case the following notation:

$$\circ M(s) : \mathcal{A}^p \to \mathcal{A}^q,\ a(s) \mapsto b(s) = a(s)M(s),\ \text{i.e., } b_j(s) = \sum_{i=1}^{p} a_i(s)m_{ij}(s).$$

Therefore, the kernel and image of a matrix $M(s) \in \mathcal{A}^{p\times q}$ depend on the operator it represents. When it operates "on the right," usually on $\mathcal{E}$, we have

$$\begin{aligned} \ker_{\mathcal{E}} M(s) &\triangleq \{w \in \mathcal{E}^q \text{ such that } M(s)w = 0\}, \\ \operatorname{im}_{\mathcal{E}} M(s) &\triangleq \{M(s)w \in \mathcal{E}^p \text{ with } w \in \mathcal{E}^q\}. \end{aligned}$$

Conversely, if $M(s)$ represents the linear transformation acting "on the left" on vectors, whose entries are usually in $\mathcal{A}$, we get

$$\begin{aligned} \ker_{\mathcal{A}} \circ M(s) &\triangleq \{a(s) \in \mathcal{A}^p \text{ such that } a(s)M(s) = 0\}, \\ \operatorname{im}_{\mathcal{A}} \circ M(s) &\triangleq \{a(s)M(s) \in \mathcal{A}^q \text{ with } a(s) \in \mathcal{A}^p\} = \mathcal{A}^p M(s). \end{aligned}$$

We remark that, with this convention, $\circ M(s)$ is the adjoint of $M(s)$, and, if we define orthogonals of subsets $E \subseteq \mathcal{E}^q$ or $A \subseteq \mathcal{A}^q$ as

$$E^\perp \triangleq \{a(s) \in \mathcal{A}^q : a(s)w = 0 \ \ \forall w \in E\}, \quad A^\perp \triangleq \{w \in \mathcal{E}^q : a(s)w = 0 \ \ \forall a(s) \in A\},$$

then we can write in a simple way a fundamental result about duality between adjoint operators. (For the proof see, e.g., [24, p. 388], which states the proposition in terms of "polars" [24, p. 196], which in our context coincide with orthogonals.)

PROPOSITION 2.1. *For every $M(s) \in \mathcal{A}^{p\times q}$,*

$$\begin{aligned} \ker_{\mathcal{E}} M(s) &= \operatorname{im}_{\mathcal{A}} \circ M(s)^\perp, & \ker_{\mathcal{E}} M(s)^\perp &= \overline{\operatorname{im}_{\mathcal{A}} \circ M(s)}, \\ \ker_{\mathcal{A}} \circ M(s) &= \operatorname{im}_{\mathcal{E}} M(s)^\perp, & \ker_{\mathcal{A}} \circ M(s)^\perp &= \overline{\operatorname{im}_{\mathcal{E}} M(s)}. \end{aligned}$$

Another useful property of adjoint operators is the following proposition (see [16, Prop. 21.9]).

PROPOSITION 2.2. *For every $M(s) \in \mathcal{A}^{p\times q}$, $\operatorname{im}_{\mathcal{E}} M(s)$ is closed if and only if $\operatorname{im}_{\mathcal{A}} \circ M(s)$ is closed.*

2.3. Operator subalgebras of $\mathcal{A}$.

The notation we have introduced so far permits us to treat differential or delay-differential polynomial operators in a unified manner. Indeed, the action on smooth functions of both the derivative operator $\frac{d}{dt}$ and of the shift operator σ_τ corresponds to a convolution with the distributions in $\mathcal{E}'$ having Laplace transforms s and $e^{-s\tau}$, respectively.

This fact explains why polynomials in $\frac{d}{dt}$ and σ are also called exponential polynomials, being actually isomorphic, through Laplace transform, to elements in the ring $\mathbb{R}\left[s, e^{-s}\right]$ which is in turn isomorphic to the ring of polynomials in two variables $\mathbb{R}[z_0, z_1]$.

Consider now equations involving more delays: if the delays belong to the set $T = \{t_j,\, j = 1, \dots, M\}$, the ring of polynomials in σ_{t_j} is still isomorphic to the ring of polynomials in e^{-st_j}, but not to the ring of polynomials in M indeterminates. However, consider the $\mathbb{Z}$-module generated by $t_1, \dots, t_M$. Being free, it has a basis

$\tau_1, \dots, \tau_m$ composed by positive elements that are also $\mathbb{Q}$-independent. Thus they are called noncommensurate. Observe that in this case polynomials in the delays σ_{τ_i}, polynomials in $e^{-s\tau_i}$, and polynomials in m variables are isomorphic [15, Thm. 1], i.e.,

$$\mathbb{R}[e^{-s\tau_1}, \dots, e^{-s\tau_m}] \cong \mathbb{R}[z_1, \dots, z_m]. \tag{3}$$

However, in order to represent the operators $\sigma_{t_1}, \dots, \sigma_{t_M}$ as a linear combination of powers of $\sigma_{\tau_1}, \dots, \sigma_{\tau_m}$, we have to consider polynomials also with negative powers in σ_{τ_i}, called Laurent polynomials. It can be seen that

$$\mathcal{R}_m \triangleq \mathbb{R}[e^{-s\tau_1}, \dots, e^{-s\tau_m}, e^{s\tau_1}, \dots, e^{s\tau_m}] \cong \mathbb{R}[e^{-st_1}, \dots, e^{-st_M}, e^{st_1}, \dots, e^{st_M}],$$

while a similar result does not hold if we consider the ring of standard polynomials. Observe that, by virtue of (3), we obtain that

$$\mathcal{R}_m \cong \mathbb{R}[z_1, \dots, z_m, z_1^{-1}, \dots, z_m^{-1}] \cong \mathbb{R}[\sigma_{\tau_1}, \dots, \sigma_{\tau_m}, \sigma_{\tau_1}^{-1}, \dots, \sigma_{\tau_m}^{-1}].$$

Delay–differential polynomial operators with time delays belonging to T are thus expressible as polynomials in $\frac{d}{dt}$ and in σ_{τ_i}, i.e., they are elements of the ring $\mathcal{R}_m[s]$. We note that the use of operators like $\sigma_{\tau_i}^{-1}$, which are well defined, only introduces finite anticipative (noncausal) operators. Anyway, their use is the standard practice within behavioral theory of discrete time (i.e., difference) behaviors.

A generalization of the ring of delay-differential polynomial operators was first introduced in [9] in case of commensurate delays. We give here its definition in the general case of m noncommensurate delays.

Proposition 2.3. *The set of holomorphic fractions of exponential polynomials with m delays*

$$\mathcal{H}_m \triangleq \left\{ \frac{n(s)}{d(s)} \text{ such that } n(s), d(s) \in \mathcal{R}_m[s] \right\} \cap \mathcal{O} \tag{4}$$

satisfies the following properties.

1. *$\mathcal{H}_m$ coincides with the set of Laurent polynomials in $e^{-s\tau_i}$, with coefficients in $\mathbb{R}(s)$, that are holomorphic. This means that every element in $\mathcal{H}_m$ can be written as the quotient of a Laurent exponential polynomial in $\mathcal{R}_m[s]$ and a polynomial in $\mathbb{R}[s]$.*
2. *Whenever $n(s), d(s) \in \mathcal{H}_m$, and $\frac{n(s)}{d(s)} \in \mathcal{O}$, then $\frac{n(s)}{d(s)} \in \mathcal{H}_m$.*
3. *If $n(s) \in \mathcal{A}$, $d(s) \in \mathcal{H}_m$, and $\frac{n(s)}{d(s)} \in \mathcal{O}$, then $\frac{n(s)}{d(s)} \in \mathcal{A}$.*
4. *$\mathcal{H}_m$ is a subalgebra of $\mathcal{A}$: every $a(s) \in \mathcal{H}_m$ is an operator of $\mathcal{E}$ unto itself.*
5. *Every nonzero $a(s) \in \mathcal{H}_m$ is a surjective operator: $\operatorname{im}_{\mathcal{E}} a(s) = \mathcal{E}$.*
6. *If $n(s), d(s) \in \mathcal{H}_m$, and $\frac{n(s)}{d(s)} \in \mathcal{H}_m$, then $\ker_{\mathcal{E}} d(s) \subseteq \ker_{\mathcal{E}} n(s)$.*

Proof. Property 1 was proved in [1] for more generic polynomials in $\mathbb{C}^n$; see [11, App. A] for an alternative proof. Properties 5 [6] and 6 [18, pp. 282, 318] are classical results in functional analysis; property 2 trivially follows from the definition of $\mathcal{H}_m$, while properties 3 and 4 can be deduced using the fifth property and [2, Thm. 2.7, 2.8]. □

The way in which elements in $\mathcal{H}_m$ (as well as more generic fractions with denominator in $\mathcal{H}_m$, which were introduced in Proposition 2.3-3) operate on $\mathcal{E}$ is the following: any $a(s) \in \mathcal{H}_m$ is the holomorphic fraction of two exponential polynomials $n(s)$ and $d(s)$ in $\mathcal{R}_m[s]$. Given $v \in \mathcal{E}$, we can find a function $x \in \mathcal{E}$ such that $d(s)x = v$

by surjectivity of $d(s)$, which is ensured by Proposition 2.3-5. Then let $w = a(s)v \in \mathcal{E}$, which is always well defined by Proposition 2.3-4, be given by $w = n(s)x$. Indeed, since $n(s) = a(s)d(s)$ and convolution is an associative operation, we obtain that $a(s)v = a(s)d(s)x = n(s)x = w$.

Observe that x is not uniquely determined. However, the generic solution $\bar{x} = x + k$, with $k \in \ker_{\mathcal{E}} d(s)$, gives $w = n(s)\bar{x}$ since $n(s)k = 0$ by Proposition 2.3-6.

Example 2.4. Let $a(s) = \frac{1-e^{-s}}{s}$. Actually, $a(s)$ is a holomorphic function, since the unique zero of its denominator $d(s) = s$ is common to its numerator $n(s) = 1-e^{-s}$, and thus it is canceled. Therefore $a(s) \in \mathcal{H}_m$ by definition (4).

The function $a(s)$ acts as follows: for every $v \in \mathcal{E}$, $a(s)v = w$ if and only if there is an $x \in \mathcal{E}$ such that $d(s)x = v$ and $n(s)x = w$. The first equation is equivalent to $d(s)x = sx = \frac{d}{dt}x = v$, i.e., $x(t) = \int_0^t v(\tau)\,d\tau + C$, with C an arbitrary constant. Finally, $w = n(s)x = (1 - e^{-s})x = (1 - \sigma)x$, i.e.,

$$w = \frac{1 - e^{-s}}{s} v \;\Leftrightarrow\; w(t) = \int_{t-1}^{t} v(\tau)\,d\tau.$$

2.4. Bézout equations. Bézout equations constitute a fundamental tool in algebraic systems theory. A finite set of elements $r_1, \dots, r_l$ in a ring $\mathcal{R}$ satisfies a Bézout equation if there are $x_i \in \mathcal{R}$ such that $\sum_1^l x_i r_i = 1$ or, equivalently, if the ideal generated by $r_1, \dots, r_l$ coincides with $\mathcal{R}$. The ring of polynomials in one variable, which is the operator ring employed within the theory of linear differential (or difference) systems, is a Bézout domain, i.e., every finitely generated ideal is principal. In this case polynomials without common zeros always satisfy a Bézout equation and thus constitute a set of generators of the whole ring.

The ring $\mathcal{H}_1$ is a Bézout domain, as it was shown in [9, Thm. 3.2]. This property, along with the fact that every matrix admits the Smith form [9, Thm. 3.5-5], permits to extend many theorems on differential systems to systems with one delay. Also $\mathcal{O}$ is a Bézout domain [12, Thm. 9], while this is not the case for the rings $\mathcal{H}_m$ and $\mathcal{A}$, as we will show in the proposition which follows. An analogous example can be found in [19]. For $\mathcal{H}_m$, a different counterexample is proposed in [11, Ex. 5.13], and Gröbner basis theory is there employed to achieve the claimed result.

We need the following preliminary result.

Lemma 2.5. *Given an element $a(s) \in \mathcal{A}$, the following three facts are equivalent.*

(i) *$a(s)$ is invertible in $\mathcal{A}$.*

(ii) *$a(s)$ has no zeros.*

(iii) *$a(s) = ke^{s\tau}$ for some $\tau, k \in \mathbb{R}$, $k \neq 0$.*

Proof. It is clear that exponentials have no zeros. Moreover, a function in $\mathcal{A}$ with no zeros, being of exponential type by definition (2), has the form $e^{h(s)}$ with $h(s)$ a polynomial of degree at most one by Hadamard's theorem (see [17, p. 24]), and therefore it has inverse $e^{-h(s)}$, which is still in $\mathcal{A}$.

We have to show that every invertible element in $\mathcal{A}$ is an exponential like $ke^{s\tau}$. Since $\mathcal{A} \cong \mathcal{E}'$, this corresponds to prove that the invertible distributions are $k\delta_\tau$, where δ_τ is the Dirac measure at τ ($\langle \delta_\tau, f \rangle = f(\tau)$), whose Laplace transform is indeed $e^{-s\tau}$.

Let $\alpha \in \mathcal{E}'$ be an invertible distribution. Then there is a $\beta \in \mathcal{E}'$ such that $\delta = \alpha\star\beta$. If we denote by $[\alpha]$ the smallest closed interval that contains the support of α, by the Titchmarsh–Lions theorem on supports [18, p. 277], $\{0\} = [\delta] = [\alpha \star \beta] = [\alpha] + [\beta]$. This implies that the supports of α and β have to be $\{\tau\}$ and $\{-\tau\}$ for some $\tau \in \mathbb{R}$. Hence α must be a linear combination of δ_τ and its derivatives [24, Thm. 24.6], i.e., its Laplace transform is $\hat{\alpha}(s) = a(s)e^{-s\tau}$, $a(s) \in \mathbb{R}[s]$. In the same way, $\hat{\beta}(s) = b(s)e^{s\tau}$,

$b(s) \in \mathbb{R}[s]$, and hence $1 = \hat{\alpha}(s)\hat{\beta}(s) = a(s)b(s)$. The proof is complete since the only invertible polynomials are constant. □

PROPOSITION 2.6. *The rings $\mathcal{H}_m$ with $m > 1$ and $\mathcal{A}$ are not Bézout domains.*

Proof. We choose the following two functions in $\mathcal{H}_2 \subseteq \mathcal{A}$:

$$r_1(s) = \frac{1 - e^{-s}}{s} \text{ and } r_2(s) = 1 - e^{-s\tau}. \tag{5}$$

We want to show that, for particular values of $\tau \in \mathbb{R}$, the ideal in $\mathcal{A}$ generated by $r_1(s)$ and $r_2(s)$ is not principal. This would imply also that the ideal in $\mathcal{H}_2$ generated by $r_1(s)$ and $r_2(s)$ cannot be principal.

Let $\tau \notin \mathbb{Q}$. So the functions $r_1(s)$ and $r_2(s)$ have no common zeros. Observe preliminarly that, if the ideal in $\mathcal{A}$ generated by $r_1(s)$ and $r_2(s)$ was principal, then the single generator of this ideal should be an element in $\mathcal{A}$ with no zeros and so invertible by Lemma 2.5. This would imply that $r_1(s)$ and $r_2(s)$ should satisfy a Bézout equation. We show now that this is not possible.

Let τ be a Liouville number, i.e., for all $C \in \mathbb{N}$ there are infinitely many $\frac{n}{d} \in \mathbb{Q}$ such that

$$\left|\tau - \frac{n}{d}\right| \leq d^{-1-C}. \tag{6}$$

Suppose, moreover, that $r_i(s)$ satisfy a Bézout equation in $\mathcal{A}$, i.e., that there exist $a_1(s), a_2(s) \in \mathcal{A}$ such that

$$a_1(s)r_1(s) + a_2(s)r_2(s) = 1. \tag{7}$$

Note that $r_2(s) = -2ie^{-\frac{s\tau}{2}} \sin\left(\frac{is\tau}{2}\right)$. So if we evaluate (7) in $s = 2d\pi i$, with $d \in \mathbb{N}\backslash\{0\}$, since $r_1(2d\pi i) = 0$, we get $a_2(2d\pi i)2ie^{-\tau d\pi i} \sin \tau d\pi = 1$. Using basic trigonometry and relation (6), we have $|\sin \tau d\pi| = |\sin(\tau d\pi - n\pi)| \leq |\tau d\pi - n\pi| \leq \pi d^{-C}$. Therefore,

$$1 = |a_2(2d\pi i)|\,|2ie^{-\tau d\pi i}|\,|\sin \tau d\pi| \leq |a_2(2d\pi i)|2\pi d^{-C}.$$

But $a_2(s) \in \mathcal{A}$ and therefore, by definition (2), simplified since $\operatorname{Re} s = 0$, there exist $A, B > 0$ such that $|a_2(2d\pi i)| \leq A(1 + 2d\pi)^B$. Thus, employing the above equation, we obtain

$$1 \leq |a_2(2d\pi i)|2\pi d^{-C} \leq A2\pi(1 + 2d\pi)^B d^{-C}.$$

If we choose $C > B$ and let $d \to \infty$, we get a contradiction. □

Nevertheless, even if functions in $\mathcal{A}$ that do not have common zeros do not generate the whole ring, the ideal they generate is always dense in $\mathcal{A}$, as the following theorem states.

THEOREM 2.7. *Let $a_i(s) \in \mathcal{A}$, $i = 1, \dots, l$ be Paley–Wiener functions without common zeros. Then the closure of the ideal they generate over $\mathcal{A}$ coincides with $\mathcal{A}$.*

Proof. This theorem is a direct consequence of an important result due to Schwartz, called the spectral analysis theorem [2, Thm. 2.11]: it states that if $a_i(s)$ is the Laplace transform of $\alpha_i \in \mathcal{E}'$, then the unique solution $w \in \mathcal{E}$ of $\alpha_i \star w = 0$ for every $i = 1, \dots, l$ is $w = 0$. Therefore, if $R(s) \in \mathcal{A}^{n \times 1}$ is the column containing $a_i(s)$, by the spectral analysis theorem $\ker_{\mathcal{E}} R(s) = \{0\}$. By Proposition 2.1, $\operatorname{im}_{\mathcal{A}} \circ R(s) = \{0\}^{\perp} = \mathcal{A}$, which is exactly what is claimed. □

2.5. Generalized inverses of matrices. Bézout equations are important for our purposes due to their connection with particular properties of matrices. Actually, it is known that a full row rank matrix is left invertible if and only if its maximal minors satisfy a Bézout equation. This result may be extended to matrices which are not full rank.

To this aim we introduce a terminology which will be used throughout this paper. Given a matrix R of rank r, $r \times r$ minors of R will be called rank minors of R.

Definition 2.8. *Given a domain $\mathcal{S}$ and a matrix $R \in \mathcal{S}^{p\times q}$, we say that $G \in \mathcal{S}^{q\times p}$ is the* 1*-inverse of R if $RGR = R$. It is a* 1, 2*-inverse if it is a* 1*-inverse and $GRG = G$.*

Since a matrix admits a 1-inverse if and only if it admits a $1,2$-inverse (it is easy to check that if G is a 1-inverse, then GRG is a $1,2$-inverse), we will consider only $1,2$-inverses and call them simply generalized inverses.

The following theorem [4, Thm. 8] generalizes the aforementioned equivalence of invertibility and the existence of a Bézout equation to matrices which are not full rank.

Theorem 2.9. *Every matrix with entries in a domain has a generalized inverse if and only if its rank minors satisfy a Bézout equation. The knowledge of the coefficients of the Bézout equation permits us to construct the generalized inverse.*

Remark 2.10. A matrix $R(s)$ with entries in $\mathcal{O}$ admits a generalized inverse in $\mathcal{O}$ if and only if

$$\operatorname{rank}_{\mathbb{C}} R(\lambda) = r \text{ for every } \lambda \in \mathbb{C}.$$

Indeed, this happens if and only if its rank minors have no common zeros. Since $\mathcal{O}$ is a Bézout domain, this is equivalent to satisfy a Bézout equation with coefficients in $\mathcal{O}$.

We report now two other facts on matrices that admit a generalized inverse.

Lemma 2.11. *Let $\mathcal{S}$ be a subring of $\mathcal{O}$. If $R(s) \in \mathcal{S}^{p\times q}$ admits a generalized inverse $G(s) \in \mathcal{S}^{q\times p}$, then*

$$\ker_{\mathcal{S}} \circ R(s) = \operatorname{im}_{\mathcal{S}} \circ (I - R(s)G(s)), \quad \operatorname{im}_{\mathcal{S}} \circ R(s) = \ker_{\mathcal{S}} \circ (I - G(s)R(s)). \tag{8}$$

If, moreover, the elements of $\mathcal{S}$ are operators on $\mathcal{E}$,

$$\operatorname{im}_{\mathcal{E}} R(s) = \ker_{\mathcal{E}} (I - R(s)G(s)), \qquad \ker_{\mathcal{E}} R(s) = \operatorname{im}_{\mathcal{E}} (I - G(s)R(s)). \tag{9}$$

Proof. We prove only (9). The proof of (8) follows similarly. Since $R(s) = R(s)G(s)R(s)$, we have $(I - R(s)G(s))R(s) = 0$ and $R(s)(I - G(s)R(s)) = 0$, and so $\operatorname{im}_{\mathcal{E}} R(s) \subseteq \ker_{\mathcal{E}}(I - R(s)G(s))$ and $\operatorname{im}_{\mathcal{E}}(I - G(s)R(s)) \subseteq \ker_{\mathcal{E}} R(s)$.

Conversely, if $w \in \ker_{\mathcal{E}}(I - R(s)G(s))$, then $0 = (I - R(s)G(s))w = w - R(s)G(s)w$, and so $w = R(s)G(s)w \in \operatorname{im}_{\mathcal{E}} R(s)$. Thus $\ker_{\mathcal{E}}(I - R(s)G(s)) \subseteq \operatorname{im}_{\mathcal{E}} R(s)$. Even more trivially, we obtain that $w \in \ker_{\mathcal{E}} R(s)$ implies $w = (I - G(s)R(s))w$ and therefore $w \in \operatorname{im}_{\mathcal{E}}(I - G(s)R(s))$. □

The following theorem plays a fundamental role in many propositions that we will prove in the following sections.

Theorem 2.12. *Let $\mathcal{S}$ be a subring of $\mathcal{O}$. Suppose that $R(s) \in \mathcal{S}^{p\times q}$ has rank r and admits a generalized inverse over $\mathcal{O}$. Then for some $d \in \mathbb{N}$ there is a matrix $M(s) \in \mathcal{S}^{q\times d}$, with rank $q - r$, such that*

$$\ker_{\mathcal{O}} R(s)\circ = \operatorname{im}_{\mathcal{O}} M(s)\circ \text{ and } \operatorname{im}_{\mathcal{O}} \circ R(s) = \ker_{\mathcal{O}} \circ M(s). \tag{10}$$

Furthermore, $M(s)$ also admits a generalized inverse over $\mathcal{O}$.

Since the proof is quite involved (it needs a rather cumbersome notation), it is postponed in Appendix A. Observe that $M(s)$ can be constructed employing only the rank minors of $R(s)$.

3. Controllability of convolutional systems.

In this section we aim to introduce a set of conditions related to the concept of controllability for the class of dynamical systems described by homogeneous convolutional equations. In the rest of the paper we will show the relations which occur between them.

Definition 3.1. *Assume that $R(s) \in \mathcal{A}^{p\times q}$ is a matrix of Paley–Wiener functions and consider the behavior $\mathcal{B} = \ker_{\mathcal{E}} R(s)$. We will be concerned with the following properties of $\mathcal{B}$.*

SC *$\mathcal{B}$ is* spectrally controllable*: $\mathrm{rank}_{\mathbb{C}}\, R(\lambda) = r$ for every $\lambda \in \mathbb{C}$ or, equivalently, the rank minors of $R(s)$ have no common zeros (see Remark* 2.10*). This is a direct generalization of the PBH controllability test for differential systems.*

BC *$\mathcal{B}$ is controllable in the behavioral sense of Definition* 1.1.

IR *$\mathcal{B}$ admits an* image representation*: $\mathcal{B} = \mathrm{im}_{\mathcal{E}}\, M(s)$ for some matrix of operators $M(s) \in \mathcal{A}^{q\times d}$.*

DCS *The subset of $\mathcal{B}$ consisting of the trajectories having* compact support*,i.e., $\mathcal{B}_{cs} \triangleq \mathcal{B} \cap \mathcal{D}^q = \ker_{\mathcal{D}} R(s)$ is* dense *in $\mathcal{B}$: $\mathcal{B} = \overline{\mathcal{B}_{cs}}$.*

DIR *There is a* dense image representation *of $\mathcal{B}$: $\mathcal{B} = \overline{\mathrm{im}_{\mathcal{E}}\, M(s)}$ for some matrix of operators $M(s) \in \mathcal{A}^{q\times d}$.*

GI *There exists a* generalized inverse *of $R(s)$: there is a matrix $G(s) \in \mathcal{A}^{q\times p}$ such that $R(s)G(s)R(s) = R(s)$.*

Note that **SC** and **GI** can be reformulated within the module theoretic framework proposed by Fliess and Mounier [8, 20]. Actually, spectral controllability and existence of a generalized inverse are “algebraic,” while the other are more “analytic” conditions.

The relation between spectral controllability of $\mathcal{B} = \ker_{\mathcal{E}} R(s)$, existence of a generalized inverse of $R(s)$ and null controllability, i.e., the possibility to steer to zero every trajectory of $\mathcal{B}$, was investigated in [21] within a different framework.

Remark 3.2. Definition 3.1 is stated for general behaviors which are kernels of convolutional operators. Matrices over the ring $\mathcal{A}$ are more difficult to handle than matrices over the delay-differential operator ring $\mathcal{R}_m[s]$ or its “fraction” ring $\mathcal{H}_m$. However, this general framework is necessary to obtain some important results, even if the starting point is a matrix $R(s)$, which has delay-differential entries.

Indeed, theorems establishing the existence of an image representation in $\mathcal{A}$ can be used as a preliminary step for obtaining an image representation in $\mathcal{R}_m[s]$ or $\mathcal{H}_m$. This happens when $\mathcal{B}$ is the kernel of a matrix $R(s)$ with entries in $\mathcal{H}_m$, as stated in the following proposition.

Proposition 3.3. *Let $R(s) \in \mathcal{H}_m^{p\times q}$ have rank r. Suppose that $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ admits a (dense) image representation. Then it admits a (dense) image representation in $\mathcal{R}_m[s]$, i.e., there exists a full column rank matrix $M(s) \in \mathcal{R}_m[s]^{q\times(q-r)}$ such that $\mathcal{B}$ is the (closure of the) image of $M(s)$.*

Proof. Let us suppose that $\mathcal{B} = \overline{\mathrm{im}_{\mathcal{E}}\, N(s)}$, where $N(s) \in \mathcal{A}^{q\times d}$. As we shall show in Theorem 3.5, this assumption implies that $\mathcal{B}$ is spectrally controllable and therefore, by Theorem 2.12, we can construct $L(s) \in \mathcal{H}_m^{q\times e}$ such that $\ker_{\mathcal{O}} R(s)^{\circ} = \mathrm{im}_{\mathcal{O}}\, L(s)^{\circ}$. Since $R(s)N(s) = 0$, the columns of $N(s)$ belong to the image over $\mathcal{O}$ of $L(s)$, i.e., there exists an $X(s) \in \mathcal{O}^{e\times d}$ such that $N(s) = L(s)X(s)$.

Furthermore, if we denote by $\mathcal{K}_m$ the field of fractions of $\mathcal{H}_m$, by standard linear algebra arguments there exists a basis of $\ker_{\mathcal{K}_m} R(s)^{\circ}$, which means that there exists a full column rank matrix $\bar{M}(s) \in \mathcal{K}_m^{q\times(q-r)}$ such that $\ker_{\mathcal{K}_m} R(s)\circ = \operatorname{im}_{\mathcal{K}_m} \bar{M}(s)\circ$. Since also $R(s)L(s) = 0$, $L(s) = \bar{M}(s)\bar{Y}(s)$, where $\bar{Y}(s) \in \mathcal{K}_m^{(q-r)\times e}$, and, multiplying both members by an appropriate element $l(s) \in \mathcal{H}_m$, we get the relation

$$l(s)L(s) = M(s)Y(s),$$

where both $M(s)$ and $Y(s)$ have entries in $\mathcal{R}_m[s]$.

Since $\mathcal{K}_m$ is necessarily a Bézout domain, by Theorem 2.9 we can find a generalized inverse $\bar{G}(s) \in \mathcal{K}_m^{e\times q}$ of $L(s)$ such that $L(s)\bar{G}(s)L(s) = L(s)$ or, multiplying by a suitable $g(s) \in \mathcal{H}_m$, a matrix $G(s) \in \mathcal{H}_m^{e\times q}$ such that

$$L(s)G(s)L(s) = g(s)L(s).$$

So, putting together the equations, we found

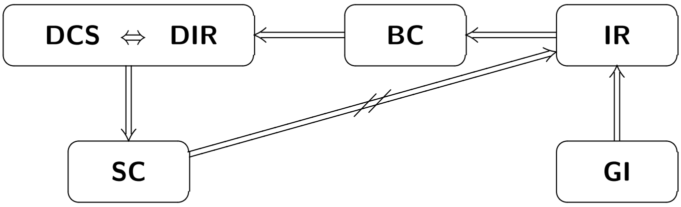
$$l(s)g(s)N(s) = l(s)g(s)L(s)X(s) = l(s)L(s)G(s)L(s)X(s) = M(s)Y(s)G(s)N(s).$$

Since $l(s)g(s) \in \mathcal{H}_m$ is a surjective operator by Proposition 2.3-5, we obtain that

$$\begin{aligned} \operatorname{im}_{\mathcal{E}} N(s) &= \operatorname{im}_{\mathcal{E}} l(s)g(s)N(s) = \operatorname{im}_{\mathcal{E}} M(s)Y(s)G(s)N(s) \\ &\subseteq \operatorname{im}_{\mathcal{E}} M(s) \subseteq \ker_{\mathcal{E}} R(s) = \overline{\operatorname{im}_{\mathcal{E}} N(s)}. \end{aligned}$$

So, if $\operatorname{im}_{\mathcal{E}} N(s)$ is closed, it is equal to $\operatorname{im}_{\mathcal{E}} M(s)$. In any case, the closures of these sets are equal. $\square$

3.1. The general case. The true and false implications described in the following scheme hold without any further assumption.



As our first step, we prove that **SC** $\not\Rightarrow$ **IR**, which shows that the properties we listed above are not equivalent in general. In particular, note that the following example shows that Theorem 1.3 cannot be generalized to $\mathcal{H}_m$ and to $\mathcal{A}$.

In fact, we will present a matrix $R(s)$ with entries in $\mathcal{H}_m$ such that $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ is spectrally controllable, i.e., $\operatorname{rank}_{\mathbb{C}} R(\lambda)$ does not depend on $\lambda \in \mathbb{C}$, but $\mathcal{B}$ does not admit an image representation, i.e., there is no matrix $M(s)$ with entries in $\mathcal{A}$ such that $\mathcal{B} = \operatorname{im}_{\mathcal{E}} M(s)$.

Example 3.4. Let $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ be the kernel representation of the behavior $\mathcal{B}$, where the entries of $R(s)$ were defined in Proposition 2.6.

$$R(s) \triangleq [r_2(s) \;\; -r_1(s)] = \left[1 - e^{-s\tau} \quad -\frac{1-e^{-s}}{s} \right]. \tag{11}$$

As we have already shown in Proposition 2.6, if τ is a Liouville number, $\mathcal{B}$ is spectrally controllable, but $r_1(s)$ and $r_2(s)$ do not satisfy any Bézout equation. Assume by contradiction that there exists $N(s) = [n_{ij}(s)] \in \mathcal{A}^{2\times d}$ such that $\ker_{\mathcal{E}} R(s) = \operatorname{im}_{\mathcal{E}} N(s)$. Since $R(s)N(s) = 0$, it must be

$$r_1(s)n_{2j}(s) = r_2(s)n_{1j}(s) \text{ for every } j = 1, \dots, d. \tag{12}$$

The above equation shows that, if s_0 is a zero of $r_i(s)$ with multiplicity μ, then it is also a zero of $n_{ij}(s)$ with multiplicity greater than or equal to μ. Actually, this is a consequence of the **SC** condition: we know that if $r_1(s_0) = 0$ for some $s_0 \in \mathbb{C}$, then $r_2(s_0) \neq 0$ and so $n_{1j}(s_0) = 0$. Therefore,

$$y_j(s) \triangleq \frac{n_{1j}(s)}{r_1(s)} = \frac{n_{2j}(s)}{r_2(s)} \in \mathcal{O}.$$

By Proposition 2.3-3, $y_j(s) \in \mathcal{A}$ and, if we let $M(s) \triangleq [r_1(s)\ r_2(s)]^\top$ and $Y(s) \triangleq [y_j(s)] \in \mathcal{A}^d$, then $R(s)M(s) = 0$ and $N(s) = M(s)Y(s)$. This implies that

$$\ker_{\mathcal{E}} R(s) = \operatorname{im}_{\mathcal{E}} N(s) = \operatorname{im}_{\mathcal{E}} M(s)Y(s) \subseteq \operatorname{im}_{\mathcal{E}} M(s) \subseteq \ker_{\mathcal{E}} R(s).$$

This equation shows that $\operatorname{im}_{\mathcal{E}} M(s)$ is closed, being equal to $\ker_{\mathcal{E}} R(s)$, and therefore, by Proposition 2.2, $\operatorname{im}_{\mathcal{A}} \circ M(s)$ is closed also. But this is the ideal generated by $r_1(s)$ and $r_2(s)$ and hence, by Theorem 2.7, $\operatorname{im}_{\mathcal{A}} \circ M(s) = \mathcal{A}$, i.e., there are two elements $a_i(s) \in \mathcal{A}$ such that $a_1(s)r_1(s) + a_2(s)r_2(s) = 1$, which is in contradiction with what was obtained in Proposition 2.6.

We present now the main theorem of this section in which we prove the implications shown in the previous scheme.

THEOREM 3.5. *Given any behavior in kernel representation $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ with $R(s) \in \mathcal{A}^{p\times q}$, the following chain of implications always holds:* **GI** $\Rightarrow$ **IR** $\Rightarrow$ **BC** $\Rightarrow$ **DCS** $\Leftrightarrow$ **DIR** $\Rightarrow$ **SC**.

Proof. We will prove each implication separately.

GI $\Rightarrow$ **IR**. It is a direct consequence of Lemma 2.11.

IR $\Rightarrow$ **BC**. If $\mathcal{B} = \operatorname{im}_{\mathcal{E}} M(s)$, then every $w \in \mathcal{B}$ is the image of some smooth function $v \in \mathcal{E}^d$, i.e., $w = M(s)v$. Since $M(s)$ is the Laplace transform of a distribution with compact support, $w(t)$ does not depend on $v(\tau)$ if $\tau \notin [t+a, t+b]$ for some $a \leq b$, both depending only on $M(s)$.

Therefore, if we choose a $T > b - a$, we have that $t + T + a > t + b$. Thus, if $w_i = M(s)v_i$ for $i = 1, 2$ and we define $v(\tau) \triangleq v_1(\tau)$ for $\tau < b$, $v(\tau) \triangleq v_2(\tau - T)$ for $\tau > T+a$ and completing $v(\tau)$ smoothly in the interval $\tau \in [b, T-a]$, then $w = M(s)v$ is such that $w \in \mathcal{B}$, $w(t) = w_1(t)$ as $t \leq 0$ and $w(t) = w_2(t - T)$ as $t > T$.

BC $\Rightarrow$ **DCS**. First, we prove that if $\mathcal{B}$ is controllable, it is possible to steer every trajectory to zero also in the past, i.e. for every $w \in \mathcal{B}$ there exists a $\tilde{w} \in \mathcal{B}$ and a $T > 0$ such that

$$\tilde{w}(t) = 0 \ \ \forall t < -T \text{ and } \tilde{w}(t) = w(t) \ \ \forall t > 0.$$

Actually, given $w_1 = 0$ and $w_2 = w$, by Definition 1.1 there is a $\tau > 0$ and a $\bar{w} \in \mathcal{B}$ such that $\bar{w}(t) = 0$ for $t \leq 0$ and $\bar{w}(t) = \sigma_\tau w(t)$ for $t \geq \tau$. If we take $T \triangleq \tau$, then $\tilde{w} \triangleq \sigma_{-\tau}\bar{w}$ is the desired function.

Next, given any $w \in \mathcal{B}$, consider an increasing sequence of compact intervals

$$[t_i, \tau_i] = K_i \subset K_{i+1} \text{ such that } \cup_i K_i = \mathbb{R}.$$

For every i we can find a trajectory $u_i \in \mathcal{B}$ that is equal to $w(t)$ for $t \geq t_i$ and zero in the "past"; we can also find a trajectory $v_i \in \mathcal{B}$ that is equal to $u_i(t)$ for $t \leq \tau_i$ and zero in the "future." Clearly,

$$v_i \in \mathcal{B}_{\text{cs}} \text{ and } v_i(t) = w(t) \text{ for every } t \in K_i.$$

The sequence v_i converges to w in the topology of $\mathcal{E}$ and therefore w is a limit point of $\mathcal{B}_{\mathrm{cs}}$. Therefore $\mathcal{B} \subseteq \overline{\mathcal{B}_{\mathrm{cs}}}$.

The converse inclusion is easier to establish: since $\mathcal{B}$ is closed and $\mathcal{B}_{\mathrm{cs}} \subseteq \mathcal{B}$, $\overline{\mathcal{B}_{\mathrm{cs}}} \subseteq \mathcal{B}$ also.

DCS $\Rightarrow$ **SC**. It is well known that matrices of holomorphic functions admit the Smith form [13]. A direct consequence of this fact (see, e.g., [25, Ch. 4.1.1]) is the following: since $R(s)$ admits a Smith form, then there exist two matrices $U_1(s) \in \mathcal{O}^{r\times p}$ and $U_2(s) \in \mathcal{O}^{(p-r)\times p}$ such that $U(s) \triangleq \left[\begin{smallmatrix} U_1(s) \\ U_2(s)\end{smallmatrix}\right] \in \mathcal{O}^{p\times p}$ is a square and invertible matrix in $\mathcal{O}$. Thus

$$\operatorname{im}_{\mathbb{C}} \circ U_1(s_0) \oplus \operatorname{im}_{\mathbb{C}} \circ U_2(s_0) = \mathbb{C}^p \text{ for every } s_0 \in \mathbb{C}, \tag{13}$$

and, moreover,

$$\ker_{\mathcal{O}} \circ R(s) = \operatorname{im}_{\mathcal{O}} \circ U_2(s) = \mathcal{O}^{p-r} U_2(s). \tag{14}$$

Note that the dimension of $\ker_{\mathbb{C}} \circ R(s_0)$ is greater than or equal to the dimension of $\ker_{\mathcal{O}} \circ R(s)$. In particular, this inequality holds in a strict sense if and only if $\operatorname{rank}_{\mathbb{C}} R(s_0) < \operatorname{rank}_{\mathcal{O}} R(s)$, i.e., if the behavior $\mathcal{B}$ is not spectrally controllable. Therefore, considering (13) and (14), we can derive the following equivalence:

$$\textbf{SC} \Leftrightarrow \ker_{\mathbb{C}} \circ R(s_0) \cap \operatorname{im}_{\mathbb{C}} \circ U_1(s_0) = \{0\} \text{ for every } s_0 \in \mathbb{C}. \tag{15}$$

We want to prove that **DCS** implies the second condition in (15): let us take $s_0 \in \mathbb{C}$ and

$$c \in \ker_{\mathbb{C}} \circ R(s_0) \cap \operatorname{im}_{\mathbb{C}} \circ U_1(s_0) \tag{16}$$

and construct the operator (well defined by Proposition 2.3-3 because $cR(s_0) = 0$)

$$a(s) \triangleq \frac{1}{s - s_0} cR(s) \in \mathcal{A}^q.$$

We aim to show that $\mathcal{B} \subseteq \ker_{\mathcal{E}} a(s)$.

Indeed, take a $w \in \mathcal{B}$. The way in which $a(s)$ operates implies that if $v = a(s)w$, then $(s - s_0)v = cR(s)w = 0$. This means that $\frac{d}{dt}v = s_0 v$, i.e., $v(t) = v(0)e^{s_0 t}$. Consequently, the image $a(\mathcal{B})$ of $\mathcal{B}$ through $a(s)$ consists only in exponentials.

If we take $w \in \mathcal{B}_{\mathrm{cs}} \subseteq \mathcal{B}$ and $v = a(s)w$, then $v(\tau) = 0$ for $|\tau|$ sufficiently large, since it is the convolution between a distribution and a function both with compact support. Since v is an exponential, it must be the zero function. Employing the hypothesis that $\mathcal{B} = \overline{\mathcal{B}_{\mathrm{cs}}}$, by (18) we can argue that

$$a(\mathcal{B}) = a(\overline{\mathcal{B}_{\mathrm{cs}}}) \subseteq \overline{a(\mathcal{B}_{\mathrm{cs}})} = \overline{\{0\}} = \{0\} \Rightarrow \mathcal{B} = \ker_{\mathcal{E}} R(s) \subseteq \ker_{\mathcal{E}} a(s).$$

This result implies, by a theorem of Malgrange [18, p. 282], that there exists an $x(s) \in \mathcal{O}^p$ such that $a(s) = x(s)R(s)$. By definition of $a(s)$, we also have that $(s - s_0)a(s) = cR(s)$ and hence $(c - (s - s_0)x(s))R(s) = 0$. This implies, by (14) that there exists an $y(s) \in \mathcal{O}^{p-r}$ such that $c - (s - s_0)x(s) = y(s)U_2(s)$.

We deduce that $c = y(s_0)U_2(s_0)$ and so $c \in \operatorname{im}_{\mathbb{C}} \circ U_2(s_0)$. But, as assumed in (16), we also have $c \in \operatorname{im}_{\mathbb{C}} \circ U_1(s_0)$, and hence, by (13), we can argue that $c = 0$. By (15) this implies that the system is spectrally controllable.

DCS $\Rightarrow$ **DIR**. Condition **DCS** implies **SC** and therefore, by theorem 2.12, there exists a matrix $M(s) \in \mathcal{A}^{q\times d}$ with rank $q - r$ such that $R(s)M(s) = 0$. We shall show that $\mathcal{B} = \overline{\mathrm{im}_{\mathcal{E}}\, M(s)}$ or, equivalently, by Proposition 2.1, that $\overline{\mathrm{im}_{\mathcal{A}} \circ R(s)} = \mathcal{B}^{\perp} = \ker_{\mathcal{A}} \circ M(s)$. Since the inclusion $\mathcal{B}^{\perp} \subseteq \ker_{\mathcal{A}} \circ M(s)$ is straightforward, we need to prove only the other one.

First observe that, using hypothesis **DCS** and [24, Cor. 1, 2, p. 363], we obtain that $\mathcal{B}^{\perp} = (\overline{\mathcal{B}_{\mathrm{cs}}})^{\perp} = (\mathcal{B}_{\mathrm{cs}}^{\perp\perp})^{\perp} = \mathcal{B}_{\mathrm{cs}}^{\perp}$. Thus, our aim is to prove that $\ker_{\mathcal{A}} \circ M(s) \subseteq \mathcal{B}_{\mathrm{cs}}^{\perp}$.

Let $x(s) \in \ker_{\mathcal{A}} \circ M(s)$. Denoting by $\mathcal{F}$ the fraction field of $\mathcal{A}$, we have that the subspaces $\mathrm{im}_{\mathcal{F}} \circ R(s) \subseteq \ker_{\mathcal{F}} \circ M(s)$ have the same dimension r and thus coincide. Since $x(s) \in \ker_{\mathcal{F}} \circ M(s)$, there exists a $\bar{y}(s) \in \mathcal{F}^p$ such that $x(s) = \bar{y}(s)R(s)$. Since $\bar{y}(s)$ is a quotient of elements in $\mathcal{A}$, there must be an $a(s) \in \mathcal{A}$ such that $y(s) = a(s)\bar{y}(s) \in \mathcal{A}^p$, and so $a(s)x(s) = y(s)R(s)$.

As an immediate consequence, for every $w \in \mathcal{B}_{\mathrm{cs}}$ we have

$$a(s)x(s)w = y(s)R(s)w = 0. \tag{17}$$

But w has compact support, and hence it admits that the Laplace transform $\hat{w}(s)$ and the convolutional equation (17) can be rewritten as product of Laplace transforms:

$$a(s)x(s)\hat{w}(s) = 0.$$

Since $\mathcal{A}$ is a domain, the last equation holds if and only if $x(s)\hat{w}(s) = 0$, and this implies that $x(s) \in \mathcal{B}_{\mathrm{cs}}^{\perp}$.

DIR ⇒ **DCS**. The only difficult thing to prove is that $\mathcal{B} \subseteq \overline{\mathcal{B}_{\mathrm{cs}}}$. One of the equivalent definitions of continuity is the following [5, Thm. III.8.3]. A function $f : V \to W$ is continuous if and only if for every subset $U \subseteq V$,

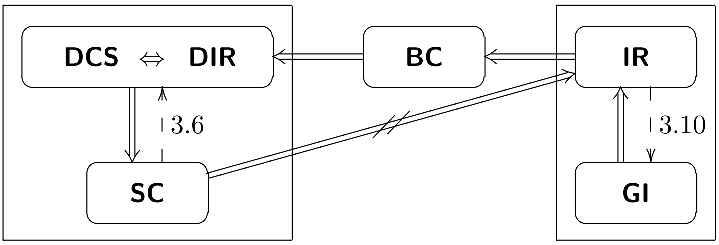
$$\mathrm{im}_{\overline{U}}\, f \subseteq \overline{\mathrm{im}_U\, f}. \tag{18}$$

Since $\mathcal{D}$ is dense in $\mathcal{E}$, then $\mathrm{im}_{\mathcal{E}}\, M(s) = \mathrm{im}_{\overline{\mathcal{D}}}\, M(s) \subseteq \overline{\mathrm{im}_{\mathcal{D}}\, M(s)}$.

We note now that $\mathrm{im}_{\mathcal{D}}\, M(s) \subseteq \ker_{\mathcal{D}} R(s)$. Therefore, taking the closure of the equation written above, we get

$$\mathcal{B} = \overline{\mathrm{im}_{\mathcal{E}}\, M(s)} \subseteq \overline{\mathrm{im}_{\mathcal{D}}\, M(s)} \subseteq \overline{\ker_{\mathcal{D}} R(s)} = \overline{\mathcal{B}_{\mathrm{cs}}}. \qquad \square$$

3.2. The full row rank case: Regular behaviors. In this section we will show that, under a rather mild assumption, conditions **SC**, **DCS**, and **DIR** are equivalent and, adding another stronger hypothesis, even the equivalence **IR** ⇔ **GI** holds true. The situation is presented in the following picture. The numbers over the dashed lines refer to the theorems that prove the equivalences of the conditions in the boxed regions and that also contain the assumptions under which such equivalences hold.



Before going into the detailed analysis of these facts, it is useful to say something more about the *density* conditions **DCS** and **DIR**.

Kernels of continuous operators are always closed, if we do not consider pathological topological spaces, while images need not be closed. Actually, even the image $\operatorname{im}_{\mathcal{E}} a(s)$ of an element $a(s) \in \mathcal{A}$ may be not closed (see [2, Thm. 2.7, 2.8]). Observe that this cannot occur if $a(s) \in \mathcal{H}_m$, since in this case $a(s)$ is surjective by Proposition 2.3-5. However, matrices with entries in $\mathcal{H}_m$ may have an image which is not closed. This can be seen taking the matrix $M(s) \in \mathcal{H}_2^{2\times 1}$ which has been defined in Example 3.4.

As suggested in [22, p. 208], we could define directly the image representation of a behavior as the closure of the image of a convolutional operator. This would make sense, especially from a practical point of view, because it is difficult to understand the concrete relevance of the system trajectories which belong to the closure of the image but not to the image itself. However, employing this definition and therefore identifying conditions **IR** and **DIR**, the existence of an image representation would have in general no relation at all with behavioral controllability, as far as we know.

The hypothesis we are assuming in this section is that $\mathcal{B} = \ker_{\mathcal{E}} R(s)$, where we suppose that the matrix $R(s) \in \mathcal{A}^{p\times q}$ has full row rank, i.e., that the convolutional equations that constitute the homogeneous system whose set of solutions is $\mathcal{B}$, are linearly independent. In this case the behavior is called *regular*. This is, in general, a weak assumption, and if $R(s)$ is in $\mathcal{H}_1$, it is known [9] that there always exists a full row rank matrix whose kernel is $\mathcal{B}$ or, in other words, the behavior of a delay-differential system with commensurate delays is always regular. However, it is unknown whether this property continues to hold for delay-differential systems with noncommensurate delays.

THEOREM 3.6. *Let $R(s) \in \mathcal{A}^{p\times q}$ be full row rank and $\mathcal{B} = \ker_{\mathcal{E}} R(s)$. If $\mathcal{B}$ is spectrally controllable, then there exists a matrix $M(s) \in \mathcal{A}^{q\times d}$ such that $\mathcal{B} = \overline{\operatorname{im}_{\mathcal{E}} M(s)}$.*

Proof. By Theorem 2.12 we know that there is a matrix $M(s) \in \mathcal{A}^{q\times d}$ such that

$$\operatorname{im}_{\mathcal{O}} \circ R(s) = \ker_{\mathcal{O}} \circ M(s). \tag{19}$$

Since this implies that $R(s)M(s) = 0$, we have that also

$$\operatorname{im}_{\mathcal{A}} \circ R(s) \subseteq \ker_{\mathcal{A}} \circ M(s). \tag{20}$$

We want to prove that $\overline{\operatorname{im}_{\mathcal{A}} \circ R(s)} \supseteq \ker_{\mathcal{A}} \circ M(s)$.

Let $x(s) \in \ker_{\mathcal{A}} \circ M(s)$. By (19) there is a $y(s) \in \mathcal{O}^p$ such that

$$x(s) = y(s)R(s). \tag{21}$$

Let us suppose, without loss of generality, that $R(s) = [R_1(s)\ R_2(s)]$, where $R_1(s)$ is a square full rank submatrix of $R(s)$. Let $\operatorname{adj} R_1(s)$ be the adjoint matrix of $R_1(s)$ and let $x(s)$ be partitioned in the same way as $R(s)$ so that $x_1(s) = y(s)R_1(s)$. We obtain

$$x_1(s) \operatorname{adj} R_1(s) = y(s)R_1(s) \operatorname{adj} R_1(s) = y(s) \det R_1(s). \tag{22}$$

We need now the following important result [18, p. 308]. If we define

$$H(d) \triangleq \left\{ a(s) \in \mathcal{A} \text{ such that } a(s)\frac{n(s)}{d(s)} \in \mathcal{A}, \text{ whenever } \frac{n(s)}{d(s)} \in \mathcal{O} \text{ and } n(s) \in \mathcal{A} \right\}, \tag{23}$$

then for any nonzero Paley–Wiener function $d(s) \in \mathcal{A}$ we have that

$$\overline{H(d)} = \mathcal{A}. \tag{24}$$

In other words, in general, if $n(s)$ and $d(s)$ are Paley–Wiener functions and $h(s) \triangleq n(s)/d(s)$ is holomorphic, then $h(s)$ does not necessarily belong to $\mathcal{A}$. However, even if $h(s) \notin \mathcal{A}$, the functions $a(s) \in H(d)$, as, for instance, $d(s)$ itself, are such that $a(s)h(s) \in \mathcal{A}$. Equation (24) tells us that the set $H(d)$ of functions $a(s)$ that map, by multiplication, *every* holomorphic fraction with denominator $d(s)$ into $\mathcal{A}$, is not only nontrivial, but also dense in $\mathcal{A}$.

If we let $d(s) \triangleq \det R_1(s)$ and $n(s) \triangleq x_1(s) \operatorname{adj} R_1(s) \in \mathcal{A}^p$, then (22) becomes

$$n(s) = y(s)d(s) \tag{25}$$

and so $n(s)/d(s) \in \mathcal{O}^p$. Thus, by definition (23) of $H(d)$, we have that

$$a(s) \in H(d) \;\Rightarrow\; a(s)\frac{n(s)}{d(s)} \in \mathcal{A}^p. \tag{26}$$

Although $H(d)$ was defined only for scalar equations, we remark that $H(d)$ depends only on $d(s)$, and hence (26) is true componentwise.

Since $H(d)$ is dense in $\mathcal{A}$, by (24) there must be a sequence $a_n(s) \in H(d)$ converging to $1 \in \mathcal{A}$. From (25) and (26) we obtain that

$$a_n(s)\frac{n(s)}{d(s)} = a_n(s)y(s) \in \mathcal{A}^p.$$

If we multiply by $a_n(s)$ both members of (21), we obtain

$$a_n(s)x(s) = a_n(s)y(s)R(s) \in \mathcal{A}^p R(s).$$

Therefore, $a_n(s)x(s)$ is a sequence in $\mathcal{A}^p R(s)$ and its limit lies in the closure of this set. Since $a_n(s)$ converges to 1, $a_n(s)x(s) \to x(s) \in \overline{\mathcal{A}^p R(s)}$. In other words,

$$\ker_{\mathcal{A}} \circ M(s) \subseteq \overline{\operatorname{im}_{\mathcal{A}} \circ R(s)}.$$

Considering also (20), if we take the orthogonals that invert the inclusions [24, p. 195], we obtain

$$\overline{\operatorname{im}_{\mathcal{A}} \circ R(s)}^{\perp} \subseteq \ker_{\mathcal{A}} \circ M(s)^{\perp} \subseteq \operatorname{im}_{\mathcal{A}} \circ R(s)^{\perp}.$$

By Proposition 2.1, $\overline{\operatorname{im}_{\mathcal{A}} \circ R(s)}^{\perp} = \ker_{\mathcal{E}} R(s)^{\perp\perp} = \operatorname{im}_{\mathcal{A}} \circ R(s)^{\perp\perp\perp}$, and the last term is equal [24, Cor. 1, p. 363] to $\operatorname{im}_{\mathcal{A}} \circ R(s)^{\perp} = \ker_{\mathcal{E}} R(s)$. Therefore,

$$\mathcal{B} = \ker_{\mathcal{E}} R(s) = \ker_{\mathcal{A}} \circ M(s)^{\perp} = \overline{\operatorname{im}_{\mathcal{E}} M(s)}. \qquad \square$$

3.2.1. Single input behaviors. In this section we concentrate our attention on the relation between conditions **IR** and **GI**, i.e., between the existence of an image representation and the existence of a generalized inverse of the matrix providing the kernel representation. We have already shown that **GI** ⇒ **IR** and that there exists an image representation in $\mathcal{H}_m$ whenever $R(s) \in \mathcal{H}_m^{p\times q}$.

In this section we will show that also the converse is true under a rank condition that can be better understood if we introduce the concept of input/output representation of a behavior.

DEFINITION 3.7. *An input/output representation of a behavior $\mathcal{B} \subseteq \mathcal{E}^q$ is a partition of its variables $w \in \mathcal{B}$ into input variables $u \in \mathcal{E}^m$, $m = q - r$, and output variables $y \in \mathcal{E}^r$, such that the input is the following.*

Free. *For every $u \in \mathcal{E}^m$ there is a $y \in \mathcal{E}^r$ such that the trajectory w consisting of y and u is in $\mathcal{B}$.*

Maximal. *Once u has been fixed, y does not contain other free variables.*

Note that we are disregarding properness issues for the sake of simplicity. For more details, see [22, ch. 3.3].

In general, a behavior $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ with $R(s) \in \mathcal{A}^{p\times q}$ may not admit an input/output representation. However, delay-differential systems always have such a representation.

THEOREM 3.8. *Let $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ with $R(s) \in \mathcal{H}_m^{p\times q}$ with rank r. Then $\mathcal{B}$ admits an input/output representation with r outputs and $q - r$ inputs.*

Proof. After a suitable permutation of its columns, we can partition $R(s)$ as

$$R(s) = [P(s) \ \ -Q(s)],$$

and $w \in \mathcal{B}$ consistently in the following way: $w^\top = [y^\top \ u^\top]$. So $P(s) \in \mathcal{H}_m^{p\times r}$ is a full column rank matrix. The description of $\mathcal{B}$ becomes

$$w \in \mathcal{B} \ \Leftrightarrow \ R(s)w = 0 \ \Leftrightarrow \ P(s)y = Q(s)u. \tag{27}$$

We prove that this is an input/output representation. Indeed, there is a matrix $C(s) \in \mathcal{H}_m^{r\times p}$ such that

$$C(s)P(s) = r(s)I, \tag{28}$$

where $r(s) \in \mathcal{H}_m$ is nonzero. Moreover, by hypothesis every column of $Q(s)$ is not independent from the columns of $P(s)$. This means that there is a scalar $a(s) \in \mathcal{H}_m$ and a matrix $F(s) \in \mathcal{H}_m^{r\times(q-r)}$ such that $a(s)Q(s) = P(s)F(s)$. This relation implies that, since $\mathcal{H}_m$ is a domain, $\ker_{\mathcal{H}_m} \circ P(s) \subseteq \ker_{\mathcal{H}_m} \circ Q(s)$. Therefore, if we multiply (28) by $P(s)$ on the left, we get

$$P(s)C(s)P(s) - P(s)r(s) = (P(s)C(s) - r(s)I)P(s) = 0,$$

and so even $(P(s)C(s) - r(s)I)Q(s) = 0$. Thus

$$P(s)C(s)Q(s) = Q(s)r(s). \tag{29}$$

Now, to see that (27) is an input/output representation, we have to show first of all that the input u is free. Fix any $u \in \mathcal{E}^{q-r}$. Since $r(s)$ is surjective on $\mathcal{E}$ by Proposition 2.3-5, there exists $v \in \mathcal{E}^{q-r}$ such that $r(s)v = u$, and so, if we let $y \triangleq C(s)Q(s)v$ and use identity (29), we obtain that

$$P(s)y = P(s)C(s)Q(s)v = r(s)Q(s)v = Q(s)u.$$

Finally, fixing $u = 0$, $P(s)y = 0$ implies that $C(s)P(s)y = r(s)y = 0$, and hence y is not free since every component is a solution of the same delay-differential equation. □

Remark 3.9. Theorem 3.8 holds more generally for a behavior $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ with $R(s) \in \mathcal{A}^{p\times q}$, under the additional assumption that at least one of its rank minors belongs to $\mathcal{H}_m$.

The following theorem shows in which case the existence of an image representation of $\ker_{\mathcal{E}} R(s)$ implies the existence of a generalized inverse of $R(s)$ over $\mathcal{A}$.

THEOREM 3.10. *Let $R(s) \in \mathcal{H}_m^{p\times q}$ and suppose that $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ is a regular behavior with a single input. Then, if $\mathcal{B}$ admits an image representation, $R(s)$ admits a generalized inverse.*

Proof. By Theorem 2.12 and (38), there is a column $M(s) \in \mathcal{H}_m^{q\times 1}$ that is constructed with the q rank minors of $R(s)$, such that

$$\ker_{\mathcal{O}} R(s)\circ = \operatorname{im}_{\mathcal{O}} M(s)\circ.$$

If we show that $1 \in \operatorname{im}_{\mathcal{A}} \circ M(s)$, we have proved that the rank minors of $R(s)$ satisfy a Bézout equation over $\mathcal{A}$ and, by Theorem 2.9, $R(s)$ admits a generalized inverse.

Since the behavior admits an image representation, say $\mathcal{B} = \operatorname{im}_{\mathcal{E}} N(s)$ with $N(s) \in \mathcal{A}^{q\times d}$, then $R(s)N(s) = 0$. Thus each row of $N(s)$ is in $\ker_{\mathcal{O}} R(s)\circ$, and so we have that

$$\exists Y(s) \in \mathcal{O}^{1\times d} : \ M(s)Y(s) = N(s) \ \Rightarrow \ m_i(s)y_j(s) = n_{ij}(s).$$

By Proposition 2.3-3 $n_{ij}(s)/m_i(s) = y_j(s) \in \mathcal{O}$ is a Paley–Wiener function and so $Y(s) \in \mathcal{A}^{1\times d}$. Now, since $M(s)Y(s) = N(s)$, where every matrix is an operator, $\operatorname{im}_{\mathcal{E}} N(s) \subseteq \operatorname{im}_{\mathcal{E}} M(s)$. Therefore,

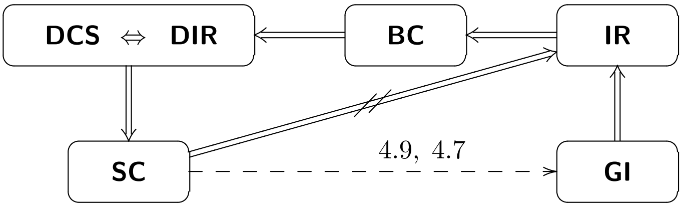
$$\ker_{\mathcal{E}} R(s) = \operatorname{im}_{\mathcal{E}} N(s) \subseteq \operatorname{im}_{\mathcal{E}} M(s) \subseteq \ker_{\mathcal{E}} R(s),$$

so $\operatorname{im}_{\mathcal{E}} M(s)$ is closed and, by Propositions 2.1 and 2.2, $\operatorname{im}_{\mathcal{A}} \circ M(s)$ is also closed.

We know that the rank minors of $R(s)$ that are the elements of $M(s)$ have no common zeros, and thus by Theorem 2.7 $\operatorname{im}_{\mathcal{A}} \circ M(s) = \mathcal{A}$. □

4. Controllability of multidelay differential systems. In this section we will show that the equivalence between all the conditions introduced in Definition 3.1 does hold if we restrict our attention to a particular class of delay-differential systems that contains delay systems in state space form.

The following scheme describes the relations already established and two other results that give sufficient conditions for spectral controllability to imply the existence of a generalized inverse, yielding in this way the equivalence of all the conditions listed in Definition 3.1.



In order to illustrate the assumptions that the class of systems which we will consider must satisfy, we need preliminary definitions and results that concern exponential polynomials in $\mathcal{R}_m[s]$ and elements in $\mathcal{H}_m$.

We remind the reader that $\mathcal{R}_m$ is isomorphic to the ring of Laurent polynomials in m variables and that $\mathcal{R}_m[s]$ is isomorphic to the ring of polynomials in $m + 1$

variables to which we refer for factorization properties. We extend now the definition of monic polynomials to $\mathcal{H}_m$ following [10, Def. 2.2].

DEFINITION 4.1. *An element $r(s) \in \mathcal{R}_m[s]$ is* monic *if the corresponding polynomial in $m+1$ variables is monic with respect to s, i.e., the highest degree power of s is contained in one single monomial of the form $ks^n e^{s\tau}$, $k, \tau \in \mathbb{R}$, $k \neq 0$. An element $h(s) \in \mathcal{H}_m$ is* monic *if it can be written as $h(s) = n(s)/d(s)$ with $n(s) \in \mathcal{R}_m[s]$ monic and $d(s) \in \mathbb{R}[s]$.*

The following proposition concerns the solvability of Bézout equations over $\mathcal{A}$ for delay-differential elements.

PROPOSITION 4.2. *Suppose that the elements $r_1(s), \dots, r_l(s) \in \mathcal{H}_m$ have no common zeros and let $\mathcal{I} \triangleq (r_1(s), \dots, r_l(s))_{\mathcal{A}}$ be the ideal over $\mathcal{A}$ that they generate. Then the following conditions are equivalent.*

1. *$\mathcal{I} = \mathcal{A}$.*
2. *There exists $p(s) \in \mathbb{R}[s]$ such that $p(s) \in \mathcal{I}$.*
3. *There exists $h(s) \in \mathcal{H}_m$ monic such that $h(s) \in \mathcal{I}$.*

In order to prove this proposition we need several technical results.

This first lemma shows that the ideal generated over $\mathcal{H}_m$ by elements in the same ring that have no common zeros contains an exponential polynomial with a particular property.

LEMMA 4.3. *If the elements $r_i(s) \in \mathcal{H}_m$, $i = 1 \dots, l$, do not have common zeros, then there exist $x_i \in \mathcal{R}_m[s]$, $d(s) \in \mathbb{R}[s]$, and $n(s) \in \mathcal{R}_m$ such that*

$$\sum_{i=1}^{l} x_i(s) r_i(s) = d(s)n(s).$$

Proof. By Proposition 2.3-1, $r_i(s) = n_i(s)/d_i(s)$, with $n_i(s) \in \mathcal{R}_m[s]$ and $d_i(s) \in \mathbb{R}[s]$. Let $g(s)$ be the common factor of $n_i(s)$ (viewed as polynomials), and suppose that $g(s_0) = 0$. Then for every i, $n_i(s_0) = r_i(s_0)d_i(s_0) = 0$. Observe that $r_1(s), \dots, r_l(s)$ have no common zeros and thus there is at least a j such that $d_j(s_0) = 0$. This shows that every zero of $g(s)$ is a zero of $d_1(s) \cdots d_l(s) \in \mathbb{R}[s]$, and therefore $g(s)$ has only a finite number of zeros.

Since by Lemma 2.5 the only elements without zeros in $\mathcal{R}_m[s]$ are exponentials, there is a $d(s) \in \mathbb{R}[s]$ and a $\tau \in \mathbb{R}$ such that $g(s) = e^{s\tau} d(s)$, and we can factor $n_i(s) = \bar{n}_i(s)d(s)$ with $\bar{n}_i(s) \in \mathcal{R}_m[s]$ without common (polynomial) factors.

It is known [28, Thm. 2, part 2] that there always exists a linear combination of factor coprime polynomials that is independent of one variable, i.e., there are exponential polynomials $\bar{x}_i(s) \in \mathcal{R}_m[s]$ such that

$$\sum_{i=1}^{l} \bar{x}_i(s)\bar{n}_i(s) = n(s) \in \mathcal{R}_m.$$

So, if we put $x_i(s) = \bar{x}_i(s)d_i(s)$, we get

$$\sum_{i=1}^{l} x_i(s)r_i(s) = \sum_{i=1}^{l} \bar{x}_i(s)d_i(s)r_i(s) = \sum_{i=1}^{l} \bar{x}_i(s)n_i(s) = d(s)\sum_{i=1}^{l} \bar{x}_i(s)\bar{n}_i(s) = d(s)n(s). \qquad \square$$

We will be concerned with properties of holomorphic functions regarding the placement of their zeros. The following notation will be very useful.

Definition 4.4. *For any holomorphic function $a(s) \in \mathcal{O}$, we let $\mathcal{Z}(a)$ be the set of zeros of $a(s)$.*

We remark that $\mathcal{Z}(a)$ has no limit points in $\mathbb{C}$. This is a fundamental property of holomorphic functions. Moreover, we note that the definition of $\mathcal{Z}(a)$ does not take multiplicities into account; they are, in this particular context, an unnecessary complication.

In the next lemma we give an estimate of the position of zeros of two classes of exponential polynomials.

Lemma 4.5.

1. *If $a(s) \in \mathcal{R}_m$, there exists $C > 0$ such that $|\operatorname{Re} s| \leq C$ for every $s \in \mathcal{Z}(a)$.*
2. *If $a(s) \in \mathcal{R}_m[s]$ is monic, there exist two constants $A, B > 0$ such that $|\operatorname{Im} s| \leq Ae^{B|\operatorname{Re} s|}$ for every $s \in \mathcal{Z}(a)$.*

Proof. We prove that if $a(s) \in \mathcal{R}_m$, then there exists a constant $C \geq 0$ such that if $a(s_0) = 0$, then $\operatorname{Re} s_0 \leq C$, the opposite being analogous. We can suppose that $a(s) = 1 + \sum a_i e^{-b_i s}$ with $b_i > 0$; otherwise we could collect a suitable exponential factor ke^{bs}. Now, assume that $a(s_0)$ is zero and $\operatorname{Re} s_0 \geq 0$. Then $1 = |\sum a_i e^{-b_i s_0}|$. If we let $A = \sum |a_i|$ and $B = \min\{b_i\}$, then we obtain $1 = |\sum a_i e^{-b_i s_0}| \leq \sum |a_i|\, e^{-b_i \operatorname{Re} s_0} \leq Ae^{-B \operatorname{Re} s_0}$, which implies that $\operatorname{Re} s_0 \leq \frac{1}{B} \log A$.

Regarding the second inequality, it is not restrictive to suppose that $a(s) = s^n + \sum_{i=0}^{n-1} a_i(s) s^i$ with $a_i(s) \in \mathcal{R}_m$. Consider first only complex numbers $s_0 \in \mathbb{C}$ such that $|s_0| \geq 1$. Then, whenever s_0 is a zero of $a(s)$, we obtain

$$s_0^n = -\sum_{i=0}^{n-1} a_i(s_0) s_0^i \;\Rightarrow\; s_0 = -\sum_{i=0}^{n-1} a_i(s_0) s_0^{i-n+1},$$

and, employing elementary inequalities, we obtain

$$|\operatorname{Im} s_0| \leq |s_0| \leq \sum_{i=0}^{n-1} |a_i(s_0)|\, |s_0^{i-n+1}| \leq \sum_{i=0}^{n-1} |a_i(s_0)|.$$

Note that every polynomial $a_i(s) \in \mathcal{R}_m$ can be written as $a_i(s) = \sum_{j=1}^{\nu_i} a_{ij} e^{b_{ij} s}$, and so

$$|a_i(s_0)| \leq \sum_{j=1}^{\nu_i} |a_{ij}|\, |e^{b_{ij} s_0}| \leq \nu_i \max_j\{|a_{ij}|\} e^{\max_j\{|b_{ij}|\} |\operatorname{Re} s_0|}.$$

Therefore, for some $\bar{A} > 0, B > 0$, we have $|\operatorname{Im} s_0| \leq \bar{A} e^{B|\operatorname{Re} s_0|}$ for $|s_0| \geq 1$. Taking $A = \max\{1, \bar{A}\}$, we get the claimed result. □

The following proposition extends to $\mathcal{H}_m$ an estimate from above that is known for exponential polynomials in $\mathcal{R}_m[s]$.

Proposition 4.6. *For every $h(s) \in \mathcal{H}_m$ there exist real constants $K, M, N, E > 0$ such that*

$$|h(s)| \geq \frac{K \operatorname{dist}(s, \mathcal{Z}(h))^M e^{-E|\operatorname{Re} s|}}{(1 + |s|)^N}. \tag{30}$$

Proof. Write $h(s)$ as $n(s)/d(s)$, where, by Proposition 2.3-1, $n(s) \in \mathcal{R}_m[s]$ and $d(s) \in \mathbb{R}[s]$. Notice that if $d(s)$ has degree ν, there is a $D > 0$ such that $|d(s)| \leq D(1+|s|)^\nu$. Indeed, if $d(s) = \sum_0^\nu d_i s^i$, let $D \triangleq \max\{|d_i|/\binom{\nu}{i}\}$ and in this way we have

$|d(s)| \leq \sum |d_i| \, |s|^i \leq D \sum \binom{\nu}{i} |s|^i = D(1+|s|)^\nu$. As stated in [3, Prop. 1], since $n(s)$ is an exponential polynomial, there are real constants $\tilde{K}, \tilde{N}, M, E > 0$ such that

$$|n(s)| \geq \frac{\tilde{K} \operatorname{dist}(s, \mathcal{Z}(n))^M e^{-E|\operatorname{Re} s|}}{(1+|s|)^{\tilde{N}}}.$$

Therefore, we obtain

$$|h(s)| = \frac{|n(s)|}{|d(s)|} \geq \frac{\tilde{K} \operatorname{dist}(s, \mathcal{Z}(n))^M e^{-E|\operatorname{Re} s|}}{D(1+|s|)^{\tilde{N}+\nu}}. \tag{31}$$

Now let $\mathcal{Z}_e \triangleq \mathcal{Z}(n) \setminus \mathcal{Z}(h)$ be that subset of zeros of $d(s)$ that eliminate, by division, some of the zeros of $n(s)$. We employ now Lemma B.1 by letting $\mathcal{V} = \mathcal{Z}(h)$ and $\mathcal{W} = \mathcal{Z}_e$, which is finite and thus compact. We obtain that fixing any positive $L < 1$, there is an $R > 0$ such that

$$\operatorname{dist}(s, \mathcal{Z}(n)) \geq L \operatorname{dist}(s, \mathcal{Z}(h)) \text{ as } |s| > R.$$

Therefore, if we let $N \triangleq \tilde{N} + \nu$, from (31) we get

$$|h(s)| \geq \frac{\tilde{K} L^M}{D} f(s) \text{ for every } s \text{ such that } |s| > R, \tag{32}$$

where $f(s) \triangleq \operatorname{dist}(s, \mathcal{Z}(h))^M e^{-E|\operatorname{Re} s|}(1+|s|)^{-N}$.

Note that, since $L < 1$, this relation still holds inside the closed disk, i.e., for $|s| \leq R$, wherever we have $\operatorname{dist}(s, \mathcal{Z}(n)) = \operatorname{dist}(s, \mathcal{Z}(h))$, that corresponds to the condition $\operatorname{dist}(s, \mathcal{Z}(h)) \leq \operatorname{dist}(s, \mathcal{Z}_e)$.

Now we have only to consider the compact subset $\mathcal{U}$ of the closed disk constituted by $s \in \mathbb{C}$ such that $|s| \leq R$ and $\operatorname{dist}(s, \mathcal{Z}(h)) \geq \operatorname{dist}(s, \mathcal{Z}_e)$. The function $h(s)$ has no zeros in $\mathcal{U}$, and therefore there exists a constant $H > 0$ such that $|h(s)| \geq H$ for all $s \in \mathcal{U}$. Moreover, $f(s)$ has maximum F on the compact $\mathcal{U}$. So, if we let $K \triangleq \min\{\frac{H}{F}, \frac{\tilde{K}L^M}{D}\}$, then

$$|h(s)| \geq H \geq KF \geq Kf(s) \ \ \forall s \in \mathcal{U},$$

and, by (32), on the remaining points of $\mathbb{C}$ we have

$$|h(s)| \geq \frac{\tilde{K} L^M}{D} f(s) \geq K f(s) \text{ for every } s \in \mathbb{C} \setminus \mathcal{U},$$

thus completing the proof of the Proposition. □

We are now in a position to prove Proposition 4.2.

Proof. The first condition implies obviously the last two. We have to prove the converse.

($2 \Rightarrow 1$) Let $R(s) = [r_i(s)] \in \mathcal{H}_m^{1 \times l}$ be the row vector containing the given polynomials. By hypothesis we know that there is a column vector $A(s) \in \mathcal{A}^{l \times 1}$ such that we have

$$p(s) \triangleq R(s)A(s) = \sum_i r_i(s) a_i(s) \in \mathbb{R}[s].$$

If s_0 is a zero of $p(s)$, then $R(s_0)A(s_0) = 0$. Since $r_i(s)$ have no common zeros, $R(s_0) \neq 0$ and hence $A(s_0) \in \ker_{\mathbb{C}} R(s_0)^\circ$. By Theorem 2.12 there is a matrix $M(s) \in$

$\mathcal{H}_m^{t\times d}$ with constant $\operatorname{rank}_{\mathbb{C}} M(\lambda)$ for every $\lambda \in \mathbb{C}$, such that $\ker_{\mathcal{O}} R(s)\circ = \operatorname{im}_{\mathcal{O}} M(s)\circ$. Therefore, $\ker_{\mathbb{C}} R(s_0)\circ = \operatorname{im}_{\mathbb{C}} M(s_0)\circ$, and so there exists a column $c \in \mathbb{C}^{d\times 1}$ such that $A(s_0) = M(s_0)c$. Since $R(s)M(s)c = 0$, we can write

$$p(s) = R(s)(A(s)-M(s)c) \;\Rightarrow\; \tilde{p}(s) \triangleq \frac{p(s)}{s-s_0} = R(s)\frac{A(s)-M(s)c}{s-s_0} = R(s)\tilde{A}(s),$$

where $\tilde{p}(s)$ is a polynomial with lower degree than $p(s)$ and $\tilde{A}(s)$ is a vector with entries in $\mathcal{A}$ by Proposition 2.3-3. Iterating this procedure, we get a Bézout equation for $r_i(s)$ with coefficients in $\mathcal{A}$.

($3 \Rightarrow 2$) The element $h(s) \in \mathcal{I}$ may be written as a quotient in $\mathcal{R}_m[s]$ whose numerator $a(s) \in \mathcal{R}_m[s]$ is monic and belongs to $\mathcal{I}$. By Lemma 4.5-2, we have that $|\operatorname{Im} s| \le Ae^{B|\operatorname{Re} s|}$ for every $s \in \mathcal{Z}(a)$. Moreover, by Lemma 4.3, $r_i(s)$ generate an exponential polynomial $b(s) = d(s)n(s)$ such that $d(s) \in \mathbb{R}[s]$ and $n(s) \in \mathcal{R}_m$. Since $d(s)$ has a finite number of zeros and the real part of the zeros of $n(s)$ is bounded by Lemma 4.5-1, there is a constant $C > 0$ such that $|\operatorname{Re} s| \le C$ for every $s \in \mathcal{Z}(b)$.

So, if we consider the closed disk $\mathcal{C}$ centered at the origin with radius R such that $R^2 > A^2e^{2BC} + C^2$, it contains (strictly) the region containing the common zeros of $a(s)$ and $b(s)$. We can build two polynomials $p(s)$ and $q(s)$ having those zeros of $a(s)$ and $b(s)$, respectively, that lie in $\mathcal{C}$. In this way we can define the elements in $\mathcal{H}_m$

$$h_a(s) \triangleq \frac{a(s)}{p(s)} \in \mathcal{H}_m \text{ and } h_b(s) \triangleq \frac{b(s)}{q(s)} \in \mathcal{H}_m$$

that have no zeros inside $\mathcal{C}$ and thus, in particular, have no common zeros. Moreover, by construction there exists a constant $D > 0$ such that $\operatorname{dist}(\mathcal{Z}(h_a), \mathcal{Z}(h_b)) \ge 2D$. Therefore, we can define the sets

$$\mathcal{C}_a \triangleq \{s \in \mathbb{C} \text{ such that } \operatorname{dist}(s, \mathcal{Z}(h_a)) \le \operatorname{dist}(s, \mathcal{Z}(h_b))\},$$
$$\mathcal{C}_b \triangleq \{s \in \mathbb{C} \text{ such that } \operatorname{dist}(s, \mathcal{Z}(h_a)) \ge \operatorname{dist}(s, \mathcal{Z}(h_b))\},$$

and so $\operatorname{dist}(s, \mathcal{Z}(h_a)) \ge D$ for every $s \in \mathcal{C}_b$ and $\operatorname{dist}(s, \mathcal{Z}(h_b)) \ge D$ for every $s \in \mathcal{C}_a$. As stated in Proposition 4.6, there are suitable positive constants such that

$$|h_a(s)| \ge \frac{K_a \operatorname{dist}(s, \mathcal{Z}(h_a))^{M_a} e^{-E_a|\operatorname{Re} s|}}{(1+|s|)^{N_a}} \ge \frac{K_a D^{M_a} e^{-E_a|\operatorname{Re} s|}}{(1+|s|)^{N_a}} \;\forall s \in \mathcal{C}_b,$$
$$|h_b(s)| \ge \frac{K_b \operatorname{dist}(s, \mathcal{Z}(h_b))^{M_b} e^{-E_b|\operatorname{Re} s|}}{(1+|s|)^{N_b}} \ge \frac{K_b D^{M_b} e^{-E_b|\operatorname{Re} s|}}{(1+|s|)^{N_b}} \;\forall s \in \mathcal{C}_a.$$

So, since $\mathbb{C} = \mathcal{C}_a \cup \mathcal{C}_b$, if we let $K \triangleq \min\{K_a D^{M_a}, K_b D^{M_b}\}$, $E \triangleq \max\{E_a, E_b\}$, and $N \triangleq \max\{N_a, N_b\}$, we obtain

$$|h_a(s)| + |h_b(s)| \ge \frac{Ke^{-E|\operatorname{Re} s|}}{(1+|s|)^N} \;\; \forall s \in \mathbb{C}.$$

We know [14] that this condition ensures the existence of two Paley–Wiener functions $x_a(s), x_b(s) \in \mathcal{A}$ such that $h_a(s)x_a(s) + h_b(s)x_b(s) = 1$, i.e.,

$$a(s)q(s)x_a(s) + b(s)p(s)x_b(s) = p(s)q(s),$$

and therefore the ideal $\mathcal{I}$ contains the polynomial $p(s)q(s)$. $\square$

An immediate consequence of the previous proposition is the following result for delay-differential systems.

THEOREM 4.7. *Let $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ with $R(s) \in \mathcal{H}_m^{p\times q}$. If the ideal generated by the rank minors of $R(s)$ over $\mathcal{A}$ contains a monic element $a(s) \in \mathcal{H}_m$, then the conditions in Definition* 3.1 *are all equivalent.*

Proof. We have only to prove that, under this hypothesis, **SC** $\Rightarrow$ **GI**, or, equivalently, by Theorem 2.9, that the rank minors satisfy a Bézout equation in $\mathcal{A}$. This is true by Proposition 4.2. □

Remark 4.8. Note that for systems with only one delay, spectral controllability always implies that the ideal generated by the rank minors contains a polynomial only in s, and therefore the hypothesis of Theorem 4.7 always holds. We have in this way that all the conditions of Definition 3.1 are always equivalent for systems with one delay, as already proved in [9, 23].

Remark 4.9. The previous theorem does not hold in general for a behavior $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ with $R(s) \in \mathcal{A}^{p\times q}$, unless its rank minors belong to $\mathcal{H}_m$. However, note that the proof ($2 \Rightarrow 1$) of Proposition 4.2 still holds if $r_i(s) \in \mathcal{A}$, and therefore we have the following result.

Let $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ with $R(s) \in \mathcal{A}^{p\times q}$. If the ideal generated by the rank minors of $R(s)$ over $\mathcal{A}$ contains a polynomial $p(s) \in \mathbb{R}[s]$, then the conditions in Definition 3.1 are all equivalent.

Theorem 4.7 constitutes a powerful tool even though the check of the fact that there exists a monic element in the ideal over $\mathcal{A}$ generated by the rank minors is difficult to perform in practice. On the other hand, if $R(s) \in \mathcal{H}_m^{p\times q}$, by Gröbner bases techniques it can be checked whether there exists a monic polynomial in the ideal over $\mathcal{H}_m$ generated by the rank minors, and this is actually still a sufficient condition for the equivalence of the conditions of Definition 3.1. Indeed, by Proposition 2.3-1 we can write the rank minors of $R(s)$ as $r_i(s) = p_i(s)/\rho(s)$, where $p_i(s) \in \mathcal{R}_m[s]$ and $\rho(s) \in \mathbb{R}[s]$. It is not difficult to prove that there exists a monic $h(s) \in \mathcal{H}_m$ in the ideal over $\mathcal{H}_m$ generated by the rank minors if and only if there exists a monic $p(s)$ in the ideal over $\mathcal{R}_m[s]$ generated by the Laurent exponential polynomials $p_i(s)$.

The nicest situation in which the previous theorem can be applied is in relation with the class of systems in state space form

$$\dot{x} = A(\sigma_{\tau_1}, \dots, \sigma_{\tau_m})x + B(\sigma_{\tau_1}, \dots, \sigma_{\tau_m})u. \tag{33}$$

Actually, the first rank minor of the matrix

$$R(s) = [sI - A(e^{-s\tau_1}, \dots, e^{s\tau_m})\ B(e^{-s\tau_1}, \dots, e^{s\tau_m})],$$

which provides a kernel representation of the system (33), is monic.

5. Conclusions.

In this paper we have shown some remarkable properties related to controllability of systems described by delay-differential or convolutional equations. We have shown, however, that the equivalence between spectral controllability, behavior controllability, and the existence of an image representation does not hold in this general setup, essentially due to the fact that images may not be closed in general.

There are two ways to overcome this difficulty. One is to weaken the notion of image representation. The second is to find subclasses of systems for which the equivalence holds. We showed that for the class of systems in state space form such equivalence holds.

Several problems remain unsolved. We conclude this paper by giving a brief list of open problems, which will be the object of our future investigation.

1. It would be interesting to understand if the equivalence of conditions **SC**, **DCS**, and **DIR** can be extended to nonregular behaviors, i.e., systems admitting a kernel representation $\mathcal{B} = \ker_{\mathcal{E}} R(s)$ in which the matrix $R(s)$ is not full row rank.

2. Another open problem is connected with the possibility of extending Theorem 3.10, showing that **IR** and **GI** are equivalent for regular systems with a single input to a more general situation. As pointed out by H. Glüsing-Lüerßen in a personal communication, it is not possible to extend such a result to nonregular systems, as proved by the following example:

$$\mathcal{B} = \ker_{\mathcal{E}} \begin{bmatrix} r_1(s) & 0 \\ r_2(s) & 0 \end{bmatrix} = \mathrm{im}_{\mathcal{E}} \begin{bmatrix} 0 \\ 1 \end{bmatrix},$$

where $r_1(s), r_2(s)$ are defined in (5) within the proof of Proposition 2.6. The matrix providing the kernel representation of $\mathcal{B}$ has no generalized inverse over $\mathcal{A}$.

3. An interesting direction of future research concerns a very detailed investigation of the class of systems for which all the conditions of Definition 3.1 are equivalent. We conjecture that the lack of such equivalence is the typical property of systems whose spectral controllability is not robust with respect to variations of the delays.

Appendix A. Proof of Theorem 2.12. The proof needs a rather involved notation that two simple examples will help to explain.

Let $R(s) = [a\ b\ c\ d] \in \mathcal{A}^{1\times 4}$. (We omit the dependence of the elements on s.) By Remark 2.10, the hypotheses of Theorem 2.12 are satisfied with $r = p = 1$, $q = 4$ as soon as $R(\lambda) \neq 0$ for all $\lambda \in \mathbb{C}$.

We show how we can construct a matrix $M(s) \in \mathcal{A}^{4\times 6}$ of rank $q - r = q - p = 3$ such that $R(s)M(s) = 0$. Consider the matrix

$$\tilde{R}(s) = \begin{bmatrix} w & x & y & z \\ a & b & c & d \end{bmatrix},$$

where the vector $[w\ x\ y\ z]$ belongs to the image of $\circ R(s)$; i.e., it is a scalar multiple of $R(s)$. In this case $\tilde{R}(s)$ has still rank $p = 1$ and therefore its minors of order $p+1$ are zero. Note that the minors of $\tilde{R}(s)$ are linear functions of w, x, y, or z. We will show that we can write them as particular row-column products.

We have $6 = \binom{4}{2} = \binom{q}{p+1}$ different (ordered) sets of $2 = p + 1$ columns of $R(s)$,

$$\rho_1 = \{1,4\}, \ \rho_2 = \{2,4\}, \ \rho_3 = \{3,4\}, \ \rho_4 = \{1,3\}, \ \rho_5 = \{2,3\}, \ \rho_6 = \{1,2\},$$

that correspond to every minor of order $p+1$ of $\tilde{R}(s)$. The minor given by ρ_1 is $wd - za = 0$, which can be written (up to multiplication by -1) as

$$\begin{bmatrix} w & x & y & z \end{bmatrix} \begin{bmatrix} -d \\ 0 \\ 0 \\ a \end{bmatrix},$$

i.e., the first element in the column is $-d$, the minor of $R(s)$ corresponding to the set of columns $\{4\} = \rho_1 \setminus \{1\}$. (We consider it with the opposite sign if the row we are considering, 1, occupies an odd position in ρ.) The second and third elements are zero ($2, 3 \notin \rho_1$), the fourth element is a, and the minor of column $\{1\} = \rho_1 \setminus \{4\}$ of $R(s)$.

From every ρ_i we can construct such a row and obtain the matrix

$$M(s) = \begin{bmatrix} -d & 0 & 0 & -c & 0 & -b \\ 0 & -d & 0 & 0 & -c & a \\ 0 & 0 & -d & a & b & 0 \\ a & b & c & 0 & 0 & 0 \end{bmatrix},$$

which satisfies the equation $R(s)M(s) = 0$.

Note that $-d^3$ is a minor of order $3 = q - p$ of $M(s)$. The third power of every other minor of $R(s)$ is a minor of order 3 of $M(s)$. Some of the rank minors of $R(s)$ are not zero, so $M(s)$ has at least rank 3. It cannot have rank 4 because otherwise the equation $R(s)M(s) = 0$ would imply that $R(s) = 0$.

Without being so detailed, we show what happens with a full rank matrix having dimensions $p = 2$ and $q = 4$:

$$R(s) = \begin{bmatrix} a & b & c & d \\ \alpha & \beta & \gamma & \delta \end{bmatrix}.$$

Matrix $\tilde{R}(s)$ is now

$$\tilde{R}(s) = \begin{bmatrix} w & x & y & z \\ a & b & c & d \\ \alpha & \beta & \gamma & \delta \end{bmatrix},$$

where $[w\ x\ y\ z]$ is any linear combination of the rows of $R(s)$. Its minors of order $p + 1 = 3$ correspond to columns in the $d = \binom{q}{p+1} = \binom{4}{3} = 4$ sets

$$\rho_1 = \{1, 3, 4\},\ \rho_2 = \{2, 3, 4\},\ \rho_3 = \{1, 2, 4\},\ \rho_4 = \{1, 2, 3\}$$

and permit us to construct $M(s)$ in the following way:

$$M(s) = \begin{bmatrix} d\gamma - c\delta & 0 & d\beta - b\delta & c\beta - b\gamma \\ 0 & d\gamma - c\delta & a\delta - d\alpha & a\gamma - c\alpha \\ a\delta - d\alpha & b\delta - d\beta & 0 & b\alpha - a\beta \\ c\alpha - a\gamma & c\beta - b\gamma & b\alpha - a\beta & 0 \end{bmatrix}.$$

$M(s)$ has obviously rank $2 = q - p$, since among its minors of order 2 there are the squares of the minors of order $p = 2$ of $R(s)$.

Proof of Theorem 2.12. Since this proof is quite long, we divide it into steps.

First step. We prove the existence of $M(s)$ such that $R(s)M(s) = 0$. If $r = q$, then $R(s)$ is left invertible over $\mathcal{O}$. There exists $G(s) \in \mathcal{O}^{q \times p}$ such that $G(s)R(s) = I$. This implies that $R(s)\circ$ is injective and $\circ R(s)$ surjective over $\mathcal{O}$. Therefore, $M(s) = 0 \in \mathcal{S}^{q \times 1}$ satisfies the given conditions.

Let us suppose that $r < q$. If $r(s)$ is any element in $\mathcal{O}^p R(s)$ and $\bar{R}(s) \in \mathcal{O}^{r \times q}$ is one of the $\binom{p}{r}$ submatrices of $R(s)$ with r rows, we can build the matrix

$$\tilde{R}(s) = \begin{bmatrix} r(s) \\ \bar{R}(s) \end{bmatrix}. \tag{34}$$

$\tilde{R}(s)$ has rank at most r, so every minor of order $r+1$ is zero and is a linear combination of $r+1$ elements of $r(s)$, the coefficients being $r+1$ minors of order r of $\bar{R}(s)$ and thus rank minors of $R(s)$.

More precisely, let $\rho \subseteq \mathbb{N}$ be a subset of $r+1$ elements of the set $\{1, 2, \ldots, q\}$. We suppose that ρ is ordered and write $\rho(i)$ to indicate the ith element of ρ. Furthermore, we denote by

$$\bar{\rho}(i) \triangleq \rho \setminus \{i\} \tag{35}$$

the ordered set with r elements which has the elements of ρ except of i, and we let

$$n_\rho(i) \triangleq \begin{cases} 0 & \text{if } i \notin \rho, \\ (-1)^k & \text{if } \rho(k) = i. \end{cases} \tag{36}$$

That is to say if $i \in \rho$, then $n_\rho(i)$ is equal to 1 when i occupies an even "position" in ρ.

We know by basic combinatorics that there are exactly $\bar{d} = \binom{q}{r+1}$ different sets ρ_j, so we can construct a matrix $\bar{M}(s) \in \mathcal{S}^{q \times \bar{d}}$ with elements $\bar{m}_{ij}(s)$ defined as

$$\bar{m}_{ij}(s) \triangleq n_{\rho_j}(i) \bar{R}(s)_{\bar{\rho}_j(i)}, \tag{37}$$

where $\bar{R}(s)_\rho$ is the determinant of the matrix formed by those columns of $\bar{R}(s)$ which are indexed by elements in the set ρ.

We see that if $r(s)$ in (34) has elements $r_i(s)$ and $\bar{M}_j(s)$ is the jth column of $\bar{M}(s)$, then, remembering that by definition (36) $n_{\rho_j}(i) = 0$ when $i \notin \rho_j$, we have

$$0 = \tilde{R}(s)_{\rho_j} = \sum_{i \in \rho_j} r_i(s) n_{\rho_j}(i) \bar{R}(s)_{\bar{\rho}_j(i)} = \sum_{i=1}^{q} r_i(s) n_{\rho_j}(i) \bar{R}(s)_{\bar{\rho}_j(i)} = r(s) \bar{M}_j(s).$$

Since $r(s)$ may be any row in $\mathcal{O}^p R(s)$ and thus any row of $R(s)$, this proves that $R(s)\bar{M}(s) = 0$. Then, if we let

$$d \triangleq \bar{d} \binom{p}{r} = \binom{q}{r+1} \binom{p}{r} \tag{38}$$

and $M(s) \in \mathcal{S}^{q \times d}$ be the block column matrix containing the $\binom{p}{r}$ matrices $\bar{M}(s)$ obtained by varying the set of rows defining $\bar{R}(s)$, we still have

$$R(s) M(s) = 0. \tag{39}$$

Second step. $M(s)$ has rank $q - r$ and admits a generalized inverse over $\mathcal{O}$. Let $\bar{R}(s) \in \mathcal{O}^{r \times q}$ be a submatrix of $R(s)$ with r rows, as in the previous step, and consider $\bar{M}(s)$ defined by (37). Let $\rho \triangleq \{q-r+1, q-r+2, \ldots, q-1, q\}$ be the set that indicates the last r columns of $\bar{R}(s)$, and assume that the sets ρ_j, $j = 1, \ldots, \bar{d}$ are such that

$$\rho_j = \{j\} \cup \rho \quad \forall j \in \{1, 2, \ldots, q-r\}.$$

By definition (35) $\bar{\rho}_j(j) = \rho$, and thus by (37)

$$|\bar{m}_{jj}(s)| = |\bar{R}(s)_\rho| \quad \forall j \in \{1, 2, \ldots, q-r\}.$$

Again the definition (37) of $\bar{m}_{ij}(s)$ and (36) imply that

$$\forall i,j \in \{1,2,\dots,q-r\}\,,\; i \neq j \;\Rightarrow\; n_{\rho_j}(i) = 0, \text{and therefore } \bar{m}_{ij}(s) = 0,$$

so the submatrix containing the first $q-r$ rows and columns of $\bar{M}(s)$ has nonzero entries only on the main diagonal and these are equal, up to the sign, to the minor $\bar{R}(s)_\rho$ of $R(s)$.

It is obvious, by the symmetric structure of the problem, that the set of minors of order $q-r$ of $M(s)$ contains every $(q-r)$th power of the rank minors of $R(s)$. This shows that $M(s)$ has rank $m \geq q-r$.

If we denote by $\mathcal{M}$ the field of fractions of $\mathcal{O}$, then the dimension of $\ker_{\mathcal{M}} R(s)\circ$ is $q-r$ and the dimension of $\operatorname{im}_{\mathcal{M}} M(s)\circ$ is m. Therefore, since $R(s)M(s) = 0$, the first vector space includes the second; hence $m \leq q-r$ and therefore $m = q-r$.

Since the maximal minors of $R(s)$ have no common zeros and their mth power is contained in the set of rank minors of $M(s)$, even these minors cannot have common zeros. Therefore, by Theorem 2.9, $M(s)$ also has a generalized inverse.

Third step. We prove that $\operatorname{im}_{\mathcal{O}} \circ R(s) = \ker_{\mathcal{O}} \circ M(s)$ and $\ker_{\mathcal{O}} R(s)\circ = \operatorname{im}_{\mathcal{O}} M(s)\circ$. Equation (39) implies that $\operatorname{im}_{\mathcal{O}} \circ R(s) \subseteq \ker_{\mathcal{O}} \circ M(s)$. In order to prove the converse inclusion, let us consider again kernels and images over the field of fractions of $\mathcal{O}$. In this case $\operatorname{im}_{\mathcal{M}} \circ R(s)$ is a subspace of $\ker_{\mathcal{M}} \circ M(s)$. However, $\operatorname{im}_{\mathcal{M}} \circ R(s)$ has dimension r and $\ker_{\mathcal{M}} \circ M(s)$ has dimension $q-m = r$, and therefore they coincide. So, for every $x(s) \in \ker_{\mathcal{O}} \circ M(s)$ there is an $\bar{y}(s) \in \mathcal{M}^p$ such that $x(s) = \bar{y}(s)R(s)$. Multiplying by a suitable $d(s) \in \mathcal{O}$, we obtain $d(s)x(s) = y(s)R(s)$ with $y(s) \in \mathcal{O}^p$. By Lemma 2.11, $d(s)x(s) \in \operatorname{im}_{\mathcal{O}} \circ R(s) = \ker_{\mathcal{O}} \circ (I - G(s)R(s))$. Since $\mathcal{O}$ is a domain, also $x(s) \in \ker_{\mathcal{O}} \circ (I - G(s)R(s)) = \operatorname{im}_{\mathcal{O}} \circ R(s)$, and this proves that $\ker_{\mathcal{O}} \circ M(s) \subseteq \operatorname{im}_{\mathcal{O}} \circ R(s)$.

The equation $\ker_{\mathcal{O}} R(s)\circ = \operatorname{im}_{\mathcal{O}} M(s)\circ$ follows analogously, since $\ker_{\mathcal{M}} R(s)\circ$ and $\operatorname{im}_{\mathcal{M}} M(s)\circ$ are the same vector space with dimension $q-r$. □

Appendix B. A technical lemma.

Lemma B.1. *Let* $\emptyset \neq \mathcal{V}, \mathcal{W} \subset \mathbb{C}$ *with* $\mathcal{W}$ *compact, and let* $0 < L < 1$. *Then there exists an* $R > 0$ *such that for every* $s \in \mathbb{C}$ *such that* $|s| > R$*,*

$$\operatorname{dist}(s, \mathcal{V} \cup \mathcal{W}) \geq L \operatorname{dist}(s, \mathcal{V}). \tag{40}$$

Proof. Since the function $\operatorname{dist}(w, \mathcal{V})$ of w is continuous [5, Thm. IX.4.3], it has a maximum over the compact $\mathcal{W}$ that we denote by $D \geq 0$. We want to show that the following inequality holds true:

$$\operatorname{dist}(s, \mathcal{V}) \leq \operatorname{dist}(s, \mathcal{V} \cup \mathcal{W}) + D \quad \forall s \in \mathbb{C}. \tag{41}$$

Define the set

$$\mathcal{U} \triangleq \{s \in \mathbb{C} \text{ such that } \operatorname{dist}(s, \mathcal{V}) > \operatorname{dist}(s, \mathcal{W})\}\,. \tag{42}$$

Observe that $\operatorname{dist}(s, \mathcal{V} \cup \mathcal{W}) = \min\{\operatorname{dist}(s, \mathcal{V}), \operatorname{dist}(s, \mathcal{W})\}$. Thus, inequality (41) is trivial if $s \notin \mathcal{U}$, because in this case $\operatorname{dist}(s, \mathcal{V} \cup \mathcal{W}) = \operatorname{dist}(s, \mathcal{V})$. So, assume that $\operatorname{dist}(s, \mathcal{V} \cup \mathcal{W}) = \operatorname{dist}(s, \mathcal{W})$. By definition of distance, the relation

$$\operatorname{dist}(s, \mathcal{V}) = \inf_{v \in \mathcal{V}} |s - v| \leq |s - w| + \inf_{v \in \mathcal{V}} |w - v| = |s - w| + \operatorname{dist}(w, \mathcal{V}) \leq |s - w| + D$$

holds for every $w \in \mathcal{W}$. Therefore, it is true for $|s - w| = \operatorname{dist}(s, \mathcal{W})$, so proving (41).

Fix now $0 < L < 1$. Note that, if $s \notin \mathcal{U}$, condition (40) is always satisfied. Therefore, if $\mathcal{U}$ is bounded, the claim is proved choosing an $R > 0$ such that $|s| > R$ implies that $s \notin \mathcal{U}$.

Suppose, conversely, that $\mathcal{U}$ is not bounded and that s belongs to $\mathcal{U}$. As $|s| \to \infty$, even $\operatorname{dist}(s, \mathcal{W}) \to \infty$, being that $\mathcal{W}$ is compact, and so does $\operatorname{dist}(s, \mathcal{V})$, by definition (42). Therefore, there is an $R > 0$ such that $\operatorname{dist}(s, \mathcal{V}) \geq D/(1-L)$ for every s such that $|s| > R$. This is equivalent to

$$1 - \frac{D}{\operatorname{dist}(s, \mathcal{V})} \geq L.$$

Thus, using this inequality and formula (41), we obtain that

$$\operatorname{dist}(s, \mathcal{V} \cup \mathcal{W}) \geq \operatorname{dist}(s, \mathcal{V}) - D = \operatorname{dist}(s, \mathcal{V}) \left(1 - \frac{D}{\operatorname{dist}(s, \mathcal{V})}\right) \geq L \operatorname{dist}(s, \mathcal{V}),$$

which proves condition (40) for every s such that $|s| > R$. □

ON THE DUALITY BETWEEN FILTERING AND NEVANLINNA–PICK INTERPOLATION[*]

CHRISTOPHER I. BYRNES[†] AND ANDERS LINDQUIST[‡]

Abstract. Positive real rational functions play a central role in both deterministic and stochastic linear systems theory, as well as in circuit synthesis, spectral analysis, and speech processing. For this reason, results about positive real transfer functions and their realizations typically have many applications and manifestations.

In this paper, we study certain manifolds and submanifolds of positive real transfer functions, describing a fundamental geometric duality between filtering and Nevanlinna–Pick interpolation. Not surprisingly, then, this duality, while interesting in its own right, has several corollaries which provide solutions and insight into some very interesting and intensely researched problems. One of these is the problem of parameterizing all rational solutions *of bounded degree* of the Nevanlinna–Pick interpolation problem, which plays a central role in robust control, and for which the duality theorem yields a complete solution. In this paper, we shall describe the duality theorem, which we motivate in terms of both the interpolation problem and a fast algorithm for Kalman filtering, viewed as a nonlinear dynamical system on the space of positive real transfer functions.

We also outline a new proof of the recent solution to the rational Nevanlinna–Pick interpolation problem, using an algebraic topological generalization of Hadamard's global inverse function theorem.

Key words. Nevanlinna–Pick interpolation, filtering, positive real functions, foliations, degree constraint

1. Introduction.

Modulo a conformal equivalence, the classical Nevanlinna–Pick problem amounts to determining a function which is *positive real*, i.e., is analytic and has nonnegative real part in $\mathbb{D}^c := \{z \in \mathbb{C} \mid |z| > 1\}$, and which satisfies the interpolation condition

$$f(z_k) = w_k \quad \text{for } k = 0, 1, \dots, n, \tag{1.1}$$

where $z_0, z_1, \dots, z_n \in \mathbb{D}^c$ and $w_0, w_1, \dots, w_n \in \mathbb{C}$. This problem has a solution if and only if the associated Pick matrix P is positive semidefinite. It is unique if P is singular, and there are infinitely many solutions if $P > 0$ (see [35, 33]). We are interested in a particular subset of these solutions, namely those which are rational of degree at most n, and we shall refer to the problem of determining these as the *Nevanlinna–Pick problem with degree constraints* [12].

For simplicity, in this paper we shall consider the special case that the interpolation points are all distinct and fixed and with $z_0 = \infty$. Then the Pick matrix becomes

$$P = \left[\frac{w_k + \bar{w}_\ell}{1 - z_k^{-1} \bar{z}_\ell^{-1}} \right]_{k,\ell=0}^{n}.$$

Moreover, we assume that the sets $z_0, z_1, \dots, z_n$ and $w_0, w_1, \dots, w_n$ are self-conjugate so that only real interpolants f need to be considered. We also normalize the problem by setting

$$w_0 = 1$$

so that $f(\infty) = 1$. Finally, we assume that the interpolant is *strictly positive real* in the sense that

$$f(e^{i\theta}) + f(e^{-i\theta}) > 0 \quad \text{for all } \theta \in [-\pi, \pi].$$

Any such function can, in a unique fashion, be written as

$$f(z) + f(z^{-1}) = v(z)v(z^{-1}), \tag{1.2}$$

where v is a *minimum-phase spectral factor* having all zeros in the open unit disc. These zeros will be called *the spectral zeros* of f. As we have remarked above, there are several conformal equivalents of this problem, including Nevanlinna–Pick interpolation for bounded-real, or Schur, functions. Indeed, even for positive real functions there are two conventions, one dealing with interpolation problems inside the unit disc and one outside the disc, as considered here. Our convention is motivated by the desire to have spectral factors which are stable and minimum-phase and therefore may be realized, in control engineering terms, by a stable discrete-time linear system.

We shall show that the space of all strictly positive real, rational functions of at most degree n, $\mathcal{P}_n$, admits two foliations: an *interpolation foliation* with one leaf for each choice of interpolation values $w_1, w_2, \dots, w_n$ satisfying the Pick condition, and a *filtering foliation* with one leaf for each choice of spectral zeros. These foliations are complementary, each pair of leaves with one from each foliation intersecting in one point under nonzero angle. This result is analogous to that obtained in [6] for the case that $z_0 = z_1 = \cdots = z_n = \infty$, the rational covariance extension problem. We note that the corresponding decompositions for the space of functions which are positive real, rather than strictly positive real, are not necessarily disjoint, nor are the equivalence classes necessarily smooth manifolds. For these reasons, we shall work with strictly positive real functions.

More generally, in section 6 we also prove that $\mathcal{P}_n$ is diffeomorphic to $\mathcal{W}_n^+ \times \mathcal{S}_n$, where $\mathcal{W}_n^+$ is the space of all $w_1, w_2, \dots, w_n$ satisfying the Pick condition, and $\mathcal{S}_n$ is the space of (real) *Schur polynomials* of degree n, i.e., real monic polynomials of degree n with all zeros in the open unit disc. Since, in addition, it can be shown that both $\mathcal{W}_n^+$ and $\mathcal{S}_n$ are diffeomorphic to $\mathbb{R}^n$, this implies that $\mathcal{P}_n$ is Euclidean of dimension $2n$.

2. Preliminaries. Let H_2 be the Hardy space of all real functions which are analytic in the exterior of the unit disc, $\mathbb{D}^c := \{z \in \mathbb{C} \mid |z| < 1\}$, and have square-integrable radial limits

$$\lim_{r \to +1} \frac{1}{2\pi} \int_{-\pi}^{\pi} |f(re^{i\theta})|^2 d\theta < \infty$$

on the boundary. Denoting by L_2 the space of all real functions which are square-integrable on the unit circle, we may identify H_2 with the subspace of L_2 consisting of those functions with vanishing positively indexed Fourier coefficients. More precisely, for $f \in H_2$,

$$f(z) = f_0 + f_1 z^{-1} + f_2 z^{-2} + \cdots .$$

Similarly, let $\bar{H}_2$ be the conjugate Hardy space of L_2-functions which are analytic in the open unit disc and thus have vanishing negatively indexed Fourier coefficients so that

$$f(z) = f_0 + f_1 z + f_2 z^2 + \cdots$$

for $f \in \bar{H}_2$. Hence, if $f^*(z) := f(z^{-1})$, $f \in H_2$ if and only if $f^* \in \bar{H}_2$.

The space L_2 is a Hilbert space with inner product

$$\langle f, g \rangle = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(e^{i\theta}) g^*(e^{i\theta}) d\theta.$$

Next, given the interpolation points $z_1, z_2, \dots, z_n$, define the Blaschke product

$$B(z) := \prod_{k=1}^{n} \frac{1 - z_k^{-1} z}{z - \bar{z}_k^{-1}}.$$

As is well known, the subspace BH_2 is invariant under the shift z^{-1}. In order to set notation, we remark that BH_2 is the kernel of the evaluation operator $E : H_2 \to \mathbb{C}^n$ defined

$$E(f) = \begin{bmatrix} f(z_1) \\ \vdots \\ f(z_n) \end{bmatrix},$$

and, if $z_0 = \infty$, $z^{-1}BH_2$ is the kernel of

$$\hat{E}(f) = \begin{bmatrix} f(z_0) \\ f(z_1) \\ \vdots \\ f(z_n) \end{bmatrix}.$$

In this paper, the coinvariant subspaces $H(B) := H_2 \ominus BH_2$,

$$\mathcal{K} := H(z^{-1}B) = H_2 \ominus z^{-1}BH_2, \quad \text{and} \quad \mathcal{L} := z^{-1}H(B) \tag{2.1}$$

will play an important part. They are all finite-dimensional. In fact, given the polynomial

$$\tau(z) = \prod_{k=1}^{n} (z - \bar{z}_k^{-1}), \tag{2.2}$$

$\mathcal{K}$ consists of all rational functions

$$r(z) = \frac{\pi(z)}{\tau(z)}$$

for which the polynomial π is of degree at most n, and hence $\mathcal{K}$ is $(n+1)$-dimensional. The spaces $H(B)$ and $\mathcal{L}$ are n-dimensional subspaces of $\mathcal{K}$. In particular, $\mathcal{L}$ consists of those rational functions $r \in \mathcal{K}$ for which $r(\infty) = 0$. We shall also need the subset $\mathcal{R}$ of functions in $r \in \mathcal{K}$ with the property that $r - 1 \in \mathcal{L}$ and r is *minimum-phase* in the sense that the numerator polynomial π has all its zeros in the open unit disc.

In fact, to say that $r \in \mathcal{R}$ is to say that $\pi \in \mathcal{S}_n$, the n-dimensional space of (monic) Schur polynomials defined in section 1.

Finally, we shall need the subspace

$$\mathcal{Q} := \mathcal{K} + \mathcal{K}^*, \tag{2.3}$$

in terms of which we have the orthogonal decomposition

$$L_2 = zB^*\bar{H}^2 \oplus \mathcal{Q} \oplus z^{-1}BH^2 \tag{2.4}$$

and the subspace $\mathcal{D} \subset \mathcal{Q}$ defined as

$$\mathcal{D} := \{Q = q + q^* \mid q \in \mathcal{K}\}. \tag{2.5}$$

An important convex $(n+1)$-dimensional subset $\mathcal{D}_n^+$ of $\mathcal{D}$ consists of those $D \in \mathcal{D}$ which are positive real, i.e., satisfy the condition that $D(e^{i\theta}) > 0$ for all $\theta \in [-\pi, \pi]$. Also define the n-dimensional subset $\mathcal{Z}_n^+$ of $\mathcal{D}_n^+$ of all $D \in \mathcal{D}_n^+$ which are normalized so that $D(1) = 1$. It is immediately seen that $\mathcal{Z}_n^+$ is also convex.

The following lemma is a trivial modification of the unit circle version of Orlando's formula [15] (also see [5, Lemma 5.5]).

LEMMA 2.1. *Let $a \in \mathcal{R}$, and define $S(a) : \mathcal{K} \to \mathcal{D}$ to be the linear mapping defined by*

$$S(a)v = av^* + a^*v.$$

Then $\ker S(a) = 0$.

3. The interpolation foliation.

3. The interpolation foliation. Any rational function f of degree at most n has a representation

$$f(z) = \frac{b(z)}{a(z)}, \quad a, b \in \mathcal{K}. \tag{3.1}$$

If, in addition, f is strictly positive real, the zeros of the rational functions a and b in (3.1) must be located in the open unit disc. Therefore, if we also assume that $f(\infty) = 1$, it is no restriction to choose $a, b \in \mathcal{R}$. Consequently, we define $\mathcal{P}_n$ to be the space of all pairs (a, b) with $a, b \in \mathcal{R}$ such that f is strictly positive real. The following result was established in [6]. We note that $\mathcal{R}$ is diffeomorphic to Euclidean space $\mathbb{R}^n$ because $\mathcal{S}_n \simeq \mathbb{R}^n$ [4].

PROPOSITION 3.1. *The space $\mathcal{P}_n$ is a smooth, connected, real manifold of dimension $2n$.*

Next, denote by $\mathcal{W}_n^+$ the space of all $w \in \mathbb{C}^n$ with components $w_1, w_2, \dots, w_n \in \mathbb{C}$ satisfying the Pick condition $P > 0$ and forming a self-conjugate set.

PROPOSITION 3.2. *$\mathcal{W}_n^+$ is a smooth, connected, real manifold of dimension n.*

Proof. It is clear that $\mathcal{W}_n^+$ is a smooth manifold having real dimension n. From the form of the Pick matrix, one can also see that $\mathcal{W}_n^+$ is convex and hence connected. □

Let $\eta : \mathcal{P}_n \to \mathcal{W}_n^+$ be the restriction of the evaluation operator E to $\mathcal{P}_n$. Then, for each $w \in \mathcal{W}_n^+$,

$$\mathcal{P}_n(w) = \eta^{-1}(w) \tag{3.2}$$

is the space of all $f \in \mathcal{P}_n$ satisfying the interpolation condition (1.1) corresponding to w.

THEOREM 3.3. *The connected components of the sets $\{\mathcal{P}_n(w) \mid w \in \mathcal{W}_+\}$ form the leaves of an n-dimensional foliation of $\mathcal{P}_n$.*

Remark 3.4. Below, we shall prove that the submanifold $\mathcal{P}_n(w)$ is actually connected. This fact is a nontrivial consequence of the transversality lemma we shall prove in section 5.

To prove this theorem, we need to show that η is a submersion [26], i.e., that the Jacobian $\mathrm{Jac}(\eta)|_{(a,b)}$ is everywhere surjective. To this end, for any $u, v \in \mathcal{L}$, first form the directional derivative of f in the direction (u, v), i.e.,

$$D_{(u,v)}f = \lim_{\epsilon \to 0} \frac{1}{\epsilon} \left[\frac{b + \epsilon v}{a + \epsilon u} - \frac{b}{a} \right] = \frac{av - bu}{a^2}.$$

Then, the directional derivative of η in the direction (u, v) is

$$D_{(u,v)}\eta = \begin{bmatrix} D_{(u,v)}f(z_1) \\ D_{(u,v)}f(z_2) \\ \vdots \\ D_{(u,v)}f(z_n) \end{bmatrix},$$

which is zero if and only if

$$av - bu = rB, \quad \text{where } r \in \mathcal{L}.$$

Consequently,

$$\ker \mathrm{Jac}(\eta)|_{(a,b)} = \{(u, v) \in \mathcal{L} \times \mathcal{L} \mid av - bu \in B\mathcal{L}\}.$$

LEMMA 3.5. *The tangent space of $\mathcal{P}_n(w)$ at (a, b) has dimension n and is given by*

$$T_{(a,b)}\mathcal{P}_n(w) = \{(u, v) \in \mathcal{L} \times \mathcal{L} \mid av - bu \in B\mathcal{L}\}.$$

Proof. The tangent vectors of $\mathcal{P}_n(w)$, as defined by (3.2), are precisely the vectors in the nullspace of the Jacobian of η at (a, b). For simplicity of notation, denote this space by V. To prove that $\dim V = n$, let $M_{(a,b)} : V \to B\mathcal{L}$ be the mapping $M_{(a,b)}(u, v) = av - bu$. Let n_0 be the number of common zeros of a and b. Then there are three proper rational functions, each taking the value 1 at infinity, namely θ of degree n_0 and $\tilde{a}$ and $\tilde{b}$ of degree $n - n_0$, such that $a = \theta\tilde{a}$ and $b = \theta\tilde{b}$ and $\tilde{a}$ and $\tilde{b}$ have no nontrivial common factors. Now, if $(u, v) \in \ker M_{(a,b)}$, we have $av - bu = 0$, and hence

$$\frac{v}{u} = \frac{b}{a} = \frac{\tilde{b}}{\tilde{a}},$$

so there must be a rational function ϑ of degree n_0 vanishing at infinity such that $u = \vartheta\tilde{a}$ and $v = \vartheta\tilde{b}$. Consequently, since ϑ is completely arbitrary,

$$\dim \ker M_{(a,b)} = n_0.$$

Moreover, for $(u, v) \in V$,

$$av - bu = \theta(\tilde{a}v - \tilde{b}u) = Br \quad \text{for some } r \in \mathcal{L}.$$

Therefore, since $\dim \mathcal{L} = n$ and θ is fixed of degree n_0,

$$\dim M_{(a,b)}(V) = n - n_0.$$

Therefore, by complementarity between rank and nullity,

$$\dim V = \dim M_{(a,b)}(V) + \dim \ker M_{(a,b)} = n,$$

as claimed. □

Proof of Theorem 3.3. Since the Jacobian $\mathrm{Jac}(\eta)$ is a linear map from the $2n$-dimensional tangent space of $\mathcal{P}_n$ to the n-dimensional tangent space of $\mathcal{W}_+$, complementarity of rank and nullity for $\ker \mathrm{Jac}(\eta)$ and the fact that $\dim \ker \mathrm{Jac}(\eta) = n$ (Lemma 3.5) imply that the range of $\mathrm{Jac}(\eta)$ has dimension n. Hence η is a submersion, proving the statement of the theorem [26, p. 2]. □

4. The filtering foliation. The following lemma is a trivial reformulation of results presented in [28, 29] concerning a fast filtering algorithm for Kalman filtering [27] (see also [5]).

LEMMA 4.1. *Given any $(a, b) \in \mathcal{P}_n$, consider the dynamical system*

$$\begin{aligned} a_{t+1}(z) &= \frac{1}{2(1+\gamma_t)}[(1+z)a_t(z) + (1-z)b_t(z)], \quad a_0(z) = a(z), \\ b_{t+1}(z) &= \frac{1}{2(1-\gamma_t)}[(1-z)a_t(z) + (1+z)b_t(z)], \quad b_0(z) = b(z), \end{aligned} \tag{4.1}$$

where

$$\gamma_t = \left(z\frac{b_t(z) - a_t(z)}{2} \right) |_{z=\infty}. \tag{4.2}$$

Then, for $t = 0, 1, 2, \dots,$

$$(a_t, b_t) \in \mathcal{P}_n \tag{4.3}$$

and

$$r_t S(a_t) b_t = S(a)b, \quad \textit{where} \quad r_t = \prod_{k=0}^{t-1}(1 - \gamma_k^2). \tag{4.4}$$

Moreover, as $t \to \infty$, $\gamma_t \to 0$, $r_t \to r_\infty$, and

$$(a_t, b_t) \to (\sigma, \sigma), \quad \textit{where } \sigma \in \mathcal{R}. \tag{4.5}$$

The parameters (4.2) are the Schur parameters (reflection coefficients) corresponding to the function f, and, consequently, $|\gamma_t| < 1, t = 0, 1, 2, \dots,$ whenever f is strictly positive real. The connection to the Schur algorithm and Kalman filtering is explained in the appendix, where, for convenience, an independent proof of Lemma 4.1 is given. For initial conditions $(a, b) \notin \mathcal{P}_n$, the fast filtering algorithm exhibits much more complicated (and interesting) dynamical behavior, which is investigated in detail in [5]. Here, however, we are only interested in its behavior on the set $\mathcal{P}_n$.

In view of (3.1), we have

$$f(z) + f(z^{-1}) = \frac{S(a)b}{aa^*}, \tag{4.6}$$

and hence Lemma 4.1 implies that

$$f(z) + f(z^{-1}) = r_\infty \frac{\sigma(z)\sigma(z^{-1})}{a(z)a(z^{-1})}, \tag{4.7}$$

showing that the spectral factor in (1.2) is

$$v(z) = \sqrt{r_\infty}\frac{\sigma(z)}{a(z)}.$$

We note that $\mathcal{P}_n$ is invariant under the dynamical system (4.1); i.e., whenever the initial condition $(a, b) \in \mathcal{P}_n$, the iterates $(a_t, b_t) \in \mathcal{P}_n$. Moreover, the dynamical system (4.1) converges to the limit point (σ, σ) along the invariant manifold (4.4) [5]. Hence, the equilibrium set is

$$\mathcal{P}_n(\hat{w}), \quad \text{where } \hat{w} := \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix}. \tag{4.8}$$

Furthermore, (4.8) defines the center manifold for the dynamical system (4.1) evolving on $\mathcal{P}_n$, and no equilibrium in the center fold has a nontrivial unstable manifold. The invariant set (4.4) may also be written as

$$\rho_t S(a_t)b_t = S(\sigma)\sigma, \quad \text{where } \rho_t = \Pi_{k=t}^{\infty}(1-\gamma_k^2)^{-1}.$$

Then, for each $\sigma \in \mathcal{R}$,

$$\mathcal{W}^s(\sigma) = \{(a, b) \in \mathcal{P}_n \mid \rho S(a)b = S(\sigma)\sigma \quad \text{for some } \rho \in \mathbb{R}_+\} \tag{4.9}$$

is the stable manifold in $\mathcal{P}_n$ through (σ, σ). In view of (4.6), $S(a)b$ is positive on the unit circle for all $(a, b) \in \mathcal{P}_n$, and hence we can eliminate the variable ρ in $\rho S(a)b = S(\sigma)\sigma$ by dividing by $[S(a)b](1)$. Therefore, we define the mapping $h : \mathcal{P}_n \to \mathcal{Z}_n^+$ as

$$h(a, b) = \frac{S(a)b}{[S(a)b](1)}, \tag{4.10}$$

where $\mathcal{Z}_n^+$ is the n-dimensional convex space defined in section 2. Then, the manifold (4.9) may also be written as

$$\mathcal{W}^s(\sigma) = h^{-1}(\kappa(\sigma)), \tag{4.11}$$

where

$$\kappa(\sigma) := \frac{S(\sigma)\sigma}{[S(\sigma)\sigma](1)} \in \mathcal{Z}_n^+.$$

THEOREM 4.2. *The connected components of the sets* $\{\mathcal{W}^s(\sigma) \mid \sigma \in \mathcal{R}\}$ *form the leaves of an n-dimensional foliation of* $\mathcal{P}_n$.

Remark 4.3. The stable manifolds $\mathcal{W}^s(\sigma)$ are in fact connected. In this paper we shall sketch a proof of this fact based on the transversality lemma.

For the proof we need to show that the Jacobian $\mathrm{Jac}(h)|_{(a,b)}$ has full rank. To this end, we compute the directional derivative of h in the direction (u,v) for arbitrary $u,v \in \mathcal{L}$ as

$$D_{(u,v)}h = \lim_{\epsilon \to 0} \frac{h(a+\epsilon u, b+\epsilon v) - h(a,b)}{\epsilon} = \frac{S(a)q + S(b)p}{[S(a)b](1)}, \tag{4.12}$$

where

$$p = u - \mu b, \quad q = v - \mu a, \quad \mu = \frac{1}{2}\left[\frac{S(a)v + S(b)u}{S(a)b}\right](1). \tag{4.13}$$

In this computation, we have also used the fact that $S(a)b = S(b)a$.

LEMMA 4.4. *The tangent space of* $\mathcal{W}^s(\sigma)$ *at* (a,b) *has dimension* n *and is given by*

$$T_{(a,b)}\mathcal{W}^s(\sigma) = \{(u,v) \in \mathcal{L} \times \mathcal{L} \mid S(a)q + S(b)p = 0\},$$

where $p, q \in \mathcal{K}$ *depend on* (u,v) *as in* (4.13).

Proof. The tangent space $T_{(a,b)}\mathcal{W}(\sigma)$ is precisely the kernel of the Jacobian $\mathrm{Jac}(h)|_{(a,b)}$ of $h^{-1}(\kappa(\sigma))$, i.e., the space of (u,v) for which the directional derivative (4.12) is zero. This yields the expression of the lemma. Since the n algebraic equations contained in

$$h(a,b) = \kappa(\sigma)$$

are obtained by eliminating the variable ρ from the $n+1$ algebraic equations contained in

$$\rho S(a)b = S(\sigma)\sigma,$$

$T_{(a,b)}\mathcal{W}(\sigma)$ has the same dimension as $\ker \mathrm{Jac}(F)|_{(\rho,a,b)}$, where $F : \mathbb{R}_+ \times \mathcal{P}_n \to \mathcal{D}_+$ is defined as

$$F(\rho, a, b) = \rho S(a)b.$$

Now, the directional derivative of F in the direction $(\lambda, u, v) \in \mathbb{R} \times \mathcal{L} \times \mathcal{L}$ is given by

$$D_{(\lambda,u,v)}F(\rho,a,b) = S(a)[\rho v + \lambda b] + S(b)u,$$

so $T_{(a,b)}\mathcal{W}(\sigma)$ has the same dimension as

$$W := \{(r,u) \in \mathcal{K} \times \mathcal{L} \mid S(a)r + S(b)u = 0\}.$$

Then, exactly the same proof as in [5, Lemma 5.11] shows that $\dim W = n$. □

We note in passing that Lemma 5.11 in [5] also shows that if we extend $\mathcal{W}(\sigma)$ outside the positive region $\mathcal{P}_n$ we encounter singularities where the rank of the Jacobian is deficient precisely at the points where a and b have common reciprocal zeros.

Proof of Theorem 4.2. Given Lemma 4.4 and hence that $\ker \mathrm{Jac}(h) = n$, the rest of the proof is completely analogous to that of Theorem 3.3. □

5. The transversality lemma and the geometry of positive real functions. The following result is modeled after the corresponding result in [6, Lemma 4.5].

THEOREM 5.1 (transversality lemma). *Let $\mathcal{K}$ and $\mathcal{L}$ be the spaces defined in* (2.1)*. Then there are no nonzero p and q in $\mathcal{K}$ such that*

$$aq - bp \in B\mathcal{L} \tag{5.1}$$

and

$$S(a)q + S(b)p = 0. \tag{5.2}$$

Proof. We want to prove that if $p \in \mathcal{K}$ and $q \in \mathcal{K}$ satisfy (5.1) and (5.2), then $p = q = 0$. To this end, first note that (5.2) may be written as

$$h(z) + h(z^{-1}) = 0, \tag{5.3}$$

where

$$h(z) := a(z^{-1})q(z) + b(z)p(z^{-1}),$$

and that $h \in \mathcal{Q}$, where $\mathcal{Q}$ is defined by (2.3). Moreover, in view of (5.1),

$$g(z) := \frac{q(z)}{b(z)} - \frac{p(z)}{a(z)} = B(z)\frac{r(z)}{a(z)b(z)}, \quad \text{where } r \in \mathcal{L}.$$

Since $a(\infty) = b(\infty) = 1$ and $r(\infty) = 0$, the rational function $\frac{r}{ab}$ has a Laurent expansion

$$\frac{r(z)}{a(z)b(z)} = c_1 z^{-1} + c_2 z^{-2} + c_3 z^{-3} + \cdots$$

about infinity which holds on and outside the unit circle, and hence $g \in z^{-1}BH^2$. Therefore, $g^* \in zB^*\bar{H}^2$, and, consequently, by (2.4), both g and g^* are orthogonal to $\mathcal{Q}$ and hence to h. In particular,

$$\langle h, g - g^* \rangle = 0. \tag{5.4}$$

Now, a simple calculation shows that

$$g - g^* = \frac{h}{ba^*} - \frac{h^*}{ab^*} = \frac{S(a)b}{aa^*bb^*}h,$$

where (5.3) has been used to obtain the second equality, and therefore (5.4) yields

$$\left\langle h, \frac{S(a)b}{aa^*bb^*}h \right\rangle = 0.$$

However, since $(a, b) \in \mathcal{P}_n$ is positive real, $S(a)b$ is positive on the unit circle, and so is aa^*bb^*. Hence h must be zero, implying that $g = g^*$, i.e., g is constant and thus contained in $\mathcal{Q}$. But g is orthogonal to $\mathcal{Q}$, so g must be zero also. Then

$$q(z) = \frac{b(z)}{a(z)}p(z),$$

which, substituted into (5.2), yields

$$\left[\frac{b}{a}+\frac{b^*}{a^*}\right][ap^*+a^*p]=0.$$

Since $(a,b)\in\mathcal{P}_n$, the first factor is positive on the unit circle, and so

$$a(e^{i\theta})p(e^{-i\theta})+a(e^{-i\theta})p(e^{i\theta})=0$$

for all θ, and therefore, by the identity theorem,

$$S(a)p=0.$$

However, by Lemma 2.1, $S(a)$ has full rank, so p, and hence q, are zero. □

The transversality lemma has the following important consequence.

LEMMA 5.2. *Suppose that the point $(a,b)\in\mathcal{P}_n$ lies on the submanifolds $\mathcal{P}_n(w)$ and $\mathcal{W}^s(\sigma)$. Then*

$$T_{(a,b)}\mathcal{P}_n(w)\cap T_{(a,b)}\mathcal{W}^s(\sigma)=0.$$

Proof. Taking $(u,v)\in T_{(a,b)}\mathcal{P}_n(w)\cap T_{(a,b)}\mathcal{W}(\sigma)$, we see from Lemma 4.4 that (5.2) holds with p and q defined by (4.13). Moreover, since

$$aq-bp=av-\mu ab-bu+\mu ab=av-bu$$

for this choice of p and q, (5.1) also holds by Lemma 3.5. Hence, by Theorem 5.1, we must have $p=q=0$. But then evaluating at ∞, we obtain from (4.13) that $\mu=p(\infty)=q(\infty)$, which a fortiori must be zero, hence implying that $(u,v)=0$. □

It remains to show that the submanifolds $\mathcal{W}^s(\sigma)$ and $\mathcal{P}_n(w)$ are connected and thus constitute the leaves of the filtering foliation and the interpolation foliation, respectively.

COROLLARY 5.3. *The stable manifolds $\{\mathcal{W}^s(\sigma)\mid\sigma\in\mathcal{R}\}$ are diffeomorphic to $\mathcal{W}_n^+$ and thus connected. In particular, the stable manifolds of the fast filtering algorithm* (4.1) *decompose the space $\mathcal{P}_n$ into the leaves of a foliation.*

Proof. Consider again the mapping

$$\eta:\,\mathcal{P}_n\to\mathcal{W}_n^+$$

with $\eta^{-1}(w)=\mathcal{P}_n$. The restriction η_σ of η to $\mathcal{W}^s(\sigma)$ is a map of n-manifolds

$$\eta_\sigma:\,\mathcal{W}^s(\sigma)\to\mathcal{W}_n^+.$$

We claim that

$$\det\operatorname{Jac}(\eta_\sigma)|_{(a,b)}\neq 0$$

for all $(a,b)\in\mathcal{W}^s(\sigma)$. To prove this, we need to show that the directional derivative

$$D_{(u,v)}\eta_\sigma=\operatorname{Jac}(\eta_\sigma)\begin{bmatrix}u\\v\end{bmatrix}$$

is zero for any $(u,v)\in T_{(a,b)}\mathcal{W}^s(\sigma)$ only if $(u,v)=0$. However,

$$\ker\operatorname{Jac}(\eta_\sigma)\subset\ker\operatorname{Jac}(\eta)=T_{(a,b)}\mathcal{P}_n(w)$$

(Lemma 3.5), and hence this follows from Lemma 5.2. To proceed, we also need to show that η_σ is *proper*, i.e., that the inverse image $\eta_\sigma^{-1}(K)$ is compact for each compact set in the range space.

LEMMA 5.4. *The mapping η_σ is proper.*

Proof. Suppose $w_k \to w$ in $\mathcal{W}_n^+$ with $w_k = \eta_\sigma(a_k, b_k)$. Since $\mathcal{P}_n$ and hence $\overline{\mathcal{W}^s(\sigma)}$ are relatively compact, the sequence (a_k, b_k) has a cluster point (a, b) in $\overline{\mathcal{W}^s(\sigma)} \subset \overline{\mathcal{P}_n}$, where a and b have all their zeros in the closed unit disc. We need to show that $(a, b) \in \mathcal{W}^s(\sigma)$. Now, suppose instead that $(a, b) \in \partial\mathcal{W}^s(\sigma)$, the boundary of $\mathcal{W}^s(\sigma)$. Then $(a, b) \in \partial\mathcal{P}_n$. In fact, if $(a, b) \in \mathcal{P}_n$, then, by Theorem 4.2, $(a, b) \in \mathcal{W}^s(\hat{\sigma})$ for some $\hat{\sigma} \in \mathcal{R}$ such that $\hat{\sigma} \neq \sigma$. But then

$$\frac{S(a)b}{[S(a)b](1)} = \kappa(\hat{\sigma}) \neq \kappa(\sigma),$$

which is impossible by continuity. Now, the boundary $\partial\mathcal{P}_n$ consists of those (a, b) for which either $S(a)b$ has a zero on the unit circle or $S(a)b$ is identically zero. Since the zeros of $S(a_k)b_k$ are fixed and therefore independent of k and lie inside the unit disc, $S(a)b$ cannot have zeros on the unit circle without being identically zero. Therefore, the function $f = b/a$ has the property $f + f^* = 0$, and hence f must have all poles and zeros on the unit circle. Then, it is well known [23] and easy to check that f takes the form

$$f(z) = \prod_{k=1}^{m} \frac{z - \mu_k}{z + \mu_k}, \quad |\mu_k| = 1, \quad m \leq n,$$

and, consequently,

$$F(z) = \frac{f(z) - 1}{f(z) + 1}$$

is a Blaschke product of degree m. Thus, modulo a trivial conformal equivalence, Corollary 2.3 in [16, p. 9] states that the rank of the corresponding Pick matrix equals m. Therefore, since $m < n + 1$, the Pick matrix is singular, and the corresponding value vector w must lie in the boundary of $\mathcal{W}_n^+$, contrary to assumption. Consequently, $(a, b) \notin \partial\mathcal{W}^s(\sigma)$, and thus $(a, b) \in \mathcal{W}^s(\sigma)$ as claimed. □

Since η_σ is proper and has a nowhere vanishing Jacobian, $\eta_\sigma^{-1}(w)$ is a finite set with cardinality δ, which is independent of w [30]. Therefore, $\eta_\sigma : \mathcal{W}^s(\sigma) \to \mathcal{W}_n^+$ is a δ-fold covering $\mathcal{W}_n^+$ [30]. Consider the point $\hat{w} \in \mathcal{W}_n^+$ defined by (4.8). For $(a, b) \in \mathcal{W}^s(\sigma)$, to say that $\eta_\sigma(a, b) = \hat{w}$ is to say that $a = b$. Since (a, a) is an equilibrium for the fast filtering algorithm of Lemma 4.1 and lies on the stable manifold of the equilibrium (σ, σ), we must have $(a, a) = (\sigma, \sigma)$, or $(a, b) = (\sigma, \sigma)$. Therefore, $\delta = 1$ and the map $\eta_\sigma : \mathcal{W}^s(\sigma) \to \mathcal{W}_n^+$ is a diffeomorphism. □

COROLLARY 5.5. *The submanifolds $\{\mathcal{P}_n(w) \mid w \in \mathcal{W}_+\}$ are connected. In particular, Nevanlinna–Pick interpolation defines a foliation of the space $\mathcal{P}_n$.*

Proof. Suppose $(a^{(1)}, b^{(1)})$ and $(a^{(2)}, b^{(2)})$ lie in $\mathcal{P}_n(w)$. Since $\mathcal{P}_n$ is connected, there is a continuous path $\gamma : [0, 1] \to \mathcal{P}_n$ with $\gamma(0) = (a^{(1)}, b^{(1)})$ and $\gamma(1) = (a^{(2)}, b^{(2)})$. Composing γ with η, we obtain a closed curve

$$\tilde{\gamma} = \eta \circ \gamma : \quad [0, 1] \to \mathcal{W}_+$$

with initial (and final) point w, i.e., $w = \eta(a^{(i)}, b^{(i)})$, $i = 1, 2$. Since $\mathcal{W}_n^+$ is convex, it is simply connected and therefore $\tilde{\gamma}$ can be contracted to the "constant curve" w

through a homotopy $\tilde{H}$ [22]; i.e.,

$$\tilde{H} : [0,1] \times [0,1] \to \mathcal{W}_+$$

jointly continuous and satisfying

$$\begin{aligned} \tilde{H}(r,0) &= \tilde{\gamma}(r), \\ \tilde{H}(r,1) &= w, \\ \tilde{H}(0,t) &= w, \\ \tilde{H}(1,t) &= w. \end{aligned}$$

We now construct a lifting of the homotopy $\tilde{H}$ to a homotopy H, with values in $\mathcal{P}_n$, covering $\tilde{H}$; i.e., $\eta \circ H = \tilde{H}$. Returning first to the curve γ, each point $\gamma(r)$ lies in a unique stable manifold, which we denote by $\mathcal{W}^s(\sigma(r))$. Since η_σ is a diffeomorphism for each σ, for each r fixed we can lift the curve $\tilde{H}_r$, defined as $\tilde{H}_r(t) = \tilde{H}(r,t)$ for $t \in [0,1]$, to a curve in $\mathcal{W}^s(\sigma(r))$ covering $\tilde{H}_r$ by defining $H_r(t) = \eta^{-1}_{\sigma(r)}(\tilde{H}_r(t))$. Note that H_r is a curve lying in $\mathcal{P}_n$ with initial point $\gamma(r)$. Now define $H : [0,1]\times[0,1] \to \mathcal{P}_n$ via

$$H(r,t) = H_r(t) = \eta^{-1}_{\sigma(r)}(\tilde{H}(r,t)).$$

We claim that H is jointly continuous. To see this, suppose $(r_k, t_k) \to (r,t)$ and set

$$(a_k, b_k) = H(r_k, t_k), \quad (a,b) = H(r,t).$$

We next note that $w_k := \tilde{H}(r_k, t_k) \to \tilde{H}(r,t) =: \tilde{w}$, $\gamma(r_k) \to \sigma(r)$, and consequently that $\sigma(r_k) \to \sigma(r)$, as $k \to \infty$. To prove that H is jointly continuous, it suffices to prove that every neighborhood of (a,b) contains the points (a_k, b_k) for all k sufficiently large. Now, $(a,b) \in \mathcal{P}_n(\tilde{w})$, and, using the implicit function theorem, we can choose neighborhoods $N(a,b)$ which are rectangular in the sense that a neighborhood of (a,b) in $\mathcal{P}_n(\tilde{w})$ serves as the vertical axis, while the horizontal axes consist of unique "slices" consisting of n-manifolds to which the restriction of η will be a diffeomorphism.

That is, the horizontal slices will be open subsets of $\mathcal{W}^s(\sigma)$. Since $\sigma(r_k) \to \sigma(r)$, and since the foliation defined by the stable manifolds of the fast filtering algorithm is itself defined by a submersion, such a neighborhood $N(a,b)$ will intersect $\mathcal{W}^s(\sigma(r_k))$ for all k sufficiently large. Now, (a_k, b_k) is the endpoint of the unique curve $H_{r_k}(t)$ for $t \in [0, t_k]$ in $\mathcal{W}^s(\sigma(r_k))$ covering $\tilde{H}_{r_k}$. Similarly, for any $\bar{t}$ satisfying $0 \le \bar{t} < t_k$, (a_k, b_k) is the endpoint of the unique curve in $\mathcal{W}^s(\sigma(r_k))$ covering $\tilde{H}_{r_k}$ on $[\bar{t}, t_k]$. Since $\eta(N(a,b))$ is open, there exists a $\bar{t}$, $0 \le \bar{t} \le t_k$, for all k sufficiently large so that

$$\tilde{H}_{r_k}[\bar{t}, t_k] \subset \eta(N(a,b)).$$

In particular, since $\eta_{\sigma(r_k)}$ is a (global) diffeomorphism, there exist unique lifts γ_k of these curves in $\mathcal{P}_n$ which lie in $\mathcal{W}^s(\sigma(r_k)) \cap N(a,b)$ and cover $\tilde{H}_{r_k}$ on $[\bar{t}, t_k]$ and have initial points $\eta^{-1}_{\sigma(r_k)}(\tilde{H}(r_k, \bar{t}))$. Since such liftings are unique, it follows that γ_k and H_{r_k} coincide on the subinterval $[\bar{t}, t_k]$, and therefore

$$H_{r_k}(t) \subset N(a,b) \quad \text{for } t \in [\bar{t}, t_k].$$

Consequently,

$$(a_k, b_k) = H_{r_k}(t_k) \in N(a,b)$$

for all k sufficiently large.

We have established that H is jointly continuous. The mapping H also satisfies

$$\begin{aligned} &H(r,0)=\gamma(r),\\ &H(r,1)\subset \mathcal{P}_n(w) \quad \text{for } 0\le r\le 1,\\ &H(0,t)=\gamma(0)=(a^{(1)},b^{(1)}),\\ &H(1,t)=\gamma(1)=(a^{(2)},b^{(2)}). \end{aligned}$$

In particular, $H(\cdot,1)$ is a continuous path in $\mathcal{P}_n(w)$ joining $(a^{(1)},b^{(1)})$ and $(a^{(2)},b^{(2)})$. Since these points are arbitrary in $\mathcal{P}_n(w)$, this manifold is path connected and hence connected. □

Remark 5.6. The foliation by stable manifolds does, of course, define an integrable connection on the distribution tangent to the interpolation foliation, and it is tempting to believe that we can deduce a path-lifting result from the existence of this connection. At this point in the proofs we do not, however, know whether $\eta : \mathcal{P}_n \to \mathcal{W}_n^+$ is a fiber bundle or even a fibration. Moreover, η is definitely not proper, so one could at best expect a path lifting on a sufficiently small subinterval. For this reason, we directly established the homotopy lifting property for curves. We remark that it is possible to go further, showing that $\eta : \mathcal{P}_n \to \mathcal{W}_n^+$ is a fibration. In this case, one could then deduce path connectedness of the fiber from the fact that $\mathcal{W}_n^+$ is simply connected, using the long exact homotopy sequence of the fibration. Since we only needed the sequence for curves and connected components, we instead used a constructive approach to defining the boundary operator in the sequence.

6. Main results.

Another consequence of the transversality lemma is that the leaves of the interpolation foliation intersect the leaves of the filtering foliation transversely; i.e., the two foliations are complementary. Actually, a much deeper relationship exists between these foliations, having several interesting corollaries.

THEOREM 6.1. *The filtering foliation and the interpolation foliation are complementary. Moreover, each leaf $\mathcal{P}_n(w)$ intersects each leaf $\mathcal{W}^s(\sigma)$ of the filtering foliation in one, and only one, point in $\mathcal{P}_n$.*

The first assertion follows immediately from Lemma 5.2 after it has been established that $\mathcal{P}_n(w)$ and $\mathcal{W}^s(\sigma)$ are connected and so are the leaves of respective foliation (Corollary 5.5 and Corollary 5.3). Consequently, there are two complementary foliations of $\mathcal{P}_n$, namely,

$$\mathcal{F}_1 : \quad \mathcal{P}_n = \bigcup_{w\in\mathcal{W}_+} \mathcal{P}_n(w), \tag{6.1}$$

indexed by the interpolation values $w \in \mathcal{W}_+$, and

$$\mathcal{F}_2 : \quad \mathcal{P}_n = \bigcup_{\sigma\in\mathcal{R}} \mathcal{W}(\sigma), \tag{6.2}$$

indexed by the equilibrium points (4.8) of the dynamical system (4.1), or, equivalently, by the spectral zeros in the form of a point in $\mathcal{S}_n$. This suggests that, given a set of admissible interpolation values and a set of stable spectral zeros, there is a unique solution of the Nevanlinna–Pick problem represented by the intersection between the corresponding leaves of the foliations $\mathcal{F}_1$ and $\mathcal{F}_2$. This is precisely the second assertion of the theorem and is a consequence of Proposition 6.3 to be proven below.

To this end, first note that the fact that the filtering foliation and the interpolation foliation are complementary says that this uniqueness does occur to first order, in the following sense.

LEMMA 6.2. *Let $h_w : \mathcal{P}_n(w) \to \mathcal{Z}_n^+$ be the restriction of h, defined by* (4.10), *to $\mathcal{P}_n(w)$. Then, for each $(a,b) \in \mathcal{P}_n(w)$, the Jacobian matrix Jac(h_w) of h_w is nonsingular.*

Proof. To prove this, we need to show that the directional derivative

$$D_{(u,v)}h = \mathrm{Jac}(h_w)\begin{bmatrix} u \\ v \end{bmatrix}$$

is zero for any $(u,v) \in T_{(a,b)}\mathcal{P}_n(w)$ only if $(u,v) = 0$. But this follows from Lemma 5.2 precisely as in the proof of Corollary 5.3. $\square$

It is interesting to note that the duality between interpolation and filtering is reflected in a symmetry between the restricted mappings

$$\eta_\sigma : \mathcal{W}^s(\sigma) \to \mathcal{W}_n^+$$

and

$$h_w : \mathcal{P}_n(w) \to \mathcal{Z}_n^+.$$

Recall that η_σ is the restriction of $\eta : \mathcal{P}_n \to \mathcal{W}_n^+$ to $\mathcal{W}^s(\sigma) = h^{-1}(\kappa(\sigma))$, and h_w is the restriction of $h : \mathcal{P}_n \to \mathcal{Z}_n^+$ to $\mathcal{P}_n(w) = \eta^{-1}(w)$. Moreover, we have the following result.

PROPOSITION 6.3. *The mappings η_σ and h_w are diffeomorphisms. In particular, each choice of σ and w determines and is determined by precisely one element $(a,b) \in \mathcal{P}_n$.*

Proof. We have already shown in the proof of Corollary 5.3 that η_σ is a diffeomorphism. Concerning h_w, we first establish properness.

LEMMA 6.4. *The mapping h_w is proper.*

Proof. To show this, consider a sequence (κ_k) in $\mathcal{Z}_n^+$ with $\kappa_k = h_w(a_k, b_k)$ which converges to $\kappa \in \mathcal{Z}_n^+$ as $k \to \infty$, and prove that any cluster point (a,b) of (a_k,b_k) lies in $\mathcal{P}_n(w)$. Since $\mathcal{P}_n$ is relatively compact, $(a,b) \in \overline{\mathcal{P}_n(w)} \in \overline{\mathcal{P}_n}$. Now, suppose (a,b) is not in $\mathcal{P}_n(w)$ but in the boundary $\partial\mathcal{P}_n(w)$. Then $(a,b) \in \partial\mathcal{P}_n$ because if $(a,b) \in \mathcal{P}_n$, then, by Theorem 3.3, $(a,b) \in \mathcal{P}_n(\hat{w})$ for some $\hat{w} \neq w$, which contradicts continuity of $\eta(a,b)$. But if $(a,b) \in \partial\mathcal{P}_n$, then $S(a)b$ either has a zero on the unit circle or is identically zero, while $a, b \in \mathcal{R}$ of course remain nonzero. Therefore, if there is no zero at $z = 1$, $\kappa_k \to \partial\mathcal{Z}_n^+$ and if $[S(a)b](1) = 0$, then $\kappa_k \to \infty$, contradicting the assumption that $\kappa \in \mathcal{Z}_n^+$ in both cases. $\square$

Since h_w is a proper map with nonvanishing Jacobian (Lemma 6.2), $h_w : \mathcal{P}_n(w) \to \mathcal{Z}_n^+$ is a δ-fold covering. Since $\mathcal{P}_n(w)$ is connected and $\mathcal{Z}_n^+$ is convex, and hence simply connected, the number, δ, of sheets must be one [30]. Therefore, h_w is a diffeomorphism. $\square$

This concludes the proof of Theorem 6.1.

These geometric implications of the transversality lemma allow us to give an alternative geometric proof and amplification of the following result in [20], where, however, spectral zeros on the unit circle are also allowed, and in [12], using convex analysis to the minima of a functional defined using generalized entropy gains.

COROLLARY 6.5 (spectral zero assignability theorem for Nevanlinna–Pick interpolation). *Suppose w determines a positive definite Pick matrix. The positive real* *interpolants* (a, b) *in* $\mathcal{P}_n(w)$ *can be uniquely determined by a choice of stable spectral zeros.*

This corollary shows that the spectral zeros are design parameters which can be used, for example, in designing robust bounded real closed loop systems. This result also holds in the case that all the interpolation points $z_0 = z_1 = \cdots = z_n = \infty$, a situation of great interest in signal processing, spectral analysis, and stochastic systems [6, 7, 8, 9, 10, 11] (see also [17, 18], where the first proofs of existence were presented). In this case, the design parameter is intuitively very appealing, since it represents a choice of zeros for shaping filters which can shape white noise into a process matching a finite window of covariance data.

The following theorem, finally, is also a consequence of the transversality lemma. Here $\simeq$ denotes "diffeomorphic," and $\mathcal{S}_n$ is the space of Schur polynomials of degree n introduced in section 1.

THEOREM 6.6. *The space* $\mathcal{P}_n$ *is Euclidean of dimension* $2n$. *More specifically,*

$$\mathcal{P}_n \simeq \mathcal{W}_n^+ \times \mathcal{Z}_n^+ \simeq \mathcal{W}_n^+ \times \mathcal{S}_n,$$

where $\mathcal{W}_n^+$, $\mathcal{Z}_n^+$, *and* $\mathcal{S}_n$ *are all diffeomorphic to* $\mathbb{R}^n$.

For the proof we need the following "folk theorem," for which we have been unable to find a direct reference.

LEMMA 6.7. *An open, convex set* $D \in \mathbb{R}^n$ *is diffeomorphic to* $\mathbb{R}^n$.

It is well known and easy to see that an open convex set $D \in \mathbb{R}^n$ is homeomorphic to $\mathbb{R}^n$ [3, p. 2]. Except for $n = 4$, this implies that D is also diffeomorphic to $\mathbb{R}^n$, so the problem is only for $n = 4$ [31, p. 5]. However, convexity gives us much more, and it is simpler to give a direct proof. The following is an outline of a proof provided by O. Viro.[1]

Convexity allows us to construct a C^∞-function $\varphi : \mathbb{R}^n \to [0, 1]$, such that $\varphi(0) = 1$, $\varphi(x) > 0$ in D, and $\varphi(x) = 0$ outside D, which is monotonely nondecreasing along any ray $\{\lambda y \mid \|y\| = 1, \lambda \geq 0\}$. (We place the origin inside D.) In fact, for each supporting hyperplane H_k to D, one can construct a function φ_k which is zero in the half-space not containing D and which is monotonely nonincreasing along the normal direction from the origin, with the value one on a parallel hyperplane $\hat{H}_k$ and in the whole half-space beyond it. If D is a polytope, there are finitely many supporting hyperplanes H_k, and we may take $\varphi(x) = \prod_k \varphi_k(x)$. In general, we choose the hyperplanes H_k on a dense set of the boundary and let the distances d_k between each pair $\hat{H}_k$ and H_k be a sequence which tends to zero. Then, only a finite number of φ_k are different from one at any point in D, and hence the construction still works. The function $\psi : D \to \mathbb{R}^n$, with $\psi(0) = 1$ and $\psi(x) = x/\varphi(x)$ otherwise, is then a diffeomorphism. In fact, the monotonicity implies that the Jacobian does not vanish in D.

Proof of Theorem 6.6. Since $\mathcal{W}_n^+$ and $\mathcal{Z}_n^+$ are open and convex sets, they are diffeomorphic to $\mathbb{R}^n$ by Lemma 6.7. In the case of $\mathcal{Z}_n^+$, this can also be seen from the facts that $\mathcal{Z}_n^+ \simeq \mathcal{S}_n$ [6, p. 1849] and $\mathcal{S}_n \simeq \mathbb{R}^n$ [4]. Then, the rest follows from Proposition 6.3. □

Appendix. Fast Kalman filtering and the Schur algorithm.

Modulo a trivial reformulation, Lemma 4.1 is proven in [27, 28, 29] in the context of Kalman filtering, using the Szegö polynomials orthogonal on the unit circle and the Levinson recursion. Obviously, the recursion (4.1) is related to the Schur algorithm

[1] Similar ideas of a proof have also been suggested to us by H. Shapiro and M. Benedicks.

[1], as was established in, for example, [13]. In this appendix, we give a simple proof in this context.

Given any $(a,b) \in \mathcal{P}_n$ and the corresponding strictly positive real function $f = b/a$, define

$$\varphi(z) := \frac{f(z)-1}{f(z)+1} = \frac{b(z)-a(z)}{b(z)+a(z)} =: \frac{P(z)}{Q(z)},$$

which is a *Schur function* in the sense that it maps the exterior of the unit disc, $\mathbb{D}^c$, into the open unit disc $\mathbb{D}$. The Schur algorithm

$$\varphi_{t+1}(z) = z\frac{\varphi_t(z)-\varphi_t(\infty)}{1-\varphi_t(\infty)\varphi_t(z)}, \quad \varphi_0(z) = \varphi(z), \tag{A.1}$$

defines a sequence $\varphi_t(z)$, $t = 0,1,2,\dots$, of Schur functions, and the Schur parameters

$$\gamma_t = \varphi_{t+1}(\infty), \quad t = 0,1,2,\dots, \tag{A.2}$$

are less than one in modulus [1].

Proposition A.1. *For* $t = 0,1,2,\dots$,

$$\varphi_{t+1}(z) = \frac{zP_t(z)}{Q_t(z)}, \tag{A.3}$$

where P_t *and* Q_t *are polynomials satisfying the recursions*

$$\begin{cases} Q_{t+1}(z) = Q_t(z) - \gamma_t z P_t(z), & Q_0(z) = Q(z), \\ P_{t+1}(z) = zP_t(z) - \gamma_t Q_t(z), & P_0(z) = P(z). \end{cases} \tag{A.4}$$

Here Q_t *is of degree* n *having leading coefficient*

$$r_t = \prod_{k=0}^{t-1}(1-\gamma_k^2). \tag{A.5}$$

Proof. Clearly,

$$\varphi_1(z) = z\varphi_0(z) = \frac{zP(z)}{Q(z)},$$

so (A.3) holds for $t = 0$. Now let $t \geq 1$, and suppose that

$$\varphi_t(z) = \frac{zP_{t-1}(z)}{Q_{t-1}(z)}.$$

Then, the Schur algorithm (A.1) together with (A.2) yields

$$\varphi_{t+1}(z) = z\frac{zP_{t-1}(z) - \gamma_{t-1}Q_{t-1}(z)}{Q_{t-1}(z) - \gamma_{t-1}zP_{t-1}(z)} = \frac{zP_t(z)}{Q_t(z)},$$

and hence (A.3) holds for $t = 1,2,\dots$ by induction. Moreover, (A.3) and (A.4) yield

$$\frac{Q_{t+1}(z)}{Q_t(z)} = 1 - \gamma_t\varphi_{t+1}(z),$$

which, evaluated at $z = \infty$, becomes $1 - \gamma_t^2$ by (A.2). But $|\gamma_t| < 1$, and hence $\deg Q_{t+1} = n$ whenever $\deg Q_t = n$. Since $\deg Q_0 = n$, it thus follows by induction that $\deg Q_t = n$ for $t = 0, 1, 2, \ldots$. More precisely, r_t, given by (A.5), is the leading coefficient of $Q_t(z)$. $\square$

The recursion (A.4) is precisely the fast algorithm for Kalman filtering [27] in the formulation of [28]. In fact, suppose $\{y_0, y_1, y_2, \ldots\}$ is a stationary stochastic process with spectral density

$$\Phi(z) = \frac{1}{2}[f(z) + f(z^{-1})],$$

where $f = b/a$ has a minimal realization

$$f(z) = 1 + 2h(zI - F)^{-1}g.$$

Then the linear least squares estimate $\hat{y}_t$ of y_t given $y_0, y_1, \ldots, y_{t-1}$ is generated by the Kalman filter

$$\begin{cases} \hat{x}_{t+1} = F\hat{x}_t + k_t(y_t - \hat{y}_t), \\ \hat{y}_t = h\hat{x}_t, \end{cases}$$

where k_t is determined from $Q_t(z)$ in the following way: If (F, g, h) is chosen so that $h = (1, 0, \ldots, 0)$, F has characteristic polynomial $\chi_F(z) = z^n + \alpha_1 z^{n-1} + \cdots + \alpha_n$, and

$$Q_t(z) = r_t[z^n + q_1(t)z^{n-1} + \cdots + q_n(t)],$$

then the gain k_t is given by

$$k_t = q(t) - \alpha.$$

Moreover, Q_t/r_t is the characteristic polynomial of the feedback matrix

$$F - k_t h, \tag{A.6}$$

which hence is stable.

In the same way as in [28], a direct calculation using (A.4) yields

$$\begin{aligned} &Q_{t+1}(z)Q_{t+1}(z^{-1}) - P_{t+1}(z)P_{t+1}(z^{-1}) \\ &\qquad = (1 - \gamma_t^2)[Q_t(z)Q_t(z^{-1}) - P_t(z)P_t(z^{-1})] \end{aligned} \tag{A.7}$$

for $t = 0, 1, 2, \ldots$.

Now set

$$a_t(z) := \frac{Q_t(z) - P_t(z)}{2r_t\tau(z)}, \quad b_t(z) := \frac{Q_t(z) + P_t(z)}{2r_t\tau(z)}. \tag{A.8}$$

We first note that $a_0 = a$ and $b_0 = b$. Moreover, since $|z^{-1}| < 1$ in $\mathbb{D}^c$, $z^{-1}\varphi_{t+1}(z)$ is a Schur function, and, consequently,

$$f_t(z) := \frac{b_t(z)}{a_t(z)} = \frac{1 + z^{-1}\varphi_{t+1}(z)}{1 - z^{-1}\varphi_{t+1}(z)} \tag{A.9}$$

is strictly positive real for $t = 0, 1, 2, \ldots$ so that $(a_t, b_t) \in \mathcal{P}_n$. This verifies (4.3).

From (A.4) we readily obtain the recursion (4.1), Moreover, in view of (A.9),

$$\varphi_{t+1}(z) = z\frac{b_t(z) - a_t(z)}{b_t(z) + a_t(z)},$$

and hence (4.2) follows from (A.2). We also note that (4.4) is equivalent to (A.7). It now only remains to verify (4.5). To this end, we recall that, for rational positive real functions, the Schur parameters form an ℓ_2 sequence [18, p. 447], and hence $\gamma_t \to 0$ as $t \to \infty$. Consequently, r_t tends to some limit r_∞ as $t \to \infty$, and it follows from (A.4) that $Q_t(z)$ tends to a constant polynomial Q_∞, which is the characteristic polynomial of the steady-state feedback matrix (A.6) defined by the steady-state Kalman gain. Hence $r_\infty^{-1} Q_\infty \in \mathcal{S}_n$. It also follows that $P_t(z)$ tends to zero. Therefore, by (A.8), a_t and b_t tend to σ as $t \to \infty$, where

$$\sigma(z) = \frac{Q_\infty(z)}{r_\infty \tau(z)}.$$

Clearly, $\sigma \in \mathfrak{R}$, as claimed.

This proves the claims made in Lemma 4.1. In [5], a much more refined analysis of the global phase portrait of the fast filtering algorithm is given, with the explicit derivation of the global stable manifolds which we employ in section 6. This analysis has many other consequences. For example, it can be shown [6] that for a rational strictly positive real function the sequence of Schur parameters decays to zero geometrically, generalizing previous results in the literature on conditional and absolute summability of the corresponding series of Schur parameters [21, 2, 18].

Acknowledgments. We would like to thank Professors H. Shapiro, M. Benedicks, and O. Viro for technical advice.

OPTIMALITY OF ENERGY ESTIMATES FOR THE WAVE EQUATION WITH NONLINEAR BOUNDARY VELOCITY FEEDBACKS*

JUDITH VANCOSTENOBLE† AND PATRICK MARTINEZ†

Abstract. We consider the wave equation damped by a nonlinear boundary velocity feedback $q(u_t)$.

First we consider the case where q has a linear growth at infinity. We prove that the usual decay rate estimates proved by Nakao [*Differential Integral Equations,* 8 (1995), pp. 681–688], Haraux and Zuazua [*Arch. Rational Mech. Anal.,* 100 (1988), pp. 191–206], Conrad, Leblond, and Marmorat [in *Proceedings of the Fifth International Federation of Automatic Control Symposium on Control of Distributed Parameter Systems*, Perpignan, 1989, pp. 101–116], Zuazua [*SIAM J. Control Optim.,* 28 (1990), pp. 466–477], and Komornik [in *Control and Estimation of Distributed Parameter Systems: Nonlinear Phenomena, Internat. Ser. Numer. Math.* 118, Birkhäuser, Basel, 1994, pp. 253–266] when q has a polynomial behavior at zero and by the second author [*ESAIM Control Optim. Calc. Var.,* 4 (1999), pp. 419–444] in the general case are in fact optimal in one space dimension. More generally, we prove that the energy decays exactly like the solution of an explicit and simple ordinary differential equation.

Next we study the problem when q is bounded at infinity. We prove that strong solutions decay exponentially to zero, and we exhibit a sequence of weak solutions for which the associated energy decays to zero at infinity as slowly as the iterated logarithms go to infinity at infinity.

Key words. damped wave equation, asymptotic behavior, boundary feedback, optimal energy estimates

1. Introduction.

We consider the wave equation in one space dimension, damped by a boundary velocity feedback $q(u_t)$, where $q : \mathbb{R} \longrightarrow \mathbb{R}$ is a nonlinear function:

$$(1.1)\qquad \begin{cases} u_{tt} - u_{xx} = 0, & x \in (0,1),\ t \geq 0, \\ u(0,t) = 0, & t \geq 0, \\ u_x(1,t) = -q(u_t(1,t)), & t \geq 0, \\ (u(x,0), u_t(x,0)) = (u^0(x), v^0(x)), & x \in (0,1), \end{cases}$$

where $(u^0(x), v^0(x))$ is given in $V \times L^2(0,1)$ (with $V = \{v \in H^1(0,1) \mid v(0) = 0\}$). We refer to [22] for the physical motivations of this model.

We define the energy of u by

$$\forall t \geq 0, \quad E_u(t) = \frac{1}{2}\int_0^1 (u_x^2(x,t) + u_t^2(x,t))\,dx.$$

First we study the problem of asymptotic decay of $E_u(t)$ as $t \to +\infty$. When $q : \mathbb{R} \longrightarrow \mathbb{R}$ is a continuous nondecreasing function, has a polynomial behavior at zero, and a linear growth at infinity, it means that when there exist four positive

†M.I.P., Université Paul Sabatier Toulouse III, 118 route de Narbonne, 31 062 Toulouse Cedex 4, France (vancoste@mip.ups-tlse.fr, martinez@mip.ups-tlse.fr).

constants C_1, C_2, C_3, and C_4 such that

$$\begin{cases} \forall |s| \le 1,\ C_1|s|^p \le |q(s)| \le C_2|s|^{1/p} \quad \text{with } p>1, \\ \forall |s| \ge 1,\ C_3|s| \le |q(s)| \le C_4|s|, \end{cases} \tag{1.2}$$

then $E_u(t)$ satisfies the estimate

$$\forall t \ge 0, \quad E_u(t) \le \frac{C(E_u(0))}{(1+t)^{2/(p-1)}}, \tag{1.3}$$

where $C(E_u(0)) > 0$ is a constant which depends on $E_u(0)$. (See [23, 10, 5] for (1.1) and see also [17, 6, 9, 4, 2, 11, 19, 12, 20] for the similar problem of the wave equation damped by a distributed nonlinear feedback (2.2). More generally, these authors studied the case of higher space dimensions.)

More recently, the previous results were completed in [15] with explicit estimates under weaker assumptions than (1.2) on the function q (in particular, when q is weaker than any polynomial in zero; see also Lasiecka and Tataru [13] and Liu and Zuazua [14]). For example, we proved that, if $q(s) = \operatorname{sgn}(s)\, e^{-1/|s|}$ in a neighborhood of zero (with linear growth at infinity), then $E_u(t)$ satisfies the estimate

$$\forall t \ge 2, \quad E_u(t) \le \frac{C}{(\ln t)^2}. \tag{1.4}$$

The purpose of this article is to establish the optimality of these estimates in case of (1.1), i.e., in the case of a boundary feedback in one space dimension. Note that we use here the term of "optimality of estimates" in the sense of "two-sides estimates." (For example, in (1.3), we wonder if $2/(p-1)$ is the best choice of the exponent. In some cases, our method will also lead to the best choice of the factor $C(E_u(0))$ but it is not the main object of this paper.) First, we treat the polynomial case with a method announced in [21]: for particular solutions (we choose particular initial conditions which simplify the problem), this method produces an explicit equivalent of the energy and proves the optimality of (1.3). We exhibit some solutions u of (1.1) that satisfy

$$E_u(t) \underset{t\to+\infty}{\sim} \frac{C_p}{t^{2/(p-1)}}$$

(see Theorem 2.1). Then we extend the preceding result in the case of general feedbacks. In general, we prove that the solutions decay exactly like the solutions of a very simple ordinary differential equation. Moreover, under some additional assumptions, we give lower bounds of the energy, which prove, in particular, the optimality of estimates like (1.3) and (1.4) (see Theorem 3.1, and Propositions 3.1, 3.2, and 3.3). Our method also gives similar results of optimality for other examples: we can treat the one-dimensional wave equation with boundary feedbacks at both extremities and also the wave equation with a boundary feedback *in dimension* 3.

Next we turn to another optimality problem: in a previous paper [16], we studied the decay rate of *strong* solutions of the wave equation damped with an internal nonlinear weak feedback (that means $\frac{q(s)}{s} \longrightarrow 0$ when $|s| \longrightarrow +\infty$) in space dimension 2. We proved that, if $q'(0) \neq 0$, *strong* solutions decay exponentially to zero, but with a decay rate depending on the norm of the initial conditions in $H^2(\Omega) \times H_0^1(\Omega)$. Haraux and Conrad asked us if the decay rate really depends on that quantity, and what can be said about *weak* solutions.

Here we study this question in the case of the one-dimensional wave equation with boundary damping (1.1): with a carefully chosen function q, which satisfies

$$q'(0) \neq 0 \quad \text{and} \quad q(s) \longrightarrow \pm 1 \quad \text{when} \quad s \longrightarrow \pm\infty,$$

we prove that *strong* solutions decay exponentially but *not uniformly* to zero: more precisely, we prove that given (u^0, v^0) in $W^{1,\infty}(0,1) \times L^\infty(0,1)$ (and $u^0(0) = 0$), there exists some (explicit) constant $C^0 = C^0(\|(u^0, v^0)\|_{W^{1,\infty} \times L^\infty})$ such that

$$\forall t \geq 0, \; E_u(t) \leq C^0 \, 3^{-t};$$

and on the other hand we construct a sequence $(u_m)_{m \geq 1}$ of solutions of (1.1), corresponding to initial conditions $({u_m}^0, {v_m}^0)$ in $W^{1,\infty}(0,1) \times L^\infty(0,1)$ that satisfy

$$E_{u_m}(0) = 1 \quad \text{and} \quad \|({u_m}^0, {v_m}^0)\|_{W^{1,\infty} \times L^\infty} = 2m,$$

and

$$\forall t \geq m, \; E_{u_m}(t) = \frac{9^m}{9m^2} \, 3^{-t};$$

hence the exponential decrease of the energy to zero cannot be uniform.

Concerning *weak* solutions, we consider, motivated by a recent work of Cannarsa, Komornik, and Loreti [3], the sequence of iterated logarithms

$$\begin{cases} \ln_1(t) = \ln(t), \\ \ln_{p+1}(t) = \ln(\ln_p(t)); \end{cases}$$

given $p \geq 1$, we exhibit a weak solution u_p of (1.1) such that the energy of u_p decays very slowly to zero. Indeed, for t large enough, we have (see Theorem 4.1)

$$E_{u_p}(t) \geq \frac{1}{\ln_p(t)}.$$

The paper is organized as follows: in section 2, we treat the polynomial case; in section 3, we extend the previous result in the case of general feedbacks; in section 4, we study the case of a special weak dissipation; the last section is devoted to the proofs of the results.

2. Polynomial feedbacks.

2.1. Optimality of the energy estimates for (1.1). We assume that $q : \mathbb{R} \longrightarrow \mathbb{R}$ is a continuous nondecreasing function given by

$$\forall s \in [-s_0, s_0], \quad q(s) = s\,|s|^{p-1}, \quad \text{with} \quad p > 1, \tag{2.1}$$

in a neighborhood $[-s_0, s_0]$ of zero, and that q has a linear growth at infinity. For all initial data $(u^0(x), v^0(x)) \in V \times L^2(0,1)$, there exists a unique solution u of (1.1) with the regularity $u \in \mathcal{C}(\mathbb{R}_+, V) \cap \mathcal{C}^1(\mathbb{R}_+, L^2(0,1))$. This solution u verifies the estimate (1.3).

There are very few results of optimality. Although this has not been proved until now, it was reasonable to think that the estimates (1.3) were optimal (at least for some particular solutions). Haraux [8] obtained partial results on the problem of the wave equation damped by a distributed feedback:

$$\begin{array}{ll} u_{tt} - u_{xx} = -q(u_t), & x \in (0,1), \; t \geq 0, \\ u(0,t) = u(1,t) = 0, & t \geq 0, \\ (u(x,0), u_t(x,0)) = (u^0(x), v^0(x)), & x \in (0,1), \end{array} \tag{2.2}$$

where $(u^0(x), v^0(x))$ is given in $H^1_0(0,1) \times L^2(0,1)$, where $H^1_0(0,1) := \{u \in H^1(0,1) \mid u(0) = 0 = u(1)\}$. For smooth solutions, he proved that

$$\limsup_{t \to +\infty} \; E_u(t)(1+t)^{3/(p-1)} > 0.$$

However, the problem of optimality is unsolved, since we would like to obtain (at least for some solutions)

$$\limsup_{t \to +\infty} \; E_u(t)(1+t)^{2/(p-1)} > 0. \tag{2.3}$$

Haraux [8] noted also that, when we change the Dirichlet conditions in (2.2) by the homogeneous Neumann conditions $u_x(0,t) = u_x(1,t) = 0$ and when $q(s) = s|s|^{p-1}$, then the nontrivial spatially homogeneous solutions decay precisely like $t^{-1/(p-1)}$ as $t \to +\infty$. (See also Haraux [7, p. 46] for another result of optimality for an ordinary differential equation.)

Concerning (1.1), no result of optimality was known before (even in the case of dimension 1). Note that Aassila [1] obtained estimates like (1.3) and proved their optimality for a nonlinear wave equation (with a nonlinear term in u' and a nonlinear term in ∇u), but his proof cannot be extended to (1.1) or (2.2).

We prove that (1.3) is optimal for particular initial conditions.

Theorem 2.1. *Assume* (2.1). *For* $(u^0(x), v^0(x)) = (2A_0 x, 0)$, *with* $A_0 \in \mathbb{R}$, $A_0 \neq 0$, *the solution* u *of* (1.1) *satisfies*

$$E_u(t) \underset{t \to +\infty}{\sim} \frac{C_p}{t^{2/(p-1)}}, \qquad \textit{with} \;\; C_p = \frac{1}{2\,(p-1)^{2/(p-1)}}. \tag{2.4}$$

Remarks. 1. Theorem 2.1 is still true if we replace (2.1) by

$$q(0) = 0 \;\; \text{and} \quad \forall s \in [-s_0, s_0],\; s \neq 0, \quad q(s) = \operatorname{sgn}(s)\,|s|^{1/p}, \text{ with } p > 1. \tag{2.5}$$

(For all $s \neq 0$, we denote $\operatorname{sgn}(s)$ the sign of s.) Note that the two inverse functions defined by (2.1) and (2.5) lead exactly to the same equivalent for the energy.

2. In fact, (2.3) is true for more general initial conditions (see Proposition 3.2 and the following remarks).

3. The proof of (2.4) does not yield any information on the time T_1 for which we can say that if $t \geq T_1$, $E_u(t)$ is close to $C_p t^{-2/(p-1)}$. From a practical point of view, this could also be interesting. In Propositions 3.1 and 3.2, we will give explicit lower bounds for the energy, which gives us explicit constants $c_0 > 0$ and $T_0 > 0$ such that

$$\forall t \geq T_0,\; E_u(t) \geq \frac{c_0}{t^{2/(p-1)}}.$$

2.2. Other examples. We can also study the damped wave equation with feedbacks at both extremities: let $q_1,\ q_2\ : \mathbb{R} \longrightarrow \mathbb{R}$ be two continuous nondecreasing functions and consider the following system:

$$\begin{cases} u_{tt} - u_{xx} = 0, & x \in (0,1),\; t \geq 0, \\ u_x(0,t) = q_1(u_t(0,t)), & t \geq 0, \\ u_x(1,t) = -q_2(u_t(1,t)), & t \geq 0, \\ (u(x,0), u_t(x,0)) = (u^0(x), v^0(x)), & x \in (0,1), \end{cases} \tag{2.6}$$

where $(u^0(x), v^0(x))$ is given in $H^1(0,1) \times L^2(0,1)$.

We define the energy of the solution u by

$$\forall t \geq 0, \quad E_u(t) = \frac{1}{2} \int_0^1 (u_x^2(x,t) + u_t^2(x,t))\, dx.$$

Assume that

$$\forall s \in [-s_0, s_0], \quad q_1(s) = s\, |s|^{p_1 - 1}, \quad \text{with} \quad p_1 > 1, \tag{2.7}$$

and

$$\forall s \in [-s_0, s_0], \quad q_2(s) = s\, |s|^{p_2 - 1}, \quad \text{with} \quad p_2 > 1. \tag{2.8}$$

Then we have the following.

Proposition 2.1. *Assume* (2.7) *and* (2.8). *For* $(u^0(x), v^0(x)) = (2A_0 x, 0)$, *with* $A_0 \in \mathbb{R}$, $A_0 \neq 0$, *the solution* u *of* (2.6) *satisfies the following:*

(i) *if* $p_1 = p_2 = p$,

$$E_u(t) \underset{t \to +\infty}{\sim} \frac{C'_p}{t^{2/(p-1)}}, \qquad \textit{with } C'_p = \frac{2}{(2^p\,(p-1))^{2/(p-1)}}; \tag{2.9}$$

(ii) *if* $p_1 \neq p_2 = p$,

$$E_u(t) \underset{t \to +\infty}{\sim} \frac{C_{p_0}}{t^{2/(p_0-1)}}, \qquad \textit{with } C_{p_0} = \frac{1}{2\,(p_0 - 1)^{2/(p_0-1)}}, \tag{2.10}$$

where $p_0 = \min(p_1, p_2)$.

Remark. The result of Proposition 2.1 holds true if we replace the assumptions (2.7) and (2.8) by the assumptions (2.11) and (2.8), or by (2.7) and (2.12), or by (2.11) and (2.12) with

$$q_1(0) = 0 \ \text{ and } \ \forall s \in [-s_0, s_0],\ s \neq 0,\ \ q_1(s) = \operatorname{sgn}(s)\, |s|^{1/p_1}, \tag{2.11}$$

and

$$q_2(0) = 0 \ \text{ and } \ \forall s \in [-s_0, s_0],\ s \neq 0,\ \ q_2(s) = \operatorname{sgn}(s)\, |s|^{1/p_2} \tag{2.12}$$

(always with $p_1 > 1$ and $p_2 > 1$).

2.3. Example in dimension 3. With the same method, we also obtain similar results for the wave equation with boundary feedback *in dimension* 3, which show that the previous results of optimality are not specific to dimension 1.

In space dimension 3, set $B_1 = B(0,1)$ and $B_2 = B(0,2)$ and let Ω be the open subset $B_2 \setminus B_1$ of $\mathbb{R}^3$ with boundary $\Gamma = \partial B_1 \cup \partial B_2$. Then we consider the following system:

$$\begin{cases} u_{tt} - \Delta u = 0, & x \in \Omega,\ t \geq 0, \\ u = 0, & x \in \partial B_1,\ t \geq 0, \\ \partial_\nu u + \frac{1}{2} u = -q(u_t), & x \in \partial B_2,\ t \geq 0, \\ (u(x,0), u_t(x,0)) = (u^0(x), v^0(x)), & x \in \Omega, \end{cases} \tag{2.13}$$

where $(u^0(x), v^0(x))$ is given in $\tilde{V} \times L^2(\Omega)$ (with $\tilde{V} = \{v \in H^1(\Omega) \mid v_{|\Gamma_1} = 0\}$).

Under (1.2), the energy E_u of the solution satisfies the estimate (1.3) (see, e.g., Zuazua [23]). Here we prove that (1.3) is optimal.

Proposition 2.2. *Assume that q is odd and satisfies* (2.1). *Then there exist* $(u^0, v^0) \in \tilde{V} \times L^2(\Omega)$ *and* $\tilde{C}_p > 0$ *such that*

$$E_u(t) \underset{t\to+\infty}{\sim} \frac{\tilde{C}_p}{t^{2/(p-1)}}. \tag{2.14}$$

(Note that we construct *radial* solutions satisfying (2.14).)

3. General feedbacks.

3.1. Known estimates.

When the feedback q has no polynomial behavior in zero, like (1.2), and has a linear growth at infinity, Lasiecka and Tataru [13] prove that the energy decays as fast as the solution of some associated differential equation. In [14], Liu and Zuazua give another proof of this result, which provides a simpler dissipative ordinary differential equation describing the decay rate.

In subsection 3.2, we will prove that the solutions of (1.1) decay exactly like the solution of an ordinary differential equation (which is very simple in this case).

On the other hand, in [15], we obtained explicit estimates of the decay rate of the energy. Let us recall these estimates: assume that $q : \mathbb{R} \longrightarrow \mathbb{R}$ is a strictly continuous increasing function (with linear growth at infinity) such that

$$|g(s)| \le |q(s)| \le |g^{-1}(s)|$$

in a neighborhood of zero, where $g : \mathbb{R} \longrightarrow \mathbb{R}$ is a strictly increasing and odd function of class $\mathcal{C}^1$ (and where g^{-1} denotes the inverse function of g). Set $H(s) = g(s)/s$ and assume that $H(0) = 0$ and that H is increasing on $[0, \eta]$ for some $\eta > 0$. Then, for (1.1), $E_u(t)$ satisfies the estimate

$$\forall t \ge 1, \quad E_u(t) \le C(E_u(0)) \left[g^{-1}\left(\frac{1}{t}\right)\right]^2. \tag{3.1}$$

For example, if g is defined on some $[0, \eta]$ by

$$g(s) = e^{-1/y^p} \tag{3.2}$$

for some $p > 0$, then

$$\forall t \ge 2, \quad E_u(t) \le \frac{C}{(\ln t)^{2/p}}. \tag{3.3}$$

And if

$$g(s) = e^{-e^{1/y}}, \tag{3.4}$$

then

$$\forall t \ge 3, \quad E_u(t) \le \frac{C}{(\ln(\ln t))^2}. \tag{3.5}$$

(Note that (3.1) does not directly give the optimal estimate (1.3) when g has a polynomial behavior in zero, but still allows us to get it after some additional computations.) In subsection 3.3, we prove that (3.3) and (3.5) are optimal. And more generally, in subsection 3.4, we prove that (3.1) is optimal for a class of nonpolynomial feedbacks (including (3.2) and (3.4)).

3.2. Behavior of the energy in the general case.

THEOREM 3.1. *Let $g : \mathbb{R} \to \mathbb{R}$ be a strictly increasing and odd function of class $\mathcal{C}^1$ such that $g(0) = 0$ and $g'(0) = 0$. Assume $q : \mathbb{R} \to \mathbb{R}$ is a continuous nondecreasing function such that*

$$q = g \quad \text{or} \quad q = g^{-1}$$

in a neighborhood of zero.

For all $(u^0(x), v^0(x)) = (2A_0x, 0)$ with $A_0 \in \mathbb{R}$, $A_0 \neq 0$, the solution u of (1.1) *satisfies*

$$\exists n_0 \in \mathbb{N},\ \forall n \geq n_0, \quad E_u(2n) = \frac{1}{2}V(2t_n)^2, \tag{3.6}$$

where $(t_n)_{n \geq n_0}$ is a real positive increasing sequence such that $t_n \sim n$ as $n \to +\infty$, and where $V : \mathbb{R}_+ \to \mathbb{R}_+$ is the solution of the ordinary differential equation

$$V'(s) = -g(V(s)), \quad s \geq 0, \tag{3.7}$$

with $V(0) = 2\sqrt{E_u(2n_0)/2}$.

Remarks. 1. Note that $q = g$ and $q = g^{-1}$ lead exactly to the same estimate.

2. By solving the differential equation (3.7), we find that the estimates (1.3), (3.3), and (3.5) are optimal. However, this needs some computations, which is why we give two explicit lower bound of the energy in the following.

3.3. Some explicit lower bounds of the energy. It is interesting to study if the result of Theorem 2.1 can be extended to more general initial conditions (which means if (2.3) holds true for more general initial conditions) and to have an explicit lower bound of the energy when q has no polynomial growth in zero. In the following, we provide two formulae that allow us to prove the optimality of the estimates of (1.3), (3.3), and (3.5) even when we consider more general initial conditions than the special ones used in Theorem 2.1.

PROPOSITION 3.1. *Let $g : \mathbb{R} \to \mathbb{R}$ be a strictly increasing, odd, and convex function of class $\mathcal{C}^1$ such that $g(0) = 0$ and $g'(0) = 0$. Assume $q : \mathbb{R} \to \mathbb{R}$ is a continuous nondecreasing function such that*

$$|q(s)| \leq |g(s)| \quad \text{or} \quad |q(s)| \geq |g^{-1}(s)|$$

$\forall s$ in a neighborhood of 0. *Moreover we denote $h = \frac{1}{2}g^{-1}$ and we assume that*

$$s \mapsto s(h'(s) - 1) \quad \text{is increasing in a neighborhood of zero.} \tag{3.8}$$

Then $\forall (u^0(x), v^0(x)) = (2A_0x, 0)$ with $A_0 \in \mathbb{R}$, $A_0 \neq 0$, the solution u of (1.1) *satisfies*

$$\exists n_0, n_1 \in \mathbb{N},\ \forall n \geq n_0, \quad E_u(2n) \geq \frac{1}{2}\left[(g')^{-1}\left(\frac{1}{2(n+n_1)}\right)\right]^2. \tag{3.9}$$

Remark. It is easy to check that (3.8) is satisfied when

$$g(s) = s^p \quad \text{or} \quad g(s) = e^{-1/s^p} \quad \text{or} \quad g(s) = e^{-e^{1/s}}$$

on $[0, \eta]$ for some $\eta > 0$; then (3.9) gives the optimality of the corresponding estimates (1.3), (3.3), and (3.5) if q has a linear growth at infinity.

Since it may be not easy to compute $(g')^{-1}$, we give a simpler lower bound of the energy.

PROPOSITION 3.2. *Let $g : \mathbb{R} \to \mathbb{R}$ be a strictly increasing and convex function of class $\mathcal{C}^1$ such that $g(0) = 0$ and $g'(0) = 0$. Assume $q : \mathbb{R} \to \mathbb{R}$ is a continuous nondecreasing function such that*

$$|q(s)| \leq |g(s)| \quad \text{or} \quad |q(s)| \geq |g^{-1}(s)|$$

$\forall s$ in a neighborhood of 0. Moreover we denote $h = \frac{1}{2}g^{-1}$ and we assume that there exist $\beta > 0$ and $k \geq 1$ such that

$$\forall n \geq 1,\ h'\left(\frac{\beta}{n^k}\right) \geq n + 1. \tag{3.10}$$

For all $(u^0(x), v^0(x)) = (2A_0 x, 0)$ with $A_0 \in \mathbb{R},\ A_0 \neq 0$, the solution u of (1.1) *satisfies*

$$\exists \gamma > 0,\ \exists n_0 \in \mathbb{N},\ \forall n \geq n_0, \quad E_u(2n) \geq \frac{1}{2}\left[g^{-1}\left(\frac{\gamma}{n^k}\right)\right]^2. \tag{3.11}$$

As an application of Proposition 3.2, we can easily check the optimality of (1.3) and also of (3.3), and (3.5): it is sufficient to choose $k = \frac{p}{p-1}$ when $g(s) = s^p$ and $k = 2$ in the two other examples.

Remark. With the same proof, we can also obtain similar results for more general initial conditions $(u^0, v^0) \in (W^{1,\infty}(0,1) \cap V) \times L^\infty(0,1)$ provided that $\|(u^0, v^0)\|_{W^{1,\infty}\times L^\infty}$ is small enough.

3.4. Optimality of estimate (3.1) for a class of nonpolynomial feedbacks. At last, we prove that the estimate (3.1) is optimal for a class of nonpolynomial feedbacks (including (3.2) and (3.4)): we have the following.

PROPOSITION 3.3. *Let $g : \mathbb{R} \to \mathbb{R}$ be a strictly increasing and convex function of class $\mathcal{C}^1$ such that $g(0) = 0$ and $g'(0) = 0$. Assume $q : \mathbb{R} \to \mathbb{R}$ is a continuous nondecreasing function such that*

$$|q(s)| \leq |g(s)| \quad \text{or} \quad |q(s)| \geq |g^{-1}(s)|$$

$\forall s$ in a neighborhood of 0. Moreover, we assume that there exist $\alpha > 0$ and $M > 0$ such that

$$2\alpha \frac{g(2s)g'(\alpha s)}{g(\alpha s)^2} \leq M. \tag{3.12}$$

For all $(u^0(x), v^0(x)) = (2A_0 x, 0)$ with $A_0 \in \mathbb{R},\ A_0 \neq 0$, the solution u of (1.1) *satisfies*

$$\exists C > 0,\ \exists n_0 \in \mathbb{N},\ \forall n \geq n_0, \quad E_u(2n) \geq \frac{2}{\alpha^2}\left[g^{-1}\left(\frac{1}{Mn + C}\right)\right]^2. \tag{3.13}$$

3.5. Remark concerning (2.2). Even in the polynomial case, we have no result of optimality of energy estimates for (2.2). However, if we change the Dirichlet conditions by the homogeneous Neumann conditions $u_x(0,t) = u_x(1,t) = 0$, then we can prove similar results of optimality as for (1.1).

We consider the nontrivial homogeneous solutions of

$$\left\{ \begin{array}{ll} u_{tt} - u_{xx} = -q(u_t), & x \in (0,1),\ t \geq 0, \\ u_x(0,t) = u_x(1,t) = 0, & t \geq 0. \end{array} \right. \tag{3.14}$$

We set $v = u_t$. Then $v(t)$ is solution of the ordinary differential equation

$$v'(t) = -q(v(t)), \quad t \geq 0, \tag{3.15}$$

which is the same as (3.7) when $q = g$. In particular, under the hypotheses of Theorem 3.1 and Propositions 3.1 and 3.2, we can easily obtain similar lower bounds of the energy. (Note that when $q = g^{-1}$, the asymptotic behavior is different: in this case v converges to 0 in finite time.)

4. Decay rate estimates when the feedback is weak at infinity. In a previous paper (see [16]), we studied the behavior of the energy of the solutions of the following problem:

$$\left\{ \begin{array}{ll} u_{tt} - \Delta u = -q(u_t), & x \in \Omega,\ t \geq 0, \\ u(y,t) = 0, & y \in \partial\Omega,\ t \geq 0, \\ (u(x,0), u_t(x,0)) = (u^0(x), v^0(x)), & x \in \Omega, \end{array} \right. \tag{4.1}$$

where Ω is a bounded domain of class $\mathcal{C}^2$ of $\mathbb{R}^2$ and q is a nondecreasing function that satisfies

$$\frac{q(s)}{s} \longrightarrow 0 \text{ when } |s| \longrightarrow +\infty$$

(in this case, the feedback is called *weak*). When $q'(0) \neq 0$, we proved that the energy of strong solutions decays exponentially to zero, but with a decay rate depending on the norm of the initial conditions in $H^2(\Omega) \times H_0^1(\Omega)$: given $(u^0, v^0) \in H^2(\Omega) \times H_0^1(\Omega)$, there exists $\omega = \omega(\|(u^0, v^0)\|_{H^2(\Omega) \times H_0^1(\Omega)}) > 0$ such that

$$\forall t \geq 0,\ E(t) \leq E(0) e^{1-\omega t}.$$

This result improved previous results of Komornik [11] and of Nakao [18] (who also treated more general cases). Haraux and Conrad asked us if the decay rate really depends on the quantity $\|(u^0, v^0)\|_{H^2(\Omega) \times H_0^1(\Omega)}$. We are able to give some answers in the case of (1.1): consider the special function q defined by

$$\left\{ \begin{array}{l} \forall |s| \leq 2,\ q(s) = \frac{s}{2}, \\ \forall |s| \geq 2,\ q(s) = \text{sgn }(s) 1. \end{array} \right. \tag{4.2}$$

We also consider the sequence of iterated logarithms

$$\left\{ \begin{array}{l} \forall t > 1,\ \ln_1(t) = \ln(t), \\ \forall t > T_{p+1},\ \ln_{p+1}(t) = \ln(\ln_p(t)), \end{array} \right. \tag{4.3}$$

where $(T_p)_p$ is defined by

$$\left\{ \begin{array}{l} T_1 = 1, \\ T_{p+1} = e^{T_p}. \end{array} \right.$$

The functions $\ln_p$ are well defined on $[T_p, +\infty[$ and go slowly to infinity at infinity.

We have the following.

THEOREM 4.1. 1. *Let q be the function defined by* (4.2). *If $(u^0, v^0) \in W^{1,\infty}(0,1) \times L^\infty(0,1)$, then the energy of the strong solution of* (1.1) *decays exponentially to zero, but not uniformly with respect to (u^0, v^0).*

2. *Given $p \geq 1$, there exist $(u^0, v^0) \in V \times L^2(0,1)$, $T'_p > T_p$, such that the energy of the associated solution u of* (1.1) *satisfies*

$$\forall t \geq T'_p,\ E_u(t) \geq \frac{1}{\ln_p(t)}. \tag{4.4}$$

Remarks. 1. This result allows us to measure the gap between the decrease of the energy of strong solutions and the one of weak solutions. Therefore, when the feedback is weak at infinity, the behavior of q at infinity has a great importance on the decrease of the energy.

2. We conjecture that the following stronger result is also true: given $f : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$ a decreasing function that goes to zero at infinity, there exist $(u^0, v^0) \in H^1_0(0,1) \times L^2(0,1)$ and $\varepsilon > 0$ such that the energy of the associated solution u of (1.1) satisfies

$$\forall t \geq 0,\ E_u(t) \geq \varepsilon f(t).$$

3. More precisely about the nonuniform exponential decay of the energy of strong solutions, we prove that given (u^0, v^0) in $W^{1,\infty}(0,1) \times L^\infty(0,1)$ (and $u^0(0) = 0$), there exists some (explicit) constant $C^0 = C^0(\|(u^0, v^0)\|_{W^{1,\infty} \times L^\infty})$ such that

$$\forall t \geq 0,\ E_u(t) \leq C^0\ 3^{-t};$$

and on the other hand we construct a sequence $(u_m)_{m \geq 1}$ of solutions of (1.1), corresponding to initial conditions $({u_m}^0, {v_m}^0)$ in $W^{1,\infty}(0,1) \times L^\infty(0,1)$ that satisfy

$$E_{u_m}(0) = 1 \text{ and } \|({u_m}^0, {v_m}^0)\|_{W^{1,\infty} \times L^\infty} = 2m,$$

and

$$\forall t \geq m,\ E_{u_m}(t) = \frac{9^m}{9m^2}\ 3^{-t};$$

hence the exponential decrease of the energy to zero cannot be uniform.

4. The proof of (4.4) is based on the construction of explicit special initial conditions.

5. Proofs.

5.1. Polynomial feedbacks. In order to prove Theorem 2.1 and Proposition 2.1, we first prove the following.

LEMMA 5.1. *We denote by $F : \mathbb{R} \longrightarrow \mathbb{R}$ the continuous strictly increasing function defined by $F = \mathrm{Id} + q$ where q satisfies* (2.1) *or* (2.5). *Then we have the following:*

(i) *if q satisfies* (2.1),

$$F^{-1}(r) = r - r|r|^{p-1} + o\left(|r|^p\right) \quad \text{as } r \to 0,$$

(ii) *if q satisfies* (2.5),

$$F^{-1}(r) = r|r|^{p-1} + o\left(|r|^p\right) \quad \text{as } r \to 0.$$

Remark. Note that in both cases, this implies that

$$(r+F^{-1}(-2r))^2 = r^2\Big(1-2^p|r|^{p-1}+\mathrm{o}\left(|r|^{p-1}\right)\Big)^2$$
$$= r^2\Big(1-2^{p+1}|r|^{p-1}+\mathrm{o}\left(|r|^{p-1}\right)\Big), \quad \text{as } r\to 0.$$

We will see in the proof that the behavior of the solution is closely related to the behavior at 0 of the function $r \longrightarrow (r+F^{-1}(-2r))^2$. In particular, since their behavior at 0 is the same in both cases, we will obtain exactly the same equivalent of the energy in both cases.

Proof of Lemma 5.1.

(i) Assume (2.1). Set $r = F(s) = s + s|s|^{p-1}$ $\forall s\in\mathbb{R}$. Note that $r\to 0$ as $s\to 0$ and

$$\frac{r}{F^{-1}(r)} = \frac{F(s)}{s} = 1+|s|^{p-1} \underset{s\to 0}{\to} 1.$$

Thus $F^{-1}(r) = r + o(|r|)$ as $r\to 0$. And since

$$r = s + \operatorname{sgn}(s)\,|s|^p = F^{-1}(r) + \operatorname{sgn}(r)\,|F^{-1}(r)|^p,$$

we obtain

$$F^{-1}(r) = r - \operatorname{sgn}(r)\,|r|^p + o(|r|^p), \quad \text{as } r\to 0.$$

(ii) Assume (2.5). Set $r = F(s) = s + \operatorname{sgn}(s)\,|s|^{1/p}$ $\forall s\in\mathbb{R}$. Then

$$\frac{F^{-1}(r)}{\operatorname{sgn}(r)\,|r|^p} = \frac{s}{\operatorname{sgn}(s)\,|F(s)|^p} = \left(\frac{|s|^{1/p}}{\left|s+\operatorname{sgn}(s)\,|s|^{1/p}\right|}\right)^p \underset{s\to 0}{\to} 1.$$

Thus

$$F^{-1}(r) = \operatorname{sgn}(r)\,|r|^p + o(|r|^p), \quad \text{as } r\to 0. \qquad \square$$

Proof of Theorem 2.1. Let $A_0\in\mathbb{R}$ be such that $A_0\neq 0$. First we introduce the real sequence $(A_n)_{n\in\mathbb{N}}$ defined by

$$\forall n\in\mathbb{N},\quad A_{n+1}+A_n = -q(A_{n+1}-A_n). \tag{5.1}$$

This sequence is well defined since (5.1) can also be written like

$$\forall n\in\mathbb{N},\ A_{n+1} = A_n + F^{-1}(-2A_n), \tag{5.2}$$

where $F:\mathbb{R}\longrightarrow\mathbb{R}$ is the continuous strictly increasing function defined by $F = \mathrm{Id}+q$.

Assume for a moment the following.

LEMMA 5.2.

$$A_n^2 \underset{n\to+\infty}{\sim} \frac{C_p'}{n^{2/(p-1)}}, \qquad \textit{with} \quad C_p' = \left(\frac{1}{2^p\,(p-1)}\right)^{2/(p-1)}.$$

Then we define an absolutely continuous function $f:(-1,+\infty)\longrightarrow\mathbb{R}$ such that

$$\forall n\in\mathbb{N},\quad \forall s\in(2n-1,2n+1),\quad f'(s) = A_n.$$

Note that (5.1) implies

$$f'(t+1)+f'(t-1)=-q(f'(t+1)-f'(t-1)) \tag{5.3}$$

almost everywhere (a.e.) $t\geq 0$.

Then, u defined by

$$u(x,t)=f(t+x)-f(t-x),\quad (x,t)\in(0,1)\times(0,\infty),$$

is the solution of problem (1.1). (Relation (5.3) gives $u_x(1,t)=-q(u_t(1,t))$.) And the energy of u is given by

$$\forall t\geq 0,\quad E_u(t)=\frac{1}{2}\int_0^1 (u_x^2(x,t)+u_t^2(x,t))\,dx=\int_{-1}^1 f'(t+s)^2\,ds.$$

In particular, Lemma 5.2 gives

$$E_u(2n)=\int_{2n-1}^{2n+1} f'(s)^2\,ds=2A_n^2 \underset{n\to+\infty}{\sim} \frac{2\,C_p'}{n^{2/(p-1)}}.$$

And since $t\mapsto E_u(t)$ is nonincreasing, we deduce

$$E_u(t) \underset{t\to+\infty}{\sim} \frac{C_p}{t^{2/(p-1)}}\quad \text{with } C_p=\frac{1}{2(p-1)^{2/(p-1)}}. \qquad \square$$

Proof of Lemma 5.2. First, let us prove that $A_n \underset{n\to+\infty}{\to} 0$. From (5.1), we have, $\forall n\in\mathbb{N}$,

$$A_{n+1}^2-A_n^2=-(A_{n+1}-A_n)\,q(A_{n+1}-A_n)\ \leq\ 0. \tag{5.4}$$

The sequence $(A_n^2)_{n\in\mathbb{N}}$ is nonincreasing and convergent. Thus $A_{n+1}^2-A_n^2 \underset{n\to+\infty}{\to} 0$. Relation (5.4) implies $(A_{n+1}-A_n)\,q(A_{n+1}-A_n) \underset{n\to+\infty}{\to} 0$ and consequently $A_{n+1}-A_n \underset{n\to+\infty}{\to} 0$. From (5.1), we also deduce $A_{n+1}+A_n \underset{n\to+\infty}{\to} 0$, and finally, $A_n \underset{n\to+\infty}{\to} 0$.

Then (5.2) and Lemma 5.1 give

$$A_{n+1}=-A_n+2^pA_n|A_n|^{p-1}+\mathrm{o}\,(|A_n|^p),\quad n\to+\infty,$$

when q is given by (2.1). (Note that in this case, for some $n_0\in\mathbb{N}$ large enough, the sign of the sequence $(A_n)_{n\geq n_0}$ is alternating.) On the other hand Lemma 5.1 gives

$$A_{n+1}=A_n-2^pA_n|A_n|^{p-1}+\mathrm{o}\,(|A_n|^p),\quad n\to+\infty,$$

when q is given by (2.5). (In this case, for some $n_0'\in\mathbb{N}$ large enough, the sign of the sequence $(A_n)_{n\geq n_0'}$ is constant.)

In both cases, we obtain

$$\begin{aligned} A_{n+1}^2 &= A_n^2\Big(1-2^p|A_n|^{p-1}+\mathrm{o}\,(|A_n|^{p-1})\Big)^2 \\ &= A_n^2\Big(1-2^{p+1}|A_n|^{p-1}+\mathrm{o}\,(|A_n|^{p-1})\Big). \end{aligned} \tag{5.5}$$

Note that (5.5) implies in particular that $|A_{n+1}| \underset{n\to+\infty}{\sim} |A_n|$. We deduce

$$\frac{1}{(A_{n+1})^{2\ (p-1)/2}} - \frac{1}{(A_n)^{2\ (p-1)/2}} = \frac{1 - \left(1 - 2^{p+1}|A_n|^{p-1} + \mathrm{o}\left(|A_n|^{p-1}\right)\right)^{(p-1)/2}}{|A_{n+1}|^{p-1}}$$

$$= \frac{\frac{p-1}{2}\, 2^{p+1}\, |A_n|^{p-1} + \mathrm{o}\left(|A_n|^{p-1}\right)}{|A_{n+1}|^{p-1}} \underset{n\to+\infty}{\to} 2^p\,(p-1).$$

Finally, Cesàro's theorem gives

$$\frac{1}{(A_n)^{2\ (p-1)/2}} \underset{n\to+\infty}{\sim} \sum_{k=0}^{n-1} \left(\frac{1}{(A_{k+1})^{2\ (p-1)/2}} - \frac{1}{(A_k)^{2\ (p-1)/2}} \right) \underset{n\to+\infty}{\sim} 2^p(p-1)\,n,$$

which proves Lemma 5.2. □

Idea of the proof of Proposition 2.1. Let $A_0 \in \mathbb{R}$ be such that $A_0 \neq 0$. We introduce the two real sequences $(A_n)_{n\geq 0}$ and $(B_n)_{n\geq -1}$ defined by $B_{-1} = A_0$ and

$$\forall n \geq 0, \quad A_n - B_n = q_1(A_n + B_n), \tag{5.6}$$

$$\forall n \geq -1, \quad A_{n+2} - B_n = -q_2(A_{n+2} + B_n). \tag{5.7}$$

We denote by F_1 and $F_2 : \mathbb{R} \to \mathbb{R}$ the two continuous strictly increasing functions defined by $F_1 = \mathrm{Id} + q_1$ and $F_2 = \mathrm{Id} + q_2$. Then (5.6) and (5.7) become

$$\forall n \geq 0,\ B_n = -A_n + F_1^{-1}(2A_n), \tag{5.8}$$

$$\forall n \geq -1,\ A_{n+2} = -B_n + F_2^{-1}(2B_n). \tag{5.9}$$

We define $f : (0,+\infty) \longrightarrow \mathbb{R}$ and $g : (-1,+\infty) \longrightarrow \mathbb{R}$ two absolutely continuous functions such that

$$\forall n \geq 0, \quad \forall s \in (n, n+1), \quad f'(s) = A_n,$$

and

$$\forall n \geq -1, \quad \forall s \in (n, n+1), \quad g'(s) = B_n.$$

Note that (5.6) and (5.7) imply

$$f'(t) - g'(t) = q_1(f'(t) + g'(t)) \quad \text{a.e. } t \geq 0, \tag{5.10}$$

and

$$f'(t+1) - g'(t-1) = -q_2(f'(t+1) + g'(t-1)) \quad \text{a.e. } t \geq 0. \tag{5.11}$$

Then, u defined by

$$u(x,t) = f(t+x) + g(t-x), \quad (x,t) \in (0,1) \times (0,\infty),$$

is the solution of problem (2.6). (Relation (5.10) gives $u_x(0,t) = q_1(u_t(0,t))$ and (5.11) gives $u_x(1,t) = -q_2(u_t(1,t))$.) The energy of u is given by

$$\forall t \geq 0, \quad E_u(t) = \frac{1}{2} \int_0^1 f'(t+x)^2 + g'(t-x)^2\, dx = \int_t^{t+1} f'(s)^2\, ds + \int_{t-1}^{t} g'(s)^2\, ds.$$

In particular,

$$\forall n \in \mathbb{N}, \quad E_u(n) = A_n^2 + B_{n-1}^2.$$

First applying the same reasoning as in Lemma 5.2, we easily see that

$$\forall n \geq -1, \quad A_{n+2}^2 \leq B_n^2 \leq A_n^2 \leq B_{n-2}^2$$

and that the sequences $(A_n)_n$ and $(B_n)_n$ go to zero as $n \to +\infty$.

Next assume (2.7) or (2.11). We use (5.6) and Lemma 5.1 to get that

$$B_n^2 = A_n^2\Big(1 - 2^{p_1+1}|A_n|^{p_1-1} + \mathrm{o}\left(|A_n|^{p_1-1}\right)\Big). \tag{5.12}$$

Similarly, under (2.8) or (2.12), (5.7) and Lemma 5.1 give that

$$A_{n+2}^2 = B_n^2\Big(1 - 2^{p_2+1}|B_n|^{p_2-1} + \mathrm{o}\left(|B_n|^{p_2-1}\right)\Big). \tag{5.13}$$

Note that $|A_n| \underset{n\to+\infty}{\sim} |B_n|$ and $|A_{n+2}| \underset{n\to+\infty}{\sim} |A_n|$. We distinguish the cases $p_1 = p_2$ and $p_1 < p_2$. The strategy we used in Lemma 5.2 allows one to prove (2.9) and (2.10).

Idea of the proof of Proposition 2.2. We will use the spherical coordinates $r \in [1,2]$, $\phi \in [0, 2\pi]$, $\theta \in [0,\pi]$ and we will construct *radial* solutions satisfying (2.14). Let $A_0 \in \mathbb{R}$ be such that $A_0 \neq 0$ and define $\tilde{q}$ by $\tilde{q}(s) = 2q(s/2)$ $\forall s \in \mathbb{R}$. We introduce the real sequence $(A_n)_{n\in\mathbb{N}}$ defined by (5.1) in the proof of Theorem 2.1 with $\tilde{q}$ instead of q. Thus Lemma 5.2 is still true with a constant $\tilde{C}_p'$ instead of C_p'.

We define an absolutely continuous function $\Phi : (-2, +\infty) \to \mathbb{R}$ such that

$$\forall n \in \mathbb{N}, \quad \forall s \in (2n-2, 2n), \quad \Phi'(s) = A_n.$$

Then, u defined by

$$u(r,t) = \frac{1}{r}(-\Phi(t+r-2) + \Phi(t-r))$$

is the solution of problem (2.13) since

$$\partial_\nu u(2,t) + \frac{1}{2}u(2,t) = u_r(2,t) + \frac{1}{2}u(2,t) = -q(u_t(2,t)).$$

It is not difficult to verify that the energy of this radial solution defined as usual by the formula

$$E_u(t) = \frac{1}{2}\int_\Omega {u_t}^2 + |\nabla u|^2\,dx + \frac{1}{2}\int_{\partial B_2} \frac{1}{2}u^2\,d\sigma$$

satisfies

$$\begin{aligned}\forall t \geq 0, \quad E_u(t) &= \frac{1}{2}\int_1^2\int_0^{2\pi}\int_0^\pi \left(u_t^2 + \left(\frac{1}{r}\frac{d}{dr}(ru)\right)^2\right) r^2 \sin\theta\,d\theta\,d\phi\,dr \\ &= 2\pi\int_1^2 \left(\Phi'(t+r-2)^2 + \Phi'(t-r)^2\right)dr.\end{aligned}$$

Consequently,

$$\forall n \in \mathbb{N}, \ E_u(2n) = 4\pi A_n^2$$

and Proposition 2.2 follows from Lemma 5.2. □

5.2. Behavior of the energy in the general case.

Proof of Theorem 3.1. Let $A_0 \in \mathbb{R}$ be such that $A_0 \neq 0$. As for Theorem 2.1, $E_u(2n) = 2A_n^2$ $\forall n \in \mathbb{N}$, where $(A_n)_{n\in\mathbb{N}}$ is the real sequence defined by (5.1). Denote $u_n := |A_n|$. We know that the sequence $(u_n)_{n\in\mathbb{N}}$ is nonincreasing and that $u_n \underset{n\to+\infty}{\to} 0$.

First we will prove that in both cases $q = g$ or $q = g^{-1}$, there exists some $n_0 \in \mathbb{N}$ such that the corresponding sequences $(u_n)_{n\geq n_0}$ will satisfy exactly the same relation:

$$\forall n \geq n_0, \quad u_{n+1} - u_n = -g(u_{n+1} + u_n). \tag{5.14}$$

We denote by $[-s_0, s_0]$ a neighborhood of 0 where q is given by $q = g$ or by $q = g^{-1}$. Since $g'(0) = 0$, we can assume that $0 \leq g'(s) < 1/2$ $\forall s \in [-s_0, s_0]$. Then we introduce $n_0 \in \mathbb{N}$ such that, $\forall n \geq n_0$, $A_n \in [-\frac{s_0}{2}, \frac{s_0}{2}]$. Note that this implies in particular $|g(A_n)| < |A_n|$ $\forall n \geq n_0$.

Assume $q = g$. Then the sequence $(A_n)_{n\in\mathbb{N}}$ satisfies

$$\forall n \geq n_0, \quad A_{n+1} + A_n = -g(A_{n+1} - A_n). \tag{5.15}$$

Fix $n \geq n_0$ and assume, for example, $A_n > 0$. We introduce the strictly increasing function $\phi : s \in [-\frac{s_0}{2}, \frac{s_0}{2}] \mapsto s + g(s - A_n)$. Then

$$\phi(0) = g(-A_n) > -A_n = \phi(A_{n+1}).$$

Therefore $A_{n+1} < 0$. So the sign of the sequence $(A_n)_{n\geq n_0}$ is alternating and (5.15) becomes, since g is odd,

$$\forall n \geq n_0, \quad |A_{n+1}| - |A_n| = -g(|A_{n+1}| + |A_n|),$$

which proves (5.14).

Assume now $q = g^{-1}$. Then the sequence $(A_n)_{n\in\mathbb{N}}$ satisfies

$$\forall n \geq n_0, \quad A_{n+1} + A_n = -g^{-1}(A_{n+1} - A_n),$$

or

$$\forall n \geq n_0, \quad A_{n+1} - A_n = -g(A_{n+1} + A_n). \tag{5.16}$$

Fix $n \geq n_0$ and assume, for example, $A_n > 0$. We introduce the strictly increasing function $\psi : s \in [-\frac{s_0}{2}, \frac{s_0}{2}] \mapsto s + g(s + A_n)$. Then

$$\psi(0) = g(A_n) < A_n = \psi(A_{n+1}).$$

Therefore $A_{n+1} > 0$. So the sign of the sequence $(A_n)_{n\geq n_0}$ is constant and (5.16) becomes

$$\forall n \geq n_0, \quad |A_{n+1}| - |A_n| = -g(|A_{n+1}| + |A_n|),$$

which proves (5.14).

Finally, in both cases ($q = g$ and $q = g^{-1}$), since $E_u(2n) = 2A_n^2 = 2u_n^2$, the problem reduces to studying the positive nonincreasing sequence $(u_n)_{n\geq n_0}$ defined by (5.14).

Let us introduce two other sequences $(v_n)_{n\geq n_0}$ and $(w_n)_{n\geq n_0}$ defined by $v_{n_0} = w_{n_0} = u_{n_0}$ and by

$$\forall n \geq n_0, \quad v_{n+1} = v_n - g(2v_n) = G(v_n), \tag{5.17}$$

and

$$\forall n \geq n_0, \quad w_n = w_{n+1} + g(2w_{n+1}) = H(w_{n+1}) \quad \text{or} \quad w_{n+1} = H^{-1}(w_n), \tag{5.18}$$

where $G : [0, \frac{s_0}{2}] \to \mathbb{R}$ and $H : [0, \frac{s_0}{2}] \to \mathbb{R}$ are the two strictly increasing functions defined by $G(s) = s - g(2s)$ and $H(s) = s + g(2s)$ $\forall s \in [0, \frac{s_0}{2}]$. We verify that $(v_n)_{n\geq n_0}$ and $(w_n)_{n\geq n_0}$ are positive nonincreasing sequences such that $v_n \to 0$ and $w_n \to 0$ as $n \to +\infty$. And, with these notations, we prove that

$$\forall n \geq n_0, \quad 0 \leq v_n \leq u_n \leq w_n. \tag{5.19}$$

Indeed, $v_{n_0} = w_{n_0} = u_{n_0}$. Assume for some $p > n_0$, $v_p \leq u_p \leq w_p$. Then

$$u_{p+1} = u_p - g(u_{p+1} + u_p) \geq u_p - g(2u_p) = G(u_p) \geq G(v_p) = v_{p+1},$$

and

$$u_p = u_{p+1} + g(u_{p+1} + u_p) \geq u_{p+1} + g(2u_{p+1}) = H(u_{p+1}).$$

Thus

$$u_{p+1} \leq H^{-1}(u_p) \leq H^{-1}(w_p) = w_{p+1}.$$

Let U be the solution of the ordinary differential equation

$$U'(s) = -g(2U(s)), \qquad s \geq 0, \tag{5.20}$$

such that $U(0) = u_{n_0} > 0$. The function $s \mapsto U(s)$ is strictly positive and decreasing and $U(s) \to 0$ as $s \to +\infty$.

We denote by $(s_n)_{n\geq n_0}$, $(t_n)_{n\geq n_0}$, and $(r_n)_{n\geq n_0}$ the increasing sequences defined by $s_n = U^{-1}(v_n)$, $t_n = U^{-1}(u_n)$, and $r_n = U^{-1}(w_n)$ $\forall n \geq n_0$. Since U^{-1} is decreasing, we have $s_n \geq t_n \geq r_n$. Note also, since v_n, u_n, $w_n \underset{n\to+\infty}{\to} 0$, that $U(s_n)$, $U'(s_n), U(t_n)$, $U'(t_n), U(r_n)$, $U'(r_n) \underset{n\to+\infty}{\to} 0$.

First we prove that $s_n \underset{n\to+\infty}{\sim} n$: the relation (5.17) becomes

$$U(s_{n+1}) = U(s_n) + U'(s_n).$$

Thus

$$\begin{aligned} s_{n+1} &= U^{-1}(U(s_n) + U'(s_n)) \\ &= U^{-1}(U(s_n)) + U'(s_n)(U^{-1})'(U(s_n)) + \frac{1}{2}U'(s_n)^2(U^{-1})''(U(s_n')) \\ &= s_n + 1 + \frac{1}{2}U'(s_n)^2 \left(\frac{-U''(s_n')}{U'(s_n')^3} \right) \\ &= s_n + 1 + \frac{1}{2}U'(s_n)^2 \frac{2g'(2U(s_n'))}{U'(s_n')^2} \\ &= s_n + 1 + g'(2U(s_n')) \frac{g(2U(s_n))^2}{g(2U(s_n'))^2}, \end{aligned}$$

with $s_n \leq s'_n \leq s_{n+1}$. Since U and g are, respectively, decreasing and increasing, we have

$$1 \leq \frac{g(2U(s_n))}{g(2U(s'_n))} \leq \frac{g(2U(s_n))}{g(2U(s_{n+1}))} = \frac{g(2v_n)}{g(2v_{n+1})}.$$

Moreover,

$$g(2v_{n+1}) = g(2v_n) + 2(v_{n+1} - v_n)g'(2\alpha_n) = g(2v_n) - 2g(2v_n)g'(2\alpha_n),$$

with $v_{n+1} \leq \alpha_n \leq v_n$. Thus, since $g'(0) = 0$, $g(2v_{n+1})/g(2v_n) \to 1$ as $n \to +\infty$. Thus

$$g'(2U(s'_n))\frac{g(2U(s_n))^2}{g(2U(s'_n))^2} \underset{n\to+\infty}{\longrightarrow} 0.$$

And we conclude that

$$s_{n+1} = s_n + 1 + o(1).$$

Therefore $s_n \underset{n\to+\infty}{\sim} n$.

In the same way we prove that $r_n \underset{n\to+\infty}{\sim} n$. Since $s_n \geq t_n \geq r_n$, we have $t_n \underset{n\to+\infty}{\sim} n$. We still introduce $V : \mathbb{R}_+ \to \mathbb{R}_+$ defined by $V(s) = 2U(s/2)$ $\forall s \geq 0$. Then $E_u(2n) = 2U(t_n)^2 = \frac{1}{2}V(2t_n)^2$, where $t_n \underset{n\to+\infty}{\sim} n$. □

5.3. Some explicit lower bounds of the energy.

Proof of Proposition 3.1. Let $A_0 \in \mathbb{R}$ be such that $A_0 \neq 0$. We use the notations of the proof of Theorem 3.1. Then $E_u(2n) = 2A_n^2$ $\forall n \in \mathbb{N}$, where $(A_n)_{n\in\mathbb{N}}$ is the real sequence defined by (5.1). As for Theorem 3.1, we can prove that, in both cases $|q| \leq |g|$ or $|q| \geq |g^{-1}|$ in a neighborhood of zero, there exists some $n_0 \in \mathbb{N}$ such that the sequence $(u_n)_{n\geq n_0} = (|A_n|)_{n\geq n_0}$ satisfies

$$(5.21) \qquad \forall n \geq n_0, \quad u_{n+1} - u_n \geq -g(u_{n+1} + u_n) \geq -g(2u_n).$$

We introduce $h = \frac{1}{2}g^{-1}$. Set $n_1 \in \mathbb{N}$, and let $(\lambda_n)_{n\geq n_0}$ be the real decreasing sequence (convergent to 0) defined by $h'(\lambda_n) = n + n_1$. Note that $\forall n \geq n_0$,

$$h(\lambda_n) = \frac{1}{2}(g')^{-1}\left(\frac{1}{2(n+n_1)}\right).$$

Choose $n_1 \in \mathbb{N}$ such that $h(\lambda_{n_0}) \leq u_{n_0}$. We prove by induction that

$$\forall n \geq n_0,\ u_n \geq h(\lambda_n).$$

Assume $u_n \geq h(\lambda_n)$. Then

$$u_{n+1} \geq u_n - g(2u_n) = G(u_n) \geq G(h(\lambda_n)) \geq h(\lambda_n) - \lambda_n.$$

On the other hand,

$$h(\lambda_n) - h(\lambda_{n+1}) = (\lambda_n - \lambda_{n+1})h'(\mu_n) \geq (\lambda_n - \lambda_{n+1})h'(\lambda_n)$$

(where $\lambda_{n+1} \leq \mu_n \leq \lambda_n$). Since

$$\lambda_n(h'(\lambda_n) - 1) \geq \lambda_{n+1}(h'(\lambda_{n+1}) - 1) = \lambda_{n+1}h'(\lambda_n),$$

we see that

$$(\lambda_n - \lambda_{n+1})h'(\lambda_n) \geq \lambda_n,$$

and so $u_{n+1} \geq h(\lambda_{n+1})$. □

Proof of Proposition 3.2. We still use the notations of the proof of Proposition 3.1 and we study the sequence $(u_n)_{n \geq n_0} = (|A_n|)_{n \geq n_0}$ that satisfies (5.21). Let $0 < \gamma \leq \beta$ be such that $u_{n_0} \geq h(\frac{\gamma}{n_0^k})$. We prove by induction that

$$u_n \geq h\left(\frac{\gamma}{n^k}\right).$$

Assume that $u_n \geq h(\frac{\gamma}{n^k})$. Then

$$u_{n+1} \geq u_n - g(2u_n) = G(u_n) \geq G\left(h\left(\frac{\gamma}{n^k}\right)\right) \geq h\left(\frac{\gamma}{n^k}\right) - \frac{\gamma}{n^k}.$$

On the other hand,

$$\begin{aligned} h\left(\frac{\gamma}{n^k}\right) - h\left(\frac{\gamma}{(n+1)^k}\right) &\geq \left(\frac{\gamma}{n^k} - \frac{\gamma}{(n+1)^k}\right) h'\left(\frac{\gamma}{n^k}\right) \\ &\geq \gamma(n+1)\left(\frac{1}{n^k} - \frac{1}{(n+1)^k}\right) \geq \frac{\gamma}{n^k}. \end{aligned}$$

Thus

$$u_{n+1} \geq h\left(\frac{\gamma}{(n+1)^k}\right). \qquad \square$$

Lower bound for the energy of a more general class of initial conditions. The reasoning is exactly the same: set $(u^0, v^0) \in W^{1,\infty}(0,1) \times L^\infty(0,1)$ such that $\|(u^0, v^0)\|_{W^{1,\infty} \times L^\infty}$ is small enough. The solution of (1.1) can be written as

$$u(x,t) = f(t+x) - f(t-x),$$

and the boundary condition implies that the sequence $(A_n(s) = f'(s+2n))_{n \in \mathbb{N}}$ for $s \in (-1,1)$ satisfies

$$A_{n+1}(s) + A_n(s) + q(A_{n+1}(s) - A_n(s)) = 0. \tag{5.22}$$

Note that $(u^0, v^0) \in W^{1,\infty}(0,1) \times L^\infty(0,1)$ if and only if $A_0 \in L^\infty(0,1)$, and $(u^0, v^0) \in V \times L^2(0,1)$ if and only if $A_0 \in L^2(0,1)$. Similarly

$$E_u(2n) = \int_{2n-1}^{2n+1} f'(s)^2 \, ds = \int_{-1}^{1} A_n(s)^2 \, ds.$$

Then the reasoning applied to prove Proposition 3.2 shows that under the assumption (3.10) we can find $\gamma(s) \in [0, \beta]$ such that

$$|A_n(s)| = u_n(s) \geq h\left(\frac{\gamma(s)}{n^k}\right).$$

Since (u^0, v^0) is not equal to zero, the function γ is bounded from below by some positive constant γ_0 on some subinterval J of $(-1,1)$. Then

$$E_u(2n) \geq |J| \, h\left(\frac{\gamma_0}{n^k}\right)^2,$$

where $|J|$ denotes the length of J. □

5.4. Optimality of estimate (3.1) for a class of nonpolynomial feedbacks.

Proof of Proposition 3.3. We still use the notations of the proof of Proposition 3.1 and we study the sequence $(u_n)_{n\geq n_0} = (|A_n|)_{n\geq n_0}$ that satisfies (5.21). There exists $r_n \in [u_{n+1}, u_n]$ such that

$$\begin{aligned} g(\alpha u_{n+1}) &= g(\alpha u_n) + \alpha(u_{n+1} - u_n) g'(\alpha r_n) \\ &\qquad\geq g(\alpha u_n) - \alpha g(2u_n) g'(\alpha r_n) \geq g(\alpha u_n) - \alpha g(2u_n) g'(\alpha u_n). \end{aligned}$$

Note that (3.12) gives that $g(\alpha u_n) - \alpha g(2u_n) g'(\alpha u_n) > 0$. We deduce that

$$\begin{aligned} \frac{1}{g(\alpha u_{n+1})} - \frac{1}{g(\alpha u_n)} &\leq \frac{1}{g(\alpha u_n)} \left(\frac{1}{1 - \frac{\alpha g(2u_n) g'(\alpha u_n)}{g(\alpha u_n)}} - 1 \right) \\ &\leq \frac{1}{g(\alpha u_n)} \left(1 + 2\alpha \frac{g(2u_n) g'(\alpha u_n)}{g(\alpha u_n)} - 1 \right) \\ &\leq 2\alpha \frac{g(2u_n) g'(\alpha u_n)}{g(\alpha u_n)^2} \leq M. \end{aligned}$$

Thus

$$\frac{1}{g(\alpha u_n)} \leq Mn + C,$$

where $C > 0$ is a constant, which proves the result. □

5.5. Remark concerning (2.2). Let v be the solution of (3.15). Note that

$$v(n+1) - v(n) = v'(\alpha_n) = -q(v(\alpha_n)),$$

with $\alpha_n \in [n, n+1]$. Since q is increasing and v nonincreasing, we have

$$-q(v(n)) \leq v(n+1) - v(n) \leq -q(v(n+1)).$$

Thus, under the hypotheses of Theorem 3.1 and Propositions 3.1 and 3.2 and with similar proofs, we can obtain similar lower bounds of the energy.

5.6. Decay rate when the feedback is weak at infinity. Consider now the special function q defined by

$$\begin{cases} \forall |s| \leq 2, \ q(s) = \frac{s}{2}, \\ \forall |s| \geq 2, \ q(s) = \text{ sgn } (s) 1. \end{cases}$$

We solve (5.22) to deduce that

$$\begin{cases} \text{if } |A_n(s)| \geq \frac{3}{2}, \text{ then } |A_{n+1}(s)| = |A_n(s)| - 1, \\ \text{if } |A_n(s)| \leq \frac{3}{2}, \text{ then } |A_{n+1}(s)| = k|A_n(s)| \text{ with } k := \frac{1}{3}. \end{cases}$$

Set $s \in (0, 1)$ and let $p(s)$ be the smallest nonnegative integer such that

$$|A_0(s)| \leq p(s) + \frac{3}{2}.$$

We deduce easily that

$$\left\{\begin{array}{l} \text{if } q \leq p(s), \text{ then } |A_q(s)| = |A_0(s)| - q, \\ \text{if } q \geq p(s), \text{ then } |A_q(s)| = k^{q-p(s)}|A_{p(s)}(s)|. \end{array}\right. \tag{5.23}$$

Exponential decay of strong solutions: set $(u^0, v^0) \in W^{1,\infty}(0,1) \times L^\infty(0,1)$, then $A_0 \in L^\infty(-1,1)$, and so the energy of the solution u decays exponentially to zero. Indeed, there exists p_0 such that

$$\|A_0\|_\infty \leq p_0 + \frac{3}{2};$$

then $|A_{p_0}(s)| \leq \frac{3}{2}$ and

$$\forall n \geq p_0,\ E_u(2n) = \int_{-1}^{1} A_n(s)^2\, ds \leq \frac{9}{2} k^{2(n-p_0)}. \qquad \square$$

The strong solutions do not decay uniformly exponentially to zero: consider the sequence of initial conditions

$$\left\{\begin{array}{l} A_0^{(m)}(s) = m \text{ if } s \in (-\frac{1}{2m^2}, \frac{1}{2m^2}), \\ A_0^{(m)}(s) = 0 \text{ if } s \in (-1,1) \setminus (-\frac{1}{2m^2}, \frac{1}{2m^2}). \end{array}\right.$$

All these initial conditions satisfy $E^{(m)}(0) = 1$. We easily deduce from (5.23) that

$$\forall r \in \mathbb{N},\ E^{(m)}(2m + 2r) = \frac{1}{9m^2}\frac{1}{9^r}.$$

Thus we cannot expect that there exist $C > 0$ and $\omega > 0$ that do not depend on m such that all strong solutions satisfy

$$\forall t \geq 0,\ E(t) \leq CE(0)e^{-\omega t}.$$

Indeed, that would mean

$$\forall m \in \mathbb{N},\ \frac{1}{9m^2} = E^{(m)}(2m) \leq Ce^{-2\omega m}. \qquad \square$$

The study of the decrease of the energy of weak solutions: first we prove that weak solutions do not decay uniformly polynomially to zero. Fix $\varepsilon \in (0,1)$ and consider the following initial conditions:

$$\left\{\begin{array}{l} \forall s \in (0,1),\ A_0(s) = \frac{1}{s^{(1-\varepsilon)/2}}, \\ \forall s \in (-1,0),\ A_0(s) = 0. \end{array}\right.$$

Then we deduce from (5.23) that

$$\text{if } A_0(s) \geq n + \frac{1}{2}, \text{ then } A_n(s) = A_0(s) - n.$$

Set $a := \frac{1-\varepsilon}{2}$. Thus

$$E_u(2n) = \int_0^1 A_n(s)^2\, ds \geq \int_0^{(n+1)^{-1/a}} A_n(s)^2\, ds = \int_0^{(n+1)^{-1/a}} \left(\frac{1}{s^a} - n\right)^2 ds.$$

Easy computations lead to

$$\int_0^{(n+1)^{-1/a}} \left(\frac{1}{s^a} - n\right)^2 ds \underset{n\to+\infty}{\sim} \frac{2a^2}{(1-2a)(1-a)} \frac{1}{n^{(1-2a)/a}}.$$

Since $\frac{1-2a}{a} = \frac{2\varepsilon}{1-\varepsilon}$ can be chosen as close to zero as we want, the energy of weak solutions does not decay uniformly polynomially to zero.

We need only to refine this study to prove (4.4): fix $p \geq 2$ and consider

$$\forall s \in (0, T_p^{-1}),\ A_0(s) = \left(\frac{1}{s \ln_1(s^{-1}) \ln_2(s^{-1}) \cdots \ln_{p-1}(s^{-1})(\ln_p(s^{-1}))^2}\right)^{1/2},$$

and $A_0(s) = 0$ in $(-1,0) \cup (T_p^{-1}, 1)$. We verify that $A_0 \in L^2(0,1)$: we use several times the change of variables $z = \ln s$ to get

$$\begin{aligned}\int_{-1}^1 A_0(s)^2\, ds &= \int_0^{T_p^{-1}} \frac{ds}{s \ln_1(s^{-1}) \ln_2(s^{-1}) \cdots \ln_{p-1}(s^{-1})(\ln_p(s^{-1}))^2} \\ &= \int_{\ln T_p}^{+\infty} \frac{dz}{z \ln_1(z) \ln_2(z) \cdots \ln_{p-2}(z)(\ln_{p-1}(z))^2} \\ &= \cdots = \int_{\ln_p(T_p)}^{+\infty} \frac{dz}{z^2} = \frac{1}{\ln_p(T_p)}.\end{aligned}$$

Next we use the same strategy: set $\alpha > 0$ and define for n large enough

$$s_n = \frac{\alpha}{n^2 \ln_1(n) \ln_2(n) \cdots \ln_{p-1}(n)(\ln_p(n))^2}.$$

We easily see that

$$A_0(s_n)^2 \underset{n\to+\infty}{\sim} \frac{n^2}{2\alpha}.$$

Therefore, if we choose, for example, $\alpha := \frac{1}{4}$, for n large enough we have

$$A_0(s_n) \geq n + \frac{1}{2}.$$

Therefore

$$\begin{aligned}E_u(2n) = \int_{-1}^1 A_n(s)^2\, ds \geq \int_0^{s_n} A_n(s)^2\, ds &= \int_0^{s_n} (A_0(s) - n)^2\, ds \\ &\geq \frac{1}{2} \int_0^{s_n} A_0(s)^2\, ds - n^2 s_n \\ &\geq \frac{1}{2} \frac{1}{\ln_p(s_n^{-1})} - n^2 s_n \underset{n\to+\infty}{\sim} \frac{1}{2} \frac{1}{\ln_p(s_n^{-1})}.\end{aligned}$$

Thus, we obtain that for n large enough,

$$E_u(2n) \geq \frac{1}{8} \frac{1}{\ln_p(n)} \geq \frac{1}{\ln_{p-1}(n)}. \qquad \square$$

SUB-FINSLERIAN METRIC ASSOCIATED TO AN OPTIMAL CONTROL SYSTEM*

C. LÓPEZ† AND E. MARTÍNEZ†

Abstract. The problem of minimizing the cost functional of an optimal control system through the use of constrained variational calculus is a generalization of the geodetic problem in Riemannian geometry. In the framework of a geometric formulation of optimal control, we define a metric structure associated to the optimal control system on the enlarged space of state and time variables, such that the minimal length curves of the metric are the optimal solutions of the system. A twofold generalization of metric structure is applied, considering Finslerian-type metrics as well as allowed and forbidden directions (like in sub-Riemannian geometry). Free (null Hamiltonian) or fixed final parameter problems are identified with constant *energy* leaves, and the restriction of the metric to these leaves gives way to a family of metric structures on the usual state manifold.

Key words. optimal control for ordinary differential equations, Finsler metrics

1. Introduction.

A positive definite symmetric tensor g on a manifold M is named a Riemannian metric structure (M, g). It allows us to measure lengths of curves by first calculating the norm of the velocity vector associated to a parametrized curve, and then integrating it along the curve

$$\ell(\gamma) = \int_{t_0}^{t_1} \sqrt{g(\gamma^c, \gamma^c)}dt,$$

where $\gamma^c(t)$ is the lifting of the curve $\gamma\colon [t_0, t_1] \to M$ to TM, the tangent bundle. In local coordinates, if $\gamma(t) = (x^i(t))$, and g is given by $g_{ij}(x)dx^i dx^j$, the norm of the velocity vector is $|\gamma^c(t)| = \sqrt{g_{ij}(x(t))\frac{dx^i}{dt}\frac{dx^j}{dt}}$.

Length has the property of being invariant under reparametrization of the curve, because the norm is a homogeneous positive function on the velocities. Curves of minimal length joining two points are said to be geodesics, and, through classical variational calculus, a set of necessary conditions is obtained for these curves, the geodetic equations or Euler–Lagrange equations for the Lagrangian $L = \sqrt{g(v, v)}$. But (M, g) has much more structural content: associated connection, scalar product of vectors, and the whole exhaustively studied machinery of Riemannian geometry.

If we are just interested in measuring the length of curves, we only need a homogeneous positive function F in TM (not necessarily the square root of a quadratic function) to be integrated along the curves, giving an invariant under reparametrization length. This defines a Finslerian metric structure on (M, F), which was, in fact, the original theme of work in the early study by Riemann (see [5] and references therein), and many properties of Riemannian geometry can be generalized to this

case. In this paper, the extra conditions of convexity, $\frac{\partial^2 F}{\partial v \partial v} > 0$, and central symmetry $F(-v) = F(v)$ (see, for example, [6]), will not be imposed, so that our Finslerian structure will be more general than usual.

Another simple generalization of the Riemannian metric structure is given by constraining the set of allowed directions for the curves to be measured, i.e., by considering a cone of directions $D \subset TM$ or, equivalently, a subset of the positive projective space $SM \equiv TM/\Delta$, where Δ is the Liouville or dilation vector field. Only curves whose lifting to TM lies in D can be measured, and we have a Riemannian metric g defined on D. This is the case of sub-Riemannian geometry [2, 9], where a linear distribution E (usually completely nonintegrable) is considered as the set of allowed directions on M. (M, E, g) is a sub-Riemannian structure, and the length of curves γ whose lifting lies in E is given by the usual integral functional. The unexpected existence of abnormal geodesics has been clarified by using the optimal control machinery, identifying those abnormal curves with the solutions of the problem with $p_0 = 0$. Optimal control, as a generalization of classical variational calculus, is therefore an appropriate framework for the study of metric structures.

The joining of both ideas, that of Finslerian functions and that of a constrained directional set, would give way to sub-Finslerian metric structures (M, D, F), where D is a cone of allowed directions and F is a homogeneous positive function on D. Of course, in this generalization process we have lost properties, but the basic one of measuring lengths of curves is preserved. The visualization of the indicatrix (set of vectors with norm 1) helps to understand the differences between metrics; the indicatrix is a hyperellipsoid centered at the origin for Riemannian metrics, a general convex hypersurface around the origin for Finslerian metrics, and a very general set (neither convex nor intersecting all directional rays) for a more general sub-Finslerian metric. Our aim in this paper is to point out that optimal control systems can be understood as metric structures of this generalized sub-Finslerian type, and to show how typical properties of optimal control, as bang-bang phenomena or allowed but never optimal directions, can be illustrated through the indicatrix of the associated metric structure.

A typical system where allowed velocities are constrained is a control system of ordinary differential equations. A control system is defined through a set of differential equations (usually in normal form) $\frac{dx^i}{dt} = f^i(x, u)$, where the u^a variables are named controls. In geometric terms [11], it corresponds to a bundle map $X : U \to TM$ over the identity in the state manifold M from the control bundle (U, η, M) to the tangent bundle (TM, τ, M), where the image of the map X is the set of allowed velocities. If we want to minimize a cost functional $C(\gamma) = \int f^0(x(t), u(t))dt$ for allowed curves of the control system joining two points, we face an optimal control problem [8, 12]. In other words, we are given a way to measure the cost for allowed curves. It is like a generalized metric structure as presented before, but we do not have the invariance under reparametrization property because the cost functional is not obtained from a Finslerian function.

Using the machinery of optimal control (the Pontryagin maximum principle [12]), we can associate to the optimal control problem a sub-Finslerian structure, i.e., a cone of directions D and a Finslerian function F, such that the cost value of a curve solution of the control system is just the length of the curve (or of any reparametrization of the curve). Therefore, the geodetic curves of the metric system are the curves making minimal the cost, the solutions of the optimal control problem. This metric structure is defined in an enlarged space of states and time (parameter of evolution) $N = M \times \mathbb{R}$

for the general case; for free or fixed final parameter problems, we obtain through restriction and projection a family of metric structures on M, parametrized by the energy, in classical mechanical language.

The paper is organized as follows. Section 2 is devoted to present a geometric description of optimal control systems based on the geometry of control systems as presented in [1, 11], and a geometric version of Pontryagin maximum principle, which gives way to a Dirac type constraint algorithm [7]. In section 3 the metric structure associated to a time optimal problem (the simplest case) is defined on M (the state space), and academic examples are presented where some graphic representation of the indicatrix helps to understand the basic ideas. Section 4 considers the general optimal control problem, defining a metric structure on the manifold $N = M \times \mathbb{R}$ of states and time; the generalization is based on a simple reparametrization of the system which transforms it into a time optimal problem. As an illustrative example, the Finslerian metric associated to a mechanical Lagrangian system is presented. The restriction of the metric to certain energy leaves, associated to free or fixed final parameter problems, is developed in section 5. In the former example of Lagrangian mechanics, this restriction gives way to the well-known Jacobi metrics. A final section with conclusions and possible applications is also included.

2. Geometry of optimal control. A (continuous) control system of (autonomous) ordinary differential equations is a family of differential equations in normal form $\frac{dx^i}{dt} = f^i(x,u)$, where x^i are named state variables, t is the parameter of evolution (usually the time), and u^a are the controls. From the geometric point of view [11], it can be understood as a fibered mapping $X\colon U \to TM$ from a control fiber bundle (U, η, M) over the state manifold M to the tangent bundle (TM, τ, M). Using local coordinates $(x^i)_{i=1}^n$ in M, adapted coordinates $(x^i, u^a)_{a=1}^k$ in U, and natural coordinates (x^i, v^i) in TM, the coordinate expression for X is $X(x,u) = f^i(x,u)\frac{\partial}{\partial x^i}$, or $v^i = f^i(x,u)$, the family of control equations. Allowed curves of the control system are curves $\rho\colon I \subset \mathbb{R} \to U$ such that $(\eta \circ \rho)^c = X \circ \rho$, where γ^c is the natural lifting to TM of a curve γ in M. In local coordinates, $\rho(t) = (x^i(t), u^a(t))$ is a solution integral curve of the control system if $\frac{dx^i}{dt} = f^i(x(t), u(t))$, i.e., if $(\eta \circ \rho)^c = (x^i(t), \frac{dx^i}{dt})$ equals $X \circ \rho = (x^i(t), f^i(x(t), u(t)))$. Note that the evolution on the state manifold M is totally characterized by the image set $S = \mathrm{Im}(X) \subset TM$, while the map $X_S\colon U \to S$ can be understood as a parametrization (perhaps redundant) of S. A particular problem of the control system can always be solved in two steps; the first solves the problem in the *basic* control system $i\colon S \to TM$, obtained from the natural injection of S into TM, and the second determines a particular inverse of X over the solution. In the usual control system language, we are just selecting the *essential* controls (all of them whenever X_S is a diffeomorphism [14]). Therefore, we sometimes will understand (x^i, u^a) as a nonnatural system of coordinates in the allowed velocities space $S \subset TM$, and we will identify the control set $U_x = \eta^{-1}(x)$ for a fixed $x \in M$ with the set of allowed velocities $S_x = S \cap \tau^{-1}(x)$ on x.

In optimal control theory [8, 12], a cost functional $C(\rho) = \int f^0(x(t), u(t))dt$ is given, and the problem is to obtain allowed curves of the control system satisfying some boundary conditions (e.g., $x(0) = x_0$, $x(T) = x_1$) and minimizing the cost functional. It is therefore a classical variational problem with nonintegrable constraints defined by the control equations. Pontryagin's maximum principle [12] gives a set of necessary conditions for a curve $(x(t), u(t))$ to be optimal; introducing a Hamiltonian function

$$H(x, p_0, p, u) = p_0 f^0(x, u) + p_i f^i(x, u), \tag{2.1}$$

where the variables (p_0, p_i) are momenta coordinates, the optimal curves $(x(t), u^*(t))$ must satisfy the control system equations

$$\frac{dx^i}{dt} = \frac{\partial H}{\partial p_i} = f^i(x(t), u^*(t)), \tag{2.2}$$

and there must exist a solution curve for the adjoint differential equations

$$\frac{dp_i}{dt} = -\frac{\partial H}{\partial x^i} = -p_0 \frac{\partial f^0}{\partial x^i}\Big|_{(x(t),u^*(t))} - p_j \frac{\partial f^j}{\partial x^i}\Big|_{(x(t),u^*(t))} \tag{2.3}$$

with the optimal control u^* satisfying the algebraic condition of maximality

$$H(x, p, u^*) \geq H(x, p, u) \qquad \forall u \in U_x = \eta^{-1}(x). \tag{2.4}$$

Here p_0 is a nonpositive constant, the case $p_0 = 0$ is named abnormal, and for $p_0 < 0$ it can be fixed to -1 by homogeneity of the adjoint equations and the Hamiltonian. Moreover, the Hamiltonian vanishes when the final parameter T is not fixed.

This set of Hamiltonian differential equations and the algebraic condition of maximality are the cornerstone of optimal control theory. The so-called transversality conditions on the momenta must be added to the boundary conditions when the initial and final endpoints are not fixed but are restricted to belong to some subsets of the state space. When the set of controls U is a manifold with boundary, the algebraic condition of maximality can be achieved in an interior point (and a weaker algebraic equation could be used, $\frac{\partial H}{\partial u^a} = 0$ for stationary points) or in the boundary. Sometimes the values u^{*a} can be determined explicitly as $u^{*a}(x, p)$, which can be understood as a dynamical feedback, and we reduce the problem to a set of $2n$ differential equations with boundary conditions, but this is not the case in many complex situations. It is interesting to observe that the former Hamiltonian is of a mixed type, with explicit dependence on velocity (through the control variables) as well as momenta coordinates. This is similar to the approach used in [13] to study the relationship between Lagrangian and Hamiltonian formulations of classical mechanics: given a Lagrangian function $L(x, v)$ on the tangent bundle, a Hamiltonian function $H(x, v, p) = \langle p, v\rangle - L(x, v)$ (where $\langle p, v\rangle$ is the natural pairing between covectors and vectors) is defined on the Whitney sum of tangent and cotangent bundles $W_M = TM \times_M T^*M$. The Hamiltonian equations (obtained through a natural presymplectic form on W)

$$\frac{dx}{dt} = \frac{\partial H}{\partial p} = v, \qquad \frac{dp}{dt} = -\frac{\partial H}{\partial x} = \frac{\partial L}{\partial x}$$

and algebraic condition

$$\frac{\partial H}{\partial v} = 0 = p - \frac{\partial L}{\partial v}$$

are equivalent to the Euler–Lagrange equations for the Lagrangian L. Only for regular Lagrangians, when the velocities $v(x, p)$ can be determined uniquely through the algebraic condition $p - \frac{\partial L}{\partial v} = 0$, the usual Hamiltonian $H_0(x, p) = \langle p, v(x, p)\rangle - L(x, v(x, p))$

living on T^*M gives way to an equivalent system of differential equations, but this is not the case for singular Lagrangians.

Therefore, a geometric transcription of Pontryagin's maximum principle is naturally developed in the framework of the Whitney sum $W = U \times_M T^*M$ (or the subset $S \times_M T^*M$ of W_M for basic systems) for the normal case $p_0 = -1$, the one presented here for simplicity. The Hamiltonian function $H(x, p, u) = \langle p, X(x, u)\rangle - f^0(x, u)$ is defined on W, and the pull-back of the canonical symplectic form $\omega = dx^i \wedge dp_i$ on T^*M to W, $\Omega = \mathrm{pr}_2^*(\omega)$, with $\mathrm{pr}_2\colon W \to T^*M$ the natural projection, determines a presymplectic Hamiltonian structure (W, Ω, H). The algebraic condition of maximality defines a subset $W_1 \subset W$ by taking on every fiber of pr_2 the point (or points) where H is maximal

$$W_1 = \{(x, p, u^*) \in W | H(x, p, u^*) \geq H(x, p, u) \quad \forall (x, p, u) \in \mathrm{pr}_2^{-1}(x, p), (x, p) \in T^*M\}.$$

The optimal vector field Γ solution of the optimal control system is determined by

$$i(Z)(i(\Gamma)\Omega - dH)\Big|_{W_1} \geq 0$$

for every arbitrary *allowed* vector Z in $T_{W_1}W$, i.e., an arbitrary vector in an interior point (in this case the condition is simply $(i(\Gamma)\Omega - dH)|_{W_1} = 0$) or a vector tangent to the boundary or pointing to the interior of W for a point in the boundary of W. The optimal curves are integral curves of Γ. In local coordinates, the points (x, p, u^*) of W_1 are just those satisfying the algebraic condition of maximality (2.4); given $\Gamma = a^i \frac{\partial}{\partial x^i} + b_i \frac{\partial}{\partial p_i} + c^a \frac{\partial}{\partial u^a}$, we get

$$i(\Gamma)\Omega - dH = \left(-b_i - \frac{\partial H}{\partial x^i}\right) dx^i + \left(a^i - \frac{\partial H}{\partial p_i}\right) dp_i - \frac{\partial H}{\partial u^a} du^a.$$

Therefore, $i(Z)(i(\Gamma)\Omega - dH)|_{W_1} \geq 0$ gives way to

$$a^i = \frac{\partial H}{\partial p_i}, \quad b_i = -\frac{\partial H}{\partial x^i},$$

and to the condition of local maximum in the fiber for H, which is certainly fulfilled in the global maximum point of W_1. A similar geometric description can be obtained to include the abnormal case $p_0 = 0$ and to formulate nonautonomous systems, by taking into account the cost and/or the time variables in an enlarged state manifold $M \times \mathbb{R}$ or $M \times \mathbb{R}^2$, with extra coordinates x^0 (the cost variable) and $x^{n+1} \equiv t$, and extra control equations

$$\frac{dx^0}{dt} = f^0(x, u), \qquad \frac{dx^{n+1}}{dt} = 1.$$

We present in the next section the simpler case of autonomous time optimal problems, where $f^0(x, u) = 1$, and those extra variables are not necessary to define the associated metric.

Notice that the solution Γ is not necessarily unique (the c^a components can be underdetermined) and it should be tangent to W_1. This compatibility condition is solved by applying a constraint algorithm similar to the one developed in [7] for presymplectic Hamiltonian systems, defining a chain of constraint submanifolds. In many cases the algorithm is trivial and W_1 is the final constraint submanifold, but sometimes the compatibility condition can be nontrivial, as it is in the case of sub-Riemannian geometry for the abnormal solutions.

3. Time optimal problems and the associated metric. For a time optimal problem we try to minimize the final time T (we take $t = 0$ as initial value), so that $f^0(x,u) = 1$, and the Hamiltonian (for the normal case) becomes

$$H(x,p,u) = p_i f^i(x,u) - 1 = \langle p, X(x,u)\rangle - 1. \tag{3.1}$$

The final parameter is obviously free (it is the unknown cost), and therefore the optimal curves take values on the subset $H = 0$ of W. In order to define a sub-Finslerian metric structure on M we need a set of allowed directions, a cone bundle $D \subset TM$, and a Finslerian (homogeneous) function defined on D. The construction is made pointwise, i.e., fixing an $x \in M$ and defining $D_x = D \cap \tau^{-1}(x)$ and $F_x\colon D_x \to \mathbb{R}$.

Once fixed x, the algebraic condition of maximality (2.4) determines a subset U_x^* of $U_x = \eta^{-1}(x)$ of possible optimal controls

$$U_x^* = \{(x,u_o) \in U_x \,|\, \exists (x,p) \in T_x^*M \quad \text{such that} \quad H(x,p,u_o) \geq H(x,p,u) \quad \forall u \in U_x\},$$

from which the actual optimal control $u^*(x,p)$ is determined for every p. Note that $U^* = \cup_{x\in M} U_x^*$ is just the projection of W_1 to U. The image subset $S_x^* = X(U_x^*) \subset S_x$ is made of some of the longest allowed velocity vectors, because, for a given momentum covector $p_i dx^i$, the Hamiltonian is maximal for the vector $f^i(x,u)\frac{\partial}{\partial x^i}$ with the greatest projection, $\max\langle p, f(x,u)\rangle$, i.e., the longest in some particular ray direction. (Note that for the actual solutions of the adjoint equations the projection is always positive by the nullity of the Hamiltonian, $\langle p, f(x,u)\rangle = 1$, and therefore the shortest vector in a given direction is never optimal.) So we have

$$S_x^* \subset S_x^o = \{(x,v) \in T_xM | v \in S_x \quad \text{and} \quad \lambda v \notin S_x \quad \forall \lambda > 1\}. \tag{3.2}$$

Now, the invariance under reparametrization needed to define a metric can be obtained by considering the cone D_x of rays generated by elements of S_x^o (the curves can be followed at arbitrary positive speed)

$$D_x = \{(x,v) \,|\, \exists (x,v_o) \in S_x^o \quad \text{such that} \quad v = \lambda v_o, \quad \lambda > 0\}. \tag{3.3}$$

The *norm* of the velocity is now defined to obtain a length equal to the original cost; we associate to every $(x,v) \in D_x$ the norm λ, which is the factor between it and the element of S_x^o in the same ray

$$F_x\colon D_x \to \mathbb{R}^+, \qquad F_x(v) = \lambda, \quad \text{where } v = \lambda v_o, \text{ with } v_o \in S_x^o. \tag{3.4}$$

An optimal curve $\rho(t) = (x(t), u^*(t))$, with cost $\int_0^T dt = T$, will have, once arbitrarily reparametrized by $t(\tau)$ ($\frac{dt}{d\tau} > 0$), the length

$$\int_{\tau_i}^{\tau_f} F(x(\tau), v(\tau)) d\tau = \int_{\tau_i}^{\tau_f} \lambda(\tau) d\tau = \int_{\tau_i}^{\tau_f} \frac{dt}{d\tau} d\tau = \int_0^T dt = T,$$

because

$$v(\tau) = \frac{dx}{d\tau} = \frac{dx}{dt}\frac{dt}{d\tau} = v_o \frac{dt}{d\tau}$$

so that $F(x(\tau), v(\tau)) = \lambda(\tau) = \frac{dt}{d\tau}$. Note that $S_x^o \subset D_x$ is the indicatrix of the defined metric, the set of unit norm velocities.

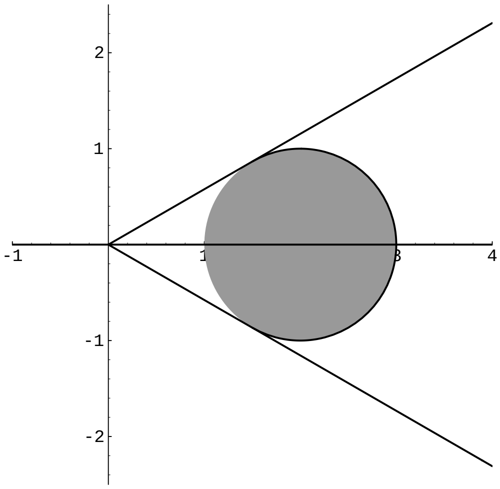

FIG. 1. *Allowed velocities, optimal velocities, and the cone of directions.*

For example, let us consider in $\mathbb{R}^2$ the control system

$$\frac{dx}{dt} = 2 + u^1 \cos(u^2), \quad \frac{dy}{dt} = u^1 \sin(u^2), \qquad 0 \leq u^1 \leq 1, \quad u^2 \in S^1,$$

for which, in a particular point $(x_0, y_0) \in \mathbb{R}^2$, the subset $S_{(x_0,y_0)}$ is the unit disk centered at $(2, 0)$. In a time optimal problem for this control system, the subset of possible optimal allowed velocities $S^*_{(x_0,y_0)}$ ($\equiv S^o_{(x_0,y_0)}$ in this case) is determined by $u^1 = 1$ and $\frac{-2\pi}{3} \leq u^2 \leq \frac{2\pi}{3}$, the boundary of the disk made of the longest vectors. (See Figure 1.)

$D_{(x_0,y_0)}$ is determined by the conditions $|\frac{v_y}{v_x}| \leq \frac{1}{\sqrt{3}}$ and $v_x > 0$. The Finslerian function, the factor between elements of $D_{(x_0,y_0)}$ and the element of $S^o_{(x_0,y_0)}$ on the same ray, is explicitly given by

$$F_{(x_0,y_0)}(v_x, v_y) = \frac{v_x^2 + v_y^2}{2v_x + \sqrt{v_x^2 - 3v_y^2}},$$

a not very simple homogeneous function defined on $D_{(x_0,y_0)}$.

Next we present another illustrative example of a time optimal problem, where the bang-bang phenomenon is clearly illustrated through the indicatrix of the associated metric. Given the system of control equations

$$\frac{dx}{dt} = u_1 |\cos u_2| \cos u_2, \qquad \frac{dy}{dt} = u_1 |\cos u_2| \sin u_2,$$

with $0 \leq u_1 \leq 2$, $0 \leq u_2 < 2\pi$, the problem is to find the curve solution of the system joining two fixed endpoints with minimum parameter increasing ($(x, y)(0) = (x_1, y_1)$, $(x, y)(T) = (x_2, y_2)$, T minimum). It is a typical optimal control problem, defined in this case through the map $X \colon R \times \mathbb{R}^2 \to T\mathbb{R}^2$ given by

$$X(x, y, u_1, u_2) = u_1 |\cos u_2| \cos u_2 \frac{\partial}{\partial x} + u_1 |\cos u_2| \sin u_2 \frac{\partial}{\partial y},$$

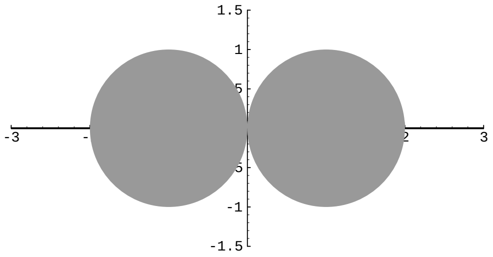

FIG. 2. *The set S in a generic $T_{(x,y)}\mathbb{R}^2$.*

where R is the direct product $[0, 2] \times S^1$. The image set $\mathrm{Im}(X) = S$ is given at every point of the plane by the union of two unit disks centered at $(1, 0)$ and $(-1, 0)$, respectively (see Figure 2). The family of functions (x, y, u_1, u_2) is a system of coordinates for $S \subset T\mathbb{R}^2$ which are related to the natural coordinates (x, y, v_x, v_y) by

$$v_x = u_1|\cos u_2|\cos u_2, \qquad v_y = u_1|\cos u_2|\sin u_2,$$

with inverse transformation

$$u_1 = \frac{v_x^2 + v_y^2}{|v_x|}, \qquad u_2 = \arctan\left(\frac{v_y}{v_x}\right).$$

Being a minimum time problem, the Hamiltonian of the optimal control system, defined on $R \times T^*\mathbb{R}^2$, is given by

$$H = (p_x \cos u_2 + p_y \sin u_2)u_1|\cos u_2| - 1.$$

In a first step, maximality is obtained on every direction of S for $u_1 = 2$, i.e., S^o is the boundary of the disks (see Figure 3), where coordinates (x, y, u_2) can be used. The cone of allowed ray directions is $D = \{v \in T\mathbb{R}^2; v_x \neq 0\}$, and every vector (v_x, v_y) in D is positive proportional to a vector (v_{xo}, v_{yo}) in S^o (see Figure 3) by a factor λ which determines the metric function F:

$$F(x, y, v_x, v_y) = \frac{v_x^2 + v_y^2}{2|v_x|}.$$

F is homogeneous positive of degree 1, and note that $F = 1$ reproduces the set S^o, the indicatrix. In a usual metric notation, we have defined, associated to the optimal control system, the Finslerian metric $ds = \frac{(dx)^2+(dy)^2}{2|dx|}$ on the allowed directions $\langle dx, v\rangle \neq 0$.

Now, by concavity it is clear in Figure 4 that for $u_2 \in (\pi/4, 3\pi/4) \cup (5\pi/4, 7\pi/4)$ the corresponding direction is never a maximum of the Hamiltonian (the movable normal line to the momentum vector never first contacts the indicatrix in this interval), and we have as optimal set S^* of allowed directions those of slope $(v_y/v_x)^2 \leq 1$ on S^o. Geodetic curves of the metric are segments of straight lines. (This fact can be easily determined by obtaining the Euler–Lagrange equations for the singular Lagrangian $L = \frac{v_x^2+v_y^2}{2|v_x|}$, which are equivalent to the condition v_y/v_x constant.)

Therefore, although we can measure lengths of curves with slope $(v_y/v_x)^2 > 1$, those curves will never be geodesics and, if the initial and final points are, for example, $(0, 0)$ and $(2, 1)$, the straight segment between them is not the geodesic. The geodesic

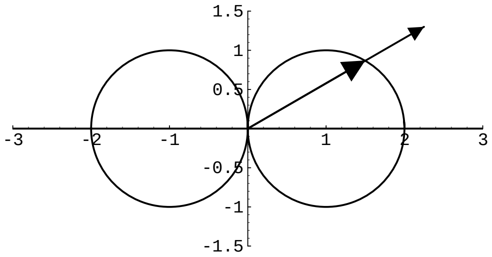

FIG. 3. *The set S^0, i.e., the indicatrix. The length of a vector is the factor between it and the parallel vector on the indicatrix.*

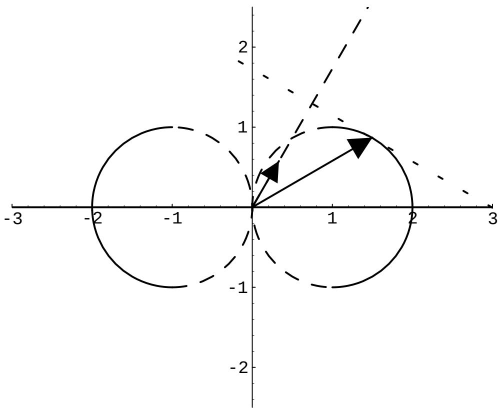

FIG. 4. *A given momentum vector and its corresponding optimal velocity. Dashed directions on the indicatrix can never be optimal and do not belong to S^*.*

(not unique) is a succession of segments with slopes 1 and -1, as, for example, $(0,0) \to (\frac{3}{2}, \frac{3}{2}) \to (2,1)$, and it contains at least one point of discontinuity on the derivative, a bang-bang on the control u_2 between $\pi/4$ and $3\pi/4$. The bang-bang phenomenon is here understood by the concavity-convexity properties of the indicatrix, i.e., by the fact that S^* is a proper subset of S^o.

4. The general case: The metric on state-time space. As it was pointed out in section 2, Pontryagin's maximum principle for the abnormal case as well as for nonautonomous systems can be formulated in the same framework by considering extra variables. Given a nonautonomous control system $\frac{dx^i}{dt} = f^i(x,t,u)$, a cost function $f^0(x,t,u)$, and some boundary conditions (for example, $x(t_0) = x_0$, $x(t_1) = x_1$, t_0, and t_1 fixed), let us consider the enlarged state space $Q = M \times \mathbb{R}^2$ with coordinates $(x^0, x^i|_{i=1,\cdots,n}, x^{n+1})$ and the enlarged (but autonomous) control system

$$\frac{dx^0}{d\tau} = f^0(x, x^{n+1}, u), \qquad \frac{dx^i}{d\tau} = f^i(x, x^{n+1}, u), \qquad \frac{dx^{n+1}}{d\tau} = 1,$$

with boundary conditions

$$x^0(\tau_0) = 0, \quad x^i(\tau_0) = x^i_0, \quad x^i(\tau_1) = x^i_1, \quad x^{n+1}(\tau_0) = t_0 \equiv \tau_0, \quad x^{n+1}(\tau_1) = t_1,$$

with τ_1 not fixed (although it is determined by the last control equation). It is clear that there is a correspondence between allowed curves for both systems, and optimal curves of the first system are curves of the second system with minimal final value $x^0(\tau_1)$. The Hamiltonian function in $U \times_Q T^*Q$ is defined, as before, as

$$H(x^0, x, x^{n+1}, p_0, p, p_{n+1}, u) = p_0 f^0(x, x^{n+1}, u) + p_i f^i(x, x^{n+1}, u) + p_{n+1},$$

and the same machinery works. It is immediate that p_0 is constant because there is no dependence of x^0 on H, and we can consider the abnormal case $p_0 = 0$ on the same foot as the normal one. The final parameter is free, so that $H = 0$ is an extra condition; in the case of autonomous systems, p_{n+1} is also constant by the adjoint equations, and we recover the constant autonomous Hamiltonian (for free t_1 the transversality condition $p_{n+1} = 0$ reproduces the vanishing autonomous Hamiltonian).

From another point of view, we can think of the optimal control system as a Pfaffian problem [6, 14] characterized by the family of the form

$$\mathcal{F} = \{dx^i - f^i(x, x^{n+1}, u)dx^{n+1}, dx^0 - f^0(x, x^{n+1}, u)dx^{n+1}\},$$

where allowed curves are now $\gamma(\epsilon) = (x^0(\epsilon), x(\epsilon), x^{n+1}(\epsilon))$, such that $\gamma^*(\mathcal{F}) = 0$. Tangent vectors to the allowed curves are therefore $\lambda \left(f^0 \frac{\partial}{\partial x^0} + f^i \frac{\partial}{\partial x^i} + \frac{\partial}{\partial x^{n+1}}\right)$ with $\lambda > 0$ arbitrary, i.e., arbitrary positive reparametrizations of the allowed curves for the enlarged control system.

Taking $\lambda = 1/f^0$ and discarding those directions for which $f^0 = 0$, we obtain an equivalent control system, $(f^i/f^0)\frac{\partial}{\partial x^i} + (1/f^0)\frac{\partial}{\partial x^{n+1}} + \frac{\partial}{\partial x^0}$. It is just a reparametrization of the allowed curves by the cost variable x^0, and for this new control system, the Hamiltonian is $H_c = p_i g^i + p_{n+1} g^{n+1} + p_0$, with $g^{n+1} = 1/f^0$ and $g^i = f^i/f^0$, defined again in $U \times_Q T^*Q$. This new optimal control system is the translation of the original optimal control system to a x^0-time optimal problem. Therefore, the construction of the metric can be made similarly to the one presented in section 3 for time optimal problems. In particular, we restrict ourselves to the normal case $p_0 = -1$, so that the explicit coordinate x^0 is not needed, and our state space will be $N = M \times \mathbb{R}$. The control system is $Y : U \to TN$

$$\frac{dx^i}{ds} = g^i(x, x^{n+1}, u), \quad \frac{dx^{n+1}}{ds} = g^{n+1}(x, x^{n+1}, u), \tag{4.1}$$

where s is the new parameter (the arc-length parameter in metric notation) and the Hamiltonian is defined on $W = U \times T^*N$

$$H(x, x^{n+1}, u, p, p_{n+1}) = p_i g^i(x, x^{n+1}, u) + p_{n+1} g^{n+1}(x, x^{n+1}, u) - 1 = \langle p, Y \rangle - 1.$$

Note that this construction is valid for an original autonomous system, where there is not dependence of the g on x^{n+1}, and p_{n+1} is a constant.

Once we fix a point (x_0, x_0^{n+1}) in N, we find a set of possible optimal controls $U^*_{(x_0, x_0^{n+1})}$, such that its image $Y(U^*) = S^*$ is made of some of the longest vectors in the set S of allowed velocities:

$$S^o = \{(x, x^{n+1}, v, v^{n+1}) \in S \mid \quad \lambda(v, v^{n+1}) \notin S \quad \forall \lambda > 1\}. \tag{4.2}$$

The metric is defined on the cone of directions

$$D = \{(v, v^{n+1}) | (v, v^{n+1}) = \lambda(v_o, v_o^{n+1}) \quad \text{with} \quad \lambda > 0 \quad \text{and} \quad (v_o, v_o^{n+1}) \in S^o\},$$

and the Finslerian function is $F(v, v^{n+1}) = \lambda$. For the actual solution, the curves are constrained to satisfy the condition $H = 0$; the algebraic condition of maximality determines the same velocities for (p_i, p_{n+1}) that for $\mu(p_i, p_{n+1})$, $\mu > 0$ (it is just the maximal projection $\max\langle(p_i, p_{n+1}), (v^i, v^{n+1})\rangle$ into the momentum ray). But the actual momentum vector of the ray is determined by

$$\langle (p_i, p_{n+1})^*, (v^i, v^{n+1})\rangle = 1, \qquad (v^i, v^{n+1}) \in S^*. \tag{4.3}$$

Let us develop as an example the classical Lagrangian mechanics, where the control space is the whole tangent space $S = TM$ and $f^0 = L = \frac{1}{2}g_{ij}(x)u^i u^j - V(x)$. We have the control equations $\frac{dx^i}{dt} = u^i$, and the cost function is the Lagrangian L. The associated optimal control system lives on $N = M \times \mathbb{R}$ of local coordinates $(x^i, x^{n+1} \equiv t)$. For the transformed minimal s-time problem, we have the Hamiltonian

$$H = p_i \frac{u^i}{L} + p_{n+1}\frac{1}{L} - 1$$

living in $W_N = TN \times_N T^*N$.

There is a unique vector on every allowed direction $(v_o^i, v_o^{n+1}) = (u^i/L, 1/L)$, and the points of S_x^* satisfy, eliminating the parameters u^i, the equation

$$\frac{1}{2}g_{ij}v_o^i v_o^j - V(x)(v_o^{n+1})^2 - v_o^{n+1} = 0,$$

which is an ellipsoid $V(x) < 0$ (e.g., the Kepler problem), paraboloid $V(x) = 0$ (free particle), or hyperboloid $V(x) > 0$ (harmonic oscillator; we must take the future branch of the hyperboloid for time increasing curves), always containing the origin.

The metric function F is obtained by looking for the factor between (v^i, v^{n+1}) $(v^{n+1} > 0)$ and the parallel element of S^*,

$$F(v^i, v^{n+1}) = v^{n+1}L = v^{n+1}\left[\frac{1}{2}g_{ij}\left(\frac{v^i}{v^{n+1}}\right)\left(\frac{v^j}{v^{n+1}}\right) - V(x)\right],$$

which is clearly homogeneous. It is simply the Lagrangian under an arbitrary change of parameter,

$$\int L(x,\dot{x})dt = \int L\frac{dt}{d\tau}d\tau = \int F d\tau,$$

with $\frac{dt}{d\tau} = v^{n+1}$ and $\frac{dx^i}{d\tau} = v^i$, i.e., $\dot{x} = \frac{dx^i}{dt} = \frac{v^i}{v^{n+1}}$. The consequence of this example is that the trajectories of a Lagrangian mechanical system can be seen as the geodesics of a Finslerian metric on space-time. We analyze in the next section the possibility of restricting the metric to constant energy leaves (by means of seeing it as an isoperimetric problem), and projecting the restricted metric to the state space; we obtain in this way a family of metric structures parametrized by the energy.

5. Restrictions of the metric. Let us note that the vanishing of the Hamiltonian on $W = U \times_N T^*N$ determines $-p_{n+1} = p_i f^i - f^0$, similar to the usual energy function in Lagrangian mechanics. For autonomous systems $\frac{\partial H}{\partial x^{n+1}} = 0$ gives $p_{n+1} = -E$ constant, usually nonvanishing for fixed final time problems, and $E = 0$ for free final time problems by transversality. We now restrict our attention to autonomous systems, and we try to find the restriction of the metric to a constant energy leaf. As we have pointed out before, the algebraic condition of optimality (2.4) for s-time optimal problems determines not only the elements (v_o^i, v_o^{n+1}) on S^o, the longest allowed velocity vectors, by

$$\max H(x,p,u) \equiv \max\langle(p_i, p_{n+1}), (v^i, v^{n+1})\rangle \qquad \forall u \in U_x,$$

once fixed $x \in M$ and a ray $\mu(p_i, p_{n+1})$ ($\mu > 0$), but also the particular momentum element $(p_i, p_{n+1})^*$ of the ray fulfilling the condition $\langle (p_i, p_{n+1})^*, (v_o^i, v_o^{n+1})\rangle = 1$. Let us denote by $P^o \subset T^*N$ this set of momentum vectors; it is made of one element on every ray of T^*N with positive projection over S^o. We can find the elements of P^o following the next steps.

1. Take a ray $\mu(p_i, p_{n+1})$ ($\mu > 0$) such that there are elements $(v^i, v^{n+1}) \in S$ for which $\langle (p_i, p_{n+1}), (v^i, v^{n+1})\rangle$ is positive.

2. Find the optimal velocity, the element $(v_o^i, v_o^{n+1}) \in S^o$, with maximal projection over the ray $\mu(p_i, p_{n+1})$.

3. Find the element $(p_i, p_{n+1})^*$ on the ray such that $\langle (p_i, p_{n+1})^*, (v_o^i, v_o^{n+1})\rangle = 1$.

There is generically a one-to-one correspondence between elements of S^o and elements of P^o, except in bang-bang situations, where a momentum vector is associated to two (or more) possible velocities. For the restriction to energy E leaves on S^o, we can begin by considering the subset P^E of P^o, made by the elements with $p_{n+1} = -E$, $P^E = \{(p_i, p_{n+1}) \in P^o \,|\, p_{n+1} = -E\}$. Its corresponding elements on S^o define the subset S^E of allowed optimal velocities with energy E. They are obtained by taking every element $p^E \in P^E$ and looking for the $g_E \in S^o$ with maximal projection; the condition $\langle p^E, g_E\rangle = 1$ is automatic by definition.

The restriction of the metric structure (N, D, F) to the energy leaves is obtained by defining a subset $D^E \subset D$ of the cone of allowed directions, and a Finslerian function F_E on D^E. D^E is the cone generated by the velocities in S^E

$$D^E = \{v = \lambda g_E | \quad \forall g_E \in S^E \quad \forall \lambda > 0\},$$

while $F_E\colon D^E \to \mathbb{R}$ is, as usual, $F_E(v) = \lambda$, the restriction of F to D^E.

This metric can be projected to the state space M by simply projecting S^E to a subset of velocities $T^E \subset TM$ through the natural projection $\mathrm{pr}_1\colon N = M \times \mathbb{R} \to M$, $T^E = \mathrm{pr}_{1*}(S^E)$, and considering the cone of directions C^E generated by T^E, $C^E = \mathrm{pr}_{1*}(D^E)$. Again, the Finslerian function (which will be denoted with the same letter F_E) is given by $F_E(v) = \lambda$ for $v \in C^E$ and $v = \lambda v_E$, $v_E \in T^E$.

As we said, the constancy of $p_{n+1} = -E$ is associated to fixed final parameter T. Therefore, we can think of the problem of restriction as an isoperimetric problem of minimizing the s-length among the curves with fixed t-length. Using a Lagrange multiplier α for the constraint $\int_0^T dt = T$, the complete restricted metric will be $G_E = F_E + \alpha F_t$, where F_E has already been defined and F_t is the t-metric, i.e., the metric whose associated length is the time increase of the curve measured. The Finslerian function F_t is simply given by $F_t(v, v^{n+1}) = v^{n+1}$ so that

$$\int_{\tau_i}^{\tau_f} F_t(x(\tau), v(\tau))d\tau = \int_{\tau_i}^{\tau_f} v^{n+1} d\tau = \int_{\tau_i}^{\tau_f} \frac{dt}{d\tau} d\tau = T.$$

A careful view to the Hamiltonian form $Hdt = p_i dx^i - (ds - p_{n+1}dt)$ shows that the value of the Lagrange multiplier is $\alpha = -p_{n+1} = E$, so that our restricted metric on D^E is given by the Finslerian function $G_E = F_E + EF_t$, and similarly for its projection to M. (We must project the function $F_t = v^{n+1}$ to C^E similarly to the defined projection of F_E.)

We have built a family of metric structures (M, C^E, G_E) on the state space, parametrized by the energy. Geodetic curves of these metrics are reparametrizations of the optimal solution curves of the optimal control system for different final parameters; i.e., fixed x_0 and x_1 on M, the family of optimal curves with boundary conditions

$x(0) = x_0$, $x(T) = x_1$, parametrized by T, is identified with the family of geodesics for the metrics G_E with those fixed endpoints, parametrized by E.

Continuing with the example of a Lagrangian mechanical system, let us consider a Lagrangian with kinetic term derived from a Riemannian metric $\frac{1}{2}g_{ij}v^iv^j$, and negative potential function $V(x) < 0$ (so that we have negative as well as positive energies), as, for example, the Kepler problem. Remember that the indicatrix in space-time is in this case an ellipsoid on the future semispace containing the origin. If we restrict our curves to the zero level energy (free final parameter), then covectors are $(p_i, 0)^* \in P^{E=0}$, optimality is obtained on the *equator* of the ellipsoid $v_o^{n+1} = \frac{-1}{2V(x)}$, and projection to the space manifold generates the metric

$$F_{E=0}(v) = \sqrt{-2V(x)g_{ij}v^iv^j}.$$

For another energy level E, optimality associated to the covector $(p_i, -E)^* \in P^E$ determines a closed set on the ellipsoid, south ($E > 0$) or north ($E < 0$) of the equator, determined by the equation of the ellipsoid, the condition $(p_i, -E)\cdot(v^i, v^{n+1})$ maximal and vanishing of the Hamiltonian, giving $g^{ij}p_ip_j = g_{ij}u^iu^j = 2(E - V)$, i.e., $v_o^{n+1} = 1/(E - 2V)$, intersection of the ellipsoid with a horizontal hyperplane. Projection to the spatial directions determines a particular metric F_E,

$$F_E(v) = \frac{E - 2V}{\sqrt{2(E - V)}}\sqrt{g_{ij}v^iv^j}.$$

Now, the t-metric $F_t(v) = v^{n+1}$ is projected to M giving

$$F_t(v) = v^{n+1} = F_E v_o^{n+1} = \frac{\sqrt{g_{ij}v^iv^j}}{\sqrt{2(E - V)}}.$$

Finally, the complete metric in the state space, obtained from F_E and F_t with Lagrange multiplier the energy, is

$$G_E = F_E + EF_t = \sqrt{2(E - V(x))}\sqrt{g_{ij}(x)v^iv^j},$$

and its geodesic curves are the trajectories of energy E for the Lagrangian system, i.e., the geodesics of the classical Jacobi metrics.

6. Conclusions and outlook. We have seen the relationship between a natural generalization of metric structure, using Finslerian functions and constrained directions, and time optimal problems in control systems. This relationship is clearly stated through the indicatrix of the metric (a simple way to define metric structures is to consider the set of unit norm velocities [4]), which is identified with the set of longest (optimal) velocities for the control system. The bang-bang phenomenon is, for example, associated to *holes* on the indicatrix. A reparametrization for general optimal control problems, using the control parameter as arc-length, allows us to extend the relationship to this general case where the metric is now defined on state-time space. The trajectories of a Lagrangian mechanical system are understood in this way as the geodesics of a Finslerian metric in space-time. A process of restriction to constant energy leaves determines a family of metric structures on state space parametrized by the energy, whose geodesics are the solutions of the optimal control problem for different final times. In the example of classical mechanics, this family is nothing but the Jacobi metrics associated to the Lagrangian, whose geodesics are the classical trajectories of a given energy. In some other analyzed examples [3, 10], the metric point of view for the optimal control problems has also been useful, at least qualitatively. The generalization of some concepts in Riemannian geometry to a Finslerian metric structure has been a field of research during recent years [6, 14, 4]. The link with optimal control problems allows us to think of giving one more step and try to generalize the study to metrics with restricted allowed directions. For example, the abnormal solutions of minimal length in sub-Riemannian geometry are naturally included on the set of geodesics [1, 2, 9] as the solutions with $p_0 = 0$ when the problem is seen from the optimal control point of view.

EXPLICIT OBSERVABILITY INEQUALITIES FOR THE WAVE EQUATION WITH LOWER ORDER TERMS BY MEANS OF CARLEMAN INEQUALITIES[*]

XU ZHANG[†]

Abstract. In this paper, by means of Carleman estimates and the usual energy estimate, we obtain directly two observability inequalities for the linear wave equation with time-variant nonsmooth lower order terms. We do not need any unique continuation property of the linear equation a priori, since this is actually one of the by-products of our analysis. Furthermore, the constant in the observability inequality is estimated by an explicit function of the norm of the involved coefficients in the equation. Also, we apply our observability estimates to exact controllability for wave equations.

Key words. Carleman estimate, energy estimate, observability, controllability, wave equation

1. Introduction.

Let us consider the following wave equation:

$$\begin{cases} w_{tt} - \Delta w = q_1(t,x)w + q_2(t,x)w_t + \langle\, q_3(t,x), \nabla w\,\rangle & \text{in } Q,\\ w = 0 & \text{on } \Sigma,\\ w(0) = w_0, \quad w_t(0) = w_1 & \text{in } \Omega. \end{cases} \tag{1.1}$$

In (1.1), $Q \overset{\triangle}{=} (0,T)\times\Omega$, $\Sigma \overset{\triangle}{=} (0,T)\times\Gamma$, $T>0$, $\Omega\subset\mathbb{R}^n$ is a bounded domain with a C^2 boundary $\Gamma \overset{\triangle}{=} \partial\Omega$, $q_i(\cdot)$ $(i=1,2,3)$ are given functions allowed to be *time-variant and nonsmooth.* We are concerned about the following two observability problems.

Problem 1. Given an open subset Γ_0 of Γ and a $T>0$, find (if possible) a constant $\mathcal{C}>0$ such that

$$|w_0|^2_{H^1_0(\Omega)} + |w_1|^2_{L^2(\Omega)} \le \mathcal{C}\left|\frac{\partial w}{\partial\nu}\right|^2_{L^2(\Sigma_0)} \tag{1.2}$$

for all weak solutions $w\in C([0,T];H^1_0(\Omega))\cap C^1([0,T];L^2(\Omega))$ of (1.1). Here, ν is the unit outward normal vector of Ω on Γ, $\Sigma_0 \overset{\triangle}{=} (0,T)\times\Gamma_0$.

Problem 2. Given an open subset Γ_0 of Γ and a $T>0$, find (if possible) a constant $\mathcal{C}>0$ such that

$$|w_0|^2_{L^2(\Omega)} + |w_1|^2_{H^{-1}(\Omega)} \le \mathcal{C}\left|\frac{\partial w}{\partial\nu}\right|^2_{H^{-1}(\Sigma_0)} \tag{1.3}$$

for all weak solutions $w\in C([0,T];L^2(\Omega))\cap C^1([0,T];H^{-1}(\Omega))$ (in the sense of transposition) of (1.1) with $q_2=0$ and $q_3=0$.

Present address: School of Mathematics, Sichuan University, Chengdu 610064, Sichuan Province, People's Republic of China (xuzhang@fudan.edu). This research was partially supported by NSF of China under grant 19901024 and the Chinese Education Ministry Science Foundation.

Note that the constant $\mathcal{C}$ in (1.2) and/or (1.3) depends on the lower order term coefficients $q_i(\cdot)$ $(i = 1, 2, 3)$ in (1.1). The explicit estimate of $\mathcal{C}$ via the norm of coefficients is a part of the problem and it is the main novelty of this paper. We remark that explicit observability estimates are crucial for some problems (see, for example, [19] and [32] and so on).

It is well known that the above observability estimates are closely related to the exact controllability of the following wave equation:

$$\begin{cases} y_{tt} - \Delta y = p_1(t,x)y + p_2(t,x)y_t + \langle p_3(t,x), \nabla y \rangle & \text{in } Q, \\ y = u\chi_{\Sigma_0}(t,x) & \text{on } \Sigma, \\ y(0) = y_0, \quad y_t(0) = y_1 & \text{in } \Omega, \end{cases} \tag{1.4}$$

where χ_{Σ_0} stands for the characteristic function of set Σ_0. The exact controllability problem may be formulated as follows: For any (y_0, y_1), $(z_0, z_1) \in L^2(\Omega) \times H^{-1}(\Omega)$, find a control $u \in L^2(\Sigma_0)$ such that the weak solution of (1.4) satisfies

$$y(T) = z_0, \quad y_t(T) = z_1. \tag{1.5}$$

If $p_i(t,x) \equiv p_i(x)$ $(i = 1, 2, 3)$, system (1.4) is a linear time-invariant system, and the study of exact controllability for this case seems to be complete, especially for the case $p_i(\cdot) \equiv 0$ $(i = 1, 2, 3)$ (see [2, 3, 7, 16, 17, 30]). Two classical references in the theory of controllability are Russell's work [21] and Lions's monograph [17]. Other interesting related works can be found in [8, 11, 12, 15, 18, 22, 23, 26, 31, 32, 33] and the references cited therein.

By duality arguments [7, 16, 17, 30], we know that the exact controllability of a linear system can be reduced to the observability estimate of its dual system. On the other hand, by Zuazua's method in [31, 32], we know that the exact controllability of the semilinear system can be reduced to such a sort of estimate, provided also we know how the observability constant depends on the coefficients in the "linearized" systems. Thus, one of the main problems in the theory of exact controllability is how to construct the observability estimate for the linear system.

In the literature, one can find two important methods to derive observability estimates. The first one combines multiplier techniques and compactness-uniqueness arguments (see [2, 4, 7, 16, 17, 26, 30] and the rich references cited therein). The second one replaces the multipliers techniques by Carleman-type inequalities (see, [3, 11, 12, 22, 23][1]). We remark that, to the best of our knowledge, both of these methods do not give any estimate on the observability constant $\mathcal{C}$ in (1.2) or (1.3) because of the contradiction argument that is needed to absorb lower order terms. Furthermore, we note that, except for some special cases, both of these methods depend one way or another on some sort of uniqueness (i.e., unique continuation property (UCP for short) of the involved linear system. By this, for example, for system (1.1) we mean that if whenever $w \in H^1(Q)$ satisfies (1.1) and $\partial w/\partial\nu\big|_{\Sigma_0} = 0$, w is then identically zero in Q). There are many related UCP results in the literature (see [5, 20, 24, 25] and the rich references cited therein). However, to our knowledge, these results may not be applied directly to the exact controllability of system (1.4). For example, Ruiz's UCP theorem [20] applies only to the case $\Gamma_0 \equiv \Gamma$. On the other hand, the results in [24, 25] are of a *local* nature, compared with the *global* UCP property defined

[1] In [3], Fursikov and Imanuvilov derived the observability estimate for the parabolic equations without using the compact-uniqueness argument. However, they have used such a sort of argument when they constructed the observability estimate for the hyperbolic equations.

above; furthermore, the results in [24, 25] need at least *partial analyticity.* It would be natural to expect that the local UCP can be iterated or "patched" together to produce global ones. However, this remains to be done. On the other hand, it was showed in [1] that local UCP may fail for the wave equations with *time-variant nonanalytic* coefficients.

In this paper, we will use a different method combining Carleman and energy estimates to derive the desired observability estimates (1.2) and (1.3) directly. Our method was stimulated by the work of [6] and [14], which has the following advantages: (1) We can give explicit estimates on the constants $\mathcal{C}$ in (1.2) and (1.3); (2) We do not need a priori any UCP for (1.1). Indeed, in our approach, UCP is a by-product consequence of the observability inequality.

In what follows, we will denote the norms in $L^s(Q)$ and in $W^{1,s}(Q)$ ($s \in [1,\infty]$) simply by $|\cdot|_s$ and $|\cdot|_{1,s}$, respectively. Furthermore, we will use C to denote a generic positive constant which may change from line to line.

The rest of this paper is organized as follows. In section 2, we collect some preliminaries. The main results are stated and proved in section 3. In section 4, we apply our observability estimates to exact controllability problem related to wave equations.

2. Preliminaries. We need the following preliminaries, which are essentially known although most of which are not explicitly listed in the literature (but follow directly from the known references).

First, let us consider

$$\begin{cases} w_{tt} - \Delta w = F & \text{in } Q, \\ w = g & \text{on } \Sigma, \\ w(0) = w_0, \quad w_t(0) = w_1 & \text{in } \Omega. \end{cases} \tag{2.1}$$

The following result is well known (see [9, Theorem 2.1 and Remark 2.2]).

LEMMA 2.1. *Let $T > 0$ be given. Suppose that*

$$\begin{cases} F \in L^1(0,T;L^2(\Omega)), \\ g \in H^1(\Sigma), \\ w_0 \in H^1(\Omega), \ w_1 \in L^2(\Omega), \end{cases} \tag{2.2}$$

satisfying the compatibility condition $g\big|_{t=0} = w_0\big|_\Gamma$. Then the unique weak solution w of (2.1) *satisfies*

$$\begin{cases} w \in C([0,T];H^1(\Omega)) \cap C^1([0,T];L^2(\Omega)), \\ \dfrac{\partial w}{\partial \nu} \in L^2(\Sigma). \end{cases} \tag{2.3}$$

Furthermore, there is a constant $C = C(T,\Omega) > 0$ such that

$$\begin{aligned} &|w|_{C([0,T];H^1(\Omega))\cap C^1([0,T];L^2(\Omega))} + \left|\frac{\partial w}{\partial \nu}\right|_{L^2(\Sigma)} \\ &\le C\Big(|F|_{L^1(0,T;L^2(\Omega))} + |g|_{H^1(\Sigma)} + |w_0|_{H^1(\Omega)} + |w_1|_{L^2(\Omega)}\Big). \end{aligned} \tag{2.4}$$

Combining the results in [9] and [17], one can get the following lemma.

Lemma 2.2. *Let $T > 0$ be given. Suppose that*

$$\begin{cases} F \in L^1(0,T;H^{-1}(\Omega)), \\ g \in L^2(\Sigma), \\ w_0 \in L^2(\Omega), \; w_1 \in H^{-1}(\Omega). \end{cases} \tag{2.5}$$

Then the unique weak solution w of (2.1) *satisfies*

$$\begin{cases} w \in C([0,T];L^2(\Omega)) \cap C^1([0,T];H^{-1}(\Omega)), \\ \dfrac{\partial w}{\partial \nu} \in H^{-1}(\Sigma). \end{cases} \tag{2.6}$$

Furthermore, there is a constant $C = C(T,\Omega) > 0$ such that

$$\begin{aligned} |w|_{C([0,T];L^2(\Omega))\cap C^1([0,T];H^{-1}(\Omega))} + \Big|\frac{\partial w}{\partial \nu}\Big|_{H^{-1}(\Sigma)} & \\ \le C\Big(|F|_{L^1(0,T;H^{-1}(\Omega))} + |w_0|_{L^2(\Omega)} & \\ +|w_1|_{H^{-1}(\Omega)} + |g|_{L^2(\Sigma)}\Big). & \end{aligned} \tag{2.7}$$

We refer to Appendix A at the end of this paper for the proof of Lemma 2.2.

Next, let us consider

$$\begin{cases} w_{tt} - \Delta w = p_1(t,x)w + p_2(t,x)w_t + \langle\, p_3(t,x), \nabla w\,\rangle + g_1 & \text{in } Q, \\ w = g_2 & \text{on } \Sigma, \\ w(0) = w_0, \quad w_t(0) = w_1 & \text{in } \Omega. \end{cases} \tag{2.8}$$

Using the usual energy estimate and noting the time reversibility of (2.8), proceeding as in [32], one can obtain the following result.

Lemma 2.3. *We have the following two conclusions:*

(1) *Let $T > 0$, $p_1 \in L^1(0,T;L^n(\Omega))$, $p_2 \in L^\infty(Q)$, $p_3 \in L^\infty(Q;\mathbb{R}^n)$, $g_1 \in L^1(0,T;L^2(\Omega))$, $g_2 = 0$, $w_0 \in H_0^1(\Omega)$, and $w_1 \in L^2(\Omega)$. Then* (2.8) *admits a unique weak solution $w(\cdot) \in C([0,T];H_0^1(\Omega)) \cap C^1([0,T];L^2(\Omega))$, which satisfies*

$$\mathcal{E}(t) \le C(\mathcal{E}(s) + |g_1|^2_{L^1(0,T;L^2(\Omega))})e^{C(|p_1|^{1/2}_{L^1(0,T;L^n(\Omega))}+|p_2|_\infty+|p_3|_\infty)} \quad \forall\, t,s \in [0,T] \tag{2.9}$$

for some constant $C = C(T,\Omega) > 0$, where

$$\mathcal{E}(t) \overset{\triangle}{=} |w_t(t,\cdot)|^2_{L^2(\Omega)} + |w(t,\cdot)|^2_{H_0^1(\Omega)}. \tag{2.10}$$

(2) *Let $T > 0$, $p_1 \in L^1(0,T;L^n(\Omega))$, $p_2 \in W^{1,\infty}(Q)$, $p_3 \in W^{1,\infty}(Q;\mathbb{R}^n)$, $g_1 = 0$, $g_2 = 0$, $w_0 \in L^2(\Omega)$, and $w_1 \in H^{-1}(\Omega)$. Then* (2.8) *admits a unique weak solution $w(\cdot) \in C([0,T];L^2(\Omega)) \cap C^1([0,T];H^{-1}(\Omega))$, which satisfies*

$$E(t) \le CE(s)e^{C(|p_1|_{L^1(0,T;L^n(\Omega))}+|p_2|_{1,\infty}+|p_3|_{1,\infty})} \quad \forall\, t,s \in [0,T] \tag{2.11}$$

for some constant $C = C(T,\Omega) > 0$, where

$$E(t) \overset{\triangle}{=} |w_t(t,\cdot)|^2_{H^{-1}(\Omega)} + |w(t,\cdot)|^2_{L^2(\Omega)}. \tag{2.12}$$

Further, suppose $p_2 = 0$ and $p_3 = 0$. Then there is a constant $C = C(T, \Omega) > 0$ such that

$$E(t) \le CE(s)e^{C|p_1|^{1/2}_{L^1(0,T;L^n(\Omega))}} \quad \forall\ t, s \in [0, T]. \tag{2.13}$$

We also need the following result, which is a simple consequence of Lemmas 2.1 and 2.3.

LEMMA 2.4. *Let $T > 0$, $p_1 \in L^1(0, T; L^n(\Omega))$, $p_2 \in L^\infty(Q)$, $p_3 \in L^\infty(Q; \mathbb{R}^n)$, $g_1 \in L^1(0, T; L^2(\Omega))$, $g_2 = 0$, $w_0 \in H_0^1(\Omega)$, and $w_1 \in L^2(\Omega)$. Then the unique weak solution $w \in C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$ of* (2.8) *satisfies*

$$\frac{\partial w}{\partial \nu} \in L^2(\Sigma). \tag{2.14}$$

Furthermore, there is a constant $C = C(T, \Omega, p_1, p_2, p_3) > 0$ such that

$$\begin{aligned} &|w|_{C([0,T];H_0^1(\Omega))\cap C^1([0,T];L^2(\Omega))} + \left|\frac{\partial w}{\partial \nu}\right|_{L^2(\Sigma)} \\ &\le C\Big(|g_1|_{L^1(0,T;L^2(\Omega))} + |w_0|_{H_0^1(\Omega)} + |w_1|_{L^2(\Omega)}\Big). \end{aligned} \tag{2.15}$$

Further, we need the following result, which is a simple consequence of Lemma 2.2.

THEOREM 2.5. *Let $T > 0$, $p_1 \in L^1(0, T; L^n(\Omega))$, $p_2 \in W^{1,\infty}(Q)$, $p_3 \in W^{1,\infty}(Q; \mathbb{R}^n)$, $g_1 = 0$, $g_2 \in L^2(\Sigma)$, $w_0 \in L^2(\Omega)$, and $w_1 \in H^{-1}(\Omega)$. Then system* (2.8) *admits a unique weak solution $w \in C([0, T]; L^2(\Omega)) \cap C^1([0, T]; H^{-1}(\Omega))$. Furthermore, there is a constant $C = C(T, \Omega, p_1, p_2, p_3) > 0$ such that*

$$\begin{aligned} &|w|_{C(0,T;L^2(\Omega))\cap C^1([0,T];H^{-1}(\Omega))} + \left|\frac{\partial w}{\partial \nu}\right|_{H^{-1}(\Sigma)} \\ &\le C(|w_0|_{L^2(\Omega)} + |w_1|_{H^{-1}(\Omega)} + |g_2|_{L^2(\Sigma)}). \end{aligned} \tag{2.16}$$

Remark 2.6. Take $p_2 \equiv 0$ and $p_i(t, x) \equiv p_i(x)$ $(i = 1, 3)$ in Theorem 2.5, and thus we obtain the main result in [10].

Proof of Theorem 2.5. Let us use the transposition method [17]. First of all, we note that without loss of generality, we may assume $p_2 \equiv 0$. In fact, one can always reduce the general problems to such a special case by means of the following simple transformation:

$$\bar{w}(t, x) \overset{\triangle}{=} w(t, x)e^{-\frac{1}{2}\int_0^t p_2(s,x)ds}, \qquad (t, x) \in Q. \tag{2.17}$$

We define a linear functional $L(f)$ on the space $L^1(0, T; L^2(\Omega))$ by

$$\begin{aligned} L(f) \overset{\triangle}{=} \langle\, w_1, \theta(0)\, \rangle_{H^{-1}(\Omega),H_0^1(\Omega)} - \int_\Omega w_0(x)\theta_t(0, x)dx - \int_\Sigma g_2 \frac{\partial \theta}{\partial \nu} d\Sigma& \\ \forall\, f \in L^1(0, T; L^2(\Omega)),& \end{aligned} \tag{2.18}$$

where $\theta \in C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$ solves

$$\begin{cases} \theta_{tt} - \Delta\theta - p_1\theta + \nabla \cdot (p_3\theta) = f & \text{in } Q, \\ \theta = 0 & \text{on } \Sigma, \\ \theta(T) = \theta_t(T) = 0 & \text{in } \Omega. \end{cases} \tag{2.19}$$

We assert that the functional $L(f)$ is bounded. In fact, by (2.18) and Lemma 2.4, and noting the time reversibility of (2.19), one gets

$$\begin{aligned}|L(f)| &\leq |\langle\, w_1, \theta(0)\,\rangle_{H^{-1}(\Omega),H_0^1(\Omega)}| + \left|\int_\Omega w_0\theta_t(0)dx\right| + \left|\int_\Sigma g_2 \frac{\partial\theta}{\partial\nu} d\Sigma\right| \\ &\leq C(|w_0|_{L^2(\Omega)} + |w_1|_{H^{-1}(\Omega)} + |g_2|_{L^2(\Sigma)}) \\ &\quad \times \left(|\theta|_{C([0,T];H_0^1(\Omega))\cap C^1([0,T];L^2(\Omega))} + \left|\frac{\partial\theta}{\partial\nu}\right|_{L^2(\Sigma)}\right) \\ &\leq C(|w_0|_{L^2(\Omega)} + |w_1|_{H^{-1}(\Omega)} + |g_2|_{L^2(\Sigma)})|f|_{L^1(0,T;L^2(\Omega))}.\end{aligned} \tag{2.20}$$

It is known that any linear bounded functional on the space $L^1(0,T;L^2(\Omega))$ can be written as

$$L(f) = \int_Q wf dxdt, \tag{2.21}$$

where w is some function from the space $L^\infty(0,T;L^2(\Omega))$. Thus, system (2.8) admits a weak solution $w \in L^\infty(0,T;L^2(\Omega))$, which satisfies

$$|w|_{L^\infty(0,T;L^2(\Omega))} \leq C(|w_0|_{L^2(\Omega)} + |w_1|_{H^{-1}(\Omega)} + |g_2|_{L^2(\Sigma)}). \tag{2.22}$$

Now, denote $F \overset{\triangle}{=} p_1 w + \langle\, p_3, \nabla w\,\rangle \equiv (p_1 - \nabla\cdot p_3)w + \nabla\cdot(p_3 w)$ (recall that without loss of generality, we have assumed $p_2 \equiv 0$). Then, by $w \in L^\infty(0,T;L^2(\Omega))$, we see that $F \in L^1(0,T;H^{-1}(\Omega))$. Thus, the desired result follows from Lemma 2.2 and (2.22) immediately. □

In what follows, we use the notation

$$f_i = f_i(x) \overset{\triangle}{=} \frac{\partial f(x)}{\partial x_i}, \qquad i = 1,2,\ldots,n; \qquad \sum_i \overset{\triangle}{=} \sum_{i=1}^n$$

(on the other hand, x_i is always the ith coordinate of the point x).

Finally, we need the following known pointwise estimate, which is a special case of [14, Lemma 1, p. 124] and [19, Lemma 5.1].

LEMMA 2.7. *Let $\lambda > 0$ and $\alpha_1, \alpha_2 \in (0,1)$ be constant. Let $x_0 \in \mathbb{R}^n$, $T > 0$, and*

$$\begin{cases} \psi(t,s,x) = [|x-x_0|^2 - \alpha_1(t-T/2)^2 - \alpha_2(s-T/2)^2]/2, \\ \ell = \lambda\psi, \\ \beta \overset{\triangle}{=} \min(n+\alpha_1-1, n+\alpha_2-1), \quad \Psi = \beta\lambda. \end{cases} \tag{2.23}$$

Let $z = z(t,s,x) \in C^2(\mathbb{R}^{2+n})$. Denote

$$v \overset{\triangle}{=} \theta z \quad \textit{with} \quad \theta = e^\ell. \tag{2.24}$$

Then

$$
\begin{aligned}
&\theta^2|z_{tt}+z_{ss}-\Delta z|^2\\
&\geq \left[-2\ell_t\left(v_t^2-v_s^2+\sum_j v_j^2\right)-4\ell_s v_t v_s+4\sum_j(\ell_j v_t v_j)+2\Psi v_t v-2\ell_t(A+\Psi)v^2\right]_t\\
&\quad+\left[-2\ell_s\left(v_s^2-v_t^2+\sum_j v_j^2\right)-4\ell_t v_t v_s+4\sum_j(\ell_j v_s v_j)+2\Psi v_s v-2\ell_s(A+\Psi)v^2\right]_s\\
&\quad-2\sum_j\left[2\sum_i(\ell_i v_i v_j)-\ell_j\sum_i v_i^2-2\ell_t v_t v_j-2\ell_s v_s v_j\right.\\

&\quad+2(n-\alpha_1+\alpha_2-\beta)\lambda v_t^2+2(n+\alpha_1-\alpha_2-\beta)\lambda v_s^2\\
&\quad+2(2-n-\alpha_1-\alpha_2+\beta)\lambda\sum_j v_j^2+Bv^2,
\end{aligned}
\tag{2.25}
$$

where

$$
A=\lambda^2\Big[\alpha_1^2(t-T/2)^2+\alpha_2^2(s-T/2)^2-|x-x_0|^2\Big]+(n+\alpha_1+\alpha_2-\beta)\lambda \tag{2.26}
$$

and

$$
\begin{aligned}
B=&2\lambda^3\Big[(2+n-\beta+\alpha_1+\alpha_2)|x-x_0|^2\\
&+\alpha_1^2(\beta-n-3\alpha_1-\alpha_2)(t-T/2)^2+\alpha_2^2(\beta-n-3\alpha_2-\alpha_1)(s-T/2)^2\Big]\\
&-\Big[2(\beta-n)(n-\beta+\alpha_1+\alpha_2)-2(\alpha_1+\alpha_2)(n+\alpha_1+\alpha_2)+\beta^2-2n\beta\Big]\lambda^2.
\end{aligned}
\tag{2.27}
$$

3. Statement and proof of the main results.

3.1. Statement of the main results. We need the following assumption:

(H) *Let* Γ_0 *be given by*

$$
\Gamma_0=\left\{x\in\Gamma\;\Big|\;(x-x_0)\cdot\nu(x)>0\right\},
$$

where $x_0\in\mathbb{R}^n\setminus\overline{\Omega}$ *is a fixed point,* $\nu(x)$ *denotes the unit outward normal vector of* Ω *at* $x\in\Gamma$.

The main results in this paper can be stated as follows.

Theorem 3.1. *Let* (H) *hold,* $T>2\max_{x\in\Omega}|x-x_0|$, $q_1\in L^{n+1}(Q)$, $q_2\in L^\infty(Q)$, *and* $q_3\in L^\infty(Q;\mathbb{R}^n)$. *Then for any weak solution* $w\in C([0,T];H_0^1(\Omega))\cap C^1([0,T];L^2(\Omega))$ *of* (1.1), *it holds that*

$$
|w_0|^2_{H_0^1(\Omega)}+|w_1|^2_{L^2(\Omega)}\leq\mathcal{C}(r)\Big|\frac{\partial w}{\partial\nu}\Big|^2_{L^2(\Sigma_0)}\qquad\forall\;(w_0,w_1)\in H_0^1(\Omega)\times L^2(\Omega) \tag{3.1}
$$

for some constant $\mathcal{C}(r)>0$ *with* $r\overset{\triangle}{=}|q_1|_{n+1}+|q_2|_\infty+|q_3|_\infty$. *Furthermore, the constant* $\mathcal{C}(r)$ *in* (3.1) *may be bounded as*

$$
\mathcal{C}(r)=C\exp(Cr^2) \tag{3.2}
$$

for some constant $C = C(T, \Omega) > 0$.

THEOREM 3.2. *Let* (H) *hold,* $T > 2\max_{x\in\Omega}|x - x_0|$, $q_1 \in L^\infty(Q)$, $q_2 = 0$, *and* $q_3 = 0$. *Then for any weak solution* $w \in C([0,T]; L^2(\Omega)) \cap C^1([0,T]; H^{-1}(\Omega))$ *of* (1.1), *it holds that*

$$(3.3)\, |w_0|^2_{L^2(\Omega)} + |w_1|^2_{H^{-1}(\Omega)} \leq \mathcal{C}(h)\left|\frac{\partial w}{\partial \nu}\right|^2_{H^{-1}(\Sigma_0)} \qquad \forall\ (w_0, w_1) \in L^2(\Omega) \times H^{-1}(\Omega)$$

for some constant $\mathcal{C}(h) > 0$ *with* $h \overset{\triangle}{=} |q_1|_\infty$. *Furthermore, the constant* $\mathcal{C}(h)$ *in* (3.3) *may be bounded as*

$$(3.4) \qquad \mathcal{C}(h) = C\exp(Ch^2)$$

for some constant $C = C(T, \Omega) > 0$.

The proof of Theorems 3.1 and 3.2 will be given in the next two subsections. Now several remarks are in order.

Remark 3.3. In (H), we assume a technical condition $x_0 \notin \overline{\Omega}$. This is a key condition in our approach (to guarantee a controlled "right" sign of the lower-order term Bv^2 in (3.19) and (3.48)). In the case $x_0 \in \Omega$, proceeding as in [19], one can prove the same results as in Theorems 3.1–3.2 provided Σ_0 in (3.1) and (3.3) is replaced by $(0,T) \times \big(\mathcal{O}_\delta(\Gamma_0) \cap \Gamma\big)$, where $\delta > 0$ is any given constant and $\mathcal{O}_\delta(\Gamma_0) \overset{\triangle}{=} \{y \in \mathbb{R}^n \,\big|\, |y - x| < \delta \text{ for some } x \in \Gamma_0\}$.

Remark 3.4. From the proofs of Theorems 3.1–3.2 in the next two subsections, we see that the above results remain valid if (1.1) is replaced by the following inequality:

$$(1.1)' \qquad \begin{cases} |w_{tt} - \Delta w| \leq |q_1(t,x)w + q_2(t,x)w_t + \langle\, q_3(t,x), \nabla w\,\rangle\,| & \text{in } Q, \\ w = 0 & \text{on } \Sigma, \\ w(0) = w_0, \quad w_t(0) = w_1 & \text{in } \Omega. \end{cases}$$

Thus, by taking $q_2 \equiv 0$, $q_1 \in L^\infty(Q)$, and $w \in H^2(Q)$ in Theorem 3.1, we can obtain the main result in [6]. Furthermore, we see that the scalar function w can be replaced by a vector-valued function, i.e., (1.1) can be replaced by a system with *coupled* lower order terms.

Remark 3.5. The originality of our method consists in the fact that we can give explicit estimates (3.2) and (3.4) of the constant $\mathcal{C}(r)$ in (3.1) and $\mathcal{C}(h)$ in (3.3), respectively, via the norm of the coefficients of (1.1). To the best of our knowledge, such sorts of estimates for dimensions $n \geq 2$ are not available in the literature. For the case $n = 1$, Zuazua [32] obtained a similar estimate, and such an estimate played a crucial role in the proof of his main result on exact controllability for the subcritical semilinear wave equations in one space dimension. However, we would like to point out that estimate (3.2) (resp., (3.4)) is not sharp. In fact, one may expect an estimate of the order of $e^{Cr^{1/2}}$ (resp., $e^{Ch^{1/2}}$), as indicated by [32] for the case $n = 1$.

Remark 3.6. Take $q_1 \in L^\infty(Q)$ in Theorem 3.1 (and noting Remark 3.4), we may obtain some of the main results of Lasiecka and Triggiani in [11]. On the other hand, Tataru [22, 23] has obtained observability results for a large class of partial differential equations without explicit estimates on the observability constant like that of (3.2) or (3.4) in our Theorems 3.1 and 3.2.

Remark 3.7. Our method is rather general, and it can be applied to internal observability estimate [19, 28], and/or other boundary conditions [13], and/or other equations [29].

3.2. Proof of Theorem 3.1.

Proof of Theorem 3.1. We divide the proof into several steps.

Step 1. The main idea of our proof is to use the pointwise estimate (2.25) in Lemma 2.7 (this idea is borrowed from [6]). For this purpose, we need to choose a suitable pseudoconvex function ψ, that is, to choose x_0, α_1, and α_2.

In order to choose x_0, α_1, and α_2, we proceed as in [6]. Put

$$R_0 \overset{\triangle}{=} \min_{x\in\Omega} |x - x_0|, \quad R_1 \overset{\triangle}{=} \max_{x\in\Omega} |x - x_0|, \tag{3.5}$$

where x_0 is given in (H). Then $R_0 > 0$ and $T > 2R_1$. Thus we can choose a constant $\alpha \in (0, 1)$ (close to 1) such that

$$R_1^2 < \alpha T^2/4. \tag{3.6}$$

Having chosen x_0 and α as above, we next introduce the desired pseudoconvex function ψ by setting

$$\psi = \psi(t, x) \overset{\triangle}{=} [|x - x_0|^2 - \alpha(t - T/2)^2]/2. \tag{3.7}$$

Step 2. We need the following notations. First, denote

$$\Lambda_j \overset{\triangle}{=} \{(t, x) \in Q \mid 2\psi(t, x) > R_0^2/(j + 2)\}, \tag{3.8}$$

where $j = 0, 1, 2$. Next, denote

$$\begin{cases} T_i \overset{\triangle}{=} T/2 - \varepsilon_i T, \quad T_i' \overset{\triangle}{=} T/2 + \varepsilon_i T, \\ Q_i \overset{\triangle}{=} (T_i, T_i') \times \Omega, \end{cases} \tag{3.9}$$

where $i = 0, 1$; $0 < \varepsilon_0 < \varepsilon_1 < 1/2$ will be given below.

In order to determine ε_i $(i = 0, 1)$, we need an idea in [11] (see also [13]). First of all, by (3.5)–(3.7), one sees that

$$\psi(0, x) = \psi(T, x) = (R_1^2 - \alpha T^2/4)/2 < 0 \quad \forall\, x \in \Omega. \tag{3.10}$$

Thus, one can find an $\varepsilon_1 \in (0, 1/2)$ (close to 1/2) such that (recall (3.8)–(3.9) for Λ_2, Q_1, T_1, and T_1')

$$\Lambda_2 \subset Q_1 \tag{3.11}$$

and for any $(t, x) \in ((0, T_1) \cup (T_1', T)) \times \Omega$ it holds that

$$\psi(t, x) < 0. \tag{3.12}$$

Next, noting that since $\{T/2\} \times \Omega \subset \Lambda_0$, one can find a small $\varepsilon_0 \in (0, \varepsilon_1)$ such that (recall (3.8) and (3.9) for Λ_0 and Q_0, respectively)

$$Q_0 \subset \Lambda_0. \tag{3.13}$$

Now, we note that (recall (2.27) for B)

$$B = B\chi_{\Lambda_2}(t, x) + B\chi_{Q\setminus\Lambda_2}(t, x). \tag{3.14}$$

By (3.7), we see that (recall (2.23) for α_1, α_2, and β)

$$\alpha_1 = \alpha, \quad \alpha_2 = 0, \quad \beta = n - 1, \tag{3.15}$$

where α is given in (3.6). Thus, by (2.27), (3.8), and (3.15), one sees easily that there exists a constant $\lambda_1 > 1$ such that for any $\lambda > \lambda_1$, it holds that

$$B\chi_{\Lambda_2}(t,x) \geq c_0\lambda^3\chi_{\Lambda_2}(t,x) \tag{3.16}$$

and

$$\left|B\chi_{Q\setminus\Lambda_2}(t,x)\right| \leq C\lambda^3 \tag{3.17}$$

for some constants $c_0 > 0$ and $C > 0$, which depend only on T and Ω.

Step 3. Let us use Lemma 2.7. For any given $\tau \in (0, T_1)$ and $\tau' \in (T_1', T)$ (recall (3.9) for T_1 and T_1'), denote

$$Q_\tau^{\tau'} \overset{\triangle}{=} (\tau, \tau') \times \Omega. \tag{3.18}$$

Let us observe (2.25), where $z = z(t,s,x)$ is replaced by $w = w(t,x)$, and ψ is given by (3.7). Integrating (2.25) on $Q_\tau^{\tau'}$, using integration by parts, and taking (1.1) into account, we arrive at (noting that by (2.24), $v = \theta w$)

$$\begin{aligned}
&2(1-\alpha)\lambda\int_{Q_\tau^{\tau'}}\left(v_t^2 + \sum_i v_i^2\right)dxdt + \int_{Q_\tau^{\tau'}} Bv^2dxdt\\
&\leq \int_Q \theta^2|q_1w + q_2w_t + \langle\, q_3, \nabla w\,\rangle\,|^2dxdt + \int_{\Sigma_0}\left|\frac{\partial v}{\partial\nu}\right|^2 d\Sigma_0\\
&\quad + C\lambda^3\left[\int_\Omega\Big(|v(\tau,x)|^2 + |v_t(\tau,x)|^2 + \sum_i|v_i(\tau,x)|^2\right.\\
&\qquad\left. + |v(\tau',x)|^2 + |v_t(\tau',x)|^2 + \sum_i|v_i(\tau',x)|^2\Big)dx\right] \qquad \forall\,\lambda > 1.
\end{aligned} \tag{3.19}$$

However, by $v = \theta w$ and $\theta = e^\ell$, by (2.23), (3.7), and (3.12), we get

$$\begin{aligned}
&\int_\Omega\left(|v(\tau,x)|^2 + |v_t(\tau,x)|^2 + \sum_i|v_i(\tau,x)|^2\right.\\
&\qquad\left. + |v(\tau',x)|^2 + |v_t(\tau',x)|^2 + \sum_i|v_i(\tau',x)|^2\right)dx\\
&\leq C\lambda^2\left[\int_\Omega\left(|w(\tau,x)|^2 + |w_t(\tau,x)|^2 + \sum_i|w_i(\tau,x)|^2\right.\right.\\
&\qquad\left.\left. + |w(\tau',x)|^2 + |w_t(\tau',x)|^2 + \sum_i|w_i(\tau',x)|^2\right)dx\right].
\end{aligned} \tag{3.20}$$

Further, by (3.7)–(3.8), (2.23)–(2.24), (3.14), and (3.16)–(3.18), we get

$$\begin{aligned}
\int_{Q_\tau^{\tau'}} Bv^2dxdt &= \int_{Q_\tau^{\tau'}\cap\Lambda_2} Bv^2dxdt + \int_{Q_\tau^{\tau'}\setminus\Lambda_2} Bv^2dxdt\\
&\geq c_0\lambda^3\int_{Q_\tau^{\tau'}\cap\Lambda_2} v^2dxdt - C\lambda^3e^{R_0^2\lambda/4}\int_Q w^2dxdt \quad \forall\,\lambda > \lambda_1.
\end{aligned} \tag{3.21}$$

Note that by (3.8), (3.11), and (3.18), we have $Q_\tau^{\tau'} \supset \Lambda_1$. Thus, by (3.21), for any $\lambda > \lambda_1$, we have

$$\begin{aligned}
&2(1-\alpha)\lambda \int_{Q_\tau^{\tau'}} \left(v_t^2 + \sum_i v_i^2 \right) dxdt + \int_{Q_\tau^{\tau'}} Bv^2 dxdt \\
&\geq c_1 \left[\lambda \int_{\Lambda_1} \left(v_t^2 + \sum_i v_i^2 \right) dxdt + \lambda^3 \int_{\Lambda_1} v^2 dxdt \right] \qquad (3.22)\\
&\quad - C\lambda^3 e^{R_0^2\lambda/4} \int_Q w^2 dxdt,
\end{aligned}$$

where $c_1 > 0$ and $C > 0$ are two constants which depend only on T and Ω.

Now, combining (3.19)–(3.20) and (3.22), we conclude that for any $\lambda > \lambda_1$, it holds that

$$\begin{aligned}
&\int_{\Lambda_1} \left(v_t^2 + \sum_i v_i^2 \right) dxdt + \lambda^2 \int_{\Lambda_1} \theta^2 v^2 dxdt \\
&\leq C\lambda^{-1} \left\{ \int_Q \theta^2 |q_1 w + q_2 w_t + \langle\, q_3, \nabla w \,\rangle|^2 dxdt + \int_{\Sigma_0} \left|\frac{\partial v}{\partial \nu}\right|^2 d\Sigma_0 \right. \\
&\quad + \lambda^5 \left[\int_\Omega \left(|w(\tau,x)|^2 + |w_t(\tau,x)|^2 + \sum_i |w_i(\tau,x)|^2 \right.\right. \qquad (3.23)\\
&\quad \left.\left. + |w(\tau',x)|^2 + |w_t(\tau',x)|^2 + \sum_i |w_i(\tau',x)|^2 \right) dx \right] \\
&\quad \left. + \lambda^3 e^{R_0^2\lambda/4} \int_Q w^2 dxdt \right\}.
\end{aligned}$$

Integrating (3.23) with respect to τ and τ' from T_2, T_1 and T_1', T_2', respectively, we get

$$\begin{aligned}
&\int_{\Lambda_1} \left(v_t^2 + \sum_i v_i^2 \right) dxdt + \lambda^2 \int_{\Lambda_1} v^2 dxdt \\
&\leq C\lambda^{-1} \left\{ \int_Q \theta^2 |q_1 w + q_2 w_t + \langle\, q_3, \nabla w \,\rangle|^2 dxdt + \int_{\Sigma_0} \left|\frac{\partial v}{\partial \nu}\right|^2 d\Sigma_0 \right. \qquad (3.24)\\
&\quad \left. + \lambda^5 \int_Q \left(w^2 + w_t^2 + \sum_i w_i^2 \right) dxdt + \lambda^3 e^{R_0^2\lambda/4} \int_Q w^2 dxdt \right\}.
\end{aligned}$$

Consequently, by (2.22)–(2.23) and (3.7), recalling that $w = \theta^{-1} v$ with $\theta = e^\ell$, and using (3.24) and (1.1), we see that for any $\lambda > \lambda_1$, it holds that

$$\begin{aligned}
&\int_{\Lambda_1} \theta^2 \left(w_t^2 + \sum_i w_i^2 \right) dxdt + \lambda^2 \int_{\Lambda_1} \theta^2 w^2 dxdt \\
&\leq C\lambda^{-1} \left\{ \int_Q \theta^2 |q_1 w + q_2 w_t + \langle\, q_3, \nabla w \,\rangle|^2 dxdt + \int_{\Sigma_0} \theta^2 \left|\frac{\partial w}{\partial \nu}\right. |^2 d\Sigma_0 \right. \qquad (3.25)\\
&\quad \left. + \lambda^5 \int_Q \left(w^2 + w_t^2 + \sum_i w_i^2 \right) dxdt + \lambda^3 e^{R_0^2\lambda/4} \int_Q w^2 dxdt \right\}.
\end{aligned}$$

Step 4. Let us estimate "$\int_Q \theta^2|q_1 w + q_2 w_t + \langle\, q_3, \nabla w\,\rangle\,|^2 dxdt$." By the Hölder inequality, the Sobolev embedding theorem, and the Poincaré inequality, we get (recalling $r \overset{\triangle}{=} |q_1|_{n+1} + |q_2|_\infty + |q_3|_\infty$)

$$\begin{aligned}
&\int_Q \theta^2|q_1 w + q_2 w_t + \langle\, q_3, \nabla w\,\rangle\,|^2 dxdt \\
&\qquad = \left\{\int_{\Lambda_1} + \int_{Q\setminus\Lambda_1}\right\} \theta^2 |q_1 w + q_2 w_t + \langle\, q_3, \nabla w\,\rangle\,|^2 dxdt \\
&\le C\left\{\int_{\Lambda_1} \theta^2 q_1^2 w^2 dxdt + \int_{\Lambda_1} \theta^2 (q_2^2 + |q_3|^2)(w_t^2 + |\nabla w|^2) dxdt \right.\\
&\qquad \left. + e^{R_0^2\lambda/3} \int_Q (q_1^2 w^2 + q_2^2 w_t^2 + |q_3|^2|\nabla w|^2) dxdt \right\}\\
&\le C\left\{ |q_1|_{n+1}^2 |\theta w|^2_{L^{2(n+1)/(n-1)}(\Lambda_1)} + \int_{\Lambda_1} \theta^2 (q_2^2 + |q_3|^2)(w_t^2 + |\nabla w|^2) dxdt \right.\\
&\qquad \left. + e^{R_0^2\lambda/3} \int_Q (q_1^2 w^2 + q_2^2 w_t^2 + |q_3|^2|\nabla w|^2) dxdt \right\}\\
&\le Cr^2 \left[|\theta w|^2_{H^1(\Lambda_1)} + \int_{\Lambda_1} \theta^2 (w_t^2 + |\nabla w|^2) dxdt + e^{R_0^2\lambda/3} \int_Q (w_t^2 + |\nabla w|^2) dxdt \right]\\
&\le Cr^2 \left[\int_{\Lambda_1} \theta^2 (w_t^2 + |\nabla w|^2) dxdt + (1+\lambda^2) \int_{\Lambda_1} \theta^2 w^2 dxdt + e^{R_0^2\lambda/3} \int_Q (w_t^2 + |\nabla w|^2) dxdt \right].
\end{aligned}$$

(3.26)

Thus, combining (3.25) and (3.26), we see that for any $\lambda > \lambda_1$, it holds that

$$\begin{aligned}
&\int_{\Lambda_1} \theta^2 (w_t^2 + |\nabla w|^2) dxdt + \lambda^2 \int_{\Lambda_1} \theta^2 w^2 dxdt \\
&\le C_1 \lambda^{-1} \left\{ r^2 \left[\int_{\Lambda_1} \theta^2 (w_t^2 + |\nabla w|^2) dxdt \right.\right.\\
&\qquad\qquad \left. + \lambda^2 \int_{\Lambda_1} \theta^2 w^2 dxdt + e^{R_0^2\lambda/3} \int_Q (w_t^2 + |\nabla w|^2) dxdt \right]\\
&\qquad \left. + \int_{\Sigma_0} \theta^2 \left|\frac{\partial w}{\partial \nu}\right|^2 d\Sigma_0 + \lambda^5 \int_Q \left(w^2 + w_t^2 + \sum_i w_i^2 \right) dxdt + \lambda^3 e^{R_0^2\lambda/4} \int_Q w^2 dxdt \right\},
\end{aligned}$$

(3.27)

where $C_1 > 0$ is a constant. Now, taking

$$\lambda_2 \overset{\triangle}{=} \max(\lambda_1, 2 + C_1 r^2), \tag{3.28}$$

by (3.27)–(3.28), we see that for any $\lambda > \lambda_2$ it holds that

$$\begin{aligned}
\int_{\Lambda_1} \theta^2 (w_t^2 + |\nabla w|^2) dxdt \le C\lambda^{-1} &\left\{ \int_{\Sigma_0} \theta^2 \left|\frac{\partial w}{\partial \nu}\right|^2 d\Sigma_0 + r^2 e^{R_0^2\lambda/3} \int_Q (w_t^2 + |\nabla w|^2) dxdt \right.\\
&\left. + \lambda^5 \int_Q \left(w^2 + w_t^2 + \sum_i w_i^2 \right) dxdt + \lambda^3 e^{R_0^2\lambda/4} \int_Q w^2 dxdt \right\}.
\end{aligned}$$

(3.29)

Note that by (3.8) and (3.13), we have

$$\begin{aligned}\int_{\Lambda_1}\theta^2(w_t^2+|\nabla w|^2)dxdt &\geq \int_{\Lambda_0}\theta^2(w_t^2+|\nabla w|^2)dxdt\\ &\geq e^{R_0^2\lambda/2}\int_{Q_0}(w_t^2+|\nabla w|^2)dxdt.\end{aligned} \tag{3.30}$$

Thus, by (3.29)–(3.30), we see that for any $\lambda > \lambda_2$, it holds that

$$\begin{aligned}&\int_{Q_0}(|w_t|^2+|\nabla w|^2)dxdt\\ &\quad\leq C\lambda^{-1}\left\{e^{C\lambda}\int_{\Sigma_0}\left|\frac{\partial w}{\partial\nu}\right|^2 d\Sigma_0 + r^2e^{-R_0^2\lambda/6}\int_Q(|w_t|^2+|\nabla w|^2)dxdt\right.\\ &\qquad\left.+\lambda^5e^{-R_0^2\lambda/2}\int_Q\left(w^2+w_t^2+\sum_i w_i^2\right)dxdt+\lambda^3e^{-R_0^2\lambda/4}\int_Q w^2dxdt\right\}.\end{aligned} \tag{3.31}$$

Step 5. Let us complete the proof of Theorem 3.1. By (3.31), (2.10), and (3.28), using Poincaré inequality, we conclude that there is a constant $\lambda_3 > 0$, which depends only on T and Ω, such that (recall (3.9) for T_0 and T_0')

$$\int_{T_0}^{T_0'}\mathcal{E}(t)dt \leq C\left\{e^{C\lambda}\int_{\Sigma_0}\left|\frac{\partial w}{\partial\nu}\right|^2 d\Sigma_0+e^{-R_0^2\lambda/8}\int_0^T\mathcal{E}(t)dt\right\} \qquad \forall\,\lambda>\lambda_2+\lambda_3. \tag{3.32}$$

On the other hand, by (2.9) in Lemma 2.3 and (3.32), we arrive at

$$\mathcal{E}(0)\leq C_2\left\{e^{C_2\lambda}\int_{\Sigma_0}\left|\frac{\partial w}{\partial\nu}\right|^2 d\Sigma_0+e^{-R_0^2\lambda/8+C_2r}\mathcal{E}(0)\right\} \qquad \forall\,\lambda>\lambda_2+\lambda_3, \tag{3.33}$$

where $C_2 = C_2(T,\Omega)$ is a positive constant. However, it is easy to find a constant $\lambda_4 = \lambda_4(R_0, C_2) > 0$ such that

$$C_2e^{-R_0^2\lambda_4/8+C_2r}\leq 1/2. \tag{3.34}$$

Thus, by (3.33)–(3.34), one gets

$$\mathcal{E}(0)\leq Ce^{C\lambda}\int_{\Sigma_0}\left|\frac{\partial w}{\partial\nu}\right|^2 d\Sigma_0 \qquad \forall\,\lambda>\max(\lambda_2+\lambda_3,\lambda_4), \tag{3.35}$$

which is exactly the desired inequality (3.1). On the other hand, the explicit estimate (3.2) follows from (3.28) and (3.34)–(3.35) immediately. □

3.3. Proof of Theorem 3.2.

Proof of Theorem 3.2. The main idea of our proof is similar to that of Theorem 3.1. Also, the proof is divided into several steps.

Step 1. Let us introduce some notations. First, denote R_0 and R_1 as in (3.5) and choose α as in (3.6). Then we introduce the desired pseudoconvex function ψ by setting

$$\psi=\psi(t,s,x)\overset{\triangle}{=}[|x-x_0|^2-\alpha(t-T/2)^2-\alpha(s-T/2)^2]/2, \tag{3.36}$$

where x_0 is given in (H).

Next, denote

$$\begin{cases} \mathcal{Q} \overset{\triangle}{=} (0,T)\times(0,T)\times\Omega, \quad \mathcal{S} \overset{\triangle}{=} (0,T)\times(0,T)\times\Gamma, \quad \mathcal{S}_0 \overset{\triangle}{=} (0,T)\times(0,T)\times\Gamma_0, \\ T_i \overset{\triangle}{=} T/2-\varepsilon_i T, \quad T_i' \overset{\triangle}{=} T/2+\varepsilon_i T, \quad \mathcal{Q}_i \overset{\triangle}{=} (T_i,T_i')\times(T_i,T_i')\times\Omega \end{cases}$$

(3.37)

and

$$\Xi_j \overset{\triangle}{=} \left\{(t,s,x)\in\mathcal{Q} \,\middle|\, 2\psi(t,s,x) \geq R_0^2/(j+2)\right\}, \tag{3.38}$$

where $i=0,1,2$; $j=0,1,2$ and $0<\varepsilon_0<\varepsilon_1<\varepsilon_2<1/2$ will be given below.

In order to determine ε_i $(i=0,1,2)$, we proceed as in (3.10)–(3.13). First of all, by (3.5)–(3.6) and (3.36), one gets

$$\psi(0,s,x)=\psi(T,s,x)=(R_1^2-\alpha T^2/4)/2<0 \quad \forall\,(s,x)\in Q. \tag{3.39}$$

Thus, one can find an $\varepsilon_1\in(0,1/2)$ (close to $1/2$) such that (recall (3.37)–(3.38) for Ξ_2, $\mathcal{Q}_1$, T_1 and T_1')

$$\Xi_2\subset\mathcal{Q}_1 \tag{3.40}$$

and for any $(t,s,x)\in((0,T_1)\cup(T_1',T))\times Q$ and any $(s,t,x)\in((0,T_1)\cup(T_1',T))\times Q$ it holds that

$$\psi(t,s,x)<0. \tag{3.41}$$

Next, noting that since $\{T/2\}\times\{T/2\}\times\Omega\subset\Xi_0$, one can find a small $\varepsilon_0\in(0,\varepsilon_1)$ such that (recall (3.38) and (3.37) for Ξ_0 and $\mathcal{Q}_0$, respectively)

$$\mathcal{Q}_0\subset\Xi_0. \tag{3.42}$$

Finally, we fix any constant $\varepsilon_2\in(\varepsilon_1,1/2)$.

Now, let us observe B defined by (2.27), where x_0, α_1, α_2, and β are given in (3.36) and (2.23). Similar to (3.16)–(3.17), by (2.27) and (3.38), one can find a constant $\lambda_1>1$ such that for any $\lambda>\lambda_1$, it holds that

$$B\chi_{\Xi_2}(t,s,x)\geq c_0\lambda^3\chi_{\Xi_2}(t,s,x) \tag{3.43}$$

and

$$\left|B\chi_{\mathcal{Q}\setminus\Xi_2}(t,s,x)\right|\leq C\lambda^3 \tag{3.44}$$

for some constants $c_0>0$ and $C>0$, which depend only on T and Ω.

Finally, put

$$z(t,s,x)\overset{\triangle}{=}\int_s^t w(\xi,x)d\xi \qquad \forall\,(t,s,x)\in\mathcal{Q}, \tag{3.45}$$

where w is the weak solution of (1.1). One sees that z satisfies (recall $q_2=0$ and $q_3=0$)

$$\begin{cases} z_{tt}+z_{ss}-\Delta z=\displaystyle\int_s^t q_1(\xi,x)z_t(\xi,s,x)d\xi & \text{in } \mathcal{Q}, \\ z=0 & \text{on } \mathcal{S}. \end{cases} \tag{3.46}$$

Step 2. Let us use Lemma 2.7. We proceed as in [19]. For any given $\tau \in (T_2, T_1)$ and $\tau' \in (T_1', T_2')$ (recall (3.37) for T_i and T_i'), denote

$$\mathcal{Q}_\tau^{\tau'} \overset{\triangle}{=} (\tau, \tau') \times (\tau, \tau') \times \Omega. \tag{3.47}$$

Let us observe (2.25), where $z = z(t, s, x)$ is given by (3.45) and ψ is given by (3.36). Integrating (2.25) on $\mathcal{Q}_\tau^{\tau'}$, using integration by parts, and taking (3.46) into account, we arrive at (noting that by (2.24), $v = \theta z$)

$$\begin{aligned}
&2(1-\alpha)\lambda \int_{\mathcal{Q}_\tau^{\tau'}} \left(v_t^2 + v_s^2 + \sum_i v_i^2 \right) dxdtds + \int_{\mathcal{Q}_\tau^{\tau'}} Bv^2 dxdtds \\
&\le \int_{\mathcal{Q}} \theta^2 \left| \int_s^t q_1(\xi, x) z_t(\xi, s, x) d\xi \right|^2 dxdtds + \int_{\mathcal{S}_0} \left| \frac{\partial v}{\partial \nu} \right|^2 d\mathcal{S}_0 \\
&\quad + C\lambda^3 \Bigg[\int_{T_2}^{T_2'} \int_\Omega \Bigg(|v(\tau, s, x)|^2 + |v_t(\tau, s, x)|^2 + |v_s(\tau, s, x)|^2 + \sum_i |v_i(\tau, s, x)|^2 \\
&\quad + |v(\tau', s, x)|^2 + |v_t(\tau', s, x)|^2 + |v_s(\tau', s, x)|^2 + \sum_i |v_i(\tau', s, x)|^2 \Bigg) dxds \\
&\quad + \int_{T_2}^{T_2'} \int_\Omega \Bigg(|v(t, \tau, x)|^2 + |v_t(t, \tau, x)|^2 + |v_s(t, \tau, x)|^2 + \sum_i |v_i(t, \tau, x)|^2 \\
&\quad + |v(t, \tau', x)|^2 + |v_t(t, \tau', x)|^2 + |v_s(t, \tau', x)|^2 + \sum_i |v_i(t, \tau', x)|^2 \Bigg) dxdt \Bigg] \qquad \forall\, \lambda > 1.
\end{aligned} \tag{3.48}$$

However, recalling $v = \theta z$ with $\theta = e^\ell$, by (2.23), (3.36), and (3.41), we get

$$\begin{aligned}
&\int_{T_2}^{T_2'} \int_\Omega \Bigg(|v(\tau, s, x)|^2 + |v_t(\tau, s, x)|^2 + |v_s(\tau, s, x)|^2 + \sum_i |v_i(\tau, s, x)|^2 \\
&\quad + |v(\tau', s, x)|^2 + |v_t(\tau', s, x)|^2 + |v_s(\tau', s, x)|^2 + \sum_i |v_i(\tau', s, x)|^2 \Bigg) dxds \\
&\quad + \int_{T_2}^{T_2'} \int_\Omega \Bigg(|v(t, \tau, x)|^2 + |v_t(t, \tau, x)|^2 + |v_s(t, \tau, x)|^2 + \sum_i |v_i(t, \tau, x)|^2 \\
&\quad + |v(t, \tau', x)|^2 + |v_t(t, \tau', x)|^2 + |v_s(t, \tau', x)|^2 + \sum_i |v_i(t, \tau', x)|^2 \Bigg) dxdt \\
&\le C\lambda^2 \Bigg[\int_{T_2}^{T_2'} \int_\Omega \Bigg(|z(\tau, s, x)|^2 + |z_t(\tau, s, x)|^2 + |z_s(\tau, s, x)|^2 + \sum_i |z_i(\tau, s, x)|^2 \\
&\quad + |z(\tau', s, x)|^2 + |z_t(\tau', s, x)|^2 + |z_s(\tau', s, x)|^2 + \sum_i |z_i(\tau', s, x)|^2 \Bigg) dxds \\
&\quad + \int_{T_2}^{T_2'} \int_\Omega \Bigg(|z(t, \tau, x)|^2 + |z_t(t, \tau, x)|^2 + |z_s(t, \tau, x)|^2 + \sum_i |z_i(t, \tau, x)|^2 \\
&\quad + |z(t, \tau', x)|^2 + |z_t(t, \tau', x)|^2 + |z_s(t, \tau', x)|^2 + \sum_i |z_i(t, \tau', x)|^2 \Bigg) dxdt \Bigg].
\end{aligned} \tag{3.49}$$

Further, similar to (3.21), by (3.38), (2.23)–(2.24), (3.36), and (3.43)–(3.44), we get

$$\begin{aligned}\int_{\mathcal{Q}_\tau^{\tau'}} Bv^2 dxdtds &= \int_{\mathcal{Q}_\tau^{\tau'}\cap\Xi_2} Bv^2 dxdtds + \int_{\mathcal{Q}_\tau^{\tau'}\setminus\Xi_2} Bv^2 dxdtds \\ &\geq c_0\lambda^3 \int_{\mathcal{Q}_\tau^{\tau'}\cap\Xi_2} v^2 dxdtds - C\lambda^3 e^{R_0^2\lambda/4}\int_{\mathcal{Q}} z^2 dxdtds \quad \forall\,\lambda > \lambda_1.\end{aligned} \tag{3.50}$$

Note that by (3.38), (3.40), and (3.47) we have $\mathcal{Q}_\tau^{\tau'} \supset \Xi_1$. Thus, by (3.50), for any $\lambda > \lambda_1$, we have

$$\begin{aligned}&2(1-\alpha)\lambda\int_{\mathcal{Q}_\tau^{\tau'}}\left(v_t^2+v_s^2+\sum_i v_i^2\right)dxdtds + \int_{\mathcal{Q}_\tau^{\tau'}} Bv^2 dxdtds \\ &\geq c_1\left[\lambda\int_{\Xi_1}\left(v_t^2+v_s^2+\sum_i v_i^2\right)dxdtds + \lambda^3\int_{\Xi_1} v^2 dxdtds\right] - C\lambda^3 e^{R_0^2\lambda/4}\int_{\mathcal{Q}} z^2 dxdtds,\end{aligned} \tag{3.51}$$

where $c_1 > 0$ and $C > 0$ are two constants that depend only on T and Ω.

Now, combining (3.48)–(3.49) and (3.51), we conclude that for any $\lambda > \lambda_1$, it holds that

$$\begin{aligned}&\int_{\Xi_1}\left(v_t^2+v_s^2+\sum_i v_i^2\right)dxdtds + \lambda^2\int_{\Xi_1}\theta^2 v^2 dxdtds \\ &\leq C\lambda^{-1}\left\{\int_{\mathcal{Q}}\theta^2\left|\int_s^t q_1(\xi,x)z_t(\xi,s,x)d\xi\right|^2 dxdtds + \int_{\mathcal{S}_0}\left|\frac{\partial v}{\partial\nu}\right|^2 d\mathcal{S}_0\right. \\ &\quad + \lambda^5\left[\int_{T_2}^{T_2'}\int_\Omega\left(|z(\tau,s,x)|^2+|z_t(\tau,s,x)|^2+|z_s(\tau,s,x)|^2+\sum_i|z_i(\tau,s,x)|^2\right.\right. \\ &\quad \left. + |z(\tau',s,x)|^2+|z_t(\tau',s,x)|^2+|z_s(\tau',s,x)|^2+\sum_i|z_i(\tau',s,x)|^2\right)dxds \\ &\quad + \int_{T_2}^{T_2'}\int_\Omega\left(|z(t,\tau,x)|^2+|z_t(t,\tau,x)|^2+|z_s(t,\tau,x)|^2+\sum_i|z_i(t,\tau,x)|^2\right. \\ &\quad \left.\left. + |z(t,\tau',x)|^2+|z_t(t,\tau',x)|^2+|z_s(t,\tau',x)|^2+\sum_i|z_i(t,\tau',x)|^2\right)dxdt\right] \\ &\quad \left. + \lambda^3 e^{R_0^2\lambda/4}\int_{\mathcal{Q}} z^2 dxdtds\right\}.\end{aligned} \tag{3.52}$$

Integrating (3.52) with respect to τ and τ' from T_2 to T_1 and from T_1' to T_2', respectively, we get

$$\begin{aligned}&\int_{\Xi_1}\left(v_t^2+v_s^2+\sum_i v_i^2\right)dxdtds + \lambda^2\int_{\Xi_1}\theta^2 v^2 dxdtds \\ &\leq C\lambda^{-1}\left\{\int_{\mathcal{Q}}\theta^2\left|\int_s^t q_1(\xi,x)z_t(\xi,s,x)d\xi\right|^2 dxdtds + \int_{\mathcal{S}_0}\left|\frac{\partial v}{\partial\nu}\right|^2 d\mathcal{S}_0\right. \\ &\quad \left. + \lambda^5\int_{\mathcal{Q}_2}\left(z^2+z_t^2+z_s^2+\sum_i z_i^2\right)dxdtds + \lambda^3 e^{R_0^2\lambda/4}\int_{\mathcal{Q}} z^2 dxdtds\right\}.\end{aligned} \tag{3.53}$$

Consequently, by (2.23)–(2.24) and (3.36), recalling that $z = \theta^{-1}v$ with $\theta = e^{\ell}$, and using (3.53), we see that for any $\lambda > \lambda_1$, it holds that

$$\begin{aligned}
&\int_{\Xi_1}\theta^2\left(z_t^2+z_s^2+\sum_i z_i^2\right)dxdtds+\lambda^2\int_{\Xi_1}\theta^2 z^2dxdtds\\
&\le C\lambda^{-1}\left\{\int_{\mathcal{Q}}\theta^2\left|\int_s^t q_1(\xi,x)z_t(\xi,s,x)d\xi\right|^2dxdtds+e^{C\lambda}\int_{\mathcal{S}_0}\left|\frac{\partial z}{\partial\nu}\right|^2d\mathcal{S}_0\right.\\
&\quad\left.+\lambda^5\int_{\mathcal{Q}_2}\left(z^2+z_t^2+z_s^2+\sum_i z_i^2\right)dxdtds+\lambda^3e^{R_0^2\lambda/4}\int_{\mathcal{Q}}z^2dxdtds\right\}.
\end{aligned}\tag{3.54}$$

Step 3. Let us now estimate "$\int_{\mathcal{Q}_2}\theta^2\ \ |\int_s^t q_1(\xi,x)z_t(\xi,s,x)d\xi|^2dxdtds$" and "$\int_{\mathcal{Q}_2}\sum_i z_i^2dxdtds$." First, similar to [28], we get (recalling $h\overset{\triangle}{=}|q_1|_\infty$)

$$\begin{aligned}
\int_{\mathcal{Q}}\theta^2\left|\int_s^t q_1(\xi,x)z_t(\xi,s,x)d\xi\ \right|^2dxdtds&\le Ch^2\int_{\mathcal{Q}}\theta^2(z_t^2+z_s^2)dxdtds\\
&=Ch^2\left(\int_{\Xi_1}+\int_{\mathcal{Q}\setminus\Xi_1}\right)\theta^2(z_t^2+z_s^2)dxdtds\\
&\le Ch^2\left[\int_{\Xi_1}\theta^2(z_t^2+z_s^2)dxdtds\right.\\
&\qquad\left.+e^{R_0^2\lambda/3}\int_{\mathcal{Q}}(z_t^2+z_s^2)dxdtds\ \right].
\end{aligned}\tag{3.55}$$

Next, denote

$$\eta=\eta(t,s)\overset{\triangle}{=}t(T-t)s(T-s).\tag{3.56}$$

Multiplying the first equation of (3.46) by ηz, integrating it on $\mathcal{Q}$, using integration by parts, by (3.56) and noting that

$$\eta(t,s)\ge(T_2-T)^2(T-T_2)^2\quad\forall\, t\,,s\in(T_2,T_2'),$$

we get (recalling $h\overset{\triangle}{=}|q_1|_\infty$)

$$\int_{\mathcal{Q}_2}\sum_i z_i^2dxdtds\le C\left[\int_{\mathcal{Q}}(z_t^2+z_s^2+z^2)dxdtds+h\int_{\mathcal{Q}}(z_t^2+z_s^2+z^2)dxdtds\right].\tag{3.57}$$

Now, combining (3.54)–(3.55) and (3.57), we conclude that for any $\lambda > \lambda_1$, it holds that

$$\begin{aligned}
&\int_{\Xi_1}\theta^2\left(z_t^2+z_s^2+\sum_i z_i^2\right)dxdtds+\lambda^2\int_{\Xi_1}\theta^2z^2dxdtds\\
&\le C_1\lambda^{-1}\left\{e^{C_1\lambda}\int_{\mathcal{S}_0}\left|\frac{\partial z}{\partial\nu}\right|^2d\mathcal{S}_0\right.\\
&\qquad+h^2\left[\int_{\Xi_1}\theta^2(z_t^2+z_s^2)dxdtds+e^{R_0^2\lambda/3}\int_{\mathcal{Q}}(z_t^2+z_s^2)dxdtds\right]\\
&\quad+\lambda^5\left[\int_{\mathcal{Q}}(z_t^2+z_s^2+z^2)dxdtds+h\int_{\mathcal{Q}}(z_t^2+z_s^2+z^2)dxdtds\right]\\
&\quad\left.+\lambda^3e^{R_0^2\lambda/4}\int_{\mathcal{Q}}z^2dxdtds\ \right\},
\end{aligned}\tag{3.58}$$

where $C_1 = C_1(T, \Omega) > 0$ is a constant.

Let us take

$$\lambda_2 \overset{\triangle}{=} \max(\lambda_1, 2 + C_1 h^2). \tag{3.59}$$

Then by (3.58)–(3.59), we see that for any $\lambda > \lambda_2$ it holds that

$$\begin{aligned}&\int {}_{\Xi_1}\theta^2(z_t^2 + z_s^2)dxdtds \\ &\leq C\lambda^{-1}\left\{e^{C\lambda}\int_{\mathcal{S}_0}\left|\frac{\partial z}{\partial\nu}\right|^2 d\mathcal{S}_0 + \lambda^5 e^{R_0^2\lambda/3}\int_{\mathcal{Q}}(z_t^2 + z_s^2 + z^2)dxdtds\right\}.\end{aligned} \tag{3.60}$$

Note that by (3.38) and (3.42), we have

$$\int_{\Xi_1}\theta^2(z_t^2 + z_s^2)dxdt \geq \int_{\Xi_0}\theta^2(z_t^2 + z_s^2)dxdt \geq e^{R_0^2\lambda/2}\int_{\mathcal{Q}_0}(z_t^2 + z_s^2)dxdt. \tag{3.61}$$

Thus, by (3.60)–(3.61), we conclude that for any $\lambda > \lambda_2$ it holds that

$$\int_{\mathcal{Q}_0}(z_t^2+z_s^2)dxdt \leq C\left\{e^{C\lambda}\int_{\mathcal{S}_0}\left|\frac{\partial z}{\partial\nu}\right|^2 d\mathcal{S}_0 + \lambda^5 e^{-R_0^2\lambda/6}\int_{\mathcal{Q}}(z_t^2 + z_s^2 + z^2)dxdtds\right\}. \tag{3.62}$$

Step 4. Let us complete the proof of Theorem 3.2. By (3.62) and (3.45), we get (recalling (3.37) for T_0 and T_0')

$$\int_{T_0}^{T_0'}\int_\Omega w^2 dxdt \leq C\left\{e^{C\lambda}\left|\frac{\partial w}{\partial\nu}\right|^2_{H^{-1}(\Sigma_0)} + \lambda^5 e^{-R_0^2\lambda/6}\int_0^T E(t)dt\right\} \qquad \forall\, \lambda > \lambda_2, \tag{3.63}$$

where $E(t)$ is defined by (2.12).

Fix $S_0 \in (T_0, T/2)$ and $S_0' \in (T/2, T_0')$; then it is easy to check that

$$\int_{S_0}^{S_0'} E(t)dt \leq C(1+h)\int_{T_0}^{T_0'}\int_\Omega w^2 dxdt. \tag{3.64}$$

Thus, by (3.63)–(3.64) and (3.59), one can find a constant $\lambda_3 = \lambda_3(R_0) > 0$ such that

$$\int_{S_0}^{S_0'} E(t)dt \leq C\left\{e^{C\lambda}\left|\frac{\partial w}{\partial\nu}\right|^2_{H^{-1}(\Sigma_0)} + e^{-R_0^2\lambda/8}\int_0^T E(t)dt\right\} \qquad \forall\, \lambda > \lambda_2 + \lambda_3. \tag{3.65}$$

Finally, by (2.13) (in Lemma 2.3) and (3.65), one gets

$$E(0) \leq C_2\left\{e^{C_2\lambda}\left|\frac{\partial w}{\partial\nu}\right|^2_{H^{-1}(\Sigma_0)} + e^{-R_0^2\lambda/8 + C_2\sqrt{h}}E(0)\right\} \qquad \forall\, \lambda > \lambda_2 + \lambda_3, \tag{3.66}$$

where $C_2 = C_2(T, \Omega)$ is a positive constant. However, it is easy to find a constant $\lambda_4 = \lambda_4(R_0, C_2)$ such that

$$C_2 e^{-R_0^2\lambda_4/8 + C_2\sqrt{h}} \leq 1/2. \tag{3.67}$$

Thus, by (3.66)–(3.67), we see that for any $\lambda > \max(\lambda_2 + \lambda_3, \lambda_4)$ it holds that

$$E(0) \leq Ce^{C\lambda}\left|\frac{\partial w}{\partial\nu}\right|^2_{H^{-1}(\Sigma_0)}. \tag{3.68}$$

Equation (3.68) is exactly the desired result. Thus, the proof of Theorem 3.2 is completed. □

4. Exact controllability of the linear and semilinear wave equations. In this section, we apply our observability estimates (3.1) and (3.3) to exact controllability for wave equations. First of all, let us consider the exact controllability of system (1.4). We have the following result.

THEOREM 4.1. *Let* (H) *hold,* $T > 2\max_{x\in\Omega}|x-x_0|$. *Let* $p_1 \in L^{n+1}(Q)$, $p_2 \in C^1(\overline{Q})$, *and* $p_3 \in C^1(\overline{Q};\mathbb{R}^n)$. *Then for any given* (y_0,y_1), $(z_0,z_1) \in L^2(\Omega)\times H^{-1}(\Omega)$, *there is a control* $u \in L^2(\Sigma_0)$ *such that the weak solution* y *of* (1.4) *satisfies* (1.5). *Furthermore, concerning the control* u, *we have the following estimate:*

$$|u|_{L^2(\Sigma_0)} \le \mathcal{C}(r_1)(|y_0|_{L^2(\Omega)} + |y_1|_{H^{-1}(\Omega)} + |z_0|_{L^2(\Omega)} + |z_1|_{H^{-1}(\Omega)}), \tag{4.1}$$

where $\mathcal{C}(r_1)$ *is given by* (3.2) *with* r *replaced by* $r_1 \overset{\triangle}{=} |p_1|_{n+1} + |p_2|_{1,\infty} + |p_3|_{1,\infty}$.

Proof. Let us use Lions's Hilbert uniqueness method (see [7, 16, 17, 30]). First, we solve

$$\begin{cases} v_{tt} - \Delta v = p_1 v + p_2 v_t + \langle p_3, \nabla v\rangle & \text{in } Q,\\ v = 0 & \text{on } \Sigma,\\ v(T) = z_0, \quad v_t(T) = z_1 & \text{in } \Omega. \end{cases} \tag{4.2}$$

Next, for any $(\varphi_0,\varphi_1) \in X \overset{\triangle}{=} H_0^1(\Omega)\times L^2(\Omega)$, we solve

$$\begin{cases} \varphi_{tt} - \Delta\varphi = [p_1 - (p_2)_t - \nabla\cdot p_3]\varphi - p_2\varphi_t - \langle p_3, \nabla\varphi\rangle & \text{in } Q,\\ \varphi = 0 & \text{on } \Sigma,\\ \varphi(0) = \varphi_0, \quad \varphi_t(0) = \varphi_1 & \text{in } \Omega \end{cases} \tag{4.3}$$

and

$$\begin{cases} \eta_{tt} - \Delta\eta = p_1\eta + p_2\eta_t + \langle p_3, \nabla\eta\rangle & \text{in } Q,\\ \eta = \big(\partial\varphi/\partial\nu\big)\chi_{\Sigma_0}(t,x) & \text{on } \Sigma,\\ \eta(T) = 0, \quad \eta_t(T) = 0 & \text{in } \Omega. \end{cases} \tag{4.4}$$

Then, we define a linear and continuous operator $\Lambda : X \to X'(\equiv H^{-1}(\Omega)\times L^2(\Omega))$ by

$$\Lambda(\varphi_0,\varphi_1) = \big(p_2(0)\eta(0) - \eta_t(0), \eta(0)\big), \tag{4.5}$$

where $\eta \in C([0,T];L^2(\Omega)) \cap C^1([0,T];H^{-1}(\Omega))$ is the weak solution of (4.4). It is sufficient to prove the existence of some $(\varphi_0,\varphi_1) \in X$ such that

$$\Lambda(\varphi_0,\varphi_1) = \Big(p_2(0)(y_0 - v(0)) - y_1 + v_t(0),\, y_0 - v(0)\Big), \tag{4.6}$$

where $v \in C([0,T];L^2(\Omega)) \cap C^1([0,T];H^{-1}(\Omega))$ is the weak solution of (4.2). In order to solve (4.6), we observe that (by (4.3)–(4.4))

$$\langle \Lambda(\varphi_0,\varphi_1), (\varphi_0,\varphi_1)\rangle_{X',X} = \int_{\Sigma_0} \left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\Sigma_0. \tag{4.7}$$

However, by Theorem 3.1 and (4.7), we have

$$|(\varphi_0,\varphi_1)|_X^2 \le \mathcal{C}(r_1)\langle \Lambda(\varphi_0,\varphi_1), (\varphi_0,\varphi_1)\rangle_{X',X} \qquad \forall\, (\varphi_0,\varphi_1) \in X\,, \tag{4.8}$$

where $\mathcal{C}(r_1)$ is given by (3.2) with r replaced by $r_1 \overset{\triangle}{=} |p_1|_{n+1} + |q_2|_{1,\infty} + |q_3|_{1,\infty}$. Therefore $\Lambda : X \to X'$ is an isomorphism. Thus (4.6) admits a unique solution $(\varphi_0, \varphi_1) \in X$ and

$$u = \partial\varphi/\partial\nu \tag{4.9}$$

is the desired control such that the weak solution of (1.4) satisfies (1.5).

Now, let us prove (4.1). Concerning (4.2), by Lemma 2.3, we obtain that

$$|(v_t(0), v(0))|_{X'} \leq Ce^{Cr_1}|(z_1, z_0)|_{X'}. \tag{4.10}$$

Consequently, by (4.6)–(4.9) and (4.10), we get

$$\begin{aligned} |u|_{L^2(\Sigma_0)} &\leq \mathcal{C}(r_1)\big|\big(p_2(0)(y_0 - v(0)) - y_1 + v_t(0),\, y_0 - v(0)\big)\big|_{X'} \\ &\leq \mathcal{C}(r_1)(|(y_1, y_0)|_{X'} + |(z_1, z_0)|_{X'}), \end{aligned} \tag{4.11}$$

which proves (4.1). □

Next, let us consider the exact controllability of the following semilinear wave equation:

$$\begin{cases} y_{tt} - \Delta y = f(y) & \text{in } Q, \\ y = u\chi_{\Sigma_0}(t, x) & \text{on } \Sigma, \\ y(0) = y_0, \quad y_t(0) = y_1 & \text{in } \Omega. \end{cases} \tag{4.12}$$

We have the following result.

Theorem 4.2. *Let Γ_0 satisfy* (H). *Let $f(\cdot) : \mathbb{R}^1 \to \mathbb{R}^1$ be of class $C^1(\mathbb{R})$ with $f'(\cdot) \in L^\infty(\mathbb{R})$ and $T > 2\max_{x\in\Omega}|x - x_0|$. Then, for any $s \in (0, 1)$, the semilinear wave equation* (4.12) *is exactly controllable in $H_0^s(\Omega) \times H^{s-1}(\Omega)$ at time T with control u in $H^s(0, T; L^2(\Gamma_0))$.*

Proof. By [31, Remark 2.3] and by our Theorem 3.2 (which implies a UCP for the wave equations), we obtain Theorem 4.2 immediately. □

Appendix A. Proof of Lemma 2.2.

This appendix is devoted to giving a proof of Lemma 2.2. For this purpose, we need the following known result (see [17, p. 46]).

Lemma A.1. *Let $T > 0$ and $F = 0$. Suppose that*

$$(g, w_0, w_1) \in L^2(\Sigma) \times L^2(\Omega) \times H^{-1}(\Omega). \tag{A.1}$$

Then the unique weak solution w of (2.1) *satisfies*

$$w \in C([0, T]; L^2(\Omega)) \cap C^1([0, T]; H^{-1}(\Omega)). \tag{A.2}$$

Furthermore, there is a constant $C = C(T, \Omega) > 0$ such that

$$\begin{aligned} |w|_{C([0,T];L^2(\Omega))\cap C^1([0,T];H^{-1}(\Omega))} \leq &C\big(|g|_{L^2(\Sigma)} + |w_0|_{L^2(\Omega)} + |w_1|_{H^{-1}(\Omega)}\big) \\ &\forall\, (g, w_0, w_1) \in L^2(\Sigma) \times L^2(\Omega) \times H^{-1}(\Omega). \end{aligned} \tag{A.3}$$

Now, let us prove Lemma 2.2. We divide the proof into two steps.

Step 1. We decompose the solution w of (2.1) as

$$w = \xi + \eta, \tag{A.4}$$

with ξ and η, respectively, solutions of

$$\text{(A.5)}\qquad \begin{cases} \xi_{tt} - \Delta\xi = 0 & \text{in } Q, \\ \xi = g & \text{on } \Sigma, \\ \xi(0) = w_0, \quad \xi_t(0) = w_1 & \text{in } \Omega \end{cases}$$

and

$$\text{(A.6)}\qquad \begin{cases} \eta_{tt} - \Delta\eta = F & \text{in } Q, \\ \eta = 0 & \text{on } \Sigma, \\ \eta(0) = 0, \quad \eta_t(0) = 0 & \text{in } \Omega. \end{cases}$$

First of all, by Lemma A.1, we see that $\xi \in C([0,T]; L^2(\Omega)) \cap C^1([0,T]; H^{-1}(\Omega))$; furthermore, there is a constant $C = C(T, \Omega) > 0$ such that

$$\text{(A.7)}\qquad |\xi|_{C([0,T];L^2(\Omega))\cap C^1([0,T];H^{-1}(\Omega))} \leq C\big(|g|_{L^2(\Sigma)} + |w_0|_{L^2(\Omega)} + |w_1|_{H^{-1}(\Omega)}\big).$$

Next, denote

$$\text{(A.8)}\qquad \begin{cases} \mathcal{A} \overset{\triangle}{=} -\Delta, \\ D(\mathcal{A}) = H^2(\Omega) \cap H_0^1(\Omega). \end{cases}$$

Put

$$\text{(A.9)}\qquad Z \overset{\triangle}{=} \mathcal{A}^{-1/2}\eta.$$

Then, by (A.6) and (A.9), we see that

$$\text{(A.10)}\qquad \begin{cases} Z_{tt} - \Delta Z = \mathcal{A}^{-1/2}F & \text{in } Q, \\ Z = 0 & \text{on } \Sigma, \\ Z(0) = 0, \quad Z_t(0) = 0 & \text{in } \Omega. \end{cases}$$

However, by (2.5), we have $\mathcal{A}^{-1/2}F \in L^1(0,T; L^2(\Omega))$. Thus, by (A.9)–(A.10) and Lemma 2.1, we see that $\eta \in C([0,T]; L^2(\Omega)) \cap C^1([0,T]; H^{-1}(\Omega))$; furthermore, there is a constant $C = C(T, \Omega) > 0$ such that

$$\text{(A.11)}\qquad |\eta|_{C([0,T];L^2(\Omega))\cap C^1([0,T];H^{-1}(\Omega))} \leq C|F|_{L^1(0,T;H^{-1}(\Omega))}.$$

Combining (A.4), (A.7), and (A.11), we see that $w \in C([0,T]; L^2(\Omega)) \cap C^1([0,T]; H^{-1}(\Omega))$; furthermore, there is a constant $C = C(T, \Omega) > 0$ such that

$$\text{(A.12)}\qquad \begin{aligned} &|w|_{C([0,T];L^2(\Omega))\cap C^1([0,T];H^{-1}(\Omega))} \\ &\leq C\big(|F|_{L^1(0,T;H^{-1}(\Omega))} + |g|_{L^2(\Sigma)} + |w_0|_{L^2(\Omega)} + |w_1|_{H^{-1}(\Omega)}\big). \end{aligned}$$

Step 2. It remains to prove $\partial w/\partial\nu \in H^{-1}(\Sigma)$ and

$$\text{(A.13)}\qquad \Big|\frac{\partial w}{\partial \nu}\Big|_{H^{-1}(\Sigma)} \leq C\Big(|F|_{L^1(0,T;H^{-1}(\Omega))} + |g|_{L^2(\Sigma)} + |w_0|_{L^2(\Omega)} + |w_1|_{H^{-1}(\Omega)}\Big).$$

This is essentially known (see [9, Theorem 2.3]), but we give the proof for the readers' convenience. Let W be the solution of

$$\text{(A.14)}\qquad \begin{cases} W_{tt} - \Delta W = 0 & \text{in } Q, \\ W = h & \text{on } \Sigma, \\ W(T) = 0, \quad W_t(T) = 0 & \text{in } \Omega, \end{cases}$$

where h is given such that

$$h \in H^1(\Sigma), \quad h(0) = h(T) = 0 \text{ on } \Gamma. \tag{A.15}$$

Then, by Lemma 2.1, we obtain

$$|W|_{C([0,T];H^1(\Omega))\cap C^1([0,T];L^2(\Omega))} + \left|\frac{\partial W}{\partial \nu}\right|_{L^2(\Sigma)} \leq C|h|_{H^1(\Sigma)} \tag{A.16}$$

for some constant $C = C(T, \Omega) > 0$. Assuming all data are smooth (we then extend by continuity), multiplying the first equation of (A.14) by w, integrating it on Q, and using integration by parts, by (A.14) and (2.1), we get

$$\int_\Sigma \frac{\partial w}{\partial \nu} h d\Sigma = -(F, W)_Q + \int_\Sigma g \frac{\partial W}{\partial \nu} d\Sigma - (w_1, W(0))_\Omega + (w_0, W_t(0))_\Omega. \tag{A.17}$$

Now, by (A.16)–(A.17), we see that there is a constant $C = C(T, \Omega) > 0$ such that

$$\left|\int_\Sigma \frac{\partial w}{\partial \nu} h d\Sigma\right| \leq C|h|_{H^1(\Sigma)}\big(|F|_{L^1(0,T;H^{-1}(\Omega))} + |g|_{L^2(\Sigma)} + |w_0|_{L^2(\Omega)} + |w_1|_{H^{-1}(\Omega)}\big), \tag{A.18}$$

which implies (A.13) immediately. □

Acknowledgments. The author heartily thanks Professor J. E. Lagnese (Georgetown University), Professors I. Lasiecka and R. Triggiani (University of Virginia), Professor M. Yamamoto (The University of Tokyo), and Professor E. Zuazua (Universidad Complutense) for fruitful discussions and useful help. This paper is an improved version of one chapter of the author's Ph.D. thesis [27] accomplished at Fudan University under the guidance of Professors X. Li and J. Yong. The author would like to take this opportunity to thank them deeply for their encouragement and suggestions. Also, the author gratefully acknowledges the anonymous referees for their criticism and suggestions which led to this improved version.

OPTIMAL CONTROL OF A CLASS OF LINEAR HYBRID SYSTEMS WITH SATURATION*

BART DE SCHUTTER†

Abstract. We consider a class of first order linear hybrid systems with saturation. A system that belongs to this class can operate in several modes or phases; in each phase each state variable of the system exhibits a linear growth until a specified upper or lower saturation level is reached, and after that the state variable stays at that saturation level until the end of the phase. A typical example of such a system is a traffic signal controlled intersection. We develop methods to determine optimal switching time sequences for first order linear hybrid systems with saturation that minimize criteria such as average queue length, worst case queue length, average waiting time, and so on. First we show how the extended linear complementarity problem (ELCP), which is a mathematical programming problem, can be used to describe the set of system trajectories of a first order linear hybrid system with saturation. Optimization over the solution set of the ELCP then yields an optimal switching time sequence. Although this method yields globally optimal switching time sequences, it is not feasible in practice due to its computational complexity. Therefore, we also present some methods to compute suboptimal switching time sequences. Furthermore, we show that if there is no upper saturation, then for some objective functions the globally optimal switching time sequence can be computed very efficiently. We also discuss some approximations that lead to suboptimal switching time sequences that can be computed very efficiently. Finally, we use these results to design optimal switching time sequences for traffic signal controlled intersections.

1. Introduction.

Hybrid systems arise from the interaction between continuous variable systems[1] and discrete event systems.[2] In general we could say that a hybrid system can be in one of several modes whereby in each mode the behavior of the system can be described by a system of difference or differential equations, and that the system switches from one mode to another due to the occurrence of an event. There are many frameworks to model, analyze, and control hybrid systems (see, e.g., [1, 11, 12, 17] and the references cited therein). An important trade-off in this context is that of modeling power versus decision power: the more accurate the model is the less we can analytically say about its properties. Furthermore, many analysis and control problems lead to computationally hard problems for even the most elementary hybrid systems [2]. Therefore, we focus on a specific class of hybrid systems that can be analyzed using a mathematical programming problem that is called the extended linear complementarity problem (ECLP). More specifically, we study the design of optimal switching time sequences for a class of first order linear hybrid systems subject to saturation.

[1] Continuous variable systems are systems that can be described by a difference or differential equation.

[2] Discrete event systems are asynchronous systems where the state transitions are initiated by events; in general the time instants at which these events occur are not equidistant.

This work is an extension of the work reported in [8] in which we developed some algorithms to design optimal traffic signal switching schemes for single intersections. In [8] we considered only fixed amber durations and we could efficiently compute only suboptimal switching schemes for *approximations* of the real objective functions. Now we allow variable durations for the amber phases, and we show that if there is no upper saturation, then for certain objective functions the optimal switching scheme can be computed very efficiently without making any approximations. Furthermore, in this paper we also consider a more general class of systems than the traffic signal controlled intersections of [8].

The work reported here is closely related to optimal traffic signal control (see, e.g., [10, 14, 15, 16]). The main difference between the model presented in this paper applied to traffic signal optimization and the models used by most other researchers is that in our approach the length of the green-amber-red cycles may vary from cycle to cycle, i.e., we optimize over a fixed number of switch-overs instead of over a fixed number of time steps. This allows us to optimize not only the split but also the cycle time with continuous optimization variables (usually the optimization of split and cycle time is performed using boolean variables at each time step, each variable corresponding to the decision of switching or not the traffic signals as in UTOPIA, OPAC, SCOOT, or SCATS). Our method adds an extra degree of freedom, which will in general lead to a more optimal switching scheme.

This paper is organized as follows. In section 2 we discuss model predictive control, which is the framework in which our approach can be embedded. Next we give the definition and a brief description of the ELCP. In section 3 we introduce a class of first order linear hybrid systems with saturation. We show that computing the optimal switching time instants in general leads to a nonconvex optimization problem or to an optimization problem over the solution set of an extended linear complementarity problem. In section 4 we show that if there is no upper saturation, then for some objective functions the feasible set of the optimal switching problem can be replaced by a convex set without changing the optimum. In that case the optimal switching time sequence can be computed very efficiently. Furthermore, by making some approximations the problem becomes a linear programming problem. These results will be illustrated in section 5 in which we compute optimal traffic signal switching time sequences for traffic signal controlled intersections.

2. Preliminaries.

2.1. Notation. Let a and b be vectors with n components. The ith component of a is denoted by a_i or $(a)_i$. We use $a \geqslant b$ to indicate that $a_i \geqslant b_i$ for all i. The maximum operator on vectors is defined as follows: $\big(\max(a,b)\big)_i = \max(a_i, b_i)$ for all i. The minimum operator on vectors is defined analogously. The zero vector with n components is denoted by 0_n, or by 0 if the dimension is clear from the context. The n by n identity matrix is denoted by I_n, or by I if the dimension is clear from the context. The set of the real numbers is denoted by $\mathbb{R}$.

2.2. Model predictive control. Model predictive control (MPC) [3, 4, 9] is a very popular controller design method in the process industry. An important advantage of MPC is that it allows the inclusion of constraints on the inputs and outputs, and that it can handle changes in the system parameters by using a moving horizon approach, in which the model and the control strategy are continuously updated. We will use the MPC framework to design optimal switching schemes for a class of hybrid systems. In general the resulting optimization problem is nonlinear and nonconvex.

However, if the control objective and the constraints depend monotonically on the outputs of the system, the MPC problem can be recast as problem with a convex feasible set. As a consequence, the problem can be solved very efficiently so that on-line computation is feasible.

In each step of the conventional MPC algorithm for discrete-time systems an optimal input sequence is computed that minimizes a given cost criterion over a given prediction horizon N_{p}. Furthermore, for the optimization the control input u is taken to be constant from a certain point on: $u(k+j) = u(k+N_{\mathrm{c}}-1)$ for $j = N_{\mathrm{c}}, N_{\mathrm{c}}+1, \ldots, N_{\mathrm{p}}-1$, where N_{c} is the control horizon and where k is the first sampling index of the period under consideration. MPC uses a receding horizon principle: after computation of the optimal control sequence $u(k), u(k+1), \ldots, u(k+N_{\mathrm{c}}-1)$, only the first control input sample $u(k)$ will be implemented; subsequently the horizon is shifted one sample, the estimates of the state and the parameters of the system are updated using information coming from new measurements, and the optimization is restarted. Note that the continuous updating of the model and of the estimates of the states also introduces a kind of feedback in the control system. In general feedback is necessary to obtain good performance and tracking in most control applications (see, e.g., [13] for applications of feedback control in traffic).

The parameters N_{p} and N_{c} are the basic tuning parameters of the MPC algorithm:

(i) In general the prediction horizon N_{p} is selected such that the time interval $[k, k+N_{\mathrm{p}}-1]$ contains the crucial dynamics of the process.

(ii) An important effect of a small control horizon N_{c} is the smoothing of the control signal (because of the emphasis on the average behavior rather than on aggressive noise reduction). The control horizon forces the control signal to a constant value. This also has a stabilizing effect since the output signal is forced to its steady-state value. Another important consequence of decreasing N_{c} is the reduction of the number of optimization variables, which results in a decrease of the computational effort.

2.3. The ELCP. The ELCP is a mathematical programming problem which is defined as follows [7]:

Given $A \in \mathbb{R}^{p\times n}$, $B \in \mathbb{R}^{q\times n}$, $c \in \mathbb{R}^p$, $d \in \mathbb{R}^q$ and m subsets ϕ_1, ϕ_2, $\ldots$, ϕ_m of $\{1, 2, \ldots, p\}$, find $x \in \mathbb{R}^n$ such that

$$\sum_{j=1}^{m} \prod_{i\in\phi_j} (Ax-c)_i = 0 \tag{1}$$

subject to $Ax \geqslant c$ and $Bx = d$, or show that no such x exists.

The ELCP can be considered as a system of linear equations and inequalities ($Ax \geqslant c$, $Bx = d$), where there are m groups of linear inequalities (one group for each index set ϕ_j) such that in each group at least one inequality should hold with equality. In [7] we have developed an algorithm to compute the complete solution set of an ELCP. In general this solution set consists of the union of a subset of faces of the polyhedron $\mathcal{P}$ defined by the system $Ax \geqslant c$, $Bx = d$ (i.e., the solution set contains all the points of $\mathcal{P}$ that satisfy condition (1)). Our ELCP algorithm yields a compact representation of the solution set of an ELCP by vertices, extreme rays, and a basis of the linear subspace corresponding to the largest affine subspace of the solution set. In [7] we have also shown that the general ELCP is NP-hard.

In the next section we shall show that the ELCP can be used to determine optimal switching time instants for a special class of hybrid systems.

3. Optimal switching time sequences for a class of linear hybrid systems with saturation.

3.1. First order linear hybrid systems with saturation. Consider a system the evolution of which is characterized by consecutive phases. In each phase each state variable of the system exhibits a linear growth or decrease until a certain upper or lower saturation level is reached; then the state variable stays constant until the end of the phase. A system, the behavior of which satisfies this description, will be called a *first order linear hybrid system with saturation.*

A typical example of a first order linear hybrid system with saturation is a traffic signal controlled intersection, provided that we use a continuous approximation for the queue lengths (see section 5 and [8]). The state variables of this system correspond to the queue lengths in the different lanes. For a traffic signal controlled intersection the lower bound for the queue length is equal to 0. The upper bound could correspond to the maximal available storage space due to the distance to the preceding junction or due to the layout of the intersection. We assume that if this upper bound is reached then newly arriving cars take another route to get to their destination. Another example of a first order linear hybrid system with saturation is a system consisting of several fluid containers that are connected by tubes with valves and that have two outlets—one at the bottom (with a tube that leads to another fluid container) and one at the top (so that the fluid level in the containers can never exceed a given level)—provided that we assume that the increase or decrease of the fluid levels is linear if the system is not saturated.

Now we derive the equations that describe the evolution of the state variables in a first order linear hybrid system with saturation. Analogous to a traffic signal controlled intersection, we will use the phrase "queue lengths" to refer to the state variables of the system. Note, however, that our definition of a first order linear hybrid system with saturation is not limited to queuing systems only.

Let M be the number of "queues." The length of queue i at time t is denoted by $q_i(t)$. Let $\alpha_{i,k}$, $b^{\mathrm{ls}}_{i,k}$, and $b^{\mathrm{us}}_{i,k}$ be, respectively, the queue length growth rate for queue i in phase k, the lower saturation bound for the queue length q_i in phase k, and the upper saturation bound for the queue length q_i in phase k. The evolution of the system begins at time t_0. Let $t_1, t_2, t_3, \ldots$ be the switching time instants, i.e., the time instants at which the system switches from one phase to another. Note that in general the sequence $t_0, t_1, t_2, \ldots$ is *not* an equidistant sequence. The length of the kth phase is equal to $\delta_k \overset{\mathrm{def}}{=} t_{k+1} - t_k$. Note that $\delta_k > 0$ for all k. We assume that $0 \leqslant b^{\mathrm{ls}}_{i,k+1} \leqslant q_i(t_{k+1}) \leqslant b^{\mathrm{us}}_{i,k+1}$ for all i, k such that the queue lengths are always nonnegative and such that there are no sudden jumps in the queue lengths due to a change in the saturation level at one of the switching time instants. For queue i we have

$$\frac{dq_i(t)}{dt} = \begin{cases} \alpha_{i,k} & \text{if } b^{\mathrm{ls}}_{i,k} < q_i(t) < b^{\mathrm{us}}_{i,k}, \\ 0 & \text{otherwise} \end{cases} \tag{2}$$

for $t \in (t_k, t_{k+1})$. This implies that the evolution of the queue lengths at the switching time instants is given by

$$q_i(t_{k+1}) = \max\big(\min(q_i(t_k) + \alpha_{i,k}\delta_k,\ b^{\mathrm{us}}_{i,k}),\ b^{\mathrm{ls}}_{i,k}\big) \tag{3}$$

for $k = 0, 1, 2, \ldots$. If we define $q_{i,k} = q_i(t_k)$ and

$$q_k = \begin{bmatrix} q_{1,k} \\ q_{2,k} \\ \vdots \\ q_{M,k} \end{bmatrix}, \quad \alpha_k = \begin{bmatrix} \alpha_{1,k} \\ \alpha_{2,k} \\ \vdots \\ \alpha_{M,k} \end{bmatrix}, \quad b_k^{\mathrm{ls}} = \begin{bmatrix} b_{1,k}^{\mathrm{ls}} \\ b_{2,k}^{\mathrm{ls}} \\ \vdots \\ b_{M,k}^{\mathrm{ls}} \end{bmatrix}, \quad b_k^{\mathrm{us}} = \begin{bmatrix} b_{1,k}^{\mathrm{us}} \\ b_{2,k}^{\mathrm{us}} \\ \vdots \\ b_{M,k}^{\mathrm{us}} \end{bmatrix},$$

we obtain the vector equation

$$q_{k+1} = \max\bigl(\min(q_k + \alpha_k \delta_k,\, b_k^{\mathrm{us}}),\, b_k^{\mathrm{ls}}\bigr). \tag{4}$$

If we introduce dummy vectors z_k, then (3) can be rewritten as

$$z_{k+1} = \min(q_k + \alpha_k \delta_k, b_k^{\mathrm{us}}), \tag{5}$$

$$q_{k+1} = \max(z_{k+1}, b_k^{\mathrm{ls}}). \tag{6}$$

3.2. Optimal switching time sequences for linear hybrid systems with saturation. Now we consider the problem of computing an optimal (finite) sequence of switching time instants for a system described by a system of equations of the form (4) using an MPC approach.

We may assume without loss of generality that t_0 will be the first switching time instant in each step of the MPC algorithm. Note that this implies that switching time instant t_1 of the current MPC step will correspond to switching time instant t_0 of the next MPC step. The queue length vector $q_0 = q(t_0)$ at time $t = t_0$ can be measured[3] or estimated. Now we want to determine the optimal switching time sequence $t_0, t_1, \ldots, t_{N_{\mathrm{p}}}$ for a given performance criterion J. For the class of systems we consider it makes more sense to replace the condition that the control input is constant after the control horizon by the condition

$$\delta_k = \delta_{k-K_{\mathrm{c}}} \qquad \text{for } k = N_{\mathrm{c}}, N_{\mathrm{c}}+1, \ldots, N_{\mathrm{p}}-1, \tag{7}$$

where K_{c} is the number of switching phases in one larger cycle of the system (e.g., in traffic signal control for an intersection of two streets K_{c} could be equal to 4 corresponding to the combinations red-green, red-amber, green-red, amber-red for the traffic signals on the crossing roads (see also section 5)). Possible performance criteria are

1. (weighted) average queue length over all queues:

$$J_1 = \sum_{i=1}^{M} w_i \, \frac{1}{t_{N_{\mathrm{p}}} - t_0} \int_{t_0}^{t_{N_{\mathrm{p}}}} q_i(t)\, dt, \tag{8}$$

2. (weighted) average queue length over the worst queue:

$$J_2 = \max_i \left(w_i \, \frac{1}{t_{N_{\mathrm{p}}} - t_0} \int_{t_0}^{t_{N_{\mathrm{p}}}} q_i(t)\, dt \right), \tag{9}$$

3. (weighted) worst case queue length:

$$J_3 = \max_{i,\, t} \bigl(w_i \, q_i(t) \bigr), \tag{10}$$

[3] Note that if we compute the switching time sequence fast enough (i.e., if the computation time is less than $\delta_0 = t_1 - t_0$), we can wait to compute the optimal sequence until after t_0.

4. (weighted) average "waiting time" over all queues:[4]

$$J_4 = \sum_{i=1}^{M} w_i \, \frac{\displaystyle\int_{t_0}^{t_{N_\mathrm{p}}} q_i(t)\,dt}{\displaystyle\sum_{k=0}^{N_\mathrm{p}-1} \alpha_{i,k}^{\mathrm{a}} \delta_k}, \tag{11}$$

5. (weighted) average "waiting time" over the worst queue:

$$J_5 = \max_i \left(w_i \, \frac{\displaystyle\int_{t_0}^{t_{N_\mathrm{p}}} q_i(t)\,dt}{\displaystyle\sum_{k=0}^{N_\mathrm{p}-1} \alpha_{i,k}^{\mathrm{a}} \delta_k} \right), \tag{12}$$

where $w_i > 0$ for all i and $\alpha_{i,k}^{\mathrm{a}}$ is the arrival rate of "customers" for queue i in phase k.

We can impose extra conditions such as minimum or maximum queue lengths (which could be useful in order to prevent saturation at the lower or upper level for some queues), minimum and maximum durations for the switching time intervals, and so on.

This leads to the following optimization problem that should be solved in each MPC step:

$$\operatorname*{minimize}_{\delta_0,\delta_1,\ldots,\delta_{N_\mathrm{c}-1}} \; J \tag{13}$$

subject to

$$\delta_k = \delta_{k-K_\mathrm{c}} \qquad \text{for } k = N_\mathrm{c}, N_\mathrm{c}+1, \ldots, N_\mathrm{p}-1, \tag{14}$$

$$\delta_{\min,k} \leqslant \delta_k \leqslant \delta_{\max,k} \qquad \text{for } k = 0,1,\ldots,N_\mathrm{c}-1, \tag{15}$$

$$q_{\min,k} \leqslant q_{k+1} \leqslant q_{\max,k} \qquad \text{for} k = 0,1,\ldots,N_\mathrm{p}-1, \tag{16}$$

$$z_{k+1} = \min(q_k + \alpha_k \delta_k,\, b_k^{\mathrm{us}}) \qquad \text{for } k = 0,1,\ldots,N_\mathrm{p}-1, \tag{17}$$

$$q_{k+1} = \max(z_{k+1},\, b_k^{\mathrm{ls}}) \qquad \text{for } k = 0,1,\ldots,N_\mathrm{p}-1 \tag{18}$$

with $q_0 = q(t_0)$, and where $\delta_{\min,k}$ and $\delta_{\max,k}$ are, respectively, the minimum and the maximum values of δ_k, and $(q_{\min,k})_i$ and $(q_{\max,k})_i$ are, respectively, the minimum and the maximum queue lengths for queue i at time instant t_{k+1}.

Remark 3.1. We can also use a first order linear hybrid system with saturation as an approximate model if we have a hybrid system with saturation in which the queue length growth or decrease rates are slowly time-varying since in MPC we use a moving horizon approach in which the model of the system and the estimate of the initial condition can be updated at the beginning of each control cycle. This also introduces a feedback into the control system.

[4] The average waiting time is equal to the total waiting time divided by the number of arrivals. If the initial and final queue lengths are 0, then the average waiting time for queue i is given by the fraction in the expression on the right-hand side of (11). So J_4 is in fact an approximation of the (weighted) average waiting time.

3.3. The ELCP and optimal switching time sequences. Now we show that the system (14)–(18) can be reformulated as an ELCP.

Consider (17) for an arbitrary index k. This equation can be rewritten as follows:

$$
\begin{gathered}
z_{k+1} \leqslant q_k + \alpha_k \delta_k, \\
z_{k+1} \leqslant b_k^{\mathrm{us}}, \\
(z_{k+1})_i = (q_k + \alpha_k \delta_k)_i \quad \text{or} \quad (z_{k+1})_i = (b_k^{\mathrm{us}})_i \qquad \text{for } i = 1, 2, \ldots, M,
\end{gathered}
$$

or equivalently

$$q_k + \alpha_k \delta_k - z_{k+1} \geqslant 0, \tag{19}$$

$$b_k^{\mathrm{us}} - z_{k+1} \geqslant 0, \tag{20}$$

$$(q_k + \alpha_k \delta_k - z_{k+1})_i \, (b_k^{\mathrm{us}} - z_{k+1})_i = 0 \qquad \text{for } i = 1, 2, \ldots, M. \tag{21}$$

Since a sum of nonnegative numbers is equal to 0 if and only if all the numbers are equal to 0, (21) is equivalent to

$$\sum_{i=1}^{M} (q_k + \alpha_k \delta_k - z_{k+1})_i \, (b_k^{\mathrm{us}} - z_{k+1})_i = (q_k + \alpha_k \delta_k - z_{k+1})^T \, (b_k^{\mathrm{us}} - z_{k+1}) = 0.$$

Hence, (17) can be rewritten as

$$q_k + \alpha_k \delta_k - z_{k+1} \geqslant 0, \tag{22}$$

$$b_k^{\mathrm{us}} - z_{k+1} \geqslant 0, \tag{23}$$

$$(q_k + \alpha_k \delta_k - z_{k+1})^T \, (b_k^{\mathrm{us}} - z_{k+1}) = 0. \tag{24}$$

We can repeat this reasoning for (18) and for each index k. So if we define

$$x_q = \begin{bmatrix} q_1 \\ q_2 \\ \vdots \\ q_{N_{\mathrm{p}}} \end{bmatrix}, \quad x_z = \begin{bmatrix} z_1 \\ z_2 \\ \vdots \\ z_{N_{\mathrm{p}}} \end{bmatrix}, \quad x_\delta = \begin{bmatrix} \delta_0 \\ \delta_1 \\ \vdots \\ \delta_{N_{\mathrm{c}}-1} \end{bmatrix},$$

and if we replace all δ_k's with index $k \geqslant N_{\mathrm{c}}$ using (14), we finally get a problem of the form

$$\underset{x_\delta}{\text{minimize}} \; J \tag{25}$$

subject to

$$A x_q + B x_z + C x_\delta + d \geqslant 0, \tag{26}$$

$$E x_q + F x_z + g \geqslant 0, \tag{27}$$

$$H x_q + K x_\delta + l \geqslant 0, \tag{28}$$

$$(A x_q + B x_z + C x_\delta + d)^T (E x_q + F x_z + g) = 0 \tag{29}$$

for appropriately defined matrices A, B, C, E, F, H, K and vectors d, g, l. Equations (26), (27), and (29) correspond to (22), (23), and (24), respectively, and the system of linear inequalities (28) contains the conditions (15) and (16). It is easy to verify that the system (26)–(29) is (a special case of) an ELCP.

The time evolution of the queue lengths in a first order linear hybrid system with saturation is given by piecewise-affine functions. The link between piecewise-affine functions and (ordinary) linear complementarity problems has also been explored by several other authors (see, e.g., [5] and the references therein).

Remark 3.2. If we introduce additional linear equality or inequality constraints on the components of x_δ such as, e.g., a maximum or total duration for the N_p phases ($\delta_0 + \delta_1 + \cdots + \delta_{N_\mathrm{p}} \leqslant T_\mathrm{max}$ or $\delta_0 + \delta_1 + \cdots + \delta_{N_\mathrm{p}} = T_\mathrm{tot}$), maximum or total durations for two or more consecutive phases (e.g., $\delta_{2k} + \delta_{2k+1} \leqslant T_{\mathrm{max},k}$ or $\delta_{2k} + \delta_{2k+1} = T_{\mathrm{tot},k}$), we still obtain an ELCP. The additional linear inequality constraints lead to extra inequalities in (28), and the additional linear equality constraints lead to an extra equation of the form $Px_\delta + q = 0$, which also fits in the ELCP framework.

The ELCP (26)–(29) describes all feasible system trajectories for the first order linear hybrid system with saturation. In order to determine the optimal switching time sequence we could minimize the objective function J over the solution set of the ELCP as follows. If we assume that x_q and x_δ are bounded,[5] then the solution set of the ELCP consists of a union of faces of the (finite and bounded) polytope defined by (26)–(28). Each face of the polyhedron can be represented by its vertices, and the points of the face can be written as convex combinations of these vertices. For each face we could determine for which convex combination of the vertices the objective function J reaches a global minimum over the face and afterwards select the overall minimum.

However, the general ELCP is an NP-hard problem [7]. Furthermore, the algorithm of [7] to compute the solution set of a general ELCP requires exponential execution times. This implies that the ELCP approach sketched above is not feasible if the number of variables is large. Since the number of variables in the ELCP is equal to $2MN_\mathrm{p} + N_\mathrm{c}$, this implies that the ELCP should not be used if M, N_p, or N_c are large.

If the ELCP is not tractable, either we could select lower values for N_c and N_p (which would result in less optimal solutions) or we could use multistart local optimization to determine the optimal switching scheme. For given N_p, N_c, K_c, q_0, $\alpha_{i,k}$'s, $b^\mathrm{ls}_{i,k}$'s, and $b^\mathrm{us}_{i,k}$'s, the evolution of the system to be optimized is uniquely determined by the sequence $\delta_0, \delta_1, \ldots, \delta_{N_\mathrm{c}-1}$ since the remaining δ_k's, the queue lengths $q_i(t)$, and the components of x_q and x_z are given by (7), (2), (5), and (6), respectively. Therefore, we can consider (13)–(18) as a constrained optimization problem in x_δ, where the constraints (16)–(18) are nonlinear constraints. Alternatively, these constraints can be taken into account by adding an extra penalty term to the objective function J if $q_{i,k} < (q_{\mathrm{min},k})_i$ or $q_{i,k} > (q_{\mathrm{max},k})_i$. If we use the penalty function[6] approach, the only remaining constraints on x_δ are the simple upper and lower bound constraints (15). However, the major disadvantage of the multistart local minimization approaches discussed above is that in general the minimization routine will return only a local minimum and that several starting points are necessary to obtain a good approximation to the global optimum. Note that the final solution $x_\delta^\mathrm{opt,curr}$ of the current MPC step can be used to obtain a good initial solution $x_\delta^\mathrm{init,next}$ for the next MPC stepping by setting $\delta_k^\mathrm{init,next} = \delta_{k-1}^\mathrm{opt,curr}$ for $k = 1, 2, \ldots, N_\mathrm{c}$.

Recall that in each MPC step the problem (13)–(18) has to be solved. In order to be able to do this on-line, it is important to have efficient algorithms to solve the

[5] A sufficient condition for this is that $\delta_{\mathrm{min},k}$ and $\delta_{\mathrm{max},k}$ are defined and finite for all k.

[6] Note that in this case a barrier function approach is not advantageous since the optimal solution will often lie on the boundary of the feasible region.

problem. Therefore, we shall now discuss some other approaches to compute solutions very efficiently if there is no saturation at the upper level.

4. Optimal and suboptimal switching time sequences for systems with saturation at a lower level only.

4.1. Optimal switching time sequences.

In this section we consider systems with saturation at the lower level only. So $b_{i,k}^{\mathrm{us}}$ is equal to ∞ for all i, k, or equivalently $(q_{\max,k})_i \leqslant b_{i,k}^{\mathrm{us}}$ for all i, k. We also assume that $q_{\min,k} \leqslant b_k^{\mathrm{ls}}$ for all k, i.e., we do not impose extra lower bound conditions on the queue lengths. The optimal switching problem (13)–(18) then reduces to

$$\underset{x_\delta}{\text{minimize}}\ J \tag{30}$$

subject to

$$\delta_k = \delta_{k-K_{\mathrm{c}}} \quad \text{for } k = N_{\mathrm{c}}, N_{\mathrm{c}}+1, \ldots, N_{\mathrm{p}}-1, \tag{31}$$

$$\delta_{\min,k} \leqslant \delta_k \leqslant \delta_{\max,k} \quad \text{for } k = 0, 1, \ldots, N_{\mathrm{c}}-1, \tag{32}$$

$$q_{k+1} \leqslant q_{\max,k} \quad \text{for } k = 0, 1, \ldots, N_{\mathrm{p}}-1, \tag{33}$$

$$q_{k+1} = \max(q_k + \alpha_k\delta_k,\, b_k^{\mathrm{ls}}) \quad \text{for } k = 0, 1, \ldots, N_{\mathrm{p}}-1. \tag{34}$$

We call this problem $\mathcal{P}$. We define the "relaxed" problem $\tilde{\mathcal{P}}$ corresponding to $\mathcal{P}$ as

$$\underset{x_q, x_\delta}{\text{minimize}}\ J \tag{35}$$

subject to

$$\delta_k = \delta_{k-K_{\mathrm{c}}} \quad \text{for } k = N_{\mathrm{c}}, N_{\mathrm{c}}+1, \ldots, N_{\mathrm{p}}-1, \tag{36}$$

$$\delta_{\min,k} \leqslant \delta_k \leqslant \delta_{\max,k} \quad \text{for } k = 0, 1, \ldots, N_{\mathrm{c}}-1, \tag{37}$$

$$q_{k+1} \leqslant q_{\max,k} \quad \text{for } k = 0, 1, \ldots, N_{\mathrm{p}}-1, \tag{38}$$

$$q_{k+1} \geqslant q_k + \alpha_k\delta_k \quad \text{for } k = 0, 1, \ldots, N_{\mathrm{p}}-1, \tag{39}$$

$$q_{k+1} \geqslant b_k^{\mathrm{ls}} \quad \text{for } k = 0, 1, \ldots, N_{\mathrm{p}}-1. \tag{40}$$

Thus compared to the original problem we have replaced (34) by relaxed equations of the form (22)–(23) without taking (24) into account. As a consequence, x_q and x_δ are not directly coupled anymore. The set of feasible solutions of $\tilde{\mathcal{P}}$ is a convex set, whereas the set of feasible solutions of $\mathcal{P}$ is in general not convex since (34) is a nonconvex constraint. Therefore, the relaxed problem $\tilde{\mathcal{P}}$ will in general be easier to solve than the problem $\mathcal{P}$.

The objective function J is a monotonically nondecreasing function of x_q if for every x_δ and for every $\tilde{x}_q, \hat{x}_q$ with $\tilde{x}_q \leqslant \hat{x}_q$, we have $J(\tilde{x}_q, x_\delta) \leqslant J(\hat{x}_q, x_\delta)$. The following proposition shows that for monotonically nondecreasing objective functions any optimal solution of the relaxed problem $\tilde{\mathcal{P}}$ can be transformed into an optimal solution of the problem $\mathcal{P}$.

PROPOSITION 4.1. *Let the objective function J be a monotonically nondecreasing function of x_q and let (x_q^*, x_δ^*) be an optimal solution of $\tilde{\mathcal{P}}$. If we construct $x_q^\sharp$ such that*

$$q_1^\sharp = \max(q_0 + \alpha_0\delta_0^*, b_0^{\mathrm{ls}}), \tag{41}$$

$$q^\sharp_{k+1} = \max(q^\sharp_k + \alpha_k \delta^*_k, b^{\mathrm{ls}}_k) \qquad \textit{for } k = 1, 2, \ldots, N_\mathrm{p} - 1, \tag{42}$$

then $(x^\sharp_q, x^*_\delta)$ *is an optimal solution of the problem* $\mathcal{P}$.

Proof. Let (x^*_q, x^*_δ) be an optimal solution of $\tilde{\mathcal{P}}$ and let $x^\sharp_q$ be defined by (41)–(42). Clearly, $(x^\sharp_q, x^*_\delta)$ is a feasible solution of $\tilde{\mathcal{P}}$. Define $q^*_0 = q^\sharp_0 = q_0$. Since x^*_q satisfies (39)–(40), we have $\max(q^*_k + \alpha_k \delta^*_k, b^{\mathrm{ls}}_k) \leqslant q^*_{k+1}$ for all k. Since $q^*_0 = q^\sharp_0$, this implies that $q^\sharp_1 \leqslant q^*_1$ and, by induction, also that $q^\sharp_k \leqslant q^*_k$ for $k = 2, 3, \ldots, N_\mathrm{p}$. As a consequence, we have $x^\sharp_q \leqslant x^*_q$ and thus also $J(x^\sharp_q, x^*_\delta) \leqslant J(x^*_q, x^*_\delta)$ since J is a monotonically nondecreasing function of x_q. Since $(x^\sharp_q, x^*_\delta)$ is a feasible solution of $\tilde{\mathcal{P}}$ and since (x^*_q, x^*_δ) is an optimal solution of $\tilde{\mathcal{P}}$, this implies that $(x^\sharp_q, x^*_\delta)$ is also an optimal solution of $\tilde{\mathcal{P}}$.

The set of feasible solutions of $\mathcal{P}$ is a subset of the set of feasible solutions of $\tilde{\mathcal{P}}$. Hence, the minimal value of J over the set of feasible solutions of $\tilde{\mathcal{P}}$ will be less than or equal to the minimal value of J over the set of feasible solutions of $\mathcal{P}$. Since $(x^\sharp_q, x^*_\delta)$ is a feasible solution of $\mathcal{P}$ and an optimal solution of $\tilde{\mathcal{P}}$, this implies that $(x^\sharp_q, x^*_\delta)$ is an optimal solution of $\mathcal{P}$. □

Recall that the objective functions J_1, J_2, J_3, J_4, and J_5 do not explicitly depend on x_q, since x_q can be computed from x_δ (and eliminated from the expressions for the objective functions before considering the relaxation of $\mathcal{P}$). So we have $J_l(\tilde{x}_q, x_\delta) = J_l(\hat{x}_q, x_\delta)$ for any $\tilde{x}_q, \hat{x}_q$ and for $l \in \{1, 2, 3, 4, 5\}$. This implies that J_1, J_2, J_3, J_4, and J_5 are monotonically nondecreasing functions of x_q. So we can use Proposition 4.1 to transform the optimal switching problem for the objective functions J_1 up to J_5 into an optimization problem with a convex feasible set. The resulting (global) solution of the relaxed problem can then be transformed into an optimal switching scheme using (41)–(42). Note, however, that although the feasible set of the relaxed problem is convex, the objective functions J_1 up to J_5 are not convex, so that the overall problem is still nonconvex (and thus in general not easily solvable). Therefore, we now introduce two subsequent approximations of the objective functions J_1 and J_4 that will lead to a linear programming problem, which can be solved very efficiently. The resulting solution can then be used as an initial starting point for the optimization of the relaxed problem.

4.2. A linear programming approximation.

The objective function J is a monotonically increasing function of x_q if for every x_δ and for every $\tilde{x}_q, \hat{x}_q$ with $\tilde{x}_q \leqslant \hat{x}_q$ and $\tilde{x}_q \neq \hat{x}_q$, we have $J(\tilde{x}_q, x_\delta) < J(\hat{x}_q, x_\delta)$. The optimal solution of $\tilde{\mathcal{P}}$ will in general not be a feasible solution of $\mathcal{P}$ unless J is a monotonically increasing function of x_q.

PROPOSITION 4.2. *If J is a monotonically increasing function of x_q, then any optimal solution of the relaxed problem $\tilde{\mathcal{P}}$ is also an optimal solution of the problem $\mathcal{P}$.*

Proof. Let (x^*_q, x^*_δ) be an optimal solution of $\tilde{\mathcal{P}}$ and construct $(x^\sharp_q, x^*_\delta)$ as in the proof of Proposition 4.1. So $x^\sharp_q \leqslant x^*_q$ and $(x^\sharp_q, x^*_\delta)$ is also a feasible solution of $\tilde{\mathcal{P}}$.

Now we show by contradiction that (x^*_q, x^*_δ) is also a feasible solution of $\mathcal{P}$, i.e., that it satisfies (34). Suppose that (x^*_q, x^*_δ) does not satisfy (34). So $x^\sharp_q \neq x^*_q$. Since $x^\sharp_q \leqslant x^*_q$, this implies that $J(x^\sharp_q, x^*_\delta) < J(x^*_q, x^*_\delta)$, which would mean that (x^*_q, x^*_δ) is not an optimal solution of $\tilde{\mathcal{P}}$. Since this is a contradiction, our initial assumption that (x^*_q, x^*_δ) does not satisfy (34) was wrong. Hence, $(x^*_q,\, x^*_\delta)$ also is a feasible solution of the problem $\mathcal{P}$. Since the set of feasible solutions of $\mathcal{P}$ is a subset of the set of feasible solutions of $\tilde{\mathcal{P}}$, this implies that $(x^*_q,\, x^*_\delta)$ is also an optimal solution of $\mathcal{P}$. □

Note that the objective functions J_1, J_2, J_3, J_4, and J_5 are not monotonically increasing functions of x_q. Now we introduce some approximations to the objective functions J_1 and J_4 that are strictly monotonically increasing functions of x_q and for which Proposition 4.2 can be used.[7] This will lead to suboptimal switching time sequences that can be computed very efficiently. We will consider only the approximations for J_1, but for J_4 a similar reasoning can be made.

For a given q_0 and t_0, we define the function $\tilde{q}_i(\cdot, x_q, x_\delta)$ as the piecewise-affine function with breakpoints $(t_k, q_{i,k})$ for $k = 0, 1, \ldots, N_\mathrm{p}$. The approximate objective function $\tilde{J}_1$ is also defined by (8) but with q_i replaced by $\tilde{q}_i$. The value of the objective functions J_1 and $\tilde{J}_1$ depends on the surface under the functions q_i and $\tilde{q}_i$, respectively.[8] If we are computing optimal traffic switching sequences, then the surface under the function $\tilde{q}_i$ will be a reasonable approximation of the surface under the function q_i and then the optimal value of $\tilde{J}_1$ will be a reasonably good approximation of the optimal value of J_1 (see also [6, 8]). Note that the values of J_1 and $\tilde{J}_1$ coincide if there is no saturation in the period under consideration. Since $\tilde{q}_i$ is a piecewise-affine with breakpoints $(t_k, q_{i,k})$ for $k = 0, 1, \ldots, N_\mathrm{p}$, we have [6]

$$\tilde{J}_1(x_q, x_\delta) = \sum_{i=1}^{M} \left(\frac{w_i}{2(\delta_0 + \delta_1 + \cdots + \delta_{N_\mathrm{p}-1})} \sum_{k=0}^{N_\mathrm{p}-1} \delta_k (q_{i,k} + q_{i,k+1}) \right), \tag{43}$$

where $\delta_{N_\mathrm{c}}, \ldots, \delta_{N_\mathrm{p}-c}$ can be replaced using (7). Since $\delta_k > 0$ for all k, $\tilde{J}_1$ is a monotonically increasing function of x_q, which implies that Proposition 4.2 can be applied.

Now we discuss a further approximation of $\tilde{J}_1$ that will lead to a linear programming problem, which can be solved very efficiently. Sometimes we already have a good idea about the relative lengths of the different phases (in a traffic signal situation we know, e.g., that the green phases will be much longer than the amber phases). If we assume that $\delta_k = \rho_k \bar{\delta}$ for all k and for some yet unknown $\bar{\delta}$, then (43) leads to

$$\tilde{J}_1(x_q, x_\delta) = \sum_{i=1}^{M} \frac{w_i}{2\rho_\mathrm{tot}} \left(\rho_0 q_{i,0} + \sum_{k=1}^{N_\mathrm{p}-1} (\rho_k + \rho_{k-1}) q_{i,k} + \rho_{N-1} q_{i,N_\mathrm{p}} \right) \overset{\mathrm{def}}{=} \hat{J}_1(x_q),$$

with $\rho_\mathrm{tot} = \rho_0 + \rho_1 + \cdots + \rho_{N_\mathrm{p}-1}$. Note that $\hat{J}_1$ is an affine function of x_q. Since $w_i > 0$ for all i and $\rho_k > 0$ for all k, $\hat{J}_1$ is a monotonically increasing function of x_q. Hence, by Proposition 4.2 any optimal solution of $\tilde{\mathcal{P}}$ with objective function $\hat{J}_1$ will also be an optimal solution of $\mathcal{P}$ (with objective function $\hat{J}_1$). So the optimal switching problem then reduces to a linear programming problem, which can be solved efficiently using a simplex or an interior point method.

Remark 4.3. The values of the ρ_k's are usually determined on the basis of an educated guess. Alternatively, if we have already performed an MPC step, then we can use the shifted values of the δ_k's of the previous MPC step to obtain an initial guess for the current ρ_k's. Furthermore, we could also use an iterative procedure in which we first select values for the ρ_k's, compute the optimal solution, use the resulting δ_k's to determine new values for the ρ_k's, after which we can again compute the optimal solution, and so on.

[7] This derivation is an extension of our work in [8] where we have considered a special subclass of first order linear hybrid systems with saturation at the lower level only. Although we did not yet use Proposition 4.1 there, we did use a proposition that is similar to Proposition 4.2.

[8] Recall that $q_i(t) \geqslant 0$ for all i, t since we have assumed that $b^{\mathrm{ls}}_{i,k} \geqslant 0$ for all i, k.

TABLE 1
The traffic signal switching scheme.

Period	T_1, T_3	T_2, T_4
t_0–t_1	red	green
t_1–t_2	red	amber
t_2–t_3	green	red
t_3–t_4	amber	red
t_4–t_5	red	green
t_5–t_6	red	amber
⋮	⋮	⋮

Also note that the assumption on the relative lengths ($\delta_k = \rho_k \bar{\delta}$ for all k) is only used to simplify the objective function; it will not be included explicitly in the linear programming problem. So the variables in this problem are still x_q and x_δ, but the objective depends only on x_q. As a consequence, the optimal δ_k's will in general not satisfy the assumption on the relative lengths (see, e.g., the example of section 5.2).

5. Application: Optimal traffic signal control.

5.1. Optimal traffic signal control. In order to illustrate the effectiveness of Proposition 4.1 we shall use the different approaches presented in this paper to design an optimal switching time sequence for a traffic signal controlled intersection and compare the results.

Consider an intersection of two two-way streets (see Figure 1) with lanes L_i and a traffic signal T_i on each corner of the intersection ($i = 1, 2, 3, 4$). The switching time sequence for the intersection is given in Table 1. Since queue lengths can never become negative and since all the cars can leave a queue provided that we make the length of the green phase large enough, we have $b_k^{\text{ls}} = 0$ for all k. We assume that there is no saturation at the upper level, either due to the fact that there is enough buffer space before the traffic signal in each lane or due to the fact that we impose additional maximal queue length conditions such that $q_{\max,k} \leqslant b_k^{\text{us}}$.

In order to obtain a model that is amenable to mathematical analysis, we shall make two extra assumptions (see also [8]):

(i) the queue lengths are continuous variables,

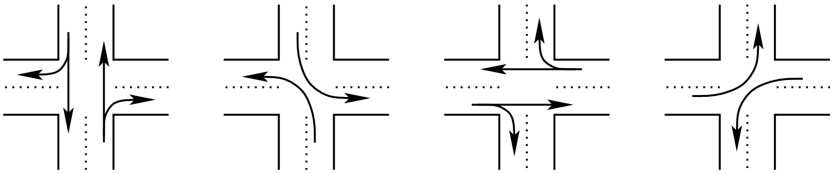

FIG. 2. *The four main phases of a more complex traffic signal switching scheme. The arrows indicate possible directions for the cars that receive a green signal.*

(ii) the average arrival and departure rates of the cars are constant or slowly time-varying.

These assumptions deserve a few remarks:

(i) Recall that the main purpose is to compute optimal traffic signal switching time sequences. Designing optimal switching time sequences is useful only if the arrival and departure rates of vehicles at the intersection are high since then the queue lengths will in general also be large and then approximating the queue lengths by continuous variables will introduce only small errors.

(ii) If we keep in mind that one of the main purposes of the model that we shall derive is the design of optimal traffic signal switching time sequences, then assuming that the average arrival and departure rates are constant is not a serious restriction provided that we use an MPC approach in which we can regularly update the estimates of the arrival and departure rates and of the state of the system.

Let α_i^{a} be the average arrival rate of cars in lane L_i, and let $\alpha_i^{\mathrm{d,green}}$ and $\alpha_i^{\mathrm{d,amber}}$ be the departure rates of cars in lane L_i when the traffic signal T_i is green, respectively, amber. If we define

$$\alpha_{i,k} = \begin{cases} \alpha_i^{\mathrm{a}} & \text{if } T_i \text{ is red in } (t_k, t_{k+1}), \\ \alpha_i^{\mathrm{a}} - \alpha_i^{\mathrm{d,green}} & \text{if } T_i \text{ is green in } (t_k, t_{k+1}), \\ \alpha_i^{\mathrm{a}} - \alpha_i^{\mathrm{d,amber}} & \text{if } T_i \text{ is amber in } (t_k, t_{k+1}) \end{cases}$$

for all i, k, then the relation between the switching time instants and the queue lengths is described by a system of equations of the form

$$\frac{dq_i(t)}{dt} = \begin{cases} \alpha_{i,k} & \text{if } b_{i,k}^{\mathrm{ls}} < q_i(t), \\ 0 & \text{otherwise.} \end{cases}$$

Thus the system can be considered as a first order linear hybrid system with lower saturation only. Hence, we can use the techniques presented in sections 3.2 and 4 to compute optimal and suboptimal traffic signal switching schemes.

In the simple traffic signal set-up discussed above we did not make a distinction between cars that turn left, right, or that go straight ahead. However, the approach presented in this paper can also be applied to more complex set-ups or more complex traffic signal switching schemes for single intersections such as, e.g., the one depicted in Figure 2 which consists of four main phases with amber phases in between, where in the first main phase cars on the north-south axis can go straight ahead or turn right, in the next main phase they can turn left, and in the next two main phases the same process is repeated for the traffic on the east-west axis.

5.2. Worked example. The following traffic signal control example illustrates that using Proposition 4.1 leads to efficient computation of optimal switching time sequences and that the approximations introduced in section 4.2 lead to reasonably good suboptimal solutions. Since we are mainly interested in the computation times, we will consider only one step of the MPC algorithm. All times will be expressed in seconds and all rates in vehicles per second. The numerical results will be given up to two decimal places.

Consider the intersection of Figure 1 with the switching scheme of Table 1 and with the following data: $N_\mathrm{p} = 14$, $N_\mathrm{c} = 8$, $\alpha_1^\mathrm{a} = 0.23$, $\alpha_2^\mathrm{a} = 0.12$, $\alpha_3^\mathrm{a} = 0.19$, $\alpha_4^\mathrm{a} = 0.11$, $\alpha_1^\mathrm{d,green} = 0.50$, $\alpha_2^\mathrm{d,green} = \alpha_4^\mathrm{d,green} = 0.35$, $\alpha_3^\mathrm{d,green} = 0.45$, $\alpha_1^\mathrm{d,amber} = \alpha_3^\mathrm{d,amber} = 0.03$, $\alpha_2^\mathrm{d,amber} = \alpha_4^\mathrm{d,amber} = 0.02$, $q_0 = [\,17 \;\; 12 \;\; 14 \;\; 8\,]^T$, and $q_{\max,k} = [\,20 \;\; 15 \;\; 20 \;\; 15\,]^T$ for all k. Since a green-amber-red cycle consists of four consecutive phases (see Table 1) we set $K_\mathrm{c} = 4$.

We want to compute a traffic signal switching sequence $t_0, t_1, \dots, t_{N_\mathrm{c}-1}$ that minimizes J_1 with $w = [\,2 \;\; 1 \;\; 2 \;\; 1\,]^T$. The minimum and maximum length of the green phases are, respectively, 9 and 90. Note that for the simple setup of this example and for the objective function J_1 it does not make sense to consider a varying amber duration since during the amber phases the average queue length always increases, which implies that the optimal duration of the amber phases in this case will always be equal to the given lower bound for the amber phase. Therefore, we fix the length of the amber phase by setting the minimal and the maximal length of the amber phases equal to 3.

We have computed an optimal switching interval vector $x^*_{\delta,\mathrm{elcp}}$ using the ELCP method, a suboptimal switching vector $x^*_{\delta,\mathrm{nlcon}}$ using constrained optimization with nonlinear constraints,[9] and a suboptimal solution $x^*_{\delta,\mathrm{penalty}}$ using constrained optimization[10] with a quadratic penalty function for queue lengths that exceed $q_{\max,k}$. Based on Propositions 4.1 and 4.2 we have computed a solution $x^*_{\delta,\mathrm{relaxed}}$ that minimizes J_1 for the relaxed problem $\tilde{\mathcal{P}}$ and a solution $x^*_{\delta,\mathrm{approx}}$ that minimizes the approximate objective function $\tilde{J}_1$ for the relaxed problem $\tilde{\mathcal{P}}$. Finally, we computed a switching interval vector $x^*_{\delta,\mathrm{lp}}$ that minimizes $\hat{J}_1$ for the relaxed problem $\tilde{\mathcal{P}}$ with the affine objective function obtained by assuming that for the east-west axis the length of the green phases is 1.5 times the length of the red phases and 10 times the length of the amber phases. (Note that this is just a rough guess.)

We have used the sequential quadratic programming function `e04ucc` of the NAG C Library for the nonlinear optimizations. To solve the linear programming problem we have used the function `e04mfc` of the NAG C library, which uses an active set method.

In Table 2 we have listed the value of the objective functions J_1, $\tilde{J}_1$, and $\hat{J}_1$ for the various switching interval vectors and the CPU time needed to compute the switching interval vectors on a Pentium II 300 MHz PC running Linux and with 64 MB RAM. The CPU time values listed in the table are average values over 10 experiments.[11] All the routines used in the computations either have been implemented in C or were

[9] We give the best solution over 20 runs with random initial points. Only 14 runs resulted in a feasible solution. For these 14 runs the mean of the objective values of the local minima returned by the minimization routine was 48.50 with a standard deviation of 3.38.

[10] We give the best solution over 10 runs with random initial points. For the 9 runs that resulted in a feasible solution, the mean of the objective values was 46.45 with a standard deviation of 0.08.

[11] For $x^*_{\delta,\mathrm{nlcon}}$ we have listed the CPU time needed for 20 runs with random initial points and for $x^*_{\delta,\mathrm{penalty}}$ we have listed the CPU time needed for 10 runs with random initial points (see also footnotes 9 and 10). Note, however, that even for a single run the average CPU time needed for these solutions is much higher that the CPU time needed for the $x^*_{\delta,\mathrm{relaxed}}$ solutions.

TABLE 2

The values of the objective functions J_1, $\tilde{J}_1$, and $\hat{J}_1$, and the CPU time needed to compute the (sub-)optimal switching vectors of the example of section 5.2.

x_δ^*	$J_1(x_\delta^*)$	$\tilde{J}_1(x_\delta^*)$	$\hat{J}_1(x_\delta^*)$	CPU time
$x_{\delta,\mathrm{elcp}}^*$	46.41	49.05	53.66	64 619.07
$x_{\delta,\mathrm{nlcon}}^*$	46.41	49.05	53.66	216.71
$x_{\delta,\mathrm{penalty}}^*$	46.41	49.05	53.66	29.71
$x_{\delta,\mathrm{relaxed}}^*$	46.41	49.05	53.66	0.36
$x_{\delta,\mathrm{approx}}^*$	46.41	49.05	53.66	3.56
$x_{\delta,\mathrm{lp}}^*$	46.63	49.12	53.62	0.16

compiled to object code. As a consequence, all the CPU times can be considered as a measure for the number of floating point operations that were needed to compute the various (sub-)optimal switching interval vectors.

Note that the optimal values of J_1 and $\tilde{J}_1$ differ by about 5 %, so that in this case the optimal value of $\tilde{J}_1$ is indeed a reasonably good approximation of the optimal value of J_1. While computing $x_{\delta,\mathrm{relaxed}}^*$ we have only N_c optimization variables (i.e., the δ_k's, since the q_k's do not appear in the objective function and since they can be eliminated from the constraints). However, for $x_{\delta,\mathrm{approx}}^*$ we have $N_\mathrm{c}+MN_\mathrm{p}$ optimization variables (i.e., the δ_k's and the components of the q_k's since in this case the q_k's appear in the objective function and thus cannot be eliminated). This is one of the reasons why the computation of $x_{\delta,\mathrm{relaxed}}^*$ requires less CPU time than the computation of $x_{\delta,\mathrm{approx}}^*$. Additional numerical experiments and simulations can be found in [6].

In this example the ELCP solution is only given as a reference since the CPU time needed to compute the optimal switching interval vector using the ELCP algorithm of [7] increases exponentially as M, N_p, or N_c increase (see also [6]). This implies that the ELCP approach should never be used in practice, but one of the other approaches should be used instead.

If we look at Table 2, then we see that the $x_{\delta,\mathrm{relaxed}}^*$ solution—which is based on Proposition 4.1—is clearly the most interesting. If we take the trade-off between optimality and efficiency into account, the $x_{\delta,\mathrm{relaxed}}^*$ solution outperforms the solutions obtained using the other approaches (see also [6]).

If we use an MPC approach, then the computation time required for the $x_{\delta,\mathrm{relaxed}}^*$ solution is less than the minimum lower bound for the phase lengths, which implies that we can first measure the queue lengths at t_0 and start the computation at time t_0. In that way we can use the exact initial state q_0. Note that using the exact initial state q_0 (or a good estimate) also introduces a kind of feedback in the control loop.

6. Conclusions and future research. We have considered the determination of optimal switching time sequences for a class of first order linear hybrid systems subject to saturation. First we have introduced the ELCP and indicated how it can be used to describe the set of feasible system trajectories for a first order linear hybrid system with saturation. Optimization over the solution set of the ELCP then yields the optimal switching time sequence. Since the ELCP is NP-hard, we have also discussed several other techniques to compute optimal and suboptimal switching time sequences for first order linear hybrid systems subject to saturation at the lower level only. We have shown that if the objective function is a monotonically nondecreasing function of the queue lengths, then the optimal switching problem can be transformed into an optimization problem with a convex feasible set and then the optimal switching time sequence can be computed more efficiently. By making some approximations, the optimal switching problem can even be transformed into a linear programming problem. We have illustrated these approaches by computing (sub-)optimal switching time sequences for a traffic signal controlled intersection. Since the time required for the computations using the most efficient approach is less than the minimum time between two consecutive switchings, our method can be used in a model predictive control framework in which the model of the system and the optimal switching sequence are re-estimated or recomputed after each switching.

In this paper we have derived methods to optimize quantitative performance measures such as average or worst case waiting times and queue lengths for a linear hybrid system with saturation. If we are more interested in qualitative properties such as, e.g., safety, we could use the techniques presented in [18].

An important topic for future research is the extension of the results obtained in this paper to networks of dependent queues, i.e., a situation where the outputs of some queues will be connected to the inputs of some other queues. If we use an MPC strategy in combination with a *decentralized control* solution, we can still apply the approach given in this paper: if we know or measure all routing rates[12] and all traveling times from one queue to another, we can use measurements from one queue to predict the arrival rates at the other queues. Other topics for further research include development of other efficient algorithms and/or approximations to compute optimal switching time sequences for first order linear hybrid systems with saturation, investigation of the use of the ELCP to model and to control other classes of hybrid systems, and extension of the results presented in this paper to more general classes of hybrid systems.

Acknowledgment. We would like to thank the anonymous referees for their useful suggestions and comments, which have certainly contributed to improving the presentation of the paper.

A BAYES FORMULA FOR GAUSSIAN NOISE PROCESSES AND ITS APPLICATIONS*

PRANAB K. MANDAL† AND V. MANDREKAR‡

Abstract. An elementary approach is used to derive a Bayes-type formula, extending the Kallianpur–Striebel formula for the nonlinear filters associated with the Gaussian noise processes. In the particular cases of certain Gaussian processes, recent results of Kunita and of Le Breton on fractional Brownian motion are derived. We also use the classical approximation of the Brownian motion by the Ornstein–Uhlenbeck dispersion process to solve the "instrumentability" problem of Balakrishnan. We give precise conditions for the convergence of the filter based on the Ornstein–Uhlenbeck dispersion process to the filter based on the Brownian motion. It is also shown that the solution of the Zakai equation can be approximated by that of a (deterministic) partial differential equation.

1. Introduction.

The general filtering problem can be described as follows. The *signal* or *system process* $(X_t, 0 \le t \le T)$ is unobservable. Information about (X_t) is obtained by observing another process Y which is a function of X corrupted by noise, i.e.,

$$Y_t = \beta_t + N_t, \quad 0 \le t \le T, \tag{1.1}$$

where β_t is measurable with respect to $\mathcal{F}_t^X$, the σ-field generated by the signal $\{X_u,\ 0 \le u \le t\}$ (augmented by the inclusion of zero probability sets), and (N_t) is some noise process. The observation σ-field $\mathcal{F}_t^Y = \sigma\{Y_u,\ 0 \le u \le t\}$ contains all the available information about X_t. The primary aim of filtering theory is to get an estimate of X_t based on the information $\mathcal{F}_t^Y$. This is given by the conditional distribution ν_t of X_t given $\mathcal{F}_t^Y$, or equivalently, the conditional expectation $E(f(X_t)|\mathcal{F}_t^Y)$ for a rich enough class of functions f. Since this estimate minimizes the squared error loss, ν is called the *optimal filter.*

In the classical case one considers the observation model

$$dY_t = h(t, X_t)\,dt + dW_t, \tag{1.2}$$

where W is the Wiener process independent of X and h satisfies the conditions for the Girsanov theorem (for details, see [10]). Kallianpur and Striebel [12] derived a Bayes-type formula for the conditional distribution ν_t of the form $\nu_t = \frac{\sigma_t}{\langle \sigma_t, 1\rangle}$, where σ_t is the so-called unnormalized conditional distribution. In the case when the signal process X_t is a Markov process, satisfying the SDE

$$dX_t = A(t, X_t)\,dt + B(t, X_t)\,d\tilde{W}_t,$$

where $\tilde{W}$ is another Wiener process independent of W, Zakai [20] showed that σ_t is the unique solution of a measure valued stochastic differential equation. It is also known that the filter $\mathcal{V}_t$ satisfies a stochastic differential equation widely known as the *Kushner* or *FKK* equation (see, e.g., [14] and [8]).

That the noise process (N_t) is a Wiener process plays an important part in deriving all of the above equations and formulas. However, in the real physical system, the noise process (N_t) may not be exactly a Wiener process. In this case no effective way of computing the filter is known. In a recent paper Kunita [13] considered the filtering problem with the observation process

$$Y_t = \int_0^t h(X_s)\, ds + N_t,$$

where N_t is a particular Gaussian process connected to W_t by a kernel. He derived a Bayes-type formula extending the one by Kallianpur and Striebel. We generalize this result to any Gaussian noise process N_t with β in the model (1.1) belonging almost surely (a.s.) to the reproducing kernel Hilbert space (RKHS) of the covariance of (N_t). It should be noted that this result with a modified Kallianpur–Striebel proof was first obtained by one of the authors [19]. However, the proof presented here is entirely new and is based on an extension of a one-dimensional result which makes (Y_t), under a change of measure, Gaussian with the same distribution as that of (N_t) and independent of (X_t). As an immediate consequence we get the result of Kunita and Kallianpur and Striebel with a simple proof.

In case (X_t) is a diffusion process, one can attempt to obtain a Zakai-type equation whose solution gives a recursive form of the filter. Unfortunately, in the full generality of the problem, it does not seem easy to even formulate such an equation. However, we have indicated how to obtain such an equation for the Ornstein–Uhlenbeck dispersion process. We have partial results in this direction for the case of Kunita and that of the fractional Brownian motion (fBm). The solution of these equations requires new methods. We shall present this work elsewhere once it becomes complete.

Recently, stochastic models appropriate for long-range dependent phenomena have been given a great deal of interest and numerous theoretical resets and successful applications have been already reported (see, e.g., Beran [4] and references therein). In this view we consider the filtering problem with the fBm noise process. We obtain a general form of the filter in this case. In particular, if $X_t = \eta$ for all t, then we obtain all the results in [6] under his assumptions.

We also discuss the issue raised by Balakrishnan [2] regarding "instrumenting" the filtering problem. An approach to this problem using finitely additive measures was given by Kallianpur and Karandikar in their well-known monograph [11]. They work on the Cameron–Martin space with a finitely additive measure and approximate the filter through an extension. Our method is to follow the classical approach of physics; namely, to approximate the Wiener noise process by the Ornstein–Uhlenbeck dispersion process (see, e.g., Nelson [16]). Using our Bayes formula we show that the usual filtering theory with the Wiener process can be obtained as a limit. The latter uses the ideas of Kunita [13] on stability. We give here the precise conditions for the validity of stability. It should be observed that the theory with the Ornstein–Uhlenbeck dispersion process can be instrumented. We approximate the dispersion process by neglecting a term of order σ^{-1} for σ large (cf. (6.15)) and for this process we obtain a Zakai equation which can be approximated by an ordinary partial differential equation.

The article is organized as follows. In section 2, we give a brief overview of RKHS and its connection with stochastic processes. The extension of the Kallianpur–Striebel formula is obtained in section 3. We discuss Kunita's result in section 4. Section 5 deals with the filtering problem with the fBm as the noise process. Finally, in section 6, the filtering problem corresponding to the Ornstein–Uhlenbeck dispersion noise process is considered along with its limit.

2. Reproducing kernel Hilbert space and stochastic processes. A Hilbert space H consisting of real-valued functions on some set $\mathbf{T}$ is said to be an RKHS if there exists a function K on $\mathbf{T}\times\mathbf{T}$ with the following two properties: for every t in $\mathbf{T}$ and g in H,

(i) $K(\cdot,t)\in H$,

(ii) $(g(\cdot),K(\cdot,t))=g(t)$ (the reproducing property).

K is called the *reproducing kernel* of H. The following basic properties can be found in Aronszajn [1].

(1^o) If a reproducing kernel exists, then it is unique.

(2^o) If K is the reproducing kernel of H, then $\{K(\cdot,t),t\in\mathbf{T}\}$ spans H.

(3^o) If K is the reproducing kernel of H, then it is nonnegative definite in the sense that for all $t_1,\dots,t_n$ in $\mathbf{T}$ and $a_1,\dots,a_n\in\mathbb{R}$

$$\sum_{i,j=1}^{n} K(t_i,t_j)a_ia_j \;\geq\; 0.$$

The converse of (3^o), stated in Theorem 2.1 below, is fundamental toward understanding the RKHS representation of Gaussian processes. A proof of the theorem can be found in Aronszajn [1].

THEOREM 2.1 (E. H. Moore). *A symmetric nonnegative definite function K on $\mathbf{T}\times\mathbf{T}$ generates a unique Hilbert space, which we denote by $H(K)$ or sometimes by $H(K,\mathbf{T})$, of which K is the reproducing kernel.*

Now suppose $K(s,t),\ s,t\in\mathbf{T}$, is a nonnegative definite function. Then, by Theorem 2.1, there is an RKHS, $H(K,\mathbf{T})$, with K as its reproducing kernel. If we restrict K to $\mathbf{T}'\times\mathbf{T}'$ where $\mathbf{T}'\subset\mathbf{T}$, then K is still a nonnegative definite function. Hence K restricted to $\mathbf{T}'\times\mathbf{T}'$ will also correspond to an RKHS $H(K,\mathbf{T}')$ of functions defined on $\mathbf{T}'$. The following result from Aronszajn [1, p. 351] explains the relationship between these two.

THEOREM 2.2. *Suppose $K_{\mathbf{T}}$, defined on $\mathbf{T}\times\mathbf{T}$, is the reproducing kernel of the Hilbert space $H(K_{\mathbf{T}})$ with the norm $\|\cdot\|$. Let $\mathbf{T}'\subset\mathbf{T}$, and $K_{\mathbf{T}'}$ be the restriction of $K_{\mathbf{T}}$ on $\mathbf{T}'\times\mathbf{T}'$. Then $H(K_{\mathbf{T}'})$ consists of all f in $H(K_{\mathbf{T}})$ restricted to $\mathbf{T}'$. Further, for such a restriction $f'\in H(K_{\mathbf{T}'})$ the norm $\|f'\|_{H(K_{\mathbf{T}'})}$ is the minimum of $\|f\|_{H(K_{\mathbf{T}})}$ for all $f\in H(K_{\mathbf{T}})$ whose restriction to $\mathbf{T}'$ is f'.*

If $K(s,t)$ is the covariance function for some zero mean process $Z_t,t\in\mathbf{T}$, then, by Theorem 2.1, there exists a unique RKHS, $H(K,\mathbf{T})$, for which K is the reproducing kernel. It is also easy to see (e.g., see Theorem 3D in [18]) that there exists a congruence (linear, one-to-one, inner product preserving map) between $H(K)$ and $\overline{\mathrm{sp}}^{L^2}\{Z_t,t\in\mathbf{T}\}$ which takes $K(\cdot,t)$ to Z_t. Let us denote by $\langle Z,h\rangle\in\overline{\mathrm{sp}}^{L^2}\{Z_t,t\in\mathbf{T}\}$ the image of $h\in H(K,\mathbf{T})$ under the congruence.

We conclude the section with an important special case.

2.1. A useful example. Suppose the stochastic process Z_t is a Gaussian process given by

$$Z_t = \int_0^t F(t,u) dW_u, \ 0 \le t \le T,$$

where $\int_0^t F^2(t,u)du < \infty$ for all $0 \le t \le T$. Then the covariance function

$$K(s,t) \equiv E(Z_s Z_t) = \int_0^{t \wedge s} F(t,u)F(s,u)du \tag{2.1}$$

and the corresponding RKHS is given by

$$H(K) = \left\{ g : g(t) = \int_0^t F(t,u)g^*(u)du, 0 \le t \le T \right\} \tag{2.2}$$

for some (necessarily unique) $g^* \in \overline{\text{sp}}^{L^2}\{F(t,\cdot)1_{[0,t]}(\cdot), 0 \le t \le T\}$ with the inner product

$$(g_1, g_2)_{H(K)} = \int_0^T g_1^*(u) g_2^*(u) du,$$

where

$$g_1(s) = \int_0^s F(s,u)g_1^*(u)du \quad \text{and} \quad g_2(s) = \int_0^s F(s,u)g_2^*(u)du.$$

For $0 \le t \le T$, by taking $K(\cdot,t)^*$ to be $F(t,\cdot)1_{[0,t]}(\cdot)$, we see, from (2.1) and (2.2), that $K(\cdot,t) \in H(K)$. To check the reproducing property suppose $h(t) = \int_0^t F(t,u)h^*(u)\,du \in H(K)$. Then

$$(h, K(\cdot,t))_{H(K)} = \int_0^T h^*(u)K(\cdot,t)^*\,du = \int_0^t h^*(u)F(t,u)\,du = h(t).$$

Also, in this case, it is very easy to check (cf. [17], Theorem 4D) that the congruence between $H(K)$ and $\overline{\text{sp}}^{L^2}\{Z_t, t \in \mathbf{T}\}$ is given by

$$\langle Z, g \rangle \ = \int_0^T g^*(u) dW_u. \tag{2.3}$$

3. Extension of the Kallianpur–Striebel formula.

Suppose $X_t, 0 \le t \le T$, is a real-valued signal process and the observation process is given by

$$Y_t = \beta(t,X) + N_t, \quad 0 \le t \le T, \tag{3.1}$$

where $\beta : [0,T] \times \mathbb{R}^{[0,T]} \to \mathbb{R}$ is a nonanticipative function and the noise process (N_t) is independent of the signal process (X_t). We are interested in finding the best estimate of $f(X_t)$ based on $\mathcal{F}_t^Y$, which is given by the conditional expectation $E(f(X_t)|\mathcal{F}_t^Y)$. First we consider the one-dimensional analogue of the problem which captures the main idea of obtaining a Bayes-type formula for $E(f(X_t)|\mathcal{F}_t^Y)$.

Let $(\Omega, \mathcal{F}, P)$ be a probability space. Suppose Z is a standard normal random variable independent of X and $Y = X + Z$. Consider the problem of computing $E(X|Y)$. Suppose $P \ll Q$ and $\mathcal{G} \subset \mathcal{F}$ is a sub-σ-field. Then

$$E_P(X|\mathcal{G}) = \frac{E_Q\left(X\, \frac{dP}{dQ}\middle|\, \mathcal{G}\right)}{E_Q\left(\frac{dP}{dQ}\middle|\, \mathcal{G}\right)}.$$

If we define

$$dQ = \exp\left\{-XY + \frac{1}{2}X^2\right\} dP,$$

then Q is a probability measure. Also, considering the joint characteristic function, under Q, of X and Y it is easy to see that under Q, Y is a standard normal random variable independent of X, and X has the same probability distribution as under P.

We now give the analogue of the above-mentioned result for the general Gaussian processes. Suppose N_t is a Gaussian process with zero mean, i.e., $m_t \equiv E(N_t) = 0$ and with the covariance function $R(s,t) \equiv E(N_s N_t)$. Suppose that R is continuous on $[0,T] \times [0,T]$. Let $\{\xi_t, 0 \le t \le T\}$ be another process with values in a space $\mathcal{S}$ and independent of $\{N_t, 0 \le t \le T\}$. Suppose

$$Y_t = f(t, \xi) + N_t, \quad 0 \le t \le T, \tag{3.2}$$

where f is a measurable nonanticipative functional on $[0,T] \times \mathcal{S}^{[0,T]}$.

Let $H(R;t)$ denote the RKHS corresponding to $R|_{[0,t]\times[0,t]}$, with norm $\|\cdot\|_t$ and $H(R) = H(R;T)$. Also, let $\langle N, \cdot\rangle_t$ denote the congruence between $H(R;t)$ and $\overline{\text{sp}}^{L^2}\{N_s, 0 \le s \le t\}$ so that for $g, h \in H(R;t)$, the random variables $\langle N, g\rangle_t$ and $\langle N, h\rangle_t$ are normal random variables with mean zero and covariance $E(\langle N, g\rangle_t\, \langle N, h\rangle_t)$ $= (g,h)_{H(R;t)}$. Then we have the following.

THEOREM 3.1. *Suppose $f(\cdot) \equiv f(\cdot, \xi)$ in* (3.2) *is in $H(R)$ a.s. Define for each t, $(0 \le t \le T)$,*

$$dQ_t = e^{-\langle N, f\rangle_t - \frac{1}{2}\|f\|_t^2} dP. \tag{3.3}$$

Then Q_t is a probability measure, and under Q_t, we have that

(i) *$(Y_s)_{0 \le s \le t}$ is a Gaussian process with zero mean and covariance function R, and is independent of $(\xi_s)_{0 \le s \le T}$;*

(ii) *$(\xi_s)_{0 \le s \le T}$ has the same distribution as under P.*

Remark. It should be noted that, in case (N_t) is the Brownian motion, one can interpret (i) of the theorem as the analogue of the Girsanov theorem except that the functions f are from a smaller class than those considered by Girsanov. The property that Q_t is a probability measure is automatically satisfied in this case due to the independence of the processes (ξ_t) and (N_t). For this one uses the Cameron–Martin result for each fixed value of (ξ_t).

Proof of Theorem 3.1. Fix $0 \le t \le T$. First note that since $f(\cdot) \in H(R)$ a.s., by Theorem 2.2, $f|_{[0,t]} \in H(R;t)$ a.s. That Q_t is a probability measure follows from the fact that N and ξ are independent and for $g \in H(R;t)$, $\langle N, g\rangle_t$ is a zero mean normal random variable with variance $\|g\|_t^2$. Now suppose $0 \le s_1, \dots, s_m \le t$, $0 \le t_1, \dots, t_n \le T$, $g_1, \dots, g_n : \mathcal{S} \to \mathbb{R}$ are measurable, and $\alpha_1, \dots, \alpha_n, \gamma_1, \dots, \gamma_m$ are real numbers. Consider the joint characteristic function

$$\begin{aligned}
&E_{Q_t}\left[e^{i(\alpha_1 g_1(\xi_{t_1})+\cdots+\alpha_n g_n(\xi_{t_n}))+i(\gamma_1 Y_{s_1}+\cdots+\gamma_m Y_{s_m})}\right]\\
&= E_P\left[e^{i\sum_{k=1}^n \alpha_k g_k(\xi_{t_k})+i\sum_{j=1}^m \gamma_j Y_{s_j}}e^{-\langle N,f\rangle_t-\frac{1}{2}\|f\|_t^2}\right]\\
&= E_P\left[e^{i\sum_{k=1}^n \alpha_k g_k(\xi_{t_k})-\frac{1}{2}\|f\|_t^2+i\sum_{j=1}^m \gamma_j f(s_j)}e^{i\sum_{j=1}^m \gamma_j N_{s_j}-\langle N,f\rangle_t}\right]\\
&= E_P\left[e^{i\sum_{k=1}^n \alpha_k g_k(\xi_{t_k})-\frac{1}{2}\|f\|_t^2+i\sum_{j=1}^m \gamma_j f(s_j)}E_P\left(e^{i\sum_{j=1}^m \gamma_j N_{s_j}-\langle N,f\rangle_t}\middle|\mathcal{F}_T^\xi\right)\right]\\
&= E_P\left[e^{i\sum_{k=1}^n \alpha_k g_k(\xi_{t_k})-\frac{1}{2}\|f\|_t^2+i\sum_{j=1}^m \gamma_j f(s_j)}\right.\\
&\qquad\left.\times\, e^{-\sum_{j,l=1}^m \gamma_j\gamma_l R(s_j,s_l)-\frac{1}{2}2i\sum_{j=1}^m \gamma_j f(s_j)+\frac{1}{2}\|f\|_t^2}\right]\\
&= E_P\left[e^{i\sum_{k=1}^n \alpha_k g_k(\xi_{t_k})}\right]e^{-\sum_{j,l=1}^m \gamma_j\gamma_l R(s_j,s_l)}.
\end{aligned}$$

Hence the assertions (i) and (ii) follow. □

Let us now consider the observation process (Y_t) given by (3.1). Suppose that the noise process (N_t) is Gaussian with continuous covariance function R. It is easy to see, from (3.3) with $\mathcal{S}=\mathbb{R}$, $\xi = X$, and $f(\cdot,\xi)=\beta(\cdot,X)$, that

$$\frac{dP}{dQ_t} = \exp\left\{\langle Y,\beta(\cdot,X)\rangle_t - \frac{1}{2}\|\beta(\cdot,X)\|_t^2\right\} \quad \text{a.s. } [Q_t].$$

This is because if $\beta^n(\cdot)=\sum_{j=1}^{k_n} a_{nj}R(\cdot,t_j^n)\in H(R;t)$, $n=1,2,\ldots$, are such that $\beta^n\to\beta\equiv\beta(\cdot,X)$ in $H(R;t)$, then

$$\begin{aligned}
\langle Y,\beta\rangle_t &= \lim_{n\to\infty}\langle Y,\beta^n\rangle_t \quad (Q_t\text{-a.s. and hence } P\text{-a.s.})\\
&= \lim_{n\to\infty}\sum_{j=1}^{k_n} a_{nj}Y_{t_j^n} = \lim_{n\to\infty}\sum_{j=1}^{k_n} a_{nj}N_{t_j^n} + \lim_{n\to\infty}\sum_{j=1}^{k_n} a_{nj}\beta_{t_j^n}\\
&= \lim_{n\to\infty}\langle N,\beta^n\rangle_t + \lim_{n\to\infty}(\beta,\beta^n)_{H(R;t)} = \langle N,\beta\rangle_t + \|\beta\|_t^2 \quad P\text{-a.s.}
\end{aligned}\tag{3.4}$$

Then for any $\mathcal{F}_T^X$-measurable integrable function $g(T,X)$, we have

$$\begin{aligned}
E_P(g(T,X)|\mathcal{F}_t^Y) &= \frac{E_{Q_t}\left(g(T,X)\frac{dP}{dQ_t}\middle|\mathcal{F}_t^Y\right)}{E_{Q_t}\left(\frac{dP}{dQ_t}\middle|\mathcal{F}_t^Y\right)}\\
&= \frac{E_{Q_t}\left(g(T,X)e^{\langle Y,\beta(\cdot,X)\rangle_t-\frac{1}{2}\|\beta(\cdot,X)\|_t^2}\middle|\mathcal{F}_t^Y\right)}{E_{Q_t}\left(e^{\langle Y,\beta(\cdot,X)\rangle_t-\frac{1}{2}\|\beta(\cdot,X)\|_t^2}\middle|\mathcal{F}_t^Y\right)}.
\end{aligned}\tag{3.5}$$

From Theorem 3.1, $\{Y_s, 0\le s\le t\}$, under Q_t, is independent of $\{X_s, 0\le s\le T\}$ and the distribution of X, under Q_t, is the same as that under P. Hence the conditional expectations of the form $E_{Q_t}(\phi(X,Y)|\mathcal{F}_t^Y)$ can be evaluated as

$$E_{Q_t}(\phi(X,Y)|\mathcal{F}_t^Y)(\omega) = \int_\Omega \phi(X(\omega'),Y(\omega))Q_t(d\omega') = \int \phi(x,Y(\omega))dP_X(x),$$

where P_X is the probability distribution of X. Hence, from (3.5), we have the following.

THEOREM 3.2. *Suppose that the observation process* Y_t *is as in* (3.1) *and that* (N_t) *is Gaussian with continuous covariance kernel* R. *Let*

$$\beta(\cdot, X(\omega)) \in H(R) \quad \textit{for almost all } \omega. \tag{3.6}$$

Then for any $\mathcal{F}_T^X$*-measurable and integrable function* $g(T, X)$,

$$E\left(g(T,X)\,\middle|\mathcal{F}_t^Y\right) = \frac{\displaystyle\int g(T,x)e^{\langle Y,\beta(\cdot,x)\rangle_t - \frac{1}{2}\|\beta(\cdot,x)\|_t^2}\,dP_X(x)}{\displaystyle\int e^{\langle Y,\beta(\cdot,x)\rangle_t - \frac{1}{2}\|\beta(\cdot,x)\|_t^2}\,dP_X(x)}. \tag{3.7}$$

We next consider an important special case from which it can be easily shown that the formula (3.7) extends the Kallianpur–Striebel formula, as well as the one by Kunita.

3.1. An important special case.

Suppose the noise N_t is of the form

$$N_t = \int_0^t F(t,u)dW_u, \tag{3.8}$$

where $F(t,s)$ is continuous on $\{0 \le s \le t \le T\}$. It is easy to check that the covariance function of (N_t), $R(t,s) = \int_0^{t\wedge s} F(t,u)F(s,u)du$ is continuous on $[0,T]\times[0,T]$. Then from the example considered in section 2.1 we have

$$H(R;t) = \left\{\phi : \phi(s) = \int_0^s F(s,u)\phi^*(u)du, \phi^* \in \overline{sp}^{L^2}\{F(s,\cdot)1_{[0,s]}(\cdot), 0 \le s \le t\}\right\} \tag{3.9}$$

with the inner product

$$(\phi_1,\phi_2)_{H(R;t)} = \int_0^t \phi_1^*(u)\phi_2^*(u)du,$$

where

$$\phi_1(s) = \int_0^s F(s,u)\phi_1^*(u)du \;\text{ and }\; \phi_2(s) = \int_0^s F(s,u)\phi_2^*(u)du.$$

Suppose the observation process is given by

$$Y_t = \int_0^t F(t,u)\tilde{h}(u,X_u)du + N_t, \tag{3.10}$$

such that

$$\tilde{h}(\cdot, X_{(\cdot)}) \in \overline{sp}^{L^2}\{F(s,\cdot)1_{[0,s]}(\cdot), 0 \le s \le t\}.$$

Then, by (2.3) and by an argument similar to the one used in (3.4), we have for $\phi(\cdot) = \int_0^{(\cdot)} F(\cdot,u)\phi^*(u)du \in H(R)$,

$$\langle Y,\phi\rangle_t \;=\; \int_0^t \phi^*(u)\tilde{h}(u,X_u)du + \int_0^t \phi^*(u)dW_u \;=\; \int_0^t \phi^*(u)d\hat{Y}_u,$$

where

$$\hat{Y}_s = \int_0^s \tilde{h}(u, X_u)du + W_s, \quad 0 \le s \le T.$$

Hence the Bayes formula (3.7) becomes

$$E\left(g(T,X)\,\middle|\mathcal{F}_t^Y\right) = \frac{\displaystyle\int g(T,x)e^{\int_0^t \tilde{h}(u,x_u)d\hat{Y}_u - \frac{1}{2}\int_0^t |\tilde{h}(u,x_u)|^2 du}\, dP_X(x)}{\displaystyle\int e^{\int_0^t \tilde{h}(u,x_u)d\hat{Y}_u - \frac{1}{2}\int_0^t |\tilde{h}(u,x_u)|^2 du}\, dP_X(x)}. \tag{3.11}$$

Remark. It is now easy to see that the Bayes formula (3.7) is indeed an extension of the Kallianpur–Striebel formula. Take $F(t,u) \equiv 1$ in the model (3.8) and $\tilde{h}$ in the model (3.10) to be $h \in L^2[0,T] \equiv \overline{\mathrm{sp}}^{L^2}\{1_{[0,t]}(\cdot), 0 \le t \le T\}$, so that $N_t = W_t$ and the observation process satisfies the usual model

$$Y_t = \int_0^t h(u, X_u)du + W_t.$$

Note that, in this case, $\hat{Y}_t = Y_t$. Therefore the Bayes formula (3.7) reduces to the Kallianpur–Striebel formula

$$E\left(g(T,X)\,\middle|\mathcal{F}_t^Y\right) = \frac{\displaystyle\int g(T,x)e^{\int_0^t h(u,x_u)dY_u - \frac{1}{2}\int_0^t |h(u,x_u)|^2 du}\, dP_X(x)}{\displaystyle\int e^{\int_0^t h(u,x_u)dY_u - \frac{1}{2}\int_0^t |h(u,x_u)|^2 du}\, dP_X(x)}.$$

Our result also generalizes a similar result by Kunita. We show that in the next section.

4. Kunita's result. In this section we shall derive Kunita's result ([13], Theorem 2.1), when $d = 1$, as a corollary of our result. Suppose the signal process (X_t) is a continuous process taking values in a complete metric space S. Suppose the observation process is given by

$$Y_t = \int_0^t h(X_s)\, ds + N_t, \quad 0 \le t \le T, \tag{4.1}$$

where h is a continuous map from S into $\mathbb{R}$ and the noise process (N_t) is given by

$$N_t = m_t + \int_0^t \psi(t,s)\, dW_s, \quad 0 \le t \le T, \tag{4.2}$$

with $\psi(t,s)$ and m_t satisfying the following three conditions.

Condition 1. $\psi(t,s)$ is continuously differentiable in $(t,s) \in [0,T] \times [0,T]$.

Let $\mathbf{C}_0^r$ be the set of all r-times continuously differentiable functions from $[0,T]$ to $\mathbb{R}$ which vanish at zero. Define $\Psi : \mathbf{C}_0 \equiv \mathbf{C}_0^0 \to \mathbf{C}_0$ such that

$$(\Psi\phi)_t = \int_0^t \psi(t,s)\phi'(s)\, ds \tag{4.3}$$

for $\phi \in \mathbf{C}_0^1$. For general $\phi \in \mathbf{C}_0$, it is extended by integration by parts as

$$(\Psi\phi)_t = \psi(t,t)\phi(t) - \int_0^t \phi(s)\frac{\partial\psi}{\partial s}(t,s)\, ds. \tag{4.4}$$

Let $\mathcal{R}(\Psi) = \{\Psi\phi : \phi \in \mathbf{C}_0\}$. Note that for $f, g \in \mathbf{C}_0$ and $0 \le u \le t \le T$,

$$(\Psi f)_u - (\Psi g)_u = \psi(u,u)\,(f(u) - g(u)) - \int_0^u (f(s) - g(s))\,\frac{\partial\psi}{\partial s}(u,s)\,ds.$$

Hence Ψ is causal in the sense that

$$(\Psi f)_u = (\Psi g)_u \text{ holds for } u \le t \text{ if } f(s) = g(s) \text{ holds for } s \le t. \tag{4.5}$$

Condition 2. The transformation Ψ has a causal inverse transformation $K : \mathcal{R}(\Psi) \to \mathbf{C}_0$ such that $K\Psi\phi = \phi$ holds for all $\phi \in \mathbf{C}_0$. Further, Kg is differentiable whenever $g \in \mathbf{C}_0^1 \cap \mathcal{R}(\Psi)$ and the derivative is in $L^2[0,T]$.

Condition 3. m_t is continuously differentiable in t and it belongs to $\mathcal{R}(\Psi)$.

Set

$$\dot{m}_t = \frac{dm_t}{dt}, \tag{4.6}$$

$$(Lf)_t = \frac{d}{dt}(Kg)_t, \quad \text{where } g_t = \int_0^t f_s\,ds. \tag{4.7}$$

Since $R(s,t) = E(N_sN_t) = \int_0^{t\wedge s} \psi(t,u)\psi(s,u)\,du$ is as in the special case considered in section 2.1, from (3.9) we have

$$H(R) = \left\{ g : g(t) = \int_0^t g^*(u)\psi(t,u)\,du, g^* \in \overline{\text{sp}}^{L^2}\{\psi(t,\cdot)1_{[0,t]}(\cdot) : 0 \le t \le T\} \right\}. \tag{4.8}$$

With the help of Lemma 4.1 we can further simplify the form of $H(R)$.

Lemma 4.1. *If ψ satisfies Condition 1 and Condition 2, then*

$$\overline{sp}^{L^2}\{\psi(t,\cdot)1_{[0,t]}(\cdot) : 0 \le t \le T\} = L^2[0,T].$$

Proof. It suffices to show that if $f \in L^2[0,T]$ is such that $f \perp \psi(t,\cdot)1_{[0,t]}(\cdot)$ for all $t \in [0,T]$, then $f = 0$. So suppose $f \in L^2[0,T]$.

$$\int_0^t \psi(t,s)f(s)\,ds = 0 \quad \text{for all } t$$

$$\Rightarrow \Psi g = 0, \quad \text{where } g(t) = \int_0^t f(s)\,ds$$

$$\Rightarrow g = K\Psi g = 0 \;\Rightarrow \int_0^t f(s)\,ds = 0 \quad \text{for all } t \;\Rightarrow f = 0.$$

Hence the lemma is proved. □

Therefore, from Lemma 4.1 and from (4.8), we have

$$H(R) = \left\{ g : g(t) = \int_0^t g^*(u)\psi(t,u)\,du \text{ for some } g^* \in L^2[0,T] \right\}. \tag{4.9}$$

The following proposition describes a relationship between the spaces $\mathcal{R}(\Psi)$ and $H(R)$.

PROPOSITION 4.2. *Let $\mathcal{R}(\Psi)$ and $H(R)$ be as above. Then*

$$\boldsymbol{C}_0^1 \cap \mathcal{R}(\Psi) \subseteq H(R) \subseteq \mathcal{R}(\Psi).$$

Furthermore, for $g \in H(R)$, $(Kg)_t = \int_0^t g^*(u)\,du$ and if $f \in \boldsymbol{C}_0^1 \cap \mathcal{R}(\Psi)$, then $f^* = L(f')$, where L is given by (4.7).

Proof. Let $g \in H(R)$. From (4.9),

$$g(t) = \int_0^t \psi(t,s) g^*(s)\,ds. \tag{4.10}$$

Considering $\phi = \int_0^{(\cdot)} g^*(u)\,du$, we have $\phi \in \mathbf{C}_0$ and from (4.4),

$$\begin{aligned}
(\Psi\phi)_t &= \psi(t,t)\phi(t) - \int_0^t \frac{\partial\psi}{\partial s}(t,s)\phi(s)\,ds \\
&= \psi(t,t)\int_0^t g^*(u)\,du - \int_0^t \left\{\frac{\partial\psi}{\partial s}(t,s)\int_0^s g^*(u)\,du\right\} ds \\
&= \int_0^t \psi(t,s) g^*(s)\,ds \quad \text{(using integration by parts)} \\
&= g(t) \quad \text{(by (4.10))}.
\end{aligned}$$

Hence $H(R) \subset \mathcal{R}(\Psi)$ and for $g \in H(R)$, $(Kg)_t = \int_0^t g^*(u)\,du$.

On the other hand, for $f \in \mathbf{C}_0^1 \cap \mathcal{R}(\Psi)$, letting $\phi \in \mathbf{C}_0$ to be such that $\Psi\phi = f$, by Condition 2, we have that $\phi = K\Psi\phi = Kf$ is differentiable with $\phi' = L(f') \in L^2[0,T]$. Now

$$\begin{aligned}
f(t) = \Psi\phi(t) &= \psi(t,t)\phi(t) - \int_0^t \phi(s)\frac{\partial\psi}{\partial s}(t,s)\,ds \\
&= \int_0^t \psi(t,s)\phi'(s)\,ds \quad \text{using integration by parts.} \qquad (4.11)
\end{aligned}$$

Hence the proposition follows from (4.9). □

We are now ready to derive the result of Kunita ([13], Theorem 2.1) as a corollary of our result, Theorem 3.2.

THEOREM 4.3 (Kunita). *Suppose the noise process (N_t), given by* (4.2), *satisfies Conditions* $1-3$, *and the observation process (Y_t) is given by* (4.1). *Let P_X denote the probability distribution of X on $C[0,T]$. Assume further that $(\int_0^t h(X_s)\,ds)$ belongs to $\mathcal{R}(\Psi)$ a.s. Then for any measurable function g on S, the signal state space, such that $E(|g(X_t)|) < \infty$*

$$E(g(X_t)|\mathcal{F}_t^Y) = \frac{\int \alpha_t(x,Y) g(x(t))\,dP_X(x)}{\int \alpha_t(x,Y)\,dP_X(x)},$$

where

$$\alpha_t(x,Y) = \exp\left\{\int_0^t L(h(x)+\dot{m})_s\,d\hat{Y}_s - \frac{1}{2}\int_0^t |L(h(x)+\dot{m})_s|^2\,ds\right\}$$

and

$$\hat{Y}_t = \int_0^t Lh(x)_s\,ds + \int_0^t (L\dot{m})_s\,ds + W_t.$$

Remark. To check that $\alpha_t(x,Y)$ in the theorem is in fact $\mathcal{F}_t^Y$-measurable it has been shown in Kunita [13] that $\hat{Y}_t = (KY)_t$ and then the causality of K is used. In the proof given below we show that $\alpha_t(x,Y) = \langle Y, \beta(\cdot,x)\rangle_t$ which proves that it is indeed $\mathcal{F}_t^Y$-measurable.

Proof of Theorem 4.3. Let Ω_0 with $P(\Omega_0)=1$ be such that $\int_0^t h(X_s(\omega))\,ds \in \mathcal{R}(\Psi)$ for all $\omega \in \Omega_0$. Fix $\omega \in \Omega_0$. Since $h(X_s(\omega))$ is continuous in $s \in [0,T]$, $\int_0^{(\cdot)} h(X_s(\omega))\,ds \in \mathbf{C}_0^1 \cap \mathcal{R}(\Psi)$. So, by Proposition 4.2, $\int_0^{(\cdot)} h(X_s(\omega))\,ds$ belongs to $H(R)$. Hence $(\int_0^t h(X_s)\,ds)$ belongs to $H(R)$ a.s. with $(\int_0^{(\cdot)} h(X_s)\,ds)^*(t) = (Lh(x))_t$. Similarly, since by Condition 3, $m \in \mathbf{C}_0^1 \cap \mathcal{R}(\Psi)$, we have $m \in H(R)$ with $m^* = L\dot{m}$. Rewriting the observation model (4.1), we have

$$\begin{aligned} Y_t &= \int_0^t h(X_s)ds + m_t + \int_0^t \psi(t,s)dW_s \\ &= \int_0^t L(h(x)+\dot{m})_s \psi(t,s)ds + \int_0^t \psi(t,s)dW_s. \end{aligned}$$

The theorem then follows from the special case considered in section 3.1 with $F(t,s) = \psi(t,s)$ and $\tilde{h} = L(h(x)+\dot{m}) \in L^2[0,T]$. □

5. Fractional Brownian motion noise process. Suppose the observation process is given by

$$Y_t = \int_0^t h(X_u)du + B_H(t), \quad 0 \le t \le T, \tag{5.1}$$

where $B_H(t)$ is an fBm with Hurst parameter $H \in (\frac{1}{2},1)$ and is independent of the signal process (X_t). Here $R(s,t) = E[B_H(t)B_H(s)] = 1/2\{|t|^{2H} + |s|^{2H} - |t-s|^{2H}\}$. Assume that $h(u) \equiv h(X_u)$ is continuous a.s. To apply Theorem 3.2 we shall need the following lemma about the representation of functions in $H(R)$. It can be obtained from Theorem 4.4 of Barton and Poor [3], where a characterization of the functions in $H(R)$ is given. However, it takes some effort to relate it to our notation and concepts used in Theorem 3.2. We therefore give a self-contained short proof below.

LEMMA 5.1. *Let $(B_H(t), 0 \le t \le T)$ be an fBm with $H \in (\frac{1}{2},1)$ and the covariance function $R(s,t)$. For any continuous function $c(\cdot)$ on $[0,\tau]$ $(\tau > 0)$, suppose $g_c^\tau(\cdot)$ satisfies the equation (see Carleman* [7]*)*

$$\int_0^\tau g_c^\tau(u)H(2H-1)|v-u|^{2H-2}du = c(v), \quad 0 \le v \le \tau. \tag{5.2}$$

Suppose $a(\cdot)$ is continuous on $[0,T]$. Then $\int_0^{(\cdot)} a(u)du \in H(R)$ with

$$\left\langle \int_0^{(\cdot)} a(u)du, B_H \right\rangle_t = \int_0^t g_a^t(u)dB_H(u) \quad \textit{and} \quad \left\| \int_0^{(\cdot)} a(u)du \right\|_t^2 = \int_0^t g_a^t(u)a(u)du.$$

Proof. Recall that there exists a congruence between the RKHS, $H(R)$, and $\overline{\mathrm{sp}}^{L^2}\{B_H(s) : s \in [0,T]\}$ under which $R(\cdot,t) \mapsto B_H(t)$. Clearly, $\int_0^T g_a^T(u)dB_H(u) \in \overline{\mathrm{sp}}^{L^2}\{B_H(s) : 0 \le s \le T\}$. Hence there exists $\tilde{g} \in H(R)$ such that the image of $\tilde{g}$, under the congruence, is $\int_0^T g_a^T(u)dB_H(u)$. Then for $0 \le s \le T$, by (5.2),

$$\begin{aligned}\tilde{g}(s) = (R(\cdot, s), \tilde{g})_{H(R)} \ &= \ E\left(B_H(s)\int_0^T g_a^T(u)dB_H(u)\right)\\ &= \int_0^s\int_0^T g_a^T(u)H(2H-1)|v-u|^{2H-2}dudv \ = \ \int_0^s a(v)dv.\end{aligned}$$

This proves that $\int_0^{(\cdot)} a(u)du \in H(R)$ and following the notation of section 2 we have $\langle \int_0^{(\cdot)} a(u)du, B_H\rangle = \int_0^T g_a^T(u)dB_H(u)$. Exactly in the same way it follows that $\langle \int_0^{(\cdot)} a(u)du, B_H\rangle_t = \int_0^t g_a^t(u)dB_H(u)$. Finally,

$$\begin{aligned}\left\|\int_0^{(\cdot)} a(u)du\right\|_t^2 &= E\left(\int_0^t g_a^t(u)dB_H(u)\int_0^t g_a^t(u)dB_H(u)\right)\\ &= \int_0^t\int_0^t g_a^t(u)g_a^t(v)H(2H-1)|u-v|^{2H-2}dvdu\\ &= \int_0^t g_a^t(u)a(u)du \quad \text{from (5.2).} \qquad \Box\end{aligned}$$

Clearly, R is continuous on $[0,T]\times[0,T]$. Then from Theorem 3.1, under a suitable change of measure (Y_t) becomes an fBm. Therefore, from the Bayes formula (3.7) with $\beta(t,X) = \int_0^t h(u)du$ and $N_t = B_H(t)$, and from Lemma 5.1, we have

$$(5.3)\quad E\left[f(X_t)\,|\mathcal{F}_t^Y\right] = \frac{\displaystyle\int f(x_t)\exp\left\{\int_0^t g_h^t(u)dY(u) - \frac{1}{2}\int_0^t g_h^t(u)h(u)du\right\}dP_X(x)}{\displaystyle\int \exp\left\{\int_0^t g_h^t(u)dY(u) - \frac{1}{2}\int_0^t g_h^t(u)h(u)du\right\}dP_X(x)}.$$

When the signal process is actually a random variable η (independent of the noise process $B_H(t)$) such that $h(u) = \eta a(u)$, where a is a continuous (deterministic) function, then using the fact that for a constant k, $g_{ka}^t = kg_a^t$, from (5.3) we have

$$(5.4)\quad E\left[f(\eta)\,|\mathcal{F}_t^Y\right] = \frac{\displaystyle\int f(x)\exp\left\{x\int_0^t g_a^t(u)dY(u) - \frac{1}{2}x^2\int_0^t g_a^t(u)a(u)du\right\}dP_\eta(x)}{\displaystyle\int \exp\left\{x\int_0^t g_a^t(u)dY(u) - \frac{1}{2}x^2\int_0^t g_a^t(u)a(u)du\right\}dP_\eta(x)}.$$

If we further assume that η is a Gaussian random variable with mean η_0 and variance γ_0, then η being independent of $(B_H(t))$, we have (η, Y) jointly Gaussian. Hence the conditional distribution of η given $\mathcal{F}_t^Y$ is also Gaussian with mean $E(\eta|\mathcal{F}_t^Y) = \hat{\eta}_t$, say, and variance $E\left((\eta-\hat{\eta}_t)^2\,|\mathcal{F}_t^Y\right) = \hat{\gamma}_t$, say. Then

$$E\left(e^{\alpha\eta}\,|\mathcal{F}_t^Y\right) = \exp\left\{\alpha\hat{\eta} + \frac{1}{2}\alpha^2\hat{\gamma}_t\right\}.$$

Now from (5.4), taking $f(x) = e^{\alpha x}$, we have

$$(5.5)\quad \begin{aligned}&E\left[e^{\alpha\eta}\,|\mathcal{F}_t^Y\right]\\ &= \frac{\displaystyle\int e^{\alpha x}\exp\left\{x\int_0^t g_a^t(u)dY(u) - \frac{1}{2}x^2\int_0^t g_a^t(u)a(u)du\right\}\phi(x;\eta_0,\gamma_0)dx}{\displaystyle\int \exp\left\{x\int_0^t g_a^t(u)dY(u) - \frac{1}{2}x^2\int_0^t g_a^t(u)a(u)du\right\}\phi(x;\eta_0,\gamma_0)dx},\end{aligned}$$

where $\phi(x;\eta_0,\gamma_0)$ is the density of a Gaussian random variable with mean η_0 and variance γ_0.

Let us consider the numerator of the right-hand side of (5.5):

$$\begin{aligned}
&\int e^{x\left(\alpha+\int_0^t g_a^t(u)dY(u)\right)-\frac{1}{2}x^2\int_0^t g_a^t(u)a(u)du}\ \frac{1}{\sqrt{2\pi\gamma_0}}\ e^{-\frac{1}{2\gamma_0}(x-\eta_0)^2}dx\\
&\quad=\frac{1}{\sqrt{2\pi\gamma_0}}\int e^{-\frac{1}{2}\left[x^2\left(\gamma_0^{-1}+\int_0^t g_a^t(u)a(u)du\right)-2x\left(\alpha+\gamma_0^{-1}+\eta_0\int_0^t g_a^t(u)dY(u)\right)+\gamma_0^{-1}\eta_0^2\right]}dx\\
&\quad=\frac{1}{\sqrt{2\pi\gamma_0}}\int e^{-\frac{1}{2\gamma_t}\left[x^2-2x(\alpha+m_t)\gamma_t+(\alpha+m_t)^2\gamma_t^2\right]}e^{-\frac{1}{2}\gamma_0^{-1}\eta_0^2+\frac{1}{2}\gamma_t(\alpha+m_t)^2}dx,
\end{aligned}$$

$$\text{where } \gamma_t^{-1}=\gamma_0^{-1}+\int_0^t g_a^t(u)a(u)du \ \text{ and } \ m_t=\gamma_0^{-1}\eta_0+\int_0^t g_a^t(u)dY(u) \tag{5.6}$$

$$=\sqrt{\gamma_0^{-1}\gamma_t}\ e^{-\frac{1}{2}\gamma_0^{-1}\eta_0^2+\frac{1}{2}\gamma_t(\alpha+m_t)^2}. \tag{5.7}$$

Putting $\alpha=0$ in (5.7) we get the denominator of the right-hand side of (5.5):

$$\text{Denominator } =\sqrt{\gamma_0^{-1}\gamma_t}\ e^{-\frac{1}{2}\gamma_0^{-1}\eta_0^2+\frac{1}{2}\gamma_t m_t^2}.$$

Therefore, from (5.5), we have

$$E\left[e^{\alpha\eta}\left|\mathcal{F}_t^Y\right.\right]=e^{\frac{1}{2}\left[\gamma_t(\alpha+m_t)^2-\gamma_t m_t^2\right]}=e^{\frac{1}{2}\gamma_t\alpha(\alpha+2m_t)}.$$

Collecting the coefficients of α and α^2 and using (5.6), we get

$$\hat{\eta}_t=\gamma_t m_t=\gamma_t\left(\gamma_0^{-1}\eta_0+\int_0^t g_a^t(u)dY(u)\right),$$

$$\hat{\gamma}_t=\gamma_t=\left(\gamma_0^{-1}+\int_0^t g_a^t(u)a(u)du\right)^{-1}.$$

Note that these equations for the filter are exactly the same as those obtained by Le Breton [6].

Remark. Recently, Le Breton [5] considered the parametric estimation problem in a simple deterministic regression model setup with the fBm noise process. Our general Bayes formula can be used to study the parametric estimation problem in a more general setup with the fBm noise process, as done in Liptser and Shiryayev [15] in parameter estimation of the drift coefficient for diffusion-type processes with the Wiener noise. We leave that for a future note.

6. Ornstein–Uhlenbeck noise process. Although the use of the Wiener process as noise produces elegant, powerful mathematical techniques to calculate the optimal filter, one of the main criticisms against it (as expressed by Balakrishnan [2]) is from the practical point of view. Since the sample paths of a Wiener process are of unbounded variation with probability one, the actual data samples have zero probability of occurring and hence the results obtained cannot be instrumented. On the other hand, it has been argued by Nelson [16] that the Ornstein–Uhlenbeck (dispersion) process is natural to consider as an approximation to the Wiener process and the Ornstein–Uhlenbeck processes are realizable. In this section we consider the filtering problem corresponding to the Ornstein–Uhlenbeck noise process and show that it leads to the conventional theory with the Wiener noise process.

Suppose $v(t)$ is an Ornstein–Uhlenbeck velocity process satisfying the stochastic differential equation

$$dv(t) = -\beta v(t)dt + \sigma dW(t) \qquad (\beta > 0,\ \sigma > 0) \tag{6.1}$$

with the initial value $v(0) = 0$. Consider the Ornstein–Uhlenbeck (dispersion) process given by

$$\xi(t) = \int_0^t v(s)ds. \tag{6.2}$$

It is easy to see that if β and σ tend to infinity in such a way that $\sigma^2/\beta^2 \to 1$, then $\xi(t)$ converges in distribution to the standard Wiener process. See, for example, Theorem 9.5 of Nelson [16].

Now suppose the noise process (N_t) is given by an Ornstein–Uhlenbeck process so that, from (6.2) and (6.1), we have

$$N_t = \int_0^t \sigma \int_0^s \exp\{-\beta(s-r)\}dW_r ds = \int_0^t \frac{\sigma}{\beta}\left(1 - e^{-\beta(t-s)}\right) dW_s.$$

Also, suppose that the signal process X is independent of W and the observation process is given by

$$Y_t^{\beta,\sigma} = \int_0^t h(X_u)du + N_t, \tag{6.3}$$

where $h(u) \equiv h(X_u)$ is differentiable in $[0,T]$ and $h'(u) \in L^2[0,T]$.

Then, the covariance $R(t,s)$ of (N_t) is given by

$$R(s,t) = E(N_s N_t) = \int_0^{t\wedge s} F(t,u)F(s,u)du,$$

where

$$F(t,u) = \frac{\sigma}{\beta}\left(1 - e^{-\beta(t-u)}\right), \quad 0 \le u \le t \le T. \tag{6.4}$$

Also, it is easy to see that

$$\overline{sp}^{L^2}\{F(t,\cdot)1_{[0,t]}(\cdot), 0 \le t \le T\} = L^2[0,T].$$

This is because if $f \in L^2[0,T]$ such that $f \perp F(t,\cdot)1_{[0,t]}(\cdot)$ for all $0 \le t \le T$, then

$$\begin{aligned}
&\int_0^t f(u)F(t,u)du = 0 \quad \text{ for all } t\\
&\Rightarrow \int_0^t f(u)\frac{\sigma}{\beta}\left(1 - e^{-\beta(t-u)}\right) du = 0 \quad \text{ for all } t\\
&\Rightarrow \int_0^t f(u)du - e^{-\beta t}\int_0^t e^{\beta u} f(u)du = 0 \quad \text{ for all } t\\
&\Rightarrow f(t) + \beta e^{-\beta t}\int_0^t e^{\beta u} f(u)du - e^{-\beta t}e^{\beta t} f(t) = 0 \quad \text{ almost everywhere (a.e.) } [t]\\
&\Rightarrow \int_0^t e^{\beta u} f(u)du = 0 \quad \text{ a.e. } [t]\\
&\Rightarrow f(t) = 0 \quad \text{ a.e. } [t].
\end{aligned}$$

Hence from (3.9) we have

$$H(R) = \left\{ g : g(s) = \int_0^s F(s,u) g^*(u) du \text{ for some } g^* \in L^2[0,T] \right\}.$$

It is also easy to check (assuming, without loss of generality, $h(X_0) = 0$) that

$$\int_0^t h(X_u) du = \int_0^t F(t,u) \left[\frac{\beta}{\sigma} h(X_u) + \frac{1}{\sigma} h'(u) \right] du.$$

Hence the noise process and the observation process are as in the special case considered in section 3.1, that is, N_t is of the form (3.8) with $F(t,s)$ given by (6.4) and $Y_t^{\beta,\sigma}$ is of the form (3.10) with

$$\tilde{h}(u, X_u) = \frac{\beta}{\sigma} h(X_u) + \frac{1}{\sigma} h'(u).$$

In this case, therefore, from (3.11), we have

$$\nu_t^{\beta,\sigma}(f)(Y^{\beta,\sigma}) := E(f(X_t)|\mathcal{F}_t^{Y^{\beta,\sigma}}) = \frac{\int f(x_t) \alpha_t^{\beta,\sigma}(x, Y^{\beta,\sigma}) P_X(dx)}{\int \alpha_t^{\beta,\sigma}(x, Y^{\beta,\sigma}) P_X(dx)},$$

where

$$\begin{aligned} &\alpha_t^{\beta,\sigma}(x, Y^{\beta,\sigma}) \\ &= \exp\left\{ \int_0^t \left[\frac{\beta}{\sigma} h(x_u) + \frac{1}{\sigma} h'(u) \right] d\tilde{Y}_u^{\beta,\sigma} - \frac{1}{2} \int_0^t \left[\frac{\beta}{\sigma} h(x_u) + \frac{1}{\sigma} h'(u) \right]^2 du \right\} \end{aligned} \tag{6.5}$$

and

$$\tilde{Y}_t^{\beta,\sigma} = \int_0^t \left[\frac{\beta}{\sigma} h(x_u) + \frac{1}{\sigma} h'(u) \right] du + W_t. \tag{6.6}$$

Now suppose that ν_t is the classical filter based on the observation process

$$Y_t = \int_0^t h(X_s) ds + W_t.$$

Recall from the Kallianpur–Striebel formula that

$$\nu_t(f)(Y) := E(f(X_t)|\mathcal{F}_t^Y) = \frac{\int f(x_t) \alpha_t(x, Y) P_X(dx)}{\int \alpha_t(x, Y) P_X(dx)},$$

where

$$\alpha_t(x, Y) = \exp\left\{ \int_0^t h(x_u) dY_u - \frac{1}{2} \int_0^t h^2(x_u) du \right\}. \tag{6.7}$$

The following result shows that the conventional filter can be approximated by suitable filters corresponding to the Ornstein–Uhlenbeck noise process.

Theorem 6.1. *Suppose h satisfies the following condition*

$$E\left[\exp\left\{ 7 \int_0^T h^2(X_u) du + \int_0^T (h'(u))^2 du \right\} \right] < \infty. \tag{6.8}$$

Then for bounded function f, as $\beta,\ \sigma \to \infty$, with $\sigma^2/\beta^2 \to 1$,

$$\nu_t^{\beta,\sigma}(f)(Y^{\beta,\sigma}) \longrightarrow \nu_t(f)(Y) \qquad a.s. \tag{6.9}$$

through an appropriate subsequence.

Proof. Denote by $a_t(\beta,\sigma)$ and a_t the expressions in the curly brackets in (6.5) and (6.7), respectively. Then as $\beta\to\infty,\sigma\to\infty$ such that $\sigma^2/\beta^2\to 1$, we have

$$\begin{aligned} a_t(\beta,\sigma) &= \int_0^t \left[\frac{\beta}{\sigma}h(x_u)+\frac{1}{\sigma}h'(u)\right]dW_u+\frac{1}{2}\int_0^t\left[\frac{\beta}{\sigma}h(x_u)+\frac{1}{\sigma}h'(u)\right]^2du \\ &= \frac{\beta}{\sigma}\int_0^t h(x_u)dW_u+\frac{1}{\sigma}\int_0^t h'(u)dW_u+\frac{1}{2}\int_0^t\left[\frac{\beta}{\sigma}h(x_u)+\frac{1}{\sigma}h'(u)\right]^2du \\ &\longrightarrow \int_0^t h(x_u)dW_u+\frac{1}{2}\int_0^t |h(x_u)|^2du \ = \ a_t \ \text{ a.e. } x\ [P_X] \text{ and a.e. } [P]. \end{aligned} \tag{6.10}$$

Hence it is enough to show that

$$\int \alpha_t^{\beta,\sigma}(x,Y^{\beta,\sigma})P_X(dx)\longrightarrow\int\alpha_t(x,Y)P_X(dx) \quad \text{in } \ L^1, \tag{6.11}$$

for L^1-convergence will imply a.s. convergence through a subsequence and then the theorem will follow from Scheffe's theorem.

It is easy to check that for any numbers a and b,

$$|e^a-e^b|\le|a-b|\cdot\max\left(e^{|a|},e^{|b|}\right).$$

Then

$$\begin{aligned} &E\left(\left|\int\alpha_t^{\beta,\sigma}(x,Y^{\beta,\sigma})P_X(dx)-\int\alpha_t(x,Y)P_X(dx)\right|\right) \\ &\quad\le E\left(\int|\exp\{a_t(\beta,\sigma)\}-\exp\{a_t\}|P_X(dx)\right) \\ &\quad\le E\left(\int|a_t(\beta,\sigma)-a_t|\cdot\max\left(e^{|a_t(\beta,\sigma)|},e^{|a_t|}\right)P_X(dx)\right) \\ &\quad\le\left\{\int E\left(|a_t(\beta,\sigma)-a_t|^2\right)P_X(dx)\cdot\int E\left(e^{2|a_t(\beta,\sigma)|}+e^{2|a_t|}\right)P_X(dx)\right\}^{1/2} \\ &\quad\le\left(\int I_1P_X(dx)\right)^{1/2}\left(\int I_2P_X(dx)\right)^{1/2}, \ \text{ say.} \end{aligned} \tag{6.12}$$

Then

$$\begin{aligned} I_1 &= E\left(|a_t(\beta,\sigma)\}-a_t|^2\right) \\ &= E\Bigg(\bigg|\int_0^t\left\{\left(\frac{\beta}{\sigma}-1\right)h(x_u)+\frac{1}{\sigma}h'(u)\right\}dW_u \\ &\qquad\qquad +\frac{1}{2}\int_0^t\left\{\left(\frac{\beta}{\sigma}h(x_u)+\frac{1}{\sigma}h'(u)\right)^2-h^2(x_u)\right\}du\bigg|^2\Bigg) \\ &\le 2E\left(\left|\int_0^t\left\{\left(\frac{\beta}{\sigma}-1\right)h(x_u)+\frac{1}{\sigma}h'(u)\right\}dW_u\right|^2\right) \end{aligned}$$

$$
\begin{aligned}
&\qquad + 2\cdot\frac{1}{4}\left|\int_0^t \left(\frac{2\beta^2}{\sigma^2}-1\right) h^2(x_u)du + \int_0^t \frac{2}{\sigma^2}\left(h'(u)\right)^2 du\right|^2 \\
&\le 2\int_0^t \left\{\left(\frac{\beta}{\sigma}-1\right)h(x_u) + \frac{1}{\sigma}h'(u)\right\}^2 du \\
&\qquad + \frac{1}{2}\cdot 2\left\{\left(\frac{2\beta^2}{\sigma^2}-1\right)^2\left(\int_0^t h^2(x_u)du\right)^2 + \frac{4}{\sigma^4}\left(\int_0^t \left(h'(u)\right)^2 du\right)^2\right\} \\
&\le 4\left(\frac{\beta}{\sigma}-1\right)^2 \int_0^t h^2(x_u)du + \frac{4}{\sigma^2}\int_0^t \left(h'(u)\right)^2 du \\
&\qquad + \left(\frac{2\beta^2}{\sigma^2}-1\right)^2\left(\int_0^t h^2(x_u)du\right)^2 + \frac{4}{\sigma^4}\left(\int_0^t \left(h'(u)\right)^2 du\right)^2 .
\end{aligned}
$$

Hence, from (6.8), it follows that

$$
\int I_1 P_X(dx) \longrightarrow 0 \text{ as } \beta,\ \sigma\to\infty,\ \text{with } \frac{\sigma^2}{\beta^2}\to 1. \tag{6.13}
$$

Now, using the fact that for a normal random variable Z with zero mean and variance σ^2, $E(e^{|Z|}) \le 2e^{\sigma^2/2}$, we have

$$
\begin{aligned}
I_2 &= E\left(e^{2|a_t(\beta,\sigma)|} + e^{2|a_t|}\right) \\
&= E\left(\exp\left\{\left|2\int_0^t \left[\frac{\beta}{\sigma}h(x_u) + \frac{1}{\sigma}h'(u)\right]dW_u + \int_0^t \left[\frac{\beta}{\sigma}h(x_u)+\frac{1}{\sigma}h'(u)\right]^2 du\right|\right\}\right) \\
&\qquad + E\left(\exp\left\{\left|2\int_0^t h(x_u)dW_u + \int_0^t |h(x_u)|^2 du\right|\right\}\right) \\
&\le 2\exp\left\{3\int_0^t \left[\frac{\beta}{\sigma}h(x_u)+\frac{1}{\sigma}h'(u)\right]^2 du\right\} + 2\exp\left\{3\int_0^t |h(x_u)|^2 du\right\} \\
&\le 2\exp\left\{\frac{6\beta^2}{\sigma^2}\int_0^t h^2(x_u)du + \frac{6}{\sigma^2}\int_0^t \left(h'(u)\right)^2 du\right\} + 2\exp\left\{3\int_0^t h^2(x_u)du\right\}.
\end{aligned}
$$

Therefore, from (6.8), we have for large σ and β, $\int I_2 P_X(dx)$ is bounded and consequently, (6.11) follows from (6.12) and (6.13). □

Remark. Note that the condition (6.8) in Theorem 6.1 will hold if one assumes that the functions $h(\cdot)$ and $h'(\cdot)$ are bounded.

Next we address the issue of implementation of the results obtained by considering the Ornstein–Uhlenbeck dispersion process as the observation noise process. We would like to obtain a Zakai-type evolution equation for the so-called unnormalized conditional density of X_t given the observations up to time "t." So let us assume that the signal process X_t is a Markov process.

First, we shall prove the following properties of $\tilde{Y}_t \equiv \tilde{Y}_t^{\beta,\sigma}$ and its relationship with $Y_t \equiv Y_t^{\beta,\sigma}$.

LEMMA 6.2. *Suppose $\tilde{Y}_t$ is given by* (6.6). *Suppose Q is defined by*

$$
dP = \exp\left\{\int_0^T \left[\frac{\beta}{\sigma}h(X_u)+\frac{1}{\sigma}h'(u)\right]d\tilde{Y}_u - \frac{1}{2}\int_0^T \left[\frac{\beta}{\sigma}h(X_u)+\frac{1}{\sigma}h'(u)\right]^2 du\right\} dQ.
$$

Then

(i) *under Q, $\tilde{Y}_t$ is a Wiener process,*

(ii) $\overline{sp}^{L^2(Q)}\{Y_s, 0 \le s \le t\} = \overline{sp}^{L^2(Q)}\{\tilde{Y}_s, 0 \le s \le t\}$,

(iii) $\mathcal{F}_t^Y = \mathcal{F}_t^{\tilde{Y}}$.

Proof. Clearly (iii) follows from (ii) as, under Q, (Y_t) and $(\tilde{Y}_t)$ are Gaussian. (i) follows from Lemma 11.3.1 of [10] since (X_t) is independent of (W_t). For (ii) note that

$$\begin{aligned} Y_t &= \int_0^t h(X_u)du + \int_0^t F(t,u)dW_u \\ &= \int_0^t F(t,u)\left[\frac{\beta}{\sigma}h(X_u) + \frac{1}{\sigma}h'(u)\right]du + \int_0^t F(t,u)dW_u \\ &= \int_0^t F(t,u)d\tilde{Y}_u. \end{aligned} \tag{6.14}$$

Hence

$$\overline{\mathrm{sp}}^{L^2(Q)}\{Y_s, 0 \le s \le t\} \subset \overline{\mathrm{sp}}^{L^2(Q)}\{\tilde{Y}_s, 0 \le s \le t\}.$$

To show the reverse inclusion suppose $\xi \in \overline{\mathrm{sp}}^{L^2(Q)}\{\tilde{Y}_s, 0 \le s \le t\}$ and $E_Q(\xi Y_s) = 0$ for all $0 \le s \le t$. Since $\tilde{Y}_t$, under Q, is a Wiener process we can express ξ as an Ito integral, say, $\xi = \int_0^t \phi(u)d\tilde{Y}_u$. Then

$$\begin{aligned} &E_Q(\xi Y_s) = 0 \quad \text{for all } 0 \le s \le t \\ &\Rightarrow E_Q\left(\int_0^t \phi(u)d\tilde{Y}_u \int_0^s F(s,u)d\tilde{Y}_u\right) = 0 \quad \text{for all } 0 \le s \le t \\ &\Rightarrow \int_0^s \phi(u)F(s,u)du = 0 \quad \text{for all } 0 \le s \le t \\ &\Rightarrow \int_0^s \phi(u)\frac{\sigma}{\beta}\left(1 - e^{-\beta(s-u)}\right)du = 0 \quad \text{for all } 0 \le s \le t \\ &\Rightarrow \int_0^s \phi(u)du - e^{-\beta s}\int_0^s \phi(u)e^{\beta u}du = 0 \quad \text{for all } 0 \le s \le t \\ &\Rightarrow \text{(by differentiating) } \beta e^{-\beta s}\int_0^s \phi(u)e^{\beta u}du = 0 \quad \text{a.e. } s \in [0,t] \\ &\Rightarrow \phi(u) = 0 \quad \text{a.e. } u \in [0,t]. \end{aligned}$$

Hence

$$\overline{\mathrm{sp}}^{L^2(Q)}\{\tilde{Y}_s, 0 \le s \le t\} \subset \overline{\mathrm{sp}}^{L^2(Q)}\{Y_s, 0 \le s \le t\}.$$

This completes the proof of part (ii). □

Because of property (iii) of Lemma 6.2, the filter based on $\{Y_s, 0 \le s \le t\}$ will coincide with the filter based on $\{\tilde{Y}_s, 0 \le s \le t\}$, where

$$\tilde{Y}_t = \int_0^t \left[\frac{\beta}{\sigma}h(X_u) + \frac{1}{\sigma}h'(u)\right]du + W_t.$$

We shall, however, consider the observation process to be given by

$$\hat{Y}_t = \int_0^t \frac{\beta}{\sigma}h(X_u)du + W_t, \tag{6.15}$$

which, for large σ, will approximate $\tilde{Y}_t$. We can then use the classical theory with the Wiener noise process to obtain the following result.

Suppose A_t with domain $\mathcal{D}$ is the generator of the Markov signal process (X_t). Denote by $\Phi(u,t)$ the unnormalized conditional density of X_t given $\mathcal{F}_t^{\hat{Y}}$. Then

$$\Phi(u,t) = \Phi(u,0) + \int_0^t A_s^* \Phi(u,s) ds + \int_0^t \left[\frac{\beta}{\sigma} h(X_s) \right] \Phi(u,s) d\hat{Y}_s, \tag{6.16}$$

where A_s^* is the formal adjoint of A_s.

Now note that from (6.14) and the form (6.4) of F we have

$$\begin{aligned} Y_t = \frac{\sigma}{\beta} \int_0^t \left[1 - e^{-\beta(t-u)} \right] d\tilde{Y}_u &= \frac{\sigma}{\beta} \left[\tilde{Y}_t - e^{-\beta t} \int_0^t e^{\beta u} d\tilde{Y}_u \right] \\ = \frac{\sigma}{\beta} \left[\tilde{Y}_t - e^{-\beta t} \left\{ e^{\beta t} \tilde{Y}_t - \int_0^t \beta e^{\beta u} \tilde{Y}_u du \right\} \right] &= \sigma e^{-\beta t} \int_0^t e^{\beta u} \tilde{Y}_u du. \end{aligned}$$

Hence,

$$y_t := \frac{d}{dt} Y_t \ = \ \sigma e^{-\beta t} (-\beta) \int_0^t e^{\beta u} \tilde{Y}_u du + \sigma e^{-\beta t} e^{\beta t} \tilde{Y}_t \ = \ \sigma \tilde{Y}_t - \beta Y_t,$$

that is,

$$\hat{Y}_t \ = \ \tilde{Y}_t - \frac{1}{\sigma} \int_0^t h'(u) du \ = \ \frac{1}{\sigma} \left\{ y_t - \int_0^t h'(u) du \right\} + \frac{\beta}{\sigma} Y_t.$$

Therefore ignoring the first term in the expression for $\hat{Y}_t$ above, which is of the order of σ^{-1}, we see that the solution of the Zakai equation (6.16), for large σ, can be approximated by the solution of the following ordinary partial differential equation

$$\frac{d}{dt} \Phi(u,t) = A_t^* \Phi(u,t) + \left(\frac{\beta}{\sigma} \right)^2 h(X_t) \ \Phi(u,t) \ y_t.$$

Acknowledgment. We thank the referees for their insightful suggestions, which led to the improvement of our presentation.

ON A PERTURBATION APPROACH FOR THE ANALYSIS OF STOCHASTIC TRACKING ALGORITHMS[*]

RAFIK AGUECH[†], ERIC MOULINES[‡], AND PIERRE PRIOURET[†]

Abstract. In this paper, a perturbation expansion technique is introduced to decompose the tracking error of a general adaptive tracking algorithm in a linear regression model. This method results in a tracking error bound and tight approximate expressions for the moments of the tracking error. These expressions allow the evaluation, both qualitatively and quantitatively, of the impact of several factors on the tracking error performance.

Key words. adaptive tracking algorithms, expansion techniques, performance analysis

1. Introduction.

An important issue in system identification, signal processing, and automatic control is that of tracking the parameter variations of a linear dynamical system with observable stochastic inputs and noise-corrupted outputs:

$$y_t = \phi_t^T \theta_t + v_t, \quad t \geq 0, \tag{1}$$

where $\{y_t\}_{t\geq 0}$ and $\{v_t\}_{t\geq 0}$ are, respectively, the scalar observation and noise, and $\{\phi_t\}_{t\geq 0}$ and $\{\theta_t\}_{t\geq 0}$ are the d-dimensional stochastic regressors and the unknown time-varying parameter. This model encompasses many different applications, including channel equalization, time delay estimation, and echo cancellation (see [34] for other signal processing and automatic control applications; see also [18]). To track the variations of the parameter, it is customary to use a recursive algorithm for updating an estimate $\hat{\theta}_t$ of the parameter (see, for example, [21], [22], [23], [34], [13], [18], and the references therein). These algorithms may take many different forms depending on what one is willing to assume on the observation noise, the parameter variations, and the amount of computation that is acceptable; e.g., standard stochastic approximation with fixed step-size, recursive least-squares with forgetting factor, or adaptations of Kalman–Bucy filters. In this work, we focus on the fixed step-size stochastic approximation algorithm,

$$\hat{\theta}_{t+1} = \hat{\theta}_t + \mu P_t(\mu)\phi_t(y_t - \phi_t^T \hat{\theta}_t), \tag{2}$$

where μ is referred to as the adaptation step-size and $\{P_t(\mu)\}_{t\geq 0}$ is a sequence of random matrices (possibly depending on the step-size μ) which can be chosen in a number of different ways.

Least mean square (LMS) algorithm. By far the most popular algorithm in that class is the least mean square algorithm (LMS), introduced in a landmark paper by [36]. In that case, $P_t(\mu) = I$. Such an algorithm is referred to as a gradient algorithm, because the increment of the algorithm is opposite to the (stochastic)

gradient of the mean-square error, $e_t(\theta) = E(y_t - \phi_t^T\theta)^2$. A useful variant of the LMS is the normalized LMS, in which the gradient is normalized by its norm,

$$P_t = \frac{1}{1+\epsilon\|\phi_t\|^2}, \quad \epsilon > 0.$$

Recursive least square (RLS) algorithm. This algorithm is derived by minimizing $\sum_{i=0}^{t}(1-\mu)^{t-i}(y_i - \theta^T\phi_i)^2$ ("old" measurements are exponentially discounted, with a "forgetting factor" $(1-\mu)$, where μ controls the effective memory of the algorithm). The minimization of the least-squares criterion can be performed recursively using (2) with

$$P_t(\mu)^{-1} = (1-\mu)P_{t-1}^{-1}(\mu) + \mu\phi_t\phi_t^T, \quad t \geq 1, \tag{3}$$

$$P_t(\mu) = (1-\mu)^{-1}\left(P_{t-1}(\mu) - \mu\frac{P_{t-1}(\mu)\phi_t\phi_t^T P_{t-1}(\mu)}{(1-\mu)+\mu\phi_t^T P_{t-1}(\mu)\phi_t}\right), \tag{4}$$

where $P_0 > 0$.

Kalman filter. In this case,

$$P_t(\mu) = [K_t(\mu) - \mu Q]R^{-1}, \tag{5}$$

$$K_t(\mu) = [K_{t-1}(\mu)^{-1} + \mu R^{-1}\phi_t\phi_t^T]^{-1} + \mu Q, \tag{6}$$

where $P_0 \geq 0$, $R > 0$, and $Q > 0$ are deterministic and can be arbitrarily chosen. It is well known (see, e.g., Caines [5, Chapter 5]) that if ϕ_t is $\sigma(y_i, i \leq t)$ measurable and $(v_t, w_t) \triangleq (v_t, \theta_t - \theta_{t-1})$ is a Gaussian white noise process, then θ_t is the minimum variance estimate for θ_t, $\hat{\theta}_t = E(\theta_t|\mathcal{F}_{t-1})$ and $P_t(\mu) = E(\theta_t\theta_t^T|\mathcal{F}_{t-1})$, provided that $E\Delta_t\Delta_t^T = \mu Q$ and $R = Ev_t^2$, $\hat{\theta}_0 = E\theta_0$ and $P_0 = E((\hat{\theta}_0 - \theta_0)(\hat{\theta}_0 - \theta_0)^T) - P_0$.

There is a vast literature on the analysis of algorithms of type (2). In most contributions, the main goal is to obtain bounds on the tracking errors. Preliminary results in that direction have been obtained by [3], [8]; see [9] for a review of these early contributions.

As pointed out in [19], it is also of interest to have not only tracking bounds but "approximate" and "tractable" expressions for the moment of the tracking error, and in particular, for the covariance of the tracking error. Such expressions enable the evaluation of the impact, both qualitatively and quantitatively, of different factors on the tracking performance (e.g., the dependence structure of the regressor sequence, the observation noise, and the lag noise). The dependence on this quantity does not appear clearly in the expressions of the bounds.

The main purpose of this paper is to present a method enabling us to obtain "approximate" expansions of the tracking error covariance (as well as higher-order moments) of "arbitrary" accuracy. The proposed method, based on a technique initially proposed by [29], [30] (see also [31], [32]) to analyze the LMS algorithm, consists in approximating the process defined in (2) by a family of nested processes, with simpler structure than the original error process. This decomposition enables us to compute approximations for the moments of the tracking errors and other related quantities which are valid up to any arbitrary order. These approximations are obtained as solutions of linear equations with coefficients that can be readily deduced from the moments of the regression sequence, the regression noise, and the lag noise.

The paper is organized as follows. In section 2, the perturbation expansion method is presented. In section 3, the main results of this contribution are stated. An illustration of these results is presented in section 5.

2. Perturbation expansion: The method.

To analyze any adaptive algorithm, it is usually convenient to convert it to a so-called error form; indeed from (1) and (2), we can write

$$\tilde{\theta}_{t+1} = (I - \mu P_t(\mu)\phi_t\phi_t^T)\tilde{\theta}_t + \mu P_t(\mu)\phi_t v_t - w_{t+1}, \tag{7}$$

where $\tilde{\theta}_t \triangleq \hat{\theta}_t - \theta_t$ is the weight-error vector and $w_{t+1} \triangleq \theta_{t+1} - \theta_t$ is the lag noise. This is a time-varying nonhomogeneous difference equation. Since this equation is linear, $\tilde{\theta}_{t+1}$ can further be decomposed as

$$\tilde{\theta}_t = {}^{u}\tilde{\theta}_t + \mu\,{}^{v}\tilde{\theta}_t +{}^{w}\,\tilde{\theta}_t, \tag{8}$$

$${}^{u}\tilde{\theta}_{t+1} = (I - \mu P_t(\mu)\phi_t\phi_t^T)\,{}^{u}\tilde{\theta}_t, \qquad {}^{u}\tilde{\theta}_0 = \tilde{\theta}_0 = -\theta_0, \tag{9}$$

$${}^{v}\tilde{\theta}_{t+1} = (I - \mu P_t(\mu)\phi_t\phi_t^T)\,{}^{v}\tilde{\theta}_t + P_t(\mu)\phi_t v_t, \qquad {}^{v}\tilde{\theta}_0 = 0, \tag{10}$$

$${}^{w}\tilde{\theta}_{t+1} = (I - \mu P_t(\mu)\phi_t\phi_t^T)\,{}^{w}\tilde{\theta}_t - w_{t+1}, \qquad {}^{w}\tilde{\theta}_0 = 0. \tag{11}$$

$\{{}^{u}\tilde{\theta}_t\}$ is a transient term, reflecting the way the successive estimates of the regression coefficients forget the initial conditions. $\{{}^{v}\tilde{\theta}_t\}$ accounts for the errors introduced by the measurement noise, $\{v_t\}$; similarly, $\{{}^{w}\tilde{\theta}_{t+1}\}$ accounts for the errors associated with lag noise $\{w_t\}$. According to these definitions, ${}^{v}\tilde{\theta}_t$ and ${}^{w}\tilde{\theta}_t$ obey an inhomogeneous stochastic recurrence equation

$$\delta_{t+1} = (I - \mu F_t(\mu))\delta_t + \xi_t(\mu) = \sum_{s=0}^{t} \Phi(t, s; \mu)\xi_s, \quad \delta_0 = 0, \tag{12}$$

where $\{F_t(\mu)\}_{t\geq 0}$ is a $(d \times d)$ matrix valued random process, $\{\xi_t(\mu)\}_{t\geq 0}$ is a $(d \times 1)$ vector-valued random process, and $\Phi(t, s; \mu)$ is defined as

$$\Phi(t, s; \mu) = \begin{cases} (I - \mu F_t(\mu))(I - \mu F_{t-1}(\mu)) \cdots (I - \mu F_{s+1}(\mu)), & t > s, \\ I, & t = s, \\ 0 & \text{otherwise.} \end{cases}$$

Equations (10) and (11) may be rewritten as (12) with $F_t(\mu) = P_t(\mu)\phi_t\phi_t^T$ and

$$\xi_t(\mu) = P_t(\mu)\phi_t v_t \quad \text{measurement noise}, \quad \xi_t = -w_{t+1} \quad \text{lag noise}. \tag{13}$$

In what follows, we will for ease of notation omit the dependence in the step-size μ when this dependence can be readily inferred from the context.

In this section, we concentrate on the general recurrence equation (12). We apply the results to the lag-error term $\tilde{\theta}_t$ in the next section. Equations of the form (12) have received considerable attention in the literature.

The approach developed in this contribution relies upon a perturbation technique (see [24]). Applied to the recurrence equation (12), the whole procedure goes as follows. The basic idea consists in replacing the random matrix $F_t(\mu)$ by an appropriately chosen *deterministic* matrix $\bar{F}_t(\mu)$, and then decomposing the recurrence equations (12) into two separate recursions:

$$J_{t+1}^{(0)} = (I - \mu\bar{F}_t(\mu))J_t^{(0)} + \xi_t, \quad J_0^{(0)} = 0, \tag{14}$$

$$H_{t+1}^{(0)} = (I - \mu F_t(\mu))H_t^{(0)} + \mu Z_t J_t^{(0)}, \qquad H_0^{(0)} = 0, \tag{15}$$

$$\delta_t = J_t^{(0)} + H_t^{(0)}, \tag{16}$$

where $Z_t = \bar{F}_t(\mu) - F_t(\mu)$. In the original construction by [30], the deterministic matrix $\bar{F}_t(\mu)$ was chosen to be the expectation of $F_t(\mu)$. This choice is adequate for the LMS algorithm, but not for more general tracking algorithms (RLS/Kalman algorithms). Explicit constructions of "appropriate" deterministic sequences $\{\bar{F}_t(\mu)\}$ for such cases will be given later.

According to (14), $J_t^{(0)}$ satisfies a deterministic inhomogeneous first-order linear difference equation

$$J_{t+1}^{(0)} = \sum_{s=0}^{t} \psi(t,s)\xi_s, \tag{17}$$

where, as above,

$$\psi(t,s) = \begin{cases} (I-\mu\bar{F}_t)(I-\mu\bar{F}_{t-1})\cdots(I-\mu\bar{F}_{s+1}), & t > s, \\ I, & t = s, \\ 0 & \text{otherwise.} \end{cases}$$

Under appropriate assumptions on the matrix valued sequences $\{F_t\}_{t\geq 0}$ and on the excitation $\{\xi_t\}$, it will be shown that, for some $p > 0$, there exists a constant $C < \infty$ and $\mu_0 > 0$ such that $\forall\ 0 < \mu \leq \mu_0$,

$$\sup_{t\geq 0} \|J_t^{(0)}\|_p \leq C/\sqrt{\mu} \quad \text{and} \quad \sup_{t\geq 0} \|H_t^{(0)}\|_p \leq C, \tag{18}$$

where $C < \infty$ is a constant depending on $\{F_t\}$ and $\{\xi_t\}$ (see below). Thus, $J_t^{(0)}$ may be considered as the leading term in the expansion, while $H_t^{(0)}$ may be seen as a correction term. The same procedure can be iterated to obtain higher-order approximations. For that purpose, it suffices to iterate the decomposition up to the desired order $n > 1$. Using this technique, the weight-error vector δ_t may be decomposed as

$$\delta_t = J_t^{(0)} + J_t^{(1)} + \cdots + J_t^{(n)} + H_t^{(n)}, \tag{19}$$

where the processes $J_t^{(r)}$, $0 \leq r \leq n$, and $H_t^{(n)}$ are respectively defined as

$$J_{t+1}^{(0)} = (I-\mu\bar{F}_t)J_t^{(0)} + \xi_t, \qquad J_0^{(0)} = 0, \tag{20}$$

$$J_{t+1}^{(r)} = (I-\mu\bar{F}_t)J_t^{(r)} + \mu Z_t J_t^{(r-1)}, \qquad J_t^{(r)} = 0,\ 0 \leq t < r, \tag{21}$$

$$H_{t+1}^{(n)} = (I-\mu F_t)H_t^{(n)} + \mu Z_t J_t^{(n)}, \qquad H_t^{(n)} = 0,\ 0 \leq t < n. \tag{22}$$

The processes $J_t^{(r)}$ depend linearly on ξ_t and polynomially in the error $Z_t = \bar{F}_t - F_t$. It is thus feasible (examples are given below) to compute the joint moments of these processes and to obtain expressions for the moments of $\tilde{\delta}_t^{(n)} = J_t^{(0)} + \cdots + J_t^{(n)}$. The residual term $H_t^{(n)}$ is, under appropriate conditions, uniformly bounded, i.e., there exists some constant $C < \infty$ and $\mu_0 > 0$, such that, $\forall\ 0 < \mu \leq \mu_0$, we have

$$\sup_{t\geq 0} \|H_t^{(n)}\|_p \leq C\mu^{n/2}. \tag{23}$$

Upper bounds for the constant C (depending upon the regression sequence, the observation noise, and the lag noise) are given below. $\tilde{\delta}_t^{(n)}$ is thus the leading term of the expansion, whereas $H_t^{(n)}$ is a remainder, which is uniformly bounded in L_p. By computing the moments of $\tilde{\delta}_t^{(n)}$, one can obtain an approximation of the moments of the tracking error δ_t, the error between the exact and the approximate expressions being uniformly bounded by $\mu^{n/2}$.

Remark.

- First-order expansion has been used by many contributors to obtain an approximate expression of the tracking error covariance matrix; see, e.g., [9], [10], [20], [11], [12], [13], [14], [15] for applications of this method.
- Solo in [29], [30] (see also [34], [33]) was the first to propose a construction allowing the computation of higher-order approximations for the covariance matrix of the tracking error of the LMS algorithm (extensions of this construction to general tracking algorithms are presented in [34]). [30] and [34] used this construction to obtain explicitly a second-order expansion of the covariance of the tracking error of the LMS algorithm. The construction by [29], [30] is essentially equivalent to the perturbation expansion outlined above.

3. Main results.

3.1. Preliminaries.

Before stating the main assumptions and results, it is necessary to state some definitions. All the processes are assumed to be defined on the same probability space $(\Omega, \mathcal{A}, P)$. Let $X \overset{\Delta}{=} \{X_t\}_{t\in\mathbb{Z}}$ be a vector-valued random process. The σ-field generated by the random variables X_t, $a \le t \le b$, is denoted $\mathcal{M}_a^b(X)$.

Boundedness in L_p. For $p > 0$, and $\mathcal{B} \subset \mathcal{A}$, denote $L_p(\Omega, \mathcal{B}, P)$ as the space of $\mathcal{B}$-measurable random variables such that $\|X\|_p < \infty$; for brevity, we set $L_p(\Omega, \mathcal{A}, P) = L_p$. A random matrix sequence $\{X_t\}_{t\ge 0}$ is called L_p-bounded if $\sup_{t\ge 0} \|X_t\|_p < \infty$.

Exponential stability. After [12], define, for $p \ge 1$, $\mu^* > 0$, and $0 < \beta < 1/\mu^*$, $\mathcal{S}(p, \beta, \mu^*)$ as the set of *random* matrix-valued processes $\{A_k(\mu)\}_{k\in\mathbb{N}}$ satisfying

$$\mathcal{S}(p,\beta,\mu^*) = \left\{ A(\mu) = \{A_k(\mu)\}_{k\in\mathbb{N}} : \left\| \prod_{j=i+1}^{k} (I - \mu A_j(\mu)) \right\|_p \right.$$
$$\left. \le K_{\beta,\mu^*}(A)\,(1-\beta\mu)^{k-i} \qquad \forall\, \mu \in (0,\mu^*],\ \forall\, k \ge i \ge 0 \right\},$$

where the constant $K_{\beta,\mu^*}(A)$ does not depend on μ. $\mathcal{S}(p,\beta,\mu^*)$ is referred to as the L_p *exponentially stable* family. Likewise, define the *averaged exponentially stable* family as the set of deterministic matrix-valued processes $\{A_k(\mu)\}_{k\in\mathbb{N}}$:

$$\mathcal{S}(\beta,\mu^*) = \left\{ \bar{A}(\mu) = \{\bar{A}_k(\mu)\}_{k\in\mathbb{N}} : \left| \prod_{j=i+1}^{k} (I - \mu \bar{A}_j(\mu)) \right| \right.$$
$$\left. \le K_{\beta,\mu^*}(\bar{A})\,(1-\beta\mu)^{k-i} \qquad \forall\, \mu \in (0,\mu^*],\ \forall\, k \ge i \ge 0 \right\}.$$

Weak dependence. After [7], we define weak-dependence as follows. Let $q \geq 1$ and let $X = \{X_n\}_{n \geq 0}$ be an $(l \times 1)$ matrix-valued process. Let $\delta = (\delta(r))_{r \in \mathbb{N}}$ be a sequence of positive numbers decreasing to zero at infinity. The process $X = \{X_n\}_{n \geq 0}$ is said to be (δ, q)-weak dependent if there exist finite constants $C = \{C_1, \ldots, C_q\}$ such that for any $1 \leq m < s \leq q$, any $m$tuple $t_1, \ldots, t_m$, and any $(s-m)$tuple $t_{m+1}, \ldots, t_s$, with $t_1 \leq \cdots \leq t_m < t_m + r \leq t_{m+1} \leq \ldots t_s$, it holds

$$\sup_{1 \leq i_1, \cdots, i_s \leq l} \left| \operatorname{cov}\left(\tilde{X}_{t_1,i_1} \cdots \tilde{X}_{t_m,i_m}, \tilde{X}_{t_{m+1},i_{m+1}} \cdots \tilde{X}_{t_s,i_s} \right) \right| \leq C_s \delta(r),$$

where $\tilde{X}_{n,i}$ denotes the ith component of $X_n - E(X_n)$.

Rosenthal's class. Rosenthal's class is defined as the class of vector-valued stochastic processes $\epsilon \triangleq \{\epsilon_k\}_{k \geq 0}$ verifying Rosenthal's inequality (see, e.g., [27, Theorem 2.9]). More specifically,

$$(24) \quad \mathcal{N}(p) = \left\{ \epsilon : \left\| \sum_{k=s}^{t} D_k \epsilon_k \right\|_p \leq \rho_p(\epsilon) \left(\sum_{k=s}^{t} |D_k|^2 \right)^{1/2} \quad \forall\, 0 \leq s \leq t \text{ and } \right.$$
$$\left. \forall\, D = \{D_k\}_{k \in \mathbb{N}}\ (q \times l) \text{ deterministic matrices} \right\}.$$

Exponential stability. L_p exponential stability forms the basis of the stability analysis of linear state space systems (see, e.g., [10], [12], [13], [14], [34, sec. C6], [33]). It is a natural extension of the notion of exponential stability for deterministic linear systems. To our knowledge, the notion of L_p exponential stability was introduced by [8]; these authors provide restrictive conditions (m-independence and moment conditions) for a family of random matrices to be in $\mathcal{S}(p, \beta, \mu_0)$. As evidenced by many authors since then, L_p exponential stability is the crux of the analysis of stochastic difference equations of the form (12) and many practical methods and criteria to establish this property have been obtained. Without entering into too much detail, L_p exponential stability requires some strengthening of the classical "persistence of excitation" condition, which is the classical condition to study the stability of nonstationary deterministic linear systems. The type of strengthening precisely needed depends upon the algorithm under consideration, but generally involves moments and mixing conditions. Early contributions in this direction include the work of [10] on the Kalman algorithm and [1], [2], and [11] on the RLS algorithm. Some general conditions to check L_p exponential stability are presented in [12] (with applications to the LMS, the RLS, and the Kalman algorithm); some improvements of these results can be found in a series of papers coauthored by [13], [14], [15]. Necessary and sufficient conditions for the LMS algorithm are presented in [15]. Alternate conditions implying exponential stability have been obtained in the case where the matrix valued process $\{F_t\}_{t \geq 0}$ is Markovian symmetric [28].

Weak-dependence. Weak-dependence states a kind of "decorrelation" between the past and the future of the process. Weak-dependence is essential in the developments that follow and appear at several places. The notion of weak-dependence, introduced by [7], is a way to weaken more classical "strong mixing" assumptions. As shown in [7], weak-dependent processes encompass a large class of models and in particular strongly mixing processes, weak shift processes, or models with a Markovian representation. The following lemma shows that strong-mixing processes also are weak-mixing and give the relation between the strong-mixing coefficient $\alpha_X(\tau)$ and the sequence $\delta(\tau)$ appearing in the definition of weak-dependent processes. We have the following lemma.

LEMMA 1. *Assume that $X = \{X_t\}_{t\geq 0}$ is an $(l \times 1)$ strongly mixing process and that*

$$\sup_{t\geq 0} \sup_{1\leq i\leq l} \|X_{t,i}\|_{q'} < \infty$$

for some $q' > q$. Then $X = \{X_t\}_{t\geq 0}$ is (δ, q)-weak dependent, with, for $s \in \{1, \dots, q\}$,

$$\delta(r) = \alpha(r)^{(q'-q)/q'}, \quad r \geq 1,$$
$$C_s = 12 \left(\sup_{t\geq 0} \sup_{1\leq i\leq l} \|X_{t,i}\|_{s+q'-q} \right)^s .$$

This proof is directly adapted from [7] (see also [6], [35] for similar results and arguments).

Rosenthal's inequality. Rosenthal's class gathers all the processes that verify a Rosenthal's type inequality. By direct applications of the Rosenthal's inequality [27], $\mathcal{N}(p)$ includes sequences $\epsilon = \{\epsilon_k\}_{k\geq 0}$ of independent random variables with zero-mean and uniformly bounded pth order moment. By application of Burkholder's inequality for martingales, martingales with L_p stable increments also belong to this class. Of course, the class of processes belonging to this class is much larger than that, including many processes satisfying moment and mixing conditions. Some typical examples of processes belonging to $\mathcal{N}(p)$ are given in the proposition below.

PROPOSITION 2. *$\{\epsilon_t\}$ belongs to $\mathcal{N}(p)$ if*

(i) *$\{\epsilon_t\}_{t\geq 0}$ is an L_p-bounded martingale increment:* $\sup_{t\geq 0} \|\epsilon_t\|_p < \infty$. *In this case, $\rho_p(\epsilon)$ in* (24) *may be chosen to be*

$$\rho_p(\epsilon) = B_p \sup_{s\geq 0} \|\epsilon_s\|_p, \tag{25}$$

where B_p is a universal constant that depends only on p and l (the dimension of the $\{\epsilon_s\}$).

(ii) *$\{\epsilon_t\}_{t\geq 0}$ is zero-mean and (δ, q) weak-dependent with $q = 2[(p+1)/2]$ and $\sum_{r=1}^{\infty}(r+1)^{(q/2-1)}\delta(r) < \infty$ (the constant $\rho_p(\epsilon)$ can be found from the proof).*

As mentioned above, (i) is a consequence of Burkholder's inequality for martingales (see [16]). (ii) can be adapted from the results of [7]. A proof is in Appendix A (see also [17, Proposition 10, Corollary 11], where a Rosenthal's inequality is proved for α-mixing processes).

To conclude this section, it is worthwhile to note that $\mathcal{N}(p)$ is invariant under stable linear time-varying transformation. This means that, if $\{\epsilon_k\} \in \mathcal{N}(p)$, then the process $\{\epsilon'_k\}$ defined as

$$\epsilon'_k = \sum_{j=-\infty}^{\infty} A(k,j)\epsilon_{k-j} \qquad \sum_{j=-\infty}^{\infty} \sup_k |A(k,j)| < \infty,$$

where $A(k,j)$ are deterministic matrices, also belongs to $\mathcal{N}(p)$. Moreover, the constants are upper bounded by

$$\rho_p(\epsilon') \leq \rho_p(\epsilon) \left(\sum_{j=-\infty}^{\infty} \sup_k |A(k,j)| \right). \tag{26}$$

Thus, random processes generated from martingale differences or (δ, q) weak-dependent processes via an infinite order time-varying linear filter can all be included in $\mathcal{N}(p)$.

3.2. Assumptions on $\{F_k\}_{k\geq 0}$.

According to the structure of the recursion involved in the definition of the LMS, RLS, and Kalman algorithms, it is assumed in what follows that the sequence of matrices $\{F_k(\mu)\}_{k\geq 0}$ may be decomposed as a product

$$F_k(\mu) = P_k(\mu) G_k, \tag{27}$$

where $\{P_k(\mu)\}_{k\geq 0}$ is a sequence of random matrices that can be approximated (in a sense given below) by a sequence of deterministic matrices $\{\bar{P}_k(\mu)\}_{k\geq 0}$ and $\{G_k\}_{k\geq 0}$ is a sequence of random matrices (that do not depend on the step-size μ) and that verify some moment and weak-dependence conditions. For the three different tracking algorithms considered in this paper, we set $G_k = \phi_k \phi_k^T$, while $P_k(\mu)$ is a random weight whose specific form depends upon the tracking algorithm. The sequence of matrices $\bar{F}_k(\mu)$ needed to construct the approximations is defined as $\bar{F}_k(\mu) = \bar{P}_k(\mu) E(G_k)$. The conditions that are typically required for the sequence $F_k(\mu)$ and $\bar{F}_k(\mu)$ are that, for some $r, q \in \mathbb{N}$, $\mu_0 > 0$, and $0 < \beta < 1/\mu_0$,

(F1) (r, β, μ_0). $\{F_k(\mu)\}_{k\geq 0}$ is in $\mathcal{S}(r, \beta, \mu_0)$, i.e., $\{F_k(\mu)\}$ is L_r-exponentially stable,
(F2) (β, μ_0). $\{\bar{F}_k(\mu)\}_{k\geq 0}$ is in $\mathcal{S}(\beta, \mu_0)$, i.e., $\{\bar{F}_k(\mu)\}_{k\geq 0}$ is averaged exponentially stable,
(F3) (q, μ_0). $\sup_{t\in\mathbb{N}} \sup_{\mu\in(0,\mu_0]} \|P_t(\mu)\|_q < \infty$, $\sup_{t\in\mathbb{N}} \sup_{\mu\in(0,\mu_0]} |\bar{P}_t(\mu)| < \infty$,
(F4) (q, μ_0). $\sup_{t\in\mathbb{N}} \sup_{\mu\in(0,\mu_0]} \mu^{-1/2} \|P_t(\mu) - \bar{P}_t(\mu)\|_q < \infty$.

As mentioned above, assumptions (F1)–(F2) are classical in the study of random linear systems, and hold under "generalized persistence of excitation" conditions (see the discussion above on exponential stability). The same conditions typically imply (F3) (see, e.g., [20], [11], and [12]; see also [1], [2] for related results on the forgetting factor RLS alogorithm).

The last condition (F4), meaning that the random matrices $P_t(\mu)$ differ only by a (small) amount (controlled by the step-size μ) from a deterministic matrix $\bar{P}_t(\mu)$, is perhaps less classical, though it has often been used to study the forgetting factor RLS algorithm [1], [2] (see also [11], for the Kalman filter). For the LMS algorithm, $P_k(\mu) = I$ and we set $\bar{P}_k(\mu) = I$ and this assumption is trivially fulfilled. For the RLS algorithm and the Kalman algorithm, the situation is slightly more complicated. For completeness, we treat the matter in some detail for the RLS algorithm and only outline the necessary ingredients of the construction for the Kalman algorithm.

RLS algorithm. For the RLS algorithm, the deterministic sequence of matrices $\{\bar{P}_k(\mu)\}_{k\geq 0}$ is recursively defined as

$$\bar{P}_{k+1}^{-1}(\mu) = (1-\mu)\bar{P}_k^{-1}(\mu) + \mu E(\phi_{k+1}\phi_{k+1}^T), \qquad \bar{P}_0(\mu) = R_0, \tag{28}$$

where R_0 is the initial condition for $P_0(\mu)$, i.e., the same initial condition is used for $P_0(\mu)$ and $\bar{P}_0(\mu)$. Note that

$$P_k^{-1}(\mu) = \mu^k P_0 + \mu \sum_{j=0}^{k} (1-\mu)^{k-j} \phi_j \phi_j^T, \tag{29}$$

$$\bar{P}_k^{-1}(\mu) = \mu^k P_0 + \mu \sum_{j=0}^{k} (1-\mu)^{k-j} E(\phi_j \phi_j^T) \tag{30}$$

so that $P_k^{-1}(\mu) - \bar{P}_k^{-1}(\mu) = \mu \sum_{j=0}^k (1-\mu)^{k-j}(\phi_j \phi_j^T - E(\phi_j\phi_j^T))$. Provided that the sequence $\{\phi_k\phi_k^T - E(\phi_k\phi_k^T)\}_{k\geq 0}$ belongs to Rosenthal's class $\mathcal{N}(b)$ $(b > 1)$, it holds that

$$\|P_k^{-1}(\mu) - \bar{P}_k^{-1}(\mu)\|_b \leq \rho_b(\phi\phi^T)\mu \left(\sum_{j=0}^k (1-\mu)^{2(k-j)}\right)^{1/2} \leq C_b(\phi\phi^T)\sqrt{\mu} \tag{31}$$

for $0 < \mu < 1$. Since, by applying the Holder inequality

$$\|P_k(\mu) - \bar{P}_k(\mu)\|_p \leq \|P_k(\mu)\|_a \|P_k^{-1}(\mu) - \bar{P}_k^{-1}(\mu)\|_b \; |\bar{P}_k(\mu)|$$

for any $a > 0$, $b > 0$ such that $a^{-1} + b^{-1} = p^{-1}$, (31) shows that assumption (F4) holds as soon as (F3) (a, μ_0)) is satisfied.

Kalman algorithm. For the Kalman algorithm, the deterministic sequence of matrices $\bar{P}_k(\mu)$ is defined as

$$\bar{P}_k(\mu) = [\bar{K}_k(\mu) - \mu Q]R^{-1}, \tag{32}$$

$$\bar{K}_k(\mu) = [\bar{K}_{k-1}(\mu)^{-1} + \mu R^{-1} E(\phi_k\phi_k^T)]^{-1} + \mu Q, \tag{33}$$

where, by convention, we set $\bar{P}_0(\mu) = P_0(\mu) = P_0$. Assumption (F4) may be verified along the same lines as above (see, e.g., [13]).

3.3. Assumptions on the excitation sequence $\boldsymbol{\xi = \{\xi_k\}_{k\geq 0}}$. In addition to the above stated assumptions on the matrix process $F = \{F_k\}_{k\geq 0}$, we need to impose some conditions on the excitation sequence $\xi = \{\xi_k\}_{k\geq 0}$. To cover the analysis of stochastic tracking algorithms, it is convenient to assume that the excitation $\xi_t(\mu)$ may be decomposed as

$$\xi_t(\mu) = M_t(\mu)\epsilon_t, \tag{34}$$

where the process $M = \{M_t(\mu)\}_{t\geq 0}$ is a $(d \times l)$ matrix-valued process, $\epsilon = \{\epsilon_t\}_{t\geq 0}$ is an $(l \times 1)$ vector-valued process, and both processes verify the following assumptions.

(EXC1) $\{M_t(\mu)\}_{t\in\mathbb{Z}}$ is $\mathcal{M}_0^t(\phi)$-adapted and $\mathcal{M}_0^t(\epsilon)$ and $\mathcal{M}_0^t(\phi)$ are independent.

(EXC2) $(r, \mu 0)$, $(r > 0,\ \mu_0 > 0)$ $\sup_{\mu\in(0,\mu_0]} \ \sup_{t\geq 0} \ \|M_t(\mu)\|_r < \infty$.

(EXC3) (p, μ_0) $(p > 0,\ \mu_0 > 0)$ $\epsilon = \{\epsilon_t\}_{t\in\mathbb{N}}$ belongs to Rosenthal's class $\mathcal{N}(p)$.

Recall that, in the application to stochastic tracking algorithms, $M_t(\mu)$ is equal either to $P_t(\mu)\phi_t$ (for the measurement noise) or to the identity $M_t = I$ (for the lag noise). For general tracking algorithms, the sequence $P_t(\mu)$ is computed recursively from the sequence of regressors, so that $P_t(\mu)$ is adapted to the sequence of σ-subfields $\sigma(\phi_s, 0 \leq s \leq t)$. The noise ϵ_t is either equal to the measurement noise v_t or to the lag noise w_t. Assumption (EXC1) thus covers the case where the measurement noise and the lag noise are independent of the regressor sequence. It excludes some applications of interest, where the regressors ϕ_t depend on the past of θ_t (occurring in tracking in ARX models).

For the LMS algorithm, $M_t(\mu) = \phi_t$ (for the measurement) noise, and the boundedness of $M_t(\mu)$ (assumption (EXC2)) follows from the stability of the regressor sequence. For the RLS and Kalman algorithms, $M_t(\mu) = P_t(\mu)\phi_t$, and the boundedness of $M_t(\mu)$ follows from the boundedness of $P_t(\mu)$ and the stability of the regressor sequence. This assumption is a consequence of the generalized persistence of excitation condition, as mentioned above.

The third condition states that $\{v_t\}$ and $\{w_t\}$ belong to Rosenthal's class provided that $\{v_t\}$ and $\{w_t\}$ are either martingale increments or zero-mean weakly dependent sequences, with uniformly bounded moments. This assumption covers many cases of practical interest. When specialized to the study of the "tracking" component ($\xi_t = w_t$), it means that θ_t follows a generalized random walk, with nonstationary and dependent increment. The L_p moment of the parameter to track $\|\theta_t\|_p$ is assumed to grow like $\sqrt{t}$. The result can be adapted to the case where θ_t is zero-mean L_p stable (but the results are in that case slightly different). Tracking of deterministic trends is not covered.[1]

Because of the independence of the noise $\{\epsilon_k\}$ and of the regression sequence $\{\phi_k\}$, the following is easily shown.

PROPOSITION 3. *Let $q > p$ and $\mu_0 > 0$. Assume* (EXC1), (EXC2($pq/(q-p), \mu_0$), *and* (EXC3(p)). *Let $\{G_k(\mu)\}_{k\geq 0}$ be an $\mathcal{M}_0^t(\phi)$ adapted sequence, such that $\|G_k(\mu)\|_q < \infty$. Then,*

$$\left\| \sum_{k=s}^{t} G_k(\mu) M_k(\mu) \epsilon_k \right\|_p \leq \rho_p(\epsilon) \sup_{k\geq 0} \|M_k\|_{pq/(q-p)} \left(\sum_{k=s}^{t} \|G_k(\mu)\|_q^2 \right)^{1/2} . \tag{35}$$

3.4. The main results. We may now formulate the central results of our contribution. The first result gives condition upon which $J_s^{(r)}$ is uniformly bounded in L_p and provides an expression for that bound.

THEOREM 4. *Let $n \in \mathbb{N}$ and let $q \geq p \geq 2$. Assume* (EXC1), (EXC2($pq/(q-p), \mu_0$)), *and* (EXC3(p)). *For $a, b, \beta > 0$, $a^{-1} + b^{-1} = 1$, and some $\mu_0 > 0$, assume in addition* (F2(β, μ_0)), (F4(aqn, μ_0)) *and*

(i) $\{G_t\}_{t\geq 0}$ *is* $(\delta, (q+2)n)$ *weakly dependent, and* $\sum (r+1)^{((q+2)n/2)-1} \delta(r) < \infty$,

(ii) $\sup_{t\geq 0} \|G_t\|_{bqn} < \infty$.

Then, there exists a constant $K < \infty$ (depending on $\delta(k)$, $k \geq 0$, and on the numerical constants $p, q, n, a, b, \mu_0, \beta$ but not *otherwise on $\{\phi_t\}$, $\{\epsilon_t\}$ or on the step-size parameter μ), such that $\forall 0 < \mu \leq \mu_0$, $\forall\ 0 \leq r \leq n$,*

$$\sup_{s\geq 1} \|J_s^{(r)}\|_p \leq K\ \rho_p(\epsilon) \sup_{k\geq 0} \|M_k\|_{pq/(q-p)}\ \mu^{(r-1)/2}. \tag{36}$$

(The precise value of the constant K may be found from the proof.)

The proof is given in Appendix B. To complete our program, we need to bound the remainder term $H_s^{(n)}$. We will prove that, under appropriate conditions, the moments of $H_s^{(n)}$ are bounded by the moments of $J_s^{(n+1)}$. Since Theorem 4 states conditions upon which $\|J_s^{(n+1)}\|_p \leq K\mu^{n/2}$, this will in turn allow us to specify technical conditions upon which the remainder $H_s^{(n)}$ is bounded in L_p, i.e., $\sup_{s\geq 0} \|H_s^{(n)}\| \leq K\mu^{n/2}$.

THEOREM 5. *Let $p \geq 2$ and let $a, b, c > 0$ such that $1/a + 1/b + 1/c = 1/p$. Let $n \in \mathbb{N}$. Assume* (F1(a, β, μ_0)) *and*

(i) $\sup_{s\geq 0} \|Z_s\|_b < \infty$ *and*

(ii) $\sup_{s\geq 0} \|J_s^{(n+1)}\|_c < \infty$.

Then, there exists a constant $K' < \infty$ (depending on the numerical constants a, b, c, β, μ_0, n but not on the process $\{\epsilon_t\}$ or on the step-size parameter μ), such that

[1] It should be stressed, however, that the perturbation expansion technique can be adapted to the study of such tracking problems. This particular setting is not studied in detail due to space limitations.

$\forall\ 0 < \mu \leq \mu_0$,

$$\sup_{s \geq 0} \| H_s^{(n)} \|_p \leq K' \sup_{s \geq 0} \| J_s^{(n+1)} \|_c. \tag{37}$$

(The precise value of K' may be found from the proof.)

The proof of Theorem 5 is based on the decomposition $H_s^{(n)} = J_s^{(n+1)} + H_s^{(n+1)}$. It thus amounts to showing that $H_s^{(n+1)}$ is bounded in L_p. Since

$$H_t^{(n+1)} = \mu \sum_{s=0}^{t} \Phi(t,s) Z_t J_t^{(n+1)},$$

the proof stems directly from the exponential stability of $\Phi(t,s)$, the uniform boundedness of moments of $\{Z_s\}$ (which can be also translated in terms of boundedness of moments of $P_t(\mu)$ and of the driving terms G_t). Details are given in Appendix B.

4. Performance of adaptive tracking algorithms. A number of useful error bounds or expressions can be derived from the results above. We use the notations of section 1. According to (8), the tracking error may be expanded as $\tilde{\theta}_t =^u \tilde{\theta}_t + \mu^v \tilde{\theta}_t +^w$ $\tilde{\theta}_t$, where ${}^u\tilde{\theta}_t$, ${}^v\tilde{\theta}_t$, and ${}^w\tilde{\theta}_t$ are respectively defined in (9), (10), and (11). The terms ${}^v\tilde{\theta}_t$ and ${}^w\tilde{\theta}_t$ may further be decomposed as

$${}^v\tilde{\theta}_t = \sum_{k=0}^{r_v} {}^vJ_t^{(k)} + {}^vH_t^{(r_v)}, \tag{38}$$

$${}^w\tilde{\theta}_t = \sum_{k=0}^{r_w} {}^wJ_t^{(k)} + {}^wH_t^{(r_w)}, \tag{39}$$

where r_v and r_w are two integers (not necessarily equal) such that $0 \leq r_v \leq n-1$ and $0 \leq r_w \leq n-1$. To apply Theorems 4 and 5, we need only to check that the assumptions are fulfilled for the measurement noise term and the lag-noise term. Because the particular form of the random matrix sequence $F_t(\mu) = P_t(\mu)\phi_t\phi_t^T$ and of the excitation term $\xi_t(\mu) = P_t(\mu)\phi_t v_t$ (measurement noise) or $\xi_t = -w_t$ (lag noise) have been tailored for studying general tracking algorithms, the assumptions of these theorems easily translate (see the discussion above) into general conditions on the regression sequence, on the measurement and lag noise (in terms of existence and boundedness of moments, mixing coefficients, etc.), and to some "algorithm-dependent" conditions, mainly involving more or less stringent conditions on the regression sequence, in terms of moment and mixing conditions. By direct adaptations of the assumptions of Theorems 4 and 5, it may be shown that

$$\sup_t \| {}^vJ_t^{(k)} \|_p \leq K\rho_p(v) \sup_{k \geq 0} \| P_k(\mu)\phi_k \|_{pq/(q-p)} \mu^{(k-1)/2}, \quad k \in \{0, \ldots, r_v\}, \tag{40}$$

$$\sup_t \| {}^vH_t^{(r_v)} \|_p \leq K\rho_p(v) \sup_{k \geq 0} \| P_k(\mu)\phi_k \|_{pq/(q-p)} \mu^{r_v/2}, \tag{41}$$

$$\sup_t \| {}^wJ_t^{(k)} \|_p \leq K\rho_p(w) \mu^{(k-1)/2}, \quad k \in \{0, \ldots, r_w\}, \tag{42}$$

$$\sup_t \| {}^wH_t^{(r_w)} \| \leq K\rho_p(w) \mu^{r_w/2}. \tag{43}$$

Setting $r_v = r_w = 0$, one obtains the expansion of the tracking error bounds presented in [20], [11], [12] and later extended to more general algorithms by [13], [14], [15].

Higher-order expansions can be used to obtain refined approximation of the tracking error moments (see the discussion below).

Of particular interest is the covariance of the tracking error. If one assumes that the measurement noise and the lag noise are independent, the covariance of the tracking error may be expressed as

$$\Gamma(t) \triangleq E(\tilde{\theta}_t \tilde{\theta}_t^T) =^u \Gamma(t) + \mu^2 \, {}^v\Gamma(t) +^w \Gamma(t),$$

where ${}^u\Gamma(t) = E({}^u\tilde{\theta}(t) {}^u\tilde{\theta}(t)^T)$, ${}^v\Gamma(t) = E({}^v\tilde{\theta}_t^v \tilde{\theta}_t^T)$, and ${}^w\Gamma(t) = E({}^w\tilde{\theta}_t^w \tilde{\theta}_t^T)$. Equation (38) then implies that, e.g., ${}^v\Gamma(t)$ may be expanded as

$${}^v\Gamma(t) = \sum_{k+l=0}^{r_v} E({}^v J_t^{(k)^v} J_t^{(l)\,T}) + O(\mu^{(r_v-1)/2})$$

yielding to a valid approximation to order $(r_v - 1)/2$ (a similar result holds for the lag noise). Two illustrative examples are worked out in the next section.

Remark. The evaluation of the covariance $E({}^v J_t^{(k)^v} J_t^{(l)\,T})$ involves the computation of moments of the form

$$(44) \quad E(\psi(t, s_1) Z_{s_1} \psi(s_1 - 1, s_2) Z_{s_2} \cdots \\ \psi(s_k - 1, s) P_s(\mu) \phi_s v_s^2 \phi_s^T P_s(\mu)^T \psi^T(s, s_l' - 1) Z_{s_l'} \cdots Z_{s_1'} \psi^T(t, s_1')),$$

where $Z_s = \bar{F}_t - F_t = -P_t(\mu)\phi_t\phi_t^T + \bar{P}_t(\mu) E(\phi_t\phi_t^T)$. The evaluation of such moments is straightforward for the LMS algorithm (see below for a worked-out example). The direct evaluation of this moment is not possible when dealing with the RLS algorithm or the Kalman algorithm. When one is willing to obtain an approximation of the moment of the tracking error valid up to order n, it suffices to determine an order n approximation of the moment of the form (44). The way to derive such approximations can be obtained for the RLS algorithm, as shown below (a similar derivation can be done for the Kalman algorithm). The basic ingredients to derive such an expansion are (i) $P_t(\mu)$ differs by $\sqrt{\mu}$ for $\bar{P}_t(\mu)$ and (ii) the joint moments on $P_t^{-1}(\mu)$ can easily be evaluated, because $P_t^{-1}(\mu)$ depends linearly on $\{\phi_s\phi_s^T\}_{1 \le s \le t}$. We focus on the RLS algorithm; similar results can be derived for the Kalman algorithm. Note that, for any integer n, we may write

(45)

$$P_t(\mu) = (\bar{P}_t^{-1}(\mu) - (\bar{P}_t^{-1}(\mu) - P_t^{-1}(\mu)))^{-1} = (I - \bar{P}_t(\mu)(\bar{P}_t^{-1}(\mu) - P_t^{-1}(\mu)))^{-1}\bar{P}_t(\mu),$$

(46)

$$= \sum_{k=0}^{n} [\bar{P}_t(\mu)(\bar{P}_t^{-1}(\mu) - P_t^{-1}(\mu))]^k \bar{P}_t(\mu) + [(\bar{P}_t^{-1}(\mu) - P_t^{-1}(\mu))\bar{P}_t(\mu)]^{n+1} P_t(\mu).$$

Equation (31) shows that, when $\{\phi_s\phi_s^T\}_{s\in\mathbb{N}}$ belongs to Rosenthal's class $\mathcal{N}((n+1)p)$, it holds that

$$\sup_{t\in\mathbb{N}} \sup_{(0<\mu<1)} \mu^{-1/2} \|P_t^{-1}(\mu) - \bar{P}_t^{-1}(\mu)\|_{(n+1)p} < \infty.$$

In addition, under (F3(q, μ_0)), $\sup_{t\in\mathbb{N}} \sup_{\mu\in(0,\mu_0]} \|P_t(\mu)\|_q < \infty$ and $\sup_{t\in\mathbb{N}} \sup_{\mu\in(0,\mu_0]} |\bar{P}_t(\mu)| < \infty$. Hence, for $r, p, q > 0$ and $n \in \mathbb{N}$, $r^{-1} = p^{-1} + q^{-1}$, it holds that there exists some constant $K < \infty$ such that, $\forall\ \mu \in (0, \mu_0]$,

$$\sup_{t\in\mathbb{N}} \left\| P_t(\mu) - \sum_{k=0}^{n} [\bar{P}_t(\mu)(\bar{P}_t^{-1}(\mu) - P_t^{-1}(\mu))]^k \bar{P}_t(\mu) \right\|_r \leq K\mu^{(n+1)/2}$$

and the constant K can be chosen as

$$K = \sup_{t\in\mathbb{N}} \sup_{\mu\in(0,\mu_0]} \|P_t(\mu)\|_q |\bar{P}_t(\mu)|^{n+1} \sup_{t\in\mathbb{N}} \sup_{\mu\in(0,\mu_0]} \mu^{-1/2} \|P_t^{-1}(\mu) - \bar{P}_t^{-1}(\mu)\|_{(n+1)p} < \infty.$$

5. Some worked-out examples. In this section, approximate expressions for the tracking error covariance matrix for the LMS and the RLS algorithm are derived. To illustrate our findings, it is shown in this section that first-order approximation of the tracking error covariance may fail, in certain situations, to capture the behavior of the algorithm. It is argued that a second-order expansion leads to significantly better approximation, in many situations of practical interest; moreover, second-order approximation reveals the impact of certain factors which do not influence the first-order approximation, in particular the dependence between the successive regression vectors. To illustrate these effects without obscuring the presentation with cumbersome notations and details, a very simple situation is considered. Theoretical results are validated by means of a small-scale Monte Carlo experiment. More details will be given in a forthcoming paper.

(M1) The regressor $\{\phi_t\}_{t\geq 0}$ is a strict-sense stationary vector autoregressive process

$$\phi_{t+1} = \kappa\phi_t + u_{t+1},$$

where κ $(-1 < \kappa < 1)$ is a scalar, $\{u_t\}_{t\in\mathbb{Z}}$ is a sequence of independent and identically distributed Gaussian random vectors with zero-mean and covariance matrix $\sigma_u^2 I$.

(M2) The measurement noise process $\{v_t\}_{t\geq 0}$ and the lag-noise process $\{w_t\}_{t\geq 0}$ are two sequences of zero-mean independently and identically distributed (i.i.d) random variables (vectors), with bounded moments of order r, where $r > 2$. We denote $E(v_0^2) = \sigma_v^2$ and $E(w_0 w_0^T) = \gamma^2 I$.

(M3) $\mathcal{M}_0^\infty(v)$, $\mathcal{M}_0^\infty(\phi)$, and $\mathcal{M}(\theta)$ are independent.

Because our main concern in this section is the asymptotic regime, we set $\tilde{\theta}_0 = 0$. To apply the results in section 4, that one may apply Theorems 4 and 5 under (M1–3), we set $b = c = 2r$, $a = 2r/(r-2)$, and $d = r + \delta$, where $\delta > 0$ but is otherwise arbitrary. Note that $a^{-1} + b^{-1} + c^{-1} = p^{-1}$ with $p = 2$.

It follows from [25] that, under (M1), $\{\phi_t\}$ is geometrically completely regular (see also [4]), so that $F_t \triangleq \phi_t\phi_t^T$ is strongly mixing with exponentially decaying strong-mixing coefficient and thus, by Lemma 1 (see Appendix A), weak-dependent with exponentially decaying weak-dependent coefficient. It follows from [28, Theorem 1] that F_t is exponentially stable, i.e., for any $p \geq 1$ there exists $\mu_0 > 0$ and $0 < \beta < 1/\mu_0$ such that $\{F_t\} \in \mathcal{S}(\beta, \mu_0) \cap \mathcal{S}(p, \beta, \mu_0)$. Since $\{v_t\}$ and $\{w_t\}$ are i.i.d, $\{v_t\}$ and $\{w_t\}$ belong to $\mathcal{N}(r)$, with constants $\rho_r(v)$ and $\rho_r(w)$ defined as

$$\rho_r(v) = B_r\sigma_v\mu_r(v), \quad \rho_r(w) = B_r\gamma\mu_r(w),$$

where $\mu_r(v)$ and $\mu_r(w)$ are the standardized rth order moments of v and w, respectively, and B_r is a universal constant (see [27]). Under (M3), the processes $\{{}^v\tilde{\theta}_t\}_{t\geq 0}$ and $\{{}^w\tilde{\theta}_t\}$ are independent. Thus,

$$\Gamma = \lim_{t\to\infty} E(\tilde{\theta}_t\tilde{\theta}_t^T) = {}^v\Gamma\mu^2 + {}^w\Gamma,$$

where ${}^v\Gamma = \lim_{t\to\infty} E({}^v\tilde{\theta}_t^v\tilde{\theta}_t^T)$ and ${}^w\Gamma = \lim_{t\to\infty} E({}^w\tilde{\theta}_t^w\tilde{\theta}_t^T)$. We wish to obtain approximate expressions for ${}^v\Gamma$ and ${}^w\Gamma$, denoted ${}^v\bar{\Gamma}$ and ${}^w\bar{\Gamma}$, such that, $\forall\ \mu \in (0, \mu_0]$,

$$|{}^v\Gamma -{}^v \bar{\Gamma}| \leq K\mu^{1/2} \text{ and } |{}^w\Gamma -{}^w \bar{\Gamma}| \leq K\gamma^2\mu^{1/2},$$

where $K < \infty$ is some constant. To that purpose, we expand ${}^v\tilde{\theta}_t$ and ${}^w\tilde{\theta}_t$ to the second-order:

$$\begin{aligned}{}^v\tilde{\theta}_t &= {}^vJ_t^{(0)} + {}^vJ_t^{(1)} + {}^vJ_t^{(2)} + {}^vH_t^{(2)},\\ {}^w\tilde{\theta}_t &= {}^wJ_t^{(0)} + {}^wJ_t^{(1)} + {}^wJ_t^{(2)} + {}^wH_t^{(2)}.\end{aligned}$$

Under the stated assumptions, it follows from Theorems 4 and 5, that there exists some constant $C < \infty$, such that $\forall\ \mu \in (0, \mu_0]$, we have

$$\begin{aligned}&\sup_{t\geq 0}\left|E({}^vJ_t^{(1)}({}^vJ_t^{(2)} + {}^vH_t^{(2)})^T\right| \leq C\ \ \|\phi_0\|_{r(r+\delta)/\delta}\ \rho_r^2(v)\mu^{1/2}\quad \sup_{t\geq 0}\left|E({}^vJ_t^{(0)v}H_t^{(2)})\right|\\ &\leq C\rho_r(v)\|\phi_0\|_{r(r+\delta)/\delta}\mu^{1/2}\sup_{t\geq 0}\left|E({}^wJ_t^{(1)}({}^wJ_t^{(2)} +^w H_t^{(2)})^T\right|\\ &\leq C\gamma^2\mu_r^2(w)\mu^{1/2}\sup_{t\geq 0}\left|E({}^wJ_t^{(0)w}H_t^{(2)})\right| \leq C\gamma^2\mu_r^2(w)\mu^{1/2}.\end{aligned}$$

It remains to evaluate $\lim_{t\to\infty} E({}^vJ_t^{(0)v}J_t^{(i)})$, $\lim_{t\to\infty} E({}^wJ_t^{(0)w}J_t^{(i)})$, $i = 0, 1, 2$, and $E({}^vJ_t^{(1)v}J_t^{(1)})$ and $E({}^wJ_t^{(1)w}J_t^{(1)})$. Denote $\alpha = \sigma_u^2/(1-\kappa^2)$. Tedious but straightforward calculations show that

$$\begin{aligned}\lim_{t\to\infty} E({}^vJ_t^{(0)v}J_t^{(0)^T}) &= \frac{\sigma_v^2}{\mu(2-\mu\alpha)}I,\\ \lim_{t\to\infty} E({}^vJ_t^{(0)v}J_t^{(1)^T}) &= -\frac{\kappa^2\sigma_v^2(d+1)\alpha}{2(1-\kappa^2)}I + O(\mu),\\ \lim_{t\to\infty} E({}^vJ_t^{(0)v}J_t^{(2)^T}) &= \frac{\kappa^2\sigma_v^2\alpha(d+1)\alpha}{4(1-\kappa^2)}I + O(\mu),\\ \lim_{t\to\infty} E({}^vJ_t^{(1)v}J_t^{(1)^T}) &= \frac{(1+\kappa^2)\sigma_v^2\alpha(d+1)}{4(1-\kappa^2)}I + O(\mu),\end{aligned}$$

yielding the following expression for ${}^v\bar{\Gamma}$:

$$ {}^v\bar{\Gamma} = \frac{\sigma_v^2}{2\mu}I + \alpha\sigma_v^2\frac{d+2}{4}I + O(\mu). \tag{47}$$

It is worthwhile to note that the first-order correction does not depend upon the autoregressive coefficient κ, i.e., the dependence among the successive regressors does not influence the covariance ${}^v\bar{\Gamma}$ up to the second order in the step-size μ. It may be shown that this result holds under much weaker assumptions on the regression sequence $\{\phi_t\}$ (see [26] for a more general discussion), as long as $\{v_t\}$ is a martingale increment and is independent from $\{\phi_t\}$. Similarly, it can be shown that

$$\begin{aligned}
&\lim_{t\to\infty} E({}^wJ_t^{(0)}\,{}^wJ_t^{(0)^T}) = \frac{\gamma^2}{\mu\alpha(2-\mu\alpha)}I,\\
&\lim_{t\to\infty} E({}^wJ_t^{(0)}\,{}^wJ_t^{(1)^T}) = 0,\\
&\lim_{t\to\infty} E({}^wJ_t^{(0)}\,{}^wJ_t^{(2)^T}) = \frac{\gamma^2\kappa^2(d+1)}{4(1-\kappa^2)}I + O(\gamma^2\mu),\\
&\lim_{t\to\infty} E({}^wJ_t^{(1)}\,{}^wJ_t^{(1)^T}) = \frac{\gamma^2(1+\kappa^2)(d+1)}{4(1-\kappa^2)}I + O(\gamma^2\mu),
\end{aligned}$$

yielding the following approximate expression for ${}^w\Gamma$:

$$(48)\qquad {}^w\bar{\Gamma} = \frac{\gamma^2}{2\mu\alpha}I + \frac{\gamma^2}{4}\left(1 + (d+1)\frac{1+2\kappa^2}{1-\kappa^2}\right)I + O(\gamma^2\mu).$$

It is interesting to note that the first-order correction depends upon the autoregressive coefficient κ: when κ is close to 1, the correction term becomes large. This behavior is illustrated in Figures 1 and 2, where the asymptotic tracking error variance $\lim_{t\to\infty}\|\tilde{\theta}_t\|^2$ is displayed as a function of the step-size μ. In both cases, we set $\gamma = 0.05$, $d = 10$, $\sigma_v^2 = 3$ and, for every value of κ, $\sigma_u^2 = 1-\kappa^2$ (so that $\alpha = 1$). Two values of κ are considered: $\kappa = 0$ (Figure 1) and $\kappa = 0.9$ (Figure 2). On the figures, the value of the asymptotic tracking error variance obtained by Monte Carlo simulations (solid line) are compared with the approximate expressions obtained by (i) retaining only the first term in (47) and (48) (dashed line) or (ii) including the two terms in (47) and (48) (dashed-dotted line). As seen in these figures, the autoregressive coefficient strongly affects the asymptotic tracking error variance, as predicted by the second-order approximation (whereas the first-order approximation does not predict any effect with respect to the variation of the autoregressive parameter). It is, however, interesting to note that the optimal value for the step-size (the value which minimizes the asymptotic tracking error variance) obtained by minimizing the second-order approximation does not vary with κ and is reasonably close to the one obtained by minimizing the first-order approximation.

The study of the tracking behavior of the RLS algorithm is more involved than for the LMS algorithm. To illustrate our results, we only sketch how the results presented in this paper can be obtained, and we postpone a complete discussion on the potential advantages of the RLS algorithm with respect to the LMS algorithm in a forthcoming paper. For simplicity, we study only the contribution of the lag noise to the total weight-error covariance matrix. The contribution of the measurement noise can be studied along the same lines. The low order terms in the decomposition of the contribution of the lag noise to the weight error may be expressed as

$${}^wJ_{n+1}^{(0)} = \gamma\sum_{k=0}^{n}(1-\mu)^{n-k}w_{k+1},\quad \bar{P}_0 = \bar{P}_s = E(\phi_0\phi_0^T)^{-1} = \alpha^{-1}I,\qquad \forall\, s>0,$$

$$\begin{aligned}
{}^wJ_{n+1}^{(1)} &= \mu\gamma\sum_{s=1}^{n}(1-\mu)^{n-s}Z_s\sum_{k=0}^{s-1}(1-\mu)^{s-k}\,w_{k+1}\\
&= \mu\gamma\sum_{k=0}^{n-1}(1-\mu)^{n-k}\left(\sum_{s=k+1}^{n}Z_s\right)w_{k+1},
\end{aligned}$$

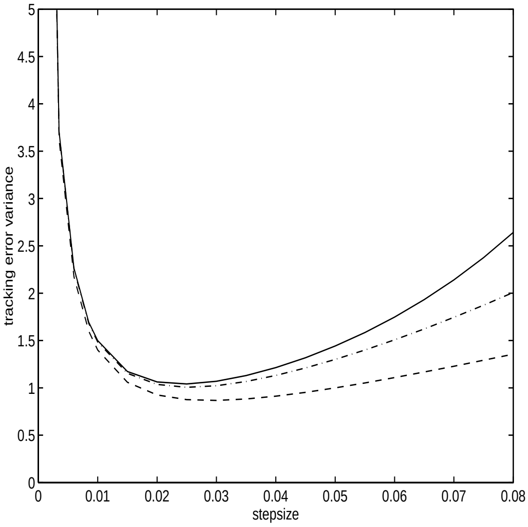

FIG. 1. $\kappa = 0$. *Solid line: Monte Carlo simulation. Dashed line: first-order approximation. Dashed-dotted line: second-order approximation.*

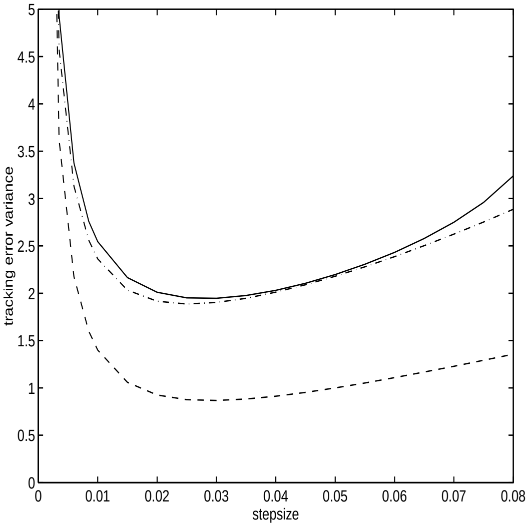

FIG. 2. $\kappa = 0.9$. *Solid line: Monte Carlo simulation. Dashed line: first-order approximation. Dashed-dotted line: second-order approximation.*

where the error term is given by

$$Z_s = \bar{P}_s \, E\{\phi_s \phi_s^T\} - P_s \, \phi_s \phi_s^T .$$

It is easily seen that

$$\lim_{t\to\infty} E({}^w J_t^{(0)} {}^w J_t^{(0)^T}) = \gamma^2/\mu(2-\mu)I.$$

Since $\{\phi_s\}$ is independent of $\{w_s\}$, we may write

$$E[{}^wJ^{(0)}_{n+1}\,{}^wJ^{(1)}_{n+1}{}^T] = \mu\gamma^2 \sum_{k=0}^{n-1}(1-\mu)^{2(n-k)} \sum_{s=k+1}^{n} E[Z_s].$$

Note that this cross-term was equal to zero for the LMS algorithm but does not vanish for the RLS algorithm, because $E(Z_s) \neq 0$. Before going further, we need to compute $E\{Z_s\}$. We proceed as outlined in section 4. We have

$$\begin{aligned} E[Z_s] &= E[(\bar{P}_s - P_s)\phi_s\phi_s^T] \\ &= E[\bar{P}_s(P_s^{-1} - \bar{P}_s^{-1})\bar{P}_s\phi_s\phi_s^T] - E[\bar{P}_s(P_s^{-1} - \bar{P}_s^{-1})^2\bar{P}_s\phi_s\phi_s^T] + O(\mu^{3/2}). \end{aligned}$$

Using tedious but straightforward calculations it may be shown that

$$\begin{aligned} E\{(P_s^{-1} - \bar{P}_s^{-1})\phi_s\phi_s^T\} &= \frac{\mu(d+1)}{1-\kappa^2(1-\mu)}(1-(\kappa(1-\mu))^s), \\ E[(P_s^{-1} - \bar{P}_s^{-1})^2\phi_s\phi_s^T] &= \mu^2[A_1(s) + 2A_2(s)], \\ A_1(s) &= \frac{(d^2+d+2)}{1-\kappa^2(1-\mu)^2}[1-(\kappa(1-\mu))^{2s}] + \frac{d}{\mu}(1-(1-\mu)^{2s}), \\ A_2(s) &= \frac{(d^2+3d+4)}{\mu}\left[\frac{(1-(\kappa^2(1-\mu))^s)}{1-\kappa^2(1-\mu)} - \frac{(1-(\kappa(1-\mu))^{2s})}{1-\kappa^2(1-\mu)^2}\right] \\ &\quad + \frac{d+1}{1-\kappa^2(1-\mu)}\left[\frac{1-(1-\mu)^s}{\mu} - \frac{1-(\kappa(1-\mu))^{2s}}{1-\kappa^2(1-\mu)^2}\right]. \end{aligned}$$

Thus,

$$\begin{aligned} \lim_n \mu^3\gamma^2\sum_{k=0}^{n-1}(1-\mu)^{2(n-k)}\sum_{s=k+1}^{n} A_1(s) &= \mu\gamma^2\frac{d^2+d+2}{4(1-\kappa^2(1-\mu)^2)}I + O(\gamma^2), \\ \lim_n \mu^3\gamma^2\sum_{k=0}^{n-1}(1-\mu)^{2(n-k)}\sum_{s=k+1}^{n} A_2(s) &= \frac{\gamma^2}{2}(d^2+3d+4) \\ &\quad \left[\frac{1}{1-\kappa^2(1-\mu)} - \frac{1}{1-\kappa^2(1-\mu)^2}\right] \\ &\quad + \frac{\gamma^2}{2}\frac{d+1}{(1-\kappa^2(1-\mu))}\left[1 - \frac{\mu}{1-\kappa^2(1-\mu)^2}\right] \\ &\quad + O(\mu+\gamma^2), \end{aligned}$$

yielding the following expression for the asymptotic weight-error covariance matrix $\bar{\Gamma}^w$:

$$\begin{aligned} \bar{\Gamma}^w = \frac{\gamma^2}{2\mu}I &+ \frac{\gamma^2(d+1)}{(1-\kappa^2(1-\mu))}I - \gamma^2(d^2+3d+4)\left[\frac{1}{1-\kappa^2(1-\mu)} - \frac{1}{1-\kappa^2(1-\mu)^2}\right]I \\ &- \frac{\gamma^2(d+1)}{1-\kappa^2(1-\mu)}\left[1/2 - \frac{\mu}{1-\kappa^2(1-\mu)^2}\right]I + O(\mu+\gamma^2). \end{aligned}$$

As before, this correction term depends upon the autoregressive coefficient: when κ is close to 1 (e.g., when the regressors are strongly positively correlated), the corrections terms can become very large. Also, it is interesting to note that the magnitude of the correction term is proportional to the square of the size of the regressors. This also shows that the correction can become very significant when d is large.

Appendix A. Proof of Proposition 2. In this section, we will show some useful extensions of Rosenthal's inequality for weakly dependent processes.

PROPOSITION 6. *Let $G = \{G_t\}_{t\geq 0}$ be a $(d \times d)$ zero-mean matrix-valued process. Let q be an* even *integer and $j \in \mathbb{N}$. Assume that G is (δ, qj)-weak dependent. Assume in addition that*

$$\sum_{r=0}^{\infty}(r+1)^{qj/2-1}\delta(r) < \infty. \tag{49}$$

Then, there exists a finite constant $\bar{D}_{q,j}(G)$, such that

$$\left\| \sum_{s\leq i_1<\cdots<i_j\leq t} G_{i_1}\cdots G_{i_j} \right\|_q \leq \bar{D}_{q,j}(G)\ (t-s)^{j/2} \tag{50}$$

$\forall\ 0 \leq s \leq t$.

Proof of Proposition 6. The proof is a direct application of the following result.

LEMMA 7. *Let $q \geq 2$ and let $X = \{X_t\}_{t\geq 0}$ be an $(l \times 1)$ zero-mean vector-valued (δ, q)-weak dependent process. Assume in addition that $\sum_0^\infty (r+1)^{q/2-1}\delta(r) < \infty$. Then, there exist finite constants $\gamma = \{\gamma_2, \dots, \gamma_q\}$ such that, $\forall\ 1 \leq s \leq q$ and $\forall\ n \geq 1$,*

$$\sup_{(i_1,\cdots,i_s)} \left(\sum_{1\leq t_1,\cdots,t_s\leq n} |E(X_{t_1,i_1}\cdots X_{t_s,i_s})| \right)\ \leq\ \gamma_s\ s!\ n^{s/2}. \tag{51}$$

Remark. The constants $\gamma_2, \dots, \gamma_q$ can be evaluated recursively as follows. Let $\sigma_s = \sum_{r=0}^\infty (r+1)^{s/2-1}\delta(r)$ for $1 < s \leq q$. Set $\gamma_1 = 0$, $\gamma_2 = C_2\sigma_2$ and evaluate, for $2 < s \leq q$,

$$\gamma_s = \sum_{m=1}^{s-1} \gamma_m\gamma_{s-m} + (s-1)C_s\sigma_s. \tag{52}$$

Proof of Lemma 7. The proof is adapted from [7]. Define, for $1 < s \leq q$,

$$I(n,s) = \{(t_1, t_2, \dots, t_s) :\ 1 \leq t_1 \leq \cdots \leq t_s \leq n\}, \tag{53}$$

$$A(n,s) = \sup_{(i_1,\dots,i_s)} \sum_{I(n,s)} |E(X_{t_1,i_1}\dots X_{t_s,i_s})|. \tag{54}$$

Note that

$$\sup_{(i_1,\dots,i_s)} \sum_{1\leq t_1,\dots,t_s\leq n} |E(X_{t_1,i_1}\dots X_{t_s,i_s})| \leq s!A(n,s).$$

Define for $1 \leq m \leq s-1$ and $0 \leq r \leq n-1$ the sets

$$I(n,s,m,r) = \{(t_1, \dots, t_s) \in I(n,s) :\ t_{m+1} - t_m = r = \max(t_{i+1} - t_i)\},$$

$$I(n,s,m) = \bigcup_{r=0}^{n-1} I(n,s,m,r).$$

It is easily seen that

$$I(n,s) = \bigcup_{m=1}^{s-1} I(n,s,m) = \bigcup_{m=1}^{s-1} \bigcup_{r=0}^{n-1} I(n,s,m,r)$$

and the cardinal of set $I(n,s,m,r)$ is bounded by $n(r+1)^{s-2}$. Let $1 \leq m \leq s-1$. Note that

$$\begin{aligned} E(X_{t_1,i_1} \dots X_{t_s,i_s}) &= E(X_{t_1,i_1} \dots X_{t_m,i_m}) \\ &\quad \times E(X_{t_{m+1},i_{m+1}} \dots X_{t_s,i_s}) + \operatorname{cov}(X_{t_1,i_1} \dots X_{t_m,i_m}, X_{t_{m+1},i_{m+1}} \dots X_{t_s,i_s}). \end{aligned}$$

This implies, under the weak-dependence condition, that

$$\sup_{(i_1,\dots,i_s)} \sum_{I(n,s,m)} |E(X_{t_1,i_1} \dots X_{t_s,i_s})| \leq A(n,m)A(n,s-m) + C_s \sum_{r=0}^{n-1} \delta(r) n (r+1)^{s-2}.$$

For $0 \leq r \leq n-1$, $n(r+1)^{s-2} \leq n^{s/2}(r+1)^{s/2-1}$. Thus

$$A(n,s) \leq \sum_{m=1}^{s-1} A(n,m)A(n,s-m) + (s-1)C_s n^{s/2} \sum_{r=0}^{n-1} (r+1)^{s/2-1}\delta(r). \tag{55}$$

The proof and the expression of the constant are obtained by a straightforward induction. □

COROLLARY 8. *Let $p \geq 1$ and $n \in \mathbb{N}$. Let $G = \{G_t\}_{t \geq 0}$ be a $(d \times d)$ matrix-valued process. Assume that $\{G_t\}_{t\geq 0}$ is $(\delta, (p+2)n)$-weak dependent and that*

$$\sum (r+1)^{(p+2)n/2-1} \delta(r) < \infty.$$

Then, there exists a finite constant $D_{p,n}(G)$, such that $\forall\ j \in \{1,\dots,n\}$ and $\forall\ 0 \leq s \leq t < \infty$, we have

$$\left\| \sum_{s \leq i_1 < \cdots < i_j \leq t} (G_{i_1} - E(G_{i_1})) \dots (G_{i_j} - E(G_{i_j})) \right\|_{pn/j} \leq D_{p,n}(G)(t-s)^{j/2}. \tag{56}$$

Proof of Corollary 8. For $j \in \{1,\dots,n\}$, denote $q(n,j)$ the smallest even integer verifying $pn/j \leq q(n,j)$. It is easily seen that $pn/j \leq q(n,j) \leq pn/j+2$, which implies that $\max_{j \in \{1,\dots,n\}} jq(n,j) \leq (p+2)n$. Under the stated assumption, Proposition 6 implies that, $\forall\ 0 \leq s \leq t$,

$$\begin{aligned} \left\| \sum_{s \leq i_1 < \cdots < i_j \leq t} G_{i_1} \dots G_{i_j} \right\|_{pn/j} &\leq \left\| \sum_{s \leq i_1 < \cdots < i_j \leq t} G_{i_1} \dots G_{i_j} \right\|_{q(n,j)}, \\ &\leq \bar{D}_{q(n,j),j}(G)(t-s)^{j/2} \end{aligned}$$

which concludes the proof. □

In what follows, we will have to work with sums of products of the form

$$\sum_{s \leq i_1 < i_2 < \cdots < i_j \leq t} (P_{i_1} G_{i_1} - \bar{P}_{i_1} E(G_{i_1})) \dots (P_{i_j} G_{i_j} - \bar{P}_{i_j} E(G_{i_j})),$$

where $\{P_i\}_{i\in\mathbb{N}}$ is a matrix-valued random process (indexed by μ), and $\{\bar{P}_i\}_{i\in\mathbb{N}}$ is a set of deterministic matrices such that $\sup_{i\in\mathbb{N}}\|P_i-\bar{P}_i\|_c = O(\sqrt{\mu})$ as $\mu\to 0^+$. It is easily seen that $E(P_iG_i)\neq \bar{P}_iE(G_i)$ and that $\{P_iG_i\}_{i\geq 0}$ is not weak-dependent and the proposition above cannot be directly applied. An extension (based on the fact that $\{P_i\}$ is well "approximated" by a set of deterministic matrices) is given below.

PROPOSITION 9. *Let $p\geq 1$ and $n\in\mathbb{N}$. Let $G=\{G_t\}_{t\geq 0}$ be a $(d\times d)$ matrix-valued process. Assume that $\{G_t\}_{t\geq 0}$ is $(\delta,(p+2)n)$-weak dependent and*

$$\sum (r+1)^{(p+2)n/2-1}\delta(r)<\infty.$$

Assume in addition that (i) *there exist $\mu_0>0$ and a constant $C_{p,n}(\mu_0,P)<\infty$ such that* $\sup_{t\geq 0}\|P_t-\bar{P}_t\|_{\alpha pn}<C_{p,n}(\mu_0,P)\sqrt{\mu}$ *and* (ii) $\sup_{t\geq 0}\|G_t\|_{\beta pn}<\infty$, *where $\alpha,\beta>0$ and $\alpha^{-1}+\beta^{-1}=1$. Then, there exists a finite constant $D_{p,n}(G)$ such that $\forall\ j\in\{1,\dots,n\}$ and $\forall\ 0\leq s\leq t<\infty$, we have*

$$\left\|\sum_{s\leq i_1<\cdots<i_j\leq t}(P_{i_1}G_{i_1}-\bar{P}_{i_1}E(G_{i_1}))\cdots(P_{i_j}G_{i_j}-\bar{P}_{i_j}E(G_{i_j}))\right\|_{pn/j} \leq D_{p,n}(G)(t-s)^{j/2}\sum_{l=0}^{j}\mu^{l/2}(t-s)^{l/2}. \tag{57}$$

Proof of Proposition 9. Denote $\bar{G}_i=E(G_i)$, and, for $t\geq s$,

$$D_1(t,s)=\sum_{u=s}^{t}(P_uG_u-\bar{P}_u\bar{G}_u),\quad \tilde{D}_1(t,s)=\sum_{u=s}^{t}\bar{P}_u(G_u-\bar{G}_u), \tag{58}$$

$$D_k(t,s)=\sum_{u=s}^{t}D_{k-1}(t,u+1)(P_uG_u-\bar{P}_u\bar{G}_u), \tag{59}$$

$$\tilde{D}_k(t,s)=\sum_{u=s}^{t}\tilde{D}_{k-1}(t,u+1)\bar{P}_u(G_u-\bar{G}_u).$$

By convention, we set $D_k(t,s)=\tilde{D}_k(t,s)=0$ for $s<t+k$ and $D_0(t,s)=\tilde{D}_0(t,s)=0\ \forall\ t,s$. Since $\sup_{0\leq\mu\leq\mu_0}\sup_{u\geq 0}|\bar{P}_u|<\infty$, and $\{G_u-\bar{G}_u\}_{u\geq 0}$ is $(\delta,p(n+2))$-weak dependent, then $\{\bar{P}_u(G_u-\bar{G}_u)\}_{u\geq 0}$ also is $(\delta,p(n+2))$-weak dependent, so that, by application of Proposition 2, there exists a constant $D_{p,n}(\bar{P}G)$ (*independent* from μ), such that, for $j\in\{1,\dots,n\}$ and all $0\leq s\leq t<\infty$, it holds that

$$\|\tilde{D}_j(t,s)\|_{pn/j}\leq D_{p,n}(\bar{P}G)(t-s)^{j/2}. \tag{60}$$

The proof is by induction. We have

$$\sum_{s\leq u\leq t}(P_uG_u-\bar{P}_u\bar{G}_u)=\sum_{s\leq u\leq t}(P_u-\bar{P}_u)G_u+\sum_{s\leq u\leq t}\bar{P}_u(G_u-\bar{G}_u).$$

Thus,

$$\left\|\sum_{u=s}^{t}(P_uG_u-\bar{P}_u\bar{G}_u)\right\|_{pn}\leq (t-s)\sup_{u\geq 0}\|P_u-\bar{P}_u\|_{\alpha qn}\sup_{u\geq 0}\|G_u\|_{\beta qn}+D_{p,n}(\bar{P}G)(t-s)1/2$$

showing that there exists a constant $C_1 < \infty$ such that $\|D_1(t,s)\|_{pn} \le C_1(t-s)^{1/2}(1+\sqrt{\mu}(t-s)^{1/2})$ $\forall$ $0 \le s \le t$ and $\mu \in (0,\mu_0]$. Let $j \in \{1,\dots,n-1\}$. Assume that for $i \in \{1,\dots,j-1\}$, there exists $C_i < \infty$ such that, $\forall$ $0 \le s \le t$ and $\mu \in (0,\mu_0]$, we have $\|D_i(t,s)\|_{pn/i} \le C_i(t-s)^{i/2}\sum_{l=0}^{i}\mu^{l/2}(t-s)^{l/2}$. It holds that

$$D_j(t,s) = \tilde{D}_j(t,s) + \sum_{r=1}^{j}\sum_{i_r=s}^{t} D_{r-1}(i_r,s)(P_{i_r} - \bar{P}_{i_r})G_{i_r}\tilde{D}_{j-r}(t,i_{j-1}+1),$$

$$\begin{aligned}\|D_j(t,s)\|_{pn/j} \le\ & \|\tilde{D}_j(t,s)\|_{pn/j} \\ & + \sum_{r=1}^{j}\sum_{i_r=s}^{t} \|D_{r-1}(i_r,s)\|_{pn/(r-1)}\|\tilde{D}_{j-r}(t,i_r+1)\|_{pn/(j-r)}\|P_{i_r} \\ & - \bar{P}_{i_r}\|_{\alpha pn}\|G_{i_r}\|_{\beta pn}, \\ & \le D_{p,n}(\bar{P}G)\left((t-s)^{1/2} + \sum_{r=1}^{j} C_r(t-s)^{j/2}\sum_{l=0}^{r}\mu^{l/2}(t-s)^{l/2}\right),\end{aligned}$$

which concludes the proof. □

Proof of Proposition 2. It is assumed (without any loss of generality) that $\{D_k\}_{k\ge0}$ and $\{\epsilon_k\}_{k\ge0}$ are scalar-valued. (i) Assume first that $\{\epsilon_k\}_{k\ge0}$ is an L_p stable martingale increment. According to Burkholder's inequality, there exists a universal constant $B_p < \infty$ (independent of the sequence of scalar weights $\{D_k\}_{k\ge0}$ and on the process $\{\epsilon_k\}_{k\ge0}$) such that

$$\begin{aligned}E\left|\sum_{k=s}^{t} D_k\epsilon_k\right|^p & \le B_p\left\|\sum_{k=s}^{t} D_k^2\epsilon_k^2\right\|_{p/2}^{p/2} \\ & \le B_p \sup_k \|\epsilon_k\|_p^p \left(\sum_{k=s}^{t} D_k^2\right)^{p/2},\end{aligned}$$

which concludes the proof for martingale increments. (ii) Assume that q is an even integer. For $n \ge 0$, we have

$$\begin{aligned}E\left|\sum_{k=1}^{n} D_k\epsilon_k\right|^q & = \sum_{1\le i_1,\dots,i_q\le n} E(D_{i_1}\dots D_{i_p}\epsilon_{i_1}\dots\epsilon_{i_p}), \\ & \le \sum_{1\le i_1,\dots,i_q\le n} |D_{i_1}\dots D_{i_q}||E(\epsilon_{i_1}\dots\epsilon_{i_q})|, \\ & \le q!\ A_q(n),\end{aligned}$$

where $A_q(n) \triangleq \sum_{1\le i_1\le\dots\le i_q\le n}|D_{i_1}\dots D_iq||E(\epsilon_{i_1}\dots\epsilon_{i_q})|$. We will conclude the proof by showing that $A_q(n) \le C\sum_{i=1}^{n}(|D_i|^2)^{q/2}$, uniformly in n, where $C < \infty$ is a constant which is related to the weak-dependence constants of the process ϵ (see the definition above), i.e., $C_1,\dots,C_q$ and $\{\delta(k)\}_{k\ge0}$. The proof is by induction. Let

$1 \leq s \leq q$. We have

$$A_s(n) = \sum_{m=1}^{s-1} \sum_{r=0}^{n-1} \sum_{I(n,s,m,r)} |D_{i_1} \dots D_{i_s}| \, |E(\epsilon_{i_1} \dots \epsilon_{i_m})| \, |E(\epsilon_{i_{m+1}} \dots \epsilon_{i_s})| \tag{61}$$

$$+ V_s(n) \tag{62}$$

$$\leq \sum_{m=1}^{s-1} A_m(n) A_{s-m}(n) + V_s(n), \tag{63}$$

$$V_s(n) = \sum_{m=1}^{s-1} \sum_{r=0}^{n-1} V_s(n, r, m), \tag{64}$$

$$V_s(n, r, m) = \sum_{I(n,s,m,r)} |D_{i_1} \dots D_{i_s}| |\mathrm{cov}(\epsilon_{i_1} \dots \epsilon_{i_m}, \epsilon_{i_{m+1}} \dots \epsilon_{i_s})|. \tag{65}$$

Denote $b_r = \max_{1 \leq t \leq n} \sum_{i=t+1}^{t+r} |D_i|$. We have

$$\begin{aligned} V_s(n, r, m) \leq C_s \sum_{i_m=1}^{n-r} |D_{i_m}||D_{i_m+r}| \delta(r) \sum_{i_{m-1}=\max(i_m-r,0)}^{i_m} |D_{i_{m-1}}| \dots \sum_{i_1=\max(i_2-r,0)}^{i_2} |D_{i_1}| \\ \times \sum_{i_{m+2}=i_{m+1}}^{\min(i_{m+1}+r,n)} |D_{i_{m+2}}| \dots \sum_{i_s=i_{s-1}}^{\min(i_{s-1}+r,n} |D_{i_s}|, \\ \leq C_s b_r^{s-2} \delta(r) \sum_{i=1}^{n} |D_i|^2. \end{aligned}$$

Note that the bound for $V_s(n, r, m)$ does not depend on m. Hence,

$$V_s(n) \leq s \; C_s \sum_{r=0}^{n-1} \delta(r) b_r^{q-2} \sum_{i=1}^{n} |D_i|^2. \tag{66}$$

We have

$$b_r \leq \sqrt{r} \max_{1 \leq t \leq n} \left(\sum_{i=1}^{t+r} |D_i|^2 \right)^{1/2} \leq \left(\sum_{i=1}^{n} |D_i|^2 \right)^{1/2} \sqrt{r}.$$

Plugging this latter relation into (66) yields

$$V_s(n) \leq \left(\sum_{i=1}^{n} |D_i|^2 \right)^{s/2} \sum_{r=0}^{n-1} (r+1)^{s/2-1} \delta(r).$$

The proof is now concluded by an easy induction.

Appendix B. Proof of Theorems 4 and 5.

Proof of Theorem 4. Before going further, we need some additional notation. Define $S_0(t, s) = \psi(t, s)$ for $t \geq s$ and $S_0(t, s) = 0$ for $s > t$ (the dependence in the step-size μ is implicit). For $k \geq 1$, define $S_k(t, s)$ recursively as

$$S_k(t, s) = \sum_{u=s}^{t} \psi(t, u) Z_u S_{k-1}(u-1, s) = \sum_{u=s}^{t} S_{k-1}(t, u) Z_u \psi(u-1, s). \tag{67}$$

Denote, respectively,

$$D_1(t,s) = \sum_{u=s}^{t} Z_u, \quad t \geq s, \quad D_1(t,s) = 0, \quad s > t, \tag{68}$$

$$D_k(t,s) = \sum_{u=s}^{t} D_{k-1}(t,u+1) Z_u. \tag{69}$$

Note that, by construction, for $k \geq 0$,

$$S_k(t,s) = 0, \quad s > t-k, \quad \text{and } D_k(t,s) = 0, \quad s > t-k+1.$$

From (20), (21), and (67), it is easily seen that $J_{t+1}^{(r)}$ may be decomposed as

$$J_{t+1}^{(r)} = \mu^r \sum_{s=0}^{t} S_r(t,s) \xi_s. \tag{70}$$

Let r be an integer and c, μ_0, β some real numbers such that $c > 0$, $\mu_0 > 0$, and $0 < \beta < 1/\mu_0$. Consider $W(\mu) \triangleq \{W(u,v;\mu)\}_{(u,v)\in\mathbb{N}\times\mathbb{N}}$ a family of processes on $\mathbb{N}\times\mathbb{N}$ indexed by $\mu \in \mathbb{R}^+$. We say that $W(\mu)$ belongs to the set $\mathcal{L}(\beta,\mu_0,c,r)$ if there exist a *finite* constant $C(W)$ and a *finite* integer $q(W)$, such that, $\forall\ 0 \leq u \leq v$ and $0 < \mu \leq \mu_0$

$$\|W(u,v;\mu)\|_c \leq C(W)(1-\beta\mu)^{v-u}(v-u)^{r/2} \sum_{k=0}^{q(W)} \mu^{k/2}(v-u)^{k/2}. \tag{71}$$

It is easily seen that the subspaces $\mathcal{L}(\beta,\mu_0,c,r)$ are nested in the sense that for $c' \geq c$ and $r' \geq r$, we have $\mathcal{L}(\beta,\mu_0,c,r) \subset \mathcal{L}(\beta,\mu_0,c',r')$. Similarly, we say that $W(\mu)$ belongs to the $\mathcal{M}(\mu_0,c,r)$ if there exist a finite constant $C_{\mathcal{M}}(W)$ and a finite integer $q(W)$, such that, $\forall\ 0 \leq u \leq v$ and $0 < \mu \leq \mu_0$,

$$\|W(u,v;\mu)\|_c \leq C_{\mathcal{M}}(W)(v-u)^{r/2} \sum_{j=0}^{q(W)} \mu^{j/2}(v-u)^{j/2}. \tag{72}$$

LEMMA 10. *Assume that $S_r \triangleq \{S_r(t,s)\} \in \mathcal{L}(\beta,\mu_0,q,r)$ and $\xi \triangleq \{\xi_k\} \in \mathcal{N}(p)$. Then, there exists a constant $C(S_r) < \infty$ (depending upon $\beta,\mu_0,p,q,r,$ and $\{F_k\}$ but not on $\{\xi_k\}$ or on the step-size μ) such that*

$$\sup_{t\geq 0} \|J_t^{(r)}\|_p \leq C(S_r)\ \rho_p(\xi)\mu^{(r-1)/2} \qquad \forall\ \mu\ \in\ (0,\mu_0].$$

Proof of Lemma 10. Since $\{\xi_t\} \in \mathcal{N}(p)$, there exists a constant $\rho_{p,q}(\xi)$ such that

$$\|J_{t+1}^{(r)}\|_p \leq \rho_{p,q}(\xi)\mu^r \left(\sum_{s=0}^{t} \|S_r(t,s)\|_q^2\right)^{1/2}.$$

Under the stated assumptions, $S_r(t,s) \in \mathcal{L}(\beta,\mu_0,q,r)$: there exist a constant $C(S_r) < \infty$ and $q(S_r) \in \mathbb{N}$ such that, $\forall\ t \geq s \geq 0$,

$$\|S_r(t,s)\|_q \leq C(S_r)\ (1-\beta\mu)^{t-s}(t-s)^{r/2} \sum_{k=0}^{q(S_r)} \mu^{k/2}(t-s)^{k/2} \qquad \forall\ \mu\ \in\ (0,\mu_0].$$

This latter relation implies that

$$\sum_{s=0}^{t} \|S_r(t,s)\|_q^2 \leq q(S_r)\, C^2(S_r) \sum_{k=0}^{q(S_r)} \mu^k \sum_{u=0}^{t} (1-\beta\mu)^{2u} u^{k+r} \qquad \forall\, \mu \,\in\, (0,\mu_0].$$

For all $\alpha \geq 0$, there exists a constant $D_\alpha < \infty$, such that, $\forall\ 0 < \mu \leq 1/\beta$,

$$\sum_{u=0}^{\infty} (1-\beta\mu)^{2u} u^\alpha \leq D_\alpha/(\beta\mu)^{1+\alpha}$$

which concludes the proof. □

The previous lemma will allow us to conclude the proof of Theorem 4 if we are able to prove that

$$\{S_r(t,s)\} \ \in \mathcal{L}(\beta,\mu_0,q,r), \text{ for } r \in \{1,\dots,n\}.$$

In fact, we will prove a slightly stronger property: $S_r(t,s) \in \mathcal{L}(\beta,\mu_0,qn/r,r)$, for $r \in \{1,\dots,n\}$. This part is more intricate and requires some preparatory lemmas.

LEMMA 11. *Let $j \in \{1,\dots,r-1\}$. Denote $\Delta_j(v,u) = D_j(v,u) - D_j(v,u+1)$. We have, for $t \geq s$ and for $j \in \{1,\dots,r-1\}$,*

$$\begin{aligned}&\sum_{u=s}^{t} \psi(t,u)\Delta_j(t,u)S_{r-j}(u-1,s) - \sum_{u=s}^{t} \psi(t,u)\Delta_{j+1}(t,u)S_{r-j-1}(u-1,s)\\ &= \mu\sum_{u=s}^{t} \psi(t,u)\bar{F}_{u-1}D_j(t,u)S_{r-j}(u-2,s) - \mu\sum_{u=s}^{t} \psi(t,u)D_j(t,u)\bar{F}_{u-1}S_{r-j}(u-2,s).\end{aligned}$$

In addition,

$$\begin{aligned}&\sum_{u=s}^{t} \psi(t,u)\Delta_r(t,u)\psi(u-1,s) - \psi(t,s+1)D_r(t,s+1)\\ &\qquad = \mu\sum_{u=s}^{t} \psi(t,u)\bar{F}_{u-1}D_r(t,u)\psi(u-2,s) - \mu\sum_{u=s}^{t} \psi(t,u)D_r(t,u)\bar{F}_{u-1}\psi(u-2,s).\end{aligned}$$

Proof of Lemma 11. The proof basically amounts to applying the Abel transform recursively. Hence, it involves only simple algebraic manipulations. First note that

$$\begin{aligned}\sum_{u=s}^{t} \psi(t,u)\Delta_j(t,u)S_{r-j}(u-1,s) &= \sum_{u=s}^{t} \left(\psi(t,u) - \psi(t,u-1)\right) D_j(t,u)S_{r-j}(u-2,s)\\ &\quad + \sum_{u=s}^{t} \psi(t,u)D_j(t,u)\left(S_{r-j}(u-1,s) - S_{r-j}(u-2,s)\right).\end{aligned}$$

For $t \geq s$ we have

$$\begin{aligned}&\psi(t,s) - \psi(t,s-1) = \mu\psi(t,s)\bar{F}_{s-1},\\ &\psi(t,s) - \psi(t-1,s) = \begin{cases} -\mu\bar{F}_t\psi(t-1,s), & t > s,\\ I, & t = s,\end{cases}\\ &S_k(t,s) - S_k(t-1,s) = Z_tS_{k-1}(t-1,s) - \mu\bar{F}_tS_k(t-1,s).\end{aligned}$$

The proof of this lemma is concluded by noting that

$$D_j(t,u)Z_{u-1} = D_{j+1}(t,u-1) - D_{j+1}(t,u). \qquad \square$$

LEMMA 12. *Let $r \in \mathbb{N}$ and $j \in \{1,\dots,r-1\}$ and let $V(\mu) \triangleq \{V(u,v;\mu)\}_{(u,v)\in\mathbb{N}\times Nset}$ and $W(\mu) \triangleq \{W(u,v;\mu)\}_{(u,v)\in\mathbb{N}\times\mathbb{N}}$ be such that $V(\mu) \in \mathcal{M}(\mu_0, cr/j, j)$ and $W \in \mathcal{L}(\beta,\mu_0,cr/(r-j), r-j)$, for some $c,\mu_0 > 0$, $0 < \beta < 1/\mu_0$. Then, the process $U(\mu) \triangleq \{U(t,s;\mu)\}_{(u,v)\in\mathbb{N}\times\mathbb{N}}$ defined by*

$$U(t,s;\mu) = \mu \sum_{u=s}^{t-1} \psi(t,u) V(t,u;\mu) W(u,s;\mu)$$

belongs to the set $\mathcal{L}(\beta,\mu_0,c,r)$.

Proof of Lemma 12. The proof is elementary. Let $t \ge s \ge 0$. Since $\{F_t\} \in \mathcal{S}(\beta,\mu_0)$, $|\psi(t,s)| \le K_{\beta,\mu_0}(F)(1-\beta\mu)^{t-s}$ $\forall$ $\mu \in (0,\mu_0]$ and $0 \le s \le t$. This implies

$$\|U(t,s;\mu)\|_c \le K_{\beta,\mu_0}(F)\mu \sum_{u=s}^{t} (1-\beta\mu)^{t-u} \|V(t,u;\mu)\|_{cr/j} \|W(u,s;\mu)\|_{cr/(r-j)}$$
$$\le K_{\beta,\mu_0}(F)\mu \sup_{s\le u\le t} \left(\|V(t,u;\mu)\|_{cr/j}\right) \sup_{s\le u\le t} \left(\|W(u,s;\mu)\|_{cr/(r-j)}/(1-\beta\mu)^{u-s}\right)$$
$$(t-s)(1-\beta\mu)^{t-s}.$$

Under the stated assumptions, there exist constants $C(V) < \infty$, $q(V) \in \mathbb{N}$, $C(W) < \infty$, and $q(W) \in \mathbb{N}$ such that, $\forall$ $0 \le s \le t$ and $\forall$ $0 < \mu \le \mu_0$,

$$\sup_{s\le u\le t} \|V(t,u;\mu)\|_{cr/j} \le C(V)(t-s)^{j/2} \sum_{l=0}^{q(V)} \mu^{l/2}(t-s)^{l/2},$$

$$\sup_{s\le u\le t} \left(\|W(u,s;\mu)\|_{cr/(r-j)}/(1-\beta\mu)^{u-s}\right) \le C(W)(t-s)^{(r-j)/2} \left(\sum_{k=0}^{q(W)} \mu^{k/2}(t-s)^{k/2}\right),$$

so that

$$\|U(t,s;\mu)\|_c \le C(U)(1-\beta\mu)^{t-s}(t-s)^{r/2} \sum_{l=0}^{q(W)+q(V)+2} \mu^{l/2}(t-s)^{l/2}$$

for some finite constant $C(U)$. $\square$

By combining the two preceding lemmas, we obtain the following useful criterion.

LEMMA 13. *Let $c > 0$ and $r \in \mathbb{N}$. Assume in addition that $\{D_j(t,s)\} \in \mathcal{M}(cr/j, j)$ for $1 \le j \le r$ and $\{S_j(t,s)\} \in \mathcal{L}(\beta,\mu_0,cr/j,j)$ for $1 \le j < r$. Then, $\{S_r(t,s)\} \in \mathcal{L}(\beta,\mu_0,c,r)$.*

Proof of Lemma 13. By iterated application of Lemma 11, we have for $t \ge s \ge 0$

$$S_r(t,s) = \sum_{u=s}^{t} \psi(t,u)\Delta_r(t,u)\psi(u-1,s) + \sum_{j=1}^{r-1} G_j(t,s), \tag{73}$$

where for $1 \le j \le r-1$, the processes $G_j(t,s)$ are defined as

$$G_j(t,s) = \mu \sum_{u=s}^{t} \psi(t,u)\bar{F}_{u-1} D_j(t,u) S_{r-j}(u-2,s)$$
$$- \mu \sum_{u=s}^{t} \psi(t,u) D_j(t,u) \bar{F}_{u-1} S_{r-j}(u-2,s).$$

Under the stated assumptions, Lemma 12 shows that $G_j(t,s) \in \mathcal{L}(\beta,\mu_0,c,r)$ for $1 \leq j \leq r-1$. The first term on the RHS of (73) may be decomposed (Lemma 11) as

$$\sum_{u=s}^{t} \psi(t,u)\Delta_r(t,u)\psi(u-1,s) = \psi(t,s+1)D_r(t,s+1)$$
$$+ \mu \left(\sum_{u=s}^{t} \psi(t,u)\bar{F}_{u-1}D_r(t,u)\psi(u-2,s) - \sum_{u=s}^{t} \psi(t,u)D_r(t,u)\bar{F}_{u-1}\psi(u-2,s) \right).$$

Since $D_r(t,s) \in \mathcal{M}(\mu_0,c,r)$, $\|D_r(t,s)\|_c \leq C(D_r)(t-s)^{r/2}\sum_{l=0}^{q(D_r)}\mu^{l/2}(t-s)^{l/2}$ for some $C(D_r) < \infty$, $q(D_r) \in \mathbb{N}$, $\forall\ t \geq s \geq 0$ and all $0 < \mu \leq \mu_0$. Thus,

$$\left\| \sum_{u=s}^{t} \psi(t,u)\Delta_r(t,u)\psi(u-1,s) \right\|_c$$
$$\leq K_{\beta,\mu_0}(F)C(D_r)(1-\beta\mu)^{t-s}(t-s)^{r/2}\left(\sum_{l=0}^{q(D_r)}\mu^{l/2}(t-s)^{l/2}\right)\left(1+\mu\sup_{s\geq 0}|\bar{F}_s|(t-s)\right)$$

$\forall\ t \geq s \geq 0$ and all $0 < \mu \leq \mu_0$, which concludes the proof. □

Under assumption (ii) of Theorem 4, an application of Proposition 2 shows that $\{D_r(t,s)\} \in \mathcal{M}(qn/r,r)$, $r \in \{1,\ldots,n\}$; Lemma 13 leads us to a condition upon which $S_r(t,s)$ belongs to $\mathcal{L}(\beta,\mu_0,qn/r,r)$, $r \in \{1,\ldots,n\}$.

LEMMA 14. *Under the assumptions of Theorem* 4, *it holds that*

$$\textit{for}\ \ r \in \{1,\ldots,n\},\quad \{S_r(t,s)\} \in \mathcal{L}(\beta,\mu_0,qn/r,r).$$

Proof of Lemma 14. The proof is by induction on r. By application of Proposition 2, we have $D_1(t,s) \in \mathcal{M}(qn,1)$. This implies by Lemma 13 that $S_1(t,s) \in \mathcal{L}(\beta,\mu_0,qn,1)$. Assume now that the property is verified up to order $r-1$ with $1 < r \leq n$. Set $c = qn/r$. By application of Proposition 2, we have $D_j(t,s) \in \mathcal{M}(qn/j,j) = \mathcal{M}(cr/j,j)$. The induction hypothesis implies that $S_j(t,s) \in \mathcal{L}(\beta,\mu_0,qn/j,j) = \mathcal{L}(\beta,\mu_0,cr/j,j)$ for $1 \leq j < r$. We have $S_r(t,s) \in \mathcal{L}(\beta,\mu_0,c,r) = \mathcal{L}(\beta,\mu_0,qn/r,r)$ by Lemma 13, which concludes the proof. □

The proof of Theorem 4 is concluded by applying Lemma 10 and Lemma 14.

Proof of Theorem 5. Solving recursively the difference equation (22), we may express $H_{t+1}^{(n+1)}$ as a linear combination of $J_s^{(n+1)}$, with random matrix-valued weights $\Phi(t,s)$

$$H_{t+1}^{(n+1)} = \mu\sum_{s=0}^{t}\Phi(t,s)Z_sJ_s^{(n+1)}. \tag{74}$$

Since $\{F_t\} \in \mathcal{S}(a,\beta,\mu_0)$ we have, $\forall\ 0 < \mu \leq \mu_0$ and all $0 \leq s \leq t$, $\|\Phi(t,s)\|_a \leq K'_{a,\beta,\mu_0}(F)(1-\beta\mu)^{t-s}$, which implies

$$\|H_{t+1}^{(n+1)}\|_p \leq K'_{a,\beta,\mu_0}(F)\beta^{-1}\sup_{s\geq 0}\|Z_s\|_b\sup_{s\geq 0}\|J_s^{(n+1)}\|_c.$$

By construction, $H_s^{(n)}$ may be decomposed as $H_s^{(n)} = J_s^{(n+1)} + H_s^{(n+1)}$; the Minkowski inequality implies

$$\|H_s^{(n)}\|_p \leq \|J_s^{(n+1)}\|_p + \|H_s^{(n+1}\|_p \leq \left(1 + K'_{a,\beta,\mu_0}(F)\beta^{-1}\sup_{s\geq 0}\|Z_s\|_b\right)\sup_{s\geq 0}\|J_s^{(n+1)}\|_c,$$

which concludes the proof. □

BROCKETT'S PROBLEM OF CLASSIFICATION OF FINITE-DIMENSIONAL ESTIMATION ALGEBRAS FOR NONLINEAR FILTERING SYSTEMS[*]

SHANJIAN TANG[†]

Abstract. In his talk at the International Congress of Mathematicians in 1982, Brockett proposed to classify all finite-dimensional estimation algebras arising in nonlinear filters. Recently, Chen, Yau, and Leung [*SIAM J. Control Optim.*, 35 (1997), pp. 1132–1141] claimed that they had classified all finite-dimensional estimation algebras of maximal rank when the dimension of the state-space is less than or equal to four. In this paper, we introduce a series of completely new computations about the estimation algebra, and we find two sets of new equations about the Ω-matrix. As a consequence, we can prove, without any dimension assumption on the state-space, that the Ω-matrix is a constant matrix, and thus we succeed in classifying all finite-dimensional estimation algebras of maximal rank with the state-space dimension being arbitrary.

Key words. finite-dimensional filter, estimation algebra of maximal rank, nonlinear drift, arbitrary state-space dimension

1. Introduction.

Brockett and Clark [3], Brockett [2], and Mitter [14] initially began to use estimation algebras to construct finite-dimensional nonlinear filters. The study of estimation algebras then became important. Ocone [15] observed the following property of finite-dimensional estimation algebras: a function in a finite-dimensional estimation algebra must be a polynomial of degree less than or equal to two. This observation turns out to be a fundamental tool in later studies of finite-dimensional estimation algebras.

In his talk at the International Congress of Mathematicians in 1982, Brockett [1] proposed to classify all finite-dimensional estimation algebras. Since then, a number of progresses have been made on Brockett's classification problem. Tam, Wong, and Yau [17] classified all finite-dimensional exact estimation algebras of maximal rank with arbitrary state-space dimension. Chiou and Yau [8] introduced the concept of maximal rank estimation algebras and classified all finite-dimensional estimation algebras of maximal rank with the state-space dimension less than or equal to two. Later, Chen, Yau, and Leung [4, 7] improved Chiou and Yau's result in that the dimension of the state-space is assumed to be less than or equal to three and four, respectively. But their proofs strongly depend on the dimension assumptions that $n \leq 3$ and that $n \leq 4$, and they are difficult to be generalized to the case of arbitrary dimension n.

In this paper, we classify all finite-dimensional estimation algebras of maximal rank with arbitrary state-space dimension. Our result is stated as follows.

FIG. 1.1. *The computation chart.*

THEOREM 1.1. *Let $\mathcal{E}$ be a finite-dimensional estimation algebra of* (2.1) *of maximal rank, and let $\mathcal{E}_0$ be the real vector space of dimension $2n+2$ with basis given by $1, x_1, \dots, x_n, D_1, \dots, D_n$ and L_0. Then,*

1. *the drift term f must be a linear vector field (i.e., each component is a polynomial of degree less than or equal to one) plus a gradient vector field;*
2. *$\mathcal{E} = \mathcal{E}_0$;*
3. *η is a polynomial of degree less than or equal to two.*

Theorem 1.1 improves both results of Tam, Wong, and Yau [17] and Chen, Yau, and Leung [7] in that it neither assumes that the finite-dimensional estimation algebra under consideration is exact nor assumes that the state-space dimension ≤ 4.

The difficulty of proving Theorem 1.1 is to prove that ω_{ij} is constant for $k+1 \leq i \leq n$ and $k+1 \leq j \leq n$ (where k denotes the quadratic rank of the finite-dimensional estimation algebra under consideration), which is stated as Lemma 3.5. This difficulty can be known from Chen and Yau [5, 6], Yau [22], and Yau's recent work coauthored with Guoqing Hu.

In this paper, in order to overcome the above difficulty, we first establish Lemma 3.4, which plays a key role in the proof of Lemma 3.5. After Lemma 3.5 has been proved, the rest of the proof of Theorem 1.1 is straightforward.

In order to establish Lemma 3.4, we develop a series of computations about the estimation algebra $\mathcal{E}$, which is inspired by Ocone's series of computations in his paper [15]. Figure 1.1 is our computation chart and is helpful for the reader to trace our proof.

As shown in Fig. 1.1, we construct the two elements $[[V_j, D_j], D_l]$ and $[[[W_j, D_j], D_j], D_j]$ in $\mathcal{E}$. These two elements can be computed by using the last six formulas (10)–(15) of Lemma 2.2, and they turn out to have the same form:

"a polynomial of degree two" + "an element of $\mathcal{E}_0$."

In this way, we obtain two polynomials in $\mathcal{E}$ of degree two, and then by analyzing the coefficients of x_j^2 $(j > k)$ in these two polynomials and by applying Theorem 2.3, we establish two sets of new equations about the ω_{ij}, which are formulated as Lemmas 3.2 and 3.3, respectively. Lemmas 3.2 and 3.3 together immediately imply the elegant equation

$$A_j^4(j, j) = 0, \quad j = k+1, \dots, n, \tag{1.1}$$

which leads to Lemma 3.4.

In the proof of Lemma 3.4, it is important to think of proving (1.1), while in our arguments, the term $A_j^4(j,j)$ appears automatically when we compute the coefficients of x_j^2 $(j > k)$ in $[[[W_j, D_j], D_j], D_j]$.

There are many other striking works which are related to this paper. Among these are Cohen De Lara [9, 10], Davis and Marcus [11], Dong, Tam, Wong, and Yau [12], Duncan [13], Marcus [16], Wong [19, 20, 21], and Yau [22]. The recent perspective paper [13] by Professor Tyrone E. Duncan provides a good account of the past and the present of the filtering theory.

The rest of this paper is organized as follows. Section 2 contains some basic concepts and previous results from Ocone [15], Chiou and Yau [8], Yau [22], and Chen and Yau [5]. Section 3 contains the proof of Theorem 1.1.

2. Preliminaries.

Consider the signal observation model:

$$\begin{cases} dx(t) = f(x(t))dt + g(x(t))dv(t), & x(0) = x_0, \\ dy(t) = h(x(t))dt + dw(t), & y(0) = 0, \end{cases} \tag{2.1}$$

in which x, v, y, and w are, respectively, $\mathbb{R}^n$-, $\mathbb{R}^n$-, $\mathbb{R}^m$-, and $\mathbb{R}^m$-valued processes and v and w are independent, standard Brownian processes. Suppose that the vector functions f and h are C^∞ smooth and that $g(x)$ is an orthogonal matrix for each $x \in \mathbb{R}^n$. We shall refer to $x(t)$ as the state of the system at time t and $y(t)$ as the observation at time t. $\rho(t,x)$, the conditional probability density of the state, $x(t)$, given the observation $\{y(s) : 0 \le s \le t\}$ is determined by the Duncan–Mortensen–Zakai equation, which in the unnormalized form is given by

$$d\rho(t,x) = L_0\rho(t,x)dt + \sum_{i=1}^m L_i\rho(t,x)dy_i(t), \quad \rho(0,x) = \rho_0(x), \tag{2.2}$$

where

$$L_0 = \frac{1}{2}\sum_{i=1}^n \frac{\partial^2}{\partial x_i^2} - \sum_{i=1}^n f_i\frac{\partial}{\partial x_i} - \sum_{i=1}^n \frac{\partial f_i}{\partial x_i} - \frac{1}{2}\sum_{i=1}^m h_i^2 \tag{2.3}$$

and for $i = 1, \dots, m, L_i$ is the zero-degree differential operator of multiplication by h_i. (If a is a vector, we use the notation a_i to denote the ith component of a.) ρ_0 is the probability density of the initial point x_0.

Define

$$D_i = \frac{\partial}{\partial x_i} - f_i \tag{2.4}$$

and

$$\eta = \sum_{i=1}^n \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^n f_i^2 + \sum_{i=1}^m h_i^2. \tag{2.5}$$

Then

$$L_0 = \frac{1}{2}\left(\sum_{i=1}^n D_i^2 - \eta\right). \tag{2.6}$$

Throughout this paper, we denote by $\mathcal{P}_i$ the totality of all the polynomials of degree less than or equal to i. Whenever necessary, we use $\mathcal{P}_i(x_1, \dots, x_r)$ to specify the dependent variables of $\mathcal{P}_i$. The default dependent variables are $x_1, \dots, x_n$.

DEFINITION 2.1. *The estimation algebra $\mathcal{E}$ of the filtering system* (2.1) *is defined to be the Lie algebra generated by $\{L_0, L_1, \dots, L_m\}$.*

Ocone [15] observed the following basic property for an estimation algebra $\mathcal{E}$ to be finite-dimensional.

THEOREM 2.1. *Let $\mathcal{E}$ be a finite-dimensional estimation algebra. If φ is a function in $\mathcal{E}$, then φ is a polynomial of degree less than or equal to two, i.e., $\varphi \in \mathcal{P}_2$.*

DEFINITION 2.2. *An estimation algebra $\mathcal{E}$ is said to be of maximal rank if for every $1 \le i \le n$ there exists a constant c_i such that $x_i + c_i \in \mathcal{E}$.*

Let $\mathcal{E}_0$ be the real vector space spanned by $1, x_1, \dots, x_n, D_1, \dots, D_n$ and L_0. The following lemma is valid for an estimation algebra of maximal rank with arbitrary dimension, and it can be found in Chen, Yau, and Leung [7].

LEMMA 2.1. *Let $\mathcal{E}$ be an estimation algebra of maximal rank associated with the filtering system* (2.1)*. Then $\mathcal{E} \supset \mathcal{E}_0$.*

If $\mathcal{E}$ is an estimation algebra of maximal rank, we have by Lemma 2.1 that

$$\mathcal{E} \ni [D_j, D_i] = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j} =: \omega_{ij}, \quad 1 \le i,\ j \le n.$$

If, further, $\mathcal{E}$ is finite-dimensional, then $\omega_{ij} \in \mathcal{P}_2$ for $1 \le i,\ j \le n$ by Theorem 2.1.

Note that f_i as a tensor field is the differential 1-form $\sum_{i=1}^n f_i \, dx_i$ and ω_{ij} as a tensor field is the differential 2-form $\sum_{1 \le i < j \le n} \omega_{ij} \, dx_i \wedge dx_j$. The exterior derivative of the former is just the latter, i.e., they have the following relation:

$$d\left(\sum_{i=1}^n f_i \, dx_i\right) = \sum_{1 \le i < j \le n} \omega_{ij} \, dx_i \wedge dx_j.$$

On one hand, since $d^2 = 0$, we deduce that ω_{ij}'s satisfy the cyclic relation

$$\frac{\partial \omega_{ij}}{\partial x_l} + \frac{\partial \omega_{li}}{\partial x_j} + \frac{\partial \omega_{jl}}{\partial x_i} = 0, \quad 1 \le i,\ j,\ l \le n. \tag{2.7}$$

On the other hand, the Poincaré lemma means that every d-closed differential form in $\mathbb{R}^n$ is d-exact. Then, $\omega_{ij} \equiv 0$ for $1 \le i,\ j \le n$ means that f_i is d-closed and thus is d-exact, i.e., f_i is a gradient vector field.

Theorem 2.2 summarizes some results of Yau [22].

THEOREM 2.2. *Let $\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$ be constant functions. Then Theorem* 1.1 *holds.*

The proof of Theorem 1.1 is then reduced to showing that $\omega_{ij}, 1 \le i,\ j \le n$ are all constants. In the following, we recall the existing results about the constant structure of the Ω-matrix.

Denote by $\mathcal{H}_2$ the space of quadratic forms in n variables, i.e., the real vector space spanned by $x_i x_j$, with $1 \le i \le j \le n$. Let $X = (x_1, \dots, x_n)'$.

DEFINITION 2.3. *For any quadratic form $p \in \mathcal{H}_2$, there exists a symmetric $n \times n$ matrix A such that $p(x) = X'AX$. The rank of the quadratic form p denoted by* $\mathrm{r}(p)$ *is defined to be the rank of the matrix A.*

DEFINITION 2.4. *A fundamental quadratic form of the estimation algebra $\mathcal{E}$ is an element $p_0 \in \mathcal{E} \cap \mathcal{H}_2$ with the biggest positive rank, i.e.,* $\mathrm{r}(p_0) \ge \mathrm{r}(p)$ *for any*

$p \in \mathcal{E} \cap \mathcal{H}_2$. The quadratic rank of the estimation algebra $\mathcal{E}$ is defined to be the rank of a fundamental quadratic form of $\mathcal{E}$.

Let p_0 be a fundamental quadratic form of $\mathcal{E}$ and $k := r(p_0)$. After an orthogonal transformation on x, p_0 can be written as

$$p_0 = \sum_{i=1}^{k} c_i x_i^2, \quad c_i \neq 0.$$

From p_0, we can construct a sequence of quadratic forms in $\mathcal{E} \cap \mathcal{H}_2$ as follows:

$$\begin{aligned} q_0 :=& p_0, \\ q_j :=& [[L_0, q_{j-1}], q_0] = \sum_{i=1}^{k} 4^j c_i^{j+1} x_i^2, \quad j = 1, 2, \ldots . \end{aligned}$$

In view of the invertibility of the Vandermonde matrix, we can assume that

$$p_0 = \sum_{i=1}^{k} x_i^2. \tag{2.8}$$

Chen and Yau [5, 6] (see also a recent work by Yau and Hu) introduced the above concepts and proved Theorems 2.3 and 2.4.

THEOREM 2.3. *Let $\mathcal{E}$ be a finite-dimensional estimation algebra of maximal rank. Let k be the quadratic rank of $\mathcal{E}$, and let p_0 (defined by (2.8)) be a fundamental quadratic form of $\mathcal{E}$. Then $p \in \mathcal{E} \cap \mathcal{P}_2$ implies that the coefficients of $x_i x_j$ in p are equal to zero for $i = k+1, \ldots, n$ and $j = 1, \ldots, n$.*

THEOREM 2.4. *Let $\mathcal{E}$ be a finite-dimensional estimation algebra of maximal rank. Let k be the quadratic rank of $\mathcal{E}$. Then*

(1) *the observation terms $h_i \in \mathcal{P}_1$ for $1 \leq i \leq m$;*

(2) *ω_{ij} are constants for $1 \leq i \leq k$ or $1 \leq j \leq k$; and $\omega_{ij} \in \mathcal{P}_1(x_{k+1}, \ldots, x_n)$ for $k+1 \leq i,\ j \leq n$.*

For the sake of convenience, we also provide the following lemma without proof, which can be checked out directly.

LEMMA 2.2. *Assume that g and h are C^∞ functions defined on $\mathbb{R}^n$. Then, we have the following.*

(1) $[XY, Z] = X[Y, Z] + [X, Z]Y$, *where X, Y, and Z are differential operators.*

(2) $[gD_i, h] = g\frac{\partial h}{\partial x_i}$.

(3) $[gD_i, hD_j] = gh\omega_{ji} + g\frac{\partial h}{\partial x_i}D_j - h\frac{\partial g}{\partial x_j}D_i$.

(4) $[gD_i^2, h] = 2g\frac{\partial h}{\partial x_i}D_i + g\frac{\partial^2 h}{\partial x_i^2}$.

(5) $[D_i^2, hD_j] = 2\frac{\partial h}{\partial x_i}D_iD_j + 2h\omega_{ji}D_i + \frac{\partial^2 h}{\partial x_i^2}D_j + h\frac{\partial \omega_{ji}}{\partial x_i}$.

(6) $[D_i^2, D_j^2] = 4\omega_{ji}D_jD_i + 2\frac{\partial \omega_{ji}}{\partial x_j}D_i + 2\frac{\partial \omega_{ji}}{\partial x_i}D_j + \frac{\partial^2 \omega_{ji}}{\partial x_i \partial x_j} + 2\omega_{ji}^2$.

(7) $[D_r^2, hD_iD_j] = 2\frac{\partial h}{\partial x_r}D_rD_iD_j + 2h\omega_{jr}D_iD_r + 2h\omega_{ir}D_rD_j + \frac{\partial^2 h}{\partial x_r^2}D_iD_j + 2h\frac{\partial \omega_{jr}}{\partial x_i}D_r$
$+ h\frac{\partial \omega_{jr}}{\partial x_r}D_i + h\frac{\partial \omega_{ir}}{\partial x_r}D_j + h\frac{\partial^2 \omega_{jr}}{\partial x_i \partial x_r}$.

(8) $[gD_iD_j, hD_r] = g\frac{\partial h}{\partial x_j}D_iD_r + g\frac{\partial h}{\partial x_i}D_jD_r + gh\omega_{rj}D_i + gh\omega_{ri}D_j + g\frac{\partial^2 h}{\partial x_i \partial x_j}D_r$
$+ gh\frac{\partial \omega_{rj}}{\partial x_i} - h\frac{\partial g}{\partial x_r}D_iD_j$.

(9) $[D_iD_j, h] = \frac{\partial h}{\partial x_i}D_j + \frac{\partial h}{\partial x_j}D_i + \frac{\partial^2 h}{\partial x_i \partial x_j}$.

(10) $[[g, D_j], D_l] = \frac{\partial^2 g}{\partial x_l \partial x_j}$.

(11) $[[[g, D_i], D_j], D_l] = -\frac{\partial^3 g}{\partial x_l \partial x_j \partial x_i}$.

(12) $[[gD_i, D_j], D_l] = \frac{\partial^2 g}{\partial x_l \partial x_j} D_i - \frac{\partial (g\omega_{ji})}{\partial x_l} - \frac{\partial g}{\partial x_j}\omega_{li}$.

(13) $[[[gD_i, D_j], D_j], D_j] = -\frac{\partial^3 g}{\partial x_j^3} D_i + 3\frac{\partial^2 g}{\partial x_j^2}\omega_{ji} + 3\frac{\partial g}{\partial x_j}\frac{\partial \omega_{ji}}{\partial x_j} + g\frac{\partial^2 \omega_{ji}}{\partial x_j^2}$.

(14) $[[D_i D_r, D_j], D_l] = -\frac{\partial \omega_{jr}}{\partial x_l} D_i - \frac{\partial \omega_{ji}}{\partial x_l} D_r + \omega_{ji}\omega_{lr} + \omega_{jr}\omega_{li} - \frac{\partial^2 \omega_{jr}}{\partial x_l \partial x_i}$.

(15) *Assume that* $g \in \mathcal{P}_1$ *and* $\omega_{ij} \in \mathcal{P}_1$. *Then, we have*

$$\begin{aligned}[[[gD_iD_r, D_j], D_j], D_j] =& 3\frac{\partial g}{\partial x_j}\left(\frac{\partial \omega_{jr}}{\partial x_j} D_i + \frac{\partial \omega_{ji}}{\partial x_j} D_r\right) \\ & - 3\left(\frac{\partial g}{\partial x_j}\omega_{jr}\omega_{ji} + \frac{\partial (g\omega_{jr}\omega_{ji})}{\partial x_j}\right).\end{aligned}$$

3. Proof of Theorem 1.1. By Theorem 2.4, we have $\omega_{ij} \in \mathcal{P}_1 \ \forall\, i, j = 1, \dots, n$. In the following, denote by $A_r(i,j)$ the coefficient of x_r in ω_{ij}, and denote by A_r the matrix whose (i,j)-component is $A_r(i,j)$. That is,

$$A_r(i,j) = \frac{\partial \omega_{ij}}{\partial x_r}, \quad A_r := (A_r(i,j))_{1\le i,j\le n}. \tag{3.1}$$

Note that A_r is a *constant skew-symmetric* matrix.

For convenience of notation, we also write

$$C(j,l) := \sum_{r=1}^{n} \omega_{jr}\omega_{lr} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_l \partial x_j} \qquad (\in \mathcal{P}_2;\ \text{see (3.7) below}). \tag{3.2}$$

LEMMA 3.1. *For* $i = k+1, \dots, n$, *we have*

$$\begin{aligned}\sum_{r=1}^{n} A_i(j,r)A_i(r,j) &= \sum_{r=1}^{n} A_j(i,r)A_j(r,i) \\ =& \frac{1}{2}\sum_{r=1}^{n}[A_i(i,r)A_j(r,j) + A_j(i,r)A_i(r,j)], \quad j = k+1, \dots, n\end{aligned} \tag{3.3}$$

and

$$\sum_{r=1}^{n} A_i(i,r)A_i(r,j) = \sum_{r=1}^{n} A_i(i,r)A_j(r,i), \quad j = 1, \dots, n. \tag{3.4}$$

Lemma 3.1 has been derived by Chen, Yau, and Leung [7, pp. 1137–1138], and the following proof refines some of their arguments.

Proof of Lemma 3.1. Introduce U_j and compute $[[L_0, D_j], D_l]$. By (2), (3), and (5) of Lemma 2.2, we have

$$\begin{aligned}U_j :=& [L_0, D_j] = \frac{1}{2}\sum_{r=1}^{n}[D_r^2, D_j] - \frac{1}{2}[\eta, D_j] \\ &= \sum_{r=1}^{n}\left(\omega_{jr}D_r + \frac{1}{2}\frac{\partial \omega_{jr}}{\partial x_r}\right) + \frac{1}{2}\frac{\partial \eta}{\partial x_j} \in \mathcal{E}\end{aligned} \tag{3.5}$$

and

$$
\begin{aligned}
[U_j, D_l] &= \sum_{r=1}^{n} [\omega_{jr} D_r, D_l] - \frac{1}{2}\left[D_l, \frac{\partial \eta}{\partial x_j}\right] \\
&= \sum_{r=1}^{n} \left(\omega_{jr}\omega_{lr} - \frac{\partial \omega_{jr}}{\partial x_l} D_r\right) - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_l \partial x_j} \\
&= C(j,l) - \sum_{r=1}^{n} A_l(j,r) D_r \in \mathcal{E}.
\end{aligned}
\tag{3.6}
$$

Since the last sum of (3.6) is an element of $\mathcal{E}$ by Lemma 2.1 and by the fact that A_r is a constant matrix, we deduce (noting Theorem 2.1) that

$$C(j,l) \in \mathcal{E} \cap \mathcal{P}_2, \quad 1 \le l,\ j \le n. \tag{3.7}$$

Then by (3.2), we conclude that $\eta \in \mathcal{P}_4$ and that $\forall i > k$ or $\forall q > k$,

$$C_{iq}(j,l) := \frac{\partial^2 (C(j,l))}{\partial x_i \partial x_q} = 0 \qquad \text{(by Theorem 2.3)}, \tag{3.8}$$

which implies (by (3.2)) that

$$\frac{1}{2}\frac{\partial^4 \eta}{\partial x_i \partial x_q \partial x_l \partial x_j} = \sum_{r=1}^{n} (A_i(j,r)A_q(l,r) + A_q(j,r)A_i(l,r)). \tag{3.9}$$

Note that (i,q,l,j) is permutable in the left-hand side of (3.9), and this property immediately gives (3.3) and (3.4), using the fact that A_r is skew-symmetric. □

In the following, please keep in mind the following three facts: (1) $\omega_{ij} \in \mathcal{P}_1$, (2) $\eta \in \mathcal{P}_4$, and (3) A_r is skew-symmetric.

Next we analyze the two elements $[[V_j, D_j], D_l]$ and $[[[W_j, D_j], D_j], D_j]$ in $\mathcal{E}$. As a consequence, we establish two sets of new equations among ω_{ij}. They are formulated as Lemmas 3.2 and 3.3, respectively, below.

LEMMA 3.2. *For $j = k+1, \dots, n$ and $l = 1, \dots, n$, we have*

$$\sum_{i,r=1}^{n} A_j(j,r) A_r(j,i) A_j(i,l) = 0. \tag{3.10}$$

Proof of Lemma 3.2. Recall that U_j is given by (3.5), and note that it can be rewritten as

$$U_j = \sum_{i=1}^{n} \left(\omega_{ji} D_i + \frac{1}{2}\frac{\partial \omega_{ji}}{\partial x_i}\right) + \frac{1}{2}\frac{\partial \eta}{\partial x_j} \in \mathcal{E}.$$

Introduce V_j and compute $[[V_j, D_j], D_l]$.

(3.11)
$$\begin{aligned}
V_j :=&[L_0, U_j]\\
=&\frac{1}{2}\sum_{i,r=1}^{n}[D_r^2, \omega_{ji}D_i] + \frac{1}{4}\sum_{r=1}^{n}\left[D_r^2, \frac{\partial\eta}{\partial x_j}\right] + \frac{1}{2}\sum_{i=1}^{n}[\omega_{ji}D_i, \eta]\\
=&\sum_{i,r=1}^{n}\frac{\partial\omega_{ji}}{\partial x_r}D_rD_i + \sum_{i,r=1}^{n}\omega_{ji}\omega_{ir}D_r + \frac{1}{2}\sum_{i,r=1}^{n}\omega_{ji}\frac{\partial\omega_{ir}}{\partial x_r} \qquad \text{by (5) of Lemma 2.2}\\
&+\frac{1}{4}\sum_{r=1}^{n}\left(2\frac{\partial^2\eta}{\partial x_r\partial x_j}D_r + \frac{\partial^3\eta}{\partial x_r^2\partial x_j}\right) + \frac{1}{2}\sum_{i=1}^{n}\omega_{ji}\frac{\partial\eta}{\partial x_i} \qquad \text{by (4) and (2)}\\
=&\sum_{i,r=1}^{n}\frac{\partial\omega_{ji}}{\partial x_r}D_rD_i - \sum_{r=1}^{n}C(j,r)D_r + p_4 + p_1 \in \mathcal{E} \qquad \text{by (3.2),}
\end{aligned}$$

where the notation p_4 and p_1 are defined, respectively, as

$$\begin{aligned}
p_4 :=&\frac{1}{2}\sum_{i=1}^{n}\omega_{ji}\frac{\partial\eta}{\partial x_i} \in \mathcal{P}_4,\\
p_1 :=&\frac{1}{2}\sum_{i,r=1}^{n}\omega_{ji}\frac{\partial\omega_{ir}}{\partial x_r} + \frac{1}{4}\sum_{r=1}^{n}\frac{\partial^3\eta}{\partial x_r^2\partial x_j} \in \mathcal{P}_1.
\end{aligned}$$

We use (10), (12), and (14) of Lemma 2.2 to compute $[[V_j, D_j], D_l]$ as follows. Since $[[p_1, D_j], D_l] = 0$, we have

$$\begin{aligned}
&[[V_j, D_j], D_l]\\
&= \sum_{i,r=1}^{n}\frac{\partial\omega_{ji}}{\partial x_r}[[D_rD_i, D_j], D_l] - \sum_{r=1}^{n}[[C(j,r)D_r, D_j], D_l] + [[p_4, D_j], D_l]\\
&= \sum_{i,r=1}^{n}\frac{\partial\omega_{ji}}{\partial x_r}\left(-\frac{\partial\omega_{jr}}{\partial x_l}D_i - \frac{\partial\omega_{ji}}{\partial x_l}D_r + \omega_{ji}\omega_{lr} + \omega_{jr}\omega_{li}\right) \qquad \text{by (14)}\\
&-\sum_{r=1}^{n}\left(\frac{\partial^2C(j,r)}{\partial x_j\partial x_l}D_r - \frac{\partial(\omega_{jr}C(j,r))}{\partial x_l} - \frac{\partial C(j,r)}{\partial x_j}\omega_{lr}\right) \qquad \text{by (12)}\\
&+\frac{1}{2}\sum_{i=1}^{n}\left(\frac{\partial\omega_{ji}}{\partial x_j}\frac{\partial^2\eta}{\partial x_l\partial x_i} + \frac{\partial\omega_{ji}}{\partial x_l}\frac{\partial^2\eta}{\partial x_j\partial x_i} + \omega_{ji}\frac{\partial^3\eta}{\partial x_j\partial x_i\partial x_l}\right) \qquad \text{by (10).}
\end{aligned} \tag{3.12}$$

So, $[[V_j, D_j], D_l]$ is a first-order differential operator in $\mathcal{E}$ with the coefficients of $D_1, \dots, D_n$ being constants. In view of Lemma 2.1 and Theorem 2.1, we derive from (3.12) that

$$\begin{aligned}
&\sum_{i,r=1}^{n}\frac{\partial\omega_{ji}}{\partial x_r}(\omega_{ji}\omega_{lr} + \omega_{jr}\omega_{li}) + \sum_{i=1}^{n}\left(\frac{\partial(\omega_{ji}C(j,i))}{\partial x_l} + \frac{\partial C(j,i)}{\partial x_j}\omega_{li}\right)\\
&\quad+\frac{1}{2}\sum_{i=1}^{n}\left(\frac{\partial\omega_{ji}}{\partial x_j}\frac{\partial^2\eta}{\partial x_l\partial x_i} + \frac{\partial\omega_{ji}}{\partial x_l}\frac{\partial^2\eta}{\partial x_j\partial x_i} + \omega_{ji}\frac{\partial^3\eta}{\partial x_j\partial x_i\partial x_l}\right) \in \mathcal{E}\cap\mathcal{P}_2.
\end{aligned} \tag{3.13}$$

In view of the notation (3.1) and (3.2), we have

$$\begin{aligned}\sum_{i,r=1}^{n}\Bigg(&A_r(j,i)\omega_{jr}\omega_{li}+A_r(j,i)\omega_{ji}\omega_{lr}-A_j(j,i)\omega_{lr}\omega_{ri}\\ &-\frac{\partial(\omega_{ji}\omega_{jr}\omega_{ri})}{\partial x_l}\Bigg)+\sum_{i=1}^{n}\left(\frac{\partial(C(j,i))}{\partial x_j}\omega_{li}-A_j(j,i)C(l,i)\right)\in\mathcal{E}\cap\mathcal{P}_2.\end{aligned}\tag{3.14}$$

For $l=1,\ldots,n$, the coefficient of x_j^2 $(j\geq k+1)$ in (3.14) is

$$\begin{aligned}&\sum_{i,r=1}^{n}(A_r(j,i)A_j(j,r)A_j(l,i)+A_r(j,i)A_j(j,i)A_j(l,r)\\ &-A_j(j,i)A_j(l,r)A_j(r,i)-A_l(j,i)A_j(j,r)A_j(r,i)\\ &-A_j(j,i)A_l(j,r)A_j(r,i)-A_j(j,i)A_j(j,r)A_l(r,i))\\ &+\sum_{i=1}^{n}\left(C_{jj}(j,i)A_j(l,i)-\frac{1}{2}A_j(j,i)C_{jj}(l,i)\right)\\ =&\sum_{i,r=1}^{n}[-A_j(j,r)A_r(j,i)A_j(i,l)+A_j(j,i)A_j(i,r)A_j(r,l)\\ &-A_j(j,i)A_j(i,r)A_j(r,l)+A_j(j,r)A_j(r,i)A_l(i,j)\\ &-A_j(j,i)A_j(i,r)A_l(r,j)-A_j(j,i)A_l(i,r)A_j(r,j)]\\ &\left(\text{since }\sum_{i,r=1}^{n}A_r(j,i)A_j(j,i)=\sum_{i,r=1}^{n}A_j(r,i)A_j(j,i)\quad\text{by (3.4)},\right.\\ &\left.\text{and since }C_{jj}(j,i)=0=C_{jj}(l,i)\quad\text{by (3.8)}\right)\\ =&-\sum_{i,r=1}^{n}A_j(j,r)A_r(j,i)A_j(i,l)+A_j^3(j,l)-A_j^3(j,l)\\ &+(A_j^2A_l)(j,j)-(A_j^2A_l)(j,j)-(A_jA_lA_j)(j,j)\\ =&-\sum_{i,r=1}^{n}A_j(j,r)A_r(j,i)A_j(i,l)-(A_jA_lA_j)(j,j)\\ =&-\sum_{i,r=1}^{n}A_j(j,r)A_r(j,i)A_j(i,l)\\ &\text{(since }A_jA_lA_j\text{ is skew-symmetric).}\end{aligned}\tag{3.15}$$

This coefficient should be zero as $j\geq k+1$ by Theorem 2.3. So,

$$\begin{aligned}&\sum_{i,r=1}^{n}A_j(j,r)A_r(j,i)A_j(i,l)=0,\\ &j=k+1,\ldots,n,\quad l=1,\ldots,n.\qquad\square\end{aligned}\tag{3.16}$$

Lemma 3.3. *We have*

$$A_j^4(j,j) = \frac{1}{4}\sum_{i,l,r=1}^{n} A_j(j,r)A_r(j,i)A_j(i,l)A_j(l,j), \quad j = k+1, \dots, n. \tag{3.17}$$

Proof of Lemma 3.3. Introduce W_j and compute $[[[W_j, D_j], D_j], D_j]$. Recall that $\omega_{ji} \in \mathcal{P}_1$, so that all of the terms

$$\frac{\partial \omega_{ji}}{\partial x_l}, \quad i,\ j,\ l = 1, \dots, n,$$

are constants. Also recall that V_j is given by (3.11) and note that it can be rewritten as

$$V_j = \sum_{i,l=1}^{n} \frac{\partial \omega_{ji}}{\partial x_l} D_l D_i - \sum_{i=1}^{n} C(j,i) D_i + p_4 + p_1 \in \mathcal{E}.$$

Therefore, we have

$$\begin{aligned}
W_j :=& [L_0, V_j] \\
=& \frac{1}{2}\sum_{i,l,r=1}^{n} \frac{\partial \omega_{ji}}{\partial x_l}[D_r^2, D_l D_i] + \frac{1}{2}\sum_{i,l=1}^{n} \frac{\partial \omega_{ji}}{\partial x_l}[D_l D_i, \eta] \\
& - \frac{1}{2}\sum_{i,r=1}^{n}[D_r^2, C(j,i)D_i] - \frac{1}{2}\sum_{i=1}^{n}[C(j,i)D_i, \eta] + \frac{1}{2}\sum_{r=1}^{n}[D_r^2, p_4 + p_1] \\
=& \frac{1}{2}\sum_{i,l,r=1}^{n} \frac{\partial \omega_{ji}}{\partial x_l}\left(2\omega_{ir}D_l D_r + 2\omega_{lr}D_r D_i + 2\frac{\partial \omega_{ir}}{\partial x_l}D_r + \frac{\partial \omega_{ir}}{\partial x_r}D_l + \frac{\partial \omega_{lr}}{\partial x_r}D_i\right) \quad \text{by (7)} \\
& + \frac{1}{2}\sum_{i,l=1}^{n} \frac{\partial \omega_{ji}}{\partial x_l}\left(\frac{\partial \eta}{\partial x_i}D_l + \frac{\partial \eta}{\partial x_l}D_i + \frac{\partial^2 \eta}{\partial x_l \partial x_i}\right) \qquad \text{by (9)} \\
& - \sum_{i,r=1}^{n} \frac{\partial (C(j,i))}{\partial x_r}D_r D_i - \sum_{i,r=1}^{n} C(j,i)\omega_{ir}D_r - \frac{1}{2}\sum_{i,r=1}^{n} \frac{\partial^2 (C(j,i))}{\partial x_r^2}D_i \\
& - \frac{1}{2}\sum_{i,r=1}^{n} C(j,i)\frac{\partial \omega_{ir}}{\partial x_r} - \frac{1}{2}\sum_{i=1}^{n} C(j,i)\frac{\partial \eta}{\partial x_i} \qquad \text{by (5) and (2)} \\
& + \frac{1}{2}\sum_{r=1}^{n}\left(2\frac{\partial (p_4 + p_1)}{\partial x_r}D_r + \frac{\partial^2 p_4}{\partial x_r^2}\right) \qquad \text{by (4).}
\end{aligned}$$

Then W_j can be written in the following form:

$$W_j = \sum_{l,r=1}^{n} B_{lr}^j D_l D_r + \sum_{r=1}^{n}(b_r^j + \overline{b}_r^j)D_r + p_5 + p_2 \in \mathcal{E}, \tag{3.18}$$

where

$$
\begin{aligned}
B_{lr}^j :=& \sum_{i=1}^n \left(\frac{\partial \omega_{ji}}{\partial x_l} \omega_{ir} + \frac{\partial \omega_{jr}}{\partial x_i} \omega_{il} \right) - \frac{\partial (C(j,r))}{\partial x_l} \in \mathcal{P}_1, \\
b_r^j :=& \sum_{i=1}^n \left(\frac{\partial \omega_{ji}}{\partial x_r} \frac{\partial \eta}{\partial x_i} + \frac{1}{2} \omega_{ji} \frac{\partial^2 \eta}{\partial x_r \partial x_i} - C(j,i)\omega_{ir} + \frac{1}{2} \frac{\partial \omega_{jr}}{\partial x_i} \frac{\partial \eta}{\partial x_i} \right) \in \mathcal{P}_3, \\
\overline{b}_r^j :=& \sum_{i,l=1}^n \left(\frac{\partial \omega_{ji}}{\partial x_l} \frac{\partial \omega_{ir}}{\partial x_l} + \frac{1}{2} \frac{\partial \omega_{ji}}{\partial x_r} \frac{\partial \omega_{il}}{\partial x_l} + \frac{1}{2} \frac{\partial \omega_{jr}}{\partial x_l} \frac{\partial \omega_{li}}{\partial x_i} \right) \\
& - \frac{1}{2} \sum_{l=1}^n \frac{\partial^2 (C(j,r))}{\partial x_l^2} + \frac{\partial p_1}{\partial x_r} \equiv \text{a constant}, \\
p_5 :=& -\frac{1}{2} \sum_{i=1}^n C(j,i) \frac{\partial \eta}{\partial x_i} \in \mathcal{P}_5, \\
p_2 :=& \frac{1}{2} \sum_{r=1}^n \frac{\partial^2 p_4}{\partial x_r^2} + \frac{1}{2} \sum_{i,r=1}^n \frac{\partial \omega_{ji}}{\partial x_r} \frac{\partial^2 \eta}{\partial x_r \partial x_i} - \frac{1}{2} \sum_{i,r=1}^n C(j,i) \frac{\partial \omega_{ir}}{\partial x_r} \in \mathcal{P}_2.
\end{aligned}
\tag{3.19}
$$

Next we use the formulas (11), (13), and (15) in Lemma 2.2 to compute $[[[W_j, D_j], D_j], D_j]$ as follows. Noting that

$$
\begin{aligned}
[[[D_r, D_j], D_j], D_j] &= \frac{\partial^2 \omega_{jr}}{\partial x_j^2} = 0, \\
[[[p_2, D_j], D_j], D_j] &= -\frac{\partial^3 p_2}{\partial x_j^3} = 0,
\end{aligned}
$$

we have

$$
\begin{aligned}
& [[[W_j, D_j], D_j], D_j] \\
& \qquad = \sum_{l,r=1}^n [[[B_{lr}^j D_l D_r, D_j], D_j], D_j] + \sum_{r=1}^n [[[b_r^j D_r, D_j], D_j], D_j] \\
& + \sum_{r=1}^n \overline{b}_r^j [[[D_r, D_j], D_j], D_j] + [[[p_5, D_j], D_j], D_j] \\
& \qquad = \sum_{l,r=1}^n 3 \frac{\partial B_{lr}^j}{\partial x_j} \left(\frac{\partial \omega_{jr}}{\partial x_j} D_l + \frac{\partial \omega_{jl}}{\partial x_j} D_r \right) \\
& - 3 \sum_{l,r=1}^n \left(\frac{\partial B_{lr}^j}{\partial x_j} \omega_{jr} \omega_{jl} + \frac{\partial (B_{lr}^j \omega_{jr} \omega_{jl})}{\partial x_j} \right) \qquad \text{since } B_{lr}^j \in \mathcal{P}_1 \text{ and then by (15)} \\
& - \sum_{r=1}^n \frac{\partial^3 b_r^j}{\partial x_j^3} D_r + \sum_{r=1}^n \left(3 \frac{\partial^2 b_r^j}{\partial x_j^2} \omega_{jr} + 3 \frac{\partial b_r^j}{\partial x_j} \frac{\partial \omega_{jr}}{\partial x_j} \right) \qquad \text{by (13)} \\
& - \frac{\partial^3 p_5}{\partial x_j^3} \in \mathcal{E} \qquad \text{by (11).}
\end{aligned}
\tag{3.20}
$$

So, $[[[W_j, D_j], D_j], D_j]$ is a first-order differential operator in $\mathcal{E}$. Note that the first and third sums in (3.20) are linear combinations of $D_1, \ldots, D_n$ and are elements of $\mathcal{E}$ since $b^j_{lr} \in \mathcal{P}_3$. Hence,

$$\begin{aligned} &-3\sum_{l,r=1}^{n}\left(\frac{\partial B^j_{lr}}{\partial x_j}\omega_{jr}\omega_{jl} + \frac{\partial(B^j_{lr}\omega_{jr}\omega_{jl})}{\partial x_j}\right) \\ &\quad + \sum_{r=1}^{n}\left(3\frac{\partial^2 b^j_r}{\partial x_j^2}\omega_{jr} + 3\frac{\partial b^j_r}{\partial x_j}\frac{\partial \omega_{jr}}{\partial x_j}\right) - \frac{\partial^3 p_5}{\partial x_j^3} \in \mathcal{E}\cap\mathcal{P}_2. \end{aligned} \tag{3.21}$$

Let $j > k$. The coefficients of x_j^2 in (3.21) should be zero by Theorem 2.3; that is,

$$-12\sum_{l,r=1}^{n}\frac{\partial B^j_{lr}}{\partial x_j}A_j(j,r)A_j(j,l) + \frac{9}{2}\sum_{r=1}^{n}\frac{\partial^3 b^j_r}{\partial x_j^3}A_j(j,r) - \frac{1}{2}\frac{\partial^5 p_5}{\partial x_j^5} = 0. \tag{3.22}$$

In view of (3.19), we easily check that for $j > k$

$$\begin{aligned} \frac{\partial B^j_{lr}}{\partial x_j} &= \sum_{i=1}^{n}(A_l(j,i)A_j(i,r) + A_i(j,r)A_j(i,l)) - C_{jl}(j,r) \\ &= \sum_{i=1}^{n}(A_l(j,i)A_j(i,r) + A_i(j,r)A_j(i,l)) \qquad \text{by (3.8)}, \\ \frac{\partial^3 b^j_r}{\partial x_j^3} &= \sum_{i=1}^{n}\Bigg(A_r(j,i)\frac{\partial^4\eta}{\partial x_j^3\partial x_i} + \frac{3}{2}A_j(j,i)\frac{\partial^4\eta}{\partial x_j^2\partial x_r\partial x_i} \\ &\qquad + \frac{1}{2}A_i(j,r)\frac{\partial^4\eta}{\partial x_j^3\partial x_i} - 3C_{jj}(j,i)A_j(i,r)\Bigg) \\ &= \sum_{i,l=1}^{n}(-4A_r(j,i)A_j(j,l)A_j(l,i) - 6A_j(j,i)A_j(r,l)A_j(l,i) \\ &\qquad - 2A_i(j,r)A_j(j,l)A_j(l,i)) \qquad \text{by (3.8)}, \\ \frac{\partial^5 p_5}{\partial x_j^5} &= -\sum_{i=1}^{n}\frac{1}{2}\times 10C_{jj}(j,i)\frac{\partial^4\eta}{\partial x_j^3\partial x_i} = 0 \qquad \text{by (3.8)}. \end{aligned} \tag{3.23}$$

Note that the following two terms

$$\frac{\partial^4\eta}{\partial x_j^2\partial x_r\partial x_i}, \qquad \frac{\partial^4\eta}{\partial x_j^3\partial x_i},$$

which have appeared in (3.23), can be computed in the following way. We use (3.9) with i, q, l, j being replaced, respectively, by j, j, r, i, so as to get the equation

$$\frac{\partial^4\eta}{\partial x_j^2\partial x_r\partial x_i} = -4\sum_{l=1}^{n}A_j(r,l)A_j(l,i).$$

Then, letting r be equal to j in the above equation, we have

$$\frac{\partial^4\eta}{\partial x_j^3\partial x_i} = -4\sum_{l=1}^{n}A_j(j,l)A_j(l,i).$$

Substituting (3.23) into (3.22), the left-hand side of (3.22) is equal to

$$
\begin{aligned}
(3.24)\qquad & \\
& -12\sum_{i,l,r=1}^{n}(A_l(j,i)A_j(i,r)+A_i(j,r)A_j(i,l))A_j(j,r)A_j(j,l)\\
& +\frac{9}{2}\sum_{i,l,r=1}^{n}(-4A_r(j,i)A_j(j,l)A_j(l,i)-6A_j(j,i)A_j(r,l)A_j(l,i)\\
& -2A_i(j,r)A_j(j,l)A_j(l,i))A_j(j,r)\\
=&12\sum_{i,l,r=1}^{n}(A_j(j,l)A_l(j,i)A_j(i,r)A_j(r,j)-A_j(j,l)A_j(l,i)A_i(j,r)A_j(r,j))\\
& +\sum_{i,l,r=1}^{n}(-18A_j(j,r)A_r(j,i)A_j(i,l)A_j(l,j)+27A_j(j,r)A_j(r,l)A_j(l,i)A_j(i,j)\\
& +9A_j(j,l)A_j(l,i)A_i(j,r)A_j(r,j))\\
=&\sum_{i,l,r=1}^{n}(12A_j(j,l)A_l(j,i)A_j(i,r)A_j(r,j)-3A_j(j,l)A_j(l,i)A_i(j,r)A_j(r,j))\\
& +\sum_{i,l,r=1}^{n}(-18A_j(j,r)A_r(j,i)A_j(i,l)A_j(l,j)+27A_j(j,r)A_j(r,l)A_j(l,i)A_j(i,j))\\
=&12\sum_{i,l,r=1}^{n}A_j(j,l)A_l(j,i)A_j(i,r)A_j(r,j)-3A_j^4(j,j)\\
& \qquad\left(\text{since }\sum_{r=1}^{n}A_i(j,r)A_j(r,j)=\sum_{r=1}^{n}A_j(j,r)A_j(r,i)\qquad\text{by (3.4)}\right)\\
& -18\sum_{i,l,r=1}^{n}A_j(j,r)A_r(j,i)A_j(i,l)A_j(l,j)+27A_j^4(j,j)\\
=&24A_j^4(j,j)-6\sum_{i,l,r=1}^{n}A_j(j,r)A_r(j,i)A_j(i,l)A_j(l,j),
\end{aligned}
$$

with the last equality holding since

$$\sum_{i,l,r=1}^{n}A_j(j,l)A_l(j,i)A_j(i,r)A_j(r,j)=\sum_{i,l,r=1}^{n}A_j(j,r)A_r(j,i)A_j(i,l)A_j(l,j).$$

This completes the proof. □

Lemmas 3.2 and 3.3 serve to prove Lemma 3.4, which is a new crucial result and will play a key role in the proof of Lemma 3.5.

LEMMA 3.4. *Let $\mathcal{E}$ be a finite-dimensional estimation algebra of maximal rank. Then we have*

$$A_j(j,r)=0,\qquad j=k+1,\dots,n,\quad r=1,\dots,n. \tag{3.25}$$

Proof of Lemma 3.4. We have obtained two sets of elegant equations (3.10) and (3.17). Combining them, we get

$$A_j^4(j,j) = \frac{1}{4}\sum_{l=1}^{n} A_j(l,j)\left(\sum_{r,i=1}^{n} A_j(j,r)A_r(j,i)A_j(i,l)\right) = 0, \qquad j = k+1,\dots,n. \tag{3.26}$$

Since A_j^2 is symmetric, we have

$$\begin{aligned} 0 = & A_j^4(j,j) = (A_j^2A_j^2)(j,j) = \sum_{i=1}^{n} A_j^2(j,i)A_j^2(i,j) \\ = & \sum_{i=1}^{n}[A_j^2(j,i)]^2, \qquad j = k+1,\dots,n \end{aligned} \tag{3.27}$$

and, therefore,

$$A_j^2(j,i) = 0, \quad j = k+1,\dots,n, \quad i = 1,2,\dots,n. \tag{3.28}$$

In particular,

$$A_j^2(j,j) = 0, \quad j = k+1,\dots,n. \tag{3.29}$$

While by the skew-symmetry of A_j,

$$A_j^2(j,j) = \sum_{r=1}^{n} A_j(j,r)A_j(r,j) = -\sum_{r=1}^{n}[A_j(j,r)]^2. \tag{3.30}$$

We have

$$\sum_{r=1}^{n}[A_j(j,r)]^2 = 0, \tag{3.31}$$

which immediately implies (3.25). □

REMARK 3.1. *In the original version of this paper, to prove Lemma* 3.4, *we considered the second-order differential operator W_j and then used Theorem* 3.3 *of Chen and Yau* [6, p. 1122] *to conclude that* (*for $j > k$*)

$$0 = \frac{\partial B_{jj}^j}{\partial x_j} = \sum_{i=1}^{n} \frac{\partial \omega_{ji}}{\partial x_j}\frac{\partial \omega_{ij}}{\partial x_j} = -\sum_{i=1}^{n}[A_j(j,i)]^2, \tag{3.32}$$

which immediately implies Lemma 3.4. *Unfortunately, the proof of Theorem* 3.3 *of Chen and Yau* [6] *is incorrect. In the second version, we do not use it any more. Instead, we consider the two elements* $[[V_j, D_j], D_l]$ *and* $[[[W_j, D_j], D_j], D_j]$ (*which turn out to be first-order differential operators*) *in* $\mathcal{E}$, *and through analyzing the coefficients of* x_j^2 *in these two elements, we obtain Lemmas* 3.2 *and* 3.3, *which together imply* (3.32) *and thus Lemma* 3.4 *as well.*

After Lemma 3.4 has been obtained, it is easy to deduce from (3.3) of Lemma 3.1 the following lemma.

Lemma 3.5. *Let the estimation algebra $\mathcal{E}$ be both of finite dimension and of maximal rank. Then, ω_{ij}, $k+1 \leq i,\ j \leq n$, are constants.*

Proof of Lemma 3.5. Thanks to Lemma 3.4, (3.3) of Lemma 3.1 gives

$$\sum_{r=1}^{n}[A_i(j,r)]^2 = \sum_{r=1}^{n}[A_j(i,r)]^2 = \frac{1}{2}\sum_{r=1}^{n}A_j(i,r)A_i(j,r), \qquad i,\ j = k+1,\dots,n. \tag{3.33}$$

Therefore, for $i,\ j = k+1,\dots,n$,

$$\begin{aligned} &\sum_{r=1}^{n}[A_i(j,r)]^2 + \sum_{r=1}^{n}[A_j(i,r)]^2 + \sum_{r=1}^{n}[A_j(i,r) - A_i(j,r)]^2 \\ =&2\sum_{r=1}^{n}[A_i(j,r)]^2 + 2\sum_{r=1}^{n}[A_j(i,r)]^2 - 2\sum_{r=1}^{n}A_j(i,r)A_i(j,r) = 0, \end{aligned} \tag{3.34}$$

which immediately implies

$$A_i(j,r) = 0 \quad \forall\ i,\ j = k+1,\dots,n, \quad r = 1,\dots,n. \tag{3.35}$$

Noting the cyclic relation (2.7), we get

$$A_r(i,j) = -A_j(r,i) - A_i(j,r) = A_j(i,r) - A_i(j,r) \quad \forall\, i,j = k+1,\dots,n, \quad r = 1,\dots,n,$$

which, together with (3.35), gives

$$A_r(i,j) = 0 \quad \forall\ i,\ j = k+1,\dots,n, \quad r = 1,\dots,n. \tag{3.36}$$

Recall that $\omega_{ij} \in \mathcal{P}_1$ for $i,\ j = 1,\dots,n$, so that (3.36) implies that $\omega_{i,j},\ k+1 \leq i,\ j \leq n$ are constants. □

Remark 3.2. *Here we realize a new scheme to prove Lemma* 3.5. *First show $A_j(j,r) = 0$ (Lemma* 3.4*) and then show $A_i(j,r) = 0$ for $i \neq j$ and $i \neq r$. This is different from Chen, Yau, and Leung* [7, pp. 1137–1138]*, who first used the dimension assumption $n \leq 4$ and Lemma* 3.1 *to show $A_i(j,r) = 0$ for $i \neq j$ and $i \neq r$, and then to show $A_j(j,r) = 0$.*

Remark 3.3. *Lemma* 3.5 *can also be derived from the inequality* (3.16) *of Chen, Yau, and Leung* [7, p. 1138] *by applying our new result, Lemma* 3.4*. However, Chen, Yau, and Leung* [7] *did not obtain Lemma* 3.4 *for arbitrary dimension n, and nothing shows that they had realized the importance of proving Lemma* 3.4*. A crucial point of this paper is that we have realized* (*since the original version of this paper*) *the key role of Lemma* 3.4 *and that we succeed in establishing Lemma* 3.4*.*

Proof of Theorem 1.1. From Lemma 3.5 and Theorem 2.4, we conclude that all ω_{ij}, $1 \leq i,\ j \leq n$, are constants. Then Theorem 2.2 concludes our proof. □

Acknowledgments. The author would like to thank one anonymous referee for his or her careful reading of the original and the revised versions of this paper. The author would like to acknowledge the support from the International Mathematical Union and the local German organizing committee, who provided the author an opportunity to present the result of this paper (as a short communication) at the International Congress of Mathematicians of 1998 in Berlin. The third and the fourth (the final) versions of this paper were done during the author's visit to Germany in the years of 1999 and 2000, and the author gratefully acknowledges the support from the Alexander von Humboldt Foundation. In addition, the author thanks Professor Tyrone E. Duncan, Professor Xunjing Li, and Professor Shige Peng for their helpful discussions, and the author thanks Professor Michael Kohlmann for his help in preparing the third version of this paper. The author would like to thank the editor Professor Steven I. Marcus for calling the author's attention on May 2, 2000 to the paper of Yau, Wu, and Wong [23]. The paper of Yau, Wu and Wong [23] is quite related to this paper. This paper had been submitted before the publication of [23], and it is independent of [23]. And last but not least, special gratitude should be given to Ms. Luis Pfferkorn, who works at the Göthe Institute in Schwäbisch Hall, and who helped the author so much in preparing the third version of this paper.

ASYMPTOTIC OPTIMALITY OF APPROXIMATE FILTERS IN STOCHASTIC SYSTEMS WITH COLORED NOISES*

ALAIN LE BRETON† AND MARIE-CHRISTINE ROUBAUD‡

Abstract. Approximate filters are proposed for semilinear and nonlinear stochastic systems with colored noises. Basically these filters are defined as those which are optimal when the noises are white. Their long time behavior is investigated and their asymptotic optimality is shown in two cases under some reasonable assumptions.

Key words. nonlinear filtering, colored noises, approximate filters, asymptotic optimality

1. Introduction.

Let $(\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P})$ be a filtered probability space. Let $X = (X_t,\, t \geq 0)$ and $Y = (Y_t,\, t \geq 0)$ be processes, taking values in $\mathbb{R}^d$ and $\mathbb{R}^p$, respectively, uniquely defined by the system of stochastic differential equations

$$(1)\qquad \left\{ \begin{array}{lcll} dX_t &=& b(X_t)dt + d\xi_t, & t \geq 0,\ X_0, \\ dY_t &=& h(X_t)dt + d\eta_t, & t \geq 0, \quad Y_0 = 0. \end{array} \right.$$

Here X_0 stands for some $\mathcal{F}_0$-measurable random initial condition for X, with a given distribution ν_0, and $\xi = (\xi_t,\, t \geq 0)$ and $\eta = (\eta_t,\, t \geq 0)$ are $(\mathcal{F}_t)$-adapted noise processes. Supposing that only Y is observed but one wishes to know X, the classical problem of filtering the signal X at time t from the observation of Y up to time t occurs. The solution to this problem is the conditional distribution Π_t of X_t given $\mathcal{Y}_t = \sigma(\{Y_s\,,\, 0 \leq s \leq t\})$, which we shall call the *exact filter.*

If in model (1) the functions b and h are linear and the processes ξ and η are $(\mathcal{F}_t)$-Brownian motions, then it is known from Ocone and Pardoux [9] that, under stabilizability and detectability assumptions, for any distribution of ν_0 such that $\mathbb{E}[|X_0|^2] < +\infty$, the exact filter is, asymptotically in time, approached by a Kalman filter. In the same paper, Ocone and Pardoux proved also that in the case of a signal with limiting ergodic behavior observed in additive white noise through a nonlinear channel, the solution to the filtering equations initialized with an incorrect prior distribution approaches the exact filter as time goes to infinity.

In the present paper we consider the filtering model (1) when the processes ξ and η are possibly nonindependent and non-Gaussian colored noises. We assume that

$$(2)\qquad \left\{ \begin{array}{lcll} d\xi_t &=& b_\zeta(\zeta_t)dt + dV_t, & t \geq 0, \quad \xi_0 = 0, \\ d\eta_t &=& h_\zeta(\zeta_t)dt + dW_t, & t \geq 0, \quad \eta_0 = 0. \end{array} \right.$$

Here $V = (V_t,\, t \geq 0)$ and $W = (W_t,\, t \geq 0)$ are independent $(\mathcal{F}_t)$-Brownian motions in $\mathbb{R}^d$ and $\mathbb{R}^p$, respectively. We assume that $\mathbb{E}[V_1 V_1'] = \Sigma_V$ for some given symmetric

nonnegative definite matrix Σ_V, and $\mathbb{E}[W_1 W_1'] = I_p$, where I_p denotes the $p \times p$ identity matrix. Moreover, $\zeta = (\zeta_t,\, t \geq 0)$ is an $(\mathcal{F}_t)$-adapted perturbation process taking values in $\mathbb{R}^k$. We suppose also that the pair (ζ, X_0) is independent of (V, W). Of course, in model (1)–(2), the exact filter Π_t for X is nothing but the marginal distribution of the exact filter for the pair (ζ, X). The determination of Π_t, which is in general an infinite dimensional problem, requires the complete knowledge of the joint probabilistic structure of ζ, X, and Y and leads to computations in a space dimension which is larger than that of the system of interest. Hence it is interesting to elaborate *approximate filters* which ignore a part of the actual structure of the system, and then are more easily computable, but may have a long time behavior close to that of the exact filter. Here this question is addressed under the assumptions that

$$(\mathrm{A}_0) \qquad b_\zeta(0) = 0, \qquad h_\zeta(0) = 0,$$

and the perturbation process ζ converges to zero in some appropriate sense which will be made precise later. We propose approximate filters which are basically the optimal filters when the noises are independent white noises, i.e., $\zeta \equiv 0$ since then, from (A_0), $\xi \equiv V$ and $\eta \equiv W$.

Actually, it is convenient to work on the canonical probability space of the process (ζ, X, Y). We suppose that the paths of ζ belong to the set $\Omega_0 = \mathcal{L}^2_{loc}(\mathbb{R}^+ \,;\, \mathbb{R}^k)$ of locally square integrable functions from $\mathbb{R}^+$ into $\mathbb{R}^k$. Let us denote by $\Omega_1 = \mathcal{C}(\mathbb{R}^+ \,;\, \mathbb{R}^d)$ (resp., $\Omega_2 = \mathcal{C}_0(\mathbb{R}^+ \,;\, \mathbb{R}^p)$) the set of continuous functions from $\mathbb{R}^+$ into $\mathbb{R}^d$ (resp., $\mathbb{R}^p$ with value zero at $t = 0$). Define $\Omega = \Omega_0 \times \Omega_1 \times \Omega_2$, $\mathcal{F}$ as its Borel field, $(\mathcal{F}_t)$ as the canonical Borel filtration on Ω, and $(\zeta_t, X_t, Y_t)(z, x, y) = (z_t, x_t, y_t)$ for any $(z, x, y) \in \Omega$. Let $\mathbb{P}$ be the distribution on Ω corresponding to the filtering model defined by (1)–(2). Similarly, let $\mathbb{P}^0$ be the distribution on Ω corresponding to the filtering model defined by (1)–(2) when the noises are white, i.e., $\zeta \equiv 0$ since we assume that (A_0) is fulfilled. Of course, $\mathbb{P}^0$ is nothing but the product probability $\delta_0 \otimes P$, where δ_0 is the Dirac measure on Ω_0 concentrated at 0 and P is the distribution on $\Omega_1 \times \Omega_2$ corresponding to the filtering model (1) when ξ and η are independent Brownian motions and the distribution of X_0 is ν_0. In what follows the symbols $\mathbb{E}[.]$ and $\mathbb{E}^0[.]$ will stand for an expectation or a conditional expectation computed with respect to $\mathbb{P}$ and $\mathbb{P}^0$, respectively. So for the exact filter Π_t of X_t, we write

$$\Pi_t(\varphi) := \mathbb{E}[\varphi(X_t) \,|\, \mathcal{Y}_t]$$

for any φ in the set $\mathcal{M}_b(\mathbb{R}^d)$ of all bounded measurable functions from $\mathbb{R}^d$ into $\mathbb{R}$. Similarly, when X_t is $\mathbb{P}$-integrable, for the conditional expectation we write $\hat{X}_t := \mathbb{E}[X_t \,|\, \mathcal{Y}_t]$.

The basic approximate filter is taken as the conditional distribution Π^0_t of X_t given $\mathcal{Y}_t$ with respect to $\mathbb{P}^0$, and we write also $\Pi^0_t(\varphi) := \mathbb{E}^0[\varphi(X_t) \,|\, \mathcal{Y}_t]$ for any function φ as above and, when it is well defined, $\hat{X}^0_t := \mathbb{E}^0[X_t \,|\, \mathcal{Y}_t]$. We shall also consider approximate filters defined similarly to Π^0 but with some more convenient prior distribution ν in place of the true one ν_0. This will be made precise later.

The paper is organized as follows. In section 2, we consider what we call the *semilinear case,* where the functions b and h are linear but functions b_ζ and h_ζ may be nonlinear. We derive a representation of the exact filter which extends a formula obtained by Makowski [8] and Beněs and Karatzas [1] (see also Haussmann and Pardoux [4]) for a linear system with white noises and non-Gaussian initial conditions. Here Kalman filters can be taken as approximate filters and their asymptotic analysis is led under some stabilizability and detectability assumptions. In section 3, a *nonlinear case* where the signal has a limiting ergodic behavior is investigated. Here the approximate filter appears as the optimal filter corresponding to an incorrect prior distribution, and the asymptotic study uses the results of Ocone and Pardoux [9] on the asymptotic stability of optimal filters with respect to their initial condition.

2. The semilinear case.

In this section, we are interested in the case of a *semilinear system* where the signal and observation dynamics are linear with respect to the state but the action of the pertubation process ζ can be nonlinear. Precisely, here we assume that in model (1)–(2) the condition (A$_0$) is fulfilled and, moreover, the following conditions hold:

(A$_1$) $b(x) = Bx,\ h(x) = Hx,\ x \in \mathbb{R}^d$, and b_ζ and h_ζ are Lipschitzian functions;

(A$_2$) $(B, \Sigma_V^{\frac{1}{2}})$ is a stabilizable pair, and (B, H) is a detectable pair;

(A$_3$) for all $t \geq 0$ $\mathbb{E}\left[\int_0^t |\zeta_s|^2 ds\right] < +\infty$, and $\lim_{t \to +\infty} \mathbb{E}[|\zeta_t|^2] = 0$.

Then the process (X, Y) taken under $\mathbb{P}$ is the solution to the filtering model

$$\left\{ \begin{array}{rcl} dX_t & = & BX_t dt + b_\zeta(\zeta_t)dt + dV_t, \quad t \geq 0,\ X_0, \\ dY_t & = & HX_t dt + h_\zeta(\zeta_t)dt + dW_t, \quad t \geq 0, \quad Y_0 = 0. \end{array} \right. \tag{3}$$

Obviously under the probability $\mathbb{P}^0$, which corresponds to $\zeta \equiv 0$, the system may be reduced to the linear system

$$\left\{ \begin{array}{rcl} dX_t & = & BX_t\, dt + dV_t, \quad t \geq 0,\ X_0, \\ dY_t & = & HX_t\, dt + dW_t, \quad t \geq 0, \quad Y_0 = 0. \end{array} \right. \tag{4}$$

In what follows, the notation $\mathcal{N}(\mu, \Lambda)$ will be used for the Gaussian law on some space $\mathbb{R}^l$ with mean $\mu \in \mathbb{R}^l$ and covariance matrix Λ. For any vector $x \in \mathbb{R}^d$ and any $d \times d$ matrix $R \geq 0$, let $\hat{X}_t^{x,R}$ and Q_t^R be the solutions to the Kalman filtering equations corresponding to model (4) initialized with (x, R), i.e.,

$$d\hat{X}_t^{x,R} = B\hat{X}_t^{x,R}\, dt + Q_t^R H^{'} [dY_t - H\hat{X}_t^{x,R} dt], \quad t \geq 0, \quad \hat{X}_0^{x,R} = x, \tag{5}$$

$$\dot{Q}_t^R = BQ_t^R + Q_t^R B^{'} + \Sigma_V - Q_t^R H^{'} HQ_t^R, \quad t \geq 0, \quad Q_0^R = R. \tag{6}$$

The Gaussian distribution $\Pi_t^{x,R} = \mathcal{N}(\hat{X}_t^{x,R}, Q_t^R)$ will be referred to as a Kalman filter initialized with (x, R). Of course, if $\nu_0 = \mathcal{N}(m_0, Q^0)$, the basic approximate filter Π_t^0 in model (3) is the Kalman filter initialized with (m_0, Q_0). Actually, whatever is the prior distribution ν_0, all Kalman filters $\Pi_t^{x,R} = \mathcal{N}(\hat{X}_t^{x,R}, Q_t^R)$, $x \in \mathbb{R}^d$, $R \geq 0$, are candidates as approximate filters. The key point for the asymptotic study of these filters relies on a representation of the exact filter Π_t which we derive now.

2.1. Representation of the exact filter.

For any $z = (z_t, t \geq 0) \in \Omega_0$ and $x_0 \in \mathbb{R}^d$, let us set

$$\zeta_t^*(z, x_0) = e^{Bt}x_0 + \int_0^t e^{B(t-s)} b_\zeta(z_s) ds, \quad t \geq 0, \tag{7}$$

$$\langle K\rangle_t^*(z,x_0) := \int_0^t |H\zeta_s^*(z,x_0)+h_\zeta(z_s)|^2 ds. \tag{8}$$

Omitting the dependencies on (z,x_0) as will be done often from now on, we introduce also the Kalman-type equations for processes $\hat{X}_t^* \in \mathbb{R}^d$, $\hat{K}_t^* \in \mathbb{R}$ and functions $Q_t^* \in \mathbb{R}^{d\times d}$, $S_t \in \mathbb{R}^d$, and $T_t \in \mathbb{R}$.

$$d\hat{X}_t^* = B\hat{X}_t^* dt + Q_t^* H^{'}[dY_t - H\hat{X}_t^* dt], \quad t \geq 0, \quad \hat{X}_0^* = 0, \tag{9}$$

$$d\hat{K}_t^* = [H\zeta_t^* + h_\zeta(z_t) + HS_t]^{'}[dY_t - H\hat{X}_t^* dt], \quad t \geq 0, \quad \hat{K}_0^* = 0, \tag{10}$$

$$\dot{Q}_t^* = BQ_t^* + Q_t^* B^{'} + \Sigma_V - Q_t^* H^{'} H Q_t^*, \quad t \geq 0, \quad Q_0^* = O, \tag{11}$$

$$\dot{S}_t = (B - Q_t^* H^{'} H)S_t - Q_t^* H^{'}[H\zeta_t^* + h_\zeta(z_t)], \quad t \geq 0, \quad S_0 = 0, \tag{12}$$

$$\dot{T}_t = -2[H\zeta_t^* + h_\zeta(z_t)]^{'} HS_t - S_t^{'} H^{'} HS_t, \quad t \geq 0, \quad T_0 = 0. \tag{13}$$

Finally, we define

$$C_t := \begin{pmatrix} Q_t^* & S_t \\ S_t^{'} & T_t \end{pmatrix}. \tag{14}$$

The following statement extends to the semilinear model (3) a formula obtained by Makowski [8] and Beněs and Karatzas [1] (see also Haussmann and Pardoux [4]) for a linear system with white noises and non-Gaussian initial conditions.

Proposition 2.1. *Let Π_t be the exact filter in model* (3) *(taken under $\mathbb{P}$). Then for any $\varphi \in \mathcal{M}^+(\mathbb{R}^d)$ the following holds:*

$$\Pi_t(\varphi) = \frac{\displaystyle\int_{\Omega_0\times\mathbb{R}^d} e^{[-\frac{1}{2}\langle K\rangle_t^* + \frac{1}{2}T_t + \hat{K}_t^*](z,x_0)} J_t(z,x_0) d\mathbb{P}_{(\zeta,X_0)}(z,x_0)}{\displaystyle\int_{\Omega_0\times\mathbb{R}^d} e^{[-\frac{1}{2}\langle K\rangle_t^* + \frac{1}{2}T_t + \hat{K}_t^*](z,x_0)} d\mathbb{P}_{(\zeta,X_0)}(z,x_0)}, \tag{15}$$

with

$$J_t(z,x_0) = \int_{\mathbb{R}^{d+1}} \varphi(\zeta_t^*(z,x_0)+u)\bar{n}_t^{z,x_0}(du,dv), \tag{16}$$

where for all $z = (z_t, t \geq 0) \in \Omega_0$, $x_0 \in \mathbb{R}^d$, and $t \geq 0$ the symbol $\bar{n}_t^{z,x_0}$ stands for the Gaussian distribution on $\mathbb{R}^{d+1}$ with mean $([\hat{X}_t^* + S_t(z,x_0)]', \hat{K}_t^*(z,x_0) + T_t(z,x_0))'$ and covariance $C_t(z,x_0)$. Here the quantities depending on (z,x_0) are defined by (7)–(14).

Proof. From (3) we may decompose the signal X as

$$X_t = \zeta_t^* + X_t^*, \quad t \geq 0, \tag{17}$$

where

$$\zeta_t^* = \zeta_t^*(\zeta, X_0); \quad X_t^* = \int_0^t e^{B(t-s)} dV_s, \quad t \geq 0.$$

Then by means of an appropriate change of probability (see Le Breton and Roubaud [7] for details), applying the Girsanov theorem and the classical Bayes formula, one can show that

$$\Pi_t(\varphi) = \frac{\displaystyle\int_{\Omega_0\times\mathbb{R}^d} e^{-\frac{1}{2}\langle K\rangle_t^*(z,x_0)} I_t^{(1)}(z,x_0)d\mathbb{P}_{(\zeta,X_0)}(z,x_0)}{\displaystyle\int_{\Omega_0\times\mathbb{R}^d} e^{-\frac{1}{2}\langle K\rangle_t^*(z,x_0)} I_t^{(2)}(z,x_0)d\mathbb{P}_{(\zeta,X_0)}(z,x_0)},$$

with

$$I_t^{(1)}(z,x_0) = \int_{\mathbb{R}^{d+1}} \varphi(\zeta_t^*(z,x_0)+u)e^v n_t^{z,x_0}(du,dv),$$
$$I_t^{(2)}(z,x_0) = \int_{\mathbb{R}^{d+1}} e^v n_t^{z,x_0}(du,dv).$$

Here n_t^{z,x_0} is the conditional distribution of $Z_t(z,x_0) = (X_t^{*\prime}, K_t^*(z,x_0))'$ given $\mathcal{Y}_t$ in the model

$$\begin{cases} dX_t^* &= BX_t^*dt + dV_t, \quad t\geq 0, \quad X_0^* = 0, \\ dK_t^*(z,x_0) &= [H\zeta_t^*(z,x_0) + h_\zeta(z_t)]'dW_t^*, \quad t\geq 0, \quad K_0^*(z,x_0) = 0, \\ dY_t &= HX_t^*dt + dW_t^*, \quad t \geq 0, \quad Y = 0, \end{cases}$$

where W^* is some Brownian motion independent of V.

Actually, n_t^{z,x_0} is nothing but the Gaussian distribution $\mathcal{N}(\hat{Z}_t(z,x_0),\ C_t(z,x_0))$, where $\hat{Z}_t(z,x_0) = (\hat{X}_t^{*'}, \hat{K}_t^*(z,x_0))'$ and $C_t(z,x_0)$ are given by (9)–(14). Hence in order to get (15)–(16) it remains to show that the probability distribution $\bar{n}_t^{z,x_0}$ defined by

$$\bar{n_t}^{z,x_0}(du,dv) := e^{[-\frac{1}{2}T_t - \hat{K}_t^*](z,x_0)}e^v n_t^{z,x_0}(du,dv)$$

is nothing but the Gaussian distribution on $\mathbb{R}^{d+1}$ with mean $([\hat{X}_t^* + S_t(z,x_0)]', \hat{K}_t^*(z,x_0) + T_t(z,x_0))'$ and covariance $C_t(z,x_0)$. A direct calculation of the characteristic functional of $\bar{n}_t^{z,x_0}$ gives the result. □

Remark 2.2. Notice that substituting $\mathbb{P}^0$ for $\mathbb{P}$ in Proposition 2.1, i.e., taking $\zeta\equiv 0$ and then also $\zeta_t^*(z,x_0)\equiv e^{Bt}x_0$, gives a representation of the approximate filter Π_t^0. Of course, the corresponding formula reduces to the one already known for the optimal filter in a linear system with non-Gaussian initial condition.

Remark 2.3. Comparing (9) and (11) to (5)–(6), it is clear that $\hat{X}_t^* = \hat{X}_t^{0,O}$ and $Q_t^* = \hat{Q}_t^O$, where $\hat{X}_t^{0,O}$ and Q_t^O are the solutions of (5) and (6) corresponding to initial conditions 0 and O, respectively. In other words, the marginal distribution of n_t^{z,x_0} on $\mathbb{R}^d$ is nothing but the approximate Kalman filter $\Pi_t^{0,O}$ for X_t, defined by (5)–(6), initialized with $(0,O)$.

2.2. Asymptotic optimality of the approximate filter. Now we can show that an approximate Kalman filter $\Pi_t^{x,R} = \mathcal{N}(\hat{X}_t^{x,R}, Q_t^R)$, defined by (5)–(6) and initialized with arbitrary $x\in\mathbb{R}^d$ and $R\geq 0$, is asymptotically optimal when $\mathbb{E}[|X_0|^2] < +\infty$. The following extends to the case of colored noises in the signal and in the observation, the statement obtained for white noises by Ocone and Pardoux [9, Theorem 2.6].

PROPOSITION 2.4. *Assume that in model* (3)*, the conditions* $(A_0), (A_1), (A_2)$*, and* (A_3) *are fulfilled. Suppose also that* $\mathbb{E}[|X_0|^2] < +\infty$*. Then for any* $x\in\mathbb{R}^d$ *and any* $d\times d$ *matrix* $R\geq 0$*,*

$$\lim_{t\,\to\,\infty} \mathbb{E}[|\hat{X}_t - \hat{X}_t^{x,R}|^2] = 0, \tag{18}$$

and for all uniformly continuous $\varphi \in \mathcal{M}_b(\mathbb{R}^d)$,

$$\lim_{t \to \infty} \mathbb{E}[|\Pi_t(\varphi) - \Pi_t^{x,R}(\varphi)|^2] = 0. \tag{19}$$

Proof. The proof parallels that of [9, Theorem 2.6], and we refer to Le Breton and Roubaud [7] for details. Concerning the limiting property (19), let us point out the fact that the key point is to show that

$$\lim_{t \to \infty} \mathbb{E}[|\Pi_t(\varphi) - \mathcal{N}(\hat{X}_t^*, Q_t^*)(\varphi)|^2] = 0 \tag{20}$$

for any uniformly continuous function $\varphi \in \mathcal{M}_b(\mathbb{R}^d)$. Observe that

$$\Pi_t(\varphi) - \mathcal{N}(\hat{X}_t^*, Q_t^*)(\varphi) = \mathbb{E}[\varphi(X_t) \,|\, \mathcal{Y}_t] - \mathbb{E}[\varphi(\hat{X}_t^* + U_t)],$$

where for each $t \geq 0$, U_t is a Gaussian vector with mean zero and covariance matrix Q_t^*. From (15)–(16) we have

$$\begin{aligned} &\Pi_t(\varphi) - \mathcal{N}(\hat{X}_t^*, Q_t^*)(\varphi) \\ &\qquad = \frac{\displaystyle\int_{\Omega_0 \times \mathbb{R}^d} e^{\left(-\frac{1}{2}\langle K\rangle_t^* + \frac{1}{2}T_t + \hat{K}_t^*\right)(z,x_0)} \Delta_t(z, x_0) d\mathbb{P}_{(\zeta, X_0)}(z, x_0)}{\displaystyle\int_{\Omega_0 \times \mathbb{R}^d} e^{\left(-\frac{1}{2}\langle K\rangle_t^* + \frac{1}{2}T_t + \hat{K}_t^*\right)(z,x_0)} d\mathbb{P}_{(\zeta, X_0)}(z, x_0)}, \end{aligned} \tag{21}$$

where

$$\Delta_t(z, x_0) = \mathbb{E}[\varphi(\hat{X}_t^* + (S_t + \zeta_t^*)(z, x_0) + U_t)] - \mathbb{E}[\varphi(\hat{X}_t^* + U_t)].$$

Let $\varepsilon > 0$. Choose $\eta > 0$ such that for all y and $y' \in \mathbb{R}^d$, if $|y - y'| \leq \eta$, then

$$|\varphi(y) - \varphi(y')|^2 < \frac{\varepsilon}{4}.$$

Decompose the integral in the numerator of (21) into the sum of the integral over the region $\{|(\zeta_t^* + S_t)(z, x_0)| < \eta\}$ and the integral over the region $\{|(\zeta_t^* + S_t)(z, x_0)| \geq \eta\}$. We obtain

$$|\Pi_t(\varphi) - \mathcal{N}(\hat{X}_t^*, Q_t^*)(\varphi)| \leq \sup_{|y - y'| < \eta} |\varphi(y) - \varphi(y')| + 2||\varphi||_\infty \mathbb{E}[\mathbb{1}_{\{|(\zeta_t^* + S_t)| \geq \eta\}} \,|\, \mathcal{Y}_t],$$

and therefore,

$$\mathbb{E}[|\Pi_t(\varphi) - \mathcal{N}(\hat{X}_t^*, Q_t^*)(\varphi)|^2] \leq \frac{\varepsilon}{2} + \frac{8||\varphi||_\infty^2}{\eta^2} \mathbb{E}[|\zeta_t^* + S_t|^2].$$

Since actually $\lim_{t \to \infty} \mathbb{E}[|\zeta_t^* + S_t|^2] = 0$, there is a $T > 0$ such that for all $t > T$,

$$\mathbb{E}[|\Pi_t(\varphi) - \mathcal{N}(\hat{X}_t^*, Q_t^*)(\varphi)|^2] \leq \varepsilon.$$

Thus (20) is obtained, which achieves the proof. □

Remark 2.5. One consequence of Proposition 2.4 is that in the considered case of a nonlinear action of the pertubation process ζ on the basically linear dynamics of the signal-observation process, the approximate filter is "asymptotically insensitive to perturbations of its initial condition."

Remark 2.6. Actually, it is possible to allow some correlation between the signal X and the observation noise in model (3). The statement of Proposition 2.4 can be easily extended to the case where in the state equation for X a term of the form $D\,dY_t$, $D \in \mathbb{R}^{d \times p}$, is added.

3. The nonlinear case. In this section we consider the case where in model (1)–(2) all functions b, b_ζ, h, and h_ζ may be nonlinear but the system has a limiting ergodic behavior. Here, additionally to (A_0), we assume that the following conditions hold.

(A_1^*) b, b_ζ, and h_ζ are Lipschitzian; h is continuous; h_ζ and h are bounded.

(A_2^*) There exist two constants $r > 0$ and $\alpha > 0$ such that for $x \in \mathbb{R}^d$,

$$x'b(x) \leq -\alpha|x| \quad \text{if} \quad |x| > r.$$

We suppose also that the process ζ is generated by the ordinary differential equation

$$\dot{\zeta}_t = a(\zeta_t), \quad t \geq 0, \quad \zeta_0,$$

where a is a Lipschitzian function from $\mathbb{R}^k$ into $\mathbb{R}^k$. Concerning the deterministic flow $\phi = (\phi_t, t \geq 0)$ associated with that equation and the initial condition ζ_0, we assume that

(A_3^*) $\phi(0) \equiv 0$ and ϕ is contracting with some exponential rate $\lambda > 0$, i.e.,

$$|\phi_t(z_1) - \phi_t(z_2)| \leq e^{-\lambda t}|z_1 - z_2|, \quad t \geq 0, \quad z_1, z_2 \in \mathbb{R}^k.$$

The random variable ζ_0 is $\mathcal{F}_0$-measurable and $\mathbb{E}[\exp c_0|\zeta_0|^2] < +\infty$ for $c_0 = K_\zeta^2/\lambda$, where K_ζ is the maximum of the Lipschitz constants for b_ζ and h_ζ. Finally here we assume that the Brownian motion V is nondegenerate, i.e., the matrix Σ_V is positive.

The concerned process (ζ, X, Y) taken under $\mathbb{P}$ on Ω (where actually Ω_0 may be reduced to $\mathcal{C}(\mathbb{R}^+; \mathbb{R}^k)$) is the $(\mathcal{F}_t)$-Markov diffusion process solution of the system

$$(22) \qquad \begin{cases} d\zeta_t &= a(\zeta_t)dt, \, t \geq 0, \; \zeta_0, \\ dX_t &= b(X_t)dt + b_\zeta(\zeta_t)dt + dV_t, \quad t \geq 0, \; X_0, \\ dY_t &= h(X_t)dt + h_\zeta(\zeta_t)dt + dW_t, \quad t \geq 0, \quad Y_0 = 0. \end{cases}$$

The determination of the exact filter Π_t is, in general, an infinite dimensional problem. Actually, the evolution in time of Π_t can be described by the so-called Zakai equation (cf. [11] or, e.g., [2], [10]), where, of course, the spatial dimension is $k + d$ and the initial condition is $\mathbb{P}_{(\zeta_0, X_0)}$, which will be denoted by π_0.

Under the probability $\mathbb{P}^0$, which here corresponds to $\zeta_0 = 0$, the system may be reduced to

$$(23) \qquad \begin{cases} dX_t &= b(X_t)dt + dV_t, \quad t \geq 0, \; X_0, \\ dY_t &= h(X_t)dt + dW_t, \quad t \geq 0, \quad Y_0 = 0. \end{cases}$$

Then the evolution in time of the approximate filter Π_t^0 is described by a Zakai equation for which numerical computations are easier since the spatial dimension is d only and the initial condition is the distribution ν_0 of X_0.

Here the asymptotic study of the approximate filter will use results of Ocone and Pardoux [9] on the asymptotic stability of optimal filters with respect to perturbations to their initial condition for systems with ergodic limiting behavior. So now we summarize the material we need from [9], restricting ourselves to a specific situation which is appropriate to our purpose.

3.1. Stability of filters with respect to their initial condition. Consider a filtering model specified by a signal-observation pair (Z, Y) such that the following hold.

- The signal $Z = (Z_t,\, t \geq 0)$ is a continuous, $\mathbb{R}^n$-valued homogeneous Markov process with some initial distribution π on $\mathbb{R}^n$.
- The $\mathbb{R}^p$-valued observation process Y is defined by

$$Y_t = \int_0^t H(Z_s)\, ds \,+\, W_t, \quad t \geq 0,$$

where W is a $\mathbb{R}^p$-valued standard Brownian motion independent of Z and H is a bounded continuous function from $\mathbb{R}^n$ into $\mathbb{R}^p$.

Let us work as before on the canonical stochastic basis, which here can be taken as $\Omega = \mathcal{C}(\mathbb{R}^+; \mathbb{R}^n) \times \mathcal{C}_0(\mathbb{R}^+; \mathbb{R}^p)$. We denote by $\mathbb{P}^\pi$ the distribution on Ω corresponding to the above model specified by the initial condition π. We denote also by $\mathbb{E}^\pi[.]$ an expectation computed with respect to $\mathbb{P}^\pi$ so that the optimal filter Π_t^π for Z_t corresponding to the prior distribution π is defined by

$$\Pi_t^\pi(\psi) = \mathbb{E}^\pi[\psi(Z_t)|\mathcal{Y}_t], \quad \psi \in \mathcal{M}_b(\mathbb{R}^n).$$

Given two different initial conditions π_0 (the *true prior distribution*, say) and $\bar{\pi}_0$ (an *incorrect prior distribution*), Ocone and Pardoux [9] studied the long time behavior of the difference $\Pi_t^{\pi_0}(\psi) - \Pi_t^{\bar{\pi}_0}(\psi)$ under the probability $\mathbb{P}^{\pi_0}$. They introduce some conditions which in the present case may be stated as follows. Let $\mathcal{C}_b(\mathbb{R}^n)$ be the set of those functions in $\mathcal{M}_b(\mathbb{R}^n)$ which are continuous, and let $(S_t, t \geq 0)$ denote the transition semigroup of the process Z.

Assume the following.

(H$_1$) $(S_t, t \geq 0)$ is a strongly continuous semigroup satisfying the Feller property, i.e., $S_t(\mathcal{C}_b(\mathbb{R}^n)) \subset \mathcal{C}_b(\mathbb{R}^n)$ for all $t \geq 0$, and admitting a unique invariant measure μ such that for all $\psi \in \mathcal{C}_b(\mathbb{R}^n)$

$$\limsup_{t \,\to\, +\infty} \int_{\mathbb{R}^n} |S_t\psi(z) - \mu(\psi)|\, \mu(dz) = 0.$$

Then, denoting by πS_t the distribution of the random variable Z_t under $\mathbb{P}^\pi$, it is said that $(S_t, t \geq 0)$ forgets π for μ if

$$(\mathrm{H}_2(\pi)) \qquad \pi S_t \,\to\, \mu \;\text{ weakly as }\; t \,\to\, +\infty.$$

In what follows, R^π denotes the marginal distribution of $\mathbb{P}^\pi$ on $\Omega_2 = \mathcal{C}_0(\mathbb{R}^+; \mathbb{R}^p)$, i.e., the distribution of the observation process Y corresponding to the initial distribution π for the signal Z. Then, applying [9, Theorem 3.2] to the just described situation, we get the following lemma.

LEMMA 3.1. *Assume that*

(i) $(S_t, t \geq 0)$ *satisfies* (H1),

(ii) $(\mathrm{H}_2(\pi_0))$ *and* $(\mathrm{H}_2(\bar{\pi}_0))$ *are both satisfied, and*

(iii) R^{π_0} *is absolutely continuous with respect to* $R^{\bar{\pi}_0}$.

Then, for every continuous $\psi \in \mathcal{M}_b(\mathbb{R}^n)$,

$$\lim_{t \,\to\, +\infty} \mathbb{E}^{\pi_0}[|\Pi_t^{\pi_0}(\psi) - \Pi_t^{\bar{\pi}_0}(\psi)|^2] = 0.$$

3.2. Asymptotic optimality of the approximate filter. Now we show that the version above of the result of Ocone and Pardoux is appropriate to address our problem concerning the asymptotic optimality of the approximate filter in model (22). Of course, we may look at this model as a signal-observation model of the type which has just been discussed in section 3.1. The process $Z = (\zeta', X')'$ is the $\mathbb{R}^{k+d}$-valued Markovian signal with initial condition $\pi_0 = \mathbb{P}_{(\zeta_0, X_0)}$. The exact (resp., approximate) filter Π_t (resp., Π_t^0) is the optimal filter $\Pi_t^{\pi_0}$ (resp., $\Pi_t^{\bar{\pi}_0}$) corresponding to the true (resp., incorrect) prior distribution π_0 (resp., $\bar{\pi}_0 = \delta_0 \otimes \nu_0$, where ν_0 is the distribution of X_0, i.e., the second marginal of π_0).

Now we can prove the asymptotic optimality of the approximate filter Π_t^0 in the following sense.

PROPOSITION 3.2. *Assume that in model* (22), *the conditions* $(\mathrm{A}_0), (\mathrm{A}_1^*), (\mathrm{A}_2^*)$, *and* (A_3^*) *are fulfilled. Then for every continuous* $\varphi \in \mathcal{M}_b(\mathbb{R}^d)$,

$$\lim_{t \to +\infty} \mathbb{E}[|\Pi_t(\varphi) - \Pi_t^0(\varphi)|^2] = 0. \tag{24}$$

Proof. The proof consists of showing that the conditions of Lemma 3.1 are all satisfied.

Condition (i). At first let us notice that, from Hasminski [3], condition (A_2^*) is a sufficient condition for the ergodicity of a Markov diffusion process X^0 associated with the first stochastic differential equation in (23). Under this condition the corresponding semigroup $(S_t^0, t \geq 0)$ admits a unique invariant measure μ^0 and $(S_t^0, t \geq 0)$ forgets any probability measure ν on $\mathbb{R}^d$ for μ^0, i.e.,

$$\nu S_t^0 \to \mu^0 \text{ weakly as } t \to +\infty, \tag{25}$$

where νS_t^0 denotes the law of X_t^0 when the distribution of X_0^0 is ν.

Now let $(S_t, t \geq 0)$ be the transition semigroup of the diffusion process $Z = (\zeta^{'}, X^{'})^{'}$ generated by (22). Under our assumptions, it is well known that $(S_t)_{t \geq 0}$ is a strongly continuous semigroup satisfying the Feller property. Moreover, from the discussion above about the consequences of (A_2^*) for the first equation in (23), it is straightforward to show that the measure $\mu = \delta_0 \otimes \mu^0$, where μ^0 is the unique invariant measure of $(S_t^0, t \geq 0)$, is an invariant measure of $(S_t, t \geq 0)$. The uniqueness of μ^0 implies the uniqueness of μ, and from (25), (H_1) can be obtained easily.

Condition (ii). Since the law $\pi_0 S_t$ of Z_t under $\mathbb{P}^0 = \mathbb{P}^{\bar{\pi}_0}$ coincides with the law $\delta_0 \otimes (\nu_0 S_t^0)$ on $\Omega_0 \times \Omega_1$, the condition $(\mathrm{H}_2(\bar{\pi}_0))$ is directly obtained from (25). It remains to verify that $(\mathrm{H}_2(\pi_0))$ is fulfilled. Since $(S_t, t \geq 0)$ admits a unique invariant measure, it suffices to show that the family of laws $\{\mathbb{P}_{Z_t},\, t \geq 0\}$, where $\mathbb{P}_{Z_t} = \pi_0 S_t$, is uniformly tight, i.e., for any $\varepsilon > 0$, there is a compact set $K \subset \mathbb{R}^n$ such that

$$\mathbb{P}([Z_t \in K]) \geq 1 - \varepsilon \text{ for all } t \geq 0.$$

But from (A_3^*), ζ converges to 0 in probability under $\mathbb{P} = \mathbb{P}^{\pi_0}$. Then, denoting $\mathbb{P}_{X_t}$ the distribution of X_t under $\mathbb{P}$, it suffices to prove that the family $\{\mathbb{P}_{X_t}, t \geq 0\}$ is uniformly tight. Let us introduce the new probability $\widetilde{\mathbb{P}}$ which is locally absolutely continuous with respect to $\mathbb{P}$ with the local Radon–Nikodým derivative L_t, where

$$\begin{aligned}
L_t &:= \exp\left\{-K_t - \frac{1}{2}\langle K \rangle_t\right\}, \\
K_t &:= \int_0^t b_\zeta(\zeta_s)^{'}\, dV_s + \int_0^t h_\zeta(\zeta_s)^{'}\, dW_s, \quad t \geq 0, \\
\langle K \rangle_t &:= \int_0^t |b_\zeta(\zeta_s)|^2\, ds + \int_0^t |h_\zeta(\zeta_s)|^2\, ds, \quad t \geq 0.
\end{aligned}$$

Then also $\mathbb{P}$ is locally absolutely continuous with respect to $\widetilde{\mathbb{P}}$ with the local Radon–Nikodým derivative L_t^{-1}. Then, for any $r > 0$, we have

$$\mathbb{P}([|X_t| > r]) = \widetilde{\mathbb{E}}[\mathbb{1}_{\{|X_t|>r\}} L_t^{-1}].$$

But under $\widetilde{\mathbb{P}}$, the process X satisfies the stochastic differential equation

$$dX_t = b(X_t)\,dt + d\widetilde{V}_t, \quad t \geq 0, X_0,$$

where $\widetilde{V}$ is a Brownian motion and X_0 has still distribution ν_0 and is independent of $\widetilde{V}$. Therefore, under $\widetilde{\mathbb{P}}$ the distribution of the random variable X_t coincides with $\nu_0 S_t^0$. Hence by the Cauchy–Schwarz inequality, for any $r > 0$ we get

$$\mathbb{P}([|X_t| > r]) \leq [\widetilde{\mathbb{P}}([|X_t| > r])]^{\frac{1}{2}} [\widetilde{\mathbb{E}}(L_t^{-2})]^{\frac{1}{2}},$$

or, equivalently,

$$\mathbb{P}([|X_t| > r]) \leq \left[\nu_0 S_t^0(\{x \in \mathbb{R}^d : |x| > r\})\right]^{\frac{1}{2}} \left[\mathbb{E}(L_t^{-1})\right]^{\frac{1}{2}}. \tag{26}$$

But, taking into account the independence of ζ and (V, W) under $\mathbb{P}$, conditioning on ζ, it is easy to check that

$$\mathbb{E}(L_t^{-1}) = \mathbb{E}(\exp\langle K\rangle_t).$$

Then, making use of assumptions $(\mathrm{A}_0), (\mathrm{A}_1^*)$, and (A_3^*), it is readily seen that there exists some positive constant C such that

$$\mathbb{E}(L_t^{-1}) \leq C < +\infty. \tag{27}$$

Moreover, assumption (A_2^*) implies that the family of distributions $\{\nu_0 S_t^0, t \geq 0\}$ is uniformly tight. Therefore, for given $\varepsilon > 0$ and $C > 0$, there exists an $r > 0$ such that

$$\nu_0 S_t^0(\{x \in \mathbb{R}^d : |x| > r\}) \leq \frac{\varepsilon^2}{C} \text{ for all } t \geq 0.$$

Hence, due to (26) and (27), for this r it follows that

$$\mathbb{P}([|X_t| > r]) \leq \varepsilon \text{ for all } t \geq 0.$$

This means that the family of laws $\{\mathbb{P}_{X_t}, t \geq 0\}$ is uniformly tight and we can conclude that $(\mathrm{H}_2(\pi_0))$ is fulfilled.

Condition (iii). Recall that R^{π_0} and $R^{\bar{\pi}_0}$ are the marginal distributions on Ω_2 of $\mathbb{P} = \mathbb{P}^{\pi_0}$ and $\mathbb{P}^0 = \mathbb{P}^{\bar{\pi}_0}$, respectively. The probability $\widetilde{\mathbb{P}}$, already used above, has the same marginal distribution on $\Omega_1 \times \Omega_2$ as the probability $\mathbb{P}^0$, and hence its marginal distribution on Ω_2 is nothing but $R^{\bar{\pi}_0}$. Therefore, to prove that R^{π_0} is absolutely continuous with respect to $R^{\bar{\pi}_0}$, it is sufficient to show that, in fact, $\mathbb{P}$ is absolutely continuous with respect to $\widetilde{\mathbb{P}}$ on $(\Omega, \mathcal{F})$. Thanks to [5, Proposition III.3.5], to conclude it is enough to show that the local density process L_t^{-1} of $\mathbb{P}$ with respect to $\widetilde{\mathbb{P}}$ is a square-integrable martingale with respect to $\widetilde{\mathbb{P}}$, i.e.,

$$\sup_t \widetilde{\mathbb{E}}(L_t^{-2}) < +\infty,$$

or, equivalently,

$$\sup_t \mathbb{E}(L_t^{-1}) < +\infty.$$

Actually, this is true because of the bound (27) obtained above, and so condition (iii) is fulfilled. □

Remark 3.3. It is interesting to emphasize that the constant c_0 appearing in the condition (A_3^*), which ensures the existence of an exponential moment for ζ_0, depends on the convergence rate λ of the flow ϕ and on the Lipschitz constants of b_ζ and h_ζ in (A_1^*). In particular, not surprisingly, it appears that the larger λ is, the smaller the constant c_0 is.

Remark 3.4. With slight modifications in the proof of Proposition 3.2, one can show that the same asymptotic result holds for any initial law of the form $\bar{\pi}_0 = \delta_0 \otimes \nu$ in place of $\bar{\pi}_0 = \delta_0 \otimes \nu_0$, provided that the incorrect prior distribution ν for X_0 dominates the true one ν_0, i.e., $\nu_0 \ll \nu$. So for two different initial conditions of this form the asymptotic behavior of the approximate filter is unchanged. In the particular case of the filtering model (23), this reduces to the fact that, under the assumptions "b Lipschitzian," "h continuous bounded," and (A_2^*), a filter initialized with an erroneous prior distribution ν such that $\nu_0 \ll \nu$ has the same asymptotic behavior as the optimal filter (initialized with ν_0). Actually, that property in model (23) is a direct consequence of [9, Theorem 3.2, Remark 3.3].

Acknowledgments. We are very grateful to Marina Kleptsyna for valuable discussions concerning ergodic properties of diffusion processes and also to the reviewers and the editors for their comments, which helped to improve the presentation of this paper.

MARKOV PROPERTY AND ERGODICITY OF THE NONLINEAR FILTER[*]

A. G. BHATT[†], A. BUDHIRAJA[‡], AND R. L. KARANDIKAR[†]

Abstract. In this paper we first prove, under quite general conditions, that the nonlinear filter and the pair (signal, filter) are Feller–Markov processes. The state space of the signal is allowed to be nonlocally compact and the observation function h can be unbounded. Our proofs, in contrast to those of Kunita [*J. Multivariate Anal.,* 1 (1971), pp. 365–393; *Spatial Stochastic Processes,* Birkhäuser, 1991, pp. 233–256] and Stettner [*Stochastic Differential Equations,* Springer-Verlag, 1989, pp. 279–292], do not depend upon the uniqueness of the solutions to the filtering equations. We then obtain conditions for existence and uniqueness of invariant measures for the nonlinear filter and the pair process. These results extend those of Kunita and Stettner, which hold for locally compact state space and bounded h, to our general framework. Finally we show that the recent results of Ocone and Pardoux [*SIAM J. Control Optim.,* 34 (1996), pp. 226–243] on asymptotic stability of the nonlinear filter, which use the Kunita–Stettner setup, hold for the general situation considered in this paper.

Key words. nonlinear filtering, invariant measures, asymptotic stability, measure valued processes

1. Introduction.

Kunita's pioneering paper [9] showed the way for analyzing asymptotic behavior of the nonlinear filter. Kunita showed for the case of compact state space valued Markov signal process that the nonlinear filter itself is a Markov process. This proof was based on the fact that the filter is the unique solution to the Kushner–Stratonovich equation (or the Fujisaki–Kallianpur–Kunita equation). Kunita also showed that if the signal is ergodic, then so is the filter. These results were extended to the case of locally compact state space (with a bounded observation function h) by Kunita [10] and Stettner [12]. The proofs of these results also crucially used the uniqueness of the solution to the filtering equation.

In this article, we first show that in the signal and noise independent case (which is also the case treated in the above-stated papers), when the signal is a Markov process, then so is the filter. This proof does not depend upon uniqueness of filtering equations. It just uses the Bayes formula to explicitly evaluate various conditional expectations and deduce that the filter is Markov. Using recent results in Bhatt, Kallianpur, and Karandikar [2], we deduce that under fairly general conditions on h, the filter is a Feller–Markov process. We also show that under the same conditions, the pair process (signal, filter) is a Feller–Markov process. Once this is done, we can obtain results of Kunita [10], Stettner [12], and Ocone and Pardoux [11] on ergodicity and asymptotic stability of the filter in our framework, where the state space is a

complete separable metric space and the function h is allowed to be unbounded and minimal conditions are imposed on it.

Let us begin with listing some common notation used in this article. For a complete separable metric space S, let $C(S)$ be the class of continuous functions on S, $C_b(S)$ be the class of bounded continuous functions on S, $\mathcal{B}(S)$ be the Borel σ-field on S, $\mathcal{P}(S)$ be the space of probability measures on $(S, \mathcal{B}(S))$ endowed with the weak convergence topology, $\mathcal{M}_+(S)$ be the class of positive finite measures on $(S, \mathcal{B}(S))$ with the weak convergence topology, $D([0,\infty), S)$ be the class of functions, which are right continuous and have left limits (r.c.l.l.), from $[0,\infty)$ into S with Skorokhod topology, and $C([0,\infty), S)$ be the class of continuous functions from $[0,\infty)$ into S with topology of uniform convergence on compact subsets of $[0,\infty)$.

2. Preliminaries.

Consider the nonlinear filtering model

$$Y_t = \int_0^t h(X_u)du + W_t, \tag{2.1}$$

where (X_t) is the signal process, taking values in a complete separable metric space E; $h : E \to \mathbb{R}^d$ is a continuous mapping; and (W_t) is an $\mathbb{R}^d$-valued standard Wiener process, assumed to be independent of (X_t). (Y_t) is the observation process. (X_t), (W_t) are defined on a probability space $(\Omega, \mathcal{F}, P)$.

The object of interest in filtering theory is the conditional distribution π_t of X_t given the observations up until time t, i.e., given $\sigma(Y_u; u \le t)$.

We are going to assume that the signal process (X_t) is a Markov process with transition probability function $p(s,x,t,B)$: for $0 \le s < t$, $x \in E$, $B \in \mathcal{B}(E)$,

$$P(X_t \in B | \sigma(X_u : u \le s)) = p(s, X_s, t, B) \text{ almost surely (a.s.).} \tag{2.2}$$

The initial distribution of (X_t) will be denoted by γ, i.e.,

$$\gamma = P \circ (X_0)^{-1}. \tag{2.3}$$

Let $\xi_t(\cdot)$ be the coordinate process on $\mathcal{D} \doteq D([0,\infty), E)$, i.e., $\xi_t(\theta) \doteq \theta(t)$ for $\theta \in \mathcal{D}$. We assume that for all $(s,x) \in [0,\infty) \times E$ there exists a probability measure $P_{s,x}$ on $\mathcal{D}$ such that for $0 \le s < t < \infty$ and $U \in \mathcal{B}(E)$,

$$P_{s,x}(\xi_t \in U | \sigma(\xi_u : u \le s)) = p(s, \xi_s, t, U) \text{ a.s. } P_{s,x} \tag{2.4}$$

and

$$P_{s,x}(\xi_u = x, 0 \le u \le s) = 1. \tag{2.5}$$

Further, we assume that the mapping

$$(s,x) \longrightarrow P_{s,x} \text{ is continuous.} \tag{2.6}$$

As usual, for $\nu \in \mathcal{P}(E)$ and $B \in \mathcal{B}(\mathcal{D})$, let

$$P_{s,\nu}(B) \doteq \int P_{s,x}(B)\nu(dx), \quad B \in \mathcal{B}(\mathcal{D}).$$

Note that

$$P \circ (X)^{-1} = P_{0,\gamma}. \tag{2.7}$$

The Markov property implies that (T_t) defined below is a semigroup:

$$(T_t f)(s,x) \doteq \int f(s+t,y)p(s,x,s+t,dy), \quad (s,x) \in [0,\infty) \times E \tag{2.8}$$

for $f \in C_b([0,\infty)\times E)$, $0 \le t < \infty$. The assumption (2.6) implies that (T_t) is a Feller semigroup, i.e.,

$$T_t\left(C_b([0,\infty)\times E)\right) \subset C_b([0,\infty)\times E). \tag{2.9}$$

It is well known (and easy to verify) that (2.9) implies that (X_t) is continuous in probability. As a consequence, the filter (π_t) admits a continuous version (see [3]).

In order to study the Markov properties of (π_t), we first present the following preliminary result.

3. Pathwise integration formula. We cite the following result from [8]. As we shall see in the next section, this formulation of a stochastic integral is very useful when dealing with a family of measures on a measurable space.

The result is Theorem 3 in [8]. The mapping $\mathcal{I}$ is explicitly constructed in that paper.

THEOREM 3.1. *There exists a measurable mapping* $\mathcal{I} : D([0,\infty),\mathbb{R}) \times D([0,\infty),\mathbb{R}) \to D([0,\infty),\mathbb{R})$ *with the property that if* (U_t) *is a semimartingale (assumed to have r.c.l.l. paths) on a probability space* $(\Omega',\mathcal{F}',P')$ *with respect to a filtration* $(\mathcal{F}'_t)$ *and if* (V_t) *is an r.c.l.l.* $(\mathcal{F}'_t)$*-adapted process, then*

$$Z_t(w') := \mathcal{I}(V.(w'),U.(w'))(t), \quad w' \in \Omega',$$

is a version of the stochastic integral $\int_0^t V_- dU$*, i.e.,*

$$Z_t = \int_0^t V_{s-} dU_s \quad \textit{for all } t \textit{ a.s. } P'.$$

4. Markov properties of the filter. In this section we will study the Markov properties of the filter. The first main result is Theorem 4.5 in which we show that $\{\pi_t, \sigma\{Y_u : u \le t\}\}$ is a Markov process on $(\Omega,\mathcal{F},P)$. The second central result of this section is Theorem 4.8 in which we show that if $\overline{\pi}_t$ is a suboptimal filter defined via an incorrect initialization of the filtering process (to be made precise later in the section), then $\{(\overline{\pi}_t, X_t), \mathcal{F}_t\}$ is a Markov process on $(\Omega,\mathcal{F},P)$ with state space $\mathcal{P}(E)\times E$, where $\mathcal{F}_t \doteq \sigma\{(X_s,Y_s) : s \le t\}$. In particular, this result implies that $\{(\pi_t, X_t), \mathcal{F}_t\}$ is a Markov process on $(\Omega,\mathcal{F},P)$.

Let $\beta_t(\cdot)$ be the coordinate process on $\mathcal{C} \doteq C([0,\infty),\mathbb{R}^d)$, i.e., $\beta_t(\eta) \doteq \eta(t)$ for $\eta \in \mathcal{C}$. Let Q be the standard Wiener measure on $(\mathcal{C},\mathcal{B}(\mathcal{C}))$. Let

$$(\hat{\Omega},\hat{\mathcal{F}}) \doteq (\mathcal{D},\mathcal{B}(\mathcal{D})) \otimes (\mathcal{C},\mathcal{B}(\mathcal{C})),$$

and for $0 \le s < \infty, \nu \in P(E)$,

$$R_{s,\nu} \doteq P_{s,\nu} \otimes Q.$$

Let

$$Z_t(\theta,\eta) \doteq \sum_{j=1}^d \mathcal{I}(h^j(\xi(\theta)),\beta^j(\eta))(t), \tag{4.1}$$

where $h(x) \equiv (h^1(x),\ldots,h^d(x))$ and $\beta_t(\eta) \equiv (\beta^1_t(\eta),\ldots,\beta^d_t(\eta))$ for $x \in E$ and $\eta \in \mathcal{C}$.

Since (β_t), considered as a process on $(\hat{\Omega}, \hat{\mathcal{F}})$, is a Wiener process under $R_{s,\nu}$, it follows from Theorem 3.1 that

$$Z_t - Z_s = \sum_{j=1}^{d} \int_s^t h^j(\xi_u) d\beta_u^j \quad \text{a.s. } R_{s,\nu} \tag{4.2}$$

for every $0 \leq s < t < \infty$ and $\nu \in \mathcal{P}(E)$. The main thing to note is that we have been able to construct a common version of the stochastic integral appearing in (4.2) for the family of probability measures $\{R_{s,\nu}\}$.

For $0 \leq s < t < \infty$, let

$$q_{st}(\theta, \eta) \doteq \exp\left(Z_t(\theta, \eta) - Z_s(\theta, \eta) - \frac{1}{2} \sum_{j=1}^{d} \int_s^t (h^j(\xi_u(\theta))^2 du \right). \tag{4.3}$$

It is well known (and easy to verify) that $\{q_{st} : t \geq s\}$ is a $\{R_{s,\nu}\}$ martingale for every $\nu \in \mathcal{P}(E)$.

Let us note that for $0 \leq s < t$,

$$q_{0t}(\theta, \eta) = q_{0s}(\theta, \eta) q_{st}(\theta, \eta) \quad \text{for all } (\theta, \eta) \in \hat{\Omega}. \tag{4.4}$$

For $0 \leq s < t < \infty$, $\eta \in \mathcal{C}$, and $\nu \in \mathcal{M}_+(E)$, let $\Gamma_{st}(\nu, \cdot)(\eta) \in \mathcal{M}_+(E)$ and $\Lambda_{st}(\nu, \cdot)(\eta) \in \mathcal{P}(E)$ be defined as follows. For $B \in \mathcal{B}(E)$

$$\Gamma_{st}(\nu, B)(\eta) \doteq \int_E \int_{\mathcal{D}} 1_B(\xi_t(\theta)) q_{st}(\theta, \eta) dP_{s,x}(\theta) d\nu(x) \tag{4.5}$$

and

$$\Lambda_{st}(\nu, B)(\eta) \doteq \Gamma_{st}(\nu, B)(\eta) / \Gamma_{st}(\nu, E)(\eta). \tag{4.6}$$

The measure $\Gamma_{st}(\nu, \cdot)(\eta)$ will also be denoted by $\Gamma_{st}(\nu)(\eta)$ and likewise, $\Lambda_{st}(\nu, \cdot)(\eta)$ will be denoted by $\Lambda_{st}(\nu)(\eta)$. Since $\mathbb{E}_{R_{s,\nu}}[q_{st}] = 1$, it follows that

$$\mathbb{E}_Q[\Gamma_{st}(\nu, E)] = \nu(E). \tag{4.7}$$

Note that for $\nu \in \mathcal{M}_+(E)$, if $\hat{\nu}$ is defined by

$$\hat{\nu}(B) \doteq \frac{\nu(B)}{\nu(E)},$$

then

$$\Gamma_{st}(\nu, B)(\eta) = \nu(E) \Gamma_{st}(\hat{\nu}, B)(\eta) \tag{4.8}$$

and

$$\Lambda_{st}(\nu, B)(\eta) = \Lambda_{st}(\hat{\nu}, B)(\eta). \tag{4.9}$$

As a consequence of the Kallianpur–Striebel formula (see [1], [2], [6], [7]) it follows that

$$\pi_t(\omega)(B) \doteq \Lambda_{0t}(\gamma, B)(Y_{\cdot}(\omega)) \tag{4.10}$$

is a version of the filter $\mathbb{E}_P[1_B(X_t)|\sigma(Y_u : u \le t)]$. Furthermore, a.s. P, π_t has continuous paths (see [3]). Here is a technical result needed later.

THEOREM 4.1. *Fix $0 \le s < t$, $\nu \in \mathcal{P}(E)$. Let $\mathcal{F}^*$ be the completion of $\hat{\mathcal{F}}$ under $R_{0,\nu}$. Let $\mathcal{N}$ be the class of $R_{0,\nu}$ null sets in $\mathcal{F}^*$. Considering ξ, β as processes defined on $(\hat{\Omega}, \mathcal{F}^*, R_{0,\nu})$, let us define the following sub-σ fields of $\mathcal{F}^*$:*

$$\begin{aligned} \mathcal{G}_s^t &= \sigma(\sigma(\xi_u : s \le u \le t) \cup \mathcal{N}), \\ \mathcal{E}_0 &= \sigma(\sigma(\beta_u : u \ge 0) \cup \mathcal{N}), \\ \mathcal{E}_1 &= \sigma(\mathcal{G}_0^s \cup \mathcal{E}_0), \\ \mathcal{E}_2 &= \sigma(\mathcal{G}_s^\infty \cup \mathcal{E}_0). \end{aligned} \tag{4.11}$$

Let g be a $\mathcal{E}_2$-measurable, $R_{0,\nu}$-integrable random variable. Then

$$\mathbb{E}_{R_{0,\nu}}[g|\mathcal{E}_1] = g_1 \;\; a.s.,$$

where

$$g_1(\theta, \eta) = \int_{\mathcal{D}} g(\theta_1, \eta) dP_{s,\xi_s(\theta)}(\theta_1). \tag{4.12}$$

Remark 4.1. In (4.11) above, when $t = \infty$, the right-hand side is to be interpreted as $\sigma(\sigma(\xi_u : s \le u < \infty) \cup \mathcal{N})$.

Proof. When g is $\mathcal{G}_s^\infty$-measurable bounded random variable, the result follows from the Markov property of the family $\{P_{s,x}\}$ and independence of β and ξ under $R_{0,\nu}$. When g is of the form

$$g = \sum_{j=1}^{k} g_j f_j, \tag{4.13}$$

where g_j are $\mathcal{G}_s^\infty$-measurable bounded functions and f_j are $\mathcal{E}_0$-measurable bounded functions, the result follows from the preceding observation. Since the class of functions as in (4.13) forms an algebra that generates the σ field $\mathcal{E}_2$, the result follows. □

The next result connects $\{\Gamma_{st}\}$ with each other and is a key step in the proof of the Markov property.

THEOREM 4.2. *Fix $0 \le s < t < \infty$, $\nu \in \mathcal{P}(E)$. Then*

$$\Gamma_{0t}(\nu, B)(\eta) = \Gamma_{st}(\Gamma_{0s}(\nu)(\eta), B)(\eta) \;\; for\ all\ B \in \mathcal{B}(E), \;\; \eta - \;\; a.s.\ [Q] \tag{4.14}$$

and

$$\Lambda_{0t}(\nu, B)(\eta) = \Lambda_{st}(\Lambda_{0s}(\nu)(\eta), B)(\eta) \;\; for\ all\ B \in \mathcal{B}(E), \;\; \eta - \;\; a.s.\ [Q]. \tag{4.15}$$

Proof. Fix $A \in \mathcal{B}(\mathcal{C}), B \in \mathcal{B}(E)$. Let

$$G(A, B) \doteq \int_{\mathcal{C}} \Gamma_{0t}(\nu, B)(\eta) 1_A(\eta) dQ(\eta).$$

Using Fubini's theorem, the definition of Γ_{st}, and the relation (4.4), it follows that

$$G(A, B) = \int_E \int_{\hat{\Omega}} 1_A(\eta) q_{0s}(\theta, \eta) g(\theta, \eta) dR_{0,x}(\theta, \eta) d\nu(x), \tag{4.16}$$

where

$$g(\theta, \eta) = 1_B(\xi_t(\theta)) q_{st}(\theta, \eta).$$

Let $\mathcal{E}_1, \mathcal{E}_2$ be as in Theorem 4.1. Note that $1_A(\eta) q_{0s}(\theta, \eta)$ is $\mathcal{E}_1$-measurable and g is $\mathcal{E}_2$-measurable. It follows from Theorem 4.1 that

$$\mathbb{E}_{R_{0,x}}[g|\mathcal{E}_1](\theta, \eta) = f(\xi_s(\theta), \eta) \quad \text{a.s. } (\theta, \eta) \ [R_{0,x}], \tag{4.17}$$

where

$$\begin{aligned} f(x, \eta) &\doteq \int_{\mathcal{D}} g(\theta_1, \eta) dP_{s,x}(\theta_1) \\ &= \int_{\mathcal{D}} 1_B(\xi_t(\theta_1)) q_{st}(\theta_1, \eta) dP_{s,x}(\theta_1). \end{aligned}$$

Before proceeding, let us note that for $\nu \in P(E)$

$$\int_E f(y, \eta) d\nu(y) = \Gamma_{st}(\nu, B)(\eta). \tag{4.18}$$

Using (4.16), (4.17), and the fact that $1_A(\eta) q_{0s}(\theta, \eta)$ is $\mathcal{E}_1$-measurable, it follows that

$$G(A, B) = \int_E \int_{\hat{\Omega}} 1_A(\eta) q_{0s}(\theta, \eta) f(\xi_s(\theta), \eta) dR_{0,x}(\theta, \eta) d\nu(x).$$

Now applying the definition of Γ_{0s}, we have that

$$G(A, B) = \int_{\mathcal{C}} 1_A(\eta) \left[\int_E f(y, \eta) \Gamma_{0s}(\nu, dy)(\eta) \right] dQ(\eta)$$

and as a consequence on using (4.18) we have that

$$G(A, B) = \int_{\mathcal{C}} 1_A(\eta) \Gamma_{st}(\Gamma_{0s}(\nu)(\eta), B)(\eta) dQ(\eta). \tag{4.19}$$

Since (4.19) holds for all $A \in \mathcal{B}(\mathcal{C})$ and the σ field $\mathcal{B}(E)$ is countably generated, the relation (4.14) follows. The identity (4.15) is a consequence of (4.14) and (4.8)–(4.9). □

We are now in a position to prove that $\{\Gamma_{0t} : t \geq 0\}$, $\{\Lambda_{0t} : t \geq 0\}$ are Markov processes on $(\mathcal{C}, \mathcal{B}(\mathcal{C}), Q)$ with state spaces $\mathcal{M}_+(E)$ and $\mathcal{P}(E)$, respectively. Let $\tilde{\mathcal{F}}$ be the Q-completion of $\mathcal{B}(\mathcal{C})$ and $\tilde{\mathcal{N}}$ be the class of Q null sets in $\tilde{\mathcal{F}}$. For $0 \leq s \leq t \leq \infty$, let $\mathcal{A}_s^t$ be the sub-σ fields of $\tilde{\mathcal{F}}$ defined by

$$\mathcal{A}_s^t = \sigma(\sigma(\beta_u - \beta_s : s \leq u \leq t) \cup \tilde{\mathcal{N}}). \tag{4.20}$$

Here and in what follows, we will consider β and ξ as processes on $\hat{\Omega}$. It is easy to see that

$$\Gamma_{0t}(\nu), \Lambda_{0t}(\nu) \text{ are } \mathcal{A}_0^t\text{-measurable} \tag{4.21}$$

and for $s < t$

$$\Gamma_{st}(\nu), \Lambda_{st}(\nu) \text{ are } \mathcal{A}_s^\infty\text{-measurable.} \tag{4.22}$$

These observations lead us to the following theorem.

THEOREM 4.3. *Let $\nu \in \mathcal{P}(E)$. Then $(\Gamma_{0t}(\nu), \mathcal{A}_0^t)$ and $(\Lambda_{0t}(\nu), \mathcal{A}_0^t)$ are Markov processes on $(\mathcal{C}, \tilde{\mathcal{F}}, Q)$. Furthermore, for fixed $0 \le s < t < \infty$ and real valued Borel measurable functions ψ and φ on $\mathcal{M}_+(E)$ and $\mathcal{P}(E)$, respectively, which satisfy*

$$\mathbb{E}_Q[|\psi(\Gamma_{ut}(\lambda))|] < \infty$$

and

$$\mathbb{E}_Q[|\varphi(\Lambda_{ut}(\lambda))|] < \infty$$

for all $0 \le u \le t$ and $\lambda \in \mathcal{M}_+(E)$ we have that

$$\mathbb{E}_Q[\psi(\Gamma_{0t}(\nu))|\mathcal{A}_0^s] = \psi_1(\Gamma_{0s}(\nu)), \tag{4.23}$$

$$\mathbb{E}_Q[\varphi(\Lambda_{0t}(\nu))|\mathcal{A}_0^s] = \varphi_1(\Lambda_{0s}(\nu)), \tag{4.24}$$

where

$$\psi_1(\lambda) \doteq \mathbb{E}_Q[\psi(\Gamma_{st}(\lambda))], \quad \lambda \in \mathcal{M}_+(E), \tag{4.25}$$

and

$$\varphi_1(\nu) \doteq \mathbb{E}_Q[\varphi(\Lambda_{st}(\nu))], \quad \nu \in \mathcal{P}(E). \tag{4.26}$$

Proof. We will prove only the result for the case where φ and ψ are bounded. The general case follows by the usual approximation arguments (using the observation (4.7)).

We have observed that

$$\psi(\Gamma_{0t}(\nu)) = \psi(\Gamma_{st}(\Gamma_{0s}(\nu)));$$

$\Gamma_{0s}(\nu)$ is $\mathcal{A}_0^s$-measurable and $\Gamma_{st}(\lambda)$ is $\mathcal{A}_s^\infty$-measurable (for all $\lambda \in \mathcal{M}_+(E)$). Also, $\mathcal{A}_0^s$ and $\mathcal{A}_s^\infty$ are independent under Q. This implies (4.23) with ψ_1 defined by (4.25).

For $\varphi \in C_b(\mathcal{P}(E))$ define $\psi \in C_b(\mathcal{M}_+(E))$ by

$$\psi(\lambda) \doteq \varphi\left(\frac{1}{\lambda(E)}\lambda\right).$$

Then, for $\nu \in \mathcal{P}(E)$

$$\varphi(\Lambda_{0t}(\nu)) = \psi(\Gamma_{0t}(\nu)).$$

As a result

$$\mathbb{E}_Q[\varphi(\Lambda_{0t}(\nu))|\mathcal{A}_0^s] = \psi_1(\Gamma_{0s}(\nu)), \tag{4.27}$$

where for $\lambda \in \mathcal{M}_+(E)$

$$\begin{aligned}\psi_1(\lambda) &= \mathbb{E}_Q[\psi(\Gamma_{st}(\lambda))] \\ &= \mathbb{E}_Q[\varphi(\Lambda_{st}(\lambda))].\end{aligned}$$

Given $\lambda \in \mathcal{M}_+(E)$, define $\hat{\lambda} \in \mathcal{P}(E)$ by

$$\hat{\lambda}(B) \doteq \frac{1}{\lambda(E)}\lambda(B), \quad B \in \mathcal{B}(E).$$

Then from (4.9) and the definition of ϕ_1 (see (4.26)), we have that

$$\begin{aligned}\phi_1(\hat{\lambda}) &= \mathbb{E}_Q[\varphi(\Lambda_{st}(\hat{\lambda}))]\\ &= \mathbb{E}_Q[\varphi(\Lambda_{st}(\lambda))]\\ &= \psi_1(\lambda).\end{aligned}$$

As a consequence,

$$\psi_1(\Gamma_{0s}(\nu)) = \phi_1(\Lambda_{0s}(\nu)).$$

This in view of (4.27) proves (4.24). □

As noted earlier, on $(\hat{\Omega}, \hat{\mathcal{F}}, R_{s,\nu})$, $\nu \in \mathcal{P}(E)$,

$$(q_{st})_{t\geq s} \text{ is a martingale with respect to } \sigma(\xi_u, \beta_u : u \leq t)$$

and hence that

$$\rho_{st} = \begin{cases} \Gamma_{st}(\nu, E), & t \geq s, \\ 1, & t \leq s, \end{cases} \tag{4.28}$$

is a martingale on $(\mathcal{C}, \mathcal{B}(\mathcal{C}), Q)$ with respect to $(\mathcal{A}_0^t)$. Let $Q_{s,\nu} \in P(\mathcal{C})$ be defined by

$$\frac{dQ_{s,\nu}}{dQ} = \rho_{st} \text{ on } \mathcal{A}_0^t. \tag{4.29}$$

From Girsanov's theorem, it follows that $Q_{0,\gamma}$ is the law of the observation process Y, i.e., $PoY^{-1} = Q_{0,\gamma}$ (see [6]).

We are going to prove that $\{\Gamma_{0t}(\nu)\}$, $\{\Lambda_{0t}(\nu)\}$ are Markov processes on $(\mathcal{C}, \mathcal{B}(\mathcal{C}), Q_{0,\nu})$ as well.

THEOREM 4.4. *Let $\nu \in \mathcal{P}(E)$. Then $(\Gamma_{0t}(\nu), \mathcal{A}_0^t)$ and $(\Lambda_{0t}(\nu), \mathcal{A}_0^t)$ are Markov processes on $(\mathcal{C}, \tilde{\mathcal{F}}, Q_{0,\nu})$. Furthermore, for $f \in C_b(\mathcal{M}_+(E)), g \in C_b(\mathcal{P}(E))$,*

$$\mathbb{E}_{Q_{0,\nu}}[f(\Gamma_{0t}(\nu))|\mathcal{A}_0^s] = f_1(\Gamma_{0s}(\nu)) \tag{4.30}$$

and

$$\mathbb{E}_{Q_{0,\nu}}[g(\Lambda_{0t}(\nu))|\mathcal{A}_0^s] = g_1(\Lambda_{0s}(\nu)), \tag{4.31}$$

where f_1, g_1 are defined as follows. For $\lambda \in \mathcal{M}_+(E)$, $\nu \in \mathcal{P}(E)$

$$f_1(\lambda) \doteq \mathbb{E}_{Q_{s,\hat{\lambda}}}[f(\Gamma_{st}(\lambda))], \tag{4.32}$$

where $\hat{\lambda}(A) \doteq \frac{1}{\lambda(E)}\lambda(A)$ and

$$g_1(\nu) \doteq \mathbb{E}_{Q_{s,\nu}}[g(\Lambda_{st}(\nu))]. \tag{4.33}$$

Proof. We will first prove (4.30). Fix $0 \leq s < t < \infty$, $\nu \in \mathcal{P}(E)$, and $A \in \mathcal{A}_0^s$. Then

$$\begin{aligned}\int_A f(\Gamma_{0t}(\nu))dQ_{0,\nu} &= \int_A f(\Gamma_{0t}(\nu))\Gamma_{0t}(\nu, E)dQ\\ &= \int_A \psi(\Gamma_{0t}(\nu))dQ\\ &= \int_A \psi_1(\Gamma_{0s}(\nu))dQ,\end{aligned}$$

where $\psi(\lambda) \doteq f(\lambda)\lambda(E)$ and ψ_1 is given by (4.25). Thus defining $f_1(\lambda) = \frac{\psi_1(\lambda)}{\lambda(E)}$, it follows that

$$\begin{aligned} \int_A f(\Gamma_{0t}(\nu)) dQ_{0,\nu} &= \int_A f_1(\Gamma_{0s}(\nu))\Gamma_{0s}(\nu, E) dQ \\ &= \int_A f_1(\Gamma_{0s}(\nu)) dQ_{0,\nu} \end{aligned}$$

and hence (4.30) holds. Further note that

$$\begin{aligned} f_1(\lambda) &= \frac{1}{\lambda(E)}\psi_1(\lambda) \\ &= \frac{1}{\lambda(E)} \int_{\mathcal{C}} f(\Gamma_{st}(\lambda))\Gamma_{st}(\lambda, E) dQ \\ &= \int_{\mathcal{C}} f(\Gamma_{st}(\lambda))\Gamma_{st}(\hat{\lambda}, E) dQ \\ &= \mathbb{E}_{Q_{s,\hat{\lambda}}}[f(\Gamma_{st}(\lambda))]. \end{aligned}$$

Thus, f_1 is given by (4.32).

Now we prove (4.31). Let $g \in C_b(P(E))$ be as in the statement of the theorem. Let $f \in C_b(\mathcal{M}_+(E))$ be defined as

$$f(\lambda) \doteq g\left(\frac{1}{\lambda(E)}\lambda\right)$$

so that $f(\Gamma_{0t}(\nu)) = g(\Lambda_{0t}(\nu))$. Thus,

$$\mathbb{E}_{Q_{0,\nu}}[g(\Lambda_{0t}(\nu)) | \mathcal{A}_0^s] = f_1(\Gamma_{0s}(\nu)),$$

where f_1 is given by (4.32). Note that

$$\begin{aligned} f_1(\lambda) &= \mathbb{E}_{Q_{s,\hat{\lambda}}}[f(\Gamma_{st}(\lambda))] \\ &= \mathbb{E}_{Q_{s,\hat{\lambda}}}\left[g\left(\frac{1}{\Gamma_{st}(\lambda, E)}\Gamma_{st}(\lambda)\right)\right] \\ &= \mathbb{E}_{Q_{s,\hat{\lambda}}}[g(\Lambda_{st}(\lambda))] \\ &= \mathbb{E}_{Q_{s,\hat{\lambda}}}[g(\Lambda_{st}(\hat{\lambda}))] \\ &= g_1(\hat{\lambda}), \end{aligned}$$

where g_1 is defined by (4.33). Thus we have in particular that

$$\mathbb{E}_{Q_{0,\nu}}[g(\Lambda_{0t}(\nu)) | \mathcal{A}_0^s] = f_1(\Gamma_{0s}(\nu)) = g_1(\Lambda_{0s}(\nu)). \qquad \square$$

An immediate consequence of the above result is that for bounded measurable function G on $\mathcal{P}(E)$,

$$(\mathcal{T}_{st}G)(\nu) \doteq \mathbb{E}_{Q_{s,\nu}}[G(\Lambda_{st}(\nu))]$$

defines a two parameter semigroup, i.e., for $0 \leq s < t < u$

$$\mathcal{T}_{st} \circ \mathcal{T}_{tu} = \mathcal{T}_{su}.$$

Moreover, as noted earlier, $\pi_t(\omega) = \Lambda_{0t}(\gamma)(Y_{\cdot}(\omega))$ is a version of the filter $\mathbb{E}_P[X_t \in .|Y_u : u \leq t]$, while $Q_{0,\gamma}$ is the law of the observation process Y. Thus we have the following result.

THEOREM 4.5. *$\{\pi_t\}$ is a $\mathcal{P}(E)$-valued Markov process on $(\Omega, \mathcal{F}, P)$ with associated two parameter semigroup $\{\mathcal{T}_{st}\}$.*

Further, if the signal process (X_t) is a time homogeneous Markov process, then so is $\{\pi_t\}$ with

$$\mathcal{T}_{st} = \mathcal{T}_{0u}, \quad u = t - s.$$

Proof. The first part follows easily from the preceding theorem. For the second part, let us note that the law of $\{(\xi_{s+u}, \beta_{s+u} - \beta_s) : u \geq 0\}$ under $R_{s,\gamma}$ is $R_{0,\gamma}$. As a consequence, the law of $\Gamma_{st}(\gamma)$ under $R_{s,\gamma}$ is same as the law of $\Gamma_{0,(t-s)}(\gamma)$ under $R_{0,\gamma}$.

This yields the required result. □

Let $\nu \in \mathcal{P}(E)$. Define the process

$$\overline{\pi}_t(\omega) \doteq \Lambda_{0t}(\nu)(Y_{\cdot}(\omega)). \tag{4.34}$$

Then $(\overline{\pi}_t)$ considered as a process on $(\Omega, \mathcal{F}, P)$ represents a suboptimal filtering process which has been initiated at the incorrect initial law ν rather than the actual initial law γ. In the final part of this section we study the Markov properties of the process $(\overline{\pi}_t, X_t)$. The importance of Markov property and ergodicity of the pair process in the study of asymptotic robustness questions in nonlinear filtering has been pointed out in [4], [5]. Define the stochastic process (Ψ^{ν}_t) on $(\hat{\Omega}, \hat{\mathcal{F}})$ with values in $\mathcal{P}(E) \times E$ as follows:

$$\Psi^{\nu}_t(\theta, \eta) \doteq (\Lambda_{0t}(\nu)(\eta), \xi_t(\theta)).$$

Let $\mathcal{G}^t_s$ be as in Theorem 4.1, where $\mathcal{N}$ is the class of all $R_{0,\gamma}$ null sets. $\mathcal{G}^t_s$ are sub-σ fields of the completion $\mathcal{F}^*$ of $\mathcal{F}$ under the measure $R_{s,\gamma}$. We now define the following sub-σ fields of $\mathcal{F}^*$: for $0 \leq s \leq t \leq \infty$

$$\mathcal{H}^t_s \doteq \sigma(\sigma\{\beta_u - \beta_s : s \leq u \leq t\} \cup \mathcal{N}), \tag{4.35}$$

$$\mathcal{K}^t_s \doteq \sigma(\mathcal{G}^t_s \cup \mathcal{H}^t_s). \tag{4.36}$$

(See Remark 4.1 above for the case $t = \infty$.) The following theorem is essentially a consequence of Theorem 4.3.

THEOREM 4.6. *Let $\gamma, \nu \in \mathcal{P}(E)$. Then $(\Psi^{\nu}_t, \mathcal{K}^t_0)$ is a Markov process on $(\hat{\Omega}, \hat{F}, R_{0,\gamma})$. Furthermore, for $0 \leq s < t < \infty$ and a bounded measurable function f on $\mathcal{P}(E) \times E$ we have*

$$\mathbb{E}_{R_{0,\gamma}}[f(\Lambda_{0t}(\nu), \xi_t)q_{0t}|\mathcal{K}^s_0] = f_1(\Lambda_{0s}(\nu), \xi_s)q_{0s} \ \ a.s., \tag{4.37}$$

where $f_1 : \mathcal{P}(E) \times E \to \mathbb{R}$ is defined as follows: for $(\lambda, x) \in \mathcal{P}(E) \times E$

$$f_1(\lambda, x) \doteq \mathbb{E}_{R_{s,x}}[f(\Lambda_{st}(\lambda), \xi_t)q_{st}]. \tag{4.38}$$

Proof. The Markov property of $(\Psi^{\nu}_t, \mathcal{K}^t_0)$ is a direct consequence of Theorem 4.3 on noting that under $R_{0,\gamma}$ the σ fields $\mathcal{G}^s_0, \mathcal{H}^s_0$ are independent and $(\Lambda_{0t}(\nu), \mathcal{H}^t_0, R_{0,\gamma})$ and $(\xi_t, \mathcal{G}^t_0, R_{0,\gamma})$ are Markov processes. We now consider the second part of the theorem. Since $q_{0t} = q_{0s} q_{st}$ and q_{st} is $\mathcal{K}_s^\infty$-measurable, it suffices to prove that for a $\mathcal{K}_s^\infty$-measurable random variable Z with $\mathbb{E}_{R_{0,\gamma}}[\,|Z|\,] < \infty$

$$\mathbb{E}_{R_{0,\gamma}}[f(\Lambda_{0t}(\nu), \xi_t) Z | \mathcal{K}_0^s] = f_2(\Lambda_{0s}(\nu), \xi_s) \ \text{ a.s.,} \tag{4.39}$$

where $f_2 : \mathcal{P}(E) \times E \to \mathbb{R}$ is defined as follows: for $(\lambda, x) \in \mathcal{P}(E) \times E$

$$f_2(\lambda, x) \doteq \mathbb{E}_{R_{s,x}}[f(\Lambda_{st}(\lambda), \xi_t) Z]. \tag{4.40}$$

Using the usual approximation arguments, the proof of (4.39)–(4.40) can be reduced to the case when $f(\lambda, x) = g(\lambda)h(x)$ for bounded measurable functions g, h and $Z = UV$, with U being bounded $\mathcal{G}_s^\infty$-measurable and V being bounded $\mathcal{H}_s^\infty$-measurable.

Note that $\mathcal{H}_0^\infty = \sigma(\cup_t \mathcal{H}_0^t)$ and $\mathcal{G}_0^\infty = \sigma(\cup_t \mathcal{G}_0^t)$ are independent under $R_{0,\gamma}$. Also, $g(\Lambda_{0t}(\nu))V$ is $\mathcal{H}_0^\infty$-measurable, $\mathcal{H}_s^\infty \subseteq \mathcal{H}_0^\infty$, $h(\xi_t)U$ is $\mathcal{G}_0^\infty$-measurable and $\mathcal{G}_s^\infty \subseteq \mathcal{G}_0^\infty$. Further, $\mathcal{K}_0^s = \sigma(\mathcal{G}_0^s \cup \mathcal{H}_0^s)$. These observations imply that

$$\mathbb{E}_{R_{0,\gamma}}[g(\Lambda_{0t}(\nu)) V h(\xi_t) U | \mathcal{K}_0^s] = \mathbb{E}_{R_{0,\gamma}}[g(\Lambda_{0t}(\nu)) V | \mathcal{H}_0^s] \mathbb{E}_{R_{0,\gamma}}[h(\xi_t) U | \mathcal{G}_0^s]. \tag{4.41}$$

In turn, using $\Lambda_{0t}(\nu) = \Lambda_{st}(\Lambda_{0s}(\nu))$ and the independence of $\mathcal{H}_0^s$ and $\mathcal{H}_s^\infty$, it follows that

$$\mathbb{E}_{R_{0,\gamma}}[g(\Lambda_{0t}(\nu)) V | \mathcal{H}_0^s] = g_2(\Lambda_{0s}(\nu)) \tag{4.42}$$

with

$$\begin{aligned} g_2(\lambda) &= \mathbb{E}_{R_{s,x}}[g(\Lambda_{st}(\lambda)) V] \\ &= \int_{\mathcal{C}} g(\Lambda_{st}(\lambda)) V dQ, \end{aligned} \tag{4.43}$$

where the second display above follows on recalling that $R_{s,x} = P_{s,x} \otimes Q$. Using the Markov property of (ξ_t) it follows that

$$\mathbb{E}_{R_{0,\gamma}}[h(\xi_t) U | \mathcal{G}_0^s] = h_2(\xi_s) \tag{4.44}$$

with

$$h_2(x) = \mathbb{E}_{R_{s,x}}[h(\xi_t) U]. \tag{4.45}$$

The equations (4.41)–(4.45) imply that (4.39) holds with $f_2(\lambda, x) = g_2(\lambda) h_2(x)$. Using independence of $g(\Lambda_{st}(\lambda))V$ and $h(\xi_t)U$, it follows that (4.40) also holds. As noted at the beginning of the proof, this in turn implies the second part of the theorem, namely (4.37)–(4.38). □

Now for fixed $\nu \in \mathcal{P}(E)$ and $s \geq 0$ define $\hat{R}_{s,\nu}$ on $(\hat{\Omega}, \hat{\mathcal{F}})$ as follows:

$$\frac{d\hat{R}_{s,\nu}}{dR_{s,\nu}}(\theta, \eta) \doteq \ q_{st}(\theta, \eta) \quad \text{on } \mathcal{K}_0^t,\ t \geq s. \tag{4.46}$$

Recall the definition (4.29) of $Q_{s,\nu}$ and that $R_{s,\nu} \doteq P_{s,\nu} \otimes Q$. It now follows from (4.5) that

$$\hat{R}_{s,\nu}(\mathcal{D} \times B) = Q_{s,\nu}(B), \ \ B \in \mathcal{B}(\mathcal{C}). \tag{4.47}$$

The following result is the key step in the proof of the Markov property of $((X_t, \overline{\pi}_t), \mathcal{F}_t)$ on $(\Omega, \mathcal{F}, P)$.

THEOREM 4.7. *Let $\nu \in \mathcal{P}(E)$. Then $(\Psi_t^\nu, \mathcal{K}_0^t)$ is a Markov process on $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{R}_{0,\gamma})$.*

Proof. Fix $0 \leq s < t < \infty$. Let $f : \mathcal{P}(E) \times E \to \mathbb{R}$ be a bounded measurable function and let $A \in \mathcal{K}_0^s$. Then using (4.37) it follows that

$$\begin{aligned}\int_A f(\Lambda_{0t}(\nu), \xi_t) d\hat{R}_{0,\gamma} &= \int_A f(\Lambda_{0t}(\nu), \xi_t)\ q_{0t}\ dR_{0,\gamma} \\ &= \int_A f_1(\Lambda_{0s}(\nu), \xi_s)\ q_{0s}\ dR_{0,\gamma}.\end{aligned} \tag{4.48}$$

Hence

$$\mathbb{E}_{\hat{R}_{0,\gamma}}[f(\Lambda_{0t}(\nu), \xi_t) | \mathcal{K}_0^s] = f_1(\Lambda_{0s}(\nu), \xi_s), \tag{4.49}$$

where f_1 is given by (4.38). □

Remark 4.2. The relation defining f_1 can be recast as

$$f_1(\lambda, x) \doteq \mathbb{E}_{\hat{R}_{s,x}}[f(\Lambda_{st}(\lambda), \xi_t)]. \tag{4.50}$$

Now we come to the Markov property of the filter and signal.

THEOREM 4.8. *Fix $\nu \in \mathcal{P}(E)$. Let $\overline{\pi}_t$ be as in (4.34). Then $((\overline{\pi}_t, X_t), \mathcal{F}_t)$ is a $\mathcal{P}(E) \times E$-valued Markov process on $(\Omega, \mathcal{F}, P)$ with associated two parameter semigroup $\{\mathcal{S}_{s,t}\}_{0 \leq s < t < \infty}$ defined as follows. For a real bounded measurable map f on $\mathcal{P}(E) \times E$,*

$$(\mathcal{S}_{st} f)(\lambda, x) \doteq \mathbb{E}_{\hat{R}_{s,x}}[f(\Lambda_{st}(\lambda), \xi_t)]$$

for $(\lambda, x) \in \mathcal{P}(E) \times E$. Furthermore, if (X_t) is time homogeneous, then so is $(\overline{\pi}_t, X_t)$, i.e., $\mathcal{S}_{st} = \mathcal{S}_{0,t-s}$.

Proof. The Markov property follows on applying Theorem 4.7 and observing that the law of $\{(X_t, \overline{\pi}_t, Y_t) : t \geq 0\}$ under P is the same as the law of $\{(\xi_t, \Lambda_{0t}(\nu), \beta_t) : t \geq 0\}$ under $\hat{R}_{0,\gamma}$. The identities (4.49)–(4.50) imply the assertion made about the semigroup $\mathcal{S}_{st}$. □

5. Time homogeneous signal: Feller properties of the filter.

We will now examine the case of time homogeneous signal. In this case, we write

$$P_\nu = P_{0,\nu}, R_\nu = R_{0,\nu}, Q_\nu = Q_{0,\nu}, \hat{R}_\nu = \hat{R}_{0\nu},$$

$$\Gamma_t = \Gamma_{0t}, \Lambda_t = \Lambda_{0t}, \mathcal{T}_t = \mathcal{T}_{0t}, \mathcal{S}_t = \mathcal{S}_{0t}.$$

We will now show that under a suitable condition, $\{\mathcal{T}_t\}$ and $\{\mathcal{S}_t\}$ are Feller semigroups. The key step in the proof of the Feller property is a result on robustness of the filter from [2]. It is shown there that under a suitable condition on h, ν_n converging to ν implies that

$$Q_{\nu_n} \circ (\Lambda(\nu_n))^{-1} \to Q_\nu \circ (\Lambda(\nu))^{-1}.$$

This would immediately give the Feller property of $\mathcal{T}_t$. The following is essentially proved in [2]. We include here an outline of the proof as the exact result stated below is not given in [2]. This would enable us to conclude that $\mathcal{S}_t$ is a Feller semigroup.

THEOREM 5.1. *Let h be a continuous map from E to $\mathbb{R}^d$. Let $\{\nu_n\} \subset \mathcal{P}(E)$ be a sequence converging to ν weakly. Then the following hold.*

(a) *For all $t \geq 0$, $\Lambda_t(\nu_n) \to \Lambda_t(\nu)$ in Q probability.*

(b) *For all $t > 0$, $\Gamma_t(\nu_n, E) \to \Gamma_t(\nu, E)$ in $L^1(Q)$.*

Proof. For (a) note that continuity of h and continuity of the mapping $x \mapsto P_x$ imply that

$$\lim_{N\to\infty}\left[\sup_{x\in K} P_x\left(\int_0^T \|h(\xi_t)\|^2 1_{\{\|h(\xi_t)\|\geq N\}}dt > \varepsilon\right)\right] = 0 \tag{5.1}$$

for all $\varepsilon > 0$, $T < \infty$ and for all compact subsets $K \subset E$. The result now follows from Theorem 3.2 in [2].

Since $\nu_n \to \nu$ weakly as $n \to \infty$, in view of our assumption on $\{P_x\}$ we have that $P_{\nu_n} \to P_\nu$ weakly as $n \to \infty$. Now let $\{\tilde{X}_t^n\}$ and $\{\tilde{X}_t\}$ be processes with values in $\mathcal{D}$ defined on some probability space $(\overline{\Omega}, \overline{\mathcal{F}}, \overline{P})$ such that $\mathcal{L}(\tilde{X}_\cdot^n) = P_{\nu_n}$, $\mathcal{L}(\tilde{X}_\cdot) = P_\nu$, and $\tilde{X}_\cdot^n \to \tilde{X}_\cdot$ a.s. $\overline{P}$. Define

$$(\Omega_0, \mathcal{F}_0, R_0) \doteq (\overline{\Omega} \times \mathcal{C}, \overline{\mathcal{F}} \otimes \mathcal{B}(\mathcal{C}), \overline{P} \otimes Q)$$

and the processes $Z_\cdot^n$, $Z_\cdot$ on this space as

$$Z_t^n(\overline{\omega}, \eta) \doteq q_{0t}(\tilde{X}^n(\overline{\omega}), \eta),$$

$$Z_t(\overline{\omega}, \eta) \doteq q_{0t}(\tilde{X}(\overline{\omega}), \eta).$$

Then note that

$$\Gamma_t(\nu_n, B)(\eta) = \int_{\overline{\Omega}} 1_B(\tilde{X}^n(\overline{\omega})) Z_t^n(\overline{\omega}, \eta) d\overline{P}$$

and

$$\Gamma_t(\nu, B)(\eta) = \int_{\overline{\Omega}} 1_B(\tilde{X}(\overline{\omega})) Z_t(\overline{\omega}, \eta) d\overline{P}.$$

It is shown in [2] that $Z_t^n \to Z_t$ in $L^1(R_0)$ and this implies part (b). □

As a consequence of the above theorem we have the following results.

THEOREM 5.2. *Let h be continuous map from E to $\mathbb{R}^d$. Then $(\mathcal{T}_t)$ is a Feller semigroup.*

Proof. Let $\{\nu_n\}$ be a sequence in $\mathcal{P}(E)$. Suppose that ν_n converges weakly to ν. Let G be a bounded and continuous real function on $\mathcal{P}(E)$. We need to show that

$$(\mathcal{T}_t G)(\nu_n) \to (\mathcal{T}_t G)(\nu).$$

This follows from Theorem 5.1 upon observing that

$$\begin{aligned}(\mathcal{T}_t G)(\nu_n) &= \mathbb{E}_{Q_{\nu_n}}(G(\Lambda_t(\nu_n))) \\ &= \mathbb{E}_Q(G(\Lambda_t(\nu_n))\Gamma_t(\nu_n, E))\end{aligned} \tag{5.2}$$

and similarly,

$$(\mathcal{T}_t G)(\nu) = \mathbb{E}_Q(G(\Lambda_t(\nu))\Gamma_t(\nu, E)). \qquad \square \tag{5.3}$$

In the following theorem we prove the Feller property of $(\overline{\pi}_t, X_t)$.

THEOREM 5.3. *Let h be continuous map from E to $\mathbb{R}^d$. Then $\{\mathcal{S}_t\}$ is a Feller semigroup.*

Proof. Let F be a real bounded and continuous function on $\mathcal{P}(E) \times E$. Let $\{(\nu_n, x_n)\}$ be a sequence in $\mathcal{P}(E) \times E$ such that $(\nu_n, x_n) \to (\nu, x)$. We need to show that

$$(\mathcal{S}_t F)(\nu_n, x_n) \to (\mathcal{S}_t F)(\nu, x).$$

Now observe that

$$\begin{aligned}(\mathcal{S}_t F)(\nu_n, x_n) &= \mathbb{E}_{\hat{R}_{x_n}}(F(\Lambda_t(\nu_n), \xi_t)) \\ &= \mathbb{E}_{R_{x_n}}(F(\Lambda_t(\nu_n), \xi_t) q_{0t}) \\ &= \mathbb{E}_{R_0}(F(\Lambda_t(\nu_n), \tilde{X}^n_t) Z^n_t), \qquad (5.4)\end{aligned}$$

where $\tilde{X}^n_\cdot, Z^n, R_0$ are as in the proof of Theorem 5.1 with ν_n replaced by δ_{x_n}. Now the result follows once more by an application of Theorem 5.1 and recalling that $\tilde{X}^n_\cdot \to \tilde{X}_\cdot$ a.s. as $n \to \infty$. □

In the final result of this section we study the connection between the invariant measures for the semigroups $\mathcal{T}_t$ and $\mathcal{S}_t$. For a real measurable function φ on a Polish space S and a measure ν on $(S, \mathcal{B}(S))$ we will write $\int_S \varphi(x) d\nu(x)$ as $\nu(\varphi)$ when the former makes sense.

PROPOSITION 5.4. *Let $\overline{M}$ be an $(\mathcal{S}_t)$ invariant probability measure. Define the probability measures μ on $(E, \mathcal{B}(E))$ and M on $(\mathcal{P}(E), \mathcal{B}(\mathcal{P}(E)))$ as follows.*

$$\mu(B) \doteq \overline{M}(\mathcal{P}(E) \times B), \quad B \in \mathcal{B}(E),$$

and

$$M(C) \doteq \overline{M}(C \times E), \quad C \in \mathcal{B}(\mathcal{P}(E)).$$

Then μ is a (T_t) invariant measure. Furthermore, if for all real bounded measurable functions f on E and F on $\mathcal{P}(E)$

$$\int_{\mathcal{P}(E) \times E} F(\nu) f(x) \overline{M}(d\nu, dx) = \int_{\mathcal{P}(E)} \nu(f) F(\nu) M(d\nu), \qquad (5.5)$$

then M is a $(\mathcal{T}_t)$ invariant measure.

Proof. Let f be a bounded measurable function on E. Define $\tilde{f} : \mathcal{P}(E) \times E \to \mathbb{R}$ as $\tilde{f}(\nu, x) \doteq f(x)$. Then

$$\begin{aligned}\int_E (T_t f)(x) \mu(dx) &= \int_{\mathcal{P}(E) \times E} (T_t f)(x) \overline{M}(d\nu, dx) \\ &= \int_{\mathcal{P}(E) \times E} \mathbb{E}_{\hat{R}_x}(\tilde{f}(\Lambda_{0t}(\nu), \xi_t)) \overline{M}(d\nu, dx) \\ &= \int_{\mathcal{P}(E) \times E} (S_t \tilde{f})(\nu, x) \overline{M}(d\nu, dx) \\ &= \int_{\mathcal{P}(E) \times E} \tilde{f}(\nu, x) \overline{M}(d\nu, dx) \\ &= \int_E f(x) \mu(dx).\end{aligned}$$

This proves that μ is (T_t) invariant.

Next let G be a real bounded measurable function on $\mathcal{P}(E)$ and suppose that (5.5) holds. Then for all real bounded measurable functions Φ on $\mathcal{P}(E) \times E$,

$$\int_{\mathcal{P}(E)\times E} \Phi(\nu, x)\overline{M}(d\nu, dx) = \int_{\mathcal{P}(E)} \left(\int_E \Phi(\nu, x)\nu(dx)\right) M(d\nu). \tag{5.6}$$

Define $\tilde{G} : \mathcal{P}(E) \times E \to \mathbb{R}$ as $\tilde{G}(\nu, x) \doteq G(\nu)$. Then, recalling (4.47)

$$\begin{aligned}
\int_{\mathcal{P}(E)} (\mathcal{T}_t G)(\nu) M(d\nu) &= \int_{\mathcal{P}(E)} \mathbb{E}_{Q_\nu}(G(\Lambda_t(\nu)))M(d\nu)\\
&= \int_{\mathcal{P}(E)} \mathbb{E}_{\hat{R}_\nu}(G(\Lambda_t(\nu)))M(d\nu)\\
&= \int_{\mathcal{P}(E)} \left(\int_E \mathbb{E}_{\hat{R}_x}(G(\Lambda_t(\nu, \cdot)))\nu(dx)\right) M(d\nu)\\
&= \int_{\mathcal{P}(E)} \left(\int_E (\mathcal{S}_t\tilde{G})(\nu, x)\nu(dx)\right) M(d\nu)\\
&= \int_{\mathcal{P}(E)\times E} (\mathcal{S}_t\tilde{G})(\nu, x)\overline{M}(d\nu, dx)\\
&= \int_{\mathcal{P}(E)\times E} \tilde{G}(\nu, x)\overline{M}(d\nu, dx)\\
&= \int_{\mathcal{P}(E)} G(\nu)M(d\nu).
\end{aligned}$$

This proves that M is $(\mathcal{T}_t)$ invariant. □

6. Ergodic properties of the filter. In this section we will use the notation of section 5. We will also assume throughout the rest of the paper that h is a continuous function. Thus, $\{\mathcal{T}_t\}$ and $\{\mathcal{S}_t\}$ are Feller semigroups. We will obtain conditions for uniqueness of invariant measures corresponding to these semigroups. These questions have been studied in great detail for compact [9] and locally compact [12, 10, 11] state spaces. The proofs of the results in the above papers rely on the uniqueness of the solution to the Fujisaki–Kallianpur–Kunita or Kushner–Stratonovich equations; in fact even the proof of the Feller–Markov property of the filtering process crucially uses the uniqueness of the solution to the above-mentioned equation. Nevertheless, using the methods and results of sections 4 and 5 many statements and theorems in the above papers carry over to our general setup with almost identical proofs. We will now present the main ergodicity results for the filtering model considered in this paper. In order to avoid tedious repetition, we will provide proofs only when they differ from the proofs of the analogous statements in [9, 12, 10, 11].

Let $C_c(E)$ be the class of all convex functions in $C_b(E)$. Following Stettner [12], denote for $\nu \in \mathcal{P}(E)$ and $A \in \mathcal{B}(\mathcal{P}(E))$

$$m_t^\nu(A) \doteq (\mathcal{T}_t\mathcal{I}_A)(\nu) = E_{Q_\nu}(\mathcal{I}_A(\Lambda_t(\nu, \cdot)))$$

and

$$M_t^\nu(A) \doteq \int_E (\mathcal{T}_t\mathcal{I}_A)(\delta_x)\nu(dx),$$

where $\mathcal{I}_A$ is the indicator function of the set A. We will now give alternative representations for m_t^ν and M_t^ν as the laws of certain filtering processes.

We begin with the following setup. Let μ be a (T_t) invariant measure. $\mathcal{D}_{\mathbb{R}} \equiv D((-\infty, \infty); E)$ will denote the space of r.c.l.l. functions from $(-\infty, \infty)$ into E with Skorokhod topology and $\mathcal{C}_{\mathbb{R}} \equiv C((-\infty, \infty); \mathbb{R}^d)$ will denote the space of continuous functions from $(-\infty, \infty)$ into $\mathbb{R}^d$ with topology of uniform convergence on compact subsets of $(-\infty, \infty)$. Let the coordinate processes on $\mathcal{D}_{\mathbb{R}}$ and $\mathcal{C}_{\mathbb{R}}$ be denoted once more by $(\xi_t(\cdot))$ and $(\beta_t(\cdot))$, respectively. Let $P_\mu^{(1)}$ be the unique measure on $(\mathcal{D}_{\mathbb{R}}, \mathcal{B}(\mathcal{D}_{\mathbb{R}}))$ which satisfies for $E_1, \ldots, E_n \in \mathcal{B}(\mathbb{R})$ and $-\infty < t_1 < t_2 \cdots < t_n < \infty$

$$\begin{aligned} &P_\mu^{(1)}(\xi_{t_1} \in E_1, \ldots, \xi_{t_n} \in E_n) \\ &\quad = \int_{E_1 \times \cdots \times E_n} \mu(dx_1) p(t_1, x_1, t_2, dx_2) \cdots p(t_{n-1}, x_{n-1}, t_n, dx_n). \end{aligned}$$

Now let $Q^{(1)}$ be a probability measure on $(C_{\mathbb{R}}, \mathcal{B}(C_{\mathbb{R}}))$ such that for $-\infty < t_0 < t_1 \cdots < t_n < \infty$,

$$\left(\frac{1}{\sqrt{t_1 - t_0}} (\beta_{t_1} - \beta_{t_0}), \ldots, \frac{1}{\sqrt{t_n - t_{n-1}}} (\beta_{t_n} - \beta_{t_{n-1}}) \right)$$

are independent $N(0, I_{d \times d})$.

Now let $\Omega^1 \doteq \mathcal{D}_{\mathbb{R}} \times C_{\mathbb{R}}$. Let $R_\mu^{(1)} = P_\mu^{(1)} \otimes Q^{(1)}$. In this section, we will consider the coordinate processes $(\xi_t), (\beta_t)$ to be defined on the product space $(\Omega^1, \mathcal{B}(\Omega^1), R_\mu^{(1)})$. Define the observation process

$$\alpha_t - \alpha_s \doteq \int_s^t h(\xi_u) du + \beta_t - \beta_s$$

and the observation σ fields

$$\mathcal{Z}_s^t \doteq \sigma(\alpha_v - \alpha_u; s \le u \le v \le t),$$

where $-\infty \le s < t \le \infty$. Further, for s, t such that $-\infty \le s < t \le \infty$, let $\mathcal{G}_s^t, \mathcal{H}_s^t$ be defined, respectively, by (4.11) and (4.35). The cases $s = -\infty$ and $t = \infty$ are treated as in Remark 4.1. Here, these are sub-σ fields of $\mathcal{B}(\Omega^1)$. Further, let $\mathcal{G}_{-\infty}^{-\infty}$ be defined by

$$\mathcal{G}_{-\infty}^{-\infty} = \cap_{-\infty < t < \infty} \mathcal{G}_{-\infty}^t.$$

Now define for $-\infty < s < t < \infty$,

$$\overline{\pi}_{s,t}^{(0)} \doteq \Lambda_{t-s}(\mu)(\alpha^s),$$

where $\alpha^s : \Omega^1 \to C([0, \infty); \mathbb{R}^d)$ is defined as $\alpha_u^s(\omega) \doteq \alpha_{s+u}(\omega) - \alpha_s(\omega)$. Also define

$$\overline{\pi}_{s,t}^{(1)} \doteq \Lambda_{t-s}(\delta_{\xi_s})(\alpha^s).$$

Observe that for the bounded and continuous function f on E

$$\overline{\pi}_{s,t}^{(0)}(f) = \mathbb{E}_{R_\mu^{(1)}}[f(\xi_t) | \mathcal{Z}_s^t]$$

and

$$\overline{\pi}_{s,t}^{(1)}(f) = \mathbb{E}_{R_\mu^{(1)}}[f(\xi_t) | \mathcal{Z}_s^t \vee \sigma(\xi_s)]$$

(for two σ fields $\mathcal{L}_1$ and $\mathcal{L}_2$, $\mathcal{L}_1 \vee \mathcal{L}_2 \doteq \sigma(\mathcal{L}1 \cup \mathcal{L}_2)$). Also note that for the real bounded measurable function F on $\mathcal{P}(E)$

$$\begin{aligned}
\mathbb{E}_{R_\mu^{(1)}}[F(\overline{\pi}_{s,t}^{(1)})] &= \mathbb{E}_{R_\mu^{(1)}}[F(\Lambda_{t-s}(\delta_{\xi_s})(\alpha^s))] \\
&= \int_E \mathbb{E}_{Q_x} F(\Lambda_{t-s}(\delta_x))\mu(dx) \\
&= \int_E (\mathcal{T}_{t-s}F)(\delta_x)\mu(dx) \qquad (6.1) \\
&= M_{t-s}^\mu(F). \qquad (6.2)
\end{aligned}$$

In a similar manner it is seen that

$$\mathbb{E}_{R_\mu^{(1)}}[F(\overline{\pi}_{s,t}^{(0)})] = m_{t-s}^\mu(F). \tag{6.3}$$

A straightforward application of martingale convergence theorem shows that as $s \to -\infty$, a.s. the measure $\overline{\pi}_{s,t}^{(0)}$ converges weakly to the measure $\overline{\pi}_t^{(0)}$ defined as follows: for a bounded and continuous function f on E

$$\overline{\pi}_t^{(0)}(f) \doteq \mathbb{E}_{R_\mu^{(1)}}[f(\xi_t)|\mathcal{Z}_{-\infty}^t].$$

Furthermore we have that (cf. Lemma 3.3 of Kunita [9])

$$\overline{\pi}_{s,t}^{(1)}(f) = \mathbb{E}_{R_\mu^{(1)}}[f(\xi_t)|\mathcal{Z}_{-\infty}^t \vee \mathcal{G}_{-\infty}^s]$$

and thus by the reverse martingale convergence theorem we have that as $s \to -\infty$, $\overline{\pi}_{s,t}^{(1)}$ converges weakly to the measure $\overline{\pi}_t^{(1)}$ defined as

$$\overline{\pi}_t^{(1)}(f) \doteq \mathbb{E}_{R_\mu^{(1)}}[f(\xi_t)|\mathcal{Z}_{-\infty}^t \vee \mathcal{G}_{-\infty}^{-\infty}].$$

Thus in view of (6.2) and (6.3) we have that M_s^μ and m_s^μ converge weakly as $s \to \infty$ to the law of $\overline{\pi}_t^{(0)}$, $\overline{\pi}_t^{(1)}$, respectively, which also shows that the laws of $\overline{\pi}_t^{(0)}$ $\overline{\pi}_t^{(1)}$ are independent of t. Denote these laws as m^μ and M^μ, respectively. Also note that since m^μ and M^μ are the limits of m_t^μ and M_t^μ as $t \to \infty$ and $(\mathcal{T}_t)$ is a Feller semigroup, both m^μ and M^μ have to be $(\mathcal{T}_t)$ invariant. We now recall the following definition from [9].

Definition 6.1. *A measure $\nu \in \mathcal{P}(E)$ is the barycenter of the measure $\Phi \in \mathcal{P}(\mathcal{P}(E))$ if and only if for every $\varphi \in C_b(E)$,*

$$\nu(\varphi) = \int_{\mathcal{P}(E)} \nu'(\varphi)\Phi(d\nu').$$

From Theorem 3.1 of Kunita [9] we have that both m^μ and M^μ have barycenters μ and if Φ is another $\mathcal{T}_t$ invariant measure with barycenter μ, then for all $F \in C_c(E)$,

$$m^\mu(F) \le \Phi(F) \le M^\mu(F). \tag{6.4}$$

Next recalling that m^μ and M^μ are the laws of $\overline{\pi}_t^{(0)}$ and $\overline{\pi}_t^{(1)}$, respectively, we have that m^μ equals M^μ if $\mathcal{G}_{-\infty}^{-\infty}$ is trivial. From (6.4) we observe that the equality of m^μ and M^μ implies that $\mathcal{T}_t$ admits a unique invariant measure with barycenter μ. We thus have the following result.

THEOREM 6.2. *Suppose that there is a unique* (T_t) *invariant measure* μ. *Then there is a unique* $\mathcal{T}_t$ *invariant measure if for all* $f \in C_b(E)$

$$\limsup_{t\to\infty} \int_E |T_t f(x) - \mu(f)|\mu(dx) = 0. \tag{6.5}$$

Proof. As pointed out in [9], (6.5) is equivalent to the condition that $\mathcal{G}_{-\infty}^{-\infty}$ is trivial. This proves the uniqueness of $(\mathcal{T}_t)$ invariant measure. □

We remark that our proof of the theorem above is different from the proof in [9]. The proof in [9] requires showing that $(\overline{\pi}_t^{(0)})$ and $(\overline{\pi}_t^{(1)})$ are Markov with semigroup $\mathcal{T}_t$ which is shown in [9] by appealing to the uniqueness of the solution to Kushner–Stratonovich equation. Although we don't need the Markov properties for our proof above, using the Feller property of $\mathcal{T}_t$ nevertheless, they are seen to hold as argued below.

PROPOSITION 6.3. *Let* μ *be a* (T_t) *invariant measure. For* $i = 0, 1$, $(\overline{\pi}_t^{(i)})$ *is a stationary Markov process on* $(\Omega^1, \mathcal{B}(\Omega^1), R_\mu^{(1)})$ *with semigroup* $\mathcal{T}_t$.

Proof. Let $g \in C_b(\mathcal{P}(E))$ and fix $-\infty < u < t < \infty$. Then from an application of martingale convergence theorem and the observation that a.s., $\overline{\pi}_{s,t}^{(0)}$ converges weakly to the measure $\overline{\pi}_t^{(0)}$ as $s \to -\infty$ we have that

$$\begin{aligned}
\mathbb{E}\left(g(\overline{\pi}_t^{(0)})|\mathcal{Z}_{-\infty}^u\right) &= \lim_{s\to-\infty} \mathbb{E}\left(g(\overline{\pi}_{s,t}^{(0)})|\mathcal{Z}_s^u\right)\\
&= \lim_{s\to-\infty} \mathbb{E}\left(g(\Lambda_{t-s}(\mu)(\alpha^s))|\sigma(\alpha_v^s; 0 \le v \le u-s)\right)\\
&= \lim_{s\to-\infty} g_1(\Lambda_{u-s}(\mu)(\alpha^s))\\
&= \lim_{s\to-\infty} g_1(\overline{\pi}_{s,u}^{(0)})\\
&= g_1(\overline{\pi}_u^{(0)}),
\end{aligned} \tag{6.6}$$

where all the limits in (6.6) are taken in probability and g_1 is the real valued function on $\mathcal{P}(E)$ defined in (4.33) with s there replaced by u, i.e.,

$$g_1(\nu) \doteq \mathbb{E}_{Q_\nu}[g(\Lambda_{t-u}(\nu))]. \tag{6.7}$$

Note that g_1 is independent of s and the last step in the above display follows on observing that the Feller property of $\mathcal{T}_t$ implies that g_1 is continuous. This proves the Markov property of $(\overline{\pi}_t^{(0)})$ and that the semigroup for this Markov process is $(\mathcal{T}_t)$. As is already seen, the law of $(\overline{\pi}_t^{(0)})$ does not depend on t and thus this Markov process is stationary. Finally consider the process $(\overline{\pi}_t^{(1)})$. Let g be as before. Then

$$\begin{aligned}
&\mathbb{E}_{R_\mu^{(1)}}[g(\overline{\pi}_t^{(1)})|\mathcal{Z}_{-\infty}^u \vee \mathcal{G}_{-\infty}^{-\infty}]\\
&\quad= \lim_{s\to-\infty} \mathbb{E}_{R_\mu^{(1)}}[g(\overline{\pi}_{s,t}^{(1)})|\mathcal{Z}_{-\infty}^u \vee \mathcal{G}_{-\infty}^s]\\
&\quad= \lim_{s\to-\infty} \mathbb{E}_{R_\mu^{(1)}}[g(\overline{\pi}_{s,t}^{(1)})|\mathcal{Z}_s^u \vee \mathcal{G}_{-\infty}^s]\\
&\quad= \lim_{s\to-\infty} \mathbb{E}_{R_\mu^{(1)}}[g(\Lambda_{t-s}(\delta_{\xi_s})(\alpha^s))|\sigma(\alpha_v^s : 0 \le v \le u-s) \vee \mathcal{G}_{-\infty}^s]\\
&\quad= \lim_{s\to-\infty} g_1(\Lambda_{u-s}(\delta_{\xi_s})(\alpha^s))\\
&\quad= \lim_{s\to-\infty} g_1(\overline{\pi}_{s,u}^{(1)})\\
&\quad= g_1(\overline{\pi}_u^{(1)}),
\end{aligned} \tag{6.8}$$

where g_1 is as in (6.7). Hence, $(\overline{\pi}_t^{(1)})$ is a Markov process with semigroup $(\mathcal{T}_t)$. The stationarity of this process follows as before. □

We now turn our attention to the semigroup $(\mathcal{S}_t)$. Let μ, as before, be a (T_t) invariant probability measure. Define the probability measures $\overline{m}_t^\mu$ and $\overline{M}_t^\mu$ on $(\mathcal{P}(E)\times E)$ as follows. For $A\in\mathcal{B}(\mathcal{P}(E))\otimes\mathcal{B}(E)$,

$$\overline{m}_t^\mu(A)=\int_E(\mathcal{S}_t\mathcal{I}_A)(\mu,x)\mu(dx)$$

and

$$\overline{M}_t^\mu(A)=\int_E(\mathcal{S}_t\mathcal{I}_A)(\delta_x,x)\mu(dx).$$

Observe that for real measurable bounded function F on $\mathcal{P}(E)\times E$ and $-\infty<s<t<\infty$,

$$\begin{aligned}\mathbb{E}_{R_\mu^{(1)}}[F(\overline{\pi}_{s,t}^{(1)},\xi_t)]&=\mathbb{E}_{R_\mu^{(1)}}[F(\Lambda_{t-s}(\delta_{\xi_s})(\alpha^s),\xi_t)]\\&=\int_E\mathbb{E}_{\hat{R}_x}F(\Lambda_{t-s}(\delta_x),\xi_{t-s})\mu(dx)\\&=\int_E(\mathcal{S}_{t-s}F)(\delta_x,x)\mu(dx)\\&=\overline{M}_{t-s}^\mu(F).\end{aligned}$$

In a similar way it is seen that

$$\mathbb{E}_{R_\mu^{(1)}}[F(\overline{\pi}_{s,t}^{(0)},\xi_t)]=\overline{m}_{t-s}^\mu(F).$$

Now the almost sure convergence, as $s\to-\infty$, of $(\overline{\pi}_{s,t}^{(0)},\xi_t)$ and $(\overline{\pi}_{s,t}^{(1)},\xi_t)$ to $(\overline{\pi}_t^{(0)},\xi_t)$ and $(\overline{\pi}_t^{(1)},\xi_t)$, respectively, implies that $\overline{m}_u^\mu$ and $\overline{M}_u^\mu$ converge weakly to the law of $(\overline{\pi}_t^{(0)},\xi_t)$ and $(\overline{\pi}_t^{(1)},\xi_t)$, respectively, and also that these laws don't depend on t. Denote the law of $(\overline{\pi}_t^{(0)},\xi_t)$ by $\overline{m}^\mu$ and the law of $(\overline{\pi}_t^{(1)},\xi_t)$ by $\overline{M}^\mu$. Once more the Feller property of the semigroup $(\mathcal{S}_t)$ implies that since $\overline{m}_t^\mu$ and $\overline{M}_t^\mu$ converge weakly to $\overline{m}^\mu$ and $\overline{M}^\mu$, respectively, these latter measures are $(\mathcal{S}_t)$ invariant. Next note that for $C\in\mathcal{B}(\mathcal{P}(E))$

$$\overline{m}^\mu(C\times E)=m^\mu(C)$$

and

$$\overline{M}^\mu(C\times E)=M^\mu(C).$$

Further note that for real bounded measurable functions f and F on E and $\mathcal{P}(E)$, respectively,

$$\begin{aligned}\int_{\mathcal{P}(E)\times E}F(\nu)f(x)\overline{m}^\mu(d\nu,dx)&=\mathbb{E}_{R_\mu^{(1)}}[(F(\overline{\pi}_t^{(0)})f(\xi_t))]\\&=\mathbb{E}_{R_\mu^{(1)}}[F(\overline{\pi}_t^{(0)})\mathbb{E}_{R_\mu^{(1)}}(f(\xi_t)|\mathcal{Z}_{-\infty}^t)]\\&=\int_E F(\nu)\nu(f)m^\mu(d\nu).\end{aligned}$$

Similarly,

$$\int_{\mathcal{P}(E)\times E} F(\nu)f(x)\overline{M}^{\mu}(d\nu,dx) = \int_E F(\nu)\nu(f)M^{\mu}(d\nu).$$

Thus $\overline{m}^{\mu}, \overline{M}^{\mu}$ are $(\mathcal{S}_t)$ invariant measures for which (5.5) holds. Also, in the class of $(\mathcal{S}_t)$ invariant probability measures for which (5.5) holds, $\overline{m}^{\mu}$ is the minimal and $\overline{M}^{\mu}$ is the maximal in the sense of Kunita (cf. Theorem 2.2 in [10]). Finally note that if $\mathcal{G}_{-\infty}^{-\infty}$ is trivial, $(\overline{\pi}_t^{(0)}, \xi_t) = (\overline{\pi}_t^{(1)}, \xi_t)$ a.s. and thus $\overline{m}^{\mu} = \overline{M}^{\mu}$. Hence the following theorem holds.

THEOREM 6.4. *Suppose that there is a unique* (T_t) *invariant measure* μ *and suppose that* (6.5) *holds for all* $f \in C_b(E)$. *Then there is a unique* $(\mathcal{S}_t)$ *invariant measure for which* (5.5) *holds.*

7. Asymptotic stability. In this section, we will study the asymptotic behavior of the filter when it is initialized at an incorrect initial condition. The results extend the results of Ocone and Pardoux [11] to the case of unbounded h and we also do away with the assumption in [11] that the state space is locally compact.

We will once more use the notations of section 5 and assume continuity of h. In particular, recall that the signal process X is an E-valued time homogeneous Markov process with a Feller semigroup T_t and initial distribution (law of X_0) γ. Further, we assume that T_t admits a unique invariant probability measure μ and that (6.5) holds. We have noted in the previous section that in this case the semigroup $\mathcal{T}_t$ is Feller and also admits a unique invariant probability measure. Here is the first result on asymptotic stability

THEOREM 7.1. *Suppose that* γ *satisfies*

$$\gamma T_t \to \mu. \tag{7.1}$$

Let

$$\pi_t(B)(\omega) = \Lambda_t(\gamma, B)(Y_{\cdot}(\omega)) \tag{7.2}$$

be the filter. Then the law of π_t *on* $(\Omega, \mathcal{F}, P)$ *converges to* M*—the invariant measure for the semigroup* $\mathcal{T}_t$.

Proof. This result can be proved exactly following the steps in the proof of Theorem 3 in Stettner [12]. Note that we have already proved the Feller property of $\mathcal{T}_t$ and hence it follows that if ν_n converges to ν, then $m_t^{\nu_n}$ converges in law to m_t^{ν}. This is a crucial step in the proof of Theorem 3 in [12]. The tightness of $\{m_t^{\gamma} : t \geq 0\}$ follows from (7.1) exactly as in Stettner. Also, we have already proved that there exists a unique $\mathcal{T}_t$ invariant probability measure M. □

The previous result gives the asymptotics of the filter π_t when the signal process is a purely nondeterministic ergodic Markov process.

Ocone and Pardoux [11] consider the behavior of the filter when the initial distribution of the signal is wrongly taken to be ν instead of γ. So whereas the correct filter is given by (7.2), the incorrectly initialized filter is given as

$$\bar{\pi}_t(B)(\omega) = \Lambda_t(\nu, B)(Y_{\cdot}(\omega). \tag{7.3}$$

In [11] it was shown that under appropriate conditions

$$\mathbb{E}_P[(\langle \pi_t, \varphi\rangle - \langle \bar{\pi}_t, \varphi\rangle)^2] \to 0 \tag{7.4}$$

as t tends to ∞. The paper [11] assumes that h is bounded and that E is locally compact. We will now show that (7.4) holds in our framework.

We need the following auxiliary result for this purpose.

THEOREM 7.2. *Let $\gamma^n, \nu^n \in \mathcal{P}(E)$ be such that*

$$\gamma^n \to \mu, \quad \nu^n \to \mu.$$

Let $T > 0$ be fixed. Then for a bounded continuous function φ on E,

$$\mathbb{E}_{Q_{\gamma^n}}[|\langle \Lambda_T(\gamma^n), \varphi\rangle - \langle \Lambda_T(\nu^n), \varphi\rangle|] \to 0.$$

Proof. In view of (4.28)–(4.29)

$$\mathbb{E}_{Q_{\gamma^n}}[|\langle \Lambda_T(\gamma^n), \varphi\rangle - \langle \Lambda_T(\nu^n), \varphi\rangle|] = \mathbb{E}_Q[|\langle \Lambda_T(\gamma^n), \varphi\rangle - \langle \Lambda_T(\nu^n), \varphi\rangle|\Gamma_T(\gamma^n, E)]. \tag{7.5}$$

By Theorem 5.1

$$|\langle \Lambda_T(\gamma^n), \varphi\rangle - \langle \Lambda_T(\nu^n), \varphi\rangle| \to 0 \text{ in } Q \text{ probability}$$

and

$$\Gamma_T(\gamma^n, E) \text{ is } Q \text{ uniformly integrable.}$$

The required result follows from these observations. □

This is the analog of the result in [11] for our setup.

THEOREM 7.3. *Let $\nu \in \mathcal{P}(E)$ be given. Suppose that ν, γ satisfy*

$$\gamma T_t \to \mu \quad \nu T_t \to \mu. \tag{7.6}$$

Further, suppose that

$$Q_\gamma \textit{ is absolutely continuous with respect to } Q_\nu. \tag{7.7}$$

Then the filter π_t (defined by (7.2)) and the erroneous filter $\bar{\pi}_t$ wrongly computed with initial measure ν (defined by (7.3)) satisfy

$$\mathbb{E}_P[(\langle \pi_t, \varphi\rangle - \langle \bar{\pi}_t, \varphi\rangle)^2] \to 0. \tag{7.8}$$

Proof. As in [11], let the finite memory approximations $\pi_{t-\tau,t}$, $\bar{\pi}_{t-\tau,t}$ of π_t, $\bar{\pi}_t$, respectively, be defined by

$$\pi_{t-\tau,t} = \Lambda_\tau(\gamma T_{t-\tau}),$$

$$\bar{\pi}_{t-\tau,t} = \Lambda_\tau(\nu T_{t-\tau}).$$

Then given $\varepsilon > 0$, there exists τ_ε such that for $\tau > \tau_\varepsilon$ we have for $\varphi \in C(E)$

$$\mathbb{E}_P[(\langle \pi_t, \varphi\rangle - \langle \pi_{t-\tau,t}, \varphi\rangle)^2] \to 0 \tag{7.9}$$

and

$$\mathbb{E}_P[(\langle \bar{\pi}_t, \varphi\rangle - \langle \bar{\pi}_{t-\tau,t}, \varphi\rangle)^2] \to 0 \tag{7.10}$$

as t tends to infinity. These statements are proven in [11, Lemma 3.4]. The proof given there does not use boundedness of h or the underlying assumption in that paper that E is locally compact and hence carries over the present setup. Since φ is bounded, say, by K, we have

$$\mathbb{E}_P[(\langle \pi_{t-\tau,t}, \varphi\rangle - \langle \bar{\pi}_{t-\tau,t}, \varphi\rangle)^2] \leq 2K\mathbb{E}_P[|\langle \pi_{t-\tau,t}, \varphi\rangle - \langle \bar{\pi}_{t-\tau,t}, \varphi\rangle|]$$

and hence to complete the proof it remains to show that

$$\lim_{t\to\infty} \mathbb{E}_P[|\langle \pi_{t-\tau,t}, \varphi\rangle - \langle \bar{\pi}_{t-\tau,t}, \varphi\rangle|] = 0. \tag{7.11}$$

This in turn follows from Theorem 7.2 and the assumption (7.6) upon observing that $\pi_{t-\tau,t} = \Lambda_\tau(\gamma T_{t-\tau})$ and $\bar{\pi}_{t-\tau,t} = \Lambda_\tau(\nu T_{t-\tau})$. □

Acknowledgment. The authors would like to thank Professor T. G. Kurtz who pointed out that (5.1) is a consequence of the Feller property of (T_t). Equation (5.1) had been included as an assumption in an earlier version.

NONPARAMETRIC IDENTIFICATION OF CONTROLLED NONLINEAR TIME VARYING PROCESSES*

NADINE HILGERT†, RACHID SENOUSSI‡, and JEAN-PIERRE VILA†

Abstract. We are interested in the identification of an unknown time varying additive component of a controlled nonlinear autoregressive model, a problem of interest in the modeling and control of uncertain systems, such as those met in biotechnological processes. A kernel-based nonparametric estimator is proposed whose almost sure convergence is studied by means of a Lyapunov stabilizability assumption and laws of large numbers for martingales. We then adapt the general result to several classes of deterministic or random functional model uncertainties.

Key words. autoregressive process, stabilization, nonparametric estimation, convolution kernels

AMS subject classifications. 60F15, 62G05, 60G42

1. Introduction.

Let $(\Omega, \mathcal{A}, \mathbb{P})$ be a probability space endowed with a filtration $\mathbb{F} = (\mathcal{F}_n)_{n\geq 0}$. We consider controlled autoregressive processes of the form

$$X_{n+1} = f_n(X_n) + F_n(X_n, U_n) + \varepsilon_{n+1} \tag{1.1}$$

with

- (X_n) a sequence of random variables taking values in $\mathbb{R}^s$,
- (U_n) a sequence of control variables taking values in $\mathbb{R}^m$,
- $(F_n(.,.))$ a sequence of known measurable functions,
- $(f_n(.))$ a sequence of unknown deterministic or random functions of $\mathcal{C}(\mathbb{R}^s, \mathbb{R}^s)$, the space of continuous functions endowed with the topology of uniform convergence on compacts,
- (ε_n) an unobservable white noise.

This setting can be extended to a more general type of model, frequently used in process control, especially in biotechnology, where $f_n(x) = H_n(x)\, g_n(x)$, H_n is a known matricial mapping from $\mathbb{R}^s$ to $\mathbb{R}^{s\times l}$, $l \leq s$, and g_n an unknown mapping from $\mathbb{R}^s$ to $\mathbb{R}^l$.

The model (1.1), thus adapted, represents, for example, the real time evolution of biomasses (microorganisms) and substrates concentrations in bioreactions (see [1]). Such reactions are very common in depollution or in the agro-food industry. In that case, $g_n(x)$ characterizes the microbial growth rate, which is a time varying quantity, influenced by many factors (biomasses and substrates concentrations, temperature, pH,...). For a given bioreaction the analytic form of $g_n(x)$ is generally not well known, in spite of its importance for a good modeling of the reaction dynamic and then its control.

The (X_n) process is assumed to be observed, and we are interested in estimating the functional sequence (f_n). A good estimation of this sequence is prerequisite to any control of the process.

To the best of our knowledge, the identification of a random functional sequence (f_n) as in (1.1) has not yet been studied. This stochastic point of view allows a realistic treatment of the modeling of time varying dynamics. Until now only the estimation of unknown deterministic functions has been considered.

Georgiev [4] considered the model

$$X_{n+1} = f(X_n, U_n) + \varepsilon_{n+1},$$

where (X_n, U_n) is a specific stationary Markov process and $f(.,.)$ is the unknown functional component. He proved the weak consistency of a kernel estimator of f.

The use of kernel estimators for the adaptive control of nonlinear autoregressive processes was pioneered by Hernandez-Lerma and Doukhan [6] who faced the problem of the unavailability of any mixing property. Then, for the model

$$X_{n+1} = f(X_n) + F(X_n, U_n) + \varepsilon_{n+1},$$

where f is an unknown mapping from $\mathbb{R}^s$ to $\mathbb{R}^s$, Senoussi [9] showed the uniform convergence on compact subsets of a kernel estimator of f through a notion of stabilization of the process (X_n) and produced the related rates of convergence. For the same model, Portier [7] investigated adaptive control, i.e., determination of (U_n) through an adaptive functional estimator of f and a control objective. He got encouraging results in simple cases.

The identification of a sequence of unknown deterministic functions (f_n), rather than a unique function f, has been studied by Rutkowski [8] in the regression framework

$$Y_n = f_n(Z_n) + \varepsilon_n.$$

Under some restrictive assumptions (among them the convergence of f_n), he showed the strong point consistency of a kernel estimator of f.

The classes of sequences (f_n) we consider are more general.

In the context of model (1.1), we prove (section 2) the strong uniform consistency of a kernel estimator of the deterministic or random sequence (f_n). Results are then adapted to several types of sequences (f_n) of interest (section 2.4 and section 2.5).

2. Nonparametric approach of the identification problem. Convolution kernels were first used for probability density function estimation (Rosenblatt (1956), Parzen (1962), Wolverton and Wagner (1969) in [10]) and then for regression function estimation (Nadaraya (1964), Watson (1964), Härdle (1990) in [5]). A recent synthesis is in Bosq [2]. We consider the following estimator of $f_n(x)$ for all $x \in \mathbb{R}^s$:

$$\widehat{f}_n(x) = \frac{\sum_{i=0}^{n-1} h_i^{-s} K(\frac{x-X_i}{h_i})(X_{i+1} - F_i(X_i, U_i))}{\sum_{i=0}^{n-1} h_i^{-s} K(\frac{x-X_i}{h_i})}, \tag{2.1}$$

where $K(.)$ is an s-dimensional kernel, i.e., a bounded symmetric density with respect to Lebesgue measure, and h_i is a bandwidth parameter.

The kernel estimator (2.1) is said to be recursive since the bandwidth h_i depends on the current step i in the weighted sum and not on the number n of observations taken into account in the estimation. This recursive property is useful in the adaptive control framework, because $\widehat{f}_n(x)$ can easily be updated when a new observation is available. Besides, it allows the use of martingale tools [2, 3, 7, 9], which is, to our knowledge, the only way to provide asymptotic results with controlled processes.

2.1. Definitions. We define a control policy, or strategy, as a sequence of deterministic mappings $\delta = (\delta_k)$, $k \geq 0$, from $(\mathbb{R}^s)^k$ to the space of controls $\mathcal{U}$, such that $U_k = \delta_k(X_1, \ldots, X_k)$. For all $x \in \mathbb{R}^s$ we shall consider the set of admissible controls, with respect to x, to be a subset $A(x)$ of $\mathcal{U}$, for which $\delta_k(x_1, \ldots, x_{k-1}, x) \in A(x)$. A policy (δ_k) will be said to be *A-admissible*, or *admissible* for short, if for all k, $U_k \in A(X_k)$.

Moreover, model (1.1) is said to be *stabilized* by the use of any admissible policy, if we can choose a class $\mathcal{D}$ of strategies such that, for any $\varepsilon > 0$, there exists a compact set $\mathcal{C}$ of $\mathbb{R}^s$ satisfying the following property: for any initial law of X_0 and any strategy $\delta \in \mathcal{D}$,

$$\liminf_{n\to\infty} \frac{1}{n+1} \sum_{i=0}^{n} 1\!\!1_{\mathcal{C}}(X_i) \geq 1 - \varepsilon \quad \text{almost surely (a.s.),}$$

where $1\!\!1_{\mathcal{C}}$ stands for the indicator function of the set $\mathcal{C}$.

2.2. Main result. We assume that the control sequence (U_n) is adapted to the filtration $\mathbb{F}$, and that X_0 is $\mathcal{F}_0$-measurable. In the case of random functions f_n, the sequence (f_n) is also assumed to be $\mathbb{F}$-adapted. Moreover, (ε_n) is supposed to be an $\mathbb{F}$-adapted white noise. Let us recall that a random sequence (ξ_n) is said to be an $\mathbb{F}$-*adapted white noise* if for all $n \in \mathbb{N}$, ξ_{n+1} is $\mathcal{F}_{n+1}$-measurable and independent of $\mathcal{F}_n$.

The problem we are concerned with is to show the almost sure convergence of the kernel estimator (2.1). We shall require four different sets of hypotheses.

ASSUMPTION 2.1. *The noise $\varepsilon = (\varepsilon_n)$ is a sequence of independent and identically distributed (i.i.d. for short) random vectors with mean* 0 *and covariance matrix* Γ. *Its distribution is absolutely continuous (with respect to the Lebesgue measure), with a probability density function p supposed to be positive and C^1-class, p and its gradient are bounded.*

ASSUMPTION 2.2. *There exists a constant $\theta < 1$ such that*

$$\limsup_{||x||\to\infty} \frac{\sup_{i\in\mathbb{N}} \sup_{u\in A(x)}(||f_i(x) + F_i(x,u)||)}{||x||} \leq \theta \quad a.s. \tag{2.2}$$

ASSUMPTION 2.3. (a) *The sequence (f_n) is a.s. equicontinuous on compacts.*

(b) *There exists a function f such that, for all $x \in \mathbb{R}^s$,*

$$\lim_{n\to\infty} \frac{\sum_{i=0}^{n} i^{\alpha s} K(i^\alpha(X_i - x)) f_i(x)}{\sum_{i=0}^{n} i^{\alpha s} K(i^\alpha(X_i - x))} = f(x) \quad a.s. \tag{2.3}$$

Assumptions 2.1 and 2.2 are quite standard for nonlinear autoregressive control models; see, for instance, [2, 3, 5, 7, 9]. Let us note that Assumption 2.1 is satisfied with a classical nondegenerate Gaussian white noise. Assumption 2.2, also known as a stability criterion of Lyapunov, characterizes the stabilization ability of the model. It can be softened in numerous cases (see [3]), but generally requires exponential moments of the noise ε. Moreover, Assumption 2.3 obviously holds if the sequence (f_n) is a constant and continuous function f. Other cases that verify this hypothesis are developed as corollaries in section 2.4. Finally, the following Assumption 2.4 is made on the kernel K and the bandwidth (h_i).

ASSUMPTION 2.4. *The kernel K has a compact support and is Lipschitz continuous. The bandwidth $h_i := i^{-\alpha}$, $i \in \mathbb{N}$, is used, with $\alpha \in (0, 1)$.*

We shall now state our main result, which is proved in section 2.3.

Theorem 2.5. *Suppose that Assumptions* 2.1 *to* 2.4 *hold. Then*

(a) *for any* $0 < \alpha < 1/s$, *any admissible control policy and any initial probability distribution* ν *of* X_0, *we have for all* $x \in \mathbb{R}^s$

$$\widehat{f}_n(x) \longrightarrow f(x) \quad \text{a.s.} \quad \text{as } n \to \infty, \tag{2.4}$$

(b) *for* $0 < \alpha < 1/2s$, *if* ε *admits a finite moment of order strictly greater than* 2, *the almost sure convergence of* $\widehat{f}_n$ *to* f *is uniform on compacts.*

2.3. Proof. The proof of Theorem 2.5 requires two preliminary results. For all $x \in \mathbb{R}^s, \alpha \in (0, 1/s)$ and $n \in \mathbb{N}$, let us first denote by $D_n(x)$ the denominator of (2.1), i.e.,

$$D_n(x) := \sum_{i=1}^{n} i^{\alpha s} K\left(i^{\alpha}(x_i - x)\right).$$

Moreover, let $B(0, r)$ be the ball of radius r $(r > 0)$ centered on 0. The empirical measure of $B(0, r)$ associated to the transitions of the process (X_i) is given by

$$\Lambda_n(B(0, r)) := \sum_{i=0}^{n} 1\!\!1_{(||X_i|| \leq r)}. \tag{2.5}$$

Lemma 2.6. (a) *Under Assumptions* 2.1 *and* 2.2, *there exists a finite constant* r_0 *such that, for any initial distribution and any policy,*

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \|X_i\|^2 \leq r_0 \quad a.s. \tag{2.6}$$

(b) *It follows that for all* $r > r_0$,

$$\liminf_{n\to\infty} \frac{1}{n+1} \Lambda_n(B(0, r)) \geq 1 - r_0/r^2 \quad a.s., \tag{2.7}$$

that is to say, the process (X_n) *is stabilized by the use of any admissible policy.*

Proof of Lemma 2.6. (a) Let us define the new control variable for all $k \in \mathbb{N}$, $\widetilde{U}_k := (U_k, k) \in \widetilde{\mathcal{U}} = \mathcal{U} \times \mathbb{N}$ and the new admissible set $\widetilde{A}(x) := A(x) \times \mathbb{N}$. If δ_k is A-admissible, then $\widetilde{\delta}_k(x_1, \ldots, x_{k-1}, x) = (\delta_k(x_1, \ldots, x_{k-1}, x), k)$ is $\widetilde{A}$-admissible and model (1.1) can be rewritten as $X_{n+1} = g(X_n, \widetilde{U}_n) + \varepsilon_{n+1}$ with

$$g(x, \widetilde{u}) := g(x, u, m) = f_m(x) + F_m(x, u).$$

Assumption 2.2 is equivalently stated as follows:

$$\limsup_{\|x\|\to\infty} \frac{\sup_{\tilde{u}\in\tilde{A}(x)}(\|g(x, \widetilde{u})\|)}{\|x\|} < 1 \quad \text{a.s.},$$

and thus, applying Proposition 7.3.19 in Duflo [3] on the stabilization of controlled iterative models, there exists a finite constant r_0 such that (2.6) holds.

(b) Inequality (2.7) can easily be deduced from (2.5) and (2.6), since $\|X_i\|^2 \geq r^2 1\!\!1_{\{\|X_i\| \geq r\}}$. □

LEMMA 2.7. *Suppose that Assumptions* 2.1, 2.2, *and* 2.4 *hold. For any $a > 0$, there exist two constants m and M such that*

(a) *for $\alpha < 1/s$ and all x such that $\|x\| \leq a$,*

$$0 < m \leq \liminf_{n\to\infty} n^{-1} D_n(x) \leq \limsup_{n\to\infty} n^{-1} D_n(x) \leq M < \infty, \tag{2.8}$$

(b) *for $\alpha < 1/2s$, the previous inequalities hold uniformly on x, i.e.,*

$$0 < m \leq \liminf_{n\to\infty} \inf_{\|x\|\leq a} n^{-1} D_n(x) \leq \limsup_{n\to\infty} \sup_{\|x\|\leq a} n^{-1} D_n(x) \leq M < \infty. \tag{2.9}$$

Proof of Lemma 2.7. Since f_{i-1}, X_{i-1} and U_{i-1} are $\mathcal{F}_{i-1}$-measurable, and ε_i is independent of $\mathcal{F}_{i-1}$, we have, from (1.1),

$$\begin{aligned} &E(K(i^\alpha(X_i - x))/\mathcal{F}_{i-1}) \\ &= \int p(z - f_{i-1}(X_{i-1}) - F_{i-1}(X_{i-1}, U_{i-1}))K(i^\alpha(z-x))dz \\ &= i^{-\alpha s} \int K(z)p(i^{-\alpha}z + x - f_{i-1}(X_{i-1}) - F_{i-1}(X_{i-1}, U_{i-1}))dz. \end{aligned}$$

Let D_n^c be the compensator of D_n, i.e.,

$$\begin{aligned} D_n^c(x) &:= \sum_{i=1}^n i^{\alpha s} E(K(i^\alpha(X_i - x))/\mathcal{F}_{i-1}) \\ &= \sum_{i=1}^n \int K(z)p(i^{-\alpha}z + x - f_{i-1}(X_{i-1}) - F_{i-1}(X_{i-1}, U_{i-1}))dz. \end{aligned} \tag{2.10}$$

Let r_K be such that the compact support of K is included in the ball $B(0, r_K)$—see Assumption 2.4. We denote for $a > 0$ and $r > 0$

$$\begin{aligned} c_r &:= \sup\left(\|f_i(x) + F_i(x,u)\| \ : \ \|x\| \leq r, \ u \in A(x), \ i \in \mathbb{N}\right), \\ \gamma_{r,a} &:= \inf(p(z) \ : \ \|z\| \leq a + r_K + c_r). \end{aligned}$$

For r sufficiently large, Assumption 2.2 implies that $c_r < r$ and Assumption 2.1 yields that $\gamma_{r,a} > 0$. It follows, with $\|p\| := \sup_x \|p(x)\|$, that for all $i = 1, 2, \ldots,$

$$\begin{aligned} \|p\| &\geq \int K(z)p(i^{-\alpha}z + x - f_{i-1}(X_{i-1}) - F_{i-1}(X_{i-1}, U_{i-1}))dz \\ &\geq \int K(z)p(i^{-\alpha}z + x - f_{i-1}(X_{i-1}) - F_{i-1}(X_{i-1}, U_{i-1})) \\ &\qquad \times \mathbb{1}_{(\|x\|\leq a, \|z\|\leq r_K, \|X_{i-1}\|\leq r)} dz \\ &\geq \gamma_{r,a} \ \mathbb{1}_{(\|x\|\leq a, \|X_{i-1}\|\leq r)}, \end{aligned}$$

which, according to (2.5) and (2.10), gives

$$\|p\| \geq n^{-1} D_n^c(x) \geq \gamma_{r,a} \Lambda_n(B(0,r))$$

for all x such that $\|x\| \leq a$. Taking $r > \sqrt{2} r_0$, we then deduce by Assumption 2.2 that

$$\liminf_{n\to\infty} \inf_{\|x\|\leq a} n^{-1} D_n^c(x) \geq \gamma_{r,a}/2 = m > 0 \tag{2.11}$$

$$\text{and} \quad \limsup_{n\to\infty} \sup_{\|x\|\leq a} n^{-1} D_n^c(x) \leq \|p\| = M < \infty. \tag{2.12}$$

(a) Now, let us decompose $D_n(x)$ as $D_n(x) = M_n(x) + D_n^c(x)$, where $M_n(x) := D_n(x) - D_n^c(x)$. For all x, $M_n(x)$ is a martingale whose *hook*, $\langle M(x)\rangle_n$, defined by

$$\langle M(x)\rangle_n - \langle M(x)\rangle_{n-1} = E\Big((M_n(x) - M_{n-1}(x))^2/\mathcal{F}_{n-1}\Big), \tag{2.13}$$

satisfies

$$\begin{aligned}\langle M(x)\rangle_n &\le \sum_{i=1}^{n} i^{\alpha s} \int K(z)^2 p\big(i^{-\alpha} z + x - f_{i-1}(X_{i-1}) - F_{i-1}(U_{i-1}, X_{i-1})\big) dz\\ &\le cst\; n^{\alpha s+1},\end{aligned}$$

where *cst* stands for any finite constant. Thus $(n^{-(\alpha s+1)} E\langle M(x)\rangle_n)$ is bounded. The second law of large numbers for martingales (see [3]) then yields, for $\alpha s < 1$,

$$n^{-1}\big(D_n(x) - D_n^c(x)\big) \longrightarrow 0 \quad \text{a.s.},$$

which, together with (2.11) and (2.12), implies (2.8).

(b) To get the uniform version, let us consider the martingale $H_n(x, y) = M_n(x) - M_n(y)$ and recall that, for a Lipschitz continuous kernel K with compact support, for any $\rho > 0$, there exists a finite constant C such that

$$\|K(x) - K(y)\| \le C\|x - y\|^{\rho} \quad \text{for all } (x, y) \in \mathbb{R}^s \times \mathbb{R}^s. \tag{2.14}$$

Straightforward calculations easily yield that

$$\begin{aligned}(\langle H\rangle_n - \langle H\rangle_{n-1})(x, y) &\le n^{2\alpha s} E\Big((K(n^{\alpha}(X_n - x)) - K(n^{\alpha}(X_n - y)))^2/\mathcal{F}_{n-1}\Big)\\ &\le C^2 n^{2\alpha(s+\rho)} \|x - y\|^{2\rho}.\end{aligned}$$

It follows then, from the definition (2.13), that

$$E((M_n(x) - M_n(y))^2) \le cst \times n^{1+2\alpha(s+\rho)} \|x - y\|^{2\rho}.$$

As ρ is arbitrary, the uniform law of large numbers given in the appendix applies to M_n, i.e., if $\alpha < 1/2s$,

$$\lim_{n\to\infty} \sup_{\{\|x\|\le a\}} n^{-1} M_n(x) = 0 \quad \text{a.s.},$$

and then the inequalities (2.9) hold. □

Proof of Theorem 2.5. Let us write $\widehat{f}_n(x) - f(x)$ as follows:

$$\widehat{f}_n(x) - f(x) = \frac{1}{D_{n-1}(x)}(S_n(x) + R_{n,1}(x) + R_{n,2}(x)), \tag{2.15}$$

where

$$S_n(x) = \sum_{i=1}^{n-1} i^{\alpha s} K\big(i^{\alpha}(X_i - x)\big)\varepsilon_{i+1}, \tag{2.16}$$

$$R_{n,1}(x) = \sum_{i=1}^{n-1} i^{\alpha s} K\big(i^{\alpha}(X_i - x)\big)\big(f_i(X_i) - f_i(x)\big), \tag{2.17}$$

$$\text{and} \quad R_{n,2}(x) = \sum_{i=1}^{n-1} i^{\alpha s} K\big(i^{\alpha}(X_i - x)\big)\big(f_i(x) - f(x)\big). \tag{2.18}$$

The proof consists in studying separately S_n, $R_{n,1}$, and $R_{n,2}$ and then combining the different convergence results together with (2.8) and (2.9) in Lemma 2.7.

Study of S_n: $S_n(x)$ is for all x, a vector martingale whose hook—see (2.13)—in the sense of semipositive definite matrices, is

$$\langle S(x)\rangle_n = \sum_{i=1}^{n-1} i^{2\alpha s} K^2\big(i^\alpha(X_i - x)\big)\,\Gamma, \tag{2.19}$$

where Γ is the covariance matrix of ε. Now take the expectation of (2.19), and after an easy change of variable, we get

(2.20)

$$E\langle S(x)\rangle_n = \Gamma \sum_{i=1}^{n-1} i^{\alpha s} E\left(\int K^2(z) p\big(i^{-\alpha}z + x - f_i(X_{i-1}) - F_i(X_{i-1}, U_{i-1})\big)dz\right).$$

(a) From (2.20), we have trace $(E\langle S(x)\rangle_n) \leq cst \times n^{\alpha s+1}$. The second law of large numbers on martingales [3] then applies whenever $\alpha s < 1$, and yields that $n^{-1}S_n(x) \xrightarrow{a.s.} 0$.

(b) The proof of the uniform convergence of S_n is similar to the proof of Lemma 2.7(b), done with the martingale $M_n(x) = D_n(x) - D_n^c(x)$. Let us define the martingale $G_n(x, y) := S_n(x) - S_n(y)$. From the Lipschitz property (2.14), we deduce

$$\begin{aligned}(\langle G\rangle_{n+1} - \langle G\rangle_n)(x, y) &= n^{2\alpha s}(K(n^\alpha(X_n - x)) - K(n^\alpha(X_n - y)))^2\ \Gamma \\ &\leq C^2 n^{2\alpha(s+\rho)}\|x - y\|^{2\rho}\Gamma.\end{aligned}$$

Thus

$$E\|S_n(x) - S_n(y)\|^2 \leq cst\ n^{1+2\alpha(s+\rho)}\|x - y\|^{2\rho}.$$

As $\rho > 0$ is arbitrary, we conclude, using the uniform law of large numbers given in the appendix, that, whenever $2\alpha s < 1$ for all $a > 0$,

$$\lim_{n\to\infty} \sup_{\{\|x\|\leq a\}} n^{-1}S_n(x) = 0 \quad \text{a.s.}$$

Study of $R_{n,1}$: Since the compact support of K is included in $B(0, r_K)$, then $K(z) = 0$ when $||z|| > b$. Let $\eta > 0$ and $a > 0$. From Assumption 2.3(a), the sequence (f_n) is equicontinuous. Let us then denote by $\omega(\eta)$ the modulus of uniform continuity of (f_n), associated with η on the ball $B(0, a + r_k)$, i.e., for any pair (x, y) in the ball such that $||x - y|| < \eta$, we have

$$\sup_{i\in\mathbb{N}} ||f_i(x) - f_i(y)|| \leq \omega(\eta).$$

Then, for the first rank n_1 such that $bn_1^{-\alpha} < \eta$, we have

$$\sum_{i=n_1}^{n-1} i^{\alpha s}K\big(i^\alpha(X_i - x)\big)||f_i(X_i) - f_i(x)|| \leq \omega(\eta)\sum_{i=n_1}^{n-1} i^{\alpha s}K(i^\alpha(X_i - x)), \tag{2.21}$$

since, when $||i^\alpha(X_i - x)|| \leq b$ for $i \geq n_1$, we have

$$||X_i - x|| \leq bi^{-\alpha} \leq bn_1^{-\alpha} < \eta.$$

From (2.17) and (2.21), it follows that

$$\frac{1}{n-1}\|R_{n,1}(x)\| \leq \frac{cst}{n-1} + \frac{\omega(\eta)}{n-1}D_{n-1}(x). \tag{2.22}$$

(a) Let $\alpha < 1/s$ and x be such that $\|x\| \leq a$. From (2.8) and (2.22), we deduce

$$\limsup_{n\to\infty} \frac{1}{n-1}\|R_{n,1}(x)\| \leq \omega(\eta)\ M \quad \text{a.s.},$$

and then, $\limsup_{n\to\infty} \|R_{n,1}(x)\|/n = 0$ a.s., since $\lim_{\eta\to 0}\omega(\eta) = 0$.

(b) Similarly, for $\alpha < 1/2s$, (2.9) and (2.22) easily yield

$$\limsup_{n\to\infty} \sup_{\{\|x\|\leq a\}} \frac{1}{n}\|R_{n,1}(x)\| = 0 \quad \text{a.s.}$$

Study of $R_{n,2}$: By Assumption 2.3(a), the almost sure equicontinuity on compacts of the sequence (f_n) induces the almost sure equicontinuity on compacts of the weighted sums $R_{n,2}(x)/D_{n-1}(x)$. Then the pointwise convergence of $R_{n,2}/D_{n-1}$, given in Assumption 2.3(b), is strengthened to the uniform convergence on compacts, that is, for $\alpha s < 1$ and all $a > 0$,

$$\lim_{n\to\infty} \sup_{\{\|x\|\leq a\}} R_{n,2}(x)/D_{n-1}(x) = 0 \text{ a.s.}$$

Finally, from (2.15), combining the results obtained for each term D_n, S_n, $R_{n,1}$, and $R_{n,2}$ completes the proof of Theorem 2.5. □

2.4. Corollaries. The previous theorem can be adapted in several ways with respect to the nature of the unknown functional sequence (f_n). Recall also that only the pointwise convergence in (2.3) is required if (f_n) is a.s. equicontinuous.

2.4.1. The case of convergent sequences.

COROLLARY 2.8. *Assumption* 2.3 *holds with any sequence of continuous deterministic (resp., random) functions* f_n*, converging (resp., converging a.s.) uniformly on the compact subsets of* $\mathbb{R}^s$.

Proof. Let us note first that the uniform convergence of (f_n) implies the equicontinuity of the sequence. Thus, since $D_n = \sum_{i=0}^{\infty} i^{\alpha s}K(i^{\alpha}(X_i - x)) = \infty$ a.s., the application of the Toeplitz lemma yields (2.3) and Assumption 2.3 holds. □

REMARK 2.9.

- *The deterministic case* $f_n = f$ *includes the model of Senoussi* [9].
- *The regression model of Rutkowski* [8] *of independent sequences* (Z_n, Y_n) *is reproduced by letting* $X_n^1 = Z_{n+1}$, $X_n^2 = Y_n$, *and* $f_n(x) = E(Y_n \mid Z_n = x)$.

2.4.2. The case of martingale increments. Let (f_n) be a random sequence in $\mathcal{C}(\mathbb{R}^s, \mathbb{R}^s)$ and let us define the filtration $\mathbb{G} = (\mathcal{G}_n)_{n\geq 1}$, where $\mathcal{G}_n := \sigma(X_0, X_i, f_{i-1}, 1 \leq i \leq n)$.

COROLLARY 2.10. *Assumption* 2.3 *is satisfied if a.s. the sequence* (f_n) *is equicontinuous and if there exist two continuous and deterministic functions* f *and* γ *such that for all* $x \in \mathbb{R}^s$ *and* $n \in \mathbb{N}$,

$$f(x) := E\Big(f_n(x)/\mathcal{G}_n\Big) \text{ and } E\Big(\|f_n - f\|^2(x)/\mathcal{G}_n\Big) \leq \gamma(x). \tag{2.23}$$

Proof. For all x, the process

$$\widetilde{R}_n(x) := R_{n,2}(x) = \sum_{i=1}^{n-1} i^{\alpha s} K(i^{\alpha}(X_i - x))(f_i - f)(x)$$

is a $\mathbb{G}$-martingale of hook

$$\langle \widetilde{R} \rangle_n(x) = \sum_{i=1}^{n-1} i^{2\alpha s} K^2(i^{\alpha}(X_i - x)) E\Big((f_i - f)^t (f_i - f)(x)/\mathcal{G}_i\Big).$$

Following the proof of the asymptotic behavior of $S_n(x)$ (cf. section 2.3), we obtain

$$\begin{aligned} \text{trace} E\Big(\langle \widetilde{R} \rangle_n(x)\Big) &\leq \gamma(x) \sum_{i=1}^{n-1} i^{2\alpha s} E\Big(K^2(i^{\alpha}(X_i - x))\Big) \\ &\leq cst\ \gamma(x)\ n^{\alpha s + 1}. \end{aligned}$$

Since $\gamma(.)$ is continuous, it is finite on each compact. Thus, the second law of large numbers on martingales applies whenever $\alpha s < 1$, i.e., for all $a > 0$ and $\|x\| \leq a$, we have $n^{-1}\widetilde{R}_n(x) \to 0$, a.s. By Lemma 2.7(a), we deduce the almost sure pointwise convergence of $\widetilde{R}_n/D_{n-1}(x)$ to 0, that is to say, (2.3) holds. □

COROLLARY 2.11. *A sequence in an equicontinuous subset $\mathcal{A} \subset \mathcal{C}(\mathbb{R}^s, \mathbb{R}^s)$ of i.i.d. random functions f_n satisfying $E(\|f_i(0)\|^2) < \infty$ verifies Assumption* 2.3.

Proof. If $\omega(.)$ denotes the modulus of continuity of (f_n) on $\mathcal{A}$, then for $a > 0$ and $\|x\| \leq a$, it follows that

$$E\Big(\|f_i(x)\|^2\Big) \leq 2\omega^2(a) + 2E\Big(\|f_i(0)\|^2\Big),$$

since $\|f_i(x)\| \leq \|f_i(x) - f_i(0)\| + \|f_i(0)\| \leq \omega(a) + \|f_i(0)\|$. Thus, the functions $f(x) := E(f_i(x))$ and $\Gamma_f(x) := E((f_i - f)^t(f_i - f)(x))$ exist. They are continuous because of the almost sure equicontinuity of (f_n) and the pointwise convergence (by ergodicity) of $n^{-1}\sum_i f_i(x)$ and $n^{-1}\sum_i (f_i - f)^t(f_i - f)(x)$ to $f(x)$ and $\Gamma_f(x)$, respectively. Let us define $\gamma(x) := \text{trace}(\Gamma_f(x))$. Then (2.23) is satisfied and Corollary 2.10 holds. □

2.5. A special class of models. Let us consider models of the form $f_i(x) = H_i(x)g_i(x), i = 1, 2, \ldots$, where (H_i) is a sequence of known mappings from $\mathbb{R}^s$ into $\mathcal{M}_{s\times l}$, the set of $s \times l$ real matrices with $l \leq s$, and (g_i) is a sequence of unknown mappings from $\mathbb{R}^s$ into $\mathbb{R}^l$. This type of model is frequently met in biotechnological process control. The following lemma is needed for the definition of an appropriate estimator of the sequence (g_i).

LEMMA 2.12. *Let $H(.)$ denote a mapping from $\mathbb{R}^s$ into $\mathcal{M}_{s\times l}$, the set of $s \times l$ real matrices with $l \leq s$.*

(a) *If $H(.)$ has a constant rank l, it admits a left inverse in $\mathcal{M}_{l\times s}$, denoted by $H^-(.)$, of constant rank l, such that for all $x, H^-(x)H(x) = I_l$ the identity matrix of dimension l.*

(b) *Furthermore, if $H(.)$ is a continuous mapping, so is $H^-(.)$.*

Proof. As the rank of H is l, the square matrix ${}^tH.H$ is invertible for all x and one can take $H^- = ({}^tH.H)^{-1}\,{}^tH$. Since it is a composition of matrix transposition, product, and inversion, this mapping is continuous, irrespective of the norms considered. □

One can then define the following estimator of $g_n(x)$:

$$\widehat{g}_n(x) = \frac{\sum_{i=1}^{n-1} h_i^{-s} K(h_i^{-1}(x - X_i)) H_i^{-}(X_i)(X_{i+1} - F_i(X_i, U_i))}{\sum_{i=1}^{n-1} h_i^{-s} K(h_i^{-1}(x - X_i))} . \tag{2.24}$$

Assumption 2.3 about the sequence (g_i) can be strengthened by the following finiteness assumption.

ASSUMPTION 2.13. *For all* $r > 0$, $\sup\{||H_i^{-}(x)|| \,;\, i \geq 0, ||x|| \leq r\} := w(r) < \infty$.

COROLLARY 2.14. *Under Assumptions* 2.1, 2.2, 2.3, 2.4, *and* 2.13, *the estimator* $\widehat{g}_n$ *converges a.s. to* g *and uniformly on the compact subsets.*

Proof. It suffices to consider the martingale

$$S_n'(x) = \sum_{i=0}^{n} i^{\alpha s} K(i^{\alpha}(X_i - x)) H_i^{-}(X_i) \varepsilon_{i+1}.$$

As for $S_n(.)$, one can apply the uniform law of large numbers, by noticing that

$$\text{for all } x \,:\, ||x|| \leq r \,,\, K(i^{\alpha}(X_i - x))||H_i^{-}(X_i)|| \leq K(i^{\alpha}(X_i - x)) w(r + r_K),$$

where $B(0, r_K)$ is the ball containing the support of K. □

COROLLARY 2.15. *If* $H_i(x) = H(x)$ *is continuous, Assumption* 2.13 *is satisfied.*

Proof. H^{-} is a continuous mapping according to Lemma 2.12(b). H^{-} is then bounded on every compact. □

REMARK 2.16. *Corollaries* 2.8, 2.10, *and* 2.11 *can easily be adapted to the sequence* (g_i).

REMARK 2.17. *One could think of replacing* $H_i^{-}(X_i)$ *by* $H_n^{-}(x)$ *in the estimator given by* (2.24), *which amounts to first computing* $\widehat{f}_n(x) = \widehat{H_n(x) g_n}(x)$ *and then deducing an estimator of* $g_n(x)$ *by multiplying it by* $H_n^{-}(x)$. *But as it has been shown by simulation, the behavior of this estimator is less satisfactory than that of the previous one. This is not surprising since it does not make use of the knowledge of the* (H_i).

3. Concluding remarks. We have used convolution kernels for the nonparametric identification of an unknown component in an autoregressive nonlinear controlled process. This procedure could certainly be improved by some appropriate optimization of the bandwidth parameter and of course the type of kernel. Finally, let us point out that this nonparametric approach can be the first step towards a nonparametric adaptive process control.

Appendix. Let $(M_n(.))_{n \geq 0}$ be a random sequence of continuous functions, such that for all x, $(M_n(x))_n$ is a square-integrable martingale adapted to a filtration $\mathbb{F}$. The following theorem has been proved in Senoussi [9] and corresponds to Proposition 6.4.33 in Duflo [3].

THEOREM. *If there exist* $\alpha > 0$ *and* $\gamma > 0$ *such that*

(1) $E\big(||M_n(0)||^2\big) = \mathcal{O}(n^{\alpha})$,

(2) *given any* $A > 0$, *there exists* η *such that for all* x, y *with moduli less than* A,

$$E\Big(||M_n(x) - M_n(y)||^2\Big) \leq \eta n^{\alpha} ||x - y||^{s+\gamma},$$

then for $\beta > \alpha/2$ *and any* $A < \infty$, $\sup_{||x|| \leq A} n^{-\beta} ||M_n(x)|| \to 0$ *a.s.*

UNIFORM CONVERGENCE AND MESH INDEPENDENCE OF NEWTON'S METHOD FOR DISCRETIZED VARIATIONAL PROBLEMS[*]

A. L. DONTCHEV[†], W. W. HAGER[‡], AND V. M. VELIOV[§]

Abstract. In an abstract framework, we study local convergence properties of Newton's method for a sequence of generalized equations which models a discretized variational inequality. We identify conditions under which the method is locally quadratically convergent, uniformly in the discretization. Moreover, we show that the distance between the Newton sequence for the continuous problem and the Newton sequence for the discretized problem is bounded by the norm of a residual. As an application, we present mesh-independence results for an optimal control problem with control constraints.

Key words. Newton's method, variational inequality, optimal control, sequential quadratic programming, discrete approximation, mesh independence

1. Introduction.

In this paper we study local convergence properties of Newton-type methods applied to discretized variational problems. Our target problem is the variational inequality representing the first-order optimality conditions in constrained optimal control. In an abstract framework, the optimality conditions are modeled by a "generalized equation," a term coined by S. Robinson [12], where the normal cone mapping is replaced by an arbitrary map with closed graph. In this setting, Newton's method solves at each step a linearized generalized equation. When the generalized equation describes first-order optimality conditions, Newton's method becomes the well-known sequential quadratic programming (SQP) method.

We identify conditions under which Newton's method is not only locally quadratically convergent, but the convergence is uniform with respect to the discretization. Moreover, we derive an estimate for the number of steps required to achieve a given accuracy. Under some additional assumptions, which are natural in the context of the target problem, we prove that the distance between the Newton sequence for the continuous problem and the Newton sequence for the discretized problem, measured in the discrete metric, can be estimated by the norm of a residual. Normally, the residual tends to zero when the approximation becomes finer, and the two Newton sequences approach each other. In the context of the target optimal control problem, the residual is proportional to the mesh spacing h, uniformly along the Newton sequence. In particular, this implies that the least number of steps needed to reach a point at distance ε from the solution of the discrete problem does not depend on the mesh spacing; that is, the method is mesh independent.

The convergence of the SQP method applied to nonlinear optimal control problems has been studied in several papers recently. In [5, 6] we proved local convergence of the method for a class of constrained optimal control problems. In parallel, Alt and Malanowski obtained related results for state constrained problems [3]. Along the same lines, Tröltzsch [13] studied the SQP method for a problem involving a parabolic partial differential equation.

Kelley and Sachs [10] were the first to obtain a mesh-independence result in constrained optimal control; they studied the gradient projection method. More recently, uniform convergence and mesh-independence results for an augmented Lagrangian version of the SQP method, applied to a discretization of an abstract optimization problem with equality constraints, were presented by Kunisch and Volkwein [11]. Alt [2] studied the mesh independence of Newton's method for generalized equations in the framework of the analysis of operator equations in Allgower et al. [1]. An abstract theory of mesh independence for infinite-dimensional optimization problems with equality constraints, together with applications to optimal control of partial differential equations and an extended survey of the field, can be found in the thesis of Volkwein [14].

The local convergence analysis of numerical procedures is closely tied to the problem's stability. The analysis is complicated for optimization problems with inequality constraints or for related variational inequalities. In this context, the problem solution typically depends on perturbation parameters in a nonsmooth way. In section 2 we present an implicit function theorem which provides a basis for our further analysis. In section 3 we obtain a result on uniform convergence of Newton's method applied to a sequence of generalized equations, while section 4 presents our mesh-independence results. Although in part parallel, our approach is different from the one used by Alt in [2], who adopted the framework of [1]. First, we study the uniform local convergence of Newton's method, which is not considered in [2]. In the mesh-independence analysis, we avoid consistency conditions for the solutions of the continuous and the discretized problems; instead, we consider the residual obtained when the Newton sequence of the continuous problem is substituted into the discrete necessary conditions. This allows us to obtain mesh independence under conditions weaker than those in [2] and, at the same time, to significantly simplify the analysis.

In section 5 we apply the abstract results to the constrained optimal control problem studied in our previous paper [5]. We show that under the smoothness and coercivity conditions given in [5] and assuming that the optimal control of the continuous problem is a Lipschitz continuous function of time, the SQP method applied to the discretized problem is Q-quadratically convergent, and the region of attraction and the constant of the convergence are independent of discretization, for a sufficiently small mesh size. Moreover, the l_∞ distance between the Newton sequence for the continuous problem at the mesh points and the Newton sequence for the discretized problem is of order $O(h)$. In particular, this estimate implies the mesh-independence result in Alt [2].

2. Lipschitzian localization.

Let X and Y be metric spaces. We denote both metrics by $\rho(\cdot,\cdot)$; it will be clear from the context which metric we are using. $B_r(x)$ denotes the closed ball with center x and radius r. In writing "f maps X into Y" we adopt the convention that the domain of f is a (possibly proper) subset of X. Accordingly, a set-valued map F from X to the subsets of Y may have empty values.

DEFINITION 2.1. *Let Γ map Y to the subsets of X and let $x^* \in \Gamma(y^*)$. We say that Γ has a Lipschitzian localization with constants a, b, and M around (y^*, x^*), if* *the map $y \mapsto \Gamma(y) \cap B_a(x^*)$ is single valued (a function) and Lipschitz continuous in $B_b(y^*)$ with a Lipschitz constant M.*

THEOREM 2.1. *Let G map X into the subsets of Y and let $y^* \in G(x^*)$. Let G^{-1} have a Lipschitzian localization with constants a, b, and M around (y^*, x^*). In addition, suppose that the intersection of the graph of G with $B_a(x^*) \times B_b(y^*)$ is closed and $B_a(x^*)$ is complete. Let the real numbers λ, $\bar{M}$, $\bar{a}$, m, and δ satisfy the relations*

$$\lambda M < 1, \quad \bar{M} = \frac{M}{1 - \lambda M}, \quad m + \delta < b, \quad \text{and} \quad \bar{a} + \bar{M}\delta < a. \tag{1}$$

Suppose that the function $g : B_a(x^*) \mapsto Y$ is Lipschitz continuous with a constant λ in the ball $B_a(x^*)$, that

$$\sup_{x \in B_a(x^*)} \rho(g(x), y^*) \le m, \tag{2}$$

and that the set

$$\Delta := \{x \in B_{\bar{a}}(x^*) : \operatorname{dist}(g(x), G(x)) \le \delta\} \tag{3}$$

is nonempty.

Then the set $\{x \in B_a(x^*) \mid g(x) \in G(x)\}$ consists of exactly one point, $\hat{x}$, and for each $x' \in \Delta$ we have

$$\rho(x', \hat{x}) \le \bar{M} \operatorname{dist}(g(x'), G(x')). \tag{4}$$

Proof. Let us choose positive $\lambda, \bar{M}, m, \bar{a}$, and δ such that the relations in (1) hold. We first show that the set $T := \{x \in B_a(x^*) \mid g(x) \in G(x)\}$ is nonempty. Let $x' \in \Delta$ and put $x_0 = x'$. Take an arbitrary $\varepsilon > 0$ such that

$$m + \delta + \varepsilon \le b \quad \text{and} \quad \bar{a} + \bar{M}(\delta + \varepsilon) \le a.$$

Choose an $y' \in G(x')$ such that $\rho(y', g(x')) \le \operatorname{dist}(g(x'), G(x')) + \varepsilon$. Since

$$\rho(y', y^*) \le \rho(y^*, g(x')) + \operatorname{dist}(g(x'), G(x')) + \varepsilon \le m + \delta + \varepsilon \le b$$

and

$$\rho(g(x_0), y^*) \le m \le b,$$

from the Lipschitzian localization property, there exists x_1 such that

$$g(x_0) \in G(x_1), \quad \rho(x_1, x_0) \le M\rho(y', g(x_0)) \le M(\operatorname{dist}(g(x'), G(x')) + \varepsilon). \tag{5}$$

We define inductively a sequence x_k in the following way. Let $x_0, \ldots, x_k$ be already defined for some $k \ge 1$ in such a way that

$$\rho(x_i, x_{i-1}) \le (\lambda M)^{i-1} \rho(x_1, x_0), \quad i = 1, \ldots, k, \tag{6}$$

and

$$g(x_{k-1}) \in G(x_k). \tag{7}$$

Clearly, x_0 and x_1 satisfy these relations. Using the second inequality in (5), we estimate

$$\begin{aligned} \rho(x_i, x^*) &\le \rho(x_0, x^*) + \sum_{j=1}^{i} \rho(x_j, x_{j-1}) \le \rho(x', x^*) + \sum_{j=0}^{\infty} (\lambda M)^j \rho(x_1, x_0) \\ &\le \bar{a} + \frac{1}{1 - \lambda M} M(\operatorname{dist}(g(x'), G(x')) + \varepsilon) \le \bar{a} + \bar{M}(\delta + \varepsilon) \le a. \end{aligned}$$

Thus both x_{k-1} and x_k are in $B_a(x^*)$ from which we obtain by (2)

$$\rho(g(x_i), y^*) \leq m \leq b$$

for $i = k-1$ and for $i = k$. Due to the assumed Lipschitzian localization property of G, there exists x_{k+1} such that (7), with k replaced by $k+1$, is satisfied and

$$\rho(x_{k+1}, x_k) \leq M\rho(g(x_k), g(x_{k-1})).$$

By (6) we obtain

$$\rho(x_{k+1}, x_k) \leq M\lambda\rho(x_k, x_{k-1}) \leq (\lambda M)^k \rho(x_1, x_0),$$

and hence (6) with k replaced by $k+1$, is satisfied. The definition of the sequence x_k is complete.

From (6) and the condition $\lambda M < 1$, $\{x_k\}$ is a Cauchy sequence. Since all $x_k \in B_a(x^*)$, the sequence $\{x_k\}$ has a limit $x'' \in B_a(x^*)$. Passing to the limit in (7), we obtain $g(x'') \in G(x'')$. Hence $x'' \in T$ and the set T is nonempty. Note that x'' may depend on the choice of ε. If we prove that the set T is a singleton, say $\hat{x}$, the point $x'' = \hat{x}$ would not depend on ε.

Suppose that there exist $x'' \in T$ and $\bar{x}'' \in T$ with $\rho(x'', \bar{x}'') > 0$. It follows that $\rho(g(x), y^*) \leq m \leq b$ for $x = x''$ and $x = \bar{x}''$. From the definition of the Lipschitzian localization, we obtain

$$\rho(x'', \bar{x}'') \leq M\rho(g(x''), g(\bar{x}'')) \leq M\lambda\rho(x'', \bar{x}'') < \rho(x'', \bar{x}''),$$

which is a contradiction. Thus T consists of exactly one point, $\hat{x}$, which does not depend on ε. To prove (4) observe that for any choice of $k > 1$,

$$\begin{aligned} \rho(x', x'') \leq \rho(x_0, x_k) + \rho(x_k, x'') &\leq \sum_{i=0}^{k-1} \rho(x_{i+1}, x_i) + \rho(x_k, x'') \\ &\leq \sum_{i=0}^{k-1} (\lambda M)^i \rho(x_1, x_0) + \rho(x_k, x''). \end{aligned}$$

Passing to the limit in the latter inequality and using (5), we obtain

$$\rho(x', x'') \leq \bar{M}(\operatorname{dist}(g(x'), G(x')) + \varepsilon). \tag{8}$$

Since $x'' = \hat{x}$ does not depend on the choice of ε, one can take $\varepsilon = 0$ in (8) and the proof is complete. □

3. Newton's method. Theorem 2.1 provides a basis for the analysis of the error of approximation and the convergence of numerical procedures for solving variational problems. In this and the following section we consider a sequence of so-called generalized equations. Specifically, for each $N = 1, 2, \ldots$, let X^N be a closed and convex subset of a Banach space, let Y^N be a linear normed space, let $f_N : X^N \mapsto Y^N$ be a function, and let $F_N : X^N \mapsto 2^{Y^N}$ be a set-valued map with closed graph. We denote by $\|\cdot\|_N$ the norms of both X^N and Y^N. We study the following sequence of problems:

$$\text{Find } x \in X^N \text{ such that } 0 \in f_N(x) + F_N(x). \tag{9}$$

We assume that there exist constants α, β, γ, and L, as well as points $x_N^* \in X^N$ and $z_N^* \in Y^N$, that satisfy the following conditions for each N:

(A1) $z_N^* \in f_N(x_N^*) + F_N(x_N^*)$.

(A2) The function f_N is Frechét differentiable in $B_\alpha(x_N^*)$ and the derivative ∇f_N is Lipschitz continuous in $B_\alpha(x_N^*)$ with a Lipschitz constant L.

(A3) The map

$$y \mapsto \Big(f_N(x_N^*) + \nabla f_N(x_N^*)(\cdot - x_N^*) + F_N(\cdot)\Big)^{-1}(y)$$

has a Lipschitzian localization with constants α, β, and γ around the point (z_N^*, x_N^*).

We study the Newton method for solving (9) for a fixed N which has the following form: If x^k is the current iterate, the next iterate x^{k+1} satisfies

$$0 \in f_N(x^k) + \nabla f_N(x^k)(x^{k+1} - x^k) + F_N(x^{k+1}), \quad k = 0, 1, \ldots, \tag{10}$$

where x^0 is a given starting point. If the range of the map F is just the origin, then (9) is an equation and (10) becomes the standard Newton method. If F is the normal cone mapping in a variational inequality describing first-order optimality conditions, then (10) represents the first-order optimality condition for the auxiliary quadratic program associated with the SQP method.

In the following theorem, by applying Theorem 2.1, we obtain the existence of a locally unique solution of the problem (9) which is at a distance from the reference point proportional to the norm of the residual z_N^*. We also show that the method (10) converges Q-quadratically and this convergence is uniform in N and in the choice of the initial point from a ball around the reference point x_N^* with radius independent of N. Note that for obtaining this result we do not pass to a limit and consequently we do not need to consider sequences of generalized equations.

THEOREM 3.1. *For every $\gamma' > \gamma$ there exist positive constants κ and σ such that if $\|z_N^*\| \leq \sigma$, then the generalized equation* (9) *has a unique solution x_N in $B_\kappa(x_N^*)$; moreover, x_N satisfies*

$$\|x_N - x_N^*\|_N \leq \gamma' \|z_N^*\|_N. \tag{11}$$

Furthermore, for every initial point $x^0 \in B_\kappa(x_N^*)$ there is a unique Newton sequence $\{x^k\}$, with $x^k \in B_\kappa(x_N^*)$, $k = 1, 2, \ldots$, and this Newton sequence is Q-quadratically convergent to x_N, that is,

$$\|x^{k+1} - x_N\|_N \leq \Theta \|x^k - x_N\|_N^2, \quad k = 0, 1, \ldots, \tag{12}$$

where Θ is independent of k, N and $x^0 \in B_\kappa(x_N^*)$.

Proof. Define

$$\kappa = \min\left\{\alpha, \gamma\beta, \frac{\gamma' - \gamma}{L\gamma\gamma'}, \frac{1}{5L\gamma'}\right\}, \quad \sigma = \frac{1}{\gamma'} \min\left\{\frac{\kappa}{4}, \sqrt{\frac{\kappa}{3L\gamma'}}, \frac{1}{6L\gamma'}\right\}, \quad \Theta = \frac{\gamma' L}{2}.$$

We will prove the existence and uniqueness of x_N by using Theorem 2.1 with

$$a = \kappa,\ b = \kappa/\gamma,\ M = \gamma,\ \lambda = \kappa L,\ \bar{M} = \gamma',\ \bar{a} = 0,\ m = \kappa^2 L/2 + \sigma,\ \delta = \sigma$$

and

$$g(x) = -f_N(x) + f_N(x_N^*) + \nabla f_N(x_N^*)(x - x_N^*),$$
$$G(x) = f_N(x_N^*) + \nabla f_N(x_N^*)(x - x_N^*) + F_N(x).$$

Observe that $a \le \alpha, b \le \beta$ and $\gamma b \le a$. By (A3) the map G has a Lipschitzian localization around (x_N^*, z_N^*) with constants a, b, and γ. One can check that the relations (1) are satisfied. Further, for x, x', and $x'' \in B_\kappa(x_N^*)$, we have

$$\|g(x) - z_N^*\|_N \le \|z_N^*\|_N + L\|x - x_N^*\|_N^2/2 \le \sigma + L\kappa^2/2 = m,$$

$$\begin{aligned}\|g(x') - g(x'')\|_N &\le \| - f_N(x') + f_N(x'') + \nabla f(x_N^*)(x' - x'')\|_N \\ &\le L\kappa\|x' - x''\|_N = \lambda\|x' - x''\|_N,\end{aligned}$$

$$\mathrm{dist}(g(x_N^*), G(x_N^*)) = \mathrm{dist}(0, f_N(x_N^*) + F(x_N^*)) \le \|z_N^*\|_N \le \sigma = \delta.$$

Obviously, $x_N^* \in B_0(x_N^*)$ and $x_N^* \in \Delta$, with Δ defined in (3). The assumptions of Theorem 2.1 are satisfied; hence there exists a unique x_N in $B_\kappa(x_N^*)$ for which $g(x_N) \in G(x_N)$. Hence x_N is a unique solution of (9) in $B_\kappa(x_N^*)$ and (11) holds. This completes the first part of the proof.

Given $x^k \in B_\kappa(x_N^*)$, a point x is a Newton step from x^k if and only if x satisfies the inclusion

$$g(x) \in G(x), \tag{13}$$

where G is the same as above, but now

$$g(x) = -f_N(x^k) - \nabla f_N(x^k)(x - x^k) + f_N(x_N^*) + \nabla f_N(x_N^*)(x - x_N^*).$$

The proof will be completed if we show that (13) has a unique solution x^{k+1} in $B_\kappa(x_N^*)$ and this solution satisfies (12). To this end we apply again Theorem 2.1 with $a, b, M, \bar{M}$, and λ the same as in the first part of the proof and with

$$\bar{a} = \sigma\gamma', \quad m = \sigma + \frac{5L\kappa^2}{2}, \quad \delta = \frac{L}{2}(\gamma'\sigma + \kappa)^2.$$

With these identifications, it can be checked that the assumptions (1) and (2) hold, and that g is Lipschitz continuous in $B_\kappa(x_N^*)$ with a Lipschitz constant λ. Further, by using the solution x_N obtained in the first part of the proof, we have

$$\begin{aligned}\mathrm{dist}(g(x_N), G(x_N)) &= \mathrm{dist}(0, f_N(x^k) + \nabla f_N(x^k)(x_N - x^k) + F_N(x_N)) \\ &\le \frac{L}{2}\|x_N - x^k\|_N^2 + \mathrm{dist}(0, f(x_N) + F_N(x_N)) = \frac{L}{2}\|x_N - x^k\|_N^2.\end{aligned} \tag{14}$$

The last expression has the estimate

$$\frac{L}{2}\|x_N - x^k\|_N^2 \le \frac{L}{2}\left(\|x_N - x_N^*\|_N + \|x_N^* - x^k\|_N\right)^2 \le \frac{L}{2}(\gamma'\sigma + \kappa)^2 = \delta.$$

Thus $x_N \in \Delta \ne \emptyset$ and the assumptions of Theorem 2.1 are satisfied. Hence, there exists a unique Newton step x^{k+1} in $B_\kappa(x_N^*)$ and by Theorem 2.1 and (14) it satisfies

$$\|x^{k+1} - x_N\|_N \le \frac{\gamma' L}{2}\|x^k - x_N\|_N^2 = \Theta\|x^k - x_N\|_N^2. \qquad \square$$

4. Mesh independence. Consider the generalized equation (9) under the assumptions (A1)–(A3). We present first a lemma in which, for simplicity, we suppress the dependence of N.

LEMMA 4.1. *For every $\gamma' > \gamma$, every $\mu > 0$, and every sufficiently small $\xi > 0$, there exists a positive η such that the map*

$$(y, w) \mapsto P(y, w) := (f(w) + \nabla f(w)(\cdot - w) + F(\cdot))^{-1}(y) \cap B_\alpha(x^*) \tag{15}$$

is a Lipschitz continuous function from $B_\eta(z^*) \times B_\xi(x^*)$ into $B_\xi(x^*)$ with Lipschitz constants γ' for y and μ for w.

Proof. Let $\gamma' > \gamma$ and $\mu > 0$. We choose the positive constants ξ and η as a solution of the following system of inequalities:

$$\gamma L\xi < 1, \quad \xi \le \frac{\gamma - \gamma'}{\gamma\gamma' L}, \quad 3\eta + \frac{15}{2}L\xi^2 + L\xi\alpha \le \beta,$$

$$\xi + \gamma'(2\eta + 6L\xi^2) \le \alpha, \quad 3L\xi\gamma' \le \mu, \quad \gamma'(\eta + 3L\xi^2) \le \xi.$$

This system of inequalities is satisfied by first taking ξ sufficiently small and then taking η sufficiently small. In particular, we have $\xi \le \alpha$ and $\eta \le \beta$.

Take $(y'', w'') \in B_\eta(z^*) \times B_\xi(x^*)$. We apply Theorem 2.1 with $a = \alpha$, $b = \beta$, $M = \gamma$, $\bar{a} = \xi$, $\bar{b} = \eta$, $\bar{M} = \gamma'$, $\lambda = L\xi$, $m = \eta + \frac{3}{2}L\xi^2 + L\xi\alpha$, $\delta = 2\eta + 6L\xi^2$,

$$g(x) = y'' + f(x^*) + \nabla f(x^*)(x - x^*) - f(w'') - \nabla f(w'')(x - w''),$$

and

$$G(x) = f(x^*) + \nabla f(x^*)(x - x^*) + F(x).$$

We have

$$\begin{aligned}\|g(x_1) - g(x_2)\| &= \|(\nabla f(x^*) - \nabla f(w''))(x_1 - x_2)\| \\ &\le L\|w'' - x^*\|\|x_1 - x_2\| \le L\xi\|x_1 - x_2\|\end{aligned}$$

for all $x_1, x_2 \in B_\alpha(x^*)$. Hence the function g is Lipschitz continuous with a Lipschitz constant λ. For $x \in B_\alpha(x^*)$ we have

$$\begin{aligned}\|g(x) - z^*\| &\le \|y'' - z^*\| + \|f(w'') - f(x^*) - \nabla f(x^*)(w'' - x^*)\| \\ &\quad + \|(\nabla f(x^*) - \nabla f(w''))(x - w'')\| \\ &\le \eta + \frac{L}{2}\|w'' - x^*\|^2 + L\|w'' - x^*\|\|x - w''\| \\ &\le \eta + \frac{1}{2}L\xi^2 + L\xi(\xi + \alpha) = m.\end{aligned}$$

Note that a point x is in the set $P(y'', w'')$ if and only if $g(x) \in G(x)$. Since

$$\begin{aligned}\operatorname{dist}(g(x^*), G(x^*)) &\le \|y'' - z^*\| + \operatorname{dist}(z^* - f(w'') - \nabla f(w'')(x^* - w''), F(x^*)) \\ &\le \eta + \operatorname{dist}(z^*, f(x^*) + F(x^*)) + \frac{L}{2}\|x^* - w''\|^2 \le \eta + \frac{L}{2}\xi^2 < \delta,\end{aligned}$$

the set Δ defined in (3) is not empty. Hence, from Theorem 2.1 the set $P(y'', w'') \cap B_\alpha(x^*)$ consists of exactly one point. Let us call it x''. Applying the same argument to an arbitrary point $(y', w') \in B_\eta(z^*) \times B_\xi(x^*)$, we obtain that there is exactly one point $x' \in P(y', w') \cap B_\alpha(x^*)$. Furthermore,

$$\begin{aligned}\operatorname{dist}(g(x'), G(x')) &\leq \|y' - y''\| + \|f(w'') - \nabla f(w'')(x' - w'') - f(w') - \nabla f(w')(x' - w')\| \\ &\leq \|y' - y''\| + \|f(w'') - f(w') - \nabla f(w')(w'' - w')\| \\ &\qquad\qquad\qquad + \|\nabla f(w'') - \nabla f(w')\|\|x' - w''\| \\ &\leq \|y' - y''\| + \frac{L}{2}\|w' - w''\|^2 + 2L\xi\|w' - w''\| \\ &\leq \|y' - y''\| + 3L\xi\|w' - w''\|.\end{aligned}$$

Hence $x' \in \Delta$ and we obtain

$$\rho(x', x'') \leq \gamma'(\|y' - y''\| + 3L\xi\|w' - w''\|) \leq \gamma'\|y' - y''\| + \mu\|w' - w''\|.$$

It remains to prove that P maps $B_\eta(z^*) \times B_\xi(x^*)$ into $B_\xi(x^*)$. From the last inequality with $x' = x^*$ and $w' = x^*$, we have

$$\rho(x'', x^*) \leq \gamma'(\|y'' - z^*\| + 3L\xi\|w'' - x^*\|) \leq \gamma'(\eta + 3L\xi^2) \leq \xi.$$

Thus $x'' \in B_\xi(x^*)$. □

In the remaining part of this section, we fix $\gamma' > \gamma$ and $0 < \mu < 1$, and we choose the constants κ and σ according to Theorem 3.1. For a positive ξ with $\xi \leq \kappa$, let η be the constant whose existence is claimed in Lemma 4.1. Note that η can be chosen arbitrarily small; we take $0 < \eta \leq \sigma$. Also, we assume that $\|z_N^*\| \leq \eta$ and consider Newton sequences with initial points $x^0 \in B_\xi(x_N^*)$. In such a way, the assumptions of Theorem 3.1 hold and we have a unique Newton sequence which is convergent quadratically to a solution.

Suppose that Newton's method (10) is supplied with the following stopping test: Given $\varepsilon > 0$, at the kth step the point x^k is accepted as an approximate solution if

$$\operatorname{dist}(0, f_N(x^k) + F_N(x^k)) < \varepsilon. \tag{16}$$

Denote by k_ε the first step at which the stopping test (16) is satisfied.

Theorem 4.1. *For any positive $\varepsilon < \eta$, if x^{k_ε} is the approximate solution obtained using the stopping test* (16) *at the step $k = k_\varepsilon$, then*

$$\|x^{k_\varepsilon} - x_N\|_N \leq \frac{\gamma'\varepsilon}{1 - \mu} \tag{17}$$

and

$$k_\varepsilon \leq 2 + \frac{1}{2}\log_\mu\left(\frac{\varepsilon}{2L\xi^2}\right). \tag{18}$$

Proof. Choose an ε such that $0 < \varepsilon < \eta$. If the stopping test (16) is satisfied at x^{k_ε}, then there exists v_ε^k with $\| v_\varepsilon^k \|_N \leq \varepsilon$ such that

$$v_\varepsilon^k \in f_N(x^{k_\varepsilon}) + F_N(x^{k_\varepsilon}).$$

Let P^N be defined as in (15) on the basis of f_N and F_N. Since

$$x^{k_\varepsilon} = P^N(v_\varepsilon^k, x^{k_\varepsilon}) \quad \text{and} \quad x_N \in P^N(0, x_N),$$

Lemma 4.1 implies that

$$\|x^{k_\varepsilon} - x_N\|_N \le \gamma' \parallel v_\varepsilon^k \parallel_N + \mu \|x^{k_\varepsilon} - x_N\|_N.$$

The latter inequality yields (17). For all $k < k_\varepsilon$, we obtain

$$\varepsilon \le \operatorname{dist}(0, f_N(x^k) + F_N(x^k)).$$

Since x^k is a Newton iterate, we have

$$f_N(x^k) - f_N(x^{k-1}) - \nabla f_N(x^{k-1})(x^k - x^{k-1}) \in f_N(x^k) + F_N(x^k).$$

Hence

$$\begin{aligned} \operatorname{dist}(0, f_N(x^k) + F_N(x^k)) &\le \parallel f_N(x^k) - f_N(x^{k-1}) - \nabla f_N(x^{k-1})(x^k - x^{k-1}) \parallel_N \\ &\le L\|x^k - x^{k-1}\|_N^2/2. \end{aligned} \tag{19}$$

By the definition of the map P^N, the Newton step x^1 from x^0 satisfies

$$x^1 = P^N(0, x^0),$$

while the Newton step x^2 from x^1 is

$$x^2 = P^N(0, x^1).$$

Since P^N is Lipschitz continuous with a constant μ, we have

$$\|x^2 - x^1\|_N \le \mu \|x^1 - x^0\|_N.$$

By induction, the $(k+1)$st Newton step x^{k+1} satisfies

$$\|x^{k+1} - x^k\|_N \le \mu^k \|x^1 - x^0\|_N. \tag{20}$$

Combining (19) and (20) and we obtain the estimate

$$\varepsilon \le 2L\xi^2 \mu^{2(k-1)},$$

which yields (18). □

Our next result provides a basis for establishing the mesh independence of Newton's method (10). Namely, we compare the Newton sequence x_N^k for the "discrete" problem (9) and the Newton sequence for a "continuous" problem which is again described by (9) but with index $N = 0$. Let us assume that the conditions (A1)–(A3) hold for the generalized equation (9) with $N = 0$. According to Theorem 3.1, for each starting point x_0^0 close to a solution x_0, there is a unique Newton sequence x_0^k which converges to x_0 Q-quadratically. To relate the continuous problem to the discrete one, we introduce a mapping π_N from X^0 to X^N. Having in mind the application to optimal control presented in the following section, X^0 can be thought as a space of continuous functions $x(\cdot)$ in $[0, 1]$ and, for a given natural number N, $t_0 = 0$ and $t_i = i/N$, X^N will be the space of sequences $\{x_i, i = 0, 1, \ldots, N\}$. In this case the operator π_N is the interpolation map $\pi_N(x(\cdot)) = (x(t_0), \ldots, x(t_N))$.

Theorem 4.2. *Suppose that for every k and N there exists $r_N^k \in Y^N$ such that*

$$r_N^k \in f_N(\pi_N(x_0^k)) + \nabla f_N(\pi_N(x_0^k))(\pi_N(x_0^{k+1}) - \pi_N(x_0^k)) + F_N(\pi_N(x_0^{k+1}))$$

and

$$\omega_N := \sup_k \parallel r_N^k \parallel_N < \eta. \tag{21}$$

In addition, let

$$\|\pi_N(x_0^k) - x_N^*\|_N \leq \xi$$

for all k and N. Then for all $k = 1, 2, \ldots$ and N

$$\|x_N^{k+1} - \pi_N(x_0^{k+1})\|_N \leq \frac{\gamma'}{1-\mu}\omega_N + \mu^{k+1}\|x_N^0 - \pi_N(x_0^0)\|_N. \tag{22}$$

Proof. By definition, we have

$$\pi_N(x_0^{k+1}) = P^N(r_N^k, \pi_N(x_0^k)) \quad \text{and} \quad x_N^{k+1} = P^N(0, x_N^k).$$

Using Lemma 4.1 we have

$$\|x_N^{k+1} - \pi_N(x_0^{k+1})\|_N \leq \gamma' \parallel r_N^k \parallel_N + \mu\|x_N^k - \pi_N(x_0^k)\|_N \leq \gamma'\omega_N + \mu\|x_N^k - \pi_N(x_0^k)\|_N.$$

By induction we obtain (22). □

The above result means that, under our assumptions, the distance between the Newton sequence for the continuous problem and the Newton sequence for the discretized problem, measured in the discrete metric, can be estimated by the sup-norm ω_N of the residual obtained when the Newton sequence for the continuous problem is inserted into the discretized generalized equations. If the sup-norm of the residual tends to zero when the approximation becomes finer, that is, when $N \to \infty$, then the two Newton sequences approach each other. In the next section, we will present an application of the abstract analysis to an optimal control problem for which the residual is proportional to the mesh spacing h, uniformly along the Newton sequence. For this particular problem Theorem 4.2 implies that the distance between the Newton sequences for the continuous problem and the Newton sequence for the discretized problem is $O(h)$.

For simplicity, let us assume that if the continuous Newton process starts from the point x_N^0, then the discrete Newton process starts from $\pi_N(x_0^0)$. Also, suppose that for any fixed $w, v \in X^0$,

$$\|\pi_N(w) - \pi_N(v)\|_N \to \|w - v\|_0 \quad \text{as} \quad N \to \infty. \tag{23}$$

In addition, let

$$\omega_N \to 0 \quad \text{as} \quad N \to \infty, \tag{24}$$

where ω_N is defined in (21). Letting k tend to infinity and assuming that π_N is a continuous mapping for each N, Theorem 4.2 gives us the following estimate for the distance between the solution x_N of the discrete problem and the discrete representation $\pi_N(x_0)$ of the solution x_0 of the continuous problem:

$$\|x_N - \pi_N(x_0)\|_N \leq \frac{\gamma'}{1-\mu}\omega_N. \tag{25}$$

Choose a real number ε satisfying

$$0 < \varepsilon < 1/(5\Theta), \tag{26}$$

where Θ is as in Theorem 3.1. Theorem 4.2 yields the following result.

THEOREM 4.3. *Let* (23) *and* (24) *hold and let* ε *satisfy* (26). *Then for all* N *sufficiently large,*

$$|\min\left\{k \in \mathbf{N} : \|x_0^k - x_0\|_0 < \varepsilon\right\} - \min\left\{k \in \mathbf{N} : \|x_N^k - x_N\|_N < \varepsilon\right\}| \leq 1. \tag{27}$$

Proof. Let m be such that

$$\|x_0^{m+1} - x_0\|_0 < \varepsilon \leq \|x_0^m - x_0\|_0. \tag{28}$$

Choose N so large that

$$\frac{\gamma'}{1-\mu}\omega_N < \varepsilon/2$$

and

$$\|\pi_N(x_0^{m+1}) - \pi_N(x_0)\|_N \leq \varepsilon.$$

Using Theorem 3.1, Theorem 4.2, (25), and (29), we obtain

$$\begin{aligned}\|x_N^{m+2} - x_N\|_N &\leq \Theta\|x_N^{m+1} - x_N\|_N^2\\ &\leq \Theta\left(\|x_N^{m+1} - \pi_N(x_0^{m+1})\|_N + \|\pi_N(x_0^{m+1}) - \pi_N(x_0)\|_N + \|\pi_N(x_0) - x_N\|_N\right)^2\\ &\leq \Theta(\varepsilon/2 + \varepsilon + \varepsilon/2)^2 = 4\Theta\varepsilon^2 < \varepsilon.\end{aligned}$$

This means that if the continuous Newton sequence achieves accuracy ε (measured by the distance to the exact solution) at the mth step, then the discrete Newton sequences should achieve the same accuracy ε at the $(m+1)$st step or earlier. Now we show that the latter cannot happen earlier than at the $(m-1)$st step. Choose N so large that

$$\|x_0^{m-1} - x_0\|_0^2 \leq \|\pi_N(x_0^{m-1}) - \pi_N(x_0)\|_N^2 + \varepsilon^2 \tag{29}$$

and suppose that

$$\|x_N^{m-1} - x_N\|_N < \varepsilon.$$

From Theorem 3.1, (22), (25), (28), and (29), we get

$$\begin{aligned}\varepsilon \leq \|x_0^m - x_0\|_0 \leq \Theta\|x_0^{m-1} - x_0\|_0^2 &\leq \Theta\|\pi_N(x_0^{m-1}) - \pi_N(x_0)\|_N^2 + \varepsilon^2\\ &\leq \Theta\left(\|\pi_N(x_0^{m-1}) - x_N^{m-1}\|_N + \|x_N^{m-1} - x_N\|_N + \|x_N - \pi_N(x_0)\|_N\right)^2 + \varepsilon^2\\ &\leq \Theta(\varepsilon/2 + \varepsilon + \varepsilon/2)^2 + \varepsilon^2 = 5\Theta\varepsilon^2,\end{aligned}$$

which contradicts the choice of ε in (26). □

5. Application to optimal control.

We consider the following optimal control problem:

$$\text{minimize } G(y(1)) + \int_0^1 \varphi(y(t), u(t))\, dt \tag{30}$$

$$\text{subject to} \quad \dot{y}(t) = g(y(t), u(t)) \text{ and } u(t) \in U \text{ for almost every (a.e.) } t \in [0,1],$$
$$y(0) = y_0,\ y \in W^{1,\infty}(\mathbb{R}^n), \text{ and } u \in L^\infty(\mathbb{R}^m),$$

where $\varphi : \mathbb{R}^{n+m} \to \mathbb{R}$, $g : \mathbb{R}^{n+m} \to \mathbb{R}^n$, $G : \mathbb{R}^n \to \mathbb{R}$, U is a nonempty, closed and convex set in $\mathbb{R}^m$, and y_0 is a fixed vector in $\mathbb{R}^n$. $L^\infty(\mathbb{R}^m)$ denotes the space of essentially bounded and measurable functions with values in $\mathbb{R}^m$ and $W^{1,\infty}(\mathbb{R}^n)$ is the space of Lipschitz continuous functions with values in $\mathbb{R}^n$.

We are concerned with local analysis of the problem (30) around a fixed local minimizer (y^*, u^*) for which we assume certain regularity. Our first standing assumption is the following:

Smoothness. *The optimal control u^* is Lipschitz continuous in $[0,1]$. There exists a positive number δ such that the first three derivatives of φ and g exist and are continuous in the set $\{(y,u) \in \mathbb{R}^{n+m} : |y - y^*(t)| + |u - u^*(t)| \le \delta$ for all $t \in [0,1]\}$.*

Defining the Hamiltonian H by

$$H(y,u,\psi) = \varphi(y,u) + \psi^\mathsf{T} g(y,u),$$

it is well known that the first-order necessary optimality conditions at the solution (y^*, u^*) can be expressed in the following way: There exists $\psi^* \in W^{1,\infty}(\mathbb{R}^n)$ such that (y^*, u^*, ψ^*) is a solution of the variational inequality

$$\dot{y}(t) = g(y(t), u(t)), \quad y(0) = y_0, \tag{31}$$

$$\dot{\psi}(t) = -\nabla_y H(y(t), u(t), \psi(t)), \quad \psi(1) = \nabla G(y(1)), \tag{32}$$

$$0 \in \nabla_u H(y(t), u(t), \psi(t)) + N_U(u(t)) \quad \text{for a.e. } t \in [0,1], \tag{33}$$

where $N_U(u)$ is the normal cone to the set U at the point u; that is, $N_U(u)$ is empty if $u \notin U$, while for $u \in U$,

$$N_U(u) = \{p \in \mathbb{R}^m : p^\mathsf{T}(q - u) \le 0 \text{ for all } q \in U\}.$$

Although the problem (30) is posed in L^∞ and the optimality system (31)–(33) is satisfied a.e. in $[0,1]$, the regularity we assume for the particular optimal solution implies that at (y^*, u^*, ψ^*) the relations (31)–(33) hold everywhere in $[0,1]$.

Defining the matrices

$$A(t) = \nabla_y g(z^*(t)), \quad B(t) = \nabla_u g(z^*(t)), \quad V = \nabla^2 G(y^*(1)),$$
$$Q(t) = \nabla^2_{yy} H(x^*(t)), \quad R(t) = \nabla^2_{uu} H(x^*(t)), \quad S(t) = \nabla^2_{yu} H(x^*(t)),$$

where $z^* = (y^*, u^*)$ and $x^* = (y^*, u^*, \psi^*)$, we employ the following coercivity condition.

Coercivity. *There exists $\alpha > 0$ such that*

$$y(1)^\mathsf{T} V y(1) + \int_0^1 [y(t)^\mathsf{T} Q(t) y(t) + u(t)^\mathsf{T} R(t) u(t) + 2y(t)^\mathsf{T} S(t) u(t)]\, dt \ge \alpha \int_0^1 |u(t)|^2\, dt \tag{34}$$

whenever $y \in W^{1,2}(\mathbb{R}^n)$, $y(0) = 0, u \in L^2(\mathbb{R}^n), \dot{y} = Ay + Bu, u(t) \in U - U$ for a.e. $t \in [0,1]$.

Let N be a natural number, let $h = 1/N$ be the mesh spacing, let $t_i = ih$, and let y_i' denote the forward difference operator defined by

$$y_i' = \frac{y_{i+1} - y_i}{h}.$$

We consider the following Euler discretization of the optimality system (31)–(33):

$$y_i' = \nabla_\psi H(y_i, u_i, \psi_i), \tag{35}$$

$$\psi_{i-1}' = -\nabla_y H(y_i, u_i, \psi_i), \quad \psi_{N-1} = \nabla G(y_N), \tag{36}$$

$$0 \in \nabla_u H(y_i, u_i, \psi_i) + N_U(u_i), \quad i = 0, 1, \ldots, N-1. \tag{37}$$

The system (35)–(37) is a discrete-time variational inequality depending on the step size h. It represents the first-order necessary optimality condition for the following discretization of the original problem (30):

$$\text{minimize} \quad G(y_N) + \sum_{i=0}^{N-1} h\varphi(y_i, u_i) \tag{38}$$
$$\text{subject to} \;\; y_i' = g(y_i, u_i), \;\; u_i \in U, \; i = 0, 1, \dots, N-1.$$

In this section we examine the following version of the Newton method for solving the variational system (35)–(37), which correspond to the SQP method for solving the optimization problem (38). Let $x^k = (y^k, u^k, \psi^k)$ denote the kth iterate. Let the superscript k and the subscript i attached to the derivatives of H and G denote their values at x_i^k. Then the new iterate $x^{k+1} = (y^{k+1}, u^{k+1}, \psi^{k+1})$ is a solution of the following linear variational inequality for the variable $x = (y, u, \psi)$:

$$y_i' = \nabla_\psi H_i^k + \nabla^2_{\psi x} H_i^k (x_i - x_i^k), \tag{39}$$
$$\psi_{i-1}' = -\nabla_y H_i^k - \nabla^2_{yx} H_i^k (x_i - x_i^k), \quad \psi_{N-1} = \nabla G^k + \nabla^2 G^k (y_N - y_N^k), \tag{40}$$
$$0 \in \nabla_u H_i^k + \nabla^2_{ux} H_i^k (x_i - x_i^k) + N_U(u_i), \quad i = 0, 1, \dots, N-1. \tag{41}$$

In [5, Appendix 2], it was proved that the coercivity condition (34) is stable under the Euler discretization, then the variational system (39)–(41) is equivalent, for x^k near $x^* = (y^*, u^*, \psi^*)$, to the following linear-quadratic discrete-time optimal control problem which is expressed in terms of the variables y, u, and $z = (y, u)$:

$$\begin{aligned} \text{minimize} \quad & \left(\nabla G^k + \frac{1}{2}\nabla^2 G^k (y_N - y_N^k)\right)^{\mathsf{T}} (y_N - y_N^k) \\ & + \; h \sum_{i=0}^{N-1} \left(\nabla_z \varphi_i^k + \frac{1}{2}\nabla^2_{zz} H_i^k (z_i - z_i^k)\right)^{\mathsf{T}} (z_i - z_i^k) \\ \text{subject to} \quad & y_i' = g_i^k + \nabla_z g_i^k (z_i - z_i^k), \quad u_i \in U, \quad i = 0, 1, \dots, N-1. \end{aligned}$$

A natural stopping criterion for the problem at hand is the following: Given $\varepsilon > 0$, a control $\tilde{u}^k$ obtained at the kth iteration is considered an ε-optimal solution if

$$\max_{0 \le i \le N-1} \operatorname{dist}(\nabla_u H(\tilde{y}_i^k, \tilde{u}_i^k, \tilde{\psi}_i^k), N_U(\tilde{u}_i^k)) \le \varepsilon, \tag{42}$$

where $\tilde{y}_i^k$ and $\tilde{\psi}_i^k$ are the solutions of the state and the adjoint equations (35) and (36) correspond to $u = \tilde{u}^k$.

We now apply the general approach developed in the previous section to the discrete-time variational inequality (35)–(36). The discrete L_N^∞ norm is defined by

$$\|v\|_N^\infty = \max_{0 \le i \le N-1} |v_i|.$$

The variable x is the triple (y, u, ψ) while X^N is the space of all finite sequences $x_0, x_1, \dots, x_{N-1}$, with y_0 given, equipped with the L_N^∞ norm. The space Y^N is the Cartesian product $L_N^\infty \times L_N^\infty \times \mathbb{R}^n \times L_N^\infty$ corresponding to the four components of the function f_N defined by

$$f_N(x)_i = \begin{pmatrix} y_i' - g(y_i, u_i) \\ -\psi_{i-1}' + \nabla_y H(y_i, u_i, \psi_i) \\ \psi_{N-1} - \nabla G(y_N) \\ -\nabla_u H(y_i, u_i, \psi_i) \end{pmatrix} \quad \text{and} \quad F_N(x)_i = \begin{pmatrix} 0 \\ 0 \\ 0 \\ N_U(u_i) \end{pmatrix}.$$

With the choice $(x_N^*)_i = (y^*(t_i), u^*(t_i), \psi^*(t_i))$, the general condition (A1) is satisfied by taking

$$(z_N^*)_i = \begin{pmatrix} (y^*(t_{i+1}) - y^*(t_i))/h - g(y^*(t_i), u^*(t_i)) \\ (\psi^*(t_{i-1}) - \psi^*(t_i))/h - \nabla_x H(y^*(t_i), u^*(t_i), \psi^*(t_i)) \\ 0 \\ 0 \end{pmatrix}.$$

The first component of z_N^* is estimated in the following way:

$$\sup_i \left| \frac{y^*(t_{i+1}) - y^*(t_i)}{h} - g(y^*(t_i), u^*(t_i)) \right| \\ \leq \sup_i \frac{1}{h} \int_{t_i}^{t_{i+1}} |g(y^*(t_i), u^*(t_i)) - g(y^*(t), u^*(t))| dt.$$

Since g is smooth and both y^* and u^* are Lipschitz continuous, the above expression is bounded by $O(h)$. The same bound applies for the second component of z_N^*, while the third and fourth components are zero. Thus the norm of z_N^* can be made arbitrarily small for all sufficiently large N. Condition (A2) follows from the smoothness assumption. A proof of condition (A3) is contained in the proof of Theorem 6 in [5]. Applying Theorems 3.1 and 4.1 and using the result from [5, Appendix 2], that the discretized coercivity condition is a second-order sufficient condition for the discrete problem, we obtain the following theorem.

THEOREM 5.1. *If smoothness and coercivity hold, then there exist positive constants K, c, σ, $\bar{\varepsilon}$, and $\bar{N}$ with the property that for every $N > \bar{N}$ there is a unique solution (y_h, u_h, ψ_h) of the variational system* (35)–(37) *and (y_h, u_h) is a local minimizer for the discrete problem* (38). *For every starting point (y^0, u^0, ψ^0) with*

$$\max_{0 \leq i \leq N} \left(|(y^0)_i - y^*(t_i)| + |(u^0)_i - u^*(t_i)| + |(\psi^0)_i - \psi^*(t_i)| \right) \leq \sigma,$$

there is a unique SQP sequence (y^k, u^k, ψ^k) and it is Q-quadratically convergent, with a constant K, to the solution (y_h, u_h, ψ_h). In particular, for the sequence of controls we have

$$\max_{0 \leq i \leq N-1} |(u^{k+1})_i - (u_h)_i| \leq K \left(\max_{0 \leq i \leq N-1} |(u^k)_i - (u_h)_i| \right)^2.$$

Moreover, if the stopping test (42) *is applied with an $\varepsilon \in [0, \bar{\varepsilon}]$, then the resulting ε-optimal control u^{k_ε} satisfies*

$$\max_{0 \leq i \leq N-1} |u_i^{k_\varepsilon} - u^*(t_i)| \leq c(\varepsilon + h).$$

Note that the termination step k_ε corresponding to the assumed accuracy of the stopping test can be estimated by Theorem 4.1. Combining the error in the discrete control with the discrete state equation (35) and the discrete adjoint equation (36), yield corresponding estimates for discrete state and adjoint variables.

Remark. Following the approach developed in [5] one can obtain an analogue of Theorem 5.1 by assuming that the optimal control u^* is merely bounded and Riemann integrable in $[0, 1]$ and employing the so-called averaged modulus of smoothness to obtain error estimates.. The stronger Lipschitz continuity condition for the optimal control is, however, needed in our analysis of the mesh independence.

The SQP method applied to the continuous-time optimal control problem (30) has the following form: If $x^0 = (y^0, u^0, \psi^0)$ is a starting point, the iterate $x^{k+1} = (y^{k+1}, u^{k+1}, \psi^{k+1})$ satisfies

$$\dot{y}(t) = \nabla_\psi H^k(t) + \nabla^2_{\psi x} H^k(t)(x(t) - x^k(t)),\ y(0) = y_0, \tag{43}$$

$$\dot{\psi}(t) = -\nabla_y H^k(t) - \nabla^2_{yx} H^k(t)(x(t) - x^k(t)), \tag{44}$$

$$\psi(1) = \nabla G^k(1) + \nabla^2 G^k(y(1) - y^k(1)), \tag{45}$$

$$0 \in \nabla_u H^k(t) + \nabla^2_{ux} H^k(t)(x(t) - x^k(t)) + N_U(u(t)) \tag{46}$$

for a.e. $t \in [0,1]$, where the superscript k attached to the derivatives of H and G denotes their values at x^k. In particular, (43)–(46) is a variational inequality to which we can apply the general theory from the previous sections. We attach the index $N = 0$ to the continuous problem and for $x = (y, u, \psi)$ we choose $X^0 = C^1_0(\mathbb{R}^n) \times C(\mathbb{R}^m) \times C^1(\mathbb{R}^n)$, where $C^1_0 = \{y \in C^1 \mid y(0) = y_0\}$, and $Y^0 = C(\mathbb{R}^n) \times C(\mathbb{R}^n) \times \mathbb{R}^n \times C(\mathbb{R}^m)$. Condition (A1) is clearly satisfied with $x^*_0 = x^* := (y^*, u^*, \psi^*)$ and $z^*_0 = 0$. Condition (A2) follows from the smoothness assumption. Condition (A3) follows from the coercivity assumption as proved in [9, Lemma 3] (see also [4, section 2.3.4], for an earlier version of this result in the convex case). Hence, we can apply Theorem 3.1 obtaining that for any sufficiently small ball $\mathcal{B}$ around x^* (in the norm of X^0), if the starting point x^0 is chosen from $\mathcal{B}$, then the SQP method produces a unique sequence $x^k \in \mathcal{B}$ which is Q-quadratically convergent to x^* (in the norm of X^0). Moreover, from Theorem 4.1 we obtain an estimate for the number of steps needed to achieve a given accuracy.

In order to derive a mesh-independence result from the general theory, we first study the regularity of the SQP sequence for the continuous problem.

LEMMA 5.1. *There exist positive constants p and q such that for every $x^0 \in B_p(x^*)$ with $u^0(\cdot)$ Lipschitz continuous in* $[0,1]$*, for every $k = 1, 2, \ldots,$ and for every $t_1, t_2 \in [0,1]$,*

$$|u^k(t_1) - u^k(t_2)| \le q|t_1 - t_2|.$$

Proof. In [5, section 6], extending a previous result in [7], see also [6], Lemma 2, we showed that the coercivity condition implies pointwise coercivity almost everywhere. In the present circumstances, the latter condition is satisfied everywhere in $[0,1]$; that is, there exists a constant $\alpha > 0$ such that for every $v \in U - U$ and for all $t \in [0,1]$,

$$v^\mathsf{T} R(t) v \ge \alpha v^\mathsf{T} v. \tag{47}$$

For a positive parameter p, consider the SQP sequence x^k starting from $x^0 \in B_p(x^*)$ such that the initial control u^0 is a Lipschitz continuous function in $[0,1]$. Throughout the proof we will choose p sufficiently small and check the dependence of the constants of p. By (46) the iterate x^k satisfies

$$\begin{aligned}(\nabla_u H^k(t) + \nabla^2_{uu} H(x^k(t))(u^{k+1}(t) - u^k(t)) + \nabla^2_{uy} H(x^k(t))(y^{k+1}(t) - y^k(t))\\ +\nabla^2_{u\psi} H(x^k(t))(\psi^{k+1}(t) - \psi^k(t)))^\mathsf{T}(u - u^{k+1}(t)) \ge 0\end{aligned} \tag{48}$$

for every $t \in [0,1]$ and for every $u \in U$. Let $t_1, t_2 \in [0,1]$. Note that x^k are contained in $B_p(x^*)$ for all k and therefore both y'^k and ψ'^k are bounded by a constant independent of k; hence, y^k and ψ^k are Lipschitz continuous functions in time with Lipschitz constants independent of k. We have from (48)

$$\begin{aligned}(\nabla_u H^k(t_1) + \nabla^2_{uu}H(x^k(t_1))(u^{k+1}(t_1) - u^k(t_1)) + \nabla^2_{uy}H(x^k(t_1))(y^{k+1}(t_1) - y^k(t_1))\\ + \nabla^2_{u\psi}H(x^k(t_1))(\psi^{k+1}(t_1) - \psi^k(t_1)))^{\mathsf{T}}(u^{k+1}(t_2) - u^{k+1}(t_1)) \geq 0\end{aligned}$$

and the analogous inequality with t_1 and t_2 interchanged. Adding these two inequalities and adding and subtracting the expressions $\nabla^2_{uu}H(x^k(t_1))u^{k+1}(t_2)$ and $\nabla^2_{uu}H(x^k(t_1))u^*(t_1) - \nabla^2_{uu}H(x^k(t_2))u^*(t_2)$ we obtain

$$\begin{aligned}(\theta^k(t_1) - \theta^k(t_2) - \nabla^2_{uu}H(x^k(t_1))u^*(t_1) + \nabla^2_{uu}H(x^k(t_2))u^*(t_2)\\ +(\nabla^2_{uu}H(x^k(t_1)) - \nabla^2_{uu}H(x^k(t_2)))u^{k+1}(t_2)\\ +\nabla^2_{uy}H(x^k(t_1))(y^{k+1}(t_1) - y^k(t_1))\\ +\nabla^2_{u\psi}H(x^k(t_1))(\psi^{k+1}(t_1) - \psi^k(t_1)))^{\mathsf{T}}(u^{k+1}(t_2) - u^{k+1}(t_1))\\ \geq (\nabla^2_{uu}H(x^k(t_1))(u^{k+1}(t_1) - u^{k+1}(t_2)))^{\mathsf{T}}(u^{k+1}(t_1) - u^{k+1}(t_2))\end{aligned} \tag{49}$$

where the function θ^k is defined as

$$\theta^k(t) = \nabla_u H^k(t) + \nabla^2_{uu}H(x^k(t))(u^k(t) - u^*(t)).$$

By (47), for a sufficiently small p the right-hand side of the inequality (49) satisfies

$$\begin{aligned}(\nabla^2_{uu}H(x^k(t_1))(u^{k+1}(t_1) - u^{k+1}(t_2)))^{\mathsf{T}}(u^{k+1}(t_1) - u^{k+1}(t_2))\\ \geq \frac{\alpha}{2}|u^{k+1}(t_1) - u^{k+1}(t_2)|^2.\end{aligned} \tag{50}$$

Combining (49) and (50) we obtain

$$\begin{aligned}&\frac{\alpha}{2}|u^{k+1}(t_1) - u^{k+1}(t_2)| \leq |\theta^k(t_1) - \theta^k(t_2)|\\ &+|(\nabla^2_{uu}H(x^k(t_1)) - \nabla^2_{uu}H(x^k(t_2)))(u^{k+1}(t_2) - u^*(t_2))|\\ &+|\nabla^2_{uu}H(x^k(t_1))(u^*(t_1) - u^*(t_2))|\\ &+|(\nabla^2_{uy}H(x^k(t_1)) - \nabla^2_{uy}H(x^k(t_2)))(y^{k+1}(t_1) - y^k(t_1))|\\ &+|\nabla^2_{uy}H(x^k(t_2))((y^{k+1}(t_1) - y^{k+1}(t_2)) - (y^k(t_1) - y^k(t_2)))|\\ &+|(\nabla^2_{u\psi}H(x^k(t_1)) - \nabla^2_{u\psi}H(x^k(t_2)))(\psi^{k+1}(t_1) - \psi^k(t_1))|\\ &+|\nabla^2_{u\psi}H(x^k(t_2))((\psi^{k+1}(t_1) - \psi^{k+1}(t_2)) - (\psi^k(t_1) - \psi^k(t_2)))|.\end{aligned} \tag{51}$$

Let u_k be Lipschitz continuous in time with a constant L_k. Then the function θ^k is almost everywhere differentiable and its derivative is given by

$$\begin{aligned}\dot\theta(t) = \nabla^2_{uy}H^k(t)\dot y_k(t) + \nabla^2_{u\psi}H^k(t)\dot\psi_k(t) - \nabla^3_{uuu}H^k(t)\dot u^k(t)(u^k(t) - u^*(t))\\ - \nabla^3_{uuy}H^k(t)\dot y^k(t)(u^k(t) - u^*(t)) - \nabla^3_{uu\psi}H^k(t)\dot\psi^k(t)(u^k(t) - u^*(t)) - \nabla^2_{uu}H^k(t)\dot u^*(t).\end{aligned}$$

From this expression we obtain that there exists a constant c_1, independent of k and t and bounded from above when $p \to 0$, such that

$$\|\dot\theta\|_{L^\infty} \leq cp\|\dot{u^k}\|_{L^\infty} + c_1 \leq c_1(pL_k + 1).$$

Estimating the expressions in the right-hand side of (51) we obtain that there exists a constant c_2, independent of k and t and bounded from above when $p \to 0$, such that

$$|u^{k+1}(t_1) - u^{k+1}(t_2)| \le c_2(pL_k + 1)|t_1 - t_2|.$$

Hence, u^{k+1} is Lipschitz continuous and, for some constants c of the same kind as c_1, c_2, its Lipschitz constant L_{k+1} satisfies

$$L_{k+1} \le c(pL_k + 1).$$

Since p can be chosen arbitrarily small, the sequence $L_i, i = 1, 2, \ldots,$ is bounded, i.e., by a constant q. The proof is complete. □

To apply the general mesh-independence result presented in Theorem 4.2 we need to estimate the residual r_N^k obtained when the SQP sequence of the continuous problem is substituted into the relations determining the SQP sequence of the discretized problem. Specifically, the residual is the remainder term associated with the Euler scheme applied to (43)–(46); that is,

$$r_N^k = \begin{pmatrix} \frac{1}{h}\int_{t_i}^{t_{i+1}} (\nabla_\psi H^k(t) + \nabla^2_{\psi x} H^k(t)(x^{k+1}(t) - x^k(t)) \\ \qquad - (\nabla_\psi H_i^k + \nabla^2_{\psi x} H_i^k(x_i^{k+1} - x_i^k)))dt \\ \frac{1}{h}\int_{t_i}^{t_{i+1}} (-\nabla_x H^k(t) - \nabla^2_{xx} H^k(t)(x^{k+1}(t) - x^k(t)) \\ \qquad - (-\nabla_x H_i^k - \nabla^2_{xx} H_i^k(x_i^{k+1} - x_i^k)))dt \\ \psi^{k+1}(1-h) - \psi^{k+1}(1) \\ 0 \end{pmatrix},$$

where the subscript i denotes the value at t_i. From the regularity of the Newton sequence established in Lemma 5.1, the uniform norm of the residual is bounded by ch, where c is independent of k. Note that the map $\pi_N(x)$ defined in section 4, acting on a function $x \in X^0$, gives the sequence $x(t_i), i = 0, 1, \ldots N$. Condition (23) is satisfied because the space X^0 is a subset of the space of continuous functions. Summarizing, we obtain the following result.

Theorem 5.2. *Suppose that smoothness and coercivity conditions hold. Then there exists a neighborhood $\mathcal{W}$, in the norm of X^0, of the solution $x^* = (y^*, u^*, \psi^*)$ such that for all sufficiently small step-sizes h, the following mesh-independence property holds:*

$$\sup_k \max_{0 \le i \le N-1} |u^k(t_i) - (u_h^k)_i| = O(h), \tag{52}$$

where $u^k(\cdot)$ is the control in the SQP sequence $(y^k(\cdot), u^k(\cdot), \psi^k(\cdot))$ for the continuous problem starting from a point $x^0 = (y^0, u^0, \psi^0) \in \mathcal{W}$ with $u^0(\cdot)$ Lipschitz continuous in $[0,1]$, and u_h^k is the control in the SQP sequence (y_h^k, u_h^k, ψ_h^k) for the discretized problem starting from the point $\pi_N(x^0)$.

Applying Theorem 4.3 to the optimal control problem considered we obtain the mesh-independence property (27) which relates the number of steps for the continuous and the discretized problem needed to achieve certain accuracy. The latter property can be also easily deduced from the estimate (52) in Theorem 5.2, in a way analogous to the proof of Theorem 4.3. Therefore the estimate (52) is a stronger mesh-independence property than (27).

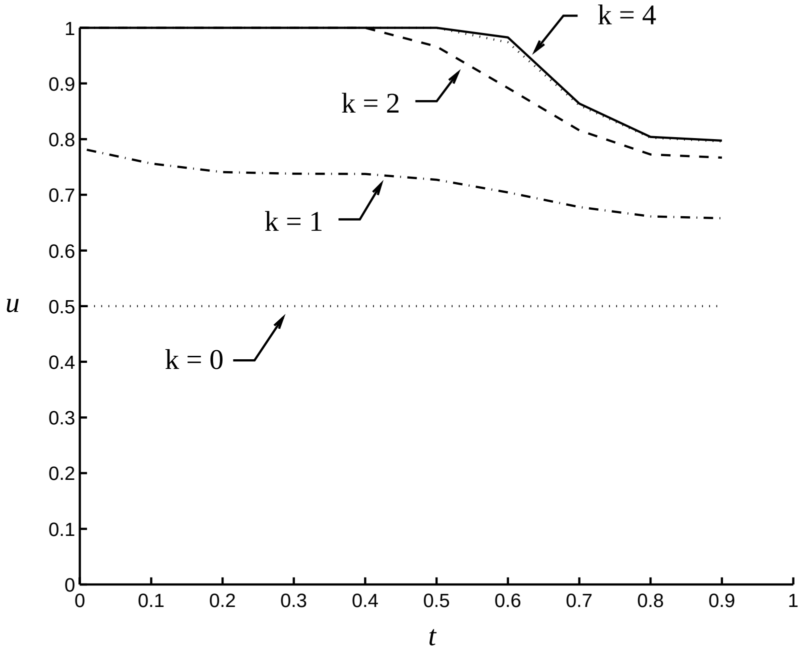

FIG. 1. *SQP iterates for the control with $N = 10$.*

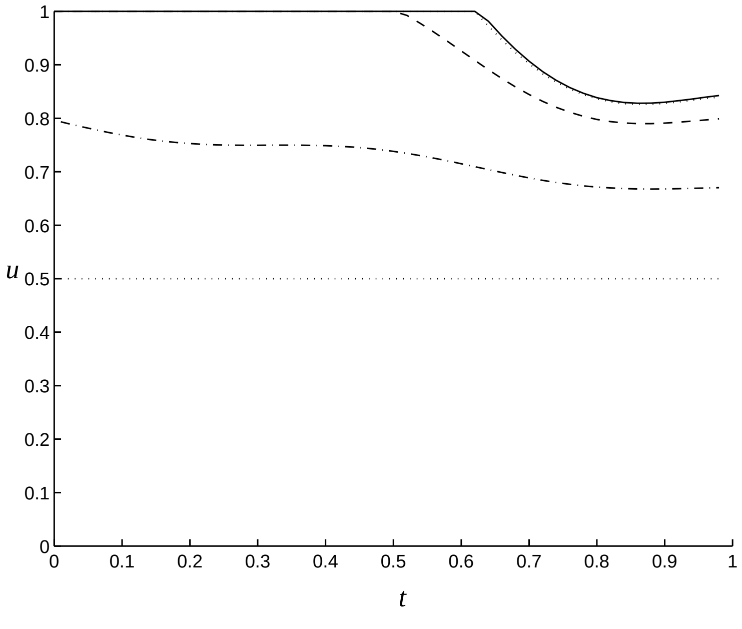

FIG. 2. *SQP iterates for the control with $N = 50$.*

6. Numerical examples. The convergence estimate of Theorem 5.2 is illustrated using the following example:

$$\text{minimize} \int_0^1 \left(\tfrac{1}{2}(y(t)^4 + u(t)^2 + u(t)y(t)) + \tfrac{1}{4}\sin(10t)u(t) + u(t)^{-1}\right) dt$$

$$\text{subject to } \ \dot{y}(t) = -u(t)/(2y(t)), \ y(0) = \sqrt{\tfrac{1+3e}{2(e-1)}}, \ u(t) \leq 1.$$

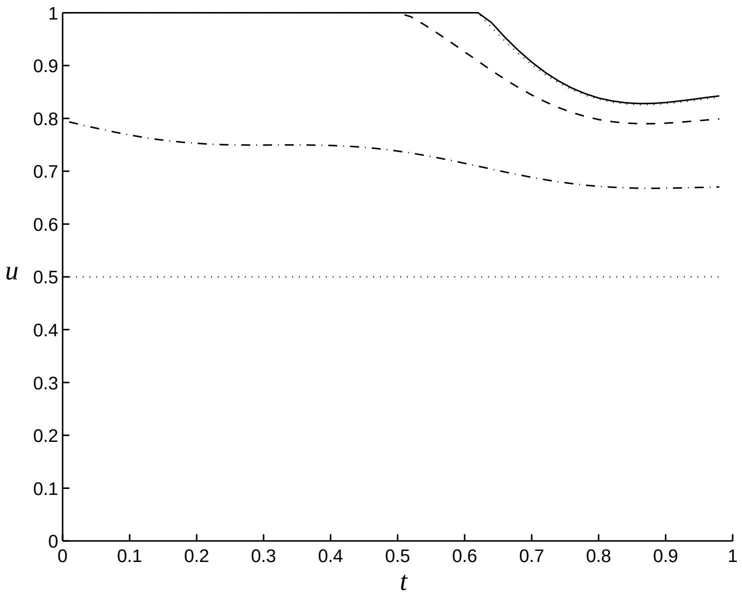

FIG. 3. *SQP iterates for the control with N=250.*

TABLE 1
L^∞ error in the control for various choices of the mesh.

Iteration	$N = 10$	$N = 50$	$N = 250$
0	.500000	.500000	.500000
1	.278473	.290428	.291671
2	.090857	.091727	.097923
3	.008928	.008971	.010185
4	.000082	.000084	.000105

TABLE 2
Error in current iterate divided by error in prior iterate squared.

Iteration	$N = 10$	$N = 50$	$N = 250$
1	1.113	1.161	1.166
2	1.171	1.087	1.151
3	1.081	1.066	1.062
4	1.027	1.039	1.013

This problem is a variation of Problem I in [8] that has been converted from a linear-quadratic problem to a fully nonlinear problem by making the substitution $x = -y^2$ and by adding additional terms to the cost function that degrade the speed of the SQP iteration so that the convergence is readily visible (without these additional terms, the SQP iteration converges to computing precision within 2 iterations). Figures 1–3 show the control iterates for successively finer meshes. The control corresponding to $k = 3$ is barely visible beneath the $k = 4$ iterate. Observe that the SQP iterations are relatively insensitive to the choice of the mesh. Specifically, $N = 10$ is already sufficiently large to obtain mesh independence. In Table 1 we give the L^∞ error in the successive iterates. In Table 2 we observe that the ratio of the error in the current iterate to the error in the prior iterate squared is slightly larger than 1.

INTERPOLATION THEORY AND QUANTUM COHOMOLOGY[*]

M. S. RAVI[†]

Abstract. We show that the quantum cohomology ring of the Grassmannian can be used to find the minimal degree of the solution to various interpolation problems involving matrices of rational functions. We also use computations in the quantum cohomology ring to formalize the notion of linearity in this context and distinguish between linear problems such as matrix and tangential interpolation and nonlinear problems such as pole placement.

Key words. interpolation problems, quantum cohomology

Introduction. A number of rational matrix interpolation problems were reformulated in terms of intersection theory on the space of maps from the projective line $\mathbb{P}^1$ into a Grassmannian in [2]. The general problem posed in [2] was shown to include a wide range of problems of interest, but a solution to the general problem itself was not presented.

The first goal of our paper is to show that the quantum cohomology ring of the Grassmannian provides a general solution to the intersection theory problem posed in [2]. This by itself seems to be a well-known fact among people who deal with quantum cohomology, but we aim to make the connection clear to the interpolation theory community. The second objective of our paper is to use the quantum cohomology ring of the Grassmannian to make specific computations in the cases of the matrix and tangential interpolation problems and to use these computations to show that these problems are "linear" in the sense that they have a unique solution, no solution, or infinitely many solutions. As far as the author knows, there does not seem to be any known explanation of the well-known fact that the matrix and tangential interpolation problems have linear algorithms [1], [8], whereas other problems like the pole placement problem are known to be nonlinear [10]. In the process, we also try to formalize the notion of linearity in this context. We believe that our computations provide the first convincing explanation of the difference between these problems.

1. Preliminaries.

In this section we recall the problem formulated in [2] and introduce some notation.

Let $G = \text{Grass}(p, p+m)$ denote the Grassmannian of all p-dimensional subspaces of $\mathbb{C}^{m+p}$. We recall some of the facts of interest related to the Grassmannian. Each point in G may be identified with the row space of a $p \times (m+p)$ matrix of full row rank. From this point of view, one sees that the Grassmannian has an open cover $\{U_I\}$, where for a choice of a multi-index $I = (i_1, \dots, i_p)$, the open set $U_I \subset G$ consists of subspaces represented by $p \times (m+p)$ matrices whose maximal minor corresponding to the index I is nonzero. Let us fix a flag V of subspaces $V_1 \subset \cdots \subset V_{m+p} = \mathbb{C}^{m+p}$ where $\dim V_i = i$. For any p-tuple of integers $0 < a_1 < \cdots < a_p \leq m+p$, we define

the subvariety

$$\Omega_V(a_1,\dots,a_p)=\{\Lambda\in G\,|\,\dim\Lambda\cap V_{a_i}\geq i \text{ for } 1\leq i\leq p\}.$$

The varieties defined above are called Schubert varieties. The homology class of the subvariety $\Omega_V(a_1,\dots,a_p)$ in the homology ring $H_*(G,\mathbb{C})$ is independent of the flag V and depends only on the index $a=(a_1,\dots,a_p)$, since there is an invertible linear map of $\mathbb{C}^{m+p}$ that takes the flag V to any other flag W, and the set of invertible linear maps of $\mathbb{C}^{m+p}$ is connected. The homology class of $\Omega_V(a_1,\dots,a_p)$ is usually denoted by $(a_1,\dots,a_p)$. It is well known that these homology classes for the various possible choices of the index a form an additive basis for the homology ring of the Grassmannian. The intersection theory of these homology classes in the Grassmannian is usually described in terms of the dual object, namely the cohomology ring, the duality being given by the Poincaré duality map from $H_{2i}(G,\mathbb{C})\to H^{2mp-2i}(G,\mathbb{C})$. Under this duality, the intersection pairing corresponds to the product in the cohomology ring. With this in mind, we next describe a presentation of the cohomology ring of the Grassmannian.

The Grassmannian comes with two canonical vector bundles on it, the subbundle $\mathcal{S}$ that associates to each point $\Lambda\in \text{Grass}(p,p+m)$ the p-dimensional subspace corresponding to Λ, and the quotient bundle $\mathcal{Q}$ that associates to Λ the quotient vector space $\mathbb{C}^{m+p}/\Lambda$. Let $X_i\in H^{2i}(G,\mathbb{C})$ denote the ith Chern class of the subbundle $\mathcal{S}$ and let $Y_i\in H^{2i}(G,\mathbb{C})$ denote the ith Chern class of the quotient bundle $\mathcal{Q}$. Then the cohomology ring $H^*(G,\mathbb{C})$ is the polynomial ring $\mathbb{C}[X_1,\dots,X_p]$ modulo the ideal generated by $(Y_{m+1},\dots,Y_{p+m})$, where the polynomials Y_i are defined as follows: $Y_1=-X_1$ and for $i>1$,

$$Y_i=-Y_{i-1}X_1-\cdots-Y_1X_{i-1}-X_i \tag{1}$$

with the convention that $X_i=0$ for $i>p$. Alternatively, one can describe $H^*(G,\mathbb{C})$ as the polynomial ring $\mathbb{C}[Y_1,\dots,Y_m]$ modulo the ideal generated by $(X_{p+1},\dots,X_{p+m})$, where $X_1=-Y_1$ and for $i>1$,

$$X_i=-X_{i-1}Y_1-\cdots-X_1Y_{i-1}-Y_i$$

with the convention that $Y_i=0$ for $i>m$. Thus, one can switch from a presentation in terms of X_i or Y_i, depending on which is more convenient. The homology class $(a_1,\dots,a_p)$ is Poincaré dual to the cohomology class denoted by $\{m+1-a_1,\dots,m+p-a_p\}$, where

$$\{\lambda_1,\dots,\lambda_p\}=\det(Y_{\lambda_i+j-i})_{1\leq i,j\leq p}.$$

(As before, $Y_j=0$ for $j\notin\{0,1,\dots,m\}$.) For more details on cohomology of Grasmannians, see [7, pp. 193–206].

There are two specific classes of Schubert varieties that will be of interest to us. Let $R_i=\{\Lambda\in G\,|\,\Lambda\subset M_i\}$, where M_i is a fixed subspace of $\mathbb{C}^{m+p}$ of codimension i. The homology class of R_i is $(m{+}1{-}i,m{+}2{-}i,\dots,m{+}p{-}i)$, so that its Poincaré dual is the cohomology class $\{i,\dots,i\}$. In terms of the X_i, one sees that the Poincaré dual of the homology class of $[R_1]$ is the class $(-1)^pX_p$ and the class of $[R_i]$ is Poincaré dual to $(-1)^{pi}X_p^i$. Similarly, let $L_i=\{\Lambda\in G\,|\,N_i\subset\Lambda\}$, where N_i is a fixed subspace of $\mathbb{C}^{m+p}$ of dimension i. The homology class of L_i is $(1,2,\dots,i,m+i+1,\dots,m+p)$, so that its Poincaré dual is the cohomology class $\{m,\dots,m,0,\dots,0\}$, where the m occurs i

times. In terms of the Y_i, the Poincaré dual of the homology class of $[L_1]$ is given by Y_m, and that of $[L_i]$ is given by Y_m^i. The whole Grassmannian can be thought of as the homology class $(m+1,\dots,m+p)$ and the homology class of a point is $(1,\dots,p)$. So the class of a point in the Grassmannian is dual to $(-1)^{mp}X_p^m = Y_m^p$. The Schubert varieties L_i and R_i are called sub-Grassmannians in the algebraic geometry literature.

Given two arbitrary Schubert varieties Ω_1 and Ω_2, in order to determine if their intersection is nonempty, one follows the following procedure. Let ξ_i be the Poincaré duals of the homology classes of Ω_i. If the product $\xi_1 \cdot \xi_2 \in H^*(G,\mathbb{C})$ is nonzero, then one knows that $\Omega_1 \cap \Omega_2$ is nonempty and further the homology class of $\Omega_1 \cap \Omega_2$ is the Poincaré dual of $\xi_1 \cdot \xi_2$, if the intersection is proper. On the other hand, if $\xi_1 \cdot \xi_2 = 0$, and the two Schubert varieties are in "general" position, then their intersection is empty.

We try to develop this intersection theoretic approach to solving interpolation problems involving rational matrix functions in this paper, and show that using the quantum cohomology ring of the Grassmannian, all necessary computations can be made quite easily. Let us first recall the following problem formulated in [2].

Problem 1.1. *Given ℓ points $x_1,\dots,x_\ell$ on the projective line $\mathbb{P}^1$, and ℓ Schubert subvarieties $W_1,\dots,W_\ell$ of Grass$(p,p+m)$, find the lowest integer n for which there is a map of degree n from $\mathbb{P}^1$ into Grass$(p,p+m)$ that maps the point x_i into W_i for $i=1,\dots,\ell$. Further, parameterize the space of all solutions of lowest degree.*

We wish to rephrase this as a problem in intersection theory, and eventually in terms of multiplying cohomology classes. The first step is to identify the space in which the solutions are sought. Let $\mathcal{M}_n$ be the space of all maps ϕ of degree n from $\mathbb{P}^1$ into G and let $\overline{\mathcal{M}_n}$ be the compactification of this space, constructed in [13] and [9]. The space $\overline{\mathcal{M}_n}$ is a smooth, connected, compact manifold and therefore one can use intersection theory on this space. The next step is to identify the subsets of $\overline{\mathcal{M}_n}$ which are being intersected. We observe that for each of the points $x_i \in \mathbb{P}^1$, there is an evaluation map $\mathrm{ev}_i : \mathcal{M}_n \to G$ that takes a map $\phi \in \mathcal{M}_n$ to its value at x_i. Now we want to decide if $\cap_{i=1}^{\ell}\mathrm{ev}_i^{-1}(W_i)$ is empty and more specifically, we want to parameterize the intersection. We also note that by [4, Lemma 2.2A], if $x_1,\dots,x_\ell$ are distinct points and the W_i are in general position, then $\cap_{i=1}^{\ell}\mathrm{ev}_i^{-1}(W_i)$ is Zariski dense in $\cap_{i=1}^{\ell}\overline{\mathrm{ev}_i^{-1}(W_i)}$.

The next step is to identify the cohomology ring of $\overline{\mathcal{M}_n}$, identify the Poincaré duals of the subvarieties $\overline{\mathrm{ev}_i^{-1}(W_i)}$, and compute their product. We note that we are not interested in arbitrary products in the cohomology ring $H^*(\overline{\mathcal{M}_n},\mathbb{C})$ but only of those classes that arise from pullbacks of Schubert varieties through evaluation maps. It turns out that the quantum cohomology ring is set up to do precisely such calculations. Now we need to identify the cohomology classes involved. It would be most convenient to express the cohomology classes of $\mathrm{ev}_i^{-1}(W_i)$ as pullbacks of the Poincaré duals of W_i through the map on cohomology induced by the evaluation maps ev_i. While this description is quite simple, there are some technical problems. The evaluation map is not defined on all of $\overline{\mathcal{M}_n}$, but only on an open set and does not directly induce a map on cohomology rings. We will specify one way of getting around these difficulties in what follows.

The space $\overline{\mathcal{M}_n}$ has a cellular decomposition [13, Theorem 1.3], so its cohomology ring is isomorphic to its Chow ring. Specifically, $H^{2k+1}(\overline{\mathcal{M}_n},\mathbb{C}) = 0$ and $H^{2k}(\overline{\mathcal{M}_n},\mathbb{C}) \simeq A^k(\overline{\mathcal{M}_n},\mathbb{C})$, the group of codimension k cycles on $\overline{\mathcal{M}_n}$ (with complex coefficients) modulo rational equivalence. The evaluation maps can be thought of as rational maps from the compactification $\overline{\mathcal{M}_n}$ to G that are defined on at least the open set $\mathcal{M}_n \subset \overline{\mathcal{M}_n}$. The closure of the graph of this map in $\overline{\mathcal{M}_n} \times G$ is a correspondence, which gives a map $\mathrm{ev}_i^* : A^*(G, \mathbb{C}) \to A^*(\overline{\mathcal{M}_n}, \mathbb{C})$ [6, Chapter 16]. Since we can identify the Chow ring with the cohomology ring, for both $\overline{\mathcal{M}_n}$ and G, we get a map on cohomology: $\mathrm{ev}_i^* : H^*(G, \mathbb{C}) \to H^*(\overline{\mathcal{M}_n}, \mathbb{C})$. We should point out that the maps ev_i^* are *not* ring homomorphisms but just linear maps between vector spaces. The map induced on cohomology by the evaluation map is independent of the point x_i, namely, the maps $\mathrm{ev}_i^* = \mathrm{ev}^*$ for all i [4, Cor. 2.3]. Also, if ξ_i is Poincaré dual to the class of the Schubert variety W_i in G, then $\mathrm{ev}_i^*(\xi_i) = \mathrm{ev}^*(\xi_i)$ is Poincaré dual to $\overline{\mathrm{ev}_i^{-1}(W_i)}$ in $\overline{\mathcal{M}_n}$.

With all of these preliminaries out of the way, Problem 1.1 can be reformulated as follows.

PROBLEM 1.2. *Let ξ_i be the Poincaré dual of the class of the subvariety W_i in $H^*(G, \mathbb{C})$. Find the lowest integer n, such that the product $ev^*(\xi_1) \cdots ev^*(\xi_\ell) \in H^*(\overline{\mathcal{M}_n}, \mathbb{C})$ is not zero and find the product for such an n.*

The answer to the question posed above will be given in terms of the quantum cohomology ring of the Grassmannian.

We will first recall the definition of the quantum cohomology ring, as given in [3]. Recall that there is a nondegenerate inner product $(\cdot \mid \cdot)$ on $H^*(G, \mathbb{C})$ defined as follows. For ξ and $\eta \in H^*(G, \mathbb{C})$, define

$$(\xi \,|\, \eta) = \int_G \xi\eta.$$

This inner product is dual, via Poincaré duality, to the intersection pairing on homology. Note that if ξ is dual to η with respect to the inner product $(\cdot \mid \cdot)$, then $\deg \eta + \deg \xi = \dim G = mp$ (all references to dimension and codimension in this paper will be to complex dimension and complex codimension). For future reference we note that the dual of the cohomology class Y_m^i with respect to the inner product $(\cdot \,|\, \cdot)$ is Y_m^{p-i} and the dual of $(-1)^i X_p^i$ is $(-1)^{m-i} X_p^{m-i}$.

Now, given two cohomology classes ξ and η as above, their quantum product $\xi \star \eta$ is defined as follows:

$$\xi \star \eta = (\xi \star \eta)_0 + q(\xi \star \eta)_1 + \cdots q^j (\xi \star \eta)_j + \cdots ,$$

where

$$((\xi \star \eta)_j \,|\, \alpha) = \int_{\overline{\mathcal{M}_j}} \mathrm{ev}^*(\xi)\mathrm{ev}^*(\eta)\mathrm{ev}^*(\alpha) \tag{2}$$

In particular, $(\xi \star \eta)_0 = \xi \cdot \eta$ is the usual cohomology product. Further, since the product in (2) is zero unless $\deg \xi + \deg \eta + \deg \alpha = \dim \overline{\mathcal{M}_j} = mp + (m+p)j$, the series in (2) is a polynomial with only finitely many nonzero terms and the degree of $(\xi \star \eta)_j$ is $\deg \xi + \deg \eta - (m+p)j$.

Let $W_1, \ldots, W_{\ell+1}$ be subvarieties of the Grassmannian in general position, and let ξ_i be the cohomology class in $H^*(G, \mathbb{C})$ that is Poincaré dual to W_i. Suppose $\xi_1 \star \cdots \star \xi_\ell = \sum_{d \geq 0} q^d \alpha_d$ and $(\alpha_d \,|\, \xi_{\ell+1}) \neq 0$. Then if the points x_i are distinct, the intersection $\cap_{i=1}^{\ell+1} \overline{\mathrm{ev}_i^{-1}(W_i)}$ in $\overline{\mathcal{M}_d}$ is nonempty. Further, $\cap_{i=1}^{\ell} \mathrm{ev}_i^{-1}(W_i) \subset \mathcal{M}_d$ is also nonempty.

PROPOSITION 1.3. *Let ξ_i be the Poincaré dual of the class of the subvarieties $W_i \subset G$. Let the quantum product*

$$\xi_1 \star \cdots \star \xi_\ell = \sum_{d \geq 0} q^d \alpha_d,$$

where $\alpha_d \in H^*(G,\mathbb{C})$, and let n be the smallest integer such that $\alpha_n \neq 0$. Then, for subvarieties W_i in general position and n distinct points $x_i \in \mathbb{P}^1$, the lowest degree of a curve $\phi : \mathbb{P}^1 \to G$ such that $\phi(x_i) \in W_i$ is equal to n.

The final piece of the puzzle comes from an explicit characterization of the quantum cohomology ring of the Grassmannian.

THEOREM 1.4 (see [12]). *The quantum cohomology ring $QH^*(G)$ of the Grassmannian is the polynomial ring $\mathbb{C}[X_1,\dots,X_p,q]$ modulo the ideal generated by $(Y_{m+1},\dots,Y_{m+p}+(-1)^p q)$, where the Y_i are as defined in* (1).

We will denote the i-fold quantum product $\xi \star \cdots \star \xi$ by $\xi^{\star i}$ and the regular i-fold cohomology product $\xi \cdots \xi$ by ξ^i, as we have already used this notation in the introduction where we identified the Poincaré duals of $[R_i]$ and $[L_i]$.

LEMMA 1.5. *For $1 \le i \le p$, $Y_m^{\star i} = Y_m^i$, and for $1 \le j \le m$, $X_p^{\star i} = X_p^i$.*

Proof. We will use the quantum Pieri formula proved in [4]. The particular case of the formula that we need can be stated as follows:

$$\{m,0,\dots,0\} \star \{\lambda_1,\dots,\lambda_p\} = \{m,0,\dots,0\} \cdot \{\lambda_1,\dots,\lambda_p\} + q\left(\sum \{\mu_1,\dots,\mu_p\}\right), \tag{3}$$

where the last sum ranges over all p-tuples μ that satisfy the following conditions:

$$\sum \mu_i = \left(\sum \lambda_i\right) - p \text{ and } \lambda_1 - 1 \ge \mu_1 \ge \lambda_2 - 1 \ge \mu_2 \cdots \ge \lambda_p - 1 \ge \mu_p \ge 0. \tag{4}$$

As we have noted before $Y_m^i = \{\lambda_1,\dots,\lambda_p\}$, where $\lambda_1 = \cdots = \lambda_i = m$ and $\lambda_{i+1} = \cdots = \lambda_p = 0$. Therefore for $i \le p-1$, the quantum product $Y_m \star Y_m^i = Y_m^{i+1}$, since there are no p-tuples μ that can satisfy the condition $-1 = \lambda_p - 1 \ge \mu_p \ge 0$.

Let $G' = \text{Grass}(m, p+m)$ be the Grassmannian of m-dimensional planes in $\mathbb{C}^{p+m}$. Then $QH^*(G') = \mathbb{C}[\sigma_1,\dots,\sigma_m]/(\tau_{p+1},\dots,\tau_{p+m}+(-1)^m q)$, where the τ_i are defined analogously to the Y_i in (1), namely,

$$\tau_i = -\tau_{i-1}\sigma_1 - \cdots - \tau_1\sigma_{i-1} - \sigma_i.$$

Then, according to [5, Proposition 4.1], the map from $QH^*(G)$ to $QH^*(G')$ that takes X_i to τ_i is an isomorphism. Now, it follows from the first half of the proof that $\tau_p^{\star i} = \tau_p^i$ for $1 \le i \le m$. Thus $X_p^{\star i} = X_p^i$ for $1 \le i \le m$. □

2. Interpolation problems. In this section we use the machinery set up in the introduction to solve the matrix interpolation and the left and right tangential interpolation problems. First we briefly recall the statement of these problems, along with their reformulation in [2] as special cases of Problem 1.1, and then their reformulation in terms of quantum cohomology.

2.1. Matrix interpolation problem. Given ℓ points $x_1,\dots,x_\ell \in \mathbb{P}^1$ and $p \times m$ scalar matrices $Z_1,\dots,Z_\ell$, we wish to find a rational matrix of least McMillan degree $Z(s)$ such that $Z(x_i) = Z_i$. The solution to this problem is known; see [1] and [8].

If $Z(s) = D_L^{-1}N_L$ is a left coprime factorization of $Z(s)$, then the condition that $Z(x_i) = Z_i$ can be restated as $(D_L(s) \,|\, N_L(s))(x_i) = (I_p \,|\, Z_i)$. Thus as reformulated in [2], the solutions to this problem consist of maps ϕ from $\mathbb{P}^1$ into G, such that $\phi(x_i) = (I_p \,|\, Z_i)$ for $i = 1,\dots,\ell$ and the McMillan degree of $Z(s)$ equals the degree of the map ϕ from $\mathbb{P}^1$ to G. The conditions being imposed at each point x_i are that the evaluation at that point should be a specified point in the Grassmannian. As seen before the Poincaré dual of the class of a point is Y_m^p. Thus according to

Proposition 1.3, the quantum product that represents the solution to this problem is $(Y_m^p)^{\star\ell}$. By Lemma 1.5 this is equal to $Y_m^{\star p\ell}$.

We will now compute this product using our description of the quantum cohomology ring. First we let $p\ell = a(m+p)+b$, where $a \geq 0$ and $0 \leq b < m+p$. Then $Y_m^{\star p\ell} = (Y_m^{\star(m+p)})^{\star a} Y_m^{\star b}$. Now since $Y_m^{\star p} = Y_m^p = (-1)^{mp}(X_p)^m = (-1)^{mp} X_p^{\star m}$, we have $Y_m^{\star(m+p)} = (-1)^{mp} Y_m^{\star m} \star X_p^{\star m}$. The last relation in the ideal of the quantum cohomology ring implies that $X_p \star Y_m = (-1)^p q$. Therefore $Y_m^{\star(m+p)} = (-1)^{2mp} q^m = q^m$. Finally, if $p < b < m+p$, then we can write

$$\begin{aligned} Y_m^{\star b} &= Y_m^{\star p} Y_m^{\star(b-p)} = (-1)^{mp} X_p^{\star m} \star Y_m^{\star(b-p)} = (-1)^{mp+p(b-p)} q^{b-p} X_p^{\star(m+p-b)} \\ &= ((-1)^p X_p)^{\star(m+p-b)} q^{b-p}. \end{aligned}$$

Putting all of this together,

$$Y_m^{\star p\ell} = \begin{cases} q^{am} Y_m^b & \text{if } b \leq p, \\ q^{am+b-p}((-1)^p X_p)^{m+p-b} & \text{if } p < b < m+p. \end{cases}$$

In either of these cases, it is easy to verify that the exponent of q can also be characterized as the smallest integer n such that the dimension of $\overline{\mathcal{M}_n}$ which is $n(m+p)+mp$ is greater than or equal to $mp\ell$, which can be thought of as the "number of conditions imposed."

2.2. Right tangential interpolation. Here we are given ℓ distinct points, $x_1, \dots, x_\ell \in \mathbb{C}$ and $m \times s_i$ matrices W_i and $p \times s_i$ matrices Z_i, such that the rank of $W_i = s_i \leq m$. We wish to find the lowest degree of all $p \times m$ rational matrices $Z(s)$ such that $Z(x_i)W_i = M_i$ for $i = 1, \dots, \ell$. If $Z = D_L^{-1} N_L$ is a left coprime factorization of the matrix $Z(s)$, then one can rewrite the interpolating condition as $N_L(x_i)W_i = D_L(x_i)Z_i$. Thus in terms of curves from $\mathbb{P}^1$ into G, one is looking for a map ϕ such that $\phi(x_i) \subset M_i$, where M_i is a linear subspace of $\mathbb{C}^{m+p}$ of codimension s_i, defined by $M_i \cdot \left(\begin{smallmatrix} W_i \\ -Z_i \end{smallmatrix} \right) = 0$. Now the Poincaré dual of the Schubert variety R_i, consisting of all points in G whose span is contained in M_i, is $(-1)^{ps_i} X_p^{s_i}$. So the quantum product to be computed here is $(-1)^{ps_1} X_p^{s_1} \star \cdots \star (-1)^{ps_\ell} X_p^{s_\ell}$ which by Lemma 1.5 is $(-1)^{ps} X_p^{\star s}$, where $s = \sum s_i$.

As in the previous section, we start by writing $s = a(m+p)+b$, where $0 \leq b < m+p$. Further, $(-1)^{p(m+p)} X_p^{\star(m+p)} = (-1)^{p^2} X_p^p \star Y_m^p = q^p$ by a calculation similar to the last section. If $m < b < m+p$, we can write

$$\begin{aligned} (-1)^{pb} X_p^{\star b} &= (-1)^{pb} X_p^m \star X_p^{b-m} = (-1)^{p(b-m)} Y_m^p \star X_p^{b-m} = (-1)^{2p(b-m)} q^{b-m} Y_m^{m+p-b} \\ &= q^{b-m} Y_m^{m+p-b}. \end{aligned}$$

Thus, as in the previous section we get two cases:

$$(-1)^{ps} X_p^{\star s} = \begin{cases} q^a (-1)^{pb} X_p^b & \text{if } b \leq m, \\ q^{a+b-m} Y_m^{m+p-b} & \text{if } m < b < m+p. \end{cases} \tag{5}$$

One can again characterize the exponent of q in either of these cases as the smallest integer n such that $n(m+p)+mp \geq ps$.

2.3. Left tangential interpolation. Here we are given ℓ distinct points, $x_1, \dots, x_\ell \in k$ and $r_i \times p$ matrices V_i and $r_i \times m$ matrices Z_i, such that rank of $V_i = r_i \leq p$. We wish to find the lowest degree of a $p \times m$ rational matrix $Z(s)$ such that $V_i Z(x_i) = Z_i$ for $i = 1, \dots, \ell$. As in [2], if we let $Z(s) = N_R D_R^{-1}$ be the right coprime factorization, then the required condition can be expressed as $(V_i \mid Z_i) \cdot \left(\begin{smallmatrix} N_R \\ -D_R \end{smallmatrix}\right)(x_i) = 0$. The relation $(D_L \mid N_L) \cdot \left(\begin{smallmatrix} N_R \\ -D_R \end{smallmatrix}\right) = 0$ between the left and right coprime factorizations implies that one wants the row span N_i of $(V_i \mid Z_i)$ to be contained in the row span of $(D_L \mid N_L)(x_i)$, where N_i is a subspace of $\mathbb{C}^{m+p}$ of dimension r_i. The Poincaré dual of the Schubert variety L_i of all points in G whose span contains N_i is $Y_m^{r_i}$. The quantum product to be computed here is $Y_m^{r_1} \star \cdots \star Y_m^{r_\ell}$ which by Lemma 1.5 is $Y_m^{\star r}$, where $r = \sum r_i$.

As in section 2.1 if one writes $r = a(m+p) + b$, where $0 \leq b < m+p$, then

$$Y_m^{\star r} = \begin{cases} q^a Y_m^b & \text{if } b \leq p, \\ q^{a+b-p}((-1)^p X_p)^{m+p-b} & \text{if } m+p > b > p. \end{cases} \tag{6}$$

The calculations that we have made in each of the three cases above can all be put together in the following lemma. The lemma is of independent interest because it deals with the quantum computation needed for the bitangential interpolation problem, and also provides a justification for the definition of linear interpolation problems.

Lemma 2.1. *The product $(-1)^{pa} X_p^{\star a} \star Y_m^{\star b}$ in the quantum cohomology ring $QH^*(G)$ can be rewritten as a power of q times $(-1)^{pc} X_p^c$, where $c \leq m$, or as a power of q times Y_m^d, where $d \leq p$.*

Proof. The last relation in the presentation of the quantum cohomology ring given in Theorem 1.4 specifies that $X_p \star Y_m = (-1)^p q$ in the quantum cohomology ring. Using this relation, one can rewrite $(-1)^{pa} X_p^{\star a} \star Y_m^{\star b}$ as $(-1)^{2pa} q^a Y_m^{\star(b-a)} = q^a Y_m^{\star(b-a)}$, if $b > a$ and as $(-1)^{p(a+b)} q^b X_p^{\star(a-b)} = (-1)^{p(a-b)} q^b X_p^{\star(a-b)}$ if $a \geq b$. As we have seen in (5) and (6), any quantum power of Y_m or $(-1)^p X_p$ can be rewritten as claimed in the lemma. □

Given an interpolation problem of the form given in Problem 1.1, where the interpolating conditions can be expressed in terms of the cohomology classes Y_m and $(-1)^p X_p$ alone, the lemma above shows that there exists a unique interpolating condition, corresponding to a cohomology class which can also be given in terms of these cohomology classes, namely $(-1)^{p(m-c)} X_p^{m-c}$ or Y_m^{p-d}, such that imposing this additional condition on the original interpolation problem yields a unique solution of minimal degree. In this sense the solution set to the original interpolation problem is "weakly dual" to that of the interpolation problem corresponding to the condition given by the classes $(-1)^{p(m-c)} X_p^{m-c}$ or Y_m^{p-d}. A stronger duality statement, which we had hoped to prove at first, would be to say that the cohomology class corresponding to the product of the interpolating conditions is dual in the cohomology ring $H^*(\overline{\mathcal{M}_n}, \mathbb{C})$ to the pullback of $(-1)^{p(m-c)} X_p^{m-c}$ or Y_m^{p-d}, where n is the minimal degree of the interpolants, and the duality is taken with respect to the inner product $(\cdot \mid \cdot)$ in $H^*(\overline{\mathcal{M}_n}, \mathbb{C})$. We are unable to prove this statement. The problem arises because the product of cohomology classes of the interpolating conditions in $H^*(\overline{\mathcal{M}_n}, \mathbb{C})$ might contain some boundary components that are not in general identifiable using quantum products which only compute the products of pullbacks of classes from $H^*(G, \mathbb{C})$.

The matrix interpolation and the tangential problems form a distinguished class of interpolation conditions in the following sense: given any problem in this class the solution set is weakly dual to that of another interpolation problem from this same class. So we can call the interpolation conditions from this class as linear conditions. This should be contrasted with the pole placement problem which is equivalent to finding maps ϕ from $\mathbb{P}^1$ to G such that at the specified points x_i the span of $\phi(x_i)$ has a nontrivial intersection with a specified m-plane Λ_i. One checks easily that the quantum cohomology product that needs to be computed in this case is $(-X_1)^{\star\ell}$, where ℓ is the number of points at which this condition is imposed. The term of lowest degree in q in this product was computed explicitly in [10] and [11]. The main point of interest for the present discussion is that the product $(-X_1)^{\star\ell}$ has terms of multiplicity greater than one, and in particular for the values of ℓ for which there are only finitely many solutions of minimal degree, the solutions are not unique. Hence these interpolation conditions are *nonlinear* by any reasonable definition of the term.

An important question in this context, which we cannot answer at this point, is the following: Given that the intersection multiplicity of a class of interpolation problems is always one, does the existence of a linear algorithm necessarily follow? In other words, can one find a linear algorithm based on the intersection computations alone?

Acknowledgments. We would like to thank the anonymous referees for a thorough reading and their constructive criticisms.

DEGENERATE OPTIMAL CONTROL PROBLEMS WITH STATE CONSTRAINTS*

FRANCO RAMPAZZO[†] AND RICHARD VINTER[‡]

Abstract. Standard necessary conditions for optimal control problems with pathwise state constraints supply no useful information about minimizers in a number of cases of interest, e.g., when the left endpoint of state trajectories is fixed at x_0 and x_0 lies in the boundary of the state constraint set; in these cases a nonzero, but nevertheless trivial, set of multipliers exists. We give conditions for the existence of nontrivial multipliers. A feature of these conditions is that they allow nonconvex velocity sets and measurably time-dependent data. The proof techniques are based on refined estimates of the distance of a given state trajectory from the set of state trajectories satisfying the state constraint, originating in the dynamic programming literature.

Key words. optimal control, necessary conditions, nonsmooth analysis, state constraints

1. Introduction.

Consider the optimal control problem

$$
\text{(P)} \qquad \begin{cases} \text{Minimize } g(x(0), x(1)) \\ \text{over } x \in W^{1,1}([0,1]; R^n) \text{ satisfying} \\ \dot{x}(t) \in F(t, x(t)) \text{ almost everywhere (a.e.),} \\ (x(0), x(1)) \in C_0 \times C_1, \\ x(t) \in A \text{ for all } t \in [0,1] \end{cases}
$$

for which the data comprises a function $g : R^n \times R^n \to R$, closed sets A, C_0, and C_1 in R^n, and a multifunction $F : [0,1] \times R^n \rightsquigarrow R^n$. Here, $W^{1,1}([a,b]; R^n)$ denotes the Banach space of absolutely continuous R^n valued functions on the interval $[a,b]$, with norm

$$
||x||_{W^{1,1}} := |x(a)| + \int_a^b |\dot{x}(t)| dt.
$$

Interest centers on the presence of the state constraint $x(t) \in A$. We shall assume that A is expressible as the set of points satisfying a finite number of functional inequality constraints

$$
A = \bigcap_{j=1}^{m} \{x \in R^n \, : \, h_j(x) \le 0\}.
$$

Here, $h_j : R^n \to R$, $j = 1, \dots, m$, are given functions of class $C^{1,1}$ (functions which are continuously differentiable with locally Lipschitz continuous derivatives). For

simplicity of exposition in this introduction we restrict attention to the case when $m = 1$.

Let $\bar{x}$ be a $W^{1,1}$ local minimizer. This means that $\bar{x}$ is a $W^{1,1}([0,1]; R^n)$ function which satisfies the constraints of (P) and there exists $\delta > 0$ such that, for all $x \in W^{1,1}([0,1]; R^n)$ satisfying the constraints of (P) and also the condition

$$||x - \bar{x}||_{W^{1,1}([0,1];R^n)} \leq \delta,$$

we have

$$g(x(0), x(1)) \geq g(\bar{x}(0), \bar{x}(1)).$$

Necessary conditions for this "differential inclusion problem" with state constraints have been known for many years. (Many advances in this area were prefigured by the work of A. Ja. Dubovitskii and Milyutin in the early 1960s on problems with "mixed" constraints, e.g., [12]. Later publications, making extensive use of nonsmooth analysis, include [9], [26], [19], [30].) The following conditions, which can be deduced from those in [19] or [30], are typical. Under suitable hypotheses on the data for problem (P) (which include the hypothesis that F is convex valued), there exist $p \in W^{1,1}([0,1]; R^n)$, a nonnegative Borel measure $\mu \in C^*([0,1]; R)$, and $\lambda \geq 0$ such that

$$\begin{aligned}
&\lambda + \int_{[0,1]} \mu(ds) + ||p||_{L^\infty} \neq 0, \\
&\text{supp } \{\mu\} \subset \{t : h_1(\bar{x}(t)) = 0\}, \\
(1.1) \quad &-\dot{p}(t) \in \\
&\quad \text{co} \left\{ q : (q, \dot{\bar{x}}(t)) \in \partial H \left(t, \bar{x}(t), p(t) + \int_{[0,t)} \nabla h_1(\bar{x}(t))\mu(ds) \right) \right\} \quad \text{a.e.}, \\
&\left(p(0), -\left[p(1) + \int_{[0,1]} \nabla h_1(\bar{x}(t))\mu(ds) \right] \right) \\
&\quad \in \lambda \partial g(\bar{x}(0), \bar{x}(1)) + N_{C_0}(\bar{x}(0)) \times N_{C_1}(\bar{x}(1)).
\end{aligned}$$

Here, ∂H is the limiting subdifferential of the Hamiltonian

$$H(t, x, p) := \max_{v \in F(t,x)} p \cdot v$$

with respect to the (x, p) variables. $N_S(y)$ denotes the limiting normal cone of the closed set S at the point $y \in S$. $\partial g(y)$ is the limiting subdifferential of g at y. (These constructs are defined below.)

Necessary conditions for optimal control problems with state constraints, in which the dynamic constraint takes the traditional form of a parameterized family of differential equations, have an even longer history. (See, for example, [11], [22], [31].)

Now, necessary conditions such as those above convey no useful information about minimizers in certain important special cases. Consider, for example,

$$C_0 = \{x_0\} \text{ and } h_1(x_0) = 0$$

for some point $x_0 \in R^n$ such that $\nabla h_1(x_0) \neq 0$ (the case when the left endpoint is fixed at x_0 , and x_0 lies in the boundary of the state constraint set). Then the above conditions are satisfied with the nonzero multiplier set

$$(1.2) \qquad \lambda = 0, \ \mu = \delta_{\{0\}}, \ \text{ and } \ p(.) \equiv -\nabla h_1(x_0)$$

for *any* arc $\bar{x}$ which satisfies the constraints of problem (P). Here $\delta_{\{0\}}$ is the unit measure concentrated at $\{0\}$.

There is a growing literature, nondegenerate necessary conditions, which aims at supplying useful information about minimizers in cases such as that just described. (Early papers were [7], [3], [10].) Refinements of the standard necessary conditions have been proved which assert that, under a suitable constraint qualification concerning the dynamic constraint and the state constraint, the existence of a multiplier set (λ, μ, p) *distinct* from the trivial multiplier set (1.2) is guaranteed. We note, in particular, recent advances due to Arutyunov, Aseev, and Blagodat-Skikh [4], Arutyunov and Aseer [5], [6], and Aseev [8], in which the traditional conditions are supplemented with a new boundary condition on the Hamiltonian which, when coupled with a constraint qualification, excludes the trivial multiplier set.

For the most part, nondegenerate necessary conditions for problems with general endpoint constraints and nonsmooth data have been derived under hypotheses which require the following.

(i) $F(t, x)$ is Lipschitz continuous with respect to both t and x variables.

(ii) F takes values convex sets.

The proof techniques of [4], for example, depend critically on such hypotheses. This is because time is treated as a state-like variable (and the more stringent hypotheses governing x-dependence of F for purposes of deriving necessary conditions must therefore be extended to t-dependence) and because the perturbational analysis, based on weak convergence of velocities, breaks down when F is not convex valued.

The contribution of this paper is a methodology for deriving nondegenerate necessary conditions under hypotheses *which apply to problems with general endpoint constraints and which at the same time allow measurable time dependence and also nonconvex F's.* The methodology is to exploit estimates on the distance of a given state trajectory (which violates the state constraint) from the set of state trajectories which satisfy the state constraint. The original motivation for deriving estimates of this nature was their relevance to dynamic programming, specifically their role in proving regularity properties of value functions for optimal control problems with state constraints. The main contribution of this paper is to demonstrate the significance of these estimates also to the derivation of necessary conditions.

Different methods were used in [15] and [16] to derive nondegenerate necessary conditions for nonconvex problems, based on singular transformations and state constraint relaxation at the endpoints, respectively. The optimality conditions of [16] are formulated for a more general class of state constraints than that considered here. However, the present paper improves on these earlier results, in respect of the constraint qualifications invoked to validate optimality conditions. The constraint qualifications of [15] and [16] are expressed in terms of the minimizer we seek and therefore are not, in general, open to direct verification. The constraint qualification of this paper, like that of [4], is a simple hypothesis on the problem data, requiring the existence of inward pointing admissible velocities at all relevant points of the state constraint boundary.

Throughout, B will denote the closed unit ball in Euclidean space. We shall write $d_S : R^k \to R$ for the Euclidean distance function from a set $S \subset R^k$:

$$d_S(x) := \inf \{|x - y| : y \in S\}.$$

The *limiting normal cone* $N_S(x)$ of a closed set $S \subset R^k$ at $x \in S$ is defined to be

$$N_S(x) := \{\xi \,:\, \exists \text{ sequences } \{M_i\} \text{ in } (0, \infty),\, x_i \to x,\, \xi_i \to \xi \quad \text{such that}$$

$$x_i \in S \text{ and } \xi_i \cdot (y - x_i) \le M|y - x_i|^2 \quad \text{for all } y \in R^k,\ i = 1, 2, \ldots\}.$$

Given a lower semicontinuous function $f : R^k \to R \cup \{\infty\}$, the *limiting subdifferential* of f at a point $x \in R^k$ such that $f(x) < +\infty$ is the set

$$\partial f(x) := \{\xi : (\xi, -1) \in N_{\text{epi}\, f}(x, f(x))\}\,.$$

Here, epi f denotes the epigraph set of the function f. Properties of these constructs from nonsmooth analysis are reviewed in detail in [25] and [28]. See also [18], [20].

2. Nondegenerate necessary conditions. In this section are stated the main results of the paper, namely nondegenerate necessary conditions for problem (P), covering cases when the velocity set $F(t, x)$ is nonconvex valued, and measurably time-dependent.

We shall assume, as in the preceding section, that the state constraint set A takes the form

$$A = \bigcap_{j=1}^{m} \{x : h_j(x) \le 0\}$$

for some functions $h_j : R^n \to R$, $j = 1, \ldots, m$, of class $C^{1,1}$, but now we allow $m > 1$.

THEOREM 2.1. *Let $\bar{x}$ be a $W^{1,1}$ local minimizer for problem* (P). *Assume that, for some $k_F \in L^1$ and positive constants δ, ϵ, c, and r, the following hypotheses are satisfied.*

(H1) *F has values closed sets, $F(., x)$ is measurable for each $x \in R^n$,*

$$\begin{aligned} &F(t, x) \subset cB \quad \text{for all } x \in \bar{x}(t) + \delta B,\ t \in [0, 1], and \\ &F(t, x) \subset F(t, x') + k_F(t)|x - x'|B \quad \text{for all } x, x' \in \bar{x}(t) + \delta B, t \in [0, 1]. \end{aligned}$$

(H2) *g is Lipschitz continuous on $(\bar{x}(0), \bar{x}(1)) + \delta(B \times B)$.*

We impose, furthermore, the following constraint qualification.

(CQ) *For each $t \in [0, \epsilon]$ and $\xi \in \bar{x}(0) + \delta B$,*

$$\min\nolimits_{v \in F(t,\xi)} \nabla h_j(\xi) \cdot v < -r \tag{2.1}$$

for all index values j such that $h_j(\bar{x}(0)) = 0\}$.

Then there exist $p \in W^{1,1}([0, 1]; R^n)$, $\lambda \ge 0$, and nonnegative Borel measures $\mu_j \in C^*([0, 1]; R^n)$, $j = 1, \ldots, m$, such that

$$\lambda + \int_{(0,1]} \sum_j \mu_j(ds) + \left| p(0) + \sum_j \nabla h_j(\bar{x}(0))\mu_j(\{0\}) \right| \ne 0,$$

$$\begin{aligned} \dot{p}(t) \in co \Bigg\{ q : \Bigg(q, p(t) + \int_{[0,t)} \sum_j \nabla h_j(\bar{x}(s))\mu_j(ds) \Bigg) \\ \in N_{\text{Gr}F(t,.)}(\bar{x}(t), \dot{\bar{x}}(t)) \Bigg\} \quad a.e., \end{aligned} \tag{2.2}$$

$$\begin{aligned} \Bigg(p(0), -\Bigg(p(1) + \int_{[0,1]} \sum_j \nabla h_j(\bar{x}(s))\mu_j(ds) \Bigg)\Bigg) \\ \in \lambda \partial g(\bar{x}(0), \bar{x}(1)) + N_{C_0 \cap A}(\bar{x}(0)) \times N_{C_1}(\bar{x}(1)), \end{aligned}$$

$$\left(p(t)+\int_{[0,t)}\sum_j \nabla h_j(\bar{x}(s))\mu_j(ds)\right)\cdot\dot{\bar{x}}(t) \tag{2.3}$$
$$=\max_{v\in F(t,\bar{x}(t))}\left(p(t)+\int_{[0,t)}\sum_j \nabla h_j(\bar{x}(s))\mu_j(ds)\right)\cdot v \quad a.e.,$$
$$\operatorname{supp}\{\mu_j\}\subset\{t:h_j(\bar{x}(t))=0\}\quad \textit{for } j=1,\dots,m.$$

If, furthermore, it is assumed that F is convex valued, then (2.2) *implies condition* (2.3) *and also*

$$\dot{p}(t)\in co\left\{q:(-q,\dot{\bar{x}}(t))\right.$$
$$\left.\in\left(t,\bar{x}(t),p(t)+\int_{[0,t)}\sum_j\nabla h_j(\bar{x}(s))\mu_j(ds)\right)\right\}\quad a.e. \tag{2.4}$$

Remarks.

(i) The most significant feature of this theorem is that the customary condition

$$\lambda+||p||_{L^\infty}+\int_{[0,1]}\sum_j\mu_j(ds)\neq 0$$

has been replaced by the condition

$$\lambda+\int_{(0,1]}\sum_j\mu_j(ds)+\left|p(0)+\sum_j\nabla h_j(\bar{x}(0))\mu_j(\{0\})\right|\neq 0.$$

Notice that, if $C_0=\{x_0\}$ and $m=1$, then the theorem does not allow the trivial choice of multipliers

$$\lambda=0,\ p\equiv-\nabla h_1(\bar{x}(0)),\ \mu_1=\delta_{\{0\}},$$

since, for this choice,

$$\lambda=0,\ \int_{(0,1]}\mu_1(ds)=0,$$

and

$$p(0)+\nabla h_1(\bar{x}(0))\mu_1(\{0\})=-\nabla h_1(\bar{x}(0))+\nabla h_1(\bar{x}(0))=0.$$

(ii) The hypotheses of the theorem are less restrictive than those representative of earlier work, in so far as they allow the dynamic constraint multifunction F to be discontinuous as a function of the time variable and to take values nonconvex sets. On the other hand, we restrict attention to problems with a state constraint set which is independent of time and is represented by a finite collection of "smooth" inequality constraints.

(iii) The need for some kind of constraint qualification, of which (2.1) is an example, is clarified by an example devised by A. Ya. and V. A. Dubovitskii and reproduced in [6], in which there are no "inward pointing" velocities at the left endpoint and the only Lagrange multipliers are trivial ones.

(iv) The “adjoint inclusion” (2.2) appearing in these optimality conditions is a “partially convexified” version of the nonsmooth Euler Lagrange condition

$$\left(\dot{p}(t), p(t) + \int_{[0,t)} \sum_{j=1}^{m} \nabla_j h_j(\bar{x}(s))\mu(ds)\right) \in \operatorname{co} N_{\mathrm{Gr}F(t,.)}(\bar{x}(t), \dot{\bar{x}}(t)).$$

Necessary conditions involving the adjoint inclusion (2.2) have attracted attention in recent years, because of the unrestrictive nature of the hypotheses under which they can be derived. They are valid, in particular, when F is no longer assumed to be convex valued. (See [17], [21], [29]). This adjoint inclusion has been used in connection with nondegenerate necessary conditions by Aseev [8] (for “convex” state constrained problems with Lipschitz time-dependent data).

(v) The theorem will be proved by applying necessary conditions (involving the partially convexified Euler Lagrange inclusion above) along a suitably chosen sequence of auxiliary optimization problems, and passage to the limit. We stress, however, that the analysis in this paper is independent of the particular necessary conditions applied to the auxiliary problem. Indeed, we provide a methodology for supplementing a given set of necessary conditions with additional information to ensure nondegeneracy in the sense described in section 1. Other known necessary conditions of choice may be inserted into the analysis to follow. In particular, our methods can be used to prove a nondegenerate form of the Pontryagin maximum principle for state constrained problems. (See [23].)

(vi) Theorem 2.1 does not exclude the degenerate set of multipliers when there is a fixed *right* endpoint ($C_1 = \{x_1\}$) with x_1 a boundary point of A. In this respect, Theorem 2.1, when specialized to the case when F is convex valued and Lipschitz continuous with respect to t, is weaker than the corresponding necessary conditions in [6]. This pathology does not arise, however, in the cases when $\bar{x}(1)$ is interior to either A or C_1.

3. Existence of locally feasible arcs. Take a multifunction $F : [0,1] \times R^n \rightsquigarrow R^n$ and a closed subset $A \subset R^n$.

In the framework of viability theory [1], conditions have been extensively studied under which there exists an F-trajectory $\hat{x}(\cdot)$ with a specified initial value, which satisfies the state constraint

$$\hat{x}(t) \in A \qquad \text{for all } t \in [0, \epsilon']$$

for some $\epsilon' > 0$.

Now suppose

$$A = \bigcap_{j=1}^{m} \{x : h_j(x) \leq 0\}$$

for some functions $h_j : R^n \to R$, $j = 1, \ldots, m$, of class $C^{1,1}$.

Take a nominal F-trajectory x with initial value in A but which possibly fails to satisfy the state constraint on $[0, \epsilon']$. In this paper we shall make use of a refinement of basic existence theorems of viability theory, in which we not only assert (under appropriate additional hypotheses) the existence of an F-trajectory $\hat{x}$ with initial value $x(0)$ satisfying the state constraint but also estimate its "distance" from the nominal trajectory x. Specifically, we show that x can be chosen to satisfy

$$||x - \hat{x}||_{W^{1,1}} \leq K \max_{t \in [0,\epsilon']} h^+(x(t)) \tag{3.1}$$

for some K, independent of the nominal trajectory x. Here

$$h^+(x) := \max\{0, h_1(x), \dots, h_m(x)\}.$$

The right side of (3.1) is a measure of the extent to which the nominal arc x violates the state constraint. These estimates tell us, not unreasonably, that the smaller the margin by which the nominal trajectory x fails to satisfy the state constraint on $[0, \epsilon']$, the closer we can choose $\hat{x}$ to x.

The earliest results along these lines are apparently due to Soner [27], who gave conditions under which it is possible to construct an F-trajectory $\hat{x}$ obeying the state constraint on $[0, 1]$ and which satisfies the L^∞ estimate

$$||x - \hat{x}||_{L^\infty([0,1];R^n)} \leq K \max_{t \in [0,1]} h^+(x(t)). \tag{3.2}$$

Their role in this earlier application was to establish regularity properties of value functions of optimal control problems with state constraints. Soner assumed that the differential inclusion is parameterizable, i.e., it arises from a differential equation parameterized by a control variable.

The applications in this article require a local, sharpened version of Soner's estimate, which is valid when F is possibly nonconvex valued and nonparameterizable and in which the L^∞ estimate (3.2) is replaced by the $W^{1,1}([0, 1]; R^n)$ estimate

$$||x - \hat{x}||_{W^{1,1}([0,1];R^n)} \leq K \max_{t \in [0,\epsilon']} h^+(x(t)). \tag{3.3}$$

Since the $W^{1,1}([0, 1]; R^n)$ norm is stronger than the $L^\infty([0, 1]; R^n)$ norm, (3.3) conveys more information than (3.2). The extra information is precisely what is required to remove the convexity hypotheses commonly invoked in derivation of nondegenerate necessary conditions in optimal control.

The following theorem is a "local" version (we require satisfaction of the state constraint only on a neighborhood of $t = 0$) of a related "global" existence theorem (accompanied by $W^{1,1}$ estimates) proved in [14].

THEOREM 3.1 (existence of neighboring feasible trajectories). *Take an F-trajectory $\bar{x}$ satisfying*

$$\bar{x}(t) \in A \quad \textit{for all } t \in [0, 1].$$

Assume that, for some $k_F(.) \in L^1$ and positive constants c, δ, r, and ϵ, hypotheses (H1) *and* (H2) *and also the constraint qualification* (CQ) *of Theorem* 2.1 *are satisfied.*

Then there exist constants $\delta' \in (0, \delta)$, $\epsilon' \in (0, \epsilon)$, and $K > 0$ with the following properties. Corresponding to any F-trajectory x which satisfies the conditions

$$x(0) \in A \quad \textit{and} \quad ||x - \bar{x}||_{L^\infty([0,1];R^n)} \leq \delta',$$

an F-trajectory $\hat{x}$ can be found, such that $\hat{x}(0) = x(0)$,

$$\hat{x}(t) \in A \quad \textit{for all } t \in [0, \epsilon'],$$

and

$$||x - \hat{x}||_{W^{1,1}([0,1];R^n)} \;\leq\; K \max_{t \in [0,\epsilon']} h^+(x(t)). \tag{3.4}$$

Proof. We note at the outset that if

$$h_j(\bar{x}(0)) \;<\; 0 \quad \text{for some } j,$$

then, by choosing $\delta' > 0$ and $\epsilon' > 0$ sufficiently small, we can arrange that

$$h_j(x(t)) < 0 \quad \text{for all } t \in [0, \epsilon'],$$

for any F-trajectory satisfying $||x - \bar{x}||_{L^\infty} \leq \delta'$. This means that h_j does not contribute to the estimate (3.4) and can be ignored. Accordingly, we assume

$$h_j(\bar{x}(0)) \;=\; 0 \quad \text{for } j = 1, \ldots, m.$$

Notice also that, by scaling the h_j's (this has no effect on the state constraint set they define), we can also arrange that, for $j = 1, \ldots, m$,

$$|\nabla h_j(y)| \leq 1 \text{ for } y \in \bar{x}(0) + \delta B.$$

Fix $r' \in (0, r)$. Let $\omega : R^+ \to R^+$ be a modulus of uniform continuity for $t \to \int_0^t k_F(s)ds$, i.e., $\omega(s) \downarrow 0$ as $s \downarrow 0$ and $\omega(t - s) \geq \int_s^t k_F(\sigma)d\sigma$ for all $[s,t] \in [0,1]$. Let κ be a Lipschitz constant for ∇h on $\bar{x}(0) + \delta\, B$.

Choose a positive number τ which satisfies

$$\tau < \epsilon,\, \tau < (r - r')(c^2\kappa)^{-1},\, \omega(\tau) < \log\left(\frac{r - r'}{8c} + 1\right),\, 2c\tau e^{\omega(\tau)} < \delta/2. \tag{3.5}$$

Claim. For every $\xi \in A \cap (\bar{x}(0) + (\delta/2)B)$ there exists an F-trajectory $\tilde{x} \in W^{1,1}([0,\tau]; R^n)$ such that $\tilde{x}(0) = \xi$ and

$$h_j(\tilde{x}(t)) \;\leq\; -r't \;\text{ for all } t \in [0,\tau],\, j = 1, \ldots, m.$$

We verify the claim. We can select a measurable map $v : [0,\epsilon] \to R^n$ such that $v(t) \in F(t,\xi)$ a.e. $t \in [0,\epsilon]$, and, for $j = 1, \ldots, m$,

$$\nabla h_j(\xi) \cdot v(t) \;\leq\; -r \quad \text{a.e. } t \in [0,\epsilon].$$

Define

$$z(t) \;=\; \xi + \int_0^t v(s)ds.$$

Note that $z(t) \in \bar{x}(0) + \delta B$ for all $t \in [0,\tau]$. From (3.5) we deduce that, for all $t \in [0,\tau]$ and $j = 1, \ldots, m$,

$$\begin{aligned} h_j(z(t)) &= h_j(\xi) + \int_0^t \nabla h_j(z(t)) \cdot v(s)ds \\ &\leq 0 + \int_0^t \nabla h_j(z(t)) \cdot v(s)ds \\ &\leq \int_0^t \nabla h_j(\xi) \cdot v(s)ds + \int_0^t |\nabla h_j(z(t)) - \nabla h_j(\xi)| \cdot |v(s)|ds \\ &\leq -rt + \kappa c^2 t^2/2 \;\leq\; t(-r + (r - r')/2) \leq -\left(\frac{r + r'}{2}\right) t. \end{aligned}$$

By the Filippov Wazewski theorem [2, p.120], applied to the reference arc z, there exists an F-trajectory $\tilde{x} \in W^{1,1}([0,\tau];R^n)$ such that $\tilde{x}(0)=\xi$ and

$$\begin{aligned}|\tilde{x}(t)-z(t)| &\leq \int_0^t d_{F(s,z(s))}(\dot{z}(s))\exp\left(\int_s^t k_F(\sigma)d\sigma\right)ds\\ &\leq ct\int_0^t k_F(s)\exp\left(\int_s^t k_F(\sigma)d\sigma\right)ds\\ &\leq ct\left(\exp\left(\int_0^t k_F(s)ds\right)-1\right)\\ &\leq ct\left(e^{\omega(t)}-1\right) \;\leq\; \frac{r-r'}{8}t \;\text{ for all } t\in[0,\tau].\end{aligned}$$

But then, since each h_j has a Lipschitz constant not exceeding 1 on $\bar{x}(0)+\delta B$, we have, for $j=1,\ldots,m$,

$$\begin{aligned}h_j(\tilde{x}(t)) &\leq |\tilde{x}(t)-z(t)|+h_j(z(t))\\ &\leq \left(\frac{r-r'}{8}-\frac{r+r'}{2}\right)t \;\leq\; -r't \;\text{ for all } t\in[0,\tau].\end{aligned}$$

The claim is confirmed.

Choose $\epsilon' \in (0,\tau)$ and $\delta' \in (0,\delta/2)$ such that

$$(6c/r')(\kappa c e^{\omega(\epsilon')}\epsilon' + (e^{\omega(\epsilon')}-1)) < 1,\; (6c\delta'/r')\exp\left(\int_0^1 k_F(s)ds\right) \leq \delta/2 \;\text{ and }\; \delta' < \epsilon' r'/3.$$

Let x be any F-trajectory such that $x(0) \in A$ and

$$||x-\bar{x}||_{L^\infty([0,1];R^n)} \;\leq\; \delta'.$$

Define

$$\Delta \;:=\; \max_{t\in[0,\epsilon']} h^+(x(t)).$$

We can assume that $\Delta > 0$ since, otherwise, the assertions of the theorem hold good with $\hat{x}=x$.

Notice that since the h_j's, and therefore also h^+, have Lipschitz constant at most 1 on $\bar{x}(0)+\delta B$,

$$\Delta \;\leq\; \max_{t\in[0,\epsilon']} h(\bar{x}(t)) + ||x-\bar{x}||_{L^\infty([0,\epsilon'];R^n)} \;\leq\; 0+\delta'.$$

Set

$$\tilde{\tau} \;:=\; 3\Delta/r'.$$

Observe that $\tilde{\tau} \leq 3\delta'/r' \leq \epsilon' \leq \tau$. We know from our earlier analysis that there exists an F-trajectory $\hat{x}:[0,\tau]\to R^n$ such that $\hat{x}(0)=x(0)$ and $h_j(\hat{x}(s)) \leq -r's$ for all $s\in[0,\tilde{\tau}]$, $j\in\{1,\ldots,m\}$. We have, in particular,

$$h_j(\hat{x}(\tilde{\tau})) \;\leq\; -r'\tilde{\tau} \;=\; -3\Delta \quad \text{for } j=1,\ldots,m.$$

By the Filippov Wazewski theorem, there exists an F-trajectory $y : [\tilde{\tau}, 1] \to R^n$ such that

$$\begin{cases} \dot{y}(t) \;=\; F(t, y(t)) \quad \text{a.e. } t \in [\tilde{\tau}, 1], \\ y(\tilde{\tau}) = \hat{x}(\tilde{\tau}), \end{cases}$$

and, for a.e. $t \in [\tilde{\tau}, 1]$,

$$\begin{aligned} |y(t) - x(t)| &\leq \exp\left(\int_{\tilde{\tau}}^{t} k_F(s)ds\right) |\hat{x}(\tilde{\tau}) - x(\tilde{\tau})| \\ &\leq \exp\left(\int_{\tilde{\tau}}^{t} k_F(s)ds\right) 2c\tilde{\tau}, \qquad (3.6) \\ |\dot{y}(t) - \dot{x}(t)| &\leq k_F(t)\text{exp}\left(\int_{\tilde{\tau}}^{t} k_F(s)ds\right) |\hat{x}(\tilde{\tau}) - x(\tilde{\tau})| \\ &\leq k_F(t)\text{exp}\left(\int_{\tilde{\tau}}^{t} k_F(s)ds\right) 2c\tilde{\tau}. \qquad (3.7) \end{aligned}$$

Now extend $\hat{x}$ to all of $[0, 1]$ by setting

$$\hat{x}(t) \;:=\; y(t) \quad \text{for all } t \in (\tilde{\tau}, 1].$$

Since $\hat{x}(0) = x(0)$, we have from (3.7)

$$\begin{aligned} ||\hat{x} - x||_{W^{1,1}([0,1];R^n)} &= ||\dot{\hat{x}} - \dot{x}||_{L^1([0,\tilde{\tau}];R^n)} + ||\dot{\hat{x}} - \dot{x}||_{L^1([\tilde{\tau},1];R^n)} \\ &\leq 2c\tilde{\tau} + 2c\tilde{\tau}\left(\exp\left(\int_{\tilde{\tau}}^{1} (k_F(s)ds\right) - 1\right) \\ &= 2c\tilde{\tau}\text{exp}\left(\int_{\tilde{\tau}}^{1} k_F(s)ds\right) \\ &\leq (6c/r')\text{exp}\left(\int_{\tilde{\tau}}^{1} k_F(s)ds\right) \Delta. \end{aligned}$$

We have shown that

$$||\hat{x} - x||_{W^{1,1}([0,1];R^n)} \;\leq\; K \max_{t \in [0,\epsilon']} h^+(x(t)),$$

in which

$$K \;:=\; (6c/r')\text{exp}\left(\int_{\tilde{\tau}}^{1} k_F(s)ds\right).$$

It remains to show that

$$\hat{x} \in A \;\text{ for all } t \in [0, \epsilon'].$$

The condition is clearly satisfied for any $t \in [0, \tilde{\tau}]$. On the other hand, for any $t \in [\tilde{\tau}, \epsilon']$

and $j \in \{1, \dots, m\}$, we have from (3.6) and (3.7)

$$\begin{aligned} h_j(\hat{x}(t)) &= h_j(\hat{x}(\tilde{\tau})) + \int_{\tilde{\tau}}^{t} \nabla h_j(\hat{x}(s)) \cdot \dot{\hat{x}}(s) ds \\ &= h_j(\hat{x}(\tilde{\tau})) + \int_{\tilde{\tau}}^{t} \nabla h_j(x(s)) \cdot \dot{x}(s) ds + \int_{\tilde{\tau}}^{t} (\nabla h_j(\hat{x}(s)) - \nabla h_j(x(s))) \cdot \dot{x}(s) ds \\ &\qquad + \int_{\tilde{\tau}}^{t} \nabla h_j(\hat{x}(s)) \cdot (\dot{\hat{x}}(s) - \dot{x}(s)) ds \\ &\le -3\Delta + 2\Delta + (6c^2\kappa/r')\epsilon' e^{\omega(\epsilon')}\Delta + (e^{\omega(\epsilon')} - 1) 2c(3/r')\Delta \\ &\le (-1 + (6c/r')(\kappa c \epsilon' e^{\omega(\epsilon')} + (e^{\omega(\epsilon')-1})))\Delta \ \le \ 0, \end{aligned}$$

as required. We have confirmed that $\hat{x}(t) \in A$ for all $t \in [0, \epsilon']$. The proof is complete.

4. Proof of Theorem 2.1. We precede the proof by a summary of key ideas. Consider to begin with the free right endpoint problem (the case when $C_1 = R^n$). For simplicity, assume $m = 1$. It can be deduced from Theorem 3.1 that, for some $K > 0$ and $\epsilon' \in (0, 1]$, the $W^{1,1}$ local minimizer $\bar{x}$ for (P) is a $W^{1,1}$ local minimizer also for the problem

$$\begin{cases} \text{Minimize } g(x(0), x(1)) + K \max_{t \in [0,\epsilon']} \ (\max\{0, h_1(x(t))\}) \\ \text{over arcs } x \text{ satisfying} \\ \dot{x} \ \in \ F(t, x), \\ x(0) \in C_0 \cap A, \\ h_1(x(t)) \ \le \ 0 \quad \text{for all } t \in [\epsilon, 1]. \end{cases}$$

The notable feature of this problem is that the state constraint on $[0, \epsilon']$ has been replaced by a term in the cost penalizing state constraint violations on this subinterval.

The above problem can, in turn, be reformulated as a standard state-constrained optimal control problem, for which [30] provides necessary conditions of optimality. If λ is the cost multiplier and μ is the multiplier associated with the state constraint, then it can be deduced from the transversality condition for the reformulated problem that

$$\int_{[0,\epsilon']} \mu(ds) \ \le \ \lambda.$$

This condition obviously precludes degenerate multipliers sets in which $\lambda = 0$ and μ is a nonzero measure concentrated on $\{0\}$.

Of course if a right endpoint constraint is present, the analysis is more complicated. In this broader setting, we approximate the optimal control problem by a sequence of right endpoint constraint free problems (in a manner earlier employed by Clarke [9]), derive nondegenerate necessary conditions along the sequence as above and deduce nondegenerate necessary conditions for the original problem by passing to the limit.

After these preliminary comments, we are ready to initiate the proof. Allow once again $m > 1$. Define the scalar valued function h to be

$$h(x) \ = \ \max\{h_1(x), \dots, h_m(x)\}.$$

Let $\delta' \in (0, \delta)$, $\epsilon' \in (0, \epsilon)$ and K be the constants with the properties asserted in Theorem 3.1. Define

$$\begin{aligned} D := \{x \in W^{1,1}([0,1]; R^n) : \dot{x} \in F(t, x(t)) \text{ a.e., } \ x(0) \in C_0 \cap A, \\ \text{and } ||x - \bar{x}||_{L^\infty([0,1];R^n)} \le \delta'\}. \end{aligned}$$

Choose an arbitrary sequence $\epsilon_i \downarrow 0$ and define

$$\eta_i(x_0, x_1, y) := \max\left\{g(x_0, x_1) - g(\bar{x}(0), \bar{x}(1)) + \epsilon_i^2, y, d_{C_1}(x_1)\right\}.$$

The set $\{x \in D : x(t) \in A \text{ for all } t \in [0, \epsilon']\}$ is closed and the function

$$x \to \eta_i(x(0), x(1), \max_{t\in[\epsilon',1]} h^+(x(t)))$$

is continuous on D (with respect to the strong $W^{1,1}([0,1]; R^n)$ topology). Since η_i is nonnegative valued and

$$\eta_i(\bar{x}(0), \bar{x}(1), \max_{t\in[\epsilon',1]} h^+(\bar{x}(t))) = \epsilon_i^2,$$

it follows that

$$\begin{aligned}&\eta_i(\bar{x}(0), \bar{x}(1), \max_{t\in[\epsilon',1]} h^+(\bar{x}(t)))\\ &\quad\le \inf\{\eta_i(x(0), x(1), \max_{t\in[\epsilon',1]} h^+(x(t))) : x \in D,\ x(t) \in A \text{ for all } t \in [0, \epsilon']\} + \epsilon_i^2.\end{aligned}$$

By Ekeland's theorem [9, p. 265] then, there exists $x_i \in W^{1,1,}([0,1]; R^n)$ with the properties

$$||x_i - \bar{x}||_{W^{1,1}([0,1];R^n)} \le \epsilon_i \tag{4.1}$$

and x_i is a minimizer for

$$\text{Minimize } \{J_i(x) : x \in D,\ x(t) \in A \text{ for all } t \in [0, \epsilon']\},$$

where

$$J_i(x) := \eta_i(x(0), x(1), \max_{t\in[\epsilon',1]} h^+(x(t))) + \epsilon_i ||x - x_i||_{W^{1,1}([0,1];R^n)}.$$

In view of (4.1), we can arrange, by subsequence extraction, that

$$x_i \to \bar{x}_i \text{ uniformly} \quad \text{and } \dot{x}_i \to \dot{\bar{x}} \text{ a.e.}$$

Set

$$y_i \ := \ \max_{t\in[\epsilon',1]} h^+(x_i(t)).$$

LEMMA 4.1. *For each i sufficently large,*

$$(a, b, c) \in \partial\eta_i(x_i(0), x_i(1), y_i)$$

implies that $c \ge 0$ and

$$(a, b) \in \alpha\partial g(x_i(0), x_i(1)) + (0, \xi)$$

for some $\alpha \ge 0$ and some $\xi \in N_{C_1}(x_i(1))$ satisfying

$$\alpha + |\xi| + c = 1.$$

Proof. Note, to begin with, that, for all i sufficently large,

$$\eta_i(x_i(0), x_i(1), \max_{t\in[\epsilon',1]} h^+(x_i(t))) > 0.$$

Indeed, by choosing i sufficiently large we can make $||x_i - \bar{x}||_{W^{1,1}}$ arbitrarily small. If the above strict inequality is not satisfied, then x_i satisfies the constraints of (P) and has cost less than $\bar{x}$, in contradiction to our assumption that $\bar{x}$ is a $W^{1,1}$ local minimizer.

There are two cases to consider.

Case 1. $d_{C_1}(x_i(1)) = 0$. In view of the preceding strict inequality, we deduce from the max rule for limiting subdifferentials [25] that

$$a \in \alpha\partial g(x_i(0), x_i(1))$$

for some $\alpha \geq 0$ such that $\alpha + c = 1$. The assertions of the lemma are satisfied with $\xi = 0$.

Case 2. $d_{C_1}(x_i(1)) > 0$. In this case (by well-known properties of the distance function)

$$\xi \in \partial d_{C_1}(x_i(1)) \text{ implies } |\xi| = 1.$$

The max rule now asserts that $c \geq 0$ and that there exist $\alpha \geq 0$ and $\lambda \geq 0$ such that $\alpha + \lambda + c = 1$ and

$$(a, b) \in \alpha\partial g(x_i(0), x_i(1)) + (0, \lambda\xi')$$

for some $\xi' \in \partial d_{C_1}(x_i(1))$ such that $|\xi'| = 1$. Writing $\xi = \lambda\xi'$, we find that

$$(a, b) \in \alpha\partial g(x_i(0), x_i(1)) + (0, \xi)$$

and $\alpha + |\xi| + c = 1$. Since $\xi \in N_{C_1}(x_i(1))$, the lemma is proved. □

In the proof of the next lemma we shall use the easily confirmed fact that there exists some $k > 0$ (independent of i) such that, for any $x, x' \in D$,

$$|J_i(x) - J_i(x')| \leq k||x - x'||_{W^{1,1}([0,1];R^n)}.$$

LEMMA 4.2. *For all i sufficiently large, x_i is a $W^{1,1}$ local minimizer for the optimization problem*

$$(\mathrm{Q_i}) \qquad \textit{Minimize}\left\{ J_i(x) + kK \max_{t\in[0,\epsilon']} h^+(x(t)) : x \in D \right\}.$$

Proof. Define

$$\tilde{J}_i(x) := J_i(x) + kK \max_{t\in[0,\epsilon']} h^+(x(t)).$$

Suppose the assertions of the lemma are false. Take any $\delta'' \in (0, \delta')$. Then for any index value i_0 there exists $i \geq i_0$ and $x \in D$ such that $||x - x_i||_{W^{1,1}} \leq \delta''$ and

$$\tilde{J}_i(x) \, < \, \tilde{J}_i(x_i).$$

According to Theorem 3.1, there exists an F-trajectory $\hat{x}$ such that $\hat{x}(0) = x(0)$,

$$h(\hat{x}(t)) \, \leq \, 0 \quad \text{for } t \in [0, \epsilon'],$$

and

$$||\hat{x} - x||_{W^{1,1}([0,1];R^n)} \leq K \max_{t\in[0,\epsilon']} h^+(x(t)).$$

By choosing i_0 sufficiently large and δ'' sufficiently small we can arrange that $\hat{x}$ lies in D. It then follows from the minimizing properties of x_i that

$$\begin{aligned}\tilde{J}_i(x_i) \leq \tilde{J}_i(\hat{x}) &= J_i(\hat{x}) \\ &\leq J_i(x) + k||\hat{x} - x||_{W^{1,1}([0,1];R^n)} \\ &\leq J_i(x) + kK \max_{t\in[0,\epsilon']} h^+(x(t)) = \tilde{J}_i(x) < \tilde{J}_i(x_i),\end{aligned}$$

which is not possible. The lemma is proved. □

We deduce from the preceding lemma that, for i sufficiently large,

$$\left(x_i, y_i \equiv \max_{t\in[\epsilon',1]} h^+(x_i(t)), z_i \equiv 0\right)$$

is a strong local minimizer for the optimal control problem

$$\left\{\begin{array}{l}\text{Minimize } \max\{g(x(0),x(1)) - g(\bar{x}(0),\bar{x}(1)) + \epsilon_i^2, y(1), d_{C_1}(x(1))\} \\ \qquad\qquad +\epsilon_i|x(0) - x_i(0)| + \epsilon_i \int_0^1 |\dot{x}(t) - \dot{x}_i(t)|dt + kK \max\{0, z(1)\} \\ \text{over } x \in W^{1,1}([0,1];R^n),\ y \in W^{1,1}([0,1];R) \text{ and } z \in W^{1,1}([0,1];R) \text{ satisfying} \\ (\dot{x}(t), \dot{y}(t), \dot{z}(t)) \in F(t, x(t)) \times \{0\} \times \{0\} \text{ a.e.,} \\ x(0) \in C_0 \cap A, \\ \tilde{h}(t, x(t), y(t), z(t)) \leq 0 \text{ for all } t \in [0,1].\end{array}\right.$$

Here, $\tilde{h} : [0,1] \times R^n \times R \times R$ is the function

$$\tilde{h}(t,x,y,z) := \left\{\begin{array}{ll} h(x) - z & \text{for } t \in [0,\epsilon), \\ h(x) + \max\{-z,-y\} & \text{for } t = \epsilon, \\ h(x) - y & \text{for } t \in (\epsilon,1]. \end{array}\right.$$

We have arrived at a problem to which the Euler Lagrange type conditions of [30] are applicable. (Note, in particular, that the state constraint functional $\tilde{h}$ has the requisite upper semicontinuity properties.)

Taking note of Lemma 4.1, we draw the following conclusions: there exist $p_i \in W^{1,1}([0,1];R^n)$, $q_i \in W^{1,1}([0,1];R)$, and $r_i \in W^{1,1}([0,1];R)$ (the costate functions associated with x_i, y_i, and z_i, respectively), constants $\lambda'_i \geq 0$, $\alpha_i \in [0,1]$, $\beta_i \in [0,1]$, $\pi_i^0 \in [0,1]$, $\pi_i^1 \in [0,1]$, $\xi_i \in R^n$, a Borel measurable function $\gamma_i : [0,1] \to R^n$, and nonnegative Borel measures $\nu_i \in C^*([0,1];R)$ such that

$$(4.2)\quad ||p_i||_{L^\infty} + ||q_i||_{L^\infty} + ||r_i||_{L^\infty} + \lambda'_i + \int_{[0,1]} \nu_i(ds) = 1,$$

$$(4.3)\quad \alpha_i + \beta_i + |\xi_i| = 1,\ \pi_i^0 + \pi_i^1 = 1,$$

$$(4.4)\quad \left.\begin{array}{l}\dot{p}_i(t) \in \text{co}\left\{\eta : \left(\eta, p_i(t) + \displaystyle\int_{[0,t)} \gamma_i(s)\nu_i(ds)\right)\right. \\ \qquad\qquad \in N_{\text{Gr}F(t,.)}(x_i(t), \dot{x}_i(t)) + \{0\} \times \lambda'_i\epsilon_i B\end{array}\right\} \text{ a.e.,}$$

$$\begin{aligned}
&\left(p_i(0), -\left(p_i(1) + \int_{[0,1]} \gamma_i(s)\nu_i(ds)\right)\right) \in \alpha_i\lambda_i'\partial g(x_i(0), x_i(1)) \\
&\qquad\qquad\qquad + \epsilon_i\lambda_i' B \times \{\lambda_i'\xi_i\} + N_{C_0\cap A}(x_i(0)) \times \{0\}, \\
&q_i(0) = 0,\ \dot{q}_i = 0,\ \int_{(\epsilon',1]} \nu_i(ds) + \pi_i^0\nu_i(\{\epsilon'\}) = \beta_i\lambda_i', \\
&r_i(0) = 0,\ \dot{r}_i = 0,\ \int_{[0,\epsilon')} \nu_i(ds) + \pi_i^1\nu_i(\{\epsilon'\})\ \le\ kK\lambda_i', \\
&\xi_i \in N_{C_1}(x_i(1)), \\
&\left(p_i(t) + \int_{[0,t)} \gamma_i(s)\nu_i(ds)\right) \cdot \dot{x}_i(t) \\
&\quad = \ \max\nolimits_{v\in F(t,x_i(t))} \left(p_i(t) + \int_{[0,t)} \gamma_i(s)\nu_i(ds)\right) \cdot v - \epsilon_i|v - \dot{x}_i(t)| \quad \text{a.e.}, \\
&\operatorname{supp}\{\nu_i\} \subset \{t \in [0,\epsilon'] : h(x_i(t)) = 0\} \cup \{t \in [\epsilon', 1] : h(x_i(t)) = y_i\}, \\
&\gamma_i(t)\ \in \operatorname{co}\partial h(x_i(t)) \quad \nu\text{-a.e.}
\end{aligned}$$

It can be deduced from (4.4) (see [20]) that, for each i,

$$|\dot{p}_i(t)|\ \le\ k_F(t)\left|p_i(t) + \int_{[0,t)} \gamma(s)\nu_i(ds)\right| \quad \text{a.e.}$$

(We remark on the significance of the "partially convexified" adjoint inclusion (4.4): if (4.4) were replaced by the coarser inclusion $(\dot{p}_i, p_i) \in \operatorname{co} N_{\mathrm{Gr}\,F}$, then this pointwise bound on the $\dot{p}_i$, which has an important role in the convergence analysis, would no longer be valid under the hypotheses of Theorem 2.1.)

From (4.2), $\{p_i\}$ is a bounded sequence. By Gronwall's lemma then, the p_i's are uniformly bounded and the $\dot{p}_i$'s are uniformly integrably bounded. It can be deduced from the Dunford Pettis theorem that, along some subsequence,

$$p_i \to p \quad \text{uniformly} \qquad \text{and} \qquad \dot{p}_i \to \dot{p} \ \text{ weakly in } L^1$$

for some $p \in W^{1,1}([0,1]; R^n)$. In view of (4.2), and (4.3), we can arrange, by further subsequence extraction, that

$$\nu_i(dt) \to \nu(dt) \text{ and } \gamma_i(t)\nu_i(dt) \to \gamma(t)\nu(dt) \text{ weakly}^*$$

for some nonnegative Borel measure $\nu \in C^*([0,1]; R)$ and some ν-integrable function γ. Also,

$$(\lambda_i', \alpha_i, \beta_i, \xi_i, \pi_i^0\pi_i^1) \to (\lambda', \alpha, \beta, \xi, \pi^0, \pi^1)$$

for some $\xi \in R^n$, $\lambda' \ge 0$, $\alpha \in [0,1]$ $\beta \in [0,1]$, $\pi^0 \in [0,1]$, and $\pi^1 \in [0,1]$.

Using an analysis similar to that of [29] and [30], we may pass to the limit in the above relationships. We thereby arrive at the following relationships:

(4.5) $\quad ||p||_{L^\infty} + \lambda' + \int_{[0,1]} \nu(ds) = 1,$

(4.6) $\quad \alpha + \beta + |\xi| = 1,\ \pi^0 + \pi^1 = 1,$

$$\dot p(t) \in \operatorname{co}\left\{\eta : \left(\eta, p(t) + \int_{[0,t)} \gamma(s)\nu(ds)\right) \in N_{\mathrm{Gr}F(t,.)}(\bar x(t), \dot{\bar x}(t))\right\} \text{ a.e.,} \tag{4.7}$$

$$\left(p(0), -\left(p(1) + \int_{[0,1]} \gamma(s)\nu(ds)\right)\right) \tag{4.8}$$

$$\in \alpha\lambda'\partial g(\bar x(0), \bar x(0)) + N_{C_0 \cap A}(\bar x(0)) \times \{\lambda'\xi\},$$

$$\int_{(\epsilon',1]} \nu(ds) + \pi^0\nu_i(\{\epsilon'\}) \;=\; \beta\lambda', \tag{4.9}$$

$$\int_{[0,\epsilon')} \nu_i(ds) + \pi_i^1\nu_i(\{\epsilon'\}) \;\le\; kK\lambda', \tag{4.10}$$

$$\xi \in N_{C_1}(\bar x(1)),$$

$$\left(p(t) + \int_{[0,t)} \gamma(s)\nu(ds)\right) \cdot \dot{\bar x}(t) \;=\; \max\nolimits_{v \in F(t, x_i(t))} \left(p(t) + \int_{[0,t)} \gamma(s)\nu(ds)\right) \cdot v$$

$$\gamma(t) \in \operatorname{co}\partial h(\bar x(t)) \ \nu\text{-a.e.}$$

$$\operatorname{supp}\{\nu\} \subset \{t : h(\bar x(t)) = 0\}.$$

The most challenging task in justifying these relationships is to confirm the adjoint inclusion (4.7); we give details of this step alone. The following conclusions can be drawn from Mazur's and Carathéodory's theorems. For each i there exist integers $0 \le k_{i0} \le \cdots \le k_{in}$ and a convex combination $\{\alpha_{i0}, \ldots, \alpha_{in}\}$ such that $\sum_{j=0}^{n} \alpha_{ij}\dot p_{i+k_{ij}}(t)$, $i = 1, 2, \ldots$, converges strongly in L^1 to $\dot p$. We can arrange by subsequence extraction that convergence is pointwise on some set $\mathcal{D}$ of full measure. By modifying the set $\mathcal{D}$, if necessary, we can also arrange that $\dot x_i \to \dot{\bar x}$ pointwise on $\mathcal{D}$. Fix $t \in \mathcal{D}$. For each j, $\alpha_{ij}, i = 1, 2, \ldots$, and $\dot p_{i+k_{ij}}(t), i = 1, 2, \ldots$, are bounded. After further subsequences have been extracted, we have that, for $j = 0, \ldots, n$, $\alpha_{ij} \to \alpha_j$ for some α_j and $\dot p_{i+k_{ij}}(t) \to p_j$ for some $\tilde p_j$. Again making use of Carathéodory's theorem, we deduce that, for each k,

$$\tilde p_j \;\in\; \operatorname{co}\left\{\eta : \left(\eta, p(t) + \int_{[0,t)} \gamma(s)\nu(ds)\right) \in N_{\mathrm{Gr}F(t,.)}(x(t), \dot x(t))\right\}.$$

Clearly, the α_j's are nonnegative and sum to one, so

$$\dot p(t) = \sum_{j=0}^{n} \alpha_j \tilde p_j(t)$$

$$\in \operatorname{co}\left\{\eta : \left(\eta, p(t) + \int_{[0,t)} \gamma(s)\nu(ds)\right) \in N_{\mathrm{Gr}F(t,.)}(x(t), \dot x(t))\right\} \quad \text{a.e.}$$

Note that (4.7) implies

$$|\dot p(t)| \;\le\; k_F(t)\left|p(t) + \int_{[0,t)} \gamma(s)\nu(ds)\right| \quad \text{a.e.} \tag{4.11}$$

We see immediately that $\lambda' \neq 0$, for otherwise (4.8), (4.9), (4.10), and (4.11) (together with Gronwall's inequality) imply that $\nu = 0$ and $p = 0$, which contradicts (4.5).

Now define $\lambda = \alpha\lambda'$. We claim that

$$\lambda + \int_{(0,1]} \nu(ds) + |p(0) + \gamma(0)\nu(\{0\})| \neq 0. \tag{4.12}$$

Suppose that this condition is violated. Then $\alpha = 0$ and (by (4.9)) $\beta = 0$. It follows from (4.6) that $|\xi| = 1$. But then, by (4.8),

$$\left| p(1) + \int_{[0,1]} \gamma(s)\nu(ds) \right| \neq 0.$$

However, we have assumed that $\int_{(0,1]} \nu(ds) = 0$ and $|p(0) + \gamma(0)\nu(\{0\})| = 0$. It follows from (4.11) and Gronwall's inequality that $|p(1) + \int_{[0,1]} \gamma(s)\nu(ds)| = 0$. This contradiction confirms (4.12).

It can be deduced from the inclusion

$$\gamma(t) \in \operatorname{co} \partial h^+(\bar{x}(t)) \quad \nu\text{-a.e.},$$

the max rule for limiting subdifferentials and a measurable selection theorem, that there exist Borel measurable functions $\alpha_1, \dots, \alpha_m : [0,1] \to [0,1]$ such that, ν-a.e.,

$$\gamma(t) = \sum_j \alpha_j(t) \nabla h_j(\bar{x}(t)), \quad \sum_j \alpha_j(t) = 1,$$

and

$$h_j(\bar{x}(t)) < h(\bar{x}(t)) \text{ implies } \alpha_j(t) = 0 \text{ for } j \in \{1, \dots, m\}.$$

Define the nonnegative Borel measures $\mu_j \in C^*([0,1]; R)$, $j = 1, \dots, m$, to be

$$\mu_j(dt) := \alpha_j(t)\nu(dt).$$

We note that, for any Borel subset $I \subset [0,1]$,

$$\int_I \gamma(s)\nu(ds) = \int_I \sum_j \nabla h_j(\bar{x}(s))\mu_j(ds),$$

$$\int_I \nu(ds) = \int_I \left(\sum_j \alpha_j(s) \right) \nu(ds) = \int_I \sum_j \mu_j(ds).$$

Since $\operatorname{supp}\{\nu\} \subset \{t : h(\bar{x}(t)) = 0\}$, we conclude that

$$\operatorname{supp}\{\mu_j\} \subset \{t : h_j(\bar{x}(t)) = 0\} \quad \text{for } j = 1, \dots, m.$$

The earlier relationships, expressed in terms of the μ_j's in place of ν, amount to the assertions of the theorem, with the exception of the additional claims when F is convex valued. Notice in particular that, from (4.12), we can deduce the nondegeneracy condition

$$\lambda + \int_{(0,1]} \sum_j \mu_j(ds) + \left| p(0) + \sum_j \nabla h_j(\bar{x}(0))\mu_j(\{0\}) \right| \neq 0.$$

Finally suppose that F is convex valued. In this case and under the hypotheses of the theorem, equivalence of the adjoint inclusion (2.2) and the generalized Hamiltonian condition (2.4) is established in [24]. (See also [17].) The fact that (in the convex case) the Hamiltonian inclusion (2.4) implies the Weierstrass condition (2.3) is well known. (See, for example, [9].)

ON THE SYNTHESIS PROBLEM FOR OPTIMAL CONTROL SYSTEMS*

R. GABASOV†, F. M. KIRILLOVA‡, AND N. V. BALASHEVICH‡

Abstract. A new approach to the synthesis problem of optimal controls of feedback type is considered. Algorithms of operating optimal controllers which are able to calculate values of optimal feedbacks during each particular control process in real time are described. The algorithm of operating the controller of the first type (continuous controller) is based on solving special (defining) equations in real time using the Newton method. For operating the optimal controller of the second type (discrete controller) the dual method of linear programming is used. In control problems for systems under uncertainty, a nonstochastic model is used, around which guaranteed results are obtained. Under incomplete and inexact information, problems of optimal observation and identification are introduced. Algorithms of operating the optimal estimator and identifier which are able to construct estimates of available information required for operating the optimal output controller in real time are described. Results are illustrated by optimization problems of the fourth order control system.

Key words. optimal control problem, optimal state and output feedbacks, synthesis of optimal systems, optimal controllers, optimal observation and identification problems, optimal estimators and identifiers

1. Introduction.

Problems of optimal control (OC) have been intensively investigated in the world literature for over forty years. During this period, a series of fundamental results have been obtained, among which should be noted the maximum principle [53] and dynamic programming [6, 7]. For many of the problems of the optimal control theory (OCT) adequate solutions are found [1, 8, 51]. Results of the theory were taken up in various fields of science, engineering, and economics. However, it is generally recognized that one of the central problems of the OCT, which is, undoubtedly, the problem of synthesis of optimal feedback, has not yet been solved even for linear systems apart from special cases [9, 12]. This essentially retards the deeper integration of the results of the OCT to practice because controls of feedback type but not open-loop controls (which are investigated in a great deal of published works) are used for solving many practical problems. This is also evidenced by the fact that synthesis of OC in the Kalman–Letov linear-quadratic problem [46, 52] is extraordinarily widely used for solving various applied problems. The Kalman–Letov problem, by virtue of its specific character, takes a particular place in the OCT. This problem is, in fact, a problem of the classical calculus of variations because in this problem there are no geometric constraints of controls which have defined the origin of the modern trend of the calculus of variations named the OCT. It is worth noting that geometric constraints are a typical nonlinearity most often met in applied problems.

The purpose of the article is to present some results of investigations on the problem of optimal synthesis conducted in Minsk since the beginning of 90's. These investigations rely on a new approach to the problem [19, 41]. Analysis of the classical statement of the optimal synthesis problem showed that it could not be solved for more or less serious cases. This problem imposes extremely stringent requirements on the result, and these requirements cannot be satisfied by analytical mathematical methods. It turns out that for applications it is sufficient to have much less information on optimal synthesis, and this information does not have to be in analytical form. By virtue of this, the basis for the approach described below is the idea of reasonable combination of analytical mathematical methods and potentials of modern computing. It is obvious that such an idea could not arise at the time when the classical statement of the optimal synthesis problem appeared (the beginning of 50's). In modern times it is, in our opinion, quite natural.

As well as in the case of the Kalman–Letov problem, the obtained results on optimal synthesis were taken up for solving actual problems of both the classical and modern control theory which in initial statement does not have extremal nature. But in this work we do not dwell on these problems.

The work has the following structure. In section 2 the terminal OC problem is formulated, and the notions of a realization of optimal feedback and an optimal controller are introduced. In sections 3–5 algorithms of operating three types of optimal controllers (continuous, discrete, combined open-closed loop) are described. In section 6 the terminal OC problem under constantly acting disturbances is investigated, and four various types of feedback are discussed. In section 7 the terminal OC problem under incomplete and inexact information on a current system state is considered, and the notion of a realization of optimal output feedback is introduced. In section 8 a linear optimal observation problem (OO) is introduced, and an algorithm of operating a continuous estimator, which calculates estimates of an a posteriori distribution of the initial state, is described. In section 9 an algorithm of operating a discrete estimator is described. This estimator uses measurements of output signals only at discrete moments. In section 10 an OO problem under constantly affecting bounded disturbances is solved. The cases of different information on disturbances with identification or without identification of parameters are considered. In section 11 a realization of optimal output feedback without outside disturbances is constructed. Realization of optimal output feedback under constantly affecting disturbances is described in section 12.

2. Problem statement. In the class of piecewise continuous functions $u(t)$, $t \in T = [0, t^*]$, consider a linear OC problem

$$\begin{gathered} J(u) = c'x(t^*) \longrightarrow \max, \quad \dot{x} = Ax + bu, \quad x(0) = x_0, \\ Hx(t^*) = g, \quad |u(t)| \leq 1, \quad t \in T. \end{gathered} \tag{2.1}$$

Here $x = x(t)$ is an n-vector of a state of the control system at a moment t, $u = u(t)$ is a value of a scalar (one-dimensional) control, g is an m-vector of given values of output signals, and t^* is a terminal (fixed) moment; vectors participate in operations as columns, and transposition $'$ (prime) is used for obtaining a row vector.

Suppose that rank $(b, Ab, \dots, A^{n-1}b) = n$ and rank $H = m < n$.

Problem (2.1) is the simplest OC problem in the sense that removal of any element from this problem makes it trivial. On the other hand, it contains almost all typical elements of the OC problem. Some other statements of OC problems are considered in [3, 4, 14, 38, 40]. From the qualitative point of view, problem (2.1) has been investigated very deeply. Also, there exist effective numerical methods of constructing its open-loop solutions.

By an open-loop solution to problem (2.1), it is meant a piecewise continuous function $u^0(t)$, $t \in T$, which (1) satisfies the geometric constraint $|u^0(t)| \leq 1$, $t \in T$, (2) generates the trajectory $x^0(t)$, $t \in T$, satisfying the terminal constraint $Hx^0(t^*) = g$, and (3) provides the maximum value of the control criterion: $J(u^0) = \max J(u)$.

In spite of the significance of open-loop solutions for many applied problems, in the majority of applications of the control theory preference is given to positional solutions or (in another terminology) OCs of feedback type. To define such controls let us imbed problem (2.1) into a family of problems

$$\begin{gathered} J(u) = c'x(t^*) \longrightarrow \max, \quad \dot{x} = Ax + bu, \quad x(\tau) = z, \\ Hx(t^*) = g, \quad |u(t)| \leq 1, \quad t \in T(\tau) = [\tau, t^*], \end{gathered} \tag{2.2}$$

depending on a scalar $\tau \in T$ and an n-vector $z \in R^n$.

Denote by $u^0(t|\tau, z)$, $t \in T(\tau)$, an optimal open-loop control for problem (2.2) for a fixed pair (τ, z) called a position. Let X_τ be a set of all vectors $z \in R^n$ for which problem (2.2) has a solution for a fixed moment τ.

Definition. A function

$$u^0(\tau, z) = u^0(\tau|\tau, z), \quad z \in X_\tau, \quad \tau \in T, \tag{2.3}$$

is said to be an OC of feedback type (a positional solution) of problem (2.2).

Constructing function (2.3) is called the synthesis of the optimal system.

Unlike an open-loop solution, a positional solution to problem (2.2) cannot be effectively constructed either by the maximum principle or by the dynamic programming. The maximum principle, first of all, is oriented to optimal open-loop controls although time-optimal systems can be synthesized with its help on plane ($n = 2$). In due time great hopes were pinned on the dynamic programming. Really, a result obtained by this method has the form of OC of feedback type. However, to obtain this result it is necessary, first of all, to define the corresponding solution to the Bellman equation and then to find a method for its constructing. Even if one manages to overcome these difficulties, the famous "curse of dimension" arises. Due to this it is impossible to tabulate functions of many variables to the high enough precision in the course of numerical solving of the Bellman equation for problem (2.2) with $n \geq 3$.

Sources of difficulties under the classical approach to the problem are, at our glance, in the classical statement of the optimal synthesis problem itself. First of all, one should take into account that the problem was stated by engineers as early as the beginning of 50's when potentials of today's computing could not even be inferred. Engineers working with heuristic feedback and synthesizing time-optimal linear two-dimensional systems thought that invoking more powerful mathematical methods could solve the problem also in the general case (if only for linear problems of OC). Furthermore, the problem statement of optimal synthesis was also influenced by the traditional (school) concept of the solution to mathematical problems when the main purpose was to obtain an answer in terms of a formula that will allow one to solve the problem once and for all. Certainly, knowing the history of mathematics, one could foresee unsolvability of the optimal synthesis problem formulated at that time. Finally, the problem statement of optimal synthesis could have been considerably influenced by the conventional (in those years) form of realization of feedback with the help of mechanical, hydraulic, electrical, etc. devices.

To leave an impasse, let us analyze the use of optimal feedbacks in actual practice as if they have been constructed in some way. First of all, it is necessary to understand that even though optimal feedback (2.3) is introduced by determined model (2.1), engineers well know that it is needed for operating a control system under real conditions when the system is affected by unaccounted and unknown disturbances in (2.1). That alone is reason enough to say that open-loop controls are useless. In mathematical works no attention is given to this circumstance. Thus, assume that for problem (2.2) optimal feedback (2.3) is constructed. Let us close control system (2.1) by it and study the behavior of the closed system[1] at the presence of unknown disturbances $w(t)$, $t \geq 0$,

$$\dot{x} = Ax + bu^0(t,x) + w(t), \quad x(0) = x_0. \tag{2.4}$$

Denote by $w^*(t)$, $t \in T$, a disturbance realized in some particular control process. It generates a trajectory $x^*(t)$, $t \in T$, of (2.4),[2] i.e., for almost all $t \in T$ the identity

$$\dot{x}^*(t) \equiv Ax^*(t) + bu^0(t, x^*(t)) + w^*(t), \quad t \in T, \quad x^*(0) = x_0^*, \tag{2.5}$$

is fulfilled.

From (2.5) it is obvious that in the process under consideration the input of control system (2.1) is fed only by the signals

$$u^*(t) = u^0(t, x^*(t)), \quad t \in T. \tag{2.6}$$

Thus, in a particular control process, not all of the optimal feedback is used, but its values are necessary only along the isolated continuous curve $x^*(t)$, $t \in T$. Moreover, for each current moment $\tau \in T$ the value $u^*(\tau) = u^0(\tau, x^*(\tau))$ does not have to be known beforehand; it is enough to know how to calculate it at the moment τ, when the system appears in a current state $x^*(\tau)$. The purpose of the proposed approach is to show that in view of the finite rate of real processes and the high speed of up-to-date computer facilities it is possible to obtain the values of the function $u^*(t)$, $t \in T$, in real time[3] for many problems (2.1).

Definition. Function (2.6) is said to be a realization of optimal feedback (2.3), and a device able to calculate its values in real time is called an optimal controller.

Thus, the problem of synthesis of optimal systems in the new statement is reduced to constructing an algorithm of operating the optimal controller.

3. Defining equations and an algorithm of operating the optimal controller. Suppose that an algorithm of operating the optimal controller has been created and the optimal controller has been operating on the interval $[0, \tau[$. Denote by $u^*(t)$, $t \in [0, \tau[$, a control produced by the controller up to the moment τ, denote by $w^*(t)$, $t \in [0, \tau[$, a realized disturbance, by $x^*(\tau)$ a state of the control system at the moment τ corresponding to $u^*(t)$, $w^*(t)$, $t \in [0, \tau[$, and the initial state $x(0) = x_0$. To calculate the current value $u^*(\tau)$ of the control $u^0(\tau, x^*(\tau))$, according to definition (2.3), the optimal controller has to know the open-loop solution $u^0(t|\tau, x^*(\tau))$, $t \in T(\tau)$, to the OC problem

[1] To simplify notations let us consider model (2.1) to be exact.

[2] For simplicity it is assumed that (2.4) has a solution, although for the classical statement of optimal synthesis problem it is not a simple question, because function (2.3) is discontinuous with respect to x.

[3] The concept "real time mode" is explained below in section 3.

$$c'x(t^*) \longrightarrow \max, \quad \dot{x} = Ax + bu, \quad x(\tau) = x^*(\tau), \tag{3.1}$$

$$Hx(t^*) = g, \quad |u(t)| \le 1, \quad t \in T(\tau).$$

From the Pontryagin maximum principle [53] it follows that the optimal open-loop control $u^0(t|\tau, x^*(\tau))$, $t \in T(\tau)$, has the form

$$u^0(t|\tau, x^*(\tau)) = \mathrm{sgn}\Delta(t|\tau, x^*(\tau)), \quad t \in T(\tau), \tag{3.2}$$

where $\Delta(t|\tau, x^*(\tau)) = \psi'(t|\tau, x^*(\tau))b$, $\dot{\psi} = -A'\psi$, $\psi(t^*) = c - H'y(\tau, x^*(\tau))$, $y(\tau, x^*(\tau))$ is the Lagrange optimal vector.

From (3.2) it is obvious that the open-loop solution to problem (3.1) is completely defined by the set

$$\text{æ}(\tau) = \big(t_1 = t_1(\tau, x^*(\tau)), \ldots, t_p = t_p(\tau, x^*(\tau)); \quad y = y(\tau, x^*(\tau))\big), \tag{3.3}$$

consisting of switching points of the OC and the Lagrange vector. Set (3.3) is said to be the defining elements of the OC. They satisfy the equations

$$F(\text{æ}|\tau) = 0 \Longleftrightarrow \begin{cases} Hx(t^*) = g, \\ \Delta(t_k|\tau, x^*(\tau)) = 0, \quad k = \overline{1,p} = p(\tau, x^*(\tau)). \end{cases} \tag{3.4}$$

Equations (3.4) are said to be the defining equations of the optimal controller. When $\dot{\Delta}(t_k) \ne 0$, $k = \overline{1,p}$, the Jacobi matrix of (3.4) is nonsingular on the OC with respect to variables (3.3). So the solution to the defining equations can be constructed by the Newton method if a good enough initial approximation is known.

Based on these properties, it is possible to propose the following algorithm of operating the optimal controller. The algorithm consists of three procedures: (1) the starting procedure, (2) the procedure of constructing the defining elements on regular intervals and on sliding intervals, and (3) the procedure of changing the structure (the set of the defining equations and variables).

The first procedure constructs the initial values

$$\text{æ}(0) = \big(t_1(0, x_0), \ldots, t_{p(0)}(0, x_0); \quad y(0, x_0)\big) \tag{3.5}$$

of defining elements (3.3). For this purpose, the optimal open-loop control $u^0(t|0, x_0)$, $t \in T$, of problem (2.1) is constructed before the beginning of the control process, based on a priori information. In doing so there are no limitations on the time of calculation. The switching points and the Lagrange vector of the constructed solution set vector (3.5).

The second procedure is used on intervals of control where the number of defining equations (3.4) does not change and on intervals where sliding modes arise ((2.4) does not have the classical solution). In the first case, the earlier constructed solution æ(τ) is used as an initial approximation for constructing a solution æ$(\tau + h)$ to the defining equations at the moment $\tau + h$. The number $h > 0$ is chosen in such a way that it would take no more than three iterations to obtain the solution æ$(\tau + h)$ by the Newton method with given accuracy. This allows us to evaluate the number of calculations. If the time the computer device takes to carry out this work does not exceed h units, one can say that the optimal controller using this device realizes the optimal feedback in real time. The appropriate estimates are easy to obtain from the properties of the Newton method [5]. The algorithm of operating the optimal

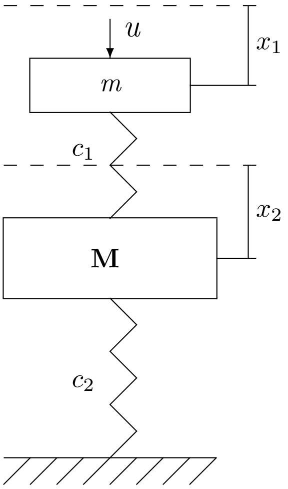

FIG. 3.1.

controller changes on sliding intervals. In [2] several alternative algorithms for sliding intervals are described.

The third procedure is intended for revealing moments for changing the structure of the defining equations and for calculating initial values for the defining elements on new intervals of constancy of the structure. Details are presented in [32, 33].

The described approach to solving the synthesis problem of optimal systems allows us, on the one hand, to select a computer device able to realize the optimal feedback for the given OC problem and, on the other hand, to point out problems in which the given computer device may be used for synthesizing the OC.

As an example of using the described approach, consider the synthesis of the optimal feedback for the problem of damping a two-mass oscillating system (Figure 3.1).

Denote by m, M masses of the objects, by x_1, x_2 their coordinates, by c_1, c_2 the coefficients of elasticity of springs, and by u the damping action. The mathematical model of the problem has the form

$$\int_0^{t^*} u(t)dt \longrightarrow \min, \quad \dot{x}_1 = x_3, \quad \dot{x}_2 = x_4,$$
$$\dot{x}_3 = (-c_1x_1 + c_1x_2 + u)/m, \quad \dot{x}_4 = (c_1x_1 - (c_1 + c_2)x_2)/M,$$
$$x(0) = \big(x_1(0), x_2(0), x_3(0), x_4(0)\big) = x_0, \quad x(t^*) = 0, \quad 0 \le u(t) \le 1, \quad t \in [0, t^*[.$$

Set the following values of parameters: $m = 1$, $M = 10$, $c_1 = 1$, $c_2 = 9.2$, $t^* = 20$. The vector $x_0 = (2, 0.5, 0, 0)$ is chosen as an initial state. Introducing a new variable $\dot{x}_5 = u$, $x_5(0) = 0$, we obtain the problem of form (2.1)

$$\begin{gathered} -x_5 \longrightarrow \max, \quad \dot{x}_1 = x_3, \quad \dot{x}_2 = x_4, \\ \dot{x}_3 = -x_1 + x_2 + u, \quad \dot{x}_4 = 0.1x_1 - 1.02x_2, \\ x_i(0) = x_{0i}, \ i = \overline{1,4}, \ x_5(0) = 0, \quad x_i(20) = 0, \ i = \overline{1,4}, \quad 0 \le u(t) \le 1, \ t \in [0, 20[. \end{gathered} \tag{3.6}$$

In Figure 3.2 dashed lines present the phase trajectories of the objects under the optimal open-loop control. The optimal value of the control criterion equals 3.040471.

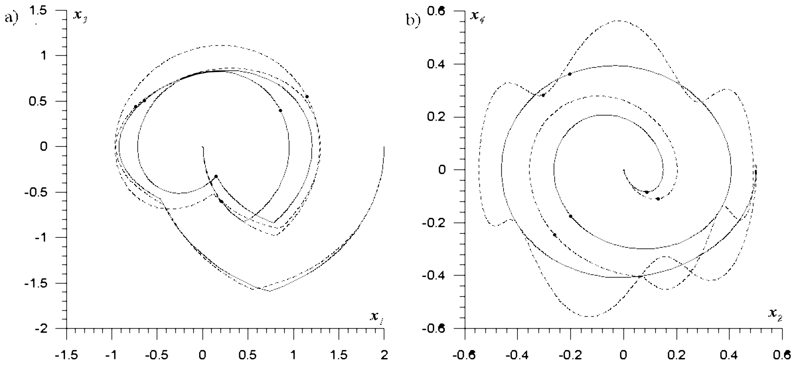

FIG. 3.2.

Let the unknown for the controller disturbance $w(t) = 0.5 \sin 5t$, $t \in [0, 9[$, $w(t) = 0$, $t \in [9, 20]$, affect the system so that the behavior of the system is described by the equations

$$\dot{x}_1 = x_3, \quad \dot{x}_2 = x_4,$$
$$\dot{x}_3 = -x_1 + x_2 + u, \quad \dot{x}_4 = 0.1x_1 - 1.02x_2 + w(t).$$

The phase trajectories corresponding to the realized disturbance and the control produced by the optimal controller are presented in Figure 3.2 (solid lines). The control criterion takes the value 3.210243. In the curves the states of the system realized at the moments $t = 5$, 10, 15 are marked.

4. Synthesis of optimal discrete controls of feedback type. When including discrete-acting devices in control channels, it is natural to use discrete controls. A control $u(t)$, $t \in T$, is said to be discrete with the quantization period $\nu > 0$ if it takes the form

$$u(t) = u_k, \quad t \in [k\nu, (k+1)\nu[, \quad k = 0, 1, 2, \dots,$$

i.e., a discrete control is described by a piecewise constant function in which discontinuities are possible only at moments $t_k = k\nu$, $k = 0, 1, 2, \dots$.

Consider problem (2.1) once again but this time in the class of discrete controls, assuming for simplicity that $t^* = N\nu$.

To define the optimal discrete control of feedback type, the family of problems (2.2) will be considered for $\tau = k\nu$, $k = 0, 1, \dots, N-1$, $z \in R^n$. The optimal discrete control of feedback type is again defined by formula (2.3), where $\tau = k\nu$, $k = \overline{0, N-1}$. Introduction of discrete time does not facilitate the search of function (2.3) considerably. Therefore, in the discrete case, by analogy with the continuous case, we introduce the concept of realization $u^*(t) = u^0(t, x^*(t))$, $t = k\nu$, $k = \overline{0, N-1}$, of the optimal discrete feedback and the concept of the optimal discrete controller. However, the algorithm of operating the optimal discrete controller differs fundamentally from the analogous one in the continuous case [43, 44, 45].

Suppose once again that the optimal discrete controller has been constructed and the control process is in the position $(\tau = k\nu, x^*(\tau))$. To calculate the value $u^*(k\nu)$ the discrete controller has to solve problem (2.2) with $\tau = k\nu$, $z = x^*(k\nu)$. This problem is equivalent to the linear programming (LP) problem. By the assumption,

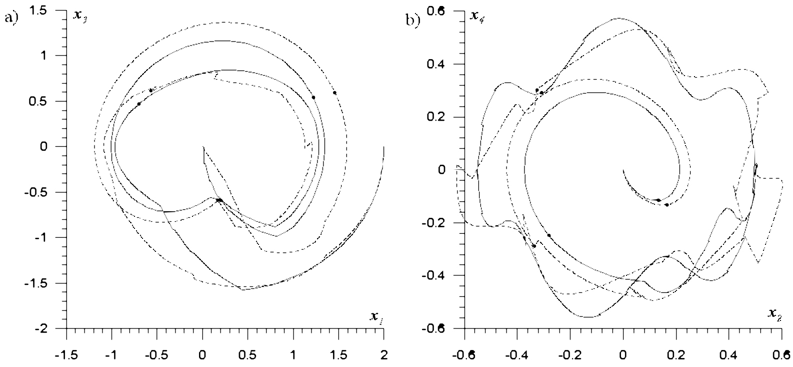

FIG. 4.1.

the controller has already faced the similar problem at the previous moment $\tau - \nu = (k-1)\nu$. Therefore instead of solving a new LP problem for τ, it is sufficient to correct the previous solution. In LP, there exists an extraordinarily effective dual method [10, 13] performing this work in a small number of iterations. If the mentioned work is performed by the available computer device in a time not exceeding ν, one can remark again about the realization of the optimal discrete feedback in real time. The initial value $u^*(0)$ is obtained after solving problem (2.2) with $\tau = 0$, $z = x_0$. This problem can be solved beforehand because it does not contain uncertain elements. In the discrete case the procedure for constructing a new structure is eliminated and the question of sliding modes does not arise. From this point of view, optimal discrete controllers are especially convenient for practical problems.

In conclusion, let us describe the starting procedure. The optimal controller begins its work at the moment $t = 0$. In calculation of the initial control signal $u^*(0) = u^0(0, x^*(0))$, two situations are possible: (1) the initial state $x^*(0)$ is known beforehand (up to the moment $t = 0$), and (2) it is only known that initial state $x^*(0)$ belongs to the bounded set G_0. In the case (1), before starting the control process, the open-loop solution $u^0(t|0, x^*(0))$, $t \in T$, is constructed based on a priori available information. In doing so, there are no restrictions on the time of solving the problem. Following definition (2.6), at the initial moment $t = 0$ the optimal controller sets $u^*(0) = u^0(0|0, x^*(0))$. In the case (2) the domain G_0 is covered with sufficiently dense finite grid. Before the beginning of the control process the optimal controller calculates optimal open-loop controls $u^0(t|0, x^{(i)})$, $t \in T$, for nodes $x^{(i)}$, $i = \overline{1, q}$, of the grid. At the initial moment $t = 0$ of the control process any initial state $x^*(0) \in G_0$ is realized. The optimal controller seeks the closest to $x^*(0)$ node $x^{(k)}$. According to the above described scheme, the controller corrects the optimal open-loop control $u^0(t|0, x^{(k)})$, $t \in T$, to the control $u^0(t|0, x^*(0))$, $t \in T$, by the dual method and sets $u^*(0) = u^0(0|0, x^*(0))$. It is clear that for a given domain G_0 one can choose a grid such that it takes no more than ν units of time to calculate $u^*(0)$. Then the whole control process can be realized in real time.

Operation of the optimal discrete controller is illustrated by the example considered earlier (section 3). Choose various values of the quantization period $\nu = 0.2$, $\nu = 1$. On the optimal open-loop control the value of the control criterion is equal to 3.046312 for $\nu = 0.2$, and 3.216836 for $\nu = 1$. As in section 3, the system is affected by unknown disturbance $w(t) = 0.5 \sin 5t$, $t \in [0, 9[$; $w(t) = 0$, $t \in [9, 20]$. The phase trajectories of the control objects are presented in Figure 4.1. Solid lines correspond to $\nu = 0.2$, and dash lines correspond to $\nu = 1$. The points identify the states of the system realized at the moments $t = 5$, 10, 15. The value of the control criterion is equal to 3.292034 for $\nu = 0.2$ and 4.223683 for $\nu = 1$.

5. Realization of combined open-closed-loop solutions to optimal control problems. Generalization of positional (section 3) and discrete (section 4) solutions to OC problems is a combined open-closed-loop solution. Consider a family of problems (2.2) in the class of piecewise continuous controls.

Definition. For a given $\nu = t^*/M > 0$ the function

$$u^0_\nu(t,x), \quad t \in [0,\nu[, \quad x \in X_\tau, \quad \tau \in T, \tag{5.1}$$

is said to be a combined open-closed-loop solution to problem (2.2) if

(1) $u^0_\nu(t,x) = u^0(\tau + t|\tau, x)$, $t \in [0,\nu[$, $x \in X_\tau$, $\tau \in T$,

(2) the trajectory $x(t)$, $t \in T$, of the system

$$\dot{x} = Ax + bu^0_\nu(t,x), \quad x(0) = x_0,$$

obtained from (2.1) with the help of closure by combined open-closed-loop feedback (5.1) presents a continuous solution to the control system

$$\dot{x} = Ax + bu(t), \quad x(0) = x_0,$$
$$u(t) = u^0_\nu(t - k\nu, x(k\nu)), \quad t \in [k\nu, (k+1)\nu[, \quad k = \overline{0, N-1}.$$

Thus, optimal combined open-closed-loop control (5.1) is corrected not at each moment $\tau \in T$ (as it was with positional solution) but only at discrete moments $\tau = k\nu$, $k = \overline{0, N-1}$, (as in the case of discrete controls). However, unlike the discrete positional control the combined open-closed-loop control does not remain constant on intervals $[k\nu, (k+1)\nu[$, $k = \overline{0, N-1}$, and can appear to be an arbitrary piecewise continuous function.

The combined open-closed-loop solution to problem (2.1) can be realized both by the continuous controller (section 3) and by its discrete analogue (section 4). For definiteness we describe only the algorithm of operating the second controller. (The continuous one is described in [27].) Restrict the class of accessible controls of problem (2.1) by discrete controls with quantization period $\mu = t^*/M$, assuming for simplicity that $\nu = K\mu$, $K \geq 1$, is an integer.

Up to the initial moment $\tau = 0$ the optimal controller solves problem (2.1) in the class of discrete controls with quantization period μ. (This problem is equivalent to the LP problem.) The controller feeds the constructed optimal open-loop control $u^0(t|0, x_0)$, $t \in T$, into the input of the system during the period of time $[0,\nu[$. Suppose that the controller has operated at the moments $0, \nu, \dots, (k-1)\nu$ and the control system at the moment $\tau = k\nu$ appears in the state $x^*(\tau)$. Using the results of the solution to LP problem at the moment $\tau - \nu$, the controller constructs the solution to the current LP problem at the moment τ using the dual method [13, 18].

The constructed optimal open-loop control $u^0(t|\tau, x^*(\tau))$, $t \in [\tau, t^*]$, is fed into the input of system (2.4) on the interval $[\tau, \tau + \nu[$.

Remark. For a large ν the correction of the OC may require a significant number of iterations of the dual method. To reduce the time of correction, one can correct the solutions to the LP problems at moments $\tau - \nu + \mu$, $\tau - \nu + 2\mu$, …, $\tau - \mu$. For small $\mu > 0$ these corrections require small work. Then the control $u^*(t)$, $t \in [\tau, \tau + \nu[$, is obtained by correcting the control $u^0(t|\tau - \mu, x^*(\tau - \mu))$, $t \in [\tau - \mu, t^*]$. Clearly, results of intermediate corrections at moments $\tau - \nu + \mu$, …, $\tau - \mu$ are not used in control of system (2.4).

6. Optimal controls of feedback type for systems under disturbances. As was mentioned in the classical statement of the optimal synthesis problem the OC of feedback type is constructed by the determined model even though it is intended for systems functioning under unknown disturbances. And in so doing, no information on disturbances is used; it is incorrect to remark on estimating the quality of the feedback with respect to disturbances. Engineers, of course, understood [12] that the reasonable use of information on disturbances can only increase the quality of the feedback. However, it was clear that in the new statement the optimal synthesis problem was considerably more difficult than the classical synthesis problem and for its solution new methods are required.

In studies of systems under disturbances it is necessary, first of all, to agree about a model of disturbances. At present time, two types of models of disturbances are distinguished: stochastic and nonstochastic. In the first case, disturbances are described in terms of the theory of stochastic processes, and in the second case only the class of possible realizations and the set of possible values of disturbances are given. Effective results on synthesis of optimal systems with the use of the first model of disturbances were obtained in stochastic analogues of the Kalman–Letov problem with the Gauss disturbances [50]. The investigations of this trend are not discussed in this work. We are dealing with OC problems based on nonstochastic models of disturbances [26, 35]. The possibility of investigation of similar problems appeared only with the creation of the OCT, with its development on differential games and nonsmooth analysis.

The inclusion of disturbances in the mathematical model of the OC problem, first of all, considerably expands the set of possible types of optimal feedback. It was, at first, noted by S. E. Dreyfus [11] in one stochastic extremal problem. In OC problems with disturbances four types of feedback are distinguished: (1) unclosed feedbacks (open-loop controls) which are closed only at the initial moment, i.e., use only a priori information; (2) unclosable feedbacks (an analogue of the classical feedback for systems without disturbances) which are closed at each current moment but do not use the fact that the closure is possible in future moments too, i.e., their action is based only on current information on the state of the system; (3) closable feedbacks which are closed at each current moment and additionally take into account that closure certainly will happen at some given future moments; (4) closed feedbacks which use information on the current states of the system and know that such information will be accessible at all future moments.

Extreme (the first and the fourth) types of feedback are not considered below because the first type does not relate to the discussed topic and the second one is so complicated that at the present moment there are not any interesting constructive results for it.

The unclosable feedback in the framework of the accepted approach in this paper was investigated in [37]. Let us briefly give only the principal moments of this work.

Instead of problem (2.1), let us introduce the problem

$$\begin{gathered} J(u) = c'x(t^*) \longrightarrow \max, \quad \dot{x} = Ax + bu + dw, \quad x(0) = x_0, \\ x(t^*) \in X^* = \{x \in R^n : \ h_i'x \geq g_i, \ i = \overline{1,m}\}, \quad |u(t)| \leq 1, \quad t \in T, \end{gathered} \tag{6.1}$$

where $w(t)$, $t \in T$, is a piecewise continuous disturbance satisfying the condition

$$|w(t)| \leq 1, \quad t \in T.$$

To define the optimal unclosable feedback, problem (6.1) is imbedded into the family of problems

$$\begin{gathered} c'x(t^*) \longrightarrow \max, \quad \dot{x} = Ax + bu + dw, \quad x(\tau) = z, \\ x(t^*) \in X^*, \quad |u(t)| \leq 1, \quad t \in T(\tau). \end{gathered} \tag{6.2}$$

A piecewise continuous function $u(t)$, $|u(t)| \leq 1$, $t \in T(\tau)$, is said to be an accessible (guaranteeing) open-loop control for the position (τ, z) if all solutions (for all possible $w(t)$, $t \in T(\tau)$) to the equation

$$\dot{x} = Ax + bu(t) + dw(t), \quad x(\tau) = z, \tag{6.3}$$

satisfy the condition

$$x(t^*) \in X^*. \tag{6.4}$$

Denote by $X(t|u_\tau(\cdot))$ $\big(u_\tau(\cdot) = (u(t),\, t \in T(\tau))\big)$ the set of all possible states $x(t)$ of system (6.3). Then requirement (6.4) can be written in the form $X(t^*|u_\tau(\cdot)) \subset X^*$.

The quality of the accessible control $u_\tau(\cdot)$ is evaluated by the value of the functional

$$J(u_\tau) = \min c'x, \quad x \in X(t^*|u_\tau(\cdot)).$$

An accessible control $u^0(t|\tau, z)$, $t \in T(\tau)$, is said to be an optimal (guaranteeing) open-loop control for the position (τ, z) if

$$J(u^0_\tau) = \max J(u_\tau).$$

From here at $\tau = 0$, $z = x_0$ we obtain the exact nature of problem (6.2).

Let X_τ be a set of all the vectors for which problem (6.2) with a fixed τ has an open-loop solution $u^0(t|\tau, z)$, $t \in T(\tau)$.

Definition. The function

$$u^0(\tau, z) = u^0(\tau|\tau, z), \quad z \in X_\tau, \quad \tau \in T,$$

is said to be an optimal (guaranteeing) control of feedback type (or, briefly, optimal unclosable feedback).

Realization $u^*(t) = u^0(t, x^*(t))$, $t \in T$, of the optimal unclosable feedback and the optimal controller calculating this realization are defined by analogy with section 3.

To describe an algorithm of operating the optimal controller, let us consider an arbitrary current moment τ and a current state $x^*(\tau)$. In the position $(\tau, x^*(\tau))$, in order to calculate the current value $u^*(\tau)$ of the realization of the optimal unclosable feedback, the optimal controller has to know the open-loop guaranteeing solution to the following problem:

$$\begin{gathered} c'x(t^*) \longrightarrow \max, \quad \dot{x} = Ax + bu + dw, \quad x(\tau) = x^*(\tau), \\ x(t^*) \in X^*, \quad |u(t)| \leq 1, \quad t \in T(\tau). \end{gathered}$$

In [37] it is shown that the solution $u^0(t|\tau, x^*(\tau))$, $t \in T(\tau)$, to this problem coincides with the optimal open-loop control of the determined problem

$$\begin{gathered} c'x(t^*) \longrightarrow \max, \quad \dot{x} = Ax + bu, \quad x(\tau) = 0, \\ h_i'x(t^*) \geq g_i(\tau), \quad i = \overline{1, m}; \quad |u(t)| \leq 1, \quad t \in T(\tau), \end{gathered} \tag{6.5}$$

where $g_i(\tau) = g_i - h_i' F(t^* - \tau)x^*(\tau) + \int_\tau^{t^*} |h_i' F(t^* - t)d|dt$, $F(t)$, $t \geq 0$, is a fundamental matrix of solutions to the homogeneous equation $\dot{x} = Ax$.

The optimal controller for problem (6.5) is constructed by the scheme of section 3. It will be an optimal controller for problem (6.1). At this point, the process of solving the synthesis problem of the optimal unclosable feedback is finished.

It is more difficult to construct a realization of an optimal closable feedback. This work was carried out in [25, 29, 30, 31], but due to massive calculations it is not possible to give the obtained results here. From the analysis of the method [29] it is obvious that the complexity of the optimal closable feedback grows rapidly as the number of moments of closure increases. However, in doing so, the quality of the optimal closable feedback approaches the optimal closed feedback which "in principle" is obtained from the Bellman–Isaacs equation. So it may be inferred that optimal closed feedback is such an ideal that cannot be achieved as yet but there are ways of steering (with appropriate efforts) to as small as one likes its neighborhood.

7. Optimal output feedbacks. So far it has been assumed that at each current moment $\tau \in T$ of the control process a complete and exact information on the current state $x^*(\tau)$ of the control system is available. Therein lies one of the features of the classical statement of the synthesis problem. It was possible for this assumption to be accepted in the 50's as the order of systems being studied was not very high. But today this assumption is considered too restrictive because available information on states of modern complex control systems is, as a rule, incomplete and inexact. Now one comes to a decision based on the readings of a measurer able to measure only some output signals of the system with limited accuracy.

That is why the output feedbacks defined not on system states but on its available output signals are urgent for the modern theory of control. Feedbacks described in previous sections are usually called state feedbacks. The problem of constructing optimal output feedbacks has been much studied in the framework of the Kalman–Letov stochastic problem [50]. Below, only nonstochastic OC problems are considered.

The essence of the new problem is illustrated by the simplest problem. More complex statements are studied in [20, 23, 24, 36]. In formal terms, the problem has the form

$$\begin{gathered} h_0' x(t^*) \longrightarrow \max, \quad \dot{x} = Ax + bu, \\ x(0) = x_0 \in X_0 = \{x \in R^n : Dx = \delta, \;\; d_* \leq x \leq d^*\}, \quad x(t^*) \in X^*, \\ y(t) = c'x(t) + \xi(t), \quad \xi_* \leq \xi(t) \leq \xi^*, \quad |u(t)| \leq 1, \quad t \in T, \\ \operatorname{rank} D = l < n. \end{gathered} \tag{7.1}$$

The problem has the following sense. The initial state of the optimized system is not known exactly. A priori information on the initial state is exhausted by the inclusion $x_0 \in X_0$. By analogy with the theory of filtration we say that the set X_0 is an a priori distribution of the initial state of the control system, omitting the adjective "probable." In the control process current states are not available; only the output signal $c'x(t)$, $t \in T$, of the system is measured and the measurer does it with the error $\xi(t)$, $t \in T$, so at each moment of the control only a number $y(t)$ is at our disposal. As an error of measurement, any piecewise continuous function $\xi(t)$, $t \in T$, satisfying the inequalities $\xi_* \leq \xi(t) \leq \xi^*$, $t \in T$, may be realized. At each moment $\tau \in T$ based on the written signal $y_\tau(\cdot) = (y(t), t \in T_\tau = [0, \tau])$, the optimal controller has to produce controls $u^0(\tau, y_\tau(\cdot))$, $|u^0(\tau, y_\tau(\cdot))| \leq 1$, $\tau \in T$, which at the moment $t = t^*$ steer the system to the terminal set X^* with assurance and give the maximal guaranteed value for the control criterion $h_0'x(t^*)$.

For more precise definitions let us consider a particular control process at any current moment $\tau \in T$. Denote by $y_\tau^*(\cdot) = (y^*(t),\ t \in T_\tau)$ a signal of the measurer written by that time, and by $u_\tau^*(\cdot)$ the control used (fed into the system). As the information, available at the moment τ, contains, in the general case, additional knowledge of the initial state x_0^* realized in the process, so let us use this knowledge to decrease an a priori uncertainty. A vector $x^* \in X_0$ is called an initial state compatible with the functions $u_\tau^*(\cdot)$, $y_\tau^*(\cdot)$ if the corresponding trajectory of system (7.1) together with some possible function of errors $\xi^*(t)$, $t \in T_\tau$, generates the signal $c'x^*(t)+\xi^*(t)$, $t \in T_\tau$, coinciding with the written signal $y^*(t)$, $t \in T_\tau$: $y^*(t) \equiv c'x^*(t)+\xi^*(t)$, $t \in T_\tau$.

Denote by $\hat{X}_0(\tau)$ the set of all vectors $x^* \in X_0$ compatible with $u_\tau^*(\cdot)$, $y_\tau^*(\cdot)$, and call it the τ-a-posteriori distribution of the initial state. The set

$$\hat{X}_\tau(\tau) = \left\{ x : x = F(\tau)x_0 + \int_0^\tau F(\tau - s)bu^*(t)dt, \quad x_0 \in \hat{X}_0(\tau) \right\}$$

is said to be the τ-a-posteriori distribution of the state $x(\tau)$.

A piecewise continuous function $u_\tau(\cdot) = (u(t),\ t \in T(\tau))$, $|u(t)| \le 1$, $t \in T(\tau)$, is said to be an admissible (guaranteeing) control if at the moment $t = t^*$ it steers all states from the set $\hat{X}_\tau(\tau)$ to the terminal set X^*. Let

$$X(t^*|u_\tau(\cdot)) = \left\{ x : x = F(t^* - \tau)x_\tau + \int_\tau^{t^*} F(t^* - s)bu(s)ds, \quad x_\tau \in \hat{X}_\tau(\tau) \right\}.$$

Then the admissibility of the control $u_\tau(\cdot)$ can be written briefly: $X(t^*|u_\tau(\cdot)) \subset X^*$.

As a control criterion, the functional

$$J(u_\tau(\cdot)) = \min h_0'x, \quad x \in X(t^*|u_\tau(\cdot)),$$

is considered.

An admissible control $u^0(t|\tau, \hat{X}_\tau(\tau))$, $t \in T(\tau)$, is called a τ-a-posteriori optimal (guaranteeing) open-loop control [21] if it satisfies the equality

$$J(u_\tau^0(\cdot)) = \max J(u_\tau(\cdot)).$$

The optimal (guaranteeing) output feedback is defined by the equality

$$u^0(\tau, y_\tau(\cdot)) = u^0(\tau|\tau, \hat{X}_\tau(\tau)), \quad y_\tau(\cdot) \in Y_\tau, \quad \tau \in T,$$

where Y_τ is the set of all signals of measurer for which there exists $u^0(t|\tau, \hat{X}_\tau(\tau))$, $t \in T(\tau)$.

Following section 2, one can introduce the notion of the realization of the optimal output feedback $u^*(\tau) = u(\tau, y_\tau^*(\cdot))$, $\tau \in T$, and the optimal controller able to calculate its values in real time.

It is shown in [36] that for calculating $u^*(\tau)$ it is sufficient to solve the determined OC problem

$$\begin{gathered} h_0'x(t^*) \longrightarrow \max, \quad \dot{x} = Ax + bu, \quad x(\tau) = 0, \\ h_i'x(t^*) \ge g_i(\tau), \quad i = \overline{1,m}, \quad |u(t)| \le 1, \quad t \in T(\tau), \end{gathered} \tag{7.2}$$

in real time, where $g_i(\tau) = g_i - \alpha_i(\tau)$, $i = \overline{1,m}$, are obtained by solving m linear problems of OO

$$\alpha_i(\tau) = \min_{x \in \hat{X}_\tau(\tau)} h_i' F(t^* - \tau)x, \quad i = \overline{1,m}, \tag{7.3}$$

in real time.

Let us dwell on the latter problem.

8. OO problem, defining equations, and algorithm of operating optimal estimator. In "pure form" the OO problem used for solving the OC problem under uncertainty consists in the following.

On the interval $T = [0, t^*]$ the behavior of the dynamic system is described by the equation

$$\dot{x} = Ax \quad (x \in R^n). \tag{8.1}$$

The initial state of system (8.1) is not known exactly. It is only known that the vector x_0 belongs to the set

$$X_0 = \{x \in R^n : Dx = \delta, \quad d_* \leq x \leq d^*\}, \tag{8.2}$$

which above was called the a priori distribution of an initial state.

To refine the actual initial state x_0^* realized in some particular process the behavior of system (8.1) is observed and readings $y(t)$, $t \in T$, of the measurer

$$y = c'x + \xi, \quad \xi_* \leq \xi(t) \leq \xi^*, \quad t \in T, \tag{8.3}$$

are obtained.

According to relation (8.3) the measurer at each moment $t \in T$ can measure the given linear combination $c'x(t) = \sum_{j=1}^{n} c_j x_j(t)$ of the components $x_1(t), \ldots, x_n(t)$ of the current state $x(t)$ of system (8.1) with an error $\xi(t)$. Suppose that the function $\xi(t)$, $t \in T$, of measuring errors, an arbitrary piecewise continuous function satisfying inequalities (8.3), may be realized.

Denote by $y(t)$, $t \in T$, a signal written by the device (8.3) in some observation process. The information inherent in the signal $y(t)$, $t \in T$, allows us to decrease the a priori uncertainty of the realized vector x_0^*.

Definition. A set $\hat{X}_0$ is called the a posteriori distribution of the initial state of system (8.1) if it consists of those and only those elements of the set X_0 which together with admissible functions $\xi(t)$, $t \in T$, can produce the written signal $y(t)$, $t \in T$.

The analytical description of the set $\hat{X}_0$ has the form: a vector $x \in \hat{X}_0$ if and only if it satisfies the relations

$$\xi_* \leq y(t) - c'F(t)x \leq \xi^*, \quad t \in T; \quad Dx = \delta, \quad d_* \leq x \leq d^*. \tag{8.4}$$

The description of the set $\hat{X}_0$ contains a continuum of inequalities; thus, its structure may be very complex for effective tabulation. Luckily, in many applied problems the set $\hat{X}_0$ is not used entirely, all one has to do is to know some of its estimates (numerical characteristics). Thus, in order to solve problem (7.1), the estimates of the form

$$p'x \longrightarrow \max, \quad x \in \hat{X}_0, \tag{8.5}$$

are necessary, i.e., the extension of the set $\hat{X}_0$ in the direction of the vector $p \in R^n$.

Problem (8.5) is called a linear OO problem. In view of (8.4) this problem is a linear semi-infinite extremal problem. Similar problems occur in various applications and have a sufficiently developed theory [47]. It is interesting to note that problem (8.5) in some sense is a "dual" to the OC problem (2.1): there is a finite number of variables but an infinite number of general constraints in problem (8.5) and, conversely, there is an infinite number of variables and a finite number of general constraints in problem (2.1).

A finite method of solving problem (8.5) is described in [48].

To define positional solutions to problem (8.5) let us imbed it into the family of the problems

$$p'x \longrightarrow \max, \quad x \in \hat{X}_0(\tau), \tag{8.6}$$

where $\hat{X}_0(\tau)$ is an a posteriori distribution of an initial state of system (8.1) corresponding to the observation $y_\tau(\cdot)$.

A vector $x^0_\tau = x^0(\tau, y_\tau(\cdot)) \in \hat{X}_0(\tau)$, which gives the control criterion of problem (8.6) the maximum value, is called the optimal open-loop solution to problem (8.6).

Let $Y(\tau)$ be a set of signals $y_\tau(\cdot)$ which can be realized on the interval $[0, \tau]$ for any initial states $x_0 \in X_0$ and any measuring errors $\xi_* \le \xi(t) \le \xi^*$, $t \in T_\tau$. The functional $x^0(\tau, y_\tau(\cdot))$, $y_\tau(\cdot) \in Y(\tau)$, $\tau \in T$, is said to be a positional solution to the OO problem (8.5).

Constructing a positional solution to the OO problem in an explicit form is an extraordinarily complex problem. As in the case of the OC problem, consider a particular observation process in which an output signal $y^*(t)$, $t \in T$, is realized. It is clear that in this process values of the functional $x^0(\tau, y_\tau(\cdot))$, $y_\tau(\cdot) \in Y(\tau)$, $\tau \in T$, are necessary only along the curve $y^*(t)$, $t \in T$.

The function $x^*(\tau) = x^0(\tau, y^*_\tau(\cdot))$, $y^*_\tau(\cdot) \in Y(\tau)$, $\tau \in T$, is said to be a realization of the positional solution to the OO problem, and any device able to calculate its values in real time is called an optimal continuous estimator.

Describe an algorithm of operating the optimal estimator.

Suppose that the estimator has been constructed and operated on the interval T_τ. Using the written signal $y^*(t)$, $t \in T_\tau$, at the moment τ the estimator has to solve problem (8.6). In detailed notation, problem (8.6) has the form

$$\begin{gathered} p'x \longrightarrow \max, \quad \alpha_*(t) \le a'(t)x \le \alpha^*(t), \quad t \in T_\tau, \\ Dx = \delta, \quad d_* \le x \le d^*, \end{gathered} \tag{8.7}$$

where $\alpha_*(t) = \xi_* - y^*(t)$, $\alpha^*(t) = \xi^* - y^*(t)$, $a'(t) = (a_j(t),\ j \in J) = -c'F(t)$, $J = \{1, 2, \dots, n\}$.

Let $\hat{x}_\tau$ be an optimal feasible point of problem (8.7). Introduce the sets where constraints of problem (8.7) are active:

$$\begin{gathered} T_a(\tau) = T_a^+(\tau) \cup T_a^-(\tau), \quad T_a^+(\tau) = \{t \in T_\tau : a'(t)\hat{x}_\tau = \alpha^*(t)\}, \\ T_a^-(\tau) = \{t \in T_\tau : a'(t)\hat{x}_\tau = \alpha_*(t)\}, \\ J^+(\tau) = \{j \in J : \hat{x}_{\tau j} = d^*_j\}, \quad J^-(\tau) = \{j \in J : \hat{x}_{\tau j} = d_{*j}\}. \end{gathered}$$

The optimal feasible point $\hat{x}_\tau$ satisfies the relations

$$\begin{gathered} \Delta_j(\tau) \ge 0 \text{ if } j \in J^-(\tau), \quad \Delta_j(\tau) \le 0 \text{ if } j \in J^+(\tau), \\ \Delta_j(\tau) = 0 \text{ if } j \in J \backslash (J^+(\tau) \cup J^-(\tau)), \end{gathered}$$

where $\Delta_j(\tau) = \sum_{t\in T_a(\tau)} a_j(t)\eta(t) + \eta' D_j + p_j$, $\eta_\tau = (\eta(t),\, t \in T_a(\tau);\, \eta)$, is an optimal dual feasible point of problem (8.7) [39]:

$$\eta(t) \geq 0, \quad t \in T_a^+(\tau); \quad \eta(t) \leq 0, \quad t \in T_a^-(\tau); \quad \eta \in R^l.$$

A pair $\{\hat{x}_\tau, \eta_\tau\}$ is called a positional solution to problem (8.7).

Introduce a set $J_0(\tau) = \{j \in J : \Delta_j(\tau) = 0\}$. A solution to problem (8.7) is called nonsingular if

(1) $\operatorname{rank}(D_j';\, a_j(t), t \in T_a(\tau);\, \dot{a}_j(t), t \in T_a(\tau)\backslash\ \{0,\tau\};\, j \in J_0(\tau)) = |J_0(\tau)|$,
(2) $\operatorname{rank}(D_j';\, a_j(t), t \in T_a(\tau);\, j \in J_0(\tau)) = |T_a(\tau)| + l$,
(3) $d_*j < \hat{x}_{\tau j} < d_j^*,\ j \in J_0(\tau)$,
(4) $\eta(t) \neq 0,\ t \in T_a(\tau)$.

Here $J_0(\tau) = \{j \in J : \Delta_j(\tau) = 0\}$. Suppose that $\{0\} \notin T_a(\tau)$, $\tau > 0$.

Let $\{\hat{x}_{\tau_*}, \eta_{\tau_*}\}$ be a nonsingular solution to (8.7) at $\tau = \tau_*$. Describe rules of constructing solution to problem (8.7) for $\tau \in]\tau_*, t^*]$. Two situations are possible: (1) $\tau_* \in T_a(\tau_*)$, (2) $\tau_* \notin T_a(\tau_*)$.

Consider case (1). Assume $a'(\tau_*)\hat{x}_{\tau_*} = \alpha_*(\tau_*)$, $\dot{a}'(\tau_*)\hat{x}_{\tau_*} \neq \dot{\alpha}_*(\tau_*)$.

As is shown in [39], the set

$$\text{(8.8)} \qquad \text{æ}(\tau) = \{\hat{x}_\tau, \eta_\tau, T_a(\tau)\},$$

consisting of the optimal primal and dual feasible points of problem (8.7) and the active moments, is sought from the equations

$$\text{(8.9)}\ F(\text{æ}|\tau) = 0 \Longleftrightarrow \begin{cases} \hat{x}_{\tau j} = d_j^*, \quad j \in J^-; \quad \hat{x}_{\tau j} = d_{*j}, \quad j \in J^+; \quad D\hat{x}_\tau = \delta, \\ a'(t_i(\tau))\hat{x}_\tau = \alpha_i(t_i(\tau)), \quad i = \overline{1,q}, \\ \dot{a}'(t_i(\tau))\hat{x}_\tau = \dot{\alpha}_i(t_i(\tau)), \quad i = \overline{1,q-1}; \quad t_q(\tau) = \tau, \\ \Delta_j(t_i(\tau)) = 0, \quad j \in J_0. \end{cases}$$

Here $q = |T_a(\tau)|$, $J_0 = J_0(\tau_*)$, $I_0 = \{1,\ldots,q\}$, $I_0^+ = \{i \in I_0 :\ t_i(\tau) \in T_a^+(\tau)\}$, $I_0^- = I_0\backslash I_0^+$, $J^+ = (J\backslash J_0) \cap J^+(\tau)$, $J^- = (J\backslash J_0) \cap J^-(\tau)$, $\alpha_i(t) = \alpha^*(t)$ for $i \in I_0^+$; $\alpha_i(t) = \alpha_*(t)$ for $i \in I_0^-$.

Equations (8.9) are said to be the defining equations of the optimal estimator. The set

$$\{q,\ J_0,\ J^+,\ J^-,\ I_0^+,\ I_0^-\}$$

is called a structure of the defining equations.

A moment $\bar{\tau}$ of changing the structure of equations (8.9) is characterized by one of the following properties.

(1) At any $t_0 \in [0,\bar{\tau}]\backslash\{t_i(\bar{\tau}),\ i = \overline{1,q}\}$ one of the inequalities $\alpha_*(t_0) \leq a'(t_0)\hat{x}_{\bar{\tau}} \leq \alpha^*(t_0)$ becomes an equality.
(2) For any $j_0 \in J_0$ one of the inequalities $d_{*j_0} \leq \hat{x}_{\bar{\tau}j_0} \leq d_{j_0}^*$ becomes an equality.
(3) For any $i_0 \in I_0\backslash\{q\}$ the equality $\eta(t_{i_0}(\bar{\tau})) = 0$ takes place.
(4) For any $j_0 \in J\backslash J_0$ the equality $\Delta_{j_0}(\bar{\tau}) = 0$ takes place.
(5) The equality $\dot{a}'(\bar{\tau})\hat{x}(\bar{\tau}) = \bar{\alpha}_q(\bar{\tau})$ takes place.

Consider case (2). For $\tau \in T^+(\tau_*)$ elements (8.8) has the form

$$\text{(8.10)} \qquad \hat{x}_\tau = \hat{x}_{\tau_*},\ \eta_\tau = \eta_{\tau_*},\ T_a(\tau) = T_a(\tau_*).$$

A solution to problem (8.7) is constructed according to rule (8.10) till a moment $\bar{\tau} \in [\tau_*, t^*]$ where $a'(\bar{\tau})\hat{x}_{\bar{\tau}} = \alpha_*(\bar{\tau})$, $\dot{a}'(\bar{\tau})\hat{x}_{\bar{\tau}} \neq \dot{\alpha}_*(\bar{\tau})$ or $a'(\bar{\tau})\hat{x}_{\bar{\tau}} = \alpha^*(\bar{\tau})$, $\dot{a}'(\bar{\tau})\hat{x}_{\bar{\tau}} \neq \dot{\alpha}^*(\bar{\tau})$.

For $\tau \in T^+(\bar{\tau})$ a solution to problem (8.7) is constructed according to case (1).

As in the case of an optimal controller, the algorithm of operating the optimal estimator consists of three procedures: (1) the starting procedure, (2) the procedure of constructing defining elements (8.8) on intervals with constant structure, and (3) the procedure of changing the structure.

Details of these procedures are described in [34, 39].

9. Optimal discrete estimator. To introduce a discrete estimator let us change some conditions of observation. The object of observation remains as before (see (8.1)). Formally (8.3) of the measurer also remains. But this time, suppose that on the interval $[0, t^*]$ measurements are written at discrete moments $t_k = k\nu$, $k = 0, 1, \dots, N$, $\nu = t^*/N$. Errors of measurements are numbers ξ_k, $k = 0, 1, \dots, N$, satisfying the inequalities $\xi_* \le \xi_k \le \xi^*$, $k = 0, 1, \dots, N$. Formally, the notion of a posteriori distribution $\hat{X}_0$ of an initial state (see section 8) remains, but its analytical form is radically changed: a vector $x_0 \in \hat{X}_0$ if and only if it satisfies the finite set of inequalities

$$\begin{gathered} \xi_* \le y(k\nu) - c'F(k\nu)x_0 \le \xi^*, \quad k = \overline{0, N}, \\ Dx_0 = \delta, \quad d_* \le x_0 \le d^*. \end{gathered}$$

Of course now, the structure of the set $\hat{X}_0$ is also essentially more complex than that of the set X_0. But this structure allows one to solve OO problems considerably more easily and without any demand on analytical properties of available signals $y(t)$, $t \in T$. This is very important for solving applied problems.

Now, the OO problem takes the form

$$\begin{gathered} p'x \longrightarrow \max, \quad \xi_* \le y(k\nu) - c'F(k\nu)x \le \xi^*, \quad k = \overline{0, N}, \\ Dx = \delta, \quad d_* \le x \le d^*, \end{gathered} \tag{9.1}$$

i.e., it is an LP problem. The optimal feasible point x^0 of problem (9.1) presents an open-loop solution to the discrete OO problem.

To introduce a positional solution to the OO problem let us imbed problem (9.1) into a family of problems (8.6) where as τ discrete moments $k\nu$, $k = \overline{0, N}$, are considered, the sets $\hat{X}_0(\tau)$ are appropriately changed to $\hat{X}_0(\tau) = \{x : \xi_* \le y(i\nu) - c'F(i\nu)x \le \xi^*,\ i = \overline{0, k},\ \ Dx = \delta,\ d_* \le x \le d^*\}$, $y_\tau(\cdot) = \{y(i\nu),\ i = \overline{0, k}\}$.

Let $x^0_\tau = x^0(\tau, y_\tau(\cdot)) \in \hat{X}_0(\tau)$ be an optimal feasible point of problem (8.6) at $\tau = k\nu$. The functional

$$x^0(\tau, y_\tau(\cdot)), \quad y_\tau(\cdot) \in Y(\tau), \quad \tau \in T_\nu = [0, \nu, \dots, N\nu], \tag{9.2}$$

is said to be a positional solution to the discrete OO problem. In spite of simplification of the OO problem in the discrete case, it is very difficult to construct functional (9.2). So let us follow the approach described above for the continuous OO problem. Suppose that functional (9.2) is constructed. Use it in a particular observation process when the signal $y^*(k\nu)$, $k = \overline{0, N}$, is written. This signal corresponds to the estimates $\alpha^*(k\nu) = p'x^0(k\nu, y^*_{k\nu}(\cdot))$ of a posteriori distribution $\hat{X}_0(k\nu)$. It is clear that in order to obtain these estimates the entire functional (9.2) is not used, but it is sufficient to know its values along the sequence $y^*(k\nu)$, $k = \overline{0, N}$. The function $x^*(k\nu) = x^0(k\nu, y^*_{k\nu}(\cdot))$, $y^*_{k\nu}(\cdot) \in Y(k\nu)$, $k = \overline{0, N}$, is said to be a discrete realization of a positional solution to the OO problem, and a device able to calculate its values in real time is called an optimal discrete estimator. Algorithms of operating optimal discrete estimators are given in [15, 44].

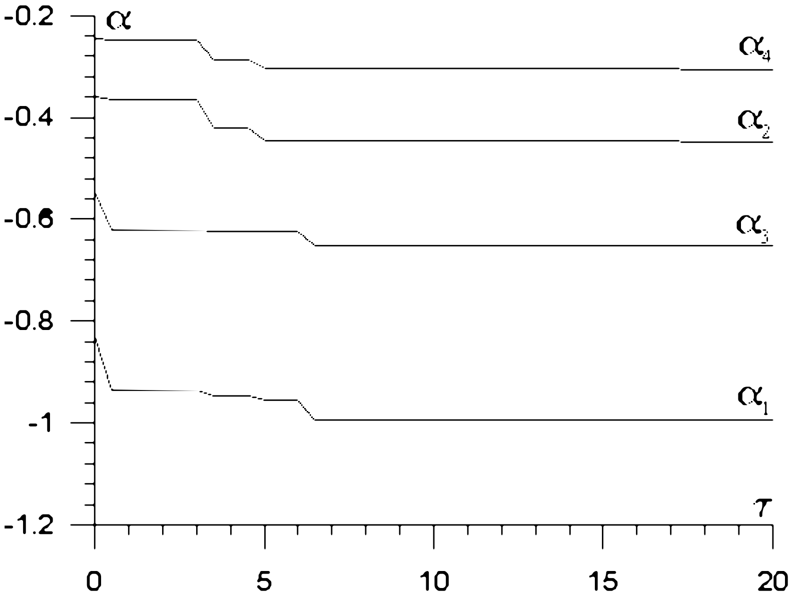

FIG. 9.1.

To describe an algorithm of operating a discrete estimator let us study a situation at an arbitrary moment $\tau = k\nu$. According to the definition, in order to calculate $\alpha^*(\tau)$, the optimal estimator needs to know a solution to the LP problem

$$\begin{gathered} p'x \longrightarrow \max, \quad \xi_* - y^*(i\nu) \le -c'F(i\nu)x \le \xi^* - y^*(i\nu), \quad i = \overline{0,k}, \\ Dx = \delta, \quad d_* \le x \le d^*. \end{gathered} \tag{9.3}$$

At the previous moment $(k-1)\nu$ the estimator dealt with the problem

$$\begin{gathered} p'x \longrightarrow \max, \quad \xi_* - y^*(i\nu) \le -c'F(i\nu)x \le \xi^* - y^*(i\nu), \quad i = \overline{0,k-1}, \\ Dx = \delta, \quad d_* \le x \le d^*. \end{gathered} \tag{9.4}$$

As problems (9.3) and (9.4) differ only by one constraint, knowing the solution to problem (9.4) makes it possible that a very few iterations would be sufficient to construct a solution $x^0(k\nu, y^*_{k\nu}(\cdot))$ to problem (9.3) with the help of the dual method of LP. If the time that it takes to do this work does not exceed ν, then one may say that the positional solution to the OO problem is realized in real time.

Return to example (3.6) and eliminate a control from the equation. The mathematical model of the system becomes of the form

$$\dot{x}_1 = x_3, \quad \dot{x}_2 = x_4, \quad \dot{x}_3 = -x_1 + x_2, \quad \dot{x}_4 = 0.1x_1 - 1.02x_2. \tag{9.5}$$

Suppose that the information on the initial state of the system is

$$x_1 = 0, \quad x_2 = 0, \quad 0.8 \le x_3 \le 1.1, \quad 0.4 \le x_4 \le 0.6,$$

and a measurer has the form

$$y = x_1 + \xi, \quad |\xi| \le 0.5.$$

Observation is conducted on the interval $T = [0, 20]$ with $\nu = 0.5$. The components of the initial state unknown for the estimator are $x_3^* = 1$, $x_4^* = 0.5$; the function of measuring errors unknown for the estimator has the form $\xi^*(t) = 0.5 \sin 2t$, $t \in T$.

In Figure 9.1 results of solving four OO problems are presented. In these problems the estimates

$$\alpha_i = x_i(t^*) \longrightarrow \max, \quad i = \overline{1, 4},$$

are calculated.

10. Observation under constantly affecting bounded disturbances. In sections 8 and 9, the OO problem, in which motion of the system takes place under ideal conditions according to equation (8.1), is considered. In this section the OO problem is studied for the case when the dynamic system is under bounded disturbances.

10.1. Observation without identification of disturbances. Suppose that on the interval $T = [0, t^*]$ the behavior of the dynamic system is described by the equation

$$\dot{x} = Ax + dw, \quad \bigl(x \in R^n, \quad w \in R\bigr), \tag{10.1}$$

where $w(t)$, $t \in T$, is an unknown piecewise continuous function of disturbances satisfying the constraint $w_* \le w(t) \le w^*$, $t \in T$.

The a priori distribution X_0 of the initial state x_0 of system (10.1) and the equation of the measurer remain in the form of (8.2), (8.3).

Reformulate the main notions of section 8 with regard to disturbances in model (10.1).

A set $\hat{X}_0$ is said to be an a posteriori distribution of the initial state of system (10.1) corresponding to the written signal $y(t)$, $t \in T$, if it consists of those and only those elements of the set X_0 which together with some admissible functions $w(t)$, $\xi(t)$, $t \in T$, can generate the signal $y(t)$, $t \in T$. The set $\hat{X}_0$ is described analytically by the following: a vector $x \in \hat{X}_0$ if and only if there exists a piecewise continuous function $w(t)$, $w_* \le w(t) \le w^*$, $t \in T$, such that the relations

$$\xi_* \le y(t) - c'F(t)x - \int_0^t c'F(t-s)dw(s)ds \le \xi^*, \quad t \in T,$$
$$Dx = \delta, \quad d_* \le x \le d^*,$$

are fulfilled.

The OO problem for system (10.1) also takes the form of (8.5), but as the description of the set $\hat{X}_0$ contains an infinite-dimensional variable $w(t)$, $t \in T$, so now problem (8.5) is an “infinite” extremal problem, i.e., it contains an unknown element of the infinite-dimensional space and a continuum of constraints.

For the purpose of numerically constructing a positional solution to problem (8.5), let us make an assumption that the function of disturbances $w(t)$, $t \in T$, is a piecewise constant function with a quantization period $\nu = t^*/N$, where N is an integer. Signals of the measurer will be correspondingly written at the moments[4] $t_k = k\nu$, $k = \overline{0, N}$.

[4] The quantization period of the disturbance $w(t)$, $t \in T$, and intervals between two written signals $y(t)$, $t \in T$, may be chosen to be different.

Then problem (8.5) takes the form

$$\begin{gathered} p'x \longrightarrow \max, \quad \xi_* - y(k\nu) \leq -c'F(k\nu)x \\ -\sum_{j=0}^{k-1} \int_{j\nu}^{(j+1)\nu} c'F(k\nu - s)ddsw_j \leq \xi^* - y(k\nu), \quad k = \overline{0,N}, \\ Dx = \delta, \quad d_* \leq x \leq d^*, \quad w_* \leq w_j \leq w^*, \quad j = \overline{0,N-1}, \end{gathered} \tag{10.2}$$

where $w_j = w(t)$, $t \in [j\nu, (j+1)\nu[$, $j = \overline{0,N-1}$.

Problem (10.2) is an LP problem with $n + N$ variables x_i, $i = \overline{1,n}$; w_j, $j = \overline{0,N-1}$. The optimal feasible point (x^0, w^0) provides the open-loop solution x^0 to the OO problem (8.5). As in the case of the OO problem without disturbances, for defining a positional solution to problem (8.5) let us imbed it into a family of problems (8.6) where

$$\begin{gathered} \hat{X}_0(\tau) = \hat{X}_0(k\nu) = \{x : \xi_* \leq y(i\nu) - c'F(i\nu)x \\ -\sum_{j=0}^{k-1} \int_{j\nu}^{(j+1)\nu} c'F(k\nu - s)ddsw_j \leq \xi^*, \ i = \overline{0,k}, \ \ Dx = \delta, \ d_* \leq x \leq d^*, \\ w_* \leq w_j \leq w^*, \ j = \overline{0,N-1}\}, \quad y_\tau(\cdot) = \{y(i\nu), \ i = \overline{0,k}\}. \end{gathered}$$

Let $x^0_\tau = x^0(\tau, y_\tau(\cdot)) \in \hat{X}_0(\tau)$ be an open-loop solution to problem (8.6) at $\tau = k\nu$. For the problem under consideration $Y(\tau)$ is the set of signals $y_\tau(\cdot)$ which can be realized on the interval $[0, \tau]$ for any initial states $x_0 \in X_0$, any disturbances $w(t)$, $|w(t)| \leq 1$, $t \in T_\tau$, and any measuring errors $\xi(t)$, $\xi_* \leq \xi(t) \leq \xi^*$, $t \in T_\tau$.

A functional

$$x^0(\tau, y_\tau(\cdot)), \quad y_\tau(\cdot) \in Y(\tau), \quad \tau \in T_\nu,$$

is said to be a positional solution to the discrete OO problem under constantly affecting disturbances.

By analogy with section 9 consider a particular observation process, in which a signal $y^*(k\nu)$, $k = \overline{0,N}$, is written, and introduce a notion of a discrete realization $x^*(k\nu) = x^0(k\nu, y^*_{k\nu}(\cdot))$, $y^*_{k\nu}(\cdot) \in Y(k\nu)$, $k = \overline{0,N}$, of a positional solution to the OO problem.

Thus, at the moment $\tau = k\nu$ in order to calculate the estimate $\alpha^*(k\nu) = p'x^0(k\nu, y^*_{k\nu}(\cdot))$, the optimal estimator solves the following LP problem:

$$\begin{gathered} p'x \longrightarrow \max, \quad \xi_* - y^*(i\nu) \leq -c'F(i\nu)x \\ -\sum_{j=0}^{i-1} \int_{j\nu}^{(j+1)\nu} c'F(i\nu - s)ddsw_j \leq \xi^* - y^*(i\nu), \quad i = \overline{0,k}, \\ Dx = \delta, \quad d_* \leq x \leq d^*, \quad w_* \leq w_j \leq w^*, \ \ j = \overline{0,k-1}. \end{gathered}$$

This problem differs from the one solved at the previous moment $(k-1)\nu$ by a new constraint and a new variable w_k. In order to solve it, the dual method of LP is used.

10.2. Optimal identification problem of parametric disturbances. Let us consider a dynamic system on the interval $T = [0, t^*]$ with a known initial state

$$\dot{x} = Ax + d\mu, \quad x(0) = x_0 \quad (x \in R^n, \quad \mu \in R). \tag{10.3}$$

Mathematical model (10.3) contains the disturbances $\mu(t)$, $t \in T$, and the following a priori information about them is known: (1) functions $\mu(t)$, $t \in T$, admit the representation

$$\mu(t) = \mu(t, w) = w_1\omega_1(t) + \cdots + w_q\omega_q(t), \quad t \in T,$$

where $\omega_1(t), \ldots, \omega_q(t)$, $t \in T$, are known piecewise continuous functions, and $w_1, \ldots, w_q$ are constant numbers; and (2) the vector $w = (w_1, \ldots, w_q)$ is not known exactly, and it can take any value from the bounded set

$$\check{W} = \{w \in R^q : f_* \leq w \leq f^*\}. \tag{10.4}$$

The set $\check{W}$ is said to be an a priori distribution of parameters of a disturbance.

The measurement of the output signal is made by measurer (8.3). In the course of observation of the output signal $y(t)$, $t \in T$, there appears additional information on realized values of parameters w of the disturbance.

A set $\hat{W}$ is called an a posteriori distribution of parameters of the disturbance of system (10.3) corresponding to the written signal $y(t)$, $t \in T$, if it consists of those and only those elements of the set $\check{W}$ which together with admissible functions $\xi(t)$, $t \in T$, can generate the signal $y(t)$, $t \in T$, for the initial state x_0.

The problem of optimal identification (OI) of parametric disturbances [42, 49] consists of calculating an estimate α of the set $\hat{W}$:

$$\alpha = \max p'w, \quad w \in \hat{W}. \tag{10.5}$$

In detailed notation, problem (10.5) takes the form

$$p'w \longrightarrow \max, \quad \xi_* - y(t) + c'F(t)x_0$$
$$\leq -\sum_{j=1}^{q} \int_0^t c'F(t-s)d\omega_j(s)dsw_j \leq \xi^* - y(t) + c'F(t)x_0, \quad f_* \leq w \leq f^*, \quad t \in T.$$

As well as problem (8.5), problem (10.5) is a semi-infinite extremal problem.

In order to define positional solutions to problem (10.5) let us imbed it into a family of problems

$$p'w \longrightarrow \max, \quad w \in \hat{W}(\tau), \tag{10.6}$$

where $\hat{W}(\tau)$ is an a posteriori distribution of parameters of the disturbance corresponding to the observation $y_\tau(\cdot)$.

Let $w^0_\tau = w^0(\tau, y_\tau(\cdot)) \in \hat{W}(\tau)$ be the optimal feasible point of problem (10.6), and let $Y(\tau)$ be the set of signals $y_\tau(\cdot)$ which can be realized on the interval $[0, \tau]$ for any parameters $w \in \check{W}$ of a disturbance and any measuring errors $\xi_* \leq \xi(t) \leq \xi^*$, $t \in T_\tau$. A functional $w^0(\tau, y_\tau(\cdot))$, $y_\tau(\cdot) \in Y(\tau)$, $\tau \in T$, is said to be a positional solution to the OI problem of parametric disturbances.

Consider some particular identification process in the course of which an output signal $y^*(t)$, $t \in T$, is realized. The function $w^*(\tau) = w^0(\tau, y^*_\tau(\cdot))$, $y^*_\tau(\cdot) \in Y(\tau)$, $\tau \in T$, is called a realization of the positional solution to the OI problem of parametric disturbances. Any device able to calculate its values in real time is said to be an optimal identifier of parametric disturbances.

In order to calculate the estimate $\alpha^*(\tau) = p'w^0(\tau, y^*_\tau(\cdot))$ the identifier solves problem (10.6) with $y(t) = y^*(t)$, $t \in T_\tau$:

$$p'w \longrightarrow \max, \quad \xi_* - y^*(t) + c'F(t)x_0$$
$$\leq -\sum_{j=1}^{q} \int_0^t c'F(t-s)d\omega_j(s)dsw_j \leq \xi^* - y^*(t) + c'F(t)x_0, \quad f_* \leq w \leq f^*, \quad t \in T_\tau.$$

In the case of constructing a discrete realization $w^*(k\nu) = w^0(k\nu, y^*_{k\nu}(\cdot))$, $y^*_{k\nu}(\cdot) \in Y(k\nu)$, $k = \overline{0, N}$, of the positional solution to the OI problem of parametric disturbances, the identifier solves the LP problem with q variables w_j, $j = \overline{1, q}$:

$$p'w \longrightarrow \max,$$
$$\xi_* - y^*(i\nu) + c'F(i\nu)x_0 \leq -\sum_{j=1}^{q} \int_0^{i\nu} c'F(i\nu - s)d\omega_j(s)dsw_j$$
$$\leq \xi^* - y^*(i\nu) + c'F(i\nu)x_0, \quad i = \overline{0, k}, \quad f_* \leq w \leq f^*,$$

using the dual method.

10.3. Observation with identification of parametric disturbances. Let us expand the above studied OI problem of parametric identification by the element of the OO problem—uncertainty in the initial state. Now we consider the situation when in system (10.3) the initial state x_0 is not known exactly; it is only known that it belongs to a given set X_0 (8.2).

Vectors $x_0 \in X_0$, $w \in \check{W}$ are said to be compatible with the written signal $y(t)$, $t \in T$, if the trajectory $x(t) = x(t|x_0, w)$, $t \in T$, corresponding to the initial state x_0 and the disturbance $\mu(t, w) = \sum_{i=1}^{q} w_i\omega_i(t)$, $t \in T$, together with any admissible error function $\xi(t)$, $t \in T$, generates the signal $y(t)$, $t \in T$.

The set of all pairs (x_0, w) of vectors $x_0 \in X_0$, $w \in \check{W}$, compatible with a $y(t)$, $t \in T$, is denoted by $\hat{X}_0 \times \hat{W}$ and is called an a posteriori distribution of the initial state and parameters of the disturbance.

The problem of optimal observation-identification (OOI) consists in calculating an estimate α of the set $\hat{X}_0 \times \hat{W}$:

$$\alpha = \max(p_1'x + p_2'w), \quad x \in \hat{X}_0, \quad w \in \hat{W}. \tag{10.7}$$

Problem (10.7) is a semi-infinite LP problem with $n+q$ variables x_i, $i = \overline{1, n}$; w_j, $j = \overline{1, q}$.

To introduce positional solutions to problem (10.7) let us imbed it into the family of problems

$$p_1'x + p_2'w \longrightarrow \max, \quad x \in \hat{X}_0(\tau), \quad w \in \hat{W}(\tau), \tag{10.8}$$

where $\hat{X}_0(\tau) \times \hat{W}(\tau)$ is an a posteriori distribution of an initial state and parameters of a disturbance corresponding to the observation $y_\tau(\cdot)$.

Let $x^0_\tau = x^0(\tau, y_\tau(\cdot)) \in \hat{X}_0(\tau)$, $w^0_\tau = w^0(\tau, y_\tau(\cdot)) \in \hat{W}(\tau)$ be an optimal feasible point of problem (10.7), and let $Y(\tau)$ be a set of signals $y_\tau(\cdot)$ which can be realized on the interval $[0, \tau]$ for any initial state $x_0 \in X_0$, any parameters $w \in \check{W}$ of a disturbance, and any measuring error $\xi_* \leq \xi(t) \leq \xi^*$, $t \in T_\tau$. A pair

$$\big(x^0(\tau, y_\tau(\cdot)), w^0(\tau, y_\tau(\cdot))\big), \quad y_\tau(\cdot) \in Y(\tau), \quad \tau \in T, \tag{10.9}$$

is said to be a positional solution to the OOI problem.

As well as in the OO problem, consider a particular process in the course of which the output signal $y^*(t)$, $t \in T$, is realized. A pair

$$(10.10)\quad \big(x^*(\tau) = x^0(\tau, y^*_\tau(\cdot)),\ w^*(\tau) = w^0(\tau, y^*_\tau(\cdot))\big), \quad y^*_\tau(\cdot) \in Y(\tau), \quad \tau \in T,$$

is said to be a realization of the positional solution to the OOI problem.

In order to calculate the estimate $\alpha^*(\tau) = p'_1 x^0(\tau, y^*_\tau(\cdot)) + p'_2 w^0(\tau, y^*_\tau(\cdot))$, problem (10.8), solved by the optimal estimator in detailed notation, takes the form

$$p'_1 x + p'_2 w \longrightarrow \max,$$
$$\xi_* - y^*(t) \le -c'F(t)x - \sum_{j=1}^{q} \int_0^t c'F(t-s)d\omega_j(s)ds w_j \le \xi^* - y^*(t),$$
$$Dx = \delta, \quad d_* \le x \le d^*, \quad f_* \le w \le f^*, \quad t \in T_\tau.$$

In the case of constructing a discrete realization $x^*(k\nu) = x^0(k\nu, y^*_{k\nu}(\cdot))$, $w^*(k\nu) = w^0(k\nu, y^*_{k\nu}(\cdot))$, $y^*_{k\nu}(\cdot) \in Y(k\nu)$, $k = \overline{0,N}$, of the positional solution to the OOI problem, the estimator solves the LP problem

$$p'_1 x + p'_2 w \longrightarrow \max,$$
$$\xi_* - y^*(i\nu) \le -c'F(i\nu)x - \sum_{j=1}^{q} \int_0^{i\nu} c'F(i\nu - s)d\omega_j(s)ds w_j$$
$$\le \xi^* - y^*(i\nu), \quad i = \overline{0,k}, \quad Dx = \delta, \quad d_* \le x \le d^*, \quad f_* \le w \le f^*,$$

by the dual method.

10.4. Observation with partial identification of parametric disturbances. Suppose that on the interval $T = [0, t^*]$ the behavior of a dynamic system is described by the equation

$$(10.11)\qquad \dot{x} = Ax + d_1\mu + d_2 v, \quad x_0 \in X_0 \quad (x \in R^n,\ \mu, v \in R).$$

System (10.11) contains the uncertainties studied in systems (10.1) and (10.3): the initial state of system (10.11) is not known exactly; it is only known that it belongs to a set X_0 (8.2); a disturbance $\mu(t)$, $t \in T$, affecting the system in the course of observation process is a linear combination of known piecewise continuous functions $\omega_j(t)$, $t \in T$, $j = \overline{1,q}$, with unknown coefficients $w = (w_j,\ j = \overline{1,q})$ from the set $\check{W}$ (10.4); furthermore, there are unknown piecewise continuous disturbances $v(t)$, $t \in T$, satisfying the constraints $v_* \le v(t) \le v^*$, $t \in T$, in the system.

Vectors $x_0 \in X_0$, $w \in \check{W}$ are said to be compatible with the written signal $y(t)$, $t \in T$, if the trajectory $x(t) = x(t|x_0, w)$, $t \in T$, of system (10.11) corresponding to the initial state x_0 and the disturbance $\mu(t, w) = \sum_{i=1}^{q} w_i\omega_i(t)$, $t \in T$, together with some admissible functions $v(t)$, $\xi(t)$, $t \in T$, generates the signal $y(t)$, $t \in T$.

A set of all vectors $x_0 \in X_0$, $w \in \check{W}$ compatible with $y(t)$, $t \in T$, is denoted by $\hat{X}_0 \times \hat{W}$ and is called an a posteriori distribution of an initial state and parameters of a disturbance.

A pair $(x, w) \in \hat{X}_0 \times \hat{W}$ if and only if there exists a piecewise continuous function $v(t)$, $v_* \le v(t) \le v^*$, $t \in T$, such that the relations

$$\xi_* \le y(t) - c'F(t)x - \sum_{j=1}^{q} \int_0^t c'F(t-s)d_1\omega_j(s)ds w_j - \int_0^t c'F(t-s)d_2 v(s)ds \le \xi^*,$$
$$Dx = \delta, \quad d_* \le x \le d^*, \quad f_* \le w \le f^*, \quad t \in T,$$

hold.

The OOI problem for system (10.11) has the form of (10.7). As there is the infinite-dimensional variable $v(t)$, $t \in T$, in description of the set $\hat{X}_0 \times \hat{W}$, so let us move on to the discrete form of the OOI problem; namely, consider that the function $v(t)$, $t \in T$, is piecewise continuous with a quantization period $\nu = t^*/N$ and measurements are conducted at the moments $t_k = k\nu$, $k = \overline{0, N}$. Problem (10.7) becomes of the form

$$
\begin{gathered}
p_1'x + p_2'w \longrightarrow \max, \\
\xi_* - y(i\nu) \le -c'F(i\nu)x - \sum_{j=1}^{q} \int_0^{i\nu} c'F(i\nu - s)d_1\omega_j(s)ds w_j \\
-\sum_{j=0}^{i-1} \int_{j\nu}^{(j+1)\nu} c'F(i\nu - s)d_2 ds v_j \le \xi^* - y(i\nu), \quad i = \overline{0, N}, \\
Dx = \delta, \quad d_* \le x \le d^*, \quad f_* \le w \le f^*, \quad v_* \le v_j \le v^*, \quad j = \overline{0, N-1},
\end{gathered}
\tag{10.12}
$$

where $v(t) = v_j$, $t \in [j\nu, (j+1)\nu[$, $j = \overline{0, N-1}$.

Problem (10.12) is an LP problem with $n+q+N$ variables x_i, $i = \overline{1, n}$; w_i, $i = \overline{1, q}$; v_i, $i = \overline{0, N-1}$. As before, in order to define positional solutions, problem (10.12) is imbedded into a family of problems (10.8), the positional solution to problem (10.12) is defined by relation (10.9), and the notion of realization of the positional solution (10.10) to the OOI problem is introduced.

To calculate the estimate $\alpha^*(k\nu) = p_1'x^0(k\nu, y_\tau^*(\cdot)) + p_2'w^0(k\nu, y_\tau^*(\cdot))$, the optimal estimator at the moment $\tau = k\nu$ solves the LP problem

$$
\begin{gathered}
p_1'x + p_2'w \longrightarrow \max, \\
\xi_* - y^*(i\nu) \le -c'F(i\nu)x - \sum_{j=1}^{q} \int_0^{i\nu} c'F(i\nu - s)d\omega_j(s)ds w_j \\
-\sum_{j=0}^{i-1} \int_{j\nu}^{(j+1)\nu} c'F(i\nu - s)d_2 ds v_j \le \xi^* - y^*(i\nu), \quad i = \overline{0, k}, \\
Dx = \delta, \quad d_* \le x \le d^*, \quad f_* \le w \le f^*, \quad v_* \le v_j \le v^*, \quad j = \overline{0, k-1},
\end{gathered}
$$

by the dual method.

10.5. Example. Consider system (9.5) under unknown bounded disturbances $w(t)$, $t \in T = [0, 20]$:

$$\dot{x}_1 = x_3, \quad \dot{x}_2 = x_4, \quad \dot{x}_3 = -x_1 + x_2, \quad \dot{x}_4 = 0.1x_1 - 1.02x_2 + w.$$

There is the following information on an initial state of the system:

$$x_1 = 0, \quad x_2 = 0, \quad 0.8 \le x_3 \le 1.1, \quad 0.4 \le x_4 \le 0.6.$$

In the course of the observation process, the output signal

$$y = x_1 + \xi, \quad |\xi| \le 0.2,$$

is available.

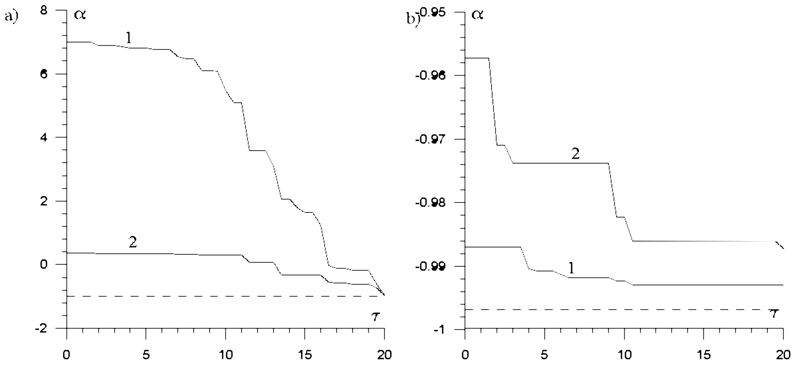

FIG. 10.1.

The parameter of the method ν is put to be equal to 0.5, the components of the initial state unknown for the estimator take the values $x_2^* = 1$, $x_4^* = 0.5$, and the function of measuring errors has the form $\xi^*(t) = 0.2\sin 3t$, $t \in T$. As an unknown disturbance, the function of the form $w(t) = w_1\omega_1(t) + w_2\omega_2(t) + w_3\omega_3(t)$, $t \in T$, is taken: $w^*(t) = 0.15\sin 0.5t + 0.1\sin 2t + 0.05\sin 5t$, $t \in T$.

In the course of the observation process, the value of the estimate $\alpha = \max x_1(20)$ is calculated. With the help of the Cauchy formula it can be written in the form

$$\alpha = \max\left(h_1' F(20)x_0 + \int_0^{20} h_1' F(20-s)w(s)ds\right), \tag{10.13}$$

where $h_1 = (1, 0, 0, 0)$.

Curve 1 in Figure 10.1a presents the behavior of the estimates $\alpha^*(\tau)$, $\tau \in T$, calculated by the optimal estimator without identification of disturbances with regard to the constraints $|w_j| \leq 0.3$, $j = \overline{0, 39}$. Curve 2 is constructed as a result of observation with partial identification of disturbances: the functions $\omega_1(t) = \sin 0.5t$, $\omega_2(t) = \sin 2t$, $t \in T$, were considered to be known for the estimator, the coefficients w_1, w_2 were identified during observation process, and the inequalities $0 \leq w_j \leq 0.2$, $j = 1, 2$, were set for them. The addend $v(t) = 0.05\sin 5t$, $t \in T$, was unknown for the estimator. The estimator knew only that this addend had satisfied the constraint $|v_j| \leq 0.05$, $j = \overline{0, 39}$.

In Figure 10.1b there are the values of the estimate $\alpha^*(\tau)$, $\tau \in T$, obtained by solving the OI problem of parametric disturbances with the known initial state (curve 1) and solving the OOI problem (curve 2). As the identified parameters, the coefficients w_1, w_2, w_3 satisfying the inequalities $0 \leq w_j \leq 0.2$, $j = 1, 2$, $0 \leq w_3 \leq 0.1$ were considered. The functions $\omega_1(t) = \sin 0.5t$, $\omega_2(t) = \sin 2t$, $\omega_3(t) = \sin 5t$, $t \in T$, were considered to be known for the estimator.

The actual value of the estimate calculated according to (10.13) on the base of the exact values x_0 and $w(t)$, $t \in T$, is equal to $\alpha^0 = -0.996845$, and it is presented by dashed lines in the figures.

11. Realization of optimal output feedback. As was noted in section 7, the calculation of the realization of the optimal output feedback $u^*(\tau)$, $\tau \in T$, is performed by solving problems (7.2), (7.3) in real time [24, 36].

Problem (7.2) differs form the previously studied OC problem (2.1) by the presence of terminal constraints-inequalities.

According to the Pontryagin maximum principle [53] the optimal open-loop control $u^0(t|\tau)$, $t \in T(\tau)$, of problem (7.2) has the form of (3.2), where the adjoint system becomes of the form

$$\dot{\psi} = -A'\psi, \quad \psi(t^*) = h_0 - \sum_{i \in I(\tau)} h_i \nu_i(\tau),$$

where $\nu(\tau) = (\nu_i(\tau),\ \ i \in I(\tau))$ is the Lagrange optimal vector, and $I(\tau) = \{i \in I : h_i' x_\tau^0(t^*) = g_i(\tau)\}$, $I = \{1, 2, \dots, m\}$, $x_\tau^0(t)$, $t \in T(\tau)$, is the optimal trajectory of problem (7.2).

Thus, the defining elements of problem (7.2) are the switching points of OC and the Lagrange vector

$$\text{æ}(\tau) = \big(t_1(\tau), \dots, t_p(\tau);\ \ \nu(\tau))\big). \tag{11.1}$$

Elements (11.1) satisfy the equations

$$F(\text{æ}|\tau) = 0 \Longleftrightarrow \begin{cases} h_i' x(t^*) = g_i(\tau), & i \in I(\tau), \\ \Delta(t_k|\tau) = 0, & k = \overline{1, p(\tau)}. \end{cases} \tag{11.2}$$

The algorithm of operating the optimal controller is analogous to the one discussed in section 3.

The values $g_i(\tau) = g_i - \alpha_i(\tau)$, $i = \overline{1, m}$, used in problem (7.2), are calculated by solving problems (7.3).

Consider one (ith) of problems (7.3). With the help of the Cauchy formula it can be written in the form

$$\begin{gathered} \alpha_i(\tau) = h_i' F(t^*) x + \int_0^\tau h_i' F(t^* - t) b u^*(t) dt \longrightarrow \min_x, \\ \alpha_*(t) \le a'(t) x \le \alpha^*(t), \quad t \in T_\tau, \quad Dx = \delta, \quad d_* \le x \le d^*, \end{gathered} \tag{11.3}$$

where $\alpha_*(t) = \xi_* - y^*(t) + \int_0^t h_i' F(t - s) b u^*(s) ds$, $\alpha^*(t) = \xi^* - y^*(t) + \int_0^t h_i' F(t - s) b u^*(s) ds$, $t \in T_\tau$, and $a'(t) = -h_i' F(t)$.

According to the scheme described in section 8, the optimal estimator at a current moment $\tau \in T$ constructs a solution $x^0(\tau, y_\tau^*(\cdot))$ to problem (11.3) and calculates an estimate $\alpha_i(\tau) = h_i' F(t^*) x^0(\tau, y_\tau^*(\cdot)) + \int_0^\tau h_i' F(t^* - t) b u^*(t) dt$.

All m problems (11.3) are solved in parallel based on the known values of the output signal $y_\tau^*(\cdot)$ and the realization of the optimal feedback $u^*(t)$, $t \in T_\tau$. Constructed values $\alpha_i(\tau)$, $i = \overline{1, m}$, are used by the optimal controller for calculating the realization $u^*(\tau)$.

In the case of constructing a discrete realization of the optimal output feedback $u^*(k\nu) = u^0(k\nu, y_{k\nu}^*(\cdot))$, $k = \overline{0, N-1}$, the optimal controller at each current moment $\tau = k\nu$ uses a solution to the LP problem

$$\begin{gathered} h_0'\sum_{j=1}^{N-k}\int_{(k+j-1)\nu}^{(k+j)\nu}F(t^*-t)bdtu_j \longrightarrow \max, \\ h_i'\sum_{j=1}^{N-k}\int_{(k+j-1)\nu}^{(k+j)\nu}F(t^*-t)bdtu_j \geq g_i(k\nu), \quad i=\overline{1,m}, \\ |u_j|\leq 1, \quad j=\overline{1,N-k}, \end{gathered} \tag{11.4}$$

which is equivalent to problem (7.2).

The solution (u_j^0, $j=\overline{1,N-k}$) to problem (11.4) is constructed by the dual method according to section 4. The value $u^*(k\nu)=u_1^0$ is fed into the input of system (7.1).

The OO problems (7.3) for the moment $\tau=k\nu$ in the discrete case take the form

$$\begin{gathered} \alpha_i(k\nu)=h_i'F(t^*)x+\sum_{j=0}^{k-1}\int_{j\nu}^{(j+1)\nu}h_i'F(t^*-t)bdtu^*(j\nu)\longrightarrow \min_x, \\ \alpha_*(j\nu)\leq a'(j\nu)x\leq \alpha^*(j\nu), \quad j=\overline{0,k}, \quad Dx=\delta, \quad d_*\leq x\leq d^*, \end{gathered} \tag{11.5}$$

where $\alpha_*(j\nu)=\xi_*-y^*(j\nu)+\sum_{r=0}^{j-1}\int_{r\nu}^{(r+1)\nu}h_i'F(j\nu-s)bdsu^*(r\nu)$, $\alpha^*(j\nu)=\xi^*-y^*(j\nu)+\sum_{r=0}^{j-1}\int_{r\nu}^{(r+1)\nu}h_i'F(j\nu-s)bdsu^*(r\nu)$, $a'(j\nu)=-h_i'F(j\nu)$.

According to the scheme described in section 9, the optimal estimator at a current moment $\tau\in T$ constructs a solution $x^0(k\nu,y^*_{k\nu}(\cdot))$ to problem (11.5) and calculates an estimate $\alpha_i(k\nu)=h_i'F(t^*)x^0(k\nu,y^*_{k\nu}(\cdot))+\sum_{j=0}^{k-1}\int_{j\nu}^{(j+1)\nu}h_i'F(t^*-t)bdtu^*(j\nu)$.

As in the case of continuous realization, problems (11.5) are solved in parallel by m estimators, and constructed values $\alpha_i(k\nu)$, $k=\overline{0,N-1}$, are used by the optimal controller for calculating the realization $u^*(k\nu)$.

Discrete realization of optimal output feedback is considered in detail in [28, 44].

12. Optimal output feedback under constantly affecting disturbances.

In section 11 the optimization problem of control systems with uncertainty in the initial state is considered. In this section the case in point is the optimization problem of a dynamic system under uncertainty both in an initial state and in an equation of motion [16, 17, 22, 37].

12.1. Optimization of a control system under uncertainty without identification of disturbances.

In the class of piecewise continuous controls $u(t)$, $t\in T$, consider the problem

$$\begin{gathered} J(u)=h_0'x(t^*)\longrightarrow \max, \quad \dot{x}=Ax+bu+d\mu, \\ x(0)=x_0\in X_0=\{x\in R^n : Dx=\delta, \quad d_*\leq x\leq d^*\}, \\ x(t^*)\in X^*=\{x\in R^n : \quad h_i'x\geq g_i, \ i=\overline{1,m}\}, \quad |u(t)|\leq 1, \quad t\in T, \end{gathered} \tag{12.1}$$

where $\mu(t)$, $t\in T$, is an unknown piecewise continuous function of disturbances satisfying the inequality $w_*\leq\mu(t)\leq w^*$, $t\in T$. In the course of the control process the measurement of the output signal $y=c'x+\xi$, $\xi_*\leq\xi(t)\leq\xi^*$, $t\in T$, is conducted.

Give the necessary definitions for problem (12.1).

Consider some particular control process at an arbitrary current moment $\tau\in T$. Denote by $y^*_\tau(\cdot)=(y^*(t),\ t\in T_\tau)$ a signal of the measurer written up until this moment, and denote by $u^*_\tau(\cdot)$ a control fed into the system.

A vector $x^* \in X_0$ is said to be compatible with the functions $u^*_\tau(\cdot)$, $y^*_\tau(\cdot)$ if the trajectory $x^*(t) = x^*(t|x^*)$ corresponding to the initial state x^*, and the control $u^*_\tau(\cdot)$ together with some admissible functions of disturbances $\mu^*(t)$, $t \in T_\tau$, and errors $\xi^*(t)$, $t \in T_\tau$, generates the written signal $y^*(t)$, $t \in T_\tau$. The set of all vectors $x^* \in X_0$ compatible with $u^*_\tau(\cdot)$, $y^*_\tau(\cdot)$ is denoted by $\hat{X}_0(\tau)$ and is called a τ-a-posteriori distribution of the initial state. The set

$$\hat{X}_\tau(\tau) = \left\{ x : x = F(\tau)x_0 + \int_0^\tau F(\tau - t)bu^*(t)dt + \int_0^\tau F(\tau - t)d\mu^*(t)dt, \right.$$
$$\left. x_0 \in \hat{X}_0(\tau), w_* \le \mu^*(t) \le w^*, t \in T_\tau \right\}$$

is called a τ-a-posteriori distribution of a state $x(\tau)$.

As in section 7, the notion of a τ-a-posteriori optimal open-loop control is introduced. The optimal output feedback is defined by the equation

$$u^0(\tau, y_\tau(\cdot)) = u^0(\tau|\tau, \hat{X}_\tau(\tau)), \quad y_\tau \in Y_\tau, \quad \tau \in T,$$

where Y_τ is a set of all signals of the measurer for which there exists $u^0(t|\tau, \hat{X}_\tau(\tau))$, $t \in T(\tau)$.

As there is the infinite-dimensional variable $\mu^*(t)$, $t \in T_\tau$, in description of the set $\hat{X}_\tau(\tau)$, so let us describe a way of constructing a discrete realization $u^*(k\nu) = u^0(k\nu, y^*_{k\nu}(\cdot))$, $k = \overline{0, N-1}$, of the optimal feedback. In order to calculate the value $u^*(k\nu)$ at the current moment $k\nu$, the optimal controller solves the determined LP problem (11.4) in real time. In the problem the values $g_i(k\nu) = g_i - \alpha_i(k\nu)$, $i = \overline{1, m}$, are necessary. They are calculated as a result of solving in real time m problems

$$\begin{aligned} \alpha_i(k\nu) = \min \Bigg[h_i' F(t^*)x + \sum_{j=0}^{k-1} \int_{j\nu}^{(j+1)\nu} h_i' F(t^* - s) dds\mu_j \Bigg] \\ + \sum_{j=0}^{k-1} \int_{j\nu}^{(j+1)\nu} h_i' F(t^* - s) bdsu^*(j\nu), \\ \alpha_*(j\nu) \le -h_i' F(j\nu)x - \sum_{r=0}^{j-1} \int_{r\nu}^{(r+1)\nu} h_i' F(j\nu - s) dds\mu_j \le \alpha^*(j\nu), \quad j = \overline{0, k}, \\ Dx = \delta, \quad d_* \le x \le d^*, \quad w_* \le \mu_j \le w^*, \quad j = \overline{0, N-1}, \end{aligned} \tag{12.2}$$

where $\alpha_*(j\nu) = \xi_* - y^*(j\nu) + \sum_{r=0}^{j-1} \int_{r\nu}^{(r+1)\nu} h_i' F(j\nu - s) bdsu^*(r\nu)$ and $\alpha^*(j\nu) = \xi^* - y^*(j\nu) + \sum_{r=0}^{j-1} \int_{r\nu}^{(r+1)\nu} h_i' F(j\nu - s) bdsu^*(r\nu)$.

The optimal estimator at a current moment $k\nu$ constructs a solution $(x^0; \mu_j, j = \overline{0, N-1})$ to problem (12.2) and calculates an estimate $\alpha_i(k\nu)$. Problems (12.2) are solved in parallel mode by m estimators. Calculated values $\alpha_i(k\nu)$, $i = \overline{1, m}$, are given to the optimal controller. The optimal controller constructs the solution $(u^0_j, j = \overline{1, N-k})$ to problem (11.4) by the dual method and feeds the value $u^*(k\nu) = u^0_1$ into the system input.

12.2. Optimization of control systems under uncertainty with identification of parametric disturbances. Let a disturbance $\mu(t)$, $t \in T$, in problem (12.1) contain known piecewise continuous functions $\omega_j(t)$, $t \in T$, $j = \overline{1,q}$, and unknown parameters $w = (w_j,\ j = \overline{1,q})$ from the set $\check{W}$:

$$\begin{aligned} &\mu(t) = \mu(t,w) = w_1\omega_1(t) + \cdots + w_q\omega_q(t), \quad t \in T,\\ &w = (w_1, \ldots, w_q) \in \check{W} = \{w \in R^q : f_* \leq w \leq f^*\}. \end{aligned}$$

Suppose that in some particular process by the time $\tau \in T$ an output signal $y^*_\tau(\cdot)$ and a control $u^*_\tau(\cdot)$ have been realized.

Vectors $x^* \in X_0$, $w^* \in \check{W}$ are said to be compatible with the functions $u^*_\tau(\cdot)$, $y^*_\tau(\cdot)$ if the trajectory $x^*(t) = x^*(t|x^*, w^*)$, $t \in T_\tau$, corresponding to the initial state x^*, the disturbance $\mu(t, w^*)$, $t \in T_\tau$, and the control $u^*_\tau(\cdot)$ together with some admissible error function $\xi^*(t)$, $t \in T_\tau$, generates the signal $y^*(t)$, $t \in T_\tau$. The set of all pairs (x^*, w^*) of vectors $x^* \in X_0$, $w^* \in \check{W}$ compatible with $u^*_\tau(\cdot)$, $y^*_\tau(\cdot)$ is denoted by $\hat{X}_0(\tau) \times \hat{W}(\tau)$ and is called a τ-a-posteriori distribution of an initial state and parameters of a disturbance. The set

$$\hat{X}_\tau(\tau) = \left\{ x : x = F(\tau)x_0 + \int_0^\tau F(\tau - t)bu^*(t)dt + \int_0^\tau F(\tau - t)d\mu(t, w^*)dt, \right.$$
$$\left. x_0 \in \hat{X}_0(\tau), \quad w^* \in \hat{W}(\tau) \right\}$$

is called a τ-a-posteriori distribution of a state $x(\tau)$. As in section 7, introduce the notion of an optimal output feedback

$$u^0(\tau, y_\tau(\cdot)) = u^0(\tau|\tau, \hat{X}_\tau(\tau)), \quad y_\tau \in Y_\tau, \quad \tau \in T, \tag{12.3}$$

where Y_τ is a set of all admissible signals of the measurer for which there exists a τ-a-posteriori optimal open-loop control $u^0(t|\tau, \hat{X}_\tau(\tau))$, $t \in T(\tau)$.

Similarly, the notion of a realization of the optimal output feedback $u^*(\tau) = u^0(\tau, y^*_\tau(\cdot))$, $\tau \in T$, and an optimal controller able to construct its values in real time are introduced.

It can be shown that values $u^*(\tau)$, $\tau \in T$, are calculated by solving the determined OC problem (7.2) in real time, where

$$g_i(\tau) = g_i - \alpha_i(\tau), \quad i = \overline{1,m},$$

$\alpha_i(\tau)$, $i = \overline{1,m}$, are estimates calculated as a result of solving in real time m OOI problems

$$\alpha_i(\tau) = \min \left[h_i' F(t^*)x + \sum_{j=1}^q \int_0^\tau h_i' F(t^* - t)d\omega_j(t)dtw_j \right] + \int_0^\tau h_i' F(t^* - t)bu^*(t)dt,$$

$$\begin{aligned} &\alpha_*(t) \leq -h_i' F(t)x - \sum_{j=1}^q \int_0^t h_i' F(t - s)d\omega_j(s)dsw_j \leq \alpha^*(t), \quad t \in T_\tau, \\ &Dx = \delta, \quad d_* \leq x \leq d^*, \quad f_* \leq w \leq f^*, \end{aligned} \tag{12.4}$$

where $\alpha_*(t) = \xi_* - y^*(t) + \int_0^t h_i' F(t - s)bu^*(s)ds$ and $\alpha^*(t) = \xi^* - y^*(t) + \int_0^t h_i' F(t - s)bu^*(s)ds$, $t \in T_\tau$.

Problems (7.2), (12.4) are solved in real time according to the scheme of section 11.

In the case of constructing a discrete realization $u^*(k\nu)$, $k=\overline{0,N-1}$, of optimal feedback the controller in real time solves the determined LP problem (11.4) in which the values $g_i(k\nu)=g_i-\alpha_i(k\nu)$, $i=\overline{1,m}$, are calculated as a result of solving m discrete OOI problems in real time

$$\begin{gathered}\alpha_i(k\nu)=\min\left[h_i'F(t^*)x+\sum_{j=1}^{q}\sum_{r=0}^{k-1}\int_{r\nu}^{(r+1)\nu}h_i'F(t^*-s)d\omega_j(s)dsw_j\right]\\+\sum_{j=0}^{k-1}\int_{j\nu}^{(j+1)\nu}h_i'F(t^*-s)bdsu^*(j\nu),\\\alpha_*(j\nu)\leq -h_i'F(j\nu)x-\sum_{l=1}^{q}\sum_{r=0}^{j-1}\int_{r\nu}^{(r+1)\nu}h_i'F(j\nu-s)ddds\mu_j\leq\alpha^*(j\nu),\quad j=\overline{0,k},\\Dx=\delta,\quad d_*\leq x\leq d^*,\quad w_*\leq\mu_j\leq w^*,\quad j=\overline{0,N-1},\end{gathered}\tag{12.5}$$

where $\alpha_*(j\nu)=\xi_*-y^*(j\nu)+\sum_{r=0}^{j-1}\int_{r\nu}^{(r+1)\nu}h_i'F(j\nu-s)bdsu^*(r\nu)$ and $\alpha^*(j\nu)=\xi^*-y^*(j\nu)+\sum_{r=0}^{j-1}\int_{r\nu}^{(r+1)\nu}h_i'F(j\nu-s)bdsu^*(r\nu)$.

The scheme of solving problems (7.2), (12.5) is analogous to the one given in section 11.

12.3. Optimization of control systems under uncertainty with partial identification of parametric disturbances. In the class of piecewise continuous controls $u(t)$, $t\in T$, consider the problem

$$\begin{gathered}J(u)=h_0'x(t^*)\longrightarrow\max,\quad\dot{x}=Ax+bu+d_1\mu+d_2v,\\x(0)=x_0\in X_0,\quad x(t^*)\in X^*,\quad|u(t)|\leq 1,\quad t\in T,\end{gathered}\tag{12.6}$$

where $\mu(t)=\mu(t,w)=w_1\omega_1(t)+\cdots+w_q\omega_q(t)$, $t\in T$, $w=(w_1,\ldots,w_q)\in\check{W}$; $\omega_j(t)$, $j=\overline{1,q}$, $t\in T$, are known piecewise continuous functions and $v(t)$, $t\in T$, is an unknown piecewise continuous function of disturbances satisfying the inequality $v_*\leq v(t)\leq v^*$, $t\in T$. The equation of the measurer has form (8.3).

Vectors $x^*\in X_0$, $w^*\in\check{W}$ are said to be compatible with a written signal $y_\tau^*(\cdot)$ and the control $u_\tau^*(\cdot)$ if the trajectory $x^*(t)=x^*(t|x^*,w^*)$, $t\in T_\tau$, corresponding to the initial state x^*, the disturbance $\mu(t,w^*)$, $t\in T_\tau$, and the control $u_\tau^*(\cdot)$ together with some admissible functions $v^*(t)$, $\xi^*(t)$, $t\in T_\tau$, generates the signal $y^*(t)$, $t\in T_\tau$. The set of all pairs (x^*,w^*) of vectors $x^*\in X_0$, $w^*\in\check{W}$ compatible with $u_\tau^*(\cdot)$, $y_\tau^*(\cdot)$ is denoted by $\hat{X}_0(\tau)\times\hat{W}(\tau)$ and is called a τ-a-posteriori distribution of an initial state and parameters of a disturbance. The set

$$\begin{gathered}\hat{X}_\tau(\tau)=\left\{x:x=F(\tau)x_0+\int_0^\tau F(\tau-t)bu^*(t)dt+\int_0^\tau F(\tau-t)d_1\mu(t,w^*)dt\right.\\\left.+\int_0^\tau F(\tau-t)d_2v(t)dt,\quad x_0\in\hat{X}_0(\tau),\quad w^*\in\hat{W}(\tau),\quad v_*\leq v(t)\leq v^*\right\}\end{gathered}$$

is called a τ-a-posteriori distribution of a state $x(\tau)$. The optimal output feedback is defined by equality (12.3).

As in the case of optimal feedback without identification of disturbances, move on to a discrete realization $u^*(k\nu)=u^0(k\nu,y_{k\nu}^*(\cdot))$, $k=\overline{0,N-1}$.

Values $u^*(k\nu)$, $k=\overline{0,N-1}$ are calculated by the optimal controller in real time as a result of solving the LP problem (11.4). In order to calculate the values $g_i(k\nu)=g_i-\alpha_i(k\nu)$, $i=\overline{1,m}$, in real time m, discrete OOI problems

$$\alpha_i(k\nu)=\min\left[h_i'F(t^*)x+\sum_{j=1}^{q}\sum_{r=0}^{k-1}\int_{r\nu}^{(r+1)\nu}h_i'F(t^*-s)d_1\omega_j(s)dsw_j\right.$$

$$\left.+\sum_{r=0}^{k-1}\int_{r\nu}^{(r+1)\nu}h_i'F(t^*-s)d_2dsv_r\right]+\sum_{r=0}^{k-1}\int_{r\nu}^{(r+1)\nu}h_i'F(t^*-s)bdsu^*(r\nu),$$

$$(12.7)\qquad \alpha_*(j\nu)\le -h_i'F(j\nu)x-\sum_{l=1}^{q}\sum_{r=0}^{j-1}\int_{r\nu}^{(r+1)\nu}h_i'F(j\nu-s)d_1\omega_l(s)dsw_l$$

$$-\sum_{r=0}^{j-1}\int_{r\nu}^{(r+1)\nu}h_i'F(j\nu-s)d_2dsv_r\le\alpha^*(j\nu),\quad j=\overline{0,k},$$

$$Dx=\delta,\quad d_*\le x\le d^*,\quad w_*\le w_j\le w^*,\quad v_*\le v_j\le v^*,\quad j=\overline{0,N-1},$$

are solved where $\alpha_*(j\nu)=\xi_*-y^*(j\nu)+\sum_{r=0}^{j-1}\int_{r\nu}^{(r+1)\nu}h_i'F(j\nu-s)bdsu^*(r\nu)$, and $\alpha^*(j\nu)=\xi^*-y^*(j\nu)+\sum_{r=0}^{j-1}\int_{r\nu}^{(r+1)\nu}h_i'F(j\nu-s)bdsu^*(r\nu)$.

Problem (12.7) contains $n+2N$ variables x_j, $j=\overline{1,n}$; w_j, v_j, $j=\overline{0,N-1}$.

Problems (7.2), (12.7) are solved in real time by the scheme of section 11.

12.4. Numerical modelling. The operation of the proposed optimal feedbacks is illustrated by the problem of minimization of fuel consumption in steering a two-mass mechanical system (Figure 3.1) in the vicinity of the equilibrium state. The mathematical model of the problem has the form

$$\int_0^{20}u(t)dt\longrightarrow\min,$$

$$\dot{x}_1=x_3,\quad \dot{x}_2=x_4,\quad \dot{x}_3=-x_1+x_2,\quad \dot{x}_4=0.1x_1-1.02x_2+w,$$

$$x(0)\in X_0,\quad x(20)\le 0.$$

The set X_0 is described by the relations

$$x_1=0,\quad x_2=0,\quad 0.8\le x_3\le 1.1,\quad 0.4\le x_4\le 0.6.$$

Three types of feedback are studied: (1) classical state feedback (section 2), (2) guaranteeing state feedback (section 6), and (3) guaranteeing output feedback.

In all cases the initial state is the vector $x(0)=(0,0,1,0.5)$.

The following information on disturbances is available: (a) a controller knows that a disturbance does not affect the system (classical determined case); (b) a disturbance affecting the system is known; (c) it is known that the system is under disturbances but there is no information on disturbances; (d) the system is under a bounded disturbance of general form (a piecewise continuous disturbance with a known set of values $|w(t)|\le 0.3$, $t\in T$); (e) a disturbance is a sum of a bounded disturbance of general form and a disturbance is known with a precision of parameters (section 12.3); (f) a disturbance is parametric (section 12.2).

When constructing the optimal output feedback, the measurer $y=x_1+\xi$, $|\xi(t)|\le 0.2$ is used.

Table 12.1
Results of numerical modelling.

		Type of feedback			
		State 1		Output 2	
N	Information on disturbances	J	Terminal state	J	Terminal state
		a) Classical feedback			
1	Disturbances are absent	2.6014	0 0 0 0	2.6082	0.00377 0.00069 0.00269 0.00050
2	Controller knows disturbances	2.9232	0 0 0 0	3.1324	0.00377 0.00070 0.00270 0.00050
3	There is not any information on disturbances	8.4457	3.9889 0.02551 2.17137 0.12837	9.36812	2.82342 0.31323 2.43286 0.39572
		b) Unclosable feedback			
				Disturbance is not identified	
4	Disturbances of general form with known set of values	8.8744	3.98291 0.06223 2.17727 0.27214	13.4163	2.27723 1.25260 4.85734 1.01632
				Parameters of disturbance are identified	
5	Disturbance: Sum of bounded disturbance of general form with known set of values and parametric disturbance	3.8132	0.24984 0.10335 0.14617 0.13778	9.7320	0.69001 1.09105 1.38797 1.05552
6	Parametric disturbance	3.7163	0.15076 0.09622 0.15070 0.11869	3.1619	0.00659 0.01533 0.05437 0.10126

In each case a discrete realization of the optimal feedback is constructed. The parameter ν is put to be equal to 0.5, and the realized error function has the form $\xi^*(t) = 0.2\sin 3t$, $t \in T$. The system is under the disturbance of the form $w(t) = w_1\omega_1(t) + w_2\omega_2(t) + w_3\omega_3(t)$, $t \in T$: $w^*(t) = 0.15\sin 0.5t + 0.1\sin 2t + 0.05\sin 5t$, $t \in T$. OO problems are solved with the same data as in section 10.5.

Results of numerical experiments are listed in Table 12.1. In the table, for each situation under consideration, fuel consumption and coordinates of the terminal state are presented. The ideal situation (determined system, optimal state feedback) is identified by a box (1, 1) placed in the first row and in the first column. It is seen from the table that results are impaired as uncertainty increases: fuel consumption grows, and the terminal state moves away from the equilibrium state; additional efforts on identification of parametric disturbances improve efficiency of control.

In Figure 12.1a the phase trajectories of the optimized control system closed by the optimal output feedback are presented. The dashed line corresponds to the case when a disturbance does not affect the system. The solid line is constructed

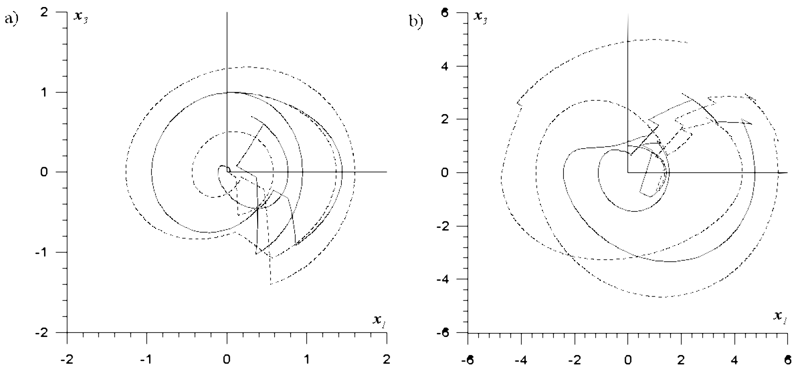

FIG. 12.1.

for the case of identification of parametric disturbances. In Figure 12.1b the dashed line presents the phase trajectory constructed without identification of disturbances, and the solid line is constructed for the case of partial identification of parametric disturbances.

Acknowledgments. The authors thank Professors R. Bulirsch, M. Hautus, K. Malanowski, K. Malinowski, B. Mordukhovich, and M. Thoma for favorable discussions of results on the first, especially difficult, stages of our investigations in the optimal synthesis problem. We are also very grateful to B. Shulkin for his help in preparing the English version of the paper.

EXISTENCE OF LIPSCHITZ AND SEMICONCAVE CONTROL-LYAPUNOV FUNCTIONS*

LUDOVIC RIFFORD†

Abstract. Given a locally Lipschitz control system which is globally asymptotically controllable at the origin, we construct a control-Lyapunov function for the system which is Lipschitz on bounded sets, and we deduce the existence of another one which is semiconcave (and so locally Lipschitz) outside the origin. The proof relies on value functions and nonsmooth calculus.

Key words. asymptotic stabilizability, semiconcave Lyapunov function, nonsmooth analysis, viscosity solutions

1. Introduction.

This paper is concerned with the stabilization problem for a standard control system of the form $\dot{x}(t) = f(x(t), u(t))$. Lyapunov-like techniques have been successfully used in many problems in control theory, such as stabilizability, asymptotic controllability, and stability. Stabilization by smooth feedback has been a subject of research by many authors. Among them, Artstein provided an important contribution (see [3]), proving that a control system admits a smooth Lyapunov function if and only if there is a stabilizing relaxed feedback. Moreover, if the system is affine in the control, there exists an ordinary stabilizing feedback continuous outside the origin. In general, however, such a feedback fails to exist, as pointed out by Sontag and Sussmann [27] and by Brockett [8] among others [25],[12]. Consequently, a smooth Lyapunov function in general does not exist. This fact leads to the design of time-varying (see [15],[16]) or discontinuous feedbacks. The construction of the latter (see [11]) has used the existence of a continuous control-Lyapunov function (CLF) whose decrease condition is stated in terms of Dini derivates or, equivalently, of proximal subgradients. Moreover, more recently, Clarke, Ledyaev, Stern, and Rifford [10] invoked the existence of such a CLF which is locally Lipschitz in order to construct a discontinuous feedback law which stabilizes the underlying system to any given tolerance and which possesses a robustness property relative to measurement error. The first result of this article is that, under certain mild assumptions on f (a local Lipschitz condition and bounded dynamics near the origin), for globally asymptotically controllable (GAC) systems, such locally Lipschitz CLF always exist. This fact extends the well-known result of Sontag [26] and brings an affirmative answer to a conjecture that has been attributed to Sontag and Sussmann. Furthermore, the main result shows that a semiconcave CLF outside the origin always exists under the same assumptions. The semiconcavity is an intermediate property between Lipschitz continuity and continuous differentiability. Semiconcave functions have been used, for instance, to obtain uniqueness results for weak solutions of Hamilton–Jacobi equations (see [19],[20]). More recently, attention has been focused on the differential properties of such functions (see [1], [2]). In the case of the stabilization problem, the semicon-

†Institut Girard Desargues, Université Claude Bernard Lyon I 69622 Villeurbanne, France (rifford@desargues.univ-lyon1.fr).

cavity will be exploited to derive an efficient construction for stabilizing discontinuous feedbacks by means of Euler trajectories. Furthermore, the semiconcave regularity of the CLF will be used to obtain some regularity of our discontinuous feedback outside a set of singularities which will be proven small on account of semiconcavity. These results will appear in forthcoming articles [22], [23], [21]. Some works and general references related to this article include [5], [6], [17], [18], [24].

2. Definitions and statements of the results. In this paper, we study systems of the general form

$$\dot{x}(t) = f(x(t), u(t)), \tag{2.1}$$

where the state $x(t)$ takes values in a Euclidean space $\mathbb{X} = \mathbb{R}^n$, the control $u(t)$ takes values in a given set U, and f satisfies the following hypotheses.

Assumption 2.1. *f is locally Lipschitz in x(uniformly in u). That is, for all $x \in \mathbb{X}$, there exists $\mathcal{V}_x$, a neighborhood of x, and $L_x \geq 0$ such that*

$$\|f(y', u) - f(y, u)\| \leq L_x \|y' - y\| \quad \forall y, y' \in \mathcal{V}_x, \quad \forall u \in U.$$

Assumption 2.2. *f is bounded on the ball $R\bar{B} \times U$ for all $R > 0$ (or, equivalently, in view of the preceding assumption for some $R > 0$).*

A special element "0" is distinguished in U, and the state $x = 0$ of $\mathbb{X}$ is an equilibrium point, i.e., $f(0, 0) = 0$. (No linear structure on U is used, however.) The set of admissible controls is the set of measurable and locally essentially bounded functions $u : \mathbb{R}_{\geq 0} \longrightarrow U$. $\mathbb{R}_{\geq 0}$ denotes nonnegative reals, B denotes the open ball $B(0, 1) := \{x : \|x\| < 1\}$ in $\mathbb{X}$, and $\bar{B}$ denotes the closure of B.

We now introduce our definitions and the main result.

Definition 2.3. *The system* (2.1) *is GAC if there exist a nondecreasing function $M : \mathbb{R}_{>0} \longrightarrow \mathbb{R}_{>0}$ such that $\lim_{R \downarrow 0} M(R) = 0$ and a function $T : \mathbb{R}_{>0} \times \mathbb{R}_{>0} \longrightarrow \mathbb{R}_{\geq 0}$ with the following property.*

For any $0 < r < R$, for each initial state ξ, $\|\xi\| \leq R$, there exist a control $u : \mathbb{R}_{\geq 0} \longrightarrow U$ and corresponding trajectory $x(\cdot) : \mathbb{R}_{\geq 0} \longrightarrow \mathbb{X}$ such that

1. $\lim_{t \to \infty} x(t) = 0$,
2. *for all $t \geq 0, \|x(t)\| \leq M(R)$,*
3. *for all $t \geq T(r, R), \|x(t)\| \leq r$.*

Remark 2.4. *A routine argument involving continuity of trajectories with respect to initial states shows that the requirements of the above standard definition are equivalent to the following apparently weaker pair of conditions used in some references (see* [28], [29]*).*

1. *For each $\xi \in \mathbb{X}$ there is a control $u : \mathbb{R}_{\geq 0} \longrightarrow U$ that drives ξ asymptotically to* 0.
2. *For each $\epsilon > 0$, there is a $\delta > 0$ such that for each $\xi \in \mathbb{X}$ with $\|\xi\| \leq \delta$ there is a control $u : \mathbb{R}_{\geq 0} \longrightarrow U$ that drives ξ asymptotically to* 0 *and such that the corresponding trajectory $x(\cdot)$ satisfies $\|x(t)\| \leq \epsilon$ for all $t \geq 0$.*

Moreover, the authors of [28], [29] *add a condition on bounded controls; this one implies Assumption* 2.2 *by restriction to the system near the origin.*

A function $V : \mathbb{X} \longrightarrow \mathbb{R}_{\geq 0}$ is *positive definite* if $V(0) = 0$ and $V(x) > 0$ for $x \neq 0$, and *proper* if $V(x) \to +\infty$ as $\|x\| \to +\infty$.

Definition 2.5. *A Lyapunov pair for the system* (2.1) *is a pair (V, W) consisting of a continuous, positive definite, proper function $V : \mathbb{X} \longrightarrow \mathbb{R}$ and a positive definite* *continuous function $W : \mathbb{X} \longrightarrow \mathbb{R}$, with the property that for each $x \in \mathbb{X} \setminus \{0\}$ we have*

$$\forall \zeta \in \partial_P V(x), \inf_{u \in U} \langle \zeta, f(x,u) \rangle \leq -W(x). \tag{2.2}$$

Here $\partial_P V(x)$ refers to the *proximal subdifferential* of V at x (which may be empty): ζ belongs to $\partial_P V(x)$ if and only if there exists σ and $\eta > 0$ such that

$$V(y) - V(x) + \sigma \|y - x\|^2 \geq \langle \zeta, y - x \rangle \quad \forall y \in x + \eta B.$$

The condition (2.2) is, in fact, equivalent to another one often used in the definition of a nonsmooth Lyapunov function (see [26], [28], [29]); this other notion is based on the notion of directional or Dini subderivate. The equivalence between these two conditions is a consequence of Subbotin's theorem (see, for example, [14], our principal source for the theory of nonsmooth analysis, and [10] for a discussion of the equivalence). We remark that there exists a complete calculus of proximal subdifferentials, one that extends all the theorems of the usual smooth calculus.

DEFINITION 2.6. *A CLF for the system* (2.1) *is a function $V : \mathbb{X} \longrightarrow \mathbb{R}$ such that there exists a continuous positive definite $W : \mathbb{X} \longrightarrow \mathbb{R}$ with the property that (V, W) is a Lyapunov pair for* (2.1)*.*

We will say that V is a locally Lipschitz CLF if V is a CLF which is locally Lipschitz on $\mathbb{X}$. We claim the following theorem.

THEOREM 1. *Let (f, U) be a control system as described above. Then under Assumptions* 2.1 *and* 2.2*, if the system is GAC, there exists a locally Lipschitz CLF.*

REMARK 2.7. *The converse is true and relatively easy if we suppose that f is continuous in u (we need this to obtain the existence of trajectories); we refer to Sontag* [26].

We now recall the definition of a *semiconcave* function [19] in an open set Ω of $\mathbb{X}$.

DEFINITION 2.8. *Let $g : \Omega \longrightarrow \mathbb{R}$ be a continuous function on Ω; it is said to be semiconcave on Ω if for any point $x_0 \in \Omega$ there exist $\rho, C > 0$ such that*

$$g(x) + g(y) - 2g\left(\frac{x+y}{2}\right) \leq C\|x - y\|^2 \tag{2.3}$$

for all $x, y \in x_0 + \rho B$.

We shall deduce as a corollary of the preceding theorem the main result of this article.

THEOREM 2. *Let (f, U) be a control system as described above. Then under Assumptions* 2.1 *and* 2.2*, if the system is GAC, there exists a CLF which is semiconcave on $\mathbb{X} \setminus \{0\}$.*

REMARK 2.9. *The CLF is a viscosity supersolution of*

$$\sup_{u \in U}\{-\langle f(x,u), DV \rangle\} - W \geq 0.$$

We begin by giving some regularity results about certain value functions. Then we give the proof of Theorem 1. In the last section, we conclude with the proof of Theorem 2.

3. A result on value functions in finite time.

Throughout this section, we are given a multifunction F mapping $\mathbb{X}$ to the subsets of $\mathbb{X}$, and we consider the differential inclusion

$$\dot{x}(t) \in F(x(t)) \quad \text{almost everywhere (a.e.).} \tag{3.1}$$

We say that $x(\cdot)$ is a solution of (3.1) on the interval $[a, b]$ if it is an absolutely continuous function $x : [a, b] \longrightarrow \mathbb{X}$ which, together with $\dot{x}$, satisfies (3.1); such an arc will be called an F-trajectory on the interval $[a, b]$. We need for this section two properties of F which turn out to be particularly important.

ASSUMPTION 3.1. *The multifunction F is locally Lipschitz with nonempty compact convex values.*

ASSUMPTION 3.2. *For some positive constants K and M, and for all $x \in \mathbb{X}$,*

$$v \in F(x) \Longrightarrow \|v\| \leq K\|x\| + M$$

(that is called the linear growth condition).

Under these two conditions, for all $x_0 \in \mathbb{X}$, there exists a trajectory of (3.1) defined on $\mathbb{R}_{\geq 0}$ such that $x(0) = x_0$, and for any trajectory with initial data x_0 we have the following estimate:

$$\forall t \geq 0, \|x(t)\| \leq \|x_0\|e^{Kt} + Mte^{Kt}. \tag{3.2}$$

This inequality is an easy consequence of Gronwall's lemma (see [14]).

Let us consider a function $L : \mathbb{X} \longrightarrow \mathbb{R}_{\geq 0}$ and a compact set $\mathcal{T}$ of $\mathbb{X}$ satisfying the following assumption.

ASSUMPTION 3.3. *L is locally Lipschitz and for all $x \in \mathbb{X}$, $L(x) \geq 1$.*

ASSUMPTION 3.4. *There exists $\delta > 0$ such that for all $x \in \mathcal{T}, \delta\bar{B} \subset F(x)$.*

We proceed now to define a value function $V(\cdot)$ on $\mathbb{X}$ in terms of trajectories of F as follows:

$$V(x) := \inf\left\{\int_0^T L(x(t))dt : x(0) = x, \dot{x}(t) \in F(x(t)) \text{ a.e. and } x(T) \in \mathcal{T}\right\}.$$

(Note that T is a choice variable in this "free-time" problem.)

We introduce the notation

$$\mathcal{R} := \{x \in \mathbb{X} : V(x) < +\infty\}.$$

The letter $\mathcal{R}$ stands for reachable; the set of points where V is finite is the set of points which can be driven to the target $\mathcal{T}$ in finite time. We have the following theorem.

THEOREM 3. *Assume* (3.1)–(3.4). *Then*

(i) *$\mathcal{R}$ is open,*

(ii) *V is locally Lipschitz in $\mathcal{R}$,*

(iii) *for all $x \in \mathcal{R} \setminus \mathcal{T}$, for all $\zeta \in \partial_P V(x), \min_{v\in F(x)}\langle\zeta, v\rangle \leq -L(x)$.*

Proof. First, by the Lipschitz condition on F and (3.4), there exists $0 < r \leq 1$ such that for all $x \in \mathcal{T} + r\bar{B}$, $\frac{\delta}{2}\bar{B} \subset F(x)$. Hence, each state x of $\mathcal{T} + r\bar{B}$ can be driven to $\mathcal{T}$ by a trajectory of (3.1) in time $\frac{2}{\delta}d(x, \mathcal{T})$ (where $d(x, \mathcal{T})$ denotes $\min_{\tau\in\mathcal{T}} \|x - \tau\|$). This proves that V is finite on $\mathcal{T} + r\bar{B}$. If we set $m := \max_{x\in\mathcal{T}+r\bar{B}} L(x)$, we have

$$\forall x \in \mathcal{T} + r\bar{B}, V(x) \leq \frac{2m}{\delta}d(x, \mathcal{T}). \tag{3.3}$$

Now fix $x_0 \notin \mathcal{T}$ such that $V(x_0) < +\infty$.

By the definition of V, there exists an F-trajectory $x_0(\cdot)$ and $T > 0$ such that $x_0(0) = x_0, x_0(T) \in \mathcal{T}$ and

$$\int_0^T L(x(s))ds \leq V(x_0) + 1. \tag{3.4}$$

The estimate (3.2) gives

$$\forall t \in [0,T], \|x_0(t)\| \leq \|x_0\| e^{KT} + MTe^{KT}.$$

Let $A := [\|x_0\| + MT]e^{KT}$, and let λ_F be the Lipschitz constant of F on the ball $(A+1)\bar{B}$. Fix $y \in B(x_0, re^{-\lambda_F T})$.

By [4, Cor. 1, p. 121], there exists an F-trajectory $y(\cdot)$ such that $y(0) = y$, verifying

$$\forall t \in [0,T], \|y(t) - x_0(t)\| \leq e^{\lambda_F T}\|y - x_0\|, \text{and } \|y(t)\| \leq A+1. \tag{3.5}$$

Consequently, if we set λ_L as the Lipschitz constant of L on the ball $(A+1)\bar{B}$, we obtain

$$\begin{aligned}\int_0^T L(y(s))ds &\leq \int_0^T L(x_0(s))ds + \int_0^T [L(y(s)) - L(x_0(s))]ds \\ &\leq V(x_0) + 1 + \int_0^T \lambda_L \|y(s) - x_0(s)\| ds \\ &\leq V(x_0) + 1 + T\lambda_L e^{\lambda_F T}\|y - x_0\| \\ &\leq V(x_0) + 1 + T\lambda_L r.\end{aligned}$$

On the other hand, $d(y(T), \mathcal{T}) \leq \|y(T) - x_0(T)\| \leq e^{\lambda_F T}\|y - x_0\| \leq r$; this implies by (3.3) that

$$V(y(T)) \leq \frac{2m}{\delta} d(y(T), \mathcal{T}) \leq \frac{2mr}{\delta}.$$

Consequently, we have that for all $y \in B(x_0, re^{-\lambda_F T})$,

$$V(y) \leq \int_0^T L(y(s))ds + \frac{2mr}{\delta} \tag{3.6}$$

$$\leq V(x_0) + 1 + T\lambda_L r + \frac{2mr}{\delta} =: c < +\infty. \tag{3.7}$$

We have shown that $B(x_0, re^{-\lambda_F T}) \subset \mathcal{R}$, which gives (i).

Now, let $x \in B(x_0, re^{-\lambda_F T})$; then for each positive integer n, there exists an F-trajectory $x_n(\cdot)$ and $T_x^n \geq 0$ such that $x_n(0) = x$, $x_n(T_x^n) \in \mathcal{T}$, and

$$\int_0^{T_x^n} L(x_n(s))ds \leq V(x) + \frac{1}{n}.$$

Thus $L \geq 1$ implies $T_x^n \leq V(x) + \frac{1}{n} \leq c + \frac{1}{n}$ by (3.6). As before, the estimate (3.2) gives for each n

$$\begin{aligned}\forall t \in [0, T_x^n], \|x_n(t)\| &\leq \|x\| e^{KT_x^n} + MT_x e^{KT_x^n} \\ &\leq [\|x\| + M(c+1)]e^{K(c+1)} \\ &\leq [\|x_0\| + 1 + M(c+1)]e^{K(c+1)}.\end{aligned}$$

So we find a uniform bound for $\|\dot{x}_n(\cdot)\|$ on the intervals $[0, T_x^n] \subset [0, V(x)+1]$. Hence, since our trajectories $x_n(\cdot)$ are uniformly bounded and equicontinuous on the compact interval $[0, c+\frac{1}{n}]$, the theorem of Arzela–Ascoli and the compactness of trajectories (see

[14]) imply that there exists a trajectory $x(\cdot)$ with initial data x such that $x(T_x) \in \mathcal{T}$ and

$$V(x) = \int_0^{T_x} L(x(s))ds,$$

with $T \leq V(x)$. That means that the infimum is attained in the definition of V.

We set $A' := [\|x_0\| + 1 + M(c+1)]e^{K(c+1)}$, and λ'_F is the Lipschitz constant of F on the ball $(A'+1)\bar{B}$. We proceed to show that V is Lipschitz on the ball $\bar{B}(x_0, \frac{r}{2}e^{-\lambda'_F(c+1)})$.

Fix x, y in $\bar{B}(x_0, \frac{r}{2}e^{-\lambda'_F(c+1)})$. Then there exists, as above, $x(\cdot)$ as an F-trajectory and $T_x \geq 0$ such that $x(0) = x, x(T_x) \in \mathcal{T}$, and

$$V(x) = \int_0^{T_x} L(x(s))ds.$$

By [4, Cor. 1, p. 121], there exists an F-trajectory $y(\cdot)$ such that $y(0) = y$, verifying

$$\forall t \in [0, T_x], \|y(t) - x(t)\| \leq e^{\lambda'_F T_x}\|y - x\|, \text{and } \|y(t)\| \leq A' + 1.$$

Consequently, if we set, as before, λ'_L as the Lipschitz constant of L on the ball $(A'+1)\bar{B}$, we obtain

$$\begin{aligned}\int_0^{T_x} L(y(s))ds &\leq \int_0^{T_x} L(x(s))ds + \int_0^{T_x} \lambda'_L\|y(s) - x(s)\|ds \\ &\leq V(x) + T_x\lambda'_L e^{\lambda'_F T_x}\|y - x\| \\ &\leq V(x) + c\lambda'_L e^{\lambda'_F c}\|y - x\|.\end{aligned}$$

Now, $V(y(T_x)) \leq \frac{2m}{\delta} d(y(T_x), \mathcal{T}) \leq \frac{2m}{\delta} e^{\lambda'_F c}\|y - x\|$. Hence, we conclude that

$$V(y) \leq V(x) + \left[c\lambda'_L + \frac{2m}{\delta}\right] e^{\lambda'_F c}\|y - x\|.$$

Thus, since all the constants in the preceding inequality are independent of x and y, we find

$$|V(y) - V(x)| \leq \left[(c+1)\lambda'_L + \frac{2m}{\delta}\right] e^{\lambda'_F(c+1)}\|y - x\|,$$

which proves (ii). We now have to prove (iii). For that, consider $x \in \mathcal{R} \setminus \mathcal{T}$ and a trajectory $x(\cdot)$ of (3.1) attaining the infimum in the definition of $V(x)$. Let ζ belong to $\partial_P V(x)$; then there exists σ and $\eta > 0$ such that

$$V(y) - V(x) + \sigma\|y - x\|^2 \geq \langle \zeta, y - x\rangle \quad \forall y \in x + \eta B.$$

By the optimality of the trajectory $x(\cdot)$, for all $t \in [0, T], V(x(t)) = \int_t^T L(x(s))ds$. Then, for t sufficiently small,

$$\int_t^T L(x(s))ds - \int_0^T L(x(s))ds + \sigma\|x(t) - x\|^2 \geq \langle \zeta, x(t) - x\rangle,$$

which gives

$$-\frac{1}{t}\int_0^t L(x(s))ds + t\sigma\left\|\frac{x(t) - x}{t}\right\|^2 \geq \left\langle \zeta, \frac{x(t) - x}{t}\right\rangle.$$

We find (iii) by passing to the limit $t \downarrow 0$. □

REMARK 3.5. *In* [10], *a result of this type is proven differently by an argument based on Hamiltonian necessary conditions.*

REMARK 3.6. *The conclusions of Theorem* 3 *remain true if we weaken Assumption* 3.4 *to the proximal condition*

$$\min_{v \in F(x)} \langle \zeta, v \rangle \leq -\delta \|\zeta\|$$

for all $x \in \mathcal{T}$ and $\zeta \in N^P_{\mathcal{T}}(x)$, where $N^P_{\mathcal{T}}(x)$ denotes the proximal normal cone to $\mathcal{T}$ at x (see the book of Clarke, Ledyaev, Stern, and Wolenski [14]*). (This result is a consequence of proximal criteria for attainability; see* [13], [14]*.) This kind of condition added to the smooth regularity of F is used in* [9] *to obtain the semiconcavity of the minimum-time function. However, these results (on the Lipschitz property or on the semiconcavity property) do not hold if we omit the linear growth condition* (3.2)*; see, for example,* [7, Ex. 1.3, p. 238].

REMARK 3.7. *The conclusion* (iii) *can be strengthened to equality. The value function V is the viscosity solution of a certain Hamilton–Jacobi equation (see* [7], [14]*).*

4. Proof of Theorem 1. We suppose first that we have constructed a CLF V which is continuous on $\mathbb{X}$ and locally Lipschitz on $\mathbb{X} \setminus \{0\}$. Thus, there exists another continuous positive definite function $W : \mathbb{X} \longrightarrow \mathbb{R}_{\geq 0}$ such that (V, W) is a Lyapunov pair for (2.1). We proceed to show that we can deduce the existence of a new CLF which is locally Lipschitz on all the space $\mathbb{X}$. We set for any $0 \leq a \leq b$

$$S_V(b) := \{x; V(x) \leq b\} \text{ and } S_V[a, b] := \{x; a \leq V(x) \leq b\};$$

these are compact sets of $\mathbb{X}$. We proceed to construct a sequence of functions on $\mathbb{X}$ which will converge uniformly to our desired locally Lipschitz CLF.

First, we set $\mathcal{V}_0(x) := \max\{V(x), 1\}$. This function is locally Lipschitz on $\mathbb{X}$, proper, positive, constant on $S_V(1)$, and it verifies

$$\forall x \notin S_V(1), \forall \zeta \in \partial_P \mathcal{V}_0(x), \inf_{u \in \mathcal{U}} \langle \zeta, f(x, u) \rangle \leq -W(x).$$

By assumption, for all $n \geq 0$, V is Lipschitz on $S_V[\frac{1}{2^{n+1}}, \frac{1}{2^n}]$; we denote by $K(\frac{1}{2^{n+1}}, \frac{1}{2^n}) = K_n$ its Lipschitz constant on this set. (Without loss of generality we can choose this constant greater than 1.)

We define now a sequence inductively. Suppose $\mathcal{V}_n$ is given; we set

$$\mathcal{V}_{n+1}(x) := \begin{cases} \mathcal{V}_n(x) & \text{if } x \notin S_V(\frac{1}{2^n}), \\ \mathcal{V}_n(x) + \frac{1}{K_n}[V(x) - \frac{1}{2^n}] & \text{if } x \in S_V[\frac{1}{2^{n+1}}, \frac{1}{2^n}], \\ \mathcal{V}_n(x) - \frac{1}{2^{n+1} K_n} & \text{if } x \in S_V(\frac{1}{2^{n+1}}). \end{cases}$$

We have the following lemma.

LEMMA 4.1. *For all $n \geq 1$, $\mathcal{V}_n$ is 1-Lipschitz on $S_V(1)$, proper, and constant on $S_V(\frac{1}{2^n})$. Moreover, $\mathcal{V}_n$ satisfies the following properties:*

$$\forall x \in \mathbb{X}, \mathcal{V}_n(x) \geq 1 - \sum_{k=1}^{n} \frac{1}{2^k K_{k-1}},$$

and for all $x \in S_V(\frac{1}{2^{n-1}}) \setminus S_V(\frac{1}{2^n})$, *for all* $\zeta \in \partial_P \mathcal{V}_n(x)$,

$$\inf_{u\in\mathcal{U}} \langle \zeta, f(x,u)\rangle \leq -\frac{W(x)}{K_{n-1}}. \tag{4.1}$$

Proof. We are going to prove only the last assertion. The other ones are left to the reader; they are the consequence of an easy inductive proof.

Let $n \geq 1, x \in S_V(\frac{1}{2^{n-1}}) \setminus S_V(\frac{1}{2^n})$, and $\zeta \in \partial_P \mathcal{V}_n(x)$.

We remark that for all y not in $S_V(\frac{1}{2^n})$, we have

$$\mathcal{V}_n(y) = \min\left\{\mathcal{V}_{n-1}(y), \mathcal{V}_{n-1}(y) + \frac{V(y) - \frac{1}{2^{n-1}}}{K_{n-1}}\right\}.$$

For the x chosen above, the minimum is attained in the second term, so

$$\zeta \in \partial_P\left[\mathcal{V}_{n-1}(x) + \frac{V(x) - \frac{1}{2^{n-1}}}{K_{n-1}}\right] = \partial_P\left[\mathcal{V}_{n-1}(x) + \frac{V(x)}{K_{n-1}}\right]. \tag{4.2}$$

First case. $n > 1$. We remark now that for all $y \in S_V(\frac{1}{2^{n-2}})$,

$$\mathcal{V}_{n-1}(y) = \max\left\{C_{n-2} + \frac{V(y) - \frac{1}{2^{n-2}}}{K_{n-2}}, C_{n-2} - \frac{1}{2^{n-1}K_{n-2}}\right\},$$

where C_{n-2} is the value of $\mathcal{V}_{n-2}$ on the set $S_V(\frac{1}{2^{n-2}})$. We deduce by (4.2) that

$$\zeta \in \partial_P\left[\max\left\{\frac{V(x)}{K_{n-2}} + A, A'\right\} + \frac{V(x)}{K_{n-1}}\right],$$

where $A = C_{n-2} - \frac{1}{2^{n-2}K_{n-2}}$ and $A' = C_{n-2} - \frac{1}{2^{n-1}K_{n-2}}$.
Hence, we obtain that ζ is in the set

$$\partial_P\left[\max\left\{\left(\frac{1}{K_{n-2}} + \frac{1}{K_{n-1}}\right)V(x) + A, \frac{V(x)}{K_{n-1}} + A'\right\}\right].$$

Now, by the basic calculus on the proximal subgradients, we have

$$\zeta \in \operatorname{co}\left\{\left(\frac{1}{K_{n-2}} + \frac{1}{K_{n-1}}\right)\partial_P V(x), \frac{1}{K_{n-1}}\partial_P V(x)\right\}.$$

Then, there exists ζ_1 and ζ_2 in $\partial_P V(x)$ and $t \in [0,1]$ such that

$$\begin{aligned}\zeta &= t\left(\frac{1}{K_{n-2}} + \frac{1}{K_{n-1}}\right)\zeta_1 + (1-t)\frac{1}{K_{n-1}}\zeta_2\\ &= \left[t\left(\frac{1}{K_{n-2}} + \frac{1}{K_{n-1}}\right) + (1-t)\frac{1}{K_{n-1}}\right]\hat{\zeta},\end{aligned}$$

where $\hat{\zeta} \in \partial_P V(x)$, because $\partial_P V(x)$ is a convex set. Now, we invoke the decrease property of V, $\inf_{u\in\mathcal{U}}\langle\hat{\zeta}, f(x,u)\rangle \leq -W(x)$. Then

$$\inf_{u\in\mathcal{U}} \langle \zeta, f(x,u)\rangle \leq -\frac{W(x)}{K_{n-1}},$$

which gives the result.

Second case. If $n = 1$, the proof is similar. □

Now, note that for each $x \neq 0$, the sequence $(\mathcal{V}_n(x))_{n\geq 0}$ is stationary; thus it converges. So, we can define

$$\mathcal{V}(x) := \lim_{n\to\infty} \mathcal{V}_n(x) - C,$$

where $C := 1 - \sum_{n=0}^{+\infty} \frac{1}{2^{n+1}K_n} \in [0,1]$ (because the Lipschitz constants have been chosen greater than 1).

By the preceding lemma, $\mathcal{V}_n$ is always positive and for $x = 0$,

$$\mathcal{V}_n(0) = 1 - \sum_{k=1}^{n} \frac{1}{2^k K_{k-1}} \rightarrow_{n\to\infty} C =: \mathcal{V}(0) + C.$$

We deduce that $\mathcal{V}(0) = 0$ and then that $\mathcal{V}$ is positive definite. On the other hand, it is locally Lipschitz everywhere as a simple limit of Lipschitz functions (with the same constant in each compact set on $\mathbb{X}$), and it verifies the decreasing property (2.2) with a continuous positive definite function $\mathcal{W}$ defined as follows:

$$\mathcal{W}(x) := \inf_{y\in\mathbb{X}} \{w(y) + \|x - y\|\} \ \forall\ x \in \mathbb{X},$$

where

$$w(x) := \begin{cases} W(x) & \text{if } x \notin S_V(1), \\ \frac{W(x)}{K_n} & \text{if } x \in S_V(\frac{1}{2^n}) \setminus S_V(\frac{1}{2^{n+1}}), \\ 0 & \text{if } x = 0. \end{cases}$$

The decrease property is an immediate consequence of (4.1).

To complete the proof of Theorem 1, we now have to prove the existence of a CLF which is continuous on $\mathbb{X}$ and locally Lipschitz outside the origin. We begin by defining a multifunction F, which is useful because it is uniformly bounded:

$$\forall x \in \mathbb{X}, F(x) := \text{cl} \quad \text{co} \left\{ \frac{f(x,u)}{1 + \|f(x,u)\|}, u \in \mathcal{U} \right\}.$$

We study the differential inclusion

$$\dot{x}(t) \in F(x(t)) \quad \text{a.e.}$$

This dynamic has the same properties as the system (2.1).

PROPOSITION 1.

(i) *F is locally Lipschitz and compact convex valued.*

(ii) *The system $\dot{x}(t) \in F(x(t))$ is GAC.*

Proof.

(i) First of all, it is clear by construction that for all $x \in \mathbb{X}$, the set $F(x)$ is compact convex. Moreover, since the function

$$x \mapsto \frac{f(x,u)}{1 + \|f(x,u)\|}$$

is locally Lipschitz uniformly in u, we deduce that the multifunction F is also locally Lipschitz.

(ii) We now prove the global asymptotic controllability of the differential inclusion

$$\dot{x}(t) \in F(x(t)) \quad \text{a.e.} \tag{4.3}$$

Let $x \in \mathbb{X}$ with $\|x\| \leq R$ be given. By assumption, there is a trajectory $x(\cdot)$ of (2.1) on $[0, \infty)$ which verifies the assumptions of global asymptotic controllability (Definition 2.3). We set

$$\phi(t) := \int_0^t [1 + \|\dot{x}(s)\|] ds,$$

and we define a function $\tilde{x}$ on $[0, \infty]$ by

$$\tilde{x}(\tau) := x(t),$$

where $t = t(\tau)$ is determined in $[0, \infty]$ by

$$\tau = \int_0^t [1 + \|\dot{x}(s)\|] ds.$$

(This change of variables or time scale is known as the Erdmann transform.) Then

$$\frac{d\tilde{x}}{d\tau} = \frac{\dot{x}(t)}{1 + \|\dot{x}(t)\|} \in F(\tilde{x}(\tau)) \quad \text{a.e.},$$

so that $\tilde{x}$ is an F-trajectory.

But by construction, for all $\tau \geq 0, \|\tilde{x}(\tau)\| \leq M(R)$, and if $\tau \geq \phi(T(r, R))$, then $\|\tilde{x}(\tau)\| \leq r$.

The trajectory $x(\cdot)$ remains in the ball $M(R)\bar{B}$, so if N_R denotes the maximum of $\|f(x, u)\|$ for $x \in M(R)\bar{B}$ and $u \in U$ (finite by Assumption 2.2), we have

$$\forall t \geq 0, \phi(t) \leq t(1 + N_R).$$

We deduce that if $\tau \geq T(r, R)(1+N_R)$, then $\tau \geq \phi(T(r, R))$ and consequently $\|\tilde{x}(\tau)\| \leq r$.

The differential inclusion (4.3) is GAC with suitable values $M(R)$ and $\tilde{T}(r, R) := T(r, R)(1 + N_R)$. □

We shall use the notation $M(\cdot)$ and $\tilde{T}(\cdot, \cdot)$ for the functions of the global asymptotic stability of F.

Remark 4.2. *We have, in fact, by a similar proof the following property.*

Proposition 2. *Let $\beta : \mathbb{X} \longrightarrow \mathbb{R}_{>0}$ be locally Lipschitz. Then the differential inclusion*

$$\dot{x}(t) \in \beta(x(t))F(x(t)) \quad \textit{a.e.}$$

is locally Lipschitz with convex compact values and it is GAC with appropriate constants $M(R) \downarrow 0$ and $\tilde{T}_\beta(r, R) = T(r, R) \max_{x \in M(R)\bar{B}} \{\beta(x)^{-1}\}$.

We proceed now to define iteratively a sequence of value functions for targets shrinking down to the equilibrium. We make an inductive proof which is mainly based on the Theorem 3. In the first step we define the first value function V_0, and then in order to set out the idea of the induction, we construct explicitly the second value function V_1 in the second step. Finally, we finish our proof by giving the induction for all n (third step) and by defining our definitive CLF in the fourth step.

First step. We begin the inductive proof by setting a first value function V_0.

First of all, we define a new multifunction Γ_0 as follows:

$$\Gamma_0(x) := \begin{cases} \left[1 + (\|x\| - M(1))\frac{\tilde{T}(\frac{1}{2},1)}{M(1)^2}\right]^{-1} F(x) & \text{for } \|x\| \geq M(1), \\ F(x) & \text{for } 1 \leq \|x\| \leq M(1), \\ F(x) + 4[1 - \|x\|]\bar{B} & \text{for } \frac{1}{2} \leq \|x\| \leq 1, \\ F(x) + 2\bar{B} & \text{for } \|x\| \leq \frac{1}{2}. \end{cases}$$

By construction (and by Proposition 2), we have immediately the following lemma.

Lemma 4.3. *Γ_0 is compact convex valued, locally Lipschitz, uniformly bounded (by 1), and the differential inclusion $\dot{x} \in \Gamma_0(x(t))$ is GAC.*

On the other hand, $\bar{B} \subset \Gamma_0(x)$ for all x in $\frac{1}{2}\bar{B}$. Hence, Theorem 3 can be applied with $\mathcal{T} = \mathcal{T}_0 := \frac{1}{2}\bar{B}$ and $L = L_0 := 1$. So we define the value function

$$V_0(x) := \inf\left\{T : x(0) = x, \dot{x}(t) \in \Gamma_0(x(t)) \text{ a.e. and } x(T) \in \frac{1}{2}\bar{B}\right\}$$

for all $x \in \mathbb{X}$.

Lemma 4.4. *V_0 is locally Lipschitz on $\mathbb{X}$, positive, proper, and for all $x \notin B$,*

$$\forall \zeta \in \partial_P V_0(x), \min_{v \in F(x)} \langle \zeta, v \rangle \leq -1.$$

Proof. This is an easy corollary of Theorem 3. □

We set $m_0 := \max\{V_0(x); \|x\| \leq 1\}$ and $S_0 := \{x; V_0(x) \leq m_0\}$. We define a new function $\tilde{V_0}$ as follows:

$$\tilde{V_0}(x) := \max\{0, V_0(x) - m_0\}.$$

Lemma 4.5.

(a) *$\tilde{V_0}(x) = 0 \Longleftrightarrow x \in S_0$.*

(b) *$\bar{B} \subset S_0 \subset 3M(1)\bar{B}$.*

(c) *For all $x \notin S_0$, for all $\zeta \in \partial_P \tilde{V_0}(x), \min_{v \in F(x)} \langle \zeta, v \rangle \leq -1$.*

Proof.

(a) The proof of (a) is obvious by the definition of $\tilde{V_0}$.

(b) The first inclusion is given by the definition of S_0. However, the second one is less easy. Since the system $\dot{x} \in F(x)$ is GAC, for all $\alpha \in \bar{B}$ there exists a F-trajectory $x(\cdot)$ such that
   (1) $x(0) = \alpha$ and $\dot{x}(t) \in F(x(t))$ a.e.,
   (2) for all $t \geq 0, \|x(t)\| \leq M(1)$,
   (3) for all $t \geq \tilde{T}(\frac{1}{2}, 1), \|x(t)\| \leq \frac{1}{2}$.

   Now, from the definition of Γ_0, for all $x \in M(1)\bar{B},\ F(x) \subset \Gamma_0(x)$; then

$$V_0(\alpha) \leq \tilde{T}\left(\frac{1}{2}, 1\right).$$

   Consequently, $m_0 \leq \tilde{T}(\frac{1}{2}, 1)$.

   Let us consider now $\alpha \in \mathbb{X}$ such that $\|\alpha\| \geq 3M(1)$.

We remark that for $\|x\| \geq 2M(1)$, we have

$$\|\Gamma_0(x)\| \leq \left[1 + \frac{\tilde{T}(\frac{1}{2},1)}{M(1)}\right]^{-1}.$$

Then the time needed by a Γ_0 trajectory with initial condition α to reach the ball $2M(1)\bar{B}$ is greater than $[1 + \frac{\tilde{T}(\frac{1}{2},1)}{M(1)}]M(1)$.

Hence, $V_0(\alpha) \geq M(1) + \tilde{T}(\frac{1}{2},1) > m_0$.

Consequently, $S_0 \subset 3M(1)\bar{B}$.

(c) This last assertion is a consequence of Lemma 4.4. □

Second step. We present now the construction of the second value function V_1 in order to give the idea of our inductive proof.

We set

$$\Gamma_1(x) := \begin{cases} \left[1 + (\|x\| - M(\frac{1}{2}))\frac{\tilde{T}(\frac{1}{4},\frac{1}{2})}{M(\frac{1}{2})^2}\right]^{-1} F(x) & \text{for } \|x\| \geq M(\frac{1}{2}), \\ F(x) & \text{for } \frac{1}{2} \leq \|x\| \leq M(\frac{1}{2}), \\ F(x) + 8\left[\frac{1}{2} - \|x\|\right]\bar{B} & \text{for } \frac{1}{4} \leq \|x\| \leq \frac{1}{2}, \\ F(x) + 2\bar{B} & \text{for } \|x\| \leq \frac{1}{4}. \end{cases}$$

We have immediately the following result.

LEMMA 4.6. *Γ_1 is compact convex valued, and the differential inclusion $\dot{x}(t) \in \Gamma_1(x(t))$ is GAC (with possible constants $M_1(R) = M(R) \downarrow 0$ and $\tilde{T}_1(r,R)$).*

We need an auxiliary function with the local Lipschitz property. We define for all $x \in \mathbb{X}$

$$B_0(x) := \max\{V_0(y) : \|y\| \leq \|x\| + M(1)\}.$$

As before, the new multifunction leads to a value function R_1 associated to the set $\mathcal{T}_1 := \frac{1}{4}\bar{B}$. We set for all x in $\mathbb{X}$

$$R_1(x) := \inf\left\{\int_0^T L_1(x(t))dt : x(0) = x, \dot{x} \in \Gamma_1(x) \text{ a.e. and } x(T) \in \mathcal{T}_1\right\},$$

where $L_1(x) := 1 + \max\{0, \|x\| - 3M(1)\}\frac{B_0(x)}{\rho_1 M(1)^2}$ and

$$\rho_1 := \frac{m_0/2}{m_0\left[1 + (3M(1) - M(\frac{1}{2}))\frac{\tilde{T}(\frac{1}{4},\frac{1}{2})}{M(\frac{1}{2})^2}\right] + \tilde{T}_1(\frac{1}{4},1)} \leq 1.$$

Theorem 3 gives the following lemma.

LEMMA 4.7.

(a) *R_1 is locally Lipschitz on $\mathbb{X}$.*

(b) *For all $\|x\| \geq \frac{1}{2}$, for all $\zeta \in \partial_P R_1(x), \min_{v \in F(x)}\langle\zeta, v\rangle \leq -L_1(x)$.*

Proof. Since L_1 and Γ_1 are locally Lipschitz and the system associated to Γ_1 is GAC, R_1 is finite everywhere and Theorem 3 proves the assertions. □

As in the first step, we are going to evaluate the size of a certain level set given by R_1. We set $m_{R_1} := \max\{R_1(y) : y \in \frac{1}{2}\bar{B}\}$ and

$$S_{R_1}(m_{R_1}) = \{x : R_1(x) \leq m_{R_1}\}.$$

By Proposition 1, for any $x \in \frac{1}{2}\bar{B}$, there exists an F-trajectory $x(\cdot)$ such that

1. $x(0) = x$,
2. for all $t \geq 0, \|x(t)\| \leq M(\frac{1}{2})$,
3. for all $t \geq \tilde{T}(\frac{1}{4}, \frac{1}{2}), x(t) \in \mathcal{T}_1$.

Moreover, for all $x \in M(\frac{1}{2})\bar{B}$, $F(x) \subset \Gamma_1(x)$ and $L_1(x) = 1$; then

$$R_1(x) \leq \tilde{T}\left(\frac{1}{4}, \frac{1}{2}\right).$$

Consequently, $m_{R_1} \leq \tilde{T}(\frac{1}{4}, \frac{1}{2})$.

Now, we consider an initial state α such that $\|\alpha\| \geq 3M(\frac{1}{2})$.

We remark that for $\|x\| \geq 2M(1)$, we have

$$\|\Gamma_1(x)\| \leq \left[1 + \frac{\tilde{T}(\frac{1}{4}, \frac{1}{2})}{M(\frac{1}{2})}\right]^{-1}.$$

Then the time used by a Γ_1-trajectory with initial condition α to reach the ball $2M(\frac{1}{2})\bar{B}$ is greater than $[1 + \frac{\tilde{T}(\frac{1}{4}, \frac{1}{2})}{M(\frac{1}{2})}]M(\frac{1}{2})$.

Hence, $L_1 \geq 1$ implies $R_1(\alpha) \geq M(\frac{1}{2}) + \tilde{T}(\frac{1}{4}, \frac{1}{2}) > m_{R_1}$.

Consequently,

$$S_{R_1}(m_{R_1}) \subset 3M\left(\frac{1}{2}\right)\bar{B}.$$

Indeed, from the proof follows the following lemma.

Lemma 4.8. *$\frac{1}{2}\bar{B} \subset S_{R_1}(m_{R_1}) \subset 3M(\frac{1}{2})\bar{B}$.*

We want now to compare R_1 with V_0.

Lemma 4.9.

(a) *For all $x \in S_0, \rho_1 R_1(x) \leq \frac{m_0}{2}$.*

(b) *If $\|x\| \geq 5M(1)$, then $V_0(x) \leq \rho_1 R_1(x)$.*

Proof.

(a) Let $x \in S_0$. Indeed, there exists a Γ_0-trajectory $x(\cdot)$ which connects x to the set $\bar{B}$ in time $T_x \leq V_0(x) \leq m_0$. Hence, for all $t \geq 0,\ x(t) \in S_0 \subset 3M(1)\bar{B}$ (by Lemma 4.5(b)). In the zone $\|x\| \in [1, 3M(1)]$ we can write $\Gamma_1(x) \subset \beta(x)\Gamma_0(x)$ with $\beta(x)$ as follows (assuming that $M(\frac{1}{2}) \geq 1$):

$$\beta(x) := \begin{cases} 1 & \text{if } \|x\| \in [\frac{1}{2}, M(\frac{1}{2})], \\ \left[1 + (\|x\| - M(\frac{1}{2}))\frac{\tilde{T}(\frac{1}{4}, \frac{1}{2})}{M(\frac{1}{2})^2}\right]^{-1} & \text{if } \|x\| \in [M(\frac{1}{2}), M(1)], \\ \dfrac{\left[1 + (\|x\| - M(\frac{1}{2}))\frac{\tilde{T}(\frac{1}{4}, \frac{1}{2})}{M(\frac{1}{2})^2}\right]^{-1}}{\left[1 + (\|x\| - M(1))\frac{\tilde{T}(\frac{1}{2}, 1)}{M(1)^2}\right]^{-1}} & \text{if } \|x\| \in [M(1), 3M(1)]. \end{cases}$$

We observe that if $M(\frac{1}{2}) < 1$, we have to omit it in the definition of β. Now, an appropriate change of variables (see Proposition 2) shows that there exists a Γ_1-trajectory $x(\cdot)$ which remains in $3M(1)\bar{B}$ and drives x to $\bar{B}$ in a time $T \leq T_x \max_{\|x\| \in [1, 3M(1)]} \beta(x)^{-1}$.

Thus, we obtain $T \leq m_0[1 + (3M(1) - M(\frac{1}{2}))\frac{\tilde{T}(\frac{1}{4}, \frac{1}{2})}{M(\frac{1}{2})^2}]$.

Now, we can extend this trajectory to $\mathcal{T}_1$ with the following property (by

Lemma 4.6): for all $t \geq T, x(t) \in M(1)\bar{B}$ and $x(T + \tilde{T}_1(\frac{1}{4}, 1)) \in \frac{1}{4}\bar{B}$. Thus, we have constructed a trajectory which remains in $3M(1)\bar{B}$ (where $L_1 = 1$) and reaches the set $\mathcal{T}_1$.

Consequently, $R_1(x) \leq m_0[1 + (3M(1) - M(\frac{1}{2}))\frac{\tilde{T}(\frac{1}{4},\frac{1}{2})}{M(\frac{1}{2})^2}] + \tilde{T}_1(\frac{1}{4}, 1)$.

We conclude by the definition of ρ_1.

(b) Let x be such that $\|x\| \geq 5M(1)$. By the definition of B_0 we have

$$\|y\| \geq \|x\| - M(1) \Longrightarrow B_0(y) \geq V_0(x) \Longrightarrow L_1(y) \geq 1 + \frac{V_0(x)}{\rho_1 M(1)^2}.$$

On the other hand, the time required to go from $\{\|y\| \geq \|x\| - M(1)\}$ to $\{\|y\| \geq \|x\| - 2M(1)\}$ is greater than $M(1)$. (The dynamic is bounded by 1.) Consequently,

$$\begin{aligned} R_1(x) &\geq M(1)\left[1 + \frac{V_0(x)}{\rho_1 M(1)}\right] \\ &\geq \frac{V_0(x)}{\rho_1}. \qquad \square \end{aligned}$$

We finish this step by defining a new function V_1 as follows.

$$\forall x \in \mathbb{X}, V_1(x) := \min\{\tilde{V_0}(x) + m_0, \rho_1 R_1(x)\}.$$

We set $m_1 := \max\{V_1(x) : x \in \frac{1}{2}\bar{B}\}$ and $S_1 := \{x : V_1(x) \leq m_1\}$. We have the following lemma.

Lemma 4.10. *V_1 is locally Lipschitz on $\mathbb{X}$. Moreover, we have*

(a) *$m_1 \leq \frac{m_0}{2}$;*

(b) *for all $x \in S_0 \cup S_1, V_1(x) = \rho_1 R_1(x)$;*

(c) *$\frac{1}{2}\bar{B} \subset S_1 \subset 3M(\frac{1}{2})\bar{B}$;*

(d) *if $\|x\| \geq 5M(1)$, then $V_1(x) = V_0(x)$;*

(e) *for $\frac{1}{2} \leq \|x\| \leq 5M(1)$, for all $\zeta \in \partial_P V_1(x), \min_{v\in F(x)}\langle\zeta, v\rangle \leq -\rho_1$;*

(f) *for $\|x\| > 5M(1)$, for all $\zeta \in \partial_P V_1(x), \min_{v\in F(x)}\langle\zeta, v\rangle \leq -1$.*

Proof.

(a) By Lemma 4.9 (a), for any $x \in S_0, \rho_1 R_1(x) \leq \frac{m_0}{2}$. Hence by definition of V_1, for all $x \in S_0, V_1(x) = \rho_1 R_1(x)$. Thus we conclude by remarking that $\frac{1}{2}\bar{B} \subset S_0$. We have, in fact, $m_1 = \rho_1 m_{R_1}$.

(b) Let $x \in S_0 \cup S_1$. If $x \in S_0$, we have shown the equality in the first assertion. Otherwise, $V_1(x) \leq m_1 \leq \frac{m_0}{2}$ implies the equality.

(c) If $x \in S_1$, then $V_1(x) = \rho_1 R_1(x) \leq m_1$. And by the remark in (a), $R_1(x) \leq m_{R_1}$, which gives the inclusion.

(d) For $\|x\| \geq 5M(1)$, we have that $V_0(x) = \tilde{V_0}(x) + m_0$ (because $S_0 \subset 3M(1)\bar{B}$). We conclude by Lemma 4.9(b).

(e) Let $x \in \mathbb{X}$ such that $\frac{1}{2} \leq \|x\| \leq 5M(1)$ and $\zeta \in \partial_P V_1(x)$. We recall the definition of $V_1(x)$:

$$V_1(x) := \min\{\tilde{V_0}(x) + m_0, \rho_1 R_1(x)\}.$$

First case. The minimum is attained by the second term. Then $\zeta \in \partial_P \rho_1 R_1(x) = \rho_1 \partial_P R_1(x)$. We conclude by Lemma 4.7 (b).

Second case. The minimum is attained by the first term and not by the second one. In this case, $x \notin S_0$ and $\zeta \in \partial_P(\tilde{V_0} + m_0)(x) = \partial_P \tilde{V_0}(x)$. We conclude by Lemma 4.5 (c).

(f) This is an easy consequence of Lemma 4.9(b). □

Third step. We finish the construction of the sequence $(V_n)_{n\geq 0}$ by induction on n.

Assume $(V_k, \mathcal{T}_k, L_k, R_k, \Gamma_k)$ have already been defined for $1 \leq k \leq n$ with the following properties:

1. $\frac{1}{2^k}\bar{B} \subset S_k \subset 3M(\frac{1}{2^k})\bar{B}$,
2. for $\|x\| \geq 5M(\frac{1}{2^{k-1}}), V_k(x) = V_{k-1}(x)$,
3. for $\frac{1}{2^k} \leq \|x\| \leq 5M(\frac{1}{2^{k-1}})$, for all $\zeta \in \partial_P V_k(x), \min_{v\in F(x)}\langle \zeta, v\rangle \leq -\rho_k$,
4. $L_k = 1$ on the ball $3M(\frac{1}{2^{k-1}})\bar{B}$,
5. for all $x \in \mathbb{R}^N, V_k(x) = 0 \iff x \in \frac{1}{2^{k+1}}\bar{B} =: \mathcal{T}_k$,
6. for all $k \in [1, n], m_k \leq \frac{m_{k-1}}{2}$, and $\rho_k \leq \rho_{k-1} \leq 1 =: \rho_0$,

where

$$m_k := \max\left\{V_k(x); \|x\| \leq \frac{1}{2^k}\right\},\ S_k := \{x; V_k(x) \leq m_k\},$$

and the ρ_k's are some positive constants.

As before, we can define a new function V_{n+1}. We proceed as follows: for all $x \in \mathbb{X}$, we set $\Gamma_{n+1}(x) :=$

$$\begin{cases} \left[1 + (\|x\| - M(\frac{1}{2^{n+1}}))\frac{\tilde{T}(\frac{1}{2^{n+2}}, \frac{1}{2^{n+1}})}{M(\frac{1}{2^{n+1}})^2}\right]^{-1} F(x) & \text{if } \|x\| \geq M(\frac{1}{2^{n+1}}), \\ F(x) & \text{if } \|x\| \in [\frac{1}{2^{n+1}}, M(\frac{1}{2^{n+1}})], \\ F(x) + 2^{n+3}[\frac{1}{2^{n+1}} - \|x\|]\bar{B} & \text{if } \|x\| \in [\frac{1}{2^{n+2}}, \frac{1}{2^{n+1}}], \\ F(x) + 2\bar{B} & \text{if } \|x\| \leq \frac{1}{2^{n+2}}. \end{cases}$$

As before, we need an auxiliary function with the local Lipschitz property. We define for all $x \in \mathbb{X}$

$$B_n(x) := \max\left\{V_n(y) : \|y\| \leq \|x\| + M\left(\frac{1}{2^n}\right)\right\}.$$

From this multifunction, we define a value function associated to the set $\mathcal{T}_{n+1} := \frac{1}{2^{n+2}}\bar{B}$. We set for any $x \in \mathbb{X}$

$$R_{n+1}(x) := \inf\left\{\int_0^T L_{n+1}(x(t))dt : x(0) = x, \dot{x} \in \Gamma_{n+1}(x),\ \text{and } x(T) \in \mathcal{T}_{n+1}\right\},$$

where $L_{n+1}(x) := 1 + \max\{0, \|x\| - 3M(\frac{1}{2^n})\}\frac{B_n(x)}{\rho_{n+1}M(\frac{1}{2^n})^2}$ with

$$\rho_{n+1} := \frac{\rho_n m_n/2}{m_n\left[1 + (3M(\frac{1}{2^n}) - M(\frac{1}{2^{n+1}}))\frac{\tilde{T}(\frac{1}{2^{n+2}}, \frac{1}{2^{n+1}})}{M(\frac{1}{2^{n+1}})^2}\right] + \tilde{T}_{n+1}(\frac{1}{2^{n+2}}, \frac{1}{2^n})} \leq \rho_n.$$

The differential inclusion $\dot{x} \in \Gamma_{n+1}(x)$ is GAC; we denote by $\tilde{T}_{n+1}(\cdot, \cdot)$ its new constant. (We saw that we can choose $\tilde{M}_{n+1} = M$.) On the other hand, we set

$$m_{R_{n+1}} := \max\left\{R_{n+1}(y) : y \in \frac{1}{2^{n+1}}\bar{B}\right\},$$

$$\text{and } S_{R_{n+1}}(m_{R_{n+1}}) := \{x : R_{n+1}(x) \leq m_{R_{n+1}}\}.$$

LEMMA 4.11.

(a) *R_{n+1} is locally Lipschitz on $\mathbb{X}$.*

(b) *For all $\|x\| \geq \frac{1}{2^{n+1}}$, for all $\zeta \in \partial_P R_{n+1}(x), \min_{v \in F(x)} \langle \zeta, v \rangle \leq -L_{n+1}(x)$.*

(c) *$\frac{1}{2^{n+1}} \bar{B} \subset S_{R_{n+1}}(m_{R_{n+1}}) \subset 3M(\frac{1}{2^{n+1}})\bar{B}$.*

(d) *For all $x \in S_n, \rho_{n+1} R_{n+1}(x) \leq \frac{m_n}{2}$.*

(e) *If $\|x\| \geq 5M(\frac{1}{2^n})$, then $V_n(x) \leq \rho_{n+1} R_{n+1}(x)$.*

Proof. (a) and (b) are evident by Theorem 1. The assertion (c) is proved as before (Lemma 4.8). We prove now (d) and (e); we begin with (e).

Let $\|x\| \geq 5M(\frac{1}{2^n})$ be given. By the definition of B_n we have

$$\|y\| \geq \|x\| - M\left(\frac{1}{2^n}\right) \Longrightarrow B_n(y) \geq V_n(x) \Longrightarrow L_{n+1}(y) \geq 1 + \frac{V_n(x)}{\rho_{n+1} M(\frac{1}{2^n})^2}.$$

On the other hand, the time required for driving from $\{\|y\| \geq \|x\| - M(\frac{1}{2^n})\}$ to $\{\|y\| \geq \|x\| - 2M(\frac{1}{2^n})\}$ is greater than $M(\frac{1}{2^n})$. (The dynamic is bounded by 1.) Consequently,

$$\begin{aligned} R_{n+1}(x) &\geq M\left(\frac{1}{2^n}\right)\left[1 + \frac{V_n(x)}{\rho_{n+1} M(\frac{1}{2^n})}\right] \\ &\geq \frac{V_n(x)}{\rho_{n+1}}. \end{aligned}$$

We prove now (d). Let $x \in S_n$. Indeed, there exists a Γ_n-trajectory $x(\cdot)$ which takes x to the set $\frac{1}{2^n}\bar{B}$ in time $T_x \leq V_n(x) \leq m_n$ and which remains in S_n (because $S_n \subset 3M(\frac{1}{2^n}\bar{B}$ and $L_n = 1$ on $3M(\frac{1}{2^n}\bar{B})$. In the zone $\|x\| \in [\frac{1}{2^n}, 3M(\frac{1}{2^n})]$ we can write $\Gamma_{n+1}(x) \subset \beta(x)\Gamma_n(x)$ with $\beta(x)$ as follows (assuming that $M(\frac{1}{2^{n+1}}) \geq \frac{1}{2^n}$; we adapt otherwise):

$$\beta(x) := \begin{cases} 1 & \text{for } \|x\| \in [\frac{1}{2^n}, M(\frac{1}{2^{n+1}})], \\ \left[1 + (\|x\| - M(\frac{1}{2^{n+1}}))\frac{\tilde{T}(\frac{1}{2^{n+2}}, \frac{1}{2^{n+1}})}{M(\frac{1}{2^{n+1}})^2}\right]^{-1} & \text{for } \|x\| \in [M(\frac{1}{2^{n+1}}), M(\frac{1}{2^n})], \\ \dfrac{\left[1+(\|x\|-M(\frac{1}{2^{n+1}}))\frac{\tilde{T}(\frac{1}{2^{n+2}}, \frac{1}{2^{n+1}})}{M(\frac{1}{2^{n+1}})^2}\right]^{-1}}{\left[1+(\|x\|-M(\frac{1}{2^n}))\frac{\tilde{T}(\frac{1}{2^{n+1}}, 2^n)}{M(\frac{1}{2^n})^2}\right]^{-1}} & \text{for } \|x\| \in [M(\frac{1}{2^n}), 3M(\frac{1}{2^n})]. \end{cases}$$

An appropriate change of variables (see Proposition 2) shows that there exists a Γ_{n+1}-trajectory $x(\cdot)$ which remains in $3M(\frac{1}{2^n})\bar{B}$ and takes x to $\frac{1}{2^n}\bar{B}$ in a time $T \leq T_x \max_{\|x\| \in [\frac{1}{2^n}, 3M(\frac{1}{2^n})]} \beta(x)^{-1}$.

Thus, we have $T \leq m_n[1 + (3M(\frac{1}{2^n}) - M(\frac{1}{2^{n+1}}))\frac{\tilde{T}(\frac{1}{2^{n+2}}, \frac{1}{2^{n+1}})}{M(\frac{1}{2^{n+1}})^2}]$.

Now, we can extend this trajectory to $\mathcal{T}_{n+1}$ with the following property (by Lemma 4.6): for all $t \geq T, x(t) \in M(\frac{1}{2^n})\bar{B}$ and $x(T + \tilde{T}_{n+1}(\frac{1}{2^{n+2}}, \frac{1}{2^n})) \in \mathcal{T}_{n+1}$. In this way, we have constructed a trajectory which remains in $3M(\frac{1}{2^n})\bar{B}$ (where $L_{n+1} = 1$) and reaches the set $\mathcal{T}_{n+1}$.

Consequently,

$$R_{n+1}(x) \leq m_n \left[1 + \left(3M\left(\frac{1}{2^n}\right) - M\left(\frac{1}{2^{n+1}}\right)\right)\frac{\tilde{T}(\frac{1}{2^{n+2}}, \frac{1}{2^{n+1}})}{M(\frac{1}{2^{n+1}})^2}\right] + \tilde{T}_1\left(\frac{1}{2^{n+2}}, \frac{1}{2^n}\right).$$

We conclude by the definition of ρ_{n+1}. □

We can now define the new function V_{n+1}. We set for all $x \in \mathbb{X}$

$$V_{n+1}(x) := \min\{\tilde{V_n}(x) + m_n, \rho_{n+1} R_{n+1}(x)\},$$

where $\tilde{V_n}(x) := \max\{0, V_n(x) - m_n\}$.

As before, we consider

$$m_{n+1} := \max\left\{V_{n+1}(x) : x \in \frac{1}{2^{n+1}}\bar{B}\right\} \text{ and } S_{n+1} := \{x : V_{n+1}(x) \leq m_{n+1}\}.$$

We have the following lemma.

Lemma 4.12. *V_{n+1} is locally Lipschitz on $\mathbb{X}$. Moreover, we have the following.*

(a) $m_{n+1} \leq \frac{m_n}{2}$.

(b) $\frac{1}{2^{n+1}}\bar{B} \subset S_{n+1} \subset 3M(\frac{1}{2^{n+1}})\bar{B}$.

(c) *If* $\|x\| \geq 5M(\frac{1}{2^n})$, *then* $V_{n+1}(x) = V_n(x)$.

(d) *For* $\frac{1}{2^{n+1}} \leq \|x\| \leq 5M(\frac{1}{2^n})$, *for all* $\zeta \in \partial_P V_{n+1}(x), \min_{v \in F(x)}\langle \zeta, v\rangle \leq -\rho_{n+1}$.

Proof. The proof is similar to the proof of Lemma 4.10. This is left to the reader. □

Fourth step. The function *V*.

We study the convergence of the sequence $(V_n)_{n\geq 0}$; for that, we need a last lemma.

Lemma 4.13. *For all* $k, 0 \leq k \leq n$, *for all* $x \in S_k, V_n(x) \leq m_k$.

Proof. We do an inductive proof. Since the result has already been proved for n=1 (Lemma 4.10), we assume that we have proved the result for $n \geq 1$; we establish the property for $n+1$.

Let us consider $0 \leq k \leq n+1$ and $x \in S_k$.

First case. $k \leq n$.

If $x \notin S_n$, then by definition of V_n, $V_n(x) = \tilde{V_n}(x) + m_n$. Hence, $V_{n+1}(x) \leq V_n(x) \leq m_k$ by induction.

Otherwise, $x \in S_n$. In this case, $\tilde{V_n}(x) = 0$ implies $V_{n+1}(x) \leq m_n \leq m_k$ by the property on the sequence (m_k).

Second case. $k = n+1$.

The property follows from the definition of S_{n+1}. □

We can now conclude. Let us consider a compact set K in $\mathbb{X} \setminus \{0\}$. Then, as $\lim_{n\to\infty} M(\frac{1}{2^n}) = 0$, there exists a positive integer n_K such that

$$\|x\| \geq 5M\left(\frac{1}{2^{n_K}}\right) \quad \forall x \in K.$$

By the second property of the sequence $(V_n)_{n\geq 0}$, for any $n \geq n_K, V_n(x) = V_{n_K}(x)$.

Hence, the sequence $(V_n(x))_{n\geq 0}$ converges for all x in K and the limit is a locally Lipschitz function in K (as a stationary limit of locally Lipschitz functions). On the other hand, for any $n \geq 0, V_n(0) = 0$; so we can define for all $x \in \mathbb{X}$

$$V(x) := \lim_{n\to\infty} V_n(x).$$

By the proof above, V is locally Lipschitz on $\mathbb{X} \setminus \{0\}$, positive definite, and proper (since $V_n = V_0, \quad$ for all n if $\|x\| \geq 5M(1)$); we have to show that V is continuous at the origin. This fact is a consequence of the preceding lemma.

Let us consider $x_p \longrightarrow_{p\to\infty} 0$. We want to show that $f(x_p) \longrightarrow_{p\to\infty} 0$.

Let $\epsilon > 0$. There exists $n_0 \geq 0$ such that $m_{n_0} \leq \epsilon$ (because $m_n \leq \frac{m_0}{2^n}$). Thus, by the last lemma, for all $n \geq n_0$, for all $x \in S_{n_0}, V_n(x) \leq \epsilon$.

There exists $P > 0$ such that if $p \geq P$,

$$x_p \in \frac{1}{2^{n_0}} \bar{B} \subset S_{n_0}.$$

We deduce that for all $n \geq n_0$, for all $p \geq P, V_n(x_p) \leq \epsilon$. By passing to the limit: for all $p \geq P, V(x_p) \leq \epsilon$, which gives the continuity on the origin.

Now, we set for all $x \in \mathbb{X}$

$$w(x) := \begin{cases} \rho_n & \text{if } 5M(\frac{1}{2^{n+1}}) < \|x\| \leq 5M(\frac{1}{2^n}), \\ 1 & \text{if } \|x\| > 5M(1), \\ 0 & \text{if } x = 0. \end{cases}$$

We can now define the function W by

$$\forall x \in \mathbb{X}, W(x) := \inf_{y \in \mathbb{X}} \{w(y) + \|x - y\|\}.$$

W is a positive definite and locally Lipschitz function. The decrease condition (2.2) is the consequence of the stationarity of the sequence $(V_n(x))_{n \geq 0}$ outside the origin and of Lemma 4.12 (d). This completes the proof of Theorem 1.

5. Existence of a semiconcave CLF. We begin with some preliminaries on semiconcavity. It is easy to show that any semiconcave function in Ω is locally Lipschitz. Concave functions are of course semiconcave. Another class of semiconcave functions is that of C^1 functions with locally Lipschitz gradients. Moreover we have the two following lemmas.

LEMMA 5.1. *Let $\Psi : \mathbb{R} \longrightarrow \mathbb{R}$ be an increasing semiconcave function, and let $g : \Omega \longrightarrow \mathbb{R}$ be a semiconcave function on Ω. Then $\Psi \circ g$ is a semiconcave function on Ω.*

LEMMA 5.2. *Let $g, h : \Omega \longrightarrow \mathbb{R}$ be two semiconcave functions on Ω. Then the function* $\min\{g, h\}$ *is semiconcave on Ω.*

A convenient way to build semiconcave approximations of a given function is provided by the method of inf-*convolution*, a standard tool in convex and nonsmooth analysis. Let Ω be a subset of $\mathbb{X}$, and let g be a positive function in Ω. Define, for any $\alpha > 0$,

$$g_\alpha(x) := \inf_{y \in \Omega} \{g(y) + \alpha \|x - y\|^2\}. \tag{5.1}$$

LEMMA 5.3. *Let $g : \mathbb{X} \longrightarrow \mathbb{R}$ be a locally Lipschitz and proper function. Then g_α is semiconcave on $\mathbb{X}$ (in* (5.1) *the infimum is actually a minimum) and, moreover, $g_\alpha \nearrow g$, as $\alpha \rightarrow +\infty$, locally uniformly in $\mathbb{X}$.*

Proof. We leave the proof to the reader. □

We can link the proximal subdifferentials of u and its inf-convolution. We have the following lemma. (We refer to [14, Thm. 5.1, p. 44] for the proof.)

LEMMA 5.4. *Suppose that $x \in \mathbb{X}$ is such that $\partial_P g_\alpha(x)$ is nonempty. Then there exists a point $\bar{y} \in \mathbb{X}$ satisfying the following.*

a) *The infimum in* (5.1) *is attained uniquely at $\bar{y}$.*

b) *The proximal subgradient $\partial_P g_\alpha(x)$ is the singleton $\{2\alpha(x - \bar{y})\}$.*

c) $2\alpha(x - \bar{y}) \in \partial_P g(\bar{y})$.

Proof of Theorem 2. By Theorem 1, there exists a control-Lyapunov pair for the system (2.1); without loss of generality, we can suppose that the function W is

1-Lipschitz on $\mathbb{X}$. (Otherwise, we can set $\tilde{W}(x) := \inf_{y\in\mathbb{X}}\{W(y) + \|x-y\|\}$.) For any $0 < r < R$, we define the following sets:

$$S_V[r,R] := \{x \in \mathbb{X} : V(x) \in [r,R]\} \text{ and } S_V(R) := \{x \in \mathbb{X} : V(x) \leq R\}.$$

Let us consider an integer $n \in \mathbb{N}^*$. By the Lipschitz property of f and V, we can consider $L_f^n \geq 1$ (respectively, $L_V^n \geq 1$) the Lipschitz constant of $f(\cdot,u)$ (respectively, of V) on the level set $S_V(M_n)$, where the constant M_n is defined by

$$M_n := \max\{V(x) : x \in S_V(11n) + \bar{B}\}.$$

On the other hand, we denote by w_n the minimum of W on $S_V[\frac{1}{2n}, 11n]$, and we set

$$\alpha_n := \max\left\{8n(L_V^n)^2 + 1, \frac{2L_V^n(1 + L_V^n L_f^n)}{w_n} + 1, 11n\right\}. \tag{5.2}$$

We define by inf-convolution the function V_{α_n} as follows:

$$V_{\alpha_n}(x) := \inf_{y\in\mathbb{X}}\{V(y) + \alpha_n\|x-y\|^2\}. \tag{5.3}$$

LEMMA 5.5. *Let $x_0 \in S_V(M_n)$. If the infimum in the definition of $V_{\alpha_n}(x_0)$ is attained at $\bar{y}$, then $\|x_0 - \bar{y}\| \leq \min\{\frac{1}{8nL_V^n}, \frac{w_n}{2(1+L_V^n L_f^n)}\}$ and*

$$V(x_0) - \frac{1}{8n} \leq V_{\alpha_n}(x_0) \leq V(x_0).$$

Proof. If the infimum is attained for $\bar{y}$, then $V(\bar{y}) \leq V(x_0) \leq M_n \implies \bar{y} \in S_V(M_n)$. Hence, if $\|x_0 - \bar{y}\| > \min\{\frac{1}{8nL_V^n}, \frac{w_n}{2(1+L_V^n L_f^n)}\}$, then, by definition of L_f^n and L_V^n,

$$\begin{aligned}
V_{\alpha_n}(x_0) &= V(\bar{y}) + \alpha_n\|x_0 - \bar{y}\|^2 \\
&\geq V(x_0) - L_V^n\|x_0 - \bar{y}\| + \alpha_n\|x_0 - \bar{y}\|^2 \\
&\geq V(x_0) + \|x_0 - \bar{y}\|[\alpha_n\|x_0 - \bar{y}\| - L_V^n] \\
&\geq V(x_0) + \|x_0 - \bar{y}\|\left[\alpha_n \min\left\{\frac{1}{8nL_V^n}, \frac{w_n}{2(1+L_V^n L_f^n)}\right\} - L_V^n\right] \\
&> V(x),
\end{aligned}$$

we find a contradiction. Hence, $\|x_0 - \bar{y}\| \leq \min\{\frac{1}{8nL_V^n}, \frac{w_n}{2(1+L_V^n L_f^n)}\}$. On the other hand, we have found the estimate

$$V_{\alpha_n}(x_0) \geq V(x_0) + \|x_0 - \bar{y}\|[\alpha_n\|x_0 - \bar{y}\| - L_V^n].$$

Consequently, $V_{\alpha_n}(x_0) \geq V(x_0) - L_V^n\|x_0 - \bar{y}\|$, which implies the desired inequality by the bound on $\|x_0 - \bar{y}\|$. □

LEMMA 5.6. *Let $x_0 \in S_V[\frac{1}{2n}, 11n]$ and $\zeta \in \partial_P V_{\alpha_n}(x_0)$; then*

$$\inf_{u\in U}\langle\zeta, f(x_0,u)\rangle \leq -\frac{W(x_0)}{2}.$$

Proof. By Lemmas 5.4 and 5.5, the infimum in the definition of $V_{\alpha_n}(x_0)$ is attained uniquely at a point $\bar{y} \in S_V(11n)$ which satisfies $\|x_0 - \bar{y}\| \leq \frac{w_n}{2(1+L_V^n L_f^n)}$ and such that

$\zeta \in \partial_P V(\bar{y})$. Thus, by the Lipschitz properties of f, V, and W, we can write

$$\begin{aligned}\inf_{u\in U}\langle \zeta, f(x_0,u)\rangle &\le \inf_{u\in U}\langle \zeta, f(\bar{y},u)\rangle + \sup_{u\in U}\|\zeta\|\|f(x_0,u)-f(\bar{y},u)\|\\ &\le -W(\bar{y}) + L_V^n L_f^n\|x_0-\bar{y}\| \quad \text{(decrease condition)}\\ &\le -W(x_0) + (1+L_V^n L_f^n)\|x_0-\bar{y}\|\\ &\le -W(x_0) + \frac{w_n}{2} \le -\frac{W(x_0)}{2}. \qquad \square\end{aligned}$$

LEMMA 5.7. *For each n, there exists an increasing, C^∞ function $\Psi_n : \mathbb{R}_{\ge 0} \longrightarrow \mathbb{R}_{\ge 0}$ satisfying the following properties.*

(i) *For all $t \in [0, \frac{1}{2n}], \Psi_n(t) = t + \frac{1}{8n}$.*

(ii) *For all $t \in [\frac{1}{n} - \frac{1}{8n}, 10n], \Psi_n(t) = t$.*

(iii) *For all $t \in [11n - \frac{1}{8n}, \infty), \Psi_n(t) \ge 11n + \max\{V(x) : V_{\alpha_n}(x) \le t\}$.*

(iv) *For all $t \ge 0, \Psi_n'(t) \ge \frac{1}{2}$.*

Proof. The different intervals being disjoint, the different properties (i)–(iv) allow us to define an increasing, piecewise, affine function that can be regularized in order to get a C^∞ function Ψ_n. $\square$

The function $\tilde{V}_n := \Psi_n \circ V_{\alpha_n}$ is semiconcave on $\mathbb{X}$ by Lemma 5.1. The definitive Lyapunov pair $(\mathcal{V}, \mathcal{W})$ is defined for all $x \in \mathbb{X}$ by

$$\mathcal{V}(x) := \min_{n\in\mathbb{N}^*}\{\tilde{V}_n(x)\} \quad \text{and } \mathcal{W}(x) := \frac{W(x)}{4}. \tag{5.4}$$

LEMMA 5.8. *For all $n \in \mathbb{N}^*$, for all $x_0 \in S_V[\frac{1}{n}, 10n], \mathcal{V}(x_0) = \min_{1\le p\le n}\tilde{V}_p(x_0)$. Furthermore, if $\zeta \in \partial_P\mathcal{V}(x_0)$, then*

$$\inf_{u\in U}\langle \zeta, f(x_0,u)\rangle \le -\frac{W(x_0)}{4}. \tag{5.5}$$

Proof. Let be given $n \in \mathbb{N}^*$ and $x_0 \in S_V[\frac{1}{n}, 10n]$. By Lemma 5.5, $V_{\alpha_n}(x_0) \in [\frac{1}{n} - \frac{1}{8n}, 10n]$. Hence, Lemma 5.7 implies that $\tilde{V}_n(x_0) = V_{\alpha_n}(x_0)$. On the other hand, for any $p \ge n$, by construction $\alpha_p \ge \alpha_n$ and then $V_{\alpha_p}(x_0) \ge V_{\alpha_n}(x_0)$. The same argument as above on Ψ_p leads to

$$\tilde{V}_p(x_0) = V_{\alpha_p}(x_0) \ge \tilde{V}_n(x_0) = V_{\alpha_n}(x_0).$$

Consequently, we have shown that $\mathcal{V}(x_0) = \min_{1\le p\le n}\tilde{V}_p(x_0)$. Now, if the minimum in the definition of $\mathcal{V}(x_0)$ is attained for $\tilde{V}_{n_0}(x_0)$ (with $1 \le n_0 \le n$) then

$$\zeta \in \partial_P\mathcal{V}(x_0) \Longrightarrow \zeta \in \partial_P\tilde{V}_{n_0}(x_0) = \Psi'(V_{\alpha_{n_0}}(x_0))\partial_P V_{\alpha_{n_0}}(x_0).$$

We now have to show the inequality (5.5).

First case. If $V(x_0) > 11n_0$ and $V_{\alpha_{n_0}(x_0)} \le 11n_0$, then there exists $\bar{y} \in x_0 + \bar{B}$ (because $\alpha_{n_0} \ge 11n_0$) such that $V_{\alpha_{n_0}}(x_0) = V(\bar{y}) + \alpha_{n_0}\|x_0 - \bar{y}\|^2$. Therefore, $\bar{y} \in S_V(11n_0)$ and $x_0 \in S_V(M_{n_0})$ by definition of M_{n_0}. By Lemmas 5.5 and 5.7 (iii), we obtain $V_{\alpha_{n_0}(x_0)} \ge 11n_0 - \frac{1}{8n_0}$ and $\tilde{V}_{n_0}(x_0) \ge 11n_0 + V(x_0)$. But Lemma 5.7(ii) implies that

$$\tilde{V}_n(x_0) = V_{\alpha_n}(x_0) \le V(x_0).$$

Since n_0 is optimal and $\tilde{V}_{n_0}(x_0) \ge V(x_0)$, we get a contradiction. Therefore, this case cannot appear.

Second case. If $V(x_0) > 11n_0$ and $V_{\alpha_{n_0}(x_0)} > 11n_0$, then Lemma 5.7(iii) implies $\tilde{V}_{n_0}(x_0) \geq 11n_0 + V(x_0)$, and we conclude as in the first case.

Third case. If $V(x_0) < \frac{1}{2n_0}$, then

$$V_{\alpha_{n_0}}(x_0) \leq V(x_0) < \frac{1}{2n_0} \Longrightarrow \tilde{V}_{n_0}(x_0) = V_{\alpha_{n_0}}(x_0) + \frac{1}{8n_0} \geq V(x_0).$$

But we proved that $\tilde{V}_n(x_0) = V_{\alpha_n}(x_0) \leq V(x_0)$, so the minimum is also attained for n; then we have (5.5) by Lemma 5.6.

Fourth case. If $x_0 \in S_V[\frac{1}{2n_0}, 11n_0]$, then we conclude by Lemmas 5.6 and 5.7 (iv). □

This last lemma shows that the minimum in the definition of $\mathcal{V}(x)$ is always attained for $x \neq 0$. Therefore, the function $\mathcal{V}$ is semiconcave outside the origin (by Lemma 5.2). On the other hand, $\mathcal{V}$ is continuous at the origin (because $0 \leq \mathcal{V} \leq V$) and satisfies the decrease condition by (5.5). Consequently, $\mathcal{V}$ provides a CLF, which proves the Theorem 2.

Acknowledgments. The author thanks Professor Francis Clarke for his comments and his suggestions, and two anonymous referees who read the paper with great care pointed out a large number of misprints and made interesting remarks.

STOCHASTIC LINEAR QUADRATIC REGULATORS WITH INDEFINITE CONTROL WEIGHT COSTS. II[*]

SHUPING CHEN[†] AND XUN YU ZHOU[‡]

Abstract. In part I of this paper [S. Chen, X. Li, and X. Zhou, *SIAM J. Control Optim.*, 36 (1998), pp. 1685–1702], an optimization model of stochastic linear quadratic regulators (LQRs) with *indefinite* control cost weighting matrices is proposed and studied. In this sequel, the problem of solving LQR models with system diffusions dependent on *both* state and control variables, which is left open in part I, is tackled. First, the solvability of the associated stochastic Riccati equations (SREs) is studied in the normal case (namely, all the state and control weighting matrices and the terminal matrix in the cost functional are nonnegative definite, with at least one positive definite), which in turn leads to an optimal state feedback control of the LQR problem. In the general indefinite case, the problem is decomposed into two optimal LQR problems, one with a forward dynamics and the other with a *backward* dynamics. The well-posedness and solvability of the original LQR problem are then obtained by solving these two subproblems, and an optimal control is explicitly constructed. Examples are presented to illustrate the results.

Key words. stochastic linear quadratic regulator, well-posedness, stochastic Riccati equation, backward stochastic differential equation

1. Introduction.

The optimal linear quadratic regulator (LQR) problem, initiated by Kalman [15], is one of the most important classes of optimal control problems. In the deterministic case, it is well known that when the control weighting matrix R in the cost function is positive definite, the problem can be solved elegantly via the Riccati equation; see, e.g., [2] for a thorough study of the Riccati approach. For the case when R is possibly singular, the deterministic LQR problem has also been extensively studied as the problem of singular LQ control; refer to, e.g., [11, 14, 22]. The stochastic LQR problem was first studied by Wonham [23] and has since been studied by many other researchers (see, for example, [4, 12, 3] and the references therein); its theory is widely believed to have been well developed and established. However, this belief is challenged by our recent finding [9] that a class of stochastic LQR problems with *indefinite* control weight cost is sensible and well-posed. (A related observation in the context of stochastic stability, namely, that the corresponding Lyapunov function exists even if R is indefinite, was made in [7].) To be precise, let us consider the following stochastic LQR problem:

$$\begin{aligned}&\text{Minimize} \quad J = E\left\{\int_0^T \frac{1}{2}[x(t)'Q(t)x(t) + u(t)'R(t)u(t)]dt + \frac{1}{2}x(T)'Hx(T)\right\}\\ &\text{subject to} \quad \begin{cases} dx(t) = [A(t)x(t) + B(t)u(t)]dt + [C(t)x(t) + D(t)u(t)]dW(t),\\ x(0) = x_0.\end{cases}\end{aligned}$$

Here $W(t)$ is a Brownian motion and the control variable $u(t)$ takes value in some Euclidean space. In part I of this paper [9], it is revealed that the above problem may be well-posed even when R, the so-called control cost weighting matrix, is *indefinite* (in particular, *negative definite*). This is quite contrary to the finite-dimensional, deterministic case[1] and has very deep reasons behind it, due to the uncertainty present in the system. On the other hand, this phenomenon may occur only when the diffusion coefficient of the system dynamics depends on the control (i.e., $D \neq 0$), meaning that controls *would* or *could* influence the uncertainty scale in the system. For a detailed discussion and many examples, see [9].

In [9], a *stochastic Riccati equation* (SRE) is introduced to solve the LQR problem. In general, when all the coefficients A, B, etc., are random processes, the SRE is a nonlinear *backward stochastic differential equation* (BSDE) of the Pardoux–Peng [20] type. If all the coefficients are deterministic, then the SRE reduces to the following (deterministic) ODE:

$$(1.1)\qquad \begin{cases} \dot{P}(t) = -(P(t)A(t) + A(t)'P(t) + C(t)'P(t)C(t) + Q(t)) \\ \qquad\qquad +(P(t)B(t) + C(t)'P(t)D(t))(R(t) + D(t)'P(t)D(t))^{-1} \\ \qquad\qquad\qquad \times(B(t)'P(t) + D(t)'P(t)C(t)), \\ P(T) = H, \\ K(t) \equiv R(t) + D(t)'P(t)D(t) > 0 \ \ \forall t \in [0, T]. \end{cases}$$

If the SRE admits a solution, then it is shown in [9] that an optimal control of the LQR problem can be constructed explicitly as a linear state feedback via the solution to the SRE. However, note that the SRE is in general different from the conventional Riccati equation (for the deterministic case) due to the presence of the term $(R + D'PD)^{-1}$, and is in fact substantially more difficult to handle. In [9], a special case when $C(t) \equiv 0$ is treated, and necessary and sufficient conditions of solvability of the SRE (1.1) are obtained. The general case when $C(t) \not\equiv 0$ remains an outstanding open problem.

This paper proceeds to tackle this open problem. We study two cases. The first one is the so-called *normal case*, namely, when Q, R, H are all nonnegative definite, with at least one positive definite. The solvability of the SRE (1.1) in this case is shown under the assumption that either R or $D'D$ is nonsingular, via a constructive proof. This case is interesting in its own right, particularly in view of many financial application problems where R is typically zero, whereas $D'D$ is nonsingular under the assumption of a complete market; refer to [26, 16]. Moreover, the normal case is useful in solving the second case, the *indefinite case* with indefinite control weights. In the indefinite case, we propose to decompose the original LQR problem into two LQR problems, one with a forward dynamics (which is solvable via the SRE) and the other with a *backward* dynamics. The stochastic maximum principle for systems with backward dynamics [21, 13] is applied to solve the second problem. This leads to the necessary conditions of the well-posedness and solvability of the original problem as well as an explicit construction of its optimal control.

The rest of the paper is organized as follows. In section 2 the formulation of optimal stochastic LQR models is given and some preliminary results are presented. In section 3 we study a stochastic LQR problem with nonhomogeneous dynamics. Sections 4 and 5 are devoted to the normal and indefinite cases, respectively. Finally, section 6 gives some concluding remarks.

[1] It was recently found that some infinite-dimensional deterministic LQR problems are well-posed, even though the control weight operator is negative; see [19, 8].

2. Problem formulation and preliminaries. We consider in this paper a stochastic optimal control problem. The system is governed by the following linear Ito's stochastic differential equation (SDE):

$$\left\{\begin{array}{l} dx(t) = [A(t)x(t) + B(t)u(t)]dt + [C(t)x(t) + D(t)u(t)]dW(t), \\ x(0) = x_0, \end{array}\right. \tag{2.1}$$

where $W(t)$ is a given one-dimensional standard Brownian motion on $[0, T]$ (with $W(0) = 0$); and $u(\cdot)$, an admissible control, is an R^m-valued, square integrable $\mathcal{F}_t$-adapted measurable process with

$$\mathcal{F}_t = \sigma\{W(s) : 0 \le s \le t\}. \tag{2.2}$$

The set of all such admissible controls is denoted by U_{ad}. Note that we assumed the Brownian motion to be one-dimensional just for simplicity; there is no essential difficulty in the analysis below for the multidimensional case.

For each $u(\cdot) \in U_{ad}$, the associated cost is

$$J(u(\cdot)) = E\left\{\int_0^T \frac{1}{2}[x(t)'Q(t)x(t) + u(t)'R(t)u(t)]dt + \frac{1}{2}x(T)'Hx(T)\right\}. \tag{2.3}$$

The solution $x(\cdot)$ of the SDE (2.1) is called the *response* of the control $u(\cdot) \in U_{ad}$, and $(x(\cdot), u(\cdot))$ is called an *admissible pair.* The objective of the optimal control problem is to minimize the cost function $J(u(\cdot))$ over all $u(\cdot) \in U_{ad}$. An admissible pair $(x^*(\cdot), u^*(\cdot))$ is called *optimal* if $u^*(\cdot)$ achieves the infimum of $J(u(\cdot))$. The optimization problem (2.1)–(2.3) is called *well-posed* if $\inf_{u(\cdot)\in U_{ad}} J(u(\cdot)) > -\infty$. Since the data (A, B, C, D, Q, R, H) completely determine the optimal LQR problem (2.1)–(2.3), sometimes for simplicity we may interchangeably use (A, B, C, D, Q, R, H) to denote the problem.

Notation. We use the following notation in this paper:

M' : the transpose of any vector or matrix M;
M^j : the jth entry of any vector M;
$|M|$: $= \sqrt{\sum_{i,j} m_{ij}^2}$ for any matrix or vector $M = (m_{ij})$;
S^n : the space of all $n \times n$ symmetric matrices;
S_+^n : the subspace of all nonnegative definite matrices of S^n;
$\hat{S}_+^n$: the subspace of all positive definite matrices of S^n;
$C([0, T]; X)$: the Banach space of X-valued continuous functions on $[0, T]$ endowed with the maximum norm $\|\cdot\|$ for a given Hilbert space X;
ρ_x : the gradient or Jacobian of a function ρ with respect to the variable x;
ρ_{xx} : the Hessian of a scalar function ρ with respect to the variable x.

Given a probability space $(\Omega, \mathcal{F}, P)$ with a filtration $\{\mathcal{F}_t : a \le t \le b\}$ $(-\infty \le a < b \le +\infty)$, a Hilbert space X with the norm $\|\cdot\|_X$, and p $(1 \le p \le +\infty)$, define the Banach space $L^p_{\mathcal{F}}(a, b; X) = \{\phi(\cdot) = \{\phi(t, \omega) : a \le t \le b\} |\ \phi(\cdot)$ is an $\mathcal{F}_t$-adapted,

X-valued measurable process on $[a,b]$, and $E\int_a^b \parallel \phi(t,\omega) \parallel_X^p \, dt < +\infty\}$, with the norm

$$\parallel \phi(\cdot) \parallel_{\mathcal{F},p} = \left(E\int_a^b \parallel \phi(t,\omega) \parallel_X^p \, dt \right)^{\frac{1}{p}}.$$

In the rest of this paper, we shall employ the usual convention of suppressing the ω-dependence of all random functions. Sometimes we even write A for a (deterministic or stochastic) process $A(t)$, omitting the variable t, whenever no confusion arises. Under this convention, when $A \in C([0,T];S^n)$, $A \geq (>) 0$ means $A(t) \geq (>) 0$ $\forall t \in [0,T]$.

The following basic assumption will be in force throughout this paper.

(A) The data appearing in the LQR problem satisfy

$$\begin{array}{l} A, C \in L^\infty(0,T;R^{n\times n}), \\ B, D \in L^\infty(0,T;R^{n\times m}), \\ Q \in L^\infty(0,T;S^n_+), \\ R \in L^\infty(0,T;S^m), \\ H \in S^n_+. \end{array}$$

Note that we restrict Q and H, but *not* R, to be nonnegative definite.

Let us consider the SRE (1.1). A function $P \in C([0,T];S^n)$ is called a solution of (1.1) if it satisfies *all* the constraints in (1.1) (in particular, the third inequality constraint). The following result is taken from [9, Theorem 3.2].

THEOREM 2.1. *If the SRE* (1.1) *admits a solution P, then the stochastic LQR problem (A,B,C,D,Q,R,H) is well-posed. In addition, the feedback control*

$$u^*(t,x) = -K^{-1}(t)[B(t)'P(t) + D(t)'P(t)C(t)]x, \tag{2.4}$$

which results in a unique solution of the state equation (2.1), *is optimal with the optimal value*

$$\inf_{u(\cdot)\in U_{ad}} J(u(\cdot)) = \frac{1}{2}x_0'P(0)x_0. \tag{2.5}$$

Remark 2.1. Theorem 2.1 implies that if the SRE (1.1) is solvable, then the original LQR problem is completely solved. In general we call the problem (A,B,C,D,Q,R,H) solvable via SRE if (1.1) admits a solution P and (2.4) gives an optimal feedback control. Note that, completely different from the deterministic case, the solvability of the problem (A,B,C,D,Q,R,H) does not necessarily imply its solvability via SRE, or the solvability of (1.1).

While the existence of the SRE (1.1) remains a hard problem, the uniqueness can be proved in a rather routine way, which is presented in the following theorem for the readers' convenience.

THEOREM 2.2. *There is at most one solution to* (1.1).

Proof. Suppose $P_1, P_2 \in C([0,T];S^n)$ are two solutions to (1.1). Consider the following LQR problem:

$$\begin{array}{ll} \text{Minimize} & J(s,y;u(\cdot)) = E\left\{ \int_s^T \frac{1}{2}[x(t)'Q(t)x(t) + u(t)'R(t)u(t)]dt + \frac{1}{2}x(T)'Hx(T) \right\} \\ \text{subject to} & \left\{ \begin{array}{l} dx(t) = [A(t)x(t) + B(t)u(t)]dt + [C(t)x(t) + D(t)u(t)]dW(t), \\ x(s) = y, \end{array} \right. \end{array}$$

where $(s,y)\in[0,T]\times R^n$. Theorem 2.1 implies that both $\frac{1}{2}y'P_1(s)y$ and $\frac{1}{2}y'P_2(s)y$ are the minimum value of the cost functional $J(s,y;u(\cdot))$, and hence they must be identical. The desired result follows then from the arbitrariness of (s,y). □

3. Nonhomogeneous LQR problem.

In this section we consider the optimal LQR problem where the cost is the same as that of (2.3) while there are *random* nonhomogeneous terms in the dynamics:

$$\begin{cases} dx(t)=[A(t)x(t)+B(t)u(t)+f(t)]dt+[C(t)x(t)+D(t)u(t)+g(t)]dW(t),\\ x(0)=x_0, \end{cases} \tag{3.1}$$

with $f,g\in L^2_{\mathcal{F}}(0,T;R^n)$. While the study of this kind of system is interesting on its own, it will be useful later in section 5.

Introduce an equation

$$\begin{cases} d\phi(t)=-[\bar{A}(t)'\phi(t)+\bar{C}(t)'\lambda(t)+P(t)f(t)+\bar{C}(t)'P(t)g(t)]dt+\lambda(t)dW(t),\\ \phi(T)=0, \end{cases} \tag{3.2}$$

where

$$\bar{A}=A-BK^{-1}L,\quad \bar{C}=C-DK^{-1}L,\quad L=B'P+D'PC,\quad K=R+D'PD, \tag{3.3}$$

and $P(\cdot)$ is the solution to the SRE (1.1) (assuming that (1.1) is solvable). Equation (3.2) is a BSDE whose solution is a *pair* of processes (ϕ,λ). If (1.1) admits a solution $P\in C([0,T];S^n)$, then it is well known that (3.2) must have an $\mathcal{F}_t$-adapted solution $(\phi,\lambda)\in L^2_{\mathcal{F}}(0,T;R^n)\times L^2_{\mathcal{F}}(0,T;R^n)$. See [5, 6] for the origin of the linear BSDE and [25, Chapter 7] for a systematic account of the latest BSDE theory.

THEOREM 3.1. *If equations* (1.1) *and* (3.2) *admit solutions* $P\in C([0,T];S^n)$ *and* $(\phi,\lambda)\in L^2_{\mathcal{F}}(0,T;R^n)\times L^2_{\mathcal{F}}(0,T;R^n)$, *respectively, then the stochastic LQR problem consisting of* (3.1) *and* (2.3) *has an optimal feedback control*

$$u^*(t,x)=-K^{-1}(t)[L(t)x+h(t)], \tag{3.4}$$

where $h(t)=B(t)'\phi(t)+D(t)'\lambda(t)+D(t)'P(t)g(t)$. *Moreover, the optimal value is*

$$\begin{aligned}\inf_{u(\cdot)\in U_{ad}} J(u(\cdot))=\frac{1}{2}E\int_0^T&[-h'K^{-1}h+g'Pg+2\phi'f+2\lambda'g](t)dt\\ &+\frac{1}{2}x_0'P(0)x_0+\phi(0)'x_0.\end{aligned} \tag{3.5}$$

Proof. Applying Ito's formula, we get

$$\begin{aligned}\frac{1}{2}d(x'Px)=&\frac{1}{2}[u'D'PDu+x'(-Q+L'K^{-1}L)x\\ &+2u'Lx+2x'(Pf+C'Pg)+2u'D'Pg+g'Pg](t)dt\\ &+\frac{1}{2}\{\ldots\}dW(t)\end{aligned} \tag{3.6}$$

and

$$\begin{aligned}d(x'\phi)=\ &[x'(L'K^{-1}B'\phi-Pf-C'Pg+L'K^{-1}D'Pg+L'K^{-1}D'\lambda)\\ &+u'B'\phi+u'D'\lambda+\phi'f+\lambda'g](t)dt+\{\ldots\}dW(t).\end{aligned} \tag{3.7}$$

Integrating both (3.6) and (3.7) from 0 to T, taking expectations, adding them together, and noting (2.3), one obtains

(3.8)
$$
\begin{aligned}
J(u(\cdot)) &\equiv J(u(\cdot)) + E\left\{\int_0^T d\left(\frac{1}{2}x'Px + x'\phi\right) - \left(\frac{1}{2}x'Px + x'\phi\right)\Big|_0^T\right\} \\
&= \frac{1}{2}E\int_0^T [u'Ku + 2u'(B'Px + D'PCx + D'Pg + B'\phi + D'\lambda) + x'L'K^{-1}Lx \\
&\qquad +2x'L'K^{-1}B'\phi + 2x'L'K^{-1}D'(Pg+\lambda) + g'Pg + 2\phi'f + 2\lambda'g](t)dt \\
&\qquad +\frac{1}{2}x_0'P(0)x_0 + \phi(0)'x_0 \\
&= \frac{1}{2}E\int_0^T \{[u + K^{-1}(Lx+h)]'K[u + K^{-1}(Lx+h)] - h'K^{-1}h \\
&\qquad\qquad +g'Pg + 2\phi'f + 2\lambda'g\}(t)dt + \frac{1}{2}x_0'P(0)x_0 + \phi(0)'x_0.
\end{aligned}
$$

It follows immediately that the optimal feedback control is given by (3.4) and the optimal value by (3.5), provided that the corresponding state exists under such a feedback control. To see if the latter assertion is true, notice that under (3.4), the system (3.1) reduces to

$$
(3.9)\qquad \begin{cases} dx(t) = [\bar{A}(t)x(t) + \bar{f}(t)]dt + [\bar{C}(t)x(t) + \bar{g}(t)]dW(t), \\ x(0) = x_0, \end{cases}
$$

where $\bar{A}$ and $\bar{C}$ are given by (3.3), $\bar{f} = f - BK^{-1}h$, and $\bar{g} = g - DK^{-1}h$. Equation (3.9) is a nonhomogeneous linear SDE. Since $P \in C([0,T];S^n)$, $K^{-1} \in C([0,T];S^n_+)$, and $(\phi,\lambda) \in L^2_{\mathcal{F}}(0,T;R^n) \times L^2_{\mathcal{F}}(0,T;R^n)$, the coefficients $\bar{A}(t)$ and $\bar{C}(t)$ are uniformly bounded functions and the nonhomogeneous terms $\bar{f},\bar{g} \in L^2_{\mathcal{F}}(0,T;R^n)$. Hence (3.9) admits one and only one solution by standard SDE theory. This completes the proof. □

4. Solvability of SRE in normal case. We say that the (homogeneous) LQR problem (2.1)–(2.3) (or (A,B,C,D,Q,R,H) or even (Q,R,H)) is in the *normal case* if

$$
(4.1)\qquad Q \geq 0, \quad R \geq 0, \quad H \geq 0,
$$

with *at least* one *strictly* positive definite at *any* time. It is seen directly from the cost functional (2.3) that the LQR problem must be well-posed in the normal case (with a nonnegative infimum). As we mentioned, the well-posedness of the LQR problem in general does not necessarily lead to the solvability of the SRE (1.1). However, we will show that in the normal case there does exist a solution to the SRE (1.1), under the additional assumption that either R or $D'D$ is positive definite, and therefore the LQR problem is solvable via SRE. Note that, once again, the existence result to be presented in this section is not only interesting for its own sake but also useful in dealing with the case with indefinite control weights in section 5.

First we give a technical lemma.

LEMMA 4.1. *Given $F,G \in L^\infty(0,T;R^{n\times n})$, $Q \in L^\infty(0,T;S^n)$, and $H \in S^n$, the linear matrix equation*

$$
(4.2)\qquad \begin{cases} \dot{X}(t) + X(t)F(t) + F(t)'X(t) + G(t)'X(t)G(t) + Q(t) = 0, \\ X(T) = H, \end{cases}
$$

admits a unique solution $X \in C([0,T]; S^n)$. *Moreover,* $X(t)$ *is nonnegative definite for all* $t \in [0,T]$ *if* $Q(t)$ *and* H *are nonnegative definite for all* $t \in [0,T]$, *and* $X(t)$ *is positive definite for all* $t \in [0,T]$ *if either* $Q(t)$ *or* H *is positive definite for all* $t \in [0,T]$.

Proof. Since (4.2) is linear with bounded coefficients, the existence and uniqueness are clear. Now let Φ be the solution of the following matrix stochastic differential equation:

$$\begin{cases} d\Phi(t) = F(t)\Phi(t)dt + G(t)\Phi(t)dW(t), \\ \Phi(0) = I. \end{cases} \tag{4.3}$$

Clearly this equation admits a unique solution. Moreover, $\Phi(t)$ is invertible for all $t \in [0,T]$, P-a.s. Indeed, by Ito's formula, it is easy to show that the solution $\Psi(\cdot)$ to the following equation:

$$\begin{cases} d\Psi(t) = -\Psi(t)[F(t) - G^2(t)]dt - \Psi(t)G(t)dW(t), \\ \Phi(0) = I, \end{cases} \tag{4.4}$$

satisfies $\Psi(t)\Phi(t) = I$ for all $t \in [0,T]$, P-a.s. Now applying Ito's formula again, we obtain

$$d(\Phi(t)'X(t)\Phi(t)) = -\Phi(t)'Q(t)\Phi(t)dt + \Phi(t)'[G(t)'X(t) + X(t)G(t)]\Phi(t)dW(t).$$

Hence, noting that $X(t)$ is deterministic, we have

$$X(t) = E\left\{\Phi^{-1}(t)'\Phi(T)'H\Phi(T)\Phi^{-1}(t) + \int_t^T [\Phi^{-1}(t)'\Phi'(r)Q(r)\Phi(r)\Phi^{-1}(t)]dr\right\}. \tag{4.5}$$

This proves the second part of the lemma. □

THEOREM 4.1. *In the normal case, the SRE* (1.1) *admits a solution* $P \in C([0,T]; S^n_+)$ *if either of the following two conditions holds:*

(a) $R(t) > 0$ $\forall t \in [0,T]$*;*

(b) $R(t)$ *is singular, and* $D(t)'D(t) > 0$ $\forall t \in [0,T]$.

Proof. First, (1.1) can be rewritten as

$$\begin{cases} \dot{P} + PF + F'P + G'PG + M'RM + Q = 0, \\ P(T) = H, \end{cases} \tag{4.6}$$

where

$$F = A - BM, \;\; G = C - DM, \;\; M = K^{-1}L \equiv (R + D'PD)^{-1}(B'P + D'PC). \tag{4.7}$$

We now introduce an iterative scheme to construct the solution to (4.6). Initially, let

$$P_0 \equiv I, \; M_0 = (R + D'P_0D)^{-1}(B'P_0 + D'P_0C), \qquad F_0 = A - BM_0, \; G_0 = C - DM_0. \tag{4.8}$$

Note that $R + D'P_0D = R + D'D$ is invertible at any time under either of the cases (a) or (b). For $i = 0, 1, 2, \ldots$, let P_{i+1} be the solution to the following linear matrix equation:

$$\begin{cases} \dot{P}_{i+1} + P_{i+1}F_i + F_i'P_{i+1} + G_i'P_{i+1}G_i + M_i'RM_i + Q = 0, \\ P_{i+1}(T) = H, \end{cases} \tag{4.9}$$

and set

$$M_{i+1}=(R+D'P_{i+1}D)^{-1}(B'P_{i+1}+D'P_{i+1}C),\ F_{i+1}=A-BM_{i+1},\ G_{i+1}=C-DM_{i+1}. \tag{4.10}$$

Note that in the normal case, (4.9) must admit a solution $P_{i+1}\in C([0,T];S^n_+)$ in view of Lemma 4.1. In case (a), $R+D'P_{i+1}D$ always has an inverse. In case (b), either $Q(t)$ or H is positive definite for all $t\in[0,T]$, resulting in $P_{i+1}>0$ by Lemma 4.1. Therefore, in either case (a) or (b), the inverse in defining M_{i+1} in (4.10) always exists. Setting $\Delta_{i+1}=P_{i+1}-P_i$, one can show that Δ_{i+1} satisfies the following:

$$\begin{cases}\dot\Delta_{i+1}+\Delta_{i+1}F_i+F_i'\Delta_{i+1}+G_i'\Delta_{i+1}G_i-(M_i-M_{i-1})'(R+D'P_iD)(M_i-M_{i-1})=0,\\ \Delta_{i+1}(T)=0.\end{cases} \tag{4.11}$$

Once again, by Lemma 4.1 we conclude that $\Delta_{i+1}\le 0$. Hence $\{P_i(\cdot)\}$ is a decreasing sequence in $C([0,T];S^n_+)$ and therefore has a limit (with respect to the max norm of $C([0,T];S^n_+)$), denoted by $P(\cdot)$. Clearly $P(\cdot)$ is the solution to (4.6), and hence to (1.1). □

Equations (4.8)–(4.10) actually constitute a numerical algorithm to compute the solution of the SRE (1.1). The following proposition presents an estimate for the convergence speed of this algorithm.

PROPOSITION 4.1. *Let the assumptions of Theorem* 4.1 *hold. Let*

$$\{P_i\}\subset C([0,T];S^n_+)$$

be constructed by the algorithm (4.8)–(4.10) *and* $P\in C([0,T];S^n_+)$ *be the solution to the Riccati equation* (1.1). *Then*

$$|P_i(t)-P(t)|\le c\sum_{j=i}^{\infty}\frac{(c')^{j-2}}{(j-2)!}(T-t)^{j-2},\qquad i=2,3,\dots, \tag{4.12}$$

where c *and* c' *are constants that depend only on the coefficients of* (1.1).

Proof. Note that $\Delta_{i+1}\equiv P_{i+1}-P_i$ satisfies (4.11). Set $K_i=R+D'P_iD$; then

$$M_i-M_{i-1}=K_i^{-1}(B'\Delta_i+D'\Delta_iC)-K_{i-1}^{-1}D'\Delta_iDK_i^{-1}(B'P_{i-1}+D'P_{i-1}C). \tag{4.13}$$

Putting this into (4.11) and taking integration, we obtain

$$\begin{aligned}\Delta_{i+1}(t)=\int_t^T&[\Delta_{i+1}F_i+F_i'\Delta_{i+1}+G_i'\Delta_{i+1}G_i\\ &-(\Delta_iB+C'\Delta_iD)K_i^{-1}(B'\Delta_i+D'\Delta_iC)\\ &+2(\Delta_iB+C'\Delta_iD)K_{i-1}^{-1}D'\Delta_iDK_i^{-1}(B'P_{i-1}+D'P_{i-1}C)\\ &-(P_{i-1}B+C'P_{i-1}D)K_i^{-1}D'\Delta_iDK_{i-1}^{-1}K_iK_{i-1}^{-1}D'\Delta_iDK_i^{-1}\\ &\times(B'P_{i-1}+D'P_{i-1}C)](s)ds.\end{aligned} \tag{4.14}$$

By the proof of Theorem 4.1, the sequences $\{|P_i|\},\{|K_i|\}$, and $\{|K_i^{-1}|\}$ are uniformly bounded, and as a consequence so are the other sequences involved in (4.14). Hence,

$$|\Delta_{i+1}(t)|\le c\int_t^T[|\Delta_{i+1}(s)|+|\Delta_i(s)|]ds. \tag{4.15}$$

Denote $v_i(t) = \int_t^T |\Delta_{i+1}(s)|ds$. Then (4.15) reads

$$\dot{v}_i(t) + cv_i(t) + cv_{i-1}(t) \geq 0,$$

which implies

$$v_i(t) \leq ce^{cT} \int_t^T v_{i-1}(s)ds \equiv c' \int_t^T v_{i-1}(s)ds.$$

By induction, we deduce that

$$v_i(t) \leq \frac{(c')^{i-1}}{(i-1)!}(T-t)^{i-1}v_1(0).$$

It then follows from (4.15) that

$$|\Delta_{i+1}(t)| \leq c\left\{\frac{(c')^{i-1}}{(i-1)!}(T-t)^{i-1} + \frac{(c')^{i-2}}{(i-2)!}(T-t)^{i-2}\right\}v_1(0). \tag{4.16}$$

This easily yields (4.12). □

Remark 4.1. Theorem 4.1 gives sufficient conditions for an LQR problem to be solved completely via the solution to the SRE in the normal case, with an optimal linear feedback control explicitly given by (2.4). It should be noted that the assumptions of Theorem 4.1 do not exclude the possibility that the control weights $R(t)$ might be singular or even identically zero. In this case $D(t)'D(t)$ needs to be positive definite in order for the problem to be well-posed (see condition (b) of Theorem 4.1). The term $D(t)'D(t)$ measures how the control would influence the uncertainty, leading to what we call the *uncertainty cost* or *risk cost*. It is this indirect cost that makes the problem meaningful despite the fact that there is no direct control cost. Such a situation typically occurs in financial applications. For example, in a mean-variance portfolio selection problem, the risk (measured by the covariance matrix) is the only factor that concerns the investor, which can be translated into an uncertainty cost for the investor to make a decision. See Zhou and Li [26] for a detailed investigation of such a model and Kohlmann and Zhou [16] for a related Black–Scholes model.

5. LQR control with indefinite control weights.

Now we consider the problem where the control weighting matrix R is possibly indefinite. In view of Theorem 2.1, the problem boils down to the one of finding solutions to the SRE (1.1). However, the solvability of (1.1) in general remains an open problem at the moment. In this section, we are going to derive some necessary conditions for the LQR problem to be solvable without directly dealing with the SRE (1.1). The problem that we are able to handle is one that can be decomposed into two subproblems: one can be solved via SRE, and the other cannot. Let us make it more precise. Since $R(t)$ is symmetric, it may be assumed to be a diagonal matrix for simplicity of exposition. Write $R(t)$ as

$$R(t) = \begin{pmatrix} R_1(t) & 0 \\ 0 & R_2(t) \end{pmatrix}, \tag{5.1}$$

where the sizes of $R_1(t)$ and $R_2(t)$ are m_1 and m_2 (independent of t), respectively, with $m_1 > 0$ and $m_1 + m_2 = m$. We then divide the matrices B and D accordingly, namely,

$$B(t) = (B_1(t), B_2(t)), \qquad D(t) = (D_1(t), D_2(t)). \tag{5.2}$$

Suppose that the LQR problem $(A, B_1, C, D_1, Q, R_1, H)$ is solvable via SRE. A typical case is when $(A, B_1, C, D_1, Q, R_1, H)$ satisfies the assumptions of Theorem 4.1 or, in particular, when $R_1 > 0$; see section 4.

Using the above decomposition, we can rewrite system (2.1) and cost functional (2.3) as

$$\begin{cases} dx(t) = [A(t)x(t) + B_1(t)u_1(t) + B_2(t)u_2(t)]dt \\ \qquad\qquad +[C(t)x(t) + D_1(t)u_1(t) + D_2(t)u_2(t)]dW(t), \\ x(0) = x_0, \end{cases} \tag{5.3}$$

and

$$\begin{aligned} J(u(\cdot)) = E\Bigg\{ \int_0^T \frac{1}{2}[x(t)'Q(t)x(t) + u_1(t)'R_1(t)u_1(t) \\ +u_2(t)'R_2(t)u_2(t)]dt + \frac{1}{2}x(T)'Hx(T) \Bigg\}. \end{aligned} \tag{5.4}$$

The main idea of our approach is to first fix $u_2(\cdot)$, viewing $f(t) \equiv B_2(t)u_2(t)$ and $g(t) \equiv D_2(t)u_2(t)$ as nonhomogeneous terms (which are random since $u_2(\cdot)$ is random in general) for an LQR problem where the dynamics is (5.3) with the control $u_1(\cdot)$ and the cost is (5.4). After this problem (parameterized by $u_2(\cdot)$) is solved, we solve the remaining control problem in terms of $u_2(\cdot)$. Namely, we carry out a two-step procedure, which is made precise by the following lemma.

LEMMA 5.1. *We have the following:*

(a) $\inf_{u(\cdot)} J(u(\cdot)) \equiv \inf_{(u_1(\cdot),u_2(\cdot))} J(u_1(\cdot), u_2(\cdot)) = \inf_{u_2(\cdot)} \inf_{u_1(\cdot)} J(u_1(\cdot), u_2(\cdot))$.

(b) $u^*(\cdot) = (u_1^*(\cdot), u_2^*(\cdot))$ *minimizes* $J(u(\cdot))$ *if and only if* $u_2^*(\cdot)$ *minimizes* $\inf_{u_1(\cdot)} J(u_1(\cdot), u_2(\cdot))$ *and* $u_1^*(\cdot)$ *minimizes* $J(u_1(\cdot), u_2^*(\cdot))$.

Proof. (a) The conclusion is straightforward by the definition of infimum.

(b) *Necessity.* If $u_2^*(\cdot)$ does not minimize $\inf_{u_1(\cdot)} J(u_1(\cdot), u_2(\cdot))$, then there exists $\bar{u}_2(\cdot)$ so that

$$\inf_{u_1(\cdot)} J(u_1(\cdot), \bar{u}_2(\cdot)) < \inf_{u_1(\cdot)} J(u_1(\cdot), u_2^*(\cdot)).$$

By (a), we have

$$\begin{aligned} J(u_1^*(\cdot), u_2^*(\cdot)) &= \inf_{u_2(\cdot)} \inf_{u_1(\cdot)} J(u_1(\cdot), u_2(\cdot)) \\ &\le \inf_{u_1(\cdot)} J(u_1(\cdot), \bar{u}_2(\cdot)) \\ &< \inf_{u_1(\cdot)} J(u_1(\cdot), u_2^*(\cdot)) \\ &\le J(u_1^*(\cdot), u_2^*(\cdot)), \end{aligned}$$

which leads to a contradiction. This proves the first assertion. As a consequence,

$$\inf_{u_1(\cdot)} J(u_1(\cdot), u_2^*(\cdot)) = \inf_{u_2(\cdot)} \inf_{u_1(\cdot)} J(u_1(\cdot), u_2(\cdot)) = J(u_1^*(\cdot), u_2^*(\cdot)).$$

This shows the second assertion.

Sufficiency. If $u^*(\cdot) = (u_1^*(\cdot), u_2^*(\cdot))$ does not minimize $J(u(\cdot))$, then there is $\bar{u}(\cdot) = (\bar{u}_1(\cdot), \bar{u}_2(\cdot)) \in U_{ad}$ such that

$$J(\bar{u}_1(\cdot), \bar{u}_2(\cdot)) < J(u_1^*(\cdot), u_2^*(\cdot)) = \inf_{u_1(\cdot)} J(u_1(\cdot), u_2^*(\cdot)).$$

On the other hand,

$$J(\bar{u}_1(\cdot),\bar{u}_2(\cdot)) \geq \inf_{u_2(\cdot)}\inf_{u_1(\cdot)} J(u_1(\cdot),u_2(\cdot)) = \inf_{u_1(\cdot)} J(u_1(\cdot),u_2^*(\cdot)).$$

This leads to a contradiction. □

In the first step, we consider the parameterized LQR problem (5.3)–(5.4), where the state and control variables are $x(\cdot)$ and $u_1(\cdot)$, respectively, with $u_2(\cdot)$ regarded as a parameter. This problem is one with nonhomogeneous terms which has been studied in section 3. Equations (1.1) and (3.2) specialize to the following equations in the present case:

$$(5.5)\qquad \begin{cases} \dot{P} + PA + A'P + C'PC + Q \\ \qquad -(PB_1 + C'PD_1)(R_1 + D_1'PD_1)^{-1}(B_1'P + D_1'PC) = 0, \\ P(T) = H, \\ K_1(t) \equiv R_1(t) + D_1'(t)P(t)D_1(t) > 0 \ \forall t \in [0,T], \end{cases}$$

and

$$(5.6)\qquad \begin{cases} d\phi = -[A_1'\phi + C_1'\lambda + (B_2'P + D_2'PC)'u_2]dt + \lambda dW(t), \\ \phi(T) = 0, \end{cases}$$

where P is the solution to (5.5), and

$$(5.7)\quad A_1 = A - B_1K_1^{-1}(B_1'P + D_1'PC), \quad C_1 = C - D_1K_1^{-1}(B_1'P + D_1'PC).$$

Owing to the way we decompose the matrix R into R_1 and R_2, the SRE (5.5) admits a solution $P \in C([0,T];S^n)$. Then by Theorem 3.1, an optimal feedback control of the problem (5.3)–(5.4) (with $u_2(\cdot)$ regarded as a parameter) is

$$(5.8)\qquad \begin{aligned} u_1(t,x) = -K_1^{-1}(t)\{&[B_1(t)'P(t) + D_1(t)'P(t)C(t)]x + B_1(t)'\phi(t) \\ &+D_1(t)'\lambda(t) + D_1(t)'P(t)D_2(t)u_2(t)\}, \end{aligned}$$

with the optimal value (which is a functional of $u_2(\cdot)$)

(5.9)

$$\begin{aligned} J_2(u_2(\cdot)) &\equiv \inf_{u_1(\cdot)} J(u_1(\cdot),u_2(\cdot)) \\ &= \frac{1}{2}E\int_0^T \{u_2'[D_2'(P - PD_1K_1^{-1}D_1'P)D_2 + R_2]u_2 \\ &\qquad +2\phi'(B_2 - B_1K_1^{-1}D_1'PD_2)u_2 + 2\lambda'(D_2 - D_1K_1^{-1}D_1'PD_2)u_2 \\ &\qquad -2\phi'B_1K_1^{-1}D_1'\lambda - \lambda'D_1K_1^{-1}D_1'\lambda - \phi'B_1K_1^{-1}B_1'\phi\}(t)dt \\ &\quad +\frac{1}{2}x_0'P(0)x_0 + \phi(0)'x_0 \\ &= \frac{1}{2}E\int_0^T \{u_2'\bar{R}u_2 + 2\phi'\bar{B}u_2 + 2\lambda'\bar{D}u_2 - (B_1'\phi + D_1'\lambda)'K_1^{-1}(B_1'\phi + D_1'\lambda)\}(t)dt \\ &\quad +\frac{1}{2}x_0'P(0)x_0 + \phi(0)'x_0, \end{aligned}$$

where

$$(5.10)\qquad \begin{cases} \bar{R} = D_2'(P - PD_1K_1^{-1}D_1'P)D_2 + R_2, \\ \bar{B} = B_2 - B_1K_1^{-1}D_1'PD_2, \\ \bar{D} = D_2 - D_1K_1^{-1}D_1'PD_2. \end{cases}$$

The next step is then to choose $u_2(\cdot)$ so as to minimize (5.9) subject to (5.6). We see that this is an LQR problem where the system dynamics (5.6) is a linear *backward* stochastic differential equation (with $(\phi(\cdot), \lambda(\cdot))$ as a *pair* of state variables) and the cost functional (5.9) involves an *initial* cost. Let us call such a problem a *backward LQR problem.* Our objective now is to solve this problem.

Peng [21] derived a set of necessary conditions (maximum principle) for optimal controls of nonlinear forward-backward systems, which include the backward LQR problem as a special space. However, the maximum principle presented in [21] is in a local form. Recently Dokuchaev and Zhou [13] proved the global maximum principle. For the readers' convenience, let us first state the maximum principle for nonlinear backward systems and then specialize to the backward LQR model.

Given $\xi \in R^n$,

$$\text{minimize } J(u(\cdot)) = E\left[\int_0^T l(t,x(t),z(t),u(t))dt + h(x(0))\right] \tag{5.11}$$

$$\text{subject to } \begin{cases} dx(t) = f(t,x(t),z(t),u(t))dt + z(t)dW(t), \\ x(T) = \xi. \end{cases} \tag{5.12}$$

The set of admissible controls is defined as $BU_{ad} = L^2_{\mathcal{F}}(0,T;R^m)$. We assume that

(B) f, l, h are continuous in their argument(s) and continuously differentiable in (x,z,u). Moreover, the derivatives of f are uniformly bounded, the derivatives of l are bounded by $C(1+|x|+|z|+|u|)$, and the derivative of h is bounded by $C(1+|x|)$.

Under the above assumption, given $u(\cdot) \in BU_{ad}$, the nonlinear backward SDE (5.12) admits a unique $\mathcal{F}_t$-adapted solution pair $(x(\cdot), z(\cdot))$ (see Pardoux and Peng [20]) and the cost (5.11) is well defined.

Define a Hamiltonian

$$H(t,x,z,u,q) = q'f(t,x,z,u) - l(t,x,z,u) \tag{5.13}$$

for $(t,x,z,u,q) \in [0,T] \times R^n \times R^n \times R^m \times R^n$.

THEOREM 5.1 (see [13, Theorem 3.1]). *If $(x^*(\cdot), z^*(\cdot), u^*(\cdot))$ is optimal for problem* (5.11)–(5.12), *then it must satisfy*

(5.14)
$$H(t,x^*(t),z^*(t),u^*(t),q(t)) = \max_{u\in R^m} H(t,x^*(t),z^*(t),u,q(t)), \quad P\text{-a.s.}, \quad \text{a.e. } t \in [0,T],$$

where $q(\cdot)$ is the solution of the adjoint equation

(5.15)
$$\begin{cases} dq(t) = -H_x(t,x^*(t),z^*(t),u^*(t),q(t))dt - H_z(t,x^*(t),z^*(t),u^*(t),q(t))dW(t), \\ q(0) = -h_x(x^*(0)). \end{cases}$$

We now apply the above result to the backward LQR problem consisting of (5.6) and (5.9). If $(\phi^*(\cdot), \lambda^*(\cdot), u_2^*(\cdot))$ is an optimal triple, then the corresponding adjoint equation (5.15) reduces to

$$\begin{cases} dq(t) = [A_1q + B_1u_2^* - B_1K_1^{-1}B_1'\phi^* - B_1K_1^{-1}D_1'\lambda^*](t)dt \\ \qquad\qquad +[C_1q + D_1u_2^* - D_1K_1^{-1}B_1'\phi^* - D_1K_1^{-1}D_1'\lambda^*](t)dW(t), \\ q(0) = -x_0. \end{cases} \tag{5.16}$$

Theorem 5.2. *If* $(\phi^*(\cdot), \lambda^*(\cdot), u_2^*(\cdot))$ *is optimal for* (5.6) *and* (5.9), *then*

$$\bar{R}(t) \equiv D_2(t)'[P(t) - P(t)D_1(t)K_1^{-1}(t)D_1(t)'P(t)]D_2(t) + R_2(t) \geq 0 \;\; \forall t \in [0,T]. \tag{5.17}$$

Moreover, if $\bar{R}(t) > 0 \; \forall t \in [0,T]$, *then the optimal control* $u_2^*(\cdot)$ *must satisfy*

$$u_2^*(t) = -\bar{R}^{-1}(t)[(B_2'P + D_2'PC_1)q + B_1'\phi^* + D_1'\lambda^*](t). \tag{5.18}$$

Proof. The derivative of the Hamiltonian in u in the present LQR case is

$$H_u(t,\phi,\lambda,u_2,q) = -\bar{R}(t)u_2 - [(B_2'P + D_2'PC_1)(t)q + B_1(t)'\phi + D_1(t)'\lambda]. \tag{5.19}$$

Therefore the desired (5.18) and (5.17) follow from the first-order and second-order necessary conditions of the maximum condition (5.14), respectively. □

To summarize the above results, we have the following theorem.

Theorem 5.3. *Assume that* $R(t)$ *is decomposed according to* (5.1) *such that the SRE* (5.5) *has a solution* $P(\cdot)$. *If the stochastic LQR problem* (5.3)–(5.4) *has an optimal control* $u^*(\cdot) = (u_1^*(\cdot), u_2^*(\cdot))$, *then the following must hold:*

$$D_2'[P - PD_1(R_1 + D_1'PD_1)^{-1}D_1'P]D_2 + R_2 \geq 0. \tag{5.20}$$

Moreover, if we assume that the inequality in (5.20) *is strict* (*for all* $t \in [0,T]$), *then the optimal control* $u^*(\cdot) = (u_1^*(\cdot), u_2^*(\cdot))$ *can be obtained by the following:*

$$u_2^*(t) = -\bar{R}^{-1}(t)\{[B_2(t)'P(t) + D_2(t)'P(t)C_1(t)]q(t) + B_1(t)'\phi(t) + D_1(t)'\lambda(t)\}, \tag{5.21}$$

where $(q(\cdot), \phi(\cdot), \lambda(\cdot))$ *is the solution to the following forward-backward SDE:*

$$\begin{cases} dq(t) = \{[A_1 - B_1\bar{R}^{-1}(B_2'P + D_2'PC_1)]q - B_1(\bar{R}^{-1} + K_1^{-1})B_1'\phi \\ \qquad -B_1(\bar{R}^{-1} + K_1^{-1})D_1'\lambda\}(t)dt \\ \qquad +\{[C_1 - D_1\bar{R}^{-1}(B_2'P + D_2'PC_1)]q - D_1(\bar{R}^{-1} + K_1^{-1})B_1'\phi \\ \qquad -D_1(\bar{R}^{-1} + K_1^{-1})D_1'\lambda\}(t)dW(t), \\ d\phi(t) = -\{[A_1 - B_1\bar{R}^{-1}(B_2'P + D_2'PC_1)]'\phi + [C_1 - D_1\bar{R}^{-1}(B_2'P + D_2'PC_1)]'\lambda \\ \qquad +(B_2'P + D_2'PC_1)'\bar{R}^{-1}(B_2'P + D_2'PC_1)\}(t)dt + \lambda(t)dW(t), \\ q(0) = -x_0, \\ \phi(T) = 0, \end{cases} \tag{5.22}$$

and

$$\begin{aligned} u_1^*(t) = -K_1^{-1}(t)\{&[B_1(t)'P(t) + D_1(t)'P(t)C(t)]x(t) + B_1(t)'\phi(t) \\ &+D_1(t)'\lambda(t) + D_1(t)'P(t)D_2(t)u_2^*(t)\}, \end{aligned} \tag{5.23}$$

with $x(\cdot)$ *being the solution to the following SDE:*

$$\begin{cases} dx(t) = [A_1x - (B_1K_1^{-1}D_1'PD_2 - B_2)u_2^* - B_1K_1^{-1}B_1'\phi - B_1K_1^{-1}D_1'\lambda](t)dt \\ \qquad +[C_1x - (D_1K_1^{-1}D_1'PD_2 - D_2)u_2^* - D_1K_1^{-1}B_1'\phi - D_1K_1^{-1}D_1'\lambda](t)dW(t), \\ x(0) = x_0. \end{cases} \tag{5.24}$$

Proof. First, (5.22) is obtained by replacing $u_2^*(t)$ with the right-hand side of (5.18) in (5.16) and (5.6). This is an essentially *decoupled* forward-backward SDE. Therefore, one can first solve the backward equation for (ϕ, λ) and then solve the forward equation for q. The existence and uniqueness of the solutions to the two equations are clear, as they are linear with bounded coefficients and square-integrable nonhomogeneous terms. Next, if $u^*(\cdot) = (u_1^*(\cdot), u_2^*(\cdot))$ is optimal for the problem (5.3)–(5.4), then by Lemma 5.1, $u_2^*(\cdot)$ must minimize $J_2(u_2(\cdot)) \equiv \inf_{u_1(\cdot)} J(u_1(\cdot), u_2(\cdot))$, which is a backward LQR problem where the dynamics is (5.6) and the cost is (5.9). Then (5.20) is implied by Theorem 5.2. Furthermore, as mentioned, if we substitute the optimal control obtained in (5.18) to (5.6) and (5.16), then we get exactly (5.22). Thus (5.21) is given by (5.18). Second, (5.24) is obtained by replacing $u_1^*(t)$ with (5.8) in (5.3), which evidently has a unique solution. Then (5.23) is identical to (5.8). This completes the proof. □

Remark 5.1. Condition (5.20) gives the precise trade-off between the "good" part (R_1, D_1) and the "bad" part (R_2, D_2) of the overall system in order for the problem to be well-posed and solvable. For example, suppose $R_1 > 0$ and $R_2 \leq 0$. Then (5.20) shows that R_2 cannot be more negative than $-D_2'[P - PD_1(R_1 + D_1'PD_1)^{-1}D_1'P]D_2$. On the other hand, we see that the larger D_2 is (which is the part of the noise corresponding to the "bad" component), or the smaller D_1 is (which is the part of the noise corresponding to the "good" component), the more likely it is that the LQR problem will be well-posed.

Example 5.1. Consider the following LQR problem:

$$\begin{array}{ll} \text{Minimize} & J = E\left\{\int_0^1 \frac{1}{2}[x^2(t) + r_1(t)u_1^2(t) + r_2(t)u_2(t)^2]dt + \frac{1}{2}x(1)^2\right\} \\ \text{subject to} & \begin{cases} dx(t) = (u_1(t) + u_2(t))dW(t), \\ x(0) = 0, \end{cases} \end{array} \tag{5.25}$$

where both $r_1(t)$ and $r_2(t)$ are possibly negative. In this case, $A(t) = B_1(t) = B_2(t) = C(t) = 0$, $D_1(t) = D_2(t) = 1$, $Q(t) = 1$, $(R_1(t), R_2(t)) = (r_1(t), r_2(t))$, and $H = 1$. The SRE (5.5) corresponding to u_1 is

$$\dot{P}(t) = -1, \qquad P(1) = 1.$$

Hence $P(t) = 2 - t$. The equation has a solution when $r_1(t) + 2 - t > 0$ $\forall t \in [0, 1]$, which is equivalent to $r_1(t) > -1$. In this case $K_1(t) = r_1(t) + 2 - t$. It is easy to see that the necessary condition (5.20) for the overall problem to be well-posed reduces to

$$\frac{r_1(t)(2-t)}{r_1(t) + 2 - t} + r_2(t) \geq 0 \qquad \forall t \in [0, 1]. \tag{5.26}$$

Moreover, when the above inequality is strict, the forward-backward equation (5.22) specializes to

$$\begin{cases} dq(t) = 0, \;\; d\phi(t) = \lambda(t)dW(t), \\ q(0) = 0, \;\; \phi(1) = 0, \end{cases}$$

which, by the uniqueness of its solutions, has the solution $(q(t), \phi(t), \lambda(t)) = (0, 0, 0)$. Therefore the optimal (feedback) controls (5.23) and (5.21) (if they exist) reduce to $u_1^*(t) = u_2^*(t) = 0$.

To see that the above control is indeed optimal under (5.26), by applying Ito's formula to $x(t)^2$ one easily gets the following:

$$\begin{aligned} J(u(\cdot)) &= \frac{1}{2}E\int_0^1 \{(2-t)[u_1(t)+u_2(t)]^2 + r_1(t)u_1(t)^2 + r_2(t)u_2(t)^2\}dt \\ &= \frac{1}{2}E\int_0^1 [(r_1(t)+2-t)u_1(t)^2 + 2(2-t)u_1(t)u_2(t) + (2-t+r_2(t))u_2(t)^2]dt \\ &\geq \frac{1}{2}E\int_0^1 \left[(r_1(t)+2-t)u_1(t)^2 + 2(2-t)u_1(t)u_2(t) + \frac{(2-t)^2}{r_1(t)+2-t}u_2(t)^2\right]dt \\ &= \frac{1}{2}E\int_0^1 (r_1(t)+2-t)\left[u_1(t) + \frac{2-t}{r_1(t)+2-t}u_2(t)\right]^2 dt, \end{aligned}$$

where the last inequality is due to (5.26). Therefore the optimal value must be nonnegative. However, the control $(u_1^*(t), u_2^*(t)) = (0,0)$ gives rise to the zero cost, and hence must be optimal.

Let us now look at a more substantial example.

Example 5.2. Consider the following LQR problem:

$$\text{(5.27)} \qquad \begin{array}{ll} \text{Minimize} & J = E\left\{\displaystyle\int_0^1 \frac{1}{2}[r_1u_1(t)^2 + r_2u_2(t)^2]dt + \frac{1}{2}x(1)^2\right\} \\ \text{subject to} & \left\{\begin{array}{l} dx(t) = u_1(t)dt + u_2(t)dW(t), \\ x(0) = x_0, \end{array}\right. \end{array}$$

where $r_1 > 0$ and r_2 are given constants. In this case, $A(t) = B_2(t) = C(t) = D_1(t) = 0$, $B_1(t) = D_2(t) = 1$, $Q(t) = 0$, $(R_1(t), R_2(t)) = (r_1, r_2)$, and $H = 1$. We see that $u_1(\cdot)$ and $u_2(\cdot)$ control the drift and diffusion parts, respectively. The SRE (5.5) corresponding to u_1 is

$$\text{(5.28)} \qquad \left\{\begin{array}{l} \dot{P}(t) - P(t)^2r_1^{-1} = 0, \\ P(1) = 1, \\ r_1 > 0. \end{array}\right.$$

The solution to this equation is

$$\text{(5.29)} \qquad P(t) = \frac{r_1}{1+r_1-t}.$$

We can then calculate via (5.7) to get

$$\text{(5.30)} \qquad A_1(t) = \frac{1}{t-1-r_1}, \qquad C_1(t) = 0.$$

Moreover, condition (5.20) reduces to

$$\text{(5.31)} \qquad \bar{R}(t) \equiv \frac{r_1}{1+r_1-t} + r_2 \geq 0 \;\; \forall t \in [0,1],$$

or, equivalently,

$$\text{(5.32)} \qquad \frac{r_1}{1+r_1} + r_2 \geq 0.$$

This gives the trade-off between r_1 and r_2. Furthermore, when the above inequality is strict, the equation for $(\phi(\cdot), \lambda(\cdot))$ in (5.22) becomes a homogeneous linear equation with terminal value being 0. Hence by the uniqueness of its solution we have $\phi(t) \equiv \lambda(t) \equiv 0$. Therefore (5.21) gives $u_2^*(t) = 0$. Putting $u_2^*(\cdot), \phi(\cdot)$ and $\lambda(\cdot)$ into (5.24), we get

$$\dot{x}(t) = \frac{1}{t-1-r_1}x(t), \quad x(0) = x_0. \tag{5.33}$$

The solution to this equation is $x(t) = \frac{1+r_1-t}{1+r_1}x_0$. From (5.23), it follows that $u_1^*(t) = -\frac{1}{1+r_1}x_0$. To conclude, the optimal control of this problem, if it ever exists, must be given by $u^*(t) = (-\frac{1}{1+r_1}x_0, 0)$. A direct computation shows that the corresponding optimal value is $\frac{1}{2}\frac{r_1}{1+r_1}x_0^2$ (which is nonnegative).

6. Concluding remarks.

The stochastic LQR problem with indefinite control weights is not only mathematically interesting and challenging, but also practically important in touching the deep nature of the uncertainty as well as suggesting how to control the uncertainty. In [9], it is shown that the stochastic LQR problem can be completely solved if the corresponding SRE has a solution. In this paper, we presented the sufficient conditions for the existence and uniqueness of solutions to SRE in the normal case. As for the indefinite case (with $C \neq 0$), we are still not able to prove the solvability of SRE. However, we construct an optimal feedback control for the original LQR problem based on a decomposition approach.

It is interesting to see that the above decomposition approach leads to a *backward* LQR problem. This problem is actually interesting in its own right. More generally, we may consider a nonlinear stochastic control problem with backward dynamics. This kind of problem may also have potential applications in finance.

The work in [9] has led to a series of in-depth research projects on indefinite stochastic LQR control. For example, the problem with integral constraints was studied in [17], and the discrete-time case was treated in [18]. In [10] the problem with random coefficients was tackled by using functional analysis and forward-backward SDE theory. The computational aspect of the problem was first investigated in [1] by means of linear matrix inequalities and semidefinite programming, followed by a thorough study in [24]. Applications to finance problems were discussed in [26, 16].

To conclude, this is a very exciting research domain. Many fundamentally important problems remain open, and the resolutions to these problems will in turn give rise to new problems.

Acknowledgment. The authors would like to thank the two referees for their constructive comments that led to an improved version of the paper.

ON STATE CONSTRAINT REPRESENTATIONS AND MESH-DEPENDENT GRADIENT PROJECTION CONVERGENCE RATES FOR OPTIMAL CONTROL PROBLEMS*

J. C. DUNN†

Abstract. Two distinct nonlinear programming formulations are investigated for ODE optimal control problems with pointwise state and control constraints. The first formulation treats the differential equations of state as an equality constraint in the conventional manner. The second formulation employs a different equality constraint entailing the integrated state transition map. Related convergence rate estimates are developed for augmented gradient projection methods and discrete-time approximations to a large representative class of ODE control problems. In the first formulation, the rate estimates are mesh-dependent, and the predicted number of inner loop gradient projection iterations needed to achieve a fixed small deviation from the optimal value of the augmented Lagrangian is inversely proportional to the square of the mesh width. In the second formulation, the convergence rates and predicted iteration counts are mesh-invariant. The computational costs-per-iteration in the two formulations are comparable. These estimates elucidate previously published numerical experiments with augmented gradient projection methods and constrained regulator problems.

Key words. optimal control, pointwise state/control constraints, regulator problems, nonlinear programs, constraint representations, discrete-time approximations, gradient projection methods, mesh-dependent convergence rates

1. Introduction.

An ODE or PDE optimal control problem can be formulated in various ways as an infinite-dimensional nonlinear program (NLP) with specially structured cost function and constraints. Each such formulation, combined with a standard iterative NLP method and an approximate finite difference or finite element representation for the differential equations of state, yields a different numerical algorithm for the control problem. In general, the effectiveness of the resulting algorithm depends not only on the iterative method and discrete approximation scheme, but also on the underlying NLP formulation. The numerical experiments reported in [17] demonstrate this for an unscaled augmented gradient projection (AGP) method and the Euler finite difference approximation expressed in two different NLP formulations of a prototype ODE regulator problem with pointwise state and control constraints.

The first NLP formulation addressed in [17] is the conventional one for state constrained control problems, i.e., state and control vectors x and u are the primal variables and the discrete approximation to the differential equations of state is treated as an equality constraint that implicitly defines a functional relationship between x and u. The second formulation in [17] is new for control problems with pointwise state constraints. In this scheme, the state vectors in the primal variable set are replaced by artificial variables v linked to u through an equality constraint $\phi(u)-v=0$ that entails the explicit "integrated" state solution map $u \to x = \phi(u)$ for the discrete equations of state. Computational costs-per-iteration for efficient implementations of the unscaled

AGP method are similar in the two NLP formulations, and inversely proportional to the Euler mesh width in each case. On the other hand, the mesh-dependent convergence properties of the AGP method are very different in the two schemes. In the conventional NLP formulation, the number of inner and outer AGP iterates required to achieve fixed residual tolerances increases rapidly with decreasing mesh width, whereas the comparable iteration counts in the alternative formulation are essentially mesh-invariant. This formulation-dependent disparity in iteration counts is clearly reflected in the ordinates of the FLOP count graphs of [17], which can already differ by several orders of magnitude even on meshes that are still too coarse to support good approximations to the limiting ODE control problem.

The present article reinforces the numerical experiments of [17] with an analysis of the AGP inner loop based on the convergence theory of [11] and new root-mean-square (RMS) norm quadratic growth and Lipschitz norm estimates for the augmented Lagrangian and its gradient. The latter estimates are derived separately for the two NLP formulations of the uniform mesh Euler discrete-time approximation for an important class of ODE optimal control problems with strongly convex costs, linear state equations, and pointwise quasi-convex inequality constraints on control and state vectors. The Lagrangian quadratic growth constants behave similarly in both formulations as the Euler mesh-width approaches zero; however, the corresponding Lagrangian gradient Lipschitz norms act quite differently. In the conventional formulation, the Lipschitz norm is inversely proportional to the square of the mesh width. In the alternative formulation, the Lipschitz norm remains bounded as the mesh width approaches zero. These estimates produce disparate cost value convergence rate bounds that mirror the behavior observed in the numerical calculations of [17]. Although a comparable analysis for higher order discrete approximation schemes with uniform or nonuniform time steps is not attempted in the present investigation, a consideration of the $\mathbb{L}^2$ continuity properties of the continuous-time augmented Lagrangians suggests that similar formulation-dependent convergence rate disparities are likely to occur for any consistent numerical integration scheme. It is interesting to note here that mesh-invariant Lipschitz continuity properties for derivatives are also crucial in the mesh independence principle of Allgower et al. [2] for consistent finite-dimensional implementations of Newton's method for nonlinear equations $F(x) = 0$ in Banach spaces.

When pointwise constraints are imposed separately on the state and control variables, the associated alternative NLP formulation proposed in [17] enjoys two additional advantages. In this commonly encountered situation, the sets of admissible primal variable values $(u(t), v(t))$ are finite-dimensional Cartesian products, the corresponding augmented Lagrangian can be minimized *explicitly* with respect to the artificial variable v, the resulting reduced augmented Lagrangian is often locally Lipschitz continuously differentiable, and hence gradient projection methods can be used to minimize this reduced Lagrangian approximately with respect to the remaining primal variable u. (Augmented Lagrangian methods employing similar reduced Lagrangians have been proposed by Rockafellar [28] and Bertsekas [5] in conjunction with squared slack variable treatments of general inequality-constrained finite-dimensional NLPs.) It is readily seen that the elimination of v from the primal variable set will generally yield a major reduction in the cost of each inner iteration in the AGP scheme. Moreover, estimates derived here for a gradient projection (GP) method prototype applied with and without explicit minimization of the augmented Lagrangian in v

indicate that the former AGP scheme not only has a smaller computational cost per inner iteration, but also may converge more rapidly.

An extreme instance of separated pointwise constraints occurs when the state is entirely unrestricted. In this case, the augmented Lagrangian in the alternative NLP formulation of [17] is trivially minimized over v for each admissible u by setting the (unconstrained) artificial variable v equal to the $\phi(u) + \lambda/c$, where λ is the equality constraint's multiplier and c is the penalty constant in the augmented Lagrangian. The resulting reduced augmented Lagrangian is then merely the control problem's cost function with x replaced by $\phi(u)$, the artificial variable v, and the equality constraint and the multiplier λ disappear from the formulation at the first AGP multiplier update, and the AGP scheme effectively collapses to a basic single loop GP iteration for the given control-constrained optimal control problem. Certain mesh-independent ϵ-active constraint identification results have already been proved by Kelley and Sachs [23] for a standard GP method and Euler discrete-time approximations to ODE optimal control problems with bounded scalar control variables and unrestricted states. In addition, infinite-dimensional local convergence rate theorems have also been proved in [29] and [16] for this class of bounded input ODE optimal control problems, and for vector-valued extensions with polyhedral admissible control input sets.

For general NLPs, deteriorating convergence rates are also seen in AGP inner loop iterations when the penalty constant c is increased without bound and the corresponding inner relaxed AGP optimization problem thereby becomes increasingly ill-conditioned. First order scaling operators designed to address this issue have been investigated by Luenberger [25] and Hager [20] for unconstrained relaxed optimization problems with penalty terms, and by Hager [21] for analogous constrained problems with penalized objective functions. These scaling operators are prima facie well suited to the conventional NLP formulation of the pointwise constrained ODE optimal control problem, since they derive from the Jacobian of the penalized dynamic equation constraint, and the inherent sparse "staircase structure" in this Jacobian should be exploitable in the calculation of the iteration maps for associated scaled gradient-related descent methods. (This is clearly true for the unconstrained relaxed penalized problems that arise in the absence of pointwise constraints, but somewhat less obvious for pointwise inequality-constrained relaxed penalized problems and related scaled GP methods.) Moreover, since the mesh width parameter appears explicitly in the discrete-time dynamic equation constraints, it has been suggested that the scaling principles in [25], [20], and [21] may enhance the convergence behavior of associated gradient-related descent methods, not only as c increases without bound *but also as the mesh width approaches* 0. Unfortunately, this interesting conjecture is at present completely unsupported by any numerical or theoretical investigations for pointwise inequality-constrained ODE control problems and related AGP methods. Even in the absence of pointwise constraints, there are no pertinent published numerical results, and it is not known how the c-invariant upper limits on geometric convergence ratios in the extant general scaled steepest descent convergence theorems of [25] and [20] behave as the mesh width approaches 0. In particular, if these upper limits are not bounded away from 1 as the mesh width approaches 0, the associated scaled steepest descent methods may exhibit mesh-dependent deteriorating convergence rates.

2. The ODE optimal control problem. In the continuous-time optimal control problems treated here, the control schedules $u(\cdot)$ are considered to be bounded measurable functions from $[0, 1]$ to $\mathbb{R}^m$, the state trajectories $x(\cdot)$ are absolutely continuous functions from $[0,1]$ to $\mathbb{R}^n$, the cost functionals are integrated running loss functions,

$$\int_0^1 f^0(t,u(t),x(t))\,dt, \tag{2.1}$$

and the constraints are differential side conditions,

$$\frac{dx}{dt}(t) \overset{a.e.}{=} f(t,u(t),x(t)), \qquad t \in [0,1], \tag{2.2a}$$

$$x(0) = \eta_0, \tag{2.2b}$$

and pointwise vector-valued inequalities,

$$\gamma(t,u(t),x(t)) \leq 0, \qquad t \in [0,1]. \tag{2.3}$$

The ensuing analysis is restricted to Lipschitz continuously differentiable strongly convex cost functionals, continuous quasi-convex constraint component functions $\gamma_1(t,\cdot),\ldots,\gamma_r(t,\cdot)$, and linear rate functions,

$$f(t,\xi,\eta) = A(t)\eta + B(t)\xi, \tag{2.4}$$

with bounded measurable matrix-valued coefficient functions $A(\cdot)$ and $B(\cdot)$. The class of optimal control problems that meet these restrictions is broadly representative, and includes the prototype ODE linear-quadratic regulator (LQR) problem with pointwise bounds on the state and control vector components.

3. Nonlinear programming formulations.

The ODE optimal control problem of section 2 can be cast as an infinite-dimensional NLP,

$$\min_{w\in\mathbb{S}} J(w), \tag{3.1a}$$

subject to the constraints

$$g(w) \leq 0 \tag{3.1b}$$

and

$$h(w) = 0, \tag{3.1c}$$

where $\mathbb{S}$ is a linear variety (i.e., translated subspace) in a normed vector space $\mathbb{W}$, J is a real-valued functional on $\mathbb{W}$, g and h map $\mathbb{W}$ to normed vector spaces $\mathbb{Z}_g$ and $\mathbb{Z}_h$, respectively, and "$\leq$" is a partial order relation on $\mathbb{Z}_g$. Many such formulations are possible. Two are considered here.

3.1. Formulation I.

The ODE optimal control problem of section 2 is commonly treated as an infinite-dimensional nonlinear program (3.1) in a direct sum $\mathbb{W} = \mathbb{U} \oplus \mathbb{X}$, where $\mathbb{U}$ is a vector space of bounded measurable functions $u(\cdot) : [0,1] \to \mathbb{R}^m$, $\mathbb{X}$ is a vector space of absolutely continuous functions $x(\cdot) : [0,1] \to \mathbb{R}^n$ with bounded measurable derivatives, $\mathbb{S}$ is the linear variety of pairs $w = (u,x) \in \mathbb{W}$ for which $x(0) = \eta_0$, $\mathbb{Z}_g$ is a space of bounded measurable functions from $[0,1]$ to $\mathbb{R}^r$ with the standard pointwise partial order relation, $\mathbb{Z}_h$ is a space of bounded measurable functions from $[0,1]$ to $\mathbb{R}^n$, and J, g, and h are defined by

$$J(w) = \int_0^1 f^0(t, u(t), x(t))\, dt, \tag{3.2a}$$

$$g(w)(t) = \gamma(t, u(t), x(t)), \tag{3.2b}$$

and

$$h(w)(t) \overset{a.e}{=} \frac{dx}{dt}(t) - A(t)x(t) - B(t)u(t) \tag{3.2c}$$

for $t \in [0,1]$. Most often, $\mathbb{Z}_g$ and $\mathbb{Z}_h$ are equipped with standard $\mathbb{L}^\infty$ norms, and the norm on $\mathbb{W}$ is comprised of matching $\mathbb{L}^\infty$ and Sobolev norms on the u and x components of w, respectively. Under reasonable conditions on f^0 and γ, the functions J, g, and h are then well defined and continuously Fréchet differentiable at least once. However, since finite-dimensional discrete-time augmented gradient projection calculations are typically implemented in simple RMS norms on the vectors that approximate w and $h(w)$, it can be seen that smoothness properties of J, g, and h relative to function space $\mathbb{L}^2$ counterparts of the RMS norms on x are potentially more interesting for present considerations than the contrasting $\mathbb{L}^\infty$-Sobolev properties. Hence, it is significant that the equality constraint map h in (3.2c) and an associated augmented Lagrangian,

$$\begin{aligned} L(\lambda, w) &= J(w) + \langle \lambda, h(w) \rangle + \frac{1}{2}c\, \|h(w)\|^2 \\ &= J(w) + \frac{1}{2}c \left(\left\| \frac{\lambda}{c} + h(w) \right\|^2 - \left\| \frac{\lambda}{c} \right\|^2 \right), \end{aligned} \tag{3.3}$$

are not even continuous, much less continuously differentiable, when $\mathbb{U}$, $\mathbb{X}$, and $\mathbb{Z}_h$ are provided with $\mathbb{L}^2$ inner products and norms. This $\mathbb{L}^2$ smoothness singularity suggests that the convergence properties of discrete-time AGP implementations related to the present continuous-time NLP formulation may deteriorate on increasingly refined meshes.

Note 1. When the subspaces $\mathbb{X}$ and $\mathbb{Z}_h$ are equipped with $\mathbb{L}^2$ norms, it is easily shown that the linear differential operator in (3.2c) is unbounded and hence discontinuous. As might be expected, a related construction in Example 1 of section 7 demonstrates that the RMS norms of the associated bounded Euler finite-difference operators on uniform meshes for the interval $[0,1]$ increase without limit as the mesh width approaches zero, and the resulting unbounded growth in Lipschitz norms of the Lagrangian gradient has potentially adverse consequences for AGP convergence rates.

On the other hand, suppose that $\mathbb{X}$ is supplied with the inner product induced $\mathbb{X}_1^2$ Sobolev norm, and that $\mathbb{U}$, $\mathbb{Z}_g$, and $\mathbb{Z}_h$ are provided with the inner product induced $\mathbb{L}^2$ norms. The differential operator d/dt is now trivially bounded, and for a restricted but still important class of functions f^0 and γ, the related maps h, g and J and L are Lipschitz continuously Fréchet differentiable with respect to the inherited inner product induced norm on the direct sum $\mathbb{W} = \mathbb{U} \oplus \mathbb{X}$, and in addition, the augmented Lagrangian L simultaneously satisfies strong convexity and quadratic coercivity conditions in this norm. (The latter properties can be established with constructions similar to those used in the proof of Lemma 8.3.) This suggests that discrete-time AGP implementations in finite-dimensional inner product space counterparts of $\mathbb{W}$ may exhibit asymptotically mesh-independent convergence rates as mesh widths are reduced to zero. Unfortunately, in practice, the required gradient/projection computations in the Sobolev-like finite-dimensional weighted inner products are prohibitively expensive.

3.2. Formulation II. Reference [17] proposes an alternative NLP formulation for the optimal control problem of section 2 in a direct sum $\mathbb{W} = \mathbb{U} \oplus \mathbb{V}$, where $\mathbb{U}$ and $\mathbb{V}$ are vector spaces of bounded measurable functions from $[0,1]$ to $\mathbb{R}^m$ and $\mathbb{R}^n$, respectively, the linear variety $\mathbb{S}$ is $\mathbb{W}$ itself, and $\mathbb{Z}_g$ and $\mathbb{Z}_h$ are as before in section 3.1. In this setting, J, g, and h are prescribed by

$$J(u) = \int_0^1 f^0(t, u(t), \phi(u)(t))\, dt, \tag{3.4a}$$

$$g(w)(t) = \gamma(t, u(t), v(t)) \tag{3.4b}$$

and

$$h(w)(t) = \phi(u)(t) - v(t) \tag{3.4c}$$

for $t \in [0,1]$, where $\phi(u)$ is the unique absolutely continuous solution of the linear ODE initial value problem

$$\frac{dx}{dt}(t) \overset{a.e.}{=} A(t)x(t) + B(t)u(t), \qquad t \in [0,1], \tag{3.5a}$$

$$x(0) = \eta_0. \tag{3.5b}$$

Equivalently, ϕ is the affine map defined by

$$\phi(u) = \Theta u + \theta, \tag{3.6a}$$

where

$$(\Theta u)(t) = \int_0^t \Phi(t,s)B(s)u(s)\, ds \tag{3.6b}$$

and

$$\theta(t) = \Phi(t,0)\eta_0 \tag{3.6c}$$

for $t \in [0,1]$, and $\Phi(\cdot, s)$ is the fundamental solution matrix prescribed by the initial value problem

$$\frac{\partial}{\partial t}\Phi(t,s) \overset{a.e.}{=} A(t)\Phi(t,s), \qquad t \in [0,1], \tag{3.7a}$$

$$\Phi(s,s) = I \tag{3.7b}$$

for $s \in [0,1]$ [8]. Note that the cost J in (3.4a) depends only on the u component of w. Note also that if v and the equality constraint function (3.4c) were removed and if $x(t)$ were replaced by $\phi(u)(t)$ in γ, then the resulting inequality constraints $g(u)(t) = \gamma(t, u(t), \phi(u)(t)) \leq 0$ would also refer only to u but would *not* impose simple pointwise conditions on u in the interesting cases where $\gamma(t, u, x) \leq 0$ implies nontrivial restrictions on the state variable x.

The introduction of v and the equality constraint function (3.4c) not only simplifies the inequality constraint $g(w) \leq 0$ in this context, but also ensures differentiability of the corresponding augmented Lagrangian (3.3) in norms suitable for AGP methods. If the function spaces $\mathbb{U}$, $\mathbb{V}$, and $\mathbb{Z}_h$ in this NLP formulation are considered to be pre-Hilbert spaces with $\mathbb{L}^2$ inner products and norms, then the affine constraint function h in (3.4c) is Lipschitz continuously Fréchet differentiable, and for a large and important class of running loss functions f^0, the augmented Lagrangian (3.3) is also $\mathbb{L}^2$-Lipschitz continuously differentiable [16]. In such cases, there is no $\mathbb{L}^2$ smoothness singularity for the augmented Lagrangian in the present alternative continuous-time NLP formulation, and it seems plausible that the convergence properties of the related discrete-time AGP implementations may *not* deteriorate on increasingly refined meshes.

The heuristic arguments set forth here and in section 3.1 are vindicated by the subsequent AGP convergence analyses for finite-dimensional discrete-time approximations to the continuous-time optimal control problem of section 2.

4. Riemann–Euler discrete-time approximations.

Let k be a positive integer greater than 1, put $\Delta t = 1/k$, and construct the uniform mesh

$$0 = t_0 < \cdots < t_k = 1 \tag{4.1a}$$

with

$$t_{i+1} = t_i + \Delta t \tag{4.1b}$$

for $i = 0, \ldots, k-1$. Then the integral cost functional, linear ODE state equations, and pointwise inequality constraints in the optimal control formulation of section 2 have the corresponding first order Riemann–Euler approximations:

$$\sum_{i=0}^{k-1} f^0(t_i, u_i, x_i)\, \Delta t, \tag{4.2}$$

$$\frac{x_{i+1} - x_i}{\Delta t} = A(t_i)x_i + B(t_i)u_i, \qquad 0 = 1, \ldots, k-2, \tag{4.3a}$$

$$x_0 = \eta_0, \tag{4.3b}$$

and

$$\gamma(t_i, u_i, x_i) \leq 0, \qquad i = 0, \ldots, k-1. \tag{4.4}$$

For each control sequence $u = (u_0, \ldots, u_{k-1}) \in \mathbb{R}^{km}$, the discrete-time state equations (4.3) have a unique solution $\phi(u) = (\phi(u)_0, \ldots, \phi(u)_{k-1}) \in \mathbb{R}^{kn}$. More specifically, ϕ is the affine map defined by

$$\phi(u) = \Theta u + \theta, \tag{4.5a}$$

where

$$(\Theta u)_0 = 0, \tag{4.5b}$$

$$(\Theta u)_i = \sum_{j=0}^{i-1} \Phi_{i,j} B(t_j) u_j \Delta t, \qquad i = 1, \dots, k-1, \tag{4.5c}$$

$$\theta_i = \Phi_{i,0}\eta_0, \qquad i = 0, \dots, k-1, \tag{4.5d}$$

and $\Phi_{\cdot,j}$ is the fundamental solution matrix prescribed by the initial value problem

$$\frac{\Phi_{i+1,j} - \Phi_{i,j}}{\Delta t} = A(t_i)\Phi_{i,j}, \qquad i = j, \dots, k-2, \tag{4.6a}$$

$$\Phi_{j,j} = I \tag{4.6b}$$

for $j = 0, \dots, k-2$. Note that (4.5) immediately yields

$$\Phi_{i,j} = \prod_{l=j}^{i-1} (I + A(t_l)\Delta t) \tag{4.7}$$

for $0 \leq j < i \leq k-1$.

The foregoing constructions now lead directly to discrete-time counterparts of the NLP formulations in sections 3.1 and 3.2.

4.1. Formulation I. A discrete-time approximation to the continuous-time NLP formulation (3.2) is obtained by letting $\mathbb{U} = \mathbb{R}^{km}$, $\mathbb{X} = \mathbb{R}^{kn}$, $\mathbb{W} = \mathbb{U} \oplus \mathbb{X}$, $\mathbb{S} = \{w \in \mathbb{W} : x_0 = \eta_0\}$, $\mathbb{Z}_g = \mathbb{R}^{kr}$, $\mathbb{Z}_h = \mathbb{R}^{(k-1)n}$ and defining the cost and constraint functions J, g, and h by

$$J(w) = \sum_{i=0}^{k-1} f^0(t_i, u_i, x_i)\, \Delta t, \tag{4.8a}$$

$$g(w)_i = \gamma(t_i, u_i, x_i), \qquad i = 0, \dots, k-1, \tag{4.8b}$$

and

$$h(w)_i = \frac{x_{i+1} - x_i}{\Delta t} - A(t_i)x_i - B(t_i)u_i, \qquad i = 0, \dots, k-2. \tag{4.8c}$$

RMS inner products and norms are provided here for the spaces $\mathbb{U}$, $\mathbb{X}$, $\mathbb{W}$, $\mathbb{Z}_g$, and $\mathbb{Z}_h$ as natural discrete-time analogues of continuous-time $\mathbb{L}^2$ inner products and norms. In particular, on $\mathbb{W}$,

$$\langle w^a, w^b \rangle_{rms} = \langle u^a, u^b \rangle_{rms} + \langle x^a, x^b \rangle_{rms} \tag{4.9a}$$

and

$$\|w\|_{rms}^2 = \|u\|_{rms}^2 + \|x\|_{rms}^2, \tag{4.9b}$$

where

$$\langle u^a, u^b\rangle_{rms} = \sum_{i=0}^{k-1} \langle u_i^a, u_i^b\rangle \,\Delta t, \qquad \langle x^a, x^b\rangle_{rms} = \sum_{i=0}^{k-1} \langle x_i^a, x_i^b\rangle \,\Delta t \tag{4.9c}$$

and

$$\|u\|_{rms}^2 = \sum_{i=0}^{k-1} \|u_i\|^2 \,\Delta t, \qquad \|x\|_{rms}^2 = \sum_{i=0}^{k-1} \|x_i\|^2 \,\Delta t, \tag{4.9d}$$

and where $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$ denote the ordinary Euclidean inner product and norm on $\mathbb{R}^m$ or $\mathbb{R}^n$.

4.2. Formulation II. A discrete-time approximation to the alternative continuous-time NLP formulation (3.4) is obtained by letting $\mathbb{U} = \mathbb{R}^{km}$, $\mathbb{V} = \mathbb{R}^{kn}$, $\mathbb{W} = \mathbb{U}\oplus\mathbb{V}$, $\mathbb{S} = \mathbb{W}$, $\mathbb{Z}_g = \mathbb{R}^{kr}$, $\mathbb{Z}_h = \mathbb{R}^{kn}$, and defining the cost and constraint functions J, g, and h by

$$J(u) = \sum_{i=0}^{k-1} f^0(t_i, u_i, \phi(u)_i) \,\Delta t, \tag{4.10a}$$

$$g(w)_i = \gamma(t_i, u_i, v_i), \tag{4.10b}$$

and

$$h(w)_i = \phi(u)_i - v_i \tag{4.10c}$$

for $i = 0, \ldots, k-1$, where $\phi(\cdot)$ is the affine state equation solution map in (4.5)–(4.6).

As in section 4.1, RMS inner products and norms are provided for the spaces $\mathbb{U}$, $\mathbb{V}$, $\mathbb{W}$, $\mathbb{Z}_g$, and $\mathbb{Z}_h$. In particular, on $\mathbb{W}$,

$$\langle w^a, w^b\rangle_{rms} = \langle u^a, u^b\rangle_{rms} + \langle v^a, v^b\rangle_{rms} \tag{4.11a}$$

and

$$\|w\|_{rms}^2 = \|u\|_{rms}^2 + \|v\|_{rms}^2, \tag{4.11b}$$

where

$$\langle u^a, u^b\rangle_{rms} = \sum_{i=0}^{k-1} \langle u_i^a, u_i^b\rangle \,\Delta t, \qquad \langle v^a, v^b\rangle_{rms} = \sum_{i=0}^{k-1} \langle v_i^a, v_i^b\rangle \,\Delta t \tag{4.11c}$$

and

$$\|u\|_{rms}^2 = \sum_{i=0}^{k-1} \|u_i\|^2 \,\Delta t, \qquad \|v\|_{rms}^2 = \sum_{i=0}^{k-1} \|v_i\|^2 \,\Delta t, \tag{4.11d}$$

and where $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$ once again denote the Euclidean inner product and norm on $\mathbb{R}^m$ or $\mathbb{R}^n$.

5. Multiplier methods. The multiplier method proposed by Hestenes [22] and Powell [27] treats finite-dimensional equality-constrained minimization problems,

$$\min_{w\in\mathbb{R}^N} J(w) \tag{5.1a}$$

subject to

$$h(w) = 0, \tag{5.1b}$$

by solving a related sequence of relaxed unconstrained minimization problems,

$$\min_{w\in\mathbb{R}^N} L(\lambda^{(i)}, w), \tag{5.2}$$

where $L(\lambda, w)$ is an augmented Lagrangian (3.3) with nonnegative penalty constant c, and $\{\lambda^{(i)}\}$ is a sequence of multiplier vectors generated by the recursion

$$\lambda^{(i+1)} = \lambda^{(i)} + c\, h(w^{(i+1)}) \tag{5.3}$$

in which $w^{(i+1)}$ denotes an approximation to some exact solution of the unconstrained minimization problem (5.2). The exact solution is generally inaccessible and the approximate minimizer $w^{(i+1)}$ is typically produced by a truncated inner iterative calculation that begins at $w^{(i)}$ for the unconstrained problem (5.2). In the classic formulations of [22] and [27], the domain $\mathbb{W} = \mathbb{R}^N$ is equipped with the standard Euclidean norm, the codomain $\mathbb{Z}_h$ is $\mathbb{R}^q$, λ is a vector in $\mathbb{R}^q$, and $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$ in (3.3) are the standard Euclidean inner product and norm on $\mathbb{R}^q$.

5.1. AGP methods. Many elaborations of the Hestenes–Powell multiplier method have been proposed and analyzed for equality-constrained minimization problems and NLPs with equality and inequality constraints (see [5], [6], and the bibliographies therein). The AGP methods addressed in [3], [15], [17], and the present investigation are intended for NLPs (3.1) that have difficult equality constraints but tractable quasi-convex inequality constraints with simple closed convex solutions sets,

$$\Omega_g = \{w \in \mathbb{S} : g(w) \le 0\}, \tag{5.4}$$

whose associated proximal point projector maps P_{Ω_g} are easily computed. The simplest of these methods employs the first order Hestenes–Powell multiplier rule (5.3) and a Goldstein–Levitin–Polyak GP method [18], [24] to compute approximate solutions $w^{(i)}$ for the corresponding relaxed NLPs,

$$\min_{w\in\Omega_g} L(\lambda^{(i)}, w). \tag{5.5}$$

More specifically, $w^{(i+1)}$ is obtained from $w^{(i)}$ by a truncated GP iteration,

$$\zeta^{(0)} = w^{(i)}, \tag{5.6a}$$

$$\zeta^{(j+1)} = P_{\Omega_g}(\zeta^{(j)} - \alpha s_j \nabla_w L(\lambda^{(i)}, \zeta^{(j)})), \qquad j = 0, \dots, j_i, \tag{5.6b}$$

$$w^{(i+1)} = \zeta^{(j_i+1)}, \tag{5.6c}$$

where α is a positive scaling parameter and s_j is a real number in $(0,1]$ prescribed by the Bertsekas–Armijo step length rule [4], i.e., with β and δ fixed in $(0,1)$, s_j is the largest number s such that

$$s \in \{1, \beta, \beta^2, \ldots\} \tag{5.7a}$$

and

(5.7b)
$$L(\lambda,\zeta) - L(\lambda, P_{\Omega_g}(\zeta - \alpha s \nabla_w L(\lambda,\zeta))) \geq \delta \langle \nabla_w L(\lambda,\zeta), \zeta - P_{\Omega_g}(\zeta - \alpha s \nabla_w L(\lambda,\zeta))\rangle$$

with $\lambda = \lambda^{(i)}$ and $\zeta = \zeta^{(j)}$. In these formulas, α, β, and δ are constants; however, the convergence rate estimates in subsequent sections are readily modified to accomodate variable scaling parameters $\alpha^{(j)}$ that are bounded away from 0 and ∞, and step length parameters $\beta^{(j)}$ and $\delta^{(j)}$ that are bounded away from 0 and 1.

5.2. Reduced AGP methods. If $\mathbb{W}$ is a direct sum $\mathbb{W}^a \oplus \mathbb{W}^b$ and the feasible set in the relaxed NLP (5.5) is also a Cartesian product,

$$\Omega_g = \Omega_g^a \times \Omega_g^b, \tag{5.8}$$

of closed convex sets $\Omega_g^a \subset \mathbb{W}^a$ and $\Omega_g^b \subset \mathbb{W}^b$, then (5.5) reduces to

$$\min_{w^a \in \Omega_g^a} \hat{L}(\lambda, w^a), \tag{5.9a}$$

where

$$\hat{L}(\lambda, w^a) = \min_{w^b \in \Omega_g^b} L(\lambda, (w^a, w^b)). \tag{5.9b}$$

In some cases, explicit formulas can be found for an *exact* minimizer $\hat{w}^b(\lambda, w^a)$ of $L(\lambda, (w^a, \cdot))$ in Ω_g^b, and for the corresponding reduced augmented Lagrangian $\hat{L}(\lambda, w^a)$. If $\hat{L}(\lambda, w^a)$ retains sufficient smoothness in the variable w^a, then GP methods can be applied to the simpler reduced NLP (5.9) to obtain an approximate minimizer $w = (w^a, \hat{w}^b(\lambda, w^a))$ for $L(\lambda, w)$ in Ω_g. A reduced augmented gradient projection (RAGP) method of this type for control problems with separated pointwise constraints on the control and state variables was proposed in [17], and is investigated further here. Similar strategies for slack variable formulations of general finite-dimensional inequality-constrained NLPs are proposed and analyzed in [28] and [5].

5.3. The AGP method in formulation I. For the discrete-time NLP of section 4.1, the primal variable is a vector $w = (u, x)$ in the direct sum $\mathbb{W} = \mathbb{R}^{km} \oplus \mathbb{R}^{kn}$, and the relaxed NLP (5.5) becomes

$$\min_{w \in \Omega_g} L(\lambda, w), \tag{5.10a}$$

with

$$\Omega_g = \{w : x_0 = \eta_0,\ \gamma(t_i, u_i, x_i) \leq 0, \quad i = 0, \ldots, k-1\}, \tag{5.10b}$$

and

$$L(\lambda, w) = J(w) + \frac{1}{2} c \left(\left\| \frac{\lambda}{c} + \mathcal{D}x - \mathcal{A}x - \mathcal{B}u \right\|_{rms}^2 - \left\| \frac{\lambda}{c} \right\|_{rms}^2 \right), \tag{5.10c}$$

where

$$J(w) = \sum_{i=0}^{k-1} f^0(t_i, u_i, x_i)\,\Delta t, \tag{5.10d}$$

$$\lambda = (\lambda_0, \ldots, \lambda_{k-2}) \in \mathbb{R}^{(k-1)n}, \tag{5.10e}$$

$$(\mathcal{A}x)_i = A(t_i)x_i, \tag{5.10f}$$

$$(\mathcal{B}u)_i = B(t_i)u_i, \tag{5.10g}$$

and

$$(\mathcal{D}x)_i = \frac{x_{i+1} - x_i}{\Delta t} \tag{5.10h}$$

for $i = 0, \ldots, k-2$.

For AGP methods, it is significant that the RMS projection operator for the set Ω_g has the pointwise decomposition formula

$$P_{\Omega_g}(u, x) = (\xi, \eta) \tag{5.11a}$$

with

$$(\xi_i, \eta_i) = P_{Z_i}(u_i, x_i), \qquad i = 0, \ldots, k-1, \tag{5.11b}$$

$$Z_0 = \{(u_0, x_0) : x_0 = \eta_0, \;\; \gamma(t_0, u_0, x_0) \le 0\}, \tag{5.11c}$$

and

$$Z_i = \{(u_i, x_i) : \gamma(t_i, u_i, x_i) \le 0\}, \qquad i = 1, \ldots, k-1. \tag{5.11d}$$

In these equations, P_{Z_i} denotes the standard Euclidean projection operator for sets $Z_i \subset \mathbb{R}^m \oplus \mathbb{R}^n$.

5.4. The AGP method in formulation II. The primal variable in the discrete-time NLP of section 4.2 is a vector $w = (u, v)$ in the direct sum $\mathbb{W} = \mathbb{R}^{km} \oplus \mathbb{R}^{kn}$, and the relaxed NLP (5.5) becomes

$$\min_{w \in \Omega_g} \; L(\lambda, w) \tag{5.12a}$$

with

$$\Omega_g = \{w : \gamma(t_i, u_i, v_i) \le 0, \quad i = 0, \ldots, k-1\}, \tag{5.12b}$$

and

$$L(\lambda, w) = J(u) + \frac{1}{2}c\left(\left\|\frac{\lambda}{c} + \phi(u) - v\right\|_{rms}^2 - \left\|\frac{\lambda}{c}\right\|_{rms}^2\right), \tag{5.12c}$$

where

$$J(u) = \sum_{i=0}^{k-1} f^0(t_i, u_i, \phi(u)_i)\ \Delta t, \tag{5.12d}$$

$$\lambda = (\lambda_0, \ldots, \lambda_{k-1}) \in \mathbb{R}^{kn}, \tag{5.12e}$$

and $\phi(\cdot)$ is the affine state equation solution map in (4.5)–(4.6).

Once again, the RMS projection operator for the set Ω_g in this scheme has the useful pointwise decomposition formula

$$P_{\Omega_g}(u, v) = (\xi, \eta) \tag{5.13a}$$

with

$$(\xi_i, \eta_i) = P_{Z_i}(u_i, v_i), \qquad i = 0, \ldots, k-1, \tag{5.13b}$$

and

$$Z_i = \{(u_i, v_i) : \gamma(t_i, u_i, v_i) \leq 0\}, \qquad 0 = 1, \ldots, k-1. \tag{5.13c}$$

As before, the symbol P_{Z_i} in these equations denotes the standard Euclidean projection operator for sets $Z_i \subset \mathbb{R}^m \oplus \mathbb{R}^n$.

Note that formula (5.12c) can be rewritten as

$$L(\lambda, w) = \sum_{i=0}^{k-1} l^0(t_i.\lambda_i, u_i, v_i, \phi(u)_i)\ \Delta t, \tag{5.14a}$$

where

$$\begin{aligned} l^0(t_i.\lambda_i, u_i, v_i, x_i) &= f^0(t_i, u_i, x_i) \\ &\quad + \frac{1}{2} c \left(\left\| \frac{\lambda_i}{c} + x_i - v_i \right\|^2 - \left\| \frac{\lambda_i}{c} \right\|^2 \right). \end{aligned} \tag{5.14b}$$

Thus, the relaxed NLP (5.12) amounts to a new discrete-time optimal control problem with unconstrained states, pointwise constrained control inputs (u_i, v_i), running losses $l^0(t_i.\lambda_i, u_i, v_i, x_i)$, and the original state equations (4.3). As explained in [17], it follows that the RMS gradient of $L(\lambda, \cdot)$ can be calculated efficiently in $O(k)$ floating point operations (FLOPS) with adjoint recursions for the Euler discrete-time equations (4.3). In fact, when f^0 is twice continuously differentiable, it is also possible to compute Newtonian scaling operators for $L(\lambda, \cdot)$ in $O(k)$FLOPS with auxiliary dynamic programming recursions [13], [14].

5.5. The RAGP method in formulation II. The reduced augmented gradient projection scheme is applicable in formulation II when the pointwise inequality constraints on state and control variables are "separated" in the sense that

$$\gamma(t, \xi, \eta) = (\gamma^u(t, \xi), \gamma^x(t, \eta)), \tag{5.15}$$

where γ^u maps $\mathbb{R}^1 \oplus \mathbb{R}^m$ to $\mathbb{R}^{r_u}$, γ^x maps $\mathbb{R}^1 \oplus \mathbb{R}^n$ to $\mathbb{R}^{r_x}$, and $r_u + r_x = r$. In this frequently encountered special case, the feasible set Ω_g in (5.12b) is a Cartesian product,

$$\Omega_g = \Omega_g^u \times \Omega_g^v, \tag{5.16a}$$

where

$$\Omega_g^u = \{u : \gamma^u(t_i, u_i) \le 0, \quad i = 0, \ldots, k-1\} \tag{5.16b}$$

and

$$\Omega_g^v = \{v : \gamma^x(t_i, v_i) \le 0, \quad i = 0, \ldots, k-1\}. \tag{5.16c}$$

Hence, the corresponding reduced NLP (5.9) becomes

$$\min_{u \in \Omega_g^u} \hat{L}(\lambda, u) \tag{5.17a}$$

with

$$\begin{aligned} \hat{L}(\lambda, u) &= \left(J(u) - \frac{1}{2} c \left\| \frac{\lambda}{c} \right\|_{rms}^2 \right) + \frac{1}{2} c \min_{v \in \Omega_g^v} \left\| \left(\frac{\lambda}{c} + \phi(u) \right) - v \right\|_{rms}^2 \\ &= \left(J(u) - \frac{1}{2} c \left\| \frac{\lambda}{c} \right\|_{rms}^2 \right) + \frac{1}{2} c \left\| \left(\frac{\lambda}{c} + \phi(u) \right) - P_{\Omega_g^v} \left(\frac{\lambda}{c} + \phi(u) \right) \right\|_{rms}^2 , \end{aligned} \tag{5.17b}$$

where

$$J(u) = \sum_{i=0}^{k-1} f^0(t_i, u_i, \phi(u)_i) \, \Delta t, \tag{5.17c}$$

and

$$\lambda = (\lambda_0, \ldots, \lambda_{k-1}) \in \mathbb{R}^{kn}. \tag{5.17d}$$

Note that the components of the product set Ω_g are now also Cartesian products with associated RMS projector decomposition formulas. More specifically,

$$\Omega_g^u = \prod_{i=0}^{k-1} U_i \qquad \Omega_g^v = \prod_{i=0}^{k-1} V_i \tag{5.18a}$$

with

$$U_i = \{\xi \in \mathbb{R}^m : \gamma^u(t_i, \xi) \le 0\}, \qquad V_i = \{\eta \in \mathbb{R}^n : \gamma^x(t_i, \eta) \le 0\} \tag{5.18b}$$

for $i = 0, \ldots, k-1$ and

$$P_{\Omega_g^u}(u)_i = P_{U_i}(u_i), \qquad P_{\Omega_g^v}(v)_i = P_{V_i}(v_i) \tag{5.19}$$

for $i = 0, \ldots, k-1$. The decomposition formula for $P_{\Omega_g^u}$ facilitates the implementation of GP methods for the reduced NLP (5.17). On the other hand, the formula for $P_{\Omega_g^v}$ simplifies the construction of $\hat{L}(\lambda, \cdot)$ and its RMS gradient. By rewriting (5.9b) as

$$\hat{L}(\lambda, u) = \sum_{i=0}^{k-1} \hat{l}^0(t_i, \lambda_i, u_i, \phi(u)_i) \, \Delta t \tag{5.20a}$$

with

$$\hat{l}^0(t_i,\lambda_i,u_i,x_i) = \left(f^0(t_i,u_i,x_i) - \frac{1}{2}c\left\|\frac{\lambda_i}{c}\right\|^2\right)$$

$$+\frac{1}{2}c\left\|\left(\frac{\lambda_i}{c}+x_i\right) - P_{V_i}\left(\frac{\lambda_i}{c}+x_i\right)\right\|^2, \tag{5.20b}$$

it becomes evident that the reduced NLP (5.17) is a discrete-time control problem with unconstrained states, pointwise constrained control inputs u_i, running loss functions $\hat{l}^0(t_i,\lambda_i,u_i,x_i)$, and the original state equations (4.3). Moreover, it turns out that $\hat{l}^0$ is smooth enough in (u_i,x_i) to admit the standard efficient adjoint recursive calculation of the RMS gradient of $\hat{L}(\lambda,\cdot)$ (cf. section 8.2 and [17]).

6. General GP convergence rate estimates. Reference [11] provides a comprehensive convergence rate analysis of basic GP methods for constrained minimization problems,

$$\min_{w\in\Omega} F(w), \tag{6.1}$$

with closed convex feasible sets Ω in a real Hilbert space $\mathbb{W}$, and convex Lipschitz continuously Fréchet differentiable cost functions $F:\mathbb{W}\to\mathbb{R}^1$. The convergence rate estimates in [11] are directly applicable to the AGP inner loop calculation outlined in section 5 for discrete-time optimal control problems cast as NLPs in finite-dimensional Euclidean spaces with RMS inner products. In this setting, Ω is a solution set for the control problem's pointwise quasi-convex state/control inequality constraints, and $F(\cdot)$ is either an augmented Lagrangian $L(\lambda,\cdot)$ or a reduced augmented Lagrangian $\hat{L}(\lambda,\cdot)$. The structure of the feasible set is similar in NLP formulations I and II of section 4; however, the augmented Lagrangians in these formulations are quite different, and these differences are strongly manifested in the corresponding GP convergence estimates as the mesh width Δt approaches zero.

In the general context of (6.1), the GP iteration of section 5.1 becomes

$$w^{(j+1)} = P_\Omega(w^{(j)} - \alpha s_j\nabla F(w^{(j)})), \qquad j=0,1,2,\ldots, \tag{6.2a}$$

where α is a fixed positive scaling parameter and s_j is the largest number s such that

$$s\in\{1,\beta,\beta^2,\ldots\} \tag{6.2b}$$

and

$$F(w) - F(P_\Omega(w-\alpha s\nabla F(w))) \geq \delta\langle\nabla F(w), w - P_\Omega(w-\alpha s\nabla F(w))\rangle \tag{6.2c}$$

with $w=w^{(j)}$, and β and δ fixed in $(0,1)$. When the convex function F has a unique minimizer $\overline{w}\in\Omega$, the convergence rate of the value sequences $\{F(w^{(n)}\}$ generated by (6.2) correlates strongly with the gradient Lipschitz norm,

$$\Lambda = \sup_{w^a\neq w^b}\frac{\|\nabla F(w^a)-\nabla F(w^b)\|}{\|w^a-w^b\|}, \tag{6.3}$$

and the growth properties of the nondecreasing nonnegative real function,

$$\gamma(d) = \inf\{F(w)-F(\overline{w}) : w\in\Omega \text{ and } \|w-\overline{w}\|\geq d\} \qquad (d\geq 0). \tag{6.4}$$

Roughly speaking, the convergence rate estimates derived in [11] for $\{F(w^{(n)})\}$ improve as Λ decreases or the growth rate of $\gamma(\cdot)$ increases. One such estimate will suffice for present purposes.

THEOREM 6.1. *Suppose that* Ω *is a nonempty closed convex set in a real Hilbert space* $\mathbb{W}$, *that* F *is a convex Lipschitz continuously Fréchet differentiable real function on* $\mathbb{W}$, *and that* Λ *is the Lipschitz norm of* ∇F *in* (6.3). *In addition, suppose that* F *has a unique minimizer* $\overline{w}$ *in* Ω *and that the corresponding function* $\gamma(\cdot)$ *in* (6.4) *grows quadratically with*

$$\Gamma = \inf_{d>0} \frac{\gamma(d)}{d^2} > 0. \tag{6.5}$$

Let $\{w^{(j)}\}$ *be any sequence in* Ω *generated by the gradient projection method* (6.2). *For* $j = 0, 1, 2, \ldots$, *let* s_j *be the associated Bertsekas–Armijo step length and let* $r_j = F(w^{(j)}) - F(\overline{w}) \geq 0$. *Then* $\{s_j\}$ *is bounded away from zero by*

$$\sigma = \min\left\{\alpha, \frac{2\beta(1-\delta)}{\Lambda}\right\}. \tag{6.6}$$

Moreover, either $r_j = 0$ *eventually or* $\{r_j\}$ *converges geometrically to zero with*

$$0 \leq \frac{r_{j+1}}{r_j} \leq \nu, \qquad j = 0, 1, 2, \ldots, \tag{6.7a}$$

and

$$\nu = 1 - \frac{4\Gamma\sigma\delta}{(\sqrt{1+4\Gamma\sigma}+1)^2}. \tag{6.7b}$$

Proof. Directly from the proof of Theorem 4.3 in [11], and the step length lower bound estimate in [4]. □

Note that in all cases, the convergence factor ν in (6.7) lies in the interval $1-\delta < \nu < 1$. Moreover, if $\alpha \geq \frac{2\beta(1-\delta)}{\Lambda}$, then $\sigma = \frac{2\beta(1-\delta)}{\Lambda}$ and the formula for ν in Theorem 6.1 can be written as

$$\nu = (1-\delta) + \delta\left(\frac{2}{\sqrt{1+\rho}+1}\right) \tag{6.8a}$$

with

$$\rho = 8\beta(1-\delta)\left(\frac{\Gamma}{\Lambda}\right). \tag{6.8b}$$

It is now apparent that if $\alpha \geq \frac{2\beta(1-\delta)}{\Lambda}$, then the convergence factor ν is independent of the scale factor α, and $\nu \to 1^-$ as $\Gamma/\Lambda \to 0^+$. On the other hand, if $\alpha < \frac{2\beta(1-\delta)}{\Lambda}$, then $\sigma = \alpha$ and

$$\nu = 1 - \frac{4\Gamma\alpha\delta}{(\sqrt{1+4\Gamma\alpha}+1)^2},$$

in which case ν is independent of Λ and $\nu \to 1^-$ as $\Gamma\alpha \to 0^+$.

Note also that for convex cost functions on finite-dimensional spaces $\mathbb{W}$, the growth function γ for a unique minimizer $\overline{w}$ is always positive-definite [12]; however, in general, the rate at which γ grows with d depends on the structure of F and Ω. For present purposes, consideration is limited to Lipschitz continuously differentiable cost functions F whose gradients satisfy the *strong monotonicity* condition

$$\exists \mu > 0 \text{ for all } w^a, w^b \in \mathbb{W}, \quad \langle \nabla F(w^a) - \nabla F(w^b), w^a - w^b \rangle \geq \mu \|w^a - w^b\|^2 \tag{6.9}$$

(cf. [30]). Such functions are *strongly convex*, and the following result is readily proved with elementary techniques originally developed by Vainberg, Zarantonello, and Browder et al. (e.g., [30], [7], and the still earlier unpublished and currently inaccessible technical report [31] cited in [7]).

THEOREM 6.2. *Suppose that Ω is a nonempty closed convex set in a real Hilbert space $\mathbb{W}$, that F is a Lipschitz continuously Fréchet differentiable real function on $\mathbb{W}$, and that ∇F satisfies the strong monotonicity condition* (6.9). *Then F is strongly convex in the sense of* [6], *the corresponding convex program* (6.1) *has a unique minimizer $\overline{w}$, and the quadratic growth condition* (6.5) *in Theorem* 6.1 *holds with $\Gamma \geq \frac{1}{2}\mu$.*

Proof. The existence and uniqueness of a minimizer $\overline{w}$ for F in the closed convex set Ω can be established with the contraction mapping principle, as outlined in [7]. For $s > 0$, define the associated map $T_s : \Omega \to \Omega$ by the rule

$$\text{for all } w \in \Omega \quad T_s(w) = P_\Omega(w - s\nabla F(w)).$$

With elementary calculus and the Hilbert space projection theorem, it is now easily seen that the following statements are equivalent for all $\overline{w}$:

(a) $\overline{w}$ is a minimizer of the convex real function F in the nonempty closed convex set Ω.

(b) For all $w \in \Omega$, $\langle \nabla F(\overline{w}), w - \overline{w} \rangle \geq 0$.

(c) For some $s > 0$, $\overline{w} = T_s(\overline{w})$.

(d) For all $s > 0$, $\overline{w} = T_s(\overline{w})$.

Moreover, since the projector map P_Ω is nonexpansive [26], it follows from (6.9) and the Lipschitz continuity of $\nabla F(\cdot)$ that

$$\begin{aligned} \|T_s(w^a) - T_s(w^b)\|^2 &\leq \|w^a - w^b - s(\nabla F(w^a) - \nabla F(w^b))\|^2 \\ &\leq (1 - 2\mu s + \Lambda^2 s^2)\ \|w^a - w^b\|^2 \end{aligned}$$

for all $s > 0$ and all w^a and w^b in Ω, where μ is the positive constant in the strong monotonicity condition (6.9) and Λ is the finite Lipschitz norm for $\nabla F(\cdot)$ in (6.3). Evidentially, T_s is a contraction map for sufficiently small fixed positive values of s. In addition, since $\mathbb{W}$ is complete, the closed set Ω is also complete in the metric induced by $\langle \cdot, \cdot \rangle$. Hence the assertions developed above imply that the maps T_s have a common unique fixed point $\overline{w}$, that $\overline{w}$ is the unique global minimizer of F in Ω, and that $\langle \nabla F(\overline{w}), w - \overline{w} \rangle \geq 0$ for all $w \in \Omega$. Now note that for all w in $\mathbb{W}$,

$$\begin{aligned} F(w) - F(\overline{w}) &= \int_0^1 \frac{d}{dt} F(\overline{w} + t(w - \overline{w}))\ dt \\ &= \int_0^1 \langle \nabla F(\overline{w} + t(w - \overline{w})), w - \overline{w} \rangle\ dt, \end{aligned}$$

and hence for all w in Ω,

$$\begin{aligned} F(w) - F(\overline{w}) &\geq \int_0^1 \langle \nabla F(\overline{w} + t(w - \overline{w})) - \nabla F(\overline{w}), w - \overline{w} \rangle\ dt \\ &\geq \frac{1}{2}\mu\ \|w - \overline{w}\|^2. \qquad \square \end{aligned}$$

Note 2. The Lipschitz continuity hypothesis and strong monotonicity condition (6.9) in Theorem 6.2 automatically hold if F is twice continuously Fréchet differentiable and the spectral sets for the corresponding Hessian operators $\nabla^2 F(w)$ are bounded away from zero and infinity as w ranges over $\mathbb{W}$.

Note 3. The proof strategy employed here for Theorem 6.2 is valid in infinite-dimensional Hilbert spaces; hence this theorem applies to certain continuous-time ODE optimal control problems cast in $\mathbb{L}^2$ function spaces, as well as their finite-dimensional discrete-time RMS approximations. A finite-dimensional counterpart of Theorem 6.2 can be proved with a compactness argument when F is merely continuously differentiable (however, even in finite-dimensional spaces, the GP convergence rate estimate in Theorem 6.1 still requires Lipschitz continuity of $\nabla F(\cdot)$). More specifically, if $\nabla F(\cdot)$ is continuous, then, as in the proof of Theorem 6.2, the strong monotonicity condition (6.9) yields

$$F(w) - F(w_0) \geq \frac{1}{2}\mu \left\| w - w_0 \right\|^2 + \langle \nabla F(w_0), w - w_0 \rangle$$

for all w and w_0. It is now easily seen that every level set of F is bounded and closed, and therefore compact in finite-dimensional normed spaces. But in this case, F must attain its infimum at some $\overline{w}$ in the closed set Ω. Since Ω is convex, it follows that $\langle \nabla F(\overline{w}), w - \overline{w} \rangle \geq 0$ for all w in Ω, and the foregoing estimate applied to the increment $F(w) - F(\overline{w})$ immediately proves uniqueness of $\overline{w}$ and the quadratic growth property (6.5).

7. Mesh-dependent rate estimates in formulation I. Theorem 6.1 yields AGP inner loop convergence factors ν that can approach 1 as Δt goes to zero in the discrete-time formulation I of section 5.3. This does not prove that the *actual* cost value errors $r_j = L(\lambda, w_j) - L(\lambda, \overline{w})$ converge more slowly on increasingly refined meshes, since ν^j provides only an *upper* bound on the ratio r_j/r_0. On the other hand, the numerical results in [17] do demonstrate rapidly deteriorating mesh-dependent convergence behavior in formulation I that is at least qualitatively consistent with the behavior of ν as Δt goes to zero. Accordingly, it seems worthwhile to explore briefly how ν may depend on Δt in formulation I for a representative linear-quadratic curve follower problem with pointwise bounds on the state variable.

Example 1. Let $x^{ref}(\cdot)$ be a fixed continuous real valued function on $[0, 1]$ and let $m = n = r = 1$, $f^0(t, \xi, \eta) = \frac{1}{2}(\xi^2 + (\eta - x^{ref}(t))^2)$, $f(t, \xi, \eta) = \xi$, $\gamma(t, \xi, \eta) = |\eta| - 1$ and $|\eta_0| \leq 1$ in the continuous-time ODE model (2.1)–(2.3). With reference to (5.10b)–(5.10c), the associated discrete-time feasible set and augmented Lagrangian in formulation I are then

$$\Omega_g = \{w = (u, x) : x_0 = \eta_0,\ |x_i| \leq 1, \quad i = 0, \ldots, k-1\} \tag{7.1a}$$

and

$$L(\lambda, w) = \frac{1}{2}\|w - w^{ref}\|^2_{rms} + \frac{1}{2}c\left(\left\|\frac{\lambda}{c} + \mathcal{D}x - \mathcal{B}u\right\|^2_{rms} - \left\|\frac{\lambda}{c}\right\|^2_{rms}\right), \tag{7.1b}$$

where

$$w^{ref} = (0, x^{ref}), \tag{7.1c}$$

$$(\mathcal{B}u)_i = u_i, \tag{7.1d}$$

and

$$(\mathcal{D}x)_i = \frac{x_{i+1} - x_i}{\Delta t} \tag{7.1e}$$

for $i = 0, \ldots, k-2$. It will now be shown that the corresponding growth constant Γ for $L(\lambda, \cdot)$ and Lipschitz norm Λ for $\nabla_w L(\lambda, \cdot)$ satisfy

$$\Gamma \leq \frac{1}{2}(1 + c) \tag{7.2}$$

and

$$\Lambda \geq 1 + 2\left(\frac{c}{\Delta t^2}\right) \tag{7.3}$$

for $0 < \Delta t \leq \frac{1}{2}$ and $\lambda \in \mathbb{R}^{k-1}$. With these estimates and (6.7), it is readily seen that $\nu = 1 - O(\Delta t^2)$. More specifically, if $\alpha \geq 1$ and $c \geq 1$, then

$$\nu \geq 1 - \beta \Delta t^2 \tag{7.4}$$

for all $\Delta t \in (0, 1/2]$, uniformly in λ.

To prove (7.2), fix λ and note that both terms in the augmented Lagrangian (7.1b) are convex and Lipschitz continuously differentiable in the RMS norm, and that the first term satisfies the strong monotonicity condition (6.9) with $\mu = 1$. Hence, $L(\lambda, \cdot)$ satisfies (6.9) with some $\mu \geq 1$, and by Theorem 6.2, must therefore have a unique minimizer $\overline{w}$ in the nonempty closed convex set (7.1a) with an associated quadratic growth constant $\Gamma > 0$ that depends on Δt (i.e., on k). Since the pointwise constraints in (7.1a) restrict x alone, assertions (a)–(d) in the proof of Theorem 6.2 yield the first order optimality condition

$$\nabla_u L(\lambda, \overline{w}) = 0. \tag{7.5}$$

A simple "completion of squares" now gives

$$\begin{aligned} L(\lambda, w) - L(\lambda, \overline{w}) = {} & \langle \nabla_x L(\lambda, \overline{w}), x - \overline{x} \rangle_{rms} \\ & + \frac{1}{2}\|w - \overline{w}\|_{rms}^2 + \frac{1}{2}c\, \|\mathcal{D}(x - \overline{x}) - \mathcal{B}(u - \overline{u})\|_{rms}^2. \end{aligned} \tag{7.6}$$

Moreover, the pairs $(u, \overline{x})$ lie in Ω_g for all $u \in \mathbb{R}^k$, and thus the growth function γ for $L(\lambda, \cdot)$ satisfies

$$\begin{aligned} \gamma(d) &= \inf\{L(\lambda, w) - L(\lambda, \overline{w}) : w \in \Omega_g \text{ and } \|w - \overline{w}\|_{rms} \geq d\} \\ &\leq \inf\{L(\lambda, (u, \overline{x})) - L(\lambda, (\overline{u}, \overline{x})) : u \in \mathbb{R}^k \text{ and } \|u - \overline{u}\|_{rms} \geq d\} \\ &= \inf\left\{\frac{1}{2}\|u - \overline{u}\|_{rms}^2 + \frac{1}{2}c\, \|\mathcal{B}(u - \overline{u})\|_{rms}^2 : u \in \mathbb{R}^k \text{ and } \|u - \overline{u}\|_{rms} \geq d\right\} \\ &\leq \inf\left\{\frac{1}{2}(1 + c)\|u - \overline{u}\|_{rms}^2 : u \in \mathbb{R}^k \text{ and } \|u - \overline{u}\|_{rms} \geq d\right\} \\ &= \frac{1}{2}(1 + c)d^2, \end{aligned} \tag{7.7}$$

in which case

$$\Gamma = \inf_{d > 0} \frac{\gamma(d)}{d^2} \leq \frac{1}{2}(1 + c)$$

for all k and $\lambda \in \mathbb{R}^{k-1}$, as claimed.

To prove (7.3), note that the augmented Lagrangian $L(\lambda, \cdot)$ in (7.1b) has the partial RMS gradients

$$\nabla_u L(\lambda, w) = u - \mathcal{B}^*(\lambda + c(\mathcal{D}x - \mathcal{B}u)) \tag{7.8a}$$

and

$$\nabla_x L(\lambda, w) = x - x^{ref} + \mathcal{D}^*(\lambda + c(\mathcal{D}x - \mathcal{B}u)), \tag{7.8b}$$

where $\mathcal{D}^*$ and $\mathcal{B}^*$ denote RMS adjoints of the bounded linear operators $\mathcal{D}$ and $\mathcal{B}$. Therefore, for all w^a and w^b in $\mathbb{R}^k \oplus \mathbb{R}^k$, Cauchy's inequality produces

$$\begin{aligned} &\|w^a - w^b\|_{rms} \cdot \|\nabla_w L(\lambda, w^a) - \nabla_w L(\lambda, w^b)\|_{rms} \\ &\quad \geq \langle w^a - w^b, \nabla_w L(\lambda, w^a) - \nabla_w L(\lambda, w^b)\rangle_{rms} = \|w^a - w^b\|^2_{rms} \\ &\qquad\qquad + c\, \|\mathcal{D}(x^a - x^b) - \mathcal{B}(u^a - u^b)\|^2_{rms}, \end{aligned} \tag{7.9}$$

and therefore

$$\begin{aligned} \Lambda &= \sup_{w^a \neq w^b} \frac{\|\nabla_w L(\lambda, w^a) - \nabla_w L(\lambda, w^b)\|_{rms}}{\|w^a - w^b\|_{rms}} \\ &\geq 1 + c \sup_{(\xi,\eta)\neq 0} \frac{\|\mathcal{D}\eta - \mathcal{B}\xi\|^2_{rms}}{\|\xi\|^2_{rms} + \|\eta\|^2_{rms}} \\ &\geq 1 + c \left(\sup_{\|\eta\|_{rms}=1} \|\mathcal{D}\eta\|_{rms} \right)^2 . \end{aligned} \tag{7.10}$$

Now construct $\hat{\eta} \in \mathbb{R}^k$ with $\hat{\eta}_i = (-1)^i$ for $i = 0, 1, \ldots k-1$, and consider that

$$\begin{aligned} \|\hat{\eta}\|^2_{rms} &= \sum_{i=0}^{k-1} [(-1)^i]^2\, \Delta t \\ &= \sum_{i=0}^{k-1} \frac{1}{k} \\ &= 1 \end{aligned} \tag{7.11}$$

and

$$\begin{aligned} \|\mathcal{D}\hat{\eta}\|^2_{rms} &= \sum_{i=0}^{k-2} \left(\frac{\hat{\eta}_{i+1} - \hat{\eta}_i}{\Delta t} \right)^2 \Delta t \\ &= \frac{k-1}{k} \left(\frac{2}{\Delta t} \right)^2 \\ &\geq \frac{2}{\Delta t^2} \end{aligned} \tag{7.12}$$

for all $k \geq 2$ and $\lambda \in \mathbb{R}^{k-1}$ (cf. Note 1). Thus,

$$\Lambda \geq 1 + 2 \left(\frac{c}{\Delta t^2} \right) \tag{7.13}$$

for $0 < \Delta t \leq \frac{1}{2}$ and $\lambda \in \mathbb{R}^{k-1}$, as claimed.

Note 4. If c is decreased to keep $c/\Delta t^2$ constant as $\Delta t \to 0$, then the Lipschitz norms Λ in (7.3) need not increase without bound and the AGP inner loop geometric convergence ratios ν in (7.4) may remain bounded away from 1. On the other hand, such reductions in c would quickly destroy convergence of the Hestenes–Powell multiplier iteration

$$\lambda_i^{(j+1)} = \lambda_i^{(j)} + c\left(\frac{x_{i+1}^{(j+1)} - x_i^{(j+1)}}{\Delta t} - f(t_i, u_i^{(j+1)}, x_i^{(j+1)})\right),$$

and other AGP outer loop multiplier update formulas. Note that the c-reduction scheme just described amounts to employing augmented Lagrangian and multiplier update formulas in which λ is replaced by $\hat{\lambda} = \lambda/\Delta t$, c is replaced by $\hat{c} = c/\Delta t^2$, the "rate" form of the Euler discrete-time equality constraint function is replaced by the difference form,

$$h(u,x)_i = x_{i+1} - x_i - f(t_i, u_i, x_i)\,\Delta t,$$

and $\hat{c}$ is kept constant as $\Delta t \to 0$. To maintain adequate AGP outer loop convergence in this scheme, it would be necessary to *increase* $\hat{c}$ as $\Delta t \to 0$, and this would drive the inner loop GP convergence ratios ν toward 1 as before.

The inequality (7.4) for ν immediately yields a corresponding lower bound N_ϵ on the number of GP iterations needed to make the error estimate ν^j in (6.7) smaller than some fixed value $\epsilon \in (0,1]$, namely,

$$\begin{aligned} N_\epsilon &> \frac{|\ln \epsilon|}{|\ln(1-\beta\Delta t^2)|} \\ &\geq \frac{3|\ln\epsilon|}{4\beta}\left(\frac{1}{\Delta t^2}\right) \\ &= \frac{3|\ln\epsilon|}{4\beta}k^2 \end{aligned} \tag{7.14}$$

for $k \geq 2$. Since the cost of computing one GP iterate for discrete-time optimal control problems is proportional to k, the estimate (7.14) suggests that the total number of FLOPS required to make the AGP inner loop errors $r = L(\lambda, w) - L(\lambda, \overline{w})$ smaller than a fixed threshold ϵ may increase like k^3. Direct comparisons with the numerical results in [17] are not possible here since the exact solution for the example in [17] is unknown and it was therefore necessary to terminate inner loop AGP iterations on small computed residuals related to the first order necessary conditions. Nevertheless, the monotonically increasing concave graphs of FLOPS versus k in [17] are again qualitatively like the potential $O(k^3)$ growth admitted by the present analysis.

8. Mesh-invariant rate estimates in formulation II. In the convergence theorems of this section, the discrete-time cost functions $J(\cdot)$ in (4.10a) are required to be RMS strongly convex and Lipschitz continuously differentiable uniformly in the mesh width Δt (i.e., uniformly in the number k of mesh points). Related mesh-invariant RMS strong convexity and gradient Lipschitz continuity conditions can then be deduced for the associated discrete-time augmented Lagrangians (5.12c) and reduced augmented Lagrangians (5.17b). By Theorems 6.1 and 6.2, the Lagrangian properties then support mesh-invariant geometric convergence rate estimates for the related AGP and RAGP inner loop iterations.

The required mesh-invariant properties for J in (4.10a) are implied by a k-uniform boundedness property of the discrete-time state transition operators Θ defined in (4.5)–(4.6) and by certain t-uniform convexity and gradient Lipschitz continuity conditions on the continuous-time running loss functions $f^0(t,\cdot)$, $t \in [0,1]$.

LEMMA 8.1. *For each positive integer $k \geq 2$, let $\Theta : \mathbb{R}^{km} \to \mathbb{R}^{kn}$ be the bounded linear operator in the discrete-time state equation solution* (4.5)–(4.6) *with RMS norm*

$$\|\Theta\|_{rms} = \sup_{\|u\|_{rms}=1} \|\Theta u\|_{rms}. \tag{8.1}$$

In addition, let

$$a = \sup_{t\in[0,1]} \|A(t)\| < \infty, \qquad b = \sup_{t\in[0,1]} \|B(t)\| < \infty, \tag{8.2}$$

where $A(t) : \mathbb{R}^n \to \mathbb{R}^n$ and $B(t) : \mathbb{R}^m \to \mathbb{R}^n$ are the uniformly bounded coefficient operators in the continuous-time rate functions (2.4) *and $\|\cdot\|$ denotes the associated Euclidean operator norm in either case. Then*

$$\text{for all } k \geq 2, \qquad \|\Theta\|_{rms} \leq b \ \exp a. \tag{8.3}$$

Proof. By a straightforward application of (4.5)–(4.7), Cauchy's inequality, the formula $\sum_{i=1}^{n}, \ i = n(n+1)/2$, and the estimate, $(1 + a/k)^k < \exp a$ for $a > 0$ and all positive integers k. □

LEMMA 8.2. *For $t \in [0,1]$, let $f^0(t,\cdot) : \mathbb{R}^m \oplus \mathbb{R}^n \to \mathbb{R}^1$ be the running loss functions in* (4.10a) *for the discrete-time cost functions $J(\cdot) : \mathbb{R}^{km} \to \mathbb{R}^1$ in formulation* II. *Put $\zeta = (\xi, \eta) \in \mathbb{R}^m \oplus \mathbb{R}^n$ and let $\nabla_\zeta f^0(t,\zeta)$ denote the standard Euclidean gradient of $f^0(t,\cdot)$ at ζ. Assume that there are numbers $\mu_0 > 0$ and $\Lambda_0 \geq 0$ such that for all $t \in [0,1]$ and all ζ^a and ζ^b in $\mathbb{R}^m \oplus \mathbb{R}^n$,*

$$\langle \nabla_\zeta f^0(t,\zeta^a) - \nabla_\zeta f^0(t,\zeta^b), \zeta^a - \zeta^b \rangle \geq \mu_0 \ \|\xi^a - \xi^b\|^2, \tag{8.4}$$

and

$$\|\nabla_\zeta f^0(t,\zeta^a) - \nabla_\zeta f^0(t,\zeta^b)\| \leq \Lambda_0 \ \|\zeta^a - \zeta^b\|, \tag{8.5}$$

where $\langle\cdot,\cdot\rangle$ is the Euclidean inner product on $\mathbb{R}^m \oplus \mathbb{R}^n$, and $\|\cdot\|$ signifies the norm on $\mathbb{R}^m$ and $\mathbb{R}^m \oplus \mathbb{R}^n$ in (8.4) *and* (8.5), *respectively. Then $J(\cdot)$ is strongly convex and Lipschitz continuously differentiable in the RMS sense,* uniformly for all positive integers $k \geq 2$. *More precisely, there are numbers $\mu_J > 0$ and $\Lambda_J \geq 0$ such that for all $k \geq 2$ and all u^a and u^b in $\mathbb{R}^{km}$,*

$$\langle \nabla J(u^a) - \nabla J(u^b), u^a - u^b \rangle_{rms} \geq \mu_J \ \|u^a - u^b\|_{rms}^2 \tag{8.6}$$

and

$$\|\nabla J(u^a) - \nabla J(u^b)\|_{rms} \leq \Lambda_J \ \|u^a - u^b\|_{rms}. \tag{8.7}$$

Proof. Let $\theta \in \mathbb{R}^{kn}$ and $\Theta : \mathbb{R}^{km} \to \mathbb{R}^{kn}$ be the vector and bounded linear operator in the discrete-time state equation solution formula (4.5)–(4.6). For $u \in \mathbb{R}^{km}$, define $\alpha_u(u) \in \mathbb{R}^{km}$ and $\alpha_x(u) \in \mathbb{R}^{kn}$ by the rules

$$\alpha_u(u)_i = \nabla_\xi f^0(t_i, u_i, \phi(u)_i), \qquad \alpha_x(u)_i = \nabla_\eta f^0(t_i, u_i, \phi(u)_i) \tag{8.8}$$

for $i = 0, \dots, k-1$, where $\nabla_\xi f^0$ and $\nabla_\eta f^0$ are the (ξ, η) components of $\nabla_\zeta f^0$. In addition, let $\Theta^* : \mathbb{R}^{kn} \to \mathbb{R}^{km}$ denote the RMS bounded linear adjoint operator for Θ, i.e., for all $x \in \mathbb{R}^{kn}$ and $u \in \mathbb{R}^{km}$,

$$\langle x, \Theta u \rangle_{rms} = \langle \Theta^* x, u \rangle_{rms}, \tag{8.9}$$

where $\langle \cdot, \cdot \rangle_{rms}$ signifies the RMS inner product in $\mathbb{R}^{kn}$ and $\mathbb{R}^{km}$ on the left and right sides of (8.9), respectively. Then for all $u \in \mathbb{R}^{km}$, the corresponding RMS gradient of $J(\cdot)$ is readily shown to be

$$\nabla J(u) = \alpha_u(u) + \Theta^* \alpha_x(u). \tag{8.10}$$

Hence for all u^a and u^b in $\mathbb{R}^{km}$, conditions (8.4) and (8.9) imply that

$$\begin{aligned}\langle \nabla J(u^a) - \nabla J(u^b), u^a - u^b \rangle_{rms} &\geq \langle \alpha_u(u^a) - \alpha_u(u^b), u^a - u^b \rangle_{rms} \\ &\qquad + \langle \alpha_x(u^a) - \alpha_x(u^b), \Theta(u^a - u^b) \rangle_{rms} \\ &= \langle \alpha_u(u^a) - \alpha_u(u^b), u^a - u^b \rangle_{rms} \\ &\qquad + \langle \alpha_x(u^a) - \alpha_x(u^b), \phi(u^a) - \phi(u^b) \rangle_{rms} \\ &\geq \mu_0 \, \|u^a - u^b\|^2_{rms}.\end{aligned}$$

Furthermore, since it is known that $\|\Theta^*\|_{rms} = \|\Theta\|_{rms}$, condition (8.5) yields

$$\begin{aligned}\|\nabla J(u^a) - \nabla J(u^b)\|^2_{rms} &\leq 2(\|\alpha_u(u^a) - \alpha_u(u^b)\|^2 + \|\Theta^*(\alpha_x(u^a) - \alpha_x(u^b))\|^2_{rms}) \\ &\leq 2 \ \max\{1, \|\Theta^*\|^2_{rms}\}(\|\alpha_u(u^a) - \alpha_u(u^b)\|^2_{rms} \\ &\qquad + \|\alpha_x(u^a) - \alpha_x(u^b)\|^2_{rms}) \\ &\leq 2 \ \max\{1, \|\Theta\|^2_{rms}\} \Lambda_0^2 \ (\|u^a - u^b\|^2_{rms} \\ &\qquad + \|\phi(u^a) - \phi(u^b)\|^2_{rms}) \\ &= 2 \ \max\{1, \|\Theta\|^2_{rms}\} \Lambda_0^2 \ (\|u^a - u^b\|^2_{rms} \\ &\qquad + \|\Theta(u^a - u^b)\|^2_{rms}) \\ &\leq 2 \ \max\{1, \|\Theta\|^2_{rms}\}(1 + \|\Theta\|^2_{rms}) \Lambda_0^2 \ \|u^a - u^b\|^2_{rms}.\end{aligned}$$

With reference to Lemma 8.1, these estimates now give (8.6) and (8.7) with $\mu_J = \mu_0$ and $\Lambda_J = \Lambda_0 \sqrt{2 \max\{1, b^2 \exp 2a\}(1 + b^2 \exp 2a)}$. □

Note 5. The t-uniform convexity and Lipschitz continuity conditions (8.4) and (8.5) are satisfied by the prototype autonomous LQR loss function

$$f^0(t, \xi, \eta) = \frac{1}{2} \ \langle \xi, S\xi \rangle + \frac{1}{2} \ \langle \eta, Q\eta \rangle$$

when $S : \mathbb{R}^m \to \mathbb{R}^m$ is a symmetric positive-definite bounded linear operator and $Q : \mathbb{R}^n \to \mathbb{R}^n$ is a symmetric positive-semidefinite bounded linear operator.

Note 6. The linear operator Θ in the continuous-time state equation solution (3.6) is bounded in the $\mathbb{L}^2$ sense, and an $\mathbb{L}^2$ counterpart of Lemma 8.2 can therefore be proved for the continuous-time cost function $J(\cdot)$ in (3.4a) of formulation II, provided that measurabilty restrictions of the Carathéodory type [8], [1] for $f^0(\cdot, \zeta)$ are added to the hypotheses on $f^0(t, \cdot)$ in (8.4) and (8.5).

8.1. Unseparated pointwise constraints. The following key lemma establishes (k, λ)-uniform RMS strong convexity and Lipschitz continuity results for the discrete-time augmented Lagrangians in formulation II. These results lead directly to a mesh-invariant and λ-invariant AGP inner loop convergence rate estimate in closed convex feasible sets $\Omega_g \subset \mathbb{R}^{km} \oplus \mathbb{R}^{kn}$ prescribed by general unseparated continuous quasi-convex inequality constraint functions $\gamma(t,\cdot) : \mathbb{R}^m \oplus \mathbb{R}^n \to \mathbb{R}^r$.

LEMMA 8.3. *Assume that the discrete-time cost functions* $J(\cdot) : \mathbb{R}^{km} \to \mathbb{R}^1$ *defined by* (4.10*a*) *in formulation* II *are convex, with gradients that satisfy the* k*-uniform RMS strong monotonicity and Lipschitz continuity conditions* (8.6) *and* (8.7). *Then the corresponding augmented Lagrangians* $L(\lambda,\cdot) : \mathbb{R}^{km} \oplus \mathbb{R}^{kn} \to \mathbb{R}^1$ *in* (5.12c) *satisfy analogous conditions uniformly for* $k \geq 2$ *and* $\lambda \in \mathbb{R}^{kn}$. *More precisely, for all* $k \geq 2$, $\lambda \in \mathbb{R}^{kn}$, *and* w^a *and* w^b *in* $\mathbb{R}^{km} \oplus \mathbb{R}^{kn}$,

$$\langle \nabla L(\lambda, w^a) - \nabla L(\lambda, w^b), w^a - w^b \rangle_{rms} \geq \mu_L \, \|w^a - w^b\|^2_{rms} \tag{8.11a}$$

with

$$\mu_L = \frac{c\,\mu_J}{\mu_J + c\,(1 + b^2 \exp 2a)} \tag{8.11b}$$

and

$$\|\nabla L(\lambda, w^a) - \nabla L(\lambda, w^b)\|_{rms} \leq \Lambda_L \, \|w^a - w^b\|_{rms} \tag{8.12a}$$

with

$$\Lambda_L = \Lambda_J + c\,\sqrt{2 \max\{1, b^2 \exp 2a\}(1 + b^2 \exp 2a)}, \tag{8.12b}$$

where a *and* b *are the coefficient bounds in Lemma* 8.1.

Proof. Let $F(\lambda, u, v)$ denote the shifted penalty term in the augmented Lagrangians (5.12c), i.e.,

$$F(\lambda, u, v) = \frac{1}{2} c \, \left\| \frac{\lambda}{c} + \Theta u + \theta - v \right\|^2_{rms}. \tag{8.13}$$

Then for all $w = (u, v) \in \mathbb{R}^{km} \oplus \mathbb{R}^{kn}$,

$$\nabla_w L(\lambda, w) = (\nabla J(u) + \nabla_u F(\lambda, u, v) \, , \, \nabla_v F(\lambda, u, v)) \tag{8.14a}$$

with

$$\nabla_u F(\lambda, u, v) = c\,\Theta^* \, \left(\frac{\lambda}{c} + \Theta u + \theta - v \right), \tag{8.14b}$$

$$\nabla_v F(\lambda, u, v) = -c \, \left(\frac{\lambda}{c} + \Theta u + \theta - v \right). \tag{8.14c}$$

Hence,

$$\begin{aligned} &\langle \nabla_w L(\lambda, w^a) - \nabla_w L(\lambda, w^b), w^a - w^b \rangle_{rms} \geq \mu_J \|u^a - u^b\|^2_{rms} \\ &+c\,(\|\Theta(u^a - u^b)\|^2_{rms} - 2\|\Theta(u^a - u^b)\|_{rms}\|v^a - v^b\|_{rms} + \|v^a - v^b\|^2_{rms}). \end{aligned} \tag{8.15}$$

Let $\xi = u^a - u^b$ and $\eta = v^a - v^b$, and observe that $\|\Theta\xi\|_{rms} \leq \|\Theta\|_{rms}\|\xi\|_{rms}$. Then for any fixed $\epsilon > 0$, the right side of the inequality (8.15) is bounded below by

$$(\mu_J - \epsilon c\, \|\Theta\|^2_{rms})\|\xi\|^2_{rms} + c\,((1 + \epsilon)\|\Theta\xi\|^2_{rms} - 2\|\Theta\xi\|_{rms}\|\eta\|_{rms} + \|\eta\|^2_{rms}). \tag{8.16}$$

Consider that the polynomial $(1+\epsilon)z^2 - 2z + 1$ has the minimum value $\epsilon/(1+\epsilon)$ in $\mathbb{R}^1$. This fact and the k-uniform upper bound for $\|\Theta\|_{rms}$ in Lemma 8.1 proves that the expression in (8.16) is itself bounded below by

$$(\mu_J - \epsilon c\, b^2 \exp 2a)\|\xi\|_{rms}^2 + \frac{c\,\epsilon}{1+\epsilon}\|\eta\|_{rms}^2 \tag{8.17}$$

for all $\epsilon > 0$, $k \geq 2$ and all (ξ, η) in $\mathbb{R}^{km} \oplus \mathbb{R}^{kn}$. The estimate (8.11) is now obtained by verifying that

$$\max_{\epsilon>0}\ \min\left\{\mu_J - \epsilon c\, b^2 \exp 2a, \frac{c\,\epsilon}{1+\epsilon}\right\} = \frac{c\,\mu_J}{\frac{\mu_J + c\,(1+b^2\exp 2a)}{2} + \sqrt{(\frac{\mu_J + c\,(1+b^2\exp 2a)}{2})^2 - c\,\mu_J}}$$
$$\geq \frac{c\,\mu_J}{\mu_J + c\,(1+b^2\exp 2a)}.$$

To prove (8.12), note that by (8.14)

$$\begin{aligned}\|\nabla_w L(\lambda, w^a) - \nabla_w L(\lambda, w^b)\|_{rms} &\leq \Lambda_J \|u^a - u^b\|_{rms} \\ &\quad + c\,\sqrt{1 + \|\Theta^*\|_{rms}^2}\|\Theta(u^a - u^b) - (v^a - v^b)\|_{rms}.\end{aligned} \tag{8.18}$$

Moreover, since $\|\Theta^*\|_{rms} = \|\Theta\|_{rms}$ and

$$\|\Theta(u^a - u^b) - (v^a - v^b)\|_{rms}^2 \leq 2(\|\Theta\|_{rms}^2\|u^a - u^b\|_{rms}^2 + \|v^a - v^b\|_{rms}^2),$$

it now follows from Lemma 8.1 that the right side of the inequality (8.18) is bounded above by

$$[\Lambda_J + c\,\sqrt{2\max\{1, b^2\exp 2a\}(1 + b^2\exp 2a)}\ ]\ \|w^a - w^b\|_{rms}$$

for all $k \geq 2$, $\lambda \in \mathbb{R}^{kn}$, and w^a and w^b in $\mathbb{R}^{km} \oplus \mathbb{R}^{kn}$. □

THEOREM 8.4. *Assume that the discrete-time cost functions $J(\cdot) : \mathbb{R}^{km} \to \mathbb{R}^1$ defined by* (4.10a) *in formulation II are convex with gradients that satisfy the k-uniform RMS strong monotonicity and Lipschitz continuity conditions* (8.6) *and* (8.7). *Suppose that the inequality constraint functions $\gamma(t, \cdot) : \mathbb{R}^m \oplus \mathbb{R}^n \to \mathbb{R}^r$ that prescribe the relaxed feasible sets $\Omega_g \subset \mathbb{R}^{km} \oplus \mathbb{R}^{kn}$ in* (5.12b) *are continuous and quasi-convex for all $t \in [0,1]$. Let $L(\lambda, \cdot) : \mathbb{R}^{km} \oplus \mathbb{R}^{kn} \to \mathbb{R}^1$ denote the augmented Lagrangians in* (5.12c). *Then for each $k \geq 2$ and $\lambda \in \mathbb{R}^{kn}$, the relaxed NLP* (5.12) *has a corresponding unique solution $\overline{w}(\lambda)$. Moreover, let $\{w^{(j)}\}$ be any sequence in Ω_g generated by the AGP inner loop iteration* (5.6)–(5.7), *and let $r_j = L(\lambda, w^{(j)}) - L(\lambda, \overline{w}(\lambda))$. Then for all $k \geq 2$ and $\lambda \in \mathbb{R}^{kn}$, the sequence $\{r_j\}$ converges geometrically to zero with*

$$0 \leq \frac{r_j}{r_0} \leq (\nu_L)^j, \qquad j = 0, 1, 2, \ldots, \tag{8.19a}$$

where

$$\nu_L = 1 - \frac{2\mu_L\sigma_L\delta}{(\sqrt{1 + 2\mu_L\sigma_L} + 1)^2}, \tag{8.19b}$$

$$\sigma_L = \min\left\{\alpha, \frac{2\beta(1-\delta)}{\Lambda_L}\right\}, \tag{8.19c}$$

and μ_L and Λ_L are the (k, λ)-invariant numbers in Lemma 8.3.

Proof. Immediate from Lemma 8.3, and Theorems 6.1 and 6.2. □

8.2. Separated pointwise constraints. An RAGP counterpart of Theorem 8.4 is established below for problems with separated inequality constraint functions $\gamma(t,\cdot) = (\gamma^u(t,\cdot), \gamma^x(t,\cdot))$ that have continuous quasi-convex components $\gamma^u(t,\cdot) : \mathbb{R}^m \to \mathbb{R}^{r_u}$ and $\gamma^u(t,\cdot) : \mathbb{R}^n \to \mathbb{R}^{r_x}$ for $t \in [0,1]$. The following lemmas are needed in this development.

LEMMA 8.5. *Let Y be a nonempty convex set in $\mathbb{R}^N$ that is closed relative to a norm $\|\cdot\|$ induced by some inner product $\langle\cdot,\cdot\rangle$. Define $g : \mathbb{R}^N \oplus \mathbb{R}^N \to \mathbb{R}^1$ and $\hat{g} : \mathbb{R}^N \to \mathbb{R}^1$ by the rules*

$$g(x,y) = \frac{1}{2}\,\|x-y\|^2$$

and

$$\hat{g} = \min_{y\in Y}\; g(x,y),$$

and let $P_Y(x)$ denote the unique minimizer of $g(x,\cdot)$ in Y. Then $\hat{g}(\cdot)$ is Lipschitz continuously differentiable relative to $\|\cdot\|$, and the formula

$$\nabla\hat{g}(x) = \nabla_x g(x, P_Y) = x - P_Y(x) \tag{8.20}$$

prescribes the gradient of $\hat{g}(\cdot)$ relative to the inner product $\langle\cdot,\cdot\rangle$.

Proof. Since $\{\mathbb{R}^N, \langle\cdot,\cdot\rangle, \|\cdot\|\}$ is a Hilbert space, the projection theorem establishes the existence and uniqueness of the proximal point map P_Y. If the closed set Y is bounded and hence compact, then the assertions of the lemma follow directly from results in [9] and [10]. On the other hand, suppose that Y is not bounded. Fix $x_0 \in \mathbb{R}^N$ and $\delta_0 > 0$, and put $\rho_0 = \|x_0 - P_Y(x_0)\| + \delta_0$. By the triangle inequality and the nonexpansive property for P_Y [26], it follows that for $\|x - x_0\| < \delta_0$,

$$\begin{aligned}\|x_0 - P_Y(x)\| &\le \|x_0 - P_Y(x_0)\| + \|P_Y(x_0) - P_Y(x)\|\\ &\le \|x_0 - P_Y(x_0)\| + \|x_0 - x\|\\ &\le \rho_0\end{aligned}$$

and therefore

$$\hat{g}(x) = \min_{y\in Y(\rho_0)}\; g(x,y),$$

where $Y(\rho_0)$ is the compact set $\{y \in Y : \|y - x_0\| \le \rho_0\}$. But in this case, the assertions of the lemma follow again from trivial adjustments to the proofs in [9] and [10].

Finally, note that if (8.20) holds, then $\nabla\hat{g}(\cdot)$ is Lipschitz continuous with

$$\begin{aligned}\|\nabla\hat{g}(x_1) - \nabla\hat{g}(x_2)\| &\le \|x_1 - x_2\| + \|P_Y(x_1) - P_Y(x_2)\|\\ &\le 2\,\|x_1 - x_2\|\end{aligned} \tag{8.21}$$

for all x_1 and x_2. □

LEMMA 8.6. *Suppose that the relaxed feasible sets $\Omega_g \subset \mathbb{R}^{km} \oplus \mathbb{R}^{kn}$ are Cartesian products $\Omega_g^u \times \Omega_g^v$ prescribed by separated continuous quasi-convex inequality constraint functions in* (5.15). *Assume that the discrete-time cost functions $J(\cdot) : \mathbb{R}^{km} \to \mathbb{R}^1$ defined by equation* (4.10a) *in formulation* II *are convex with gradients that satisfy the k-uniform RMS strong monotonicity and Lipschitz continuity conditions* (8.6) *and*

(8.7). *Then the corresponding reduced augmented Lagrangians* $\hat{L}(\lambda,\cdot):\mathbb{R}^{km}\to\mathbb{R}^1$ *in* (5.17b) *satisfy analogous conditions uniformly for* $k\geq 2$ *and* $\lambda\in\mathbb{R}^{kn}$*. More precisely, for all* $k\geq 2$*,* $\lambda\in\mathbb{R}^{kn}$*, and* u^a *and* u^b *in* $\mathbb{R}^{km}$*,*

$$\langle\nabla\hat{L}(\lambda,u^a)-\nabla\hat{L}(\lambda,u^b),u^a-u^b\rangle_{rms}\geq\mu_{\hat{L}}\;\|u^a-u^b\|^2_{rms}\tag{8.22a}$$

with

$$\mu_{\hat{L}}=\mu_J\tag{8.22b}$$

and

$$\|\nabla\hat{L}(\lambda,u^a)-\nabla\hat{L}(\lambda,u^b)\|_{rms}\leq\Lambda_{\hat{L}}\;\|u^a-u^b\|_{rms}\tag{8.23a}$$

with

$$\Lambda_{\hat{L}}=\Lambda_J+\sqrt{2}cb^2\exp 2a.\tag{8.23b}$$

Proof. For $\lambda\in\mathbb{R}^{kn}$ and $u\in\mathbb{R}^{km}$, let

$$\hat{F}(\lambda,u)=\min_{v\in\Omega_g^v}\;F(\lambda,u,v),$$

where $F(\lambda,u,v)$ is the shifted penalty term (8.13) in the augmented Lagrangians (5.12c). Then

$$\hat{F}(\lambda,u)=J(u)+\hat{F}(\lambda,u)-\frac{1}{2}c\;\left\|\frac{\lambda}{c}\right\|^2_{rms}.\tag{8.24}$$

By Lemma 8.5 and the chain rule, $\hat{F}(\lambda,\cdot)$ is Lipschitz continuously differentiable with

$$\nabla_u\hat{F}(\lambda,u)=c\;\Theta^*\left(\frac{\lambda}{c}+\Theta u+\theta-P_{\Omega_g^v}\left(\frac{\lambda}{c}+\Theta u+\theta\right)\right).\tag{8.25}$$

For u^a and u^b in $\mathbb{R}^{km}$, put $x^a=\frac{\lambda}{c}+\Theta u^a+\theta$ and $x^b=\frac{\lambda}{c}+\Theta u^b+\theta$. Since $P_{\Omega_g^v}$ is nonexpansive and monotone nondecreasing [26], [32], and $\|\Theta^*\|_{rms}=\|\Theta\|_{rms}$, it follows from (8.25) and Lemma 8.1 that for all $k\geq 2$, $\lambda\in\mathbb{R}^{km}$, and u^a and u^b in $\mathbb{R}^{km}$,

$$\begin{aligned}&\langle\nabla_u\hat{F}(\lambda,u^a)-\nabla_u\hat{F}(\lambda,u^b),u^a-u^b\rangle_{rms}=c\;\|\Theta(u^a-u^b)\|^2_{rms}\\&-c\;\langle P_{\Omega_g^v}(x^a)-P_{\Omega_g^v}(x^b),\Theta(u^a-u^b)\rangle_{rms}\geq c\;\|\Theta(u^a-u^b)\|^2_{rms}\\&-\|P_{\Omega_g^v}(x^a)-P_{\Omega_g^v}(x^b)\|_{rms}\;\|\Theta(u^a-u^b)\|_{rms}\geq 0\end{aligned}\tag{8.26}$$

and

$$\begin{aligned}\|\nabla_u\hat{F}(\lambda,u^a)-\nabla_u\hat{F}(\lambda,u^b)\|^2_{rms}\leq{}&c^2\|\Theta^*\|^2_{rms}(\|\Theta(u^a-u^b)\|^2_{rms}\\&-2\langle x^a-x^b,P_{\Omega_g^v}(x^a)-P_{\Omega_g^v}(x^b)\rangle\\&+\|P_{\Omega_g^v}(x^a)-P_{\Omega_g^v}(x^b)\|^2_{rms})\\\leq{}&2c^2(b^2\exp 2a)^2\|u^a-u^b\|^2_{rms}.\end{aligned}\tag{8.27}$$

The (k,λ)-uniform estimates (8.22) and (8.23) are immediate consequences of (8.26), (8.27), (8.24), and the hypotheses for $J(\cdot)$. □

THEOREM 8.7. *Suppose that the relaxed feasible sets* $\Omega_g \subset \mathbb{R}^{km} \oplus \mathbb{R}^{kn}$ *are Cartesian products* $\Omega_g^u \times \Omega_g^v$ *prescribed by separated continuous quasi-convex inequality constraint functions in* (5.16)*. Assume that the discrete-time cost functions* $J(\cdot) : \mathbb{R}^{km} \to \mathbb{R}^1$ *defined by* (4.10a) *in formulation* II *are convex with gradients that satisfy the k-uniform RMS strong monotonicity and Lipschitz continuity conditions* (8.6) *and* (8.7)*. Let* $\hat{L}(\lambda, \cdot) : \mathbb{R}^{km} \to \mathbb{R}^1$ *denote the reduced augmented Lagrangians in* (5.17b)*. Then for each* $k \geq 2$ *and* $\lambda \in \mathbb{R}^{kn}$*, the reduced NLP* (5.17) *has a corresponding unique solution* $\overline{u}(\lambda)$*. Moreover, let* $\{u^{(j)}\}$ *be any sequence in* Ω_g^u *generated by the RAGP counterpart of the inner loop iteration* (5.6)–(5.7) *for* (5.17) *and let* $r_j = \hat{L}(\lambda, u^{(j)}) - \hat{L}(\lambda, \overline{u}(\lambda))$*. Then for all* $k \geq 2$ *and* $\lambda \in \mathbb{R}^{kn}$*, the sequence* $\{r_j\}$ *converges geometrically to zero with*

$$0 \leq \frac{r_j}{r_0} \leq (\nu_{\hat{L}})^j, \qquad j = 0, 1, 2, \ldots, \tag{8.28a}$$

where

$$\nu_{\hat{L}} = 1 - \frac{2\mu_{\hat{L}}\sigma_{\hat{L}}\delta}{(\sqrt{1 + 2\mu_{\hat{L}}\sigma_{\hat{L}}} + 1)^2}, \tag{8.28b}$$

$$\sigma_{\hat{L}} = \min\left\{\alpha, \frac{2\beta(1-\delta)}{\Lambda_{\hat{L}}}\right\}, \tag{8.28c}$$

and $\mu_{\hat{L}}$ *and* $\Lambda_{\hat{L}}$ *are the* (k, λ)*-invariant constants in Lemma* 8.6.

Proof. Immediate from Lemma 8.6 and Theorems 6.1 and 6.2. □

Note 7. As $c \to \infty$, the growth constants μ_L and $\mu_{\hat{L}}$ in Theorems 8.4 and 8.7 remain bounded, the Lipschitz constants Λ_L and $\Lambda_{\hat{L}}$ increase without bound, and the corresponding (k, λ)-invariant AGP and RAGP inner loop convergence rate factors ν_L and $\nu_{\hat{L}}$ approach 1. Moreover, this deterioration in convergence rate bounds is reflected in the actual convergence rate properties of the subject algorithms in formulation II. Augmented Lagrangian methods in formulation I are also adversely affected by large values of c, although the estimates in section 7 are too crude to show this. In fact, such large penalty constant ill-conditioning is a familiar feature of unscaled augmented Lagrangian methods applied to general NLPs, and preconditioning schemes designed specifically to address this issue for penalized objective functions have been proposed in [25], [20], and [21]. In the present optimal control context, the implementation of such methods remain to be explored. (See the final paragraph in section 1 for additional comments on the application of these preconditioners to control problems in formulation I.) Note that the estimates in Theorems 8.4 and 8.7 also predict deteriorating convergence rates for the AGP and RAGP methods when the state transition operator norms $\|\Theta\|_{rms}$ are large compared to 1.

Note 8. For optimal control problems with separated simple pointwise inequality constraints (e.g., bounds on the components of the state and control vectors), the RAGP iteration map typically costs significantly less to compute than its AGP counterpart. What is more, the estimates in Theorems 8.4 and 8.7 indicate that the RAGP method may have a convergence rate advantage over AGP as well, in cases where both methods are applicable. To see this, observe that

$$\begin{aligned}\Lambda_L &= \Lambda_J + c\sqrt{2\ \max\{1, b^2 \exp 2a\}(1 + b^2 \exp 2a)} \\ &\geq \Lambda_J + \sqrt{2}cb^2 \exp 2a \\ &= \Lambda_{\hat{L}},\end{aligned}$$

and therefore

$$\begin{aligned}\sigma_L &= \min\left\{\alpha, \frac{2\beta(1-\delta)}{\Lambda_L}\right\}\\ &\le \min\left\{\alpha, \frac{2\beta(1-\delta)}{\Lambda_{\hat{L}}}\right\}\\ &= \sigma_{\hat{L}}.\end{aligned}$$

Moreover,

$$\begin{aligned}\mu_L &= \frac{c\,\mu_J}{\mu_J + c\,(1 + b^2 \exp 2a)}\\ &< \frac{\mu_J}{1 + b^2 \exp 2a}\\ &= \frac{\mu_{\hat{L}}}{1 + b^2 \exp 2a}.\end{aligned}$$

Consequently,

$$\mu_L \sigma_L < \frac{\mu_{\hat{L}} \sigma_{\hat{L}}}{1 + b^2 \exp 2a},$$

and therefore $\nu_{\hat{L}} < \nu_L < 1$. It remains to be shown that this disparity in convergence rate *estimates* reflects the actual convergence behavior observed in numerical implementations of AGP and RAGP methods for the class of optimal control problems treated here.

Note 9. Reference [19] describes effective alternative primal/dual Lagrangian algorithms for specially structured fine-mesh ill-conditioned discrete-time optimal control problems.

ON A CLASS OF DIFFEOMORPHIC MATCHING PROBLEMS IN ONE DIMENSION*

ALAIN TROUVÉ[†] AND LAURENT YOUNES[‡]

Abstract. We study a class of functional which can be used for matching objects which can be represented as mappings from a fixed interval, I, to some "feature space." This class of functionals corresponds to "elastic matching" in which a symmetry condition and a "focus invariance" are imposed. We provide sufficient conditions under which an optimal matching can be found between two such mappings, the optimal matching being a homeomorphism of the interval I. The differentiability of this matching is also studied, and an application to plane curve comparison is provided.

Key words. calculus of variations, shape representation and recognition, elastic matching, geodesic distance

AMS subject classifications. Primary, 49J45; Secondary, 68T10, 53A04

1. Introduction.

In many applications, objects of interest can be represented as numerical functions θ which are defined on some interval $I \subset \mathbb{R}$ and take values in $\mathbb{R}^d$. Several examples may come from signal processing, in which measurements are made during a certain time interval (e.g., speech recognition), analysis of one-dimensional (1D) geological data (e.g., measurements in wells, I being a depth interval), or shape recognition, in which an object can represent a two-dimensional (2D) or three-dimensional (3D) curve.

A problem one typically has to face when dealing with such *functional objects* is to find ways to compare them. This comparison problem is most of the time posed as a *matching problem*, which may be described as "finding similar structures appearing at similar places (or similar times)." To be more explicit, given two "objects" θ and θ', expressed as functions defined on the same interval I, the issue is to find, for each $x \in I$, some $x' \in I$ such that $x \simeq x'$ and $\theta(x) \simeq \theta'(x')$. The matching is *consistent* if the correspondence $x \mapsto x'$ is one-to-one, i.e., there cannot be two distinct locations on θ which are associated to the same location on θ'; it is *complete* if each location in θ is matched to some location in θ', and *bicomplete* if, in addition, each location in θ' is matched to some location in θ. Consistent bicomplete matchings thus can be represented by bijections $\phi : I \to I$, and the matching problem can be formulated as finding such a ϕ such that $\phi \simeq \mathrm{id}$ (where id is the identity function $x \mapsto x$) and $\theta \simeq \theta' \circ \phi$ (in this last sentence, $\simeq$ must be understood as "as close as possible to").

A common approach to realize this program is to minimize some functional $L_{\theta,\theta'}(\phi)$ which is small when the requirements above are satisfied. One simple example is (letting $\dot\phi = \frac{d\phi}{dx}$)

$$L_{\theta,\theta'}(\phi) = \int_I (\dot\phi - 1)^2 dx + \lambda \int_I (\theta(x) - \theta' \circ \phi(x))^2 dx, \tag{1.1}$$

and many functionals which are used in the literature fall into this category, with some variations. One of the drawbacks in this formulation is the lack of symmetry in θ and θ'. In general, matching θ to θ' or θ' to θ would yield distinct results. This is undesirable, unless there is some reason to privilege one object to the other, and symmetrical matching seems appealing in many contexts. A sufficient condition yielding symmetrical matching would be

$$L_{\theta,\theta'}(\phi) = L_{\theta',\theta}(\phi^{-1}),$$

which is true for functionals of the kind (see section 2)

$$L_{\theta,\theta'}(\phi) = \int_I F(\dot\phi, \theta, \theta' \circ \phi) dx \tag{1.2}$$

with $\xi F(1/\xi, v, u) = F(\xi, u, v)$.

One way to modify (1.1) in order to put it into the above form could be to set

$$F(\xi, u, v) = (\sqrt{\xi} - 1)^2 + \lambda\sqrt{\xi}(u - v)^2.$$

Note that, denoting by $|I|$ the length of the interval I, one has, in this case, (because ϕ is increasing from I onto I)

$$\int_I F(\dot\phi, \theta(x), \theta' \circ \phi(x))dx = 2|I| - \int_I \sqrt{\dot\phi}\left(2 - \lambda(\theta(x) - \theta' \circ \phi(x))^2\right) dx,$$

and the problem is equivalent to *maximizing* $\int_I \sqrt{\dot\phi}\left(2 - \lambda(\theta(x) - \theta' \circ \phi(x))^2\right) dx$.

The problem which has motivated this paper is the functional which has been designed in [9], [10]. In this case, F is given by

$$F(\xi, u, v) = \sqrt{\xi}\left|\cos \frac{u - v}{2}\right| . \tag{1.3}$$

The functional can be used to compare and match plane curves, θ being in this case the angle between the tangent and some reference axis. It has been shown that the minimum, over ϕ, of $\arccos L_{\theta,\theta'}(\phi)$ provides a distance between plane curves seen up to translation and scaling. (That is, it is not only symmetrical but also satisfies the triangular inequality.) In fact, this function F comes in a very natural way from the computation of paths of minimal energy in the space of plane curves.

In the present paper, we only consider the case when F can be written as $\sqrt{\xi}G(u, v)$, and one tries to maximize

$$\int_0^1 \sqrt{\dot\phi}G(\theta, \theta' \circ \phi)dx.$$

Some discussion on how this formulation can be seen as a consequence of some simple assumptions on the matching will be provided in section 2. We shall then study the existence and the properties of solutions of this type of variational problem. More precisely, we shall ask whether there exists some optimal matchings ϕ, *which are bijective.* When such a ϕ exists, we then want to discuss on its smoothness properties, and check, in particular, that the normalization by $\sqrt{\dot\phi}$ has not harmed too much of the smoothing properties of the initial formulation (1.1).

If we forget about θ and θ', we must thus deal with variational problems which fit into the following framework. Without loss of generality, we take $I = [0,1]$ for the rest of the paper and we introduce some notations.

Notation 1. Let Hom^+ be the set of increasing homeomorphisms on $[0,1]$, i.e., the set of continuous strictly increasing functions $\phi : [0,1] \to [0,1]$ such that $\phi(0) = 0$, $\phi(1) = 1$.

Since $\phi \in \mathrm{Hom}^+$ is continuous and increasing, ϕ is differentiable almost everywhere (a.e.). This derivative is denoted $\dot{\phi}$.

Given a measurable function $f : [0,1] \times [0,1] \to \mathbb{R}_+$, we define, for $\phi \in \mathrm{Hom}^+$,

$$U_f(\phi) = \int_0^1 \sqrt{\dot{\phi}} f(\phi(x), x) dx\,.$$

We also let $\tilde{f}(x,y) = f(y,x)$.

Most of the paper (sections 4, 5, and 6) will be devoted to proving the results which are stated in section 3. Some auxiliary results will also be given in section 7. We start with a discussion on which general form a matching function $F(\xi, u, v)$ may assume when some simple invariance properties are required.

2. Invariance properties of the matching. Let a function F be defined on $[0,+\infty[\times\mathbb{R}^d\times\mathbb{R}^d$, and specify the problem of optimal matching between two functions θ and θ', defined on $[0,1]$, and with values in $\mathbb{R}^d$ through the functional, defined for all ϕ, which are increasing diffeomorphisms of $[0,1]$,

$$L_{\theta,\theta'}(\phi) = \int_0^1 F(\dot{\phi}(x), \theta(x), \theta' \circ \phi(x)) dx.$$

As said before, one desirable property is symmetry: for any functions θ and θ', we want that

$$\phi = \mathrm{argmax} L_{\theta,\theta'} \Leftrightarrow \phi^{-1} = \mathrm{argmax} L_{\theta',\theta}.$$

Since

$$L_{\theta',\theta}(\phi^{-1}) = \int_0^1 \dot{\phi}(x) F\left(\frac{1}{\dot{\phi}(x)}, \theta' \circ \phi(c), \theta(x)\right) dx,$$

a sufficient condition for symmetry is the following.

[C1] For all $(\xi, u, v) \in [0,+\infty[\times\mathbb{R}^d \times \mathbb{R}^d$, one has $F(\xi,u,v) = \xi F(1/\xi, v, u)$.

Since we maximize $L_{\theta,\theta'}$, one should build F with suitable properties with respect to maximization. One such property is that F should be concave with respect to its first variable ξ. (To understand why concavity in the first variable is essential for this kind of problem, one can refer to [2].) This is stated in condition [C2].

[C2] For all u, v, $\xi \mapsto F(\xi, u, v)$ is concave on $[0, +\infty[$.

It is important to notice that this concavity assumption is consistent with the symmetry [C1] in the following sense. If [C1] is not true, it is natural to try to symmetrize F by replacing it by

$$F^s(\xi, u, v) = F(\xi, u, v) + \xi F\left(\frac{1}{\xi}, v, u\right).$$

It is easily shown, then, that condition [C2] is true for F^s as soon as it was originally true for F.

Another natural condition for the functional is that, when comparing a function θ with itself, the optimal ϕ is $\phi = \mathrm{id}$. In other terms, one should have, for all functions θ and all diffeomorphisms ϕ,

$$\int_0^1 F(\dot\phi, \theta, \theta \circ \phi)dx \leq \int_0^1 F(1, \theta, \theta)dx.$$

A sufficient condition for this can be that, for all ξ, u, v, $F(\xi, u, v) \leq F(1, u, u)$. If one takes into account the constraint $\int_0^1 \dot\phi = 1$, this can be weakened into the following condition (which can be shown to be necessary and sufficient [8]).

[C3] There exists a measurable function $\lambda : \mathbb{R}^d \to \mathbb{R}$ such that, for all $\xi > 0, u, v \in \mathbb{R}^d$,

$$F(\xi, u, v) \leq F(1, u, u) + \lambda(v)\xi - \lambda(u).$$

Indeed, assuming [C3], we have

$$\int_0^1 F(\dot\phi, \theta, \theta \circ \phi)dx \leq \int_0^1 F(1, \theta, \theta)dx + \int_0^1 \dot\phi\lambda \circ \theta \circ \phi dx - \int_0^1 \lambda \circ \theta dx,$$

and the last two integrals are equal by a change of variables.

Additional constraints may come from invariance properties which may be imposed on the matching. The first invariance property we consider will be called "focus invariance." Consider θ and θ' as signals, defined on $[0, 1]$, and assume that they have been matched by some function ϕ^*. Let $[a, b]$ be a subinterval of $[0, 1]$, and set $[a', b'] = [\phi^*(a), \phi^*(b)]$. We want to refocus the matching on these intervals. For this, we can rescale the functions θ and θ' on these intervals to get new signals defined on $[0, 1]$, and match the new signals. The question which arises then is whether this new matching is consistent with the one which has been obtained initially.

Let us be more precise. To rescale θ (resp., θ'), we define $\theta_{ab}(x) = \theta(a + (b - a)x)$ (resp., $\theta'_{a'b'}(x) = \theta'(a' + (b' - a')x)$), $x \in [0, 1]$. Comparing these signals with the functional F yields an optimal matching which, if it exists, maximizes

$$\int_0^1 F(\dot\phi(x), \theta_{a,b}(x), \theta'_{a',b'} \circ \phi(x))dx. \tag{2.1}$$

The optimal matching between the initial functions θ and θ' clearly maximizes

$$\int_a^b F(\dot\phi(y), \theta(y), \theta' \circ \phi(y))dy$$

with the constraints $\phi(a) = a'$ and $\phi(b) = b'$. Making the change of variables $y = a + (b - a)x$ and setting $\psi(x) = (\phi(y) - a')/(b' - a')$, this integral can be written as

$$(b - a) \int_0^1 F(\lambda\dot\psi(x), \theta_{a,b}(x), \theta'_{a',b'} \circ \psi(x))dx \tag{2.2}$$

with $\lambda = \frac{b'-a'}{b-a}$. We say that F satisfies a focus invariance propertyies if, for any θ and θ', the maximizer of (2.1) is the same as the maximizer of (2.2). One possible condition ensuring such a property is that F is itself (relatively) invariant under the transformation $(\xi, u, v) = (\lambda\xi, u, v)$.

[Focus] For some $\alpha > 0$, for all $\xi > 0$, $u, v \in \mathbb{R}^d$, $F(\lambda\xi, u, v) = \lambda^\alpha F(\xi, u, v)$.

This condition trivially implies that $F(\xi, u, v) = \xi^\alpha F(1, u, v)$. If condition [C1] is imposed, one sees that α has to be equal to $1/2$. We thus get the following.

The only matching functionals which satisfy [C1] *and* [Focus] *take the form*

$$F(\xi, u, v) = \sqrt{\xi} F_1(u, v) \tag{2.3}$$

with $F_1(u, v) = F_1(v, u)$.

These functionals satisfy [C2] as soon as $F_1 \geq 0$. For [C3], we must have, for all $u, v \in \mathbb{R}^d$,

$$F_1(u, v) \leq \sqrt{F_1(u, u) F_1(v, v)}. \tag{2.4}$$

Indeed, assuming [C3], we must have, for some function λ,

$$F_1(u, u) - \lambda(u) = \max_{v, \xi} \sqrt{\xi} F_1(u, v) - \lambda(v)\xi.$$

For a fixed v, $\sqrt{\xi} F_1(u, v) - \lambda(v)\xi$ has a finite maximum if $\lambda(v) > 0$, or if $F_1(u, v) = \lambda(v) = 0$. In the first case, the maximum is given by

$$\frac{F_1(u, v)^2}{4\lambda(v)}.$$

This implies that

$$F_1(u, u) - \lambda(u) = \max_v \frac{F_1(u, v)^2}{4\lambda(v)} \tag{2.5}$$

with the convention $0/0 = 0$. In particular, taking $v = u$, one has

$$F_1(u, u)^2 - 4\lambda(u) F_1(u, u) + 4\lambda(u)^2 \leq 0,$$

which is possible only if $F_1(u, u) = 2\lambda(u)$. Given this fact, (2.5) clearly implies (2.4). We thus have the following.

The only matching functionals which satisfy [C1]–[C3] *and* [Focus] *take the form*

$$F(\xi, u, v) = \sqrt{\xi} F_1(u, v) \tag{2.6}$$

with $F_1(u, v) = F_1(v, u)$, $F_1(u, v) \geq 0$, *and* $F_1(u, v) \leq \sqrt{F_1(u, u) F_1(v, v)}$.

The functional in (1.3) satisfies this property.

One must note, however, that focus invariance under the above form is not a suitable constraint for every matching problem. Let us restrict our attention to the comparison of plane curves, which has initially motivated the present paper. In this case, the functions θ are typically geometrical features computed along the curve and expressed as functions of the (euclidean) arc-length. In such a context, focusing should rather be interpreted from a geometrical point of view, as rescaling (a portion of) a plane curve to length 1. But, in this case, applying such a scale change may have some impact not only on the variable x (which here represents the length), but also on the *values* of the geometric features θ. In example (1.3), the geometric features were the orientation of the tangents, which are not affected by scale change, so that focus invariance is in this case equivalent to geometric scale invariance. Letting κ be the curvature computed along the curve, the same invariance would be true if we had taken $\theta = \kappa'/\kappa^2$ (which is the "curvature" which characterizes curves up to similitudes). But if we had chosen to compare precisely euclidean curvatures, the invariance constraints on the matching would be different. Since curvatures are scaled by λ^{-1} when a curve is scaled by λ, the correct condition should be (instead of [Focus])

$$F(\lambda\xi, \lambda u, v) = \lambda^{\alpha} F(\xi, u, v).$$

This comes from rescaling only the first curve. Rescaling the second curve yields

$$F(\lambda\xi, u, v/\lambda) = \lambda^{\beta} F(\xi, u, v).$$

Note that, if the symmetry condition is valid, we must have $\beta = 1 - \alpha$, which we assume hereafter.

One can solve this identity and compute all the (continuously differentiable) functions which satisfy it. This yields functions F of the kind

$$F(\xi, u, v) = H\left(\xi \frac{v}{u}\right) u^{\alpha} v^{\alpha - 1}.$$

Note that, since F should be concave as a function of ξ, H itself should be concave. The symmetry condition is ensured as soon as $xH(1/x) = H(x)$ for all x. One may set

$$F(\xi, u, v) = -|\xi v - u|,$$

which satisfies [C1]–[C3].

Many variations can be done on these computations. Inspiration on how devising functionals which satisfy given criteria of invariance can be obtained from the first chapters of [4].

We now return to our original problem, which contains, according to the above terminology, symmetrical, focus invariant matchings.

3. Main results.

3.1. Existence results.

Notation 2. Let a and b be two points in $[0,1]^2$ such that $a = (a_1, a_2)$ and $b = (b_1, b_2)$. We denote by $[a, b]$ the closed segment from a to b, i.e., the set of points $a + t(b - a)$, for $0 \leq t \leq 1$, and by $]a, b[$ the open segment from a to b defined by $]a, b[= [a, b] \setminus \{a, b\}$. Moreover, we say that such a segment is horizontal (resp., vertical) if $a_2 = b_2$ (resp., $a_1 = b_1$).

Notation 3. Denote by Δ_f the integral $\Delta_f = \int_0^1 f(x, x)dx$.

Let Ω_f be the set

$$\Omega_f = \left\{ (y, x) \in [0,1]^2 \mid |x - y| \leq \sqrt{1 - \left(\frac{\Delta_f}{\|f\|_\infty}\right)^2} \right\}.$$

THEOREM 3.1. *Assume that $f \geq 0$ is bounded and satisfies conditions* [H1] *and* [H2].

[H1] *There exists a finite family of closed segments $([a_j, b_j])_{j \in J}$ such that each of them is horizontal or vertical and f is continuous on $[0,1]^2 \setminus F$, where $F = \bigcup_{j \in J} [a_j, b_j]$.*

[H2] *Let f_s be defined by*

$$f_s(x) = \lim_{\delta \to 0} \left(\inf\{ f(u) \mid u \in [0,1]^2 \setminus F, \ |u - x| < \delta \} \right).$$

There does not exist any nonempty open vertical or horizontal segment $]a, b[$ *such that* $]a, b[\subset \Omega_f$ *and* f_s *vanishes on* $]a, b[$.

Then there exists $\phi^* \in Hom^+$ *such that* $U_f(\phi^*) = \max\{U_f(\phi), \phi \in Hom^+\}$. *Moreover, if* ϕ *is a maximizer of* U_f*, one has, for all* $x \in [0, 1]$, $(\phi(x), x) \in \Omega_f$.

3.2. Regularity of the optimal matching. We now give some conditions under which the optimal matching satisfies some smoothness properties.

DEFINITION 3.2. *We say that* $f : [0, 1]^2 \to \mathbb{R}$ *is Hölder continuous at* (y, x) *if there exist* $\alpha > 0$ *and* $C > 0$ *such that*

$$|f(y', x') - f(y, x)| \leq C \max(|y' - y|^\alpha, |x' - x|^\alpha) \tag{3.1}$$

for any $(y', x') \in [0, 1]^2$.

We say that f *is locally uniformly Hölder continuous at* (y_0, x_0) *if there exists a neighborhood* V *of* (y_0, x_0) *such that* f *is Hölder continuous at all* $(y, x) \in V$*, with constants* C *and* α*, which are uniform over* V.

THEOREM 3.3. *Let* f *be a nonnegative real-valued measurable function on* $[0, 1]^2$ *and assume that* U_f *reaches its maximal value on* Hom^+ *at* ϕ^*. *Then for any* $x_0 \in [0, 1]$*, if* $f(\phi(x_0), x_0) > 0$ *and if* f *is Hölder continuous at* $(\phi(x_0), x_0)$*, then* ϕ^* *is differentiable at* x_0 *with strictly positive derivative.*

Moreover, if f *is locally uniformly Hölder continuous, then* $\dot{\phi}^*$ *is continuous in a neighborhood of* x_0.

THEOREM 3.4. *Assume that* f *is continuously differentiable in both variables. Let* $\phi \in Hom^+$ *be such that* $U_f(\phi) = \max\{U_f(\psi) \mid \psi \in Hom^+\}$ *and that, for all* $x \in [0, 1]$*, one has* $f(\phi(x), x) > 0$. *Then,* ϕ *is twice continuously differentiable.*

4. Remarks.

4.1. Positivity of *f*. It is necessary to control the vanishing sets of the function f (as in condition [H2]) to obtain a homeomorphism. One simple example is when f vanishes on a square $S =]\frac{1}{2} - a, \frac{1}{2} + a[^2 \subset [0, 1]^2$, and $f = 1$ outside. (Such an f satisfies condition [H1].) Using the fact that (as a consequence of Lemma 5.16 below), ϕ must be linear on any section which does not encounter S, it is not very difficult to prove that the maximum is attained for ϕ which is *discontinuous* at $x = a + 1/2$, more precisely such that $\phi(x) = \frac{1}{2} - a$ and $\phi(x + 0) = \frac{1}{2} + a$.

4.2. Piecewise constant functions. A particular and important case in which condition [H1] is valid is the case of piecewise constant functions f. We state this as a corollary.

COROLLARY 4.1. *Assume that there exists* $0 = x_0 < x_1 < \cdots < x_m = 1$ *(resp.,* $0 = x'_0 < x'_1 < \cdots < x'_n = 1$*) and constants* $f_{kl} > 0$, $1 \leq k \leq m$, $1 \leq l \leq n$ *such that*

$$f(x, x') = \sum_{k=1}^{m} \sum_{l=1}^{n} f_{kl} \mathbf{1}_{[x_{k-1}, x_k[\times[x'_{l-1}, x'_l[}(x, x').$$

Then, there exists $\phi^* \in Hom^+$*, which is piecewise linear such that*

$$U_f(\phi^*) = \max\{U_f(\phi) \mid \phi \in Hom^+\}.$$

Remark. In fact, one needs to assume only that $f_{kl} > 0$ for k and l such that $[x_{k-1}, x_k[\times[x'_{l-1}, x'_l[$ is sufficiently close from the diagonal of the unit square, i.e., intersects the set Ω_f.

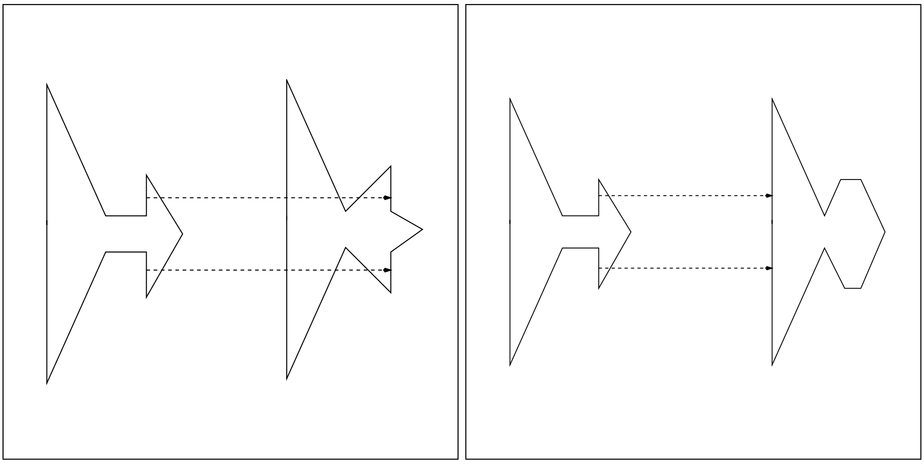

FIG. 4.1. *Matching of flat sections. Left: Situation in which* [H2] *is not true. A point on the first curve has a whole interval of possible matches on the second one with an opposite orientation of the tangent. Right: In this situation, there still exist portions in the second curve with opposite tangents, but because their respectve arc-lengths are far apart, they can be ignored (using the set* Ω_f*):* [H2] *is true.*

Proof. We need to show only that the optimal ϕ is piecewise linear. But we have

$$U_f(\phi) = \sum_{k=1}^{m} \sum_{l=1}^{n} f_{kl} \int_{x_{k-1}}^{x_k} \sqrt{\dot{\phi}(x)}\mathbf{1}_{[x_{l-1},x_l[}(\phi(x))dx.$$

Let $y_k = \phi(x_k)$, $k = 0, \dots, m$. Let $y'_l = \phi^{-1}(x'_l)$, $l = 0, \dots, n$. We have, writing $a \vee b = \max(a, b)$ and $a \wedge b = \min(a, b)$,

$$U_f(\phi) = \sum_{k=1}^{m} \sum_{l=1}^{n} f_{kl} \int_{x_{k-1} \vee y'_{l-1}}^{x_k \wedge y'_l} \sqrt{\dot{\phi}(x)}dx,$$

and Lemma 5.16 yields the result. □

4.3. Application to optimal matching of functions. Let us see what conditions [H1] and [H2] mean when f is of the kind

$$f(y, x) = F_1(\theta(y), \theta'(x))\,.$$

One of the examples we have in mind is the case when $\theta(y)$ and $\theta'(y)$ take values in $[0, 2\pi[$, and $F_1(u, v) = |\cos[(u - v)/2]|$. In this case, these functions, θ and θ', correspond to *rotation angles* of the unitary tangents to some plane curves, and matching is used to compare shapes on the basis of their silhouettes.

In this particular case, F_1 is continuous, but not continuously differentiable. It is, however, smooth enough to fit into the regularity condition [H1], so that the true constraint is on θ and θ'. Note that f is discontinuous on a horizontal (resp., vertical) segment as soon as θ (resp., θ') is discontinuous at the position of the segment in the horizontal (resp., vertical) axis. Thus [H1] implies that θ and θ' are continuous except at a finite number of points. Points of discontinuity of θ and θ' are angular points for the plane curves they represent; thus condition [H1] implies that one can safely perform a matching between shapes having a finite number of angular points, which is the case of most of the objects which can be observed in a standard environment. Note that, in this case, piecewise constant f corresponds to polygonal shapes, which is also an important example to deal with.

Condition [H2] essentially means that one cannot have intervals on which, for a given x_0, $F(\theta(.), \theta'(x_0)) = 0$. In the case of curve matching, when θ is an angle, and formula (1.3) is used, this means that one of the curves cannot have a flat portion which may be matched to a point of the other curve with opposite tangent. (Note that one can restrict this condition to points which are located at close enough positions on both curves; see Figure 4.1 for an illustration.) In particular, the condition is always true if the compared curves contain no flat sections.

5. Proof of the existence.

5.1. Sketch of the proof. In the next section, we will introduce a compact set $\mathcal{D}^*$, containing Hom^+, and extend the functional U_f to this space. We first prove the existence of the maximum for this extended functional through the following proposition.

PROPOSITION 5.1. *If f satisfies condition* [H1]*, then U_f is upper-semicontinuous on $\mathcal{D}^*$. Since $\mathcal{D}^*$ is compact, there exists $\phi^* \in \mathcal{D}^*$ such that*

$$U_f(\phi^*) = \sup\{U_f(\psi) \,|\, \psi \in \mathcal{D}^*\}.$$

Moreover, if ϕ is a maximizer of U_f, one has, for all $x \in [0,1]$, $(\phi(x), x) \in \Omega_f$.

Theorem 3.1 will then be a consequence of the following proposition.

PROPOSITION 5.2. *If f satisfies condition* [H2] *in Theorem* 3.1 *and $\phi^* \in \mathcal{D}^*$ is such that*

$$U_f(\phi^*) = \sup\{U_f(\psi) \,|\, \psi \in \mathcal{D}^*\},$$

then $\phi \in Hom^+$.

Before proving these propositions, we introduce $\mathcal{D}^*$.

5.2. The set $\mathcal{D}^*$.

5.2.1. Definition. Let $\mathcal{M}_1$ be the set of the positive Radon measures μ on $[0,1]$ such that $\mu([0,1]) = 1$. Let $\mathcal{M}$ be the set of measures on $[0,1]$ such that $\mu([0,1]) \leq 1$. We let $\mathcal{D}^*$ be the set of all ϕ which can be written as

$$\phi(s) = \mu([0,s[)$$

for some $\mu \in \mathcal{M}_1$. Such ϕ are nondecreasing, left continuous, and satisfy $\phi(0) = 0$ and $\phi(1) \leq 1$. Conversely, any ϕ satisfying these properties is in $\mathcal{D}^*$, and the associated measure is unique and will be denoted by μ_ϕ. Note that $\mu_\phi(\{1\}) = 1 - \phi(1)$ for all $x \in [0,1[$, $\mu_\phi(\{x\}) = \phi(x+0) - \phi(x)$, where $\phi(x+0)$ is the right limit of ϕ at x.

Any $\mu \in \mathcal{M}_1$ can be written in a unique way under the form

$$\mu = \omega dx + \nu,$$

where dx is the Lebesgue measure on $[0,1]$, ω is a measurable, nonnegative, function on $[0,1]$, and ν is singular. (There exists a set E of Lebesgue measure 0 such that $\nu(A) = \nu(A \cap E)$ for every Borel set $A \subset [0,1]$.) For $\phi \in \mathcal{D}^*$, we take the notation

$$d\mu_\phi = \omega_\phi ds + d\nu_\phi.$$

DEFINITION 5.3. *For a function $\phi \in [0,1]$, we let $\dot{\phi}(x)$ be the limit when $\epsilon \to 0$ of $\frac{\phi(x+\epsilon)-\phi(x)}{\epsilon}$ when this limit exists and $\dot{\phi}(x) = 0$ otherwise. If $\phi \in \mathcal{D}^*$, one has $\dot{\phi} = \omega_\phi$ a.e.* [7, Theorem 8.18].

Following [6], we extend the functional U_f to $\mathcal{D}^*$ by letting

$$U_f(\phi) = \int_0^1 \sqrt{\dot{\phi}(x)} f(\phi(x), x) ds\,.$$

We also denote by $\mathcal{D}^*_+$ the set of functions $\phi \in \mathcal{D}^*$ for which $\int_a^b \dot{\phi} > 0$ for any $0 \leq a < b \leq 1$. We have $\phi \in \mathrm{Hom}^+$ if $\phi \in \mathcal{D}^*_+$, and ν_ϕ is diffuse, i.e., $\nu_\phi(\{x\}) = 0$ for any $x \in [0,1]$. (Note that this is not a necessary condition: there exists functions in Hom^+ such that $\dot{\phi} = 0$ a.e. See [3, example 18–8] .

5.2.2. Weak convergence in $\mathcal{D}^*$.

Measures $\mu_n \in \mathcal{M}, n \geq 0$ are said to converge for the weak*-topology to a limit μ if, for every continuous function F on $[0,1]$, one has

$$\lim_{n\to\infty} \int_0^1 F d\mu_n = \int_0^1 F d\mu.$$

Since this is the only kind of convergence we use on $\mathcal{M}$ and $\mathcal{M}_1$, the statement "μ_n converges to μ" will always mean convergence in the weak*-topology. We say that $\phi_n \in \mathcal{D}^*$ weakly converges to $\phi \in \mathcal{D}^*$ if μ_{ϕ_n} converges to μ_ϕ.

We list some results related to this convergence.

PROPOSITION 5.4 (see [5]). *The sets $\mathcal{M}$ and $\mathcal{M}_1$ are compact for the weak*-topology.*

If ϕ_n weakly converges to ϕ, then, for all $x \in [0,1]$ such that ϕ is continuous at x, one has $\phi_n(x) \to \phi(x)$.

Note that, since ϕ is increasing, its discontinuity set is at most countable.

PROPOSITION 5.5. *Let ϕ_n be a sequence in $\mathcal{D}^*$, such that $\dot{\phi}_n dx$ and ν_{ϕ_n} both converge in $\mathcal{M}$, respectively, to $\alpha dx + \rho$ and $\beta dx + \tau$. Then μ_{ϕ_n} converges to $\mu \in \mathcal{M}_1$ such that $\mu = (\alpha + \beta)dx + (\rho + \tau)$.*

This is obvious. Note that, by compactness of $\mathcal{M}$, from any sequence ϕ_n one can extract a subsequence such that both $\dot{\phi}_n dx$ and ν_{ϕ_n} converge.

We introduce, here and for what follows, a mollifier g, i.e., an infinitely differentiable mapping $g : \mathbb{R} \to \mathbb{R}$, with compact support included in $]-1,1[$, such that $\int_{-1}^1 g(x)dx = 1$. For $\epsilon > 0$, we let $g_\epsilon(x) = g(x/\epsilon)/\epsilon$. One has the following lemma.

LEMMA 5.6 (see [6]). *Let $\mu_n = \omega_n dx$ be a sequence of absolutely continuous measures in $\mathcal{M}$ which converges to $\alpha dx + \rho$. Then, for any $\epsilon > 0$, one has*

$$\lim_{n\to\infty} \int_0^1 |\omega_n * g_\epsilon - \alpha * g_\epsilon - \rho * g_\epsilon|\, dx = 0.$$

Here, $\mu * g_\epsilon$ denotes (as usually) the convolution of μ by g_ϵ,

$$\mu * g_\epsilon(x) = \int_0^1 g_\epsilon(x-y) d\mu(y)\,.$$

5.2.3. A symmetry property of U_f.

For $\phi \in \mathcal{D}^*$, we define, for $y \in [0,1]$,

$$\phi^-(y) = \sup\{x \in [0,1] \,|\, \phi(x) < y\},$$

with the convention that $\sup\emptyset = 0$.

Our purpose is to prove the following proposition (recall that we have denoted $\tilde{f}(x,y) = f(y,x)$).

PROPOSITION 5.7. *For all $\phi \in \mathcal{D}^*$, one has*

$$U_f(\phi) = U_{\tilde{f}}(\phi^-).$$

The proof will be carried on with several lemmas.

LEMMA 5.8. *Let $\phi \in \mathcal{D}^*$.*

1. *We have $\phi^- \in \mathcal{D}^*$ and $(\phi^-)^- = \phi$.*
2. *For any $x \in [0,1]$,*

$$\phi^-(\phi(x)) \le x \le \phi^-(\phi(x)+0) \tag{5.1}$$

so that $\phi^- \circ \phi(x) = x$ as soon as ϕ^- is continuous at $\phi(x)$.

3. *For any $y \in [0,1]$,*

$$\phi(\phi^-(y)) \le y \le \phi(\phi^-(y)+0) \tag{5.2}$$

so that $\phi \circ \phi^-(y) = y$ as soon as ϕ is continuous at $\phi^-(y)$.

Moreover, if $\phi \in \mathcal{D}^*_+$, then ϕ^- is continuous.

Proof. ϕ^- is nondecreasing, $\phi^-(0) = 0$, $\phi^-(1) \le 1$, and ϕ^- is left continuous, since

$$\phi^-(y) = \sup_{h>0}\left(\sup\{x, \phi(x) < y-h\}\right) = \sup_{h>0}\phi^-(y-h)$$

so that $\phi^- \in \mathcal{D}^*$. Now, let us show that for any $(x,y) \in [0,1]^2$,

$$\phi(x) > y \Rightarrow \phi^-(y) < x. \tag{5.3}$$

Indeed (assume $x \ne 0$—otherwise the result is trivial), if $\phi(x) > y$, since ϕ is left continuous, there exists $h > 0$ such that $\phi(x-h) > y$ so that $\phi^-(y) \le x - h < x$. Moreover, we deduce from the definition of ϕ^- that for any $x, y \in [0,1]$,

$$\phi^-(y) < x \Rightarrow \phi(x) \ge y. \tag{5.4}$$

Now, since $\phi(x) = \sup\{\ y \in [0,1] \mid y < \phi(x)\ \}$, using (5.3) and (5.4), we get

$$\phi(x) \le \sup\{y \in [0,1] | \ \phi^-(y) < x\} = (\phi^-)^-(x) \le \sup\{y \in [0,1] | \phi(x) \ge y\} = \phi(x)$$

so that 1 is proved.

From 1, we deduce that $2 \iff 3$ so that it is sufficient to prove 3. For any y, there exists an increasing sequence x_n which converges to $\phi^-(y)$ such that $\phi(x_n) < y$. Since ϕ is left continuous, this yields $\phi \circ \phi^-(y) \le y$. Moreover, for all $h > 0$, one has $\phi(\phi^-(y)+h) \ge y$ so that $y \le \phi(\phi^-(y)+0)$.

Now, assume that $\phi \in \mathcal{D}^*_+$ and assume that ϕ^- is discontinuous at $y_0 \in [0,1[$. Then $\phi^-(y_0+0) > \phi^-(y_0)$ so that $(\phi^-)^-$ has the constant value y_0 on $]\phi^-(y_0), \phi^-(y_0+0)]$. Since $(\phi^-)^- = \phi$, we get a contradiction with the fact that ϕ is strictly increasing. □

Note that ϕ is continuous at $\phi^-(y)$ if and only if $\mu_\phi(\{\phi^-(y)\}) = \nu_\phi(\{\phi^-(y)\}) = 0$.

LEMMA 5.9. *Let $\phi \in \mathcal{D}^*$. If ϕ is derivable at x, then*

$$\lim_{h\to 0}\frac{\phi(x+h+0) - \phi(x)}{h} = \dot{\phi}(x).$$

Proof. Let us show that, for any sequence x_n which converges to x, $x_n \neq x$, one has $\frac{\phi(x_n+0)-\phi(x)}{x_n-x} \to \dot{\phi}(x)$. Since ϕ is increasing, the limit is clearly larger than $\dot{\phi}(x)$. Letting $\epsilon_n = (x_n - x)^2 > 0$, we have

$$\frac{\phi(x_n+0)-\phi(x)}{x_n-x} \leq \frac{\phi(x_n+\epsilon_n)-\phi(x)}{x_n-x} = \frac{\phi(x_n+\epsilon_n)-\phi(x)}{x_n+\epsilon_n-x}(1+|x_n-x|),$$

and the last term converges to $\dot{\phi}(x)$. □

Define $P_\phi = \{\, x \in [0,1] \mid \dot{\phi}(x) > 0 \,\}$ to be the set of locations where the derivative of ϕ exists and is strictly positive (see Definition 5.3). One has the following lemma.

Lemma 5.10. *For any $x_0 \in [0,1]$, $x_0 \in P_\phi \iff \phi(x_0) \in P_{\phi^-}$. Hence,*

$$\dot{\phi}(x) = \frac{1}{\dot{\phi^-}(\phi(x))}\mathbf{1}_{P_{\phi^-}}(\phi(x))$$

(with the convention $0/0 = 0$).

Proof. ($\Leftarrow$) Assume that $\phi(x_0) \in P_{\phi^-}$; then ϕ is continuous at x_0. Indeed, if $\phi(x_0) < \phi(x_0+0)$, then ϕ^- is constant on $]\phi(x_0), \phi(x_0+0)[$ so that $\dot{\phi^-}(\phi(x_0)) = 0$ and $\phi(x_0) \notin P_{\phi^-}$ (which is a contradiction). Moreover, since ϕ^- is continuous at $\phi(x_0)$, we deduce from Lemma 5.8 that $\phi^-(y_0) = x_0$, where $y_0 = \phi(x_0)$. Now, noting that for any $h \in \mathbb{R}^*$ such that $x_0 + h \in [0,1]$, $\phi(x_0+h) \neq \phi(x_0)$ (otherwise ϕ^- should be discontinuous at $y_0 = \phi(x_0)$), we get using (5.1) and the fact that $\phi^-(\phi(x_0)) = x_0$

$$\frac{\phi(x_0+h)-\phi(x_0)}{\phi^-[\phi(x_0+h)+0]-\phi^-[\phi(x_0)]} \leq \frac{\phi(x_0+h)-\phi(x_0)}{h} \leq \frac{\phi(x_0+h)-\phi(x_0)}{\phi^-[\phi(x_0+h)]-\phi^-[\phi(x_0)]}.$$

Since ϕ is continuous at x_0, Lemma 5.9 applied to ϕ^- implies that $[\phi(x_0+h)-\phi(x_0)]/h$ converges to $(\dot{\phi^-} \circ \phi(x_0))^{-1} > 0$ when h tends to 0 so that $x_0 \in P_\phi$.

($\Rightarrow$) Now, assume that $x_0 \in P_\phi$. Then if $y_0 = \phi(x_0)$, ϕ^- is continuous at y_0. Indeed, if $\phi^-(y_0) < \phi^-(y_0+0)$, then since $\phi = (\phi^-)^-$, ϕ is constant on $]\phi^-(y_0), \phi^-(y_0+0)]$. However, from (5.1), we get that $x_0 \in [\phi^-(y_0), \phi^-(y_0+0)]$ so that $\dot{\phi}(x_0) = 0$ (which is a contradiction). Hence, ϕ^- is continuous at $y_0 = \phi(x_0)$ and $\phi^-(y_0) = x_0$. Now, using the part ($\Leftarrow$) for ϕ^-, we deduce that $y_0 = \phi^-(y_0) \in P_\phi = P_{(\phi^-)^-}$ implies $y_0 \in P_{\phi^-}$, i.e., $\phi(x_0) \in P_{\phi^-}$ so that the proof is finished. □

Lemma 5.11. *If $\phi \in \mathcal{D}^*$ and g is a measurable function, one has, for all $x \in [0,1]$,*

$$\int_0^{\phi(x)} g \circ \phi^-(v)dv = \int_0^x g(u)\dot{\phi}(u)du + \int \mathbf{1}_{[0,x[}(u)g(u)d\nu_\phi(u). \tag{5.5}$$

Proof. This lemma can be proved first for $g = \mathbf{1}_{[0,b[}$ and extended to any g in a standard way. □

We can now prove Proposition 5.7. Applying Lemma 5.10 to ϕ^- instead of ϕ, we get

$$\begin{aligned} U_{\tilde{f}}(\phi^-) &= \int_0^1 \frac{\mathbf{1}_{P_\phi}(\phi^-(u))}{\sqrt{\dot{\phi} \circ \phi^-(u)}} f(u, \phi^-(u))du \\ &= \int_0^{\phi(1)} \frac{\mathbf{1}_{P_\phi}(\phi^-(u))}{\sqrt{\dot{\phi} \circ \phi^-(u)}} f(\phi \circ \phi^-(u), \phi^-(u))du. \end{aligned}$$

To justify this equality, we must show that the replacements of 1 by $\phi(1)$ and of u by $\phi \circ \phi^-(u)$ are valid. Assume that $\phi(1) < 1$. This implies that $\nu_\phi(\{1\}) > 0$ and thus that $1 \notin P_\phi$; for $u > \phi(1)$, one has $\phi^-(u) = 1$, so that $\mathbf{1}_{P_\phi}(\phi^-(u)) = 0$, which justifies the first replacement. For the second one, one has $\phi \circ \phi^-(x) \neq x$ only if ϕ is discontinuous at $\phi^-(x)$ and so not differentiable at $\phi^-(x)$, so that $\phi^-(x) \notin P_\phi$.

Now, Lemma 5.11 implies $U_{\tilde{f}}(\phi^-) = U_f(\phi)$ since ϕ is not derivable (hence, with our convention $\dot{\phi} = 0$) ν_ϕ a.e. [7, Theorem 8.11].

5.3. Proof of Proposition 5.1. We prove that U_f is upper-semicontinuous on $\mathcal{D}^*$. Let us consider the following lemma.

LEMMA 5.12. *Let f be a nonnegative function on $[0,1]^2$ which satisfies* [H1]. *Then, there exists a sequence $(f_n)_{n\geq 0}$ of continuous and nonnegative functions on $[0,1]^2$ such that for all $\phi \in \mathcal{D}^*$*

$$U_f(\phi) = \inf_{n\geq 0} U_{f_n}(\phi).$$

Proof. Let $F = \bigcup_{j\in J}[a_j, b_j]$ be the compact set defined in Theorem 3.1, let $M = \|f\|_\infty$, and consider the sequence $(f_n)_{n\geq 0}$ of nonnegative functions defined by

$$f_n(x) = (1 - \alpha_n(x))M + \alpha_n(x)f(x),$$

where $\alpha_n(x) = (Cd(x,F))^{1/n}$ and $d(x,F)$ is the usual distance from x to F and $0 < C < 1/\sqrt{2}$. One easily shows that f_n is continuous on $[0,1]$ and that $(f_n(x))_{n\geq 0}$ is a decreasing sequence converging to $f(x)$ for any $x \in [0,1]^2 \setminus F$.

Now consider $\phi \in \mathcal{D}^*$. By definition of the f_n's, $U_{f_n}(\phi)$ is a decreasing sequence. To show the result, it is sufficient to prove that

$$\sqrt{\dot{\phi}} f_n(\phi(x), x) \to \sqrt{\dot{\phi}} f(\phi(x), x) \text{ a.e.}$$

The result is obviously true for $x \in \{\ z \in [0,1] \mid \dot{\phi}(z) = 0 \ \text{ or } (\phi(z), z) \in [0,1]^2 \setminus F\}$. However, the set $\mathcal{F} = \{\ z \in [0,1] \mid \dot{\phi}(z) > 0,\ (\phi(z), z) \in F\ \}$ contains only isolated points, so that the result is proved: indeed, by contradiction assume that there exist $x \in \mathcal{F}$ and a sequence $(x_n)_{n\geq 0}$ of points of $\mathcal{F} \setminus \{x\}$ converging to x. Since F contains only a finite number of segments, there exists $j_0 \in J$ such that (up to the extraction of a subsequence) $x_n \in [a_{j_0}, b_{j_0}]$ for all $n \geq 0$. Moreover, since there exist n and n' such that $x_n \neq x_{n'}$, the segment $[a_{j_0}, b_{j_0}]$ is vertical so that $\phi(x_n)$ has a constant value and $\dot{\phi}(x) = 0$, which is a contradiction. □

Using Lemma 5.12, we deduce that if Theorem 3.1 is proved for nonnegative and continuous f, then, using the fact that the infimum of a family of upper-semicontinuous functions is upper-semicontinuous, we will get the result for any f nonnegative and satisfying condition [H1]. Hence, we can assume that f is continuous and nonnegative and prove that U_f is upper-semicontinuous.

For this, we consider a sequence $\phi_n \in \mathcal{D}^*$ such that ϕ_n weakly converges to ϕ in $\mathcal{D}^*$ (i.e., μ_{ϕ_n} converges to μ_ϕ in $\mathcal{M}$). Replacing, if needed, ϕ_n by a subsequence, we assume that both $\dot{\phi}_n dx$ and ν_{ϕ_n} converge in $\mathcal{M}$, respectively to $\alpha dx + \rho$ and $\beta dx + \tau$. By Proposition 5.5, ϕ_n weakly converges to $\phi \in \mathcal{D}^*$ with $\mu_\phi = (\alpha + \beta)dx + (\rho + \tau)$. We shall show that $\limsup U_f(\phi_n) \leq U_f(\phi)$. We have

$$U_f(\phi) - U_f(\phi_n) = \int_0^1 \left(\sqrt{\dot{\phi}(x)} - \sqrt{\dot{\phi}_n(x)}\right) f(\phi(x), x)dx + \int_0^1 \sqrt{\dot{\phi}_n(x)}(f(\phi(x), x) - f(\phi_n(x), x))dx.$$

Moreover,

$$\begin{aligned}
&\left|\int_0^1 \sqrt{\dot{\phi}_n}(x)(f(\phi(x),x) - f(\phi_n(x),x))dx\right| \\
&\quad\le \int_0^1 \sqrt{\dot{\phi}_n}(x)\left|(f(\phi(x),x) - f(\phi_n(x),x))\right| dx \\
&\quad\le \left[\int_0^1 \dot{\phi}_n(x)dx\right]^{1/2} \left[\int_0^1 \left|(f(\phi(x),x) - f(\phi_n(x),x))\right|^2 dx\right]^{1/2} \\
&\quad= \left[\int_0^1 \left|(f(\phi(x),x) - f(\phi_n(x),x))\right|^2 dx\right]^{1/2}.
\end{aligned}$$

This last integral tends to 0 by dominated convergence, since ϕ_n converges to ϕ a.e. (Proposition 5.4) and f is continuous. We thus have

$$\lim_{n\to\infty} \int_0^1 \sqrt{\dot{\phi}_n}(x)(f(\phi(x),x) - f(\phi_n(x),x))dx = 0. \tag{5.6}$$

We now study

$$\int_0^1 \left(\sqrt{\dot{\phi}}(x) - \sqrt{\dot{\phi}_n}(x)\right) f(\phi(x),x)dx.$$

We show that

$$\limsup \int_0^1 \sqrt{\dot{\phi}_n}(x) f(\phi(x),x)dx$$

is smaller than

$$\int_0^1 \sqrt{\alpha(x)} f(\phi(x),x)dx.$$

Since

$$\int_0^1 \sqrt{\dot{\phi}}(x) f(\phi(x),x)dx = \int_0^1 \sqrt{\alpha(x)+\beta(x)} f(\phi(x),x)dx,$$

this will prove Proposition 5.1.

We follow the method of [6], using the mollifier g_ϵ. We first prove the following lemmas.

Lemma 5.13. *For any $\epsilon > 0$, we have*

$$\lim_{n\to\infty} \int_0^1 \sqrt{\dot{\phi}_n * g_\epsilon(x)} f(\phi(x),x)dx = \int_0^1 \sqrt{\alpha * g_\epsilon(x) + \rho * g_\epsilon(x)} f(\phi(x),x)dx. \tag{5.7}$$

Proof. Indeed, we have

$$\begin{aligned}
&\int_0^1 \left|\sqrt{\dot{\phi}_n * g_\epsilon(x)} - \sqrt{\alpha * g_\epsilon(x) + \rho * g_\epsilon(x)}\right| f(\phi(x),x)dx \\
&\quad\le \|f\|_\infty \int_0^1 \left|\sqrt{\dot{\phi}_n * g_\epsilon(x)} - \sqrt{\alpha * g_\epsilon(x) + \rho * g_\epsilon(x)}\right| dx \\
&\quad\le \|f\|_\infty \left[\int_0^1 |\dot{\phi}_n * g_\epsilon(x) - (\alpha * g_\epsilon(x) + \rho * g_\epsilon(x))|dx\right]^{1/2} \\
&\quad\le \|f\|_\infty \left[\int_{-\infty}^{\infty} |\dot{\phi}_n * g_\epsilon(x) - (\alpha * g_\epsilon(x) + \rho * g_\epsilon(x))|dx\right]^{1/2},
\end{aligned}$$

which tends to 0 by Lemma 5.6. We have used the inequality $|\sqrt{a}-\sqrt{b}|^2 \leq |a-b|$, which is true for all $a, b \geq 0$. □

Lemma 5.14. *We have*

$$\lim_{\epsilon\to 0}\sup_n \left|\int_0^1 \sqrt{\dot\phi_n} * g_\epsilon(x) f(\phi(x),x)dx - \int_0^1 \sqrt{\dot\phi_n} f(\phi(x),x)dx\right|.$$

Proof. For any $\eta > 0$ one can find a continuous function F_η on $[0,1]$ such that

$$\int_0^1 |F_\eta(x) - f(\phi(x),x)|^2 dx < \eta^2 .$$

Fixing such an η, one has

$$\int_0^1 \sqrt{\dot\phi_n} * g_\epsilon(x)\,|f(\phi(x),x) - F_\eta(x)|\,dx \leq \eta\left[\int_0^1 \dot\phi_n * g_\epsilon(x)dx\right]^{1/2} \leq \eta,$$

where we have used the fact that, by Jensen's inequality, we have for all $n \geq 0$

$$\sqrt{\dot\phi_n} * g_\epsilon(x) \leq \sqrt{\dot\phi_n * g_\epsilon}.$$

Similarly,

$$\int_0^1 \sqrt{\dot\phi_n(x)}\,|f(\phi(x),x) - F_\eta(x)|\,dx \leq \eta.$$

We have

$$\begin{aligned}
&\left|\int_0^1 \sqrt{\dot\phi_n} * g_\epsilon(x) F_\eta(x)dx - \int_0^1 \sqrt{\dot\phi_n(y)} F_\eta(y)dy\right| \\
&\leq \int_{-\epsilon}^{1+\epsilon} dx \int_0^1 dy \sqrt{\dot\phi_n}(y) g_\epsilon(x-y)|F_\eta(x) - F_\eta(y)| \\
&\leq K_\eta(\epsilon)\int_0^1 \sqrt{\dot\phi_n}(y)dy \int_{-\epsilon}^{1+\epsilon} g_\epsilon(x-y)dx \\
&\leq K_\eta(\epsilon)\int_0^1 \sqrt{\dot\phi_n}(y)dy \leq K_\eta(\epsilon),
\end{aligned}$$

where $K_\eta(\epsilon) = \sup_{|y-x|\leq\epsilon}(|F_\eta(x) - F_\eta(y)|)$: we have used the fact that, for all y,

$$\int_{-\epsilon}^{1+\epsilon} g_\epsilon(x-y)dx \leq \int_{-\infty}^{\infty} g_\epsilon(x-y)dx = \int_{-\infty}^{\infty} g_\epsilon(x)dx = 1$$

and

$$\int_0^1 \sqrt{\dot\phi_n}(y)dy \leq 1.$$

Hence, we deduce that, for all n,

$$\left|\int_0^1 \left(\sqrt{\dot\phi_n} * g_\epsilon(x) - \sqrt{\dot\phi_n(x)}\right) f(\phi(x),x)dx\right| \leq 2\eta + K_\eta(\epsilon).$$

Since for $\eta > 0$, $K_\eta(\epsilon) \to 0$ when ϵ vanishes, we get the result. □

We end with the following lemma.

LEMMA 5.15. *We have*

$$\lim_{\epsilon\to 0}\int_0^1 \sqrt{\alpha * g_\epsilon(x) + \rho * g_\epsilon(x)}f(\phi(x),x)dx = \int_0^1 \sqrt{\alpha(x)}f(\phi(x),x)dx. \tag{5.8}$$

Proof. Indeed,

$$\begin{aligned}
&\left|\int_0^1 \left[\sqrt{\alpha * g_\epsilon(x) + \rho * g_\epsilon(x)} - \sqrt{\alpha(x)}\right] f(\phi(x),x)dx\right| \\
&\quad\le \left|\int_0^1 \left[\sqrt{\alpha * g_\epsilon(x) + \rho * g_\epsilon(x)} - \sqrt{\alpha * g_\epsilon(x)}\right] f(\phi(x),x)dx\right| \\
&\quad + \left|\int_0^1 \left[\sqrt{\alpha * g_\epsilon(x)} - \sqrt{\alpha(x)}\right] f(\phi(x),x)dx\right| \\
&\quad\le \|f\|_\infty \left|\int_0^1 \sqrt{\rho * g_\epsilon(x)}dx\right| + \|f\|_\infty \left|\int_0^1 \left[\sqrt{\alpha * g_\epsilon(x)} - \sqrt{\alpha(x)}\right] dx\right|.
\end{aligned}$$

One has $\rho * g_\epsilon(x) = \int_0^1 g_\epsilon(x-y)d\rho(y) \le \frac{1}{\epsilon}\rho(]x-\epsilon, x+\epsilon[)$. Since ρ is singular, this upper-bound tends to 0 a.e. (cf., for example, [7, Theorem 8.6]). Thus

$$\begin{aligned}
\int_0^1 \sqrt{\rho * g_\epsilon(x)}dx &\le \int_0^1 \sqrt{\rho * g_\epsilon(x)}\mathbf{1}_{\rho * g_\epsilon(x)\le 1}dx + \int_0^1 \sqrt{\rho * g_\epsilon(x)}\mathbf{1}_{\rho * g_\epsilon(x)> 1}dx \\
&\le \int_0^1 \sqrt{\rho * g_\epsilon(x)}\mathbf{1}_{\rho * g_\epsilon(x)\le 1}dx \\
&\quad + \left[\int_0^1 \rho * g_\epsilon(x)dx\right]^{1/2}\left[\int_0^1 \mathbf{1}_{\rho * g_\epsilon(x)> 1}dx\right]^{1/2} \\
&\le \int_0^1 \sqrt{\rho * g_\epsilon(x)}\mathbf{1}_{\rho * g_\epsilon(x)\le 1}dx + \left[\int_0^1 \mathbf{1}_{\rho * g_\epsilon(x)> 1}dx\right]^{1/2},
\end{aligned}$$

which tends to 0 by dominated convergence. We have used the fact that $\int_0^1 \rho * g_\epsilon(x)dx \le 1$.

On the other hand,

$$\left|\int_0^1 \left[\sqrt{\alpha * g_\epsilon(x)} - \sqrt{\alpha(x)}\right] dx\right|^2 \le \int_0^1 |\alpha * g_\epsilon(x) - \alpha(x)|dx,$$

which tends to 0 by [1, Theorem IV.22] . □

We can now end the proof of Proposition 5.1. For any $\eta > 0$, we deduce from Lemmas 5.15 and 5.14 that there exists $\epsilon > 0$ so that

$$\int_0^1 \sqrt{\alpha * g_\epsilon(x) + \rho * \epsilon(x)}f(\phi(x),x)dx \le \int_0^1 \sqrt{\alpha(x)}f(\phi(x),x)dx + \eta,$$

and for all $n \ge 0$

$$\int_0^1 \sqrt{\dot\phi_n}f(\phi(x),x)dx \le \int_0^1 \sqrt{\dot\phi_n} * g_\epsilon(x)f(\phi(x),x)dx + \eta.$$

Now, using Lemma 5.13, we deduce that for n sufficiently large, we have

$$\int_0^1 \sqrt{\dot\phi_n * g_\epsilon(x)} f(\phi(x), x) dx \le \int_0^1 \sqrt{\alpha * g_\epsilon(x) + \rho * \epsilon(x)} f(\phi(x), x) dx + \eta.$$

Moreover, by Jensen's inequality, we have, for all n, $\sqrt{\dot\phi_n} * g_\epsilon(x) \le \sqrt{\dot\phi_n * g_\epsilon}$ so that, using the previous inequalities, we get for sufficiently large n

$$\int_0^1 \sqrt{\dot\phi_n} f(\phi(x), x) dx \le \int_0^1 \sqrt{\alpha(x)} f(\phi(x), x) dx + 3\eta.$$

Taking the lim sup and since η is arbitrary, we get the result.

We now prove the last statement of Proposition 5.1, that is, the fact that if ϕ is a miximizer of U_f, then, for all $x \in [0, 1]$, one has $(\phi(x), x) \in \Omega_f$. We start with a simple fact.

LEMMA 5.16. *Let* $[a, b] \subset [0, 1]$ *and* $[\tilde a, \tilde b] \subset [0, 1]$. *Then*

$$\max \left\{ \int_a^b \sqrt{\dot\phi(x)} dx \mid \phi \in \mathcal{D}^*, \phi(a) = \tilde a, \phi(b) = \tilde b \right\} = \sqrt{b - a}\sqrt{\tilde b - \tilde a},$$

and the maximum is attained for ϕ *linear between* a *and* b.

Proof. Indeed,

$$\left[\int_a^b \sqrt{\dot\phi} \right]^2 \le (b - a) \int_a^b \dot\phi \le (b - a)(\tilde b - \tilde a)$$

with equality if ϕ is linear. □

LEMMA 5.17.

$$U_f(\phi) \le \|f\|_\infty \sqrt{1 - \|\phi - \mathrm{id}\|_\infty^2}.$$

Proof. Take $x \in [0, 1]$ and set $M = |\phi(x) - x|$. Assume first that $\phi(x) = x + M$. Applying Lemma 5.16 between 0 and x and between x and 1, we get

$$U_f(\phi) \le \|f\|_\infty \int_0^1 \sqrt{\dot\phi} dx \le \|f\|_\infty \left(\sqrt{x}\sqrt{x + M} + \sqrt{1 - x}\sqrt{1 - x - M} \right),$$

and elementary calculus yields that the right-hand side is always smaller than

$$\|f\|_\infty \sqrt{1 - M^2}\,.$$

The case $\phi(x) = x - M$ is handled similarly and yields the same upper-bound.

We thus have that, for all $x \in [0, 1]$,

$$U_f(\phi) \le \|f\|_\infty \sqrt{1 - |\phi(x) - x|^2},$$

and taking the infimum of the upper-bound over all x yields the conclusion of the lemma. □

Now, if $U_f^* = \sup\{U_f(\phi), \phi \in \mathcal{D}^*\}$, we always have

$$U_f^* \ge U_f(\mathrm{id}) = \int_0^1 f(x, x) dx = \Delta_f\,.$$

Thus, if $U_f(\phi) = U_f^*$, we have

$$\Delta_f \leq U_f(\phi) \leq \|f\|_\infty \sqrt{1 - \|\phi - \mathrm{id}\,\|_\infty^2}\,;$$

that is,

$$\|\phi - \mathrm{id}\,\|_\infty \leq \sqrt{1 - \left(\frac{\Delta_f}{\|f\|_\infty}\right)^2}\,,$$

which concludes the proof of Proposition 5.1.

5.4. Proof of Proposition 5.2. Let $\phi \in \mathcal{D}^*$ such that $U_f(\phi)$ is maximal. We denote by m the Lebesgue's measure on $[0,1]$. Proposition 5.2 is an obvious consequence of the two following lemmas.

Lemma 5.18. *For any* $0 \leq a < b \leq 1$*, we have* $\int_a^b \dot\phi(x)dx > 0$*, i.e.,* $\phi \in \mathcal{D}_+^*$*.*

Proof. Let us assume that Ω_f has a nonempty interior; that is, $\Delta_f < \|f\|_\infty$. (If this is not the case, Proposition 5.1 implies that the only maximizer is $\phi = \mathrm{id}\,$, which trivially belongs to $\mathcal{D}_+^*$.)

First, let us prove that $U_f(\phi) > 0$. Indeed, from condition [H2], we get that there exists a point (y_0, x_0) in the interior of $[0,1]^2$ such that $f_s(y_0, x_0) > 0$. Since f_s is lower-semicontinuous, f_s is strictly positive in a small neighborhood of (y_0, x_0). Now, define $\tilde\phi$ such that $\tilde\phi(0) = 0$, and $\tilde\phi(1) = 1$, $\tilde\phi(x_0) = y_0$, and $\tilde\phi$ is linear on $[0, x_0]$ and $[x_0, 1]$ (by Lemma 5.16). Since $\tilde\phi$ is strictly increasing on $[0,1]$, we deduce from [H1] that except possibly for a finite number of x, $(\phi(x), x) \notin F$ so that $f(\phi(x), x) = f_s(\phi(x), x)$. Hence, $U_f(\phi) \geq U_f(\tilde\phi) = U_{f_s}(\tilde\phi) > 0$.

Now assume that there exists $0 \leq a < b \leq 1$ such that $\int_a^b \dot\phi(x)dx = 0$. Let $a' = \inf\{z \in [0,a] \mid \int_z^b \dot\phi(x)dx = 0\}$ and $b' = \sup\{\, z \in [b,1] \mid \int_b^z \dot\phi(x)dx = 0\,\}$. We have $\int_{a'}^{b'} \dot\phi(x)dx = 0$, and since $U_f(\phi) > 0$, we have $a' > 0$ or $b' < 1$. Assume that $b' < 1$. (The case $a' > 0$ can be handled similarly.)

Now, for any $\eta > 0$ such that $b' + \eta \leq 1$, and any $\alpha \in]0,1[$, let us define

$$\omega^{\alpha,\eta}(x) = \dot\phi(x)\mathbf{1}_{x \notin [a', b'+\eta]} + (1-\alpha)\dot\phi(x)\mathbf{1}_{x \in]b', b'+\eta]} + \alpha\frac{K_\phi^\eta}{b'-a'}\mathbf{1}_{[a',b']},$$

where $K_\phi^\eta = \int_{a'}^{b'+\eta} \dot\phi(x)dx = \int_{b'}^{b'+\eta} \dot\phi(x)dx$. Let $\mu_{\alpha,\eta} = \omega^{\alpha,\eta}m + \nu_\phi$. One has $\mu_{\alpha,\eta} \in \mathcal{M}_1$, and, letting $\phi_{\alpha,\eta}(x) = \mu_{\alpha,\eta}([0,x[)$, one has

$$|\phi_{\alpha,\eta}(x) - \phi(x)| = \alpha\left|\int_0^x \left(\frac{K_\phi^\eta}{b'-a'}\mathbf{1}_{[a',b']} - \dot\phi\mathbf{1}_{]b',b'+\eta]}\right)\right| \leq \alpha \int_0^1 \dot\phi \leq \alpha,$$

so that $\|\phi_{\alpha,\eta} - \phi\|_\infty \leq \alpha$.

Let us show that $\phi(a') = \phi(b')$. Let R be the rectangle containing the points (y, x) such that $x \in]a', b'[$ and $y \in]\phi(a'), \phi(b')[$. If $\phi(a') < \phi(b')$, then this rectangle has a nonempty interior. Since $(\phi(a'), a') \in \Omega_f$ and $(\phi(b'), b') \in \Omega_f$, the intersection $R \cap \Omega_f$ also has a nonempty interior and, in particular, contains horizontal segments on which f cannot identically vanish. Thus, if $\phi(a') < \phi(b')$, there exist $x_0 \in]a', b'[$ and $y_0 \in\,]\phi(a'), \phi(b')[$ such that $f_s(y_0, x_0) > 0$, and this in turn implies that f_s is strictly positive in a small neighborhood of (y_0, x_0). Now considering $\tilde\phi$ such that $\tilde\phi(x) = \phi(x)$ on $[0, a'] \cup [b', 1]$, $\tilde\phi(x_0) = y_0$, and $\tilde\phi$ is linear on $[a', x_0]$ and on $[x_0, b']$, we have (using the same argument as in the beginning of the proof) $U_f(\phi) < U_f(\tilde{\phi})$ with $\tilde{\phi} \in \mathcal{D}^*$, which is a contradiction.

Since $\phi(a') = \phi(b')$, the segment with end points $(\phi(a'), a')$ and $(\phi(b'), b')$ is vertical and clearly lies in Ω_f, so that by condition [H2] there exists $x_0 \in]a', b'[$ such that $f_s(\phi(x_0), x_0) > 0$. Using the fact that $\|\phi_{\alpha,\eta} - \phi\|_\infty \leq \alpha$, we deduce that there exist $\delta > 0$ and $c > 0$ such that for any sufficiently small α and any $x \in [0,1]$, except eventually a finite number (we use here the fact that $\phi_{\alpha,\eta}$ is strictly increasing on $[a', b']$ and condition [H1]), if $|x - x_0| < \delta$, we have $f(\phi_{\alpha,\eta}(x), x) = f_s(\phi_{\alpha,\eta}(x), x) \geq c$.

Now we have

$$\begin{aligned} U_f(\phi_{\alpha,\eta}) - U_f(\phi) = &\int_{a'}^{b'} \sqrt{\frac{\alpha K_\phi^\eta}{b' - a'}} f(\phi_{\alpha,\eta}(x), x) dx \\ &+ \int_{b'}^{b'+\eta} \left[\sqrt{(1-\alpha)\dot{\phi}(x)} f(\phi_{\alpha,\eta}(x), x) - \sqrt{\dot{\phi}(x)} f(\phi(x), x) \right] dx. \end{aligned}$$

However, for α sufficiently small,

$$\int_{a'}^{b'} \sqrt{\frac{\alpha K_\phi^\eta}{b' - a'}} f(\phi_{\alpha,\eta}(x), x) dx \geq \left(\frac{2c\delta}{\sqrt{b' - a'}} \right) \sqrt{\alpha K_\phi^\eta},$$

and

$$\begin{aligned} &\left| \int_{b'}^{b'+\eta} \sqrt{(1-\alpha)\dot{\phi}(x)} f(\phi_{\alpha,\eta}(x), x) - \sqrt{\dot{\phi}(x)} f(\phi(x), x) dx \right| \\ &\qquad \leq 2\|f\|_\infty \int_{b'}^{b'+\eta} \sqrt{\dot{\phi}(x)} dx \leq 2\sqrt{\eta}\|f\|_\infty \sqrt{K_\phi^\eta}, \end{aligned}$$

so that

$$U_f(\phi_{\alpha,\eta}) - U_f(\phi) \geq \sqrt{K_\phi^\eta} \left(\frac{2c\delta}{\sqrt{b' - a'}} \sqrt{\alpha} - 2\sqrt{\eta}\|f\|_\infty \right).$$

Hence, choosing η sufficiently small, say $\eta < \frac{4\eta^2\delta^2\alpha}{(b'-a')\|f\|_\infty}$, we get $U_f(\phi_{\alpha,\eta}) - U_f(\phi) > 0$, which is a contradiction with the definition of ϕ as a maximizer. □

LEMMA 5.19. *For any* $a \in [0,1]$, $\nu_\phi(\{a\}) = 0$.

Proof. Let $\phi \in \mathcal{D}_+^*$ such that $U_f(\phi) = \max_{\mathcal{D}^*} U_f$. Proposition 5.7 implies that $U_{\tilde{f}}(\phi^-) = \max_{\mathcal{D}^*} U_{\tilde{f}}$. But if f satisfies conditions [H1] and [H2], so does $\tilde{f}$, and thus, one has $\phi^- \in \mathcal{D}_+^*$. Lemma 5.8 now implies that $\phi = (\phi^-)^-$ is continuous, which concludes the proof. □

6. Proof of the regularity results.

Proof of Theorem 3.3. The idea of the proof is to use the fact that after a proper change of variable and rescaling, ϕ^* is the solution of a local variational problem around any point x. Hence, the behavior of ϕ^* at x depends only on the properties of the locally optimal solutions involving the values of f in a small neighborhood of $(\phi^*(x), x)$.

Let $0 \leq a < b \leq 1$, and define for any $\phi \in \mathrm{Hom}^+$ the new "focusing" functions $\phi_{a,b} \in \mathrm{Hom}^+$ and $f_{a,b}^\phi : [0,1]^2 \to \mathbb{R}$ by

$$\phi_{a,b}(x') = \frac{\phi(a + x'(b-a)) - \phi(a)}{\phi(b) - \phi(a)} \; \forall x' \in [0,1],$$

and

$$f^{\phi}_{a,b}(y',x') = f(\phi(a) + y'(\phi(b) - \phi(a)), a + x'(b-a)).$$

One has, after a simple computation,

$$\int_a^b \sqrt{\dot\phi(x)} f(\phi(x),x)dx = \sqrt{(b-a)(\phi(b)-\phi(a))}U_{f^{\phi}_{a,b}}(\phi_{a,b})$$

so that

$$U_{f^{\phi^*}_{a,b}}(\phi^*_{a,b}) = \max_{\phi\in\mathrm{Hom}^+} U_{f^{\phi^*}_{a,b}}(\phi).$$

Let $\delta_{a,b} = \|f^{\phi^*}_{a,b}\|_\infty - \int_0^1 f^{\phi^*}_{a,b}(x',x')dx'$ and assume that $\|f^{\phi^*}_{a,b}\|_\infty > 0$; then we deduce from Theorem 3.1 that

$$\|\phi^*_{a,b} - \mathrm{Id}\|_\infty \le \sqrt{1 - \left(\frac{\|f^{\phi^*}_{a,b}\|_\infty - \delta_{a,b}}{\|f^{\phi^*}_{a,b}\|_\infty}\right)^2} \le \sqrt{2\frac{\delta_{a,b}}{\|f^{\phi^*}_{a,b}\|_\infty}}. \tag{6.1}$$

Hence, if $x_0 \in [a,b]$ and f is Hölder continuous with parameter $\alpha > 0$ at $(\phi^*(x_0),x_0)$ and if $f(\phi^*(x_0),x_0) > 0$, then we get easily that there exists a constant k_{x_0} (depending only on $(\phi^*(x_0),x_0)$) such that

$$\delta_{a,b} \le k_{x_0}\max(|\phi^*(b) - \phi^*(a)|^\alpha, (b-a)^\alpha)\,.$$

Using the fact that $\|f^{\phi^*}_{a,b}\|_\infty \ge f(\phi^*(x_0),x_0) > 0$, we deduce from inequality (6.1) that

$$\|\phi^*_{a,b} - \mathrm{Id}\|_\infty \le C_{x_0}(b-a)^{\alpha/2}\max\left(\left(\frac{|\phi^*(b)-\phi^*(a)|}{b-a}\right)^{\alpha/2}, 1\right), \tag{6.2}$$

with $C_{x_0} = \sqrt{\frac{2k_{x_0}}{f(\phi^*(x_0),x_0)}}$. Choosing $a = x_0$ and $b = x_0 + h$ with any $h > 0$ such that $x_0 + h \le 1$, we deduce from the previous inequality that, for all $u \in]0,1]$,

$$|\Delta\phi^*(x_0,uh) - \Delta\phi^*(x_0,h)| \le \Delta\phi^*(x_0,h)C_{x_0}\frac{h^{\alpha/2}}{u}\max(\Delta\phi^*(x_0,h)^{\alpha/2},1), \tag{6.3}$$

where for any $h' > 0$ we have $\Delta\phi^*(x_0,h') = (\phi^*(x_0+h') - \phi^*(x_0))/h'$. The fact that

$$\lim_{h\to 0, h'>0} \Delta\phi^*(x_0,h')$$

exists and is positive is a consequence of the following lemma, applied to $F(h) = \Delta\phi^*(x_0,h)$. (Note that $hF(h) \to 0$ if $h \to 0$, since ϕ^* is continuous.)

LEMMA 6.1. *Let $F > 0$ be a function defined on $]0,\beta]$ (for some $\beta > 0$) and such that, for all $h \in]0,\beta]$ and for all $u \in]0,1]$, and for some constants $K > 0$, $\rho > 0$, and $\beta > 0$,*

$$|F(uh) - F(h)| \le K.F(h)(1 + F(h)^\rho)\frac{h^\rho}{u}\,. \tag{6.4}$$

Assume, moreover, that $\lim_{h\to 0} hF(h) = 0$. Then, $\lim_{h\to 0} F(h)$ exists and is strictly positive.

Proof of Lemma 6.1. Let $h_0 \in]0, \beta]$, and let, for $n \geq 1$, $v_n = F(h_0 2^{-n})$. From (6.4), we get, for some constant K',

$$|v_{n+1} - v_n| \leq K' h_0^\rho v_n (1 + v_n^\rho) 2^{-\rho n} \,. \tag{6.5}$$

Clearly, to prove that v_n converges, it suffices to prove that it is bounded. In fact, it merely suffices to prove that $v_n \leq C.2^{\gamma n}$ for some $\gamma < 1$, since, in this case, (6.5) yields an inequality of the kind

$$|v_{n+1} - v_n| \leq K'' v_n 2^{-\rho' n}$$

for some constants K'' and $\rho' > 0$, which implies in turn that v_n is bounded, since $\prod_{k=0}^{\infty} (1 + K'' 2^{-\rho' k}) < \infty$.

So, fix $\gamma < 1$ and let us prove that, if h_0 is taken to be small enough, one has, for all n, $v_n \leq F(h_0) 2^{\gamma n}$. Assuming that this is true for $n \geq 0$ (recall that $v_0 = F(h_0)$, so that it is true for $n = 0$), we show that this is true for $n + 1$. We have

$$v_{n+1} \leq F(h_0).2^{\gamma n} (1 + K' h_0^\rho (1 + F(h_0)^\rho 2^{\rho \gamma n}) 2^{-\rho n}) \leq F(h_0) 2^{\gamma n} (1 + K' h_0^\rho (1 + F(h_0)^\rho))$$

so that it suffices to take h_0 such that $1 + K' h_0^\rho (1 + F(h_0)^\rho) < 2^\gamma$ to get the desired conclusion.

Thus, v_n converges to a limit v. But since (6.5) implies that

$$v_{n+1} \geq v_n (1 - K' h_0^\rho 2^{-\rho n}),$$

we have, letting n_0 such that $K' h_0^\rho 2^{-\rho n_0} < 1$, for all $n \geq n_0$,

$$0 < v_{n_0} \prod_{k=n_0}^{\infty} (1 - K' h_0^\rho 2^{-\rho k}) \leq v_n, \tag{6.6}$$

which imples that $v > 0$.

Now, if h_n is any sequence which tends to 0 from above, one can find, for all n, an integer k_n such that $h_0 2^{-k_n - 1} < h_n \leq h_0 2^{-k_n}$, and (6.4) implies that

$$|F(h_n) - v_{k_n}| \leq K' |v_{k_n}| 2^{-\rho k_n}$$

so that, since k_n tends to infinity, $F(h_n)$ tends to v, which proves Lemma 6.1. □

We thus have proved that ϕ^* has a strictly positive right derivative denoted $\dot{\phi}_r^*(x_0)$. In the same way, we can prove that the left derivative denoted $\dot{\phi}_l^*(x_0)$ exists and is stricly positive. It thus remains to prove that both derivatives coincide. In fact, relation (6.2) with $a = x_0 - h$ and $b = x_0 + h$ yields

$$\lim_{h \to 0} \left| \frac{\phi^*(x_0) - \phi^*(x_0 - h)}{\phi^*(x_0 + h) - \phi^*(x_0 - h)} - \frac{1}{2} \right| = 0 \,.$$

Since the left-hand part of the inequality also tends to $\frac{\dot{\phi}_l^*}{\dot{\phi}_l^* + \dot{\phi}_r^*} - \frac{1}{2}$, we get the result. Hence the first part of the theorem is proved.

Now, if f is locally uniformly Hölder continuous at x_0, there exists (since ϕ^* is continuous) an $\epsilon > 0$ in $[0, 1]$ such that (3.1) holds at point $(\phi(x), x)$ for all x such that $|x - x_0| < \epsilon$. As a consequence, ϕ^* will thus be differentiable at all such $x \in]x_0 - \epsilon, x_0 + \epsilon[$ and the increments $\Delta\phi^*(x, h)$ will converge, as $h \to 0$, uniformly to $\dot{\phi}^*(x)$. Since these increments are continuous, $\dot{\phi}^*$ is also continuous on $]x_0 - \epsilon, x_0 + \epsilon[$. □

Proof of Theorem 3.4. By Theorem 3.3, ϕ is continuously differentiable. Moreover, one has, for any ψ smooth diffeomorphism of $[0, 1]$,

$$\int_0^1 \sqrt{\dot{\phi}}(x)\sqrt{\dot{\psi}}(x) f(\phi(x), \psi(x))dx \leq \int_0^1 \sqrt{\dot{\phi}}(x) f(\phi(x), x)dx \tag{6.7}$$

(simply using that the left-hand term is $U_f(\phi \circ \psi^{-1})$). If h is any smooth function in $[0, 1]$ such that $h(0) = h(1) = 0$, there exists a small enough t such that $\psi(x) = x + th(x)$ is a diffeomorphism, and, after computation of the first variation in the left-hand term of (6.7), one gets that, for all smooth h with $h(0) = h(1) = 0$,

$$\int_0^1 \sqrt{\dot{\phi}}(x)\dot{h}(x) f(\phi(x), x) = -2\int_0^1 \sqrt{\dot{\phi}}(x)\frac{\partial f}{\partial y}(\phi(x), x).h(x)dx.$$

So, letting $q(x) = \sqrt{\dot{\phi}}(x) f(\phi(x), x)$, one has

$$q(x) = q(0) + 2\int_0^x \sqrt{\dot{\phi}}(u)\frac{\partial f}{\partial y}(\phi(u), u)du$$

so that q is differentiable in the ordinary sense, with derivative $2\sqrt{\dot{\phi}}\frac{\partial f}{\partial y}(\phi(.), .)$, which is continuous. Since

$$\dot{\phi}(x) = \frac{q^2(x)}{f(\phi(x), x)},$$

the numerator being positive and continuously differentiable, we get the fact that $\dot{\phi}$ is continuously differentiable. □

7. Auxiliary results.

We conclude this paper with two simple results which have important practical applications. The first one validates the possibility of implementing a matching combined with the fitting of some registration parameters. This enables us to recover some invariance properties which have not directly been incorporated in F.

The second result provides an approximation scheme, which permits us to work safely with discretized versions of a signal. It also naturally yields consistent multiscale minimization procedures, which is important for efficiency of numerical implementations.

7.1. Handling additional parameters.

In many practical situations, a matching is searched for up to some given finite-dimensional parameter which performs some registration between the two quantities which are compared. For example, in the formulation $f(\phi(x), x) = F(\theta \circ \phi(x), \theta'(x))$, one may consider that the functions θ should be identified to $\theta + b$ for any $b \in \mathbb{R}$ (in order to get a translation invariant matching), so that the complete problem becomes maximizing

$$\int_0^1 \sqrt{\dot{\phi}} F(\theta \circ \phi(x) + b, \theta'(x))dx$$

over all ϕ and b. For example, in [9], translation on θ represented rotations of plane curves, rotation-invariant comparison being a desirable feature for shape comparison.

More generally, we shall deal in this section with a function f, which depends on an additional extraneous parameter $\lambda \in \mathbb{R}^d$, and we shall try to find ϕ^* and λ^* which maximize

$$V_f(\phi, \lambda) = \int_0^1 \sqrt{\dot{\phi}(x) f(\phi(x), x, \lambda)} dx$$

for $\phi \in \mathcal{D}$ and $\lambda \in K$, where K is a compact subset of $\mathbb{R}^2$. Sufficient conditions for existence are provided in the following theorem. We let f_λ be the function $(x, y) \mapsto f(x, y, \lambda)$.

THEOREM 7.1. *We assume that f is continuous in $\lambda \in K$, uniformly in (x, y), and that, for all λ, the function f_λ satisfies conditions* [H1] *and* [H2] *of Theorem* 3.1. *Then, there exist $\lambda^* \in K$ and $\phi^* \in Hom^+$ such that*

$$V_f(\phi^*, \lambda^*) = \max\{V_f(\phi, \lambda) \mid \phi \in Hom^+, \lambda \in K\}.$$

Proof. By Theorem 3.1, for all $\lambda \in K$, the functional $\phi \mapsto V_f(\phi, \lambda)$ is upper-semicontinuous in $\phi \in \mathcal{D}^*$. Moreover, it is uniformly continuous in λ, since

$$\begin{aligned}|V_f(\phi, \lambda) - V_f(\phi, \lambda')| &\leq \int_0^1 \sqrt{\dot{\phi}} |f(\phi(x), x, \lambda) - f(\phi(x), x, \lambda')| dx \\ &\leq \sup_{x,y} |f(x, y, \lambda) - f(x, y, \lambda')|,\end{aligned}$$

which tends to 0 if λ tends to λ'. This implies that U is upper-semicontinuous as a function of the two variables ϕ and λ, and thus that there exists a maximizer $(\phi^*, \lambda^*) \in \mathcal{D}^* \times K$. Now, since ϕ^* is a maximizer of $U_f(., \lambda^*)$ over $\mathcal{D}^*$, Proposition 5.2 implies that $\phi^* \in \mathrm{Hom}^+$. □

7.2. Approximation schemes.

THEOREM 7.2. *Let $(f_n, n \geq 0)$ and f be functions defined on $[0, 1]^2 \times K$ such that*

$$\lim_{n \to \infty} \sup_{x,y,\lambda} |f_n(x, y, \lambda) - f(x, y, \lambda)| = 0.$$

Assume that all f_n and f satisfy the conditions of Theorem 7.1. *Let (ϕ_n^*, λ_n^*) be maximizers of V_{f_n} over $\mathcal{D}^* \times K$; then, there exists a subsequence of (ϕ_n^*, λ_n^*) which converges in $\mathcal{D}^* \times K$ to a maximizer (ϕ^*, λ^*) of V_f.*

Proof. Indeed, the hypotheses trivially imply that U_n converges to U uniformly on $\mathcal{D}^* \times K$, so that $\max U_n \to \max U$ and

$$\lim_{n \to \infty} U(\phi_n^*, \lambda_n^*) = \max U\,.$$

Now from (ϕ_n^*, λ_n^*) one can extract a converging subsequence in the compact space $\mathcal{D}^* \times K$ to a limit denoted (ϕ, λ), and one must have $U(\phi, \lambda) = \max U$ because U is upper-semicontinuous. □

One application of the theorem is the following. Assume, for example, that f is continuous and f_λ satisfies condition [H2] of Theorem 3.1 for all $\lambda \in K$. Let $g_n(x, y, \lambda)$ be a piecewise constant approximation of f, and let $f_n = \epsilon_n + g_n$, where ϵ_n is a sequence which tends to 0. Then, each f_n satisfies the conditions of Theorem 7.1 so that Theorem 7.2 applies. Such a situation is typical in numerical procedures.

PROXIMAL POINT APPROACH AND APPROXIMATION OF VARIATIONAL INEQUALITIES*

A. KAPLAN† AND R. TICHATSCHKE†

Abstract. A general approach to analyze convergence of the proximal-like methods for variational inequalities with set-valued maximal monotone operators is developed. It is oriented to methods coupling successive approximation of the variational inequality with the proximal point algorithm as well as to related methods using regularization on a subspace and weak regularization. This approach also covers so-called multistep regularization methods, in which the number of proximal iterations in the approximated problems is controlled by a criterion characterizing these iterations as to be effective. The conditions on convergence require control of the exactness of the approximation only in a certain region of the original space. Conditions ensuring linear convergence of the methods are established.

Key words. variational inequalities, monotone operators, convex programming, proximal point methods, weak regularization

1. Introduction.

Variational inequalities with maximal monotone operators include convex programs, convex-concave saddle point problems, equations, and inclusions with maximal monotone operators and a series of other problems.

The proximal point method, introduced by Martinet [28] and later investigated in a more general setting by Rockafellar [34], has initiated a couple of new algorithms for solving these problems. We refer to [2], [14], [35], [42] for algorithms based on multiplier methods and to [1], [4], [15], [16], [17] for modifications of the penalty technique. Proximal variants of bundle methods for nonsmooth convex optimization problems are given in [3], [22], [25], [29], and for partial inverses of monotone operators as well as for decomposition and parallel optimization methods; see [5], [6], [9], [39], and [40]. The number of papers dealing with the proximal point approach is growing fast and we can cite here only a few of them. Moreover, it is known (see [16], [24], [34]) that some classical numerical methods can be interpreted as special applications of this approach. In [8] this fact was established concerning the *Douglas–Rachford splitting method* for finding a zero of the sum of two monotone operators. This points out new applications of the proximal technique, in particular, to problems in mathematical physics; for such problems, see, for instance, [26].

The basic results of Rockafellar [34] on convergence of the proximal point method for solving variational inequalities with maximal monotone operators were generalized in [27] concerning the rate of convergence, and in [11] a similar analysis was made for methods using the proximal technique on a subspace. More precisely, in the papers mentioned the methods were studied for the equivalent problem of finding a zero of a maximal monotone operator under the assumption that the proximal iterations can be performed inexactly. However, an approximation of the data of the problem was not considered there.

†Department of Mathematics, University of Trier, D-54286 Trier, Germany (a.a.kaplan@tiscalinet.de, tichat@uni-trier.de).

In this paper the convergence analysis covers methods which couple a successive approximation of the variational inequality with the proximal point approach, as well as related methods using a regularization on a subspace or a weak regularization.

The problem under consideration is the following variational inequality:

$$\text{(1.1)} \qquad \text{find } u \in K \text{ such that } \exists\, y \in \mathcal{T}u: \quad \langle y, v-u\rangle \geq 0 \;\; \forall v \in K,$$

with K a convex, closed subset of a Hilbert space V, $\mathcal{T} : V \to 2^{V'}$ a monotone operator, $D(\mathcal{T}) \equiv \{v \in V : \mathcal{T}v \neq \emptyset\} \supset K$, V' the dual space of V, and $\langle\cdot,\cdot\rangle$ the duality pairing between V and V'.

We recall that an operator $\mathcal{A} : V \to 2^{V'}$ is said to be *monotone* if

$$\langle w-z, u-v\rangle \geq 0 \;\text{ whenever }\; w \in \mathcal{A}u,\; z \in \mathcal{A}v,$$

and *strongly monotone* if

$$\langle w-z, u-v\rangle \geq \gamma\|u-v\|^2 \;\text{ with some } \gamma > 0.$$

A monotone operator $\mathcal{A}$ is called *maximal monotone* if its graph is not properly contained in the graph of any other monotone operator $\mathcal{A}^1 : V \to 2^{V'}$.

Throughout the whole paper it is supposed that H is a given Hilbert space such that V can be continuously embedded into H, V_1 is a given closed subspace of V, and $\mathcal{P} : V \to V_1$ is the orthogonal projection operator (orthoprojector). If V_1 is also closed in H, then $\mathcal{P}$ can be defined as the orthoprojector according to the norm of H. In the framework of the approach considered, the solution of (1.1) is obtained by solving approximately the sequence of variational inequalities

$$\text{(1.2)} \qquad \begin{aligned} &u \in K_i : \langle \mathcal{T}_i u, v-u\rangle + \chi_i(\mathcal{P}u - \mathcal{P}u^{i,s-1}, \mathcal{P}v - \mathcal{P}u)_H \geq 0 \;\; \forall v \in K_i,\\ &\qquad s = 1,\dots,s(i);\; i = 1,2,\dots, \end{aligned}$$

with $\mathcal{T}_i : V \to V'$, and K_i certain approximations for $\mathcal{T}$ and K, respectively, $(\cdot,\cdot)_H$ the inner product in H, $u^{i,s-1}$ a solution of the previous problem ($u^{i,0} \equiv u^{i-1,s(i-1)}$), $0 < \chi_i \leq \bar{\chi}$.

For example, treating variational problems in mechanics, often K_i is an internal approximation of K constructed by means of a finite element method, and $\mathcal{T}_i$ is the gradient of a smoothened energy functional (cf. the approximation of the linear model of elasticity with friction in [10, section 4.2] that corresponds formally to (1.2) with $\chi_i \equiv 0$; by the way, we avoid the identification of V and V' taking into account the standard estimation technique in finite element methods).

The choice of the space H as well as of the subspace $V_1 \subset V$ depends on specific properties of the problem under consideration. In particular, this choice has to ensure the strong monotonicity of the operators $\mathcal{T}_i + \chi_i\mathcal{M}$, where $\mathcal{M} : V \to V'$ is defined by $\langle \mathcal{M}u, v\rangle = (\mathcal{P}u, \mathcal{P}v)_H \; \forall u, v \in V$. For variational inequalities studied in [19], the space V is of the type $H^1(\Omega)$ and the operator $\mathcal{T}$ is not strongly monotone in V. However, (weak) regularization with $V_1 = V$, $H = L_2(\Omega)$ ensures strong monotonicity of the operators $\mathcal{T} + \chi_i\mathcal{M}$, $\mathcal{T}_i + \chi_i\mathcal{M}$ and weak convergence of the iterates in V, i.e., it leads to the same quality of convergence as in the case of applying the standard (strong) proximal regularization with $V_1 = V$, $H = V$.

The situation, that a subspace $V_1 \neq V$ with appropriate properties is known, is typical for problems in mathematical physics. Referring again to [19], for a two-body contact problem considered there, V_1 is a known 3-dimensional subspace of the rigid displacements of one of the bodies.

A suitable choice of V_1 and H can accelerate essentially the numerical calculation (see the analysis of some examples in [16], [18], and numerical experiments with real-life problems in [36], [37].)

The strong formalization of method (1.2) is described in section 2 as *multistep regularization method* (MSR-method). The notion "multistep regularization" reflects the presence of an inner cycle (with respect to s) of proximal iterations.

The case that $\mathcal{T}$ is a subdifferential of a convex functional, $H = V = V_1$, and $s(i) = 1\ \forall i$, includes several "diagonal" variants of the proximal point method for convex optimization (cf. [16, sections 9 and 12], [23] and the references therein).

There are a lot of papers concerning the *diagonal approximation* of the ill-posed problem (1.1) with the use of the *Browder–Tikhonov regularization.* In this case the auxiliary problems have the form

$$u \in K_i \ :\quad \langle \mathcal{T}_i u + \chi_i \mathcal{M}_0(u - \hat{u}), v - u\rangle \geq 0 \quad \forall v \in K_i,$$

where $\mathcal{M}_0 : V \to V'$ is a strongly monotone operator, $\hat{u} \in V$ is a fixed element, and $\chi_i > 0, \lim\ \chi_i = 0$. Fundamental results in this direction were obtained by Mosco [30]; for concrete algorithms see Vasil'ev [41].

In as much as $\chi_i \to 0$ is not necessary for the convergence of proximal methods, they possess a better stability and provide a better efficiency of fast convergent algorithms solving the regularized auxiliary problems.

In methods of type (1.2) the iterations with respect to s (for a fixed approximation level i) continue "as long as they remain effective" (see Remark 3.12 below). The MSR-methods were developed in [16] for convex variational problems, i.e., in the case that $\mathcal{T}$ is a subdifferential of a convex functional. In [19], [12], [13], and [20] they were adapted to some problems in elasticity theory and optimal control with PDEs. In comparison with diagonal proximal processes, the MSR-methods allow better approximations of a sought solution of the original problem under the same approximate data $\mathcal{T}_i,\ K_i$ and the same χ_i, ϵ_i, so that the numerical expense can be reduced. This has been confirmed, in particular, by numerical experiments for Bingham problems in [37] and for optimal control problems governed by elliptic equations in [36].

Here we investigate the convergence of such methods in the more general setting that the operator $\mathcal{T}$ may be nonpotential. This permits consideration of new applications, in particular, saddle point problems and complementarity problems. The principal distinction to the convergence analysis made in [16] is caused by the fact that the condition about the uniform approximation of the objective functional used in [16] cannot be adapted in order to describe the closeness between $\mathcal{T}$ and $\mathcal{T}_i$.

In comparison to the present paper, in [21] the convergence (without rate of convergence) of scheme (1.2) is investigated for the particular case $H = V = V_1$ (hence, $\mathcal{P}$ is the identity operator) and under more restrictive assumptions concerning the approximation of the operator $\mathcal{T}$ and the set K; cf. conditions (c$'$), (d$'$), (e$'$) below in Remark 3.5(ii) and Assumptions 3.4(c), (d), (e).

The paper is organized as follows. Section 2 contains the description of a generalized MSR-scheme. Its convergence is studied in section 3 and estimates of the rate of convergence for the basic variant (with $H = V = V_1$) are given in section 4.

We do not consider here the adaptation of the generalized MSR-scheme to particular problems. This will be the object of a forthcoming paper. For some applications of the basic variant to variational inequalities with potential and nonpotential operators $\mathcal{T}$ we refer to [21].

2. Multistep proximal regularization scheme. We denote by $\|\cdot\|, \|\cdot\|_{V'}$, and $\|\cdot\|_H$ the norms in V, V', and H, respectively. With z, C, D from V (respectively, from V'), let

$$dist(z,D) = \inf_{w\in D} \|z-w\|, \quad dist(C,D) = \sup_{z\in C} dist(z,D),$$
$$(\text{resp., } dist_{V'}(z,D) = \inf_{w\in D} \|z-w\|_{V'},\ dist_{V'}(C,D) = \sup_{z\in C} dist_{V'}(z,D)).$$

The following assumption concerns the chosen triple H, V_1, and $\mathcal{P}$.

ASSUMPTION 2.1. *For a given linear, continuous, and monotone operator $\mathcal{B} : V \to V'$ with the symmetry property*

$$\langle \mathcal{B}u, v\rangle = \langle \mathcal{B}v, u\rangle \quad \forall u, v \in V$$

and a given $\tilde{\chi} > 0$ there exists $\beta_0 > 0$ such that

$$\tilde{\chi}\langle \mathcal{B}u, u\rangle + \|\mathcal{P}u\|_H^2 \geq \beta_0\|u\|^2 \quad \forall u \in V. \tag{2.1}$$

If this assumption is valid, one can introduce on V a new norm $|||\cdot|||$ by

$$|||u|||^2 = \tilde{\chi}\langle \mathcal{B}u, u\rangle + \|\mathcal{P}u\|_H^2, \tag{2.2}$$

which is equivalent to the original one $\|\cdot\|$ because of

$$\beta_0\|u\|^2 \leq |||u|||^2 \leq (\beta_1\tilde{\chi} + \beta_2^2)\|u\|^2, \tag{2.3}$$

with $\beta_1 = \sup_{u\neq 0} \frac{\|\mathcal{B}u\|_{V'}}{\|u\|}$ and $\beta_2 : \|u\|_H \leq \beta_2\|u\| \quad \forall u \in V$.

Denote $S_\tau = \{u \in V : |||u||| \leq \tau\}$. Let $\{\mathcal{T}_i\}, \mathcal{T}_i : V \to V'$, be a sequence of monotone and hemicontinuous (i.e., weak continuous along each line segment in V) operators, approximating $\mathcal{T}$, and $\{K_i\}$, $K_i \subset D(\mathcal{T}_i) \subset V$, be a sequence of convex closed sets, approximating K.

Henceforth it is supposed that the solution set U^* of problem (1.1) is nonempty, Assumption 2.1 is fulfilled, and radii r and r^* are chosen such that

$$U^* \cap S_{r^*/8} \neq \emptyset \quad \text{and} \quad r \geq r^*. \tag{2.4}$$

MULTISTEP REGULARIZATION METHOD.
Let $\{\chi_i\}, \{\epsilon_i\}, \{\delta_i\}$ be positive controlling sequences with

$$\sup_i \ \chi_i \leq \bar{\chi} < \infty, \quad \lim_{i\to\infty} \ \epsilon_i = 0,$$

and $u^0 \in S_{r^*/4}$.
Step i: *Given u^{i-1}.*
(a) *Set $u^{i,0} := u^{i-1}$, $s := 1$.*
(b) *Given $u^{i,s-1}$, define*

$$u^{i,s} : \quad \|u^{i,s} - \bar{u}^{i,s}\| \leq \epsilon_i, \tag{2.5}$$

where $\bar{u}^{i,s}$ is the exact solution of the variational inequality

$$u \in K_i : \langle \mathcal{T}_i u, v - u\rangle + \chi_i(\mathcal{P}u - \mathcal{P}u^{i,s-1}, \mathcal{P}v - \mathcal{P}u)_H \geq 0 \quad \forall v \in K_i. \tag{2.6}$$

(c) *If* $\|\mathcal{P}u^{i,s} - \mathcal{P}u^{i,s-1}\|_H > \delta_i$, *then set* $s := s+1$ *and repeat* (b).
Otherwise, set $s(i) := s, u^i := u^{i,s}, i := i+1$ *and repeat Step* i.

The choice $H = V = V_1$ corresponds to the *basic variant of the MSR-method* [16], and $V_1 \neq V$ reflects the *(MSR-) method with regularization on a subspace* (cf. [16], [12], [13], [20]). If $V_1 = V$ and $\| \cdot \|_H$ is weaker than $\| \cdot \|$, one deals with the *(MSR-) method with a weak regularization* (see [16], [19], [37]). For the diagonal method with regularization on a subspace we refer to [11] and to Rockafellar's interpretation for the multiplier method in [35].

Of course, condition (2.5) is not a practicable criterion. However, it is convenient to unify the investigation of algorithms with different stopping rules for the auxiliary problems: in fact, (2.6) is a variational inequality with a strongly monotone operator (see Remark 3.5(i)), and therefore, criterion (2.5) can be satisfied by means of the own stopping rule of an algorithm inserted into the MSR-method to solve the auxiliary problems (2.6). In Remark 3.14 we discuss the use of the criterion

$$\begin{aligned}
&u^{i,s} \in K_i : \\
&\langle \mathcal{T}_i u^{i,s}, v - u^{i,s}\rangle + \chi_i \left(\mathcal{P}u^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}v - \mathcal{P}u^{i,s}\right)_H \geq -\epsilon_i' \|v - u^{i,s}\| \\
&\forall v \in K_i.
\end{aligned}$$

One should refer also to [7], [38] for practicable notions of inexact proximal iterations.

3. Convergence analysis. According to Riesz's representation theorem, the variational inequality (2.6) can be rewritten in the form

$$u \in K_i : \langle \mathcal{T}_i u + \chi_i \mathcal{M}(u - u^{i,s-1}), v - u\rangle \geq 0 \quad \forall v \in K_i, \tag{3.1}$$

where the linear operator $\mathcal{M} : V \to V'$ is defined by

$$\langle \mathcal{M}u, v\rangle = (\mathcal{P}u, \mathcal{P}v)_H \quad \forall u, v \in V.$$

In order to prove convergence of this method, we need some auxiliary statements.

LEMMA 3.1. *Let $G \subset V$ be a closed convex set, and let $\mathcal{A} : V \to V'$ be a single-valued operator with $D(\mathcal{A}) \supset G$. Suppose that the inequality*

$$\langle \mathcal{A}u - \mathcal{A}v, u - v\rangle \geq \langle \mathcal{B}u - \mathcal{B}v, u - v\rangle \quad \forall u, v \in G \tag{3.2}$$

is valid with $\mathcal{B}$ as in Assumption 2.1. *Moreover, for arbitrary $a^0 \in V$ and $\chi \in (0, 2\tilde{\chi}^{-1}]$, let a^1 be a solution of the variational inequality*

$$u \in G \ : \ \langle \mathcal{A}u, v - u\rangle + \chi(\mathcal{P}u - \mathcal{P}a^0, \mathcal{P}v - \mathcal{P}u)_H \geq 0 \quad \forall v \in G. \tag{3.3}$$

Then the inequality

$$|||a^1 - v|||^2 - |||a^0 - v|||^2 \leq -\|\mathcal{P}a^1 - \mathcal{P}a^0\|_H^2 + \frac{2}{\chi}\langle \mathcal{A}v, v - a^1\rangle \tag{3.4}$$

is true for each $v \in G$.

Proof. From the definition of $||| \cdot |||$ we obtain

$$\begin{aligned}
&|||a^1 - v|||^2 - |||a^0 - v|||^2 = -\|\mathcal{P}a^1 - \mathcal{P}a^0\|_H^2 \\
&-2(\mathcal{P}a^1 - \mathcal{P}a^0, \mathcal{P}v - \mathcal{P}a^1)_H \\
&+\tilde{\chi}\langle \mathcal{B}(a^1 - v), a^1 - v\rangle - \tilde{\chi}\langle \mathcal{B}(a^0 - v), a^0 - v\rangle.
\end{aligned}$$

Using this inequality together with (3.3) one can conclude that

$$\begin{aligned} &|||a^1 - v|||^2 - |||a^0 - v|||^2 \le -\|\mathcal{P}a^1 - \mathcal{P}a^0\|_H^2 + \frac{2}{\chi}\langle \mathcal{A}a^1, v - a^1\rangle \\ &+\tilde{\chi}\langle \mathcal{B}(a^1 - v), a^1 - v\rangle - \tilde{\chi}\langle \mathcal{B}(a^0 - v), a^0 - v\rangle, \end{aligned} \tag{3.5}$$

and, due to (3.2) and $0 < \chi \le 2\tilde{\chi}^{-1}$, this yields

$$\begin{aligned} |||a^1 - v|||^2 - |||a^0 - v|||^2 &\le -\|\mathcal{P}a^1 - \mathcal{P}a^0\|_H^2 - \frac{2}{\chi}\langle \mathcal{A}v - \mathcal{A}a^1, v - a^1\rangle \\ &+\frac{2}{\chi}\langle \mathcal{A}v, v - a^1\rangle + \tilde{\chi}\langle \mathcal{B}(v - a^1), v - a^1\rangle - \tilde{\chi}\langle \mathcal{B}(a^0 - v), a^0 - v\rangle \\ &\le -\|\mathcal{P}a^1 - \mathcal{P}a^0\|_H^2 + \frac{2}{\chi}\langle \mathcal{A}v, v - a^1\rangle. \qquad \square \end{aligned}$$

LEMMA 3.2. *Let $G \subset V$, $G_1 \subset V$, and G be a convex closed set. For a given $y \in Y'$, let a solution $\bar{u}$ of the problem*

$$\textit{find} \quad u \in G \cap G_1 \ : \ \langle y, v - u\rangle \ge 0 \quad \forall v \in G \cap G_1 \tag{3.6}$$

belong to $\mathrm{int}G_1$. *Then $\bar{u}$ is also a solution of the problem*

$$\textit{find} \quad u \in G \ : \ \langle y, v - u\rangle \ge 0 \quad \forall v \in G. \tag{3.7}$$

Proof. Take an arbitrary $w \in G\backslash G_1$. Because $\bar{u} \in \mathrm{int}G_1$, there exists $\lambda = \lambda(w) \in (0,1)$ such that $\bar{u} + \lambda(w - \bar{u}) \in G_1$; hence $\bar{u} + \lambda(w - \bar{u}) \in G \cap G_1$. Therefore, we get from (3.6) that

$$\langle y, \bar{u} + \lambda(w - \bar{u}) - \bar{u}\rangle \ge 0,$$

thus

$$\langle y, w - \bar{u}\rangle \ge 0 \quad \forall w \in G\backslash G_1, \tag{3.8}$$

and combining (3.6), (3.8) we obtain that $\bar{u}$ solves (3.7). $\square$

LEMMA 3.3. *Let $G \subset V$ be a closed convex set, and let $\mathcal{A} : V \to 2^{V'}$ be a maximal monotone operator with $D(\mathcal{A}) \supset G$, $G \cap \mathrm{int}D(\mathcal{A}) \ne \emptyset$. Assume that*

$$\sup_{v\in G} \sup_{y\in\mathcal{A}v} \|y\|_{V'} < \infty, \tag{3.9}$$

and for some $u \in G$ and each $v \in G$, there exists $y(v) \in \mathcal{A}v$ satisfying

$$\langle y(v), v - u\rangle \ge 0. \tag{3.10}$$

Then, with some $y \in \mathcal{A}u$, the inequality

$$\langle y, v - u\rangle \ge 0$$

holds for each $v \in G$.

Proof. Let $\mathcal{A}_1 v = \mathcal{A}v + \mathcal{I}(v - u)$, with $\mathcal{I} : V \to V'$ the operator of the canonical isometry. The operator $\mathcal{A}_1$ is strongly monotone, and due to Theorem 1 in [33], it is maximal monotone.

For fixed $q(u) \in \mathcal{A}u$, using the inequality

$$\begin{aligned}\langle q(v) + \mathcal{I}(v-u), v-u\rangle &\geq \langle q(u), v-u\rangle + \|v-u\|^2 \\ &\geq \|v-u\| \left(\|v-u\| - \|q(u)\|_{V'}\right),\end{aligned}$$

which holds for any $q(v) \in \mathcal{A}v$, one can conclude that

$$\langle q(v) + \mathcal{I}(v-u), v-u\rangle \geq 0 \tag{3.11}$$

if

$$\|v\| \geq \|u\| + \|q(u)\|_{V'}.$$

Taking into account (3.11) and $G \cap \mathrm{int} D(\mathcal{A}) \neq \emptyset$, the straightforward application[1] of Theorem 5 in [33] guarantees that the variational inequality

$$\text{find} \quad w \in G \quad \text{such that} \quad \exists\, y_1(w) \in \mathcal{A}_1 w \ : \ \langle y_1(w), v-w\rangle \geq 0 \quad \forall v \in G$$

is solvable. If $w = u$, then of course $y_1(w) \in \mathcal{A}u$; hence the statement of the lemma is true.

Otherwise, we use the relation

$$\langle \bar{y}(v), v-u\rangle \geq 0 \quad \forall v \in G, \tag{3.12}$$

which follows from (3.10) with $\bar{y}(v) = y(v) + \mathcal{I}(v-u) \in \mathcal{A}_1 v$. Let $w_\lambda = u + \lambda(w-u)$ for $\lambda \in (0,1]$. Obviously, $w_\lambda \in G$, and according to (3.12), there exists $\bar{y}(w_\lambda) \in \mathcal{A}_1 w_\lambda$ such that

$$\langle \bar{y}(w_\lambda), w-u\rangle \geq 0.$$

Due to (3.9), the set $\{\bar{y}(w_\lambda) : \lambda \in (0,1]\}$ is bounded in V'. Hence, if λ tends to 0 in a suitable manner, the corresponding sequence $\{\bar{y}(w_\lambda)\}$ converges weakly in V' to some $\bar{y}$. Because also $w_\lambda \to u$ in V, the maximal monotonicity of $\mathcal{A}_1$ yields $\bar{y} \in \mathcal{A}_1 u$ and

$$0 \leq \lim \langle \bar{y}(w_\lambda), w-u\rangle = \langle \bar{y}, w-u\rangle.$$

From the last inequality and the inequality $\langle y_1(w), v-w\rangle \geq 0$, given with $v = u$, we obtain

$$\langle \bar{y} - y_1(w), u-w\rangle \leq 0,$$

but this contradicts the strong monotonicity of $\mathcal{A}_1$. □

Let us recall that Assumption 2.1 is supposed to be fulfilled and r, r^* are chosen according to (2.4). Set

$$Q_i = K_i \cap S_r, \qquad Q = K \cap S_r, \qquad Q^* = U^* \cap S_{r^*}. \tag{3.13}$$

To investigate the convergence of the MSR-method for problem (1.1) we make the following general assumption.

ASSUMPTION 3.4.

(a) $\sup_{u\in Q} \ \sup_{y\in\mathcal{T}u} \ \|y\|_{V'} \leq \mu(r) < \infty$ *and* $Q \cap \mathrm{int} D(\mathcal{T}) \neq \emptyset$*;*

[1] Condition $G \cap \mathrm{int} D(\mathcal{A}) \neq \emptyset$ corresponds to the case (b) in the theorem mentioned, and (3.11) ensures that $\langle q_1, v-u\rangle \geq 0$ whenever $v \in D(\mathcal{A}_1) \cap G$, $\|v\| > \alpha \equiv \|u\| + \|q(u)\|_{V'}$, and $q_1 \in \mathcal{A}_1(v)$.

(b) *with* $\mathcal{B}$ *and* $\tilde{\chi}$ *from Assumption* 2.1, *for each* i, *the relation*

$$\langle \mathcal{T}_i u - \mathcal{T}_i v, u - v\rangle \geq \langle \mathcal{B}u - \mathcal{B}v, u - v\rangle \quad \forall u, v \in Q_i$$

is valid, and $\tilde{\chi} \leq 2\bar{\chi}^{-1}$;

(c) *for each* $z \in Q$ *there exist points* $v_i(z) \in Q_i$ *and a compact set* $\Lambda(z) \subset \mathcal{T}z$ *such that*

$$\lim_{i\to\infty} \langle y, v_i(z) - z\rangle = 0 \ \forall y \in \Lambda(z), \quad \lim_{i\to\infty} dist_{V'}(\mathcal{T}_i v_i(z), \Lambda(z)) = 0$$

($\Lambda(z)$ may depend on $\{v_i(z)\}$).

For given sequences $\{\varphi_i\}, \{\sigma_i\}$, *such that* $\lim_{i\to\infty}\varphi_i = \lim_{i\to\infty}\sigma_i = 0$, *it holds that*

(d) *for each* $u \in Q^*$ *there exist points* $w_i \in Q_i$, *satisfying*

$$\|u - w_i\| \leq \varphi_i, \quad dist_{V'}(\mathcal{T}_i w_i, \hat{\Lambda}(u)) < \sqrt{\beta_0}\sigma_i, \ i = 1, 2, \ldots,$$

where $\hat{\Lambda}(u) = \{y \in \mathcal{T}u : \langle y, v - u\rangle \geq 0 \ \ \forall v \in Q\}$;

(e) *for each triple* $u \in Q^*, \ y \in \hat{\Lambda}(u)$, *and* $v_i \in Q_i$ *there exists* $w_i \in Q$ *such that*

$$\langle y, w_i - v_i\rangle \leq \varphi_i \|y\|_{V'} \quad (i = 1, 2, \ldots);$$

(f) *all weak limit points of an arbitrary sequence* $\{v_i\}, \ v_i \in Q_i$, *belong to* Q.

Remark 3.5.

(i) According to Assumption 3.4(b), the operator $\mathcal{T}_i + \chi_i\mathcal{M}$ is strongly monotone on Q_i.

(ii) If $V_1 = V = H$, then Assumption 2.1 is fulfilled with $\mathcal{B} = 0$. Therefore, $|||u||| = \|u\| \ \forall u \in V$, and Assumption 3.4(b) follows from the monotonicity of $\mathcal{T}_i$. In this case all results given below hold also true with $\beta_1 = 0, \ \beta_2 = 1$ if, instead of Assumptions 3.4(c), (d), and (e), the following conditions are valid (cf. [21]):

(c′) for each $z \in Q$ there exist points $v_i(z) \in Q_i$ and a compact set $\Lambda(z) \subset \mathcal{T}z$ such that

$$\lim_{i\to\infty} \|v_i(z) - z\| = 0, \quad \lim_{i\to\infty} dist_{V'}(\mathcal{T}_i v_i(z), \Lambda(z)) = 0;$$

(d′) $dist(Q^*, Q_i) \leq \varphi_i, \quad i = 1, 2, \ldots;$

(e′) for each i and $u_i \in Q_i$ there exists $v_i \in Q$, satisfying

$$\|u_i - v_i\| \leq \varphi_i, \quad dist_{V'}(\mathcal{T}_i u_i, \mathcal{T}v_i) < \sigma_i.$$

We underline that estimate (3.19) and relation (3.34) below remain true also. In section 4 we shall use the modified Assumption 3.4 with (d′) and (e′) instead of (d) and (e).

LEMMA 3.6. *Let Assumptions* 3.4(a), (b), (d), (e) *be fulfilled, and let the relations*

$$\frac{1}{4r}\left(\frac{4}{\chi_i}\left(\mu(r)\varphi_i + r\sigma_i\right) - \tilde{\epsilon}_i^2\right) + \beta_3\epsilon_i < 0, \qquad \tilde{\epsilon}_i = \delta_i - \beta_2\epsilon_i > 0 \tag{3.14}$$

hold for $i \leq i_0$, *with* $\beta_3 = \left(2\beta_1\bar{\chi}^{-1} + \beta_2^2\right)^{1/2}$. *Moreover, assume that in the MSR-method the relations* $s(i) < \infty$ *for* $i < i_0$, *and* $|||u^{i_0,s}||| < r^*$, $|||\bar{u}^{i_0,s}||| < r^*$ *for each* s *are valid. Then* $s(i_0) < \infty$ *is true.*

Proof. Fix $u^{**} \in U^* \cap S_{r^*}$. Due to Assumptions 3.4(d), (e), one can choose $v^{i_0} \in Q_{i_0},\ v^{i_0,s} \in Q$ such that

$$\|u^{**} - v^{i_0}\| \le \varphi_{i_0},$$

and, for some $y \in \hat{\Lambda}(u^{**})$,

$$\langle y, v^{i_0,s} - \bar{u}^{i_0,s}\rangle \le \varphi_i \|y\|_{V'}, \qquad \left\|\mathcal{T}_{i_0} v^{i_0} - y\right\|_{V'} \le \sqrt{\beta_0}\,\sigma_{i_0}.$$

Then, regarding Assumption 3.4(a) and (2.3),

$$\begin{aligned}
&\left\langle \mathcal{T}_{i_0} v^{i_0}, v^{i_0} - \bar{u}^{i_0,s}\right\rangle \\
&= \left\langle y, v^{i_0} - \bar{u}^{i_0,s}\right\rangle + \left\langle \mathcal{T}_{i_0} v^{i_0} - y, v^{i_0} - \bar{u}^{i_0,s}\right\rangle \\
&= \left\langle y, u^{**} - v^{i_0,s}\right\rangle + \left\langle y, v^{i_0} - u^{**}\right\rangle \\
&\quad + \left\langle y, v^{i_0,s} - \bar{u}^{i_0,s}\right\rangle + \left\langle \mathcal{T}_{i_0} v^{i_0} - y, v^{i_0} - \bar{u}^{i_0,s}\right\rangle \\
&\le \left\langle y, u^{**} - v^{i_0,s}\right\rangle + 2r\sigma_{i_0} + 2\mu(r)\varphi_{i_0}.
\end{aligned}$$

However, from the definition of $\hat{\Lambda}(u)$ and $v^{i_0,s} \in Q$, one can conclude that

$$\langle y, u^{**} - v^{i_0,s}\rangle \le 0;$$

hence,

$$\left\langle \mathcal{T}_{i_0} v^{i_0}, v^{i_0} - \bar{u}^{i_0,s}\right\rangle \le 2r\sigma_{i_0} + 2\mu(r)\varphi_{i_0}. \tag{3.15}$$

Now, using Assumption 3.4(b) and Lemma 3.1 with $\mathcal{A} = \mathcal{T}_{i_0},\ G = K_{i_0},\ \chi = \chi_{i_0},\ v = v^{i_0}$, and $a^0 = u^{i_0,s-1}$, in view of (2.6) and (3.15) we obtain

$$\begin{aligned}
&|||\bar{u}^{i_0,s} - v^{i_0}|||^2 - |||u^{i_0,s-1} - v^{i_0}|||^2 \\
&\le -\|\mathcal{P}\bar{u}^{i_0,s} - \mathcal{P}u^{i_0,s-1}\|_H^2 + \frac{2}{\chi_{i_0}}\langle \mathcal{T}_{i_0} v^{i_0}, v^{i_0} - \bar{u}^{i_0,s}\rangle \\
&\le -\|\mathcal{P}\bar{u}^{i_0,s} - \mathcal{P}u^{i_0,s-1}\|_H^2 + \frac{4}{\chi_{i_0}}\left(r\sigma_{i_0} + \mu(r)\varphi_{i_0}\right).
\end{aligned} \tag{3.16}$$

With regard to (2.5) and $\|\mathcal{P}u\|_H \le \beta_2\|u\|\ \ \forall u \in V$, the second inequality in (3.14) ensures

$$\begin{aligned}
&\|\mathcal{P}\bar{u}^{i_0,s} - \mathcal{P}u^{i_0,s-1}\|_H \ge \|\mathcal{P}u^{i_0,s} - \mathcal{P}u^{i_0,s-1}\|_H - \|\mathcal{P}u^{i_0,s} - \mathcal{P}\bar{u}^{i_0,s}\|_H \\
&\ge \|\mathcal{P}u^{i_0,s} - \mathcal{P}u^{i_0,s-1}\|_H - \beta_2\|u^{i_0,s} - \bar{u}^{i_0,s}\| > \delta_{i_0} - \beta_2\epsilon_{i_0} > 0
\end{aligned}$$

for $1 \le s < s(i_0)$. Together with (3.16) this yields

$$\begin{aligned}
&|||\bar{u}^{i_0,s} - v^{i_0}|||^2 - |||u^{i_0,s-1} - v^{i_0}|||^2 \\
&< -\tilde{\epsilon}_{i_0}^2 + \frac{4}{\chi_{i_0}}\left(r\sigma_{i_0} + \mu(r)\varphi_{i_0}\right),
\end{aligned} \tag{3.17}$$

and taking into account the first inequality in (3.14), we have

$$|||\bar{u}^{i_0,s} - v^{i_0}||| < |||u^{i_0,s-1} - v^{i_0}|||.$$

Also, the straightforward application of (2.3), (2.5), and $\tilde{\chi} \le 2\bar{\chi}^{-1}$ gives

$$|||\bar{u}^{i_0,s} - u^{i_0,s}||| \le \beta_3\epsilon_{i_0}.$$

Moreover, from the last inequality, (3.14), and (3.17), due to $|||u^{i_0,s-1}||| < r^*$, $|||\bar{u}^{i_0,s}||| < r^*$, $|||v^{i_0}||| \le r$, $r^* \le r$, we obtain immediately that

$$\begin{aligned} &|||u^{i_0,s} - v^{i_0}||| - |||u^{i_0,s-1} - v^{i_0}||| \\ &< \frac{1}{4r}\left[\frac{4}{\chi_{i_0}}\left(r\sigma_{i_0} + \mu(r)\varphi_{i_0}\right) - \tilde{\epsilon}_{i_0}^2\right] + \beta_3\epsilon_{i_0} < 0 \end{aligned} \tag{3.18}$$

is valid for $1 \le s < s(i_0)$.

Summing up the inequalities (3.18) for $s = 1, \dots, \bar{s}$, with $\bar{s} < s(i_0)$ arbitrarily chosen, one gets

$$|||u^{i_0,\bar{s}} - v^{i_0}||| < |||u^{i_0,0} - v^{i_0}||| + \bar{s}\left[\frac{1}{4r}\left(\frac{4}{\chi_{i_0}}\left(r\sigma_{i_0} + \mu(r)\varphi_{i_0}\right) - \tilde{\epsilon}_{i_0}^2\right) + \beta_3\epsilon_{i_0}\right];$$

therefore,

$$\bar{s} < |||u^{i_0,0} - v^{i_0}||| \left[\frac{1}{4r}\left(\tilde{\epsilon}_{i_0}^2 - \frac{4}{\chi_{i_0}}\left(r\sigma_{i_0} + \mu(r)\varphi_{i_0}\right)\right) - \beta_3\epsilon_{i_0}\right]^{-1},$$

and

$$s(i_0) < |||u^{i_0,0} - v^{i_0}||| \left[\frac{1}{4r}\left(\tilde{\epsilon}_{i_0}^2 - \frac{4}{\chi_{i_0}}\left(r\sigma_{i_0} + \mu(r)\varphi_{i_0}\right)\right) - \beta_3\epsilon_{i_0}\right]^{-1} + 1 \tag{3.19}$$

proves the lemma. □

COROLLARY 3.7. *Let Assumptions* 3.4(a), (b), (d), (e), *and (for each i) the relations* (3.14) *be satisfied. Moreover, assume that the inequalities* $|||\bar{u}^{i,s}||| < r^*$, $|||u^{i,s}||| < r^*$ *are fulfilled step by step. Then the relation* $s(i) < \infty$ *holds for each* i, *i.e., the method suggested is well defined.*

LEMMA 3.8. *Let Assumptions* 3.4(a), (b), (d), (e) *be fulfilled, and let the controlling parameters* ϵ_i, χ_i, δ_i, σ_i, *and* φ_i *satisfy*

$$\frac{1}{4r}\left(\frac{4}{\chi_i}\left(\mu(r)\varphi_i + r\sigma_i\right) - (\delta_i - \beta_2\epsilon_i)^2\right) + \beta_3\epsilon_i < 0 \tag{3.20}$$

and

$$\sum_{i=1}^{\infty}\left(2\left(\frac{\mu(r)\varphi_i + r\sigma_i}{\chi_i}\right)^{1/2} + \beta_3(\epsilon_i + 2\varphi_i)\right) < \frac{1}{2}r^*, \tag{3.21}$$

with $\beta_2 : \ \|u\|_H \le \beta_2\|u\| \ \forall u \in V$ *and* β_3 *defined in Lemma* 3.6. *Then,* (3.14) *holds and in the MSR-method* $s(i) < \infty$ *is valid for each* i*; variational inequality* (2.6) *is uniquely solvable, and* $|||u^{i,s}||| < r^*$, $|||\bar{u}^{i,s}||| < r^*$ *are true for all* (i, s).

Proof. The inequality $\delta_i - \beta_2\epsilon_i > 0$ follows immediately from (3.20), (3.21).

Indeed, (3.21) yields $\beta_3\epsilon_i < \frac{1}{2}r^*$, and due to (3.20), $\beta_3\epsilon_i < \frac{1}{4r}(\delta_i - \beta_2\epsilon_i)^2$. If $\delta_i \le \beta_2\epsilon_i$, then $(\delta_i - \beta_2\epsilon_i)^2 \le (\beta_2\epsilon_i)^2$; hence,

$$\beta_3\epsilon_i < \frac{1}{4r}(\beta_2\epsilon_i)^2.$$

In view of $\beta_3 = \left(2\beta_1\bar{\chi}^{-1} + \beta_2^2\right)^{1/2} \ge \beta_2$, we have $\beta_2\epsilon_i \le \beta_3\epsilon_i < \frac{1}{2}r^*$; therefore

$$\beta_3\epsilon_i < \frac{1}{4r}(\beta_2\epsilon_i)^2 < \frac{r^*}{8r}\beta_2\epsilon_i.$$

However, this contradicts $\beta_3 \ge \beta_2, r^* < r$.

Suppose that i_0 and s_0 are kept fixed, $s(i) < \infty$ for $i < i_0$, and that $0 \leq s_0 < s(i_0)$. Denote

$$\Theta_0 = \{(i, s) \ : \ i < i_0,\ 0 < s \leq s(i) \text{ and } \ i = i_0,\ 0 < s \leq s_0\}.$$

Assume, moreover, that for all $(i, s) \in \Theta_0$ the variational inequality (2.6) is uniquely solvable[2] and the inequalities $|||u^{i,s}||| < r^*$, $|||\bar{u}^{i,s}||| < r^*$ are true.

For fixed $u^{**} \in S_{r^*/8} \cap U^*$ and each i, due to Assumption 3.4(d), one can choose $v^i \in Q_i$ and $y^i \in \hat{\Lambda}(u^{**})$ such that

$$\|v^i - u^{**}\| \leq \varphi_i, \quad \|\mathcal{T}_i v^i - y^i\|_{V'} \leq \sqrt{\beta_0}\sigma_i. \tag{3.22}$$

Then, as in the proof of Lemma 3.6, we obtain (cf. (3.18)) for $i < i_0,\ 0 < s < s(i)$, and $i = i_0,\ 0 < s \leq s_0$ that

$$|||u^{i,s} - v^i||| - |||u^{i,s-1} - v^i||| \leq \frac{1}{4r}\left(\tau_i - \tilde{\epsilon}_i^2\right) + \beta_3\epsilon_i < 0, \tag{3.23}$$

with $\tau_i = \frac{4}{\chi_i}\left(\mu(r)\varphi_i + r\sigma_i\right),\ \tilde{\epsilon}_i = \delta_i - \beta_2\epsilon_i$.

Also for $i < i_0,\ s = s(i)$, similarly to (3.16), one can conclude that

$$|||\bar{u}^{i,s(i)} - v^i|||^2 - |||u^{i,s(i)-1} - v^i|||^2 \leq \tau_i,$$

and regarding $|||\bar{u}^{i,s(i)} - u^{i,s(i)}||| < \beta_3\epsilon_i$ and the implication $a^2 - b^2 < c^2 \ \Rightarrow\ a - |b| < |c|$, it follows that

$$|||u^{i,s(i)} - v^i||| - |||u^{i,s(i)-1} - v^i||| \leq \sqrt{\tau_i} + \beta_3\epsilon_i. \tag{3.24}$$

Summing up the inequalities (3.23), where $i < i_0$ is fixed and $0 < s < s(i)$, together with (3.24), we get

$$|||u^{i,s(i)} - v^i||| - |||u^{i,0} - v^i||| \leq \sqrt{\tau_i} + \beta_3\epsilon_i.$$

Due to (2.3) and (3.22), this yields

$$|||u^{i,s(i)} - u^{**}||| - |||u^{i,0} - u^{**}||| \leq \sqrt{\tau_i} + \beta_3(\epsilon_i + 2\varphi_i). \tag{3.25}$$

Because the mapping $u \to \mathcal{T}_{i_0}u + \chi_{i_0}\mathcal{M}(u - u^{i_0,s_0})$ is monotone and hemicontinuous on Q_{i_0} and Q_{i_0} is a convex closed and bounded set, by Theorem 5 in [33], Remark 3.5(i), and (3.1) the variational inequality

$$u \in Q_{i_0} \ : \ \langle \mathcal{T}_{i_0}u, v - u\rangle + \chi_{i_0}\left(\mathcal{P}u - \mathcal{P}u^{i_0,s_0}, \mathcal{P}v - \mathcal{P}u\right)_H \geq 0 \ \ \forall v \in Q_{i_0} \tag{3.26}$$

is uniquely solvable. We denote its solution by $\hat{u}^{i_0,s_0+1}$. The use of Lemma 3.1 (as in the proof of estimate (3.16)) leads to

$$|||\hat{u}^{i_0,s_0+1} - v^{i_0}||| \leq |||u^{i_0,s_0} - v^{i_0}||| + \sqrt{\tau_{i_0}}. \tag{3.27}$$

Observing (3.22), (3.23) (taken with $i = i_0,\ 0 < s \leq s_0$), and (3.27), the inequality

$$|||\hat{u}^{i_0,s_0+1} - u^{**}||| \leq |||u^{i_0,0} - u^{**}||| + \sqrt{\tau_{i_0}} + 2\beta_3\varphi_{i_0} \tag{3.28}$$

[2] This can be proved directly. We shall get solvability of (2.6) from the solvability of (3.26) below.

can be obtained similarly to (3.25). Regarding that $u^{i+1,0} := u^{i,s(i)}$ (cf. Step (c) of the MSR-method), the inequalities (3.25) and (3.28) imply

$$\begin{aligned}|||\hat{u}^{i_0,s_0+1} - u^{**}||| &\leq |||u^{1,0} - u^{**}||| \\ &+ \sum_{k=1}^{i_0-1} (\sqrt{\tau_k} + \beta_3(\epsilon_k + 2\varphi_k)) + \sqrt{\tau_{i_0}} + 2\beta_3\varphi_{i_0}.\end{aligned} \tag{3.29}$$

Due to (3.21) and the choice of u^{**} and $u^{1,0}$, estimate (3.29) yields

$$|||\hat{u}^{i_0,s_0+1}||| < r^* - \beta_3\epsilon_{i_0}. \tag{3.30}$$

Thus, we are in the situation of Lemma 3.2 (for $y = \mathcal{T}_{i_0}\hat{u}^{i_0,s_0+1} + \chi_{i_0}\mathcal{M}(\hat{u}^{i_0,s_0+1} - u^{i_0,s_0})$, $G = Q_{i_0}$, $G_1 = S_{r^*}$) and Remark 3.5(i), and hence, the variational inequality (2.6) with $i = i_0$ and $s = s_0 + 1$ is uniquely solvable, $\bar{u}^{i_0,s_0+1} = \hat{u}^{i_0,s_0+1}$, and

$$|||u^{i_0,s_0+1}||| < r^*. \tag{3.31}$$

This enables us to conclude that

$$|||\bar{u}^{i_0,s}||| < r^*, \ \ |||u^{i_0,s}||| < r^* \ \forall s,$$

and Lemma 3.6 ensures that $s(i_0) < \infty$. To complete the induction, note that the unique solvability of (2.6) with $i = 1, s = 1$, as well as the inequalities

$$|||\bar{u}^{1,1}||| < r^*, \ \ |||u^{1,1}||| < r^*$$

and the finiteness of $s(1)$, can be established quite analogously. □

Notice for the future that, using (3.21) and (3.29), one can conclude that $\sup_{i,s} |||\bar{u}^{i,s}||| < r^*$, too.

THEOREM 3.9. *Let $\mathcal{T}$ be a maximal monotone operator, Assumption* 3.4 *be fulfilled, and suppose that the points $u^{i,s}$, generated by the MSR-method, as well as the points $\bar{u}^{i,s}$ which solve the variational inequalities* (2.6)*, satisfy the relations*

$$|||\bar{u}^{i,s}||| < r^* \text{ and } |||u^{i,s}||| < r^* \ \forall i, s.$$

Moreover, assume that the controlling parameters satisfy (3.14) *and*

$$\sum_{i=1}^{\infty} \sqrt{\frac{\sigma_i}{\chi_i}} < \infty, \quad \sum_{i=1}^{\infty} \sqrt{\frac{\varphi_i}{\chi_i}} < \infty, \quad \sum_{i=1}^{\infty} \epsilon_i < \infty. \tag{3.32}$$

Then, $s(i) < \infty$ holds for each i and the sequences $\{u^{i,s}\}$, $\{\bar{u}^{i,s}\}$ converge weakly in V to an element $u^* \in U^*$.

Proof. Corollary 3.7 ensures that $s(i) < \infty$ for each i. With an arbitrary $w \in U^* \cap S_{r^*}$, the inequality

$$|||u^{i+1,0} - w||| - |||u^{i,0} - w||| \leq \sqrt{\tau_i} + \beta_3(\epsilon_i + 2\varphi_i)$$

with the same $\tau_i = \frac{4}{\chi_i}(\mu(r)\varphi_i + r\sigma_i)$, $\beta_3 = (2\beta_1\bar{\chi}^{-1} + \beta_2^2)^{1/2}$ can be established similarly to (3.25). Therefore, condition (3.32) and Lemma 2.2.2 in [32] imply the convergence of the sequence $\{|||u^{i,0} - w|||\}$.

Note that the inequalities (3.23), (3.24) remain true with a "new" $v^i \in Q_i$ which is chosen according to Assumption 3.4(d) such that

$$\|v^i - w\| \le \varphi_i, \quad \inf_{y \in \hat{\Lambda}(w)} \|\mathcal{T}_i v^i - y\|_{V'} < \sqrt{\beta_0}\sigma_i.$$

For $1 \le s < s(i)$ this leads to the relation

$$\begin{aligned} -(\sqrt{\tau_i} + \beta_3(\epsilon_i + 2\varphi_i)) + |||u^{i+1,0} - w||| &\le |||u^{i,s} - w||| \\ &< |||u^{i,0} - w||| + 2\beta_3\varphi_i. \end{aligned} \tag{3.33}$$

Indeed, from (3.23) we get immediately

$$|||u^{i,s} - v^i||| < |||u^{i,0} - v^i||| \text{ if } 1 \le s < s(i),$$

and from (3.24) it follows that

$$-\sqrt{\tau_i} - \beta_3\epsilon_i + |||u^{i+1,0} - v^i||| \le |||u^{i,s} - v^i||| < |||u^{i,0} - v^i|||.$$

The latter inequality together with $|||v^i - w||| \le \beta_3\varphi_i$ proves (3.33).

Hence, the sequences $\{|||u^{i,s} - w|||\}$ and $\{|||\bar{u}^{i,s} - w|||\}$ converge to the same limit as $\{|||u^{i,0} - w|||\}$.

Now, from inequality (3.16), which can be extended to each i and $1 \le s \le s(i)$, taking into account that

$$|||v^i - w||| \le \beta_3\varphi_i, \quad |||\bar{u}^{i,s}||| < r^*, \quad |||u^{i,s-1}||| < r^*, \quad |||v^i||| \le r,$$

one can conclude that

$$\begin{aligned} &\|\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}\|_H^2 \\ &\le -|||\bar{u}^{i,s} - v^i|||^2 + |||u^{i,s-1} - v^i|||^2 + \tau_i \\ &\le 4r\left|-|||\bar{u}^{i,s} - v^i||| + |||u^{i,s-1} - v^i|||\right| + \tau_i \\ &\le 4r\left(\left|-|||\bar{u}^{i,s} - w||| + |||u^{i,s-1} - w|||\right| + 2\beta_3\varphi_i\right) + \tau_i. \end{aligned}$$

Therefore,

$$\lim_{i\to\infty} \max_{1 \le s \le s(i)} \|\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}\|_H = 0. \tag{3.34}$$

Using the definition of $\bar{u}^{i,s}$, we get

$$\langle \mathcal{T}_i\bar{u}^{i,s}, v - \bar{u}^{i,s}\rangle + \chi_i\left(\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}v - \mathcal{P}\bar{u}^{i,s}\right)_H \ge 0 \quad \forall v \in Q_i, \tag{3.35}$$

and, in view of the monotonicity of $\mathcal{T}_i$, this yields

$$\langle \mathcal{T}_i v, v - \bar{u}^{i,s}\rangle + \chi_i\left(\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}v - \mathcal{P}\bar{u}^{i,s}\right)_H \ge 0 \quad \forall v \in Q_i. \tag{3.36}$$

For an arbitrary $z \in Q$, let us choose $v^i(z) \in Q_i$ and $y^i \in \Lambda(z)$ such that

$$\lim_{i\to\infty} \langle y, v^i(z) - z\rangle = 0 \ \forall y \in \Lambda(z), \quad \lim_{i\to\infty} \|\mathcal{T}_i v^i(z) - y^i\|_{V'} = 0. \tag{3.37}$$

This choice is possible due to Assumption 3.4(c). Then,

$$\begin{aligned} &\langle y^i, z - \bar{u}^{i,s}\rangle + \chi_i\left(\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}z - \mathcal{P}\bar{u}^{i,s}\right)_H \\ &= \langle y^i, z - v^i(z)\rangle + \chi_i\left(\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}z - \mathcal{P}v^i(z)\right)_H \\ &+ \langle y^i - \mathcal{T}_i v^i(z), v^i(z) - \bar{u}^{i,s}\rangle \\ &+ \left[\langle \mathcal{T}_i v^i(z), v^i(z) - \bar{u}^{i,s}\rangle + \chi_i\left(\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}v^i(z) - \mathcal{P}\bar{u}^{i,s}\right)_H\right], \end{aligned} \tag{3.38}$$

and in view of (3.36) the term in the square brackets is nonnegative.

Let $\left\{\bar{u}^{i,s}\right\}_{(i,s)\in\Gamma}$ be a subsequence of $\left\{\bar{u}^{i,s}\right\}$, which converges weakly in V to some u^*. With regard to $\sup_{i,s}|||\bar{u}^{i,s}||| < r^*$ and Assumption 3.4(f) one can easily show that $u^* \in K \cap \mathrm{int} S_r$. Now, we choose from $\left\{\bar{u}^{i,s}\right\}_{(i,s)\in\Gamma}$ an infinite subsequence $\left\{\bar{u}^{i,s_i}\right\}_{i\in I}$ and, without loss of generality, suppose that $\{y^i\}_{i\in I}$ converges in V' to an element y (according to Assumption 3.4(c), $\{y^i\}$ belongs to the compact set $\Lambda(z)$). Maximal monotonicity of $\mathcal{T}$ yields $y \in \mathcal{T}z$. Passing to the limit with $s = s_i,\ i \to \infty,\ i \in I$ in equality (3.38), in view of the relations (3.34), (3.37), and the boundedness of the sequences $\{\chi_i\}, \{\bar{u}^{i,s}\}$, we obtain

$$\langle y, z - u^*\rangle \geq 0.$$

Now, on using Assumption 3.4(a), Lemma 3.3 permits us to conclude that

$$\langle y^*, z - u^*\rangle \geq 0 \text{ for some } y^* \in \mathcal{T}u^* \text{ and all } z \in Q.$$

Since $u^* \in \text{int } S_r$, Lemma 3.2 guarantees that $\langle y^*, z-u^*\rangle \geq 0\ \forall z \in K$, hence $u^* \in U^*$. Now, due to Lemma 1 in [31], both sequences $\left\{\bar{u}^{i,s}\right\}$ and $\left\{u^{i,s}\right\}$ converge weakly in V to u^*. □

Remark 3.10. Theorem 3.9 establishes convergence of the MSR-method if the set K is bounded and $dist_V(K_i, K) \leq \sup_i \varphi_i$. Indeed, if r^* is chosen such that $K \subset S_\tau$ holds with some $\tau < r^* - \beta_3(\sup_i\ \varphi_i + \sup_i\ \epsilon_i)$, we get

$$|||\bar{u}^{i,s}||| < r^*,\ \ |||u^{i,s}||| < r^*\ \forall i, s.$$

Thus, the conditions (3.14) (used for all i) and (3.32) ensure weak convergence of $\left\{\bar{u}^{i,s}\right\}$ and $\left\{u^{i,s}\right\}$ to an element $u^* \in U^*$.

If boundedness of K is not supposed, compiling Lemma 3.8 and Theorem 3.9, the following statement on convergence of the MSR-method can be obtained immediately.

THEOREM 3.11. *Let $\mathcal{T}$ be a maximal monotone operator and let Assumption* 3.4 *as well as the conditions* (3.20), (3.21) *be fulfilled. Then, the MSR-method started with arbitrary $u^0 \in S_{r^*/4}$ has the following properties:*

(i) $s(i) < \infty\ \ \forall i$*;*

(ii) $|||u^{i,s}||| < r^*,\ \ |||\bar{u}^{i,s}||| < r^*$ *for each* (i, s);

(iii) *both sequences $\left\{u^{i,s}\right\}$ and $\left\{\bar{u}^{i,s}\right\}$ converge weakly in V to an element $u^* \in U^*$.*

Remark 3.12. Now we are ready to specify the notion “effective iteration” used in the introduction. The (i, s)th iteration is considered to be effective if $\|\mathcal{P}u^{i,s} - \mathcal{P}u^{i,s-1}\|_H > \delta_i$, where δ_i and the other controlling parameters satisfy the conditions (3.20), (3.21) (or (3.14), (3.32) in case K is bounded). To fulfill condition (3.14), (3.32), the parameters can be chosen a priori, for instance in the following way:

$$\chi_i \equiv \chi \in (0, \bar{\chi}],\quad \varphi_i = \sigma_i = \frac{1}{(a+i)^{2+\alpha}},\quad \epsilon_i = \frac{1}{(a+i)^{1+\alpha}},$$

with α a small positive number and an arbitrary $a \geq 0$. Then, the values δ_i can be easily calculated from (3.14). In case the conditions (3.20), (3.21) are used, the choice of $a \geq 0$ in the ratios above has to ensure (3.21), and then δ_i has to be calculated from (3.20). In both cases, under appropriate φ_i, σ_i, and ϵ_i, it makes sense to take δ_i as small as possible.

Of course, a faster decrease of $\varphi_i,\ \sigma_i,\ \epsilon_i$ (and hence, δ_i) is admissible, too.

Remark 3.13. If δ_i is chosen sufficiently large (for instance, $\delta_i > 2r^*\ \ \forall i$), then from Theorem 3.11 (also from Remark 3.10) it follows that $s(i) = 1$ for each i. Indeed, successively for $i = 1, 2, \ldots$ we obtain (without the use of (3.20)) that $|||u^{i,0}||| < r^*$, $|||u^{i,1}||| < r^*$, and regarding (2.2),

$$\|\mathcal{P}u^{i,1} - \mathcal{P}u^{i,0}\|_H \le |||u^{i,1} - u^{i,0}||| < 2r^*$$

holds true, and thus $\|\mathcal{P}u^{i,1} - \mathcal{P}u^{i,0}\|_H < \delta_i$.

This means that the MSR-method passes over to the usual (one-step) diagonal method. Obviously, in this case condition (3.20) can be omitted in Lemma 3.8 and Theorem 3.11.

Remark 3.14. Now let us return to the stopping rule for the auxiliary problems (2.6). Suppose that $\tilde{\chi} \le 2\bar{\chi}^{-1}$,

$$\langle \mathcal{T}_i u - \mathcal{T}_i v, u - v\rangle \ge \langle \mathcal{B}u - \mathcal{B}v, u - v\rangle \;\forall u, v \in K_i,$$

(a modification of Assumption 3.4(b)) and that Assumption 2.1 is valid also. Moreover, instead of (2.5), let $u^{i,s} \in K_i$ be defined by

$$\begin{aligned} &\langle \mathcal{T}_i u^{i,s}, v - u^{i,s}\rangle \\ &\quad + \chi_i(\mathcal{P}u^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}v - \mathcal{P}u^{i,s})_H \ge -\epsilon_i' \|v - u^{i,s}\| \quad \forall v \in K_i. \end{aligned} \tag{3.39}$$

Then, inserting in this inequality $v = \bar{u}^{i,s}$ and summing up the result with the obvious inequality

$$\langle \mathcal{T}_i \bar{u}^{i,s}, u^{i,s} - \bar{u}^{i,s}\rangle + \chi_i(\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}u^{i,s} - \mathcal{P}\bar{u}^{i,s})_H \ge 0,$$

we obtain

$$\langle \mathcal{T}_i \bar{u}^{i,s} - \mathcal{T}_i u^{i,s}, \bar{u}^{i,s} - u^{i,s}\rangle + \chi_i(\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s}, \mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s})_H \le \epsilon_i' \|\bar{u}^{i,s} - u^{i,s}\|.$$

With regard to this inequality, the modified Assumption 3.4(b) and formula (2.1) lead to

$$\frac{\beta_0}{2}\|\bar{u}^{i,s} - u^{i,s}\|^2 \le \frac{\epsilon_i'}{\chi_i}\|\bar{u}^{i,s} - u^{i,s}\|;$$

hence $\|\bar{u}^{i,s} - u^{i,s}\| \le \frac{2\epsilon_i'}{\beta_0 \chi_i}$.

Thus, under the mentioned modification of Assumption 3.4(b) the convergence results above remain true if $u^{i,s}$ is defined by criterion (3.39) with $\epsilon_i' \le \frac{1}{2}\beta_0 \epsilon_i \chi_i$.

THEOREM 3.15. *Let the conditions of Theorem* 3.9 *or Theorem* 3.11 *be fulfilled and let*

$$\lim_{i\to\infty} \max_{1\le s\le s(i)} \|\mathcal{P}u^{i,s} - \mathcal{P}u^*\|_H = 0, \tag{3.40}$$

with u^* a weak limit of $\{u^{i,s}\}$. Then both sequences $\{u^{i,s}\}$ and $\{\bar{u}^{i,s}\}$ converge to u^* (strongly) in V.

In particular, if $\dim V_1 < \infty$, condition (3.40) follows from the weak convergence of $\{u^{i,s}\}$, taking into account that the orthoprojector is a continuous operator and in the finite dimensional space weak and strong convergence coincides. Also, if the embedding of V into H is compact, (3.40) is obviously fulfilled.

Proof. Due to (2.5) and the continuous embedding of V into H, relation (3.40) leads to

$$\lim_{i\to\infty} \max_{1\le s\le s(i)} \|\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^*\|_H = 0. \tag{3.41}$$

Assumptions 3.4(d), (e) permit one to choose $v^i \in Q_i, y^i \in \hat{\Lambda}(u^*)$, and $v^{i,s} \in Q$ such that

$$\|u^* - v^i\| \le \varphi_i, \qquad \|\mathcal{T}_i v^i - y^i\|_{V'} \le \sqrt{\beta_0}\sigma_i, \qquad i = 1, 2, \dots, \tag{3.42}$$

and

$$\langle y^i, v^{i,s} - \bar{u}^{i,s}\rangle \le \varphi_i \|y^i\|_{V'} \quad \text{for each } i \text{ and } 1 \le s \le s(i). \tag{3.43}$$

On account of Assumption 3.4(b) and the symmetry of the operator $\mathcal{B}$, one gets

$$\begin{aligned}
&\langle \mathcal{B}\bar{u}^{i,s} - \mathcal{B}u^*, \bar{u}^{i,s} - u^*\rangle \\
&= \langle \mathcal{B}\bar{u}^{i,s} - \mathcal{B}v^i, \bar{u}^{i,s} - v^i + v^i - u^*\rangle + \langle \mathcal{B}v^i - \mathcal{B}u^*, \bar{u}^{i,s} - u^*\rangle \\
&= \langle \mathcal{B}\bar{u}^{i,s} - \mathcal{B}v^i, \bar{u}^{i,s} - v^i\rangle - \langle \mathcal{B}u^* - \mathcal{B}v^i, \bar{u}^{i,s} - u^*\rangle - \langle \mathcal{B}\bar{u}^{i,s} - \mathcal{B}v^i, u^* - v^i\rangle \\
&\le \langle \mathcal{T}_i\bar{u}^{i,s} - \mathcal{T}_i v^i, \bar{u}^{i,s} - v^i\rangle - \langle \mathcal{B}\bar{u}^{i,s} - \mathcal{B}u^*, u^* - v^i\rangle - \langle \mathcal{B}\bar{u}^{i,s} - \mathcal{B}v^i, u^* - v^i\rangle,
\end{aligned}$$

and the use of inequality (3.35) with $v = v^i$ yields

$$\begin{aligned}
&\langle \mathcal{B}\bar{u}^{i,s} - \mathcal{B}u^*, \bar{u}^{i,s} - u^*\rangle \\
&\le \langle \mathcal{T}_i v^i, v^i - \bar{u}^{i,s}\rangle + \chi_i \left(\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}v^i - \mathcal{P}\bar{u}^{i,s}\right)_H \\
&\quad + \langle \mathcal{B}u^* + \mathcal{B}v^i - 2\mathcal{B}\bar{u}^{i,s}, u^* - v^i\rangle \\
&= \langle \mathcal{T}_i v^i - y^i, v^i - \bar{u}^{i,s}\rangle + \langle y^i, v^i - u^*\rangle + \langle y^i, v^{i,s} - \bar{u}^{i,s}\rangle + \langle y^i, u^* - v^{i,s}\rangle \\
&\quad + \chi_i \left(\mathcal{P}\bar{u}^{i,s} - \mathcal{P}u^{i,s-1}, \mathcal{P}v^i - \mathcal{P}\bar{u}^{i,s}\right)_H \\
&\quad + \langle \mathcal{B}u^* + \mathcal{B}v^i - 2\mathcal{B}\bar{u}^{i,s}, u^* - v^i\rangle.
\end{aligned} \tag{3.44}$$

Now, in view of $\langle y^i, u^* - v^{i,s}\rangle \le 0$, the boundedness of $\{\chi_i\}$ and $\{y^i\}$ (see the definition of $\hat{\Lambda}(u)$ and Assumption 3.4(a)) and of the monotonicity of $\mathcal{B}$, from (3.34), (3.42), and (3.43) we obtain

$$\lim_{i\to\infty} \max_{1\le s\le s(i)} \langle \mathcal{B}\bar{u}^{i,s} - \mathcal{B}u^*, \bar{u}^{i,s} - u^*\rangle = 0.$$

The last relation together with (3.41) leads to

$$\lim_{i\to\infty} \max_{1\le s\le s(i)} |||\bar{u}^{i,s} - u^*||| = 0,$$

and all we have to do is to use (2.3) and (2.5). □

The proximal point method studied in [34], applied to the variational inequality (1.1), corresponds formally to the MSR-scheme with $H = V = V_1$, $\mathcal{T}_i = \mathcal{T}$, $K_i = K$, $s(i) = 1$. However, because we have supposed above that $\mathcal{T}_i$ belongs to the class of hemicontinuous operators, convergence of the method in [34] does not follow from our Theorem 3.11.

Remark 3.16. Lemma 3.1 remains true without any change in the proofs if we suppose that $\mathcal{A}$ is a multivalued operator and inequality (3.2) is fulfilled for any pair of elements belonging to $\mathcal{A}u$ and $\mathcal{A}v$, respectively.

Lemmas 3.6 and 3.8 and Theorems 3.9, 3.11, and 3.15 remain true with minor (and straightforward) modifications in the proofs if, instead of the hemicontinuity of $\mathcal{T}_i$, we suppose that $\mathcal{T}_i : V \to 2^{V'}$ are maximal monotone operators and the following alterations in Assumption 3.4 are performed:

- replace $\lim_{i\to\infty}\ dist_{V'}\ (\mathcal{T}_i v_i(z), \Lambda(z)) = 0$ by $\lim_{i\to\infty}\ \inf_{\eta\in\mathcal{T}_i v_i(z)}\ dist_{V'}\ (\eta, \Lambda(z)) = 0$ in (c);
- replace $dist_{V'}\ (\mathcal{T}_i w_i, \hat{\Lambda}(u)) < \sqrt{\beta_0}\sigma_i$ by $\inf_{\eta\in\mathcal{T}_i w_i(z)}\ dist_{V'}\ (\eta, \hat{\Lambda}(u)) < \sqrt{\beta_0}\sigma_i$ in (d);
- add any condition which provides the solvability of (3.26).
  Taking into account that in this case the operator $\mathcal{T}_i + \chi_i\mathcal{M}$ is also maximal monotone (cf. [33, Theorem 1]) and Q_i is a bounded set, it suffices to suppose that $K_i \cap \mathrm{int}D(\mathcal{T}_i) \neq \emptyset$ or $\mathcal{T}_i$ is locally bounded at some $u \in K_i$ (Theorem 5 in [33]).

The inequality

$$\langle \mathcal{T}_i u - \mathcal{T}_i v, u - v\rangle \geq \langle \mathcal{B}u - \mathcal{B}v, u - v\rangle$$

in Assumption 3.4(b) means in this case that

$$\langle \eta(u) - \eta(v), u - v\rangle \geq \langle \mathcal{B}u - \mathcal{B}v, u - v\rangle \quad \forall \eta(u) \in \mathcal{T}_i u, \forall \eta(v) \in \mathcal{T}_i v.$$

4. Rate of convergence. In this section we investigate the rate of convergence of the basic variant of the MSR-method that corresponds to $H = V = V_1, \mathcal{B} = 0$, and hence, the norms $|||\cdot|||$ and $\|\cdot\|$ coincide.

Let $\delta \in (0, 2r^*), l > 0$, be fixed and denote $U_\delta = \{u \in Q : dist(u, Q^*) \leq \delta\}$. We need the following additional assumption.

ASSUMPTION 4.1. *There exists a constant $d_0 > 0$ such that, for each $u \in U_\delta$ and each $y \in \mathcal{T}u$, the inequality*

$$\inf_{v\in Q^*}\ \langle y, u - v\rangle \geq d_0\|u - u^*(u)\|^l \tag{4.1}$$

holds with $u^*(u) = \arg\min_{w\in Q^*}\ \|u - w\|$.

Assumption 4.1 supposes implicitly that $r^* = r$ or $U^* = Q^*$ has to be.

LEMMA 4.2. *Let Assumption 4.1 be fulfilled. Then, for each $u \in Q$ and each $y \in \mathcal{T}u$, the inequality*

$$\inf_{v\in Q^*}\ \langle y, u - v\rangle \geq d\|u - u^*(u)\|^l \tag{4.2}$$

is valid with $d = (\frac{\delta}{r+r^*})^l d_0$.

Proof. Consider the nontrivial case $Q\backslash U_\delta \neq \emptyset$ and let $u \in Q\backslash U_\delta,\ v \in Q^*$ be chosen arbitrarily. Define $\lambda = \lambda(u, v) \in (0, 1)$ such that $\tilde{u} = \lambda u + (1-\lambda)v \in \partial U_\delta$ (∂U_δ is the boundary of U_δ). Obviously, $\tilde{u} - v = \lambda(u - v),\ \frac{1-\lambda}{\lambda}(\tilde{u} - v) = u - \tilde{u}$, and regarding the monotonicity of $\mathcal{T}$, we obtain that

$$\frac{1-\lambda}{\lambda}\langle y(u) - y(\tilde{u}), \tilde{u} - v\rangle = \langle y(u) - y(\tilde{u}), u - \tilde{u}\rangle \geq 0$$

for any $y(u) \in \mathcal{T}u,\ y(\tilde{u}) \in \mathcal{T}\tilde{u}$.

Hence, due to Assumption 4.1,

$$\langle y(u), \tilde{u} - v\rangle \geq \langle y(\tilde{u}), \tilde{u} - v\rangle \geq d_0\|\tilde{u} - u^*(\tilde{u})\|^l$$

and

$$\langle y(u), u - v\rangle \geq \frac{d_0}{\lambda}\|\tilde{u} - u^*(\tilde{u})\|^l > d_0\|\tilde{u} - u^*(\tilde{u})\|^l.$$

But $\|\tilde{u} - u^*(\tilde{u})\| = \delta,\ \|u - u^*(u)\| < r + r^*$; therefore

$$\langle y(u), u - v\rangle > \left(\frac{\delta}{r + r^*}\right)^l d_0\|u - u^*(u)\|^l.$$

Because v is an arbitrary point in Q^*, this leads to (4.2). But if $u \in U_\delta$, then (4.2) follows immediately from (4.1) and $\delta < 2r^*$. □

Let

$$\begin{aligned}
\rho_{i,s} &= dist^2\left(u^{i,s}, Q^*\right),\\
\gamma_i &= 4r(\epsilon_i + \varphi_i) + \frac{4}{\chi_i}\left[r\sigma_i + (\mu(r) + 2dr)\,\varphi_i + 2dr\epsilon_i\right],\\
c_i &= \rho_{1,0}\prod_{k=1}^{i}\left(1 + \frac{2d}{\chi_k}\right)^{-s(k)+\frac{1}{2}} \quad \text{for } i \geq 1, \quad c_0 = \rho_{1,0},
\end{aligned}$$

and define by $\bar{s}(i)$ the largest integer not exceeding $\sqrt{c_{i-1}}\varphi_i^{-1} + 2$.

Theorem 4.3. *Let Assumptions* 3.4(a), (d′), (e′) *(see Remark* 3.5(ii)*) be fulfilled. Moreover, suppose that the controlling parameters of the MSR-method satisfy the relations* (3.21)*.*

(i) *If Assumption* 4.1 *with* $l = 2$ *is valid, as well as*

$$\gamma_i \leq c_{i-1}\left(1 + \frac{2d}{\chi_i}\right)^{-\bar{s}(i)+1}\left[\left(1 + \frac{2d}{\chi_i}\right)^{1/2} - 1\right] \tag{4.3}$$

and

$$\begin{aligned}
&-(\delta_i - \epsilon_i)^2 + \frac{4}{\chi_i}\left(r\sigma_i + \mu(r)\varphi_i\right)\\
&+ 4r\epsilon_i + \frac{8d}{\chi_i}r\epsilon_i + \left(4 + \frac{8d}{\chi_i}\right)r\varphi_i < 0,
\end{aligned} \tag{4.4}$$

then, for each i and $0 \leq s < s(i)$, the estimate

$$\begin{aligned}
\rho_{i,s} &\leq c_{i-1}\left(1 + \frac{2d}{\chi_i}\right)^{-s}\\
&= \rho_{1,0}\left(1 + \frac{2d}{\chi_i}\right)^{-s}\prod_{k=1}^{i-1}\left(1 + \frac{2d}{\chi_k}\right)^{-s(k)+\frac{1}{2}}
\end{aligned} \tag{4.5}$$

holds true.

(ii) *If Assumption* 4.1 *(with* $l = 1$*) and relation* (3.20) *are valid, then there exists* i_0 *such that the estimate*

$$\begin{aligned}
&dist(u^{i,s}, U^* \cap S_{r^*})\\
&\leq \left(3 + \frac{4r\overline{\chi}}{d}\right)\epsilon_i + 2\left(1 + \frac{2r\overline{\chi}}{d} + \frac{2\mu(r)}{d}\right)\varphi_i + \frac{4r}{d}\sigma_i
\end{aligned} \tag{4.6}$$

holds for $i \geq i_0$ and $1 \leq s \leq s(i)$.

Proof. Because (4.4) implies (3.20), and also since (3.20), (3.21) imply (3.14), the conclusions of Lemmas 3.6 and 3.8 remain true (see Remark 3.5(ii)). For a fixed pair (i,s) with $1 \le s \le s(i)$, choose $v^{i,s} \in Q, y^{i,s} \in \mathcal{T} v^{i,s}$, and $q^{i,s-1} \in Q_i$ such that

$$\|v^{i,s} - \bar{u}^{i,s}\| \le \varphi_i, \qquad \|\mathcal{T}_i \bar{u}^{i,s} - y^{i,s}\|_{V'} \le \sigma_i$$

and

$$\|q^{i,s-1} - u^*(u^{i,s-1})\| \le \varphi_i.$$

This is possible due to Assumptions 3.4(d′) and (e′). Then we get

$$\begin{aligned}
&\langle \mathcal{T}_i \bar{u}^{i,s}, q^{i,s-1} - \bar{u}^{i,s}\rangle \\
&= \langle \mathcal{T}_i \bar{u}^{i,s} - y^{i,s}, q^{i,s-1} - \bar{u}^{i,s}\rangle + \langle y^{i,s}, q^{i,s-1} - u^*(u^{i,s-1})\rangle \\
&\ + \langle y^{i,s}, u^*(u^{i,s-1}) - v^{i,s}\rangle + \langle y^{i,s}, v^{i,s} - \bar{u}^{i,s}\rangle \\
&\le \langle y^{i,s}, u^*(u^{i,s-1}) - v^{i,s}\rangle + 2(r\sigma_i + \mu(r)\varphi_i).
\end{aligned}$$

However, with regard to Remark 3.5(ii), inequality (3.5) given with $H = V$, $\mathcal{P}$ the identity operator, $\mathcal{B} = 0, \mathcal{A} = \mathcal{T}_i, \chi = \chi_i, a^0 = u^{i,s-1}, a^1 = \bar{u}^{i,s}, v = q^{i,s-1}$ leads to

$$\begin{aligned}
&\|\bar{u}^{i,s} - q^{i,s-1}\|^2 - \|u^{i,s-1} - q^{i,s-1}\|^2 \\
&\le -\|\bar{u}^{i,s} - u^{i,s-1}\|^2 + \frac{2}{\chi_i}\langle \mathcal{T}_i \bar{u}^{i,s}, q^{i,s-1} - \bar{u}^{i,s}\rangle.
\end{aligned}$$

Therefore

$$\begin{aligned}
&\|\bar{u}^{i,s} - q^{i,s-1}\|^2 - \|u^{i,s-1} - q^{i,s-1}\|^2 \\
&\le -\|\bar{u}^{i,s} - u^{i,s-1}\|^2 + \frac{2}{\chi_i}\langle y^{i,s}, u^*(u^{i,s-1}) - v^{i,s}\rangle + \frac{4}{\chi_i}(r\sigma_i + \mu(r)\varphi_i).
\end{aligned}$$

Using Assumption 4.1 and Lemma 4.2, this yields

$$\begin{aligned}
&\|\bar{u}^{i,s} - q^{i,s-1}\|^2 - \|u^{i,s-1} - q^{i,s-1}\|^2 \\
&\le -\|\bar{u}^{i,s} - u^{i,s-1}\|^2 - \frac{2d}{\chi_i}\|v^{i,s} - u^*(v^{i,s})\|^l + \frac{4}{\chi_i}(r\sigma_i + \mu(r)\varphi_i).
\end{aligned} \tag{4.7}$$

Now, we prove statement (i) and use the relations

$$\begin{aligned}
&\|\bar{u}^{i,s} - q^{i,s-1}\|^2 - \|u^{i,s-1} - q^{i,s-1}\|^2 \\
&= \big(u^{i,s} - u^*(u^{i,s-1}) - u^{i,s-1} + u^*(u^{i,s-1}) + \bar{u}^{i,s} - u^{i,s}, \\
&\ \ u^{i,s} + u^{i,s-1} - 2u^*(u^{i,s-1}) + \bar{u}^{i,s} - u^{i,s} + 2u^*(u^{i,s-1}) - 2q^{i,s-1}\big) \\
&\ge \|u^{i,s} - u^*(u^{i,s-1})\|^2 - \|u^{i,s-1} - u^*(u^{i,s-1})\|^2 - 4r(\epsilon_i + \varphi_i),
\end{aligned}$$

$$\|v^{i,s} - u^*(v^{i,s})\|^2 \ge \|u^{i,s} - u^*(v^{i,s})\|^2 - 4r(\varphi_i + \epsilon_i),$$

and

$$\|\bar{u}^{i,s} - u^{i,s-1}\|^2 \ge d_{i,s},$$

with

$$d_{i,s} = \begin{cases} (\delta_i - \epsilon_i)^2 & \text{if } 1 \le s < s(i), \\ 0 & \text{if } s = s(i). \end{cases}$$

Inserting these relations in (4.7), which is now valid with $l = 2$, one gets

$$\|u^{i,s} - u^*(u^{i,s-1})\|^2 + \frac{2d}{\chi_i}\|u^{i,s} - u^*(v^{i,s})\|^2 - \|u^{i,s-1} - u^*(u^{i,s-1})\|^2 \\ \le -d_{i,s} + \gamma_i. \tag{4.8}$$

By the use of the definition of $u^*(u)$ and $\rho_{i,s}$, inequality (4.8) leads to

$$\left(1 + \frac{2d}{\chi_i}\right)\rho_{i,s} - \rho_{i,s-1} \le -d_{i,s} + \gamma_i. \tag{4.9}$$

Obviously, condition (4.4) is stronger than the first condition (3.14) given with $\beta_2 = \beta_3 = 1$. Thus, the estimate

$$s(i) < \|u^{i,0} - v^i\| \left[\frac{1}{4r}\left((\delta_i - \epsilon_i)^2 - \frac{4}{\chi_i}(r\sigma_i + \mu(r)\varphi_i)\right) - \epsilon_i\right]^{-1} + 1 \tag{4.10}$$

remains true with some v^i satisfying $\|u^*(u^{i,0}) - v^i\| \le \varphi_i$ (see Remark 3.5(ii) and (3.19)).

Suppose now that for a given pair (i, s) with $0 \le s < s(i)$ the estimate

$$\rho_{i,s} \le c_{i-1}\left(1 + \frac{2d}{\chi_i}\right)^{-s} \tag{4.11}$$

is valid. Then (4.4), (4.10), and $\|u^*(u^{i,0}) - v^i\| \le \varphi_i$ ensure that

$$s(i) \le \bar{s}(i). \tag{4.12}$$

If $s < s(i) - 1$, then from (4.4), we obtain $-d_{i,s+1} + \gamma_i < 0$, and from (4.9) it follows that

$$\rho_{i,s+1} \le c_{i-1}\left(1 + \frac{2d}{\chi_i}\right)^{-s-1}. \tag{4.13}$$

But, if $s = s(i) - 1$, then $d_{i,s+1} = 0$, and (4.9) leads to

$$\left(1 + \frac{2d}{\chi_i}\right)\rho_{i,s(i)} - \rho_{i,s(i)-1} \le \gamma_i. \tag{4.14}$$

Combining (4.3), (4.12), (4.11), and (4.14), one can conclude that

$$\begin{aligned}\rho_{i+1,0} = \rho_{i,s(i)} \le & \left(1 + \frac{2d}{\chi_i}\right)^{-1}\left[c_{i-1}\left(1 + \frac{2d}{\chi_i}\right)^{-s(i)+1}\right. \\ & \left. + c_{i-1}\left(1 + \frac{2d}{\chi_i}\right)^{-s(i)+1}\left(\left(1 + \frac{2d}{\chi_i}\right)^{1/2} - 1\right)\right] \\ & = c_{i-1}\left(1 + \frac{2d}{\chi_i}\right)^{-s(i)+1/2} = c_i.\end{aligned}$$

To prove statement (ii), we start with the estimate

$$\|u^{i,s} - u^*(u^{i,s})\| \le \|u^{i,s} - u^*(v^{i,s})\| \le \|v^{i,s} - u^*(v^{i,s})\| + (\epsilon_i + \varphi_i). \tag{4.15}$$

Inserting (4.15) in inequality (4.7) (with $l = 1$), one gets

$$\begin{aligned}
&\frac{2d}{\chi_i}\|u^{i,s} - u^*(u^{i,s})\| \leq -\|\bar{u}^{i,s} - u^{i,s-1}\|^2 + \|u^{i,s-1} - q^{i,s-1}\|^2 \\
&\quad - \|\bar{u}^{i,s} - q^{i,s-1}\|^2 + \frac{4}{\chi_i}(r\sigma_i + \mu(r)\varphi_i) + \frac{2d}{\chi_i}(\epsilon_i + \varphi_i) \\
&\leq -\|\bar{u}^{i,s} - u^{i,s-1}\|^2 + \frac{4}{\chi_i}(r\sigma_i + \mu(r)\varphi_i) \ + \frac{2d}{\chi_i}(\epsilon_i + \varphi_i) \\
&\quad + \big(u^{i,s-1} - u^*(u^{i,s-1}) - u^{i,s} + u^*(u^{i,s-1}) + u^{i,s} - \bar{u}^{i,s}, \\
&\quad u^{i,s-1} - u^*(u^{i,s-1}) + u^{i,s} - u^*(u^{i,s-1}) \\
&\quad - u^{i,s} + \bar{u}^{i,s} + 2u^*(u^{i,s-1}) - 2q^{i,s-1}\big) \\
&\leq -\|\bar{u}^{i,s} - u^{i,s-1}\|^2 + \|u^{i,s-1} - u^*(u^{i,s-1})\|^2 - \|u^{i,s} - u^*(u^{i,s-1})\|^2 + \theta_i \\
&\leq -\|\bar{u}^{i,s} - u^{i,s-1}\|^2 + \|u^{i,s-1} - u^*(u^{i,s})\|^2 \\
&\quad - \|u^{i,s} - u^*(u^{i,s})\|^2 + \theta_i,
\end{aligned} \tag{4.16}$$

where $\theta_i = (4r + \frac{4\mu(r)+2d}{\chi_i})\varphi_i + (4r + \frac{2d}{\chi_i})\epsilon_i + \frac{4r}{\chi_i}\sigma_i$.

If $\|u^{i,s} - u^{i,s-1}\| \leq \epsilon_i$, then inequality (4.16) yields

$$\begin{aligned}
&\frac{2d}{\chi_i}\|u^{i,s} - u^*(u^{i,s})\| \\
&\leq \|u^{i,s-1} - u^{i,s}\| \left(\|u^{i,s-1} - u^*(u^{i,s})\| + \|u^{i,s} - u^*(u^{i,s})\|\right) + \theta_i \\
&\leq \|u^{i,s-1} - u^{i,s}\| \left(2\|u^{i,s} - u^*(u^{i,s})\| + \epsilon_i\right) + \theta_i.
\end{aligned} \tag{4.17}$$

But if $\|u^{i,s} - u^{i,s-1}\| > \epsilon_i$, then

$$\|\bar{u}^{i,s} - u^{i,s-1}\|^2 \geq \|u^{i,s} - u^{i,s-1}\|^2 + \epsilon_i^2 - 2\epsilon_i\|u^{i,s} - u^{i,s-1}\|,$$

and (4.16) leads to

$$\begin{aligned}
&\frac{2d}{\chi_i}\|u^{i,s} - u^*(u^{i,s})\| \\
&< -\|u^{i,s} - u^{i,s-1}\|^2 + 2\epsilon_i\|u^{i,s} - u^{i,s-1}\| + \|u^{i,s-1} - u^*(u^{i,s})\|^2 \\
&\quad - \|u^{i,s} - u^*(u^{i,s})\|^2 + \theta_i \\
&= 2\left(u^{i,s-1} - u^{i,s}, u^{i,s} - u^*(u^{i,s})\right) + 2\epsilon_i\|u^{i,s} - u^{i,s-1}\| + \theta_i \\
&\leq 2\|u^{i,s-1} - u^{i,s}\| \left(\|u^{i,s} - u^*(u^{i,s})\| + \epsilon_i\right) + \theta_i.
\end{aligned} \tag{4.18}$$

Due to the relation (2.5) and (3.34) (see also Remark 3.5(ii)), there exists i_0 such that

$$\|u^{i,s-1} - u^{i,s}\| \leq \frac{d}{2\bar{\chi}} \quad \text{for } i \geq i_0, 1 \leq s \leq s(i).$$

Together with (4.17), (4.18), and $\chi_i \leq \bar{\chi}$, this gives

$$\frac{d}{\chi_i}\|u^{i,s} - u^*(u^{i,s})\| \leq \frac{d\epsilon_i}{\bar{\chi}} + \theta_i,$$

proving relation (4.6). □

Remark 4.4. If problem (1.1) is uniquely solvable, estimate (4.5) shows that $\{u^{i,s}\}$ converges to u^* not slower than a geometrical progression with the factor $(1+\frac{2d}{\bar{\chi}})^{-1/4}$.

In the general case, analogous estimates can be proved for the distance of $u^{i,s}$ to U^*. If, moreover, Assumption 3.4(c$'$) is valid, then using the proof of Theorem 14.6 in [16], linear convergence of $\{u^{i,s}\}$ to an element $u^* \in U^*$ can be established, too.

Estimate (4.6), in particular, leads to the known result on “finite convergence” of the exact proximal point method (cf. [34], [27]).

It should be emphasized that statement (i) in Theorem 4.3 is mainly qualitative, because a very fast decrease of the parameters φ_i, σ_i, and ϵ_i could be necessary. The choice of the parameters according to statement (ii) can be performed in the same manner as described in Remark 3.12.

In [27], sections 2–3, and [34], section 3, the rate of convergence of the classical proximal point method applied to the problem

$$\text{find } \ u \in V: \quad 0 \in \tilde{\mathcal{T}} u \tag{4.19}$$

with $\tilde{\mathcal{T}} : V \to 2^V$ a maximal monotone operator, has been investigated. In these papers a data approximation is not included. If problem (1.1) is considered with $V' = V$, then it can be rewritten in the form (4.19) with

$$\tilde{\mathcal{T}} u = \begin{cases} \mathcal{T} u + N_K(u) & \text{if } u \in K, \\ \emptyset & \text{if } u \notin K, \end{cases} \tag{4.20}$$

where $N_K(u)$ is the normal cone to K at the point u. The operator $\tilde{\mathcal{T}}$ in (4.20) is maximal monotone, for instance, if $K \cap \text{int} D(\mathcal{T}) \neq \emptyset$ [33, Theorem 1].

To prove linear convergence, in [34] it is supposed that

(a) problem (4.19) is uniquely solvable and, for some $a > 0, \theta > 0$,

$$\|u - \bar{u}\| \leq a\|w\| \text{ whenever } u \in \tilde{\mathcal{T}}^{-1} w \text{ and } \|w\| \leq \theta$$

($\bar{u}$ is the solution of (4.19)).

In [27] this assumption is generalized to the case that problem (4.19) may have more than one solution. Here, denoting by $\bar{U}$ the solution set of (4.19), the corresponding assumption is

(b) for some $a > 0, \theta > 0$,

$$dist(u, \bar{U}) \leq a\|w\| \text{ whenever } u \in \tilde{\mathcal{T}}^{-1} w \text{ and } \|w\| \leq \theta.$$

The “finite convergence” of the exact method is established in [34] under the condition

(c) $0 \in \text{int} \tilde{\mathcal{T}} \bar{u}$,

which is generalized in [27] as follows:

(d) for some $\theta > 0$, the inclusion $u \in \bar{U}$ holds if $u \in \tilde{\mathcal{T}}^{-1} w$ and $\|w\| \leq \theta$.

The correlation between these conditions and Assumption 4.1 is not completely clear. There exist simple examples where Assumption 4.1 with $l = 1$ (resp., $l = 2$) is fulfilled, whereas conditions (a), (b) (resp., (c), (d)) are disturbed. Moreover, one can prove the following relations for the case $r^* = r$:

- If $\mathcal{T}$ is a potential operator, then (a) $\Rightarrow$ Assumption 4.1 ($l = 2$);
- (c) $\Rightarrow$ Assumption 4.1 ($l = 1$).

However, if $r^* = r$ and $K \subset S_r$, then Assumption 4.1 ($l = 2$) $\Rightarrow$ (b) and Assumption 4.1 ($l = 1$) $\Rightarrow$ (d).

Note that Assumption 4.1 as well as the conditions (b), (d) do not prevent from unboundedness or/and infinite-dimensionality of the solution set.

STABILIZATION OF BERNOULLI–EULER BEAMS BY MEANS OF A POINTWISE FEEDBACK FORCE*

KAIS AMMARI[†] AND MARIUS TUCSNAK[‡]

Abstract. We study the energy decay of a Bernoulli–Euler beam which is subject to a pointwise feedback force. We show that both uniform and nonuniform energy decay may occur. The uniform or nonuniform decay depends on the boundary conditions. In the case of nonuniform decay in the energy space we give explicit polynomial decay estimates valid for regular initial data. Our method consists of deducing the decay estimates from observability inequalities for the associated undamped problem via sharp trace regularity results.

Key words. pointwise stabilization, observability inequality, unbounded feedback, exponential stability

1. Introduction.

The aim of this paper is to study the pointwise feedback stabilization of a Bernoulli–Euler beam. More precisely, we consider the following initial and boundary value problems:

$$\frac{\partial^2 u}{\partial t^2}(x,t) + \frac{\partial^4 u}{\partial x^4}(x,t) + \frac{\partial u}{\partial t}(\xi,t)\,\delta_\xi = 0, \quad 0 < x < \pi,\ t > 0, \tag{1.1}$$

$$u(0,t) = u(\pi,t) = \frac{\partial^2 u}{\partial x^2}(0,t) = \frac{\partial^2 u}{\partial x^2}(\pi,t) = 0, \quad t > 0, \tag{1.2}$$

$$u(x,0) = u^0(x), \frac{\partial u}{\partial t}(x,0) = u^1(x), \quad 0 < x < \pi, \tag{1.3}$$

and

$$\frac{\partial^2 u}{\partial t^2}(x,t) + \frac{\partial^4 u}{\partial x^4}(x,t) + \frac{\partial u}{\partial t}(\xi,t)\,\delta_\xi = 0, \quad 0 < x < \pi,\ t > 0, \tag{1.4}$$

$$u(0,t) = \frac{\partial u}{\partial x}(\pi,t) = \frac{\partial^2 u}{\partial x^2}(0,t) = \frac{\partial^3 u}{\partial x^3}(\pi,t) = 0, \quad t > 0, \tag{1.5}$$

$$u(x,0) = u^0(x), \frac{\partial u}{\partial t}(x,0) = u^1(x), \quad 0 < x < \pi. \tag{1.6}$$

Here u denotes the transverse displacement of the beam, δ_ξ is the Dirac mass concentrated in the point $\xi \in (0,\pi)$, and we suppose that the length of the beam is equal to π. The boundary condition (1.2) means that both ends of the beam are simply supported, whereas (1.5) signifies that the end $x = 0$ is simply supported and at $x = \pi$ there is a shear hinge end. Simple calculation shows that (1.1) is equivalent to the

equations modelling the vibrations of two Bernoulli–Euler beams with a dissipative joint (see [4] for further discussion of the model).

Pointwise stabilization of Bernoulli–Euler beams, or, equivalently, stabilization of serially connected beams with dissipative joints, has been widely studied in recent literature (see [4], [5], [6], [7], [17], [23]). In [4], [5], [6], [20], and [23] the authors give several examples showing that both uniform and nonuniform decay may occur. Their method is based on a classical result of Huang and Prüss (see [14] and [22]) combined with elaborate eigenvalues, calculations, or with concepts in system theory. In the cases when we have strong, but not exponential decay, as far as we know, no estimates were given in the literature.

In the present paper we give a simple proof of the fact that for any $\xi \in (0, \pi)$ solutions of (1.1)–(1.3) are not uniformly stable in the energy space. For the solutions of (1.4)–(1.6) we give a complete characterization of points ξ for which the solutions are uniformly stable in the energy space. The main novelty of the paper consists in the fact that, even in the cases when we have no uniform energy decay, we give explicit decay estimates for regular initial data. These estimates depend on the diophantine approximations properties of ξ. As far as we know, the results in previous literature concerning beam equations with pointwise feedbacks are essentially devoted to exponential stabilization. In the case of strong, but not exponential stability, no estimates were given. In the case of bounded feedback controls, similar estimates were given by Russell in [24]. Russell's method cannot be extended to unbounded feedbacks and, namely, to the case of pointwise stabilizers.

Even for the particular case of exponential decay our method is different from those previously used in pointwise stabilization problems. Our approach, avoiding frequency domain methods and spectrum calculations, is based on sharp trace regularity results combined with observability inequalities valid for solutions of appropriate conservative problems. As far as we know this is the first example in which observability estimates for the *undamped problem* are used to derive stability estimates in the presence of an *unbounded feedback*. Due to the appropriate choice of the associated undamped problem the basic observability estimates are simply obtained by applying Ingham's inequality. For bounded feedbacks a similar method was used in [13] in order to study uniform stabilization of second-order equations. Since in our case the feedback is unbounded we have to use new arguments, namely, some sharp trace regularity results.

The plan of the paper is as follows. In section 2 we give precise statements of the main results. Section 3 contains some new trace regularity results needed in the following sections. In section 4 we prove exact pointwise observability results for the associated undamped problem. The proof of the main result is given in section 5.

2. Statement of the main results.

If u is a solution of (1.1)–(1.3) or of (1.4)–(1.6), we define the energy of u at instant t by

$$E(u(t)) = \frac{1}{2}\int_0^\pi \left(\left|\frac{\partial u}{\partial t}(x,t)\right|^2 + \left|\frac{\partial^2 u}{\partial x^2}(x,t)\right|^2 \right) dx. \tag{2.1}$$

Simple formal calculations show that a sufficiently smooth solution of (1.1)–(1.3) or of (1.4)–(1.6) satisfies the energy estimate

$$E(u(0)) - E(u(t)) = \int_0^t \left|\frac{\partial u}{\partial t}(\xi, s)\right|^2 ds \qquad \forall\, t \ge 0. \tag{2.2}$$

In particular, (2.2) implies that

$$E(u(t)) \leq E(u(0)) \quad \forall t \geq 0.$$

The estimate above suggests that the natural wellposedness spaces for (1.1)–(1.3) (respectively, for (1.4)–(1.6)) are $V_1 \times L^2(0,\pi)$ (respectively, $V_2 \times L^2(0,\pi)$), where

$$V_1 = H^2(0,\pi) \cap H_0^1(0,\pi),\ V_2 = \left\{\phi \in H^2(0,\pi) | \phi(0) = \frac{d\phi}{dx}(\pi) = 0\right\}$$

are Hilbert spaces for the inner product

$$\left\langle \begin{pmatrix} u_1 \\ v_1 \end{pmatrix}, \begin{pmatrix} u_2 \\ v_2 \end{pmatrix} \right\rangle_{V_i \times L^2(0,\pi)} = \int_0^\pi \left[\frac{d^2 u_1}{dx^2}\frac{d^2 \bar{u}_2}{dx^2} + v_1 \bar{v}_2\right],\ i = 1, 2.$$

Denote

$$Y = \left[H^2(0,\pi) \cap H^4(0,\xi) \cap H^4(\xi,\pi)\right] \times H^2(0,\pi), \tag{2.3}$$

$$\begin{aligned}\mathcal{D}(A_1) =& \Big\{(u,v) \in Y,\ \ u(0) = v(0) = u(\pi) = v(\pi) = \tfrac{d^2u}{dx^2}(0) = \tfrac{d^2u}{dx^2}(\pi) = 0, \\ & \tfrac{d^2u}{dx^2}(\xi+) = \tfrac{d^2u}{dx^2}(\xi-),\ \tfrac{d^3u}{dx^3}(\xi+) - \tfrac{d^3u}{dx^3}(\xi-) = -v(\xi)\Big\},\end{aligned} \tag{2.4}$$

$$\begin{aligned}\mathcal{D}(A_2) =& \Big\{(u,v) \in Y,\ \ u(0) = v(0) = \tfrac{du}{dx}(\pi) = \tfrac{dv}{dx}(\pi) = \tfrac{d^2u}{dx^2}(0) = \tfrac{d^3u}{dx^3}(\pi) = 0, \\ & \tfrac{d^2u}{dx^2}(\xi+) = \tfrac{d^2u}{dx^2}(\xi-),\ \tfrac{d^3u}{dx^3}(\xi+) - \tfrac{d^3u}{dx^3}(\xi-) = -v(\xi)\Big\}.\end{aligned} \quad . \tag{2.5}$$

The corresponding operators A_1 and A_2 will be defined in section 5. If $(u^0, u^1) \in Y$, we denote

$$||(u^0, u^1)||_Y^2 = \|u^0\|_{H^4(0,\xi)}^2 + \|u^0\|_{H^4(\xi,\pi)}^2 + \|u^1\|_{H^2(0,\pi)}^2. \tag{2.6}$$

We first check that (1.1)–(1.3) (respectively, (1.4)–(1.6)) are well posed in the spaces above. Then we study the behavior of $E(u(t))$ when $t \to \infty$. The wellposedness and strong stability properties are summarized in the result below.

Proposition 2.1. *The following assertions hold true.*

1. *Suppose that* $(u^0, u^1) \in \mathcal{D}(A_1)$ *(respectively, that* $(u^0, u^1) \in \mathcal{D}(A_2)$*). Then the problem* (1.1)–(1.3) *(respectively,* (1.4)–(1.6)*) admits a unique solution*

$$\begin{pmatrix} u \\ \frac{\partial u}{\partial t} \end{pmatrix} \in C(0,T;\mathcal{D}(A_1)) \ \left(\textit{respectively, } \begin{pmatrix} u \\ \frac{\partial u}{\partial t} \end{pmatrix} \in C(0,T;\mathcal{D}(A_2))\right).$$

2. *If* $(u^0, u^1) \in V_1 \times L^2(0,\pi)$ *(respectively,* $(u^0, u^1) \in V_2 \times L^2(0,\pi)$*), then the problem* (1.1)–(1.3) *(respectively,* (1.4)–(1.6)*) admits a unique solution*

$$u \in C(0,T;V_1) \cap C^1(0,T;L^2(0,\pi)) \ (\textit{respectively, } u \in C(0,T;V_2)$$

$$\cap C^1(0,T;L^2(0,\pi))),$$

such that $u(\xi,\cdot) \in H^1(0,T)$ *and*

$$\|u(\xi,\cdot)\|_{H^1(0,T)}^2 \leq C(\|u^0\|_{H^2(0,\pi)}^2 + \|u^1\|_{L^2(0,\pi)}^2), \tag{2.7}$$

where the constant $C > 0$ *depends only on* ξ *and* T*. Moreover,* u *satisfies the energy estimate* (2.2).

3. *The estimate* $\lim_{t\to\infty} E(u(t)) = 0$ *holds true for any finite energy solution of* (1.1)–(1.3) *(respectively, of* (1.4)–(1.6)*) if and only if* $\frac{\xi}{\pi} \notin \mathbf{Q}$ *(respectively,* $\frac{\xi}{\pi} \neq \frac{2p}{2q-1}$ $\forall p, q \in \mathbb{N}$*).*

Remark 1. *The result above shows, in particular, that one cannot expect strong stabilization* $\forall \xi \in (0, \pi)$*.*

The main results in this paper concern the precise asymptotic behavior of the solutions of (1.1)–(1.3) and of (1.4)–(1.6). As we will see below, the systems (1.1)–(1.3) and (1.4)–(1.6) are generally not uniformly stable in the natural energy spaces. However, we prove that, in some cases of strong but not exponential stability, the energy decay is uniform for all initial data lying in more regular spaces.

Denote by $\mathbf{Q}$ the set of all rational numbers. Let us also denote by $\mathcal{S}$ the set of all numbers $\rho \in (0, \pi)$ such that $\frac{\rho}{\pi} \notin \mathbf{Q}$ and if $[0, a_1, \ldots, a_n, \ldots]$ is the expansion of $\frac{\rho}{\pi}$ as a continued fraction, then (a_n) is bounded. Let us notice that $\mathcal{S}$ is obviously uncountable and, by classical results on diophantine approximation (cf. [3, p. 120]), its Lebesgue measure is equal to zero. Roughly speaking, the set $\mathcal{S}$ contains the irrationals which are "badly" approximable by rational numbers. In particular, by the Euler–Lagrange theorem (cf. [18, p. 57]) $\mathcal{S}$ contains all $\xi \in (0, \pi)$ such that $\frac{\xi}{\pi}$ is an irrational quadratic number (i.e., satisfying a second degree equation with rational coefficients). According to a classical result (see, for instance, [26] and the references therein), if $\xi \in \mathcal{S}$, then there exists a constant $C_\xi > 0$ such that

$$|\sin(n\xi)| \geq \frac{C_\xi}{n} \qquad \forall\, n \geq 1. \tag{2.8}$$

Our main results can now be stated as follows.

Theorem 2.2.

1. *For any* $\xi \in (0, \pi)$*, the system described by* (1.1)–(1.3) *is not exponentially stable in* $V_1 \times L^2(0, \pi)$*.*
2. $\forall \xi \in \mathcal{S}$ *and* $\forall t \geq 0$ *we have*

$$E(u(t)) \leq \frac{C_\xi}{(t+1)^2} ||(u^0, u^1)||_Y^2 \qquad \forall\, (u^0, u^1) \in \mathcal{D}(A_1), \tag{2.9}$$

where $C_\xi > 0$ *is a constant depending only on* ξ*.*

3. $\forall \epsilon > 0$ *there exists a set* $B_\epsilon \subset [(0, \pi) \setminus \pi\mathbf{Q}]$*, the Lebesgue measure of* B_ϵ *being equal to* π*, such that* $\forall \xi \in B_\epsilon$ *and* $\forall t \geq 0$ *we have*

$$E(u(t)) \leq \frac{C_{\xi,\epsilon}}{(t+1)^{\frac{2}{1+\epsilon}}} ||(u^0, u^1)||_Y^2 \qquad \forall\, (u^0, u^1) \in \mathcal{D}(A_1), \tag{2.10}$$

where $C_{\xi,\epsilon} > 0$ *is a constant depending only on* ξ *and* ϵ*.*

Theorem 2.3.

1. *The system described by* (1.4)–(1.6) *is exponentially stable in* $V_2 \times L^2(0, \pi)$ *if and only if* $\frac{\xi}{\pi}$ *is a rational number with coprime factorization*

$$\frac{\xi}{\pi} = \frac{p}{q}, \quad \textit{where } p \textit{ is odd.} \tag{2.11}$$

2. $\forall \xi \in \mathcal{S}$ *and* $\forall t \geq 0$ *we have*

$$E(u(t)) \leq \frac{C_\xi}{(t+1)^2} ||(u^0, u^1)||_Y^2 \qquad \forall\, (u^0, u^1) \in \mathcal{D}(A_2), \tag{2.12}$$

where $C_\xi > 0$ *is a constant depending only on* ξ*.*

3. $\forall \epsilon > 0$ *there exists a set* $B_\epsilon \subset [(0,\pi) \setminus \pi\mathbf{Q}]$, *the Lebesgue measure of* B_ϵ *being equal to* π, *such that* $\forall \xi \in B_\epsilon$ *and* $\forall t \geq 0$ *we have*

$$E(u(t)) \leq \frac{C_{\xi,\epsilon}}{(t+1)^{\frac{2}{1+\epsilon}}} ||(u^0, u^1)||_Y^2 \qquad \forall \, (u^0, u^1) \in \mathcal{D}(A_2), \tag{2.13}$$

where $C_{\xi,\epsilon} > 0$ *is a constant depending only on* ξ *and* ϵ.

REMARK 2. *In the case of a string with pointwise stabilizer, the explicit eigenvalue calculation in* [27] *suggests that one cannot expect polynomial decay estimates like* (2.10) *for any* ξ *satisfying the assumption in the third assertion of Proposition* 2.1. *By analogy with the result in* [27] *we conjecture that* $\forall \epsilon > 0$ *there exists* ξ *satisfying the assumption in the third assertion of Proposition* 2.1 *and the sequences* (t_n) *(of real numbers), and* (u_n) *(of finite energy solutions), with* $t_n \to \infty$, *such that*

$$\lim_{n\to\infty} t_n^\epsilon \frac{E(u_n(t_n))}{\|(u_n(0), \frac{\partial u_n}{\partial t}(0))\|_Y^2} = \infty.$$

3. Some regularity results. Consider the initial and boundary value problems

$$\frac{\partial^2 v}{\partial t^2}(x,t) + \frac{\partial^4 v}{\partial x^4}(x,t) \; = k(t)\delta_\xi, \quad 0 < x < \pi, \; t > 0, \tag{3.1}$$

$$v(x,0) = 0, \frac{\partial v}{\partial t}(x,0) = 0, \quad 0 < x < \pi, \tag{3.2}$$

and either

$$v(0,t) = v(\pi,t) = \frac{\partial^2 v}{\partial x^2}(0,t) = \frac{\partial^2 v}{\partial x^2}(\pi,t) = 0, \quad t > 0, \tag{3.3}$$

or

$$v(0,t) = \frac{\partial v}{\partial x}(\pi,t) = \frac{\partial^2 v}{\partial x^2}(0,t) = \frac{\partial^3 v}{\partial x^3}(\pi,t) = 0, \quad t > 0. \tag{3.4}$$

The equations above are models for the vibrations of an undamped Bernoulli–Euler beam, in the presence of a pointwise force. The main result of this section gives regularity properties of the solutions of (3.1)–(3.3) and of (3.1),(3.2), and (3.4). These regularity results are sharp (according to Remark 4 below).

PROPOSITION 3.1. *Suppose that* $k \in L^2(0,T)$. *Then the problem* (3.1)–(3.3) *(respectively,* (3.1),(3.2),(3.4)*) admits a unique solution having the regularity*

$$v \in C(0,T;V_1) \cap C^1(0,T;L^2(0,\pi)) \quad (\textit{respectively}, \tag{3.5}$$

$$v \in C(0,T;V_2) \cap C^1(0,T;L^2(0,\pi))). \tag{3.6}$$

Moreover, $v(\xi,\cdot) \in H^1(0,T)$ *and there exists a constant* $C > 0$, *depending only on* T, *such that*

$$\|v(\xi,\cdot)\|_{H^1(0,T)} \leq C\|k\|_{L^2(0,T)} \qquad \forall \, k \in L^2(0,T). \tag{3.7}$$

REMARK 3. *We notice that the interior regularity* (3.5) *(respectively,* (3.6)*) does not follow from the Sobolev regularity of the right-hand side of* (3.1) *or from the results* *in* [25]*. Moreover, estimate* (3.7) *is not a consequence of the interior regularity* (3.5) *(respectively,* (3.6)*).*

In order to prove Proposition 3.1 we first study the case of free vibrations of an undamped beam, i.e., we consider the initial and boundary value problem

$$\frac{\partial^2\phi}{\partial t^2}(x,t)+\frac{\partial^4\phi}{\partial x^4}(x,t)=0, \quad 0<x<\pi,\ t>0, \tag{3.8}$$

$$\phi(0,t)=\phi(\pi,t)=\frac{\partial^2\phi}{\partial x^2}(0,t)=\frac{\partial^2\phi}{\partial x^2}(\pi,t)=0, \quad t>0, \tag{3.9}$$

$$\phi(x,0)=u^0(x),\frac{\partial\phi}{\partial t}(x,0)=u^1(x), \quad 0<x<\pi, \tag{3.10}$$

and the problem formed by (3.8), (3.10), and the boundary conditions

$$\phi(0,t)=\frac{\partial\phi}{\partial x}(\pi,t)=\frac{\partial^2\phi}{\partial x^2}(0,t)=\frac{\partial^3\phi}{\partial x^3}(\pi,t)=0, \quad t>0. \tag{3.11}$$

The following result, besides showing that the problems above are well posed in the natural energy spaces, gives a sharp inequality on the trace of ϕ at the point ξ.

LEMMA 3.2. *Suppose that* $(u^0,u^1)\in V_1\times L^2(0,\pi)$ *(respectively,* $(u^0,u^1)\in V_2\times L^2(0,\pi)$*). Then the initial and boundary value problem* (3.8)–(3.10) *(respectively,* (3.8),(3.10)*, and* (3.11)*) admits a unique solution*

$$\phi\in C(0,T;V_1)\cap C^1(0,T;L^2(0,\pi)), \tag{3.12}$$

respectively,

$$\phi\in C(0,T;V_2)\cap C^1(0,T;;L^2(0,\pi)), \tag{3.13}$$

satisfying

$$\phi(\xi,\cdot)\in H^1(0,T).$$

Moreover, there exists a constant $C>0$*, depending only on* T*, such that*

$$\|\phi(\xi,\cdot)\|^2_{H^1(0,T)}\le C(\|u^0\|^2_{H^2(0,\pi)}+\|u^1\|^2_{L^2(0,\pi)}). \tag{3.14}$$

Proof. We first notice that problem (3.8)–(3.10) can be written as

$$\frac{\partial}{\partial t}\begin{pmatrix}\phi\\ \dfrac{\partial\phi}{\partial t}\end{pmatrix}=A_0\begin{pmatrix}\phi\\ \dfrac{\partial\phi}{\partial t}\end{pmatrix},$$

where

$$\mathcal{D}(A_0)=\left\{\begin{pmatrix}u\\ v\end{pmatrix}\in\big(H^4(0,\pi)\cap H^1_0(0,\pi)\big)\times\big(H^2(0,\pi)\cap H^1_0(0,\pi)\big)\right.$$

$$\left.\left|\frac{d^2u}{dx^2}(0)=\frac{d^2u}{dx^2}(\pi)=0\right.\right\}, \tag{3.15}$$

and

$$A_0 : \mathcal{D}(A_0) \to V_1 \times L^2(0,\pi),\ A_0 \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} v \\ -\dfrac{d^4 u}{dx^4} \end{pmatrix}. \tag{3.16}$$

One can easily check that A_0 is skew-adjoint. So, by Stone's theorem, it generates a semigroup of isometries in $V_1 \times L^2(0,\pi)$. This implies that (3.8)–(3.10) admits a unique solution ϕ satisfying (3.12).

In order to prove (3.14) we put

$$u^0(x) = \sum_{n=1}^{\infty} a_n \sin(nx),\ u^1(x) = \sum_{n=1}^{\infty} n^2 b_n \sin(nx), \tag{3.17}$$

with $\sum_{n=1}^{\infty} n^4(a_n^2 + b_n^2) < \infty$. In this case the solution of (3.8)–(3.10) is given by

$$\phi(x,t) = \sum_{n\geq 1} [a_n \cos(n^2 t)\sin(nx) + b_n \sin(n^2 t)\sin(nx)], \tag{3.18}$$

which implies that

$$\phi(\xi,t) = \sum_{n=1}^{\infty} \left[a_n \cos(n^2 t)\sin(n\xi) + b_n \sin(n^2 t)\sin(n\xi)\right]. \tag{3.19}$$

If we consider the right-hand side of (3.19) as a Fourier series in t (see Theorem 4.1 from [10] for details) we obtain the existence of a constant C depending on T such that

$$\|\phi(\xi,\cdot)\|^2_{H^1(0,T)} \leq C \sum_{n=1}^{\infty} n^4(a_n^2 + b_n^2), \tag{3.20}$$

which obviously implies (3.14).

The problem (3.8), (3.10), (3.11) can be treated in a completely similar manner. It suffices to replace formulas (3.17) and (3.18) by the relations

$$u^0(x) = \sum_{n=0}^{\infty} a_n \sin\left(\frac{2n+1}{2}x\right),\ u^1(x) = \sum_{n=0}^{\infty} \frac{(2n+1)^2}{4} b_n \sin\left(\frac{2n+1}{2}x\right),$$

$$\begin{aligned} \phi(x,t) = \sum_{n=0}^{\infty} \Bigg[& a_n \cos\left(\frac{(2n+1)^2}{4}t\right)\sin\left(\frac{2n+1}{2}x\right) \\ & + b_n \sin\left(\frac{(2n+1)^2}{4}t\right)\sin\left(\frac{2n+1}{2}x\right)\Bigg]. \end{aligned} \tag{3.21}$$

The relations above clearly imply (3.14). □

In order to prove Proposition 3.1 we need the following technical result.

Lemma 3.3. *Let $\gamma > 0$, $\xi \in (0,\pi)$ be two fixed real numbers and $C_\gamma = \{w \in \mathbb{C} \mid Re(w)Im(w) = -\frac{\gamma}{2}\}$. Then the functions*

$$f_1(w) = \frac{i}{2w}\left\{-\frac{\sin(w\xi)\,\sin[w\,(\xi-\pi)]}{\sin(w\pi)} + \frac{sh(w\xi)\,sh[w\,(\xi-\pi)]}{sh(w\pi)}\right\} \tag{3.22}$$

and

$$f_2(w) = \frac{i}{2w}\left\{-\frac{\sin(w\,\xi)\,\cos[w\,(\xi-\pi)]}{\cos(w\pi)} + \frac{sh(w\,\xi)\,ch[w\,(\xi-\pi)]}{ch(w\pi)}\right\} \tag{3.23}$$

are bounded on C_γ, uniformly with respect to $\xi \in [0,\pi]$.

Proof. Let us suppose that f_1 is not bounded on C_γ. In this case there exists a sequence $(w_n) \subset C_\gamma$ such that

$$\lim_{n\to+\infty} |f_1(w_n)| = +\infty. \tag{3.24}$$

As f_1 is analytical in the open set $D = \{w \in \mathbb{C} \mid Re(w)Im(w) < 0\}$ and $C_\gamma \subset D$, relation (3.24) clearly implies that $|w_n| \to +\infty$. Due to the definition of C_γ this can happen in two situations:

$$|Re(w_n)| \to +\infty,\ |Im(w_n)| = \frac{\gamma}{2\,|Re(w_n)|} \to 0, \tag{3.25}$$

or

$$|Im(w_n)| \to +\infty,\ |Re(w_n)| = \frac{\gamma}{2\,|Im(w_n)|} \to 0. \tag{3.26}$$

Suppose that (3.25) holds true. In this case a simple calculation shows that

$$\lim_{n\to+\infty}\left|\frac{sh(w_n\,\xi)\,sh[w_n\,(\xi-\pi)]}{sh(w_n\pi)}\right| = \frac{1}{2}, \tag{3.27}$$

and

$$\limsup_{n\to+\infty} |\sin(w_n\,\xi)\,\sin[w_n\,(\xi-\pi)]| \leq 1. \tag{3.28}$$

Relations (3.24), (3.27), and (3.28) imply that

$$\lim_{n\to+\infty} |w_n\,\sin(w_n\,\pi)| = 0. \tag{3.29}$$

Since $\lim\limits_{n\to+\infty} |w_n| = +\infty$, relation (3.29) yields

$$\lim_{n\to+\infty} |\sin(w_n\,\pi)| = 0.$$

It is easily checked that the relation above implies the existence of a subsequence of (w_n), denoted also by (w_n), and of the sequences $(\alpha_n) \subset \mathbb{N}$, $(\beta_n) \subset [0,1[$, satisfying

$$|Re(w_n)| = \alpha_n + \beta_n,\ \lim_{n\to+\infty} \beta_n = 0. \tag{3.30}$$

We obviously have

$$|w_n \sin(w_n\pi)| = \left|\frac{w_n}{Re(w_n)}\right| \left|\frac{\sin\left(\beta_n\pi - i\pi\frac{\gamma}{2Re(w_n)}\right)}{\beta_n\pi - i\pi\frac{\gamma}{2Re(w_n)}}\right| \left|\beta_n\pi Re(w_n) - i\pi\frac{\gamma}{2}\right|. \tag{3.31}$$

On the other hand, (3.25) and (3.30) imply

$$\lim_{n\to+\infty}\left|\frac{\sin\left(\beta_n\pi - i\pi\frac{\gamma}{2Re(w_n)}\right)}{\beta_n\pi - i\pi\frac{\gamma}{2Re(w_n)}}\right| = 1,\ \lim_{n\to\infty}\left|\frac{w_n}{Re(w_n)}\right| = 1. \tag{3.32}$$

Moreover, we obviously have

$$\left|\beta_n \pi Re(w_n) - i\pi\frac{\gamma}{2}\right| \geq \frac{\pi\gamma}{2} \qquad \forall\, n \geq 1. \tag{3.33}$$

Relations (3.31)–(3.33) contradict (3.29). It follows that (3.24) and (3.25) cannot both be true. By a similar method we can show that (3.24) and (3.26) cannot both hold true. This means that assumption (3.24) is false, i.e., that f_1 is bounded on C_γ. The proof that f_2 is also bounded on C_γ can be done in a completely similar manner. The bounds are uniform with respect to ξ since $\sup_{w\in C_\gamma} |f_i(w)|$, $i = 1, 2$ depends continuously on $\xi \in [0, \pi]$. □

We can now give the proof of the main result of this section.

Proof of Proposition 3.1. We use the method of transposition. Let $\mathcal{D}(A_0)$ be the space defined in (3.15), and denote by $\mathcal{D}[(A_0)]'$ the dual space of $\mathcal{D}(A_0)$ with respect to the pivot space $V_1 \times L^2(0, \pi)$. It is well known that A_0 can be extended to a skew-adjoint operator (denoted also by A_0),

$$A_0 : V_1 \times L^2(0, \pi) \to [\mathcal{D}(A_0)]',$$

such that A_0 generates a group of isometries in $[\mathcal{D}(A_0)]'$, denoted by $S(t)$.

Moreover, we define the operator

$$B_0 : \mathbb{R} \to [\mathcal{D}(A_0)]',\ B_0 r = \begin{pmatrix} 0 \\ r\delta_\xi \end{pmatrix}\ \forall r \in \mathbb{R}. \tag{3.34}$$

With the notation above the problem (3.1)–(3.3) can be written as a Cauchy problem in $[\mathcal{D}(A_0)]'$ under the form

$$\frac{\partial}{\partial t}\begin{pmatrix} v(t) \\ \frac{\partial v}{\partial t}(t) \end{pmatrix} = A_0 \begin{pmatrix} v(t) \\ \frac{\partial v}{\partial t}(t) \end{pmatrix} + B_0 k(t) \quad \forall\, t > 0, \tag{3.35}$$

$$v(0) = \frac{\partial v}{\partial t}(0) = 0. \tag{3.36}$$

After a simple calculation we get that the operator $B_0^* : \mathcal{D}(A_0) \to \mathbb{R}$ is given by

$$B_0^* \begin{pmatrix} u \\ v \end{pmatrix} = v(\xi) \qquad \forall \begin{pmatrix} u \\ v \end{pmatrix} \in \mathcal{D}(A_0).$$

This implies that

$$B_0^* S^*(t) \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} = \frac{\partial \phi}{\partial t}(\xi, t) \qquad \forall \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} \in \mathcal{D}(A_0), \tag{3.37}$$

with ϕ satisfying (3.8)–(3.10). From (3.14) and (3.37) we deduce that there exists a constant $C > 0$ such that

$$\int_0^T \left| B_0^* S^*(t) \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} \right|^2 dt \leq C \left\| \begin{matrix} u^0 \\ u^1 \end{matrix} \right\|^2_{V_1 \times L^2(0,\pi)} \qquad \forall \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} \in \mathcal{D}(A_0). \tag{3.38}$$

According to Theorem 3.1 in [2, p. 173], inequality (3.38) implies that (3.35), (3.36) admit a unique solution

$$\begin{pmatrix} v \\ \frac{\partial v}{\partial t} \end{pmatrix} \in C(0, T; V_1 \times L^2(0, \pi)),$$

which obviously implies the conclusion (3.5). The proof that the interior regularity property (3.6) holds true for all solutions of (3.1), (3.2), and (3.4) can be obtained in a completely similar manner, so we skip it here.

We still have to prove the trace regularity property (3.7).

As (3.1) is time reversible, after extending k by zero for $t \in \mathbb{R} \setminus [0,T]$, we can solve (3.1)–(3.3) for $t \in \mathbb{R}$. In this way we obtain a function, denoted also by v, such that

$$v \in C(0,T;V_1) \cap C^1(0,T;L^2(0,\pi)),\ v(x,t)=0, \qquad \forall\, t \le 0, \tag{3.39}$$

and v satisfies (3.1)–(3.3) $\forall (x,t) \in [0,\pi] \times \mathbb{R}$.

Let $\widehat{v}(x,\lambda)$, where $\lambda = \gamma + i\eta,\ \gamma > 0$, and $\eta \in \mathbb{R}$, be the Laplace (with respect to time) transform of v. Since v satisfies (3.39), estimate (3.7) is equivalent to the fact that the function $t \to e^{-\gamma t} v(\xi,t)$ belongs to $H^1(\mathbb{R})$ and that there exists a constant $M_1 > 0$ such that

$$\|e^{-\gamma \cdot} v(\xi,\cdot)\|^2_{H^1(-\infty,\infty)} \le M_1 \|k\|^2_{L^2(-\infty,\infty)}.$$

Equivalently, by the Parseval identity (see, for instance, [9, p. 212]), it suffices to prove that the function

$$\eta \to (\gamma + i\eta)\widehat{v}(\xi, \gamma + i\eta)$$

belongs to $L^2(\mathbb{R}_\eta)$ for some $\gamma > 0$, and that there exists a constant $M_2 > 0$ such that

$$\|(\gamma + i\eta)\widehat{v}(\xi,\gamma + i\eta)\|^2_{L^2(\mathbb{R}_\eta)} \le M_2 \int_{-\infty}^{\infty} |k(\gamma + i\eta)|^2 d\eta. \tag{3.40}$$

It can be easily checked that $\widehat{v}$ satisfies

$$\lambda^2 \widehat{v}(x,\lambda) + \frac{\partial^4 \widehat{v}}{\partial x^4}(x,\lambda) = 0,\ x \in (0,\xi) \cup (\xi,1),\ Re\lambda > 0, \tag{3.41}$$

$$\widehat{v}(0,\lambda) = \widehat{v}(\pi,\lambda) = \frac{\partial^2 \widehat{v}}{\partial x^2}(0,\lambda) = \frac{\partial^2 \widehat{v}}{\partial x^2}(\pi,\lambda) = 0,\ Re\lambda > 0, \tag{3.42}$$

$$[\widehat{v}]_\xi = \left[\frac{\partial \widehat{v}}{\partial x}\right]_\xi = \left[\frac{\partial^2 \widehat{v}}{\partial x^2}\right]_\xi = 0, \tag{3.43}$$

$$\left[\frac{\partial^3 \widehat{v}}{\partial x^3}\right]_\xi = \widehat{k}(\lambda),\ Re\lambda > 0, \tag{3.44}$$

where we denote by $[f]_\xi$ the jump of the function f at the point ξ. As the equations above are linear, we deduce that, for every $\lambda \in \mathbb{C},\ Re\lambda > 0$, we can find $H_1(\lambda) \in \mathbb{C}$, such that

$$\lambda\, \widehat{v}(\xi,\lambda) = H_1(\lambda)\widehat{k}(\lambda) \quad \forall Re\,\lambda > 0. \tag{3.45}$$

In order to compute $H_1(\lambda)$ we notice that the solutions of (3.41) have the form

$$\widehat{v}(x,\lambda) = \begin{cases} Ae^{iwx} + Be^{-iwx} + Ce^{wx} + De^{-wx}, & x \in (0,\xi), \\ A_1 e^{iw(x-\pi)} + B_1 e^{-iw(x-\pi)} + C_1 e^{w(x-\pi)} + D_1 e^{-w(x-\pi)}, & x \in (\xi,\pi), \end{cases}$$

where $A, B, C, D, A_1, B_1, C_1$, and D_1 are constants and w is the unique complex number satisfying the conditions

$$\lambda = iw^2,\ w = re^{i\theta},\ \text{with } r > 0 \text{ and } \theta \in \left[-\frac{\pi}{2}, 0\right]. \tag{3.46}$$

Using (3.42), we obtain

$$\widehat{v}(x,\lambda) = \begin{cases} 2iA\sin(wx) + 2Csh(wx), & x \in (0,\xi), \\ 2iA_1\sin[w(x-\pi)] + 2C_1sh[w(x-\pi)], & x \in (\xi,\pi). \end{cases}$$

Consequently, the solutions of (3.41)–(3.43) have the following form:

$$\widehat{v}(x,\lambda) = \begin{cases} 2iA\sin(wx) - 2iA\dfrac{\sin(w\pi)sh[w(\xi-\pi)]}{sh(w\pi)\sin[w(\xi-\pi)]}sh(wx), & x \in (0,\xi), \\ 2iA\dfrac{\sin(w\xi)}{\sin[w(\xi-\pi)]}\sin[w(x-\pi)] & \\ -2iA\dfrac{\sin(w\pi)sh(w\xi)}{sh(w\pi)\sin[w(\xi-\pi)]}sh[w(x-\pi)], & x \in (\xi,\pi). \end{cases} \tag{3.47}$$

Then, using (3.44) and (3.45), we obtain

$$H_1(\lambda) = f_1(w), \tag{3.48}$$

where f_1 is defined by (3.22). By (3.46), the relation $Re\,\lambda = \gamma > 0$ implies that $w \in C_\gamma$, with C_γ defined in Lemma 3.3 . We can now apply Lemma 3.3 to obtain the existence of a constant $M_2 > 0$ such that (3.40) holds true. This ends the proof of the fact that (3.7) holds for all solutions of (3.1)–(3.3).

If v is the solution of (3.1), (3.2), and (3.4), similar calculations (see also [23]) imply that

$$\lambda\,\widehat{v}(\xi,\lambda) = H_2(\lambda)\widehat{k}(\lambda) \quad \forall Re\,\lambda > 0,$$

where $H_2(iw^2) = f_2(w)$ and f_2 is defined in (3.23). Again applying Lemma 3.3 and the method above, we can easily conclude that (3.7) holds for all solutions of (3.1), (3.2), and (3.4). □

REMARK 4. *It can be easily checked that* $\forall\varepsilon > 0$, $\lambda^\varepsilon H_i(\lambda), i = 1, 2$, *is not bounded on* C_γ. *This means that estimate* (3.7) *is no longer valid if we replace the* H^1 *norm by the* $H^{1+\varepsilon}$ *norm in the left-hand side of* (3.7). *This means that* (3.7) *is a sharp estimate.*

REMARK 5. *In* [23] *it is shown that the system* (3.1), (3.2), (3.4) *can be written as*

$$\dot{z} + Az = Bk$$

in an appropriate Hilbert space, with the input k *and the output* $y = B^*k$. *The results we proved in this section say that this system is well posed, in the sense used in* [23]. *According to classical results (see again* [23] *and the references therein), this fact is equivalent to the boundedness of* H_2 *on some half plane* $Re\lambda \geq \gamma > 0$. *This boundedness was proved in the appendix of* [23]. *Since we didn't use* H_2 *for the proof of the interior regularity, we a priori needed only the boundedness of* H_2 *on the line* $Re\,\lambda = \gamma > 0$. *Due to this fact, our approach can be easily adapted for other systems such as strings or Kirchhoff beams.*

4. Some observability inequalities. In this section we gather, for easy reference, some observability inequalities concerning the trace at the point $x = \xi$ of the solutions of (3.8)–(3.10) and of (3.8), (3.9), (3.11). The results in this section are similar to those obtained in [26] in a slightly different situation. Our first result concerns problem (3.8)–(3.10), and it can be stated as follows.

PROPOSITION 4.1. *Let $T > 0$ be fixed and $\mathcal{S} \subset [0, \pi]$ be the set introduced in section* 2. *Then we have the following.*

1. *$\forall \xi \in \mathcal{S}$ the solution ϕ of* (3.8)–(3.10) *satisfies*

$$\int_0^T \left|\frac{\partial \phi}{\partial t}(\xi, t)\right|^2 dt \geq C_\xi \left(\|u^0\|^2_{H^1(0,\pi)} + \|u^1\|^2_{H^{-1}(0,\pi)}\right)$$

$$\forall (u^0, u^1) \in V_1 \times L^2(0, \pi), \tag{4.1}$$

where $C_\xi > 0$ is a constant depending only on ξ.

2. *$\forall \epsilon > 0$ and for almost all $\xi \in (0, \pi)$ the solution ϕ of* (3.8)–(3.10) *satisfies*

$$\int_0^T \left|\frac{\partial \phi}{\partial t}(\xi, t)\right|^2 dt \geq C_{\xi,\epsilon} \left(\|u^0\|^2_{H^{1-\epsilon}(0,\pi)} + \|u^1\|^2_{H^{-1-\epsilon}(0,\pi)}\right)$$

$$\forall (u^0, u^1) \in V_1 \times L^2(0, \pi), \tag{4.2}$$

where $C_{\xi,\epsilon} > 0$ is a constant depending only on ξ and ϵ.

3. *The result in assertion* 1 *is sharp in the sense that, $\forall \xi \in (0, \pi)$, there exists a sequence $(u^0_m, u^1_m) \subset V_1 \times L^2(0, \pi)$ such that the corresponding sequence of solutions (ϕ_m) of* (3.8), (3.9) *with initial data (u^0_m, u^1_m) satisfies $\forall \epsilon > 0$*

$$\lim_{m \to \infty} \frac{\int_0^T \left|\frac{\partial \phi_m}{\partial t}(\xi, t)\right|^2 dt}{\|u^0_m\|^2_{H^{1+\epsilon}(0,\pi)} + \|u^1_m\|^2_{H^{-1+\epsilon}(0,\pi)}} = 0. \tag{4.3}$$

Proof. Notice first that, thanks to Lemma 3.2, the left-hand side of (4.1) is well defined and

$$\frac{\partial \phi}{\partial t}(\xi, t) = \sum_{n=1}^{\infty} \left[-n^2 a_n \sin(n^2 t) \sin(n\xi) + n^2 b_n \cos(n^2 t) \sin(n\xi)\right] \tag{4.4}$$

in $L^2(0, T)$, provided that u^0, u^1 are given by (3.17). Moreover, from (4.4) and the Ball–Slemrod generalization of Ingham's inequality (cf. [1], [11]) we obtain that, $\forall T > 0$, there exists a constant $C_T > 0$ such that

$$\int_0^T \left|\frac{\partial \phi}{\partial t}(\xi, t)\right|^2 dt \geq C_T \sum_{n=1}^{\infty} \left[n^4 a_n^2 \sin^2(n\xi) + n^4 b_n^2 \sin^2(n\xi)\right]. \tag{4.5}$$

Suppose now that ξ belongs to the set $\mathcal{S}$ defined in section 2. Then relations (4.5) and (2.8) imply the existence of a constant $K_{T,\xi} > 0$ such that

$$\int_0^T \left|\frac{\partial \phi}{\partial t}(\xi, t)\right|^2 dt \geq K_{T,\xi} \sum_{n=1}^{\infty} \left[n^2 a_n^2 + n^2 b_n^2\right] \qquad \forall\, \xi \in \mathcal{S},$$

which is exactly (4.1).

In order to prove (4.2) we use a result in [3, p. 120] (see also Proposition 2.4 in [26]) to get that $\forall \epsilon > 0$ there exists a set $B_\epsilon \subset (0,\pi)$ having the Lebesgue measure equal to π and a constant $C > 0$, such that for any $\rho \in B_\epsilon$

$$|\sin(n\rho)| \geq \frac{C}{n^{1+\epsilon}} \qquad \forall\, n \geq 1. \tag{4.6}$$

Let us notice that by Roth's theorem B_ϵ contains all numbers in $(0,\pi)$ having the property that $\frac{\xi}{\pi}$ is an algebraic irrational (see, for instance, [3, p. 104]). Inequalities (4.5) and (4.6) obviously imply (4.2).

We still have to show the existence of a sequence satisfying (4.3). By using continuous fractions (see again [26] and the references therein for details) we can construct a sequence $(q_m) \subset \mathbb{N}$ such that $q_m \to \infty$ and

$$|\sin(q_m\xi)| \leq \frac{\pi}{q_m} \qquad \forall\, m \geq 1. \tag{4.7}$$

Using (4.4) and (4.7), a simple calculation shows that the sequence $(\phi_m^0, \phi_m^1) = (\sin(q_m\pi x), 0)$ satisfies (4.3). □

The observability results for (3.8), (3.9), and (3.11) are given in the proposition below.

PROPOSITION 4.2. *Let $T > 0$ be fixed and $\mathcal{S}$ be the set introduced in section* 2. *Then the following assertions hold true.*

1. *The existence of a constant $C_\xi > 0$, such that the solutions ϕ of* (3.8), (3.10), *and* (3.11) *satisfy*

$$\int_0^T \left|\frac{\partial\phi}{\partial t}(\xi,t)\right|^2 dt \geq C_\xi \left(\|u^0\|^2_{H^2(0,\pi)} + \|u^1\|^2_{L^2(0,\pi)}\right)$$

$$\forall (u^0,u^1) \in V_1 \times L^2(0,\pi), \tag{4.8}$$

is equivalent to the fact that ξ satisfies (2.11).

2. *$\forall \xi \in \mathcal{S}$ the solution ϕ of* (3.8), (3.10), *and* (3.11) *satisfies* (4.1).
3. *$\forall \epsilon > 0$ and for almost all $\xi \in (0,\pi)$ the solution ϕ of* (3.8), (3.10), *and* (3.11) *satisfies* (4.2).

Proof. From (3.21) and the Ball–Slemrod generalization of Ingham's inequality we obtain the existence of a constant $C_T > 0$ such that the solution ϕ of (3.8), (3.10), and (3.11) satisfies

$$\int_0^T \left|\frac{\partial\phi}{\partial t}(\xi,t)\right|^2 dt \geq C_T \sum_{n\geq 0} \frac{(2n+1)^4}{16}(a_n^2+b_n^2)\left|\sin\left(\frac{2n+1}{2}\xi\right)\right|^2. \tag{4.9}$$

If ξ satisfies (2.11), then, by Lemma 2.9 in [23], there exists a constant $k_\xi > 0$ such that

$$\left|\sin\left[\frac{(2n+1)\xi}{2}\right]\right| \geq k_\xi \qquad \forall\, n \geq 0. \tag{4.10}$$

Inequalities (4.9) and (4.10) imply that (4.8) holds true $\forall \xi$ satisfying (2.11).

On the other hand, if ξ does not satisfy (2.11), we can again apply Lemma 2.9 from [23] to get the existence of a sequence $(p_m) \subset \mathbb{N}$, $\lim_{m\to\infty} p_m = \infty$ such that

$$\lim_{m\to\infty} \sin\left[\frac{(2p_m+1)\xi}{2}\right] = 0. \tag{4.11}$$

If we denote by ϕ_m the solution of (3.8), (3.11) with initial data

$$\phi_m(x,0) = \sin\left[\frac{(2p_m+1)x}{2}\right], \frac{\partial \phi_m}{\partial t}(x,0) = 0 \qquad \forall\, x \in (0,\pi),$$

a simple calculation using (4.11) implies that

$$\lim_{m\to\infty} \frac{\int_0^T \left|\frac{\partial \phi_m}{\partial t}(\xi,t)\right|^2 dt}{\|\phi_m(0)\|^2_{H^2(0,\pi)} + \|\frac{\partial \phi_m}{\partial t}(0)\|^2_{L^2(0,\pi)}} = 0,$$

so (4.8) is false for any ξ not satisfying (2.11). Assertions 2 and 3 of the proposition can be proved by simply adapting the proof of Proposition 4.1, so we skip the details. □

5. Proof of the main results.

Proof of Proposition 2.1. The existence and uniqueness of finite energy solutions of (1.1)–(1.3) (respectively, the problem (1.4)–(1.6)) can be obtained by standard semigroup methods. However, for the sake of completeness we sketch the proof here.

Consider the unbounded linear operator

$$A_1 : \mathcal{D}(A_1) \to V_1 \times L^2(0,\pi),\ A_1\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} v \\ -\frac{d^4u}{dx^4} - v(\xi)\delta_\xi \end{pmatrix},$$

where the derivatives with respect to x are calculated in $\mathcal{D}'(0,\pi)$, and $\mathcal{D}(A_1)$ is defined in (2.4). If $(u,v) \in \mathcal{D}(A_1)$, we denote by h_1 (respectively, by h_2) the function in $L^2(0,\xi)$ (respectively, in $L^2(\xi,\pi)$) defined by

$$h_1(x) = \frac{d^4u}{dx^4}, \text{ calculated in } \mathcal{D}'(0,\xi),$$

$$h_2(x) = \frac{d^4u}{dx^4}, \text{ calculated in } \mathcal{D}'(\xi,\pi).$$

Moreover, we define $\{\frac{d^4u}{dx^4}\} \in L^2(0,\pi)$ by

$$\left\{\frac{d^4u}{dx^4}\right\} = \begin{cases} h_1(x) & \text{if} \quad x \in (0,\xi), \\ h_2(x) & \text{if} \quad x \in (\xi,\pi). \end{cases}$$

A simple calculation shows that

$$A_1\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} v \\ -\left\{\frac{d^4u}{dx^4}\right\} \end{pmatrix} \qquad \forall \begin{pmatrix} u \\ v \end{pmatrix} \in \mathcal{D}(A_1). \tag{5.1}$$

We remark that $\mathcal{D}(A_1) \subset Y$ and that the graph norm in $\mathcal{D}(A_1)$ is equivalent to $\|\cdot\|_Y$. A simple calculation gives

$$\left\langle A_1\begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} u \\ v \end{pmatrix}\right\rangle_{V_1\times L^2(0,\pi)} = -|v(\xi)|^2 \qquad \forall \begin{pmatrix} u \\ v \end{pmatrix} \in \mathcal{D}(A_1),$$

so A_1 is a dissipative operator. Moreover, it can be easily checked that A_1 is onto, so, according to Theorems 4.3 and 4.6 from [21, p. 14–15], we obtain that A_1 generates a continuous semigroup of linear contractions acting on $V_1 \times L^2(0,\pi)$.

This implies the existence and uniqueness of solutions u of (1.1)–(1.3) satisfying

$$\begin{pmatrix} u \\ \frac{\partial u}{\partial t} \end{pmatrix} \in C(0,T;\mathcal{D}(A_1)), \text{ if } (u^0,u^1) \in \mathcal{D}(A_1),$$

and

$$u \in C(0,T;V_1) \cap C^1(0,T;L^2(0,\pi)), \text{ if } (u^0,u^1) \in V_1 \times L^2(0,\pi).$$

In order to prove estimate (2.2) and the trace regularity property (2.7), it suffices to remark that, through simple integration by parts, they hold true for regular solutions (i.e., $\left(\begin{smallmatrix} u \\ \frac{\partial u}{\partial t} \end{smallmatrix}\right) \in C(0,T;\mathcal{D}(A_1))$. We can then use the density of $\mathcal{D}(A_1)$ in $V_1 \times L^2(0,\pi)$. The similar properties for problem (1.4)–(1.6) can be proved by simply replacing A_1 by the operator

$$A_2 : \mathcal{D}(A_2) \to V_2 \times L^2(0,\pi), \; A_2 \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} v \\ -\frac{d^4u}{dx^4} - v(\xi)\delta_\xi \end{pmatrix},$$

where $\mathcal{D}(A_2)$ is defined in (2.5).

The strong stability estimates at the end of Proposition 2.1 can be obtained by a simple application of LaSalle's invariance principle. However, for the sake of completeness we give here the proof. Let $S(t)$ be the semigroup of contractions generated by the operator A_1, already introduced. In order to prove the strong stability of the solutions of (1.1)–(1.3), it clearly suffices to show that

$$\lim_{t\to\infty} S(t) \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} = 0 \qquad \forall \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} \text{ in } \mathcal{D}(A_1).$$

We will show that this holds true provided that

$$\frac{\xi}{\pi} \notin \mathbf{Q}. \tag{5.2}$$

Since the imbedding $\mathcal{D}(A_1) \subset V_1 \times L^2(0,\pi)$ is compact, the set

$$\text{orb} \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} = \cup_{t\geq 0} S(t) \begin{pmatrix} u^0 \\ u^1 \end{pmatrix}$$

is precompact in $V_1 \times L^2(0,\pi)$ for any $\left(\begin{smallmatrix} u^0 \\ u^1 \end{smallmatrix}\right)$ in $\mathcal{D}(A_1)$. In this case the ω-limit set of $\left(\begin{smallmatrix} u^0 \\ u^1 \end{smallmatrix}\right)$ defined by

$$\omega \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} = \left\{ U \in V_1 \times L^2(0,\pi), \exists (t_n), \; t_n \to \infty, S(t_n) \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} \to U, \quad n \to \infty \right\}$$

is nonvoid for any $\left(\begin{smallmatrix} u^0 \\ u^1 \end{smallmatrix}\right)$ in $\mathcal{D}(A_1)$. On the other hand, by LaSalle's invariance principle (we refer to [8], [12, p. 18] for more details),

$$\text{if } \begin{pmatrix} \phi^0 \\ \phi^1 \end{pmatrix} \in \omega \begin{pmatrix} u^0 \\ u^1 \end{pmatrix},$$

then

$$\begin{aligned} \left\| \begin{pmatrix} \phi^0 \\ \phi^1 \end{pmatrix} \right\|_{V_1 \times L^2(0,\pi)} &= \lim_{t_n \to +\infty} \left\| S(t_n) \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} \right\|_{V_1 \times L^2(0,\pi)} \\ &= \lim_{n\to+\infty} \left\| S(t+t_n) \begin{pmatrix} u^0 \\ u^1 \end{pmatrix} \right\|_{V_1 \times L^2(0,\pi)} \\ &= \left\| S(t) \begin{pmatrix} \phi^0 \\ \phi^1 \end{pmatrix} \right\|_{V_1 \times L^2(0,\pi)}. \end{aligned}$$

Thus,

$$\left\| \begin{pmatrix} \phi(.,t) \\ \frac{\partial \phi}{\partial t}(\cdot,t) \end{pmatrix} \right\|_{V_1 \times L^2(0,\pi)} = \left\| \begin{pmatrix} \phi^0 \\ \phi^1 \end{pmatrix} \right\|_{V_1 \times L^2(0,\pi)} \text{ for any } t \geq 0.$$

The relation above and (2.2) imply that ϕ satisfies the system (1.1)–(1.2) together with

$$\frac{\partial \phi}{\partial t}(\xi, t) = 0 \quad \forall\, t \in (0,T). \tag{5.3}$$

In particular, this implies that ϕ is the solution of (3.8)–(3.9) with $\phi(x,0) = \phi^0(x)$, $\frac{\partial \phi}{\partial t}(x,0) = \phi^1(x)$. If we put

$$\phi^0(x) = \sum_{n \geq 1} c_n \sin(nx), \phi^1(x) = \sum_{n \geq 1} n^2 d_n \sin(nx),$$

with $(c_n),\ (d_n) \subset l^2(\mathbb{R})$, we have

$$\frac{\partial \phi}{\partial t}(\xi,t) = \sum_{n \geq 1} n^2 \Big\{ - c_n \sin(n^2 t) + d_n \cos(n^2 t) \Big\} \sin(n\xi).$$

The relation above, (5.2), and Ingham's inequality imply that $c_n = d_n = 0\ \forall n \in \mathbb{N}$ so $\phi^0 \equiv \phi^1 \equiv 0$. We can now conclude that condition (5.2) is sufficient for the strong stability of the solutions of (1.1)–(1.3).

If we suppose that ξ doesn't satisfy (5.2), i.e., that $\frac{\xi}{\pi} = \frac{p}{q}$, with $p, q \in \mathbb{Z}$, one can easily check that the solution u of (1.1)–(1.3) with initial data $u^0 = \sin(qx),\ u^1 = 0$ satisfies $E(u(t)) = E(u(0))\ \forall t \geq 0$, so (5.2) is also necessary for the strong stability of the solutions of (1.1)–(1.3).

In a completely similar manner we can tackle the strong stability for (1.4)–(1.6). □

Let $u \in C(0,T;V_1) \cap C^1(0,T;L^2(0,\pi))$ be the solution of (1.1)–(1.3). Then u can be written as

$$u = \phi + \psi, \tag{5.4}$$

where ϕ is the solution of (3.8)–(3.10) and ψ satisfies

$$\frac{\partial^2 \psi}{\partial t^2} + \frac{\partial^4 \psi}{\partial x^4} + \frac{\partial u}{\partial t}(\xi,t)\, \delta_\xi = 0 \quad \text{in } (0,\pi) \times (0,T), \tag{5.5}$$

$$\psi(0,t) = \psi(\pi,t) = \frac{\partial^2 \psi}{\partial x^2}(0,t) = \frac{\partial^2 \psi}{\partial x^2}(\pi,t) = 0,\ t \in (0,T), \tag{5.6}$$

$$\psi(x,0) = \frac{\partial \psi}{\partial t}(x,0) = 0,\ x \in (0,\pi). \tag{5.7}$$

In the same way the solution of (1.4)–(1.6) can be decomposed as in (5.4), where ϕ is the solution of (3.8), (3.10), (3.11), and ψ satisfies (5.5), (5.7) together with

$$\psi(0,t)=\frac{\partial^2\psi}{\partial x^2}(0,t)=\frac{\partial\psi}{\partial x}(\pi,t)=\frac{\partial^3\psi}{\partial x^3}(\pi,t)=0,\ t\in(0,T). \tag{5.8}$$

The main ingredient of the proofs of Theorems 2.2 and 2.3 is the following result.

LEMMA 5.1. *Suppose that* $(u^0,u^1)\in V_1\times L^2(0,\pi)$ *(respectively,* $(u^0,u^1)\in V_2\times L^2(0,\pi)$*). Then the solutions* u *of* (1.1)–(1.3) *(respectively, of* (1.4)–(1.6)*) and the solution* ϕ *of* (3.8)–(3.10) *(respectively, of* (3.8), (3.10), (3.11)*) satisfy*

$$C_1\int_0^T\left|\frac{\partial\phi}{\partial t}(\xi,t)\right|^2dt\le\int_0^T\left|\frac{\partial u}{\partial t}(\xi,t)\right|^2dt\le 4\int_0^T\left|\frac{\partial\phi}{\partial t}(\xi,t)\right|^2dt, \tag{5.9}$$

where $C_1>0$ *is a constant independent of* (u^0,u^1).

REMARK 6. *By Proposition* 2.1, $\frac{\partial u}{\partial t}(\xi,\cdot)\in L^2(0,T)$. *So,* (5.5) *makes sense. The result above shows that the* L^2 *norm of* $\frac{\partial u}{\partial t}(\xi,\cdot)$ *is equivalent to the* L^2 *norm of* $\frac{\partial\phi}{\partial t}(\xi,\cdot)$. *(Notice that* $\frac{\partial\phi}{\partial t}(\xi,\cdot)\in L^2(0,T)$ *by Lemma* 3.2.)

Proof of Lemma 5.1. We prove (5.9) only for u satisfying (1.1)–(1.3) and the ϕ solution of (3.8)–(3.10). As for u satisfying (1.4)–(1.6) and the ϕ solution of (3.8), (3.10), (3.11), the proof is a completely similar one.

Relation (5.4) implies that

$$\int_0^T\left|\frac{\partial\phi}{\partial t}(\xi,t)\right|^2dt\le 2\left\{\int_0^T\left|\frac{\partial u}{\partial t}(\xi,t)\right|^2dt+\int_0^T\left|\frac{\partial\psi}{\partial t}(\xi,t)\right|^2dt\right\}.$$

The estimate above combined with inequality (3.7) in Proposition 3.1 implies the existence of a constant $C_1>0$, independent of (u^0,u^1), such that

$$C_1\int_0^T\left|\frac{\partial\phi}{\partial t}(\xi,t)\right|^2dt\le\int_0^T\left|\frac{\partial u}{\partial t}(\xi,t)\right|^2dt. \tag{5.10}$$

On the other hand, according to Remark 6 and to relation (5.4), we have that $\frac{\partial\phi}{\partial t}(\xi,\cdot)\in L^2(0,T)$. This means that (5.5) can be rewritten as

$$\frac{\partial^2\psi}{\partial t^2}(x,t)+\frac{\partial^4\psi}{\partial x^4}(x,t)+\frac{\partial\psi}{\partial t}(\xi,t)\,\delta_\xi=-\frac{\partial\phi}{\partial t}(\xi,t)\,\delta_\xi\quad\text{in }(0,\pi)\times(0,T). \tag{5.11}$$

If we formally multiply (5.11) by $\frac{\partial\bar\psi}{\partial t}$ (this can be done rigorously by considering a regularizing sequence), we obtain

$$\int_0^T\left|\frac{\partial\psi}{\partial t}(\xi,t)\right|^2dt\le\left|\int_0^T\frac{\partial\phi}{\partial t}(\xi,t)\frac{\partial\bar\psi}{\partial t}(\xi,t)dt\right|,$$

which obviously yields

$$\left\|\frac{\partial\psi}{\partial t}(\xi,t)\right\|^2_{L^2(0,T)}\le\left\|\frac{\partial\phi}{\partial t}(\xi,t)\right\|^2_{L^2(0,T)}.$$

Relation (5.4) and the inequality above imply that

$$\left\|\frac{\partial u}{\partial t}(\xi,t)\right\|^2_{L^2(0,T)}\le 4\left\|\frac{\partial\phi}{\partial t}(\xi,t)\right\|^2_{L^2(0,T)}. \tag{5.12}$$

Inequalities (5.10) and (5.12) obviously yield the conclusion (5.9). □

Before giving the proof of the main results we need one more technical lemma. This lemma extends a result in [16].

LEMMA 5.2. *Let $(\mathcal{E}_k)$ be a sequence of positive real numbers satisfying*

$$\mathcal{E}_{k+1} \leq \mathcal{E}_k - C\mathcal{E}_{k+1}^{2+\alpha} \quad \forall k \geq 0, \tag{5.13}$$

where $C > 0$ and $\alpha > -1$ are constants. Then there exists a positive constant M (depending on α and C) such that

$$\mathcal{E}_k \leq \frac{M}{(k+1)^{\frac{1}{(1+\alpha)}}} \quad \forall k \geq 0. \tag{5.14}$$

Proof. Consider the sequence

$$\mathcal{F}_k = \frac{M}{(k+1)^{\frac{1}{1+\alpha}}},$$

where $M > 0$ is to be determined. After a simple calculation we obtain that

$$\frac{1}{M} \lim_{k\to\infty} \left[(\mathcal{F}_k - \mathcal{F}_{k+1})k(k+2)^{\frac{1}{1+\alpha}}\right] = \frac{1}{1+\alpha}, \tag{5.15}$$

so there exists $k_0 > 0$ such that

$$\mathcal{F}_k - \mathcal{F}_{k+1} \leq \frac{2M}{(1+\alpha)k(k+2)^{\frac{1}{1+\alpha}}} \quad \forall k \geq k_0.$$

The relation above implies that

$$\mathcal{F}_k - \mathcal{F}_{k+1} \leq \frac{4}{(1+\alpha)M^{1+\alpha}}\mathcal{F}_{k+1}^{2+\alpha} \quad \forall k \geq k_1 = \max\{k_0, 2\}. \tag{5.16}$$

If we suppose now that

$$\frac{4}{(1+\alpha)M^{1+\alpha}} < C \text{ and } \frac{M}{(k_1+1)^{\frac{1}{1+\alpha}}} \geq \mathcal{E}_{k_1}, \tag{5.17}$$

from (5.16) we get

$$\mathcal{F}_k - \mathcal{F}_{k+1} \leq C\mathcal{F}_{k+1}^{2+\alpha} \quad \forall k \geq k_1. \tag{5.18}$$

It obviously suffices to show that

$$\mathcal{E}_k \leq \mathcal{F}_k \quad \forall k \geq k_1. \tag{5.19}$$

We shall do that by induction over k.

For $k = k_1$, (5.19) follows directly from (5.17). If we suppose that (5.19) holds true for $k \leq m$, by combining (5.13) and (5.18) we obtain

$$\mathcal{E}_{m+1} + C\mathcal{E}_{m+1}^{2+\alpha} \leq \mathcal{F}_{m+1} + C\mathcal{F}_{m+1}^{2+\alpha},$$

which obviously implies that $\mathcal{E}_{m+1} \leq \mathcal{F}_{m+1}$. ☐

We can now prove the main results.

Proof of Theorem 2.2. 1. Suppose that there exists $\xi \in (0,\pi)$ such that solutions of (1.1)–(1.3) satisfy the estimate

$$E(u(t)) \leq Me^{-\omega t}E(u(0)) \qquad \forall\, t \geq 0, \tag{5.20}$$

where $M, \omega > 0$ are constants depending only on ξ. Relation (5.20) implies the existence of a time $T > 0$ and of a constant $C > 0$ (depending on T) such that

$$E(u(0)) - E(u(T)) \geq CE(u(0)) \qquad \forall\, (u^0, u^1) \in V_1 \times L^2(0,\pi).$$

The relation above combined with (2.2) yields

$$\int_0^T \left|\frac{\partial u}{\partial t}(\xi, s)\right|^2 ds \geq CE(u(0)) \qquad \forall\, (u^0, u^1) \in V_1 \times L^2(0,\pi),$$

which, by Lemma 5.1, implies that the solution ϕ of (3.8)–(3.10) satisfies

$$\int_0^T \left|\frac{\partial \phi}{\partial t}(\xi, s)\right|^2 ds \geq \frac{C}{4}E(u(0)) \qquad \forall\, (u^0, u^1) \in V_1 \times L^2(0,\pi).$$

The inequality above clearly contradicts assertion 3 in Proposition 4.1. So assumption (5.20) is false. We end in this way the proof of the first assertion of Theorem 2.2.

We pass now to the proof of the second assertion of this theorem. Let $\xi \in \mathcal{S}$. By Proposition 4.1 and Lemma 5.1, the solution u of (1.1)–(1.3) satisfies the inequality

$$\int_0^T \left|\frac{\partial u}{\partial t}(\xi, t)\right|^2 dt \geq K_1 \left(\|u^0\|^2_{H^1(0,\pi)} + \|u^1\|^2_{H^{-1}(0,\pi)}\right) \quad \forall (u^0, u^1) \in V_1 \times L^2(0,\pi),$$

where $K_1 > 0$ is a constant. The relation above and (2.2) imply that

$$\|\{u(T), u'(T)\}\|^2_{V_1 \times L^2(0,\pi)} \leq \|\{u^0, u^1\}\|^2_{V_1 \times L^2(0,\pi)}$$

$$-K_1 \|\{u^0, u^1\}\|^2_{H^1(0,\pi) \times H^{-1}(0,\pi)} \qquad \forall\, (u^0, u^1) \in \mathcal{D}(A_1). \tag{5.21}$$

By using a simple interpolation inequality (cf. [19, p. 49]), the fact that the function $t \rightarrow \|\{u(t), u'(t)\}\|^2_{V_1 \times L^2(0,\pi)}$ is nonincreasing, and relation (5.21), we obtain the existence of a constant $K_2 > 0$ such that

$$\|\{u(T), u'(T)\}\|^2_{V_1 \times L^2(0,\pi)} \leq \|\{u^0, u^1\}\|^2_{V_1 \times L^2(0,\pi)}$$

$$-K_2 \frac{\|\{u(T), u'(T)\}\|^3_{V_1 \times L^2(0,\pi)}}{\|\{u^0, u^1\}\|_Y}. \tag{5.22}$$

We follow now the method used in [24]. Estimate (5.22) remains valid in successive intervals $[kT, (k+1)T]$. So, $\forall k \geq 0$, we have

$$\|\{u((k+1)T), u'((k+1)T)\}\|^2_{V_1 \times L^2(0,\pi)}$$

$$\leq \|\{u(kT), u'(kT)\}\|^2_{V_1 \times L^2(0,\pi)} - K_2 \frac{\|\{u((k+1)T), u'((k+1)T)\}\|^3_{V_1 \times L^2(0,\pi)}}{\|\{u(kT), u'(kT)\}\|_Y}.$$

Since A_1 generates a semigroup of contractions in $\mathcal{D}(A_1)$ and the graph norm on $\mathcal{D}(A_1)$ is equivalent to $\|\cdot\|_Y$, the relation above implies the existence of a constant $K_3 > 0$ such that

$$\|\{u((k+1)T), u'((k+1)T)\}\|^2_{V_1\times L^2(0,\pi)} \leq \|\{u(kT), u'(kT)\}\|^2_{V_1\times L^2(0,\pi)}$$

$$(5.23)\quad -K_3\frac{\|\{u((k+1)T), u'((k+1)T)\}\|^3_{V_1\times L^2(0,\pi)}}{\|\{u^0, u^1\}\|_Y} \qquad \forall\ (u^0, u^1) \in \mathcal{D}(A_1).$$

If we adopt now the notation

$$(5.24)\qquad \mathcal{E}_k = \frac{\|\{u(kT), u'(kT)\}\|^2_{V_1\times L^2(0,\pi)}}{\|\{u^0, u^1\}\|^2_Y},$$

relation (5.23) gives

$$(5.25)\qquad \mathcal{E}_{k+1} \leq \mathcal{E}_k - K_3\mathcal{E}_{k+1}^{\frac{3}{2}} \quad \forall k \geq 0.$$

By applying Lemma 5.2 for $\alpha = -\frac{1}{2}$ and using relation (5.25), we obtain the existence of a constant $M > 0$ such that

$$\|\{u(kT), u'(kT)\}\|^2_{V_1\times L^2(0,\pi)} \leq \frac{M\|\{u^0, u^1\}\|^2_Y}{(k+1)^2} \quad \forall k \geq 0.$$

The conclusion (2.9) follows now by simply using the fact that the function

$$t \to \|\{u(t), u'(t)\}\|^2_{V_1\times L^2(0,\pi)}$$

is nonincreasing.

Let us now suppose that $\epsilon > 0$ and that ξ belongs to the set B_ϵ, introduced in section 4. From (2.2), (4.2), and Lemma 5.1, it follows that

$$\|\{u(T), u'(T)\}\|^2_{V_1\times L^2(0,\pi)} \leq \|\{u^0, u^1\}\|^2_{V_1\times L^2(0,\pi)}$$

$$-C\|\{u^0, u^1\}\|^2_{H^{1-\epsilon}(0,\pi)\times H^{-1-\epsilon}(0,\pi)}.$$

Using now the same method as above and the interpolation theorem from [19, p. 81], we obtain that the sequence $\mathcal{E}_k$, defined by (5.24), satisfies

$$\mathcal{E}_{k+1} \leq \mathcal{E}_k - K\mathcal{E}_{k+1}^{\frac{3+\epsilon}{2}} \quad \forall k \geq 1.$$

The relation above and Lemma 5.2 (with $\alpha = \frac{\epsilon-1}{2}$) give

$$\mathcal{E}_k \leq \frac{M}{(k+1)^{\frac{2}{1+\epsilon}}} \quad \forall k \geq 1,$$

which obviously implies (2.10). □

Proof of Theorem 2.3. As above, we use the fact that all finite energy solutions of (1.4)–(1.6) are exponentially stable in $V_2 \times L^2(0,\pi)$ if and only if there exist the positive constants T and K_T such that

$$(5.26)\qquad E(u(0)) - E(u(T)) \geq K_T E(u(0)) \qquad \forall\ (u^0, u^1) \in V_2 \times L^2(0,\pi).$$

Using now (2.2), (5.26), and Lemma 5.1, we obtain the existence of a constant $C_\xi > 0$ such that all solutions ϕ of (3.8), (3.9), and (3.11) satisfy (4.8). By Proposition 4.2, inequality (4.8) holds true if and only if ξ satisfies (2.11). Consequently, we obtain that the finite energy solutions of (1.4)–(1.6) are exponentially stable in $V_2 \times L^2(0,\pi)$ if and only if ξ satisfies (2.11).

The proof of estimates (2.12), (2.13) can be done by using obvious adaptations of the proof of estimates (2.9), (2.10), so it is omitted. □

PONTRYAGIN'S PRINCIPLE FOR LOCAL SOLUTIONS OF CONTROL PROBLEMS WITH MIXED CONTROL-STATE CONSTRAINTS*

E. CASAS†, J.-P. RAYMOND‡, AND H. ZIDANI§

Abstract. This paper deals with optimal control problems of semilinear parabolic equations with pointwise state constraints and coupled integral state-control constraints. We obtain necessary optimality conditions in the form of a Pontryagin's minimum principle for local solutions in the sense of L^p, $p \leq +\infty$.

Key words. optimal control, nonlinear boundary controls, semilinear parabolic equations, state constraints, Pontryagin's minimum principle, unbounded controls

1. Introduction. Let T be a positive number, Ω be a bounded open subset in $\mathbb{R}^N$ $(N \geq 2)$ with a Lipschitz boundary Γ, and q, σ, and $\bar{\sigma}$ be numbers satisfying

$$q > N/2 + 1 \quad \text{and} \quad \sigma > \bar{\sigma} > N + 1.$$

Consider the parabolic system

$$\frac{\partial y}{\partial t} + Ay + f(x,t,y) = 0 \text{ in } Q,\ \frac{\partial y}{\partial n_A} + g(s,t,y,v) = 0 \text{ on } \Sigma,\ y(0) = y_0 \text{ in } \Omega \tag{1.1}$$

(where $Q := \Omega\times]0,T[$, $\Sigma := \Gamma\times]0,T[$, $T > 0$, v is a boundary control, $y_0 \in C(\overline{\Omega})$, A is a second order elliptic operator) and the following control and state constraints:

$$v \in \widetilde{V}_{ad} := \{v \in L^\sigma(\Sigma) \mid v(s,t) \in V(s,t) \quad \text{for almost every (a.e.) } (s,t) \in \Sigma\},$$

$$\Phi(y) \in \mathcal{C}, \tag{1.2}$$

$$\begin{aligned} &\int_\Sigma \Psi_i(s,t,y(s,t),v(s,t))\,dsdt = 0, \quad 1 \leq i \leq m_0,\\ &\int_\Sigma \Psi_i(s,t,y(s,t),v(s,t))\,dsdt \leq 0, \quad m_0 + 1 \leq i \leq m. \end{aligned} \tag{1.3}$$

(V is a measurable set-valued mapping from Σ with closed and nonempty values in $\mathcal{P}(\mathbb{R}^k)$, the set of all subsets of $\mathbb{R}^k$, $\Psi = (\Psi_1, \ldots, \Psi_m)$, is a function with values in

$\mathbb{R}^m$, Φ is a continuous mapping from $C(\overline{D})$ into $C(\overline{D})$, $\mathcal{C} \subset C(\overline{D})$, $\overline{D}$ is a nonempty compact subset of $\overline{Q}$.) Let us consider the following class of optimal control problems:

$$\text{(P)} \qquad \inf\{J(y,v) \mid y \in W(0,T) \cap C(\overline{Q}), v \in V_{ad}, (y,v) \text{ satisfies } (1.1), (1.2), (1.3)\},$$

where V_{ad} is a subset of $\widetilde{V}_{ad}$ (to be stated precisely later), and the cost functional is defined by

$$J(y,v) = \int_Q F(x,t,y(x,t))\,dx\,dt + \int_\Sigma G(s,t,y(s,t),v(s,t))\,ds\,dt + \int_\Omega L(x,y(x,T))dx.$$

We are mainly interested in optimality conditions for such problems, in the form of Pontryagin's principles. The existence of optimal solutions for (P) is a priori supposed.

In the case where $V_{ad} \equiv \widetilde{V}_{ad}$, and $\widetilde{V}_{ad}$ is a bounded subset in $L^\infty(\Sigma)$ (the case of bounded controls), Pontryagin's principles for (P) have been obtained in [3, 9, 16, 17, 11, 25, 26, 4]. In this case the Pontryagin's principle is of the form

$$H_\Sigma(\bar{y},\bar{v},\bar{p},\bar{\nu},\bar{\lambda}) = \min_{v \in \widetilde{V}_{ad}} H_\Sigma(\bar{y},v,\bar{p},\bar{\nu},\bar{\lambda}), \tag{1.4}$$

where

$$H_\Sigma(y,v,p,\nu,\lambda) = \int_\Sigma [\nu G(s,t,y,v) - pg(s,t,y,v) + \lambda \Psi(s,t,y,v)]\; dsdt,$$

$(\bar{y},\bar{v})$ is an optimal solution, $\bar{\lambda}$ is a multiplier associated with the mixed control-state constraints (1.3), $\bar{\nu}$ is a multiplier of the cost functional, $\bar{p}$ is the adjoint state (the multiplier associated with the state constraints (1.2) only intervenes in the adjoint equation satisfied by $\bar{p}$). Notice that (1.4) can also be replaced by a pointwise Pontryagin's principle.

Observe that in [9, 16, 17, 11, 4] there is no mixed control-state constraint. Results with mixed control-state constraint are obtained in [2].

As explained in [8, p. 595] and in [21], the case of unbounded controls, that is, when $V_{ad} \equiv \widetilde{V}_{ad}$ is not bounded in $L^\infty(\Sigma)$, leads to some difficulties. In this case Pontryagin's principles are more recent results [8, 10, 21].

Now consider a control set of the form

$$V_{ad} = \{v \in \widetilde{V}_{ad} \mid v \text{ satisfies } (1.6)\} \tag{1.5}$$

with

$$\begin{aligned} &\int_\Sigma h_i(s,t,v(s,t))\,dsdt = 0, \;\; 1 \le i \le \ell_0, \\ &\int_\Sigma h_i(s,t,v(s,t))\,dsdt \le 0, \;\; \ell_0 + 1 \le i \le \ell, \end{aligned} \tag{1.6}$$

where $h = (h_1, \ldots, h_\ell)$ is a function with values in $\mathbb{R}^\ell$. Obviously control constraints (1.6) can be considered as a particular case of mixed control-state constraints (1.3). The corresponding Pontryagin's principle for the problem (P), with the control set V_{ad} defined by (1.5), may be written in the form

$$H_\Sigma(\bar{y},\bar{v},\bar{p},\bar{\nu},\bar{\lambda},\hat{\lambda}) = \min_{v \in \widetilde{V}_{ad}} H_\Sigma(\bar{y},v,\bar{p},\bar{\nu},\bar{\lambda},\hat{\lambda}), \tag{1.7}$$

where $\hat{\lambda}$ is a multiplier for the control constraints (1.6).

The novelty of our paper is the following Pontryagin's principle for the problem (P) (Theorem 2.1):

$$H_\Sigma(\bar{y}, \bar{v}, \bar{p}, \bar{\nu}, \bar{\lambda}) = \min_{v \in V_{ad}} H_\Sigma(\bar{y}, v, \bar{p}, \bar{\nu}, \bar{\lambda}), \tag{1.8}$$

when the control set V_{ad} is defined by (1.5). Let us insist on the fact that the minimum in (1.7) is stated with controls in $\widetilde{V}_{ad}$, while in (1.8) it is stated with controls in V_{ad}. Since V_{ad} takes integral control constraints of isoperimetric type into account, the result is of a different nature. As an application, we are able to prove a Pontryagin's principle (Corollary 2.2) for local solutions of (P) (local in the $L^\sigma(\Sigma)$-sense). To our knowledge, this result is completely new. Control problems for semilinear elliptic equations, with integral control constraints, are considered in [5], but the Pontryagin's principle for local solutions was not obtained there. Also we can deduce from (1.8) the classical pointwise Pontryagin's principle for local solutions in $L^\sigma(\Sigma)$ of the previous control problems; see Corollaries 2.3 and 2.4.

Let us finally mention that we deal with parabolic equations of the form (1.1), where the coefficients of the operator A are not regular, and where the nonlinear terms $f(x,t,\cdot)$ and $g(s,t,\cdot)$ are neither Lipschitz nor monotone with respect to y. When $g(s,t,\cdot,v)$ is Lipschitz and monotone such an equation is studied in [4] for bounded controls. For unbounded controls, when $g(s,t,\cdot,v)$ is neither Lipschitz nor monotone, but when the coefficients of A are time independent and regular, (1.1) is studied in [20, 21] by means of estimates on analytic semigroups. Here we combine these different difficulties. Equation (1.1) and the adjoint state equation are studied in section 3.

Our main results are stated in section 2. Section 4 is devoted to the study of the metric space of the controls and to the existence of diffuse perturbations of controls. These perturbations are the key for the proof of Pontryagin's principle, which is done in section 5.

2. Main results.

We set $\overline{\Omega}_0 = \overline{\Omega} \times \{0\}$ and $\overline{\Omega}_T = \overline{\Omega} \times \{T\}$. For every $1 \le \tau \le \infty$, the usual norms of the spaces $L^\tau(\Omega)$, $L^\tau(\Gamma)$, $L^\tau(Q)$, $L^\tau(\Sigma)$ will be denoted by $\|\cdot\|_{\tau,\Omega}$, $\|\cdot\|_{\tau,\Gamma}$, $\|\cdot\|_{\tau,Q}$, $\|\cdot\|_{\tau,\Sigma}$. For every $t > 0$, we define the norm $\|.\|_{Q(t)}$ by $\|y\|^2_{Q(t)} := \|y\|^2_{L^2(0,t;H^1(\Omega))} + \|y\|^2_{L^\infty(0,t;L^2(\Omega))}$. The Hilbert space $W(0,T;H^1(\Omega),(H^1(\Omega))') = \{y \in L^2(0,T;H^1(\Omega)) \mid \frac{dy}{dt} \in L^2(0,T;(H^1(\Omega))')\}$, endowed with its usual norm, will be denoted by $W(0,T)$. We denote by V_{ad} the set of admissible controls

$$V_{ad} := \{v \in \widetilde{V}_{ad} \mid v \text{ satisfies } (1.6)\}.$$

2.1. Assumptions.

(A1) The operator A is defined by

$$Ay(x,t) = -\sum_{i=1}^N D_i\left(\sum_{j=1}^N (a_{ij}(x,t)D_j y(x,t)) + a_i(x,t)y(x,t)\right) + \sum_{i=1}^N (b_i(x,t)D_i y(x,t)),$$

the coefficients a_{ij} belong to $L^\infty(Q)$, a_i and b_i belong to $L^{2q}(Q)$, and

$$\Lambda|\xi|^2 \le \sum_{i,j=1}^N a_{ij}(x,t)\xi_j\xi_i \quad \text{for all } \xi \in \mathbb{R}^N \text{ and for a.e. } (x,t) \in Q \text{ with } \Lambda > 0. \tag{2.1}$$

We make the following assumptions on f, g, F, G, L, Φ, Ψ.

(A2) For every $y \in \mathbb{R}$, $f(\cdot, y)$ is measurable on Q. For almost every $(x,t) \in Q$, $f(x,t,\cdot)$ is of class C^1 on $\mathbb{R}$. The following estimates hold:

$$|f(x,t,0)| \leq M_1(x,t), \qquad C_0 \leq f'_y(x,t,y) \leq M_1(x,t)\eta(|y|),$$

where M_1 belongs to $L^q(Q)$, η is a nondecreasing function from $\mathbb{R}^+$ to $\mathbb{R}^+$ and $C_0 \in \mathbb{R}$. (We have denoted by f'_y the partial derivative of f with respect to y, throughout what follows we adopt the same kind of notation for other functions.)

(A3) For every $(y,v) \in \mathbb{R}^2$, $g(\cdot, y, v)$ is measurable on Σ. For almost every $(s,t) \in \Sigma$ and every $v \in \mathbb{R}$, $g(s,t,\cdot,v)$ is of class C^1 on $\mathbb{R}$. For almost every $(s,t) \in \Sigma$, $g(s,t,\cdot)$ and $g'_y(s,t,\cdot)$ are continuous on $\mathbb{R} \times \mathbb{R}$. The following estimates hold:

$$|g(s,t,0,v)| \leq M_2(s,t) + \Lambda_1|v|, \qquad C_0 \leq g'_y(s,t,y,v) \leq (M_2(s,t) + \Lambda_1|v|)\eta(|y|),$$

where M_2 belongs to $L^\sigma(\Sigma)$, $\Lambda_1 > 0$, C_0 and η are as in (A2).

(A4) For every $y \in \mathbb{R}$, $L(\cdot, y)$ is measurable on Ω. For almost every $x \in \Omega$, $L(x,\cdot)$ is of class C^1 on $\mathbb{R}$. The following estimate holds:

$$|L(x,y)| + |L'_y(x,y)| \leq M_3(x)\eta(|y|),$$

where $M_3 \in L^1(\Omega)$, η is as in (A2).

(A5) For every $y \in \mathbb{R}$, $F(\cdot, y)$ is measurable on Q. For almost every $(x,t) \in Q$, $F(x,t,\cdot)$ is of class C^1 on $\mathbb{R}$. The following estimate holds:

$$|F(x,t,y)| + |F'_y(x,t,y)| \leq M_4(x,t)\eta(|y|),$$

where $M_4 \in L^1(Q)$, η is as in (A2).

(A6) For every $(y,v) \in \mathbb{R}^2$, $G(\cdot, y, v)$ is measurable on Σ. For almost every $(s,t) \in \Sigma$ and every $v \in \mathbb{R}$, $G(s,t,\cdot,v)$ is of class C^1 on $\mathbb{R}$. For almost every $(s,t) \in \Sigma$, $G(s,t,\cdot)$ and $G'_y(s,t,\cdot)$ are continuous on $\mathbb{R} \times \mathbb{R}$. The following estimates hold:

$$-M_5(s,t) - \Lambda_1|v|^{\bar{\sigma}} \leq G(s,t,0,v) \leq M_5(s,t) + \Lambda_1|v|^\sigma,$$

$$|G'_y(s,t,y,v)| \leq (M_5(s,t) + \Lambda_1|v|^{\bar{\sigma}})\eta(|y|),$$

where $M_5 \in L^1(\Sigma)$, Λ_1 and η are as in (A3).

(A7) The function $h = (h_1, \ldots, h_\ell)$ is a Carathéodory function from $\Sigma \times \mathbb{R}$ into $\mathbb{R}^\ell$ satisfying

$$|h_i(s,t,v)| \leq M_5(s,t) + \Lambda_1|v|^{\bar{\sigma}} \quad \text{for } i = 1, \ldots, \ell_0,$$

$$-M_5(s,t) - \Lambda_1|v|^{\bar{\sigma}} \leq h_i(s,t,v) \leq M_5(s,t) + \Lambda_1|v|^\sigma \quad \text{for } i = \ell_0 + 1, \ldots, \ell;$$

Λ_1 and M_5 are the same as above.

(A8) The function $\Psi = (\Psi_1, \ldots, \Psi_m)$ is a Carathéodory function from $\Sigma \times \mathbb{R}^2$ into $\mathbb{R}^m$. For almost every $(s,t) \in \Sigma$ and every $v \in \mathbb{R}$, $\Psi(s,t,\cdot,v)$ is of class C^1 on $\mathbb{R}$.

For almost every $(s,t)\in\Sigma$, $\Psi'_y(s,t,\cdot)$ is continuous on $\mathbb{R}\times\mathbb{R}$. The following estimates hold:

$$|\Psi_i(s,t,0,v)|\le M_5(s,t)+\Lambda_1|v|^{\bar\sigma}\quad\text{for } i=1,\dots,m_0,$$

$$-M_5(s,t)-\Lambda_1|v|^{\bar\sigma}\le\Psi_i(s,t,0,v)\le M_5(s,t)+\Lambda_1|v|^{\sigma}\quad\text{for } i=m_0+1,\dots,m,$$

$$|\Psi'_{iy}(s,t,y,v)|\le(M_5(s,t)+\Lambda_1|v|^{\bar\sigma})\eta(|y|)\quad\text{for } i=1,\dots,m,$$

where Λ_1, M_5, η are as before. We also suppose that the function $\Phi : C(\overline{D})\to C(\overline{D})$ is of class C^1, and that $\mathcal{C}\subset C(\overline{D})$ is a closed convex subset of finite codimension in $C(\overline{D})$, where $\overline{D}$ is a compact subset of $\overline{Q}$.

2.2. Statement of the main result. We define the boundary Hamiltonian function by

$$H_\Sigma(y,v,p,\nu,\lambda)=\int_\Sigma[\nu G(s,t,y,v)-pg(s,t,y,v)+\lambda\Psi(s,t,y,v)]\,dsdt$$

for every $(y,v,p,\nu,\lambda)\in C(\overline{Q})\times L^\sigma(\Sigma)\times L^{\sigma'}(\Sigma)\times\mathbb{R}^{1+m}$. (Here $\lambda=(\lambda^1,\dots,\lambda^m)$, $\lambda\Psi(s,t,y,v)=\sum_{i=1}^m\lambda^i\Psi_i(s,t,y,v)$. Throughout the paper we adopt the same kind of notation for scalar products in $\mathbb{R}^m$.)

THEOREM 2.1. *If* (A1)–(A8) *are fulfilled and if* $(\bar y,\bar v)$ *is a solution of* (P), *then there exist* $\bar p\in L^1(0,T;W^{1,1}(\Omega))$, $\bar\nu\in\mathbb{R}$, $\bar\lambda\in\mathbb{R}^m$, $\bar\mu\in\mathcal{M}(\overline{D})$ (*the space of Radon measures on* $\overline{D}$) *such that*

$$(\bar\nu,\bar\lambda,\bar\mu)\ne0,\ \ \bar\nu\ge0,\ \textit{for } m_0+1\le i\le m,\ \bar\lambda_i\ge0,\ \bar\lambda_i\int_\Sigma\Psi_i(s,t,\bar y,\bar v)\,dsdt=0, \tag{2.2}$$

$$\langle\bar\mu,z-\Phi(\bar y)\rangle_{\overline{D}}\le0\qquad\textit{for all } z\in\mathcal{C}, \tag{2.3}$$

$$\begin{cases}-\dfrac{\partial\bar p}{\partial t}+A^*\bar p+f'_y(x,t,\bar y)\bar p=\bar\nu F'_y(x,t,\bar y)+[\Phi'(\bar y)^*\bar\mu]|_Q & \textit{in } Q,\\[2ex] \dfrac{\partial\bar p}{\partial n_{A^*}}+g'_y(s,t,\bar y,\bar v)\bar p=\bar\nu G'_y(s,t,\bar y,\bar v)+\bar\lambda\Psi'_y(s,t,\bar y,\bar v)+[\Phi'(\bar y)^*\bar\mu]|_\Sigma & \textit{on } \Sigma,\\[2ex] \bar p(T)=\bar\nu L'_y(x,\bar y(T))+[\Phi'(\bar y)^*\bar\mu]|_{\overline{\Omega}_T} & \textit{on } \overline{\Omega},\end{cases} \tag{2.4}$$

$$\bar p\in L^{\delta'}(0,T;W^{1,d'}(\Omega))\qquad\textit{for every } (\delta,d)\ \textit{satisfying}\ \frac{N}{2d}+\frac{1}{\delta}<\frac{1}{2}, \tag{2.5}$$

$$H_\Sigma(\bar y,\bar v,\bar p,\bar\nu,\bar\lambda)=\min_{v\in V_{ad}}H_\Sigma(\bar y,v,\bar p,\bar\nu,\bar\lambda), \tag{2.6}$$

where $[\Phi'(\bar y)^*\bar\mu]|_Q$ *is the restriction of* $[\Phi'(\bar y)^*\bar\mu]$ *to* Q, $[\Phi'(\bar y)^*\bar\mu]|_\Sigma$ *is the restriction of* $[\Phi'(\bar y)^*\bar\mu]$ *to* Σ, *and* $[\Phi'(\bar y)^*\bar\mu]|_{\overline{\Omega}_T}$ *is the restriction of* $[\Phi'(\bar y)^*\bar\mu]$ *to* $\overline{\Omega}_T$, $[\Phi'(\bar y)^*\bar\mu]$ *is the Radon measure on* $\overline{D}$ *defined by* $z\longmapsto\langle\bar\mu,\Phi'(\bar y)z\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})}$ *for* $z\in C(\overline{D})$, $\langle\cdot,\cdot\rangle_{\overline{D}}$

denotes the duality pairing between $\mathcal{M}(\overline{D})$ *and* $C(\overline{D})$*,* A^* *is the formal adjoint of* A*, that is,*

$$A^*y(x,t) = -\sum_{i=1}^{N} D_i\left(\sum_{i=1}^{N}(a_{ji}(x,t)D_jy(x,t)) + b_i(x,t)y(x,t)\right) + \sum_{i=1}^{N} a_i(x,t)D_iy(x,t).$$

2.3. Pontryagin's principles for local solutions. By definition, a local solution $(\bar{y}, \bar{v})$ of (P) in $L^\sigma(\Sigma)$ is a solution of the problem

$$(\mathrm{P}_{\bar{v},\epsilon})\quad \inf\{J(y,v) \mid y \in C(\overline{Q}),\ v \in \widetilde{V}_{ad},\quad (y,v) \text{ satisfies (1.1)–(1.3)},\ \|\bar{v} - v\|_{\sigma,\Sigma} \leq \epsilon\}$$

for some $\epsilon > 0$. The following Pontryagin's principle for local solutions of (P) is a direct consequence of Theorem 2.1.

Corollary 2.2. *If* (A1)–(A8) *are fulfilled and if* $(\bar{y}, \bar{v})$ *is a solution of* $(\mathrm{P}_{\bar{v},\epsilon})$*, there then exist* $\bar{p} \in L^1(0,T; W^{1,1}(\Omega))$*,* $\bar{\nu} \in \mathbb{R}$*,* $\bar{\lambda} \in \mathbb{R}^m$*,* $\bar{\mu} \in \mathcal{M}(\overline{D})$ *satisfying* (2.2)–(2.5) *along with*

$$H_\Sigma(\bar{y}, \bar{v}, \bar{p}, \bar{\nu}, \bar{\lambda}) = \min_{v \in V_{ad}, \|\bar{v}-v\|_{\sigma,\Sigma} \leq \epsilon} H_\Sigma(\bar{y}, v, \bar{p}, \bar{\nu}, \bar{\lambda}).$$

As a consequence of this corollary we can get the classical pointwise Pontryagin principle for a local solution in $L^\sigma(\Sigma)$ of the control problem

$$(\tilde{\mathrm{P}})\qquad \inf\{J(y,v) \mid y \in W(0,T) \cap C(\overline{Q}), v \in \widetilde{V}_{ad}, (y,v) \text{ satisfies } (1.1), (1.2), (1.3)\}.$$

Corollary 2.3. *If* (A1)–(A8) *are fulfilled and if* $(\bar{y}, \bar{v})$ *is a local solution of* $(\tilde{\mathrm{P}})$ *in* $L^\sigma(\Sigma)$*, there then exist* $\bar{p} \in L^1(0,T; W^{1,1}(\Omega))$*,* $\bar{\nu} \in \mathbb{R}$*,* $\bar{\lambda} \in \mathbb{R}^m$*,* $\bar{\mu} \in \mathcal{M}(\overline{D})$ *satisfying* (2.2)–(2.5) *along with*

$$\mathcal{H}_\Sigma(s,t,\bar{y}(s,t),\bar{v}(s,t),\bar{p}(s,t),\bar{\nu},\bar{\lambda}) = \min_{\xi \in V(s,t)} \mathcal{H}_\Sigma(s,t,\bar{y}(s,t),\xi,\bar{p}(s,t),\bar{\nu},\bar{\lambda})$$

for almost all $(s,t) \in \Sigma$*, where*

$$\mathcal{H}_\Sigma(s,t,y,\xi,p,\nu,\lambda) = \nu G(s,t,y,\xi) - pg(s,t,y,\xi) + \lambda\Psi(s,t,y,\xi).$$

Proof. The pointwise Pontryagin's principle stated in the corollary may be derived from the integral Pontryagin's principle of Corollary 2.2 by using the same construction as in [21, proof of Theorem 2.1]. The idea in the proof of [21] is to construct a pointwise perturbation v_n of $\bar{v}$ such that $\lim_{(s,t)\to(s_0,t_0)} v_n(s,t) = \xi$, $\lim_n \mathcal{L}^N(\{(s,t) \in \Sigma \mid v_n(s,t) \neq \bar{v}(s,t)\}) = 0$, where $\xi \in V(s_0,t_0)$, $(s_0,t_0) \in \Sigma$, $\mathcal{L}^N$ denotes the N-dimensional Lebesgue measure. We obtain the pointwise Pontryagin's principle by replacing v by v_n in the integral Pontryagin's principle of Corollary 2.2, by dividing by $\mathcal{L}^N(\{(s,t) \in \Sigma \mid v_n(s,t) \neq \bar{v}(s,t)\}) \neq 0$, and by passing to the limit when n tends to infinity. The only difference with [21] is that v_n must satisfy $\|\bar{v} - v_n\|_{\sigma,\Sigma} \leq \epsilon$. Due to the condition $\lim_n \mathcal{L}^N(\{(s,t) \in \Sigma \mid v_n(s,t) \neq \bar{v}(s,t)\}) = 0$, it is clear that this condition will be realized for n big enough. □

Let us observe that integral control constraints can be studied in the framework of the problem $(\tilde{\mathrm{P}})$. Indeed, the mixed constraints (1.3) can include the integral control constraints. Then Corollary 2.3 provides a Pontryagin's principle for problems with integral constraints on the control and the state, even with mixed integral constraints, as well as pointwise constraints on the control and state too. The corresponding result is stated in the following corollary.

Corollary 2.4. *If* (A1)–(A8) *are fulfilled and if* $(\bar{y}, \bar{v})$ *is a local solution of* $(\tilde{\mathrm{P}})$ *in* $L^\sigma(\Sigma)$*, there then exist* $\bar{p} \in L^1(0, T; W^{1,1}(\Omega))$*,* $\bar{\nu} \in \mathbb{R}$*,* $\bar{\lambda} \in \mathbb{R}^m$*,* $\hat{\lambda} \in \mathbb{R}^\ell$*, and* $\bar{\mu} \in \mathcal{M}(\overline{D})$ *such that*

$$(\bar{\nu}, \bar{\lambda}, \hat{\lambda}, \bar{\mu}) \neq 0, \quad \bar{\nu} \geq 0, \quad \langle \bar{\mu}, z - \Phi(\bar{y}) \rangle_{\overline{D}} \leq 0 \quad \textit{for all } z \in \mathcal{C},$$

$$\bar{\lambda}_i \int_\Sigma \Psi_i(s, t, \bar{y}, \bar{v})\, dsdt = 0 \;\; \textit{for} \;\; 1 \leq i \leq m, \;\; \bar{\lambda}_i \geq 0 \;\; \textit{for} \;\; m_0 + 1 \leq i \leq m,$$

$$\hat{\lambda}_i \int_\Sigma h_i(s, t, \bar{v})\, dsdt = 0 \;\; \textit{for} \;\; 1 \leq i \leq \ell, \;\; \hat{\lambda}_i \geq 0 \;\; \textit{for} \;\; \ell_0 + 1 \leq i \leq \ell,$$

$$\begin{cases} -\dfrac{\partial \bar{p}}{\partial t} + A^* \bar{p} + \bar{f}'_y\, \bar{p} = \bar{\nu} \bar{F}'_y + [\Phi'(\bar{y})^* \bar{\mu}]|_Q & \textit{in } Q, \\[2ex] \dfrac{\partial \bar{p}}{\partial n_{A^*}} + \bar{g}'_y\, \bar{p} = \bar{\nu} \bar{G}'_y + \bar{\lambda} \bar{\Psi}'_y + \hat{\lambda} \bar{h} + [\Phi'(\bar{y})^* \bar{\mu}]|_\Sigma & \textit{on } \Sigma, \\[2ex] \bar{p}(T) = \bar{\nu} L'_y(x, \bar{y}(T)) + [\Phi'(\bar{y})^* \bar{\mu}]|_{\overline{\Omega}_T} & \textit{on } \overline{\Omega}, \end{cases}$$

where $\bar{f}'_y$ *stands for* $\bar{f}'_y(x, t, \bar{y})$*,* $\bar{G}'_y$ *for* $\bar{G}'_y(s, t, \bar{y}, \bar{v})$*, and the same convention is used for other functions. Also, the following pointwise Pontryagin's principle holds:*

$$\mathcal{H}_\Sigma(s, t, \bar{y}(s, t), \bar{v}(s, t), \bar{p}(s, t), \bar{\nu}, \bar{\lambda}, \hat{\lambda}) = \min_{\xi \in V(s,t)} \mathcal{H}_\Sigma(s, t, \bar{y}(s, t), \xi, \bar{p}(s, t), \bar{\nu}, \bar{\lambda}, \hat{\lambda})$$

for almost all $(s, t) \in \Sigma$*, where*

$$\mathcal{H}_\Sigma(s, t, y, \xi, p, \nu, \bar{\lambda}, \hat{\lambda}) = \nu G(s, t, y, \xi) - p g(s, t, y, \xi) + \bar{\lambda} \Psi(s, t, y, \xi) + \hat{\lambda} h(s, t, \xi).$$

3. State and adjoint equations.

3.1. State equation. Existence and regularity results for (1.1) and (2.4) rely on estimates in $C(\overline{Q})$ for solutions of linear equations of the form

$$(3.1)\quad \frac{\partial y}{\partial t} + Ay + ay = \phi - \mathrm{div}\xi \quad \text{in } Q, \quad \frac{\partial y}{\partial n_A} + by = \psi \quad \text{on } \Sigma, \quad y(0) = y_0 \quad \text{in } \Omega.$$

If assumption (A1) is satisfied, if $(a, \phi) \in L^q(Q) \times L^q(Q)$, $(b, \psi) \in L^{\bar{\sigma}}(\Sigma) \times L^{\bar{\sigma}}(\Sigma)$, the existence of a unique solution in $C([0, T]; L^2(\Omega)) \cap L^2([0, T]; H^1(\Omega))$ for (3.1) is proved in [12, Chapter 3, Theorem 5.1] when $\xi \equiv 0$. The result can be extended to (3.1) by the same method if the support of ξ is compact in Q and if ξ belongs to $L^\delta(0, T, (L^d(\Omega))^N)$ with $d > 1, \delta > 1, N/2d + 1/\delta < 1/2$. Recall that a weak solution in $L^2(0, T; H^1(\Omega)) \cap C([0, T]; L^2(\Omega))$ of (3.1) is a function $y \in L^2(0, T; H^1(\Omega)) \cap C([0, T]; L^2(\Omega))$ satisfying

$$\int_Q \left(-y \frac{\partial z}{\partial t} + \sum_{i,j} a_{ij} D_j y D_i z + \sum_i (a_i y D_i z + b_i D_i y z) + ayz \right) dxdt + \int_\Sigma byz\, dsdt$$
$$= \int_Q \left[\phi z + \sum_i \xi_i D_i z \right] dxdt + \int_\Sigma \psi z\, dsdt + \int_\Omega y(0) z(0)\, dx$$

for every $z \in C^1(\overline{Q})$ such that $z(\cdot, T) = 0$ on $\overline{\Omega}$. For linear equations with Dirichlet boundary conditions

$$\frac{\partial y}{\partial t} + Ay + ay = \phi - \text{div}\xi \quad \text{in } Q, \qquad y = \psi \quad \text{on } \Sigma, \qquad y(0) = y_0 \quad \text{in } \Omega,$$

estimates of the form

$$\|y\|_{L^\infty(Q)} \leq C \left(\|\phi\|_{q,Q} + \|\psi\|_{\infty,\Sigma} + \sum_i \|\xi_i\|_{d,\delta,\Omega} + \|y_0\|_{C(\overline{\Omega})} \right) \tag{3.2}$$

are obtained in [12, Chapter 3, Theorem 7.1] for $d > 1, \delta > 1, N/2d + 1/\delta < 1/2$. In this estimate the constant C depends on $T, \Omega, N, \Lambda, q, \bar{\sigma}, \delta, d, \sum_i \|a_i^2\|_{q,Q}, \sum_i \|b_i^2\|_{q,Q}$, but also on $\|a\|_{q,Q}$. The case of Robin boundary conditions is considered in [4] to study nonlinear equations of the form (1.1) when the function $g(s, t, \cdot, v)$, in the boundary condition, is monotone and Lipschitz, and when the boundary control v is bounded [4, Theorem 5.1]. The case when the function $g(s, t, \cdot, v)$ in (1.1) is neither Lipschitz nor monotone (g satisfies (A3)), and when the control v belongs to $L^{\bar{\sigma}}(\Sigma)$, but when the coefficients of the operator A are regular and independent of the time variable, is studied in [19]. Estimates in $C(\overline{Q})$ are obtained by semigroup techniques and comparison principles [19, Proposition 3.3 and Theorem 3.1]. Here we emphasize the fact that assumptions on the operator A are minimal (bounded leading coefficients, unbounded coefficients of order zero), that we deal with nonhomogeneous boundary conditions, and that source terms in the domain and in the boundary conditions are unbounded.

THEOREM 3.1. *Under assumptions* (A1)–(A3), *if* $v \in L^{\bar{\sigma}}(\Sigma)$, *then* (1.1) *admits a unique weak solution* y_v *in* $W(0, T) \cap C(\overline{Q})$. *This solution obeys*

$$\|y_v\|_{C(\overline{Q})} \leq C_1(\|v\|_{\bar{\sigma},\Sigma} + 1),$$

where $C_1 = C_1(T, \Omega, N, C_0, q, \bar{\sigma})$. *Moreover, the mapping* $v \longmapsto y_v$ *is continuous from* $L^{\bar{\sigma}}(\Sigma)$ *into* $C(\overline{Q})$.

Proof. The proof relies on Theorem 3.2 (see [19]). □

THEOREM 3.2. *Suppose that* (A1) *is satisfied,* $(a, \phi) \in L^q(Q) \times L^q(Q)$, $(b, \psi) \in L^{\bar{\sigma}}(\Sigma) \times L^{\bar{\sigma}}(\Sigma)$, *and* ξ *belongs to* $(\mathcal{D}(Q))^N$. *If in addition* $a \geq C_0$ *a.e. in* Q *and* $b \geq C_0$ *a.e. in* Σ *(for some* $C_0 \in \mathbb{R}$*), then the unique weak solution* y *of* (3.1) *belongs to* $C(\overline{Q})$ *and satisfies the following estimate:*

$$\|y\|_{C(\overline{Q})} \leq C_2 \left(\|\phi\|_{q,Q} + \|\psi\|_{\bar{\sigma},\Sigma} + \sum_i \|\xi_i\|_{L^\delta(0,T;L^d(\Omega))} + \|y_0\|_{C(\overline{\Omega})} \right),$$

where $d > 1$, $\delta > 1$ *satisfy* $N/2d + 1/\delta < 1/2$ *and the constant* C_2 *only depends on* T, Ω, N, C_0, Λ, q, $\bar{\sigma}$, δ, d, $\sum_i \|a_i^2\|_{q,Q}$, $\sum_i \|b_i^2\|_{q,Q}$.

Remark 3.3. Notice that the constant C_2 does not depend on $\|a\|_{q,Q}$ and $\|b\|_{\bar{\sigma},\Sigma}$. As in [12] (see the above estimate (3.2)), the assumption $a \geq C_0$ may be dropped out, and in this case the constant C_2 must be replaced by a constant also depending on $\|a\|_{q,Q}$. But the corresponding estimate cannot be used to treat nonlinear equations of the form (1.1).

Proof. To prove this theorem, we need only to establish the L^∞-estimate; the rest is classical. We prove the L^∞-estimate by using the so-called truncation method as in [12, Chapter 3, proof of Theorem 7.1]. If y is a weak solution of (3.1), then we have

$$\int_\Omega [y(x,t)z(x,t) - y(x,0)z(x,0)]\,dx$$

$$+\int_0^t\int_\Omega \left[-y\frac{\partial z}{\partial t} + \sum_{i,j} a_{ij}D_jyD_iz + \sum_i (a_iyD_iz + b_iD_iyz) + ayz\right] dxd\tau$$

$$+\int_0^t\int_\Gamma byz\,dsd\tau = \int_0^t\int_\Omega \left[\phi z + \sum_i \xi_iD_iz\right] dxd\tau + \int_0^t\int_\Gamma \psi z\,dsd\tau$$

for every $t \in [0,T]$ and every $z \in W_2^{1,1}(Q)$. We establish only the upper bound for y. (The lower bound can be obtained in the same way.) For $k \geq 0$ we set $y^k(x,t) = \max(y(x,t) - k, 0)$. By using Steklov averagings, as in [12, p. 183], we prove that

$$\frac{1}{2}\int_\Omega [y^k(x,t)^2 - y^k(x,0)^2]\,dx \tag{3.3}$$

$$+\int_0^t\int_\Omega \left[\sum_{i,j} a_{ij}D_jy^kD_iy^k + \sum_i (a_iyD_iy^k + b_iD_iy^ky^k) + ayy^k\right] dxd\tau$$

$$+\int_0^t\int_\Gamma byy^k\,dsd\tau = \int_0^t\int_\Omega \left[\phi y^k + \sum_i \xi_iD_iy^k\right] dxd\tau + \int_0^t\int_\Gamma \psi y^k\,dsd\tau$$

for every $t \in]0,T]$. Thus, it follows that

$$\frac{1}{2}\int_\Omega y^k(x,t)^2\,dx + \int_0^t\!\!\int_\Omega \left[\sum_{i,j} a_{ij}D_jy^kD_iy^k + (a - C_0 + \Lambda)yy^k\right] dxd\tau \tag{3.4}$$

$$+\int_0^t\!\!\int_\Gamma (b - C_0)yy^k\,dsd\tau = -\int_0^t\!\!\int_\Omega \left[\sum_i (a_iyD_iy^k + b_iD_iy^ky^k) + (C_0 - \Lambda)yy^k\right] dxd\tau$$

$$-\int_0^t\!\!\int_\Gamma C_0yy^k\,dsd\tau + \int_0^t\!\!\int_\Omega \left[\phi y^k + \sum_i \xi_iD_iy^k\right] dxd\tau + \int_0^t\int_\Gamma \psi y^k\,dsd\tau$$

for every $k > \tilde{k} := \|y_0\|_{C(\overline{\Omega})}$. Since $a - C_0 \geq 0$ a.e. in Q, $b - C_0 \geq 0$ a.e. on Σ, and $yy^k \geq (y^k)^2$ a.e. in Q, with (2.1) we obtain

$$\|y^k(t)\|_{2,\Omega}^2 + 2\Lambda\|y^k\|_{L^2(0,t;H^1(\Omega))}^2 \tag{3.5}$$

$$\leq -2\int_0^t\!\!\int_\Omega \left[\sum_i (a_iyD_iy^k + b_iD_iy^ky^k) + (C_0 - \Lambda)yy^k\right] dxd\tau$$

$$-2\int_0^t\!\!\int_\Gamma C_0yy^k\,dsd\tau + 2\int_0^t\!\!\int_\Omega \left[\phi y^k + \sum_i \xi_iD_iy^k\right] dxd\tau + 2\int_0^t\!\!\int_\Gamma \psi y^k\,dsd\tau$$

for every $k > \tilde{k}$. Set $A_k(t) = \{x \in \Omega \mid y(x,t) > k\}$, $B_k(t) = \{s \in \Gamma \mid y(s,t) > k\}$, $Q_k(t) = \{(x,\tau) \in \Omega\times]0,t[| \ y(x,\tau) > k\}$, $\Sigma_k(t) = \{(s,\tau) \in \Gamma\times]0,t[| \ y(s,\tau) > k\}$. We estimate the terms in the right-hand side of (3.5) by means of Young's inequality and we obtain

$$\|y^k(t)\|_{2,\Omega}^2 + \Lambda\|y^k\|_{L^2(0,t;H^1(\Omega))}^2$$

$$\leq \frac{3}{\Lambda}\int_0^t\int_{A_k(\tau)}\left[\sum_i((a_iy)^2 + (b_iy^k)^2) + (C_0 - \Lambda)^2y^2\right] dxd\tau + \frac{3K^2}{\Lambda}\int_0^t\int_{B_k(\tau)} C_0^2y^2\, dsd\tau$$

$$+2\int_0^t\int_{A_k(\tau)}\left[|\phi||y^k| + \sum_i|\xi_i||D_iy^k|\right] dxd\tau + 2\int_0^t\int_{B_k(\tau)}|\psi||y^k|\, dsd\tau,$$

where $K > 0$ satisfies $\|\varphi\|_{2,\Gamma} \leq K\|\varphi\|_{H^1(\Omega)}$ for all $\varphi \in H^1(\Omega)$. Since $y = y^k + k$ in $A_k(\tau)$ and $B_k(\tau)$ for a.e. τ, it follows that

$$\|y^k(t)\|_{2,\Omega}^2 + \Lambda\|y^k\|_{L^2(0,t;H^1(\Omega))}^2$$

$$\leq \frac{6}{\Lambda}\int_0^t\int_{A_k(\tau)}\left[\sum_i(a_i^2 + b_i^2) + (C_0 - \Lambda)^2\right]((y^k)^2 + k^2)\, dxd\tau$$

$$+\frac{6K^2}{\Lambda}\int_0^t\int_{B_k(\tau)} C_0^2((y^k)^2 + k^2)\, dsd\tau + 2\int_0^t\int_{A_k(\tau)}\left[|\phi||y^k| + \sum_i|\xi_i||D_iy^k|\right] dxd\tau$$

$$+2\int_0^t\int_{B_k(\tau)}|\psi||y^k|\, dsd\tau$$

for every $t \in [0,T]$ and every $k > \tilde{k}$. With Hölder's inequality we have

$$\|y^k(t)\|_{2,\Omega}^2 + \Lambda\|y^k\|_{L^2(0,t;H^1(\Omega))}^2 \tag{3.6}$$

$$\leq \Big(K_1(|Q_k(t)|^{\frac{1}{q'}} + |Q_k(t)|) + K_2|\Sigma_k(t)|\Big)\, k^2$$

$$+K_1(|Q_k(t)|^{\frac{2}{N+2}} + |Q_k(t)|^{\frac{1}{q'}-\frac{N}{N+2}})\|y^k\|_{\frac{2(N+2)}{N},\Omega\times]0,t[}^2$$

$$+2\|\phi\|_{q,Q}|Q_k(t)|^{\frac{1}{q'}-\frac{N}{2(N+2)}}\|y^k\|_{\frac{2(N+2)}{N},\Omega\times]0,t[}$$

$$+K_2|\Sigma_k(t)|^{\frac{1}{N+1}}\|y^k\|_{\frac{2(N+1)}{N},\Gamma\times]0,t[}^2 + 2\|\psi\|_{\bar{\sigma},\Sigma}|\Sigma_k(t)|^{\frac{1}{\bar{\sigma}'}-\frac{N}{2(N+1)}}\|y^k\|_{\frac{2(N+1)}{N},\Gamma\times]0,t[}$$

$$+\frac{\Lambda}{2}\|y^k\|_{L^2(0,t;H^1(\Omega))}^2 + \frac{2K_3}{\Lambda}\left(\int_0^t |A_k(\tau)|^{\frac{\delta(d-2)}{d(\delta-2)}}\, d\tau\right)^{\frac{\delta-2}{\delta}},$$

where

$$K_1 = \frac{6}{\Lambda}\left[\sum_i(\|a_i^2\|_{q,Q} + \|b_i^2\|_{q,Q}) + (C_0 - \Lambda)^2\right],$$

$$K_2 = \frac{6K^2}{\Lambda} C_0^2 \quad \text{and} \quad K_3 = \sum_i \|\xi_i\|^2_{L^\delta(0,T;L^d(\Omega))},$$

$|Q_k(t)|$ denotes the $(N+1)$-dimensional Lebesgue measure of $Q_k(t)$, $|\Sigma_k(t)|$ denotes the N-dimensional Lebesgue measure of $\Sigma_k(t)$, and $|A_k(\tau)|$ denotes the N-dimensional Lebesgue measure of $A_k(\tau)$. Notice that $\frac{N(d-2)}{2d} + \frac{\delta-2}{\delta} > \frac{N}{2}$. Then there exists $\tilde{r} > \frac{2\delta}{\delta-2} > 2$ such that $\frac{N(d-2)}{2d} + \frac{\delta-2}{\delta} > \frac{N}{2}\frac{\tilde{r}(\delta-2)}{2\delta} > \frac{N}{2}$. For such an $\tilde{r}$ we have $\frac{1}{\tilde{r}}(\frac{N}{2}\frac{\delta}{\delta-2}\frac{d-2}{d} + 1) > \frac{N}{4}$. We define $r > 2$ by $\frac{1}{r} = \frac{1}{\tilde{r}}\frac{\delta}{\delta-2}\frac{d-2}{d} < \frac{d-2}{2d} < \frac{1}{2}$ and we obtain $\frac{N}{2r} + \frac{1}{\tilde{r}} > \frac{N}{4}$. Thus the imbedding from $L^2(0,t;H^1(\Omega)) \cap C([0,t];L^2(\Omega))$ into $L^{\tilde{r}}(0,t;L^r(\Omega))$ is continuous; see [12, p. 75]. Observe that

$$|Q_k(t)|^{\frac{2}{N+2}} + |Q_k(t)|^{\frac{1}{q'}-\frac{N}{N+2}} \le (t|\Omega|)^{\frac{2}{N+2}} + (t|\Omega|)^{\frac{1}{q'}-\frac{N}{N+2}}, \qquad |\Sigma_k(t)|^{\frac{1}{N+1}} \le (t|\Gamma|)^{\frac{1}{N+1}}.$$

Let us choose $\bar{t} > 0$ small enough to have

$$(3.7)\quad K_1((\bar{t}|\Omega|)^{\frac{2}{N+2}} + (\bar{t}|\Omega|)^{\frac{1}{q'}-\frac{N}{N+2}})\|y\|^2_{\frac{2(N+2)}{N},\Omega\times]0,\bar{t}[} + K_2(\bar{t}|\Gamma|)^{\frac{1}{N+1}}\|y\|^2_{\frac{2(N+1)}{N},\Gamma\times]0,\bar{t}[}$$
$$\le \frac{1}{2}\min\left(1, \frac{\Lambda}{2}\right)\|y\|^2_{Q(\bar{t})}$$

for every $y \in L^2(0,\bar{t};H^1(\Omega)) \cap C([0,\bar{t}];L^2(\Omega))$. Then from (3.6) and imbedding theorems, it follows that

$$(3.8)\qquad \nu(\|y^k\|_{\frac{2(N+2)}{N},\Omega\times]0,\bar{t}[} + \|y^k\|_{\frac{2(N+1)}{N},\Gamma\times]0,\bar{t}[} + \|y^k\|_{L^{\tilde{r}}(0,\bar{t};L^r(\Omega))}) \le$$
$$\le \|y\|_{Q(\bar{t})} \le K_4\left(|Q_k(\bar{t})|^{\frac{1}{2q'}} + |Q_k(\bar{t})|^{\frac{1}{2}} + |\Sigma_k(\bar{t})|^{\frac{1}{2}}\right)k$$
$$+K_4\left(|Q_k(\bar{t})|^{\frac{1}{q'}-\frac{N}{2(N+2)}} + |\Sigma_k(\bar{t})|^{\frac{1}{\bar{\sigma}'}-\frac{N}{2(N+1)}}\right) + K_4\left(\int_0^{\bar{t}} |A_k(\tau)|^{\frac{\delta(d-2)}{d(\delta-2)}}\,d\tau\right)^{\frac{\delta-2}{2\delta}},$$

for $k > \tilde{k}$, where $\nu > 0$ depends on Λ, and where K_4 depends on K_1, K_2, K_3, $\|\phi\|_{q,Q}$, $\|\psi\|_{\bar{\sigma},\Sigma}$, and Λ. Now, we set $\theta(k) = |Q_k(\bar{t})|^{\frac{N}{2(N+2)}} + |\Sigma_k(\bar{t})|^{\frac{N}{2(N+1)}} + (\int_0^{\bar{t}} |A_k(\tau)|^{\frac{\tilde{r}}{r}}d\tau)^{\frac{1}{\tilde{r}}}$. Observe that, for every $\ell \ge k \ge 0$, we have $y^k \ge \ell - k$ a.e. in $Q_\ell(\bar{t})$, a.e. on $\Sigma_\ell(\bar{t})$, and a.e. in $A_\ell(\tau)$ for a.e. $\tau \in]0,\bar{t}[$; therefore

$$(3.9)\quad (\ell - k)\theta(\ell) \le \|y^k\|_{\frac{2(N+2)}{N},\Omega\times]0,\bar{t}[} + \|y^k\|_{\frac{2(N+1)}{N},\Gamma\times]0,\bar{t}[} + \|y^k\|_{L^{\tilde{r}}(0,\bar{t};L^r(\Omega))}.$$

Taking $k = 0$ in the above inequality, with the definition of the function θ we first obtain $\ell\theta(\ell) \le K_0$ for all $\ell \ge 0$, where $K_0 = \|y\|_{\frac{2(N+2)}{N},\Omega\times]0,\bar{t}[} + \|y\|_{\frac{2(N+1)}{N},\Gamma\times]0,\bar{t}[} + \|y\|_{L^{\tilde{r}}(0,\bar{t};L^r(\Omega))}$. In particular, for $\ell = K_0$, this implies $\theta(K_0) \le 1$. On the other hand, (3.8) and (3.9) give

$$(3.10)\qquad (\ell - k)\theta(\ell) \le \frac{K_4}{\nu}\left(|Q_k(\bar{t})|^{\frac{1}{2q'}} + |Q_k(\bar{t})|^{\frac{1}{2}} + |\Sigma_k(\bar{t})|^{\frac{1}{2}}\right.$$
$$\left.+|Q_k(\bar{t})|^{\frac{1}{q'}-\frac{N}{2(N+2)}} + |\Sigma_k(\bar{t})|^{\frac{1}{\bar{\sigma}'}-\frac{N}{2(N+1)}}\right)k + \frac{K_4}{\nu}\left(\int_0^{\bar{t}} |A_k(\tau)|^{\frac{\delta(d-2)}{d(\delta-2)}}d\tau\right)^{\frac{\delta-2}{2\delta}}$$

for all $\ell \geq k > \max(K_0, 1, \tilde{k})$. Set

$$\alpha_1 = \frac{N+2}{Nq'}, \quad \alpha_2 = \frac{N+1}{N\bar{\sigma}'}, \quad \alpha_3 = \tilde{r}\frac{\delta-2}{2\delta}, \quad \alpha = \min(\alpha_1, \alpha_2, \alpha_3),$$

and observe that $\alpha > 1$. Since $\theta(K_0) \leq 1$, and since θ is a nonincreasing function, we also have $|Q_k(\bar{t})| \leq 1$, $|\Sigma_k(\bar{t})| \leq 1$, and $\int_0^{\bar{t}} |A_k(\tau)|^{\frac{\tilde{r}}{r}} d\tau \leq 1$ for all $k \geq K_0$. Thus it follows that

$$|Q_k(\bar{t})|^{\frac{1}{2q'}} + |\Sigma_k(\bar{t})|^{\frac{1}{2}} + |Q_k(\bar{t})|^{\frac{1}{2}}$$

$$+|Q_k(\bar{t})|^{\frac{1}{q'} - \frac{N}{2(N+2)}} + |\Sigma_k(\bar{t})|^{\frac{1}{\bar{\sigma}'} - \frac{N}{2(N+1)}} + \left(\int_0^{\bar{t}} |A_k(\tau)|^{\frac{\tilde{r}}{r}} \, d\tau \right)^{\frac{\delta-2}{2\delta}} \leq 3\theta(k)^{\alpha}.$$

From (3.10), we deduce

$$(\ell - k)\theta(\ell) \leq K_5 \theta(k)^{\alpha} k \tag{3.11}$$

for every $\ell \geq k > \max(K_0, 1, \tilde{k})$. With the same arguments as in [12, Chapter 3, p. 186], still using (3.8), we finally obtain

$$\|y\|_{\infty,Q} \leq K_6, \tag{3.12}$$

where K_6 depends not only on $T, \Omega, N, C_0, \Lambda, q, \bar{\sigma}, \delta, d, \sum_i \|a_i^2\|_{q,Q}, \sum_i \|b_i^2\|_{q,Q}$, but also on K_0, $\|y_0\|_{C(\overline{\Omega})}$, $\|\phi\|_{q,Q}$, $\|\psi\|_{\bar{\sigma},\Sigma}$, and $\sum_i \|\xi_i\|^2_{L^{\delta}(0,T;L^d(\Omega))}$. The constant K_6 depends on $K_0 = \|y\|_{\frac{2(N+2)}{N},\Omega\times]0,\bar{t}[} + \|y\|_{\frac{2(N+1)}{N},\Gamma\times]0,\bar{t}[} + \|y\|_{L^{\tilde{r}}(0,\bar{t};L^r(\Omega))} \leq C\|y\|_{Q(\bar{t})}$. By using the same trick as in (3.4), we can obtain an estimate of $\|y\|_{Q(\bar{t})}$ depending on T, Ω, N, C_0, Λ, q, $\bar{\sigma}$, δ, d, $\sum_i \|a_i^2\|_{q,Q}$, $\sum_i \|b_i^2\|_{q,Q}$, $\|y_0\|_{C(\overline{\Omega})}$, $\sum_i \|\xi_i\|^2_{L^{\delta}(0,T;L^d(\Omega))}$, $\|\phi\|_{q,Q}$, and $\|\psi\|_{\bar{\sigma},\Sigma}$, but independent of $\|a\|_{q,Q}$ and $\|b\|_{\bar{\sigma},\Sigma}$. Since (3.1) is linear, the estimate given in Theorem 3.2 can be easily deduced from (3.12). □

3.2. Adjoint equation. Let (a, b) be in $L^q(Q) \times L^{\bar{\sigma}}(\Sigma)$ with $a \geq C_0$ and $b \geq C_0$. We consider the terminal boundary value problem

$$-\frac{\partial p}{\partial t} + A^* p + ap = \mu_Q \text{ in } Q, \quad \frac{\partial p}{\partial n_{A^*}} + bp = \mu_\Sigma \text{ on } \Sigma, \quad p(T) = \mu_{\overline{\Omega}_T} \text{ on } \overline{\Omega}, \tag{3.13}$$

where $\mu = \mu_Q + \mu_\Sigma + \mu_{\overline{\Omega}_T}$ is a bounded Radon measure on $\overline{Q} \backslash \overline{\Omega}_0$, μ_Q is the restriction of μ to Q, μ_Σ is the restriction of μ to Σ, and $\mu_{\overline{\Omega}_T}$ is the restriction of μ to $\overline{\Omega}_T$. A function $p \in L^1(0, T; W^{1,1}(\Omega))$ is a weak solution of (3.13) if

$$ap \in L^1(Q), \quad bp \in L^1(\Sigma), \quad a_i D_i p \in L^1(Q), \quad \text{and} \quad b_i p \in L^1(Q) \quad \text{for } i = 1, \ldots, N,$$

$$\int_Q \left(p\frac{\partial y}{\partial t} + \sum_{i,j} a_{ji} D_j p D_i y + \sum_i (a_i D_i p y + b_i p D_i y) + apy \right) dxdt + \int_\Sigma bpy \, dsdt$$

$$= \int_{\overline{Q} \backslash \overline{\Omega}_0} y d\mu(x,t) \quad \text{for every } y \in C^1(\overline{Q}) \text{ satisfying } y(x, 0) = 0 \text{ on } \overline{\Omega}.$$

As for elliptic equations [23], it is well known that (3.13) may admit more than one solution. However, uniqueness is guaranteed if we look for solutions of (3.13) satisfying some Green formula. (Such uniqueness results are proved in [1] for elliptic equations and in [4] for parabolic equations.)

THEOREM 3.4. *Let μ be in $\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)$ and let (a,b) be in $L^q(Q)\times L^{\bar\sigma}(\Sigma)$ satisfying $a\ge C_0$ a.e. in Q, $b\ge C_0$ a.e. Σ, for some $C_0\in\mathbb{R}$. Equation* (3.13) *admits a unique solution p in $L^1(0,T;W^{1,1}(\Omega))$ satisfying*

$$\int_Q p\left\{\frac{\partial y}{\partial t}+Ay+ay\right\}dxdt+\int_\Sigma p\left\{\frac{\partial y}{\partial n_A}+by\right\}dsdt=\langle y,\mu\rangle_{C_b(\overline{Q}\setminus\overline{\Omega}_0)\times\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)}$$

for every $y\in\{y\in W(0,T)\cap C(\overline{Q})\mid \frac{\partial y}{\partial t}+Ay\in L^q(Q),\ \frac{\partial y}{\partial n_A}\in L^{\bar\sigma}(\Sigma),\ y(x,0)=0$ on $\overline{\Omega}\}$. Moreover p belongs to $L^{\delta'}(0,T;W^{1,d'}(\Omega))$ for every $\delta>2$, $d>2$ satisfying $\frac{N}{2d}+\frac{1}{\delta}<\frac{1}{2}$ and we have

$$\|p\|_{L^{\delta'}(0,T;W^{1,d'}(\Omega))}\le C_4(\delta,d)\|\mu\|_{\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)},$$

where $C_4(\delta,d)=C_4(T,\Omega,N,C_0,q,\bar\sigma,\delta,d,\|a_i\|_{L^{2q}(Q)},\|b_i\|_{L^{2q}(Q)})$, but C_4 is independent of a and b.

Proof. Due to Theorem 3.2, the proof of Theorem 3.3 follows the lines of the proofs of Theorem 6.3 in [4] and of Theorem 4.2 in [18]. Since we improve the results given in [4, 18], we sketch the main points of the proof. Let $(h_n)_n$ be a sequence in $C_c(Q)$ (the space of continuous functions with compact support in Q), $(k_n)_n$ be a sequence in $C_c(\Sigma)$, and $(\ell_n)_n$ be a sequence in $C(\overline{\Omega})$ such that

$$\|h_n\|_{L^1(Q)}=\|\mu_Q\|_{\mathcal{M}_b(Q)},\quad \|k_n\|_{L^1(\Sigma)}=\|\mu_\Sigma\|_{\mathcal{M}_b(\Sigma)},\ \|\ell_n\|_{L^1(\Omega)}=\|\mu_{\overline{\Omega}_T}\|_{\mathcal{M}(\overline{\Omega}_T)},$$

$$\lim{}_n\int_Q h_n\phi dxdt=\langle\phi,\mu_Q\rangle_{C_b(Q)\times\mathcal{M}_b(Q)},$$

$$\lim{}_n\int_\Sigma k_n\phi dsdt=\langle\phi,\mu_\Sigma\rangle_{C_b(\Sigma)\times\mathcal{M}_b(\Sigma)},$$

$$\lim{}_n\int_\Omega \ell_n\phi dx=\langle\phi,\mu_{\bar\Omega_T}\rangle_{C(\overline{\Omega}_T)\times\mathcal{M}(\overline{\Omega}_T)}$$

for every $\phi\in C(\overline{Q})$. Let $(p_n)_n$ be the sequence in $W(0,T)$ defined by

$$-\frac{\partial p_n}{\partial t}+Ap_n+ap_n=h_n\quad\text{in } Q,\quad \frac{\partial p_n}{\partial n_A}+bp_n=k_n\quad\text{on }\Sigma,\quad p_n(T)=\ell_n\quad\text{in }\Omega.$$

Due to Theorem 3.2, and by using the same arguments as in [4, 18], we can prove that there exists a constant $C_5(\delta,d)=C_5(T,\Omega,N,C_0,q,\bar\sigma,\delta,d,\|a_i\|_{L^{2q}(Q)},\|b_i\|_{L^{2q}(Q)})$ such that

$$\|p_n\|_{L^{\delta'}(0,T;W^{1,d'}(\Omega))}\le C_5(\delta,d)\|\mu\|_{\mathcal{M}_b(\bar Q\setminus\bar\Omega_0)}$$

for every (δ,d) satisfying $\frac{N}{2d}+\frac{1}{\delta}<\frac{1}{2}$. Since $q>\frac{N}{2}+1$ and $\bar\sigma>N+1$, there exist (δ_1,d_1), (δ_2,d_2), (δ_3,d_3) satisfying $\frac{N}{2d_i}+\frac{1}{\delta_i}<\frac{1}{2}$ for $i=1,2,3$, such that $\delta_1'\ge q'$, $d_1'^{*}=\frac{Nd_1'}{N-d_1'}\ge q'$, $\delta_2'\ge\bar\sigma'$, $\frac{(N-1)d_2d_2'}{(N-1)d_2-d_2'}\ge\bar\sigma'$, $\delta_3'\ge(2q)'$, and $d_3'\ge(2q)'$. Therefore

$$\|p_n\|_{L^{q'}(Q)}\le C\|p_n\|_{L^{\delta'_1}(0,T;W^{1,d'_1}(\Omega))}\le CC_5(\delta_1,d_1)\|\mu\|_{\mathcal{M}_b(\bar Q\setminus\bar\Omega_0)},$$

$$\|p_n\|_{L^{\bar\sigma'}(\Sigma)} \le C\|p_n\|_{L^{\delta_2'}(0,T;W^{1,d_2'}(\Omega))} \le CC_5(\delta_2,d_2)\|\mu\|_{\mathcal{M}_b(\bar Q\setminus\bar\Omega_0)},$$

$$\|p_n\|_{L^{(2q)'}(0,T;W^{1,(2q)'}(\Omega))} \le C\|p_n\|_{L^{\delta_3'}(0,T;W^{1,d_3'}(\Omega))} \le CC_5(\delta_3,d_3)\|\mu\|_{\mathcal{M}_b(\bar Q\setminus\bar\Omega_0)}.$$

Then, there exist a subsequence, still indexed by n, and p such that $(p_n)_n$ converges to p for the weak-star topology of $L^{\delta'}(0,T;W^{1,d'}(\Omega))$ for every (δ,d) satisfying $\frac{N}{2d}+\frac{1}{\delta}<\frac{1}{2}$. By passing to the limit in the variational formulation satisfied by $(p_n)_n$, we prove that p is a solution of (3.13). The uniqueness can be proved as in [1, 4]. □

4. Technical results.

4.1. Metric space of controls. To apply the Ekeland variational principle, we have to define a metric space of controls in such a way that the mapping $v \longmapsto y_v$ be continuous from this metric space to $C(\overline{Q})$. Due to Theorem 3.1, this continuity condition will be realized if convergence in the metric space of controls implies convergence in $L^{\bar\sigma}(\Sigma)$. In the case where boundary controls are bounded, convergence in (V_{ad},d) (where d is the so-called Ekeland's distance) implies convergence in $L^{\bar\sigma}(\Sigma)$. This condition is no longer true for unbounded controls; see [10, p. 227]. To overcome this difficulty, we proceed as in [5] and we define a new metric space in the following way. Let $\tilde v$ be in V_{ad}. (In section 5, $\tilde v$ will be an optimal boundary control that we want to characterize.) For $0<M<\infty$, we define the set

$$V_{ad}(\tilde v,M)=\{v\in V_{ad}\mid \|v-\tilde v\|_{\sigma,\Sigma}\le M\}.$$

We endow the set $V_{ad}(\tilde v,M)$ with the Ekeland metric

$$d(v_1,v_2)=\mathcal{L}^N(\{(s,t)\in\Sigma\mid v_1(s,t)\ne v_2(s,t)\}).$$

PROPOSITION 4.1. *Let $\tilde v$ be in V_{ad}. Let $M>0$ and $\{(v_n)_n,v\}\subset V(\tilde v,M)$. If $(v_n)_n$ tends to v in $(V(\tilde v,M),d)$, then $(v_n)_n$ tends to v in $L^{\bar\sigma}(\Sigma)$.*

Proof. Since $1\le\bar\sigma<\sigma$, the proof is immediate if we notice that we have

$$\int_\Sigma |v-v_n|^{\bar\sigma}\,ds \le \|v-v_n\|^{\bar\sigma}_{\sigma,\Sigma}(d(v_n,v))^{\frac{\sigma-\bar\sigma}{\sigma}} \le (2M)^{\bar\sigma}(d(v_n,v))^{\frac{\sigma-\bar\sigma}{\sigma}}. \qquad \square$$

PROPOSITION 4.2. *For every $M>0$, we have that*

(i) *$(V_{ad}(\tilde v,M),d)$ is a complete metric space;*

(ii) *the mapping which associates y_v with v is continuous from $(V_{ad}(\tilde v,M),d)$ into $C(\overline{Q})$;*

(iii) *the mappings $v\to J(y_v,v)$ and $v\to\int_\Sigma \Psi_i(s,t,y_v,v)\,dsdt$ are continuous (respectively, lower semicontinuous) on $(V_{ad}(\tilde v,M),d)$ for $1\le i\le m_0$ (respectively, $m_0+1\le i\le m$).*

Proof. Claims (i) and (ii) are proved in [5], for control problems of elliptic equations; this proof can be repeated here with the obvious modifications. Contrary to [4], [21], the mapping $v\to J(y_v,v)$ is not necessarily continuous on the space of "truncated controls" endowed with the Ekeland metric. We can prove only a lower semicontinuity result. This result is stated in [5, Proposition 3.1] under the additional assumption that $G(s,t,y,\cdot)$ is convex. In fact we can prove the same result without this convexity assumption. Let $(v_n)_n$ be a sequence converging to v in $(V_{ad}(\tilde v,M),d)$. From Proposition 4.1 and Theorem 3.1 we know that $(v_n)_n$ converges to v in $L^{\bar\sigma}(\Sigma)$

and $(y_{v_n})_n$ converges to y_v uniformly on $\overline{Q}$. With assumption (A6), with Fatou's lemma, and with Lebesgue's dominated convergence theorem we have

$$\text{liminf}_n \int_\Sigma G(s,t,0,v_n)\,dsdt \geq \int_\Sigma G(s,t,0,v)\,dsdt,$$

$$\text{lim}_n \int_\Sigma \int_0^1 G'_y(s,t,\theta y_{v_n},v_n) y_{v_n} d\theta\,dsdt = \int_\Sigma \int_0^1 G'_y(s,t,\theta y_v,v) y_v d\theta\,dsdt.$$

Therefore we obtain

$$\text{liminf}_n \int_\Sigma G(s,t,y_{v_n},v_n)\,dsdt = \text{liminf}_n \int_\Sigma G(s,t,0,v_n)\,dsdt$$

$$+\text{lim}_n \int_\Sigma \int_0^1 G'_y(s,t,\theta y_{v_n},v_n) y_{v_n} d\theta\,dsdt$$

$$\geq \int_\Sigma G(s,t,0,v)\,dsdt + \int_\Sigma \int_0^1 G'_y(s,t,\theta y_v,v) y_v d\theta\,dsdt = \int_\Sigma G(s,t,y_v,v)\,dsdt.$$

Following the same ideas, we can prove the continuity (for $1 \leq i \leq m_0$) or the lower semicontinuity (for $m_0 + 1 \leq i \leq m$) of $v \to \int_\Sigma \Psi_i(s,t,y_v,v)\,dsdt$. □

4.2. Existence of diffuse perturbations. Let $\tilde{v}$ be an admissible control, and let v_1 and v_2 be in $V_{ad}(\tilde{v},M)$. A diffuse perturbation of v_1 by v_2 is a family of functions $(v_\rho)_{\rho>0}$ defined by

$$v_\rho(s,t) = \begin{cases} v_1(s,t) & \text{on } \Sigma \setminus E_\rho, \\ v_2(s,t) & \text{on } E_\rho, \end{cases}$$

where E_ρ is a measurable subset of Σ satisfying some conditions. Such perturbations are used to derive Pontryagin's principles from the Ekeland variational principle. In the case of bounded controls (when $V_{ad}(\tilde{v},M) \equiv V_{ad}$) the use of this kind of perturbations goes back to Yao [24, 25] and Li [13] (see also [17, 11, 26, 14]). Some variants have been developed in [4] for bounded controls, and in [21] for unbounded controls. In [5] we have investigated the case of unbounded controls with integral control constraints. Here we prove that the diffuse perturbations defined in [21] may be extended to derive a Pontryagin's principle for problems with integral coupled control-state constraints. Before proving the existence of such diffuse perturbations let us state an auxiliary lemma analogous to Lemma 3.2 of [5].

LEMMA 4.3. *Let ρ be such that $0 < \rho < 1$. For every $v_1, v_2, v_3 \in V_{ad}$, there exists a sequence of measurable sets $(E^n_\rho)_n$ in Σ such that*

$$\mathcal{L}^N(E^n_\rho) = \rho \mathcal{L}^N(\Sigma), \tag{4.1}$$

$$\int_{E^n_\rho} |v_i - v_3|^\sigma\,dsdt = \rho \int_\Sigma |v_i - v_3|^\sigma\,dsdt \quad \textit{for } i = 1,2, \tag{4.2}$$

$$\int_{E^n_\rho} h(s,t,v_i)\,dsdt = \rho \int_\Sigma h(s,t,v_i)\,dsdt \quad \textit{for } i = 1,2, \tag{4.3}$$

$$\frac{1}{\rho}\chi_{E^n_\rho} \rightharpoonup 1 \quad \textit{weakly-star in } L^\infty(\Sigma) \textit{ when } n \textit{ tends to infinity}, \tag{4.4}$$

where $\chi_{E^n_\rho}$ is the characteristic function of E^n_ρ.

Proof. We follow the ideas of [21, Lemma 4.1]. Let us take a sequence $(\varphi_n)_n$ dense in $L^1(\Sigma)$. For $n \geq 1$ we define $f^n \in (L^1(\Sigma))^{n+2\ell+3}$ by

$$f^n = (1, \varphi_1, \ldots, \varphi_n, |v_1 - v_3|^\sigma, |v_2 - v_3|^\sigma, h(\cdot, \cdot, v_1), h(\cdot, \cdot, v_2)).$$

Thanks to Lyapunov's convexity theorem, for every $n \geq 1$ and every $\rho \in (0, 1)$, there exists a measurable subset $E^n_\rho \subset \Sigma$ satisfying

$$\int_{E^n_\rho} f^n \, dsdt = \rho \int_\Sigma f^n \, dsdt.$$

As in [21], it is easy to prove that (4.1)–(4.4) hold for the sequence $(E^n_\rho)_n$. □

THEOREM 4.4. *Let ρ be such that $0 < \rho < 1$. For every $v_1, v_2, v_3 \in V_{ad}$, there exists a measurable subset $E_\rho \subset \Sigma$ such that*

$$\mathcal{L}^N(E_\rho) = \rho \mathcal{L}^N(\Sigma), \tag{4.5}$$

$$\begin{aligned}&\int_{\Sigma \setminus E_\rho} |v_1 - v_3|^\sigma \, dsdt + \int_{E_\rho} |v_2 - v_3|^\sigma \, dsdt \\ &= (1 - \rho) \int_\Sigma |v_1 - v_3|^\sigma \, dsdt + \rho \int_\Sigma |v_2 - v_3|^\sigma \, dsdt,\end{aligned} \tag{4.6}$$

$$\begin{aligned}&\int_{\Sigma \setminus E_\rho} h(s, t, v_1) \, dsdt + \int_{E_\rho} h(s, t, v_2) \, dsdt \\ &= (1 - \rho) \int_\Sigma h(s, t, v_1) \, dsdt + \rho \int_\Sigma h(s, t, v_2) \, dsdt,\end{aligned} \tag{4.7}$$

$$y_\rho = y_1 + \rho z + r_\rho \quad \textit{with} \quad \lim_{\rho \to 0} \frac{1}{\rho} ||r_\rho||_{C(\bar{Q})} = 0, \tag{4.8}$$

$$J(y_\rho, v_\rho) = J(y_1, v_1) + \rho[J'_y(y_1, v_1)z + J(y_1, v_2) - J(y_1, v_1)] + o(\rho), \tag{4.9}$$

$$\begin{aligned}&\int_\Sigma \Psi(s, t, y_\rho, v_\rho) \, dsdt \\ = &\int_\Sigma \Big(\Psi(s, t, y_1, v_1) + \rho[\Psi'_y(s, t, y_1, v_1)z + \Psi(s, t, y_1, v_2) - \Psi(s, t, y_1, v_1)] \Big) \, dsdt + o(\rho),\end{aligned} \tag{4.10}$$

where v_ρ is the control defined by

$$v_\rho(s, t) = \begin{cases} v_1(s, t) & \textit{on } \Sigma \setminus E_\rho, \\ v_2(s, t) & \textit{on } E_\rho, \end{cases} \tag{4.11}$$

y_ρ, y_1 are the solutions of (1.1) *corresponding, respectively, to v_ρ and to v_1, z is the weak solution of*

$$\begin{cases} \dfrac{\partial z}{\partial t} + Az + f'_y(x, t, y_1)z = 0 & \textit{in } Q, \\ \dfrac{\partial z}{\partial n_A} + g'_y(s, t, y_1, v_1)z = g(s, t, y_1, v_1) - g(s, t, y_1, v_2) & \textit{on } \Sigma, \\ z(0) = 0 & \textit{in } \Omega. \end{cases} \tag{4.12}$$

Proof. Using Lemma 4.3, the proof is similar to the one of Theorem 4.1 in [21] and the one of Theorem 3.4 in [4]. The relation (4.10), which does not appear in our previous papers, is deduced with the help of (4.4) and (4.8). □

5. Proof of Pontryagin's principle.

5.1. Penalized problem. Following [15, 16], since $C(\overline{D})$ is separable, there exists a norm $|\cdot|_{C(\overline{D})}$, which is equivalent to the usual norm $\|\cdot\|_{C(\overline{D})}$ such that $(C(\overline{D}), |\cdot|_{C(\overline{D})})$ is strictly convex, and $\mathcal{M}(\overline{D})$, endowed with the dual norm of $|\cdot|_{C(\overline{D})}$ (denoted by $|\cdot|_{\mathcal{M}(\overline{D})}$), is also strictly convex; see [7, Corollary 2, p. 148 or Corollary 2, p. 167]. We define the distance function to $\mathcal{C}$ (for the new norm $|\cdot|_{C(\overline{D})}$) by

$$d_{\mathcal{C}}(\varphi) = \inf_{z \in \mathcal{C}} |\varphi - z|_{C(\overline{D})}.$$

Since $\mathcal{C}$ is convex, then $d_{\mathcal{C}}$ is convex and Lipschitz of rank 1, and we have

$$\limsup_{\substack{\rho \searrow 0, \\ \varphi' \to \varphi}} \frac{d_{\mathcal{C}}(\varphi' + \rho z) - d_{\mathcal{C}}(\varphi')}{\rho} = \max\{\langle \xi, z \rangle_{\mathcal{M}(\overline{D}) \times C(\overline{D})} \mid \xi \in \partial d_{\mathcal{C}}(\varphi)\} \tag{5.1}$$

for every $\varphi, z \in C(\overline{D})$, where $\partial d_{\mathcal{C}}$ is the subdifferential in the sense of convex analysis (see [6]). Therefore, for a given $\varphi \in C(\overline{D})$ we have

(5.2)

$$\langle \xi, z - \varphi \rangle_{\mathcal{M}(\overline{D}) \times C(\overline{D})} + d_{\mathcal{C}}(\varphi) \le d_{\mathcal{C}}(z) \quad \text{for all } \xi \in \partial d_{\mathcal{C}}(\varphi) \text{ and for all } z \in C(\overline{D}),$$
$$|\xi|_{\mathcal{M}(\overline{D})} \le 1 \quad \text{for every } \xi \in \partial d_{\mathcal{C}}(\varphi).$$

Moreover it is proved in [16, Lemma 3.4] that, since $\mathcal{C}$ is a closed convex subset of $C(\overline{D})$, for every $\varphi \notin \mathcal{C}$, and every $\xi \in \partial d_{\mathcal{C}}(\varphi)$, then $|\xi|_{\mathcal{M}(\overline{D})} = 1$. Since $\partial d_{\mathcal{C}}(\varphi)$ is convex in $\mathcal{M}(\overline{D})$ and $(\mathcal{M}(\overline{D}), |\cdot|_{\mathcal{M}(\overline{D})})$ is strictly convex, if $\varphi \notin \mathcal{C}$, then $\partial d_{\mathcal{C}}(\varphi)$ is a singleton and $d_{\mathcal{C}}$ is Gâteaux-differentiable at φ.

Let $(\bar{y}, \bar{v})$ be an optimal solution of (P). Consider the penalized functional

$$J_k(y,v) = \left\{ \left[\left(J(y,v) - J(\bar{y},\bar{v}) + \frac{1}{k^2} \right)^+ \right]^2 + (d_{\mathcal{C}}(\Phi(y)))^2 \right.$$
$$\left. + \sum_{i=1}^{m_0} \left[\int_\Sigma \Psi_i(s,t,y,v)\, dsdt \right]^2 + \sum_{i=m_0+1}^{m} \left[\left(\int_\Sigma \Psi_i(s,t,y,v)\, dsdt \right)^+ \right]^2 \right\}^{\frac{1}{2}}.$$

We easily verify that $(\bar{y}, \bar{v})$ is a $\frac{1}{k^2}$-solution of the penalized problem

$$(\mathrm{P}_k^M) \qquad \inf\{J_k(y,v) \mid y \in W(0,T) \cap C(\overline{Q}), v \in V_{ad}(\bar{v}, M),\ (y,v) \text{ satisfies } (1.1)\}$$

for every $M > 0$ and every $k > 0$. For every $k > 0$, we set $M_k = k^{(\frac{1}{2\bar{\sigma}} - \frac{1}{2\sigma})}$ and we denote by (P^k) the penalized problem $(\mathrm{P}_k^{M_k})$.

5.2. Proof of Theorem 2.1. Step 1. For every $k \ge 1$, the metric space $(V_{ad}(\bar{v}, M_k), d)$ is complete; see Proposition 4.2. Let us prove that the functional $v \longmapsto J_k(y_v, v)$ is lower semicontinuous on this metric space. Since the mappings

$v \to J(y_v, v)$ and $v \to \int_\Sigma \Psi_i(s,t,y_v,v)\,dsdt$ ($m_0+1 \le i \le m$) are lower semicontinuous on $(V_{ad}(\tilde v, M_k), d)$, it is clear that $v \to \big(J(y_v,v) - J(\bar y, \bar v) + \frac{1}{k^2}\big)^+$ and $v \to \big(\int_\Sigma \Psi_i(s,t,y_v,v)\,dsdt\big)^+$ ($m_0+1 \le i \le m$) are also lower semicontinuous on $(V_{ad}(\tilde v, M_k), d)$ because $r \to r^+$ is a nondecreasing continuous mapping from $\mathbb{R}$ into $\mathbb{R}^+$. On the other hand, the mappings $v \to \int_\Sigma \Psi_i(s,t,y_v,v)\,dsdt$ ($1 \le i \le m_0$) are continuous on $(V_{ad}(\tilde v, M_k), d)$. Since the mappings $r \to r^2$ and $r \to r^{\frac12}$ are nondecreasing and continuous from $\mathbb{R}^+$ into $\mathbb{R}^+$, then $v \to J_k(y_v, v)$ is lower semicontinuous. Due to Ekeland's variational principle, for every $k \ge 1$, there exists $v_k \in V_{ad}(\bar v, M_k)$ such that

$$(5.3)\quad d(v_k, \bar v) \le \frac{1}{k} \text{ and } J_k(y_k, v_k) \le J_k(y_v, v) + \frac{1}{k} d(v_k, v) \text{ for every } v \in V_{ad}(\bar v, M_k).$$

(y_k and y_v are the solutions of (1.1) corresponding, respectively, to v_k and v.) Let v_0 be in V_{ad}. Let k_0 be large enough so that v_0 belong to $V_{ad}(\bar v, M_k)$ for every $k \ge k_0$. Observe that, for the above choice of M_k, $(v_k)_k$ tends to $\bar v$ in $L^{\bar\sigma}(\Sigma)$. Let us check this. Denote by Σ_k the set of points $(s,t) \in \Sigma$ where $v_k(s,t) \ne \bar v(s,t)$. From (5.3) we know that $\mathcal{L}^N(\Sigma_k) \le 1/k$. Then

$$(5.4)\qquad \begin{aligned} \int_\Sigma |\bar v - v_k|^{\bar\sigma} dsdt = \int_{\Sigma_k} |\bar v - v_k|^{\bar\sigma} dsdt &\le \|\bar v - v_k\|^{\bar\sigma}_{\sigma,\Sigma} \mathcal{L}^N(\Sigma_k)^{1-\frac{\bar\sigma}{\sigma}} \\ &\le M_k^{\bar\sigma} k^{\frac{\bar\sigma}{\sigma}-1} = k^{\frac12(\frac{\bar\sigma}{\sigma}-1)} \longrightarrow 0 \text{ when } k \to +\infty. \end{aligned}$$

Step 2. Theorem 3.1 gives the existence of measurable sets $E^k_\rho \subset \Sigma$, such that $\mathcal{L}^N(E^k_\rho) = \rho \mathcal{L}^N(\Sigma)$,

$$(5.5)\qquad \begin{aligned} &\int_{\Sigma \setminus E^k_\rho} |v_k - \bar v|^\sigma\, dsdt + \int_{E^k_\rho} |v_0 - \bar v|^\sigma\, dsdt \\ &\quad = (1-\rho)\int_\Sigma |v_k - \bar v|^\sigma\, dsdt + \rho \int_\Sigma |v_0 - \bar v|^\sigma\, dsdt, \end{aligned}$$

$$(5.6)\qquad \begin{aligned} &\int_{\Sigma \setminus E^k_\rho} h(s,t,v_k)\, dsdt + \int_{E^k_\rho} h(s,t,v_0)\, dsdt \\ &\quad = (1-\rho)\int_\Sigma h(s,t,v_k)\, dsdt + \rho \int_\Sigma h(s,t,v_0)\, dsdt, \end{aligned}$$

$$(5.7)\qquad \begin{aligned} &\int_\Sigma (\Psi(s,t,y^k_\rho, v^k_\rho) - \Psi(s,t,y_k,v_k))\, dsdt \\ &\quad = \rho \int_\Sigma (\Psi'_y(s,t,y_k,v_k) z_k + \Psi(s,t,y_k,v_0) - \Psi(s,t,y_k,v_k))\, dsdt + o(\rho), \end{aligned}$$

$$(5.8)\qquad y^k_\rho = y_k + \rho z_k + r^k_\rho, \quad \lim_{\rho \to 0} \frac{1}{\rho} \|r^k_\rho\|_{C(\overline{Q})} = 0,$$

$$(5.9)\qquad J(y^k_\rho, v^k_\rho) = J(y_k, v_k) + \rho \Delta J_k + o(\rho),$$

where v^k_ρ is defined by

$$(5.10)\qquad v^k_\rho(s,t) = \begin{cases} v_k(s,t) & \text{on } \Sigma \setminus E^k_\rho, \\ v_0(s,t) & \text{on } E^k_\rho, \end{cases}$$

y_ρ^k is the state corresponding to v_ρ^k, z_k is the weak solution of

$$\begin{cases} \dfrac{\partial z_k}{\partial t} + Az_k + f'_y(x,t,y_k)z_k = 0 & \text{in } Q, \\[2ex] \dfrac{\partial z_k}{\partial n_A} + g'_y(s,t,y_k,v_k)z_k = g(s,t,y_k,v_k) - g(s,t,y_k,v_0) & \text{on } \Sigma, \\[2ex] z_k(0) = 0 & \text{in } \Omega, \end{cases}$$

and

$$\Delta J_k = \int_Q F'_y(x,t,y_k(x,t))z_k(x,t)\,dxdt + \int_\Sigma G'_y(s,t,y_k(s,t),v_k(s,t))z_k(s,t)\,dsdt$$

$$+ \int_\Sigma [G(s,t,y_k(s,t),v_0(s,t)) - G(s,t,y_k(s,t),v_k(s,t))]\,dsdt + \int_\Omega L'_y(x,y_k(T))z_k(T)\,dx.$$

On the other hand, for every $k > k_0$ and every $0 < \rho < 1$, due to (5.5) and (5.6), v_ρ^k belongs to $V_{ad}(\bar{v}, M_k)$. If we set $v = v_\rho^k$ in (5.3), it follows that

$$\lim_{\rho\to 0} \frac{J_k(y_k,v_k) - J_k(y_\rho^k, v_\rho^k)}{\rho} \le \frac{1}{k}\mathcal{L}^N(\Sigma). \tag{5.11}$$

Taking (5.1), (5.7), (5.9), and the definition of J_k into account, we obtain

$$\begin{gathered} -\nu_k \Delta J_k \lambda_k \int_\Sigma \left[\Psi(\cdot,y_k,v_0) - \Psi(\cdot,y_k,v_k) + \Psi'_y(\cdot,y_k,v_k)z_k\right]\,dsdt \\ -\langle \mu_k, \Phi'(y_k)z_k\rangle_{\overline{D}} \le \frac{1}{k}\mathcal{L}^N(\Sigma), \end{gathered} \tag{5.12}$$

where

$$\lambda_k^i = \frac{\int_\Sigma \Psi_i(s,t,y_k,v_k)\,dsdt}{J_k(y_k,v_k)} \quad \text{for } 1 \le i \le m_0,$$

$$\lambda_k^i = \frac{\left(\int_\Sigma \Psi_i(s,t,y_k,v_k)\,dsdt\right)^+}{J_k(y_k,v_k)} \quad \text{for } m_0+1 \le i \le m,$$

$$\nu_k = \frac{(J(y_k,v_k) - J(\bar{y},\bar{v}) + \frac{1}{k^2})^+}{J_k(y_k,v_k)}, \quad \mu_k = \begin{cases} \dfrac{d_{\mathcal{C}}(\Phi(y_k))\nabla d_{\mathcal{C}}(\Phi(y_k))}{J_k(y_k,v_k)} & \text{if } \Phi(y_k) \notin \mathcal{C}, \\ 0 & \text{otherwise.} \end{cases}$$

For every $k > 0$, we consider the weak solution p_k of

$$\begin{cases} -\dfrac{\partial p_k}{\partial t} + A^* p_k + f'_y(x,t,y_k)p_k = \nu_k F'_y(x,t,y_k) + [\Phi'(y_k)^*\mu_k]|_Q, \\[2ex] \dfrac{\partial p_k}{\partial n_{A^*}} + g'_y(\cdot,y_k,v_k)p_k = \nu_k G'_y(\cdot,y_k,v_k) + \lambda_k \Psi'_y(\cdot,y_k,v_k) + [\Phi'(y_k)^*\mu_k]|_\Sigma, \\[2ex] p_k(T) = \nu_k L'_y(x,y_k(T)) + [\Phi'(y_k)^*\mu_k]|_{\overline{\Omega}_T}, \end{cases} \tag{5.13}$$

where $[\Phi'(y_k)^*\mu_k]|_Q$, $[\Phi'(y_k)^*\mu_k]|_\Sigma$, and $[\Phi'(y_k)^*\mu_k]|_{\bar\Omega_T}$ have the same meaning as in Theorem 2.1. By using the Green formula of Theorem 3.4, we obtain

$$\nu_k \int_Q F'_y(x,t,y_k)z_k\,dxdt + \nu_k \int_\Sigma G'_y(s,t,y_k,v_k)z_k\,dsdt + \nu_k \int_\Omega L'_y(x,y_k(T))z_k(T)\,dx$$

$$+\lambda_k \int_\Sigma \Psi'_y(s,t,y_k,v_k)z_k\,dsdt + \langle \mu_k, \Phi'(y_k)z_k\rangle_{\overline{D}}$$

$$= \int_Q p_k\left(\frac{\partial z_k}{\partial t} + Az_k + f'_y(x,t,y_k)z_k\right)dxdt + \int_\Sigma p_k\left(\frac{\partial z_k}{\partial n_A} + g'_y(s,t,y_k,v_k)z_k\right)dsdt$$

$$= \int_\Sigma p_k[g(s,t,y_k,v_k) - g(s,t,y_k,v_0)]\,dsdt.$$

With this equality, (5.12), and the definition of ΔJ_k, we have

$$(5.14)\qquad \int_\Sigma [\nu_k G(s,t,y_k,v_k) + \lambda_k\Psi(s,t,y_k,v_k) - p_k g(s,t,y_k,v_k)]\,dsdt$$

$$\leq \int_\Sigma [\nu_k G(s,t,y_k,v_0) + \lambda_k\Psi(s,t,y_k,v_0) - p_k g(s,t,y_k,v_0)]\,dsdt + \frac{1}{k}\mathcal{L}^N(\Sigma)$$

for every $k \geq k_0$.

Step 3. Notice that $\nu_k^2 + \sum_i(\lambda_k^i)^2 + |\mu_k|^2_{\mathcal{M}(\overline{D})} = 1$. Then there exist an element $(\bar\nu,\bar\lambda,\bar\mu)$ in $\mathbb{R}^{1+m}\times\mathcal{M}(\overline{D})$ with $\bar\nu \geq 0$ and $\bar\lambda_i \geq 0$ for $m_0+1 \leq i \leq m$, and a subsequence, still denoted by $(\nu_k,\lambda_k,\mu_k)_k$, such that

$$(\nu_k,\lambda_k) \longrightarrow (\bar\nu,\bar\lambda) \text{ in } \mathbb{R}^{1+m},\ \mu_k \rightharpoonup \bar\mu \text{ weak-star in } \mathcal{M}(\overline{D}).$$

From Theorem 3.4, we obtain the estimate

$$\|p_k\|_{L^{\delta'}(0,T;W^{1,d'}(\Omega))} \leq C_4(\delta,d)\Big\{\|F'_y(\cdot,y_k)\|_{1,Q} + \|G'_y(\cdot,y_k,v_k)\|_{1,\Sigma} +$$

$$\|L'_y(\cdot,y_k(T))\|_{1,\Omega} + |\lambda_k|\|\Psi'_y(.,y_k,v_k)\|_{1,\Sigma} + |\mu_k|_{\mathcal{M}(\overline{D})}\|\Phi'_y(y_k)\|_{\mathcal{L}(C(\overline{D});C(\overline{D}))}\Big\}$$

for every (δ,d) satisfying $\frac{N}{2d}+\frac{1}{\delta}<\frac{1}{2}$, where $\mathcal{L}(C(\overline{D});C(\overline{D}))$ denotes the space of linear continuous mappings from $C(\overline{D})$ to $C(\overline{D})$.

Since the sequences $(\nu_k)_k, (\lambda_k)_k, (\mu_k)_k, (y_k)_k$, and $(v_k)_k$ are bounded, respectively, in $\mathbb{R}$, $\mathbb{R}^m$, $\mathcal{M}(\overline{D})$, $C(\overline{Q})$, and in $L^{\bar\sigma}(\Sigma)$, the sequence $(p_k)_k$ is bounded in $L^{\delta'}(0,T;W^{1,d'}(\Omega))$. Then there exist $\bar p \in L^{\delta'}(0,T;W^{1,d'}(\Omega))$ and a subsequence, still denoted by $(p_k)_k$, such that $(p_k)_k$ weakly converges to $\bar p$ in $L^{\delta'}(0,T;W^{1,d'}(\Omega))$ for every (δ,d) satisfying $\frac{N}{2d}+\frac{1}{\delta}<\frac{1}{2}$. By using the same arguments as in [21], we can prove that $\bar p$ is the weak solution of (2.4).

Step 4. Recall that $(v_k)_k$ tends to $\bar v$ in $L^{\bar\sigma}(\Sigma)$ (see (5.4)).

By passing to the limit when k tends to infinity in (5.14), with Fatou's lemma (applied to the sequence of functions $(\nu_k G(\cdot,0,v_k(\cdot)), \lambda_k\Psi(\cdot,0,v_k(\cdot)))_k$ and the convergence results stated in Step 2, we obtain

$$(5.15)\qquad H_\Sigma(\bar y,\bar v,\bar p,\bar\nu,\bar\lambda) \leq H_\Sigma(\bar y,v_0,\bar p,\bar\nu,\bar\lambda),$$

for every $v_0 \in V_{ad}$. On the other hand, from definitions of μ_k and λ_k, and from (5.2), we deduce

$$\lambda_k^i \int_\Sigma \Psi_i(s,t,y_k,v_k)\,dsdt = 0,\ m_0+1 \le i \le m,$$

$$\langle \mu_k, z - \Phi(y_k)\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})} \le 0 \ \text{ for all } z \in \mathcal{C}.$$

We obtain (2.2) and (2.3) by passing to the limit in these expressions. Since $\mathcal{C}$ is of finite codimension, by using the same arguments as in [22], we prove that $(\bar\nu, \bar\lambda, \bar\mu)$ is nonzero. □

OPTIMIZABILITY AND ESTIMATABILITY FOR INFINITE-DIMENSIONAL LINEAR SYSTEMS[*]

GEORGE WEISS[†] AND RICHARD REBARBER[‡]

Abstract. An infinite-dimensional linear system described by $\dot{x}(t) = Ax(t) + Bu(t)$ $(t \geq 0)$ is said to be optimizable if for every initial state $x(0)$, an input $u \in L^2$ can be found such that $x \in L^2$. Here, A is the generator of a strongly continuous semigroup on a Hilbert space and B is an admissible control operator for this semigroup. In this paper we investigate optimizability (also known as the finite cost condition) and its dual, estimatability. We explore the connections with stabilizability and detectability. We give a very general theorem about the equivalence of input-output stability and exponential stability of well-posed linear systems: the two are equivalent if the system is optimizable and estimatable. We conclude that a well-posed system is exponentially stable if and only if it is dynamically stabilizable and input-output stable. We illustrate the theory by two examples based on PDEs in two or more space dimensions: the wave equation and a structural acoustics model.

Key words. strongly continuous semigroup, well-posed linear system, regular linear system, stabilizability, optimizability, detectability, input-output stability, dynamic stabilization

1. Introduction and outline of the results.

This paper is mainly about linear infinite-dimensional systems described either by

$$\left\{ \begin{array}{llll} \dot{x}(t) & = Ax(t) + Bu(t), & & x(0) = x_0, \\ y(t) & = x(t), & & t \geq 0, \end{array} \right. \tag{1.1}$$

or (in the dual situation) by

$$\left\{ \begin{array}{llll} \dot{x}(t) & = Ax(t) + u(t), & & x(-\infty) = 0, \\ y(t) & = C_\Lambda x(t), & & t \leq 0. \end{array} \right. \tag{1.2}$$

Here, A is the generator of a strongly continuous semigroup of operators $\mathbb{T}$ on the state space X, B is an admissible control operator for $\mathbb{T}$, defined on the input space U, and $C : \mathcal{D}(A) \rightarrow Y$ is an admissible observation operator for $\mathbb{T}$. U, X, and Y are Hilbert spaces and the operator C_Λ is the Λ-extension of C:

$$C_\Lambda z = \lim_{\lambda \rightarrow +\infty} C\lambda(\lambda I - A)^{-1} z \tag{1.3}$$

for all $z \in X$ for which the limit exists. In both types of systems, u is the input function, x is the state trajectory, and y is the output function. The first system is determined by the pair (A, B) and the second by the pair (A, C).

The pair (A, B) is called *optimizable* if for every $x_0 \in X$, a function u in L^2 can be found such that x is in L^2. If B is bounded, then optimizability is equivalent to

stabilizability via a bounded state feedback operator: $u(t) = Fy(t)$ in (1.1); see [12]. For unbounded B, stabilizability implies optimizability, but we do not know if the converse holds. Here, by stabilizability we mean a rather general concept, which will be recalled in section 2 and which involves an unbounded state feedback operator. Obviously, exact controllability implies optimizability.

Estimatability is (by definition) the dual of optimizability: the pair (A, C) is *estimatable* if (A^*, C^*) is optimizable. If C is bounded, then estimatability is equivalent to detectability via a bounded output injection operator: $u(t) = Hy(t)$ in (1.2). For unbounded C, detectability implies estimatability, but we do not know if the converse holds. For the precise meaning of detectability which we have in mind, we refer to section 2. Obviously, exact observability implies estimatability.

In this paper we investigate the concepts of optimizability and estimatability. Optimizability (sometimes called the finite cost condition) has received some attention in recent years; see, for example, Flandoli, Lasiecka, and Triggiani [13], Jacob and Zwart [16], Rebarber and Zwart [23] and the references therein. As far as we know, estimatability has not yet been considered. Of course, every statement about optimizability can be translated into a dual statement about estimatability, but there is more to estimatability than just this. For example, it is interesting to derive the duality-free definition of estimatability, namely, that a final state estimator exists for the system (1.2). Also, certain estimates appear to be natural in the context of estimatability, but not in the dual context. It will be interesting to look at well-posed linear systems which are both optimizable and estimatable.

We now outline the contents of the sections and state some of the results. In section 2 we recall the necessary background on admissible control and observation operators, well-posed linear systems, stabilizability, and detectability.

In section 3 we study the concept of optimizability. We are concerned with systems described by (1.1). We review some LQ optimal control theory results for optimizable systems and derive some simple consequences. We derive a Hautus test for optimizability. We introduce the *open-loop L^2-stabilization problem,* which is to find a bounded operator $\mathbf{F}$ from X to $L^2([0, \infty), U)$ such that, taking in (1.1) $u = \mathbf{F}x_0$, the state trajectory x is in $L^2([0, \infty), X)$ and depends continuously on x_0. As is easy to guess, it turns out that this problem (and its optimal version, also defined in section 3) is solvable if and only if (A, B) is optimizable.

In section 4 we study the concept of estimatability. We show that estimatability of (A, C) is equivalent to the solvability of the associated *final state estimation problem.* This concerns systems described by (1.2). The function u is in $L^2((-\infty, 0], X)$, it has compact support, and $x(t) = 0$ for large negative t. The problem is to estimate $x(0)$, based on the knowledge of y, such that the estimation error depends continuously on u (with its L^2-norm). This is difficult because, unless $\mathbb{T}$ is exponentially stable, $x(0)$ and y do not depend continuously on u (with its L^2-norm). Indeed, if the system is unstable and the support of u is far from zero (i.e., it is in the "distant past"), then its influence on $x(0)$ and on the "recent past" of y can be very large.

A stronger version of this problem is the *optimal final state estimation problem*, which turns out to be the dual of the optimal open-loop L^2-stabilization problem introduced in section 3. Based on this duality, we derive that the estimatability of (A, C) implies the existence of a $K > 0$ such that

$$\int_0^T \|\mathbb{T}_t x_0\|^2 dt \le K^2 \left(\|x_0\|^2 + \int_0^T \|C\mathbb{T}_t x_0\|^2 dt \right)$$

for all $x_0 \in \mathcal{D}(A)$ and for all $T \geq 0$. We do not know if this estimate is sufficient for estimatability. Another consequence of estimatability is the following: there exist $\delta > 0$ and $m > 0$ such that for all $s \in \mathbb{C}$ with Re $s > -\delta$

$$\|(sI - A)z\| + \|Cz\| \geq m\|z\| \qquad \forall\, z \in \mathcal{D}(A).$$

Again, we do not know if the converse holds.

In section 5 we investigate the relation between two stability concepts. A well-posed linear system with input space U and output space Y is called *input-output stable* if it maps inputs in $L^2([0,\infty), U)$ into outputs in $L^2([0,\infty), Y)$. Here, the initial state is considered to be zero. Input-output stability is equivalent to the fact that the transfer function $\mathbf{G}$ of the system is an $\mathcal{L}(U,Y)$-valued H^∞ function (i.e., $\mathbf{G}$ is bounded on the open right half-plane). A well-posed linear system is called *exponentially stable* if its semigroup is exponentially stable.

It is well known that exponential stability implies input-output stability (see, e.g., [36]), but the converse is not true (not even for finite-dimensional systems). There has been much interest in recent years in finding additional conditions on the system which imply that these two kinds of stability are equivalent (we shall give a short account of this). The main result of section 7 is a generalization of all the results known to us in this direction. Our result is the following.

THEOREM 1.1. *A well-posed linear system is exponentially stable if and only if it is optimizable, estimatable, and input-output stable.*

In section 6 we show that optimizability and estimatability are preserved under output feedback. This is needed in the study of the dynamic stabilizability of well-posed linear systems. Such a system is called *dynamically stabilizable* if it can be embedded as a subsystem of a larger, exponentially stable well-posed linear system. The "other half" of this larger system is a so-called *stabilizing controller with internal loop* (see section 6 for the precise definition). Our definition of dynamic stabilization includes stabilization by static feedback, as well as stabilization by a controller in the usual sense, as discussed, for example, in Chapter 4 of Curtain and Zwart [12] (where the control and observation operators are assumed to be bounded, which simplifies the analysis). Sufficient conditions for dynamic stabilizability in our general sense (and a design procedure) were given in Weiss and Curtain [40], in the context of regular linear systems. (Regular linear systems are a large subclass of well-posed linear systems; see section 2.) The main result of section 6 is the following.

THEOREM 1.2. *A well-posed linear system is dynamically stabilized by a controller with internal loop if and only if* (1) *both subsystems are optimizable and estimatable,* (2) *the closed-loop system is input-output stable.*

This, combined with Theorem 1.1, implies the following useful corollary.

COROLLARY 1.3. *A well-posed linear system is exponentially stable if and only if it is dynamically stabilizable and input-output stable.*

We give examples of transfer functions which cannot be associated to dynamically stabilizable systems. For example, if $\mathbf{G}$ is a Blaschke product with zeros at $\frac{1}{n} \pm in$, then no system with transfer function $\mathbf{G}$ can be dynamically stabilizable.

In section 7 we give two examples based on partial differential equations (PDEs). One concerns the n-dimensional wave equation with mixed boundary control and boundary observation on a subset of the boundary, and the other is a structural acoustic system (the two-dimensional wave equation interacting with a beam equation). Both examples use the last corollary to conclude that the system is not dynamically stabilizable. Since the proof of Corollary 1.3 relies on a majority of the other results derived in this paper, these results about PDE systems rely on a complex chain of abstract systems-theoretical results.

2. Some background on infinite-dimensional systems. In this section we gather, for easy reference, some basic facts about admissible control and observation operators, about well-posed and regular linear systems, and about stabilizability and detectability. However, the material cannot be learned from this section, and for details we refer to the literature.

Throughout this section, X is a Hilbert space and $A : \mathcal{D}(A) \to X$ is the generator of a strongly continuous semigroup $\mathbb{T}$ on X. The Hilbert space X_1 is $\mathcal{D}(A)$ with the norm $\|z\|_1 = \|(\beta I - A)z\|$, where $\beta \in \rho(A)$ is fixed (this norm is equivalent to the graph norm). The Hilbert space X_{-1} is the completion of X with respect to the norm $\|z\|_{-1} = \|(\beta I - A)^{-1} z\|$. This space is isomorphic to $\mathcal{D}(A^*)^*$, and we have

$$X_1 \subset X \subset X_{-1}$$

densely and with continuous embeddings. $\mathbb{T}$ extends to a semigroup on X_{-1}, denoted by the same symbol. The generator of this extended semigroup is an extension of A, whose domain is X, so that $A : X \to X_{-1}$.

U is a Hilbert space and $B \in \mathcal{L}(U, X_{-1})$ is an *admissible control operator* for $\mathbb{T}$, defined as in Weiss [33]. This means that if x is the solution of

$$\dot{x}(t) = Ax(t) + Bu(t)\,, \tag{2.1}$$

with $x(0) = x_0 \in X$ and $u \in L^2([0,\infty), U)$, then $x(t) \in X$ for all $t \geq 0$. In this case, x is a continuous X-valued function of t. We have $x(t) = \mathbb{T}_t x_0 + \Phi_t u$, where $\Phi_t \in \mathcal{L}(L^2([0,\infty), U), X)$ is defined by

$$\Phi_t u = \int_0^t \mathbb{T}_{t-\sigma} B u(\sigma)\, d\sigma\,. \tag{2.2}$$

The above integration is done in X_{-1}, but the result is in X. The Laplace transform of x is

$$\hat{x}(s) = (sI - A)^{-1} \left[x_0 + B\hat{u}(s) \right] .$$

B is called *bounded* if $B \in \mathcal{L}(U, X)$ (and unbounded otherwise).

Y is another Hilbert space and $C \in \mathcal{L}(X_1, Y)$ is an *admissible observation operator* for $\mathbb{T}$, defined as in Weiss [35]. This means that for every $T > 0$ there exists a $K_T \geq 0$ such that

$$\int_0^T \|C\mathbb{T}_t x_0\|^2 dt \leq K_T^2 \|x_0\|^2 \qquad \forall\, x_0 \in \mathcal{D}(A)\,. \tag{2.3}$$

C is called *bounded* if it can be extended such that $C \in \mathcal{L}(X, Y)$.

We regard $L^2_{loc}([0,\infty), Y)$ as a Fréchet space with the seminorms being the L^2-norms on the intervals $[0,n]$, $n \in \mathbb{N}$. Then the admissibility of C means that there is a continuous operator $\Psi : X \to L^2_{loc}([0,\infty), Y)$ such that

$$(\Psi x_0)(t) = C\mathbb{T}_t x_0 \qquad \forall\, x_0 \in \mathcal{D}(A)\,. \tag{2.4}$$

The operator Ψ is completely determined by (2.4), because $\mathcal{D}(A)$ is dense in X. However, replacing C by its Λ-extension C_Λ, defined in (1.3), formula (2.4) becomes true for all $x_0 \in X$ and for almost every $t \geq 0$. If $y = \Psi x_0$, then its Laplace transform is

$$\hat{y}(s) = C(sI - A)^{-1} x_0 . \tag{2.5}$$

The operator Ψ is an *extended output map* for $\mathbb{T}$, which means that

$$\mathbf{S}_\tau^* \Psi = \Psi \mathbb{T}_\tau \qquad \forall\, \tau \geq 0 , \tag{2.6}$$

where $\mathbf{S}_\tau^*$ denotes the left shift by τ on $L^2_{loc}([0,\infty), Y)$. There is a representation theorem stating that every extended output map for $\mathbb{T}$ is of the form (2.4) for some admissible observation operator C.

By a *well-posed linear system* we mean a linear time-invariant system such that on any finite time interval, the operator from the initial state and the input function to the final state and the output function is bounded. The input, state, and output spaces are Hilbert spaces, and the input and output functions are of class L^2_{loc}. For the detailed definition, background, and examples we refer to Salamon [27], [28], Staffans [29], [30], Weiss [36], [37], Avalos and Weiss [5], and Weiss^2 [41].

We recall some necessary facts about well-posed linear systems. Let Σ be such a system, with input space U, state space X, and output space Y. We consider positive time, $t \geq 0$. The state trajectories of Σ satisfy (2.1) and the comments from the beginning of this section apply. $\mathbb{T}$ is called the *semigroup* of Σ and B is called the *control operator* of Σ. If u is the input function of Σ, x_0 is its initial state, and y is the corresponding output function, then

$$y = \Psi x_0 + \mathbb{F} u . \tag{2.7}$$

Here, Ψ is an extended output map for $\mathbb{T}$, so that it can be represented by (2.4), and C is called the *observation operator* of Σ.

The operator $\mathbb{F} : L^2_{loc}([0,\infty), U) \to L^2_{loc}([0,\infty), Y)$ satisfies the following functional equation:

$$\mathbf{S}_\tau^* \mathbb{F} = \Psi \Phi_\tau + \mathbb{F} \mathbf{S}_\tau^* \qquad \forall\, \tau \geq 0 , \tag{2.8}$$

where Φ_τ is the operator from (2.2) and $\mathbf{S}_\tau^*$ is as in (2.6). It follows from (2.6) and (2.8) that if $x(\tau) = \mathbb{T}_\tau x_0 + \Phi_\tau u$ and y is given by (2.7), then

$$\mathbf{S}_\tau^* y = \Psi x(\tau) + \mathbb{F} \mathbf{S}_\tau^* u . \tag{2.9}$$

$\mathbb{F}$ is easiest to represent using Laplace transforms. An operator-valued analytic function is called *well-posed* if its domain contains a right half-plane in $\mathbb{C}$ such that the function is uniformly bounded on this half-plane. We do not distinguish between two well-posed functions if one is a restriction of the other. There exists a unique $\mathcal{L}(U,Y)$-valued well-posed function $\mathbf{G}$, called the *transfer function* of Σ, which determines $\mathbb{F}$ as follows: if $u \in L^2([0,\infty), U)$ and $y = \mathbb{F} u$, then y has a Laplace transform $\hat{y}$ and, for Re s sufficiently large,

$$\hat{y}(s) = \mathbf{G}(s) \hat{u}(s) .$$

This determines $\mathbb{F}$, since L^2 is dense in L^2_{loc}. We have

$$\mathbf{G}(s) - \mathbf{G}(\beta) = C \left[(sI - A)^{-1} - (\beta I - A)^{-1} \right] B$$

for any s, β in the open right half-plane determined by the growth bound of $\mathbb{T}$. This shows that $\mathbf{G}$ is determined by A, B, and C up to an additive constant operator. If $\mathbb{T}$ is exponentially stable, then $\mathbf{G}$ is in H^∞, i.e., it is bounded on the half-plane where Re $s > 0$ (and even on a larger half-plane).

An operator $K \in \mathcal{L}(Y, U)$ is called an *admissible feedback operator* for Σ (or for $\mathbf{G}$) if $I - \mathbf{G}K$ has a well-posed inverse (equivalently, if $I - K\mathbf{G}$ has a well-posed inverse). If this is the case, then the system with output feedback shown in Figure 1 is well-posed (its input is v, its state and output are the same as for Σ). This new system is called the *closed-loop system* corresponding to Σ and K, and it is denoted by Σ^K. Its transfer function is $\mathbf{G}^K = \mathbf{G}(I - K\mathbf{G})^{-1} = (I - \mathbf{G}K)^{-1}\mathbf{G}$. We have that $-K$ is an admissible feedback operator for Σ^K and the corresponding closed-loop system is Σ. For more details on closed-loop systems we refer to [37]. Any interconnection of finitely many well-posed systems can be thought of as a closed-loop system in the above sense.

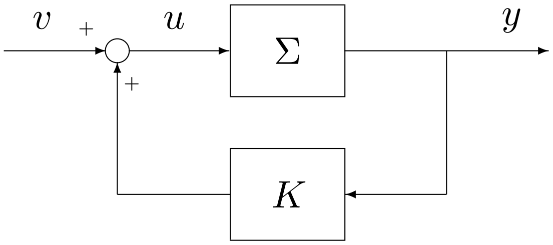

FIG. 1. *A well-posed linear system Σ with output feedback via K. If K is admissible, then this is a new well-posed linear system Σ^K, called the closed-loop system.*

The system Σ is called *regular* if the limit

$$\lim_{s \to +\infty} \mathbf{G}(s)\mathrm{v} = D\mathrm{v}$$

exists for every $\mathrm{v} \in U$, where s is real (see [36]). In this case, the operator $D \in \mathcal{L}(U, Y)$ is called the *feedthrough operator* of Σ. Regularity is equivalent to the fact that the product $C_\Lambda(sI - A)^{-1}B$ makes sense. In this case,

$$\mathbf{G}(s) = C_\Lambda(sI - A)^{-1}B + D, \tag{2.10}$$

as in finite dimensions. Moreover, the function y from (2.7) satisfies, for almost every $t \geq 0$,

$$y(t) = C_\Lambda x(t) + Du(t), \tag{2.11}$$

where x is the state trajectory of the system. The operators A, B, C, D are called the *generating operators* of Σ because they determine Σ via (2.1) and (2.11). Regular linear systems are usually considered on the time interval $[0, \infty)$, but other intervals are possible, for example, $(-\infty, 0]$. We refer to section 5 of [41] for a discussion of this latter case. The equations (2.1) and (2.11) are not affected by the time interval chosen. (A, B, C) is called a *regular triple* if $A, B, C, 0$ are the generating operators of a regular linear system. Equivalently, A generates a semigroup, B and C are admissible, the product $C_\Lambda(sI - A)^{-1}B$ exists and it is bounded on some right half-plane (see section 2 of [40]). In particular, if A is a generator, one of B and C is admissible and the other is bounded, then (A, B, C) is a regular triple. Thus, the systems in (1.1) and (1.2) are both regular and their generating operators are $A, B, I, 0$ for (1.1) and $A, I, C, 0$ for (1.2).

The generator of a semigroup is called *exponentially stable* if the corresponding semigroup is exponentially stable.

DEFINITION 2.1. *(A, B) is stabilizable if there exists $F \in \mathcal{L}(X_1, U)$ such that*

(i) *(A, B, F) is a regular triple;*

(ii) *I is an admissible feedback operator for $F_\Lambda(sI - A)^{-1}B$;*

(iii) *$A + BF_\Lambda$ (with its natural domain) is exponentially stable.*

In this case we say that F stabilizes (A, B).

For the concepts appearing in this definition and for further comments we refer to [22] and [40], but we summarize here the main facts in a few sentences. Since (A, B, F) is a regular triple, the transfer function $\mathbf{G}(s) = F_\Lambda(sI - A)^{-1}B$ is well defined. Recall that I being an admissible feedback operator for $\mathbf{G}$ means that $(I - \mathbf{G})^{-1}$ exists and is well-posed. The natural domain of $A^f = A + BF_\Lambda$ is

$$\mathcal{D}(A^f) = \left\{ z \in \mathcal{D}(F_\Lambda) \,\middle|\, Az + BF_\Lambda z \in X \right\} .$$

Conditions (i) and (ii) imply (see [37]) that A^f is the generator of a strongly continuous semigroup $\mathbb{T}^f$ on X and we have

$$\mathbb{T}^f_t x_0 = \mathbb{T}_t x_0 + \int_0^t \mathbb{T}_{t-\sigma} BF_\Lambda \mathbb{T}^f_\sigma x_0 \, d\sigma \,. \tag{2.12}$$

Moreover, (A^f, B, F_Λ) is a regular triple and

$$(I - \mathbf{G}(s))^{-1} = I + F_\Lambda(sI - A^f)^{-1}B \,.$$

It follows from the assumed exponential stability of $\mathbb{T}^f$ (point (iii) in the definition) that $(I - \mathbf{G})^{-1} \in H^\infty(\mathcal{L}(U))$, the space of bounded analytic $\mathcal{L}(U)$-valued functions on the half-plane where Re $s > 0$. Definition 2.1 is rather general, but we mention that Staffans [30] and Morris [19] have proposed a more general (and difficult) definition, with no regularity assumptions. It is not known if their definition is genuinely more general, i.e., if there exists a pair (A, B) which is stabilizable in the sense of [30] and [19], but not in the sense of Definition 2.1.

DEFINITION 2.2. *(A, C) is detectable if there exists $H \in \mathcal{L}(Y, X_{-1})$ such that*

(i) *(A, H, C) is a regular triple;*

(ii) *I is an admissible feedback operator for $C_\Lambda(sI - A)^{-1}H$;*

(iii) *$A + HC_\Lambda$ is exponentially stable.*

In this case we say that H detects (A, C).

The comments that can be made about the conditions above are similar to those at Definition 2.1, so we do not repeat them. This concept is almost the dual of stabilizability, but not quite: the trouble is that if (A, H, C) is a regular triple, it does not follow that (A^*, C^*, H^*) is a regular triple (it is weakly regular; see [41]). If Y is finite-dimensional, then the duality holds (i.e., (A, C) is detectable if and only if (A^*, C^*) is stabilizable); see section 3 of [40].

3. Optimizability.

In this section we are concerned with systems of the type (1.1). We use the notation X, X_{-1}, U, A, B, and $\mathbb{T}$ from sections 1 and 2.

DEFINITION 3.1. *The pair (A, B) is optimizable if for every $x_0 \in X$, there exists a $u \in L^2([0, \infty), U)$ such that $x \in L^2([0, \infty), X)$, where*

$$x(t) = \mathbb{T}_t x_0 + \int_0^t \mathbb{T}_{t-\tau} Bu(\tau) \, d\tau \,. \tag{3.1}$$

Note that x in (3.1) is the solution of (2.1) with $x(0) = x_0$.

REMARK 1. *It is easy to see that stabilizability implies optimizability. Indeed, assume that (A, B) is stabilized by F and let $\mathbb{T}^f$ be the semigroup generated by $A + BF_\Lambda$. For $x_0 \in X$, define the function u by $u(t) = F_\Lambda \mathbb{T}^f_t x_0$ for almost every $t \geq 0$. The exponential stability of $\mathbb{T}^f$ implies that $u \in L^2([0,\infty), U)$. From* (2.12) *we see that the function x from* (3.1) *is in fact $x(t) = \mathbb{T}^f_t x_0$, so that $x \in L^2$.*

We shall need the following cost functional associated with the pair (A, B): for every $x_0 \in X$ and every $u \in L^2([0,\infty), U)$, define

$$J(x_0, u) = \int_0^\infty (\|x(t)\|^2 + \|u(t)\|^2)\, dt, \tag{3.2}$$

where $x(t)$ is as in (3.1). Note that $J(x_0, u)$ might be infinite, and optimizability means that for every x_0, J can be made finite.

The following three results are known from linear quadratic optimal control theory, as developed in Flandoli, Lasiecka and Triggiani [13] (see also Staffans [31] or Zwart [42]). In [13], optimizability is called the finite cost condition. (In Weiss[2] [41], the particular case of a stable system is treated, and our notation follows this paper.)

PROPOSITION 3.2. *Suppose that (A, B) is optimizable. Then for every $x_0 \in X$ there is a unique function $u^{\rm opt} \in L^2([0,\infty), U)$ such that*

$$J(x_0, u^{\rm opt}) = \min_u J(x_0, u). \tag{3.3}$$

There is a positive operator $P \in \mathcal{L}(X)$ such that for all x_0 and $u^{\rm opt}$ as above,

$$J(x_0, u^{\rm opt}) = \langle P x_0, x_0 \rangle.$$

The following proposition tells us that the optimal state trajectories of the system (1.1), given by (3.1) with $u = u^{\rm opt}$, determine a semigroup.

PROPOSITION 3.3. *Suppose that (A, B) is optimizable. Then there is a strongly continuous semigroup $\mathbb{T}^{\rm opt}$ on X such that for every $x_0 \in X$, if $u^{\rm opt}$ is as in* (3.3), *then*

$$\mathbb{T}^{\rm opt}_t x_0 = \mathbb{T}_t x_0 + \int_0^t \mathbb{T}_{t-\sigma} B u^{\rm opt}(\sigma)\, d\sigma. \tag{3.4}$$

The semigroup $\mathbb{T}^{\rm opt}$ is exponentially stable.

The third result concerns an operator $F^{\rm opt}$, which in some weak sense can be thought of as an optimal feedback operator.

PROPOSITION 3.4. *With the notation of the previous two propositions, let $A^{\rm opt} : \mathcal{D}(A^{\rm opt}) \to X$ denote the generator of $\mathbb{T}^{\rm opt}$. Then $P : \mathcal{D}(A^{\rm opt}) \to \mathcal{D}(A^*)$, so that we can define $F^{\rm opt} : \mathcal{D}(A^{\rm opt}) \to U$ by*

$$F^{\rm opt} x_0 = -B^* P x_0 \qquad \forall\, x_0 \in \mathcal{D}(A^{\rm opt}). \tag{3.5}$$

$F^{\rm opt}$ is an admissible observation operator for $\mathbb{T}^{\rm opt}$, and for every $x_0 \in \mathcal{D}(A^{\rm opt})$,

$$u^{\rm opt}(t) = F^{\rm opt} \mathbb{T}^{\rm opt}_t x_0 \qquad \forall\, t \geq 0, \tag{3.6}$$

$$A^{\rm opt} x_0 = (A + BF^{\rm opt}) x_0. \tag{3.7}$$

The operator P satisfies a Riccati equation on $\mathcal{D}(A^{\rm opt})$ and possibly also on $\mathcal{D}(A)$, but this is not needed here, so we only refer to [13], [31], [41], [42].

It follows from (3.6) that, denoting by $F_\Lambda^{\rm opt}$ the Λ-extension of $F^{\rm opt}$, as in (1.3),

$$u^{\rm opt}(t) = F_\Lambda^{\rm opt}\mathbb{T}_t^{\rm opt}x_0\,, \tag{3.8}$$

for every $x_0 \in X$ and almost every $t \geq 0$. The Laplace transform of $u^{\rm opt}$ is

$$\hat{u}^{\rm opt}(s) = F^{\rm opt}(sI - A^{\rm opt})^{-1}x_0\,. \tag{3.9}$$

Combining (3.8) with (3.4), we get that

$$\mathbb{T}_t^{\rm opt}x_0 = \mathbb{T}_t x_0 + \int_0^t \mathbb{T}_{t-\sigma}BF_\Lambda^{\rm opt}\mathbb{T}_\sigma^{\rm opt}x_0\,d\sigma\,. \tag{3.10}$$

This formula resembles (2.12), but the context is different: for example, we do not know if B is an admissible control operator for $\mathbb{T}^{\rm opt}$. The formula (3.7) can be derived from (3.10) using the Laplace transformation.

The following proposition is an extension of the Hautus test for stabilizability to infinite-dimensional systems. It is a simple particular case of a result in section 2 of Rebarber and Zwart [23]. We denote by Ran $[sI - A\,|\,B]$ the subspace of X_{-1} which consists of all vectors of the form $(sI - A)z + B{\rm v}$, where $z \in X$ and ${\rm v} \in U$.

Proposition 3.5. *If (A, B) is optimizable, then there exists a $\delta > 0$ such that, for all $s \in \mathbb{C}$ with* Re $s > -\delta$,

$$\text{Ran }[sI - A\,|\,B] \supset X\,.$$

Proof. Let $A^{\rm opt}$ and $F^{\rm opt}$ be the operators from Proposition 3.4. Since $A^{\rm opt}$ is exponentially stable, there exists a $\delta > 0$ such that $sI - A^{\rm opt}$ is invertible for all s with Re $s > -\delta$. We have for every such s and for every $x_0 \in X$,

$$\begin{aligned} x_0 &= (sI - A^{\rm opt})(sI - A^{\rm opt})^{-1}x_0 \\ &= (sI - A)(sI - A^{\rm opt})^{-1}x_0 - BF^{\rm opt}(sI - A^{\rm opt})^{-1}x_0\,. \end{aligned}$$

Denoting $z = (sI - A^{\rm opt})^{-1}x_0$ and ${\rm v} = -F^{\rm opt}(sI - A^{\rm opt})^{-1}x_0$, we get the desired representation of x_0: $x_0 = (sI - A)z + B{\rm v}$. □

Definition 3.6. *The open-loop L^2-stabilization problem for (A, B) is to find a bounded linear operator*

$$\mathbf{F} : X \rightarrow L^2([0, \infty), U)$$

such that, taking in (3.1) $u = \mathbf{F}x_0$, *x should depend continuously on x_0, i.e.,*

$$\sup_{\|x_0\| \leq 1} \|x\|_{L^2([0,\infty),X)} < \infty\,. \tag{3.11}$$

It looks as if the solvability of this problem is a more restrictive condition than optimizability, but the optimal control theory results listed earlier imply that they are in fact equivalent (this will be needed in section 4).

Proposition 3.7. *The open-loop L^2-stabilization problem for (A, B) is solvable if and only if (A, B) is optimizable. If the latter condition holds, then one solution of the open-loop L^2-stabilization problem is the operator $\mathbf{F}^{\rm opt}$ defined by*

$$(\mathbf{F}^{\rm opt}x_0)(t) = F_\Lambda^{\rm opt}\mathbb{T}_t^{\rm opt}x_0 \tag{3.12}$$

for every $x_0 \in X$ *and almost every* $t \geq 0$*, where* F_Λ^{opt} *and* $\mathbb{T}^{\text{opt}}$ *are as in* (3.8)*.*

Proof. It is obvious that the solvability of the open-loop L^2-stabilization problem via an operator $\mathbf{F}$ implies optimizability by choosing $u = \mathbf{F}x_0$.

Conversely, suppose that (A, B) is optimizable. Since $\mathbb{T}^{\text{opt}}$ is exponentially stable and F^{opt} is admissible for $\mathbb{T}^{\text{opt}}$, the operator $\mathbf{F}^{\text{opt}}$ from (3.12) is bounded, as required in Definition 3.6. If we take in (3.1) $u = \mathbf{F}^{\text{opt}}x_0$, then $u = u^{\text{opt}}$ and by (3.4), $x(t) = \mathbb{T}_t^{\text{opt}}x_0$. Since $\mathbb{T}^{\text{opt}}$ is exponentially stable, the above operator from x_0 to the function x in $L^2([0,\infty), X)$ is bounded, i.e., (3.11) holds. □

We want to introduce the optimal version of the open-loop L^2-stabilization problem. For this, we introduce the operators

$$\Psi : X \to L^2_{loc}([0,\infty), X), \qquad \mathbb{F} : L^2([0,\infty), U) \to L^2_{loc}([0,\infty), X)$$

by

$$(\Psi x_0)(t) = \mathbb{T}_t x_0, \qquad (\mathbb{F}u)(t) = \int_0^t \mathbb{T}_{t-\sigma} Bu(\sigma)\, d\sigma. \tag{3.13}$$

(Both Ψx_0 and $\mathbb{F}u$ are in fact continuous X-valued functions of t.) Ψ and $\mathbb{F}$ are the operators from (2.7) for the regular linear system described by (1.1). If the semigroup $\mathbb{T}$ is exponentially stable, then the operators Ψ and $\mathbb{F}$ are bounded if we apply the L^2-norm to Ψx_0 and to $\mathbb{F}u$. Without exponential stability, Ψ and $\mathbb{F}$ are in general unbounded, and this is the case of interest.

The function x from (3.1) is $x = \Psi x_0 + \mathbb{F}u$, so that if $\mathbf{F}$ is an operator from X to $L^2([0,\infty), U)$, then taking $u = \mathbf{F}x_0$, x can be written as

$$x = (\mathbb{F}\mathbf{F} + \Psi)x_0. \tag{3.14}$$

This shows that the supremum appearing on the left of (3.11) is the norm of the operator $\mathbb{F}\mathbf{F} + \Psi$ (from X to $L^2([0,\infty), X)$). Thus, we obtain the following reformulation of the open-loop L^2-stabilization problem for (A, B): find a bounded linear operator $\mathbf{F} : X \to L^2([0,\infty), U)$ such that $\mathbb{F}\mathbf{F} + \Psi$ is bounded.

Definition 3.8. *The optimal open-loop L^2-stabilization problem for (A, B) is to find a bounded operator*

$$\mathbf{F}^{\text{opt}} : X \to L^2([0,\infty), U)$$

such that $\mathbb{F}\mathbf{F}^{\text{opt}} + \Psi$ *is bounded (from* X *to* $L^2([0,\infty), X)$*) and*

$$\left\| \begin{bmatrix} \mathbb{F}\mathbf{F}^{\text{opt}} + \Psi \\ \mathbf{F}^{\text{opt}} \end{bmatrix} \right\| = \min_{\mathbf{F}} \left\| \begin{bmatrix} \mathbb{F}\mathbf{F} + \Psi \\ \mathbf{F} \end{bmatrix} \right\|.$$

Proposition 3.9. *The optimal open-loop L^2-stabilization problem for (A, B) is solvable if and only if (A, B) is optimizable.*

If the latter condition holds, then one solution of the optimal open-loop L^2-stabilization problem is the operator $\mathbf{F}^{\text{opt}}$ *defined in* (3.12)*.*

Proof. It is clear that the solvability of the optimal open-loop L^2-stabilization problem via an operator $\mathbf{F}^{\text{opt}}$ implies optimizability, by choosing $u = \mathbf{F}^{\text{opt}}x_0$.

Conversely, suppose that (A, B) is optimizable, and let $\mathbf{F}^{\text{opt}}$ be defined by (3.12). We know from Proposition 3.7 that $\mathbf{F}^{\text{opt}}$ solves the open-loop L^2-stabilization problem, so that (using the reformulation of this problem given before Definition 3.8) $\mathbb{F}\mathbf{F}^{\text{opt}} + \Psi$ is bounded. From (3.14) it is easy to see that

$$J(x_0, \mathbf{F}x_0) = \left\| \begin{bmatrix} \mathbb{F}\mathbf{F} + \Psi \\ \mathbf{F} \end{bmatrix} x_0 \right\|^2,$$

where J is the cost functional from (3.2). For each $x_0 \in X$, the left-hand side above is minimized for $\mathbf{F} = \mathbf{F}^{\rm opt}$ (this follows from Proposition 3.4), so that the norm of the operator appearing on the right-hand side must be minimal for $\mathbf{F} = \mathbf{F}^{\rm opt}$. □

Recently, Jacob and Zwart [16] have obtained interesting necessary conditions for optimizability of systems with a finite-dimensional input space. These conditions concern the spectrum of A and the multiplicity of its eigenvalues.

4. Estimatability. In this section we are concerned with systems of the type (1.2). We use the notation $X, X_1, Y, A, C, C_\Lambda$, and $\mathbb{T}$ from sections 1 and 2. If we denote by X^*_{-1} the completion of X with respect to the norm $\|x\|^*_{-1} = \|(\beta I - A^*)^{-1}x\|$, then $X^*_{-1} = (X_1)^*$ and $C^* \in \mathcal{L}(Y, X^*_{-1})$. As is well known, C^* is an admissible control operator for $\mathbb{T}^*$. We have $A^* : \mathcal{D}(A^*) \to X$, which can be extended to $A^* : X \to X^*_{-1}$.

DEFINITION 4.1. *The pair* (A, C) *is estimatable if* (A^*, C^*) *is optimizable.*

Estimatability is equivalent to the solvability of the final state estimation problem, which we describe in what follows.

Consider the system Σ described by (1.2). Recall that the time is negative. We assume that $u \in L^2((-\infty, 0], X)$ and u has compact support. The system is at rest before u becomes active, i.e., $x(t) = 0$ if $u(\tau) = 0$ for all $\tau \le t$.

DEFINITION 4.2. *The final state estimation problem for* (A, C) *is to find a bounded linear operator*

$$\mathbf{E} : L^2((-\infty, 0], Y) \to X$$

such that for the system Σ *in* (1.2), *denoting* $e = \mathbf{E}y - x(0)$, e *should depend continuously on* u, *i.e,*

$$\sup_{\|u\| \le 1} \|e\| < \infty . \tag{4.1}$$

If (4.1) holds, then $\mathbf{E}y$ is a reasonable estimate (or guess) of $x(0)$, based only on the information y, and e is the estimation error; see Figure 2 (with $w = 0$). The operator $\mathbf{E}$ could be called a *final state estimator* for the system in (1.2).

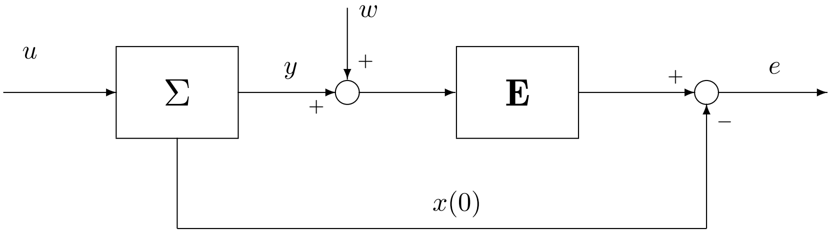

FIG. 2. *The final state estimation problem. The system* Σ *is described by* (1.2), *the time is negative, and* $w = 0$. *We are looking for a bounded operator* $\mathbf{E}$ *(the estimator) such that the operator from* u *to* e *should be bounded. Here,* e *is the estimation error. In the optimal version of this problem, the output noise* w *is in* L^2 *and we want to minimize the norm of the operator from the pair* (u, w) *to* e.

It follows from the description of Σ in (1.2) that

$$x(0) = \Phi u, \qquad y = \mathbb{L}u,$$

where

$$\Phi u = \int_0^\infty \mathbb{T}_\sigma u(-\sigma)\, d\sigma, \qquad (\mathbb{L}u)(t) = C_\Lambda \int_t^\infty \mathbb{T}_{t+\sigma} u(-\sigma)\, d\sigma . \tag{4.2}$$

If $\mathbb{T}$ is exponentially stable, then these operators are bounded if we apply the L^2-norm to u. If $\mathbb{T}$ is not exponentially stable, then the operators Φ and $\mathbb{L}$ are in general unbounded (this is the case of interest) and their domain contains the L^2-functions with compact support. With this notation, the formula for e becomes

$$e = (\mathbf{E}\mathbb{L} - \Phi)u. \tag{4.3}$$

The expression on the left of (4.1) is the norm of the operator $\mathbf{E}\mathbb{L} - \Phi$ (from $L^2((-\infty, 0], X)$ to X). Thus, we obtain the following reformulation of the final state estimation problem for (A, C): find a bounded linear operator $\mathbf{E}$ from $L^2((-\infty, 0], Y)$ to X such that $\mathbf{E}\mathbb{L} - \Phi$ is bounded.

The time-reflection operator $\mathbf{Я} : L^2((-\infty, 0], W) \to L^2([0, \infty), W)$ is defined by

$$(\mathbf{Я}w)(t) = w(-t) \qquad \forall t \geq 0,$$

where W is an arbitrary Hilbert space. Note that $(\mathbf{Я}^* v)(t) = v(-t)$ for all v in $L^2([0, \infty), W)$, so that $\mathbf{Я}\mathbf{Я}^* = I$ and $\mathbf{Я}^*\mathbf{Я} = I$.

THEOREM 4.3. *The final state estimation problem for* (A, C) *is solvable if and only if* (A, C) *is estimatable. If the latter condition holds, then one solution of the final state estimation problem is the operator* $\mathbf{E}^{\rm opt}$ *defined by*

$$\mathbf{E}^{\rm opt} = -\left(\mathbf{F}^{\rm opt}\right)^* \mathbf{Я}, \tag{4.4}$$

where $\mathbf{F}^{\rm opt}$ *is the operator from Proposition* 3.7*, but with* (A^*, C^*) *in place of* (A, B).

A system-theoretic interpretation of (4.4) will be given after the proof.

Proof. Suppose that (A, C) is estimatable. By Proposition 3.7, the open-loop L^2-stabilization problem is solvable for (A^*, C^*), and one solution is the operator $\mathbf{F}^{\rm opt}$ from (3.12). Thus, with the notation from (3.13) (with $\mathbb{T}^*$ and C^* in place of $\mathbb{T}$ and B) we have that $\mathbb{F}\mathbf{F}^{\rm opt} + \Psi$ is bounded (from X to $L^2([0, \infty), X)$).

We claim that $\mathbf{E}^{\rm opt}\mathbb{L} - \Phi$ is bounded and

$$\mathbf{E}^{\rm opt}\mathbb{L} - \Phi = -\left(\mathbb{F}\mathbf{F}^{\rm opt} + \Psi\right)^* \mathbf{Я}. \tag{4.5}$$

We have to be careful with the proof of (4.5), because the operators $\mathbb{L}$, Φ, $\mathbb{F}$, and Ψ are in general unbounded. Let $u \in L^2((-\infty, 0], X)$ have compact support and take $z \in X$ and $v \in L^2([0, \infty), Y)$. We need the identities

$$\langle \mathbf{Я}\mathbb{L}u, v\rangle = \langle \mathbf{Я}u, \mathbb{F}v\rangle, \qquad \langle \Phi u, z\rangle = \langle \mathbf{Я}u, \Psi z\rangle. \tag{4.6}$$

By $\langle \mathbf{Я}u, \mathbb{F}v\rangle$ we mean $\int_0^\infty \langle u(-t), (\mathbb{F}v)(t)\rangle dt$, which makes sense because u has compact support, and a similar explanation applies to $\langle \mathbf{Я}u, \Psi z\rangle$. The formulas (4.6) are verified by simple computations, using (3.13) and (4.2).

We have, using (4.4) and (4.6),

$$\begin{aligned}
\langle (\mathbf{E}^{\rm opt}\mathbb{L} - \Phi)u, z\rangle &= -\langle \mathbf{Я}\mathbb{L}u, \mathbf{F}^{\rm opt}z\rangle - \langle \Phi u, z\rangle \\
&= -\langle \mathbf{Я}u, \mathbb{F}\mathbf{F}^{\rm opt}z\rangle - \langle \mathbf{Я}u, \Psi z\rangle \\
&= -\langle \mathbf{Я}u, (\mathbb{F}\mathbf{F}^{\rm opt} + \Psi)z\rangle .
\end{aligned}$$

Since functions with compact support are dense in $L^2((-\infty,0],X)$, this shows that $\mathbf{E}^{\rm opt}\mathbb{L}-\Phi$ is bounded and (4.5) holds. Thus, $\mathbf{E}^{\rm opt}$ is a solution of the final state estimation problem for (A,C) (it is a final state estimator).

Conversely, suppose that the final state estimation problem for (A,C) is solvable and let $\mathbf{E}$ be a final state estimator for the system in (1.2), i.e., $\mathbf{E}\mathbb{L}-\Phi$ is bounded (from $L^2((-\infty,0],X)$ to X). Define $\mathbf{F}: X \rightarrow L^2([0,\infty),X)$ by

$$\mathbf{F} = -\boldsymbol{Я}\mathbf{E}^*,$$

so that $\mathbf{E}=-\mathbf{F}^*\boldsymbol{Я}$, like in (4.4). Then by a similar argument as in the first part of this proof, we obtain that

$$\langle(\mathbf{E}\mathbb{L}-\Phi)u, z\rangle = -\langle\boldsymbol{Я}u, (\mathbb{F}\mathbf{F}+\Psi)z\rangle, \tag{4.7}$$

which shows that $\mathbb{F}\mathbf{F}+\Psi$ is bounded. This means that the open-loop L^2-stabilization problem is solvable for (A^*,C^*). By Proposition 3.7, (A^*,C^*) is optimizable, i.e., (A,C) is estimatable. □

To understand the meaning of (4.4), we write it in a more explicit way. Let $\mathbb{T}^{\rm opt}$ denote the optimal semigroup from (3.4), corresponding to the optimal control problem (3.1), (3.2), (3.3), but with (A,B) replaced by (A^*,C^*) (in particular, $\mathbb{T}$ is replaced by its adjoint semigroup $\mathbb{T}^*$). We denote by $A^{\rm opt}$ the generator of $\mathbb{T}^{\rm opt}$ and by $F^{\rm opt}$ the operator from (3.5), so that $F^{\rm opt}\in\mathcal{L}(X_1^{\rm opt},Y)$, where $X_1^{\rm opt}$ is $\mathcal{D}(A^{\rm opt})$ with the graph norm. By Proposition 3.4, $F^{\rm opt}$ is an admissible observation operator for $\mathbb{T}^{\rm opt}$ and, according to (3.5), $F^{\rm opt}=-CP$.

Let $A_d^{\rm opt}$ and $H^{\rm opt}$ denote the adjoints of $A^{\rm opt}$ and $F^{\rm opt}$. Thus, $H^{\rm opt}\in\mathcal{L}(Y,X_{-1}^d)$, where X_{-1}^d is the dual of $X_1^{\rm opt}$ (the completion of X with respect to the norm $\|z\|_{-1}^d = \|(A_d^{\rm opt})^{-1}z\|$). $A_d^{\rm opt}$ is the generator of the semigroup $\mathbb{S}^{\rm opt}$, which is the adjoint of the semigroup $\mathbb{T}^{\rm opt}$. By duality we know that $H^{\rm opt}$ is an admissible control operator for $\mathbb{S}^{\rm opt}$. By an easy computation we can write

$$\left(\mathbf{F}^{\rm opt}\right)^* v = \int_0^\infty \mathbb{S}_t^{\rm opt}H^{\rm opt}v(t)\,dt. \tag{4.8}$$

Now we can rewrite the formula for $\mathbf{E}^{\rm opt}$:

$$\mathbf{E}^{\rm opt}y = -\int_0^\infty \mathbb{S}_t^{\rm opt}H^{\rm opt}y(-t)\,dt. \tag{4.9}$$

This corresponds to the following system:

$$\dot z(t) = A_d^{\rm opt}z(t) - H^{\rm opt}y(t) \tag{4.10}$$

with $t\le 0$ and $z(-\infty)=0$. The final state $z(0)$ of this system is $\mathbf{E}^{\rm opt}y$. For bounded C, see also the comments after Proposition 4.4.

Now we derive the dual counterparts of (3.10) and (3.7).

Proposition 4.4. *Assume that (A,C) is estimatable. Let $\mathbb{S}^{\rm opt}$ and $H^{\rm opt}$ be as in* (4.9) *and let $A_d^{\rm opt}$ be the generator of $\mathbb{S}^{\rm opt}$. Then for every $x_0\in X$,*

$$\mathbb{S}_t^{\rm opt}x_0 = \mathbb{T}_t x_0 + \int_0^t \mathbb{S}_{t-\sigma}^{\rm opt}H^{\rm opt}C_\Lambda\mathbb{T}_\sigma x_0\,d\sigma \tag{4.11}$$

and, for every $z_0\in\mathcal{D}(A)$,

$$Az_0 = \left(A_d^{\rm opt} - H^{\rm opt}C\right)z_0\,. \tag{4.12}$$

Proof. The formula (4.11) follows from (3.10) (with $\mathbb{T}_t^*$ and C^* in place of $\mathbb{T}_t$ and B) by taking adjoints and making some simple computations. Applying the Laplace transformation to (4.11), we obtain

$$(4.13)\quad (sI - A_d^{\rm opt})^{-1}x_0 - (sI-A)^{-1}x_0 \,=\, (sI - A_d^{\rm opt})^{-1}H^{\rm opt}C(sI-A)^{-1}x_0\,.$$

Applying $(sI - A_d^{\rm opt})$ to both sides and denoting $z_0 = (sI-A)^{-1}x_0$, we get

$$(sI-A)z_0 - (sI - A_d^{\rm opt})z_0 \,=\, H^{\rm opt}Cz_0$$

(this is an identity in X_{-1}^d). From here, (4.12) follows. □

Assuming for a moment that C (and hence also $H^{\rm opt}$) is bounded, using (4.12), we can rewrite (4.10) of the final state estimator in the form

$$\dot z(t) \,=\, Az(t) + H^{\rm opt}(Cz(t) - y(t))\,.$$

Here we recognize the equation of a Kalman estimator from finite-dimensional systems theory (this estimator has no access to the driving noise u).

Proposition 4.5. *If (A, C) is estimatable, then there is a $K > 0$ such that for every $x_0 \in D(A)$ and every $T \geq 0$*

$$\int_0^T \|\mathbb{T}_t x_0\|^2 dt \,\leq\, K^2\left(\|x_0\|^2 + \int_0^T \|C\mathbb{T}_t x_0\|^2 dt\right).$$

Proof. Since $H^{\rm opt}$ from (4.9) is admissible for $\mathbb{S}^{\rm opt}$ and $\mathbb{S}^{\rm opt}$ is exponentially stable, it follows that $(sI - A_d^{\rm opt})^{-1}H^{\rm opt}$ is in H^∞; see, for example, [38]. Denote

$$k \,=\, \sup_{{\rm Re}\, s>0} \|(sI - A_d^{\rm opt})^{-1}H^{\rm opt}\|_{\mathcal{L}(Y,X)}\,.$$

If $y \in L^2_{loc}([0,\infty), Y)$ and $w : [0,\infty)\to X$ is defined by

$$w(t) \,=\, \int_0^t \mathbb{S}_{t-\sigma}^{\rm opt} H^{\rm opt} y(\sigma)d\sigma,$$

then, since $\hat w(s) = (sI - A_d^{\rm opt})^{-1}H^{\rm opt}\hat y(s)$, we have that for all $T \geq 0$,

$$\int_0^T \|w(t)\|^2 dt \,\leq\, k^2 \int_0^T \|y(t)\|^2 dt.$$

Take in this inequality $y(t) = C_\Lambda \mathbb{T}_t x_0$. Then (4.11) implies that for all $T \geq 0$,

$$\left(\int_0^T \|\mathbb{T}_t x_0\|^2 dt\right)^{\frac12} \;\leq\; \left(\int_0^T \|\mathbb{S}_t^{\rm opt} x_0\|^2 dt\right)^{\frac12} + k\left(\int_0^T \|C_\Lambda \mathbb{T}_t x_0\|^2 dt\right)^{\frac12}.$$

Since the first term on the right-hand side is $\leq M\|x_0\|$, denoting $K^2 = M^2 + k^2$ we get the estimate in the proposition. □

Now consider the situation when there is an output noise (or uncertainty) w added to the output y of the plant from (1.2), as shown in Figure 2. The function w is in $L^2((-\infty, 0], Y)$. It is easy to see that in this situation, if $\mathbf{E}$ is a final state estimator for the system in (1.2), then the estimation error will be

$$(4.14)\qquad e \,=\, \begin{bmatrix} \mathbf{E}\mathbb{L} - \Phi & \mathbf{E} \end{bmatrix} \begin{bmatrix} u \\ w \end{bmatrix}.$$

Trying to minimize this error leads to the following problem.

DEFINITION 4.6. *The optimal final state estimation problem for* (A, C) *is to find a bounded linear operator*

$$\mathbf{E}^{\mathrm{opt}} : L^2((-\infty, 0], Y) \to X$$

such that $\mathbf{E}^{\mathrm{opt}}\mathbb{L} - \Phi$ *is bounded (from* $L^2((-\infty, 0], X)$ *to* X*) and*

$$\left[\begin{array}{cc} \mathbf{E}^{\mathrm{opt}}\mathbb{L} - \Phi & \mathbf{E}^{\mathrm{opt}} \end{array}\right] = \min_{\mathbf{E}} \left[\begin{array}{cc} \mathbf{E}\mathbb{L} - \Phi & \mathbf{E} \end{array}\right].$$

Note that this problem is the dual of the optimal open-loop L^2-stabilization problem introduced in Definition 3.8.

PROPOSITION 4.7. *The optimal final state estimation problem for* (A, C) *is solvable if and only if* (A, C) *is estimatable. If the latter condition holds, then one solution of the optimal final state estimation problem is the operator* $\mathbf{E}^{\mathrm{opt}}$ *defined in* (4.4).

The above result is the dual counterpart of Proposition 3.9 and it follows from it by duality, using formula (4.7).

PROPOSITION 4.8. *If* (A, C) *is estimatable, then there exist* $\delta > 0$ *and* $m > 0$ *such that, for all* $s \in \mathbb{C}$ *with* $\mathrm{Re}\ s > -\delta$,

$$\|(sI - A)z\| + \|Cz\| \geq m\|z\| \qquad \forall\, z \in \mathcal{D}(A). \tag{4.15}$$

This is approximately the dual version of Proposition 3.5 (the Hautus test). Actually, it is somewhat stronger than the dual of Proposition 3.5 because we prove a uniform lower bound instead of just a lower bound for each individual s.

Proof. According to (4.12), we have for every $z \in \mathcal{D}(A)$,

$$(sI - A_d^{\mathrm{opt}})^{-1}(sI - A - H^{\mathrm{opt}}C)z = z,$$

which means that

$$\left[(sI - A_d^{\mathrm{opt}})^{-1} \quad -(sI - A_d^{\mathrm{opt}})^{-1}H^{\mathrm{opt}}\right] \left[\begin{array}{c} sI - A \\ C \end{array}\right] z = z.$$

Since A_d^{opt} is exponentially stable, there is a $\delta > 0$ such that both $(sI - A_d^{\mathrm{opt}})^{-1}$ and $(sI - A_d^{\mathrm{opt}})^{-1}H^{\mathrm{opt}}$ are uniformly bounded on the half-plane where $\mathrm{Re}\ s > -\delta$; see, for example, [38]. Thus, there is an $M > 0$ such that, for all $s \in \mathbb{C}$ with $\mathrm{Re}\ s > -\delta$,

$$\left\|\left[(sI - A_d^{\mathrm{opt}})^{-1} \quad -(sI - A_d^{\mathrm{opt}})^{-1}H^{\mathrm{opt}}\right]\right\| \leq M$$

with the norm evaluated in $\mathcal{L}(X \times Y, X)$. Hence, for such s and every $z \in \mathcal{D}(A)$,

$$\begin{aligned} \|z\| &\leq M \left\| \left[\begin{array}{c} sI - A \\ C \end{array}\right] z \right\| \\ &\leq M\left(\|(sI - A)z\| + \|Cz\|\right). \end{aligned}$$

Denoting $m = \frac{1}{M}$, we get the desired estimate. □

It would be interesting to know whether the converse of Proposition 4.8 is true.

REMARK 2. *The estimate* (4.15) *can be replaced by the stronger looking*

$$\|(sI - A)z\| + \|Cz\| \geq m(1 + |\mathrm{Re}\, s|)\|z\| \qquad \forall\, z \in \mathcal{D}(A),$$

but this does not really tell more than (4.15)*. The last estimate holds because for large* Re s*, it holds even with* $C = 0$*, by semigroup theory. For this reason, numbers* s *with large* Re s *are not very interesting in this context: what is interesting is the area around* $\sigma(A)$ *in the half-plane where* Re $s > -\delta$*.*

For other infinite-dimensional extensions of the Hautus test we refer to Jacob and Zwart [16], Grabowski and Callier [14], and Russell and Weiss [26].

REMARK 3. *Using the operators* Φ *and* $\mathbb{L}$ *defined in* (4.2)*, it is possible to prove the following:* (A, C) *is estimatable if and only if the estimate*

$$\|\Phi u\|^2 \leq K^2 \left(\|u\|^2 + \|\mathbb{L}u\|^2\right)$$

holds for some $K > 0$ *and for all* $u \in L^2((-\infty, 0], X)$ *with compact support. The proof is a bit involved and we omit it, since this does not seem to be a practical way to check estimatability. The key step is that* $\mathbb{L}(I + \mathbb{L}^*\mathbb{L})^{-1}\Phi^*$ *is bounded.*

5. Equivalence of exponential and input-output stability. The purpose of this section is to prove Theorem 1.1. Before doing so, we say a few words about the history of this result. For finite-dimensional systems, it is well known that if the system is stabilizable, detectable and the transfer function is stable (i.e., all the poles are in the open left half-plane), then the system is stable (i.e., all the eigenvalues are in the open left half-plane). We cannot point to a specific source of this proposition. In the 1980s, this result was generalized to infinite-dimensional systems with bounded control and observation operators and finite-dimensional input and output spaces by S. A. Nefedov and F. A. Sholokhovich and by C. A. Jacobson and C. N. Nett. Related results were derived by H. Logemann. For precise bibliographic details on this period we refer to Curtain [8]. For a time-varying finite-dimensional version we refer to Ravi and Khargonekar [21].

The result was generalized to Pritchard–Salamon systems in [8] and then again to well-posed linear systems in Curtain [9]. In the latter reference, however, the definitions of stabilizability, of detectability, and of input-output stability are much more restrictive than the concepts used in this paper. In Rebarber [22] it was shown that a regular linear system is exponentially stable if and only if it is stabilizable, detectable, and input-output stable (see also section 3 of [40]). The papers [22] and [40] use exactly the same terminology which is used here. The result of [22] was generalized by Staffans [30] and (independently) by Morris [19]. Both of them have eliminated all the regularity assumptions: they consider well-posed linear systems, and their definitions of stabilizability and of detectability are also regularity-free, so that they are less restrictive (and more difficult) than the concepts used here. (Actually, in [30] input-output stability is replaced by a more restrictive condition, so that the result in [19] is stronger.) Their definitions of exponential stabilizability and detectability imply optimizability and estimatability, respectively, so that our Theorem 1.1 is a generalization of their result. We mention that [30] gives also related results concerning the strong stability of the semigroup.

To prove Theorem 1.1, we need some preliminary results. We use the notation $X, X_1, X_{-1}, U, Y, A, B, C$ from section 2.

PROPOSITION 5.1. *The following two statements are equivalent:*

(a) (A, B) *is optimizable and* $(sI - A)^{-1}B$ *is in* H^∞*,*

(b) A *is exponentially stable.*

Recall that by "$(sI - A)^{-1}B$ is in H^∞" we mean that $(sI - A)^{-1}B$, as an $\mathcal{L}(U, X)$-valued analytic function of s, is bounded on the half-plane where Re $s > 0$.

Proof. It is clear that (b) implies (a). Now assume that (a) holds. Applying the Laplace transformation to (3.4) and using (3.9), we obtain

$$(sI - A^{\rm opt})^{-1} - (sI - A)^{-1} \,=\, (sI - A)^{-1} B F^{\rm opt} (sI - A^{\rm opt})^{-1} \,. \tag{5.1}$$

Since $\mathbb{T}^{\rm opt}$ is exponentially stable and $F^{\rm opt}$ is admissible for $\mathbb{T}^{\rm opt}$, we have that $F^{\rm opt}(sI - A^{\rm opt})^{-1} \in H^\infty$. Since $(sI - A)^{-1} B \in H^\infty$, it follows that the right-hand side of (5.1) is in H^∞. Since $(sI - A^{\rm opt})^{-1} \in H^\infty$, it follows that $(sI - A)^{-1} \in H^\infty$. By a result of Prüss [20] (see also section 4 of [34]), $\mathbb{T}$ is exponentially stable. □

The following proposition is just the dual version of Proposition 5.1, so that no proof is necessary.

PROPOSITION 5.2. *The following two statements are equivalent:*

(a) *(A, C) is estimatable and $C(sI - A)^{-1}$ is in H^∞,*

(b) *A is exponentially stable.*

We now restate Theorem 1.1.

THEOREM 5.3. *Let Σ be a well-posed linear system with semigroup generator A, control operator B, observation operator C, and transfer function $\mathbf{G}$. Then Σ is exponentially stable if and only if*

(1) *(A, B) is optimizable,*

(2) *(A, C) is estimatable,*

(3) *$\mathbf{G} \in H^\infty$ (i.e, Σ is input-output stable).*

Proof. We denote by $\mathbb{T}$ the semigroup of Σ. It is clear that the exponential stability of $\mathbb{T}$ implies the properties (1), (2), and (3). To prove the converse, we assume that these properties hold. By Propositions 3.2 and 3.3, there is a semigroup $\mathbb{T}^{\rm opt}$ on X such that (3.4) holds. Let Ψ and $\mathbb{F}$ be the operators from (2.7) and $\mathbf{F}^{\rm opt}$ the operator from (3.12). Using the operator Φ_τ from (2.2), we rewrite (3.4):

$$\mathbb{T}^{\rm opt}_\tau x_0 \,=\, \mathbb{T}_\tau x_0 + \Phi_\tau u^{\rm opt} \,. \tag{5.2}$$

We define $\Psi^{\rm opt} = \Psi + \mathbb{F}\mathbf{F}^{\rm opt}$, so that

$$\Psi^{\rm opt} x_0 \,=\, \Psi x_0 + \mathbb{F} u^{\rm opt} \tag{5.3}$$

($\Psi^{\rm opt} x_0$ is the output function of the optimally controlled system).

We claim that $\Psi^{\rm opt}$ is an extended output map for $\mathbb{T}^{\rm opt}$, i.e.,

$$\mathbf{S}^*_\tau \Psi^{\rm opt} \,=\, \Psi^{\rm opt} \mathbb{T}^{\rm opt}_\tau \qquad \forall\, \tau \geq 0 \,, \tag{5.4}$$

as explained in section 2. Indeed, from (5.3), (2.8), and (5.2) we see that

$$\begin{aligned} \mathbf{S}^*_\tau \Psi^{\rm opt} x_0 \;&=\; \mathbf{S}^*_\tau \Psi x_0 + \mathbf{S}^*_\tau \mathbb{F} u^{\rm opt} \\ &=\; \Psi\, \mathbb{T}_\tau x_0 + \Psi \Phi_\tau u^{\rm opt} + \mathbb{F}\, \mathbf{S}^*_\tau u^{\rm opt} \\ &=\; \Psi\, \mathbb{T}^{\rm opt}_\tau x_0 + \mathbb{F}\, \mathbf{S}^*_\tau \mathbf{F}^{\rm opt} x_0 \,. \end{aligned}$$

We know that $\mathbf{F}^{\rm opt}$ is an extended output map for $\mathbb{T}^{\rm opt}$, i.e.,

$$\mathbf{S}^*_\tau \mathbf{F}^{\rm opt} \,=\, \mathbf{F}^{\rm opt} \mathbb{T}^{\rm opt}_\tau \qquad \forall\, \tau \geq 0 \,.$$

Substituting this into the previous formula, we get

$$\mathbf{S}^*_\tau \Psi^{\rm opt} x_0 \,=\, \left(\Psi + \mathbb{F}\mathbf{F}^{\rm opt} \right) \mathbb{T}^{\rm opt}_\tau x_0 \,.$$

Now by the definition of Ψ^{opt} we obtain that (5.4) holds.

By the representation theorem for extended output maps (explained in section 2), there is an operator $C^{\mathrm{opt}}:\mathcal{D}(A^{\mathrm{opt}})\to Y$ with

$$(\Psi^{\mathrm{opt}}x_0)(t) = C^{\mathrm{opt}}\mathbb{T}_t^{\mathrm{opt}}x_0 \qquad \forall\, x_0\in\mathcal{D}(A^{\mathrm{opt}})\,.$$

Applying the Laplace transformation to (5.3) and using (2.5) and (3.9), we get

$$C^{\mathrm{opt}}(sI-A^{\mathrm{opt}})^{-1} = C(sI-A)^{-1} + \mathbf{G}(s)F^{\mathrm{opt}}(sI-A^{\mathrm{opt}})^{-1}\,. \tag{5.5}$$

According to Proposition 3.4, F^{opt} (like C^{opt}) is an admissible observation operator for $\mathbb{T}^{\mathrm{opt}}$. Moreover, according to Proposition 3.3, $\mathbb{T}^{\mathrm{opt}}$ is exponentially stable. This implies (see, e.g., Weiss [38]) that

$$F^{\mathrm{opt}}(sI-A^{\mathrm{opt}})^{-1}\in H^\infty\,, \qquad C^{\mathrm{opt}}(sI-A^{\mathrm{opt}})^{-1}\in H^\infty\,.$$

Using this and property (3) in the theorem, we conclude from (5.5) that $C(sI-A)^{-1}\in H^\infty$. By Proposition 5.2, A is exponentially stable. □

We make a remark about the particular case when Σ is regular, with feedthrough operator D. Then from (5.1) and (2.10) we see that $\mathcal{D}(A^{\mathrm{opt}})\subset\mathcal{D}(C_\Lambda)$ and

$$C_\Lambda(sI-A^{\mathrm{opt}})^{-1} - C(sI-A)^{-1} = [\mathbf{G}(s)-D]\,F^{\mathrm{opt}}(sI-A^{\mathrm{opt}})^{-1}\,.$$

Comparing this with (5.5), we conclude that

$$C^{\mathrm{opt}}z = (C_\Lambda + DF^{\mathrm{opt}})z \qquad \forall\, z\in\mathcal{D}(A^{\mathrm{opt}})\,.$$

We introduce two more concepts. We say that (A,C) is *exactly observable* if (A^*,C^*) is exactly controllable. It is clear that if (A,C) is exactly observable, then it is also estimatable. We say that a transfer function $\mathbf{G}$ is in H^∞_α (with $\alpha\in\mathbb{R}$) if $\mathbf{G}$ is bounded (and analytic) on the half-plane where Re $s>\alpha$.

COROLLARY 5.4. *Let Σ, A, B, C, and $\mathbf{G}$ be as in Theorem 5.3 and let $\mathbb{T}$ be the semigroup of Σ. If (A,B) is exactly controllable, (A,C) is exactly observable and if $\mathbf{G}\in H^\infty_\alpha$, then there exist $\beta<\alpha$ and $M\geq 1$ such that*

$$\|\mathbb{T}_t\| \leq M\,e^{\beta t} \qquad \forall\, t\geq 0\,. \tag{5.6}$$

Proof. Introduce the "shifted" well-posed linear system Σ^α with semigroup generator $A-\alpha I$, control operator B, observation operator C, and transfer function $\mathbf{G}^\alpha(s)=\mathbf{G}(s+\alpha)$. This system is again exactly controllable and exactly observable, so that it is optimizable and estimatable. Its transfer function is in H^∞, so that by Theorem 5.3, $A-\alpha I$ is exponentially stable. This is equivalent to (5.6). □

Finally, we give a proposition which is related to Proposition 5.2. For this, we need the following concept: C is called *infinite-time admissible* for $\mathbb{T}$ if it is possible to take $T=\infty$ in (2.3). For a detailed discussion of this concept (e.g., its relation to Lyapunov equations) we refer to Grabowski and Callier [14] and to Hansen and Weiss [15]. Recall that, according to the notation used in this section, C is an admissible observation operator for $\mathbb{T}$, the semigroup generated by A.

PROPOSITION 5.5. *The following two statements are equivalent:*

(a) *(A,C) is estimatable and C is infinite-time admissible for $\mathbb{T}$,*

(b) *A is exponentially stable.*

Proof. It is clear that (b) imples (a). Conversely, if C is infinite-time admissible, then for every $x_0\in X$, $C(sI-A)^{-1}x_0$ is in the Hardy space H^2 (since it is the Laplace transform of a function in L^2). Since (A, C) is estimatable, Proposition 4.4 applies and, in particular, the formula (4.13) from its proof holds. Since A_d^{opt} is exponentially stable, we have that $(sI - A_d^{\text{opt}})^{-1} H^{\text{opt}} \in H^\infty$. This implies that the right-hand side of (4.13) is in H^2. On the left-hand side, $(sI - A_d^{\text{opt}})^{-1} x_0$ is in H^2, so that $(sI - A)^{-1} x_0$ must also be in H^2. Thus, the trajectories of $\mathbb{T}$ are in L^2. By a well-known proposition of Datko, $\mathbb{T}$ is exponentially stable. □

We leave it to the reader to formulate the dual version of this proposition.

6. Dynamic stabilization. In the first part of this section we prove that optimizability and estimatability are invariant under feedback. In what follows, U, X, Y, and R are Hilbert spaces.

LEMMA 6.1. *Let A be the generator of a strongly continuous semigroup $\mathbb{T}$ on X and let $B \in \mathcal{L}(U, X_{-1})$ be an admissible control operator for $\mathbb{T}$. Assume that $x_0 \in X$ and $u \in L^2([0,\infty), U)$ are such that $x \in L^2([0,\infty), X)$, where x is the state trajectory defined by* (3.1). *Then for every $\tau > 0$, we have that*

$$\sum_{n=1}^{\infty} \|x(n\tau)\|^2 < \infty .$$

Proof. We define the sequences $u_n \in L^2([0,\tau], U)$ and $x_n \in L^2([0,\tau], X)$ by $u_n(t) = u((n-1)\tau + t)$ and $x_n(t) = x((n-1)\tau + t)$, so that the sequences $\|u_n\|$ and $\|x_n\|$ are square summable. Using the notation from (2.2) and (2.6), we have that for every $n \in \mathbb{N}$ and every $t \in [0,\tau]$,

$$x(n\tau) = \mathbb{T}_t x_n(\tau - t) + \Phi_t \mathbf{S}^*_{\tau - t} u_n .$$

Denoting $m_1 = \sup_{t\in[0,\tau]} \|\mathbb{T}_t\|$ and $m_2 = \|\Phi_\tau\|$ (so that $\|\Phi_t\| \le m_2$ for all $t \in [0,\tau]$), we have that

$$\|x(n\tau)\| \le m_1 \|x_n(\tau - t)\| + m_2 \|u_n\| ,$$

so that, denoting $m = m_1^2 + m_2^2$, $\|x(n\tau)\|^2 \le m \left(\|x_n(\tau - t)\|^2 + \|u_n\|^2\right)$. Integrating this inequality with respect to $t \in [0,\tau]$, we obtain

$$\tau \|x(n\tau)\|^2 \le m \|x_n\|^2 + m\tau \|u_n\|^2 .$$

This shows that the sequence $\|x(n\tau)\|$ is square summable. □

LEMMA 6.2. *Let Σ be a well-posed linear system with input space U, state space X, and output space Y. We denote by $\mathbb{T}$ the semigroup of Σ and by B its control operator. Assume that $x_0 \in X$ and $u \in L^2([0,\infty), U)$ are such that $x \in L^2([0,\infty), X)$, where x is the state trajectory defined by* (3.1). *Let y be the corresponding output function, given by* (2.7). *Then $y \in L^2([0,\infty), Y)$.*

Proof. Take $\tau > 0$. We define the sequences $u_n \in L^2([0,\tau], U)$ and $y_n \in L^2([0,\tau], Y)$ by $u_n(t) = u((n-1)\tau + t)$ and $y_n(t) = y((n-1)\tau + t)$. We denote by $\mathbf{P}_\tau$ the projection from $L^2_{loc}([0,\infty), Y)$ to $L^2([0,\tau], Y)$ (by truncation). It follows from (2.9) that (with the notation from (2.7))

$$y_n = \mathbf{P}_\tau \Psi x((n-1)\tau) + \mathbf{P}_\tau \mathbb{F} u_n .$$

Since $\mathbf{P}_\tau \Psi$ and $\mathbf{P}_\tau \mathbb{F}$ are bounded operators, there is a $k > 0$ such that

$$\|y_n\| \le k \left(\|x((n-1)\tau)\| + \|u_n\|\right) .$$

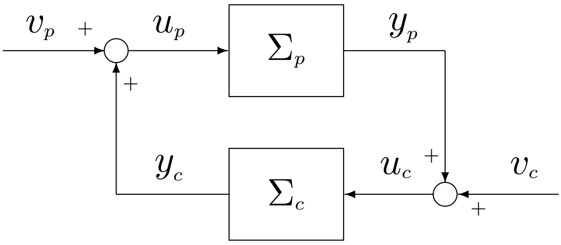

FIG. 3. *A plant Σ_p with a stabilizing controller Σ_c. The closed-loop system is well-posed and exponentially stable.*

By the assumption and by Lemma 6.1, both sequences $\|u_n\|$ and $\|x((n-1)\tau)\|$ are square summable, so that $\|y_n\|$ is square summable. □

THEOREM 6.3. *Let Σ be a well-posed linear system, let K be an admissible feedback operator for Σ, and let Σ^K be the corresponding closed-loop system (see Figure* 1*). We denote by A the semigroup generator of Σ, by B the control operator of Σ, and by C the observation operator of Σ. We denote by A^K, B^K, and C^K the corresponding operators for Σ^K. Then the following holds:*

(a) *(A, B) is optimizable if and only if (A^K, B^K) is optimizable.*

(b) *(A, C) is estimatable if and only if (A^K, C^K) is estimatable.*

Proof. We denote by U, X, and Y the input, state, and output space of Σ (and also of Σ^K). First we prove statement (a). Suppose that (A^K, B^K) is optimizable, let $x_0 \in X$ be an initial state for Σ^K, and let $v \in L^2([0,\infty), U)$ be an input function which causes the state trajectory of Σ^K to be in $L^2([0,\infty), X)$. Let y be the corresponding output function of Σ^K. We know from Lemma 6.2 that $y \in L^2([0,\infty), Y)$. If u is the corresponding input function of Σ (which causes the same state trajectory and the same output function in Σ) then $u = v + Ky$ (see Figure 1). Thus, $u \in L^2([0,\infty), U)$, so that (A, B) is optimizable. To prove the converse direction, assuming that (A, B) is optimizable, we follow the same argument but we regard Σ as a closed-loop system obtained from Σ^K via the output feedback through $-K$.

Now we prove statement (b). We introduce the dual systems Σ^d and Σ^{Kd} (see section 6 of [41] or [39]). Then Σ^{Kd} is the closed-loop system obtained from Σ^d via the output feedback K^*. The semigroup generator of Σ^d is A^*, its control operator is C^*, and its observation operator is B^*. A similar characterization applies to Σ^{Kd}. Now statement (b) is equivalent to statement (a) applied to these dual systems. □

We mention that, with the notation of the last theorem, for every $x_0 \in \mathcal{D}(A^K)$ and for every $z_0 \in \mathcal{D}(A)$,

$$A^K x_0 = \left(A + BKC^K\right) x_0\,, \qquad A z_0 = \left(A^K - B^K KC\right) z_0\,.$$

For the proof of these formulas and for further details we refer to [37].

We say that a well-posed linear system is *optimizable* if the corresponding pair (A, B) is optimizable. The meaning of a system being *estimatable* is similar.

Let Σ_p be a well-posed linear system. A *stabilizing controller* for Σ_p is another well-posed linear system Σ_c such that the interconnection shown in Figure 3 is well-posed and the closed-loop system is exponentially stable. The input signals of the closed-loop system are v_p and v_c and the output signals are y_p and y_c.

This is the framework for dynamic stabilization in Chapters 4, 5, and 9 of Curtain and Zwart [12] and many earlier references, where the systems are assumed to have bounded B and C operators. A rather different concept of dynamic control can be found in Russell [25], to model “indirect damping.” The original system (more precisely, its semigroup generator) is embedded in (the semigroup generator of) a larger, coupled system. The input and output signals are not restricted to be in L^2_{loc}, like they are in our framework. This approach is applied in [25] to modelling thermal effects in vibrating systems.

The concept of a stabilizing controller as in Figure 3, while much used and intuitively appealing, is too narrow: it does not admit all the observer-based controllers for Σ_p, and the Youla parametrization of such stabilizing controllers is not clean, requiring extra invertibility and well-posedness conditions. This is the case even for finite-dimensional plants Σ_p if they are not strictly proper. To overcome these difficulties, the following generalization was introduced in Weiss and Curtain [40] (and was further investigated in Curtain, Weiss, and Weiss [10] and [11]).

A *stabilizing controller with internal loop* for Σ_p is a well-posed linear system Σ_k with two inputs and two outputs such that the interconnection shown in Figure 4 is a well-posed linear system $\Sigma_{p,k}$ and this system is exponentially stable. The inputs of the *closed-loop system* $\Sigma_{p,k}$ are the three external signals going to the summation points, and the outputs are the outputs of the two subsystems.

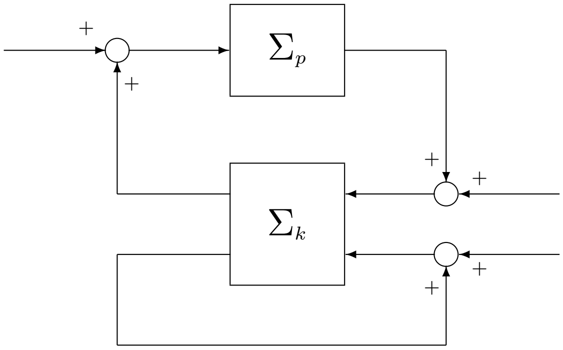

FIG. 4. *A plant Σ_p with a stabilizing controller with internal loop Σ_k. Again, the closed-loop system is well-posed and exponentially stable. Closing only one of the two loops may lead to a non-well-posed system.*

Each of the signals in Figure 4 may be Hilbert space-valued, of course. The lower loop in Figure 4 is referred to as the *internal loop* of the controller. Closing only one of the two loops may lead to a non-well-posed system. Thus, in particular, it may be impossible to close the internal loop in the absence of the plant Σ_p, in which case the controller with internal loop cannot be reduced to a usual stabilizing controller (as in Figure 3). Examples for this are given in section 6 of [40]. However, every stabilizing controller can be thought of as a stabilizing controller with internal loop (with no signal in the internal loop). We say that Σ_p is *dynamically stabilizable* if there exists a stabilizing controller with internal loop for Σ_p. Broadly speaking, Σ_p is dynamically stabilizable if it can be made into a subsystem of a stable system.

In Proposition 5.3 of [40], a list of three conditions were given which imply dynamic stabilizability for a regular linear system (a design procedure for Σ_k was also provided). The first two of these conditions are stabilizability and detectability. We do not know if these two conditions alone imply dynamic stabilizability, and we also do not know if dynamic stabilizability implies stabilizability and detectability. Some of the results from [40] were generalized to well-posed linear systems by Staffans [30].

For systems with bounded B and C, dynamic stabilizability is equivalent to stabilizability by a bounded F and detectability by a bounded H (see Exercise 6.13 in

Curtain and Zwart [12]) and no internal loop is needed in this case. For systems with bounded control and observation operators, stabilizability and detectability in the general sense which we are using are equivalent to stabilizability and detectability in the more restrictive sense of [12], i.e., with bounded F and H. This follows from the results in section 3 (in particular, formula (3.5)) and duality.

Now we look at dynamic stabilization from the point of view of transfer functions. We denote by $\mathbf{P}$ the transfer function of the plant Σ_p and by $\mathbf{K}$ the transfer function of the controller Σ_k. Thus, if the input and output spaces of Σ_p are U and Y, then $\mathbf{P}(s) \in \mathcal{L}(U, Y)$. We denote by R the Hilbert space where the signal of the internal loop takes values, so that $\mathbf{K} \in \mathcal{L}(Y \times R, U \times R)$. $\mathbf{K}$ is naturally partitioned into $\mathbf{K}_{11}$, $\mathbf{K}_{12}$, $\mathbf{K}_{21}$, and $\mathbf{K}_{22}$. We introduce Σ_l, the *parallel connection* of Σ_p and Σ_k, which is a well-posed linear system with two components, Σ_p and Σ_k, operating independently (see also section 4 of [40]). The transfer function of Σ_l is

$$\mathbf{L} = \begin{bmatrix} 0 & \mathbf{K}_{11} & \mathbf{K}_{12} \\ \mathbf{P} & 0 & 0 \\ 0 & \mathbf{K}_{21} & \mathbf{K}_{22} \end{bmatrix}. \tag{6.1}$$

The closed-loop system $\Sigma_{p,k}$ from Figure 4 is obtained from Σ_l via the output feedback operator I (acting on $U \times Y \times R$). Thus, its transfer function is $\mathbf{L}(I - \mathbf{L})^{-1} = (I - \mathbf{L})^{-1} - I$. The following result, a restatement of Theorem 1.2, is a strengthened version of Proposition 4.11 from [40]. (By this we mean that the result in [40] is an immediate consequence of the theorem below, but not conversely.)

THEOREM 6.4. *Let Σ_p and Σ_k be well-posed linear systems, with transfer functions $\mathbf{P}$ and $\mathbf{K}$, such that $\mathbf{P}(s) \in \mathcal{L}(U, Y)$ and $\mathbf{K}(s) \in \mathcal{L}(Y \times R, U \times R)$. After a proper partitioning of $\mathbf{K}$, we define $\mathbf{L}$ by* (6.1). *Then Σ_k is a stabilizing controller with internal loop for Σ_p if and only if the following two conditions hold:*

(1) *Both Σ_p and Σ_k are optimizable and estimatable.*

(2) *$(I - \mathbf{L})^{-1} \in H^\infty$ (i.e., the closed-loop system is input-output stable).*

Proof. First assume that Σ_k is a stabilizing controller with internal loop for Σ_p, i.e., the closed-loop system $\Sigma_{p,k}$ from Figure 4 is exponentially stable. As explained earlier, its transfer function is $(I - \mathbf{L})^{-1} - I$. Since exponential stability implies input-output stability, we have that $(I - \mathbf{L})^{-1} \in H^\infty$. The system $\Sigma_{p,k}$ is obtained from the parallel connection Σ_l (introduced before (6.1)) via the output feedback operator I. Since $\Sigma_{p,k}$ is obviously optimizable and estimatable, by Theorem 6.3 these properties are shared also by Σ_l. Because of the nature of Σ_l, this implies that Σ_p and Σ_k are optimizable and estimatable.

Conversely, assume that (1) and (2) hold. Then (1) implies that Σ_l is optimizable and estimatable. By Theorem 6.3, $\Sigma_{p,k}$ is also optimizable and estimatable. By (2), $\Sigma_{p,k}$ is input-output stable. By Theorem 5.3, $\Sigma_{p,k}$ is exponentially stable. □

REMARK 4. *It follows from Theorems* 5.3 *and* 6.4 *that a well-posed linear system is exponentially stable if and only if it is dynamically stabilizable and input-output stable. This is stated in Corollary* 1.3 *and it will be useful in the examples in section* 7. *Hence, if an unstable system (i.e., one that is not exponentially stable) has its transfer function in H^∞, then it cannot be dynamically stabilizable.*

REMARK 5. *If for some $\alpha \geq 0$ we have that $\mathbf{G} \in H^\infty_\alpha$ (defined in section* 5*), but for all $\varepsilon > 0$, $\mathbf{G}$ cannot be extended to a function in $H^\infty_{\alpha-\varepsilon}$, then any system with transfer function $\mathbf{G}$ is not dynamically stabilizable. For $\alpha = 0$, the proof goes as follows: If a system Σ with transfer function $\mathbf{G}$ were dynamically stabilizable, then by Theorem* 6.4 *it would be optimizable and estimatable. Now Theorem* 5.3 *would imply* *that Σ is exponentially stable, and this would imply (see* [36]*) that $\mathbf{G} \in H^\infty_{-\varepsilon}$ for some $\varepsilon > 0$. To extend this argument to $\alpha > 0$, we have to use shifted systems, as in the proof of Corollary* 5.4*. For example, a system whose transfer function is $e^{-\frac{1}{s}}$, or a Blaschke product with zeros arbitrarily close to the imaginary axis (as described at the end of section* 1*), cannot be dynamically stabilizable.*

7. Examples.

Example 1. In this example we illustrate Corollary 1.3 (Remark 4) with two results about a model for elastic structure/acoustics interaction. These results are improvements on results in Avalos, Lasiecka, and Rebarber [2].

Let Ω be either a rectangular region in $\mathbb{R}^2$ or a region in $\mathbb{R}^2$ with Lipschitz boundary Γ. Let Γ_0 be a smooth (C^2) segment of Γ with endpoints a and b, called the active boundary. Let $z = z(t,\zeta)$ for $t \in [0,\infty)$ and $\zeta \in \Omega$, let $v = v(t,\xi)$ for $t \in [0,\infty)$ and $\xi \in \Gamma_0$, and let $\partial/\partial\nu$ denote the outward normal derivative to Γ. Let $U = \mathbb{R}^r$ and $\mathcal{B} \in \mathcal{L}(U, H^{-\alpha}(\Gamma_0))$, where $\alpha = 7/4$ when Ω is rectangular, and $\alpha = 5/3$ when Ω has a smooth boundary. In applications Ω is a cross section of an acoustic cavity, z is the acoustic velocity potential, and v is the normal displacement of the active wall. The following model has been studied extensively in recent years—see Banks and Smith [6] for a discussion of the modelling:

$$\begin{aligned} z_{tt} &= \Delta z \quad \text{on } [0,\infty)\times\Omega\,,\\ \frac{\partial z}{\partial\nu} &= v_t \quad \text{on } [0,\infty)\times\Gamma_0\,,\\ \frac{\partial z}{\partial\nu} &= 0 \quad \text{on } [0,\infty)\times\Gamma\setminus\Gamma_0\,,\\ v_{tt} &= -\Delta^2 v - \Delta^2 v_t - z_t + \mathcal{B}u \quad \text{on } [0,\infty)\times\Gamma_0\,,\\ v(a,t) = v(b,t) &= v_x(a,t) = v_x(b,t) = 0 \quad \text{for } t\in[0,\infty)\,. \end{aligned} \tag{7.1}$$

We consider three natural quantities that can be observed for (7.1): the active boundary displacement v, the active boundary velocity v_t, and the acoustic velocity z_t, which is proportional to the acoustic pressure. The observation of these quantities is typically taken at points on Γ_0 for v and v_t, and at points in $\overline{\Omega}$ for z_t. The output signal may be a vector of such measurements.

Define the state space

$$X := H^1(\Omega)/\mathbb{R} \times L^2(\Omega)/\mathbb{R} \times H^2_0(\Gamma_0) \times L^2(\Gamma_0),$$

where $H^r(\Omega)/\mathbb{R} = \{f \in H^r(\Omega) \mid \int_\Omega f\,dx = 0\}$ for $r > 0$. Letting

$$x(t) = [z(t,\cdot), z_t(t,\cdot), v(t,\cdot), v_t(t,\cdot)]^T,$$

it is shown in Avalos and Lasiecka [1] that (7.1) can be put in the form

$$\dot{x}(t) = Ax(t) + Bu(t).$$

Here, A generates a strongly stable but not exponentially stable semigroup $\mathbb{T}$ on X, and B is an admissible control operator for $\mathbb{T}$. If $Y = \mathbb{R}^{k+j}$ and

$$y(t) = C_1 x(t) := [v(\alpha_1),\ldots,v(\alpha_j), v_t(\beta_1),\ldots,v_t(\beta_k)]^T \tag{7.2}$$

with $\alpha_i, \beta_i \in \Gamma_0$, then it is shown in [2] that (7.1), (7.2) is a regular linear system with feedthrough operator 0. In Theorem 5.9 of [2] it is shown that if there exists a stabilizing controller for (7.1), (7.2), then the stabilization is not robust with respect to delays in the feedback loop. In this context, when we say that stabilization is "not robust with respect to delays," we mean that there exist sequences $\{\varepsilon_n\}$ and $\{p_n\}$, with $\varepsilon_n > 0$, $\varepsilon_n \to 0$, and $p_n \in \mathbb{C}_0$ such that if a delay of length ε_n is introduced into the feedback loop, then the closed-loop transfer function has a pole at p_n; for details see [2] or Logemann, Rebarber, and Weiss [18]. This result in [2] uses Remark 4 from this paper, and "stabilizing controller" can be easily replaced with the more general "stabilizing controller with internal loop."

In Remark 5.11 of [2] it is mentioned that it might not even be possible to dynamically stabilize (7.1), (7.2). Using a recent result from Avalos, Lasiecka, and Rebarber [4], we prove that this lack of stabilization is indeed the case.

THEOREM 7.1. *Let* $Y = H_0^2(\Gamma_0) \times H_0^2(\Gamma_0)$ *and define the observation*

$$y(t) = [\,v(t),\, v_t(t)\,]^T . \tag{7.3}$$

Then (7.1)*,* (7.3) *cannot be dynamically stabilized.*

Proof. It is shown in [4] that if the initial state for (7.1) is zero, then there exists an $M > 0$ such that

$$\int_0^\infty \left(\|v(t,\cdot)\|^2_{H_0^2(\Gamma_0)} + \|v_t(t,\cdot)\|^2_{H_0^2(\Gamma_0)} \right) dt \le M \int_0^\infty \|u(t)\|_U^2 \, dt.$$

Hence (7.1), (7.3) is input-output stable. Since $\mathbb{T}$ is not exponentially stable, by Remark 4 this system is not dynamically stabilizable. □

COROLLARY 7.2. *The system* (7.1)*,* (7.2) *is not dynamically stabilizable.*

Proof. Clearly, the output signal in (7.2) is obtained by applying a (static) bounded operator to y from (7.3). Using Theorem 7.1, we see that (7.1), (7.2) is not dynamically stabilizable. □

Since it is impossible to stabilize (7.1) with observations taken only along the beam component, we turn our attention to output signals which include point observations of the acoustic pressure. Let $Y = \mathbb{R}^{j+k+l}$ and

$$C_2 x(t) = [v(\alpha_1), \ldots, v(\alpha_j), v_t(\beta_1), \ldots, v_t(\beta_k), z_t(\zeta_i), \ldots, z_t(\zeta_l)]^T \tag{7.4}$$

for $\alpha_i, \beta_i \in \Gamma_0$, and $\zeta_i \in \overline{\Omega}$. It is easy to verify that C_2 is not admissible for $\mathbb{T}$ when the state space is X, and for this reason, in [2] the lack-of-robustness result was only given in the input-output setting. In particular, it was shown that if the open-loop transfer function for (7.1), (7.4) is not stable, and there exists a controller (without internal loop) which input-output stabilizes (7.1), (7.4), then this stabilization is not robust with respect to delays—see Theorem 5.12 in [2] for details. Using recent results from Avalos, Lasiecka, and Rebarber [3], we can put this lack of robustness into a state space setting. We use the following result, which also appears in a slightly less general form in [2] (where it was also a corollary of Remark 4).

COROLLARY 7.3. *Suppose that* Σ_p *is a regular linear system with semigroup generator* A*, input space* U *and output space* Y*,* U*, and* Y *are finite-dimensional,* $\sigma(A)$ *is contained in the open left half-plane but* A *is not exponentially stable.*

If there exists a regular stabilizing controller Σ_c *for* Σ_p *(as in Figure* 3*), then the stability of the closed-loop system is not robust with respect to delays.*

Proof. Remark 4 shows that if there exists a stabilizing controller for Σ_p, then $\mathbf{P}$ is unbounded on $\mathbb{C}_0$, where $\mathbf{P}$ is the transfer function of Σ_p. Since $(sI - A)^{-1}$ is analytic on a set containing the closed right half-plane, the same is true for $\mathbf{P}$, in particular, $\mathbf{P}$ is continuous on the closed right half-plane. This, together with its unboundedness implies that

$$\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} \|\mathbf{P}(s)\|_{\mathcal{L}(X)} = \infty .$$

Now we can apply Theorem 8.5 from [18] to conclude that if the closed-loop system is stable, then its stability is not robust with respect to delays. $\Box$

REMARK 6. *If the feedthrough operator of Σ_p is zero, then Corollary* 7.3 *is true even if Σ_c is not regular. This is because* $\mathbf{PC}$ *will still be regular, where* $\mathbf{C}$ *is the transfer function of Σ_c.*

In [2] this result was not applied to (7.1), (7.4) because at the time that paper was written no natural state space was identified for this system. In Avalos, Lasiecka, and Rebarber [3] a state space is given so that the natural (A, B, C) representation for (7.1), (7.4) is a regular system. This state space is

$$X := \left\{ [z_0, z_1, v_0, v_1] \in \frac{H^{\frac{3}{2}}(\Omega)}{\mathbb{R}} \times \frac{H^{\frac{1}{2}}(\Omega)}{\mathbb{R}} \times H_0^2(\Gamma_0) \times L^2(\Gamma_0), \;\middle|\; z_0 - Nv_1 \in \mathcal{H} \right\},$$

where N is the Neumann map and

$$\mathcal{H} = \left\{ f \in \frac{H^{\frac{3}{2}}(\Omega)}{\mathbb{R}} \;\middle|\; \nabla f \in L^2_{-\frac{1}{2}}(\Omega) \right\}.$$

Here, $L^2_{-\frac{1}{2}}(\Omega)$ denotes the space of functions h on Ω such that $h\varrho^{-\frac{1}{2}} \in L^2(\Omega)$, with $\varrho(x)$ being the distance from x to Γ; see [3] for details.

We can apply Corollary 7.3 to (7.1), (7.4) to conclude the following.

COROLLARY 7.4. *Suppose Σ_p is stabilized (in the state space X given above) by a stabilizing controller Σ_c. Then this stability is not robust with respect to delays.*

Example 2. We consider the linear infinite-dimensional system described by the wave equation on an n-dimensional domain, with mixed boundary control and mixed boundary observation. The bounded domain $\Omega \subset \mathbb{R}^n$ is assumed to have a C^2 boundary Γ, and Ω is locally on one side of Γ. Γ_0 and Γ_1 are nonempty open subsets of Γ such that $\Gamma_0 \cap \Gamma_1 = \emptyset$ and $\overline{\Gamma_0 \cup \Gamma_1} = \Gamma$. We denote by x the space variable $(x \in \Omega)$. The equations of the system are

$$\left\{ \begin{array}{ll} w_{tt}(x,t) = \Delta w(x,t) & \text{on } \Omega \times [0,\infty), \\ w(x,t) = 0 & \text{on } \Gamma_0 \times [0,\infty), \\ \frac{\partial}{\partial\nu} w(x,t) + w_t(x,t) = u(x,t) & \text{on } \Gamma_1 \times [0,\infty), \\ \frac{\partial}{\partial\nu} w(x,t) - w_t(x,t) = y(x,t) & \text{on } \Gamma_1 \times [0,\infty), \\ w(x,0) = w_1(x), \; w_t(x,0) = w_2(x) & \text{on } \Omega, \end{array} \right. \tag{7.5}$$

where u is the input function, and y is the output function. The functions w_1 and w_2 are the initial state of the system. The part Γ_0 of the boundary is just reflecting waves, while the active portion Γ_1 is where both the observation and the control take place. We shall often write $w(t)$ to denote a function of x, meaning that $w(t)(x) = w(x,t)$, and similarly for other functions. The state of the system is

$$z(t) = \begin{bmatrix} w(t) \\ \dot{w}(t) \end{bmatrix}.$$

We introduce the input space U and the state space X by

$$U = L^2(\Gamma_1), \qquad X = H^1_{\Gamma_0}(\Omega) \times L^2(\Omega), \tag{7.6}$$

where $H^1_{\Gamma_0}(\Omega) = \{v \in H^1(\Omega) \mid v|_{\Gamma_0} = 0\}$. The output space is also U. The norm on X is defined by

$$\left\| \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} \right\|_X^2 = 2\, \|\nabla w_1\|^2_{L^2(\Omega)} + 2\, \|w_2\|^2_{L^2(\Omega)}. \tag{7.7}$$

The equations (7.5) are well-posed, i.e., they determine a well-posed linear system Σ with the input, state, and output spaces indicated. This can be shown using the general theory of well-posed boundary control systems as developed in Salamon [28]. This well-posedness result, formulated in a different terminology (and for a different but closely related system) is due to Rodriguez-Bernal and Zuazua [24].

The above system is studied in detail in Avalos and Weiss [5], which contains also the proofs of all the other claims that we make in this example. An important fact is that Σ is *conservative.* This means that for every $\tau > 0$,

$$\|z(\tau)\|^2 + \int_0^\tau \|y(t)\|^2\, dt = \|z(0)\|^2 + \int_0^\tau \|u(t)\|^2\, dt, \tag{7.8}$$

and a similar equality holds for the dual system. We may think of u as the "incoming wave" (which brings energy into the system) and of y as the "outgoing wave."

We now introduce several spaces and operators, mainly following Triggiani [32]. More related information can be found in Rodriguez-Bernal and Zuazua [24]. We define the self-adjoint and positive $\Lambda : D(\Lambda) \subset L^2(\Omega) \rightarrow L^2(\Omega)$ by

$$\Lambda w = -\Delta w, \quad D(\Lambda) = \left\{ w \in H^2(\Omega) \;\middle|\; w|_{\Gamma_0} = 0,\ \frac{\partial}{\partial \nu} w|_{\Gamma_1} = 0 \right\}.$$

Then Λ is boundedly invertible and $D(\Lambda^{\frac{1}{2}}) = H^1_{\Gamma_0}(\Omega)$. From Green's theorem and continuous extension we have the middle equality in

$$\|w\|^2_{H^1_{\Gamma_0}(\Omega)} = \int_\Omega |\nabla w|^2 dx = \left\| \Lambda^{\frac{1}{2}} w \right\|^2_{L^2(\Omega)} = \|w\|^2_{D(\Lambda^{\frac{1}{2}})}.$$

The other two equalities above hold by definition. We denote by $H^{-1}_{\Gamma_0}(\Omega)$ the dual of $H^1_{\Gamma_0}$ with respect to the pivot space $L^2(\Omega)$. Then Λ has an extension to a bounded operator $\Lambda : H^1_{\Gamma_0}(\Omega) \rightarrow H^{-1}_{\Gamma_0}(\Omega)$.

We define the Neumann map $N : L^2(\Gamma_1) \rightarrow L^2(\Omega)$ by $Nf = g$ if and only if

$$\Delta g = 0, \quad g|_{\Gamma_0} = 0, \quad \frac{\partial}{\partial \nu} g|_{\Gamma_1} = f.$$

By elliptic theory we have that $N \in \mathcal{L}(L^2(\Gamma_1), H^1_{\Gamma_0}(\Omega))$.

The Dirichlet trace γ_0 satisfies for any continuous function f on Ω

$$\gamma_0 f = f|_{\Gamma_1}.$$

After continuous extension we have that $\gamma_0 \in \mathcal{L}(H^1(\Omega), H^{\frac{1}{2}}(\Gamma_1))$.

The Neumann trace γ_1 satisfies for any C^1 function f on Ω

$$\gamma_1 f = \frac{\partial}{\partial \nu} f|_{\Gamma_1}.$$

Thus, γ_1 is the outward normal derivative restricted to Γ_1. We extend γ_1 to the space of all functions $w \in H^1_{\Gamma_0}(\Omega)$ which satisfy $\Delta w \in L^2(\Omega)$, and then $\gamma_1 w \in H^{-\frac{1}{2}}(\Gamma_1)$. By Green's theorem and by continuous extension, we have that for all $w \in D(\Lambda^{\frac{1}{2}})$,

$$N^*\Lambda w = w|_{\Gamma_1} = \gamma_0 w. \tag{7.9}$$

We define $A : D(A) \subset X \to X$ by

$$A = \begin{bmatrix} 0 & I \\ -\Lambda & -\Lambda N N^* \Lambda \end{bmatrix},$$

$$D(A) = \left\{ \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} \in \begin{matrix} D(\Lambda^{\frac{1}{2}}) \\ \times \\ D(\Lambda^{\frac{1}{2}}) \end{matrix} \;\middle|\; w_1 + NN^*\Lambda w_2 \in D(\Lambda) \right\}.$$

Note that we have the equivalent characterization

$$A \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} w_2 \\ \Delta w_1 \end{bmatrix}, \tag{7.10}$$

$$D(A) = \left\{ \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} \in \begin{matrix} H^1_{\Gamma_0} \\ \times \\ H^1_{\Gamma_0} \end{matrix} \;\middle|\; \begin{matrix} \Delta w_1 \in L^2(\Omega) \\ \\ \gamma_1 w_1 + \gamma_0 w_2 = 0 \end{matrix} \right\}. \tag{7.11}$$

Then A generates a strongly continuous semigroup of contractions on X, which we denote by $\mathbb{T}$. The resolvent of A is compact and $\sigma(A)$ is in the open left half-plane. All these facts about A are proved in [32] and in [24], which also contain relevant earlier references. This A is the semigroup generator of the system Σ.

The control operator B and the observation operator C of Σ are given by

$$B = \begin{bmatrix} 0 \\ \Lambda N \end{bmatrix} \qquad \text{and} \qquad C = \frac{1}{\sqrt{2}} \begin{bmatrix} \gamma_1 & -\gamma_0 \end{bmatrix}.$$

This is proved in Avalos and Weiss [5]. It follows from (7.9) and (7.11) that C can be rewritten in the form $C = \begin{bmatrix} 0 & -2N^*\Lambda \end{bmatrix}$.

The system Σ is regular and its feedthrough operator is $D = 0$. Hence, the transfer function of Σ is $\mathbf{G}(s) = C_\Lambda(sI - A)^{-1}B$, which is analytic with values in $\mathcal{L}(U)$. The fact that Σ is conservative implies that $\mathbf{G} \in H^\infty$ and moreover, $\mathbf{G}(i\omega)$ is a unitary operator for each $\omega \in \mathbb{R}$. In particular, it is easy to check that $\mathbf{G}(0) = I$.

It is not difficult to see that every conservative system is exactly observable if and only if it is exponentially stable. It is shown in [5] that our system Σ is isomorphic to its dual. Thus, Σ is exactly controllable if and only if it is exactly observable if and only if it is exponentially stable. These properties all hold if Γ_1 is sufficiently large, in an appropriate sense. A sharp characterization of such sets Γ_1 was given in Bardos, Lebeau, and Rauch [7]. Earlier, sufficient conditions for Γ_1 to be large enough (in the above sense) were given, for example, in Lasiecka and Triggiani [17].

If the active boundary Γ_1 is "too small," then Σ is not exponentially stable. However, it remains input-output stable ($\mathbf{G} \in H^\infty$) regardless of Γ_1. Then it follows from Remark 4 that the system is not dynamically stabilizable. Thus, the wave equation with the control and observation as in (7.5) is either exponentially stable to begin with, or it is not stabilizable by any controller.

A TWOFOLD SPLINE APPROXIMATION FOR FINITE HORIZON LQG CONTROL OF HEREDITARY SYSTEMS*

A. GERMANI†, C. MANES†, AND P. PEPE†

Abstract. In this paper an approximation scheme is developed for the solution of the linear quadratic Gaussian (LQG) control on a finite time interval for hereditary systems with multiple noncommensurate delays and distributed delay. The solution here proposed is achieved by means of two approximating subspaces: the first one to approximate the Riccati equation for control and the second one to approximate the filtering equations. Since the approximating subspaces have finite dimension, the resulting equations can be implemented. The convergence of the approximated control law to the optimal one is proved. Simulation results are reported on a wind tunnel model, showing the high performance of the method.

1. Introduction.

It is well known that the solution of the linear quadratic regulation problem and of the optimal Gaussian filtering problem for linear delay systems is found in terms of infinite dimensional operators [7, 8, 9, 10, 11, 12, 13, 17, 23, 31, 36, 37, 39]. On the other hand, implementation of a control/filtering scheme in this case requires a finite dimensional approximation of such operators.

Although much attention has been devoted to separately developing an approximation theory for the linear quadratic (LQ) regulation [4, 11, 12, 16, 24, 26, 27, 30, 33, 40] and the optimal Gaussian filtering [14, 20] of delay systems, the approximation problem of the overall linear quadratic Gaussian (LQG) regulator has not been conveniently treated in the literature.

The averaging approximation scheme has been used in [24], for both the finite and infinite horizon LQ problem of delay systems, and convergence results are obtained by considering a conjecture, later proved to be true [41], that is the question of whether the sequence of approximating systems gives uniformly exponentially stable systems for sufficiently large indexes if the underlying retarded functional differential equation is stable.

The spline approximation scheme developed in [3] has been applied to the LQ problem of delay systems in [4]. Although numerical simulations show better performance than the averaging scheme, no theoretical convergence results are so far available. In [6], it is proved that the adjoint of the approximate semigroup governing the system does not converge in a strong way to the adjoint of such semigroup. As a consequence, the main hypothesis which guarantees the convergence results in [24] cannot be satisfied, and therefore this spline approximation scheme cannot be safely applied.

A new spline approximation scheme has been developed in [27], for the LQ prob-

lem of delay systems with any number of pure delay terms, assuming the absolute continuity of the kernel in the distributed delay integral. Theoretical convergence results are obtained in the finite horizon case, as this approximation scheme does not guarantee the uniform exponential stability of the approximate semigroups. However, it is proved in [28, 29] that, in the case of commensurate delays and without distributed delay, a weaker condition is sufficient to obtain the strong convergence of the approximated LQ algebraic Riccati equation solution. The authors call this condition *uniform output stability.* It is proved that the spline approximation scheme developed in [27] does satisfy this condition, so that the above convergence result is available for the infinite horizon case. But, as pointed out by Morris on page 9 of paper [36], the convergence properties of this approximation scheme are not sufficient to ensure convergence of the closed loop response.

In [40], a piecewise linear approximation theory has been developed for the finite and infinite horizon LQ of general delay systems. Theoretical convergence results are obtained both in the finite and infinite horizon cases, as the condition of uniform exponential stability is verified.

In [32] error estimates are established for the approximation of delay systems by means of the averaging scheme. In [26] a scheme using first order splines is developed satisfying the uniform exponential stability condition, and error estimates are established too, as is done in [32] for the averaging scheme. Such a scheme uses the classic averaging subspace of piecewise constant functions to define the approximated system equation, but defines the approximated infinitesimal generator in that subspace not in the usual averaging methodology but by using an inverse projector from such subspace to the subspace built up using splines. Such a scheme, which is a mixed averaging spline one, is used in [26] for the infinite horizon LQ problem of general hereditary systems.

The matter of uniform exponential stability for spline approximation schemes has been investigated in [15], in the scalar open loop case. There the real eigenvalue (unique if the coefficient on delay term is positive, in the hereditary equation) of the infinitesimal generator of the semigroup governing the system is used, in order to define a particular inner product, by which Galerkin spline approximations [3] preserve the uniform exponential stability of the approximated semigroups. How this can be applied to optimal multivariables regulator problems is an open and interesting question.

In the synthesis of approximate optimal controllers developed by all above approximation schemes [4, 24, 26, 27, 40] it is assumed that the system state is completely accessible. Moreover, the approximated control input is generated by a finite rank feedback operator applied to the true state in the delay time interval. From an engineering point of view, the resulting controller is still infinite dimensional and therefore not directly implementable.

The synthesis of finite dimensional dynamic output feedback compensators for hereditary systems in a deterministic setting is considered in paper [25, section 4.2]. The proposed controller is composed of an observer and of a feedback control law from the observed state. Both the gains, for the finite dimensional observer and control, are obtained by approximating the solutions of two algebraic Riccati equations. The resulting controller resembles the solution of an LQG problem, although no reference to an optimal stochastic control problem is made in the paper. The main tool is the use of the averaging approximation scheme [2, 24] and the main result is the stability of the overall closed loop system.

In [35] the same problem is investigated with reference to a general class of deterministic distributed systems.

An approximation theory that provides an implementable scheme for the filtering problem of systems evolving on Hilbert spaces has been studied in [14, 18, 20, 22]. This theory has been successfully applied to delay systems.

In the literature the case with one pure delay term is usually completely reported [2, 24, 28, 29, 40] and the general case with multiple noncommensurate delays is usually just briefly indicated. However, the extension of all results to the general case is not straightforward [2, 3, 24, 40] or even unfeasible [28, 29].

As a final point of this bibliographic review, we must stress the existence of a large amount of spline approximation schemes [3, 4, 26, 27, 40] for the deterministic optimal quadratic state regulator (LQ problem), where the control gain operator is approximated by approximating the relevant Riccati equation. In principle, the same approximation schemes could be adapted for approximating the covariance operator defined by the solution of the dual Riccati equation, and the Kalman filter equation that solves the LQG problem in the stochastic setting. On the other hand, the applicability of such schemes to the case of stochastic delay systems with partial noisy state observations is not a trivial question and it has not been investigated up to now, and the main problem of proving the convergence remains unsolved.

The control problem with partial state observation has been treated in literature employing the averaging scheme in a deterministic setting [25]. On the other hand, a known result [4] is the superiority of spline approximation schemes with respect to averaging ones, with respect to numerical convergence rate.

On the basis of these considerations the aim of this paper is to define a finite dimensional scheme that approximates the solution of the finite horizon linear quadratic Gaussian control problem for stochastic delay systems with partial observations. The resulting implementable scheme has the following features:

(i) the optimal closed loop response of the LQG problem can be approximated with arbitrarily small error;

(ii) the scheme can be applied also in the LQ problem;

(iii) the approximation method is based on splines and not on averaging;

(iv) the matrices that implement the approximation of the optimal filter-controller scheme are easily parametrized as a function of the approximation order and can be easily computed;

(v) the scheme allows one to deal with general hereditary systems, that is, with multiple noncommensurate delays and distributed delay;

(vi) simultaneous approximation of a semigroup and of its adjoint is not required, so that problems arising from nondensity of the intersection of the respective generator domains are avoided;

(vii) the scheme allows a quite natural extension to be used for the solution of the infinite horizon LQG problem;

(viii) the scheme has nice numerical properties, in that it shows good performances even with a low finite dimensional approximation order;

(ix) the scheme allows one to get a faster convergence of the approximation by increasing the order of the spline degree.

Of course for most of the above-mentioned points, the scientific literature offers effective algorithms. Nevertheless, the problem of considering all these issues at the same time remains an interesting point.

The paper is organized as follows. In section 2 stochastic hereditary systems are written in state-space form and the infinitesimal generator of the adjoint of the semigroup that governs the system is studied. It is proved that such an operator has a deeply different structure if a weighted inner product is used instead of the usual one. In section 3 the finite horizon LQG is presented, and theorems for a suitable approximation scheme are proved. In section 4 an approximation scheme which satisfies hypotheses of section 3 is described for the general case. In section 5 matrices which represent finite dimensional linear operators are calculated to implement the method. In section 6 the infinite horizon case is addressed. In section 7 simulation results are reported, showing the effectiveness of the proposed method. Section 8 contains the conclusions.

2. Stochastic delay systems. In this paper we deal with the class of those dynamical systems that in technical literature are generally known as *linear delay systems*, sometimes also called *hereditary systems.* When state and observation noise are present, these are described, for $t \geq 0$, by stochastic equations of the type

$$\begin{aligned} \dot{\boldsymbol{z}}(t) &= \boldsymbol{A}_0\boldsymbol{z}(t) + \sum_{h=1}^{\delta} \boldsymbol{A}_h\boldsymbol{z}(t-r_h) \\ &\qquad + \int_{-r}^{0} \boldsymbol{A}_{01}(\vartheta)\boldsymbol{z}(t+\vartheta)d\vartheta + \boldsymbol{B}_0\boldsymbol{u}(t) + \boldsymbol{F}_0\boldsymbol{\omega}(t), \\ \boldsymbol{y}(t) &= \boldsymbol{C}_0\boldsymbol{z}(t) + \boldsymbol{G}\boldsymbol{\omega}(t) \end{aligned} \tag{2.1}$$

with $\boldsymbol{z}(t) \in \mathbb{R}^N$, $\boldsymbol{u}(t) \in \mathbb{R}^p$, $\boldsymbol{y}(t) \in \mathbb{R}^q$, $\boldsymbol{\omega}(t) \in \mathbb{R}^s$, $r_\delta = r > r_{\delta-1} > \cdots r_1 > r_0 = 0$, $\boldsymbol{A}_h \in \mathbb{R}^{N\times N}$, $\boldsymbol{A}_{01} \in L_2([-r,0];\mathbb{R}^{N\times N})$, $\boldsymbol{B}_0 \in \mathbb{R}^{N\times p}$, $\boldsymbol{C}_0 \in \mathbb{R}^{q\times N}$, $\boldsymbol{G} \in \mathbb{R}^{q\times s}$, $\boldsymbol{F}_0 \in \mathbb{R}^{N\times s}$.

The noise $\boldsymbol{\omega}$ belongs to the Hilbert space $L_2([0,t_f];\mathbb{R}^s)$ equipped with the standard Gaussian cylinder measure (this corresponds to model $\boldsymbol{\omega}$ as a white-noise process [1]). Independence of state and observation noises is assumed, that is, $\boldsymbol{F}_0\boldsymbol{G}^{\mathrm{T}} = \boldsymbol{0}$ and, without loss of generality, $\boldsymbol{G}\boldsymbol{G}^{\mathrm{T}} = \boldsymbol{I}_q$, where $\boldsymbol{I}_q$ denotes the identity matrix in $\mathbb{R}^{q\times q}$.

The variable $\boldsymbol{z}$ in the interval $[-r,0]$ is assumed to be generated as follows:

$$\boldsymbol{z}(\vartheta) = \bar{\boldsymbol{z}}(\vartheta) + \int_{-r}^{0} k(\vartheta,\tau)\bar{\boldsymbol{\omega}}(\tau)d\tau, \quad \vartheta \in [-r,0], \tag{2.2}$$

where $\bar{\boldsymbol{z}}$ is absolutely continuous with derivative in $L_2([-r,0];\mathbb{R}^N)$ and the process $\bar{\boldsymbol{\omega}}$, independent of $\boldsymbol{\omega}$, belongs to the Hilbert space $L_2([-r,0];\mathbb{R}^{\bar{s}})$ equipped with the standard Gaussian cylinder measure, and the kernel $k(\vartheta,\tau)$ is integrable for $\tau \in [-r,0]$.

As is well known, system (2.1) can be rewritten in state-space form in the Hilbert space $\boldsymbol{M}_2 = \mathbb{R}^N \times L_2([-r,0];\mathbb{R}^N)$, endowed with the following weighted inner product [3]:

$$\left(\begin{bmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{bmatrix}, \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{bmatrix} \right)_{\boldsymbol{M}_2} = \boldsymbol{x}_0^{\mathrm{T}}\boldsymbol{y}_0 + \int_{-r}^{0} \boldsymbol{x}_1^{\mathrm{T}}(\vartheta)\boldsymbol{y}_1(\vartheta)g(\vartheta)d\vartheta, \tag{2.3}$$

where $g(\vartheta)$ is the piecewise constant nondecreasing function defined as

$$g(\vartheta) = \chi_{[-r_\delta,-r_{\delta-1}]}(\vartheta) + \sum_{j=1}^{\delta-1}(\delta-j+1)\chi_{(-r_j,-r_{j-1}]}(\vartheta), \tag{2.4}$$

where χ_S denotes the characteristic function of the interval S.

Here and in the following the standard assumption is made that summations vanish when the upper limit is smaller than the lower one (e.g., $\delta = 1$ in (2.4)).

In this paper, for the sake of brevity and whenever it does not cause confusion, the space $L_2([-r,0];\mathbb{R}^N)$ will be simply indicated as L_2. In the same way C^k will denote the space $C^k([-r,0];\mathbb{R}^N)$ of functions with values in $\mathbb{R}^N$ that have continuous derivatives until order k, while the symbol $W^{1,2}$ will indicate the space of absolutely continuous functions from $[-r,0]$ in $\mathbb{R}^N$, with derivative in L_2.

In $\boldsymbol{M}_2$ the system (2.1), (2.2) assumes the form

$$\dot{\boldsymbol{x}}(t) = \boldsymbol{A}\boldsymbol{x}(t) + \boldsymbol{B}\boldsymbol{u}(t) + \boldsymbol{F}\boldsymbol{\omega}(t), \quad \boldsymbol{x}(0) = \begin{bmatrix} \bar{\boldsymbol{z}}(0) \\ \bar{\boldsymbol{z}} \end{bmatrix} + \begin{bmatrix} \mathcal{L}_0 \\ \mathcal{L}_1 \end{bmatrix} \bar{\boldsymbol{\omega}}, \tag{2.5}$$

$$\boldsymbol{y}(t) = \boldsymbol{C}\boldsymbol{x}(t) + \boldsymbol{G}\boldsymbol{\omega}(t), \tag{2.6}$$

where $\boldsymbol{A} : \mathcal{D}(\boldsymbol{A}) \mapsto \boldsymbol{M}_2$ is defined as

$$\boldsymbol{A}\begin{bmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{bmatrix} = \begin{bmatrix} \boldsymbol{A}_0\boldsymbol{x}_0 + \sum_{h=1}^{\delta} \boldsymbol{A}_h \boldsymbol{x}_1(-r_h) + \int_{-r}^{0} \boldsymbol{A}_{01}(\vartheta)\boldsymbol{x}_1(\vartheta)d\vartheta \\ \frac{d}{d\vartheta}\boldsymbol{x}_1 \end{bmatrix} \tag{2.7}$$

with domain

$$\mathcal{D}(\boldsymbol{A}) = \left\{ \begin{bmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{bmatrix} \middle| \begin{matrix} \boldsymbol{x}_0 \in \mathbb{R}^N \\ \boldsymbol{x}_1 \in W^{1,2} \end{matrix} \quad \boldsymbol{x}_0 = \boldsymbol{x}_1(0) \right\}, \tag{2.8}$$

and the linear operators $\boldsymbol{B}, \boldsymbol{C}, \boldsymbol{F}$ are defined as

$$\boldsymbol{B} : \mathbb{R}^p \mapsto \boldsymbol{M}_2, \qquad \boldsymbol{B}\boldsymbol{u}(t) = \begin{bmatrix} \boldsymbol{B}_0\boldsymbol{u}(t) \\ \boldsymbol{0} \end{bmatrix}, \tag{2.9}$$

$$\boldsymbol{C} : \boldsymbol{M}_2 \mapsto \mathbb{R}^q, \qquad \boldsymbol{C}\begin{bmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{bmatrix} = \boldsymbol{C}_0\boldsymbol{x}_0, \tag{2.10}$$

$$\boldsymbol{F} : \mathbb{R}^s \mapsto \boldsymbol{M}_2, \qquad \boldsymbol{F}\boldsymbol{\omega}(t) = \begin{bmatrix} \boldsymbol{F}_0 \ \boldsymbol{\omega}(t) \\ \boldsymbol{0} \end{bmatrix}. \tag{2.11}$$

The Hilbert–Schmidt operator $\mathcal{L} = \left[\begin{smallmatrix} \mathcal{L}_0 \\ \mathcal{L}_1 \end{smallmatrix}\right]$, which defines the stochastic initial state $\boldsymbol{x}(0)$, derives from definition (2.2) and is defined as follows:

$$\begin{aligned} &\mathcal{L}_0 : \ L_2([-r,0];\mathbb{R}^{\bar{s}}) \mapsto \mathbb{R}^N; \qquad && \mathcal{L}_0\boldsymbol{\omega} = \int_{-r}^{0} k(0,\tau)\bar{\boldsymbol{\omega}}(\tau)d\tau, \\ &\mathcal{L}_1 : \ L_2([-r,0];\mathbb{R}^{\bar{s}}) \mapsto W^{1,2}; \qquad && \mathcal{L}_1\boldsymbol{\omega}(\vartheta) = \int_{-r}^{0} k(\vartheta,\tau)\bar{\boldsymbol{\omega}}(\tau)d\tau. \end{aligned} \tag{2.12}$$

The mean value and nuclear covariance of the initial state $\boldsymbol{x}_0$ are as follows:

$$\bar{\boldsymbol{x}}_0 = \begin{bmatrix} \bar{\boldsymbol{z}}(0) \\ \bar{\boldsymbol{z}} \end{bmatrix}, \qquad \boldsymbol{P}_0 = \mathcal{L}\mathcal{L}^*. \tag{2.13}$$

Remark 2.1. Note that the weighted scalar product (2.3), (2.4) assures that there exist real α such that $\boldsymbol{A}-\alpha\boldsymbol{I}$ has the nice property to be dissipative [3]. This property is used in the paper to prove the convergence of the approximation scheme.

For the reader's convenience, the definitions of some operators related to the system (2.5), (2.6) that will be extensively used in the paper are reported below.

PROPOSITION 2.2. *The operators $\boldsymbol{B}^*$, $\boldsymbol{C}^*$, $\boldsymbol{F}^*$, $\boldsymbol{B}\boldsymbol{B}^*$, $\boldsymbol{C}^*\boldsymbol{C}$, $\boldsymbol{F}\boldsymbol{F}^*$, and $\boldsymbol{A}^*$ are as follows:*

$$\boldsymbol{B}^* : \boldsymbol{M}_2 \mapsto \mathbb{R}^p, \qquad \boldsymbol{B}^* \begin{bmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{bmatrix} = \boldsymbol{B}_0^{\mathrm{T}} \boldsymbol{x}_0; \tag{2.14}$$

$$\boldsymbol{C}^* : \mathbb{R}^q \mapsto \boldsymbol{M}_2, \qquad \boldsymbol{C}^* \boldsymbol{y} = \begin{bmatrix} \boldsymbol{C}_0^{\mathrm{T}} \boldsymbol{y} \\ 0 \end{bmatrix}; \tag{2.15}$$

$$\boldsymbol{F}^* : \boldsymbol{M}_2 \mapsto \mathbb{R}^s, \qquad \boldsymbol{F}^* \begin{bmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{bmatrix} = \begin{bmatrix} \boldsymbol{F}_0^{\mathrm{T}} \boldsymbol{x}_0 \\ \boldsymbol{0} \end{bmatrix}; \tag{2.16}$$

$$\boldsymbol{B}\boldsymbol{B}^* : \boldsymbol{M}_2 \mapsto \boldsymbol{M}_2, \qquad \boldsymbol{B}\boldsymbol{B}^* \begin{bmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{bmatrix} = \begin{bmatrix} \boldsymbol{B}_0 \boldsymbol{B}_0^{\mathrm{T}} \boldsymbol{x}_0 \\ 0 \end{bmatrix}; \tag{2.17}$$

$$\boldsymbol{C}^*\boldsymbol{C} : \boldsymbol{M}_2 \mapsto \boldsymbol{M}_2, \qquad \boldsymbol{C}^*\boldsymbol{C} \begin{bmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{bmatrix} = \begin{bmatrix} \boldsymbol{C}_0^{\mathrm{T}} \boldsymbol{C}_0 \boldsymbol{x}_0 \\ 0 \end{bmatrix}; \tag{2.18}$$

$$\boldsymbol{F}\boldsymbol{F}^* : \boldsymbol{M}_2 \mapsto \boldsymbol{M}_2, \qquad \boldsymbol{F}\boldsymbol{F}^* \begin{bmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{bmatrix} = \begin{bmatrix} \boldsymbol{F}_0 \boldsymbol{F}_0^{\mathrm{T}} \boldsymbol{x}_0 \\ 0 \end{bmatrix}; \tag{2.19}$$

$$\begin{aligned} &\boldsymbol{A}^* : \mathcal{D}(\boldsymbol{A}^*) \mapsto \boldsymbol{M}_2, \\ &\boldsymbol{A}^* \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{bmatrix} = \begin{bmatrix} \delta\, \boldsymbol{y}_1(0) + \boldsymbol{A}_0^{\mathrm{T}} \boldsymbol{y}_0 \\ \dfrac{1}{g} \boldsymbol{A}_{01}^{\mathrm{T}} \boldsymbol{y}_0 - \dfrac{d}{d\vartheta} \left(\boldsymbol{y}_1 - \displaystyle\sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{y}_0, \boldsymbol{y}_1) \chi_{[-r,-r_j]} \right) \end{bmatrix}, \end{aligned} \tag{2.20}$$

with dense domain

$$\mathcal{D}(\boldsymbol{A}^*) = \left\{ \begin{bmatrix} \boldsymbol{y}_0 \\ \\ \boldsymbol{y}_1 \end{bmatrix} \middle| \begin{array}{c} \boldsymbol{y}_0 \in \mathbb{R}^N, \quad \boldsymbol{A}_\delta^{\mathrm{T}} \boldsymbol{y}_0 = \boldsymbol{y}_1(-r), \\ \left(\boldsymbol{y}_1 - \displaystyle\sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{y}_0, \boldsymbol{y}_1) \chi_{[-r,-r_j]} \right) \in W^{1,2} \end{array} \right\}, \tag{2.21}$$

where

$$\boldsymbol{k}_j(\boldsymbol{y}_0, \boldsymbol{y}_1) = \frac{\boldsymbol{y}_1(-r_j) - \boldsymbol{A}_j^{\mathrm{T}} \boldsymbol{y}_0}{\delta - j + 1}, \qquad j = 1, \ldots, \delta - 1. \tag{2.22}$$

The proof that the operator defined by (2.20), (2.21), (2.22) is in fact the adjoint of operator $\boldsymbol{A}$ is reported in appendix.

Remark 2.3. The difference between the case of just one pure delay and of multiple pure delays is given by summations in (2.20), (2.21), which vanish in the first case and complicate the analysis very much in the second one.

3. The finite horizon LQG for delay systems. In this section the problem of defining a feedback control law for the stochastic delay system (2.1), (2.2) is considered. In particular we are interested in the problem of synthesizing the control law that minimizes the cost functional

$$J_f(\boldsymbol{u}) = \int_0^{t_f} E[\boldsymbol{z}^{\mathrm{T}}(t)\boldsymbol{Q}_0\boldsymbol{z}(t) + \boldsymbol{u}^{\mathrm{T}}(t)\boldsymbol{u}(t)]dt, \tag{3.1}$$

with $0 < t_f < \infty$, where matrix $\boldsymbol{Q}_0$ is symmetric nonnegative definite. It can be readily recognized that the functional (3.1) admits the following representation in $\boldsymbol{M}_2$:

$$J_f(\boldsymbol{u}) = \int_0^{t_f} E[\big(\boldsymbol{Q}\boldsymbol{x}(t), \boldsymbol{x}(t)\big) + \boldsymbol{u}^{\mathrm{T}}(t)\boldsymbol{u}(t)]dt, \tag{3.2}$$

where $\boldsymbol{Q} : \boldsymbol{M}_2 \mapsto \boldsymbol{M}_2$ is defined as

$$\boldsymbol{Q}\begin{bmatrix}\boldsymbol{x}_0\\ \boldsymbol{x}_1\end{bmatrix} = \begin{bmatrix}\boldsymbol{Q}_0\boldsymbol{x}_0\\ \boldsymbol{0}\end{bmatrix} \tag{3.3}$$

and $\boldsymbol{x}(t)$ satisfies system equations (2.5), (2.6). The solution of this problem, as is well known, is the classical LQG controller given by the following equations [1]:

$$\boldsymbol{u}(t) = -\boldsymbol{B}^*\boldsymbol{R}(t_f - t)\hat{\boldsymbol{x}}(t), \tag{3.4}$$

$$\boldsymbol{R}(t) = \int_0^t \boldsymbol{T}^*(t-\tau)[\boldsymbol{Q} - \boldsymbol{R}(\tau)\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{R}(\tau)]\boldsymbol{T}(t-\tau)d\tau, \tag{3.5}$$

$$\hat{\boldsymbol{x}}(t) = \boldsymbol{T}(t)\hat{\boldsymbol{x}}_0 + \int_0^t \boldsymbol{T}(t-\tau)\left[\boldsymbol{P}(\tau)\boldsymbol{C}^*[\boldsymbol{y}(\tau) - \boldsymbol{C}\hat{\boldsymbol{x}}(\tau)] + \boldsymbol{B}\boldsymbol{u}(\tau)\right]d\tau, \tag{3.6}$$

$$\boldsymbol{P}(t) = \boldsymbol{T}(t)\boldsymbol{P}_0\boldsymbol{T}^*(t) + \int_0^t \boldsymbol{T}(t-\tau)[\boldsymbol{F}\boldsymbol{F}^* - \boldsymbol{P}(\tau)\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{P}(\tau)]\boldsymbol{T}^*(t-\tau)d\tau, \tag{3.7}$$

where $\boldsymbol{T}(t)$ is the semigroup governing the system, that is, the semigroup generated by the operator $\boldsymbol{A}$ in (2.7), (2.8), and $\hat{\boldsymbol{x}}_0$ and $\boldsymbol{P}_0$ are the expected value and the covariance operator of the initial state $\boldsymbol{x}(0)$ in $\boldsymbol{M}_2$, respectively. The solution given by these equations is a very important result only from a theoretical point of view. For our purposes we need to recall that the solutions of the Riccati equations (3.5), (3.7) evolve in the Hilbert space of Hilbert–Schmidt operators and moreover, for every $t_f < \infty$, there exist constants K_P and K_R such that [20]

$$\begin{aligned} \sup_{t\in[0,t_f]} \|\boldsymbol{P}(t)\|_{H.S.} &= K_P < \infty, \\ \sup_{t\in[0,t_f]} \|\boldsymbol{R}(t)\|_{H.S.} &= K_R < \infty, \end{aligned} \tag{3.8}$$

where, as usual, $\|\cdot\|_{H.S.}$ denotes the Hilbert–Schmidt norm [1].

In engineering applications, due to its infinite dimensional nature, such a solution is not directly implementable. Therefore it becomes important to investigate when such a solution admits a finite dimensional approximation.

Throughout the paper, given a Hilbert space $\mathcal{X}$ and a closed subspace $\mathcal{S} \subset \mathcal{X}$, the orthogonal projection operator from $\mathcal{X}$ to $\mathcal{S}$ will be denoted as $\boldsymbol{\Pi}_{\mathcal{S}}$.

In the next lemma, the linear space of bounded operators on a Hilbert space H is denoted $L(H)$.

LEMMA 3.1. *Let H_1, H_2 be separable Hilbert spaces. Let $\{G_m(t),\ t \in [0,t_f]\}$ be a sequence of strongly continuous $L(H_2)$ valued functions, strongly convergent to $\{G(t),\ t \in [0,t_f]\}$, uniformly on $[0,t_f]$. Let K be a compact subset in the Hilbert space of Hilbert–Schmidt operators mapping H_1 to H_2.*

Then $\|G_m(t)N - G(t)N\|_{H.S.}$ converges to zero, uniformly with respect to $N \in K$ and $t \in [0,t_f]$.

Proof. See [20]. □

LEMMA 3.2. *Let H_1 and H_2 be separable Hilbert spaces. Let $G(t)$ be a semigroup on H_2 and $G_n(t)$ a sequence of semigroups on H_2 strongly convergent to $G(t)$ uniformly with respect to $t \in [0,t_f]$. For $0 \le \tau \le t$, let $\Gamma(t,\tau)$ be the mild evolution operator*

$$\Gamma(t,\tau) = G(t-\tau) + \int_\tau^t G(t-\vartheta)Op(\vartheta)\Gamma(\vartheta,\tau)d\vartheta, \tag{3.9}$$

where $Op \in C\left([0,t_f];L(H_2)\right)$ and let $\Gamma_n(t,\tau)$ be the sequence of mild evolution operators

$$\Gamma_n(t,\tau) = G_n(t-\tau) + \int_\tau^t G_n(t-\vartheta)Op_n(\vartheta)\Gamma_n(\vartheta,\tau)d\vartheta, \tag{3.10}$$

where $Op_n \in C\left([0,t_f];L(H_2)\right)$ converges pointwise strongly to Op, uniformly in $[0,t_f]$. Let K be a compact subset in the Hilbert space of Hilbert–Schmidt operators mapping H_1 to H_2.

Then $\|\Gamma(t,\tau)N - \Gamma_n(t,\tau)N\|_{H.S.}$ converges to zero, uniformly with respect to $N \in K$ and $0 \le \tau \le t \le t_f$.

Proof. It is

$$\begin{aligned}\|\Gamma(t,\tau)N - \Gamma_n(t,\tau)N\|_{H.S.} &\le \|G(t-\tau)N - G_n(t-\tau)N\|_{H.S.}\\ &+ \int_\tau^t \|G(t-\vartheta)Op(\vartheta)\| \cdot \|\Gamma(\vartheta,\tau)N - \Gamma_n(\vartheta,\tau)N\|_{H.S.}d\vartheta\\ &+ \int_\tau^t \|G(t-\vartheta)Op(\vartheta) - G_n(t-\vartheta)Op_n(\vartheta)\|\\ &\qquad \cdot\|\Gamma_n(\vartheta,\tau)N - \Gamma(\vartheta,\tau)N\|_{H.S.}d\vartheta\\ &+ \int_\tau^t \|(G(t-\vartheta)Op(\vartheta) - G_n(t-\vartheta)Op_n(\vartheta))\Gamma(\vartheta,\tau)N\|_{H.S.}d\vartheta.\end{aligned} \tag{3.11}$$

Let M be a positive real such that

$$\begin{aligned} M &\ge \sup_{(t,\vartheta)\in[0,t_f]\times[0,t_f]} \|G(t)\|\|Op(\vartheta)\|,\\ M &\ge \sup_{(t,\vartheta,n)\in[0,t_f]\times[0,t_f]\times Z^+} \|G_n(t)\|\|Op_n(\vartheta)\|.\end{aligned} \tag{3.12}$$

Then

$$\begin{aligned}\|\Gamma(t,\tau)N - &\Gamma_n(t,\tau)N\|_{H.S.} \leq \|G(t-\tau)N - G_n(t-\tau)N\|_{H.S.}\\ &+\int_\tau^t \|(G(t-\vartheta)Op(\vartheta) - G_n(t-\vartheta)Op_n(\vartheta))\Gamma(\vartheta,\tau)N\|_{H.S.}d\vartheta\\ &+3M\int_\tau^t \|\big(\Gamma_n(\vartheta,\tau) - \Gamma(\vartheta,\tau)\big)N\|_{H.S.}d\vartheta.\end{aligned} \tag{3.13}$$

Applying the Gronwall's inequality,

$$\begin{aligned}\|\Gamma(t,\tau)N - &\Gamma_n(t,\tau)N\|_{H.S.} \leq e^{3Mt_f}\Big(\|G(t-\tau)N - G_n(t-\tau)N\|_{H.S.}\\ &+\int_\tau^t \big\|\big(G(t-\vartheta)Op(\vartheta) - G_n(t-\vartheta)Op_n(\vartheta)\big)\Gamma(\vartheta,\tau)N\big\|_{H.S.}d\vartheta\Big)\\ &\leq e^{3Mt_f}\Big(\|G(t-\tau)N - G_n(t-\tau)N\|_{H.S.}\\ &+\int_\tau^t \big\|\big(G(t-\vartheta) - G_n(t-\vartheta)\big)Op(\vartheta)\Gamma(\vartheta,\tau)N\big\|_{H.S.}d\vartheta\\ &+\int_\tau^t M\big\|\big(Op(\vartheta) - Op_n(\vartheta)\big)\Gamma(\vartheta,\tau)N\big\|_{H.S.}d\vartheta\Big).\end{aligned} \tag{3.14}$$

Since the set of operators $\{Op(\vartheta)\Gamma(t,\tau)N, \vartheta\in[0,t_f], 0\leq\tau\leq t\leq t_f\}$ and the set $\{\Gamma(t,\tau)N,\ 0\leq\tau\leq t\leq t_f\}$ are compact in the Hilbert space of Hilbert–Schmidt operators mapping H_1 to H_2, by Lemma 3.1 the right-hand side of inequality (3.14) tends to zero for $n\to\infty$, and the lemma is proved. □

THEOREM 3.3. *Let Ψ_n and Ψ'_n be sequences of finite dimensional subspaces of $\boldsymbol{M}_2$ contained in $\mathcal{D}(\boldsymbol{A})$ and in $\mathcal{D}(\boldsymbol{A}^*)$, respectively. Let $\boldsymbol{\Pi}_{\Psi_n}:\boldsymbol{M}_2\mapsto\Psi_n$ and $\boldsymbol{\Pi}_{\Psi'_n}:\boldsymbol{M}_2\mapsto\Psi'_n$ be the sequences of orthoprojection operators in Ψ_n and Ψ'_n, respectively. Let $\boldsymbol{T}_{\Psi_n}(t)$ be the semigroup generated by the operator $\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{A}\boldsymbol{\Pi}_{\Psi_n}:\boldsymbol{M}_2\mapsto\Psi_n$ and $\boldsymbol{T}^*_{\Psi'_n}(t)$ the semigroup generated by the operator $\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{A}^*\boldsymbol{\Pi}_{\Psi'_n}:\boldsymbol{M}_2\mapsto\Psi'_n$. Let $\boldsymbol{P}_n(t)$ and $\boldsymbol{R}_n(t)$ be the solutions of the finite dimensional differential Riccati equations*

$$\begin{aligned}\dot{\boldsymbol{P}}_n(t) &= \boldsymbol{\Pi}_{\Psi_n}\boldsymbol{A}\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}_n(t) + \boldsymbol{P}_n(t)(\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{A}\boldsymbol{\Pi}_{\Psi_n})^*\\ &\qquad -\boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}_n(t) + \boldsymbol{\Pi}_{\Psi_n}\boldsymbol{F}\boldsymbol{F}^*\boldsymbol{\Pi}_{\Psi_n},\\ \boldsymbol{P}_n(0) &= \boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}_0\boldsymbol{\Pi}_{\Psi_n},\end{aligned} \tag{3.15}$$

$$\begin{aligned}\dot{\boldsymbol{R}}_n(t) &= \boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{A}^*\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{R}_n(t) + \boldsymbol{R}_n(t)(\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{A}^*\boldsymbol{\Pi}_{\Psi'_n})^*\\ &\qquad -\boldsymbol{R}_n(t)\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{R}_n(t) + \boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{Q}\boldsymbol{\Pi}_{\Psi'_n},\\ \boldsymbol{R}_n(0) &= \boldsymbol{0}.\end{aligned} \tag{3.16}$$

Assume the following hypotheses are satisfied:

(Hp$_1$) $\boldsymbol{\Pi}_{\Psi_n}$ *converges strongly to the identity operator;*

(Hp$_2$) $\boldsymbol{\Pi}_{\Psi'_n}$ *converges strongly to the identity operator;*

(Hp$_3$) $\boldsymbol{T}_{\Psi_n}(t)$ *converges strongly to* $\boldsymbol{T}(t)$ *uniformly in* $[0,t_f]$*;*

(Hp$_4$) $\boldsymbol{T}^*_{\Psi'_n}(t)$ *converges strongly to* $\boldsymbol{T}^*(t)$ *uniformly in* $[0,t_f]$.

Then

$$\begin{aligned} &\|\boldsymbol{P}_n(t) - \boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}\|_{H.S.} \to 0, \\ &\|\boldsymbol{R}_n(t) - \boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{R}(t)\boldsymbol{\Pi}_{\Psi'_n}\|_{H.S.} \to 0, \end{aligned} \qquad \textit{uniformly in} \quad [0, t_f]. \tag{3.17}$$

Proof. See the proof of Theorem 3 in [20]. □

Remark 3.4. Note that, with the given definitions, in general the semigroup $\boldsymbol{T}^*_{\Psi'_n}(t)$ generated by the operator $\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{A}^*\boldsymbol{\Pi}_{\Psi'_n}$ is different from the semigroup $\boldsymbol{T}^*_{\Psi_n}(t)$, the adjoint of the semigroup generated by $\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{A}\boldsymbol{\Pi}_{\Psi_n}$.

LEMMA 3.5. *Let Ψ_n and Ψ'_n be sequences of finite dimensional subspaces of $\boldsymbol{M}_2$ contained in $\mathcal{D}(\boldsymbol{A})$ and in $\mathcal{D}(\boldsymbol{A}^*)$, respectively. Let $\boldsymbol{\Pi}_{\Psi_n} : \boldsymbol{M}_2 \mapsto \Psi_n$ and $\boldsymbol{\Pi}_{\Psi'_n} : \boldsymbol{M}_2 \mapsto \Psi'_n$ be the corresponding sequences of orthoprojection operators. Let $\mathcal{H} = \boldsymbol{M}_2 \times \boldsymbol{M}_2$ and $\mathcal{H}_n = \boldsymbol{M}_2 \times \Psi_n$. Consider the following operators:*

$$\mathcal{A} = \begin{bmatrix} \boldsymbol{A} & 0 \\ 0 & \boldsymbol{A} \end{bmatrix} : \mathcal{D}(\boldsymbol{A}) \times \mathcal{D}(\boldsymbol{A}) \mapsto \mathcal{H}, \tag{3.18}$$

$$\mathcal{A}_n = \begin{bmatrix} \boldsymbol{A} & 0 \\ 0 & \boldsymbol{\Pi}_{\Psi_n}\boldsymbol{A}\boldsymbol{\Pi}_{\Psi_n} \end{bmatrix} : \mathcal{D}(\boldsymbol{A}) \times \boldsymbol{M}_2 \mapsto \mathcal{H}_n, \tag{3.19}$$

$$\boldsymbol{D}(t) = \begin{bmatrix} 0 & -\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{R}(t_f - t) \\ \boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{C} & -\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{R}(t_f - t) - \boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{C} \end{bmatrix} : \mathcal{H} \mapsto \mathcal{H}, \tag{3.20}$$

$$\boldsymbol{D}_n(t) = \begin{bmatrix} 0 & -\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{R}_n(t_f - t)\boldsymbol{\Pi}_{\Psi'_n} \\ \boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C} & -\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{R}_n(t_f - t)\boldsymbol{\Pi}_{\Psi'_n} - \boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{\Pi}_{\Psi_n} \end{bmatrix} :$$

$$\mathcal{H} \mapsto \mathcal{H}_n, \tag{3.21}$$

$$\boldsymbol{O}(t) = \begin{bmatrix} \boldsymbol{F} \\ \boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{G} \end{bmatrix} : \mathbb{R}^s \mapsto \mathcal{H}, \tag{3.22}$$

$$\boldsymbol{O}_n(t) = \begin{bmatrix} \boldsymbol{F} \\ \boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{G} \end{bmatrix} : \mathbb{R}^s \mapsto \mathcal{H}_n. \tag{3.23}$$

Let $\boldsymbol{S}(t)$ and $\boldsymbol{S}_n(t)$ be the semigroups generated by operators $\mathcal{A}$ and $\mathcal{A}_n$, respectively.

Let $\boldsymbol{\Pi}_{\mathcal{H}_n}$ be the following sequence of orthoprojection operators, strongly converging to identity,

$$\boldsymbol{\Pi}_{\mathcal{H}_n} = \begin{bmatrix} \boldsymbol{I} & 0 \\ 0 & \boldsymbol{\Pi}_{\Psi_n} \end{bmatrix} : \mathcal{H} \mapsto \mathcal{H}_n \tag{3.24}$$

Assume that assumptions Hp_1–Hp_4 of Theorem 3.3 *are satisfied.*

Then

(Th$_1$) $\boldsymbol{S}_n(t)$*converges strongly to* $\boldsymbol{S}(t)$ *uniformly in* $[0, t_f]$;

(Th$_2$) $\|\boldsymbol{\Pi}_{\mathcal{H}_n}\boldsymbol{O}(t) - \boldsymbol{O}_n(t)\|_{H.S.} \to 0$ *uniformly in* $[0, t_f]$;

(Th$_3$) $\|\boldsymbol{\Pi}_{\mathcal{H}_n}\boldsymbol{D}(t) - \boldsymbol{D}_n(t)\|_{H.S.} \to 0$ *uniformly in* $[0, t_f]$.

Proof. Thesis Th$_1$ is an immediate consequence of hypothesis Hp$_3$.

As far as Th$_2$ is concerned, we have

$$\begin{aligned}\|\boldsymbol{\Pi}_{\mathcal{H}_n}\boldsymbol{O}(t)-\boldsymbol{O}_n(t)\|_{H.S.}&=\|\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{G}-\boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{G}\|_{H.S.}\\ &\le \Big\|\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{G}-\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{G}\\ &\qquad +\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{G}-\boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{G}\|_{H.S.}\\ &\le \|\boldsymbol{\Pi}_{\Psi_n}\|\|\boldsymbol{P}(t)\|_{H.S.}\|\boldsymbol{C}^*\boldsymbol{G}-\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{G}\|_{H.S.}\\ &\qquad +\|\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}-\boldsymbol{P}_n(t)\|_{H.S.}\|\boldsymbol{\Pi}_{\Psi_n}\|\|\boldsymbol{C}^*\boldsymbol{G}\|.\end{aligned}\tag{3.25}$$

From (3.25) it follows that $\|\boldsymbol{\Pi}_{\mathcal{H}_n}\boldsymbol{O}(t)-\boldsymbol{O}_n(t)\|_{H.S.}\to 0$ uniformly with respect to $t\in[0,t_f]$ because of the boundedness of $\|\boldsymbol{P}(t)\|_{H.S}$ and the uniform convergence of $\boldsymbol{P}_n(t)$ stated in Theorem 3.3.

As for thesis Th$_3$, it is

$$\boldsymbol{\Pi}_{\mathcal{H}_n}\boldsymbol{D}(t)-\boldsymbol{D}_n(t)=\begin{bmatrix}0 & \boldsymbol{O}p^n_{1,2}(t)\\ \boldsymbol{O}p^n_{2,1}(t) & \boldsymbol{O}p^n_{2,2}(t)\end{bmatrix},\tag{3.26}$$

where

$$\begin{aligned}\boldsymbol{O}p^n_{1,2}(t)&=\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{R}_n(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}-\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{R}(t_f-t);\\ \boldsymbol{O}p^n_{2,1}(t)&=\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{C}-\boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C};\\ \boldsymbol{O}p^n_{2,2}(t)&=\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{R}_n(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}\\ &\qquad+\boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{\Pi}_{\Psi_n}-\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{R}(t_f-t)-\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{C}.\end{aligned}\tag{3.27}$$

To prove Th$_3$ it is sufficient to prove that the three operators in (3.27) converge uniformly to zero in the $H.S.$ norm. Let us start with operator $\boldsymbol{O}p^n_{1,2}(t)$. We have

$$\begin{aligned}\|\boldsymbol{O}p^n_{1,2}(t)\|&\le\|\boldsymbol{B}\boldsymbol{B}^*\|\big\|\boldsymbol{R}_n(t_f-t)-\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{R}(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}\big\|_{H.S.}\|\boldsymbol{\Pi}_{\Psi'_n}\|\\ &\qquad+\|\boldsymbol{B}\boldsymbol{B}^*\|\big\|\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{R}(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}-\boldsymbol{R}(t_f-t)\big\|_{H.S.}.\end{aligned}\tag{3.28}$$

Moreover, from the uniform convergence of $\boldsymbol{R}_n(t)$ stated in Theorem 3.3, $\boldsymbol{R}$ being self-adjoint, and for Lemma 3.1, by

$$\begin{aligned}&\|\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{R}(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}-\boldsymbol{R}(t_f-t)\|_{H.S.}\\ &\quad\le\|\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{R}(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}-\boldsymbol{R}(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}+\boldsymbol{R}(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}-\boldsymbol{R}(t_f-t)\|_{H.S.}\\ &\quad\le 2\|\boldsymbol{\Pi}_{\Psi'_n}\boldsymbol{R}(t_f-t)-\boldsymbol{R}(t_f-t)\|,\end{aligned}\tag{3.29}$$

it follows that $\|\boldsymbol{O}p^n_{1,2}(t)\|_{H.S.}\to 0$ uniformly in $[0,t_f]$. Consider now the term $\boldsymbol{O}p^n_{2,1}(t)$. Its Hilbert–Schmidt norm satisfies

$$\begin{aligned}&\|\boldsymbol{O}p^n_{2,1}(t)\|_{H.S.}\\ &\quad\le\ \big\|\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)-\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}+\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}-\boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\big\|_{H.S.}\|\boldsymbol{C}^*\boldsymbol{C}\|\\ &\quad\le\ \Big(\|\boldsymbol{P}(t)-\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}\|_{H.S.}+\|(\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}-\boldsymbol{P}_n(t))\boldsymbol{\Pi}_{\Psi_n}\|_{H.S.}\Big)\|\boldsymbol{C}^*\boldsymbol{C}\|.\end{aligned}\tag{3.30}$$

Since, by Lemma 3.1, $\|\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)-\boldsymbol{P}(t)\|_{H.S.}\to 0$ uniformly and $\|(\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}-\boldsymbol{P}_n(t))\boldsymbol{\Pi}_{\Psi_n}\|_{H.S.}\to 0$ by Theorem 3.3, it follows that the norm of $\boldsymbol{Op}^n_{2,1}(t)$ tends to zero uniformly in $[0,t_f]$.

It remains to prove that $\|\boldsymbol{Op}^n_{2,2}(t)\|_{H.S.}\to 0$ uniformly.

$$\begin{aligned}\|\boldsymbol{Op}^n_{2,2}(t)\|_{H.S.}\le \|\boldsymbol{\Pi}_{\Psi_n}\|\big\|\boldsymbol{BB}^*\boldsymbol{R}(t_f-t)-\boldsymbol{BB}^*\boldsymbol{R}_n(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}\big\|_{H.S.}&\\ +\big\|\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{C}-\boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{\Pi}_{\Psi_n}\big\|_{H.S.}&\end{aligned}\tag{3.31}$$

Uniform convergence to zero of $\|\boldsymbol{BB}^*\boldsymbol{R}(t_f-t)-\boldsymbol{BB}^*\boldsymbol{R}_n(t_f-t)\boldsymbol{\Pi}_{\Psi'_n}\|_{H.S.}$ has already been proved. Moreover,

$$\begin{aligned}&\|\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{C}-\boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{\Pi}_{\Psi_n}\|_{H.S.}\\ &\quad\le\ \|\boldsymbol{\Pi}_{\Psi_n}\|\|\boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{C}-\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{\Pi}_{\Psi_n}\|_{H.S.}\\ &\qquad+\big\|\big(\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}-\boldsymbol{P}_n(t)\big)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C}\big\|_{H.S.}\|\boldsymbol{\Pi}_{\Psi_n}\|.\end{aligned}\tag{3.32}$$

Again, as proved in [20], the term $\|(\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{\Pi}_{\Psi_n}-\boldsymbol{P}_n(t))\boldsymbol{\Pi}_{\Psi_n}\|_{H.S.}\to 0$ uniformly and thanks to Lemma 3.1 also $\|\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{P}(t)-\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\|_{H.S.}\to 0$ uniformly. From (3.32) it follows that $\|\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{P}(t)\boldsymbol{C}^*\boldsymbol{C}-\boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{\Pi}_{\Psi_n}\|_{H.S.}\to 0$ uniformly, so that $\|\boldsymbol{Op}^n_{2,2}(t)\|_{H.S.}\to 0$ uniformly in $[0,t_f]$, and the lemma is proved. □

LEMMA 3.6. *Let $\boldsymbol{U}(t,\tau), 0\le\tau\le t$, be the mild evolution operator*

$$\boldsymbol{U}(t,\tau)=\boldsymbol{S}(t-\tau)+\int_\tau^t \boldsymbol{S}(t-\vartheta)\boldsymbol{D}(\vartheta)\boldsymbol{U}(\vartheta,\tau)d\vartheta.\tag{3.33}$$

Let $\{\boldsymbol{U}_n(t,\tau)\}$ be the sequence of mild evolution operators

$$\boldsymbol{U}_n(t,\tau)=\boldsymbol{S}_n(t-\tau)+\int_\tau^t \boldsymbol{S}_n(t-\vartheta)\boldsymbol{D}_n(\vartheta)\boldsymbol{U}_n(\vartheta,\tau)d\vartheta.\tag{3.34}$$

Then $\{\boldsymbol{U}_n(t,\tau)\}$ converges strongly to $\boldsymbol{U}(t,\tau)$ uniformly in $0\le\tau\le t\le t_f$, that is, given any $X\in\mathcal{H}$,

$$\lim_{n\to\infty}\sup_{0\le\tau\le t\le t_f}\|\boldsymbol{U}_n(t,\tau)X-\boldsymbol{U}(t,\tau)X\|=0.\tag{3.35}$$

Proof. Let us denote by $g(t,\tau)$ and $g_n(t,\tau)$ the quantities

$$g(t,\tau)=\boldsymbol{U}(t,\tau)X,\tag{3.36}$$

$$g_n(t,\tau)=\boldsymbol{U}_n(t,\tau)X,\tag{3.37}$$

from which, denoting the approximation error by $e_n(t,\tau)$

$$e_n(t,\tau)=g(t,\tau)-g_n(t,\tau),\tag{3.38}$$

we have

$$\begin{aligned}e_n(t,\tau)=\boldsymbol{S}(t-\tau)X+\int_\tau^t \boldsymbol{S}(t-\vartheta)\boldsymbol{D}(\vartheta)g(\vartheta,\tau)d\vartheta&\\ -\boldsymbol{S}_n(t-\tau)X-\int_\tau^t \boldsymbol{S}_n(t-\vartheta)\boldsymbol{D}_n(\vartheta)g_n(\vartheta,\tau)d\vartheta,&\end{aligned}\tag{3.39}$$

and therefore

$$\begin{aligned} e_n(t,\tau) &= (\boldsymbol{S}(t-\tau) - \boldsymbol{S}_n(t-\tau))X \\ &\quad + \int_\tau^t \Big(\boldsymbol{S}(t-\vartheta)\boldsymbol{D}(\vartheta)g(\vartheta,\tau) - \boldsymbol{S}_n(t-\vartheta)\boldsymbol{D}_n(\vartheta)g_n(\vartheta,\tau)\Big)d\vartheta \end{aligned} \tag{3.40}$$

from which

$$\begin{aligned} \|e_n(t,\tau)\| &\le \|(\boldsymbol{S}(t-\tau) - \boldsymbol{S}_n(t-\tau))X\| \\ &\quad + \int_\tau^t \|\boldsymbol{S}(t-\vartheta)\boldsymbol{D}(\vartheta) - \boldsymbol{S}_n(t-\vartheta)\boldsymbol{D}(\vartheta)\|\|g(\vartheta,\tau)\|d\vartheta \\ &\quad + \int_\tau^t \|\boldsymbol{S}_n(t-\vartheta)\|\|\boldsymbol{\Pi}_{\mathcal{H}_n}\boldsymbol{D}(\vartheta) - \boldsymbol{D}_n(\vartheta)\|\|g(\vartheta,\tau)\|d\vartheta \\ &\quad + \int_\tau^t \|\boldsymbol{S}_n(t-\vartheta)\boldsymbol{D}_n(\vartheta)\|\|e_n(\vartheta,\tau)\|d\vartheta. \end{aligned} \tag{3.41}$$

Now, given $\epsilon > 0$, by Lemma 3.1 there exists an integer $\nu_{\epsilon,X}$ such that, for all $n > \nu_{\epsilon,X}$, we have

$$\|e_n(t,\tau)\| \le \epsilon + \bar{S}\bar{D}\int_\tau^t \|e_n(\vartheta,\tau)\|d\vartheta, \tag{3.42}$$

where

$$\begin{aligned} \bar{S} &= \sup_{n,t\in[0,t_f]} \|\boldsymbol{S}_n(t)\|, \\ \bar{D} &= \sup_{n,t\in[0,t_f]} \|\boldsymbol{D}_n(t)\|. \end{aligned} \tag{3.43}$$

By Gronwall's lemma,

$$\|e_n(t,\tau)\| \le \epsilon e^{\bar{S}\bar{D}(t-\tau)}, \tag{3.44}$$

and therefore

$$\sup_{0\le\tau\le t\le t_f} \|e_n(t,\tau)\| \le \epsilon e^{\bar{S}\bar{D}t_f}. \tag{3.45}$$

This concluded the proof. □

Now, the main theorem can be given.

THEOREM 3.7. *Using the same hypotheses of Theorem* 3.3, *let* $\boldsymbol{u}_n(t)$ *be the input obtained by the following finite dimensional equations:*

$$\begin{aligned} &\dot{\hat{\boldsymbol{x}}}_n(t) = \boldsymbol{\Pi}_{\Psi_n}\boldsymbol{A}\boldsymbol{\Pi}_{\Psi_n}\hat{\boldsymbol{x}}_n(t) + \boldsymbol{\Pi}_{\Psi_n}\boldsymbol{B}\boldsymbol{u}_n(t) + \boldsymbol{P}_n(t)\boldsymbol{\Pi}_{\Psi_n}\boldsymbol{C}^*\big(\boldsymbol{y}(t) - \boldsymbol{C}\boldsymbol{\Pi}_{\Psi_n}\hat{\boldsymbol{x}}_n(t)\big), \\ &\hat{\boldsymbol{x}}_n(0) = \boldsymbol{\Pi}_{\Psi_n}\hat{\boldsymbol{x}}(0), \end{aligned} \tag{3.46}$$

$$\boldsymbol{u}_n(t) = -\boldsymbol{B}^*\boldsymbol{R}_n(t_f - t)\boldsymbol{\Pi}_{\Psi'_n}\hat{\boldsymbol{x}}_n(t), \tag{3.47}$$

where $\boldsymbol{P}_n$ *and* $\boldsymbol{R}_n$ *are given by* (3.15) *and* (3.16). *Let* $\boldsymbol{u}(t)$ *be the optimal input,* $\hat{\boldsymbol{x}}(t)$ *the optimal estimated state,* $\boldsymbol{x}_n(t)$ *and* $\boldsymbol{x}(t)$ *the actual state evolving when* $\boldsymbol{u}_n(t)$ *and* $\boldsymbol{u}(t)$ *are applied to system* (2.1), (2.2), *respectively.*

Then

$$\lim_{n\to\infty} E\|\boldsymbol{x}_n - \boldsymbol{x}\|^2_{L_2([0,t_f];\boldsymbol{M}_2)} = 0, \tag{3.48}$$

$$\lim_{n\to\infty} E\|\hat{\boldsymbol{x}}_n - \hat{\boldsymbol{x}}\|^2_{L_2([0,t_f];\boldsymbol{M}_2)} = 0, \tag{3.49}$$

$$\lim_{n\to\infty} E\|\boldsymbol{u}_n - \boldsymbol{u}\|^2_{L_2([0,t_f];\mathbb{R}^p)} = 0, \tag{3.50}$$

$$\lim_{n\to\infty} |J_f(\boldsymbol{u}_n) - J_f(\boldsymbol{u})| = 0. \tag{3.51}$$

Proof. Let $\boldsymbol{X} = \left[\begin{smallmatrix}\boldsymbol{x}\\ \hat{\boldsymbol{x}}\end{smallmatrix}\right]$ and $\boldsymbol{X}_n = \left[\begin{smallmatrix}\boldsymbol{x}_n\\ \hat{\boldsymbol{x}}_n\end{smallmatrix}\right]$. It is

$$\begin{aligned}\dot{\boldsymbol{X}}(t) &= \mathcal{A}\boldsymbol{X}(t) + \boldsymbol{D}(t)\boldsymbol{X}(t) + \boldsymbol{O}(t)\boldsymbol{\omega}(t),\\ \dot{\boldsymbol{X}}_n(t) &= \mathcal{A}_n\boldsymbol{X}_n(t) + \boldsymbol{D}_n(t)\boldsymbol{X}_n(t) + \boldsymbol{O}_n(t)\boldsymbol{\omega}(t),\\ \boldsymbol{X}(0) &= \begin{bmatrix}\boldsymbol{x}(0)\\ \hat{\boldsymbol{x}}(0)\end{bmatrix}, \qquad \boldsymbol{X}_n(0) = \begin{bmatrix}\boldsymbol{x}(0)\\ \boldsymbol{\Pi}_{\Psi_n}\hat{\boldsymbol{x}}(0)\end{bmatrix},\end{aligned} \tag{3.52}$$

where $\mathcal{A}, \mathcal{A}_n, \boldsymbol{D}(t), \boldsymbol{D}_n(t), \boldsymbol{O}(t), \boldsymbol{O}_n(t)$ have been defined in Lemma 3.5.

Let $\boldsymbol{S}(t)$, $\boldsymbol{S}_n(t)$, $\boldsymbol{U}(t,\tau)$, $\boldsymbol{U}_n(t,\tau)$ be as in Lemmas 3.5, 3.6. We have

$$\boldsymbol{X}(t) = \boldsymbol{S}(t)\boldsymbol{X}(0) + \int_0^t \boldsymbol{S}(t-\tau)\big(\boldsymbol{D}(\tau)\boldsymbol{X}(\tau) + \boldsymbol{O}(\tau)\boldsymbol{\omega}(\tau)\big)d\tau, \tag{3.53}$$

$$\boldsymbol{X}_n(t) = \boldsymbol{S}_n(t)\boldsymbol{X}_n(0) + \int_0^t \boldsymbol{S}_n(t-\tau)\big(\boldsymbol{D}_n(\tau)\boldsymbol{X}_n(\tau) + \boldsymbol{O}_n(\tau)\boldsymbol{\omega}(\tau)\big)d\tau, \tag{3.54}$$

which can be rewritten as

$$\boldsymbol{X}(t) = \boldsymbol{U}(t,0)\boldsymbol{X}(0) + \int_0^t \boldsymbol{U}(t,\tau)\boldsymbol{O}(\tau)\boldsymbol{\omega}(\tau)d\tau, \tag{3.55}$$

$$\boldsymbol{X}_n(t) = \boldsymbol{U}_n(t,0)\boldsymbol{X}_n(0) + \int_0^t \boldsymbol{U}_n(t,\tau)\boldsymbol{O}_n(\tau)\boldsymbol{\omega}(\tau)d\tau. \tag{3.56}$$

Let us introduce the Hilbert spaces

$$\boldsymbol{W}_{\boldsymbol{X},t} = L_2([0,t];\mathcal{H}), \qquad \boldsymbol{W}_{\omega,t} = L_2([0,t];\mathbb{R}^s), \tag{3.57}$$

and define the operators

$$\begin{aligned}&\boldsymbol{L}_t : \boldsymbol{W}_{\omega,t} \mapsto \boldsymbol{W}_{\boldsymbol{X},t},\\ &f = \boldsymbol{L}_t\, g, \qquad f(\tau) = \int_0^\tau \boldsymbol{U}(\tau,\vartheta)\boldsymbol{O}(\vartheta)g(\vartheta)d\vartheta,\end{aligned} \tag{3.58}$$

$$\begin{aligned}&\boldsymbol{L}_{t,n} : \boldsymbol{W}_{\omega,t} \mapsto \boldsymbol{W}_{\boldsymbol{X},t},\\ &f = \boldsymbol{L}_{t,n}\, g, \qquad f(\tau) = \int_0^\tau \boldsymbol{U}_n(\tau,\vartheta)\boldsymbol{O}_n(\vartheta)g(\vartheta)d\vartheta,\end{aligned} \tag{3.59}$$

and the functions

$$\boldsymbol{X}_0 : \quad \boldsymbol{X}_0(\tau) = \boldsymbol{U}(\tau,0)\boldsymbol{X}(0), \tag{3.60}$$

$$\boldsymbol{X}_{0,n} : \quad \boldsymbol{X}_{0,n}(\tau) = \boldsymbol{U}_n(\tau,0)\boldsymbol{X}_n(0). \tag{3.61}$$

In the space $\boldsymbol{W}_{\boldsymbol{X},t}$, (3.55), (3.56) can be expressed as

$$\boldsymbol{X} = \boldsymbol{X}_0 + \boldsymbol{L}_t\boldsymbol{\omega}, \tag{3.62}$$

$$\boldsymbol{X}_n = \boldsymbol{X}_{0,n} + \boldsymbol{L}_{t,n}\boldsymbol{\omega}, \tag{3.63}$$

so that

$$\begin{aligned} E\|\boldsymbol{X} - \boldsymbol{X}_n\|^2_{\boldsymbol{W}_{\boldsymbol{X},t}} &= E\|\boldsymbol{X}_0 - \boldsymbol{X}_{0,n} + (\boldsymbol{L}_t - \boldsymbol{L}_{t,n})\boldsymbol{\omega}\|^2_{\boldsymbol{W}_{\boldsymbol{X},t}} \\ &\le 2E\|\boldsymbol{X}_0 - \boldsymbol{X}_{0,n}\|^2_{\boldsymbol{W}_{\boldsymbol{X},t}} + 2E\|(\boldsymbol{L}_t - \boldsymbol{L}_{t,n})\boldsymbol{\omega}\|^2_{\boldsymbol{W}_{\boldsymbol{X},t}}. \end{aligned} \tag{3.64}$$

The first term in the right-hand side goes to zero thanks to Lemma 3.6.

For the second term we have

$$\begin{aligned} E\|(\boldsymbol{L}_t - \boldsymbol{L}_{t,n})\boldsymbol{\omega}\|^2_{\boldsymbol{W}_{(\boldsymbol{X},t)}} &= \|\boldsymbol{L}_t - \boldsymbol{L}_{t,n}\|^2_{H.S.} \\ &= \int_0^t \int_0^\tau \left\|\boldsymbol{U}(\tau,\vartheta)\boldsymbol{O}(\vartheta) - \boldsymbol{U}_n(\tau,\vartheta)\boldsymbol{O}_n(\vartheta)\right\|^2_{H.S.} d\vartheta d\tau \\ &\le 2\int_0^t \int_0^\tau \left\|\big(\boldsymbol{U}(\tau,\vartheta) - \boldsymbol{U}_n(\tau,\vartheta)\big)\boldsymbol{O}(\vartheta)\right\|^2_{H.S.} d\vartheta d\tau \\ &\quad + 2\int_0^t \int_0^\tau \left\|\boldsymbol{U}_n(\tau,\vartheta)\big(\boldsymbol{O}(\vartheta) - \boldsymbol{O}_n(\vartheta)\big)\right\|^2_{H.S.} d\vartheta d\tau \\ &\le \sup_{0\le\vartheta\le\tau\le t} \ \sup_{\boldsymbol{M}\in\{\boldsymbol{O}(\vartheta),\vartheta\in[0,t]\}} \left\|\big(\boldsymbol{U}(\tau,\vartheta) - \boldsymbol{U}_n(\tau,\vartheta)\big)M\right\|^2_{H.S.} t^2 \\ &\quad + \sup_{0\le\vartheta\le\tau\le t, \ n\in Z^+} \|\boldsymbol{U}_n(\tau,\vartheta)\| t^2 \sup_{\vartheta\in[0,t]} \|\boldsymbol{O}(\vartheta) - \boldsymbol{O}_n(\vartheta)\|^2_{H.S.} \end{aligned} \tag{3.65}$$

which goes to zero by using Lemmas 3.1, 3.5, and 3.6. This concludes the proof. □

4. The approximation scheme. In this section, we will derive the approximation scheme for the *LQG* controller (3.4)–(3.7). The first step is the definition of the sequences Ψ_n and Ψ'_n of subspaces approximating $\mathcal{D}(\boldsymbol{A})$ and $\mathcal{D}(\boldsymbol{A}^*)$. This is made by a suitable definition of basis vectors for subspaces $\Psi_n \subset \mathcal{D}(\boldsymbol{A})$ and $\Psi'_n \subset \mathcal{D}(\boldsymbol{A}^*)$. In order to avoid confusion with the general settings in section 3, the forthcoming choice for Ψ_n and Ψ'_n will be denoted by Φ_n and Φ'_n respectively. In [3] the dynamics of linear delay systems is approximated using classical first order splines uniformly distributed over the interval $[-r, 0]$. With this choice the computation of matrix representation of the approximated operators is quite complex due to the fact that in general, for a given number n of subintervals of $[-r, 0]$, the delay instants $-r_j$ do not coincide with knots of splines.

It is useful to define a multi-index $s = (n_1, \ldots, n_\delta)$ that characterizes the partition of each interval $[-r_i, -r_{i-1}]$, for $i = 1, \ldots, \delta$, into n_i subintervals of length $(r_i - r_{i-1})/n_i$, in which $n_i + 1$ classical first order splines are considered (see Figure 1), numbered from 0 to n_i.

DEFINITION 4.1. *A sequence $\{s_n\}$ of multi-indexes, defined for $n = 1, 2, \ldots$, where n is the lowest of indexes n_j of the multi-index (i.e., $n = \min\{s_n\}$), is denoted a test sequence if there exists a constant $\bar{c}$ such that for each n it is* $\max\{s_n\}/n \le \bar{c}$.

Let $t^i_j = -r_{i-1} - (r_i - r_{i-1})j/n_i$, for $j = 0, 1, \ldots, n_i$, $i = 1, \ldots, \delta$. Let *spline*^i_j be the spline j of interval i, that is, the spline with knot in t^i_j. Let ϕ_k, $k = 1, 2, \ldots, N$, be the canonical base in $\mathbb{R}^N$.

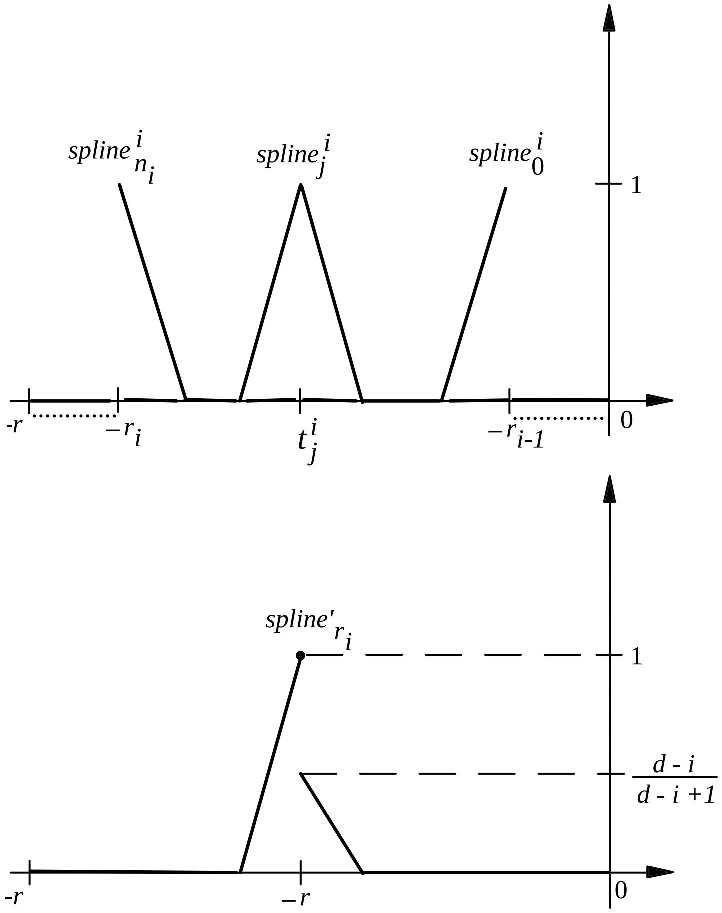

FIG. 1. *First order splines used for the approximation schemes.*

The approximating subspace Φ_n and Φ'_n are defined as follows.

DEFINITION 4.2. *For any given multi-index s_n of a test sequence let Φ_n be the subspace of linear combinations of vectors v^i_h, $v^{r_i}_k$ defined as follows:*

$$v^1_k = \begin{bmatrix} \phi_k \\ \phi_k spline^1_0 \end{bmatrix}, \quad k = 1, \dots, N, \tag{4.1}$$

$$v^i_{jN+k} = \begin{bmatrix} 0 \\ \phi_k spline^i_j \end{bmatrix}, \quad k = 1, \dots, N, \quad j = 1, \dots, n_i - 1, \tag{4.2}$$

$$v^\delta_{n_\delta N+k} = \begin{bmatrix} 0 \\ \phi_k spline^\delta_{n_\delta} \end{bmatrix}, \quad k = 1, \dots, N, \tag{4.3}$$

$$v^{r_i}_k = \begin{bmatrix} 0 \\ \phi_k spline_{r_i} \end{bmatrix}, \quad \begin{array}{l} i = 1, \dots, \delta - 1, \\ k = 1, \dots, N, \end{array} \tag{4.4}$$

where

$$spline_{r_i} = spline^i_{n_i} \cdot \chi_{(-r_i,-r_{i-1}]} + spline^{i+1}_0, \quad i = 1, \ldots, \delta - 1. \tag{4.5}$$

Definition 4.3. *For any given multi-index s_n of a test sequence let Φ'_n be the subspace of linear combinations of vectors w^i_h, $w^{r_i}_k$, w'_k defined as follows:*

$$w^1_k = \begin{bmatrix} 0 \\ \phi_k spline^1_0 \end{bmatrix}, \qquad k = 1, \ldots, N, \tag{4.6}$$

$$w^i_{jN+k} = v^i_{jN+k}, \qquad k = 1, \ldots, N, \qquad \begin{array}{l} i = 1, \ldots, \delta, \\ j = 1, \ldots, n_i - 1, \end{array} \tag{4.7}$$

$$w^{r_j}_k = \begin{bmatrix} 0 \\ \phi_k spline'_{r_j} \end{bmatrix}, \quad j = 1, \ldots, \delta - 1, \quad k = 1, \ldots, N, \tag{4.8}$$

where

$$spline'_{r_j} = \frac{(\delta - j)}{(\delta - j + 1)} spline^j_{n_j} \cdot \chi_{(-r_j,-r_{j-1}]} + spline^{j+1}_0, \tag{4.9}$$

$$spline''_{r_j} = spline^j_{n_j} \cdot \chi_{(-r_j,-r_{j-1}]}, \qquad j = 1, \ldots, \delta - 1, \tag{4.10}$$

$$w'_k = \begin{bmatrix} \phi_k \\ a_{\delta k} spline^\delta_{n_\delta} + \sum_{j=1}^{\delta-1} \frac{1}{(\delta-j+1)} a_{jk} spline''_{r_j} \end{bmatrix}, \quad k = 1, \ldots, N, \tag{4.11}$$

where a_{jk} is the k column of matrix $\boldsymbol{A}^{\mathrm{T}}_j$ for $j = 1, \ldots, \delta$.

Theorem 4.4. *For each multi-index s_n of a test sequence, it is $\Phi_n \subset \mathcal{D}(\boldsymbol{A})$ and $\Phi'_n \subset \mathcal{D}(\boldsymbol{A}^*)$.*

Proof. It is immediate to verify that $\Phi_n \subset \mathcal{D}(\boldsymbol{A})$. A more detailed proof is required to show that $\Phi'_n \subset \mathcal{D}(\boldsymbol{A}^*)$. To this aim it is sufficient to verify that each vector w belongs to it. It is easy to check that vectors w^i_{jN+k}, for $i = 1, \ldots, \delta$, $k = 1, \ldots, N$, $j = 1, \ldots, n_i - 1$, and vectors w^1_k, for $k = 1, \ldots, N$, belong to $\boldsymbol{D}(\boldsymbol{A}^*)$. Let us consider now the vectors $w^{r_i}_k$, for $i = 1, \ldots, \delta - 1$, $k = 1, \ldots, N$ (as usual, we shall indicate the part in $\mathbb{R}^N$ by using the subscript 0 and the part in L_2 by using the subscript 1).

From the definition, for each k it is

$$\begin{aligned} &(w^{r_i}_k)_0 = 0, \\ &(w^{r_i}_k)_1(-r_j) = 0, \quad i, j = 1, \ldots, \delta - 1, \ i \neq j, \\ &(w^{r_i}_k)_1(-r) = 0, \quad i = 1, \ldots, \delta - 1, \end{aligned} \tag{4.12}$$

so that for $k = 1, \ldots, N$, $\ i = 1, \ldots, \delta - 1$,

$$(w^{r_i}_k)_1(-r) = \boldsymbol{A}^{\mathrm{T}}_\delta (w^{r_i}_k)_0 \tag{4.13}$$

and

$$\begin{aligned} \sum_{j=1}^{\delta-1} \boldsymbol{k}_j\left((w^{r_i}_k)_0, (w^{r_i}_k)_1\right) \chi_{[-r,-r_j]} &= \sum_{j=1}^{\delta-1} \frac{(w^{r_i}_k)_1(-r_j) - \boldsymbol{A}^{\mathrm{T}}_j (w^{r_i}_k)_0}{\delta - j + 1} \chi_{[-r,-r_j]} \\ &= \frac{(w^{r_i}_k)_1(-r_i)}{\delta - i + 1} \chi_{[-r,-r_i]}. \end{aligned} \tag{4.14}$$

So it is only to be verified that for $i = 1, \ldots, \delta - 1,\ k = 1, \ldots, N$,

$$(w_k^{r_i})_1 - \frac{1}{(\delta - i + 1)} (w_k^{r_i})_1 (-r_i) \chi_{[-r,-r_i]} \in W^{1,2}. \tag{4.15}$$

Since

$$spline'_{r_i}(-r_i) - \frac{1}{\delta - i + 1} = \frac{\delta - i}{\delta - i + 1} = \lim_{\vartheta \to -r_i^+} spline'_{r_i}(\vartheta), \tag{4.16}$$

(4.15) is clearly true.

For vectors w'_k defined in (4.11), for $k = 1, \ldots, N$, it is

$$(w'_k)_1(-r) = a_{\delta k} = \boldsymbol{A}_\delta^{\mathrm{T}} \phi_k = \boldsymbol{A}_\delta^{\mathrm{T}} (w'_k)_0. \tag{4.17}$$

It is also

$$(w'_k)_1(-r_i) = 0, \quad i = 1, \ldots, \delta - 1, \tag{4.18}$$

and therefore

$$\begin{aligned} \sum_{j=1}^{\delta-1} \boldsymbol{k}_j \left((w'_k)_0, (w'_k)_1\right) \chi_{[-r,-r_j]} &= \sum_{j=1}^{\delta-1} \frac{(w'_k)_1 (-r_j) - \boldsymbol{A}_j^{\mathrm{T}} (w'_k)_0}{\delta - j + 1} \chi_{[-r,-r_j]} \\ &= \sum_{j=1}^{\delta-1} \frac{-\boldsymbol{A}_j^{\mathrm{T}} (w'_k)_0}{(\delta - j + 1)} \chi_{[-r,-r_j]} = \sum_{j=1}^{\delta-1} \frac{-a_{jk}}{(\delta - j + 1)} \chi_{[-r,-r_j]}. \end{aligned} \tag{4.19}$$

From

$$\lim_{\vartheta \mapsto -r_j^+} (w'_k)_1 (\vartheta) = \frac{a_{jk}}{\delta - j + 1} \tag{4.20}$$

it follows, for $i = 1, \ldots, \delta - 1$,

$$\begin{aligned} \left((w'_k)_1 + \sum_{j=1}^{\delta-1} \frac{a_{jk}}{(\delta - j + 1)} \chi_{[-r,-r_j]} \right) (-r_i) &= (w'_k)_1(-r_i) + \sum_{j=1}^{i} \frac{a_{jk}}{(\delta - j + 1)} \\ = \sum_{j=1}^{i} \frac{a_{jk}}{\delta - j + 1} &= \frac{a_{ik}}{\delta - i + 1} + \sum_{j=1}^{i-1} \frac{a_{jk}}{\delta - j + 1} \\ = \lim_{\vartheta \mapsto -r_i^+} (w'_k)_1 (\vartheta) &+ \lim_{\vartheta \mapsto -r_i^+} \sum_{j=1}^{\delta-1} \frac{a_{jk}}{\delta - j + 1} \chi_{[-r,-r_j]}(\vartheta), \end{aligned} \tag{4.21}$$

and so

$$\left((w'_k)_1 + \sum_{j=1}^{\delta-1} \frac{a_{jk}}{\delta - j + 1} \chi_{[-r,-r_j]} \right) \in \boldsymbol{W}^{1,2}, \tag{4.22}$$

(4.17) and (4.22) prove that vectors w'_k, $k = 1, \ldots, N$, belong to $\boldsymbol{D}(\boldsymbol{A}^*)$. □

Remark 4.5. Note that a key idea for the previous theorem is the choice of a type of not uniformly distributed splines.

Remark 4.6. In the case of just one pure delay, vectors generating subspaces Φ_n and Φ'_n become, respectively,

$$v_{jN+k} = \begin{bmatrix} 0 \\ \boldsymbol{\phi}_k spline_j \end{bmatrix}, \quad k = 1, \dots, N, \quad j = 1, 2, \dots, n, \tag{4.23}$$

$$v_k = \begin{bmatrix} \boldsymbol{\phi}_k \\ \boldsymbol{\phi}_k spline_0 \end{bmatrix}, \quad k = 1, \dots, N \tag{4.24}$$

for Φ_n, and

$$w_k^1 = \begin{bmatrix} 0 \\ \boldsymbol{\phi}_k spline_0 \end{bmatrix}, \quad k = 1, \dots, N, \tag{4.25}$$

$$w_{jN+k} = v_{jN+k} \qquad k = 1, \dots, N, \qquad j = 1, 2, \dots, n-1, \tag{4.26}$$

$$w'_k = \begin{bmatrix} \boldsymbol{\phi}_k \\ a_{1k} spline_n \end{bmatrix}, \quad k = 1, \dots, N \tag{4.27}$$

for Φ'_n. As can be seen, a great simplification is obtained with respect to the general case. Vectors v are just the ones in [3], and vectors w differ just for the fact that the nonzero term in $\mathbb{R}^N$ is taken from the first N vectors to the last ones, and the L_2 part of these last N vectors is multiplied for the columns of matrix $\boldsymbol{A}_1^{\mathrm{T}}$. This simplification with respect to the general case is due to the much simpler domain (2.21).

Consider now a test sequence of multi-indexes $\{s_n\}$, and consider the associated sequence of orthoprojection operators $\boldsymbol{\Pi}_{\Phi_n} : \boldsymbol{M}_2 \mapsto \Phi_n$ and $\boldsymbol{\Pi}_{\Phi'_n} : \boldsymbol{M}_2 \mapsto \Phi'_n$. For brevity, from now on the following notation is used:

$$\boldsymbol{\Pi}_n = \boldsymbol{\Pi}_{\Phi_n}, \qquad \boldsymbol{\Pi}'_n = \boldsymbol{\Pi}_{\Phi'_n}. \tag{4.28}$$

Recall that operators $\boldsymbol{\Pi}_n$ and $\boldsymbol{\Pi}'_n$, being orthogonal projectors, have the following properties:

$$\forall \boldsymbol{y} \in \boldsymbol{M}_2, \quad \|\boldsymbol{\Pi}_n \boldsymbol{y} - \boldsymbol{y}\| \leq \|\boldsymbol{x} - \boldsymbol{y}\| \quad \forall \boldsymbol{x} \in \Phi_n, \tag{4.29}$$

$$\forall \boldsymbol{y} \in \boldsymbol{M}_2, \quad \|\boldsymbol{\Pi}'_n \boldsymbol{y} - \boldsymbol{y}\| \leq \|\boldsymbol{x} - \boldsymbol{y}\| \quad \forall \boldsymbol{x} \in \Phi'_n. \tag{4.30}$$

The following results can be given on the convergence of the sequences of projectors $\boldsymbol{\Pi}_n$, $\boldsymbol{\Pi}'_n$, and of the sequence of semigroups generated by $\boldsymbol{\Pi}_n \boldsymbol{A} \boldsymbol{\Pi}_n$ and $\boldsymbol{\Pi}'_n \boldsymbol{A}^* \boldsymbol{\Pi}'_n$.

THEOREM 4.7. *The sequence of orthoprojection operators* $\boldsymbol{\Pi}_n : \boldsymbol{M}_2 \mapsto \Phi_n$ *converges strongly to the identity operator.*

Proof. Let $D = \{\left[\begin{smallmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{smallmatrix}\right] \in \boldsymbol{M}_2 | \boldsymbol{y}_0 = \boldsymbol{y}_1(0), \boldsymbol{y}_1 \in C^2([-r, 0]; \mathbb{R}^N)\}$. Such set D is dense in $\boldsymbol{M}_2$ (see the proof of Lemma 2.2 and Remark 3.2 in [3]). Let $\boldsymbol{x} = \left[\begin{smallmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{smallmatrix}\right] \in D$ and let

$$\begin{aligned} \boldsymbol{x}^n = \begin{bmatrix} \boldsymbol{x}_0^n \\ \boldsymbol{x}_1^n \end{bmatrix} &= \sum_{k=1}^{N} (\boldsymbol{x}_1(-r)^{\mathrm{T}} \phi_k) v_{n_\delta N+k}^{\delta} + \sum_{k=1}^{N} \sum_{i=1}^{\delta-1} (\boldsymbol{x}_1(-r_i)^{\mathrm{T}} \phi_k) v_k^{r_i} \\ &+ \sum_{i=1}^{\delta} \sum_{k=1}^{N} \sum_{j=1}^{n_i-1} (\boldsymbol{x}_1(t_j^i)^{\mathrm{T}} \phi_k) v_{jN+k}^i + \sum_{k=1}^{N} (\boldsymbol{x}_1(0)^{\mathrm{T}} \phi_k) v_k^1. \end{aligned} \tag{4.31}$$

By Theorem 2.5 in [42] it is $\|\boldsymbol{x}_1^n - \boldsymbol{x}_1\| \to 0$, and the thesis follows by

$$\|\boldsymbol{x}^n - \boldsymbol{x}\|_{\boldsymbol{M}_2} = \|\boldsymbol{x}_1^n - \boldsymbol{x}_1\|_{\boldsymbol{L}_2} \tag{4.32}$$

and by property (4.29). □

THEOREM 4.8. *The sequence of semigroups $\boldsymbol{T}_{\Phi_n}$ generated by the operators $\boldsymbol{\Pi}_n \boldsymbol{A} \boldsymbol{\Pi}_n$ converges strongly to the semigroup governing the system* (2.5), (2.6).

Proof. Let D be the set in the proof of the previous theorem. There exists $\lambda > 0$ such that $(\boldsymbol{A} - \lambda \boldsymbol{I})D$ is dense in $\boldsymbol{M}_2$ (see Lemma 2.2 in [3]). There exists α such that $(\boldsymbol{A} - \alpha \boldsymbol{I})$ e $(\boldsymbol{\Pi}_n \boldsymbol{A} \boldsymbol{\Pi}_n - \alpha \boldsymbol{I})$ are dissipative (see Lemma 2.3 and proof of Theorem 3.1 in [3]). Let $\boldsymbol{x} = \left[\begin{smallmatrix} \boldsymbol{x}_0 \\ \boldsymbol{x}_1 \end{smallmatrix}\right] \in D$. Let $\boldsymbol{\Pi}_n \boldsymbol{x} = \left[\begin{smallmatrix} (\boldsymbol{\Pi}_n \boldsymbol{x})_0 \\ (\boldsymbol{\Pi}_n \boldsymbol{x})_1 \end{smallmatrix}\right]$. From

$$(\boldsymbol{\Pi}_n \boldsymbol{x})_1(-r_i) = (\boldsymbol{\Pi}_n \boldsymbol{x})_1(-r_{i-1}) - \int_{-r_i}^{-r_{i-1}} \frac{d(\boldsymbol{\Pi}_n \boldsymbol{x})_1(\vartheta)}{d\vartheta} d\vartheta \tag{4.33}$$

and as $\|\frac{d(\boldsymbol{x}_1 - (\boldsymbol{\Pi}_n \boldsymbol{x})_1)}{d\vartheta}\| \to 0$, (see Theorem 4.1 in [3], and Theorems 1.5, 2.5 in [42]), it follows that $\|\boldsymbol{A}\boldsymbol{\Pi}_n \boldsymbol{x} - \boldsymbol{A}\boldsymbol{x}\| \to 0$. Take into account that $(\boldsymbol{\Pi}_n \boldsymbol{x})_1(0) = (\boldsymbol{\Pi}_n \boldsymbol{x})_0$ and that $\|(\boldsymbol{\Pi}_n \boldsymbol{x})_0 - \boldsymbol{x}_0\| \to 0$.

Thus the Trotter–Kato theorem hypotheses are satisfied ([38], Lemma 3.1 in [3]). □

As can be seen, the proofs of the above two theorems follow the same lines of the proofs in [3], developed for the case of first order splines uniformly distributed in the interval $[-r, 0]$.

LEMMA 4.9. *The subspace*

$$U = \left\{ \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{bmatrix} \middle| \begin{array}{ll} \boldsymbol{y}_0 \in \mathbb{R}^N, & \boldsymbol{y}_1(0) = \boldsymbol{y}_0, \\ \boldsymbol{y}_1 \in W^{1,2} & \boldsymbol{y}_1(-r_j) = \boldsymbol{A}_j^{\mathrm{T}} \boldsymbol{y}_0,\ j = 1, \dots, \delta \end{array} \right\} \tag{4.34}$$

is dense in $\boldsymbol{M}_2$.

Proof. As usual, let us prove density in $\mathbb{R}^N \times W^{1,2}$. Let $\boldsymbol{y} = \left[\begin{smallmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{smallmatrix}\right] \in \mathbb{R}^N \times W^{1,2}$. Let us define the following sequence of functions $f_n : [-r, 0] \to \mathbb{R}^N$, $n > \sup_{i=1,2,\dots,\delta} \frac{r}{r_i - r_{i-1}}$,

$$\begin{aligned} f_n(\vartheta) = {} & \left(\boldsymbol{y}_0 - \frac{n}{r}\vartheta \left(\boldsymbol{y}_1 \left(\frac{-r}{n} \right) - \boldsymbol{y}_0 \right) \right) \chi_{[\frac{-r}{n}, 0]} \\ & + \left(\boldsymbol{A}_\delta^{\mathrm{T}} \boldsymbol{y}_0 + \frac{n}{r}(\vartheta + r) \left(\boldsymbol{y}_1 \left(-r + \frac{r}{n} \right) - \boldsymbol{A}_\delta^{\mathrm{T}} \boldsymbol{y}_0 \right) \right) \chi_{[-r, -r + \frac{r}{n}]} \\ & + \sum_{i=1}^{\delta} \left(\boldsymbol{A}_i^{\mathrm{T}} \boldsymbol{y}_0 + \frac{n}{r}(\vartheta + r_i) \left(\boldsymbol{y}_1 \left(-r_i + \frac{r}{n} \right) - \boldsymbol{A}_i^{\mathrm{T}} \boldsymbol{y}_0 \right) \right) \chi_{[-r_i, -r_i + \frac{r}{n}]} \\ & \quad + \left(\boldsymbol{A}_i^{\mathrm{T}} \boldsymbol{y}_0 - \frac{n}{r}(\vartheta + r_i) \left(\boldsymbol{y}_1 \left(-r_i - \frac{r}{n} \right) - \boldsymbol{A}_i^{\mathrm{T}} \boldsymbol{y}_0 \right) \right) \chi_{[-r_i - \frac{r}{n}, -r_i)}. \end{aligned} \tag{4.35}$$

Consider the sequence of elements in U,

$$\boldsymbol{y}_n = \begin{bmatrix} \boldsymbol{y}_0 \\ f_n + \sum_{i=1}^{\delta} \boldsymbol{y}_1 \chi_{(-r_i + \frac{r}{n}, -r_{i-1} - \frac{r}{n})} \end{bmatrix}. \tag{4.36}$$

As $\boldsymbol{y}_1$ is bounded, f_n is bounded too, uniformly on n. It follows that

$$\|\boldsymbol{y}_n - \boldsymbol{y}\|^2 \le \left(\sup_{\vartheta, n} \|\boldsymbol{y}_1(\vartheta) - f_n(\vartheta)\|^2 \right) \frac{2\delta r}{n}. \qquad \square \tag{4.37}$$

Remark 4.10. The previous lemma proves that the intersection between the domain of $\boldsymbol{A}$ and the domain of $\boldsymbol{A}^*$ is dense in $\boldsymbol{M}_2$ if the weighted inner product is used. See that the subspace U is contained in both the domains. It is a standard result that such an intersection is in general not dense if the usual inner product is used [11, 14, 24, 27, 43].

THEOREM 4.11. *The sequence of orthoprojection operators* $\boldsymbol{\Pi}'_n : \boldsymbol{M}_2 \mapsto \Phi'_n$ *converges strongly to the identity operator.*

Proof. It is sufficient to prove strong convergence in a dense subspace of $\boldsymbol{M}_2$. Therefore, consider the subspace U in (4.34).

It is shown below that for any $\boldsymbol{y} = \left[\begin{smallmatrix}\boldsymbol{y}_0\\ \boldsymbol{y}_1\end{smallmatrix}\right] \in U$ there exists a sequence of approximations $\boldsymbol{y}^n \in \Phi'_n$ such that $\lim_{n\to\infty} \|\boldsymbol{y}^n - \boldsymbol{y}\|_{\boldsymbol{M}_2} = 0$. Consider the following definition of $\boldsymbol{y}^n \in \Phi'_n$:

$$\begin{aligned}\boldsymbol{y}^n &= \sum_{k=1}^{N}(\boldsymbol{y}_0^{\mathrm{T}}\phi_k)w'_k + \sum_{k=1}^{N}\sum_{i=1}^{\delta-1}(\boldsymbol{y}_1(-r_i)^{\mathrm{T}}\phi_k)w_k^{r_i},\\ &\quad + \sum_{i=1}^{\delta}\sum_{k=1}^{N}\sum_{j=1}^{n_i-1}(\boldsymbol{y}_1(t_j^i)^{\mathrm{T}}\phi_k)w^i_{jN+k} + \sum_{k=1}^{N}(\boldsymbol{y}_1(0)^{\mathrm{T}}\phi_k)w_k^1.\end{aligned} \tag{4.38}$$

It is, by substituting expressions of vectors generating the subspace Φ'_n (4.6), (4.7), (4.8), (4.11),

$$\begin{aligned}\boldsymbol{y}^n = \begin{bmatrix}\boldsymbol{y}_0^n\\ \boldsymbol{y}_1^n\end{bmatrix} &= \begin{bmatrix}\boldsymbol{y}_0\\ \displaystyle\sum_{k=1}^{N}(\boldsymbol{y}_1(-r)^{\mathrm{T}}\phi_k)\phi_k\, spline^{\delta}_{n_\delta}\end{bmatrix}\\ &+ \begin{bmatrix}0\\ \displaystyle\sum_{k=1}^{N}\sum_{j=1}^{\delta-1}\left(\frac{(\boldsymbol{y}_0^{\mathrm{T}}\phi_k)a_{jk}}{\delta-j+1}spline''_{r_j} + (\boldsymbol{y}_1(-r_j)^{\mathrm{T}}\phi_k)\phi_k\, spline'_{r_j}\right)\end{bmatrix}\\ &+ \begin{bmatrix}0\\ \displaystyle\sum_{i=1}^{\delta}\sum_{k=1}^{N}\sum_{j=1}^{n_i-1}(\boldsymbol{y}_1(t_j^i)^{\mathrm{T}}\phi_k)\phi_k\, spline^i_j\end{bmatrix} + \begin{bmatrix}0\\ \displaystyle\sum_{k=1}^{N}(\boldsymbol{y}_1(0)^{\mathrm{T}}\phi_k)\phi_k\, spline^1_0\end{bmatrix}.\end{aligned} \tag{4.39}$$

Moreover, it is readily recognized that

$$\sum_{k=1}^{N}(\boldsymbol{y}_0^{\mathrm{T}}\phi_k)a_{AK} = \boldsymbol{A}_j^{\mathrm{T}}\boldsymbol{y}_0 = \sum_{k=1}^{N}(\boldsymbol{y}_1(-r_j)^{\mathrm{T}}\phi_k)\phi_k, \quad j = 1,\dots,\delta, \tag{4.40}$$

$$\frac{1}{\delta-j+1}spline''_{r_j} + spline'_{r_j} = spline_{r_j}, \quad j = 1,\dots,\delta-1, \tag{4.41}$$

so that

$$\begin{aligned}\|\boldsymbol{y}^n - \boldsymbol{y}\|_{\boldsymbol{M}_2} = \Bigg\| &\sum_{k=1}^{N}(\boldsymbol{y}_1(-r)^{\mathrm{T}}\phi_k)\phi_k\, spline^{\delta}_{n_\delta}\\ &+ \sum_{j=1}^{\delta-1}\boldsymbol{A}_j^{\mathrm{T}}\boldsymbol{y}_0\Big(\frac{1}{\delta-j+1}spline''_{r_j} + spline'_{r_j}\Big)\end{aligned}$$

$$
\begin{aligned}
&+\sum_{i=1}^{\delta}\sum_{k=1}^{N}\sum_{j=1}^{n_i-1}(\boldsymbol{y}_1(t_j^i)^{\mathrm{T}}\phi_k)\phi_k\, spline_j^i\\
&+\sum_{k=1}^{N}(\boldsymbol{y}_1(0)^{\mathrm{T}}\phi_k)\phi_k\, spline_0^1-\boldsymbol{y}_1\Big\|_{L_2}\\
&=\Big\|\sum_{k=1}^{N}(\boldsymbol{y}_1(-r)^{\mathrm{T}}\phi_k)\phi_k\, spline_{n_\delta}^{\delta}+\sum_{j=1}^{\delta-1}\boldsymbol{y}_1(-r_j)\, spline_{r_j}\\
&+\sum_{i=1}^{\delta}\sum_{k=1}^{N}\sum_{j=1}^{n_i-1}(\boldsymbol{y}_1(t_j^i)^{\mathrm{T}}\phi_k)\phi_k\, spline_j^i\\
&+\sum_{k=1}^{N}(\boldsymbol{y}_1(0)^{\mathrm{T}}\phi_k)\phi_k\, spline_0^1-\boldsymbol{y}_1\Big\|_{L_2}\\
&=\Big\|\sum_{i=1}^{\delta}\sum_{k=1}^{N}\sum_{j=0}^{n_i}(\boldsymbol{y}_1(t_j^i)^{\mathrm{T}}\phi_k)\phi_k\, spline_j^i-\boldsymbol{y}_1\Big\|_{L_2}\\
&=\sum_{i=1}^{\delta}\Big\|\sum_{k=1}^{N}\sum_{j=0}^{n_i}(\boldsymbol{y}_1(t_j^i)^{\mathrm{T}}\phi_k)\phi_k\, spline_j^i-\boldsymbol{y}_1\cdot\chi_{[-r_i,-r_{i-1}]}\Big\|_{L_2},
\end{aligned}
\tag{4.42}
$$

which gives the norm of the error between a function $\boldsymbol{y}_1\in W^{1,2}$ and its approximation with first order splines in which the value at each spline knot (the instants t_j^i) is exactly the value of the function at time t_j^i. It is a standard result that the error tends to zero in L_2 norm for $n\to\infty$ (Theorem 2.4 in [42]) and therefore $\lim_{n\to\infty}\|\boldsymbol{y}^n-\boldsymbol{y}\|_{\boldsymbol{M}_2}=0$. This implies, by property (4.30), the strong convergence to identity of operator $\boldsymbol{\Pi}_n'$. □

LEMMA 4.12. *There exists a real constant α such that the operator $\boldsymbol{A}^*-\alpha\boldsymbol{I}$ and operators $\boldsymbol{\Pi}_n'\boldsymbol{A}^*\boldsymbol{\Pi}_n'-\alpha\boldsymbol{I}$ are dissipative.*

Proof. In [3] it has been proved that there exists α such that operator $\boldsymbol{A}-\alpha\boldsymbol{I}$ is dissipative and therefore generates a semigroup which is a contraction one. This implies that the adjoint semigroup is a contraction one too and therefore its infinitesimal generator $\boldsymbol{A}^*-\alpha\boldsymbol{I}$ is dissipative [1]. Dissipativity of $\boldsymbol{A}^*-\alpha\boldsymbol{I}$ implies that for any n the operator $\boldsymbol{\Pi}_n'\boldsymbol{A}^*\boldsymbol{\Pi}_n'-\alpha\boldsymbol{I}$ is dissipative. This happens because for any $\boldsymbol{x}\in\boldsymbol{M}_2$

$$
\begin{aligned}
\big((\boldsymbol{\Pi}_n'\boldsymbol{A}^*\boldsymbol{\Pi}_n'-\alpha\boldsymbol{I})\boldsymbol{x},\boldsymbol{x}\big)&=(\boldsymbol{A}^*\boldsymbol{\Pi}_n'\boldsymbol{x},\boldsymbol{\Pi}_n'\boldsymbol{x})-\alpha(\boldsymbol{x},\boldsymbol{x})\\
&\le(\boldsymbol{A}^*\boldsymbol{\Pi}_n'\boldsymbol{x},\boldsymbol{\Pi}_n'\boldsymbol{x})-\alpha(\boldsymbol{\Pi}_n'\boldsymbol{x},\boldsymbol{\Pi}_n'\boldsymbol{x})\\
&=\big((\boldsymbol{A}^*-\alpha\boldsymbol{I})\boldsymbol{\Pi}_n'\boldsymbol{x},\boldsymbol{\Pi}_n'\boldsymbol{x}\big)\le 0.
\end{aligned}
\tag{4.43}
$$

□

LEMMA 4.13. *Let $\boldsymbol{D}$ be the dense subspace of $\boldsymbol{M}_2$ defined as*

$$
\boldsymbol{D}=\left\{\begin{bmatrix}\boldsymbol{y}_0\\ \boldsymbol{y}_1\end{bmatrix}\;\middle|\;\begin{array}{c}\boldsymbol{y}_0\in\mathbb{R}^N,\quad \boldsymbol{A}_\delta^{\mathrm{T}}\boldsymbol{y}_0=\boldsymbol{y}_1(-r),\\ \left(\boldsymbol{y}_1-\displaystyle\sum_{j=1}^{\delta-1}\boldsymbol{k}_j(\boldsymbol{y}_0,\boldsymbol{y}_1)\chi_{[-r,-r_j]}\right)\in C^2\end{array}\right\}.
\tag{4.44}
$$

Then there exists $\lambda>0$ such that $(\boldsymbol{A}^*-\lambda\boldsymbol{I})\boldsymbol{D}$ is dense in $\boldsymbol{M}_2$.

Proof. Let us at first assume the following additional property on the term $\boldsymbol{A}_{01}$ in the definition of operator $\boldsymbol{A}^*$:

$$(\mathrm{Hp}_0): \quad \frac{1}{g}\boldsymbol{A}_{01}^{\mathrm{T}} \quad \text{is a matrix of functions in } C^1([-r,0];\mathbb{R}),$$

where g is the weighting function in the inner product (2.4).

Hypothesis (Hp_0) will be removed at the end of the proof.

First, it will be shown that under assumption (Hp_0) there exists a sufficiently large λ and matrices $P_0^j(\lambda) \in \mathbb{R}^{N\times N}$ and $P_1^j(\lambda) \in \mathbb{R}^{N\times \delta N}$, $j = 1, 2, \ldots, \delta - 1$, such that for any $\boldsymbol{z} = \left[\begin{smallmatrix}\boldsymbol{z}_0\\ \boldsymbol{z}_1\end{smallmatrix}\right] \in \mathbb{R}^N \times C^1([-r,0];\mathbb{R}^N)$ there exists $\boldsymbol{y} \in \boldsymbol{D}$ such that

$$(4.45)\qquad \begin{gathered}(\boldsymbol{A}^* - \lambda\boldsymbol{I})\boldsymbol{y} = \begin{bmatrix}\boldsymbol{z}_0\\ \tilde{\boldsymbol{z}}_1(\boldsymbol{z};\lambda)\end{bmatrix},\\ \text{where}\quad \tilde{\boldsymbol{z}}_1(\boldsymbol{z};\lambda) = \boldsymbol{z}_1 + \sum_{j=1}^{\delta-1}\big(P_0^j(\lambda)\boldsymbol{z}_0 + P_1^j(\lambda)F_\lambda(\boldsymbol{z}_1)\big)\chi_{[-r,-r_j]},\end{gathered}$$

in which the linear functional $F_\lambda(\boldsymbol{z}_1) : C^1([-r,0];\mathbb{R}^N) \mapsto \mathbb{R}^{N\delta}$ is defined as follows:

$$(4.46)\qquad F_\lambda(\boldsymbol{z}_1) = \begin{pmatrix}\displaystyle\int_{-r}^{0} e^{\lambda\tau}\boldsymbol{z}_1(\tau)d\tau\\ \displaystyle\int_{-r}^{-r_1} e^{-\lambda(-r_1-\tau)}\boldsymbol{z}_1(\tau)d\tau\\ \vdots\\ \displaystyle\int_{-r}^{-r_{\delta-1}} e^{-\lambda(-r_{\delta-1}-\tau)}\boldsymbol{z}_1(\tau)d\tau\end{pmatrix}.$$

Next, it will be shown that there exists a sufficiently large λ such that for any given $\boldsymbol{x} = \left[\begin{smallmatrix}\boldsymbol{x}_0\\ \boldsymbol{x}_1\end{smallmatrix}\right] \in \boldsymbol{M}_2$ and for any $\varepsilon > 0$ there exists $\boldsymbol{z} = \left[\begin{smallmatrix}\boldsymbol{z}_0\\ \boldsymbol{z}_1\end{smallmatrix}\right] \in \mathbb{R}^N \times C^1([-r,0];\mathbb{R}^N)$ such that

$$(4.47)\qquad \left\| \begin{bmatrix}\boldsymbol{x}_0\\ \boldsymbol{x}_1\end{bmatrix} - \begin{bmatrix}\boldsymbol{z}_0\\ \tilde{\boldsymbol{z}}_1(\boldsymbol{z};\lambda)\end{bmatrix} \right\|_{\boldsymbol{M}_2} \le \varepsilon$$

and therefore, from (4.45),

$$(4.48)\qquad \forall \boldsymbol{x} \in \boldsymbol{M}_2,\ \forall\varepsilon > 0, \quad \exists \boldsymbol{y} \in \boldsymbol{D}: \ \big\|\boldsymbol{x} - (\boldsymbol{A}^* - \lambda\boldsymbol{I})\boldsymbol{y}\big\|_{\boldsymbol{M}_2} \le \varepsilon,$$

that is, the density of $(\boldsymbol{A}^* - \lambda\boldsymbol{I})\boldsymbol{D}$ in $\boldsymbol{M}_2$.

In order to prove (4.45) as a first step it is shown how to find a function $\bar{Y}_1(\boldsymbol{y}_0, \boldsymbol{z}_1)$ such that for any $\boldsymbol{y}_0 \in \mathbb{R}^N$ and $\boldsymbol{z}_1 \in C^1([-r,0];\mathbb{R}^N)$ it is $\left[\begin{smallmatrix}\boldsymbol{y}_0\\ \bar{Y}_1(\boldsymbol{y}_0,\boldsymbol{z}_1)\end{smallmatrix}\right] \in \boldsymbol{D}$. Next, it is shown how to define a function $Y_0(\boldsymbol{z}_0, \boldsymbol{z}_1) : \mathbb{R}^N \times C^1([-r,0];\mathbb{R}^N) \to \mathbb{R}^N$ such that the composed function $Y_1(\boldsymbol{z}_0, \boldsymbol{z}_1) = \bar{Y}_1(Y_0(\boldsymbol{z}_0, \boldsymbol{z}_1), \boldsymbol{z}_1)$ has the property

$$(4.49)\qquad (\boldsymbol{A}^* - \lambda\boldsymbol{I})\begin{bmatrix}Y_0(\boldsymbol{z}_0,\boldsymbol{z}_1)\\ Y_1(\boldsymbol{z}_0,\boldsymbol{z}_1)\end{bmatrix} = \begin{bmatrix}\boldsymbol{z}_0\\ \tilde{\boldsymbol{z}}_1(\boldsymbol{z}_1;\lambda)\end{bmatrix}.$$

For any given pair $\boldsymbol{y}_0 \in \mathbb{R}^N$ and $\boldsymbol{z}_1 \in C^1([-r,0];\mathbb{R}^N)$ let us consider the differential equation in $C^2([-r,0];\mathbb{R}^N)$,

$$(4.50)\qquad \frac{d}{d\vartheta}\boldsymbol{f}(\vartheta) + \lambda\boldsymbol{f}(\vartheta) = -\Big(\boldsymbol{z}_1(\vartheta) - \frac{1}{g(\vartheta)}\boldsymbol{A}_{01}^{\mathrm{T}}(\vartheta)\boldsymbol{y}_0\Big),$$

whose solution is

$$\boldsymbol{f}(\vartheta) = e^{-\lambda(\vartheta+r)}\boldsymbol{f}(-r) - \int_{-r}^{\vartheta} e^{-\lambda(\vartheta-\tau)}\Big(\boldsymbol{z}_1(\tau) - \frac{1}{g(\tau)}\boldsymbol{A}_{01}^{\mathrm{T}}(\tau)\boldsymbol{y}_0\Big)d\tau. \tag{4.51}$$

By Lemma A.1 in the appendix, there exists a unique left-continuous function $\boldsymbol{y}_1$ that satisfies condition (A.1), with $\boldsymbol{f}$ given by (4.51). Such $\boldsymbol{y}_1$ is given by expression (A.6), and its values at the delay instants are such that

$$(\boldsymbol{I}_{(\delta-1)N} - H_{\delta,2})\begin{bmatrix} \boldsymbol{y}_1(-r_1) \\ \vdots \\ \boldsymbol{y}_1(-r_{\delta-1}) \end{bmatrix} = \begin{bmatrix} \boldsymbol{f}(-r_1) \\ \vdots \\ \boldsymbol{f}(-r_{\delta-1}) \end{bmatrix} - H_{\delta,2}\begin{bmatrix} \boldsymbol{A}_1^{\mathrm{T}} \\ \vdots \\ \boldsymbol{A}_{\delta-1}^{\mathrm{T}} \end{bmatrix}\boldsymbol{y}_0, \tag{4.52}$$

where $H_{\delta,2}$ is defined in (A.4), Lemma A.1, in the appendix.

In order to guarantee that $\boldsymbol{y} = \left[\begin{smallmatrix}\boldsymbol{y}_0 \\ \boldsymbol{y}_1\end{smallmatrix}\right] \in \boldsymbol{D}$, $\boldsymbol{y}_1$ must satisfy the additional condition

$$\boldsymbol{y}_1(-r) = \boldsymbol{A}_\delta^{\mathrm{T}}\boldsymbol{y}_0. \tag{4.53}$$

By substituting (4.53) in (A.1) one has

$$\boldsymbol{f}(-r) = \boldsymbol{A}_\delta^{\mathrm{T}}\boldsymbol{y}_0 - \sum_{j=1}^{\delta-1}\frac{\boldsymbol{y}_1(-r_j) - \boldsymbol{A}_j^{\mathrm{T}}\boldsymbol{y}_0}{\delta - j + 1}, \tag{4.54}$$

which can be rewritten as

$$\boldsymbol{f}(-r) = h_{\delta,1}\begin{bmatrix} \boldsymbol{y}_1(-r_1) \\ \vdots \\ \boldsymbol{y}_1(-r_{\delta-1}) \end{bmatrix} - h_{\delta,2}\begin{bmatrix} \boldsymbol{A}_1^{\mathrm{T}} \\ \vdots \\ \boldsymbol{A}_{\delta-1}^{\mathrm{T}} \end{bmatrix}\boldsymbol{y}_0, \tag{4.55}$$

where

$$\begin{aligned} h_{\delta,1} &= \left[\frac{1}{\delta}\boldsymbol{I}_N \quad \cdots \quad \frac{1}{2}\boldsymbol{I}_N \quad \boldsymbol{I}_N\right], \\ h_{\delta,2} &= \left[\frac{1}{\delta}\boldsymbol{I}_N \quad \cdots \quad \frac{1}{2}\boldsymbol{I}_N\right]. \end{aligned} \tag{4.56}$$

By (4.51) the values of function $\boldsymbol{f}$ at the delay instants are as follows:

$$\begin{bmatrix} \boldsymbol{f}(-r_1) \\ \vdots \\ \boldsymbol{f}(-r_{\delta-1}) \end{bmatrix} = \begin{bmatrix} \boldsymbol{I}_N e^{-\lambda(r-r_1)} \\ \vdots \\ \boldsymbol{I}_N e^{-\lambda(r-r_{\delta-1})} \end{bmatrix} \boldsymbol{f}(-r) \quad - \left[0_{(\delta-1)N\times N}\ \boldsymbol{I}_{(\delta-1)N}\right] F_\lambda\left(\boldsymbol{z}_1 - \frac{1}{g}A_{01}^{\mathrm{T}}\boldsymbol{y}_0\right). \tag{4.57}$$

By substituting (4.52) and (4.55) into (4.57) and rearranging we have

$$H_p(\lambda)\begin{bmatrix} \boldsymbol{y}_1(-r_1) \\ \vdots \\ \boldsymbol{y}_1(-r_{\delta-1}) \end{bmatrix} = H_q(\lambda)\begin{bmatrix} \boldsymbol{A}_1^{\mathrm{T}} \\ \vdots \\ \boldsymbol{A}_{\delta-1}^{\mathrm{T}} \end{bmatrix} \boldsymbol{y}_0 - \left[0_{(\delta-1)N\times N}\ \boldsymbol{I}_{(\delta-1)N}\right]\left(F_\lambda(\boldsymbol{z}_1) - F_\lambda\left(\frac{1}{g}A_{01}^{\mathrm{T}}\right)\boldsymbol{y}_0\right), \tag{4.58}$$

in which matrices H_p and H_q are defined as

$$H_p(\lambda) = \boldsymbol{I}_{(\delta-1)N} - H_{\delta,2} + \begin{bmatrix} \boldsymbol{I}_N e^{-\lambda(r-r_1)} \\ \vdots \\ \boldsymbol{I}_N e^{-\lambda(r-r_{\delta-1})} \end{bmatrix} h_{\delta,2}, \tag{4.59}$$

$$H_q(\lambda) = \begin{bmatrix} \boldsymbol{I}_N e^{-\lambda(r-r_1)} \\ \vdots \\ \boldsymbol{I}_N e^{-\lambda(r-r_{\delta-1})} \end{bmatrix} h_{\delta,1} - \begin{bmatrix} H_{\delta,2} \\ 0_{N\times\delta N} \end{bmatrix}. \tag{4.60}$$

Because H_p is nonsingular (Lemma A.3 in the appendix), by (4.58) it results that

$$\begin{aligned} \begin{bmatrix} \boldsymbol{y}_1(-r_1) \\ \vdots \\ \boldsymbol{y}_1(-r_{\delta-1}) \end{bmatrix} = &\left(H_p^{-1}(\lambda) H_q(\lambda) \begin{bmatrix} \boldsymbol{A}_1^{\mathrm{T}} \\ \vdots \\ \boldsymbol{A}_{\delta-1}^{\mathrm{T}} \end{bmatrix} + \begin{bmatrix} 0_{(\delta-1)N\times N} & H_p^{-1}(\lambda) \end{bmatrix} F_\lambda \left(\frac{1}{g} \boldsymbol{A}_{01}^{\mathrm{T}} \right) \right) \boldsymbol{y}_0 \\ &- \begin{bmatrix} 0_{(\delta-1)N\times N} & H_p^{-1}(\lambda) \end{bmatrix} F_\lambda(\boldsymbol{z}_1). \end{aligned} \tag{4.61}$$

From (4.61) and (4.53), recalling that $r_\delta = r$, matrices $N_j(\lambda)$ and $M_j(\lambda)$, $j = 1, \dots, \delta$ are defined such that

$$\boldsymbol{y}_1(-r_j) = N_j(\lambda)\boldsymbol{y}_0 + M_j(\lambda) F_\lambda(\boldsymbol{z}_1). \tag{4.62}$$

The left-continuous function $\boldsymbol{y}_1 = \bar{Y}_1(\boldsymbol{y}_0, \boldsymbol{z}_1)$ we were looking for is given by

$$\boldsymbol{y}_1(\vartheta) = \begin{cases} \boldsymbol{y}_1(-r_i), & \vartheta = -r_i, \\ \boldsymbol{f}(\vartheta) + \displaystyle\sum_{j=1}^{\delta-1} \frac{\boldsymbol{y}_1(-r_j) - \boldsymbol{A}_j^{\mathrm{T}} \boldsymbol{y}_0}{\delta - j + 1} \chi_{[-r,-r_j]}(\vartheta), & \vartheta \neq -r_i, \end{cases} \quad i = 1, \dots, \delta - 1, \tag{4.63}$$

in which $\boldsymbol{f}(\vartheta)$ is given by (4.51). This is such that $\left[\begin{smallmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{smallmatrix}\right] \in \boldsymbol{D}$. Let $(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y} = \left[\begin{smallmatrix} [(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}]_0 \\ [(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}]_1 \end{smallmatrix}\right]$. It is

$$\begin{aligned} [(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}]_1 &= \frac{1}{g} \boldsymbol{A}_{01}^{\mathrm{T}} \boldsymbol{y}_0 - \frac{d}{d\vartheta} \left(\boldsymbol{y}_1 - \sum_{j=1}^{\delta-1} \frac{\boldsymbol{y}_1(-r_j) - \boldsymbol{A}_j^{\mathrm{T}} \boldsymbol{y}_0}{\delta - j + 1} \chi_{[-r,-r_j]} \right) - \lambda \boldsymbol{y}_1 \\ &= \frac{1}{g} \boldsymbol{A}_{01}^{\mathrm{T}} \boldsymbol{y}_0 - \frac{d}{d\vartheta} \boldsymbol{f} - \lambda \boldsymbol{f} - \lambda \sum_{j=1}^{\delta-1} \frac{\boldsymbol{y}_1(-r_j) - \boldsymbol{A}_j^{\mathrm{T}} \boldsymbol{y}_0}{\delta - j + 1} \chi_{[-r,-r_j]}. \end{aligned} \tag{4.64}$$

Finally, recalling the definition (4.50) of function $\boldsymbol{f}$, it is

$$[(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}]_1 = \boldsymbol{z}_1 - \lambda \sum_{j=1}^{\delta-1} \frac{\left(N_j(\lambda) - \boldsymbol{A}_j^{\mathrm{T}}\right)\boldsymbol{y}_0 + M_j(\lambda) F_\lambda(\boldsymbol{z}_1)}{\delta - j + 1} \chi_{[-r,-r_j]}. \tag{4.65}$$

Until now we have showed that, for any $\boldsymbol{y}_0 \in \mathbb{R}^N$ and for any $\boldsymbol{z}_1 \in C^1([-r, 0]; \mathbb{R}^N)$ it is possible to find $\boldsymbol{y}_1$ such that $\boldsymbol{y} = \left[\begin{smallmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{smallmatrix}\right] \in \boldsymbol{D}$ and satisfies (4.65).

Now, using the computed $\boldsymbol{y}_1 = \bar{Y}_1(\boldsymbol{y}_0, \boldsymbol{z}_1)$, we are ready to prove that there exists a positive λ such that for any $\boldsymbol{z}_0 \in \mathbb{R}^N$ and $\boldsymbol{z}_1 \in C^1([-r,0];\mathbb{R}^N)$, a $\boldsymbol{y}_0$ can be found such that $\boldsymbol{y} = \left[\begin{smallmatrix}\boldsymbol{y}_0\\ \boldsymbol{y}_1\end{smallmatrix}\right] \in \boldsymbol{D}$ and satisfies (4.45). The application of operator $(\boldsymbol{A}^* - \lambda \boldsymbol{I})$ gives, for the part in $\mathbb{R}^N$,

$$[(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}]_0 = \delta\, \boldsymbol{y}_1(0) + \boldsymbol{A}_0^{\mathrm{T}} \boldsymbol{y}_0 - \lambda \boldsymbol{y}_0. \tag{4.66}$$

Note that from (4.63) $\boldsymbol{y}_1(0) = \boldsymbol{f}(0)$ and evaluation of $\boldsymbol{f}(0)$ according to (4.51), in which expression (4.54) of $\boldsymbol{f}(-r)$ is substituted, gives

$$[(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}]_0 = Q_0(\lambda)\boldsymbol{y}_0 + Q_1(\lambda) F_\lambda(\boldsymbol{z}_1), \tag{4.67}$$

in which

$$\begin{aligned} Q_0(\lambda) &= \delta e^{-\lambda r} \boldsymbol{A}_\delta^{\mathrm{T}} - \delta e^{-\lambda r} \sum_{j=1}^{\delta-1} \frac{N_j(\lambda) - \boldsymbol{A}_j^{\mathrm{T}}}{(\delta - j + 1)} + \delta \int_{-r}^{0} e^{\lambda \tau} \frac{1}{g} \boldsymbol{A}_{01}^{\mathrm{T}} d\tau + \boldsymbol{A}_0^{\mathrm{T}} - \lambda \boldsymbol{I}_N, \\ Q_1(\lambda) &= -\delta \left[\boldsymbol{I}_{N\times N} 0_{N \times N(\delta-1)} \right] - \sum_{j=1}^{\delta-1} \frac{\delta e^{-\lambda r}}{\delta - j + 1} M_j(\lambda). \end{aligned} \tag{4.68}$$

It is clear that there exists a sufficiently large λ such that $Q_0(\lambda)$ is nonsingular, due to the presence of the term $-\lambda \boldsymbol{I}_N$ (the other terms are all bounded functions of λ). Therefore, given $\boldsymbol{z}_0 \in \mathbb{R}^N$ and $\boldsymbol{z}_1 \in C^1([-r,0];\mathbb{R}^N)$, the function $Y_0(\boldsymbol{z}_0, \boldsymbol{z}_1) = \boldsymbol{y}_0 \in \mathbb{R}^N$ such that $[(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}]_0 = \boldsymbol{z}_0$, thanks to (4.67), is given by

$$\boldsymbol{y}_0 = Y_0(\boldsymbol{z}_0, \boldsymbol{z}_1) = Q_0^{-1}(\lambda)(\boldsymbol{z}_0 - Q_1(\lambda) F_\lambda(\boldsymbol{z}_1)). \tag{4.69}$$

Substitution of (4.69) in the expression (4.65) for $[(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}]_1$ gives

$$\begin{aligned} [(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}]_1 = \boldsymbol{z}_1 &- \lambda \sum_{j=1}^{\delta-1} \frac{\left(N_j(\lambda) - \boldsymbol{A}_j^{\mathrm{T}}\right) Q_0^{-1}(\lambda) \boldsymbol{z}_0}{(\delta - j + 1)} \chi_{[-r,-r_j]} \\ &- \lambda \sum_{j=1}^{\delta-1} \frac{\left(N_j(\lambda) - \boldsymbol{A}_j^{\mathrm{T}}\right) Q_0^{-1}(\lambda) Q_1(\lambda) F_\lambda(\boldsymbol{z}_1) + M_j(\lambda) F_\lambda(\boldsymbol{z}_1)}{(\delta - j + 1)} \chi_{[-r,-r_j]}. \end{aligned} \tag{4.70}$$

This expression allows one to define the matrices $P_0^j(\lambda)$ and $P_1^j(\lambda)$ used in (4.45) as

$$\begin{aligned} P_0^j &= -\lambda \frac{\left(N_j(\lambda) - \boldsymbol{A}_j^{\mathrm{T}}\right) Q_0^{-1}(\lambda)}{(\delta - j + 1)}, \\ P_1^j &= -\lambda \frac{\left(N_j(\lambda) - \boldsymbol{A}_j^{\mathrm{T}}\right) Q_0^{-1}(\lambda) Q_1(\lambda) + M_j(\lambda)}{(\delta - j + 1)}. \end{aligned} \tag{4.71}$$

Composition of functions $\bar{Y}_1(\boldsymbol{y}_0, \boldsymbol{z}_1)$ and $Y_0(\boldsymbol{z}_0, \boldsymbol{z}_1)$ gives the announced function $Y_1(\boldsymbol{z}_0, \boldsymbol{z}_1)$. This concludes the proof that, for λ sufficiently large, for any $\left[\begin{smallmatrix}\boldsymbol{z}_0\\ \boldsymbol{z}_1\end{smallmatrix}\right] \in \mathbb{R}^N \times C^1([-r,0];\mathbb{R}^N)$ there exists $\left[\begin{smallmatrix}\boldsymbol{y}_0\\ \boldsymbol{y}_1\end{smallmatrix}\right] \in \boldsymbol{D}$ such that (4.45) holds.

Consider now the continuous linear function Φ_λ defined as follows:

$$\begin{aligned} &\Phi^{(\lambda)} : L_2([-r,0];\mathbb{R}^N) \mapsto L_2([-r,0];\mathbb{R}^N), \\ &\Phi^{(\lambda)}(\boldsymbol{g}) = \boldsymbol{g} + \sum_{j=1}^{\delta-1} P_1^j(\lambda) F_\lambda(\boldsymbol{g}) \chi_{[-r,-r_j]}. \end{aligned} \tag{4.72}$$

Let us define the following subspace of $L_2([-r,0];\mathbb{R}^N)$:

$$\mathcal{R} = \Phi^{(\lambda)}(C^1([-r,0];\mathbb{R}^N)). \tag{4.73}$$

The proof of the lemma is obtained if the set $\mathcal{R}$ is proved to be dense in $L_2([-r,0];\mathbb{R}^N)$. This is true because it can be readily shown that density of $\mathcal{R}$ is sufficient to conclude that $\forall \boldsymbol{x} \in \boldsymbol{M}_2$, for any $\varepsilon > 0$, there exists a $\boldsymbol{y} \in \boldsymbol{D}$ such that $\|\boldsymbol{x} - (\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}\|_{\boldsymbol{M}_2} \leq \varepsilon$ (i.e., density of $(\boldsymbol{A}^* - \lambda\boldsymbol{I})\boldsymbol{D}$).

Given a $\boldsymbol{x} = \left[\begin{smallmatrix}\boldsymbol{x}_0\\ \boldsymbol{x}_1\end{smallmatrix}\right] \in \boldsymbol{M}_2$, take $\boldsymbol{y}_A \in \boldsymbol{D}$ as follows: $\boldsymbol{y}_{A,0} = Y_0(\boldsymbol{x}_0, 0) = Q_0^{-1}(\lambda)\boldsymbol{x}_0$ and $\boldsymbol{y}_{A,1} = Y_1(\boldsymbol{x}_0, 0)$. It is, by construction,

$$(\boldsymbol{A}^* - \lambda\boldsymbol{I})\boldsymbol{y}_A = \begin{bmatrix} \boldsymbol{x}_0 \\ \sum_{j=1}^{\delta-1} P_0^j(\lambda)\boldsymbol{x}_0\chi_{[-r,-r_j]} \end{bmatrix}. \tag{4.74}$$

From the density of $\mathcal{R}$, there exists $\boldsymbol{z}_{B,1} \in C^1([-r,0];\mathbb{R}^N)$ such that the function

$$\tilde{\boldsymbol{z}}_{B,1} = \boldsymbol{z}_{B,1} + \sum_{j=1}^{\delta-1} P_1^j(\lambda)F_\lambda(\boldsymbol{z}_{B,1})\chi_{[-r,-r_j]} \tag{4.75}$$

satisfies

$$\left\|\sum_{j=1}^{\delta-1} P_0^j(\lambda)\boldsymbol{x}_0\chi_{[-r,-r_j]} - \tilde{\boldsymbol{z}}_{B,1}\right\|_{L_2} \leq \frac{\varepsilon}{2}, \tag{4.76}$$

and from result (4.45) there exists $\boldsymbol{y}_B \in \boldsymbol{D}$ such that $(\boldsymbol{A}^* - \lambda\boldsymbol{I})\boldsymbol{y}_B = \left[\begin{smallmatrix}0\\ \tilde{\boldsymbol{z}}_{B,1}\end{smallmatrix}\right]$.

Exploiting again the density of $\mathcal{R}$ there exists $\boldsymbol{z}_{C,1} \in C^1([-r,0];\mathbb{R}^N)$ such that the function

$$\tilde{\boldsymbol{z}}_{C,1} = \boldsymbol{z}_{C,1} + \sum_{j=1}^{\delta-1} P_1^j(\lambda)F_\lambda(\boldsymbol{z}_{C,1})\chi_{[-r,-r_j]} \tag{4.77}$$

satisfies

$$\left\|\boldsymbol{x}_1 - \tilde{\boldsymbol{z}}_{C,1}\right\|_{L_2} \leq \frac{\varepsilon}{2}. \tag{4.78}$$

Again, from result (4.45) there exists $\boldsymbol{y}_C \in \boldsymbol{D}$ such that $(\boldsymbol{A}^* - \lambda\boldsymbol{I})\boldsymbol{y}_C = \left[\begin{smallmatrix}0\\ \tilde{\boldsymbol{z}}_{C,1}\end{smallmatrix}\right]$. It is now an easy matter to show that vector $\boldsymbol{y} = \boldsymbol{y}_A - \boldsymbol{y}_B + \boldsymbol{y}_C$ is such that

$$\begin{aligned} \|\boldsymbol{x} - (A^* - \lambda\boldsymbol{I})\boldsymbol{y}\|_{M_2} &= \|\boldsymbol{x} - (A^* - \lambda\boldsymbol{I})(\boldsymbol{y}_A - \boldsymbol{y}_B + \boldsymbol{y}_C)\|_{\boldsymbol{M}_2} \\ &\leq \left\| \begin{bmatrix} 0 \\ \boldsymbol{x}_1 - [(A^* - \lambda\boldsymbol{I})\boldsymbol{y}_A]_1 + \tilde{\boldsymbol{z}}_{B,1} - \tilde{\boldsymbol{z}}_{C,1} \end{bmatrix} \right\|_{\boldsymbol{M}_2} \\ &\leq \left\|\boldsymbol{x}_1 - \tilde{\boldsymbol{z}}_{C,1}\right\|_{L_2} + \left\|\sum_{j=1}^{\delta-1} P_0^j(\lambda)\boldsymbol{x}_0\chi_{[-r,-r_j]} - \tilde{\boldsymbol{z}}_{B,1}\right\|_{L_2} \leq \varepsilon. \end{aligned} \tag{4.79}$$

It remains to prove that $\mathcal{R}$ is dense for sufficiently large λ. We will show that if for any $\boldsymbol{f} \in L_2([-r,0];\mathbb{R}^N)$ there exists a vector $\alpha \in \mathbb{R}^{N\delta}$ such that

$$F_\lambda(\boldsymbol{f}) - F_\lambda\left(\sum_{j=1}^{\delta-1} P_1^j \alpha\chi_{[-r,-r_j]}\right) - \alpha = 0, \tag{4.80}$$

then for any $\boldsymbol{f} \in L_2([-r,0];\mathbb{R}^N)$ a sequence $\{\boldsymbol{f}_k\}$, $\boldsymbol{f}_k \in \mathcal{R}\ \forall k \geq 0$ can be found such that $\|\boldsymbol{f} - \boldsymbol{f}_k\|_{L_2} \to 0$. Existence of α in (4.80) for any $\boldsymbol{f}$ is ensured by the nonsingularity of matrix

$$\Gamma(\lambda) = \boldsymbol{I}_{N\delta\times N\delta} + \sum_{j=1}^{\delta-1} F_\lambda\big(P_1^j(\lambda)\chi_{[-r,-r_j]}\big) \tag{4.81}$$

for sufficiently large λ, and this is a sufficient condition for density of $\mathcal{R}$.

To this purpose consider a $\boldsymbol{f} \in L_2$, let α be the solution of (4.80), and define the function

$$\bar{\boldsymbol{f}} = \boldsymbol{f} - \sum_{j=1}^{\delta-1} P_1^j \alpha \chi_{[-r,-r_j]}. \tag{4.82}$$

It is such that $\Phi^{(\lambda)}(\bar{\boldsymbol{f}}) = \boldsymbol{f}$. Let $\{\boldsymbol{g}_k\}$ be a sequence of functions in $C^1([-r,0];\mathbb{R}^N)$ such that $\|\bar{\boldsymbol{f}} - \boldsymbol{g}_k\|_{L_2} \to 0$. From the continuity of function $\Phi^{(\lambda)}$ it is $\|\Phi^{(\lambda)}(\bar{\boldsymbol{f}}) - \Phi^{(\lambda)}(\boldsymbol{g}_k)\|_{L_2} \to 0$. Defining functions $\boldsymbol{f}_k = \Phi^{(\lambda)}(\boldsymbol{g}_k) \in \mathcal{R}$, the sequence $\{\boldsymbol{f}_k\}$ converges to $\Phi^{(\lambda)}(\bar{\boldsymbol{f}})$, that is, $\boldsymbol{f}$ and density of $\mathcal{R}$, under nonsingularity of $\Gamma(\lambda)$, is proved.

It remains to prove the nonsingularity of the $\delta N \times \delta N$ matrix $\Gamma(\lambda)$ defined in (4.81) for a sufficiently large λ. Such a proof is reported in [39] and is worked out by showing that $\det\big(\Gamma(\lambda)\big)$ is a continuous function of λ and that there exists the limit matrix $\bar{\Gamma} = \lim_{\lambda\to+\infty}\Gamma(\lambda)$. Such a matrix can be easily proved to be nonsingular, because it is block triangular (each block is $N \times N$), in which the diagonal consists of the following nonsingular δ blocks: block 1 is $\boldsymbol{I}_N$, block j, for $j = 2,\ldots,\delta$, is $\boldsymbol{I} + \frac{1}{\delta-j+1}\boldsymbol{I}_N$. It follows that $\lim_{\lambda\to+\infty}\det\big(\Gamma(\lambda)\big) = \det\big(\bar{\Gamma}\big) \neq 0$, and therefore there exists λ_0 such that for every $\lambda > \lambda_0$ matrix $\Gamma(\lambda)$ is nonsingular.

So, chosen λ such that $\Gamma(\lambda)$ and $Q_0(\lambda)$ are both nonsingular, the proof of this lemma is completed in the case of hypothesis Hp_0.

To remove such a hypothesis it is sufficient to consider a sequence $\boldsymbol{A}_{01}^k$ in the space $L_2([-r,0];\mathbb{R}^{N\times N})$, which converges to $\boldsymbol{A}_{01}$ and satisfies hypothesis Hp_0. Let $\boldsymbol{A}_k^*$ be the corresponding sequence of operators. Let $D_k \in L(\boldsymbol{M}_2)$ be defined as

$$D_k \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{bmatrix} = \begin{bmatrix} 0 \\ \frac{1}{g}(\boldsymbol{A}_{01}^k - \boldsymbol{A}_{01})^{\mathrm{T}}\boldsymbol{y}_0 \end{bmatrix}.$$

Thus $\boldsymbol{A}_k^* = \boldsymbol{A}^* + D_k$ and $\|D_k\|_{L(\boldsymbol{M}_2)} \leq \|\boldsymbol{A}_{01}^k - \boldsymbol{A}_{01}\|_{L_2([-r,0];\mathbb{R}^{N\times N})}$. From Proposition 2.3 in [5, page 28], and Theorem 1.1 in [38, page 76], it follows that any λ with $Re(\lambda) > \omega_0 + \sup_k \|D_k\|$ belongs to the resolvent set of $\boldsymbol{A}^*$ and $\boldsymbol{A}_k^*$, for every k, where ω_0 is such that $\|T(t)\| \leq e^{\omega_0 t}$, $\boldsymbol{T}(t)$ being the semigroup generated by $\boldsymbol{A}$ (see Lemma 2.3 in [3]). Let us choose a λ in the resolvent sets of $\boldsymbol{A}^*$ and $\boldsymbol{A}_k^*$, such that $(\boldsymbol{A}_k^* - \lambda\boldsymbol{I})\boldsymbol{D}$ is dense in $\boldsymbol{M}_2$ for every k. It is sufficient that corresponding matrices $\Gamma^k(\lambda)$ in (4.81) and $Q_0^k(\lambda)$ in (4.68) are nonsingular. Thus, given $\boldsymbol{x} \in M_2$, given $\epsilon > 0$, a sequence $\boldsymbol{y}_k$ can be found such that

$$\|(\boldsymbol{A}_k^* - \lambda\boldsymbol{I})\boldsymbol{y}_k - \boldsymbol{x}\| < \frac{\epsilon}{2}. \tag{4.83}$$

From

$$\|(\boldsymbol{A}^* - \lambda\boldsymbol{I})\boldsymbol{y}_k - \boldsymbol{x}\| \leq \|(\boldsymbol{A}_k^* - \lambda\boldsymbol{I})\boldsymbol{y}_k - \boldsymbol{x}\| + \|D_k\|\|\boldsymbol{y}_k\| \tag{4.84}$$

it follows that there exist k_0 such that $\|(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{y}_{k_0} - \boldsymbol{x}\| < \epsilon$, provided $\boldsymbol{y}_k$ is uniformly bounded. It is sufficient that $\|D_{k_0}\| < \frac{\epsilon}{2\sup_k \|\boldsymbol{y}_k\|}$. It remains to prove uniform boundedness of $\boldsymbol{y}_k$. Let $v_k = (\boldsymbol{A}_k^* - \lambda \boldsymbol{I})\boldsymbol{y}_k - \boldsymbol{x}$. From (4.83) it is $\|v_k\| < \frac{\epsilon}{2}$ for every k. From

$$(\boldsymbol{A}_k^* - \lambda \boldsymbol{I})^{-1} = (\boldsymbol{A}^* + D_k - \lambda \boldsymbol{I})^{-1} = [\boldsymbol{I} - (\lambda \boldsymbol{I} - \boldsymbol{A}^*)^{-1} D_k]^{-1} (\boldsymbol{A}^* - \lambda \boldsymbol{I})^{-1} \tag{4.85}$$

it follows that

$$\|(\boldsymbol{A}_k^* - \lambda \boldsymbol{I})^{-1}\| \le \|[\boldsymbol{I} - (\lambda \boldsymbol{I} - \boldsymbol{A}^*)^{-1} D_k]^{-1}\| \|(\boldsymbol{A}^* - \lambda \boldsymbol{I})^{-1}\|. \tag{4.86}$$

If k is sufficiently large such that $\|(\lambda \boldsymbol{I} - \boldsymbol{A}^*)^{-1} D_k\| \le d < 1$, the following inequality holds:

$$\|[\boldsymbol{I} - (\lambda \boldsymbol{I} - \boldsymbol{A}^*)^{-1} D_k]^{-1}\| \le \sum_{l=0}^{\infty} \|(\lambda \boldsymbol{I} - \boldsymbol{A}^*)^{-1} D_k\|^l \le \frac{1}{1-d}, \tag{4.87}$$

which proves the uniform boundedness of $\|(\boldsymbol{A}_k^* - \lambda \boldsymbol{I})^{-1}\|$. The uniform boundedness of $\boldsymbol{y}_k$ follows by

$$\boldsymbol{y}_k = (\boldsymbol{A}_k^* - \lambda \boldsymbol{I})^{-1}(v_k - \boldsymbol{x}). \tag{4.88}$$

Such a device to prove the density of $(\boldsymbol{A}^* - \lambda \boldsymbol{I})\boldsymbol{D}$ in $\boldsymbol{M}_2$ when hypothesis Hp_0 is not satisfied has been introduced in [24, Theorem 7.2] for the one delay case. □

LEMMA 4.14. *The operator* $\boldsymbol{\Pi}'_n \boldsymbol{A}^* \boldsymbol{\Pi}'_n$ *converges strongly to the operator* $\boldsymbol{A}^*$ *in the subspace* $\boldsymbol{D}$ *defined in Lemma* 4.13.

Proof. Since it is

$$\|\boldsymbol{\Pi}'_n \boldsymbol{A}^* \boldsymbol{\Pi}'_n \boldsymbol{x} - \boldsymbol{A}^* \boldsymbol{x}\|_{M_2} \le \|\boldsymbol{\Pi}'_n (\boldsymbol{A}^* \boldsymbol{\Pi}'_n - \boldsymbol{A}^*)\boldsymbol{x}\|_{M_2} + \|\boldsymbol{\Pi}'_n \boldsymbol{A}^* \boldsymbol{x} - \boldsymbol{A}^* \boldsymbol{x}\|_{M_2}, \tag{4.89}$$

and $\lim_{n\to\infty} \|\boldsymbol{\Pi}'_n \boldsymbol{y} - \boldsymbol{y}\|_{M_2} = 0$, $\forall \boldsymbol{y} \in \boldsymbol{M}_2$ (strong convergence), the lemma is proved if for any $\boldsymbol{x} \in \boldsymbol{D}$

$$\|\boldsymbol{A}^* \boldsymbol{\Pi}'_n \boldsymbol{x} - \boldsymbol{A}^* \boldsymbol{x}\| \to 0. \tag{4.90}$$

It is

$$\begin{aligned}
\|\boldsymbol{A}^* \boldsymbol{\Pi}'_n \boldsymbol{x} - \boldsymbol{A}^* \boldsymbol{x}\|^2 &= \|\delta \boldsymbol{x}_1(0) + \boldsymbol{A}_0^{\mathrm{T}} \boldsymbol{x}_0 - \delta(\boldsymbol{\Pi}'_n \boldsymbol{x})_1(0) - \boldsymbol{A}_0^{\mathrm{T}} (\boldsymbol{\Pi}'_n \boldsymbol{x})_0\|^2 \\
&\quad + \left\| \frac{1}{g} \boldsymbol{A}_{01} \boldsymbol{x}_0 - \frac{1}{g} \boldsymbol{A}_{01} (\boldsymbol{\Pi}'_n \boldsymbol{x})_0 - \frac{d}{d\vartheta} \left(\boldsymbol{x}_1 - \sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{x}_0, \boldsymbol{x}_1) \chi_{[-r,-r_j]} \right) \right. \\
&\quad \left. + \frac{d}{d\vartheta} \left((\boldsymbol{\Pi}'_n \boldsymbol{x})_1 - \sum_{j=1}^{\delta-1} \boldsymbol{k}_j((\boldsymbol{\Pi}'_n \boldsymbol{x})_0, (\boldsymbol{\Pi}'_n \boldsymbol{x})_1) \chi_{[-r,-r_j]} \right) \right\|_{L_2}^2 \\
&\le \delta^2 \|\boldsymbol{x}_1(0) - (\boldsymbol{\Pi}'_n \boldsymbol{x})_1(0)\|^2 + \left(\|\boldsymbol{A}_0^{\mathrm{T}}\| + 2 \left\| \frac{1}{g} \boldsymbol{A}_{01}^{\mathrm{T}} \right\|_{L_2} \right) \cdot \left\| \boldsymbol{x}_0 - (\boldsymbol{\Pi}'_n \boldsymbol{x})_0 \right\|^2 + 2 S_n^2(\boldsymbol{x}),
\end{aligned} \tag{4.91}$$

where

$$\begin{aligned}
S_n(\boldsymbol{x}) = \Bigg\| & \frac{d}{d\vartheta} \left(\boldsymbol{x}_1 - \sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{x}_0, \boldsymbol{x}_1) \chi_{[-r,-r_j]} \right) \\
& - \frac{d}{d\vartheta} \left((\boldsymbol{\Pi}'_n \boldsymbol{x})_1 - \sum_{j=1}^{\delta-1} \boldsymbol{k}_j((\boldsymbol{\Pi}'_n \boldsymbol{x})_0, (\boldsymbol{\Pi}'_n \boldsymbol{x})_1) \chi_{[-r,-r_j]} \right) \Bigg\|_{L_2}.
\end{aligned} \tag{4.92}$$

Strong convergence of $\mathbf{\Pi}'_n$ ensures that for $n \to \infty$ the second term in the right-hand side of (4.91) goes to zero.

To prove that the term $S_n(\boldsymbol{x})$ goes to zero too, let

$$\begin{aligned}\bar{\boldsymbol{x}} = \begin{bmatrix} \bar{\boldsymbol{x}}_0 \\ \bar{\boldsymbol{x}}_1 \end{bmatrix} &= \sum_{k=1}^{N} \boldsymbol{x}_0(k) w'_k + \sum_{i=1}^{\delta-1} \sum_{k=1}^{N} (\boldsymbol{x}_1(-r_i)^{\mathrm{T}} \phi_k) w_k^{r_i} \\ &\quad + \sum_{i=1}^{\delta} \sum_{j=1}^{n_i} \sum_{k=1}^{N} (\boldsymbol{x}_1(t_j^i)^{\mathrm{T}} \phi_k) w_{jN+k}^i + \sum_{k=1}^{N} (\boldsymbol{x}_1(0)^{\mathrm{T}} \phi_k) w_k^1.\end{aligned} \tag{4.93}$$

It is such that $\bar{\boldsymbol{x}}_0 = \boldsymbol{x}_0$, so that $\|\boldsymbol{x} - \bar{\boldsymbol{x}}\|_{\boldsymbol{M}_2} = \|\boldsymbol{x}_1 - \bar{\boldsymbol{x}}_1\|_{L_2}$ and therefore

$$\|\boldsymbol{x} - \mathbf{\Pi}'_n \boldsymbol{x}\|_{\boldsymbol{M}_2} \leq \|\boldsymbol{x}_1 - \bar{\boldsymbol{x}}_1\|_{L_2}. \tag{4.94}$$

Considering that the function $\sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\cdot,\cdot)\chi_{[-r,-r_j]}$ is piecewise constant it is

$$S_n(\boldsymbol{x}) = \left\| \frac{d}{d\vartheta} \boldsymbol{x}_1 - \frac{d}{d\vartheta} (\mathbf{\Pi}'_n \boldsymbol{x})_1 \right\|_{L_2} \tag{4.95}$$

and

$$S_n(\boldsymbol{x}) \leq \left\| \frac{d}{d\vartheta} \boldsymbol{x}_1 - \frac{d}{d\vartheta} \bar{\boldsymbol{x}}_1 \right\|_{L_2} + \left\| \frac{d}{d\vartheta} \bar{\boldsymbol{x}}_1 - \frac{d}{d\vartheta} (\mathbf{\Pi}'_n \boldsymbol{x})_1 \right\|_{L_2}. \tag{4.96}$$

As for the first term at the right-hand side of inequality (4.96), since it is

$$\left\| \frac{d}{d\vartheta} \boldsymbol{x}_1 - \frac{d}{d\vartheta} \bar{\boldsymbol{x}}_1 \right\|_{L_2} = \left(\sum_{i=1}^{\delta} \left\| \frac{d}{d\vartheta} \boldsymbol{x}_1 \chi_{[-r_i,-r_{i-1}]} - \frac{d}{d\vartheta} \bar{\boldsymbol{x}}_1 \chi_{[-r_i,-r_{i-1}]} \right\|_{L_2}^2 \right)^{\frac{1}{2}}, \tag{4.97}$$

by standard results of spline analysis (see Theorem 2.5 in [42]), each term in the summation goes to zero for $n \to \infty$.

As for the second term, from definition of vectors w that generate V'_n, it is, by applying the Schmidt inequality (see Theorem 1.5 in [42]),

$$\begin{aligned}\left\| \frac{d}{d\vartheta} \bar{\boldsymbol{x}}_1 - \frac{d}{d\vartheta} (\mathbf{\Pi}'_n \boldsymbol{x})_1 \right\|_{L_2} &= \left(\sum_{i=1}^{\delta} \left\| \frac{d}{d\vartheta} \bar{\boldsymbol{x}}_1 \chi_{[-r_i,-r_{i-1}]} - \frac{d}{d\vartheta} (\mathbf{\Pi}'_n \boldsymbol{x})_1 \chi_{[-r_i,-r_{i-1}]} \right\|_{L_2}^2 \right)^{\frac{1}{2}} \\ &\leq \left(\sum_{i=1}^{\delta} \left(\sqrt{12} \frac{n_i}{r_i - r_{i-1}} \left\| \left(\bar{\boldsymbol{x}}_1 - (\mathbf{\Pi}'_n \boldsymbol{x})_1 \right) \chi_{[-r_i,-r_{i-1}]} \right\|_{L_2} \right)^2 \right)^{\frac{1}{2}}.\end{aligned}$$

For each term in the summation it is

$$\begin{aligned}\left\| \left(\bar{\boldsymbol{x}}_1 - (\mathbf{\Pi}'_n \boldsymbol{x})_1 \right) \chi_{[-r_i,-r_{i-1}]} \right\|_{L_2} &\leq \left\| \bar{\boldsymbol{x}}_1 - (\mathbf{\Pi}'_n \boldsymbol{x})_1 \right\|_{L_2} \\ &\leq \left\| \bar{\boldsymbol{x}}_1 - \boldsymbol{x}_1 \right\|_{L_2} + \left\| \boldsymbol{x}_1 - (\mathbf{\Pi}'_n \boldsymbol{x})_1 \right\|_{L_2} \leq 2\|\bar{\boldsymbol{x}}_1 - \boldsymbol{x}_1\| \\ &\leq \left(\sum_{i=1}^{\delta} \left(\left\| \left(\bar{\boldsymbol{x}}_1 - \boldsymbol{x}_1 \right) \chi_{[-r_i,-r_{i-1}]} \right\|_{L_2} \right)^2 \right)^{\frac{1}{2}}.\end{aligned} \tag{4.98}$$

Again, by standard results on spline approximation (Theorem 2.5 in [42]), each term in the summation goes to zero for $n \to \infty$. This proves that $S_n(\boldsymbol{x})$ goes to zero for $n \to \infty$.

It remains to prove that the term $\delta\|\boldsymbol{x}_1(0) - (\boldsymbol{\Pi}'_n\boldsymbol{x})_1(0)\|^2$ in the right-hand side of (4.91) goes to zero for $n \to \infty$.

First, note that being $\boldsymbol{x} \in \mathcal{D}(\boldsymbol{A}^*)$ it is such that for $i = 1, \dots, \delta - 1$

$$\boldsymbol{x}_1(-r_i^+) - \sum_{j=1}^{i-1} \boldsymbol{k}_j(\boldsymbol{x}_0, \boldsymbol{x}_1) = \boldsymbol{x}_1(-r_i) - \sum_{j=1}^{i} \boldsymbol{k}_j(\boldsymbol{x}_0, \boldsymbol{x}_1), \tag{4.99}$$

where $\boldsymbol{x}_1(-r_i^+)$ denotes the limit of $\boldsymbol{x}_1(\vartheta)$ for ϑ approaching $-r_i$ from the right (note that in general $\boldsymbol{x}_1(-r_i^+) \neq \boldsymbol{x}_1(-r_i)$). Simple computations, taking into account definition (2.22) of $\boldsymbol{k}_j$, give

$$\boldsymbol{x}_1(-r_i^+) = \frac{\delta - i + 2}{\delta - i + 1}\boldsymbol{x}_1(-r_i) - \frac{1}{\delta - i + 1}\boldsymbol{A}_i^{\mathrm{T}}\boldsymbol{x}_0. \tag{4.100}$$

Since also $\boldsymbol{\Pi}'_n\boldsymbol{x} \in \mathcal{D}(\boldsymbol{A}^*)$, it is such that

$$(\boldsymbol{\Pi}'_n\boldsymbol{x})_1(-r_i^+) = \frac{\delta - i + 2}{\delta - i + 1}(\boldsymbol{\Pi}'_n\boldsymbol{x})_1(-r_i) - \frac{1}{\delta - i + 1}\boldsymbol{A}_i^{\mathrm{T}}(\boldsymbol{\Pi}'_n\boldsymbol{x})_0. \tag{4.101}$$

At point $-r$ it is

$$\boldsymbol{x}_1(-r) = \boldsymbol{A}_\delta^{\mathrm{T}}\boldsymbol{x}_0, \qquad (\boldsymbol{\Pi}'_n\boldsymbol{x})_1(-r) = \boldsymbol{A}_\delta^{\mathrm{T}}(\boldsymbol{\Pi}'_n\boldsymbol{x})_0. \tag{4.102}$$

Since it has been proved that $\lim_{n\to\infty} \|\boldsymbol{x}_0 - (\boldsymbol{\Pi}'_n\boldsymbol{x})_0\| = 0$, from (4.102) it follows

$$\lim_{n\to\infty} \|\boldsymbol{x}_1(-r) - (\boldsymbol{\Pi}'_n\boldsymbol{x})_1(-r)\| = 0. \tag{4.103}$$

Starting from (4.103), the proof that $\|\boldsymbol{x}_1(0) - (\boldsymbol{\Pi}'_n\boldsymbol{x})_1(0)\|$ goes to zero is obtained if we prove the following recursive implication:

$$\lim_{n\to\infty} \|\boldsymbol{x}_1(-r_i) - (\boldsymbol{\Pi}'_n\boldsymbol{x})_1(-r_i)\| = 0, \tag{4.104}$$

$$\Downarrow$$

$$\lim_{n\to\infty} \|\boldsymbol{x}_1(-r_{i-1}) - (\boldsymbol{\Pi}'_n\boldsymbol{x})_1(-r_{i-1})\| = 0. \tag{4.105}$$

First note that if (4.104) is true, then comparing (4.100) and (4.101), recalling that $\|\boldsymbol{x}_0 - (\boldsymbol{\Pi}'_n\boldsymbol{x})_0\| \to 0$, it follows

$$\lim_{n\to\infty} \|\boldsymbol{x}_1(-r_i^+) - (\boldsymbol{\Pi}'_n\boldsymbol{x})_1(-r_i^+)\| = 0. \tag{4.106}$$

From (4.106), since it has been proved that in any interval $[-r_i, -r_{i-1}]$

$$\lim_{n\to\infty} \left\| \left(\frac{d}{d\vartheta}\boldsymbol{x}_1 - \frac{d}{d\vartheta}(\boldsymbol{\Pi}'_n\boldsymbol{x})_1 \right) \chi_{[-r_i, -r_{i-1}]} \right\|_{L_2} = 0, \tag{4.107}$$

implication (4.105) is easily obtained. This completes the proof of the Lemma. □

THEOREM 4.15. *The sequence of semigroups $\boldsymbol{T}^*_{\Phi'_n}$ generated by the operators $\boldsymbol{\Pi}'_n\boldsymbol{A}^*\boldsymbol{\Pi}'_n$ converges strongly to $\boldsymbol{T}^*$, the adjoint of the semigroup generated by $\boldsymbol{A}$.*

Proof. The results in Lemmas 4.12, 4.13, and 4.14 imply that the hypotheses of the Trotter–Kato theorem, as stated in [38] and reported also in Lemma 3.1 in [3], are satisfied, and this proves the convergence of $\boldsymbol{T}^*_{\Phi'_n}$ to $\boldsymbol{T}^*$. □

Now the main result of the paper can be given, that is, the theorem on the convergence of the proposed finite dimensional approximation scheme of the LQG controller for hereditary systems.

THEOREM 4.16. *Let* Φ_n *and* Φ'_n *be the sequences of finite dimension subspaces of* $\boldsymbol{M}_2$ *in Definitions* 4.2, 4.3. *Let* $\boldsymbol{u}_n(t)$ *be the input function obtained by*

$$\boldsymbol{u}_n(t) = -\boldsymbol{B}^* \boldsymbol{R}_n(t_f - t)\boldsymbol{\Pi}'_n \hat{\boldsymbol{x}}_n(t), \tag{4.108}$$

where

$$\begin{aligned} \dot{\hat{\boldsymbol{x}}}_n(t) &= \boldsymbol{\Pi}_n \boldsymbol{A}\boldsymbol{\Pi}_n \hat{\boldsymbol{x}}_n(t) + \boldsymbol{\Pi}_n \boldsymbol{B}\boldsymbol{u}_n(t) + \boldsymbol{P}_n(t)\boldsymbol{\Pi}_n \boldsymbol{C}^*\big(\boldsymbol{y}(t) - \boldsymbol{C}\boldsymbol{\Pi}_n \hat{\boldsymbol{x}}_n(t)\big),\\ \hat{\boldsymbol{x}}_n(0) &= \boldsymbol{\Pi}_n \hat{\boldsymbol{x}}(0) \end{aligned} \tag{4.109}$$

in which $\boldsymbol{P}_n$ *and* $\boldsymbol{R}_n$ *are the finite dimensional solutions of the Riccati equations* (3.15) *and* (3.16) *in which the projectors* $\boldsymbol{\Pi}_n$ *and* $\boldsymbol{\Pi}'_n$ *are considered. Let* $\boldsymbol{u}(t)$ *be the optimal input,* $\hat{\boldsymbol{x}}(t)$ *the optimal estimated state,* $\boldsymbol{x}_n(t)$ *and* $\boldsymbol{x}(t)$ *the actual state evolving when* $\boldsymbol{u}_n(t)$ *and* $\boldsymbol{u}(t)$ *are applied to system* (2.1), (2.2), *respectively.*

Then

$$\lim_{n\to\infty} E\|\boldsymbol{x}_n - \boldsymbol{x}\|^2_{L_2([0,t_f];\boldsymbol{M}_2)} = 0, \tag{4.110}$$

$$\lim_{n\to\infty} E\|\hat{\boldsymbol{x}}_n - \hat{\boldsymbol{x}}\|^2_{L_2([0,t_f];\boldsymbol{M}_2)} = 0, \tag{4.111}$$

$$\lim_{n\to\infty} E\|\boldsymbol{u}_n - \boldsymbol{u}\|^2_{L_2([0,t_f];\mathbb{R}^p)} = 0, \tag{4.112}$$

$$\lim_{n\to\infty} |J_f(\boldsymbol{u}_n) - J_f(\boldsymbol{u})| = 0. \tag{4.113}$$

Proof. The proof comes from Theorem 3.7, whose assumptions (from Hp_1 to Hp_4) are satisfied thanks to Theorems 4.7, 4.8, 4.11, and 4.15. □

5. Implementation of the method.

In this section the numerical implementation of the approximation scheme described in the previous section, and which satisfies all properties listed in the introduction, is reported.

Consider two Hilbert spaces $\mathcal{U}$ and $\mathcal{V}$ and two finite dimensional subspaces $U_n \subset \mathcal{U}$ and $V_m \subset \mathcal{V}$ of dimension n and m, respectively. Let $(\boldsymbol{u}_1, \dots, \boldsymbol{u}_n)$ be a basis of U_n and $(\boldsymbol{v}_1, \dots, \boldsymbol{v}_m)$ a basis of V_m. Consider the nonsingular matrices $\boldsymbol{T}_n \in \mathbb{R}^{n\times n}$ and $Z_m \in \mathbb{R}^{m\times m}$, whose components are defined as

$$\begin{aligned} T_n(i,j) &= (\boldsymbol{u}_i, \boldsymbol{u}_j)_{\mathcal{U}}, \quad i,j = 1,\dots,n,\\ Z_m(h,k) &= (\boldsymbol{v}_i, \boldsymbol{v}_j)_{\mathcal{V}}, \quad i,j = 1,\dots,m. \end{aligned} \tag{5.1}$$

Recall that the orthoprojection operator from $\mathcal{U}$ to U_n performs the following operation on a vector $\boldsymbol{x} \in \mathcal{U}$:

$$\boldsymbol{\Pi}(\boldsymbol{x}; U_n) = \sum_{i=1}^n \alpha_i \boldsymbol{u}_i \quad \text{with} \quad \begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{bmatrix} = T_n^{-1} \begin{bmatrix} (\boldsymbol{x}, \boldsymbol{u}_1)_{\mathcal{U}} \\ \vdots \\ (\boldsymbol{x}, \boldsymbol{u}_n)_{\mathcal{U}} \end{bmatrix}, \tag{5.2}$$

and the orthoprojection operator from $\mathcal{V}$ to V_m performs the following operation on a vector $\boldsymbol{y} \in H_2$:

$$\boldsymbol{\Pi}(\boldsymbol{y}; V_m) = \sum_{i=1}^m \beta_i \boldsymbol{v}_i \quad \text{with} \quad \begin{bmatrix} \beta_1 \\ \vdots \\ \beta_m \end{bmatrix} = Z_m^{-1} \begin{bmatrix} (\boldsymbol{y}, \boldsymbol{v}_1)_{\mathcal{V}} \\ \vdots \\ (\boldsymbol{y}, \boldsymbol{v}_m)_{\mathcal{V}} \end{bmatrix}. \tag{5.3}$$

Let us denote as ξ_n the isomorphism that associates to a vector $\boldsymbol{x} \in U_n$ its coordinate representation

$$\xi_n : \; U_n \mapsto \mathbb{R}^n; \quad \xi_n(\boldsymbol{x}) = T_n^{-1} \begin{bmatrix} (\boldsymbol{x}, \boldsymbol{u}_1)_{\mathcal{U}} \\ \vdots \\ (\boldsymbol{x}, \boldsymbol{u}_n)_{\mathcal{U}} \end{bmatrix} \tag{5.4}$$

and as ξ_m the isomorphism

$$\xi_m : \; V_m \mapsto \mathbb{R}^m; \quad \xi_m(\boldsymbol{y}) = Z_m^{-1} \begin{bmatrix} (\boldsymbol{y}, \boldsymbol{v}_1)_{\mathcal{V}} \\ \vdots \\ (\boldsymbol{y}, \boldsymbol{v}_m)_{\mathcal{V}} \end{bmatrix}. \tag{5.5}$$

Consider now the algebra $\mathcal{S}$ of linear operators from U_n to V_m. It is

$$S \in \mathcal{S}, \quad \xi_m(S(\boldsymbol{u}_i)) = Z_m^{-1} \begin{bmatrix} (S(\boldsymbol{u}_i), \boldsymbol{v}_1)_{\mathcal{V}} \\ \vdots \\ (S(\boldsymbol{u}_i), \boldsymbol{v}_m)_{\mathcal{V}} \end{bmatrix}. \tag{5.6}$$

The following isomorphism η_n^m is induced between $\mathcal{S}$ and the algebra of matrices $m \times n$:

$$S \in \mathcal{S}, \;\; \eta_n^m(S) = Z_m^{-1}\bar{S}, \quad \bar{S} \in \mathbb{R}^{m \times n}, \quad \bar{S}_{i,j} = (S(\boldsymbol{u}_j), \boldsymbol{v}_i)_{\mathcal{V}}, \tag{5.7}$$

that is, such that

$$\xi_m(S(\boldsymbol{x})) = \eta_n^m(S)\, \xi_n(\boldsymbol{x}), \quad \boldsymbol{x} \in U_n. \tag{5.8}$$

Isomorphisms between points of finite dimensional spaces and their coordinate representations and between linear operators on finite dimensional spaces and their matrix representations allow us to write the approximated Riccati equations for control (3.16) and for filtering (3.15) as

$$\begin{aligned} \dot{\widetilde{\boldsymbol{P}}}_n(t) &= \widetilde{\boldsymbol{A}}_n \boldsymbol{W}_n^{-1} \widetilde{\boldsymbol{P}}_n(t) + \widetilde{\boldsymbol{P}}_n(t) \boldsymbol{W}_n^{-1} \widetilde{\boldsymbol{A}}_n^{\mathrm{T}} + \widetilde{\boldsymbol{\Lambda}}_n b - \widetilde{\boldsymbol{P}}_n(t) \boldsymbol{W}_n^{-1} \widetilde{\boldsymbol{\Sigma}}_n \boldsymbol{W}_n^{-1} \widetilde{\boldsymbol{P}}_n(t), \\ \dot{\widetilde{\boldsymbol{R}}}_n(t) &= \widetilde{\boldsymbol{\mathcal{A}}}_n \mathbb{W}_n^{-1} \widetilde{\boldsymbol{R}}_n(t) + \widetilde{\boldsymbol{R}}_n(t) \mathbb{W}_n^{-1} \widetilde{\boldsymbol{\mathcal{A}}}_n^{\mathrm{T}} + \widetilde{\boldsymbol{L}}_n - \widetilde{\boldsymbol{R}}_n(t) \mathbb{W}_n^{-1} \widetilde{\boldsymbol{S}}_n \mathbb{W}^{-1} \widetilde{\boldsymbol{R}}_n(t) \end{aligned} \tag{5.9}$$

and the approximated filter equation (3.46) and control equation (3.47) in the form

$$\begin{aligned} \dot{\hat{\boldsymbol{x}}}_{n,C}(t) &= \boldsymbol{W}_n^{-1}([\widetilde{\boldsymbol{A}}_n - \widetilde{\boldsymbol{P}}_n(t)\widetilde{\boldsymbol{\Sigma}}_n]\hat{\boldsymbol{x}}_{n,C}(t) + \widetilde{\boldsymbol{P}}_n(t)\boldsymbol{W}_n^{-1}\bar{\Gamma}_n \boldsymbol{y}(t) - \widetilde{\boldsymbol{T}}_n(t_f - t)\hat{\boldsymbol{x}}_{n,C}(t)), \\ \boldsymbol{u}_n(t) &= -\begin{bmatrix} 0 & \boldsymbol{B}_0^T \end{bmatrix} \mathbb{W}_n^{-1} \widetilde{\boldsymbol{R}}_n(t_f - t) \mathbb{W}_n^{-1} \widetilde{\boldsymbol{T}}_{n,2} \hat{\boldsymbol{x}}_{n,C}(t), \\ \hat{\boldsymbol{z}}_n(t) &= [\, \boldsymbol{I}_{N \times N} \quad 0_{N \times nN} \,]\, \hat{\boldsymbol{x}}_{n,C}(t). \end{aligned} \tag{5.10}$$

In (5.9) and (5.10) $\hat{\boldsymbol{x}}_{n,C}$ is the coordinate expression of vector $\hat{\boldsymbol{x}}_n$ in the basis of Φ_n, $\hat{\boldsymbol{z}}_n(t)$ is the approximation of the optimal estimate of $\boldsymbol{z}(t)$, $\widetilde{\boldsymbol{P}}_n(t)$ and $\widetilde{\boldsymbol{R}}_n(t)$ are square matrices whose components are defined as $\{\widetilde{\boldsymbol{P}}_n(t)\}_{i,j} = (\boldsymbol{P}_n(t)\boldsymbol{v}_j, \boldsymbol{v}_i)$ and $\{\widetilde{\boldsymbol{R}}_n(t)\}_{i,j} = (\boldsymbol{R}_n(t)\boldsymbol{w}_j, \boldsymbol{w}_i)$. Matrices $\widetilde{\boldsymbol{\Lambda}}_n$, $\widetilde{\boldsymbol{\Sigma}}_n$, $\bar{\boldsymbol{\Gamma}}_n$, $\boldsymbol{W}_n$, $\widetilde{\boldsymbol{A}}_n$, $\widetilde{\boldsymbol{T}}_{n,1}$, $\mathbb{W}_n$, $\widetilde{\boldsymbol{T}}_{n,2}(t)$,

$\widetilde{\mathcal{A}}_n$, $\widetilde{\boldsymbol{L}}_n$, $\widetilde{\boldsymbol{S}}_n$ are numerical matrices computed by simple scalar products of elements in finite dimensional subspaces as follows:

$$
\begin{aligned}
\widetilde{\boldsymbol{\Lambda}}_n(i,j) &= (\boldsymbol{F}\boldsymbol{F}^*\boldsymbol{v}_j, \boldsymbol{v}_i)\,,\\
\widetilde{\boldsymbol{\Sigma}}_n(i,j) &= (\boldsymbol{C}^*\boldsymbol{C}\boldsymbol{v}_j, \boldsymbol{v}_i)\,,\\
\bar{\boldsymbol{\Gamma}}_n(i,j) &= (\boldsymbol{C}^*\phi_j, \boldsymbol{v}_i)\,,\\
\boldsymbol{W}_n(i,j) &= (\boldsymbol{v}_i, \boldsymbol{v}_j),\\
\widetilde{\boldsymbol{A}}_n(i,j) &= (\boldsymbol{A}\boldsymbol{v}_j, \boldsymbol{v}_i),\\
\widetilde{\boldsymbol{T}}_{n,1}(i,j) &= (\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{w}_j, \boldsymbol{v}_i)\,,\\
\mathbb{W}_n(i,j) &= (\boldsymbol{w}_i, \boldsymbol{w}_j),\\
\widetilde{\boldsymbol{T}}_{n,2}(i,j) &= (\boldsymbol{v}_j, \boldsymbol{w}_i),\\
\widetilde{\mathcal{A}}_n(i,j) &= (\boldsymbol{A}^*\boldsymbol{w}_j, \boldsymbol{w}_i)\,,\\
\widetilde{\boldsymbol{L}}_n(i,j) &= (\boldsymbol{Q}\boldsymbol{w}_j, \boldsymbol{w}_i),\\
\widetilde{\boldsymbol{S}}_n(i,j) &= (\boldsymbol{B}\boldsymbol{B}^*\boldsymbol{w}_j, \boldsymbol{w}_i).
\end{aligned}
\tag{5.11}
$$

Finally, it is $\widetilde{\boldsymbol{T}}_n(t) = \widetilde{\boldsymbol{T}}_{n,1}\mathbb{W}_n^{-1}\widetilde{\boldsymbol{R}}_n(t)\mathbb{W}_n^{-1}\widetilde{\boldsymbol{T}}_{n,2}$.

Thus, denoting by

$$
\begin{aligned}
S_c(n,t) &= \boldsymbol{W}_n^{-1}(\widetilde{\boldsymbol{A}}_n - \widetilde{\boldsymbol{P}}_n(t)\boldsymbol{W}_n^{-1}\widetilde{\boldsymbol{\Sigma}}_n - \widetilde{\boldsymbol{T}}_{n,1}\mathbb{W}_n^{-1}\widetilde{\boldsymbol{R}}_n(t_f - t)\mathbb{W}_n^{-1}\widetilde{\boldsymbol{T}}_{n,2}),\\
P_c(n,t) &= \boldsymbol{W}_n^{-1}\widetilde{\boldsymbol{P}}_n(t)\boldsymbol{W}_n^{-1}\bar{\boldsymbol{\Gamma}}_n,\\
Q_c(n,t) &= -\,[\,0 \quad \boldsymbol{B}_0^{\mathrm{T}}\,]\,\mathbb{W}_n^{-1}\widetilde{\boldsymbol{R}}_n(t_f - t)\mathbb{W}_n^{-1}\widetilde{\boldsymbol{T}}_{n,2}
\end{aligned}
\tag{5.12}
$$

with $\widetilde{\boldsymbol{P}}_n(t)$ and $\widetilde{\boldsymbol{R}}_n(t)$ solutions of the matrix differential equations (Riccati) in (5.9), the approximate LQG controller can be written as follows:

$$
\begin{aligned}
\dot{\hat{\boldsymbol{x}}}_{n,C}(t) &= S_c(n,t)\hat{\boldsymbol{x}}_{n,C}(t) + P_c(n,t)\boldsymbol{y}(t),\\
\boldsymbol{u}_n(t) &= Q_c(n,t)\hat{\boldsymbol{x}}_{n,C}(t).
\end{aligned}
\tag{5.13}
$$

The vector $\hat{\boldsymbol{x}}_{n,C}(t) \in \mathbb{R}^{(n_1+1+\sum_{i=2}^{\delta} n_i)N}$.

Remark 5.1. It is important to stress the fact that matrices in (5.11) have a fixed structure and, in the case of hereditary systems without distributed delay, such matrices depend only on the multiindex s_n and on the matrices $\boldsymbol{A}_j$ $(j = 0, 1, \dots, \delta)$, $\boldsymbol{B}_0$, $\boldsymbol{C}_0$, $\boldsymbol{F}_0$, $\boldsymbol{G}$ that describe the system and on the weight matrix Q_0 that defines the cost functional. This property follows from the fact that splines are not uniformly distributed over the interval $[-r, 0]$: each interval $[-r_i, -r_{i-1}]$ has an independent spline distribution.

The numerical computation of matrices (5.11) is a straightforward function of the multi-index s_n and of the system matrices. As an example, the expressions of matrices in (5.11) are reported for systems with two pure delay terms (multi-index $s_n = (n_1, n_2)$ with $n = \inf(n_1, n_2)$) and no distributed delay.

$$
\boldsymbol{W}_n = \begin{bmatrix} \boldsymbol{W}_{n,a} & \boldsymbol{W}_{n,b} \\ 0_{n_2N\times n_1N} & \boldsymbol{W}_{n,c} \end{bmatrix},
\tag{5.14}
$$

$$\boldsymbol{W}_{n,a} = \left(\frac{r_1}{n_1}\right) \begin{bmatrix} \frac{n_1}{r_1} + 2/3 & 1/3 & 0 & \dots & 0 \\ 1/3 & 4/3 & 1/3 & \ddots & \vdots \\ 0 & 1/3 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 4/3 & 1/3 \\ 0 & \cdot & 0 & 1/3 & 2/3 + \frac{n_1}{r_1}\frac{r-r_1}{3n_2} \end{bmatrix}_{(n_1+1)\times(n_1+1)} \otimes \boldsymbol{I}_{N\times N},$$

$$\boldsymbol{W}_{n,b} = \begin{bmatrix} 0 & \dots & \dots & 0 \\ \frac{r-r_1}{6n_2}\boldsymbol{I}_{N\times N} & 0 & \dots & 0 \end{bmatrix}_{(n_1+1)N\times n_2 N},$$

$$\boldsymbol{W}_{n,c} = \left(\frac{r-r_1}{n_2}\right) \begin{bmatrix} 1/6 & 2/3 & 1/6 & 0 & \dots \\ 0 & 1/6 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 2/3 & 1/6 \\ 0 & \cdot & 0 & 1/6 & 1/3 \end{bmatrix}_{n_2\times(n_2+1)} \otimes \boldsymbol{I}_{N\times N}.$$

$$\widetilde{\boldsymbol{A}}_n = \widetilde{\boldsymbol{A}}_{n,1} + \widetilde{\boldsymbol{A}}_{n,2}, \tag{5.15}$$

$$\widetilde{\boldsymbol{A}}_{n,1} = \begin{bmatrix} \boldsymbol{A}_0 & 0 & \dots & 0 & \boldsymbol{A}_1 & 0 & \dots & 0 & \boldsymbol{A}_2 \\ 0 & \dots & \dots & \dots & \dots & \dots & \dots & \dots & 0 \end{bmatrix},$$

$$\widetilde{\boldsymbol{A}}_{n,2} = \begin{bmatrix} \widetilde{\boldsymbol{A}}_{n,2,a} & \widetilde{\boldsymbol{A}}_{n,2,b} \\ 0_{n_2 N\times n_1 N} & \widetilde{\boldsymbol{A}}_{n,2,c} \end{bmatrix},$$

$$\widetilde{\boldsymbol{A}}_{n,2,a} = \begin{bmatrix} 1 & -1 & 0 & \dots & 0 \\ 1 & 0 & -1 & \ddots & \vdots \\ 0 & 1 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 0 & -1 \\ 0 & \vdots & 0 & 1 & -1/2 \end{bmatrix}_{n_1+1\times(n_1+1)} \otimes \boldsymbol{I}_{N\times N},$$

$$\widetilde{\boldsymbol{A}}_{n,2,b} = \begin{bmatrix} 0_{n_1 N\times n_2 N} \\ [-1/2\boldsymbol{I}_{N\times N} \quad 0 \quad \dots \quad 0] \end{bmatrix},$$

$$\widetilde{\boldsymbol{A}}_{n,2,c} = \begin{bmatrix} 1/2 & 0 & -1/2 & 0 & \dots \\ 0 & 1/2 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 0 & -1/2 \\ 0 & \vdots & 0 & 1/2 & -1/2 \end{bmatrix}_{n_2\times(n_2+1)} \otimes \boldsymbol{I}_{N\times N}.$$

$$\mathbb{W}_n = \begin{bmatrix} \mathbb{W}_{n,a} & \mathbb{W}_{n,b} \\ \mathbb{W}_{n,b}^{\mathrm{T}} & \mathbb{W}_{n,c} \end{bmatrix} \tag{5.16}$$

with

$$\mathbb{W}_{n,a} = \frac{r_1}{n_1}\begin{bmatrix} 2/3 & 1/3 & 0 & \dots & 0 \\ 1/3 & 4/3 & 1/3 & \ddots & \vdots \\ 0 & 1/3 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 4/3 & 1/3 \\ 0 & \cdot & 0 & 1/3 & 4/3 \end{bmatrix}_{n_1\times n_1} \otimes \boldsymbol{I}_{N\times N},$$

$$\mathbb{W}_{n,b} = \begin{bmatrix} \boldsymbol{0}_{(n_1-1)N\times(n_2+1)N} \\ [\,\frac{r_1}{6n_1}\boldsymbol{I}_{N\times N} \quad 0 \quad \dots \quad 0 \quad \frac{r_1}{6n_1}\boldsymbol{A}_1^{\mathrm{T}}\,] \end{bmatrix}_{n_1N\times(n2+1)N},$$

$$\mathbb{W}_{n,c} = \mathbb{W}_{n,c,1} + \mathbb{W}_{n,c,2},$$

$$\mathbb{W}_{n,c,1} = \left(\frac{r-r_1}{n_2}\right)\begin{bmatrix} 1/3 & 1/6 & 0 & \dots & 0 \\ 1/6 & 2/3 & 1/6 & \ddots & \vdots \\ 0 & 1/6 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 2/3 & 1/6\boldsymbol{A}_2^{\mathrm{T}} \\ 0 & \cdot & 0 & 1/6\boldsymbol{A}_2 & 0 \end{bmatrix}_{(n_2+1)\times(n_2+1)} \otimes \boldsymbol{I}_{N\times N},$$

$$\mathbb{W}_{n,c,2} = \begin{bmatrix} \frac{r_1}{6n_1}\boldsymbol{I}_{N\times N} & 0 & \dots & 0 & \frac{r_1}{6n_1}\boldsymbol{A}_1^{\mathrm{T}} \\ 0 & \dots & \dots & \dots & 0 \\ \frac{r_1}{6n_1}\boldsymbol{A}_1 & 0 & \dots & 0 & \boldsymbol{I} + \frac{r_1}{6n_1}\boldsymbol{A}_1\boldsymbol{A}_1^{\mathrm{T}} + \frac{r-r_1}{3n_2}\boldsymbol{A}_2\boldsymbol{A}_2^{\mathrm{T}} \end{bmatrix}.$$

$$\widetilde{\boldsymbol{T}}_{n,2} = \begin{bmatrix} \widetilde{\boldsymbol{T}}_{n,2,a} & \widetilde{\boldsymbol{T}}_{n,2,b} \\ \widetilde{\boldsymbol{T}}_{n,2,c} & \widetilde{\boldsymbol{T}}_{n,2,d} \\ \widetilde{\boldsymbol{T}}_{n,2,e} & \widetilde{\boldsymbol{T}}_{n,2,f} \\ \widetilde{\boldsymbol{T}}_{n,2,g} & \widetilde{\boldsymbol{T}}_{n,2,h} \end{bmatrix}_{(n_1+n_2+1)N\times(n_1+n_2+1)N}, \tag{5.17}$$

$$\widetilde{\boldsymbol{T}}_{n,2,a} = \left(\frac{r_1}{n_1}\right)\begin{bmatrix} \begin{bmatrix} 2/3 & 1/3 & 0 & \dots & 0 \\ 1/3 & 4/3 & 1/3 & \ddots & \vdots \\ 0 & 1/3 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 4/3 & 1/3 \\ 0 & \cdot & 0 & 1/3 & 4/3 \end{bmatrix}_{n_1\times n_1} \otimes \boldsymbol{I}_{N\times N} & \begin{bmatrix} \boldsymbol{0} \\ \frac{1}{3}\boldsymbol{I}_{N\times N} \end{bmatrix} \end{bmatrix}_{n_1N\times(n_1+1)N},$$

$$\widetilde{\boldsymbol{T}}_{n,2,b} = 0_{n_1N\times n_2N},$$

$$\widetilde{\boldsymbol{T}}_{n,2,c} = [\,0 \quad \dots \quad 0 \quad \tfrac{r_1}{6n_1}\boldsymbol{I}_{N\times N} \quad \tfrac{r-r_1}{3n_2}\boldsymbol{I}_{N\times N} + \tfrac{r_1}{3n_1}\boldsymbol{I}_{N\times N}\,]_{N\times(n_1+1)N},$$

$$\widetilde{\boldsymbol{T}}_{n,2,d} = [\,\tfrac{r-r_1}{6n_2}\boldsymbol{I}_{N\times N}0 \quad \dots \quad 0]_{N\times n_2N},$$

$$\widetilde{\boldsymbol{T}}_{n,2,e} = \begin{bmatrix} 0 & \dots & 0 & \frac{r-r_1}{6n_2}\boldsymbol{I}_{N\times N} \\ 0 & \dots & \dots & 0 \end{bmatrix}_{(n_2-1)N\times(n_1+1)N},$$

$$\widetilde{\boldsymbol{T}}_{n,2,f} = \left(\frac{r-r_1}{n_2}\right)\left[\begin{bmatrix} 2/3 & 1/6 & 0 & \dots \\ 1/6 & \ddots & \ddots & 0 \\ 0 & \ddots & 2/3 & 1/6 \\ \dots & 0 & 1/6 & 2/3 \end{bmatrix}_{(n_2-1)\times n_2} \otimes \boldsymbol{I}_{N\times N} \quad \begin{bmatrix} \boldsymbol{0} \\ \frac{1}{6}\boldsymbol{I}_{N\times N} \end{bmatrix}\right]_{(n_2-1)N\times(n_2-1)N},$$

$$\widetilde{\boldsymbol{T}}_{n,2,g} = [\,\boldsymbol{I}_{N\times N} \quad \boldsymbol{0} \quad \tfrac{r_1}{6n_1}\boldsymbol{A}_1 \quad \tfrac{r_1}{3n_1}\boldsymbol{A}_1\,]_{N\times(n_1+1)N},$$

$$\widetilde{\boldsymbol{T}}_{n,2,h} = [\,\boldsymbol{0} \quad \dots \quad 0 \quad \tfrac{r-r_1}{6n_2}\boldsymbol{A}_2 \quad \tfrac{r-r_1}{3n_2}\boldsymbol{A}_2\,]_{N\times n_2 N}.$$

$$\widetilde{\mathcal{A}}_n = \widetilde{\mathcal{A}}_{n,1} + \widetilde{\mathcal{A}}_{n,2}, \tag{5.18}$$

$$\widetilde{\mathcal{A}}_{n,1} = \begin{bmatrix} 0 & \dots & \dots & \dots & 0 \\ 2\boldsymbol{I}_{N\times N} & 0 & \dots & 0 & \boldsymbol{A}_0^{\mathrm{T}} \end{bmatrix}_{(n_1+n_2+1)N\times(n_1+n_2+1)N},$$

$$\widetilde{\mathcal{A}}_{n,2} = \begin{bmatrix} \widetilde{\mathcal{A}}_{n,2,a} & \widetilde{\mathcal{A}}_{n,2,b} \\ \widetilde{\mathcal{A}}_{n,2,c} & \widetilde{\mathcal{A}}_{n,2,d} \end{bmatrix}_{(n_1+n_2+1)N\times(n_1+n_2+1)N},$$

$$\widetilde{\mathcal{A}}_{n,2,a} = \begin{bmatrix} -1 & 1 & 0 & \dots & 0 \\ -1 & 0 & 1 & \ddots & \vdots \\ 0 & -1 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 0 & 1 \\ 0 & \vdots & 0 & -1 & 0 \end{bmatrix}_{n_1\times n_1} \otimes \boldsymbol{I}_{N\times N},$$

$$\widetilde{\mathcal{A}}_{n,2,b} = \begin{bmatrix} 0 & \dots & \dots & \dots & 0 \\ 1/2\boldsymbol{I}_{N\times N} & 0 & \dots & 0 & 1/2\boldsymbol{A}_1^{\mathrm{T}} \end{bmatrix}_{n_1 N\times(n_2+1)N},$$

$$\widetilde{\mathcal{A}}_{n,2,c} = \begin{bmatrix} 0 & \dots & 0 & -1/2\boldsymbol{I}_{N\times N} \\ \vdots & \vdots & \vdots & 0 \\ 0 & \dots & 0 & -1/2\boldsymbol{A}_1 \end{bmatrix}_{(n_2+1)N\times n_1 N},$$

$$\widetilde{\mathcal{A}}_{n,2,d} = \left[\begin{array}{c|c} \begin{bmatrix} -1/4 & 1/2 & 0 & \dots & 0 \\ -1/2 & 0 & 1/2 & \ddots & \vdots \\ 0 & -1/2 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 0 & 1/2 \\ 0 & \vdots & 0 & -1/2 & 0 \end{bmatrix}_{n_2\times n_2} \otimes \boldsymbol{I}_{N\times N} & \begin{matrix} 1/4\boldsymbol{A}_1^{\mathrm{T}} \\ 0 \\ \vdots \\ 0 \\ \frac{1}{2}\boldsymbol{A}_2^{\mathrm{T}} \end{matrix} \\ \hline 1/4\boldsymbol{A}_1 \quad 0 \quad \dots \quad 0 \quad -\frac{1}{2}\boldsymbol{A}_2 & \frac{1}{4}\boldsymbol{A}_1\boldsymbol{A}_1^{\mathrm{T}} + 1/2\boldsymbol{A}_2\boldsymbol{A}_2^{\mathrm{T}} \end{array}\right].$$

Remark 5.2. In the case of just one pure delay, matrices in (5.11) are much simpler, due to the fact that vectors v and w are much simpler. Matrices which involve v vectors have been computed in [3]. Here, just to have an idea of such a simplification, matrix $\widetilde{\mathcal{A}}_n$ in (5.18) is reported in the case of one pure delay term.

$$\widetilde{\mathcal{A}}_n = \widetilde{\mathcal{A}}_{n,1} + \widetilde{\mathcal{A}}_{n,2}, \tag{5.19}$$

$$\widetilde{\mathcal{A}}_{n,1} = \begin{bmatrix} \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \boldsymbol{I}_{N\times N} & \mathbf{0} & \boldsymbol{A}_0^{\mathrm{T}} \end{bmatrix},$$

$$\widetilde{\mathcal{A}}_{n,2} = \left[\begin{array}{c|c} \begin{bmatrix} -1/2 & 1/2 & 0 & \dots & 0 \\ -1/2 & 0 & 1/2 & \ddots & \vdots \\ 0 & -1/2 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 0 & 1/2 \\ 0 & \vdots & 0 & -1/2 & 0 \end{bmatrix}_{n\times n} \otimes \boldsymbol{I}_{N\times N} & \begin{array}{c} \mathbf{0} \\ \frac{1}{2}\boldsymbol{A}_1^{\mathrm{T}} \end{array} \\ \hline \mathbf{0} \quad -\frac{1}{2}\boldsymbol{A}_1 & \frac{1}{2}\boldsymbol{A}_1\boldsymbol{A}_1^{\mathrm{T}} \end{array}\right].$$

If there is the distributed delay too, then the following matrix must be added in the right-hand side of (5.19):

$$\widetilde{\mathcal{A}}_{n,3} = \begin{bmatrix} \mathbf{0} & (\boldsymbol{D}_0'^{n})^{\mathrm{T}} \\ \vdots & \vdots \\ \mathbf{0} & (\boldsymbol{D}_{n-1}'^{n})^{\mathrm{T}} \\ \mathbf{0} & \boldsymbol{A}_1(\boldsymbol{D}_n'^{n})^{\mathrm{T}} \end{bmatrix},$$

where

$$\boldsymbol{D}_j'^{n} = \int_{-r}^{0} \boldsymbol{A}_{01}(s)\, spline_j(s) ds \qquad j = 0, 1, \dots, n.$$

6. Remarks on the infinite horizon case. The methodology here presented for LQG control of hereditary systems over a finite time-horizon can be applied also for LQG control over infinite time-horizon. The basis is the paper [14] in which, under suitable conditions, the convergence of the solution of an approximate Riccati differential equation, evaluated in a sufficiently large time, to the solution of the corresponding infinite dimensional algebraic Riccati equation is proved. The hypotheses required in [14] for such a convergence are satisfied by hereditary systems and by the approximation scheme here presented. Such hypotheses are the Hilbert–Schmidt property of operators $\boldsymbol{Q}$ and $\boldsymbol{F}\boldsymbol{F}^*$, the convergence of the sequence of projection operators involved, and the convergence of the semigroups approximating the semigroup generated by the operator which, in the algebraic Riccati equation, multiplies on the left the unknown Riccati operator. Structural properties are requested in paper [14] of approximate controllability of pairs $(\boldsymbol{A}, \boldsymbol{F})$ and $(\boldsymbol{A}^*, \boldsymbol{Q})$. In that paper the approximate solution of an algebraic Riccati equation is found by exploiting the approximability of the corresponding dynamical Riccati equation and its time convergence toward the steady state, and finding a large enough time-horizon T to approximate the steady-state solution. Such a solving method, which requires only convergence of one approximating semigroup, does not allow for a uniform convergence of the approximate solution toward the actual one (see Theorem 3.2 of [14], relationship among ϵ, T, and n). On the other hand, such a solving method does not require the uniform exponential stability of the approximating semigroups nor the convergence of the adjoint approximate semigroups.

Using the approximate solutions of the Riccati algebraic equations, by using the above paper, the infinite horizon LQG controller can be built. The problem of guaranteeing the convergence of the approximation schemes in infinite horizon case continues to be worthy of attention.

Nevertheless, when the state is fully available, the approximation scheme here presented has the nice property to guarantee convergence also in the infinite horizon case, as stated in the following theorem.

Theorem 6.1. *Consider system* (2.5)*, with fully available state, that is,*

$$\boldsymbol{y}(t) = \boldsymbol{x}(t) \tag{6.1}$$

and the following cost functional

$$J_I(\boldsymbol{u}) = \lim_{t_f \to \infty} \frac{1}{t_f} \int_0^{t_f} E[(\boldsymbol{Q}\boldsymbol{x}(t), \boldsymbol{x}(t)) + \boldsymbol{u}^{\mathrm{T}}(t)\boldsymbol{u}(t)]dt, \tag{6.2}$$

with $\boldsymbol{Q} : \boldsymbol{M}_2 \mapsto \boldsymbol{M}_2$ *as in* (3.2)*. Let the pair* $(\boldsymbol{A}, \boldsymbol{B})$ *be stabilizable and the pair* $(\boldsymbol{A}, \boldsymbol{Q})$ *be detectable. Let*

$$\boldsymbol{u}_n(t) = -\boldsymbol{B}^{\star}\boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n\boldsymbol{x}_n(t), \tag{6.3}$$

where $\boldsymbol{R}_n(T)$ *is the approximate solution of the algebraic Riccati equation for control*

$$\boldsymbol{A}^{\star}\boldsymbol{R} + \boldsymbol{R}\boldsymbol{A} - \boldsymbol{R}\boldsymbol{B}\boldsymbol{B}^{\star}\boldsymbol{R} + \boldsymbol{Q} = 0 \tag{6.4}$$

obtained [14] *by evaluating the approximate dynamic Riccati equation* (3.16) *in a suitable time* T*, and* $\boldsymbol{x}_n(t)$ *is the corresponding evolving state. Let* $\boldsymbol{x}(t)$ *be the state evolving when the optimal infinite horizon LQG control law is applied to the system. Then, for every* $\epsilon > 0$*, there exists a* T_ϵ*, such that for every* $T > T_\epsilon$ *there exists an* n_T*, such that for every* $n > n_T$ *the semigroup which governs the closed loop system, that is, the one generated by* $\boldsymbol{A} - \boldsymbol{B}\boldsymbol{B}^{\star}\boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n$*, is exponentially stable and, moreover,*

$$E\|\boldsymbol{x}_n(t) - \boldsymbol{x}(t)\| < \epsilon \qquad \forall t \in [0, \infty). \tag{6.5}$$
