DEGENERATE VARIANCE CONTROL OF A ONE-DIMENSIONAL DIFFUSION*

DANIEL OCONE† AND ANANDA WEERASINGHE‡

Abstract. Consider an Itô equation for a scalar-valued process that is controlled through a dynamic and adaptive choice of its diffusion coefficient. Such a control is called a variance control and is said to degenerate when it becomes zero. We consider the problem of choosing a control to minimize a discounted, infinite-horizon cost that penalizes state values close to an equilibrium point of the drift and also imposes a control cost. Admissible controls are required to take values in the closed, bounded interval $[0, \sigma_0]$, where $\sigma_0 > 0$; in particular, the control can be degenerate. In general, there will be a bang-bang optimal control that takes the value σ_0 in some open set and is zero otherwise. We discuss the existence and properties of solutions to stochastic differential equations with such controls and characterize the value function and optimal control in more detail, in the case of both linear and nonlinear drift. Employing the Hamilton–Jacobi–Bellman equation and results of [N. V. Krylov, *Theory Probab. Appl.*, 17 (1973), pp. 114–131] and [P.-L. Lions, *Comm. Pure Appl. Math.*, 34 (1981), pp. 121–147], we derive sufficient conditions for the existence of single-region optimal controls, construct examples of multiple-region controls, and provide bounds on the number and size of the regions in which the optimal control is positive.

1. Introduction.

The simplest model for a scalar diffusion with variance control is the stochastic differential equation

$$X_x^u(t) = x + \int_0^t b(X_x^u(s))\,ds + \int_0^t u(s)\,dW(s). \tag{1.1}$$

This paper analyzes the problem of control to minimize the discounted cost

$$J(x,u) = E\left[\int_0^\infty e^{-\alpha t}\left[c(X_x^u(t)) + \lambda u^2(t)\right]\,dt\right], \tag{1.2}$$

where the state dynamics, the location cost c, and the controls have the following special structure. First, the differential equation $\dot{x} = b(x)$, corresponding to zero variance control, has a unique, global, asymptotically stable equilibrium point, set arbitrarily at $x = 0$. Second, c is a bounded function that achieves its unique maximum at the equilibrium point $x = 0$ and decreases as x moves away from $x = 0$. The precise definition of an admissible control is given at the beginning of section 3. The main point is that the control is bounded and allowed to degenerate to the value zero; that is,

$$0 \le u(t) \le \sigma_0 \qquad \text{for all } t, \tag{1.3}$$

where σ_0 is a given constant. Throughout, λ is a given positive constant. To lend the problem a simplifying symmetry, we shall also assume throughout that c is an

even function and that b is odd. Our work was motivated by the desire to understand qualitative properties of optimal controls when degeneration is allowed, and the special structure assumed here allows some intuition that gives insight into this question. A recent, specific example with similar cost and dynamic structure, but with a long run average criterion and potentially unbounded ($\sigma_0 = \infty$) controls, appears in a dynamic sampling application in Assaf [1].

Early specific examples of degenerate variance control problems appear in Genis and Krylov [7] and Krylov [12]. In particular, they find that the value function is C^1 and piecewise C^2. General (previscosity solution) theory for degenerate problems is established in Krylov [12] and Lions [13] and shows under what hypothesis the value function for degenerate control problems is C^1.

When the cost c and drift b have the structure specified above, there are two opposing tendencies. If zero variance control (u=0) is applied, no control cost is incurred, but the state moves monotonically to regions of higher and higher location cost. On the other hand, if positive control is exercised, it will spread the state out in an average sense and so tend to stall its progression toward the equilibrium. This effect will be of greatest advantage in a region about the equilibrium point, where c is concave. Conversely, when the state is far away from 0 in a region where c is reasonably flat or convex, one expects that the advantage of a positive diffusion control either does not exist or is outweighed by the control cost. Intuition thus suggests that *single-region bang-bang* feedback controls, which set $u = \sigma_0$ when $|x| < a$ and $u = 0$ when $x \geq a$ for some a, should provide good candidates for optimal controls. This control structure is evident in the example in Assaf [1]. The same intuition also applies in the example of Genis and Krylov [7].

This paper addresses the following questions. First, bang-bang, degenerate controls give rise to stochastic differential equations with discontinuous diffusion coefficients. Do solutions exist for such equations, and how do they behave? In section 2, it is shown that a weak solution will always exist in some probability space if the diffusion coefficient has the form $\mathbf{1}_G(x)$, where G is the indicator function of set G, as long as G is open, and the behavior of the solutions is described. Second, what conditions suffice to imply the existence of single-region optimal controls and how can the optimal region be characterized? More generally, what factors determine where positive diffusion control should be exercised? In this paper, we analyze in some detail how the C^1 condition and the Hamilton–Jacobi–Bellman (HJB) equation determine the optimal value function and how the structure of b and c determine where the regions of degeneracy for the optimal control occur. Section 3 recalls the theory of the HJB equation for the value function and develops the extensions and refinements which are needed to study problem (1.1)–(1.3). Section 4 analyzes this problem when the drift is linear, which is treated separately since our results in this case are more complete. It is shown that the decisive factor for turning on the diffusion is the degree of concavity of c. To illustrate, sufficient conditions are given for the optimal control to be single-region and a class of problems with multiple-region optimal controls are constructed. In section 5, sufficient conditions are derived for single-region control in the more delicate case of nonlinear drift b.

Several assumptions in (1.1)–(1.3) can be generalized without changing the results. For example, the constraint (1.3) is equivalent to $|u(t)| \leq \sigma_0$ because of the symmetry of Brownian motion. Also, the particular form $u^2(t)$ of the control cost could be replaced by $\ell(u)$, where $\ell(u)$ is any strictly increasing function satisfying $\ell(0) = 0$. Because the optimal controls turn out to be bang-bang, taking values either 0 or σ_0, the results in either case will be qualitatively the same and will depend quantitatively only on $\ell(\sigma_0)$.

Several authors have studied variance control problems with nondegenerate controls. McNamara [15] considers maximization of terminal reward for a drift-less diffusion with feedback controls u satisfying $\sigma_1 \le u(t) \le \sigma_2$ for strictly positive constants σ_1 and σ_2. In [16] he considers controls which switch between two drift-diffusion pairs, both nonsingular in the diffusion term. A simple variance control problem is treated as an example in Rogers and Williams [18]. Dorroh, Ferreyra, and Sundar [3] treat problems with control in both drift and noise when the control is allowed to be unbounded.

2. Stochastic differential equations with bang-bang diffusion. A formal analysis of the HJB equation (see section 3) for the problem (1.1)–(1.3) suggests that optimal controls will have a feedback form $\sigma_0 \mathbf{1}_G(x)$, where $\mathbf{1}_G(x)$ is the indicator function of a subset G in$R$. To make sense of such controls, it is necessary to show that (1.1) admits a solution when u is replaced by $\mathbf{1}_G(X(t))$. The assumption made in section 1 that $\dot{x} = b(x)$ has a unique stable equilibrium point is irrelevant to this problem; thus, in this section we consider the one-dimensional equation

$$dX(t) = f(X(t))\,dt + \sigma_0 \mathbf{1}_G(X(t))\,dW(t), \qquad X(0) = x_0, \tag{2.1}$$

where it is assumed only that

(2.2) f is locally Lipschitz; and

(2.3) $\sup_R x f(x) < K(1+|x|^2)$ for some constant $K < \infty$ and all x.

By a *solution* to (2.1), we always mean a weak solution with continuous paths and almost surely (a.s.) infinite lifetimes defined on some probability space $(\Omega, \mathcal{F}, P)$ with a filtration $\{\mathcal{F}_t\}$ and an $\{\mathcal{F}_t\}$-Wiener process W. The condition (2.3) implies that lifetimes of solutions to (2.1) are infinite, once existence is established locally; see Friedman [6, p. 125].

Solutions to (2.1) do not exist for arbitrary G. For example, the equation $dX(t) = \mathbf{1}_{[0,\infty)}(X)\,dW$, $X(0) = 0$, does not admit a solution even in a weak sense. If a solution did exist, it would clearly have to remain in $[0,\infty)$ for all time. This would imply that $dX = dW$, and hence that $X = W$. However, Brownian motion exits $[0,\infty)$ with probability one in any time interval $[0,\epsilon)$ for any $\epsilon > 0$, and so a contradiction is obtained. On the other hand, $dX = \mathbf{1}_{(0,\infty)}(X)\,dW$, $X(0) = x_0$, is easy to solve for any x_0; if $x_0 \le 0$, then $X(t) \equiv x_0$ is the solution; if $x_0 > 0$, a solution is $X(t) = x_0 + W(t \wedge \tau)$, where τ is the first time $x_0 + W(t)$ hits 0.

That the removal of the boundary point 0 from $[0,\infty)$ changes an unsolvable equation into a solvable one reflects the main result, Theorem 2.3, of this section: if G is open, then (2.1) admits a weak solution. This is a useful piece of information for the control problem. The HJB equation by itself does not indicate whether the boundary points should be included in the optimal G. The analysis of this section shows that they should be excluded in the construction of optimal feedback controls.

Solutions to (2.1) with open G are not unique in general. For example, both $X \equiv W$ and $X \equiv 0$ solve $dx = \mathbf{1}_G(X)dW$, $X(0) = 0$, where $G = R - \{0\}$, because the Lebesgue measure of the total time a Brownian motion spends at the origin is zero. For the control problem, solutions that are guided strictly by the drift when the diffusion is zero are preferred. We shall say that a continuous process X *passes through* *a point y in one direction* if the event that there are times $0 \leq t_1 < t_2 < t_3$ such that either $X(t_1) < y$, $X(t_2) > y$, $X(t_3) < y$, or $X(t_1) > y$, $X(t_2) < y$, $X(t_3) > y$, has probability zero. Theorem 2.3 shows that weak solutions to (2.1) for open G may be constructed to pass through points of G^c in one direction only.

The proof for general open G ultimately reduces to the case in which G is simply an open interval. This case is studied carefully in Lemma 2.1 and Theorem 2.2, which are stated separately from Theorem 2.3 because of their particular importance to the control problem. After deriving Theorem 2.3 in the first version of the paper, we learned of the recent book of Assing and Schmidt [2], which provides very general theorems about strong Markov processes on the real line from which the existence of solutions to (2.1) can be deduced. The direct proof here relies only on standard methods.

It will be convenient to let ϕ denote the flow associated to the drift f when no diffusion term is present; $\phi(t,x)$, $t \geq 0$, $x \in R$, solves $\frac{\partial\phi(t,x)}{\partial t} = f(\phi(t,x))$, $\phi(0,x) = x$.

LEMMA 2.1. *Let $G = (r,q)$. Then* (2.1) *admits a unique weak solution. If $f(r) > 0$ and $f(q) < 0$ and if the solution enters (r,q), it will remain in (r,q) for all future time. If $f(r) \leq 0$ (respectively, if $f(q) \geq 0$), the solution will exit (r,q) never to return, once it hits r (respectively, q).*

Proof. Without loss of generality, set $\sigma_0 = 1$. There are three cases to treat, depending on the signs of the drift at the endpoints of (r,q). In the first case, $f(r) \leq 0$ and $f(q) \geq 0$; we say that the drift points out of (r,q) at each endpoint. Then, if $x_0 \notin (r,q)$, the solution $\phi(t,x_0)$ to $\dot{z} = f(z)$, $z(0) = x_0$, never enters (r,q) and thus solves (2.1) for $G = (r,q)$. If $x_0 \in (r,q)$, let $\tilde{X}_{x_0}$ denote the solution starting at x_0 to $d\tilde{X} = f(\tilde{X})\,dt + dW$. Then a solution to (2.1) is constructed by first following $\tilde{X}(t)$ until the first time τ that it exits (r,q) and then following $\phi(t-\tau, \tilde{X}(\tau))$. Strong uniqueness of the solution is obvious, at least until the first time, if any, that X_{x_0} reaches either r or q. So it remains to establish uniqueness starting from the boundary points. For example, let $X_r(t)$ be any solution starting from r. We want to show $X_r(t) = \phi(t,r)$. For this, apply the generalized Itô rule of problem 7.3 on p. 209 in Karatzas and Shreve [11] to $(X_r(t)-r)^+$ and take expectations. Then, if $\tau_\epsilon = \inf\{t \mid X_r(t) \notin (r-\epsilon, r+\epsilon)\}$,

$$E\left[(X_r(t)-r)^+\right] = E\left[\int_0^{t\wedge\tau_\epsilon} f(X_r(s))\mathbf{1}_{(r,q)}(X_r(s))\,ds\right]. \tag{2.4}$$

By the local Lipschitz property of f, there is an $\epsilon > 0$ and $K < \infty$ so that for $s \leq \tau_\epsilon$, $(f(X_r(s)) - f(r))\,\mathbf{1}_{(r,q)}(X_r(s)) \leq K\,(X_r(s)-r)^+$. Thus, using the fact that $f(r) \leq 0$ and some rearrangement of terms, it follows that

$$E\left[(X_r(t)-r)^+\right] \leq KE\left[\int_0^{t\wedge\tau_\epsilon} (X_r(s)-r)^+\,ds\right]. \tag{2.5}$$

The Gronwall–Bellman inequality then implies that $0 \leq E\left[(X_r(t)-r)^+\right] \leq 0$ for all t. Hence the solution X does not enter (r,q) a.s., which means that $dX_r(t)/dt = f(X_r(t))$, $t \geq 0$, as desired.

To handle the remaining cases, it will be enough to consider $G = (r,\infty)$ when $f(r) > 0$; here, f points into G at r. The result is an immediate application of Theorem 7.1 in Chapter 4 of Ikeda and Watanabe [8], taking $d = 1$. We briefly sketch the construction for the insight it affords. Let B be a Brownian motion with filtration

$\{\widetilde{\mathcal{F}}_t\}$ and let $x_0 \geq r$. Then the diffusion process Z that reflects at r and has drift $f(\cdot)$ and diffusion coefficient σ_0^2 satisfies

$$Z(t) = x_0 + \int_0^t f(Z(s))\,ds + \int_0^t \sigma_0 \mathbf{1}_{(r,\infty)}(Z(s))\,dB(s) + L(t),$$

where L is the local time of the process Z at r. Now define $T(t) = t + (L(t)/f(r))$, and let B^* be a Brownian motion independent of B. Set $W(t) = B(T^{-1}(t)) + \int_0^t \mathbf{1}_{\{r\}}\left(Z(T^{-1}(s))\right) dB^*(s)$, $X(t) = Z(T^{-1}(t))$, and $\mathcal{F}_t := \widetilde{\mathcal{F}}_{T^{-1}(t)} \wedge \sigma\{B^*(s); s \leq t\}$. Then W is an $\{\mathcal{F}_t\}$-Brownian motion and (X, W) is a weak solution of (2.1). Indeed X is a Markov process with a sticky boundary at r; the set of times that X spends at r has positive Lebesgue measure but contains no open interval. If $x_0 \notin [r, \infty)$, then the solution is constructed by following the flow $\phi(t, x_0)$ until the time S when the flow hits r, if finite, and then following $X_r(t - S)$.

Now suppose that $G = (r, q)$, where $f(r) > 0$ and $f(q) \geq 0$. To construct the solution, simply follow the solution with the same drift f, but $G = (r, \infty)$ until it hits $[q, \infty)$ and from that time onward, follow the solution ϕ to the deterministic equation.

Finally, suppose that $G = (r, q)$ and that the drift points in at both boundaries, i.e., $f(r) > 0$ and $f(q) < 0$. If $x_0 < q$, construct X_{x_0} by first following the solution to (2.1) with G replaced by (r, ∞) until the first time it hits q, and then switch to an independent solution to (2.1) with G replaced by $(-\infty, q)$. Follow this solution until it hits r, then switch to an independent solution of (2.1) with $G = (r, \infty)$, and so forth. For $x_0 \geq q$, start instead with the solution to (2.1) for $G = (-\infty, q)$ and continue in the same way. Notice that once this solution enters $[r, q]$, it stays there forever. Weak uniqueness is a simple consequence of the analytic characterization of this process, which is given in the next result. □

THEOREM 2.2. *Let* $G= (r, q)$ *and assume* $f(r) > 0$ *and* $f(q) < 0$.

(a) *If* $r \leq x_0 \leq q$, *the solution* X_{x_0} *to* (2.1) *is a Markov diffusion in* $[r, q]$ *whose conservative, Feller transition semigroup is generated by the operator*

$$A = (\sigma_0^2/2)\frac{d^2}{dx^2} + f(x)\frac{d}{dx} \quad \text{on the domain}$$

$$\mathcal{D}(A) = \{\psi \in C^2[r, q]; \psi''(r) = 0, \psi''(q) = 0\}.$$

(b) *For any constants* $\alpha > 0$, $\lambda > 0$, *and function* $c \in C[r, q]$,

$$Az(x) - \alpha z(x) + \sigma_0^2\lambda + c(x) = 0, \qquad z \in C^2[r, q], \tag{2.6}$$

$$z''(r) = -2\lambda, \quad z''(q) = -2\lambda \tag{2.7}$$

has the unique solution

$$z(x) = E\left[\int_0^\infty e^{-\alpha t}\left(c(X_x(t)) + \lambda\sigma_0^2\mathbf{1}_{(r,q)}(X_x(t))\right) dt\right], \quad r \leq x \leq q. \tag{2.8}$$

Proof. To prove part (a), apply Theorem 4 on page 44 of Mandl [14] to conclude that the operator A on $\mathcal{D}(A)$ generates a unique, conservative, Feller transition semigroup on $C[r, q]$. Now let X_{x_0} solve (2.1) for $r \leq x_0 \leq q$. Then an application of Itô's lemma shows that X_{x_0} solves the martingale problem for $(A, \mathcal{D}(A))$. We leave the calculation to the reader; note only that, because $\psi''(r) = \psi''(q) = 0$ for $\psi \in \mathcal{D}(A)$,

$$\frac{\sigma_0^2}{2}\mathbf{1}_{(r,q)}(X_{x_0}(t))\psi''(X_x(t)) + f(X_{x_0}(t))\psi'(X_{x_0}(t)) = A\psi(X_{x_0}(t)) \qquad \text{for all } t.$$

It follows by a general theorem—see, for example, Theorem 4.1 in Ethier and Kurtz [4]—that X_{x_0} is a Markov process generated by $(A, \mathcal{D}(A))$, as claimed. This conclusion also proves the uniqueness in law of the solution.

Next, consider part (b). If $z \in C^2[r,q]$ satisfies (2.6)–(2.7), then the representation (2.8) is derived using Itô's rule in the usual way. To show the existence of a solution to (2.6)–(2.7), apply standard o.d.e. theory, as expressed, for example, in Mandl [14, Lemma 5, p. 43] for the case $\lambda = 0$. If $\lambda \neq 0$, let u solve $Au(x) - \alpha u(x) = -c(x) + 2\lambda(x-q)f(x) - \alpha\lambda(x-q)^2$, $u''(r) = 0$, $u''(q) = 0$; then $z(x) = u(x) - \lambda(x-q)^2$ solves (2.7). □

We turn now to the case of a general open set G. We intend to construct a weak solution to (2.1) in the path space $C[0,\infty)$.

THEOREM 2.3. *Let $G \subset R$ be an open set. Equation* (2.1) *admits a weak solution X_{x_0} with the property that it passes through points of G^c in one direction.*

Proof. Let $\{(r_i, q_i);\ i \in I\}$ denote the countable collection of connected components of G; thus $G = \cup_{i \in I}(r_i, q_i)$. When I is finite, it is easy to construct a solution to (2.1). Suppose the initial point x lies in (r_j, q_j). Take a solution $X^{(j)}$ to (2.1) when G is replaced by (r_j, q_j) and follow this solution until the first time, if any, that it enters a different interval $[r_i, q_i]$. Then switch to a solution $X^{(i)}$ of (2.1), initialized at the point of entry into $[r_i, q_i]$, when G is replaced by (r_i, q_i). Continue in this manner, switching to a solution $X^{(k)}$ corresponding to (r_k, q_k) each time a new interval $[r_k, q_k]$ is entered.

The same technique works easily when G has an infinite number of components as long as only a finite number of them intersect any compact set. For general open sets, a patching method can still be used, but care must be taken when X crosses an infinite number of intervals of G in finite time. Instead, we complete the proof by using martingale problem theory and taking weak limits.

For an open set G, let $A_G = \frac{1}{2}\sigma_0^2 \mathbf{1}_G(x)\frac{d^2}{dx^2} + f(x)\frac{d}{dx}$. Let ξ be the canonical process on the space $\Omega := C([0,\infty))$ of continuous, real-valued paths, let $\mathcal{F}_t$ denote the filtration generated by ξ, and set $\mathcal{F} := \mathcal{F}_\infty$. A solution to the martingale problem for A_G and initial value x_0 (in the sense of Stroock and Varadhan [19]) is a probability measure P_{x_0} on Ω such that $P(\xi(0) = x_0) = 1$ and $\psi(\xi(t)) - \int_0^t A_G\psi(\xi(s))\,ds$ is a P_{x_0}-martingale for any $\psi \in C_0^2$, the twice continuously differentiable functions with compact support. As is well known, the existence of a solution to the martingale problem for A_G is equivalent to the existence of a weak solution to (2.1).

Without loss of generality, we may assume that the initial value x_0 lies in G^c and satisfies $f(x_0) > 0$ and $(x_0, \infty) \cap G \neq \emptyset$. Indeed, if x_0 is in the component (r_j, q_j) of G, we may follow the solution $X^{(j)}$ until it exits (r_j, q_j) and then solve (2.1) from the exit point, which is not in G. If $f(x_0) > 0$ but $(x_0, \infty) \cap G = \emptyset$, then $X(t) = \phi(t, x_0)$ solves (2.1), while if $x_0 \in G^c$ and $f(x_0) = 0$, then $X(t) \equiv x_0$ solves (2.1), so we need not treat these cases. Finally, an argument analogous to the one below handles the case $f(x_0) < 0$. For convenience, we assume also that

$$x_1 := \inf\{y \in G^c; f(y) \leq 0\} < \infty. \tag{2.9}$$

This will be removed later. Notice that $x_1 \in G^c$ and $f(x_1) \leq 0$, because G^c is closed and f is continuous. Therefore, the solution we construct will not take values beyond x_1, and hence it can be assumed that $G \subset [x_0, x_1]$. Now define $G_n = \cup\left\{(r_i, q_i)\ ;\ q_i - r_i \geq \frac{1}{n}\right\}$. Since G is contained in a bounded set by our assumptions, G_n is a finite union of disjoint open intervals. Thus for each n, there is a solution to (2.1) with G replaced by G_n, and hence a solution Q_n to the martingale problem for A_{G_n} starting from x_0. Because $f(x_0) > 0$ and $f(x_1) \leq 0$, $Q_n(x_0 \leq \xi \leq x_1$, for all $t \geq 0) = 1$ for each n. Since $\sup_{[x_0,x_1]} |f(x)| < \infty$, it is an immediate consequence of Theorem 1.4.6 in [19], for example, that the sequence $\{Q_n\}$ is tight as a family of probability measures on Ω. Let Q denote a weak limit of some subsequence $Q_{n'}$. The aim is to show that Q solves the martingale problem for A_G and initial condition x_0.

We first show that for any $\psi \in W^{2,\infty}$ such that $\mathbf{1}_G(x)\psi''(x)$ has a continuous version, the process

$$\theta_\psi(t) := \psi(\xi(t)) - \int_0^t A_G\psi(\xi(s))\,ds \quad \text{is a martingale on } (\Omega, \mathcal{F}, Q). \tag{2.10}$$

For this, it suffices to show that

$$E^Q\left[H\left(\theta_\psi(t) - \theta_\psi(s)\right)\right] = 0 \tag{2.11}$$

for any $s < t$ and for any function H on Ω which is bounded, continuous (in the topology of uniform convergence on compact time intervals), and $\mathcal{F}_s$ measurable. Because ψ has been constrained so that $A_G\psi$ is continuous, the integrand $H(\theta_\psi(t) - \theta_\psi(s))$ is a continuous function of ξ, and thus the expectation in (2.11) is equal to the limit of $E^{Q_{n'}}[H(\theta_\psi(t) - \theta_\psi(s))]$ as $n' \to \infty$. However, since Itô's rule is valid for $\psi \in W^{2,\infty}(R)$ (see Karatzas and Shreve [11, p. 219]), its application shows that

$$E^{Q_{n'}}\left[H\left(\theta_\psi(t) - \theta_\psi(s)\right)\right] = E^{Q_{n'}}\left[H\int_s^t \frac{\sigma_0^2}{2}\mathbf{1}_{G-G_n}(\xi(v))\psi''(\xi(v))\,dv\right].$$

Under the measure $Q_{n'}$, ξ solves $\xi'(t) = f(\xi(t))$ when $\xi(t) \in G - G_{n'}$. Thus, $\int_{x_0}^{x_1-\delta} \mathbf{1}_{G-G_n}(z)\frac{1}{f(z)}\,dz$ represents the total time ξ spends in $G - G_n \cap [x_o, x_1 - \delta]$. Hence

$$E\left[\left|\int_s^t \mathbf{1}_{G-G_n}(\xi(v))\psi''(\xi(v))\,dv\right|\right] \leq \|\psi''\|_\infty \int_{x_0}^{x_1-\delta} \frac{\mathbf{1}_{G-G_n}(z)}{f(z)}\,dz. \tag{2.12}$$

However, the definition of x_1 and the continuity of f imply that the quantity $\triangle := \inf\{f(x);\ x \in [x_0, x_1 - \delta] \cap G^c\} > 0$. Since f is uniformly continuous on $[x_0, x_1]$, it follows that there is an N_δ such that

$$\inf\{f(x);\ x \in [x_0, x_1 - \delta] \cap (G - G_n)\} > \triangle/2 \qquad \text{for } n \geq N_\delta,$$

because any point in $[x_0, x_1 - \delta] \cap (G - G_n)$ is within a distance of $1/n$ from G^c. Therefore

$$\lim_{n\to\infty} \int_{x_0}^{x_1-\delta} \mathbf{1}_{G-G_n}(z)\frac{1}{f(z)}\,dz = 0,$$

which shows by (2.12) that $E^{Q_{n'}}\left[H\left(\theta_\psi(t) - \theta_\psi(s)\right)\right] \to 0$ as $n' \to \infty$, thus completing the proof of (2.11).

Now let $\psi \in C_0^2$. For any positive integer m, define

$$\rho_m(z) = \begin{cases} \psi''(z), & \text{if } z \in (G \cup [x_1 - m^{-1}, x_1)])^c, \\ \psi''(z)\left(m \cdot \operatorname{dist}\left(z, G^c \cup [x_1 - m^{-1}, x_1]\right) \wedge 1\right) & \text{otherwise.} \end{cases}$$

For a point a such that support$(\psi) \subset (a, \infty)$, define $\psi_m(z) = \int_a^x \int_a^y \rho_m(z)\,dz\,dy$. From the definition, it is evident that $\mathbf{1}_G(z)\rho_m(z) = \mathbf{1}_G(z)\psi_m''(z)$ is continuous and that $\psi_m''(z) = 0$ on $[x_1 - m^{-1}, x_1]$. Thus θ_{ψ_m} is a martingale on $(\Omega, \mathcal{F}, Q)$ for every m. Moreover, $\lim_{m\to\infty} \rho_m(z) = \psi''(z)$ for all $z \neq x_1$, and the functions $\rho_m(z)$, $m \geq 1$ are uniformly bounded. It follows that ψ is the bounded pointwise limit of the sequence $\{\psi_m\}$ and $A\psi$ is the bounded pointwise limit of $\{A\psi_m\}$. Taking limits as $m \to \infty$, θ_ψ is also a martingale on $(\Omega, \mathcal{F}, Q)$, as we needed to prove.

If (2.9) fails, if G is bounded, and if x_1 is an upper bound of G, the same construction works, but now with $\delta = 0$, to produce a solution up to the hitting time of x_1. If (2.9) fails and G contains a component (r, ∞), one can first solve the problem for $A_{G-(r,\infty)}$ and then patch to the solution of $dX = f(X)\,dt + \sigma_0\,dW$ when it hits r, because the solution will stay in (r, ∞) after this hitting time. If (2.9) fails, G is unbounded, and there is a sequence of points $\{a_i\}$, $x_0 = a_0 < a_1 < \cdots$ such that $a_i \in G^c$ for every i, the martingale problem for A_G can be solved by successively patching together the solutions for $A_{G\cap[a_{i-1},a_i]}$.

Fix a $y \in G^c$ and assume that $f(y) \geq 0$. To show that paths pass through y in the positive direction only with Q-probability one, it suffices to show that

$$E^Q[\phi(\xi(t) - y)\phi(y - \xi(s_1))\phi(y - \xi(s_2))] = 0$$

for any bounded, continuous function ϕ which is strictly positive on $(0, \infty)$ and 0 on $(-\infty, 0]$ and for any times $0 \leq s_1 < t < s_2$. But by construction, the set of paths that pass through y in one direction only has Q_n-probability one. Hence $E^{Q_n}[\phi(\xi(t) - y)\phi(y - \xi(s_1))\phi(y - s_2)] = 0$ for each n. Taking limits along a subsequence of Q_n converging weakly to Q gives the result. This has been done for a single $y \in G^c$. However, by taking a countable dense subset of G^c, it is true with probability one for all $y \in G^c$. □

3. The HJB equation for the value function. In this section, we discuss the HJB equation for the value function of the control problem (1.1)–(1.3). The results stated here are used in sections 4 and 5.

First, it is necessary to give a rigorous definition of an admissible control. An admissible control consists of a probability space $(\Omega, \mathcal{F}, P)$ endowed with a right continuous, complete filtration, $\{\mathcal{F}_t\}$, an $\{\mathcal{F}_t\}$-Wiener process W, and an $\{\mathcal{F}_t\}$-progressively measurable process u satisfying the constraint (1.3), where σ_0 is a fixed constant. The class of admissible controls is denoted by $\mathcal{U}$. We shall abuse terminology slightly by speaking of an admissible control u, without explicit mention of the underlying space or Brownian motion, and with the understanding that different spaces and Brownian motions may be attached to different u. A function $\alpha : [0, \infty) \times R \to [0, \sigma_0]$ is called an *admissible feedback control from* x if the equation

$$dX_x(t) = b(X(t))\,dt + \alpha(t, X_x(t))\,dW, \qquad X_x(0) = x,$$

admits a weak solution. In this case, $u(t) = \alpha(t, X_x(t))$ is an admissible control.

We assume without further mention that b is at least locally Lipschitz and satisfies (2.3). Additional hypotheses will be placed on b in the theorem statements. However, these minimal assumptions imply that, given any admissible control, (1.1) admits a unique, continuous, $\{\mathcal{F}_t\}_{t\geq 0}$-adapted solution $X_x^u(t)$, $t \geq 0$, for all $x \in R$; see Theorem 5.1 and problem 1 in Chapter 5 of Friedman [6]. This fact makes our definition of admissible control the same as that in Lions [13].

The value function for the control problem is $V(x) := \inf_{u\in\mathcal{U}} J(x, u)$, where $J(x, u)$ is defined in (1.2). The formal HJB equation for V is

$$\inf_{u\in[0,\sigma_0]} \frac{u^2}{2}\left(V''(x) + 2\lambda\right) + b(x)V'(x) - \alpha V(x) + c(x) = 0. \tag{3.1}$$

The rigorous interpretation of this equation requires specifying the appropriate class of functions to which the solution belongs. This issue was resolved by Krylov [12] for control problems with possibly degenerate diffusion coefficients; he showed in some generality that the value function is a solution in the Sobolev space $W^{2,p}$ for all $p \geq 1$ to its HJB equation. Lions [13] improved the regularity to $W^{2,\infty}$. In this theory, the value function satisfies the HJB equation for (Lebesgue) almost everywhere (a.e.) x. We apply Lions's theorem to (3.1) in Theorem 3.2.

The first result, Theorem 3.1, restates (3.1) in a convenient form, presents a verification theorem for suitably regular solutions, and derives an optimal control from this solution. Theorem 3.2 states the converse, namely that the value function is indeed a solution of (3.1). These two results are stated separately here because we wish to distinguish them when used in the subsequent analysis; many of the results in sections 4 and 5 are proved by direct construction and application of the verification theorem, which is elementary, while Theorem 3.2 requires a sophisticated theoretical result; see [13]. Theorem 3.3 elaborates on how C^1 and C^2 smooth fit conditions help determine V. The final lemmas establish some general qualitative facts about the optimal control.

THEOREM 3.1. *Assume that b is C^2 and that c is a bounded C^2 function. Suppose $\bar{V} \in L^\infty \cap C^1$ is piecewise C^2 and is a solution of*

$$\frac{\sigma_0^2}{2}\mathbf{1}_G(x)\left(\bar{V}''(x)+2\lambda\right)+b(x)\bar{V}'(x)-\alpha\bar{V}(x)+c(x)=0 \qquad \textit{for all } x, \tag{3.2}$$

and

$$\bar{V}''(x) \geq -2\lambda \qquad \textit{a.e. on } G^c, \tag{3.3}$$

where G is the open set $\{x\,;\, b(x)\bar{V}'(x)-\alpha\bar{V}(x)+c(x)>0\}$. Then $\bar{V}=V$ and the solution X_x^* of

$$X_x^*(t)=x+\int_0^t b(X_x^*(s))\,ds+\sigma_0\int_0^t \mathbf{1}_G(X_x^*(s))\,dW(s), \tag{3.4}$$

using the feedback control $u(t)=\sigma_0\mathbf{1}_G(X_x^*(s))$, is the optimal process.

Remark 3.1. On each bounded, connected component (r_i,q_i) of G, $\bar{V}$ is a C^4 solution of

$$\frac{\sigma_0^2}{2}\left(\bar{V}''(x)+2\lambda\right)+b(x)\bar{V}'(x)-\alpha\bar{V}(x)+c(x)=0, \quad r_i<x<q_i, \tag{3.5}$$

$$\bar{V}''(r_i+)=-2\lambda, \qquad \bar{V}''(q_i-)=-2\lambda. \tag{3.6}$$

This is an easy consequence of the assumption that $\bar{V} \in C^1$ and that $b \in C^2$ and $c \in C^2$.

Remark 3.2. The general theory (see Theorem 3.2) states that V solves the HJB equation in the sense that (3.1) holds for a.e. x. However, $V \in W^{2,\infty}_{\text{loc}}$ implies that $V \in C^1$ and V' is absolutely continuous, and once this is known it is not hard to show that V must satisfy (3.2) everywhere. The proof is omitted.

Proof of Theorem 3.1. The proof follows the usual method for verification lemmas. Because V is piecewise C^2, one can still apply Itô's lemma to $V(X_x^u(t))$; see [11, p. 209]. Let u be an admissible control such that $u(s) \geq \delta > 0$ for all s and some positive δ, and recall that $J(x,u)$ is its corresponding cost function. Then, if A is any set of zero Lebesgue measure, $E\left[\int_0^\infty \mathbf{1}_A(X_x^u(t))\,dt\right]=0$. (This is a consequence of the existence of a local time process $\{\Lambda_t(a)\,;\, t \geq 0, a \in R\}$ for X_x^u and the identity $\int_0^t g(X_x^u(s))u^2(s)\,ds = 2\int_{-\infty}^{\infty} g(a)\Lambda_t(a)\,da$, a.s. for bounded, measurable g; see [11, p. 218].) Then, by (3.3),

$$\inf_{u\in[0,\sigma_0]} \frac{u^2}{2}\left(\bar{V}''(X_x^u(t)) + 2\lambda\right) = \frac{\sigma_0^2}{2}\mathbf{1}_G(X_x^u(t))\left(\bar{V}''(X_x^u(t)) + 2\lambda\right) \quad \text{for a.e. } t.$$

Now apply Itô's lemma to $\bar{V}(X_x^u(t))e^{-\alpha t}$, use (3.2), take expectations, and let $t \to \infty$ in the usual way to conclude that $\bar{V}(x) \leq J(x,u)$.

If u is a given control, let $u_n(t) = n^{-1}\mathbf{1}_{\{u(t)\leq 1/n\}} + u(t)\mathbf{1}_{\{u(t)>1/n\}}$. Then $E[\int_0^T (u_n(t) - u(t))^2\,dt] \to 0$ as $n \to \infty$. From this, one can deduce by standard methods that $E[\sup_{[0,T]}|X_x^u(t) - X_x^{u_n}(t)|^2] \to 0$ as $n \to \infty$ for every $T > 0$. As a consequence, $J(x,u) = \lim_{n\to\infty} J(x,u_n) \geq \bar{V}(x)$. Since u was an arbitrary admissible control, $V(x) \geq \bar{V}(x)$.

Using Itô's rule and (3.2), one finds easily that

$$\bar{V}(x) = E\left[\int_0^\infty e^{-\alpha t}\left[c(X_x^*(t)) + \lambda\sigma_0^2\mathbf{1}_G(X_x^*(t))\right]\,dt\right],$$

and thus X_x^* is an optimal process, and $\bar{V} = V$. □

The next result states that the value function must indeed be a sufficiently regular solution of the HJB equation (3.1). It is a minor extension of a result of Lions [13] for multidimensional, degenerate control. Lions's theorem allows the drift b and the cost c to have linear growth. For the purposes of sections 4 and 5, we wish instead to assume

(B.1) $b \in C^3$, $xb(x) < 0$ for all $x \neq 0$, and b is decreasing,
(C.1) $c \in C_b^2$.

(C_b^2 is the set of C^2 functions whose derivatives of order 0 to 2 are bounded functions.) In condition (B.1), b may admit more than linear growth, but since (B.1) implies (2.3), the solutions to (1.1) have infinite lifetimes and bounded moments. One could relax assumption (B.1), but it allows a simple proof of the regularity of V.

Theorem 3.2. *Assume* (B.1) *and* (C.1). *Then the value function V is in $W^{1,\infty} \cap W_{loc}^{2,\infty}$ and is the unique such function solving*

$$\inf_{u\in[0,\sigma_0]} \frac{u^2}{2}\left(V''(x) + 2\lambda\right) + b(x)V'(x) - \alpha V(x) + c(x) = 0 \quad \textit{for a.e. } x. \tag{3.7}$$

Proof of Theorem 3.2. The uniqueness claim is proved in Theorem 3.1 because it is shown that if V does solve (3.7), it must be the value function.

For a given drift b, let V_b denote the associated value function. To prove that V_b is the solution of (3.7), we start with the case that $b \in C_b^2$. Without additional assumptions on b, Lions [13] establishes a general, multidimensional result which implies Theorem 3.2 for any $\alpha > \alpha_0$, where α_0 is a constant such that $J(x,u) \in W^{2,\infty}$ for any admissible control. To prove the theorem for $b \in C_b^2$ we need to show that $\alpha_0 = 0$ if (B.1) holds. This requires showing $J(\cdot,u) \in W^{2,\infty}$ for any $\alpha > 0$. To this end, let u be a fixed admissible control. First, elementary estimates show that

$$||V_b(x)||_\infty \leq \|J(x,u)\|_\infty \leq \frac{1}{\alpha}(\|c\|_\infty + \lambda\sigma_0^2).$$

Next, following a computation similar to [13], we observe that the solution $X_x^u(t)$ to (1.1) has a version which is a.s. $C^{0,2}([0,\infty)\times R)$ as a function of t and x. Furthermore, the first and second partial derivatives satisfy

$$\partial_x X_x^u(t) = 1 + \int_0^t b'(X_x^u(s))\partial_x X_x^u(s)\,ds, \tag{3.8}$$

$$\partial_x^2 X_x^u(t) = \int_0^t b''(X_x^u(s))(\partial_x X_x^u(s))^2 + b'(X_x^u(s))\partial_x^2 X_x^u(s)\,ds. \tag{3.9}$$

Since (B.1) requires b to be decreasing, $b' \le 0$, and thus (3.8) implies $\partial_x X_x^u(t) \le 1$ for all t a.s. Using (B.1), the assumption that b is decreasing, and the boundedness of b'', there is a constant K such that $E[\partial_x^2 X_x^u(t)] \le Kt$. In view of these estimates, it is easy to prove that $J(x,u)$ is twice continuously differentiable for any $\alpha > 0$. For example, $\partial_x J(x,u) = E\left[\int_0^\infty e^{-\alpha t} c'(X_x^u(t))\partial_x X_x^u(t)\,dt\right]$, from which follows

$$\|\partial_x J(\cdot,u)\|_\infty \le \frac{\|c'\|_\infty}{\alpha}. \tag{3.10}$$

Similarly,

$$\partial_x^2 J(x,u) = E\left[\int_0^\infty e^{-\alpha t}\left(c'(X_x^u(t))\partial_x^2 X_x^u(t) + c''(X_x^u(t))(\partial_x X_x^u(t))^2\right)\,dt\right],$$

from which follows the estimate

$$|\partial_x^2 J(x,u)| \le \alpha^{-1}\|c''\|_\infty + K\alpha^{-2}\|c'\|_\infty.$$

Thus $\alpha_0 = 0$ and Theorem 3.2 is valid when $b \in C_b^2$. In addition, from (3.10), as in Lions [13],

$$\|V_b'\|_\infty \le \frac{\|c'\|_\infty}{\alpha}. \tag{3.11}$$

Now let b satisfy only (B.1). For each positive integer n, choose a $b_n \in C_b^2$ such that b_n also satisfies (B.1) and agrees with b on $[-n,n]$. Let $J_n(x,u)$ and $V_n(x)$ be the cost and optimal value functions when the drift is b_n, and let $J_b(x,u)$ and $V_b(x)$ be the corresponding functions for drift b. Let $G_n = \{x\ ;\ b_n(x)V_n'(x) - \alpha V_n(x) + c(x) > 0\}$. Then we know from Theorems 3.1 and 3.2 for $b \in C^2$ (see Remark 3.2) that $\mathbf{1}_{G_n}(x)$ is the optimal feedback control, and that V_n solves the HJB equation with b replaced by b_n. We show that for every compact $K \subset R$, there is an N such that $V_b(x) = V_n(x)$ on K for all $n \ge N$. Theorem 3.2 for b then follows easily.

The following facts will be used:

(a) For any admissible control u and any x, $J(x,u) = \lim_{n\to\infty} J_n(x,u)$.

(b) There is a positive constant M (independent of n) such that any interval of length M contains a point z_n in G_n^c for every n.

We first complete the proof assuming these facts. Let $n > M$, where M is as in (b). Then for each $m \ge n$ and $x \in [-n+M, n-M]$, let $X_{x,m}^*$ be the optimal process when the drift coefficient is b_m. The corresponding optimal control is given by $u_m^*(t) = \mathbf{1}_{G_m}(X_{x,m}^*(t))$. From (b) the set G_m^c has nonempty intersections with $[-n,-n+M]$ and $[n-M,n]$, and therefore, by Theorem 2.3, the process $X_{x,m}^*(t)$ stays in the set $[-n,n]$ for all time. But on the set $[-n,n]$, $b_m \equiv b_n \equiv b$, $u_m^*(t) = \mathbf{1}_{G_m\cap[-n,n]}(X_{x,m}^*(t))$ and u_m^* is an admissible control for b_n as well as b. Therefore

$V_m(x) \geq V_n(x)$ and $V_m(x) \geq V_b(x)$ for x in $[-n+M, n-M]$. Similarly, u_n^* is admissible for b_m and $V_n(x) \geq V_m(x)$ on $[-n+M, n-M]$. Consequently, for all $m \geq n$, $V_m(x) = V_n(x) \geq V_b(x)$ for all x in $[-n+M, n-M]$. However, from (a), $J_b(x,u) = \lim_{n\to\infty} J_n(x,u) \geq \limsup_{n\to\infty} V_n(x)$. Thus, taking an infimum over admissible u gives $V_b(x) \geq \limsup_{n\to\infty} V_n(x)$. In conclusion, $V_b(x) = V_m(x)$ for all $m \geq n$ and x in $[-n+M, n-M]$.

It remains to prove (a) and (b). Fact (a) is a straightforward consequence of the following: for any x, admissible control u, and $T > 0$, $\lim_{n\to\infty} P(\tau_n \leq T) = 0$, where τ_n is the first time that X_x^u exits $[-n, n]$.

To prove fact (b), let $b \in C_b^2$ and let (r, q) be any connected component of G_b, where G_b is as in Theorem 3.1. Because $V_b''(x) < -2\lambda$ on G_b, $V_b(q) - V_b(r) \leq V_b'(r)(q-r) - \lambda(q-r)^2$. Since $|V_b'(r)(q-r)| \leq (\lambda/4)(q-r)^2 + |V_b'(r)|^2/\lambda$, it follows, using (3.11), that

$$\frac{3}{4}\lambda(q-r)^2 \leq V_b(r) - V_b(q) + |V_b'(r)|^2/\lambda \leq \frac{2}{\alpha}(\|c\|_\infty + \lambda\sigma_0^2) + \frac{\|c'\|_\infty^2}{\alpha^2\lambda}.$$

Thus the length of any component of G is bounded by a constant independent of b, and this establishes (b). □

Although the value function V is a C^1 function, as shown by Theorems 3.1 and 3.2, it is not in general C^2; the second derivative may have jumps at boundary points of G. However, the fact that V is C^1 and satisfies (3.2) determines how the second derivative jumps at boundary points of G. In particular, the next theorem will show that C^2 smooth fit must hold at an endpoint of a component of G if the drift points into G at that endpoint. As above, $G = \cup_{i\in I}(r_i, q_i)$ is the decomposition of G into its connected components.

THEOREM 3.3. *Assume $b \in C^2$ satisfies $xb(x) < 0$ for all $x \neq 0$, let $c \in C_b^2$, and suppose that $\bar{V}$ and G are as in Theorem* 3.1. *For each $i \in I$ such that $q_i > 0$, $\bar{V}'$ is differentiable at q_i and $\bar{V}'''(q_i-) = 0$. For each $i \in I$ such that $r_i < 0$, $\bar{V}'$ is differentiable at r_i and $\bar{V}'''(r_i+) = 0$.*

Remark 3.3. The assumption that $xb(x) < 0$ is made for convenience only. The extension to more general b follows from the same arguments.

Proof. Recall that $\bar{V}$ satisfies (3.5) on (r_i, q_i) and $\bar{V}''(r_i+) = \bar{V}''(q_i-) = -2\lambda$. Suppose that q_i is an isolated point of G^c, and, equivalently, that $q_i = r_j$ for some j. Then $\bar{V}''(q_i-) = -2\lambda = \bar{V}''(q_i+)$, and so $\bar{V}''$ is defined and continuous at q_i. Since $\bar{V}$ satisfies (3.5) on both sides of q_i, it is actually a solution of (3.5) in a neighborhood of q_i, and hence, because of the smoothness of b and c, $\bar{V}$ is C^4 in a neighborhood of q_i. Since $\bar{V}''$ has a local maximum at q_i, it follows that $\bar{V}'''(q_i) = 0$.

Suppose now $q_i > 0$, so that $b(q_i) < 0$. We need some preliminary observations. If $x \in G^c$ is not an isolated point of G^c, and if $\bar{V}'$ is differentiable at x, then

$$(b'(x) - \alpha)\,\bar{V}'(x) + c'(x) = -b(x)\bar{V}''(x), \tag{3.12}$$

because on G^c, $b\bar{V}' - \alpha\bar{V} + c = 0$.

Suppose q_i is not an isolated point of G^c. Observe first that $\bar{V}'''(q_i-) \geq 0$, because $\bar{V}'' < -2\lambda$ on (r_i, q_i) and $\bar{V}''(q_i-) = -2\lambda$. By differentiation of (3.5) and then evaluation at q_i-,

$$(b'(q_i) - \alpha)\,\bar{V}'(q_i) + c'(q_i) = b(q_i)2\lambda - \frac{\sigma_0^2}{2}\bar{V}'''(q_i-) \leq b(q_i)2\lambda. \tag{3.13}$$

By comparing (3.12) to (3.13), it is clear that if $\bar{V}'$ is differentiable at q_i, then $\bar{V}'''(q_i-) = 0$.

Let η be a version of the distributional second derivative $\bar{V}''$, which, because $\bar{V} \in W^{2,\infty}_{\text{loc}}$, is a locally bounded function. To prove that $\bar{V}'$ is differentiable at q_i it suffices to show that there is a set A of zero Lebesgue measure such that

$$\lim_{x_n \downarrow q_i, x_n \notin A} \eta(x_n) = -2\lambda. \tag{3.14}$$

Let A consist of those points x at which either $\bar{V}'$ is not differentiable, $\bar{V}''$ and η are not equal, x is an isolated point of G^c or $x \in G^c$, but $\bar{V}''(x) < -2\lambda$. Since $\bar{V}'$ is absolutely continuous, it is differentiable a.e., and its derivative coincides a.e. with η. Also we know $\bar{V}''(x) \geq -2\lambda$ a.e. on G^c, and isolated points of G are in the countable set $\{r_i, q_i\,;\, i \in I\}$. Thus A has measure zero. Now, because $b(q_i) < 0$,

$$-b(q_i)2\lambda \geq \lim_{x_n \downarrow q_i, x_n \in G^c \cap A^c} b(x_n)\eta(x_n) = -(b'(q_i) - \alpha)\bar{V}'(q_i) - c(q_i) \geq -b(q_i)2\lambda,$$

where we have used (3.12) and the continuity of $(b' - \alpha)\bar{V}' - c$, and the last inequality comes from (3.13). Thus $\lim_{x_n \downarrow q_i, x_n \in G^c \cap A^c} \eta(x_n) = -2\lambda$. On the other hand, if $x_n \in G$, $\bar{V}''(x_n) = \frac{2}{\sigma_0^2}\left[-b(x_n)\bar{V}'(x_n) + \alpha\bar{V}(x_n) - c(x_n) + \sigma_0^2\lambda\right]$, and, since the right-hand side is continuous and equal to $\bar{V}''(q_i-) = -2\lambda$ at q_i, $\lim_{x_n \downarrow q_i, x_n \in G \cap A^c} \bar{V}''(x_n) = -2\lambda$ also. Thus, we have shown (3.14). □

Remark 3.4. Suppose $0 < r_i < q_i$ for some component (r_i, q_i) of G. The value function V is determined on (r_i, q_i) by the differential equation (3.5) and the values of $V(r_i)$ and $V'(r_i)$. The values of $V(r_i)$ and $V'(r_i)$ are constrained first by the requirement that $r_i \in G^c$, which implies $b(r_i)V'(r_i) - \alpha V(r_i) + c(r_i) = 0$. The smooth fit condition of V' at q_i imposes a second rigid constraint; $V(r_i)$ and $V'(r_i)$ must be so related that V''' equals 0 at the first q after r at which $V''(q) = -2\lambda$. This fact is very useful in understanding how to piece together a solution of the HJB equation. In fact, the third derivative condition is sufficient as well as necessary for a C^2 smooth fit. We state this explicitly for later use. Suppose that $q \neq 0$. Let S be a function on a neighborhood of $(q - \delta, q + \delta)$ satisfying

$$\begin{aligned} &\tfrac{\sigma_0^2}{2}(S'' + 2\lambda) + bS' - \alpha S + c = 0 \quad &&\text{for } x \in (q-\delta, q) \text{ (resp., } x \in (q, q+\delta)),\\ &bS' - \alpha S + c = 0 &&\text{for } x \in (q, q+\delta) \text{ (resp., } x \in (q-\delta, q)). \end{aligned} \tag{3.15}$$

Assume that S is C^1 on $(q - \delta, q + \delta)$ and that S'' is continuous except possibly at q. Then

$$S'' \text{ is continuous at } q \text{ iff } S'''(q-) = 0 \text{ (resp., } S'''(q+) = 0). \tag{3.16}$$

Indeed, by differentiating (3.15) on both sides of q and using the continuity of S and S',

$$\begin{aligned} &b(q)[S''(q-) - S''(q+)] = -\tfrac{\sigma_0^2}{2}S'''(q-)\\ &\Big(\text{resp., } \; b(q)[S''(q+) - S''(q-)] = -\tfrac{\sigma_0^2}{2}S'''(q+)\Big). \end{aligned} \tag{3.17}$$

Hence (3.16) follows.

In the sections that follow, the cost function c will be even and decreasing on $(0, \infty)$ in addition to belonging to C_b^2, and b will be odd. Here are some general facts concerning V and G under these assumptions.

LEMMA 3.4. *Assume that c is a bounded, even function decreasing on* $(0, \infty)$. *Assume that b is an odd function satisfying* (B.1). *Then V is even and decreasing on* $(0, \infty)$.

Proof. Let u be an admissible control. Suppose $0 < y < z$. Let X_y and X_z be the solutions to (1.1) using the same control u, and define $\tau = \inf\{t > 0\,;\, X_y = -X_z\}$. The difference $Z = X_z - X_y$ satisfies $\dot{Z} = b(X_z) - b(X_y)$ and hence remains nonnegative for all time. Thus, using the evenness and unimodality of c, $c(X_z) \leq c(X_y)$ if $t \leq \tau$. Define a new process $\tilde{X}_z(t) = X_z(t)$ if $t \leq \tau$ and $\tilde{X}_z(t) = -X_y(t)$ if $t > \tau$. Then, using the oddness of b, $\tilde{X}_z$ solves (1.1) with Brownian motion $\tilde{W}(t) := W(t)\mathbf{1}_{\{t\leq\tau\}} + (W(\tau) - (W(t) - W(\tau)))\,\mathbf{1}_{\{t>\tau\}}$ and the same control u. To emphasize that the Brownian motion is a different one in $\tilde{X}_z$ than in X_y, let us denote the control for $\tilde{X}_z$ by $\tilde{u}$. Clearly $c(\tilde{X}_z(t)) \leq c(X_y(t))$ for all t. Hence $J(z, \tilde{u}) \leq J(y, u)$. As this construction is valid for any admissible u, it follows that $V(z) \leq V(y)$. □

LEMMA 3.5. *Let b be an odd function satisfying* (B.1).

(a) *If $c \in C_b^2$ is even and positive, and if G contains a connected component of the form $(-a, a)$, then $a < \sqrt{c(0)/\lambda\alpha}$.*

(b) *If $c \in C_b^2$ is even, positive, and decreasing on $(0, \infty)$, and if $G = \cup_i(r_i, q_i)$ is the decomposition of G into disjoint connected components, then $\sum_i (q_i - r_i)^2 < 4c(0)/\lambda\alpha$.*

Proof. V is even, positive, and C^1. Thus $V'(0) = 0$. Clearly $V(0) \leq c(0)/\alpha$, since if zero control is applied starting from $x = 0$, the solution of (1.1) remains at 0, and then $J(0, 0) = c(0)/\alpha$. Because $V'' < -2\lambda$ on $(-a, a)$,

$$0 < V(a) = V(0) + \int_0^a \int_0^y V''(z)\,dz\,dy < \frac{c(0)}{\alpha} - \lambda a^2.$$

The inequality $a^2 < c(0)/\lambda\alpha$ is immediate.

Lemma 3.4 implies that V decreases on $(0, \infty)$. If (r, q) is a connected component of $(0, \infty) \cap G$, it follows that $V' \leq 0$ and $V'' < -2\lambda$ on (r, q). Hence $V(q) - V(r) < -\lambda(q - r)^2$. Thus if $q_i > 0$,

$$0 \leq V(q_i) \leq V(0) + \sum_{j, 0\leq q_j \leq q_i} V(q_j) - V(r_j \vee 0) < \frac{c(0)}{\alpha} - \lambda \sum_{j, 0\leq q_j\leq q_i} (q_j - (r_j \vee 0))^2.$$

Combining this with a similar inequality for negative q_i and letting $|q_i| \to \sup_j |q_j|$ gives the result. □

4. Linear drift.

In this section we consider the stochastic control problem (1.1)–(1.3) when the drift is a linear function $b(x) = -\theta x$, with $\theta > 0$. Thus b satisfies (B.1) and there is a unique equilibrium point at $x = 0$ for (1.1) when $u \equiv 0$. The class of admissible controls is defined precisely at the beginning of section 3. For convenience, we set $\lambda = 1$; all results can be restated for a general λ by rescaling the cost c.

The work of this section was motivated by a conjecture that the optimal control will be a single-region feedback control of the form $u(t) = \mathbf{1}_{(-a,a)}(X(t))$, if the cost c satisfies (C.1) and the following additional hypotheses.

(C.2) c is even.

(C.3) c is continuous, positive, and decreasing on $(0, \infty)$.

We discovered instead that the location of regions of positive control action is determined by the behavior of the function

$$\hat{c}(x) := c''(x) + 2(2\theta + \alpha), \tag{4.1}$$

and hence by convexity properties of c. We know from section 3 that the optimal feedback control has the form $\mathbf{1}_G(x)$, where G is open. The main point of this section is that the number and location of the components of G are constrained by the set $\{x; \hat{c}(x) < 0\}$. Theorem 4.1 shows that positivity of $\hat{c}$ implies optimality of $u \equiv 0$. Theorem 4.2 establishes a sufficient condition for the optimality of single-region feedback controls in terms of $\hat{c}$. Lemma 4.5 shows in general how the number of components of G can be bounded using the number of component intervals of the set $\{\hat{c} < 0\}$. Theorem 4.7 provides a class of examples for which c satisfies (C.1), (C.2), and (C.3), but for which the optimal control is *not* of single-region form, contradicting the original conjecture. In Theorem 4.2, an interesting connection is made between the optimal control problem (1.1)–(1.3) and an optimal stopping problem.

THEOREM 4.1. *Assume that $c \in C^2$, and, for some positive K and m, $|c(x)| \leq K(1+|x|^m)$. If $\hat{c}(x) \geq 0$ for all x, then the control $u \equiv 0$ is optimal, and $Z^*(t) = xe^{-\theta t}$ is the optimal process.*

Remark 4.1. A particular case occurs when $c''(x) \geq 0$ for all x, so that c is convex. In fact, if c is convex, whether it is differentiable or not, $u \equiv 0$ is optimal. Indeed, for any admissible control $E[X_x^u(t)] = Z^*(t)$, and so, for convex c, $E[c(X_x^u(t))] \geq c(Z^*(t))$ by Jensen's inequality for any $t \geq 0$. Hence Z^* is optimal.

Proof of Theorem 4.1. When $u \equiv 0$, $X_x^u(t) = Z^*(t) = xe^{-\theta t}$, and the corresponding payoff is $Q(x) = \int_0^\infty e^{-\alpha t} c(xe^{-\theta t})\, dt$. The following properties are immediate.

(a) Q is a C^2 function, and $|Q(x)| \leq \tilde{K}(1+|x|^m)$ for some $\tilde{K} < \infty$.

(b) $\theta x Q'(x) + \alpha Q(x) = c(x)$.

Moreover, nonnegativity of $\hat{c}$ implies $Q''(x) \geq -2$ for all x. Thus Q is a C^2 solution to the HJB equation (3.1). Next, one can apply Itô's lemma together with standard verification-theorem arguments from stochastic control [5, pp. 145–146] to verify that Q is the value function. This proves Theorem 4.1. □

The next theorem discusses optimality of single-region feedback controls. For its statement, it is useful to define $\tilde{V}_a$ to be the solution to

$$\text{(4.2)} \qquad \begin{cases} \frac{\sigma_0^2}{2}(\tilde{V}_a''(x) + 2) - \theta x \tilde{V}_a'(x) - \alpha \tilde{V}_a(x) + c(x) = 0, \\ \tilde{V}_a''(-a) = \tilde{V}_a''(a) = -2. \end{cases}$$

THEOREM 4.2. *Assume* (C.1)–(C.2). *Suppose that there exists an open interval $(-\ell, \ell)$ such that*

$$\text{(4.3)} \qquad \{x; \hat{c}(x) < 0\} = (-\ell, \ell).$$

Let

$$\text{(4.4)} \qquad a^* = \sup\left\{a\,;\, \tilde{V}_a''(x) < -2 \textit{ for } -a < x < a\right\}.$$

Then $a^* > \ell$ and the solution to $Z_x^*(t) = x - \int_0^t \theta Z_x^*(s)\, ds + \int_0^t \sigma_0 \mathbf{1}_{(-a^*,a^*)}(Z_x^*(s))\, dW(s)$ is an optimal process for the control problem (1.1)–(1.2) *for every x.*

Examples. (a) Let $c(x) = (1+x^2)^{-1}$. Note that c also satisfies (C.3). If $(2\theta+\alpha) \geq 1$, then $\hat{c}(x) \geq 0$ for all x and $u \equiv 0$ is optimal. If $2\theta + \alpha < 1$, then there is an $\ell > 0$ so that (4.3) holds, and hence it will be optimal to turn on the diffusion in an interval about 0.

(b) More generally, (4.3) will hold for a function c satisfying (C.1)–(C.2) if c admits only one positive inflection point z and c'' is increasing on $(0, z)$.

We first prove Theorem 4.2 by direct construction of a solution V^* to (3.2) and (3.3) with $G = (-a^*, a^*)$, where G is defined as in Theorem 3.1. Later, we give an alternate derivation using developments based on Theorem 3.2.

To present the construction of V^*, it is convenient and interesting to convert the original problem of minimizing $J(x,u)$ to an optimal stopping problem. Given a Brownian motion W on any probability space, let Y_x denote the Ornstein–Uhlenbeck process solving

$$Y_x(t) = x - \int_0^t \theta Y_x(s)\,ds + \sigma_0 W(t). \tag{4.5}$$

Let

$$U(x) = \inf_\tau E\left[\int_0^\tau e^{-(2\theta+\alpha)t}\hat{c}(Y_x(t))\,dt\right], \tag{4.6}$$

where the infimum is taken over all $\{\mathcal{F}_t^W\}$ stopping times, $\{\mathcal{F}_t^W\}$ being the filtration generated by W, and $\hat{c}$ is given by (4.1). It will turn out that U is related to the optimal value function V by $U(x) = (V''(x)+2)\mathbf{1}_{\{V''(x)+2<0\}}$. The connection between value functions of optimal control and optimal stopping problems is a common theme of stochastic control. For example, see [9] and [10] and references therein.

Consider next a particular class of stopping times for the optimal stopping problem. For $a \geq |x|$, define

$$\tau_a^x := \inf\{t \geq 0\,;\, |Y_x(t)| \geq a\}. \tag{4.7}$$

If $|x| > a$, set $\tau_a^x = 0$. For any a, τ_a^x is finite a.s. since Y_x satisfies (4.5). Define the function U_a on $[-a,a]$ by

$$U_a(x) = E\left[\int_0^{\tau_a^x} e^{-(2\theta+\alpha)t}\hat{c}(Y_x(t))\,dt\right], \quad |x| \leq a. \tag{4.8}$$

Then U_a satisfies the differential equation

$$\left.\begin{array}{c} \frac{\sigma_0^2}{2}U_a'' - \theta x U_a' - (2\theta+\alpha)U_a + \hat{c} = 0 \;\text{ for } |x| < a, \\ U_a(-a) = U_a(a) = 0. \end{array}\right\} \tag{4.9}$$

For each positive a, U_a can be extended to R so that it satisfies the differential equation everywhere, and henceforth we represent this extension by U_a. Notice that each U_a is an even function, because $\hat{c}$ is even and the boundary conditions are symmetrical. Thus $U_a'(0) = 0$.

The next result contains the technical work necessary for constructing an optimal policy for the stopping problem.

LEMMA 4.3. *Assume* (C.1) and (C.2). *Then*

(a) *There exists a point $a^* > \ell$ such that U_{a^*}, the solution of* (4.9) *for $a = a^*$, also satisfies*

$$U_{a^*}'(a^*) = U_{a^*}'(-a^*) = 0. \tag{4.10}$$

(b) *The point $a^* > 0$, and hence the solution U_{a^*} satisfying* (4.10)*, are unique. Also, if $A := \{a > 0\,;\, U_a(x) < 0, \quad x \text{ in } (-a,a)\}$, then A is nonempty and $a^* = \sup A$.*

Proof. We indicate the idea of the proof and omit elementary details.

Let ℓ be given by (4.5); then $\ell \in A$ and $U'(\ell) > 0$. This follows from the boundary point lemma [17]. Consider the solution ϕ to the homogeneous equation

$$\frac{\sigma_0^2}{2}\phi'' - \theta x\phi' - (2\theta+\alpha)\phi = 0, \qquad \phi(0) = 1, \;\; \phi'(0) = 0. \tag{4.11}$$

Then ϕ is a nonnegative, even function. Also, $U(x)$ defined in (4.6) satisfies

$$U(x) \geq \frac{\inf_y \hat{c}(y)}{2\theta + \alpha}. \tag{4.12}$$

In particular, $U_a(x)$ also satisfies (4.12) for $|x| \leq a$, for each $a \in A$. For each $t > 0$, we consider $U_\ell(x) - t\phi(x)$, which solves (4.9). Introduce the set $T := \{t > 0\,;\, \exists a > \ell,\ U_\ell(a) - t\phi(a) = 0\}$. Then T is nonempty since $U_\ell'(\ell) > 0$, and (4.12) implies that T is bounded. Let $t^* := \sup T$, and introduce $a^* = \inf\{a > 0\,;\, U_\ell(a) - t^*\phi(a) = 0\}$. Then $a^* \in A$ and elementary arguments show that $A = (0, a^*]$, $U_{a^*}(a^*) = 0$, $U_{a^*}'(a^*) = 0$, and $U(x) < 0$ for $a^* > x \geq 0$. Hence, a^* satisfies the conditions in the lemma. Since $A = (0, a^*]$, uniqueness of a^* also follows. □

Lemma 4.3 allows us to solve the optimal stopping problem and calculate U.

Theorem 4.4. *Assume* (C.1) *and* (C.2). *Let a^* be defined as in Lemma* 4.3, *and τ_a^x as in* (4.7). *Then $\tau_{a^*}^x$ is the optimal stopping policy for the problem* (4.5)–(4.6) *and*

$$U(x) = \begin{cases} U_{a^*}(x) & \text{if } |x| \leq a^*, \\ 0 & \text{if } |x| > a^*. \end{cases}$$

Proof. Let $U^*(x) = U_{a^*}(x)\mathbf{1}_{[-a^*,a^*]}(x)$. Certainly, $U^*(x) \geq U(x)$, so we need only to verify the opposite inequality. By Lemma 4.3, U^* is a C^1 function and the second derivative of U^* is continuous everywhere except at $\pm a^*$. But we may apply Itô's rule to $U^*(Y_x(t))e^{-(2\theta+\alpha)t}$ (see [11, p. 219]) and use (4.9) to verify that $U^*(x) \leq U(x)$. □

Proof of Theorem 4.2. We will show that Theorem 4.2 holds when a^* is defined as in Lemma 4.3. For this a^*, let Z_x^* be the process defined in the statement of Theorem 4.2. The existence of Z_x^* and its uniqueness in law are treated in Theorem 2.2. Let V^* be the payoff from Z^*;

$$V^*(x) = E\left[\int_0^\infty e^{-\alpha t}\left(c(Z_x^*(t)) + \sigma_0^2 \mathbf{1}_{(-a^*,a^*)}(Z_x^*(t))\right) dt\right]. \tag{4.13}$$

We intend to employ Theorem 3.1. Observe that V^* satisfies (3.2) for all $x \neq \pm a^*$, with $G = (-a^*, a^*)$ and $\lambda = 1$. This follows from Theorem 2.2 and the fact that $Z_x^*(t)$ is the solution of the deterministic equation $\dot{x} = b(x)$, as long as it remains in $(-\infty, -a^*) \cup (a^*, \infty)$. In particular, Theorem 2.2 shows that

$$(V^*)''(-a^*+) = (V^*)''(a^*-) = -2. \tag{4.14}$$

Now let $\hat{U} := (V^*)'' + 2$. By differentiating the differential equation for V^* on $(-a^*, a^*)$ and using the boundary conditions (4.14), it follows that $\hat{U}$ satisfies (4.9) on $(-a^*, a^*)$. Thus, $(V^*)''(x) + 2 = U_{a^*}(x)$ on $(-a^*, a^*)$, and since $a^* \in A$, by Lemma 4.3, $(V^*)''(x) + 2 < 0$ on $(-a^*, a^*)$. By Lemma 4.3, it follows that, $(V^*)'''(-a^*+) = (V^*)'''(a^*-) = U_{a^*}'(\pm a^*) = 0$. Hence, condition (3.16) applies, implying that V^* is a C^2 function. Direct differentiation and the continuity of $(V^*)''$ imply

$$\theta x \hat{U}' + (2\theta + \alpha)\hat{U} = \hat{c} \quad \text{for } x > a^*, \quad \hat{U}(a^*) = (V^*)''(a^*) + 2 = 0. \tag{4.15}$$

By directly solving this equation and using the fact that $\hat{c} > 0$ on (a^*, ∞), $(V^*)'' + 2 = \hat{U} > 0$ on (a^*, ∞). By symmetry, $(V^*)'' + 2 > 0$ for $|x| > a^*$. Hence all the conditions of Theorem 3.1 are fulfilled, which completes the proof. □

The proof of Theorem 4.2 relied on direct construction and an application of the verification lemma of Theorem 3.1 We now invoke Theorem 3.2 to show that the characterization of a^* in Theorem 4.2 and the relation of the set $\{\hat{c} < 0\}$ to $(-a^*, a^*)$ reflects deeper and more general facts about the optimal value function. Let $G := \{x\,;\, -\theta x V'(x) - \alpha V(x) + c(x) > 0\}$ as in Theorem 3.1. General bounds on the size of the components of G are presented in Lemmas 3.4 and 3.5. The following result bounds the number of connected components of G. Note that it implies that G consists of at most one interval, symmetric about zero, under the assumptions of Theorem 4.2.

LEMMA 4.5. *Let c satisfy* (C.1) *and* (C.2), *and suppose the open set $\{x\,;\,\hat{c}(x) < 0\}$ has N connected components. Then G contains at most $N+1$ connected components. If G contains a connected component of the form $(-\delta, \delta)$, then G has at most N connected components.*

Proof. We intend to show that

(a) each connected component of G intersects with a connected component of the set $\{x\,;\,\hat{c}(x) < 0\}$, and that

(b) each connected component of $\{x\,;\,\hat{c}(x) < 0\}$ intersects with at most one connected component of G.

The proof of the lemma is an easy consequence of these facts.

Let (r, q) be a connected component of G with $q > 0$. Then V is a C^4 solution of (3.5) and (3.6) on (r, q) by Theorems 3.1 and 3.2. Let $U := V'' + 2$. Then $U < 0$ on (r, q) and there is an x_0 in (r, q) such that $U(x_0) = \min_{(r,q)} U$. By differentiating (3.5) twice and applying (3.6), U is a solution of

$$\left.\begin{array}{r} \frac{\sigma_0^2}{2}U'' - \theta x U' - (2\theta + \alpha)U + \hat{c} = 0 \quad \text{for } x \in (r, q), \\ U(r) = U(q) = 0. \end{array}\right\} \tag{4.16}$$

From (4.16), it follows that $\hat{c}(x_0) < 0$. This proves (a). Also, $\hat{c}(q)$ cannot be negative by (4.16) and the boundary point lemma. If (a_1, a_2) is a connected component of $(0, \infty) \cap \{\hat{c} < 0\}$ such that $(a_1, a_2) \cap (r, q) \neq \emptyset$, then $q \notin (a_1, a_2)$, and (b) follows.

If G contains zero, then the above argument shows that G contains at most N connected components. □

The next result shows that the characterization of a^* in Theorem 4.2 defines the limits of the connected component of G containing 0, in the general case.

THEOREM 4.6. *Let c satisfy* (C.1) *and* (C.2), *and define a^* by* (4.6) *and the set A as in Lemma* 4.3. *Assume that A is nonempty. Then $(-a^*, a^*)$ is one of the connected components of G.*

Proof. Let $a \in A$ and let $\tilde{V}_a$ be the payoff function associated with the feedback control $\mathbf{1}_{(-a,a)}(X(t))$. By Theorem 2.2, $\tilde{V}_a(x)$ solves (4.2). Because $\tilde{V}_a$ is even, $\tilde{V}_a'(0) = 0$, and by definition of A, $\tilde{V}_a'' + 2 < 0$ on $(-a, a)$. Hence, evaluation of (4.2) at 0 gives

$$\alpha V(0) \leq \alpha V_a(0) = c(0) + \sigma_O^2(V_a''(0) + 2) < c(0).$$

Since $V'(0) = 0$ and V is even, it follows that $0 \in G$. Thus there is a connected component $(-\bar{a}, \bar{a})$ of G. Consequently, by (4.2) and Theorem 3.1, we deduce $V(x) = V_{\bar{a}}(x)$ for $|x| \leq \bar{a}$. Therefore $\bar{a} \in A$ and $\bar{a} \leq a^*$. To show $a^* \leq \bar{a}$, let $a \in A$. If $x \in [-a, a]$ and if u is an admissible control that keeps the process X_x^u in $[-a, a]$ for all time, then a verification-lemma-type argument shows that $\tilde{V}_a(x) \leq J(x, u)$ for $|x| \leq a$. In particular, $\tilde{V}_{a_2}(x) \leq \tilde{V}_{a_1}(x)$ for all x in $[-a_1, a_1]$ whenever $0 < a_1 < a_2$ and a_1 and a_2 belong to A. If u^* denotes the optimal feedback control $\mathbf{1}_G(X(t))$ and

$(-\bar{a}, \bar{a})$ is the connected component of G containing 0, $V(x) = V_{\bar{a}}(x)$ for $|x| \leq \bar{a}$. Thus, if $\bar{a} \leq a$ and $a \in A$, then $\tilde{V}_a(x) = V(x)$ for $|x| \leq a$, and it follows that $a = \bar{a}$. In summary, $a \in A$ and $\bar{a} \leq a$ imply $\bar{a} = a$. Consequently, $\bar{a} \geq \sup A = a^*$, which completes the proof. □

Remark 4.2. Lemma 4.5 and Theorem 4.6 together show that if $\{\hat{c} < 0\}$ is an interval $(-\ell, \ell)$ and A is nonempty, then $G = (-a^*, a^*)$ with $a^* > 0$. Using the simple proof of the nonemptiness of A derived above in Lemma 4.3 yields an alternative proof of Theorem 4.2.

In the rest of this section, we consider cost functions c which satisfy (C.1), (C.2), and (C.3), and positive constants θ and α such that the set $\{x\,;\,\hat{c}(x) < 0\}$ is the union of three disjoint intervals. Under the additional assumption (C.4), (C.5), and (C.6) listed below, it will be shown that the optimal strategy is bang-bang and consists of multiple switchings of the control. This is rather technical but the intuition is simple. Since c satisfies (C.3), it is decreasing on $(0, \infty)$. Now suppose that at some very large value of x_0, c suddenly decreases to a fraction of the value $c(x_0)$ in a short interval beyond x_0. If the state process starts above x_0 and no control is exercised, it decreases, passing quickly through x_0 into a region of much higher cost. However, using positive diffusion control in a region near or above x_0 will delay arrival at x_0 and, despite the control cost, this might be worthwhile.

Because of Theorem 4.3, the value function is C^2 in a problem with a single-region optimal control. For multiple-region optimal controls, such as those constructed here, C^2 smoothness will fail at some of the switching points. See Remark 4.3 below.

Here are the precise hypotheses placed on c, θ, and α, in addition to (C.1)–(C.3).

(C.4) $\{x\,;\,\hat{c}(x) < 0\} = (-\delta_0, \delta_0) \cup (\delta_1, \delta_2) I_2 \cup (-\delta_2, -\delta_1)$, where $0 < \delta_0 < \delta_1 < \delta_2$.

(C.5) There exists a z_0, with $\sqrt{c(0)/\alpha} \leq \delta_0 < z_0 < \delta_1$, such that $\int_{\delta_0}^{x} \hat{c}(u)\,du > 0$ if $\delta_0 < x < z_0$.

(C.6) $\int_{\delta_0}^{\delta_2} u^{1+\alpha/\theta} \hat{c}(u)\,du < 0$.

Assumptions (C.4)–(C.6) guarantee the multiple switching of the optimal control.

Example. The idea is to start with a function c satisfying the assumptions of Theorem 4.2 and then to modify it far away from 0 by a sudden dip. The location and width of the dip are controlled by defining a "dip" function ρ and scaling it appropriately. Choose a function ρ such that (a) ρ is C^∞, decreasing, and odd; (b) $\rho(x) = 1$ if $x \leq -1$, and $\rho(x) = -1$ if $x \geq 1$; (c) $\rho''(x) \leq 0$ if $x < 0$, and $\rho''(x) \geq 0$ if $x \geq 0$; and (d) ρ'' admits a single local maximum and a single local minimum. Notice that $\rho''(x) = 0$ at $x = 0$ and for $|x| \geq 1$. Condition (d) on ρ is imposed so that if $\max_{[0,1]} \rho'' = -\min_{[-1,0]} \rho'' = k > 0$, then $\{\rho'' < 0\}$ is an interval (s_1, s_2) with $-1 < s_1 < s_2 < 0$. For $\epsilon > 0$ define scaled versions ρ_ϵ of ρ by $\rho_\epsilon(x) := \rho(x/\epsilon)$. Assume that $\gamma := 2\theta + \alpha < 1$. Fix an $R > \sqrt{c(0)/\alpha}$, and let c_ϵ be an even, nonnegative, C^3 function which satisfies

$$\begin{array}{ll} c_\epsilon(x) = 1 - x^2 & \text{if } |x| \leq 1/2, \\ c_\epsilon(x) = 1/2 & \text{if } 1 \leq |x| \leq R, \\ c_\epsilon(x) = 1/4 + (1/4)\rho_\epsilon\left(|x| - (R{+}\epsilon)\right) & \text{if } |x| > R. \end{array}$$

Assume also that c_ϵ is decreasing on $(0, \infty)$ and that $c \vee (1/2)$ satisfies the condition (4.3) of Theorem 4.2. Then $(-R, R) \cap \{\hat{c} < 0\}$ is a single interval of the form $(-\delta_0, \delta_0)$ contained in $(-1, 1)$. Clearly, (C.5) is satisfied for this construction.

We shall show that ϵ may be chosen to satisfy (C.4) and (C.6) as well. Observe that $c''(x) = \epsilon^{-2}\rho((x - R - \epsilon)/\epsilon)$ when $x > R$. Therefore, when $\max_{[0,1]} \rho'' > \epsilon^2 2\gamma$, it follows from the shape of ρ'' that $(R, \infty) \cap \{\hat{c} < 0\} = (\delta_1(\epsilon), \delta_2(\epsilon))$, where $R < \delta_1(\epsilon) <$

$\delta_2(\epsilon) < R + \epsilon$. In fact $(\delta_i - R - \epsilon)/\epsilon = z_i(\epsilon)$, where $z_1(\epsilon)$ and $z_2(\epsilon)$ are the solutions of $\rho''(x) = -2\epsilon^2\gamma$. This verifies (C.4). It is easy to see that $z_1(\epsilon) \downarrow -1$ and $z_2(\epsilon) \uparrow 0$ as $\epsilon \downarrow 0$. A calculation and using change of variables shows that

$$\int_{\delta_0}^{\delta_2} u^{1+\alpha/\theta}\hat{c}(u)\,du \le K + \epsilon^{-1}\int_{z_1(\epsilon)}^{z_2(\epsilon)} \rho''(u)(R+\epsilon(u+1))^{1+\alpha/\theta}\,du,$$

where K is a positive constant independent of ϵ. Therefore, since ρ'' is negative on $(-1,0)$, the last integral can be made as negative as desired by choosing ϵ small enough. Hence (C.6) will be satisfied for small enough ϵ.

THEOREM 4.7. *Assume* (C.1)–(C.6). *Then there exist* $0 < a_0^* < a_1^* < a_2^*$ *such that the optimal control is determined by the feedback function* $\sigma_0\mathbf{1}_G(x)$, *where*

$$G := (-a_2^*, -a_1^*) \cup (-a_0^*, a_0^*) \cup (a_1^*, a_2^*).$$

Moreover, $\delta_0 < a_0^* < z_0$ *and* $a_1^* < \delta_2 < a_2^*$, *where* δ_0, z_0, *and* δ_2 *are as defined in* (C.4)–(C.6).

Proof. Let $a_0^* = \sup A$, where A is defined as in Theorem 4.2. Then we know from Theorem 4.6 that $(-a_0^*, a_0^*)$ is a connected component of G. By Lemma 3.5 and the proof of Lemma 4.5, we know that $\delta_0 < a_0^* < z_0$. Suppose that G contains no more components. Then on $|x| > a_0^*$, V satisfies (3.7) and hence $U = V'' + 2$ satisfies (4.15). The solution of (4.15) is

$$U(x) = \frac{1}{\theta}\frac{1}{(a_0^*)^{2+\alpha/\theta}}\int_{a_0}^{x} u^{1+\alpha/\theta}\hat{c}(u)\,du.$$

However, this becomes negative by (C.6) in some interval about δ_2. Since $U(x) \ge 0$ a.e. on G^c, we obtain a contradiction to the assumption that $(-a_0^*, a_0^*)$ is the single component of G. Therefore G must contain at least two other components, symmetrically placed about 0. By Lemma 4.5 it can contain no more components. By the proof of Lemma 4.5, the additional positive component (a_1^*, a_2^*) must intersect (δ_1, δ_2), and it must be true that $\delta_2 < a_2^*$. □

Remark 4.3. In this example, the value function V is an even function which is C^2 everywhere except at $\pm a_1^*$. At $x = a_1$, $(\sigma_0^2/2)V'''(a_1^*+) + \theta a_1^*(V''(a_1^*-) + 2) = 0$. This condition can be easily verified by differentiating (3.2) near a_1^* and using the continuity of V'.

5. Nonlinear drift.

In this section we consider problem (1.1)–(1.3) when the drift b is nonlinear. In the treatment of linear drift, the function $\hat{c}$ defined in (4.1) played a crucial role. The generalization of this function, which we continue to denote by $\hat{c}$, is

$$\hat{c}(x) = c''(x) + 2\left(\alpha - 2b'(x)\right), \tag{5.1}$$

and this coincides with $\hat{c}$ defined in (4.1) when the drift is linear. The nonlinearity of b will make itself felt through a second auxiliary function g_c defined as

$$g_c(x) = \hat{c}(x) + \frac{b''(x)\left(c'(x) - 2b(x)\right)}{\alpha - b'(x)}. \tag{5.2}$$

The first result is a generalization of Theorem 4.1. It is proved in the same way, and so the proof is omitted.

THEOREM 5.1. *Assume that $b \in C^2$ is decreasing and $xb(x) < 0$ if $x \neq 0$. Assume that $c \in C^2$ and there exist constants K and m such that $0 \leq c(x) \leq K(1 + |x|^m)$ for all x. If*

$$g_c(x) \geq 0 \qquad \text{for all } x,$$

then $u \equiv 0$ is the optimal control for problem (1.1)–(1.3).

For the rest of the section it is a standard assumption that c satisfies (C.1)–(C.3), b satisfies (B.1), and

$$\text{(B.2)} \qquad b \text{ is odd.}$$

Again, by adding a constant to c, we may and do make the harmless assumptions that c is nonnegative and, in fact, $\lim_{|x|\to\infty} c(x) = 0$. Also, without loss of generality, $\lambda = 1$.

For each $a > 0$, let V_a denote the cost from the control strategy defined by $u(t) = \sigma_0 \mathbf{1}_{(-a,a)}(X_x(t))$. Then by Theorem 2.2, on $(-a,a)$, the function V_a satisfies

$$\text{(5.3)} \quad \frac{\sigma_0^2}{2}\left(V_a'' + 2\right) + b(x)V_a' - \alpha V_a + c(x) = 0, \quad V''(-a+) = -2, \ V''(a-) = -2,$$

and for $|x| > a$, $b(x)V_a'(x) - \alpha V_a(x) + c(x) = 0$. Hence V_a solves (3.2) with $G = (-a,a)$ for $x \neq \pm a$, but it does not in general satisfy (3.3). Our next concern is to find conditions under which a single-region control is optimal. In this section we take a direct approach. We verify directly that V_a is a solution to (3.2)–(3.3) for a suitable choice of a when b and c satisfy certain conditions; then application of Theorem 3.1 proves optimality of the single-region control.

Define the set A exactly as in section 4: $A := \{a > 0\,;\, V_a'' + 2 < 0 \text{ on } (-a,a)\}$.

LEMMA 5.2. *Assume that A is nonempty. Let $a \in A$ and assume that*

$$\text{(5.4)} \qquad V_a'''(a-) = 0 \qquad \text{and} \qquad V_a''(x) + 2 > 0 \qquad \text{for } |x| > a.$$

Then V_a is a C^2 solution to (3.2)–(3.3) *and $\sigma_0 \mathbf{1}_{(-a,a)}(x)$ defines an optimal feedback control.*

Proof. The argument is very similar to the proof of Theorem 4.2. It was shown in (5.3) that V_a satisfies (3.2) with $G = (-a,a)$ for all $x \neq \pm a$. Condition (5.4) asserts both that (3.3) is satisfied and that V_a is a C^2 function (see Remark 3.4 in section 3). Hence, Theorem 3.2 can be applied. □

To establish when the conditions of 5.2 are true, define again $W_a = V_a'' + 2$. This function is not necessarily defined at $\pm a$, but it will have limits from the left and right at these points. By differentiating (5.3) twice, we find

$$\text{(5.5)} \qquad LW_a = -g_c(x), \qquad W_a(-a+) = W_a(a-) = 0,$$

where L is the differential operator

$$L = \frac{\sigma_0^2}{2}\frac{d^2}{dx^2} + \left(b(x) + \frac{\sigma_0^2 b''(x)}{2(\alpha - b'(x))}\right)\frac{d}{dx} - \left[(\alpha - 2b'(x)) - \frac{b(x)b''(x)}{\alpha - b'(x)}\right].$$

On $|x| > a$, a similar derivation shows

$$\text{(5.6)} \qquad b(x)W_a' - \left(\alpha - 2b'(x) - \frac{b(x)b''(x)}{\alpha - b'(x)}\right)W_a = -g_c(x).$$

The following facts are needed. First, for any $a > 0$, any continuous function g, and any constant η,

$$\begin{cases} \frac{\sigma_0^2}{2}(Z'' + 2) + b(x)Z' - \alpha Z + g(x) = 0 \;\; \text{for } x \in (-a, a), \\ Z''(-a) = Z''(a) = \eta \end{cases} \tag{5.7}$$

has a unique solution. This is an immediate consequence of part (b) of Theorem 2.2. Second, $V_a''(x)$ is continuous in a for $|x| < a$. This can be deduced from elementary o.d.e. arguments. The next lemma generalizes the characterization of a^* in section 4.

LEMMA 5.3. (a) *Assume that* $\hat{c}(0) < 0$*. Then the set* A *is nonempty.*

(b) *Assume that* A *is nonempty. Then* A *is a closed, bounded set. If* $a^* = \sup A$*, then* $V_{a^*}'''(a^*-) = 0$.

Proof. Observe that $g_c(0) = \hat{c}(0) < 0$ by assumption. We pick ϵ small enough so that $g_c(x) < 0$ on $(-\epsilon, \epsilon)$ and $\alpha - 2b'(x) > b(x)b''(x)/(\alpha - b'(x))$ for all x in $(-\epsilon, \epsilon)$. Now we pick any a such that $0 < a < \epsilon$. Then $W_a(\pm a) = 0$ and from (5.5) we have $LW_a > 0$ on $(-a, a)$. Thus, $W_a < 0$ on $(-a, a)$ by applying the maximum principle to (5.5). Hence $a \in A$.

Consider now part (b). To show A is bounded we follow the proof of Lemma 3.5.

To show that $a^* \in A$, first let $a_1 < a_2$, where both $a_1, a_2 \in A$. Then, since W_{a_1} and W_{a_2} both solve the same differential equation in (5.5) on $[-a_1, a_1]$, it follows that $V_{a_2}''(x) < V_{a_1}''(x)$ on $[-a_1, a_1]$. Now let $a_n \to a^*$, where all the a_n are in A. Then if $|x| < a^*$, $V_{a^*}''(x) = \lim_{n\to\infty} V_{a_n}''(x) < -2$, where we have used the continuity in a noted above. Thus $a^* \in A$.

Since $a^* \in A$, $V_{a^*}'''(a^*-) \geq 0$. We show that if $a \in A$ and $V_a'''(a) > 0$, then $a < a^*$. This will complete the proof of part (b). Let $\tilde{V}_a$ denote the function which satisfies (5.3) for all x and coincides with V_a on $[-a, a]$. If we assume that $V_a'''(a-) > 0$, then $V_a''(x) > -2$ in an interval $(a, a + \epsilon)$ for some positive ϵ. Consider V_{a_1} for some $a < a_1 < a + \epsilon$. Then $V_{a_1}''(a_1) = -2 < \tilde{V}_a(a_1)$. By uniqueness of solutions to (5.7), it then follows that $V_{a_1}''(x) < \tilde{V}_a''(x)$ for all x. In particular $V_{a_1}''(x) < -2$ on $[-a, a]$. Let $a_2 = \inf\{x\,;\, V_{a_1}''(x) \geq -2\}$. Then $a_1 \geq a_2 > a$ and $a_2 \in A$ because V_{a_1} and V_{a_2} will coincide on $[-a_2, a_2]$. Thus $a < a^*$, as claimed. □

According to Lemma 5.2, V_{a^*} is the optimal value function if the second condition in (5.4) holds. This requires further conditions on b and c. We state and prove two theorems in this vein. Define the conditions: for some $\delta_0 > 0$ and some $x_0 > 0$,

(H.1) $\{\hat{c} < 0\} = (-\delta_0, \delta_0)$ and $\hat{c}$ increases on $[0, \delta_0]$,

(H.2) $c'(x) \geq 2b(x)$ for $x \geq x_0$,

(H.3) $b'''(x) < 0$ on $[0, \delta_0]$ and $b''(x) \leq 0$ on $[0, x_0]$, and

(H.4) g_c has exactly one zero in $[0, \delta_0]$.

Remark 5.1. The assumption (H.2) is not very restrictive when b is negative and decreasing on $(0, \infty)$, since, typically, $\lim_{|x|\to\infty} c'(x) = 0$.

In regard to (H.4), observe that (H.1) implies $g_c(0) = \hat{c}(0) < 0$. If we assume $c'(x) - 2b'(x)$ is negative on $[0, \delta_0]$, it follows from (H.1) and (H.3) that $g_c(\delta_0) > 0$, and hence g_c has at least one zero on $(0, \delta_0)$.

THEOREM 5.4. *Assume* (H.1)–(H.4) *in addition to* (B.1)–(B.2) *and* (C.1)–(C.3). *Then* A *is nonempty,* V_{a^*} *is the optimal value function, and* $u(x) = \sigma_0 \mathbf{1}_{(-a^*, a^*)}(x)$ *is an optimal feedback control.*

The proof is established through several lemmas. Using the assumptions (C.1) and (C.2) and applying the maximum principle [17], one can easily show that for each $a > 0$, $V_a'(x) \leq 0$ for all $x > 0$. This will be used in the following proofs.

Lemma 5.5. *Assume* (H.1), (H.2), *and* (H.3) *as well as* (B.1)–(B.2) *and* (C.1)–(C.3). *Then*

(a) $W_{a^*}(x) \geq 0$ *on* $[x_0, \infty)$ *where* x_0 *is defined in* (H.2),

(b) A *is nonempty and* $a^* = \sup A \leq x_0$, *and*

(c) $V'''_{a^*}(x) \geq 0$ *on* $[0, a^*)$.

Proof. On $|x| > a$, differentiate the equality $b(x)V'_a(x) - \alpha V_a(x) + c(x) = 0$ to derive

$$b(x)W_{a^*}(x) = (\alpha - b'(x))V'_{a^*}(x) - (c'(x) - 2b(x)), \qquad |x| > a. \tag{5.8}$$

Since $V'_a(x) \leq 0$ for $x \geq 0$, and, by (B.2), $b(x) < 0$ for $x > 0$, and, by (H.2), $c'(x) - 2b(x) \geq 0$ for $|x| \geq x_0$, conclusion (a) follows. The assumption $\hat{c}(0) < 0$ in (H.1) implies that A is nonempty, as in Lemma 5.3. Also, $W_{a^*}(x) < 0$ for $|x| < a^*$, and hence $a^* \leq x_0$. The proof of part (c) follows from the maximum principle applied to $LW'_{a^*} = -[\hat{c}' + 3b''W_{a^*} + b'''V_{a^*}]$ in $[0, a^*)$ and $W'_{a^*}(0) = W'_{a^*}(a^*-) = 0$. □

The final lemma finishes the proof of Theorem 5.4 by verifying (5.4).

Lemma 5.6. *Let the assumptions of Theorem* 5.4 *hold. Then* $V''_{a^*} + 2 \geq 0$ *on* $[a^*, \infty)$.

Proof. Because of the previous lemma, it suffices to show that $W_{a^*} \geq 0$ on $[a^*, x_0]$. Introduce ξ in $[a^*, x_0]$ by $W_{a^*}(\xi) = \min_{[a^*, x_0]} W_{a^*}(x)$. Assume that $W_{a^*}(\xi) < 0$. Then $a^* < \xi < x_0$ since $W_{a^*}(x_0) \geq W_{a^*}(a^*) = 0$. By differentiation of (5.8),

$$bW'_{a^*} - (\alpha - 2b')\,W_{a^*} = -\hat{c} - b''V'_{a^*} \qquad \text{for } |x| > a^*. \tag{5.9}$$

Evaluating at $x = \xi$ implies $\hat{c}(\xi) + b''(\xi)V'_{a^*}(\xi) < 0$. But since $V'_{a^*} \leq 0$ on $(0, \infty)$ and $b''(x) \leq 0$ on $[0, x_0]$, we must have $\hat{c}(\xi) < 0$, and therefore $a^* < \xi < x_0 \leq \delta_0$. However, this is not possible. By (H.4), g_c has exactly one zero in $[0, \delta_0]$, and $g_c(0) = \hat{c}(0) < 0$, $g_c(a^*) \geq 0$. Therefore, $g_c > 0$ on $(a^*, x_0]$. For all $x > a$, W_{a^*} satisfies (5.6) and $W_{a^*}(a^*) = 0$. Also, $b(x) < 0$ for $x > 0$, and hence (5.6) implies that $W_{a^*} > 0$ on $(a^*, \delta_0]$. This contradicts $W_{a^*}(\xi) < 0$ for $a^* < \xi < \delta_0$. Hence $W_{a^*} \geq 0$ on $[a^*, x_0]$. □

In the next theorem, we show optimality of one-region control under hypotheses that require $b'' \geq 0$ on $(0, x_0)$, rather than (H.3).

Theorem 5.7. *Assume that* (B.1), (B.2), (C.1)–(C.3), *and* (H.2) *hold and that* $\hat{c}(0) < 0$. *Assume also that* $b''' \geq 0$, $b'' \geq c'''/6$, *and* $b'' > 0$ *on* $(0, x_0)$, *where* x_0 *is as in* (H.2). *Then the conclusions of Theorem* 5.4 *hold.*

Proof. Because we assume $\hat{c}(0) < 0$, we know that A is nonempty, and we conclude from Lemma 5.1 and the smooth fit condition (3.16) that V_{a^*} is a bounded, C^2 function. Thus, we need only to verify $W_{a^*} \geq 0$ on (a^*, ∞). Using (H.2), we can follow the proof of Lemma 5.5 to conclude that $W_{a^*} \geq 0$ on $[x_0, \infty)$. Hence it remains to show that W_{a^*} is nonnegative on $[a^*, x_0]$. By differentiating (5.9) on the interval (a^*, x_0) once more, we obtain

$$-bW''_{a^*} + (\alpha - 3b')\,W'_{a^*} - 3b''W_{a^*} = c''' - 6b'' + b'''V'_{a^*}. \tag{5.10}$$

We also know $W_{a^*}(a^*) = 0$, and $W_{a^*}(x_0) \geq 0$. The maximum principle applied to (5.10) on the interval $[a^*, x_0]$, using the assumptions placed on b'' and b''', implies that W_{a^*} cannot admit a strictly negative minimum in (a^*, x_0). This completes the proof. □

6. Conclusion. We have derived some explicit characterizations of the optimal control and optimal value functions in scalar problems with possibly degenerate variance control in which the variance is used to keep the diffusion away from regions of high running cost.

Throughout our analysis the discount rate α and the control cost multiplier λ were fixed. It is interesting to ask how the solutions behave as either $\lambda \to \infty$ or $\alpha \to 0$, with appropriate scaling of the cost. When $\alpha \to 0$ and the cost is scaled by α, one expects a limit which corresponds to an average cost control problem. The paper of Assaf [1] treats an example of average cost minimization using unbounded variance control directly.

FEEDBACK STABILIZATION AND LYAPUNOV FUNCTIONS[*]

F. H. CLARKE[†], YU. S. LEDYAEV[‡], L. RIFFORD[†], AND R. J. STERN[§]

Abstract. Given a locally defined, nondifferentiable but Lipschitz Lyapunov function, we employ it in order to construct a (discontinuous) feedback law which stabilizes the underlying system to any given tolerance. A converse result shows that suitable Lyapunov functions of this type exist under mild assumptions. We also establish that the feedback in question possesses a robustness property relative to measurement error, despite the fact that it may not be continuous.

Key words. asymptotic stabilizability, discontinuous feedback law, system sampling, locally Lipschitz Lyapunov function, nonsmooth analysis, robustness

1. Introduction.

Consider a standard control system of the form

$$\dot{x}(t) = f(x(t), u(t)) \quad \text{almost everywhere (a.e.)}, \qquad u(t) \in \mathcal{U}, \tag{1.1}$$

and let V be a smooth Lyapunov function for the system; thus we have

$$V(x) \geq 0, \qquad V(x) = 0 \text{ iff } x = 0, \qquad V(x) \to \infty \text{ as } \|x\| \to \infty$$

and (for some function W) the infinitesimal decrease condition

$$\min_{u \in \mathcal{U}} \langle \nabla V(x), f(x,u) \rangle \leq -W(x) < 0, \qquad x \neq 0. \tag{1.2}$$

It is well known (but true) that the existence of such a "control-Lyapunov function" (V, W) (a framework introduced by Eduardo Sontag) implies (open-loop) asymptotic controllability to the origin: for every $\alpha \in \mathbb{R}^n$, there is a control $u(t)$ such that the solution $x(\cdot)$ of (1.1) with initial condition $x(0) = \alpha$ satisfies $x(t) \to 0$ as $t \to \infty$. (In addition, convergence to 0 takes place in a certain uniform and stable manner that we will not dwell upon here.) A related and important goal in many situations is to produce a state feedback $k(\cdot) : \mathbb{R}^n \to \mathcal{U}$ which stabilizes the system, i.e., such that the system $\dot{x} = f(x, k(x))$ is globally asymptotically stable. This article explores the question of how to define such a feedback law through the use of a given Lyapunov function V.

The ideal case, a well-known heuristic useful for motivational purposes, is the one in which we can find a continuous function $k(x)$ that selects a value of $u \in \mathcal{U}$ attaining

(or almost) the minimum in (1.2):

$$\langle \nabla V(x), f(x, k(x))\rangle \le -W(x) \quad \forall x \neq 0.$$

Then any solution of $\dot{x} = f(x, k(x))$ is such that

$$\frac{d}{dt} V(x(t)) = \langle \nabla V(x(t)), \dot{x}(t)\rangle \le -W(x(t)) < 0,$$

a monotonicity conclusion that, together with the growth property of V, assures that $x(t) \to 0$ as $t \to \infty$.

There are two fundamental difficulties with this ideal picture, and both concern regularity issues. The first is that a differentiable Lyapunov function may not exist, and the second is that even when a smooth V exists, the continuous selection $k(\cdot)$ does not generally exist. If we have recourse to a discontinuous feedback $k(\cdot)$, then the issue arises of how to interpret the discontinuous differential equation $\dot{x} = f(x, k(x))$.

The primary goal of this article is to give a general answer to the problem of defining a (discontinuous) stabilizing feedback based upon a given (nondifferentiable) Lyapunov function, one for which a nonsmooth version of infinitesimal decrease is known to hold only on a restricted set. The construction is described in section 1, while section 2 establishes the converse result that under mild conditions, a Lyapunov function of the type required in the previous section always exists. In the final section, we address the issue of robustness of the feedback with respect to measurement error and small perturbations of the dynamics, a particularly important issue when discontinuity is present. Some works and general references related to this article include [2, 3, 8, 11, 12, 13, 15, 17, 18, 20, 23, 24, 26, 27, 28, 29, 31, 32]. We proceed now to situate our results with respect to the literature.

The possible nonexistence of continuous stabilizing feedback was brought to light in the seminal work of Sontag and Sussmann [30] and of Brockett [4]. The latter developed a necessary condition for continuous stabilizability and adduced the following example, the "nonholonomic integrator":

$$\begin{cases} \dot{x}_1 &= u_1, \\ \dot{x}_2 &= u_2, \qquad\qquad (u_1, u_2) \in \bar{B} =: \mathcal{U}. \\ \dot{x}_3 &= x_1 u_2 - x_2 u_1, \end{cases}$$

This system is globally asymptotically controllable yet fails to admit a continuous stabilizing feedback (by Brockett's condition). In considering the use of discontinuous feedback laws $k(\cdot)$, one could have recourse to the Filippov solution concept [14]: x is said to be a solution of $\dot{x} = f(x, k(x)) =: g(x)$ provided that we have

$$\dot{x} \in \bigcap_{\substack{\delta > 0 \\ \mathrm{meas}(\Omega) = 0}} \mathrm{cl}\,\mathrm{co}(g([x + \delta B] \setminus \Omega)).$$

However, as shown by Ryan [25] and by Coron and Rosier [12], Brockett's condition continues to hold for this solution concept, so that the nonholonomic integrator (for example) cannot be stabilized by a discontinuous feedback in the Filippov sense.

In [6] it was shown that any globally asymptotically controllable system is stabilizable by a (possibly discontinuous) feedback if the trajectory $x(\cdot)$ associated to the feedback is defined in a natural way that involves discretizing the control law (closed-loop system sampling) in a manner similar to that used in differential games by Krasovskii and Subbotin [19]. We proceed now to describe this concept, which is the one used in this article.

Let $\pi = \{t_i\}_{i\geq 0}$ be a partition of $[0, \infty)$, by which we mean a countable, strictly increasing sequence t_i with $t_0 = 0$ such that $t_i \to \infty$ as $i \to \infty$. The diameter of π, denoted $\operatorname{diam}(\pi)$, is defined as $\sup_{i\geq 0}(t_{i+1} - t_i)$. Given an initial condition x_0, the π-trajectory $x(\cdot)$ corresponding to π and an arbitrary feedback law $k : \mathbb{R}^n \to \mathcal{U}$ are defined in a step-by-step fashion as follows. Between t_0 and t_1, x is a classical solution of the differential equation

$$\dot{x}(t) = f(x(t), k(x_0)), \qquad x(0) = x_0, \qquad t_0 \leq t \leq t_1.$$

(Of course in general we do not have uniqueness of the solution, nor is there necessarily even one solution, although nonexistence will be ruled out by the feedback constructed in section 1, which will preclude blow-up of the solution in finite time.) We then set $x_1 := x(t_1)$ and restart the system with control value $k(x_1)$:

$$\dot{x}(t) = f(x(t), k(x_1)), \qquad x(t_1) = x_1, \qquad t_1 \leq t \leq t_2,$$

and so on in this fashion. The resulting trajectory x is a physically meaningful one that corresponds to a natural sampling procedure and piecewise constant controls; the smaller $\operatorname{diam}(\pi)$, the greater the sampling rate. Since our results are couched in terms of π-trajectories, the issue of defining a solution concept for discontinuous differential equations is effectively sidestepped. Our approach will lead to precise estimates of how small the step size $\operatorname{diam}(\pi)$ must be for a prescribed stabilization tolerance to ensue, and of the resulting stabilization time, in terms of the given data.

The next major point to address concerns the nonsmoothness of the Lyapunov function V. An early and important result of Artstein [1] implies in particular that the nonholonomic integrator fails to admit a smooth V (see [7] for related results). It has been shown by Sontag [26], however, that globally asymptotically controllable systems always admit a continuous Lyapunov function V satisfying the following nonsmooth version of the infinitesimal decrease condition:

$$\inf_{u\in\mathcal{U}} DV(x; f(x,u)) \leq -W(x) < 0, \qquad x \neq 0, \tag{1.3}$$

where the lower Dini derivate DV is defined by

$$DV(x; v) := \liminf_{\substack{t\downarrow 0 \\ v'\to v}} \frac{V(x + tv') - V(x)}{t}. \tag{1.4}$$

Among the several important ways in which the theory of nonsmooth analysis intervenes in this article is that of asserting the equivalence to (1.3) of another, and for our purposes more useful, form of the infinitesimal decrease condition:

$$\inf_{u\in\mathcal{U}} \langle f(x,u), \zeta\rangle \leq -W(x) < 0 \quad \forall x \neq 0, \qquad \forall \zeta \in \partial_P V(x). \tag{1.5}$$

Here $\partial_P V(x)$ refers to the proximal subdifferential of V at x (which may very well be empty); ζ belongs to $\partial_P V(x)$ iff there exist σ and $\eta > 0$ such that

$$V(y) - V(x) + \sigma\|y - x\|^2 \geq \langle \zeta, y - x\rangle \qquad \forall y \in x + \eta B.$$

(B denotes the open unit ball, and the open ball of radius r centered at x is written as either $x + rB$ or $B(x, r)$.) The equivalence of (1.3) and (1.5) is a consequence of Subbotin's theorem, which links Dini derivates to proximal calculus (see for example [6] or [9], our principal sources for the theory of nonsmooth analysis).

The essential reason for which proximal calculus is well suited to our approach has to do with its relation to metric projection onto sets, upon which is based the "proximal aiming" method that we employ. The crux is this: when $x(t_i) = x$ lies outside a level set $S = S(c) := \{V \leq c\}$ and admits closest point (or projection) s in S, then $x - s$ is a "proximal normal" to S at s, and for some $\lambda > 0$ we have $\lambda(x - s) \in \partial_P V(s)$. Then (1.5) can be invoked at s to find a suitable value of the control u which moves the state toward S, in the sense that the Euclidean distance d_S decreases at a certain positive rate Δ:

$$d_S(x(t)) - d_S(x(t_i)) \leq -\Delta(t - t_i), \qquad t_i \leq t \leq t_{i+1},$$

provided $x(t_i)$ is close enough to S to start with and provided $\operatorname{diam}(\pi)$ is small enough. A sequence of such feedbacks is amalgamated in the first section to produce the stabilizing feedback $k(\cdot)$ that is sought.

Our approach requires the Lyapunov function V to be Lipschitz (in the zone under consideration). In the case of a system which is globally asymptotically controllable to the origin, which has received considerable attention, it is not known whether a suitable V exists that is Lipschitz near 0, but that is somewhat beside the point in the setting in which we work. Theorem 2.1 derives finite-time stabilizability, to a close approximation of some level set $S(a)$, as a consequence of the supposed existence of a Lipschitz Lyapunov function. When applied to the special case of global asymptotic controllability, this requires only a Lipschitz V defined on the complement of a small ball around the origin, and the stabilization takes place not asymptotically to the origin, but rather in finite time to a small neighborhood of it. (This has been called "practical" stabilization.) In contrast, [6] obtains asymptotic stabilizability to the origin (the case $S(a) = \{0\}$); the proof uses the Moreau–Yosida inf convolution to make a continuous Lyapunov function Lipschitz as an intermediate step. This methodology was also employed earlier [10], in a differential game setting. The direct use of a Lipschitz Lyapunov function, when it is possible, leads to a far more transparent feedback construction with direct stabilization estimates and has the important consequence of yielding robustness, as we discuss presently. The fact that under mild assumptions suitable Lipschitz Lyapunov functions do exist leading to practical stabilization to any required tolerance is proven in section 2.

Ledyaev and Sontag [22] have recently proved that there is a close relationship between the issues of "how regular a Lyapunov function does the system admit" and "how robust a stabilizing feedback does the system admit." Consider, for example, a perturbed equation $\dot{x} = f(x, k(x + p))$, where p represents a measurement error. Full robustness of the feedback k is taken to mean that for any ϵ, there is a $\delta > 0$ such that whenever the perturbation $p(t)$ satisfies $\|p(t)\| \leq \delta$ for all t, then stabilization to the ϵ-ball takes place. Then [22] asserts that the system admits a fully robust stabilizing feedback iff it admits a smooth (C^1 or C^∞) Lyapunov function. Thus the nonholonomic integrator, which *can* be stabilized by a discontinuous feedback (in view of [6]), does *not* admit a fully robust stabilizing feedback. It is possible to recover robustness, however, through the use of a dynamic feedback; see [21]. The issue of the robustness of discontinuous feedbacks with respect to measurement error seems to have been raised first by Hermes [16].

The concept of full robustness, unrelated as it is to the system sampling method that we employ, is not the one discussed in this article. Instead, we introduce a type of relative robustness in which we require the size of the measurement error to be limited as a function of the maximum step size δ of the underlying partition. This step size δ must still be small enough (for stabilization), but at the same time the individual steps must be big enough to preclude a possible chattering phenomenon, even in the presence of small errors. This consideration, which leads us to specify "reasonably uniform" sampling in section 3, appears to be new in this context. The term "reasonably uniform" is taken here to mean that the following holds:

$$\frac{\delta}{2} \leq t_{i+1} - t_i \leq \delta \quad \forall i \geq 0,$$

although it is possible to replace the factor 1/2 by any constant in $(0, 1)$.

To conclude with the nonholonomic integrator, then, it turns out that the system does admit a relatively robust stabilizing feedback to within any prescribed tolerance r, in the sense that for all initial conditions in a bounded set, we will have $\|x(t)\| \leq r$ for all $t \geq T$, whenever x is a π-trajectory, if π is a reasonably uniform partition whose diameter is sufficiently small, and whenever measurement and external error do not exceed a critical level related to the sampling rate. It is possible to exhibit a Lipschitz Lyapunov function for the system, and to make explicit the resulting feedback, as will be shown in a forthcoming article.

2. A feedback construction. For a given function $V : \mathbb{R}^n \longrightarrow (-\infty, \infty]$, we shall deal frequently with the sublevel sets $S(r)$ defined as follows:

$$S(r) := \{x \in \mathbb{R}^n : V(r) \leq r\}.$$

In addition, the following sets are considered:

$$S(a, b) := \{x \in \mathbb{R}^n : a \leq V(x) \leq b\}.$$

Let a and b be two given numbers with $a < b$. The following hypotheses are made concerning the function V and the system function f.

(H1) V is lower semicontinuous, $S(b) \neq \emptyset$, and for some $\eta > 0$, V is Lipschitz of rank L_V on $S(a, b) + \eta B$:

$$|V(x) - V(y)| \leq L_V \|x - y\| \quad \forall (x, y) \in S(a, b) + \eta B.$$

(H2) There exists $\delta_1 \in (0, b - a)$ and $\delta_2 > 0$ such that

$$S(a + \delta_1) + \delta_2 B \subset S(b).$$

(H3) $f(x, u)$ is continuous on $S(b) + \eta B$ as a function of x for each $u \in \mathcal{U}$, and there exists $m > 0$ such that

$$\|f(x, u)\| \leq m \quad \forall x \in S(b) + \eta B, \qquad \forall u \in \mathcal{U}.$$

(H4) f is Lipschitz in x of rank L_f on $S(a, b) + \eta B$:

$$\|f(x, u) - f(y, u)\| \leq L_f \|x - y\| \quad \forall (x, y) \in S(a, b) + \eta B, \qquad \forall u \in \mathcal{U}.$$

(H5) There exists $\omega > 0$ such that, for every $x \in S(a, b) + \eta B$, we have

$$\inf_{v \in \operatorname{co} f(x, \mathcal{U})} DV(x; v) \leq -\omega.$$

Remark 2.1. We do not require that f and V be defined except on $S(b)+\eta B$; the Lipschitz conditions on these functions, as well as the infinitesimal decrease condition (H5), are posited only on a neighborhood of $S(a,b)$. No hypotheses are made concerning the abstract set $\mathcal{U}$, nor on the nature of the dependence of f on the control variable. It is shown in section 2 that (H2) automatically holds when $S(b)$ is compact and V is continuous on $S(b)+\eta B$; see Lemma 2.9. The set $S(a)$ is not assumed to be nonempty a priori, but that fact is a consequence of the following theorem.

THEOREM 2.1. *For any $\gamma > 0$ sufficiently small, there exist positive numbers δ, T, and a feedback $k : S(b)+\eta B \longrightarrow \mathcal{U}$ such that whenever a partition π satisfies* $\operatorname{diam}(\pi) < \delta$, *then any π-trajectory $x(\cdot)$ having $x(0) \in S(b)+\gamma B$ satisfies*

$$x(t) \in S(b)+\gamma B \quad \forall t \geq 0,$$

$$x(t) \in S(a)+\gamma B \quad \forall t \geq T.$$

Remark 2.2. Thus we almost recover the conclusion of the "ideal case" discussed in the Introduction (with $\{0\}$ replaced by the more general $S(a)$), but in approximate terms (to tolerance γ), with a discontinuous feedback, and for a nonsmooth Lyapunov function satisfying only local hypotheses. The proof is constructive and provides explicit estimates of γ, δ, and T in terms of the given data.

Remark 2.3. Taking $W(x) = \omega$ for purposes of comparison, note that (H5) is an apparently weaker hypothesis than (1.3); in fact, each is equivalent to (1.5). Because V is Lipschitz and f continuous in x near the points in question, this in turn is equivalent to the following:

$$\inf_{u \in \mathcal{U}} \langle \zeta, f(x,u) \rangle \leq -\omega \quad \forall x \in S(a,b)+\eta B, \qquad \forall \zeta \in \partial_L V(x),$$

where $\partial_L V$ is the limiting subdifferential of V (see [9]).

Proof of Theorem 2.1. The proof of Theorem 2.1 is based upon defining a feedback control via projections. The first two lemmas below guarantee that the projections lie in the set where the hypotheses are active.

LEMMA 2.2. *Let ϵ lie in $[0, \delta_1]$ and suppose that x is a point in the set*

$$[S(a+\epsilon) + \min\{\delta_2, \eta\} B] \setminus S(a+\epsilon).$$

Then $x \in S(a,b)$, and if $s \in \operatorname{proj}(x, S(a+\epsilon))$, then $s \in S(a,b)+\eta B$.

Proof. Since we have $S(a+\delta_1)+\delta_2 B$ contained in $S(b)$ by hypothesis, it follows that x lies in $S(b)$. Since x does not belong to $S(a+\epsilon)$, we deduce $x \in S(a,b)$. Finally, we have

$$\|s-x\| < \min\{\delta_2, \eta\} \leq \eta,$$

whence $s \in S(a,b)+\eta B$. □

LEMMA 2.3. *Let $0 < \gamma < \eta/2$, and suppose that for some r' and r with $a \leq r' < r \leq b$ we have $x \in [S(r)+\gamma B] \setminus [S(r')+\gamma B]$. Then $x \in S(a,b)+\gamma B$, and if $s \in \operatorname{proj}(x, S(r))$, then $s \in S(a,b)+\eta B$.*

Proof. There exists $y \in S(r)$ having $\|y-x\| < \gamma$. Since x does not belong to $S(r')+\gamma B$, we have $V(y) > r'$ necessarily. Thus $y \in S(a,b)$ and $x \in S(a,b)+\gamma B$. Finally, we note $\|x-s\| < \gamma$, whence $\|y-s\| < 2\gamma$ and s lies in $S(a,b)+\eta B$. □

The next "solvability" result is central to our approach. The notation u_+ stands for $\max\{u, 0\}$.

LEMMA 2.4. *For any $r \in [a,b]$, for any $x \in S(a,b)$, we have*

$$d(x, S(r)) \leq \frac{m}{\omega}(V(x) - r)_+.$$

Proof. We shall invoke results (and terminology) from [9] to give a short proof of this result, whose proof from first principles would be lengthy.

We define a lower semicontinuous function $g : \mathbb{R}^n \longrightarrow [0, \infty]$ as follows:

$$g(x) := (V(x) - r)_+ + I_{S(b)}(x),$$

where $I_{S(b)}(\cdot)$ is the indicator function of the set $S(b)$. At any point x in the open set $C := \{y : g(y) > 0\}$ at which g is finite, we have $x \in S(a,b)$, and the infinitesimal decrease condition implies that

$$\inf\{Dg(x; v) : v \in \mathrm{co} f(x, \mathcal{U})\} \leq -\omega.$$

It follows from this that for any $\epsilon > 0$, for any $x \in C$, for any $\zeta \in \partial_P g(x)$, there exists $u \in \mathcal{U}$ such that

$$\langle \zeta, f(x,u) \rangle \leq -\omega + \epsilon.$$

Since $\|f(x,u)\| \leq m$ and since $\epsilon > 0$ is arbitrary, we derive $\|\zeta\| \geq \omega/m$. This verifies the hypothesis of the solvability theorem [9, Theorem 3.3.1] (with the sets labeled there as V and Ω both taken to be $\mathbb{R}^n$), whose conclusion is precisely the desired one since $S(r) = \{x : g(x) = 0\}$. We remark that an alternate proof can be based upon weak monotonicity: the infinitesimal decrease condition implies the existence of a trajectory x with $x(0) = x$ and along which $V(x(t)) + t\omega$ is decreasing (see [9, Theorem 4.5.7]), which implies the result. □

We now proceed to fix $\gamma > 0$ such that

$$\gamma < \min\left\{\delta_1, \frac{\eta}{2}, \frac{\omega}{12L_f L_V}\right\}, \tag{2.1}$$

and we define

$$\beta := \min\left\{\delta_1, \frac{(b-a)}{2}, \frac{\gamma\omega}{4m}\right\}. \tag{2.2}$$

Let N be the first integer such that

$$b - N\beta > a \geq b - (N+1)\beta.$$

Note that $N \geq 1$ since $\beta < b - a$. We proceed to define certain sets $\Omega_i (i = 0, 1, \ldots, N+1)$ that lie at the heart of our construction.

For $0 \leq i \leq N-1$, we set

$$\Omega_i := [S(b - i\beta) + \gamma B] \setminus [S(b - (i+1)\beta) + \gamma B];$$

for $i = N$ we set

$$\Omega_N := [S(b - N\beta) + \gamma B] \setminus \left[S(b - N\beta) + \frac{\gamma}{4}B\right];$$

and finally, we define

$$\Omega_{N+1} := S(b - N\beta) + \frac{\gamma}{4}B.$$

We now gather some facts about these sets.

LEMMA 2.5.

(a) *The Ω_i are disjoint, and Ω_i is contained in $S(a,b) + \gamma B$ for $i \leq N$.*

(b) $\bigcup_{i=0}^{N+1} \Omega_i = S(b) + \gamma B$.

(c) *If $x \in \Omega_i$ for some $i \in \{0, 1, \ldots, N\}$ and $s \in \mathrm{proj}(x, S(b - i\beta))$, then $s \in S(a,b) + \eta B$.*

(d) $S(b - i\beta) + \frac{\gamma}{4}B \subset S(b - (i+1)\beta) + \gamma B (i = 0, 1, \ldots, N-1)$.

(e) *For every $i \in \{0, 1, \ldots, N\}, \forall x \in \Omega_i$, we have $\frac{\gamma}{4} \leq d(x, S(b - i\beta)) < \gamma$.*

(f) $S(b - N\beta) + \frac{\gamma}{2}B \subset S(a) + \gamma B$, *so that $\Omega_{N+1} \subset S(a) + \gamma B$.*

Proof.

(a) That the Ω_i are disjoint is evident; that they lie in $S(a,b) + \gamma B$ for $i \leq N$ follows from Lemma 2.3 for $i < N$ and from Lemma 2.2 for $i = N$ (recall that $b - N\beta - a \leq \beta \leq \delta_1$ and $\gamma < \delta_2$).

(b) Evident.

(c) Direct from Lemma 2.3 ($i < N$) or Lemma 2.2 ($i = N$).

(d) Let x lie in $S(b - i\beta) + \gamma/4B$, and let $s \in S(b - i\beta)$ satisfy $\|x - s\| < \gamma/4$. Then $V(s) \leq b - i\beta$, and if $V(s) \leq b - (i+1)\beta$ the conclusion is immediate. Otherwise we have

$$V(s) > b - (i+1)\beta > a,$$

so that $s \in S(a,b)$. By Lemma 2.4 there exists $y \in S(b - (i+1)\beta)$ such that

$$\|s - y\| \leq \frac{m}{\omega}[V(s) - b + (i+1)\beta] \leq \frac{m\beta}{\omega} \leq \frac{\gamma}{2}$$

in view of (2.2). Then

$$\|x - y\| \leq \|x - s\| + \|s - y\| < \frac{\gamma}{4} + \frac{\gamma}{2} < \gamma,$$

which establishes the desired conclusion.

(e) For $i = N$, this is immediate from the definition of Ω_N; for $i < N$, it is a consequence of (d).

(f) Let x belong to $S(b - N\beta) + \gamma/2B$, and let $s \in S(b - N\beta)$ satisfy $\|x - s\| < \gamma/2$. If $V(s) \leq a$, then $x \in S(a) + \gamma B$. Otherwise, s belongs to $S(a,b)$, and Lemma 2.4 implies the existence of $y \in S(a)$ such that

$$\|y - s\| \leq \frac{m}{\omega}[V(s) - a] \leq \frac{m}{\omega}[b - N\beta - a] \leq \frac{m\beta}{\omega} \leq \frac{\gamma}{2}.$$

But then $\|x - y\| < \gamma$, so again $x \in S(a) + \gamma B$. □

LEMMA 2.6. *Let $x \in \Omega_i$ ($i = 0, 1, \ldots, N$), and let $s \in \mathrm{proj}(x, S(b - i\beta))$. Then there exists $u \in \mathcal{U}$ such that*

$$\langle x - s, f(s,u) \rangle \leq \frac{-\omega}{2L_V}\|x - s\|.$$

Proof. By definition, $x - s$ lies in the proximal normal cone $N^P(s, S(b - i\beta))$. Note that s lies in $S(a,b) + \eta B$ (by Lemma 2.3 for $i < N$, by Lemma 2.2 for $i = N$), so that V is Lipschitz of rank L_V in a neighborhood of s. A basic calculus result [9, 1.11.26] yields the existence of $\lambda > 0$ such that $\lambda(x-s) \in \partial_L V(s)$ and necessarily $\lambda\|x-s\| \le L_V$. In accord with Remark 2.1, there exists $u \in \mathcal{U}$ such that

$$\langle \lambda(x-s), f(s,u)\rangle \le \frac{-\omega}{2}.$$

The result follows. □

Defining the feedback. We now define a feedback $k(\cdot)$ on $S(b)+\gamma B$ as follows. If $x \in \Omega_i$ for some $i \in \{0,1,\ldots,N\}$, then we set $k(x) = u$, where u is one of the points corresponding to x (and a projection s) as in Lemma 2.6. There remain the points x in Ω_{N+1} to consider (see Lemma 2.5(b)). For such x, we define $k(x)$ to be any point in $\mathcal{U}$. (We remark that we have phrased the definition of $k(x)$ in such a way that the choice of u as indicated above is made once and for all, but in fact a different choice could be made if the same state x recurred subsequently, without at all affecting what follows; this fact is relevant for real-time control.)

The remainder of the proof consists in establishing that for suitably small mesh size, any π-trajectory generated by $k(\cdot)$ with initial condition in $S(b)+\gamma B$ remains in $S(b)+\gamma B$, enters $S(a)+\gamma B$ within a certain (uniform) time and then remains in that set subsequently.

We consider countable partitions $\{t_j\}$ such that $t_0 = 0, \lim_{j\to\infty} t_j = \infty$, and such that $0 < t_{j+1} - t_j \le \delta$ for all $j \ge 0$, where δ is any positive number satisfying

$$\delta < \min\left\{\frac{\gamma}{4m}, \frac{\omega}{6mL_fL_V}, \frac{\gamma\omega}{48m^2L_V}, 1\right\}. \tag{2.3}$$

For such a partition, let x_0 be any point in $S(b)+\gamma B$, and let $x(\cdot)$ be a π-trajectory with $x(0) = x_0$. We denote $x(t_j)$ by x_j, and we set

$$\Delta := \frac{\omega}{60L_V}.$$

Lemma 2.7. *For some $t_j \in \pi$, suppose that $x_j \in \Omega_i, i \in \{0,1,\ldots,N\}$. Then*

$$x(t) \in S(b)+\gamma B \qquad \forall t \in [t_j,t_{j+1}], \text{ and}$$

$$d(x(t), S(b-i\beta)) \le d(x_j, S(b-i\beta)) - \Delta(t-t_j) \qquad \forall t \in [t_j, t_{j+1}].$$

Proof. We have $x_j \in S(a,b)+\gamma B$ by Lemma 2.5(a) and $\|\dot{x}(t)\| \le m$ while $x(t)$ lies in $S(b)+\eta B$. Since $\delta m < \gamma/4$ by (2.3) and $\gamma < \eta/2$, it follows that $x(t)$ lies in $S(a,b)+\eta B$ for $t \in [t_j, t_{j+1}]$, as does the point s that figures in the definition of $k(x_j)$; this was pointed out in the proof of Lemma 2.6, where we also deduced the inequality

$$\langle x_j - s, f(s,k(x_j))\rangle \le \frac{-\omega}{2L_V}\|x_j - s\|. \tag{2.4}$$

We fix $t \in (t_j, t_{j+1})$ and set

$$\Psi := \frac{x(t)-s}{\|x(t)-s\|}.$$

Note that $x(t) \ne s$, since $\|x_j - s\| \ge \gamma/4$ by Lemma 2.5(e) and since

$$\|x(t) - x_j\| < \delta m < \frac{\gamma}{4}.$$

We now observe two inequalities:

$$d(x(t), S(b - i\beta)) \leq \|x(t) - s\| = \langle \Psi, x(t) - s \rangle,$$

$$d(x_j, S(b - i\beta)) = \|x_j - s\| \geq \langle \Psi, x_j - s \rangle.$$

These together imply

$$\begin{aligned} d(x(t), S(b - i\beta)) - d(x_j, S(b - i\beta)) &\leq \langle \Psi, x(t) - x_j \rangle \\ &= \tau \langle \Psi, f_j \rangle, \end{aligned} \tag{2.5}$$

where we introduce the notation $\tau := t - t_j$,

$$x(t) = x_j + \tau f_j, \qquad f_j := \frac{1}{\tau} \int_{t_j}^{t} f(x(r), k(x_j)) dr.$$

We also set

$$\hat{f}_j := f(s, k(x_j)) = \frac{1}{\tau} \int_{t_j}^{t} f(s, k(x_j)) dr.$$

Note that

$$\begin{aligned} \|f_j - \hat{f}_j\| &\leq \frac{1}{\tau} \int_{t_j}^{t} L_f \|x(r) - s\| dr \\ &\qquad \text{(the Lipschitz condition holds since we are in } S(a, b) + \eta B) \\ &\leq \frac{1}{\tau} \int_{t_j}^{t} L_f (\|x(r) - x_j\| + \|x_j - s\|) dr \\ &\leq L_f (\tau m + d(x_j, S(b - i\beta))). \end{aligned}$$

It follows from this and (2.4) that we have

$$\begin{aligned} \langle x_j - s, f_j \rangle &= \langle x_j - s, \hat{f}_j + f_j - \hat{f}_j \rangle \\ &\leq \frac{-\omega}{2L_V} \|x_j - s\| + L_f d(x_j, S(b - i\beta)) \{\tau m + d(x_j, S(b - i\beta))\} \\ &\leq d(x_j, S(b - i\beta)) \left[\frac{-\omega}{2L_V} + L_f \delta m + \gamma L_f \right] \\ &\qquad \text{(since } \tau < \delta \text{ and } d(x_j, S(b - i\beta)) \leq \gamma) \\ &\leq d(x_j, S(b - i\beta)) \left[\frac{-\omega}{2L_V} + \frac{\omega}{6L_V} + \frac{\omega}{6L_V} \right] \\ &\qquad \text{(we have invoked (2.3) and (2.1))} \\ &\leq -\frac{\gamma\omega}{24L_V} \\ &\qquad \text{(since } d(x_j, S(b - i\beta)) \geq \gamma/4 \text{ by Lemma 2.5(e)).} \end{aligned}$$

We shall use this bound on $\langle x_j - s, f_j \rangle$ to derive one on $\langle x(t) - s, f_j \rangle$ as follows:

$$\begin{aligned} \langle x(t) - s, f_j \rangle = \langle x_j + \tau f_j - s, f_j \rangle &\leq \langle x_j - s, f_j \rangle + \tau \|f_j\|^2 \\ &\leq \frac{-\gamma\omega}{24L_V} + \delta m^2 \leq \frac{-\gamma\omega}{48L_V} \end{aligned} \tag{2.6}$$

(in light of (2.3)). We also have

$$\begin{aligned}\|x(t) - s\| = \|x_j + \tau f_j - s\| \le \|x_j - s\| + \tau\|f_j\| &\le \gamma + \delta m \\ &< \frac{5\gamma}{4} \text{ (by (2.3))}.\end{aligned}$$

Combining this with (2.6) we arrive at

$$\langle \Psi, f_j \rangle = \left\langle \frac{x(t) - s}{\|x(t) - s\|}, f_j \right\rangle \le \frac{-\gamma\omega}{48L_V} \Big/ \frac{5\gamma}{4} = -\Delta.$$

Together with (2.5), this gives the inequality asserted by the lemma. Since this inequality evidently implies

$$d(x(t), S(b - i\beta)) < \gamma,$$

it also follows that $x(t) \in S(b) + \gamma B$. □

LEMMA 2.8. *If $x_j \in \Omega_i$ where $0 \le i \le N$, then x_{j+1} lies in $\Omega_{i'}$ for some $i' \ge i$.*

Proof. Since $x_j \in \Omega_i$, we have $d(x_j, S(b - i\beta)) < \gamma$, and (by Lemma 2.7) $d(x_{j+1}, S(b - i\beta)) < \gamma$. Now let $1 \le k < i$. Since $S(b - i\beta) \subset S(b - (k+1)\beta)$, we deduce $d(x_{j+1}, S(b - (k+1)\beta)) < \gamma$. But then $x_{j+1} \notin \Omega_k$ by definition of Ω_k. Since $x_{j+1} \in S(b) + \gamma B$ by Lemma 2.7, we must have $x_{j+1} \in \Omega_{i'}$ for some $i' \ge i$, in view of Lemma 2.5(b). □

LEMMA 2.9. *If $x(\tau) \in \Omega_{N+1}$ for some $\tau \in \pi$, then $x(t) \in S(a) + \gamma B$ $\forall t \ge \tau$.*

Proof. We know that $x(\tau)$ lies in the interior of $S(a) + \gamma B$ by Lemma 2.5(f). For $t > \tau$, as long as $d(x(t), S(b - N\beta))$ does not attain or exceed $\gamma/2$, then $x(t)$ remains in $S(a) + \gamma B$. Thus $\|\dot{x}(t)\|$ remains bounded by m and no blow-up occurs (i.e., $x(t)$ is well defined).

It suffices therefore to prove that the continuous function

$$g(t) := d(x(t), S(b - N\beta))$$

does not become greater than or equal to $\gamma/2$ for some $t_0 > \tau$. We have $g(\tau) < \gamma/4$.

Since we have chosen δ to satisfy $\delta m < \gamma/4$, at the next node τ_1 following τ we have $g(\tau_1) < \gamma/2$, and two cases arise. The first is when $\gamma/4 \le g(\tau_1) < \gamma/2$; in that case, $x(\tau_1)$ belongs to Ω_N, and Lemma 2.7 shows that at the next node $\tau_2, g(\tau_2)$ will have decreased relative to $g(\tau_1)$. The other case is when $g(\tau_1) < \gamma/4$; but then we are in the same situation as we were with τ. The conclusion is that $g(t)$ never exceeds $\gamma/2$, as required. □

One last lemma and the proof is complete. We set

$$T := \left(1 + \frac{b - a}{\beta}\right)\left(1 + \frac{45\gamma L_V}{\omega}\right).$$

LEMMA 2.10.

$$x(t) \in S(a) + \gamma B \qquad \forall t \ge T.$$

Proof. In view of Lemma 2.9 and Lemma 2.5(f), it suffices to prove that there is a node $\tau \in \pi$ with $\tau \le T$ for which $x(\tau) \in \Omega_{N+1}$. Note that $x(0)$ belongs to some $\Omega_i (0 \le i \le N + 1)$ by Lemma 2.5(b); if $i = N + 1$ we are done, so assume $i \le N$. Since $\delta < 1$ by (2.3), there is a node τ_1 lying in the open interval $(\sigma, \sigma + 1)$, where

$\sigma := (3\gamma)/(4\Delta)$. By Lemma 2.8, $x(\tau_1)$ belongs either to Ω_i or to $\Omega_{i'}$ for some $i' > i$. In the former case, it follows that $x(t)$ lies in Ω_i for every node $t \in \pi$ lying between 0 and τ_1, and the inequality of Lemma 2.7 applies to give

$$\begin{aligned} d(x(\tau_1), S(b - i\beta)) &\leq d(x(0), S(b - i\beta)) - \Delta\tau_1 \\ &< \gamma - \frac{3\gamma}{4} = \frac{\gamma}{4}. \end{aligned}$$

However, the left side is no less than $\gamma/4$ by Lemma 2.5(e). This contradiction shows that, in fact, $x(\tau_1)$ must belong to some $\Omega_{i'}$ for an index $i' > i$. If $i' = N + 1$, we are done; otherwise, the same argument, beginning now at $(\tau_1, x(\tau_1))$, yields the existence of a node $\tau_2 \in \pi$ with $\tau_2 \leq 2\sigma + 2$ such that $x(\tau_2)$ belongs to $\Omega_{i''}$, where $i'' > i'$. Continuing in this manner, we find that (since there are at most $N + 1$ steps as above prior to landing in Ω_{N+1}), there is a node $\tau \in \pi$ with $\tau \leq (N + 1)(\sigma + 1)$ such that $x(\tau) \in \Omega_{N+1}$. But $N < (b - a)/\beta$ implies that T as defined above is greater than $(N + 1)(\sigma + 1)$. □

Remark 2.4. It is a consequence of the construction that for suitably small $\delta > 0$, the set $A := S(a + \delta)$ is attained in a time that approaches 0 as $x(0)$ approaches A. This is the key property that is needed in the converse Lyapunov theorem that we now proceed to develop.

3. Construction of a Lyapunov function. We show in this section that under reasonable assumptions, there always exist Lyapunov functions having the properties required for the feedback construction of the preceding section and giving rise to practical feedback stabilization of an arbitrarily prescribed range. While the result below appears to be new and the approach to proving it has some novel features, there is a familiar heuristic at work: the Lyapunov function is constructed as the value function associated with a parametrized family of optimal control problems.

The function $f(x, u)$ describing the dynamics is supposed in this section to satisfy much the same regularity conditions as before. Specifically, we require that for any bounded subset S of $\mathbb{R}^n$, there exist constants $m = m(S)$ and $L = L(S)$ such that

$$\|f(x, u)\| \leq m \quad \forall x \in S, \qquad \forall u \in \mathcal{U},$$

$$\|f(x, u) - f(y, u)\| \leq L\|x - y\| \quad \forall x, y \in S, \qquad \forall u \in \mathcal{U}.$$

(As before, $\mathcal{U}$ is just an abstract set, and no hypotheses are made concerning the nature of the dependence of f on u.)

In addition, we require "nice" controllability to a given compact set A via relaxed trajectories. Let us now proceed to make this precise. We define a multifunction Γ on $\mathbb{R}^n$ by

$$\Gamma(x) := \text{cl co}\{f(x, u) : u \in \mathcal{U}\}.$$

By "trajectory" (or "Γ-trajectory") we mean an absolutely continuous function $x(\cdot)$ on an interval $[0, T]$ such that

$$\dot{x}(t) \in \Gamma(x(t)) \quad \text{a.e.} \quad t \in [0, T].$$

Given $\alpha \in \mathbb{R}^n$, we define $T_A(\alpha)$ as the least time required for a trajectory to go from α to the set A:

$$T_A(\alpha) := \inf\{T \geq 0 : x(\cdot) \text{ is a trajectory on } [0, T], x(0) = \alpha, x(T) \in A\}.$$

The controllability hypothesis that we make is that every α admits a trajectory steering it to A in finite time, a time which goes to 0 as α approaches A.
Equivalently,

$$\text{(CH)} \qquad T_A(\alpha) < \infty \quad \forall \alpha \in \mathbb{R}^n, \qquad \text{and} \lim_{d(\alpha,A)\downarrow 0} T_A(\alpha) = 0.$$

We remark that proximal criteria exist ensuring that A satisfies (CH); see [9, 4.6.7]. Now fix a point $a_0 \in A$. Below, $\operatorname{diam}(A)$ refers to the usual diameter of A as a subset of $\mathbb{R}^n$.

THEOREM 3.1. *For any $r > 0$ and $R > \operatorname{diam}(A)+r$, there exist numbers a, b, γ, η, and a function $V : \mathbb{R}^n \longrightarrow \mathbb{R}$ such that*

$$S(a) + \gamma B \subset A + rB \subset \bar{B}(a_0, R) \subset S(b) + \gamma B$$

and such that all the hypotheses of Theorem 2.1 *are satisfied and, in addition, $S(b)$ is compact. The feedback defined in Theorem* 2.1 *stabilizes $S(b) + \gamma B$ to $A + rB$.*

The following addresses the issue of practical semiglobal stabilization of globally asymptotically controllable systems.

COROLLARY 3.2. *Let the system be globally asymptotically controllable to the origin. Then, for any $0 < r < R$, there exists a feedback of the type constructed in Theorem* 2.1 *which is defined on a neighborhood of $\bar{B}(0, R)$, and which stabilizes every initial point in $B(0, R)$ to the ball $B(0, r)$.*

Proof. It is known that a continuous global Lyapunov function exists for the problem of stabilization to the origin [26], and every level set $S(a)$ for $a > 0$ of that function satisfies (CH) [9, 4.6.7]. It suffices now to take such a level set A contained in the ball $B(r/2, 0)$, and to apply Theorem 3.1 with $r := r/2$ and $a_0 := 0$. □

Proof of Theorem 3.1. We begin the proof by defining another multifunction $\tilde{\Gamma}$ (more useful than Γ for being uniformly bounded):

$$\tilde{\Gamma}(x) := \text{cl co}\left\{\frac{v}{1 + \|v\|} : v \in \Gamma(x)\right\}.$$

We set

$$\tilde{T_A}(\alpha) := \inf\{T \geq 0 : x(\cdot) \text{ is a } \tilde{\Gamma}\text{-trajectory on } [0, T], x(0) = \alpha, x(T) \in A\}.$$

Evidently (or by convention) we have $\tilde{T_A} = 0$ on A.

LEMMA 3.3.

(a) $\tilde{\Gamma}$ *is locally Lipschitz and has nonempty convex compact values in $\bar{B}(0, 1)$.*

(b) $\tilde{T_A}(\alpha)$ *is finite* $\forall \alpha \in \mathbb{R}^n$.

(c) $\lim_{d(\alpha,A)\downarrow 0} \tilde{T_A}(\alpha) = 0$.

(d) *There exists a positive number ϵ such that whenever $\alpha \in A+\epsilon B$, and whenever the $\tilde{\Gamma}$-trajectory $x(\cdot)$ has $x(0) = \alpha$ and $x(T) \in A$ for some $T \leq \tilde{T_A}(\alpha) + \epsilon$, then we have $\|x - a_0\|_\infty \leq \operatorname{diam}(A) + 1$. We can suppose $\epsilon < 1, \epsilon < r$, and*

$$\text{(3.1)} \qquad \sup\{\tilde{T_A}(\alpha) : \alpha \in A + \epsilon B\} < \frac{r^2}{4(1 + \operatorname{diam}(A))}.$$

Proof. We omit the routine proof of (a). For (b), let $\alpha \in \mathbb{R}^n$ be given. By assumption, there is a Γ-trajectory x on an interval $[0, T]$ such that $x(0) = \alpha, x(T) \in A$. We set

$$\tilde{T} := \int_0^T (1 + \|\dot{x}(t)\|)dt$$

and we define a function $\tilde{x}$ on $[0, \tilde{T}]$ by

$$\tilde{x}(\tau) := x(t),$$

where $t = t(\tau)$ is determined in $[0, T]$ by

$$\tau = \int_0^t (1 + \|\dot{x}(r)\|)dr.$$

(This change of variables or time scale is known as the Erdmann transform.) Then

$$\frac{d\tilde{x}}{d\tau} = \frac{\dot{x}(t)}{1 + \|\dot{x}(t)\|} \in \tilde{\Gamma}(\tilde{x}(\tau)) \quad \text{a.e.}$$

so that $\tilde{x}$ is a $\tilde{\Gamma}$-trajectory. Hence $\tilde{T_A}(\alpha) \leq \tilde{T} < \infty$.

We turn now to (c). Let α_i be a sequence for which $d(\alpha_i, A)$ decreases to 0. Then $T_A(\alpha_i) \to 0$ by assumption. Let m be such that $\|f(x,u)\| \leq m$ for $(x,u) \in (A + \bar{B}) \times \mathcal{U}$. Then, as soon as $T_A(\alpha_i)$ is strictly less than $1/m$, there is a Γ-trajectory x_i on an interval $[0, T_i]$ such that

$$x_i(0) = \alpha_i, \qquad x_i(T_i) \in A, \qquad T_i < \frac{1}{m}, \qquad T_i < T_A(\alpha_i) + \frac{1}{i}.$$

It follows that $x_i(t) \in A + \bar{B}$ for $t \in [0, T_i]$. Now let $\tilde{x_i}$ be the Erdmann transform of x_i as given above. Then

$$\tilde{T_A}(\alpha_i) \leq \tilde{T_i} = \int_0^{T_i} (1 + \|\dot{x_i}(t)\|)dt \leq (1+m)T_i < (1+m)\left(T_A(\alpha_i) + \frac{1}{i}\right).$$

It follows that $\tilde{T_A}(\alpha_i) \to 0$, as required.

We now examine (d). If the assertion is false, there exists a sequence α_i with $d(\alpha_i, A) \downarrow 0$ and corresponding $\tilde{\Gamma}$-trajectories x_i with $x_i(0) = \alpha_i, x_i(T_i) \in A$ such that

$$T_i \leq \tilde{T_A}(\alpha_i) + \frac{1}{i}, \qquad \|x_i - a_0\|_\infty > \operatorname{diam}(A) + 1.$$

Since $\tilde{T_A}(\alpha_i) \to 0$ by (c), we have $T_i \to 0$. On the other hand, there is a subinterval of $[0, T_i]$ in which $\|x_i - a_0\|$ goes from being $\operatorname{diam}(A) + 1$ to at most $\operatorname{diam}(A)$, and since $\|\dot{x_i}(t)\| \leq 1$ the length of that subinterval (and hence, T_i) is at least 1. This contradiction establishes the first part of (d); the rest follows immediately by shrinking ϵ as required, in light of (c). □

Defining a value function. We proceed now to define a new multifunction $F(x)$ whose effect is to enlarge the set $\tilde{\Gamma}(x)$ for $d(x, A) < \epsilon$. We set

$$F(x) := \begin{cases} \tilde{\Gamma}(x) & \text{for } d(x,A) \geq \epsilon, \\ \tilde{\Gamma}(x) + 2[\frac{\epsilon - d(x,A)}{\epsilon}]\bar{B} & \text{for } d(x,A) \leq \epsilon. \end{cases}$$

Having done this, we define a value function $V(\cdot)$ on $\mathbb{R}^n$ in terms of the trajectories of F as follows:

$$V(\alpha) := \inf\left\{\int_0^T \|x(t) - a_0\|dt : T \geq 0, x(0) = \alpha, \dot{x} \in F(x) \text{ a.e.}, x(T) \in A\right\}.$$

We stress that T is a choice variable here, in this free time problem.

Lemma 3.4.

(a) *F is compact and convex-valued, uniformly bounded, and locally Lipschitz.*

(b) *$V(\cdot)$ is nonnegative, finite-valued, and lower semicontinuous, and the infimum defining $V(\alpha)$ is attained for every α.*

(c) *$V(\alpha) = 0$ iff $\alpha \in A$, and $\lim_{d(\alpha,A)\downarrow 0} V(\alpha) = 0$.*

(d) *The sublevel sets $S(b) := \{\alpha : V(\alpha) \le b\}$ of V are compact.*

Proof. The assertions of (a) are immediate. Since $F(x)$ is uniformly bounded, the attainment and the lower semicontinuity asserted in (b) follow from standard "compactness of trajectories" arguments; see [9, Chapter 4] for details. The first assertion of (c) is clear, and the other one stems from Lemma 3.3 as follows.

Let $\alpha \in A + \epsilon B$, and let the $\tilde{\Gamma}$-trajectory x satisfy $x(0) = \alpha$, $x(T) \in A$, and $T \le \tilde{T_A}(\alpha) + \delta$, for some $\delta \in (0, \epsilon)$. Then $\|x - a_0\|_\infty \le \mathrm{diam}(A) + 1$ (by choice of ϵ), and we deduce

$$V(\alpha) \le \int_0^T \|x(t) - a_0\| dt \le (\tilde{T_A}(\alpha) + \delta)(\mathrm{diam}(A) + 1).$$

Since $\tilde{T_A}(\alpha) \downarrow 0$ as $d(\alpha, A) \downarrow 0$, (c) follows.

Finally we turn to (d). If $\|\alpha - a_0\| > \mathrm{diam}(A) + \epsilon$, then the time required for a trajectory x to go from $x = \alpha$ to the boundary of $A + \epsilon B$ is at least $\|\alpha - a_0\| - \mathrm{diam}(A) - \epsilon$. But then $V(\alpha) \ge \epsilon(\|\alpha - a_0\| - \mathrm{diam}(A) - \epsilon)$. This implies assertion (d). □

The next step invokes Hamiltonian conditions for optimal control and uses the lower Hamiltonian h associated with F:

$$h(x, p) := \min\{\langle p, v\rangle : v \in F(x)\}.$$

Lemma 3.5. *Let $\zeta \in \partial_P V(\alpha)$, where α does not lie in A. Let x be a trajectory solving the problem that defines $V(\alpha)$ with associated time T. Then there exists an absolutely continuous function p on $[0, T]$ such that*

$$\left(-\dot{p} - \frac{x - a_0}{\|x - a_0\|}, \dot{x}\right) \in \partial_C h(x, p) \quad \text{a.e.} \quad t \in [0, T], \tag{3.2}$$

$$p(0) = \zeta, \tag{3.3}$$

$$h(x(t), p(t)) + \|x(t) - a_0\| = 0 \qquad \forall t \in [0, T]. \tag{3.4}$$

Proof. By definition of $\partial_P V(\alpha)$, we have for some $\sigma \ge 0$ and for all α' near α

$$V(\alpha') + \sigma\|\alpha' - \alpha\|^2 - \langle\zeta, \alpha'\rangle \ge -\langle\zeta, \alpha\rangle.$$

Let x' be a trajectory near x (in the L^∞ norm), put $\alpha' = x'(0)$ and $\alpha = x(0)$, and rearrange to derive that $x'(\cdot) = x(\cdot)$ solves locally the problem of minimizing

$$\int_0^{T'} \|x'(t) - a_0\| dt - \langle\zeta, x'(0)\rangle + \sigma\|x'(0) - x(0)\|^2$$

over the trajectories x' for F satisfying $x'(T') \in A$. (Here T' and $x'(0)$ are free.) We apply the corollary of Theorem 3.6.1 of [5] (with time reversed) to deduce the existence of an absolutely continuous function q on $[0, T]$ satisfying

$$(-\dot{q}, \dot{x}) \in \partial_C[H(x, q) - \|x - a_0\|](x, q) \quad \text{a.e.} \quad t \in [0, T], \tag{3.5}$$

$$q(0) = -\zeta, \tag{3.6}$$

$$H(x(t), q(t)) = \|x(t) - a_0\|, \quad t \in [0, T], \tag{3.7}$$

where $H(x,p)$ is the function $-h(x,-p)$ and ∂_C denotes the generalized gradient. The Hamiltonian inclusion above implies

$$\left(\dot{q} - \frac{x-a_0}{\|x-a_0\|}, \dot{x}\right) \in \partial_C h(x,-q) \quad \text{a.e.,} \qquad t \in [0,T].$$

Now putting $p := -q$ gives to these conclusions the form asserted in the statement of the lemma. □

LEMMA 3.6. *For any constant $c > 0$, there is a constant M_c with the following property. If $\alpha \in S(c)$ and if the trajectory x on $[0,T]$ attains the infimum defining $V(\alpha)$, then $\|x-a_0\|_\infty \le M_c, T \le M_c$.*

Proof. If $\|x-a_0\|_\infty > c+\mathrm{diam}(A)+1$, then the time required for $\|x-a_0\|$ to attain the value $\mathrm{diam}(A)+1$ exceeds c (since $\|\dot{x}\| \le 1$). But then $V(\alpha) \ge (1+\mathrm{diam}(A))c > c$. This shows that $\|x-a_0\|_\infty$ is bounded by $c+\mathrm{diam}(A)+1$. By Lemma 3.3(c), $\lim_{d(\alpha,A)\downarrow 0} \tilde{T_A}(\alpha) = 0$. So there exists $\rho > 0$ such that

$$\tilde{T_A}(x) \le 1 \quad \forall x \in A + \rho\bar{B}.$$

Now take α outside $A+\rho\bar{B}$, and let τ_ρ denote the first time t that $x(t)$ attains $A+\rho\bar{B}$. Then $V(\alpha) \ge \rho\tau_\rho$, whence $\tau_\rho \le c/\rho$ for $\alpha \in S(c)$.

We deduce that

$$\begin{aligned} \tilde{T_A}(\alpha) &\le \tau_\rho + 1 \quad \text{(by choice of } \rho) \\ &\le \frac{c}{\rho} + 1. \end{aligned}$$

If $\alpha \in A+\rho\bar{B}$, the same bound evidently holds. It suffices now to set

$$M_c := \max\left\{\frac{c}{\rho}+1, c+\mathrm{diam}(A)+1\right\}. \qquad \square$$

LEMMA 3.7. *V is locally Lipschitz on $\mathbb{R}^n$.*

Proof. We prove first that V is locally Lipschitz on the open set $\{V > 0\} = \mathrm{comp}(A)$. Let α_0 belong to this set; take any $\delta > 0$ such that $\delta < d(\alpha_0, A)$, and any element $\zeta \in \partial_P V(\alpha)$, where

$$\|\alpha-\alpha_0\| < \delta, \qquad V(\alpha) \le V(\alpha_0)+\delta =: c. \tag{3.8}$$

The conclusions of Lemma 3.6 are available for any trajectory solving the $V(\alpha)$ problem. If K is a Lipschitz constant for F on the ball $B(0, M_c+1+\|a_0\|)$ (where M_c comes from Lemma 3.6), then the Hamiltonian inclusion (3.2) implies

$$\|\dot{p}\| \le K\|p\| + 1. \tag{3.9}$$

The condition (3.4) at $t = T$ gives $\|p(T)\| \le \mathrm{diam}(A)$ since $x(T) \in A$ and since $F(x(T)) = \tilde{\Gamma}(x(T)) + 2\bar{B} \supset \bar{B}$. This, together with (3.9) and Gronwall's Lemma, leads to

$$\begin{aligned} \|\zeta\| = \|p(0)\| &\le e^{KT}\|p(T)\| + \int_0^T e^{K(T-s)}ds \\ &\le \mathrm{diam}(A)e^{KT} + \frac{e^{KT}-1}{K} \\ &\le \mathrm{diam}(A)e^{KM_c} + \frac{e^{KM_c}-1}{K}, \end{aligned}$$

since $T \leq M_c$ by Lemma 3.6. This establishes a uniform bound on elements of $\partial_P V(\alpha)$ whenever α satisfies (3.8), which proves that V is Lipschitz on a neighborhood of α_0 [9, 1.11.11]. Thus V is locally Lipschitz on the set where it is strictly positive.

There is a neighborhood N of A on which V is bounded above, in view of Lemma 3.4(c). The argument above therefore yields a bound L on elements of $\partial_P V(\alpha)$ for all $\alpha \in N \setminus A$, so that V is uniformly Lipschitz of rank L on $\alpha \in N \setminus A$ by [9, Theorem 1.7.3]. Of course, $V = 0$ on A and is continuous at each point of A in view again of Lemma 3.4(c). That V is Lipschitz on N, and hence locally Lipschitz on $\mathbb{R}^n$, now follows. □

Lemma 3.8.

$$\sup\{V(\alpha) : \alpha \in A + \epsilon B\} < \inf\{V(\alpha) : d(\alpha, A) \geq r\}$$

Proof. Let $d(\alpha, A) < \epsilon$, fix $\delta \in (0, \epsilon)$, and let the trajectory x on $[0, T]$ satisfy $x(0) = \alpha, x(T) \in A, T < \tilde{T_A}(\alpha) + \delta$. Then by Lemma 3.3 we have $\|x - a_0\|_\infty \leq \operatorname{diam}(A) + 1$ and so

$$V(\alpha) \leq \int_0^T \|x(t) - a_0\| dt \leq (\tilde{T_A}(\alpha) + \delta)(\operatorname{diam}(A) + 1).$$

We derive $V(\alpha) \leq (\operatorname{diam}(A) + 1)\tilde{T_A}(\alpha)$, and (from (3.1))

$$V(\alpha) \leq \sup\{\tilde{T_A}(\alpha) : d(\alpha, A) \leq \epsilon\}(\operatorname{diam}(A) + 1) < \frac{r^2}{4}.$$

Now let $d(\alpha, A) \geq r$, and let x solve the problem defining $V(\alpha)$. There is an interval of length at least $r/2$ during which $\|x(t) - a_0\| \geq r/2$ (since $\|\dot{x}\| \leq 1$), whence

$$V(\alpha) > \frac{r^2}{4}.$$

The result follows. □

Lemma 3.9. *There exist positive numbers a, b, η with $a < b$ such that*

$$S(a) + \eta B \subset A + rB \subset \bar{B}(a_0, R) \subset S(b)$$

and

$$S(a, b) + \eta B \subset \{\alpha : d(\alpha, A) > \epsilon\}.$$

Proof. Pick a number $a > 0$ lying between the two quantities in the statement of Lemma 3.8. Then evidently the compact set $S(a)$ satisfies

$$S(a) \subset \operatorname{comp}\{d(\alpha, A) \geq r\} = A + rB,$$

whence $S(a) + \eta B \subset A + rB$ for $\eta > 0$ suitably small. It also follows that (for any $b > a$) the compact set $S(a, b)$ is contained in the open set $\{\alpha : d(\alpha, A) > \epsilon\}$. Any b suitably large will satisfy $\bar{B}(a_0, R) \subset S(b)$, since V is bounded on bounded sets. Finally, by shrinking η further if necessary, we will have the final conclusion of the lemma as well. □

Lemma 3.10. *The infinitesimal decrease condition* (H5) *of section* 1 *holds on $S(a, b) + \eta B$, with $\omega := \epsilon$.*

Proof. As pointed out in Remark 2.3, it suffices to show that for any $\alpha \in S(a,b) + \eta B$, for any $\zeta \in \partial_P V(\alpha)$, one has

$$\inf\{\langle \zeta, f(\alpha,u)\rangle : u \in \mathcal{U}\} \leq -\epsilon. \tag{3.10}$$

Let x be a trajectory solving the problem defining $V(\alpha)$. Then, by Lemma 3.5, we have (at $t = 0$)

$$h(\alpha,\zeta) + \|\alpha - a_0\| = 0.$$

Since $d(\alpha, A) > \epsilon$ by Lemma 3.9, we have $F(\alpha) = \tilde{\Gamma}(\alpha)$, so that the preceding equality yields, for any $\delta > 0$, the existence of some element $v \in \Gamma(\alpha)$ such that

$$\left\langle \zeta, \frac{v}{1 + \|v\|} \right\rangle \leq -\|\alpha - a_0\| + \delta < -\epsilon + \delta.$$

For δ small enough, the right side is negative, whence

$$\langle \zeta, v\rangle < -\epsilon + \delta.$$

Given that $\Gamma(\alpha) := \text{cl co} f(\alpha,\mathcal{U})$, this yields the existence of $u \in \mathcal{U}$ for which

$$\langle \zeta, f(\alpha,u)\rangle < -\epsilon + 2\delta.$$

Since δ is arbitrarily small, (3.10) ensues. □

Since $S(b)$ is compact, f is Lipschitz in x and bounded on $S(b) + \eta B$, in accord with hypotheses (H3) and (H4) of section 1. When the level sets are compact and V is continuous, (H2) always holds. The verification of this fact is the last property to confirm.

LEMMA 3.11. *Hypothesis* (H2) *holds.*

Proof. If (H2) fails, then there exist sequences $\alpha_i \in \mathbb{R}^n$, $\epsilon_i \downarrow 0$, and $u_i \in B(0,1)$ such that

$$V(\alpha_i) \leq a + \epsilon_i \text{ and } V(\alpha_i + \epsilon_i u_i) > b.$$

Since $S(b)$ is compact, we can suppose by passing to a subsequence that $\alpha_i \to \alpha_0$. Then, since V is continuous, we have $V(\alpha_0) \geq b > a \geq V(\alpha_0)$, a contradiction. □

The setting of Theorem 2.1 is established, and Theorem 3.1 is proved.

4. Robustness.

We prove in this section that the feedback constructed in section 1 is robust with respect to small measurement error and persistent external disturbance, in a precise sense that requires two stipulations. The first is that the measurement error must not exceed in order of magnitude the step size of the underlying discretization, a condition which appears to be rather natural. The second requirement is perhaps more surprising and surfaces from the nature of the feedback construction. It dictates that each step be "big enough" (while continuing to be "small enough") so as to counteract the measurement error by means of the attractive effect inherent in the construction. Thus the partitions used to discretize the effect of the control are taken to be "reasonably uniform."

Our perturbed system is modeled by

$$\dot{x} = f(x, k(x+p)) + q,$$

where the external disturbance $q : [0,\infty) \longrightarrow \mathbb{R}^n$ is a bounded measurable function:

$$\|q(t)\| \leq E_q, \qquad t \geq 0 \quad \text{a.e.}$$

Given a partition $\pi = \{t_i\}_{i\geq 0}$ of $[0,\infty)$ and the initial condition x_0, the resulting π-trajectory of our perturbed system is defined by successively solving the differential equation

$$\dot{x}(t) = f(x(t), k(x(t_i) + p_i)) + q(t), \qquad t \in [t_i, t_{i+1}],$$

with $x(0) = x_0$. The continuous function $x(t)$ is the real state of the system, while the sequence $\{x(t_i) + p_i\}$ corresponds to the inexact measurements used to select control values.

THEOREM 4.1. *The feedback $k : S(b) + \gamma B \to \mathcal{U}$ constructed in Theorem* 2.1 *is robust in the sense that there exist positive numbers δ_0, T, and E_q such that, for every $\delta \in (0, \delta_0)$ there exists $E_p(\delta) > 0$ having the following property: for any partition $\pi = \{t_i\}_{i\geq 0}$ having*

$$\frac{\delta}{2} \leq t_{i+1} - t_i \leq \delta, \qquad i \geq 0,$$

where $0 < \delta < \delta_0$, for any set of measurement errors $\{p_i\}_{i\geq 0}$ having

$$\|p_i\| \leq E_p(\delta), \qquad i \geq 0,$$

for any initial condition x_0 such that $x_0 + p_0 \in S(b) + \gamma B$, for any disturbance q having $\|q\|_\infty \leq E_q$, the resulting π-trajectory x satisfies

$$x(t_i) + p_i \in S(b) + \gamma B \quad \forall i \geq 0,$$

$$x(t) \in S(b) + 2\gamma B \quad \forall t \geq 0,$$

$$x(t) \in S(a) + \gamma B \quad \forall t \geq T.$$

Remarks 4.1.

(a) Note that unlike T and E_q, the maximum admissible measurement error E_p depends on δ. Also note that (in contrast to Theorem 2.1) $x(t)$ may not lie in $S(b) + \gamma B \ \forall\ t$, although for large t it must do so. We prove, however, that the "observed values" of the state, namely the values $x(t_i) + p_i (i \geq 0)$, all fall in $S(b) + \gamma B$, the domain of definition of k.

(b) Certain other kinds of error, for example a disturbance $d(\cdot)$ entering into the dynamics in the form $\dot{x} = f(x, k(x) + d)$, can be reduced to that of an external disturbance by positing suitable continuity of f in the control variable.

(c) The maximum admissible disturbance measure E_q will be seen to be proportional to ω/L_V. This has a natural physical meaning, as can easily be seen in the case of smooth V and a continuous feedback $k(x)$ such that

$$\langle \nabla V(x), f(x, k(x)) \rangle \leq -W(x).$$

Then we see that the perturbed system

$$\dot{x} = f(x, k(x)) + q$$

is stabilized by k if $\|q\|_\infty < W(x)/\|\nabla V(x)\|$ for every x, a bound akin to that involving ω/L_V.

Proof of Theorem 4.1. We adapt the proof of Theorem 2.1, whose first five lemmas hold with no change whatever, as does the definition of $k(\cdot)$. Recall that γ, β, and N were introduced earlier; see (2.1) and (2.2). We now define our upper bound for δ:

$$\delta_0 := \min\left\{\frac{6\gamma L_V}{\omega}, 1, \frac{\gamma\omega}{24L_V(m+\frac{\omega}{6L_V}+1)^2}, \frac{\gamma}{20m}\right\}, \tag{4.1}$$

$$E_q := \frac{\omega}{6L_V}, \tag{4.2}$$

$$T := \left(1+\frac{b-a}{\beta}\right)\left(1+\frac{81\gamma L_V}{\omega}\right) \tag{4.3}$$

(this T differs slightly from the one in Theorem 2.1), and we let $\pi = \{t_i\}_{i\geq 0}$ be a partition as described in the statement of Theorem 4.1, with corresponding measurement errors $\{p_i\}_{i\geq 0}$ having $\|p_i\| \leq E_p$ for some $E_p > 0$ satisfying

$$E_p < \min\left\{\frac{3\gamma}{80}, \delta, \frac{\delta\omega}{432L_V}\right\}. \tag{4.4}$$

We also admit any disturbance $q(\cdot)$ for which $\|q\|_\infty \leq E_q$, and we take x_0 such that $x_0 + p_0 \in S(b) + \gamma B$. We shall show that the corresponding π-trajectory has the required properties. We introduce the notation

$$x_i := x(t_i), y_i := x_i + p_i$$

for the actual and the measured state values at time t_i and proceed to develop modified versions of the four last lemmas figuring in the proof of Theorem 2.1. We set

$$\tilde{\Delta} := \frac{\omega}{108L_V}.$$

LEMMA 4.2. *For some $t_j \in \pi$, suppose that $y_j \in \Omega_i$, $i \in \{0, 1, \ldots, N\}$. Then*

$$x(t) \in S(b) + 2\gamma B \subset S(b) + \eta B, \qquad t_j \leq t \leq t_{j+1},$$

$$y_j \in S(b) + \gamma B, \qquad y_{j+1} \in S(b) + \gamma B,$$

$$d(y_{j+1}, S(b-i\beta)) \leq d(y_j, S(b-i\beta)) - \tilde{\Delta}(t_{j+1}-t_j).$$

Proof. Note that $y_j \in S(b) + \gamma B$ by Lemma 2.5; it will follow from the last conclusion of the current lemma that $y_{j+1} \in S(b) + \gamma B$. Also, $\|x_j - y_j\| = \|p_j\| \leq E_p$, together with $\|x(t) - x_j\| \leq \delta m$, yield

$$x(t) \in S(a, b) + \gamma B + (E_p + \delta m)B \subset S(b) + 2\gamma B,$$

since $E_p + \delta m < \gamma$ in view of (4.1) and (4.4). Since $2\gamma < \eta$ by (2.1), this gives $x(t) \in S(b) + \eta B$. By Lemma 2.6 we have

$$\langle y_j - s, f(s, k(y_j))\rangle \leq -\frac{\omega}{2L_V}\|y_j - s\|, \tag{4.5}$$

where $s \in \operatorname{proj}(y_j, S(b-i\beta))$. Fix $t \in (t_j, t_{j+1})$ and set

$$\Psi := \frac{x(t) - s}{\|x(t) - s\|}.$$

Note that $x(t) \neq s$ since $\|y_j - s\| \geq \gamma/4$ by Lemma 2.5(e), while

$$\|y_j - x(t)\| \leq \|y_j - x_j\| + \|x_j - x(t)\| < E_p + \delta m < \frac{\gamma}{4},$$

as already noted. We observe the relations

$$\begin{aligned} d(x(t), S(b - i\beta)) &\leq \|x(t) - s\| = \langle \Psi, x(t) - s \rangle, \\ d(y_j, S(b - i\beta)) &= \|y_j - s\| \geq \langle \Psi, y_j - s \rangle, \end{aligned}$$

whence

$$\begin{aligned} d(x(t), S(b - i\beta)) - d(y_j, S(b - i\beta)) &\leq \langle \Psi, x(t) - y_j \rangle \\ &= \langle \Psi, x_j + \tau(f_j + q_j) - y_j \rangle \\ &\leq \tau \langle \Psi, f_j + q_j \rangle + \|p_j\|, \end{aligned} \tag{4.6}$$

where we have introduced

$$\begin{aligned} \tau &:= t - t_j, \\ f_j &:= \frac{1}{\tau} \int_{t_j}^{t} f(x(r), k(y_j)) dr, \\ q_j &:= \frac{1}{\tau} \int_{t_j}^{t} q(r) dr. \end{aligned}$$

We also set $\hat{f}_j := f(s, k(y_j))$; note $\|\hat{f}_j\| \leq m$. We have

$$\begin{aligned} \|f_j - \hat{f}_j\| &\leq \frac{1}{\tau} \int_{t_j}^{t} L_f \|x(r) - s\| dr \leq \frac{L_f}{\tau} \int_{t_j}^{t} (\|x(r) - x_j\| + \|x_j - s\|) dr \\ &\leq L_f(\delta m + \|x_j - y_j\| + \|y_j - s\|) \\ &\leq L_f(\delta m + E_p + \gamma) \leq \frac{5}{4} L_f \gamma. \end{aligned} \tag{4.7}$$

We deduce

$$\begin{aligned} \langle x(t) - s, f_j + q_j \rangle &= \langle x_j + \tau(f_j + q_j) - s, f_j + q_j \rangle \\ &= \langle y_j - s - p_j, f_j + q_j \rangle + \tau \|f_j + q_j\|^2 \\ &\leq \langle y_j - s, f_j \rangle + E_p(m + E_q) + \delta(m + E_q)^2 \\ &= \langle y_j - s, \hat{f}_j \rangle + \langle y_j - s, f_j - \hat{f}_j \rangle + (m + E_q)[\delta m + \delta E_q + E_p] \\ &\leq -\frac{\omega}{2L_V} \|y_j - s\| + \frac{5}{4} \|y_j - s\| L_f \gamma + (m + E_q)[\delta m + \delta E_q + E_p] \\ &\qquad \text{(where we have used (4.5) and (4.7))} \\ &\leq d(y_j, S(b - i\beta)) \left[-\frac{\omega}{2L_V} + \frac{\omega}{6L_V} \right] + \delta[m + E_q + 1]^2 \\ &\qquad \text{(by (2.1), and since } E_p < \delta \text{ by (4.4))} \\ &\leq \frac{\gamma}{4} \left[-\frac{\omega}{3L_V} \right] + \frac{\gamma\omega}{24L_V} = -\frac{\gamma\omega}{24L_V} \end{aligned}$$

(since $d(y_j, S(b - i\beta)) \geq \gamma/4$ by Lemma 2.5, and since $\delta < \delta_0$ defined by (4.1)). Note also that

$$\begin{aligned} \|x(t) - s\| &= \|y_j - p_j + \tau(f_j + q_j) - s\| \\ &\leq \gamma + E_p + \delta(m + E_q) \leq \frac{5\gamma}{4} + \delta E_q < \frac{9\gamma}{4} \end{aligned}$$

(note $\delta E_q < \gamma$ because of $\delta < \delta_0$, in view of (4.1) and (4.2)).

It follows that

$$\langle \Psi, f_j + q_j \rangle = \left\langle \frac{x(t) - s}{\|x(t) - s\|}, f_j + q_j \right\rangle \leq -\frac{(\gamma\omega)/(24L_V)}{(9\gamma)/4} = -\frac{\omega}{54L_V}.$$

Substituting into (4.6) leads to

$$d(x(t), S(b - i\beta)) - d(y_j, S(b - i\beta)) \leq -2\tilde{\Delta}(t - t_j) + E_p.$$

We obtain from this

$$\begin{aligned} d(y_{j+1}, S(b - i\beta)) - d(y_j, S(b - i\beta)) &\leq \|y_{j+1} - x(t_{j+1})\| - 2\tilde{\Delta}(t - t_j) + E_p \\ &\leq -\tilde{\Delta}(t_{j+1} - t_j) + [2E_p - \tilde{\Delta}(t_{j+1} - t_j)] \\ &\leq -\tilde{\Delta}(t_{j+1} - t_j), \end{aligned}$$

by (4.4), and since $t_{j+1} - t_j \geq \delta/2$. □

LEMMA 4.3. *If $y_j \in \Omega_i$, where $i \leq N$, then y_{j+1} lies in Ω_k for some $k \geq i$.*

Proof. We know that $y_{j+1} \in \Omega_k$ for some k, since y_{j+1} belongs to $S(b) + \gamma B$ by Lemma 4.2. Suppose that $k < i$. We have $d(y_j, S(b - i\beta)) < \gamma$ by definition of Ω_i, and Lemma 4.2 implies $d(y_{j+1}, S(b - i\beta)) < \gamma$. But $S(b - i\beta) \subset S(b - (k+1)\beta)$, so that $d(y_{j+1}, S(b - (k+1)\beta)) < \gamma$. But then $y_{j+1} \notin \Omega_k$ by definition of Ω_k (note that $k \leq N$). This contradiction proves the lemma. □

LEMMA 4.4. *If $\tau \in \pi$ is such that $y(\tau) \in \Omega_{N+1}$, then*

$$x(t) \in S(a) + \gamma B \quad \forall t \geq \tau.$$

Proof. We first establish

$$d(y(\tau'), S(b - N\beta)) \leq \frac{2\gamma}{5} \qquad \forall \text{ nodes } \tau' \geq \tau. \tag{4.8}$$

We consider first $\tau' = \tau + 1$. We have $d(y(\tau), S(b - N\beta)) \leq \gamma/4$, whence

$$\begin{aligned} d(y(\tau+1), S(b - N\beta)) &\leq d(x(\tau+1), S(b - N\beta)) + E_p \\ &\leq d(x(\tau), S(b - N\beta)) + E_p + m\delta \\ &\leq d(y(\tau), S(b - N\beta)) + 2E_p + m\delta \\ &< \frac{\gamma}{4} + \frac{3\gamma}{20} = \frac{2\gamma}{5} \text{ (by (4.4))}. \end{aligned}$$

If $d(y(\tau+1), S(b - N\beta))$ is in fact $\leq \gamma/4$, then this same argument yields

$$d(y(\tau+2), S(b - N\beta)) \leq \frac{2\gamma}{5}.$$

If however $d(y(\tau+1), S(b - N\beta)) > \gamma/4$, then $y(\tau+1)$ lies in Ω_N by definition, and Lemma 4.2 again yields $d(y(\tau+2), S(b - N\beta)) < 2\gamma/5$. Continuing in this way, we obtain (4.8) for all nodes $\tau' \geq \tau$.

We use (4.8) to argue as follows: let $t \geq \tau$, and let $\tau' \geq \tau$ be a node adjacent to t; then

$$\begin{aligned} d(x(t), S(b - N\beta)) &\leq d(x(\tau'), S(b - N\beta)) + \delta m \\ &\leq d(y(\tau'), S(b - N\beta)) + E_p + \delta m \\ &< \frac{2\gamma}{5} + \frac{\gamma}{10} = \frac{\gamma}{2} \text{ (by (4.4))}. \end{aligned}$$

This gives $x(t) \in S(a) + \gamma B$ by Lemma 2.5(f). □

LEMMA 4.5. *Let*

$$T := \left(1 + \frac{b-a}{\beta}\right)\left(1 + \frac{81\gamma L_V}{\omega}\right).$$

Then $x(t) \in S(a) + \gamma B \quad \forall t \geq T$.

Proof. In view of Lemma 4.4, it suffices to prove that some node $\tau \in \pi$ with $\tau \leq T$ is such that $y(\tau) \in \Omega_{N+1}$. The argument is identical to that used to prove Lemma 2.9, with Δ replaced by $\tilde{\Delta}$ and applied to the y_i rather than the x_i. □

ASYMPTOTIC ALMOST SURE EFFICIENCY OF AVERAGED STOCHASTIC ALGORITHMS[*]

MARIANE PELLETIER[†]

Abstract. First, we define the notion of almost sure efficiency for a decreasing stepsize stochastic algorithm, and then we show that the averaging method, which gives asymptotically efficient algorithms, also gives asymptotically almost surely efficient algorithms. Moreover, we prove that the averaged algorithm also satisfies a law of the iterated logarithm, as well as an almost sure central limit theorem.

Key words. stochastic algorithms, central limit theorem, almost sure invariance principles

1. Introduction.

Many vectorial algorithms are written in the form

$$Z_{n+1} = Z_n + \gamma_n \left[F\left(Z_n, \eta_{n+1} \right) \right],$$

where the gain $(\gamma_n)_{n\geq 0}$ is a nonrandom sequence decreasing to 0 with $\sum \gamma_n = \infty$ and the observed quantity at time $n+1$ is $F(Z_n, \eta_{n+1})$, η_{n+1} being a stochastic disturbance. Such an algorithm is often studied when rewritten as an algorithm used for the search of zeros of a function h,

$$Z_{n+1} = Z_n + \gamma_n \left[h\left(Z_n \right) + e_{n+1} \right], \tag{1}$$

where (e_n) is a "small disturbance" and $h(Z_n)$ corresponds to a mean effect of $F(Z_n, \eta_{n+1})$, given the past. The classical Robbins–Monro algorithm is obtained when (η_n) is a sequence of independent identically distributed random variables and $h(z) = E[F(z, \eta)]$. Extensions to a Markovian disturbance (η_n) are developed in [1].

Throughout this paper, the algorithm (1) is considered in the following framework: (e_n) is a sequence of d-dimensional random vectors defined on a probability space $(\Omega, \mathcal{A}, P)$, adapted to a filtration $\mathcal{F} = (\mathcal{F}_n)_{n\geq 0}$, and Z_0 is $\mathcal{F}_0$-measurable. The function h is defined on $\mathbb{R}^d$ and $\mathbb{R}^d$-valued, and z^* is a zero of h such that, on a neighborhood of z^*,

$$h(z) = H\left(z - z^* \right) + O\left(\|z - z^*\|^a \right),$$

where $a > 1$ and H is a stable matrix (i.e., all the real parts of the eigenvalues of H are strictly negative).

Many criteria ensure the almost sure convergence or the convergence with a strictly positive probability of (Z_n) towards z^* (see among many others [1], [9], [12], and [18]). In order to ensure their applications to various cases, our results are conditional with respect to the event $\Gamma(z^*) = \{Z_n \to z^*\}$.

[†] Laboratoire de Mathematiques, Bâtiment Fermat, Université de Versailles Saint-Quentin, 45 Avenue des Etats-Unis, 78035 Versailles Cedex, France (pelletier@math.uvsq.fr).

It was proved, under some local assumptions stated in section 2, that if $P\left[\Gamma\left(z^*\right)\right]>0$, then the sequence (Z_n) satisfies a conditional central limit theorem (CLT):

$$\text{given } \Gamma\left(z^*\right), \ \Psi_n=\sqrt{\frac{1}{\gamma_n}}\left(Z_n-z^*\right) \overset{\mathcal{D}}{\to} \mathcal{N}(0, \Sigma), \tag{2}$$

with $\overset{\mathcal{D}}{\to}$ denoting the convergence in distribution, $\mathcal{N}$ denoting the Gaussian distribution, and Σ being a positive definite matrix (see, for instance, [1], [12], [18], [19] for the case $P\left[\Gamma\left(z^*\right)\right]=1$ and [9] or [20] for the case $P\left[\Gamma\left(z^*\right)\right]>0$). (Equation (2) means that the asymptotic conditional law of Ψ_n with respect to $\Gamma\left(z^*\right)$ is $\mathcal{N}(0, \Sigma)$.)

Moreover, the sequence (Z_n) is known to fulfill the three following almost sure properties ([21], [22]), where Σ is the limit covariance matrix of (2), δ_x denotes the point mass at x, and $\Longrightarrow$ is the weak convergence. (Throughout the paper, we say that a property $\mathcal{P}$ holds almost surely (a.s.) on $\Gamma\left(z^*\right)$ if there exists a subset $N \subset \Gamma\left(z^*\right)$ such that $P(N)=0$ and $\mathcal{P}$ holds $\forall \omega \in \Gamma\left(z^*\right) \setminus N$.)

- A quadratic strong law of large numbers:

$$\text{a.s. on } \Gamma\left(z^*\right), \ \lim_{n \to \infty} \frac{1}{\sum_{k=1}^n \gamma_k} \sum_{k=1}^n \left(Z_k-z^*\right)\left(Z_k-z^*\right)^T=\Sigma. \tag{3}$$

- A law of the iterated logarithm: for any eigenvector of H^T, $w \in \mathbb{R}^d$,

$$\text{a.s. on } \Gamma\left(z^*\right), \ \limsup_{n \to \infty} \frac{1}{2\gamma_n \ln\left(\sum_{k=1}^n \gamma_k\right)} w^T\left(Z_k-z^*\right)\left(Z_k-z^*\right)^T w=w^T \Sigma w. \tag{4}$$

- An almost sure central limit theorem (a.s.CLT):

$$\text{a.s. on } \Gamma\left(z^*\right), \ \frac{1}{\sum_{k=1}^n \gamma_k} \sum_{k=1}^n \gamma_k \delta_{\sqrt{\frac{1}{\gamma_k}}\left(Z_k-z^*\right)} \Longrightarrow \mathcal{N}(0, \Sigma), \tag{5}$$

i.e., there exists a P-null set $N \subset \Gamma\left(z^*\right)$ such that $\forall \omega \in \Gamma\left(z^*\right) \setminus N$,

$$\frac{1}{\sum_{k=1}^n \gamma_k} \sum_{k=1}^n \gamma_k \delta_{\sqrt{\frac{1}{\gamma_k}}\left(Z_k(\omega)-z^*\right)} \Longrightarrow \mathcal{N}(0, \Sigma).$$

The optimal weak convergence rate of (1) given $\Gamma\left(z^*\right)$ is reached when $\gamma_n=\gamma_0/n$ with $2L\gamma_0>1$ ($-L$ denoting the greatest real part of the eigenvalues of H), since (2) is then equivalent to

$$\text{Given } \Gamma\left(z^*\right), \ \sqrt{n}\left(Z_n-z^*\right) \overset{\mathcal{D}}{\to} \mathcal{N}\left(0, \gamma_0 \Sigma\right).$$

The question arises as to what the optimal covariance matrix is. For that, let us consider the following class of algorithms:

$$Z_{n+1}=Z_n+\frac{A}{n}\left[h\left(Z_n\right)+e_{n+1}\right], \tag{6}$$

where A is an invertible $d \times d$ matrix such that $AH+I/2$ is stable. For such algorithms (see [9]), it follows from (2) that

$$\text{Given } \Gamma\left(z^*\right), \ \sqrt{n}\left(Z_n-z^*\right) \overset{\mathcal{D}}{\to} \mathcal{N}\left(0, \Sigma(A)\right),$$

where $\Sigma(A)$ is the solution of the Lyapunov equation

$$\left[AH + \frac{I}{2}\right]\Sigma(A) + \Sigma(A)\left[H^T A^T + \frac{I}{2}\right] = -ACA^T,$$

with $C = \lim_{n\to+\infty} E\left(e_{n+1}e_{n+1}^T|\mathcal{F}_n\right)$ a.s. on $\Gamma(z^*)$. The optimal choice of the matrix A in (6) is $A = -H^{-1}$, which leads to $\Sigma(A) = H^{-1}C(H^{-1})^T$, since it minimizes the covariance $\Sigma(A)$ (with respect to the order of the symmetric matrices).

When A is replaced by H^{-1}, (6) is Newton's algorithm, which thus has an asymptotically optimal behavior in distribution. Unfortunately, it is often impossible to use this algorithm, the matrix H being generally unknown.

These considerations lead us to set the following definition.

DEFINITION 1. *If $(Y_n)_{n\geq 0}$ is given by a stochastic algorithm used for the search of zeros of a function h observable only together with a disturbance (e_n), h and (e_n) satisfying the assumptions previously given and y^* being a zero of h, we say that the algorithm is* asymptotically efficient given $\{Y_n \to y^*\}$ *if*

$$\text{Given } \{Y_n \to y^*\},\ \sqrt{n}\,(Y_n - y^*) \xrightarrow{\mathcal{D}} \mathcal{N}(0, H^{-1}C(H^{-1})^T).$$

The averaging method, simultaneously introduced by Polyak [23] and Ruppert [25], is known to give asymptotically efficient algorithms (see among others Delyon–Juditsky [5], [6], Dippon–Renz [7], Kushner–Yang [13], Polyak–Juditsky [24], and Yin [31]).

The averaged algorithm is built up in the following way; each iteration requires two steps.

Step 1. Z_{n+1} is found from the algorithm (1) where the gain γ_n is "slow;" typically

$$\gamma_n = \frac{\gamma_0}{n^\alpha},\ \frac{1}{2} < \alpha < 1.$$

Step 2. We compute the empirical mean of all the previous observations,

$$\overline{Z}_{n+1} = \frac{1}{n+1}\sum_{k=1}^{n+1} Z_k.$$

Note that $\overline{Z}_{n+1}$ can be recursively written as

$$\overline{Z}_{n+1} = \overline{Z}_n + \frac{1}{n+1}\left(Z_{n+1} - \overline{Z}_n\right).$$

The aim of this paper is to prove that, conditionally on the set of consistency $\Gamma(z^*)$, the averaged algorithm is not only asymptotically efficient, but that it also satisfies the almost sure properties (3), (4), and (5) with the optimal rate and the optimal covariance matrix Σ. Moreover, the law of the iterated logarithm (4) is obtained for any vector w (and not only for eigenvectors of H^T).

Before stating our main results, let us first introduce the almost sure version of the notion of asymptotic efficiency. When $\gamma_n = \gamma_0/n$ with $2L\gamma_0 > 1$, (3) is equivalent to

$$\text{a.s. on } \Gamma(z^*),\ \lim_{n\to\infty}\frac{1}{\ln n}\sum_{k=1}^{n}(Z_k - z^*)(Z_k - z^*)^T = \gamma_0\Sigma, \tag{7}$$

and, for slower gains $\gamma_n = \dfrac{\gamma_0}{n^\alpha}$, $\dfrac{1}{2} < \alpha < 1$, to

$$\text{a.s. on } \Gamma\left(z^*\right), \ \lim_{n\to\infty} \frac{1-\alpha}{n^{1-\alpha}} \sum_{k=1}^{n} \left(Z_k - z^*\right)\left(Z_k - z^*\right)^T = \gamma_0 \Sigma.$$

Thus, the sum of the "squared" differences between Z_k and the estimated parameter z^* is optimal when (7) is fulfilled with $\gamma_0\Sigma = H^{-1}C(H^{-1})^T$. By analogy with the definition of the asymptotic efficiency, and taking up the terminology introduced by Touati [28] for statistical problems, we introduce the following definition.

DEFINITION 2. *If (Y_n) is given by a stochastic algorithm used for the search of zeros of a function h observable only together with a disturbance (e_n), h and (e_n) satisfying the assumptions previously given and y^* being a zero of h, we say that the algorithm is* asymptotically almost surely efficient on $\{Y_n \to y^*\}$ *if*

$$\text{a.s. on } \left\{Y_n \to y^*\right\}, \ \lim_{n\to\infty} \frac{1}{\ln n} \sum_{k=1}^{n} \left(Y_k - y^*\right)\left(Y_k - y^*\right)^T = H^{-1}C(H^{-1})^T.$$

We shall prove that the averaged algorithm is a.s. efficient on $\Gamma\left(z^*\right)$, i.e., that

$$\text{a.s. on } \Gamma(z^*), \ \lim_{n\to\infty} \frac{1}{\ln n} \sum_{k=1}^{n} (\overline{Z}_k - z^*)(\overline{Z}_k - z^*)^T = H^{-1}C(H^{-1})^T.$$

We shall also show that the averaged algorithm fulfills the following law of the iterated logarithm,

$$\text{a.s. on } \Gamma\left(z^*\right), \ \forall w \in \mathbb{R}^d,$$

$$\limsup_{n\to\infty} \frac{n}{2\ln(\ln n)} w^T \big(\overline{Z}_n - z^*\big)\big(\overline{Z}_n - z^*\big)^T w = w^T H^{-1} C \big(H^{-1}\big)^T w,$$

and the following a.s.CLT:

$$\text{a.s. on } \Gamma\left(z^*\right), \ \frac{1}{\ln n} \sum_{k=1}^{n} \frac{1}{k} \delta_{\sqrt{k}(\overline{Z}_k - z^*)} \Longrightarrow \mathcal{N}(0, H^{-1}C(H^{-1})^T).$$

In fact, we shall extend our framework and study the more general algorithm (including the Kiefer–Wolfowitz algorithm [9])

$$Z_{n+1} = Z_n + \gamma_n \left[h\left(Z_n\right) + r_{n+1}\right] + \sigma_n \varepsilon_{n+1}, \tag{8}$$

where (ε_n) is a noise (i.e., a sequence of martingale increments), (r_n) a residual term, and (σ_n) a nonrandom sequence decreasing to 0 such that $\gamma_n = O\left(\sigma_n\right)$; the algorithm (1) corresponds then to the particular case $\gamma_n = \sigma_n$ and $e_n = r_n + \varepsilon_n$.

Our results are precisely stated in section 2. In section 3, we give an application to efficient recursive estimators. Finally, section 4 is devoted to the proofs.

2. Assumptions and main results. We first precise the required assumptions on (8).

Assumption (A1) *about the function h*: There exist $a > 1$, a stable matrix H, and a neighborhood $\mathcal{U}$ of z^*, such that for any z in $\mathcal{U}$,

$$h(z) = H\left(z - z^*\right) + O\left(\|z - z^*\|^a\right).$$

Assumption (A2) *about the noise* (ε_n):

(i) There exist $M > 0$ and $b > 2$ such that a.s.

$$E\left(\varepsilon_{n+1}|\mathcal{F}_n\right) 1_{\{\|Z_n - z^*\| \le M\}} = 0 \quad \text{and} \quad \sup_{n \ge 0} E(\|\varepsilon_{n+1}\|^b|\mathcal{F}_n) 1_{\{\|Z_n - z^*\| \le M\}} < \infty.$$

(ii) There exists a nonrandom symmetric positive definite matrix C such that $\lim_{n\to\infty} C_n = C$ a.s. on $\Gamma(z^*)$, where $C_n = E\left(\varepsilon_{n+1}\varepsilon_{n+1}^T|\mathcal{F}_n\right)$.

Assumption (A3) *about the gains:* There exist two decreasing positive functions γ and σ, defined over $[0, +\infty[$ such that $\gamma_n = \gamma(n)$ and $\sigma_n = \sigma(n)$ $\forall$ integer n. We define the function v by $v(t) = \gamma(t)/\sigma^2(t)$ and assume there exist two positive real numbers α and β such that the following conditions are fulfilled.

(i) v is a differentiable increasing function, $v(\infty) = \infty$, and its differential v' varies regularly with exponent $(\beta - 1)$ (i.e., $\lim_{t\to\infty} v'(tx)/v'(t) = x^{\beta-1}$; see [11] or [26]).

(ii) γ is differentiable, varies regularly with exponent $(-\alpha)$, and $\theta = (1/\gamma)'$ is decreasing and varies regularly with exponent $(\alpha - 1)$.

(iii) One of the two following conditions (A3.a) or (A3.b) holds.
(A3.a) $\min\{\frac{1}{2}, \frac{2}{b}\} < \alpha < 1$ and $\frac{1-\alpha}{a-1} < \beta \le 1$,
(A3.b) $\frac{1}{2} < \alpha < 1$ and $\frac{1-\alpha}{a-1}(1 + \frac{2a}{b}) < \beta \le 1$.

Assumption (A4) *about the residual term* (r_n): We set

$$J(t) = \int_0^t \frac{1}{\gamma(s)v(s)} ds, \tag{9}$$

and assume $r_{n+1} = r_{n+1}^{(1)} + r_{n+1}^{(2)}$ with

(i) $r_{n+1}^{(2)} = O\left(\|Z_n - z^*\|^a\right)$ a.s.,

(ii) the weak assumption (A4.w) or the stronger one (A4.s) is fulfilled:
(A4.w) There exists $M > 0$ such that

$$\|r_{n+1}^{(1)}\| 1_{\{\|Z_n - z^*\| \le M\}} = O([\sqrt{J(n)}\gamma_n v(n)]^{-1})$$

a.s.;

(A4.s) There exist $M > 0$ and $\rho > \frac{1}{2}(1+\beta-\alpha)$ such that $\|r_{n+1}^{(1)}\| 1_{\{\|Z_n - z^*\| \le M\}} = O\left(n^{-\rho}\right)$ a.s.

Comments on the assumptions.

(a) Our assumptions are *local*. Thus, the results stated below can be applied as soon as $P\left[\Gamma(z^*)\right] > 0$, whatever the behavior of (Z_n) outside of $\Gamma(z^*)$ may be. In particular, they apply to algorithms obtained by projection or truncation in the framework of [3] or [12].

(b) Since the function $s \mapsto \sqrt{J(s)}\gamma(s)v(s)$ varies regularly with exponent $(1 + \beta - \alpha)/2$, assumption (A4.s) implies (A4.w).

(c) Assumptions (A2) about the noise and (A4) about the residual term can be applied to Markovian disturbances in the framework of [1], whose application to the averaged method is precised in [6].

(d) When the conditional moment of order 4 of the noise (ε_n) is bounded (i.e., when $b \ge 4$), assumption (A3)(iii) reduces to

$$\frac{1}{2} < \alpha < 1 \quad \text{and} \quad \frac{1-\alpha}{a-1} < \beta \le 1;$$

thus, the condition (A3.b) is useful only in the case $2 < b < 4$.

(e) In most cases, the function h is regular enough so that assumption (A1) holds with $a = 2$. In this case, assumption (A3) is fulfilled, for instance, by the gains

$$\begin{cases} \gamma_n = \dfrac{\gamma_0}{n^\alpha},\ \sigma_n = \dfrac{\sigma_0}{\sqrt{n^{\alpha+\beta}}}\ (\gamma_0 > 0,\ \sigma_0 > 0), \\ \text{with } \dfrac{2}{3} \leq \alpha < 1 \text{ and } 3(1-\alpha) \leq \beta \leq 1. \end{cases}$$

For these gains, we have

$$v(n) = \frac{\gamma_0 n^\beta}{\sigma_0^2},\quad J(n) = \frac{\sigma_0^2 n^{1+\alpha-\beta}}{\gamma_0^2(1+\alpha-\beta)},$$

and assumption (A4.w) can be rewritten as:

$$\text{there exists } M > 0 \text{ such that } \|r_{n+1}^{(1)}\| 1_{\{\|Z_n - z^*\| \leq M\}} = O(\sqrt{n^{1-\alpha+\beta}}) \text{ a.s.}$$

The Robbins–Monro algorithm is given by (8) with $\gamma_n = \sigma_n$ and $r_n = 0$; we have then $\beta = \alpha$, $J(n) = n$, and, if (A1) holds with $a = 2$, assumptions (A3) and (A4) are fulfilled, for instance, by the gains

$$\gamma_n = \sigma_n = \frac{\gamma_0}{n^\alpha}\quad (\gamma_0 > 0)\quad \text{with } \frac{3}{4} \leq \alpha < 1.$$

The Kiefer–Wolfowitz algorithm corresponds to the case $h = -\nabla V$, where the function V is observable only together with a noise. This algorithm can be written as (8) with $\gamma_n = \dfrac{\gamma_0}{n^\alpha}$ ($\gamma_0 > 0$), $1/2 < \alpha \leq 1$, and $\sigma_n = n^\tau \gamma_n$, $0 < \tau < \alpha/2$. We have then $\beta = \alpha - 2\tau$ and $J(n) = n^{1+2\tau}/(1+2\tau)$. Since $(n^{2\tau} r_{n+1})$ is known to converge a.s. on $\Gamma(z^*)$ toward a deterministic, usually nonzero constant, assumption (A4.w) (respectively, (A4.s)) requires $1/6 \leq \tau < \alpha/2$ (respectively, $1/6 < \tau < \alpha/2$). Consequently, if (A1) holds with $a = 2$, our assumptions (A3) and (A4) are fulfilled by the gains

$$\begin{cases} \gamma_n = \dfrac{\gamma_0}{n^\alpha},\ \sigma_n = n^\tau \gamma_n, \\ \text{with } \gamma_0 > 0,\ \dfrac{3}{4} + \dfrac{\tau}{2} \leq \alpha < 1, \text{ and} \begin{cases} \dfrac{1}{6} \leq \tau < \dfrac{\alpha}{2} & \text{for (A4.w)}, \\ \dfrac{1}{6} < \tau < \dfrac{\alpha}{2} & \text{for (A4.s)}. \end{cases} \end{cases} \tag{10}$$

Our first main result is the following quadratic strong law of large numbers.

THEOREM 3 (quadratic strong law of large numbers). *Assume* (A1), (A2), (A3), *and* (A4.s) *hold. Then, a.s. on* $\Gamma(z^*)$,

$$\lim_{n\to\infty} \frac{1}{\ln n} \sum_{k=1}^{n} k[J(k)]^{-1} \left(\overline{Z}_k - z^*\right) \left(\overline{Z}_k - z^*\right)^T = H^{-1} C \left(H^{-1}\right)^T.$$

COROLLARY 4 (almost sure efficiency). *Assume that* (A1), (A2), (A3), *and* (A4.s) *hold and that* $\gamma_n = \sigma_n$. *Then, a.s. on* $\Gamma(z^*)$,

$$\lim_{n\to\infty} \frac{1}{\ln n} \sum_{k=1}^{n} \left(\overline{Z}_k - z^*\right) \left(\overline{Z}_k - z^*\right)^T = H^{-1} C \left(H^{-1}\right)^T$$

and the almost sure asymptotic efficiency is obtained.

Remarks and examples.

(a) Under the assumptions of Theorem 3, Duflo [9] proved the following conditional CLT:

$$\text{given } \Gamma(z^*), \; Y_n = n[J(n)]^{-1/2}\left(\overline{Z}_n - z^*\right) \xrightarrow{\mathcal{D}} \mathcal{N}(0, H^{-1}C(H^{-1})^T). \tag{11}$$

Moreover, the quadratic strong law of large numbers can clearly be rewritten as:

$$\text{a.s. on } \Gamma(z^*),$$

$$\lim_{n\to\infty} \frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\left[k[J(k)]^{-1/2}(\overline{Z}_k - z^*)\right]\left[k[J(k)]^{-1/2}(\overline{Z}_k - z^*)\right]^T = H^{-1}C\big(H^{-1}\big)^T.$$

Thus, the quadratic strong law of large numbers ensures that the logarithmic average of the $Y_k Y_k^T$ converges a.s. toward the covariance matrix of the asymptotic distribution of (11).

(b) The averaged Robbins–Monro algorithm is asymptotically a.s. efficient on $\Gamma(z^*)$.

(c) In the case of the Kiefer–Wolfowitz algorithm, assumption (A4.s) requires that the parameter τ in (10) satisfies $\tau > 1/6$, and we then have

$$\text{a.s. on } \Gamma(z^*), \; \lim_{n\to\infty}\frac{1+2\tau}{\ln n}\sum_{k=1}^{n}\frac{1}{k^{2\tau}}\left(\overline{Z}_k - z^*\right)\left(\overline{Z}_k - z^*\right)^T = H^{-1}C\big(H^{-1}\big)^T.$$

However, we failed in proving a quadratic strong law of large numbers when $\tau = 1/6$. In view of remark (a), it is not surprising since, in this case, $n[J(n)]^{-1/2}\left(\overline{Z}_n - z^*\right)$ is known to converge weakly to a $\mathcal{N}(m, H^{-1}C(H^{-1})^T)$ distribution, where m is a deterministic, usually nonzero constant.

The following corollary gives an estimator of the asymptotic covariance matrix $H^{-1}C\big(H^{-1}\big)^T$, $\overline{Z}_n$ standing for z^* in Theorem 3.

COROLLARY 5 (strongly consistent estimator of the asymptotic covariance). *Set*

$$\widehat{\Sigma}_n = \frac{1}{\ln n}\sum_{k=1}^{n} k[J(k)]^{-1}\left(\overline{Z}_k - \overline{Z}_n\right)\left(\overline{Z}_k - \overline{Z}_n\right)^T.$$

Under assumptions (A1), (A2), (A3), *and* (A4.s), $\widehat{\Sigma}_n$ *is a strongly consistent estimator of* $H^{-1}C\big(H^{-1}\big)^T$ *on* $\Gamma(z^*)$.

Remark. The combination of (11) and Corollary 5 implies the following conditional CLT:

$$\text{given } \Gamma(z^*), \; n[J(n)]^{-1/2}\widehat{\Sigma}_n^{-1/2}\left(\overline{Z}_n - z^*\right) \xrightarrow{\mathcal{D}} \mathcal{N}(0, I),$$

which permits the construction of confidence regions for z^*.

Our second main result is the following law of the iterated logarithm.

THEOREM 6 (law of the iterated logarithm). *Assume* (A1), (A2), (A3), *and* (A4.w) *hold. Then, for any vector* u *of* $\mathbb{R}^d$, *we have, a.s. on* $\Gamma(z^*)$,

$$\begin{aligned}\limsup_{n\to\infty}\frac{n}{\sqrt{2J(n)\ln(\ln n)}}u^T\left(\overline{Z}_n - z^*\right) &= -\liminf_{n\to\infty}\frac{n}{\sqrt{2J(n)\ln(\ln n)}}u^T\left(\overline{Z}_n - z^*\right)\\ &= \sqrt{u^T H^{-1}C(H^{-1})^T u}.\end{aligned}$$

Moreover, we have, a.s. on $\Gamma(z^*)$,

(12)
$$\forall u \in \mathbb{R}^d, \limsup_{n\to\infty} \frac{n^2}{2J(n)\ln(\ln n)} u^T\left(\overline{Z}_n - z^*\right)\left(\overline{Z}_n - z^*\right)^T u = u^T H^{-1}C\left(H^{-1}\right)^T u.$$

Remarks.

(a) Referring to the order of the symmetric matrices, property (12) can be written as:

$$\text{a.s. on } \Gamma(z^*),\ \limsup_{n\to\infty} \frac{n^2}{2J(n)\ln(\ln n)}\left(\overline{Z}_n - z^*\right)\left(\overline{Z}_n - z^*\right)^T = H^{-1}C\left(H^{-1}\right)^T.$$

(b) When $\gamma_n = \sigma_n$ (in particular, for the Robbins–Monro algorithm), we obtain

$$\text{a.s. on } \Gamma(z^*),\ \limsup_{n\to\infty} \frac{n}{2\ln(\ln n)}\left(\overline{Z}_n - z^*\right)\left(\overline{Z}_n - z^*\right)^T = H^{-1}C\left(H^{-1}\right)^T.$$

We see again that the asymptotic almost sure convergence rate of the averaged algorithm is optimal since the rate $(2\ln(\ln n))/n$ is known to be optimal and the limit covariance matrix $H^{-1}C\left(H^{-1}\right)^T$ is the smallest one (with respect to the order of the symmetric matrices).

(c) In the case of the Kiefer–Wolfowitz algorithm, we have

$$\text{a.s. on } \Gamma(z^*),\ \limsup_{n\to\infty} \frac{(1+2\tau)n^{1-2\tau}}{2\ln(\ln n)}\left(\overline{Z}_n - z^*\right)\left(\overline{Z}_n - z^*\right)^T = H^{-1}C\left(H^{-1}\right)^T$$

for any τ satisfying (10), and here we can choose $\tau = 1/6$, which ensures the optimal convergence rate of the averaged Kiefer–Wolfowitz algorithm.

(d) Theorems 3 and 6 extend previous results of Le Breton [15] and Le Breton and Novikov [16], [17]. They obtained Theorem 3 under the restriction that h is linear; under the same restriction, they obtained Theorem 6 in the unidimensional case ($d = 1$), whereas they obtained only an upper bound of $\left(\overline{Z}_n - z^*\right)$ when $d > 1$.

Our last main result is the following a.s.CLT.

THEOREM 7 (a.s.CLT). *Assume* (A1), (A2), (A3), *and* (A4.s) *hold. Then, a.s. on* $\Gamma(z^*)$,

$$\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\delta_{k[J(k)]^{-1/2}\left(\overline{Z}_k - z^*\right)} \Longrightarrow \mathcal{N}(0, H^{-1}C(H^{-1})^T).$$

The following corollary is a straightforward consequence of Theorems 3 and 7.

COROLLARY 8 (logarithmic strong law of large numbers). *Assume* (A1), (A2), (A3), *and* (A4.s) *hold. Let* $\phi : \mathbb{R}^d \to \mathbb{R}$ *be an almost everywhere continuous function such that, for a positive constant* K, $|\phi(x)| \le K(1 + \|x\|^2)$. *Then, a.s. on* $\Gamma(z^*)$,

$$\lim_{n\to\infty}\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\phi\left[k[J(k)]^{-1/2}\left(Z_k - z^*\right)\right] = \int \phi(x)dF(x),$$

where F *is the* $\mathcal{N}(0, H^{-1}C(H^{-1})^T)$ *distribution.*

3. Application to efficient recursive estimation. Let (Y_k) be a sequence of independent identically distributed random vectors absolutely continuous with respect to some positive σ-finite measure λ. Let us denote by $f(\theta, .)$ the probability density of Y_k, where $\theta \in \Theta$, Θ is an open subset of $\mathbb{R}^d$, and assume this statistical model to be regular [4].

According to the classical asymptotic theory, the maximum likelihood estimator θ_n^*, which maximizes the likelihood of the sample $(Y_1, \dots, Y_n)$, is strongly consistent and asymptotically efficient, i.e.,

$$\theta_n^* \to \theta \text{ a.s. and } \sqrt{n}\,(\theta_n^* - \theta) \xrightarrow{\mathcal{D}} \mathcal{N}(0, [I(\theta)]^{-1}),$$

where $I(\theta) = E_\theta([\nabla \ln f(\theta, Y_k)]\,[\nabla \ln f(\theta, Y_k)]^T)$ is the Fisher information of the model. Touati [28] proved that θ_n^* is also a.s. asymptotically efficient, i.e.,

$$\frac{1}{\ln n} \sum_{k=1}^{n} (\theta_k^* - \theta)\,(\theta_k^* - \theta)^T \overset{\text{a.s.}}{\to} [I(\theta)]^{-1}.$$

However, the explicit computation of the maximum likelihood estimator is often impossible or very complicated and some approximation procedure is then necessary. For instance, Newton's recursive estimator is given by

$$\widehat{\theta}_{n+1}^* = \widehat{\theta}_n^* + \frac{\left[I(\widehat{\theta}_n^*)\right]^{-1}}{n} \nabla(\ln f(\widehat{\theta}_n^*, Y_{n+1})), \tag{13}$$

i.e.,

$$\widehat{\theta}_{n+1}^* = \widehat{\theta}_n^* + \frac{1}{n}\left[h(\widehat{\theta}_n^*) + \varepsilon_{n+1}\right],$$

where $h(t) = [I(t)]^{-1} \int \nabla\,(\ln f\,(t, x))\, dF_\theta(x)$.

Let us assume that there exists a constant $b > 2$ such that the function

$$t \mapsto \int \|\nabla(\ln f(t, x))\|^b dF_\theta(x)$$

exists and is bounded in the neighborhood of θ for each $\theta \in \Theta$.

It follows from a straightforward application of (2) and (3) (see [9, p. 168]) that

$$\text{given } \{\widehat{\theta}_n^* \to \theta\},\ \sqrt{n}(\widehat{\theta}_n^* - \theta) \xrightarrow{\mathcal{D}} \mathcal{N}(0, [I(\theta)]^{-1}),$$

and

$$\text{a.s. on } \{\widehat{\theta}_n^* \to \theta\},\ \frac{1}{\ln n} \sum_{k=1}^{n} (\widehat{\theta}_k^* - \theta)(\widehat{\theta}_k^* - \theta)^T \to [I(\theta)]^{-1}.$$

Thus, as soon as Newton's estimater is strongly consistent, it is also asymptotically efficient and a.s. asymptotically efficient.

However, the algorithm (13) requires at each step the computation of the inverse of the Fisher information matrix $[I(.)]^{-1}$. The use of an averaged algorithm does not require such a computation; for that, we proceed as follows. We determine $(\widehat{\theta}_n^*)$ from the gradient algorithm

$$\widehat{\theta}_{n+1}^* = \widehat{\theta}_n^* + \frac{1}{n^\alpha} \nabla(\ln f(\widehat{\theta}_n^*, Y_{n+1})), \quad \frac{3}{4} \leq \alpha < 1,$$

and we compute the empirical mean $\overline{\theta}_n^* = \frac{1}{n}\sum_{k=1}^n \widehat{\theta}_k^*$. It follows from a straightforward application of (11) and Theorem 3 that $\overline{\theta}_n^*$ has the same asymptotic properties as the $\widehat{\theta}_n^*$ given by (13); more precisely, given the event $\{\widehat{\theta}_n^* \to \theta\}$, $\overline{\theta}_n^*$ is a strongly consistent estimator, asymptotically efficient and a.s. asymptotically efficient. Moreover, applying Theorems 6 and 7, we also have

$$\text{a.s. on } \{\widehat{\theta}_n^* \to \theta\},\ \limsup_{n\to\infty} \frac{n}{2\ln(\ln n)} (\overline{\theta}_n^* - \theta)(\overline{\theta}_n^* - \theta)^T = [I(\theta)]^{-1}$$

and

$$\text{a.s. on } \{\widehat{\theta}_n^* \to \theta\},\ \frac{1}{\ln n}\sum_{k=1}^n \frac{1}{k}\delta_{\sqrt{k}(\overline{\theta}_k^* - \theta)} \Longrightarrow \mathcal{N}(0, [I(\theta)]^{-1}).$$

4. Proofs. In view of assumptions (A1) and (A4), the algorithm (8) can be rewritten as

$$Z_{n+1} = Z_n + \gamma_n H(Z_n - z^*) + \gamma_n r_{n+1} + \sigma_n \varepsilon_{n+1},$$

and we have

$$H(Z_n - z^*) = \frac{1}{\gamma_n}[(Z_{n+1} - z^*) - (Z_n - z^*)] - r_{n+1} - \frac{\sigma_n}{\gamma_n}\varepsilon_{n+1}.$$

Let us define the sequences (T_n), $(\overline{T}_n)$, (M_n), and (K_n) by

$$T_n = Z_n - z^*,\ \overline{T}_n = \frac{1}{n}\sum_{k=1}^n T_k,\ M_{n+1} = \sum_{k=1}^n \frac{\sigma_k}{\gamma_k}\varepsilon_{k+1},$$

$$K_n = -\frac{T_1}{\gamma_1} + \frac{T_{n+1}}{\gamma_n} - \sum_{k=2}^n T_k\left[\frac{1}{\gamma_k} - \frac{1}{\gamma_{k-1}}\right].$$

Then we have

$$nH\overline{T}_n = K_n - M_{n+1} - \sum_{k=1}^n r_{k+1}. \tag{14}$$

The proofs of the results stated in section 2 are constructed in the following way. First we establish the almost sure asymptotic properties (a quadratic strong law of large numbers, a law of the iterated logarithm, and an a.s.CLT) of the sequence (M_n). Then we show that (K_n) and $(\sum_{k=1}^n r_{k+1})$ are small enough on $\Gamma(z^*)$ so that the properties obtained for (M_n) are also satisfied by the sequence $\big(nH\overline{T}_n\big)$.

Let us first show how we can strengthen assumptions (A2) and (A4.w).

Note that in order to establish an almost sure property on $\Gamma(z^*)$, it is sufficient to prove it a.s. on $\Gamma_N = \Gamma(z^*) \cap \{\sup_{n\geq N}\|Z_n - z^*\| \leq M\}$ for any N such that $P(\Gamma_N) \neq 0$.

Let $\Gamma_{N,K}$ be the set of the trajectories of Γ_N such that, for a positive integer K,

$$\sup_{n\geq N} E(\|\varepsilon_{n+1}\|^b|\mathcal{F}_n) \leq K \text{ and } \sup_{n\geq N}(\sqrt{J(n)}\gamma_n v(n)\|r_{n+1}^{(1)}\|) \leq K.$$

Since Γ_N equals $\cup_K \Gamma_{N,K}$ up to a negligible set, it is sufficient to establish a property a.s. on $\Gamma_{N,K}$ for each K such that $P\left(\Gamma_{N,K}\right) \neq 0$, in order to prove it on Γ_N.

According to a technique often used by Lai and Wei (see [14], for instance), we modify the algorithm (8), without changing it on $\Gamma_{N,K}$, in order to have, a.s. on *the whole set* Ω,

(15)

$$E\left(\varepsilon_{n+1}|\mathcal{F}_n\right) = 0,\ \sup_{n\geq N} E(\|\varepsilon_{n+1}\|^b|\mathcal{F}_n) \leq K,\ \text{and}\ \sup_{n\geq N}(\sqrt{J(n)}\gamma_n v(n)\|r^{(1)}_{n+1}\|) \leq K.$$

To this end, we replace $r^{(1)}_{n+1}$ by $\widetilde{r}^{(1)}_{n+1} = r^{(1)}_{n+1}.1_{\sqrt{J(n)}\gamma_n v(n)\left\|r^{(1)}_{n+1}\right\|\leq K}$ and ε_{n+1} by $\widetilde{\varepsilon}_{n+1} = \varepsilon_{n+1}1_{B_n}$ with

$$B_n = \{E(\varepsilon_{n+1}|\mathcal{F}_n) = 0 \text{ and } E(\|\varepsilon_{n+1}\|^b|\mathcal{F}_n) \leq K\}.$$

From now on, we shall assume that these modifications have been made. Moreover, substituting (Z_n) for $(Z'_n) = (Z_{n+N})$, we shall assume that (15) is fulfilled with $N = 0$, i.e., that the following condition holds: there exists $K > 0$ such that, a.s. on Ω,

$$E\left(\varepsilon_{n+1}|\mathcal{F}_n\right) = 0,\ \sup_{n\geq 0} E(\|\varepsilon_{n+1}\|^b|\mathcal{F}_n) \leq K,\ \text{and}\ \sup_{n\geq 0}(\sqrt{J(n)}\gamma_n v(n)\|r^{(1)}_{n+1}\|) \leq K.$$

In the same way, we strengthen assumption (A4.s) and assume that there exists $\rho > (1-\alpha+\beta)/2$ such that $\sup_{n\geq 0}(n^\rho\|r^{(1)}_{n+1}\|) \leq K$ a.s. on Ω.

We now state the three lemmas, which give the almost sure properties of the square-integrable martingale (M_n); Lemmas 9 and 10 give, respectively, a law of the iterated logarithm and a quadratic strong law of large numbers for (M_n), whereas Lemma 11 establishes an a.s.CLT for the unidimensional sequence $\left(u^T M_n\right)$ for any vector u of $\mathbb{R}^d$.

Lemma 9 (law of the iterated logarithm for (M_n)). *Assume* (A2) *and* (A3). *Then, for any vector* $u \in \mathbb{R}^d$,

$$\limsup_{n\to\infty}\left[2J(n)\ln(\ln n)\right]^{-1/2} u^T M_n = -\liminf_{n\to\infty}\left[2J(n)\ln(\ln n)\right]^{-1/2} u^T M_n = \sqrt{u^T C u}\ a.s.$$

In particular, $\|M_n\|^2 = O\left(J(n)\ln(\ln n)\right)$ *a.s.*

Lemma 10 (quadratic strong law of large numbers for (M_n)). *Assume* (A2) *and* (A3). *Then,*

$$\lim_{n\to\infty}\frac{1}{\ln n}\sum_{k=1}^{n}[kJ(k)]^{-1}M_k M_k^T = C\ a.s.$$

Lemma 11 (a.s.CLT for $(u^T M_n)$). *Assume* (A2) *and* (A3). *Then, for any vector* $u \in \mathbb{R}^d$,

$$\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\delta_{[J(k)]^{-1/2}u^T M_k} \Longrightarrow \mathcal{N}\left(0, u^T C u\right)\ a.s.$$

Our proofs are now organized as follows. First, we show in section 4.1 how Theorems 3, 6, and 7 can be deduced from Lemmas 9, 10, and 11. Then, Corollary 5 is established in section 4.2. Finally, section 4.3 is devoted to the proofs of Lemmas 9, 10, and 11.

Throughout the proofs, $\mathcal{L}$ denotes a generic, increasing, and slowly varying function.

4.1. Proof of Theorems 3, 6, and 7. In the case assumptions (A2) and (A3.b) hold, we have $\frac{1}{b} < \min\{\frac{1}{2}\ ;\ \frac{1}{2a}[\frac{(a-1)\beta}{1-\alpha} - 1]\}$; throughout this subsection, we then set δ such that

$$\frac{1}{b} < \delta < \min\left\{\frac{1}{2}\ ;\ \frac{1}{2a}\left[\frac{(a-1)\beta}{1-\alpha} - 1\right]\right\}. \tag{16}$$

4.1.1. Preliminaries. In this subsection, we establish two lemmas we shall use in the proofs of Theorems 3, 6, and 7.

LEMMA 12. *Assume* (A1), (A2), *and* (A4.w) *hold. Then, we have, a.s. on* $\Gamma(z^*)$,

(i) *under* (A3.a), $\|K_n\| = O[(1 + n^{\alpha - \frac{\beta}{2}})\mathcal{L}(n)]$ *and*

$$\sum_{k=1}^{n} \|r_{k+1}^{(2)}\| = O\big[(1 + n^{1-\frac{a\beta}{2}})\mathcal{L}(n)\big],$$

(ii) *under* (A3.b), $\|K_n\| = O[(1 + n^{\delta(1-\alpha)-\frac{\beta}{2}+\alpha})\mathcal{L}(n)]$ and $\sum_{k=1}^{n} \|r_{k+1}^{(2)}\| = O[(1 + n^{1+\frac{a}{2}[2\delta(1-\alpha)-\beta]})\mathcal{L}(n)]$, *where* δ *is given by* (16).

Proof of Lemma 12. In view of assumption (A3)(ii), we have

$$\|K_n\| = O\left[1 + \frac{\|T_{n+1}\|}{\gamma_n} + \sum_{k=2}^{n} \|T_k\|\,\theta(k)\right]$$

with $\theta = (1/\gamma)'$. Let us apply the following result proved in [21].

RESULT 1 (almost sure upper bounds of $(Z_n - z^*)$ on $\Gamma(z^*)$). *Assume* (A1), (A2), *and* (A4.w) *hold. Then, we have*

(i) *under* (A3.a), $\|Z_n - z^*\| = O([v(n)]^{-1/2}[\ln(\sum_{k=1}^{n}\gamma_k)]^{1/2})$ *a.s. on* $\Gamma(z^*)$,

(ii) *under* (A3.b), *for any* ζ *such that* $\zeta > \frac{1}{b}$, $\|Z_n - z^*\| = O([v(n)]^{-1/2}(\sum_{k=1}^{n}\gamma_k)^{\zeta})$ *a.s. on* $\Gamma(z^*)$.

It follows that, under assumption (A3.a), we have

$$\begin{aligned}\|K_n\| &= O\left[1 + \frac{[\ln(\sum_{k=1}^{n+1}\gamma_k)]^{1/2}}{\gamma_n\sqrt{v(n+1)}} + \sum_{k=2}^{n}\frac{[\ln(\sum_{k=1}^{n}\gamma_k)]^{1/2}\theta(k)}{\sqrt{v(k)}}\right] \\ &= O\big[(1 + n^{\alpha-\frac{\beta}{2}})\mathcal{L}(n)\big] \text{ a.s. on } \Gamma(z^*)\end{aligned}$$

and, under assumption (A3.b),

$$\begin{aligned}\|K_n\| &= O\left[1 + \frac{(\sum_{k=1}^{n+1}\gamma_k)^{\delta}}{\gamma_n\sqrt{v(n+1)}} + \sum_{k=2}^{n}\frac{(\sum_{j=1}^{k}\gamma_j)^{\delta}\theta(k)}{\sqrt{v(k)}}\right] \\ &= O\big[(1 + n^{\delta(1-\alpha)+\alpha-\frac{\beta}{2}})\mathcal{L}(n)\big] \text{ a.s. on } \Gamma(z^*).\end{aligned}$$

On the other hand, since $\|r_{k+1}^{(2)}\| = O(\|Z_k - z^*\|^{a})$, we deduce from Result 1 that, under assumption (A3.a),

$$\begin{aligned}\sum_{k=1}^{n}\|r_{k+1}^{(2)}\| &= O\left[\sum_{k=1}^{n}([\ln(\textstyle\sum_{j=1}^{k}\gamma_j)]^{a/2}[v(k)]^{-a/2})\right] \\ &= O[(1 + n^{1-\frac{a\beta}{2}})\mathcal{L}(n)] \text{ a.s. on } \Gamma(z^*)\end{aligned}$$

and, under assumption (A3.b),

$$\begin{aligned}\sum_{k=1}^{n} \|r_{k+1}^{(2)}\| &= O\left[\sum_{k=1}^{n} ([\textstyle\sum_{j=1}^{k} \gamma_j]^{a\delta} [v(k)]^{-a/2})\right] \\ &= O[(1 + n^{1+\frac{a}{2}[2\delta(1-\alpha)-\beta]})\mathcal{L}(n)] \text{ a.s. on } \Gamma(z^*),\end{aligned}$$

which concludes the proof of Lemma 12.

LEMMA 13. *Assume* (A1), (A2), *and* (A3) *hold. Then,*

(i) *under* (A4.w), *we have* $[J(n)]^{-1/2} (\|K_n\| + \sum_{k=1}^{n} \|r_{k+1}\|) = O(1)$ *a.s. on* $\Gamma(z^*)$,

(ii) *under* (A4.s), *there exists* $c > 0$ *such that* $[J(n)]^{-1/2} (\|K_n\| + \sum_{k=1}^{n} \|r_{k+1}\|) = O(n^{-c})$ *a.s. on* $\Gamma(z^*)$.

Proof of Lemma 13. The application of Lemma 12 leads to the following almost sure upper bounds on $\Gamma(z^*)$:

Sequence	Under assumption (A3.a)
$[J(n)]^{-1/2} \|K_n\|$ $[J(n)]^{-1/2} \sum_{k=1}^{n} \|r_{k+1}^{(2)}\|$	$O[(n^{-\frac{1}{2}(1-\beta+\alpha)} + n^{-\frac{1}{2}(1-\alpha)})\mathcal{L}(n)]$ $O[(n^{-\frac{1}{2}(1-\beta+\alpha)} + n^{\frac{1}{2}[(1-\alpha)-(a-1)\beta]})\mathcal{L}(n)]$
Sequence	Under assumption (A3.b)
$[J(n)]^{-1/2} \|K_n\|$ $[J(n)]^{-1/2} \sum_{k=1}^{n} \|r_{k+1}^{(2)}\|$	$O[(n^{-\frac{1}{2}(1-\beta+\alpha)} + n^{(\delta-\frac{1}{2})(1-\alpha)})\mathcal{L}(n)]$ $O[(n^{-\frac{1}{2}(1-\beta+\alpha)} + n^{\frac{1}{2}[(1+2a\delta)(1-\alpha)-(a-1)\beta]})\mathcal{L}(n)]$

.

Since all the exponents are strictly negative, there exists $c_1 > 0$ such that

$$[J(n)]^{-1/2} \left(\|K_n\| + \sum_{k=1}^{n} \|r_{k+1}^{(2)}\|\right) = O(n^{-c_1}) \text{ a.s. on } \Gamma(z^*). \tag{17}$$

Now, under assumption (A4.w), we have

$$[J(n)]^{-1/2} \sum_{k=1}^{n} \|r_{k+1}^{(1)}\| = O\left([J(n)]^{-1/2} \sum_{k=1}^{n} \left[\sqrt{J(k)}\gamma_k v(k)\right]^{-1}\right) \quad \text{a.s. on } \Gamma(z^*).$$

Since the function $s \mapsto [\sqrt{J(s)}\gamma(s)v(s)]^{-1}$ varies regularly with exponent $-(1-\alpha+\beta)/2 > -1$, we have [11, p. 281]

$$\lim_{t\to\infty} \frac{t\left[\sqrt{J(t)}\gamma(t)v(t)\right]^{-1}}{\int_0^t \left[\sqrt{J(s)}\gamma(s)v(s)\right]^{-1}} = \frac{1}{2}[(1-\beta)+\alpha], \quad \frac{1}{2}[(1-\beta)+\alpha] \neq 0.$$

It follows that

$$\sum_{k=1}^{n} \left[\sqrt{J(k)}\gamma_k v(k)\right]^{-1} = O\left(n\left[\sqrt{J(n)}\gamma_n v(n)\right]^{-1}\right)$$

$$\text{and } [J(n)]^{-1/2} \sum_{k=1}^{n} \|r_{k+1}^{(1)}\| = O(n[J(n)\gamma_n v(n)]^{-1}) \quad \text{a.s. on } \Gamma(z^*).$$

However, the function $s \mapsto \gamma(s)v(s)$ varies regularly with exponent $\alpha - \beta > -1$; thus

$$\frac{t[\gamma(t)v(t)]^{-1}}{J(t)} \to (1-\beta)+\alpha \neq 0,$$

which implies that

$$[J(n)]^{-1/2}\sum_{k=1}^{n}\|r_{k+1}^{(1)}\| = O(1) \text{ a.s. on } \Gamma(z^*). \tag{18}$$

The first part of Lemma 13 then follows from the combination of (17) and (18).

Now, under assumption (A4.s), we have

$$\begin{aligned}[J(n)]^{-1/2}\sum_{k=1}^{n}\|r_{k+1}^{(1)}\| &= O\left([J(n)]^{-1/2}\sum_{k=1}^{n}k^{-\rho}\right)\\ &= O(n^{-\frac{1}{2}(1+\alpha-\beta)}\mathcal{L}(n)[n^{1-\rho}+\ln n])\\ &= O([n^{\frac{1}{2}(1-\alpha+\beta)-\rho}+n^{-\frac{1}{2}(1+\alpha-\beta)}]\mathcal{L}(n))\\ &= O(n^{-c_2}) \text{ with } c_2>0, \qquad (19)\end{aligned}$$

and the second part of Lemma 13 follows from the combination of (17) and (19).

4.1.2. Proof of Theorem 6. In view of (14) and Lemma 13 (i), we have, for any $u \in \mathbb{R}^d$,

$$\begin{aligned}\frac{u^T nH\overline{T}_n}{\sqrt{2J(n)\ln(\ln n)}} &= \frac{-u^T M_{n+1}}{\sqrt{2J(n)\ln(\ln n)}} + \frac{u^T\left(K_n - \sum_{k=1}^{n} r_{k+1}\right)}{\sqrt{2J(n)\ln(\ln n)}}\\ &= \frac{-u^T M_{n+1}}{\sqrt{2J(n)\ln(\ln n)}} + o(1) \text{ a.s.}\end{aligned}$$

It then follows from Lemma 9 that, a.s. on $\Gamma(z^*)$,

$$\limsup_{n\to\infty}\frac{nu^T H\left(\overline{Z}_n - z^*\right)}{\sqrt{2J(n)\ln(\ln n)}} = -\liminf_{n\to\infty}\frac{nu^T H\left(\overline{Z}_n - z^*\right)}{\sqrt{2J(n)\ln(\ln n)}} = \sqrt{u^T C u}$$

and, replacing u by $[(H^T)^{-1}u]$ (H^T is nonsingular), we deduce that, a.s. on $\Gamma(z^*)$,

$$\limsup_{n\to\infty}\frac{nu^T\left(\overline{Z}_n - z^*\right)}{\sqrt{2J(n)\ln(\ln n)}} = -\liminf_{n\to\infty}\frac{nu^T\left(\overline{Z}_n - z^*\right)}{\sqrt{2J(n)\ln(\ln n)}} = \sqrt{u^T H^{-1}C(H^T)^{-1}u}, \tag{20}$$

which concludes the proof of the first assertion of Theorem 6.

Now, (20) implies that for any $u \in \mathbb{R}^d$, a.s. on $\Gamma(z^*)$,

$$\limsup_{n\to\infty}\frac{n^2}{2J(n)\ln(\ln n)}u^T\left(\overline{Z}_n - z^*\right)\left(\overline{Z}_n - z^*\right)^T u = u^T H^{-1}C\left(H^T\right)^{-1}u$$

and, $\mathbb{Q}$ being a countable set, there exists a P-null set N such that $\forall\omega \in \Gamma(z^*)\setminus N$, $\forall u \in \mathbb{Q}^d$,

$$\limsup_{n\to\infty}\frac{n^2}{2J(n)\ln(\ln n)}u^T\left(\overline{Z}_n(\omega) - z^*\right)\left(\overline{Z}_n(\omega) - z^*\right)^T u = u^T H^{-1}C\left(H^T\right)^{-1}u. \tag{21}$$

To conclude the proof of Theorem 6, we have to show that for any $\omega_0 \in \Gamma(z^*)\setminus N$ and any $v \in \mathbb{R}^d$

$$\limsup_{n\to\infty} v^T\Sigma_n v = v^T\Sigma v, \tag{22}$$

$$\text{where } \Sigma_n = \frac{n^2\left(\overline{Z}_n(\omega_0)-z^*\right)\left(\overline{Z}_n(\omega_0)-z^*\right)^T}{2J(n)\ln(\ln n)} \text{ and } \Sigma = H^{-1}C(H^T)^{-1}.$$

Set $\varepsilon > 0$ and $u \in \mathbb{Q}^d$ such that $\|v-u\| \le \varepsilon$; we have

$$\begin{aligned} v^T\left(\Sigma_n-\Sigma\right)v &\le u^T\left(\Sigma_n-\Sigma\right)u + \left\|(v-u)^T\left(\Sigma_n-\Sigma\right)v + u^T\left(\Sigma_n-\Sigma\right)(v-u)\right\|, \\ \limsup_{n\to\infty} v^T\left(\Sigma_n-\Sigma\right)v &\le \limsup_{n\to\infty} u^T\left(\Sigma_n-\Sigma\right)u \\ &\quad + \limsup_{n\to\infty}\left[\|v-u\|\left(\|\Sigma_n\|+\|\Sigma\|\right)\left(\|u\|+\|v\|\right)\right], \\ &\le \limsup_{n\to\infty}\left[\varepsilon\left(\|\Sigma_n\|+\|\Sigma\|\right)\left(\varepsilon+2\|v\|\right)\right] \text{ in view of (21).} \end{aligned}$$

However, (21) implies that $\|\overline{Z}_n(\omega_0)-z^*\| = O(1)$; thus

$$\limsup_{n\to\infty} v^T\left(\Sigma_n-\Sigma\right)v \le \varepsilon C(\varepsilon+2\|v\|), \text{ where } C>0.$$

It follows that $\limsup_{n\to\infty} v^T\Sigma_n v \le v^T\Sigma v$.

On the other hand, (21) implies that there exists a sequence of integers $(t(n))$ and $n_0 \in \mathbb{N}$ such that $\lim_{n\to\infty} t(n) = \infty$ and $\forall n \ge n_0$, $\|u^T(\Sigma_{t(n)}-\Sigma)u\| \le \varepsilon$. We then have, $\forall n \ge n_0$,

$$\left\|v^T\left(\Sigma_{t(n)}-\Sigma\right)v\right\| \le \varepsilon C(\varepsilon+2\|v\|).$$

Thus $\lim_{n\to\infty} v^T\Sigma_{t(n)}v = v^T\Sigma v$ and (22) is proved.

4.1.3. Proof of Theorem 3. In view of (14), we have

$$\begin{aligned} n^2 H\overline{T}_n\overline{T}_n^T H^T &= \left(K_n - M_{n+1} - \sum_{k=1}^n r_{k+1}\right)\left(K_n - M_{n+1} - \sum_{k=1}^n r_{k+1}\right)^T \\ &= M_n M_n^T + \widetilde{R}_n, \end{aligned}$$

where $\widetilde{R}_n = n^2 H\overline{T}_n\overline{T}_n^T H^T - M_{n+1}M_{n+1}^T$; thus

$$\frac{1}{\ln n}\sum_{k=1}^n k[J(k)]^{-1}H\overline{T}_k\overline{T}_k^T H^T = \frac{1}{\ln n}\sum_{k=1}^n [kJ(k)]^{-1}M_k M_k^T + \frac{1}{\ln n}\sum_{k=1}^n [kJ(k)]^{-1}\widetilde{R}_k.$$

Lemmas 9 and 12 and assumption (A4.s) lead to the following almost sure upper bounds on $\Gamma(z^*)$:

Sequence	Under assumption (A3.a)
$[J(k)]^{-1}\Vert K_k\Vert^2$	$O[(k^{-(1-\beta+\alpha)}+k^{-(1-\alpha)})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert\sum_{j=1}^k r_{j+1}^{(1)}\Vert^2$	$O[(k^{-(1-\beta+\alpha)}+k^{(1+\beta-\alpha)-2\rho})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert\sum_{j=1}^k r_{j+1}^{(2)}\Vert^2$	$O[(k^{-(1-\beta+\alpha)}+k^{(1-\alpha)-(a-1)\beta})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert K_k\Vert\Vert M_k\Vert$	$O[(k^{-\frac{1}{2}(1+\alpha-\beta)}+k^{-\frac{1}{2}(1-\alpha)})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert\sum_{j=1}^k r_{j+1}^{(1)}\Vert\Vert M_k\Vert$	$O[(k^{-\frac{1}{2}(1+\alpha-\beta)}+k^{\frac{1}{2}(1+\beta-\alpha)-\rho})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert\sum_{j=1}^k r_{j+1}^{(2)}\Vert\Vert M_k\Vert$	$O[(k^{-\frac{1}{2}(1+\alpha-\beta)}+k^{\frac{1}{2}[(1-\alpha)-(a-1)\beta]})\mathcal{L}(k)]$

Sequence	Under assumption (A3.b)
$[J(k)]^{-1}\Vert K_k\Vert^2$	$O[(k^{-(1-\beta+\alpha)}+k^{(2\delta-1)(1-\alpha)})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert\sum_{j=1}^k r_{j+1}^{(1)}\Vert^2$	$O[(k^{-(1-\beta+\alpha)}+k^{(1+\beta-\alpha)-2\rho})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert\sum_{j=1}^k r_{j+1}^{(2)}\Vert^2$	$O[(k^{-(1-\beta+\alpha)}+k^{(1+2a\delta)(1-\alpha)-(a-1)\beta})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert K_k\Vert\Vert M_k\Vert$	$O[(k^{-\frac{1}{2}(1+\alpha-\beta)}+k^{(\delta-\frac{1}{2})(1-\alpha)})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert\sum_{j=1}^k r_{j+1}^{(1)}\Vert\Vert M_k\Vert$	$O[(k^{-\frac{1}{2}(1+\alpha-\beta)}+k^{\frac{1}{2}(1+\beta-\alpha)-\rho})\mathcal{L}(k)]$
$[J(k)]^{-1}\Vert\sum_{j=1}^k r_{j+1}^{(2)}\Vert\Vert M_k\Vert$	$O[(k^{-\frac{1}{2}(1+\alpha-\beta)}+k^{\frac{1}{2}[(1+2a\delta)(1-\alpha)-(a-1)\beta]})\mathcal{L}(k)]$

Since all the exponents are strictly negative, we deduce that $\sum[kJ(k)]^{-1}\|\widetilde{R}_k\|<\infty$ a.s. on $\Gamma(z^*)$, and thus

$$\frac{1}{\ln n}\sum_{k=1}^{n}k[J(k)]^{-1}H\overline{T}_k\overline{T}_k^T H^T=\frac{1}{\ln n}\sum_{k=1}^{n}[kJ(k)]^{-1}M_kM_k^T+o(1)\text{ a.s. on }\Gamma(z^*).$$

Lemma 10 then implies

$$\lim_{n\to\infty}\frac{1}{\ln n}\sum_{k=1}^{n}k[J(k)]^{-1}H\overline{T}_k\overline{T}_k^T H^T=C\text{ a.s. on }\Gamma(z^*)$$

and thus

$$\lim_{n\to\infty}\frac{1}{\ln n}\sum_{k=1}^{n}k[J(k)]^{-1}\left(\overline{Z}_k-z^*\right)\left(\overline{Z}_k-z^*\right)^T=H^{-1}C\big(H^{-1}\big)^T\text{ a.s. on }\Gamma(z^*).$$

4.1.4. Proof of Theorem 7. We have to prove that there exists a P-null set N such that $\forall\omega\in\Gamma(z^*)\setminus N$

$$\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\delta_{k[J(k)]^{-1/2}\left(\overline{Z}_k(\omega)-z^*\right)}\Longrightarrow\mathcal{N}(0,H^{-1}C(H^{-1})^T).$$

We first study the behavior of the characteristic functions of the random measures $\frac{1}{\ln n}\sum_{k=1}^n\frac{1}{k}\delta_{k[J(k)]^{-1/2}\left(\overline{Z}_k-z^*\right)}$.

Let u be any vector of $\mathbb{R}^d$. In view of (14), we have

$$\begin{aligned}&\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\exp[i[J(k)]^{-1/2}u^T(kH\overline{T}_k)]\\&=\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\exp\left[i[J(k)]^{-1/2}u^T\bigg(-M_{k+1}+K_k-\sum_{j=1}^{k}r_{j+1}\bigg)\right].\end{aligned}$$

Applying Lemma 13 (ii), it follows that, a.s. on $\Gamma(z^*)$,

$$\begin{aligned}\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}&\exp[i[J(k)]^{-1/2}u^T(kH\overline{T}_k)]\\&=\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\exp[-i[J(k)]^{-1/2}u^TM_{k+1}+O(k^{-c})]\\&=\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\exp[-i[J(k)]^{-1/2}u^TM_{k+1}]+o(1).\end{aligned}$$

Thus, in view of Lemma 11,

$$\lim_{n\to\infty}\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\exp[i(H^Tu)^T(k[J(k)]^{-1/2}\overline{T}_k)]=\exp\left[\frac{-u^TCu}{2}\right].$$

It follows that, for any vector u in $\mathbb{R}^d$, we have, a.s. on $\Gamma(z^*)$,

$$\lim_{n\to\infty}\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\exp[iu^T(k[J(k)]^{-1/2}(\overline{Z}_k-z^*))]=\exp\left[\frac{-u^TH^{-1}C\big(H^{-1}\big)^Tu}{2}\right].$$

Since $\mathbb{Q}$ is a countable set, there exists a P-null set $N\subset\Gamma(z^*)$ such that $\forall\omega\in\Gamma(z^*)\setminus N$, $\forall u\in\mathbb{Q}^d$,

(23)
$$\lim_{n\to\infty}\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\exp[iu^T(k[J(k)]^{-1/2}(\overline{Z}_k(\omega)-z^*))]=\exp\left[\frac{-u^TH^{-1}C\big(H^{-1}\big)^Tu}{2}\right].$$

Let us now set $\omega_0\in\Gamma(z^*)\setminus N$ and prove that the sequence of the deterministic measures $(\mu_n(\omega_0))$ defined by

$$\mu_n(\omega_0)=\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\delta_{k[J(k)]^{-1/2}(\overline{Z}_k(\omega_0)-z^*)}$$

converges weakly to the $\mathcal{N}(0,H^{-1}C(H^{-1})^T)$ distribution.

Let μ_0 be a closure point of $(\mu_n(\omega_0))$ and $\mu_{p(n)}(\omega_0)$ a subsequence such that $\mu_{p(n)}(\omega_0)\Longrightarrow\mu_0$. Since $(\mu_{p(n)}(\omega_0))$ is a bounded sequence of measures, μ_0 is a bounded measure; let ϕ_0 (respectively, $\phi_{p(n)}$) be the characteristic function of μ_0 (respectively, $\mu_{p(n)}(\omega_0)$). We then have $\lim_{n\to\infty}\phi_{p(n)}(u)=\phi_0(u)$ for any $u\in\mathbb{R}^d$, and, in view of (23), $\phi_0(u)=\exp[-u^TH^{-1}C(H^{-1})^Tu/2]$ for any $u\in\mathbb{Q}^d$. However, the function ϕ_0 is continuous, thus $\phi_0(u)=\exp[-u^TH^{-1}C(H^{-1})^Tu/2]$ for any $u\in\mathbb{R}^d$. We finally deduce that μ_0 is the $\mathcal{N}(0,H^{-1}C(H^{-1})^T)$ distribution and $\mu_n(\omega_0)\Longrightarrow\mathcal{N}(0,H^{-1}C(H^{-1})^T)$, which concludes the proof of Theorem 7.

4.2. Proof of Corollary 5. The estimator $\widehat{\Sigma}_n$ can be written as

$$\begin{aligned}\widehat{\Sigma}_n=&\frac{1}{\ln n}\sum_{k=1}^{n}k[J(k)]^{-1}\left(\overline{Z}_k-z^*\right)\left(\overline{Z}_k-z^*\right)^T+\frac{1}{\ln n}\sum_{k=1}^{n}k[J(k)]^{-1}\left(\overline{Z}_n-z^*\right)\left(\overline{Z}_n-z^*\right)^T\\&-\frac{1}{\ln n}\sum_{k=1}^{n}k[J(k)]^{-1}\left(\overline{Z}_k-z^*\right)\left(\overline{Z}_n-z^*\right)^T-\frac{1}{\ln n}\sum_{k=1}^{n}k[J(k)]^{-1}\left(\overline{Z}_n-z^*\right)\left(\overline{Z}_k-z^*\right)^T.\end{aligned}$$

Applying Theorem 6, we have, a.s. on $\Gamma\left(z^{*}\right)$,

$$\left(\sum_{k=1}^{n} k[J(k)]^{-1}\right)\left\|\overline{Z}_{n}-z^{*}\right\|^{2}=O\left[\left(\int_{1}^{n} s[J(s)]^{-1} d s\right) \frac{J(n) \ln (\ln n)}{n^{2}}\right].$$

Since the function $s \mapsto s[J(s)]^{-1}$ varies regularly with exponent $\beta-\alpha>-1$, we have

$$\lim_{n \rightarrow \infty} \frac{n^{2}[J(n)]^{-1}}{\int_{1}^{n} s[J(s)]^{-1} d s}=1+\beta-\alpha, \quad 1+\beta-\alpha \neq 0;$$

thus, a.s. on $\Gamma\left(z^{*}\right)$,

$$\left(\sum_{k=1}^{n} k[J(k)]^{-1}\right)\left\|\overline{Z}_{n}-z^{*}\right\|^{2}=O[\ln (\ln n)]$$

and

$$\lim_{n \rightarrow \infty} \frac{1}{\ln n} \sum_{k=1}^{n} k[J(k)]^{-1}\left(\overline{Z}_{n}-z^{*}\right)\left(\overline{Z}_{n}-z^{*}\right)^{T}=0.$$

On the other hand, applying Theorem 6 again, we obtain, a.s. on $\Gamma\left(z^{*}\right)$,

$$\begin{aligned}
&\left(\sum_{k=1}^{n} k[J(k)]^{-1}\left\|\overline{Z}_{k}-z^{*}\right\|\right)\left\|\overline{Z}_{n}-z^{*}\right\| \\
&\quad=O\left[\left(\sum_{k=1}^{n}[J(k)]^{-1/2} \sqrt{\ln (\ln k)}\right) \frac{\sqrt{J(n) \ln (\ln n)}}{n}\right] \\
&\quad=O\left[\left(\int_{1}^{n}[J(s)]^{-1/2} \sqrt{\ln (\ln s)} d s\right) \frac{\sqrt{J(n) \ln (\ln n)}}{n}\right].
\end{aligned}$$

Since the function $s \mapsto [J(s)]^{-1/2} \sqrt{\ln (\ln s)}$ varies regularly with exponent $-\frac{1}{2}(1+\alpha-\beta)<1$, we have

$$\lim_{n \rightarrow \infty} \frac{n[J(n)]^{-1/2} \sqrt{\ln \ln n}}{\int_{1}^{n}[J(s)]^{-1/2} \sqrt{\ln (\ln s)} d s}=\frac{1}{2}(1-\alpha+\beta), \quad \frac{1}{2}(1-\alpha+\beta) \neq 0.$$

Thus, a.s. on $\Gamma\left(z^{*}\right)$,

$$\left(\sum_{k=1}^{n} k[J(k)]^{-1}\left\|\overline{Z}_{k}-z^{*}\right\|\right)\left\|\overline{Z}_{n}-z^{*}\right\|=O(\ln \ln n)$$

and

$$\begin{aligned}
\lim_{n \rightarrow \infty} & \left[\frac{1}{\ln n} \sum_{k=1}^{n} k[J(k)]^{-1}\left(\overline{Z}_{k}-z^{*}\right)\left(\overline{Z}_{n}-z^{*}\right)^{T}\right. \\
&\left.+\frac{1}{\ln n} \sum_{k=1}^{n} k[J(k)]^{-1}\left(\overline{Z}_{n}-z^{*}\right)\left(\overline{Z}_{k}-z^{*}\right)^{T}\right]=0.
\end{aligned}$$

Applying Theorem 3, we finally deduce that $\lim_{n \rightarrow \infty} \widehat{\Sigma}_{n}=H^{-1} C\left(H^{-1}\right)^{T}$ a.s. on $\Gamma\left(z^{*}\right)$.

4.3. Proof of Lemmas 9, 10, and 11. Throughout this subsection, $\mathrm{Tr}(A)$ denotes the trace of a matrix A, and $\langle\widetilde{M}\rangle_n$ the increasing process of a square-integrable martingale $(\widetilde{M}_n)$. Recall that $\langle\widetilde{M}\rangle_0 = I$ and $E((\widetilde{M}_{n+1} - \widetilde{M}_n)(\widetilde{M}_{n+1} - \widetilde{M}_n)^T|\mathcal{F}_n) = \langle\widetilde{M}\rangle_{n+1} - \langle\widetilde{M}\rangle_n$.

4.3.1. Proof of Lemma 9. The proof of Lemma 9 is based upon the following adaptation of the law of the iterated logarithm of Stout [27] (see [8] or [10]).

Result 2 (law of the iterated logarithm for unidimensional martingales). *Let (η_n) be a sequence of unidimensional random variables adapted to a filtration $\mathcal{F}$ such that*

$$E(\eta_{n+1}|\mathcal{F}_n) = 0\ \forall n \geq 0, \quad \limsup_{n\to\infty} E(|\eta_{n+1}|^2|\mathcal{F}_n) = c^2 < \infty, \quad \textit{and}$$

$$\exists \xi \in]0,1[\ \textit{s.t.}\ \sup_{n\geq 0} E(|\eta_{n+1}|^{2(1+\xi)}|\mathcal{F}_n) < +\infty \quad \textit{a.s.}$$

Let (Φ_n) be a sequence of unidimensional random variables adapted to $\mathcal{F}$ and set $\tau_n = \sum_{k=0}^n \Phi_k^2$; if $\tau_\infty = +\infty$, $\sum \Phi_n^{2+2\xi}\tau_n^{-1-\xi} < +\infty$ and $\Phi_n^2 = o(\tau_n(\ln\ln\tau_n)^{-1/\xi})$ a.s.; then

$$\limsup_{n\to\infty} [2\tau_n \ln(\ln\tau_n)]^{-1/2} \sum_{k=0}^n \Phi_k\eta_{k+1} = -\liminf_{n\to\infty} [2\tau_n \ln(\ln\tau_n)]^{-1/2} \sum_{k=0}^n \Phi_k\eta_{k+1} = c \ \textit{a.s.}$$

Set $u \in \mathbb{R}^d$; the application of Result 2 with $\Phi_n = \sigma_n\gamma_n^{-1}$ and $\eta_{n+1} = u^T\varepsilon_{n+1}$ leads to

$$\begin{aligned}
&\limsup_{n\to\infty} \frac{\sum_{k=1}^n \sigma_k\gamma_k^{-1}u^T\varepsilon_{k+1}}{\left[2\left(\sum_{k=1}^n \sigma_k^2\gamma_k^{-2}\right)\ln\ln\left(\sum_{k=1}^n \sigma_k^2\gamma_k^{-2}\right)\right]^{1/2}} \\
&\quad = -\liminf_{n\to\infty} \frac{\sum_{k=1}^n \sigma_k\gamma_k^{-1}u^T\varepsilon_{k+1}}{\left[2\left(\sum_{k=1}^n \sigma_k^2\gamma_k^{-2}\right)\ln\ln\left(\sum_{k=1}^n \sigma_k^2\gamma_k^{-2}\right)\right]^{1/2}} \\
&\quad = \sqrt{u^TCu} \quad \text{a.s.}
\end{aligned}$$

However, $\sigma_k^2\gamma_k^{-2} = [\gamma_k v(k)]^{-1}$; thus $\sum_{k=1}^n \sigma_k^2\gamma_k^{-2} \sim J(n)$ and we obtain

$$\limsup_{n\to\infty} [2J(n)\ln(\ln n)]^{-1/2}u^TM_n = -\liminf_{n\to\infty} [2J(n)\ln(\ln n)]^{-1/2}u^TM_n = \sqrt{u^TCu} \ \text{a.s.}$$

4.3.2. Proof of Lemma 10. The proof of Lemma 10 is based upon the following martingale version of a result established by Wei [30] for regressive sequences.

Lemma 14 (a strong law of large numbers for martingales). *Let $(\widetilde{M}_n)$ be a d-dimensional, square-integrable martingale with respect to a filtration $\mathcal{F}$.*

Set

$$H_n = \sum_{k=1}^n \widetilde{M}_k^T[\langle\widetilde{M}\rangle_{k-1}^{-1} - \langle\widetilde{M}\rangle_k^{-1}]\widetilde{M}_k,$$

$$f_n = \mathrm{Tr}(\langle\widetilde{M}\rangle_{n+1}^{-1/2}[\langle\widetilde{M}\rangle_{n+1} - \langle\widetilde{M}\rangle_n]\langle\widetilde{M}\rangle_{n+1}^{-1/2}) = d - \mathrm{Tr}(\langle\widetilde{M}\rangle_n\langle\widetilde{M}\rangle_{n+1}^{-1}),$$

$$F_n = f_0 + \cdots + f_n,$$

and assume there exists a constant $a > 1$ such that

$$\sup_n E(([\widetilde{M}_{n+1} - \widetilde{M}_n]^T \langle \widetilde{M} \rangle_{n+1}^{-1} [\widetilde{M}_{n+1} - \widetilde{M}_n])^a | \mathcal{F}_n) < \infty \ a.s.$$

Then, a.s. on $\{F_n \to +\infty\}$,

$$\lim_{n \to \infty} \frac{\widetilde{M}_n^T \langle \widetilde{M} \rangle_n^{-1} \widetilde{M}_n + H_n}{F_n} = 1.$$

Let us first take up briefly the outlines of the proof of Lemma 14. Setting $V_n = \widetilde{M}_n^T \langle \widetilde{M} \rangle_n^{-1} \widetilde{M}_n$, we have

$$\begin{aligned} V_{n+1} &= [\widetilde{M}_n + (\widetilde{M}_{n+1} - \widetilde{M}_n)]^T \langle \widetilde{M} \rangle_{n+1}^{-1} [\widetilde{M}_n + (\widetilde{M}_{n+1} - \widetilde{M}_n)] \\ &= V_n - A_n + B_{n+1} + D_n + D_n^T \end{aligned}$$

with $A_n = \widetilde{M}_n^T (\langle \widetilde{M} \rangle_n^{-1} - \langle \widetilde{M} \rangle_{n+1}^{-1}) \widetilde{M}_n$, $B_{n+1} = (\widetilde{M}_{n+1} - \widetilde{M}_n)^T \langle \widetilde{M} \rangle_{n+1}^{-1} (\widetilde{M}_{n+1} - \widetilde{M}_n)$, and $D_n = (\widetilde{M}_{n+1} - \widetilde{M}_n)^T \langle \widetilde{M} \rangle_{n+1}^{-1} \widetilde{M}_n$. We deduce that

$$V_{n+1} = V_1 - H_n + \sum_{k=1}^{n} B_{k+1} + \sum_{k=1}^{n} \left(D_k^T + D_k \right).$$

Under the moment assumption, $\lim_{n \to \infty} \left(\sum_{k=1}^n B_{k+1} \right) / F_n = 1$ a.s. on $\{F_n \to +\infty\}$. On the other hand,

$$E(|D_{n+1}|^2 | \mathcal{F}_n) = \widetilde{M}_n^T \langle \widetilde{M} \rangle_{n+1}^{-1} [\langle \widetilde{M} \rangle_{n+1} - \langle \widetilde{M} \rangle_n] \langle \widetilde{M} \rangle_{n+1}^{-1} \widetilde{M}_n = O(A_n).$$

Thus the series $\sum_{k=1}^\infty (D_k^T + D_k)$ converges a.s. on $\{H_n < +\infty\}$ and $\sum_{k=1}^n (D_k^T + D_k) = o(H_n)$ a.s. on $\{H_n \to +\infty\}$. It follows that, a.s. on $\{F_n \to +\infty\}$,

$$\lim_{n \to \infty} \frac{V_{n+1} + H_n + o\left(H_n\right) 1_{\{H_n \to +\infty\}}}{F_n} = 1$$

and thus

$$\lim_{n \to \infty} \frac{V_{n+1} + H_n}{F_n} = 1,$$

which concludes the proof of Lemma 14.

We now prove Lemma 10. Let u be any nonzero vector of $\mathbb{R}^d$, and set $W_n = u^T M_n$; (W_n) is a square-integrable martingale, whose increasing process $\langle W \rangle_{n+1} = \Sigma_{k=1}^n \sigma_k^2 \gamma_k^{-2} u^T C_k u = \Sigma_{k=1}^n [\gamma_k v(k)]^{-1} u^T C_k u$ satisfies

$$\langle W \rangle_{n+1} \sim J(n) u^T C u. \tag{24}$$

We have

$$\begin{aligned} [W_{n+1} - W_n]^T \langle W \rangle_{n+1}^{-1} [W_{n+1} - W_n] &= \left[u^T \left(M_{n+1} - M_n \right) \right]^2 \langle W \rangle_{n+1}^{-1} \\ &= \left(\frac{1}{\gamma_n v(n)} \right) \left[u^T \varepsilon_{n+1} \right]^2 \langle W \rangle_{n+1}^{-1}. \end{aligned}$$

Thus,

$$E(([W_{n+1}-W_n]^T\langle W\rangle_{n+1}^{-1}[W_{n+1}-W_n])^{b/2}|\mathcal{F}_n)$$
$$=\left(\frac{1}{\gamma_n v(n)}\right)^{b/2}\langle W\rangle_{n+1}^{-b/2}E(|u^T\varepsilon_{n+1}|^b|\mathcal{F}_n)$$

and, in view of (24),

$$(25)\qquad E(([W_{n+1}-W_n]^T\langle W\rangle_{n+1}^{-1}[W_{n+1}-W_n])^{b/2}|\mathcal{F}_n)=O([\gamma_n v(n)J(n)]^{-b/2}) \\ =O[n^{-b/2}\mathcal{L}(n)].$$

Since $b>2$, (W_n) fulfills the moment assumption of Lemma 14, and we deduce that, a.s. on $\{\Sigma_{k=1}^n(1-\langle W\rangle_k\langle W\rangle_{k+1}^{-1})\to+\infty\}$,

$$(26)\qquad \lim_{n\to\infty}\frac{W_n^T\langle W\rangle_n^{-1}W_n+\sum_{k=1}^n W_k^T[\langle W\rangle_{k-1}^{-1}-\langle W\rangle_k^{-1}]W_k}{\sum_{k=1}^n(1-\langle W\rangle_k\langle W\rangle_{k+1}^{-1})}=1.$$

Now, in view of (24), $(1-\langle W\rangle_k\langle W\rangle_{k+1}^{-1})\sim 1-J(k-1)[J(k)]^{-1}$. Since J' varies regularly with exponent $\alpha-\beta$, we have $J(k-1)[J(k)]^{-1}=1-(\alpha-\beta+1)k^{-1}+o(k^{-1})$; thus

$$(27)\qquad 1-\langle W\rangle_k\langle W\rangle_{k+1}^{-1}\sim\frac{(\alpha-\beta+1)}{k}$$

and

$$(28)\qquad \sum_{k=1}^n(1-\langle W\rangle_k\langle W\rangle_{k+1}^{-1})\sim(\alpha-\beta+1)\ln n.$$

On the other hand, Lemma 9 gives $\|W_n\|^2=O(J(n)\ln(\ln n))$ a.s. Using (24) again, we obtain $\|W_n^T\langle W\rangle_{n+1}^{-1}W_n\|=O(\ln(\ln n))$ and, in view of (28),

$$(29)\qquad W_n^T\langle W\rangle_{n+1}^{-1}W_n=o\left[\sum_{k=1}^n(1-\langle W\rangle_k\langle W\rangle_{k+1}^{-1})\right].$$

Finally,

$$\sum_{k=1}^n W_k^T[\langle W\rangle_{k-1}^{-1}-\langle W\rangle_k^{-1}]W_k=\sum_{k=1}^n\langle W\rangle_{k-1}^{-1}[1-\langle W\rangle_{k-1}\langle W\rangle_k^{-1}]W_kW_k^T$$

and, in view of (24) and (27),

$$(30)\qquad \sum_{k=1}^n W_k^T[\langle W\rangle_{k-1}^{-1}-\langle W\rangle_k^{-1}]W_k\sim\frac{(\alpha-\beta+1)}{u^TCu}\sum_{k=1}^n[kJ(k)]^{-1}u^TM_kM_k^Tu.$$

It follows from the combination of (26), (28), (29), and (30) that

$$(31)\qquad \lim_{n\to\infty}\frac{1}{\ln n}\sum_{k=1}^n[kJ(k)]^{-1}u^TM_kM_k^Tu=u^TCu\text{ a.s.}$$

Let us define Σ_n by

$$\Sigma_n = \frac{1}{\ln n}\left(\sum_{k=1}^{n}[kJ(k)]^{-1}M_k M_k^T\right) - C$$

and denote by $\Sigma_n^{(i,j)}$ the coefficient of the ith line and jth column of Σ_n. Let $(e_1,\ldots,e_d)$ be the canonical basis of $\mathbb{R}^d$. It is easy to see that, for $i,j\in\{1,\ldots,d\}$,

$$\Sigma_n^{(i,j)} = \frac{1}{2}[(e_i+e_j)^T\Sigma_n(e_i+e_j) - e_i^T\Sigma_n e_i - e_j^T\Sigma_n e_j].$$

Applying (31) to the three terms of the right-hand side of this equation, it follows that $\lim_{n\to\infty}\Sigma_n^{(i,j)} = 0$ a.s. and thus $\lim_{n\to\infty}\Sigma_n = 0$ a.s., which completes the proof of Lemma 10.

4.3.3. Proof of Lemma 11. The proof of Lemma 11 is based upon the following result proved by Chaabane [2].

Result 3 (an a.s.CLT for unidimensional martingales). *Let $(\widetilde{M}_n)$ be an unidimensional square integrable martingale with respect to a filtration $\mathcal{F}$ and assume there exists $a>1$ such that*

$$\sum_{n\geq 1} E(([\widetilde{M}_{n+1}-\widetilde{M}_n]^T\langle\widetilde{M}\rangle_{n+1}^{-1}[\widetilde{M}_{n+1}-\widetilde{M}_n])^a|\mathcal{F}_n) < \infty \text{ a.s.}$$

Then,

$$\frac{1}{\ln\langle\widetilde{M}\rangle_n}\sum_{k=1}^{n}\frac{\langle\widetilde{M}\rangle_k-\langle\widetilde{M}\rangle_{k-1}}{\langle\widetilde{M}\rangle_k}\delta_{\langle\widetilde{M}\rangle_k^{-1/2}\widetilde{M}_k}\Longrightarrow\mathcal{N}(0,1) \text{ a.s.}$$

Set $u\in\mathbb{R}^d$, $u\neq 0$, and $W_n = u^T M_n$. In view of (25), (W_n) satisfies the assumption of Result 3. It follows that

$$\frac{1}{\ln\langle W\rangle_n}\sum_{k=1}^{n}[1-\langle W\rangle_{k-1}\langle W\rangle_k^{-1}]\delta_{\langle W\rangle_k^{-1/2}W_k}\Longrightarrow\mathcal{N}(0,1)\text{ a.s.}$$

Then, in view of (24) and (27),

$$\frac{1}{(\alpha-\beta+1)\ln n}\sum_{k=1}^{n}\frac{\alpha-\beta+1}{k}\delta_{[u^TCuJ(k)]^{-1/2}u^TM_k}\Longrightarrow\mathcal{N}\left(0,1\right)\text{ a.s.}$$

and thus

$$\frac{1}{\ln n}\sum_{k=1}^{n}\frac{1}{k}\delta_{[J(k)]^{-1/2}u^TM_k}\Longrightarrow\mathcal{N}\left(0,u^TCu\right)\text{ a.s.}$$

This last property is also clearly satisfied by $u=0$, and thus the proof of Lemma 11 is completed.

Acknowledgments. I gratefully acknowledge Marie Duflo for her invaluable help. I also deeply thank Abdelkader Mokkadem for his thoughtful comments and an anonymous referee whose suggestions have significantly improved the overall presentation.

SUPERREPLICATION UNDER GAMMA CONSTRAINTS[*]

H. METE SONER[†] AND NIZAR TOUZI[‡]

Abstract. In a financial market consisting of a nonrisky asset and a risky one, we study the minimal initial capital needed in order to superreplicate a given contingent claim under a gamma constraint. This is a constraint on the unbounded variation part of the hedging portfolio. We first consider the case in which the prices are given as general Markov diffusion processes and prove a verification theorem which characterizes the superreplication cost as the unique solution of a quasi-variational inequality. In the context of the Black–Scholes model (i.e., when volatility is constant), this theorem allows us to derive an explicit solution of the problem. These results are based on a new dynamic programming principle for general "stochastic target" problems.

Key words. stochastic control, viscosity solutions, stochastic analysis, superreplication, gamma constraint

1. Introduction.

We study the problem of superreplicating a contingent claim under a *gamma* constraint. This is a constraint on the unbounded part of the hedging portfolio.

To explain this constraint and the idea of superreplication, let us first consider the classical Black–Scholes framework with one riskless asset which is normalized to $S^0 = 1$ and one risky asset whose price process evolves according to the stochastic differential equation $dS(t)/S(t) = \mu dt + \sigma dW(t)$. Then given a European contingent claim of the type $g(S(T))$, the unconstrained superreplication cost $v^{BS}(0, S(0))$ is defined as the minimal initial capital which allows us to hedge $g(S(T))$ through some portfolio strategy on the assets S^0 and S. It is known that the solution of this problem coincides with the Black–Scholes arbitrage price of $g(S(T))$ and therefore it is given by $v^{BS}(t, s) = E^Q[g(S(T))|S(t) = s]$. Here $E^Q(.)$ is the expectation operator under the equivalent martingale measure, i.e., Q is the probability measure equivalent to P under which the process S is a martingale. Then the optimal hedging strategy consists of holding $\Delta(t, S(t)) := v_s^{BS}(t, S(t))$ units of the risky asset at each time $t \in [0, T]$.

In practice, traders are faced with shortselling, borrowing, or another type of constraint. These restrictions render this optimal strategy impossible to use in practice, and the notion of superreplication is introduced to replace the no-arbitrage price of Black and Scholes, in the presence of such constraints. We refer to Jouini and Kallal (1995) and Cvitanič and Karatzas (1993) for the superreplication problem with general portfolio constraints. They provide a characterization of the minimal superreplication cost as the value of a stochastic optimal control problem. Broadie, Cvitanič, and Soner (1998) observe that, for a contingent claim of the type $g(S(T))$, this con-

trol problem can be explicitly solved by proving that the minimal superreplication cost is the unconstrained Black–Scholes price of a modified claim. For the stochastic volatility model, a similar explicit solution is provided in Cvitanič, Pham, and Touzi (1999).

Another problem which in practice faces traders is the variation of the optimal hedging strategy. The gamma associated to the optimal hedging strategy is defined by $\gamma(t, S(t)) := v_{ss}^{BS}(t, S(t))$ and describes the variation of the holdings in S, in the optimal hedging strategy, with respect to an infinitesimal change of the process S. Since traders act only in discrete-time, a large γ induces an important risk exposure between two transaction dates. This problem was raised by Broadie, Cvitanić, and Soner (1998) who provided an upper bound for the superreplication cost under gamma constraint, as well as the associated hedging strategy. However, they did not formulate a precise statement of the problem.

The chief goals of this paper are first to define the superreplication problem under a gamma constraint and then to obtain an explicit solution.

Formulation of the problem is obtained by observing that the gamma constraint is equivalent to a bound on the variation of the hedging portfolio. We then provide a simple solution to this problem. To describe this solution, let $\hat{g}$ be the smallest function greater than g which satisfies the gamma constraint. Then the minimal superreplicating cost with a gamma constraint solves a variational inequality with terminal condition $\hat{g}$. When the volatility is a given constant, the solution of the problem is given by $E^Q[\hat{g}(S(t))]$, i.e., the Black and Scholes no-arbitrage price of the contingent claim $\hat{g}(S(T))$. We explicitly calculate the $\hat{g}$ function for several standard options such as European calls, puts, and digital options.

Previously, the convex duality argument was used to characterize the minimal superreplicating cost. In this approach, the dual formulation of the problem is obtained by suitable changes of measure. However, in the case of gamma constraints, it seems that the diffusion coefficients need to be modified in order to follow a similar technique. Since this cannot be accomplished by equivalent changes of measure, we were not able to use the convex duality arguments. Instead, we introduce a dynamic programming argument to identify the superreplication cost as the viscosity solution of a differential inequality. To our knowledge, this is the first use of dynamic programming in this context. We believe that this is a powerful tool in analyzing "stochastic target" problems and establishing the connection between the backward-forward stochastic differential equations and viscosity solutions as developed in an accompanying paper by the authors Soner and Touzi (2000).

A technical contribution of this paper is a result on the behavior of double stochastic integrals with respect to Brownian motion. This is needed because our formulation of the problem involves a nonclassical constraint on the unbounded variation part of the portfolio process, which is itself the integrand of the martingale part of the state process.

This paper is organized as follows. Section 2 describes the general problem. We introduce the modified terminal data in section 3 and state the assumptions in section 4. After stating the dynamic programming in section 5, we state and prove the main result in section 6. Section 7 focuses on the constant coefficient (i.e., the Black–Scholes) case, and several examples are discussed in section 8. The remainder of the paper is devoted to technical results: section 9 proves the viscosity property, a comparison result is proved in section 10, and finally a property of stochastic double integrals is proved in section 11.

2. Problem. We consider a financial market which consists of one bank account, with constant price process $S^0(t) = 1$ for all $t \in [0, T]$, and one risky asset with price process evolving according to the following stochastic differential equation:

$$S_{t,s}(t) = s \quad \text{and} \quad \frac{dS_{t,s}(u)}{S_{t,s}(u)} = \mu(u, S_{t,s}(u))dt + \sigma(u, S_{t,s}(u))dW^0(u), \qquad t \le u \le T.$$

Here W^0 is a standard Brownian motion in $\mathbb{R}$ defined on a complete probability space $(\Omega, \mathcal{F}, P^0)$. We shall denote by $\mathbb{F} = \{\mathcal{F}(t),\, 0 \le t \le T\}$ the P^0-augmentation of the filtration generated by W^0. The drift and the volatility functions $s\mu(t, s)$ and $s\sigma(t, s)$ satisfy the usual Lipschitz and linear growth conditions in order for the process $S_{t,s}$ to be well defined; we also assume that $\sigma(t, s) > 0$ for all $(t, s) \in [0, T] \times (0, \infty)$ and

$$E^{P^0}\left[\mathcal{E}\left(-\int_0^T \frac{\mu(t, S_{0,s}(t))}{\sigma(t, S_{0,s}(t))} dW^0(t)\right)\right] = 1,$$

where $E^{P^0}(.)$ is the expectation operator under the probability measure P^0 and $\mathcal{E}(.)$ is the Doléans–Dade exponential martingale, i.e.,

$$\mathcal{E}\left(\int_0^T b(t)dW^0(t)\right) = \exp\left(\int_0^T b(t)dW^0(t) - \frac{1}{2}\int_0^T b^2(t)dt\right).$$

As usual, the assumption that the interest rate of the bank account is zero can be easily dispensed with by appropriate discounting.

Consider now an economic agent, endowed with an initial capital x at time t, who invests at each time $u \in [t, T]$ an amount $Y(u)S(u)$ of his wealth in the risky asset and the remaining wealth in the bank account. The process $Y = \{Y(u),\, t \le u \le T\}$ represents the number of shares of risky asset S held by the agent during the time interval $[t, T]$. Then, by the self-financing condition, the wealth process evolves according to the stochastic differential equation

$$X(t) = x \qquad \text{and} \qquad dX(u) = Y(u)dS(u), \quad t \le u \le T.$$

The purpose of this paper is to introduce constraints on the variations of the hedging portfolio Y. We consider portfolios which are continuous semimartingales with respect to the filtration $\mathbb{F}$. Since $\mathbb{F}$ is the Brownian filtration, we define the controlled portfolio strategy $Y^{\alpha,\gamma}_{t,s,y}$ by

$$\begin{aligned} Y^{\alpha,\gamma}_{t,s,y}(t) &= y, \\ dY^{\alpha,\gamma}_{t,s,y}(u) &= \alpha(u)du + \gamma(u)\frac{dS_{t,s}(u)}{S_{t,s}(u)}, \quad t \le u \le T, \end{aligned} \tag{2.1}$$

where $y \in \mathbb{R}$ is the initial portfolio and the control pair (α, γ) takes values in

$$\mathcal{D}_t := (L^\infty([t, T] \times \Omega;\ \text{Lebesgue} \otimes P^0))^2.$$

Hence a *trading strategy* is defined by the triple (y, α, γ) with $y \in \mathbb{R}$ and $(\alpha, \gamma) \in \mathcal{D}_t$. Then the associated wealth process, denoted by $X^{\alpha,\gamma}_{t,x,s,y}$, satisfies

$$X^{\alpha,\gamma}_{t,x,s,y}(u) = x + \int_t^u Y^{\alpha,\gamma}_{t,s,y}(r)dS_{t,s}(r), \quad t \le u \le T. \tag{2.2}$$

We shall formulate the gamma constraint by requiring that the process γ be bounded from above. Before making this definition precise, we give a formal discussion. Formally, we expect the hedging portfolio to satisfy

$$Y(u) = v_s(u, S_{t,s}(u)),$$

where v is the minimal superreplication cost. Indeed, this is true in the classical Black–Scholes theory as well as in the case of portfolio constraints; see Broadie, Cvitanič, and Soner (1998). Assuming enough regularity, we apply the Itô formula. The result is

$$dY(u) = A(u)du + \sigma(u, S_{t,s}(u))S_{t,s}(u)v_{ss}(u, S_{t,s}(u))dW^0(u),$$

where $A(u)$ is given in terms of derivatives of v. Compare this equation with (2.1) to conclude that

$$\gamma(u) = S_{t,s}(u)\ v_{ss}(u, S_{t,s}(u)).$$

Therefore a bound on the process γ translates to a bound on sv_{ss}. Notice that, by changing the definition of the process γ in (2.1), we may bound v_{ss} instead of sv_{ss}. However, we choose to study sv_{ss} because it is a dimensionless quantity, i.e., if all the parameters in the problem are increased by the same factor, sv_{ss} remains unchanged.

We now formulate the gamma constraint in the following way. Let Γ be a constant fixed throughout the paper. Given some initial capital $x > 0$, a trading strategy (y, α, γ) is said to be x-admissible if it satisfies the gamma constraint $\gamma(u) \leq \Gamma$ for all $t \leq u \leq T$ almost surely (a.s.) and the associated wealth process $X^{\alpha,\gamma}_{t,x,s,y}$ is nonnegative. We shall denote by

$$\mathcal{A}_{t,s}(x) := \left\{(y, \alpha, \gamma) \in \mathbb{R} \times \mathcal{D}_t : \gamma(.) \leq \Gamma \text{ and } X^{\alpha,\gamma}_{t,x,s,y}(.) \geq 0\right\}$$

the set of all admissible trading strategies.

We consider a European-type contingent claim $g(S_{t,s}(T))$ defined by the terminal payoff function g. Given such a contingent claim, we then consider the infimum $v(t, s)$ of initial capitals x which induce a wealth process $X^{\alpha,\gamma}_{t,x,s,y}$ through some admissible trading strategy (y, α, γ) such that $X^{\alpha,\gamma}_{t,x,s,y}$ hedges $g(S_{t,s}(T))$, i.e.,

$$(2.3) \qquad v(t, s) = \inf\left\{x : \exists\ (y, \alpha, \gamma) \in \mathcal{A}_{t,s}(x),\ \ X^{\alpha,\gamma}_{t,x,s,y}(T) \geq g(S_{t,s}(T)) \text{ a.s.}\right\}.$$

Note that if g is convex so is v in the s-variable; hence, in this case, gamma is bounded from below as well.

Our goal is to prove that function $v(t, s)$ solves a variational inequality and that its terminal value is given by some function $\hat{g}$ dominating g. When we focus on the constant volatility case, these observations allow us to derive an explicit solution of the hedging problem (2.3): $v(t, s)$ is the (unconstrained) Black and Scholes price of the modified contingent claim $\hat{g}(S_{t,s}(T))$. This function $\hat{g}$ can be easily computed and several examples are provided in section 7.

Throughout this paper, we shall introduce a probability measure $P \sim P^0$ defined by

$$P(A) = E^{P^0}\left[1_A \mathcal{E}\left(-\int_0^T \frac{\mu(t, S_{0,s}(t))}{\sigma(t, S_{0,s}(t))} dW^0(t)\right)\right] \qquad \text{for all } A \in \mathcal{F}.$$

We shall denote by $E(.)$ the expectation operator under the probability measure P. By Girsanov's theorem, the process W defined by

$$W(u) := W^0(u) + \int_t^u \frac{\mu(r, S_{t,s}(r))}{\sigma(r, S_{t,s}(r))} dr, \qquad t \le u \le T,$$

is a Brownian motion under P. In terms of the Brownian motion W, the risky asset price process is defined by

$$\text{(2.4)} \qquad S_{t,s}(t) = s \qquad \text{and} \qquad \frac{dS_{t,s}(u)}{S_{t,s}(u)} = \sigma(u, S_{t,s}(u))dW(u), \qquad t \le u \le T.$$

3. Modified terminal data. Due to the constraint, the limit of the value function $v(t,s)$ of (2.3), as t tends to the terminal time T, may not be equal to the contingent claim g. Indeed the determination of this limit is an important step toward the solution of the problem.

We will show in the following sections that the following function $\hat{g}$ is equal to the limit

$$\hat{g}(s) := h^{\mathrm{conc}}(s) + \Gamma s \ln(s), \quad s > 0,$$

where $h(s) = g(s) - \Gamma s \ln(s)$ and h^{conc} is the concave envelope of h, i.e., the smallest concave function greater than h. In other words, function $\hat{g}(s) - \Gamma s \ln(s)$ is the concave envelope of function $g(s) - \Gamma s \ln(s)$. The chief property of $\hat{g}$ that we will use is the following.

LEMMA 3.1. *$\hat{g}$ is the smallest function satisfying the following two conditions:* (i) *$\hat{g} \ge g$ and* (ii) *$\hat{g}(s) - \Gamma s \ln(s)$ is concave.*

Proof. Clearly, $\hat{g}$ satisfies these conditions. Let u be another function satisfying both of them. Set $w(s) := u(s) - \Gamma s \ln(s)$. Clearly $w \ge h$. Since w is concave and $w \ge h$, by the definition of the concave envelope of h, $w \ge h^{\mathrm{conc}}$. Therefore,

$$u(s) = w(s) + \Gamma s \ln(s) \ge h^{\mathrm{conc}}(s) + \Gamma s \ln(s) = \hat{g}(s). \qquad \square$$

In section 6 below, we will show that the terminal data of the minimal superreplicating cost are equal to $\hat{g}$. The formal reason for this is that if v is sufficiently smooth, we formally expect $v(t,s)$ to satisfy the gamma constraint $sv_{ss}(t,s) \le \Gamma$. This is equivalent to the statement that $v(t,s) + \Gamma s \ln(s)$ is concave. Therefore we formally expect the terminal data $\lim_{t \uparrow T} v(T,s)$ to be the smallest function satisfying the two conditions of the previous lemma.

4. Assumptions. We always assume that

$$\text{(4.1)} \qquad \text{function } g \text{ is nonnegative and lower semicontinuous.}$$

We start with several assumptions on the payoff function g and $\hat{g}$. In sections 7 and 8 below, we will verify that all these assumptions are satisfied by standard claims in the Black–Scholes model, i.e., in the case of a constant volatility function $\sigma(t,s)$; see section 7 below.

Assumption 4.1. We assume that $\hat{g}$ is finite and there exists a nonnegative, strictly concave function $\phi \in C^2$ with $\lim_{s \to \infty} \phi(s) = \infty$ such that

$$\text{(4.2)} \qquad \limsup_{s \to \infty} \frac{\hat{g}^{\mathrm{conc}}(s) - E\left[\hat{g}^{\mathrm{conc}}(S_{t,s}(T))\right]}{\phi(s)} < \infty.$$

Remark 4.2. Any function g which is growing at most linearly at infinity satisfies $\hat{g}^{\rm conc}(.) < \infty$. Indeed in this case, $h(s) \le H(s) := K - \Gamma s \ln(s)/2$ for some constant K. Since H is concave, $h^{\rm conc} \le H$, and therefore $\hat{g}$ is finite.

The main use of Assumption 4.1 is to prove a comparison result. The statement and the proof of this result are given in section 10.

Our final assumption is the existence of a smooth solution to the variational inequality

$$\min\left\{-\mathcal{L}u;\ \Gamma - su_{ss}\right\}(t,s) = 0 \quad \text{on } [0,T)\times(0,\infty) \tag{4.3}$$

together with the terminal condition

$$u(T,s) = \hat{g}(s) \qquad \text{for all } s > 0, \tag{4.4}$$

where $\mathcal{L}$ is the parabolic operator related to the infinitesimal generator of the stock price process,

$$\mathcal{L} := \frac{\partial}{\partial t} + \frac{1}{2}\sigma^2(t,s)s^2\frac{\partial^2}{\partial s^2}.$$

We will prove in section 6 that this solution is equal to the minimal superreplication cost.

Assumption 4.3. The variational inequality (4.3)–(4.4) has a $C^{1,2}\left([0,T),(0,\infty)\right)$ solution $\hat{v}$ satisfying

(i) $\hat{v}(t,0) = \hat{g}(0)$ for all $t \in [0,T]$,

(ii) $\hat{v}$ is polynomially growing in its s variable at infinity,

(iii) $s\hat{v}_{ss}$, $\mathcal{L}\hat{v}$ are bounded,

(iv) v_s is a $W^{1,2}$ function with generalized derivatives satisfying $\mathcal{L}\hat{v}_s$ bounded.

In section 7, for the constant volatility model, we verify this assumption by providing an explicit solution.

Remark 4.4. By a classical comparison theorem for the equation $\mathcal{L}v = 0$ (see, for instance, Friedman (1964)), we see that $\hat{v}(t,s) \ge E[\hat{g}(S_{t,s}(T))]$. Since g is nonnegative, so is $\hat{g}$; therefore we have

$$\hat{v}(t,s) \ge E\left[\hat{g}(S_{t,s}(T))\right] \ge 0 \qquad \text{for all } (t,s) \in [0,T]\times(0,\infty).$$

5. Dynamic programming. The following is the analogue of the principle of dynamic programming which is standard in the theory of stochastic optimal control theory first proved by R. Bellman.

LEMMA 5.1. *Let $(t,s) \in [0,T)\times[0,\infty)$ and consider an arbitrary stopping time θ valued in $[t,T]$. Suppose that $X^{\alpha,\gamma}_{t,x,s,y}(T) \ge g(S_{t,s}(T))$ P-a.s. for some $(\alpha,\gamma) \in \mathcal{A}_{t,s}(x)$, $y \in \mathbb{R}$, and initial wealth $x \in \mathbb{R}$. Then, for the value function v of* (2.3)*, we have*

$$X^{\alpha,\gamma}_{t,x,s,y}(\theta) \ge v\left(\theta, S_{t,s}(\theta)\right), \quad P\text{-a.s.}$$

Proof. Let x, y, θ, and (α,γ) be as in the above statement. Set $\hat{x} = X^{\alpha,\gamma}_{t,x,s,y}(\theta)$, $\hat{s} = S_{t,s}(\theta)$, $\hat{y} = Y^{\alpha,\gamma}_{t,s,y}(\theta)$. Clearly $Y_{t,s,y} = Y_{\theta,\hat{s},\hat{y}}$. By definition of the wealth process (2.2), this provides

$$X^{\alpha,\gamma}_{t,x,s,y}(T) = X^{\alpha,\gamma}_{\theta,\hat{x},\hat{s},\hat{y}}(T).$$

Also, by uniqueness of the solution for the stochastic differential equation defining the stock price S, we have $S_{t,s} = S_{\theta,\hat{s}}$. Since $X^{\alpha,\gamma}_{\theta,\hat{x},\hat{s},\hat{y}}(T) = X^{\alpha,\gamma}_{t,x,s,y}(T) \ge g\left(S_{t,s}(T)\right)$

$= g\left(S_{\theta,\hat{s}}(T)\right)$, it follows that $\hat{x} \geq v(\theta, \hat{s})$ by definition of the control problem $v(\theta, \hat{s})$. □

Remark 5.2. As in optimal control theory, the second part of the dynamic programming is also available. A systematic study of dynamic programming is given in an accompanying paper by the authors. Since we do not need the second part of the dynamic programming in this paper, we refer the reader to Soner and Touzi (2000) for a discussion of the full dynamic programming.

6. Main result. Let $\hat{v}$ be the solution of the variational inequality (4.3)–(4.4) introduced in Assumption 4.3.

THEOREM 6.1. *Let Assumptions* 4.1 *and* 4.3 *hold. Then, the value function* v *of the hedging problem* (2.3) *is equal to the unique smooth solution of the variational inequality* (4.3)–(4.4), *i.e.,*

$$v = \hat{v}.$$

Notice that the variational inequality (4.3)–(4.4) was not assumed to have a unique solution satisfying the requirement of Assumption 4.3. Uniqueness is obtained as a consequence of the above theorem.

Let v_* be the lower semicontinuous envelope of v:

$$v_*(t,s) := \liminf_{(t',s')\to(t,s)} v(t,s). \tag{6.1}$$

We prove the theorem after assuming two properties of the value function v.

P1. Function $s \longmapsto v_*(t,s) - \Gamma s \ln(s)$ is concave for all $t \in [0,T)$.

P2. v_* is a viscosity supersolution of the equation $-\mathcal{L}u = 0$ on $[0,T) \times (0,\infty)$.

These properties will be verified in section 9 below.

Proof. We start with the inequality $v \leq \hat{v}$. For $t \leq u \leq T$, set

$$y = \hat{v}_s(t,s), \qquad \alpha(u) = \mathcal{L}\hat{v}_s(u, S(u)), \qquad \gamma(u) = S_{t,s}(u)\hat{v}_{ss}(u, S(u)).$$

Since $\mathcal{L}\hat{v} \leq 0$,

$$\begin{aligned} g\left(S_{t,s}(T)\right) &\leq \hat{g}\left(S_{t,s}(T)\right) = \hat{v}\left(T, S_{t,s}(T)\right) \\ &= \hat{v}(t,s) + \int_t^T \mathcal{L}\hat{v}(u, S_{t,s}(u))du + \hat{v}_s(u, S_{t,s}(u))dS_{t,s}(u) \\ &\leq \hat{v}(t,s) + \int_t^T Y_{t,y}^{\alpha,\gamma}(u)dS_{t,s}(u); \end{aligned}$$

in the last step we applied the generalized Itô's formula to $v_s \in W^{1,2}$. (See Krylov (1980, Theorem 1, p. 122) for Itô's formula with generalized derivatives.) By Assumption 4.3, $(\alpha,\gamma) \in \mathcal{D}_t$. Furthermore, since $\hat{v}$ solves the variational inequality (4.3), $\gamma(u) \leq \Gamma$ for all $u \in [t,T]$. By Remark 4.4, $\hat{v}(u, S_{t,s}(u)) = X_{t,x,s,y}^{\alpha,\gamma}(u) \geq 0$ with $x = \hat{v}(t,s)$. Hence $(y,\alpha,\gamma) \in \mathcal{A}_{t,s}(\hat{v}(t,s))$, and by the definition of the minimal replicating price, we conclude that $v \leq \hat{v}$.

We now prove the reverse inequality. Fix $(t,s) \in (0,T) \times (0,\infty)$, and $\delta > 0$. By the definition of v, there exist an initial wealth $x \in [v(t,s), v(t,s)+\delta)$ and a trading strategy $(y^t, \alpha^t, \gamma^t) \in \mathcal{A}_{t,s}(x)$ satisfying

$$X_{t,x,s,y^t}^{\alpha^t,\gamma^t}(T) \geq g\left(S_{t,s}(T)\right) \quad P\text{-a.s.}$$

Therefore,

$$\delta + v(t,s) + \int_t^T Y_{t,s,y^t}^{\alpha^t,\gamma^t}(u)dS_{t,s}(u) \geq g\left(S_{t,s}(T)\right) \qquad P\text{-a.s.}$$

By the definition of $\mathcal{A}_{t,s}(x)$, the local martingale $\{\int_t^u Y_{t,s,y^t}^{\alpha^t,\gamma^t}(r)dS_{t,s}(r),\ u \geq t\}$ is bounded from below and is therefore a supermartingale. We take the expected value in the last inequality and then use this fact. The result is

$$\delta + v(t,s) \geq E\left[g(S_{t,s}(T))\right].$$

Since $\delta > 0$ is arbitrary and g is lower semicontinuous, Fatou's lemma yields

$$v_*(T,s) = \liminf_{(t,s')\to(T,s)} v(t,s') \geq g(s) \qquad \text{for all } s > 0.$$

In view of the property P1, $v_*(T,\cdot)$ satisfies both conditions stated in Lemma 3.1, and therefore $v_*(T,s) \geq \hat{g}(s)$.

By dynamic programming, for any $(y,\alpha,\gamma) \in \mathcal{A}_{t,s}(x)$ satisfying $X_{t,x,s,y}^{\alpha,\gamma}(T) \geq g(S_{t,s}(T))$,

$$X_{t,x,s,y}^{\alpha,\gamma}(u) \geq v(u, S_{t,s}(u)) \qquad \text{for all } u \in [t,T].$$

Since we have shown that $v_*(T,s) \geq \hat{g}(s)$, by taking the limit as u tends to T, we conclude that

$$X_{t,x,s,y}^{\alpha,\gamma}(T) \geq \hat{g}(S_{t,s}(T)).$$

Therefore, any strategy that dominates g also dominates $\hat{g}$. Since $\hat{g} \geq g$, this provides

$$v(t,s) = \inf\left\{x : \exists\ (y,\alpha,\gamma) \in \mathcal{A}_{t,s}(x),\ \ X_{t,x,s,y}^{\alpha,\gamma}(T) \geq \hat{g}(S_{t,s}(T))\ \text{ a.s.}\right\}, \tag{6.2}$$

i.e., v is the minimal superreplication cost for the claim $\hat{g}$. By definition, the Black–Scholes price (i.e., unconstrained superreplication cost) is always smaller than the superreplication cost with gamma constraint,

$$v(t,s) \geq E\left[\hat{g}(S_{t,s}(T))\right] \qquad \text{for all } (t,s) \in [0,T) \times (0,\infty). \tag{6.3}$$

Moreover, by (6.2), $v(t,0+) = \hat{g}(0)$ for all $t \in [0,T)$. Therefore, $v_*(t,0) \leq v(t,0) = \hat{g}(0)$. Also (6.3) together with Fatou's lemma yield $v_*(t,0) \geq \hat{g}(0)$. Hence $v_*(t,0) = \hat{g}(0)$.

In view of Lemma 9.2 below, v_* is a lower semicontinuous viscosity supersolution of (4.3)–(4.4). By Theorem 10.1, $v_* \geq \hat{v}$. This completes the proof of the theorem since $v \geq v_*$. □

Remark 6.2. In the first part of the above proof, the optimal hedging strategy (y,α,γ) is expressed explicitly in terms of the derivatives of the minimal superreplication cost function $\hat{v}$.

Remark 6.3. In the proof above, it is shown (without appealing to Theorem 10.1) that the (unconstrained) Black and Scholes price of $\hat{g}(S_{t,s}(T))$ is a trivial lower bound for v

$$v(t,s) \geq E\left[\hat{g}(S_{t,s}(T))\right] \qquad \text{for all } (t,s) \in [0,T) \times (0,\infty).$$

We shall use this lower bound in the proof of the comparison Theorem 10.1.

7. The Black and Scholes model.

In this section, we focus on a discussion of the Black and Scholes model in which the volatility function $\sigma(t,s)$ is constant, i.e., $\sigma(t,s) = \sigma$ for all $(t,s) \in [0,T] \times (0,\infty)$.

We shall provide an explicit solution to the hedging problem (2.3) under the following condition.

Assumption 7.1. Function $s \longmapsto h^{\text{conc}}(s) - Cs\ln(s)$ is convex for some constant C.

Remark 7.2. Suppose that function g is such that $s \longmapsto g(s) + As\ln(s)$ is convex for some constant A. Then, since $h(s) = g(s) + As\ln(s) - (\Gamma + A)s\ln(s)$, it follows from the construction of the concave envelope that Assumption 7.1 is satisfied by $C = \Gamma + A$.

THEOREM 7.3. *Let Assumptions* 4.1 *and* 7.1 *hold. Then, Assumption* 4.3 *holds and the value function v of the hedging problem* (2.3) *is simply the unconstrained Black and Scholes price $\hat{v}$ of the contingent claim $\hat{g}(S_{t,s}(T))$, i.e.,*

$$v(t,s) = \hat{v}(t,s) = E\left[\hat{g}(S_{t,s}(T))\right] \quad \textit{for all } (t,s) \in [0,T] \times (0,\infty).$$

Proof. Denote $\tilde{v}(t,s) := E\left[\hat{g}(S_{t,s}(T))\right]$. Then $\tilde{v}$ is a classical solution to the equation

$$-\mathcal{L}u = 0 \quad \text{on } [0,T) \times (0,\infty) \qquad \text{and} \qquad u(T,s) = \hat{g}(s), \quad s > 0.$$

Furthermore, by the definition of $\hat{g}$,

$$\tilde{v}(t,s) - \Gamma s\ln(s) = E\left[h^{\text{conc}}(S_{t,s}(T))\right] + \frac{1}{2}\sigma^2(T-t)\Gamma s. \tag{7.1}$$

Since h^{conc} is concave and $S_{t,s}(T)$ is linear in s, this proves that for all $t \in [0,T]$, function $s \to \tilde{v}(t,s) - \Gamma s\ln(s)$ is concave, and therefore $s\tilde{v}_{ss}(t,s) \le \Gamma$ for all $(t,s) \in [0,T) \times (0,\infty)$. A similar argument using Assumption 7.1 shows that $s\tilde{v}_{ss}(t,s) \ge C$.

Consequently $\tilde{v} = \hat{v}$ is a classical solution of the variational inequality (4.3)–(4.4). By Friedman (1964, Theorem 10, p. 72), function $\hat{v}_s$ is $C^{1,2}$, which provides all the regularity required in Assumption 4.3, except the property (iii). To verify Assumption 4.3 (iii), we differentiate the equation $\mathcal{L}\hat{v} = \hat{v}_t(t,s) + \sigma^2 s^2 \hat{v}_{ss}(t,s) = 0$ to obtain $\mathcal{L}\hat{v}_s(t,s) = \sigma^2 s\hat{v}_{ss}(t,s)$. Since we have already proved that $s\hat{v}_{ss}$ is bounded, so is $\mathcal{L}\hat{v}$. □

Remark 7.4. Observe that Assumption 4.1 is only used in the proof of the comparison Theorem 10.1 which is needed to show that $\hat{v} \le v$. Since in the Black and Scholes case $\hat{v}(t,s) = E[\hat{g}(S_{t,s}(T))]$, the variational inequality (4.3) reduces to the linear equation $-\mathcal{L}v = 0$. Then we can appeal to the standard comparison theorem for this equation, and Assumption 4.1 can be relaxed by requiring only that $\hat{g}(.) < \infty$.

8. Examples.

European call option. Let $g(s) = (s-K)^+$, $s > 0$. Since g is convex, Assumption 7.1 is satisfied; see Remark 7.2. Next, it is easily checked that the concave envelope of function $h(s) = (s-K)^+ - \Gamma s\ln(s)$ is given by

$$h^{\text{conc}}(s) = \begin{cases} h(s), & s \in (0,\infty) \setminus [s_1,s_2], \\ h(s_1) + h'(s_1)(s-s_1), & s \in [s_1,s_2], \end{cases}$$

i.e., h^{conc} coincides with h outside the interval $[s_1,s_2]$ and is defined by a straight line in $[s_1,s_2]$. The values s_1 and s_2 are characterized by

$$s_1 < K < s_2\, h'(s_1) = h'(s_2) \qquad \text{and} \qquad h(s_2) = h(s_1) + h'(s_1)(s_2 - s_1).$$

A direct calculation yields

$$s_1 = \frac{K}{\Gamma(e^{1/\Gamma} - 1)} \qquad \text{and} \qquad s_2 = \frac{Ke^{1/\Gamma}}{\Gamma(e^{1/\Gamma} - 1)}.$$

Therefore,

$$\hat{g}(s) = \begin{cases} (s-K)^+, & s \in (0,\infty) \setminus [s_1, s_2], \\ \Gamma\left(s \ln \frac{s}{s_1} + s_1 - s\right), & s \in [s_1, s_2]. \end{cases}$$

Since $\hat{g}^{\text{conc}}(s) = s$ for all $s > 0$, Assumption 4.1 is clearly satisfied and Theorem 7.3 applies.

European put option. We now consider the case $g(s) = (K-s)^+$, $s > 0$. As in the previous example, g is convex, and therefore Assumption 7.1 is satisfied. The concave envelope of function $h(s) = (K-s)^+ - \Gamma s \ln(s)$ is given by

$$h^{\text{conc}}(s) = \begin{cases} h(s), & s \in (0,\infty) \setminus [s_1, s_2], \\ h(s_1) + h'(s_1)(s - s_1), & s \in [s_1, s_2], \end{cases}$$

i.e., h^{conc} coincides with h outside the interval $[s_1, s_2]$ and is defined by a straight line in $[s_1, s_2]$. The values s_1 and s_2 are characterized by

$$s_1 < K < s_2 \, h'(s_1) = h'(s_2) \qquad \text{and} \qquad h(s_2) = h(s_1) + h'(s_1)(s_2 - s_1).$$

We directly calculate that

$$s_1 = \frac{K}{\Gamma(e^{1/\Gamma} - 1)} \qquad \text{and} \qquad s_2 = \frac{Ke^{1/\Gamma}}{\Gamma(e^{1/\Gamma} - 1)}$$

(the same values as in the first example) and

$$\hat{g}(s) = \begin{cases} (K-s)^+, & s \in (0,\infty) \setminus [s_1, s_2], \\ K - s + \Gamma\left(s \ln \frac{s}{s_1} + s_1 - s\right), & s \in [s_1, s_2]. \end{cases}$$

Since $\hat{g}$ is bounded, Assumption 4.1 holds and therefore Theorem 7.3 applies.

Straddle option. We now study the contingent claim defined by $g(s) = (s-K)^+ + (K-s)^+$, $s > 0$. The same argument as in the previous examples yields

$$\hat{g}(s) = \begin{cases} (s-K)^+ + (K-s)^+, & s \in (0,\infty) \setminus [s_1, s_2], \\ K - s + \Gamma\left(s \ln \frac{s}{s_1} + s_1 - s\right), & s \in [s_1, s_2], \end{cases}$$

where $s_1 = \frac{2K}{\Gamma(e^{2/\Gamma}-1)}$ and $s_2 = s_1 e^{2/\Gamma}$.

Digital option. Our last example is the contingent claim defined by $g(s) = 1_{\{s>K\}}$, $s > 0$. Then, it is easily seen that the concave envelope of function $h(s) = 1_{s>K} - \Gamma s \ln(s)$ is given by

$$h^{\text{conc}}(s) = \begin{cases} h(s), & s \in (0,\infty) \setminus [s^*, K], \\ h(s^*) + h'(s^*)(s - s^*), & s^* \leq s \leq K, \end{cases}$$

where s^* is the unique solution of

$$0 < s^* < \Gamma \qquad \text{and} \qquad s^* - K\ln(s^*) = K - K\ln(K) + \frac{1}{\Gamma}.$$

Clearly, the above function satisfies Assumption 7.1. This provides the candidate for the hedging problem under the gamma constraint:

$$\hat{g}(s) = \begin{cases} 0, & s \ \leq s^*, \\ \Gamma s \ln(s) + h(s^*) + h'(s^*)(s - s^*), & s^* \leq s \leq K, \\ 1, & s \ \geq K. \end{cases}$$

Since $\hat{g} \leq 1$, we have $\hat{g}^{\text{conc}} \leq 1$ and Assumption 4.1 holds. Then, Theorem 7.3 again applies.

9. Viscosity property. In this section, we prove properties P1 and P2 of section 6.

THEOREM 9.1. *v_* is a viscosity supersolution of the variational inequality*

$$\min\{-\mathcal{L}u(t,s),\ \Gamma - su_{ss}(t,s)\} = 0 \tag{9.1}$$

on $(0,T) \times (0,\infty)$.

Proof. For $\varepsilon \in (0,1]$, set

$$\mathcal{A}^{\varepsilon}_{t,s}(x) := \left\{(y,\alpha,\gamma) \in \mathcal{A}_{t,s}(x) : |\alpha(.)| + |\gamma(.)| \leq \varepsilon^{-1}\right\},$$

and

$$v^{\varepsilon}(t,s) = \inf\left\{x : \exists\ (y,\alpha,\gamma) \in \mathcal{A}^{\varepsilon}_{t,s}(x),\ \ X^{\alpha,\gamma}_{t,x,s,y}(T) \geq g(S_{t,s}(T))\ \text{ a.s.}\right\}.$$

Let v^{ε}_* be the lower semicontinuous envelope of v^{ε}; cf. (6.1). It is clear that v^{ε} also satisfies the dynamic programming equation of Lemma 5.1.

First we will show that v^{ε}_* is a viscosity supersolution of (9.1). Let $\varphi \in C^{\infty}(\mathbb{R}^2)$ and $(t_0,s_0) \in (0,T) \times (0,\infty)$ satisfy

$$(v^{\varepsilon}_* - \varphi)(t_0,s_0) = \min_{(t,s)\in(0,T)\times(0,\infty)} (v^{\varepsilon}_* - \varphi)(t,s).$$

We need to show that

$$-\mathcal{L}\varphi(t_0,s_0) \geq 0 \qquad \text{and} \qquad s_0\varphi_{ss}(t_0,s_0) \leq \Gamma. \tag{9.2}$$

We may assume that $(v^{\varepsilon}_* - \varphi)(t_0,s_0) = 0$ so that $v^{\varepsilon}_* \geq \varphi$.

Choose $(t_n,s_n) \to (t_0,s_0)$ so that $v^{\varepsilon}(t_n,s_n)$ converges to $v^{\varepsilon}_*(t_0,s_0)$. For each n, by the definition of v^{ε} and the dynamic programming, there are $x_n \in [v^{\varepsilon}(t_n,s_n), v^{\varepsilon}(t_n,s_n)+1/n]$ hedging strategies $(y_n,\alpha_n,\gamma_n) \in \mathcal{A}^{\varepsilon}_{t_n,s_n}(x_n)$ satisfying

$$X^{\alpha_n,\gamma_n}_{t_n,x_n,s_n,y_n}(t_n+t) - v^{\varepsilon}(t_n+t, S_{t_n,s_n}(t_n+t)) \geq 0$$

for every $t > 0$. Since $v^{\varepsilon} \geq v^{\varepsilon}_* \geq \varphi$,

$$x_n + \int_{t_n}^{t_n+t} Y^{\alpha_n,\gamma_n}_{t_n,s_n,y_n}(u)dS_{t_n,s_n}(u) - \varphi(t_n+t, S_{t_n,s_n}(t_n+t)) \geq 0.$$

Set

$$\beta_n := x_n - \varphi(t_n,s_n)$$

and observe that $\beta_n \to 0$ as $n \to \infty$, since $\varphi(t_n,s_n) \to \varphi(t_0,s_0) = v^{\varepsilon}_*(t_0,s_0)$, $|x_n - v^{\varepsilon}(t_n,s_n)| \leq 1/n$, and $v^{\varepsilon}(t_n,s_n) \longrightarrow v^{\varepsilon}_*(t_0,s_0)$.

By Itô's lemma,

$$M_n(t) \le D_n(t) + \beta_n \tag{9.3}$$

for every $t \ge 0$, where

$$\begin{aligned} M_n(t) &= \int_0^t \left[\varphi_s(t_n+u, S_{t_n,s_n}(t_n+u)) - Y^{\alpha_n,\gamma_n}_{t_n,s_n,y_n}(t_n+u)\right] dS_{t_n,s_n}(t_n+u),\\ D_n(t) &= -\int_0^t \mathcal{L}\varphi(t_n+u, S_{t_n,s_n}(t_n+u))du. \end{aligned}$$

For some sufficiently large positive constant λ, define the stopping time $t_n+\theta_n$ by

$$\theta_n := \inf\left\{u > 0 : \left|\ln\left(S_{t_n,s_n}(t_n+u)/s_n\right)\right| \ge \lambda\right\}$$

and observe that the sequence of stopping times (θ_n) satisfies

$$\liminf_{n\to\infty} t \wedge \theta_n \ge \frac{1}{2} t \wedge \theta_0 \qquad P\text{-a.s.}$$

for all $t > 0$; see Remark 11.2. By the smoothness of $\mathcal{L}\varphi$, the integrand in the definition of M_n is bounded up to the stopping time θ_n and therefore, taking the expectation in (9.3) provides

$$-E\left[\int_0^{t\wedge\theta_n} \mathcal{L}\varphi(t_n+u, S_{t_n,s_n}(t_n+u))du\right] \ge -\beta_n.$$

By sending n to infinity, we obtain

$$-E\left[\int_0^{t\wedge\theta_0} \mathcal{L}\varphi(t_0+u, S_{t_0,s_0}(t_0+u))du\right] \ge 0$$

by dominated convergence and continuity of $\mathcal{L}\varphi$. Then, dividing by t and taking the limit as $t \searrow 0$, we get by dominated convergence

$$-\mathcal{L}\varphi(t_0, s_0) \ge 0,$$

which is the first part of (9.2). It remains to prove the second inequality.

By another application of Itô's lemma, it follows that

$$M_n(t) = \int_0^t \left(z_n + \int_0^u a_n(r)dr + \int_0^u b_n(r)dS_{t_n,s_n}(t_n+r)\right) dS_{t_n,s_n}(t_n+u),$$

where

$$\begin{aligned} z_n &= \varphi_s(t_n, s_n) - y_n,\\ a_n(r) &= \mathcal{L}\varphi_s(t_n+r, S_{t_n,s_n}(t_n+r)) - \alpha_n(t_n+r),\\ b_n(r) &= \varphi_{ss}(t_n+r, S_{t_n,s_n}(t_n+r)) - \frac{\gamma_n(t_n+r)}{S_{t_n,s_n}(t_n+r)}. \end{aligned}$$

Observe that the processes $a_n(.\wedge\theta_n)$ and $b_n(.\wedge\theta_n)$ are bounded uniformly in n since $\mathcal{L}\varphi_s$ and φ_{ss} are smooth functions. By (9.3),

$$M_n(t\wedge\theta_n) \le D_n(t\wedge\theta_n) + \beta_n \le Ct\wedge\theta_n + \beta_n$$

for some positive constant C. We now apply the results of Propositions 11.5 and 11.6 to the martingales M_n. The result is

$$\lim_{n\to\infty} y_n = \varphi_s(t_0, y_0) \qquad \text{and} \qquad \liminf_{n\to\infty,\, t\searrow 0} b(t) \le 0,$$

where b is the L^2 weak limit of the sequence (b_n). The remaining inequality in (9.2) is obtained after recalling that $\gamma_n(t) \le \Gamma$.

Hence v_*^ε is a viscosity supersolution of (9.1). Since

$$v_*(t,s) = \liminf_* v^\varepsilon(t,s) = \liminf_{\varepsilon\to 0,(t',s')\to(t,s)} v_*^\varepsilon(t',s'),$$

the Barles–Perthame technique implies that v_* is a viscosity supersolution of (9.1) as well. □

The following result completes the proof of the properties P1 and P2 of section 6.

LEMMA 9.2. *Let f be a lower semicontinuous function defined on $(0,\infty)$. Then, f is a viscosity supersolution of $\Gamma - sf_{ss}(s) \ge 0$ if and only if $f(s) - \Gamma s \ln(s)$ is concave.*

Proof. Suppose that $h(s) := f(s) - \Gamma s \ln(s)$ is a concave function and a smooth test function φ and $s_0 > 0$ satisfy

$$0 = (f-\varphi)(s_0) = \min \{\ (f-\varphi)(s)\ :\ s \ge 0\ \}.$$

Set $\psi(s) := \varphi(s) - \Gamma s \ln(s)$, so that for any $\delta > 0$,

$$\psi(s_0+\delta) + \psi(s_0-\delta) - 2\psi(s_0) \le h(s_0+\delta) + h(s_0-\delta) - 2h(s_0) \le 0.$$

We divide by δ^2 and let δ go to zero. The result is $\varphi_{ss}(s_0) \le \Gamma/s_0$. Hence, f is a viscosity supersolution of $-sf_{ss}(s) + \Gamma \ge 0$.

Now suppose that f is a viscosity supersolution of $-sf_{ss}(s) + \Gamma \ge 0$. We need to show that

$$h(s+\delta) + h(s-\delta) - 2h(s) \le 0$$

for any $\delta > 0$. Suppose that there exist s_0 and $\delta > 0$ such that

$$\alpha := h(s_0+\delta) + h(s_0-\delta) - 2h(s_0) > 0.$$

Set

$$\psi(s) := h(s_0) + \frac{h(s_0+\delta) - h(s_0-\delta)}{2\delta}\,(s-s_0) + \frac{\alpha}{4\delta^2}(s-s_0)^2.$$

Then, $(h-\psi)(s_0) = 0$ and

$$(h-\psi)(s_0 \pm \delta) = \frac{1}{2}\left[h(s_0+\delta) + h(s_0-\delta) - 2h(s_0)\right] - \frac{\alpha}{4} = \frac{\alpha}{4}.$$

Hence, $(h-\psi)$ attains a local minimum in $(s_0-\delta, s_0+\delta)$. Set $\varphi(s) := \psi(s) + \Gamma s \ln(s)$ so that $(f-\varphi)$ attains a local minimum in the same interval, say at s^*. We calculate that

$$\Gamma - s^*\varphi_{ss}(s^*) = -s^*\frac{\alpha}{2\delta^2} < 0.$$

This contradicts the supersolution property of f. □

10. The comparison result. This section is devoted to the proof of a comparison theorem which was used in the proof of our main result. We refer to Crandall, Ishii, and Lions (1992) and Fleming and Soner (1993) for the definition and the properties of viscosity solutions.

THEOREM 10.1. *Let Assumption* 4.1 *hold. Suppose that the variational inequality* (4.3)–(4.4) *has a solution* $\hat{v} \in C^{1,2}([0,T] \times (0,\infty))$ *which is polynomially growing and has bounded* $\mathcal{L}\hat{v}$. *Let* u *be a lower semicontinuous viscosity supersolution of* (4.3) *satisfying* $u(T,\cdot) \geq \hat{g}$, $u(\cdot,0) \geq \hat{v}(\cdot,0)$, *and* $u(t,s) \geq E\left[\hat{g}(S_{t,s}(T)\right]$. *Then,*

$$u \geq \hat{v} \qquad \text{on } [0,T] \times (0,\infty).$$

We start with deriving an upper bound for the solution $\hat{v}$ of (4.3)–(4.4).

LEMMA 10.2. *For all* $(t,s) \in [0,T] \times (0,\infty)$, $\hat{v}(t,s) \leq \hat{g}^{\mathrm{conc}}(s)$.

Proof. To prove this result, we first show that $\hat{v}$ is related to some stochastic control problem. Let $\mathcal{N}$ be the set of all bounded nonnegative progressively measurable processes. For all $\nu \in \mathcal{N}$, consider the controlled process $S^{\nu}_{t,s}$ defined by

$$\frac{dS^{\nu}_{t,s}(u)}{S^{\nu}_{t,s}(u)} = \left[\frac{\nu(u)}{1+S^{\nu}_{t,s}(u)} + \sigma^2\left(t, S^{\nu}_{t,s}(u)\right)\right]^{1/2} dW(u).$$

Notice that the random function $s \longmapsto s\left[\nu(1+s)^{-1} + \sigma^2(t,s)\right]^{1/2}$ is Lipschitz uniformly in t and therefore the process S^{ν} is well defined. Next, for some small parameter $\eta > 0$, define the stochastic control problem

$$u(t,s) := \sup_{\nu \in \mathcal{N}} E\left[\hat{g}(S^{\nu}_{t,s}(T)) - \frac{1}{2}(\Gamma - \eta)\int_t^T \nu(u)\frac{S^{\nu}_{t,s}(u)}{1+S^{\nu}_{t,s}(u)}du\right]$$

and consider the approximating problems

$$u^n(t,s) := \sup_{\nu \in \mathcal{N}^n} E\left[\hat{g}(S^{\nu}_{t,s}(T)) - \frac{1}{2}(\Gamma - \eta)\int_t^T \nu(u)\frac{S^{\nu}_{t,s}(u)}{1+S^{\nu}_{t,s}(u)}du\right]$$

with $\mathcal{N}^n$ consisting of elements in $\mathcal{N}$ which are bounded by n. Clearly, for every n we have $u^n(t,s) \leq u(t,s)$ for all $(t,s) \in [0,T] \times (0,\infty)$. By classical arguments, it is easily checked that u^n is a viscosity solution of the Hamilton–Jacobi–Bellman (HJB) equation

$$-\sup_{0 \leq \nu \leq n}\left\{w_t + \frac{1}{2}s^2\left(\sigma^2(t,s) + \frac{\nu}{1+s}\right)w_{ss} - \frac{1}{2}(\Gamma - \eta)\nu\frac{s}{1+s}\right\} = 0$$

which can be written as

$$-\mathcal{L}w - \frac{1}{2}n\frac{s}{1+s}[sw_{ss} - (\Gamma - \eta)]^+ = 0 \quad \text{on } [0,T) \times (0,\infty). \tag{10.1}$$

Now recall that $\hat{v}$ is a classical solution to (4.3).

Case 1. $s\hat{v}_{ss} < \Gamma$, then $\mathcal{L}\hat{v} = 0$ and therefore $-\mathcal{L}\hat{v} - \frac{1}{2}n\frac{s}{1+s}[s\hat{v}_{ss} - (\Gamma - \eta)]^+ \leq 0$.

Case 2. $s\hat{v}_{ss} = \Gamma$, then $\mathcal{L}\hat{v} \geq 0$ and $-\mathcal{L}\hat{v} - \frac{1}{2}n\frac{s}{1+s}[s\hat{v}_{ss} - (\Gamma - \eta)]^+ \leq -\mathcal{L}\hat{v} - \frac{1}{2}n\eta\frac{s}{1+s} \leq 0$ for sufficiently large n; recall that $\mathcal{L}\hat{v}$ is assumed to be bounded uniformly in (t,s).

We have then proved that $\hat{v}$ is a subsolution of the HJB equation (10.1) for sufficiently large n. Since $\hat{v}(T,s) = u^n(T,s) = \hat{g}(s)$, it follows from the comparison theorem (which will be verified at the end of this proof) that $\hat{v} \leq u^n$ and therefore

$$\hat{v}(t,s) \leq u(t,s) \quad \text{ for all } (t,s) \in [0,T] \times (0,\infty).$$

We then have

$$\hat{v}(t,s) \le \sup_{\nu\in\mathcal{N}} E\left[\hat{g}(S^{\nu}_{t,s}(T))\right] \le \sup_{\nu\in\mathcal{N}} E\left[\hat{g}^{\mathrm{conc}}(S^{\nu}_{t,s}(T))\right].$$

By the Jensen inequality and the martingale property of the process $S^{\nu}_{t,s}$, this provides

$$\hat{v}(t,s) \le \sup_{\nu\in\mathcal{N}} \hat{g}^{\mathrm{conc}}\left(E\left[S^{\nu}_{t,s}(T)\right]\right) = \hat{g}^{\mathrm{conc}}(s).$$

It remains to prove the comparison theorem for (10.1). Let m be the growth rate of $\hat{v}$, i.e., $\hat{v}(t,s) \le C(1+s^m)$ for some constant C. Take some $\lambda \ge m(m+1)\sigma^2(t,s)/2$ (recall that $s \longmapsto s\sigma(t,s)$ is Lipschitz uniformly in t and therefore σ is bounded). Choose a minimizer at (t_0,s_0) of

$$\psi(t,s) = e^{\lambda t}u^n(t,s) - e^{\lambda t}\hat{v}(t,s) + \varepsilon s^{m+1},$$

where ε is a small positive parameter. Since $u^n \ge 0$ and $\hat{v}$ is growing at the rate m, ϕ attains its minimum. If $s_0 = 0$ or $t_0 = T$, then $\psi(t_0,s_0) \ge 0$ by the boundary conditions. Now, suppose that $s_0 > 0$ and $t_0 < T$. Since u^n is a viscosity solution of (10.1) and $\hat{v}$ is a classical subsolution of (10.1), it follows that

$$\begin{aligned}
&\lambda e^{\lambda t_0}[u^n(t_0,s_0) - \hat{v}(t_0,s_0)] + \varepsilon\frac{1}{2}\sigma^2(t_0,s_0)m(m+1)s_0^{m(m+1)} \\
&\quad \ge e^{\lambda t_0}\frac{n}{2}\frac{s_0}{1+s_0}\left\{[s_0\hat{v}_{ss}(t_0,s_0) - \Gamma]^+ - [s_0\hat{v}_{ss}(t_0,s_0) - e^{-\lambda t_0}\Gamma - \varepsilon m(m+1)s_0^m]^+\right\} \\
&\quad \ge 0.
\end{aligned}$$

Then $\psi(t_0,s_0) \ge 0$ from the choice of the parameter λ. By sending ε to zero, we obtain the comparison result for (10.1). □

Proof of Theorem 10.1. Fix some positive scalar λ and set $\hat{w}(t,s) = \hat{v}(t,s)e^{-\lambda t}$ and $w(t,s) = u(t,s)e^{-\lambda t}$ for all $(t,s) \in [0,T]\times(0,\infty)$. Then $\hat{w}$ is a $C^{1,2}([0,T)\times(0,\infty))$ solution of the variational inequality

$$\begin{aligned}
\min\left\{\lambda\hat{w} - \mathcal{L}\hat{w};\ \Gamma e^{-\lambda t} - s\hat{w}_{ss}\right\} &= 0 \quad \text{on } [0,T)\times(0,\infty), \\
\hat{w}(T,s) &= \hat{g}(s)e^{-\lambda T}, \quad s > 0,
\end{aligned} \tag{10.2}$$

and w is a lower semicontinuous viscosity supersolution of the above equation. Given $\varepsilon > 0$, define the test function

$$\varphi(t,s) = \hat{w}(t,s) - \varepsilon\phi(s), \quad (t,s) \in [0,T)\times(0,\infty),$$

where ϕ is the function introduced in Assumption 4.1; recall that ϕ is positive, C^2 is strictly concave, and $\lim_{s\to\infty}\phi(s) = +\infty$. By Remark 6.3, we have $v(t,s) \ge E\left[\hat{g}(S_{t,s}(T))\right]$. Moreover, since g is nonnegative, we have $\hat{g} \ge 0$ and by the definition of the concave envelope, it follows that $\hat{g} \ge \hat{g}^{\mathrm{conc}} - C$ for some positive constant C. Then, from Lemma 10.2 together with condition (4.2), we can conclude that

$$\liminf_{s\to\infty}(w-\varphi)(t,s) \ge \liminf_{s\to\infty}\left\{E\left[\hat{g}(S_{t,s}(T))\right] - \hat{g}^{\mathrm{conc}}(s) + \varepsilon\phi(s)\right\} = +\infty$$

for all $t \in [0,T]$. Then there exists $(t_0,s_0) \in [0,T]\times[0,\infty)$ such that

$$(w-\varphi)(t_0,s_0) = \min_{[0,T]\times[0,\infty)}(w-\varphi).$$

In order to prove the required result, we have to show that

$$(w-\varphi)(t_0,s_0)\geq 0, \tag{10.3}$$

which implies that $w(t,s)-\hat{w}(t,s)+\varepsilon\phi(s)\geq 0$ for all $(t,s)\in[0,T]\times(0,\infty)$ and the result of the theorem follows by sending ε to zero.

Inequality (10.3) is trivially satisfied if $s_0=0$ or $t_0=T$. We then concentrate on the case $t_0<T$ and $s_0>0$. Since (t_0,s_0) is an interior minimum, it follows from the viscosity supersolution property of w that

$$\lambda w(t_0,s_0)-\mathcal{L}\varphi(t_0,s_0)\geq 0 \qquad \text{and} \qquad \Gamma e^{-\lambda t_0}-s_0\varphi_{ss}(t_0,s_0)\geq 0. \tag{10.4}$$

Recalling the definition of φ, the second inequality provides

$$\Gamma e^{-\lambda t_0}-s_0\hat{w}_{ss}(t_0,s_0)\geq -\varepsilon\phi_{ss}(s_0)>0.$$

By (10.2), we then see that $\mathcal{L}\hat{w}(t_0,s_0)=\lambda\hat{w}(t_0,s_0)$. Plugging this into the first inequality of (10.4) provides

$$\lambda(w-\varphi)(t_0,s_0)\geq\varepsilon\left[\lambda\phi(s_0)-\frac{1}{2}\sigma^2(t_0,s_0)\phi_{ss}(t_0,s_0)\right]\geq 0,$$

which is the required inequality (10.3). □

11. Appendix: Properties of stochastic integrals. In this section we prove several properties of double stochastic integrals with respect to Brownian motion. The key idea in our analysis was provided by Professor F. Delbaen. Our main result is Proposition 11.6 below.

It is known that if

$$\int_0^{t\wedge\theta}h(u)dW(u)\leq Ct\wedge\theta \qquad \text{for all } t\geq 0, \tag{11.1}$$

for some continuous adapted process $h(\cdot)$, standard Brownian motion $W(\cdot)$, positive stopping time θ, and a constant C, then $h(0)=0$. This result is contained in Soner, Shreve, and Cvitanič (1995).[1]

In the analysis of gamma constraints, in particular in proving the viscosity property of the value function in section 9, we are led to study a similar situation for double stochastic integrals such as

$$\int_0^t\int_0^u b(r)dW(r)\ dW(u)\leq Ct. \tag{11.2}$$

In this section, we analyze several inequalities of the type (11.2) ordered by increasing difficulty.

First, suppose that the process $b(\cdot)$ in (11.2) is equal to a constant b_0. Then,

$$\frac{b_0}{2}[W^2(t)-t]=\int_0^t\int_0^u b(r)dW(r)\ dW(u)\leq Ct.$$

[1] Here is an alternative simple proof of this result. Given an arbitrary $\nu\in\mathbb{R}$, introduce the exponential martingale $Z^\nu=\mathcal{E}(\nu W)$. Then, multiplying both sides of (11.1) by $Z^\nu(t\wedge\theta)$, and taking expectations, it follows from the optional sampling theorem that $\nu E[Z^\nu(t\wedge\theta)\int_0^{t\wedge\theta}h(u)du]\leq CE[Z^\nu(t\wedge\theta)(t\wedge\theta)]$. Dividing by t, sending t to zero, and recalling that the process $h(.)$ is continuous, and the stopping time θ is positive P-a.s., we see that $\nu h(0)\leq C$. By arbitrariness of ν, this proves that $h(0)=0$.

Hence, $b_0 \leq 0$ by the law of iterated logarithm.

Next, suppose that b is a bounded, progressively measurable process and (11.2) holds for all $t \in [0, \eta]$ where η is a positive constant. Delbaen proved the following:

$$P\left[\inf_{0 \leq u \leq t} b(u) \geq c\right] < 1 \qquad \text{for all } c > 0,\ t \leq \eta. \tag{11.3}$$

Suppose to the contrary, i.e., suppose that there are $c > 0, t \leq \eta$ such that $b(u) \geq c$ for all $u \in [0, t]$. Let $Z^\nu(t) := \exp\big(\nu W(t) - (\nu^2 t/2)\big)$. A direct calculation shows that

$$E\left[Z^\nu(t) \int_0^t \int_0^u b(v) dW(v) dW(u)\right] = \nu^2 E\left[\int_0^t \int_0^u b(v) Z^\nu(v) dv du\right] \geq c\nu^2 t^2/2.$$

By (11.2),

$$E\left[Z^\nu(t) \int_0^t \int_0^u b(v) dW(v) dW(u)\right] \leq Ct.$$

Hence, $c\nu^2 t^2/2 \leq Ct$ for all ν, which cannot happen. This proves (11.3).

We continue the analysis when (11.2) holds only up to a stopping time.

Lemma 11.1. *Let θ be some bounded positive stopping time and $\{b(t),\ t \geq 0\}$ be a bounded progressively measurable process satisfying* (11.2) *for all $t \leq \theta$. Then,*

$$\liminf_{t \searrow 0} b(t) \leq 0. \tag{11.4}$$

Proof. Suppose to the contrary. Then, there exist a positive stopping time τ and a constant $c > 0$ such that $b(t \wedge \tau) \geq c$ for all t. Rename the stopping time $\tau \wedge \theta$ to be θ.

Step 1. We employ a time change and then use standard properties of Brownian motion to obtain a contradiction. Set

$$h(t) := \int_0^t [b(u)^2 + 1_{\{u > \theta\}}] du, \quad t \geq 0,$$

so that h is a continuous strictly increasing function on $[0, \theta]$. Let

$$\hat{W}(t) := \int_0^{h^{-1}(t)} b(u) dW(u), \quad t \geq 0,$$

and $\mathbb{G} = \{\mathcal{G}_t,\ t \geq 0\}$ be given by $\mathcal{G}_t := \mathcal{F}_{h^{-1}(t)}$. Then the time-changed process $(\hat{W}, \mathbb{G})$ is a standard Brownian motion. By the time-change formula (see, e.g., Karatzas and Shreve (1991, Proposition 4.8, p. 176)), we rewrite (11.2) as

$$\begin{aligned} Ct \wedge \theta \geq \int_0^{t \wedge \theta} \int_0^u b(r)\ dW(r)\ dW(u) &= \int_0^{t \wedge \theta} \hat{W}(h(u))\ dW(u) \\ &= \int_0^{h(t \wedge \theta)} \phi(u) \hat{W}(u)\ d\hat{W}(u) \\ &= \frac{1}{2} \int_0^{h(t \wedge \theta)} \phi(u) d[\hat{W}(u)^2] - \frac{1}{2} \int_0^{h(t \wedge \theta)} \phi(u) du, \end{aligned}$$

where $\phi(u) := 1/b(h^{-1}(u))$. Since b is bounded away from zero, ϕ is bounded and

$$\int_0^{h(t\wedge\theta)} \phi(u)d[\hat{W}(u)^2] \leq C't \wedge \theta, \qquad t \geq 0, \tag{11.5}$$

for some constant C'.

Step 2. By the law of iterated logarithm, there exists a sequence of bounded positive $\mathbb{F}$-stopping times $(\tau_n)_n$ converging to zero such that

$$\frac{\hat{W}(\tau_n)^2}{\tau_n} \longrightarrow +\infty \qquad P\text{-a.s.}$$

Set

$$\theta_n := \theta \wedge h^{-1}(\tau_n)\ .$$

Since θ is positive, for sufficiently large n, $h(\theta_n) = h(h^{-1}(\tau_n)) = \tau_n$. Hence,

$$\frac{\hat{W}\left(h(\theta_n)\right)^2}{h(\theta_n)} \longrightarrow +\infty \qquad P\text{-a.s.} \tag{11.6}$$

Step 3. Choose M so that $|b| < M$. Let ϕ be as in Step 1. Since $b > 0$ on $[0,\theta]$, we have $\phi > 1/M$ on this interval.

Set $\ell := \liminf_{t\downarrow 0} \frac{2}{t}\int_0^t [\phi(u) - \frac{1}{M}]d[W^2(u)]$, and let $(\zeta_n)_n$ be a sequence of positive stopping times converging to zero P-a.s. such that

$$\int_0^{\zeta_n} \left[\phi(u) - \frac{1}{M}\right] d[W^2(u)] \leq \ell\zeta_n.$$

Direct calculation provides

$$\ell\ E[\zeta_n] \geq E\left[\int_0^{\zeta_n}\left[\phi(u) - \frac{1}{M}\right] d[W^2(u)]\right] = E\left[\int_0^{\zeta_n}\left[\phi(u) - \frac{1}{M}\right] du\right] \geq 0.$$

This proves that $\ell \geq 0$, and consequently

$$\liminf_{t\downarrow 0} \frac{\int_0^t \phi(u)d[\hat{W}(u)^2]}{\hat{W}(t)^2} \geq \frac{1}{M}.$$

Let θ_n be the sequence constructed in Step 2. Since θ_n tends to zero as n approaches to zero,

$$\liminf_{n\to\infty} \frac{\int_0^{h(\theta\wedge\tau_n)} \phi(u)d[\hat{W}(u)^2]}{\hat{W}\left(h(\theta\wedge\tau_n)\right)^2} \geq \frac{1}{M}. \tag{11.7}$$

Step 4. Since $b(\theta \wedge t) \geq c$, the definition of h implies that

$$\lim_{n\to\infty} \frac{h(\theta_n)}{\theta_n} \geq c^2.$$

Combining this inequality with (11.6) and (11.7), we arrive at

$$\limsup_{n\to\infty} \frac{h(\theta_n)}{\theta_n}\frac{\hat{W}\left(h(\theta_n)\right)^2}{h(\theta_n)}\frac{\int_0^{h(\theta_n)} \phi(u)d[\hat{W}(u)^2]}{\hat{W}\left(h(\theta_n)\right)^2} = +\infty.$$

Step 5. By (11.5), we have

$$\frac{h(\theta_n)}{\theta_n}\frac{\hat{W}\left(h(\theta_n)\right)^2}{h(\theta_n)}\frac{\int_0^{h(\theta_n)}\phi(u)d[\hat{W}(u)^2]}{\hat{W}\left(h(\theta_n)\right)^2}\leq C'\frac{\theta_n}{\theta_n}.$$

Clearly this is in contradiction with the previous step. □

Our next generalization is to replace W in (11.2) by the stock price process.

We introduce some notation that will be used throughout this section. Let (t_n, s_n) be a sequence converging to some $(t_0, s_0) \in [0,T) \times (0,\infty)$. To simplify the notation, we set

$$S_n(t) := S_{t_n,s_n}(t) \qquad \text{and} \qquad \bar{\sigma}_n(t) := S_{t_n,s_n}(t)\sigma\left(t, S_{t_n,s_n}(t)\right).$$

Since the processes S_n may take very large values, we need to introduce a sequence of stopping times defined as follows. For a large constant $\lambda > 0$ let

$$\bar{\tau}_n := \inf\left\{t > t_n : \left|\ln\left(S_n(t)/s_n\right)\right| \geq \lambda\right\}. \tag{11.8}$$

In our notation, we do not show the dependence of $\bar{\tau}_n$ on λ.

Remark 11.2. The sequence of stopping times $(\bar{\tau}_n)_n$ satisfies

$$\liminf_{n\to\infty} t\wedge\bar{\tau}_n \geq \frac{1}{2}t\wedge\bar{\tau}_0 \qquad P\text{-a.s.}$$

Indeed, since $(t_n, s_n) \longrightarrow (t_0, s_0)$, it follows from Protter (1990, Theorem 37, p. 246) that for almost everywhere (a.e.) $\omega \in \Omega$, we have

$$S_{t_n,s_n} \longrightarrow S_{t_0,s_0} \qquad \text{uniformly on } [t_0, t_0+t],$$

which implies the announced claim.

Lemma 11.3. *Let b, θ, C be as in Lemma* 11.1. *Suppose that*

$$\int_0^{t\wedge\theta}\int_0^r b(r)\ dS_0(r)\ dS_0(u) \leq Ct\wedge\theta \qquad \textit{for all } t \geq 0.$$

Then, b satisfies 11.4.

Proof. We follow the proof of Lemma 11.1. We replace θ by the stopping time $\bar{\theta} := \theta \wedge \bar{\tau}_0$ and the time-change function h by

$$\bar{h}(t) := \int_0^t [b(u)^2\bar{\sigma}(u)^2 + 1_{\{u>\bar{\theta}\}}]du.$$

We define the time-changed Brownian motion $\hat{W}$ in the obvious way. Then, the time-change formula implies that

$$\int_0^{t\wedge\bar{\theta}}\int_0^u b(r)dS_0(r)\ dS_0(u) = \int_0^{t\wedge\bar{\theta}}\hat{W}(u)\ dS_0(u) = \int_0^{h(t\wedge\bar{\theta})}\bar{\phi}(u)\hat{W}(u)d\hat{W}(u),$$

where $\bar{\phi} = 1/[\bar{b}(\bar{h}^{-1})]$. We then proceed as in Lemma 11.1. □

Remark 11.4. The conclusion of Lemma 11.1 is still valid if t is substituted for $t\wedge\theta$ in the right-hand side of inequality (11.2). This is easily checked by going through the proof. The same observation prevails for Lemma 11.3.

Finally, we provide two results which deal with a slightly general double integral:

$$M_n(t\wedge\theta_n) := \int_{t_n}^{t_n+t\wedge\theta_n}\left(z_n+\int_{t_n}^{u}a_n(r)dr+\int_{t_n}^{u}b_n(r)dS_n(r)\right)dS_n(u)\le\beta_n+Ct. \tag{11.9}$$

We will first show that if β_n tends to zero, then z_n also converges to zero. This is a slight generalization of the result on single stochastic integrals stated in the beginning of this section. The second result provides information on the limit behavior of the sequence $(b_n)_n$.

Proposition 11.5. *Let $(\{a_n(u),\ u\ge 0\})_n$ and $(\{b_n(u),\ u\ge 0\})_n$ be two sequences of real-valued, progressively measurable processes that are uniformly bounded in n. Suppose that* (11.9) *holds with real numbers $(z_n)_n$, $(\beta_n)_n$, and stopping times $(\theta_n)_n$. Assume further that, as n tends to zero,*

$$\beta_n \longrightarrow 0 \qquad \textit{and} \qquad t\wedge\theta_n\longrightarrow t\wedge\theta_0 \quad P\text{-a.s.},$$

where θ_0 is a strictly positive stopping time. Then

$$\lim_{n\to\infty} z_n = 0.$$

Proof. For each $n\ge 0$, define the stopping time

$$\tau_n := 1\wedge\bar\tau_n\wedge\theta_n.$$

By Remark 11.2, $\liminf_n t\wedge\tau_n \ge t\wedge\tau_0/2$ with probability one. Let ν be an arbitrary real parameter and define the local martingales Z_n^ν by

$$Z_n^\nu(t)=\mathcal{E}\left(\int_0^t\frac{\nu dW(u)}{\bar\sigma_n(u)}\right),\quad t\ge 0.$$

By the definition of τ_n in (11.8), the process $\{Z_n^\nu(t\wedge\tau_n),\ t\ge 0\}$ is a P-martingale. We then define the probability measure P_n^ν equivalent to P by its density process $\{Z_n^\nu(t\wedge\tau_n),\ t\ge 0\}$ with respect to P. We shall denote by E_n^ν the expectation operator under P_n^ν. By Girsanov's theorem, the process $W_n^\nu(.\wedge\tau_n)$ defined by

$$W_n^\nu(t)=W(t)-\int_0^t\frac{\nu\, du}{\bar\sigma_n(u)},\quad t\ge 0,$$

is a Brownian motion under P_n^ν. We also define the local martingale Z^ν by

$$Z^\nu(t)=\mathcal{E}\left(\int_0^t\frac{\nu dW(u)}{\bar\sigma_0(u)}\right),\quad t\ge 0.$$

By the same argument as above, the process $\{Z^\nu(t\wedge\tau_0),\ t\ge 0\}$ is a P-martingale and is therefore the density process of some probability measure P^ν equivalent to P. We shall denote by E^ν the expectation operator under P^ν. It is easily checked that $Z_n^\nu(.)\longrightarrow Z^\nu(.)$ P-a.s. Then, since $t\wedge\tau_0/2\le\liminf_n t\wedge\tau_n\le\limsup_n t\wedge\tau_n\le t$, it follows from the continuity of Z_n^ν and Z^ν that

$$Z_\infty^\nu := \liminf_{n\to\infty} Z_n^\nu(t \wedge \tau_n) > 0. \tag{11.10}$$

Rewrite $M_n(t \wedge \tau_n)$ in terms of W_n^ν,

$$\begin{aligned} M_n(t \wedge \tau_n) &= \mathrm{mart}(P_n^\nu) + \nu z_n t \wedge \tau_n + \nu \int_{t_n}^{t_n+t\wedge\tau_n} \int_{t_n}^{u} a_n(r) dr du \\ &\quad + \nu t \wedge \tau_n \int_{t_n}^{t_n+t\wedge\tau_n} b_n(r)\bar{\sigma}_n(r) dW_n^\nu(r) + \nu^2 \int_{t_n}^{t_n+t\wedge\tau_n} \int_{t_n}^{u} b_n(r) dr du, \end{aligned}$$

where $\mathrm{mart}(P_n^\nu)$ is a martingale under P_n^ν starting from zero. Take the expectation under P_n^ν, apply the Cauchy–Schwartz inequality for the third term on the right-hand side, and also utilize the bounds on $(a_n)_n$ and $(b_n)_n$ to obtain

$$\begin{aligned} \nu z_n E_n^\nu[t \wedge \tau_n] &\le \beta_n + C' \left(E_n^\nu[t \wedge \tau_n] + (|\nu| + \nu^2) E_n^\nu[(t \wedge \tau_n)^2]^{3/4} \right) \\ &\le \beta_n + C' \left(t + (|\nu| + \nu^2) t^{3/4} \right). \end{aligned}$$

Let ℓ denote either $\liminf_n z_n$ or $\limsup_n z_n$, and restrict ν to have the same sign as ℓ, so that $\nu\ell \ge 0$. Now, let n go to infinity. Then, it follows from Fatou's lemma together with (11.2) and (11.10) that

$$\frac{1}{2} \nu \ell E[t \wedge \tau_0 Z_\infty^\nu] \le C' \left(t + (|\nu| + \nu^2) t^{3/4} \right).$$

We now divide by t and take the limit as $t \searrow 0$. Since τ_0 and Z_∞^ν are positive P (and then P^ν)-a.s., we get by dominated convergence

$$\nu\ell \le C' \qquad \text{for all } \nu \in \mathbb{R}.$$

Since ν is arbitrary, we conclude that $\liminf_n z_n = \limsup_n z_n = 0$. □

The following result is a stronger version of Lemma 11.1 which was used in section 9. We shall denote by $\mathbb{H}^2$ the Hilbert space of all progressively measurable Lebesgue(0,T)$\otimes P$-square integrable processes.

Let $(b_n)_n$ be as in Lemma 11.5. By assumption, $(b_n)_n$ is bounded in L^∞(Lebesgue$(0, T) \otimes P)$. Then it is bounded in $\mathbb{H}^2$ and, therefore, converges weakly to some b, possibly along a subsequence.

PROPOSITION 11.6. *Assume the hypothesis of Lemma* 11.5. *Let b be as above. Then*

$$\liminf_{u\searrow 0} b(u) \le 0.$$

Proof. Define the stopping times τ_n as in the proof of Lemma 11.5. To simplify the notation, we rename process $b_n(t) 1_{t_n \le t \le t_n + t\wedge\tau_n}$ by $b_n(t)$. By Mazur's lemma, there exists a sequence of coefficients $(\lambda_k^n,\ k \ge n)_n$ with $\lambda_k^n \ge 0$ and $\sum_{k\ge n} \lambda_k^n = 1$ such that

$$\hat{b}_n := \sum_{k\ge n} \lambda_k^n b_k \longrightarrow b \qquad \text{strongly in } \mathbb{H}^2. \tag{11.11}$$

Integrating by parts and using the bound on a_n and $S_n(.\wedge\tau_n)$ provide

$$\begin{aligned}M_n(t\wedge\tau_n) &= z_n[S_n(t_n+t\wedge\tau_n)-s_n]\\ &\quad + S_n(t_n+t\wedge\tau_n)\int_{t_n}^{t_n+t\wedge\tau_n} a_n(r)dr - \int_{t_n}^{t_n+t\wedge\tau_n} S_n(u)a_n(u)du\\ &\quad + \int_{t_n}^{t_n+t\wedge\tau_n}\int_{t_n}^{u} b_n(r)dS_n(r)dS_n(u)\\ &\geq -C't\wedge\tau_n - |z_n|s_n(e^\lambda-1) + \int_{t_n}^{t_n+t\wedge\tau_n}\int_{t_n}^{u} b_n(r)dS_n(r)dS_n(u).\end{aligned}$$

Set $\hat\beta_n := \beta_n + |z_n|s_n(e^\lambda-1)$. Then, from Lemma 11.5, $\hat\beta_n \longrightarrow 0$ as $n\to\infty$ and we get from the inequality satisfied by M_n

$$\int_{t_n}^{t_n+t\wedge\tau_n}\int_{t_n}^{u} b_n(r)dS_n(r)dS_n(u) \leq \hat\beta_n + Kt\wedge\tau_n \tag{11.12}$$

for some positive constant K. Set

$$\varepsilon_n(t) := \int_{t_n}^{t_n+t\wedge\tau_n}\int_{t_n}^{u} b_n(r)dS_n(r)dS_n(u) - \int_{t_0}^{t_0+t\wedge\tau_0}\int_{t_0}^{u} b_n(r)dS_0(r)dS_0(u).$$

We shall later prove that

$$\varepsilon_n(t) \longrightarrow 0 \qquad P\text{-a.s.} \tag{11.13}$$

possibly along a subsequence. Take convex combinations in (11.12) to conclude that

$$\sum_{k\geq n}\lambda_k^n\varepsilon_k(t) + \int_{t_0}^{t_0+t\wedge\tau_0}\int_{t_0}^{u}\hat b_n(r)dS_0(r)dS_0(u) \leq \sum_{k\geq n}\lambda_k^n\left(\hat\beta_k + Kt\wedge\tau_k\right). \tag{11.14}$$

We directly calculate that

$$\begin{aligned}&E\left[\left(\int_{t_0}^{t_0+t\wedge\tau_0}\int_{t_0}^{u}\left(\hat b_n(r)-b(r)\right)dS_0(r)dS_0(u)\right)^2\right]\\ &\quad = E\left[\int_{t_0}^{t_0+t\wedge\tau_0}\left(\int_{t_0}^{u}\left(\hat b_n(r)-b(r)\right)dS_0(r)\right)^2\bar\sigma_0(u)^2du\right]\\ &\quad \leq C_1\, E\left[\int_{t_0}^{t_0+t}\left(\int_{t_0}^{u}\left(\hat b_n(r)-b(r)\right)dS_0(r)\right)^2du\right]\\ &\quad \leq C_2\, E\left[\int_{t_0}^{t_0+t}\int_{t_0}^{u}\left(\hat b_n(r)-b(r)\right)^2drdu\right]\\ &\quad \leq C_3t\|\hat b_n-b\|^2_{\mathbb{H}^2},\end{aligned}$$

where C_i's are constants independent of n. This proves that

$$\int_{t_0}^{t_0+t\wedge\tau_0}\int_{t_0}^{u}\hat b_n(r)dS_0(r)dS_0(u)\longrightarrow\int_{t_0}^{t_0+t\wedge\tau_0}\int_{t_0}^{u}b(r)dS_0(r)dS_0(u)\qquad\text{as } n\to\infty$$

in $L^2(P)$, and therefore P-a.s. along some subsequence. Then, taking a.s. limits in (11.14) and using (11.13), we get

$$\int_{t_0}^{t_0+t\wedge\tau_0} \int_{t_0}^{u} b(r)dS_0(r)dS_0(u) \leq Kt.$$

Since the limit process b inherits the bound on b_n, we apply the result of Lemma 11.3 to complete the proof; see also Remark 11.4.

It remains to prove the convergence result stated in (11.13). Set $\zeta_n = t_n + t\wedge\tau_n$ for $n \geq 0$. By Itô's lemma,

$$\varepsilon_n(t) = A_n + B_n + C_n,$$

where

$$\begin{aligned}
A_n &= [S_n(\zeta_n) - s_n] \int_{t_n}^{\zeta_n} b_n(u)dS_n(u) - [S_0(\zeta_0) - s_0] \int_{t_0}^{\zeta_0} b_n(u)dS_0(u),\\
B_n &= -\int_{t_n}^{\zeta_n} b_n(u)S_n(u)dS_n(u) + \int_{t_0}^{\zeta_0} b_n(u)S_0(u)dS_0(u),\\
C_n &= -\int_{t_n}^{\zeta_n} b_n(u)\bar{\sigma}_n(u)^2du + \int_{t_0}^{\zeta_0} b_n(u)\bar{\sigma}_0(u)^2du.
\end{aligned}$$

It suffices to prove that A_n, B_n, and C_n converge to zero P-a.s. along some subsequence. We prove only the convergence of A_n; the remaining claims are proved similarly.

(i) To simplify the presentation, set $\bar{\sigma}(.) = 0$ outside the stochastic interval $[t_n, \zeta_n]$ and observe that

$$S_n(\zeta_n) - S_0(\zeta_0) = s_n + \int_{t_n}^{\zeta_n} \bar{\sigma}_n(u)dW(u).$$

Since $\bar{\sigma}_n$ is bounded inside the stochastic interval $[t_n, \zeta_n]$, by dominated convergence,

$$\begin{aligned}
&E\left[\left(\int_{t_n}^{\zeta_n} \bar{\sigma}_n(u)dW(u) - \int_{t_0}^{\zeta_0} \bar{\sigma}_0(u)dW(u)\right)^2\right]\\
&\qquad = E\left[\int_{t_0\wedge t_n}^{\zeta_0\vee\zeta_n} (\bar{\sigma}_n(u) - \bar{\sigma}_0(u))^2\, du\right] \longrightarrow 0.
\end{aligned}$$

This proves that

$$S_n(\zeta_n) \longrightarrow S_0(\zeta_0) \qquad P\text{-a.s.}$$

along some subsequence.

(ii) Recall that we have set $b_n(.) = 0$ outside the interval $[t_n, \zeta_n]$. Thus,

$$\begin{aligned}
\int_{t_n}^{\zeta_n} b_n(u)dS_n(u) - \int_{t_0}^{\zeta_0} b_n(u)dS_0(u) = \int_{t_n}^{t_0\vee t_n} b_n(u)dS_0(u) + \int_{\zeta_0\wedge\zeta_n}^{\zeta_n} b_n(u)dS_0(u)\\
+ \int_{t_0\vee t_n}^{\zeta_0\wedge\zeta_n} b_n(u)\left(\bar{\sigma}_n(u) - \bar{\sigma}_0(u)\right)dW(u).
\end{aligned}$$

From the bound on b_n, the first two terms on the right-hand side converge to zero in $L^2(P)$ and therefore P-a.s. along some subsequence. As for the third term,

$$\begin{aligned}
E&\left[\left(\int_{t_0\vee t_n}^{\zeta_0\wedge\zeta_n} b_n(u)\left(\bar\sigma_n(u)-\bar\sigma_0(u)\right)dW(u)\right)^2\right]\\
&= E\left[\int_{t_0\vee t_n}^{\zeta_0\wedge\zeta_n} b_n(u)^2\left(\bar\sigma_n(u)-\bar\sigma_0(u)\right)^2 du\right]\\
&\le C_1 E\left[\int_{t_0\vee t_n}^{\zeta_0\wedge\zeta_n} \left(\bar\sigma_n(u)-\bar\sigma_0(u)\right)^2 du\right]\\
&\le C_2 E\left[\int_{t_0}^{\zeta_0} \left(\bar\sigma_n(u)-\bar\sigma_0(u)\right)^2 du\right],
\end{aligned}$$

where C_i's are constants and we have set $\sigma_n(.) = 0$ outside the stochastic interval $[t_n, \zeta_n]$. Since $\bar\sigma_n$ is bounded, we see by dominated convergence that the third term of interest converges to zero in $L^2(P)$ and therefore P-a.s. along some subsequence. This proves that

$$\int_{t_n}^{t_n+t\wedge\tau_n} b_n(u)dS_n(u) - \int_{t_0}^{t_0+t\wedge\tau_0} b_n(u)dS_0(u) \longrightarrow 0 \qquad P\text{-a.s.}$$

along some subsequence.

By (i) and (ii), $A_n \to 0$ P-a.s. along some subsequence. □

Acknowledgment. We gratefully acknowledge conversations with Professor F. Delbaen; in particular, he has provided us with the key idea in the proof of Lemma 11.5.

HAMILTONIAN NECESSARY CONDITIONS FOR A MULTIOBJECTIVE OPTIMAL CONTROL PROBLEM WITH ENDPOINT CONSTRAINTS*

QIJI J. ZHU†

Abstract. This paper discusses Hamiltonian necessary conditions for a nonsmooth multiobjective optimal control problem with endpoint constraints involving a general preference. The transversality condition in our necessary conditions is stated in terms of normal cones to the level sets of the preference. Examples involving a number of useful preferences are discussed.

Key words. multiobjective optimal control, Hamiltonian necessary conditions, differential inclusions, preferences, utility function, subdifferential calculus, variational principles

1. Introduction.

Practical decision problems often involve many factors and can be described by a vector-valued decision function whose components describe several competing objectives. The comparison between different values of the decision function is determined by a preference of the decision maker. The main purpose of this paper is to derive Hamiltonian necessary conditions for a nonsmooth multiobjective optimal control problem with the dynamics governed by a differential inclusion.

Historically, the concept of a preference first appeared in the value theory of economics. In the early studies of the value theory a preference is often defined by a utility function. One of the central questions in the value theory was: given a preference, is it always possible to define a utility function (with good analytic properties) that determines the preference? In terms of multiobjective optimal control problems this amounts to asking whether it is possible to reduce a multiobjective optimal control problem to an optimal control problem with a reasonable single objective function. In [13], Debreu proved a celebrated theorem which asserts that a preference $\prec$ is determined by a continuous utility function if and only if $\prec$ is continuous in the sense that, for any x, the sets $\{y : x \prec y\}$ and $\{y : y \prec x\}$ are closed. While this theorem plays a central role in the value theory, it is not of much help to us for the following reasons. First, Debreu's theorem is an existence theorem. It does not provide methods for determining the utility function for a given preference. Second, even if one can find a continuous utility function that determines the preference, an optimal control problem with a continuous decision function and endpoint constraints is not easily subject to analysis. Finally, some useful preference relations (e.g., the preference determined by the lexicographical order of the vectors) are not continuous. For these reasons we shall pursue the multiobjective optimal control problem directly.

In the area of multiobjective optimization and optimal control much research has been devoted to the weak Pareto solution and its generalizations. The preference relation for two vectors $x, y \in R^m$ in a weak Pareto sense is defined by $x \prec y$ if and

only if $x_i \leq y_i, i = 1, \dots, m$, and at least one of the inequalities is strict. In other words, $x \prec y$ if and only if $x - y \in K := \{z \in R^m : z$ has nonpositive components$\}$ and $x \neq y$. More generally, one can use other cones K in the definition of the preference relations. Necessary optimality conditions for (generalized) weak Pareto solutions were derived for optimization problems in [1, 8, 11, 25, 29, 35, 36, 39, 40] (see also the survey paper [14] for more information), for linear-quadratic and H^∞ optimal control problems in [16], and for an abstract optimal control problem in [6]. A common key step in deriving necessary conditions for generalized Pareto solutions is to apply a separation theorem to a tangent cone of the attainable set and a translate of the cone $-K$, where K is the cone that generates the preference. In this paper we take a different approach. We use a normal cone condition similar to that in the extremal principle [24, 26, 28] at the optimal point in terms of the normal cones to the attainable set and a level set of the preference. This approach enables us to handle more general preference relations: they are not necessarily defined by a cone and are not even necessarily continuous. Necessary optimality conditions for the weak Pareto solution and its generalizations can be derived and refined by using our necessary conditions.

The technical implementation of our proof relies on recent results in nonsmooth analysis, in particular, on the calculus for smooth subdifferentials of lower semicontinuous functions [2, 4, 5, 9, 10, 19], the methods for proving the extremal principle [24, 26, 28], and techniques in handling the Hamiltonians for a differential inclusion [10, 19]. To avoid technical distractions we prove here Hamiltonian necessary conditions that extend the classical Hamiltonian necessary conditions for optimal control problems derived by Clarke (see [8]). There are several recent significant refinements of the Hamiltonian necessary conditions for optimal control problems with a single objective function [18, 19, 20, 34]. It is an interesting question to what extent the methods of this paper can be used to generalize these refined Hamiltonian necessary conditions to multiobjective optimal control problems. There are also many other types of necessary conditions for optimal control problems, in particular, those that refine and generalize the maximum principle (see, e.g., [21, 22, 23, 27, 30, 31, 33, 37, 38, 41]). Whether those necessary conditions can be extended to multiobjective optimal control problems in our general setting represents a more challenging open problem.

The remainder of the paper is arranged as follows. Section 2 contains definitions and preliminary results in subdifferential calculus. We state our main result in section 3 along with some examples and discussions. The technical proofs are given in section 4.

2. Preliminaries. Let X be a real reflexive Banach space with closed unit ball B_X and with topological real dual X^*. Note that X has an equivalent Fréchet smooth norm and we will use this norm as the norm of X unless otherwise stated. Let $f : X \to \bar{R} := R \cup \{+\infty\}$ be an extended-valued function. We denote by dom $f := \{x \in X : f(x) \in R\}$ the effective domain of f. We assume all our functions are *proper* in that they take some finite values: dom $f \neq \emptyset$. Let us now recall the definitions of subdifferentials and normal cones (see [5] for greater details and historical comments).

DEFINITION 2.1. *Let $f : X \to \bar{R}$ be a lower semicontinuous function and C a closed subset of X. We say f is Fréchet-subdifferentiable and x^* is a Fréchet-subderivative of f at x if there exists a concave C^1 function g such that $g'(x) = x^*$ and $f - g$ attains a local minimum at x. We denote the set of all Fréchet-subderivatives of f at x by $D_F f(x)$. We define the Fréchet-normal cone of C at x to be $N_F(C, x) := D_F \delta_C(x)$, where δ_C is the indicator function of C defined by $\delta_C(x) := 0$ for $x \in C$*

and ∞ *otherwise.*

In the following definition, $w^* - \lim$ represents the weak-star limit. In a reflexive Banach space it coincides with the weak limit. In this paper, we only use limiting subdifferentials and normal cones in finite dimensional Euclidean spaces where the weak-star limit coincides with the usual limit.

Definition 2.2. *Let* $f : X \to \bar{R}$ *be a lower semicontinuous function. Define*

$$\partial f(x) := \{w^* - \lim_{i\to\infty} v_i : v_i \in D_F f(x_i),\, (x_i, f(x_i)) \to (x, f(x))\}$$

and

$$\partial^\infty f(x) := \{w^* - \lim_{i\to\infty} t_i v_i : v_i \in D_F f(x_i),\, t_i \to 0^+,\, (x_i, f(x_i)) \to (x, f(x))\},$$

and call $\partial f(x)$ *and* $\partial^\infty f(x)$ *the limiting subdifferential and singular subdifferential of* f *at* x*, respectively.*

Now let C *be a closed subset of* X *and*

$$N(C, x) := \{w^* - \lim_{i\to\infty} v_i : v_i \in N_F(C, x_i),\, C \ni x_i \to x\},$$

and call $N(S, x)$ *the limiting normal cone of* S *at* x*.*

We shall also need to use the Clarke subdifferential ∂_C which is derived by taking the weak-star closed convex hull of the sum of the limiting and singular subdifferentials, i.e.,

$$\partial_C f(x) := \mathrm{cl}^* \ \mathrm{co}[\partial f(x) + \partial^\infty f(x)].$$

We conclude this section with a sum rule and a chain rule for the Fréchet subdifferential. They can be viewed as nonsmooth versions of the corresponding calculus rules for derivatives. We start with the sum rule. The prototypes of this result appeared first in [17]. We use the following version, derived in [4], which refines similar results in [2, 19].

Definition 2.3 (uniform lower semicontinuity). *Let* $f_1, \ldots, f_N : X \to \bar{R}$ *be lower semicontinuous functions and* E *a closed subset of* X*. We say that* $(f_1, \ldots, f_n)$ *is uniformly lower semicontinuous on* E *if*

$$\inf_{x\in E} \sum_{n=1}^{N} f_n(x) \le \lim_{\eta\to 0} \inf \left\{ \sum_{n=1}^{N} f_n(x_n) : \|x_n - x_m\| \le \eta, x_n, x_m \in E, n, m = 1, \ldots, N \right\}.$$

We say that $(f_1, \ldots, f_N)$ *is locally uniformly lower semicontinuous at* $x \in \cap_{n=1}^N \mathrm{dom}(f_n)$ *if* $(f_1, \ldots, f_N)$ *is uniformly lower semicontinuous on every closed ball centered at* x *in a neighborhood of* x*.*

Theorem 2.4 (sum rule). *Let* $f_1, \ldots, f_N : X \to \bar{R}$ *be lower semicontinuous functions. Suppose that* $(f_1, \ldots, f_N)$ *is locally uniformly lower semicontinuous at* $\bar{x}$ *and* $\sum_{n=1}^N f_n$ *attains a local minimum at* $\bar{x}$*. Then, for any* $\varepsilon > 0$*, there exist* $x_n \in \bar{x} + \varepsilon B$ *and* $x_n^* \in D_F f_n(x_n), n = 1, \ldots, N$ *such that* $|f_n(x_n) - f_n(\bar{x})| < \varepsilon, n = 1, 2, \ldots, N,$ $\mathrm{diam}(x_1, \ldots, x_N) \cdot \max(\|x_1^*\|, \ldots, \|x_N^*\|) < \varepsilon$*, and*

$$\left\| \sum_{n=1}^{N} x_n^* \right\| < \varepsilon.$$

Following the argument of [10, Theorem 9.1], one can deduce the following Fréchet subdifferential chain rule for Lipschitz functions from the sum rule of Theorem 2.4.

THEOREM 2.5 (chain rule). *Let X and Y be reflexive Banach spaces. Let $\Phi : X \to Y$ and $f : Y \to R$ be locally Lipschitz mappings. Then for any $x^* \in D_F(f \circ \Phi)(\bar{x})$ and any $\varepsilon > 0$ there exist $x \in \bar{x} + \varepsilon B_X$, $y \in \Phi(\bar{x}) + \varepsilon B_Y$, and $y^* \in D_F f(y)$ such that $\|\Phi(x) - \Phi(\bar{x})\| < \varepsilon$ and*

$$x^* \in D_F\langle y^*, \Phi\rangle(x) + \varepsilon B_X.$$

3. The main results. Let $\prec$ be a (nonreflexive) preference for vectors in R^m. We consider the following multiobjective optimization problem with endpoint constraints.

$$\mathcal{P} \quad \text{Minimize } \phi(y(1))$$

$$\text{subject to } \dot{y}(t) \in F(y(t)) \text{ almost everywhere (a.e.) in } [0,1], y(0) = \alpha_0, \tag{3.1}$$

$$y(1) \in E. \tag{3.2}$$

Here, $\phi = (\phi_1, \dots, \phi_m)$ is a Lipschitz vector function on R^n, E is a closed subset of R^n, and F is a multifunction from R^n to R^n satisfying the following conditions.

(H1) For every x, $F(x)$ is a nonempty compact convex set.

(H2) F is Lipschitz with rank L_F, i.e., for any x, y,

$$F(x) \subset F(y) + L_F\|x - y\|B_{R^n}.$$

We say that y is a feasible trajectory for problem $\mathcal{P}$ if y is absolutely continuous and satisfies relations (3.1) and (3.2). We say x is a solution to problem $\mathcal{P}$ provided that it is a feasible trajectory for $\mathcal{P}$ and there exists no other feasible trajectory y such that $\phi(y(1)) \prec \phi(x(1))$. For any $r \in R^m$, we write $l(r) := \{s \in R^m : s \prec r\}$. We will need the following regularity assumptions on the preference.

DEFINITION 3.1. *We say that a preference $\prec$ is* closed *provided that*

(A1) *for any $r \in R^m$, $r \in \overline{l(r)}$;*

(A2) *for any $r \prec s$, $t \in \overline{l(r)}$ implies that $t \prec s$.*

We say that $\prec$ is regular *at $\bar{r} \in R^m$ provided that*

(A3) *for any sequences $r_k, \theta_k \to \bar{r}$ in R^m,*

$$\limsup_{k\to\infty} N(\overline{l(r_k)}, \theta_k) \subset N(\overline{l(\bar{r})}, \bar{r}).$$

Our main result is the following theorem.

THEOREM 3.2. *Let x be a solution to the multiobjective optimal control problem $\mathcal{P}$. Suppose that the preference $\prec$ is regular at $\phi(x(1))$. Then there exist an absolutely continuous mapping $p : [0,1] \to R^n$, a vector $\lambda \in N(\overline{l(\phi(x(1)))}, \phi(x(1)))$ with $\|\lambda\| = 1$, and a scalar $\lambda_0 = 0$ or 1 satisfying $\lambda_0 + \|p(t)\| \neq 0 \ \forall\ t \in [0,1]$ such that*

$$(-\dot{p}(t), \dot{x}(t)) \in \partial_C H(x(t), p(t)) \quad \textit{a.e. in } [0,1],$$
$$-p(1) \in \lambda_0 \partial\langle\lambda, \phi\rangle(x(1)) + N(E, x(1)).$$

Moreover, one can always choose $\lambda_0 = 1$ when $x(1) \in \operatorname{int} E$.

Here H is the Hamiltonian corresponding to F defined by

$$H(x,p) := \max\{\langle p, v\rangle : v \in F(x)\}.$$

Remark 3.3. Observing that H is positive homogeneous in p, we can scale p or, alternatively, λ in Theorem 3.2 by a positive constant.

In the remainder of this section we will examine a few examples. The proof of Theorem 3.2 is postponed to the next section.

Example 3.4 (a single objective problem). When $m = 1$ and $r \prec s \iff r < s$, Theorem 3.2 reduces to the classical Hamiltonian necessary conditions for an optimal control problem [8]. Thus, the necessary conditions in Theorem 3.2 are true generalizations of the Hamiltonian necessary conditions for single objective optimal control problems.

Example 3.5 (the weak Pareto optimal control problem). In a weak Pareto optimal control problem we define the preference by $r \prec s$ if and only if $r_i \leq s_i, i = 1, \ldots, m$, and at least one of the inequalities is strict. It is easy to check that $\prec$ defined this way satisfies assumptions (A1) and (A2) in Definition 3.1 at any $r \in R^m$. Moreover, for any $r \in R^m$, $\overline{l(r)} = r + R^m_-$, where $R^m_- := \{s \in R^m : s_i \leq 0, i = 1, \ldots, m\}$. It follows that, for any $r, \theta \in R^m$, we have $N(\overline{l(r)}, \theta) \subset R^m_+ := -R^m_-$. Since $N(\overline{l(r)}, r) = R^m_+$, we can see that $\prec$ also satisfies assumption (A3) at any $r \in R^m$ and, therefore, it is regular at any $r \in R^m$. Combining Theorem 3.2 and Remark 3.3, we obtain the following corollary.

Corollary 3.6. *Let x be a weak Pareto solution to the multiobjective optimal control problem $\mathcal{P}$. Then there exist an absolutely continuous mapping $p : [0,1] \to R^n$, a vector $\lambda \in R^m_+$ with $\sum_{i=1}^m \lambda_i = 1$, and a scalar $\lambda_0 = 0$ or 1 satisfying $\lambda_0 + \|p(t)\| \neq 0 \ \forall\ t \in [0,1]$ such that*

$$(-\dot{p}(t), \dot{x}(t)) \in \partial_C H(x(t), p(t)) \quad a.e.\ in\ [0,1],$$
$$-p(1) \in \lambda_0 \partial \langle \lambda, \phi \rangle (x(1)) + N(E, x(1)).$$

Moreover, one can always choose $\lambda_0 = 1$ when $x(1) \in \operatorname{int} E$.

Remark 3.7 (the strong Pareto optimal control problem). Problem $\mathcal{P}$, with the preference defined by $r \prec s$ if and only if $r_i < s_i$, is a strong Pareto optimal control problem. We can also check that this preference is regular at any $r \in R^m$. Thus, Theorem 3.2 can also yield a necessary condition for the strong Pareto optimal control problem. However, simple calculation yields $\overline{l(r)} = r + R^m_-$, which is the same as the corresponding result for a weak Pareto optimal problem. This means that the necessary conditions deduced from Theorem 3.2 for both weak and strong Pareto optimal control problems are the same. Clearly this loss of precision is due to the closure operation on the level sets $l(r)$.

We point out that if x is a weak Pareto optimal solution to problem $\mathcal{P}$, then it is a solution to the following single objective optimal control problem: minimize $\max(\phi_1(y(1)) - \phi_1(x(1)), \ldots, \phi_m(y(1)) - \phi_m(x(1)))$ subject to constraints (3.1) and (3.2). Then we can deduce Corollary 3.6 by combining the Hamiltonian necessary conditions for a single objective problem and the subdifferential chain rule for the max function. However, this method does not apply without additional assumptions to the following generalized weak Pareto optimal solution [1].

Example 3.8 (a generalized weak Pareto optimal control problem). Let $K \subset R^m$ be a closed cone. We now define the preference by $r \prec s$ if and only if $r - s \in K$ and $r \neq s$. Multiobjective optimal control problems with this preference are called generalized weak Pareto optimal control problems. When $K = R^m_-$, we get the weak Pareto problem. Note that we do not assume any convexity on K. Similarly to the last example, we can check that the preference $\prec$ defined here is regular at any

$r \in R^m$. Moreover, $N(\overline{l(r)}, r) = K^- := \{s \in R^m : \langle s, t\rangle \leq 0, t \in K\}$. In particular, $N(\overline{l(\phi(x(1)))}, \phi(x(1))) = K^-$. Thus, we have the following corollary.

COROLLARY 3.9. *Let x be a solution to the generalized weak Pareto multiobjective optimal control problem $\mathcal{P}$ with the preference defined by a closed cone K. Then there exist an absolutely continuous mapping $p : [0,1] \to R^n$, a vector $\lambda \in K^-$ with $\|\lambda\| = 1$, and a scalar $\lambda_0 = 0$ or 1 satisfying $\lambda_0 + \|p(t)\| \neq 0$ $\forall$ $t \in [0,1]$ such that*

$$(-\dot{p}(t), \dot{x}(t)) \in \partial_C H(x(t), p(t)) \quad a.e. \text{ in } [0,1],$$
$$-p(1) \in \lambda_0 \partial\langle\lambda, \phi\rangle(x(1)) + N(E, x(1)).$$

Moreover, one can always choose $\lambda_0 = 1$ when $x(1) \in \text{int } E$.

Example 3.10 (a preference determined by a utility function). Let u be a continuous utility function that determines the preference, i.e., $s \prec r$ if and only if $u(s) < u(r)$. We need an additional assumption to ensure the regularity of $\prec$ which we summarize in the following lemma. We will use $d(S, r) := \inf\{\|s - r\| : s \in S\}$ to denote the distance between a set S and a point r.

LEMMA 3.11. *Let u be a continuous utility function determining the preference $\prec$. Suppose that*

$$\liminf_{s \to r} d(D_F u(s), 0) > 0. \tag{3.3}$$

Then $\prec$ is regular at r and

$$N(\overline{l(r)}, r) = \partial^\infty u(r) \bigcup \left(\bigcup_{a>0} a\partial u(r) \right).$$

Proof. It follows from (3.3) that $l(r)$ is nonempty. Then conditions (A1) and (A2) in Definition 3.1 follow from the continuity of u. It remains to show that $\prec$ satisfies assumption (A3). First we observe that, for r' sufficiently close to r, $\overline{l(r')} = \{s \in R^m : u(s) - u(r') \leq 0\}$. Thus, $D_F u(r') \subset N_F(\overline{l(r')}, r')$. Taking limits, we have

$$\partial^\infty u(r) \bigcup \left(\bigcup_{a>0} a\partial u(r) \right) \subset N(\overline{l(r)}, r). \tag{3.4}$$

Let r_k, θ_k, and ξ_k be sequences satisfying $r_k, \theta_k \to r$, $\xi_k \in N(\overline{l(r_k)}, \theta_k)$, and $\xi_k \to \xi$. We need to show that $\xi \in N(\overline{l(r)}, r)$. By the definition of the limiting normal cone, and without loss of generality, we may assume that $\xi_k \in N_F(\overline{l(r_k)}, \theta_k)$. Since $N(\overline{l(r)}, r)$ always contains 0, we consider the interesting case when $\xi \neq 0$. Then, when n is sufficiently large, we have $\xi_k \neq 0$. Since $N_F(\overline{l(r_k)}, \theta_k)$ is empty when $u(\theta_k) > u(r_k)$ and $\{0\}$ when $u(\theta_k) < u(r_k)$, we must have $u(\theta_k) = u(r_k)$, i.e., $N_F(\overline{l(r_k)}, \theta_k) = N_F(\overline{l(\theta_k)}, \theta_k) = N_F(\{s : u(s) - u(\theta_k) \leq 0\}, \theta_k)$. Applying [5, Theorem 3.4] (see also [3, 32]), we conclude that there exist $a_k > 0$ and $\zeta_k \in D_F u(\theta_k)$ such that $\|a_k\zeta_k - \xi_k\| < 1/n$. It follows that

$$\lim_{k \to \infty} a_k \zeta_k = \xi.$$

Since ζ_k is bounded away from 0, a_k is bounded. Passing to a subsequence if necessary, we may assume that $a_k \to a$. If $a \neq 0$, then ζ_k converges to an element of $\partial u(r)$ and, therefore, $\xi \in a\partial u(r)$. If $a = 0$, then, by definition, $\xi \in \partial^\infty u(r)$. In view of (3.4) we have shown that $\prec$ is regular at r. The formula for $N(\overline{l(r)}, r)$ also follows. □

Using Lemma 3.11 and Remark 3.3, we have the following corollary of Theorem 3.2.

COROLLARY 3.12. *Let $\prec$ be a preference determined by a utility function u. Suppose that u satisfies the condition of Lemma* 3.11. *Let x be a solution to the multiobjective optimal control problem $\mathcal{P}$. Then there exist an absolutely continuous mapping $p : [0,1] \to R^n$, a nonzero vector $\lambda \in \partial^\infty u(\phi(x(1))) \cup \partial u(\phi(x(1)))$, and a scalar $\lambda_0 = 0$ or* 1 *satisfying $\lambda_0 + \|p(t)\| \neq 0 \ \forall\ t \in [0,1]$ such that*

$$\begin{gathered}(-\dot{p}(t), \dot{x}(t)) \in \partial_C H(x(t), p(t)) \quad a.e.\ in\ [0,1], \\ -p(1) \in \lambda_0 \partial\langle \lambda, \phi\rangle(x(1)) + N(E, x(1)).\end{gathered}$$

Moreover, one can always choose $\lambda_0 = 1$ when $x(1) \in \operatorname{int} E$.

Here we derived necessary conditions for an optimal control problem with a continuous decision function. This example also shows that, under favorable conditions, necessary optimality conditions in terms of a preference and its utility function are the same. However, the condition in terms of the normal cone of the level sets of the preference is intrinsic. In fact, if u is a (smooth) utility function corresponding to preference $\prec$, then so is $v(r) = (u(r) - u(x(1)))^3$. But v has a derivative 0 at $x(1)$. Thus, using v as a decision function, the necessary optimality conditions in Corollary 3.12 will yield no useful information.

Our next example considers the preference determined by the lexicographical order. This preference does not correspond to any real utility function [12, p. 72].

Example 3.13 (the preference determined by the lexicographical order). Write $r \prec s$ if there exist an integer $q \in \{0, 1, \dots, m-1\}$ such that $r_i = s_i, i = 1, \dots, q$, and $r_{q+1} < s_{q+1}$. It is easy to check that $\prec$ satisfies assumptions (A1) and (A2) in Definition 3.1. Straightforward calculation yields $\overline{l(r)} = \{s = (s_1, \dots, s_m) \in R^m : s_1 \leq r_1\}$. It follows that, for any $r, \theta \in R^m$, $N(\overline{l(r)}, \theta) = \{ae_1 : a \geq 0\}$. Here $e_1 = (1, 0, \dots, 0) \in R^m$. Thus, $\prec$ is regular at any $r \in R^m$. Moreover, $N(\overline{l(\phi(x(1)))}, \phi(x(1))) = \{ae_1 : a \geq 0\}$. Combining Theorem 3.2 and Remark 3.3, we have the following corollary.

COROLLARY 3.14. *Let x be a solution to the multiobjective optimal control problem $\mathcal{P}$ with the lexicographical preference. Then there exist an absolutely continuous mapping $p : [0,1] \to R^n$ and a scalar $\lambda_0 = 0$ or* 1 *satisfying $\lambda_0 + \|p(t)\| \neq 0 \ \forall\ t \in [0,1]$ such that*

$$\begin{gathered}(-\dot{p}(t), \dot{x}(t)) \in \partial_C H(x(t), p(t)) \quad a.e.\ in\ [0,1], \\ -p(1) \in \lambda_0 \partial\phi_1(x(1)) + N(E, x(1)).\end{gathered}$$

Moreover, one can always choose $\lambda_0 = 1$ when $x(1) \in \operatorname{int} E$.

Intuitively this tells us that since objective ϕ_1 is much more important than the other objectives, the necessary conditions for a multiobjective optimal control problem with the lexicographical preference are the same as the necessary conditions for an optimal control problem with a single objective function ϕ_1. To get further information one can add an additional endpoint constraint $D = \{y : \phi_1(y) = \phi_1(x(1))\}$ to obtain the following necessary conditions: there exist an absolutely continuous mapping $p : [0,1] \to R^n$ and a scalar $\lambda_0 = 0$ or 1 satisfying $\lambda_0 + \|p(t)\| \neq 0 \ \forall\ t \in [0,1]$ such that

$$\begin{gathered}(-\dot{p}(t), \dot{x}(t)) \in \partial_C H(x(t), p(t)) \quad \text{a.e. in } [0,1], \\ -p(1) \in \lambda_0 \partial\phi_2(x(1)) + N(E \cap D, x(1)).\end{gathered}$$

This process can be continued. Note that the adjoint arcs p and scalars λ_0 in this sequence of necessary conditions are not necessarily the same. Of course, these necessary conditions can also be derived by directly combining the above argument with necessary conditions for single-valued optimal control problems. What is interesting here is that this problem can be put into the framework of Theorem 3.2 along with many other problems although its preference cannot be characterized by a utility function.

We should point out that while Theorem 3.2 provides a uniform treatment of many different kinds of multiobjective optimal control problems, the cost we pay is the loss of precision in some special cases. We have briefly discussed this point in Remark 3.7. Now we can see that a similar loss of precision also occurs in the necessary conditions derived for multiobjective optimal control problems defined by a lexicographical order. As discussed in Remark 3.7, to improve the precision one has to use a normal cone concept that can distinguish level sets with an identical closure. This appears to be an interesting direction for further investigation.

4. Proof of Theorem 3.2.

We divide the proof into several steps.

Step 1. *Converting the multiobjective optimal control problem into an abstract optimization problem.* The method we use here develops a conversion for the single objective problem that can be traced back to [7] (see also [8, 10]). The way we handle the multiobjective preference is suggested by the proof of the extremal principle in [24, 26, 28]. Let $A := \{y(1) : y \text{ is a solution to (3.1)}\}$, and let $\Gamma := \{\phi(w) : w \in A \cap E\}$. We can see that Γ is the set of "the attainable values" of this multiobjective optimal control problem. Since A is compact (see [8, section 3.1]) and E is closed, Γ is a closed (compact) set. Let ε be an arbitrary positive number, and let $\eta \in (0, \min(1, \varepsilon)/8(L_\phi + 1))$, where L_ϕ is the Lipschitz rank of ϕ. Choose $\gamma_\eta \prec \phi(x(1))$ such that $\|\gamma_\eta - \phi(x(1))\| < \eta^2$ and write $\Theta := \overline{l(\gamma_\eta)}$. Here Θ is the closure of the level set of $\prec$ at γ_η. This is an approximation of $l(\phi(x(1))$, the level set of the optimal solution x. We need this approximation because the intersection of $l(\phi(x(1))$ and Γ is nonempty (contains at least $\phi(x(1))$), yet

$$\Gamma \cap \Theta = \emptyset. \tag{4.1}$$

In fact, it follows from condition (A2) on $\prec$ that $\Gamma \cap \Theta \neq \emptyset$ implies that there exists a solution y of (3.1) with $y(1) \in E$ such that $\phi(y(1)) \prec \phi(x(1))$, which is a contradiction.

Next we use a method similar to that in [24, 26, 28] for proving the extremal principle to derive a necessary condition for a series of abstract minimization problems that approximate our original multiobjective optimal control problem. Note that the extremal principle in the above references cannot be directly applied here for two reasons: (a) the separation in (4.1) is derived by moving (the closure of) the level sets of $\prec$. In order to apply the extremal principle, the move of the level sets of $\prec$ must be a translate, which only occurs in some special cases such as in a single objective problem or in a weak Pareto optimal problem. (b) Even in the cases when the extremal principle is applicable, applying it to the sets Γ and $l(\phi(x(1))$ will not give us necessary control on the locations of the "approximate" optimal solutions. In what follows, the definition of the auxiliary function f is similar to that in the proof of an extremal principle. We bring the solution of the differential inclusion into the picture by using two sets C and K defined below. Their intersection $C \cap K$ describes the solution set of (3.1) in $L^2 \times L^2$.

Let

$$f(\gamma, \theta) := \|\gamma - \theta\| + \delta_\Gamma(\gamma) + \delta_\Theta(\theta).$$

Then, for any $(\gamma,\theta) \in R^{2m}$, $f(\gamma,\theta) > 0$ and $f(\phi(x(1)),\gamma_\eta) = \|\phi(x(1)) - \gamma_\eta\| < \eta^2$. Let

$$C := \{(u,v) \in L^2([0,1],R^n) \times L^2([0,1],R^n) : v(t) \in F(u(t)) \text{ a.e. in } [0,1]\}$$

and

$$K := \left\{(\alpha,u,v) \in R^n \times L^2([0,1],R^n) \times L^2([0,1],R^n) : \right.$$
$$\left. \alpha = \alpha_0 + \int_0^1 v(s)ds \text{ and } u(t) = \alpha_0 + \int_0^t v(s)ds \right\}.$$

Then for any $\gamma = (\gamma_1,\dots,\gamma_m), \alpha, u$, and v we have

$$\delta_\Gamma(\gamma) \le \sum_{i=1}^m \delta_{\text{graph } \phi_i}(\alpha,\gamma_i) + \delta_E(\alpha) + \delta_K(\alpha,u,v) + \delta_C(u,v).$$

In fact, if $\gamma \in \Gamma$, this inequality is trivial. When $\gamma \notin \Gamma$ it is clear that the indicator functions on the right-hand side cannot be all zero. Moreover, since x is a solution of problem $\mathcal{P}$, we have

$$0 = \delta_\Gamma(\phi(x(1))) = \sum_{i=1}^m \delta_{\text{graph } \phi_i}(x(1),\phi(x(1))) + \delta_E(x(1)) + \delta_K(x(1),x,\dot{x}) + \delta_C(x,\dot{x}).$$

Now we introduce another auxiliary function similar to f which brings the solution of (3.1) into the picture. Let

$$\psi(\gamma,\theta,\alpha,u,v) := \|\gamma-\theta\| + \delta_\Theta(\theta) + \sum_{i=1}^m \delta_{\text{graph } \phi_i}(\alpha,\gamma_i) + \delta_E(\alpha) + \delta_K(\alpha,u,v) + \delta_C(u,v).$$

It is easy to check that $\psi > 0$ and $\psi(\phi(x(1)),\gamma_\eta,x(1),x,\dot{x}) = \|\phi(x(1)) - \gamma_\eta\| < \eta^2$. Moreover, since all the functions in ψ are either Lipschitz functions or indicator functions for a closed set, ψ is lower semicontinuous. By virtue of the Ekeland variational principle [15], there exist $\tilde{\gamma} \in \phi(x(1)) + \eta B_{R^m}$, $\tilde{\theta} \in (\gamma_\eta + \eta B_{R^m}) \cap \Theta \subset (\phi(x(1)) + 2\eta B_{R^m}) \cap \Theta$, $\tilde{\alpha} \in (x(1) + \eta B_{R^n}) \cap E$, $\tilde{u} \in x + \eta B_{L^2([0,1],R^n)}$, and $\tilde{v} \in \dot{x} + \eta B_{L^2([0,1],R^n)}$ such that

$$\psi(\gamma,\theta,\alpha,u,v) + \eta\|(\gamma,\theta,\alpha,u,v) - (\tilde{\gamma},\tilde{\theta},\tilde{\alpha},\tilde{u},\tilde{v})\|$$

attains a minimum at $(\gamma,\theta,\alpha,u,v) = (\tilde{\gamma},\tilde{\theta},\tilde{\alpha},\tilde{u},\tilde{v})$.

We turn to the task of decoupling information. To simplify notation we write $z := (\gamma,\theta,\alpha,u,v)$ and $Z := R^{2m+n} \times L^2([0,1],R^n) \times L^2([0,1],R^n)$. Define functions

$$f_1(z) := \|\gamma - \theta\| + \delta_\Theta(\theta) + \sum_{i=1}^m \delta_{\text{graph } \phi_i}(\alpha,\gamma_i) + \delta_E(\alpha),$$

$$f_2(z) := \delta_K(\alpha,u,v),$$

$$f_3(z) := \delta_C(u,v),$$

and

$$f_4(z) := \eta\|(\gamma,\theta,\alpha,u,v) - (\tilde{\gamma},\tilde{\theta},\tilde{\alpha},\tilde{u},\tilde{v})\|.$$

Then, f_1, f_2, f_3, f_4 are lower semicontinuous and $f_1+f_2+f_3+f_4$ attains a minimum at $\tilde{z}$ over a closed neighborhood U of $\tilde{z}$ in Z. Our next step is to apply a fuzzy sum rule to convert this into subdifferential information on $f_i, i=1,2,3,4$.

Step 2. *Applying the sum rule.* To do so, we need to check that (f_1,f_2,f_3,f_4) is uniformly lower semicontinuous around $\tilde{z}$. The argument is similar to that of [19] but somewhat simpler because of the weaker condition required in the sum rule of Theorem 2.4 (see [42] for the case of single objective problems). Let $z_1^k, z_2^k, z_3^k, z_4^k \in U$ be four sequences satisfying

$$\text{diam}(z_1^k, z_2^k, z_3^k, z_4^k) \to 0, \text{ as } k\to\infty, \tag{4.2}$$

such that

$$\lim_{n\to\infty}\sum_{i=1}^4 f_i(z_i^k) = \liminf_{h\to 0}\left\{\sum_{i=1}^4 f_i(z_i), \text{diam}(z_1,z_2,z_3,z_4)\le h\right\}.$$

Then we must have $(u_3^k, v_3^k)\in C$, i.e.,

$$v_3^k(t)\in F(u_3^k(t)) \text{ a.e. in } [0,1]. \tag{4.3}$$

Since $z_3^k\in U$, u_3^k is a bounded sequence in $L^2([0,1],R^n)$. Since F is Lipschitz with values that are compact sets, v_3^k is also a bounded sequence in $L^2([0,1],R^n)$. Without loss of generality, we may assume that v_3^k converges weakly to $\bar{v}$ in $L^2([0,1],R^n)$. Then it follows from relation (4.2) that v_2^k also converges weakly to $\bar{v}$ in $L^2([0,1],R^n)$. Since $(\alpha_2^k, u_2^k, v_2^k)\in K$, we have $\alpha_2^k = \alpha_0 + \int_0^1 v_2^k(s)ds$ and $u_2^k(t) = \alpha_0 + \int_0^t v_2^k(s)ds$. Thus, we may assume that α_2^k converges to $\bar{\alpha} = \alpha_0 + \int_0^1 \bar{v}(s)ds$ and u_2^k converges to $\bar{u}(t) = \alpha_0 + \int_0^t \bar{v}(s)ds$ in $L^2([0,1],R^n)$. By (4.2), u_3^k converges to $\bar{u}$ in $L^2([0,1],R^n)$. It follows from (4.3) that, for almost all $t\in[0,1]$,

$$\langle v^*, v_3^k(t)\rangle \le \sup\{\langle v^*, v\rangle : v\in F(u_3^k(t))\}\ \forall v^*\in R^n.$$

Taking limits as $k\to\infty$ yields, for almost all $t\in[0,1]$,

$$\langle v^*, \bar{v}(t)\rangle \le \sup\{\langle v^*, v\rangle : v\in F(\bar{u}(t))\}\ \forall v^*\in R^n.$$

Thus, $\bar{v}(t)\in F(\bar{u}(t))$ a.e. in $[0,1]$. The convergence of α_2^k to $\bar{\alpha}$ combined with (4.2) implies that α_1^k also converges to $\bar{\alpha}$. Passing to a subsequence, if necessary, we may assume that the bounded sequences γ_1^k and θ_1^k converge to $\bar{\gamma}$ and $\bar{\theta}$, respectively. Write $\bar{z} := (\bar{\gamma},\bar{\theta},\bar{\alpha},\bar{u},\bar{v})$. Since $f_2(z_2^k) = f_3(z_3^k) = 0$ for sufficiently large k, since f_1 is lower semicontinuous, and since f_4 is weakly lower semicontinuous, we have

$$\lim_{k\to\infty}\sum_{i=1}^4 f_i(z_i^k) \ge f_1(\bar{z}) + f_4(\bar{z}) = \sum_{i=1}^4 f_i(\bar{z}) \ge \sum_{i=1}^4 f_i(\tilde{z}).$$

This verifies that (f_1,f_2,f_3,f_4) is uniformly lower semicontinuous at $\tilde{z}$.

Now we can apply the fuzzy sum rule of Theorem 2.4 to $\sum_{i=1}^4 f_i$ at $\tilde{z}$. Noticing that f_4 is Lipschitzian with rank η, we conclude that there exist $z_1, z_2, z_3 \in \tilde{z} + \eta B_Z$ and $z_i^* \in D_F f_i(z_i), i=1,2,3$, such that

$$\|z_1^* + z_2^* + z_3^*\| < 2\eta. \tag{4.4}$$

Since f_1 does not depend on u and v, we have $z_1^* = (\gamma^*, \theta^*, \alpha^*, 0, 0)$. Similarly, we may write $z_2^* = (0, 0, \beta^*, u^*, v^*)$ and $z_3^* = (0, 0, 0, q, p)$. Our next task is to calculate $z_i^*, i = 1, 2, 3$.

Step 3. *Calculating* z_1^*.

Let $z_1 = (\gamma, \theta, \alpha, u_1, v_1)$, and let g be a concave C^1 function on $R^m \times R^m \times R^n$ such that $g'(\gamma, \theta, \alpha) = (\gamma^*, \theta^*, \alpha^*)$ and $f_1 - g$ attains a minimum at (γ, θ, α). In particular, let $\gamma' = \phi(\alpha')$, and we have that

$$\|\phi(\alpha') - \theta'\| - g(\phi(\alpha'), \theta', \alpha') + \delta_{E \times \Theta}(\alpha', \theta') \tag{4.5}$$

attains a minimum at (θ, α).

We apply the sum rule of Theorem 2.4 and the chain rule of Theorem 2.5 to the functions in (4.5). With some straightforward (yet somewhat tedious) calculation we conclude that there exist $\theta_0 \in (\theta + \eta B_{R^m}) \cap \Theta$, $\alpha_1 \in \alpha + \eta B_{R^n}$, $\alpha_2 \in (\alpha + \eta B_{R^n}) \cap E$, and $\lambda \in N_F(\Theta, \theta_0)$ with $\|\lambda\| \in (1 - 3\eta, 1 + 3\eta)$ such that

$$\alpha^* \in D_F \langle \lambda, \phi \rangle (\alpha_1) + N_F(E, \alpha_2) + \eta B_{R^n}. \tag{4.6}$$

Step 4. *Calculating* z_2^*.

Let $z_2^* = (0, 0, \beta^*, u^*, v^*)$ and $z_2 = (\gamma_2, \theta_2, \beta, u, v)$. Then $(\beta^*, u^*, v^*) \in N_F(K, (\beta, u, v))$. The useful information for us is summarized in the following lemma.

LEMMA 4.1. *Let* $(\beta^*, u^*, v^*) \in N_F(K, (\beta, u, v))$. *Then*

$$\beta^* + v^*(t) + \int_t^1 u^*(s) ds = 0 \ a.e. \ in \ [0, 1].$$

Proof. Since K is convex, the Fréchet normal cone of K coincides with the convex normal cone. Thus,

$$\langle \beta' - \beta, \beta^* \rangle + \langle u' - u, u^* \rangle + \langle v' - v, v^* \rangle \leq 0 \ \forall (\beta', u', v') \in K.$$

By the definition of K we have that, for any $v' \in L^2([0, 1], R^n)$,

$$\left\langle \beta^*, \int_0^1 (v'(t) - v(t)) dt \right\rangle + \int_0^1 \left\langle u^*(t), \int_0^t (v'(s) - v(s)) ds \right\rangle dt$$
$$+ \int_0^1 \langle v^*(t), v'(t) - v(t) \rangle dt \leq 0.$$

Integration by parts yeilds that, for any $v' \in L^2([0, 1], R^n)$,

$$\int_0^1 \left\langle \beta^* + \int_t^1 u^*(s) ds + v^*(t), v'(t) - v(t) \right\rangle dt \leq 0.$$

Thus, $\beta^* + \int_t^1 u^*(s) ds + v^*(t) = 0$ a.e. in $[0, 1]$. □

Step 5. *Calculating* $N_F(C, (u, v))$.

Combining (4.4), (4.6), and Lemma 4.1, we conclude that, for any $\varepsilon > 0$, there exist $\gamma_\varepsilon \in \phi(x(1)) + \varepsilon B_{R^m}$, $\theta_0 \in (\theta + \eta B_{R^m}) \cap \overline{l(\gamma_\varepsilon)} \subset (\phi(x(1)) + \varepsilon B_{R^m}) \cap \overline{l(\gamma_\varepsilon)}$, $\alpha_1 \in \alpha + \eta B_{R^n} \subset x(1) + \varepsilon B_{R^n}$, $\alpha_2 \in (\alpha + \eta B_{R^n}) \cap E \subset (x(1) + \varepsilon B_{R^n}) \cap E$, $\lambda \in N_F(\overline{l(\gamma_\varepsilon)}, \theta_0)$ with $\|\lambda\| \in (1 - \varepsilon, 1 + \varepsilon)$, $\alpha_2^* \in N_F(E, \alpha_2)$, and

$$\alpha^* \in D_F \langle \lambda, \phi \rangle (\alpha_1) + \alpha_2^* + \varepsilon B_{R^n}, \tag{4.7}$$

such that there exist $(u,v)\in(x,\dot{x})+\varepsilon B_{L^2([0,1],R^n)\times L^2([0,1],R^n)}$, $(q,p)\in N_F(C,(u,v))$, and $u^*\in L^2([0,1],R^n)$ satisfying

$$\left\|\left(u^*,-\alpha^*-\int_{\cdot}^{1}u^*(s)ds\right)-(q,p)\right\|<\varepsilon. \tag{4.8}$$

Now we need to calculate the normal cone $N_F(C,(u,v))$. This calculation is similar to [10, Lemma 9.4].

Lemma 4.2. *Let* $(q,p)\in N_F(C,(u,v))$. *Then*

$$(-q(t),v(t))\in\partial_C H(u(t),p(t)) \ \textit{a.e. in}\ [0,1].$$

Proof. Since $(q,p)\in N_F(C,(u,v))$, there exists a C^1 concave function w on $L^2([0,1],R^n)\times L^2([0,1],R^n)$ with $w(u,v)=0$ and $w'(u,v)=0$ such that, for any $(u',v')\in C$,

$$\langle q,u'-u\rangle+\langle p,v'-v\rangle+w(u',v')\le 0. \tag{4.9}$$

Let $B:=(0,1)\cap\{$the Lebesgue points of u and $v\}$. Then B has measure 1. For any $t\in B$, $(x,\nu)\in$ Graph F, and $h>0$, let

$$u_h'(s):=\begin{cases}x & \text{if } s\in[t-h,t+h],\\ u(t) & \text{otherwise,}\end{cases}$$

and

$$v_h'(s):=\begin{cases}\nu & \text{if } s\in[t-h,t+h],\\ v(t) & \text{otherwise.}\end{cases}$$

Then $\|u_h'-u\|=O(h)$, $\|v_h'-v\|=O(h)$, and $w(u_h',v_h')=o(h)$. Setting $(u',v')=(u_h',v_h')$ in (4.9), dividing by $2h$, and taking limits yields

$$\langle q(t),x-u(t)\rangle+\langle p(t),\nu-v(t)\rangle\le 0\ \forall(x,\nu)\in\text{Graph } F. \tag{4.10}$$

In particular, setting $x=u(t)$, we have

$$\langle p(t),\nu-v(t)\rangle\le 0\ \forall\nu\in F(u(t)). \tag{4.11}$$

That is to say

$$\langle p(t),v(t)\rangle=\sup_{\nu\in F(u(t))}\langle p(t),\nu\rangle=H(u(t),p(t)). \tag{4.12}$$

Let

$$\begin{aligned}g(x,p):=&\ \langle p(t)-p,v(t)\rangle+\|p(t)-p\|^2\\ &+\langle q(t),x-u(t)\rangle+H(x,p).\end{aligned}$$

Then g is Lipschitz and strictly convex in p for each x. Let U be a ball around $u(t)$, and let K be a uniform bound for $F(x)$ over U. Then $|H(x,p)|\le K\|p\|$ for $x\in U$. Thus for all $x\in U$, the function $p\to g(x,p)$ attains a unique minimum at $p=p(x)$ and $\|p(x)\|\le c$ for some constant c. We claim that

(i) $p\to g(u(t),p)$ attains a local minimum at $p=p(t)$, and

(ii) $x\to\min_p g(x,p)$ attains a local maximum at $x=u(t)$.

Then it follows from [10, Lemma 9.5] that $(0,0) \in \partial_C g(u(t), p(t))$, i.e.,

$$(-q(t), v(t)) \in \partial_C H(u(t), p(t)).$$

It remains to verify claims (i) and (ii). By the minimax theorem we have

$$\begin{aligned}\min_p g(x,p) &= \min_p \{\langle p(t)-p, v(t)\rangle + \|p(t)-p\|^2 \\ &\qquad + \langle q(t), x-u(t)\rangle + H(x,p)\} \\ &= \min_p \max_{\nu \in F(x)} \{\langle p(t)-p, v(t)\rangle + \|p(t)-p\|^2 \\ &\qquad + \langle q(t), x-u(t)\rangle + \langle p, \nu\rangle\} \\ &= \max_{\nu\in F(x)} \min_p \{\langle p, \nu - v(t)\rangle + \|p(t)-p\|^2 \\ &\qquad + \langle q(t), x-u(t)\rangle + \langle p(t), v(t)\rangle\} \\ &= \max_{\nu \in F(x)} \{\langle p(t), \nu - v(t)\rangle - \|\nu - v(t)\|^2/4 \\ &\qquad + \langle q(t), x-u(t)\rangle + \langle p(t), v(t)\rangle\}.\end{aligned} \tag{4.13}$$

In particular, when $x = u(t)$, we have, by (4.11) and (4.12),

$$\begin{aligned}\min_p g(u(t),p) &= \max_{\nu \in F(u(t))} \{\langle p(t), \nu - v(t)\rangle - \|\nu - v(t)\|^2/4 + \langle p(t), v(t)\rangle\} \\ &= \langle p(t), v(t)\rangle = g(u(t), p(t)).\end{aligned}$$

This verifies (i). On the other hand, combining (4.10) and (4.13), we have

$$\min_p g(x,p) \le \langle p(t), v(t)\rangle = g(u(t),p(t)) = \min_p g(u(t),p),$$

which verifies (ii).

Step 6. *Taking limits.*

Let $\varepsilon = 1/k$ for $k = 1, 2, \ldots$. By (4.7) and (4.8) there exist sequences $\gamma^k, \theta_0^k \to \phi(x(1))$, $\alpha_1^k, \alpha_2^k \to x(1)$, $\lambda^k \in N_F(\overline{l(\gamma^k)}, \theta_0^k)$ with $\|\lambda^k\| \to 1$, $\alpha_2^{*k} \in N_F(E, \alpha_2^k)$,

$$\alpha^{*k} \in D_F\langle\lambda^k, \phi\rangle(\alpha_1^k) + \alpha_2^{*k} + (1/k)B_{R^n}, \tag{4.14}$$

$(u^k, v^k) \to (x, \dot{x})$ in $L^2([0,1], R^n) \times L^2([0,1], R^n)$, $(q^k, p^k) \in N_F(C, (u^k, v^k))$, and $u^{*k} \in L^2([0,1], R^n)$ such that

$$\left\| \left(u^{*k}, -\alpha^{*k} - \int_\cdot^1 u^{*k}(s)ds \right) - (q^k, p^k) \right\| < 1/k. \tag{4.15}$$

We consider the limiting processes for the following two cases.

The Good Case: $\|\alpha_2^{*k}\|$ is bounded. Passing to a subsequence, we may assume that α_2^{*k} converges to $\alpha_2^* \in N(E, x(1))$. Since ϕ is Lipschitzian and $\|\lambda^k\| \to 1$, taking subsequences if necessary, we may assume that α^{*k} converges to

$$\alpha^* \in \partial\langle\lambda, \phi\rangle(x(1)) + N(E, x(1)),$$

where $\lambda \in N(\overline{l(\phi(x(1)))}, \phi(x(1)))$ and $\|\lambda\| = 1$ by (A3).

By Lemma 4.2, $(q^k, p^k) \in N_F(C, (u^k, v^k))$ implies that

$$(-q^k(t), v^k(t)) \in \partial_C H(u^k(t), p^k(t)) \text{ a.e. in } [0,1]. \tag{4.16}$$

Since F is Lipschitz of rank L_F, $H(u,p)$ is Lipschitz with respect to u of rank $L_F\|p\|$. It follows from (4.16) that

$$\|q^k(t)\| \le l\|p^k(t)\|. \tag{4.17}$$

Combining (4.15) and (4.17), we have

$$\|u^{*k}(t)\| \le L_F \left(\int_t^1 \|u^{*k}(s)\|ds + \|\alpha^{*k}\| + 2/k \right).$$

Invoking Gronwall's inequality, we may conclude that $u^{*k}(t)$ is uniformly bounded on $[0,1]$, and, therefore, u^{*k} is a bounded sequence in $L^2([0,1],R^n)$. Again, taking a subsequence if necessary, we may assume that u^{*k} converges weakly to, say, q, in $L^2([0,1],R^n)$. Then, by (4.15), q^k weakly converges to q and p^k strongly converges to $p = -\alpha^* - \int_\cdot^1 q(s)ds$ in $L^2([0,1],R^n)$. Taking limits in (4.16) as $k \to \infty$ yields

$$(-\dot{p}(t), \dot{x}(t)) \in \partial_C H(x(t), p(t)) \text{ a.e. in } [0,1].$$

It is obvious that $-p(1) = \alpha^* \in \partial\langle\lambda,\phi\rangle(x(1)) + N(E,x(1))$. Thus, we derived the necessary condition in Theorem 3.2 corresponding to the case when $\lambda_0 = 1$.

The Bad Case: $\|\alpha_2^{*k}\|$ is unbounded. Without loss of generality, we may assume that $\|\alpha_2^{*k}\| \to \infty$. Dividing sequences $\alpha^{*k}, \alpha_2^{*k}, u^{*k}, q^k$, and p^k by $\|\alpha_2^{*k}\|$ and taking limits as before yield that there exists an absolutely continuous function p satisfying

$$(-\dot{p}(t), \dot{x}(t)) \in \partial_C H(x(t), p(t)) \text{ a.e. in } [0,1]$$

with $-p(1) = \alpha^* = \lim_{k\to\infty} \alpha^{*k}/\|\alpha_2^{*k}\| = \lim_{k\to\infty} \alpha_2^{*k}/\|\alpha_2^{*k}\| \in N(E,x(1))$. Observing that $\|\alpha^*\| = 1$, we have $\|p(t)\| > 0$ for all $t \in [0,1]$. This corresponds to the necessary condition in Theorem 3.2 when $\lambda_0 = 0$.

Finally, we observe that if $x(1) \in \text{int } E$, then when k is sufficiently large $\alpha_2^{*k} = 0$, so that the good case always applies. □

ADAPTIVE FINITE ELEMENT METHODS FOR OPTIMAL CONTROL OF PARTIAL DIFFERENTIAL EQUATIONS: BASIC CONCEPT[*]

ROLAND BECKER[†], HARTMUT KAPP[†], AND ROLF RANNACHER[†]

Abstract. A new approach to error control and mesh adaptivity is described for the discretization of optimal control problems governed by elliptic partial differential equations. The Lagrangian formalism yields the first-order necessary optimality condition in form of an indefinite boundary value problem which is approximated by an adaptive Galerkin finite element method. The mesh design in the resulting reduced models is controlled by residual-based a posteriori error estimates. These are derived by duality arguments employing the cost functional of the optimization problem for controlling the discretization error. In this case, the computed state and costate variables can be used as sensitivity factors multiplying the local cell-residuals in the error estimators. This results in a generic and simple algorithm for mesh adaptation within the optimization process. This method is developed and tested for simple boundary control problems in semiconductor models.

Key words. optimal control problem, finite elements, a posteriori error estimates, mesh adaptation, model reduction

1. Introduction.

In this article, we develop an adaptive Galerkin finite element method for optimal control problems governed by elliptic partial differential equations. The main goal is the derivation of a posteriori error estimates as basis for guiding the mesh adaptation and for controlling the error in this model reduction. The problems considered have the form

$$J(u,q) \;\to\; \min!, \qquad A(u) = f + B(q), \tag{1.1}$$

where A is an elliptic differential operator for the state variable u, B an impact operator for the control variable q, and J is a cost functional. As prototypical examples, we will consider problems of boundary control in semiconductor models. Our approach utilizes the classical Lagrangian framework for reformulating the optimal control problem (1.1) as a boundary value problem for stationary points of the associated first-order necessary optimality condition. Introducing the Lagrangian functional

$$\mathcal{L}(u,\lambda,q) := J(u,q) + \langle \lambda, A(u,q) - B(q) - f\rangle, \tag{1.2}$$

with the costate variable λ (Lagrangian multiplier), the solutions of (1.1) are among the stationary points of $\mathcal{L}$, determined by the system of equations

$$\nabla\mathcal{L}(u,\lambda,q) = 0. \tag{1.3}$$

We use a standard finite element method for discretizing this saddle-point problem which results in finite dimensional problems

$$\nabla\mathcal{L}(u_h, \lambda_h, q_h) = 0, \tag{1.4}$$

for the "discrete" states u_h, controls q_h, and costates λ_h. As long as the discretization procedure uses a pure Galerkin approach the discrete problem actually corresponds to a formulation of the original minimization problem on the discrete state space. Since discretization in partial differential equations is expensive, at least for praxis-relevant models, the question of how this "model reduction" affects the quality of the optimization result is crucial for a cost-efficient computation. The need for a posteriori error control is therefore evident.

The discretization of the state equation generally leads to approximate solutions $\{u_h, q_h\}$ which are *not admissible* in the strict sense for the original constrained minimization problem. Let S denote the solution operator which associates the state variable $u = u(q)$ to a given control function. The *optimal* control minimizes the functional $j(q) := J(S(q), q)$ for all controls. Then, discretization of the state equation also changes the functional. Denoting by S_h the discrete solution operator, the discrete optimal control q_h solves

$$j_h(q_h) := J(S_h(q_h), q_h) \ \rightarrow \ \min!. \tag{1.5}$$

If we want to perform numerical computation with controlled accuracy, we have to substitute the notion of an "admissible solution" by an error estimate for the state equation. Of course, the distance between the numerical and the exact solution should be measured with respect to the specific needs of the optimization problem, i.e., its effect on the functional to be minimized. This asks for a sensitivity analysis for the optimization problem with respect to perturbations in the state equation, particularly perturbations resulting from discretization. In this sense, our a posteriori error estimation aims to control the error due to replacing the infinite dimensional problem (1.1) by its finite dimensional analogue. The crucial question is now which quality measure is appropriate for controlling the discretization error. In general, forcing this error to be small uniformly in the whole computational domain, as is often required in ODE models, is not feasible for partial differential equations. Therefore, we need to develop control of the discretization error in accordance with the sensitivity properties of the optimization problem.

Our approach to this problem uses the general method developed in [3] and [4] for error control in the Galerkin finite element discretization of differential equations of the general form $A(u) = f$. Employing the linearized dual problem

$$A'(u_h)^* z = F(\cdot) \tag{1.6}$$

for an arbitrary output functional F, an a posteriori error estimate

$$|F(u) - F(u_h)| \leq \eta_\omega(u_h) := \sum_{T\in\mathbb{T}_h} \rho_T(u_h)\, \omega_T(z) \tag{1.7}$$

can be derived. On a computational mesh $\mathbb{T}_h = \{T\}$ consisting of cells T, the local consistency errors, expressed in terms of residuals $\rho_T(u_h)$, are multiplied by weights $\omega_T(z)$ involving the "dual solution" z. These weights describe the dependence of the error on variations of the local residuals, i.e., on the local mesh size. In general the estimate (1.7) has to be approximated by numerically solving the dual problem (1.6). This results in a feedback process for generating successively more and more accurate error bounds and solution-adapted meshes. In applying this approach to saddle-point problems arising from optimal control problems, it seems natural to base the error control on the given cost functional, i.e., to choose $F := J$. In this particular case the corresponding approximate dual solution can be expressed in terms of the computed solution $\{u_h, \lambda_h, q_h\}$. Hence, the evaluation of the corresponding a posteriori error estimate

$$|J(u,q) - J(u_h,q_h)| \le \eta_\omega(u_h,\lambda_h,q_h) \tag{1.8}$$

does not require much extra work and a posteriori error estimation is almost for free. This leads to a generic and simple strategy for mesh adaptation in discretizing optimal control problems.

It may be seen as a drawback that in this approach the accuracy in the discretization of the state equation is only controlled with respect to its effect on the cost functional. This can lead to discrete models which approximate the original optimization problem with minimal cost but the obtained discrete states and controls are “admissible” only in a very weak sense, possibly insufficient for the particular application. If satisfaction of the state equation is desired in a stronger sense, we can combine our method with traditional “energy-error control” leading to an a posteriori error estimate of the form

$$|J(u,q) - J(u_h,q_h)| + \beta\,\|A(u_h) - f - B(q_h)\|_* \;\le\; \eta_{\omega,E}(u_h,\lambda_h,q_h), \tag{1.9}$$

where $\|\cdot\|_*$ denotes the dual of the natural “energy norm” corresponding to the operator $A'(u)$, and β is a tuning factor. For a discussion of adaptive finite element methods using residual-based a posteriori error estimates, we refer to the survey papers [1], [14], [8], and [12].

First, we develop our approach within a general setting in order to abstract from inessential technicalities. Then, all steps are made concrete for a linear model problem of boundary control. Despite its simplicity this problem represents the main structure of optimal control and is chosen in order to clarify the idea underlying the proposed procedure. Some numerical results illustrate the main features of the adaptive algorithm particularly in comparison to more conventional methods based on global error control for the state equation. At the end, we extend our method to problems with nonlinear state equations with an example of boundary control in semiconductor models.

2. A linear model situation. We consider an abstract setting for optimal control: Let Q, V, and H be Hilbert spaces for the control variable $q \in Q$, the state variable $u \in V$, and given observations $c_0 \in H$. The inner product and norm of H are $(\cdot,\cdot)$ and $\|\cdot\|$, respectively. The state equation is given in the form

$$a(u,\varphi) = (f,\varphi) + b(q,\varphi) \quad \forall \varphi \in V, \tag{2.1}$$

where the bilinear form $a(\cdot,\cdot)$ represents a linear elliptic operator and the bilinear form $b(\cdot,\cdot)$ expresses the action of the control. The goal is to minimize the cost functional

$$J(u,q) = \tfrac{1}{2}\|cu - c_0\|^2 + \tfrac{1}{2}n(q,q), \tag{2.2}$$

where $c : V \to H$ is a linear bounded observation operator. For simplicity, we assume that $a(\cdot,\cdot)$ and $n(\cdot,\cdot)$ induce norms on the spaces V and Q denoted by $\|\cdot\|_a$ and $\|\cdot\|_n$, respectively. This guarantees the existence of a unique solution of the optimal control problem and the classical regularity theory for elliptic equations applies (see, e.g., [11]).

Introducing a Lagrangian parameter $\lambda \in V$ and the Lagrangian function $\mathcal{L}(u,q,\lambda)$,

$$\mathcal{L}(u,q,\lambda) := J(u,q) + a(u,\lambda) - b(q,\lambda) - (f,\lambda),$$

the first-order necessary conditions (Euler–Lagrange equations) of the optimization problem,

$$\nabla\mathcal{L}(u,q,\lambda)(v,\mu,r) = 0 \quad \forall\{v,\mu,r\} \in V \times V \times Q \tag{2.3}$$

have the explicit form

$$\begin{aligned} a(v,\lambda) + (cu - c_0, cv) &= 0 \quad \forall v \in V, \\ a(u,\mu) - b(q,\mu) &= (f,\mu) \quad \forall \mu \in V, \\ -b(r,\lambda) + n(q,r) &= 0 \quad \forall r \in Q. \end{aligned} \tag{2.4}$$

This system has the usual saddle-point structure

$$\begin{aligned} (cu,cv) + a(v,\lambda) &= (c_0,cv) \quad \forall v \in V, \\ a(u,\mu) - b(q,\mu) &= (f,\mu) \quad \forall \mu \in V, \\ -b(r,\lambda) + n(q,r) &= 0 \quad \forall r \in Q. \end{aligned} \tag{2.5}$$

Introducing operators A, B, C, N which represent the corresponding bilinear forms, system (2.5) can also be written in matrix form as

$$\begin{bmatrix} C & A^T & 0 \\ A & 0 & -B \\ 0 & -B^T & N \end{bmatrix} \begin{bmatrix} u \\ \lambda \\ q \end{bmatrix} = \begin{bmatrix} c_0 \\ f \\ 0 \end{bmatrix}. \tag{2.6}$$

Below, we will consider the following realization of the foregoing abstract setting which represents the case of an elliptic linear state equation subjected to boundary control. Let $\Omega \subset \mathbb{R}^2$ be an open bounded domain with Lipschitz boundary $\partial\Omega$ which is decomposed into a homogeneous Neumann part Γ_N and a control part Γ_C on which the control acts ($\partial\Omega = \Gamma_C \cup \Gamma_N$),

$$\begin{gathered} -\Delta u + u = f \quad \text{in } \Omega, \\ \partial_n u = 0 \ \text{ on } \Gamma_N, \quad \partial_n u = q \ \text{ on } \Gamma_C. \end{gathered} \tag{2.7}$$

The observations are given on a part Γ_O of the boundary and the associated cost functional is

$$J(u,q) = \tfrac{1}{2}\|u - c_0\|^2_{\Gamma_O} + \tfrac{\alpha}{2}\|q\|^2_{\Gamma_C} \tag{2.8}$$

with a regularization parameter $\alpha > 0$. In this case the natural choice for the function spaces is $V = H^1(\Omega)$, the first-order Sobolev Hilbert-space over Ω, and $H = L^2(\Gamma_O)$, $Q = L^2(\Gamma_C)$, the usual Lebesgue Hilbert-spaces over Γ_C and Γ_O, respectively. The bilinear forms $a(\cdot,\cdot)$, $b(\cdot,\cdot)$ and $n(\cdot,\cdot)$ are given by

$$a(u,v) = (\nabla u, \nabla v)_\Omega + (u,v)_\Omega, \quad b(q,v) = (q,v)_{\Gamma_C}, \quad n(q,r) = \alpha(q,r)_{\Gamma_C},$$

where $(\cdot,\cdot)_\Sigma$ denotes the L^2-inner product on the set Σ. The operator c in the cost functional is the trace operator, $cu = u_{|\Gamma_O}$. Then, the necessary optimality condition $\nabla\mathcal{L}(u,\lambda,q) = 0$ reads as follows:

$$\begin{aligned} (u,v)_{\Gamma_O} - (c_0,v)_{\Gamma_O} + (\nabla v,\nabla\lambda)_\Omega + (v,\lambda)_\Omega &= 0 \quad \forall v \in V,\\ (\nabla u,\nabla\mu)_\Omega + (u,\mu)_\Omega - (f,\mu)_\Omega - (q,\mu)_{\Gamma_C} &= 0 \quad \forall \mu \in V,\\ \alpha(q,r)_{\Gamma_C} - (\lambda,r)_{\Gamma_C} &= 0 \quad \forall r \in Q. \end{aligned} \tag{2.9}$$

3. A priori error estimate.

3. A priori error estimate. For simplicity of notation, we introduce the product space $X = V\times V\times Q$, with elements of the form $x = \{u,\lambda,q\}$, which is equipped with the natural norm

$$\|x\|_X := \big(\|u\|_a^2 + \|\lambda\|_a^2 + \|q\|_n^2\big)^{1/2}.$$

Furthermore, we define a bilinear form $A(\cdot,\cdot)$ on X by

$$A(x,y) = A(\{u,\lambda,q\},\{v,\mu,r\}) := (cu,c\mu) + a(u,v) - b(q,v) + a(\mu,\lambda) - b(r,\lambda) + n(q,r).$$

Using this notation, system (2.5) can be written in compact form as

$$A(x,y) = F(y) \quad \forall y \in X, \tag{3.1}$$

with the linear functional $F(\cdot)$ defined by

$$F(y) = F(\{v,\mu,r\}) := (c_0,c\mu) + (f,v).$$

In order to simplify the analysis, we impose the following conditions:

$$|A(x,y)| \le c_A\|x\|_X\|y\|_X, \tag{3.2}$$

$$|b(r,v)| \le c_b\|r\|_n\|v\|_a. \tag{3.3}$$

The second condition, which relies on the presence of the regularization term $n(\cdot,\cdot)$ (requiring that $\alpha > 0$ in the above example), is rather strong. It can be substituted by an "inf-sup" condition for $b(\cdot,\cdot)$ under which the regularization could be omitted; see Remark 3.1, below. The bilinear form $A(\cdot,\cdot)$ satisfies the following stability condition.

PROPOSITION 3.1. *Under the assumptions* (3.2) *and* (3.3)*, there exists a constant* $\gamma > 0$ *such that*

$$\inf_{x\in X}\left\{\sup_{y\in X}\frac{A(x,y)}{\|x\|_X\|y\|_X}\right\} \ge \gamma. \tag{3.4}$$

Proof. For any fixed $x = \{u,\lambda,q\}$, we choose the test triple $y = \{v,\mu,r\} := \{u,\lambda,q\}$ to obtain

$$\begin{aligned} A(x,y) &= \|cu\|^2 + \|u\|_a^2 + \|\lambda\|_a^2 + \|q\|_n^2 - b(q,\lambda) - b(q,u)\\ &\ge \|cu\|^2 + \|u\|_a^2 + \|\lambda\|_a^2 + \|q\|_n^2 - \tfrac14\|q\|_n^2 - \tfrac34\|\lambda\|_a^2 - \tfrac14\|q\|_n^2 - \tfrac34\|u\|_a^2\\ &\ge \|cu\|^2 + \tfrac14\|u\|_a^2 + \tfrac14\|\lambda\|_a^2 + \tfrac12\|q\|_n^2. \end{aligned}$$

We conclude the asserted estimate by noting that $\|y\| = \|x\|$. □

We consider the discretization of the variational equation (3.1) by a standard Galerkin method using trial spaces $X_h := V_h\times V_h\times Q_h \subset X$. For each $x \in X$, there shall exist an interpolation $i_h x \in X_h$, such that $\|x - i_h x\|_X \;\to\; 0 \; (h \to 0)$. Then, approximations $x_h \in X_h$ are determined by

$$A(x_h, y_h) = F(y_h) \quad \forall y_h \in X_h. \tag{3.5}$$

This discretization is automatically stable since a discrete analogue of (3.4) is fulfilled by the same argument as used above,

$$\inf_{x_h \in X_h} \left\{ \sup_{y_h \in X_h} \frac{A(x_h, y_h)}{\|x_h\|_X \|y_h\|_X} \right\} \geq \gamma > 0. \tag{3.6}$$

Combining (3.5) and (3.1), we get the Galerkin orthogonality

$$A(x - x_h, y_h) = 0, \quad y_h \in X_h. \tag{3.7}$$

This leads us to the following abstract a priori error estimate.

Proposition 3.2. *For the Galerkin approximation in $X_h \subset X$, there holds*

$$\begin{aligned} \|u - u_h\|_a + &\|\lambda - \lambda_h\|_a + \|q - q_h\|_n \\ &\leq c\Big\{ \inf_{\mu_h \in V_h} \|u - \mu_h\|_a + \inf_{v_h \in V_h} \|\lambda - v_h\|_a + \inf_{r_h \in Q_h} \|q - r_h\|_n \Big\}. \end{aligned} \tag{3.8}$$

Proof. The stability estimate (3.6) implies that

$$\gamma \|i_h x - x_h\| \leq \sup_{y_h \in X_h} \frac{A(i_h x - x_h, y_h)}{\|y_h\|_X} = \sup_{y_h \in X_h} \frac{A(i_h x - x, y_h)}{\|y_h\|_X} \leq c_A \|i_h x - x\|_X \,.$$

Here, we have used the Galerkin relation (3.7) and the continuity estimate (3.2). □

Remark 3.1. *Of course, more precise error estimates could be given exploiting the structure of the underlying problem. For instance, it may be possible to equip the space Q with a different norm than the one induced by $n(\cdot,\cdot)$, in order to get robustness with respect to the regularization. This requires us to replace* (3.3) *by the following weaker inf-sup condition*

$$\inf_{q \in Q} \left\{ \sup_{v \in V} \frac{b(q, v)}{\|v\|_a} \right\} \geq \kappa > 0.$$

We note that for the model example with boundary control and boundary observations given above the conditions (3.2) *and* (3.3) *are satisfied.*

4. A posteriori error estimate. In this section, we derive an a posteriori error estimate for the model control problem. As discussed above, the error estimator to be derived should control the value of the cost functional. First, we carry out the analysis in the abstract functional analytic setting. Recalling the definition of the Lagrange functional $\mathcal{L}$,

$$\mathcal{L}(x) = \mathcal{L}(u, \lambda, q) = J(u, q) + a(u, \lambda) - (f, \lambda) - b(q, \lambda),$$

the continuous and discrete optimal control solutions $x = \{u, \lambda, q\} \in X$ and $x_h = \{u_h, \lambda_h, q_h\} \in X_h$ satisfy

$$\nabla\mathcal{L}(x)(\varphi) = 0, \quad \varphi \in X, \qquad \nabla\mathcal{L}(x_h)(\varphi_h) = 0, \quad \varphi_h \in X_h. \tag{4.1}$$

This implies the Galerkin orthogonality relation

$$\nabla^2\mathcal{L}(x-x_h,\varphi_h)=0,\quad \varphi_h\in X_h, \tag{4.2}$$

for which it is essential that $\mathcal{L}$ is quadratic. Since the solutions u and u_h satisfy the corresponding state equations, the cost functional and the Lagrangian functional are related by

$$J(u,q)-J(u_h,q_h)=\mathcal{L}(x)-\mathcal{L}(x_h). \tag{4.3}$$

Further, there holds

$$\mathcal{L}(x)-\mathcal{L}(x_h)=\nabla\mathcal{L}(x)(x-x_h)-\tfrac{1}{2}\nabla^2\mathcal{L}(x-x_h,x-x_h). \tag{4.4}$$

The first term on the right-hand side vanishes since x is a stationary point of $\mathcal{L}$. Using the Galerkin orthogonality relation (4.2) in the second term, we obtain for arbitrary $\varphi_h\in X_h$ that

$$\nabla^2\mathcal{L}(x-x_h,x-x_h)=\nabla^2\mathcal{L}(x-x_h,x-x_h-\varphi_h)=-\nabla\mathcal{L}(x_h)(x-x_h-\varphi_h). \tag{4.5}$$

Therefore, choosing $\varphi_h=i_hx-x_h$, we get the following error representation.

PROPOSITION 4.1. *For the abstract model problem with linear state equation and quadratic cost functional, the following error identity holds:*

$$J(u,q)-J(u_h,q_h)=\tfrac{1}{2}\nabla\mathcal{L}(x_h)(x-i_hx). \tag{4.6}$$

In order to convert the abstract error identity (4.6) into a form which can be evaluated, we need to be more specific about the setting of the underlying problem and its discretization. As an example, we demonstrate this for the linear Neumann control problem described by (2.7) and (2.8). Here, the Galerkin finite element discretization of the saddle-point problem (2.9) uses subspaces $V_h\subset V=H^1(\Omega)$ and $Q_h\subset Q=L^2(\Gamma_C)$ of piecewise polynomial functions defined on regular decompositions $\mathbb{T}_h=\{T\}$ of the domain Ω into cells T (triangles or quadrilaterals); for a detailed description of such a setting see, e.g., Brenner and Scott [5]. Here, we use quadrilateral meshes where on each cell T the local shape functions are constructed by mapping bilinear functions defined on a reference square to the cell T. This ansatz is referred to as the "isoparametric" bilinear finite element. We assume that the space Q_h of discrete controls is given by the traces along Γ_C of the finite element functions of V_h. This is not necessary for our results but simplifies the notation. In order to avoid the technicalities caused by curved boundaries, we suppose the domain Ω to be polygonal. We use the notation $h_T:=diam(T)$ and $h_\Gamma:=diam(\Gamma)$ for the width of a cell $T\in\mathbb{T}_h$ and a corresponding cell edge $\Gamma\subset\partial T$. In order to ease local mesh refinement and coarsening, "hanging nodes" are allowed, but at most one per cell edge; see Figure 4.1. The degree of freedom at such a hanging node is eliminated by interpolation in order to keep the discretization "conforming" (see, e.g., [6] and [3]).

First, we turn (4.6) into a residual based a posteriori estimate as follows.

PROPOSITION 4.2. *For error control with respect to the cost functional J, there holds the weighted a posteriori error estimate*

$$|J(u,q)-J(u_h,q_h)|\ \le\ \eta_\omega(u_h,\lambda_h,q_h)=\sum_{T\in\mathbb{T}_h}\eta_T(u_h,\lambda_h,q_h), \tag{4.7}$$

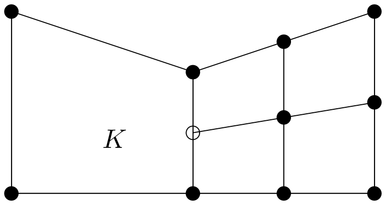

FIG. 4.1. *Quadrilateral mesh patch with a "hanging node."*

with the local error indicators

$$\eta_T(u_h,\lambda_h,q_h) := \rho_T^{(u)}\,\omega_T^{(\lambda)} + \rho_{\partial T}^{(u)}\,\omega_{\partial T}^{(\lambda)} + \rho_T^{(\lambda)}\,\omega_T^{(u)} + \rho_{\partial T}^{(\lambda)}\,\omega_{\partial T}^{(u)} + \rho_{\partial T}^{(q)}\,\omega_{\partial T}^{(q)}$$

and the cellwise residuals and weights

$$\begin{aligned}
\rho_T^{(u)} &:= \|R_h^{(u)}\|_T, & \omega_T^{(\lambda)} &:= \|\lambda - i_h\lambda\|_T,\\
\rho_{\partial T}^{(u)} &:= \|r_h^{(u)}\|_{\partial T}, & \omega_{\partial T}^{(\lambda)} &:= \|\lambda - i_h\lambda\|_{\partial T},\\
\rho_T^{(\lambda)} &:= \|R_h^{(\lambda)}\|_T, & \omega_T^{(u)} &:= \|u - i_h u\|_T,\\
\rho_{\partial T}^{(\lambda)} &:= \|r_h^{(\lambda)}\|_{\partial T}, & \omega_{\partial T}^{(u)} &:= \|u - i_h u\|_{\partial T},\\
\rho_{\partial T}^{(q)} &:= \|r_h^{(q)}\|_{\partial T\cap\Gamma_C}, & \omega_{\partial T}^{(q)} &:= \|q - j_h q\|_{\partial T\cap\Gamma_C}.
\end{aligned}$$

The "cell residuals" $R_h^{(u)}$, $R_h^{(\lambda)}$ and the "edge residuals" $r_h^{(u)}$, $r_h^{(\lambda)}$, $r_h^{(q)}$ are on cells T and cell edges Γ defined by

$$R_{h|T}^{(u)} := -\Delta u_h + u_h - f, \quad R_{h|T}^{(\lambda)} := -\Delta\lambda_h + \lambda_h, \qquad r_{h|\Gamma}^{(q)} := \alpha q_h - \lambda_h \ \text{ if } \Gamma\subset\Gamma_C,$$

$$r_{h|\Gamma}^{(u)} := \begin{cases} \frac{1}{2}h_\Gamma^{-1/2}[\partial_n\varphi_h] & \text{if } \Gamma\subset\partial T\setminus\partial\Omega,\\ h_\Gamma^{-1/2}\partial_n u_h & \text{if } \Gamma\subset\partial\Omega\backslash\Gamma_C,\\ h_\Gamma^{-1/2}(\partial_n u_h - q_h) & \text{if } \Gamma\subset\Gamma_C, \end{cases} \qquad r_{h|\Gamma}^{(\lambda)} := \begin{cases} \frac{1}{2}h_\Gamma^{-1/2}[\partial_n\varphi_h] & \text{if } \Gamma\subset\partial T\setminus\partial\Omega,\\ h_\Gamma^{-1/2}\partial_n\lambda_h & \text{if } \Gamma\subset\partial\Omega\backslash\Gamma_O,\\ h_\Gamma^{-1/2}(c_0 - u_h + \partial_n\lambda_h) & \text{if } \Gamma\subset\Gamma_O. \end{cases}$$

Here, $[\partial_n\varphi_h]$ denotes the jump of the normal derivative of φ_h across the interelement edges Γ, the boundary components Γ_C, Γ_O are the control and observation boundary, respectively, and i_h, j_h denote some local interpolation operators into the finite element spaces.

Proof. From the abstract error identity (4.6), we obtain that

$$\begin{aligned}
J(u,q) - J(u_h,q_h) &= \tfrac{1}{2}\nabla\mathcal{L}(x_h)(x - i_h x)\\
&= \tfrac{1}{2}(c_0 - u_h, u - i_h u)_{\Gamma_O} + \tfrac{1}{2}a(u - i_h u, \lambda_h)\\
&\quad + \tfrac{1}{2}a(u_h, \lambda - i_h\lambda) - \tfrac{1}{2}(f, \lambda - i_h\lambda) - \tfrac{1}{2}b(q_h, \lambda - i_h\lambda)\\
&\quad + \tfrac{1}{2}n(q_h, q - j_h q) - \tfrac{1}{2}b(q - j_h q, \lambda_h)\\
&=: I_\lambda + I_u + I_q.
\end{aligned}$$

Recalling the definition of the bilinear forms and integrating cellwise by parts, the first term I_λ is rewritten as follows:

$$\begin{aligned}
2I_\lambda &= (c_0-u_h,u-i_hu)_{\Gamma_O}+a(u-i_hu,\lambda_h)\\
&= (c_0-u_h,u-i_hu)_{\Gamma_O}+(\nabla(u-i_hu),\nabla\lambda_h)+(u-i_hu,\lambda_h)\\
&= (c_0-u_h+\partial_n\lambda_h,u-i_hu)_{\Gamma_O}+(u-i_hu,\partial_n\lambda_h)_{\partial\Omega\setminus\Gamma_O}\\
&\quad+\sum_{T\in\mathbb{T}_h}\Big\{(u-i_hu,-\Delta\lambda_h+\lambda_h)_T+(u-i_hu,\partial_n\lambda)_{\partial T\setminus\partial\Omega}\Big\}\\
&= (c_0-u_h+\partial_n\lambda_h,u-i_hu)_{\Gamma_O}+(u-i_hu,\partial_n\lambda_h)_{\partial\Omega\setminus\Gamma_O}\\
&\quad+\sum_{T\in\mathbb{T}_h}\Big\{(u-i_hu,-\Delta\lambda_h+\lambda_h)_T+\tfrac12(u-i_hu,[\partial_n\lambda])_{\partial T\setminus\partial\Omega}\Big\}.
\end{aligned}$$

Hence using the definition of the residuals $r_h^{(\lambda)}$ and $R_h^{(\lambda)}$, we find

$$\begin{aligned}
2I_\lambda &= (u-i_hu,r_h^{(\lambda)})_{\partial\Omega}+\sum_{T\in\mathbb{T}_h}\Big\{(u-i_hu,R_h^{(\lambda)})_T+(u-i_hu,r_h^{(\lambda)})_{\partial T\setminus\partial\Omega}\Big\}\\
&= \sum_{T\in\mathbb{T}_h}\Big\{(u-i_hu,R_h^{(\lambda)})_T+(u-i_hu,r_h^{(\lambda)})_{\partial T}\Big\},
\end{aligned}$$

and, consequently by the Cauchy–Schwarz inequality,

$$2|I_\lambda| \le \sum_{T\in\mathbb{T}_h}\Big\{\|u-i_hu\|_T\,\|R_h^{(\lambda)}\|_T+\|u-i_hu\|_{\partial T}\,\|r_h^{(\lambda)}\|_{\partial T}\Big\}.$$

In the same way, we get for the other terms I_λ and I_q:

$$\begin{aligned}
2I_u &= a(u_h,\lambda-i_h\lambda)-(f,\lambda-i_h\lambda)-b(q_h,\lambda-i_h\lambda)\\
&= (\nabla u_h,\nabla(\lambda-i_h\lambda))+(u_h,\lambda-i_h\lambda)-(f,\lambda-i_h\lambda)-(q_h,\lambda-i_h\lambda)_{\Gamma_C}\\
&= \sum_{T\in\mathbb{T}_h}\Big\{(-\Delta u_h+u_h-f,\lambda-i_h\lambda)_T+\tfrac12([\partial_nu_h],\lambda-i_h\lambda)_{\partial T\setminus\partial\Omega}\Big\}\\
&\quad+(\partial_nu_h,\lambda-i_h\lambda)_{\partial\Omega\setminus\Gamma_C}+(\partial_nu_h-q_h,\lambda-i_h\lambda)_{\Gamma_C}\\
&= \sum_{T\in\mathbb{T}_h}\Big\{(R_h^{(u)},\lambda-i_h\lambda)_T+(r_h^{(u)},\lambda-i_h\lambda)_{\partial T\setminus\partial\Omega}\Big\}\\
&\quad+(r_h^{(u)},\lambda-i_h\lambda)_{\partial\Omega\setminus\Gamma_C}+(r_h^{(u)},\lambda-i_h\lambda)_{\Gamma_C}\\
&= \sum_{T\in\mathbb{T}_h}\Big\{(R_h^{(u)},\lambda-i_h\lambda)_T+(r_h^{(u)},\lambda-i_h\lambda)_{\partial T}\Big\},
\end{aligned}$$

$$\begin{aligned}
2I_q &= n(q_h,q-j_hq)-b(q-j_hq,\lambda_h)\;=\;(\alpha q_h-\lambda_h,q-j_hq)_{\Gamma_C}\\
&= \sum_{\Gamma\subset\Gamma_C}(r_h^{(q)},q-j_hq)_\Gamma,
\end{aligned}$$

and, consequently,

$$\begin{aligned}
2|I_u| &\le \sum_{T\in\mathbb{T}_h}\Big\{\|R_h^{(u)}\|_T\,\|\lambda-i_h\lambda\|_T+\|r_h^{(u)}\|_{\partial T}\,\|\lambda-i_h\lambda\|\|_{\partial T}\Big\},\\
2|I_q| &\le \sum_{\Gamma\subset\Gamma_C}\|r_h^{(q)}\|_\Gamma\,\|q-j_hq\|_\Gamma\,.
\end{aligned}$$

Collecting these estimates implies the asserted result. □

REMARK 4.1. *We note that in the a posteriori error estimate* (4.7)*, the residual of the state equation is weighted by terms involving the adjoint variable* λ *from the original equation* (2.5)*. This has a natural interpretation as it is well known from sensitivity analysis that the adjoint variable is a measure for the influence of perturbations on the cost functional. Since discretization can be interpreted as a special kind of perturbation, the appearance of* λ *in the estimator is not surprising. The special form of the weights involving the interpolation* $i_h z$ *is a characteristic feature of the Galerkin discretization.*

REMARK 4.2. *The a posteriori error estimate* (4.7) *is easier to understand if one recalls the model situation of approximating the boundary value problem*

$$-\Delta u = f \ \ in\, \Omega, \quad u = 0 \ \ on\, \partial\Omega,$$

by a Galerkin finite element method. The natural variational formulation of this problem is equivalent to an unconstraint optimization problem, namely, the minimization of the "energy functional" $J(u) := \frac{1}{2}\|\nabla u\|_\Omega^2 - (f,u)_\Omega$ *over the solution space* $V := H_0^1(\Omega)$*. In this context, in view of the identity*

$$J(u) - J(u_h) = -\tfrac{1}{2}\|\nabla e\|_\Omega^2,$$

error control with respect to the energy functional is equivalent to control of the error in the energy norm, $\|\nabla e\|_\Omega$*. It is well known that the latter can be achieved without referring to an additional dual problem since in this case the corresponding dual solution coincides with the error* e *itself; see* [3] *for a discussion of energy-error control in the context of "duality techniques."*

Evaluation of error estimators. The a posteriori error estimate (4.7) still involves the *continuous* solutions $\{u, \lambda, q\}$. As proposed in [4], we use the computed solutions $\{u_h, \lambda_h, q_h\}$ for approximating the weights $\omega_{\partial T}^{(\cdot)}$ and $\omega_T^{(\cdot)}$. To this end, we recall the well-known local approximation properties of finite elements, e.g.,

$$\|u - i_h u\|_T + h_\Gamma^{1/2}\|u - i_h u\|_\Gamma \le c_I h_T\, \|\nabla^2 u\|_T, \tag{4.8}$$

where $\Gamma \subset \partial T$, and i_h is the generic operator of cellwise nodal interpolation into V_h, with interpolation constant usually in the range $c_I \sim 0.1 - 1$; for details of the interpolation theory for finite elements, we refer to [5]. Analogous estimates hold for the terms involving q and λ. Then, the derivatives are approximated by suitable difference quotients, e.g.,

$$\|\nabla^2 u\|_T \approx \|\nabla_h^2 u_h\|_T. \tag{4.9}$$

For a more detailed discussion of this evaluation of weights and some of its alternatives, we refer to [4]. We emphasize that the proposed procedure for evaluating the a posteriori error estimate (4.7) uses only information in terms of the already computed solution $\{u_h, \lambda_h, q_h\}$.

Error control for the state variable. The estimate (4.7) provides control of the error with respect to the cost functional which is the quantity of primary interest in the optimization problem. But this does not include control of the error in the state equation. Though the corresponding residuals $\rho_T^{(u)}$ and $\rho_{\partial T}^{(u)}$ are present in the error estimator, they are weighted according to their effect on the cost functional. In case that the discrete state u_h is required to be admissible in a stronger sense, the error estimate (4.7) can be extended to also include control of the error in satisfying the state equation measured in the natural energy norm

$$\|u\|_E := \left(\|u\|^2 + \|\nabla u\|^2\right)^{1/2}.$$

The standard a posteriori error analysis for the boundary value problem

$$-\Delta u + u = f \ \text{ in } \Gamma_C, \quad \partial_n u = 0 \ \text{ on } \Gamma_N, \quad \partial_n u = q \ \text{ on } \Gamma_C, \tag{4.10}$$

for frozen control q, yields the following bound for the "energy error":

$$\|u-u_h\|_E^2 \ \le\ \eta_E(u_h) := c \sum_{T\in\mathbb{T}_h} \left\{\rho_T^{(u)2} + \rho_{\partial T}^{(u)2}\right\}, \tag{4.11}$$

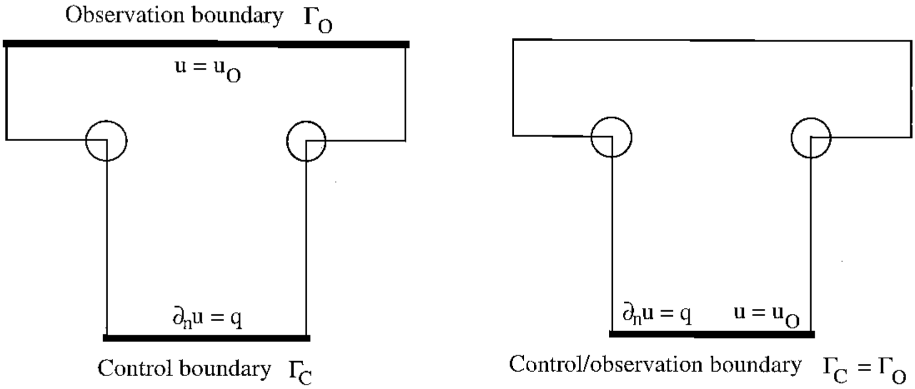
with the residuals as defined in Proposition 4.2. For the derivation of this estimate see, for example, [14], [4], and the literature cited therein. We see that all terms of $\eta_E(u_h)$ appear also in $\eta_\omega(u_h,\lambda_h,q_h)$, but are weighted in terms of the adjoint variable. The effect of this modification will be illustrated below by a numerical test. In practice, we may use a combination of our weighted error estimator and the energy-error estimator $\eta_{\omega,E}(u_h,\lambda_h,q_h) := \eta_\omega(u_h,\lambda_h,q_h) + \beta\eta_E(u_h)$, with a suitable weighting factor $\beta \ge 0$.

Strategies for mesh adaptation. Several strategies are possible for mesh adaptation on the basis of a posteriori error estimators η as developed above. Usually, a certain tolerance TOL for the error in the quantity $J(u,q)$ and an upper bound for the complexity of the discrete model, i.e. the maximum number of mesh cells $N_{\max}$, are given. It is assumed that an "optimal" mesh-size distribution is achieved if the local error indicators η_T are equilibrated over the mesh $\mathbb{T}_h$. This suggests use of the "error-balancing strategy"; i.e., we cycle through the mesh and try to equilibrate the local error indicators η_T according to $\eta_T \approx TOL/N$. This process requires iteration with respect to the number of mesh cells N and eventually results in $\eta \approx TOL$. However, this strategy may lead to very slow mesh refinement and is very delicate to use. More robust is the "fixed-fraction strategy" in which we order the cells according to the size of η_T and refine a certain threshold $X\%$ of cells with largest η_T (or those cells which contribute to a certain percentage of the error estimator η). A certain fraction $Y\%$ of cells with small η_T may be coarsened. By this strategy, one can achieve a prescribed rate of increase of N (or keep it constant as may be desirable in nonstationary computations). In the test computations described below the second version of the "Fixed-Fraction Strategy" has been used with threshold 30%.

5. Numerical results—linear case. We present a linear model problem as described in (2.7), where Ω is a T-shaped domain with maximum side length one; see Figure 5.1 (left). In this example the control acts along the lower boundary Γ_C, whereas the observation is taken along the upper boundary Γ_O. The cost functional is chosen as

$$J(u,q) := \tfrac{1}{2}\|u-c_0\|_{\Gamma_O}^2 + \tfrac{\alpha}{2}\|q\|_{\Gamma_C}^2,$$

with $c_0 \equiv 1.0$ and $\alpha = 1.0$. In this case, the regularization term $\frac{\alpha}{2}\|q\|_{\Gamma_C}^2$ may be viewed as part of the cost functional with its own physical meaning. We perform computations on a series of locally refined meshes. On each mesh, the system of the first-order necessary condition (2.5) is discretized by the Galerkin finite element



Observation boundary Γ_O
$u = u_O$
$\partial_n u = q$
Control boundary Γ_C
$\partial_n u = q$
$u = u_O$
Control/observation boundary $\Gamma_C = \Gamma_O$

method described above. The resulting discrete saddle-point problems are solved iteratively by a GMRES method with multigrid preconditioning. The adaptive mesh refinement is based on an a posteriori error estimator. The weights in the error estimator (4.7) are evaluated using the strategy indicated in (4.8) and (4.9), with an interpolation constant set to $C_I = 0.1$. The mesh refinement uses the "fixed-fraction strategy" described above.

Table 5.1 shows the quality of the error estimator (4.7) for quantitative error control. The *efficiency index* is defined by $I_{eff} := E_h/\eta_h$, where $E_h := |J(u,q) - J(u_h, q_h)|$ is the error in the cost functional and $\eta_h := \eta(u_h, q_h)$ the value of the error estimator used. The reference value is obtained on a mesh with more than 200,000 cells. We compare the weighted error estimator with a simple ad hoc approach based on the standard energy-error estimator (4.11) for the state equation. Figure 5.2 shows the computed "optimal" states over the meshes generated by the two different error estimators.

The two meshes are quite different: The energy-error estimator overemphasizes the steep gradients near the control boundary and it leaves the mesh too coarse along the observation boundary. The more selective *weighted* error estimator concentrates the mesh cells where they are needed for the optimization process. The quantitative effects on the mesh efficiency of these two different refinement criteria is shown in Figure 5.3 (E_h versus N in log/log-scale).

Finally, we check how well the approximation $\{u_h, \lambda_h, q_h\}$ obtained by the weighted error estimator (4.7) actually satisfies the state equation; for this the *global* energy-error estimator (4.11) is taken as quality measure. Table 5.2 shows a comparison of the two sequences of meshes generated by the weighted error estimator $\eta_\omega = \eta_\omega(u_h, \lambda_h, q_h)$ ("ω-meshes") and the energy-error estimator $\eta_E = \eta_E(u_h)$ ("E-meshes"). The first and second columns contain the values of η_ω and η_E on ω-meshes, while the third and fourth columns contain the values of η_ω and η_E on E-meshes.

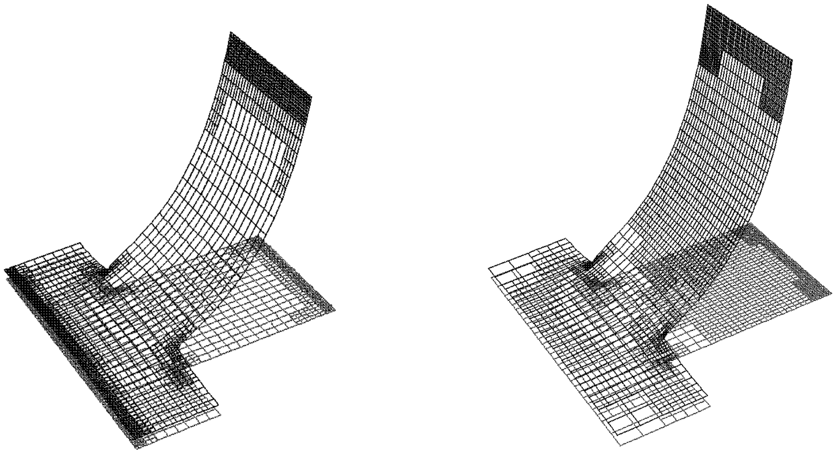

FIG. 5.2. *Linear test: Comparison of discrete solutions obtained by the weighted error estimator (left,* $N \sim 1600$ *cells) and the energy-error estimator (right,* $N \sim 1700$ *cells).*

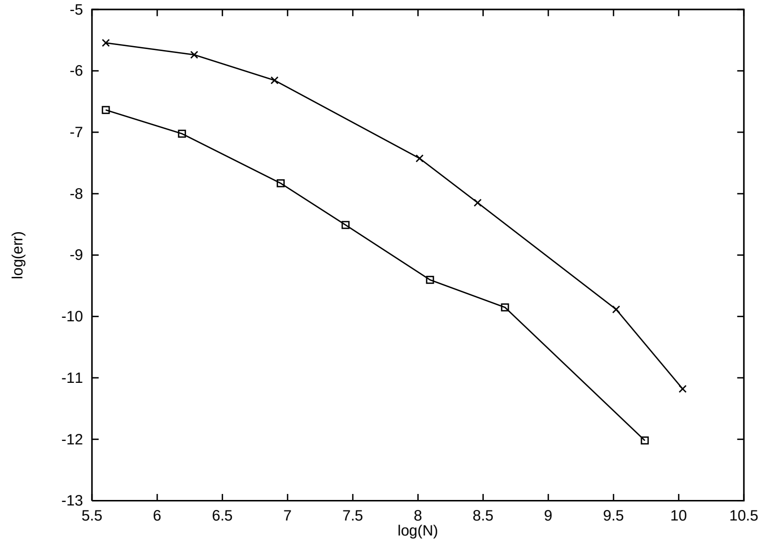

FIG. 5.3. *Linear test* (*configuration* 1): *Comparison of the efficiency of the meshes generated by the weighted error estimator (symbol* □ *) and the energy-error estimator (symbol* × *) in* log / log *scale.*

We see that the energy-norm error bound η_E for the state equation on the ω-meshes is slightly larger than on the E-meshes. This is not surprising since the ω-meshes are not so much refined in the regions where the state variable has a steep gradient. The cells are rather concentrated along the control and observation boundaries which seems to be more effective for the optimization process. Indeed, the approximate solution $\{u_h, \lambda_h, q_h\}$ obtained by the weighted error estimator η_ω achieves a much smaller value (factor ~ 0.1) of the cost functional. However, for other data, e.g., $c_0 = \cos(2x)$ and $\alpha = 0.0001$, the discrepancy between the two kinds of meshes with respect to the satisfaction of the state equation may be more significant. In those cases it would be advisable to use the combined error estimator $\eta_{\omega,E}$ described

above, if stronger "admissibility" of the discrete state u_h is required.

6. The nonlinear case. Now, we consider a nonlinear analogue of the abstract linear model problem (2.1), (2.2),

$$a(u)(\varphi) = (f,\varphi) + b(q,\varphi) \quad \forall \varphi \in V, \tag{6.1}$$

where $a(\cdot)(\cdot)$ is a semilinear form on the Hilbert space V. The cost functional $J(\cdot,\cdot)$ is the same as in the linear case. The corresponding Lagrange functional

$$\mathcal{L}(u,q,\lambda) := J(u,q) + a(u)(\lambda) - b(q,\lambda) - (f,\lambda),$$

leads to the first-order necessary optimality condition

$$\begin{aligned} a'(u)(v,\lambda) + (cu - c_0, cv) &= 0 \quad \forall v \in V,\\ a(u)(\mu) - b(q,\mu) &= (f,\mu) \quad \forall \mu \in V,\\ -b(r,\lambda) + n(q,r) &= 0 \quad \forall r \in Q, \end{aligned} \tag{6.2}$$

where $a'(u)(\cdot,\cdot)$ denotes the tangent form of $a(\cdot)(\cdot)$ at u. As in the linear case, the discrete approximations $\{u_h, \lambda_h, q_h\}$ are determined as solutions of the saddle-point problem

$$\begin{aligned} a'(u_h)(v_h,\lambda_h) + (cu_h - c_0, cv) &= 0 \quad \forall v_h \in V_h,\\ a(u_h)(\mu_h) - b(q_h,\mu_h) &= (f,\mu_h) \quad \forall \mu_h \in V_h,\\ -b(r_h,\lambda_h) + n(q_h,r_h) &= 0 \quad \forall r_h \in Q_h, \end{aligned} \tag{6.3}$$

where the discretization is the same as in the linear case. We will use again the notation $x = \{u,\lambda,q\}$ and $x_h = \{u_h,\lambda_h,q_h\}$ for points in the spaces $X := V \times V \times Q$ and $X_h := V_h \times V_h \times Q_h$, respectively.

The a posteriori error estimation in the case of a nonlinear state equation follows the same pattern as in the linear case. First, we state an abstract result.

PROPOSITION 6.1. *For the Galerkin finite element approximation* (6.3) *of the abstract model problem* (6.2) *with nonlinear state equation and quadratic cost functional there holds*

$$J(u,q) - J(u_h,q_h) = \tfrac{1}{2}\nabla\mathcal{L}(x_h)(x - i_h x) + R(x,x_h)\,, \tag{6.4}$$

where the remainder term $R(x,x_h)$ *can be estimated by*

$$|R(x,x_h)| \;\le\; \sup_{\hat{x}\in[x_h,x]} |\nabla^3\mathcal{L}(\hat{x})(x-x_h, x-x_h, x-x_h)|. \tag{6.5}$$

Proof. The Galerkin orthogonality relation now reads

$$\nabla^2\mathcal{L}(\overline{xx_h})(x-x_h,\varphi_h) = \nabla\mathcal{L}(x)(\varphi_h) - \nabla\mathcal{L}(x_h)(\varphi_h) = 0, \quad \varphi_h \in X_h, \tag{6.6}$$

with the abbreviating notation

$$\mathcal{L}(\overline{xx_h}) := \int_0^1 \mathcal{L}(x+t(x_h-x))\,dt.$$

Since the solutions u and u_h satisfy the corresponding state equations, there holds again

$$J(u,q) - J(u_h,q_h) = \mathcal{L}(x) - \mathcal{L}(x_h).$$

By Taylor expansion, there holds

$$\begin{aligned} rcl\mathcal{L}(x) - \mathcal{L}(x_h) = \nabla\mathcal{L}(x)(x-x_h) - \tfrac{1}{2}\nabla^2\mathcal{L}(x)(x-x_h,x-x_h) \\ + \tfrac{1}{6}\nabla^3\mathcal{L}(\tilde{x})(x-x_h,x-x_h,x-x_h), \end{aligned}$$

where $\tilde{x}$ lies between x and x_h. Since x is a stationary point of $\mathcal{L}$, the first term on the right vanishes. In order to relate the second term to the Galerkin relation (6.6), we use again Taylor expansion,

$$\nabla^2\mathcal{L}(x)(x-x_h,x-x_h) = \nabla^2\mathcal{L}(\overline{xx_h})(x-x_h,x-x_h) + \nabla^3\mathcal{L}(\hat{x})(x-x_h,x-x_h,x-x_h),$$

where $\hat{x}$ is another point between x and x_h. In view of the identity

$$\nabla^2\mathcal{L}(\overline{xx_h})(x-x_h,\cdot) = \nabla\mathcal{L}(x)(\cdot) - \nabla\mathcal{L}(x_h)(\cdot) = -\nabla\mathcal{L}(x_h)(\cdot),$$

and the Galerkin relation (6.6), we conclude that

$$\begin{aligned} \mathcal{L}(x) - \mathcal{L}(x_h) &= -\tfrac{1}{2}\nabla^2\mathcal{L}(\overline{xx_h})(x-x_h,x-x_h) + R(x,x_h) \\ &= -\tfrac{1}{2}\nabla^2\mathcal{L}(\overline{xx_h})(x-x_h,x-x_h-\varphi_h) + R(x,x_h) \\ &= \tfrac{1}{2}\nabla\mathcal{L}(x_h)(x-x_h-\varphi_h) + R(x,x_h), \end{aligned}$$

with an arbitrary $\varphi_h \in X_h$, and the remainder term

$$R(x,x_h) = \nabla^3\mathcal{L}(\hat{x})(x-x_h,x-x_h,x-x_h) + \tfrac{1}{6}\nabla^3\mathcal{L}(\tilde{x})(x-x_h,x-x_h,x-x_h).$$

Taking here $\varphi_h = i_hx - x_h$ eventually results in

$$\mathcal{L}(x) - \mathcal{L}(x_h) = \tfrac{1}{2}\nabla\mathcal{L}(x_h)(x-i_hx) + R(x,x_h),$$

which completes the proof. □

We note that if the cost functional $J(\cdot)$ is quadratic and the control form $b(\cdot,\cdot)$ bilinear, then the only nonzero terms in $\nabla^3\mathcal{L}$ are

$$\frac{\partial^3\mathcal{L}}{\partial\lambda\partial^2u}(x) = a''(u)(\cdot,\cdot,\cdot), \qquad \frac{\partial^3\mathcal{L}}{\partial^3u}(x) = a'''(u)(\cdot,\cdot,\cdot,\lambda).$$

Further, if additionally the state equation is linear, then the remainder term $R(x,x_h)$ vanishes.

We will apply this abstract result for a nonlinear problem of optimal control in the "Ginzburg–Landau model" of superconductivity in semiconductors; for references see Du, Gunzburger, and Peterson [7], Itô and Kunish [10], and also Tinkham [13]. It has the same structure as the linear model problem considered above,

$$\begin{gathered} -\Delta u + s(u) = f \quad \text{in } \Omega, \\ \partial_n u = 0 \ \text{ on } \Gamma_N, \quad \partial_n u = q \ \text{ on } \Gamma_C, \end{gathered} \tag{6.7}$$

with the nonlinearity $s(u) := u^3 - u$, and the quadratic cost functional

$$J(u,q) = \tfrac{1}{2}\|u - c_0\|^2_{\Gamma_O} + \tfrac{\alpha}{2}\|q\|^2_{\Gamma_C}.$$

The corresponding first-order necessary condition (6.2) uses the notation

$$a(u)(v) = (\nabla u, \nabla v)_\Omega + (s(u), v)_\Omega, \quad b(q,v) = (q,v)_{\Gamma_C}, \quad n(q,r) = \alpha(q,r)_{\Gamma_C},$$

and is approximated by the scheme (6.3). The well-posedness of this optimization problem, the existence of the adjoint variable λ, as well as a priori error estimates for its discretization have been discussed by Gunzburger and Hou [9]. From Proposition 6.1, we conclude the following a posteriori result.

PROPOSITION 6.2. *For error control with respect to the cost functional J, there holds the weighted a posteriori error estimate*

$$|J(u,q) - J(u_h,q_h)| \ \le \ \eta_\omega(u_h,\lambda_h,q_h) + R(\{u,\lambda,q\},\{u_h,\lambda_h,q_h\}), \tag{6.8}$$

where the local error indicators $\eta_T(u_h,\lambda_h,q_h)$ in the linearized error estimator

$$\eta_\omega(u_h,\lambda_h,q_h) := \sum_{T\in\mathbb{T}_h} \eta_T(u_h,\lambda_h,q_h) \tag{6.9}$$

are defined as in the linear case (Proposition 4.2), here with the "cell residuals"

$$\begin{gathered} R^{(u)}_{h|T} := -\Delta u_h + s(u_h) - f, \quad R^{(\lambda)}_{h|T} := -\Delta\lambda_h + s'(u_h)\lambda_h, \\ r^{(q)}_{h|\Gamma} := \alpha q_h - \lambda_h, \ \ \textit{if } \Gamma \subset \Gamma_C. \end{gathered} \tag{6.10}$$

For the remainder term, there holds the a priori estimate

$$\big|R(\{u,\lambda,q\},\{u_h,\lambda_h,q_h\})\big| \ \le \ 6\int_\Omega \Big\{ \max\{|u|,|u_h|\}|u-u_h|^3 + |u-u_h|^2|\lambda-\lambda_h| \Big\}\,dx. \tag{6.11}$$

As in the linear case, the weights are evaluated numerically using the approximations $\{u_h,\lambda_h,q_h\}$, but now the weighted error estimator contains an additional linearization error represented by the remainder R. Theory as well as practical experience show that, in the present case, this additional error is of higher order on well-adapted meshes and can therefore be neglected. In fact, assuming sufficient smoothness of the solution $\{u,\lambda,q\}$, there holds

$$\big|R(\{u,\lambda,q\},\{u_h,\lambda_h,q_h\})\big| \le c(u,u_h)\, h^6_{\max}, \tag{6.12}$$

with the maximum step size $h_{\max}$ of the mesh. The proof of this order-optimal estimate employing techniques from L^∞-error analysis of finite elements would be

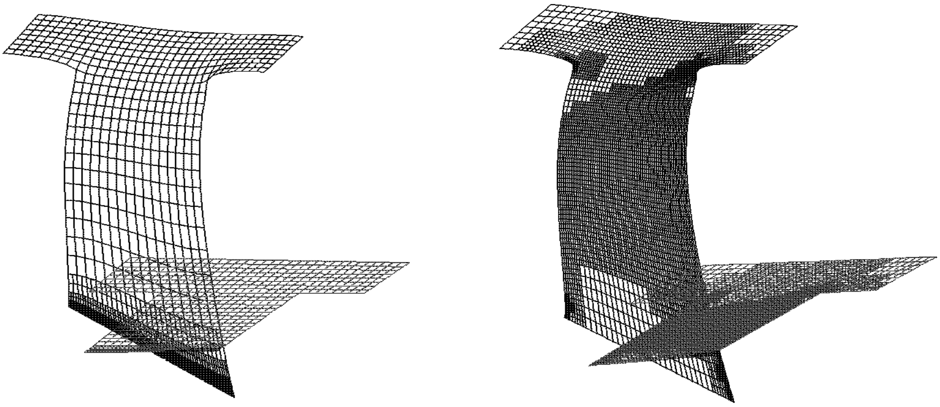

FIG. 7.1. *Nonlinear test (configuration* 2, $\alpha=0$*): Comparison of discrete solutions obtained by the weighted error estimator (left,* $N\sim 5000$ *cells) and the energy-error estimator (right,* $N\sim 4800$ *cells).*

I_{eff}	0.34	0.81	0.46	0.29	0.43

rather lengthy and is therefore omitted. In view of this observation, we neglect the remainder term in the a posteriori error estimate (6.8) and base the mesh adaptation on its main part $\eta_\omega(u_h,\lambda_h,q_h)$.

The discrete problems (6.3) are solved by a quasi-Newton iteration which is derived from a corresponding scheme formulated on the continuous level. On each discrete level the Newton iteration is carried to the limit before the error estimator is applied for mesh refinement. The results of this process may significantly differ from those obtained if each Newton step is discretized separately, mixing iteration and discretization errors together; see the preceding publication [2] for the latter approach.

7. Numerical results—nonlinear case. We again compare the weighted error estimator with a simple ad hoc energy-error estimator of the form (4.11) using the modified cell residuals (6.2). For illustrating our approach, we consider two different choices for the boundaries of control and observation shown in Figure 5.1 as configuration 1 and configuration 2. The notation I_{eff}, E_h, and η_h is as defined above.

(i) *First test:* First, we consider configuration 2 in which the same boundary is taken for control and observation, $\Gamma_C=\Gamma_O$ (lower boundary of the T-shaped domain) and set $\alpha=0$. In this configuration, we do not expect any need for strong mesh refinement "far away" from this boundary if we only want to deal with the optimization problem.

The observations are taken as $c_0(x)=\sin(0.19x)$. Table 7.1 shows the quality of the weighted error estimator for quantitative error control for this nonlinear test case. The reference value for the objective function $J(u,q)$ is computed on a refined mesh with about $130,000$ cells. Due to the special choice $\Gamma_C=\Gamma_O$, the adjoint variable λ equals zero almost everywhere away from Γ_C, i.e., the weighted error

estimator pays attention only to the neighborhood of the control boundary. The energy-error estimator mainly recognizes the singularities in the primal solution at the two reentrant corners (see Figure 7.1).

In Figure 7.2, we compare the efficiency of the meshes generated by the two

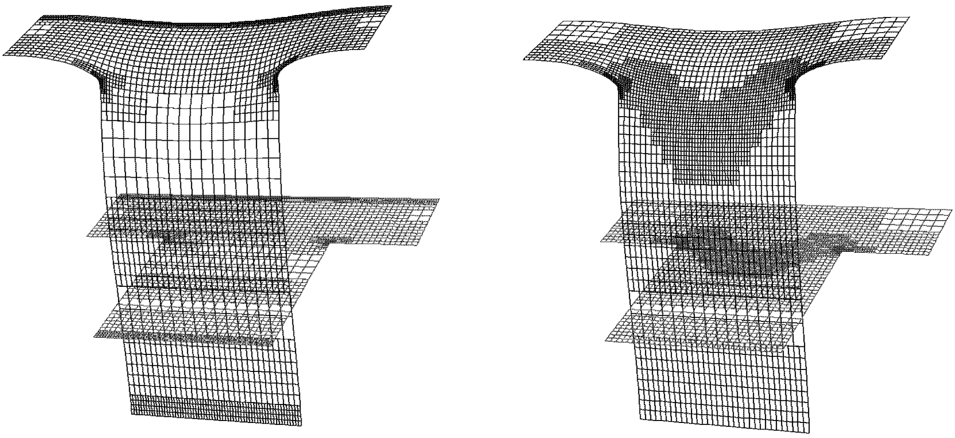

FIG. 7.4. *Nonlinear test (configuration* 1*,* $\alpha = 0.1$*): Comparison of discrete solutions obtained by the weighted error estimator* η_ω *(left,* $N \sim 3000$ *cells) and the energy-error estimator* η_E *(right,* $N \sim 3300$ *cells).*

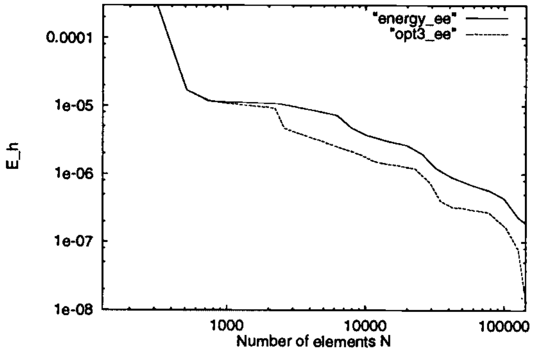

FIG. 7.5. *Nonlinear test (configuration* 1*,* $\alpha = 0.1$*): Comparison of efficiency of meshes generated by the two error estimators:* η_ω *(broken line) and* η_E *(solid line) in* log*/log scale.*

estimators. We see that in this situation, the solution of the optimization problem is approximated with significantly less cells using the weighted error estimator which exploits the "extreme" feature $\Gamma_C = \Gamma_O$ of this problem.

(ii) *Second test:* Now, we consider configuration 1 in which the control and the observation are taken on opposite boundaries, $\Gamma_C \cap \Gamma_O = \emptyset$. In this case, we expect better results for the energy-error estimator than in configuration 1, because the information must pass from the control to the observation boundary and the corner singularities will have a stronger effect. Nevertheless, the weighted error estimator should perform better since it also considers the critical control and observation boundaries.

We take the observation as $c_0 \equiv 1$, as in the linear case, and set $\alpha = 0.1$. In this configuration, there exist several stationary points of $\mathcal{L}(u, q, \lambda)$, which can be obtained by varying the starting values for the Newton iteration. One trivial solution (actually the global minimum) is a constant equal to c_0, with $q \equiv 0$. In this case, we have $J(u, q) = 0$ (up to round-off error) and match the observations already on a very coarse mesh. We do not show the results of this computation. The two other stationary points are symmetric to each other with respect to the center plane $\{x = 0\}$. Tables 7.2 and 7.3 show the quality of the weighted error estimator for quantitative error control for one of these local minima. The reference values for $J(u, q)$ are obtained on an adaptive mesh with about $550,000$ cells. The numerical results demonstrate the correct qualitative behavior of the weighted error estimator. For the choice $\alpha = 1$, we get slightly better results than for $\alpha = 0.1$ because of higher stability in the optimization problem.

Next, Figure 7.3 shows the distribution of the cell error indicators η_T in the weighted error estimator η_ω and in the energy-error estimator η_E for $\alpha = 0.1$. We clearly see the different ways in which these error estimators put their weight: η_ω observes the control and observation boundary which is critical for the optimization process while η_E emphasizes the corner singularities. Figure 7.4 shows the resulting meshes together with the computed discrete solutions. Finally, in Figure 7.5, we see the faster convergence toward the minimum of the objective functional using the weighted error estimator compared to the energy-error estimator.

PERSISTENCE OF EXCITATION PROPERTIES FOR TIME-VARYING AUTOREGRESSIVE SYSTEMS[*]

SERGIO BITTANTI[†] AND M. C. CAMPI[‡]

Abstract. It is well known that a crucial property for the effective identification of time-varying systems is that the data carry continual information on the parameters to be estimated. As a matter of fact, only in this case can the identification algorithm rely on fresh information in forming a reliable estimate of the current value of these parameters. This concept has been formalized in the system identification literature under the name of *persistence of excitation*.

In this paper, the persistence of excitation property is studied for a class of time-varying systems (that includes the standard autoregressive model as a particular case) and conditions for it to hold are derived.

Key words. time-varying models, persistence of excitation, autoregressive models, system identification

1. Introduction.

In the last two decades, a considerable effort has been put into the comprehension of identification methods for the estimation of time-varying systems.

A huge stream of research has been devoted to situations that somehow reduce to the problem of estimating constant unknown parameters. This is, for instance, the case of the so-called random coefficient autoregressive models; see, e.g., Nicholls and Quinn (1982), Chow (1983), and Beran and Hall (1992). These models are characterized by parameters which are randomly fluctuating according to the law $\vartheta(t) = \bar{\vartheta} + \delta(t)$, $\delta(t)$ being an independent sequence. In this framework the main concern is the consistent estimation of the mean value $\bar{\vartheta}$. Another kind of time-varying systems which has attracted interest in recent years are the so-called nearly nonstationary autoregressive models. In this case, the time-varying parameters are asymptotically convergent and the corresponding asymptotic invariant model exhibits singularities on the unit circle. The limiting distribution of the estimation error when the identification is performed via the standard least squares algorithm is studied, e.g., in Cox and Llatas (1991); see also Cox (1991).

In the above literature, the fact that the estimated parameters are in fact constant makes the estimation task simpler than in truly time-varying situations. As a matter of fact, when the parameters are constant, the same unknowns are estimated through time and it is expected that a consistent estimate can be formed under the sole condition that data carry enough information in the long run. On the other hand, when the goal is that of estimating truly time-varying parameters, one has to somehow guarantee that a certain amount of information is available over any finite interval of time. As a matter of fact, only in this way can the identification algorithm rely on fresh information in forming a reliable estimate of the current value of the parameters.

This idea is well known in the identification literature under the name of *persistence of excitation.*

Letting $\varphi(\cdot)$ be the observation vector, a persistence of excitation condition which has been widely used in the literature takes the form

$$\text{pr}\left(\lambda_{\min}\left\{\sum_{i=t}^{t+s-1}\frac{\varphi(i)\varphi(i)'}{1+\|\varphi(i)\|^2}\right\}\geq k_1 \,\middle|\, \sigma_{t-1}\right)\geq k_2 \qquad \forall t, \tag{1}$$

where $\lambda_{\min}$ denotes the minimum eigenvalue and σ_t is the so-called σ-algebra of the past, that is, the σ-algebra generated by all system processes up to time t. Roughly, this condition requires that, whatever the past evolution of the system might have been, the information carried by data over the next s time points spans the entire parameter space with a finite nonzero probability.

Condition (1) was first introduced in Guo (1990) in a form that is slightly different from but equivalent to (1), and has henceforth been used in many different contributions.

Under (1), Guo (1990) proves stability and convergence results for a Kalman filter based algorithm used in the estimation of time-varying parameters generated by a random-walk–type equation. In the paper of Bittanti and Campi (1994) it is proven that a forgetting factor least squares identification algorithm provides bounded estimates if condition (1) is met and the forgetting factor is chosen to be larger than a certain threshold. Another contribution using the persistence of excitation condition (1) is Campi (1994). There, an explicit expression for the asymptotic estimation error is given for a forgetting factor based least squares algorithm. This bound shows the dependence of the estimation error on the speed of the time variability of the parameters and the variance of noise.

There are many more contributions on system identification where significant properties are proven under conditions related to (1). Among others, we cite Bittanti and Campi (1991a, 1991b); Guo, Ljung, and Priouret (1993); Guo and Ljung (1995a, 1995b); and Campi (1997). An additional interesting paper is Ravikanth and Meyn (1999), where a lower bound for the estimation error valid for any identification algorithm is worked out.

In all of the above-mentioned contributions, condition (1) is taken for granted or proven only in certain specific situations. In the present paper we address the problem of verifying that such a condition is in fact satisfied for a class of time-varying systems which includes, but is not limited to, autoregressive systems. In this way, all the results proven in these contributions can in fact be applied to this class of models.

The paper is organized as follows. In section 2 the system class is introduced. The persistence of excitation condition is then discussed in section 3.

2. The system. Let us consider a time-varying state variable system described by the equation

$$\varphi(t)=G(t)\varphi(t-1)+v(t). \tag{2}$$

In (2), $\varphi(t)\in\mathbb{R}^n$ is the so-called observation vector and it is a measurable signal, and $v(t)$ is a remote unmeasurable noise that plays the role of a latent variable in the generation of $\varphi(t)$. Throughout the paper, it is assumed that matrices $G(t)$ form a strictly stationary stochastic process.

The transition matrix associated with $G(t)$ is defined as

$$\Phi(t,s) := G(s)G(s+1)\cdots G(t).$$

A typical example of system (2) is a time-varying scalar autoregressive model of the form

$$y(t) = a_1(t)y(t-1) + a_2(t)y(t-2) + \cdots + a_n(t)y(t-n) + d(t). \tag{3}$$

In this case, by letting

$$G(t) = \begin{bmatrix} a_1(t) & a_2(t) & \cdots & a_n(t) \\ 1 & & & \\ & \ddots & & \\ & & 1 & \end{bmatrix}, \quad \varphi(t) = \begin{bmatrix} y(t) \\ y(t-1) \\ \vdots \\ y(t-n+1) \end{bmatrix}, \quad v(t) = \begin{bmatrix} d(t) \\ 0 \\ \vdots \\ 0 \end{bmatrix},$$

system (2) is immediately recovered. Clearly, system (2) can accommodate many other specific situations than the autoregressive system (3).

The following assumptions are made on system (2).

Assumption 1. $v(\cdot)$ is a zero-mean, bounded independently and identically distributed (i.i.d.) sequence, independent of $G(\cdot)$.

Assumption 2. $\exists\rho$: $\rho^{-t}\|\Phi(t,0)\| \le \alpha\ \forall t$ almost surely.

Clearly, Assumption 2 is an exponential stability condition. It is worthwhile pointing out that there is a milder stability condition that could be considered.

Assumption 2$'$. $\exists\rho$: $\limsup_{t\to\infty}\rho^{-t}\|\Phi(t,0)\| = 0$ almost surely.

Assumption 2$'$ is a stability assumption of stochastic type that requires $\|\Phi(t,0)\|$ to go to zero exponentially fast with *asymptotic* deterministic rate ρ. On the other hand, Assumption 2 imposes restrictions for any *finite* t. It is in fact a truly deterministic stability assumption.

It is easy to see that Assumption 2$'$ is equivalent to

$$\limsup_{t\to\infty} t^{-1}\log\|\Phi(t,0)\| \le -\gamma < 0 \quad \text{almost surely.} \tag{4}$$

This last condition has been discussed (in a continuous-time setting) by Solo (1994). Among other things, Solo provides conditions on the eigenvalues of the stochastic matrix $G(t)$ such that (4) holds true.

Finally, notice that, since $G(\cdot)$ is strictly stationary, Assumption 2 is equivalent to

$$\|\Phi(t,s)\| \le \alpha\rho^{t-s} \quad \forall t,s \qquad \text{almost surely.}$$

3. Main result: Persistence of excitation condition. In this section, the persistence of excitation condition is discussed and necessary conditions for it to hold are derived.

For subsequent use, we introduce the σ-algebra generated by the past of $v(\cdot)$ and the past, present, and future of $G(\cdot)$:

$$\zeta_t = \sigma(v(i), \quad i \le t; \quad G(\cdot)).$$

Notice that $\varphi(t)$ is measurable with respect to ζ_t.

For the sake of clarity, we point out that the σ-algebra of the past in condition (1) is given by

$$\sigma_t = \sigma(v(j), G(j), j \leq t).$$

We start by proving the following proposition which is a law of large numbers of conditional type for system (2).

PROPOSITION 3.1. *Under Assumptions* 1 *and* 2,

$$E\left[\left\| \frac{1}{k} \sum_{i=t}^{t+k-1} (\varphi(i)\varphi(i)' - E[\varphi(i)\varphi(i)' \,|\, \zeta_t]) \right\|^2 \,\middle|\, \zeta_t \right] \longrightarrow 0 \quad \textit{as } k \to \infty,$$

uniformly with respect to both time t and probability outcome.

Proof. The following chain of inequalities holds true:

$$\begin{aligned} &E\left[\left\| \frac{1}{k} \sum_{i=t}^{t+k-1} (\varphi(i)\varphi(i)' - E[\varphi(i)\varphi(i)' \,|\, \zeta_t]) \right\|^2 \,\middle|\, \zeta_t \right] \\ &\quad \leq \frac{1}{k^2} n \left\| E\left[\sum_{i,j=t}^{t+k-1} (\varphi(i)\varphi(i)' - E[\varphi(i)\varphi(i)' \,|\, \zeta_t]) \right.\right. \\ &\qquad\qquad \left.\left. \times \; (\varphi(j)\varphi(j)' - E[\varphi(j)\varphi(j)' \,|\, \zeta_t]) \,\middle|\, \zeta_t \right] \right\| \end{aligned}$$

(since, for any stochastic matrix $M \geq 0$ of dimension n, $E[\|M\|] \leq n\|E[M]\|$)

$$\begin{aligned} &\leq \frac{1}{k^2} n \sum_{i,j=t}^{t+k-1} \|E[(\varphi(i)\varphi(i)' - E[\varphi(i)\varphi(i)' \mid \zeta_t]) \\ &\qquad\qquad \times (\varphi(j)\varphi(j)' - E[\varphi(j)\varphi(j)' \mid \zeta_t]) \mid \zeta_t]\| \\ &\leq \frac{1}{k^2} 2n \sum_{\substack{i,j=t \\ j \geq i}}^{t+k-1} \|E[(\varphi(i)\varphi(i)' - E[\varphi(i)\varphi(i)' \mid \zeta_t]) \\ &\qquad\qquad \times (E[\varphi(j)\varphi(j)' \mid \zeta_i] - E[\varphi(j)\varphi(j)' \mid \zeta_t]) \mid \zeta_t]\|. \end{aligned}$$

In this last expression, the norm of $(\varphi(i)\varphi(i)' - E[\varphi(i)\varphi(i)' \mid \zeta_t])$ is deterministically bounded in view of the boundedness of $v(\cdot)$ (Assumption 1) and the exponential stability of the system (Assumption 2).

Therefore, to complete the proof it suffices to prove that the norm of $(E[\varphi(j)\varphi(j)' \mid \zeta_i] - E[\varphi(j)\varphi(j)' \mid \zeta_t])$, $j \geq i \geq t$, is bounded by a deterministic function of $j - i$ only, which tends exponentially to zero as $j - i \to \infty$.

Set $\varphi(r \mid s) := E[\varphi(r) \mid \zeta_s]$, $r \geq s$. Since $v(\cdot)$ is an independent sequence, we have

$$\varphi(r \mid s) = \sum_{k=-\infty}^{s+1} \Phi(r,k)v(k-1).$$

Taking into account the exponential stability assumption (Assumption 2) and that the noise $v(\cdot)$ is bounded (Assumption 1), this last expression shows that $\|\varphi(r \mid s)\|$ is bounded by a deterministic function of $r-s$ only, which tends exponentially to zero as $r-s\to\infty$. The term $(E[\varphi(j)\varphi(j)' \mid \zeta_i]-E[\varphi(j)\varphi(j)' \mid \zeta_t])$ can now be handled as follows:

$$\begin{aligned}
&E[\varphi(j)\varphi(j)' \mid \zeta_i]-E[\varphi(j)\varphi(j)' \mid \zeta_t]\\
&\quad= E[(\varphi(j \mid i)+(\varphi(j)-\varphi(j \mid i)))(\varphi(j \mid i)+(\varphi(j)-\varphi(j \mid i)))' \mid \zeta_i]\\
&\qquad - E[(\varphi(j \mid t)+(\varphi(j)-\varphi(j \mid t)))(\varphi(j \mid t)+(\varphi(j)-\varphi(j \mid t)))' \mid \zeta_t]\\
&\quad= \varphi(j \mid i)\varphi(j \mid i)'-\varphi(j \mid t)\varphi(j \mid t)'-\sum_{k=t+2}^{i+1}\Phi(j,k)\Delta\phi(j,k)',
\end{aligned}$$

where $\Delta := E[v(t)v(t)']$. The thesis follows by observing that the norm of each of these three terms is bounded by a deterministic function of $j-i$ only, which tends exponentially to zero as $j-i\to\infty$. □

Notice that, up to now, no conditions have been introduced guaranteeing that vector $\varphi(\cdot)$ is somehow exciting (in fact, under Assumptions 1 and 2, $v(\cdot)$ and/or $G(\cdot)$ may well be identically zero). We now introduce an extra condition (Assumption 3 below) which can be interpreted as an excitation condition. We anticipate that, in view of Proposition 1, Assumption 3 immediately leads to concluding that $\varphi(\cdot)$ is persistently exciting in the sense of definition (1) (see Theorem 1 below). The fact that Assumption 3 holds true in many situations of interest (e.g., for the autoregressive system (2)) is discussed immediately after the theorem.

Assumption 3. $E[\varphi(i)\varphi(i)' \mid \zeta_t]\geq H>0$ $\forall i\geq t+\bar{n}$, for some integer $\bar{n}$.

THEOREM 3.2. *Under Assumptions* 1–3*, there exist an integer s and two positive real numbers k_1 and k_2 such that the persistence of excitation condition* (1) *is satisfied.*

Proof. Recalling that, for any pair of positive semidefinite matrices C and D, $\lambda_{\min}[C]\geq\lambda_{\min}[D]-\|C-D\|$, one obtains

$$\begin{aligned}
\lambda_{\min}\left\{\frac{1}{k}\sum_{i=t}^{t+k-1}\varphi(i)\varphi(i)'\right\}\geq{}&\lambda_{\min}\left\{\frac{1}{k}\sum_{i=t}^{t+k-1}E[\varphi(i)\varphi(i)' \mid \zeta_t]\right\}\\
&-\left\|\frac{1}{k}\sum_{i=t}^{t+k-1}(\varphi(i)\varphi(i)'-E[\varphi(i)\varphi(i)' \mid \zeta_t])\right\|.
\end{aligned}$$

Take now conditional expectation of this last equation with respect to ζ_t. Thanks to Assumption 3 and Proposition 1, it is then apparent that there exist an integer s and a real number β such that

$$E\left[\lambda_{\min}\left\{\frac{1}{s}\sum_{i=t}^{t+s-1}\varphi(i)\varphi(i)'\right\}\middle|\zeta_t\right]\geq\beta>0\quad\forall t.$$

Then in view of the boundedness of $\varphi(\cdot)$ (Assumptions 1 and 2), we can conclude that there exist two positive real numbers k_1 and k_2 such that

$$\mathrm{pr}\left(\lambda_{\min}\left\{\sum_{i=t}^{t+s-1}\frac{\varphi(i)\varphi(i)'}{1+\|\varphi(i)\|^2}\right\}\geq k_1 \mid \zeta_t\right)\geq k_2\quad\forall t.$$

Since the σ-algebra generated by $v(j)$ and $G(j)$, $j\leq t-1$, is coarser than ζ_t, the thesis follows. □

Next, we show that Assumption 3 holds true in the case of the autoregressive system (2). Take $\bar{n} = n$. Recalling that $\varphi(r \mid s) = E[\varphi(r) \mid \zeta_s]$, for any $j \in [i-n, i-1]$ one has

$$\begin{aligned} &E[\varphi(i)\varphi(i)' \mid \zeta_t] \\ &\quad = E[E[(\varphi(i \mid j) + (\varphi(i) - \varphi(i \mid j)))(\varphi(i \mid j) + (\varphi(i) - \varphi(i \mid j)))' \mid \zeta_j] \mid \zeta_t] \\ &\qquad \text{(since } j \geq t) \\ &\quad \geq E[(\varphi(i) - \varphi(i \mid j))(\varphi(i) - \varphi(i \mid j))' \mid \zeta_t]. \end{aligned}$$

Since $\varphi(i) - \varphi(i \mid j) = \sum_{k=j+2}^{i+1} \Phi(i,k)v(k-1)$, we have ($\sigma^2 := E[d(t)^2]$)

- for $j = i-1$,

$$E[\varphi(i)\varphi(i)' \mid \zeta_t] \geq \operatorname{diag}(\sigma^2, 0, \dots, 0) = \begin{bmatrix} \sigma^2 & 0 & 0 & \dots & 0 \\ 0 & 0 & 0 & \dots & 0 \\ 0 & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & 0 & \dots & 0 \end{bmatrix};$$

- for $j = i-2$,

$$\begin{aligned} E[\varphi(i)\varphi(i)' \mid \zeta_t] &\geq \Phi(i,i) \operatorname{diag}(\sigma^2, 0, \dots, 0)\phi(i,i)' \\ &= \begin{bmatrix} \star & \star & 0 & \dots & 0 \\ \star & \sigma^2 & 0 & \dots & 0 \\ 0 & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & 0 & \dots & 0 \end{bmatrix}; \end{aligned}$$

$(\cdots)$

- for $j = i-n$,

$$\begin{aligned} E[\varphi(i)\varphi(i)' \mid \zeta_t] &\geq \Phi(i, i-n+2) \operatorname{diag}(\sigma^2, 0, \dots, 0)\Phi(i, i-n+2)' \\ &= \begin{bmatrix} \star & \star & \star & \dots & \star \\ \star & \star & \star & \dots & \star \\ \star & \star & \star & \dots & \star \\ \vdots & \vdots & \vdots & & \vdots \\ \star & \star & \star & \dots & \sigma^2 \end{bmatrix}, \end{aligned}$$

where the $\star$'s are random entries, whose value is bounded uniformly with respect to time t and probability outcome. From the above relations, Assumption 3 easily follows with $\bar{n} = n$.

It is interesting to note that Assumption 3 holds in many extra situations. As a simple example, if $G(\cdot)$ is deterministic such that Assumption 2 holds, then Assumption 3 is met provided that the very minimal condition $E[\varphi(i)\varphi(i)'] > 0$ is satisfied.

The analysis has been conducted so far under the stability assumption, Assumption 2. It is, of course, of interest to investigate whether the persistence of excitation condition (1) still holds under the weaker stability assumption, Assumption 2$'$. Unfortunately, this is not the case, as the following simple example shows.

Example. Suppose that $\varphi(t)$ has two components and let $G(t) = \operatorname{diag}(g(t), 0)$. $g(\cdot)$ is an i.i.d. sequence such that $g(t) = 2$ with probability 0.5 and $g(t) = 0.25$ with probability 0.5. Finally, $v(t) = [v_1(t)v_2(t)]'$, where $v_1(\cdot)$ and $v_2(\cdot)$ are i.i.d. sequences independent of each other and of $g(\cdot)$ and take on values -1 and $+1$ with probability 0.5.

Assumptions 1 and 3 are trivially satisfied in this case. Assumption $2'$ is also satisfied. This is seen as follows. Since $\|\Phi(t,0)\| = g(0)g(1)\cdots g(t)$, for any given $\rho \in (0.1)$, we have

$$\frac{1}{t}\log(\rho^{-t}\|\Phi(t,0)\|) = \log\frac{1}{\rho} + \frac{1}{t}\sum_{s=0}^{t}\log g(s).$$

The second term in the left-hand side tends almost surely to $E[\log g(t)] = 0.5[\log 2 + \log 0.25] = -0.5\log 2$. Then, by taking ρ to be a real number such that $\log\frac{1}{\rho} - 0.5\log 2 < 0$, we have that $\frac{1}{t}\log(\rho^{-t}\|\Phi(t,0)\|)$ tends almost surely to a negative number. From this, we conclude that $\limsup_{t\to\infty}\rho^{-t}\|\Phi(t,0)\| = 0$ almost surely, that is, Assumption $2'$.

Next, we show that the persistence of excitation condition (1) is not satisfied in this case.

Given any real number h, let $\mathcal{A}_h := \{|\varphi_i(0)| > h\}$, where $\varphi_1(0)$ is the first component of $\varphi(0)$. Since $g(t)$ takes on value 2 with probability 0.5, $\varphi(0)$ has an unbounded distribution and so $\mathrm{pr}(\mathcal{A}_h) \neq 0 \quad \forall h$. Moreover, note that if $|\varphi_1(0)| > h$, then $|\varphi_1(t)| > (0.25)^t h - 5/4$. ($g(t)$ is either 2 or 0.25 and $|v_1(t)| = 1$.) Now, suppose by contradiction that (1) holds for certain fixed k_1, k_2, and s. Since $\varphi_2(i) = v_2(i)$ keeps bounded and $\|\varphi(i)\| \geq (0.25)^s h - 5/4(i \in [1,s])$, a real number h exists such that condition $\lambda_{\min}\{\sum_{i=1}^{s}\frac{\varphi(i)\varphi(i)'}{1+\|\varphi(i)\|^2}\} \geq k_1$ is not satisfied on $\mathcal{A}_h$. So

$$E\left[\left\{\lambda_{\min}\left\{\sum_{i=1}^{s}\frac{\varphi(i)\varphi(i)'}{1+\|\varphi(i)\|^2}\right\} \geq k_1\right\}\cdot 1(\mathcal{A}_h)\right] = 0 < k_2 \cdot 1(\mathcal{A}_h)$$

(where $1(\mathcal{A}_h)$ is the indicator function of set $\mathcal{A}_h$) and this contradicts condition (1).

The above example shows that the persistence of excitation condition (1) does not hold under Assumption $2'$. On the other hand, almost all results in the identification literature (like those in Guo (1990), Bittanti and Campi (1994), or Campi (1994)) have been worked out under this condition (1). Consequently, at the present state of the art, it is not clear how to handle situations where the system is only characterized by a mild stability condition like Assumption $2'$. The above observation raises an interesting conceptual question: one may ask if it is possible to work out a persistence of excitation condition milder than (1), that holds true under Assumption $2'$ and still permits one to prove boundedness results for the identification algorithms. This issue is certainly worthy of further investigation.

AN EXPLICIT FORMULA FOR THE DERIVATIVE OF A CLASS OF COST FUNCTIONALS WITH RESPECT TO DOMAIN VARIATIONS IN STOKES FLOW[*]

THOMAS SLAWIG[†]

Abstract. Domain optimization problems for the two-dimensional stationary Stokes equations are studied. Fréchet differentiability of a class of cost functionals with respect to the variation of the shape of the computational domain is established. An embedding domain technique provides an equivalent formulation of the problem on a fixed domain and, moreover, a simply computable formula for the derivative of the cost functional with respect to the domain. Existence of a solution to the class of domain optimization problems is proved. Numerical examples show the reliability of the derivative formula.

1. Introduction.

In this paper we show the differentiability of a certain class of cost functionals with respect to variations in the shape of the computational domain under the constraint of the stationary Stokes equations. We consider domain optimization problems in incompressible viscous flow at low velocity or high viscosity, i.e., low Reynolds number. In this case the Stokes equations are an appropriate linear approximation of the full nonlinear Navier–Stokes equations.

Many optimization techniques are based on gradient information, i.e., they require information about the derivative of the cost functional with respect to the control parameters, i.e., here the shape of the domain. Usually this information is obtained via an adjoint equation. In domain optimization problems this equation usually incorporates the normal derivative of the state variable along the boundary which is numerically unstable. In this work we use an embedding domain technique which provides a formula for the derivative of the cost functional with respect to domain variations which avoids the evaluation of normal derivatives, is efficient and numerically stable. Moreover, the embedding domain technique reduces the effort of discretization and assembling of the discrete systems for the solution of the state equations on the changing domains during the optimization process.

Embedding (or "fictitious") domain techniques have been widely applied in the treatment of PDEs. For Stokes and Navier–Stokes equations on complicated shaped domains they were studied, e.g., by Börgers [1] and Glowinski, Pan, and Periaux [2], [3]. Our Lagrange multiplier approach is similar to Glowinski's. Dankova and Haslinger [4] used a slightly different one by introducing a distributed Lagrange multiplier and applied it on domain optimization problems; see, e.g., [4]. Domain optimization for Stokes equations were studied, for example, by Pironneau [5] who computed the shape of body with minimum drag. Gunzburger and Kim [6] showed existence of an optimal shape for a minimum drag problem in a channel flow. Simon et al. [7]

proved differentiability of the drag with respect to domain variations in Navier–Stokes flow.

Here we use the embedding domain technique not only to prove differentiability of a class of cost functionals (including drag), but moreover to obtain an explicit formula for the derivative. This formula is a boundary integral which specifically does not involve normal derivatives of the state variables. This is due to a special choice of extension for the inhomogeneity of the state equation in the embedding domain method. Thus the formula is useful and fast in numerical optimization schemes using derivative information as gradient, quasi-Newton, or SQP methods. By the same technique Kunisch and Peichl [8] obtained a derivative formula for the scalar Poisson problem. In this paper we present its analogue for the two-dimensional Stokes problem with its special saddle-point structure. An extension to the full nonlinear Navier–Stokes case is possible and might be presented in another paper.

In the next two sections we define a geometric model configuration and summarize the needed results for the Stokes equations. The considered class of domain optimization problems and the embedding domain technique are presented in the next two sections. In the sixth section we show the continuous dependence of the solution of the Stokes system with respect to the variation of the domain. The main result, the explicit formula for the Fréchet derivative, is presented in section 7. Finally, we summarize the numerical methods we used and show an example.

2. The geometric model configuration. We now present a model configuration of the geometry of the computational domain. We consider domains $\Omega_\gamma := \Omega(\gamma) \subset \mathbb{R}^2$, where γ is the control parameter describing the shape of the domain. For all admissible domains the boundary $\partial\Omega_\gamma$ shall have two parts: a fixed one denoted by Γ which consists of the two lateral and the top side of the unit square, i.e., of the three segments $[(0,0),(0,1)],[(0,1),(1,1)],[(1,1),(1,0)]$, and a variable one denoted by Γ_γ which is the graph of a function $\gamma : [0,1] \to [0,1)$ with $\gamma(0) = \gamma(1) = 0$; compare Figure 2.1 left.

A sufficiently high regularity of the solution of the Stokes equations is one necessary condition for our proof of differentiability of the considered cost functionals with respect to domain variation. We thus need either a smooth or a polygonal boundary, where in the latter case the domain has to be convex. To apply the embedding domain method we have to combine these two boundary types which will become clearer later on. By the above definition Γ is a polygon. To represent the variable part Γ_γ we choose functions $\gamma \in C^2[0,1]$. To preserve the convexity of Ω_γ near the two transition points $(0,0),(1,0)$ we assume that γ is linear in neighborhoods of these points. Working in Sobolev spaces we assure the regularity by choosing $\gamma \in H^3(I)$ with $I := (0,1)$. To show existence of a solution of the domain optimization problems we assume boundedness in this space. We define the set of admissible functions γ defining the variable boundary parts Γ_γ, and thus the admissible domains Ω_γ, by

$$\begin{aligned}(2.1)\quad \mathcal{S} := \{\gamma \in H^3(I) : \|\gamma\|_{H^3(I)} \le c_0, \gamma(0) = \gamma(1) = 0, c_1 \le \gamma|_{(\delta,1-\delta)} \le c_2,\\ \gamma'|_{(0,\delta)} = c_3, \gamma'|_{(1-\delta,1)} = c_4\}.\end{aligned}$$

Here $c_1, c_2 \in (0,1), \delta \in (0,\frac{1}{2}), c_0, c_3 \in \mathbb{R}^+, c_4 \in \mathbb{R}^-$ are fixed.

3. The Stokes equations. The stationary Stokes problem on Ω_γ can be written in the following variational form: Find the pair of velocity vector and pressure $(\mathbf{u}_\gamma, p_\gamma) \in H^1(\Omega_\gamma)^2 \times L^2_0(\Omega_\gamma)$ such that

$$(3.1)\qquad \begin{array}{rcll} \nu(\nabla\mathbf{u}_\gamma, \nabla\mathbf{v})_{\Omega_\gamma} - (p_\gamma, \operatorname{div}\mathbf{v})_{\Omega_\gamma} & = & (\mathbf{f}_\gamma, \mathbf{v})_{\Omega_\gamma} & \text{for all} \quad \mathbf{v} \in H^1_0(\Omega_\gamma)^2, \\ (\operatorname{div}\mathbf{u}_\gamma, q)_{\Omega_\gamma} & = & 0 & \text{for all} \quad q \in L^2_0(\Omega_\gamma), \\ \mathbf{u}_\gamma & = & \Phi & \text{on } \Gamma, \\ \mathbf{u}_\gamma & = & \mathbf{0} & \text{on } \Gamma_\gamma. \end{array}$$

In this dimension-free formulation the parameter $\nu > 0$ represents the inverse of the Reynolds number. For scalar-valued functions $(\cdot,\cdot)_{\Omega_\gamma}$ denotes the $L^2(\Omega_\gamma)$ inner product. Furthermore, we define $(\mathbf{u},\mathbf{v})_{\Omega_\gamma} := \sum_{i=1,2}(u_i,v_i)_{\Omega_\gamma}$ and $(\nabla\mathbf{u},\nabla\mathbf{v})_{\Omega_\gamma} := \sum_{i,j=1,2}(\frac{\partial u_i}{\partial x_j}, \frac{\partial v_i}{\partial x_j})_{\Omega_\gamma}$. For the inhomogeneity in the first equation which represents external forces we assume $\mathbf{f}_\gamma \in L^2(\Omega_\gamma)^2$. The space $L^2_0(\Omega_\gamma) := \{q \in L^2(\Omega_\gamma) : \int_{\Omega_\gamma} q\,dx = 0\}$ is chosen to get uniqueness of the pressure.

The homogeneous or inhomogeneous Dirichlet boundary conditions indicate that physically the boundary represents a wall or a region with prescribed velocity, respectively. The function Φ for the boundary values of the velocity on Γ is assumed to have a divergence-free extension onto Ω_γ which is in $H^2(\Omega_\gamma)^2$. For this purpose we define

$$H(\Gamma) := \left\{\Phi \in L^2(\Gamma)^2 : \text{there is}\, \bar{\mathbf{u}}_\gamma \in H^2(\Omega_\gamma)^2 : \operatorname{div}\bar{\mathbf{u}}_\gamma = 0 \text{ in}\, \Omega_\gamma, \bar{\mathbf{u}}_\gamma|_{\Gamma_\gamma} = \mathbf{0}, \bar{\mathbf{u}}_\gamma|_\Gamma = \Phi\right\}.$$

We now slightly modify the standard existence, uniqueness, and regularity results for the Stokes equations in the following theorem.

THEOREM 3.1. *Let $\gamma \in \mathcal{S}, \mathbf{f}_\gamma \in L^2(\Omega_\gamma)^2$, and $\Phi \in H(\Gamma)$. Then there exists a unique solution $(\mathbf{u}_\gamma, p_\gamma) \in H^2(\Omega_\gamma)^2 \times [H^1(\Omega_\gamma) \cap L^2_0(\Omega_\gamma)]$ to* (3.1) *which satisfies*

$$\|\mathbf{u}_\gamma\|_{H^2(\Omega_\gamma)^2} + \|p_\gamma\|_{H^1(\Omega_\gamma)} \le C\left(\|\mathbf{f}_\gamma\|_{L^2(\Omega_\gamma)^2} + \|\Phi\|_{L^\infty(\Gamma)^2}\right)$$

with $C > 0$ independent of $\gamma, \mathbf{f}_\gamma$, and Φ, i.e., the regularity is uniform in γ.

Proof. Regularity for a smooth boundary and uniqueness are stated, e.g., in [11, Thm. I.5.4]. For a convex polygonal boundary, regularity is shown in [12], from which it can be deduced that the regularity remains valid also in our case where both boundary types are mixed. The uniform regularity for the polygonal part is stated in the same reference, whereas for the smooth part it can be deduced from [10, Sect. IV.5]. □

4. A class of domain optimization problems. We consider domain optimization problems of the following form:

$$(4.1)\qquad \min_{\gamma\in\mathcal{S}} \mathcal{J}(\gamma) := \min_{\gamma\in\mathcal{S}} \frac{1}{2}\|\mathcal{A}\mathbf{u}_\gamma - \mathbf{u}_d\|^2_{L^2(\Omega_C)^k} \quad \text{such that} \quad \mathbf{u}_\gamma \text{ solves (3.1)}$$

with an *observation operator* $\mathcal{A} \in \mathcal{L}(H^1(\Omega_\gamma)^2, L^2(\Omega_C)^k)$ for $k \in \{1,2\}$, some *desired state* $\mathbf{u}_d \in L^2(\Omega_C)^k$, and an *observation region* Ω_C satisfying $\operatorname{dist}(\Gamma_\gamma, \Omega_C) > 0$ for all $\gamma \in \mathcal{S}$. The dependence of $\mathcal{J}$ on γ is implicit due to the fact that $\mathcal{J}$ depends on $\mathbf{u}_\gamma$ which itself depends on γ. The functional $\mathcal{J}$ may also include an additional regularization term which we exclude from our theoretical study because it usually depends directly on γ and not by means of the solution $\mathbf{u}_\gamma$ of the state equations. Therefore its differentiability is obtained easily. The above definition of the cost functional is quite general. It includes typical choices as the *tracking-type* functional

$$\mathcal{J}(\gamma) := \frac{1}{2}\|\mathbf{u}_\gamma - \mathbf{u}_d\|^2_{L^2(\Omega_C)^2}$$

or the *minimum drag problem*; compare Pironneau [5], Gunzburger and Kim [6]:

$$\mathcal{J}(\gamma) := \frac{\nu}{2}\|\nabla \mathbf{u}_\gamma + \nabla^T \mathbf{u}_\gamma\|^2_{L^2(\Omega_C)^{2\times 2}}.$$

A restriction we have to make for our derivative formula is that $\mathcal{J}$ does not depend on the pressure.

5. The embedding domain technique. To solve the domain optimization problem (4.1) by a classical iterative scheme it is necessary to discretize the domain, assemble the system matrices, and solve the linear system in each iteration step. To reduce this effort we introduce a *fictitious domain* $\hat{\Omega}$ in which all admissible domains can be embedded, i.e., $\Omega_\gamma \subset \hat{\Omega}$ for all $\gamma \in \mathcal{S}$. We furthermore assume that the fixed boundary part Γ is a part of $\partial\hat{\Omega}$ whereas Γ_γ is replaced by a partition called $\hat{\Gamma}$ which is now fixed as well. Thus we have $\partial\hat{\Omega} = \bar{\Gamma} \cup \bar{\hat{\Gamma}}$; compare Figure 2.1 right. In our model problem we take $\hat{\Omega}$ as the unit square and define $\Omega^c_\gamma := \hat{\Omega} \setminus \bar{\Omega}_\gamma$.

We now formulate a problem on $\hat{\Omega}$ which is equivalent to (4.1). For this purpose we introduce a *fictitious domain formulation* of the state equations. As motivation we recall that the velocity part $\mathbf{u}_\gamma$ of the solution of the Stokes problem (3.1) is the solution of the constrained minimization problem

$$\min_{\substack{\mathbf{u} \in H^1(\Omega_\gamma)^2 \\ \mathbf{u}|_\Gamma = \Phi, \mathbf{u}|_{\Gamma_\gamma} = \mathbf{0}}} \frac{\nu}{2}\|\nabla \mathbf{u}\|^2_{L^2(\Omega_\gamma)^2} - (\mathbf{f}_\gamma, \mathbf{u})_{\Omega_\gamma} \quad \text{s.t.} \quad \operatorname{div} \mathbf{u} = 0 \ \text{ in } \Omega_\gamma.$$

Equations (3.1) are the necessary conditions for a saddle point $(\mathbf{u}_\gamma, p_\gamma)$ of the associated Lagrangian with p_γ being the Lagrange multiplier corresponding to the constraint of zero divergence.

We now denote by $\tilde{\mathbf{f}}_\gamma$ the extension of $\mathbf{f}_\gamma$ by zero onto $\hat{\Omega}$ and consider the problem

$$\min_{\substack{\hat{\mathbf{u}} \in H^1(\hat{\Omega})^2 \\ \hat{\mathbf{u}}|_\Gamma = \Phi, \hat{\mathbf{u}}|_{\hat{\Gamma}} = \mathbf{0}}} \frac{\nu}{2}\|\nabla \hat{\mathbf{u}}\|^2_{L^2(\hat{\Omega})^2} - (\tilde{\mathbf{f}}_\gamma, \hat{\mathbf{u}})_{\hat{\Omega}} \quad \text{s.t.} \quad \left\{ \begin{array}{rcll} \operatorname{div} \hat{\mathbf{u}} & = & 0 & \text{in } \hat{\Omega}, \\ \hat{\mathbf{u}} & = & \mathbf{0} & \text{on } \Gamma_\gamma. \end{array} \right. \tag{5.1}$$

The second constraint is added since Γ_γ is no longer a part of the boundary of the computational domain $\hat{\Omega}$ but an inner line. Thus we get a second Lagrange multiplier g_γ which is an element of the dual of

$$H_\gamma := H^{1/2}_{00}(\Gamma_\gamma)^2 = \left\{ \mathbf{h} \in H^{1/2}(\Gamma_\gamma)^2 : \text{there is } \tilde{\mathbf{h}} \in H^{1/2}(\partial\Omega_\gamma)^2 : \tilde{\mathbf{h}}|_{\Gamma_\gamma} = \mathbf{h}, \tilde{\mathbf{h}}|_\Gamma = \mathbf{0} \right\};$$

compare, e.g., [9, VII, Sect. 2.1, Rem. 1]. The necessary conditions for a saddle point of the Lagrangian associated with problem (5.1) result in the following equations:

Find $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma, g_\gamma) \in H^1(\hat{\Omega})^2 \times L^2_0(\hat{\Omega}) \times H^*_\gamma$ such that

$$\begin{aligned}
\nu(\nabla\hat{\mathbf{u}}_\gamma, \nabla\hat{\mathbf{v}})_{\hat{\Omega}} - (\hat{p}_\gamma, \operatorname{div}\hat{\mathbf{v}})_{\hat{\Omega}} - \langle g_\gamma, \tau_\gamma\hat{\mathbf{v}}\rangle_{H^*_\gamma, H_\gamma} &= (\tilde{\mathbf{f}}_\gamma, \hat{\mathbf{v}})_{\hat{\Omega}} && \text{for all} \quad \hat{\mathbf{v}} \in H^1_0(\hat{\Omega})^2,\\
(\operatorname{div}\hat{\mathbf{u}}_\gamma, \hat{q})_{\hat{\Omega}} &= 0 && \text{for all} \quad \hat{q} \in L^2_0(\hat{\Omega}),\\
\tau_\gamma\hat{\mathbf{u}}_\gamma &= \mathbf{0}, \\
\mathbf{u}_\gamma &= \Phi && \text{on } \Gamma,\\
\mathbf{u}_\gamma &= \mathbf{0} && \text{on } \hat{\Gamma}.
\end{aligned} \tag{5.2}$$

Here τ_γ denotes the trace operator onto Γ_γ which is a linear continuous mapping from $H^1_0(\hat{\Omega})^2$ onto H_γ. The dual pairing between H_γ and its dual is denoted by $\langle\cdot,\cdot\rangle_{H^*_\gamma, H_\gamma}$. We can now prove the equivalence of problems (3.1) and (5.2) as follows.

THEOREM 5.1. *Let $\gamma \in \mathcal{S}, \mathbf{f}_\gamma \in L^2(\Omega_\gamma)^2$, and $\Phi \in H(\Gamma)$. Then $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma, g_\gamma) \in H^1(\hat{\Omega})^2 \times L^2_0(\hat{\Omega}) \times H^*_\gamma$ is a solution of* (5.2) *if and only if*

- $(\mathbf{u}_\gamma, p_\gamma) := (\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma)|_{\Omega_\gamma} \in H^2(\Omega_\gamma)^2 \times [H_1(\Omega_\gamma) \cap L^2_0(\Omega_\gamma)]$ *solves* (3.1),
- $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma)|_{\Omega^c_\gamma} = (\mathbf{0}, 0)$,
- $\langle g_\gamma, \mathbf{h}\rangle_{H^*_\gamma, H_\gamma} = (\nu\frac{\partial\mathbf{u}_\gamma}{\partial\mathbf{n}_\gamma} - p_\gamma\mathbf{n}_\gamma, \mathbf{h})_{\Gamma_\gamma}$ *for all* $\mathbf{h} \in H_\gamma$.

Here $\mathbf{n}_\gamma$ denotes the outer (with respect to Ω_γ) normal vector on Γ_γ and

$$(\mathbf{g}, \mathbf{h})_{\Gamma_\gamma} := \int_I \mathbf{g}(x, \gamma(x)) \cdot \mathbf{h}(x, \gamma(x))\sqrt{1 + \gamma'(x)^2}\, dx$$

is the inner product on $L^2(\Gamma_\gamma)^2$.

Proof. The result is proved by testing (3.1) with appropriate functions that vanish on Ω^c_γ, applying the uniqueness result for the Stokes equations and Green's formula. Regularity of g_γ follows from Theorem 3.1. For the existence of the solution to (5.2) we need the nonsmooth transition between Γ and Γ_γ. Otherwise Ω^c_γ would not even be Lipschitz. For details see [15, Thms. 2.5 and 3.5]. □

By the regularity of $(\mathbf{u}_\gamma, p_\gamma)$ the functional $g_\gamma \in H^*_\gamma$ can be extended onto $L^2(\Gamma_\gamma)^2$ and we get

$$g_\gamma = \left(\nu\frac{\partial\mathbf{u}_\gamma}{\partial\mathbf{n}_\gamma} - p_\gamma\mathbf{n}_\gamma\right)\Bigg|_{\Gamma_\gamma} \qquad \text{in } L^2(\Gamma_\gamma)^2. \tag{5.3}$$

This relation is due to the extension of the inhomogeneity $\mathbf{f}_\gamma$ by zero onto $\hat{\Omega}$. For an arbitrary L^2 extension g_γ equals the jump of the right-hand side of (5.3) on Γ_γ; see also [3]. The equality in (5.3) is essential for the derivative formula presented below.

As a consequence of Theorems 3.1 and 5.1 we now obtain for the solutions on $\hat{\Omega}$.

COROLLARY 5.2. *Let for $\gamma \in \mathcal{S}$ denote $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma, g_\gamma)$ a solution of* (5.2). *Then the families $\{(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma)\}_{\gamma\in\mathcal{S}}$, $\{\|g_\gamma\|_{H^*_\gamma}\}_{\gamma\in\mathcal{S}}$, and $\{\|g_\gamma\|_{L^2(\Gamma_\gamma)^2}\}_{\gamma\in\mathcal{S}}$ are uniformly bounded in $H^1(\hat{\Omega})^2 \times L^2_0(\hat{\Omega})$ and $\mathbb{R}$, respectively.*

Proof. The estimates for $\hat{\mathbf{u}}_\gamma$ and $\hat{p}_\gamma$ follow from Theorem 3.1 and the fact that the solutions vanish on Ω^c_γ; those for the Lagrange multiplier follow from its representation given in Theorem 5.1 and the uniform boundedness of $\mathbf{u}_\gamma$ and p_γ. □

6. Continuous dependence of the solution on the shape of the domain.

To study convergence with respect to γ of the Lagrange multipliers $g_\gamma \in H^*_\gamma$ we introduce for $\mathbf{h} \in H_\gamma$ the mapping $\mathcal{I}_\gamma\mathbf{h}(x) := \mathbf{h}(x, \gamma(x)), x \in I$, which is an isomorphism between H_γ and

$$H_I := \left\{\mathbf{g} \in H^{1/2}(I)^2 : \int_I \frac{\|\mathbf{g}(x)\|_2^2}{x(1-x)}\, dx < \infty\right\}.$$

A function $\mathbf{h} \in H_\gamma$ has to satisfy additional conditions at the transition points between Γ and Γ_γ such that its extension $\tilde{\mathbf{h}}$ by zero onto $\partial\Omega_\gamma$ is in $H^{1/2}(\partial\Omega_\gamma)^2$: The integral

$$\int_{\tilde{I}}\int_{\tilde{I}} \frac{\|\tilde{\mathbf{h}}(x,\gamma(x)) - \tilde{\mathbf{h}}(\xi,\gamma(\xi))\|_2^2}{|x-\xi|^2}\, d\tilde{\gamma}(x) d\tilde{\gamma}(\xi)$$

has to be finite for arbitrary functions $\tilde{\gamma} : \tilde{I} \to \tilde{\gamma}(\tilde{I}) \subset \partial\Omega_\gamma$ that parameterize a part of the boundary. Critical are parameterizations which contain one of the transition points between Γ and Γ_γ. To guarantee the existence of the above integral the additional integral condition in the definition of H_I has to be satisfied; compare [15, Thm. 2.4].

We note a result concerning convergence of the transformed trace operators below.

Lemma 6.1. *Let $\gamma_n, \gamma \in \mathcal{S}$. Then $\gamma_n \to \gamma$ in $W^{1,\infty}(I)$ implies $\mathcal{I}_{\gamma_n}\tau_{\gamma_n} \to \mathcal{I}_\gamma\tau_\gamma$ as linear operators from $\{\hat{\mathbf{v}} \in H^1(\hat{\Omega})^2 : \hat{\mathbf{v}}|_{\hat{\Gamma}} = \mathbf{0}\}$ onto H_I.*

Proof. See [15, Lem. 2.1]. □

We define $\left(\mathcal{I}_\gamma^{-1}\right)^* : H_\gamma^* \to H_I^*$, i.e., the adjoint of $\mathcal{I}_\gamma^{-1}$, by

$$\langle \left(\mathcal{I}_\gamma^{-1}\right)^* g, \mathbf{g}\rangle_{H_I^*,H_I} := \langle g, \mathcal{I}_\gamma^{-1}\mathbf{g}\rangle_{H_\gamma^*,H_\gamma}, \qquad g \in H_\gamma^*,\ \mathbf{g} \in H_I.$$

Now we can formulate the following result of continuous dependence.

Theorem 6.2. *Let $\gamma, \gamma_n \in \mathcal{S}$ with $\gamma_n \to \gamma$ in $W^{1,\infty}(I), \mathbf{f} \in L^\infty(\hat{\Omega})^2$, and $\mathbf{f}_\gamma := \mathbf{f}|_{\Omega_\gamma}, \mathbf{f}_{\gamma_n} := \mathbf{f}|_{\Omega_{\gamma_n}}$. Then the corresponding solutions of problem (5.2) satisfy*

$$\begin{array}{rcll} (\hat{\mathbf{u}}_{\gamma_n}, \hat{p}_{\gamma_n}) & \to & (\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma) & \text{in } H^1(\hat{\Omega})^2 \times L_0^2(\hat{\Omega}), \\ \left(\mathcal{I}_{\gamma_n}^{-1}\right)^* g_{\gamma_n} & \overset{*}{\rightharpoonup} & \left(\mathcal{I}_\gamma^{-1}\right)^* g_\gamma & \text{in } H_I^*. \end{array}$$

Moreover, the mapping $\gamma \mapsto \hat{\mathbf{u}}_\gamma$ is Lipschitz continuous, i.e., there exists L independent of $\gamma, \bar{\gamma}$ such that

$$\|\hat{\mathbf{u}}_{\bar{\gamma}} - \hat{\mathbf{u}}_\gamma\|_{H^1(\hat{\Omega})^2} \le L\|\bar{\gamma} - \gamma\|_{L^\infty(I)} \qquad \text{for all } \bar{\gamma}, \gamma \in \mathcal{S}.$$

Proof. By Corollary 5.2 we have for a subsequence $(\hat{\mathbf{u}}_{\gamma_n}, \hat{p}_{\gamma_n}) \rightharpoonup (\hat{\mathbf{u}}, \hat{p})$ weakly in $H^1(\hat{\Omega})^2 \times L_0^2(\hat{\Omega})$ and thus using the first equation of (5.2),

$$\lim_{n\to\infty} \langle g_{\gamma_n}, \tau_{\gamma_n}\hat{\mathbf{v}}\rangle_{H_{\gamma_n}^*,H_{\gamma_n}} = \nu(\nabla\hat{\mathbf{u}}, \nabla\hat{\mathbf{v}})_{\hat{\Omega}} - (\hat{p}, \operatorname{div}\hat{\mathbf{v}})_{\hat{\Omega}} - (\tilde{\mathbf{f}}_\gamma, \hat{\mathbf{v}})_{\hat{\Omega}}$$

for all $\hat{\mathbf{v}} \in H_0^1(\hat{\Omega})^2$. For every $\mathbf{g} \in H_I$ there exists $\hat{\mathbf{v}} \in H_0^1(\hat{\Omega})^2$ with $\mathcal{I}_\gamma\tau_\gamma\hat{\mathbf{v}} = \mathbf{g}$ and

$$\langle (\mathcal{I}_{\gamma_n}^{-1})^* g_{\gamma_n}, \mathbf{g}\rangle_{H_I^*,H_I} = \langle (\mathcal{I}_{\gamma_n}^{-1})^* g_{\gamma_n}, \mathcal{I}_\gamma\tau_\gamma\hat{\mathbf{v}} - \mathcal{I}_{\gamma_n}\tau_{\gamma_n}\hat{\mathbf{v}}\rangle_{H_I^*,H_I} + \langle g_{\gamma_n}, \tau_{\gamma_n}\hat{\mathbf{v}}\rangle_{H_{\gamma_n}^*,H_{\gamma_n}},$$

where the first term on the right tends to zero by Corollary 5.2 and Lemma 6.1. Thus

$$\lim_{n\to\infty} \langle (\mathcal{I}_{\gamma_n}^{-1})^* g_{\gamma_n}, \mathbf{g}\rangle_{H_I^*,H_I} = \nu(\nabla\hat{\mathbf{u}}, \nabla\hat{\mathbf{v}})_{\hat{\Omega}} - (\hat{p}, \operatorname{div}\hat{\mathbf{v}})_{\hat{\Omega}} - (\tilde{\mathbf{f}}_\gamma, \hat{\mathbf{v}})_{\hat{\Omega}} =: \langle G, \mathbf{g}\rangle_{H_I^*,H_I}.$$

We define $g := \mathcal{I}_\gamma^* G \in H_\gamma^*$. For $\hat{\mathbf{v}} \in H_0^1(\hat{\Omega})^2$ we have $\tau_\gamma\hat{\mathbf{v}} \in H_\gamma$ and thus $(\hat{\mathbf{u}}, \hat{p}, g)$ satisfies the first equation of (5.2). Green's formula implies

$$0 = \lim_{n\to\infty} (\operatorname{div}\hat{\mathbf{u}}_{\gamma_n}, \hat{\varphi})_{\hat{\Omega}} = -\lim_{n\to\infty} (\hat{\mathbf{u}}_{\gamma_n}, \nabla\hat{\varphi})_{\hat{\Omega}} = -(\hat{\mathbf{u}}, \nabla\hat{\varphi})_{\hat{\Omega}} = (\operatorname{div}\hat{\mathbf{u}}, \hat{\varphi})_{\hat{\Omega}}$$

for all $\hat{\varphi} \in C_0^\infty(\hat{\Omega}) \cap L_0^2(\hat{\Omega})$. Thus $\hat{\mathbf{u}}$ solves the second equation of (5.2). Since it can be shown that also $\tau_\gamma\hat{\mathbf{u}} = \mathbf{0}$ (see [15, Lem. 2.12]) this implies that $(\hat{\mathbf{u}}, \hat{p}, g)$ is the unique solution to problem (5.2) and thus equals $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma, g_\gamma)$. Therefore the limits are valid for the whole sequence and not only for the chosen subsequence.

To show strong convergence of $\hat{\mathbf{u}}_{\gamma_n}$ in $H^1(\hat\Omega)^2$ we define $\hat{\mathbf{u}}_n := \hat{\mathbf{u}}_{\gamma_n} - \hat{\mathbf{u}}_\gamma \in H^1_0(\hat\Omega)^2$ which satisfies $(\operatorname{div}\hat{\mathbf{u}}_n, \hat{q})_{\hat\Omega} = 0$ for all $\hat{q} \in L^2_0(\hat\Omega)$. Choosing $\hat{\mathbf{v}} := \hat{\mathbf{u}}_n$ in the first equation of (5.2) for Ω_{γ_n} and Ω_γ and subtracting both equations we get

$$\nu|\hat{\mathbf{u}}_n|^2_{H^1(\hat\Omega)^2} = (\tilde{\mathbf{f}}_{\gamma_n} - \tilde{\mathbf{f}}_\gamma, \hat{\mathbf{u}}_n)_{\hat\Omega} + \langle g_{\gamma_n}, \tau_{\gamma_n}\hat{\mathbf{u}}_n\rangle_{H^*_{\gamma_n},H_{\gamma_n}} - \langle g_\gamma, \tau_\gamma\hat{\mathbf{u}}_n\rangle_{H^*_\gamma,H_\gamma}, \tag{6.1}$$

where $|\hat{\mathbf{u}}|_{H^1(\hat\Omega)^2} := \|\nabla\hat{\mathbf{u}}\|_{L^2(\hat\Omega)^{2\times 2}}$ denotes the H^1 seminorm. We estimate the terms on the right of (6.1) separately: First we split up I into

$$I_+ := \{x \in (0,1) : \gamma_n(x) \geq \gamma(x)\}, \quad I_- := \{x \in (0,1) : \gamma_n(x) < \gamma(x)\}$$

and obtain, using the fact that $\mathbf{f}_\gamma := \mathbf{f}|_{\Omega_\gamma}$ with $\mathbf{f} \in L^\infty(\hat\Omega)^2$ for all $\gamma \in \mathcal{S}$, that

$$(\tilde{\mathbf{f}}_{\gamma_n} - \tilde{\mathbf{f}}_\gamma, \hat{\mathbf{u}}_n)_{\hat\Omega} = \int_{I_+}\int_\gamma^{\gamma_n} \mathbf{f}(x,y)\cdot\hat{\mathbf{u}}_n(x,y)\,dydx - \int_{I_-}\int_{\gamma_n}^{\gamma} \mathbf{f}(x,y)\cdot\hat{\mathbf{u}}_n(x,y)\,dydx.$$

We denote the first integral on the right by A and use $\hat{\mathbf{u}}_n(x,\gamma(x)) = \mathbf{0}$ almost everywhere (a.e.) in I_+:

$$\begin{aligned} |A| &= \left| \int_{I_+}\int_\gamma^{\gamma_n} \mathbf{f}(x,y)\cdot[\hat{\mathbf{u}}_n(x,y) - \hat{\mathbf{u}}_n(x,\gamma)]\;dydx \right| \\ &\leq \|\mathbf{f}\|_{L^\infty(\hat\Omega)^2} \int_{I_+}\int_\gamma^{\gamma_n}\int_\gamma^y \|\hat{\mathbf{u}}_{n,y}(x,\xi)\|_2\,d\xi dydx \\ &\leq \|\mathbf{f}\|_{L^\infty(\hat\Omega)^2} \int_{I_+}\int_\gamma^{\gamma_n} \|\hat{\mathbf{u}}_{n,y}(x,\xi)\|_2(\gamma_n - \xi)\,dx \\ &\leq \frac{1}{3}\|\mathbf{f}\|_{L^\infty(\hat\Omega)^2}\|\hat{\mathbf{u}}_{n,y}\|_{L^2(\hat\Omega)^2}\|\gamma_n - \gamma\|^{3/2}_{L^\infty(I_+)} \;\leq\; C|\hat{\mathbf{u}}_n|_{H^1(\hat\Omega)^2}\|\gamma_n - \gamma\|^{3/2}_{L^\infty(I)} \end{aligned} \tag{6.2}$$

with C independent of γ_n, γ. The second integral can be estimated in a similar way using $\hat{\mathbf{u}}_n(x,\gamma_n(x)) = \mathbf{0}$ a.e. in I_-. Thus there exists L_1 independent of γ_n, γ with

$$|(\tilde{\mathbf{f}}_{\gamma_n} - \tilde{\mathbf{f}}_\gamma, \hat{\mathbf{u}}_n)_{\hat\Omega}| \leq L_1|\hat{\mathbf{u}}_n|_{H^1(\hat\Omega)^2}\|\gamma_n - \gamma\|^{3/2}_{L^\infty(I)}. \tag{6.3}$$

For the second term in (6.1) we obtain using Theorem 5.1:

$$|\langle g_{\gamma_n}, \tau_{\gamma_n}\hat{\mathbf{u}}_n\rangle_{H^*_{\gamma_n},H_{\gamma_n}}| = |(g_{\gamma_n}, \tau_{\gamma_n}\hat{\mathbf{u}}_n)_{\Gamma_{\gamma_n}}| \;\leq\; \|\mathbf{g}_{\gamma_n}\|_{L^2(\Gamma_{\gamma_n})}\|\tau_{\gamma_n}\hat{\mathbf{u}}_n\|_{L^2(\Gamma_{\gamma_n})^2}.$$

The first term on the right-hand side is bounded independently of γ_n by Theorem 5.2. For the last term we use $\hat{\mathbf{u}}_n(x,\gamma_n(x)) = \mathbf{0}$ a.e. in I_- and $\hat{\mathbf{u}}_n(x,\gamma(x)) = \mathbf{0}$ a.e. in I_+:

$$\begin{aligned} \|\tau_{\gamma_n}\hat{\mathbf{u}}_n\|^2_{L^2(\Gamma_{\gamma_n})^2} &= \int_{I_+} \|\hat{\mathbf{u}}_n(x,\gamma_n(x)) - \hat{\mathbf{u}}_n(x,\gamma(x))\|^2_2\sqrt{1+\gamma_n'(x)^2}\,dx \\ &= \int_{I_+} \left\| \int_\gamma^{\gamma_n} \hat{\mathbf{u}}_{n,y}(x,\xi)\,d\xi \right\|^2_2 \sqrt{1+\gamma_n'(x)^2}\,dx \\ &\leq \|\gamma_n - \gamma\|^2_{L^\infty(I)}|\hat{\mathbf{u}}_n|^2_{H^1(\hat\Omega)^2}\|(1 + \|\gamma_n\|^2_{W^{1,\infty}(I)}). \end{aligned}$$

Because $\mathcal{S}$ is bounded in $H^3(I)$ which is continuously embedded in $W^{1,\infty}(I)$ there exists L_2 independent of γ, γ_n such that

$$|\langle g_{\gamma_n}, \tau_{\gamma_n}\hat{\mathbf{u}}_n\rangle_{H^*_{\gamma_n},H_{\gamma_n}}| \leq L_2|\hat{\mathbf{u}}_n|_{H^1(\hat\Omega)^2}\|\gamma_n - \gamma\|_{L^\infty(I)}. \tag{6.4}$$

An analogous computation for the third term on the right-hand side of (6.1) shows the existence of L_3 independent of γ, γ_n with

$$|\langle g_\gamma, \tau_\gamma \hat{\mathbf{u}}_n \rangle_{H_\gamma^*, H_\gamma}| \le L_3 |\hat{\mathbf{u}}_n|_{H^1(\hat\Omega)^2} \|\gamma_n - \gamma\|_{L^\infty(I)}. \tag{6.5}$$

Poincaré's inequality implies $\|\hat{\mathbf{u}}_n\|_{H^1(\hat\Omega)^2} \le c |\hat{\mathbf{u}}_n|_{H^1(\hat\Omega)^2}$ with c independent of γ, γ_n and thus (6.3)–(6.5) give Lipschitz continuity of $\hat{\mathbf{u}}_\gamma$ with respect to γ.

To show strong convergence $p_{\gamma_n} \to p_\gamma$ we note that the operator $(\operatorname{div}, \tau_\gamma)$ maps $H_0^1(\hat\Omega)^2$ onto $L_0^2(\hat\Omega) \times H_\gamma$, see [15, Thm. 2.5]. Moreover, the weak divergence operator is an isomorphism between the orthogonal complement of $\{\hat{\mathbf{v}} \in H_0^1(\hat\Omega)^2 : \operatorname{div} \hat{\mathbf{v}} = 0 \text{ in } \hat\Omega\}$ and $L_0^2(\hat\Omega)$. Thus there exists $\hat{\mathbf{v}}_n \in H_0^1(\hat\Omega)^2$ satisfying $\tau_\gamma \hat{\mathbf{v}}_n = \mathbf{0}, \operatorname{div} \hat{\mathbf{v}}_n = \hat p_{\gamma_n} - \hat p_\gamma$, and $\|\hat{\mathbf{v}}_n\|_{H^1(\hat\Omega)^2} \le c \|\hat p_{\gamma_n} - \hat p_\gamma\|_{L^2(\hat\Omega)}$. We test the first equation of (5.2) with $\hat{\mathbf{v}}_n$ for γ and γ_n, and subtract both equations. With the uniform boundedness of $\{\hat p_{\gamma_n}\}_{n \in \mathbb{N}}$ in $L^2(\hat\Omega)$ we obtain

$$\|\hat p_{\gamma_n} - \hat p_\gamma\|_{0,\hat\Omega}^2 \le c \left(\nu |\hat{\mathbf{u}}_{\gamma_n} - \hat{\mathbf{u}}_\gamma|_{H^1(\hat\Omega)^2} + \|\tilde{\mathbf{f}}_{\gamma_n} - \tilde{\mathbf{f}}_\gamma\|_{L^2(\hat\Omega)^2} \right) + |\langle g_{\gamma_n}, \tau_{\gamma_n} \hat{\mathbf{v}}_n \rangle_{H_{\gamma_n}^*, H_{\gamma_n}}|$$

with c independent of n. Since $\hat{\mathbf{u}}_{\gamma_n} \to \hat{\mathbf{u}}_\gamma$ in $H^1(\Omega_\gamma)^2$ and $\tilde{\mathbf{f}}_{\gamma_n} \to \tilde{\mathbf{f}}_\gamma$ in $L^2(\hat\Omega)^2$ the first term tends to zero. In the second one we may write

$$\langle g_{\gamma_n}, \tau_{\gamma_n} \hat{\mathbf{v}}_n \rangle_{H_{\gamma_n}^*, H_{\gamma_n}} = \langle (\mathcal{I}_{\gamma_n}^{-1})^* g_{\gamma_n}, \mathcal{I}_{\gamma_n} \tau_{\gamma_n} \hat{\mathbf{v}}_n \rangle_{H_I^*, H_I}. \tag{6.6}$$

We already proved that $(\mathcal{I}_{\gamma_n}^{-1})^* g_{\gamma_n} \overset{*}{\rightharpoonup} (\mathcal{I}_\gamma^{-1})^* g_\gamma$. Lemma 6.1 implies $\mathcal{I}_{\gamma_n} \tau_{\gamma_n} \to \mathcal{I}_\gamma \tau_\gamma$ and since $\tau_\gamma \hat{\mathbf{v}}_n = \mathbf{0}$ for all n also (6.6) tends to zero. □

As a consequence of this theorem and the boundedness of $\mathcal{S}$ in $H^3(I)$ we now obtain the following.

COROLLARY 6.3. *The domain optimization problem has at least one solution $\gamma \in \mathcal{S}$.*

Proof. This result can be proved by choosing a minimizing sequence and using the compact embedding of $H^3(I)$ in $C^2(\bar I)$. □

7. Fréchet differentiability and derivative formula. To show differentiability we use the solution of the adjoint system of the domain optimization problem (4.1). We introduce a Lagrangian with two multipliers $\lambda_\gamma, \mu_\gamma$ for the constraints of the momentum and continuity equation, respectively. Then we compute the necessary optimality conditions for a saddle point of this Lagrangian which form the adjoint equations. Since the Stokes equations are linear, the adjoint problem is a Stokes system with a different inhomogeneity and homogeneous boundary conditions: Find $(\lambda_\gamma, \mu_\gamma) \in H_0^1(\Omega_\gamma)^2 \times L_0^2(\Omega_\gamma)$ such that

$$\begin{array}{rcll} \nu(\nabla\lambda_\gamma, \nabla\mathbf{v})_{\Omega_\gamma} - (\mu_\gamma, \operatorname{div}\mathbf{v})_{\Omega_\gamma} & = & -D_u\mathcal{J}(\gamma)\mathbf{v} & \text{for all} \quad \mathbf{v} \in H_0^1(\Omega_\gamma)^2, \\ (\operatorname{div}\lambda_\gamma, q)_{\Omega_\gamma} & = & 0 & \text{for all} \quad q \in L_0^2(\Omega_\gamma), \end{array} \tag{7.1}$$

where $\mathbf{u}_\gamma$ is the velocity component of a solution to (3.1), and $D_u\mathcal{J}(\gamma)\mathbf{v}$ denotes the Fréchet derivative of $\mathcal{J}$ with respect to $\mathbf{u}$ in direction $\mathbf{v}$. The equivalent fictitious domain formulation is the following: Find $(\hat\lambda_\gamma, \hat\mu_\gamma, \chi_\gamma) \in H_0^1(\hat\Omega)^2 \times L_0^2(\hat\Omega) \times H_\gamma^*$ such that

$$\begin{array}{rcll} \nu(\nabla\hat\lambda_\gamma, \nabla\hat{\mathbf{v}})_{\hat\Omega} - (\hat\mu_\gamma, \operatorname{div}\hat{\mathbf{v}})_{\hat\Omega} - \langle \chi_\gamma, \tau_\gamma\hat{\mathbf{v}} \rangle_{H_\gamma^*, H_\gamma} & = & -D_u\mathcal{J}(\gamma)\hat{\mathbf{v}} & \text{for all } \hat{\mathbf{v}} \in H_0^1(\hat\Omega)^2, \\ (\operatorname{div}\hat\lambda_\gamma, \hat q)_{\hat\Omega} & = & 0 & \text{for all } \hat q \in L_0^2(\hat\Omega), \\ \tau_\gamma\hat\lambda_\gamma & = & \mathbf{0}. & \end{array} \tag{7.2}$$

For the solution of (7.2) we get similar results of existence, uniqueness, regularity, and equivalence to (7.1) as for the Stokes equations in Theorems 3.1 and 5.1; see below.

THEOREM 7.1. *Let $\gamma \in \mathcal{S}$ and $(\mathbf{u}_\gamma, p_\gamma)$ be the solution of* (3.1). *Then problem* (7.1) *has a unique solution $(\lambda_\gamma, \mu_\gamma) \in [H^2(\Omega_\gamma)^2 \cap H^1_0(\Omega_\gamma)^2] \times [H^1(\Omega_\gamma) \cap L^2_0(\Omega_\gamma)]$. The regularity is uniform in γ.*

Moreover, $(\hat{\lambda}_\gamma, \hat{\mu}_\gamma, \chi_\gamma) \in H^1(\hat{\Omega})^2 \times L^2_0(\hat{\Omega}) \times H^*_\gamma$ is a solution of (7.2) *if and only if*

- $(\lambda_\gamma, \mu_\gamma) := (\hat{\lambda}_\gamma, \hat{\mu}_\gamma)|_{\Omega_\gamma}$ *is a solution of* (7.1),
- $(\hat{\lambda}_\gamma, \hat{\mu}_\gamma)|_{\Omega^c_\gamma} = (\mathbf{0}, 0)$,
- $\langle \chi_\gamma, \mathbf{h} \rangle_{H^*_\gamma, H_\gamma} = (\nu \frac{\partial \lambda_\gamma}{\partial \mathbf{n}_\gamma} - \mu_\gamma \mathbf{n}_\gamma, \mathbf{h})_{\Gamma_\gamma}$ *for all* $\mathbf{h} \in H_\gamma$

and we have

$$\chi_\gamma = \left(\nu \frac{\partial \lambda_\gamma}{\partial \mathbf{n}_\gamma} - \mu_\gamma \mathbf{n}_\gamma \right) \Big|_{\Gamma_\gamma} \qquad \text{in } L^2(\Gamma_\gamma)^2.$$

We now turn to the differentiability of $\mathcal{J}$ with respect to variations in γ. Since $\mathcal{S}$ is closed we consider $\gamma \in \operatorname{int} \mathcal{S}$, the interior of $\mathcal{S}$, and define the set of admissible directions as

$$\mathcal{S}' := \left\{ \bar{\gamma} \in H^3(I) : \bar{\gamma}|_{[0,\delta] \cup [1-\delta, 1]} = 0 \right\}.$$

For every $\gamma \in \operatorname{int} \mathcal{S}$ and $\bar{\gamma} \in \mathcal{S}'$ there exists $t_0 > 0$ such that $\gamma + t\bar{\gamma} \in \operatorname{int} \mathcal{S}$ for all $t \in [0, t_0)$. Thus we can properly define a directional derivative. We now define $I_+ := \{x \in I : \bar{\gamma}(x) \geq 0\}$, $I_- := \{x \in I : \bar{\gamma}(x) < 0\}$, and present three results that will be used to prove the differentiability of $\mathcal{J}$. Their proofs are given in section 9.

LEMMA 7.2. *Let $\mathbf{f} \in L^\infty(\hat{\Omega})^2, \mathbf{f}_\gamma := \mathbf{f}|_{\Omega_\gamma}, \mathbf{f}_{\gamma+t\bar{\gamma}} := \mathbf{f}|_{\Omega_{\gamma+t\bar{\gamma}}}$, and $\hat{\lambda}_\gamma$ be a solution of problem* (7.2). *Then*

$$\lim_{t \to 0} \frac{1}{t} (\tilde{\mathbf{f}}_\gamma - \tilde{\mathbf{f}}_{\gamma+t\bar{\gamma}}, \hat{\lambda}_\gamma)_{\hat{\Omega}} = 0.$$

LEMMA 7.3. *Let χ_γ be the third component of a solution of* (7.2) *and $\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}$ the first component of the solution of* (5.2) *for $\gamma + t\bar{\gamma}$. Then*

$$\lim_{t \to 0} \frac{1}{t} \langle \chi_\gamma, \tau_\gamma \hat{\mathbf{u}}_{\gamma+t\bar{\gamma}} \rangle_{H^*_\gamma, H_\gamma} = - \int_{I_+} \chi_\gamma(x, \gamma) \cdot \mathbf{u}_{\gamma,y}(x, \gamma) \bar{\gamma} \sqrt{1 + \gamma'^2} \, dx.$$

The integral on the right exists because $\bar{\gamma} \in \mathcal{S}' \subset L^\infty(I)$ and $\chi_\gamma \in L^2(\Gamma_\gamma)^2$. Furthermore $\tau_\gamma \mathbf{u}_{\gamma,y} = \mathbf{u}_{\gamma,y}(x, \gamma)$ and also its restriction on the set $\Gamma^+_\gamma := \{(x, \gamma(x)) : x \in I_+\} \subset \Gamma_\gamma$ are L^2 functions since $\mathbf{u}_\gamma \in H^2(\Omega_\gamma)^2$. Finally we will use the following.

LEMMA 7.4. *Let $g_{\gamma+t\bar{\gamma}}$ be the third component of the solution of* (5.2) *for $\gamma + t\bar{\gamma}$ and $\hat{\lambda}_\gamma$ the first component of the solution of* (7.2). *Then*

$$\lim_{t \to 0} \frac{1}{t} \langle g_{\gamma+t\bar{\gamma}}, \tau_{\gamma+t\bar{\gamma}} \hat{\lambda}_\gamma \rangle_{H^*_{\gamma+t\bar{\gamma}}, H_{\gamma+t\bar{\gamma}}} = \int_{I_-} g_\gamma(x, \gamma) \cdot \lambda_{\gamma,y}(x, \gamma) \bar{\gamma} \sqrt{1 + \gamma'^2} \, dx.$$

By arguments analogous to those for Lemma 7.3 the integral on the right exists.

Now we state the main result of this paper, namely the differentiability of the cost functional with respect to γ and an explicit formula for its derivative.

THEOREM 7.5. *Let $\gamma \in \operatorname{int} \mathcal{S}, \mathbf{f} \in L^\infty(\hat{\Omega})^2$, and $\mathbf{f}_\gamma := \mathbf{f}|_{\Omega_\gamma}$. Then $\mathcal{J}$ is Fréchet differentiable with respect to γ and the derivative in γ in direction $\bar{\gamma} \in \mathcal{S}'$ satisfies*

$$(7.3)\quad D_\gamma \mathcal{J}(\gamma)\bar{\gamma} = \frac{1}{\nu} \int_I \left[g_\gamma\big(x, \gamma(x)\big) \cdot \chi_\gamma\big(x, \gamma(x)\big) - p_\gamma\big(x, \gamma(x)\big) \mu_\gamma\big(x, \gamma(x)\big) \right] \bar{\gamma}(x) \, dx.$$

Proof. A simple computation leads to the identity

$$\begin{aligned}\frac{1}{t}\mathcal{J}(\gamma+t\bar{\gamma})-\mathcal{J}(\gamma) &= \frac{1}{2t}\|\mathcal{A}(\hat{\mathbf{u}}_{\gamma+t\gamma}-\hat{\mathbf{u}}_{\gamma})\|^2_{L^2(\Omega_C)^k}+\frac{1}{t}\big(\mathcal{A}(\hat{\mathbf{u}}_{\gamma+t\gamma}-\hat{\mathbf{u}}_{\gamma}),\mathcal{A}\hat{\mathbf{u}}_{\gamma}-\mathbf{u}_d\big)_{\Omega_C}\\ &= \frac{1}{2t}\|\mathcal{A}(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma})\|^2_{L^2(\Omega_C)^k}+\frac{1}{t}D_u\mathcal{J}(\gamma)(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma}).\end{aligned}$$

The first term on the right can be estimated using the boundedness of $\mathcal{A}$ and the Lipschitz continuity of the velocities proved in Theorem 6.2:

$$\frac{1}{2t}\|\mathcal{A}(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma})\|^2_{L^2(\Omega_C)^k}\le\frac{C}{t}\|\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma}\|^2_{H^1(\hat{\Omega})^2}\ \le\ Ct\|\bar{\gamma}\|^2_{L^\infty(I)},$$

where C is independent of $\gamma,\bar{\gamma}$, and t. Since $\bar{\gamma}\in\mathcal{S}'\subset W^{1,\infty}(I)$, this term tends to zero for $t\to 0$ and we obtain

$$D_\gamma\mathcal{J}(\gamma)\bar{\gamma}=\lim_{t\to 0}\frac{1}{t}D_u\mathcal{J}(\gamma)(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma}).$$

We show that this limit equals the right-hand side of (7.3). The first equation of (7.2) with $\hat{\mathbf{v}}=\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma}\in H^1_0(\hat{\Omega})^2$ as test function gives

$$\begin{aligned}D_u\mathcal{J}(\gamma)(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma}) = -\nu\big(\nabla\hat{\lambda}_\gamma,\nabla(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma})\big)_{\hat{\Omega}}+\big(\hat{\mu}_\gamma,\operatorname{div}(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma})\big)_{\hat{\Omega}}\\ +\langle\chi_\gamma,\tau_\gamma(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma})\rangle_{H^*_\gamma,H_\gamma}.\end{aligned}$$

As solutions to (5.2) for γ and $\gamma+t\bar{\gamma}$, respectively, the functions $\hat{\mathbf{u}}_\gamma$ and $\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}$ are weakly divergence free. Since $\hat{\mu}_\gamma\in L^2_0(\hat{\Omega})$ the second term on the right vanishes. With $\tau_\gamma\hat{\mathbf{u}}_\gamma=\mathbf{0}$ we obtain

$$D_u\mathcal{J}(\gamma)(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma})=\nu(\nabla\hat{\lambda}_\gamma,\nabla\hat{\mathbf{u}}_\gamma)_{\hat{\Omega}}-\nu(\nabla\hat{\lambda}_\gamma,\nabla\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}})_{\hat{\Omega}}+\langle\chi_\gamma,\tau_\gamma\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}\rangle_{H^*_\gamma,H_\gamma}.$$

For the first two terms on the right we use again the first equation in (5.2) for γ and $\gamma+t\bar{\gamma}$, respectively, with $\hat{\mathbf{v}}=\hat{\lambda}_\gamma\in H^1_0(\hat{\Omega})^2$. We get

$$\begin{aligned}D_u\mathcal{J}(\gamma)(\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}-\hat{\mathbf{u}}_{\gamma}) = (\tilde{\mathbf{f}}_\gamma-\tilde{\mathbf{f}}_{\gamma+t\bar{\gamma}},\hat{\lambda}_\gamma)_{\hat{\Omega}}+(\hat{p}_\gamma-\hat{p}_{\gamma+t\bar{\gamma}},\operatorname{div}\hat{\lambda}_\gamma)_{\hat{\Omega}}+\langle g_\gamma,\tau_\gamma\hat{\lambda}_\gamma\rangle_{H^*_\gamma,H_\gamma}\\ -\langle g_{\gamma+t\bar{\gamma}},\tau_{\gamma+t\bar{\gamma}}\hat{\lambda}_\gamma\rangle_{H^*_{\gamma+t\bar{\gamma}},H_{\gamma+t\bar{\gamma}}}+\langle\chi_\gamma,\tau_\gamma\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}\rangle_{H^*_\gamma,H_\gamma}.\end{aligned}$$

The second and third terms on the right both vanish since $\hat{\lambda}_\gamma$ as solution of (7.2) is weakly divergence free, $\hat{p}_\gamma-\hat{p}_{\gamma+t\bar{\gamma}}\in L^2_0(\hat{\Omega})$, and $\tau_\gamma\hat{\lambda}_\gamma=\mathbf{0}$. Thus we obtain

$$\begin{aligned}D_\gamma\mathcal{J}(\gamma)\bar{\gamma}=\lim_{t\to 0}\frac{1}{t}\Big[(\tilde{\mathbf{f}}_\gamma-\tilde{\mathbf{f}}_{\gamma+t\bar{\gamma}},\hat{\lambda}_\gamma)_{\hat{\Omega}}+\langle\chi_\gamma,\tau_\gamma\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}\rangle_{H^*_\gamma,H_\gamma}\\ -\langle g_{\gamma+t\bar{\gamma}},\tau_{\gamma+t\bar{\gamma}}\hat{\lambda}_\gamma\rangle_{H^*_{\gamma+t\bar{\gamma}},H_{\gamma+t\bar{\gamma}}}\Big].\end{aligned}$$

Using Lemmas 7.2 to 7.4, this implies

$$D_\gamma\mathcal{J}(\gamma)\bar{\gamma}=-\int_{I_+}\chi_\gamma(x,\gamma)\cdot\mathbf{u}_{\gamma,y}(x,\gamma)\bar{\gamma}\sqrt{1+\gamma'^2}dx-\int_{I_-}g_\gamma(x,\gamma)\cdot\lambda_{\gamma,y}(x,\gamma)\bar{\gamma}\sqrt{1+\gamma'^2}dx.$$

Because of $\tau_\gamma\mathbf{u}_\gamma=\tau_\gamma\lambda_\gamma=\mathbf{0}$ the partial derivatives times the arc length can be expressed as normal derivatives along Γ_γ. This leads to

$$D_\gamma\mathcal{J}(\gamma)\bar{\gamma}=\int_{I_+}\chi_\gamma(x,\gamma)\cdot\frac{\partial\mathbf{u}_\gamma(x,\gamma)}{\partial\mathbf{n}_\gamma}\,\bar{\gamma}\,dx+\int_{I_-}g_\gamma(x,\gamma)\cdot\frac{\partial\lambda_\gamma(x,\gamma)}{\partial\mathbf{n}_\gamma}\,\bar{\gamma}\,dx.$$

By the representations of g_γ and χ_γ we obtain

$$g_\gamma \cdot \frac{\partial \lambda_\gamma}{\partial \mathbf{n}_\gamma} = \frac{1}{\nu}(g_\gamma \cdot \chi_\gamma - p_\gamma \mu_\gamma) + \mu_\gamma \frac{\partial \mathbf{u}_\gamma}{\partial \mathbf{n}_\gamma} \cdot \mathbf{n}_\gamma \ = \ \frac{1}{\nu}(g_\gamma \cdot \chi_\gamma - p_\gamma \mu_\gamma).$$

The term with the normal derivative vanishes because of $\frac{\partial \hat{\mathbf{u}}_\gamma}{\partial \mathbf{n}_\gamma} \cdot \mathbf{n}_\gamma = \operatorname{div} \hat{\mathbf{u}}_\gamma$ on Γ_γ and since $\hat{\mathbf{u}}_\gamma$ has zero divergence in $\hat{\Omega}$ and thus on Γ_γ. Analogously we get

$$\chi_\gamma \cdot \frac{\partial \mathbf{u}_\gamma}{\partial \mathbf{n}_\gamma} = \frac{1}{\nu}(g_\gamma \cdot \chi_\gamma - p_\gamma \mu_\gamma).$$

Summing up we have shown that $\mathcal{J}$ has a directional derivative for every $\gamma \in \operatorname{int} \mathcal{S}$ in every direction $\bar{\gamma} \in \mathcal{S}'$ given by (7.3).

To show that the linear mapping $D_\gamma \mathcal{J}(\gamma) : \mathcal{S}' \to \mathbb{R}, \bar{\gamma} \mapsto D_\gamma \mathcal{J}(\gamma)\bar{\gamma}$ is a Gâteaux derivative we show that it is bounded on $\mathcal{S}'$. At first we have

$$(7.4)\ |D_\gamma \mathcal{J}(\gamma)\bar{\gamma}| \le \frac{1}{\nu}\left(\int_I |g_\gamma(x,\gamma) \cdot \chi_\gamma(x,\gamma)|\, dx + \int_I |p_\gamma(x,\gamma)\mu_\gamma(x,\gamma)|\, dx\right) \|\bar{\gamma}\|_{L^\infty(I)}.$$

Since $g_\gamma, \chi_\gamma \in L^2(\Gamma_\gamma)^2$ we obtain $\mathcal{I}_\gamma g_\gamma, \mathcal{I}_\gamma \chi_\gamma \in L^2(I)^2$. The first integral in brackets can be estimated by Hölder's inequality as

$$\int_I |g_\gamma(x,\gamma) \cdot \chi_\gamma(x,\gamma)|\, dx \le \|\mathcal{I}_\gamma g_\gamma\|_{L^2(I)} \|\mathcal{I}_\gamma \chi_\gamma\|_{L^2(I)}.$$

Since γ is fixed the terms on the right are constants with respect to $\bar{\gamma}$. Concerning the second integral in (7.4) we have $\tau_\gamma p_\gamma, \tau_\gamma \mu_\gamma \in L^2(\Gamma_\gamma)$ because of $p_\gamma, \mu_\gamma \in H^1(\Omega_\gamma)$. Thus it can be estimated analogously by a constant which is independent of $\bar{\gamma}$:

$$\int_I |p_\gamma(x,\gamma)\mu_\gamma(x,\gamma)| dx \le \int_I |p_\gamma(x,\gamma)\mu_\gamma(x,\gamma)| \sqrt{1+\gamma'^2} dx \le \|\tau_\gamma p_\gamma\|_{L^2(\Gamma_\gamma)} \|\tau_\gamma \mu_\gamma\|_{L^2(\Gamma_\gamma)}.$$

To prove that $D_\gamma \mathcal{J}(\gamma)$ is a Fréchet derivative we show that the mapping $\gamma \mapsto D_\gamma \mathcal{J}(\gamma)$ is continuous from $\operatorname{int} \mathcal{S}$ to $\mathcal{L}(\mathcal{S}', \mathbb{R})$. We write (7.3) as

$$D_\gamma \mathcal{J}(\gamma)\bar{\gamma} = \frac{1}{\nu} \int_I [(\mathcal{I}_\gamma g_\gamma)(x) \cdot (\mathcal{I}_\gamma \chi_\gamma)(x) - (\mathcal{I}_\gamma \tau_\gamma p_\gamma)(x)(\mathcal{I}_\gamma \tau_\gamma \mu_\gamma)(x)]\bar{\gamma}\, dx.$$

For all $\gamma \in \mathcal{S}$ the functional $g_\gamma \in H_\gamma^*$ can be extended onto $L^2(\Gamma_\gamma)^2$; see Theorem 5.1. Therefore $(\mathcal{I}_\gamma^{-1})^* g_\gamma \in H_I^*$ can be extended onto $L^2(I)^2$ by the definition

$$\begin{aligned} \langle (\mathcal{I}_\gamma^{-1})^* g_\gamma, \Psi \rangle_{(L^2(I)^2)^*, L^2(I)^2} &:= \langle g_\gamma, \mathcal{I}_\gamma^{-1}\Psi \rangle_{(L^2(\Gamma_\gamma)^2)^*, L^2(\Gamma_\gamma)^2} \\ &= (g_\gamma, \mathcal{I}_\gamma^{-1}\Psi)_{\Gamma_\gamma} \ = \ ((\mathcal{I}_\gamma^{-1})^\star g_\gamma, \Psi)_I, \qquad \Psi \in L^2(I)^2, \end{aligned}$$

where we introduced the Hilbert space adjoint of $\mathcal{I}_\gamma^{-1}$:

$$(7.5) \qquad (\mathcal{I}_\gamma^{-1})^\star :\ L^2(\Gamma_\gamma)^2 \to L^2(I)^2, \qquad g \mapsto g(\cdot, \gamma(\cdot))\sqrt{1+\gamma'(\cdot)^2}.$$

Since $\mathcal{I}_\gamma$ is an isomorphism between $L^2(I)^2$ and $L^2(\Gamma_\gamma)^2$ and $\mathcal{S}$ is bounded in $H^3(I)$ which is continuously embedded in $W^{1,\infty}(I)$ also $\{\|(\mathcal{I}_\gamma^{-1})^\star\|_{\mathcal{L}(L^2(\Gamma_\gamma)^2, L^2(I)^2)}\}_{\gamma \in \mathcal{S}}$ is bounded. This implies that the family $\{(\mathcal{I}_\gamma^{-1})^\star g_\gamma\}_{\gamma \in \mathcal{S}}$ is uniformly bounded in $L^2(I)^2$. Hence for $\gamma_n \to \gamma$ in $\mathcal{S}$ there exists a weakly convergent subsequence, i.e.,

$$((\mathcal{I}_{\gamma_n}^{-1})^\star g_{\gamma_n}, \Psi)_I \to (g, \Psi)_I \qquad \text{for all } \Psi \in L^2(I)^2$$

with some $g \in L^2(I)^2$. On the other hand, by Theorem 6.2 $(\mathcal{I}_{\gamma_n}^{-1})^* g_{\gamma_n}$ converges weak-$*$ in H_I^* to $(\mathcal{I}_\gamma^{-1})^* g_\gamma$ which means that for $n \to \infty$ and all $\Psi \in H_I$ we have

$$\langle (\mathcal{I}_{\gamma_n})^* g_{\gamma_n}, \Psi\rangle_{H_I^*,H_I} \;=\; ((\mathcal{I}_{\gamma_n}^{-1})^\star g_{\gamma_n}, \Psi)_I \to \langle (\mathcal{I}_\gamma^{-1})^* g_\gamma, \Psi\rangle_{H_I^*,H_I} \;=\; ((\mathcal{I}_\gamma^{-1})^\star g_\gamma, \Psi)_I.$$

Because H_I is dense in $L^2(I)^2$ we have $g = \left(\mathcal{I}_\gamma^{-1}\right)^\star g_\gamma$. By definition of $\left(\mathcal{I}_\gamma^{-1}\right)^\star$ this implies $\mathcal{I}_{\gamma_n} g_{\gamma_n} \to \mathcal{I}_\gamma g_\gamma$ in $L^2(I)^2$. The same arguments hold for χ_γ. Since $\mathcal{I}_\gamma$ is continuous we have shown that the mappings $\gamma \mapsto \mathcal{I}_\gamma g_\gamma$ and $\gamma \mapsto \mathcal{I}_\gamma \chi_\gamma$ are continuous from $\mathcal{S}$ to $L^2(I)^2$ which implies that $\gamma \mapsto (\mathcal{I}_\gamma g_\gamma)\cdot(\mathcal{I}_\gamma \chi_\gamma)$ is continuous from $\mathcal{S}$ to $L^1(I)$.

To show that the mapping $\gamma \mapsto \mathcal{I}_\gamma \tau_\gamma p_\gamma$ is continuous we recall that the family $\{\|p_\gamma\|_{H^1(\Omega_\gamma)}\}_{\gamma\in\mathcal{S}}$ is bounded. Since the solution $\hat{p}_\gamma$ of (5.2) is not even necessarily in $H^1(\hat{\Omega})$ we extend each p_γ to some $\bar{p}_\gamma \in H^1(\hat{\Omega})$ such that the family $\{\bar{p}_\gamma\}_{\gamma\in\mathcal{S}}$ is bounded in $H^1(\hat{\Omega})$: We can easily define a family of bijective transformations $T_\gamma : \Omega_\gamma \to \hat{\Omega}$ which together with their inverse mappings are uniformly Lipschitz continuous in $\mathcal{S}$. The family $\{T_\gamma p_\gamma\}_{\gamma\in\mathcal{S}}$ of transformed functions is uniformly bounded in $H^1(\hat{\Omega})$; see [13, Lem. II.3.2] and the proofs of this lemma and of [13, Lem. II.3.1]. Extending $T_\gamma p_\gamma$ by reflection to a function $\check{p}_\gamma$ defined on $\check{\Omega} := (0,1)\times(-1,1)$ the family $\{\check{p}_\gamma\}_{\gamma\in\mathcal{S}}$ is uniformly bounded in $H^1(\check{\Omega})$; see [14, Lem. IX.2]. Using [13, Lem. II.3.2] again we obtain $T_\gamma^{-1}\check{p}_\gamma \in H^1(T_\gamma^{-1}(\check{\Omega}))$ and the uniform boundedness of $\{\bar{p}_\gamma\}_{\gamma\in\mathcal{S}}$ in $H^1(\hat{\Omega})$ for $\bar{p}_\gamma := (T_\gamma^{-1}\check{p}_\gamma)|_{\hat{\Omega}}$. For every sequence $\gamma_n \to \gamma$ in $\mathcal{S} \subset W^{1,\infty}(I)$ we thus have for a subsequence $\bar{p}_{\gamma_n} \rightharpoonup \bar{p}$ weakly in $H^1(\hat{\Omega})$ and $\bar{p}_{\gamma_n} \to \bar{p}$ strongly in $L^2(\hat{\Omega})$. Since $\hat{p}_{\gamma_n} \to \hat{p}_\gamma$ strongly in $L^2(\hat{\Omega})$ by Theorem 6.2 and $\hat{p}_\gamma|_{\Omega_\gamma} = p_\gamma = \bar{p}_\gamma|_{\Omega_\gamma}$ this implies $\bar{p}|_{\Omega_\gamma} = p_\gamma$ and by construction $\bar{p} = \bar{p}_\gamma$ in $\hat{\Omega}$. Therefore we have $\bar{p}_{\gamma_n} \rightharpoonup \bar{p}_\gamma$ weakly in $H^1(\hat{\Omega})$ for the whole sequence. Because of $\tau_\gamma \bar{p}_\gamma = \tau_\gamma p_\gamma$ for all $\gamma \in \mathcal{S}$ we now obtain

$$\begin{aligned} &\|\mathcal{I}_{\gamma_n}\tau_{\gamma_n}p_{\gamma_n} - \mathcal{I}_\gamma\tau_\gamma p_\gamma\|_{L^2(I)} = \|\mathcal{I}_{\gamma_n}\tau_{\gamma_n}\bar{p}_{\gamma_n} - \mathcal{I}_\gamma\tau_\gamma\bar{p}_\gamma\|_{L^2(I)} \\ &\le \|(\mathcal{I}_{\gamma_n}\tau_{\gamma_n} - \mathcal{I}_\gamma\tau_\gamma)\bar{p}_{\gamma_n}\|_{L^2(I)} + \|\mathcal{I}_\gamma\|_{\mathcal{L}(L^2(\Gamma_\gamma),L^2(I))}\|\tau_\gamma(\bar{p}_{\gamma_n} - \bar{p}_\gamma)\|_{L^2(\Gamma_\gamma)}. \end{aligned}$$

The first term tends to zero because of strong convergence of the transformed trace operators $\mathcal{I}_{\gamma_n}\tau_{\gamma_n}$; see [15, Lem. 2.11]. In the second term the first factor is uniformly bounded for all $\gamma \in \mathcal{S}$, and the second one tends to zero due to the compact embedding of $H^1(\hat{\Omega})$ into $L^2(\Gamma_\gamma)$. Thus we have shown that $\gamma \mapsto \mathcal{I}_\gamma\tau_\gamma p_\gamma$ is continuous from $\mathcal{S}$ to $L^2(I)$. Using an analogous argument for μ_γ we obtain that $\gamma \mapsto (\mathcal{I}_\gamma\tau_\gamma p_\gamma)(\mathcal{I}_\gamma\tau_\gamma\mu_\gamma)$ is continuous from $\mathcal{S}$ to $L^1(I)$. This implies the Fréchet differentiability of $\mathcal{J}$ with respect to γ. □

Let us note here that this derivative formula does not include normal derivatives of the state variables along the domain boundary, but only the Lagrange multipliers introduced by the embedding domain method.

8. Numerical methods. The numerical example presented below was computed using the formula (7.3) for the derivative and an SQP method (see [16]) for the optimization. It requires one gradient and at least one cost functional evaluation in each iteration. Thus the systems (5.2) and (7.2) have to be solved several times for different γ. Both systems were discretized by stabilized linear finite elements (see [17]) for velocity and pressure and piecewise constant elements for g_γ and χ_γ. To satisfy the inf-sup condition for the latter we used a coarser mesh size for their discretization as suggested in [18]. The discretized counterparts of (5.2) and (7.2) then read

$$(8.1) \qquad \begin{pmatrix} A & B^T & D_\gamma^T \\ B & C & 0 \\ D_\gamma & 0 & 0 \end{pmatrix} \begin{pmatrix} U_\gamma \\ P_\gamma \\ G_\gamma \end{pmatrix} = \begin{pmatrix} F_\gamma \\ H \\ 0 \end{pmatrix},$$

where the matrix C and the vector H appear due to the stabilization. Only the entities with subscript γ in (8.1) change during the optimization process. Note that D_γ represents a discrete one-dimensional trace operator and thus is very sparse. Therefore the effort of rebuilding the system when γ changes is negligible. This is a typical advantage of embedding domain techniques.

For the solution of the discrete systems we used an Uzawa algorithm with an outer preconditioned conjugate gradient iteration on the pair (P_γ, G_γ). For the inner system (a discrete Laplacian) we exploited the fact that the matrix A is fixed for all γ. Thus we computed its Cholesky factorization only once using a reverse Cuthill–McKee re-ordering algorithm to obtain a minimal fill-up by the factorization. For every gradient evaluation the inner system of the Uzawa algorithm thus requires only solution of two sparse triangular systems. Once the discrete counterparts of $p_\gamma, g_\gamma, \mu_\gamma, \chi_\gamma$ are computed the evaluation of the gradient via (7.3) can be done fast since it involves only the computation of a one-dimensional integral. Furthermore, this can be evaluated *exactly* since for the used basis functions simple integration rules are exact. Thus no additional discretization error is introduced by the gradient evaluation and no normal derivatives of the velocities have to be computed. Their values are implicitly included in g_γ, χ_γ. This fast and stable algorithm is fundamentally based on the embedding domain technique by which these two Lagrange multipliers were introduced.

9. Numerical examples. We considered a driven cavity flow as test example to show feasibility of the embedding domain technique and the derivative formula (7.3). The effort into the efficiency of the optimization was restricted to the choice of the regularization type and parameter. The computational domain is a square with edge length one. On the top edge a constant positive horizontal velocity is prescribed. The other edges are regarded as walls with homogeneous Dirichlet boundary conditions. A part of the bottom wall was set to be variable. We considered a tracking type cost functional with $\mathcal{A}$ being the identity. The parameter ν was set to $\frac{1}{100}$. We chose the observation region as $\Omega_C := [0,1] \times [0.5,1]$ and the desired state $\mathbf{u}_d := \mathbf{u}_{\gamma_d}$. The curve Γ_{γ_d} for the desired state was the graph of a symmetric cubic spline function γ_d between $y = \gamma_d(x) = 0.0$ near the lateral walls and $y = \gamma_d(0.5) = 0.4$. The function γ had 13 degrees of freedom. The starting curve was a straight line at the level $y = 0.2$. We used the box constraints $\gamma \in [0.1, 0.5]$ and added a regularization term $\varepsilon\|\gamma'\|^2_{L^2(I)}$ with $\varepsilon = 10^{-5}$ to the cost functional $\mathcal{J}(\gamma)$.

As can be seen in Table 9.1 the convergence was very fast: After seven iterations and nine function evaluations the cost functional was reduced by more than 99 percent. After another iteration the error, e.g., at the point $\gamma(0.5)$, is only 1 percent. The difference at the other points is higher. The influence of the point $\gamma(0.5)$ is most important because the flow structure is mostly influenced by the height of the bottom wall and less by its form. Streamlines and pressure distributions for desired state, start configuration, and solution are depicted in Figure 9.1.

A comparison between the derivative computed by formula (7.3) and by finite difference derivatives can be seen in Table 9.2. Here only one point (in the middle) of γ was variable, the others were fixed at $\gamma = \gamma_d$ with γ_d as above. A difference in the magnitude of the derivative computed by (7.3) and the finite difference derivatives can be seen. The finite difference derivatives differ much depending on their step-size. The derivative computed by (7.3) represents the behavior of the cost functional on the whole considered interval, specifically near the optimum $\gamma(0.5) = \gamma_d(0.5) = 0.4$.

Proof of Lemma 7.2. Since $\hat{\lambda}_\gamma|_{\Omega^c_\gamma} = \mathbf{0}$ and $\tilde{\mathbf{f}}_\gamma = \tilde{\mathbf{f}}_{\gamma+t\bar{\gamma}} = \mathbf{f}$ on $\Omega_\gamma \cap \Omega_{\gamma+t\bar{\gamma}}$ the integral in $(\tilde{\mathbf{f}}_\gamma - \tilde{\mathbf{f}}_{\gamma+t\bar{\gamma}}, \hat{\lambda}_\gamma)_{\hat{\Omega}}$ has only to be taken over the set $\Omega_\gamma \setminus (\Omega_\gamma \cap \Omega_{\gamma+t\bar{\gamma}}) = I_- \times (\gamma + t\bar{\gamma}, \gamma)$, where $I_- := \{x \in I : \bar{\gamma}(x) < 0\}$. With $\tau_\gamma \lambda_\gamma = \mathbf{0}$ we obtain

$$(\tilde{\mathbf{f}}_\gamma - \tilde{\mathbf{f}}_{\gamma+t\bar{\gamma}}, \hat{\lambda}_\gamma)_{\hat{\Omega}} = \int_{I_-} \int_{\gamma+t\bar{\gamma}}^{\gamma} \mathbf{f}(x,y) \cdot [\lambda_\gamma(x,\gamma) - \lambda_\gamma(x,y)]\, dydx.$$

Estimating this term analogously to (6.2) we finally get

$$\frac{1}{t}|(\tilde{\mathbf{f}}_\gamma - \tilde{\mathbf{f}}_{\gamma+t\bar{\gamma}}, \hat{\lambda}_\gamma)_{\hat{\Omega}}| \leq \frac{1}{3}\, \|\mathbf{f}\|_{L^\infty(\hat{\Omega})^2} \|\lambda_\gamma\|_{H^1(\Omega_\gamma)^2} t^{1/2} \|\bar{\gamma}\|^{3/2}_{L^\infty(I)}.$$

Since $\mathbf{f} \in L^\infty(\hat{\Omega})^2, \lambda_\gamma \in H^1(\Omega_\gamma)^2$, and $\bar{\gamma} \in \mathcal{S}' \subset L^\infty(I)$ this tends to zero for $t \to 0$.

Proof of Lemma 7.3. Using Theorem 7.1 we obtain

$$\langle \chi_\gamma, \tau_\gamma \hat{\mathbf{u}}_{\gamma+t\bar{\gamma}} \rangle_{H^*_\gamma, H_\gamma} = \int_I \chi_\gamma(x,\gamma) \cdot \hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}(x,\gamma) \sqrt{1+\gamma'^2}\, dx.$$

By Theorem 5.1 we have $\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}|_{\Omega^c_{\gamma+t\bar{\gamma}}} = \mathbf{0}$ which implies $\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}(x,\gamma) = \mathbf{0}$ for $x \in I_-$ and $\hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}(x,\gamma) = \mathbf{u}_{\gamma+t\bar{\gamma}}(x,\gamma)$ for $x \in I_+ := I \setminus I_-$. With $\tau_{\gamma+t\bar{\gamma}} \mathbf{u}_{\gamma+t\bar{\gamma}} = \mathbf{0}$ we get

$$\langle \chi_\gamma, \tau_\gamma \hat{\mathbf{u}}_{\gamma+t\bar{\gamma}} \rangle_{H^*_\gamma, H_\gamma} = -\int_{I_+} \chi_\gamma(x,\gamma) \cdot (\mathbf{u}_{\gamma+t\bar{\gamma}}(x,\gamma+t\bar{\gamma}) - \mathbf{u}_{\gamma+t\bar{\gamma}}(x,\gamma))\, \sqrt{1+\gamma'^2}\, dx$$

$$= -\int_{I_+} \chi_\gamma(x,\gamma)\cdot\left(\int_\gamma^{\gamma+t\bar\gamma} \mathbf{u}_{\gamma+t\bar\gamma,y}(x,\xi)\,d\xi\right)\sqrt{1+\gamma'^2}\,dx.$$

Note that $\mathbf{u}_{\gamma+t\bar\gamma,y} \in H^1(\Omega_{\gamma+t\bar\gamma})^2$ and thus its trace on the segment $\{(x,\xi) : \xi \in [\gamma(x), \gamma(x)+t\bar\gamma(x)]\}$ (for fixed x) is a L^2 function. With the same argument the restriction of $\tau_\gamma \mathbf{u}_{\gamma+t\bar\gamma,y}$ onto Γ_γ^+ is an L^2 function. We show that

$$C := \frac{1}{t}\langle\chi_\gamma, \tau_\gamma\hat{\mathbf{u}}_{\gamma+t\bar\gamma}\rangle_{H_\gamma^*,H_\gamma} - \int_{I_+}\chi_\gamma(x,\gamma)\cdot\mathbf{u}_{\gamma,y}(x,\gamma)\bar\gamma\sqrt{1+\gamma'^2}\,dx$$

tends to zero. Using $\frac{1}{t}\int_\gamma^{\gamma+t\bar\gamma}\mathbf{u}_{\gamma+t\bar\gamma,y}(x,\gamma)\,d\xi = \mathbf{u}_{\gamma+t\bar\gamma,y}(x,\gamma)\,\bar\gamma$ we obtain

$$\begin{aligned} C = C_1 + C_2 \;:=\; & \int_{I_+}\chi_\gamma(x,\gamma)\cdot[\mathbf{u}_{\gamma+t\bar\gamma,y}(x,\gamma)-\mathbf{u}_{\gamma,y}(x,\gamma)]\,\bar\gamma\sqrt{1+\gamma'^2}\,dx \\ & +\frac{1}{t}\int_{I_+}\chi_\gamma(x,\gamma)\cdot\left(\int_\gamma^{\gamma+t\bar\gamma}[\mathbf{u}_{\gamma+t\bar\gamma,y}(x,\xi)-\mathbf{u}_{\gamma+t\bar\gamma,y}(x,\gamma)]\,d\xi\right)\sqrt{1+\gamma'^2}\,dx. \end{aligned}$$

We show that both terms tend to zero for $t \to 0$: With Hölder's inequality we get

$$|C_1| \le \|\bar\gamma\|_{L^\infty(I)}\|\chi_\gamma\|_{L^2(\Gamma_\gamma)^2}\|\mathbf{u}_{\gamma+t\bar\gamma,y}-\mathbf{u}_{\gamma,y}\|_{L^2(\Gamma_\gamma^+)^2}.$$

The first two terms are bounded and we show that the last one tends to zero: The family $\{\|\mathbf{u}_{\gamma+t\bar\gamma}\|_{H^2(\Omega_{\gamma+t\bar\gamma})^2}\}$ and thus $\{\|\mathbf{u}_{\gamma+t\bar\gamma,y}\|_{H^1(\Omega_{\gamma+t\bar\gamma})^2}\}$ is bounded for $t \in [0,t_0]$ with some t_0 sufficiently small. For $\Omega'_\gamma := \Omega_\gamma \cap \Omega_{\gamma+t_0\bar\gamma}$ which is contained in $\Omega_{\gamma+t\bar\gamma}$ for all $t \in [0,t_0]$ the family $\{\mathbf{u}_{\gamma+t\bar\gamma,y} : t \in [0,t_0]\}$ is bounded in $H^1(\Omega'_\gamma)^2$. This implies that for every sequence $\{t_i\} \subset [0,t_0]$ with $\lim t_i = 0$ there exists a subsequence $\{t_{i'}\}$ such that $\{\mathbf{u}_{\gamma+t_{i'}\bar\gamma,y}\}$ is weakly convergent in $H^1(\Omega'_\gamma)^2$. This implies strong convergence of the sequence $\{\mathbf{u}_{\gamma+t_{i'}\bar\gamma,y}\}$ in $L^2(\Omega'_\gamma)^2$. Theorem 6.2 implies $\hat{\mathbf{u}}_{\gamma+t\bar\gamma,y} \to \hat{\mathbf{u}}_{\gamma,y}$ strongly in $L^2(\hat\Omega)^2$ for $t \to 0$ and thus the weak convergence of $\{\mathbf{u}_{\gamma+t_i\bar\gamma,y}\}$ in $H^1(\Omega'_\gamma)^2$ is valid for the whole sequence. We consider the traces of the functions of any sequence on the set $\Gamma_\gamma^+ = \Gamma_\gamma \cap \partial\Omega'_\gamma = \{(x,\gamma(x)) : x \in I_+\}$. By a classical embedding theorem the weak convergence $\mathbf{u}_{\gamma+t\bar\gamma,y} \rightharpoonup \mathbf{u}_{\gamma,y}$ in $H^1(\Omega'_\gamma)^2$ implies strong convergence $\mathbf{u}_{\gamma+t\bar\gamma,y}|_{\Gamma_\gamma^+} \to \mathbf{u}_{\gamma,y}|_{\Gamma_\gamma^+}$ in $L^2(\Gamma_\gamma^+)^2$. Thus C_1 tends to zero for $t \to 0$. Because $\mathbf{u}_{\gamma+t\bar\gamma,yy}$ is an L^2 function on $\Omega_{\gamma+t\bar\gamma}$ and thus also on $\{(x,y) : x \in I_+, y \in (\gamma(x), \gamma(x)+t\bar\gamma(x))\}$ we write

$$\begin{aligned} C_2 &= \frac{1}{t}\int_{I_+}\chi_\gamma(x,\gamma)\cdot\left(\int_\gamma^{\gamma+t\bar\gamma}\int_\gamma^\xi \mathbf{u}_{\gamma+t\bar\gamma,yy}(x,\eta)\,d\eta d\xi\right)\sqrt{1+\gamma'^2}\,dx \\ &= \frac{1}{t}\int_{I_+}\chi_\gamma(x,\gamma)\cdot\left(\int_\gamma^{\gamma+t\bar\gamma}\mathbf{u}_{\gamma+t\bar\gamma,yy}(x,\eta)(\gamma+t\bar\gamma-\eta)\,d\eta\right)\sqrt{1+\gamma'^2}\,dx. \end{aligned}$$

For a.e. $x \in I_+$ the inner integral exists and can be estimated by Hölder's inequality:

$$\begin{aligned} \left\|\int_\gamma^{\gamma+t\bar\gamma}\mathbf{u}_{\gamma+t\bar\gamma,yy}(x,\eta)(\gamma+t\bar\gamma-\eta)\,d\eta\right\|_2 &\le \max_{\eta\in(\gamma,\gamma+t\bar\gamma)}|\gamma+t\bar\gamma-\eta|\int_\gamma^{\gamma+t\bar\gamma}\|\mathbf{u}_{\gamma+t\bar\gamma,yy}(x,\eta)\|_2\,d\eta \\ &\le t|\bar\gamma|\left(\int_\gamma^{\gamma+t\bar\gamma}d\eta\right)^{1/2}\left(\int_\gamma^{\gamma+t\bar\gamma}\|\mathbf{u}_{\gamma+t\bar\gamma,yy}(x,\eta)\|_2^2\,d\eta\right)^{1/2} \\ &= (t|\bar\gamma|)^{3/2}\left(\int_\gamma^{\gamma+t\bar\gamma}\|\mathbf{u}_{\gamma+t\bar\gamma,yy}(x,\eta)\|_2^2\,d\eta\right)^{1/2}. \end{aligned}$$

Thus we obtain

$$\begin{aligned}|C_2| &\le \frac{1}{t}\int_{I_+}\|\chi_\gamma(x,\gamma)\|_2\left\|\int_\gamma^{\gamma+t\bar{\gamma}}\mathbf{u}_{\gamma+t\bar{\gamma},yy}(x,\eta)(\gamma+t\bar{\gamma}-\eta)\,d\eta\right\|_2\sqrt{1+\gamma'^2}\,dx\\
&\le t^{1/2}\int_{I_+}\|\chi_\gamma(x,\gamma)\|_2\left(\int_\gamma^{\gamma+t\bar{\gamma}}\|\mathbf{u}_{\gamma+t\bar{\gamma},yy}(x,\eta)\|_2^2\,d\eta\right)^{1/2}|\bar{\gamma}|^{3/2}\sqrt{1+\gamma'^2}\,dx\\
&\le t^{1/2}\|\bar{\gamma}\|^{3/2}_{L^\infty(I_+)}\sqrt{1+\|\gamma\|^2_{W^{1,\infty}(I_+)}}\int_{I_+}\|\chi_\gamma(x,\gamma)\|_2\left(\int_\gamma^{\gamma+t\bar{\gamma}}\|\mathbf{u}_{\gamma+t\bar{\gamma},yy}(x,\eta)\|_2^2\,d\eta\right)^{1/2}dx\\
&\le t^{1/2}\|\bar{\gamma}\|^{3/2}_{L^\infty(I)}\sqrt{1+\|\gamma\|^2_{W^{1,\infty}(I)}}\|\chi_\gamma\|_{L^2(\Gamma_\gamma)^2}\,\|\mathbf{u}_{\gamma+t\bar{\gamma}}\|_{H^2(\Omega_{\gamma+t\bar{\gamma}})^2}.\end{aligned}$$

Boundedness of $\{\|\mathbf{u}_\gamma\|_{H^2(\Omega_\gamma)^2}\}_{\gamma\in\mathcal{S}}$, $\mathcal{S}\subset W^{1,\infty}(I)$, and $\mathcal{S}'\subset L^\infty(I)$ now imply $C_2\to 0$.

Proof of Lemma 7.4. Theorem 5.1 gives

$$\langle g_{\gamma+t\bar{\gamma}},\tau_{\gamma+t\bar{\gamma}}\hat{\lambda}_\gamma\rangle_{H^*_{\gamma+t\bar{\gamma}},H_{\gamma+t\bar{\gamma}}}=\int_{I_-}g_{\gamma+t\bar{\gamma}}(x,\gamma+t\bar{\gamma})\cdot\left(\int_\gamma^{\gamma+t\bar{\gamma}}\lambda_{\gamma,y}(x,\xi)\,d\xi\right)\sqrt{1+(\gamma'+t\bar{\gamma}')^2}dx.$$

Adding zero in an appropriate way we get for the difference

$$\begin{aligned}&\frac{1}{t}\langle g_{\gamma+t\bar{\gamma}},\tau_{\gamma+t\bar{\gamma}}\hat{\lambda}_\gamma\rangle_{H^*_{\gamma+t\bar{\gamma}},H_{\gamma+t\bar{\gamma}}}-\int_{I_-}g_\gamma(x,\gamma)\cdot\lambda_{\gamma,y}(x,\gamma)\bar{\gamma}\sqrt{1+\gamma'^2}\,dx\\
&=\int_{I_-}\left(g_{\gamma+t\bar{\gamma}}(x,\gamma+t\bar{\gamma})\sqrt{1+(\gamma'+t\bar{\gamma}')^2}-g_\gamma(x,\gamma)\sqrt{1+\gamma'^2}\right)\cdot\lambda_{\gamma,y}(x,\gamma)\bar{\gamma}\,dx\\
&\quad+\int_{I_-}g_{\gamma+t\bar{\gamma}}(x,\gamma+t\bar{\gamma})\cdot\left(\int_\gamma^{\gamma+t\bar{\gamma}}[\lambda_{\gamma,y}(x,\xi)-\lambda_{\gamma,y}(x,\gamma)]\,d\xi\right)\bar{\gamma}\sqrt{1+(\gamma'+t\bar{\gamma}')^2}\,dx\\
&=:D_1+D_2.\end{aligned}$$

Again we show that both terms tend to zero for $t\to 0$: We define the function

$$\Psi(x):=\begin{cases}\lambda_{\gamma,y}\big(x,\gamma(x)\big)\bar{\gamma}(x), & x\in I_-,\\ \mathbf{0}, & x\in I_+\end{cases}$$

which is in $L^2(I)^2$ because $\lambda_\gamma\in H^2(\Omega_\gamma)^2$ and $\bar{\gamma}\in\mathcal{S}'\subset L^\infty(I)$. Then we have

$$D_1=\int_I\left(g_{\gamma+t\bar{\gamma}}(x,\gamma+t\bar{\gamma})\sqrt{1+(\gamma'+t\bar{\gamma}')^2}-g_\gamma(x,\gamma)\sqrt{1+\gamma'^2}\right)\cdot\Psi(x)\,dx.$$

Using the Hilbert space adjoint of $\mathcal{I}_\gamma^{-1}$ defined in (7.5) we may express D_1 as

$$D_1=\langle((\mathcal{I}_{\gamma+t\bar{\gamma}})^{-1})^*g_{\gamma+t\bar{\gamma}}-(\mathcal{I}_\gamma^{-1})^*g_\gamma,\Psi\rangle_{(L^2(I)^2)^*,L^2(I)^2}.$$

It can be shown that H_I is dense in $L^2(I)^2$. Thus there exists a sequence $\{\psi_k\}_k$ in H_I with $\lim_{k\to\infty}\psi_k=\Psi$ in $L^2(I)^2$. For fixed k we may hence estimate

$$\begin{aligned}|D_1|\le{}&|\langle(\mathcal{I}_{\gamma+t\bar{\gamma}})^*g_{\gamma+t\bar{\gamma}},\Psi-\psi_k\rangle_{(L^2(I)^2)^*,L^2(I)^2}|\\
&+|\langle(\mathcal{I}_{\gamma+t\bar{\gamma}})^*g_{\gamma+t\bar{\gamma}}-(\mathcal{I}_\gamma^{-1})^*g_\gamma,\psi_k\rangle_{H_I^*,H_I}|+|\langle(\mathcal{I}_\gamma^{-1})^*g_\gamma,\psi_k-\Psi\rangle_{(L^2(I)^2)^*,L^2(I)^2}|.\end{aligned}$$

The second term tends to zero since by Theorem 6.2 the Lagrange multipliers are weak-$*$ convergent in H_I^* if $\gamma+t\bar{\gamma}\to\gamma$ in $W^{1,\infty}(I)$ which is the case since $\gamma,\gamma+t\bar{\gamma}\in\mathcal{S}\subset W^{1,\infty}(I)$. For every $k\in\mathbb{N}$ we thus obtain that

$$|D_1|\le|\langle((\mathcal{I}_{\gamma+t\bar{\gamma}})^{-1})^*g_{\gamma+t\bar{\gamma}},\Psi-\psi_k\rangle_{(L^2(I)^2)^*,L^2(I)^2}+\langle(\mathcal{I}_\gamma^{-1})^*g_\gamma,\psi_k-\Psi\rangle_{(L^2(I)^2)^*,L^2(I)^2}|.$$

Both terms on the right tend to zero because $\psi_k \to \Psi$ in $L^2(I)^2$ and the family $\{(\mathcal{I}_\gamma^{-1})^* g_\gamma\}_{\gamma\in\mathcal{S}}$ is uniformly bounded in $(L^2(I)^2)^*$. Thus D_1 tends to zero for $t \to 0$.

For D_2 we use a similar argumentation as for C_2 in the proof of Lemma 7.3. We just replace $\mathbf{u}_{\gamma+t\bar{\gamma}}$ by λ_γ, I_+ by I_-, and $\chi_\gamma(x,\gamma)\sqrt{1+\gamma'^2}$ by $g_{\gamma+t\bar{\gamma}}(x,\gamma)\sqrt{1+(\gamma'+t\bar{\gamma}')^2}$. Because $\{\|\lambda_\gamma\|_{H^2(\Omega_\gamma)^2}\}_{\gamma\in\mathcal{S}}$ is bounded by Theorem 7.1 we get that D_2 tends to zero.

LINEAR QUADRATIC OPTIMIZATION FOR SYSTEMS IN THE BEHAVIORAL APPROACH*

AUGUSTO FERRANTE† AND SANDRO ZAMPIERI‡

Abstract. In this paper the following formulation of the linear quadratic optimal control problem for dynamical systems in the behavioral setting is proposed: given a linear, time-invariant, and complete system, find the set of trajectories of the system that optimize a quadratic-type cost function and that satisfy some linear static constraints. This formulation provides a unifying framework, where several generalized versions of the classical LQ optimal control can be stated and solved.

The existence of solutions is first discussed. It is shown that a necessary and sufficient condition for the existence of solutions may be obtained as a by-product of a reduction procedure translating the problem into an equivalent one of minimum complexity. Such a procedure is based on the theory of ℓ^2-systems in the behavioral setting. Once the complexity is reduced, a parametrization of the set of optimal solutions is obtained by employing a behavioral realization technique and a two-step optimization procedure.

Key words. linear quadratic optimal control, behavioral approach, ℓ^2-systems, static constraints

1. Introduction.

In the behavioral setting, a *system* is defined as a triple

$$\Sigma = (T, W, \mathcal{B}), \tag{1.1}$$

where T is a *time set*, W is the *alphabet* of the system, and the *behavior* $\mathcal{B}$ is the set of trajectories of the system. This definition of system has been introduced by Jan C. Willems in the latter half of the 1980s [22, 23] and, starting from these classical papers, a relevant amount of work has been produced in this direction.

In the above definition, the behavior $\mathcal{B}$ is simply the set of trajectories compatible with the (equations of the) system: the classical distinction of the signal of the system in *inputs*, *states*, and *outputs* is no longer present. Also, $\mathcal{B}$ is a completely arbitrary set of trajectories which may be described by equations (or inequalities) given in *implicit* form, and no causality assumptions are made. For these reasons the behavioral set-up has been revealed to be the most suitable framework to treat modeling and identification for many physical and economic systems where the above-mentioned features are crucial.

The contribution of the present paper is to formulate and solve the *linear quadratic* (LQ) optimal control problem in the behavioral setting: as it will be clarified in section 2, this formulation encompasses as particular cases the classical LQ optimal control problem, singular and cheap optimal control problems, and optimal control for descriptor systems, and allows us to deal with very general dynamic equations, static constraints, and cost functions. This formulation has the advantage, of a methodological and practical nature, of providing a unifying and elegant framework

where a large variety of physical and economic problems can be directly stated and solved with no need of preliminary manipulations. In particular, in economical systems, dynamic and algebraic equations are often mixed together, yielding an implicit dynamic, and nonstandard static constraints are often imposed. Moreover, in such systems, the distinction of signals in inputs, states, and outputs is sometimes artificial and not built-in in the physical model, so that it results naturally to avoid an a priori distinction of such a kind in the mathematical model too.

In recent years some works on the optimal control in the behavioral setting have been produced [25, 16]. In [25] the behavioral approach to LQ optimal control was first introduced in the following form: given a system and a quadratic cost function, find the subsystem whose behavior is constituted by all the trajectories w^* whose cost cannot be decreased by a perturbation of finite support. The subbehavior $\mathcal{B}^*$ of optimal trajectories is obtained by interconnecting the original system with a suitable "optimal controller." We recall that in the behavioral setting the interconnection of systems corresponds to the classical feedback control [24].

In the present paper we propose a different formulation of the LQ optimal control problem. Such a formulation, in our opinion, is more in the spirit of the classical optimal control problems, where the optimal solution is not required a priori to be of feedback type and boundary conditions are assigned. For example, the classical LQ optimal control problem for systems described by state equations can be expressed in the following way. Find the set of controls $u^*(\cdot)$ such that the corresponding trajectories $(x^*(\cdot), u^*(\cdot))$ (with fixed initial condition $x(0) = x_0$) satisfy

$$x(t+1) = Ax(t) + Bu(t) \tag{1.2}$$

and minimize the cost function

$$J(x,u) = \sum_{t=0}^{\infty} y^T(t)y(t), \tag{1.3}$$

where

$$y(t) = Cx(t) + Du(t). \tag{1.4}$$

The search for the optimal solution is performed in the space of all possible controls and the fact that the optimal solution happens to be of closed-loop type has no relation with the formulation of the problem and it is only due to the particular choice of boundary conditions. Note that, if the initial condition $x(0)$ is not fixed, one of the optimal controls is identically zero, the optimal cost is zero, and the problem is trivial. The fact that makes the problem meaningful is that $x(0)$ is fixed a priori.

In this paper we address the following optimization problem which appears to be the direct extension to the behavioral framework of the classical LQ optimal control problem just described. Given a linear time-invariant and complete (see section 1.1 for the precise definition) system with behavior $\mathcal{B}$ and a quadratic type cost function $J(\cdot)$, find the set $\mathcal{B}^* \subseteq \mathcal{B}$ of trajectories of the behavior which minimize the cost function J and satisfy a static constraint: for example, we may require that some components of the trajectory take some fixed values at particular time instants. In the classical LQ optimal control setting, this static constraint corresponds to the position $x(0) = x_0$, which fixes the initial state to a certain value x_0.

The first issue that we address is the problem solvability, which is shown to be equivalent to the existence of trajectories of the system satisfying the static constraints and giving rise to a finite cost. We then establish a reduction procedure which allows us to substitute the original system with a system with minimal complexity (i.e., a linear time-invariant and complete system having the smallest possible set of trajectories), so that the search of optimal trajectories can be performed among a minimal set. These issues are shown to be strictly connected to the theory of ℓ^2-systems, to which the first part of the paper is dedicated. In particular, some results on ℓ^2-systems, which appear to be of independent interest, are derived in section 3.

The paper is organized as follows. In subsection 1.1 we fix the notation and briefly recall some well-known results on behavioral theory of linear systems. In section 2 we give a precise mathematical formulation of our LQ optimization problem for autoregressive (AR) systems. In section 3 we provide a very easy necessary and sufficient condition for the problem solvability, and we present a procedure to reduce the complexity of the problem by eliminating from the behavior the trajectories corresponding to infinite cost. In section 4 we finally present the solution of our problem. In section 5 we briefly draw some conclusions.

1.1. Preliminaries. The complete theory of behavioral approach to dynamical systems is really ponderous, and it is beyond the scope of this paper to illustrate such a theory; for an illustration of the theory, we refer the reader to [23]. However, for the ease of the reader and to fix the notation we now detail the class of systems that will be considered in what follows and some of the very basic properties of the systems in this class.

We deal with systems of the form (1.1) with the set of integers $\mathbb{Z}$ as the time set (discrete-time systems), with the finite dimensional vector space $\mathbb{R}^q$ as the signal alphabet, and with a behavior that coincides with the set of solutions of a linear difference equation with (matrix valued) constant coefficients.

More precisely, if σ is the usual backward shift operator, let $\mathbb{R}[\sigma,\sigma^{-1}]^{l\times q}$ be that set of matrices whose entries are Laurent polynomials in σ (i.e., polynomials with both positive and negative powers of the indeterminate). A polynomial matrix in $\mathbb{R}[\sigma,\sigma^{-1}]^{l\times q}$ induces a linear shift-invariant operator from $(\mathbb{R}^q)^{\mathbb{Z}}$ to $(\mathbb{R}^l)^{\mathbb{Z}}$ in an obvious way. This operator is called matrix shift operator. A matrix shift operator $R(\sigma)$ in $\mathbb{R}[\sigma,\sigma^{-1}]^{l\times q}$ can be represented in the following way:

$$R(\sigma) = \sum_{i=k}^{K} R_i\sigma^i,$$

where $k \le K$ and $R_i \in \mathbb{R}^{l\times q}$. The kernel of this matrix shift operator has therefore the following structure:

$$\ker R(\sigma) = \left\{ w \in (\mathbb{R}^q)^{\mathbb{Z}} : \sum_{i=k}^{K} R_i w(t+i) = 0 \quad \forall t \in \mathbb{Z} \right\}. \tag{1.5}$$

In this paper we consider dynamical systems whose behaviors coincide with kernels of matrix shift operators. We recall that the class of AR systems coincides with the class of systems whose behaviors are linear, shift-invariant, and complete, where a behavior $\mathcal{B}$ is said to be complete if

$$w \in \mathcal{B} \quad \Leftrightarrow \quad w_{|[t_1,t_2]} \in \mathcal{B}_{|[t_1,t_2]} \quad \forall t_1, t_2 \in \mathbb{Z},$$

and where the symbol $w_{|[t_1,t_2]}$ means the restriction of the trajectory w to the interval $[t_1, t_2]$.

Summarizing, we consider the class of dynamical systems $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \ker R(\sigma))$, where $R(\sigma)$ is a matrix shift operator in $\mathbb{R}[\sigma, \sigma^{-1}]^{l \times q}$. These systems are called *AR systems* and the representations of the form (1.5) are called *AR representations*. The importance and the properties of AR systems and AR representations are widely investigated, especially in [23].

2. Problem formulation. In this section we give a precise mathematical formulation of our problem. Let $\mathcal{B} = \ker R(\sigma)$, $R(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{l \times q}$, be the behavior of an AR system $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathcal{B})$. Let w be a trajectory of $\mathcal{B}$: we consider a quadratic cost function J defined by

$$J(w) := ||w_{2_{|[0,+\infty)}}||_2^2 = \sum_{t=0}^{\infty} w_2^T(t) w_2(t), \tag{2.1}$$

where we have defined $w_2 := R_2(\sigma)w$ with $R_2(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{r \times q}$ being a polynomial matrix. Observe that, since w_2 is uniquely specified by w, $J(w)$ is a well-defined quadratic cost function of w.

Clearly we have $J(w) \geq 0$ for all the trajectories w and then the set $\mathcal{B}_0$ of trajectories of $\mathcal{B}$ which minimize J is trivially $\mathcal{B}_0 = \ker R(\sigma) \cap \ker R_2(\sigma) = \ker \left[\begin{smallmatrix} R(\sigma) \\ R_2(\sigma) \end{smallmatrix} \right]$.

The above minimization may be viewed as the behavioral counterpart of the classical LQ optimal control problem in the case when the initial state is unconstrained. As we have seen in the introduction, a static constraint renders the problem meaningful. This happens in the behavioral setting too. A very general linear constraint is the following:

$$r_h w(h) + r_{h+1} w(h+1) + \cdots + r_H w(H) = b, \tag{2.2}$$

where $r_i \in \mathbb{R}^{s \times q}$ and $b \in \mathbb{R}^s$. Defining the polynomial matrix $R_1(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{s \times q}$ as $R_1(\sigma) := \sum_{i=h}^{H} r_i \sigma^i$, and setting $w_1 := R_1(\sigma)w$, the constraint (2.2) may be rewritten in the more compact form

$$w_1(0) = (R_1(\sigma)w)(0) = b. \tag{2.3}$$

The main issue of this paper is the analysis and the solution of the following optimization problem. Find the set $\mathcal{T}(b)$ of all trajectories w such that

$$\left\{ \begin{array}{l} R(\sigma)w = 0, \\ w_1(0) = b, \\ J(w) = ||w_{2|[0,+\infty)}||_2^2 \text{ is minimal,} \end{array} \right. \tag{2.4}$$

where $R(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{l \times q}$, $R_1(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{s \times q}$, $R_2(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{r \times q}$, $w_1 := R_1(\sigma)w$, and $w_2 := R_2(\sigma)w$.

Problem (2.4) presents the following features which are compared with those of the classical LQ optimal control problem.

The dynamics. The first equation of (2.4) represents a very general linear dynamics. It encompasses, as a special case, the *descriptor systems* dynamics

$$Ex(t+1) = Ax(t) + Bu(t). \tag{2.5}$$

In fact, (2.5) may be rewritten in the form $R(\sigma)w = 0$, just by setting

$$w = \left[\begin{array}{c} x \\ u \end{array} \right] \tag{2.6}$$

and $R(\sigma) := R_0 + \sigma R_1$, where $R_0 := [-A \mid -B]$ and $R_1 := [E \mid 0]$. Moreover, linear difference equations (without control variables), which are typical of calculus of variations problems, are included in the dynamics of (2.4) too.

The static constraint. Instead of just fixing the initial condition, a constraint of the form (2.3) fixes some linear combinations of the values of (some component of) the trajectory at arbitrary times. As a particular case, (2.3) can force the trajectory to assume fixed values at fixed times. This possibility is very interesting in many applications (see, e.g., [4, 3] and references therein); a further example is the *landing problem* [20]: a control tower passes to an airplane a collection of way points that are vectors of position and velocity in $\mathbb{R}^3$ together with times of arrival. This is fitted very well by the type of constraints (2.3).

The cost function. The cost index (2.1) is remarkably general because $R_2(\sigma)$ is a Laurent polynomial matrix and this allows us to weigh together values of the trajectory $w(t)$ at different times and to consider the values of the trajectory $w(t)$ for $t \geq T$ with $T \in \mathbb{Z}$ arbitrarily fixed. Singular optimal control problems may be naturally formulated into this framework. With reference to the dynamics (2.5), such problems consist in minimizing a cost function (1.3) with y being given by (1.4) and $R := D^T D$ being singular. It is clear that such a cost function is expressible in the form (2.1) just by setting w as in (2.6) and $R_2(\sigma) = [C \mid D]$. Another interesting observation is that frequency shaping techniques in classical optimal control theory (see [1]) can be expressed directly in the time domain, using the generalized cost function (2.1). Finally, notice that the cost function (2.1) can be seen to be the discrete-time version of a *quadratic differential form*, as defined in [28].

The above observations show that formulation (2.4) is pretty general and covers a variety of optimal control problems. It is particularly useful in problems with implicit dynamics which are frequent in applications (see, e.g., [5, 13, 2] and references therein). Moreover, formulation (2.4) suits very well control problems of economic systems (one of the fields in which the behavioral framework seems more natural) in which the dynamic is often implicit and it is required that at some time instants $T_1, T_2, \ldots, T_r$, some reference variables match exactly their target values. One of these cases is the Leontief model for which many types of optimization problems have been stated and studied (see, e.g., [15] and references therein).

A different version of the problem (2.4) is the case of *finite time horizon,* i.e., the case when the cost function is

$$J(w) := \sum_{t=0}^{T} w_2^T(t) w_2(t). \tag{2.7}$$

As it will be clear in what follows, the solution of the problem with cost function (2.7) may be regarded as a subproblem of (2.4). For this reason we will not address the cost (2.7).

We have defined the dynamic equations of the system over $\mathbb{Z}$, even though the cost is determined by the values of $w_2(t)$ only for $t \geq 0$. This choice is based on the fact that most of the classical literature on behavioral approach to discrete-time linear systems deals with the biinfinite time axis case, even though the theory for discrete-time linear systems over the time axis $\mathbb{N}$ is quite analogous [22]. On the other hand, the choice of cost functions depending on the restriction of the signal on the nonnegative time axis is quite natural in most of the applications.

In some cases, however, it may be natural to consider the cost function

$$J(w) := \sum_{t=-\infty}^{\infty} w_2^T(t) w_2(t), \tag{2.8}$$

depending on the whole time axis $\mathbb{Z}$. This choice of considering the whole $\mathbb{Z}$ as the time axis permits us to treat the cost function (2.8) in the same framework. The corresponding optimization can be solved employing essentially the same techniques which we propose for problem (2.4).

3. Problem solvability and reduction of complexity. In this section we provide a procedure to test the solvability of the problem and to reduce its complexity. To this aim we will derive some interesting results on ℓ^2-systems [24, 27, 8].

Define $(\ell_+^2)^r$ as the set of all $v \in (\mathbb{R}^r)^{\mathbb{Z}}$ such that

$$||v_{|[0,+\infty)}||_2^2 := \sum_{t=0}^{\infty} v^T(t) v(t) < \infty.$$

Notice that $(\ell_+^2)^r$ is not a Hilbert space, since any trajectory which is zero on the nonnegative time axis have zero norm. In order to obtain a Hilbert space structure it is enough to consider equivalent two trajectories if they coincide on the nonnegative time axis [6, p. 7].

Given the problem (2.4), let

$$\begin{aligned} \mathcal{T}(b) := \{w \in (\mathbb{R}^q)^{\mathbb{Z}} \ : \ & R(\sigma)w = 0,\ w_1(0) = b, \\ & \text{and } J(w) \text{ is finite and minimal}\} \end{aligned} \tag{3.1}$$

be the set of all optimal trajectories. An important preliminary question is to understand when the previous problem admits a solution. In other words, we want to determine the vector space

$$B = \{b \in \mathbb{R}^s : \mathcal{T}(b) \neq \emptyset\}, \tag{3.2}$$

that is the set of vectors b for which an optimal solution exists.

It is clear that only trajectories $w \in \ker R(\sigma)$ such that $R_2(\sigma)w \in (\ell_+^2)^r$ are relevant in problem (2.4). In fact, all the other trajectories give rise to an infinite cost. Then, define

$$\mathcal{B}_f := \{w \in \ker R(\sigma) : R_2(\sigma)w \in (\ell_+^2)^r\} \tag{3.3}$$

to be the set of trajectories in $\mathcal{B}$ for which the corresponding cost is finite.

This set is linear and shift-invariant. However, it is not complete and thus it cannot be described by an AR representation.

This can be overcome by introducing the concept of *completion* of a behavior. Let $\mathcal{B} \subseteq (\mathbb{R}^q)^{\mathbb{Z}}$ be any behavior. The completion of $\mathcal{B}$ is given by the following set of trajectories:

$$CP(\mathcal{B}) := \{w \in (\mathbb{R}^q)^{\mathbb{Z}} : w_{|[t_1,t_2]} \in \mathcal{B}_{|[t_1,t_2]}\ \forall\ t_1, t_2 \in \mathbb{Z}\},$$

where $\mathcal{B}_{|[t_1,t_2]}$ is defined in section 1.1. Notice that, if we consider in $(\mathbb{R}^q)^{\mathbb{Z}}$ the pointwise convergence topology [23], then the concept of completion just defined coincides with closure with respect to this topology.

It is clear that $CP(\mathcal{B})$ is always complete and that, if $\mathcal{B}$ is linear and shift-invariant, then $CP(\mathcal{B})$ is linear, shift-invariant, and complete, and so it can be characterized by an AR representation. In particular, this is the case for the behavior

$$\mathcal{B}_r := CP(\mathcal{B}_f), \tag{3.4}$$

whose importance is clarified by the following proposition.

PROPOSITION 3.1. *Let B and $\mathcal{B}_r$ be defined in* (3.2) *and in* (3.4), *respectively. Then we have*

$$B = \{b \in \mathbb{R}^s : \ \exists w_1 \in R_1(\sigma)\mathcal{B}_r \text{ such that } w_1(0) = b\}. \tag{3.5}$$

Proof. One way is easy. Suppose, conversely, that there exists $v \in \mathcal{B}_r$ such that $(R_1(\sigma)v)(0) = b$. Then for all $n \in \mathbb{N}$ there exists $w \in \ker R(\sigma)$ such that $R_2(\sigma)w \in (\ell^2_+)^r$ and $w_{|[-n,n]} = v_{|[-n,n]}$. Choosing n big enough, we have that $(R_1(\sigma)w)(0) = (R_1(\sigma)v)(0) = b$. The existence of a trajectory satisfying the restrictions and providing a finite cost implies that $\mathcal{T}(b) \neq \emptyset$. □

The previous proposition has the following straightforward corollary which connects the problem solvability with a system-theoretic property: the trimness. We recall that an AR system $\Sigma = (T, W, \mathcal{B})$ is called *trim* if for all $\alpha \in W$ there exists $w \in \mathcal{B}$ such that $w(0) = \alpha$, [23, p. 188].

COROLLARY 3.1. *Problem* (2.4) *is solvable for all $b \in \mathbb{R}^s$ if and only if the behavior $\mathcal{B}_1 := R_1(\sigma)\mathcal{B}_r$ is trim.*

An interesting consequence of Proposition 3.1 is that if we substitute $\mathcal{B}$ with $\mathcal{B}_r$, the set of optimal trajectories $\mathcal{T}(b)$ does not change. Hence it may be convenient to perform the search for the optimal trajectories in the set $\mathcal{B}_r$ since $\mathcal{B}_r \subseteq \mathcal{B}$, and so this reduction will cause a simplification of the optimization problem. For these reasons it becomes interesting to find a procedure which provides an AR representation of $\mathcal{B}_r$ starting from $R(\sigma)$ and $R_2(\sigma)$. We will call the behavior $\mathcal{B}_r$ the *reduction* of $\mathcal{B} = \ker R(\sigma)$ with respect to $R_2(\sigma)$. Moreover, we will say that $\mathcal{B}$ is *reduced* with respect to $R_2(\sigma)$ if it coincides with its reduction with respect to $R_2(\sigma)$. Notice that $\mathcal{B}$ is reduced with respect to $R_2(\sigma)$ if and only if $\mathcal{B}_1 := R_2(\sigma)\mathcal{B}$ is reduced with respect to the identity or, equivalently, if and only if

$$\mathcal{B}_1 = CP(\mathcal{B}_1 \cap (\ell^2_+)^q).$$

In this case, we will say that the behavior $\mathcal{B}_1$ is *reduced.*

It can be shown that the problem of constructing AR representations of reduced behaviors is connected with the theory of ℓ^2-systems as presented in [24, 27, 12, 8, 11, 17, 21]. In the next subsection we will present some definitions and results of this theory.

3.1. ℓ^2-systems and their properties.

A linear shift-invariant system $\tilde{\Sigma} = (\mathbb{Z}, \mathbb{R}^q, \tilde{\mathcal{B}})$ is called an ℓ^2*-system* if $\tilde{\mathcal{B}}$ is a linear shift-invariant and closed (with respect to the ℓ^2 topology) subspace of

$$(\ell^2)^q := \left\{ w \in (\mathbb{R}^q)^{\mathbb{Z}} : ||w||_2^2 := \sum_{t=-\infty}^{+\infty} w^T(t)w(t) < \ \infty \right\}.$$

A particularly important class of ℓ^2-systems is the class of so-called *finite dimensional* ℓ^2-systems (see [24, p. 280]) which is the set of ℓ^2-systems whose behavior $\tilde{\mathcal{B}}$ satisfies the condition

$$\tilde{\mathcal{B}} = CP(\tilde{\mathcal{B}}) \cap (\ell^2)^q.$$

It can be shown that in this case $CP(\tilde{\mathcal{B}})$ is always controllable [24]. Moreover, if $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathcal{B})$ is a linear shift-invariant complete system, then $\tilde{\mathcal{B}} := \mathcal{B} \cap (\ell^2)^q$ is the behavior of a finite dimensional ℓ^2-system, and in this case $CP(\tilde{\mathcal{B}})$ is the behavior of the *controllable subsystem* of Σ (see [24, p. 266]), that is, the system $\Sigma_c = (\mathbb{Z}, \mathbb{R}^q, \mathcal{B}_c)$ such that

$$\mathcal{B}_c = CP(\{w \in \mathcal{B} : w \text{ has finite support}\}),$$

and which is the largest controllable subsystem of Σ.

Analogous considerations can be done if, instead of taking ℓ^2-systems, we consider ℓ^2_+-systems. In this case finite dimensional ℓ^2_+-systems are systems $\tilde{\Sigma} = (\mathbb{Z}, \mathbb{R}^q, \tilde{\mathcal{B}})$ such that

$$\tilde{\mathcal{B}} = CP(\tilde{\mathcal{B}}) \cap (\ell^2_+)^q.$$

Also in this case, if $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathcal{B})$ is a linear shift-invariant complete system, then $\tilde{\mathcal{B}} := \mathcal{B} \cap (\ell^2_+)^q$ is the behavior of a finite dimensional ℓ^2_+-system. However, now the behavior is not controllable, but only *stabilizable* (see [26]). More precisely, $CP(\tilde{\mathcal{B}})$ is the behavior of the stabilizable subsystem of Σ namely the system $\Sigma_s = (\mathbb{Z}, \mathbb{R}^q, \mathcal{B}_s)$ such that

$$\mathcal{B}_s = CP\left(\left\{w \in \mathcal{B} : \lim_{t\to+\infty} w(t) = 0\right\}\right)$$

which is the largest stabilizable subsystem of Σ. This is a consequence of the following proposition.

PROPOSITION 3.2. *Let $R(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{p\times q}$ be full row rank and $\mathcal{B} = \ker R(\sigma)$. Moreover, let $F_s(\sigma), F_i(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{p\times p}$, and $R'(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{p\times q}$ be polynomial matrices such that $\det F_s(\sigma)$ has zeros in $\mathbb{C}_< := \{z \in \mathbb{C} : \ |z| < 1\}$, $\det F_i(\sigma)$ has zeros in $\mathbb{C}_\geq := \{z \in \mathbb{C} : \ |z| \geq 1\}$, $R'(\sigma)$ is left prime, and*

$$R(\sigma) = F_i(\sigma)F_s(\sigma)R'(\sigma). \tag{3.6}$$

Then

$$CP(\mathcal{B} \cap (\ell^2_+)^q) = \ker F_s(\sigma)R'(\sigma).$$

Proof. We show first that

$$\ker R(\sigma) \cap (\ell^2_+)^q \subseteq \ker F_s(\sigma)R'(\sigma),$$

which implies immediately that

$$CP(\mathcal{B} \cap (\ell^2_+)^q) \subseteq \ker F_s(\sigma)R'(\sigma).$$

Let $w \in \ker R(\sigma)$ and $w \in (\ell^2_+)^q$. Since $R'(\sigma)$ is left prime, then there exists a polynomial matrix $X(\sigma)$ such that $R'(\sigma)X(\sigma) = I$, where I is the identity matrix. Then define $w_1 := X(\sigma)R'(\sigma)w$ and $w_2 := w - w_1$. First notice that $w_2 \in \ker R'(\sigma)$ and so $w_2 \in \ker F_s(\sigma)R'(\sigma)$. Notice, moreover, that $w_1 \in X(\sigma)\ker F_i(\sigma)F_s(\sigma)$. Since $w \in (\ell^2_+)^q$, then it is clear that

$$\lim_{t\to+\infty} w(t) = 0.$$

We can argue that $\lim_{t\to+\infty} w_1(t) = 0$. Let $v \in \ker F_i(\sigma)F_s(\sigma)$ such $w_1 = X(\sigma)v$. Then $v = R'(\sigma)w_1$ and so $\lim_{t\to+\infty} v(t) = 0$. Therefore we have $F_s(\sigma)v \in \ker F_i(\sigma)$ and that $\lim_{t\to+\infty} F_s(\sigma)v(t) = 0$. It is easy to see that this can happen if and only if $F_s(\sigma)v = 0$. This implies that $w_1 \in \ker F_s(\sigma)R'(\sigma)$ and so $w \in \ker F_s(\sigma)R'(\sigma)$.

Suppose, conversely, that $w \in \ker F_s(\sigma)R'(\sigma)$. We want to show that for all $n \in \mathbb{N}$ there exists $w' \in \ker R(\sigma) \cap (\ell^2_+)^q$ such that $w_{|[-n,n]} = w'_{|[-n,n]}$. This implies that

$$\ker F_s(\sigma)R'(\sigma) = CP(\ker F_s(\sigma)R'(\sigma)) \subseteq \mathcal{B}.$$

Fix $n \in \mathbb{N}$ and let $w_1 := X(\sigma)R'(\sigma)w$ and $w_2 := w - w_1$. Since $R'(\sigma)w \in \ker F_s(\sigma)$, then $w_1 \in (\ell^2_+)^q$. On the other hand, since $w_2 \in R'(\sigma)$ and since $\ker R'(\sigma)$ is controllable, then there exists $w'_2 \in R'(\sigma)$ such that $w_{2|[-n,n]} = w'_{2|[-n,n]}$ and such that $w'_{|[N,+\infty)} = 0$ for $N \in \mathbb{N}$ big enough. Define $w' := w_1 + w'_2$. Then it is clear that $w' \in \ker R(\sigma) \cap (\ell^2_+)^q$ and that $w_{|[-n,n]} = w'_{|[-n,n]}$. □

As a corollary of the previous proposition, we obtain an effective characterization of stabilizable behaviors which has been already proposed in [26]. Its proof easily follows from the previous proposition and from proposition 4.3 in [23].

COROLLARY 3.2. *Let $R(\sigma) \in \mathbb{R}[\sigma,\sigma^{-1}]^{p\times q}$ be a rank r polynomial matrix. Then $\mathcal{B} := \ker R(\sigma)$ is stabilizable if and only if*

$$\operatorname{rank} R(\lambda) = r$$

for all $\lambda \in \mathbb{C}_{\geq}$.

3.2. Construction of reduced behaviors. Consider again the problem of constructing AR representations of reduced behaviors. In the particular case when $R_2(\sigma) = I$, the reduction may be obtained by employing Proposition 3.2. In order to extend such a procedure to the general case, we need the following technical lemma.

LEMMA 3.1. *Let $\mathcal{B} = \ker R(\sigma)$, where $R(\sigma) \in \mathbb{R}[\sigma,\sigma^{-1}]^{l\times q}$, and let $R_2(\sigma) \in \mathbb{R}[\sigma,\sigma^{-1}]^{r\times q}$. If $\{v_n\}_{n=0}^{\infty}$ is a sequence in $R_2(\sigma)\mathcal{B}$, converging in the pointwise convergence topology, then there exists a sequence $\{w_n\}_{n=0}^{\infty}$ in $\mathcal{B}$ converging in the pointwise convergence topology, such that $v_n = R_2(\sigma)w_n$.*

Proof. We first suppose that $\mathcal{B} = (\mathbb{R}^q)^{\mathbb{Z}}$ and consider the scalar case $p = q = 1$. Suppose that

$$R_2(\sigma) = \sum_{i=l}^{L} R_i\sigma^i,$$

where R_l, R_L are nonzero reals. Let $\{v_n\}_{n=0}^{\infty}$ be a sequence in $R_2(\sigma)\mathcal{B}$, and let $\{w_n\}_{n=0}^{\infty}$ be a sequence of trajectories satisfying

(i) $w_n(t) = 0$ for all n and for all $t \in [l, L-1]$, and

(ii) $v_n = R_2(\sigma)w_n$.

It is clear that (i) and (ii) fix uniquely w_n. We want to show that if $\{v_n\}_{n=0}^{\infty}$ converges in the pointwise convergence topology, then the sequence $\{w_n\}_{n=0}^{\infty}$ converges in the same topology, i.e., for all $\bar{t} \in \mathbb{Z}$ the sequence of real numbers $\{w_n(\bar{t})\}_{n=0}^{\infty}$ converges. This is clearly true for $\bar{t} \in [l, L-1]$. Suppose, by induction, that $\{w_n(\bar{t})\}_{n=0}^{\infty}$ for all $\bar{t}$ in an interval $[h, H]$. Then, since we have

$$v_n(H+1-L) = R_l w_n(H+1+l-L) + \cdots + R_{L-1}w_n(H) + R_L w_n(H+1)$$

and since $v_n(H+1-L), w_n(H+1-L+l), \ldots, w_n(H)$ all converge as sequences in n, then also $w_n(H+1)$ must converge. In the same way we can show that $w_n(h-1)$ must converge.

Consider now the vector case and consider the Smith form [9] of $R_2(\sigma)$,

$$U(\sigma)R_2(\sigma)V(\sigma) = \begin{bmatrix} \Lambda(\sigma) & 0 \\ 0 & 0 \end{bmatrix},$$

where $\Lambda(\sigma)$ is a diagonal matrix and $U(\sigma), V(\sigma)$ are unimodular. Take $\bar{v}_n := U^{-1}(\sigma)v_n$. Since the matrix shift operators are continuous, then $\{\bar{v}_n\}_{n=0}^{\infty}$ converges. Moreover, since $V(\sigma)$ is onto, we have that

$$\bar{v}_n \in \operatorname{im} \begin{bmatrix} \Lambda(\sigma) & 0 \\ 0 & 0 \end{bmatrix}.$$

Using the result obtained in the scalar case, we may argue that there exists a converging sequence $\{\bar{w}_n\}_{n=0}^{\infty}$ such that

$$\bar{v}_n = \begin{bmatrix} \Lambda(\sigma) & 0 \\ 0 & 0 \end{bmatrix} \bar{w}_n.$$

Finally letting $w_n = V^{-1}(\sigma)\bar{w}_n$, we have that $\{w_n\}_{n=0}^{\infty}$ converges and $v_n = R_2(\sigma)w_n$.

Suppose, finally, that $v_n \in R_2(\sigma)\mathcal{B}$ and that $\{v_n\}_{n=0}^{\infty}$ converges. Then there exists $w_n' \in \mathcal{B}$ such that $v_n = R(\sigma)w_n'$. Letting

$$\bar{R}(\sigma) := \begin{bmatrix} R(\sigma) \\ R_2(\sigma) \end{bmatrix},$$

we have that

$$\bar{R}(\sigma)w_n' = \begin{bmatrix} R(\sigma) \\ R_2(\sigma) \end{bmatrix} w_n' = \begin{bmatrix} 0 \\ v_n \end{bmatrix}$$

converges and hence, by the previous arguments, there exists a convergent sequence $\{w_n\}_{n=0}^{\infty}$ such that

$$\bar{R}(\sigma)w_n = \begin{bmatrix} R(\sigma) \\ R_2(\sigma) \end{bmatrix} w_n = \begin{bmatrix} 0 \\ v_n \end{bmatrix}.$$

This implies that $R(\sigma)w = 0$ and that $v_n = R_2(\sigma)w_n$. □

Remark. The previous lemma is equivalent to the fact that the linear map

$$\begin{array}{rcccl} R_2(\sigma)_{|\mathcal{B}} & : & \mathcal{B} & \longrightarrow & R_2(\sigma)\mathcal{B}, \\ & & w & \mapsto & R_2(\sigma)w \end{array}$$

is *open* [7, p. 221]. In fact, it can be proved that Lemma 3.1 is a particular case of the *open mapping theorem* [18].

We are now in position to prove the next proposition.

PROPOSITION 3.3. *Let $\mathcal{B} = \ker R(\sigma)$, where $R(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{l\times q}$, and let $R_2(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{r\times q}$. Then the reduced behavior $\mathcal{B}_r$ (defined in* (3.4)*) is given by the expression*

$$\mathcal{B}_r = \ker \begin{bmatrix} R(\sigma) \\ M(\sigma)R_2(\sigma) \end{bmatrix}, \tag{3.7}$$

where $M(\sigma) \in \mathbb{R}[\sigma, \sigma^{-1}]^{g\times r}$ is such that $\ker M(\sigma) = CP(R_2(\sigma)\mathcal{B} \cap (\ell_+^2)^r))$.

Proof. We first verify that

$$\mathcal{B}_r \subseteq \mathcal{B} \cap \ker M(\sigma)R_2(\sigma).$$

Clearly $\mathcal{B}_r \subseteq \mathcal{B}$. Moreover, if $w \in \mathcal{B}_r$, then $R(\sigma)w = 0$ and $R_2(\sigma)w \in (\ell^2_+)^r$, so that $R_2(\sigma)w \in R_2(\sigma)\mathcal{B} \cap (\ell^2_+)^r \subseteq \ker M(\sigma)$ or, equivalently, $w \in \ker[M(\sigma)R_2(\sigma)]$.

Suppose, conversely, that $w \in \mathcal{B} \cap \ker M(\sigma)R_2(\sigma)$. Let $\mathcal{B}_f$ be the behavior defined in (3.3). We have to show that

$$w \in CP(\mathcal{B}_f).$$

Since $w \in \ker M(\sigma)R_2(\sigma)$, then $v := R_2(\sigma)w \in \ker M(\sigma) = CP(R_2(\sigma)\mathcal{B} \cap (\ell^2_+)^r)$, and so there exists a sequence $\{v_n\}_{n=0}^\infty$ in $R_2(\sigma)\mathcal{B} \cap (\ell^2_+)^r$ converging to v in the pointwise convergence topology. By the previous lemma we can argue that there exists a sequence $\{w_n\}_{n=0}^\infty$ in $\mathcal{B}$ that converges in the pointwise convergence topology to $w' \in \mathcal{B}$ and such that $v_n = R_2(\sigma)w_n$ and hence, by the continuity of $R_2(\sigma)$, we have $R_2(\sigma)w = R_2(\sigma)w'$. Consider the new sequence $\{w_n - w' + w\}_{n=0}^\infty$ and observe that its elements are still in $\mathcal{B}$. Moreover, observe that $R_2(\sigma)w_n = v_n \in (\ell^2_+)^r$ so that $w_n \in \mathcal{B}_f$. Consequently, w is in the closure of the previous set, just as we need to show. □

By the previous proposition, an essential step in determining $\mathcal{B}_r$ is the computation of an AR representation of $CP(R_2(\sigma)\mathcal{B} \cap (\ell^2_+)^r)$. To this aim we first look for an AR representation of $R_2(\sigma)\mathcal{B}$. Since $w_2 \in R_2(\sigma)\mathcal{B}$ if and only if

$$\begin{bmatrix} I \\ 0 \end{bmatrix} w_2 = \begin{bmatrix} R_2(\sigma) \\ R(\sigma) \end{bmatrix} w \tag{3.8}$$

for some $w \in (\mathbb{R}^q)^{\mathbb{Z}}$, an AR representation of $R_2(\sigma)\mathcal{B}$,

$$R_2(\sigma)\mathcal{B} = \ker N(\sigma),$$

can be obtained by eliminating the latent variable w in (3.8) as suggested in [24, p. 265]. After this elimination we are in the range of application of Proposition 3.2. Therefore, it is possible to obtain an AR representation for $CP(R_2(\sigma)\mathcal{B} \cap (\ell^2_+)^r)$:

$$CP(R_2(\sigma)\mathcal{B} \cap (\ell^2_+)^r) = \ker M(\sigma).$$

Notice that the previous arguments prove the following result.

Corollary 3.3. *The behavior $\mathcal{B} = \ker R(\sigma)$ is reduced with respect to $R_2(\sigma)$ if and only if $R_2(\sigma)\mathcal{B}$ is stabilizable.*

Therefore, if we want to verify whether $\mathcal{B}$ is reduced with respect to $R_2(\sigma)$, we can simply apply Corollary 3.2 to any AR representation of $R_2(\sigma)\mathcal{B}$.

In view of the previous arguments, from now on, we can assume without loss of generality that in problem (2.4) the behavior $\mathcal{B} = \ker R(\sigma)$ is reduced with respect to $R_2(\sigma)$.

4. Optimal trajectories in AR systems. In this section we show how the problem of finding the set of the optimal trajectories of a system Σ can be translated into an LQ optimization problem for a system in state form. This will be done employing a driving variable state space representation of Σ. This second optimization problem is not the classical one, because it has a linear constraint on the initial state and on the initial input. However, we will give a closed form solution using a two-step optimization.

In the next subsection we derive a state space reformulation of problem (4.1). In subsection 4.2 we describe the state space counterpart of the results of section 3. More precisely, we derive a necessary and sufficient condition, based on the state space representation, for the existence of solutions. We also describe a procedure to perform the reduction described in subsection 3.2 in terms of the state space representation. These results allow us to derive in subsection 4.3 a parametrization of the set of optimal trajectories.

4.1. From AR to state space representation. We recall from [23] that given an AR system $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathcal{B})$, there exist $A \in \mathbb{R}^{n\times n}, B \in \mathbb{R}^{n\times m}, C \in \mathbb{R}^{q\times n}, D \in \mathbb{R}^{q\times m}$ such that $w \in \mathcal{B}$ if and only if there exist $x \in (\mathbb{R}^n)^{\mathbb{Z}}$ and $u \in (\mathbb{R}^m)^{\mathbb{Z}}$ such that

$$\left\{\begin{aligned} x(t+1) &= Ax(t) + Bu(t), \\ w(t) &= Cx(t) + Du(t) \end{aligned}\right. \qquad \forall t \in \mathbb{Z}. \tag{4.1}$$

The signal x is called *state variable* while the signal u is called *driving variable.* The representation (4.1) of the original system is called *driving variable state representation.* This state space representation has been introduced in [23], where the properties of minimal representations are also analyzed. For our purposes it is sufficient to recall that minimal driving variable representations exist, they may be computed by employing linear algebra techniques, and they have the *state trimness* property. The realization (4.1) is said to be *state trim* [23] if and only if

$$\begin{gathered} \{x_0 \in \mathbb{R}^n : \exists x \in (\mathbb{R}^n)^{\mathbb{Z}}, u \in (\mathbb{R}^m)^{\mathbb{Z}}, w \in \mathcal{B} \text{ satisfying (4.1)} \\ \text{such that } x(0) = x_0\} = \mathbb{R}^n. \end{gathered} \tag{4.2}$$

The procedure determining the set of all optimal trajectories $\mathcal{T}(b)$ proposed in this paper is based on the driving variable representation. Suppose that we are dealing with problem (2.4), where we can suppose that $\mathcal{B} = \ker R(\sigma)$ is reduced with respect to $R_2(\sigma)$. Consider the AR system $\bar{\Sigma} = (\mathbb{Z}, \mathbb{R}^{q+s+r}, \bar{\mathcal{B}})$, where

$$\begin{aligned} \bar{\mathcal{B}} &= \ker \begin{bmatrix} R(\sigma) & 0 & 0 \\ R_1(\sigma) & -I & 0 \\ R_2(\sigma) & 0 & -I \end{bmatrix} \\ &= \left\{ \begin{bmatrix} w \\ w_1 \\ w_2 \end{bmatrix} \in (\mathbb{R}^{q+s+r})^{\mathbb{Z}} : R(\sigma)w = 0,\ w_1 = R_1(\sigma)w,\ w_2 = R_2(\sigma)w \right\}, \end{aligned}$$

and consider a driving variable state representation of $\bar{\Sigma}$:

$$\left\{\begin{aligned} x(t+1) &= Ax(t) + Bu(t), \\ w(t) &= Cx(t) + Du(t), \\ w_1(t) &= C_1x(t) + D_1u(t), \\ w_2(t) &= C_2x(t) + D_2u(t), \end{aligned}\right. \qquad t \in \mathbb{Z}, \tag{4.3}$$

where $x \in (\mathbb{R}^n)^{\mathbb{Z}}$ is the state variable and $u \in (\mathbb{R}^m)^{\mathbb{Z}}$ is the driving variable. Since (4.3) is a state representation of the system $\bar{\Sigma}$, then $(w, w_1, w_2) \in \bar{\mathcal{B}}$ if and only if there exists a state trajectory x and a driving variable trajectory u such that (4.3) is satisfied for all $t \in \mathbb{Z}$. The complexity of the solution of our problem will depend on the dimension n of the state space of the representation (4.3). Hence, it is convenient to consider a minimal state representation of $\bar{\mathcal{B}}$. For this reason, from now on, without loss of generality, we assume that (4.3) is a minimal representation of $\bar{\mathcal{B}}$ and, in particular, that state trim property (4.2) holds true.

Consider now the following optimization problem. Find the set of trajectories $(x, u) \in (\mathbb{R}^{n+m})^{\mathbb{N}}$ such that

$$(4.4) \quad \begin{cases} x(t+1) = Ax(t) + Bu(t), \qquad t \in \mathbb{N}, \\ C_1 x(0) + D_1 u(0) = b, \\ J(x,u) := \sum_{t=0}^{\infty} [x^T(t) u^T(t)] \begin{bmatrix} C_2^T C_2 & C_2^T D_2 \\ D_2^T C_2 & D_2^T D_2 \end{bmatrix} \begin{bmatrix} x(t) \\ u(t) \end{bmatrix} \text{ is minimal.} \end{cases}$$

The following proposition shows that problem (4.4) is equivalent to problem (2.4).

PROPOSITION 4.1. *Let $\mathcal{T}(b)$ be the set of optimal trajectories defined in* (3.1). *We have that $w \in \mathcal{T}(b)$ if and only if there exists $(x, u) \in (\mathbb{R}^{n+m})^{\mathbb{N}}$ satisfying the requirements of problem* (4.4) *and such that*

$$w(t) = Cx(t) + Du(t) \qquad \forall t = 0, 1, 2, \ldots .$$

Proof. Suppose that $w \in \mathcal{T}(b)$. Then there exists $(x, u) \in (\mathbb{R}^{n+m})^{\mathbb{Z}}$ satisfying (4.3) for all $t \in \mathbb{Z}$. Let $\bar{x} := x_{|[0,+\infty)}$ and $\bar{u} := u_{|[0,+\infty)}$. Then $(\bar{x}, \bar{u})$ satisfies problem (4.4). Actually, the first two equations of (4.4) are clearly satisfied. It remains to show the minimality of $J(\bar{x}, \bar{u})$. Let $(\bar{x}', \bar{u}') \in (\mathbb{R}^{n+m})^{\mathbb{N}}$ such that

$$\begin{cases} \bar{x}'(t+1) = A\bar{x}'(t) + B\bar{u}'(t), \\ C_1 \bar{x}'(0) + D_1 \bar{u}'(0) = b. \end{cases}$$

By trimness of the state representation (4.3), there exists $(x', u') \in (\mathbb{R}^{n+m})^{\mathbb{Z}}$ such that $x'(t+1) = Ax'(t) + Bu'(t)$ for all $t \in \mathbb{Z}$ and $\bar{x}' = x'_{|[0,+\infty)}$ and $\bar{u}' = u'_{|[0,+\infty)}$. Define $w' := Cx' + Du'$, $w_1' := C_1 x' + D_1 u'$, and $w_2' := C_2 x' + D_2 u'$. Then it is clear that $R(\sigma) w' = 0$, $w_1' = R_1(\sigma) w'$, and $w_2' = R_2(\sigma) w'$, and so

$$J(\bar{x}, \bar{u}) = ||w_{2|[0,+\infty)}||_2^2 \le ||w'_{2|[0,+\infty)}||_2^2 = J(\bar{x}', \bar{u}'),$$

which shows the minimality of $J(\bar{x}, \bar{u})$.

Suppose, conversely, that $(\bar{x}, \bar{u}) \in (\mathbb{R}^{n+m})^{\mathbb{N}}$ satisfies the requirements of (4.4) and that $w(t) = Cx(t) + Du(t)$ for all $t = 0, 1, 2, \ldots$. Then, by trimness of the state representation (4.3), there exists $(x, u) \in (\mathbb{R}^{n+m})^{\mathbb{Z}}$ such that $x(t+1) = Ax(t) + Bu(t)$ for all $t \in \mathbb{Z}$ and $\bar{x} = x_{|[0,+\infty)}$ and $\bar{u} = u_{|[0,+\infty)}$. Define $w := Cx + Du$, $w_1 := C_1 x + D_1 u$, and $w_2 := C_2 x + D_2 u$. Then it is clear that $R(\sigma) w = 0$, $w_1 = R_1(\sigma) w$, $w_2 = R_2(\sigma) w$, and $w_1(0) = b$. It remains to show the minimality of $||w_{2|[0,+\infty)}||_2^2$. Actually, suppose that w' is such that $R(\sigma) w' = 0$ and let $w_1' = R_1(\sigma) w'$ and $w_2' = R_2(\sigma) w'$. Suppose, moreover, that $w_1(0) = b$. Then there exists $(x', u') \in (\mathbb{R}^{n+m})^{\mathbb{Z}}$ satisfying (4.3) for all $t \in \mathbb{Z}$. Consequently, if we define $\bar{x}' := x'_{|[0,+\infty)}$ and $\bar{u}' := u'_{|[0,+\infty)}$, then

$$||w_{2|[0,+\infty)}||_2^2 = J(\bar{x}, \bar{u}) \le J(\bar{x}', \bar{u}') = ||w'_{2|[0,+\infty)}||_2^2,$$

and this implies the minimality of $||w_{2|[0,+\infty)}||_2^2$. □

By the previous proposition we can argue that (2.4) is solvable, i.e., $\mathcal{T}(b) \neq \emptyset$ for all $b \in \mathbb{R}^s$ if and only if for any b there exists a trajectory (x, u) compatible with the equations

$$(4.5) \qquad \begin{cases} x(t+1) = Ax(t) + Bu(t), \qquad t \in \mathbb{N}, \\ C_1 x(0) + D_1 u(0) = b, \end{cases}$$

and such that $J(x, u) < \infty$.

4.2. Complexity reduction in state space representation. It is possible to find a very easy necessary and sufficient condition for the solvability of problem (2.4) based on the representation (4.3). To derive this condition we need some definitions and a technical lemma.

Given the system

$$\begin{cases} x(t+1) = Ax(t) + Bu(t), \\ y(t) = Cx(t) + Du(t), \end{cases} \tag{4.6}$$

we will denote by $\mathcal{V}_+$ the space of states $x_0 \in \mathbb{R}^n$ for which there exists a trajectory u, x, y compatible with equations of system (4.6) and such that $y(t) = 0$ for all $t \geq 0$ and $x(0) = x_0$. We will call $\mathcal{V}_+$ the *weakly unobservable space of* (A, B, C, D). Similarly, we will denote by $\mathcal{V}_-$ the space of states $x_0 \in \mathbb{R}^n$ for which there exists a trajectory u, x, y compatible with equations of system (4.6) and such that $y(t) = 0$ for all $t \leq 0$ and $x(0) = x_0$. $\mathcal{V}_-$ will be called the *backward weakly unobservable space of* (A, B, C, D). The space

$$\mathcal{X}_c := \mathcal{X}_s(A) + \langle A|\text{im } B\rangle + \mathcal{V}_+, \tag{4.7}$$

where $\mathcal{X}_s(A)$ is the stability space of A, $\langle A|\text{im } B\rangle$ is the controllability space of (A, B), and $\mathcal{V}_+$ is the weakly unobservable space of (A, B, C, D), is called the *output stabilizability space of* (A, B, C, D). We recall from [10] the following result.

Lemma 4.1. *The space $\mathcal{X}_c$ of (A, B, C_2, D_2) coincides with the set of initial condition $x(0)$ such that there exists u yielding to a finite cost $J(x, u)$ in* (4.4).

We now prove a technical result concerning the space $\mathcal{X}_c$ that will be useful below.

Lemma 4.2. *Given the system* (4.6), *let $\mathcal{R} = \langle A|\text{im } B\rangle$ be its controllability space, $\mathcal{V}_+$ be its weakly unobservable space, and $\mathcal{V}_-$ be its backward weakly unobservable space. Then we have*

$$\mathcal{V}_- \subseteq \mathcal{V}_+ + \mathcal{R}. \tag{4.8}$$

Proof. Let n be the dimension of the matrix A, and let $\bar{x}$ be a point of $\mathcal{V}_-$. By definition there exists a trajectory u, x, y compatible with equations of system (4.6) and such that $y(t) = 0$ for all $t \leq 0$ and $x(0) = \bar{x}$. This clearly implies that $x(-k)$ is an element of the set $\mathcal{V}_+^k$ of states of system (4.6) which is weakly unobservable in k steps, i.e., the set of points $x_0 \in \mathbb{R}^n$ for which there exists a trajectory u, x, y compatible with equations of system (4.6) and such that $y(t) = 0$ for all $0 \leq t \leq k$ and $x(0) = x_0$. Since the sequence of sets $\{\mathcal{V}_+^t\}_{t=1,2,\ldots}$ is decreasing and for $t \geq n$ it becomes stationary [23], we have that for k sufficiently large $x(-k) \in \mathcal{V}_+$. Hence there exists a trajectory u_+, x_+, y_+ compatible with equations of system (4.6) and such that $x_+(t) = x(t)$ for $t \leq -k$ and $y_+(t) = 0$ for $t \geq -k$. Then, $x_+(0) \in \mathcal{V}_+$. Moreover, $x_+(0) - \bar{x} \in \mathcal{R}$, since they are both reachable starting from the state $x(-k)$. Therefore, $\bar{x} \in \mathcal{R} + \mathcal{V}_+$, and this concludes the proof. □

The following result provides a link between the reduced behaviors setting and system theoretic properties of the corresponding driving variable representations.

Proposition 4.2. *Consider problem* (2.4) *and the driving variable representation* (4.3). *Moreover, let $\mathcal{X}_c$ be the output stabilizability space of (A, B, C_2, D_2). Then, $\mathcal{B} = \ker R(\sigma)$ is reduced with respect to $R_2(\sigma)$ if and only if $\mathcal{X}_c = \mathbb{R}^n$.*

Proof. Suppose that $\mathcal{X}_c = \mathbb{R}^n$. Then for any trajectory $w_2 \in R_2(\sigma)\mathcal{B}$ there exists a state trajectory x and an input trajectory u such that

$$\begin{cases} x(t+1) = Ax(t) + Bu(t), \\ \quad w_2(t) = C_2x(t) + D_2u(t), \end{cases} \qquad t \in \mathbb{Z}. \tag{4.9}$$

Then in view of Lemma 4.1 and taking into account the state separation property, it is clear that there exist $\bar{w}_2 \in R_2(\sigma)\mathcal{B}$, $\bar{x}$, and $\bar{u}$ satisfying (4.9) and such that $w_2(t) = \bar{w}_2(t)$, $x(t) = \bar{x}(t)$, $t \leq 0$, and $\lim_{t\to\infty} \bar{w}_2(t) = 0$. This is means, by definition, that $R_2(\sigma)\mathcal{B}$ is stabilizable, or, in view of Corollary 3.3, that $\mathcal{B} = \ker R(\sigma)$ is reduced with respect to $R_2(\sigma)$.

Suppose, conversely, that $\mathcal{B} = \ker R(\sigma)$ is reduced with respect to $R_2(\sigma)$, or, equivalently, that $R_2(\sigma)\mathcal{B}$ is reduced, and let $R_2(\sigma)\mathcal{B} = \ker M(\sigma)$ with $M(\sigma)$ full row rank. Then, by Proposition 3.2, $M(\sigma) = F(\sigma)M'(\sigma)$ with $F(\sigma)$ square with stable determinant and $M'(\sigma)$ left prime. Let $X(\sigma)$ be such that $M'(\sigma)X(\sigma) = I$. Suppose that $x_0 \in \mathbb{R}^n$. Then, by trimness, there exist x, w_2 satisfying the state equations in (4.3) and such that $x(0) = x_0$. Obviously, $w_2 \in R_2(\sigma)\mathcal{B}$. As in the proof of Proposition 3.2 define $w_2' := X(\sigma)M'(\sigma)w_2$ and $w_2'' := w_2 - w_2'$. Since $M'(\sigma)w_2 \in \ker F(\sigma)$, then $w_2' \in (\ell_+^2)^r$. On the other hand, since $w_2'' \in \ker M'(\sigma)$ and since $\ker M'(\sigma)$ is controllable, there exists $\bar{w}_2'' \in \ker M'(\sigma)$ such that $\bar{w}''_{2|(-\infty,0]} = w''_{2|(-\infty,0]}$ and such that $\bar{w}''_{2|[N,+\infty)} = 0$ for $N \in \mathbb{N}$ big enough. Define $\bar{w}_2 := w_2' + \bar{w}_2''$. Then it is clear that $\bar{w}_2 \in R_2(\sigma)\mathcal{B} \cap (\ell_+^2)^r$ and that $\bar{w}_{2|(-\infty,0]} = w_{2|(-\infty,0]}$. Consider the state trajectory $\bar{x}$ such that $\bar{x}, \bar{w}_2$ satisfy the state equations in (4.3). Then it is clear that $\bar{x}(0) \in \mathcal{X}_c$. From Lemma 4.2 it follows that $\bar{x}(0) - x_0 \in \mathcal{X}_c$, and hence, since $\mathcal{X}_c$ is a linear space, that $x_0 \in \mathcal{X}_c$. □

We are now ready to prove the following corollary which gives an easy necessary and sufficient condition for the solvability of our problem.

COROLLARY 4.1. *Consider problem* (2.4) *and the driving variable representation* (4.3). *Let* $\mathcal{T}(b)$ *be the set of optimal trajectories defined in* (3.1), *and let* $\mathcal{X}_c$ *be the output stabilizability space of* (A, B, C_2, D_2). *Then* $\mathcal{T}(b) \neq \emptyset$ *if and only if*

$$b = C_1 x + D_1 u, \tag{4.10}$$

where x *and* u *are such that* $Ax + Bu \in \mathcal{X}_c$.

If $\mathcal{B} = \ker R(\sigma)$ *is reduced with respect to* $R_2(\sigma)$, *then* $\mathcal{T}(b) \neq \emptyset$ *if and only if*

$$b \in \text{im } [C_1 \; D_1]. \tag{4.11}$$

Proof. The first part follows from Lemma 4.1. For the second part, notice that if $\mathcal{B} = \ker R(\sigma)$ is reduced with respect to $R_2(\sigma)$, (4.10) reduces to (4.11) since, in view of Proposition 4.2, $\mathcal{X}_c = \mathbb{R}^n$. □

Before presenting the solution of the problem, we make a brief remark which is suggested by the previous proposition. Assume that $\mathcal{B} = \ker R(\sigma)$ is not reduced with respect to $R_2(\sigma)$, and let (4.3) be a driving variable representation of $\bar{\Sigma}$. It is clear that its output stabilizability space $\mathcal{X}_c$ is A-invariant and it contains im B. Then by a suitable change of basis we can transform the representation (4.3) into the following:

$$\left\{ \begin{aligned} x(t+1) &= \bar{A}x(t) + \bar{B}u(t), \\ w(t) &= \bar{C}x(t) + \bar{D}u(t), \\ w_1(t) &= \bar{C}_1 x(t) + \bar{D}_1 u(t), \\ w_2(t) &= \bar{C}_2 x(t) + \bar{D}_2 u(t), \end{aligned} \right. \tag{4.12}$$

where

$$\bar{A} = \begin{bmatrix} A^{11} & A^{12} \\ 0 & A^{22} \end{bmatrix}, \quad \bar{B} = \begin{bmatrix} B^1 \\ 0 \end{bmatrix},$$

$\bar{C} = [C^1\ C^2]$, $\bar{C}_1 = [C_1^1\ C_1^2]$, $\bar{C}_2 = [C_2^1\ C_2^2]$, $\bar{D} = D$, $\bar{D}_1 = D_1$, $\bar{D}_2 = D_2$, and where the output stabilizability space of the reduced driving variable representation

$$\left\{ \begin{aligned} x^1(t+1) &= A^{11}x^1(t) + B^1u(t), \\ w^1(t) &= C^1x^1(t) + Du(t), \\ w_1^1(t) &= C_1^1x^1(t) + D_1u(t), \\ w_2^1(t) &= C_2^1x^1(t) + D_2u(t), \end{aligned} \right. \tag{4.13}$$

is the whole state space $\mathbb{R}^{n_1}$. It is clear that the set of trajectories w^1 compatible with system (4.13) is a subset of $\mathcal{B}$. Actually it is not difficult to show that this set is exactly the reduction $\mathcal{B}_r$ of $\mathcal{B}$ with respect to $R_2(\sigma)$:

$$\mathcal{B}_r = \{w^1 \in (\mathbb{R}^q)^{\mathbb{Z}} : \exists x^1 \in (\mathbb{R}^{n_1})^{\mathbb{Z}}, u \in (\mathbb{R}^m)^{\mathbb{Z}} \text{ such that (4.13) is satisfied } \forall t \in \mathbb{Z}\}.$$

This observation furnishes a procedure to perform the reduction of $\mathcal{B}$ with respect to $R_2(\sigma)$ in terms of the state space representation.

4.3. Computation of optimal solutions. Next we furnish a parametrization of the set of optimal trajectories $\mathcal{T}(b)$, or, equivalently (Proposition 4.1), of the set of solutions of (4.4). Set $Q := C_2^TC_2$, $S := C_2^TD_2$, and $R := D_2^TD_2$. Problem (4.4) is thus equivalent to find

$$\begin{aligned} J^* = \min_{C_1x(0)+D_1u(0)=b} &\left\{ [x^T(0)u^T(0)] \begin{bmatrix} Q & S \\ S^T & R \end{bmatrix} \begin{bmatrix} x(0) \\ u(0) \end{bmatrix} \right. \\ &\left. + \min_{u_{|[1,+\infty)}} \sum_{t=1}^{\infty} [x^T(t)u^T(t)] \begin{bmatrix} Q & S \\ S^T & R \end{bmatrix} \begin{bmatrix} x(t) \\ u(t) \end{bmatrix} \right\}. \end{aligned} \tag{4.14}$$

As we have shown in section 3 or in subsection 4.2, we can assume that $\mathcal{B}$ is reduced with respect to $R_2(\sigma)$. This assumption, in view of Proposition 4.1, implies that, in the representation (4.3), the output stabilizability space of (A, B, C_2, D_2) is the whole space $\mathbb{R}^n$. In turn, this implies that the optimization problem

$$J_1^* = \min_{u_{|[1,+\infty)}} \sum_{t=1}^{\infty} [x^T(t)u^T(t)] \begin{bmatrix} Q & S \\ S^T & R \end{bmatrix} \begin{bmatrix} x(t) \\ u(t) \end{bmatrix} \tag{4.15}$$

subject to

$$\left\{ \begin{aligned} x(t+1) &= Ax(t) + Bu(t), \\ x(1) &= x_1, \end{aligned} \right. \tag{4.16}$$

admits solutions u which render the cost function J_1 finite for all $x_1 \in \mathbb{R}^n$ [10]. Hence [10] the ARE[1]

$$M = Q + A^TMA - (S + A^TMB)(R + B^TMB)^\sharp(S^T + B^TMA) \tag{4.17}$$

admits a minimum positive semidefinite solution M_∞ which can be computed iterating the corresponding difference Riccati equation starting from $M(0) = 0$ (see [19, Chapter 4]). Moreover, minimization (4.15) can be performed in closed form yielding

[1] Given a matrix Δ, $\Delta^\sharp$ will denote the Moore–Penrose pseudoinverse of Δ.

$J_1 = x(1)^T M_\infty x(1)$, and the set of optimal state and input trajectories are given by the solution of the following linear system:

$$\left\{\begin{array}{l} x(t+1) = Fx(t) + Jv(t), \\ u(t) = Kx(t) + Gv(t), \\ x(1) = x_1, \end{array}\right. \tag{4.18}$$

where

$$K := -(R + B^T M_\infty B)^\sharp (S^T + B^T M_\infty A), \tag{4.19a}$$

$$G := I - (R + B^T M_\infty B)^\sharp (R + B^T M_\infty B), \tag{4.19b}$$

$$F := A + BK, \tag{4.19c}$$

$$J := BG, \tag{4.19d}$$

and v is an arbitrary trajectory parametrizing the set of optimal solutions.

We can now perform the first minimization of (4.14). This reduces (4.14) to the following form:

$$\begin{aligned} &\min_{C_1 x(0) + D_1 u(0) = b} [x^T(0) u^T(0)] \begin{bmatrix} Q & S \\ S^T & R \end{bmatrix} \begin{bmatrix} x(0) \\ u(0) \end{bmatrix} + x(1)^T M_\infty x(1) \\ &= \min_{C_1 x(0) + D_1 u(0) = b} [x^T(0) u^T(0)] \begin{bmatrix} Q + A^T M_\infty A & S + A^T M_\infty B \\ S^T + B^T M_\infty A & R + B^T M_\infty B \end{bmatrix} \begin{bmatrix} x(0) \\ u(0) \end{bmatrix}. \end{aligned} \tag{4.20}$$

The latter is a static optimization problem which admits solutions if and only if $b \in \text{im } [C_1 \ D_1]$. In this case the set of solutions is given by [14, p. 235]

$$\begin{bmatrix} x(0)^* \\ u(0)^* \end{bmatrix} = \Xi b + Z\xi, \tag{4.21}$$

where ξ is an arbitrary vector and the matrices Ξ and Z are given by

$$\begin{aligned} \Xi &= (\Delta + H^T H)^\sharp H^T [H(\Delta + H^T H)^\sharp H^T]^\sharp, \\ Z &= I - (\Delta + H^T H)^\sharp (\Delta + H^T H), \end{aligned} \tag{4.22}$$

where $H := [C_1 \ D_1]$ and $\Delta := \begin{bmatrix} Q + A^T M_\infty A & S + A^T M_\infty B \\ S^T + B^T M_\infty A & R + B^T M_\infty B \end{bmatrix}$.

This static optimization furnishes the set of vectors $x(0)^*$ and $u(0)^*$, which minimize the cost function. From them, using the state update equation, we find the optimal $x(1)$. Initializing system (4.18) with this $x(1)$, we have a parametrization of all the optimal trajectories x, u. Using (4.3), we immediately get a parametrization of all the optimal trajectories w of $\mathcal{B}$.

In the case when $b \notin \text{im } [C_1 \ D_1]$, all the trajectories of the behavior $\mathcal{B}$ which satisfy the static constraint give rise to an infinite cost, or, equivalently, the problem is not solvable.

5. Concluding remarks. Since in the classical LQ optimization problem, the optimal control can be expressed as a linear state feedback, the question that naturally arises is whether or not this form of the solution remains valid in our setup. In the behavioral approach, feedback control is interpreted as an interconnection of systems which corresponds to an intersection of behaviors [24]. The previous issue reduces then to the following question. Does there exist an AR system (controller) $\Sigma_{ct} =$

$(\mathbb{Z}, \mathbb{R}^q, \mathcal{B}_{ct})$ such that $\mathcal{B}_{opt} = \mathcal{B} \cap \mathcal{B}_{ct}$, where $\mathcal{B}_{opt} = \{\mathcal{T}(b) : \ b \in \mathbb{R}^s\}$? This can occur only if the set $\mathcal{B}_{opt}$ is linear shift-invariant and complete. The following examples show that this is not true in general.

Example 1. Let $\Sigma = (\mathbb{Z}, \mathbb{R}, \mathcal{B})$ and $\mathcal{B} = \mathbb{R}^{\mathbb{Z}}$, and let $w_2 = w$ and $w_1 = (1+\sigma)w$. In this case the optimization problem is

$$J(w) = \min_{w(0)+w(1)=b} \sum_{t=0}^{\infty} w^2(t) = \min_{w(0)+w(1)=b} (w(0)^2 + w(1)^2). \tag{5.1}$$

The solution is easily $w(0) = w(1) = b/2$ and $J_{opt} = b^2/2$. The set of optimal trajectories, as b spans all the real axis $\mathbb{R}$, is

$$\mathcal{B}_{opt} = \{w \in \mathbb{R}^{\mathbb{Z}} : \ w(1) = w(0)\}. \tag{5.2}$$

Clearly this set is not shift-invariant.

One may suspect that the solution may be expressed as linear feedback at least in particular cases, for example, when the behavior $\mathcal{B}$ is autonomous or in correspondence of a classical LQ problem for descriptor systems. This is not the case as the following examples show.

Example 2. Let $\mathcal{B}$ be described by the following state model:

$$\left\{ \begin{array}{c} x(t+1) = Ax(t), \\ w(t) = x(t), \end{array} \right. \qquad t \in \mathbb{Z}, \tag{5.3}$$

where $A = \operatorname{diag}(1/2, 1/4)$. Let $w_1(t) = C_1 w(t)$ and $w_2(t) = C_2 w(t)$, where $C_1 = [1 \ 1]$ and $C_2 = \operatorname{diag}(\sqrt{3}/2, \sqrt{15}/4)$. It is easy to see that, as b spans all the real axis $\mathbb{R}$, the set of optimal trajectories is

$$\mathcal{B}_{opt} = \left\{ w(t) = A^t \begin{bmatrix} a \\ a \end{bmatrix} : \ a \in \mathbb{R} \right\}. \tag{5.4}$$

Again, it is immediate to check that this set is not shift-invariant.

Example 3. Let $\mathcal{B}$ be described by the following state model:

$$\left\{ \begin{array}{c} 0 = x(t) + u(t), \\ w(t) = x(t), \end{array} \right. \qquad t \in \mathbb{Z}. \tag{5.5}$$

Let $w_1(t) = w_2(t) = w(t)$. It is easy to see that, as b spans all the real axis $\mathbb{R}$, the set of optimal trajectories is

$$\mathcal{B}_{opt} = \{b\delta(t) : \ b \in \mathbb{R}\}. \tag{5.6}$$

Clearly, this set is not shift-invariant.

Observe, moreover, that in the formulation of a practical problem in the form (2.4), the dimension of the trajectories vector w may be very large. However, the reduction described in section 3.2 and the fact that the realization (4.3) is assumed to be state trim insure that the complexity of the resulting Riccati equation is in any case minimal. In other words, the complexity of the presented method is minimal.

The last observation we want to make concerns our technique for the solution of the optimization problem. One of the basic philosophies of the behavioral approach is to express the solution of a problem directly in terms of the data in which the problem is formulated. In our case the data of the problem are the polynomial matrices $R(\sigma)$,

$R_1(\sigma)$, $R_2(\sigma)$, and the vector b, and it would be desirable to describe the optimal trajectories in terms of these data. In this paper we have not been able to achieve this goal, since the solution we propose is obtained by passing through intermediate state space representations. The research of a solution realizing this goal remains a subject of our present investigation.

FROM THE MOSCO AND SLICE CONVERGENCES FOR CONVEX NORMAL INTEGRANDS TO THAT OF INTEGRAL FUNCTIONALS ON L^p SPACES*

JÉRÔME COUVREUX†

Abstract. Given a sequence of integrands $f_n : T \times X \to R$ $(n \geq 1)$ which converges in the sense of the slice-topology to an integrand f, $(T, \mathcal{A}, \mu)$ being a complete probability space and X a nonreflexive Banach space with separable dual, we show that the sequence of integral functionals $I(f_n) : u \to \int f_n(t, u(t))d\mu$ $(n \geq 1)$ associated to the (f_n) converges to $I(f) : u \to \int f(t, u(t))d\mu$ in the sense of the slice-topology on $L^p(X)$ and that the sequence of integral functionals associated to the conjugate integrands (f_n^*) converges to $I(f^*) : u \to \int f^*(t, u(t))d\mu$ on $L^q(X^*)$ (with $1 \leq p < +\infty$ and $p^{-1} + q^{-1} = 1$). This is an extension of some results which were shown to hold by Joly and de Thélin for Painlevé–Kuratowski convergence when X is finite dimensional and by Salvadori for Mosco convergence when X is reflexive. We also need to provide some criteria for functional convergence in the slice-topology, using the strong epigraphical upper limit.

Key words. integrands, integral functionals, measurable multifunctions, epi-convergence, slice-topology

1. Introduction.

Epi-convergence was introduced by several authors for the study of minimization problems. It is known that the important fact about epi-convergence of a sequence of functions $f_n : X \to R$ $(n \geq 1)$ is that, in the presence of appropriate compactness assumptions (see [At]) this type of convergence entails nice properties of the infimal values $\inf\{f_n(x)/x \in X\}$ and of the set of minimizers *Argmin* f_n. Recall that, moreover, epi-convergence of such a sequence of functions is a special case of set convergence: it means Painlevé–Kuratowski convergence (see [Ku, At, Be1]) of the sequence of their epigraphs regarded as subsets of the product space $X \times R$. We shall be led to use natural extensions of Painlevé–Kuratowski convergence to infinite dimensional spaces, namely the Mosco type convergences. These convergences consist in the Painlevé–Kuratowski convergence of sequences of subsets with respect to, at the same time, two different topologies on a Banach space X: for example, the weak and strong topologies, which was the case originally considered by Mosco [Mo1]. Mosco convergence of epigraphs, induces a functional convergence which is often called Mosco convergence. When X is finite dimensional, Mosco and Painlevé–Kuratowski convergences coincide on $\mathcal{F}(X)$ (the space of all nonempty closed subsets of X). Further, a topology was introduced on $\mathcal{F}(X)$ by Beer [Be1], namely, the Mosco topology, which is compatible with the original Mosco convergence on $\mathcal{F}_c(X)$ (the space of all nonempty closed convex subsets of X). The most important properties of Mosco topology hold on $\mathcal{F}_c(X)$ when the Banach space X is reflexive and separable. Another topology was then introduced on $\mathcal{F}_c(X)$ (or on $\mathcal{F}(X)$), which entails a convergence stronger than Mosco's convergence and whose properties are interesting even without reflexivity: it is the slice-topology. This topology was first

considered by Joly and more recently by Sonntag and Zalinescu in a survey article (see [SZ]). The slice-topology was in fact intensively studied by Beer [Be2, Be3, Be4, Be6], who has shown its nice properties. Notice also that the term "slice" is due to Beer. As for Painlevé–Kuratowski and Mosco convergences, the slice-topology induces a useful functional convergence. The Painlevé–Kuratowski convergence, as well as the slice-topology, have interesting variational properties. More precisely, the polarity, regarded as a map from $\mathcal{F}_c(X)$ into the set of w*-closed convex subsets of X^*, is bicontinuous with respect to the slice-topology. This continuity property has already been shown to hold for the Painlevé–Kuratowski convergence by Wijsman [Wi] when X is finite dimensional and by Mosco when it is reflexive. In turn, for convex functions identified with epigraphs, this implies the continuity of conjugacy with respect to epi-convergence, which is most useful for approximating the solutions of optimization problems (see [At, Be6, Mo1]).

The purpose of this paper is to present some results about the Mosco convergence and the convergence in the slice-topology for integral functionals. Given an integrand f, that is an extended real-valued function defined on the product $T \times X$, where here $(T, \mathcal{A}, \mu)$ and X are, respectively, a complete probability space and a Banach space, we consider the integral functional defined on $L^p(X) 1 \leq p \leq +\infty$ (the space of all—equivalence classes—of Bochner integrable functions) by $I(f) : u \rightarrow \int f(t, u(t)) d\mu$. These integral functionals were introduced by Rockafellar in [Ro1, Ro2] and were studied in many papers (see, for instance, [Ro5, CV, JT, HU, Sa, CH, Cou]). The epi-convergence of integral functionals associated to a sequence of integrands $f_n : T \times X \rightarrow R$ $(n \geq 1)$ was first studied by Joly and de Thélin [JT] when X is finite dimensional. This result was extended for an infinite dimensional reflexive and separable Banach space X by Salvadori: this author shows (see [Sa, Theorem 3.1]) that when dealing with a sequence (f_n) which Mosco converges to an integrand f, the sequence $(I(f_n))$ of the integral functionals associated to the (f_n) Mosco converges to $I(f)$ on $L^1(X)$ and the sequence $(I(f_n^*))$, where f_n^* denotes the integrand conjugate of f_n, Mosco converges to $I(f^*)$ on $L^\infty(X^*)$. Our present objective is to provide a similar result where the Mosco functional convergence is replaced by the one deduced from the slice-topology. Considering a sequence of integrands $f_n : T \times X \rightarrow R$ $(n \geq 1)$ which converges in the sense of the slice-topology to an integrand f, where X is then a nonreflexive Banach space with separable dual, we show that the sequence of integral functionals associated to the (f_n) converges to $I(f)$ in the sense of the slice-topology on $L^p(X)$ and that the sequence of integral functionals associated with the conjugate integrands (f_n^*) converges to $I(f^*)$ on $L^q(X^*)$ (with $1 \leq p < +\infty$ and $p^{-1} + q^{-1} = 1$).

The paper is organized as follows. In section 2, we give the needed notations and preliminaries. In section 3 some criteria for functional convergence in the sense of the slice-topology are presented. The main results are expressed in section 4. Section 5 deals with some useful properties of integrands and integral functionals, and finally, section 6 contains the proofs of the main results.

2. Definitions and notations. Throughout this section X will be a separable Banach space whose norm is $\|\,.\,\|$. We denote by $\mathcal{P}(X)$ the space of all subsets of X, by $\mathcal{F}(X)$ (resp., $\mathcal{F}_c(X)$, $\mathcal{F}_{cb}(X)$) the family of all nonempty closed (resp., nonempty closed convex, nonempty closed convex and bounded) subsets of X for strong topology, and by $\mathcal{F}_{c^*}(X^*)$ (resp., $\mathcal{F}_{c^*b}(X^*)$) the family of nonempty closed convex (resp., nonempty closed convex and bounded) subsets of X^* for weak star topology. The indicator function associated to $A \in \mathcal{P}(X)$ is the function $\delta(.\,, A)$ such that $\delta(x, A) = 0$ if $x \in A$ and $\delta(x, A) = +\infty$ if $x \notin A$. We write also $\mathcal{B}(X)$ for the Borel tribe of X. The closed ball with center x and radius r is denoted $B(x, r)$.

The *distance function* of $F \in \mathcal{P}(X)$ and its *support function* are defined, respectively, by

$$d(x,F) = \inf\{\|x-y\|/y \in F\},\ x \in X \text{ and } s(x^*,F) = \sup\{\langle x^*,x\rangle/x \in F\},\ x^* \in X^*.$$

The *gap* between two subsets F and G of X is defined by

$$D(F,G) = \inf\{\|x-y\|/x \in F, y \in G\}.$$

Let T be an abstract space. A *multifunction* F is a map from T to $\mathcal{P}(X)$. The *domain* of F is the following subset of T:

$$dom\ F = \{t \in T/F(t) \neq \emptyset\}.$$

A *selection* of such a multifunction F is a function $s : T \to X$ such that for all $t \in dom\ F$, $s(t) \in F(t)$.

Suppose now that $(T,\mathcal{A})$ is a measurable space. A multifunction $F : T \to \mathcal{P}(X)$ is said to be *Effros-measurable* or *measurable* (see [Be2, CV, He2, Him]) if for every open set U in X

$$F^-U \in \mathcal{A}, \quad \text{where} \quad F^-U = \{t \in T/F(t) \cap U \neq \emptyset\}.$$

The *Effros sigma algebra* is denoted by $\mathcal{E}(\mathcal{F}(X))$. It is the smallest sigma algebra of subsets of $\mathcal{F}(X)$ containing all sets of the form $\{A \in \mathcal{F}(X)/A \cap V \neq \emptyset\}$, where V runs over the open subsets of X. Notice that when $\mathcal{F}(X)$ is equipped with some topology $\mathcal{T}$ (see also section 3), if the Effros tribe coincides with the Borel tribe associated with $\mathcal{T}$, then a multifunction $F : T \to \mathcal{F}(X)$ is Effros measurable if and only if it is Borel measurable.

A *measurable multifunction* defined on a probability space may be also called a *random set.* A *measurable selection* of a measurable multifunction F is a selection of F that is $(\mathcal{A},\mathcal{B}(X))$-measurable, and a *Castaing representation* of F is a sequence $s_n : T \to X$ $(n \geq 1)$ of measurable selections of F satisfying for all $t \in dom\ F$, $F(t) = cl\{s_n(t)/n \geq 1\}$. Let $f : X \to [-\infty,+\infty]$ be a function. Its *epigraph* is the following subset of $X \times R$:

$$\acute{e}pi\ f = \{(x,\alpha) \in X \times R/f(x) \leq \alpha\}.$$

Its *domain* is $dom\ f = \{x \in X/f(x) < +\infty\}$. The function f is said to be *proper* if for all $x \in X$, $f(x) > -\infty$ and if for some $x \in X$, $f(x) < +\infty$. The *conjugate* of the function f is defined by

$$f^*(x^*) = \sup\{\langle x^*,x\rangle - f(x)/x \in X\}, \quad x^* \in X^*.$$

Let T be again an abstract space. Every map $f : T \times X \to [-\infty,+\infty]$ is called an *integrand.* The *integrand conjugate* of f is $f^* : T \times X^* \to [-\infty,+\infty]$ defined by

$$f^*(t,x^*) = \sup\{\langle x^*,x\rangle - f(t,x)/x \in X\}, \quad (t,x^*) \in T \times X^*.$$

The *epigraphical multifunction* associated to an integrand f is $F : t \to epi\ f(t,.)$. Let $(T,\mathcal{A})$ be still a measurable space. If the epigraphical multifunction $F(t) = epi\ f(t,.)$ is measurable, f is called a *normal integrand.* Assume that a probability measure μ is given on $(T,\mathcal{A})$. If for almost every $t \in T$ the function $f(t,.)$ satisfies any property $(\mathcal{P})$ (for instance $f(t,.)$ is lower semicontinuous, convex, etc.), the integrand f is said to satisfy $(\mathcal{P})$. Let $(T, \mathcal{A}, \mu)$ be a complete probability space. A lower semicontinuous (lsc) integrand $f : T \times X \to [-\infty, +\infty]$ is *normal* if and only if it is $\mathcal{A} \otimes \mathcal{B}(X)$-measurable.

We write $L^\circ(T, \mathcal{A}, X)$, or $L^\circ(X)$ for the space of (equivalence classes of) $(\mathcal{A}, \mathcal{B}(X))$-measurable functions that are defined on T with values in X. We write also $L^p(T, \mathcal{A}, \mu, X)$ or $L^p(X)$ $(1 \leq p \leq +\infty)$ for the space of (classes of) functions f such that $t \to \|f(t)\|_X$ belongs to $L^p(T, \mathcal{A}, \mu, R)$. For every multifunction $F : T \to \mathcal{P}(X)$ and each p with $1 \leq p \leq +\infty$, let us set

$$S^p(F, \mathcal{A}) = \{f \in L^p(T, \mathcal{A}, \mu, X)/f(t) \in F(t) \text{ almost surely (a.s.)}.$$

The *integral function* associated to a normal and lsc integrand $f : T \times X \to [-\infty, +\infty]$ is the functional defined on $L^p(X)(1 \leq p \leq +\infty)$ by

$$I(f) : L^p(T, \mathcal{A}, \mu, X) \to [-\infty, +\infty],$$

$$u \to \int f(t, u(t))\, d\mu.$$

Let us consider now two functions f, $g : X \to [-\infty, +\infty]$. The *epi-sum* (or *infimal convolution*) of f and g is the function, denoted by $f +_e g$, defined by

$$(f +_e g)(x) = \inf\{f(w) + g(x - w)/w \in X\}, \quad x \in X.$$

An important tool in convex analysis is the method of *regularization* in which a given function f is approximated by the epi-sum of f with members of a parametrized family of smoothing kernels, such that when the parameter approaches zero from above, the epi-sums “converge” to the initial function. Regularization by kernels of the form $k\|\,.\,\|$ $(k > 0)$ is often called *Lipschitz* or *Baire–Wijsman regularization*, and regularization by kernels of the form $(k/2)\|\,.\,\|^2 (k > 0)$ is known as *Moreau–Yosida regularization* (see [Be6]). In what follows we need to use regularization by kernels of the form $\{k\|\,.\,\|^p/k > 0\}$ with $1 \leq p < +\infty$. So we set

$$f^{k,p}(x) = (f +_e k\|\,.\,\|^p)(x) = \inf\{f(u) + k\|u - x\|^p/u \in X\}.$$

Proposition 2.1. *Let $f : T \times X \to\ ]-\infty, +\infty]$ be a normal and lsc integrand. The integrand defined for each $t \in T$ by $f^{k,p}(t, .)$ is a normal and continuous integrand.*

As may be well known by the reader, the Lipschitz regularization with parameter k of some function f is the largest Lipschitz continuous function with constant k that f majorizes (see [Be6]). Considering the regularization by kernels of the form $\{k\|\,.\,\|^p/k > 0\}$ $1 \leq p < +\infty$, we have the following result.

Proposition 2.2. *Let $f : X \to\ ]-\infty, +\infty]$ be a proper function, and let k, p be such that $0 < k < +\infty$ and $1 \leq p < +\infty$. Then for each x and w in X, we have $f^{k,p}(x) \leq f^{2^{p-1}k,p}(w) + 2^{p-1}k\|x - w\|^p$.*

Proof. Let us fix x and w in X, α arbitrary such that $f^{2^{p-1}k,p}(w) < \alpha$ and choose $z \in X$ with $f(z) + 2^{p-1}k\|w - z\|^p < \alpha$. We compute

$$f^{k,p}(x) \leq f(z)+k\|x-z\|^p \leq f(z)+2^{p-1}k\|x-w\|^p+2^{p-1}k\|w-z\|^p \leq \alpha+2^{p-1}k\|x-w\|^p.$$

Since α was arbitrary, the wanted result holds. □

Throughout this paper $(T, \mathcal{A}, \mu)$ will be a complete probability space.

3. The topological concept: Definitions and criteria. Let (Y, ρ) be an abstract topological space and $f_n : Y \to [-\infty, +\infty]$ $(n \geq 1)$ a sequence of functions. We denote by $\mathcal{V}(x)$ the family of neighborhoods of $x \in Y$ relatively to topology ρ. The following functions are said to be, respectively, the *ρ-epigraphical* (*or ρ-epi*) *lower limit* and the *ρ-epigraphical* (*or ρ-epi*) *upper limit* of the sequence (f_n):

$$(\rho\text{-}li_e f_n)(x) = \sup\nolimits_{V \in \mathcal{V}(x)} \liminf\nolimits_{n \geq 1} \inf\nolimits_{u \in V} f_n(u),$$
$$(\rho\text{-}ls_e f_n)(x) = \sup\nolimits_{V \in \mathcal{V}(x)} \limsup\nolimits_{n \geq 1} \inf\nolimits_{u \in V} f_n(u).$$

When these two functions are equal, the common value is called the *ρ-epigraphical* (*or ρ-epi*) *limit* of (f_n), it is denoted by $\rho\text{-}\lim_e f_n$, and the sequence (f_n) is said to be *epi-convergent.* Moreover, let us notice (see [At, Theorem 1.13]) that if Y is a metric space whose strong topology is denoted by s, we have

$$(s\text{-}ls_e f_n)(x) = \min \{\limsup\nolimits_{n \geq 1} f_n(x_n)/(x_n) \ \textit{such that}\ x = s\text{-}\lim\, x_n\}. \tag{3.1}$$

The reader interested in studying more precisely epi-convergence and its nice properties should refer to [At].

If (C_n) is a sequence in $\mathcal{F}(Y)$, we put

$$\rho\text{-}li\ C_n = \{x \in Y/x = \rho\text{-}\lim x_n, x_n \in C_n, n \geq 1\},$$
$$\rho\text{-}ls\ C_n = \{x \in Y/x = \rho\text{-}\lim x_k, x_k \in C_{n(k)}, k \geq 1\}.$$

ρ-*li* C_n and ρ-*ls* C_n are, respectively, the *ρ-lower limit* and the *ρ-upper limit* of (C_n). We say that (C_n) *converges in the sense of Painlevé–Kuratowski* to C relatively to the topology ρ, which is denoted by $C = \rho\text{-}\lim C_n$, if the two following equalities are satisfied:

$$C = \rho\text{-}li\ C_n = \rho\text{-}ls\ C_n.$$

Let σ be another topology on Y. The sequence (C_n) is said to be *Mosco convergent* to C with respect to ρ and σ, and we write $C = M(\rho, \sigma)\text{-}\lim C_n$ if

$$C = \rho\text{-}\lim C_n = \sigma\text{-}\lim C_n.$$

In the special case where σ is finer than ρ, these last equalities are equivalent to the following inclusions: $\rho\text{-}ls\ C_n \subset C \subset \sigma\text{-}li\ C_n$. Let us now denote, respectively, by w and s the weak and strong topologies of a normed space X. Following Mosco [Mo1], a subset C is said to be the *Mosco limit* of a sequence (C_n) in $\mathcal{F}(X)$ if $C = M(w, s)\text{-}\lim C_n$, which may be denoted by $C = M\text{-}\lim C_n$. For more about Mosco convergence, the reader can refer to [Mo1] or [Be1, Be3]. A sequence of extended real functions (f_n) defined on Y is said to be *Mosco convergent* to a function f with respect to the topologies ρ and σ, which is denoted by $f = (M(\rho, \sigma), Y)\text{-}\lim f_n$ if *epi* $f = M(\rho, \sigma)\text{-}\lim\, epi\ f_n$. Moreover (see [Mo1] or [Be1]), we know that $f = (M(\rho, \sigma), Y)\text{-}\lim f_n$ (with $\rho \leq \sigma$) if and only if conditions (3.2) and (3.3) below are satisfied:

for every $x \in Y$, there exists a sequence (x_n) in Y with $x = \sigma\text{-}\lim x_n$ such that

$$\limsup f_n(x_n) \leq f(x), \tag{3.2}$$

for any subsequence (f_{n_k}) of (f_n), if $x \in Y$ is such that $x = \rho\text{-}\lim x_k$, then

$$\liminf f_{n_k}(x_k) \geq f(x). \tag{3.3}$$

Let us consider again a separable Banach space X. A *slice of a ball* is the intersection of a closed ball and a closed half space passing through the interior of the ball. The *slice-topology* on $\mathcal{F}(X)$ is the weak (or initial) topology determined by the family $\{D(B,.)/B$ is a nonempty slice of a ball$\}$. It is denoted by $\mathcal{T}_s$. About the properties of this topology the reader can refer to the intensive works of Beer [Be2, Be3, Be4 and Be6]. Further, from Beer [Be3, Theorem 5.2] we know that the slice-topology restricted to $\mathcal{F}_c(X)$ is the weak topology determined by the family $\{D(B,.)/B \in \mathcal{F}_{cb}(X)\}$. The *dual slice-topology* that is denoted by $\mathcal{T}_s^*$ is the topology on $\mathcal{F}_{c^*}(X^*)$ generated by the family $\{D(B,.)/B \in F_{c^*b}(X^*)\}$. A sequence of extended real functions (f_n) defined on X is said to be convergent to a function f in the sense of the slice-topology, which is denoted by $f = (\mathcal{T}_s, X)\text{-}\lim f_n$ if *epi* $f = \mathcal{T}_s\text{-}\lim$ *epi* f_n.

Wijsman's topology on $\mathcal{F}(X)$, which is denoted by $\mathcal{T}_w$, is the topology of pointwise convergence of distance functions. It was introduced in [Wi] when X is finite dimensional. A sequence (C_n) of closed sets is said to converge to C in the Wijsman topology if, for every $x \in X$, one has $d(x, C) = \lim d(x, C_n)$. For more about the nice properties of this topology, see [Wi, Be2, Be4, He2]. A sequence of extended real functions (f_n) defined on X is said to be convergent to a function f in the sense of the convergence deduced from Wijsman's topology, which is denoted by $f = (\mathcal{T}_w, X)\text{-}\lim f_n$ if *epi* $f = \mathcal{T}_w\text{-}\lim$ *epi* f_n. Notice that the slice-topology is the supremum of all Wijsman's topologies varying the norm on equivalent norms (see [Be4]).

X being still a Banach space, let us consider the space $\mathcal{F}(X)$ equipped with Wijsman's topology $\mathcal{T}_w$. Following Hess [He1, Theorem 3.1.1, P1.6], we know that the Effros tribe $\mathcal{E}(\mathcal{F}(X))$ coincides with the Borel tribe associated with Wijsman's topology $\mathcal{T}_w$ on $\mathcal{F}(X)$. That means that a multifunction $F : T \to \mathcal{F}(X)$ is Effros measurable if and only if it is Borel measurable. Moreover, Beer has shown that if X has a strongly separable dual X^*, then the Borel tribe associated with the slice-topology $\mathcal{T}_s$ on $\mathcal{F}(X)$ still coincides with the Effros tribe (see, for instance, Theorem 5.8 in [Be2]).

We ought to establish now some criteria for functional convergence in the slice-topology. They are given in Propositions 3.4 and 3.6, below. Proposition 3.4 is a result which is easily deduced from the fundamental statement recalled in Proposition 3.1 (Proposition 4.1 of [Be3]). Notice that a more precise result than Proposition 3.4 has been obtained by Attouch and Beer: it is Theorem 3.1 in [AB], where the given conditions need only to hold at points x in *dom* ∂f and x^* in Range ∂f. But for the convenience of the reader, in what follows, we choose to build easily Proposition 3.4 from Proposition 3.1.

In the following results, X will be a Banach space.

Proposition 3.1. *Let f, $f_n : X \to\ ]-\infty, +\infty]$ $(n \geq 1)$ be proper lsc and convex functions. Then, the following properties are equivalent.*

(a) $f = (\mathcal{T}_s, X)\text{-}\lim f_n$.

(b) *For every open subset W of X and each $\alpha \in R$, the condition epi $f \cap \{W \times]-\infty, \alpha[\} \neq \emptyset$ implies that epi $f_n \cap \{W \times]-\infty, \alpha[\} \neq \emptyset$ eventually, and for every open subset V of X^* and each $\alpha' \in R$, the condition epi $f^* \cap \{V \times]-\infty, \alpha'[\} \neq \emptyset$ implies that epi $f_n^* \cap \{V \times]-\infty, \alpha'[\} \neq \emptyset$ eventually.*

Lemma 3.2 below will be useful for proving Proposition 3.3.

Lemma 3.2. *Let (C_n) be a sequence of $\mathcal{F}(X)$. The following statements are equivalent:*

(a) *$C \subset$ s-li C_n;*

(b) *for each open subset V of X satisfying $C \cap V \neq \emptyset$, then $C_n \cap V \neq \emptyset$ eventually.*

Proof. The proof of (a) $\Longrightarrow$ (b) follows from the definition of the strong lower limit. For proving (b) $\Longrightarrow$ (a) let us consider one $x \in C$. Because of assumption (b) one has for each $k \geq 1$, $C_n \cap B(x, 1/k) \neq \emptyset$ eventually. Then, one can build a sequence $x_n \in C_n$ $(n \geq 1)$, which converges strongly to x; that is, $x \in$ *s-li* C_n. □

PROPOSITION 3.3. *Let f, $f_n : X \to \ ]-\infty, +\infty]$ $(n \geq 1)$ be proper lsc and convex functions. Then the following properties are equivalent.*

(a) *For each $x \in dom\ f$, $f(x) \geq (s\text{-}ls_e f_n)(x)$;*

(b) *For every open subset W of X and each $\alpha \in R$, the condition epi $f \cap \{W \times]-\infty, \alpha[\} \neq \emptyset$ implies that epi $f_n \cap \{W \times]-\infty, \alpha[\} \neq \emptyset$ eventually.*

Proof. First see that statement (b) is equivalent to the following: for every open subset W of $X \times R$ the condition *epi* $f \cap W \neq \emptyset$ implies that *epi* $f_n \cap W \neq \emptyset$ eventually. Thanks to Lemma 3.2, that means *epi* $f \subset$ *s-li epi* fn. As $s-li$ *epi* $f_n =$ *epi* $(s\text{-}ls_e f_n)$ (see [At, Theorem 1.36]), that provides the result. □

PROPOSITION 3.4. *Let f, $f_n : X \to \ ]-\infty, +\infty]$ $(n \geq 1)$ be proper lsc and convex functions. Then the following statements are equivalent:*

(a) *$f = (\mathcal{T}_s, X)$-lim f_n;*

(b) *for each $x \in dom\ f$, $f(x) \geq (s\text{-}ls_e f_n)(x)$, and for each $x^* \in dom\ f^*$, $f^*(x^*) \geq (s\text{-}ls_e f_n^*)(x^*)$.*

In Proposition 3.5 we ought to state some inequality between the strong epigraphical upper limit of some functions and their regularization by kernels of the form $\{k\|\,.\,\|^p/k > 0\}$ $1 \leq p < +\infty$, the result of which is vital for proving Theorem 4.1. A similar result was established in [He4] for Lipschitz regularization $(p = 1)$.

PROPOSITION 3.5. *Let $f_n : X \to \ ]-\infty, +\infty]$ $(n \geq 1)$ be a sequence of proper lsc and convex functions, and let p be such that $1 \leq p < +\infty$. Then the following properties hold.*

(1) *For every $x \in X$, $(s\text{-}ls_e f_n)(x) \geq \sup_{k>0} \limsup_{n\geq 1} f_n^{k,p}(x)$.*

(2) *If there exists $u_0 \in X$ and $(a, b) \in R^{+*} \times R$ such that for every $x \in X$, $f_n(x) \geq -a\|x - u_0\| - b$, then $(s\text{-}ls_e f_n)(x) \leq \sup_{k>0} \limsup_{n\geq 1} f_n^{k,p}(x)$.*

Proof. (1) For each $p \geq 1$, $k > 0$, $n \geq 1$, and every $x \in X$, one has $f_n(x) \geq f_n^{2^{p-1}k,p}(x)$ so that we can write, using the definition of $s\text{-}ls_e f_n$,

$$\begin{aligned}(s\text{-}ls_e f_n)(x) &= \sup_{\mu\geq 1} \limsup_{n\geq 1} \inf\{f_n(v)/v \in B(x, 1/\mu)\}\\ &\geq \sup_{\mu\geq 1} \limsup_{n\geq 1} \inf\{f_n^{2^{p-1}k,p}(v)/v \in B(x, 1/\mu)\}.\end{aligned}$$

Using Proposition 2.2, it follows that

$$\begin{aligned}&\sup_{\mu\geq 1} \limsup_{n\geq 1} \inf\{f_n(v)/v \in B(x, 1/\mu)\}\\ &\geq \ \sup_{\mu\geq 1} \limsup_{n\geq 1} \inf\{f_n^{k,p}(x) - 2^{p-1}k\|x - v\|^p/v \in B(x, 1/\mu)\}\\ &\geq \sup_{\mu\geq 1}\{\limsup_{n\geq 1}(f_n^{k,p}(x) - 2^{p-1}k/\mu^p)\} = \limsup_{n\geq 1} f_n^{k,p}(x).\end{aligned} \tag{3.4}$$

Since (3.4) is true for each $k > 0$, the wanted inequality holds.

(2) We ought to show that for every $x \in X$,

$$\sup_{\mu\geq 1} \limsup_{n\geq 1} \inf\{f_n(v)/v \in B(x, 1/\mu)\} \leq \sup_{k>0} \limsup_{n\geq 1} f_n^{k,p}(x).$$

Let us define for each $x \in X : w(x) = \sup_{k\geq 1} \limsup_{n\geq 1} f_n^{k,p}(x)$. So, we wish to prove that for all $x \in X$ $(s\text{-}ls_e f_n)(x) \leq w(x)$, the inequality of which is true if $w(x) = +\infty$. Else, let us fix $p \geq 1$ and $\alpha \in]0, 1[$. Consider for each $n \geq 1$, $k \geq 1$, and $p \geq 1$ the following statements:

$$f_n(v) + k\|x - v\|^p \geq \inf\{f_n(u) + k\|x - u\|^p/u \in X\} + \alpha \quad \text{for all } v \notin B(x, 1/\mu) \tag{3.5}$$

and

$$f_n^{k,p}(x) = \inf\{f_n(v) + k\|x - v\|^p/v \in B(x, 1/\mu)\}. \tag{3.6}$$

Clearly (3.5) implies (3.6). Further, fix $k \geq 1$. From the definition of w there exists $n_0(k) \geq 1$ such that for all $n \geq n_0(k)$, $w(x)+\alpha \geq f_n^{k,p}(x)$ so that obviously $w(x)+2\alpha \geq f_n^{k,p}(x)+\alpha$. Our goal is to obtain (3.5) for each $n \geq n_0(k)$ and every $k \geq k_0$, k_0 being chosen later in the proof. It is readily seen that this objective is reached if

$$f_n(v) + k\|x - v\|^p \geq w(x) + 2\alpha. \tag{3.7}$$

But we suppose that for all $v \in X$ and for all $n \geq 1$, $f_n(v) \geq -a\|v-u_0\|-b$. Then, (3.7) holds if $-a\|v-u_0\|-b+k\|x-v\|^p \geq w(x)+2\alpha \Leftrightarrow -a\|v-u_0\|+k\|x-v\|^p \geq w(x)+2\alpha+b$. But as $v \notin B(x, 1/\mu)$, we have $\|x - v\| \geq 1/\mu$ and $-\|u_0 - v\| \geq -\|x - v\| - \|x - u_0\|$. Therefore, (3.4) is implied by

$$k\|x - v\|^p - a\|x - v\| \geq w(x) + 2\alpha + b + a\|x - u_0\|. \tag{3.8}$$

Consequently, (3.8) is true if $k \geq k_0$, where

$$k_0 = \textit{Integer part of } \{\max\{\mu^{p-1}(\mu(w(x) + 2\alpha + b + a\|x - u_0\|) + a); a\mu^{p-1}\}\} + 1$$

Thus, if $k \geq k_0$, (3.5) is obtained (for each $n \geq n_0(k)$, and every $v \notin B(x, 1/\mu)$), which, as described above, entails (3.6):

$$f_n^{k,p}(x) = \inf\{f_n(v) + k\|x - v\|^p/v \in B(x, 1/\mu)\}.$$

Hence, it follows that for every $k \geq k_0$

$$w(x) + \alpha \geq \limsup_{n\geq 1} f_n^{k,p}(x) = \limsup_{n\geq 1} \inf\{f_n(v) + k\|x - v\|^p/v \in B(x, 1/\mu)\}.$$

This inequality being true for any $\mu \geq 1$ and any $\alpha \in]0, 1[$, then $s\text{-}ls_e f_n(x) \leq w(x)$, and then $s\text{-}ls_e f_n(x) \leq \sup_{k>0} \limsup_{n\geq 1} f_n^{k,p}(x)$, which finishes the proof. □

REMARK. *Similar inequalities could be stated with the strong epigraphical lower limit, but the proof is left to the reader.*

Proposition 3.4 together with Proposition 3.5 entails Proposition 3.6 below.

PROPOSITION 3.6. *Let f, $f_n : X \to\ ]-\infty, +\infty]$ $(n \geq 1)$ be proper lsc and convex functions, and let p be such that $1 \leq p < +\infty$.*

1. *If $f = (\mathcal{T}_s, X)\text{-}\lim f_n$, then, for each $x \in$ dom f, $f(x) = \sup_{k>0} \limsup_{n\geq 1} f_n^{k,p}(x)$ and for each $x^* \in$ dom f^*, $f^*(x^*) = \sup_{k>0} \limsup_{n\geq 1} f_n^{*k,p}(x^*)$.*
2. *Suppose that there exists $(a, b) \in R^{+*} \times R$ and $(a', b') \in R^{+*} \times R$ satisfying for each $n \geq 1$, each $x \in X$, and each $x^* \in X^*$, $f_n(x) \geq -a\|x\| - b$ and $f_n^*(x^*) \geq -a'\|x^*\| - b'$. If for each $x \in$ dom f, $f(x) \geq \sup_{k>0} \limsup_{n\geq 1} f_n^{k,p}(x)$ and for each $x^* \in$ dom f^*, $f^*(x^*) \geq \sup_{k>0} \limsup_{n\geq 1} f_n^{*k,p}(x^*)$, then $f = (\mathcal{T}_s, X)\text{-}\lim f_n$.*

Proof. As $f = (\mathcal{T}_s, X)\text{-}\lim f_n, f^* = (\mathcal{T}_x^*, X^*)\text{-}\lim f_n^*$ because of the continuity for the slice-topology of the Young–Fenchel transform (Theorem 4.2 of [Be3]), and we have $f = s\text{-}\lim_e f_n$ and $f^* = s\text{-}\lim_e f_n^*$. But epi-convergence of a sequence of functions at some points of the effective domain of the limit implies uniform linear minorization for the entire sequence (Proposition 3.7 of [Be7]). Then invoking Proposition 3.5 for f in X and for f^* in X^*, the wanted result is understood.

(2) is nothing else than Proposition 3.4 together with (2) of Proposition 3.5. □

4. Main results. This section provides the main results of this paper. From previous section, we know that a sequence of functions (f_n) converges to a function f in the sense of the slice-topology if $f \geq s\text{-}ls_e f_n$ and $f^* \geq s\text{-}ls_e f_n^*$. The purpose of Theorem 4.1 is to tell us that if such an inequality between a sequence of integrands and its strong epigraphical upper limit is almost surely satisfied, then it still holds for the integral functionals associated to them.

Theorem 4.1. *Let X be a separable Banach space, $f_n : T \times X \to \,]-\infty, +\infty\,]$ $(n \geq 1)$ a sequence of normal proper and lsc integrands, $f : T \times X \to \,]-\infty, +\infty]$ a proper integrand, p, q with $1 \leq p < +\infty$, and $p^{-1} + q^{-1} = 1$, satisfying the following assumptions:*

(a) *for almost every $t \in T$ and each $x \in dom\ f(t, .)$, $f(t, x) \geq s\text{-}ls_e f_n(t, x)$;*

(b) *there exists a sequence (u_n) in $L^p(X)$ and functions k and k_0 in $L^p(R)$, such that for each $n \geq 1$, $\|u_n(t)\| \leq k(t)$ and $f_n(t, u_n(t)) \leq k_0(t)$ a.s.;*

(c) *for almost every $t \in T$, each $x \in X$ and each $n \geq 1$, $f_n(t, x) \geq -h(t)\|x\| - h_0(t)$, where h and h_0 belong to $L^q(R)$ with $h(t) > 0$ a.s.*

Then for every function u in $L^p(X)$, $I(f)(u) \geq s\text{-}ls_e I(f_n)(u)$.

In the three following theorems, the Banach space X will have a separable dual X^*. In Theorem 4.2 we state that if a sequence of integrands converges in the sense of the slice-topology on X, then the sequence of associated integral functionals converges in the sense of the slice-topology on $L^p(X)$ $1 < p < +\infty$ and the sequence of conjugate integral functionals converges in the sense of the slice-topology on $L^q(X^*)$ $(p^{-1} + q^{-1} = 1)$.

Theorem 4.2. *Let $f_n : T \times X \to \,]-\infty, +\infty]$ $(n \geq 1)$ be a sequence of normal proper lsc and convex integrands, $f : T \times X \to \,]-\infty, +\infty]$ a proper integrand, and p, q such that $1 < p < +\infty$ and $p^{-1} + q^{-1} = 1$, satisfying the following assumptions:*

(a) *for almost every $t \in T$, $f(t, .) = (\mathcal{T}_s, X)\text{-}\lim f_n(t, .)$;*

(b) *there exists a sequence (u_n) in $L^p(X)$ and functions k and k_0 in $L^P(R)$, such that for each $n \geq 1$, $\|u_n(t)\| \leq k(t)$ and $f_n(t, u_n(t)) \leq k_0(t)$ a.s.;*

(c) *there exists a sequence (v_n) in $L^q(X^*)$ and functions h and h_0 in $L^q(R)$, such that for each $n \geq 1$, $\|v_n(t)\| \leq h(t)$ and $f_n^*(t, v_n(t)) \leq h_0(t)$ a.s.*

Then, $I(f) = (\mathcal{T}_s, L^p(X))\text{-}\lim I(f_n)$ and $I(f^*) = (\mathcal{T}_s^*, L^q(X^*))\text{-}\lim I(f_n^*)$.

The following theorem tells us about the special case of convergence for integral functionals defined on $L^1(X)$. Salvadori has shown (see [Sa, Theorem 3.1]) that if a sequence of integrands $f_n : T \times X \to \,]-\infty, +\infty]$ $(n \geq 1)$ Mosco converges to an integrand f, X being reflexive, then the sequence $(I(f_n))$ Mosco converges to $I(f)$ on $L^1(X)$ with respect to the weak and strong topologies, and the sequence $(I^*(f_n))$ Mosco converges to $I^*(f)$ on $L^\infty(X^*)$ with respect to the Mackey and weak star topologies. Theorem 4.3 below is an extension of Salvadori's property in the nonreflexive case; instead of the Mackey topology, the result deals with a stronger topology, namely, the topology of the uniform, convergence on the uniformly integrable and bounded subsets of $L^1(X)$ (for which we write $\rho(L^\infty(X^*), L^1(X))$ or ρ). Notice that because of Dunford's theorems (see [DU]), the Mackey topology and the topology $\rho(L^\infty(X^*), L^1(X))$ coincide when X is reflexive. Moreover, assuming an additional condition on integrands f and (f_n), this result of convergence holds with respect to the slice-topology.

Theorem 4.3. *Let $f_n : T \times X \to \,]-\infty, +\infty]$ $(n \geq 1)$ be a sequence of normal proper lsc and convex integrands, and let $f : T \times X \to \,]-\infty, +\infty]$ be a proper integrand, such that*

(a) *for almost every $t \in T$, $f(t, .) = (\mathcal{T}_s, X)\text{-}\lim f_n(t, .)$;*

(b) *there exists a sequence* (u_n) *in* $L^1(X)$ *and functions* k *and* k_0 *in* $L^1(R)$, *such that for each* $n \geq 1$, $\|u_n(t)\| \leq k(t)$ *and* $f_n(t, u_n(t)) \leq k_0(t)$ *a.s.;*

(c) *there exists a sequence* (v_n) *in* $L^\infty(X^*)$ *and functions* h *and* h_0 *in* $L^\infty(R)$, *such that for each* $n \geq 1$, $\|v_n(t)\| \leq h(t)$ *and* $f^*_n(t, v_n(t)) \leq h_0(t)$ *a.s.*

(1) *Then,* $I(f) = (M(w,s), L^1(X))\text{-}\lim I(f_n)$ *and* $I(f^*) = (M(w^*,\rho),\ L^\infty(X^*))\text{-}\lim I(f^*_n)$.

(2) *Moreover, if for almost every* $t \in T$, *each* $x \in X$ *and each* $n \geq 1$, $f_n(t,x) \geq f(t,x)$, *then* $I(f) = (\mathcal{T}_s, L^1(X))\text{-}\lim I(f_n)$ *and* $I(f^*) = (\mathcal{T}^*_s, L^\infty(X^*))\text{-}\lim I(f^*_n)$.

Theorem 4.4 is an application of previous theorems that gives some results about the slice-convergence of sets of integrable selections of randoms sets.

Theorem 4.4. *Let* F, $F_n : T \to F_c(X)$ $(n \geq 1)$ *be multifunctions and let* p *be with* $1 \leq p < +\infty$, *such that*

(a) *for almost every* $t \in T$, $F(t) = \mathcal{T}_s\text{-}\lim F_n(t)$;

(b) *the function* $t \to \sup\{d(0, F_n(t))/n \geq 1\}$ *belongs to* $L^p(R)$;

(1) $p = 1$. *If for almost every* $t \in T$, $F_n(t) \subset F(t)$ $(n \geq 1)$, *one has* $S^1(F, \mathcal{A}) = \mathcal{T}_s\text{-}\lim S^1(F_n, \mathcal{A})$;

(2) $1 < p < +\infty$. *One has* $S^p(F, \mathcal{A}) = \mathcal{T}_s\text{-}\lim S^p(F_n, \mathcal{A})$.

5. Some tools about integrands and integral functions. This section is devoted to some results concerning integrands and integral functionals that will be useful in the next section for proving the main results. First we wish some properties of integral functionals to be recalled. For this, the fundamental Proposition 5.1 below, which is due to Hiai and Umegaki [HU, Theorem 2.2], is useful as an important tool. It was used in particular in [Cou] for studying easily conjugacy for integral functionals; that is, if $f : T \times X \to\ ]-\infty, +\infty]$ is a normal and lsc integrand, where $(T, \mathcal{A}, \mu)$ is a complete probability space and X is a separable Banach space, then $I^*(f) = I(f^*)$. We shall use this result in what follows (it is an extension of some results of [Ro1, Ro4] where reflexivity was needed). Here we consider a Banach space with separable dual.

Proposition 5.1. *Let* $f : T \times X \to\ ]-\infty, +\infty]$ *be a normal and lsc integrand, let* $F : T \to \mathcal{F}(X)$ *be a measurable multifunction, and let* p *be such that* $1 \leq p < +\infty$. *If there exists* u_0 *in* $S^p(F)$ *satisfying* $I(f)(u_0) < +\infty$, *then* $\inf\{I(f)(u)/u \in S^p(F)\} = \int \inf\{f(t,x)/x \in F(t)\}\, d\mu$.

The preceding property entails Proposition 5.2 below, which tells us about regularization of integral functionals by kernels of the form $\{k\| \,.\, \|^p/k > 0\}$ $1 \leq p < +\infty$.

Proposition 5.2. *Let* $f : T \times X \to\ ]-\infty, +\infty]$ *be a normal and lsc integrand, and let* k, p *be such that* $k > 0$ *and* $1 \leq p < +\infty$. *If there exists* u_0 *in* $L^p(X)$ *satisfying* $I(f)(u_0) < +\infty$, *then* $I^{k,p}(f) = I(f^{k,p})$.

Proof. $I(f)$ being the integral functional associated to f, for each $u \in L^p(X)$ we compute

$$\begin{aligned} I^{k,p}(f)(u) &= \inf\{I(f)(v) + k(\|u - v\|_{L^p(X)})^p / v \in L^p(X)\} \\ &= \inf\left\{ \int (f(t, v(t)) + k(\|u(t) - v(t)\|_X)^p)\, d\mu / v \in L^p(X) \right\}. \end{aligned}$$

As there exists $u_0 \in L^p(X)$ satisfying $I(f)(u_0) < +\infty$, invoking Proposition 5.1, one has

$$I^{k,p}(f)(u) = \int \inf\{f(t,x) + k(\|u(t) - x\|_X)^p / x \in X\}\, d\mu = I(f^{k,p})(u). \qquad \square$$

In the main results, we suppose the integrands to satisfy some assumptions which were used in [JT] and [Sa]. But as in [Cou], it seems convenient to see them in Lemma 5.3 below as integrability conditions.

LEMMA 5.3. *Let f, $f_n : T \times X \to \ ]-\infty, +\infty]$ $(n \geq 1)$ be proper normal and lsc integrands satisfying for almost every $t \in T$, $f(t, .) = (\mathcal{T}_s, X)\text{-}\lim f_n(t, .)$, and let p be such that $1 \leq p < +\infty$. Let us consider the following statements.*

(a) *There exists a sequence (u_n) in $L^p(X)$ and functions k and k_0 in $L^p(R)$ such that for each $n \geq 1$, $\|u_n(t)\| \leq k(t)$ and $f_n(t, u_n(t)) \leq k_0(t)$ a.s.*

(b) *The function $t \to \sup\{d((0,0);\ epi\ f_n(t, .))/n \geq 1\}$ belongs to $L^p(R)$.*

(c) *There exists a function u_0 in $L^p(X)$ with $I(f)(u_0) < +\infty$.*

Then we have (a) $\Leftrightarrow$ (b) $\Rightarrow$ (c).

Proof. Let us define the measurable functions $t \to r_n(t) = d((0,0),\ epi\ f_n(t, .))$ $(n \geq 1)$ and $t \to r(t) = d((0,0),\ epi\ f(t, .))$.

(a) $\Rightarrow$ (b) As $r_n(t) = \inf\{\|x\| + f_n^+(t, x)/x \in X\}$ (see for instance [Cou]), we have

$$r_n(t) \leq \|u_n(t)\| + f_n^+(t, u_n(t)) \leq k(t) + k_0(t) \text{ a.s.} \quad n \geq 1.$$

(b) $\Rightarrow$ (a) The measurable selection theorem applied to the multifunctions $t \to epi\ f_n(t, .) \cap B((0,0); r_n(t) + 1)$ $(n \geq 1)$ shows the existence of a sequence $(u_n, \alpha_n) : T \to X \times R$ $(n \geq 1)$ such that

$$f_n(t, u_n(t)) \leq \alpha_n(t) \quad \text{and} \quad \|u_n(t)\| + |\alpha_n(t)| \leq r_n(t) + 1 \leq \sup_{n \geq 1} r_n(t) + 1 \text{ a.s.} \quad n \geq 1.$$

The wanted result can then be easily deduced.

(b) $\Rightarrow$ (c) Since the slice-topology is stronger than Wijsman's topology, we have $f(t, .) = (\mathcal{T}_w, X)\text{-}\lim f_n(t, .)$ a.s.; that is $r(t) = \lim_n r_n(t)$. Thus $r(t) \leq \sup_{n \geq 1} r_n(t)$ a.s. and $r \in L^p(R)$. Therefore, as in the proof of (b) $\Rightarrow$ (a), one can easily show the existence of $u_0 \in L^p(X)$ such that $f^+(\,.\,, u_0(.)) \in L^p(R)$. □

6. Proofs of the main results. It remains to provide the proofs of the main results, which is now possible according to previous sections.

Proof of Theorem 4.1. First, let us recall that on $\mathcal{F}_c(X)$ $\mathcal{T}_s$ is stronger than $\mathcal{T}_w$ and that the convergence induced by Wijsman's topology implies Painlevé–Kuratowski convergence. Therefore, see that because of assumptions on the f_n $(n \geq 1)$, f is a proper and lsc integrand. Second, Proposition 5.2 tells us that $I^{k,p}(f)(u) = I(f^{k,p})(u)$ and $I^{k,p}(f_n)(u) = I(f_n^{k,p})(u)$ for all $u \in L^p(X)$, $k > 0$, $n \geq 1$, $1 \leq p < +\infty$.

Using assumption (a) and Proposition 3.5, we have for almost every $t \in T$ and each $x \in X$

$$f(t, x) \geq s\text{-}ls_e f_n(t, x) \geq \sup_{k > 0} \limsup_{n \geq 1} f_n^{k,p}(t, x). \tag{6.1}$$

Then from (6.1) one has $f(t, u(t)) \geq s\text{-}ls_e f_n(t, u(t)) \geq \limsup_{n \geq 1} f_n^{k,p}(t, u(t))$ a.s. for all $u \in L^p(X)$ and for all $k > 0$. Further, we have $f_n^{k,p}(t, u(t)) \leq f_n(t, u_n(t)) + 2^{p-1}k\{\|u(t)\|^p + \|u_n(t)\|^p\} \leq k_0(t) + 2^{p-1}k\{\|u(t)\|^p + (k_0(t))^p\}$, and, invoking Fatou's lemma, we can write

$$\int f(t, u(t))\, d\mu \geq \int \limsup f_n^{k,p}(t, u(t))\, d\mu \geq \limsup \int f_n^{k,p}(t, u(t))\, d\mu. \tag{6.2}$$

Equation (6.2) being true for every $k > 0$, we have

$$I(f)(u) \geq \sup_{k > 0} \limsup_{n \geq 1} I^{k,p}(f_n)(u). \tag{6.3}$$

In order to apply the second property of Proposition 3.5 to the sequence $(I(f_n))$, we wish (6.4) to hold for every $n \geq 1$ and each $u \in L^p(X)$:

$$I(f_n)(u) \geq -h\|u\|_{L^p(X)} - h_0, \quad \text{where } (h, h_0) \in R^{+*} \times R. \tag{6.4}$$

Equation (6.4) can be deduced from assumption (c) and Holder's inequality. Hence, this provides the wanted result; that is, for each $u \in L^p(X)$

$$I(f)(u) \geq s\text{-}ls_e I(f_n)(u). \qquad \square$$

Proof of Theorem 4.2. On one hand, notice that assumption (c) implies that

$$f_n(t,x) \geq \langle x, u_n(t)\rangle - f_n^*(t, v_n(t)) \geq -\|x\|h(t) - h_0(t), \quad (t,x) \in T \times X, \quad n \geq 1,$$

and on the other hand that, similarly, assumption (b) implies that

$$f_n^*(t,x^*) \geq -\|x^*\|k(t) - k_0(t), \quad (t,x^*) \in T \times X^*, \quad n \geq 1.$$

Thus, Theorem 4.1 applied with the sequence $f_n : T \times X \to\ ]-\infty, +\infty]$ $(n \geq 1)$ tells us that for every $u \in L^p(X)$

$$I(f)(u) \geq s\text{-}ls_e I(f_n)(u), \tag{6.5}$$

and, since X^* is also a separable Banach space, that for every function $v \in L^q(X^*)$

$$I(f^*)(v) \geq s\text{-}ls_e I(f_n^*)(v). \tag{6.6}$$

Because of properties of conjugacy for integral functionals, we have $I^*(f) = I(f^*)$ and $I^*(f_n) = I(f_n^*)$ $(n \geq 1)$, so that (6.6) is $I^*(f)(v) \geq s\text{-}ls_e I^*(f_n)(v)$. The wanted result is then provided by (6.5), (6.6), and Proposition 3.4. $\square$

Let us now give the long proof of Theorem 4.3. It can be found in [Cou]. As in Theorem 3.1 in [Sa], we shall use for proving part (1) the well-known criteria for functional Mosco convergence recalled in (3.2) and (3.3); and for proving part (2), we shall use the criteria for functional convergence in the slice-topology expressed in section 3 (see also [Cou]). Moreover, we need to deal with Lemma 6.1, but for the convenience of the reader, we choose to express it after the following proof. Lemma 6.1 is a characterization of topology ρ in terms of measure convergence and may also be seen as an extension of a similar result for the Mackey topology due to Castaing and Grothendieck (see [Ca] and [Gr]).

Proof of Theorem 4.3. 1) Following criteria (3.2) and (3.3) for functional Mosco convergence, we know that $I(f) = (M(w,s),\, L^1(X))\text{-}\lim I(f_n)$ if and only if (6.7) and (6.8) below hold and that $I(f^*) = (M(w^*,\rho),\, L^\infty(X^*))\text{-}\lim\, I(f_n^*)$ if we have (6.9) and (6.10), where

$$\begin{gathered}\text{for each function } u \text{ in } L^1(X), \text{ there exists a sequence } (u_n) \text{ in } L^1(X)\\ \text{with } u = s\text{-}\lim u_n \text{ such that } \limsup I(f_n)(u_n) \leq I(f)(u);\end{gathered} \tag{6.7}$$

$$\begin{gathered}\text{for every sequence } (u_n) \text{ in } L^1(X) \text{ such that } u = \sigma(L^1(X), L^\infty(X^*))\text{-}\lim u_n,\\ \text{then } I(f)(u) \leq \liminf I(f_n)(u_n);\end{gathered} \tag{6.8}$$

$$\begin{gathered}\text{for each function } v \text{ in } L^\infty(X^*), \text{ there exists a sequence } (w_n) \text{ in } L^\infty(X^*) \text{ with}\\ v = \rho(L^\infty(X^*), L^1(X))\text{-}\lim w_n \text{ such that } \limsup I(f_n^*)(w_n) \leq I(f^*)(v);\end{gathered} \tag{6.9}$$

$$\begin{gathered}\text{for every sequence } (v_n) \text{ in } L^\infty(X^*) \text{ such that } v = \sigma(L^\infty(X^*), L^1(X))\text{-}\lim v_n,\\ \text{then } I(f^*)(v) \leq \liminf I(f_n^*)(v_n).\end{gathered} \tag{6.10}$$

Because of Theorem 4.1 and (3.1), (6.7) holds.

We ought to show now that (6.9) holds too. For this, let us consider $v \in L^\infty(X^*)$. If $I(f^*)(v) = +\infty$, then (6.9) is satisfied. Else, let us define the sequence of proper normal and lsc integrands (h_n) where

$$h_n : (t, x^*) \to [f_n^*(t, x^*) - f^*(t, v(t))]^+ \quad (n \geq 1) \tag{6.11}$$

and the sequence of nonempty closed convex and measurable multifunctions F_n with

$$\begin{aligned} F_n : t \to \{x^* \in B^*(t)/\|v(t) - x^*\| + h_n(t, x^*) \\ \leq \ \inf[\|v(t) - u^*\| + h_n(t, u^*)/u^* \in B^*(t)] + 1/n\} \quad (n \geq 1). \end{aligned} \tag{6.12}$$

B^* is the multifunction defined by $B^* : t \to \{x^* \in X^*/\|v(t) - x^*\| \leq R\}$, where $R = Ess\sup\{\|v(t)\| + |h(t)|/t \in T\}$ $(R > 0)$. For each $n \geq 1$, the multifunction F_n admits a measurable selection $w_n : T \to X^*$. The sequence (w_n) is bounded in $L^\infty(X^*)$ by construction. Moreover, $f(t, .) = (\mathcal{T}_s, X)\text{-}\lim f_n(t, .)$ a.s., and thanks to Proposition 3.4 and to (3.1), there exists for almost every $t \in T$ a sequence $(x_n^*(t))$ in X such that $v(t) = s\text{-}\lim x_n^*(t)$ and $f^*(t, v(t)) \geq \limsup f_n^*(t, x_n^*(t))$. Thus

$$\lim h_n(t, x_n^*(t)) = 0. \tag{6.13}$$

And for almost every $t \in T$, there exists $n_0(t)$ such that for every $n \geq n_0(t)$, $x_n^*(t) \in B^*(t)$. So that for each $n \geq n_0(t)$ we have

$$\|v(t) - w_n(t)\| + h_n(t, w_n(t)) \leq \|v(t) - x_n^*(t)\| + h_n(t, x_n^*(t)) + 1/n. \tag{6.14}$$

From (6.13) and (6.14), we can write for almost every $t \in T$

$$\lim[\|v(t) - w_n(t)\| + h_n(t, w_n(t))] = 0. \tag{6.15}$$

Because of definition of F_n and invoking the fact that $v_n(t) \in B^*(t)$ a.s., one can write $\|v(t) - w_n(t)\| + h_n(t, w_n(t)) \leq \|v(t) - v_n(t)\| + h_n(t, v_n(t)) + 1/n \leq R + [h_0(t) - f^*(t, v(t))]^+ + 1/n \leq R + h_0(t) + \|v(t)\|k(t) + k_0(t) + 1$. This last function is integrable. With (6.15), this implies that

$$\lim \int h_n(t, w_n(t))\, d\mu = 0. \tag{6.16}$$

Hence

$$\begin{aligned} &\lim \left[\int f_n^*(t, w_n(t))\, d\mu - \int f^*(t, v(t))\, d\mu\right]^+ = 0 \\ &\Rightarrow \limsup \int f_n^*(t, w_n(t))\, d\mu \leq \int f^*(t, v(t))\, d\mu, \end{aligned}$$

and that provides

$$\limsup I(f_n^*)(w_n) \leq I(f^*)(v). \tag{6.17}$$

Since the sequence (w_n) is bounded in $L^\infty(X^*)$ by construction and since $\lim \|v(t) - w_n(t)\| = 0$ a.s., which implies that (w_n) converges in measure to v, by virtue of Lemma 6.1 below, (w_n) converges to v with respect to topology ρ. This last result, together with (6.17), is nothing else than (6.9).

Now we wish to establish (6.10). So let us consider first some functions v and (v_n) in $L^\infty(X^*)$ $(n \geq 1)$ such that $v = \sigma(L^\infty(X^*),\, L^1(X))\text{-}\lim v_n$. Second, let us consider, fixed $u \in L^1(X)$, a sequence (u_n) in $L^1(X)$ obtained as in (6.7). These functions are then satisfying $I(f)(u) \geq \limsup I(f_n)(u_n)$. From the definition of the conjugate of $I(f_n)$, we can write for each $n \geq 1$

$$I^*(f_n)(v_n) = I(f_n^*)(v_n) \geq \langle v_n, u_n\rangle - I(f_n)(u_n). \tag{6.18}$$

As $v = \sigma(L^\infty(X^*),\, L^1(X))\text{-}\lim v_n$ and $u = s\text{-}\lim u_n$, we have $\lim\langle v_n, u_n\rangle = \langle v, u\rangle$. Hence

$$\begin{aligned}\liminf I(f_n^*)(v_n) &\geq \langle v, u\rangle - \limsup I(f_n)(u_n)\\ &\geq \langle v, u\rangle - I(f)(u),\end{aligned} \tag{6.19}$$

which proves that

$$\liminf I(f_n^*)(v_n) \geq I(f^*)(v). \tag{6.20}$$

Finally, we wish to prove (6.8). For this, consider first some functions u and (u_n) in $L^1(X)$ $(n \geq 1)$ such that $u = \sigma(L^1(X),\, L^\infty(X^*))\text{-}\lim u_n$. Second, fixed v in $L^\infty(X^*)$ as in (6.9), consider a bounded sequence (w_n) in $L^\infty(X^*)$ converging to v for topology ρ and such that $I(f^*)(v) \geq \limsup I(f_n^*)(w_n)$. By conjugacy it follows that

$$I(f_n)(u_n) \geq \langle u_n, w_n\rangle - I(f_n^*)(w_n). \tag{6.21}$$

It is not hard to see that $\lim\langle u_n, w_n\rangle = \langle u, v\rangle$. So we have

$$\liminf I(f_n)(u_n) \geq \langle u, v\rangle - \limsup\ I(f_n^*)(w_n) \geq \langle u, v\rangle - I(f^*)(v),$$

which implies that

$$\liminf I(f_n)(u_n) \geq I(f)(u),$$

that is (6.8).

2) In order to show that $I(f) = (\mathcal{T}_s, L^1(X))\text{-}\lim I(f_n)$, we want to establish that for each $u \in L^1(X)$ with $u \in \mathit{dom}\ I(f)$, $I(f)(u) \geq s\text{-}ls_e I(f_n)(u)$ and that for every $v \in L^\infty(X^*)$, with $v \in \mathit{dom}\ I(f^*)$, $I(f^*)(v) \geq s\text{-}ls_e I(f_n^*)(v)$. The first inequality holds thanks to Theorem 4.1. For the second one, let us consider the additional hypothesis; that is, for almost every $t \in T$ and each $x \in X$, $f_n(t,x) \geq f(t,x)$. Then, for each $x^* \in X^*$, $f_n^*(t,x^*) \leq f^*(t,x^*)$ and for every function $v \in L^\infty(X^*)$,

$$f_n^*(t, v(t)) \leq f^*(t, v(t)) \leq f^{*+}(t, v(t)) \text{ a.s.} \tag{6.22}$$

As $I(f^*)(v) < +\infty$, $f^{*+}(.\,, v(.)) \in L^1(\mathbf{R})$. And from (6.22)

$$\limsup f_n^*(t, v(t)) \leq f^*(t, v(t)). \tag{6.23}$$

Invoking (6.22), (6.23), and then Fatou's lemma, one has $\limsup \int f_n^*(t, v(t))\, d\mu \leq \int \limsup f_n^*(t, v(t))\, d\mu \leq \int f^*(t, v(t))\, d\mu$, and hence

$$\limsup I(f_n^*)(v) = \limsup I^*(f_n)(v) \leq I^*(f)(v). \tag{6.24}$$

Let us deal now with the Lipschitz approximation of the functions $I(f_n^*)$ $(n \geq 1)$. For each $v \in L^\infty(X^*)$ and every $k > 0$, one can write

$$I(f_n^*)(v) = I^*(f_n)(v) \geq I^{*k,1}(f_n)(v). \tag{6.25}$$

From (6.24) and (6.25), it follows that $I^*(f)(v) \geq \limsup I^{*k,1}(f_n)(v)$ for each $k > 0$, which entails

$$I^*(f)(v) \geq \sup_{k>0} \limsup_{n\geq 1} I^{*k,1}(f_n)(v). \tag{6.26}$$

Hypothesis (b) easily implies the existence of some real k and k_0 ($k_0 > 0$) such that $I^*(f_n) \geq -k\|v\|_{L^\infty} - k_0$. Thus, part (2) of Proposition 3.5 can be used, which tells us that $s\text{-}ls_e I^*(f_n)(v) \leq \sup_{k>0} \limsup_{n\geq 1} I^{*k,1}(f_n)(v)$, and then that

$$I^*(f)(v) \geq s\text{-}ls_e I^*(f_n)(v).$$

As $I(f)(v) \geq s\text{-}ls_e I(f_n)(v)$ and $I^*(f)(v) \geq s\text{-}ls_e I^*(f_n)(v)$, from Proposition 3.4, we finally have $I(f) = (\mathcal{T}_s, L^1(X))\text{-}\lim I(f_n)$ and then $I(f^*) = (\mathcal{T}_s^*, L^\infty(X^*))\text{-}\lim I(f_n^*)$. □

Here now is Lemma 6.1.

Lemma 6.1. *Let $(T, \mathcal{A}, \mu)$ be a finite probability space, and let X be a Banach space with strongly separable dual. Let g, $g_n : T \to X^*$ ($n \geq 1$) be some functions such that first the sequence (g_n) is bounded and second the sequence (g_n) converges in measure to g. Then, the sequence (g_n) converges to g with respect to the topology of the uniform convergence on the uniformly integrable and bounded subsets of $L^1(X)$ (which is denoted by ρ).*

Proof. We can only consider the case where $g = 0$. Let Γ be a uniformly integrable subset of $L^1(X)$. For each function $u \in \Gamma$, every $a \in R^+$, and each $n \geq 1$, we write

$$\langle g_n, u\rangle = \int \langle g_n(t), u(t)\rangle d\mu = I + J,$$

where $I = \int_{\{t/\|u(t)\|\geq a\}} \langle g_n(t),\, u(t)\rangle\, d\mu$ and $J = \int_{\{t/\|u(t)\|<a\}} \langle g_n(t),\, u(t)\rangle\, d\mu$. On one hand, see that as by hypothesis there exists $M > 0$ such that $\sup\{\|g_n\|_{L^\infty}/n \geq 1\} \leq M$, one has

$$|I| \leq \int_{\{t/\|u(t)\|\geq a\}} \|g_n(t)\|_{X^*} \|u(t)\|_X \, d\mu \leq M \int_{\{t/\|u(t)\|\geq a\}} \|u(t)\|_X \, d\mu.$$

And $\lim_{a\to+\infty} \int_{\{t/\|u(t)\|\geq a\}} \|u(t)\|_X \, d\mu = 0$ uniformly in u. Then, fixed $\varepsilon > 0$, a can be chosen (we denote it by $a(\varepsilon)$) such that $|I| < \varepsilon/2$ for every $u \in \Gamma$.

On the other hand:

$$\begin{aligned} |J| &\leq \int_{\{t/\|u(t)\|<a(\varepsilon)\}} \langle g_n(t), u(t)\rangle \, d\mu \\ &\leq a(\varepsilon) \int_{\{t/\|u(t)\|<a(\varepsilon)\}} \|g_n(t)\|_{X^*} \, d\mu \leq a(\varepsilon) \int_T \|g_n(t)\|_{X^*} d\mu. \end{aligned}$$

It is easily seen that the sequence $(\|g_n\|_{X^*})$ converges in measure to 0. As $\sup\{\|g_n\|_{L^\infty}/n \geq 1\} \leq M$, we can find n_0 such that $n \geq n_0$, $|J| \leq \varepsilon/2$. Thus, for $n \geq n_0$ and $u \in \Gamma$, $\langle g_n, u\rangle < \varepsilon$ which entails

$$\lim_n \sup \left\{ \int_T \langle g_n(t), u(t)\rangle \, d\mu/u \in \Gamma \right\} = 0. \qquad \square$$

Proof of Theorem 4.4. The proofs of (1) and (2) being similar, we only give the second one (see also [Cou]). Let us define the integrands $\delta_n : (t, x) \to \delta(x, F_n(t))$

$(n \geq 1)$ and $\delta : (t,x) \to \delta(x, F(t))$. According to Beer [Be3, Theorem 3.1], assumption (a) implies that for almost every $t \in T$

$$\delta(\,.\,, F(t)) = (\mathcal{T}_s, X)\text{-}\lim \delta(\,.\,, F_n(t)). \tag{6.27}$$

Moreover, applying the measurable selection theorem with the random sets $t \to F_n(t) \cap B(0; d(0, F_n(t))$ $(n \geq 1)$, we show the existence of a sequence $u_n \in S^p(F_n, \mathcal{A})$ $(n \geq 1)$ with $\|u_n(t)\| \leq k(t)$ a.s. where $k \in L^p(R)$. Then

$$\delta(u_n(t), F_n(t)) = 0 \text{ a.s.}, \quad n \geq 1. \tag{6.28}$$

Moreover, the support function of the random set F_n $(n \geq 1)$, which is the conjugate of the indicator function δ_n, satisfies

$$s(0, F_n(t)) = 0 \text{ a.s.}, \quad n \geq 1. \tag{6.29}$$

As (6.28) and (6.29) are nothing else than, respectively, assumptions (b) and (c) of Theorem 4.2 with $f_n = \delta_n$ and $f_n^* = s(\,.\,, F_n)$, one has $I(\delta) = (\mathcal{T}_s, L^p(X))\text{-}\lim I(\delta_n)$. But since for each function u in $L^p(X)$ $I(\delta)(u) = 0$ (resp., $I(\delta_n)(u) = 0$, $n \geq 1$) if and only if $u(t) \in F(t)$ a.s. (resp., $u(t) \in F_n(t)$ a.s. $n \geq 1$), we have $\delta(\,.\,, S^p(F, \mathcal{A})) = (\mathcal{T}_s, L^p(X))\text{-}\lim\ \delta(\,.\,, S^p(F_n, \mathcal{A}))$. Thus $S^p(F, \mathcal{A}) = \mathcal{T}_s\text{-}\lim S^p(F_n, \mathcal{A})$. □

DELAY-INDUCED INSTABILITIES IN GYROSCOPIC SYSTEMS[*]

PEDRO FREITAS[†]

Abstract. It is shown that stable linear gyroscopic systems of the form $Mx'' + Tx' + Kx = 0$ $(M > 0)$ always become unstable when an arbitrarily small delay is introduced in the gyroscopic term. In the case where K is negative definite, then the system will be unstable for all positive delays. On the other hand, examples are given showing that some of these systems may actually become asymptotically stable for larger values of the delay parameter.

Key words. gyroscopic forces, time delays, vibrating systems

AMS subject classifications. 34K, 70J25, 93D15

1. Introduction.

It is known that certain infinite-dimensional Hamiltonian systems that have been stabilized via distributed or boundary damping are not robust with respect to small time delays which might be present in the feedback stabilization mechanism (see, for example, [DLP, DY, RT]). In these cases, the effect of the introduction of the small delay is to perturb the high frequencies of the (asymptotically) stable system, giving rise to periodic or even exponentially growing solutions. Clearly this phenomenon is made possible by the fact that the spectrum of the system without delay has an infinite number of eigenvalues on an unbounded strip parallel to the imaginary axis.

Another situation where the presence of small delays might be expected to destabilize an otherwise stable system is when there are eigenvalues lying on the imaginary axis. An example of this type is provided by mechanical systems with gyroscopic forces which are modelled by systems of differential equations of the form

$$Mx''(t) + Tx'(t) + Kx(t) = 0. \tag{1.1}$$

Here M and K are real symmetric $n \times n$ matrices usually referred to as the mass and stiffness terms, corresponding to inertial and potential forces, respectively. The mass matrix will be assumed to be positive definite. The matrix T is a real $n \times n$ skew-symmetric matrix which represents the gyroscopic forces.

In order to study the stability of the trivial (zero) solution of (1.1), we look for solutions of the form $x = e^{\lambda t}u$, leading to the eigenvalue problem

$$\lambda^2 Mu + \lambda Tu + Ku = 0.$$

Throughout the paper we consider the usual definitions of different types of stability that may be found in the literature (for instance, in Chapter 5 of [HL]). The trivial solution of a system of the form (1.1) will then be stable if and only if all eigenvalues lie on the imaginary axis and are semisimple, that is, their algebraic and geometric multiplicities are equal. This is, of course, related to the Hamiltonian symmetry of the corresponding spectrum. Such a system will always be stable independent of T

[*] Received by the editors June 15, 1999; accepted for publication (in revised form) April 11, 2000; published electronically August 17, 2000. This research was partially supported by the Fundação para a Ciência e Tecnologia, Portugal.

when K is positive definite, in which case all eigenvalues are semisimple [L]. If K is allowed to have both negative and positive eigenvalues, the system may then, under certain conditions, be stabilized by using a suitable matrix T. This has been known for a long time [TT] and, in particular, it is known that a necessary condition for it to be possible is that the number of negative eigenvalues of K be even. Recently there have been several papers giving conditions on the matrix T so that the overall system is stabilized when K is negative definite (see, for instance, [BLM, HKLP]).

In this note, we show that when a small delay parameter is introduced in (1.1), this will force some of the eigenvalues into the right half of the complex plane independently of the gyroscopic, mass, and stiffness matrices, thus making the trivial solution unstable. Under certain quite general conditions given below, we shall see that the presence of small delays in the gyroscopic term always destabilizes the mode of the original system corresponding to the highest frequency. We conjecture that the lowest frequency mode is actually stabilized, but have only been able to prove this under special circumstances (K either positive or negative definite). As mentioned above, this destabilizing effect is not unexpected as all the eigenvalues of the original system are on the imaginary axis. However, it is not clear a priori whether this will always be the case or not, irrespective of the matrices M, T, and K. Besides, this seems to be the first study of a finite-dimensional system where the associated transfer function is proper and which always becomes unstable when arbitrarily small delays are introduced. For some different approaches and situations, see, for instance, [BCD, GS]. Note that in all of the examples given above the destabilizing effect relies on the fact that in the absence of delay the underlying system is already infinite-dimensional.

Under some additional restrictions ($K < 0$), we are able to show that instability then persists for all values of the delay. More surprisingly, we also show that there are situations where the system will actually become asymptotically stable for larger values of the delay parameter—note that although the original system is stable, it is not asymptotically stable. This stabilizing effect of the delay has been identified in other systems. See, for instance, [CG], where stability switching sequences for some second-order scalar differential equations were studied. When n equals two, we give a full description of these sequences in terms of a set of four positive real numbers. These are the only possible crossing points of eigenvalues on the imaginary axis in this case. We then show that although the system might become stable for some values of τ, it ultimately becomes unstable. In fact, we prove that once there are more than four unstable eigenvalues the system never stabilizes again for large values of τ.

We begin by indicating the overall hypotheses which are to be assumed throughout the paper and by presenting the main results in section 2. We then go on to study some properties of the spectrum associated with this problem, with particular focus on the derivatives with respect to the delay at purely imaginary eigenvalues. This is done in section 3. Section 4 deals with the destabilizing effect of delays, and in section 5 we show that under some circumstances it is possible for the system to become asymptotically stable for larger values of the delay. This is done by means of a full description of the 2×2 case. Finally, in section 6 we briefly discuss the results obtained.

2. Preliminaries and main results.

We shall consider only the case where M is positive definite, which implies that system (1.1) can be brought into the form

$$y''(t) + Gy'(t) + Cy(t) = 0, \tag{2.1}$$

by means of the change of variables $x = M^{-1/2}y$. Here $G = M^{-1/2}TM^{-1/2}$ and $C = M^{-1/2}KM^{-1/2}$ are real $n \times n$ skew-symmetric and symmetric matrices, respectively. We now introduce a delay in the gyroscopic term in (2.1) to obtain

$$y''(t) + Gy'(t-\tau) + Cy(t) = 0. \tag{2.2}$$

Throughout the paper we shall make the following assumptions on (2.2).

H1. In the absence of delay ($\tau = 0$) all eigenvalues are on the imaginary axis and are simple.

H2. C is nonsingular.

H3. G and C do not have any common invariant spaces.

The reason for assuming H1 has to do with the fact that if the original system has eigenvalues with positive real parts, then it will always remain unstable for small delays and there is nothing to prove. As mentioned in the introduction this will impose certain conditions on the matrices G and C. In order to have stability, it is also necessary that the eigenvalues are semisimple. To make matters simpler, we shall assume simplicity of eigenvalues, but similar results can be obtained under the weaker assumption that they are semisimple, except that the expressions for the derivatives at a multiple eigenvalue are more complicated.

Note also that H3 may be assumed without loss of generality, as it just means that system (2.2) cannot be decoupled into two or more independent blocks. If this is not the case, then we can just apply the present results to each block separately.

The main results of the paper are contained in the following two theorems. The first concerns the destabilizing effects of the delay.

THEOREM 2.1. *Assume that system* (2.2) *satisfies hypothesis* H1–H3. *Then there exists a positive number τ_1, depending on G and C, such that the trivial solution is unstable for all τ in $(0, \tau_1)$. If C is negative definite, then $\tau_1 = +\infty$; that is, the system is unstable for all positive values of the delay parameter.*

There are, however, cases where the introduction of a delay will also have a stabilizing effect for larger values of the delay parameter.

THEOREM 2.2. *There exist systems of the form* (2.2) *and positive numbers τ_1 and τ_2 with $\tau_1 < \tau_2$ such that the trivial solution is stable when there is no delay, unstable for τ in $(0, \tau_1)$, and asymptotically stable for τ in (τ_1, τ_2).*

3. Some basic facts about the associated spectrum. In order to study the stability of the trivial solution of system (2.2), we look for solutions of the form $y(t) = e^{\lambda t}u$ and obtain the spectral problem

$$L_\tau(\lambda)u := \lambda^2 u + \lambda e^{-\lambda\tau}Gu + Cu = 0. \tag{3.1}$$

This is equivalent to solving the characteristic equation

$$d(\lambda, \tau) := \det\left(\lambda^2 I + \lambda e^{-\lambda\tau}G + C\right) = 0. \tag{3.2}$$

Note that, for fixed τ, the function d defined above is analytic in λ. When τ is zero, this problem will have $2n$ eigenvalues which, since this system is assumed to be stable, will lie on the imaginary axis and be semisimple. For positive values of τ, the presence of the exponential term has the effect of bringing in an infinite number of eigenvalues from the point at infinity, and also of breaking the Hamiltonian symmetry that is present when there is no delay.

That these eigenvalues do not accumulate near the imaginary axis is fundamental in the study of the stability of such problems. This is a consequence of the fact that on the one hand the eigenvalues are zeros of an analytic function, and, on the other, the set of eigenvalues with real part larger than any given number is bounded. These properties are summarized in the following proposition.

PROPOSITION 3.1. *Let α_0 and τ_0 be given real numbers where τ_0 is assumed to be positive. There exists a constant $\kappa = \kappa(\alpha_0, \tau_0)$ such that if* $\mathrm{Re}(\lambda) > \alpha_0$ *and* $\tau \in (0, \tau_0)$, *then $|\lambda| < \kappa$. As a consequence, for any given nonnegative value of the delay, there is only a finite number of eigenvalues with real part larger than α_0.*

For a proof, see [HL], for instance. Finally, recall that the stability of the trivial solution is determined by the eigenvalues (See, for instance, [HL, section 7.6]).

3.1. Purely imaginary eigenvalues. The discussion above implies that the mechanism underlying the changes of stability of the trivial solution is related to eigenvalues which cross the imaginary axis from the left to the right (increasing the number of unstable eigenvalues) or from the right to the left (decreasing this number). Since the system coefficients are real and it is assumed that C is nonsingular, this can only happen at pairs of purely imaginary eigenvalues. We shall now look for points of this type in the spectrum.

Letting $\lambda = \omega i$ ($\omega > 0$) in (3.1) gives

$$-\omega^2 u + \omega i e^{-\omega\tau i} G u + C u = 0. \tag{3.3}$$

Taking the inner product with u and assuming the eigenvectors to be normalized by $\|u\| = 1$, we obtain

$$\omega^2 + \omega e^{-\omega\tau i} g - c = 0,$$

where $ig = (Gu, u)$ and $c = (Cu, u)$. Here $(\cdot, \cdot)$ denotes the usual (complex) inner product. Separating this equation into real and imaginary parts yields

$$\begin{cases} \omega^2 + \omega g \cos(\omega\tau) - c = 0, \\ \omega g \sin(\omega\tau) = 0. \end{cases} \tag{3.4}$$

Since C is taken to be nonsingular, ω cannot vanish, and thus we have from the second equation that either $g = 0$ or $\omega\tau = k\pi$. Let's consider the latter case first. Substituting in (3.3), we get

$$-\omega^2 u + (-1)^k \omega i G u + C u = 0. \tag{3.5}$$

Because the matrices G and C are real, if ωi is an eigenvalue, then the same is true of $-\omega i$. We thus see that we may omit the factor $(-1)^k$ without loss of generality and look for solutions of

$$\omega^2 u - i\omega G u - C u = 0$$

instead. Now this is the same as the equation when τ vanishes, and thus we see that points of this type where eigenvalues may cross the imaginary axis are just the eigenvalues of the original problem, with the same multiplicities.

At this point we shall not consider eigenvalues where the inner product $ig = (Gu, u)$ vanishes, except to remark that when this happens we have from the first equation in (3.4) that $\omega^2 = c$. In particular, this implies that such points cannot exist when the matrix C is negative definite. We shall see below that they exist under other conditions and that they will play an important role in the stabilization mentioned in the introduction.

This discussion suggests the following distinction between two types of crossing points. If a point on the imaginary axis where eigenvalues may cross from one half-plane to the other is an eigenvalue of the system at τ equal zero, we shall say that it is a *primary crossing point*. Otherwise, it will be called a *secondary crossing point*.

Assume that when τ is zero the spectrum of system (2.2) consists of the points $\pm\omega_1 i, \ldots, \pm\omega_n i$, with $(0 <)\omega_1 < \cdots < \omega_n$. Then we have that there are eigenvalues on the imaginary axis at the points $\pm\omega_j$ for $\tau_k^j = k\pi/\omega_j$, $k = 0, 1, \ldots,$ $j = 1, \ldots, n$. Note that for even k each eigenvalue has the same eigenvector as it did at $\tau = 0$, while when k is odd the eigenvector is now the complex conjugate of that same eigenvector.

3.2. Derivatives of eigenvalues at primary crossing points. In order to determine the stability of the trivial solution for τ small, we shall consider the sign of the derivative of eigenvalues on the imaginary axis when τ is zero. First note that the derivative of an eigenvalue λ with respect to τ exists provided that λ is a (finite) semisimple eigenvalue. Thus, if we know the signs of these derivatives when there is no delay, this together with the properties mentioned at the beginning of this section will enable us to study the stability for small positive values of the delay parameter.

In order to proceed, we need to consider the adjoint eigenvalue problem $L_\tau^*(\lambda)v = 0$, where the adjoint operator $L_\tau^*(\lambda)$ is defined by the equality $(L_\tau(\lambda)u, v) = (u, L_\tau^*(\lambda)v)$ for all $u, v \in \mathbb{R}^n$. This gives

$$L_\tau^*(\lambda)v = \overline{\lambda}^2 v - \overline{\lambda} e^{-\overline{\lambda}\tau} Gv + Cv.$$

We now consider the eigenvalue problems for $L_{\tau+\delta}(\lambda)$ and $L_\tau^*(\lambda)$, that is, $L_{\tau+\delta}(\lambda)u = 0$ and $L_\tau^*(\lambda)v = 0$. Taking inner products at $\tau + \delta$ and τ, we get $(L_{\tau+\delta}(\lambda)u, v) = (L_\tau^*(\lambda)v, u) = 0$. Clearly u also depends on τ and δ, but we shall omit this dependence to keep notation simple. If we now take the complex conjugate in the second equality and then subtract, we are led to

$$\left[\lambda^2(\tau+\delta) - \lambda^2(\tau)\right](u, v) + [\lambda(\tau+\delta)e^{-\lambda(\tau+\delta)(\tau+\delta)} - \lambda(\tau)e^{-\lambda(\tau)\tau}](Gu, v) = 0.$$

Dividing by δ and letting it go to zero, we finally obtain

$$\lambda'(\tau) = \frac{\lambda^2(\tau)e^{-\lambda\tau}(Gu, v)}{2\lambda(\tau)(u, v) + [1 - \tau\lambda(\tau)]\, e^{-\lambda\tau}(Gu, v)}. \tag{3.6}$$

Now note that at a point where $\lambda = \omega i$ and $\omega\tau = k\pi$, we have

$$L_\tau(\omega i)u = -\omega^2 u + \omega i e^{-k\pi i} Gu + Cu = 0$$

and

$$L_\tau^*(\omega i)v = -\omega^2 v + \omega i e^{k\pi i} Gv + Cv = 0,$$

so that u and v can actually be taken to be the same. Thus, if we normalize eigenvectors such that $(u, u) = 1$, we obtain that the derivative at a primary crossing point ω for the delay $\tau = k\pi/\omega$ is given by

$$\lambda'(\tau) = \frac{(-1)^{k+1}\omega^2 g}{2\omega + (1 - k\pi i)(-1)^k g},$$

where $ig = (Gu, u)$. Since we have

$$(-1)^k g = \frac{c}{\omega} - \omega,$$

where $c = (Cu, u)$, we finally obtain that

$$\lambda'(\tau) = \frac{\omega^2(\omega^2 - c)}{(\omega^2 + c)^2 + k^2\pi^2(c - \omega^2)^2}\left[(\omega^2 + c) + ik\pi(c - \omega^2)^2\right]. \tag{3.7}$$

From this, we see that the sign of the real part of the derivative of an eigenvalue at a primary point ωi is the same as that of the product $(\omega^2 - c)(\omega^2 + c)$. Furthermore, this sign depends only on the value of the crossing point and is actually independent of the value of τ. These results are summarized in the following proposition.

Proposition 3.2. *The sign of the real part of the derivative of an eigenvalue at a primary crossing point ωi is given for any $\tau = k\pi/\omega$ $(k \in \mathbb{Z})$ by the sign of the product $(\omega^2 - c)(\omega^2 + c)$, where $c = (Cu, u)$, with u a normalized unit eigenvector associated to the corresponding eigenvalue at τ equal to* 0.

4. The destabilizing effect of delays. We shall now show that for the largest (in absolute value) of primary crossing points, the real part of the derivative with respect to τ is positive. Since, as we have seen, the sign of this derivative does not depend on the actual value of τ for which the crossing occurs, we may consider τ to be zero. We shall thus consider the operator $L_0(\lambda)$ for $\lambda = \omega i$. This gives

$$L_0(\omega i) = -\omega^2 I + \omega H + C,$$

where $H = iG$. As G is skew-symmetric, H will be Hermitian and thus $L_0(\omega i)$ is a Hermitian quadratic pencil for real ω. For each real value of ω, there exist n real eigenvalues (counting multiplicities) of $L_0(\omega i)$. The functions describing the behavior of the eigenvalues with respect to the parameter ω are called the eigencurves of the quadratic pencil. Note that eigenvalues of the original problem correspond to zero eigenvalues of $L_0(\omega i)$ and thus to intersections of the eigencurves with the horizontal axis.

Proposition 4.1. *At the largest primary crossing point we have*

$$\lambda'(0) > 0.$$

Proof. Begin by noting that τ equal to zero corresponds to k equal to zero also, and thus from the expression (3.7) for the derivative we see that $\lambda'(0)$ is actually real.

We shall now consider the auxiliary Hermitian spectral problem

$$L_0(\omega i)u = \sigma u,$$

where ω will be taken to be a real parameter. Denote by $c_1 \leq \cdots \leq c_n$ the eigenvalues of C and assume that a change of basis has been carried out such that $C = \mathrm{diag}\{c_1, \ldots, c_n\}$. We have that if $|\omega| \geq \omega_n$, then the matrix $L_0(\omega i)$ is negative semidefinite. In particular, we get

$$L_0(\omega_n i) = -\omega_n^2 I + \omega_n H + C \leq 0,$$

which implies that the diagonal entries of $L_0(\omega_n i)$ are less than or equal to zero. It thus follows that $-w_n^2 + c_n \leq 0$. Since $c_n \geq c = (Cu, u)$ for all u with unit norm, we have that $\omega_n^2 \geq c$. Now equality can hold if and only if $c = c_n$, that is, if u is the eigenvector corresponding to c_n. But as C is in diagonal form, this would mean that $u = (0, \ldots, 0, 1)$, from which we obtain that the entries g_{jn} of G will have to vanish also for all $j = 1, \ldots, n$. This would make G singular with u as an eigenvector associated to the zero eigenvalue, which is not possible by H3. Hence $\omega_n^2 - c > 0$.

We now observe that from $-\omega^2 + \omega(Hu, u) + (Cu, u) = 0$ and the fact that $\omega_n^2 - c > 0$, we obtain that $h := (Hu, u) = \omega_n - c/\omega_n$ is positive.

For the auxiliary spectral problem considered above we have that σ is a differentiable function of the (real) variable ω, and this derivative can easily be seen to be given by

$$\sigma'(\omega) = -2\omega + h.$$

Since $\omega_n i$ is the largest (in absolute value) eigenvalue of the original problem, it follows that $\sigma'(\omega_n)$ is less than or equal to zero. (It is actually negative, since we are assuming that eigenvalues are simple.) This yields that $2\omega_n \geq h(> 0)$ and since

$$(0 <)2\omega_n - h = \pm\sqrt{h^2 + 4c},$$

we have that for the largest eigenvalue the plus sign should be taken. Hence, $4\omega_n^2 + 4c \geq h^2 + 4c > 0$, and finally $\omega_n^2 + c > 0$ as desired. □

When C is negative definite, it is possible to improve the result above and to show that there are other eigenvalues besides that with largest absolute value for which this derivative is also positive. Keep in mind that if C is negative definite, then it is a necessary condition that n be even in order for the system without delay to be stable.

COROLLARY 4.2. *Assume that C is negative definite. Then there exist at least $n/2$ primary crossing points in the upper half-plane for which the real part of the derivative with respect to τ of an eigenvalue at these points is positive.*

Proof. If C is negative definite, we automatically have that $\omega^2 - c$ is positive. On the other hand at $\omega = 0$ all the eigencurves of L_0, are below the horizontal axis. This means that, since eigenvalues are simple (it is actually enough for them to be semisimple), there must exist n intersections of the eigencurves with the horizontal axis, of which $n/2$ have σ' positive, and the remaining $n/2$ have σ' negative. Again, the derivative cannot be zero since this implies double (nonsimple) eigenvalues in the original problem. Proceeding as in the proof of the previous result, it is possible to show that those crossing points which correspond to negative values of σ' will have $\omega_j^2 + c > 0$, and so the derivative with respect to τ at these points is positive. □

Proof of Theorem 2.1. The first part of the result follows immediately from the fact that for the largest eigenvalue $\lambda'(0)$ is positive, and from the continuity of eigenvalues with respect to τ.

To prove that the system will always be unstable when C is negative definite, we begin by noting that in this case there are no secondary crossing points. This follows from the second equation in (3.4) since if g is not zero we obtain a primary crossing point, while if it vanishes we get that $\omega^2 = c$ which is impossible when C is negative definite. Denote the number of eigenvalues with positive real parts by $\nu(\tau)$. We have that $\nu(\tau)$ is completely determined once we know the primary crossing points and their derivatives. This can be done by writing down the values τ_j^k for each crossing point $\omega_j i$, and then ordering them in increasing order and taking into account the sign of the respective derivative. We can thus build a table of the form

$$\begin{array}{ccccc}
\tau_n^1 & < & \tau_n^2 & < & \cdots \\
\tau_{n-1}^1 & < & \tau_{n-1}^2 & < & \cdots \\
 & & \vdots & & \\
\tau_1^1 & < & \tau_1^2 & < & \cdots,
\end{array}$$

where we also have that $\tau_j^k < \tau_{j-1}^k$. From Corollary 4.2 we have that at least $n/2$ of the derivatives are positive. In particular, this is the case for $\omega_n i$. We can see from the table above that the smallest positive value of τ for which there will be a crossing is given by $\tau_n^1 = \pi/\omega_n$. For τ between zero and τ_n^1 we know that there exist at least n eigenvalues with positive real parts and so $\nu(\tau) \geq n$ in this interval. After τ_n^1 and until we reach the next crossing point we shall have $\nu(\tau) \geq n+2$. We now claim that the number of primary points which are smaller than a positive number τ and which have a negative derivative will never exceed by more than one the number of primary points smaller than τ and for which the derivative is positive.

To prove the claim, notice that it holds on each column of the table above since when we consider the eigencurves of the auxiliary spectral problem we see that, travelling from the right to the left along the horizontal axis (travelling down a column), the number of intersections of eigencurves with the horizontal axis which have a negative derivative cannot be exceeded by those with a positive derivative. This means that as we travel down a column the difference can never be greater than one. Since the first point on each column always corresponds to the largest crossing point, the claim follows.

We end this section with a result on the sign of the derivative of an eigenvalue at the smallest primary crossing point.

Proposition 4.3. *If C is either negative or positive definite, then the derivative at the primary crossing points with the smallest absolute value has a negative real part.*

Proof. Consider first the case where C is positive definite. Then we have that $L_0(\omega i)$ is semipositive definite at $\omega = \omega_1$. In a similar fashion to the proof of Proposition 4.1, we obtain that $\omega_1^2 \leq c_1$. Since now $c_1 \leq c = (Cu, u)$ for all u with unit norm, we get that $w_1^2 - c \leq 0$, and, as before, we get that equality cannot hold and thus $w_1^2 - c < 0$. Since C is positive definite, $w_1^2 + c > 0$ and the result follows.

When C is negative definite, $w_1^2 - c$ is always positive. The derivative of the corresponding eigencurve at this point must now be positive and so $\sigma'(\omega_1) = -\omega_1 + h > 0$. Thus $h > \omega_1 (> 0)$. This implies that $2\omega_1 - h = -\sqrt{h^2 + 4c}$, from which we obtain $2\omega_1 + \sqrt{h^2+4c} = h$. Taking squares on both sides gives that $w_1^2 + c = -\omega_1\sqrt{h^2+4c} < 0$, which in turn implies that the real part of the derivative is negative. □

5. Secondary crossing points and the stabilizing effect of delays.

The analysis of secondary crossing points is much more difficult in general than that of primary points. There are several reasons why this is so. On the one hand, now we no longer have that the eigenvectors u and v in the expression (3.6) for the derivative can be taken to be the same. On the other hand, the equation that gives these points is also not easy to obtain explicitly in general. However, and as we shall see below, these points can play a decisive role in the stability of this type of system, and it would thus be interesting to study them in more detail.

5.1. The case of $n = 2$.

We shall now consider the special case where n is two, since this is the only case where a complete study of secondary crossing points may be carried out explicitly. In this case we may assume that

$$G = \begin{bmatrix} 0 & g \\ -g & 0 \end{bmatrix} \quad \text{and} \quad C = \begin{bmatrix} c_1 & 0 \\ 0 & c_2 \end{bmatrix}$$

(with $c_1 \leq c_2$), and so the characteristic function is now given by

$$d(\omega i, \tau) = \omega^4 - (c_1 + c_2)\omega^2 + c_1 c_2 - \omega^2 g^2 e^{-2\omega\tau i}.$$

As before, we are interested in the case of real ω. Separating this equation into real and imaginary parts, we have

$$\left\{\begin{array}{l}\omega^4-(c_1+c_2)\omega^2+c_1c_2-\omega^2g^2\cos(2\omega\tau)=0,\\ \omega^2g^2\sin(2\omega\tau)=0.\end{array}\right.$$

If we assume C to be nonsingular, then ω cannot be zero. On the other hand, g must also be different from zero, for otherwise there is no gyroscopic term. It then follows from the second equation that $2\omega\tau=m\pi$. For even m, substituting this in the first equation gives the primary crossing points. We are thus interested in the case of odd m, which leads to the following equation for the secondary points:

$$\omega^4-(c_1+c_2-g^2)\omega^2+c_1c_2=0,$$

from which we obtain that

$$\omega^2=\frac{c_1+c_2-g^2\pm\sqrt{(c_1+c_2-g^2)^2-4c_1c_2}}{2}.$$

When c_1 and c_2 are both negative, we already know that there are no secondary points. This can also be easily seen from the expression above. If $c_1c_2<0$, then the number of negative eigenvalues is odd and thus the system without delay can never be stable, and so we are left with the case where C is positive definite.

Note first that under these conditions the expression for ω^2 given above can only be positive provided that $c_1+c_2-g^2$ is positive. On the other hand, in order to get a positive term under the square root, we must have

$$\left(c_1+c_2-g^2-2\sqrt{c_1c_2}\right)\left(c_1+c_2-g^2+2\sqrt{c_1c_2}\right)>0,$$

which, because of the condition above, reduces to

$$c_1+c_2-g^2-2\sqrt{c_1c_2}>0.$$

We thus have that a necessary and sufficient condition for the existence of four secondary points when C is positive definite is that

$$\sqrt{c_2}-\sqrt{c_1}>g.$$

Denote these points by $\pm\tilde{\omega}_1$ and $\pm\tilde{\omega}_2$, with $\tilde{\omega}_1<\tilde{\omega}_2$. Clearly, then, $\pm\tilde{\omega}_1$ and $\pm\tilde{\omega}_2$ correspond to the minus and plus signs in the expression for ω^2.

The equation giving these roots in λ is

$$\lambda^4+(c_1+c_2)\lambda^2+c_1c_2+\lambda^2g^2e^{-2\lambda\tau}=0,$$

from which the following expression for the derivative of λ with respect to τ can be obtained:

$$\lambda'(\tau)=\frac{\lambda^2g^2e^{-2\lambda\tau}}{2\lambda^2+c_1+c_2+g^2e^{-2\lambda\tau}-\lambda\tau g^2e^{-2\lambda\tau}}.$$

At secondary crossing points $\lambda=\omega i$ and $\omega\tau=m\pi/2$ with m odd. Hence

$$\begin{aligned}\lambda'(\tau) &= \frac{\omega^2g^2}{-2\omega^2+c_1+c_2-g^2+m\pi g^2i/2}\\ &= \frac{\omega^2g^2\left[(-2\omega^2+c_1+c_2-g^2)-m\pi g^2i/2\right]}{(2\omega^2-c_1-c_2+g^2)^2+m^2\pi^2g^4/4},\end{aligned}$$

and the sign of the real part of the derivative is the same as that of $-2\omega^2+c_1+c_2-g^2$. On the other hand, we have

$$2\omega^2 - c_1 - c_2 + g^2 = \pm\sqrt{(c_1+c_2-g^2)^2-4c_1c_2},$$

and so the real parts of the derivatives at $\pm\tilde{\omega}_1$ and $\pm\tilde{\omega}_2$ are positive and negative, respectively. The fact that now the largest of the secondary crossing points has a negative derivative enables the system to be stabilized for positive values of the delays. In particular, we have the following proposition.

PROPOSITION 5.1. *In the case where* n *is equal to two and* C *is positive definite, there will exist numbers* $\tau_1 < \tau_2$ *such that the trivial solution of* (2.2) *is asymptotically stable on the interval* (τ_1, τ_2) *if and only if* $2\tilde{\omega}_2 > \omega_2$.

Proof. Denote the values of the delays for which eigenvalues cross the imaginary axis by τ_j^k and $\tilde{\tau}_j^k$, corresponding, respectively, to ω_j and $\tilde{\omega}_j$, $j = 1,2$. From the previous discussion, we know that $\tau_j^k = k\pi/\omega_j$, while $\tilde{\tau}_j^k = (2k-1)\pi/(2\tilde{\omega}_j)$, $k = 1,\ldots$. The first crossing for positive τ will then occur either at $\tau_2^1 = \pi/\omega_2$ or at $\tilde{\tau}_2^1 = \pi/(2\tilde{\omega}_2)$. Since, at τ equal to zero, one pair of eigenvalues moved to the right, while the other went to the left, we have that $\nu(\tau)$ is two between zero and the first crossing. Clearly, if this happens at $\tilde{\tau}_2^1$, the system becomes stable.

Assume now that the first crossing is at τ_2^1, that is, that $2\tilde{\omega}_2 < \omega_2$. To show that there will always exist at least one pair of eigenvalues with positive real parts, we shall use an argument similar to that used in the proof of Theorem 2.1. To this end, we begin by noting that $\tilde{\omega}_1 > \omega_1$:

$$2(\tilde{\omega}_1^2 - \omega_1^2) = -2g^2 - \sqrt{(c_1+c_2-g^2)^2-4c_1c_2} + \sqrt{(c_1+c_2+g^2)^2-4c_1c_2}.$$

This will be positive if and only if

$$c_1 + c_2 - g^2 > \sqrt{(c_1+c_2+g^2)^2-4c_1c_2},$$

which is clearly satisfied for all positive c_1 and c_2. We shall now build a table similar to that used in the proof of Theorem 2.1, except that because we need to include transitions both at primary and secondary points, it is not possible to ensure that the order of the crossing points in the first column will be the same as in the other columns. However, since we are assuming that $\omega_2 > 2\tilde{\omega}_2$, we get that $\tau_2^k = k\pi/\omega_2 > (2k-1)\pi/(2\tilde{\omega}_2) = \tilde{\tau}_2^k$ for all k. This ensures that the first transition in a column is always from the left to the right. On the other hand, because $\tilde{\omega}_1 > \omega_1$, we have that $\tilde{\tau}_1^k = (2k-1)\pi/(2\tilde{\omega}_1) < k\pi/\omega_1 = \tau_1^k$. This implies that in each column the last element is always one corresponding to a transition from the right to the left. The result now follows in a similar way to the proof of Theorem 2.1.

Finally, note that if $2\tilde{\omega}_2 = \omega_2$, then this cancels out two of the transitions in a column, reducing it to just two terms. As we have seen that the last term in column k is always τ_1^k, we again have instability. □

As a corollary to this result, we obtain that if too many eigenvalues are on the right-hand side for a given value of τ, then the trivial solution cannot become stable again for larger values of τ.

COROLLARY 5.2. *If* $\nu(\tau_*) = \nu_*$ *for some positive* τ_*, *then* $\nu(\tau) \geq \nu_* - 4$ *for all* $\tau > \tau_*$. *In particular, if* $\nu_* = 6$, *the trivial solution is unstable for all* $\tau > \tau_*$. *Furthermore, it will always become unstable for large enough values of the delay parameter.*

Proof. From the proof of the previous result we know that the last element in column k is always τ_1^k and so in order to reach it we must go past $\tilde{\tau}_1^k$. On the other hand,

$$2(\omega_2 - \tilde{\omega}_2) = 2g^2 + \sqrt{(c_1+c_2+g^2)^2 - 4c_1c_2} - \sqrt{(c_1+c_2-g^2)^2 - 4c_1c_2} > 0,$$

which gives that

$$\omega_2 > \tilde{\omega}_2 > \frac{2k}{2k+1}\tilde{\omega}_2,$$

and so $\tilde{\tau}_2^{k+1} > \tau_2^k$. This implies that before we reach $\tau = \tilde{\tau}_2^{k+1}$ we must first pass through τ_2^k. In this way, we see that ν can never decrease by more than four.

To prove the second part of the result, just notice that for large enough values of k we have that the top entry in each column is τ_2^k, as $\omega_2 > \tilde{\omega}_2$. This gives that there exists τ_* sufficiently large for which $\nu(\tau_*)$ is 6 and the result follows. □

With these results it is possible to determine all the stability intervals for any given 2×2 system (with simple eigenvalues), together with the associated stability sequence (the sequence of integers giving the number of eigenvalues with positive real part as the delay parameter is increased).

Example 5.1. Take $c_1 = 4$, $c_2 = 16$, and $g = 1$. We then get

$$\omega_1 \approx 1.9233, \quad \omega_2 \approx 4.1594, \quad \tilde{\omega}_1 \approx 2.0920, \quad \text{and} \quad \tilde{\omega}_2 \approx 3.8241.$$

Clearly, $2\tilde{\omega}_2 > \omega_2$, and in fact there will actually exist three stability intervals:

$$\begin{aligned} (\tilde{\tau}_2^1, \tilde{\tau}_1^1) &\approx (.4108, .7509), \\ (\tilde{\tau}_2^3, \tilde{\tau}_1^2) &\approx (2.0538, 2.2526), \\ \text{and } (\tilde{\tau}_2^5, \tilde{\tau}_1^3) &\approx (3.6969, 3.7543). \end{aligned}$$

The stability sequence in this example is

$$2,0,2,4,2,4,2,0,2,4,2,4,2,0,2,4,2,4,2,4,6,4,6,4,2,4,6,4,6,4,2\ldots,$$

and from Corollary 5.2 we get that these are the only stability intervals.

By changing the coefficients, it is possible to obtain examples with more stable intervals, and also examples for which, although there exist secondary crossing points, the system is always unstable.

Example 5.2. Take $c_1 = 1$, $c_2 = 16$, and $g = 1/2$. Then the stability sequence is given by

$$\begin{gathered} 2,0,2,0,2,4,2,4,2,4,2,0,2,0,2,4,2,4,2,4,2,0,2,0,2,4,2,4,2,4,2,0, \\ 2,0,2,4,2,4,2,4,2,0,2,0,2,4,2,4,2,4,2,0,2,0,2,4,2,4,2,4,2,0,2,0, \\ 2,4,2,4,2,4,2,0,2,4,2,4,6,4,6,4,2,4,2,4,6,4,6,4,6,4,2,4,2,4,\ldots. \end{gathered}$$

Example 5.3. Take $c_1 = 1$, $c_2 = 16$, and $g = 2.9$. Then $\sqrt{c_2} - \sqrt{c_1} - g = .1$, so that there exist secondary crossing points, but now the stability sequence is

$$2,4,2,4,6,8,6,8,10,12,10,12,10,12,10,12,14,16,14,16,18,20,18,\ldots,$$

and so the system is never stable.

6. Conclusions. We have shown that the simple model for gyroscopic systems given by (1.1) is not robust with respect to small delays in the sense that the introduction of an arbitrarily small delay in the gyroscopic term will make the trivial solution unstable under a quite general set of hypotheses. This is the case, in particular, when the gyroscopic term is used to stabilize a system where the matrix K is negative definite and thus the number of eigenvalues with positive real parts for the system without feedback is the maximum possible. For this situation we have seen that the system remains unstable for all values of the delay parameter. It is thus of interest to know under what conditions these are realistic modelling assumptions and whether or not more sophisticated models should be taken into account. These models might include having different delay parameters in the different variables, introducing delays in the stiffness term, or having distributed delays.

Acknowledgment. This work was carried out while I was visiting the Department of Mathematics of the Royal Institute of Technology in Stockholm, Sweden. I would like to thank the people there and, in particular, Ari Laptev, for their hospitality.

ZERO SUM ABSORBING GAMES WITH INCOMPLETE INFORMATION ON ONE SIDE: ASYMPTOTIC ANALYSIS[*]

DINAH ROSENBERG[†]

Abstract. We prove the existence of the limit of the values of finitely repeated (resp., discounted) absorbing games with incomplete information on one side, as the number of repetitions goes to infinity (resp., the discount factor goes to zero). The main tool is the study of the Shapley operator, for which the value of the λ-discounted game is a fixed point, and of its derivative with respect to λ.

Key words. zero sum games, stochastic games, incomplete information, operator approach, recursive formula

AMS subject classification. 91A15

Introduction. We analyze the asymptotic behavior of a class of discounted and finitely repeated two player zero sum games, namely, absorbing games with incomplete information on one side. Indeed, for a given discount factor λ or for a given length n of the game, the existence of the value of the discounted game and of the n-stage game is known. The question is to provide an asymptotic analysis of the values as the players become infinitely patient, or as the length of the game increases.

The existence of the limit of the values of the n-stage games v_n or of the λ-discounted games v_λ has been proved in two main classes of games. In the case of absorbing games with complete information (see Kohlberg [5]) or, more generally, in the case of stochastic games with complete information (see Bewley and Kohlberg [2] or Mertens and Neyman [8]), these are repeated games in which at each stage the actions of the players determine not only their payoffs but also the transitions of a given Markov process; stage payoffs are a function of the pair of actions and of the state of the Markov process at that stage. And in the case of games with no absorbing states but with lack of information on one side (see Aumann and Maschler [1]) or on both sides (Mertens and Zamir [9]), these are repeated games in which the players do not perfectly know the matrix of the game they are playing; this matrix is drawn with a given probability among a given set of matrices, and the players only get partial information on the exact matrix that has been drawn.

The purpose of this paper is to generalize this result to our framework. This question has been solved by Sorin in [14, 15] for the special case of "big match" with incomplete information on one side. These are 2×2 games in which one of the players controls the transition to an absorbing state (see Blackwell and Ferguson [3]).

We analyze the asymptotic behavior of discounted and finitely repeated two player zero sum absorbing games with incomplete information on one side. The game is defined by a family of payoff matrices indexed by two parameters: the first one is private information of player 1 and is kept fixed for the whole interaction; the second one, named the state, is a Markov process in which the transitions depend on the actions of the players. This defines a stochastic game with incomplete information

on one side. In addition, the game is absorbing, meaning that all states but one are absorbing: a state is said to be absorbing if, independently of the actions of the players, the probability to leave it once it has been reached is 0. In that framework we prove the existence of the limit of the values of the λ-discounted games and of the n-stage games as λ goes to 0 or as n goes to infinity.

The argument used in this paper is an extension of the approach provided in [5]. It consists of studying a mapping T involved in the recursive formula defining the value of the repeated game. It expresses the total payoff of the repeated game as a weighted average of the first stage payoff and of a continuation payoff. The value v_λ of the λ-discounted game is the unique fixed point of $T(\lambda, .)$ (see Shapley [13]). As the length of the game increases, the weight λ of the first stage payoff tends to zero. The proof studies an expansion of this map with respect to λ. The heuristic idea behind this approach is that the most important thing for a player in a long game is to take care of his future payoffs to keep them above (resp., below) a given level; such a concern is captured in the control of the main part of the expansion. Second, given that he guarantees a good future payoff, a player should maintain the current nonabsorbing payoff above (below) this level; the second term of the expansion expresses this matter.

1. The model and the result.

1.1. The game. We consider an absorbing game with incomplete information on one side. It is defined by two finite sets of actions, I (the set of actions of player 1) and J (the set of actions of player 2), a finite set of parameters K (that represents the private information of player 1), a probability p on K, a finite set of stochastic states $\Omega = \{\omega_0\} \bigcup \Omega^*$ (Ω^* is the set of absorbing states and ω_0 is the unique nonabsorbing state), a transition $q : \Omega \times I \times J \to \Delta(\Omega)$, and an initial state $\omega_1 \in \Omega$. The transition satisfies that for any absorbing state $\omega^* \in \Omega^*$, and for any $(i, j) \in I \times J$, $q(\omega^*|\omega^*, i, j) = 1$. Note that we defined the transition to be independent of the information k. To each pair of actions (i, j) and each state $\omega \in \Omega$ is associated a vector payoff $a^\omega_{ij} = (a^{\omega,k}_{ij})_{k\in K}$. We assume without loss of generality that for all $k \in K$, $\omega \in \Omega$, $i \in I$, and $j \in J$, $a^{\omega,k}_{ij} \in [0, 1]$. The game is played as follows.

At stage 0, a parameter $k \in K$ is drawn according to probability p, and player 1 is informed of the result while player 2 is not. Both players know the probability p and the initial state ω_1.

At stage $m \geq 1$, player 1 chooses $i_m \in I$ and player 2 chooses $j_m \in J$; given the current state ω_m, a new state ω_{m+1} is drawn according to the probability $q(.|\omega_m, i_m, j_m)$, and the triple (i_m, j_m, ω_{m+1}) is announced to both players.

We assume perfect recall, i.e., both players remember what they have done and what they have known in the past. Therefore, by Kuhn's theorem, without loss of generality, one can reduce the strategy sets from mixed strategies to behavior strategies. A behavior strategy of player 1 (resp., of player 2) is a sequence $(\sigma_1, \ldots, \sigma_n, \ldots)$ (resp., $(\tau_1, \ldots, \tau_n, \ldots)$) such that σ_m is a function from $K \times \Omega \times (I \times J \times \Omega)^{m-1}$ to $\Delta(I)$ (resp., τ_m is a function from $\Omega \times (I \times J \times \Omega)^{m-1}$ to $\Delta(J)$). We set $H_n = \Omega \times (I \times J \times \Omega)^n$ and $H_\infty = (I \times J \times \Omega)^{\mathbb{N}}$. Thus $K \times H_\infty$ is the set of plays. Each $h_n \in H_n$ can be identified with a cylinder set of $K \times H_\infty$. Therefore, H_n induces a σ-algebra over $K \times H_\infty$, which we denote by $\mathcal{H}^2_n$ (the information of player 2 at stage n). Similarly, we define $\mathcal{H}^1_n$ (the information available to player 1 at stage n) as the σ-algebra induced by $K \times H_n$ over $K \times H_\infty$. The probability p, the transition q, and a pair of strategies of the players (σ, τ) induce a probability $P_{p,\sigma,\tau}$ over the set of plays.

Any play determines a stream of stage payoffs $(a^{\omega_m,k}_{i_m j_m})_{m\in\mathbb{N}}$ which can be evaluated in different ways.

In the finitely repeated game $G_n(p,\omega_1)$, the payoff is given by the expectation (according to the probability $P_{p,\sigma,\tau}$) of the average payoff: $\frac{1}{n}\big[\sum_{m=1}^{n} a^{\omega_m,k}_{i_m j_m}\big]$.

In the discounted game $G_\lambda(p,\omega_1)$, the payoff is given by the expectation of the discounted sum of payoffs (according to the probability $P_{p,\sigma,\tau}$): $\big[\sum_{m=1}^{\infty}\lambda(1-\lambda)^{m-1}a^{\omega_m,k}_{i_m j_m}\big]$.

By the minmax theorem (see [10, part A]), both $G_n(p,\omega_1)$ and $G_\lambda(p,\omega_1)$ have a value denoted, resp., by $v_n(p,\omega_1)$ and $v_\lambda(p,\omega_1)$. Our goal is to study the asymptotic behavior of these quantities as the game becomes very long, namely, as n goes to infinity or as λ goes to 0.

We denote by NR the subset of $\Delta(I)^K$ of non revealing strategies, namely the subset of $x\in\Delta(I)^K$ such that for all $(k,k')\in K^2$ and all $i\in I$, $x_i^k=x_i^{k'}$. NR can be identified with $\Delta(I)$. We aim at proving the following theorems.

THEOREM 1.1. *The family v_λ converges uniformly to a function v as λ goes to* 0.

THEOREM 1.2. *The sequence v_n converges uniformly to a function v' as n goes to infinity.*

THEOREM 1.3. $v=v'$.

One could also define the *uniform value*, the *maxmin*, and the *minmax* of the infinitely repeated game. The maxmin would be the largest quantity that player 1 can guarantee in all n-stage games for n large enough, with a strategy that is independent of n (see [10] for an exact definition); similarly, one defines the minmax; the uniform value exists if the maxmin equals the minmax. In particular, if such a uniform value exists, one can prove that it is equal both to v and to v'. The existence of such a value implies Theorems 1.1, 1.2, and 1.3.

In the case of perfect information absorbing games, Kohlberg [5] proves that indeed such a value exists. This result has been generalized for finite perfect information stochastic games by Mertens and Neyman [8]. In the case of games with incomplete information on one side, the existence of the uniform value has been proved by Aumann and Maschler [1]. Nevertheless, in the case of absorbing games with incomplete information on one side, Sorin [14] proved that the uniform value needs not exist (the maxmin and the minmax may differ). Here, we prove the weaker result stated in Theorems 1.1, 1.2, and 1.3. There is a conjecture by Sorin [15] and Mertens [7] stating that in stochastic games with incomplete information on one side the maxmin exists and is equal to v and v'. This paper gives no indication about that conjecture in our framework.

1.2. Basic properties of v_λ and v_n. A function from $\Delta(K)\times\Omega$ to $\mathbb{R}$ is said to be concave, continuous, Lipschitz, etc. if it is respectively concave, continuous, and Lipschitz in the first variable for any given $\omega\in\Omega$.

Let us recall the following properties of the functions v_n and v_λ.

LEMMA 1.4.

1. *The functions v_n and v_λ take their values in* $[0,1]$.
2. *The functions v_n and v_λ are Lipschitz with constant* 1 *in p.*
3. *The functions v_n and v_λ are concave in p.*

Proof. As all the payoffs are in $[0,1]$, so is the value that is computed as a convex combination of the payoffs in the matrices. The Lipschitz property follows also, and the concavity expresses the positive value of information in zero sum games. For detailed proofs, see the splitting lemma ([1, Lemma 5.3, p. 25] and [10, Chapter 5, p. 218]). □

We use the following uniform norm on the set of functions from $\Delta(K) \times \Omega$ to $[0, 1]$:

$$\|f\| = \sup_{p \in \Delta(K), \omega \in \Omega} |f(p, \omega)|.$$

Let $\mathcal{B}$ be the set of functions from $\Delta(K) \times \Omega$ to $[0, 1]$ that are Lipschitz with constant 1. $\mathcal{B}$ is a set of uniformly equicontinuous functions, and by Ascoli's theorem it is compact. Therefore, both the family v_λ and the sequence v_n have converging subsequences, and they converge iff all converging subsequences have the same limit.

Notation. Let v be the limit of a converging subsequence of the family $\{v_\lambda\}$. We are going to prove that such a v is unique.

PROPOSITION 1.5. *For any $\omega^* \in \Omega^*$, the functions $v_n(., \omega^*)$ and $v_\lambda(., \omega^*)$ converge uniformly to the same limit $v(., \omega^*)$.*

Proof. The game with initial absorbing state $\omega^* \in \Omega^*$ is reduced to a nonstochastic incomplete information game. In [1], Aumann and Maschler prove the convergence for such games. □

The purpose of this paper is to prove that this result generalizes to the nonabsorbing state ω_0.

2. Basic tools.

2.1. The mapping T. $\mathcal{F}$ is the set of continuous concave functions f from $\Delta(K) \times \Omega$ to $[0, 1]$. Note that the functions in $\mathcal{F}$ do not have to be Lipschitz. Actually all the functions we will use (v_λ, v_n) are not only continuous but Lipschitz with constant 1. Nevertheless, we are going to define on $\mathcal{F}$, for each λ and each pair of strategies $x \in \Delta(I)^K$ and $y \in \Delta(J)$, a map $T_{xy}(\lambda, .)$. This operator maps continuous functions to continuous functions, but it is not clear whether the image of a Lipschitz function with constant 1 is a Lipschitz function with constant 1.

The proof relies on the following mappings T and ϕ. We consider, for $f \in \mathcal{F}$, $\lambda \in [0, 1]$, $\omega_1 \in \Omega$, and $p \in \Delta(K)$ the normal form game $\Gamma(\lambda, f)(p, \omega_1)$ with strategy sets $\Delta(I)^K$, $\Delta(J)$ and where the payoff associated to the pair of strategies $(x, y) \in \Delta(I)^K \times \Delta(J)$ is

$$\begin{aligned} T_{xy}(\lambda, f)(p, \omega_1) = \Bigg[& \lambda \sum_{k \in K} \sum_{\substack{i \in I \\ j \in J}} p^k x_i^k y_j a_{ij}^{\omega_1, k} \\ & + (1 - \lambda) \sum_{k \in K} \sum_{\substack{i \in I \\ j \in J}} \sum_{\omega \in \Omega} p^k x_i^k y_j q(\omega | \omega_1, i, j) f(p_i, \omega) \Bigg], \end{aligned}$$

with $p_i \in \Delta(K)$ and $p_i^k = \frac{p^k x_i^k}{\sum_{l \in K} p^l x_i^l}$ if $\sum_{l \in K} p^l x_i^l \neq 0$ and $p_i = p^*$ if $\sum_{l \in K} p^l x_i^l = 0$ (for a given p^* in $\Delta(K)$).

The above definition of p_i as the conditional probability on K given player 1 played action i will be used throughout the paper. Notice that if x is in NR (meaning that for all $k \in K$, $k' \in K$, $i \in I$, $x_i^k = x_i^{k'}$), then for all $i \in I$, $p_i = p$.

$\Gamma(\lambda, f)(p, \omega_1)$ is a one shot representation of the repeated game in which the stream of payoffs from stage 2 on is evaluated through f. The total payoff of the repeated game is then the weighted average of the first stage payoff (with weight λ) and the continuation payoff (with weight $1-\lambda$).

Lemma 2.1. *If f is in $\mathcal{F}$, then the functions $x \mapsto T_{x,y}(\lambda, f)(p,\omega)$ and $y \mapsto T_{x,y}(\lambda, f)(p,\omega)$ defined, resp., on $\Delta(I)^K$ and $\Delta(J)$ are continuous and, resp., concave and convex.*

Proof. $y \mapsto T_{x,y}(\lambda, f)(p,\omega)$ is linear and continuous. For $x \mapsto T_{xy}(\lambda, f)(p,\omega)$, it is enough to prove that the function

$$\varphi : x \mapsto \sum_{k\in K} \sum_{\substack{i\in I\\ j\in J}} \sum_{\omega'\in\Omega} p^k x_i^k y_j q(\omega'|\omega,i,j) f(p_i,\omega')$$

is concave and continuous. The proof is analog to the one in the nonstochastic case [4].

Assume $x = \alpha x_1 + (1-\alpha)x_2$ with $\alpha \in [0,1]$; denote by $\bar{x}_i$ the quantity $\sum_{k\in K} p^k x_i^k$, and define similarly $\bar{x}_{1i}$ and $\bar{x}_{2i}$; then $p_i = \mu p_{1i} + (1-\mu)p_{2i}$ with $\mu = \alpha\bar{x}_{1i}/\bar{x}_i$ ($\mu \in [0,1]$) and $p_{1i}^k = p^k x_{1i}^k/\bar{x}_{1i}$ ($p_{1i} \in \Delta(K)$; p_{2i} is defined in an analogous way). Concavity of f then implies

$$\begin{aligned}\varphi(x) \quad \le \quad & \sum_{\substack{i\in I\\ j\in J}} \sum_{\omega'\in\Omega} \mu\bar{x}_i y_j q(\omega'|\omega,i,j) f(p_{1i},\omega') \\ & + \sum_{\substack{i\in I\\ j\in J}} \sum_{\omega'\in\Omega} (1-\mu)\bar{x}_i y_j q(\omega'|\omega,i,j) f(p_{2i},\omega').\end{aligned}$$

Using $\mu = \alpha\bar{x}_{1i}/\bar{x}_i$ and $1-\mu = (1-\alpha)\bar{x}_{2i}/\bar{x}_i$, this proves concavity of φ.

For continuity of φ at point x, fix an $\varepsilon > 0$. For all $\eta > 0$, there is an $\alpha > 0$ such that $\|x - x_1\| \le \alpha$ implies for all i satisfying $\bar{x}_i \ge \varepsilon$, $\|p_i - p_{1i}\| \le \eta$. Continuity of f therefore implies that if $\|x - x_1\| \le \alpha$, $\bar{x}_i \ge \varepsilon$, then $\max_{\omega\in\Omega} |f(p_i,\omega) - f(p_{1i},\omega)| \le \varepsilon$. The result follows. □

The sets of strategies $\Delta(I)^K$, $\Delta(J)$ are compact convex. Therefore, the previous lemma and the minmax theorem imply the existence of a value $T(\lambda, f)(p,\omega_1)$ for the game $\Gamma(\lambda, f)(p,\omega_1)$ and of optimal strategies for the players. The sets of optimal strategies of player 1 and of player 2 are denoted, resp., by $X_\lambda[f](p,\omega_1)$ and $Y_\lambda[f](p,\omega_1)$. The following lemma is a restatement of the recursive formula and the fixed point formula characterizing v_λ and v_n, in terms of the mapping T. These formulas justify the introduction of the mappings T.

Lemma 2.2.

(a) *For all $\lambda \in [0,1]$, $T(\lambda, v_\lambda) = v_\lambda$.*

(b) *For all $n \in \mathbb{N}$, $T(\frac{1}{n+1}, v_n) = v_{n+1}$.*

Proof. These formulas are proved in a more general setup in [10, p. 187]. □

Remark. *In the case of finite perfect information stochastic games, Bewley and Kohlberg* [2] *note that these formulas can be restated as:*

$$\begin{cases} \forall\omega\in\Omega,\ \forall j\in J,\ T_{x_\lambda j}(\lambda, v_\lambda)(\omega) \ge v_\lambda(\omega), \\ \forall\omega\in\Omega,\ \forall i\in I,\ T_{iy_\lambda}(\lambda, v_\lambda)(\omega) \le v_\lambda(\omega), \end{cases}$$

where $x_\lambda \in X_\lambda[v_\lambda](p,\omega)$ and $y_\lambda \in Y_\lambda[v_\lambda](p,\omega)$. This system is a finite number of polynomial inequalities and hence proves that v_λ, x_λ, and y_λ are semialgebraic in λ. Therefore they have Puiseux expansions in λ. Together with the fact that these functions are uniformly bounded, this proves Theorem 1.1. *In our framework, under x_λ, the state space can be reduced to a countable subset of $\Delta(K)\times\Omega$. The algebraic* *approach does not extend because the fixed point formula of Lemma* 2.2(a) *does not reduce to a finite number of polynomial inequalities but rather to*

$$\begin{cases} \forall \omega, p,\ \forall j \in J,\ T_{x_\lambda j}(\lambda, v_\lambda)(p,\omega) \geq v_\lambda(p,\omega), \\ \forall \omega, p,\ \forall x \in \Delta(I)^K,\ T_{x y_\lambda}(\lambda, v_\lambda)(p,\omega) \leq v_\lambda(p,\omega). \end{cases}$$

Indeed, $T_{xy_\lambda}(\lambda, v_\lambda)(p,\omega)$ is no more linear in x.

Let us now define the quantity:

$$\phi_{xy}(f)(p,\omega_1) = \frac{T_{xy}(\lambda, f)(p,\omega_1) - T_{xy}(0,f)(p,\omega_1)}{\lambda}.$$

Note that $\phi_{xy}(f)(p,\omega_1)$ is independent of λ. Indeed, for any λ,

$$\begin{aligned} \phi_{xy}(f)(p,\omega_1) &= \sum_{k\in K} \sum_{\substack{i\in I \\ j\in J}} \sum_{\omega\in\Omega} p^k x_i^k y_j q(\omega|\omega_1, i, j)(a_{ij}^{\omega_1,k} - f(p_i,\omega)) \\ &= \sum_{k\in K} \sum_{\substack{i\in I \\ j\in J}} p^k x_i^k y_j a_{ij}^{\omega_1,k} - T_{xy}(0,f)(p,\omega_1). \end{aligned} \tag{2.1}$$

Let now $\Gamma'(f)(p,\omega_1)$ be the game in which the strategy spaces are $X_0[f](p,\omega_1)$ and $Y_0[f](p,\omega_1)$, and the payoff associated to the pair of strategies (x,y) is $\phi_{xy}(f)(p,\omega_1)$.

LEMMA 2.3. *The game* $\Gamma'(f)(p,\omega_1)$ *has a value* $\phi(f)(p,\omega_1)$ *and optimal strategies for both players. Moreover,*

$$\phi(f)(p,\omega_1) = \lim_{\lambda\to 0} \frac{T(\lambda, f)(p,\omega_1) - T(0,f)(p,\omega_1)}{\lambda}.$$

Proof. The existence of $\lim_{\lambda\to 0} \frac{T(\lambda,f)(p,\omega_1)-T(0,f)(p,\omega_1)}{\lambda}$ and of the value of $\Gamma'(f)(p,\omega_1)$ as well as their equality follow from an extension of Mills' result [11] proved in [10, part A, exercise 6, p. 12]. □

This lemma implies that there are two possible interpretations of the introduction of ϕ: the first one is that since $T(\lambda, v_\lambda) = v_\lambda$, a local analysis of the mapping $T(\alpha, .)$ at the point $\alpha = 0$ should characterize the limit of (v_λ). Moreover, this limit is not completely characterized by the condition $T(0,v) = v$. That explains the introduction of ϕ as the derivative of the map T. Mills' result implies, moreover, that this derivative can be viewed as the value of an auxiliary game in which the players take care of their current payoffs under the constraint that they guarantee the value $T(0,v)$.

2.2. Idea of the proof. The functions v_λ are characterized by the fact they are fixed points of the contracting mappings $T(\lambda, f)$. Therefore, the properties of v_λ, such as convergence should follow from a study of the mappings themselves. The idea here is to study an asymptotic expansion of $T(\lambda, f)$ as λ goes to 0. Actually we will need a first-order expansion using $T(0,f)$ and the derivative $\phi(f)$ with respect to λ. Indeed, a necessary condition for v to be the limit of v_λ is that $T(0,v) = v$. But this condition is not sufficient, and we need to go one step further in the expansion. When the values are real numbers (i.e., when K is a singleton), this idea goes back to Kohlberg [5].

In the case of *complete information absorbing games*, any limit v of a converging subsequence of v_λ is a fixed point of $T(0,.)$. But Kohlberg points out that being a fixed point of $T(0,.)$ does not characterize the limit of the family $\{v_\lambda\}$. Indeed, $T(0,v)$ does not depend on nonabsorbing payoffs, and $T(0,v) = v$ implies only that player 1 can guarantee an absorbing payoff of at least v. The control of the nonabsorbing payoff is related to the sign of $\phi(v)$: the limit v is characterized, in this framework, by the following system, where w is any function such that $w(.,\omega^*)$ is equal to the limit $v(.,\omega^*)$ of $v_\lambda(.,\omega^*)$ for all absorbing states $\omega^* \in \Omega^*$:

$$\begin{cases} w > v \ \Rightarrow \ T(0,w) < w \text{ or } \{T(0,w) = w \text{ and } \phi(w) < 0\} & \mathcal{S}_1, \\ w < v \ \Rightarrow \ T(0,w) > w \text{ or } \{T(0,w) = w \text{ and } \phi(w) > 0\} & \mathcal{S}_2. \end{cases}$$

The intuition behind such a system is that if $w > v$, either $T(0,w) < w$, and therefore player 1 cannot maintain the level w, i.e., cannot prevent absorbing with a payoff smaller than w, or $T(0,w) = w$, and $\phi(w) < 0$. Due to the definition of the strategy sets in game $\Gamma'(w)(p,\omega_1)$, this means that player 1 cannot *simultaneously* maintain the level and guarantee a large enough current payoff (compared to w). Hence player 1 cannot guarantee w in the λ-discounted game for λ close to 0.

In the case of complete information absorbing games [5, 12] and in the case of incomplete information games with no absorbing states [1, 12], one can prove that any limit v of a converging subsequence of v_λ satisfies the above system $(\mathcal{S}_1, \mathcal{S}_2)$ and that this system has a unique solution, which proves the result.

The problem in the case of incomplete information games is that v is a function of p, and the study of the equation $T(0,v) = v$ does not reduce to a control of the absorbing payoffs. On the other hand, unlike in nonstochastic games with incomplete information, the equation $T(0,v) = v$ cannot be reduced to a concavity property of v. We are going to prove only that the limit v of any converging subsequence of v_λ satisfies $\mathcal{S}_1$ (see section 2.3). The idea is then to prove that this equation indeed implies that if $w > v$, player 1 cannot guarantee w in the λ-discounted games for λ close enough to 0: then this equation implies that $v = \limsup v_\lambda$, and therefore v is unique (see section 3). More precisely, in section 3 we prove the following (where ε is a positive constant and δ a positive strictly concave function of p, $\bar{\varepsilon}$ denotes the real function on Ω defined by $\bar{\varepsilon}(\omega_0) = \varepsilon$, and for all $\omega^* \in \Omega^*$, $\bar{\varepsilon}(\omega^*) = 0$).

PROPOSITION 2.4. *Let $f \in \mathcal{F}$ satisfy:*

$$T(0, f + \delta + \bar{\varepsilon}) \leq f + \delta + \bar{\varepsilon},$$
$$T(0, f + \delta + \bar{\varepsilon})(p,\omega_0) = f(p,\omega_0) + \delta(p) + \varepsilon \ \Rightarrow \ \phi(f + \delta + \bar{\varepsilon})(p,\omega_0) < 0.$$

Then $f \geq v$.

2.3. Properties. Recall that v is the limit of a converging subsequence of $\{v_\lambda\}$. In this section we prove some general properties of $T(\lambda, f)$. This section aims at proving $\mathcal{S}_1$, namely, that for functions w chosen in some class of functions that always lie above v, $T(0,w) \leq w$ and $T(0,w)(p,\omega) = w(p,\omega)$ implies that $\phi(w)(p,\omega) < 0$. This is the content of Lemmas 2.7 and 2.10. The first lemma is a contracting property of $T(\lambda,.)$ and a regularity property of the correspondences of optimal strategies $X_\lambda[f](p,\omega)$ and $Y_\lambda[f](p,\omega)$.

LEMMA 2.5.

1. *For any $f \in \mathcal{F}$ and any $g \in \mathcal{F}$, for all $p \in \Delta(K)$, $\omega \in \Omega$, and $\lambda \in [0,1]$, $\lambda' \in [0,1]$,*

$$T(\lambda, f)(p,\omega) - T(\lambda', g)(p,\omega) \leq \ (1-\lambda)\max\left[\max_{\substack{q\in\Delta(K)\\ \omega'\in\Omega}} \{f(q,\omega') - g(q,\omega')\}, 0\right] + 2|\lambda - \lambda'|.$$

2. *For any $f \in \mathcal{F}$ and any $\omega \in \Omega$, the correspondences $(\lambda, p) \to X_\lambda[f](p,\omega)$ and $(\lambda, p) \to Y_\lambda[f](p,\omega)$ are upper semicontinuous.*

Remark. *Property* 1 *implies, in particular, the contracting property of* $T(\lambda,.)$ *and the nonexpansiveness of* $T(0,.)$.

$$\|T(\lambda,f)-T(\lambda,g)\| \leq (1-\lambda)\|f-g\|.$$

Proof. Let $(f,g)\in\mathcal{F}^2$ and $(\lambda,\lambda')\in[0,1]^2$. Take $x\in X_\lambda[f](p,\omega)$ and $y\in Y_{\lambda'}[g](p,\omega)$; then

$$T(\lambda,f)(p,\omega)-T(\lambda',g)(p,\omega)\leq T_{xy}(\lambda,f)(p,\omega)-T_{xy}(\lambda',g)(p,\omega).$$

Using the fact that the payoffs and f take their values in [0,1], one gets

$$\begin{aligned}T_{xy}(\lambda,f)(p,\omega)-T_{xy}(\lambda',g)(p,\omega) \quad &\leq \quad 2|\lambda-\lambda'|\\ &+(1-\lambda)\sum_{k\in K}\sum_{\substack{i\in I\\ j\in J}}p^k x_i^k y_j q(\omega'|\omega,i,j)\left(f(p_i,\omega')-g(p_i,\omega')\right),\end{aligned}$$

which implies result 1.

Assume λ_n converges to λ and p_n converges to p. Let $x_n\in X_{\lambda_n}[f](p_n,\omega)$. It is straightforward to check that if x is the limit of a converging subsequence of x_n, then $x\in X_0[f](p,\omega)$. The argument is similar for Y. □

Lemma 2.6. *For any accumulation point* v *of* v_λ, $T(0,v)=v$.

Proof. The result is obtained by letting λ go to 0 in the formula of Lemma 2.2 and by using the continuity of T proved in Lemma 2.5 and the uniform convergence of a subsequence of v_λ to v. □

From now on, we fix $\varepsilon>0$, and we denote by $\bar\varepsilon$ the function from Ω to $[0,\varepsilon]$ satisfying $\bar\varepsilon(\omega_0)=\varepsilon$ and for $\omega^*\in\Omega^*$, $\bar\varepsilon(\omega^*)=0$. Let δ be a fixed 1-Lipschitz strictly concave function from $\Delta(K)$ to $[0,\varepsilon]$. For $f\in\mathcal{F}$, the function $f+\delta+\bar\varepsilon$ therefore satisfies $(f+\delta+\bar\varepsilon)(p,\omega_0)=f(p,\omega_0)+\delta(p)+\varepsilon$, and for $\omega^*\in\Omega^*$, $(f+\delta+\bar\varepsilon)(p,\omega^*)=f(p,\omega^*)+\delta(p)$. Lemmas 2.7 and 2.8 concern properties of the mappings T and the optimal strategies correspondences X and Y that are needed to prove the desired property stated in Lemma 2.10. The idea is that for some functions $w>v$, $T(0,w)(p,\omega_0)=w(p,\omega_0)$ implies that under optimal strategies $X_0[w](p,\omega_0)$ and $Y_0[w](p,\omega_0)$ there is no revelation of information and absorption occurs with probability 0. In addition, in Lemma 2.8 some regularity properties of the correspondences of optimal strategies are stated.

Lemma 2.7.

$$\begin{aligned}&\forall(x,y)\in\Delta(I)^K\times\Delta(J),\ \forall p,\ \forall f\in\mathcal{F},\\ &T_{xy}(0,f+\delta+\bar\varepsilon)(p,\omega_0)\leq T_{xy}(0,f)(p,\omega_0)+\delta(p)+\varepsilon.\end{aligned}$$

Assume $f\in\mathcal{F}$ *and* $p\in\Delta(K)$ *satisfy* $T(0,f)(p,\omega_0)\leq f(p,\omega_0)$; *then*

$$T(0,f+\delta+\bar\varepsilon)(p,\omega_0)\leq f(p,\omega_0)+\delta(p)+\varepsilon.$$

In particular,

$$T(0,v+\delta+\bar\varepsilon)(p,\omega_0)\leq v(p,\omega_0)+\delta(p)+\varepsilon.$$

Proof. Let $x\in\Delta(I)^K$ and $y\in\Delta(J)$. Then

$$\begin{aligned}T_{xy}(0,f+\delta+\bar\varepsilon)(p,\omega_0) \quad &\leq \quad \sum_{k\in K}\sum_{\substack{i\in I\\ j\in J}}\sum_{\omega'\in\Omega}p^k x_i^k y_j q(\omega'|\omega_0,i,j)\left(f(p_i,\omega')+\delta(p_i)+\varepsilon\right)\\ &\leq \quad T_{xy}(0,f)(p,\omega)+\sum_{k\in K}\sum_{\substack{i\in I\\ j\in J}}p^k x_i^k y_j\left(\delta(p_i)+\varepsilon\right).\end{aligned}$$

Therefore, using the concavity of δ, one gets the first assertion. By choosing $x \in X_0[f+\delta+\bar{\varepsilon}](p,\omega_0)$ and $y \in Y_0[f](p,\omega_0)$, one gets the second assertion. Lemma 2.6 implies the third assertion. $\square$

This lemma would be a direct consequence of the contracting property of $T(\lambda, v)$ if δ were a constant. As δ is a function of p, one has to take care of the splitting that occurs in $\Gamma(\lambda, v+\delta+\bar{\varepsilon})(p,\omega)$. The concavity of δ then implies that such a splitting does not increase the payoffs. We denote by $\mathcal{C}_\varepsilon(p)$ the following condition.

Condition $\mathcal{C}_\varepsilon(p)$. p is in the interior of $\Delta(K)$ and $T(0, v+\delta+\bar{\varepsilon})(p,\omega_0) = v(p,\omega_0) + \delta(p) + \varepsilon$.

The following lemma states a tightness property. The basic tightness property would be the following: if h is a positive constant and $T(0,v)(p,\omega_0) = v(p,\omega_0)$ and $T(0,v+h)(p,\omega_0) = v(p,\omega_0)+h$, then for any $h' \leq h$, $T(0,v+h')(p,\omega_0) = v(p,\omega_0)+h'$. In Lemma 2.8 we get a more precise result that allows us, in particular, to let p vary.

LEMMA 2.8. *Under condition* $\mathcal{C}_\varepsilon(p)$, *we have the following.*

(a) $X_0[v+\delta+\bar{\varepsilon}](p,\omega_0) \subset NR$.

(b) $X_0[v+\delta+\bar{\varepsilon}](p,\omega_0) \subset X_0[v+\delta+\bar{\varepsilon}'](p',\omega_0)$, *where* $\varepsilon' < \varepsilon$ *and* $\bar{\varepsilon}' : \Omega \to [0,\varepsilon]$ *is defined by* $\bar{\varepsilon}'(\omega^*) = 0$ *for* $\omega^* \in \Omega^*$ *and* $\bar{\varepsilon}'(\omega_0) = \varepsilon'$; *and*

$$|p - p'| = \sum_{k\in K} |p^k - p'^k| \leq \frac{\varepsilon - \varepsilon'}{4}.$$

Moreover,

$$T(0, v+\delta+\bar{\varepsilon}')(p',\omega_0) = v(p',\omega_0) + \delta(p') + \varepsilon'.$$

(c) $Y_0[v+\delta+\bar{\varepsilon}'](p,\omega_0) \subset Y_0[v+\delta+\bar{\varepsilon}](p,\omega_0)$ *for* $\bar{\varepsilon}'$ *defined as above.*

Notation. For a pair $(x,y) \in \Delta(I)^K \times \Delta(J)$ of mixed moves of the players, let μ^*_{xy} denote the measure on Ω^* defined by

$$\mu^*_{xy}(\omega^*) = \sum_{k\in K} \sum_{\substack{i\in I\\ j\in J}} p^k x^k_i y_j q(\omega^*|\omega_0, i, j).$$

$\mu^*_{xy}(\omega^*)$ is the probability to reach state ω^* if we are in state ω_0, and the players play (x,y). Note that μ^* is a measure but not a probability distribution on Ω^*.

Proof.

(a) Let $x \in X_0[v+\delta+\bar{\varepsilon}](p,\omega_0)$ and $y \in Y_0[v](p,\omega_0)$. Condition $\mathcal{C}_\varepsilon(p)$ and Lemma 2.6 imply

$$v(p,\omega_0) + \delta(p) + \varepsilon \quad \leq \quad T_{xy}(0, v+\delta+\bar{\varepsilon})(p,\omega_0).$$

The proof of Lemma 2.7 and the definition of y imply

$$T_{xy}(0, v+\delta+\bar{\varepsilon})(p,\omega_0) \leq v(p,\omega_0) + \sum_{\substack{k\in K\\ i\in I}} p^k x^k_i \delta(p_i) + \varepsilon.$$

These two inequalities lead to

$$\sum_{\substack{k\in K\\ i\in I}} p^k x^k_i \delta(p_i) \geq \delta(p).$$

Therefore, by strict concavity of δ, and since p is in the interior of $\Delta(K)$, the result follows.

(b) Let $x \in X_0[v+\delta+\bar{\varepsilon}](p,\omega_0)$ and $y \in \Delta(J)$. Condition $\mathcal{C}_\varepsilon(p)$ leads to:

$$T_{xy}(0,v+\delta+\bar{\varepsilon})(p,\omega_0) \geq v(p,\omega_0)+\delta(p)+\varepsilon.$$

By (a) and $x \in NR$, this inequality can be rephrased:

$$\sum_{\omega^*\in\Omega^*} \mu^*_{xy}(\omega^*)\left(v(p,\omega^*)+\delta(p)\right) \geq \sum_{\omega^*\in\Omega^*} \mu^*_{xy}(\omega^*)\left(v(p,\omega_0)+\delta(p)+\varepsilon\right).$$

By definition of p' and using the Lipschitz property of δ and v,

$$\begin{aligned}\sum_{\omega^*\in\Omega^*} \mu^*_{xy}(\omega^*)\left(v(p',\omega^*)+\delta(p')\right) &\geq \sum_{\omega^*\in\Omega^*} \mu^*_{xy}(\omega^*)\left(v(p',\omega_0)+\delta(p')+\varepsilon-4|p-p'|\right)\\ &\geq \sum_{\omega^*\in\Omega^*} \mu^*_{xy}(\omega^*)\left(v(p',\omega_0)+\delta(p')+\varepsilon'\right).\end{aligned}$$

This implies $T_{xy}(0,v+\delta+\bar{\varepsilon}')(p',\omega_0) \geq v(p',\omega_0)+\delta(p')+\varepsilon'$. By Lemma 2.7, $v(p',\omega_0)+\delta(p')+\varepsilon' \geq T(0,v+\delta+\bar{\varepsilon}')(p',\omega_0)$. Hence

$$\begin{aligned}T(0,v+\delta+\bar{\varepsilon}')(p',\omega_0) &\geq \inf_{y\in\Delta(J)} T_{xy}(0,v+\delta+\bar{\varepsilon}')(p',\omega_0)\\ &\geq v(p',\omega_0)+\delta(p')+\varepsilon'\\ &\geq T(0,v+\delta+\bar{\varepsilon}')(p',\omega_0).\end{aligned}$$

This inequality drives the desired result.

(c) Let $x \in \Delta(I)^K$ and $y \in Y_0[v+\delta+\bar{\varepsilon}'](p,\omega_0)$.

$$\begin{aligned}T_{xy}(0,v+\delta+\bar{\varepsilon})(p,\omega_0) &= T_{xy}(0,v+\delta+\bar{\varepsilon}')(p,\omega_0)\\ &+ \sum_{k\in K}\sum_{\substack{i\in I\\ j\in J}} p^k x_i^k y_j q(\omega_0|\omega_0,i,j)(\varepsilon-\varepsilon')\\ &\leq v(p,\omega_0)+\delta(p)+\varepsilon'+(\varepsilon-\varepsilon')\end{aligned}$$

by Lemma 2.7. By condition $\mathcal{C}_\varepsilon(p)$, this last inequality is the result. □

Let $d(y,y') = \max_{j\in J}|y_j - y'_j|$ for $y \in \Delta(J)$, $y' \in \Delta(J)$. For $Y \subset \Delta(J)$, $d(y,Y) = \inf_{y'\in Y} d(y,y')$ is the distance between y and the set Y.

LEMMA 2.9. *Under condition $\mathcal{C}_\varepsilon(p)$, there is an $\alpha > 0$ such that for all $y \in \Delta(J)$,*

$$\begin{aligned}&d\left(y, Y_0[v+\delta+\bar{\varepsilon}](p,\omega_0)\right) \geq \varepsilon/4\\ \Rightarrow\ &\\ &\exists x \in \Delta(I)^K,\ T_{xy}(0,v+\delta+\bar{\varepsilon})(p,\omega_0) \geq v(p,\omega_0)+\delta(p)+\varepsilon+\alpha.\end{aligned}$$

Proof. This lemma follows from the compactness of $\Delta(J)$ and the continuity of $T_{xy}(0,v+\delta+\bar{\varepsilon})(p,\omega_0)$ in y. □

The following is the key lemma.

LEMMA 2.10. *Under condition $\mathcal{C}_\varepsilon(p)$,*

$$\phi(v+\delta+\bar{\varepsilon})(p,\omega_0) < 0.$$

The idea of the proof is the following. Assume that for some p, the result is false; then there is a small enough λ such that given any strategy τ of player 2, player 1 has a reply that ensures him a payoff strictly greater than $v_\lambda(p,\omega_0)$. Indeed, if the mixed move y of player 2 is far from $Y_0[v+\delta+\bar{\varepsilon}](p,\omega_0)$, then by Lemma 2.9, player 1 has a reply that strictly increases the level of future payoffs: absorption occurs with a positive probability and a high payoff. If, on the other hand, y is close to $Y_0[v+\delta+\bar{\varepsilon}](p,\omega_0)$, then the hypothesis that $\phi(v+\delta+\bar{\varepsilon})(p,\omega_0)\geq 0$ implies that player 1 has a reply that gives him at the same time a good absorbing and a good nonabsorbing payoff.

Notation. For a function $f\in\mathcal{F}$, let us denote by $\bar{X}_0[f](p,\omega_0)$ the set of optimal strategies in $\Gamma'[f](p,\omega_0)$. This is a subset of $X_0[f](p,\omega_0)$.

Proof. Let us prove the result by contradiction, assuming that for some p, $T(0,v+\delta+\bar{\varepsilon})(p,\omega_0)=v(p,\omega_0)+\delta(p)+\varepsilon$ and $\phi(v+\delta+\bar{\varepsilon})(p,\omega_0)\geq 0$.

For ε, δ, and p, fix α as in Lemma 2.9. Then choose a λ such that

$$\begin{cases} \|v_\lambda - v\| \leq \beta = \min(\varepsilon/4,\alpha/4), \\ \lambda\leq \alpha/8. \end{cases}$$

For any $y\in\Delta(J)$, we will exhibit an $x\in\Delta(I)^K$ with $T_{xy}(\lambda,v_\lambda)(p,\omega_0)>v_\lambda(p,\omega_0)$. Hence $T(\lambda,v_\lambda)(p,\omega_0)>v_\lambda(p,\omega_0)$, which contradicts Lemma 2.2.

- If $d\left(y,Y_0[v+\delta+\bar{\varepsilon}](p,\omega_0)\right)\geq\varepsilon/4$, then by Lemma 2.9, there is an $x\in\Delta(I)^K$ such that

  $$T_{xy}(0,v+\delta+\bar{\varepsilon})(p,\omega_0)\geq v(p,\omega_0)+\delta(p)+\varepsilon+\alpha.$$

  Hence, by Lemma 2.7,

  $$T_{xy}(0,v)(p,\omega_0)\geq v(p,\omega_0)+\alpha.$$

  Let us now compute $T_{xy}(\lambda,v_\lambda)$. Lemma 2.5 implies

  $$\begin{aligned} T_{xy}(\lambda,v_\lambda)(p,\omega_0) &\geq T_{xy}(0,v)(p,\omega_0)-\alpha/4-\beta \\ &\geq v(p,\omega_0)+\alpha-\alpha/2 \\ &\geq v_\lambda(p,\omega_0)+\alpha/4. \end{aligned}$$

- If $d(y,Y_0[v+\delta+\bar{\varepsilon}](p,\omega_0)<\varepsilon/4$, let $x\in\bar{X}_0[v+\delta+\bar{\varepsilon}](p,\omega_0)$. By Lemma 2.8, x is nonrevealing; thus $T_{xy}(0,v+\delta+\bar{\varepsilon})(p,\omega_0)\geq v(p,\omega_0)+\delta(p)+\varepsilon$ and the concavity of δ imply

  $$\sum_{\omega^*\in\Omega^*}\mu^*_{xy}(\omega^*)v(p,\omega^*)\geq\sum_{\omega^*\in\Omega^*}\mu^*_{xy}(\omega^*)(v(p,\omega_0)+\varepsilon).$$

  By definition of λ,

  $$\sum_{\omega^*\in\Omega^*}\mu^*_{xy}(\omega^*)v_\lambda(p,\omega^*)\geq\sum_{\omega^*\in\Omega^*}\mu^*_{xy}(\omega^*)(v_\lambda(p,\omega_0)+\varepsilon-2\beta),$$

  and therefore

  $$T_{xy}(0,v_\lambda)(p,\omega_0)\geq v_\lambda(p,\omega_0). \tag{2.2}$$

  Define now $y_0\in Y_0[v+\delta+\bar{\varepsilon}](p,\omega_0)$ such that $\|y-y_0\|\leq\varepsilon/4$. Then

  $$\sum_{k\in K}\sum_{\substack{i\in I\\ j\in J}}p^k x_i y_{0j}(a^{\omega_0 k}_{ij}-v(p,\omega_0)-\delta(p)-\varepsilon)=\phi_{xy_0}(v+\delta+\bar{\varepsilon})(p,\omega_0)\geq 0.$$

  Thus, by continuity,

  $$\sum_{k\in K}\sum_{\substack{i\in I\\ j\in J}}p^k x_i y_j a^{\omega_0 k}_{ij} \quad\geq\quad v_\lambda(p,\omega_0)+\varepsilon-\beta-\varepsilon/4.$$

This last inequality and (2.2) imply

$$T_{xy}(\lambda, v_\lambda)(p, \omega_0) \geq v_\lambda(p, \omega_0) + \lambda\varepsilon/2.$$

- Hence for any y, we have an x such that $T_{xy}(\lambda, v_\lambda)(p, \omega_0) > v_\lambda(p, \omega_0)$, and this contradicts the recursive formula and proves the result. □

3. The proof of Theorem 1.1. Our goal is to prove that v is the unique limit of a converging subsequence of $\{v_\lambda\}$.

If in addition to Lemma 2.10, one had a symmetric result, namely that $T(0, v - \bar{\varepsilon})(p, \omega_0) \geq v(p, \omega_0) - \varepsilon$, and $T(0, v - \bar{\varepsilon})(p, \omega_0) = v(p, \omega_0) - \varepsilon \ \Rightarrow\ \phi(v - \bar{\varepsilon})(p, \omega_0) > 0$, then uniqueness of such a v would be a consequence of the definition of ϕ as the derivative of T, and of the contracting property of $T(\lambda, .)$ stated in Lemma 2.5. This is the case for incomplete information games with no absorbing states, and for absorbing games with complete information (see [5], [12]). In the case of absorbing games with incomplete information, in order to prove this property by contradiction, one should assume that for some p, $T(0, v - \bar{\varepsilon})(p, \omega_0) = v(p, \omega_0) - \varepsilon$ and $\phi(v - \bar{\varepsilon})(p, \omega_0) < 0$. But the difficulty in concluding that player 2 has a best response to any strategy of player 1 that leads to a payoff strictly inferior to v_λ in a λ-discounted game arises from the fact that since the strategies of player 1 may be revealing, the equation $T(0, v - \bar{\varepsilon})(p, \omega_0) = v(p, \omega_0) - \varepsilon$ does not lead to a bound on the absorbing payoffs.

But, without such a property Lemma 2.10 implies that player 1 cannot guarantee $v + \delta + \bar{\varepsilon}$ in a λ-discounted game with λ small, because he cannot simultaneously push his absorbing and nonabsorbing payoffs above $v + \delta + \varepsilon$. More precisely, the intuition for the end of the proof is the following: the function $v + \delta + \bar{\varepsilon}$ is such that for every p, either $T(0, v + \delta + \bar{\varepsilon})(p, \omega_0) < v(p, \omega_0) + \delta(p) + \varepsilon$ or $T(0, v + \delta + \varepsilon)(p, \omega) = v(p, \omega_0) + \delta(p) + \varepsilon$, and $\phi(v + \delta + \bar{\varepsilon})(p, \omega_0) < 0$. By Lemma 2.3, this implies that for λ small enough (depending on p)

$$T(\lambda, v + \delta + \bar{\varepsilon})(p, \omega_0) \leq v(p, \omega_0) + \delta(p) + \varepsilon.$$

Would such a λ be uniform in p, then such an inequality would prove $v_\lambda(p, \omega_0) \leq v(p, \omega_0) + \delta(p) + \varepsilon$. But λ needs not be uniform in p. Nevertheless, the remainder of the proof aims at establishing that for λ small enough $v_\lambda(p, \omega_0) \leq v(p, \omega_0) + \delta(p) + \varepsilon$. Uniformity of λ is replaced by the following proposition.

PROPOSITION 3.1. *For any sequences $\lambda_n \in [0, 1]$ and $p_{\lambda_n} \in \Delta(K)$ such that λ_n converges to 0 as n goes to infinity and p_{λ_n} converges to $\bar{p}$ in the interior of $\Delta(K)$,*

$$\exists N,\ \forall n \geq N,\ T(\lambda_n, v + \delta + \bar{\varepsilon})(p_{\lambda_n}, \omega_0) < v(p_{\lambda_n}, \omega_0) + \delta(p_{\lambda_n}) + \varepsilon.$$

Proof. Assume by contradiction that there is a sequence λ_n converging to 0 and a sequence p_{λ_n} converging to $\bar{p}$ in the interior of $\Delta(K)$ such that

$$\forall N,\ \exists n \geq N,\ T(\lambda_n, v + \delta + \bar{\varepsilon})(p_{\lambda_n}, \omega_0) \geq v(p_{\lambda_n}, \omega_0) + \delta(p_{\lambda_n}) + \varepsilon.$$

Note that, by concavity, one always has $v(p_{\lambda_n}, \omega_0) + \delta(p_{\lambda_n}) + \varepsilon \geq T(0, v + \delta + \bar{\varepsilon})(p_{\lambda_n}, \omega_0)$. In what follows, let us denote by Λ the (infinite) subset of $(\lambda_n)_{n \in \mathbb{N}}$ satisfying

$$(3.1)\quad T(\lambda, v + \delta + \bar{\varepsilon})(p_\lambda, \omega_0) \geq v(p_\lambda, \omega_0) + \delta(p_\lambda) + \varepsilon \geq T(0, v + \delta + \bar{\varepsilon})(p_\lambda, \omega_0),$$

and by $\bar{p}$ the limit of a converging subsequence of $(p_\lambda)_{\lambda \in \Lambda}$. The proposition will be a consequence of Lemmas 3.2 and 3.3. Indeed, they imply that for some λ, $T(0, v + \delta + \bar{\varepsilon}/2)(p_\lambda, \omega_0) = v(p_\lambda, \omega_0) + \delta(p_\lambda) + \varepsilon/2$ and $\phi(v + \delta + \bar{\varepsilon}/2)(p_\lambda, \omega_0) \geq 0$. This contradicts Lemma 2.10. □

Lemma 3.2.

(a) *For* $\lambda \in \Lambda$, *for all* $x_\lambda \in X_\lambda[v+\delta+\bar{\varepsilon}](p_\lambda,\omega_0)$, $y_\lambda \in Y_0[v+\delta+\bar{\varepsilon}](p_\lambda,\omega_0)$,

$$\phi_{x_\lambda y_\lambda}(v+\delta+\bar{\varepsilon})(p_\lambda,\omega_0) \geq 0.$$

(b) *For* $\varepsilon' \leq \varepsilon$,

$$T(0,v+\delta+\bar{\varepsilon}')(\bar{p},\omega_0) = v(\bar{p},\omega_0)+\delta(\bar{p})+\varepsilon'.$$

(c) *For all* ε' *satisfying* $\varepsilon/8 \leq \varepsilon' < \varepsilon$, *there is a* λ^* *such that for* $\lambda \in \Lambda$, $\lambda \leq \lambda^*$,

$$T(0,v+\delta+\bar{\varepsilon}')(p_\lambda,\omega_0) = v(p_\lambda,\omega_0)+\delta(p_\lambda)+\varepsilon',$$

$$X_0[v+\delta+\bar{\varepsilon}](\bar{p},\omega_0) \subset X_0[v+\delta+\bar{\varepsilon}'](p_\lambda,\omega_0).$$

Proof.

(a)

$$\phi_{x_\lambda y_\lambda}(v+\delta+\bar{\varepsilon})(p_\lambda,\omega_0) \quad = \frac{T_{x_\lambda y_\lambda}(\lambda,v+\delta+\bar{\varepsilon})(p_\lambda,\omega_0) - T_{x_\lambda y_\lambda}(0,v+\delta+\bar{\varepsilon})(p_\lambda,\omega_0)}{\lambda}.$$

Therefore inequality (3.1) implies the result.

(b) Inequality (3.1) and the continuity of T (Lemma 2.5) imply by going to the limit:

$$T(0,v+\delta+\bar{\varepsilon})(\bar{p},\omega_0) = v(\bar{p},\omega_0)+\delta(\bar{p})+\varepsilon.$$

This is condition $\mathcal{C}_\varepsilon(\bar{p})$. Lemma 2.8(b) leads to the result.

(c) Lemma 3.2(b) is condition $\mathcal{C}_{\varepsilon'}(\bar{p})$; Lemma 2.8(b) then implies the result. □

Lemma 3.3. *Fix* $\varepsilon' = \varepsilon/2$, *and define* λ^* *as in Lemma* 3.2(c). *There is a* $\lambda \leq \lambda^*$, $\lambda \in \Lambda$ *such that*

$$\phi(v+\delta+\bar{\varepsilon}/2)(p_\lambda,\omega_0) \geq 0.$$

Proof. Define $y_\lambda \in Y_0[v+\delta+\bar{\varepsilon}/2](p_\lambda,\omega_0)$ to be optimal in $\Gamma'[v+\delta+\bar{\varepsilon}/2](p_\lambda,\omega_0)$. For $\lambda \in \Lambda$, $\lambda \leq \lambda^*$, let $x_\lambda \in X_\lambda[v+\delta+\bar{\varepsilon}](p_\lambda,\omega_0)$, and define x to be the limit of a converging subsequence of x_λ. Choose λ such that $\|x-x_\lambda\| \leq \varepsilon/2$. By Lemma 2.5, $x \in X_0[v+\delta+\bar{\varepsilon}](\bar{p},\omega_0)$. By Lemma 3.2c, $x \in X_0[v+\delta+\bar{\varepsilon}/2](p_\lambda,\omega_0)$.

Therefore,

$$\phi_{xy_\lambda}(v+\delta+\bar{\varepsilon}/2)(p_\lambda,\omega_0) \leq \phi(v+\delta+\bar{\varepsilon}/2)(p_\lambda,\omega_0). \tag{3.2}$$

Recall that by Lemma 2.8, $x \in NR$ and $y_\lambda \in Y_0[v+\delta+\bar{\varepsilon}](p_\lambda,\omega_0)$. By (2.1) and Lemma 3.2(c),

$$\begin{aligned}\phi_{xy_\lambda}(v+\delta+\bar{\varepsilon}/2)(p_\lambda,\omega_0) \quad &= \quad \sum_{\substack{i\in I\\ j\in J}}\sum_{k\in K} p_\lambda^k x_i y_{\lambda j} a_{ij}^{k\omega_0} - (v(p_\lambda,\omega_0)+\delta(p_\lambda)+\varepsilon/2)\\ &\geq \quad \phi_{x_\lambda y_\lambda}(v+\delta+\bar{\varepsilon})(p_\lambda,\omega_0)+\varepsilon/2-\|x-x_\lambda\|.\end{aligned}$$

Lemma 3.2(a) implies $\phi_{x_\lambda y_\lambda}(v+\delta+\bar{\varepsilon})(p_\lambda,\omega_0) \geq 0$, and the result follows. □

We now establish Theorem 1.1. The proof proceeds by induction on the cardinality of K, *card* (K).

If *card* $(K) = 1$, the game is a complete information game and by [5] v_λ converges.

Assume the result is true for *card* $(K) \leq \mathcal{K}-1$, and let *card* $(K) = \mathcal{K}$. The induction hypothesis implies that on the boundary of $\Delta(K)$, v_λ converges.

Let us prove the convergence of v_λ by contradiction. Assume that there is a sequence λ_n such that λ_n goes to 0 and such that v_{λ_n} converges uniformly to some function v' different from v. By Proposition 1.5, $v(p,\omega)$ and $v'(p,\omega)$ are equal as soon as $\omega \in \Omega^*$. So, we assume the following.

Hypothesis **H**. There is a $p_0 \in \Delta(K)$ such that $v'(p_0,\omega_0) > v(p_0,\omega_0)$.

By induction hypothesis, p_0 is in the interior of $\Delta(K)$. Consider a sequence λ_n such that $\lim_{n\to\infty} \lambda_n = 0$ and v_{λ_n} converges uniformly to v' as n goes to infinity.

Let $\varepsilon > 0$ satisfy $v'(p_0,\omega_0) > v(p_0,\omega_0) + 4\varepsilon$; let δ be a strictly concave continuous function from $\Delta(K)$ to $[0,\varepsilon]$.

Now, for all λ, let $\hat{p}_\lambda$ belong to $\arg\max_{p\in\Delta(K)} [v_\lambda(p,\omega_0) - v(p,\omega_0) - \delta(p)]$. Assume $\|v_\lambda - v'\| \leq \varepsilon/16$. Then **H** and the definition of ε imply $v_\lambda(\hat{p}_\lambda,\omega_0) - v(\hat{p}_\lambda,\omega_0) - \delta(\hat{p}_\lambda) - \varepsilon > 0$.

Define $\hat{p}$ as the limit of a converging subsequence $\hat{p}_{\lambda_{s(n)}}$ of $\hat{p}_{\lambda_n}$. Then, $v'(\hat{p},\omega_0) - v(\hat{p},\omega_0) - \delta(\hat{p}) - \varepsilon \geq 0$. By induction hypothesis, $\hat{p}$ is in the interior of $\Delta(K)$.

Set Λ_0 the subset of $(\lambda_{s(n)})_{n\in\mathbb{N}}$ such that for all $\lambda \in \Lambda_0$,

$$\begin{cases} v_\lambda(\hat{p}_\lambda,\omega_0) > v(\hat{p}_\lambda,\omega_0) + \delta(\hat{p}_\lambda) + \varepsilon, \\ \hat{p}_\lambda \text{ is in the interior of } \Delta(K), \\ \|v_\lambda - v'\| \leq \varepsilon/16. \end{cases}$$

Lemma 3.4. *For all* $\lambda \in \Lambda_0$ *and all* $\varepsilon/8 \leq \varepsilon' \leq \varepsilon$,

$$T(\lambda, v+\delta+\bar{\varepsilon}')(\hat{p}_\lambda,\omega_0) \geq v(\hat{p}_\lambda,\omega_0) + \delta(\hat{p}_\lambda) + \varepsilon'.$$

Proof. For $p \in \Delta(K)$ and $\omega^* \in \Omega^*$, $v_\lambda(p,\omega^*) \leq v'(p,\omega^*) + \varepsilon/16 = v(p,\omega^*) + \varepsilon/16$. Therefore, by definition of $\hat{p}_\lambda$,

$$\begin{aligned} &T(\lambda, v_\lambda)(p,\omega_0) - T(\lambda, v+\delta+\bar{\varepsilon}')(p,\omega_0) \\ &\quad \leq \max\left\{0, \max_{\substack{r\in\Delta(K)\\ \omega'\in\Omega}} [v_\lambda(r,\omega') - v(r,\omega') - \delta(r) - \bar{\varepsilon}'(\omega')]\right\} \\ &\quad \leq v_\lambda(\hat{p}_\lambda,\omega_0) - v(\hat{p}_\lambda,\omega_0) - \delta(\hat{p}_\lambda) - \varepsilon'. \end{aligned}$$

Since $T(\lambda, v_\lambda) = v_\lambda$, the last inequality implies, for $p = \hat{p}_\lambda$,

$$T(\lambda, v+\delta+\bar{\varepsilon}')(\hat{p}_\lambda,\omega_0) \geq v(\hat{p}_\lambda,\omega_0) + \delta(\hat{p}_\lambda) + \varepsilon',$$

which is the desired result. □

Proof of Theorem 1.1. We have proved that $\hat{p}$ is in the interior of $\Delta(K)$. Therefore $(\lambda_{s(n)})$ satisfies the hypothesis of Proposition 3.1. But Lemma 3.4 and Proposition 3.1 are in contradiction. Hence the assumption **H** is impossible, and for any v' such that there is a subsequence of v_λ that converges uniformly to v',

$$\forall p,\ v'(p,\omega_0) \leq v(p,\omega_0).$$

But since v is any limit of a uniformly converging subsequence of v_λ, this implies that $v' = v$. The uniqueness of such a limit gives the result, i.e., implies the convergence of v_λ as λ goes to 0 when *card* $(K) = \mathcal{K}$. The theorem is then proved by induction. □

The previous results do not depend on the exact definition of v. The only important property of v is that $T(0, v+\delta+\bar{\varepsilon}) \leq v+\delta+\bar{\varepsilon}$ and $T(0, v+\delta+\bar{\varepsilon})(p,\omega_0) =$

$v(p,\omega_0)+\delta(p)+\varepsilon \ \Rightarrow\ \phi(v+\delta+\bar{\varepsilon})(p,\omega_0) < 0$. This property implies that there cannot be a subsequence of v_λ and p_λ such that $v(p_\lambda) < v_\lambda(p_\lambda)$. Therefore, we have proved the following proposition.

Proposition 3.5. *Let $f \in \mathcal{F}$ satisfy*

$$\begin{aligned} &T(0, f+\delta+\bar{\varepsilon}) \le f+\delta+\bar{\varepsilon},\\ &T(0, f+\delta+\bar{\varepsilon})(p,\omega_0) = f(p,\omega_0)+\delta(p)+\varepsilon \ \Rightarrow\ \phi(f+\delta+\bar{\varepsilon})(p,\omega_0) < 0; \end{aligned}$$

then $f \ge v$.

This proposition will be used in the following section.

4. The case of finitely repeated games. The same argument will apply to prove the convergence of v_n to v. Although, since v_n is no longer a fixed point of T, the proofs might be longer. We only sketch them and mention the complete argument when it is different from above.

Denote by w the limit (in the sense of the uniform norm) of a fixed converging subsequence of v_n and by v the limit of v_λ. We prove that $v = w$ and therefore that w is unique. Let $\underline{w}$ be the lim inf of (v_n). $\underline{w}$ is 1-Lipschitz and concave.

Let ε, $\bar{\varepsilon}$, and δ be defined as previously.

Lemma 4.1. *For all $p \in \Delta(K)$, we have the following.*

(a) $T(0,w)(p,\omega_0) = w(p,\omega_0)$.

(b) $T(0,\underline{w}+\delta+\bar{\varepsilon})(p,\omega_0) \le \underline{w}(p,\omega_0)+\delta(p)+\varepsilon$.

(c) $T(0,\underline{w}+\delta+\bar{\varepsilon})(p,\omega_0) = \underline{w}(p,\omega_0)+\delta(p)+\varepsilon \ \Rightarrow\ \phi(\underline{w}+\delta+\bar{\varepsilon})(p,\omega_0) < 0$.

Proof.

(a) If $(v_{s(n)})$ is a subsequence of (v_n) that converges uniformly to w, then $(v_{s(n)+1})$ also converges uniformly to w, and therefore for any p, $T(0,w)(p,\omega_0) = w(p,\omega_0)$.

(b) Lemma 4.1(a) implies that for any w and any p,

$$T(0,\underline{w})(p,\omega_0) \le T(0,w)(p,\omega_0) = w(p,\omega_0).$$

But $\underline{w}(p,\omega_0)$ is the infimum of all possible $w(p,\omega_0)$. Hence $T(0,\underline{w})(p,\omega_0) \le \underline{w}(p,\omega_0)$. The result follows from Lemma 2.7.

(c) This step is analog to Lemma 2.10. One proceeds by contradiction and assumes

$$T(0,\underline{w}+\delta+\bar{\varepsilon})(p,\omega_0) = \underline{w}(p,\omega_0)+\delta(p)+\varepsilon \text{ and } \phi(\underline{w}+\delta+\bar{\varepsilon})(p,\omega_0) \ge 0.$$

Define α as in Lemma 2.9 (applied for the function $\underline{w}$), and let $\eta \le \min(\alpha/8, \varepsilon/4)$. By definition of $\underline{w}$, there is an N such that for all $n \ge N$, $v_n \ge \underline{w} - \eta$ and $\frac{1}{n} \le \eta$.

Fix $y \in \Delta(J)$. There are two cases (see Lemma 2.9): either there is an $x \in \Delta(I)^K$ such that $T(0,\underline{w}+\delta+\bar{\varepsilon})(p,\omega_0) \ge \underline{w}(p,\omega_0)+\delta(p)+\varepsilon+\alpha$, or there is an $x \in X_0[\underline{w}+\delta+\bar{\varepsilon}](p,\omega_0)$ such that $\phi_{xy}(\underline{w}+\delta+\bar{\varepsilon})(p,\omega_0) \ge -\varepsilon/2$.

In the first case, there is an $x \in \Delta(I)^K$ such that $T(0,\underline{w}+\delta+\bar{\varepsilon})(p,\omega_0) \ge \underline{w}(p,\omega_0)+\delta(p)+\varepsilon+\alpha$. Therefore, for $n \ge N$,

$$T_{xy}\left(\frac{1}{n+1}, v_n\right)(p,\omega_0) \ge -\frac{2}{n+1} + T_{xy}(0,\underline{w}-\eta)(p,\omega_0).$$

Hence

$$T_{xy}\left(\frac{1}{n+1}, v_n\right)(p,\omega_0) \ge -\frac{2}{n+1} + w(p,\omega_0)+\alpha-\eta. \tag{4.1}$$

In the second case, there is an $x \in X_0[\underline{w} + \delta + \bar{\varepsilon}](p, \omega_0)$ such that $\phi_{xy}(\underline{w} + \delta + \bar{\varepsilon})(p, \omega_0) \geq -\varepsilon/2$. By Lemma 2.8a, $x \in NR$. Hence

$$\sum_{\substack{i\in I\\ j\in J}} \sum_{k\in K} p^k x_i y_j a_{ij}^{k\omega_0} \geq \underline{w}(p, \omega_0) + \delta(p) + \varepsilon/2.$$

Moreover, $T_{xy}(0, \underline{w} + \delta + \bar{\varepsilon})(p, \omega_0) \geq \underline{w}(p, \omega_0) + \delta(p) + \varepsilon$; therefore

$$\sum_{\omega^*\in\Omega^*} \mu_{xy}^*(\omega^*)\underline{w}(p, \omega^*) \geq \sum_{\omega^*\in\Omega^*} \mu_{xy}^*(\omega^*)(\underline{w}(p, \omega_0) + \varepsilon).$$

This leads to

$$\begin{array}{rcl} T_{xy}\left(\dfrac{1}{n+1}, v_n\right)(p, \omega_0) & \geq & \dfrac{1}{n+1}(\underline{w}(p, \omega_0) + \delta(p) + \varepsilon/2) \\ & + & \dfrac{n}{n+1} \displaystyle\sum_{\omega^*\in\Omega^*} \mu_{xy}^*(\omega^*)(\underline{w}(p, \omega_0) + \varepsilon - \eta) \\ & + & \dfrac{n}{n+1} \displaystyle\sum_{\substack{i\in I\\ j\in J}} x_i y_j q(\omega_0|\omega_0, i, j) v_n(p, \omega_0). \end{array} \tag{4.2}$$

There is an $n_0 \geq N$ such that $|v_{n_0}(p, \omega_0) - \underline{w}(p, \omega_0)| \leq \eta$. Equations (4.1) and (4.2) imply that for any n such that $|v_n(p, \omega_0) - \underline{w}(p, \omega_0)| \leq \eta$, and for any y, there is an x satisfying $T_{xy}(\frac{1}{n+1}, v_n)(p, \omega_0) \geq v_n(p, \omega_0) + \min(\eta, \frac{\varepsilon}{2n})$. Hence $v_{n+1}(p, \omega_0) \geq v_n(p, \omega_0) + \min(\eta, \frac{\varepsilon}{2n})$.

Therefore there is an $n_1 \geq N$ such that $v_{n_1}(p, \omega_0) \geq \underline{w}(p, \omega_0) + \eta$. Equations (4.1) and (4.2) imply that for any n such that $v_n(p, \omega_0) \geq \underline{w}(p, \omega_0) + \eta$, and for any y, there is an x satisfying, $T_{xy}(\frac{1}{n+1}, v_n)(p, \omega_0) \geq \underline{w}(p, \omega_0) + \eta$. Hence $v_{n+1}(p, \omega_0) \geq \underline{w}(p, \omega_0) + \eta$. Thus for any $n \geq n_1$, $v_n(p, \omega_0) \geq \underline{w}(p, \omega_0) + \eta$, which contradicts the definition of $\underline{w}$. □

LEMMA 4.2. *$\underline{w} \geq v$.*

Proof. This is a corollary of the previous lemma and Proposition 2.4 applied for the function $\underline{w}$. □

LEMMA 4.3. *$w \leq v$.*

Proof. Let us denote by p_n an element of $\arg\max\{v_n(p, \omega_0) - v(p, \omega_0) - \delta(p)\}$. Denote by d_n the quantity $v_n(p_n, \omega_0) - v(p_n, \omega_0) - \delta(p_n) - \bar{\varepsilon}(\omega_n)$. Notice that Proposition 1.5 implies that for all p, $\omega^* \in \Omega^*$, $v(p, \omega^*) = w(p, \omega^*)$. We prove the claim by induction on the cardinality of K. If *card* $(K) = 1$, it is a consequence of [5]. Assume it is true for *card* $(K) = \mathcal{K} - 1$, and let *card* $(K) = \mathcal{K}$. The induction hypothesis implies that if $p_{s(n)}$ is any converging subsequence of p_n, then its limit is in the interior of $\Delta(K)$. Thus Proposition 3.1 (with $\lambda_n = 1/n$) implies that there is an integer N such that for all $n \geq N$,

$$T\left(\frac{1}{n}, v + \delta + \bar{\varepsilon}\right)(p_n, \omega_0) < v(p_n, \omega_0) + \delta(p_n) + \varepsilon. \tag{4.3}$$

In the case of finitely repeated games, we have to consider this case that was ruled out for discounted games by Lemma 3.4. Inequality 4.3 implies

$$\begin{aligned} T\left(\frac{1}{n+1}, v + \delta + \bar{\varepsilon}\right)(p_{n+1}, \omega_0) &\leq v(p_{n+1}, \omega_0) + \delta(p_{n+1}) + \varepsilon \\ &\leq v_{n+1}(p_{n+1}, \omega_0) - d_{n+1} \\ &\leq T\left(\frac{1}{n+1}, v_n\right)(p_{n+1}, \omega_0) - d_{n+1}. \end{aligned}$$

Hence, in any case, $(n+1)\max(d_{n+1},0) \leq n\max(d_n,0)$. Thus there is a constant $C>0$ such that for all $n \geq N$, $d_n \leq \frac{C}{n}$. The result follows. □

These results imply that for any uniform limit w of a subsequence of (v_n), we have $w=v$; the result follows.

5. Concluding remarks.

1) The proof provided above gives no indication about the speed of convergence of v_n and v_λ to their limit.
2) There is no immediate generalization of the proof to the case where the transitions q depend on the parameter k. Indeed, in this case the class of nonrevealing strategies may change, and all arguments may become much more involved.
3) The limit of v_n and the limit of v_λ are equal in the situation under concern in this paper. This property is conjectured to generalize to all stochastic games with incomplete information and finite state and action sets: in [6], Lehrer and Sorin proved that for one player games the uniform convergence of v_λ is equivalent to that of v_n.
4) It is conjectured by Sorin [15] and Mertens [7] that the maxmin of infinitely repeated games with lack of information on one side exists and is also equal to v. In the case of big match games [14, 15], Sorin proved that this conjecture is satisfied. The present proof gives no insight about this conjecture, though the mappings T and ϕ, by separating the study of the absorbing and nonabsorbing payoffs, seem to be an appropriate tool to study the maxmin of the infinitely repeated game.

Acknowledgments. This work is part of my Ph.D. and has benefited from the constant help and support of my advisor Sylvain Sorin. I also owe a lot of thanks to Nicolas Vieille for the very fruitful discussions we had on the subject, the proof, and its presentation.

LYAPUNOV CHARACTERIZATIONS OF INPUT TO OUTPUT STABILITY[*]

EDUARDO SONTAG[†] AND YUAN WANG[‡]

Abstract. This paper presents necessary and sufficient characterizations of several notions of input to output stability. Similar Lyapunov characterizations have been found to play a key role in the analysis of the input to state stability property, and the results given here extend their validity to the case when the output, but not necessarily the entire internal state, is being regulated.

Key words. Lyapunov functions, output stability, ISS, robust control

1. Introduction.

This paper concerns itself with systems with outputs of the general form

$$\dot{x}(t) = f(x(t), u(t)), \quad y(t) = h(x(t)), \tag{1.1}$$

where $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ and $h : \mathbb{R}^n \to \mathbb{R}^p$ are both locally Lipschitz continuous, $f(0,0) = 0$, and $h(0) = 0$. In [19] (see also [17]), the authors introduced several notions of output stability for such systems. All these notions serve to formalize the idea of a "stable" dependence of outputs y upon inputs (which may be thought of as disturbances, actuator or measurement errors, or regulation signals). They differ in the precise formulation of the decay estimates and the overshoot, or transient behavior, characteristics of the output. Among all of them, the one of most interest is probably the one singled out for the name *input to output stability*, or IOS, for short.

Our main theorem in this paper provides a necessary and sufficient characterization of the IOS property in terms of Lyapunov functions. In the process of obtaining this characterization, we derive as well corresponding results for the variants of IOS discussed in [19]. (The relationships between those variants, shown in [19], play a role in our proofs, but otherwise the two papers are independent of each other.)

In the very special case when $y = x$, our concepts all reduce to the input to state stability (ISS) property. Much of ISS control design (cf. [2, 3, 4, 5, 6, 7, 9, 10, 13, 14, 15, 20]) relies upon the Lyapunov characterizations first obtained in [12, 16]. Thus, it is reasonable to expect a similar impact from the results given here for the more general case.

In order to review the different i/o stability concepts, let us make the following notational conventions. Euclidean norms will be denoted as $|x|$, and $\|u\|$ denotes the L^m_∞-norm (possibly infinite) of an input u (i.e., a measurable and locally essentially bounded function $u : \mathcal{I} \to \mathbb{R}^m$, where $\mathcal{I}$ is a subinterval of $\mathbb{R}$ which contains the origin;

if we do not specify the domain $\mathcal{I}$ of an input u, we mean implicitly that $\mathcal{I} = \mathbb{R}_{\geq 0}$). For each initial state $\xi \in \mathbb{R}^n$ and input u, we let $x(\cdot, \xi, u)$ be the unique maximal solution of the initial value problem $\dot{x} = f(x, u)$, $x(0) = \xi$, and write the corresponding output function $h(x(t, \xi, u))$ simply as $y(\cdot, \xi, u)$. Given a system with control-value set $\mathbb{R}^m$, we often consider the same system but with controls restricted to take values in some subset $\Omega \subseteq \mathbb{R}^m$; we use $\mathcal{M}_\Omega$ for the set of all such controls. As usual, by a $\mathcal{K}$ function we mean a function $\gamma : [0, \infty) \to [0, \infty)$ that is strictly increasing and continuous and satisfies $\gamma(0) = 0$, by a $\mathcal{K}_\infty$ function one that is in addition unbounded, and we let $\mathcal{KL}$ be the class of functions $[0, \infty)^2 \to [0, \infty)$ which are of class $\mathcal{K}$ on the first argument and decrease to zero on the second argument. When we state the various properties below, we always interpret the respective estimates as holding for all inputs u and for all initial states $\xi \in \mathbb{R}^n$.

Recall that a system is said to be *forward complete* if for every initial state ξ and input u, the solution $x(t, \xi, u)$ is defined for all $t \geq 0$.

The following four output stability properties were discussed in [19]. A forward complete system is:

- IOS, or *input to output stable*, if there exist a $\mathcal{KL}$-function β and a $\mathcal{K}$-function γ such that

  $$|y(t, \xi, u)| \;\leq\; \beta(|\xi|, t) + \gamma(\|u\|) \qquad \forall t \geq 0 \tag{1.2}$$

  (the term $\gamma(\|u\|)$ can be replaced by the norm of the restriction to past inputs $\gamma(\|u\|_{[0,t]})$, and the sum could be replaced by a “max” or two analogous terms);
- OLIOS, or *output-Lagrange input to output stable*, if it is IOS and, in addition, there exist some $\mathcal{K}$-functions σ_1, σ_2 such that

  $$|y(t, \xi, u)| \;\leq\; \max\{\sigma_1(|h(\xi)|), \sigma_2(\|u\|)\} \qquad \forall\, t \geq 0; \tag{1.3}$$
- SIIOS, or *state-independent input to output stable*, if there exist some $\beta \in \mathcal{KL}$ and some $\gamma \in \mathcal{K}$ such that

  $$|y(t, \xi, u)| \;\leq\; \beta(|h(\xi)|, t) + \gamma(\|u\|) \qquad \forall\, t \geq 0; \tag{1.4}$$
- ROS, or *robustly output stable*, if there are a smooth $\mathcal{K}_\infty$-function λ and a $\beta \in \mathcal{KL}$ such that the system

  $$\dot{x} = g(x, d) := f(x, d\lambda(|y|)), \quad y = h(x), \tag{1.5}$$

  is forward complete, and the estimate

  $$|y_\lambda(t, \xi, d)| \;\leq\; \beta(|\xi|, t) \qquad \forall\, t \geq 0 \tag{1.6}$$

  holds for all $d \in \mathcal{M}_\mathcal{B}$, where $\mathcal{B} = \{|\mu| \leq 1\} \subset \mathbb{R}^m$, and where $y_\lambda(\cdot, \xi, d)$ denote the output function of system (1.5).

The last concept corresponds to the preservation of output stability under output feedback with “robustness margin” λ. It was shown in [19] that SIIOS $\Rightarrow$ OLIOS $\Rightarrow$ IOS $\Rightarrow$ ROS, and no converses hold. It was also remarked in section 2.2 of [19] that the OLIOS property is equivalent to the existence of a $\mathcal{KL}$-function β and a $\mathcal{K}$-function γ such that the estimate

$$|y(t, \xi, u)| \leq \beta\left(|h(\xi)|, \, \frac{t}{1 + \rho(|\xi|)}\right) + \gamma(\|u\|) \qquad \forall\, t \geq 0$$

holds for all trajectories of the system. We now introduce the associated Lyapunov concepts.

Definition 1.1. *With respect to the system* (1.1), *a smooth function* $V : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ *is:*

- *an* IOS*-Lyapunov function if there exist* $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ *such that*

$$\alpha_1(|h(\xi)|) \leq V(\xi) \leq \alpha_2(|\xi|) \qquad \forall\, \xi \in \mathbb{R}^n \tag{1.7}$$

and there exist $\chi \in \mathcal{K}$ *and* $\alpha_3 \in \mathcal{KL}$ *such that*

$$V(\xi) \geq \chi(|\mu|) \Rightarrow DV(\xi)f(\xi,\mu) \leq -\alpha_3(V(\xi), |\xi|) \quad \forall\, \xi,\ \forall\, \mu, \tag{1.8}$$

- *an* OLIOS*-Lyapunov function if there exist* $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ *such that*

$$\alpha_1(|h(\xi)|) \leq V(\xi) \leq \alpha_2(|h(\xi)|) \qquad \forall\, \xi \in \mathbb{R}^n \tag{1.9}$$

and there exist $\chi \in \mathcal{K}$ *and* $\alpha_3 \in \mathcal{KL}$ *such that* (1.8) *holds,*

- *an* SIIOS*-Lyapunov function if there exist* $\chi \in \mathcal{K}$ *and* $\alpha_3 \in \mathcal{K}$ *such that*

$$V(\xi) \geq \chi(|\mu|) \Rightarrow DV(\xi)f(\xi,\mu) \leq -\alpha_3(V(\xi)) \quad \forall\, \xi,\ \forall \mu \tag{1.10}$$

and there exist $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ *such that* (1.9) *holds,*

- *an* ROS*-Lyapunov function if there exist* $\chi \in \mathcal{K}$ *and* $\alpha_3 \in \mathcal{KL}$ *such that*

$$|h(\xi)| \geq \chi(|\mu|) \ \Rightarrow DV(\xi)f(\xi,\mu) \leq -\alpha_3(V(\xi), |\xi|) \quad \forall\, \xi,\ \forall\, \mu \tag{1.11}$$

and there exist $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ *such that* (1.7) *holds.*

Observe that, if an estimate (1.7) holds, then (1.11) is implied by (1.8) in the sense that if χ and α_1 are as in the former, then $\widetilde{\chi} := \alpha_1^{-1} \circ \chi$ can be used as "χ" for the latter. Note also that, provided that (1.9) holds, condition (1.8) is equivalent to the existence of $\chi \in \mathcal{K}$ and $\alpha_3 \in \mathcal{KL}$ so that

$$|h(\xi)| \geq \chi(|\mu|) \ \Rightarrow \ DV(\xi)f(\xi,\mu) \leq -\alpha_3(V(\xi), |\xi|).$$

Our main results can be summarized as follows. We say that system (1.1) is *uniformly bounded input bounded state* stable, and write UBIBS for short, if it is forward complete and, for some function σ of class $\mathcal{K}$, the following estimate holds for all solutions:

$$|x(t,\xi,u)| \ \leq \ \max\{\sigma(|\xi|),\ \sigma(\|u\|)\} \qquad \forall t \geq 0. \tag{1.12}$$

Theorem 1.2. *A* UBIBS *system is:*

1. IOS *if and only if it admits an* IOS*-Lyapunov function;*
2. OLIOS *if and only if it admits an* OLIOS*-Lyapunov function;*
3. ROS *if and only if it admits an* ROS*-Lyapunov function; and*
4. SIIOS *if and only if it admits an* SIIOS*-Lyapunov function.*

The proofs are provided in section 4.

2. Remarks on rates of decrease. In properties (1.8) and (1.11), the decay rate of $V(x(t))$ depends on the state and on the value of $V(x(t))$. The main role of α_3 is to allow for slower convergence if $V(x(t))$ is very small or if $x(t)$ is very large. We first note two simplifications.

REMARK 2.1. Inequality (1.8) holds for some $\alpha_3 \in \mathcal{KL}$ if and only if there exist $\mathcal{K}$-functions κ_1, κ_2 such that

$$V(\xi) \geq \chi(|\mu|) \;\Rightarrow\; DV(\xi)f(\xi,\mu) \leq -\frac{\kappa_1(V(\xi))}{1+\kappa_2(|\xi|)} \tag{2.1}$$

for all $\xi \in \mathbb{R}^n$ and all $\mu \in \mathbb{R}^m$. This follows from Lemma A.2, proved in the appendix. A similar remark applies to (1.11).

REMARK 2.2. Suppose V is an IOS-Lyapunov function for the system satisfying (1.7) with some $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ and satisfying (2.1) with some $\chi, \kappa_1, \kappa_2 \in \mathcal{K}$. By the proof of Lemma 11 together with Lemma 12 in [14], one sees that there exists a C^1 $\mathcal{K}_\infty$-function ρ such that $\rho'(s)\kappa_1(s) \geq \rho(s)$ for all $s \geq 0$. Let $W = \rho \circ V$. Then W is a C^1 function satisfying the following:

$$\rho(\alpha_1(|h(\xi)|)) \leq W(\xi) \leq \rho(\alpha_2(|\xi|)) \qquad \forall\, \xi \in \mathbb{R}^n,$$

and

$$W(\xi) \geq \chi_1(|\mu|) \;\Rightarrow\; DW(\xi)f(\xi,\mu) \leq -\frac{W(\xi)}{1+\kappa_2(|\xi|)} \tag{2.2}$$

for all $\xi \in \mathbb{R}^n$ and all $\mu \in \mathbb{R}^m$, where $\chi_1 = \rho \circ \chi \in \mathcal{K}$. This shows that if a system admits an IOS-Lyapunov function, then it admits one satisfying inequality (2.2). A similar remark applies to (1.11).

Obviously, a function which satisfies a decay estimate of the stronger form

$$V(\xi) \geq \chi(|\mu|) \;\Rightarrow\; DV(\xi)f(\xi,\mu) \leq -\alpha(V(\xi)) \tag{2.3}$$

for some $\chi, \alpha \in \mathcal{K}$ is in particular an IOS Lyapunov function. It is thus natural to ask if there always exists, for an IOS system, a function with this stronger property. We now show, by means of an example, that such functions do not in general exist. Consider for that purpose the following two-dimensional single-input system:

$$\dot{x}_1 = 0, \quad \dot{x}_2 = -\frac{2x_2+u}{1+x_1^2}, \quad y = x_2. \tag{2.4}$$

This system is IOS, because with $V(x) := x_2^2$, it holds that

$$V(\xi) \geq \mu^2 \;\Rightarrow\; DV(\xi)f(\xi,\mu) = -2x_2\,\frac{2x_2+u}{1+x_1^2} \leq -\frac{2V(\xi)}{1+x_1^2}.$$

Namely, V is an IOS-Lyapunov function for the system.

Suppose that system (2.4) would admit an IOS-Lyapunov function W with a decay estimate as in (2.3), i.e., there exist some $\chi, \alpha \in \mathcal{K}$ such that

$$W(\xi) \geq \chi(|\mu|) \;\Rightarrow\; DW(\xi)f(\xi,\mu) \leq -\alpha(W(\xi)). \tag{2.5}$$

Without loss of generality, we may assume that $\chi \in \mathcal{K}_\infty$. In particular, we have that

$$DW(\xi)f(\xi, -\chi^{-1}(W(\xi))) \leq -\alpha(W(\xi)) \tag{2.6}$$

for all $\xi \in \mathbb{R}^2$. Fix any $\xi_1 \in \mathbb{R}$, and consider the one-dimensional differential equation

$$\dot{x}_2 = -\frac{2x_2 - \chi^{-1}(W(\xi_1, x_2))}{1+\xi_1^2}. \tag{2.7}$$

Since $W(\xi_1, x_2(t)) \to 0$ (because of (2.6)) and as $\alpha_1(|\xi_2|) \leq W(\xi_1, \xi_2)$ for all ξ (for some $\alpha_1 \in \mathcal{K}$), it follows that $x_2(t) \to 0$ as $t \to \infty$. This implies that $W(\xi_1, \xi_2) < \chi(2\xi_2)$ for all $\xi_1 \in \mathbb{R}$ and $\xi_2 > 0$. Together with (2.5), this implies that there exists some $\beta \in \mathcal{KL}$ such that, for every trajectory of (2.4) with $u(t) \equiv 0$, it holds that

$$|x_2(t)| \leq \beta(|x_2(0)|, t)$$

for all $\xi = (x_1(0), x_2(0))$ such that $x_2(0) > 0$. This is impossible, as it can be seen that, when $u(t) \equiv 0$, $x_2(t) = x_2(0)e^{-2t/(1+(x_1(0))^2)}$, whose decay rate depends on both $x_2(0)$ and $x_1(0)$.

Observe that, if we let $U(\xi_1, \xi_2) := [(1+\xi_1^2)\,|\xi_2|]^{(1+\xi_1^2)}$, then one obtains the following estimate:

$$|\xi_2| \geq |\mu| \;\Rightarrow\; DU(\xi)f(\xi,\mu) \leq -U(\xi) \tag{2.8}$$

for all $\xi_1 \in \mathbb{R}$, $\xi_2 \neq 0$, and all $\mu \in \mathbb{R}$. (The function U is not smooth on the set where $U(\xi) = 0$, but, using a routine smoothing argument, one may easily modify U to get a smooth Lyapunov function.) This U is not an example of a W as here (which, in any case, we know cannot exist), because (2.8) only means that U is an ROS-Lyapunov function, not necessarily an IOS-Lyapunov function (since the comparison is between $|\xi_2|$ and $|\mu|$ rather than between a function of U and $|\mu|$).

Finally, we observe that property (1.8) in the IOS-Lyapunov definition may be rephrased as follows:

$$V(\xi) > \widetilde{\chi}(|\mu|) \;\Rightarrow\; DV(\xi)f(\xi,\mu) < 0 \qquad \forall \xi \in \mathbb{R}^n,\ \forall \mu \in \mathbb{R}^m, \tag{2.9}$$

where $\widetilde{\chi}(s) := \rho\,\chi(s)$ (for any arbitrary chosen $\rho \in (0,1)$). This statement is obviously implied by (1.8). Conversely, if V satisfies this property, then there is an $\alpha \in \mathcal{KL}$ so that (1.8) holds; this follows from Lemma A.5 given in the appendix.

3. Uniform stability notions.

There is a key technical result which underlies the proofs of all our converse Lyapunov theorems. It requires yet another set of definitions, which correspond to stability uniformly on all "disturbance" inputs.

Definition 3.1. *A system* (1.1) *is* uniformly output stable *with respect to inputs in $\mathcal{M}_\Omega$, where Ω is a compact subset of $\mathbb{R}^m$, if*

- *it is forward complete, and*
- *there exists a $\mathcal{KL}$-function β such that*

$$|y(t,\xi,u)| \leq \beta(|\xi|, t) \qquad \forall t \geq 0 \tag{3.1}$$

holds for all u and all $\xi \in \mathbb{R}^n$.

If, in addition, there exists $\sigma \in \mathcal{K}$ such that

$$|y(t,\xi,u)| \leq \sigma(|h(\xi)|) \qquad \forall t \geq 0 \tag{3.2}$$

holds for all trajectories of the system with $u \in \mathcal{M}_\Omega$, then the system is output-Lagrange uniformly output stable with respect to inputs in $\mathcal{M}_\Omega$. Finally, if one strengthens (3.1) *to*

$$|y(t,\xi,u)| \leq \beta(|h(\xi)|, t) \qquad \forall t \geq 0 \tag{3.3}$$

holding for all trajectories of the system with $u \in \mathcal{M}_\Omega$, then the system is state-independent uniformly output stable with respect to inputs in $\mathcal{M}_\Omega$.

Theorem 3.2. *Let Ω be a compact subset of $\mathbb{R}^m$, and suppose that a system* (1.1) *is uniformly output stable with respect to inputs in $\mathcal{M}_\Omega$. Then the system admits a smooth Lyapunov function V satisfying the following properties:*

- *there exist* $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ *such that*

$$\alpha_1(|h(\xi)|) \le V(\xi) \le \alpha_2(|\xi|) \qquad \forall\, \xi \in \mathbb{R}^n; \tag{3.4}$$

- *there exists* $\alpha_3 \in \mathcal{KL}$ *such that*

$$DV(\xi)f(\xi,\mu) \le -\alpha_3(V(\xi),|\xi|) \qquad \forall\, \xi \in \mathbb{R}^n,\ \forall\, \mu \in \Omega. \tag{3.5}$$

Moreover, if the system is output-Lagrange uniformly output stable with respect to inputs in $\mathcal{M}_\Omega$*, then* (3.4) *can be strengthened to*

$$\alpha_1(|h(\xi)|) \le V(\xi) \le \alpha_2(|h(\xi)|) \qquad \forall\, \xi \tag{3.6}$$

for some $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$*. Finally, if the system is state-independent uniformly output stable with respect to inputs in* $\mathcal{M}_\Omega$*, then* (3.4) *can be strengthened to* (3.6) *and also* (3.5) *can be strengthened to*

$$DV(\xi)f(\xi,\mu) \le -\alpha_4(V(\xi)) \qquad \forall\, \xi \in \mathbb{R}^n,\ \forall\, \mu \in \Omega \tag{3.7}$$

for some $\alpha_4 \in \mathcal{K}$*.*

The proof of this theorem will be postponed until section 4.5.

4. Proof of Theorem 1.2.

In the proofs of the various parts of the theorem, we need the following small gain lemma for output-Lagrange stability (see Lemma 8 of [19]).

LEMMA 4.1. *For every system which satisfies* (1.3)*, there exist a* $\mathcal{K}$*-function* σ *and a* $\mathcal{K}_\infty$*-function* λ *such that the system*

$$\dot{x} = f(x,\, d\lambda(|y|)), \quad y = h(x), \tag{4.1}$$

where $d \in \mathcal{M}_\mathcal{B}$*, is forward complete, and*

$$|y_\lambda(t,\xi,d)| \le \sigma(|h(\xi)|) \tag{4.2}$$

for all $\xi \in \mathbb{R}^n$*, all* $t \ge 0$*, and all* $d \in \mathcal{M}_\mathcal{B}$*.*

4.1. Proof of Theorem 1.2, part 1.

Necessity. Consider an OLIOS system (1.1). By Lemma 4.1, there exist a smooth $\mathcal{K}_\infty$-function λ_1 and a $\mathcal{K}$-function σ such that the system

$$\dot{x} = f(x, d\lambda_1(|y|)), \qquad y = h(x),$$

where $d \in \mathcal{M}_\mathcal{B}$, is forward complete, and (4.2) holds.

Since the system is OLIOS, and, in particular, IOS, and since, as shown in [19], any IOS system is necessarily also ROS, there exists some smooth $\mathcal{K}_\infty$-function λ_2 such that the system

$$\dot{x} = f(x, d\lambda_2(|y|)),\ y = h(x), \tag{4.3}$$

where $d \in \mathcal{M}_\mathcal{B}$, is forward complete, and there exists some $\beta \in \mathcal{KL}$ such that, for all trajectories $x_{\lambda_2}(t,\xi,u)$ with the output functions $y_{\lambda_2}(t,\xi,u)$, it holds that

$$\left|y_{\lambda_2}(t,\xi,d)\right| \le \beta(|\xi|\,,t) \qquad \forall\, t \ge 0,\ \forall\, \xi \in \mathbb{R}^n,\ \forall\, d \in \mathcal{M}_\mathcal{B}.$$

Let $\lambda_3(s) = \min\{\lambda_1(s), \lambda_2(s)\}$, and let $\lambda(\cdot)$ be any smooth $\mathcal{K}_\infty$-function so that $\lambda(s) \leq \lambda_3(s)$ for all s. Then, the system

$$\dot{x} = f(x, d\lambda(|y|)), \quad y = h(x), \tag{4.4}$$

where $d \in \mathcal{M}_{\mathcal{B}}$, is forward complete, and it holds that

$$\left|y_\lambda(t,\xi,d)\right| \leq \beta(|\xi|, t) \quad \text{and} \quad \left|y_\lambda(t,\xi,d)\right| \leq \sigma(|h(\xi)|) \qquad \forall\, t \geq 0.$$

Applying Theorem 3.2, one sees that there exists some smooth function V such that:

- there exist $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that

$$\alpha_1(|h(\xi)|) \leq V(\xi) \leq \alpha_2(|h(\xi)|) \qquad \forall\, \xi; \tag{4.5}$$

- there exist some $\alpha_3 \in \mathcal{KL}$ such that

$$DV(\xi)f(\xi, \nu\lambda(|h(\xi)|)) \leq -\alpha_3(V(\xi), |\xi|) \tag{4.6}$$

for all $\xi \in \mathbb{R}^n$ and all $|\nu| \leq 1$.

It then follows that

$$DV(\xi)f(\xi,\mu) \leq -\alpha_3(V(\xi), |\xi|)$$

whenever $|\mu| \leq \lambda(|h(\xi)|)$, or, equivalently, whenever $|h(\xi)| \geq \lambda^{-1}(|\mu|)$. Let $\chi = \alpha_2^{-1} \circ \lambda^{-1}$. Then one has

$$V(\xi) \geq \chi(|\mu|) \Rightarrow DV(\xi)f(\xi,\mu) \leq -\alpha_3(V(\xi), |\xi|)$$

for all ξ and all μ. Hence, V is an OLIOS-Lyapunov function for the system. □

Sufficiency. Let V be an OLIOS-Lyapunov function for system (1.1). Let $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that (1.9) holds. By (1.8), and arguing as in Remark 2.1, one also knows that there exist some κ_1 and $\kappa_2 \in \mathcal{K}_\infty$ such that

$$V(\xi) \geq \chi(|\mu|) \Rightarrow DV(\xi)f(\xi,\mu) \leq -\frac{\kappa_1(V(\xi))}{1+\kappa_2(|\xi|)} \tag{4.7}$$

for all ξ and μ.

Let $\beta \in \mathcal{KL}$ be as in Lemma A.4 for the function κ_1. Pick any initial state ξ and any u. Let $x(t)$ and $y(t)$ denote the ensuing trajectory and output function, respectively. If for some $t_1 \geq 0$, $V(x(t_1)) \leq \chi(\|u\|)$, then $V(x(t)) \leq \chi(\|u\|)$ for all $t \geq t_1$. (Proof: pick any $\varepsilon > 0$. If $t_2 := \inf\{t > t_1 \,|\, V(x(t)) > \chi(\|u\|) + \varepsilon\}$ is finite, then $V(x(t)) > \chi(\|u\|)$ for all t in some left neighborhood of t_2, so $DV(x(t))/dt < 0$ and $V(x(t)) > V(x(t_2))$ for such t, contradicting its minimality. As ε was arbitrary, the claim follows.) Now let

$$\widetilde{t} = \inf\{t \geq 0 : \ V(x(t)) \leq \chi(\|u\|)\}$$

with the understanding that $\widetilde{t} = \infty$ if $V(x(t)) > \chi(\|u\|)$ for all $t \geq 0$. Then

$$V(x(t)) \leq \chi(\|u\|) \qquad \forall\, t \geq \widetilde{t}, \tag{4.8}$$

and on $[0, \widetilde{t})$, it holds that

$$\frac{d}{dt}V(x(t)) \leq -\frac{\kappa_1(V(x(t)))}{1+\kappa_2(|x(t)|)}.$$

Since the system is UBIBS, there exists some σ such that (1.12) holds. Hence,

$$\frac{d}{dt}V(x(t)) \leq -\frac{\kappa_1(V(x(t)))}{1+\max\{\widetilde{\kappa}_2(|\xi|),\ \widetilde{\kappa}_2(\|u\|)\}}$$

for all $t \in [0, \widetilde{t})$, where $\widetilde{\kappa}_2 = \kappa_2 \circ \sigma$. It then follows Lemma A.4 that

$$V(x(t)) \leq \beta\left(V(\xi),\ \frac{t}{1+\max\{\widetilde{\kappa}_2(|\xi|),\ \widetilde{\kappa}_2(\|u\|)\}}\right)$$

for all $t \in [0, \widetilde{t})$.

Let $v_0(s) = \max_{|\xi|\leq s} V(\xi)$. Then v_0 is nondecreasing, $v_0(0) = 0$, and $V(\xi) \leq v_0(|\xi|)$. Note then that

$$\begin{aligned}
&\beta\left(V(\xi),\ \frac{t}{1+\max\{\widetilde{\kappa}_2(|\xi|),\ \widetilde{\kappa}_2(\|u\|)\}}\right)\\
&\qquad \leq \max\left\{\beta\left(V(\xi),\ \frac{t}{1+\widetilde{\kappa}_2(|\xi|)}\right),\ \beta\left(v_0(\|u\|),\ \frac{t}{1+\widetilde{\kappa}_2(\|u\|)}\right)\right\}\\
&\qquad \leq \max\left\{\beta\left(V(\xi),\ \frac{t}{1+\widetilde{\kappa}_2(|\xi|)}\right),\ \beta\left(v_0(\|u\|),\ 0\right)\right\}
\end{aligned}$$

(consider two cases: $|\xi| \geq \|u\|$ and $|\xi| \leq \|u\|$). This shows that

$$V(x(t)) \leq \max\left\{\beta\left(V(\xi),\ \frac{t}{1+\widetilde{\kappa}_2(|\xi|)}\right),\ \widetilde{\beta}_0(\|u\|)\right\}$$

for all $t \in [0, \widetilde{t})$, where $\widetilde{\beta}_0(s) = \beta(v_0(s), 0)$. Combining this with (4.8), one sees that

$$V(x(t)) \leq \max\left\{\beta\left(V(\xi),\ \frac{t}{1+\widetilde{\kappa}_2(|\xi|)}\right),\ \widetilde{\gamma}(\|u\|)\right\} \tag{4.9}$$

for all $t \geq 0$, where $\widetilde{\gamma}(s) = \widetilde{\beta}(s) + \chi(s)$. Using the fact that $|h(\xi)| \leq \alpha_1^{-1}(V(\xi))$, we conclude that

$$|y(t)| \leq \max\left\{\widetilde{\beta}\left(|h(\xi)|,\frac{t}{1+\widetilde{\kappa}_2(|\xi|)}\right),\ \gamma(\|u\|)\right\} \tag{4.10}$$

for all $t \geq 0$, where $\widetilde{\beta}(s,r) = \alpha_1^{-1}(\beta(\alpha_2(s), r))$, and $\gamma(s) = \alpha_1^{-1}(\widetilde{\gamma}(s))$. □

4.2. Proof of Theorem 1.2, part 2.

Necessity. Consider an IOS system (1.1). By Theorem 1 in [19], there exist some locally Lipschitz map h_0 and $\chi \in \mathcal{K}_\infty$ with the property that $h_0(\xi) \geq \chi(|h(\xi)|)$ such that the system

$$\dot{x} = f(x,u), \quad y = h_0(x) \tag{4.11}$$

is OLIOS. By part 1 of this theorem, system (4.11) admits an OLIOS-Lyapunov function V. This means that there exist $\alpha_1, \alpha_2, \rho \in \mathcal{K}_\infty$, and $\alpha_3 \in \mathcal{KL}$ such that

$$\alpha_1(|h_0(\xi)|) \leq V(\xi) \leq \alpha_2(|h_0(\xi)|) \qquad \forall\, \xi \in \mathbb{R}^n,$$

and

$$V(\xi) \geq \rho(|\mu|) \Longrightarrow DV(\xi)f(\xi,\mu) \leq -\alpha_3(V(\xi), |\xi|).$$

To show that V is an IOS-Lyapunov function, it remains only to show that $V(\xi) \geq \widetilde{\alpha}_1(|h(\xi)|)$ for some $\widetilde{\alpha}_1 \in \mathcal{K}_\infty$. But this follows immediately from the fact that $|h(\xi)| \leq \chi^{-1}(h_0(\xi))$. So one can let $\widetilde{\alpha}_1 := \alpha_1 \circ \chi$. Hence, V is indeed an IOS-Lyapunov function for system (1.1). □

Sufficiency. Let V be an IOS-Lyapunov function for system (1.1). From the proof of part 1 of Theorem 1.2 (sufficiency), one can see that if V satisfies (4.7) for some $\chi, \kappa_1, \kappa_2 \in \mathcal{KL}$, then there exist $\widetilde{\beta} \in \mathcal{KL}, \widetilde{\kappa}_2, \ \widetilde{\gamma} \in \mathcal{K}_\infty$ such that (4.9) holds. This means that the system

$$\dot{x} = f(x, u), \quad y = V(x)$$

is OLIOS. Since $V(x) \geq \alpha_1(|h(\xi)|)$ for some $\alpha_1 \in \mathcal{K}_\infty$, it follows that system (1.1) is IOS. □

4.3. Proof of Theorem 1.2, part 3.

Necessity. Since the system (1.1) is ROS, there is a smooth $\mathcal{K}_\infty$-function λ such that system (1.5) is forward complete, and (1.6) holds for the corresponding system (1.5). That is, system (1.5) is uniformly output stable. By Theorem 3.2, system (1.5) admits a smooth Lyapunov function V satisfying (3.4) and

$$DV(\xi)f(\xi, \mu\lambda(|y|)) \leq -\alpha_3(V(\xi), |\xi|) \qquad \forall\, \xi \in \mathbb{R}^n,\ \forall\, |\mu| \leq 1$$

for some $\alpha_3 \in \mathcal{KL}$. This is equivalent to

$$|y| \geq \lambda^{-1}(|\nu|) \ \Rightarrow\ DV(\xi)f(\xi, \nu) \leq -\alpha_3(V(\xi), |\xi|) \qquad \forall\, \xi \in \mathbb{R}^n,\ \forall\, |\nu| \in \mathbb{R}^m.$$

Hence, one concludes that V is an ROS-Lyapunov function for system (1.1).

Sufficiency. Let V be an ROS-Lyapunov function. As in Remark 2.1, there exist $\chi, \kappa_1, \kappa_2 \in \mathcal{K}_\infty$ such that

$$DV(\xi)f(\xi, \mu) \leq -\frac{\kappa_1(V(\xi))}{1 + \kappa_2(|\xi|)}$$

whenever $|h(\xi)| \geq \chi(|\mu|)$. Let $\lambda = \chi^{-1}$. Without loss of generality, one may assume that λ is smooth. (Otherwise, one can always replace λ by a smooth $\mathcal{K}_\infty$-function that is majorized by λ.) It then follows that

$$DV(\xi)f(\xi, \nu\lambda(|h(\xi)|)) \leq -\frac{\kappa_1(V(\xi))}{1 + \kappa_2(|\xi|)}$$

for all $\xi \in \mathbb{R}^n$ and all $|\nu| \leq 1$. This implies that for any trajectory $x_{\lambda}(t) = x_{\lambda}(t, \xi, d)$ of the system

$$\dot{x} = f(x, d\lambda(|y|)), \quad y = h(x),$$

where $d \in \mathcal{M}_{\mathcal{B}}$, it holds that

$$\frac{d}{dt}V(x_{\lambda}(t)) \leq -\frac{\kappa_1(V(x_{\lambda}(t)))}{1 + \kappa_2(|x_{\lambda}(t)|)} \tag{4.12}$$

for all $t \geq 0$. It follows immediately that $V(x_{\lambda}(t)) \leq V(\xi)$ for all $t \geq 0$. Since $V(\xi) \geq \alpha_1(|h(\xi)|)$ for some $\alpha_1 \in \mathcal{K}_\infty$, it follows that, for some $\sigma \in \mathcal{K}_\infty$,

$$|y_{\lambda}(t)| \leq \sigma(|\xi|) \qquad \forall\, t \geq 0. \tag{4.13}$$

Since the system is UBIBS, there exists some $\sigma_0 \in \mathcal{K}$ such that

$$\left|x_\lambda(t,\xi,d)\right| \le \max\{\sigma_0(|\xi|), \sigma_0(\|u_d\|)\} \qquad \forall\, t \ge 0,$$

where $u_d(t) = d(t)\lambda(|y(t)|)$. Combining this with (4.13), it follows that

$$\left|x_\lambda(t,\xi,d)\right| \le \widetilde{\sigma}(|\xi|) \qquad \forall\, t \ge 0,$$

where $\widetilde{\sigma}(s) = \max\{\sigma_0(s), \sigma_0(\lambda(\sigma(s)))\}$. Substituting this back into (4.12), one has

$$\frac{d}{dt}V(x_\lambda(t)) \le -\frac{\kappa_1(V(x_\lambda(t)))}{1+\kappa_3(|\xi|)} \qquad \forall\, t \ge 0,$$

where $\kappa_3(s) = \kappa_2(\widetilde{\sigma}(s))$. Again, by Lemma A.4, one knows that there exists some $\beta \in \mathcal{KL}$ (which depends only upon κ_1) such that

$$V(x_\lambda(t)) \le \beta\left(V(\xi),\ \frac{t}{1+\kappa_3(|\xi|)}\right) \qquad \forall\, t \ge 0.$$

Together with the fact that $|h(\xi)| \le \alpha_1^{-1}(V(\xi))$, this yields

$$\left|y_\lambda(t,\xi,d)\right| \le \widetilde{\beta}(|\xi|\,,t) \qquad \forall\, t \ge 0,$$

where $\widetilde{\beta}(s,r) = \alpha_1^{-1}[\beta(\alpha_2(s), t/(1+\kappa_3(s)))]$ is in $\mathcal{KL}$, and α_2 is any $\mathcal{K}_\infty$-function such that $V(\xi) \le \alpha_2(|\xi|)$ for all ξ. This shows that the system is ROS. □

4.4. Proof of Theorem 1.2, part 4.

Necessity. Assume that a UBIBS system (1.1) admits an estimate (1.4) for some $\beta \in \mathcal{KL}$ and some $\gamma \in \mathcal{K}$. Without loss of generality, one may assume that

$$|y(t,\xi,u)| \le \max\{\beta(|h(\xi)|\,,t),\ \gamma(\|u\|)\}.$$

Let $\sigma_1(s) = \beta(s,0)$, and let $\sigma_2(s) = \gamma(s)$. Note then that (1.3) holds. By Lemma 8 in [19], there exists some smooth $\mathcal{K}_\infty$-function such that the corresponding system (1.5) is forward complete, and it holds that

$$\sigma_2(|d(t)|\,\lambda(|y_\lambda(t,\xi,d)|)) \le \frac{1}{2}\,|h(\xi)|$$

for all $\xi \in \mathbb{R}^n$, all $t \ge 0$, and all $d \in \mathcal{M}_{\mathcal{B}}$. One then can show that for the system

$$\dot{x}(t) = f(x(t), d(t)\lambda(|y(t)|)), \quad y(t) = h(x(t)),$$

there exists $\widetilde{\beta} \in \mathcal{KL}$ so that, for all trajectories $x_\lambda(t,\xi,d)$, it holds that

$$\left|y_\lambda(t,\xi,d)\right| \le \widetilde{\beta}(|h(\xi)|\,,t)$$

for all $t \ge 0$. Applying the last part of Theorem 3.2, one sees that there exists V satisfying (3.6) for some $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ and

$$DV(\xi)f(\xi, \nu\lambda(|y(\xi)|)) \le -\alpha_3(V(\xi))$$

for all ξ and all $|\nu| \le 1$. This is equivalent to the existence of $\chi \in \mathcal{K}_\infty$ such that

$$V(\xi) \ge \chi(|\mu|) \Rightarrow DV(\xi)f(\xi,u) \le -\alpha_3(V(\xi)). \tag{4.14}$$

Sufficiency. It is routine to show that if there is a smooth function V satisfying (3.6) and (4.14), then the system admits an estimate of type (1.4). □

REMARK 4.1. Note that in all the proofs of the necessity implications of Theorem 1.2, the UBIBS property is not needed. That is, to show the existence of various Lyapunov functions for the corresponding stability properties, one does not need the UBIBS property. However, the UBIBS property is indeed required in the proofs of the sufficiency implications regarding the IOS, OLIOS, and the ROS properties. It is not hard to find examples where a system admits an IOS-, OLIOS-, or ROS-Lyapunov function, without satisfying the UBIBS property, and fails to be IOS, OLIOS, or ROS, respectively.

It should also be noticed that part 4 of Theorem 1.2 also holds for all forward complete systems (not necessarily UBIBS). Without the UBIBS assumption, this result recovers the converse Lyapunov theorem obtained in [12] for systems that are uniformly globally asymptotically stable with respect to closed invariant sets, when applied using as output the distance to a closed invariant set. In fact, part 4 of Theorem 1.2 yields a more general result than the one in [12]. Because of the techniques used in the proofs in [12], the systems were required to be backward complete. Due to part 4 of Theorem 1.2, it can be seen that the backward completeness assumption is redundant.

4.5. Proof of Theorem 3.2. Consider the system

$$\dot{x}(t) = f(x(t), u(t)), \quad y = h(x(t)), \tag{4.15}$$

where the input u takes values in a compact subset Ω of $\mathbb{R}^m$. Assume that the system is UBIBS and there exists some $\beta \in \mathcal{KL}$ such that (3.1) holds for all trajectories of (4.15). Let $\omega : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ be defined by

$$\omega(\xi) := \sup \left\{ |y(t, \xi, u)| : \ t \geq 0, u \in \mathcal{M}_\Omega \right\}. \tag{4.16}$$

It then holds that

$$|h(\xi)| \leq \omega(\xi) \leq \beta_0(|\xi|) \qquad \forall \, \xi \in \mathbb{R}^n, \tag{4.17}$$

where $\beta_0(s) = \beta(s, 0)$. Moreover, if there exists some $\sigma \in \mathcal{K}$ such that (3.2) holds for all trajectories, then the above can be strengthened to

$$|h(\xi)| \leq \omega(\xi) \leq \sigma(|h(\xi)|) \qquad \forall \, \xi \in \mathbb{R}^n. \tag{4.18}$$

Observe that, for any $\xi \in \mathbb{R}^n$, $u \in \mathcal{M}_\Omega$, and $t_1 \geq 0$,

$$\omega(x(t_1, \xi, u)) \leq \sup_{t \geq 0, v \in \mathcal{M}_\Omega} |y(t_1 + t, \xi, v)| \leq \beta(|\xi|, t_1). \tag{4.19}$$

Also ω decreases along trajectories, i.e.,

$$\omega(x(t, \xi, u)) \leq \omega(\xi) \qquad \forall t \geq 0, \ \xi \in \mathbb{R}^n, \ u \in \mathcal{M}_\Omega. \tag{4.20}$$

Define

$$\mathcal{D} := \{\xi : \ y(t, \xi, u) = 0 \quad \forall \, t \geq 0, \ \forall \, u \in \mathcal{M}_\Omega\}.$$

Then $\omega(\xi) = 0$ if and only if $\xi \in \mathcal{D}$. For $\xi \notin \mathcal{D}$, it holds that

$$\omega(\xi) = \sup_{0 \leq t \leq t_\xi, \ u \in \mathcal{M}_\Omega} |y(t, \xi, u)|, \tag{4.21}$$

where $t_\xi = T_{|\xi|}(\omega(\xi)/2)$, and $T_r(s)$ is defined as in Lemma A.1 associated with the function β.

LEMMA 4.2. *The function $\omega(\xi)$ is locally Lipschitz on $\mathbb{R}^n \setminus \mathcal{D}$ and continuous everywhere.*

Proof. First notice that

$$\varliminf_{\xi\to\xi_0} \omega(\xi) \geq \omega(\xi_0) \qquad \forall\, \xi_0 \in \mathbb{R}^n; \tag{4.22}$$

that is, $\omega(\xi)$ is lower semicontinuous on $\mathbb{R}^n$. Indeed, pick ξ_0 and let $c := \omega(\xi_0)$. Take any $\varepsilon > 0$. Then there are some u_0 and t_0 so that $|y(t_0, \xi_0, u_0)| \geq c - \varepsilon/2$. By continuity of $y(t_0, \cdot, u_0)$, there is some neighborhood $\widetilde{U}_0$ of ξ_0 so that $|y(t_0, \xi, u_0)| \geq c - \varepsilon$ for all $\xi \in \widetilde{U}_0$. Thus $\omega(\xi) \geq c - \varepsilon$ for all $\xi \in \widetilde{U}_0$, and this establishes (4.22).

Fix any $\xi_0 \in \mathbb{R}^n \setminus \mathcal{D}$, and let $c_0 = \omega(\xi_0)/2$. Then there exists a bounded neighborhood U_0 of ξ_0 such that

$$\omega(\xi) \geq c_0 \qquad \forall\, \xi \in U_0.$$

Let s_0 be such that $|\xi| \leq s_0$ for all $\xi \in U_0$. Then

$$\omega(\xi) = \sup\{|y(t, \xi, u)| : \ t \in [0, t_1], u \in \mathcal{M}_\Omega\} \qquad \forall\, \xi \in U_0,$$

where $t_1 = T_{s_0}(c_0/2)$. By [12, Proposition 5.5], one knows that $x(t, \xi, u)$ is locally Lipschitz in ξ uniformly on $u \in \mathcal{M}_\Omega$ and on $t \in [0, t_1]$, and therefore, so is $y(t, \xi, u)$. Let C be a constant such that

$$|y(t, \xi, u) - y(t, \eta, u)| \leq C\, |\xi - \eta| \qquad \forall\, \xi, \eta \in U_0,\ \forall\, 0 \leq t \leq t_1,\ \forall\, u \in \mathcal{M}_\Omega.$$

For any $\varepsilon > 0$ and any $\xi \in U_0$, there exist some $t_{\xi,\varepsilon} \in [0, t_1]$ and some $u_{\xi,\varepsilon}$ such that

$$\omega(\xi) \leq |y(t_{\xi,\varepsilon},\, \xi,\, u_{\xi,\varepsilon})| + \varepsilon.$$

It then follows that, for any $\xi, \eta \in U_0$, and for any $\varepsilon > 0$,

$$\omega(\xi) - \omega(\eta) \leq |y(t_{\xi,\varepsilon},\, \xi,\, u_{\xi,\varepsilon})| + \varepsilon - |y(t_{\xi,\,\varepsilon}, \eta,\, u_{\xi,\varepsilon})| \leq C\, |\xi - \eta| + \varepsilon.$$

Consequently,

$$\omega(\xi) - \omega(\eta) \leq C\, |\xi - \eta| \qquad \forall\, \xi, \eta \in U_0.$$

By symmetry,

$$\omega(\eta) - \omega(\xi) \leq C\, |\xi - \eta| \qquad \forall\, \xi, \eta \in U_0.$$

This proves that ω is locally Lipschitz on $\mathbb{R}^n \setminus \mathcal{D}$.

We now show that ω is continuous on $\mathcal{D}$. Fix $\xi_0 \in \mathcal{D}$. One would like to show that

$$\lim_{\xi\to\xi_0} \omega(\xi) = 0. \tag{4.23}$$

Assume that this does not hold. Then there exists some $\varepsilon_0 > 0$ and a sequence $\{\xi_k\}$ with $\xi_k \to \xi_0$ such that $\omega(\xi_k) > \varepsilon_0$ for all k. Without loss of generality, one may assume that

$$|\xi_k| \leq s_1 \qquad \forall\, k$$

for some $s_1 \geq 0$. It then follows that

$$\omega(\xi_k) = \sup\left\{|y(t, \xi_k, u)| : \; t \in [0, t_2], u \in \mathcal{M}_\Omega\right\},$$

where $t_2 = T_{s_1}(\varepsilon_0/2)$. Hence, for each k, there exists some $u_k \in \mathcal{M}_\Omega$ and some $\tau_k \in [0, t_2]$ such that

$$|y(\tau_k, \xi_k, u_k)| \geq \omega(\xi_k) - \varepsilon_0/2 \geq \varepsilon_0/2.$$

Again, by the locally Lipschitz continuity of the trajectories, one knows that there is some $C_1 > 0$ such that

$$|y(t, \xi_k, u) - y(t, \xi_0, u)| \leq C_1 \, |\xi_k - \xi_0| \qquad \forall\, k \geq 0, \; \forall\, 0 \leq t \leq t_2, \; \forall\, u \in \mathcal{M}_\Omega.$$

Hence,

$$|y(\tau_k, \xi_0, u_k)| \geq \varepsilon_0/4$$

for k large enough, contradicting the fact that $y(t, \xi_0, u) \equiv 0$ for all $u \in \mathcal{M}_\Omega$. This shows that (4.23) holds if $\xi_0 \in \mathcal{D}$. □

Next, we pick any smooth and bounded function $k : \mathbb{R}_{\geq 0} \to \mathbb{R}_{>0}$ whose derivative is everywhere positive, and define $W : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ by

$$W(\xi) := \sup\left\{\omega(x(t, \xi, u))k(t) : \; t \geq 0, \; u \in \mathcal{M}_\Omega\right\}. \tag{4.24}$$

Corresponding to k there are two positive real numbers $c_1 < c_2$ such that $k(t) \in [c_1, \, c_2]$ for all $t \geq 0$, and so

$$c_1\omega(\xi) \leq W(\xi) \leq c_2\omega(\xi) \qquad \forall\, \xi \in \mathbb{R}^n,$$

which implies that

$$c_1 \, |h(\xi)| \leq W(\xi) \leq c_2\beta_0(|\xi|) \qquad \forall\, \xi \in \mathbb{R}^n. \tag{4.25}$$

Note, for future reference, that it is always possible to find a bounded, positive, and decreasing continuous function $\tau(\cdot)$ with $\tau(t) \to 0$ as $t \to \infty$ such that

$$k'(t) \geq \tau(t) \quad \forall\, t \geq 0. \tag{4.26}$$

By (4.19), one knows that $\omega(x(t, \xi, u)) \to 0$ as $t \to \infty$. It follows that there is some $\tau_\xi \geq 0$ such that

$$W(\xi) = \sup\left\{\omega(x(t, \xi, u))k(t) : \; u \in \mathcal{M}_\Omega, \; 0 \leq t \leq \tau_\xi\right\}. \tag{4.27}$$

Furthermore, one can get the following estimate, where $\{T_r\}$ is a family of functions associated to β as in Lemma A.4.

Lemma 4.3. *For any $\xi \notin \mathcal{D}$ with $|\xi| \leq r$,*

$$W(\xi) = \sup\left\{\omega(x(t, \xi, u))k(t) : \; u \in \mathcal{M}_\Omega, \; 0 \leq t \leq \tau_\xi\right\},$$

where $\tau_\xi = T_r(\frac{c_1}{2c_2}\omega(\xi))$.

Proof. If the statement is not true, then for any $\varepsilon > 0$, there exists some $t_\varepsilon > T_r(\frac{c_1}{2c_2}\omega(\xi))$ and some $u_\varepsilon \in \mathcal{M}_\Omega$ such that

$$W(\xi) \leq \omega(x(t_\varepsilon, \xi, u_\varepsilon))k(t_\varepsilon) + \varepsilon.$$

This implies the following:

$$\begin{aligned}\omega(\xi) &\leq \frac{1}{c_1}W(\xi) \leq \frac{1}{c_1}\omega(x(t_\varepsilon, \xi, u_\varepsilon))k(t_\varepsilon) + \frac{\varepsilon}{c_1}\\ &\leq \frac{c_2}{c_1}\omega(x(t_\varepsilon, \xi, u_\varepsilon)) + \frac{\varepsilon}{c_1} \leq \frac{c_2}{c_1}\cdot\frac{c_1}{2c_2}\omega(\xi) + \frac{\varepsilon}{c_1}\\ &= \frac{\omega(\xi)}{2} + \frac{\varepsilon}{c_1}.\end{aligned}$$

Taking the limit as $\varepsilon \to 0$ results in a contradiction.

LEMMA 4.4. *The function $W(\cdot)$ is locally Lipschitz on $\mathbb{R}^n \setminus \mathcal{D}$ and continuous everywhere.*

Proof. Fix $\xi_0 \notin \mathcal{D}$. Let K_0 be a compact neighborhood of ξ_0 such that $K_0 \cap \mathcal{D} = \emptyset$. Since ω is continuous, it follows that there is some $r_0 > 0$ such that $\omega(\xi) > r_0$ for all $\xi \in K_0$, and hence, $W(\xi) > r_1 := c_1 r_0$ for all $\xi \in K_0$. Let

$$T_0 = T_{s_0}\left(\frac{r_1}{8c_2}\right),$$

where $s_0 > 0$ is such that $|\xi| \leq s_0$ for all $\xi \in K_0$. Let $C > 0$ be such that

$$|y(t, \xi, u) - y(t, \eta, u)| \leq C\,|\xi - \eta| \quad \forall\, t \in [0, T_0],\ \forall\, \xi, \eta \in K_0,\ \forall\, u \in \mathcal{M}_\Omega.$$

Let

$$K_1 = K_0 \cap \left\{\xi :\ |\xi - \xi_0| \leq \frac{r_1}{16Cc_2}\right\}.$$

Fix any $\varepsilon \in (0, r_1/4)$. Then, for any $\xi \in K_1$, there exist $t_{\xi,\varepsilon} \in [0, T_0]$ and $u_{\xi,\varepsilon} \in \mathcal{M}_\Omega$ such that

$$W(\xi) \leq \omega(x(t_{\xi,\varepsilon},\, \xi,\, u_{\xi,\varepsilon}))k(t_{\xi,\varepsilon}) + \varepsilon.$$

Claim. For any $\xi, \eta \in K_1$, $\omega(x(t_{\xi,\varepsilon}, \eta, u_{\xi,\varepsilon})) \geq \frac{r_1}{8c_2}$.

Proof. First we note that for any $\xi \in K_1 \subset K_0$,

$$\omega(x(t_{\xi,\varepsilon}, \xi, u_{\xi,\varepsilon})) \geq \frac{W(\xi) - \varepsilon}{c_2} \geq \frac{W(\xi)}{2c_2} \geq r_2,$$

where $r_2 := \frac{r_1}{2c_2}$. Thus, for each $\xi \in K_1$, there exists some $v_\xi \in \mathcal{M}_\Omega$ and some $\tau_\xi > 0$ such that

$$|y(\tau_\xi, x(t_{\xi,\varepsilon}, \xi, u_{\xi,\varepsilon}), v_\xi)| \geq \omega(x(t_{\xi,\varepsilon}, \xi, u_{\xi,\varepsilon})) - r_2/2 \geq r_2/2.$$

Observe that

$$y(\tau_\xi, x(t_{\xi,\varepsilon}, \xi, u_{\xi,\varepsilon}), v_\xi) = y(\tau_\xi + t_{\xi,\varepsilon}, \xi, \overline{v}_{\xi,\varepsilon}),$$

where $\overline{v}_{\xi,\varepsilon}$ is the concatenation of $u_{\xi,\varepsilon}$ and v_ξ, i.e.,

$$\overline{v}_{\xi,\varepsilon}(t) = \begin{cases} u_{\xi,\varepsilon}(t), & \text{if } 0 \leq t < t_{\xi,\varepsilon},\\ v_\xi(t - t_{\xi,\varepsilon}), & \text{if } t \geq t_{\xi,\varepsilon}.\end{cases}$$

Noticing that $|y(t,\xi,u)| \le r_2/2$ for all $t \ge T_{s_0}(r_2/4)$, one concludes that $\tau_\xi + t_{\xi,\varepsilon} < T_{s_0}(r_2/4) = T_0$. Note also that for any $\eta \in K_1$,

$$\begin{aligned}
&|y(\tau_\xi, x(t_{\xi,\varepsilon},\eta,u_{\xi,\varepsilon}), v_\xi)| = |y(\tau_\xi + t_{\xi,\varepsilon},\eta,\overline{v}_{\xi,\varepsilon})| \\
&\ge |y(\tau_\xi + t_{\xi,\varepsilon},\xi,\overline{v}_{\xi,\varepsilon})| - |y(\tau_\xi + t_{\xi,\varepsilon},\eta,\overline{v}_{\xi,\varepsilon}) - y(\tau_\xi + t_{\xi,\varepsilon},\xi,\overline{v}_{\xi,\varepsilon})| \\
&\ge \frac{r_2}{2} - C\,|\xi-\eta| \\
&\ge \frac{r_2}{2} - 2C\,\frac{r_1}{16Cc_2} = \frac{r_1}{4c_2} - \frac{r_1}{8c_2} = \frac{r_1}{8c_2}.
\end{aligned}$$

This implies that $\omega(x(t_{\xi,\varepsilon},\eta,u_{\xi,\varepsilon})) \ge \frac{r_1}{8c_2}$ for all $\xi,\eta \in K_1$, as claimed.

According to [12, Proposition 5.1], there is some compact set K_2 such that $x(t,\xi,u) \in K_2$ for all $0 \le t \le T_0$, all $\xi \in K_1$, and all $u \in \mathcal{M}_\Omega$. Let

$$K_3 = K_2 \cap \{\xi :\ \omega(\xi) \ge r_1/8c_2\}.$$

Applying Lemma 4.2, one knows that there is some $C_1 > 0$ such that

$$|\omega(\zeta_1) - \omega(\zeta_2)| \le C_1\,|\zeta_1 - \zeta_2| \qquad \forall\,\zeta_1,\zeta_2 \in K_3.$$

Since for all $\xi,\eta \in K_1$, and all $0 < \varepsilon < r_1/4$, $x(t_{\xi,\varepsilon},\eta,u_{\xi,\varepsilon}) \in K_3$, we have

$$|\omega(x(t_{\xi,\varepsilon},\xi,u_{\xi,\varepsilon})) - \omega(x(t_{\xi,\varepsilon},\eta,u_{\xi,\varepsilon}))| \le C_1\,|x(t_{\xi,\varepsilon},\xi,u_{\xi,\varepsilon}) - x(t_{\xi,\varepsilon},\eta,u_{\xi,\varepsilon})|$$

for all $\xi,\eta \in K_1$, and all $\varepsilon \in (0, r_1/4)$. Hence,

$$\begin{aligned}
W(\xi) - W(\eta) &\le \omega(x(t_{\xi,\varepsilon},\xi,u_{\xi,\varepsilon}))k(t_{\xi,\varepsilon}) - \omega(x(t_{\xi,\varepsilon},\eta,u_{\xi,\varepsilon}))k(t_{\xi,\varepsilon}) + \varepsilon \\
&\le c_2\,|\omega(x(t_{\xi,\varepsilon},\xi,u_{\xi,\varepsilon})) - \omega(x(t_{\xi,\varepsilon},\eta,u_{\xi,\varepsilon}))| + \varepsilon \\
&\le c_2C_1\,|x(t_{\xi,\varepsilon},\xi,u_{\xi,\varepsilon}) - x(t_{\xi,\varepsilon},\eta,u_{\xi,\varepsilon})| + \varepsilon \\
&\le c_2C_1C_2\,|\xi-\eta| + \varepsilon,
\end{aligned}$$

where $C_2 > 0$ is such a constant that $|x(t,\xi,u) - x(t,\eta,u)| \le C_2\,|\xi-\eta|$ for all $\xi,\eta \in K_3$, all $t \in [0,T_0]$, and all $u \in \mathcal{M}_\Omega$. Note that the above holds for any $\varepsilon \in (0, r_1/4)$, and thus,

$$W(\xi) - W(\eta) \le C_3\,|\xi-\eta|$$

for all $\xi,\eta \in K_1$, where $C_3 = c_2C_1C_2$. By symmetry, one proves that

$$W(\eta) - W(\xi) \le C_3\,|\xi-\eta|$$

for all $\xi,\eta \in K_1$.

To prove the continuity of W on $\mathcal{D}$, it is enough to notice that for any $\xi \in \mathcal{D}$, $W(\xi) = 0$ and

$$|W(\xi) - W(\eta)| \le c_2\omega(\eta) \to 0, \qquad \text{as} \quad \eta \to \xi.$$

The proof of Lemma 4.4 is thus concluded. □

Below we show that W is decreasing along trajectories. Pick any $\xi \notin \mathcal{D}$. Let $\theta_0 > 0$ be such that

$$\omega(x(t,\xi,\mathbf{v})) \ge \omega(\xi)/2 \quad \forall\,t \in [0,\theta_0],\ \forall\,v \in \Omega,$$

where $\mathbf{v}$ denotes the constant function $\mathbf{v}(t) \equiv v$. (Observe that such a θ_0 exists because ω is continuous.) Pick any $\theta \in [0, \theta_0]$, and let $\eta_{\mathbf{v}} = x(\theta, \xi, \mathbf{v})$. For any $\varepsilon > 0$, there exists some $t_{\mathbf{v},\varepsilon}$ and $u_{\mathbf{v},\varepsilon} \in \mathcal{M}_\Omega$ such that

$$\begin{aligned} W(\eta_{\mathbf{v}}) &\le \omega(x(t_{\mathbf{v},\varepsilon}, \eta_{\mathbf{v}}, u_{\mathbf{v},\varepsilon}))k(t_{\mathbf{v},\varepsilon}) + \varepsilon \\ &= \omega(x(t_{\mathbf{v},\varepsilon} + \theta, \xi, \overline{u}_{\mathbf{v},\varepsilon}))k(t_{\mathbf{v},\varepsilon} + \theta)\left(1 - \frac{k(t_{\mathbf{v},\varepsilon} + \theta) - k(t_{\mathbf{v},\varepsilon})}{k(t_{\mathbf{v},\varepsilon} + \theta)}\right) + \varepsilon \\ &\le W(\xi)\left(1 - \frac{k(t_{\mathbf{v},\varepsilon} + \theta) - k(t_{\mathbf{v},\varepsilon})}{c_2}\right) + \varepsilon, \end{aligned} \tag{4.28}$$

where $\overline{u}_{\mathbf{v},\varepsilon}$ denotes the concatenation of $\mathbf{v}$ and $u_{\mathbf{v},\varepsilon}$. Still for the fixed ξ and θ, and for any $r > |\xi|$, define

$$T^r_{\xi,\theta} := \max_{\widetilde{v} \in \Omega} T_r\left(\frac{c_1}{2c_2}\omega(x(\theta, \xi, \widetilde{\mathbf{v}}))\right). \tag{4.29}$$

Notice that $x(\theta, \xi, \widetilde{\mathbf{v}})$ is jointly continuous as a function of $(\theta, \xi, \widetilde{v})$. Since ω and T_r are both continuous, this maximum is well defined and, moreover, $T^r_{\xi,\theta}$ is continuous as a function of θ, so, in particular,

$$\lim_{\theta \to 0^+} T^r_{\xi,\theta} \;=\; T_r\left(\frac{c_1}{c_2}\omega(\xi)\right). \tag{4.30}$$

Claim. $t_{\mathbf{v},\varepsilon} + \theta \le T^r_{\xi,\theta}$ for all $v \in \Omega$ and for all $\varepsilon \in (0, \frac{c_1}{4}\omega(\xi))$.

Proof. Assume that this is not true. Then there is some $v \in \Omega$ and some $\varepsilon \in \big(0, \frac{c_1}{4}\omega(\xi)\big)$ such that $t_{\mathbf{v},\varepsilon} + \theta > T^r_{\xi,\theta}$, and, in particular,

$$t_{\mathbf{v},\varepsilon} + \theta \ge T_r\left(\frac{c_1}{2c_2}\omega(x(\theta, \xi, \mathbf{v}))\right),$$

from which it follows that

$$\omega(x(t_{\mathbf{v},\varepsilon}, \eta_{\mathbf{v}}, u_{\mathbf{v},\varepsilon})) = \omega(x(t_{\mathbf{v},\varepsilon} + \theta, \xi, \overline{u}_{\mathbf{v},\varepsilon})) \le \frac{c_1}{2c_2}\omega(x(\theta, \xi, \mathbf{v})) = \frac{c_1}{2c_2}\omega(\eta_{\mathbf{v}})$$

for some input function $\overline{u}_{\mathbf{v},\varepsilon}$ (which we can take to be the concatenation of $\mathbf{v}$ and $u_{\mathbf{v},\varepsilon}$; note that the inequality follows from (4.19) and the definition of the functions T_r).

By the definition of W, one has

$$\begin{aligned} \omega(\eta_{\mathbf{v}}) &\le \frac{1}{c_1}W(\eta_{\mathbf{v}}) \le \frac{1}{c_1}\omega(t_{\mathbf{v},\varepsilon}, \eta_{\mathbf{v}}, u_{\mathbf{v},\varepsilon})k(t_{\mathbf{v},\varepsilon}) + \frac{\varepsilon}{c_1} \\ &\le \frac{c_2}{c_1}\omega(t_{\mathbf{v},\varepsilon} + \theta, \xi, \overline{u}_{\mathbf{v},\varepsilon}) + \frac{\varepsilon}{c_1} \\ &\le \frac{1}{2}\omega(\eta_{\mathbf{v}}) + \frac{\varepsilon}{c_1}, \end{aligned}$$

which is impossible, since $\varepsilon < \frac{c_1}{4}\omega(\xi) \le \frac{c_1}{2}\omega(\eta_{\mathbf{v}})$. This proves the claim.

From (4.28), we have, for any $v \in \mathcal{D}$ and for any ε small enough,

$$W(x(\theta, \xi, \mathbf{v})) - W(\xi) \;\le\; -\frac{W(\xi)}{c_2}\,\tau(t_{\mathbf{v},\varepsilon} + c\theta)\theta + \varepsilon$$

for some $c \in (0,1)$, where we used the mean value theorem in order to estimate the change in k, and where τ is a function as in (4.26). Using the monotonicity of $\tau(\cdot)$ and the above claim, one concludes

$$W(x(\theta,\xi,\mathbf{v})) - W(\xi) \;\leq\; -\frac{W(\xi)}{c_2}\,\tau\left(T^r_{\xi,\theta}\right)\theta + \varepsilon$$

for all ε small enough. Letting $\varepsilon \to 0$, one obtains

$$W(x(\theta,\xi,\mathbf{v})) - W(\xi) \;\leq\; -\frac{W(\xi)}{c_2}\,\tau\left(T^r_{\xi,\theta}\right)\theta \quad \forall\, v \in \Omega.$$

Thus one concludes that for any $v \in \Omega$ and any $\theta > 0$,

$$\frac{W(x(\theta,\xi,\mathbf{v})) - W(\xi)}{\theta} \leq -\frac{W(\xi)}{c_2}\,\tau(T^r_{\xi,\theta}).$$

Since W is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{D}$, it is differentiable almost everywhere on $\mathbb{R}^n \backslash \mathcal{D}$, and hence, for any $v \in \Omega$, any $r > |\xi|$, and any ξ at which W is differentiable,

$$\begin{aligned} DW(\xi)f(\xi,v) &= \lim_{\theta\to 0^+} \frac{W(x(\theta,\xi,\mathbf{v})) - W(\xi)}{\theta} \leq -\lim_{\theta\to 0^+} \frac{W(\xi)}{c_2}\,\tau(T^r_{\xi,\theta}) \\ &= -\frac{W(\xi)}{c_2}\,\tau\Big(\lim_{\theta\to 0^+} T^r_{\xi,\theta}\Big) = -\frac{W(\xi)}{c_2}\,\tau\left(T_r\left(\frac{c_1}{c_2}\omega(\xi)\right)\right) \\ &\leq -\frac{W(\xi)}{c_2}\,\tau\left(T_r\left(\frac{c_1}{c_2^2}W(\xi)\right)\right) = -\widetilde{\alpha}_3(W(\xi),r), \end{aligned} \tag{4.31}$$

where $\widetilde{\alpha}_3(s,r) = \frac{s}{c_2}\,\tau(T_r(c_3 s))$ with $c_3 = c_1/c_2^2$. Since (4.31) holds for all $r > |\xi|$, it follows that

$$DW(\xi)f(\xi,v) \leq -\widetilde{\alpha}_3(W(\xi), 2\,|\xi|) \tag{4.32}$$

for all $v \in \Omega$ and for almost all $\xi \in \mathbb{R}^n \setminus \mathcal{D}$.

Since $T_r(s)$ is defined for all $r \geq 0$ and $s > 0$, one sees that $\widetilde{\alpha}_3$ is defined on $\mathbb{R}_{>0} \times \mathbb{R}_{\geq 0}$. Extend $\widetilde{\alpha}_3$ to $\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$ by letting $\widetilde{\alpha}_3(0,r) := 0$ for all $r \geq 0$. By the continuity property of τ and $T_r(\cdot)$, one sees that $\widetilde{\alpha}_3(\cdot,r)$ is continuous for each r. (The continuity at $s = 0$ follows from $\widetilde{\alpha}_3(s,r) = s\tau(T_r(c_3 s))/c_2 \leq s\tau(0)/c_2$ for all $s > 0$.) Furthermore, since $\tau(T_r(c_3 s))$ is nondecreasing in s, it follows that $\widetilde{\alpha}_3(s,r)$ is of class $\mathcal{K}$ in s. Let $\breve{\alpha}_3(s,r) = \widetilde{\alpha}_3(s,2r)/(1+r)$. This function tends to zero as $r \to \infty$, because $\widetilde{\alpha}_3(s,r)$ is nonincreasing in r; thus $\breve{\alpha}_3(s,r)$ is of class $\mathcal{KL}$. Moreover,

$$DW(\xi)f(\xi,v) \leq -\breve{\alpha}_3(W(\xi),|\xi|) \qquad \forall\, \xi \in \mathbb{R}^n \setminus \mathcal{D},\ \forall\, v \in \Omega.$$

By Corollary A.3, there exists a continuous $\mathcal{KL}$-function $\widehat{\alpha}_3$ such that

$$DW(\xi)f(\xi,v) \leq -\widehat{\alpha}_3(W(\xi),|\xi|) \qquad \forall\, \xi \in \mathbb{R}^n \setminus \mathcal{D},\ \forall\, v \in \Omega. \tag{4.33}$$

To complete the proof, we follow the strategy used in [12] to find a smooth approximation of W. First of all, by Theorem B.1 in [12], applied on $\mathbb{R}^n \setminus \mathcal{D}$, there is a continuous function W_1 that is smooth on $\mathbb{R}^n \setminus \mathcal{D}$ such that

$$|W_1(\xi) - W(\xi)| \leq \frac{W(\xi)}{2} \qquad \forall\, \xi \in \mathbb{R}^n \setminus \mathcal{D}, \tag{4.34}$$

and

$$DW_1(\xi)f(\xi,v) \le -\widehat{\alpha}_3(W(\xi),|\xi|)/2 \qquad \forall\, \xi \in \mathbb{R}^n \setminus \mathcal{D},\ \forall\, v \in \Omega. \tag{4.35}$$

We extend W_1 to all of $\mathbb{R}^n$ by letting $W_1 \equiv 0$ on $\mathcal{D}$; thus, the approximation (4.34) holds on all of $\mathbb{R}^n$. (Note that W and $\widehat{\alpha}_3(V(\xi),|\xi|)$ are both continuous, so the result in [12] can indeed be applied.)

Next, we appeal to Lemma 4.3 in [12]. This shows that there exists some $\rho \in \mathcal{K}_\infty$ with $\rho'(s) > 0$ for all $s > 0$ such that $\rho \circ W_1$ is smooth everywhere. Let $V = \rho \circ W_1$. It follows from (4.25) and (4.34) that

$$\alpha_1(|h(\xi)|) \le V(\xi) \le \alpha_2(|\xi|) \qquad \forall\, \xi \in \mathbb{R}^n,$$

where $\alpha_1(s) = \rho(c_1 s/2)$, $\alpha_2(s) = \rho(2c_2\beta_0(s))$, and it follows from (4.34) and (4.35) that

$$DV(\xi)f(\xi,\mu) \le -\rho'(W_1(\xi))\widehat{\alpha}_3(W(\xi),|\xi|)/2 \le -\alpha_3(V(\xi),|\xi|) \tag{4.36}$$

for all $\xi \in \mathbb{R}^n \setminus \mathcal{D}$ and all $\mu \in \Omega$, where

$$\alpha_3(s,r) = \frac{\rho'(\rho^{-1}(s))\widehat{\alpha}_3(\rho^{-1}(V(\xi))/2,r)}{2}.$$

Since V has local (actually, global) minima at all points in $\mathcal{D}$, it follows that $DV(\xi) \equiv 0$ on $\mathcal{D}$, so we know that the estimate (4.36) also holds on all of $\mathbb{R}^n$.

Finally, observe that if there exists $\sigma \in \mathcal{K}$ such that (3.2) holds for all trajectories of the system, then (4.18) holds for all ξ, which, in turn, implies that

$$c_1\,|h(\xi)| \le W(\xi) \le c_2\sigma(|h(\xi)|) \qquad \forall\, \xi \in \mathbb{R}^n. \tag{4.37}$$

This results in the desired inequality

$$\alpha_1(|h(\xi)|) \le V(\xi) \le \sigma_1(|h(\xi)|) \qquad \forall\, \xi \in \mathbb{R}^n, \tag{4.38}$$

where $\sigma_1(s) = \rho(2c_2\sigma(s))$. This shows that if (3.2) holds for some $\sigma \in \mathcal{K}$, then property (3.4) can be strengthened to property (3.6).

Finally, suppose that, in the above proof, one strengthens (3.1) to (3.3). Associated to the function β there are, as before, functions $\{T_r\}$. Since we also have an estimate as in (3.1), there are functions $\{T_r\}$ associated to a β as in (3.1); without loss of generality, we will assume that the same T_r's work for both. Thus, we know that, provided $t \ge T_r(s)$, $|y(t,\xi,u)| \le s$ whenever $|h(\xi)| \le r$ or $|\xi| \le r$. The claim stated after (4.30) holds now for all $r > |h(\xi)|$ (instead of merely if $r > |\xi|$), because (4.19) can be strengthened to

$$\omega(x(t_1,\xi,u)) \;\le\; \beta(|h(\xi)|\,,t_1).$$

We now repeat the above proof to get a function $W(\xi)$ satisfying (4.37), and corresponding to (4.33), one has now also

$$DW(\xi)f(\xi,v) \le -\widehat{\alpha}_3(W(\xi),|h(\xi)|) \le -\widehat{\alpha}_3\left(W(\xi),\frac{W(\xi)}{c_1}\right)$$

for all $\xi \in \mathbb{R}^n \setminus \mathcal{D}$ and all $v \in \Omega$. Therefore, on $\mathbb{R}^n \setminus \mathcal{D}$,

$$DW(\xi)f(\xi,v) \le -\alpha_4(W(\xi)),$$

where $\widetilde{\alpha}_4(s) = \widetilde{\alpha}_3(s, s/c_1)$ is a continuous positive definite function. Using the same smoothing argument as earlier, we can show that there is a smooth function V such that (4.38) holds for some $\sigma_1, \sigma_2 \in \mathcal{K}_\infty$, and (4.36) can be strengthened to

$$DV(\xi)f(\xi, v) \leq -\widehat{\alpha}_4(V(\xi)) \tag{4.39}$$

for all $\xi \in \mathbb{R}^n$ and all $v \in \Omega$, where $\widehat{\alpha}_4(\cdot)$ is some continuous positive definite function.

Now we modify the function V to get V_1 so that V_1 satisfies inequalities of type (4.37) and (4.39) with $\widehat{\alpha}_4$ replaced by a $\mathcal{K}_\infty$ function α_5. For this purpose, let $\rho_0(\cdot)$ be a smooth $\mathcal{K}_\infty$-function such that $\rho_0(s)\widehat{\alpha}_4(s) \geq 1$ for $s \geq 1$, and let

$$\rho_1(s) = e^{\int_0^s \rho_0(s_1)\, ds_1} - 1.$$

Define $V_1(\xi) = \rho_1(V(\xi))$. It holds that

$$\widehat{\alpha}_1(|h(\xi)|) \leq V_1(\xi) \leq \widehat{\alpha}_2(|h(\xi)|) \qquad \forall\, \xi \in \mathbb{R}^n,$$

where $\widehat{\alpha}_1(s) = \rho_1(\alpha_1(s))$, $\widehat{\alpha}_2(s) = \rho_1(\alpha_2(s))$, and

$$DV_1(\xi)f(\xi, v) = -(V_1(\xi) + 1)\rho_0(V(\xi))\widehat{\alpha}_4(V(\xi)) \leq -\alpha_5(V_1(\xi))$$

for all $\xi \in \mathbb{R}^n$ and all $v \in \Omega$, where α_5 is any $\mathcal{K}_\infty$ function with the property that

$$\alpha_5(\rho_1(s)) \ \leq \ (\rho_1(s) + 1)\rho_0(s)\widehat{\alpha}_4(s)$$

for all $s \geq 0$ (such a $\mathcal{K}_\infty$-function exists because $(s + 1)\rho_0(s)\widehat{\alpha}_4(s) \geq s$ for all $s \geq 1$). Using V_1 as a Lyapunov function, this completes the proof. □

5. Remarks. The concept of IOS does not distinguish between "measured outputs," which may be used to provide information about the state of a system, and "target outputs," which are often the object of control, nor does it allow for the consideration of "robustness" to disturbances. A more general concept can be studied as well, as follows. Suppose that, instead of systems as in (1.1), we study more general systems of the following form:

$$\dot{x}(t) = f(x(t), u(t), d(t)), \quad y(t) = h(x(t)), \quad w(t) = k(x(t)), \tag{5.1}$$

where $f : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^r \to \mathbb{R}^n$, $h : \mathbb{R}^n \to \mathbb{R}^p$, and $k : \mathbb{R}^n \to \mathbb{R}^q$ are all locally Lipschitz continuous (for some nonnegative integers n, m, r, p, q). We think of the functions $d(\cdot)$ and $w(\cdot)$ as disturbances and measured outputs, respectively. Even more generality is gained if one considers, as mentioned in [17], a "measure" for states (in the sense of [11]), which we denote by $|x|_{\mathcal{A}}$ in analogy to the distance to a set $\mathcal{A}$ as in previous extensions of the ISS notion. Then, a natural definition of relative stability is given by the requirement that there should exist a $\mathcal{KL}$-function β and $\mathcal{K}$-functions γ_1 and γ_2 such that, for each initial state ξ and inputs (u, d), and for all t in the domain of definition of the corresponding maximal solution $x(\cdot)$ of (5.1),

$$|y(t)| \ \leq \ \beta(|\xi|_{\mathcal{A}}, t) + \gamma_1(\|u\|) + \gamma_2(\|w\|), \tag{5.2}$$

where y and w are the functions $h(x(\cdot))$ and $k(x(\cdot))$, respectively. Observe that, when d does not appear in the equations and when $k \equiv 0$, we recover (if $|\cdot|_{\mathcal{A}} = |\cdot|$) the IOS definition. When, again, d does not appear in the equations, but now $h(x) = x$, we recover (if $|\cdot|_{\mathcal{A}} = |\cdot|$) the input/output to state stability (IOSS) notion of zero-detectability discussed in [18] and recently completely characterized in [8]. (These notions are related by the fact that a system is ISS if and only if it is both IOSS and IOS, which generalizes the linear systems theory fact that internal stability is equivalent to detectability plus external stability.) A sufficient Lyapunov-theoretic condition for our general notion (which could be called "input/measurement to output stability") is the existence of a smooth $V : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ such that, for some $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$,

$$\alpha_1(|h(\xi)|) \leq V(\xi) \leq \alpha_2(|\xi|_{\mathcal{A}}) \qquad \forall\, \xi \in \mathbb{R}^n \tag{5.3}$$

and there exist $\chi_1, \chi_2 \in \mathcal{K}$, and $\alpha_3 \in \mathcal{KL}$ such that

$$DV(\xi)f(\xi,\mu,\delta) \leq -\alpha_3(V(\xi),|\xi|) + \chi_1(|\mu|) + \chi_2(|h(\xi)|) \quad \forall\, \xi,\ \forall \mu,\ \forall\, \delta, \tag{5.4}$$

or obvious variations of this inequality. We leave the formulation of converse theorems for future work.

Appendix A. Some facts regarding $\mathcal{KL}$ functions.

The following simple observation is proved in [19] and will be needed here too.

Lemma A.1. *For any $\mathcal{KL}$-function β, there exists a family of mappings $\{T_r\}_{r\geq 0}$ such that*

- *for each fixed $r > 0$, $T_r : \mathbb{R}_{>0} \xrightarrow{\text{onto}} \mathbb{R}_{>0}$ is continuous and strictly decreasing, and $T_0(s) \equiv 0$;*
- *for each fixed $s > 0$, $T_r(s)$ is strictly increasing as r increases and is such that $\beta(r, T_r(s)) < s$, and consequently, $\beta(r,t) < s$ for all $t \geq T_r(s)$.*

Lemma A.2. *For any $\mathcal{KL}$ function β, there exist two $\mathcal{K}$ functions κ_1 and κ_2 so that*

$$\beta(s,t) \;\geq\; \frac{\kappa_1(s)}{1+\kappa_2(t)} \tag{A.1}$$

for all $s \geq 0$ and all $t \geq 0$.

Proof. We assume that $b := \sup_s \beta(s,0) < \infty$ (otherwise, we first find a $\beta_0 \leq \beta$ with that property and prove the result for β_0). We define, for all $s \geq 0$ and $t \geq 0$,

$$\widetilde{\beta}(s,t) := \int_t^{t+1} \beta(s,\tau)\, d\tau.$$

Note that $\widetilde{\beta}$ is again of class $\mathcal{KL}$, and $\widetilde{\beta}(s,t) \leq \beta(s,t)$ for all s,t. Let

$$\widetilde{\alpha}(t) := \sup_{s\geq 0} \widetilde{\beta}(s,t).$$

This is finite everywhere, since it is bounded by b. Moreover, it is a continuous function, because

$$\widetilde{\alpha}(t) := \int_t^{t+1} \alpha(\tau)\, d\tau,$$

where α is the decreasing function (not necessarily strictly) defined by $\alpha(t) := \sup_{s\geq 0} \beta(s,t)$. We will write from now on $\widetilde{\beta}(\infty,t)$ instead of $\widetilde{\alpha}(t)$. Finally, we let

$$\rho(x) := \max\{x, 0\}$$

for all $x \in \mathbb{R}$ and introduce the following function:

$$c :\ \mathbb{R}^2 \to \mathbb{R} :\ (x,y) \mapsto -\ln \widetilde{\beta}\left(\frac{1}{\rho(x)}, \rho(y)\right) - \rho(-x) - \rho(-y),$$

where we understand $\widetilde{\beta}(\frac{1}{0}, t)$ as $\widetilde{\alpha}(t)$. As in [1], we let $\mathcal{N}$ denote the class of all functions $k : \mathbb{R} \to \mathbb{R}$ that are nondecreasing, continuous, and unbounded below. Note that c is of class $\mathcal{N}$ on each variable separately. (Continuity follows from the continuity of each of $\widetilde{\beta}(\infty, \cdot)$, $\widetilde{\beta}(s, \cdot)$ for each $s \geq 0$, and $\widetilde{\beta}(\cdot, t)$ for each $t \geq 0$ as well as continuity of ρ. The nondecreasing property is clear, using that $\widetilde{\beta}(\cdot, t)$ for each $t \geq 0$ and ρ are nondecreasing, and that $\widetilde{\beta}(\infty, \cdot)$ and $\widetilde{\beta}(s, \cdot)$ for each $s \geq 0$ are nonincreasing. Unbounded below follows from the fact that for $x \to -\infty$ we have $c(x, y_0) = a + x$, where $a = \widetilde{\beta}(\infty, \rho(y_0)) - \rho(-y_0)$ and for $y \to -\infty$ we have $c(x_0, y) = a + y$, where $a = -\ln \widetilde{\beta}\left(\frac{1}{\rho(x_0)}, 0\right) - \rho(-x_0)$.

By Proposition 3.4 in [1], there is some $k \in \mathcal{N}$ such that $c(x, y) \leq k(x) + k(y)$ for all x, y. So, we can write, after using that $\beta \geq \widetilde{\beta}$: $\beta(1/x, y) \geq e^{-k(x)} e^{-k(y)}$ for all $x, y > 0$. Equivalently,

$$\beta(s, t) \;\geq\; \frac{\kappa_1(s)}{1 + \kappa_2(t)}$$

for all $s, t > 0$, when we define

$$\kappa_1(s) := \; e^{-k(1/s) - k(0)}$$

for all $s > 0$ and

$$\kappa_2(t) := \; e^{k(t) - k(0)} - 1$$

for all $t \geq 0$. Observe that both of these functions are continuous, nondecreasing, and nonnegative. Moreover, $\kappa_2(0) = 0$, so κ_2 is in $\mathcal{K}$. From the inequality

$$[1 + \kappa_2(0)]\, \beta(s, 0) \;\geq\; \kappa_1(s)$$

for all $s > 0$, and the fact that $\beta(0, 0) = 0$, we conclude that $\lim_{s \to 0^+} \kappa_1(s) = 0$, so we may extend κ_1 by defining $\kappa_1(0) = 0$, and thus κ_1 is in $\mathcal{K}$ as well. □

As κ_1 and κ_2 in Lemma A.2 are continuous, we have, in particular, the following corollary.

COROLLARY A.3. *For any $\mathcal{KL}$-function β, there is a (jointly) continuous $\mathcal{KL}$-function β_1 such that $\beta(s, r) \geq \beta_1(s, r)$ for all $(s, r) \in \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$.*

The following is a generalization of the comparison lemma given in [12]. It plays a role in the proofs of sufficiency, which are the easier parts of the theorems.

LEMMA A.4. *For any $\mathcal{K}$-function κ, there exists a $\mathcal{KL}$ function β such that if $y(\cdot)$ is any locally absolutely continuous function defined on some interval $[0, T]$ with $y(t) \geq 0$, and if $y(\cdot)$ satisfies the differential inequality*

$$\text{(A.2)} \qquad \dot{y}(t) \leq -c\,\kappa(y(t)) \;\; \textit{for almost all} \;\; t \in [0, T]$$

for some $c \geq 0$ with $y(0) = y_0 \geq 0$, then it holds that

$$y(t) \leq \beta(y_0, ct)$$

for all $t \in [0, T]$.

Proof. First, by Lemma 4.4 in [12], for each $\kappa \in \mathcal{K}$, there exists $\beta \in \mathcal{KL}$ such that for any locally absolutely continuous function $z(t) \geq 0$, if it satisfies the inequality

$$\dot{z}(t) \leq -\kappa(z(t))$$

on $[0,T]$, it holds that $z(t) \leq \beta(z(0),t)$ for all t. (The statement in that reference applies to z defined on all of $[0,\infty)$, but exactly the same proof works for a finite interval.)

Let $y(t)$ be a function as in the statement of the lemma for some $c > 0, T > 0$. Let $\widetilde{y}(t) = y(t/c)$. Then $\widetilde{y}$ is again locally absolutely continuous and nonnegative on $[0, cT]$. Moreover, $\widetilde{y}$ satisfies the inequality

$$\frac{d}{dt}\widetilde{y}(t) \leq -\kappa(\widetilde{y}(t)).$$

Hence,

$$\widetilde{y}(t) \leq \beta(\widetilde{y}(0), t)$$

for all $t \in [0, cT]$. This then implies that

$$y(t) \leq \beta(y(0), ct)$$

for all $t \in [0,T]$. □

Finally, we have the following fact, mentioned when discussing decrease conditions.

Lemma A.5. *Let $V : \mathbb{R}^n \to \mathbb{R}$ be a C^1 positive definition function with the following property: for some $\mathcal{K}$ function χ, it holds that*

$$V(\xi) \geq \chi(|\mu|) \quad \textit{and} \quad V(\xi) \neq 0 \ \Rightarrow \ DV(\xi)f(\xi,\mu) < 0.$$

Then, there is a function $\alpha \in \mathcal{KL}$ so that

$$V(\xi) \geq \chi(|\mu|) \ \Rightarrow \ DV(\xi)f(\xi,\mu) \leq -\alpha(V(\xi), |\xi|)$$

for all $\xi \in \mathbb{R}^n, \mu \in \mathbb{R}^m$.

Proof. Without loss of generality, we assume that $\chi \in \mathcal{K}_\infty$. Define the set for each $s, t \geq 0$:

$$R(s,t) := \{(x,u) : \ |\xi| \leq t, \ V(\xi) \geq s, \ |\mu| \leq \chi^{-1}(V(\xi))\}.$$

These sets are compact (possibly empty) for each s and t. Note the following properties:

$$s > s' \ \Rightarrow \ R(s,t) \subseteq R(s',t),$$

$$t > t' \ \Rightarrow \ R(s,t') \subseteq R(s,t).$$

Now let

$$\alpha_0(s,t) = \min_{(\xi,\mu)\in R(s,t)} -DV(\xi)f(\xi,\mu)$$

(with the convention that $\alpha_0(s,t) = +\infty$ if $R(s,t) = \emptyset$). Then, $\alpha_0(s,t)$ is nonincreasing in t and nondecreasing in s. Moreover, $\alpha(s,t) > 0$ whenever $s > 0$ (by the hypothesis of the lemma). Next let

$$\widehat{\alpha}(s,t) := \min\{\alpha_0(s,t), s\}.$$

This function has the same monotonicity properties as α_0, it satisfies $\alpha_0(s,t) \geq \widehat{\alpha}(s,t)$ for all s, t, and is finite-valued. It also satisfies $\widehat{\alpha}(s,t) \neq 0$ for $s > 0$. Now pick

$$\widetilde{\alpha}(s,t) := \int_{s-1}^{s} \widehat{\alpha}(\sigma,t)\, d\sigma$$

(let $\widehat{\alpha}(s,t) := 0$ for $s < 0$). This function still has the same monotonicity properties, satisfies $\widetilde{\alpha}(s,t) > 0$ for $s > 0$, and is continuous in s. It may not be strictly increasing in s, nor need it converge to zero as $t \to 0$, so we obtain finally a $\mathcal{KL}$ function α by defining

$$\alpha(s,t) := \frac{s\widetilde{\alpha}(s,t)}{(1+s)(1+t)}.$$

This satisfies the desired properties by construction, because

$$V(\xi) \geq \chi(|\mu|) \;\Rightarrow\; DV(\xi)f(\xi,\mu) \leq -\alpha(V(\xi),|\mu|),$$

and $\alpha_0 \geq \widehat{\alpha} \geq \widetilde{\alpha} \geq \alpha$ pointwise. □

GENERIC WELL-POSEDNESS OF OPTIMAL CONTROL PROBLEMS WITHOUT CONVEXITY ASSUMPTIONS[*]

ALEXANDER J. ZASLAVSKI[†]

Abstract. The Tonelli existence theorem in the calculus of variations and its subsequent modifications were established for integrands f which satisfy convexity and growth conditions. In A. J. Zaslavski [*Nonlinear Anal.*, to appear], a generic existence and uniqueness result (with respect to variations of the integrand of the integral functional) without the convexity condition was established for a class of optimal control problems satisfying the Cesari growth condition. In this paper we extend the generic existence and uniqueness result in A. J. Zaslavski [*Nonlinear Anal.*, to appear], to a class of optimal control problems in which constraint maps are also subject to variations. The main result of the paper is obtained as a realization of a variational principle extending the variational principle introduced in A. D. Ioffe and A. J. Zaslavski [*SIAM J. Control Optim.*, 38 (2000), pp. 566–581].

Introduction. The Tonelli existence theorem in the calculus of variations [25] and its subsequent generalizations and extensions (e.g., [5, 6, 13, 18, 22, 24]) are based on two fundamental hypotheses concerning the behavior of the integrand as a function of the last argument (derivative): one that the integrand should grow superlinearly at infinity and the other that it should be convex (or exhibit a more special convexity property in case of a multiple integral with vector-valued functions) with respect to the last variable. Moreover, certain convexity assumptions are also necessary for properties of lower semicontinuity of integral functionals which are crucial in most of the existence proofs, although there are some interesting theorems without convexity (see [5, Ch. 16] and [2, 4, 7, 20, 21]).

In [27] it was shown that the convexity condition is not needed generically, and not only for the existence but also for the uniqueness of a solution and even for well-posedness of the problem (with respect to some natural topology in the space of integrands). Instead of considering the existence of a solution for a single integrand f, we investigated it for a space of integrands and showed that a unique solution exists for most of the integrands in the space. This approach has already been successfully applied in global analysis and the theory of dynamical systems [8, 9, 23], as well as in the calculus of variations (see, for example, [1, 16, 26]. Interesting generic existence results were obtained for particular cases of variational problems [3, 19]. In [27] this approach allowed us to establish the generic existence of solutions for a large class of optimal control problems without convexity assumptions.

More precisely, in [27] we considered a class of optimal control problems (with the same system of differential equations, the same functional constraints, and the same boundary conditions) which is identified with the corresponding complete metric space of cost functions (integrands), say $\mathcal{F}$. We did not impose any convexity assumptions. These integrands are only assumed to satisfy the Cesari growth condition. The main

[†] Department of Mathematics, The Technion, Haifa 32000, Israel (ajzasl@techunix.technion.ac.il).

result in [27] establishes the existence of an everywhere dense G_δ-set $\mathcal{F}' \subset \mathcal{F}$ such that for each integrand in $\mathcal{F}'$ the corresponding optimal control problem has a unique solution. At this point we do not intend to describe the topology on $\mathcal{F}$. We only note that it is rather natural and that the set $\mathcal{F}'$ has the following property:

For each $f \in \mathcal{F}$ and each positive number ϵ there exists $g \in \mathcal{F}'$ such that $|f(t,x,u) - g(t,x,u)| \le \epsilon$ for all (t,x,u).

Here t is the independent variable, x is the state variable, and u is the control variable.

The next step in this area of research was done in [14]. There we introduced a general variational principle having its prototype in the variational principle of Deville, Godefroy, and Zizler [10]. A generic existence result in the calculus of variations without convexity assumptions was then obtained as a realization of this variational principle. It was also shown in [14] that some other generic well-posedness results in optimization theory known in the literature and their modifications are obtained as a realization of this variational principle. Note that the generic existence result in [14] was established for variational problems but not for optimal control problems and that the topologies in the spaces of integrands in [27] and [14] are different.

In this paper we suggest a modification of the variational principle in [14] which can be applied to classes of optimal control problems with various topologies in the corresponding spaces of integrands. As a realization of this principle we establish a generic existence result for a class of optimal control problems in which constraint maps are also subject to variations as well as the cost functions. More precisely, we establish a generic existence result for a class of optimal control problems (with the same system of differential equations, the same boundary conditions, and without convexity assumptions) which is identified with the corresponding complete metric space of pairs (f, U) (where f is an integrand satisfying the Cesari growth condition and U is a constraint map) endowed with some natural topology. We will show that for a generic pair (f, U) the corresponding optimal control problem has a unique solution.

To understand that the generic existence result which will be established in this paper is more complicated than its prototypes in [27] and [14], we note that for the class of optimal control problems (with the same constraint map) which is identified with the corresponding space of integrands the following properties hold [27]:

- The optimal value v_f in the optimal control problem with an integrand f depends on f continuously.
- For each integrand f and each number $\delta > 0$ there exists a neighborhood $\mathcal{U}$ of f in the space of integrands such that each $(g, \delta/2)$-optimal trajectory-control pair with some $g \in \mathcal{U}$ is (f, δ)-optimal.

Here we say that a trajectory-control pair (x, u) is (g, ϵ)-optimal if the value of the integral functional with the integrand g for (x, u) does not exceed $v_g + \epsilon$.

Clearly these properties which play an important role in [27] and [14] do not have analogs when constraint maps are also subject to variations.

In the theory developed in [27], [14] and in the present paper topologies on spaces of integrands and on spaces of integrand-map pairs are of great importance. Actually one space of integrand-map pairs, say $\mathcal{A}$, considered here is a topological product of a space of integrands and a space of multivalued maps. The values of these maps are elements of the space of all nonempty convex closed subsets of a finite-dimensional Euclidean space endowed with the Hausdorff distance. In the space of multivalued maps we consider the topology of uniform convergence. For the space of integrands we consider weak and strong topologies which induce weak and strong topologies on the space $\mathcal{A}$. We will prove the existence of a set $\mathcal{A}' \subset \mathcal{A}$ which is a countable intersection of open (in the weak topology) everywhere dense (in the strong topology) sets such that for each $(f, U) \in \mathcal{A}'$ the corresponding optimal control problem has a unique solution. In fact we will establish our result for various spaces of integrands: the space of the so-called $\mathcal{L} \bigotimes \mathcal{B}$-measurable integrands, the space of lower semicontinuous integrands, and the space of continuous integrands, as well as their subspaces consisting of integrands $f(t, x, u)$ differentiable in u and subspaces consisting of integrands $f(t, x, u)$ differentiable in x and u. All these spaces are endowed with the same weak topology which is a modification of the topologies introduced in [27] and [14]. Their strong topology is always stronger than the topology of uniform convergence.

1. Definitions and the main result. In this paper we use the following notations and definitions. Let $k \geq 1$ be an integer. We denote by $\text{mes}(E)$ the Lebesgue measure of a measurable set $E \subset R^k$, by $|\cdot|$ the Euclidean norm in R^k, and by $\langle \cdot, \cdot \rangle$ the scalar product in R^k. We use the convention that $\infty - \infty = 0$. For any $f \in C^q(R^k)$ we set

$$||f||_{C^q} = ||f||_{C^q(R^k)} = \sup_{z \in R^k} \{|\partial^{|\alpha|} f(z)/\partial x_1^{\alpha_1} \dots \partial x_k^{\alpha_k}| : \tag{1.1}$$

$$\alpha_i \geq 0 \text{ is an integer, } i = 1, \dots, k, \ |\alpha| \leq q\},$$

where $|\alpha| = \sum_{i=1}^k \alpha_i$.

For each function $f : X \to [-\infty, \infty]$, where X is nonempty, we set $\inf(f) = \inf\{f(x) : x \in X\}$. For each set-valued mapping $U : X \to 2^Y \setminus \{\emptyset\}$, where X and Y are nonempty, we set

$$\text{graph}(U) = \{(x, y) \in X \times Y : y \in U(x)\}. \tag{1.2}$$

In this paper we usually consider topological spaces with two topologies where one is weaker than the other. (Note that they can coincide.) We refer to them as the weak and the strong topologies, respectively. If (X, d) is a metric space with a metric d and $Y \subset X$, then usually Y is also endowed with the metric d (unless another metric is introduced in Y). Assume that X_1 and X_2 are topological spaces and that each of them is endowed with a weak and a strong topology. Then for the product $X_1 \times X_2$ we also introduce a pair of topologies: a weak topology which is the product of the weak topologies of X_1 and X_2 and a strong topology which is the product of the strong topologies of X_1 and X_2. If $Y \subset X_1$, then we consider the topological subspace Y with the relative weak and strong topologies (unless other topologies are introduced). If (X_i, d_i), $i = 1, 2$, are metric spaces with the metrics d_1 and d_2, respectively, then the space $X_1 \times X_2$ is endowed with the metric d defined by

$$d((x_1, x_2), (y_1, y_2)) = d_1(x_1, y_1) + d_2(x_2, y_2), \quad (x_i, y_i) \in X \times Y, \quad i = 1, 2.$$

Let $m, n, N \geq 1$ be integers. In this paper we assume that Ω is a fixed bounded domain in R^m, $H(t, x, u)$ is a fixed continuous function defined on $\Omega \times R^n \times R^N$ with values in R^{mn} such that $H(t, x, u) = (H_i)_{i=1}^n$ and $H_i = (H_{ij})_{j=1}^m$, $i = 1, \dots, n$, B_1 and B_2 are fixed nonempty closed subsets of R^n, and $\theta^* = (\theta_i^*)_{i=1}^n \in (W^{1,1}(\Omega))^n$ is also fixed. Here

$$W^{1,1}(\Omega) = \{u \in L^1(\Omega) : \partial u/\partial x_j \in L^1(\Omega), \ j = 1, \dots, m\}$$

and $W_0^{1,1}(\Omega)$ is the closure of $C_0^\infty(\Omega)$ in $W^{1,1}(\Omega)$, where $C_0^\infty(\Omega)$ is the space of smooth functions $u: \ \Omega \to R^1$ with compact support in Ω.

If $m = 1$, then we assume that $\Omega = (T_1, T_2)$, where T_1 and T_2 are fixed real numbers for which $T_1 < T_2$.

For a function $u = (u_1, \dots, u_n)$, where $u_i \in W^{1,1}(\Omega)$, $i = 1, \dots, n$, we set

$$\nabla u_i = (\partial u_i/\partial x_j)_{j=1}^m, \quad i = 1, \dots, n, \quad \nabla u = (\nabla u_i)_{i=1}^n.$$

Define set-valued mappings $\tilde{A} : \Omega \to 2^{R^n} \setminus \{\emptyset\}$ and $\tilde{U} : \Omega \times R^n \to 2^{R^N} \setminus \{\emptyset\}$ by

$$\tilde{A}(t) = R^n, \quad t \in \Omega, \quad \tilde{U}(t,x) = R^N, \quad (t,x) \in \Omega \times R^n. \tag{1.3}$$

For each $A : \Omega \to 2^{R^n} \setminus \{\emptyset\}$ and each $U : \text{graph}(A) \to 2^{R^N} \setminus \{\emptyset\}$ for which graph(U) is a closed subset of the space $\Omega \times R^n \times R^N$ with the product topology, we denote by $X(A, U)$ the set of all pairs of functions (x, u), where $x = (x_1, \dots, x_n) \in (W^{1,1}(\Omega))^n$, $u = (u_1, \dots, u_N) : \ \Omega \to R^N$ is measurable, and the following relations hold:

(1.4a)
$$x(t) \in A(t), \quad t \in \Omega \text{ almost everywhere (a.e.)}, \quad u(t) \in U(t, x(t)), \quad t \in \Omega \text{ a.e.},$$

$$\nabla x(t) = H(t, x(t), u(t)), \qquad t \in \Omega \text{ a.e.}, \tag{1.4b}$$

$$\text{if } m = 1, \quad \text{ then } x(T_i) \in B_i, \quad i = 1, 2, \tag{1.4c}$$

$$\text{if } m > 1, \quad \text{ then } x - \theta^* \in (W_0^{1,1}(\Omega))^n. \tag{1.4d}$$

Note that in the definition of the space $X(A, U)$ we use the boundary condition (1.4c) in the case $m = 1$, while in the case $m > 1$ we use the boundary condition (1.4d). Both of them are common in the literature. We do this to provide a unified treatment for both cases. Note that we prove our main result in the case $m = 1$ for a class of Bolza problems (with the same boundary condition (1.4c)), while in the case $m > 1$ it will be established for a class of Lagrange problems (with the same boundary condition (1.4d)).

To be more precise, we have to define elements of $X(A, U)$ as classes of pairs equivalent in the sense that (x_1, u_1) and (x_2, u_2) are equivalent if and only if $x_2(t) = x_1(t)$, $u_2(t) = u_1(t)$, $t \in \Omega$ a.e. If $m = 1$, then by an appropriate choice of representatives, $W^{1,1}(T_1, T_2)$ can be identified with the set of absolutely continuous functions $x : [T_1, T_2] \to R^1$, and we will henceforth assume that this has been done.

Let $A : \Omega \to 2^{R^n} \setminus \{\emptyset\}$, $U : \text{graph}(A) \to 2^{R^N} \setminus \{\emptyset\}$, and let graph$(U)$ be a closed subset of the space $\Omega \times R^n \times R^N$ with the product topology.

For the set $X(A, U)$ defined above we consider the uniformity which is determined by the following base:

$$E_X(\epsilon) = \{((x_1, u_1), (x_2, u_2)) \in X(A, U) \times X(A, U) : \tag{1.5}$$

$$\text{mes}\{t \in \Omega : \ |x_1(t) - x_2(t)| + |u_1(t) - u_2(t)| \geq \epsilon\} \leq \epsilon\},$$

where $\epsilon > 0$. It is easy to see that the uniform space $X(A, U)$ is metrizable (by a metric ρ) (see [15]). In the space $X(A, U)$ we consider the topology induced by the metric ρ.

Next we define spaces of integrands associated with the maps A and U. By $\mathcal{M}(A,U)$ we denote the set of all functions f : graph$(U) \to R^1 \cup \{\infty\}$ with the following properties:

(i) f is measurable with respect to the σ-algebra generated by products of Lebesgue measurable subsets of Ω and Borel subsets of $R^n \times R^N$;

(ii) $f(t,\cdot,\cdot)$ is lower semicontinuous for almost every $t \in \Omega$;

(iii) for each $\epsilon > 0$ there exists an integrable scalar function $\psi_\epsilon(t) \geq 0,\ t \in \Omega$, such that $|H(t,x,u)| \leq \psi_\epsilon(t) + \epsilon f(t,x,u)$ for all $(t,x,u) \in$ graph (U).

The growth condition in (iii) was proposed by Cesari (see [5]), and its equivalents and modifications are rather common in the literature. Due to the property (i) for every $f \in \mathcal{M}(A,U)$ and every $(x,u) \in X(A,U)$ the function $f(t,x(t),u(t))$, $t \in \Omega$, is measurable.

Denote by $\mathcal{M}^l(A,U)$ (respectively, $\mathcal{M}^c(A,U)$) the set of all lower semicontinuous (respectively, finite-valued continuous) functions f : graph$(U) \to R^1 \cup \{\infty\}$ in $\mathcal{M}(A,U)$. Now we equip the set $\mathcal{M}(A,U)$ with the strong and weak topologies. For the space $\mathcal{M}(A,U)$ we consider the uniformity determined by the following base:

$$E_{\mathcal{M}}(\epsilon) = \{(f,g) \in \mathcal{M}(A,U) \times \mathcal{M}(A,U) : \tag{1.6}$$

$$|f(t,x,u) - g(t,x,u)| \leq \epsilon,\ (t,x,u) \in \text{ graph}(U)\},$$

where $\epsilon > 0$. It is easy to see that the uniform space $\mathcal{M}(A,U)$ with this uniformity is metrizable (by a metric $d_{\mathcal{M}}$) and complete. This uniformity generates in $\mathcal{M}(A,U)$ the strong topology. Clearly $\mathcal{M}^l(A,U)$ and $\mathcal{M}^c(A,U)$ are closed subsets of $\mathcal{M}(A,U)$ with this topology.

For each $\epsilon > 0$ we set

$$E_{\mathcal{M}w}(\epsilon) = \{(f,g) \in \mathcal{M}(A,U) \times \mathcal{M}(A,U) : \text{ there exists a nonnegative} \tag{1.7}$$

$$\phi \in L^1(\Omega) \text{ such that } \int_\Omega \phi(t)dt \leq 1, \text{ and for almost every } t \in \Omega,$$

$$|f(t,x,u) - g(t,x,u)| < \epsilon + \epsilon \max\{|f(t,x,u)|, |g(t,x,u)|\} + \epsilon\phi(t)$$

$$\text{for each } x \in A(t) \text{ and each } u \in U(t,x)\}.$$

Using the following simple lemma we can easily show that for the set $\mathcal{M}(A,U)$ there exists the uniformity which is determined by the base $E_{\mathcal{M}w}(\epsilon)$, $\epsilon > 0$. This uniformity induces in $\mathcal{M}(A,U)$ the weak topology.

Lemma 1.1. *Let $a, b \in R^1$, $\epsilon \in (0,1)$, $\Delta \geq 0$, and*

$$|a - b| < (1+\Delta)\epsilon + \epsilon \max\{|a|, |b|\}.$$

Then

$$|a - b| < (1+\Delta)(\epsilon + \epsilon^2(1-\epsilon)^{-1}) + \epsilon(1-\epsilon)^{-1}\min\{|a|, |b|\}.$$

Denote by $C_l(B_1 \times B_2)$ the set of all lower semicontinuous functions $\xi : B_1 \times B_2 \to R^1 \cup \{\infty\}$ bounded from below. We also equip the set $C_l(B_1 \times B_2)$ with strong and weak topologies. For the set $C_l(B_1 \times B_2)$ we consider the uniformity determined by the following base:

(1.8)
$$E_c(\epsilon) = \{(\xi, h) \in C_l(B_1 \times B_2) \times C_l(B_1 \times B_2) : \ |\xi(z) - h(z)| \le \epsilon, \ z \in B_1 \times B_2\},$$

where $\epsilon > 0$. It is easy to see that the uniform space $C_l(B_1 \times B_2)$ is metrizable (by a metric d_c) and complete. This metric induces in $C_l(B_1 \times B_2)$ the strong topology. We do not write down the explicit expressions for the metrics $d_{\mathcal{M}}$ and d_c because we are not going to use them in what follows.

For any $\epsilon > 0$ we set

$$E_{cw}(\epsilon) = \{(\xi, h) \in C_l(B_1 \times B_2) \times C_l(B_1 \times B_2) : \ |\xi(z) - h(z)| \tag{1.9}$$

$$< \epsilon + \epsilon \max\{|\xi(z)|, |h(z)|\}, \ z \in B_1 \times B_2\},$$

where $\epsilon > 0$. By using Lemma 1.1 we can easily show that for the set $C_l(B_1 \times B_2)$ there exists a uniformity which is determined by the base $E_{cw}(\epsilon)$, $\epsilon > 0$. This uniformity induces in $C_l(B_1 \times B_2)$ the weak topology. Denote by $C(B_1 \times B_2)$ the set of all finite-valued continuous functions h in $C_l(B_1 \times B_2)$. Clearly it is a closed subset of $C_l(B_1 \times B_2)$ with the weak topology.

In the case $m > 1$ for each $f \in \mathcal{M}(A, U)$ we define $I^{(f)} : \ X(A, U) \to R^1 \cup \{\infty\}$ by

$$I^{(f)}(x, u) = \int_{\Omega} f(t, x(t), u(t)) dt, \qquad (x, u) \in X(A, U). \tag{1.10}$$

In the case $m = 1$ for each $f \in \mathcal{M}(A, U)$ and each $\xi \in C_l(B_1 \times B_2)$ we define $I^{(f,\xi)} : \ X(A, U) \to R^1 \cup \{\infty\}$ by

$$I^{(f,\xi)}(x, u) = \int_{T_1}^{T_2} f(t, x(t), u(t)) dt + \xi(x(T_1), x(T_2)), \quad (x, u) \in X(A, U). \tag{1.11}$$

We will show (see Propositions 4.1 and 4.2) that in both cases (1.10) and (1.11) define lower semicontinuous functionals on $X(A, U)$.

From now on in this section we consider a fixed set-valued mapping $A : \Omega \to 2^{R^n} \setminus \{\emptyset\}$ for which graph(A) is a closed subset of the space $\Omega \times R^n$ with the product topology. Denote by $\tilde{U}_A$ the restriction of $\tilde{U}$ (see (1.3)) to the graph(A). Namely,

$$\tilde{U}_A : \ \text{graph}(A) \to 2^{R^N}, \quad \tilde{U}(t, x) = R^N, \quad (t, x) \in \ \text{graph}(A). \tag{1.12}$$

We consider functionals $I^{(f,\xi)}$ with $(f, \xi) \in \mathcal{M}(A, \tilde{U}_A) \times C_l(B_1 \times B_2)$ (in the case $m = 1$) and functionals $I^{(f)}$ with $f \in \mathcal{M}(A, \tilde{U}_A)$ (in the case $m > 1$) defined on the space $X(A, \tilde{U}_A)$ (see (1.4)). As we have already noted in the introduction our main result will be established for several classes of optimal control problems with different corresponding spaces of the integrands which are subsets of the space $\mathcal{M}(A, \tilde{U}_A)$. The subspaces of lower semicontinuous and continuous integrands ($\mathcal{M}^l(A, \tilde{U}_A)$ and $\mathcal{M}^c(A, \tilde{U}_A)$) have already been defined. Now we define subspaces of $\mathcal{M}(A, \tilde{U}_A)$ which consist of integrands differentiable with respect to the control variable u.

Let $k \geq 1$ be an integer. Denote by $\mathcal{M}_k(A, \tilde{U}_A)$ the set of all finite-valued $f \in \mathcal{M}(A, \tilde{U}_A)$ such that for each $(t, x) \in \text{graph}(A)$ the function $f(t, x, \cdot) \in C^k(R^N)$. We consider the topological subspace $\mathcal{M}_k(A, \tilde{U}_A) \subset \mathcal{M}(A, \tilde{U}_A)$ with the relative weak topology. The strong topology on $\mathcal{M}_k(A, \tilde{U}_A)$ is induced by the uniformity which is determined by the following base:

$$(1.13) \quad E_{\mathcal{M}k}(\epsilon) = \{(f, g) \in \mathcal{M}_k(A, \tilde{U}_A) \times \mathcal{M}_k(A, \tilde{U}_A) : \ |f(t, x, u) - g(t, x, u)| \leq \epsilon$$

$$\text{for all } (t, x, u) \in \ \text{graph}(A) \times R^N \text{ and}$$

$$||f(t, x, \cdot) - g(t, x, \cdot)||_{C^k(R^N)} \leq \epsilon \text{ for all } (t, x) \in \text{graph}(A)\},$$

where $\epsilon > 0$. It is easy to see that the space $\mathcal{M}_k(A, \tilde{U}_A)$ with this uniformity is metrizable (by a metric $d_{\mathcal{M},k}$) and complete. Define

$$(1.14) \quad \mathcal{M}_k^l(A, \tilde{U}_A) = \mathcal{M}_k(A, \tilde{U}_A) \cap \mathcal{M}^l(A, \tilde{U}_A), \ \mathcal{M}_k^c(A, \tilde{U}_A) = \mathcal{M}_k(A, \tilde{U}_A) \cap \mathcal{M}^c(A, \tilde{U}_A).$$

Clearly $\mathcal{M}_k^l(A, \tilde{U}_A)$ and $\mathcal{M}_k^c(A, \tilde{U}_A)$ are closed sets in $\mathcal{M}_k(A, \tilde{U}_A)$ with the strong topology.

Finally, we define subspaces of $\mathcal{M}(\tilde{A}, \tilde{U})$ which consist of integrands differentiable with respect to the state variable x and the control variable u. Denote by $\mathcal{M}_k^*(\tilde{A}, \tilde{U})$ the set of all $f : \Omega \times R^n \times R^N \to R^1$ in $\mathcal{M}(\tilde{A}, \tilde{U})$ (see (1.3)) such that for each $t \in \Omega$ the function $f(t, \cdot, \cdot) \in C^k(R^n \times R^N)$. We consider the topological subspace $\mathcal{M}_k^*(\tilde{A}, \tilde{U}) \subset \mathcal{M}(\tilde{A}, \tilde{U})$ with the relative weak topology. The strong topology in $\mathcal{M}_k^*(\tilde{A}, \tilde{U})$ is induced by the uniformity which is determined by the following base:

$$(1.15) \qquad E^*_{\mathcal{M}k}(\epsilon) = \{(f, g) \in \mathcal{M}_k^*(\tilde{A}, \tilde{U}) \times \mathcal{M}_k^*(\tilde{A}, \tilde{U}) :$$

$$|f(t, x, u) - g(t, x, u)| \leq \epsilon \text{ for all } (t, x, u) \in \Omega \times R^n \times R^N \text{ and}$$

$$||f(t, \cdot, \cdot) - g(t, \cdot, \cdot)||_{C^k(R^{n+N})} \leq \epsilon \text{ for all } t \in \Omega\},$$

where $\epsilon > 0$. It is easy to see that the space $\mathcal{M}_k^*(\tilde{A}, \tilde{U})$ with this uniformity is metrizable (by a metric $d^*_{\mathcal{M},k}$) and complete. Define

$$(1.16) \quad \mathcal{M}_k^{*l}(\tilde{A}, \tilde{U}) = \mathcal{M}_k^*(\tilde{A}, \tilde{U}) \cap \mathcal{M}^l(\tilde{A}, \tilde{U}), \ \mathcal{M}_k^{*c}(\tilde{A}, \tilde{U}) = \mathcal{M}_k^*(\tilde{A}, \tilde{U}) \cap \mathcal{M}^c(\tilde{A}, \tilde{U}).$$

Clearly $\mathcal{M}_k^{*l}(\tilde{A}, \tilde{U})$ and $\mathcal{M}_k^{*c}(\tilde{A}, \tilde{U})$ are closed sets in $\mathcal{M}_k^*(\tilde{A}, \tilde{U})$ with the strong topology.

Thus we have defined all the spaces of integrands for which we will prove our main result. Now we will define a space of constraint maps $\mathcal{P}_A$. Denote by $S(R^N)$ the set of all nonempty convex closed subsets of R^N. For each $x \in R^N$ and each $E \subset R^N$, set $d_H(x, E) = \inf_{y \in E} |x - y|$. For each pair of sets $C_1, C_2 \subset R^N$,

$$d_H(C_1, C_2) = \max \left\{ \sup_{y \in C_1} d_H(y, C_2), \ \sup_{x \in C_2} d_H(x, C_1) \right\}$$

is the Hausdorff distance between C_1 and C_2. For the space $S(R^N)$ we consider the uniformity determined by the following base:

$$E_{R^N}(\epsilon) = \{(C_1, C_2) \in S(R^N) \times S(R^N) : \ d_H(C_1, C_2) \le \epsilon\}, \tag{1.17}$$

where $\epsilon > 0$. It is well known that the space $S(R^N)$ with this uniformity is metrizable and complete. Denote by $\mathcal{P}_A$ the set of all set-valued mappings $U : \text{graph}(A) \to S(R^N)$ such that graph(U) is a closed subset of the space graph$(A) \times R^N$ with the product topology. For the space $\mathcal{P}_A$ we consider the uniformity determined by the following base:

$$\begin{aligned} E_{\mathcal{P}_A}(\epsilon) = \{(U_1, U_2) \in \mathcal{P}_A \times \mathcal{P}_A : \ & d_H(U_1(t,x), U_2(t,x)) \le \epsilon \\ & \text{for all } (t,x) \in \text{graph}(A)\}, \end{aligned} \tag{1.18}$$

where $\epsilon > 0$. It is easy to see that the space $\mathcal{P}_A$ with this uniformity is metrizable and complete.

We consider the space $X(A, \tilde{U}_A)$ with the metric ρ (see (1.5)). For each $U \in \mathcal{P}_A$ define

$$S_U = X(A, U) = \{(x, u) \in X(A, \tilde{U}_A) : \ u(t) \in U(t, x(t)), \ t \in \Omega \text{ a.e.}\}. \tag{1.19}$$

In the case $m = 1$ for each $U \in \mathcal{P}_A$ and each $(f, \xi) \in \mathcal{M}(A, \tilde{U}_A) \times C_l(B_1 \times B_2)$ we consider the optimal control problem

$$I^{(f,\xi)}(x, u) \to \min, \qquad (x, u) \in X(A, U),$$

and in the case $m > 1$ for each $U \in \mathcal{P}_A$ and each $f \in \mathcal{M}(A, \tilde{U}_A)$ we consider the optimal control problem

$$I^{(f)}(x, u) \to \min, \qquad (x, u) \in X(A, U).$$

We will state our main result, Theorem 1.1, in such a manner that it will be applicable to the Bolza problem in case $m = 1$ and to the Lagrange problem in case $m > 1$, and also applicable for all the spaces of integrands defined above.

To meet this goal we set $\mathcal{A}_2 = \mathcal{P}_A$ and define a space $\mathcal{A}_1$ as follows.

$$\mathcal{A}_1 = \mathcal{A}_{11} \times \mathcal{A}_{12} \quad \text{if } m = 1 \quad \text{and} \quad \mathcal{A}_1 = \mathcal{A}_{11} \quad \text{if } m > 1,$$

where $\mathcal{A}_{12}$ is either $C_l(B_1 \times B_2)$ or $C(B_1 \times B_2)$ or a singleton $\{\xi\} \subset C_l(B_1 \times B_2)$, and $\mathcal{A}_{11}$ is one of the following spaces:

$$\mathcal{M}(A, \tilde{U}_A); \ \mathcal{M}^l(A, \tilde{U}_A); \ \mathcal{M}^c(A, \tilde{U}_A);$$

$$\mathcal{M}_k(A, \tilde{U}_A); \ \mathcal{M}_k^l(A, \tilde{U}_A); \ \mathcal{M}_k^c(A, \tilde{U}_A) \ \text{ (here } k \ge 1 \text{ is an integer);}$$

$$\mathcal{M}_k^*(\tilde{A}, \tilde{U}); \ \mathcal{M}_k^{*l}(\tilde{A}, \tilde{U}); \ \mathcal{M}_k^{*c}(\tilde{A}, \tilde{U}) \text{ (here } k \ge 1 \text{ is an integer and } A = \tilde{A}).$$

For each $a = (a_1, a_2) \in \mathcal{A}_1 \times \mathcal{A}_2$ we define $J_a : X(A, \tilde{U}_A) \to R^1 \cup \{\infty\}$ by

$$J_a(x, u) = I^{(a_1)}(x, u), \quad (x, u) \in S_{a_2}, \quad J_a(x, u) = \infty, \quad (x, u) \in X(A, \tilde{U}_A) \setminus S_{a_2}.$$

We will show that J_a is lower semicontinuous for all $a \in \mathcal{A}_1 \times A_2$. Denote by $\mathcal{A}$ the closure of the set $\{a \in \mathcal{A}_1 \times \mathcal{A}_2 : \inf(J_a) < \infty\}$ in the space $\mathcal{A}_1 \times A_2$ with the strong topology. We assume that $\mathcal{A}$ is nonempty. The following theorem is the main result of this paper.

Theorem 1.1. *There exists an everywhere dense (in the strong topology) set $\mathcal{B} \subset \mathcal{A}$ which is a countable intersection of open (in the weak topology) subsets of $\mathcal{A}$ such that for any $a \in \mathcal{B}$ the following assertions hold:*

(1) $\inf(J_a)$ *is finite and attained at a unique pair* $(\bar{x}, \bar{u}) \in X(A, \tilde{U}_A)$.

(2) *For each $\epsilon > 0$ there are a neighborhood $\mathcal{V}$ of a in $\mathcal{A}$ with the weak topology and $\delta > 0$ such that for each $b \in \mathcal{V}$, $\inf(J_b)$ is finite, and if $(z, w) \in X(A, \tilde{U}_A)$ satisfies $J_b(z, w) \le \inf(J_b) + \delta$, then $\rho((\bar{x}, \bar{u}), (z, w)) \le \epsilon$ and $|J_b(z, w) - J_a(\bar{x}, \bar{u})| \le \epsilon$.*

2. Generic variational principle. We will obtain our main result as a realization of a variational principle which will be introduced in this section. This variational principle is a modification of the variational principle in [14].

We consider a metric space (X, ρ) which is called the domain space and a complete metric space $(\mathcal{A}, d)$ which is called the data space. We always consider the set X with the topology generated by the metric ρ. For the space $\mathcal{A}$ we consider the topology generated by the metric d. This topology will be called the strong topology. As mentioned in section 1 in addition to the strong topology we also consider a weaker topology on $\mathcal{A}$ which is not necessarily Hausdorff. This topology will be called the weak topology. (Note that these topologies can coincide.) We assume that with every $a \in \mathcal{A}$ a lower semicontinuous function f_a on X is associated with values in $\bar{R} = [-\infty, \infty]$. In our study we use the following basic hypotheses about the functions.

(H1) For any $a \in \mathcal{A}$, any $\epsilon > 0$, and any $\gamma > 0$ there exist a nonempty open set $\mathcal{W}$ in $\mathcal{A}$ with the weak topology, $x \in X$, $\alpha \in R^1$, and $\eta > 0$ such that

$$\mathcal{W} \cap \{b \in \mathcal{A} : \ d(a, b) < \epsilon\} \ne \emptyset,$$

and for any $b \in \mathcal{W}$

(i) $\inf(f_b)$ is finite;

(ii) if $z \in X$ is such that $f_b(z) \le \inf(f_b) + \eta$, then $\rho(z, x) \le \gamma$ and $|f_b(z) - \alpha| \le \gamma$.

(H2) If $a \in \mathcal{A}$, $\inf(f_a)$ is finite, $\{x_n\}_{n=1}^{\infty} \subset X$ is a Cauchy sequence, and the sequence $\{f_a(x_n)\}_{n=1}^{\infty}$ is bounded, then the sequence $\{x_n\}_{n=1}^{\infty}$ converges in X.

We will show (see Theorem 2.1) that if (H1) and (H2) hold, then for a generic $a \in \mathcal{A}$ the minimization problem $f_a(x) \to \min$, $x \in X$, has a unique solution. This result generalizes the variational principle in [14, Theorem 2.2] which was obtained for the complete domain space (X, ρ). Note that if (X, ρ) is complete, the weak and strong topologies on $\mathcal{A}$ coincide, and for any $a \in \mathcal{A}$ the function f_a is not identically ∞, then the variational principles in [14] and in this section are equivalent.

For the classes of optimal control problems considered in this paper the domain space is usually the space $X(A, \tilde{U}_A)$ with the metric ρ (see (1.5)) which is not complete. Since the variational principle in [14] was established only for complete domain spaces it cannot be applied to these classes of optimal control problems. Fortunately, instead of the completeness assumption we can use (H2), and this hypothesis holds for spaces of integrands (integrand-map pairs) which satisfy the Cesari growth condition.

Theorem 2.1. *Assume that* (H1) *and* (H2) *hold. Then there exists an everywhere dense (in the strong topology) set $\mathcal{B} \subset \mathcal{A}$ which is a countable intersection of open (in the weak topology) subsets of $\mathcal{A}$ such that for any $a \in \mathcal{B}$ the following assertions hold:*

(1) $\inf(f_a)$ *is finite and attained at a unique point* $\bar{x} \in X$.

(2) *For each* $\epsilon > 0$ *there are a neighborhood* $\mathcal{V}$ *of* a *in* $\mathcal{A}$ *with the weak topology and* $\delta > 0$ *such that for each* $b \in \mathcal{V}$, $\inf(f_b)$ *is finite and if* $z \in X$ *satisfies* $f_b(z) \leq \inf(f_b) + \delta$, *then* $\rho(\bar{x}, z) \leq \epsilon$ *and* $|f_b(z) - f_a(\bar{x})| \leq \epsilon$.

Following the tradition, we can summarize the theorem by saying that under the assumptions (H1) and (H2) the minimization problem for f_a on (X, ρ) *is generically strongly well posed with respect to* $\mathcal{A}$.

Proof. Let $a \in \mathcal{A}$. By (H1) for any natural $n = 1, 2, \ldots$ there are a nonempty open set $\mathcal{U}(a, n)$ in $\mathcal{A}$ with the weak topology, $x(a, n) \in X$, $\alpha(a, n) \in R^1$, and $\eta(a, n) > 0$ such that

$$\mathcal{U}(a, n) \cap \{b \in \mathcal{A} :\ d(a, b) < 1/n\} \neq \emptyset,$$

and for any $b \in \mathcal{U}(a, n)$, $\inf(f_b)$ is finite and if $z \in X$ satisfies $f_b(z) \leq \inf(f_b) + \eta(a, n)$, then

$$\rho(z, x(a, n)) \leq 1/n, \qquad |f_b(z) - \alpha(a, n)| \leq 1/n.$$

Define $\mathcal{B}_n = \cup\{\mathcal{U}(a, m) :\ a \in \mathcal{A},\ m \geq n\}$ for $n = 1, 2, \ldots$. Clearly, for each integer $n \geq 1$ the set $\mathcal{B}_n$ is open in the weak topology and everywhere dense in the strong topology. Set $\mathcal{B} = \cap_{n=1}^{\infty} \mathcal{B}_n$. Since for each integer $n \geq 1$ the set $\mathcal{B}_n$ is also open in the strong topology generated by the complete metric d we conclude that $\mathcal{B}$ is everywhere dense in the strong topology.

Let $b \in \mathcal{B}$. Evidently $\inf(f_b)$ is finite. There are a sequence $\{a_n\}_{n=1}^{\infty} \subset \mathcal{A}$ and a strictly increasing sequence of natural numbers $\{k_n\}_{n=1}^{\infty}$ such that $b \in \mathcal{U}(a_n, k_n)$, $n = 1, 2, \ldots$. Assume that $\{z_n\}_{n=1}^{\infty} \subset X$ and $\lim_{n\to\infty} f_b(z_n) = \inf(f_b)$.

Let $m \geq 1$ be an integer. Clearly for all large enough n the inequality $f_b(z_n) < \inf(f_b) + \eta(a_m, k_m)$ is true and it follows from the definition of $\mathcal{U}(a_m, k_m)$ that

$$\rho(z_n, x(a_m, k_m)) \leq k_m^{-1},\ |f_b(z_n) - \alpha(a_m, k_m)| \leq k_m^{-1} \tag{2.1}$$

for all large enough n. Since m is an arbitrary natural number we conclude that $\{z_n\}_{n=1}^{\infty} \subset X$ is a Cauchy sequence. By (H2) there is an $\bar{x} = \lim_{n\to\infty} z_n$. As f_b is lower semicontinuous, we have $f_b(\bar{x}) = \inf(f_b)$. Clearly f_b does not have another minimizer, for otherwise we would be able to construct a nonconvergent sequence $\{z_n\}_{n=1}^{\infty}$. This proves the first part of the theorem. We further note that by (2.1)

$$\rho(\bar{x}, x(a_m, k_m)) \leq k_m^{-1}, \quad |f_b(\bar{x}) - \alpha(a_m, k_m)| \leq k_m^{-1}, \quad m = 1, 2, \ldots. \tag{2.2}$$

We turn now to the second assertion. Let $\epsilon > 0$. Choose a natural number m for which $4k_m^{-1} < \epsilon$. Let $a \in \mathcal{U}(a_m, k_m)$. Clearly $\inf(f_a)$ is finite. Let $z \in X$ and $f_a(z) \leq \inf(f_a) + \eta(a_m, k_m)$. By the definition of $\mathcal{U}(a_m, k_m)$,

$$\rho(z, x(a_m, k_m)) \leq k_m^{-1}, \qquad |f_a(z) - \alpha(a_m, k_m)| \leq k_m^{-1}.$$

Together with (2.2) this implies that

$$\rho(z, \bar{x}) \leq 2k_m^{-1}, \quad |f_b(\bar{x}) - f_a(z)| \leq 2k_m^{-1} < \epsilon.$$

The second assertion is proved. □

3. Concretization of the hypothesis (H1). The proof of our main result consists in verifying that the hypotheses (H1) and (H2) hold for the space of integrand-map pairs introduced in section 1. Hypothesis (H2) will follow from Proposition 4.2, which will be proved in section 4. The verification of (H1) is more complicated. Recall that our space of integrand-map pairs is a product of the space of integrands and the space of maps. Therefore we should seek the set $\mathcal{W}$ (see (H1)) in the form $\mathcal{V} \times \mathcal{U}$, where $\mathcal{V}$ is an open set in the space of integrands and $\mathcal{U}$ is an open set in the space of maps. To simplify the verification of (H1) in this section we introduce new assumptions (A1)–(A4) and show that they imply (H1) (see Proposition 3.1). Using (A1)–(A4) we can construct the set $\mathcal{W} = \mathcal{V} \times \mathcal{U}$ step by step, roughly speaking. Namely, using (A4) we construct the set $\mathcal{U}$, using (A3) we find an integrand $\bar{a}_1$, and then using (A2) we construct the set $\mathcal{V}$, which is an open neighborhood of $\bar{a}_1$. Thus to verify (H1) we need to show that the assumptions (A1)–(A4) are valid. In fact this approach allows us to simplify the problem because each of (A2)–(A4) concerns either the space of integrands or the space of maps while it is not difficult to verify (A1).

Let (X, ρ) be a metric space with the topology generated by the metric ρ and let $(\mathcal{A}_1, d_1)$, $(\mathcal{A}_2, d_2)$ be metric spaces. For the space $\mathcal{A}_i$ $(i = 1, 2)$ we consider the topology generated by the metric d_i. This topology is called the strong topology. In addition to the strong topology we consider a weak topology on $\mathcal{A}_i$, $i = 1, 2$.

Assume that with every $a \in \mathcal{A}_1$ a lower semicontinuous function $\phi_a : X \to R^1 \cup \{\infty\}$ is associated and with every $a \in \mathcal{A}_2$ a set $S_a \subset X$ is associated. For each $a = (a_1, a_2) \in \mathcal{A}_1 \times \mathcal{A}_2$ define $f_a : X \to R^1 \cup \{\infty\}$ by

$$f_a(x) = \phi_{a_1}(x) \quad \text{for all } x \in S_{a_2}, \quad f_a(x) = \infty \quad \text{for all } x \in X \setminus S_{a_2}. \tag{3.1}$$

Denote by $\mathcal{A}$ the closure of the set $\{a \in \mathcal{A}_1 \times \mathcal{A}_2 : \inf(f_a) < \infty\}$ in the space $\mathcal{A}_1 \times \mathcal{A}_2$ with the strong topology. We assume that $\mathcal{A}$ is nonempty.

In this paper we use the following hypotheses:

(A1) For each $a_1 \in \mathcal{A}_1$, $\inf(\phi_{a_1}) > -\infty$ and for each $a \in \mathcal{A}_1 \times \mathcal{A}_2$ the function f_a is lower semicontinuous.

(A2) For each $a \in \mathcal{A}_1$ and each $D, \epsilon > 0$ there is a neighborhood $\mathcal{U}$ of a in $\mathcal{A}_1$ with the weak topology such that for each $b \in \mathcal{U}$ and each $x \in X$ satisfying $\min\{\phi_a(x), \phi_b(x)\} \le D$ the relation $|\phi_a(x) - \phi_b(x)| \le \epsilon$ holds.

(A3) For each $\gamma \in (0, 1)$ there exist positive numbers $\epsilon(\gamma)$ and $\delta(\gamma)$ such that $\epsilon(\gamma), \delta(\gamma) \to 0$ as $\gamma \to 0$ and the following property holds.

For each $\gamma \in (0, 1)$, each $a \in \mathcal{A}_1$, each nonempty set $Y \subset X$, and each $\bar{x} \in Y$ for which

$$\phi_a(\bar{x}) \le \inf\{\phi_a(z) : z \in Y\} + \delta(\gamma) < \infty, \tag{3.2}$$

there is an $\bar{a} \in \mathcal{A}_1$ such that the following conditions hold:

$$d_1(a, \bar{a}) \le \epsilon(\gamma), \quad \phi_{\bar{a}}(z) \ge \phi_a(z), \quad z \in X, \quad \phi_{\bar{a}}(\bar{x}) \le \phi_a(\bar{x}) + \delta(\gamma); \tag{3.3}$$

for each $y \in Y$ satisfying

$$\phi_{\bar{a}}(y) \le \inf\{\phi_{\bar{a}}(z) : z \in Y\} + 2\delta(\gamma) \tag{3.4}$$

the inequality $\rho(y, \bar{x}) \le \gamma$ is valid.

(A4) For each $a = (a_1, a_2) \in \mathcal{A}_1 \times \mathcal{A}_2$ satisfying $\inf(f_a) < \infty$ and each $\epsilon, \delta > 0$ there exist $\bar{a}_2 \in \mathcal{A}_2$, $\bar{x} \in S_{\bar{a}_2}$, and an open set $\mathcal{U}$ in $\mathcal{A}_2$ with the weak topology such that

$$d_2(a_2, \bar{a}_2) < \epsilon, \qquad \mathcal{U} \cap \{b \in \mathcal{A}_2 : \ d_2(b, a_2) < \epsilon\} \neq \emptyset, \tag{3.5}$$

$$\phi_{a_1}(\bar{x}) \leq \inf\{\phi_{a_1}(z) : \ z \in S_{\bar{a}_2}\} + \delta < \infty, \tag{3.6}$$

and

$$\bar{x} \in S_b \subset S_{\bar{a}_2} \quad \text{for all } b \in \mathcal{U}. \tag{3.7}$$

Assume that (A3) holds. We show that the numbers $\epsilon(\gamma)$ and $\delta(\gamma)$ can be chosen such that $0 < \delta(\gamma) \leq \epsilon(\gamma) \leq \gamma$.

Let $\epsilon(\gamma)$ and $\delta(\gamma)$, $\gamma \in (0,1)$, be as guaranteed by (A3). Assume that $\gamma \in (0,1)$. Since $\lim_{t\to 0} \epsilon(t) = 0$ and $\lim_{t \to 0} \delta(t) = 0$ there exist $\gamma_1 \in (0, \gamma)$ and $\gamma_0 \in (0, \gamma_1)$ such that $\epsilon(\gamma_1) < \gamma$ and $\epsilon(\gamma_0), \delta(\gamma_0) < \epsilon(\gamma_1)$. Set $\bar{\epsilon}(\gamma) = \epsilon(\gamma_1)$ and $\bar{\delta}(\gamma) = \delta(\gamma_0)$. Clearly $\bar{\delta}(\gamma) < \bar{\epsilon}(\gamma) < \gamma$.

Assume that $a \in \mathcal{A}_1$, Y is a nonempty subset of X, and $\bar{x} \in Y$ satisfies $\phi_a(\bar{x}) \leq \inf\{\phi_a(z) : \ z \in Y\} + \bar{\delta}(\gamma) < \infty$. By (A3) and the equality $\bar{\delta}(\gamma) = \delta(\gamma_0)$ there exists $\bar{a} \in \mathcal{A}_1$ such that the following conditions hold:

$$d_1(a, \bar{a}) \leq \epsilon(\gamma_0) < \epsilon(\gamma_1) = \bar{\epsilon}(\gamma), \quad \phi_{\bar{a}}(z) \geq \phi_a(z), \quad z \in X,$$

$$\phi_{\bar{a}}(\bar{x}) \leq \phi_a(\bar{x}) + \delta(\gamma_0) = \phi_a(\bar{x}) + \bar{\delta}(\gamma);$$

for each $y \in Y$ satisfying

$$\phi_{\bar{a}}(y) \leq \inf\{\phi_{\bar{a}}(z) : \ z \in Y\} + 2\delta(\gamma_0)$$

the inequality $\rho(y, \bar{x}) \leq \gamma_0 \leq \gamma$ is valid. Therefore (A3) holds with $\epsilon(\gamma) = \bar{\epsilon}(\gamma)$ and $\delta(\gamma) = \bar{\delta}(\gamma)$.

PROPOSITION 3.1. *Assume that* (A1)–(A4) *hold. Then* (H1) *holds for the space* $\mathcal{A}$.

Proof. Let $a = (a_1, a_2) \in \mathcal{A}$ and let $\epsilon, \gamma > 0$. We may assume that $\inf(f_a) < \infty$. Choose a positive number

$$\gamma_0 < 8^{-1} \min\{1, \epsilon, \gamma\}. \tag{3.8}$$

Let $\epsilon(\gamma_0)$, $\delta(\gamma_0) > 0$ be as guaranteed by (A3) (namely, (A3) is true with $\gamma = \gamma_0$, $\epsilon(\gamma) = \epsilon(\gamma_0)$, $\delta(\gamma) = \delta(\gamma_0)$). Choose

$$\delta_1 \in (0, 4^{-1}\delta(\gamma_0)). \tag{3.9}$$

By (A4) there are $\bar{a}_2 \in \mathcal{A}_2$, $\bar{x} \in S_{\bar{a}_2}$, and an open nonempty set $\mathcal{U}$ in $\mathcal{A}_2$ with the weak topology such that (3.7) holds,

$$d_2(a_2, \bar{a}_2) < \epsilon(\gamma_0), \qquad \mathcal{U} \cap \{b \in \mathcal{A}_2 : \ d_2(b, a_2) < \epsilon(\gamma_0)\} \neq \emptyset, \tag{3.10}$$

and

$$\phi_{a_1}(\bar{x}) \leq \inf\{\phi_{a_1}(z) : \ z \in S_{\bar{a}_2}\} + \delta_1 < \infty. \tag{3.11}$$

It follows from the definition of $\epsilon(\gamma_0)$ and $\delta(\gamma_0)$, (A3) (with $a_1 = a$ and $Y = S_{\bar{a}_2}$), and (3.11) that there is an $\bar{a}_1 \in \mathcal{A}_1$ such that

$$d_1(a_1, \bar{a}_1) \le \epsilon(\gamma_0), \quad \phi_{\bar{a}_1}(z) \ge \phi_{a_1}(z), \quad z \in X, \tag{3.12}$$

$$\phi_{\bar{a}_1}(\bar{x}) \le \phi_{a_1}(\bar{x}) + \delta(\gamma_0),$$

and the following property holds.

(Pi) For each $y \in S_{\bar{a}_2}$ satisfying

$$\phi_{\bar{a}_1}(y) \le \inf\{\phi_{\bar{a}_1}(z) : \ z \in S_{\bar{a}_2}\} + 2\delta(\gamma_0) \tag{3.13}$$

the relation $\rho(y, \bar{x}) \le \gamma_0$ is valid.

Let $b \in \mathcal{U}$. Then by the definition of $\mathcal{U}$, (3.7), and (3.11),

$$\bar{x} \in S_b \subset S_{\bar{a}_2}, \qquad \inf\{\phi_{a_1}(z) : \ z \in S_b\} \le \phi_{a_1}(\bar{x}) < \infty. \tag{3.14}$$

We will show that the following property holds.

(Pii) If $y \in S_b$ satisfies

$$\phi_{\bar{a}_1}(y) \le \inf\{\phi_{\bar{a}_1}(z) : \ z \in S_b\} + \delta_1, \tag{3.15}$$

then

$$\rho(y, \bar{x}) \le \gamma_0 \quad \text{and} \quad |\phi_{\bar{a}_1}(y) - \phi_{\bar{a}_1}(\bar{x})| \le \delta_1 + \delta(\gamma_0). \tag{3.16}$$

It follows from (3.11), (3.14), and (3.12) that

$$\phi_{a_1}(\bar{x}) - \delta_1 \le \inf\{\phi_{a_1}(z) : \ z \in S_{\bar{a}_2}\} \le \inf\{\phi_{a_1}(z) : \ z \in S_b\} \tag{3.17}$$

$$\le \inf\{\phi_{\bar{a}_1}(z) : \ z \in S_b\} \le \phi_{\bar{a}_1}(\bar{x}) \le \phi_{a_1}(\bar{x}) + \delta(\gamma_0)$$

$$\le \inf\{\phi_{a_1}(z) : \ z \in S_{\bar{a}_2}\} + \delta_1 + \delta(\gamma_0).$$

Assume that $y \in S_b$ and (3.15) is true. It follows from (3.14), (3.15), (3.17), (3.12), and (3.9) that

$$y \in S_{\bar{a}_2}, \ \phi_{\bar{a}_1}(y) \le \inf\{\phi_{a_1}(z) : \ z \in S_{\bar{a}_2}\} + \delta(\gamma_0) + 2\delta_1$$

$$< \inf\{\phi_{\bar{a}_1}(z) : \ z \in S_{\bar{a}_2}\} + 2\delta(\gamma_0).$$

By these relations and property (Pi), $\rho(y, \bar{x}) \le \gamma_0$. Relations (3.15), (3.17), (3.11), (3.14), and (3.12) imply that

$$|\phi_{\bar{a}_1}(y) - \phi_{\bar{a}_1}(\bar{x})| \le \delta_1 + \delta(\gamma_0). \tag{3.18}$$

Thus, (3.16) is valid. Therefore we have shown that for each $b \in \mathcal{U}$ relation (3.14) and property (Pii) hold. Choose a number

$$D > |\inf(\phi_{\bar{a}_1})| + 1 + |\phi_{\bar{a}_1}(\bar{x})|. \tag{3.19}$$

By (A2) there exists an open neighborhood $\mathcal{V}$ of $\bar{a}_1$ in $\mathcal{A}_1$ with the weak topology such that the following property holds.

(Piii) For each $b \in \mathcal{V}$ and each $x \in X$ for which $\min\{\phi_b(x), \phi_{\bar{a}_1}(x)\} \le D + 2$ the relation $|\phi_{\bar{a}_1}(x) - \phi_b(x)| \le 4^{-1}\delta_1$ is true.

Property (Piii) and (3.19) imply that for each $b \in \mathcal{V}$,

$$|\phi_b(\bar{x}) - \phi_{\bar{a}_1}(\bar{x})| \le 4^{-1}\delta_1, \qquad \inf(\phi_b) \le \phi_b(\bar{x}) \le D. \tag{3.20}$$

Now we will show that (H1) is true with the open set $\mathcal{W} = \mathcal{V} \times \mathcal{U}$, $x = \bar{x}$, $\alpha = \phi_{\bar{a}_1}(\bar{x})$, and $\eta = 4^{-1}\delta_1$.

Assume that $b = (b_1, b_2) \in \mathcal{V} \times \mathcal{U}$. By (3.20) and (3.14)

$$\bar{x} \in S_{b_2}, \qquad \inf(f_b) = \inf\{\phi_{b_1}(z) : \ z \in S_{b_2}\} \le \phi_{b_1}(\bar{x}) < \infty. \tag{3.21}$$

Assume now that $z \in X$ and $f_b(z) \le \inf(f_b) + 4^{-1}\delta_1$. Then

$$z \in S_{b_2}, \qquad \phi_{b_1}(z) \le \inf\{\phi_{b_1}(y) : \ y \in S_{b_2}\} + 4^{-1}\delta_1. \tag{3.22}$$

By (3.21), (3.20), and (3.19),

$$\inf\{\phi_{b_1}(y) : \ y \in S_{b_2}\} \le \phi_{b_1}(\bar{x}) \le D, \qquad \inf\{\phi_{\bar{a}_1}(y) : \ y \in S_{b_2}\} \le \phi_{\bar{a}_1}(\bar{x}) \le D.$$

These inequalities imply that

$$\inf\{\phi_{b_1}(y) : \ y \in S_{b_2}\} = \inf\{\phi_{b_1}(y) : \ y \in S_{b_2} \text{ and } \phi_{b_1}(y) \le D + 1\}$$

and

$$\inf\{\phi_{\bar{a}_1}(y) : \ y \in S_{b_2}\} = \inf\{\phi_{\bar{a}_1}(y) : \ y \in S_{b_2} \text{ and } \phi_{\bar{a}_1}(y) \le D + 1\}.$$

It follows from these two relations and property (Piii) that

$$|\inf\{\phi_{b_1}(y) : \ y \in S_{b_2}\} - \inf\{\phi_{\bar{a}_1}(y) : \ y \in S_{b_2}\}| \le 4^{-1}\delta_1. \tag{3.23}$$

Relations (3.23), (3.22), (3.21), (3.19), and property (Piii) imply that

$$|\phi_{\bar{a}_1}(z) - \phi_{b_1}(z)| \le 4^{-1}\delta_1, \tag{3.24}$$

$$\phi_{\bar{a}_1}(z) \le \inf\{\phi_{\bar{a}_1}(y) : \ y \in S_{b_2}\} + \delta_1. \tag{3.25}$$

It follows from (3.25), (3.22), and property (Pii) that

$$\rho(z, \bar{x}) \le \gamma_0 \quad \text{and} \quad |\phi_{\bar{a}_1}(z) - \phi_{\bar{a}_1}(\bar{x})| \le \delta_1 + \delta(\gamma_0).$$

Together with (3.24), (3.9), and the definition of $\delta(\gamma_0)$ this implies that

$$|\phi_{b_1}(z) - \phi_{\bar{a}_1}(\bar{x})| \le 2\delta(\gamma_0) \le 2\gamma_0 < \gamma.$$

This completes the proof of the proposition. □

Remark 3.1. In the proof of Proposition 3.1 for any $a = (a_1, a_2) \in \mathcal{A}_1 \times \mathcal{A}_2$ satisfying $\inf(f_a) < \infty$ and any $\epsilon > 0$ we constructed an open set $\mathcal{V}$ in $\mathcal{A}_1$ with the weak topology and an open set $\mathcal{U}$ in $\mathcal{A}_2$ with the weak topology which satisfy

$$\mathcal{V} \cap \{b \in \mathcal{A}_1 : \ d_1(b, a_1) < \epsilon\} \neq \emptyset \quad \text{and} \quad \mathcal{U} \cap \{b \in \mathcal{A}_2 : \ d_2(b, a_2) < \epsilon\} \neq \emptyset$$

and such that $\inf(f_b) < \infty$ for each $b = (b_1, b_2) \in \mathcal{V} \times \mathcal{U}$. This implies that there exists an open set $\mathcal{F}$ in $\mathcal{A}_1 \times \mathcal{A}_2$ with the weak topology such that $\inf(f_a) < \infty$ for all $a \in \mathcal{F}$ and $\mathcal{A}$ is the closure of $\mathcal{F}$ in the space $\mathcal{A}_1 \times \mathcal{A}_2$ with the strong topology.

4. Preliminary results for hypotheses (A2) and (H2). Assume that $A : \Omega \to 2^{R^n} \setminus \{\emptyset\}$, $U : \mathrm{graph}(A) \to 2^{R^N} \setminus \{\emptyset\}$, and that $\mathrm{graph}(U)$ is a closed subset of the space $\Omega \times R^n \times R^N$ with the product topology. Consider the spaces $X(A,U)$, $\mathcal{M}(A,U)$, and $C_l(B_1 \times B_2)$ introduced in section 1.

PROPOSITION 4.1. *Let $f \in \mathcal{M}(A,U)$, $(x,u) \in X(A,U)$, and $\{(x_i,u_i)\}_{i=1}^{\infty} \subset X(A,U)$, and let $\rho((x_i,u_i),(x,u)) \to 0$ as $i \to \infty$. Then*

$$\int_{\Omega} f(t,x(t),u(t))dt \le \liminf_{i\to\infty} \int_{\Omega} f(t,x_i(t),u_i(t))dt.$$

Proof. We may assume that there is a finite $\lim_{i\to\infty} \int_{\Omega} f(t,x_i(t),u_i(t))dt$. There is a subsequence $\{(x_{i_k},u_{i_k})\}_{k=1}^{\infty}$ such that

$$(x_{i_k}(t),u_{i_k}(t)) \to (x(t),u(t)) \quad \text{as } k \to \infty, \quad t \in \Omega \text{ a.e.}$$

(see [12, p. 68]). By property (ii) (see the definition of $\mathcal{M}(A,U)$) for almost every $t \in \Omega$,

$$\liminf_{k\to\infty} f(t,x_{i_k}(t),u_{i_k}(t)) \ge f(t,x(t),u(t)).$$

The proposition now follows from property (iii) (see the definition of $\mathcal{M}(A,U)$) and Fatou's lemma. □

The following proposition is an auxiliary result for the hypothesis (H2).

PROPOSITION 4.2. *Assume that $f \in \mathcal{M}(A,U)$, $\{(x_i,u_i)\}_{i=1}^{\infty} \subset X(A,U)$ is a Cauchy sequence, and the sequence $\{\int_{\Omega} f(t,x_i(t),u_i(t))dt\}_{i=1}^{\infty}$ is bounded. Then there is $(x_*,u_*) \in X(A,U)$ such that (x_i,u_i) converges to (x_*,u_*) as $i \to \infty$ in $X(A,U)$, and moreover, if $m = 1$, then $x_i(t) \to x_*(t)$ as $i \to \infty$ uniformly on $[T_1,T_2]$.*

Proof. To prove the proposition it is sufficient to show that there exists a subsequence $\{(x_{i_k},u_{i_k})\}_{k=1}^{\infty}$ and $(x_*,u_*) \in X(A,U)$ such that $(x_{i_k},u_{i_k}) \to (x_*,u_*)$ as $k \to \infty$ in $X(A,U)$ and if $m = 1$, then $x_{i_k}(t) \to x_*(t)$ as $k \to \infty$ uniformly on $[T_1,T_2]$. (In the case $m = 1$ this implies that each subsequence of $\{x_i\}_{i=1}^{\infty}$ has a subsequence which converges to x_* uniformly on $[T_1,T_2]$. This proves that $\{x_i\}_{i=1}^{\infty}$ converges to x_* uniformly on $[T_1,T_2]$.)

Since $\{(x_i,u_i)\}_{i=1}^{\infty}$ is a Cauchy sequence there is a strictly increasing sequence of natural numbers $\{i_k\}_{k=1}^{\infty}$ and a sequence of measurable sets $D_k \subset \Omega$, $k = 1,2,\dots$, such that for all $k = 1,2,\dots$,

$$\mathrm{mes}(D_k) \le 2^{-k}, \qquad |x_{i_{k+1}}(t) - x_{i_k}(t)| \le 2^{-k}, \tag{4.1}$$

$$|u_{i_{k+1}}(t) - u_{i_k}(t)| \le 2^{-k}, \qquad t \in \Omega \setminus D_k.$$

Set $C_k = \cup_{i=k}^{\infty} D_i$, $k = 1,2,\dots$. By (4.1) there exist measurable functions $u_* : \Omega \to R^N$ and $x_* : \Omega \to R^n$ such that

$$\lim_{k\to\infty} x_{i_k}(t) = x_*(t), \quad \lim_{k\to\infty} u_{i_k}(t) = u_*(t), \quad t \in \Omega \setminus \cap_{k=1}^{\infty} C_k. \tag{4.2}$$

Since the function $f(t,\cdot,\cdot)$ is lower semicontinuous for $t \in \Omega$ a.e. (see the definition of $\mathcal{M}(A,U)$, property (ii)) it follows from (4.2) that

$$f(t,x_*(t),u_*(t)) \le \liminf_{k\to\infty} f(t,x_{i_k}(t),u_{i_k}(t)), \qquad t \in \Omega \text{ a.e.} \tag{4.3}$$

Clearly the function $f(t, x_*(t), u_*(t))$, $t \in \Omega$, is measurable. By (4.3), Fatou's lemma, and property (iii), $\int_\Omega f(t, x_*(t), u_*(t))dt$ is finite. It follows from property (iii) and the boundedness of the sequence $\{\int_\Omega f(t, x_i(t), u_i(t))dt\}_{i=1}^\infty$ that the family of functions

$$\mathcal{E} = \{|H(t, x_*(t), u_*(t))|,\ t \in \Omega,\ |H(t, x_{i_k}(t), u_{i_k}(t))|,\ t \in \Omega,\ k = 1, 2, \dots\}$$

is uniformly integrable [11, p. 74]. Namely, for each $\epsilon > 0$ there exists $\delta > 0$ such that for each measurable set $e \subset \Omega$ satisfying $\text{mes}(e) \le \delta$ the following relations hold:

$$\int_e |H(t, x_*(t), u_*(t))|dt \le \epsilon, \quad \int_e |H(t, x_{i_k}(t), u_{i_k}(t))|dt \le \epsilon, \quad k = 1, 2, \dots.$$

It follows from this property, the continuity of H, (4.1), (4.2), and Egorov's theorem that for each measurable set $e \subset \Omega$,

$$\text{(4.4)} \qquad \int_e H(t, x_{i_k}(t), u_{i_k}(t))dt \to \int_e H(t, x_*(t), u_*(t))dt \quad \text{as } k \to \infty.$$

Now we consider the case with $m = 1$. Since the set $\mathcal{E}$ is uniformly integrable it follows from (1.4b), (4.2), and Ascoli's compactness theorem that a subsequence of the sequence $\{x_{i_k}\}_{k=1}^\infty$ converges to a continuous function $y : [T_1, T_2] \to R^n$ uniformly on $[T_1, T_2]$. By (4.2) we may assume that $x_*(t) = y(t)$, $t \in [T_1, T_2]$ a.e. Thus $x_* : \Omega \to R^n$ is continuous and some subsequence of $\{x_{i_k}\}_{k=1}^\infty$ converges to x_* uniformly on $[T_1, T_2]$. Together with (4.4) this implies that $(x_*, u_*) \in X(A, U)$. Since $\text{mes}(\cap_{k=1}^\infty C_k) = 0$ (see (4.1)) it follows from (4.2) that $(x_{i_k}, u_{i_k}) \to (x_*, u_*)$ as $k \to \infty$ in $X(A, U)$. Therefore the proposition is true in the case with $m = 1$.

We turn now to the case with $m > 1$. Since the set $\mathcal{E}$ is uniformly integrable it is easy to verify that

$$\text{(4.5)} \qquad H(\cdot, x_*(\cdot), u_*(\cdot)) \in L^1(\Omega), \quad H(\cdot, x_{i_k}(\cdot), u_{i_k}(\cdot)) \in L^1(\Omega), \quad k = 1, 2, \dots,$$

$$H(\cdot, x_{i_k}(\cdot), u_{i_k}(\cdot)) \to H(\cdot, x_*(\cdot), u_*(\cdot)) \quad \text{as } k \to \infty \quad \text{in } L^1(\Omega).$$

Note that $x_{i_k} - \theta^* \in (W_0^{1,1}(\Omega))^n$, $k = 1, 2, \dots$ (see (1.4)). By [28, Thm. 2.4.1] there is a constant $c > 0$ such that $||h||_{L^1(\Omega)} \le c||\nabla h||_{L^1(\Omega)}$ for all $h \in W_0^{1,1}(\Omega)$. Together with (4.5) and (4.2) this implies that $x_{i_k} \to x_*$ as $k \to \infty$ in $L^1(\Omega; R^n)$, $x_* \in (W^{1,1}(\Omega))^n$, $\nabla x_* = H(\cdot, x_*(\cdot), u_*(\cdot))$, and $(x_*, u_*) \in X(A, U)$. Analogously to the previous case we obtain that $(x_{i_k}, u_{i_k}) \to (x_*, u_*)$ as $k \to \infty$ in $X(A, U)$. Thus in the case $m > 1$ the proposition is proved. □

PROPOSITION 4.3. *Let $h \in C_l(B_1 \times B_2)$ and $\epsilon, D > 0$. Then there exists a neighborhood $\mathcal{V}$ of h in $C_l(B_1 \times B_2)$ with the weak topology such that for each $\xi \in \mathcal{V}$ and each $x \in B_1 \times B_2$ which satisfies* $\min\{\xi(x), h(x)\} \le D$ *the relation* $|\xi(x) - h(x)| \le \epsilon$ *holds.*

Proof. There is a $c_0 > 0$ such that $h(x) \ge -c_0$ for all $x \in B_1 \times B_2$. Choose a positive number $\epsilon_1 < 1$ for which

$$\epsilon_1 + \epsilon_1(1 - \epsilon_1)^{-1}(2 + D + c_0) < \epsilon$$

and define $\mathcal{V} = \{\xi \in C_l(B_1 \times B_2) :\ (\xi, h) \in E_{cw}(\epsilon_1)\}$ (see (1.9)). Assume that $\xi \in \mathcal{V}$, $x \in B_1 \times B_2$, and $\min\{\xi(x), h(x)\} \le D$. It follows from the definition of $\mathcal{V}$ and ϵ_1, (1.9), and Lemma 1.1 that $\xi(x), h(x)$ are finite and

$$|\xi(x)-h(x)|<\epsilon_1+\epsilon_1^2(1-\epsilon_1)^{-1}+\epsilon_1(1-\epsilon_1)^{-1}\min\{|\xi(x)|,|h(x)|\}$$

$$<\epsilon_1+\epsilon_1^2(1-\epsilon_1)^{-1}+\epsilon_1(1-\epsilon_1)^{-1}(D+c_0)<\epsilon.$$

The proposition is proved. □

Corollary 4.1. *Let $h\in C_l(B_1\times B_2)$ and $\epsilon>0$. Then there is a neighborhood $\mathcal{V}$ of h in $C_l(B_1\times B_2)$ with the weak topology such that for each $\xi\in\mathcal{V}$ the inequality $|\inf(\xi)-\inf(h)|\le\epsilon$ holds.*

Proof. We may assume that $\inf(h)$ is finite and $\epsilon<1$. By Proposition 4.3 there exists a neighborhood $\mathcal{V}$ of h in $C_l(B_1\times B_2)$ with the weak topology such that for each $\xi\in\mathcal{V}$ and each $x\in B_1\times B_2$ which satisfies $\min\{\xi(x),h(x)\}\le\inf(h)+2$ the relation $|\xi(x)-h(x)|\le 2^{-1}\epsilon$ holds.

Assume that $\xi\in\mathcal{V}$. It follows from the definition of $\mathcal{V}$ that for each $x\in B_1\times B_2$ satisfying $h(x)\le\inf(h)+2$ the relation $|\xi(x)-h(x)|\le 2^{-1}\epsilon$ is true. Choose $y\in X$ such that $h(y)\le\inf(h)+2^{-1}\epsilon$. Then

$$\inf(\xi)\le\xi(y)\le h(y)+2^{-1}\epsilon\le\inf(h)+\epsilon\le\inf(h)+1.$$

It follows from this inequality and the definition of $\mathcal{V}$ that for each $x\in B_1\times B_2$ satisfying $\xi(x)\le\inf(\xi)+1$ the relation $|\xi(x)-h(x)|\le 2^{-1}\epsilon$ holds. Choose $z\in X$ such that $\xi(z)\le\inf(\xi)+2^{-1}\epsilon$. Then

$$\inf(h)\le h(z)\le\xi(z)+2^{-1}\epsilon\le\inf(\xi)+\epsilon.$$

The corollary is proved. □

The following proposition is an auxiliary result for the assumption (A2).

Proposition 4.4. *Let $f\in\mathcal{M}(A,U)$ and $\epsilon\in(0,1)$, $D>0$. Then there exists a neighborhood $\mathcal{V}$ of f in $\mathcal{M}(A,U)$ with the weak topology such that for each $g\in\mathcal{V}$ and each $(x,u)\in X(A,U)$ satisfying*

$$\min\left\{\int_\Omega f(t,x(t),u(t))dt,\ \int_\Omega g(t,x(t),u(t))dt\right\}\le D \tag{4.6}$$

the following relation holds:

$$\left|\int_\Omega f(t,x(t),u(t))dt-\int_\Omega g(t,x(t),u(t))dt\right|\le\epsilon. \tag{4.7}$$

Proof. There is an integrable function $\phi_0(t)\ge 0$, $t\in\Omega$, such that

$$f(t,x,u)\ge-\phi_0(t)\quad\text{for all } (t,x,u)\in\ \text{graph}(U). \tag{4.8}$$

Choose a positive number ϵ_1 for which

$$\epsilon_1\left(2\text{mes}(\Omega)+2+\int_\Omega\phi_0(t)dt+D\right)<\epsilon \tag{4.9}$$

and a positive number ϵ_0 that satisfies

$$\epsilon_0+\epsilon_0(1-\epsilon_0)^{-1}<4^{-1}\epsilon_1. \tag{4.10}$$

Define

$$\mathcal{V} = \{g \in \mathcal{M}(A,U) : (g,f) \in E_{\mathcal{M}w}(\epsilon_0)\} \quad \text{(see (1.7))}. \tag{4.11}$$

Assume that $g \in \mathcal{V}$, $(x,u) \in X(A,U)$, and (4.6) is valid. By (4.11) and (1.7) there is a nonnegative function $\phi \in L^1(\Omega)$ such that $\int_\Omega \phi(t)dt \le 1$, and for almost every $t \in \Omega$ the inequality

$$|f(t,y,v) - g(t,y,v)| < \epsilon_0 + \epsilon_0\phi(t) + \epsilon_0 \max\{|f(t,y,v)|, |g(t,y,v)|\}$$

is true for each $y \in A(t)$ and each $v \in U(t,y)$. It follows from this inequality, Lemma 1.1, and (4.10) that for almost every $t \in \Omega$ the relation

$$\begin{aligned} |f(t,y,v) - g(t,y,v)| &< \epsilon_0 + \epsilon_0^2(1-\epsilon_0)^{-1} + \phi(t)(\epsilon_0^2(1-\epsilon_0)^{-1} + \epsilon_0) \\ &\quad + \epsilon_0(1-\epsilon_0)^{-1}\min\{|f(t,y,v)|, |g(t,y,v)|\} \\ &< 4^{-1}\epsilon_1 + 4^{-1}\epsilon_1\phi(t) + 4^{-1}\epsilon_1 \min\{|f(t,y,v)|, |g(t,y,v)|\} \end{aligned} \tag{4.12}$$

is valid for each $y \in A(t)$ and each $v \in U(t,y)$. Relations (4.12) and (4.8) imply that for almost every $t \in \Omega$ the inequality

$$\begin{aligned} g(t,y,v) &\ge f(t,y,v) - 4^{-1}\epsilon_1 - 4^{-1}\epsilon_1\phi(t) - 4^{-1}\epsilon_1|f(t,y,v)| \\ &\ge -4^{-1}\epsilon_1\phi(t) - 2\phi_0(t) - 4^{-1}\epsilon_1 \end{aligned} \tag{4.13}$$

holds for each $y \in A(t)$ and each $v \in U(t,y)$. Set

$$\lambda(t) = \min\{f(t,x(t),u(t)), g(t,x(t),u(t))\}, \qquad t \in \Omega. \tag{4.14}$$

It follows from (4.12), (4.8), (4.13), and (4.14) that for almost every $t \in \Omega$,

$$\begin{aligned} &|f(t,x(t),u(t)) - g(t,x(t),u(t))| < 4^{-1}\epsilon_1 + 4^{-1}\epsilon_1\phi(t) \\ &+ 4^{-1}\epsilon_1 \min\{f(t,x(t),u(t)) + 2\phi_0(t),\ g(t,x(t),u(t)) + \phi(t) + 4\phi_0(t) + 2\} \\ &\le 4^{-1}\epsilon_1 + 4^{-1}\epsilon_1\phi(t) + 4^{-1}\epsilon_1(\phi(t) + 4\phi_0(t) + 2) + 4^{-1}\epsilon_1\lambda(t). \end{aligned}$$

By this relation, (4.6), and (4.9),

$$\begin{aligned} \int_\Omega |f(t,x(t),u(t)) - g(t,x(t),u(t))|dt &\le 4^{-1}\epsilon_1 \mathrm{mes}(\Omega) + 4^{-1}\epsilon_1 \int_\Omega \phi(t)dt \\ &+ 4^{-1}\epsilon_1 \int_\Omega \phi(t)dt + \epsilon_1 \int_\Omega \phi_0(t)dt + \epsilon_1\mathrm{mes}(\Omega) + 4^{-1}\epsilon_1 D < \epsilon. \end{aligned}$$

This completes the proof of the proposition. □

Analogously to the proof of Corollary 4.1 we can show that Proposition 4.4 implies the following corollary.

Corollary 4.2. *Let $f \in \mathcal{M}(A,U)$ and $\epsilon > 0$. Then there exists a neighborhood $\mathcal{V}$ of f in $\mathcal{M}(A,U)$ with the weak topology such that for all $g \in \mathcal{V}$,*

$$\left|\inf\left\{\int_\Omega f(t,x(t),u(t))dt :\ (x,u) \in X(A,U)\right\} - \inf\left\{\int_\Omega g(t,x(t),u(t))dt :\right.\right.$$

$$\left.\left.(x,u) \in X(A,U)\right\}\right| < \epsilon.$$

Proposition 4.5. *Let $m = 1$, $f \in \mathcal{M}(A,U)$, $h \in C_l(B_1 \times B_2)$, and $\epsilon \in (0,1)$, $D > 0$. Then there exist a neighborhood $\mathcal{U}$ of f in $\mathcal{M}(A,U)$ with the weak topology and a neighborhood $\mathcal{V}$ of h in $C_l(B_1 \times B_2)$ with the weak topology such that for each $(\xi, g) \in \mathcal{V} \times \mathcal{U}$ and each $(x,u) \in X(A,U)$ which satisfies*

$$\min\{I^{(f,h)}(x,u),\ I^{(g,\xi)}(x,u)\} \le D \tag{4.15}$$

the following relations are valid:

$$|h(x(T_1),x(T_2)) - \xi(x(T_1),x(T_2))| \le \epsilon, \tag{4.16}$$

$$\left|\int_{T_1}^{T_2}[f(t,x(t),u(t)) - g(t,x(t),u(t))]dt\right| \le \epsilon. \tag{4.17}$$

Proof. We may assume that $\inf(h)$ and

$$\inf\left\{\int_{T_1}^{T_2} f(t,x(t),u(t))dt :\ (x,u) \in X(A,U)\right\}$$

are finite. Choose a number

$$c_0 > 4 + |\inf(h)| + \left|\inf\left\{\int_{T_1}^{T_2} f(t,x(t),u(t))dt :\ (x,u) \in X(A,U)\right\}\right|.$$

By Corollaries 4.1 and 4.2 there exists a neighborhood $\mathcal{V}_1$ of $h \in C_l(B_1 \times B_2)$ with the weak topology such that

$$|\inf(\xi)| < c_0 \quad \text{for all } \xi \in \mathcal{V}_1 \tag{4.18}$$

and a neighborhood $\mathcal{U}_1$ of f in $\mathcal{M}(A,U)$ with the weak topology such that

$$\left|\inf\left\{\int_{T_1}^{T_2} g(t,x(t),u(t))dt :\ (x,u) \in X(A,U)\right\}\right| < c_0 \quad \text{for all } g \in \mathcal{U}_1. \tag{4.19}$$

By Proposition 4.3 there exists a neighborhood $\mathcal{V}$ of h in $C_l(B_1 \times B_2)$ with the weak topology such that $\mathcal{V} \subset \mathcal{V}_1$ and that for each $\xi \in \mathcal{V}$ and each $z \in B_1 \times B_2$ which satisfies $\min\{\xi(z), h(z)\} \le D + c_0 + 2$ the relation $|\xi(z) - h(z)| \le \epsilon$ holds. By Proposition 4.4 there exists a neighborhood $\mathcal{U}$ of f in $\mathcal{M}(A,U)$ with the weak topology such that $\mathcal{U} \subset \mathcal{U}_1$ and that for each $g \in \mathcal{U}$ and each $(x,u) \in X(A,U)$ satisfying

$$\min\left\{\int_{T_1}^{T_2} f(t,x(t),u(t))dt,\ \int_{T_1}^{T_2} g(t,x(t),u(t))dt\right\} \le D + c_0 + 2$$

the inequality (4.17) holds.

Now assume that $(\xi, g) \in \mathcal{V} \times \mathcal{U}$ and $(x, u) \in X(A, U)$ satisfies (4.15). It follows from (4.15), (4.18), and (4.19) that

$$\min\{\xi(x(T_1), x(T_2)), h(x(T_1), x(T_2))\} - c_0 \le \min\{I^{(f,h)}(x,u),\ I^{(g,\xi)}(x,u)\} \le D$$

and

$$\min\left\{\int_{T_1}^{T_2} f(t, x(t), u(t))dt,\ \int_{T_1}^{T_2} g(t, x(t), u(t))dt\right\} - c_0$$

$$\le \min\{I^{(f,h)}(x,u),\ I^{(g,\xi)}(x,u)\} \le D.$$

By these inequalities and the definition of $\mathcal{U}$ and $\mathcal{V}$, the inequalities (4.16) and (4.17) are valid. The proposition is proved. □

5. Preliminary lemma for hypothesis (A3). Fix a number $d_0 \in (0,1)$. There is a C^∞-function $\phi_0 : R^1 \to [0,1]$ such that $\phi_0(t) = 1$ if $|t| \le d_0$, $1 > \phi_0(t) > 0$ if $d_0 < |t| < 1$, and $\phi_0(t) = 0$ if $|t| \ge 1$. Define a C^∞-function $\bar{\phi} : R^1 \to R^1$ by $\bar{\phi}(x) = \int_0^x \phi_0(t)dt$, $x \in R^1$. Clearly $\bar{\phi}$ is monotone increasing, $\bar{\phi}(x) = x$ if $|x| \le d_0$, and

$$\bar{\phi}(x) = \bar{\phi}(1) \quad \text{if } x \ge 1, \quad \bar{\phi}(x) = \bar{\phi}(-1) \quad \text{if } x \le -1, \tag{5.1}$$

$$d_0 = \bar{\phi}(d_0) \le \bar{\phi}(x) \le \bar{\phi}(1) \le 1 \qquad \text{for all } x \in (d_0, 1). \tag{5.2}$$

Now we define a set $\mathcal{L} \subset C_l(B_1 \times B_2)$. In the case $m = 1$ we set $\mathcal{L} = C_l(B_1 \times B_2)$ and in the case $m > 1$ denote by $\mathcal{L}$ a singleton $\{0\}$ where 0 is a function in $C_l(B_1 \times B_2)$ which is identically zero. In the case $m > 1$ for each $(f, \xi) \in \mathcal{M}(A, U) \times \mathcal{L}$ and each $(x, u) \in X(A, U)$ we set

$$I^{(f,\xi)}(x,u) = I^{(f)}(x,u) \tag{5.3}$$

(see (1.10) and (1.11)). For each measurable set $E \subset R^m$, each measurable set $E_0 \subset E$, and each $h \in L^1(E)$ we set

$$||h||_{L^1(E_0)} = \int_{E_0} |h(t)|dt. \tag{5.4}$$

Fix an integer $k \ge 1$. It is easy to verify that all partial derivatives of the functions $(x, y) \to \bar{\phi}(|x-y|^2)$, $(x, y) \in R^q \times R^q$ with $q = n, N$ up to the order k are bounded (by some $\bar{d} > 0$).

For each $\gamma \in (0,1)$ choose $\epsilon_0(\gamma) \in (0, \gamma)$ such that

$$E_X(8\epsilon_0(\gamma)) \subset \{((x_1, u_1), (x_2, u_2)) \in X(A,U) \times X(A,U) :\ \rho((x_1, u_1), (x_2, u_2)) \le \gamma\} \tag{5.5}$$

(see (1.5)) and

$$\epsilon_0(\gamma) < 4^{-1}\gamma(\bar{d} + 2)^{-1} \tag{5.6}$$

and choose

$$\epsilon_1(\gamma) \in (0, d_0\epsilon_0(\gamma)), \tag{5.7}$$

$$\delta(\gamma) \in (0, 16^{-1}\epsilon_1(\gamma)^4). \tag{5.8}$$

LEMMA 5.1. *Let $\gamma \in (0,1)$, $f \in \mathcal{M}(A,U)$, $\xi \in \mathcal{L}$, and let $Y \subset X(A,U)$, $(\bar{x},\bar{u}) \in Y$,*

$$I^{(f,\xi)}(\bar{x},\bar{u}) \le \inf\{I^{(f,\xi)}(x,u) : (x,u) \in Y\} + \delta(\gamma) < \infty. \tag{5.9}$$

Then there is a $g : R^m \times R^n \times R^N \to R^1$ in $C^k(R^{m+n+N})$ which satisfies

$$0 \le g(t,x,u) \le \gamma \quad \textit{for all } (t,x,u) \in R^m \times R^n \times R^N, \tag{5.10}$$

$$||g(t,\cdot,\cdot)||_{C^k(R^n \times R^N)} \le \gamma \quad \textit{for all } t \in R^m$$

such that for a function $\bar{f} \in \mathcal{M}(A,U)$ defined by

$$\bar{f}(t,x,u) = f(t,x,u) + g(t,x,u),\ (t,x,u) \in \textit{graph}(U), \tag{5.11}$$

the following properties hold:

$$I^{(\bar{f},\xi)}(\bar{x},\bar{u}) \le I^{(f,\xi)}(\bar{x},\bar{u}) + \delta(\gamma); \tag{5.12}$$

for each $(y,v) \in Y$ satisfying

$$I^{(\bar{f},\xi)}(y,v) \le \inf\{I^{(\bar{f},\xi)}(z,w) : (z,w) \in Y\} + 2\delta(\gamma) \tag{5.13}$$

the relation $\rho((y,v),(\bar{x},\bar{u})) \le \gamma$ is valid.

Moreover the function g is the sum of two functions, one of them depends only on (t,x) while the other depend only on (t,u).

Proof. Choose a positive number ϵ_2 for which

$$e_2 < (\text{mes}(\Omega) + 1)^{-1} 8^{-1} \delta(\gamma) d_0 (\bar{d} + 1)^{-1}. \tag{5.14}$$

There is a measurable set $E_0 \subset \Omega$ such that

$$\text{mes}(\Omega \setminus E_0) < 2^{-1}\epsilon_2 \tag{5.15}$$

and the functions $\bar{x}$ and $\bar{u}$ are bounded on E_0. There exist sequences of functions $\{\bar{x}_i\}_{i=1}^{\infty} \in C^{\infty}(R^m; R^n)$ and $\{\bar{u}_i\}_{i=1}^{\infty} \subset C^{\infty}(R^m; R^N)$ such that

$$||\bar{u}_i - \bar{u}||_{L^1(E_0)},\ ||\bar{x}_i - \bar{x}||_{L^1(E_0)} \to 0 \quad \text{as } i \to \infty \tag{5.16}$$

[17, p. 13]. We may assume without loss of generality that $\bar{u}_i(t) \to \bar{u}(t)$, $\bar{x}_i(t) \to \bar{x}(t)$ as $i \to \infty$, $t \in E_0$ a.e. By Egorov's theorem there is a measurable set $E_1 \subset E_0$ such that

$$\text{mes}(E_0 \setminus E_1) < 2^{-1}\epsilon_2 \tag{5.17}$$

and

$$\bar{u}_i(t) \to \bar{u}(t) \quad \text{and} \quad \bar{x}_i(t) \to \bar{x}(t) \quad \text{uniformly in } E_1 \text{ as } i \to \infty. \tag{5.18}$$

There is an integer $s \geq 1$ such that

$$\max\{|\bar{u}_s(t) - \bar{u}(t)|,\ |\bar{x}_s(t) - \bar{x}(t)|\} \leq 4^{-1}\epsilon_2(\text{mes}(\Omega) + 1)^{-1}, \qquad t \in E_1. \tag{5.19}$$

Define a function $g : R^m \times R^n \times R^N \to R^1$ by

(5.20)

$$g(t, x, u) = \epsilon_0(\gamma)\bar{\phi}(|x - \bar{x}_s(t)|^2) + \epsilon_0(\gamma)\bar{\phi}(|u - \bar{u}_s(t)|^2), \qquad (t, x, u) \in R^m \times R^n \times R^N.$$

Clearly $g \in C^\infty(R^m \times R^n \times R^N)$. Define

$$\bar{f}(t, x, u) = f(t, x, u) + g(t, x, u), \qquad (t, x, u) \in \text{ graph}(U). \tag{5.21}$$

Evidently $\bar{f} \in \mathcal{M}(A, U)$. It follows from (5.20), the definition of $\bar{d}$, (5.1), (5.2), and (5.6) that (5.10) is true. We will show that (5.12) is true. By (5.21), (5.20), (5.19), (5.1), and (5.2),

$$I^{(\bar{f},\xi)}(\bar{x}, \bar{u}) = I^{(f,\xi)}(\bar{x}, \bar{u}) + \epsilon_0(\gamma)\int_\Omega \bar{\phi}(|\bar{x}(t) - \bar{x}_s(t)|^2)dt$$

$$+ \epsilon_0(\gamma)\int_\Omega \bar{\phi}(|\bar{u}(t) - \bar{u}_s(t)|^2)dt = I^{(f,\xi)}(\bar{x}, \bar{u}) + \epsilon_0(\gamma)\int_{E_1} \bar{\phi}(|\bar{x}(t) - \bar{x}_s(t)|^2)\, dt$$

$$+ \epsilon_0(\gamma)\int_{\Omega \setminus E_1} \bar{\phi}(|\bar{x}(t) - \bar{x}_s(t)|^2)dt + \epsilon_0(\gamma)\int_{E_1} \bar{\phi}(|\bar{u}(t) - \bar{u}_s(t)|^2)dt$$

$$+ \epsilon_0(\gamma)\int_{\Omega \setminus E_1} \bar{\phi}(|\bar{u}(t) - \bar{u}_s(t)|^2)dt \leq I^{(f,\xi)}(\bar{x}, \bar{u})$$

$$+ 2(\text{mes}(\Omega))\epsilon_0(\gamma)\bar{\phi}((4^{-1}\epsilon_2)^2) + 2\epsilon_0(\gamma)\text{ mes }(\Omega \setminus E_1).$$

It follows from this relation, (5.14), (5.1), (5.2), (5.15), and (5.17) that

$$I^{(\bar{f},\xi)}(\bar{x}, \bar{u}) \leq I^{(f,\xi)}(\bar{x}, \bar{u}) + 2\text{mes}(\Omega)\epsilon_0(\gamma)(4^{-1}\epsilon_2)^2 + 2\epsilon_0(\gamma)\epsilon_2$$

$$\leq I^{(f,\xi)}(\bar{x}, \bar{u}) + 4\epsilon_0(\gamma)\epsilon_2 \leq I^{(f,\xi)}(\bar{x}, \bar{u}) + \delta(\gamma).$$

Thus (5.12) is valid. Now assume that $(y, v) \in Y$ satisfies (5.13). It follows from (5.13), (5.21), (5.20), and (5.9) that

$$I^{(f,\xi)}(y, v) + \epsilon_0(\gamma)\int_\Omega \bar{\phi}(|\bar{x}_s(t) - y(t)|^2)dt + \epsilon_0(\gamma)\int_\Omega \bar{\phi}(|v(t) - \bar{u}_s(t)|^2)dt$$

$$= I^{(\bar{f},\xi)}(y, v) \leq 2\delta(\gamma) + I^{(\bar{f},\xi)}(\bar{x}, \bar{u}) \leq 3\delta(\gamma) + I^{(f,\xi)}(\bar{x}, \bar{u}) \leq I^{(f,\xi)}(y, v) + 4\delta(\gamma).$$

This implies that

$$\int_\Omega \bar\phi(|\bar x_s(t)-y(t)|^2)dt+\int_\Omega \bar\phi(|\bar u_s(t)-v(t)|^2)dt \le 4\delta(\gamma)(\epsilon_0(\gamma))^{-1}. \tag{5.22}$$

Set

$$E_2=\{t\in\Omega:\ |y(t)-\bar x_s(t)|\ge 2^{-1}\epsilon_1(\gamma)\},\ E_3=\{t\in\Omega:\ |v(t)-\bar u_s(t)|\ge 2^{-1}\epsilon_1(\gamma)\}. \tag{5.23}$$

Then by (5.23), (5.22), (5.6), (5.7), (5.1), (5.2), and (5.8)

$$\operatorname{mes}(E_2)+\operatorname{mes}(E_3)\le 4\epsilon_1(\gamma)^{-2}\left[\int_{E_2}\bar\phi(|\bar x_s(t)-y(t)|^2)dt+\int_{E_3}\bar\phi(|\bar u_s(t)-v(t)|^2)dt\right] \tag{5.24}$$

$$\le 16\epsilon_1(\gamma)^{-2}\delta(\gamma)(\epsilon_0(\gamma))^{-1}<\epsilon_1(\gamma).$$

It follows from (5.24), (5.23), (5.19), (5.14), (5.15), and (5.17) that

$$\operatorname{mes}\{t\in\Omega:\ |y(t)-\bar x(t)|\ge\epsilon_1(\gamma)\}\le\ \operatorname{mes}(\Omega\setminus E_1)$$

$$+\operatorname{mes}\{t\in\Omega:\ |y(t)-\bar x_s(t)|\ge 2^{-1}\epsilon_1(\gamma)\}\le\epsilon_2+\epsilon_1(\gamma)\le 2\epsilon_1(\gamma)$$

and

$$\operatorname{mes}\{t\in\Omega:\ |v(t)-\bar u(t)|\ge\epsilon_1(\gamma)\}\le\operatorname{mes}(\Omega\setminus E_1)$$

$$+\operatorname{mes}\{t\in\Omega:\ |v(t)-\bar u_s(t)|\ge 2^{-1}\epsilon_1(\gamma)\}\le\epsilon_2+\epsilon_1(\gamma)\le 2\epsilon_1(\gamma).$$

These relations and (5.5) imply that $((y,v),(\bar x,\bar u))\in E_X(4\epsilon_1(\gamma))$, $\rho((y,v),(\bar x,\bar u))\le\gamma$. This completes the proof of the lemma. □

6. An auxiliary result. Let $p\ge 1$ be an integer and let $e_1=(1,0,\dots 0)$,..., $e_p=(0,\dots,0,1)$ be the standard basis in R^p. For each set $E\subset R^p$ denote by $\operatorname{conv}(E)$ its convex hull.

PROPOSITION 6.1. *Let a finite set* $E=\{h_{ij}:\ i=1,2,\dots,p,\ j=1,2\}\subset R^p$ *satisfy*

$$|h_{i1}-e_i|,\ |h_{i2}+e_i|\le(2p)^{-1},\qquad i=1,\dots,p.$$

Then the relation $0\in\operatorname{conv}(E)$ *holds.*

Proof. Let us assume the converse. Then $0\notin\operatorname{conv}(E)$ and there is $\xi=(\xi_1,\dots,\xi_p)\in R^p\setminus\{0\}$ such that $\inf\{\langle g,\xi\rangle:\ g\in\operatorname{conv}(E)\}>0$. We may assume that $|\xi_1|\ge|\xi_i|$, $i=1,\dots,p$. There are two cases: $\xi_1>0$; $\xi_1<0$. Consider the case with $\xi_1>0$. Then $0<\langle\xi,h_{12}\rangle=\langle\xi,-e_1\rangle+\langle\xi,h_{12}+e_1\rangle\le-\xi_1+(2p)^{-1}p|\xi_1|<0$, a contradiction. Analogously we obtain a contradiction in the second case. The proposition is proved. □

7. Auxiliary lemma for hypothesis (A4). Assume that $A : \Omega \to 2^{R^n} \setminus \{\emptyset\}$ and graph(A) is a closed subset of the space $\Omega \times R^n$ with the product topology. Let $e_1 = (1, 0, \dots, 0)$, $e_2 = (0, 1, \dots, 0), \dots, e_N = (0, 0, \dots, 1)$ be a standard basis in R^N. Now we define a set $\mathcal{L} \subset C_l(B_1 \times B_2)$. In the case $m = 1$ we set $\mathcal{L} = C_l(B_1 \times B_2)$ and in the case $m > 1$ we denote by $\mathcal{L}$ a singleton $\{0\}$ where 0 is a function in $C_l(B_1 \times B_2)$, which is identically zero. In the case $m > 1$ for each $(f, \xi) \in \mathcal{M}(A, \tilde{U}_A) \times \mathcal{L}$ and each $(x, u) \in X(A, \tilde{U}_A)$ we set

$$I^{(f,\xi)}(x, u) = I^{(f)}(x, u)$$

(see (1.10), (1.11), and (1.12)).

LEMMA 7.1. *Let $f \in \mathcal{M}(A, \tilde{U}_A)$, $\xi \in \mathcal{L}$, $U \in \mathcal{P}_A$,*

$$\{(x, u) \in X(A, U) : \ I^{(f,\xi)}(x, u) < \infty\} \neq \emptyset, \tag{7.1}$$

and let $\epsilon, \delta > 0$. Then there are $U_* \in \mathcal{P}_A$, $(\bar{x}, \bar{u}) \in X(A, U_*)$, and an open set $\mathcal{W}$ in $\mathcal{P}_A$ such that

$$(U_*, U) \in E_{\mathcal{P}_A}(\epsilon), \qquad \mathcal{W} \cap \{V \in \mathcal{P}_A : \ (U, V) \in E_{\mathcal{P}_A}(\epsilon)\} \neq \emptyset, \tag{7.2}$$

$$I^{(f,\xi)}(\bar{x}, \bar{u}) \leq \inf\{I^{(f,\xi)}(x, u) : \ (x, u) \in X(A, U_*)\} + \delta < \infty, \tag{7.3}$$

and for all $V \in \mathcal{W}$,

$$(\bar{x}, \bar{u}) \in X(A, V) \subset X(A, U_*). \tag{7.4}$$

Proof. For each $r \in [0, 1]$ define $U_r \in \mathcal{P}_A$ by

$$U_r(t, x) = \{u \in R^N : \ d_H(u, U(t, x)) \leq r\}, \qquad (t, x) \in \text{graph}(A), \tag{7.5}$$

and define

$$\mu(r) = \inf\{I^{(f,\xi)}(x, u) : \ (x, u) \in X(A, U_r)\}. \tag{7.6}$$

Clearly $\mu(r)$ is finite for all $r \in [0, 1]$ and the function μ is monotone decreasing. There is an $r_0 \in (0, 8^{-1}\epsilon)$ such that μ is continuous at r_0. Choose $r_1 \in (0, r_0)$ such that

$$|\mu(r_1) - \mu(r_0)| < 16^{-1}\delta. \tag{7.7}$$

There is

$$(\bar{x}, \bar{u}) \in X(A, U_{r_1}) \tag{7.8}$$

such that

$$I^{(f,\xi)}(\bar{x}, \bar{u}) \leq \mu(r_1) + 16^{-1}\delta. \tag{7.9}$$

Relations (7.7) and (7.9) imply that

$$I^{(f,\xi)}(\bar{x}, \bar{u}) \leq \mu(r_0) + 8^{-1}\delta. \tag{7.10}$$

Set

$$r_2 = 2^{-1}(r_0 + r_1). \tag{7.11}$$

Clearly

$$(U_{r_i}, U) \in E_{\mathcal{P}_A}(\epsilon), \qquad i = 0, 1, 2. \tag{7.12}$$

Choose a positive number γ for which

$$\gamma < \min\{4^{-1}\delta,\ (16N)^{-1}(r_0 - r_1)\} \tag{7.13}$$

and define

$$\mathcal{W} = \{V \in \mathcal{P}_A :\ (U_{r_2}, V) \in E_{\mathcal{P}_A}(\gamma)\}, \qquad U_* = U_{r_0}. \tag{7.14}$$

It follows from (7.12), (7.14), (7.10), and (7.6) that (7.2) and (7.3) are true.

Assume that $V \in \mathcal{W}$. Then by (7.14), (7.13), and (7.11), for each $(t, x) \in \operatorname{graph}(A)$,

$$V(t, x) \subset \{z \in R^N :\ d_H(z, U_{r_2}(t, x)) \le \gamma\}$$

$$\subset \{z \in R^N :\ d_H(z, U(t, x)) \le r_0\} = U_{r_0}(t, x).$$

Therefore

$$X(A, V) \subset X(A, U_{r_0}). \tag{7.15}$$

We will show that $(\bar{x}, \bar{u}) \in X(A, V)$. It is sufficient to show that

$$\bar{u}(t) \in V(t, \bar{x}(t)) \quad \text{for almost every } t \in \Omega. \tag{7.16}$$

By (7.8) for almost every $t \in \Omega$,

$$\bar{u}(t) \in U_{r_1}(t, \bar{x}(t)). \tag{7.17}$$

Assume that $t \in \Omega$ and (7.17) is true. By (7.17), (7.11), (7.5), and (7.14) for $i = 1, \dots, N$,

$$\bar{u}(t) + 2^{-1}(r_0 - r_1)e_i, \qquad \bar{u}(t) - 2^{-1}(r_0 - r_1)e_i \in U_{r_2}(t, \bar{x}(t)),$$

and there are $z_{i1}, z_{i2} \in R^N$ such that

(7.18)
$$\bar{u}(t) + z_{i1},\ \bar{u}(t) + z_{i2} \in V(t, \bar{x}(t)),\ |z_{i1} - 2^{-1}(r_0 - r_1)e_i|,\ |z_{i2} + 2^{-1}(r_0 - r_1)e_i| \le \gamma.$$

Since the set $V(t, \bar{x}(t))$ is convex it follows from (7.18), (7.13), and Proposition 6.1 that

$$0 \in \operatorname{conv}\{z_{ij} :\ i = 1, \dots, N,\ j = 1, 2\}, \qquad \bar{u}(t) \in V(t, \bar{x}(t)).$$

This implies that $(\bar{x}, \bar{u}) \in X(A, V)$. The lemma is proved. □

8. Proof of Theorem 1.1 and its extensions.

Proof of Theorem 1.1. By Propositions 4.1 and 4.2 (A1) holds and J_a is lower semicontinuous for all $a \in \mathcal{A}_1 \times \mathcal{A}_2$. By Theorem 2.1 we need to verify that (H1) and (H2) are valid. (H2) follows from Proposition 4.2. Therefore it is sufficient to show that (H1) holds. By Proposition 3.1 it is sufficient to show that (A2), (A3), and (A4) are valid. Hypothesis (A2) follows from Propositions 4.4 and 4.5. By Lemma 5.1, (A3) holds. Hypothesis (A4) follows from Lemma 7.1. This completes the proof of the theorem. □

As we mentioned in section 1 we proved Theorem 1.1 in such a manner that it is applicable for all the spaces of integrands introduced there. All the spaces of integrands are subspaces of $\mathcal{M}(A, U)$. Since (H2), (A1), (A2), and (A4) hold for the class of optimal control problems with the space of integrands $\mathcal{M}(A, U)$, they are also valid for all its subclasses considered here. On the other hand (A3) follows from Lemma 5.1, which establishes that $f + g$ and f belong to the same subspaces of integrands. This implies that (A3) holds for all classes of optimal control problems introduced in section 1.

As seen from the proof of Lemma 5.1 the perturbation g of the integrand f is chosen as the sum of two functions, one of them depends only on (t, x) while the other depend only on (t, u). Therefore Theorem 1.1 can be easily extended to subclasses of the classes of optimal control problems introduced in section 1 in which integrands are sums of two finite-valued functions, one of them, depending only on (t, x), is defined on graph(A), while the other, depending only on (t, u), is defined on $\Omega \times R^N$.

Finally in this section we present the extension of the generic existence and uniqueness result established in [27] for the space of lower semicontinuous integrands f : graph$(U) \to R^1$. Our generalization holds for all the spaces of integrands defined in section 1, and it is obtained as a realization of the generic variational principle established in section 2.

Assume that $A : \Omega \to 2^{R^n} \setminus \{\emptyset\}$, U : graph$(A) \to 2^{R^N} \setminus \{\emptyset\}$, and graph$(U)$ is a closed subset of $\Omega \times R^n \times R^N$ with the product topology. We consider the metric space $X(A, U)$ with the metric ρ (see (1.5)).

Now we define $\mathcal{A}_1$ as follows:

$$\mathcal{A}_1 = \mathcal{A}_{11} \times \mathcal{A}_{12} \quad \text{if } m = 1 \quad \text{and} \quad \mathcal{A}_1 = \mathcal{A}_{11} \quad \text{if } m > 1,$$

where $\mathcal{A}_{12}$ is either $C_l(B_1 \times B_2)$ or $C(B_1 \times B_2)$ or a singleton $\{\xi\} \subset C_l(B_1 \times B_2)$, and $\mathcal{A}_{11}$ is one of the following spaces:

$$\mathcal{M}(A, U);\ \mathcal{M}^l(A, U);\ \mathcal{M}^c(A, U);$$

$$\mathcal{M}_k(A, \tilde{U}_A);\ \mathcal{M}_k^l(A, \tilde{U}_A);\ \mathcal{M}_k^c(A, \tilde{U}_A) \text{ (here } k \geq 1 \text{ is an integer, } U = \tilde{U}_A,$$

$$\text{and graph}(A) \text{ is a closed subset of the space } \Omega \times R^n \text{ with the product topology);}$$

$$\mathcal{M}_k^*(\tilde{A}, \tilde{U});\ \mathcal{M}_k^{*l}(\tilde{A}, \tilde{U});\ \mathcal{M}_k^{*c}(\tilde{A}, \tilde{U}) \text{ (here } k \geq 1 \text{ is an integer and } A = \tilde{A},\ U = \tilde{U}).$$

Denote by $\mathcal{A}$ the closure of the set $\{a \in \mathcal{A}_1 : \inf(I^{(a)}) < \infty\}$ in the space $\mathcal{A}_1$ with the strong topology. We assume that $\mathcal{A}$ is nonempty. The following result is proved analogously to Theorem 1.1.

THEOREM 8.1. *The minimization problem for $I^{(a)}$ on $(X(A, U), \rho)$ is generically strongly well posed with respect to $\mathcal{A}$.*

9. Generic existence and uniqueness of solutions for variational problems without convexity assumptions. We use the notation and definitions introduced in section 1. Assume that $n = N$, $H(t, x, u) = u$, $(t, x, u) \in \Omega \times R^n \times R^n$, and B_1 and B_2 are singletons. Let $A : \Omega \to 2^{R^n} \setminus \{\emptyset\}$, $U : \mathrm{graph}(A) \to 2^{R^n} \setminus \{\emptyset\}$ and let $\mathrm{graph}(U)$ be a closed subset of the space $\Omega \times R^n \times R^n$ with the product topology. If $(x, u) \in X(A, U)$, then $u = \nabla x$ and (x, u) is identified with $x \in (W^{1,1}(\Omega))^n$. In what follows we omit the notation u in describing the elements of $X(A, U)$. For the set $X(A, U)$ we consider the metric ρ introduced in section 1 (see (1.5)) and the metric ρ_s defined by

$$\rho_s(x, y) = ||x - y||_{W^{1,1}(\Omega)} \quad \text{for all } x, y \in X(A, U).$$

Clearly $(X(A, U), \rho_s)$ is a complete metric space and its uniform structure is stronger than the uniformity that generates the metric ρ. Finally for the set $X(A, U)$ we consider the third uniformity which is determined by the following base:

$$E_{Xw}(\epsilon) = \{(x_1, x_2) \in X(A, U) \times X(A, U) : \tag{9.1}$$

$$\mathrm{mes}\{t \in \Omega : \ |\nabla x_1(t) - \nabla x_2(t)| \geq \epsilon\} \leq \epsilon\},$$

where $\epsilon > 0$. (Note that if $x, y \in X(A, U)$ and $\nabla x = \nabla y$, then $x = y$ [28, Theorem 2.4.1].) It is easy to see that this uniform structure is metrizable (by a metric ρ_w) and weaker than the uniformity which generates the metric ρ.

For variational problems considered in this section we can obtain strong versions of Theorems 1.1 and 8.1. These strong versions establish generic strong well-posedness of the minimization problem on the space (X, ρ_s), while in Theorems 1.1 and 8.1 it is obtained on (X, ρ). They are derived from Theorems 1.1 and 8.1, Proposition 4.4, and the following proposition.

PROPOSITION 9.1. *Let $f \in \mathcal{M}(A, U)$,*

$$c_0 > \inf\left\{\int_\Omega f(t, x(t), \nabla x(t))dt : \ x \in X(A, U)\right\} \tag{9.2}$$

and let

$$Y = \left\{x \in X(A, U) : \ \int_\Omega f(t, x(t), \nabla x(t))dt \leq c_0\right\}. \tag{9.3}$$

Then for each $\epsilon > 0$ there exists $\delta > 0$ such that if $x_1, x_2 \in Y$ and $(x_1, x_2) \in E_{Xw}(\delta)$, then $\rho_s(x_1, x_2) \leq \epsilon$.

Proof. Let $\epsilon > 0$. In the case $m > 1$ by [28, Theorem 2.4.1] there exists a constant $c > 0$ such that $||h||_{L^1(\Omega)} \leq c||\nabla h||_{L^1(\Omega)}$ for all $h \in W_0^{1,1}(\Omega)$. In the case $m = 1$ set $c = 1$. Choose a positive number

$$\Delta < (32(c + 1)(\mathrm{mes}(\Omega) + 1))^{-1}\epsilon.$$

By the property (iii) (see the definition of $\mathcal{M}(A, U)$) and (9.3), the family of functions $\{|\nabla x(\cdot)| : \ x \in Y\}$ is uniformly integrable. Therefore there exists $\gamma \in (0, \Delta)$ such that for each $x \in Y$ and each measurable set $e \subset \Omega$ satisfying $\mathrm{mes}(e) \leq \gamma$ the inequality $\int_e |\nabla x(t)|dt \leq \Delta$ holds. Choose a positive number $\delta < (8c + 8)^{-1}(\mathrm{mes}(\Omega) + 1)^{-2}\gamma$.

Assume that $x_1, x_2 \in Y$ and $(x_1, x_2) \in E_{Xw}(\delta)$. There exists a measurable set $e \subset \Omega$ such that $\mathrm{mes}(e) \le \delta$ and $|\nabla x_1(t) - \nabla x_2(t)| \le \delta$, $t \in \Omega \setminus e$. It follows from these inequalities and the definition of γ and δ that

$$\int_e |\nabla x_i(t)|dt \le \Delta, \qquad i = 1, 2, \int_\Omega |\nabla x_1(t) - \nabla x_2(t)|dt \tag{9.4}$$

$$\le \int_e |\nabla x_1(t) - \nabla x_2(t)|dt + \int_{\Omega\setminus e} |\nabla x_1(t) - \nabla x_2(t)|dt \le 2\Delta + \delta \mathrm{mes}(\Omega).$$

In the case $m = 1$ we have

$$|x_1(t) - x_2(t)| \le \int_\Omega |\nabla x_1(s) - \nabla x_2(s)|ds, \qquad t \in \Omega,$$

and by (9.4) and the definition of δ and Δ,

$$\rho_s(x_1, x_2) = ||x_1 - x_2||_{W^{1,1}(\Omega)} \le (\mathrm{mes}(\Omega) + 1)||\nabla x_1 - \nabla x_2||_{L^1(\Omega)}$$

$$\le (\mathrm{mes}(\Omega) + 1)(2\Delta + \delta \mathrm{mes}(\Omega)) < \epsilon.$$

In the case $m > 1$ it follows from (1.4), the definition of c, (9.4), and the definition of δ, Δ that

$$\rho_s(x_1, x_2) = ||x_1 - x_2||_{L^1(\Omega)} + ||\nabla x_1 - \nabla x_2||_{L^1(\Omega)}$$

$$\le (c + 1)||\nabla x_1 - \nabla x_2||_{L^1(\Omega)} \le (c + 1)(2\Delta + \delta \mathrm{mes}(\Omega)) < \epsilon.$$

This completes the proof of the proposition. □

Proposition 9.1 and the completeness of the space $(X(A, U), \rho_s)$ imply the following result.

PROPOSITION 9.2. *Assume that* $f \in \mathcal{M}(A, U)$, $\{x_i\}_{i=1}^\infty$ *is a Cauchy sequence in the space* $X(A, U)$ *with the metric* ρ_w, *and the sequence* $\{\int_\Omega f(t, x_i(t), \nabla x_i(t))dt\}_{i=1}^\infty$ *is bounded. Then there is* $x_* \in X(A, U)$ *such that* $\rho_s(x_i, x_*) \to 0$ *as* $i \to \infty$ *and, moreover, if* $m = 1$, *then* $x_i(t) \to x_*(t)$ *as* $i \to \infty$ *uniformly on* $[T_1, T_2]$.

From now on we consider a fixed set-valued mapping $A : \Omega \to 2^{R^n} \setminus \{\emptyset\}$ for which graph(A) is a closed subset of the space $\Omega \times R^n$ with the product topology and a set-valued mapping $\tilde{U}_A :$ graph$(A) \to 2^{R^n} \setminus \{\emptyset\}$, where $\tilde{U}_A(t, x) = R^n$, $(t, x) \in$ graph(A). For each $f \in \mathcal{M}(A, \tilde{U}_A)$ we define $I^{(f)} : X(A, \tilde{U}_A) \to R^1 \cup \{\infty\}$ by

$$I^{(f)}(x) = \int_\Omega f(t, x(t), \nabla x(t))dt, \qquad x \in X(A, \tilde{U}_A).$$

Consider the space of set-valued mappings $\mathcal{A}_2$ and the space of integrands $\mathcal{A}_{11}$ defined in section 1. Denote by $\mathcal{A}_0$ the set of all functions $f \in \mathcal{A}_{11}$ which do not depend on x. Clearly $\mathcal{A}_0$ is a closed subset of $\mathcal{A}_{11}$ with the strong topology. We consider the topological subspace $\mathcal{A}_0 \subset \mathcal{A}_{11}$ with the relative weak and strong topologies.

Let a function $F :$ graph$(A) \times R^n \to R^1 \cup \{\infty\}$ have the following properties:

F is measurable with respect to the σ-algebra generated by products of Lebesgue measurable subsets of Ω and Borel subsets of $R^n \times R^n$; $F(t, \cdot, \cdot)$ is lower semicontinuous for almost every $t \in \Omega$; there exists an integrable scalar function $\psi_F(t) \geq 0,\ t \in \Omega$, such that $F(t, x, u) \geq \psi_F(t)$ for all $(t, x, u) \in$ graph $(A) \times R^n$.

Clearly, for each $g \in \mathcal{M}(A, \tilde{U}_A)$, $g + F \in \mathcal{M}(A, \tilde{U}_A)$.

For each $a = (a_1, a_2) \in \mathcal{A}_0 \times \mathcal{A}_2$ we define $J_a : X(A, \tilde{U}_A) \to R^1 \cup \{\infty\}$ by

$$J_a(x) = I^{(a_1+F)}(x), \quad x \in S_{a_2}, \quad J_a(x) = \infty, \quad x \in X(A, \tilde{U}_A) \setminus S_{a_2}.$$

Here $S_{a_2} = X(A, a_2)$ (see (1.19)). Denote by $\mathcal{A}$ the closure of the set $\{a \in \mathcal{A}_0 \times \mathcal{A}_2 : \inf(J_a) < \infty\}$ in the space $\mathcal{A}_0 \times \mathcal{A}_2$ with the strong topology. We assume that $\mathcal{A}$ is nonempty.

THEOREM 9.1. *The minimization problem for J_a on $(X(A, \tilde{U}_A), \rho_s)$ is generically strongly well posed with respect to $\mathcal{A}$.*

Proof. We will show that the following assertion holds: The minimization problem for J_a on $(X(A, \tilde{U}_A), \rho_w)$ is generically strongly well posed with respect to $\mathcal{A}$.

This assertion is proved analogously to Theorem 1.1. Note that Propositions 4.1 and 9.2 imply the lower semicontinuity of J_a for all $a \in \mathcal{A}_0 \times \mathcal{A}_2$, (H2) follows from Proposition 9.2, and (A3) is derived from a modification of Lemma 5.1. In this modification the perturbation $g = g(t, x, u)$ does not depend on x and in the last line of the statement of Lemma 5.1 ρ is substituted by ρ_w. The proof of this modification is analogous to the proof of Lemma 5.1. In the relation (5.5), ρ is substituted by ρ_w and E_X is substituted by E_{Xw}, and in (5.20) g is defined by

$$g(t, x, u) = \epsilon_0(\gamma)\bar{\phi}(|u - \bar{u}_s(t)|^2), \qquad (t, x, u) \in R^m \times R^n \times R^n.$$

Thus there exists an everywhere dense (in the strong topology) set $\mathcal{B} \subset \mathcal{A}$ which is a countable intersection of open (in the weak topology) subsets of $\mathcal{A}$ such that for any $a \in \mathcal{B}$ the assertions (1) and (2) of Theorem 2.1 hold with $(X, \rho) = (X(A, \tilde{U}_A), \rho_w)$ and $f_b = J_b$, $b \in \mathcal{A}$.

Let $a = (a_1, a_2) \in \mathcal{B}$. By the assertion (1) of Theorem 2.1 $\inf(J_a)$ is finite and attained at a unique element $\bar{x} \in X(A, \tilde{U}_A)$. In order to complete the proof of the theorem it is sufficient to show that the assertion (2) of Theorem 2.1 holds with $(X, \rho) = (X(A, \tilde{U}_A), \rho_s)$ and $f_b = J_b$, $b \in \mathcal{A}$.

By Proposition 4.4 there exists an open (in the weak topology) neighborhood $\mathcal{V}_1$ of a_1 in $\mathcal{A}_0$ such that for each $b \in \mathcal{V}_1$ and each $x \in X(A, \tilde{U}_A)$ satisfying $I^{(b+F)}(x) \leq \inf(J_a) + 1$ the following relation holds:

$$I^{(a_1+F)}(x) \leq I^{(b+F)}(x) + 1 \leq \inf(J_a) + 2. \tag{9.5}$$

Let $\epsilon \in (0, 1)$. It follows from Proposition 9.1 that there exists $\epsilon_0 \in (0, \epsilon)$ such that for each $x_1, x_2 \in X(A, \tilde{U}_A)$ satisfying

$$I^{(a_1+F)}(x_i) \leq \inf(J_a) + 2, \quad i = 1, 2, \qquad \text{and } \rho_w(x_1, x_2) \leq \epsilon_0 \tag{9.6}$$

the relation $\rho_s(x_1, x_2) \leq \epsilon$ holds.

By the assertion (2) of Theorem 2.1 which holds for the space $(X(A, \tilde{U}_A), \rho_w)$, there are a neighborhood $\mathcal{V}$ of a in $\mathcal{A}$ with the weak topology and $\delta > 0$ such that for each $b \in \mathcal{V}$, $\inf(J_b)$ is finite, and if $z \in X(A, \tilde{U}_A)$ satisfies

$$J_b(z) \leq \inf(J_b) + \delta, \tag{9.7}$$

then

$$\rho_w(\bar{x}, z) \leq \epsilon_0 \quad \text{and} \quad |J_b(z) - J_a(\bar{x})| \leq \epsilon_0. \tag{9.8}$$

We may assume that

$$\mathcal{V} \subset \mathcal{V}_1 \times \mathcal{A}_2. \tag{9.9}$$

Now assume that $b = (b_1, b_2) \in \mathcal{V}$, and $z \in X(A, \tilde{U}_A)$ satisfies (9.7). Then (9.8) holds. By (9.8), (9.9), and the definition of $\mathcal{V}_1$ (see (9.5))

$$I^{(a_1+F)}(z) \leq \inf(J_a) + 2.$$

It follows from this inequality, (9.8), and the definition of ϵ_0 (see (9.6)) that the relation $\rho_s(\bar{x}, z) \leq \epsilon$ holds. Thus the assertion (2) of Theorem 2.1 holds with $(X, \rho) = (X(A, \tilde{U}_A), \rho_s)$ and $f_b = J_b$, $b \in \mathcal{A}$. This completes the proof of the theorem. □

Note that for the class of variational problems considered here we can also prove an analog of Theorem 8.1 in which only integrands are subject to variations.

Example. Let us consider the scalar variational problem

$$\int_0^1 f(t, x'(t))dt \to \min, \qquad x(0) = x(1) = 0,$$

where $f(t, u) = 0$ for $u \in \{-1, 1\}$ and $f(t, u) = \infty$ otherwise. Clearly the functions x_* and $\tilde{x}$ defined by

$$x_*(t) = t,\ t \in [0, 2^{-1}], \quad x_*(t) = 1 - t, \quad t \in (1/2, 1], \tag{9.10}$$

$$\tilde{x}(t) = -x_*(t), \qquad t \in [0, 1]$$

are solutions of the problem. Define a continuous function $\phi : R^2 \to R^1$ by

$$\phi(t, u) = \min\{1, |u - 1|(1/2 - t)\}, \qquad (t, u) \in (-\infty, 1/2] \times R^1,$$

$$\phi(t, u) = \min\{1, |u + 1|(t - 1/2)\}, \qquad (t, u) \in (1/2, \infty) \times R^1,$$

and for each $r \in (0, 1)$ define a function f_r by

$$f_r(t, u) = f(t, u) + r\phi(t, u), \qquad (t, u) \in [0, 1] \times R^1.$$

It is easy to see that $f_r \to f$ as $r \to 0$, and for each $r \in (0, 1)$ the variational problem

$$\int_0^1 f_r(t, x'(t))dt \to \min, \qquad x(0) = x(1) = 0$$

has a unique solution x_* defined by (9.10).

EXTENDED HAMILTON–JACOBI CHARACTERIZATION OF VALUE FUNCTIONS IN OPTIMAL CONTROL[*]

GRANT N. GALBRAITH[†]

Abstract. This paper examines generalized solutions to the Hamilton–Jacobi equation. The Hamiltonian $H(t, x, p)$ is assumed convex in p but is not constrained to have linear growth in this variable. This corresponds to a certain class of generalized Bolza problems, related to optimal control. Lower semicontinuous solutions are considered and it is shown that there is a unique solution, the so-called value function of the underlying Bolza problem. In proving the main result we use recent improved necessary optimality conditions. Viability is also used in a new way, in connection to differential inclusions with unbounded images.

Key words. Hamilton–Jacobi equation, optimal control, Bolza problem, nonsmooth analysis, viability theory, viscosity solution

1. Introduction.

The classical Cauchy problem for the Hamilton–Jacobi equation is the partial differential equation with initial condition

$$\begin{aligned} u_t(t,x) + H(t,x,u_x(t,x)) &= 0, \qquad (t,x) \in (0,\infty) \times \mathbb{R}^n, \\ u(0,x) &= \varphi(x), \quad x \in \mathbb{R}^n. \end{aligned} \tag{1.1}$$

If the Hamiltonian $H(t, x, p)$ is convex with respect to p, there are connections between solutions to (1.1) and optimization problems involving a function dual to the Hamiltonian. This function L, called the Lagrangian, is derived from H using the Legendre–Fenchel transform as follows:

$$L(t,x,v) = \sup_{p \in \mathbb{R}^n} \{ \langle\, p, v \,\rangle - H(t,x,p) \}. \tag{1.2}$$

Here $\langle\, p, v \,\rangle$ denotes the inner product of p and v. It is possible for L to assume the value $+\infty$, and it is this important feature which allows constraints to be incorporated directly into L in the form of "infinite penalties." The *generalized problem of Bolza* we parameterize here in (τ, ξ) as

$$(\mathcal{P}_{\tau,\xi}) \qquad \text{minimize} \;\; \Gamma(x) := \varphi(x(0)) + \int_0^\tau L\big(t, x(t), \dot{x}(t)\big) dt,$$

where we are minimizing Γ over $\mathcal{A}_n^1[0,\tau]$ (the space of all absolutely continuous arcs $x : [0,\tau] \to \mathbb{R}^n$) with $x(\tau) = \xi$. This has a simple appearance, and yet a wide range of problems involving optimal control, differential inclusions, and constraints can be expressed in this form. See Loewen [20] or the introductory chapter of Clarke [8] for a discussion on the equivalences between these various formulations.

An extended-real-valued function is called *proper* if it never takes on the value $-\infty$ and is not identically $+\infty$. When $H(t, x, \cdot\,)$ is proper, lower semicontinuous (lsc),

[*] Received by the editors November 20, 1998; accepted for publication (in revised form) March 28, 2000; published electronically August 24, 2000.

[†] Department of Mathematics, University of California, Davis, CA, 95616-8633 (gng@math.ucdavis.edu).

and convex for each (t, x), then $L(t, x, \cdot\,)$ also has these properties. Furthermore, we can then retrieve H from L by performing the Legendre–Fenchel transform a second time:

$$H(t, x, p) = \sup_{v \in \mathbb{R}^n} \{ \langle\, p, v \,\rangle - L(t, x, v) \}. \tag{1.3}$$

Thus we have a one-to-one correspondence between Hamiltonians and Lagrangians in this convex case, and every equation of the form (1.1) can be paired with a problem of the form $(\mathcal{P}_{\tau,\xi})$.

Definition 1.1. *The value function* $V : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R} \cup \{\pm\infty\}$ *is defined from* Γ *as follows:*

$$V(\tau, \xi) = \begin{cases} \inf\{\, \Gamma(x) \mid x \in \mathcal{A}_n^1[0, \tau],\ x(\tau) = \xi \} & \text{if } \tau > 0, \\ \varphi(\xi) & \text{if } \tau = 0, \\ +\infty & \text{if } \tau < 0. \end{cases} \tag{1.4}$$

When the value function is real-valued and differentiable, it is known to satisfy (1.1) in the classical sense, and yet in many situations the value function is extended-real-valued and merely lsc. Our goal is to provide a way to interpret (1.1) for extended-real-valued, lsc functions u in such a way that the value function V will be the unique solution. This is not the first such attempt, as the discussion below will reveal; however, we achieve this uniqueness result over a much larger class of Hamiltonians than had been previously attained.

The first of these earlier results dates back to the early 1980s when Crandall and Lions [10] introduced *viscosity solutions*, with Crandall, Evans, and Lions giving a simplified approach in [11]. Viscosity solutions attracted a lot of attention, and over subsequent years a sizable literature developed from many authors dealing with, among other issues, existence and uniqueness of solutions.

In section 2 we will go into more detail about the classes of Hamiltonians and solutions addressed by viscosity theory, but for now we will mention briefly that they typically require that the solution be uniformly continuous and bounded and that the Hamiltonian satisfy some sort of uniform continuity condition. For an up-to-date account of the subject, see the recent book of Bardi and Capuzzo-Dolcetta [4].

Another class of continuous generalized solutions, named *minimax solutions*, was developed by Subbotin, initially in [29], with a more detailed approach in [31]. For a large class of Hamiltonians, minimax solutions and viscosity solutions are equivalent.

As mentioned earlier, even continuity may fail for the value function, and thus there is a need for semicontinuous solutions to (1.1). Ishii [18] examined issues regarding the existence of possibly discontinuous solutions, which were defined using upper semicontinuous (usc) and lsc envelopes. Barles and Perthame [5] used Ishii's notion of solution and obtained an early uniqueness result. In [7], Barron and Jensen extended viscosity solutions to certain semicontinuous functions for Hamiltonians that are convex in p and provided a uniqueness result. The paper by Barles [6] provides some extensions and an informal discussion of Barron and Jensen's ideas.

Frankowska [16] also considered lsc solutions and presented a uniqueness result for the Hamilton–Jacobi equation arising from the Mayer problem in optimal control. This corresponds to considering $(\mathcal{P}_{\tau,\xi})$ with the Lagrangian $L(t, x, \cdot\,)$ as the indicator of a compact set for each (t, x). The indicator function $\Psi : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ of a set

$C \subset \mathbb{R}^n$ is defined as

$$\Psi_C(v) = \begin{cases} 0 & \text{if } v \in C, \\ +\infty & \text{otherwise.} \end{cases} \tag{1.5}$$

The Mayer problem then has $L(t,x,v) = \Psi_{F(t,x)}(v)$ for some set-valued mapping F with compact, convex images. This gives rise to a Hamiltonian which is finite and positively homogeneous in p. An important feature of [16], which inspired the approach taken here, is Frankowska's use of viability theory.

This paper will present a result on the existence and uniqueness of solutions to (1.1) with a solution concept similar to those in [7] and [16]. As in [16], viability plays an important role in deriving our main result; however, we advance by working with unbounded differential inclusions. The differential inclusions we wish to employ are epigraphical set-valued mappings, whose images by their very nature cannot be bounded.

Typically, viability properties of a set K are determined through properties of the tangent and normal cones to K. Our viability approach differs in that we use normal cone properties of the *reachable set* of K. This allows us to deal with the epigraphical differential inclusion directly, without having to resort to truncations of the epigraph. Ultimately this allows us greater range in our choice of Lagrangians and Hamiltonians. In particular, we can go beyond cases where L has the form $L(t,x,v) = L_1(t,x,v) + \Psi_{F(t,x)}(v)$ for some Lipschitz function L_1. (This case can be reduced to a Mayer problem through truncations of the epigraphs $L(t,x,\,\cdot\,)$.) More generally speaking, we are not restricting ourselves to Hamiltonians $H(t,x,p)$ which have linear growth in p (this corresponds to the essential domain of $L(t,x,v)$ being bounded in the variable v for each (t,x)). Instead we have the extremely mild growth condition (A1) on the Hamiltonian, given in the next section.

The proof of our main theorem also relies on the improved necessary optimality conditions achieved in the papers [21], [22], and [23] of Loewen and Rockafellar. The assumption (A2) used in the main theorem is designed precisely to allow the application of these necessary conditions, which are given in section 5.

Because nonsmooth analysis will be used here, we will need the notion of a subgradient. We use the notation adopted in Rockafellar and Wets [27]. The symbol $\overline{\mathbb{R}}$ is used to denote $\mathbb{R} \cup \{+\infty\} \cup \{-\infty\}$. For $v \in \mathbb{R}^n$ and an lsc function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$,

(i) v is a *regular subgradient of f at x*, written $v \in \widehat{\partial} f(x)$, if

$$\liminf_{y \to x,\ y \neq x} \frac{f(y) - f(x) - \langle v, y - x \rangle}{|y - x|} \geq 0;$$

(ii) v is a (general) *subgradient of f at x*, written $v \in \partial f(x)$, if there are sequences $x^\nu \to x$ with $f(x^\nu) \to f(x)$ and $v^\nu \in \widehat{\partial} f(x^\nu)$ with $v^\nu \to v$;

(iii) v is a *horizon subgradient of f at x*, written $v \in \partial^\infty f(x)$, if there are sequences $x^\nu \to x$ with $f(x^\nu) \to f(x)$ and $v^\nu \in \widehat{\partial} f(x^\nu)$ with $\lambda^\nu v^\nu \to v$ for some sequence $\lambda^\nu \searrow 0$.

There is another way to define regular subgradients, equivalent to the above, which is more in line with the ideas used for viscosity solutions. We can say a vector v belongs to $\widehat{\partial} f(x)$ if and only if on some neighborhood W of x, there exists a function g continuously differentiable on W with $g(x) = f(x)$, $\nabla g(x) = v$, and $g(x') < f(x')$ for all $x' \in W$ with $x' \neq x$. (See Prop. 8.5 in [27] for details.)

Given a closed set K and a point $x \in K$, we can define the general normal cone $N_K(x)$ and the regular normal cone $\widehat{N}_K(x)$ from the corresponding subgradients as follows:

$$N_K(x) = \partial \Psi_K(x), \tag{1.6}$$

$$\widehat{N}_K(x) = \widehat{\partial} \Psi_K(x). \tag{1.7}$$

We use the notation $\operatorname{dom} f$ for the *effective domain of f*, which is the set $\{x : f(x) < \infty\}$. We can now specify what we mean by a generalized solution to (1.1).

Definition 1.2. *A function $u : \mathbb{R} \times \mathbb{R}^n \to \overline{\mathbb{R}}$ is a solution to* (1.1) *if it satisfies the following:*

(a) *u is proper and lsc, with* $\operatorname{dom} u \subset [0, \infty) \times \mathbb{R}^n$*;*

(b) *$u(0, \xi) = \varphi(\xi)$ for all $\xi \in \mathbb{R}^n$;*

(c) *For every $(\tau, \xi) \in \operatorname{dom} u$, every $(\sigma, \eta) \in \partial u(\tau, \xi)$ satisfies*

$$\begin{cases} \sigma + H(\tau, \xi, \eta) \leq 0 & \textit{if } \tau = 0, \\ \sigma + H(\tau, \xi, \eta) = 0 & \textit{if } \tau > 0. \end{cases} \tag{1.8}$$

Note the use of general subgradients in the definition. This differs from the papers [7] and [16], where the emphasis is on regular subgradients. The choice of using general subgradients in our definition of solution has been made because of the richer calculus rules these subgradients enjoy and due to their emphasis in [27]. Definition 1.2 aside, the general subgradient is a better choice later in the paper when characterizing sub-Lipschitz and pseudo-Lipschitz properties of set-valued mappings (see Mordukhovich [24]). Thus we make it our subgradient of choice. Note, however, that if H is continuous, we can replace $\partial u(\tau, \xi)$ with $\widehat{\partial} u(\tau, \xi)$ in the above, and the resulting definition of solution will be equivalent to Definition 1.2. As will be seen, the continuity of H is a property that holds in the main theorem below.

Due to the viability approach we will be taking, let us introduce some notation and terminology associated with set-valued mappings. We write $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ to denote a mapping which associates a subset $F(x)$ of $\mathbb{R}^m$ to each point $x \in \mathbb{R}^n$. The graph of F, denoted $\operatorname{gph} F$, is the set of points $\{(x, y) \mid y \in F(x)\}$ in $\mathbb{R}^n \times \mathbb{R}^m$.

Of particular importance are the epigraphical mappings. These are set-valued mappings $E_f : \mathbb{R}^n \rightrightarrows \mathbb{R}^{m+1}$, defined from a function $f : \mathbb{R}^n \times \mathbb{R}^m \to \overline{\mathbb{R}}$ as $E_f(x) = \operatorname{epi} f(x, \cdot\,)$, where

$$\operatorname{epi} f(x, \cdot\,) := \{(v, \alpha) \mid v \in \operatorname{dom} f(x, \cdot\,),\ \alpha \geq f(x, v)\}. \tag{1.9}$$

Thus the graph of E_f corresponds to the epigraph of f, and the sets $E_f(x)$ are closed if and only if $f(x, \cdot\,)$ is lsc for each x.

Another way in which our Theorem 2.2 improves upon previous results is that we are able to relax the Lipschitz behavior of the Lagrangian set-valued mapping E_L. Typically, one defines Lipschitz continuity with respect to the Hausdorff metric. However, epigraphical mappings are unbounded, and placing a Lipschitz assumption on E_L proves to be rather restrictive.

The closed unit ball is denoted by $\mathbb{B}$. To say $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ is *Lipschitz* on some open set W means there exists a constant $k > 0$, a Lipschitz constant, so that

$$F(x') \subset F(x) + k|x' - x|\mathbb{B} \quad \text{for all } x', x \in W. \tag{1.10}$$

The notion of *sub-Lipschitz* continuity relaxes the condition in (1.10) by allowing a truncation on the left-hand side of this inclusion. The Lipschitz constant k is then allowed to grow with the size of the corresponding truncation. Specifically, F is sub-Lipschitz on some open set W if there exists a positive ρ_0 so that for each $\rho > \rho_0$, there exists a $k > 0$, a ρ-Lipschitz constant, so that

$$F(x') \cap \rho\mathbb{B} \subset F(x) + k|x' - x|\mathbb{B} \quad \text{for all } x', x \in W. \tag{1.11}$$

Mordukhovich (section 5 of [24]) shows how one can characterize Lipschitz and sub-Lipschitz properties of a set-valued mapping F through properties of the normal cones $N_{\operatorname{gph} F}(x, v)$ and the associated *coderivative mapping* $D^*F(x|v) : \mathbb{R}^m \to \mathbb{R}^n$ defined as

$$D^*F(x|v)(y) = \{w : (w, -y) \in N_{\operatorname{gph} F}(x, v)\}. \tag{1.12}$$

Moreover, he shows how these coderivatives can lead to bounds for the Lipschitz and ρ-Lipschitz constants (see also section 9.F of [27]). For an epigraphical set-valued mapping E_f, the coderivative can be expressed using the general and horizon subgradients of f.

Our uniqueness result applies to cases where the epigraphical mapping of the Lagrangian has a special kind of sub-Lipschitz behavior. This Lipschitz condition is given in a subgradient form on the Hamiltonian as assumption (A2) in the next section. This subgradient expression is placing bounds on a certain coderivative mapping.

Throughout this paper, H will be seen to depend on t for $t \in \mathbb{R}$, while (1.8) implies that the behavior of $H(t, x, p)$ for $t < 0$ has no effect on our notion of solution. The reason for defining H on a larger domain than is necessary is to avoid complications that may arise with relative neighborhoods of points (t, x). This shouldn't present a problem if we have a Hamiltonian defined only for $t \geq 0$. By setting $H(t, x, p) = H(0, x, p)$ for $t < 0$, we can easily extend the domain of H without affecting (1.8). We can extend L in the same manner.

2. Statement of the main result.

The main result of this paper is Theorem 2.2, which depends upon the assumptions (A) and (A0)–(A2) given below. After a comparison with other uniqueness results in the literature, the latter half of this section gives some implications of (A1) and (A2) as well as connections between the Hamiltonian and the Lagrangian under these assumptions.

When we say that a function u exhibits *linear growth*, we mean there exists a constant $k > 0$ so that $|u(x)| \leq k(1 + |x|)$ for all x. It will be useful to define the class of functions which have only "half" linear growth, in that no restrictions are placed on how the positive values of u may behave.

Definition 2.1. *A function $u : \mathbb{R}^n \to \overline{\mathbb{R}}$ satisfies the lower linear growth (LLG) condition if there exists $k > 0$ such that*

$$u(x) \geq -k(1 + |x|) \quad \textit{for all} \quad x \in \mathbb{R}^n. \tag{2.1}$$

A function $u : \mathbb{R} \times \mathbb{R}^n \to \overline{\mathbb{R}}$ satisfies the uniform lower linear growth (ULLG) condition if for each $T > 0$, there exists $k > 0$ such that

$$u(t, x) \geq -k(1 + |x|) \quad \textit{for all } (t, x) \in [-T, T] \times \mathbb{R}^n. \tag{2.2}$$

These mild conditions are effectively ruling out countercoercivity in the state variable, but not necessarily in t. A function f is *coercive* if it is bounded from below and $\liminf_{|x|\to\infty} f(x)/|x| = +\infty$, and f is *countercoercive* if $\liminf_{|x|\to\infty} f(x)/|x| = -\infty$. For example, the function $u(t,x) = -t^2$ satisfies the ULLG condition, whereas $u(t,x) = -|x|^2$ does not.

Basic assumption. We have a Hamiltonian $H : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$.

(A) *$H(t,x,\,\cdot\,)$ is proper, lsc, and convex for each $(t,x) \in \mathbb{R} \times \mathbb{R}^n$.*

Initial cost assumption. We have an extended-real-valued function $\varphi : \mathbb{R}^n \to \overline{\mathbb{R}}$.

(A0) *The function φ is proper, lsc, and satisfies the LLG condition* (2.1).

Hamiltonian assumptions. We have a Hamiltonian $H : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$.

(A1) *There exists a convex, nondecreasing function $\mu : [0,\infty) \to \mathbb{R}$ and positive constants α and β so that*

$$H(t,x,p) \le \mu(|p|) + (|t| + |x|)(\beta + \alpha|p|) \quad \textit{for all } (t,x,p) \in \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n.$$

(A2) *H is lsc on $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n$, and for each $(\bar{t},\bar{x}) \in \mathbb{R} \times \mathbb{R}^n$, there exists a neighborhood W of $(\bar{t},\bar{x})$ and a positive constant k so that at every point $(t,x,p) \in W \times \mathbb{R}^n$, every $(w_1,w_2,v) \in \partial H(t,x,p)$ satisfies*

$$|(w_1,w_2)| \le k(1 + |v| + |L(t,x,v)|)(1 + |p| + |H(t,x,p)|). \tag{2.3}$$

Assumption (A1) is a mild growth condition on H that is directly related to the *stronger growth condition* introduced by Rockafellar [25] to help guarantee the existence of optimal arcs in generalized Bolza problems. Note that taken together, (A) and (A1) imply that for each (t,x), H is finite and convex in p, which forces H to be continuous in p (see Corollary 2.36 in [27]).

Assumption (A2) is a special kind of sub-Lipschitz behavior of the epigraphical mapping $E_H : \mathbb{R} \times \mathbb{R}^n \rightrightarrows \mathbb{R}^{n+1}$, where E_H is defined as

$$E_H(t,x) = \operatorname{epi} H(t,x,\,\cdot\,). \tag{2.4}$$

See Proposition 2.6 below for a connection with the epigraphical mapping E_L of the Lagrangian.

The main theorem below shows that the value function is the unique solution to (1.1) among the class of functions satisfying the ULLG condition.

THEOREM 2.2 (existence and uniqueness). *Under* (A) *and* (A0)–(A2)*, the value function V satisfies the ULLG condition and is a solution to the Cauchy problem* (1.1) *for the Hamilton–Jacobi equation, in the sense given by Definition* 1.2.

Furthermore, if a function u is a solution to (1.1) *as given by Definition* 1.2*, and u satisfies the ULLG condition, then u must be the value function V.*

The proof of the theorem is contained in section 6.

Let us now compare our uniqueness result of Theorem 2.2 to others in the literature. We begin by mentioning that most of the uniqueness (or, comparison) results for viscosity solutions place no convexity assumptions on the Hamiltonian. However, convexity of $H(t,x,p)$ with respect to p will be present in any optimization context, due to the definition of the Hamiltonian as a maximization of functions affine in p.

Viscosity solutions are defined as functions satisfying a pair of inequalities. Originally, the definition was given in terms of smooth support functions, but we can equivalently define them using regular subgradients. A usc function u is termed a *viscosity subsolution* if

$$w + H(t,x,p) \le 0 \quad \text{whenever} \quad (w,p) \in -\widehat{\partial}(-u)(t,x),$$

whereas an lsc function u is a *viscosity supersolution* if

$$w + H(t,x,p) \geq 0 \quad \text{whenever} \quad (w,p) \in \widehat{\partial} u(t,x).$$

A viscosity solution is a continuous function which is simultaneously a subsolution and a supersolution.

Initially in [10], [11], the uniqueness results for viscosity solutions were rather restrictive as they gave uniqueness only over the class of bounded, uniformly continuous functions. Furthermore, the Hamiltonian was also required to have uniform continuity properties in all its variables.

These restrictions were relaxed somewhat in later papers. In [12] the boundedness assumption on the viscosity solution was removed, but the solution was still required to be uniformly continuous. The uniqueness of solutions was extended to the class of all continuous functions in [13], but the Hamiltonian was required to have a certain uniform continuity property and exhibit linear growth in p. The assumptions on the Hamiltonian were subsequently relaxed in [14] and [19]; however, the class of solutions had to be restricted to those with linear growth in the state variable and uniformly continuous initial condition.

For lsc solutions, the uniqueness result of [16] uses hypotheses similar to those in [31] and which are more general than those appearing in [7] or [6]. One assumption is the Lipschitz behavior in x of the mapping $\operatorname{epi} L(t,x,\cdot)$. Another assumption in [16] is that the Hamiltonian be positively homogeneous in p. This is not quite as restrictive as it first seems. For example, through a change of variables, any Bolza problem that has L of the form $L(t,x,v) = L_0(t,x,v) + \Psi_{F(t,x)}(v)$, with L_0 locally Lipschitz in v and F a locally Lipschitz compact set-valued mapping, is covered with such H. Still, this corresponds to a class of Hamiltonians H which, among other properties, must exhibit linear growth in p.

By way of a different change of variables, Subbotin (section 5 of [30]) shows how one can convert a Hamiltonian H into one which is positively homogeneous. Given $H : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$, define $h : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}$ via

$$h(t,x,r,p) = |r| H(t,x,p/|r|) \quad \text{if } r \neq 0. \tag{2.5}$$

For $r = 0$, take limits in the above expression so that h is continuous in (r,p). Then h is positively homogeneous in (r,p). (Although [30] doesn't require convexity, note that in general, h will not be convex in (r,p) unless we restrict $r \geq 0$.) In order to use this technique to gain uniqueness under the original H, the new Hamiltonian h must satisfy certain continuity conditions (for now, let us fix some (t,x) and just write $H(p)$ and $h(r,p)$). These conditions (H5 in [30]) state that h must be Lipschitz continuous on the set where $|p|^2 + r^2 \leq 1$. Assume, as in our Bolza problem context, that $H(p)$ is convex and is dual to a convex Lagrangian $L(v)$. Through subgradient calculus one can show that if $(w,v) \in \partial h(r,p)$ for some (r,p) with $r > 0$, then $v \in \partial H(p/r)$ and $w = -L(v)$. In order for h to be locally Lipschitz at $(0,0)$, $H(p)$ must be globally Lipschitz and thus have linear growth. Again, this corresponds to the Lagrangian having a bounded essential domain. But there is something even more restrictive here. With a bounded essential domain, it is still possible that L may be unbounded on this set. Assume there exists a bounded sequence v^ν with $L(v^\nu)$ unbounded. Then one can find $(r^\nu, p^\nu) \to (0,0)$ with $r^\nu > 0$ and $(-L(v^\nu), v^\nu) \in \partial h(r^\nu, p^\nu)$, so that these subgradients become unbounded, and there is no hope for h to satisfy the required Lipschitz condition.

Frankowska and Plaskasz [17] use the techniques from [16] to obtain uniqueness for lsc solutions in which state constraints are present, something which we do not consider in this paper. In [17], the Bolza problem is presented in an optimal control form. If one converts this control problem into the form $(P_{\tau,\xi})$, assumptions on the dynamics $\dot{x}(t) = f(t, x(t), u(t))$ once again force the velocity to be bounded and the Hamiltonian to have linear growth in p.

Our result covers a broader class of Hamiltonians, as there is absolutely no restriction on the growth of H other than the mild condition (A1), and in this sense Theorem 2.2 improves on previous results. Also, we can now deal with cases where the Hamiltonian does possess linear growth but arises from a Lagrangian that is unbounded in v on its essential domain (as in the discussion on [30] above). Moreover, the assumption (A2) introduces a sub-Lipschitz behavior for epigraphical set-valued mappings of a much greater scope than that of Lipschitz continuity. We hope to devote a separate paper to provide examples and an analysis of the assumption (A2), including the case of mappings which have a fully convex graph.

Rockafellar and Wolenski [28] provide an analysis of the value function and Hamilton–Jacobi theory in an autonomous, fully convex Lagrangian case. They do not present a uniqueness result, but rather they give regularity properties of the value function, develop a method of characteristics, and examine connections to a dual Bolza problem.

Let us note that (A1) and (A2) force the same restrictions on H in t and x jointly. This is not the case in [16]. If we take the case where L is of the form $\Psi_{F(t,x)}(v)$, then our assumptions would require that F be a locally Lipschitz set-valued mapping in (t, x) with compact, convex images. The assumptions in [16] would require, generally speaking, that F be locally Lipschitz in x and only continuous in t. Thus there are certain Hamiltonians not satisfying our assumptions, to which the results of Frankowska's paper can be applied.

The remainder of this section contains some lemmas and propositions giving implications of the hypotheses (A1) and (A2). These will be useful in later sections and in the proof of Theorem 2.2.

LEMMA 2.3. *Assume* (A) *and* (A2) *hold. Then for any* (t, x, p), *if* $(w_1, w_2, 0) \in \partial^\infty H(t, x, p)$, *then* $(w_1, w_2) = (0, 0)$.

Proof. Fix $(t, x, p) \in \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n$ and take W and k as given by (A2) and $(w_1, w_2, v) \in \partial^\infty H(t, x, p)$. This means there exist sequences $(t^\nu, x^\nu, p^\nu) \to (t, x, p)$ with $H(t^\nu, x^\nu, p^\nu) \to H(t, x, p)$ and $\lambda^\nu(w_1^\nu, w_2^\nu, v^\nu) \to (w_1, w_2, v)$ with $(w_1^\nu, w_2^\nu, v^\nu) \in \widehat{\partial} H(t^\nu, x^\nu, p^\nu)$ and $\lambda^\nu \searrow 0$. Assume that $(t^\nu, x^\nu) \in W$ for each ν. It follows (see Corollary 10.9 of [27]) that $v^\nu \in \widehat{\partial}_p H(t^\nu, x^\nu, p^\nu)$, and convex analysis tells us that $H(t^\nu, x^\nu, p^\nu) + L(t^\nu, x^\nu, v^\nu) = \langle p^\nu, v^\nu \rangle$ for each ν. Now using the inequality from (A2), we see that

(2.6)
$$\begin{aligned} |(w_1^\nu, w_2^\nu)| \le{}& k(1 + |v^\nu| + |L(t^\nu, x^\nu, v^\nu)|)(1 + |p^\nu| + |H(t^\nu, x^\nu, p^\nu)|) \\ \Rightarrow |\lambda^\nu(w_1^\nu, w_2^\nu)| \le{}& k(\lambda^\nu + |\lambda^\nu v^\nu| + |\lambda^\nu L(t^\nu, x^\nu, v^\nu)|)(1 + |p^\nu| + |H(t^\nu, x^\nu, p^\nu)|) \\ ={}& k(\lambda^\nu + |\lambda^\nu v^\nu| \\ &+ |\lambda^\nu(\langle v^\nu, p^\nu \rangle - H(t^\nu, x^\nu, v^\nu))|)\,(1 + |p^\nu| + |H(t^\nu, x^\nu, p^\nu)|) \\ \Rightarrow |(w_1, w_2)| \le{}& k(|v| + |\langle v, p \rangle|)(1 + |p| + |H(t, x, p)|). \end{aligned}$$

Thus if $v = 0$, this forces $(w_1, w_2) = (0, 0)$. □

The horizon subgradient condition present in Lemma 2.3 can also be expressed in terms of the coderivative D^*E_H of the set-valued mapping E_H (see (1.12)). The lemma is saying that $D^*E_H((t,x)|(p,y))(0) = \{0\}$ at every point (t,x,p,y) in the epigraph of H, from which it follows by the result of Mordukhovich [24, Thm. 5.7] that E_H has the *Aubin property* at every point of the graph of E_H (originally called the pseudo-Lipschitz property as introduced in [2]). In particular, this gives us the following proposition.

PROPOSITION 2.4. *Assume $H(t,x,\cdot)$ is finite and convex for each $(t,x) \in \mathbb{R}\times\mathbb{R}^n$ and that* (A2) *holds (this is true in particular when* (A), (A1)*, and* (A2) *hold). Then H is locally Lipschitz continuous at every $(t,x,p) \in \mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^n$.*

Proof. Fix (t,x,p). Showing H is locally Lipschitz at this point is equivalent to showing that $\partial^\infty H(t,x,p) = \{(0,0,0)\}$. This equivalence is proved in [27, Thm. 9.13]. Take $(w_1,w_2,v) \in \partial^\infty H(t,x,p)$. From Lemma 2.3, it suffices to show that v must be 0.

Take sequences defining (w_1,w_2,v) as in the proof of Lemma 2.3. The Aubin property at every point of the graph of the mapping E_H implies that E_H is continuous with respect to Painlevé–Kuratowski set convergence [27, Thm. 9.38] and that H has the so-called *epi-continuity property* discussed in [26]. This epi-continuity property of H leads to a result of Attouch [27, Thm. 12.35] which says that the subgradient mappings $\widehat{\partial}_p H(t^\nu,x^\nu,\,\cdot\,)$ graphically converge to $\widehat{\partial}_p H(t,x,\,\cdot\,)$. Since $H(t,x,\,\cdot\,)$ is finite and convex, $\widehat{\partial}_p H(t,x,p)$ is convex, nonempty, and bounded. This implies [27, Ex. 5.34] the existence of finite constants R and N such that $\widehat{\partial}_p H(t^\nu,x^\nu,p^\nu) \subset R\mathbb{B}$ for $\nu \geq N$. But we have that $v^\nu \in \widehat{\partial}_p H(t^\nu,x^\nu,p^\nu)$, so $|v^\nu| \leq R$ for $\nu \geq N$. Since $\lambda^\nu \searrow 0$, we must have $v = 0$. □

LEMMA 2.5. *Assume $H(t,x,\,\cdot\,)$ is finite and convex for each $(t,x) \in \mathbb{R}\times\mathbb{R}^n$ and that* (A2) *holds. Then at every $(\bar{t},\bar{x}) \in \mathbb{R}\times\mathbb{R}^n$, there exists a neighborhood W of $(\bar{t},\bar{x})$ and a positive constant k such that*

$$H(t,x,p) \geq -k(1+|p|) \quad \textit{for all } (t,x,p) \in W\times\mathbb{R}^n.$$

Proof. Take $(\bar{t},\bar{x}) \in \mathbb{R}\times\mathbb{R}^n$. Proposition 2.4 gives us a neighborhood $W_1\times W_2 \subset \mathbb{R}^{n+1}\times\mathbb{R}^n$ of $(\bar{t},\bar{x},0)$ on which H is Lipschitz. This implies the existence of $k_1 > 0$ such that $\widehat{\partial} H(t,x,0) \subset k_1\mathbb{B}$, which in turn says that $\widehat{\partial}_p H(t,x,0) \subset k_1\mathbb{B}$ for all $(t,x) \in W_1$. The Lipschitz property of H also implies that $H(t,x,0) \geq -k_2$ for some $k_2 > 0$ for $(t,x) \in W_1$. Finally, $H(t,x,\,\cdot\,)$ being a convex function gives us that

$$\begin{aligned} H(t,x,p) &\geq H(t,x,0) + \langle v,p\rangle \\ &\geq -k_2 - k_1|p| \end{aligned}$$

if $v \in \widehat{\partial}_p H(t,x,0)$ and $(t,x,p) \in W_1\times\mathbb{R}^n$. Now let $k = \max\{k_1,k_2\}$. □

PROPOSITION 2.6. *Take a dual pair H and L, with both $H(t,x,\,\cdot\,)$ and $L(t,x,\,\cdot\,)$ proper, lsc, and convex for every (t,x) where L can be derived from H via* (1.2) *and H can be derived from L via* (1.3)*. Then the following are equivalent.*

(i) (A2) *holds for H.*

(ii) *L is lsc on $\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^n$, and for each $(\bar{t},\bar{x})$, there exists a neighborhood W of $(\bar{t},\bar{x})$ and a positive constant k so that at every point $(t,x,v) \in W\times\mathbb{R}^n$, every $(w_1,w_2,p) \in \partial L(t,x,v)$ satisfies the relation given by* (2.3).

Proof. Assume (i). In the proof of Proposition 2.4 we saw that H has the epi-continuity property as described in [26]. Theorem 11.34 of [27] says that then L also has the epi-continuity property, which implies that the epigraph of L is closed, and so L is lsc on $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n$.

To show that the subgradient inequality holds, we would like to use Theorem 3.3 of [26], which requires checking that a condition holds on the horizon subgradients of H. This is exactly the condition shown to hold in Lemma 2.3, and so using [26, Thm. 3.3] we can conclude that, for any given (t, x, v, p),

$$\operatorname{con}\{(w_1, w_2) | (w_1, w_2, p) \in \partial L(t, x, v)\} = - \operatorname{con}\{(w_1, w_2) | (w_1, w_2, v) \in \partial H(t, x, p)\}.$$

Now choose $(\bar{t}, \bar{x})$, bounded neighborhood W, and constant k as given in (2.3). Take $(w_1, w_2, p) \in \partial L(t, x, v)$ for $(t, x, v) \in W \times \mathbb{R}^n$. Then (w_1, w_2) can be written as a finite, convex combination of points in the set $\{(-w_1', -w_2') | (w_1', w_2', v) \in \partial H(t, x, p)\}$. But this implies that

$$\begin{aligned} |(w_1, w_2)| &\le \sup\{|(-w_1', -w_2')| \bigm| (w_1', w_2', v) \in \partial H(t, x, p)\} \\ &\le k(1 + |v| + |L(t, x, v)|)(1 + |p| + |H(t, x, p)|), \end{aligned}$$

the second inequality following by assumption (i). Thus (ii) holds at $(\bar{t}, \bar{x})$ with the same constant k for our neighborhood W.

If we begin instead by assuming (ii), the entire argument presented above will go through, since at every step each result holds symmetrically in L as in H, and we can conclude that (i) holds. □

3. Viability and the value function. The concepts of viability and invariance of a differential inclusion (sometimes called weak invariance and strong invariance) are essential in the proof of Theorem 2.2. It will be seen that the epigraph of the value function is both viable and invariant with respect to a certain *unbounded* differential inclusion. The italics are meant to stress that this is an uncommon assumption. If one were to examine the main theorems on differential inclusions in texts such as [1], [3], [9], or [15], it becomes immediately apparent that set-valued mappings with compact images are the focus.

To study the viability properties of $\operatorname{epi} V$ it will be essential for us to know that this is a closed set and that solutions to the unbounded differential inclusion exist. This leads us to the following.

PROPOSITION 3.1. *Assume we have φ satisfying* (A0) *and a Lagrangian L which is lsc in all variables and that $L(t, x, \cdot\,)$ is proper and convex for each $(t, x) \in \mathbb{R} \times \mathbb{R}^n$. Further assume that* (A1) *holds for H derived from L via* (1.3). *Then the value function V for $(\mathcal{P}_{\tau,\xi})$ has the following properties.*

(a) *V is proper and lower semicontinuous on $\mathbb{R} \times \mathbb{R}^n$.*

(b) *At every $(\tau, \xi) \in \operatorname{dom} V$, there exists an optimal arc achieving the value $V(\tau, \xi)$ in $(\mathcal{P}_{\tau,\xi})$.*

Proof. Take (τ, ξ) with $V(\tau, \xi) < +\infty$ and consider the functional

$$x(\,\cdot\,) \mapsto l(x(0), x(\tau)) + \int_0^\tau L(t, x(t), \dot{x}(t))dt,$$

where $l(x(0), x(\tau)) = \varphi(x(0)) + \Psi_{\{\xi\}}(x(\tau))$. Minimizing this functional over all $x(\cdot) \in \mathcal{A}_n[0, \tau]$ is equivalent to $(\mathcal{P}_{\tau,\xi})$. The hypotheses given allow us to use "Existence Theorem 2" of [25] to conclude that the above functional attains its minimum. Thus there exists some absolutely continuous arc $x(\,\cdot\,)$ achieving the minimum in $(\mathcal{P}_{\tau,\xi})$, and (b) holds.

To see that the minimum value is not $-\infty$, note that $L(t,x,v) \geq -H(t,x,0)$ for all v, and so if x is our optimal arc, there exists a constant M with $|x(t)| \leq M$ for all $t \in [0,\tau]$, giving us

$$\begin{aligned} V(\tau,\xi) &\geq \varphi(x(0)) - \int_0^\tau H(t,x(t),0)dt \\ &\geq \varphi(x(0)) - \int_0^\tau \mu(0) + \sigma(|t| + |x(t)|)dt \\ &\geq \varphi(x(0)) - \int_0^\tau \mu(0)dt - \int_0^\tau \sigma(\tau + M)dt \\ &> -\infty. \end{aligned}$$

That V is not identically $+\infty$ follows since $V(0,\xi) = \varphi(\xi)$ and φ is proper. Thus V is a proper function.

It remains to show that V is lsc. Let $K = [a,b] \times \widetilde{K} \subset \mathbb{R} \times \mathbb{R}^n$ be a compact set with $0 \leq a < b$. For each $\tau \geq 0$ and $x(\,\cdot\,) \in \mathcal{A}_n^1[0,\tau]$, let

$$\gamma_K(\tau, x(\,\cdot\,)) = \varphi(x(0)) + \Psi_K(\tau, x(\tau)) + \int_0^\tau L(t,x(t),\dot{x}(t))dt.$$

For each $\alpha \in \mathbb{R}$, define the set $A_K^\alpha \subset \mathbb{R} \times \mathbb{R}^n$ as

$$A_K^\alpha := \{(\tau, x(\tau)) \mid \gamma_K(\tau, x(\,\cdot\,)) \leq \alpha \quad \text{for some} \quad (\tau, x(\,\cdot\,))\}.$$

These sets are related to the lower level sets of V as follows:

$$A_K^\alpha = K \cap \operatorname{lev}_{\leq\alpha} V,$$

where the notation $\operatorname{lev}_{\leq\alpha} f$ denotes the set $\{\, x \mid f(x) \leq \alpha \,\}$. So if for every compact K, A_K^α is compact for each α, this shows the lower level sets of V are closed, and V is lsc. To accomplish this, we will use the Erdmann transform to convert the above problem into one with fixed time. Let

$$L_0(t,x,v,\lambda) = \begin{cases} \Psi_{\{0\}}(v) & \text{if} \quad \lambda = 0, \\ \lambda L(t,x,v/\lambda) & \text{if} \quad \lambda > 0, \\ +\infty & \text{otherwise.} \end{cases}$$

Note that since $L(t,x,\,\cdot\,)$ is proper, convex, and coercive, $L_0(t,x,\,\cdot\,,\,\cdot\,)$ will be proper, convex, and lsc. For arcs $(\theta(\,\cdot\,), \zeta(\,\cdot\,)) \in \mathcal{A}_{n+1}^1[0,1]$ consider the functional

$$\Gamma_K(\theta(\,\cdot\,), \zeta(\,\cdot\,)) = l(\theta(0), \zeta(0), \theta(1), \zeta(1)) + \int_0^1 L_K(\theta(s), \zeta(s), \dot{\zeta}(s), \dot{\theta}(s))ds,$$

where we define $l(\theta(0), \zeta(0), \theta(1), \zeta(1)) = \Psi_{\{0\}}(\theta(0)) + \varphi(\zeta(0)) + \Psi_K(\theta(1), \zeta(1))$ and $L_K(t,x,v,\lambda) = L_0(t,x,v,\lambda) + \Psi_{[a,b]}(\lambda)$. Now consider the sets

$$B_K^\alpha := \{(\theta(1), \zeta(1)) \mid \Gamma_K(\theta(\,\cdot\,), \zeta(\,\cdot\,)) \leq \alpha \text{ for some } (\theta(\,\cdot\,), \zeta(\,\cdot\,))\}.$$

The function $\Psi_{\{0\}}(\theta(0)) + \varphi(\zeta(0))$ is not countercoercive on $\mathbb{R}^{n+1}$, while $\Psi_K(\,\cdot\,,\,\cdot\,)$ is coercive, since K is compact. Furthermore, the Hamiltonian corresponding to

L_K satisfies (A1), the stronger growth condition, and we can apply the results of "Existence Theorem 2" of [25] to conclude that the level sets

$$\{(\theta(\,\cdot\,),\zeta(\,\cdot\,)) \mid \Gamma_K(\theta(\,\cdot\,),\zeta(\,\cdot\,)) \le \alpha\}$$

are compact in the norm topology of continuous arcs from $[0,1]$ to $\mathbb{R}^{n+1}$, where the norm is the usual supremum norm. Thus B_K^α must be compact.

Now we need to relate B_K^α to A_K^α. Fix α and K, and take $(\tau, x(\tau)) \in A_K^\alpha$. Let $\theta(s) = \tau s$ and $\zeta(s) = x(\tau s)$. Note that $\tau \in [a,b]$, and $\Gamma_K(\theta(\cdot),\zeta(\cdot)) = \gamma_K(\tau, x(\cdot)) \le \alpha$. Also, $(\theta(1),\zeta(1)) = (\tau, x(\tau))$, so we have $A_K^\alpha \subset B_K^\alpha$.

If we take $K = [a,b] \times \widetilde{K}$ with $a > 0$ and consider an arc for which $\Gamma_K(\theta(\cdot),\zeta(\cdot)) \le \alpha$, then necessarily $\dot{\theta}(s) \ge a > 0$ for a.e. $s \in [0,1]$ and θ is then strictly increasing and invertible. If we then let $\tau = \theta(1)$ and $x(t) = \zeta(\theta^{-1}(t))$, substituting these arcs into the functionals above, we find $\gamma_K(\tau, x(\,\cdot\,)) = \Gamma_K(\theta(\,\cdot\,),\zeta(\,\cdot\,)) \le \alpha$, and $(\tau, x(\tau)) = (\theta(1),\zeta(1))$, showing that $B_K^\alpha \subset A_K^\alpha$. Combining this with the opposite inclusion from the previous paragraph, we see that A_K^α is compact for every α and every compact set $K = [a,b] \times \widetilde{K}$ when $a > 0$. This implies that V is lsc at every (τ,ξ) with $\tau > 0$.

To see that V is also lsc at points $(0,\xi)$, consider compact $K = [0,b] \times \widetilde{K}$, and note that if $(0,\xi) = (\theta(1),\zeta(1)) \in B_K^\alpha$, then $\dot{\theta}(s) = 0$ for a.e. s, which forces $\dot{\zeta}(s) = 0$ for a.e. s, from the way L_0 is defined. Thus $\zeta(1) = \zeta(0)$ and $\Gamma_K(\theta(\cdot),\zeta(\cdot)) = \varphi(\zeta(0))$, so $\zeta(1) \in \operatorname{lev}_{\le\alpha}\varphi$. On the other hand, if we take any $\xi \in \widetilde{K} \cap \operatorname{lev}_{\le\alpha}\varphi$, the constant arc $(\theta(s),\zeta(s)) = (0,\xi)$ gives $\Gamma_K(\theta(\,\cdot\,),\zeta(\,\cdot\,)) = \varphi(\xi) \le \alpha$, so we have shown that

$$B_K^\alpha \cap (\{0\} \times \mathbb{R}^n) = \{0\} \times (\widetilde{K} \cap \operatorname{lev}_{\le\alpha}\varphi).$$

We also know from above that B_K^α is compact and that $A_K^\alpha \subset B_K^\alpha$. So take $\xi \in \operatorname{dom}\varphi$ and $\widetilde{K}$ so that ξ lies in the interior of $\widetilde{K}$. Take $b > 0$ and any sequence $(\tau^\nu,\xi^\nu) \to (0,\xi)$ with $(\tau^\nu,\xi^\nu) \in A_K^\alpha$. So in fact (τ^ν,ξ^ν) must lie in B_K^α, whose compactness forces $(0,\xi) \in B_K^\alpha$, and so from (4.1) we have $\varphi(\xi) \le \alpha$. It must be the case then that $\liminf_{(\tau^\nu,\xi^\nu)\to(0,\xi)} V(\tau^\nu,\xi^\nu) \ge \varphi(\xi) = V(0,\xi)$, and so V is lsc at every point in its effective domain. □

At this point we introduce the set-valued mapping $\widetilde{E}_L : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \rightrightarrows \mathbb{R}^{n+2}$ as

$$\widetilde{E}_L(t,x,y) := \ \{1\} \times \operatorname{epi} L(t,x,\,\cdot\,).$$

The variable $y \in \mathbb{R}$ can be thought of as an "epigraphical variable" since we will typically be considering the setting where the points $(t,x,y) \in \operatorname{epi} V$. We wish to establish that the value function is the unique function which satisfies an endpoint condition and is simultaneously viable and invariant in a certain way with respect to $\widetilde{E}_L$.

PROPOSITION 3.2. *Assume* (A) *and* (A0)–(A2). *A function* $u : \mathbb{R} \times \mathbb{R}^n \to \overline{\mathbb{R}}$ *is the value function for* $(\mathcal{P}_{\tau,\xi})$ *if and only if it satisfies the following properties.*

(P1) *u is proper and lsc on* $\mathbb{R} \times \mathbb{R}^n$ *with* $\operatorname{dom} u \subset [0,\infty) \times \mathbb{R}^n$.

(P2) $u(0,\xi) = \varphi(\xi)$ *for all* $\xi \in \mathbb{R}^n$.

(P3) *(backward viability). For all* $(\tau,\xi,\beta) \in \operatorname{epi} u$, *there exists an absolutely continuous arc* $z(\,\cdot\,) = (t(\,\cdot\,), x(\,\cdot\,), y(\,\cdot\,))$ *such that*

(i) $z(\,\cdot\,)$ *is defined on* $[0,\tau]$, (ii) $z(0) = (\tau,\xi,\beta)$, (iii) $\dot{z}(s) \in -\widetilde{E}_L(z(s))$ *for a.e.* $s \in [0,\tau]$, *and* (iv) $z(s) \in \operatorname{epi} u$ *for all* $s \in [0,\tau]$.

(P4) *(forward invariance). For all* $(\tau,\xi,\beta) \in \operatorname{epi} u$, *for all* $r > 0$, *if an absolutely continuous arc* $z(\,\cdot\,) = (t(\,\cdot\,), x(\,\cdot\,), y(\,\cdot\,))$ *satisfies*

(i) $z(\,\cdot\,)$ *is defined on* $[0,r]$*,* (ii) $z(0)=(\tau,\xi,\beta)$*, and* (iii) $\dot z(s)\in \widetilde{E}_L(z(s))$ *for a.e.* $s\in[0,r]$*, then* $z(\,\cdot\,)$ *must also satisfy* (iv) $z(s)\in \operatorname{epi} u$ *for all* $s\in[0,r]$*.*

Proof. Take the value function V. By definition of V, $\operatorname{dom} V\subset[0,\infty)\times\mathbb{R}^n$, and also (P2) holds. Proposition 3.1(a) guarantees that the rest of condition (P1) holds. To show (P3), take $(\tau,\xi,\beta)\in\operatorname{epi}V$. Let $\bar x(\,\cdot\,)$ be an optimal arc for $(\mathcal{P}_{\tau,\xi})$, its existence guaranteed by Proposition 3.1(b). By the principle of optimality, we have $V(\tau',\bar x(\tau'))=\varphi(\bar x(0))+\int_0^{\tau'}L(t,\bar x(t),\dot{\bar x}(t))dt$ for all $\tau'\in[0,\tau]$. Thus the arc

$$z(s)=\left(\tau-s,\ \bar x(\tau-s),\ \varphi(\bar x(0))+\int_0^{\tau-s}L(t,\bar x(t),\dot{\bar x}(t))\,dt+\beta-V(\tau,\xi)\right)$$

satisfies (P3) since

$$\begin{aligned}\varphi(\bar x(0))+\int_0^{\tau-s}L(t,\bar x(t),\dot{\bar x}(t))dt+\beta-V(\tau,\xi)&=V(\tau-s,\bar x(\tau-s))+(\beta-V(\tau,\xi))\\&\geq V(\tau-s,\bar x(\tau-s))\end{aligned}$$

for all $s\in[0,\tau]$, and so $z(s)\in\operatorname{epi}V$ for all s. Also, we see that

$$\dot z(s)=(-1,-\dot{\bar x}(\tau-s),-L(\tau-s,\bar x(\tau-s),\dot{\bar x}(\tau-s)))\in-\widetilde{E}_L(z(s)).$$

Assume we have an arc $z(\,\cdot\,)$ satisfying (i)–(iii) of (P4). Then for any $\tau'\in[0,r]$, we have

$$\begin{aligned}y(\tau')=\beta+\int_0^{\tau'}\dot y(s)ds&\geq\beta+\int_0^{\tau'}L(\tau+s,x(s),\dot x(s))ds\\&\geq\beta+V(\tau'+\tau,x(\tau'))-V(\tau,x(\tau))\\&\geq V(\tau'+\tau,x(\tau')),\end{aligned}$$

and thus $z(s)\in\operatorname{epi}V$ for $s\in[0,r]$.

Now assume u satisfies (P1)–(P4). Clearly $u(\tau,\xi)=V(\tau,\xi)$ if $\tau\leq0$. So fix (τ,ξ) with $\tau>0$. Let $\beta=u(\tau,\xi)$. By (P3) there exists an arc $(t(\,\cdot\,),x(\,\cdot\,),y(\,\cdot\,))$ with $(t(0),x(0),y(0))=(\tau,\xi,\beta)$ and $(t(\tau),x(\tau),y(\tau))\in\operatorname{epi}u$. But the differential inclusion that our arc satisfies means $\dot t(s)=-1$ and so $t(s)=\tau-s$ and $t(\tau)=0$. Thus $y(\tau)\geq\varphi(x(\tau))$. Now if we imagine running our arc backward via the new arc $(\bar t(s),\bar x(s),\bar y(s))=(t(\tau-s),x(\tau-s),y(\tau-s))$, we get that $\bar t(s)=s$ and $\dot{\bar y}(s)\geq L(s,\bar x(s),\dot{\bar x}(s))$ and so

$$\begin{aligned}\beta=\bar y(0)+\int_0^{\tau}\dot{\bar y}(s)ds&\geq y(\tau)+\int_0^{\tau}L(s,\bar x(s),\dot{\bar x}(s))ds\\&\geq\varphi(\bar x(0))+\int_0^{\tau}L(s,\bar x(s),\dot{\bar x}(s))ds\\&\geq V(\tau,\xi),\end{aligned}$$

showing that $u(\tau,\xi)\geq V(\tau,\xi)$.

Now using (P4), let $\bar x(\,\cdot\,)$ be a minimizing arc giving the value of $V(\tau,\xi)$. We have then $(0,\bar x(0),\varphi(\bar x(0)))\in\operatorname{epi}u$ by (P2). Let $\bar t(s)=s$ and $\bar y(s)=\varphi(\bar x(0))+\int_0^s L(w,\bar x(w),\dot{\bar x}(w))dw$. Then the arc $z(\,\cdot\,)=(\bar t(\,\cdot\,),\bar x(\,\cdot\,),\bar y(\,\cdot\,))$ satisfies (i)–(iii) of (P4). Set $r=\tau$ and so $z(\tau)\in\operatorname{epi}u$. But since $\bar y(\tau)=V(\tau,\xi)$, we must have that $u(\tau,\xi)\leq V(\tau,\xi)$. □

4. Monotonicity and the reachable set. In the previous section it was seen that the value function uniquely satisfies certain invariance and viability properties. The goal now is to characterize these properties with the monotone behavior of a certain *reachable set.*

First consider a general setup as follows. We have a closed set $K \subset \mathbb{R}^n$ and a set valued mapping $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$. Under the differential inclusion $\dot{x}(t) \in F(x(t))$, we can define the *forward solution set* $\mathcal{S}_K^+(t)$ and the *backward solution set* $\mathcal{S}_K^-(t)$ to be

$$\mathcal{S}_K^+(t) := \{x(\,\cdot\,) \in \mathcal{A}_n^1([0,t]) \mid x(0) \in K,\ \dot{x}(s) \in F(x(s)) \ \text{ for a.e. } \ s \in [0,t]\},$$
$$\mathcal{S}_K^-(t) := \{x(\,\cdot\,) \in \mathcal{A}_n^1([0,t]) \mid x(0) \in K,\ \dot{x}(s) \in -F(x(s)) \ \text{ for a.e. } \ s \in [0,t]\},$$

and the corresponding reachable set $\mathcal{R}_K(t)$ as

$$\mathcal{R}_K(t) := \{y \in \mathbb{R}^n \mid y = x(t) \ \text{for some} \ x(\,\cdot\,) \in \mathcal{S}_K^+(t)\}.$$

Note that we are not requiring that solutions exist for all times. It is possible that $\mathcal{R}_K(t) = \emptyset$ for some t.

Proposition 4.1. *The following are equivalent.*

(i) *The set K is invariant with respect to the forward solution set. That is, for all $t \geq 0$, every $x(\,\cdot\,) \in \mathcal{S}_K^+(t)$ satisfies $x(s) \in K$ for all $s \in [0,t]$.*

(ii) *For any t_1, t_2 with $t_2 \geq t_1 \geq 0$, we have $\mathcal{R}_K(t_2) \subset \mathcal{R}_K(t_1)$.*

Proof. It should be clear that (ii) implies (i). Assume (i) and take $t_2 \geq t_1 \geq 0$. The set K being invariant tells us that $\mathcal{R}_K(t) \subset K$ for all $t > 0$. It is also true that if $A \subset B$, then $\mathcal{R}_A(t) \subset \mathcal{R}_B(t)$. By its nature, the reachable set satisfies a certain semigroup property which tells us that

$$\mathcal{R}_K(t_2) = \mathcal{R}_{\mathcal{R}_K(t_2-t_1)}(t_1).$$

But $\mathcal{R}_K(t_2 - t_1) \subset K$, and so the right-hand side of the above is contained in the set $\mathcal{R}_K(t_1)$. □

The concept of viability is related to that of invariance. To say that the set K is viable with respect to the backward solution set means for every $t \geq 0$ and for every $x_0 \in K$, there exists an $x(\,\cdot\,) \in \mathcal{S}_K^-(t)$ such that $x(0) = x_0$ and $x(s) \in K$ for all $s \in [0,t]$.

Proposition 4.2. *The following are equivalent.*

(i) *The set K is invariant with respect to the forward solution set and viable with respect to the backward solution set.*

(ii) *$\mathcal{R}_K(t) = K$ for all $t \geq 0$.*

Proof. Assume (i) and take $t_1 \geq 0$. From Proposition 4.1 we know that $\mathcal{R}_K(t) \subset K$. Take any $x_0 \in K$. That K is viable means there is an arc $x(\,\cdot\,)$ with $\dot{x}(t) \in -F(x(t))$, $x(0) = x_0$, and $x(t) \in K$ for all t. Consider the arc $y(t) = x(t_1 - t)$. Then $y \in \mathcal{S}_K^+(t_1)$ with $y(t_1) = x_0$. So $x_0 \in \mathcal{R}_K(t_1)$ giving us that $K \subset \mathcal{R}_K(t_1)$.

If we assume (ii), Proposition 4.1 tells us that K is forward invariant. Let $x_0 \in K$. Then $x_0 \in \mathcal{R}_K(t_1)$ for any $t_1 > 0$. Thus there exists an arc $x(\,\cdot\,) \in \mathcal{S}_K^+(t_1)$ with $x(t_1) = x_0$ and $x(t) \in K$ for $t \in [0, t_1]$. Again, if we consider $y(t) = x(t_1 - t)$, we get $y \in \mathcal{S}_K^-(t_1)$ with $y(0) = x_0$, and so K is viable with respect to the backward solution set. □

Note that we require minimal hypotheses on the set K and the mapping F. In particular, F can have unbounded images.

Now we wish to use this monotonicity property in the setting of the previous section. Proposition 4.2 cannot be applied directly, however, since the time interval on which the epigraph of the value function is viable depends upon the initial point we choose, and thus the general results above should be viewed as a motivating guide for the following proposition.

Proposition 4.3. *Take the set-valued mapping* $\widetilde{E}_L(t,x,y) = \{1\} \times \operatorname{epi} L(t,x,\,\cdot\,)$ *and the corresponding differential inclusion* $\dot{z}(s) \in \widetilde{E}_L(z(s))$. *Assume* $u : \mathbb{R}\times\mathbb{R}^n \to \overline{\mathbb{R}}$ *satisfies* (P1)–(P2) *of Proposition* 3.2. *Then* u *also satisfies* (P3) *and* (P4) *if and only if*

$$\mathcal{R}_{\operatorname{epi} u}(s) = \operatorname{epi} u \cap ([s,\infty)\times\mathbb{R}^n) \quad \textit{for all } s \geq 0.$$

Proof. Assume u satisfies (P1)–(P4). The condition (P4) says that $\operatorname{epi} u$ is invariant with respect to the forward solution set of the differential inclusion $\dot{z}(s) \in \widetilde{E}_L(z(s))$. Thus, by Proposition 4.1 we have $\mathcal{R}_{\operatorname{epi} u}(s) \subset \operatorname{epi} u$. Also, any $z(\,\cdot\,) = (t(\,\cdot\,), x(\,\cdot\,), y(\,\cdot\,))$ satisfying the differential inclusion must have $\dot{t}(s) = 1$ for a.e. s and $t(0) \geq 0$, so $t(s) \geq s$. Thus $\mathcal{R}_{\operatorname{epi} u}(s) \subset \operatorname{epi} u \cap ([s,\infty)\times\mathbb{R}^n)$.

Take $(\tau,\xi,\beta) \in \operatorname{epi} u \cap ([s,\infty)\times\mathbb{R}^n)$. This is equivalent to taking $(\tau,\xi,\beta) \in \operatorname{epi} u$ with $\tau \geq s$. Now take an arc $(t(\cdot), x(\cdot), y(\cdot))$ as in (P3). Since $s \in [0,\tau]$, $z(s) \in \operatorname{epi} u$. If we now consider the arc $\bar{z}(s') = z(s-s')$, we see that $\bar{z}(0) \in \operatorname{epi} u$, $\bar{z}(s) = (\tau,\xi,\beta)$, and $\dot{\bar{z}}(s') \in \widetilde{E}_L(\bar{z}(s'))$. So $(\tau,\xi,\beta) \in \mathcal{R}_{\operatorname{epi} u}(s)$ and we have $\operatorname{epi} u \cap ([s,\infty)\times\mathbb{R}^n) \subset \mathcal{R}_{\operatorname{epi} u}(s)$.

Now take a function u satisfying (P1)–(P2) and such that for all $s \geq 0$, $\mathcal{R}_{\operatorname{epi} u}(s) = \operatorname{epi} u \cap ([s,\infty)\times\mathbb{R}^n)$. Then Proposition 4.1 immediately implies that (P4) holds.

To see that (P3) holds, take $(\tau,\xi,\beta) \in \operatorname{epi} u$. So in fact $(\tau,\xi,\beta) \in \mathcal{R}_{\operatorname{epi} u}(\tau)$, and there exists a solution to the differential inclusion, $\bar{z}(\,\cdot\,) = (\bar{t}(\,\cdot\,), \bar{x}(\,\cdot\,), \bar{y}(\,\cdot\,))$ with $(\bar{t}(0), \bar{x}(0), \bar{y}(0)) \in \operatorname{epi} u$ and $(\bar{t}(\tau), \bar{x}(\tau), \bar{y}(\tau)) = (\tau,\xi,\beta)$. Again, by letting $z(s') = \bar{z}(\tau - s')$, we get an arc satisfying (i)–(iv) of (P3). □

Note that the set-valued mapping $\widetilde{E}_L(t,x,y)$ is independent of y. Thus, if $(\tau,\xi,\beta) \in \mathcal{R}_{\operatorname{epi} u}(s)$ for some s, then in fact $(\tau,\xi,\beta') \in \mathcal{R}_{\operatorname{epi} u}(s)$ for all $\beta' \geq \beta$. This means that the graph of $\mathcal{R}_{\operatorname{epi} u}$ can be thought of as the epigraph of a function whose domain lies in $\mathbb{R}\times\mathbb{R}\times\mathbb{R}^n$. Given $u : \mathbb{R}\times\mathbb{R}^n \to \overline{\mathbb{R}}$, define this associated function $\widetilde{u} : \mathbb{R}\times\mathbb{R}\times\mathbb{R}^n \to \overline{\mathbb{R}}$ as follows:

$$\widetilde{u}(s,\tau,\xi) = \begin{cases} u(\tau,\xi), & 0 \leq s \leq \tau, \\ +\infty & \text{otherwise.} \end{cases} \tag{4.1}$$

In other words, $\operatorname{epi} \widetilde{u}(s,\,\cdot\,,\,\cdot\,) = \operatorname{epi} u \cap ([s,\infty)\times\mathbb{R}^n)$ for $s \geq 0$. At this point we show that the function $\widetilde{u}$ can be characterized with subgradients.

Proposition 4.4. *Assume we have proper, lsc functions* $f : \mathbb{R}\times\mathbb{R}\times\mathbb{R}^n \to \overline{\mathbb{R}}$ *and* $u : \mathbb{R}\times\mathbb{R}^n \to \overline{\mathbb{R}}$. *Then* (i) *and* (ii) *are equivalent.*

(i) $f = \widetilde{u}$, *as defined by* (4.1).

(ii) $f(0,\,\cdot\,,\,\cdot\,) = u(\,\cdot\,,\,\cdot\,)$, *and at every* $(s,\tau,\xi) \in \operatorname{dom} f$, *every subgradient* $(\alpha,\sigma,\eta) \in \partial f(s,\tau,\xi)$ *satisfies*

$$\begin{cases} \alpha \leq 0 & \textit{if } \; 0 = s < \tau, \\ \alpha = 0 & \textit{if } \; 0 < s < \tau, \\ \alpha \geq 0 & \textit{if } \; 0 < s = \tau. \end{cases}$$

The proof of Proposition 4.4 depends on the following lemma (Proposition 8.50 in [27]).

Lemma 4.5. *For an lsc function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ and a point $\bar{x}$ where f is finite, the following are equivalent for a pair $(a, \beta) \in \mathbb{R}^n \times \mathbb{R}$.*

(i) *There exists a neighborhood W of $\bar{x}$ and $\delta > 0$ such that $\langle v, a\rangle \le \beta$ for all $v \in \partial f(x)$ when $x \in W$ and $f(x) \le f(\bar{x}) + \delta$.*

(ii) *For some neighborhood W of $\bar{x}$, $\delta > 0$, and $\varepsilon > 0$ one has*

$$\frac{f(x+ka) - f(x)}{k} \le \beta \text{ when } k \in (0, \varepsilon],\ x \in W, f(x) \le f(\bar{x}) + \delta.$$

Proof of Proposition 4.4. First we show that $\widetilde{u}$ satisfies (ii). The first condition is clearly satisfied, so we only need check that the subgradient criterion holds. First take $(0, \bar{\tau}, \bar{\xi}) \in \operatorname{dom} \widetilde{u}$ with $\bar{\tau} > 0$. Then there exists $\varepsilon > 0$ such that $(0, \bar{\tau}, \bar{\xi}) + 2\varepsilon\mathbb{B} \subset \{(s, \tau, \xi) | s < \tau\}$. Let $W = (0, \bar{\tau}, \bar{\xi}) + \varepsilon\mathbb{B}$ and let $\delta > 0$ be arbitrary. Fix $a = (1, 0, 0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n$. Then if we take any $k \in (0, \varepsilon]$ and $(s, \tau, \xi) \in W$ with $\widetilde{u}(s, \tau, \xi) \neq \infty$, we have

$$\begin{aligned}(\widetilde{u}((s,\tau,\xi) + ka) - \widetilde{u}(s,\tau,\xi))/k &= (\widetilde{u}(s+k,\tau,\xi) - \widetilde{u}(s,\tau,\xi))/k \\ &= (u(\tau,\xi) - u(\tau,\xi))/k \\ &= 0.\end{aligned}$$

So (ii) of Lemma 4.5 holds with $\beta = 0$. Thus (i) of Lemma 4.5 tells us that, in particular, $\langle(\alpha, \sigma, \eta), a\rangle \le 0$ for all $(\alpha, \sigma, \eta) \in \partial\widetilde{u}(0, \bar{\tau}, \bar{\xi})$, which reduces to saying that $\alpha \le 0$.

Now take $(\bar{s}, \bar{\tau}, \bar{\xi}) \in \operatorname{dom} \widetilde{u}$ with $0 < \bar{s} < \bar{\tau}$. In this case, the same argument as above will go through, applied to both a and $-a$. Applying part (i) of Lemma 4.5 now gives the results that $\alpha \le 0$ and $\alpha \ge 0$ for any $(\alpha, \sigma, \eta) \in \partial\widetilde{u}(\bar{s}, \bar{\tau}, \bar{\xi})$. So $\alpha = 0$.

Similarly, taking $(\bar{s}, \bar{\tau}, \bar{\xi}) \in \operatorname{dom} \widetilde{u}$ with $0 < \bar{s} = \bar{\tau}$ allows us to apply the above argument with $-a$, giving the result that $\alpha \ge 0$ for any $(\alpha, \sigma, \eta) \in \partial\widetilde{u}(\bar{s}, \bar{s}, \bar{\xi})$.

Assume now we have a proper, lsc f satisfying (ii). Then at any $(s, \tau, \xi) \in \operatorname{dom} f$ with $0 \le s < \tau$, we can find a neighborhood W so that (i) of the lemma holds for $a = (1, 0, 0)$ and $\beta = 0$ (δ arbitrary). Similarly, (i) of the lemma holds for $a = (-1, 0, 0)$ and $\beta = 0$ in a neighborhood of (s, τ, ξ) with $0 < s \le \tau$. Now applying (ii) of the lemma we see that, for fixed $(\bar{\tau}, \bar{\xi})$, $f(s, \bar{\tau}, \bar{\xi})$ is monotonically decreasing for $0 \le s < \bar{\tau}$ and is monotonically increasing for $0 < s \le \bar{\tau}$. Thus $f(s, \bar{\tau}, \bar{\xi}) = c$, a constant, for $s \in (0, \bar{\tau})$.

Now by assumption, $f(0, \bar{\tau}, \bar{\xi}) = u(\bar{\tau}, \bar{\xi})$. Since f is decreasing in s at $s = 0$, we must have $c \le u(\bar{\tau}, \bar{\xi})$. But f is lsc, so $f(0, \bar{\tau}, \bar{\xi}) \le c$. So in fact $f(s, \bar{\tau}, \bar{\xi}) = u(\bar{\tau}, \bar{\xi})$ for $s \in [0, \bar{\tau})$. But again, using lower semicontinuity and monotonicity of f in s, we get $f(\bar{\tau}, \bar{\tau}, \bar{\xi}) = c = u(\bar{\tau}, \bar{\xi})$. The only points not checked in $\operatorname{dom} f$ are of the form $(0, 0, \xi)$, but by assumption we know that $f(0, 0, \xi) = u(0, \xi)$. It should be clear from the argument just given that $(s, \tau, \xi) \in \operatorname{dom} f$ if and only if $0 \le s \le \tau$ and $(\tau, \xi) \in \operatorname{dom} u$. Thus $\operatorname{dom} f = \operatorname{dom} \widetilde{u}$ and so $f = \widetilde{u}$. □

5. Necessary conditions. This section examines the necessary conditions presented in the papers [21], [22], and [23]. Some work is required to show that our assumptions (A) and (A0)–(A2) enable us to use these papers. The approach taken in that series of articles was to take an arc known to be optimal and then impose hypotheses with respect to that particular arc. The goal of this section then is to show that under our assumptions, when the need arises to examine necessary conditions for some optimal arc, we can find a neighborhood of that arc to which Loewen and Rockafellar's hypotheses can be applied.

The main result of the paper [23] followed directly from [22], after applying the Erdmann transform to place the variable time Bolza problem in the context of a fixed time problem. This transform employs the following integrand which we will denote by L_m. For each $m > 0$, define

$$L_m(t,x,v,\lambda) = \begin{cases} \lambda L(t,x,v/\lambda) & \text{if} \quad \lambda \geq m, \\ +\infty & \text{otherwise.} \end{cases} \tag{5.1}$$

Note that $L_m(t,x,\,\cdot\,,\,\cdot\,)$ is proper and convex if and only if $L(t,x,\,\cdot\,)$ is proper and convex.

Proposition 5.1. *Assume $L(t,x,\,\cdot\,)$ is proper, lsc, coercive, and convex for each (t,x), and that* (A2) *holds. Then for each $m > 0$ and every $(\bar{t},\bar{x})$, there exists a neighborhood W of $(\bar{t},\bar{x})$ and positive constant k such that for all $(t,x,v,\lambda) \in W \times \mathbb{R}^n \times \mathbb{R}$,*

$$|(w_1,w_2)| \leq k(1 + |(v,\lambda)| + |L_m(t,x,v,\lambda)|)(1 + |(p,\pi)|) \tag{5.2}$$

for all $(w_1,w_2,p,\pi) \in \partial L_m(t,x,v,\lambda)$.

Proof. In Proposition 2.6 it was shown that (A2) implies that the subgradients of L satisfy a relation given by (2.3). Using the calculus rules ([27, Thm. 10.6 and Cor. 10.9]), and the fact that we can write $L_m(t,x,v,\lambda) = \lambda L(t,x,v/\lambda) + \Psi_{[m,\infty)}(\lambda)$, we have

$$\begin{aligned} &\partial L_m(t,x,v,\lambda) \subset \{(\lambda w_1, \lambda w_2, p, r) \mid (w_1,w_2,p) \in \partial L(t,x,v/\lambda)\}, \\ &\widehat{\partial} L_m(t,x,v,\lambda) \supset \{(\lambda w_1, \lambda w_2, p, r) \mid (w_1,w_2,p) \in \widehat{\partial} L(t,x,v/\lambda)\} \\ &\qquad \text{with } \begin{cases} r = -H(t,x,p) & \text{if } \lambda > m, \\ r \leq -H(t,x,p) & \text{if } \lambda = m. \end{cases} \end{aligned} \tag{5.3}$$

Take $m > 0$. Since L is lsc, $\operatorname{epi} L_m(\cdot,\cdot,\cdot,\lambda)$ is a closed set and from the definition of L_m is varying continuously with λ for $\lambda \geq m$. So $\operatorname{epi} L_m$ is closed, implying L_m is lsc.

Take $(\bar{t},\bar{x}) \in \mathbb{R} \times \mathbb{R}^n$ and choose a neighborhood W and constant k as given by (A2). Also let k_1 be a positive constant so that $H(t,x,p) \geq -k_1(1 + |p|)$ whenever $(t,x,p) \in W \times \mathbb{R}^n$. The existence of this constant is guaranteed by Lemma 2.5. Let $(w_1,w_2,p,\pi) \in \partial L_m(t,x,v,\lambda)$ for some $(t,x,v,\lambda) \in W \times \mathbb{R}^n \times [m,\infty)$. Then (5.3) tells us that $(w_1,w_2,p,\pi) = (\lambda w_1', \lambda w_2', p, \pi)$ for some $(w_1',w_2',p) \in \partial L(t,x,v/\lambda)$ and with $\pi \leq -H(t,x,p)$. Note that we have the estimate $|H(t,x,p)| \leq \max\{k_1(1 + |p|), |\pi|\}$. So (A2) says that

$$\begin{aligned} |(w_1',w_2')| &\leq k(1 + |v/\lambda| + |L(t,x,v/\lambda)|)(1 + |p| + |H(t,x,p)|) \\ \Rightarrow |(w_1,w_2)| &\leq k(\lambda + |v| + |L_m(t,x,v,\lambda)|)(1 + |p| + |H(t,x,p)|) \\ &\leq \sqrt{2}k(1 + |(v,\lambda)| + |L_m(t,x,v,\lambda)|)(1 + |p| + k_1(1{+}|p|{+}|\pi|)) \\ &\leq \sqrt{2}k(k_1 + 1)(1 + |(v,\lambda)| + |L_m(t,x,v,\lambda)|)(1 + |p| + |\pi|) \\ &\leq 2k(k_1 + 1)(1 + |(v,\lambda)| + |L_m(t,x,v,\lambda)|)(1 + |(p,\pi)|). \qquad \square \end{aligned}$$

Lemma 5.2. *Assume we have an autonomous Lagrangian $L : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ for which, given any $M > 0$, there exists $k_1 > 0$ such that for all $(x,v) \in M\mathbb{B} \times \mathbb{R}^n$,*

$$|w| \leq k_1(1 + |v| + |L(x,v)|)(1 + |p|) \quad \text{for all} \quad (w,p) \in \partial L(x,v). \tag{5.4}$$

Let $\bar{x}(\cdot) \in \mathcal{A}_n^1([a,b])$ so that $L(\bar{x}(t), \dot{\bar{x}}(t))$ is integrable on $[a,b]$. Then there exist $\varepsilon > 0$ and integrable $\kappa : \mathbb{R} \to \mathbb{R}$ and $\delta : \mathbb{R} \to \mathbb{R}$ so that ([22, Hypothesis H5]) *holds. That is, the ratio $\kappa(t)/\delta(t)$ is essentially bounded and for a.e. $t \in [a,b]$, one has*

$$|w| \le \kappa(t)(1+|p|) \qquad \text{for all } (w,p) \in \partial L(x,v)$$

whenever $|x - \bar{x}(t)| < \varepsilon,\ \big|\,(v, L(x,v)) - (\dot{\bar{x}}(t), L(\bar{x}(t), \dot{\bar{x}}(t)))\,\big| < \delta(t)$.

Proof. Let $M = (\sup\{|\bar{x}(t)| : t \in [a,b]\} + 1)$ and let $\varepsilon < 1$. Define

$$\begin{aligned}
&\bar{L}(t) = L(\bar{x}(t), \dot{\bar{x}}(t)),\\
&\delta(t) = |\dot{\bar{x}}(t)| + |\bar{L}(t)| + 1,\\
&\kappa(t) = k_1\big[\,1 + \sqrt{2}\,\big(\,|\dot{\bar{x}}(t)| + |\bar{L}(t)| + \delta(t)\,\big)\,\big].
\end{aligned}$$

Note that δ and κ are integrable on $[a,b]$. Choose $t \in [a,b]$ so that $\delta(t)$ is finite (this holds for a.e. t). Now take any (x,v) so that $|x - \bar{x}(t)| < \varepsilon$ and $|(v, L(x,v)) - (\dot{\bar{x}}(t), \bar{L}(t))| < \delta(t)$. Thus $|x| < M$ and $|(v, L(x,v))| < |\dot{\bar{x}}(t)| + |\bar{L}(t)| + \delta(t)$, so (5.4) states that, for every $(w,p) \in \partial L(x,v)$,

$$\begin{aligned}
|w| &\le k_1\big[\,1 + (\,|v| + |L(x,v)|\,)\,\big](1+|p|)\\
&\le k_1\big[\,1 + \sqrt{2}|(v, L(x,v))|\,\big](1+|p|)\\
&\le k_1\big[\,1 + \sqrt{2}\,\big(\,|\dot{\bar{x}}(t)| + |\bar{L}(t)| + \delta(t)\,\big)\,\big](1+|p|)\\
&= \kappa(t)(1+|p|).
\end{aligned}$$

We also have that

$$\begin{aligned}
\kappa(t)/\delta(t) &= k_1[1 + \sqrt{2}\,(\,|\dot{\bar{x}}(t)| + |\bar{L}(t)| + \delta(t))]/\delta(t)\\
&\le k_1(1 + 2\sqrt{2}\delta(t))/\delta(t)\\
&\le k_1(1 + 2\sqrt{2}).
\end{aligned}$$

Thus $\kappa(t)/\delta(t)$ is essentially bounded and so ([22, Hypothesis H5]) holds. □

Ultimately, we wish to employ the main result of [23], which gives necessary conditions on an optimal arc to the following *general time* Bolza problem: Find a nondegenerate interval $[a,b]$ and arc $x \in \mathcal{A}_n^1[a,b]$ in order to

$$(\mathcal{P}_t) \qquad\qquad \text{minimize} \quad l(a, x(a), b, x(b)) + \int_a^b L(t, x(t), \dot{x}(t))\, dt.$$

The following theorem says that if our global assumptions on H are in place, then the result in [23] holds. Again, we are assuming that H and L satisfy (1.2) and (1.3).

THEOREM 5.3. *Let the arc $\bar{x}$ and interval $[\bar{a}, \bar{b}]$ provide the minimum in $(\mathcal{P}_t)$. Assume that the endpoint function $l : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \to \overline{\mathbb{R}}$ is proper and lsc; that $L(t, x, \cdot\,)$ is proper, lsc, coercive, and convex for each (t,x); and that* (A2) *holds. Then some absolutely continuous arc (h,p) taking values in $\mathbb{R} \times \mathbb{R}^n$ satisfies either the normal conditions or singular conditions below.*

Normal conditions:

(a) $(\dot{h}(t), \dot{p}(t)) \in \mathrm{co}\{(w_1, w_2) : (w_1, -w_2, \dot{\bar{x}}(t)) \in \partial H(t, \bar{x}(t), p(t))\}$
$= \mathrm{co}\{(w_1, w_2) : (-w_1, w_2, p(t)) \in\ \partial L(t, \bar{x}(t), \dot{\bar{x}}(t))\}$ *a.e.* $t \in [\bar{a}, \bar{b}]$.

(b) $h(t) = H(t, \bar{x}(t), p(t))$ *for all* $t \in [\bar{a}, \bar{b}]$.

(c) $(-h(\bar{a}), p(\bar{a}), h(\bar{b}), -p(\bar{b})) \in \partial l(\bar{a}, \bar{x}(\bar{a}), \bar{b}, \bar{x}(\bar{b}))$.

Singular conditions: One has $|(h(t), p(t))| > 0$ *for all* $t \in [\bar{a}, \bar{b}]$, *and*

(a$^\infty$) $(\dot{h}(t), \dot{p}(t)) \in \mathrm{co}\{(w_1, w_2) : (-w_1, w_2, p(t)) \in \ \partial^\infty L(t, \bar{x}(t), \dot{\bar{x}}(t))\}$ *a.e.* $t \in [\bar{a}, \bar{b}]$.
(b$^\infty$) $h(t) = \langle p(t), \dot{\bar{x}}(t)\rangle$ *a.e.* $t \in [\bar{a}, \bar{b}]$.
(c$^\infty$) $(-h(\bar{a}), p(\bar{a}), h(\bar{b}), -p(\bar{b})) \in \partial^\infty l(\bar{a}, \bar{x}(\bar{a}), \bar{b}, \bar{x}(\bar{b}))$.

Proof. Many of the details of the proof are in the paper [23]. We must convert our problem $(\mathcal{P}_t)$ into an equivalent problem over a fixed time interval and show that we can then use the necessary conditions given in [22].

Let $[\bar{a}, \bar{b}]$ and $\bar{x}(\cdot)$ be an optimal solution to $(\mathcal{P}_t)$. First we transform the problem into a fixed-time Bolza problem by using the Erdmann transform. This transform employs the Lagrangian L_m defined in (5.1), where we choose $m < \bar{b} - \bar{a}$. In particular, we consider the problem

$$(\Pi) \qquad \text{minimize} \quad l(\theta(0), \xi(0), \theta(1), \xi(1)) + \int_0^1 L_m(\theta(s), \xi(s), \dot{\xi}(s), \dot{\theta}(s))ds$$

over absolutely continuous arcs $(\theta, \xi) \in \mathcal{A}^1_{n+1}[0, 1]$. It turns out (see [23, Lemma 4.1]) that the arc $(\bar{\theta}(s), \bar{\xi}(s)) = (\bar{a} + (\bar{b} - \bar{a})s, \bar{x}(\bar{\theta}(s)))$ solves (Π). The goal is then to apply necessary conditions from [22] to $(\bar{\theta}, \bar{\xi})$ and then relate the conditions back to the original arc $\bar{x}$.

So we need to check that the hypotheses of [22] hold for the problem (Π). It is fairly straightforward to see that the first four hypotheses of that paper are satisfied. Our assumptions allow us to conclude that the subgradient inequality (5.2) of Proposition 5.1 holds. So now we can apply Lemma 5.2 to L_m and the arc $(\bar{\theta}, \bar{\xi})$. Lemma 5.2 says that ([22, Hypothesis H5]) holds. Thus the necessary conditions of [22] apply to L_m and (θ, ξ). Translating these conditions back in terms of $\bar{x}$, H, and L is done in section 4.3 of [23], giving us the results of our theorem.

One slight adjustment we have made is in condition (b). In [23] it is shown that (b) holds for a.e. t, but in our case we know that H is continuous (Proposition 2.4), which forces this condition to hold at every $t \in [\bar{a}, \bar{b}]$. □

We note that the conditions on L in this theorem are satisfied under (A), (A1), and (A2). The coercivity condition on L is equivalent to assuming that $H(t, x, \cdot)$ is finite for every (t, x). This is a basic property of the Legendre–Fenchel transform.

6. Proof of the main result. We begin this section with a proposition that will be used in the proof of the main theorem but is also of independent interest. Recall the normal cone definitions (1.6) and (1.7).

PROPOSITION 6.1. *Let* $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ *be a locally sub-Lipschitz set-valued mapping (see* (1.11)*) with closed, convex images. Assume* K *is a closed set that is invariant with respect to the forward solution set (see Proposition* 4.1*). Then at each* $x \in K$ *we have*

$$\sup_{v \in F(x)} \langle v, y\rangle \leq 0 \quad \textit{for every } y \in N_K(x). \tag{6.1}$$

Proof. Take $\bar{x} \in K$ and $y \in N_K(\bar{x})$. Since F is locally sub-Lipschitz, there is a neighborhood W of $\bar{x}$ so that $d(0, F(x)) < \rho_0$ for all $x \in W$. Then for any $\rho \in (2\rho_0, \infty)$, the truncation mapping $F_\rho(x) := F(x) \cap \rho\mathbb{B}$ is locally Lipschitz continuous on W (from Theorem 9.33(a) in [27]). But if K is forward invariant under F, it also must be under F_ρ, since the solution set of the latter differential inclusion is contained in that of the former. Take a sequence (x^ν, y^ν) with $x^\nu \in K \cap W$ and $x^\nu \to \bar{x}$ so that $y^\nu \in \widehat{N}_K(x^\nu)$ and $y^\nu \to y$. Theorem 5.3.4 of [3] tells us then that $\sup_{v \in F_\rho(x^\nu)}\langle v, y^\nu\rangle \leq 0$. Then F_ρ being a bounded continuous mapping forces a similar inequality in the limit. That is,

$\sup_{v\in F_\rho(\bar{x})}\langle v, y\rangle \le 0$. But this is true regardless of how large we take ρ, so our result must hold. □

Proof of Theorem 2.2. First we will show that V satisfies the ULLG condition, as given in Definition 2.1. By (A0), there is a constant $k_1 > 0$ such that $\varphi(x) \ge -k_1(1+|x|)$. Fix $T>0$, and note that for $(t,x,p)\in[0,T]\times\mathbb{R}^n\times\mathbb{R}^n$, (A1) says that

$$H(t,x,p) \le H_1(t,x,p) := \mu(|p|) + (T+|x|)(\beta+\alpha|p|).$$

Let L_1 be the corresponding Lagrangian to H_1. For $(t,x,p)\in[0,T]\times\mathbb{R}^n\times\mathbb{R}^n$ it follows that $L_1(t,x,v)\le L(t,x,v)$. Thus if we let V_1 be the value function corresponding to the Bolza problem

$$\min\left\{ -k_1(1+|x(0)|) + \int_0^\tau L_1\bigl(t,x(t),\dot{x}(t)\bigr)dt \ \mid x(\tau)=\xi\right\},$$

we must have $V_1(\tau,\xi)\le V(\tau,\xi)$ for all $(\tau,\xi)\in[0,T]\times\mathbb{R}^n$. We can consider our Bolza problem to have the form of $(\mathcal{P}_t)$ by letting

$$l(a,x(a),b,x(b)) = \Psi_{\{0\}}(a) + \Psi_{\{\tau\}}(b) - k_1(1+|x(a)|) + \Psi_{\{\xi\}}(x(b)).$$

We want to apply Theorem 5.3. Clearly l is proper and lsc. Since $H_1(t,x,\,\cdot\,)$ is lsc, proper, convex, and finite for all (t,x), L_1 satisfies the hypotheses of Theorem 5.3. Furthermore, H_1 satisfies the epi-continuity condition in (t,x) as well as in p, and so by [26, Prop. 2.2], $(w_1,w_2,v)\in\partial H_1(t,x,p)$ implies that $(w_1,w_2)\in\partial_{(t,x)}H_1(t,x,p)$, from which it follows that $|(w_1,w_2)|\le(\beta+\alpha|p|)$, and thus (A2) holds.

Fix $(\bar{\tau},\bar{\xi})\in[0,T]\times\mathbb{R}^n$ and let $\bar{x}(\cdot)$ be the minimizing arc for $V_1(\bar{\tau},\bar{\xi})$, which exists by Proposition 3.1. Theorem 5.3 gives us an absolutely continuous arc $p(\,\cdot\,)$ which satisfies either normal or singular conditions. First we see that part (c) of the singular conditions cannot occur since it forces $p(\bar{a})=p(0)=0$. So the normal conditions must hold. Since $\partial l(\bar{a},\bar{x}(\bar{a}),\bar{b},\bar{x}(\bar{b}))\subset\mathbb{R}\times k_1\mathbb{B}\times\mathbb{R}\times\mathbb{R}^n$, we must have $|p(0)|\le k_1$. Part (a) of the normal conditions says that for a.e. t, $|\dot{p}(t)|\le(\beta+\alpha|p(t)|)$, and so $p(\,\cdot\,)$ must be bounded on $[0,\bar{\tau}]$, implying the existence of a constant k_2, independent of $(\bar{\tau},\bar{\xi})$, such that $\partial\mu(|p(t)|)\subset k_2\mathbb{B}$ for all $t\in[0,\bar{\tau}]$. Also implicit in normal condition (a) is that

$$\begin{aligned}\dot{\bar{x}}(t) &\in \partial_p H_1(t,\bar{x}(t),p(t))\\ &= \partial_p(\mu(|p|)+(T+|x|)(\beta+\alpha|p|))(\bar{x}(t),p(t))\\ &\subset \partial_p(\mu(|p|))(\bar{x}(t),p(t)) + \partial_p((T+|x|)(\beta+\alpha|p|))(\bar{x}(t),p(t))\\ &\subset k_2\mathbb{B}+\alpha(T+|\bar{x}(t)|)\mathbb{B}.\end{aligned}$$

So there exists a constant k_3, also independent of $(\bar{\tau},\bar{\xi})$, such that $|\dot{\bar{x}}(t)|\le k_3(1+|\bar{x}(t)|)$. This implies that $|\bar{x}(t)|\le(|\bar{\xi}|+1)e^{k_3T}$ for $t\in[0,\bar{\tau}]$. Now since $L_1(t,x,v)\ge -H_1(t,x,0)$,

$$\begin{aligned}\int_0^{\bar{\tau}} L_1(t,\bar{x}(t),\dot{\bar{x}}(t))dt &\ge \int_0^{\bar{\tau}} -\mu(0)-\beta(|T|+|\bar{x}(t)|)dt\\ &\ge \int_0^{\bar{\tau}} -\mu(0)-\beta(|T|+(|\bar{\xi}|+1)e^{k_3T})dt\\ &\ge -k_4(|\bar{\xi}|+1)\end{aligned}$$

for some constant $k_4 > 0$. Since $|\bar{x}(0)| \le (|\bar{\xi}| + 1)e^{k_3 T}$, we see then that

$$\begin{aligned} V_1(\tau, \xi) &\ge -k_1((|\xi| + 1)e^{k_3 T} + 1) - k_4(|\xi| + 1) \\ &= -k(1 + |\xi|) \end{aligned}$$

for some $k > 0$ and for all $(\tau, \xi) \in [0, T] \times \mathbb{R}^n$. So V satisfies the ULLG condition.

To see that the value function is a solution to (1.1) as given by Definition 1.2, we first note that Proposition 3.1 shows V is proper and lsc. By Definition 1.1, V satisfies (a) and (b) of Definition 1.2. The only remaining part that requires checking is the subgradient condition (c).

First we check for $\tau = 0$. Take $\xi \in \mathbb{R}^n$ and $(\sigma, \eta) \in \partial V(0, \xi)$. By Proposition 3.2, V satisfies property (P4). That is, $\operatorname{epi} V$ is invariant with respect to the differential inclusion $(\dot{t}(s), \dot{x}(s), \dot{y}(s)) \in \widetilde{E}_L((t(s), x(s), y(s))$. Assumptions (A) and (A2) imply that the mapping $\operatorname{epi} L(t, x, \,\cdot\,)$, by Proposition 2.6, is locally sub-Lipschitz. Then $\widetilde{E}_L(t, x, y) = \{1\} \times E_L(t, x)$ will also be locally sub-Lipschitz and Proposition 6.1 says that

$$\begin{aligned} &\sup_{(v,\beta) \in \operatorname{epi} L(0,\xi,\,\cdot\,)} \big\{ \big\langle\, (\sigma, \eta, -1), (1, v, \beta) \,\big\rangle \big\} \le 0, \\ &\Rightarrow \sup_{v \in \mathbb{R}^n} \big\{ \sigma + \langle \eta, v \rangle \; - L(0, \xi, v) \big\} \le 0, \\ &\Rightarrow \sigma + H(0, \xi, \eta) \le 0. \end{aligned}$$

Now take $(\sigma, \eta) \in \widehat{\partial} V(\tau, \xi)$ for some (τ, ξ) with $\tau > 0$. Let $\bar{x}(\,\cdot\,)$ be a minimizing arc for $(\mathcal{P}_{\tau,\xi})$. As mentioned in the introduction, there exists a differentiable function $g : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}$ such that $g(\tau, \xi) = V(\tau, \xi)$, but for any $(\tau', \xi') \ne (\tau, \xi)$, we have $g(\tau', \xi') < V(\tau', \xi')$. Furthermore, $\nabla g(\tau, \xi) = (\sigma, \eta)$. Consider the following general time Bolza problem:

$$(\mathcal{P}_g) \qquad\qquad \text{minimize} \quad l(a, x(a), b, x(b)) + \int_a^b L\big(t, x(t), \dot{x}(t)\big) dt,$$

where $l(a, x(a), b, x(b)) = \Psi_{\{0\}}(a) + \varphi(x(a)) - g(b, x(b))$ and we are minimizing over all nondegenerate time intervals $[a, b]$ and arcs $x \in \mathcal{A}_n^1([a, b])$. If $(\mathcal{P}_g)$ is to have a finite value, a must be 0. Evaluating the above expression for any feasible arc $x(\,\cdot\,)$ and interval $[0, b]$ must give us a nonnegative value, since

$$\begin{aligned} l(0, x(0), b, x(b)) + \int_0^b L\big(t, x(t), \dot{x}(t)\big) dt \; &\ge \varphi(x(0)) - g(b, x(b)) + \int_0^b L\big(t, x(t), \dot{x}(t)\big) dt \\ &\ge V(b, x(b)) - g(b, x(b)) \\ &\ge 0. \end{aligned}$$

It should be clear however, that taking $[a, b] = [0, \tau]$ and $x = \bar{x}(\,\cdot\,)$ gives the value 0 in the above. Thus we have an optimal solution. Now we wish to use the necessary conditions given in Theorem 5.3, which can be applied to our general time Bolza problem $(\mathcal{P}_g)$. First checking the singular conditions described in Theorem 5.3, we have

$$\begin{aligned} \partial^\infty l(0, \bar{x}(0), \tau, \bar{x}(\tau)) &\subset \partial^\infty \Psi_{\{0\}}(0) \times \partial^\infty \varphi(x(0)) \times \partial^\infty g(\tau, \bar{x}(\tau)) \\ &= \mathbb{R} \times \partial^\infty \varphi(x(0)) \times (0, 0). \end{aligned}$$

For the first containment, we have used the calculus rules in ([27, Prop. 10.5]). So there does not exist an arc (h,p) with $|(h(t),p(t))| > 0$ for $t \in [0,\tau]$ satisfying the singular conditions, since condition (c^∞) forces $(h(\tau),p(\tau)) = (0,0)$. So the normal conditions must hold. That is, there exist absolutely continuous arcs h and p satisfying the transversality condition

$$\begin{aligned}(-h(0),p(0),h(\tau),-p(\tau)) &\in \partial l(0,\bar{x}(0),\tau,\bar{x}(\tau))\\ &= \mathbb{R}\times\partial\varphi(x(0))\times(-\sigma,-\eta),\end{aligned}$$

and so $h(\tau) = -\sigma$ and $p(\tau) = \eta$. Also, condition (b) of the normal conditions says that $h(t) = H(t,\bar{x}(t),p(t))$ for all $t \in [0,\tau]$, so in particular $h(\tau) = H(\tau,\bar{x}(\tau),p(\tau))$, giving us that $\sigma + H(\tau,\xi,\eta) = 0$.

Now if we have $(\sigma,\eta) \in \partial V(\tau,\xi)$ for $\tau > 0$, by definition of the general subgradient, there exist sequences $(\tau^\nu,\xi^\nu) \to (\tau,\xi)$ with $V(\tau^\nu,\xi^\nu) \to V(\tau,\xi)$ and $(\sigma^\nu,\eta^\nu) \to (\sigma,\eta)$ with $(\sigma^\nu,\eta^\nu) \in \widehat{\partial}V(\tau^\nu,\xi^\nu)$ and $\tau^\nu > 0$. So by the result just proved, $H(\tau^\nu,\xi^\nu,\eta^\nu) = -\sigma^\nu$. But H being continuous implies $H(\tau^\nu,\xi^\nu,\eta^\nu) \to H(\tau,\xi,\eta)$ which forces $H(\tau,\xi,\eta) = -\sigma$. Thus V is a solution as given by Definition 1.2.

Let u be a solution to (1.1) as in Definition 1.2 that satisfies the ULLG condition. To prove the uniqueness part of the theorem, we need to show that $u = V$. Let $\mathcal{V} : \mathbb{R}\times\mathbb{R}\times\mathbb{R}^n \to \overline{\mathbb{R}}$ be the value function for

$$(\mathcal{P}_{\theta,\tau,\xi}) \qquad \min \quad u(t(0),x(0)) + \int_0^\theta \mathcal{L}\big(s,t(s),x(s),\dot{t}(s),\dot{x}(s)\big)ds.$$

Here we are minimizing over $(t(\,\cdot\,),x(\,\cdot\,)) \in \mathcal{A}^1_{n+1}([0,\theta])$ with $(t(\theta),x(\theta)) = (\tau,\xi)$, and the Lagrangian is

$$\mathcal{L}(s,t,x,v_1,v_2) := L(t,x,v_2) + \Psi_{\{1\}}(v_1).$$

Note that this is a generalized problem of Bolza in which we are considering (t,x) as the state variable and s as the time parameter. The corresponding Hamiltonian is then

$$\begin{aligned}\mathcal{H}(s,t,x,p_1,p_2) &= \sup_{(v_1,v_2)\in\mathbb{R}\times\mathbb{R}^n} \big\{ \langle (v_1,v_2),(p_1,p_2)\rangle - \mathcal{L}(s,t,x,v_1,v_2) \big\}\\ &= \sup_{(v_1,v_2)\in\mathbb{R}\times\mathbb{R}^n} \big\{ \langle v_1,p_1\rangle + \langle v_2,p_2\rangle \ - L(t,x,v_2) - \Psi_{\{1\}}(v_1) \big\}\\ &= \sup_{v_2\in\mathbb{R}^n} \big\{ p_1 + \langle v_2,p_2\rangle - L(t,x,v_2) \big\}\\ &= p_1 + H(t,x,p_2).\end{aligned}$$

We would like to use the existence part of Theorem 2.2, just proved above, to show that $\mathcal{V}$ is a solution to

$$\begin{aligned}\mathcal{V}_s(s,t,x) + \mathcal{H}(s,t,x,\mathcal{V}_t(s,t,x),\mathcal{V}_x(s,t,x)) = 0, &\qquad (s,t,x) \in (0,\infty)\times\mathbb{R}\times\mathbb{R}^n,\\ \mathcal{V}(0,t,x) = u(t,x), &\quad (t,x) \in \mathbb{R}\times\mathbb{R}^n,\end{aligned}$$

in the sense of Definition 1.2. Clearly $\mathcal{H}$ satisfies (A), (A1), and (A2) as long as H does. Assumption (A0) is not necessarily satisfied however, since u could behave in a countercoercive manner with respect to its first variable. We can get around this problem as follows. Let $T > 0$ and consider adding an indicator function $\Psi_{[0,T]\times\mathbb{R}^n}(t(0),x(0))$ to the initial cost $u(t(0),x(0))$ in $(\mathcal{P}_{\theta,\tau,\xi})$. Now the initial cost does satisfy (A0) and the new resulting value function $\bar{\mathcal{V}}$ is therefore a solution to (1.1) as given by Definition 1.2, and it has equation

$$\bar{\mathcal{V}}(\theta,\tau,\xi) = \begin{cases} \mathcal{V}(\theta,\tau,\xi) & \text{if } \ \tau \le T+\theta, \\ +\infty & \text{otherwise.} \end{cases}$$

This implies that $\mathcal{V}$ must satisfy (a)–(c) of Definition 1.2, and for any given $(\theta,\tau,\xi) \in \operatorname{dom}\mathcal{V}$, it suffices to take $T > \theta+\tau$ to compare $\mathcal{V}$ with $\bar{\mathcal{V}}$ and see that (1.8) holds. Thus $\mathcal{V}$ is a solution to (1.1).

First consider the case where $0 < \theta$. If we were to go through the existence proof above, we can again apply the technique of introducing a differentiable function $g \le \mathcal{V}$ whose gradient is (α,σ,η) at the point (θ,τ,ξ), and using the results from Theorem 5.3, assert the existence of absolutely continuous arcs $h(\cdot)$ and $p(\cdot)$ with the properties

(a) $h(s) = \mathcal{H}(s,\bar{t}(s),\bar{x}(s),p(s))$ for all $s \in [0,\theta]$,

(b) $(-h(0),p(0),h(\theta),-p(\theta)) \in \mathbb{R}\times\partial u(\bar{t}(0),\bar{x}(0)) \ \times(-\alpha,-\sigma,-\eta)$,

(c) $\dot{h}(s) = 0$ for a.e. $s \in [0,\theta]$.

Conditions (b) and (c) imply then that $h(s) = -\alpha$ for all $s \in [0,\theta]$. If we denote $p(0)$ by (σ_0,η_0), then (b) implies $(\sigma_0,\eta_0) \in \partial u(\bar{t}(0),\bar{x}(0))$. But then (a) gives us that

$$\begin{aligned} -\alpha &= \mathcal{H}(\theta,\tau,\xi,\sigma,\eta) \\ &= \mathcal{H}(0,\bar{t}(0),\bar{x}(0),\sigma_0,\eta_0) \\ &= \sigma_0 + H(\bar{t}(0),\bar{x}(0),\eta_0). \end{aligned}$$

By assumption, this last quantity is equal to 0 if $\bar{t}(0) > 0$ and is less than or equal to 0 if $\bar{t}(0) = 0$. Since $\dot{\bar{t}}(s) = 1$, and $\bar{t}(\theta) = \tau$, the only way $\bar{t}(0) = 0$ is if $\theta = \tau$. Thus we have

$$\begin{cases} -\alpha = 0 & \text{if } 0 < \theta < \tau, \\ -\alpha \le 0 & \text{if } 0 < \theta = \tau. \end{cases}$$

Now consider $(\alpha,\sigma,\eta) \in \widehat{\partial}\mathcal{V}(0,\tau,\xi)$ with $\tau > 0$. Again applying the existence part of Theorem 2.2 to $\mathcal{V}$, we have $\alpha + \mathcal{H}(0,\tau,\xi,\sigma,\eta) \le 0$. Using the calculus of regular subgradients (see Corollary 10.11 in [27]), we see that $(\sigma,\eta) \in \widehat{\partial}_{(t,x)}\mathcal{V}(0,\tau,\xi) = \widehat{\partial}u(\tau,\xi)$. By assumption then, $\mathcal{H}(0,\tau,\xi,\sigma,\eta) = \sigma + H(\tau,\xi,\eta) = 0$. It follows that $\alpha \le 0$.

Now looking at a general subgradient $(\alpha,\sigma,\eta) \in \partial\mathcal{V}(0,\tau,\xi)$ with $\tau > 0$, there exist sequences $(\alpha^\nu,\sigma^\nu,\eta^\nu) \to (\alpha,\sigma,\eta)$ and $(\theta^\nu,\tau^\nu,\xi^\nu) \to (0,\tau,\xi)$ with $(\alpha^\nu,\sigma^\nu,\eta^\nu) \in \widehat{\partial}\mathcal{V}(\theta^\nu,\tau^\nu,\xi^\nu)$ and $\mathcal{V}(\theta^\nu,\tau^\nu,\xi^\nu) \to \mathcal{V}(0,\tau,\xi)$. Furthermore, since $\tau > 0$, we can take $\theta^\nu < \tau^\nu$. We have just seen though that for this sequence $\alpha^\nu \le 0$, so we must have $\alpha \le 0$.

In summary then, for $(\alpha,\sigma,\eta) \in \partial\mathcal{V}(\theta,\tau,\xi)$, we have

$$\begin{cases} \alpha \le 0 & \text{if } 0 = \theta < \tau, \\ \alpha = 0 & \text{if } 0 < \theta < \tau, \\ \alpha \ge 0 & \text{if } 0 < \theta = \tau. \end{cases}$$

It should be clear from Proposition 3.1 that $\mathcal{V}$ is lsc and proper. So Proposition 4.4 says that in fact $\mathcal{V} = \widetilde{u}$. That is,

$$\mathcal{V}(\theta,\tau,\xi) = \begin{cases} u(\tau,\xi) & \text{if } 0 \le \theta \le \tau, \\ +\infty & \text{otherwise.} \end{cases}$$

But epi $\mathcal{V}(\theta,\,\cdot\,,\,\cdot\,)$ is the reachable set of epi u at time θ under the differential inclusion $\dot{z}(s) \in \widetilde{E}_L(z(s))$. That is,

$$\operatorname{epi} \mathcal{V}(\theta,\,\cdot\,,\,\cdot\,) = \mathcal{R}_{\operatorname{epi} u}(\theta).$$

Now from Proposition 4.3, we have that u satisfies conditions (P1)–(P4), and finally Proposition 3.2 implies that u is the value function V for $(\mathcal{P}_{\tau,\xi})$. □

UTILITY MAXIMIZATION WITH DISCRETIONARY STOPPING*

IOANNIS KARATZAS† AND HUI WANG‡

Abstract. Utility maximization problems of mixed *optimal stopping/control* type are considered, which can be solved by reduction to a family of related *pure optimal stopping* problems. Sufficient conditions for the existence of optimal strategies are provided in the context of continuous-time, Itô process models for complete markets. The mathematical tools used are those of optimal stopping theory, continuous-time martingales, convex analysis, and duality theory. Several examples are solved explicitly, including one which demonstrates that optimal strategies need not always exist.

Key words. utility maximization, stochastic control, optimal stopping, variational inequality, duality, convex analysis, martingale representation

1. Introduction.

Problems of expected utility maximization go back at least to the seminal articles of Samuelson and Merton (1969) and Merton (1971), and have been studied extensively in recent years, for instance by Pliska (1986), Karatzas, Lehoczky, and Shreve [KLS] (1987), and Cox and Huang (1989). Most of this literature shares the common setting of an agent who receives a deterministic initial capital, which he must then invest in a market (complete or incomplete) so as to maximize the expected utility of his wealth and/or consumption, up to a *prespecified* terminal time.

In this paper we consider a variant of these problems by allowing the agent freely to stop *before or at* a prespecified final time in order to maximize the expected utility of his wealth and/or consumption up to the stopping time. The assets available to the agent can be traded continuously, without restrictions, frictions, or transaction costs; they consist of a locally riskless money-market, and m risky stocks. (One can think, for example, of an investor or mutual fund manager who tries to invest/consume as skillfully as possible before "retiring" from the stock market and putting all his holdings in the money-market.) The stock prices are driven by m independent Brownian motions; these represent the sources of uncertainty in the market model, which is assumed to be complete in the sense of Harrison and Pliska (1981). The market coefficients, i.e., the money-market rate, the stock-appreciation rates, and the matrix of stock volatilities, are bounded random processes adapted to the driving m-dimensional Brownian motion.

The utility maximization problem studied here involves aspects of both *optimal stopping* and *stochastic control.* Such problems also arise in situations like pricing American contingent claims under constraints, selecting trading strategies in the presence of transaction costs with an American option held in the portfolio, target-tracking

followed by a decision (to engage the target or not), etc.; see Karatzas and Kou (1998), Davis and Zariphopoulou (1995), Davis and Zervos (1994), as well as Karatzas and Sudderth (1999) for such problems in different contexts. The free-boundary problem approach, based on an associated Hamilton–Jacobi–Bellman (HJB) equation of dynamic programming, is inadequate for the analysis of the general version of our model, which is not Markovian. Instead, duality theory plays an important role and leads to a family of pure optimal stopping problems which is even more amenable to analysis. Duality approaches have been used with success in treating portfolio optimization problems for financial markets which are incomplete or impose constraints on portfolio choice, as in Karatzas, Lehoczky, Shreve, and Xu [KLSX] (1991), Shreve and Xu (1992), and Cvitanić and Karatzas (1992).

The model and the utility maximization problem are described in sections 2–5. We present a solution in section 6 using a *duality approach.* However, this solution is not quite satisfactory in the sense that it leads to computationally tractable results only in very special cases and does not shed much light on the general question of existence of optimal strategies. We then introduce and analyze *a family of pure optimal stopping problems* in sections 7–8. In terms of these, we are able to provide conditions which guarantee the existence of optimal strategies. In section 9, several examples are presented, one of which demonstrates that optimal strategies need *not* always exist. For completeness, we treat in Appendix A an example which can be solved explicitly using a free-boundary problem for the associated HJB equation. In Appendix B we formulate an open problem, suggested by the referee, where consumption continues past the time of retirement from the stock market.

It is hoped that the analysis in this paper will serve as a step towards establishing a general theory for stochastic control problems with discretionary stopping in continuous time, possibly along the lines of the Dubins–Savage (1965) theory for discrete-time "leavable gambling problems" developed in Chapter 3 of Maitra and Sudderth (1996).

Remark 1.1. We denote by "standing assumption" those conditions that are always in force throughout the paper; they will not be cited in theorems. And "assumption" stands for those conditions which are in force only when theorems specifically cite them.

2. The market model.

We adopt a model consisting of a money-market, with price $P_0(\cdot)$ given by

$$dP_0(t) = P_0(t) r(t)\, dt, \qquad P_0(0) = 1, \tag{2.1}$$

and of m stocks with prices-per-share $P_i(\cdot)$ satisfying the equations

$$dP_i(t) = P_i(t) \left[b_i(t)\, dt + \sum_{j=1}^{m} \sigma_{ij}(t) dW_j(t) \right], \qquad i = 1, \dots, m. \tag{2.2}$$

Here $W(\cdot) = (W_1(\cdot), \dots, W_m(\cdot))^*$ is an m-dimensional Brownian motion on a complete probability space $(\Omega, \mathbb{F}, \mathbb{P})$. We shall denote by $\mathbb{F} = \{\mathcal{F}_t\}_{0 \le t \le T}$ the $\mathbb{P}$-augmentation of the filtration generated by $W(\cdot)$. The *coëfficients* of the model, that is, the scalar *interest rate* process $r(\cdot)$, the vector process $b(\cdot) = (b_1(\cdot), \dots, b_m(\cdot))^*$ of *appreciation rates*, and the matrix-valued *volatility process* $\sigma(\cdot) = (\sigma_{ij}(\cdot))_{1 \le i,j \le m}$, are assumed to be bounded, and progressively measurable with respect to $\mathbb{F}$. All processes encountered throughout sections 2–9 of the paper will be defined on the fixed, finite horizon $[0, T]$.

Standing Assumption 2.1. We assume that $\|b(t)\| \leq L,\ |r(t)| \leq L,\ \forall\, 0 \leq t \leq T$ hold almost surely (a.s.) for some given real constant $L > 0$.

Standing Assumption 2.2. The process $\sigma(\cdot)$ satisfies the strong nondegeneracy condition

$$\xi^* \sigma(t)\sigma^*(t)\xi \geq \epsilon \|\xi\|^2 \qquad \forall\ (t, \xi) \in [0, T] \times \mathbb{R}^m$$

a.s. for some given real constant $\epsilon > 0$. From Standing Assumption 2.2, the matrices $\sigma(t), \sigma^*(t)$ are invertible, and the norms of $(\sigma(t))^{-1}$ and $(\sigma^*(t))^{-1}$ are bounded from above and below by δ and δ^{-1}, respectively, for some $\delta \in (1, \infty)$; cf. Karatzas and Shreve (1991), p. 372. We also define the "relative risk" process

$$\theta(t) \overset{\triangle}{=} \sigma^{-1}(t)[b(t) - r(t)\mathbf{1}_m], \tag{2.3}$$

where $\mathbf{1}_m = (1, \ldots, 1)^*$, the discount process

$$\gamma(t) \overset{\triangle}{=} \frac{1}{P_0(t)} = \exp\left\{ -\int_0^t r(s)\, ds \right\}, \tag{2.4}$$

the exponential martingale (or *likelihood ratio* process)

$$Z_0(t) \overset{\triangle}{=} \exp\left\{ -\int_0^t \theta^*(s)\, dW(s) - \frac{1}{2}\int_0^t \|\theta(s)\|^2\, ds \right\}, \tag{2.5}$$

and the state-price-density process

$$H(t) \overset{\triangle}{=} \gamma(t) Z_0(t). \tag{2.6}$$

3. Portfolio and wealth processes. A *portfolio process* $\pi(\cdot) = (\pi_1(\cdot), \ldots, \pi_m(\cdot))^*$ is $\mathbb{R}^m$-valued, and a *consumption process* $c(\cdot)$ takes values in $[0, \infty)$; these are both $\mathbb{F}$-progressively measurable and satisfy

$$\int_0^T c(t)\, dt + \int_0^T \|\pi(t)\|^2\, dt < \infty$$

a.s. We regard $\pi_i(t)$ as the proportion of an agent's wealth invested in stock i at time t; the remaining proportion $1 - \pi^*(t)\mathbf{1}_m = 1 - \sum_{i=1}^m \pi_i(t)$ is invested in the money-market. These proportions are *not* constrained to take values in the interval $[0, 1]$; in other words, we allow both short-selling of stocks and borrowing at the interest rate of the bond. For a given, nonrandom, initial capital $x > 0$, let $X(\cdot) \equiv X^{x,\pi,c}(\cdot)$ denote the *wealth-process* corresponding to a portfolio/consumption process pair $\big(\pi(\cdot), c(\cdot)\big)$ as above. This wealth-process is defined by the initial condition $X^{x,\pi,c}(0) = x$ and the equation

$$\begin{aligned} dX(t) &= \sum_{i=1}^m \pi_i(t) X(t) \left\{ b_i(t)\, dt + \sum_{j=1}^m \sigma_{ij}(t) dW_j(t) \right\} \\ &\quad + \left\{ 1 - \sum_{i=1}^m \pi_i(t) \right\} X(t) r(t)\, dt - c(t)\, dt \\ &= r(t)X(t)dt + X(t)\pi^*(t)\sigma(t)dW_0(t) - c(t)\, dt, \qquad X(0) = x > 0, \end{aligned} \tag{3.1}$$

where we have set

$$W_0(t) \overset{\triangle}{=} W(t) + \int_0^t \theta(s)\, ds, \qquad 0 \le t \le T. \tag{3.2}$$

In other words,

$$d\left(\gamma(t)X^{x,\pi,c}(t)\right) = \gamma(t)X^{x,\pi,c}(t)\pi^*(t)\sigma(t)\, dW_0(t) - \gamma(t)c(t)\, dt, \quad 0 \le t \le T. \tag{3.3}$$

The process $W_0(\cdot)$ of (3.2) is Brownian motion under the *equivalent martingale measure*

$$\mathbb{P}_0(A) \overset{\triangle}{=} \mathbb{E}\big[Z_0(T)\mathbf{1}_A\big], \quad A \in \mathcal{F}_T\ , \tag{3.4}$$

by the Girsanov theorem (section 3.5 in Karatzas and Shreve (1991)). We shall say that a portfolio/consumption process pair (π, c) is *available at initial capital* $x > 0$ if the corresponding wealth-process $X^{x,\pi,c}(\cdot)$ of (3.3) is strictly positive on $[0, T]$ a.s.

An application of Itô's rule to the product of the processes $Z_0(\cdot)$ and $\gamma(\cdot)X^{x,\pi,c}(\cdot)$ leads to

$$\begin{aligned} H(t)X^{x,\pi,c}(t) &+ \int_0^t H(s)c(s)\, ds \\ &= x + \int_0^t H(s)X^{x,\pi,c}(s)(\sigma^*(s)\pi(s) - \theta(s))^*\, dW(s). \end{aligned} \tag{3.5}$$

This shows, in particular, that for any pair (π, c) available at initial capital $x > 0$, the process $H(\cdot)X^{x,\pi,c}(\cdot) + \int_0^\cdot H(s)c(s)\, ds$ is a continuous, positive local martingale, hence a supermartingale, under $\mathbb{P}$. Consequently, the optional sampling theorem gives

$$\mathbb{E}\left[H(\tau)X^{x,\pi,c}(\tau) + \int_0^\tau H(s)c(s)\, ds\right] \le x \qquad \forall\ \tau \in \mathcal{S}. \tag{3.6}$$

Here and in what follows, we denote by $\mathcal{S}_{s,t}$ the class of $\mathbb{F}$-stopping times $\tau : \Omega \longrightarrow [s, t]$ for $0 \le s \le t \le T$, and let $\mathcal{S} \equiv \mathcal{S}_{0,T}$.

4. Utility function. A function $U : (0, \infty) \longrightarrow \mathbb{R}$ will be called *utility function* if it is strictly increasing, strictly concave, continuously differentiable, and satisfies

$$U'(0+) \ \overset{\triangle}{=}\ \lim_{x \downarrow 0} U'(x) = \infty, \qquad U'(\infty)\ \overset{\triangle}{=}\ \lim_{x \uparrow \infty} U'(x) = 0. \tag{4.1}$$

We shall denote by $I(\cdot)$ the (continuous, strictly decreasing) inverse of the marginal-utility function $U'(\cdot)$; this function maps $(0, \infty)$ onto itself and satisfies $I(0+) = \infty,\ I(\infty) = 0$. We also introduce the Legendre–Fenchel transform

$$\tilde{U}(y)\ \overset{\triangle}{=}\ \max_{x>0}\, [U(x) - xy]\ =\ U(I(y)) - yI(y), \qquad 0 < y < \infty, \tag{4.2}$$

of $-U(-x)$; this function $\tilde{U}(\cdot)$ is strictly decreasing, strictly convex, and satisfies

$$\tilde{U}'(y) = -I(y), \qquad 0 < y < \infty, \tag{4.3}$$

$$U(x) = \min_{y>0}\, [\tilde{U}(y) + xy]\ =\ \tilde{U}(U'(x)) + xU'(x), \qquad 0 < x < \infty. \tag{4.4}$$

The inequality

$$U(I(y)) \ge U(x) + y[I(y) - x] \qquad \forall\ x > 0,\ y > 0, \tag{4.5}$$

is a direct consequence of (4.2).

5. The optimization problem. The agent in our model has time-dependent utility of the form $\int_0^t e^{-\beta s} U_1\big(c(s)\big)\,ds + e^{-\beta t} U_2(x)$, with $\beta \geq 0$ a real constant. The utility functions $U_1(\cdot)$, $U_2(\cdot)$ measure his utility from consumption and wealth, respectively, whereas β stands for a discount factor. If the agent uses the portfolio/consumption strategy (π, c) available at initial capital $x > 0$, and the stopping rule $\tau \in \mathcal{S}$, his *expected discounted utility* is

$$J(x; \pi, c, \tau) \overset{\triangle}{=} \mathbb{E}\left[\int_0^\tau e^{-\beta t} U_1\big(c(t)\big)\,dt + e^{-\beta\tau} U_2(X^{x,\pi,c}(\tau))\right]. \tag{5.1}$$

The optimization problem considered in this paper is the following: *to maximize the expected discounted utility in* (5.1), over the class $\mathcal{A}(x)$ of triples (π, c, τ) as above, for which the expectation in (5.1) is well defined, i.e.,

$$\mathbb{E}\left[\int_0^\tau e^{-\beta t} U_1^-\big(c(t)\big)\,dt + e^{-\beta\tau} U_2^-(X^{x,\pi,c}(\tau))\right] < \infty. \tag{5.2}$$

(Here and in what follows, x^- denotes the negative part of the real number x, namely, $x^- = \max(-x, 0)$.) The value-function of this problem will be denoted by

$$V(x) \overset{\triangle}{=} \sup_{(\pi,c,\tau)\in\mathcal{A}(x)} J(x; \pi, c, \tau), \qquad x \in (0, \infty). \tag{5.3}$$

We say that the value $V(x)$ is "attainable" if we can find a triple $(\hat\pi, \hat c, \hat\tau) \in \mathcal{A}(x)$ with $V(x) = J(x, \hat\pi, \hat c, \hat\tau)$; such a triple is then called "optimal" for problem (5.3). To ensure that this problem is meaningful, we impose the following assumption throughout.

Standing Assumption 5.1. $V(x) < \infty \quad \forall x \in (0, \infty)$.

It is fairly straightforward that the function $V(\cdot)$ is increasing on $(0, \infty)$. However, it is not clear at this stage whether $V(\cdot)$ is concave or not. We shall discuss this issue in section 8.

Remark 5.2. A sufficient condition for Standing Assumption 5.1 is that

$$\max\{U_1(x),\ U_2(x)\} \leq k_1 + k_2 x^\delta \qquad \forall\ x \in (0, \infty) \tag{5.4}$$

holds for some $k_1 > 0,\ k_2 > 0,\ \delta \in (0, 1)$; cf. Remark 3.6.8 in Karatzas and Shreve (1998).

6. Duality approach. For any *fixed* stopping time $\tau \in \mathcal{S}$, we denote by $\Pi_\tau(x)$ the set of portfolio/consumption process pairs (π, c) for which $(\pi, c, \tau) \in \mathcal{A}(x)$. The solution of the utility maximization problem

$$V_\tau(x) \overset{\triangle}{=} \sup_{(\pi,c)\in\Pi_\tau(x)} J(x; \pi, c, \tau) \tag{6.1}$$

can be derived as in KLS (1987). We review briefly the results in this section. For any triple $(\pi, c, \tau) \in \mathcal{A}(x)$ and any real number $\lambda > 0$, it follows from (4.2), (3.6) that

$$\begin{aligned}
J(x; \pi, c, \tau) &= \mathbb{E}\left[\int_0^\tau e^{-\beta t} U_1\big(c(t)\big)\,dt + e^{-\beta\tau} U_2(X^{x,\pi,c}(\tau))\right] \\
&\leq \mathbb{E}\left[\int_0^\tau e^{-\beta t} \tilde U_1(\lambda e^{\beta t} H(t))\,dt + e^{-\beta\tau} \tilde U_2(\lambda e^{\beta\tau} H(\tau))\right] \\
&\qquad + \lambda \cdot \mathbb{E}\left[H(\tau) X^{x,\pi,c}(\tau) + \int_0^\tau H(t) c(t)\,dt\right] \\
&\leq \mathbb{E}\left[\int_0^\tau e^{-\beta t} \tilde U_1(\lambda e^{\beta t} H(t))\,dt + e^{-\beta\tau} \tilde U_2(\lambda e^{\beta\tau} H(\tau))\right] + \lambda x,
\end{aligned}$$

with equality if and only if

$$X^{x,\pi,c}(\tau) = I_2(\lambda e^{\beta\tau} H(\tau)) \text{ and } c(t) = I_1\big(\lambda e^{\beta t} H(t)\big) \quad \forall\, 0 \le t \le \tau \quad \text{a.s.,} \tag{6.2}$$

$$\mathbb{E}\left[H(\tau)X^{x,\pi,c}(\tau) + \int_0^\tau H(t)c(t)\,dt\right] = x \tag{6.3}$$

hold. It develops that we have $V_\tau(x) \;\le\; \inf_{\lambda>0}\left[\tilde{J}(\lambda;\tau) + \lambda x\right] \quad \forall\, \tau \in \mathcal{S},$ as well as

$$V(x) \;=\; \sup_{\tau\in\mathcal{S}} V_\tau(x) \;\le\; \sup_{\tau\in\mathcal{S}} \inf_{\lambda>0} \left[\tilde{J}(\lambda;\tau) + \lambda x\right] \tag{6.4}$$

with the notation

$$\tilde{J}(\lambda;\tau) \overset{\triangle}{=} \mathbb{E}\left[\int_0^\tau e^{-\beta t}\tilde{U}_1\big(\lambda e^{\beta t}H(t)\big)\,dt + e^{-\beta\tau}\tilde{U}_2(\lambda e^{\beta\tau}H(\tau))\right]. \tag{6.5}$$

In order to proceed, we shall need the following assumption (see Remark 6.7 for discussion).

Assumption 6.1. $\mathbb{E}\left[\sup_{0\le t\le T}\big(H(t)\cdot I_2(\lambda e^{\beta t}H(t)\big) + \int_0^T H(t)I_1(\lambda e^{\beta t}H(t))\,dt\right]$ $< \infty \quad \forall \lambda \in (0,\infty)$.

Under this assumption, for any given $\tau \in \mathcal{S}$, the function $\mathcal{X}_\tau : (0,\infty) \to (0,\infty)$ defined by

$$\mathcal{X}_\tau(\lambda) \overset{\triangle}{=} \mathbb{E}\left[\int_0^\tau H(t)I_1\big(\lambda e^{\beta t}H(t)\big)\,dt + H(\tau)\cdot I_2(\lambda e^{\beta\tau}H(\tau))\right],\ 0<\lambda<\infty, \tag{6.6}$$

is a continuous, strictly decreasing mapping of $(0,\infty)$ onto itself with $\mathcal{X}_\tau(0+) = \infty$, $\mathcal{X}_\tau(\infty) = 0$; thus $\mathcal{X}_\tau(\cdot)$ has a continuous, strictly decreasing inverse $\mathcal{Y}_\tau(\cdot)$ from $(0,\infty)$ onto itself. We define

$$\xi^x(\tau) \overset{\triangle}{=} I_2\big(\mathcal{Y}_\tau(x)e^{\beta\tau}H(\tau)\big) \text{ and } \eta^x(t) \overset{\triangle}{=} I_1\big(\mathcal{Y}_\tau(x)e^{\beta t}H(t)\big),\ \ 0 \le t \le T, \tag{6.7}$$

so that, in particular,

$$\mathbb{E}\left[H(\tau)\xi^x(\tau) + \int_0^\tau H(t)\eta^x(t)\,dt\right] = x. \tag{6.8}$$

LEMMA 6.2. *For any $\tau \in \mathcal{S}$, the random variables of* (6.7) *satisfy*

$$\mathbb{E}\left[e^{-\beta\tau}U_2^-\big(\xi^x(\tau)\big) + \int_0^\tau e^{-\beta t}U_1^-\big(\eta^x(t)\big)\,dt\right] < \infty, \tag{6.9}$$

and for every portfolio/consumption pair $(\pi, c) \in \Pi_\tau(x)$ we have

$$\begin{aligned}&\mathbb{E}\left[\int_0^\tau U_1\big(c(t)\big)\,dt + e^{-\beta\tau}U_2(X^{x,\pi,c}(\tau))\right]\\ &\qquad \le\; \mathbb{E}\left[\int_0^\tau U_1\big(\eta^x(t)\big)\,dt + e^{-\beta\tau}U_2(\xi^x(\tau))\right].\end{aligned} \tag{6.10}$$

Lemma 6.2 can be proved by arguments similar to those used in the proof of Theorem 3.6.3 in Karatzas and Shreve (1998). We conclude from Lemma 6.2 that, if there exists a portfolio $\hat{\pi}_\tau(\cdot)$ such that $(\hat{\pi}_\tau, \hat{c}_\tau)$ is available at initial capital $x > 0$, where $\hat{c}_\tau(\cdot) \overset{\triangle}{=} \eta^x(\cdot)\mathbf{1}_{[0,\tau[}(\cdot)$, and if

$$X^{x,\hat{\pi}_\tau,\hat{c}_\tau}(\tau) = \xi^x(\tau) \tag{6.11}$$

holds a.s., then the pair $(\hat{\pi}_\tau, \hat{c}_\tau)$ belongs to $\Pi_\tau(x)$ and is optimal for the utility maximization problem (6.1). The existence of such a portfolio will need the assumption of market completeness, as we shall see in the next lemma.

LEMMA 6.3. *For any $\tau \in \mathcal{S}$, any $\mathcal{F}_\tau$-measurable random variable B with $\mathbb{P}[B > 0] = 1$, and any progressively measurable process $c(\cdot) \geq 0$ that satisfies $c(\cdot) \equiv 0$ almost everywhere (a.e.) on $[\![\tau, T]\!]$ as well as $\mathbb{E}\left[H(\tau)B + \int_0^T H(t)c(t)\,dt\right] = x$, there exists a portfolio process $\pi(\cdot)$ such that, a.s.*

$$X^{x,\pi,c}(t) > 0, \quad 0 \leq t \leq T, \qquad \text{and} \qquad X^{x,\pi,c}(\tau) = B.$$

Proof. We begin with the strictly positive, continuous process $X(\cdot)$ defined by

$$X(t) \overset{\triangle}{=} \frac{1}{\gamma(t)} \cdot \mathbb{E}_0\left[\gamma(\tau)B + \int_{t\wedge\tau}^{\tau} \gamma(s)c(s)\,ds \middle| \mathcal{F}_t\right], \qquad 0 \leq t \leq T.$$

This process satisfies

$$X(0) = \mathbb{E}_0\left[\gamma(\tau)B + \int_0^\tau \gamma(s)c(s)\,ds\right] = \mathbb{E}\left[H(\tau)B + \int_0^\tau H(s)c(s)\,ds\right] = x,$$

and $X(\tau) = B$ a.s. On the other hand, the $\mathbb{P}_0$-martingale

$$M(\cdot) \overset{\triangle}{=} \gamma(\cdot)X(\cdot) + \int_0^{\cdot} \gamma(s)c(s)\,ds = \mathbb{E}_0\left[\gamma(\tau)B + \int_0^\tau \gamma(s)c(s)\,ds|\mathcal{F}.\right]$$

admits the stochastic integral representation

$$M(t) = x + \int_0^t \psi^*(s)\,dW_0(s), \qquad 0 \leq t \leq T,$$

for some $\mathbb{F}$-adapted process $\psi(\cdot)$ that satisfies $\int_0^T \|\psi(s)\|^2\,ds < \infty$ a.s. (e.g., Karatzas and Shreve (1998), Lemma 1.6.7). Define $\pi(t) \overset{\triangle}{=} (\sigma^*(t))^{-1}\psi(t)/M(t)$, $0 \leq t \leq T$, and check from (3.3) that $X(\cdot) = X^{x,\pi,c}(\cdot)$ a.e. on $[0,T] \times \Omega$. □

Remark 6.4. Note that the martingale $M(\cdot)$ is constant, and thus we have $\psi(\cdot) \equiv 0$, $\pi(\cdot) \equiv 0$ a.e. on the stochastic interval $[\![\tau, T]\!]$; in particular, $X^{x,\pi,c}(t,\omega) = B(\omega)e^{\int_{\tau(\omega)}^t r(u,\omega)\,du}$ a.e. on $[\![\tau, T]\!]$. In other words, at the stopping time τ all investment in the stock market ceases, and all proceeds are invested in the money-market from then on.

We have proved the following result.

PROPOSITION 6.5. *Under Assumption* 6.1, *for any $\tau \in \mathcal{S}$ we have*

$$V_\tau(x) = \inf_{\lambda>0}\left[\tilde{J}(\lambda;\tau) + \lambda x\right] = \tilde{J}(\mathcal{Y}_\tau(x);\tau) + x\mathcal{Y}_\tau(x), \tag{6.12}$$

and the supremum in (6.1) *is attained by the consumption strategy* $\hat{c}_\tau(t) = I_1\big(\mathcal{Y}_\tau(x)e^{\beta t} H(t)\big)\mathbf{1}_{[0,\tau)}(t)$ *and some portfolio* $\hat{\pi}_\tau(\cdot)$ *that satisfies* (6.11). *Moreover,*

(6.13)
$$V(x) = \sup_{\tau\in\mathcal{S}} V_\tau(x) = \sup_{\tau\in\mathcal{S}}\inf_{\lambda>0}\left[\tilde{J}(\lambda;\tau) + \lambda x\right] = \sup_{\tau\in\mathcal{S}}\left[\tilde{J}(\mathcal{Y}_\tau(x);\tau) + x\mathcal{Y}_\tau(x)\right].$$

Example 6.6 (logarithmic utility functions). $U_1(x) = \delta\log x,\ U_2(x) = \log x$ for $x > 0$ and some $\delta \in [0,1]$. In this case, Assumption 6.1 is satisfied, and we have $I_1(y) = \delta/y,\ \tilde{U}_1(y) = \delta\log\delta - \delta[1+\log y]$, and $I_2(y) = 1/y,\ \tilde{U}_2(y) = -1-\log y$. Hence, with

$$Q(t) \triangleq \int_0^t \theta^*(s)\,dW(s) + \int_0^t \left(r(s) + \frac{\|\theta(s)\|^2}{2} - \beta\right) ds$$

and with the convention $\delta\log\delta \equiv 0$ for $\delta = 0$, we have

$$\tilde{J}(\lambda;\tau) = \mathbb{E}\left[e^{-\beta\tau}\left(Q(\tau) - (1+\log\lambda)\right)\right] + \delta\cdot\mathbb{E}\int_0^\tau e^{-\beta t}\big(Q(t) - (1+\log\lambda)\big)\,dt$$
$$+\delta\log\delta\cdot\mathbb{E}\int_0^\tau e^{-\beta t}\,dt$$

for any stopping time τ. It develops that $\mathcal{X}_\tau(\lambda) = K_\tau/\lambda$ and thus $\mathcal{Y}_\tau(x) = K_\tau/x$, where

$$K_\tau \triangleq \mathbb{E}\left[e^{-\beta\tau} + \delta\int_0^\tau e^{-\beta t}\,dt\right].$$

From Proposition 6.5, the value-function of problem (5.3) is given by

$$V(x) = \sup_{\tau\in\mathcal{S}}\ \mathbb{E}\left[e^{-\beta\tau}\big\{\log\big(x/K_\tau\big) + Q(\tau)\big\} + \delta\cdot\int_0^\tau e^{-\beta t}\big\{\log\big(x/K_\tau\big) + Q(t)\big\}\,dt\right],$$

a quantity that is, in general, very difficult to compute. It is not even clear whether the supremum in this expression is attained (see Example 9.3 in this regard). However, *in the special case* $\beta = 0$ *and* $\delta = 0$, the above expression can be reduced significantly to

$$V(x) = \log x + \sup_{\tau\in\mathcal{S}}\mathbb{E}\int_0^\tau \left[r(u) + \frac{1}{2}\|\theta(u)\|^2\right] du$$

and amounts to solving a standard optimal stopping problem. The latter has the trivial solution $\tau^* \equiv T$ for $r(\cdot) \geq 0$.

Remark 6.7. A sufficient condition for Assumption 6.1 is that

$$I_1(y) + I_2(y) \leq k_1 + k_2 y^{-\alpha} \qquad \forall\ y \in (0,\infty) \tag{6.14}$$

holds for some constants $k_1 > 0$, $k_2 > 0$, and $\alpha > 0$. Indeed, under (6.14) we have

$$\mathbb{E}\left[\sup_{0\leq s\leq T}\left(H(s)\cdot I_j(\lambda e^{\beta s}H(s))\right)\right] \leq k_1\mathbb{E}\left[\sup_{0\leq s\leq T}(H(s))\right] + k_2\lambda^{-\alpha}\mathbb{E}\left[\sup_{0\leq s\leq T}(H(s))^{1-\alpha}\right]$$
$$< \infty$$

for $j = 1, 2$, as is easy to check using Hölder's inequality, Doob's maximal inequality, and the boundedness of market coefficients. This is because, for any $\rho \in \mathbf{R}$, there exist positive constants $C_1,\ C_2$ such that

$$\begin{aligned}\mathbb{E}\left[\sup_{0\le t\le T}\big(H(t)\big)^{\rho}\right] &= \mathbf{E}\left[\sup_{0\le t\le T}\big(\gamma(t)Z_0(t)\big)^{\rho}\right] \ \le\ C_1\cdot\mathbb{E}\left[\sup_{0\le t\le T}\big(Z_0(t)\big)^{\rho}\right]\\ &\le C_1\cdot\mathbb{E}\left[\sup_{0\le t\le T}\left(e^{-\rho\int_0^t\theta^*(s)\,dW(s)-\frac{\rho^2}{2}\int_0^t\|\theta(s)\|^2\,ds}\right)\right.\\ &\qquad\qquad\left.\cdot\sup_{0\le t\le T}\left(e^{\frac{\rho(\rho-1)}{2}\int_0^t\|\theta(s)\|^2\,ds}\right)\right]\\ &\le C_2\cdot\mathbb{E}\left[\sup_{0\le t\le T}\left(e^{-\rho\int_0^t\theta^*(s)\,dW(s)-\frac{\rho^2}{2}\int_0^t\|\theta(s)\|^2\,ds}\right)\right]<\infty.\end{aligned}$$

7. Pure optimal stopping problems. The representation (6.13) for the solution of the utility maximization problem in section 5 is not entirely satisfactory. It is not clear how the quantities $\mathcal{Y}_\tau(x)$ are related to each other for different stopping times $\tau\in\mathcal{S}$, except in some very special cases. Furthermore, it is not easy to compute the last supremum in (6.13), or even to decide whether it is attained or not. All these points are illustrated in Example 6.6 of a logarithmic utility function. In this section, we shall try to convert the original problem into a family of *pure optimal stopping* problems, for which we can obtain a better understanding. To this end, we define, for every $\lambda\in(0,\infty)$, the *dual optimization problem*

(7.1)
$$\tilde{V}(\lambda)\overset{\triangle}{=}\sup_{\tau\in\mathcal{S}}\tilde{J}(\lambda;\tau)=\sup_{\tau\in\mathcal{S}}\ \mathbb{E}\left[\int_0^\tau e^{-\beta t}\tilde{U}_1\big(\lambda e^{\beta t}H(t)\big)\,dt+e^{-\beta\tau}\tilde{U}_2\big(\lambda e^{\beta\tau}H(\tau)\big)\right]$$

of pure optimal stopping type, in the notation of (6.5), (4.2), (2.6). To ensure that the problem of (7.1) is meaningful, we impose the following assumption throughout.

Standing Assumption 7.1. For any $\lambda\in(0,\infty)$ we have $\tilde{V}(\lambda)<\infty$, and there exists some stopping time $\hat{\tau}_\lambda$ which is optimal in (7.1), i.e., such that $\tilde{V}(\lambda)=\tilde{J}(\lambda;\hat{\tau}_\lambda)$.

Here and in what follows, we denote by $\hat{\mathcal{S}}_\lambda$ the set of stopping times that attain the supremum in (6.5) for every given $\lambda>0$. It follows from (6.4) that we have, in the notation of (7.1),

(7.2)
$$V(x)\le\sup_{\tau\in\mathcal{S}}\inf_{\lambda>0}\left[\tilde{J}(\lambda;\tau)+\lambda x\right]\le\inf_{\lambda>0}\left[\sup_{\tau\in\mathcal{S}}\tilde{J}(\lambda;\tau)+\lambda x\right]=\inf_{\lambda>0}\left[\tilde{V}(\lambda)+\lambda x\right].$$

We wish that the inequalities in (7.2) would always hold as equalities. Unfortunately, it turns out that the second inequality in (7.2) might be strict, depending on the coefficients of the model and on the initial capital x. We shall see this more clearly in the following sections.

Remark 7.2. Standing Assumption 7.1 holds if condition (5.4) is satisfied. This is because the continuous process $Y^\lambda(t)\overset{\triangle}{=}\int_0^t e^{-\beta s}\tilde{U}_1\big(\lambda e^{\beta s}H(s)\big)+e^{-\beta t}\tilde{U}_2(\lambda e^{\beta t}H(t))$, $0\le t\le T$, satisfies in this case $\mathbb{E}[\sup_{0\le t\le T}|Y^\lambda(t)|]<\infty$. Indeed, it is easy to check that (5.4) implies

(7.3)
$$\max\{\tilde{U}_1(y),\tilde{U}_2(y)\}\le k_1+k_3y^{-\alpha}\qquad\forall\ 0<\lambda<\infty$$

with $\alpha = \delta/(1-\delta)$, $k_3 = (1-\delta)(k_2\delta^\delta)^{1/(1-\delta)}$ (cf. KLSX (1991)), and it follows from Remark 6.7 that $\tilde{V}(\lambda) \le \mathbb{E}\left[\sup_{0\le t\le T} |Y^\lambda(t)|\right] \le k_4 + k_5\lambda^{-\alpha} \cdot \mathbb{E}\big[\sup_{0\le t\le T} \big(H(t)\big)^{-\alpha}\big] < \infty$. Standard results in the theory of optimal stopping (e.g., Theorem D.12 in Karatzas and Shreve (1998)) guarantee then the existence of an optimal stopping time.

8. Analysis of the optimal stopping problem. In this section we shall derive our main results for the optimization problem of (5.3), by first establishing several properties of the "dual" value function $\tilde{V}(\cdot)$ defined in (7.1). It is not a trivial matter to decide whether the value function $V(\cdot)$ of our "primal" problem (5.3) inherits the concavity of $U(\cdot)$. Indeed, even the continuity of $V(\cdot)$ is not quite clear a priori. However, properties of convexity and monotonicity are relatively straightforward for the dual value function $\tilde{V}(\cdot)$ of (7.1).

LEMMA 8.1. *The function $\tilde{V}(\cdot)$ of (7.1) is strictly convex and strictly decreasing. In particular, it is continuous and a.e. differentiable.*

Proof. For any $0 < \lambda_1 < \lambda_2 < \infty$, $0 < s < 1$, and $\lambda_0 \overset{\triangle}{=} s\lambda_1 + (1-s)\lambda_2$, we have $\tilde{V}(\lambda_2) = \tilde{J}(\lambda_2; \hat{\tau}_2) < \tilde{J}(\lambda_1; \hat{\tau}_2) \le \tilde{V}(\lambda_1)$ from Standing Assumption 7.1, where $\hat{\tau}_i \in \hat{\mathcal{S}}_{\lambda_i}$, $i = 0, 1, 2$ are optimal stopping times, and $\tilde{V}(\lambda_0) = \tilde{J}(\lambda_0; \hat{\tau}_0) < s\tilde{J}(\lambda_1; \hat{\tau}_0) + (1-s)\tilde{J}(\lambda_2; \hat{\tau}_0) \le s\tilde{V}(\lambda_1) + (1-s)\tilde{V}(\lambda_2)$. □

It follows from Lemma 8.1 that the right- and left-derivatives

$$\triangle^\pm \tilde{V}(\lambda) \overset{\triangle}{=} \lim_{h\to 0\pm} \frac{1}{h}[\tilde{V}(\lambda+h) - \tilde{V}(\lambda)] \tag{8.1}$$

of the convex function $\tilde{V}(\cdot)$ exist, and are finite for every $\lambda \in (0,\infty)$. Furthermore, the strict convexity of $\tilde{V}(\cdot)$ implies

$$\triangle^+ \tilde{V}(\lambda_1) < \triangle^- \tilde{V}(\lambda_2) \le \triangle^+ \tilde{V}(\lambda_2) \le 0 \quad \forall\, 0 < \lambda_1 < \lambda_2 < \infty, \tag{8.2}$$

and $\triangle^+\tilde{V}(\cdot)$ (respectively, $\triangle^-\tilde{V}(\cdot)$) is right- (respectively, left-) continuous.

LEMMA 8.2. *For every $\lambda \in (0,\infty)$ and any optimal stopping time $\hat{\tau}_\lambda \in \hat{\mathcal{S}}_\lambda$, we have*

$$\triangle^- \tilde{V}(\lambda) \le -\mathcal{X}_{\hat{\tau}_\lambda}(\lambda) \le \triangle^+ \tilde{V}(\lambda). \tag{8.3}$$

Proof. The convexity of $\tilde{U}_j(\cdot)$, $j = 1, 2$, gives

$$\tilde{U}_j'(y)(x-y) \le \tilde{U}_j(x) - \tilde{U}_j(y) \le \tilde{U}_j'(x)(x-y) \quad \forall\, 0 < x, y < \infty, \tag{8.4}$$

and for any real number h with $|h| < \lambda$ we obtain

$$\begin{aligned}
\tilde{V}(\lambda+h) - \tilde{V}(\lambda) &= \tilde{V}(\lambda+h) - \tilde{J}(\lambda; \hat{\tau}_\lambda) \ge \tilde{J}(\lambda+h; \hat{\tau}_\lambda) - \tilde{J}(\lambda; \hat{\tau}_\lambda) \\
&\ge h \cdot \mathbb{E}\left[\int_0^{\hat{\tau}_\lambda} H(t)\tilde{U}_1'\big(\lambda e^{\beta t} H(t)\big)\,dt + H(\hat{\tau}_\lambda)\tilde{U}_2'(\lambda e^{\beta\hat{\tau}_\lambda} H(\hat{\tau}_\lambda))\right] \\
&= -h\mathcal{X}_{\hat{\tau}_\lambda}(\lambda).
\end{aligned}$$

The last equality follows from (4.3) and the definition (6.6) of $\mathcal{X}_{\hat{\tau}}(\cdot)$. Letting $h \to 0$, we deduce for arbitrary $\lambda \in (0,\infty)$:

$$\begin{aligned}
\triangle^+\tilde{V}(\lambda) &= \lim_{h\to 0+} \frac{1}{h}[\tilde{V}(\lambda+h) - \tilde{V}(\lambda)] \\
&\ge -\mathcal{X}_{\hat{\tau}_\lambda}(\lambda) \ge \lim_{h\to 0-} \frac{1}{h}[\tilde{V}(\lambda+h) - \tilde{V}(\lambda)] \\
&= \triangle^-\tilde{V}(\lambda). \qquad \square
\end{aligned}$$

COROLLARY 8.3. *If $\tilde{V}(\cdot)$ is differentiable at $\lambda > 0$, then $\tilde{V}'(\lambda) = -\mathcal{X}_{\hat{\tau}_\lambda}(\lambda)$.*

LEMMA 8.4. *We have $\lim_{\lambda \downarrow 0} \triangle^{\pm} \tilde{V}(\lambda) = -\infty$. Moreover, if Assumption 6.1 holds, we also have $\lim_{\lambda \uparrow \infty} \triangle^{\pm} \tilde{V}(\lambda) = 0$.*

Proof. From the decrease of the function $I(\cdot)$, the monotone convergence theorem, and $I(0+) = \infty$, it follows that

$$\lim_{\lambda \downarrow 0} \mathcal{X}_{\hat{\tau}_\lambda}(\lambda) \geq \lim_{\lambda \downarrow 0} \mathbb{E}\left[\inf_{0 \leq s \leq T} \left(H(s) \cdot I_2\left(\lambda e^{\beta T} \sup_{0 \leq s \leq T} H(s)\right)\right)\right] = \infty,$$

and so by Lemma 8.2 and the inequality (8.2) we obtain $\lim_{\lambda \downarrow 0} \triangle^{\pm} \tilde{V}(\lambda) = -\infty$. Now suppose that Assumption 6.1 holds; we have then

$$\begin{aligned} 0 &\leq \lim_{\lambda \uparrow \infty} \mathcal{X}_{\hat{\tau}_\lambda}(\lambda) \\ &\leq \lim_{\lambda \uparrow \infty} \mathbb{E}\left[\sup_{0 \leq s \leq T} \left(H(s) \cdot I_2\left(\lambda e^{\beta s} H(s)\right)\right) + \int_0^T H(s) \cdot I_1\big(\lambda e^{\beta s} H(s)\big)\, ds\right] = 0 \end{aligned}$$

from the decrease of the functions $I_j(\cdot)$, the dominated convergence theorem, and $I_j(\infty) = 0$, $j = 1, 2$. It follows again from Lemma 8.2 and (8.2) that $\lim_{\lambda \uparrow \infty} \triangle^{\pm} \tilde{V}(\lambda) = 0$. □

We shall define, for each given $\lambda > 0$, the subset

$$\mathcal{G}_\lambda \overset{\triangle}{=} \left\{\mathcal{X}_{\hat{\tau}_\lambda}(\lambda) \Big/ \hat{\tau}_\lambda \text{ is optimal in (7.1), i.e., } \hat{\tau}_\lambda \in \hat{\mathcal{S}}_\lambda\right\} \tag{8.5}$$

of $\mathbb{R}^+$. It follows from (8.2) and (8.3) that the sets $\{\mathcal{G}_\lambda\}_{\lambda > 0}$ satisfy the following properties:

(i) $\mathcal{G}_\lambda$ is nonempty for every $\lambda > 0$,

(ii) $\mathcal{G}_\lambda \cap \mathcal{G}_\nu = \emptyset$, if $\lambda \neq \nu$, and

(iii) for any $0 < \nu < \lambda < \infty$ and $x \in \mathcal{G}_\lambda$, $y \in \mathcal{G}_\nu$, we have $x < y$.

Let us also introduce the set

$$\mathcal{G} \overset{\triangle}{=} \bigcup_{\lambda > 0} \mathcal{G}_\lambda. \tag{8.6}$$

We can state now the main result of the paper. This explains, in particular, when we can expect to find an optimal triple in (5.3) and to have equality in (7.2).

THEOREM 8.5. *For any $x \in \mathcal{G}$, the value $V(x)$ of (5.3) is attainable and we have*

$$V(x) = \inf_{\lambda > 0} \left[\tilde{V}(\lambda) + \lambda x\right]. \tag{8.7}$$

Conversely, for any $x \in (0, \infty)$ that satisfies (8.7) and for which the value $V(x)$ of (5.3) is attainable, we have $x \in \mathcal{G}$, provided that Assumption 6.1 holds.

Proof. Suppose $x \in \mathcal{G}_\nu$ for some $\nu > 0$, and $x = \mathcal{X}_{\hat{\tau}_\nu}(\nu)$ for some stopping time $\hat{\tau}_\nu \in \hat{\mathcal{S}}_\nu$ which is optimal in (7.1) with $\lambda = \nu$, i.e., with

$$\tilde{V}(\nu) = \tilde{J}(\nu; \hat{\tau}_\nu) = \mathbb{E}\left[\int_0^{\hat{\tau}_\nu} e^{-\beta t} \tilde{U}_1\big(\nu e^{\beta t} H(t)\big)\, dt + e^{-\beta \hat{\tau}_\nu} \tilde{U}_2\big(\nu e^{\beta \hat{\tau}_\nu} H(\hat{\tau}_\nu)\big)\right]. \tag{8.8}$$

Then we claim

$$V(x) = \tilde{V}(\nu) + \nu x = \inf_{\lambda > 0} [\tilde{V}(\lambda) + \lambda x]. \tag{8.9}$$

Indeed, by Lemma 8.2, we have $-x \in [\triangle^- \tilde{V}(\nu), \triangle^+ \tilde{V}(\nu)]$, so that $\tilde{V}(\lambda) - \tilde{V}(\nu) \geq (-x) \cdot (\lambda - \nu)$, or, equivalently, $\tilde{V}(\lambda) + \lambda x \geq \tilde{V}(\nu) + \nu x \quad \forall \lambda > 0$.

Since $x = \mathcal{X}_{\hat{\tau}_\nu}(\nu) = \mathbb{E}\big[H(\hat{\tau}_\nu) I_2(\nu e^{\beta \hat{\tau}_\nu} H(\hat{\tau}_\nu)) + \int_0^{\hat{\tau}_\nu} H(t) I_1\big(\nu e^{\beta t} H(t)\big)\, dt\big]$, it follows from Lemma 6.3 and Lemma 6.2 that there exists a portfolio process $\hat{\pi}(\cdot)$ with $X^{x,\hat{\pi},\hat{c}}(\hat{\tau}_\nu) = I_2(\nu e^{\beta \hat{\tau}_\nu} H(\hat{\tau}_\nu))$, where $\hat{c}(t) \overset{\triangle}{=} I_1\big(\nu e^{\beta t} H(t)\big) \mathbf{1}_{[0,\tau)}(t)$. The expected utility $J(x; \hat{\pi}, \hat{c}, \hat{\tau}_\nu)$, under the portfolio/consumption strategy $(\hat{\pi}, \hat{c})$ and the stopping time $\hat{\tau}_\nu$, is thus

$$\begin{aligned}
V(x) \geq J(x; \hat{\pi}, \hat{c}, \hat{\tau}_\nu) &= \mathbb{E}\left[\int_0^{\hat{\tau}_\nu} e^{-\beta t} U_1\big(I_1(\nu e^{\beta t} H(t))\big)\, dt + e^{-\beta \hat{\tau}_\nu} U_2(I_2(\nu e^{\beta \hat{\tau}_\nu} H(\hat{\tau}_\nu)))\right] \\
&= \mathbb{E}\left[\int_0^{\hat{\tau}_\nu} e^{-\beta t} \tilde{U}_1\big(\nu e^{\beta t} H(t)\big) + e^{-\beta \hat{\tau}_\nu} \tilde{U}_2(\nu e^{\beta \hat{\tau}_\nu} H(\hat{\tau}_\nu))\right] \\
&\qquad + \nu \cdot \mathbb{E}\left[H(\hat{\tau}_\nu) X^{x,\hat{\pi},\hat{c}}(\hat{\tau}_\nu) + \int_0^{\hat{\tau}_\nu} H(t) \hat{c}(t)\, dt\right] \\
&= \tilde{V}(\nu) + \nu x = \inf_{\lambda > 0} [\tilde{V}(\lambda) + \lambda x],
\end{aligned}$$

and (8.9) follows then from (7.2). In particular, the triple $(\hat{\pi}, \hat{c}, \hat{\tau}_\nu)$ in $\mathcal{A}(x)$ is optimal for the original optimization problem of (5.3).

Conversely, suppose that (8.7) holds for some positive real number x, for which the value $V(x)$ of (5.3) is attained by some optimal triple $(\pi^*, c^*, \tau^*) \in \mathcal{A}(x)$. In other words,

$$V(x) = \inf_{\lambda > 0} [\, \tilde{V}(\lambda) + \lambda x\,] = J(x; \pi^*, c^*, \tau^*) \leq V_{\tau^*}(x) \tag{8.10}$$

in the notation of (6.1). Suppose also that Assumption 6.1 holds. By Lemma 8.1 the function $\lambda \longmapsto \tilde{V}(\lambda) + \lambda x =: G(\lambda)$ is strictly convex, with $G(0+) = \tilde{V}(0+)$ and $G(\infty) = \infty$. Thus, either there exists a unique $\nu > 0$ such that

$$\tilde{V}(\nu) + \nu x = \inf_{\lambda > 0} [\, \tilde{V}(\lambda) + \lambda x\,], \tag{8.11}$$

or else we have $\tilde{V}(0+) \leq \tilde{V}(\lambda) + \lambda x \quad \forall \lambda > 0$. This latter possibility can be ruled out easily; it cannot hold if $\tilde{V}(0+) = \infty$, whereas with $\tilde{V}(0+) < \infty$ it leads to $\lim_{\lambda \downarrow 0}\big(-\triangle^+ \tilde{V}(\lambda)\big) \leq x$, which is impossible by Lemma 8.4. Therefore, (8.11) holds for a unique $\nu > 0$ and leads, with (8.10) and Proposition 6.4, to

$$V(x) = \tilde{V}(\nu) + \nu x \geq \tilde{J}(\nu; \tau^*) + \nu x \geq \inf_{\lambda > 0} [\tilde{J}(\lambda; \tau^*) + \lambda x] = V_{\tau^*}(x) \geq V(x). \tag{8.12}$$

We obtain $\tilde{V}(\nu) = \tilde{J}(\nu; \tau^*)$ as well as $\tilde{J}(\nu; \tau^*) + \nu x = \inf_{\lambda > 0} [\tilde{J}(\lambda; \tau^*) + \lambda x]$ from (8.10), (8.12), or, equivalently, $\tau^* \in \hat{\mathcal{S}}_\nu$ and $\nu = \mathcal{Y}_{\tau^*}(x)$. Thus $x = \mathcal{X}_{\tau^*}(\nu) \in \mathcal{G}_\nu$, which concludes the proof. □

COROLLARY 8.6. *Under Assumption* 6.1*, for any* $x \notin \mathcal{G} \equiv \bigcup_{\lambda > 0} \mathcal{G}_\lambda$*, we have the strict inequality ("duality gap")* $V(x) < \inf_{\lambda > 0} [\tilde{V}(\lambda) + \lambda x]$.

COROLLARY 8.7. *Under Assumption* 6.1*, and if* $\tilde{V}(\cdot)$ *is differentiable everywhere, the value* $V(x)$ *of* (5.3) *is attainable and* (8.7) *holds for every* $x \in (0, \infty)$.

Proof. Since every differentiable convex function is continuously differentiable (cf. Rockafellar (1970), Corollary 25.5.1), $\tilde{V}'(\cdot)$ is continuous. By Lemma 8.4, the range of $\tilde{V}'(\cdot)$ is $(-\infty, 0)$. It follows from Corollary 8.3 that $\mathcal{G} = (0, \infty)$, and Theorem 8.5 applies. □

COROLLARY 8.8. *Under Assumption* 6.1*, suppose that for any* $\lambda \in (0, \infty)$ *there exist two sequences* $\{\lambda_n^{(\pm)}\}$ *with* $\lambda_n^{(+)} \downarrow \lambda$, $\lambda_n^{(-)} \uparrow \lambda$, *as well as stopping times* $\hat{\tau} \in \hat{\mathcal{S}}_\lambda$, $\hat{\tau}_n^{(\pm)} \in \hat{\mathcal{S}}_{\lambda_n^{(\pm)}}$ *such that* $\hat{\tau}_n^{(\pm)} \to \hat{\tau}$ *a.s.; then the value* $V(x)$ *of* (5.3) *is attainable and* (8.7) *holds for every* $x > 0$*.*

Proof. By Corollary 8.7, we need only show that $\tilde{V}(\cdot)$ is differentiable everywhere. From (8.4) and (4.3) we have

$$\begin{aligned}
&\tilde{V}(\lambda_n^{(\pm)}) - \tilde{V}(\lambda) \le \tilde{J}(\lambda_n^{(\pm)}; \hat{\tau}_n^{(\pm)}) - \tilde{J}(\lambda; \hat{\tau}_n^{(\pm)}) \\
&\le -(\lambda_n^{(\pm)} - \lambda) \cdot \mathbb{E}\left[\int_0^{\hat{\tau}_n^{\pm}} H(t) I_1\big(\lambda_n^{(\pm)} e^{\beta t} H(t)\big)\, dt + H(\hat{\tau}_n^{(\pm)}) I_2(\lambda_n^{(\pm)} e^{\beta \hat{\tau}_n^{(\pm)}} H(\hat{\tau}_n^{(\pm)}))\right] \\
&= -(\lambda_n^{(\pm)} - \lambda) \cdot \mathcal{X}_{\hat{\tau}_n^{(\pm)}}(\lambda_n^{(\pm)}),
\end{aligned}$$

which implies

$$\begin{aligned}
\triangle^+ \tilde{V}(\lambda) &= \lim_{\lambda_n^{(+)} \downarrow \lambda} \frac{\tilde{V}(\lambda_n^{(+)}) - \tilde{V}(\lambda)}{\lambda_n^{(+)} - \lambda} \le \limsup_{\lambda_n^{(+)} \downarrow \lambda} \big(-\mathcal{X}_{\hat{\tau}_n^{(+)}}(\lambda_n^{(+)})\big) = -\mathcal{X}_{\hat{\tau}}(\lambda), \\
\triangle^- \tilde{V}(\lambda) &= \lim_{\lambda_n^{(-)} \uparrow \lambda} \frac{\tilde{V}(\lambda_n^{(-)}) - \tilde{V}(\lambda)}{\lambda_n^{(-)} - \lambda} \ge \liminf_{\lambda_n^{(-)} \downarrow \lambda} \big(-\mathcal{X}_{\hat{\tau}_n^{(-)}}(\lambda_n^{(-)})\big) = -\mathcal{X}_{\hat{\tau}}(\lambda)
\end{aligned}$$

by the dominated convergence theorem. From (8.2), $\tilde{V}'(\lambda) = \triangle^+ \tilde{V}(\lambda) = \triangle^- \tilde{V}(\lambda) = -\mathcal{X}_{\hat{\tau}}(\lambda)$. □

Corollaries 8.7 and 8.8 provide simple sufficient (but *not* necessary) conditions, under which there is no "duality gap" in (7.2), i.e., its leftmost and rightmost members are equal. The following proposition will characterize this kind of interchangeability of "inf" and "sup" operations from another point of view, namely, the concavity of the "primal" value function $V(\cdot)$.

PROPOSITION 8.9. *Under Assumption* 6.1*, the following two statements are equivalent:*

(A) $V(\cdot)$ *is concave on* $(0, +\infty)$*,*

(B) $V(x) = \inf_{\lambda > 0} [\tilde{V}(\lambda) + \lambda x]$ *holds for every* $x \in (0, \infty)$*.*

Proof of (B) $\Longrightarrow$ (A). Under condition (B), the number $-V(x)$ is the pointwise supremum of the affine functions $g(\lambda) = -\lambda x - \mu$ such that (x, μ) belongs to the epigraph of $\tilde{V}(\cdot)$. Hence $-V(\cdot)$ is a convex function (Rockafellar (1970), Theorem 12.1), or, equivalently, $V(\cdot)$ is concave.

Proof of (A) $\Longrightarrow$ (B). By Lemma 8.4 and (8.2), it is sufficient to show that for any $(\nu, x) \in (0, \infty) \times (0, \infty)$ such that $-\triangle^+ \tilde{V}(\nu) \le x \le -\triangle^- \tilde{V}(\nu)$, we have $V(x) = \tilde{V}(\nu) + \nu x$.

Let $x_0 \overset{\triangle}{=} -\triangle^+ \tilde{V}(\nu)$, $x_1 \overset{\triangle}{=} -\triangle^- \tilde{V}(\nu)$. Since $\tilde{V}(\cdot)$ is strictly convex and differentiable except on a countable set, we can find a sequence of positive real numbers $\{\lambda_n\}$, such that $\lambda_n \downarrow \nu$ as $n \to \infty$, and $\tilde{V}(\cdot)$ is differentiable at each λ_n. Define $y_n \overset{\triangle}{=} -\tilde{V}'(\lambda_n)$. It follows from the right-continuity of $\triangle^+ \tilde{V}(\cdot)$ that $-y_n = \triangle^+ \tilde{V}(\lambda_n) \downarrow \triangle^+ \tilde{V}(\nu) = -x_0$. However, Theorem 8.5 and Corollary 8.3 assert that

$$V(y_n) = \inf_{\lambda > 0} [\tilde{V}(\lambda) + \lambda y_n] = \tilde{V}(\lambda_n) + \lambda_n y_n. \tag{8.13}$$

Letting $n \to \infty$, we obtain

$$V(x_0) = \tilde{V}(\nu) + \nu x_0, \tag{8.14}$$

thanks to the continuity of $V(\cdot)$ (which is concave by assumption (A)) and of $\tilde{V}(\cdot)$ (which is convex by Lemma 8.1). Furthermore, we claim that $\triangle^- V(x_0) \le \nu$. Indeed, it follows from (8.13) and (8.14) that

$$\begin{aligned} V(y_n) - V(x_0) &= \tilde{V}(\lambda_n) + \lambda_n y_n - \tilde{V}(\nu) - \nu x_0 \ge \triangle^+ \tilde{V}(\nu)(\lambda_n - \nu) + \lambda_n y_n - \nu x_0 \\ &= \lambda_n (y_n - x_0), \end{aligned}$$

and hence

$$\triangle^- V(x_0) = \lim_{n\to\infty} \frac{V(y_n) - V(x_0)}{y_n - x_0} \le \lim_{n\to\infty} \lambda_n = \nu. \tag{8.15}$$

Similarly, we obtain

$$V(x_1) = \tilde{V}(\nu) + \nu x_1 \qquad \text{and} \qquad \triangle^+ V(x_1) \ge \nu. \tag{8.16}$$

However, $\triangle^- V(x_0) \ge \triangle^+ V(x_1)$ holds from the concavity of $V(\cdot)$. It follows from (8.15) and (8.16) that $\triangle^- V(x_0) = \nu = \triangle^+ V(x_1)$, or equivalently, $\triangle^- V(x) = \triangle^+ V(x) = V^{'}(x) = \nu \ \ \forall\ x_0 \le x \le x_1$. It is clear now that $V(x) = \tilde{V}(\nu) + \nu x = \inf_{\lambda>0} [\tilde{V}(\lambda) + \lambda x]$ holds for any $x_0 \le x \le x_1$.

9. Examples. Using the technique developed in the preceding section, we study here several examples, including one which shows that optimal strategies need not always exist (see Example 9.3). The first of these examples can also be treated using the methods of section 6, but for the second and third examples the methodology of section 8 is indispensable. The reader of this section should not fail to notice the rarity of a setting where utility functions of power-type are much easier to handle than logarithmic ones.

Example 9.1 (utility functions of power-type). $U_j(x) = x^\alpha/\alpha$, where $0 < \alpha < 1,\ j = 1, 2$. In this case, condition (5.4) is satisfied and we have $I_j(y) = y^{-1/(1-\alpha)}$ and $\tilde{U}_j(y) = y^{-\gamma}/\gamma$ with $\gamma = \alpha/(1-\alpha),\ j = 1, 2$, so that Assumption 6.1 is also satisfied (see Remark 6.7) and implies $K < \infty$ in (9.2) below. We obtain easily

(9.1)
$$\tilde{V}(\lambda) = \sup_{\tau\in\mathcal{S}} \mathbb{E}\left[\int_0^\tau e^{-\beta t}\tilde{U}_1\big(\lambda e^{\beta t} H(t)\big)\, dt + e^{-\beta\tau}\tilde{U}_2(\lambda e^{\beta\tau} H(\tau))\right] = \frac{K}{\gamma}\lambda^{-\gamma},$$

with

$$K \overset{\triangle}{=} \sup_{\tau\in\mathcal{S}} K_\tau := \sup_{\tau\in\mathcal{S}} \mathbb{E}\left[\int_0^\tau e^{-(1+\gamma)\beta t}\big(H(t)\big)^{-\gamma}\, dt + e^{-(1+\gamma)\beta\tau}\big(H(\tau)\big)^{-\gamma}\right]. \tag{9.2}$$

Clearly $\tilde{V}(\cdot)$ is differentiable everywhere, and it follows from Corollary 8.7 that $V(x) = \inf_{\lambda>0} [\tilde{V}(\lambda) + \lambda x] = K^{1-\alpha}\, x^\alpha/\alpha$. In other words, with utility functions of power-type, the original optimization problem is reduced to the pure optimal stopping problem (9.2). We can arrive at this conclusion also using Proposition 6.5, since we have $\mathcal{X}_\tau(\lambda) = K_\tau \lambda^{-1/(1-\alpha)}$, $\mathcal{Y}_\tau(x) = (K_\tau/x)^{1-\alpha}$, $\tilde{J}(\lambda; \tau) = \frac{K_\tau}{\gamma}\lambda^{-\gamma}$, and thus $V(x) = \frac{x^\alpha}{\alpha} K^{1-\alpha}$ from (6.12), (6.13).

The optimal stopping time $\hat{\tau}$ for the original problem is also optimal for the problem of (9.2); the corresponding optimal consumption $\hat{c}(\cdot)$ and wealth-level $X^{x,\hat{\pi},\hat{c}}(\hat{\tau}) \equiv \xi^x(\hat{\tau})$ are given as

$$\hat{c}(t) = \frac{x}{K} e^{-\frac{\beta t}{1-\alpha}} \big(H(t)\big)^{-\frac{1}{1-\alpha}}, \quad 0 \le t \le \hat{\tau}, \qquad \xi^x(\hat{\tau}) = \frac{x}{K} e^{-\frac{\beta\hat{\tau}}{1-\alpha}} \left(H(\hat{\tau})\right)^{-\frac{1}{1-\alpha}}$$

by (6.11), and the optimal portfolio process $\hat{\pi}(\cdot)$ can then be obtained from Lemma 6.3.

It is straightforward to check that $\hat{\tau} \equiv 0,\ K = 1$ if

$$\beta \ge \gamma \left[\frac{r(t)}{1+\gamma} + \frac{1}{2}\|\theta(t)\|^2\right] \qquad \forall\ 0 \le t \le T$$

holds a.s., and that $\hat{\tau} \equiv T,\ K = K_T$ if

$$\beta \le \gamma \left[\frac{r(t)}{1+\gamma} + \frac{1}{2}\|\theta(t)\|^2\right] \qquad \forall\ 0 \le t \le T$$

holds a.s. This observation provides a complete solution to the optimal stopping problem of (9.2) in the case of constant interest-rate $r(t) \equiv r \in \mathbb{R}$ and relative risk $\theta(t) \equiv \theta \in \mathbb{R}^m$; in particular, if $\beta = \gamma\big(\frac{r}{1+\gamma} + \frac{\|\theta\|^2}{2}\big)$, every stopping time $\tau \in \mathcal{S}_{0,T}$ is optimal in (9.2) and $K = K_\tau = 1$.

Example 9.2 (logarithmic utility function from terminal wealth only, with $\beta > 0$). $U_2(x) = \log x$ for $x > 0$ and $U_1(\cdot) \equiv 0$. This is the setting of Example 6.6 with $\delta = 0$; Assumption 6.1 is now satisfied trivially.

(i) $b(\cdot) \equiv r(\cdot)\mathbf{1}_m$. Since we have $\theta(\cdot) \equiv 0$ in this case, it follows that $\tilde{J}(\lambda;\tau) = -\mathbb{E}[e^{-\beta\tau}(1 + \log\lambda + A(\tau))]$, where

$$A(t,\omega) \overset{\triangle}{=} \beta t - \int_0^t r(s,\omega)\,ds \qquad \forall\ 0 \le t \le T.$$

We claim that

if $\frac{dA(t,\omega)}{dt} - \beta A(t,\omega)$ *is strictly increasing for almost every* $\omega \in \Omega$ *(e.g., if* $r(t) \equiv r > \beta$*), then* (8.7) *holds.*

In order to check this, let $\hat{\tau}_\lambda \overset{\triangle}{=} \inf\{t \ge 0\ /\ \frac{dA(t)}{dt} - \beta A(t) \ge \beta(1 + \log\lambda)\} \wedge T$. It is not difficult to see that $\hat{\tau}_\lambda \in \hat{\mathcal{S}}_\lambda$, since $-e^{-\beta\hat{\tau}_\lambda(\omega)}(1 + \log\lambda + A(\hat{\tau}_\lambda(\omega),\omega))$ is then the minimum of the path $e^{-\beta t}(1 + \log\lambda + A(t,\omega)),\ 0 \le t \le T$. Moreover, the condition of Corollary 8.8 is satisfied, and $\hat{\tau}_{\lambda_n} \to \hat{\tau}_\lambda$ if $\lambda_n \to \lambda$. It follows that

$$V(x) = \inf_{\lambda > 0}\,[\tilde{J}(\lambda;\hat{\tau}_\lambda) + \lambda x].$$

The optimal stopping time for the original optimization problem is $\hat{\tau} \equiv \hat{\tau}_{\hat{\lambda}}$, where $\hat{\lambda} > 0$ attains the infimum in the above expression. The corresponding optimal level of wealth $X^{x,\hat{\pi},0}(\hat{\tau}) \equiv \xi^x(\hat{\tau})$ is given by (6.11) as

$$\xi^x(\hat{\tau}) = \frac{x}{\mathbb{E}\left(e^{-\beta\hat{\tau}}\right)}\ e^{\int_0^{\hat{\tau}} r(s)\,ds - \beta\hat{\tau}},$$

and the optimal portfolio process $\hat{\pi}(\cdot)$ can be derived from Lemma 6.3.

(ii) A general result for the logarithmic utility function (from terminal wealth only) seems difficult to obtain, as we saw already in Example 6.6. Nevertheless, using the theory of section 8, we shall establish the following property:

$$\text{(9.3)} \quad \left\{ \begin{array}{l} \textit{$V(x)$ is attainable and } (8.7) \textit{ holds for every } x>0, \textit{ if there exists a} \\ \text{unique } \textit{optimal stopping time solving problem } (7.1) \textit{ for every } \lambda>0 \end{array} \right\}.$$

The rest of this paragraph is dedicated to the proof of statement (9.3). Consider the continuous process

$$Y^{\lambda}(t) \overset{\triangle}{=} e^{-\beta t}\tilde{U}(\lambda e^{\beta t}H(t)) = -e^{-\beta t}(1+\log\lambda+\beta t+\log H(t))$$

and its Snell envelope, given as a right continuous with limits from the left (RCLL) modification of the supermartingale

$$Z^{\lambda}(t) \overset{\triangle}{=} \ \mathrm{esssup}_{\tau\in\mathcal{S}_{t,T}}\,\mathbb{E}[Y^{\lambda}(\tau)|\mathcal{F}_t], \qquad 0\le t\le T,$$

with $Z^{\lambda}(0) = \sup_{\tau\in\mathcal{S}_{0,T}}\mathbb{E}Y^{\lambda}(\tau) = \tilde{V}(\lambda)$. We claim that $Z^{\lambda}(\cdot)$ is actually continuous. Indeed, since the random variable $\sup_{0\le t\le T}Y^{\lambda}(t)$ is integrable by Remark 7.2, the Snell envelope $Z^{\lambda}(\cdot)$ admits the Doob–Meyer decomposition $Z^{\lambda}(\cdot) = Z^{\lambda}(0)+M^{\lambda}(\cdot)-A^{\lambda}(\cdot)$ (Karatzas and Shreve (1998), Theorem D.13), where $M^{\lambda}(\cdot)$ is an RCLL martingale and $A^{\lambda}(\cdot)$ is continuous and nondecreasing. But any RCLL martingale of the Brownian filtration is continuous (Karatzas and Shreve (1991), Problem 3.4.16); hence $M^{\lambda}(\cdot)$ is continuous, and thus so is $Z^{\lambda}(\cdot)$. The stopping time $\tau^*_{\lambda} \overset{\triangle}{=} \inf\left\{t\in[0,T)\ /\ Z^{\lambda}(t)=Y^{\lambda}(t)\right\}\wedge T$ is the *smallest* optimal stopping time in $\hat{\mathcal{S}}_{\lambda}$, whereas the stopping time $\rho^*_{\lambda} \overset{\triangle}{=} \inf\left\{t\in[0,T)\ /\ A^{\lambda}(t)>0\right\}\wedge T$ is the *largest* optimal stopping time in $\hat{\mathcal{S}}_{\lambda}$ (Karatzas and Shreve (1998), Theorems D.12 and D.9; El Karoui (1981)). In particular, the uniqueness property (9.3) amounts to the statement $\mathbb{P}[\tau^*_{\lambda}=\rho^*_{\lambda}]=1\ \ \forall\, 0<\lambda<\infty$.

Moreover, $\lambda\mapsto\tau^*_{\lambda}$ is *increasing*; that is, for any $\lambda\ge\nu$ we have $\tau^*_{\lambda}\ge\tau^*_{\nu}$ a.s. To see this, observe that $Y^{\lambda}(t)-Y^{\nu}(t) = -e^{-\beta t}\log(\lambda/\nu)$ and obtain

$$\begin{aligned} Z^{\lambda}(t)-Z^{\nu}(t) &= \mathrm{esssup}_{\tau\in\mathcal{S}_{t,T}}\,\mathbb{E}[Y^{\lambda}(\tau)|\mathcal{F}_t] - \mathrm{esssup}_{\tau\in\mathcal{S}_{t,T}}\,\mathbb{E}\left[Y^{\lambda}(\tau)+e^{-\beta\tau}\log\left(\frac{\lambda}{\nu}\right)\middle|\mathcal{F}_t\right] \\ &\ge \mathrm{esssup}_{\tau\in\mathcal{S}_{t,T}}\,\mathbb{E}[Y^{\lambda}(\tau)|\mathcal{F}_t] - \mathrm{esssup}_{\tau\in\mathcal{S}_{t,T}}\,\mathbb{E}[Y^{\lambda}(\tau)|\mathcal{F}_t] - e^{-\beta t}\log\left(\frac{\lambda}{\nu}\right) \\ &= Y^{\lambda}(t)-Y^{\nu}(t) \end{aligned}$$

a.s. for any given $0\le t\le T$. By the continuity of $Z(\cdot)$ and $Y(\cdot)$, it follows that

$$\mathbb{P}\left[Z^{\lambda}(t)-Y^{\lambda}(t)\ge Z^{\nu}(t)-Y^{\nu}(t)\ \ \forall\, 0\le t\le T\right]=1,$$

which implies that $\tau^*_{\lambda}\ge\tau^*_{\nu}$ a.s., since $Z(\cdot)$ always dominates $Y(\cdot)$. It is not difficult to see that $\tau^{\pm}_{\lambda} \overset{\triangle}{=} \lim_{n\to\infty}\tau^*_{\lambda\pm\frac{1}{n}}$ are stopping times, thanks to the continuity of the filtration $\mathbb{F}$. Moreover, they both belong to $\hat{\mathcal{S}}_{\lambda}$, which is an easy exercise on the dominated convergence theorem (we omit the details).

Now we can prove our assertion (9.3). Clearly it must hold that $\tau^*_{\lambda}=\tau^+_{\lambda}=\tau^-_{\lambda}$ by uniqueness of optimal stopping time. It follows from Corollary 8.8 that $V(x)$ is attainable and (8.7) holds for every $x>0$.

Example 9.3 (a case where no optimal strategy exists). We present now an example which shows that optimal strategies *need not* always exist for every initial capital $x \in (0, \infty)$.

Consider the logarithmic utility functions as in Example 6.6 with $\delta = 0$, i.e., $U_1(\cdot) \equiv 0$ and $U_2(x) = \log x$, discount factor $\beta = 1$, and model parameters $m = 1$, $r(\cdot) \equiv 0$, $b(\cdot) \equiv 0$, $\sigma(\cdot) \equiv 1$ in (2.1), (2.2). In this case we may take $c(\cdot) \equiv 0$ since there is no utility from consumption, and for a given initial capital $x > 0$ the wealth-process $X^{x,\pi}(\cdot) \equiv X^{x,\pi,0}(\cdot)$ corresponding to a portfolio $\pi(\cdot)$ satisfies

$$dX^{x,\pi}(t) = X^{x,\pi}(t)\pi(t)\,dW(t), \qquad X^{x,\pi}(0) = x. \tag{9.4}$$

It is not difficult to check that

$$\tilde{V}(\lambda) = \sup_{\tau \in \mathcal{S}} \tilde{J}(\lambda;\tau) = \sup_{\tau \in \mathcal{S}} \mathbb{E}\left[-e^{-\tau}(1 + \log\lambda + \tau)\right] = \max_{0 \le t \le T} F(\lambda;t), \tag{9.5}$$

where $F(\lambda;t) \triangleq -e^{-t}(1 + \log\lambda + t)$, $\lambda > 0$, $t > 0$. Note that the function $t \mapsto F(\lambda;t)$ attains its maximum on the interval $[0,T]$ at one of its endpoints; that is, $\max_{0 \le t \le T} F(\lambda;t) = \max\{F(\lambda;0),\, F(\lambda;T)\}$, since $e^t \frac{dF}{dt}(\lambda;t) = \log\lambda + t$ is increasing. It follows then from (9.5) that

$$\tilde{V}(\lambda) = \left\{ \begin{array}{cc} -(1+\log\lambda), & 0 < \lambda \le \lambda^*(T) \\ -e^{-T}(1+\log\lambda + T), & \lambda^*(T) \le \lambda < \infty \end{array} \right\}, \tag{9.6}$$

where $\lambda^*(s) \triangleq \exp\left\{\left(s/(e^s - 1)\right) - 1\right\} \in (0,1)$ is determined by the equation

$$1 + \log\lambda^*(s) = e^{-s}(1 + \log\lambda^*(s) + s). \tag{9.7}$$

Clearly, $\tilde{V}(\cdot)$ is *not* differentiable at $\lambda = \lambda^*(T)$. Moreover, it is easy to verify that $\mathcal{G}_\lambda = \{1/\lambda\}$ for $0 < \lambda < \lambda^*(T)$ and that $\mathcal{G}_\lambda = \left\{e^{-T}/\lambda\right\}$ for $\lambda > \lambda^*(T)$, and thus

$$\mathcal{G} = \bigcup_{\lambda > 0} \mathcal{G}_\lambda = \left(0, x_0(T)\right] \cup \left[x_1(T), \infty\right) \tag{9.8}$$

with $x_0(s) \triangleq \frac{e^{-s}}{\lambda^*(s)} \in (0,1)$ and $x_1(s) \triangleq \frac{1}{\lambda^*(s)} \in (1,\infty)$; we omit the details of these computations. It should be noted that $x_1(\cdot)$ is increasing with $x_1(0+) = 1$, $x_1(\infty) = e$, whereas $x_0(\cdot)$ is decreasing with $x_0(0+) = 1$, $x_0(\infty) = 0$.

Now with $V_0(x) \triangleq e^{-T}\log x$ and $V_1(x) \triangleq \log x$, let us consider the concave function

$$\begin{aligned} G(x) &\triangleq \inf_{\lambda > 0}[\tilde{V}(\lambda) + \lambda x] \\ &= \left\{ \begin{array}{cc} V_0(x), & 0 < x \le x_0(T) \\ V_0(x_0(T))\frac{x_1(T) - x}{x_1(T) - x_0(T)} + V_1(x_1(T))\frac{x - x_0(T)}{x_1(T) - x_0(T)}, & x_0(T) < x < x_1(T) \\ V_1(x), & x_1(T) \le x < \infty \end{array} \right\} \end{aligned}$$

(see Remark 9.4 for discussion). We have $V(x) = G(x)$ for $x \in \mathcal{G}$ from Theorem 8.5, or

$$V(x) = \left\{ \begin{array}{cc} V_0(x), & 0 < x \le x_0(T) \\ V_1(x), & x_1(T) \le x < \infty \end{array} \right\}. \tag{9.9}$$

In particular, the optimal strategy is to keep all the wealth in the money-market (i.e., $\pi(\cdot) \equiv 0$) and to wait until the terminal time T, if the initial capital x is in $(0, x_0(T)]$, whereas the optimal strategy for $x \geq x_1(T)$ is to stop immediately.

But how about an initial capital $x \in (\, x_0(T), x_1(T)\,)$? From Theorem 8.5 and Proposition 8.9, we know that either $V(x) < G(x)$ for some $x \in (\, x_0(T), x_1(T)\,)$ (which will give us a nonconcave value function $V(\cdot)$), or else $V(x) \equiv G(x) \;\; \forall x \in (\, x_0(T), x_1(T)\,)$ (in which case no optimal strategy exists).

We claim that the latter is the case. In other words, $V(x) \equiv G(x) \;\; \forall x \in \mathbf{R}^+$, but *no* optimal strategy exists for $x \in (\, x_0(T), x_1(T)\,)$. Actually, for every $x \in (\, x_0(T), x_1(T)\,)$, a maximizing sequence of strategy pairs $\{(\pi_n, \tau_n)\}_{n=1}^{\infty}$ can be constructed so that $J(x; \pi_n, \tau_n) \to G(x)$ as $n \to \infty$; this proves, in particular, that $V(\cdot) \equiv G(\cdot)$ on $\big(x_0(T), x_1(T)\big)$. Indeed, consider the wealth-process $dX^{x,n}(t) = nX^{x,n}(t)\, dW(t)$, $X^{x,n}(0) = x$, and let

$$T_0^n \overset{\triangle}{=} \inf\big\{t \geq 0 \;/\; X^{x,n}(t) \leq x_0(T-t)\big\} \wedge T, \tag{9.10}$$

$$T_1^n \overset{\triangle}{=} \inf\big\{t \geq 0 \;/\; X^{x,n}(t) \geq x_1(T-t)\big\} \wedge T. \tag{9.11}$$

Recall $x_0(0+) = x_1(0+) = 1$, so that $T_0^n \wedge T_1^n < T$ holds a.s. We define the portfolio/stopping time pair (π_n, τ_n) by

$$\pi_n(t) \overset{\triangle}{=} n \cdot 1_{\{t < T_1^n \wedge T_0^n\}} \quad \text{and} \quad \tau_n \overset{\triangle}{=} T_1^n \cdot 1_{\{T_1^n < T_0^n\}} + T \cdot 1_{\{T_1^n \geq T_0^n\}}. \tag{9.12}$$

This means if the wealth reaches the curve $x_1(T-\cdot)$ before reaching the curve $x_0(T-\cdot)$, stop immediately when this happens; if the wealth reaches the curve $x_0(T-\cdot)$ before reaching the curve $x_1(T-\cdot)$, then put all the money in the bank account and wait until the terminal time T; and up until the first time that one of these curves is reached, keep an amount of n dollars invested in stock. Clearly,

$$X^{x,\pi_n}(\tau_n) = x_0(T - T_0^n) \cdot 1_{\{T_0^n < T_1^n\}} + x_1(T - T_1^n) \cdot 1_{\{T_1^n < T_0^n\}}. \tag{9.13}$$

Moreover, since $\pi_n(\cdot)$ is bounded, the wealth process $X^{x,\pi_n}(\cdot)$ is a martingale, and the optional sampling theorem gives

$$x = \mathbb{E}\left[X^{x,\pi_n}(\tau_n)\right]. \tag{9.14}$$

Because $T_0^n = \inf\big\{t \geq 0 \;/\; W(t) \leq \frac{1}{2}nt + \frac{1}{n}\log\big(\frac{x_0(T-t)}{x}\big)\big\} \wedge T \longrightarrow 0$ a.s. as $n \to \infty$, it follows from (9.13) and (9.14) that $x_0(T)p_n + x_1(T)(1-p_n) \longrightarrow x$ as $n \to \infty$, where $p_n \overset{\triangle}{=} \mathbb{P}(T_0^n < T_1^n) = 1 - \mathbb{P}(T_1^n < T_0^n)$, or, equivalently,

$$p_n \to \frac{x_1(T) - x}{x_1(T) - x_0(T)} \qquad \text{as} \quad n \to \infty. \tag{9.15}$$

On the other hand, the expected discounted utility corresponding to (π_n, τ_n) of (9.12) is

$$J(x; \pi_n, \tau_n) = \mathbb{E}\big[e^{-T}\log\left(x_0(T - T_0^n)\right) \cdot 1_{\{T_0^n < T_1^n\}} + \log\big(e^{-T_1^n} x_1(T - T_1^n)\big) \cdot 1_{\{T_1^n < T_0^n\}}\big].$$

We conclude the proof by noting from (9.15) and the dominated convergence theorem, that

$$\lim_{n\to\infty} J(x; \pi_n, \tau_n) = e^{-T}\log x_0(T) \cdot \frac{x_1(T) - x}{x_1(T) - x_0(T)} + \log x_1(T) \cdot \frac{x - x_0(T)}{x_1(T) - x_0(T)} = G(x).$$

Remark 9.4. The tangent to the graph of $V_0(\cdot)$ at $x = x_0 \overset{\triangle}{=} x_0(T)$ and the tangent to the graph of $V_1(\cdot)$ at $x = x_1 \overset{\triangle}{=} x_1(T)$ coincide. Indeed, $V_1'(x) = \frac{1}{x}$ so that the tangent $f_1(\cdot)$ to the graph of $V_1(\cdot)$, at the point $x = x_1$, is given by

$$f_1(x) = \frac{x - x_1}{x_1} + f_1(x_1) = \left(\frac{x}{x_1} - 1\right) + \log x_1 = \lambda^*(T)x - (1 + \log \lambda^*(T)).$$

On the other hand, $V_0'(x) = \frac{1}{x}e^{-T}$ so that the tangent $f_0(\cdot)$ to the graph of $V_0(\cdot)$, at the point $x = x_0$, is given by

$$\begin{aligned} f_0(x) &= \frac{x - x_0}{x_0}e^{-T} + f_0(x_0) = e^{-T}\left(x\lambda^*(T)e^T - 1\right) + e^{-T}\log x_0 \\ &= \lambda^*(T)x - e^{-T}(1 + \log \lambda^*(T) + T). \end{aligned}$$

Thanks to (9.7), these two expressions are the same.

Appendix A. In this section we provide an example which illustrates briefly, in a Markovian setting and with logarithmic utility from wealth (we set $c(\cdot) \equiv 0$ and write $X^{x,\pi}(\cdot) \equiv X^{x,\pi,0}(\cdot)$ throughout), how the optimization problem of (5.3) can be cast in the form of a free-boundary problem for a suitable HJB equation, which can then be solved explicitly.

In order to obtain such an explicit solution, we place ourselves on an infinite time-horizon so that all stopping times $\tau \in \mathcal{S}_{0,\infty}$ are admissible, and we denote the corresponding value function by

$$V_\infty(x) \;=\; \sup_{(\pi,\tau)\in\mathcal{A}(x)} \mathbb{E}\left[e^{-\beta\tau}\log X^{x,\pi}(\tau)\cdot \mathbf{1}_{\{\tau<\infty\}}\right] \tag{A.1}$$

with $\beta > 0$, for a given initial capital $x > 0$ in the notation of (9.4). Furthermore, we assume that the coefficients of the model $r(\cdot) \equiv r > 0$, $b(\cdot) \equiv b$, $\sigma(\cdot) \equiv \sigma > 0$ are all constant, and we impose the assumption $b \neq r\mathbf{1}_m$, or, equivalently, $\theta(\cdot) \equiv \theta \neq 0$. For the measure-theoretic subtleties associated with working on an infinite time-horizon, we refer the reader to section 1.7 in Karatzas and Shreve (1998).

Consider the differential operator

$$\begin{aligned} \mathcal{L}u\,(x) &\overset{\triangle}{=} -\beta u(x) + rxu'(x) + \max_{\pi\in\mathbb{R}^m}\left(xu'(x)\pi^*\sigma\theta + \frac{1}{2}x^2u''(x) \parallel \pi^*\sigma \parallel^2\right) \\ &= -\beta u(x) + rxu'(x) - \frac{(u'(x))^2\Theta^2}{2u''(x)}, \end{aligned} \tag{A.2}$$

acting on functions $u : (0,\infty) \to \mathbb{R}$ which are twice continuously differentiable with $u''(\cdot) < 0$; here $\Theta \overset{\triangle}{=} \parallel (\sigma^*)^{-1}\theta \parallel = \parallel (\sigma\sigma^*)^{-1}(b - r\mathbf{1}_m) \parallel > 0$. By analogy with section 2.7 in Karatzas and Shreve (1998), we cast the original optimization problem of (A.1) as a *variational inequality*, relying on the familar "principle of smooth–fit."

Variational Inequality A.1. *Find a number* $b \in (1,\infty)$ *and an increasing function* $g(\cdot)$ *in the space* $\mathcal{C}([0,\infty)) \cap \mathcal{C}^1((0,\infty)) \cap \mathcal{C}^2((0,\infty)\setminus\{b\})$, *such that*

$$\mathcal{L}g\,(x) = 0\;, \quad 0 < x < b, \tag{A.3}$$

$$\mathcal{L}g\,(x) < 0\;, \quad x > b, \tag{A.4}$$

$$g(x) > \log x\;, \quad 0 < x < b, \tag{A.5}$$

$$g(x) = \log x\;, \quad x \geq b, \tag{A.6}$$

$$g(x) > 0\;, \quad x > 0, \tag{A.7}$$

$$g''(x) < 0\;, \quad x \in (0,\infty)\setminus\{b\}. \tag{A.8}$$

THEOREM A.2. *Suppose that the pair $(b, g(\cdot))$ solves the Variational Inequality* A.1*, that the ratio $|g'(x)/(xg''(x))|$ is bounded away from both zero and infinity on* $(0,\infty)$*, and that the stochastic differential equation*

$$\text{(A.9)} \qquad d\hat{X}(t) = \hat{X}(t)\left[r\,dt - \frac{g'(\hat{X}(t))}{\hat{X}(t)g''(\hat{X}(t))}\,\theta^*\,dW_0(t)\right], \qquad \hat{X}(0) = x > 0,$$

has a pathwise unique, strictly positive strong solution $\hat{X}(\cdot)$. In terms of this process, define

$$\text{(A.10)} \qquad \hat{\pi}(\cdot) \overset{\triangle}{=} -\big(\sigma^*\big)^{-1}\theta\,\frac{g'(\xi)}{\xi g''(\xi)}\bigg|_{\xi=\hat{X}(\cdot)}, \qquad \hat{\tau} \overset{\triangle}{=} \inf\left\{t \geq 0/\hat{X}(t) \geq b\right\}.$$

Then the function $g(\cdot)$ coincides with the optimal expected utility $V_\infty(\cdot)$ of (A.1)*, the pair $\big(\hat{\pi}(\cdot),\,\hat{\tau}\big)$ attains the supremum in* (A.1)*, and we have $\hat{X}^{x,\hat{\pi}}(\cdot) \equiv \hat{X}(\cdot)$.*

Proof. Fix $x \in (0,\infty)$. For any available portfolio process $\pi(\cdot)$, an application of Itô's rule to $\mathcal{G}^{x,\pi}(t) \overset{\triangle}{=} e^{-\beta t}g(X^{x,\pi}(t))$, $0 \leq t < \infty$, yields, in conjunction with (3.1), (A.3), and (A.4),

$$\begin{aligned} \text{(A.11)} \quad & e^{-\beta t}g(X^{x,\pi}(t)) - g(x) - \int_0^t e^{-\beta s}\pi^*\sigma\cdot\xi g'(\xi)\big|_{\xi=X^{x,\pi}(s)}\,dW(s) \\ &= \int_0^t e^{-\beta s}\left((\pi^*\sigma\theta + r)\cdot\xi g'(\xi) + \frac{1}{2}g''(\xi)\xi^2\parallel\pi^*\sigma\parallel^2 - \beta g(\xi)\right)\bigg|_{\xi=X^{x,\pi}(s)} ds \\ &\leq \int_0^t e^{-\beta s}\mathcal{L}g(X^{x,\pi}(s))\,ds \;\leq\; 0. \end{aligned}$$

It follows that the process $\mathcal{G}^{x,\pi}(t) = e^{-\beta t}g(X^{x,\pi}(t))$, $0 \leq t < \infty$ is a local supermartingale under $\mathbf{P}$, hence also a true supermartingale because it is positive. In particular, $\mathcal{G}^{x,\pi}(\infty) \overset{\triangle}{=} \limsup_{t\to\infty}\mathcal{G}^{x,\pi}(t) \geq 0$ exists a.s., and $\{\mathcal{G}^{x,\pi}(t),\ 0 \leq t \leq \infty\}$ is a $\mathbf{P}$-supermartingale. Thus

$$\begin{aligned} \text{(A.12)} \qquad \mathbb{E}[e^{-\beta\tau}\log X^{x,\pi}(\tau)\cdot\mathbf{1}_{\{\tau<\infty\}}] &\leq \mathbb{E}[e^{-\beta\tau}g\big(X^{x,\pi}(\tau)\big)\cdot\mathbf{1}_{\{\tau<\infty\}}] \\ &\leq \mathbb{E}[\mathcal{G}^{x,\pi}(\tau))] \leq g(x) \end{aligned}$$

holds for any stopping time $\tau \in \mathcal{S}_{0,\infty}$, by the optional sampling theorem and (A.5)–(A.6); in other words, $V_\infty(x) \leq g(x)$. We complete the proof upon noticing that, thanks to (A.3) and (A.6), all the inequalities in (A.11) and (A.12) hold as equalities for the choice

$$\text{(A.13)} \qquad \hat{\pi}(t) \overset{\triangle}{=} -\frac{g'(\hat{X}(t))}{\hat{X}(t)g''(\hat{X}(t))}(\sigma^*)^{-1}\theta, \qquad \hat{\tau}_b \overset{\triangle}{=} \inf\left\{t \geq 0/\hat{X}(t) \geq b\right\},$$

since we have $0 < g(\hat{X}(\hat{\tau}_b)) \leq \log b$ and $e^{-\beta\hat{\tau}_b}g(\hat{X}(\hat{\tau}_b)) = 0$ on the event $\{\hat{\tau}_b = \infty\}$. □

We have now to construct the solution of Variational Inequality A.1 and to verify the properties for (A.9) assumed in Theorem A.2.

PROPOSITION A.3. *Let α be the unique solution of the quadratic equation*

$$\text{(A.14)} \qquad \alpha^2 - \left(1 + \frac{\Theta^2}{2r} + \frac{\beta}{r}\right)\alpha + \frac{\beta}{r} = 0$$

in the interval $(0,1)$*, set* $b \stackrel{\triangle}{=} e^{1/\alpha}$*, and consider the function*

$$g(x) \stackrel{\triangle}{=} \left\{ \begin{array}{ll} x^{\alpha}/e\alpha, & 0 \le x < b \\ \log x, & b \le x < \infty \end{array} \right\}. \tag{A.15}$$

Then the pair $(b, g(\cdot))$ *solves Variational Inequality* A.1*, and the stochastic differential equation* (A.9) *has a pathwise unique, strictly positive strong solution* $\hat{X}(\cdot)$*.*

Proof. Note that the function

$$F(u) \stackrel{\triangle}{=} u^2 - \left(1 + \frac{\frac{\Theta^2}{2} + \beta}{r}\right) u + \frac{\beta}{r}\ , \qquad 0 \le u < \infty, \tag{A.16}$$

is convex with $F(0) = \beta/r > 0$, $F(1) = -\Theta^2/2r < 0$. Thus $F(\cdot)$ has exactly one root in the interval $(0,1)$. It is clear now that (A.6)–(A.8) are satisfied since $b > 1$. Furthermore, notice from (A.15) that

$$g'(x) = \left\{ \begin{array}{ll} x^{\alpha-1}/e, & 0 < x < b \\ 1/x, & b < x < \infty \end{array} \right\} \tag{A.17}$$

is continuous across $x = b$ (principle of smooth-fit), which implies that the function $g(\cdot)$ belongs to the space of functions $\mathcal{C}([0,\infty)) \cap \mathcal{C}^1((0,\infty)) \cap \mathcal{C}^2((0,\infty) \setminus \{b\})$. It is fairly straightforward to check that (A.3) holds for $0 < x < b$, and that $|g'(x)/(xg''(x))|$ is bounded away from both zero and infinity on $(0,\infty)$ (cf. (A.19) below). As for (A.4), we need to prove that $-\beta \log x + r + \Theta^2/2 < 0 \ \ \forall\, x > b$. Since $\log b = 1/\alpha$ and $\beta > 0$, it is sufficient to verify $\alpha < \alpha^* \stackrel{\triangle}{=} \beta/(r + \frac{\Theta^2}{2})$. Indeed

$$\begin{aligned} F(\alpha^*) &= \alpha^* \left(\alpha^* - \frac{\frac{\Theta^2}{2} + \beta}{r} - 1 \right) + \frac{\beta}{r} \\ &< \alpha^* \left(\frac{\beta}{r} - \frac{\frac{\Theta^2}{2} + \beta}{r} - 1 \right) + \frac{\beta}{r} = \alpha^* \left(- \frac{\frac{\Theta^2}{2} + r}{r} \right) + \frac{\beta}{r} \ = \ 0, \end{aligned}$$

which yields $\alpha < \alpha^*$. Finally, (A.5) follows readily from

$$g'(x) - (\log x)' = \frac{1}{x}\left(\frac{1}{e}x^{\alpha} - 1\right) < \frac{1}{x}\left(\frac{1}{e}b^{\alpha} - 1\right) = 0, \quad 0 < x < b.$$

It is now clear that the pair $(b, g(\cdot))$ solves Variational Inequality A.1.

For the function $g(\cdot)$ of (A.15), the optimal wealth-process $\hat{X}(\cdot)$ of Theorem A.2 satisfies the stochastic differential equation (A.9), namely,

$$d\hat{X}(t) = \hat{X}(t)\big[r\,dt + \nu\big(\hat{X}(t)\big)\theta^*\,dW_0(t)\big], \qquad \hat{X}(0) = x > 0, \tag{A.18}$$

where

$$\nu(x) \ \stackrel{\triangle}{=} \ -\frac{g'(x)}{xg''(x)} \ = \ \left\{ \begin{array}{ll} 1/(1-\alpha), & 0 < x < b \\ 1, & b \le x < \infty \end{array} \right\}. \tag{A.19}$$

Equivalently, the process $\hat{Y}(\cdot) \stackrel{\triangle}{=} \log \hat{X}(\cdot)$ solves the stochastic differential equation

$$d\hat{Y}(t) = \left[r - \frac{||\theta||^2}{2} \cdot \nu^2\big(e^{\hat{Y}(t)}\big)\right] dt + \nu\big(e^{\hat{Y}(t)}\big)\theta^*\,dW_0(t), \ \ \hat{Y}(0) = \log x, \tag{A.20}$$

which has a pathwise unique, strong solution (cf. Nakao (1972)). This, in turn, means that (A.15) for $\hat{X}(\cdot) \equiv e^{\hat{Y}(\cdot)}$ also has a strictly positive, pathwise unique strong solution, as postulated in Theorem A.2. □

Remark A.4. For $x \geq b$, we have $\hat{\tau} \equiv 0$; on the other hand, for $0 < x < b$, we can write the stopping time $\hat{\tau} \overset{\triangle}{=} \inf \left\{ t \geq 0 \Big/ \hat{X}(t) \geq x \right\} = \inf \left\{ t \geq 0 \Big/ \hat{Y}(t) \geq \log b \right\}$ in the form of the time

$$\hat{\tau} = \inf \left\{ t \geq 0 \Bigg/ \left(r + \frac{||\theta||^2}{2} \frac{1-2\alpha}{(1-\alpha)^2} \right) t + \frac{\theta^*}{1-\alpha} W(t) \ \geq \ \log\left(\frac{b}{x}\right) \right\}$$

of first-passage to a positive level by a Brownian motion with drift. Clearly, we have $\mathbf{P}[\hat{\tau} < \infty] = 1$ if and only if $(1-\alpha)^2 + ||\theta||^2(1-2\alpha)/2r \geq 0$, and in light of (A.14) this last condition is equivalent to

$$\text{(A.21)} \qquad \left(\beta - r - ||\theta||^2 + \frac{\Theta^2}{2} \right) \cdot \alpha \ \geq \ \left(\beta - r - \frac{||\theta||^2}{2} \right).$$

In particular, if $\sigma = I_m$, the condition (A.21) amounts to

$$\text{(A.22)} \qquad \beta \leq r + ||b - r\mathbf{1}_m||^2.$$

Remark A.5. From (A.13), the optimal portfolio process is actually given as

$$\text{(A.23)} \qquad \hat{\pi}(t) \ \equiv \ \frac{(\sigma^*)^{-1}}{1-\alpha}\theta \ = \ \frac{(\sigma\sigma^*)^{-1}}{1-\alpha}[b - r\mathbf{1}_m], \qquad 0 \leq t < \hat{\tau} \ ;$$

this means that the optimal strategy is to invest a *fixed* proportion of total wealth in every stock, given by (A.3), up to the optimal stopping time $\hat{\tau}$.

Remark A.6. The assumption $\theta \neq 0$ is crucial for solving Variational Inequality A.1. When $\theta = 0$, we can have situations, as in Example 9.3, for which *no* optimal strategy exists. Actually, for $\theta = 0$ and $\beta > r$, it is easy to show that Variational Inequality A.1 has no solution (see Example 9.2 for discussion of the case $\theta = 0$, $\beta < r$).

Appendix B. As the referee points out, it would be very interesting to study optimization over a consumption stream that extends beyond the stopping time τ. Consider, for instance, the situation of an investor who remains in the stock-market up until a "retirement" time τ of his choice. At that point he consumes a lump-sum amount $\xi \geq 0$ of his choice (say, to buy a new house, or to finance some other "retirement-related" activity); and from then on he keeps his holdings in the money-market, making withdrawals for consumption at some rate, up until $t = T$.

We can capture such a situation by changing the wealth-equation of (3.1) to read

$$\text{(B.1)} \qquad dX(t) = r(t)X(t)dt + X(t)\pi^*(t)\sigma(t)dW_0(t) - dC(t), \quad X(0) = x > 0.$$

Here

$$\text{(B.2)} \qquad C(t) = \int_0^t c(u)\,du + \xi \cdot 1_{[\tau,T]}(t), \qquad 0 \leq t \leq T,$$

is the "cumulative consumption up to time t." This process consists of a stopping time $\tau \in \mathcal{S}$, a consumption-rate process $c(\cdot)$ as before, and an $\mathcal{F}_\tau$-measurable random variable $\xi : \Omega \to [0, \infty)$ representing lump-sum consumption at time τ. We say that a portfolio/cumulative-consumption process pair (π, C) is “available” to an investor with initial capital x, if the portfolio process $\pi(\cdot)$ and the wealth-process $X(\cdot) \equiv X^{x,\pi,C}(\cdot)$ of (B.1) satisfy

$$\pi(t) = 0, \qquad \tau \le t \le T, \tag{B.3}$$

$$X^{x,\pi,C}(t) > 0 \quad \forall\, 0 \le t < T, \qquad \text{and} \qquad X^{x,\pi,C}(T) \ge 0\ , \tag{B.4}$$

a.s. For any such pair (π, C), the investor’s expected discounted utility is given as

$$J^*(x; \pi, C) \ \stackrel{\triangle}{=}\ \mathbb{E}\left[\alpha \int_0^\tau e^{-\beta t} U_1\big(c(t)\big)\, dt + e^{-\beta\tau} U_2(\xi) + \gamma \int_\tau^T e^{-\beta t} U_1\big(c(t)\big)\, dt\right] \tag{B.5}$$

for some given constants $\alpha \ge 0,\ \gamma \ge 0$ and utility functions $U_1(\cdot),\ U_2(\cdot)$. With $\alpha = 1,\ \gamma = 0,$ we recover the problem of section 5. With $\alpha = 0,\ \gamma = 1,$ the expression of (B.5) tries to capture the situation of an investor who consumes nothing up until retirement, consumes a lump-sum amount ξ at that time, and afterwards keeps all holdings in the money-market while consuming at some rate $c(\cdot)$. The objective now is to maximize the expression of (B.5) over the class $\mathcal{A}^*(x)$ of pairs (π, C) that satisfy the analogue

$$\mathbb{E}\left[\alpha \int_0^\tau e^{-\beta t} U_1^-\big(c(t)\big)\, dt + e^{-\beta\tau} U_2^-(\xi) + \gamma \int_\tau^T e^{-\beta t} U_1^-\big(c(t)\big)\, dt\right] < \infty \tag{B.6}$$

of (5.2), and to see whether the value-function

$$V^*(x) \ \stackrel{\triangle}{=}\ \sup_{(\pi,C)\in\mathcal{A}^*(x)} J^*(x; \pi, C), \qquad x \in (0, \infty), \tag{B.7}$$

is attained by some optimal $(\hat{\pi}, \hat{C}) \in \mathcal{A}^*(x)$. We have not yet been able to obtain a satisfactory answer to these questions and would like to suggest their resolution as an interesting open problem.

Acknowledgments. We are indebted to the associate editor and the referees for their very careful reading of the first version of this paper and for their many helpful suggestions. In particular, the open problem presented in Appendix B was inspired by suggestions from one of the referees.

EXACT BOUNDARY CONTROLLABILITY FOR THE LINEAR KORTEWEG–DE VRIES EQUATION ON THE HALF-LINE[*]

LIONEL ROSIER[†]

Abstract. This paper is concerned with the controllability of the linear Korteweg–de Vries equation on the domain $\Omega = (0, +\infty)$, the control being applied at the left endpoint $x = 0$. It is shown that the *exact* boundary controllability holds true in $L^2(0, +\infty)$ provided that the solutions are not required to be in $L^\infty(0, T, L^2(0, +\infty))$. The proof rests on a Carleman's estimate and an approximation theorem. A similar result is obtained for the heat equation and for the Schrödinger equation.

Key words. exact boundary controllability, unbounded domain, Carleman's estimate

1. Introduction and main results.

The Korteweg–de Vries (KdV) equation

$$u_t + u_x + uu_x + u_{xxx} = 0, \quad t \geq 0,\ x \in \Omega \subset \mathbb{R}, \tag{1.1}$$

may serve as a model for (among other things) propagation of small amplitude long water waves in a uniform channel. In this context, t is time, x is the space variable, and u stands for the deviation of the liquid's surface from the equilibrium position. The boundary (resp., internal) controllability of (1.1) has been extensively studied (see [21], [22], [19], [20], and also [16] for the Benjamin–Bona–Mahony equation) when Ω is bounded, say $\Omega = (0, L)$. The (local) exact boundary controllability of (1.1) follows in [19] from the *exact* boundary controllability of the associated linear KdV equation, namely

$$u_t + u_x + u_{xxx} = 0. \tag{1.2}$$

To date, there is no result as far as the boundary controllability of (1.1) or (1.2) on some *unbounded* domain (say $\Omega = (0, +\infty)$) is concerned. The aim of this paper is to fill this gap in providing a study of the exact boundary controllability of (1.2) on $(0, +\infty)$, which may be seen as a first step in the knowledge of the control theory for (1.1) on unbounded domains. It should be observed that the *approximate* boundary controllability of (1.2) in $L^2(0, +\infty)$ is quite easy to prove, whereas the *exact* boundary controllability requires a more sophisticated analysis, due to a lack of compactness. An enlightening example of the difference between exact and approximate (internal) controllabilities for linear PDEs in unbounded domains is provided by the following result, whose (simple) proof is sketched in the appendix.

Proposition 1.1. *Consider a (real) constant coefficients differential operator* $Au = \sum_{i=0}^{n} a_i \frac{d^i u}{d x^i}$, *with domain* $\mathcal{D}(A) = \{u \in L^2(\mathbb{R});\ Au \in L^2(\mathbb{R})\}$. *Assume that*

$n \geq 2$ (with $a_n \neq 0$) and that A generates a continuous semigroup $\big(S(t)\big)_{t\geq 0}$ on $L^2(\mathbb{R})$. Let $T > 0$ and $L_1 < L_2$ be some numbers. Set

$$\mathcal{R} = \left\{ \int_0^T S(T-t)f(t,\cdot)dt; \quad f \in L^2(\mathbb{R}^2),\ \operatorname{supp} f \subset [0,T] \times [L_1, L_2] \right\},$$

where supp f *denotes the support of f. Then $\mathcal{R}$ is a* strict dense *subspace of $L^2(\mathbb{R})$.*

In other words, when considering *mild* solutions (in $C([0,T], L^2(\mathbb{R}))$) of the forced initial-value problem

$$\begin{cases} \frac{du}{dt} - Au &= f, \\ u(0) &= 0, \end{cases}$$

where f denotes any square integrable function supported in $[0,T] \times [L_1, L_2]$, the space $\mathcal{R}$ of all reachable states is dense in (but different from) $L^2(\mathbb{R})$. Notice that for $Au = -u_{xxx} - u_x$, letting $L_1 = -1 < L_2 = 0$ and taking the restrictions to $(0, +\infty)$ of the mild solutions, we readily infer the approximate *boundary* controllability of (1.2) in $L^2(0, +\infty)$. It turns out that the *exact* boundary controllability of (1.2) in $L^2(0,+\infty)$ also fails to be true if we restrict ourselves to solutions with bounded energy, that is, which belong to $L^\infty(0,T,L^2(0,+\infty))$. An *implicit* formulation (that is, without specification of the boundary conditions) of this fact is given in the following theorem, to be proved later in this paper.

THEOREM 1.2. *Let $T > 0$. Then there exists $u_0 \in L^2(0, +\infty)$ such that if u is any function in $L^\infty(0,T,L^2(0,+\infty))$ satisfying*

$$\begin{cases} u_t + u_x + u_{xxx} &= 0 \quad \text{in } \mathcal{D}'\big((0,T) \times (0,+\infty)\big), \\ u_{|_{t=0}} &= u_0, \end{cases} \tag{1.3}$$

then $u_{|_{t=T}} \neq 0$.

(Notice that $u_{|_{t=0}}$ and $u_{|_{t=T}}$ are meaningful in $H^{-3}(0,+\infty)$ for any $u \in L^\infty(0,T, L^2(0,+\infty))$ satisfying (1.3): Indeed, such a function belongs to the space $W^{1,\infty}(0,T, H^{-3}(0,+\infty))$.) Theorem 1.2 tells us that even the (boundary) *null-controllability* fails to be true for solutions with bounded energy. Nevertheless, when the bounded energy condition ($u \in L^\infty(0,T,L^2(0,+\infty))$) is dropped, the exact boundary controllability of KdV holds true, as is shown in the following theorem, which is the main result of this paper.

THEOREM 1.3. *Let T, ϵ, b be positive numbers, with $\epsilon < \frac{T}{2}$. Let $L^2((0,+\infty), e^{-2bx}dx)$ denote the space of (class of) measurable functions $u : (0,+\infty) \to \mathbb{R}$ such that $\int_0^{+\infty} u^2(x)e^{-2bx}\,dx < \infty$. Let $u_0 \in L^2(0,+\infty)$ and $u_T \in L^2((0,+\infty), e^{-2bx}dx)$. Then there exists a function*

$$u \in L^2_{loc}\big([0,T] \times [0,+\infty)\big) \cap C\big([0,\epsilon], L^2(0,+\infty)\big) \cap C\big([T-\epsilon, T], L^2((0,+\infty), e^{-2bx}dx)\big)$$

which solves

$$\begin{cases} u_t + u_x + u_{xxx} &= 0 \quad \text{in } \mathcal{D}'\big((0,T) \times (0,+\infty)\big), \\ u_{|_{t=0}} &= u_0, \\ u_{|_{t=T}} &= u_T. \end{cases} \tag{1.4}$$

Let us make some comments.

1. The proof of Theorem 1.3 combines Fursikov–Imanuvilov's approach (see [4]) for the boundary controllability of the Burgers equation on bounded domains (which

is based on a global Carleman's estimate) and, for the extension to some unbounded domain, Rosay's clever proof of Malgrange–Ehrenpreis's theorem (see [18]), which uses an approximation theorem. Roughly speaking, the approximation theorem allows us to modify a sequence of solutions of $u_t + u_x + u_{xxx} = f$, defined on an increasing sequence of domains, in such a way that it converges (strongly) in $L^2_{loc}(\mathbb{R}^2)$. It should be emphasized that our approach allows us to consider initial and final states in *different* spaces of functions, thus exploiting an *asymmetric* property of the KdV equation, namely the (forward) wellposedness of (1.2) in the asymmetric space $L^2(\mathbb{R}, e^{2bx}dx)$ for any $b > 0$ (see [9]). Notice that we may require that $u \in C([T-\epsilon, T], L^2(0, +\infty))$ if u_T is also assumed to be in $L^2(0, +\infty)$.

2. As in [2] and [13], the formulation of the previous boundary controllability result is *implicit*. Nevertheless, setting $h_0 = u_{|_{x=0}}$, $h_1 = u_{x|_{x=0}}$, and $h_2 = u_{xx|_{x=0}}$, it may be seen that $h_0, h_1, h_2 \in H^{-1}(0,T)$ and, thanks to Holmgren's uniqueness theorem, that u is the *only* solution (in the same space as above) of the initial-value boundary problem

$$\begin{cases} u_t + u_x + u_{xxx} &= 0 \quad \text{in } \mathcal{D}'\big((0,T)\times(0,+\infty)\big), \\ u_{|_{x=0}} &= h_0, \ u_{x|_{x=0}} = h_1, \ u_{xx|_{x=0}} = h_2, \\ u_{|_{t=0}} &= u_0. \end{cases}$$

Moreover u satisfies $u_{|_{t=T}} = u_T$.

3. The method described in item 1 applies also to many other linear PDEs for which the characteristic hyperplanes take the form $\{t = \text{Const.}\}$: For instance, the heat equation $u_t - \Delta u = 0$ and the Schrödinger equation $iu_t + \Delta u = 0$ are concerned. (See section 5.)

The paper is outlined as follows. The proof of Theorem 1.2 is given in section 2. It rests on a duality argument and on the behavior of the traces $u_{x|_{x=0}}$, $u_{xx|_{x=0}}$ of exponential solutions for (1.2) with the boundary condition $u_{|_{x=0}} = 0$. A global Carleman's estimate for the KdV equation (which is subsequently used) is stated and proved in section 3. The proof of Theorem 1.3 is given in section 4, together with the proof of the approximation theorem (Lemma 4.4). In the last section we sketch the proof of similar results for the heat equation and the Schrödinger equation.

From now on, for the sake of brevity, we shall write P for the operator $(\partial/\partial t) + (\partial/\partial x) + (\partial^3/\partial x^3)$.

2. Proof of Theorem 1.2. The proof of Theorem 1.2 rests on the following key result.

LEMMA 2.1. *There exists a family* $(v^\lambda)_{\lambda>0}$ *of functions in* $\cap_{n\geq 0} C^\infty([0,T], H^n(0,+\infty))$ *such that for every* $\lambda > 0$

$$P v^\lambda = 0 \quad \textit{in } (0,T)\times(0,+\infty), \tag{2.1}$$

$$v^\lambda{}_{|_{x=0}} = 0 \quad \textit{on } (0,T), \tag{2.2}$$

$$\|v^\lambda{}_{|_{t=0}}\|_{L^2(0,+\infty)} = 1, \tag{2.3}$$

and

$$\|v^\lambda_{x|_{x=0}}\|_{H^n(0,T)} + \|v^\lambda_{xx|_{x=0}}\|_{H^n(0,T)} \to 0 \ \textit{as } \lambda \to 0 \ (\textit{for every } n \geq 1). \tag{2.4}$$

Proof. Let us consider the operator $Av := -v_{xxx} - v_x$ with domain

$$D(A) = H^3(0,+\infty) \cap H_0^1(0,+\infty) \subset L^2(0,+\infty).$$

Then A generates a strongly continuous semigroup $\big(S(t)\big)_{t\geq 0}$ on $L^2(0,+\infty)$, and we shall search for v^λ in the form of an exponential solution:

$$v^\lambda(t,\cdot) = S(t)v_0^\lambda = e^{-\lambda t}v_0^\lambda,$$

where $v_0^\lambda \in D(A)$ solves $Av_0^\lambda = -\lambda v_0^\lambda$ and $\lambda \in (0,+\infty)$. The roots of the equation $-z^3 - z = -\lambda$ may be written in the form $r, -\frac{r}{2} \pm i\mu$, where $0 < r \sim \lambda$ as $\lambda \to 0^+$ and $\mu = \big(1 + \frac{3}{4}r^2\big)^{\frac{1}{2}}$. Let $w_0^\lambda(x) := \Im m\,\big(e^{(-\frac{r}{2}+i\mu)x}\big) = e^{-\frac{r}{2}x}\sin(\mu x)$ (hence $w_0^\lambda \in D(A)$ and $Aw_0^\lambda = -\lambda w_0^\lambda$). Easy calculations give

$$\|w_0^\lambda\|_{L^2(0,+\infty)} = \left(\frac{2\mu^2}{r(r^2+4\mu^2)}\right)^{\frac{1}{2}}.$$

Set $c_\lambda := (\frac{r(r^2+4\mu^2)}{2\mu^2})^{\frac{1}{2}}$, $v_0^\lambda := c_\lambda w_0^\lambda$, and $v^\lambda(t,x) := e^{-\lambda t}v_0^\lambda(x)$. Since we know that (2.1)–(2.3) are true, it remains to prove (2.4). Obviously $v_x^\lambda(t,0) = c_\lambda \mu e^{-\lambda t}$ and $v_{xx}^\lambda(t,0) = -c_\lambda \mu\, r\, e^{-\lambda t}$, and since $c_\lambda \to 0$ as $\lambda \to 0^+$, (2.4) follows. □

It will result from the next lemma that the traces $u_{|_{x=0}}$, $u_{x|_{x=0}}$, and $u_{xx|_{x=0}}$ of a bounded energy solution $u = u(t,x)$ of (1.2) belong to the dual space to $H^1(0,T)$ (which is not to be confused with $H^{-1}(0,T) = H_0^1(0,T)')$.

LEMMA 2.2. *Let T and L be positive numbers and let $u \in L^\infty(0,T,L^2(0,L))$ be such that $Pu = 0$ in $\mathcal{D}'\big((0,T)\times(0,L)\big)$. Then $u \in H^3(0,L,H^1(0,T)')$ and we have for some constant $C = C(L,T) > 0$*

$$\begin{aligned}\|u(\cdot,0)\|_{H^1(0,T)'} + \|u_x(\cdot,0)\|_{H^1(0,T)'} + \|u_{xx}(\cdot,0)\|_{H^1(0,T)'}\\ \leq C\|u\|_{L^\infty(0,T,L^2(0,L))}.\end{aligned} \tag{2.5}$$

Proof. Since $u_t = -(u_{xxx} + u_x) \in L^2(0,T,H^{-3}(0,L))$, we see that $u \in H^1(0,T,H^{-3}(0,L))$; hence for every $f \in H^1(0,T,H_0^3(0,L))$

$$\int_0^T \langle u_t, f\rangle\, dt = -\int_0^T\int_0^L u f_t\, dxdt + [\langle u,f\rangle]_{t=0}^T, \tag{2.6}$$

where $\langle\cdot,\cdot\rangle$ denotes the duality pairing $\langle\cdot,\cdot\rangle_{H^{-3}(0,L),H_0^3(0,L)}$. Since $u \in C([0,T], H^{-3}(0,L)) \cap L^\infty(0,T,L^2(0,L))$, u, as a function of t, is weakly continuous in $L^2(0,L)$. Hence

$$\begin{aligned}\left|\int_0^T \langle u_t, f\rangle\, dt\right| &\leq \|u\|_{L^2((0,T)\times(0,L))}\cdot\|f_t\|_{L^2((0,T)\times(0,L))}\\ &\quad+ \|u\|_{L^\infty(0,T,L^2(0,L))}\cdot\big(\|f(0,\cdot)\|_{L^2(0,L)} + \|f(T,\cdot)\|_{L^2(0,L)}\big)\\ &\leq C_1\|u\|_{L^\infty(0,T,L^2(0,L))}\cdot\|f\|_{L^2(0,L,H^1(0,T))}\end{aligned} \tag{2.7}$$

for some constant $C_1 = C_1(T,L) > 0$. Since $H^1(0,T,H_0^3(0,L))$ is dense in $L^2(0,L,H^1(0,T))$, we infer from (2.7) that $u_t \in L^2(0,L,H^1(0,T)')$. Integrating three times with respect to (w.r.t.) x in the equation

$$(u_{xx} + u)_x = -u_t \qquad \text{in } \mathcal{D}'(0,L,H^1(0,T)')$$

($u_t \in L^2(0,L,H^1(0,T)')$ being given by (2.6)), we deduce that $u \in H^3(0,L,H^1(0,T)')$ and (2.5) follows. □

We now proceed to the proof of Theorem 1.2. Arguing by contradiction, we assume that for every $u_0 \in L^2(0,+\infty)$ there exists a function $u \in L^\infty(0,T,L^2(0,+\infty))$ such that $Pu = 0$ in $\mathcal{D}'((0,T)\times(0,+\infty))$, $u_{|t=0} = u_0$, and $u_{|t=T} = 0$. Let E denote the space

$$\{u \in L^\infty(0,T,L^2(0,+\infty)),\ Pu = 0 \text{ in } \mathcal{D}'((0,T)\times(0,+\infty)) \text{ and } u_{|t=T} = 0\},$$

endowed with the norm $\|u\|_E = \|u\|_{L^\infty(0,T,L^2(0,+\infty))}$. It is a Banach space, since

$$\|u_{|t=T}\|_{H^{-3}(0,+\infty)} \le C\|u\|_{H^1(0,T,H^{-3}(0,+\infty))} \le C'\|u\|_E$$

for all $u \in E$ and some constants $C, C' > 0$. Also, the linear map $\Lambda : u \in E \mapsto u_{|t=0} \in H^{-3}(0,+\infty)$ is continuous. Actually, thanks to [14, Lem. 8.1], Λ takes values in $L^2(0,+\infty)$ and we readily infer from the closed graph theorem that Λ is continuous as a map from E into $L^2(0,+\infty)$. Let $N = \ker\Lambda$, let $\tilde{E}$ stand for the quotient space of E by N, and let π denote the natural projection of E onto $\tilde{E}$. Then $\tilde{E}$ is a Banach space for the norm $\|\pi(u)\|_{\tilde{E}} := \inf_{w\in\pi(u)}\|w\|_E$, and the induced map $\tilde{\Lambda} : \tilde{E} \to L^2(0,+\infty)$ (defined by $\tilde{\Lambda}(\pi(u)) = \Lambda(u)$ for any $u \in E$) has a continuous inverse by the open mapping theorem. For every $\lambda > 0$ we pick $u^\lambda \in E$ such that $\pi(u^\lambda) = \tilde{\Lambda}^{-1}(v^\lambda(0,\cdot))$ (with v^λ as in Lemma 2.1) and

$$\|u^\lambda\|_E \le 2\|\pi(u^\lambda)\|_{\tilde{E}} \le 2\|\tilde{\Lambda}^{-1}\|. \tag{2.8}$$

Let L be a positive number. Integrations by part in

$$\int_0^T\int_0^L P(u^\lambda)v^\lambda\,dxdt = 0$$

result in

$$-\int_0^L v^\lambda(0,x)^2\,dx + \left[\langle u^\lambda_{xx} + u^\lambda, v^\lambda\rangle - \langle u^\lambda_x, v^\lambda_x\rangle + \langle u^\lambda, v^\lambda_{xx}\rangle\right]_{x=0}^L = 0, \tag{2.9}$$

where $\langle\cdot,\cdot\rangle$ denotes here the duality pairing $\langle\cdot,\cdot\rangle_{H^1(0,T)',H^1(0,T)}$. Since

$$\begin{aligned}&\|u^\lambda(\cdot,L)\|_{H^1(0,T)'} + \|u^\lambda_x(\cdot,L)\|_{H^1(0,T)'} + \|u^\lambda_{xx}(\cdot,L)\|_{H^1(0,T)'}\\ &\quad\le C\|u\|_{L^\infty(0,T,L^2(L,L+1))}\\ &\quad\le C\|u\|_{L^\infty(0,T,L^2(0,+\infty))}\end{aligned}$$

(where $C = C(1,T)$ is as in Lemma 2.2) and since $v^\lambda(\cdot,L)$, $v^\lambda_x(\cdot,L)$ and $v^\lambda_{xx}(\cdot,L) \to 0$ in $H^1(0,T)$ as $L \to +\infty$, letting $L \to +\infty$ in (2.9) and using (2.2)–(2.3) we get

$$1 = \int_0^{+\infty} v^\lambda(0,x)^2\,dx = \langle u^\lambda_x, v^\lambda_x\rangle_{|x=0} - \langle u^\lambda, v^\lambda_{xx}\rangle_{|x=0}.$$

Hence, by (2.5) and (2.8) (also with $C = C(1,T)$)

$$1 \le 2C\|\tilde{\Lambda}^{-1}\|\left(\|v^\lambda_{x|x=0}\|_{H^1(0,T)} + \|v^\lambda_{xx|x=0}\|_{H^1(0,T)}\right). \tag{2.10}$$

Letting $\lambda \to 0$ in (2.10) and using (2.4) we get a contradiction. The proof of Theorem 1.2 is complete. □

3. A Carleman's estimate. Let T and L be positive numbers. Set

$$\mathcal{Z} = \{q \in C^3([0,T]\times[-L,L]);\ q(t,\pm L) = q_x(t,\pm L) = q_{xx}(t,\pm L) = 0 \text{ for } 0 \le t \le T\}.$$

This section is devoted to the proof of the following global Carleman's estimate for the KdV equation.

PROPOSITION 3.1. *There exists a smooth positive function ψ on $[-L,L]$ (which depends on L) and there exist constants $s_0 = s_0(L,T)$ and $C = C(L,T)$ such that for all $s \ge s_0$ and all $q \in \mathcal{Z}$*

$$\begin{aligned}\int_0^T\int_{-L}^L &\left\{\frac{s^5}{t^5(T-t)^5}|q|^2 + \frac{s^3}{t^3(T-t)^3}|q_x|^2 + \frac{s}{t(T-t)}|q_{xx}|^2\right\} e^{-\frac{2s\psi(x)}{t(T-t)}}\,dxdt \\ &\le C\int_0^T\int_{-L}^L |q_t + q_x + q_{xxx}|^2 e^{-\frac{2s\psi(x)}{t(T-t)}}\,dxdt.\end{aligned} \tag{3.1}$$

Proof. Let $\psi = \psi(x)$ be a positive function (to be specified later) of class C^3 in $[-L,L]$ and let $\varphi(t,x) := \frac{\psi(x)}{t(T-t)}$. Let q be given in $\mathcal{Z}$ and let $s > 0$. Set $u := e^{-s\varphi}q$ and $w := e^{-s\varphi}P(e^{s\varphi}u)$. We readily get

$$w = Au + Bu_x + Cu_{xx} + u_{xxx} + u_t, \tag{3.2}$$

with

$$\begin{aligned} A &:= s(\varphi_t + \varphi_x + \varphi_{xxx}) + 3s^2\varphi_x\varphi_{xx} + (s\varphi_x)^3,\\ B &:= 1 + 3s\varphi_{xx} + 3(s\varphi_x)^2,\\ C &:= 3s\varphi_x.\end{aligned}$$

Set $M_1(u) := u_t + u_{xxx} + Bu_x$ and $M_2(u) := Au + Cu_{xx}$. We deduce the following inequality:

$$2\iint M_1(u)\,M_2(u) \le \iint \big(M_1(u) + M_2(u)\big)^2 = \iint w^2. \tag{3.3}$$

(Here and in what follows, the integrals are extended to $(0,T)\times(-L,L)$.) To compute the integral in the left-hand side of (3.3) we perform integrations by part w.r.t. x or t. We readily get

$$\iint M_1(u)Au = -\frac{1}{2}\iint (A_t + A_{xxx} + (AB)_x)u^2 + \frac{3}{2}\iint A_x u_x^2 \tag{3.4}$$

and

$$\iint (u_{xxx} + Bu_x)Cu_{xx} = -\frac{1}{2}\iint C_x u_{xx}^2 - \frac{1}{2}\iint (BC)_x u_x^2. \tag{3.5}$$

Finally, using (3.2),

$$\begin{aligned}\iint u_tCu_{xx} &= -\iint C_xu_tu_x - \iint Cu_{tx}u_x\\ &= \iint C_x\big(Au + Bu_x + Cu_{xx} + u_{xxx} - w\big)u_x + \frac{1}{2}\iint C_tu_x^2\\ &= -\frac{1}{2}\iint (C_xA)_xu^2 + \frac{1}{2}\iint (2BC_x - (CC_x)_x + C_{xxx} + C_t)u_x^2\\ &\quad -\iint C_xu_{xx}^2 - \iint C_xwu_x.\end{aligned} \tag{3.6}$$

Combining (3.4), (3.5), and (3.6) we get

$$\begin{aligned} 2\iint M_1(u)M_2(u) &= -\iint \big(A_t + A_{xxx} + (AB)_x + (C_xA)_x\big)u^2 \\ &\quad+\iint \big(3A_x - (BC)_x + 2BC_x - (CC_x)_x + C_{xxx} + C_t\big)u_x^2 \qquad (3.7)\\ &\quad-3\iint C_x u_{xx}^2 - 2\iint C_x w u_x\cdot \end{aligned}$$

If ϵ is any number in $(0,1)$, then by the Cauchy–Schwarz inequality

$$2\iint C_x w u_x \le \epsilon \iint C_x^2 u_x^2 + \epsilon^{-1}\iint w^2\cdot$$

Hence, setting

$$\begin{aligned} D &:= -\big(A_t + A_{xxx} + (AB)_x + (C_xA)_x\big),\\ E &:= 3A_x + BC_x - B_xC - (CC_x)_x + C_{xxx} + C_t - \epsilon C_x^2,\\ F &:= -3C_x \end{aligned}$$

and using (3.3), (3.7) we get

$$\iint Du^2 + \iint Eu_x^2 + \iint Fu_{xx}^2 \le (1+\epsilon^{-1})\iint w^2. \qquad (3.8)$$

The function ψ will be chosen in such a way that D, E, and F are positive. Clearly

$$\begin{aligned} D &= -(AB)_x + \frac{1}{t^4(T-t)^4}O(s^4) \qquad (\text{as } s \to +\infty)\\ &= -\big(3(s\varphi_x)^5\big)_x + \frac{O(s^4)}{t^4(T-t)^4}\\ &= -15s^5\frac{\psi'(x)^4\psi''(x)}{t^5(T-t)^5} + \frac{O(s^4)}{t^4(T-t)^4}\cdot \end{aligned}$$

It follows that for s large enough, if

$$|\psi'(x)| > 0 \text{ and } \psi''(x) < 0 \text{ for } x \in [-L,L], \qquad (3.9)$$

we have

$$D \ge C_1\frac{s^5}{t^5(T-t)^5} \qquad (3.10)$$

for some constant $C_1 > 0$. On the other hand, expanding E in a series of powers of s, it is easy to see that there is no term in s^3 (because of cancellations) and that

$$\begin{aligned} E &= 9s^2\big((1-\epsilon)\varphi_{xx}^2 - \varphi_x\varphi_{xxx}\big) + \frac{O(s)}{t^2(T-t)^2}\\ &= 9s^2\frac{(1-\epsilon)\psi''(x)^2 - \psi'(x)\psi'''(x)}{t^2(T-t)^2} + \frac{O(s)}{t^2(T-t)^2}\cdot \end{aligned}$$

Hence for s large enough, if

$$(1-\epsilon)\psi''(x)^2 - \psi'(x)\psi'''(x) > 0 \quad \text{for all } x \in [-L,L], \qquad (3.11)$$

we get for some constant $C_2 > 0$

$$E \geq C_2 \frac{s^2}{t^2(T-t)^2}. \tag{3.12}$$

Finally, for some constant $C_3 > 0$

$$F = -\frac{9\psi''(x)s}{t(T-t)} \geq C_3 \frac{s}{t(T-t)} \tag{3.13}$$

provided that (3.9) holds true. Now pick some smooth positive function ψ on $[-L, L]$ such that (3.9) and (3.11) are fulfilled for some $\epsilon > 0$. (For instance, picking any ϵ in $(0,1)$, $\psi(x) = -x^2 + (2L+1)(x+2L)$ is convenient.) We infer from (3.8), (3.10), (3.12), and (3.13) that, for s large enough,

$$\iint \left\{ \frac{s^5}{t^5(T-t)^5} u^2 + \frac{s^2}{t^2(T-t)^2} u_x^2 + \frac{s}{t(T-t)} u_{xx}^2 \right\} \leq C_4 \iint w^2 \tag{3.14}$$

for some constant $C_4 > 0$. Actually (3.14) may be slightly improved by observing that

$$\begin{aligned} \iint \frac{s^3}{t^3(T-t)^3} u_x^2 &= -\iint \frac{s^3}{t^3(T-t)^3} u u_{xx} \\ &\leq \frac{1}{2} \left(\iint \frac{s^5}{t^5(T-t)^5} u^2 + \iint \frac{s}{t(T-t)} u_{xx}^2 \right) \\ &\leq \frac{C_4}{2} \iint w^2 \end{aligned}$$

(thanks to (3.14)); hence, for s large enough,

$$\iint \left\{ \frac{s^5}{t^5(T-t)^5} u^2 + \frac{s^3}{t^3(T-t)^3} u_x^2 + \frac{s}{t(T-t)} u_{xx}^2 \right\} \leq \frac{3}{2} C_4 \iint w^2. \tag{3.15}$$

Replacing u with $e^{-s\varphi}q$ in (3.15) we readily get (3.1) for some constant $C > 0$ and s large enough. The proof of Proposition 3.1 is complete. □

Corollary 3.2. *Let $L > 0$ and let $f = f(t,x)$ be any function in $L^2\big(\mathbb{R}_t \times (-L,L)_x\big)$ such that* $\operatorname{supp} f \subset [t_1, t_2] \times (-L, L)$, *where $-\infty < t_1 < t_2 < \infty$. Then for every $\epsilon > 0$ there exist a positive number $C = C(L, t_1, t_2, \epsilon)$ (C does not depend on f) and a function $v \in L^2\big(\mathbb{R} \times (-L,L)\big)$ such that*

$$v_t + v_x + v_{xxx} = f \text{ in } \mathcal{D}'(\mathbb{R} \times (-L,L)), \tag{3.16}$$

$$\operatorname{supp} v \subset [t_1 - \epsilon, t_2 + \epsilon] \times (-L, L), \tag{3.17}$$

$$\|v\|_{L^2\left(\mathbb{R}\times(-L,L)\right)} \leq C \|f\|_{L^2\left(\mathbb{R}\times(-L,L)\right)}. \tag{3.18}$$

Proof. Applying a translation w.r.t. time if needed, we may assume without loss of generality that $0 = t_1 - \epsilon < t_1 < t_2 < t_2 + \epsilon =: T$. We readily infer from (3.1) that for some constants $k, C_1 > 0$ and for every $q \in \mathcal{Z}$

$$\int_0^T \int_{-L}^{L} |q|^2 e^{-\frac{k}{t(T-t)}} \, dxdt \leq C_1 \int_0^T \int_{-L}^{L} |Pq|^2 \, dxdt. \tag{3.19}$$

Thus the bilinear form

$$(p,q) := \int_0^T \int_{-L}^{L} Pp\, Pq\, dxdt$$

is a scalar product on $\mathcal{Z}$. Let H denote the completion of $\mathcal{Z}$ for $(\cdot,\cdot)$. Obviously $|q|^2 e^{-\frac{k}{t(T-t)}}$ is integrable on $(0,T)\times(-L,L)$ if $q\in H$, and (3.19) holds true as well. On the other hand the linear form

$$l(q) := -\int_0^T \int_{-L}^{L} fq\, dxdt$$

is well defined and continuous on H. Indeed, using (3.19) and the assumption on the support of f, we get

$$\int_0^T \int_{-L}^{L} |fq|\, dxdt = \int_{t_1}^{t_2} \int_{-L}^{L} |fq|\, dxdt \le C_2 \|f\|_{L^2\big((t_1,t_2)\times(-L,L)\big)} \cdot (q,q)^{\frac{1}{2}} \tag{3.20}$$

for some constant $C_2>0$. It follows from the Riesz representation theorem that there exists a unique $p\in H$ such that

$$\text{for all } q\in H \quad (p,q) = l(q). \tag{3.21}$$

We set $v := P(p) \in L^2\big((0,T)\times(-L,L)\big)$. Taking $q\in\mathcal{D}\big((0,T)\times(-L,L)\big)$ as a test function in (3.21) we get

$$\langle P^*(v), q\rangle_{\mathcal{D}'(Q),\mathcal{D}(Q)} = \langle -f, q\rangle_{\mathcal{D}'(Q),\mathcal{D}(Q)},$$

where $Q=(0,T)\times(-L,L)$ and $P^*=-P$ is the (formal) adjoint to the operator P. Hence $Pv=f$ in $\mathcal{D}'(Q)$. Notice that $v\in H^1(0,T,H^{-3}(-L,L))$, since v and $v_t = f - v_{xxx} - v_x$ belong to $L^2(0,T,H^{-3}(-L,L))$; hence $v_{|_{t=0}}$ and $v_{|_{t=T}}$ are meaningful in $H^{-3}(-L,L)$. Now let $q\in\mathcal{Z}\subset H^1(0,T,H_0^3(-L,L))$. It follows from (3.21) that

$$\begin{aligned} -\int_0^T \int_{-L}^{L} fq\, dxdt &= \int_0^T \int_{-L}^{L} v(q_t + q_x + q_{xxx})\, dxdt \\ &= -\int_0^T \langle v_t + v_x + v_{xxx}, q\rangle\, dt + [\langle v,q\rangle]_{t=0}^T \\ &= -\int_0^T \int_{-L}^{L} fq\, dxdt + [\langle v,q\rangle]_{t=0}^T, \end{aligned}$$

where $\langle\cdot,\cdot\rangle$ denotes the duality pairing $\langle\cdot,\cdot\rangle_{H^{-3}(-L,L),H_0^3(-L,L)}$. Since $q_{|_{t=0}}$ and $q_{|_{t=T}}$ may be arbitrarily chosen in $\mathcal{D}(-L,L)$, we infer that $v_{|_{t=0}} = v_{|_{t=T}} = 0$ in $H^{-3}(-L,L)$. Extending v by setting $v(t,x)=0$ for $(t,x)\notin(0,T)\times(-L,L)$, we see that (3.16), (3.17), and (3.18) hold true (with $C=C_2$). □

Remark 1. Using [19, Thm. 1.2] instead of Proposition 3.1, one may prove that the result in Corollary 3.2 also holds true for $\epsilon=0$ and that the weight $e^{-\frac{k}{t(T-t)}}$ may be dropped in the integral term of the left-hand side of (3.19). Nevertheless, the proof given here is direct and shorter, and it leads to a self-contained paper. Moreover, this proof also works for the heat equation (see below the proof of Theorem 5.2).

4. The proof of Theorem 1.3. For the comfort of the reader, we first give an outline of the proof of Theorem 1.3. In the first step, we show that we are finished if, for any $f \in L^2_{loc}(\mathbb{R}^2)$ with support in some strip $[0,T] \times \mathbb{R}$ and any $\epsilon > 0$, there exists a function $u \in L^2_{loc}(\mathbb{R}^2)$ supported in $[-\epsilon, T+\epsilon] \times \mathbb{R}$, which solves $P\,u = f$. This problem has already been solved when the whole domain $\mathbb{R}^2$ is replaced by $\mathbb{R}_t \times (-n,n)_x$, $n \geq 1$. (See Corollary 3.2.) At this stage, we are given a sequence of solutions of $P\,u = f$, which are defined on an increasing sequence of domains and are supported in $[-\epsilon, T+\epsilon] \times \mathbb{R}$. To ensure the convergence of this sequence in $L^2_{loc}(\mathbb{R}^2)$, we need an approximation theorem (Lemma 4.4), which differs from the one in [18] by a careful control on the growth of the support in time. Two technical lemmas (namely, Lemmas 4.2 and 4.3) are needed to prove the approximation theorem. The final step is a standard Mittag–Leffler's procedure.

Let $u_0 \in L^2(0,+\infty)$ and $u_T \in L^2\big((0,+\infty), e^{-2bx}dx\big)$. It is well known (see [9]) that the operator $Av = -v_{xxx}$ with domain $H^3(\mathbb{R})$ (resp., $\{v \in L^2(\mathbb{R}, e^{2bx}dx),\ Av \in L^2(\mathbb{R}, e^{2bx}dx)\}$) generates a continuous semigroup on $L^2(\mathbb{R})$ (resp., $L^2(\mathbb{R}, e^{2bx}dx)$). Thanks to the standard change of functions

$$v(t,x) = u(t, t+x) \tag{4.1}$$

we easily get two functions $u_1(t,x)$, $u_2(t,x)$ such that $u_1 \in C([0,T], L^2(\mathbb{R}))$, $u_2 \in C([0,T], L^2(\mathbb{R}, e^{2bx}dx))$, and

$$Pu_1 = Pu_2 = 0 \quad \text{on } (0,T) \times \mathbb{R},$$

$$u_1(0,x) = \begin{cases} u_0(x) & \text{for a.e. } x > 0, \\ 0 & \text{for a.e. } x < 0, \end{cases} \qquad u_2(0,x) = \begin{cases} u_T(-x) & \text{for a.e. } x < 0, \\ 0 & \text{for a.e. } x > 0. \end{cases}$$

Now set $\tilde{u}_2(t,x) = u_2(T-t, -x)$. Obviously $P\,\tilde{u}_2 = 0$ and $\tilde{u}_{2_{|t=T}} = \tilde{u}_T$ on $(0,+\infty)$. Let ϵ' be any number in $(\epsilon, \frac{T}{2})$ and let $\varphi \in C^\infty([0,T])$ be such that $\varphi(t) = 1$ for $t \leq \epsilon'$ and $\varphi(t) = 0$ for $t \geq T - \epsilon'$. The change of functions

$$u(t,x) = \varphi(t) u_1(t,x) + \big(1 - \varphi(t)\big)\tilde{u}_2(t,x) + w(t,x)$$

transforms (1.4) into

$$\begin{cases} P\,w &= \frac{d\varphi}{dt}\,(\tilde{u}_2 - u_1) \quad \text{in } \mathcal{D}'\big((0,T) \times (0,+\infty)\big), \\ w_{|t=0} &= w_{|t=T} = 0 \quad \text{on } (0,+\infty). \end{cases}$$

Setting $f(t,x) = \varphi'(t)\big(\tilde{u}_2(t,x) - u_1(t,x)\big)$, it is clear that we are finished if the following result is proved.

Proposition 4.1. *Let $f = f(t,x)$ be any function in $L^2_{loc}(\mathbb{R}^2)$ such that*

$$\operatorname{supp} f \subset [t_1, t_2] \times \mathbb{R}$$

where $0 < t_1 < t_2 < T$. Let $\epsilon \in (0, \min(t_1, T - t_2))$. Then there exists $u \in L^2_{loc}(\mathbb{R}^2)$ such that

$$P\,u = f \ \textit{in } \mathcal{D}'(\mathbb{R}^2) \ \textit{ and } \ \operatorname{supp}\, u \subset [t_1 - \epsilon, t_2 + \epsilon] \times \mathbb{R}. \tag{4.2}$$

Remark 2. The question whether Proposition 4.1 remains valid with $\epsilon = 0$ is open. Notice that the answer is negative for the heat equation. (See Remark 3 below.)

As in [18] the proof of Proposition 4.1 rests on an approximation theorem (Lemma 4.4), which in turn is obtained as a consequence of two preliminary lemmas. In what follows S_L will denote the unitary group in $L^2(-L,L)$ generated by the operator $Au = -u_{xxx} - u_x$ with domain

$$\mathcal{D}(A) = \{u \in H^3(-L,L);\ u(-L) = u(L),\ u_x(-L) = u_x(L),\ u_{xx}(-L) = u_{xx}(L)\}\cdot$$

Set $e_n(x) = \frac{1}{\sqrt{2L}} e^{in\frac{\pi}{L}x}$ for $n \in \mathbb{Z}$. e_n is an eigenvector for A associated with the eigenvalue $\omega_n = i\lambda_n$, with

$$\lambda_n = \left(n\frac{\pi}{L}\right)^3 - n\frac{\pi}{L}\cdot \tag{4.3}$$

If u_0 is any complex-valued function in $L^2(-L,L)$, decomposed as $u_0 = \sum_{n\in\mathbb{Z}} c_n e_n$, we have for every $t \in \mathbb{R}$

$$S_L(t)\,u_0 = \sum_{n\in\mathbb{Z}} e^{i\lambda_n t} c_n e_n. \tag{4.4}$$

We are now ready to state the first lemma, which may be seen as a preliminary version to the approximation theorem.

LEMMA 4.2. *Let l_1, l_2, L, t_1, t_2, T be numbers such that $0 < l_1 < l_2 < L$ and $0 < t_1 < t_2 < T$. Let $u \in L^2\left((0,T)\times(-l_2,l_2)\right)$ be such that*

$$P\,u = 0 \quad in\ (0,T)\times(-l_2,l_2) \qquad and \quad \text{supp}\ u \subset [t_1,t_2]\times(-l_2,l_2). \tag{4.5}$$

Let $\delta > 0$ with $2\delta < \min(t_1, T-t_2)$ and $\eta > 0$ be given. Then there exist $v_1, v_2 \in L^2(-L,L)$ and $v \in L^2\left((0,T)\times(-L,L)\right)$ such that

$$P\,v = 0 \quad in\ (0,T)\times(-L,L), \tag{4.6}$$

$$v(t,\cdot) = S_L(t-t_1+2\delta)v_1 \quad for\ \ t_1-2\delta < t < t_1-\delta, \tag{4.7}$$

$$v(t,\cdot) = S_L(t-t_2-\delta)v_2 \quad for\ \ t_2+\delta < t < t_2+2\delta, \tag{4.8}$$

$$\|v-u\|_{L^2((t_1-2\delta,t_2+2\delta)\times(-l_1,l_1))} < \eta. \tag{4.9}$$

Roughly speaking, (4.7)–(4.8) mean that for $t \in (t_1-2\delta, t_1-\delta)\cup(t_2+\delta, t_2+2\delta)$ v satisfies (in addition to $P\,v = 0$) the boundary conditions $v(-L) = v(L)$, $v_x(-L) = v_x(L)$, and $v_{xx}(-L) = v_{xx}(L)$.

Proof of Lemma 4.2. Set $Q = (0,T)\times(-L,L)$, $Q_\delta = (t_1-2\delta, t_2+2\delta)\times(-l_1,l_1)$. Smoothing u by convolution and multiplying the regularized function by a cut-off function (of x), we easily get a function $u' \in \mathcal{D}(\mathbb{R}^2)$ such that

$$\begin{cases} \text{supp}\ u' \subset [t_1-\delta, t_2+\delta]\times[-l_2,l_2], \\ P\,u' = 0 \ \text{ in } (0,T)\times(-l_1,l_1) \text{ and} \\ \|u'-u\|_{L^2\left((0,T)\times(-l_1,l_1)\right)} < \frac{\eta}{2}. \end{cases} \tag{4.10}$$

Let

$$\mathcal{E} = \{v \in L^2(Q);\ \exists v_1, v_2 \in L^2(-L,L) \text{ s.t. } (4.6),\ (4.7),\ \text{and } (4.8) \text{ hold true}\}.$$

The lemma is proved if we may find $v \in \mathcal{E}$ such that $\|v - u'\|_{L^2(Q_\delta)} < \frac{\eta}{2}$. We are finished if we prove $u' \in \overline{\mathcal{E}} = \mathcal{E}^{\perp\,\perp}$, where the closure and the orthogonal complement are taken in the space $L^2(Q_\delta)$. Fix a function $g \in \mathcal{E}^\perp \subset L^2(Q_\delta)$. Before proving $(u', g)_{L^2(Q_\delta)} = 0$, we begin with the following claim.

Claim 1. *Let* $\mathcal{T} = \{\varphi \in C^\infty(\mathbb{R}^2);\ \operatorname{supp} \varphi \subset [t_1 - \delta, t_2 + \delta] \times \mathbb{R}\}$. *Then there exists* $C > 0$ *such that*

$$\text{for all } \varphi \in \mathcal{T} \quad |(\varphi, g)_{L^2(Q_\delta)}| \le C \|P\varphi\|_{L^2(Q)}. \tag{4.11}$$

Proof of Claim 1. Let $\varphi \in \mathcal{T}$, and set $\psi(t) := \int_0^t S_L(t-\tau) P\varphi(\tau)\, d\tau$ for $0 \le t \le T$; that is, ψ is the (strong) solution of the following boundary initial-value problem:

$$\begin{aligned} P\psi &= P\varphi \qquad \text{in } Q,\\ \psi(t,-L) &= \psi(t,L),\\ \psi_x(t,-L) &= \psi_x(t,L),\\ \psi_{xx}(t,-L) &= \psi_{xx}(t,L),\\ \psi(0,\cdot) &= 0. \end{aligned}$$

Clearly $v := \psi - \varphi \in \mathcal{E}$ ((4.7)–(4.8) hold true with $v_1 = 0$, $v_2 = \psi(t_2 + \delta)$); hence $(\psi - \varphi, g)_{L^2(Q_\delta)} = 0$. On the other hand, it is clear that

$$\text{for all } t \in [0,T] \quad \|\psi(t)\|_{L^2(-L,L)} \le \|P\varphi\|_{L^1(0,t,L^2(-L,L))} \le \sqrt{T} \|P\varphi\|_{L^2(Q)};$$

hence

$$|(\varphi, g)|_{L^2(Q_\delta)} = |(\psi, g)|_{L^2(Q_\delta)} \le T \|g\|_{L^2(Q_\delta)} \cdot \|P\varphi\|_{L^2(Q)}.$$

This completes the proof of Claim 1. We now proceed to the next claim.

Claim 2. *There exists a function* $w \in L^2(Q)$ *such that*

$$\text{for all } \varphi \in \mathcal{T} \quad (\varphi, g)_{L^2(Q_\delta)} = (P\varphi, w)_{L^2(Q)}. \tag{4.12}$$

Proof of Claim 2. Let $\mathcal{Z} := \{(P\varphi)_{|_Q};\ \varphi \in \mathcal{T}\}$. Notice first that for any $\zeta \in \mathcal{Z}$, if $\zeta = (P\varphi_1)_{|_Q} = (P\varphi_2)_{|_Q}$ for two functions $\varphi_1, \varphi_2 \in \mathcal{T}$, then $\varphi_1 - \varphi_2 \in \mathcal{E}$; hence $(\varphi_1 - \varphi_2, g)_{L^2(Q_\delta)} = 0$. It follows that the (linear) map $\Lambda : \zeta \in \mathcal{Z} \mapsto (\varphi, g)_{L^2(Q_\delta)} \in \mathbb{R}$ (if $\zeta = (P\varphi)_{|_Q}$, $\varphi \in \mathcal{T}$) is well defined. Let H denote the closure of $\mathcal{Z}$ in $L^2(Q)$. We infer from (4.11) that Λ may be extended to H in such a way that Λ is a continuous linear form on H. It follows from Riesz representation theorem that there exists $w \in H$ such that $\Lambda(\zeta) = (\zeta, w)_{L^2(Q)}$ for all $\zeta \in H$. Then (4.12) holds true.

We are now ready to prove $(u', g)_{L^2(Q_\delta)} = 0$. Extend g and w on $\mathbb{R}^2$ to $\tilde{g}$, $\tilde{w}$ by setting

$$\begin{aligned} \tilde{g}(t,x) &= 0 \quad \text{for } (t,x) \in \mathbb{R}^2 \setminus Q_\delta,\\ \tilde{w}(t,x) &= 0 \quad \text{for } (t,x) \in \mathbb{R}^2 \setminus Q. \end{aligned}$$

Set $\Omega = (t_1 - \delta, t_2 + \delta) \times \mathbb{R}$ and let $\varphi \in \mathcal{D}(\Omega) \subset \mathcal{T}$. Obviously

$$(\varphi, g)_{L^2(Q_\delta)} = (\varphi, \tilde{g})_{L^2(\Omega)} \quad \text{and} \quad (P\varphi, w)_{L^2(Q)} = (P\varphi, \tilde{w})_{L^2(\Omega)};$$

hence it follows from (4.12) that

$$\langle P^* \tilde{w}, \varphi\rangle_{\mathcal{D}'(\Omega),\mathcal{D}(\Omega)} = \langle \tilde{g}, \varphi\rangle_{\mathcal{D}'(\Omega),\mathcal{D}(\Omega)}.$$

Thus

$$P^* \tilde{w} = \tilde{g} \text{ in } \mathcal{D}'(\Omega)$$

and

$$P^* \tilde{w} = 0 \text{ for } t_1 - \delta < t < t_2 + \delta \text{ and } |x| > l_1.$$

Since

$$\tilde{w}(t,x) = 0 \text{ for } t_1 - \delta < t < t_2 + \delta \text{ and } |x| > L$$

we infer from Holmgren's uniqueness theorem (see [5, Thm. 8.6.8]) that

$$\tilde{w}(t,x) = 0 \text{ for } t_1 - \delta < t < t_2 + \delta \text{ and } |x| > l_1. \tag{4.13}$$

Applying (4.12) to $u' \in \mathcal{T}$ and using (4.10), (4.13) we get

$$\begin{aligned}(u',g)_{L^2(Q_\delta)} &= (P\,u', w)_{L^2(Q)}\\ &= (P\,u', w)_{L^2\big((t_1-\delta,t_2+\delta)\times(-l_1,l_1)\big)}\\ &= 0.\end{aligned}$$

The proof of Lemma 4.2 is complete. □

Next result is an observability result.

LEMMA 4.3. *Let l, L, T be positive numbers such that $l < L$. Then there exists a constant $C > 0$ such that for every $u_0 \in L^2(-L,L)$, if u denotes $S_L(\cdot)u_0$, we have*

$$\|u_0\|_{L^2(-L,L)} \le C\|u\|_{L^2\big((0,T)\times(-l,l)\big)}. \tag{4.14}$$

(Hence

$$\|u\|_{L^2((0,T)\times(-L,L))} \le \sqrt{T}C\|u\|_{L^2((0,T)\times(-l,l))}.) \tag{4.15}$$

Proof. Pick $T' \in (0, \frac{T}{2})$ and $\gamma > \frac{\pi}{T'}$. Let $N \in \mathbb{N}$ be such that

$$\lambda_N - \lambda_{-N} = 2\lambda_N \ge \gamma \text{ and } (n \in \mathbb{Z},\ |n| \ge N) \Rightarrow \lambda_{n+1} - \lambda_n \ge \gamma.$$

By Ingham's inequality (see [7]) there exists a constant $C^{T'} > 0$ such that for every sequence $(a_n)_{|n|\ge N}$ of complex numbers, with $a_n = 0$ for $|n|$ large enough, the following inequality holds true:

$$\sum_{|n|\ge N} |a_n|^2 \le C^{T'} \int_{-T'}^{T'} \left| \sum_{|n|\ge N} a_n e^{-i\lambda_n t} \right|^2 dt. \tag{4.16}$$

Let $\mathcal{Z}_n := \operatorname{Span}(e_n)$ for $n \in \mathbb{Z}$ and $\mathcal{Z} = \bigoplus_{n\in\mathbb{Z}} \mathcal{Z}_n \subset L^2(-L,L)$. We define a seminorm p in $\mathcal{Z}$ by

$$p(u) := \left(\int_{-l}^{l} |u(x)|^2\,dx\right)^{\frac{1}{2}} \quad \text{for } u \in \mathcal{Z}.$$

p is clearly a norm in each $\mathcal{Z}_n$. On the other hand, if $u_0 \in \mathcal{Z} \cap (\bigoplus_{|n|<N} \mathcal{Z}_n)^\perp$ (i.e., u_0 may be written in the form $u_0 = \sum_{|n|\geq N} c_n e_n$ with $c_n = 0$ for $|n|$ large enough), then applying (4.16) (with $a_n = \frac{c_n}{\sqrt{2L}} e^{i(\lambda_n T' + n\frac{\pi}{L}x)}$) and integrating w.r.t. x on $(-l, l)$, we get

$$2l \sum_{|n|\geq N} \frac{|c_n|^2}{2L} \leq C^{T'} \int_{-l}^{l} \int_0^{2T'} \left| \sum_{|n|\geq N} e^{i\lambda_n \tau} c_n e_n(x) \right|^2 d\tau dx;$$

hence, by Fubini's theorem,

$$\|u_0\|^2_{L^2(-L,L)} \leq \frac{L}{l} C^{T'} \int_0^{2T'} p\big(S_L(\tau)u_0\big)^2 \, d\tau.$$

Finally, for any $u_0 \in L^2(-L, L)$, we have

$$\int_0^{2T'} p\big(S_L(\tau)u_0\big)^2 \, d\tau \leq \|S_L(\cdot)u_0\|^2_{L^2\left((0,2T')\times(-L,L)\right)} = 2T'\|u_0\|^2_{L^2(-L,L)}.$$

Since $T > 2T'$, it follows from [10, Thm. 5.2] that there exists a constant $C > 0$ such that (4.14) holds true for all $z_0 \in \mathcal{Z}$. We get (4.14) for all $u_0 \in L^2(-L, L)$ by a density argument. □

We now proceed to the proof of the following approximation theorem, which differs from the one in [18] by an additional property on the support.

LEMMA 4.4. *Let $n \in \mathbb{N} \setminus \{0, 1\}$ and let t_1, t_2, T be numbers such that $0 < t_1 < t_2 < T$. Let $u \in L^2\big((0,T) \times (-n, n)\big)$ be such that $Pu = 0$ in $(0,T) \times (-n, n)$ and* supp $u \subset [t_1, t_2] \times (-n, n)$. *Let $0 < \epsilon < \min(t_1, T - t_2)$. Then there exists $v \in L^2\big((0,T) \times (-n-1, n+1)\big)$ such that*

$$Pv = 0 \quad \textit{in } (0,T) \times (-n-1, n+1), \tag{4.17}$$

$$\text{supp } v \subset [t_1 - \epsilon, t_2 + \epsilon] \times (-n-1, n+1), \tag{4.18}$$

$$\|v - u\|_{L^2\left((0,T)\times(-n+1,n-1)\right)} < \epsilon. \tag{4.19}$$

Proof. Let $\eta > 0$ (to be chosen later). By Lemma 4.2, applied with $L = n + 1$, there exists $\tilde{v} \in L^2\big((0,T) \times (-n-1, n+1)\big)$ such that

$$P\tilde{v} = 0 \quad \text{in} \quad (0,T) \times (-n-1, n+1),$$

$$\tilde{v}(t, \cdot) = S_{n+1}\left(t - t_1 + \frac{\epsilon}{2}\right) v_1 \quad \text{for} \quad t_1 - \frac{\epsilon}{2} < t < t_1 - \frac{\epsilon}{4}, \tag{4.20}$$

$$\tilde{v}(t, \cdot) = S_{n+1}\left(t - t_2 - \frac{\epsilon}{4}\right) v_2 \quad \text{for} \quad t_2 + \frac{\epsilon}{4} < t < t_2 + \frac{\epsilon}{2} \tag{4.21}$$

for some $v_1, v_2 \in L^2(-n-1, n+1)$ and

$$\|\tilde{v} - u\|_{L^2\left((t_1-\frac{\epsilon}{2}, t_2+\frac{\epsilon}{2})\times(-n+1,n-1)\right)} < \eta.$$

In order that (4.18) be fulfilled, we multiply $\tilde{v}$ by a cut-off function. Let $\varphi \in \mathcal{D}(0,T)$ be such that $0 \leq \varphi \leq 1$, $\varphi(t) = 1$ for all $t \in [t_1 - \frac{\epsilon}{4}, t_2 + \frac{\epsilon}{4}]$ and $\operatorname{supp}(\varphi) \subset [t_1 - \frac{\epsilon}{2}, t_2 + \frac{\epsilon}{2}]$. Set $\bar{v}(t,x) = \varphi(t)\tilde{v}(t,x)$. It follows that

$$\operatorname{supp}\, \bar{v} \subset \left[t_1 - \frac{\epsilon}{2}, t_2 + \frac{\epsilon}{2}\right] \times (-n-1, n+1)\cdot$$

Hence

$$\begin{aligned} &\|\bar{v} - u\|_{L^2\left((0,T)\times(-n+1,n-1)\right)} \\ &\quad = \|\bar{v} - u\|_{L^2\left((t_1-\frac{\epsilon}{2},t_2+\frac{\epsilon}{2})\times(-n+1,n-1)\right)} \\ &\quad \leq \|(\varphi - 1)\tilde{v}\|_{L^2\left((t_1-\frac{\epsilon}{2},t_2+\frac{\epsilon}{2})\times(-n+1,n-1)\right)} \\ &\qquad + \|\tilde{v} - u\|_{L^2\left((t_1-\frac{\epsilon}{2},t_2+\frac{\epsilon}{2})\times(-n+1,n-1)\right)}\cdot \end{aligned}$$

Since $\operatorname{supp}\, u \subset [t_1, t_2] \times (-n, n)$ and $\varphi(t) = 1$ for $t_1 - \frac{\epsilon}{4} \leq t \leq t_2 + \frac{\epsilon}{4}$, we get

$$\begin{aligned} &\|(\varphi - 1)\tilde{v}\ \|^2_{L^2\left((t_1-\frac{\epsilon}{2},t_2+\frac{\epsilon}{2})\times(-n+1,n-1)\right)} \\ &\quad \leq \|\tilde{v}\|^2_{L^2\left(\{(t_1-\frac{\epsilon}{2},t_1-\frac{\epsilon}{4})\cup(t_2+\frac{\epsilon}{4},t_2+\frac{\epsilon}{2})\}\times(-n+1,n-1)\right)} \\ &\quad \leq \|\tilde{v} - u\|^2_{L^2\left((t_1-\frac{\epsilon}{2},t_2+\frac{\epsilon}{2})\times(-n+1,n-1)\right)} \\ &\quad < \eta^2\cdot \end{aligned} \tag{4.22}$$

Hence

$$\|\bar{v} - u\|_{L^2\left((0,T)\times(-n+1,n-1)\right)} \leq 2\eta\cdot \tag{4.23}$$

Finally $P\,\bar{v} = \frac{d\varphi}{dt}\,\tilde{v}$ in $(0,T) \times (-n-1, n+1)$; hence

$$\begin{aligned} &\|P\,\bar{v}\ \|^2_{L^2\left((0,T)\times(-n-1,n+1)\right)} \\ &\quad \leq \|\tfrac{d\varphi}{dt}\|^2_{L^\infty(0,T)} \cdot \|\tilde{v}\|^2_{L^2\left(\{(t_1-\frac{\epsilon}{2},t_1-\frac{\epsilon}{4})\cup(t_2+\frac{\epsilon}{4},t_2+\frac{\epsilon}{2})\}\times(-n-1,n+1)\right)}\cdot \end{aligned}$$

Since (4.20), (4.21) hold true, we infer from Lemma 4.3 that there exists a constant $C = C(n, \epsilon) > 0$ such that

$$\|\tilde{v}\|_{L^2\left((t_1-\frac{\epsilon}{2},t_1-\frac{\epsilon}{4})\times(-n-1,n+1)\right)} \leq C\|\tilde{v}\|_{L^2\left((t_1-\frac{\epsilon}{2},t_1-\frac{\epsilon}{4})\times(-n+1,n-1)\right)}$$

and also

$$\|\tilde{v}\|_{L^2\left((t_2+\frac{\epsilon}{4},t_2+\frac{\epsilon}{2})\times(-n-1,n+1)\right)} \leq C\|\tilde{v}\|_{L^2\left((t_2+\frac{\epsilon}{4},t_2+\frac{\epsilon}{2})\times(-n+1,n-1)\right)}\cdot$$

Hence, by (4.22),

$$\|P\,\bar{v}\|_{L^2\left((0,T)\times(-n-1,n+1)\right)} \leq C\|\frac{d\varphi}{dt}\|_{L^\infty(0,T)}\,\eta\cdot \tag{4.24}$$

We finally modify $\bar{v}$ in order that (4.17) be satisfied. By Corollary 3.2 there exist a constant $C' > 0$ (which depends on n, t_1, t_2, and ϵ) and a function $w \in L^2\big((0,T) \times (-n-1, n+1)\big)$ such that

$$\begin{gathered} P\,w = P\,\bar{v} \ \text{ in } (0,T) \times (-n-1, n+1), \\ \operatorname{supp}\, w \subset [t_1 - \epsilon, t_2 + \epsilon] \times (-n-1, n+1), \end{gathered}$$

and also

$$\|w\|_{L^2\big((0,T)\times(-n-1,n+1)\big)} \leq C'\|P\,\bar{v}\|_{L^2\big((0,T)\times(-n-1,n+1)\big)}\cdot \tag{4.25}$$

Set $v := \bar{v} - w$. Then (4.17) and (4.18) are obvious, and we infer from (4.23), (4.24), and (4.25) that

$$\|v-u\|_{L^2\big((0,T)\times(-n+1,n-1)\big)} \leq \left(2 + CC'\left\|\frac{d\varphi}{dt}\right\|_{L^\infty(0,T)}\right)\eta\cdot$$

Hence (4.19) holds true provided that η is small enough. □

We now turn to the proof of Proposition 4.1, which is carried out as in [18].

Proof of Proposition 4.1. Let $(t_1^n)_{n\geq 2}$ and $(t_2^n)_{n\geq 2}$ be two sequences of numbers such that

$$\text{for all } n\geq 2 \qquad t_1-\epsilon < t_1^{n+1} < t_1^n < t_1 < t_2 < t_2^n < t_2^{n+1} < t_2+\epsilon\cdot \tag{4.26}$$

We construct (by induction on n) a sequence $(u_n)_{n\geq 2}$ of functions such that, for every $n \geq 2$,

$$u_n \in L^2\big((0,T)\times(-n,n)\big), \tag{4.27}$$

$$\text{supp } u_n \subset [t_1^n, t_2^n]\times(-n,n), \tag{4.28}$$

$$P\,u_n = f \ \text{ in } \ (0,T)\times(-n,n), \tag{4.29}$$

and, if $n > 2$,

$$\|u_n - u_{n-1}\|_{L^2\big((0,T)\times(-n+2,n-2)\big)} < 2^{-n}\cdot \tag{4.30}$$

u_2 is given by Corollary 3.2. Now let $n \geq 2$ and assume that $u_2,\ldots,u_n$ have been constructed in such a way that (4.27)–(4.30) hold true. By Corollary 3.2 there exists $w \in L^2\big((0,T)\times(-n-1,n+1)\big)$ such that

$$\text{supp } w \subset [t_1^2, t_2^2]\times(-n-1,n+1) \ \text{ and } \ P\,w = f \ \text{ in } \ (0,T)\times(-n-1,n+1)\cdot$$

Since $P(u_n - w) = 0$ in $(0,T)\times(-n,n)$ and

$$\text{supp}\,(u_n - w_{|(0,T)\times(-n,n)}) \subset [t_1^n, t_2^n]\times(-n,n),$$

with $t_1^{n+1} < t_1^n < t_2^n < t_2^{n+1}$, it follows from Lemma 4.4 that there exists a function $v \in L^2\big((0,T)\times(-n-1,n+1)\big)$ such that

$$\text{supp } v \subset [t_1^{n+1}, t_2^{n+1}]\times(-n-1,n+1), \quad P\,v = 0 \text{ in } (0,T)\times(-n-1,n+1)$$

and also

$$\|v-(u_n-w)\|_{L^2\big((0,T)\times(-n+1,n-1)\big)} < 2^{-n-1}\cdot$$

We set $u_{n+1} := v + w$. Then (4.27)–(4.30) are fulfilled. Extending the u_n's by setting $u_n(t,x) = 0$ for $(t,x) \notin (0,T)\times(-n,n)$, we infer from (4.30) that the sequence $(u_n)_{n\geq 2}$ converges in $L^2_{loc}(\mathbb{R}^2)$ towards a function u such that

$$\text{supp } u \subset [t_1-\epsilon, t_2+\epsilon]\times\mathbb{R}$$

by (4.26) and (4.28). Finally $P\,u = f$ in $\mathbb{R}^2$, because of (4.29). This completes the proof of Proposition 4.1 and also the proof of Theorem 1.3. □

5. The heat equation and the Schrödinger equation. In this section, we are concerned with the control of the heat equation and of the Schrödinger equation in unbounded domains. Let us first briefly discuss the controllability of the heat equation

$$u_t - \Delta u = 0, \tag{5.1}$$

where $\Delta u = \sum_{i=1}^N \frac{\partial^2 u}{\partial x_i^2}$, $N \geq 1$. By Proposition 1.1, the (boundary or internal) *approximate* controllability of (5.1) in unbounded domains is obvious. Notice that this result is still valid (but not so obvious) for a *semilinear* heat equation; see [23]. As far as the boundary null-controllability of (5.1) is concerned, it has been proved in [17] that no (nontrivial) function in $\mathcal{D}(\Omega)$ (the space of test functions) can be driven to 0 when $\Omega = \mathbb{R}^N_+ := \{(x', x_N) : \ x' \in \mathbb{R}^{N-1}, \ x_N > 0\}$ and solutions of (5.1) are taken in some *transposition* sense. However, if *all* the solutions of (5.1) are taken into consideration, then the null-controllability is recovered, thanks to the following result by Jones (see [8], [13]).

Theorem 5.1. *Let $g \in C^0(\mathbb{R}^N)$ and $T > 0$. Then there exists a function $u \in C^0([0,T] \times \mathbb{R}^N)$ which solves* (5.1) *in the distributional sense for $t > 0$ and satisfies $u_{|t=0} = g$, $u_{|t=T} = 0$.*

Notice that, as it has been pointed out in [13], the boundary control problem is solved once and for all without reference to any *specific* domain or set of boundary conditions. Theorem 5.1 is derived in [8] from the existence, for any $\epsilon > 0$, of a fundamental solution of the heat equation which is supported in the strip $[0,\epsilon] \times \mathbb{R}^N$. A result close to Theorem 5.1 may be proved along the same lines as in section 4.

Theorem 5.2. *Let $\big(S(t)\big)_{t \geq 0}$ denote the continuous semigroup on $L^2(\mathbb{R}^N)$ generated by the operator $Au = \Delta u$ with domain $H^2(\mathbb{R}^N)$. Let T, ϵ be positive numbers with $\epsilon < \frac{T}{2}$ and let $u_0, u_1 \in L^2(\mathbb{R}^N)$. Then there exists a function*

$$u \in L^2_{loc}\big([0,T] \times \mathbb{R}^N)\big) \cap C\big([0,\epsilon] \cup [T-\epsilon, T], L^2(\mathbb{R}^N)\big)$$

which solves

$$\begin{cases} u_t - \Delta u &= 0 \qquad \text{in } \mathcal{D}'\big((0,T) \times \mathbb{R}^N\big), \\ u_{|t=0} &= u_0, \\ u_{|t=T} &= S(T)u_1. \end{cases} \tag{5.2}$$

Proof. Set, for any $L > 0$, $\Omega_L := (-L, L)^N$. Let P_1 denote the operator $\frac{\partial}{\partial t} - \Delta$. Let $\epsilon' \in (\epsilon, \frac{T}{2})$ and let $\varphi \in C^\infty([0,T])$ be such that $\varphi(t) = 1$ for $t \leq \epsilon'$ and $\varphi(t) = 0$ for $t \geq T - \epsilon'$. The change of functions

$$u(t,\cdot) = \varphi(t)S(t)u_0 + \big(1 - \varphi(t)\big)S(t)u_1 + w(t,\cdot)$$

transforms (5.2) into

$$\begin{cases} P_1 w &= \frac{d\varphi}{dt} S(t)(u_1 - u_0) \quad \text{ in } \mathcal{D}'\big((0,T) \times \mathbb{R}^N\big), \\ w_{|t=0} &= w_{|t=T} = 0. \end{cases}$$

Once again, it is clear that we are finished if Proposition 4.1 holds true with P_1 instead of P. The estimate (see [3, Lem. 5.2], [4, Thm. 4.1])

$$\exists k > 0, \ \exists C > 0 \text{ s.t.} \quad \int_0^T \int_{\Omega_L} |q|^2 e^{-\frac{k}{t(T-t)}} dxdt \leq C \int_0^T \int_{\Omega_L} |q_t + \Delta q|^2 \, dxdt$$

for any $q \in C^2([0,T] \times [-L,L]^N)$ such that $q(t,x) = \partial_n q(t,x) = 0$ for $(t,x) \in [0,T] \times \partial\Omega_L$ shows that Corollary 3.2 holds true with P_1 instead of P. The other key ingredient in the proof of Proposition 4.1, namely the internal observability result (Lemma 4.3), may be found in the literature (see [12, Cor. 2]). If $\big(S_L(t)\big)_{t\geq 0}$ now denotes the continuous *semigroup* on $L^2(\Omega_L)$ generated by the operator $Au = \Delta u$ with domain $H^2_{per}(\Omega_L)$, then the proofs of Lemmas 4.2 and 4.4 and of Proposition 4.1 are word for word the same as those given above for the KdV equation. □

Remark 3. For the heat equation, the results in Corollary 3.2 and in Proposition 4.1 are no longer true if we do $\epsilon = 0$. Indeed, if we assume that Corollary 3.2 is true for the one-dimensional heat equation with $\epsilon = 0$ (for any f), then an argument similar to the one used in the proof of Theorem 1.2 shows that for some constant $C > 0$ we have

$$\int_0^T \int_{-L}^L |q|^2 \, dxdt \leq C \int_0^T \int_{-L}^L |q_t - q_{xx}|^2 \, dxdt \tag{5.3}$$

for any $q \in C^2([0,T] \times [-L,L])$ such that $q(t,\pm L) = q_x(t,\pm L) = 0$. Let E be the classical fundamental solution of the one-dimensional heat equation, namely

$$E(t,x) = \begin{cases} (4\pi t)^{-\frac{1}{2}} \exp(-\frac{x^2}{4t}) & \text{if } t > 0,\ x \in \mathbb{R}, \\ 0 & \text{otherwise.} \end{cases}$$

Let $\rho \in \mathcal{D}(-L,L)$ be such that $\rho(x) = 1$ for $|x| < \frac{L}{2}$. Set $q(t,x) = \rho(x)\frac{\partial E}{\partial x}(t,x)$ for $x \in (-L,L)$ and $t > 0$. Direct computations show that $\|q\|_{L^2((\epsilon,T+\epsilon)\times(-L,L))} \to +\infty$ as $\epsilon \to 0^+$, whereas $\|q_t - q_{xx}\|_{L^2((\epsilon,T+\epsilon)\times(-L,L))} = O(1)$, contradicting (5.3).

We now turn to the Schrödinger equation

$$iu_t + \Delta u = 0. \tag{5.4}$$

For the sake of simplicity, we restrict ourselves to the one-dimensional case (i.e., $N = 1$). The following result is proved in the same way as Theorem 1.3.

THEOREM 5.3. *Let T, ϵ be positive numbers with $\epsilon < \frac{T}{2}$ and let $u_0, u_T \in L^2(\mathbb{R})$. Then there exists a function*

$$u \in L^2_{loc}\big([0,T] \times \mathbb{R}\big) \cap C\big([0,\epsilon] \cup [T-\epsilon,T], L^2(\mathbb{R})\big)$$

which solves

$$\begin{cases} iu_t + u_{xx} &= 0 \quad \text{in } \mathcal{D}'\big((0,T) \times \mathbb{R}\big), \\ u_{|t=0} &= u_0, \\ u_{|t=T} &= u_T. \end{cases} \tag{5.5}$$

Proof. We shall write P_2 for the operator $\frac{\partial}{\partial t} - i\frac{\partial^2}{\partial x^2}$. Let $\big(S(t)\big)_{t\in\mathbb{R}}$ denote the unitary group on $L^2(\mathbb{R})$ generated by the operator $Au = iu_{xx}$ with domain $H^2(\mathbb{R})$. Let ϵ' and φ be as in the proof of Theorem 5.2. The change of functions

$$u(t,\cdot) = \varphi(t)S(t)u_0 + \big(1 - \varphi(t)\big)S(t-T)u_T + w(t,\cdot)$$

transforms (5.5) into

$$\begin{cases} P_2\, w &= \frac{d\varphi}{dt}\, S(t)\big(S(-T)u_T - u_0\big) \quad \text{in } \mathcal{D}'\big((0,T) \times \mathbb{R}\big), \\ w_{|t=0} &= w_{|t=T} = 0. \end{cases}$$

We are again led to prove Proposition 4.1, but with P_2 instead of P. Let S_L denote here the unitary group on $L^2(-L,L)$ generated by the operator $Au = iu_{xx}$ with domain $\{u \in H^2(-L,L);\ u(-L) = u(L),\ u_x(-L) = u_x(L)\}$. Let $e_n(x) = \frac{1}{\sqrt{2L}} e^{in\frac{\pi}{L}x}$ and $\lambda_n = (n\frac{\pi}{L})^2$ for $n \in \mathbb{Z}$. If $u_0 \in L^2(-L,L)$ is decomposed as $u_0 = \sum_{n\in\mathbb{Z}} c_n e_n$, then $S(t)u_0 = \sum_{n\in\mathbb{Z}} e^{-i\lambda_n t} c_n e_n$ for all $t \in \mathbb{R}$.

A proof of Corollary 3.2 using a controllability result in the literature instead of a Carleman's estimate is as follows. Let $w(t) := \int_{t_1}^t S_L(t-\tau) f(\tau)\, d\tau \in L^2(-L,L)$ for $t_1 \le t \le t_2$. By [15, Thm. 1.2] (the result being in fact true for any final state $y_T \in L^2(\Omega)$ instead of 0) there exists some (internal) control function $h \in L^2((t_1,t_2)\times(L,L+1))$ such that the solution $y \in C([t_1,t_2], L^2(-L,L+1))$ of

$$\begin{cases} y_t - iy_{xx} &= h\chi_{(L,L+1)} \quad \text{in } (t_1,t_2)\times(-L,L+1),\\ y &= 0 \quad\quad\quad\ \ \text{on } (t_1,t_2)\times\{-L,L+1\},\\ y_{|t=t_1} &= 0 \end{cases}$$

satisfies $y_{|t=t_2} = -w(t_2)$ on $(-L,L)$. Clearly, the function

$$v(t) := \begin{cases} w(t) + y(t) & \text{if } t_1 \le t \le t_2,\\ 0 & \text{otherwise} \end{cases}$$

fulfills $v_t - iv_{xx} = f$ in $\mathcal{D}'(\mathbb{R}\times(-L,L))$, (3.17) (with $\epsilon = 0$) and (3.18).

As for the KdV equation the proof of Lemma 4.3 rests on Ingham's inequality and on [10, Thm. 5.2]. Here $\mathcal{Z} = \bigoplus_{n\in\mathbb{N}} \mathcal{Z}_n$, with $\mathcal{Z}_0 = \mathrm{Span}(e_0)$ and $\mathcal{Z}_n = \mathrm{Span}(e_n, e_{-n})$ for $n \ge 1$. To properly handle the left-hand side in Ingham's estimate

$$\sum_{n\ge N} |a_n|^2 \le C^{T'} \int_{-T'}^{T'} \left| \sum_{n\ge N} a_n e^{-i\lambda_n t} \right|^2 dt \tag{5.6}$$

(which is applied with $a_n = (c_n e_n + c_{-n} e_{-n}) e^{-i\lambda_n T'}$) it is sufficient to observe that the estimate

$$\|c_n e_n + c_{-n} e_{-n}\|^2_{L^2(-l,l)} \ge \frac{1}{2}\left(\|c_n e_n\|^2_{L^2(-l,l)} + \|c_{-n} e_{-n}\|^2_{L^2(-l,l)}\right)$$

holds true provided that $|n|$ is large enough, which implies (for N large enough)

$$\int_{-l}^{l} \sum_{n\ge N} |c_n e_n + c_{-n} e_{-n}|^2\, dx \ge \frac{l}{2L} \sum_{|n|\ge N} |c_n|^2 = \frac{l}{2L} \|u_0\|^2_{L^2(-L,L)}.$$

The rest of the proof of Lemma 4.3 and of Proposition 4.1 is as above for the KdV equation. $\square$

Appendix. Proof of Proposition 1.1.

We argue by contradiction and assume that $\mathcal{R} = L^2(\mathbb{R})$. Consider the map

$$\Lambda : f \in L^2\big((0,T)\times(L_1,L_2)\big) \to \int_0^T S(T-t)\tilde{f}(t,\cdot)dt \in L^2(\mathbb{R})$$

(where $\tilde{f}$ is the prolongation of f by 0 on $\mathbb{R}^2$). Let $N = \ker(\Lambda)$. Then the restriction of Λ to the orthogonal complement of N in $L^2\big((0,T)\times(L_1,L_2)\big)$ is a one-to-one continuous linear map which is onto $L^2(\mathbb{R})$; hence its inverse $(\Lambda_{|_{N^\perp}})^{-1}$ is continuous.

Let $f \in \mathcal{D}\big((0,T) \times (L_1, L_2)\big)$ and let $w_T \in D(A^*)$, where A^* denotes the adjoint of the operator A. (Clearly $A^* w = \sum_{i=0}^{n} (-1)^i a_i \frac{d^i w}{dx^i}$.) Recall that A^* generates the continuous semigroup $\big(S^*(t)\big)_{t \geq 0}$ on $L^2(\mathbb{R})$. Set $w(t) := S^*(T-t) w_T$ for $t \in [0,T]$. Then w solves

$$\begin{cases} \frac{dw}{dt} & = -A^* w, \\ w_{|_{t=T}} & = w_T. \end{cases}$$

Let $u(t) = \int_0^t S(t-s) \tilde{f}(s, \cdot) ds$. Integrating by part in

$$\int_0^T \int_{\mathbb{R}} \left(\frac{dw}{dt} + A^* w \right) u \, dxdt = 0,$$

we get

$$\int_0^T \int_{L_1}^{L_2} f(t,x) w(t,x) \, dxdt = \int_{\mathbb{R}} w_T(x) u(T,x) \, dx. \tag{A.1}$$

The same equation holds true (by density) for $f \in L^2\big((0,T) \times (L_1, L_2)\big)$ and $w_T \in L^2(\mathbb{R})$. Letting $f = (\Lambda_{|_{N^\perp}})^{-1}(w_T)$, where w_T is any function in $L^2(\mathbb{R}) \setminus \{0\}$, we get

$$\|w_T\|^2_{L^2(\mathbb{R})} \leq \|f\|_{L^2\big((0,T)\times(L_1,L_2)\big)} \cdot \|w\|_{L^2\big((0,T)\times(L_1,L_2)\big)};$$

hence

$$\|w_T\|_{L^2(\mathbb{R})} \leq \|(\Lambda_{|_{N^\perp}})^{-1}\| \cdot \|w\|_{L^2\big((0,T)\times(L_1,L_2)\big)}.$$

Replacing w_T by $w_T(\cdot + n)$ (and also $w(t,x)$ by $w(t, x+n)$), we get

$$\|w_T\|_{L^2(\mathbb{R})} = \|w_T(\cdot + n)\|_{L^2(\mathbb{R})} \leq \|(\Lambda_{|_{N^\perp}})^{-1}\| \cdot \|w\|_{L^2\big((0,T)\times(L_1+n,L_2+n)\big)}.$$

Letting $n \to \infty$, we get (by Lebesgue's theorem) $w_T = 0$, a contradiction. Thus $\mathcal{R} \neq L^2(\mathbb{R})$. Now let $w_T \in \mathcal{R}^\perp$. We infer from (A.1) that

$$\int_0^T \int_{L_1}^{L_2} f(t,x) w(t,x) \, dxdt = 0$$

for all $f \in L^2\big((0,T) \times (L_1, L_2)\big)$; hence $w_{|_{(0,T)\times(L_1,L_2)}} = 0$. Since $n \geq 2$ (with $a_n \neq 0$) it follows from Holmgren's uniqueness theorem that $w = 0$ in $(0,T) \times \mathbb{R}$; hence $w_T = 0$, and we infer that $\mathcal{R}$ is dense in $L^2(\mathbb{R})$.

Acknowledgment. The author wishes to thank E. Zuazua, who introduced to him Jones and his work.

THE SOLUTION TO THE CONJECTURE ON PROPERNESS OF WEAKLY RELAXED DELAYED CONTROLS*

JAVIER F. ROSENBLUETH†

Abstract. In 1986 Warga proposed a "weak" relaxation procedure applicable to fully nonlinear problems with delays in the control variables and showed that the resulting relaxed problem has a solution. However, in the event of commensurate delays, several examples were found for which weakly relaxed controls cannot be approximated with original controls, so that this extension fails to be "proper." Although the case of commensurate delays was solved by the introduction of a "strong" model, the question of how to properly relax noncommensurately delayed controls has remained open, and a natural candidate has been precisely that of weakly relaxed controls. In this paper, a general counterexample is constructed which rules out the weak relaxation as a proper relaxation when there are two or more delays. It is hoped that this result will provide some insight into the problem of finding a general representation of properly relaxed controls.

Key words. optimal control problems, systems with time delays, proper relaxation procedures

1. Introduction.

This paper concerns the problem of finding a proper relaxation procedure for optimal control problems with nonadditively coupled delays (or, more generally, shifts) in the control variables. Usually in relaxation theory the aim is to find a relaxation procedure for a given original problem which leads us to its proper extension. This means that the set of controls for the original problem is dense in the space of controls for the relaxed problem. Such procedures are well studied for delay free problems. For problems with delays the situation is more difficult and less understood. For example, there are natural relaxation procedures which give a proper extension while there are other natural relaxation procedures which do not (see [2, 8]).

Research in this area starts in [11]. There are two basic problems:

1. the existence of a proper relaxation, and
2. the representation of the set of relaxed controls when it exists.

Problem 1 has been affirmatively answered in [11] when there is only one constant delay, in [8] when the constant delays are commensurate, in [13] for arbitrary constant delays, and in [12] for certain variable delays.

This paper deals with problem 2. Specifically, a general counterexample is constructed which rules out the weak relaxation proposed in [11] as a proper relaxation when there are two or more delays. This is a significant step forward in this direction which finally clarifies questions raised in [1, 2, 3, 4, 5, 6, 7, 8, 11]. In order to understand this contribution, let us briefly state the problem we shall be concerned with together with some basic notation and previous results.

For $T \subset \mathbf{R}$ compact and R a compact metric space, denote by $\mathcal{M}(T, R)$ the space of measurable functions mapping T to $rpm(R)$ with the weak star topology of $L^1(T, C(R))^*$, where $rpm(R)$ is the space of Radon probability measures on R with

†IIMAS–UNAM, Apartado Postal 20-726, México DF 01000, México (jfrl@leibniz.iimas.unam.mx).

the weak star topology of $C(R)^*$. Let $\mathcal{U}(T,R)$ be the space of measurable functions mapping T to R, embedded in $\mathcal{M}(T,R)$ by identifying each $u \in \mathcal{U}(T,R)$ with the function $t \mapsto \delta_{u(t)}$, where δ_a (also written as δa) is the Dirac measure at a.

It is well known that $\mathcal{M}(T,R)$ coincides with $\mathrm{cl}\,\mathcal{U}(T,R)$, the weak star closure of $\mathcal{U}(T,R)$. For optimal control problems where $\mathcal{U}(T,R)$ is the space of ordinary controls, under the usual assumptions on the data of the problem, existence of minimizers in the space $\mathcal{M}(T,R)$ of relaxed controls can thus be assured, and they can be approximated with ordinary controls. This fact is summarized by saying that $\mathcal{M}(T,R)$ provides a "proper" relaxation procedure for $\mathcal{U}(T,R)$. For a full account of these ideas, together with a thorough study of relaxation and its importance in optimal control theory, we refer to Warga's book [10].

For optimal control problems involving delays in the controls, several attempts have been made to find proper relaxation procedures. The space of *ordinary delayed controls* we shall consider (also studied in [1, 2, 3, 4, 5, 6, 7, 8]), which illustrates the main difficulties encountered when addressing relaxation questions, is given by

$$\mathcal{U}(\theta_1,\dots,\theta_k) = \{(u_0,u_1,\dots,u_k) \in \mathcal{U}(T,\Omega^{k+1}) \mid u_i(t) = u_{i-1}(t-\Delta_i) \\ \text{almost everywhere (a.e.) in } T_i \ (i=1,\dots,k)\},$$

where $T=[0,1]$, $0<\theta_1<\cdots<\theta_k<1$ are given real numbers, Ω is a given compact metric space, and $\theta_0=0$, $\Delta_i=\theta_i-\theta_{i-1}$, $T_i=[\Delta_i,1]$ $(i=1,\dots,k)$.

Warga [11] proposed (in a more general setting) a natural extension of $\mathcal{U}(\theta_1,\dots,\theta_k)$, which we call the *weak relaxation procedure*, given by

$$\mathcal{M}_{\mathrm{w}}(\theta_1,\dots,\theta_k) = \{\mu \in \mathcal{M}(T,\Omega^{k+1}) \mid \mathcal{P}_i\mu(t) = \mathcal{P}_{i-1}\mu(t-\Delta_i) \text{ a.e. in } T_i \ (i=1,\dots,k)\},$$

where if, say, $\mu \in \mathcal{M}(T,\Omega^n)$ for some $n \in \mathbf{N}$ and $S \subset \{0,1,\dots,n-1\}$, then $\mathcal{P}_S\mu(t)$ denotes the projection onto the S coordinates of $\mu(t)$. Equivalently, $\mu \in \mathcal{M}(T,\Omega^{k+1})$ is a weakly relaxed control if and only if

$$\int_{T_i} dt \int \varphi(t,r_i)\mu(t)(dr) = \int_{T_i} dt \int \varphi(t,r_{i-1})\mu(t-\Delta_i)(dr)$$

for all φ in $L^1(T,C(\Omega))$ and $i=1,\dots,k$, where $r=(r_0,\dots,r_k)$.

One readily verifies that the set of weakly relaxed controls contains the set of ordinary controls and, regarding it as a subspace of $\mathcal{M}(T,\Omega^{k+1})$ with the weak star topology, it is compact. In [11] the question of properness of this model (that is, if the equality $\mathcal{M}_{\mathrm{w}}(\theta_1,\dots,\theta_k) = \mathrm{cl}\,\mathcal{U}(\theta_1,\dots,\theta_k)$ holds) was posed but could not be proved. For the one delay case, it is shown in [3, 8] that this model is indeed a proper relaxation procedure.

In [8] Rosenblueth and Vinter introduced an abstract relaxation procedure, which we call the $\mathcal{D}$-model, and properness of this procedure was established by Warga and Zhu [13]. However, as we point out in [9], determining the set of $\mathcal{D}$-relaxed controls for specific problems is a very difficult and perhaps even a hopeless task, so there is a need to find more concrete characterizations of the closure of the space of ordinary delayed controls.

Now, the conjecture mentioned in our title, considered in [1, 2, 3, 4, 5, 6, 7, 8, 11], is that

$$\textit{for any } \Omega \subset \mathbf{R}^m \textit{ compact and } 0<\theta_1<\theta_2<1, \ \mathcal{M}_{\mathrm{w}}(\theta_1,\theta_2) = \mathrm{cl}\,\mathcal{U}(\theta_1,\theta_2).$$

This statement is false. In [8], Rosenblueth and Vinter exhibit an element of $\mathcal{M}_{\mathrm{w}}(\theta_1,\theta_2)$ lying outside $\mathrm{cl}\,\mathcal{U}(\theta_1,\theta_2)$ for the case when $\theta_2=2\theta_1$ and $\Omega=[0,1]$.

Rosenblueth [4] extends the inequality $\mathcal{M}_{\rm w}(\theta_1,\theta_2) \neq \operatorname{cl} \mathcal{U}(\theta_1,\theta_2)$ to pairs different than $(\theta_1, 2\theta_1)$ and whose quotient is a rational number (this settles a question raised by Andrews [1]). In the event of commensurate delays, a "strong" relaxation procedure was introduced in [8] and shown to be proper (see also [4, 9]). For the noncommensurate case, the problem of how to characterize $\mathcal{D}$-relaxed controls has remained unsolved, but a natural candidate has been precisely the space of weakly relaxed controls (see [1, 5, 6]). In particular, it is shown in [6] that, if $\Omega = \{0,1\}$ and θ_1/θ_2 is irrational, then any constant element of $\mathcal{M}_{\rm w}(\theta_1,\theta_2)$ can be approximated with elements of $\mathcal{U}(\theta_1,\theta_2)$. The present paper finally solves this question. We show that inequality also holds for noncommensurate θ_1, θ_2:

For any $0 < \theta_1 < \theta_2 < 1$, *there exists* $\mu \in \mathcal{M}_{\rm w}(\theta_1,\theta_2)$ *such that* $\mu \notin \operatorname{cl} \mathcal{U}(\theta_1,\theta_2)$.

It is hoped that the counterexample used to solve this question will provide some insight into the problem of finding a general representation of properly relaxed controls.

2. The solution to the conjecture.

In the following theorem we assume that $\Omega = [0,1]$. Essentially the same arguments apply if $\Omega \subset \mathbf{R}$ is any compact set containing at least two points.

THEOREM 2.1. *For any* $0 < \theta_1 < \theta_2 < 1$ *there exists* $\mu \in \mathcal{M}_{\rm w}(\theta_1,\theta_2)$ *such that* $\mu \notin \operatorname{cl} \mathcal{U}(\theta_1,\theta_2)$.

Proof. Let $0 < \theta_1 < \theta_2 < 1$ and set $\alpha := \theta_2 - \theta_1$. For all $(u,v,w) \in \Omega^3$ let

$$h(u,v,w) := \min\{|(u, v-1, w-1)|, |(u-1, v, w)|\},$$
$$g(u,v,w) := \min\{|(u, v, w-1)|, |(u-1, v-1, w)|\},$$

and, for any $t \in T$, $x_0, x_1 \in \mathbf{R}$, and $(u,v,w) \in \Omega^3$, let

$$f(t,x_0,x_1,u,v,w) := \begin{cases} (x_0 - t/2)^2 + h(u,v,w) & \text{if } t \in [0,\theta_2), \\ (x_0 - t/2)^2 + g(u,v,w) & \text{if } t \in [\theta_2, 1]. \end{cases}$$

Consider the problem (P) of minimizing $x_1(1)$ subject to

$$\begin{cases} (\dot x_0(t), \dot x_1(t)) = (u(t), f(t, x_0(t), x_1(t), u(t), v(t), w(t))) \text{ a.e. in } T, \\ (x_0(0), x_1(0)) = (0,0), \\ (u,v,w) \in \mathcal{U}(\theta_1,\theta_2). \end{cases}$$

Let $\mu \in \mathcal{M}(T, \Omega^3)$ be given by

$$\mu(t) = \begin{cases} \frac{1}{2}\delta(0,1,1) + \frac{1}{2}\delta(1,0,0) & \text{if } t \in [0,\theta_2), \\ \frac{1}{2}\delta(0,0,1) + \frac{1}{2}\delta(1,1,0) & \text{if } t \in [\theta_2, 1]. \end{cases}$$

Since

$$\mathcal{P}_i\mu(t) = \frac{1}{2}\delta_0 + \frac{1}{2}\delta_1 \qquad \text{for all } t \in T \text{ and } i = 0,1,2,$$

we have $\mu \in \mathcal{M}_{\rm w}(\theta_1,\theta_2)$. Note that its corresponding cost is zero and, since the cost cannot be negative, the minimum of the problem posed on $\mathcal{M}_{\rm w}(\theta_1,\theta_2)$ is zero.

Let $0 < a < \min\{\alpha, \theta_1, 1-\theta_2\}$ so that the intervals $I := [0,a)$, $I+\alpha$, and $I+\theta_2$ are disjoint and belong to $[0,1)$. Let (x_0,x_1,u,v,w) be any admissible original process for (P), so that $(u,v,w) \in \mathcal{U}(T,\Omega^3)$ and

$$v(t) = u(t-\theta_1) \text{ a.e. in } [\theta_1, 1], \tag{2.1}$$
$$w(t) = v(t-\alpha) \text{ a.e. in } [\alpha, 1], \tag{2.2}$$

and observe that the following relations hold a.e. in I:

$$w(t+\alpha) = v(t), \quad v(t+\theta_2) = u(t+\alpha), \quad w(t+\theta_2) = u(t).$$

Indeed, by (2), $w(t+\alpha) = v(t)$ a.e. in $[0, 1-\alpha]$ and, since $a < \theta_1 < 1-\theta_2+\theta_1 = 1-\alpha$, we have $I \subset [0, 1-\alpha]$. By (1), $v(t+\theta_2) = u(t+\alpha)$ a.e. in $[-\alpha, 1-\theta_2] \supset I$. Finally, by (2), $w(t+\theta_2) = v(t+\theta_1)$ a.e. in $[-\theta_1, 1-\theta_2]$ and, by (1), $v(t+\theta_1) = u(t)$ a.e. in $[0, 1-\theta_1]$. Hence $w(t+\theta_2) = u(t)$ a.e. in $[0, 1-\theta_2] \supset I$ and the three relations hold a.e. in I.

Therefore,

$$\begin{aligned} x_1(1) &= \int_0^{\theta_2} \{(x_0(s) - s/2)^2 + h(u(t), v(t), w(t))\} dt \\ &\quad + \int_{\theta_2}^1 \{(x_0(s) - s/2)^2 + g(u(t), v(t), w(t))\} dt \\ &\geq \int_0^a h(u(t), v(t), w(t)) dt + \int_\alpha^{\alpha+a} h(u(t), v(t), w(t)) dt \\ &\quad + \int_{\theta_2}^{\theta_2+a} g(u(t), v(t), w(t)) dt \\ &= \int_0^a \{h(u(t), v(t), w(t)) + h(u(t+\alpha), v(t+\alpha), v(t)) \\ &\quad + g(u(t+\theta_2), u(t+\alpha), u(t))\} dt. \end{aligned}$$

Fix $t \in I$ and let $r_0 = u(t)$, $r_1 = v(t)$, $r_2 = u(t+\alpha)$, $s_0 = w(t)$, $s_1 = v(t+\alpha)$, and $s_2 = u(t+\theta_2)$. Define

$$\varphi(t) := h(r_0, r_1, s_0) + h(r_2, s_1, r_1) + g(s_2, r_2, r_0),$$

and let

$$m_0 := \begin{cases} 1 & \text{if } h(r_0, r_1, s_0) = |(r_0, r_1 - 1, s_0 - 1)|, \\ 0 & \text{if } h(r_0, r_1, s_0) = |(r_0 - 1, r_1, s_0)|, \end{cases}$$

$$m_1 := \begin{cases} 1 & \text{if } h(r_2, s_1, r_1) = |(r_2, s_1 - 1, r_1 - 1)|, \\ 0 & \text{if } h(r_2, s_1, r_1) = |(r_2 - 1, s_1, r_1)|, \end{cases}$$

$$m_2 := \begin{cases} 1 & \text{if } g(s_2, r_2, r_0) = |(s_2, r_2, r_0 - 1)|, \\ 0 & \text{if } g(s_2, r_2, r_0) = |(s_2 - 1, r_2 - 1, r_0)|. \end{cases}$$

Observe now that

$$\begin{aligned} m_0 \neq m_1 &\Rightarrow \varphi(t) \geq |1 - r_1| + |r_1|, \\ m_1 \neq m_2 &\Rightarrow \varphi(t) \geq |1 - r_2| + |r_2|, \\ m_0 = m_2 &\Rightarrow \varphi(t) \geq |1 - r_0| + |r_0|. \end{aligned}$$

On the other hand, if $m_0 = m_1$ and $m_1 = m_2$, then $m_0 = m_2$ and so, in all cases, $\varphi(t) \geq 1$. It follows that

$$x_1(1) \geq \int_0^a \varphi(t) dt \geq a > 0$$

and so the infimum of (P) posed over the original admissible processes is positive. This implies that μ cannot be approximated with elements of $\mathcal{U}(\theta_1, \theta_2)$. □

3. Extensions to other delay-relaxation problems. The term "weak relaxation procedure" was first introduced in [8] referring to the model proposed by Warga in [11]. To be exact, the latter is slightly different from the one studied in [8] and mentioned in section 1. The subtle difference, which we shall explain below, leads to the study of another delay-relaxation problem for which a proof similar to the one of Theorem 2.1 can be applied.

Consider the following optimal control problem involving constant delays in the control variables. Let $T := [0,1]$ and suppose we are given real numbers $0 < \theta_1 < \cdots < \theta_k < 1$, a point $\xi \in \mathbf{R}^n$, a compact set $\Omega \subset \mathbf{R}^m$, and functions g mapping $\mathbf{R}^n$ to $\mathbf{R}$ and f mapping $T \times \mathbf{R}^n \times \mathbf{R}^{m(k+1)}$ to $\mathbf{R}^n$. Let $\hat{T} := [-\theta_k, 1]$ and consider the problem (P) of minimizing $g(x(1))$ subject to

$$\begin{cases} \dot{x}(t) = f(t, x(t), u(t), u(t-\theta_1), \ldots, u(t-\theta_k)) \text{ a.e. in } T, \\ x(0) = \xi, \\ u(t) \in \Omega \text{ a.e. in } \hat{T}, \end{cases}$$

where u is any measurable function mapping $\hat{T}$ to $\mathbf{R}^m$.

In [11] Warga reformulated this "original control problem" (P) by treating the control functions as independent variables which satisfy certain compatibility conditions in terms of the delays. The model of relaxation proposed by Warga was obtained by generalizing these conditions in the corresponding space of relaxed controls. To be specific, let

$$\begin{aligned} &\mathcal{W}(\theta_1, \ldots, \theta_k) \\ &\quad := \{(u_0, u_1, \ldots, u_k) \in \mathcal{U}(\hat{T}, \Omega^{k+1}) \mid u_i(t) = u_0(t-\theta_i) \text{ a.e. in } T \ (i = 1, \ldots, k)\} \end{aligned}$$

and consider the problem (W) of minimizing $g(x(1))$ subject to

$$\begin{cases} \dot{x}(t) = f(t, x(t), u(t)) \text{ a.e. in } T, \\ x(0) = \xi, \\ u \in \mathcal{W}(\theta_1, \ldots, \theta_k). \end{cases}$$

As Warga mentions in [11], it is a simple fact to show that (P) and (W) are equivalent. The "weak" extension of $\mathcal{W}(\theta_1, \ldots, \theta_k)$ proposed by Warga is given by

$$\mathcal{S}_{\mathrm{w}}(\theta_1, \ldots, \theta_k) := \{\mu \in \mathcal{M}(\hat{T}, \Omega^{k+1}) \mid \mathcal{P}_i\mu(t) = \mathcal{P}_0\mu(t-\theta_i) \text{ a.e. in } T \ (i = 1, \ldots, k)\}.$$

In [8] Rosenblueth and Vinter considered the problem (see the notation of section 1), which we label (RV), of minimizing $g(x(1))$ subject to

$$\begin{cases} \dot{x}(t) = f(t, x(t), u(t)) \text{ a.e. in } T, \\ x(0) = \xi, \\ u \in \mathcal{U}(\theta_1, \ldots, \theta_k). \end{cases}$$

It should be noted that, in this reformulation of the problem, ordinary controls are measurable functions defined on the interval $T = [0,1]$ and not on $\hat{T} = [-\theta_k, 1]$ as in the reformulation (W) of (P) given in [11]. As before, (P) and (RV) are equivalent (see [7] for details). The notion of "weakly relaxed controls" applied to (RV) yields the set

$$\mathcal{M}_{\mathrm{w}}(\theta_1, \ldots, \theta_k) = \{\mu \in \mathcal{M}(T, \Omega^{k+1}) \mid \mathcal{P}_i\mu(t) = \mathcal{P}_{i-1}\mu(t-\Delta_i) \text{ a.e. in } T_i \ (i = 1, \ldots, k)\}$$

and, since the three problems are equivalent, so is the question of properness of the two models of relaxed controls.

Now, in [5, 6] we studied a similar but larger space of ordinary controls to which the notion of weakly relaxed controls can also be applied. A different class of optimal control problems is derived from these spaces, and the question of properness of the weak model with respect to the larger class of ordinary controls can be posed. Consider the space of original controls

$$\begin{aligned}&\mathcal{U}'(\theta_1,\ldots,\theta_k)\\&\quad=\{(u_0,u_1,\ldots,u_k)\in\mathcal{U}(T,\Omega^{k+1})\mid u_i(t)=u_0(t-\theta_i)\text{ a.e. in }[\theta_i,1]\ (i=1,\ldots,k)\}.\end{aligned}$$

The notion of weakly relaxed controls applied to problem (R) of minimizing $g(x(1))$ subject to

$$\begin{cases}\dot{x}(t)=f(t,x(t),u(t))\text{ a.e. in }T,\\ x(0)=\xi,\\ u\in\mathcal{U}'(\theta_1,\ldots,\theta_k)\end{cases}$$

corresponds to

$$\mathcal{M}'_{\mathrm{w}}(\theta_1,\ldots,\theta_k):=\{\mu\in\mathcal{M}(T,\Omega^{k+1})\mid\mathcal{P}_i\mu(t)=\mathcal{P}_0\mu(t-\theta_i)\text{ a.e. in }[\theta_i,1]\ (i=1,\ldots,k)\},$$

which we shall call the space of *$\mathcal{R}$-weakly relaxed controls*, and the open question has been, again, if the relation $\mathcal{M}'_{\mathrm{w}}(\theta_1,\ldots,\theta_k)=\mathrm{cl}\,\mathcal{U}'(\theta_1,\ldots,\theta_k)$ holds.

Note that (R) is similar to (P) but not equivalent. The definition of $\mathcal{U}'(\theta_1,\ldots,\theta_k)$ as the space of ordinary delayed controls does not correspond to a reformulation of (P) and, as one can easily show,

$$\begin{aligned}&\mathcal{U}'(\theta_1,\ldots,\theta_k)\\&\quad=\{(u_0,u_1,\ldots,u_k)\in\mathcal{U}(T,\Omega^{k+1})\mid u_i(t)=u_{i-1}(t-\Delta_i)\text{ a.e. in }[\theta_i,1]\ (i=1,\ldots,k)\}.\end{aligned}$$

Comparing with the definition of the set $\mathcal{U}(\theta_1,\ldots,\theta_k)$, it is clear that $\mathcal{U}(\theta_1,\ldots,\theta_k)\subset\mathcal{U}'(\theta_1,\ldots,\theta_k)$, but the two sets may not coincide.

In [7] we proved an important consequence of this fact by exhibiting an element of both $\mathcal{M}_{\mathrm{w}}(\theta_1,\theta_2)$ and $\mathcal{M}'_{\mathrm{w}}(\theta_1,\theta_2)$ which belongs to the weak star closure of $\mathcal{U}'(\theta_1,\theta_2)$ but not to that of $\mathcal{U}(\theta_1,\theta_2)$. Also in [7] we showed that, for certain delays, the space of $\mathcal{R}$-weakly relaxed controls does provide a proper relaxation procedure. The result proved in [7] states that, given $0<\theta_1<\theta_2<1$ and $\Omega\subset\mathbf{R}^m$ compact, if $\theta_1\geq 1/2$, then $\mathcal{M}'_{\mathrm{w}}(\theta_1,\theta_2)=\mathrm{cl}\,\mathcal{U}'(\theta_1,\theta_2)$ and, if $\theta_1<1/2$ and θ_1 and θ_2 are commensurate, then $\mathrm{cl}\,\mathcal{U}'(\theta_1,\theta_2)$ may be strictly contained in $\mathcal{M}'_{\mathrm{w}}(\theta_1,\theta_2)$.

A new result for this model can now be obtained with a proof similar to the one of Theorem 2.1. The foregoing arguments can be applied to the conjecture stated in terms of $\mathcal{M}'_{\mathrm{w}}(\theta_1,\theta_2)$ and $\mathcal{U}'(\theta_1,\theta_2)$. If $\theta_1+\theta_2<1$, with a problem similar to the previous one, it is not difficult to see that

$$\mu(t)=\begin{cases}\frac{1}{2}\delta(0,1,1)+\frac{1}{2}\delta(1,0,0) & \text{if } t\in[0,\theta_1+\theta_2),\\ \frac{1}{2}\delta(0,0,1)+\frac{1}{2}\delta(1,1,0) & \text{if } t\in[\theta_1+\theta_2,1]\end{cases}$$

belongs to $\mathcal{M}'_{\mathrm{w}}(\theta_1,\theta_2)$ but not to $\mathrm{cl}\,\mathcal{U}'(\theta_1,\theta_2)$. We state this result.

THEOREM 3.1. *For any $0<\theta_1<\theta_2<1$ with $\theta_1+\theta_2<1$ there exists $\mu\in\mathcal{M}'_{\mathrm{w}}(\theta_1,\theta_2)$ such that $\mu\notin\mathrm{cl}\,\mathcal{U}'(\theta_1,\theta_2)$.*

REGULAR SYNTHESIS AND SUFFICIENCY CONDITIONS FOR OPTIMALITY[*]

BENEDETTO PICCOLI[†] AND HÉCTOR J. SUSSMANN[‡]

Abstract. We propose a definition of "regular synthesis" that is more general than those suggested by other authors such as Boltyanskii [SIAM J. Control Optim, 4 (1966), pp. 326–361] and Brunovský [Math. Slovaca, 28 (1978), pp. 81–100], and an even more general notion of "regular presynthesis." We give a complete proof of the corresponding sufficiency theorem, a slightly weaker version of which had been stated in an earlier article, with only a rough outline of the proof. We illustrate the strength of our result by showing that the optimal synthesis for the famous Fuller problem satisfies our hypotheses. We also compare our concept of synthesis with the simpler notion of a "family of solutions of the closed-loop equation arising from an optimal feedback law," and show by means of examples why the latter is inadequate, and why the difficulty cannot be resolved by using other concepts of solution—such as Filippov solutions, or the limits of sample-and-hold solutions recently proposed as feedback solutions by Clarke et al. [IEEE Trans. Automat. Control, 42 (1997), pp. 1394–1407]—for equations with a non-Lipschitz and possibly discontinuous right-hand side.

Key words. optimal control, regular synthesis, sufficient conditions

1. Introduction.

The purpose of the theory of "regular synthesis" is to turn into a rigorous, precise theorem the vague assertion that "if a collection Γ of extremals covers the whole space in a smooth enough way, then all the members of Γ are optimal." Naturally, a good definition should at the same time be stringent enough to lead to a correct proof of the sufficiency assertion, and broad enough to cover as large as possible a class of optimal control problems. In particular, it would be desirable for the theory to apply to well-known examples such as the famous "Fuller's problem" (cf. Fuller [13], Marchal [15], Zelikin–Borisov [32]), where the optimal controls have infinitely many switchings.

The three main goals of this paper are (a) to propose a new definition of regular synthesis, more general than those suggested by other authors (e.g., Boltyanskii [2], Brunovský [5], [6]), as well as an even more general notion of "regular presynthesis," (b) to give a detailed statement and proof of the corresponding sufficiency theorem, a slightly weaker version of which had been announced by one of us in an earlier article (Sussmann [31]), with only a rough sketch of the proof, and (c) to compare our definition with other concepts of synthesis such as those of Boltyanskii and Brunovský, and with the simpler notion of a "family of solutions of the closed-loop equation arising from an optimal feedback law."

Our main sufficiency result is Theorem 2.13. The key to the proof turns out to be a technical result—Theorem 2.14—on the relation between the adjoint vector of the maximum principle and the gradient of the cost function. This in turn depends on

results about differentiability of trajectories with respect to a parameter under weak differentiability assumptions on the dependence of the data on the parameter. These results are of interest in themselves and are presented separately in Appendix A.

Our definitions of regular presynthesis and regular synthesis are explained in section 2; cf. Definition 2.3 for the notion of "presynthesis," Definition 2.4 for that of "synthesis," and Definition 2.12 for "regularity." The strength of Theorem 2.13 is illustrated in section 3 by showing that it applies to the synthesis for Fuller's problem, where other sufficiency theorems such as those of [2] and [6] cannot be used because of the technical problem arising from the occurrence of an infinite number of switchings. (Not surprisingly, the optimality of Fuller's synthesis was originally proved without resorting to regular synthesis arguments, and using instead special symmetry properties of the problem, cf., e.g., Fuller [13], Marchal [15], Zelikin–Borisov [32].) Other definitions of synthesis—including those of Boltyanskii and Brunovský—are reviewed and compared with ours in section 4, where we also discuss in detail why the concept of "optimal synthesis" cannot just be defined by simply identifying it with that of "optimal feedback law." In particular, we explain in section 4 that if $x \to v(x)$ is an optimal feedback, then in general the concept of "solution" of the closed-loop equation $\dot{x} = f(x, v(x))$ is problematic (because $x \to f(x, v(x))$ may fail to be Lipschitz-continuous), and we compare the classical definition of solution with two other notions: (i) Filippov solutions and (ii) the limits of sample-and-hold solutions recently proposed as feedback solutions by Clarke et al. in [8], which will be referred to here as "CLSS solutions." We argue that the classical notion of solution fares better than the other two concepts, since there are situations where the optimal trajectories are not Filippov solutions of the optimal closed-loop equation, as well as cases where they are not CLSS solutions. The analysis of section 4 is supplemented in section 5 with several examples that clarify the relationship between the various definitions. Finally, a number of technical points, including some arguments pertaining to the proof of Theorem 2.13, are relegated to three appendices.

As explained in section 4, there are essentially two opposite starting points for defining the notion of a "regular" optimal synthesis. One approach, following Boltyanskii [2], Brunovský [5], [6], Cesari [7], Fleming and Rishel [11], and Sussmann [18], is to take as the primary object a smooth or "piecewise smooth" feedback control v, and then let the synthesis be the collection $Traj(v)$ of all trajectories generated by v. If this collection is too large (for example, if the closed-loop equation determined by v does not have unique solutions), then a synthesis would be a suitably defined subclass Γ of $Traj(v)$. The other strategy, proposed in Piccoli [16] and Sussmann [31], is to take a "synthesis" to be just a collection of trajectories—or, more precisely, trajectory-control pairs—not necessarily arising from a feedback control. To carry out the first strategy, Boltyanskii and Brunovský were forced to make precise sense of the notion of piecewise smoothness, which they did by requiring that the set of interest—that is, the set of initial points of optimal trajectories—be partitioned into submanifolds of various dimensions on which a smooth feedback control is specified. It turns out, however, that with this definition the feedback control by itself is not sufficient for the synthesis to be completely determined, since a discontinuous feedback control may generate too many trajectories, some of which could fail to be optimal, as shown in Example 5.3 below. So, in any case, the final outcome of the effort to implement the first strategy is a result more consistent with the second one, since one ends up with a notion of synthesis as a pair consisting of a feedback control v together with a selection Γ of a family of trajectories generated by v, suggesting that the specification of Γ is needed but that of v might not be. This leads naturally to the approach of this paper, in which v is dispensed with altogether.

An important point that ought to be further investigated but that will not be touched upon here is the relation between the geometrical approaches of [3], [4], [5], [6], [14], [17], [18], [19], [20], [21], [22], [23], [24], [26], [27], [31] and the theory of viscosity solutions (cf. Bardi and Capuzzo-Dolcetta [1], Fleming and Soner [12]). We point out that the existing results of this theory for deterministic optimal control do not appear to cover cases such as Fuller's problem. (Cf. [1], for example, where the main result is for Lagrangians that are bounded away from zero.)

2. Regular presynthesis and synthesis, and the sufficiency theorem.

We start with some definitions that will enable us to state and prove a mild generalization of the theorem whose proof was outlined in [31]. Our assumptions will be minimal, so as to achieve maximum generality.

We consider a control system,

$$\dot{x} = f(x,u), \qquad x \in \Omega, \qquad u \in U, \tag{2.1}$$

and a family $\boldsymbol{\mathcal{P}} = \boldsymbol{\mathcal{P}}(\Omega, U, f, L, \mathcal{T}, \tau) = \{\mathcal{P}(\Omega, U, f, L, \mathcal{T}, \tau, x_0)\}_{x_0 \in \Omega}$ of minimization problems, where $\mathcal{P}(\Omega, U, f, L, \mathcal{T}, \tau, x_0)$ is the problem

$$\text{minimize } \tau(x(b)) + \int_a^b L(x(t), u(t))dt \quad \text{subject to (2.1)}, \;\; x(a) = x_0, \;\; \text{and} \;\; x(b) \in \mathcal{T}. \tag{2.2}$$

(A more precise formulation of the problems $\mathcal{P}(\Omega, U, f, L, \mathcal{T}, \tau, x)$, carefully specifying the space of curves to be considered, will be given below. Since both f and L have no explicit dependence on t, we can always take $b = 0$.) We assume that

(A1) n is a positive integer and Ω—the "state space"—is an open subset of $\mathbb{R}^n$;

(A2) U—the "control set"—is a nonempty set;

(A3) $f : \Omega \times U \to \mathbb{R}^n$—the "dynamics"—and $L : \Omega \times U \to \mathbb{R}$—the "Lagrangian"—are maps;

(A4) $f(\cdot, u)$ and $L(\cdot, u)$ are maps of class $\mathcal{C}^1$ for every fixed $u \in U$;

(A5) $\mathcal{T}$—the "target"—is a nonempty subset of Ω;

(A6) $\tau : \Omega \to \mathbb{R}$ is a function of class $\mathcal{C}^1$.

We use $T_x^c S$ to denote the *contingent tangent cone* to a set S at a point $x \in S$, defined as follows: a vector v is in $T_x^c S$ if and only if there exist a sequence $\{x_j\}$ of points of S and a sequence $\{h_j\}$ of strictly positive numbers such that $h_j \to 0$ and $x_j = x + h_j v + o(h_j)$ as $j \to \infty$. We write

$$\tilde{T}_x S = T_x^c S \cap (-T_x^c S) = \{v : v \in T_x^c S \quad \text{and} \quad -v \in T_x^c S\}. \tag{2.3}$$

As in Sussmann [31], $\tilde{f}$ will denote the map $\Omega \times U \ni (x,u) \to \tilde{f}(x,u) \overset{\text{def}}{=} (f(x,u), L(x,u)) \in \mathbb{R}^{n+1}$.

If $\Omega \times \mathbb{R} \ni (x,t) \to g(x,t) \in \mathbb{R}^m$ is a time-varying vector-valued map on Ω, then $Dg(x,t)$ denotes, for each $(x,t) \in \Omega$, the Jacobian matrix at x of the map $y \to g(y,t)$, so $Dg(x,t) \in \mathbb{R}^{m \times n}$.

If $\mu : A \to B$ is a map, we use $\mathrm{Dom}(\mu)$ to indicate the domain of μ, i.e., the set A.

A *control* is a U-valued map η such that $\mathrm{Dom}(\eta)$ is a compact subinterval $[a,b]$ of $\mathbb{R}$. If η is a control, we define maps $f_\eta : \Omega \times \mathbb{R} \to \mathbb{R}^n$, $L_\eta : \Omega \times \mathbb{R} \to \mathbb{R}$, $\tilde{f}_\eta : \Omega \times \mathbb{R} \to \mathbb{R}^{n+1}$ by letting

$$\begin{array}{llll} f_\eta(x,t) = f(x,\eta(t)), & L_\eta(x,t) = L(x,\eta(t)), & \tilde{f}_\eta(x,t) = \tilde{f}(x,\eta(t)) & \text{if } t \in \mathrm{Dom}(\eta); \\ f_\eta(x,t) = 0, & L_\eta(x,t) = 0, & \tilde{f}_\eta(x,t) = 0 & \text{if } t \notin \mathrm{Dom}(\eta). \end{array}$$

A *trajectory* for a control η is an absolutely continuous map $\gamma : \mathrm{Dom}(\eta) \to \Omega$ with the property that $\dot\gamma(t) = f(\gamma(t), \eta(t))$ for almost every $t \in \mathrm{Dom}(\eta)$. If $\mathrm{Dom}(\eta) = [a, b]$ (so that $\mathrm{Dom}(\gamma) = [a, b]$ as well), and $x = \gamma(a)$, $y = \gamma(b)$, we say that γ (or the pair (γ, η)) *goes from x to y*, and that η *steers x to y*, and we write $\gamma^- = x$, $\gamma^+ = y$. We use $\mathrm{Range}(\gamma)$ to denote the range of the map γ, that is, the set $\{\gamma(t) : t \in \mathrm{Dom}(\gamma)\}$.

A control η is $\mathcal{C}^1$-*admissible* for $\tilde f$ if $\tilde f_\eta$ satisfies the following $\mathcal{C}^1$ Carathéodory conditions:

(C.i) the map $\mathrm{Dom}(\eta) \ni t \to \tilde f_\eta(x, t) \in \mathbb{R}^{n+1}$ is measurable for each $x \in \Omega$;

(C.ii) for every compact subset K of Ω there exists an integrable function $\varphi_K : \mathbb{R} \to \mathbb{R}$ such that for every $x \in K$ and $t \in \mathrm{Dom}(\eta)$

$$\|\tilde f_\eta(x, t)\| + \|D\tilde f_\eta(x, t)\| \le \varphi_K(t). \tag{2.4}$$

If η is a $\mathcal{C}^1$-admissible control for $\tilde f$, and γ is a trajectory corresponding to η, then we say that (γ, η) is a $\mathcal{C}^1$-*admissible pair* for $\tilde f$. We use $\mathrm{Adm}^{\mathcal{C}^1}(\tilde f)$ to denote the set of all $\mathcal{C}^1$-admissible pairs for $\tilde f$, and write $\mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f)$, $\mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f, \mathcal{T})$, $\mathrm{Adm}_x^{\mathcal{C}^1,0}(\tilde f, \mathcal{T})$ to denote, respectively, the set of all $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1}(\tilde f)$ such that $\mathrm{Dom}(\eta)$ is an interval of the form $[T, 0]$ with $T \le 0$, the set of those $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f)$ such that $\gamma(0) \in \mathcal{T}$, and the set of those $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f, \mathcal{T})$ such that $\gamma^- = x$. For a pair $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f, \mathcal{T})$, we use $J(\gamma, \eta)$ to denote the *cost* of (γ, η), given by

$$J(\gamma, \eta) = \tau(\gamma^+) + \int_{\mathrm{Dom}(\gamma)} L(\gamma(t), \eta(t))\, dt. \tag{2.5}$$

If $\Gamma \subseteq \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f, \mathcal{T})$ is an arbitrary set of $\mathcal{C}^1$-admissible pairs for $\tilde f$ ending at the target $\mathcal{T}$ at time 0, we define a function $V_\Gamma : \Omega \to \mathbb{R} \cup \{\pm\infty\}$, called the *cost function of* Γ, by letting

$$V_\Gamma(x) = \inf\{J(\gamma, \eta) : (\gamma, \eta) \in \Gamma,\ \gamma^- = x\} \tag{2.6}$$

for $x \in \Omega$. (In particular, $V_\Gamma(x) = +\infty$ if and only if there is no $(\gamma, \eta) \in \Gamma$ starting at x.) If $\Gamma = \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f, \mathcal{T})$, then the cost function V_Γ is the *value function* of our problem, and in that case we write $V_{\tilde f,\mathcal{T}}$ rather than $V_{\mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f,\mathcal{T})}$. Naturally, $V_\Gamma \ge V_{\tilde f,\mathcal{T}}$ pointwise for every subset Γ of $\mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f, \mathcal{T})$.

We can now formulate $\mathcal{P}(\Omega, U, f, L, \mathcal{T}, \tau, x_0)$ precisely: $\mathcal{P}(\Omega, U, f, L, \mathcal{T}, \tau, x_0)$ is the problem of finding a $(\gamma, \eta) \in \mathrm{Adm}_{x_0}^{\mathcal{C}^1,0}(\tilde f, \mathcal{T})$ such that $J(\gamma, \eta) = V_{\tilde f,\mathcal{T}}(x_0)$. Any such pair (γ, η) is said to be a *solution* of $\mathcal{P}(\Omega, U, f, L, \mathcal{T}, \tau, x_0)$. A pair $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde f, \mathcal{T})$ is *optimal* if it is a solution of $\mathcal{P}(\Omega, U, f, L, \mathcal{T}, \tau, \gamma^-)$. We use $\boldsymbol{\mathcal{P}}(\Omega, U, f, L, \mathcal{T}, \tau)$—or, simply, $\boldsymbol{\mathcal{P}}$, in any context where the meaning of Ω, U, f, L, $\mathcal{T}$, τ is clear—to denote the family of problems $\{\mathcal{P}(\Omega, U, f, L, \mathcal{T}, \tau, x_0)\}_{x_0 \in \Omega}$.

Remark 2.1. We emphasize that in the optimal control problems studied here *the trajectories have to end at the target but could pass through it before.* For example, consider the dynamical law $\dot x = 1$ in $\mathbb{R}$, with Lagrangian $L(x) \equiv -1$ and target $\mathcal{T} = \{0, 1\}$. Then the value function V is given by $V(x) = x - 1$ for $x \le 1$ and $V(x) = +\infty$ for $x > 1$. If $x < 1$, then the optimal trajectory γ_x from x to the target is given by $\gamma_x(t) = t + 1$ for $T_x \le t \le 0$, where $T_x = x - 1$. Notice that if $x < 0$, then $t = 0$ is not the first time when $\gamma_x(t)$ belongs to $\mathcal{T}$.

Given $\lambda \in \mathbb{R}_n$ (the space of row n-vectors), $\lambda^0 \in \mathbb{R}$, $x \in \Omega$, and $u \in U$, we define

$$H^c(\lambda, \lambda^0, x, u) = \langle \lambda, f(x, u)\rangle + \lambda^0 L(x, u), \tag{2.7}$$

$$H(\lambda, \lambda^0, x) = \inf\{H^c(\lambda, \lambda^0, x, u) : u \in U\}. \tag{2.8}$$

The functions $H^c : \mathbb{R}_n \times \mathbb{R} \times \Omega \times U \to \mathbb{R}$ and $H : \mathbb{R}_n \times \mathbb{R} \times \Omega \to \mathbb{R} \cup \{-\infty\}$ are known, respectively, as the *control Hamiltonian* and the *minimized Hamiltonian* of $\tilde{f}$.

Definition 2.2. *We say that the pair* $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f}, \mathcal{T})$ *is* extremal *if there exist an absolutely continuous map* $\lambda : \mathrm{Dom}(\gamma) \to \mathbb{R}_n$ *and a constant* $\lambda^0 \geq 0$ *that satisfy*

(EX1) $(\lambda^0, \lambda(t)) \neq (0, 0)$ *for some (and hence every) t;*

(EX2) $\dot{\lambda} = -\frac{\partial H^c}{\partial x}(\lambda(t), \lambda^0, \gamma(t), \eta(t))$ *for almost everywhere (a.e.)* $t \in \mathrm{Dom}(\eta)$*;*

(EX3) $H(\lambda(t), \lambda^0, \gamma(t)) = H^c(\lambda(t), \lambda^0, \gamma(t), \eta(t)) = 0$ *for a.e.* $t \in \mathrm{Dom}(\eta)$*;*

(EX4) $\langle \lambda(0), v \rangle = \lambda^0 \langle \nabla \tau(\gamma(0)), v \rangle$ *for all* $v \in \tilde{T}_{\gamma(0)}\mathcal{T}$*.*

Properties (EX1), (EX2), (EX3), (EX4) are, respectively, the *nontriviality condition*, the *adjoint equation*, the *Hamiltonian minimization condition*, and the *transversality condition.* A pair (λ, λ^0) such that (EX2) holds is called an *adjoint vector for* (γ, η). An adjoint vector for which (EX3) holds is a *minimizing adjoint vector for* (γ, η).

The maximum principle says that, under some special conditions on the target set $\mathcal{T}$, *every optimal pair* (γ, η) *is extremal.* (This is true, for example, if $\mathcal{T}$ is a submanifold of Ω of class $\mathcal{C}^1$, or a closed convex subset of Ω, or a set which is locally equivalent to a convex set via a $\mathcal{C}^1$ diffeomorphism. More generally, it is true if the cone $\tilde{T}_{\gamma(0)}\mathcal{T}$ is convex—in which case it is of course a subspace, since $v \in \tilde{T}_{\gamma(0)}\mathcal{T} \Rightarrow -v \in \tilde{T}_{\gamma(0)}\mathcal{T}$—and is an approximating cone to $\mathcal{T}$ at $\gamma(0)$. Recall that a closed convex cone C is an *approximating cone* to a set S at a point $s \in S$ if there exist a neighborhood W of 0, and a continuous map $F : W \cap C \to S$, such that $F(v) = s + v + o(||v||)$ as $v \to 0$ via values in C.)

Definition 2.3. *A presynthesis for* $\boldsymbol{\mathcal{P}}$ *is a subset* Γ *of* $\mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f}, \mathcal{T})$ *such that the following holds:*

(PS) *Whenever* $(\gamma_1, \eta_1) \in \Gamma$, $(\gamma_2, \eta_2) \in \Gamma$, *and* $\gamma_1^- = \gamma_2^-$, *it follows that* $(\gamma_1, \eta_1) = (\gamma_2, \eta_2)$.

The set $\mathrm{Dom}(\Gamma) \overset{\mathrm{def}}{=} \{\gamma^- : (\gamma, \eta) \in \Gamma\}$ *is called the* domain *of* Γ. *We say that* Γ *is a* presynthesis *on a set* S *if* Γ *is a presynthesis and* $S = \mathrm{Dom}(\Gamma)$.

Clearly, giving a presynthesis on S amounts to choosing, for each $x \in S$, a $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f}, \mathcal{T})$ such that $\gamma^- = x$.

If Γ is a presynthesis such that $\mathrm{Dom}(\Gamma)$ consists of all points that can be steered to a point of $\mathcal{T}$ by means of a pair belonging to $\mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f}, \mathcal{T})$, then we say that Γ is *total.*

Given a presynthesis Γ and a point $x \in \mathrm{Dom}(\Gamma)$, we will always use $(\gamma_x^\Gamma, \eta_x^\Gamma)$—or, simply, (γ_x, η_x) when the meaning of Γ is clear from the context—to denote the unique pair $(\gamma, \eta) \in \Gamma$ such that $\gamma^- = x$, and will write $T_x = \min \mathrm{Dom}(\gamma_x)$, so $T_x \leq 0$ and $\mathrm{Dom}(\gamma_x) = \mathrm{Dom}(\eta_x) = [T_x, 0]$.

Definition 2.4. *A presynthesis on a set* S *is* memoryless *if whenever* $x \in S$ *and* $t \in \mathrm{Dom}(\eta_x)$ *it follows that* $y = \gamma_x(t)$ *belongs to* S *and* η_y *is the restriction of* η_x *to the interval* $[t, 0]$. *A* synthesis *is a memoryless presynthesis.*

Definition 2.5. *If each pair of a presynthesis* Γ *is optimal (resp., extremal), then we say that* Γ *is* optimal *(resp.,* extremal*).*

In particular, a presynthesis Γ for $\boldsymbol{\mathcal{P}}(\Omega, U, f, L, \mathcal{T}, \tau)$ is a total optimal presynthesis if and only if $V_\Gamma \equiv V_{\tilde{f},\mathcal{T}}$.

As explained in the introduction, we wish to propose a definition of "regular synthesis" that will give rise to a sufficiency theorem. The theorem will say that a total extremal regular synthesis that satisfies the appropriate boundary conditions is optimal. We will actually define the more general notion of "regular presynthesis," and prove the sufficiency theorem in this broader setting, so the desired optimality result will be true in particular when the presynthesis is a true synthesis.

The definition will say that a "regular presynthesis" is a presynthesis that satisfies suitable regularity assumptions. So we begin by describing these regularity assumptions in detail.

Definition 2.6. *We call a function* $V : \Omega \to \mathbb{R} \cup \{+\infty\}$ weakly upper semicontinuous (w.u.s.c) *at a point* $x \in \Omega$ *if* $\liminf_{y\to x} \limsup_{z\to y} V(z) \le V(x)$.

Equivalently, V is w.u.s.c. at x if there exist sequences $\{x_j\}$, $\{\varepsilon_j\}$, and $\{\delta_j\}$ such that $x_j \in \Omega$, $\varepsilon_j > 0$, and $\delta_j > 0$ for all j, and $x_j \to x$ and $\delta_j \to 0$ as $j \to \infty$, having the property that $V(y) \le V(x) + \delta_j$ whenever $\|y - x_j\| < \varepsilon_j$.

Definition 2.7. *Suppose we are given a Lipschitz-continuous vector field* X *on* Ω *and a function* $V : \Omega \to \mathbb{R} \cup \{+\infty\}$. *We say that* V *has the* NDJ ("no downward jumps") property along X *if the following holds:*

(NDJ) If $[a,b] \ni t \to \gamma(t) \in \Omega$ is an integral curve of X, then $\liminf_{h\downarrow 0} V(\gamma(t-h)) \le V(\gamma(t))$ for every $t \in]a,b]$.

Definition 2.8. *We say that* $V : \Omega \to \mathbb{R} \cup \{+\infty\}$ *satisfies the* weak continuity conditions *for the control system* (2.1) *if* V *is lower semicontinuous and w.u.s.c. at every* $x \in \Omega$ *and has the NDJ property along the vector field* $x \to f(x,u)$ *for every* $u \in U$.

We now define the "weak differentiability conditions" for Γ. In this definition, we let $\rho_{\tilde{f},\Gamma,\bar{x},T}(v)$ be the integrable $\mathbb{R}^{n+1}$-valued function on $[T,0]$ (see definition below) given by

$$\rho_{\tilde{f},\Gamma,\bar{x},T}(v)(t) = \tilde{f}_{\eta_{\bar{x}+v}}(\gamma_{\bar{x}}(t),t) - \tilde{f}_{\eta_{\bar{x}}}(\gamma_{\bar{x}}(t),t)$$

and use the symbol $\rho_{\tilde{f},\Gamma,\bar{x},T}$ to denote the correspondence $v \to \rho_{\tilde{f},\Gamma,\bar{x},T}(v)$, regarded as a map into the space $\mathrm{Bor}([T,0],\mathbb{R}^{n+1})$ of $\mathbb{R}^{n+1}$-valued Borel measures on $[T,0]$. (Recall that $\mathrm{Bor}([T,0],\mathbb{R}^{n+1})$ is the dual of the space $C^0([T,0],\mathbb{R}^{n+1})$ of continuous $\mathbb{R}^{n+1}$-valued functions on $[T,0]$.)

Definition 2.9. *A presynthesis* $\Gamma = \{(\gamma_x,\eta_x) : x \in S\}$ *for* $\boldsymbol{\mathcal{P}}(\Omega,U,f,L,\mathcal{T},\tau)$ *is said to be* (f,L)-differentiable *at a point* $\bar{x} \in \Omega$ *if there exist* (a) *a neighborhood* N *of* $\bar{x}$ *in* Ω *such that* $N \subseteq \mathrm{Dom}(\Gamma)$, (b) *an interval* $[T,0]$ *such that* $\mathrm{Dom}(\eta_x) \subseteq [T,0]$ *for all* $x \in N$, *and* (c) *an* $\bar{\varepsilon} > 0$, *for which*

(DC1) *there are integrable functions* $\psi_\varepsilon : [T,0] \to \mathbb{R}$, *for* $\varepsilon \in]0,\bar{\varepsilon}]$, *with the property that* $\lim_{\varepsilon\to 0} \int_T^0 \psi_\varepsilon(t)\,dt = 0$, *for which the inequality*

$$\left\|\tilde{f}_{\eta_x}(y,t) - \tilde{f}_{\eta_x}(\gamma_{\bar{x}}(t),t) - D\tilde{f}_{\eta_{\bar{x}}}(\gamma_{\bar{x}}(t),t)\cdot(y-\gamma_{\bar{x}}(t))\right\| \le \psi_\varepsilon(t).(||y-\gamma_{\bar{x}}(t)|| + ||x-\bar{x}||) \tag{2.9}$$

holds for every $y \in \Omega$, $x \in N$, $t \in [T,0]$ *such that* $\|y - \gamma_{\bar{x}}(t)\| \le \varepsilon$ *and* $||x-\bar{x}|| \le \varepsilon$;

(DC2) *the map* $\rho_{\tilde{f},\Gamma,\bar{x},T}$ *is weak*-differentiable at* $v = 0$ *in the sense that, for every continuous function* $\alpha : [T,0] \to \mathbb{R}$, *the map* $\mathbb{R}^n \ni v \to \int_T^0 \alpha(t).\rho_{\tilde{f},\Gamma,\bar{x},T}(v)(t)\,dt \in \mathbb{R}^{n+1}$ *is differentiable at* $v = 0$.

Definition 2.10. *A subset* A *of* Ω *is* thin *if there exist* A_1, A_2 *such that* $A = A_1 \cup A_2$, A_1 *is a finite or countable union of connected* $\mathcal{C}^1$ *submanifolds of positive codimension, and* $\mathcal{H}^{n-1}(A_2) = 0$, *where* $\mathcal{H}^k$ *denotes* k*-dimensional Hausdorff measure.*

If S is a subset of Ω, we use $\mathring{S}$ to denote the interior of S in Ω.

DEFINITION 2.11. *If n, Ω, U, f, L, $\mathcal{T}$, τ are such that assumptions* (A1)–(A6) *hold, Γ is a presynthesis for $\boldsymbol{\mathcal{P}}(\Omega, U, f, L, \mathcal{T}, \tau)$, and $S = \mathrm{Dom}(\Gamma)$, we say that Γ has the* interior approximation property *if the following hold:*

(IAP) *If* $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$ is such that $\gamma(t) \in S$ for all $t \in \mathrm{Dom}(\gamma)$, then there exists a sequence $\{(\gamma_j, \eta_j)\}_{j=1}^{\infty}$ in $\mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$ such that

(IAP.1) $\gamma_j(t) \in \mathring{S}$ *for every* $t \in \mathrm{Dom}(\gamma_j)$*;*

(IAP.2) $V_\Gamma(\gamma_j^+) \to V_\Gamma(\gamma^+)$*;*

(IAP.3) $\gamma_j^- \to \gamma^-$*;*

(IAP.4) $\int_{\mathrm{Dom}(\gamma_j)} L(\gamma_j(t), \eta_j(t))\, dt \to \int_{\mathrm{Dom}(\gamma)} L(\gamma(t), \eta(t))\, dt.$

We are now ready to present our definition of "regular presynthesis."

DEFINITION 2.12. *Let n, Ω, U, f, L, $\mathcal{T}$, τ be such that assumptions* (A1)–(A6) *hold. Let Γ be a presynthesis for $\boldsymbol{\mathcal{P}}(\Omega, U, f, L, \mathcal{T}, \tau)$. We say that Γ is* regular *if*

(a) *the associated cost function V_Γ satisfies the weak continuity conditions;*

(b) *there exists a thin subset A of Ω such that Γ is (f, L)-differentiable at all points of* $\mathrm{Dom}(\Gamma)\backslash A$.

With this definition, our main sufficiency theorem (a weaker version of which was already stated in [31], with only an outline of the proof) says the following.

THEOREM 2.13. *Let n, Ω, U, f, L, $\mathcal{T}$, τ be such that assumptions* (A1)–(A6) *hold. Let Γ be an extremal regular presynthesis for $\boldsymbol{\mathcal{P}}(\Omega, U, f, L, \mathcal{T}, \tau)$ and let $S =$* $\mathrm{Dom}(\Gamma)$*. Then we have the following:*

(a) *The "dynamic programming inequality"*

$$V_\Gamma(\gamma^-) \le \int_{\mathrm{Dom}(\gamma)} L(\gamma(t), \eta(t))\, dt + V_\Gamma(\gamma^+) \tag{2.10}$$

holds for every $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$ *such that* $\mathrm{Range}(\gamma) \subseteq \mathring{S}$.

(b) *If V_Γ satisfies the boundary condition*

$$V_\Gamma(x) \le \tau(x) \quad \text{for every} \quad x \in \mathcal{T}, \tag{2.11}$$

then $V_\Gamma(\gamma^-) \le J(\gamma, \eta)$ for all $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f}, \mathcal{T})$ such that $\mathrm{Range}(\gamma) \subseteq \mathring{S}$.

(c) *If Γ has the interior approximation property, then* (2.10) *holds for all* $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$ *such that* $\mathrm{Range}(\gamma) \subseteq S$.

(d) *If Γ has the interior approximation property and satisfies* (2.11)*, then $V_\Gamma(\gamma^-) \le J(\gamma, \eta)$ for all $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f}, \mathcal{T})$ such that* $\mathrm{Range}(\gamma) \subseteq S$.

(e) *If Γ is total and satisfies* (2.11)*, then Γ is optimal.*

Proof. We first establish the relation between the differential of the cost function V_Γ and the adjoint fields of vectors along the extremal trajectories of the presynthesis. This result is important in its own right, so we state it as a separate theorem.

THEOREM 2.14. *Let n, Ω, U, f, L, $\mathcal{T}$, τ be such that assumptions* (A1)–(A6) *hold, and let $\Gamma = \{(\gamma_x, \eta_x) : x \in S\}$ be a presynthesis. Let $\bar{x} \in S$ be such that Γ is (f, L)-differentiable at $\bar{x}$. Then*

(a) *the function V_Γ is differentiable at $\bar{x}$;*

(b) *if the pair $(\gamma_{\bar{x}}, \eta_{\bar{x}})$ is extremal, then every minimizing adjoint vector (λ, λ^0) for $(\gamma_{\bar{x}}, \eta_{\bar{x}})$ satisfies the identity*

$$\lambda^0 (\nabla V_\Gamma)(\bar{x}) = \lambda(T_{\bar{x}}).$$

In particular, $\lambda^0 \neq 0$, and (λ, λ^0) is unique up to multiplication by a positive constant.

Proof of Theorem 2.14. We apply Theorem A.11 in Appendix A, taking P to be $\mathbb{R}^n$ and letting $f_x = f_{\eta_x}$, $L_x = L_{\eta_x}$, $\tilde{f}_x = \tilde{f}_{\eta_x}$. Then, if $y \in \Omega$ and $x \in N$, we have $f_x(y,t) = f(y, \eta_x(t))$, $L_x(y,t) = L(y, \eta_x(t))$, $\tilde{f}_x(y,t) = \tilde{f}(y, \eta_x(t))$ if $t \in [T_x, 0]$, and $f_x(y,t) = 0$, $L_x(y,t) = 0$, $\tilde{f}_x(y,t) = 0$ if $t \notin [T_x, 0]$.

We let $\hat{V}_\Gamma(x) = \int_{T_x}^0 L(\gamma_x(t), \eta_x(t))\,dt$, so $\hat{V}_\Gamma$ is the "Lagrangian part" of our cost function. We extend the curve γ_x to the interval $[T, 0]$ by letting $\gamma_x(t) = x$ for $T \leq t < T_x$, so γ_x still is an integral curve of f_{η_x} on $[T, 0]$, and $\hat{V}_\Gamma(x) = \int_T^0 L_x(\gamma_x(t), t)\,dt$.

The map $p \to \bar{x}_p$ of Theorem A.11 is the identity map, which is certainly differentiable at $\bar{x}$. So Theorem A.11 tells us that the "endpoint map" $x \to \mathcal{E}(x) \overset{\mathrm{def}}{=} \gamma_x(0)$ and the function $\hat{V}_\Gamma$ are differentiable at $\bar{x}$. This implies that the function V_Γ is differentiable at $\bar{x}$, proving Theorem 2.14(a).

Assume now that $(\gamma_{\bar{x}}, \eta_{\bar{x}})$ is extremal and (λ, λ^0) is a minimizing adjoint vector for $(\gamma_{\bar{x}}, \eta_{\bar{x}})$. We extend the adjoint vector λ to $[T, 0]$ by letting $\lambda(t) = \lambda(T_{\bar{x}})$ for $T \leq t < T_{\bar{x}}$. We then define

$$H_x^c(p, p^0, y, t) = \langle p, f_x(y,t) \rangle + p^0 L_x(y,t).$$

Then the adjoint equation $\dot{\lambda}(t) = -\nabla_y H_{\bar{x}}^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t)$ holds a.e. on $[T, 0]$. Moreover,

$$H_x^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t) \geq H_{\bar{x}}^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t) = 0 \text{ for a.e. } t \in [T, 0]. \tag{2.12}$$

(To see this, we first observe that $H_{\bar{x}}^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t) = 0$ a.e. on $[T, 0]$, because (a) the equality holds a.e. when $t \in [T_x, 0]$ thanks to (EX3), and (b) it holds everywhere when $t \in [T, T_x[$, because in this case $f_{\bar{x}}(\gamma_{\bar{x}}(t), t) = 0$ and $L_{\bar{x}}(\gamma_{\bar{x}}(t), t) = 0$. Next, we show that, if $x \in N$, then $H_x^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t) \geq 0$. The inequality follows from (EX3) for almost every t when $t \geq T_{\bar{x}}$ and $t \geq T_x$, because in this case $H_x^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t) = H^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), \eta_x(t)) \geq H(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t)) = 0$ for almost every t. When $t < T_x$, $H_x^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t)$ vanishes, because $f_x(\gamma_{\bar{x}}(t), t) = 0$ and $L_x(\gamma_{\bar{x}}(t), t) = 0$. Finally, we must consider the possibility that $T_x \leq t < T_{\bar{x}}$. For this purpose, we observe that, if $u \in U$ is arbitrary, then $H^c(\lambda(s), \lambda^0, \gamma_{\bar{x}}(s), u) \geq H(\lambda(s), \lambda^0, \gamma_{\bar{x}}(s)) \geq 0$ for almost every $s \in [T_{\bar{x}}, 0]$. Since $s \to H^c(\lambda(s), \lambda^0, \gamma_{\bar{x}}(s), u)$ is continuous, we conclude that $H^c(\lambda(s), \lambda^0, \gamma_{\bar{x}}(s), u) \geq 0$ for *all* $s \in [T_{\bar{x}}, 0]$. In particular, $H^c(\lambda(T_{\bar{x}}), \lambda^0, \bar{x}, u) \geq 0$. Since λ is constant on $[T, T_{\bar{x}}]$, we see that $H^c(\lambda(s), \lambda^0, \bar{x}, u) \geq 0$ for all $s \in [T, T_{\bar{x}}]$ and all $u \in U$. Now, if $T_x \leq t < T_{\bar{x}}$, then $H_x^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t) = H^c(\lambda(t), \lambda^0, \bar{x}, \eta_x(t)) \geq 0$, and (2.12) is proved.)

From Theorem A.11, the identity

$$\begin{aligned}
&\lambda(0).D\mathcal{E}(\bar{x}).v + \lambda^0 \nabla \hat{V}_\Gamma(\bar{x}).v - \lambda(T_{\bar{x}}) \cdot v \\
&\qquad = \lim_{\varepsilon \downarrow 0} \varepsilon^{-1} \int_T^0 \Big(H_{\bar{x}+\varepsilon v}^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t) - H_{\bar{x}}^c(\lambda(t), \lambda^0, \gamma_{\bar{x}}(t), t) \Big)\,dt
\end{aligned} \tag{2.13}$$

follows, for every vector v. Then (2.12) tells us that the right-hand side of inequality (2.13) is nonnegative. So

$$\lambda(0).D\mathcal{E}(\bar{x}).v + \lambda^0 \nabla \hat{V}_\Gamma(\bar{x}).v - \lambda(T_{\bar{x}}) \cdot v \geq 0 \qquad \text{for all } v \in \mathbb{R}^n. \tag{2.14}$$

Given v, the curve $r \to \gamma_{\bar{x}+rv}(0)$ is defined for r in a neighborhood of 0 in $\mathbb{R}$, and is differentiable at 0 with derivative $D\mathcal{E}(\bar{x}).v$. On the other hand, this curve is contained in $\mathcal{T}$, so the vector $w = D\mathcal{E}(\bar{x}).v$ belongs to $\tilde{T}_{\gamma_{\bar{x}}(0)}\mathcal{T}$. It then follows from the transversality condition (EX4) that $\langle\lambda(0), w\rangle = \lambda^0\langle\nabla\tau(\gamma(0)), w\rangle$. Therefore

$$\lambda^0(\nabla\tau(\gamma(0)).D\mathcal{E}(\bar{x}).v + \nabla\hat{V}_\Gamma(\bar{x}).v) - \lambda(T_{\bar{x}})\cdot v \geq 0 \qquad \text{for all } v \in \mathbb{R}^n. \tag{2.15}$$

Since the left-hand side of (2.15) is linear in v, it has to vanish for all v. So

$$\lambda^0\nabla V_\Gamma(\bar{x}).v = \lambda^0(\nabla\tau(\gamma(0)).D\mathcal{E}(\bar{x}).v + \nabla\hat{V}_\Gamma(\bar{x}).v) = \lambda(T_{\bar{x}})\cdot v \qquad \text{for all } v \in \mathbb{R}^n. \tag{2.16}$$

Therefore $\lambda^0\nabla V_\Gamma(\bar{x}) = \lambda(T_{\bar{x}})$.

In particular, λ^0 cannot vanish, because $\lambda^0 = 0$ would imply $\lambda(T_{\bar{x}}) = 0$, contradicting (EX1). So we may, after multiplication by a positive constant, assume that $\lambda^0 = 1$, and then $\nabla V_\Gamma(\bar{x}) = \lambda(T_{\bar{x}})$. This proves, in particular, the uniqueness of $(\lambda(\cdot), \lambda^0)$ up to multiplication by a positive constant, since the Cauchy problem for the adjoint equation has unique solutions. □

Continuation of the proof of Theorem 2.13. We first prove Theorem 2.13(a). For any given $x \in S \setminus A$, let λ_x be the unique λ such that $(\lambda, 1)$ is a minimizing adjoint vector along (γ_x, η_x). (The existence and uniqueness of λ_x follows from Theorem 2.14.) The minimization condition (EX4) of maximum principle then implies that, for any given $u \in U$, the inequality

$$\langle\lambda_x(t), f(\gamma_x(t), u)\rangle + L(\gamma_x(t), u) \geq 0$$

holds for almost all $t \in [T_x, 0]$. Since $t \to \langle\lambda_x(t), f(\gamma_x(t), u)\rangle + L(\gamma_x(t), u)$ is continuous on $[T_x, 0]$, the inequality is valid at time T_x. In view of Theorem 2.14,

$$\langle\nabla V_\Gamma(x), f(x, u)\rangle + L(x, u) \geq 0. \tag{2.17}$$

Now consider an arbitrary $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$, with domain $[T, 0]$, such that $\mathrm{Range}(\gamma) \subseteq \mathring{S}$. We want to prove that (2.10) holds. It follows from Lemma 4.1 of [28] that there exists a sequence of admissible pairs $(\gamma_j, \eta_j) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$, with domain $[T, 0]$, such that $\gamma_j(0) = \gamma(0)$, η_j is piecewise constant, $\gamma_j \to \gamma$ uniformly on $[T, 0]$, and $\int_T^0 L(\gamma_j(t), \eta_j(t))\,dt \to \int_T^0 L(\gamma(t), \eta(t))\,dt$.

Since $\mathrm{Range}(\gamma) \subseteq \mathring{S}$, we can clearly assume that $\mathrm{Range}(\gamma_j) \subseteq \mathring{S}$. Since V_Γ is lower semicontinuous, it follows that, if $V_\Gamma(\gamma_j(T)) + \int_T^0 L(\gamma_j(t), \eta_j(t))\,dt \leq V_\Gamma(\gamma(0))$ for each j, then $V_\Gamma(\gamma(T)) + \int_T^0 L(\gamma(t), \eta(t))\,dt \leq V_\Gamma(\gamma(0))$. Hence it suffices to assume that the control η is piecewise constant.

If (2.10) holds for two pairs $(\gamma_i, \eta_i) \in \mathrm{Adm}^{\mathcal{C}^1}(\tilde{f})$ such that $\mathrm{Dom}(\gamma_1) = [a, b]$, $\mathrm{Dom}(\gamma_2) = [b, c]$, and $\gamma_1(b) = \gamma_2(b)$ for some a, b, c, then it also holds for the concatenated pair (γ, η) defined in an obvious way. It therefore suffices to prove (2.10) for all $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1}(\tilde{f})$ corresponding to a constant control. Since L does not depend on time we can assume $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$ and η constant, so we make this assumption from now on.

Let $u \in U$ be such that $\eta(t) = u$ for $t \in [T, 0]$. For each $y \in \Omega$, let $t \to \zeta^y(t)$ be the trajectory of η that satisfies the terminal condition $\zeta^y(0) = y$. Let W be an open subset of Ω such that $\gamma(0) \in W$, $\zeta^y(T)$ is defined for all $y \in W$, and $\zeta^y([T, 0])$ is contained in $\mathring{S}$ whenever $y \in W$. We will show that

(#) for almost every $y \in W$ the set $B^y = \{t \in [T,0] : \zeta^y(t) \in A\}$ is finite or countable.

Since A is thin, we can write $A = A_1 \cup A_2$, where $A_1 = \bigcup_j M_j$ and $\{M_j\}_{j\in J}$ is a finite or countable family of connected submanifolds of Ω of codimension $d_j > 0$, while $\mathcal{H}^{n-1}(A_2) = 0$. After replacing each M_j by a finite or countable family of open submanifolds of M_j, we may assume that the M_j are embedded.

Define $\tilde{W} = W \times]\,T, 0\,[$, and let Φ be the map $\tilde{W} \ni (y,t) \to \zeta^y(t) \in \Omega$. Then Φ is a $\mathcal{C}^1$ submersion, because for each fixed t the partial map $y \to \Phi(y,t)$ is a $\mathcal{C}^1$ diffeomorphism. Therefore each set $\tilde{M}_j = \Phi^{-1}(M_j)$ is an embedded submanifold of $\tilde{W}$ of codimension d_j, and $\mathcal{H}^n(\Phi^{-1}(A_2)) = 0$.

Let π be the projection $\tilde{W} \ni (y,t) \to y \in W$. Let S_j be the set of points $s \in \tilde{M}_j$ such that the restriction $\pi\lceil\tilde{M}_j$ of π to $\tilde{M}_j$ is not regular at s. (Recall that, if S_1, S_2 are $\mathcal{C}^1$ manifolds, then a $\mathcal{C}^1$ map $F : S_1 \to S_2$ is *regular* at $s \in S_1$ if the differential $d\pi(s)$ maps the tangent space T_sS_1 surjectively onto $T_{F(s)}S_2$.) Then $\mathcal{H}^n(\pi(\Phi^{-1}(A_2))) = 0$ (see, for example, Federer [9]), and $\mathcal{H}^n(\pi(S_j)) = 0$ for each j, by Sard's theorem. So the "bad" set $\mathcal{B} = \pi(\Phi^{-1}(A_2)) \cup (\bigcup_j \pi(S_j))$ has Lebesgue measure zero.

Now let $y \in W \backslash \mathcal{B}$. Then $\zeta^y(t) \notin A_2$ if $T < t < 0$. (Otherwise, if $\zeta^y(t) \in A_2$, $T < t < 0$, it would follow that $(y,t) \in \Phi^{-1}(A_2)$, so $y \in \pi(\Phi^{-1}(A_2))$, and then $y \in \mathcal{B}$.) Also, we claim that the set $\{t \in [T,0] : \zeta^y(t) \in A_1\}$ is at most countable. To see this, it suffices to show that, for each j, the set $E_j = \{t : T < t < 0\,,\, \zeta^y(t) \in M_j\}$ is finite or countable. Fix j, and suppose $t \in E_j$. The manifold $\tilde{M}_j$ has codimension d_j in $\tilde{W}$. Since $d_j > 0$, the dimension ν_j of $\tilde{M}_j$ is $\leq n$. Moreover, $d\pi(y,t)$ maps $T_{y,t}\tilde{M}_j$ surjectively onto $\mathbb{R}^n$ (the tangent space to Ω at y), because $y \notin \mathcal{B}$. So $\nu_j = n$, and $d\pi(y,t)$ is injective on $T_{y,t}\tilde{M}_j$. Since $d\pi(y,t)(\frac{\partial}{\partial t})$ is obviously equal to 0, it follows that $\frac{\partial}{\partial t} \notin T_{y,t}\tilde{M}_j$. Since $\tilde{M}_j$ is embedded, $(y,t') \notin \tilde{M}_j$ if $0 < |t'-t| \leq \varepsilon$, provided that ε is sufficiently small. Therefore t is an isolated point of E_j. So E_j is a discrete subset of the open interval $]\,T, 0\,[$. Therefore E_j is finite or countable, as desired.

We have therefore proved that, if $y \in W \backslash \mathcal{B}$, then $\zeta^y(t) \notin A_2$ for all $t \in]T,0[$, and the set $\{t \in [T,0] : \zeta^y(t) \in A_1\}$ is at most countable. Since $A = A_1 \cup A_2$, and $\mathcal{B}$ has measure zero, (#) follows.

In view of the weak upper semicontinuity of V_Γ, there exist x_j, $\varepsilon_j > 0$, $\delta_j > 0$ such that $x_j \to \gamma(0)$ and $\delta_j \to 0$ as $j \to \infty$, and $V_\Gamma(y) \leq V_\Gamma(\gamma(0)) + \delta_j$ whenever $\|y - x_j\| \leq \varepsilon_j$. Choose the ε_j's so that $\|y - x_j\| \leq \varepsilon_j$ implies $y \in W$. Then, by (#), we can choose for each j a y_j such that $\|y_j - x_j\| \leq \varepsilon_j$ and the bad set B^{y_j} is at most finite or countable. Since $\zeta^{y_j}(t) \in \mathring{S}$ for every $t \in [T,0]$, (2.17) implies that the function $[T,0] \ni t \to \varphi_j(t) = V_\Gamma(\zeta^{y_j}(t)) + \int_T^t L(\zeta^{y_j}(s), \eta(s))ds \in \mathbb{R}$ is differentiable at every t, except for a finite or countable number of values, with a nonnegative derivative. Therefore φ_j satisfies assumption (a) of Lemma B.1 (Appendix B). Moreover, the lower semicontinuity of V_Γ ensures assumption (b) of Lemma B.1 for φ_j, and the NDJ condition ensures assumption (c) of Lemma B.1. Hence we can apply Lemma B.1 to φ_j, and conclude that $\varphi_j(T) \leq \varphi_j(0)$. So

$$V_\Gamma(\zeta^{y_j}(T)) \leq \int_T^0 L(\zeta^{y_j}(t), \eta(t))dt + V_\Gamma(y_j) \leq \int_T^0 L(\zeta^{y_j}(t), \eta(t))dt + V_\Gamma(\gamma(0)) + \delta_j.$$

If we let $j \to \infty$, we find, using the lower semicontinuity of V_Γ, that (2.10) holds for (γ, η), as desired. So (2.10) holds when η is constant and, as explained earlier, this completes the proof of (a).

To prove (b), we pick $(\gamma, \eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f}, \mathcal{T})$ such that γ is contained in $\mathring{S}$, and apply (a) to conclude that $V_\Gamma(\gamma^-) \leq \int_{\mathrm{Dom}(\gamma)} L(\gamma(t),\eta(t))dt + V_\Gamma(\gamma(0))$. Then (2.11) implies the inequality $V_\Gamma(\gamma(0)) \leq \tau(\gamma(0))$, so $V_\Gamma(\gamma^-) \leq J(\gamma,\eta)$ and (b) is proved.

To prove (c), we pick $(\gamma,\eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$ such that γ is contained in S, and find pairs (γ_j,η_j) such that conditions (IAP.1)–(IAP.4) hold. Then (a) implies that the inequality $V_\Gamma(\gamma_j^-) \leq \int_{\mathrm{Dom}(\gamma_j)} L(\gamma_j(t),\eta_j(t))dt + V_\Gamma(\gamma_j(0))$ holds. Using (IAP.2), (IAP.3), (IAP.4), and the lower semicontinuity of V_Γ, we conclude that (2.10) holds, completing the proof of (c).

The proof of (d) is identical to that of (b), using (c) instead of (a).

Finally, to prove (e), we assume that Γ is total and prove that it satisfies the interior approximation property. So now S is the set of all points of Ω that can be steered to a point of $\mathcal{T}$ by a pair belonging to $\mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$. Let $(\gamma,\eta) \in \mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f})$ be a trajectory-control pair such that γ is entirely contained in S. Then $\gamma(0) \in S$, so $\gamma(0) \in \mathrm{Dom}(\Gamma)$ and then $V_\Gamma(\gamma(0)) < +\infty$. The weak upper semicontinuity of V_Γ implies that there exist x_j, $\varepsilon_j > 0$, $\delta_j > 0$ such that $x_j \to \gamma(0)$ and $\delta_j \to 0$ as $j \to \infty$, and $V_\Gamma(y) \leq V_\Gamma(\gamma(0)) + \delta_j$ whenever $\|y - x_j\| \leq \varepsilon_j$. It then follows that $V_\Gamma(x_j) \to V_\Gamma(\gamma(0))$, since V_Γ is lower semicontinuous. Let $\mathrm{Dom}(\gamma) = [T,0]$. Let γ_j be the maximally defined trajectory for the control η that satisfies $\gamma_j(0) = x_j$. Then γ_j is defined on $[T,0]$ if j is large enough, and conditions (IAP.2), (IAP.3), and (IAP.4) hold with $\eta_j = \eta$. We may then assume that γ_j is defined on $[T,0]$ for all j. To prove that (IAP.1) holds as well, we observe that $y \in S$ whenever $\|y - x_j\| \leq \varepsilon_j$, because in that case $V_\Gamma(y) < +\infty$, since $V_\Gamma(y) \leq V_\Gamma(\gamma(0)) + \delta_j$, and $V_\Gamma(\gamma(0)) < +\infty$ because $\gamma(0) \in S$. Let ζ^y be the trajectory for the control η that satisfies $\zeta^y(0) = y$. Then for each j there exists a $\tilde{\varepsilon}_j$ such that $0 < \tilde{\varepsilon}_j \leq \varepsilon_j$, with the property that the curve ζ^y is defined on $[T,0]$ for all y such that $\|y - x_j\| \leq \tilde{\varepsilon}_j$. Moreover, it is clear that y is reachable from $\zeta^y(t)$ for every $t \in [T,0]$, so $\zeta^y([T,0]) \subseteq S$ if $\|y - x_j\| \leq \tilde{\varepsilon}_j$, because $y \in S$. Now, if $T \leq t \leq 0$, the map $y \to \zeta^y(t)$ is a $\mathcal{C}^1$ diffeomorphism from the neighborhood $\{x : \|x - x_j\| < \tilde{\varepsilon}_j\}$ of x_j onto a neighborhood $N_j(t)$ of $\gamma_j(t)$. Clearly, $N_j(t) \subseteq S$, so $\gamma_j(t) \in \mathring{S}$. This completes the proof of (e). □

Remark 2.15. The function V_Γ is w.u.s.c. everywhere if and only if it is w.u.s.c. at all the points of the target $\mathcal{T}$. Indeed, let $x \in \Omega$. If $x \notin S$, then $V_\Gamma(x) = +\infty$, and the conclusion follows. Next, suppose $x \in S$, and let (γ_x,η_x) be its associated admissible pair. Assume that V_Γ is w.u.s.c. at $\gamma_x(0)$. Let y_j, ε_j, δ_j be such that $y_j \to \gamma_x(0)$, $\varepsilon_j > 0$, $\delta_j > 0$, $\delta_j \to 0$, and $V_\Gamma(y) \leq V_\Gamma(\gamma_x(0)) + \delta_j$ whenever $\|y - y_j\| \leq \varepsilon_j$. Let ζ^{y_j} be the trajectory corresponding to the control η_x and such that $\zeta^{y_j}(0) = y_j$. Since $y_j \to \gamma_x(0)$, we may assume, by picking j large enough, that ζ^{y_j} is defined on $[T_x,0]$ for all j, and let $x_j = \zeta^{y_j}(T_x)$. Let $\tilde{\varepsilon}_j$ be such that $0 < \tilde{\varepsilon}_j < \frac{1}{j}$ and, if $\|z - x_j\| \leq \tilde{\varepsilon}_j$, then the trajectory θ^z of η_x with initial condition $\theta^z(T_x) = z$ is defined on $[T_x,0]$ and satisfies $\|\theta^z(0) - y_j\| < \varepsilon_j$. Then, using the same reasoning as in the proof of Theorem 2.13, we can show that

$$V_\Gamma(z) \leq \int_{T_x}^0 L(\theta^z(t),\eta_x(t))\,dt + V_\Gamma(\gamma_x(0)) + \delta_j \tag{2.18}$$

whenever $\|z - x_j\| \leq \tilde{\varepsilon}_j$. (First approximate η_x by piecewise constant controls, η^k, and let $\theta^{z,k}$ be the corresponding trajectories with terminal condition $\theta^{z,k}(0) = \theta^z(0)$. Then for each k use statement (#) of the proof of Theorem 2.13 to approximate the terminal point $\theta^z(0)$ by points $w^{z,k,i}$ with the property that, if $\tilde{\theta}^{z,k,i}$ is the trajectory for η^k for which $\tilde{\theta}^{z,k,i}(0) = w^{z,k,i}$, it follows that $V_\Gamma(\tilde{\theta}^{z,k,i}(T_x)) \leq \int_{T_x}^0 L(\tilde{\theta}^{z,k,i}(t),\eta^k(t))\,dt + V_\Gamma(w^{z,k,i})$. Since $\|\theta^z(0) - y_j\| < \varepsilon_j$, the $w^{z,k,i}$ satisfy

$\|w^{z,k,i} - y_j\| < \varepsilon_j$ if i is large enough, so $V_\Gamma(\tilde{\theta}^{z,k,i}(T_x)) \leq \int_{T_x}^0 L(\tilde{\theta}^{z,k,i}(t), \eta^k(t))\, dt + V_\Gamma(\gamma_x(0)) + \delta_j$ when i is large enough. If we let $i \to \infty$ and then let $k \to \infty$, and use the lower semicontinuity of V_Γ, we find that (2.18) holds.)

Let $\tilde{\delta}_j = \sup\{\| \int_{T_x}^0 L(\theta^z(t), \eta_x(t))\, dt - \int_{T_x}^0 L(\gamma_x(t), \eta_x(t))\, dt\| : \|z - x_j\| \leq \tilde{\varepsilon}_j\}$. Then $\tilde{\delta}_j \to 0$, because $x_j \to x$ and $\tilde{\varepsilon}_j \to 0$. On the other hand, $V_\Gamma(z) \leq V_\Gamma(x) + \delta_j + \tilde{\delta}_j$ whenever $\|z - x_j\| \leq \tilde{\varepsilon}_j$. So V_Γ is w.u.s.c. at x.

3. The Fuller phenomenon. In this section we show that the famous minimization problem considered by Fuller in [13]—and extensively studied by other authors, e.g., Zelikin–Borisov [32]—has a regular optimal synthesis in the sense of our Definitions 2.4 and 2.12.

Consider the system

$$\dot{x}_1 = x_2, \qquad \dot{x}_2 = u, \qquad |u| \leq 1 \tag{3.1}$$

and the family $\hat{\boldsymbol{\mathcal{P}}} = \{\hat{\mathcal{P}}_x\}_{x \in \mathbb{R}^2}$ of minimization problems:

$$\hat{\mathcal{P}}_x : \qquad \text{minimize} \int_0^{+\infty} x_1^2(t)\, dt \text{ subject to } \quad (x_1(0), x_2(0)) = x. \tag{3.2}$$

We proceed to describe the optimal synthesis for this problem, determined by Fuller, referring the reader to Zelikin–Borisov [32, Chap. 2] for further details. First define the "switching locus"

$$\zeta = \{(x_1, x_2) : |x_1| = Cx_2^2,\ x_1 x_2 \leq 0\},$$

where C is a constant whose precise definition will be given later. Write $\zeta = \zeta^+ \cup \zeta^- \cup \{(0,0)\}$, where $\zeta^\pm = \{(x_1, x_2) \in \zeta : \pm x_1 > 0\}$. Then the piecewise smooth curve ζ divides the plane into two regions A^- and A^+ consisting, respectively, of the points that lie above and below ζ. We define a discontinuous feedback control $k : \mathbb{R}^2 \to [-1, 1]$ by letting $k(x_1, x_2) = -1$ if $(x_1, x_2) \in A^- \cup \zeta^-$, $k(x_1, x_2) = 1$ if $(x_1, x_2) \in A^+ \cup \zeta^+$, and $k(0,0) = 0$.

Then for every $x \in \mathbb{R}^2$ there exists a unique solution $\hat{\gamma}_x : [0, \infty[\, \to \mathbb{R}^2$ of the Cauchy problem $\dot{x}_1 = x_2$, $\dot{x}_2 = k(x_1, x_2)$, $(x_1(0), x_2(0)) = x$. The corresponding open-loop control $\hat{\eta}_x$ is related to $\hat{\gamma}_x$ by $\hat{\eta}_x(t) = +1$ when $\hat{\gamma}_x(t) \in A^+$, $\hat{\eta}_x(t) = -1$ when $\hat{\gamma}_x(t) \in A^-$, and $\hat{\eta}_x(t) = 0$ when $\hat{\gamma}_x(t) = 0$.

The switchings occur when $\hat{\gamma}(t) \in \zeta$. The curve $\hat{\gamma}_x$ reaches the origin in a finite time $\hat{T}_x$ and then stays there. Therefore $\hat{\eta}_x(t) = 0$ when $\hat{\gamma}_x(t) = 0$, which happens if and only if $t \geq \hat{T}_x$ (see Figure 1). Therefore the admissible pairs $(\hat{\gamma}_x, \hat{\eta}_x)$ actually solve the family $\boldsymbol{\mathcal{P}} = \{\mathcal{P}_x\}_{x \in \mathbb{R}^2}$ of minimization problems

$$\mathcal{P}_x : \quad \text{minimize} \int_a^b x_1^2(t) dt \text{ subject to } (x_1(a), x_2(a)) = x \text{ and } (x_1(b), x_2(b)) = (0,0), \tag{3.3}$$

i.e., the problems of reaching the origin in finite time, subject to the dynamical constraints (3.1), and minimizing the cost given by (3.3).

So far, C was an arbitrary positive constant. It turns out that, if C is chosen to be equal to C^*, where C^* is the unique positive root of the polynomial $x^4 + x^2/12 - 1/18$, then the pairs $(\hat{\gamma}_x, \hat{\eta}_x)$ are extremal. (This is proved in [32]. On page 26, it is shown that C must be chosen so that $(1 - 2C)^{1/2}(1 + 2C)^{-1/2} = \mu$, where μ is such that, if $\sigma = \mu + \mu^{-1}$, then $\sigma^2 - 3\sigma - 6 = 0$. These equations easily imply $C^4 + C^2/12 - 1/18 = 0$.)

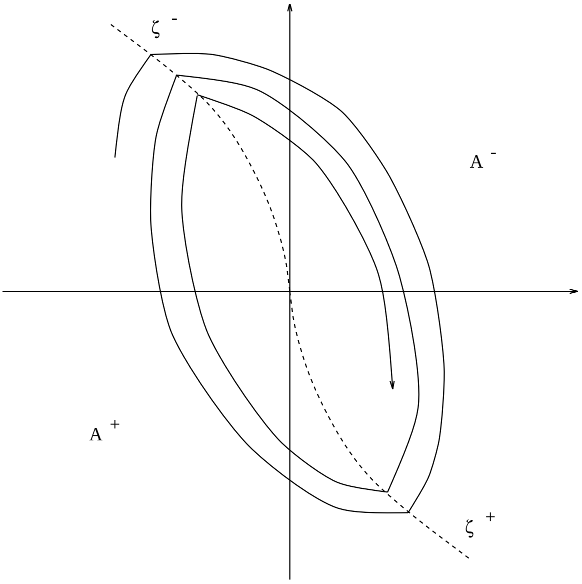

FIG. 1.

We now choose $C = C^*$, so, in particular, $0.4 < C < 0.5$. Then $\{\hat{\gamma}_x\}_{x\in\mathbb{R}^2}$ is a family of extremals reaching the target, and one would like to prove that the $\hat{\gamma}_x$ are optimal. The sufficiency theorems of [2] and [6] do not apply, since the controls $\hat{\eta}_x$ have an infinite number of switchings. For this reason, the optimality of the synthesis obtained by Fuller is usually established by other means. For example, one can prove optimality using the *dilation symmetry properties* of the problem. Precisely, there exists a one parameter family $\Delta = \{\Delta_\rho\}_{\rho>0}$ of maps from $\mathbb{R}^2$ to $\mathbb{R}^2$ such that, if (γ, η) is an admissible pair having cost c, and we let $\gamma_\rho(t) = \Delta_\rho(\gamma(\frac{t}{\rho}))$ and $\eta_\rho(t) = \eta(\frac{t}{\rho})$, then (γ_ρ, η_ρ) is an admissible pair having cost $\rho^5 c$. It then follows that the Δ_ρ map optimal trajectories to optimal trajectories.

The proof of optimality using the dilation symmetry is given, for example, in [32], and will not be repeated here. It will turn out, however, that the dilations Δ_ρ will play a role in our arguments, so we recall their definition and one simple identity that will be useful later:

(1) By definition,

$$\Delta_\rho(x_1, x_2) = (\rho^2 x_1, \rho x_2).$$

(2) It follows from (1), in particular, that

$$\Delta_\rho(x_1, x_2) - x = (\rho - 1)\,(2x_1, x_2) + (\rho - 1)^2\,(x_1, 0)$$

for all ρ, x_1, x_2.

In order to apply Theorem 2.13, we first make a time translation. We define $T_x = -\hat{T}_x$, and then let

$$\gamma_x(t) = \hat{\gamma}_x(t + \hat{T}_x)\,, \qquad \eta_x(t) = \hat{\eta}_x(t + \hat{T}_x)$$

for $T_x \leq t \leq 0$. Then $\Gamma = \{(\gamma_x, \eta_x)\}_{x\in\mathbb{R}^2}$ is a memoryless family of $\mathcal{C}^1$-admissible extremal pairs such that γ_x is defined on $[T_x, 0]$, $\gamma_x(T_x) = x$, and $\gamma_x(0) = 0$.

We want to prove that Γ is an optimal synthesis. For this purpose, we will verify the hypotheses of Theorem 2.13, and in particular the (f, L)-differentiability of Γ at every point $x \in \mathbb{R}^2 \backslash \zeta$. Since it is very easy to check property (DC1), we will verify only (DC2).

As in [32, p. 26], we let

$$\mu = \sqrt{\frac{1-2C}{1+2C}}.$$

Then $0 < \mu < 1$.

Fix a point $\bar{x} = (\bar{x}_1, \bar{x}_2)$ belonging to $\mathbb{R}^2 \backslash \{(0,0)\}$. Then there exist $s_0(\bar{x})$ and $s_1(\bar{x})$ such that $T_{\bar{x}} = s_0(\bar{x}) < s_1(\bar{x}) \leq \mu s_0(\bar{x}) < 0$, and

$$\eta_{\bar{x}} = \pm \sum_{k=0}^{+\infty} (-1)^k \chi_{_{I_k(\bar{x})}},$$

where

(a) $I_0(\bar{x}) = [s_0(\bar{x}), s_1(\bar{x})]$;

(b) $I_k(\bar{x}) = [\mu^{k-1} s_1(\bar{x}), \mu^k s_1(\bar{x})]$ for $k = 1, 2, \ldots$;

(c) $\chi_{_S}$ is the indicator function of a set S;

and

(d) the $\pm$ sign depends on $\bar{x}$ as follows: it is $+$ if $\bar{x} \in A^+ \cup \zeta^+$ and $-$ if $\bar{x} \in A^- \cup \zeta^-$.

Let T be such that $T < 0$ and the interval $[T, 0]$ contains $\mathrm{Dom}(\eta_x)$—i.e., $T \leq T_x$—for x near $\bar{x}$. To prove (DC2), we must pick a point $\bar{x} \in \mathbb{R}^2 \setminus \zeta$ and a continuous function $\alpha : [T, 0] \to \mathbb{R}$, and show that the map

$$\mathbb{R}^2 \ni x \longrightarrow J^\alpha(x) \overset{\text{def}}{=} \int_T^0 \alpha(t).\tilde{f}_{\eta_x}(\gamma_{\bar{x}}(t), t)\, dt \in \mathbb{R}^3 \tag{3.4}$$

is differentiable at $x = \bar{x}$. We will do this by showing that, for two linearly independent directions $v_1(x)$, $v_2(x)$, depending smoothly on x, the directional derivatives $D_{v_1(x)} J^\alpha$ and $D_{v_2(x)} J^\alpha$ exist and are continuous with respect to x. We choose $v_1(x)$ to be the direction of the curve $\rho \to \Delta_\rho(x)$ at $\rho = 1$, and take $v_2(x) = f(x, \eta_x(T_x))$. The determinant of $v_1(x)$ and $v_2(x)$ is then equal to $\pm(2x_1 - x_2^2)$ (the sign being as in (d)), which never vanishes on $A^+ \cup A^-$, since $C < 1/2$. So $v_1(x)$ and $v_2(x)$ are linearly independent for all $x \in A^+ \cup A^-$. We will just determine the directional derivatives at $\bar{x}$, and the result will make it obvious that they depend continuously on $\bar{x}$, so differentiability will follow.

Let us assume, for simplicity, that $\bar{x} \in A^+$. (The case when $\bar{x} \in A^-$ is similar.) We first differentiate J^α in the direction of $v_1(\bar{x})$. If $\rho > 0$, we have (letting $\bar{s}_0 = s_0(\bar{x})$, $\bar{s}_k = \mu^{k-1} s_1(\bar{x})$ for $k = 1, 2, \ldots$, $I_k = [\bar{s}_k, \bar{s}_{k+1}]$, and $I_k^\rho = [\rho \bar{s}_k, \rho \bar{s}_{k+1}]$ for $k = 0, 1, \ldots$, and writing $\bar{x}_\rho = \Delta_\rho(\bar{x})$)

$$T_{_{\bar{x}_\rho}} = \rho T_{\bar{x}}, \qquad \eta_{_{\bar{x}_\rho}} = \sum_{k=0}^{+\infty} (-1)^k \chi_{_{I_k^\rho}},$$

and

$$\tilde{f}_{\eta_{\bar{x}_\rho}}(\gamma_{\bar{x}}(t), t) - \tilde{f}_{\eta_{\bar{x}}}(\gamma_{\bar{x}}(t), t) = \begin{pmatrix} 0 \\ \eta_{_{\bar{x}_\rho}}(t) - \eta_{\bar{x}}(t) \\ 0 \end{pmatrix} + R_\rho(t), \tag{3.5}$$

where $R_\rho(t)$ is a term arising because of the possibility that $T_{\bar x} \neq T_{\bar x_\rho}$.

Then, if $\rho \geq 1$ and $\rho - 1$ is sufficiently small,

$$\begin{aligned}
\int_T^0 (\eta_{\bar x_\rho}(t) - \eta_{\bar x}(t))\alpha(t)\,dt &= \int_{\rho\bar s_0}^0 \sum_{k=0}^{+\infty}(-1)^k\Big(\chi_{I_k^\rho}(t) - \chi_{I_k}(t)\Big)\alpha(t)\,dt \\
&= \sum_{k=0}^{+\infty}(-1)^k\left(\int_{\rho\bar s_k}^{\rho\bar s_{k+1}}\alpha(t)\,dt - \int_{\bar s_k}^{\bar s_{k+1}}\alpha(t)\,dt\right) \\
&= \sum_{k=0}^{+\infty}(-1)^k\left(\int_{\rho\bar s_k}^{\bar s_k}\alpha(t)\,dt - \int_{\rho\bar s_{k+1}}^{\bar s_{k+1}}\alpha(t)\,dt\right) \\
&= \int_{\rho\bar s_0}^{\bar s_0}\alpha(t)\,dt + 2\sum_{k=1}^{+\infty}(-1)^k\left(\int_{\rho\bar s_k}^{\bar s_k}\alpha(t)\,dt\right).
\end{aligned}$$

The numbers $(\rho-1)^{-1}\|\int_{\rho\bar s_k}^{\bar s_k}\alpha(t)\,dt\|$ are bounded by $\mu^{k-1}|\bar s_1|.\|\alpha\|_{L^\infty}$, which is the general term of a convergent series, since $\mu < 1$. So we can divide by $\rho - 1$, let $\rho \longrightarrow 1$, and take the limit of each term separately. We then conclude that

$$\lim_{\rho\downarrow 1}\frac{1}{\rho-1}\int_T^0(\eta_{\bar x_\rho}(t) - \eta_{\bar x}(t))\alpha(t)dt = -\bar s_0\alpha(\bar s_0) - 2\bar s_1\sum_{k=1}^{+\infty}(-1)^k\mu^{k-1}\alpha(\mu^{k-1}\bar s_1). \tag{3.6}$$

We now find the limit of $(\rho-1)^{-1}\int_T^0\alpha(t).R_\rho(t)\,dt$ as $\rho \downarrow 1$. Clearly, $T_{\bar x_\rho} = \rho T_{\bar x} < T_{\bar x}$ if $\rho > 1$. So

$$\int_T^0 \alpha(t).R_\rho(t)\,dt = \int_{\rho T_{\bar x}}^{T_{\bar x}}\alpha(t).\begin{pmatrix}\gamma_{\bar x_\rho}^2(t)\\ 0\\ \left(\gamma_{\bar x_\rho}^1(t)\right)^2\end{pmatrix}dt,$$

where $\gamma_{\bar x_\rho}^i(t)$, for $i = 1, 2$, is the ith component of $\gamma_{\bar x_\rho}(t)$. Therefore

$$\lim_{\rho\downarrow 1}(\rho-1)^{-1}\int_T^0\alpha(t).R_\rho(t)\,dt = -T_{\bar x}\alpha(T_{\bar x}).\begin{pmatrix}\bar x_2\\ 0\\ \bar x_1^2\end{pmatrix}. \tag{3.7}$$

Similar computations show that (3.6) and (3.7) hold as well for the limits as $\rho \uparrow 1$. So the directional derivative of J^α at $x = \bar x$ in the direction of $v_1(\bar x)$ exists and is given by the sum of the right-hand sides of (3.6) and (3.7), which depend continuously on $\bar x$, since $\bar s_0$, $\bar s_1$, and $T_{\bar x}$ (which is none other than $\bar s_0$) depend continuously on $\bar x$ as long as $\bar x \in A^+$.

A much simpler argument verifies the existence of the derivative of J^α in the direction of $v_2(\bar x)$—i.e., of $f(\bar x, 1)$—whose value turns out to be the vector with components $\alpha(T_{\bar x})\bar x_2$, $\alpha(T_{\bar x})$, and $\alpha(T_{\bar x})\bar x_1^2$. Once again, this expression depends continuously on $\bar x$, so the proof of (DC2) is complete.

The other assumptions of Theorem 2.13 are easily checked. So the theorem applies, and the optimality of the synthesis described above follows.

4. Comparison with other definitions of synthesis. The purpose of this section is to compare our concept of regular presynthesis with other definitions of synthesis that either have been proposed by other authors or are sufficiently natural to be worth considering as possible ways to define this notion. For simplicity, we will only consider the case of a single-point target set $\mathcal{T}$, and take this point to be the origin. (Both Boltyanskii and Brunovský, whose definitions will be discussed in detail, do the same, so this will facilitate the comparison.) Moreover, we will consider only nonnegative Lagrangians, so a trajectory containing a loop can never be optimal, and an optimal trajectory necessarily terminates when it hits the origin.

Perhaps the simplest conceivable notion of a "regular synthesis" is that of a "feedback control." In principle, one could define a "feedback control law" on a set S to be a map $v : S \to U$. If v is such that the vector field $S \ni x \to f(x, v(x)) \in \mathbb{R}^n$ is Lipschitz-continuous, and we assume for simplicity that S is open, then v gives rise to unique maximally defined trajectories $\hat{\gamma}_x$ starting at each $x \in S$, and corresponding open-loop controls $\hat{\eta}_x$, given by $\hat{\eta}_x(t) = v(\hat{\gamma}_x(t))$. If we make the additional assumption that every trajectory $\hat{\gamma}_x$ obtained in this way reaches the target at a time $\hat{T}_x$, define $T_x = -\hat{T}_x$, and let $\gamma_x(t) = \hat{\gamma}(t+\hat{T}_x)$ and $\eta_x(t) = \hat{\eta}(t+\hat{T}_x)$ for $T_x \leq t \leq 0$, then we will have constructed a synthesis $\Gamma = \{(\gamma_x, \eta_x)\}_{x \in S}$—in the sense of Definition 2.4—with domain S.

The main drawback of such a definition is that, as is well known, for most reasonable optimal control problems there does not exist an optimal feedback that renders the map $x \to f(x, v(x))$ Lipschitz-continuous or even continuous. So it is absolutely essential to allow "discontinuous feedback laws," and when this is done one immediately runs into the problems of

(a) the lack of a truly satisfactory notion of solution

and

(b) the lack of good theorems guaranteeing existence of solutions.

Difficulty (b) can be handled in at least two ways, namely, by

(A) incorporating into the definition requirements that imply existence and uniqueness of solutions of the closed-loop equation $\dot{x} = f(x, v(x))$;

(B) incorporating into the definition requirements that imply existence—but not necessarily uniqueness—of solutions of the closed-loop equation, and adding to the specification of v a definite prescription for choosing a solution when uniqueness fails, so that the "feedback law" is no longer the closed-loop control v alone, but the *pair* (v, Γ), where $\Gamma = \{(\gamma_x, \eta_x)\}$ is a family that selects one solution of the closed-loop equation for each initial condition x.

Moreover, whether we choose (A) or (B), one has to be precise about the concept of "solution." Here we will consider three such concepts, namely,

(1) classical solutions (i.e., absolutely continuous curves $t \to x(t)$ having the property that the equality $\dot{x}(t) = f(x(t), v(x(t)))$ holds for almost every t),

(2) Filippov solutions (cf. [10]),

(3) "CLSS solutions," that is, the "feedback solutions" defined by Clarke et al. in [8].

The examples of section 5 will show that the concepts of CLSS solution and Filippov solution are not adequate. Indeed, Example 5.4 shows an optimal synthesis whose trajectories are not Filippov solutions of the optimal closed-loop equation. In this example, the optimal trajectories are CLSS solutions, but the optimal closed-loop equation has many other CLSS solutions that are not optimal (cf. Remark 5.5). In Example 5.6, we exhibit an optimal control problem whose optimal trajectories are not CLSS solutions of the optimal closed-loop equation.

This leaves the notion of classical solution as the only viable candidate for the concept of solution to be used in the definition of optimal synthesis. Example 5.3

shows that it may happen that the set of classical solutions of the optimal closed-loop equation contains, in addition to all the optimal trajectories, some other arcs that are not optimal.

It then follows that (A) is not an adequate way of handling difficulty (b), and we are left with (B). This was indeed the strategy followed by Boltyanskii in [2], Brunovský in [6], and Sussmann in [18]. In all these cases, a "regular synthesis" is defined by first specifying a—not necessarily continuous—feedback control law $x \to v(x)$. The feedback v is supposed to be "piecewise smooth" in a technical sense that, among other things, guarantees the existence of trajectories for every initial condition. Uniqueness is not assumed, but the specification of v is supplemented with a prescription for selecting a trajectory when nonuniqueness occurs. So, a "synthesis" in the sense of [2], [6], and [18] is more than just an optimal feedback: it is really a pair (v, Γ) of the kind discussed in (B).

We now review the three concepts of regular synthesis proposed in [2], [6], and [18], starting with Brunovský's definition as stated in [6], and then explaining how to modify this idea to obtain the alternative formulations suggested by Boltyanskii in [2] and Sussmann in [18]. Since the notations used in [2], [6], and [18] are different, we will give a unified account of the three definitions using a single set of symbols, and indicating which notations of [2] and [6] they correspond to. Furthermore, our accounts of [2] and [6] will be slightly modified versions of the text of the published papers, correcting what we believe are some minor imprecisions or typographical errors, and introducing some additional notations of our own for extra clarity.

Both Boltyanskii and Brunovský work with a system defined on an open subset Ω of a finite-dimensional real space (called X in [2], equal to $\mathbb{R}^n$ in [6]). Both assume that the dynamical behavior of the controlled system is given by a law $\dot{x} = f(x, u)$, where U is a subset of $\mathbb{R}^m$, and the maps f and L are of class $\mathcal{C}^1$, in the sense that they can be extended to maps of class $\mathcal{C}^1$ on an open subset of $\Omega \times \mathbb{R}^m$ that contains $\Omega \times clos_{\mathbb{R}^m}(U)$. Both assume that the synthesis is defined on an open subset S of Ω (called V in [2], G in [6]).

Brunovský's definition uses the concept of a stratification, so we review this notion first.

Definition 4.1. *Given a $k \in \{1, 2, \ldots\} \cup \{+\infty, \omega\}$, and a manifold M of class $\mathcal{C}^k$, a $\mathcal{C}^k$* stratification *in M of a subset S of M is a partition $\mathcal{P}$ of S into nonempty connected embedded submanifolds of M of class $\mathcal{C}^k$, such that $\mathcal{P}$ is locally finite in M (i.e., every compact subset of M intersects finitely many members of $\mathcal{P}$) and the following "frontier axiom" holds:*

(FA) *If $P_1, P_2 \in \mathcal{P}$, $P_1 \neq P_2$ (so that $P_1 \cap P_2 = \emptyset$), and $P_1 \cap clos_M(P_2) \neq \emptyset$, then $P_1 \subseteq clos_M(P_2)$ and $\dim(P_1) < \dim(P_2)$.*

A $\mathcal{C}^k$-stratified subset *of M is a pair $(S, \mathcal{P})$ having the property that $S \subseteq M$ and $\mathcal{P}$ is a $\mathcal{C}^k$ stratification of S in M.*

We are now ready to present Brunovský's definition, inserting some comments of our own—labeled "BP&HS"—in square brackets.

Definition 4.2. *Let $S \subseteq \Omega$ be an open subset such that the origin belongs to S. A* Brunovský regular synthesis on S for the control problem (2.1), (2.2), with target the origin, *is a* 6*-tuple $\Xi = (\mathcal{P}, \mathcal{P}_1, \mathcal{P}_2, \Pi, \Sigma, v)$ (called $(\mathcal{S}, \mathcal{S}_1, \mathcal{S}_2, \Pi, \Sigma, v)$ in* [6]*) such that*

(Br.1) *$\mathcal{P}$ is the union of $\{\{0\}\}$ and a locally finite (in S) partition $\mathcal{P}\backslash\{\{0\}\}$ of $S \setminus \{0\}$ into nonempty connected embedded $\mathcal{C}^1$ submanifolds of S (called "cells"),*

(Br.2) *$\mathcal{P}\backslash\{\{0\}\}$ is the disjoint union of $\mathcal{P}_1$ (the set of "type* I *cells") and $\mathcal{P}_2$ (the set of "type* II *cells"),* (Br.3) $v : S \to U$ *(the "closed loop control"),* $\Pi : \mathcal{P}_1 \to \mathcal{P}$*, and* $\Sigma : \mathcal{P}_2 \to \mathcal{P}_1$ *are maps such that the following properties are satisfied:*

(Br.3.A) *If* $\mathcal{P}' = \{P \in \mathcal{P} : \dim P < n\,,\, P \neq \{0\}\}$*, and* $S' = \bigcup\{P \in \mathcal{P}'\}$*, then* $(S', \mathcal{P}')$ *is a stratified subset of* S *of dimension* $< n$*.* [BP&HS: *This turns out to be equivalent to the much simpler statement that* $\mathcal{P}$ is a $\mathcal{C}^1$ stratification of S*. The proof is somewhat delicate and will be given in full detail in Appendix* C.]

(Br.3.B) *The function* v *is of class* $\mathcal{C}^1$ *on each cell.*

(Br.3.C) *If* $P_1 \in \mathcal{P}_1$*, then* $f(x, v(x)) \in T_x P_1$ *(the tangent space to* P_1 *at* x*) for every* $x \in P_1$*. In addition, for each* $x \in P_1$*, if we let* ξ_x *be the maximally defined solution of the initial value problem*

$$\dot{\xi} = f(\xi, v(\xi))\,,\ \ \xi(0) = x\,,\ \ \xi \in P_1, \tag{4.1}$$

and define $t_x = \sup \mathrm{Dom}(\xi_x)$*, then the limit* $\xi_x(t_x-) \stackrel{\mathrm{def}}{=} \lim_{t\uparrow t_x} \xi_x(t)$ *exists (in* Ω*) and belongs to* $\Pi(P_1)$*.* [BP&HS: *The limit* $\xi_x(t_x-)$ *cannot belong to* P_1*, because if it did then it would be equal to the limit of* $\xi_x(t)$ *in* P_1 *(because* P_1 *is embedded), so* $\xi_x(t)$ *would have a limit in* P_1 *as* $t \uparrow t_x$*, and then* ξ_x *would be extendable to a solution of* (4.1) *on an interval containing* $[0, t_x + \varepsilon\,[$ *for some positive* ε*, contradicting the choice of* t_x*. It then follows that* $P_1 \neq \Pi(P_1) \subseteq clos(P_1)$ *and, moreover,* $\dim(\Pi(P_1)) < \dim(P_1)$ *for all* $P_1 \in \mathcal{P}_1$*. Indeed, if* $P_1 \in \mathcal{P}_1$*, then we can pick* $x \in P_1$ *and conclude that* $\xi_x(t_x-)$ *belongs to* $\Pi(P_1)\backslash P_1$*. So* $\Pi(P_1) \cap clos(P_1) \neq \emptyset$ *and* $\Pi(P_1) \neq P_1$*. Therefore* $\Pi(P_1) \subseteq clos(P_1)$ *and* $\dim(\Pi(P_1)) < \dim(P_1)$*, since* $P_1 \in \mathcal{P}$*,* $\Pi(P_1) \in \mathcal{P}$*, and* $\mathcal{P}$ *is a stratification.*]

(Br.3.D) *If* $P_2 \in \mathcal{P}_2$*, then the control* v *is continuous on* $P_2 \cup \Sigma(P_2)$*, and for each* $x \in P_2$ *there exists a unique curve* $\xi_x : [0, t_x\,[\to \Omega$ *such that the restriction* $\xi_x \lceil\,]0, t_x\,[$ *is a maximally defined integral curve of the vector field* $f(\cdot, v(\cdot))$ *on* $\Sigma(P_2)$*, and* $\xi_x(0) = x$*.* [BP&HS: *This implies that* $\Sigma(P_2) \neq P_2$*,* $P_2 \subseteq clos(\Sigma(P_2))$*, and* $\dim(\Sigma(P_2)) > \dim(P_2)$ *for every* $P_2 \in \mathcal{P}_2$*.*]

(Br.3.E) *On every cell* P*,* $x \to t_x$ *is a continuously differentiable function, and* $(t, x) \to \xi_x(t)$*,* $(t, x) \to u_x(t) \stackrel{\mathrm{def}}{=} v(\xi_x(t))$ *are continuously differentiable maps on the set*

$$E(P) \stackrel{\mathrm{def}}{=} \{(t, x) : x \in P\,,\, t \in [0, t_x]\} \tag{4.2}$$

in the sense that they can be prolonged to maps of class $\mathcal{C}^1$ *on some open subset of* $\mathbb{R} \times P$ *containing* $E(P)$*.*

(Br.3.F) *For every* $x \in S\backslash\{0\}$*, if we let* $\tilde{\xi}_x$ *denote the curve obtained in an obvious way by piecing together the trajectories on every single cell, and write* $\tilde{\eta}_x(t) = v(\tilde{\xi}_x(t))$*, then the admissible pair* $(\tilde{\xi}_x, \tilde{\eta}_x)$ *ends at the origin after passing from one cell to another a finite number of times, and is extremal.*

(Br.3.G) *The cost function* $V^{\Xi} \stackrel{\mathrm{def}}{=} V_{\Gamma(\Xi)}$ *corresponding to the synthesis* $\Gamma(\Xi) = \{(\tilde{\xi}_x, \tilde{\eta}_x)\}_{x \in S}$ *is continuous.*

Boltyanskii's definition, as given in [2], includes an extra ingredient, namely, a subset N of S where the synthesis is allowed to have a more singular behavior. The definition is formulated in terms of a sequence $\mathbf{P} = (P^0, \ldots, P^n)$ of subsets of S such that

$$P^0 \subseteq P^1 \subseteq \cdots \subseteq P^n = S, \tag{4.3}$$

and the object that we called $\mathcal{P}$ here (that is, the set of "cells") is the union

$$\mathcal{P} = \bigcup_{i=0}^{n} \mathcal{P}^i, \tag{4.4}$$

where

(Bo.*) $\mathcal{P}^i$, for $i \geq 0$, is the set of all connected components of $P^i \setminus (P^{i-1} \cup N)$, where $P^{-1} = \emptyset$,

so now $\mathcal{P}$ is a partition of $(S \setminus N) \cup \{0\}$ rather than of S. Boltyanskii does not explicitly require that this partition be locally finite in S. He asks only that the sets P^i and N be "piecewise smooth" (that is, locally finite unions of "curvilinear polyhedra," i.e., of sets that are $\mathcal{C}^1$-diffeomorphic to closed bounded polyhedra in finite-dimensional Euclidean spaces), but this does not imply that $\mathcal{P}$ is locally finite. (In fact, in section 5, Example 5.2, we exhibit a Boltyanskii regular synthesis whose set of cells is not locally finite.)

In addition, Boltyanskii imposes some extra requirements, which imply some of the Brunovský conditions. In order to facilitate the comparison, we will include in our definition of a Boltyanskii synthesis all the Brunovský conditions that necessarily follow from the Boltyanskii assumptions, even though this will introduce a number of redundancies.

Definition 4.3. *A* Boltyanskii regular synthesis *on the open subset S of the open set $\Omega \subseteq \mathbb{R}^n$, for the control problem* (2.1), (2.2), *with target the origin, is an 8-tuple $\Xi = (\mathbf{P}, \mathcal{P}_1, \mathcal{P}_2, \Pi, \Sigma, v, N, \Xi^N)$ such that*

(Bo.1) $\mathbf{P} = (P^0, \dots, P^n)$ *is a sequence of piecewise smooth subsets of S such that* (4.3) *holds.*

(Bo.2) *N is a piecewise smooth subset of S such that* $\dim(N) < n$.

(Bo.3) *If $\mathcal{P}$—the set of "cells"—is defined by* (4.4), *with the $\mathcal{P}^i$ defined by* (*Bo.*$*$), *then all the cells are embedded submanifolds of S, of class $\mathcal{C}^1$, such that* $\dim(P) = i$ *whenever* $P \in \mathcal{P}^i$. [BP&HS: *The cells are obviously connected, by definition, and form a partition of* $(S \setminus N) \cup \{0\}$. *But $\mathcal{P}$ need not be locally finite and a fortiori $\mathcal{P}$ need not be a stratification.*]

(Bo.4) $\dim(\Pi(P)) = \dim(P) - 1$ *whenever* $P \in \mathcal{P}_1$.

(Bo.5) *The only zero-dimensional cell is* $\{0\}$.

(Bo.6) Ξ^N *is a family of pairs in* $\mathrm{Adm}^{\mathcal{C}^1,0}(\tilde{f}, \{0\})$ *such that* (a) *if $(\xi, \eta) \in \Xi^N$, then $\xi^- \in N$,* (b) *for every $x \in N$ there is a $(\xi, \eta) \in \Xi^N$ such that $\xi^- = x$, and* (c) *if (ξ_1, η_1) and (ξ_2, η_2) belong to Ξ^N, and $\xi_1^- = \xi_2^-$, then $J(\xi_1, \eta_1) = J(\xi_2, \eta_2)$.*

(Bo.7) *Conditions* (Br.2) *and* (Br.3) *of Brunovský's definition hold, with the following modifications:* (a) *v is defined on $S \setminus N$ rather than on S,* (b) *the stratification requirement* (Br3.A) *is dropped, and* (c) *$V^{\Xi}(x)$ is defined to be equal to $J(\tilde{\xi}_x, \tilde{\eta}_x)$ if $x \in S \setminus N$, and to $J(\xi, \eta)$ if $x \in N$ and (ξ, η) is any member of Ξ^N such that $\xi^- = x$.*

(Bo.8) *Whenever the trajectory $\tilde{\xi}_x$ enters a new cell, it does so "at a nonzero angle." (That is, more precisely: whenever $P \in \mathcal{P}_1$ and $x \in P$, the tangent vector to $\tilde{\xi}_x$ at time t_x is not tangent to* $\Pi(P)$ *at $\tilde{\xi}_x(t_x)$.)*

It is then clear that the two concepts of a regular synthesis defined by Boltyanskii and Brunovský are not comparable. A Brunovský synthesis can fail to be a Boltyanskii synthesis because

(a) it violates the "nonzero angle" condition (Bo.8), as in the example given by Brunovský in [6],

or

(b) it violates the dimension condition (Bo.4), as in our Example 5.4 below,

or

(c) it violates condition (Bo.5), as in Example 5.1 below.

On the other hand, a Boltyanskii synthesis can fail to be a Brunovský synthesis because, for example, the set of cells could fail to be locally finite, as in our Example 5.2. Also, the Brunovský definition, as stated in [6], does not allow for an extra "singular set" N.

The uniqueness requirement of (Br.3.D) is rather strong. In [18] Sussmann proposed an even less restrictive formulation, as we now explain. For a $P \in \mathcal{P}_2$, we not only specify a cell $\Sigma(P) \in \mathcal{P}_1$ as in (Br.3.D), but also give a continuous "exiting map" $\mathcal{E}_P$, defined on the set $\{(x,t) : x \in P, 0 \le t < \varepsilon(x)\}$ and with values in $P \cup \Sigma(P)$. Here $\varepsilon : P \to \mathbb{R}$ is a continuous strictly positive function, and the map $\mathcal{E}_P$ is required to be such that, for every $x \in P$, (a) $\mathcal{E}_P(x,0) = x$, and (b) the map $]0, \varepsilon(x)[\ni t \to \mathcal{E}_P(x,t)$ takes values in $\Sigma(P)$ and is an integral curve of $f(\cdot, v(\cdot))$. So in [18] a *synthesis* is not just a 6-tuple $\Gamma = (\mathcal{P}, \mathcal{P}_1, \mathcal{P}_2, \Pi, \Sigma, v)$ as in the Brunovský definition, but a 7-tuple $\Gamma = (\mathcal{P}, \mathcal{P}_1, \mathcal{P}_2, \Pi, \Sigma, v, \mathcal{E})$, where the extra ingredient is the family $\mathcal{E} = \{\mathcal{E}_P\}_{P \in \mathcal{P}_2}$ of exiting maps.

Remark 4.4. The map $\mathcal{E}_P$ can be thought of as way of selecting in a continuous fashion, for each $x \in P$, an initial piece $]0, \varepsilon(x)[\ni t \to \mathcal{E}_P(x,t) \in \Sigma(P)$ of an integral curve of the feedback vector field $\Sigma(P) \ni y \to f(y, v(y)) \in T_y\Sigma(P)$ such that $\lim_{t \downarrow 0} \mathcal{E}_{P,x}(t) = x$. Naturally, if (Br.3.D) was satisfied we would just choose this curve to be the restriction of ξ_x to $]0, t_x[$.

It is not hard to produce a concept of regular synthesis that contains as special cases the three definitions of [2], [6], and [18] but does not differ too much from any of them. This can be done by removing from the definitions of [2], [6], and [18] conditions that are not really needed, such as the local finiteness requirements and Boltyanskii's conditions (Bo.4), (Bo.5), and (Bo.8). One can also eliminate the requirement that the control space U be a subset of some Euclidean space $\mathbb{R}^m$, and take U to be an arbitrary set with no extra structure, provided only that all the conditions involving differentiability of the feedback control $x \to v(x)$ are replaced by a differentiability requirement for the map $x \to \tilde{f}(x, v(x))$. One possible result is the following concept, that we will call "BB-regular synthesis," using the letters BB to stand for "Boltyanskii and Brunovský."

Definition 4.5. *A* BB-regular synthesis *on the open subset S of Ω, for the control problem* (2.1), (2.2), *with target* $\{0\}$*, is a* 9*-tuple* $\Xi = (\mathcal{P}, \mathcal{P}_1, \mathcal{P}_2, \Pi, \Sigma, \mathcal{E}, v, N, \Xi^N)$ *such that*

(BB.1) $0 \in N \subseteq S$*, and* $\mathcal{P}$ *is a finite or countable partition of* $S \backslash N$ *into nonempty connected embedded submanifolds of* S *of class* $\mathcal{C}^1$ *(called "cells");*

(BB.2) $\mathcal{P}$ *is the disjoint union of* $\mathcal{P}_1$ *(the set of "type* I *cells") and* $\mathcal{P}_2$ *(the set of "type* II *cells"),*

(BB.3) $v : \bigcup\{P : P \in \mathcal{P}_1\} \to U$ *(the "closed loop control"),* $\Pi : \mathcal{P}_1 \to \mathcal{P} \cup \{\{0\}\}$*, and* $\Sigma : \mathcal{P}_2 \to \mathcal{P}_1$ *are maps, and* $\mathcal{E}$ *is a family* $\{\mathcal{E}_P\}_{P \in \mathcal{P}_2}$*, such that the following properties are satisfied:*

(BB.3.A) *If* $P \in \mathcal{P}_1$*, then the map* $P \ni x \to \tilde{f}(x, v(x))$ *is of class* $\mathcal{C}^1$*, and such that* $f(x, v(x))$ *belongs to* T_xP *(the tangent space to* P *at* x*) for every* $x \in P$*.*

(BB.3.B) *If* $P \in \mathcal{P}_2$*, then* $\Sigma(P) \in \mathcal{P}_1$*, and* $\mathcal{E}_P$ *is a map that assigns to each* $x \in P$ *a maximally defined integral curve* $\mathcal{E}_{P,x}$ *of the vector field* $\Sigma(P) \ni y \to f(y, v(y)) \in T_y\Sigma(P)$ *in such a way that* $0 = \inf \mathrm{Dom}(\mathcal{E}_{P,x})$ *and* $\lim_{t\downarrow 0} \mathcal{E}_{P,x}(t) = x$*.*

(BB.3.C) *For* $x \in P \in \mathcal{P}_2$*, define a map* $\xi_x : \{0\} \cup \mathrm{Dom}(\mathcal{E}_{P,x}) \to \Omega$ *by letting* $\xi_x(0) = x$ *and* $\xi_x(t) = \mathcal{E}_{P,x}(t)$ *for* $t \in \mathrm{Dom}(\mathcal{E}_{P,x})$*. For* $x \in P_1 \in \mathcal{P}_1$*, let* ξ_x *be the maximally defined solution of the initial value problem* (4.1)*. Define* $t_x = \sup \mathrm{Dom}(\xi_x)$ *for* $x \in P \in \mathcal{P}$*. Then for every cell* $P \in \mathcal{P}$ *the function* $P \ni x \to t_x$ *is of class* $\mathcal{C}^1$*, and the maps* $\hat{E}(P) \ni (t, x) \to \xi_x(t) \in \Omega$ *and* $\hat{E}(P) \ni (t, x) \to \tilde{f}(\xi_x(t), v(\xi_x(t))) \in \mathbb{R}^{n+1}$ *have continuously differentiable extensions to a neighborhood of* $E(P)$ *in* $\mathbb{R}\times P$*, where* $E(P)$ *is the set defined by* (4.2)*, and* $\hat{E}(P) = \{(t, x) \in E(P) : 0 < t < t_x\}$*.*

(BB.3.D) *If* $x \in P \in \mathcal{P}_1$*, then the limit* $\xi_x(t_x-) = \lim_{t\uparrow t_x} \xi_x(t)$*—which exists because of* (BB.3.C)*—belongs to* $\Pi(P)$*.*

(BB.4) *Boltyanskii's condition* (Bo.6) *holds.*

(BB.5) *Brunovský's condition* (Br.3.F) *holds for* $x \in S \setminus N$*.*

(BB.6) *Brunovský's condition* (Br.3.G) *holds, with* V^{Ξ} *defined as in* (Bo.7.c)*.*

It is then easy to show that if Ξ is a regular synthesis in the sense of Boltyanskii [2], Brunovský [6], or Sussmann [18], then it is possible to associate to Ξ in a natural way a BB-regular synthesis in the sense of Definition 4.5. Moreover, a BB-regular synthesis gives rise in a natural way to a regular presynthesis $\Gamma(\Xi)$ in the sense of our Definition 2.12, which is a synthesis if $N = \{0\}$.

Our Definition 2.12—a slightly different version of which was already proposed in [31]—is even more general, because of the following:

(a) We do not require that V_Γ be continuous, and we assume only the weak continuity conditions.

(b) We do not require that the domain of the synthesis be an open set. This is quite important because one wants the theory to apply to systems that are not locally controllable, and in those cases one usually wants to take S to be the set $\hat{S}$ of all points of Ω that can be steered to the target, and in general $\hat{S}$ is not open.

(c) We do not require the existence of a partition into "cells." From our point of view, such a partition is only needed to guarantee the weak differentiability condition (b) of Definition 2.12.

(d) Even when a good partition into "cells" exists, satisfying the most restrictive conditions of both definitions (that is, Brunovský's stratification condition (Br.3.A) and Boltyanskii's conditions (Bo.4), (Bo.5), and (Bo.8)), it may still happen that the crucial "finite number of steps" condition (Br.3.F) is violated, as in Fuller's example, but our requirements for a regular presynthesis are still met.

5. Examples.

We now present several examples of optimal regular syntheses to illustrate the differences between the various definitions.

One example showing how our notion of regular synthesis is more general than those of Boltyanskii and Brunovský was already discussed in section 3, where we showed that our theory applies to Fuller's problem while the other ones clearly do not, since they do not allow the trajectories of the synthesis to have infinitely many switchings. Another important example, relevant for the comparison of the Boltyanskii and Brunovský definitions, is the one given by Brunovský in [6], showing how the "nonzero angle" condition (Bo.8) can be violated.

We now show by means of an example how Boltyanskii's condition (Bo.5) can be violated. In principle, it is quite easy to produce examples of syntheses that satisfy all of Boltyanskii's conditions except for (Bo.5). It turns out, however, that in most such examples one can construct a new synthesis where (Bo.5) holds, for example, by incorporating the zero-dimensional cells in the singular set N, or by drawing a one-dimensional arc A_q through every q such that $\{q\}$ is a cell and making the A_q's cells of the new synthesis. To produce an example where no synthesis can possibly satisfy (Bo.5) more work is needed, but it can be done, as we now show.

Example 5.1. Let

$$S_1 = \{(x,0) : x \leq 0\}\,, \qquad S_2 = \{(x,x) : 0 \leq x \leq 1\}\,,$$
$$S_3 = \{(x,2x-1) : x \geq 1\}\,, \qquad S_4 = \{(x,0) : x \geq 0\}\,.$$

Let $\Lambda_1 = S_1 \cup S_2 \cup S_3$, $\Lambda_2 = S_1 \cup S_4$. Let A be the set of points (x,y) such that $x \geq 0$ and either $0 \leq y \leq x \leq 1$ or $0 \leq y \leq 2x-1$, and let B be the set of those (x,y) such that either $y \leq 0$, or $x \leq 0$, or $0 \leq x \leq 1$ and $x \leq y$, or $x \geq 1$ and $y \geq 2x-1$. Let $\varphi, \psi : \mathbb{R}^2 \to \mathbb{R}$ be smooth nonnegative functions such that $\varphi(x,y) = 0$ if and only if $(x,y) \in A$, and $\psi(x,y) = 0$ if and only if $(x,y) \in B$.

We consider the minimum time-optimal control problem in $\mathbb{R}^2$ with target $\{(0,0)\}$ and dynamics given by

$$\dot{x} = \frac{u_1}{1+\varphi(x,y)}\,, \qquad \dot{y} = \frac{u_2}{1+\psi(x,y)}\,,$$

where the control constraint is $|u_1| + |u_2| \leq 1$.

If $q = (\bar{x},\bar{y})$ is any point in $\mathbb{R}^2$, and $[a,b] \ni t \to \xi(t) = (x(t),y(t)) \in \mathbb{R}^2$ is any trajectory from q to the target, corresponding to a control $[a,b] \ni t \to \eta(t) = (u_1(t),u_2(t))$, then

$$b - a \geq \int_a^b \Big(|u_1(t)| + |u_2(t)|\Big)\,dt \geq \int_a^b \Big(|\dot{x}(t)| + |\dot{y}(t)|\Big)\,dt \geq |\bar{x}| + |\bar{y}|\,.$$

Moreover, a trajectory ξ_q from q to the origin whose cost is exactly $|\bar{x}| + |\bar{y}|$ can be constructed as follows:

1. If q belongs to Λ_1, then the point $\xi_q(t)$ moves along Λ_1 towards the origin, with a control vector $\eta_q(t) = (u_1(t),u_2(t))$ such that $|u_1(t)| + |u_2(t)| = 1$ (so that $\eta_q(t) = (1,0)$ if $q \in S_1$ and $\eta_q(t) = (-\frac{1}{2},-\frac{1}{2})$ if $q \in S_2$; if $q \in S_3$, then $\eta_q(t) = (-\frac{1}{3},-\frac{2}{3})$ until $\xi_q(t) = (1,1)$, and $\eta_q(t) = (-\frac{1}{2},-\frac{1}{2})$ from then on).
2. If $q \in A$, then $\xi_q(t)$ moves horizontally to the left (with control $(u_1,u_2) = (-1,0)$) until it reaches Λ_1, and then follows the trajectory described in item 1.
3. If $q \in B$ and $\bar{y} > 0$, then $\xi_q(t)$ moves vertically down (with control $(u_1,u_2) = (0,-1)$) until it reaches Λ_1, and then follows the trajectory described in item 1.
4. If $q \in B$ and $\bar{y} < 0$, then $\xi_q(t)$ moves vertically up (with control $(u_1,u_2) = (0,1)$) until it reaches Λ_2, and then moves horizontally towards the origin with control $(1,0)$ or $(-1,0)$.

The family $\Xi = \{\xi_q\}_{q\in\mathbb{R}^2}$ is an optimal synthesis. If we define P^0 to be the two-point set consisting of $(0,0)$ and $(1,1)$, and let $P^1 = \cup_{i=1}^4 S_i$, $P^2 = \mathbb{R}^2$, and $N = \emptyset$, then all the conditions of a Boltyanskii regular synthesis are satisfied (with 17 cells), except for (Bo.5). Moreover, it is easy to show that *this problem does not admit a regular* *synthesis that satisfies all the Boltyanskii conditions, including* (Bo.5). (The proof is as follows. The optimal trajectories for our problem are clearly unique for all initial points $q = (\bar{x}, \bar{y})$. So for any optimal synthesis the trajectories are the ξ_q. Assume we have a regular synthesis satisfying all of Boltyanskii's conditions. Then the point $(1, 1)$ cannot belong to the singular set N, because the definition of a Boltyanskii synthesis implies that every marked trajectory starting at a point of $\mathbb{R}^2 \setminus N$ is entirely contained in $\mathbb{R}^2 \setminus N$, so the set $U = \{(x, y) : x \geq 1\,,\, y \geq 1\}$ must be entirely contained in N—because if $q \in U$, then ξ_q goes through $(1, 1)$—and this contradicts the fact that the dimension of N is at most one (as below). Now, let C be the cell containing $(1, 1)$. Since every optimal trajectory going through $(1, 1)$ has a discontinuous velocity at $(1, 1)$, the cell C cannot be of type I. In particular, C is not two-dimensional, so (Bo.5) implies that it is one-dimensional. It follows from the definition of a Boltyanskii synthesis that the direction $\nu(q)$ of the marked trajectory ξ_q at its starting point q must be a continuous function of q as long as $q \in C$. But $\nu(1, 1) = (-\frac{1}{2}, -\frac{1}{2})$, and there is no direction along which $\nu(q)$ is continuous as $q \to (1, 1)$, so it is impossible for C to be one-dimensional.)

In our second example, we present a Boltyanskii optimal synthesis which is not a Brunovský synthesis, because the set of cells is not locally finite.

Example 5.2. Let $\psi : \mathbb{R} \to \mathbb{R}$ be a function of class $\mathcal{C}^\infty$ such that (a) $\psi(x) = 0$ whenever $x \leq 0$, (b) $0 \leq \psi(x) < x$ when $x > 0$, (c) the set of zeros of ψ is the union of $\{0\}$ and the points of a decreasing infinite sequence $\{x_k\}_{k=1}^\infty$ having an accumulation point at 0, (d) for every $k \geq 1$ there exists $\bar{x}_k \in]x_{k+1}, x_k[$ such that ψ is strictly increasing on $[x_{k+1}, \bar{x}_k]$ and strictly decreasing on $[\bar{x}_k, x_k]$ and (e) ψ is strictly increasing on $[x_1, +\infty[$. Let

$$\begin{aligned}
&A = \{(x, y) \in \mathbb{R}^2 : x \geq 0 \ \text{ and } \ -\psi(x) \leq y \leq \psi(x)\},\\
&B = \{(x, y) \in \mathbb{R}^2 : x \leq |y|\},\\
&E = \{(x, y) \in \mathbb{R}^2 : x \geq 0 \text{ and } (\psi(x) \leq y \leq x \text{ or } -x \leq y \leq -\psi(x))\}.
\end{aligned}$$

Let L be the y axis. Then A, B, E, and L are closed subsets of $\mathbb{R}^2$. Let $\sigma : \mathbb{R}^2 \to \mathbb{R}$ be a function of class $\mathcal{C}^\infty$ such that $\sigma \equiv 0$ on $A \cup B$ and $\sigma > 0$ on $\mathbb{R}^2 \setminus (A \cup B)$. Let $\tau : \mathbb{R}^2 \to \mathbb{R}$ be a function of class $\mathcal{C}^\infty$ such that $\tau \equiv 0$ on $E \cup L$ and $\tau > 0$ on $\mathbb{R}^2 \setminus (E \cup L)$.

Consider the optimal control problem in $\mathbb{R}^2$ with target $\{(0, 0)\}$, in which the dynamics is given by

$$\dot{x} = u_1, \qquad \dot{y} = u_2\,,$$

the control constraints are $u_1 \in \{-1, 0, 1\}$ and $|u_1| + |u_2| = 1$, and the cost functional to be minimized is

$$J = \int_a^b \Big(u_1(t)^2\Big(1 + \sigma(x(t), y(t))\Big) + u_2(t)^2\tau(x(t), y(t))\Big)\, dt.$$

If $q = (\bar{x}, \bar{y}) \in \mathbb{R}^2$, and $[a, b] \ni t \to \xi(t) = (x(t), y(t))$ is any trajectory going from q to the origin, then $J(\xi) \geq \int_a^b u_1(t)^2\, dt = \int_a^b |u_1(t)|\, dt \geq |\int_a^b \dot{x}(t)\, dt| = |\bar{x}|$. On the other hand, there exists a trajectory ξ_q for which $J(\xi_q) = |\bar{x}|$. To see this, observe that purely vertical motion—i.e., $|u_2| = 1$ and $u_1 = 0$—costs nothing as long as it takes place in $E \cup L$, while horizontal motion—i.e., $|u_1| = 1$ and $u_2 = 0$—has a cost per unit time equal to 1 on $A \cup B$. If $q \in B$, then we can move horizontally towards the y axis—using $u_1 = -\mathrm{sgn}(\bar{x})$—and then move vertically along the y axis and end up at the origin, thereby obtaining a trajectory whose cost is exactly $|\bar{x}|$. If $q \in E$, then we can move vertically up or down—using $u_2 = \mathrm{sgn}(\bar{y})$—until we hit the boundary of B. Once we are in B, we follow the optimal trajectory already described for points of B, and end up producing a trajectory from q to the origin whose cost is $|\bar{x}|$. If $q \in A$ and $\bar{y} = 0$, then the constant control $u_1 = -1$, $u_2 = 0$ steers q to the origin with cost $\bar{x}$. If $q \in A$ and $\bar{y} \neq 0$, then we can use the constant control $u_1 = -1$, $u_2 = 0$ until we reach a point $(\hat{x}, \hat{y})$ such that $|\hat{y}| = \psi(\hat{x})$. The cost of this is clearly $\bar{x} - \hat{x}$, and $(\hat{x}, \hat{y})$ belongs to E, so we know how to go from $(\hat{x}, \hat{y})$ to the origin with cost $\hat{x}$. So we can go from q to the origin with cost $\bar{x}$.

Therefore the value function V for this problem is given by $V(x, y) = |x|$. Moreover, we have given an explicit description of a family $\Xi = \{\xi_q\}_{q\in\mathbb{R}^2}$ which is a total optimal synthesis.

We now show that Ξ *is the family of trajectories of a Boltyanskii regular synthesis whose set of cells is not locally finite.* To see this, we define N to be the set $[0, \infty[\, \times \{0\}$, so N is clearly piecewise smooth. We take $P^0 = \{(0, 0)\}$, and let P^1 be the union of the two coordinate axes, the two half-lines $L_1 = \{(x, x) : x \geq 0\}$ and $L_2 = \{(x, -x) : x \geq 0\}$, and the graphs of ψ and $-\psi$. Finally, we let $P^2 = \mathbb{R}^2$. It is then clear that P^0, P^1, and P^2 are piecewise smooth. The connected components of $P^1 \setminus (P^0 \cup N)$ are the open half-lines

$$\begin{aligned}
&\Lambda_1 = \{(x, x) : x > 0\}\,, &&\Lambda_2 = \{(0, y) : y > 0\}\,, &&\Lambda_3 = \{(x, 0) : x < 0\}\,,\\
&\Lambda_4 = \{(0, y) : y < 0\}\,, &&\Lambda_5 = \{(x, -x) : x > 0\}
\end{aligned}$$

and the arcs

$$\begin{aligned}
A_0^+ &= \{(x, \psi(x)) : x > x_1\}\,, & A_0^- &= \{(x, -\psi(x)) : x > x_1\}\,,\\
A_k^+ &= \{(x, \psi(x)) : x_{k+1} < x < x_k\}\,, & A_k^- &= \{(x, -\psi(x)) : x_{k+1} < x < x_k\}\,.
\end{aligned}$$

The connected components of $P^2 \setminus (P^1 \cup N)$ are the sets

$$\begin{aligned}
&U_1 = \{(x, y) : x > 0\,,\, \psi(x) < y < x\}\,, &&U_2 = \{(x, y) : 0 < x < y\}\,,\\
&U_3 = \{(x, y) : x < 0 < y\}\,, &&U_4 = \{(x, y) : x < 0\,,\, y < 0\}\,,\\
&U_5 = \{(x, y) : x > 0\,,\, y < -x\}\,, &&U_6 = \{(x, y) : x > 0\,,\, -x < y < -\psi(x)\}
\end{aligned}$$

and the bounded regions

$$\begin{gathered}
W_0^+ = \{(x, y) : x > x_1\,,\, 0 < y < \psi(x)\}\,,\ \ W_0^- = \{(x, y) : x > x_1\,,\, 0 > y > -\psi(x)\}\,,\\
W_k^+ = \{(x, y) : x_{k+1} < x < x_k\,,\, 0 < y < \psi(x)\}\,,\\
W_k^- = \{(x, y) : x_{k+1} < x < x_k\,,\, 0 > y > -\psi(x)\}\,.
\end{gathered}$$

The arcs A_0^+, A_0^-, A_k^+, and A_k^- and the half-lines Λ_1, Λ_5 are declared to be type II cells, and we choose

$$\Sigma(A_0^+) = \Sigma(A_k^+) = U_1\,, \quad \Sigma(A_0^-) = \Sigma(A_k^-) = U_6\,, \quad \Sigma(\Lambda_1) = U_2\,, \quad \Sigma(\Lambda_5) = U_5\,.$$

The remaining cells (that is, Λ_2, Λ_3, Λ_4, the U_i, W_0^+, W_0^-, the W_k^+ and the W_k^-) are type I cells. The feedback v is defined by letting

$$v \equiv \begin{cases} (-1, 0) & \text{on} \quad Z\,,\\ (1, 0) & \text{on} \quad U_3 \cup U_4\,,\\ (0, 1) & \text{on} \quad U_1 \cup \Lambda_4\,,\\ (0, -1) & \text{on} \quad U_6 \cup \Lambda_2\,,\end{cases}$$

where

$$Z = (N \setminus \{(0,0)\}) \bigcup (W_0^+ \cup W_0^-) \bigcup (\cup_k W_k^+) \bigcup (\cup_k W_k^-) \bigcup U_2 \bigcup U_5 .$$

The definitions of Π and Ξ^N are the obvious ones. It is then clear that all the conditions of the Boltyanskii definition are satisfied, but the set of cells is not locally finite.

Example 5.3. We now present an example of a synthesis that satisfies all the Brunovský conditions except for the continuity requirement (Br.3.G). This example will, in addition, exhibit the phenomenon of nonuniqueness of trajectories for the closed-loop equation arising from the optimal feedback, thereby providing a concrete illustration of the reasons for including as an extra ingredient a selection of trajectories, i.e., for following strategy (B) of section 4.

We construct and study in detail the time-optimal synthesis for the planar system:

$$\dot{q} = F(q) + u\,G(q)\,, \qquad |u| \le 1, \tag{5.1}$$

where

$$q \overset{\text{def}}{=} \begin{pmatrix} x \\ \\ y \end{pmatrix} \in \mathbb{R}^2\,, \qquad F(q) \overset{\text{def}}{=} \begin{pmatrix} 1 - \frac{y}{2} \\ \\ \frac{x+1}{2} \end{pmatrix}, \qquad G(q) \overset{\text{def}}{=} \begin{pmatrix} -\frac{y}{2} \\ \\ \frac{x+1}{2} \end{pmatrix}, \tag{5.2}$$

and the target is the origin of $\mathbb{R}^2$.

The trajectories of (5.1) corresponding to the constant control $u \equiv -1$ are straight horizontal lines going from left to right, while those corresponding to $u \equiv +1$ are circles centered at the point $(-1, 1)$, running counterclockwise. The optimal synthesis, to be determined below, is shown in Figure 2.

An arc $\gamma : [a, b] \to \mathbb{R}^2$ is *simple* if γ is an injective map. Clearly, all optimal trajectories are simple.

Since $G(q) = 0$ only for $q = (-1, 0)$, it is clear that a trajectory $\gamma : [a, b] \to \mathbb{R}^2$ uniquely determines the corresponding control $u(\cdot)$, unless the set $\{t : \gamma(t) = (-1, 0)\}$

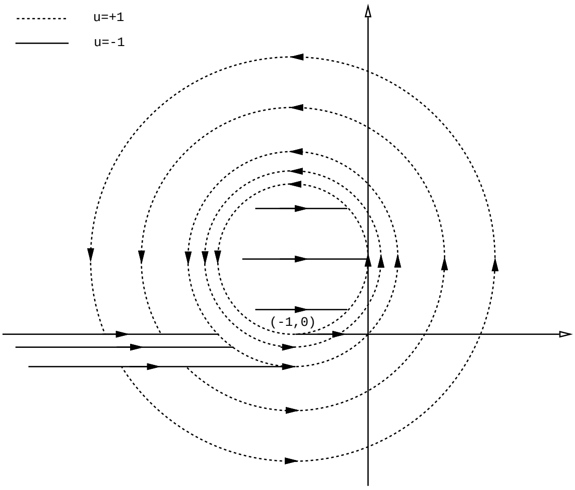

FIG. 2.

is of positive measure. In particular, for simple trajectories γ—the only ones that will be of interest to us—the control is uniquely determined by γ.

As in previous sections, we use $\mathbb{R}_k$ to denote the space of real row k-vectors. If Ω is an open subset of $\mathbb{R}^k$ and $X, Y : \Omega \to \mathbb{R}^k$ are vector fields of class C^1, then $[X, Y]$ will denote the Lie bracket of X and Y, so $[X, Y] = (DY).X - (DX).Y$.

If X, Y are $\mathbb{R}^2$-valued functions on a subset of $\mathbb{R}^2$, then (X, Y) will denote the 2×2 matrix with columns X, Y. In particular, following Sussmann [25], we define two real-valued functions Δ_A, Δ_B on $\mathbb{R}^2$, by letting

$$\Delta_A = \det(F, G) \qquad \Delta_B = \det(G, [F, G]) \tag{5.3}$$

where det stands for determinant. From the results of [25], we know that every extremal trajectory of (5.1) is a finite concatenation of "bang" and "singular" arcs. An arc is a *bang arc* if it is a B_- arc—i.e., a trajectory for the control $u = -1$—or a B_+ arc—i.e., a trajectory for $u = 1$. Singular arcs lie in the set of zeros of the function Δ_B. In our case,

$$\Delta_A = \frac{x+1}{2} \quad \text{and} \quad \Delta_B = -\frac{y}{4}, \tag{5.4}$$

so the only singular arcs are those entirely contained in the x axis, and these correspond to the control -1, so they actually are bang. So *all the extremals of our problem are bang-bang, that is, finite concatenations of bang arcs.*

If $\Delta_A(q) \neq 0$, then the vectors $F(q)$ and $G(q)$ are linearly independent, and we can define the numbers $f(q)$ and $g(q)$ as the coefficients of the linear combination:

$$[F, G](q) = f(q)F(q) + g(q)G(q). \tag{5.5}$$

Let Ω_A, Ω_B be, respectively, the sets $\{q : \Delta_A(q) \neq 0\}$, $\{q : \Delta_B(q) \neq 0\}$, and define $\Omega_{AB} = \Omega_A \cap \Omega_B$. It was proved in [25] that, if γ is an extremal trajectory and $\gamma(t) \in \Omega_{AB}$ for every t, then γ is bang-bang with at most one switching, and this switching can only be from the control value -1 to the value $+1$ if $f > 0$, and from $+1$ to -1 if $f < 0$. In our case, it follows from (5.4) that

$$\Omega_A = \{(x, y) : x \neq -1\}, \qquad \Omega_B = \{(x, y) : y \neq 0\}, \tag{5.6}$$

so Ω_{AB} is the union of four open quadrants $\Omega_{AB,i}$, $i = 1, 2, 3, 4$, defined by

$$\begin{aligned} \Omega_{AB,1} &= \{(x, y) : x > -1\,,\, y > 0\}, \\ \Omega_{AB,2} &= \{(x, y) : x < -1\,,\, y > 0\}, \\ \Omega_{AB,3} &= \{(x, y) : (x, -y) \in \Omega_{AB,2}\}, \\ \Omega_{AB,4} &= \{(x, y) : (x, -y) \in \Omega_{AB,1}\}. \end{aligned} \tag{5.7}$$

Moreover,

$$[F, G] = \begin{pmatrix} 0 \\ \frac{1}{2} \end{pmatrix} = \frac{y}{2(x+1)} F + \frac{2-y}{2(x+1)} G, \tag{5.8}$$

so $f > 0$ on $\Omega_{AB,1} \cup \Omega_{AB,3}$ and $f < 0$ on $\Omega_{AB,2} \cup \Omega_{AB,4}$. So the control switchings are from -1 to 1 on $\Omega_{AB,1} \cup \Omega_{AB,3}$ and from 1 to -1 on $\Omega_{AB,2} \cup \Omega_{AB,4}$.

To determine the optimal synthesis, we will first construct a "sufficient family" of trajectories for our problem, i.e., a collection $\mathcal{F}$ of simple trajectories such that every optimal trajectory ending at the target is in $\mathcal{F}$. We will then find, for every initial point q, a $\gamma_q \in \mathcal{F}$ such that if $\delta \in \mathcal{F}$ goes from q to 0 and $\delta \neq \gamma_q$, then δ is not optimal. Since the existence of optimal trajectories from any initial point follows by elementary arguments, we will be able to conclude that γ_q is optimal.

Suppose that $\gamma : [a,b] \to \mathbb{R}^2$ is time-optimal, $\gamma(b) = (0,0)$, $a < b$, and γ arises from an open-loop control $t \to u(t)$. Then γ is simple, and is a concatenation of finitely many maximal bang arcs. Since γ is an extremal, we can fix a nontrivial minimizing adjoint vector λ along γ and a constant $\lambda_0 \geq 0$ for which (EX4) holds. Define the *switching function*

$$\varphi(t) = \lambda(t) \cdot G(\gamma(t)).$$

The Hamiltonian minimization condition implies that

$$\varphi(t) \neq 0 \implies u(t) = -sgn(\varphi(t)). \tag{5.9}$$

Let $\delta : [c,d] \to \mathbb{R}^2$ be a maximal B_- piece of γ, so $c < d$ and δ is of the form:

$$\delta(t) = (x_0 + t, y_0). \tag{5.10}$$

For a.e. $t \in [c,d]$, we have $\dot{\lambda} = -\lambda \cdot D(F - G) = 0$. So $\lambda = (\lambda_1, \lambda_2)$ is constant, $(\lambda_1, \lambda_2) \neq (0,0)$, and

$$\varphi(t) = -\lambda_1 \frac{y_0}{2} + \lambda_2 \frac{x_0 + t + 1}{2} \tag{5.11}$$

is a linear function of t. Since a linear function cannot have more than one zero unless it vanishes identically, we conclude that $a < c < d < b$ can only be true if $\lambda_2 = y_0 = 0$. If $d = b$, then of course $y_0 = 0$, since $\gamma(b) = (0,0)$. So one of the following two possibilities occurs:

(I) δ is contained in the x axis,
(II) $a = c$.

This shows that all the maximal B_- pieces of γ are entirely contained in the x axis, with the only possible exception that the domain $[a,b]$ of γ may contain an initial segment $[a,d]$ such that $\gamma([a,d])$ is contained in a horizontal line for which $y \neq 0$.

Let us now analyze the adjoint equation for a maximal B_+ piece $\delta : [c,d] \to \mathbb{R}^2$ of γ, such that $c < d$. Clearly, δ is of the form

$$x(t) = -1 + r\cos(t+\theta)\,, \qquad y(t) = 1 + r\sin(t+\theta)\,, \qquad c \leq t \leq d, \tag{5.12}$$

where r, θ are constants, $r > 0$, and $\theta \in [0, 2\pi]$. (The possibility that $r = 0$ is obviously excluded, because γ is time-optimal and $c < d$.) The components λ_1, λ_2 of λ satisfy $\dot{\lambda}_1 = -\lambda_2$ and $\dot{\lambda}_2 = \lambda_1$, so there exist constants $A > 0$, $\theta_1 \in [0, 2\pi]$, such that

$$\lambda_1(t) = A\cos(t+\theta_1)\,, \qquad \lambda_2(t) = A\sin(t+\theta_1), \qquad c \leq t \leq d. \tag{5.13}$$

Therefore, up to multiplication by a positive constant,

$$\varphi(t) = -\cos(t+\theta_1) + r\sin(\theta_1 - \theta). \tag{5.14}$$

Now suppose that one of the two endpoints c, d of the domain of δ is a switching time and the corresponding point in $\mathbb{R}^2$ lies in the x axis. That is, we assume that $h \in \{c, d\}$ is such that $\varphi(h) = 0$ and $y(h) = 0$. Then

$$r\sin(h+\theta) = -1, \tag{5.15}$$

so

$$\begin{aligned}\varphi(t) &= -\cos(t+\theta_1) + r(\sin(h+\theta_1)\cos(h+\theta) - \cos(h+\theta_1)\sin(h+\theta)) \\ &= -\cos(t+\theta_1) + \cos(h+\theta_1) + r\sin(h+\theta_1)\cos(h+\theta).\end{aligned} \tag{5.16}$$

In particular,

$$0 = \varphi(h) = r\sin(h+\theta_1)\cos(h+\theta), \tag{5.17}$$

so $\varphi(t) = -\cos(t+\theta_1)+\cos(h+\theta_1)$. If $r \neq 1$, then (5.15) implies $0 \geq \sin(h+\theta) \neq -1$, so $\cos(h+\theta) \neq 0$. But then (5.15) implies $\sin(h+\theta_1) = 0$, so $\cos(h+\theta_1) = \pm 1$. The possibility that $\cos(h+\theta_1) = 1$ is excluded, for in that case φ would be > 0 throughout $]\,c, d\,[$, contradicting the minimization condition. So $\varphi(t) = -1 - \cos(t+\theta_1)$. This shows that $\varphi(t) < 0$ for $t \in [c,d] \setminus \{h\}$, unless $d - c = 2\pi$. But if $d - c = 2\pi$, then γ would not be simple. So $d - c < 2\pi$, and we have shown that the other endpoint h' of $[c,d]$ cannot be a switching point, and therefore $h' \in \{a, b\}$.

It then follows that one of the following possibilities must occur:

(i) $d = b$;

(ii) $a = c < d < b$ and $\gamma(d)$ lies in the x axis;

(iii) $a < c < d < b$ and $\gamma(d) = (-1, 0)$.

Indeed, if $d < b$ but $\gamma(d)$ is not in the x axis, then we could let δ' be the maximal B_- piece of γ that starts at time d, and our analysis of the B_- pieces of γ, applied to δ', would show that δ' cannot in fact occur, since δ' is not an initial segment of γ and is not contained in the x axis. So, if $d < b$, then $\gamma(d)$ lies in the x axis, and d is a switching time of γ. Our previous argument shows that $c = a$, unless $r = 1$. But if $r = 1$, and $\gamma(d)$ is in the x axis, then $\gamma(d) = (-1, 0)$. So $d < b$ implies that either (ii) or (iii) must hold.

We now combine the results about the two types of pieces and provide a complete description of the optimal trajectories ending at the origin. Let us use L, L_0, C to denote, respectively, the trajectory types "B_- and not contained in the x axis," "B_- and contained in the x axis," and "B_+." (The symbols L and C stand for "line" and "circle.") Let us use $T_1T_2\ldots T_m$ to denote the trajectory type "T_1 followed by T_2 $\ldots$ followed by T_m."

With this notation, we now show that *a nontrivial optimal trajectory γ ending at the origin is of one of the following seven types*: L_0, C, L_0C, LC, CL_0, LCL_0, CL_0C. First, concatenations of six or more types are ruled out as follows: any such concatenation would have to contain at least three different C pieces; at most one of them can satisfy (i) and at most one can satisfy (ii); if both of these possibilities occurred, then we would have a concatenation of the form $C * C * C$, i.e., five pieces rather than six; so there must be two different pieces satisfying (iii), and then γ would go at least twice through the point $(-1, 0)$, and would not be simple. Next, all concatenations containing an L_0CL_0 sequence are excluded, because if γ is any such concatenation, then the C piece that lies between the two L_0s would have to satisfy (iii), so its last switching would have to happen at $(-1, 0)$; then the C piece would have to be an arc of the circle with center $(-1, 1)$ and radius 1, which intersects the x axis only at $(-1, 0)$; then the other switching would also happen at $(-1, 0)$, and γ would not be simple. A five-piece concatenation must be CL_0CL_0C, LCL_0CL_0, or $L_0CL_0CL_0$, because every B_- piece must satisfy (I) or (II), so it cannot be an L unless it is the first piece. So all such concatenations contain an L_0CL_0 piece and are therefore excluded. A four-piece concatenation must be CL_0CL_0, L_0CL_0C, or

LCL_0C. The types CL_0CL_0 and L_0CL_0C are ruled out because they contain an L_0CL_0 triple. The type LCL_0C is excluded because the first C would have to satisfy (iii), so the switching from C to L_0 would have to happen at $(-1, 0)$; then the L_0 piece following the switching has to be a segment going from $(-1, 0)$ to a point $(\alpha, 0)$ and α must satisfy $-1 < \alpha < 0$, for if α was ≥ 0, then the L_0 piece would already reach the origin before switching to the last C; and if $-1 < \alpha < 0$, then the C arc starting at $(\alpha, 0)$ does not go through the origin. So all four-piece concatenations are excluded. Of the three-piece possibilities, CLC, LCL, and L_0CL are excluded because an L piece can occur only at the beginning of the sequence, and we also know that L_0CL_0 is excluded. So only CL_0C and LCL_0 are left. Of the two- and one-piece concatenations, CL and L are obviously excluded, and we are left with L_0, C, CL_0, L_0C, and LC.

The LCL_0 trajectories are further restricted by the condition that the switching from C to L_0 must happen at the point $(-1, 0)$. Let us call those LCL_0 trajectories that satisfy this extra condition "good."

Let $\mathcal{F}$ be the set of all simple trajectories that end at the origin and are either of one of the six types L_0, C, L_0C, LC, CL_0, CL_0C, or of type LCL_0 and good. We have shown that every optimal trajectory belongs to $\mathcal{F}$. It will turn out that the optimal synthesis involves all seven types listed above, but not all trajectories of one of these types are optimal, so we need a finer analysis.

To begin with, observe that $\dot{x} = 1 - y$ along a B_+ arc, so $\dot{x} > 1$ along a B_+ arc as long as $y < 0$. Therefore, if $q_1 = (x_1, y_1)$ and $q_2 = (x_2, y_2)$ satisfy $y_1 = y_2 \leq 0$, $x_1 < x_2$, and $x_1 + x_2 = -2$, so that q_1 and q_2 can be joined both by a C arc and an L (or L_0) arc, then the C arc is contained in the lower half-plane, and is faster than the L or L_0 arc. In particular, if we let $L_0(\beta)$ denote, for $\beta > 0$, the L_0 arc going from $(-\beta, 0)$ to $(0, 0)$, we see that $L_0(\beta)$ *is not optimal if* $1 < \beta \leq 2$, because the piece of L_0 going from $(-\beta, 0)$ to $(-2 + \beta, 0)$ can be replaced by a faster type C arc. Then the principle of optimality implies that $L_0(\beta)$ *is not optimal if* $1 < \beta$, because if $\beta > 2$, then $L_0(\beta)$ contains $L_0(2)$, which is not optimal.

Next we show that $L_0(1)$ *is optimal.* It suffices to notice that there is no trajectory from $(-1, 0)$ to $(0, 0)$ of any of the types C, LC, LCL_0, and exactly one trajectory of each of the types L_0, L_0C, CL_0, and CL_0C, but the last three are not simple, so $L_0(1)$ is left as the only possible candidate. It then follows from the principle of optimality that $L_0(\beta)$ *is optimal for* $0 \leq \beta \leq 1$.

We now study the optimal trajectories that are of one of the types C, L_0C, LC, and CL_0C. Let $\gamma : [a, b] \to \mathbb{R}^2$ be such a trajectory, and take $b = 0$, so $\gamma(0) = (0, 0)$.

If γ is a C arc, then $a > -2\pi$, for otherwise γ would contain a full loop. For $0 < a < 2\pi$, we let $C(a)$ be the C arc $\gamma : [-a, 0] \to \mathbb{R}^2$ such that $\gamma(0) = (0, 0)$. It will be shown below that the arcs $C(a)$ are all optimal.

Next suppose that γ is LC. Since the C piece satisfies (5.12), we must have $r = \sqrt{2}$ and $\theta = \frac{7\pi}{4}$. Let c be the time when the switching from L to C occurs, so $-2\pi < c < 0$, for if $c \leq -2\pi$, then γ would not be simple. On $[c, 0]$, the switching function φ is given, up to multiplication by a positive constant, by

$$\varphi(t) = \sqrt{2} \sin\Big(\theta_1 - \frac{7\pi}{4}\Big) - \cos(t + \theta_1) = \sin\theta_1 + \cos\theta_1 - \cos(t + \theta_1).$$

So

$$\varphi(t) = (1 + \sin t) \sin\theta_1 + (1 - \cos t). \cos\theta_1.$$

Suppose that $\sin\theta_1 = 0$. Then $\cos\theta_1 = \pm 1$, so $\cos\theta_1 = -1$, because $\varphi(t) < 0$ when t

is negative and close to 0, since $u(t) = +1$ for such t. So $\varphi(t) = \cos t - 1$, and then $\varphi(c) \neq 0$, since $-2\pi < c < 0$. Since $\varphi(c) = 0$, we conclude that $\sin\theta_1 \neq 0$. We can then define

$$\psi(t) = \frac{1+\sin t}{1-\cos t}\,, \qquad \nu = \frac{\cos\theta_1}{\sin\theta_1}\,.$$

Then ψ is well defined and smooth on $[c,0\,[$, and $\psi(t)$ goes to $+\infty$ as $t \uparrow 0$. Moreover, φ can be expressed as $\varphi(t) = \sin\theta_1.(1-\cos t).(\nu+\psi(t))$ for $t \in [c,0\,[$. Therefore $\sin\theta_1 < 0$, and $\psi(c) = -\nu$, since $1-\cos c \neq 0$, because $-2\pi < c < 0$. Clearly, $\psi(t) \geq 0$ for all $t \in]-2\pi, 0\,[$, and ψ attains the value 0 on $]-2\pi, 0\,[$ at $t = -\frac{\pi}{2}$ and nowhere else. A simple calculation shows that ψ is strictly increasing on $]-\frac{\pi}{2}, 0\,[$. If $\nu > 0$, then $\psi + \nu$ never vanishes on $]-2\pi, 0[$, so $\varphi(c) \neq 0$. So $\nu \leq 0$. If $\nu = 0$, then $\psi(c) = -\nu$ implies $c = -\frac{\pi}{2}$. If $\nu < 0$, then ψ must take the value $-\nu$ at some point $t(\nu)$ such that $-\frac{\pi}{2} < t(\nu) < 0$, because $\psi(-\frac{\pi}{2}) = 0$ and $\psi(0-) = +\infty$. Since ψ is strictly increasing on $]-\frac{\pi}{2}, 0\,[$, we see that $t(\nu)$ is unique, and φ changes sign at $t(\nu)$. If $c < t(\nu)$, we would contradict the fact that φ has constant sign on $[c, 0]$. On the other hand, it is impossible that $c > t(\nu)$, because then the equation $\psi(t) = -\nu$ would have two solutions on $]-\frac{\pi}{2}, 0\,[$. So $c = t(\nu)$, and we have proved that $-\frac{\pi}{2} \leq c < 0$. If $-\frac{\pi}{4} < c$, then $\gamma(c) \in \Omega_{AB,4}$, and the switching is not permitted. So the only possibility left to us is $-\frac{\pi}{2} \leq c \leq -\frac{\pi}{4}$. If $c = -\frac{\pi}{2}$, then we really have an L_0C arc rather than an LC arc. So the only LC arcs that could be optimal are those for which $-\frac{\pi}{2} < c \leq -\frac{\pi}{4}$.

For $0 < \sigma < 2\pi$, $s > 0$, let $LC(s,\sigma)$ denote the trajectory defined on the interval $[-s-\sigma, 0]$ that ends at the origin and corresponds to a $u = -1$ control on $[-s-\sigma, -\sigma]$ followed by a $u = 1$ control on $[-\sigma, 0]$. We have shown that *$LC(s,\sigma)$ is not optimal unless $\frac{\pi}{4} \leq \sigma < \frac{\pi}{2}$.* We now show that *if $\frac{\pi}{4} \leq \sigma < \frac{\pi}{2}$, then $LC(s,\sigma)$ is optimal.* To see this, let $q = (x,y)$ be the starting point of $LC(s,\sigma)$, for $s > 0$, $\frac{\pi}{4} \leq \sigma < \frac{\pi}{2}$. Then $1-\sqrt{2} \leq y < 0$. It is clear that $LC(s,\sigma)$ is the only simple LC trajectory from q to $(0,0)$. Also, it is easy to see that there are no trajectories from q to $(0,0)$ of the types L_0, C, L_0C, or good LCL_0. There is exactly one CL_0 trajectory, but it is easy to see that the time $\hat{\tau}$ along this trajectory is larger than the time τ along $LC(s,\sigma)$. (Actually, $\tau = s + \sigma < |x| < \hat{\tau} - \frac{3\pi}{2}$.) Finally, there is exactly one CL_0C trajectory γ, which can also be ruled out. (Let $\bar{x} = -1 - \sqrt{2-(y-1)^2}$, so $\bar{q} = (\bar{x}, y)$ is the point where $LC(s,\sigma)$ switches from L to C. Then both $LC(s,\sigma)$ and γ go through $\bar{q}$ and coincide from that point on. So it suffices to compare the parts of $LC(s,\sigma)$ and γ up to $\bar{q}$. The time along $LC(s,\sigma)$ up to $\bar{q}$ is $s = \bar{x} - x$ and that along γ is $> \sqrt{(1+x)^2+(1-y)^2} - \sqrt{2} + \frac{3\pi}{2}$. So we have to show that $\alpha > 0$, where

$$\begin{aligned}\alpha &= \sqrt{(1+x)^2+(1-y)^2} - \sqrt{2} + \frac{3\pi}{2} - (\bar{x}-x)\\ &= \sqrt{(1+x)^2+(1-y)^2} - \sqrt{2} + \frac{3\pi}{2} + x + 1 + \sqrt{2-(y-1)^2}.\end{aligned}$$

Then, using the fact that $\sqrt{a} + \sqrt{b} \geq \sqrt{a+b}$ when $a \geq 0$ and $b \geq 0$, we get the inequalities

$$\begin{aligned}\alpha &\geq \sqrt{(1+x)^2+2} - \sqrt{2} + \frac{3\pi}{2} + x + 1\\ &> \sqrt{(1+x)^2} + x + 1\\ &= |1+x| + 1 + x \geq 0,\end{aligned}$$

as desired.)

For $s > 0$, we let $L_0C(s)$ denote the trajectory that consists of a B_- arc during time s followed by a B_+ arc during time $\frac{\pi}{2}$, and ending at the origin. Then it is easily shown that *$L_0C(s)$ is optimal for every $s > 0$.* (Indeed, if $q = (x, 0)$ is the starting point of $L_0C(s)$, for $s > 0$, then $L_0C(s)$ is the only simple L_0C trajectory from q to $(0, 0)$, and there are no simple trajectories from q to $(0, 0)$ of the types C, LC, CL_0, LCL_0, or CL_0C. There is an L_0 arc, namely, $L_0(|x|)$, but we know that this arc is not optimal because $|x| > 1$.)

Now define

$$R_1 = \{(0,0)\}\,, \qquad R_2 =]-1,0[\times\{0\}\,, \qquad R_3 = \{(-1,0)\}.$$

For $q = (0, 0)$, let γ_q be the trajectory γ with domain $\{0\}$ such that $\gamma(0) = (0, 0)$. If $q = (x, 0)$ belongs to $R_2 \cup R_3$, let $\gamma_q = L_0(|x|)$. Then the γ_q, for $q \in R_1 \cup R_2 \cup R_3$, are optimal.

For $r > 0$, let $D(r)$ be the open disc with center $(-1, 1)$ and radius r, and let $\partial D(r)$ denote the boundary of $D(r)$. Let

$$R_4 = D(1)\,, \qquad R_5 = \partial D(1)\backslash\{(-1,0)\}.$$

Then every point $q \in R_4$ can be joined to $(0, 0)$ by a unique good LCL_0 trajectory. We use γ_q to denote this trajectory. Then *the arcs γ_q, for $q \in R_4$, are optimal.* (To see this, observe that if $q \in R_4$, then the only trajectories other than γ_q that are of one of our seven types and go from q to the origin are either LCL_0 but not good or not simple, or LC with a switching from L to C at a time c that violates the requirement that $-\frac{\pi}{2} < c$. So all the alternative candidates are excluded, and γ_q must be the optimal trajectory.)

A similar argument shows that *if $q \in R_5$ and γ_q is the unique CL_0 trajectory going from q to $(0, 0)$, then γ_q is optimal.*

Next, let

$$R_6 = D(\sqrt{2})\backslash(R_2 \cup R_3 \cup R_4 \cup R_5).$$

If $q \in R_6$, then the obvious candidate for optimality is the arc γ_q of type CL_0 obtained by following the C arc that starts at q until R_2 is reached, and then continuing along R_2 towards the origin. We now prove that *the arcs γ_q, $q \in R_6$, are optimal.* To see this, observe that if $q = (x, y) \in R_6$, then there are no simple arcs from q to $(0, 0)$ of the types C, L_0C, CL_0C. If $y \neq 0$, then there are no L_0 arcs either. If $y = 0$, then there is an L_0 arc, but it is $L_0(\beta)$ for $\beta = |x| > 1$, so it is not optimal. If $y \neq 0$, then there is an LC arc, but (i) if $y < 0$, then this arc switches from L to C in $\Omega_{AB,4}$, so it is not optimal; (ii) if $y > 0$, then the arc is $LC(s, \sigma)$ for some $\sigma \in]\,5\pi/4, 2\pi\,[$, so it is not optimal either. If $y \leq 0$, then γ_q is the only simple CL_0 arc, and if $y > 0$, then there are two such arcs, but the other one is not optimal, because it contains $L_0(\beta)$ for some $\beta > 1$. So we have ruled out all the alternative candidates to γ_q other than good LCL_0 arcs. We now exclude this possibility too, by doing it first for the case when $y \neq 2$. If $y \leq 0$ or $y > 2$ or $x \geq -1$, then there is no good LCL_0 arc. If $0 < y < 2$ and $x < -1$, then there is a good LCL_0 arc, but it switches from L to C at a point in $\Omega_{AB,2}$, so this arc is not optimal. So now all the alternative possibilities have been ruled out if $q = (x, y) \in R_6$ is such that $y \neq 2$ or $y = 2$ and $x > -1$. So γ_q is optimal for all such q's. Suppose now that $y = 2$ and $x < -1$. Then there is a good LCL_0 arc γ, which switches from L to C at the point $p = (-1, 2)$. This arc can be ruled out in a number of ways, of which the following qualitative argument appears to be the shortest. Let γ be defined on $[T,0]$. Let α be a small positive number—actually, any α such that $0<\alpha<\pi$ will do—and let $\tilde{\gamma}:[T-\alpha,0]\to\mathbb{R}^2$ be the trajectory such that $\tilde{\gamma}(t)=\gamma(t)$ for $t\in[T,0]$ and $\tilde{\gamma}$ is a B_+ arc on $[T-\alpha,T]$. Let $(\tilde{x},\tilde{y})=\tilde{q}=\tilde{\gamma}(T-\alpha)$. Then $\tilde{q}$ also belongs to R_6, but it's not true that $\tilde{y}=2$ and $\tilde{x}<-1$. So we already know that $\gamma_{\tilde{q}}$ is the unique optimal arc from $\tilde{q}$ to the origin. Since γ_q is a cofinal piece of $\gamma_{\tilde{q}}$, the principle of optimality implies that γ_q is optimal as well. If γ was optimal, then γ_q and γ would go from q to 0 in the same time, so $\gamma_q(T)=\gamma_{\tilde{q}}(T)=q$. Let $[\tilde{T},0]$ be the domain of $\gamma_{\tilde{q}}$, and define $\delta:[\tilde{T},0]\to\mathbb{R}^2$ by letting δ agree with $\gamma_{\tilde{q}}$ on $[\tilde{T},T]$ and with γ on $[T,0]$. Then δ is an optimal arc from $\tilde{q}$ to 0, and δ is $CLCL_0$. This, however, is impossible, because we know that $CLCL_0$ is excluded. So we have now completed the proof that *for each $q\in R_6$, γ_q is the unique optimal arc from q to the origin.*

Next, we define five sets R_7, R_8, R_9, R_{10}, R_{11} by letting

$$\begin{aligned}
R_7 &= \partial D(\sqrt{2})\cap\Big(\mathbb{R}\times\,]\,0,+\infty\,[\,\Big),\\
R_8 &= \Big\{(-2,0)\Big\},\\
R_9 &= \Big\{(x,y)\in\partial D(\sqrt{2}):-2<x<-1,\ y<0\Big\},\\
R_{10} &= \Big\{(-1,1-\sqrt{2})\Big\},\\
R_{11} &= \Big\{(x,y)\in\partial D(\sqrt{2}):-1<x<0,\ y<0\Big\}.
\end{aligned}$$

Then the sets R_1, R_7, R_8, R_9, R_{10}, and R_{11} are pairwise disjoint and

$$\partial D(\sqrt{2})=R_1\cup R_7\cup R_8\cup R_9\cup R_{10}\cup R_{11}.$$

For $q\in R_7\cup R_8\cup R_9\cup R_{10}\cup R_{11}$ there is a unique trajectory γ_q of type C going from q to $(0,0)$. The optimality of γ_q for $q\in R_7\cup R_8\cup R_9\cup R_{10}\cup R_{11}$ is proved by considerations similar to those used for R_6.

We let

$$\begin{aligned}
R_{12} &= \,]-\infty,-2\,[\,\times\{0\},\\
R_{13} &= \{(x,y):1-\sqrt{2}<y<0\,,\ x<-1\,,\ (x+1)^2+(1-y)^2>2\},\\
R_{14} &= \,]-\infty,-1\,[\,\times\{1-\sqrt{2}\}.
\end{aligned}$$

Then $R_{13}\cup R_{14}$ is exactly the set of starting points q of the trajectories $LC(s,\sigma)$, for $s>0$, $\frac{\pi}{4}\le\sigma<\frac{\pi}{2}$, and we know that for each $q\in R_{13}\cup R_{14}$ the $LC(s,\sigma)$ trajectory is unique and optimal. We define γ_q to be this trajectory. A similar fact is true for R_{12}, with $L_0C(s)$ rather than $LC(s,\sigma)$ in the role of γ_q.

Finally, we let

$$R_{15}=\mathbb{R}^2\backslash(R_1\cup\cdots\cup R_{14}).$$

For $q\in R_{15}$, we let γ_q be the unique simple CL_0C trajectory from q to $(0,0)$. We show that γ_q *is optimal for all $q\in R_{15}$*. Let $q\in R_{15}$, and let $\gamma\in\mathcal{F}$ be an extremal trajectory starting at q and verifying $\gamma(0)=0$. It is then obvious that γ is not of type L_0, C, or L_0C. The case LC is impossible, because in that case γ would have a switching at a time c such that $c<-\pi/2$. If γ is of type CL_0, then it contains an $L_0(\beta)$ piece, with $\beta>1$, and we know that any such piece is nonoptimal, so γ is not optimal. Finally, if γ is of type LCL_0 and good, then $\gamma(t) = p = (x_p, y_p) \in R_5$ for some t. It is clear that $y_p > 0$. If $x_p > -1$, then γ is not simple, so this possibility is excluded. If $x_p \leq -1$, then we can pick a positive ε such that $\hat{q} = \gamma(t - \varepsilon)$ is in R_6. Then the restriction $\hat{\gamma}$ of γ to the interval $[t - \varepsilon, 0]$ is a good LCL_0 trajectory from $\hat{q}$ to 0. Since $\hat{q} \in R_6$, we know that $\hat{\gamma}$ is not optimal. So γ is not optimal either, by the principle of optimality.

We have now completely analyzed the minimum time problem with target set $\{(0,0)\}$ for every initial condition q, and proved in all possible cases that γ_q is the unique solution whose terminal time is 0. So the synthesis $\Gamma = \{\gamma_q\}_{q \in \mathbb{R}^2}$ shown in Figure 2 is optimal, and is the unique optimal presynthesis. The partition $\mathcal{P} = (R_1, \ldots, R_{15})$ is a C^1—and, actually, C^ω—stratification of $\mathbb{R}^2$.

Let us define the feedback control $(x, y) \to v(x, y)$ by letting

$$v = \begin{cases} 0 & \text{on} \quad R_1\,, \\ -1 & \text{on} \quad R_2 \cup R_3 \cup R_4 \cup R_{12} \cup R_{13} \cup R_{14}\,, \\ +1 & \text{on} \quad R_5 \cup R_6 \cup R_7 \cup R_8 \cup R_9 \cup R_{10} \cup R_{11} \cup R_{15}\,. \end{cases}$$

We let

$$\begin{aligned} \mathcal{P}_1 &= \{R_2, R_4, R_5, R_6, R_7, R_9, R_{11}, R_{12}, R_{13}, R_{14}, R_{15}\}, \\ \mathcal{P}_2 &= \{R_3, R_8, R_{10}\}. \end{aligned}$$

We then define

$$\begin{array}{llll} \Pi(R_2) = R_1\,, & \Pi(R_4) = R_5\,, & \Pi(R_5) = R_3\,, & \Pi(R_6) = R_2\,, \\ \Pi(R_7) = R_8\,, & \Pi(R_9) = R_{10}\,, & \Pi(R_{11}) = R_1\,, & \Pi(R_{12}) = R_8\,, \\ \Pi(R_{13}) = R_9\,, & \Pi(R_{14}) = R_{10}\,, & \Pi(R_{15}) = R_{12}\,, & \Sigma(R_3) = R_2\,, \\ \Sigma(R_8) = R_9\,, & \Sigma(R_{10}) = R_{11}\,. & & \end{array}$$

Then $(\mathcal{P}, \mathcal{P}_1, \mathcal{P}_2, \Pi, \Sigma, v)$ is a regular synthesis that satisfies all the conditions of Brunovský's definition, except for the continuity requirement (Br.3.G) on the cost function V_Γ. On the other hand, it is easy to verify that V_Γ *satisfies the weak continuity conditions.* So $(\mathcal{P}, \mathcal{P}_1, \mathcal{P}_2, \Pi, \Sigma, v)$ gives rise to a "regular synthesis" in the sense of our definition.

Moreover, it is clear that *the* $+1$ *trajectory starting from the point* $(-1, 0)$ *is an admissible classical trajectory for the optimal feedback control but is not optimal.* So this example illustrates a very important positive aspect of the Boltyanskii–Brunovský's definition, namely, the role of the "instantaneous exit map" Σ. To understand how Σ matters, let us suppose we did not specify Σ, and allowed all the classical trajectories of the discontinuous feedback v. Then we could, for example, start from the type II cell $R_3 = \{(-1, 0)\}$ and follow the trajectory corresponding to the control $+1$ up to time 2π, returning to the starting point, after which we could go to the origin using the control -1. The curve γ_1 defined in this way is also an admissible classical trajectory of v, but it is clear that γ_1 is not time optimal. Even worse, we can define a trajectory γ_2 of v, with domain $[0, +\infty[$, corresponding to the constant control $+1$ and starting from $(-1, 0)$. This trajectory neither reaches the origin in finite time nor approaches it as time goes to infinity. Notice that the trajectories γ_1 and γ_2 satisfy the equation $\dot{\gamma}(t) = f(\gamma(t), v(\gamma(t)))$ for every t in their domain, so they satisfy the equation corresponding to the discontinuous feedback v in the classical sense. However, if we regard it as part of the specification of our synthesis that Σ has to be given as well, then the difficulty disappears.

Example 5.4. We now exhibit an optimal synthesis in Brunovský's sense that does not satisfy condition (Bo.4) of Boltyanskii's definition. We consider the minimum time problem for the system

$$\dot{x} = u, \qquad \dot{y} = v, \qquad \dot{z} = \frac{w}{\sqrt{1+x^2+y^2}},$$

with target $\{(0,0,0)\}$ and control constraint $(u,v,w) \in U$, where U is the set of those $(u,v,w) \in \mathbb{R}^3$ such that $(u^2+v^2)^{1/2} + |w| \leq 1$, i.e., the solid of revolution obtained by rotating the square $\{(u,w) : |u| + |w| \leq 1\}$ in the u,w-plane about the w axis. Define the sets

$$\begin{aligned} R_0 &= \{(0,0,0)\}, & R_3 &= \{(x,y,z) : x^2+y^2 > 0,\, z = 0\}, \\ R_1 &= \{(x,y,z) : x = y = 0,\, z > 0\}, & R_4 &= \{(x,y,z) : x^2+y^2 > 0,\, z > 0\}, \\ R_2 &= \{(x,y,z) : x = y = 0,\, z < 0\}, & R_5 &= \{(x,y,z) : x^2+y^2 > 0,\, z < 0\}. \end{aligned}$$

We then define a feedback control law $(u,v,w) : \mathbb{R}^3 \to U$ by specifying its restriction $R_i \ni (x,y,z) \to (u_i(x,y,z), v_i(x,y,z), w_i(x,y,z)) \in \mathbb{R}^3$ for every R_i as follows:

$$\begin{aligned} & u_0 = v_0 = w_0 = 0, & & u_3 = u_4 = u_5 = -\frac{x}{\sqrt{x^2+y^2}}, \\ & u_1 = v_1 = 0,\ w_1 = -1, & & v_3 = v_4 = v_5 = -\frac{y}{\sqrt{x^2+y^2}}, \\ & u_2 = v_2 = 0,\ w_2 = 1, & & w_3 = w_4 = w_5 = 0. \end{aligned} \tag{5.18}$$

If we follow the trajectories of this feedback starting from a point $(x,y,z) \in R_3 \cup R_4 \cup R_5$, we move horizontally towards the z axis with speed 1, and then, if we are not yet at the origin, we move to the origin along the z axis with speed 1. This obviously gives rise to a synthesis Γ, and it is possible to prove that Γ is optimal by applying Theorem 2.13. However, in this case it is easy to verify directly that the associated cost function

$$V_\Gamma = |z| + \sqrt{x^2+y^2}$$

is the value function of our problem. Indeed, since V_Γ is the cost function arising from the synthesis Γ, all we need is to show that the cost $b-a$ of any trajectory $[a,b] \ni t \to \xi(t) = (x(t), y(t), z(t))$ from a point $\bar{q} = (\bar{x}, \bar{y}, \bar{z})$ to the origin is bounded below by $V_\Gamma(\bar{q})$.

Assume first that $x(t)^2 + y(t)^2 > 0$ for all $t \in]\,a,b\,[$, and let $t \to (u(t), v(t), w(t))$ be the corresponding control. Write $\rho(t) = \sqrt{u(t)^2 + v(t)^2}$. Then an elementary calculation shows that

$$\begin{aligned} \frac{d}{dt}\Big(V_\Gamma(\xi(t))\Big) &= \frac{u(t).x(t) + v(t).y(t)}{\sqrt{x(t)^2+y(t)^2}} + \operatorname{sgn}(z(t)).\frac{w(t)}{\sqrt{1+x(t)^2+y(t)^2}} \\ &\geq -\rho(t) - |w(t)| \geq -1. \end{aligned}$$

Therefore, since the function $t \to V_\Gamma(\xi(t))$ is Lipschitz, and hence absolutely continuous, we can conclude that

$$V_\Gamma(\bar{q}) = -\int_a^b \frac{d}{dt}\Big(V_\Gamma(\xi(t))\Big)\,dt \leq b - a.$$

Now, if $\xi : [a, b] \to \mathbb{R}^3$ is an arbitrary trajectory from $\bar{q}$ to the origin, then ξ can be approximated by a sequence of trajectories $\xi_j : [a_j, b_j] \to \mathbb{R}^3$ from $\bar{q}$ to $(0, 0, 0)$ such that $\xi_j(t)$ is not in the z axis for $a_j < t < b_j$. Then $b_j - a_j \geq V_\Gamma(\bar{q})$ for all j, so $b - a \geq V_\Gamma(\bar{q})$. Therefore Γ is an optimal synthesis.

Notice that in this case $\Pi(R_4) = R_1$, $\Pi(R_5) = R_2$, and $\Pi(R_3) = R_0$. So the optimal synthesis Γ does not satisfy the conditions of Boltyanskii's definition, because (Bo.4) is violated, since the dimension of the exit manifold from R_i is equal to $\dim(R_i) - 2$ for $i = 3, 4, 5$.

Remark 5.5. In Example 5.4 the optimal pair (γ_q, η_q) starting at q is unique for every q, and is a classical solution of the closed-loop equation corresponding to the optimal feedback law defined by (5.18).

On the other hand, it is easy to see that *the optimal trajectories are not Filippov solutions of the optimal closed-loop equation.* Finally, we point out that, *although the optimal trajectories are CLSS solutions, it is not true that all CLSS solutions of the optimal closed-loop equation are optimal trajectories.* For example, if the initial condition is a point q which is not in the z axis and also not in the plane $z = 0$, then most CLSS solutions $t \to \gamma(t)$ will never switch at a time t such that $\gamma(t)$ lies in the z axis, and will therefore be entirely contained in a plane $z =$ constant, without ever reaching the target. □

Example 5.6. We now exhibit an example of an optimal synthesis for which it is not true that all the optimal trajectories are CLSS solutions of the optimal closed-loop equation.

Consider the optimal control problem in $\mathbb{R}$, with control space $U = \mathbb{R}$, dynamics given by $\dot{x} = u$, Lagrangian $L = (u^4 - x^2)^2$, and target $\{1\}$. The value function V is given by $V(x) \equiv 0$. The feedback control law v defined by

$$v(x) = \operatorname{sgn}(1 - x).\sqrt{|x|}$$

leads to trajectories $\gamma_x : [T_x, 0] \to \mathbb{R}$, corresponding to open-loop controls $\eta_x : [T_x, 0] \to \mathbb{R}$, given by the formulas

$$T_x = 2.\operatorname{sgn}(1 - x).\Big(\operatorname{sgn}(x).\sqrt{|x|} - 1\Big)\,,$$

$$\gamma_x(t) = \begin{cases} \dfrac{(2+t)^2}{4} & \text{if} \quad x \leq 1 \quad \text{and} \quad \max(T_x, -2) \leq t \leq 0\,, \\ -\dfrac{(2+t)^2}{4} & \text{if} \quad x \leq 1 \quad \text{and} \quad T_x \leq t \leq -2\,, \\ \dfrac{(2-t)^2}{4} & \text{if} \quad x \geq 1 \quad \text{and} \quad T_x \leq t \leq 0\,, \end{cases}$$

$$\eta_x(t) = \begin{cases} \dfrac{1}{2}|2 + t| & \text{if} \quad x \leq 1 \quad \text{and} \quad T_x \leq t \leq 0\,, \\ \dfrac{1}{2}(2 - t) & \text{if} \quad x \geq 1 \quad \text{and} \quad T_x \leq t \leq 0\,. \end{cases}$$

It is easy to see that the family $\Gamma = \{(\gamma_x, \eta_x)\}_{x\in\mathbb{R}}$ is a regular synthesis in the sense of our definition. Moreover, although the optimal trajectories are not unique, it is not hard to show that Γ *is the only optimal synthesis for our problem.* (Indeed, suppose that $\tilde{\Gamma} = \{(\tilde{\gamma}_x, \tilde{\eta}_x)\}_{x\in\mathbb{R}}$ was another optimal synthesis, and let $\operatorname{Dom}(\gamma_x) = [\tilde{T}_x, 0]$ for $x \in \mathbb{R}$. Let $x \in \mathbb{R}$. Then the cost of $(\tilde{\gamma}_x, \tilde{\eta}_x)$ must be zero, so $|\tilde{\eta}_x(t)| = \sqrt{|\tilde{\gamma}_x(t)|}$ for a.e. t. Suppose $x < 1$. Then $\tilde{\gamma}_x(t) < 1$ for all $t \in [\tilde{T}_x, 0\,[$, because if $\tilde{\gamma}_x(t) \geq 1$ for some $t \in [\tilde{T}_x, 0\,[$, then the map $\tilde{\gamma}_x$ would not be injective, and this would contradict the fact that Γ is a synthesis. If $\tilde{\eta}_x(t) < 0$ for all t in a subset E of $[\tilde{T}_x, 0]$ of positive measure, then once again the map $\tilde{\gamma}_x$ would not be injective. So $\tilde{\eta}_x(t) \geq 0$ a.e., and then $\tilde{\eta}_x(t) = v(\tilde{\gamma}_x(t))$ for a.e. t. A similar argument shows that $\tilde{\eta}_x(t) = v(\tilde{\gamma}_x(t))$ for a.e. t if $x > 1$. So the $\tilde{\gamma}_x$ are solutions of the equation $\dot{\gamma} = v(\gamma)$. This equation has unique solutions, except for the possibility that, starting at some $x < 0$, a trajectory reaching the origin may stay there for an arbitrary length of time before it resumes its motion to the right. This possibility, however, is clearly excluded for a trajectory of a synthesis. So, for each x, $\tilde{\gamma}_x$ is the unique solution of $\dot{\gamma} = v(\gamma)$ that starts at x, ends at 1 at time 0, and is one-to-one. Therefore $\tilde{\gamma}_x = \gamma_x$ for all x, so $\tilde{\Gamma} = \Gamma$.)

If we let $f(x,u) = u$, then we have established that the arcs γ_x are classical solutions of the closed-loop equation $\dot{x} = f(x, v(x))$. On the other hand, *the trajectory γ_0 corresponding to the initial condition $x = 0$ is not a CLSS solution of the closed-loop equation $\dot{x} = f(x, v(x))$* because, on an interval $[a,b]$, the only CLSS solution γ of this equation with initial condition $\gamma(a) = 0$ is $\gamma(t) \equiv 0$. $\square$

Appendix A. Differentiation of trajectories with respect to a parameter. The purpose of this appendix is to prove a general theorem on differentiation with respect to a parameter p, taking values in a normed space P, of a family of trajectories $x_p : [a,b] \to \mathbb{R}^n$ of time-varying vector fields f_p. We will state and prove the theorem under minimal hypotheses, much weaker than what is actually needed for the main results of this paper, because this result has other applications, such as the theory of envelopes (cf. Sussmann [29], [30]), where the more general statement is useful.

If $\dot{x}_p(t) = f_p(x_p(t), t)$, then formal differentiation with respect to p at $p = p_0$ in the direction of a vector v yields the variational equation

$$\text{(A.1)} \qquad \dot{y}_{p_0,v}(t) = \frac{\partial f_{p_0}}{\partial x}(x_{p_0}(t), t).y_{p_0,v}(t) + \lim_{\varepsilon \downarrow 0} \frac{W_{p_0+\varepsilon v}(t) - W_{p_0}(t)}{\varepsilon},$$

where $y_{p_0,v}(t)$ is the directional derivative of $x_p(t)$ at p_0 in the v-direction, and $W_p(t) = f_p(x_{p_0}(t), t)$.

The technical problem that will concern us here is to make (A.1) rigorous even when the limit in the right-hand side only exists in a weak sense.

For example, suppose that $n = 1$ and we are looking at the control system $\dot{x} = u$, and a family of "bang-bang" controls u_s depending on $s \in [0, \infty[$, such that $u_s(t) = 1$ for $t < s$, and $u_s(t) = -1$ for $t \geq s$. Let $x_s : [0, \infty[\to \mathbb{R}$ be the solution of $\dot{x} = u_s$, $x(0) = 0$. Then $x_s(t) = t$ for $t \leq s$, and $x_s(t) = 2s - t$ for $t \geq s$. Given any $T > 0$, the limit $\lim_{\varepsilon \to 0} \frac{u^T_{s+\varepsilon} - u^T_s}{\varepsilon}$—where u^T_s is the restriction of u_s to $[0,T]$—does not exist pointwise but exists in the weak* sense—regarding the u_s as members of the dual of the space of continuous functions on $[0,T]$—and equals $2\delta_s$, where δ_s is the Delta function at s. If we let $y_s(t)$ be the derivative of $x_s(t)$ with respect to s—so $y_s(t) = y_{s,1}(t)$—then y_s satisfies the differential equation $\dot{y}_s(t) = 2\delta_s(t)$, which makes better sense in integrated form: $y_s(t) = 2\chi_{[s,\infty[}(t)$. This says, in particular, that $y_s(T) = 2$ for $s < T$, and $y_s(T) = 0$ for $s > T$.

As this example shows, it can happen that the variational equation is a linear equation of the form $\dot{y}(t) = A(t)y(t) + w(t)$ where the "input" w is the formal derivative of a function W which is not necessarily absolutely continuous or even continuous. So our first task will be to study the solutions of linear systems with "generalized inputs" w.

Let $-\infty < a < b < \infty$, and let n be a positive integer. If $A \in L^1([a,b],\mathbb{R}^{n\times n})$, and $\bar{Y} \in \mathbb{R}^n$, then it is well known that the initial value problem

$$\dot{Y}(t) = A(t)\cdot Y(t) + w(t)\,, \qquad Y(a) = \bar{Y} \tag{A.2}$$

has a unique solution for every initial condition and every map $w \in L^1([a,b],\mathbb{R}^n)$. Since (A.2) can also be written formally as

$$dY(t) = A(t)\cdot Y(t)\,dt + w(t)\,dt\,, \qquad Y(a) = \bar{Y}, \tag{A.3}$$

we will use $Y_{A,w\,dt,\bar{Y}}$ to denote the unique solution of (A.2).

As explained before, we want to solve (A.2) for "inputs" w more general than integrable functions. The appropriate class of inputs turns out to be that of *formal derivatives of bounded measurable functions.* Precisely, we let $BM([a,b],\mathbb{R}^n)$ denote the space of all bounded Lebesgue measurable functions $W : [a,b] \to \mathbb{R}^n$, and use $BM_0([a,b],\mathbb{R}^n)$ to denote the set of those W in $BM([a,b],\mathbb{R}^n)$ such that $W(a) = 0$. (In $BM([a,b],\mathbb{R}^n)$ we do *not* identify two functions that are equal a.e.)

We endow $BM([a,b],\mathbb{R}^n)$ with the norm

$$||W||_{BM} \overset{\text{def}}{=} \sup\{||W(t)|| : t \in [a,b]\}. \tag{A.4}$$

Then $BM([a,b],\mathbb{R}^n)$ is a Banach space, and $BM_0([a,b],\mathbb{R}^n)$ is a closed subspace of $BM([a,b],\mathbb{R}^n)$. The space $C^0([a,b],\mathbb{R}^n)$ of continuous maps $W : [a,b] \to \mathbb{R}^n$ is of course a closed subspace of $BM([a,b],\mathbb{R}^n)$, but $L^\infty([a,b],\mathbb{R}^n)$ is *not* a subspace of $BM([a,b],\mathbb{R}^n)$, because in $L^\infty([a,b],\mathbb{R}^n)$ we identify functions that are equal a.e., but in $BM([a,b],\mathbb{R}^n)$ we do not.

If $W \in BM_0([a,b],\mathbb{R}^n)$ is absolutely continuous, and $w = \dot{W}$, so that, formally, $dW = w\,dt$, then we can rewrite (A.2) formally as

$$dY(t) = A(t)\cdot Y(t)\,dt + dW(t) \qquad Y(a) = \bar{Y}. \tag{A.5}$$

A solution of (A.5) is then a continuous map $t \to Y(t)$ such that

$$Y(t) = \bar{Y} + \int_a^t A(s)\cdot Y(s)\,ds + W(t) \qquad \text{for all} \quad t \in [a,b]. \tag{A.6}$$

Now (A.6) makes sense for arbitrary $Y \in BM([a,b],\mathbb{R}^n)$, $W \in BM_0([a,b],\mathbb{R}^n)$, even if W is not absolutely continuous. So we turn it into a definition: for a pair $(W,\bar{Y}) \in BM_0([a,b],\mathbb{R}^n)\times\mathbb{R}^n$, a *solution* of (A.5) is a map $Y \in BM([a,b],R^n)$ such that (A.6) holds. It then follows that

(EU) *for every $W \in BM_0([a,b],\mathbb{R}^n)$ and every $\bar{Y} \in \mathbb{R}^n$ there exists a unique solution Y of* (A.5).

Indeed, uniqueness is trivial, since the difference $Y = Y^1 - Y^2$ of two solutions is a solution of the homogeneous problem (i.e., of (A.2) with $w \equiv 0$ and $\bar{Y} = 0$), so $Y^1 - Y^2 \equiv 0$. To prove existence, we observe that (A.6) is equivalent to

(A.7)

$$Y(t) - W(t) = \bar{Y} + \int_a^t A(s)\cdot(Y(s) - W(s))\,ds + \int_a^t A(s)\cdot W(s)\,ds \qquad \text{for all} \quad t \in [a,b],$$

i.e., to $dZ = AZ\,dt + AW\,dt$, $Z(a) = \bar{Y}$, with $Z = Y - W$. Since $AW \in L^1$, because $A \in L^1$ and W is bounded and measurable, the equation $\dot{Z}(t) = A(t)\cdot Z(t) + A(t)W(t)$

has a unique solution Z^* for which $Z^*(a) = \bar{Y}$. If we let $Y(t) = Z^*(t) + W(t)$, and recall that $W(a) = 0$, we see that Y is the desired solution of (A.5).

We will use $Y_{A,dW,\bar{Y}}$ to denote the solution of (A.5), whose existence and uniqueness has just been established. In addition to proving (EU), the preceding argument also gives an explicit formula for $Y_{A,dW,\bar{Y}}$, namely,

$$Y_{A,dW,\bar{Y}} = W + Y_{A,AW\,dt,\bar{Y}}. \tag{A.8}$$

Clearly, the function $Y_{A,AW\,dt,\bar{Y}}$ is absolutely continuous, so the regularity properties of $Y_{A,dW,\bar{Y}}$—modulo absolutely continuous functions—are exactly the same as those of W. (For example, Y is continuous, right-continuous, or left-continuous at a point $t \in [a,b]$ if and only if W is; Y is of bounded variation if and only if W is; Y is absolutely continuous if and only if W is.)

Gronwall's inequality, applied to (A.7), tells us that

$$||Y_{A,dW,\bar{Y}}(t) - W(t)|| \leq e^{||A||_{L^1}}(||\bar{Y}|| + ||A||_{L^1}||W||_{BM}). \tag{A.9}$$

Therefore

$$||Y_{A,dW,\bar{Y}}||_{BM} \leq ||W||_{BM} + e^{||A||_{L^1}}(||\bar{Y}|| + ||A||_{L^1}||W||_{BM}). \tag{A.10}$$

On the other hand, (A.6) also implies that

$$||W||_{BM} \leq ||\bar{Y}|| + ||Y_{A,dW,\bar{Y}}||_{BM}(1 + ||A||_{L^1}). \tag{A.11}$$

THEOREM A.1. *Let $\{W_j\}$, $\{\bar{Y}_j\}$, $\{A_j\}$ be sequences in $BM_0([a,b],\mathbb{R}^n)$, $\mathbb{R}^n$, $L^1([a,b],\mathbb{R}^{n\times n})$, respectively. Assume that $\{A_j\}$ is bounded in $L^1([a,b],\mathbb{R}^{n\times n})$. Let $Y_j = Y_{A_j,dW_j,\bar{Y}_j}$. Then we have the following:*

(A.1.1) *$\{Y_j\}$ is bounded in $BM([a,b],\mathbb{R}^n)$ if and only if $\{W_j\}$ is bounded in $BM([a,b],\mathbb{R}^n)$ and $\{\bar{Y}_j\}$ is bounded in $\mathbb{R}^n$;*

(A.1.2) *If $\{A_j\}$ converges in $L^1([a,b],\mathbb{R}^n)$ to a limit A, $\bar{Y} \in \mathbb{R}^n$, $\bar{Y}_j \to \bar{Y}$, $\{W_j\}$ is bounded in $BM([a,b],\mathbb{R}^n)$, $W \in BM_0([a,b],\mathbb{R}^n)$, and $Y = Y_{A,dW,\bar{Y}}$, then $Y_j \to Y$ a.e. if and only if $W_j \to W$ a.e. In that case,* (a) *$Y_j - W_j$ converges to $Y - W$ uniformly on $[a,b]$ and, in particular,* (b) *for every $t \in [a,b]$, $Y_j(t) \to Y(t)$ if and only if $W_j(t) \to W(t)$.*

Proof. Statement (A.1.1) follows from the bounds (A.10) and (A.11). To prove (A.1.2), we first observe that under the hypotheses of (A.1.2) we can apply (A.1.1) and conclude that $\{Y_j\}$ is bounded in $BM([a,b],\mathbb{R}^n)$.

Let $\tilde{Y}_j = Y_j - W_j = Y_{A_j,A_jW_j\,dt,\bar{Y}_j}$, $\tilde{Y} = Y - W = Y_{A,AW\,dt,\bar{Y}_j}$. Then

$$\tilde{Y}_j(t) = \bar{Y}_j + \int_a^t A_j(s)Y_j(s)\,ds = \bar{Y}_j + \int_a^t A_j(s)\tilde{Y}_j(s)\,ds + \int_a^t A_j(s)W_j(s)\,ds, \tag{A.12}$$

so

$$\tilde{Y}_j(t) - \tilde{Y}(t) = \int_a^t A(s)(\tilde{Y}_j(s) - \tilde{Y}(s))\,ds + R_j(t), \tag{A.13}$$

where

$$R_j(t) = \bar{Y}_j - \bar{Y} + \int_a^t (A_j(s) - A(s))Y_j(s)\,ds + \int_a^t A(s)(W_j(s) - W(s))\,ds \tag{A.14}$$

and also

$$\text{(A.15)}\quad \tilde{Y}_j(t)-\tilde{Y}(t)=\bar{Y}_j-\bar{Y}+\int_a^t (A_j(s)-A(s))Y_j(s)\,ds+\int_a^t A(s)(Y_j(s)-Y(s))\,ds.$$

The assumption that the sequence $\{W_j\}$ is uniformly bounded and $\{\bar{Y}_j\}$ converges to $\bar{Y}$ implies that the sequences $\{\tilde{Y}_j\}$ and $\{Y_j\}$ are uniformly bounded as well. Since $A_j \to A$ in L^1, it is clear that the first two terms of the sum defining $R_j(t)$ go to zero uniformly as $j \to \infty$. Also,

$$\text{(A.16)}\qquad \left\|\int_a^t A(s)(W_j(s)-W(s))\,ds\right\| \le \int_a^b ||A(s)||\cdot||W_j(s)-W(s)||\,ds,$$

which goes to zero by the dominated convergence theorem if $s \to ||A(s)||$ is integrable and the sequence $\{W_j - W\}$ is uniformly bounded and goes to zero a.e. So, if we let $K_j = \sup\{||R_j(t)|| : a \le t \le b\}$, we see that $K_j \to 0$ as $j \to \infty$ if the assumptions of (A.1.2) hold and $W_j(t) \to W(t)$ for a.e. t. It then follows from Gronwall's inequality, applied to (A.13), that $||\tilde{Y}_j(t)-\tilde{Y}(t)|| \le K_j e^{||A||_{L^1}}$, so $\tilde{Y}_j - \tilde{Y} \to 0$ uniformly.

If $Y_j - Y \to 0$ a.e., then the first two terms of the right-hand side of (A.15) go to zero uniformly, and the third one is bounded by $\int_a^b ||A(s)||\cdot||Y_j(s)-Y(s)||\,ds$, which also goes to zero. So $\tilde{Y}_j - \tilde{Y} \to 0$ uniformly.

We have thus shown that $\tilde{Y}_j - \tilde{Y} \to 0$ uniformly if either $W_j \to W$ a.e. or $Y_j \to Y$ a.e. This clearly implies all the conclusions of (A.1.2). □

A very important subspace of $BM([a,b],\mathbb{R}^n)$ is $BV([a,b],\mathbb{R}^n)$, the space of all functions $W : [a,b] \to \mathbb{R}^n$ such that (a) W is of bounded variation, (b) W is right-continuous at every point of $]a,b]$, and (c) $W(a) = 0$. There is a canonical correspondence between $BV([a,b],\mathbb{R}^n)$ and the dual space $C^0([a,b],\mathbb{R}_n)^*$ of the Banach space $C^0([a,b],\mathbb{R}_n)$ of continuous functions $[a,b] \to \mathbb{R}_n$. (We write R_n rather than R^n because we want to think of the members of $C^0([a,b],\mathbb{R}_n)$ as *row-vector-valued functions*; cf. below.)

The members of $C^0([a,b],\mathbb{R}_n)^*$ are the $\mathbb{R}^n$*-valued Borel measures on* $[a,b]$. When $n = 1$, they are the *finite signed Borel measures on* $[a,b]$. The identification map from $BV([a,b],\mathbb{R}^n)$ to $C^0([a,b],\mathbb{R}_n)^*$ is the one that assigns to a function $W \in BV([a,b],\mathbb{R}^n)$ the unique Borel measure μ_W such that $\mu_W([a,t]) = W(t)$ for $a < t \le b$.

From now on we identify a function $W \in BV([a,b],\mathbb{R}^n)$ with its corresponding measure μ_W, and write $\int \alpha \cdot dW$ for $\int \alpha \cdot d\mu_W$. Clearly, $\int \alpha \cdot dW$ is defined, more generally, for an arbitrary bounded Borel measurable $\mathbb{R}_n$-valued map α on $[a,b]$.

Naturally, the integral $\int \alpha\, dW$ of a scalar bounded Borel measurable function $\alpha : [a,b] \to \mathbb{R}$ is also well defined, and is a vector in $\mathbb{R}^n$.

On $BV([a,b],R^n)$ there are at least three important topologies: (a) the one induced by the norm $||\cdots||_{BM}$, (b) the strong topology of $BV([a,b],\mathbb{R}^n)$ as the dual of the Banach space $C^0([a,b],\mathbb{R}_n)$, (c) the weak* topology, also corresponding to the duality with $C^0([a,b],\mathbb{R}_n)$. The second one is induced by the *total variation norm*:

$$\text{(A.17)}\qquad ||W||_{TV} = \sup\left\{\left|\int \alpha\cdot dW\right| : \alpha \in C^0([a,b],\mathbb{R}_n)\,,\ ||\alpha||_{BM} \le 1\right\}.$$

It is clear that $||W||_{BM} \le ||W||_{TV}$ for all W in $BV([a,b],\mathbb{R}^n)$. Therefore, *if a subset* S *of* $BV([a,b],\mathbb{R}^n)$ *is bounded in* TV *norm, then* S *is also bounded in* BM *norm.*

We will need the following.

LEMMA A.2. *If a sequence $\{W_j\}$ in $BV([a,b],\mathbb{R}^n)$ weak*-converges to a $W \in BV([a,b],\mathbb{R}^n)$, then* (a) *$\{W_j\}$ is bounded in TV norm,* (b) *$W_j(a) \to W(a)$ and $W_j(b) \to W(b)$,* (c) *every subsequence of $\{W_j\}$ has a subsequence that converges to W at all but at most countably many points of $[a,b]$,* (d) *$\int_a^b \beta(s)||W_j(t) - W(t)||\,dt \to 0$ for every function $\beta \in L^1([a,b],\mathbb{R})$.*

Proof. Statement (a) follows from the uniform boundedness theorem, and statement (b) is trivial, since $W_j(a) = 0 = W(a)$, $W_j(b) = \int 1\,dW_j$, and $W(b) = \int 1\,dW$. Statement (c) for $n = 1$ is a consequence of Helly's theorem, and the statement for arbitrary n then follows easily from the case $n = 1$. Statement (d) then clearly follows from (c), using the dominated convergence theorem together with the fact that boundedness in TV norm implies boundedness in BM norm. □

As a corollary of Lemma A.2, we get the integration by parts formula below.

LEMMA A.3. *If $\lambda : [a,b] \to \mathbb{R}_n$ is absolutely continuous, and $W \in BV([a,b],\mathbb{R}^n)$, then*

$$\lambda(b) \cdot W(b) = \int \lambda \cdot dW + \int_a^b \dot{\lambda}(t) \cdot W(t)\,dt. \tag{A.18}$$

Proof. The result is obviously true, because of the standard product rule for derivatives, if W is also absolutely continuous. In the general case, we use the fact that an arbitrary $W \in BV([a,b],\mathbb{R}^n)$ is the weak*-limit of a sequence $\{W_j\}$ of absolutely continuous functions. It then follows that (i) $\lambda(b) \cdot W_j(b) \to \lambda(b) \cdot W(b)$, because $W_j(b) \to W(b)$, (ii) $\int \lambda \cdot dW_j \to \int \lambda \cdot dW$, because $\{W_j\}$ weak*-converges to W, and λ is continuous, and (iii) $\int_a^b \dot{\lambda}(t) \cdot W_j(t)\,dt \to \int_a^b \dot{\lambda}(t) \cdot W(t)\,dt$, because part (d) of Lemma A.2 implies that $\int_a^b ||\dot{\lambda}(t)||.||W_j(t) - W(t)||\,dt \to 0$, since $\dot{\lambda} \in L^1$. □

An important consequence of Lemma A.3 is the following lemma.

LEMMA A.4. *Let $W \in BV([a,b],\mathbb{R}^n)$, $A \in L^1([a,b],\mathbb{R}^{n\times n})$, $\bar{Y} \in \mathbb{R}^n$, and write $Y = Y_{A,dW,\bar{Y}}$. Suppose $\lambda : [a,b] \to \mathbb{R}_n$ is absolutely continuous and satisfies $\dot{\lambda}(t) = -\lambda(t)A(t)$ for almost all t. Then*

$$\lambda(b) \cdot Y(b) - \lambda(a) \cdot Y(a) = \int \lambda \cdot dW. \tag{A.19}$$

Proof. Write $Y(t) = V(t) + W(t)$, where $V(t) = \bar{Y} + \int_a^t A(s).Y(s)\,ds$. Then

$$\lambda(b) \cdot Y(b) - \lambda(a) \cdot Y(a) = \lambda(b) \cdot V(b) - \lambda(a) \cdot V(a) + \lambda(b) \cdot W(b). \tag{A.20}$$

The function $t \to \lambda(t) \cdot V(t)$ is absolutely continuous and its derivative is $\dot{\lambda}(t) \cdot V(t) + \lambda(t) \cdot \dot{V}(t)$, which equals $-\lambda(t)A(t)Y(t) + \lambda(t)A(t)Y(t) - \dot{\lambda}(t) \cdot W(t)$, i.e., $-\dot{\lambda}(t) \cdot W(t)$. So

$$\lambda(b) \cdot Y(b) - \lambda(a) \cdot Y(a) = \lambda(b) \cdot W(b) - \int_a^b \dot{\lambda}(t) \cdot W(t)\,dt. \tag{A.21}$$

Equation (A.19) follows from this and the integration by parts formula (A.18). □

It is clear that, if $A \in L^1([a,b],\mathbb{R}^{n\times n})$, $\bar{Y} \in \mathbb{R}^n$, and $W \in BM_0([a,b],\mathbb{R}^n)$, then $Y_{A,dW,\bar{Y}} - W$ is absolutely continuous, so $W \in BV([a,b],\mathbb{R}^n)$ if and only if $Y_{A,dW,\bar{Y}}$ is of bounded variation, which happens if and only if $Y_{A,dW,\bar{Y}} - \bar{Y} \in BV([a,b],\mathbb{R}^n)$.

THEOREM A.5. *Let $\{W_j\}$, $\{\bar{Y}_j\}$, $\{A_j\}$ be sequences in $BV([a,b],\mathbb{R}^n)$, $\mathbb{R}^n$, $L^1([a,b],\mathbb{R}^{n\times n})$, respectively. Assume that $\{A_j\}$ is bounded in $L^1([a,b],\mathbb{R}^{n\times n})$ and $\{\bar{Y}_j\}$ is bounded in $\mathbb{R}^n$. Let $Y_j = Y_{A_j,dW_j,\bar{Y}_j}$. Then*

(A.5.1) *$\{Y_j - \bar{Y}_j\}$ is bounded in $BV([a,b],\mathbb{R}^n)$ if and only if $\{W_j\}$ is bounded in $BV([a,b],\mathbb{R}^n)$.*

(A.5.2) *If $\{A_j\}$ converges in $L^1([a,b],\mathbb{R}^n)$ to a limit A, $\bar{Y}_j \to \bar{Y}$, $W \in BV([a,b],\mathbb{R}^n)$, and we write $Y = Y_{A,dW,\bar{Y}}$, then $\{W_j\}$ weak*-converges to W if and only if $\{Y_j - \bar{Y}_j\}$ weak*-converges to $Y - \bar{Y}$. In that case, $\{Y_j - W_j - \bar{Y}_j\}$ converges to $Y - W - \bar{Y}$ strongly in $BV([a,b],\mathbb{R}^n)$. In particular,* (a) *$W_j(b) \to W(b)$,* (b) *$Y_j(b) \to Y(b)$, and* (c) *for every $t \in [a,b]$, $Y_j(t) \to Y(t)$ if and only if $W_j(t) \to W(t)$.*

Proof. We know from Theorem A.1 that $\{Y_j - \bar{Y}_j\}$ is bounded in BM norm if and only if $\{W_j\}$ is. Since boundedness in TV norm implies boundedness in BM norm, we see that boundedness of one of the two sequences in TV norm implies that there is a constant C such that $||Y_j(t)|| \le C$ for all j, t, and then the integral $I_j = \int_a^b ||A_j(t)Y_j(t)||\,dt$ is bounded by a fixed constant K. But $I_j = ||Y_j - \bar{Y}_j - W_j||_{TV}$. So boundedness in TV norm of one of the sequences $\{W_j\}$, $\{Y_j\}$ implies boundedness in TV norm of the other one.

If either $\{W_j\}$ weak*-converges to W, or $\{Y_j - \bar{Y}_j\}$ weak*-converges to $Y - \bar{Y}$, then the uniform boundedness theorem implies that either $\{W_j\}$ or $\{Y_j - \bar{Y}_j\}$ is bounded in TV norm, so both sequences are bounded in TV norm—and hence also in BM norm—by a constant C. Writing $Z_j = Y_j - \bar{Y}_j - W_j$, $Z = Y - \bar{Y} - W$, we then have $Z_j - Z = R_j^1 + R_j^2$, where

$$R_j^1(t) = \int_a^t (A_j(s) - A(s))Y_j(s)\,ds, \qquad R_j^2(t) = \int_a^t A(s)(Y_j(s) - Y(s))\,ds. \tag{A.22}$$

Then $||R_j^1||_{TV} \le C||A_j - A||_{L^1}$, so $||R_j^1||_{TV} \to 0$. Also,

$$||R_j^2||_{TV} \le ||A||_{L^1}.||\bar{Y}_j - \bar{Y}|| + \int_a^b ||A(t)||.||Y_j(t) - \bar{Y}_j - (Y(t) - \bar{Y})||\,dt. \tag{A.23}$$

If $\{Y_j - \bar{Y}_j\}$ weak*-converges to $Y - \bar{Y}$, then Lemma A.2 implies that $||R_j^2||_{TV} \to 0$, so $Z_j \to Z$ in $BV([a,b],\mathbb{R}^n)$.

If $\{W_j\}$ weak*-converges to W, then we rewrite R_j^2 as

$$R_j^2(t) = \int_a^t A(s)(Z_j(s) - Z(s))\,ds + R_j^3(t) + R_j^4(t), \tag{A.24}$$

where $R_j^3(t) = \int_a^t A(s)(\bar{Y}_j - \bar{Y})\,ds$ and $R_j^4(t) = \int_a^t A(s)(W_j(s) - W(s))\,ds$. We then have $||R_j^3||_{TV} \le ||A||_{L^1}.||\bar{Y}_j - \bar{Y}||$ and $||R_j^4||_{TV} \le \int_a^b ||A(s)||.||W_j(s) - W(s)||\,ds$. Lemma A.2 then implies that $||R_j^4||_{TV} \to 0$. So $Z_j(t) - Z(t) = \int_a^t A(s).(Z_j(s) - Z(s))\,ds + R_j(t)$, where $R_j = R_j^1 + R_j^3 + R_j^4$, so $||R_j||_{TV} \to 0$. Then Gronwall's inequality implies that $||Z_j - Z||_{BM} \le e^{||A||_{L^1}}||R_j||_{TV}$. If $Q_j(t) = \int_a^t A(s).(Z_j(s) - Z(s))\,ds$, then $||Q_j||_{TV} \le ||A||_{L^1}||Z_j - Z||_{BM}$, so $||Q_j||_{TV} \to 0$. Since $Z_j - Z = Q_j + R_j$, we see that $||Z_j - Z||_{TV} \to 0$.

So we have shown that if one of the two sequences $\{W_j - W\}$, $\{Y_j - \bar{Y}_j - (Y - \bar{Y})\}$ weak*-converges to 0, then $Y_j - \bar{Y}_j - W_j \to Y - \bar{Y} - W$ strongly in $BV([a,b],\mathbb{R}^n)$. This implies all the conclusions of (A.5.2). □

Recall that, if P, Q are normed spaces, and $F : \Omega \to Q$ is a map defined on a neighborhood Ω of a point p of P, then F is said to be *Fréchet differentiable* at p if there exists a bounded linear map L—called the *Fréchet differential* of F at p—such that $F(p') = F(p) + L(p' - p) + o(||p' - p||)$ as $p' \to p$. If X is a Banach space and $Q = X^*$, then we call F *weak* Fréchet differentiable* at p if for every $x \in X$ the map $\Omega \ni p' \to \langle F(p'), x\rangle \in \mathbb{R}$ is Fréchet differentiable at p. (We use $\langle x^*, x\rangle$, for $x \in X$, $x^* \in X^*$, as an alternative notation for $x^*(x)$.)

Suppose P is a normed space, X is a Banach space, $p \in P$, $F : \Omega \to X^*$ is a map defined on a neighborhood Ω of p, and F is weak* Fréchet differentiable at p. Then for each $x \in X$ there is a bounded linear functional θ_x on P such that $\langle F(p+v), x\rangle = \langle F(p), x\rangle + \theta_x(v) + o(||v||)$ as $v \to 0$ in P. Clearly, θ_x is unique and is given by the formula

$$\theta_x(v) = \lim_{h\to 0} h^{-1}\langle F(p+hv) - F(p), x\rangle. \tag{A.25}$$

For any given $v \in P$, use θ^v to denote the map $x \to \theta_x(v)$. Then θ^v is a limit of linear maps, so it is linear. If $\{h_j\}$ is any sequence going to 0, then the sequence of linear functionals ν_j on X given by $\nu_j(x) = h_j^{-1}\langle F(p + h_j v) - F(p), x\rangle$ converges pointwise to θ^v. Since each ν_j is a bounded linear functional on X, it follows for the uniform boundedness theorem that θ^v is bounded. Since $\theta^v(x) = \theta_x(v)$, which is linear with respect to v, we can conclude that $v \to \theta^v$ is a linear map from P to X^*. We use $D^wF(p)$ to denote this map, and $D^wF(p).v$ to denote its value for a particular v, so $D^wF(p).v = \theta^v$, and

$$\langle D^wF(p).v, x\rangle = \lim_{h\to 0} h^{-1}\langle F(p+hv) - F(p), x\rangle. \tag{A.26}$$

Lemma A.6. *Assume that P is a normed space, X is a Banach space, $p \in P$, $F : \Omega \to X^*$ is a map defined on a neighborhood Ω of p, and F is weak* Fréchet differentiable at p. Then*

(A.6.i) *there is a $C > 0$ such that*

$$||F(p+v) - F(p)|| \leq C||v|| \qquad \textit{for all sufficiently small} \qquad v \in P, \tag{A.27}$$

(A.6.ii) *the linear map $D^wF(p) : P \to X^*$ defined by* (A.26) *is bounded.*

Proof. Suppose (A.6.i) is not true. Then there exists a sequence $\{v_j\}$ in P, converging to 0 and such that $||F(p + v_j) - F(p)|| > j||v_j||$. Define, for each j, a member σ_j of X^* by

$$\sigma_j = \frac{F(p+v_j) - F(p) - \theta^{v_j}}{||v_j||}. \tag{A.28}$$

Then $\sigma_j(x) \to 0$ for each x, so the sequence $\{\sigma_j\}$ is pointwise bounded and hence uniformly bounded.

On the other hand, for each $x \in X$, the sequence $\{\frac{\theta^{v_j}(x)}{||v_j||}\}$ is bounded, because $\theta^{v_j}(x) = \theta_x(v_j)$, and θ_x is a bounded linear functional on P, so $|\theta^{v_j}(x)| \leq ||\theta_x||.||v_j||$. So, using the uniform boundedness theorem once again, we conclude that the sequence $\{\frac{\theta^{v_j}}{||v_j||}\}$ is bounded in X^*. Since $\{\sigma_j\}$ is bounded, we conclude that the sequence $\{\frac{F(p+v_j)-F(p)}{||v_j||}\}$ is bounded, contradicting the fact that $||F(p + v_j) - F(p)|| > j||v_j||$. So (A.27) holds for some $C > 0$, and we have proved (A.6.i).

It follows from (A.6.i) that $|\langle F(p + v) - F(p), x\rangle| \leq C||x||.||v||$ for all $x \in X$ if $v \in P$ is small enough. Applying this with hv in the role of v and letting $h \downarrow 0$, we find that

$$|\langle D^wF(p).v, x\rangle| \leq C||x||.||v|| \qquad \text{for all} \qquad x \in X\,,\ \ v \in P. \tag{A.29}$$

Therefore $||D^wF(p).v|| \leq C||v||$, so $D^wF(p)$ is a bounded linear map from P to X^*. $\square$

We are now ready to study the differentiability properties with respect to a parameter p, belonging to a normed space P, of a family of trajectories $x_p : [a,b] \to \mathbb{R}^n$ of time-varying vector fields f_p. We will prove, under minimal technical hypotheses, that if the initial condition map $p \to x_p(a)$ is differentiable at $p=0$, and the map $p \to f_p$ satisfies a "weak differentiability condition" at the trajectory x_0, then the map $p \to x_p$ is weak*-differentiable at $p=0$, as a map into $BV([a,b],\mathbb{R}^n)$, and in particular, the endpoint map $p \to x_p(b)$ is differentiable at $p=0$.

A *curve in* $\mathbb{R}^n$ is a continuous map $\xi : I \to \mathbb{R}^n$, whose domain $I = \mathrm{Dom}(\xi)$ is a nonempty interval. A curve ξ is an *arc* if $\mathrm{Dom}(\xi)$ is compact. The *graph* $G(\xi)$ of a curve ξ is the set $G(\xi) = \{(\xi(t),t) : t \in \mathrm{Dom}(\xi)\}$. If $\xi : [a,b] \to \mathbb{R}^n$ is an arc in $\mathbb{R}^n$, and $\varepsilon > 0$, then the *ε-tube about* ξ is the set $\mathcal{T}(\xi,\varepsilon) = \{(x,t) : x \in \mathbb{R}^n, a \leq t \leq b, ||x-\xi(t)|| \leq \varepsilon\}$.

A *time-varying vector field* on $\mathbb{R}^n$ is an $\mathbb{R}^n$-valued map f whose domain $\mathrm{Dom}(f)$ is a—possibly empty—subset S of the product $\mathbb{R}^n \times \mathbb{R}$. We use $TVVF(\mathbb{R}^n)$ to denote the set of all time-varying vector fields on $\mathbb{R}^n$. A *trajectory*, or *integral curve*, of an $f \in TVVF(\mathbb{R}^n)$ is a locally absolutely continuous curve ξ in $\mathbb{R}^n$ such that $G(\xi) \subseteq \mathrm{Dom}(f)$ and $\dot{\xi}(t) = f(\xi(t),t)$ for almost all $t \in \mathrm{Dom}(\xi)$. We use $\mathrm{Traj}(f)$ to denote the set of all trajectories of f, and $\mathrm{Traj}_c(f)$ to denote the set of all $\xi \in \mathrm{Traj}(f)$ such that $\mathrm{Dom}(\xi)$ is compact.

If $f \in TVVF(\mathbb{R}^n)$ and $\xi \in \mathrm{Traj}(f)$, we say that ξ is a *maximal* trajectory of f if it cannot be extended to a trajectory $\tilde{\xi} : \tilde{I} \to \mathbb{R}^n$ of f defined on an interval $\tilde{I}$ such that $I \subseteq \tilde{I}$ but $I \neq \tilde{I}$. We use $\mathrm{MTraj}(f)$ to denote the set of all maximal trajectories of f. Given $\bar{x} \in \mathbb{R}^n$, $\bar{t} \in \mathbb{R}$, we use $\mathrm{Traj}(f,\bar{x},\bar{t})$, $\mathrm{MTraj}(f,\bar{x},\bar{t})$ to denote, respectively, the set of all $\xi \in \mathrm{Traj}(f)$ such that $\xi(\bar{t}) = \bar{x}$, and the set $\mathrm{Traj}(f,\bar{x},\bar{t}) \cap \mathrm{MTraj}(f)$. Zorn's lemma implies that every $\xi \in \mathrm{Traj}(f,\bar{x},\bar{t})$ can be extended to a $\tilde{\xi} \in \mathrm{MTraj}(f,\bar{x},\bar{t})$, so $\mathrm{Traj}(f,\bar{x},\bar{t}) \neq \emptyset$ if and only if $\mathrm{MTraj}(f,\bar{x},\bar{t}) \neq \emptyset$. Clearly, $\mathrm{Traj}(f,\bar{x},\bar{t}) \neq \emptyset$ if and only if $(\bar{x},\bar{t}) \in \mathrm{Dom}(f)$. (Indeed, if $(\bar{x},\bar{t}) \in \mathrm{Dom}(f)$, then the map ξ with domain $\{\bar{t}\}$ such that $\xi(\bar{t}) = \bar{x}$ is in $\mathrm{Traj}(f)$.)

We say that an $f \in TVVF(\mathbb{R}^n)$ has the *forward existence property* at a point $(\bar{x},\bar{t})$ if for some $\varepsilon > 0$ there exists a $\xi \in \mathrm{Traj}(f,\bar{x},\bar{t})$ with domain $[\bar{t},\bar{t}+\varepsilon]$. We say that f has the *forward limit property* on a subset S of $\mathrm{Dom}(f)$ if, whenever $\xi : [a,b[\to \mathbb{R}^n$ is a trajectory of f which is contained in a compact subset of S, it follows that $\lim_{t\uparrow b}\xi(t)$ exists.

Suppose we are given the following data:

(D.1) a normed space P,

(D.2) a family $\mathbf{f} = \{f_p\}_{p\in P}$ of time-varying vector fields on $\mathbb{R}^n$, depending on a parameter $p \in P$,

(D.3) a $p_0 \in P$,

(D.4) a trajectory $\xi : [a,b] \to \mathbb{R}^n$ of f_{p_0}.

We then define functions $w_p : [a,b] \to \mathbb{R}^n$ by

$$w_p(t) = f_p(\xi(t),t) - f_{p_0}(\xi(t),t) \quad \text{for} \quad t \in [a,b], \tag{A.30}$$

so w_p is defined on $[a,b]$ whenever $G(\xi) \subseteq \mathrm{Dom}(f_p)$. If w_p is integrable, we let

$$W_p(t) = \int_a^t w_p(s)\,ds \qquad \text{for} \qquad t \in [a,b]. \tag{A.31}$$

We then let $\mathcal{W}$ be the map that sends p to $\mathcal{W}(p) = W_p$, with domain

$$\mathrm{Dom}(\mathcal{W}) = \{p \in P : G(\xi) \subseteq \mathrm{Dom}(f_p),\ w_p \in L^1([a,b],\mathbb{R}^n)\}. \tag{A.32}$$

We regard $\mathcal{W}$ as a map from $\mathrm{Dom}(\mathcal{W})$ to $BV([a,b],\mathbb{R}^n)$.

We then say that $\mathbf{f}$ is *weakly differentiable at* p_0 *along* ξ if there exists $\bar{\varepsilon}>0$ such that

(WD1) $\mathcal{T}(\xi,\bar{\varepsilon})\subseteq \mathrm{Dom}(f_p)$ for every p such that $||p-p_0||\le\bar{\varepsilon}$;

(WD2) for every p such that $||p-p_0||\le\bar{\varepsilon}$, f_p has the forward limit property on $\mathcal{T}(\xi,\bar{\varepsilon})$ and the forward existence property at every (x,t) such that $a\le t<b$ and $||x-\xi(t)||<\bar{\varepsilon}$;

(WD3) there exist $A\in L^1([a,b],\mathbb{R}^{n\times n})$ and functions $\psi_\varepsilon\in L^1([a,b],\mathbb{R})$, for $\varepsilon\in]0,\bar{\varepsilon}]$, such that

$$||f_p(x,t)-f_p(\xi(t),t)-A(t).(x-\xi(t))||\le\psi_\varepsilon(t)(||x-\xi(t)||+||p-p_0||) \tag{A.33}$$

whenever $a\le t\le b$, $||x-\xi(t)||\le\varepsilon$, $||p-p_0||\le\varepsilon$, and

$$\lim_{\varepsilon\downarrow 0}\int_a^b\psi_\varepsilon(t)\,dt=0; \tag{A.34}$$

(WD4) the function w_p defined by (A.30) is integrable for every p such that $||p-p_0||\le\bar{\varepsilon}$ and, if $\mathcal{W}$ is defined as above, then $\mathcal{W}$ is weak* Fréchet differentiable at p_0.

The second part of condition (WD4) says that for each $\alpha\in C^0([a,b],\mathbb{R}_n)$ the map $p\to\int\alpha\cdot dW_p$ is Fréchet differentiable at p_0. Lemma A.6 then implies—since $W_{p_0}=0$—that there exists a bounded linear map $D^w\mathcal{W}(p_0):P\to BV([a,b],\mathbb{R}^n)$ having the property that

(A.35)
$$\begin{aligned}\int\alpha\cdot dW_p&=\langle\mathcal{W}(p)-\mathcal{W}(p_0),\alpha\rangle\\&=\int\alpha\cdot d\Big(D^w\mathcal{W}(p_0).(p-p_0)\Big)+o(||p-p_0||)\qquad\text{as}\qquad p\to p_0\end{aligned}$$

for each $\alpha\in C^0([a,b],\mathbb{R}_n)$, and also that there is a constant C such that

(A.36) $||W_p||_{TV}\le C||p-p_0||$ for all $p\in P$ such that $\|p-p_0\|$ is sufficiently small.

The following result is the main theorem on differentiation of trajectories with respect to a parameter.

THEOREM A.7. *Let* P, $\mathbf{f}$, p_0, ξ *be data as in* (D.1,2,3,4). *Assume that* $\mathbf{f}$ *is weakly differentiable at* p_0 *along* ξ. *Let* $\bar{\varepsilon}>0$ *be such that* (WD1) *to* (WD4) *hold. Then the following hold:*

(A.7.a) *For every* $\varepsilon\in]\,0,\bar{\varepsilon}]$ *there exists a* $\delta\in]\,0,\varepsilon[$ *such that, whenever* $||p-p_0||\le\delta$, $||\bar{x}-\xi(a)||\le\delta$, *and* $\zeta\in\mathrm{MTraj}(f_p,\bar{x},a)$, *it follows that* $[a,b]\subseteq\mathrm{Dom}(\zeta)$ *and* $||\zeta(t)-\xi(t)||\le\varepsilon$ *for all* $t\in[a,b]$.

(A.7.b) *If* $\{\bar{x}_p\}_{||p-p_0||\le\bar{\varepsilon}}$ *is a family of points of* $\mathbb{R}^n$ *such that the map* $p\to\bar{x}_p$ *is Fréchet differentiable at* p_0 *and* $\bar{x}_{p_0}=\xi(a)$, *then, if* $\{\xi_p\}_{||p-p_0||\le\bar{\varepsilon}}$ *is a family of curves such that* $\xi_p\in\mathrm{MTraj}(f_p,\bar{x}_p,a)$, *and* x_p *denotes the restriction of* ξ_p *to* $[a,b]$—*which is well defined for small enough* $||p-p_0||$ *by* (A.7.a)—*then the map* $\mathcal{X}$ *that sends each* p *to the function* x_p *is weak* Fréchet differentiable at* p_0 *as a map from* P *to* $BV([a,b],\mathbb{R}^n)$. *Moreover,* $D^w\mathcal{X}(p_0)$ *can be computed as follows. For* $v\in P$,

$$D^w\mathcal{X}(p_0).v=Y_{A,\,d(D^w\mathcal{W}(0).v),\,L.v}, \tag{A.37}$$

where $L : P \to \mathbb{R}^n$ is the differential at p_0 of the map $p \to \bar{x}_p$.

Proof. We will assume, as we clearly may without loss of generality, that $p_0 = 0$. Also, we know that there is a $C > 0$ such that the bound (A.36) holds. So we can assume, by making $\bar{\varepsilon}$ smaller, if necessary, that $||W_p||_{TV} \leq C||p||$ whenever $||p|| \leq \bar{\varepsilon}$. By making C larger and $\bar{\varepsilon}$ smaller, if necessary, we may also assume that $C \geq 1$, and

$$8e^{||A||_{L^1}}||\psi_\varepsilon||_{L^1} < 1 \qquad \text{for} \qquad \varepsilon \in]0, \bar{\varepsilon}]. \tag{A.38}$$

Pick $\varepsilon \in]0, \bar{\varepsilon}[$, and choose $\delta > 0$ such that

$$C\delta < \varepsilon. \tag{A.39}$$

Notice that $\delta < \varepsilon$, since $C \geq 1$.

Let p, $\bar{x}$ be such that $||p|| \leq \delta$ and $||\bar{x} - \xi(a)|| \leq \delta$. Let $\zeta \in \mathrm{MTraj}(f_p, \bar{x}, a)$, and let $I = \mathrm{Dom}(\zeta)$. Then $a \in I$. Let c be the supremum of those t such that $a \leq t \leq b$ and $||\zeta(s) - \xi(s)|| \leq \varepsilon$ for $a \leq s \leq t$. Then $a < c \leq b$, $c \in I$, and either $c = b$ or $||\zeta(c) - \xi(c)|| = \varepsilon$. (The fact that $a < c$ follows from the local existence property, since $||\bar{x} - \xi(a)|| \leq \delta < \varepsilon < \bar{\varepsilon}$, and ζ is continuous. The fact that $c \in I$ follows from the forward limit property, since the graph of the restriction of ζ to $[a, c[$ is contained in $\mathcal{T}(\xi, \varepsilon)$. If $c < b$ and $||\zeta(c) - \xi(c)|| < \varepsilon$, then the forward existence property implies that ζ is not maximal.)

We will estimate $||\zeta(t) - \xi(t)||$ for $t \in [a, c]$, and show that—if ε is small enough, and δ is suitably chosen—$||\zeta(t) - \xi(t)|| < \varepsilon$ for all such t, including $t = c$. This will imply that $c = b$.

From now on, we work on the interval $[a, c]$. We have

$$\zeta(t) - \xi(t) = \bar{x} - \xi(a) + \int_a^t (f_p(\zeta(s), s) - f_0(\xi(s), s))\, ds, \tag{A.40}$$

so

$$\zeta(t) - \xi(t) = \bar{x} - \xi(a) + W_p(t) + \int_a^t (f_p(\zeta(s), s) - f_p(\xi(s), s))\, ds. \tag{A.41}$$

Let $r_p(t) = ||f_p(\zeta(t), t) - f_p(\xi(t), t) - A(t).(\zeta(t) - \xi(t))||$. Then

$$\zeta(t) - \xi(t) = \bar{x} - \xi(a) + W_p(t) + \int_a^t A(s).(\zeta(s) - \xi(s))\, ds + \int_a^t r_p(s)\, ds, \tag{A.42}$$

so

$$||\zeta(t) - \xi(t)|| \leq ||\bar{x} - \xi(a)|| + ||W_p||_{sup} + \int_a^t ||A(s)||.||\zeta(s) - \xi(s)||\, ds + \int_a^t r_p(s)\, ds, \tag{A.43}$$

and then

$$||\zeta(t) - \xi(t)|| \leq ||\bar{x} - \xi(a)|| + ||W_p||_{sup} + 2\varepsilon||\psi_\varepsilon||_{L^1} + \int_a^t ||A(s)||.||\zeta(s) - \xi(s)||\, ds, \tag{A.44}$$

because $r_p(s) \leq 2\varepsilon\psi_\varepsilon(s)$ for $s \in [a, c]$, since $||\zeta(s) - \xi(s)|| \leq \varepsilon$ and $||p|| \leq \varepsilon$.

Since $||\bar{x} - \xi(a)|| \leq \delta$, and $||W_p||_{sup} \leq ||W||_{TV} \leq C||p|| \leq C\delta$, Gronwall's inequality implies

$$||\zeta(t) - \xi(t)|| \leq e^{||A||_{L^1}}((C + 1)\delta + 2\varepsilon||\psi_\varepsilon||_{L^1}). \tag{A.45}$$

In view of (A.38), we have

$$2\varepsilon e^{||A||_{L^1}}||\psi_\varepsilon||_{L^1} < \frac{\varepsilon}{4}. \tag{A.46}$$

Now suppose that

$$\delta \le \kappa\varepsilon, \qquad \text{where} \qquad \kappa = (4C+4)^{-1}e^{-||A||_{L^1}}. \tag{A.47}$$

Then

$$||\zeta(t) - \xi(t)|| \le \frac{\varepsilon}{2} \qquad \text{for all} \qquad t \in [a,c]. \tag{A.48}$$

This is our desired estimate, from which it follows, as explained above, that $c = b$, and then $||\zeta(t) - \xi(t)|| \le \varepsilon$ for all $t \in [a,b]$. This completes the proof of (A.7.a).

Besides proving (A.7.a), we have also shown that, if κ is the constant given by (A.47), then the conclusion of (A.7.a) holds for every δ such that $0 < \delta \le \kappa\varepsilon$. (Notice that if $\delta \le \kappa\varepsilon$, then (A.39) holds.)

Now suppose we are given a map $P \ni p \to \bar{x}_p \in \mathbb{R}^n$ which is defined for $||p|| \le \bar{\delta}$ for some $\bar{\delta} > 0$. Assume that this map is Fréchet differentiable at 0, with differential L, and is such that $\bar{x}_0 = \xi(a)$. Write $z_p = Y_{A,dV_p,L.p}$, where $V_p = D^w\mathcal{W}(0).p$.

It then follows that there exist a constant $C' \ge 1$ and a $\bar{\delta}' \in]\,0, \bar{\delta}]$ such that (i) $C'\bar{\delta}' \le \kappa\bar{\varepsilon}$ and (ii) $||\bar{x}_p - \xi(a)|| \le C'||p||$ for $||p|| \le \bar{\delta}'$.

Pick in an arbitrary fashion $\xi_p \in \mathrm{MTraj}(f_p, \bar{x}_p, a)$ for $||p|| \le \bar{\delta}'$. Then, if $||p|| \le \bar{\delta}'$, it follows that (i) ξ_p is defined, (ii) $\xi_p \in \mathrm{MTraj}(f_p, \bar{x}, a)$ for an $\bar{x}$—namely, $\bar{x}_p$—such that $||\bar{x} - \xi(a)|| \le C'\bar{\delta}' \le \kappa\bar{\varepsilon}$. Since $C' \ge 1$, we also have $||p|| \le \kappa\bar{\varepsilon}$. Therefore we can conclude—using $\varepsilon = \bar{\varepsilon}$ and $\delta = \kappa\bar{\varepsilon}$—that $[a,b] \subseteq \mathrm{Dom}(\xi_p)$ and $(\xi_p(t), t) \in \mathcal{T}(\xi, \bar{\varepsilon})$ for $t \in [a,b]$.

Moreover, using (A.33) with $p = p_0$ it is easy to see that $\xi_0(t) = \xi(t)$ for every $t \in [a,b]$, since both trajectories satisfy the same initial condition.

Let x_p be the restriction of ξ_p to $[a,b]$. For $||p|| \le \bar{\delta}'$, we have

(A.49)

$$\begin{aligned} x_p(t) - \xi(t) - z_p(t) &= \bar{x}_p - \xi(a) - L.p \\ &\quad + \int_a^t A(s).(x_p(s) - \xi(s) - z_p(s))\,ds + W_p(t) - V_p(t) + R_p(t), \end{aligned}$$

where $R_p(t) = \int_a^t \tilde{r}_p(s)\,ds$ and $\tilde{r}_p(s) = f_p(x_p(s), s) - f_p(\xi(s), s) - A(s).(x_p(s) - \xi(s))$. If $p \ne 0$, let

$$\begin{aligned} Y_p &= ||p||^{-1}(x_p - x_0 - z_p), \\ U_p &= ||p||^{-1}(W_p - V_p + R_p), \\ \bar{Y}_p &= ||p||^{-1}(\bar{x}_p - x_0(a) - L.p). \end{aligned} \tag{A.50}$$

Then $Y_p = Y_{A,dU_p,\bar{Y}_p}$.

We have to prove that Y_p weak*-converges to 0 as $p \to 0$. Since $\bar{Y}_p \to 0$, using Theorem A.5 our conclusion will follow if we show that U_p weak*-converges to 0. Since $V_p = D^w\mathcal{W}(0).p$, it is clear that $||p||^{-1}(W_p - V_p)$ weak*-converges to 0. So all we need is to prove that $||p||^{-1}R_p$ weak*-converges to 0. If $||p||$ is sufficiently small, then we can apply the previous estimates using $\delta = ||p||$, $\varepsilon = \frac{\delta}{\kappa}$. We conclude that $||r_p(s)|| \leq 2\varepsilon\psi_\varepsilon(s)$ for all $s \in [a, b]$. This implies that

$$||\tilde{r}_p||_{L^1} \leq \frac{2||p||}{\kappa}||\psi_{\kappa^{-1}||p||}||_{L^1}. \tag{A.51}$$

This shows that $||R_p||_{TV} = ||r_p||_{L^1} = o(||p||)$ as $p \to 0$. So $||p||^{-1}R_p$ converges to 0 strongly—and a fortiori weakly*—in $BV([a, b], \mathbb{R}^n)$. This completes our proof. □

If $f \in TVVF(\mathbb{R}^n)$ and $\xi : [a, b] \to \mathbb{R}^n$ is a trajectory of f, we say that f *is differentiable along* ξ if the map $x \to f(x, t)$ is differentiable at $\xi(t)$ for almost every t. In that case, we write $D_\xi f(t) \overset{\text{def}}{=} \frac{\partial f}{\partial x}(\xi(t), t)$, and refer to the map $[a, b] \ni t \to D_\xi f(t) \in \mathbb{R}^{n\times n}$ as the *differential of* f *along* ξ.

Lemma A.8. *If* $\mathbf{f}$ *is weakly differentiable at* p_0 *along a trajectory* $\xi : [a, b] \to \mathbb{R}^n$ *of* f_{p_0}, *then* f_{p_0} *is differentiable along* ξ *and the map* A *of* (WD3) *is such that* $A(t) = D_\xi f_{p_0}(t)$ *for almost all* $t \in [a, b]$.

Proof. We begin by showing that the functions ψ_ε for which (WD3) holds can be chosen so that $\psi_\varepsilon(t)$ is a monotonically nonincreasing function of ε for each t. To see this, start with some family $\{\psi_\varepsilon\}_{\varepsilon\in]0,\bar{\varepsilon}]}$ of functions for which (WD3) holds, and define $\hat{\psi}_\varepsilon = \psi_{2^{-k}\bar{\varepsilon}}$ whenever $2^{-k-1}\bar{\varepsilon} < \varepsilon \leq 2^{-k}\bar{\varepsilon}$ and k is a nonnegative integer. Then (WD3) also holds if the $\hat{\psi}_\varepsilon$ are substituted for the ψ_ε. Next define $\bar{\psi}_\varepsilon(t) = \min\{\hat{\psi}_{\varepsilon'}(t) : \varepsilon \leq \varepsilon' \leq \bar{\varepsilon}\}$. Then the $\bar{\psi}_\varepsilon$ are well-defined integrable functions of t, because for each ε the set of functions $\{\hat{\psi}_{\varepsilon'} : \varepsilon \leq \varepsilon' \leq \bar{\varepsilon}\}$ is finite. It is clear that (WD3) also holds with the $\bar{\psi}_\varepsilon$ instead of the $\hat{\psi}_\varepsilon$, and in addition $\hat{\psi}_\varepsilon(t)$ is nonincreasing as a function of ε.

Now, if we pick the ψ_ε to be monotonically nonincreasing with respect to ε, it follows that the limit $\rho(t) = \lim_{\varepsilon\downarrow 0}\psi_\varepsilon(t)$ exists for every t. By the dominated convergence theorem, $\int_a^b \rho(t)dt = 0$. Since $\rho(t) \geq 0$ for all t, it follows that $\rho(t) = 0$ a.e.

Let t be such that $\rho(t) = 0$. Let $\theta(x) = \psi_{||x-\xi(t)||}(t)$. Then $\lim_{x\to\xi(t)}\theta(x) = 0$. On the other hand, (WD3) implies that

$$||f_{p_0}(x, t) - f_{p_0}(\xi(t), t) - A(t).(x - \xi(t))|| \leq \theta(x)||x - \xi(t)||. \tag{A.52}$$

Since $\theta(x) \to 0$ as $x \to \xi(t)$, (A.52) says precisely that $A(t)$ is the differential at $\xi(t)$ of the map $x \to f_{p_0}(x, t)$, completing our proof. □

If $f \in TVVF(\mathbb{R}^n)$ is differentiable along a trajectory $\xi : [a, b] \to \mathbb{R}^n$ of f, and the matrix-valued function $D_\xi f$ is integrable, then the ordinary differential equation

$$\dot{\lambda}(t) = -\lambda(t).D_\xi f(t), \tag{A.53}$$

for an $\mathbb{R}_n$-valued function λ on $[a, b]$, is the *adjoint variational equation*—or, simply, the *adjoint equation*—for f along ξ. A solution of the adjoint equation (i.e., an absolutely continuous function $\lambda : [a, b] \to \mathbb{R}_n$ such that (A.53) holds for almost all t) is known as an *adjoint vector for* f *along* ξ.

Theorem A.9. *Let* P, $\mathbf{f} = \{f_p\}_{p\in P}$, $p_0 \in P$, $\xi : [a, b] \to \mathbb{R}^n$ *be as in Theorem* A.7. *Let* $P \ni p \to \bar{x}_p\imath\mathbb{R}^n$ *be a map which is Fréchet differentiable at* p_0 *and such that* $\bar{x}_{p_0} = \xi(a)$, *and let* L_a *be its differential at* p_0. *Let* ξ_p *be, for* p *close enough to* p_0, *maximal trajectories of* f_p *such that* $\xi_p(a) = \bar{x}_p$, *and let* x_p *be the restriction of* ξ_p *to* $[a, b]$. *Then the map* $p \to x_p(b)$ *is differentiable at* p_0. *Let* L_b *be its differential at* p_0. *Let* $\lambda : [a, b] \to \mathbb{R}^n$ *be an adjoint vector for* f_{p_0} *along* ξ. *Then*

$$\lambda(b) \cdot L_b(v) - \lambda(a) \cdot L_a(v) = \lim_{\varepsilon\downarrow 0}\varepsilon^{-1}\int_a^b \langle\lambda(t), f_{p_0+\varepsilon v}(\xi(t), t) - f_{p_0}(\xi(t), t)\rangle dt \tag{A.54}$$

for every $v \in \mathbb{R}^n$.

Proof. Assume, without loss of generality, that $p_0 = 0$. According to Theorem A.7 and Lemma A.8, the map $p \to x_p$ is weak* Fréchet differentiable at 0—as a map from P to $BV([a,b],\mathbb{R}^n)$—and its differential at 0 is the map that sends $v \in P$ to $Y_{A,d(U.v),L_a(v)}$, where $U = D^w\mathcal{W}(0)$, and $\mathcal{W}$ is the map $p \to W_p$, where $W_p(t) = \int_a^t (f_p(\xi(s),s) - f_0(\xi(s),s))dt$, and $A = D_\xi f$. Then $p \to x_p(b)$ is Fréchet differentiable at 0, and the differential L_b is given by $L_b(v) = Y_{A,d(U.v),L_a(v)}(b)$. Clearly, $L_a(v) = Y_{A,d(U.v),L_a(v)}(a)$. Since λ satisfies $\dot\lambda = -\lambda.A$, Lemma A.4 tells us that

$$\lambda(b)\cdot L_b(v) - \lambda(a)\cdot L_a(v) = \int_a^b \lambda.d(U.v).$$

Since $U.v$ is the weak*-limit of $\varepsilon^{-1}W_{\varepsilon v}$ as $\varepsilon \downarrow 0$, our conclusion follows. □

We now turn to the differentiation of a Lagrangian cost functional.

If $f \in TVVF(\mathbb{R}^n)$, a *Lagrangian* for f in $\mathbb{R}^n$ is a real-valued function L such that

(L.1) $\mathrm{Dom}(f) \subseteq \mathrm{Dom}(L)$;

(L.2) the function $t \to L(\xi(t),t)$ is locally integrable for every $\xi \in \mathrm{Traj}(f)$.

If $f \in TVVF(\mathbb{R}^n)$ has components $f^1,\ldots,f^n$, and L is a Lagrangian for f, then we can consider the time-varying vector field $[L;f]$ in $\mathbb{R}^{n+1}$ whose components are $(f^0,f^1,\ldots,f^n)$, where $f^0 \equiv L$. A trajectory of $[L;f]$ can then be regarded as a pair (ξ^0,ξ), where $\xi \in \mathrm{Traj}(f)$ and ξ^0 is a real-valued locally absolutely continuous function on $\mathrm{Dom}(\xi)$ such that $\dot\xi^0(t) = L(\xi(t),t)$ for a.e. t. Any such function ξ^0 will be called a *running L-cost along* ξ. Our definition of a Lagrangian implies that a running L-cost along ξ exists for all $\xi \in \mathrm{Traj}(f)$, and it is clear that any two running L-costs along ξ must differ by a constant. If ξ is such that $\mathrm{Dom}(\xi)$ is of the form $[a,b]$ or $[a,b[$ or $[a,\infty[$, then there is a canonical choice of running L-cost along ξ, obtained by letting $\xi^0(t) = \int_a^t L(\xi(s),s)\,ds$. In that case, we will write ξ^L to denote the curve $t \to (\xi^0(t),\xi(t))$, where ξ^0 is the canonical running L-cost.

Now suppose we are given data P, $\mathbf{f}$, p_0, ξ as in (D.1,2,3,4), as well as

(D.5) a family $\mathbf{L} = \{L_p\}_{p\in P}$ such that each L_p is a Lagrangian for f_p.

Given a trajectory $\xi : [a,b] \to \mathbb{R}^n$ of f_{p_0}, we say that the pair $(\mathbf{f},\mathbf{L})$ is *weakly differentiable at* p_0 *along* ξ if the family $\{[L_p;f_p]\}_{p\in P}$ is weakly differentiable along $\xi^{L_{p_0}}$.

It is easy to see that $(\mathbf{f},\mathbf{L})$ is weakly differentiable at p_0 along ξ if and only if there exists $\bar\varepsilon > 0$ such that (WD1,2,3,4) hold, and in addition the following hold:

(WD5) *There exists* $h \in L^1([a,b],\mathbb{R}_n)$ *such that*

$$||L_p(x,t) - L_p(\xi(t),t) - h(t).(x-\xi(t))|| \le \psi_\varepsilon(t)(||x-\xi(t)|| + ||p-p_0||) \tag{A.55}$$

whenever $a \le t \le b$, $||x-\xi(t)|| \le \varepsilon$, *and* $||p-p_0|| \le \varepsilon$.

(WD6) *If we let* $w_p^0(t) = L_p(\xi(t),t) - L_{p_0}(\xi(t),t)$, $W_p^0(t) = \int_a^t w_p^0(s)\,ds$, *then the map* $\mathcal{W}^0$ *that sends* p *to* $\mathcal{W}^0(p) = W_p^0 \in BV([a,b],\mathbb{R})$ *is weak* Fréchet differentiable at* p_0.

If $f \in TVVF(\mathbb{R}^n)$, $\xi : [a,b] \to \mathbb{R}^n$ is a trajectory of f, and L is a Lagrangian for f, we say that L *is differentiable along* ξ if the map $x \to L(x,t)$ is differentiable at $\xi(t)$ for almost every t. In that case, we write $\nabla_\xi L(t) \overset{\mathrm{def}}{=} \nabla_x L(\xi(t),t)$, and refer to the map $[a,b] \ni t \to \nabla_\xi L(t) \in \mathbb{R}^n$ as the *differential of* L *along* ξ.

Lemma A.8, applied to the curve $\xi^{L_{p_0}}$, yields the following.

LEMMA A.10. *If* $(\mathbf{f},\mathbf{L})$ *is weakly differentiable at* p_0 *along a trajectory* $\xi : [a,b] \to \mathbb{R}^n$ *of* f_{p_0}, *then* f_{p_0} *and* L_{p_0} *are differentiable along* ξ *and the maps* A, h *of* (WD3,5) *are such that* $A(t) = D_\xi f_{p_0}(t)$ *and* $h(t) = \nabla_\xi L_{p_0}(\xi(t),t)$ *for almost all* $t \in [a,b]$.

Under the hypothesis of Lemma A.10, we can apply Theorem A.9 to the family $\{[L_p; f_p]\}_{p\in P}$ and the curve $\xi^{L_{p_0}}$. Define

$$J_p(\zeta) = \int_a^b L_p(\zeta(t), t)\, dt, \tag{A.56}$$

if $\zeta : [a, b] \to \mathbb{R}^n$ is a curve such that the integral exists. (We will only be using this when $\zeta \in \mathrm{Traj}(f_p)$, in which case $J_p(\zeta)$ is well defined.) An adjoint vector for $[L_{p_0}; f_{p_0}]$ along $\xi^{L_{p_0}}$ is then a pair (λ^0, λ) such that $\lambda^0 \in \mathbb{R}$, $\lambda : [a, b] \to \mathbb{R}_n$ is absolutely continuous, and

$$\dot\lambda(t) = -\lambda(t).A(t) - \lambda^0 h(t) \qquad \text{for a.e.} \qquad t \in [a, b]. \tag{A.57}$$

Theorem A.9 then implies the following.

Theorem A.11. *Assume that we are given data P, $\mathbf{f}$, p_0, ξ, $\mathbf{L}$ as in* (D.1,2,3,4,5). *Assume that $(\mathbf{f}, \mathbf{L})$ is weakly differentiable at p_0 along ξ. Let $P \ni p \to \bar x_p \in \mathbb{R}^n$ be a map which is Fréchet differentiable at p_0 and such that $\bar x_{p_0} = \xi(a)$ and let L_a be its differential at p_0. Let ξ_p be, for p close enough to p_0, maximal trajectories of f_p such that $\xi_p(a) = \bar x_p$, and let x_p be the restriction of ξ_p to $[a, b]$. Then the maps $p \to x_p(b)$ and $p \to J_p(x_p)$ are differentiable at p_0. Let L_b, L_b^0 be their differentials at p_0. Then, if (λ^0, λ) is an adjoint vector for $[L_{p_0}, f_{p_0}]$ along ξ, it follows that*

$$\begin{aligned}&\lambda(b) \cdot L_b(v) + \lambda^0 L_b^0(v) - \lambda(a) \cdot L_a(v)\\ &\quad= \lim_{\varepsilon\downarrow 0} \varepsilon^{-1} \int_a^b \Big(H_{p_0+\varepsilon v}(\lambda(t), \lambda_0, \xi(t), t) - H_{p_0}(\lambda(t), \lambda_0, \xi(t), t)\Big)\, dt,\end{aligned} \tag{A.58}$$

where

$$H_p(z, z^0, x, t) = \langle z, f_p(x, t)\rangle + z^0 L_p(x, t) \tag{A.59}$$

for $x \in \mathbb{R}^n$, $z \in \mathbb{R}_n$, $z^0 \in \mathbb{R}$, $t \in [a, b]$.

Appendix B. A lemma.

Lemma B.1. *Let f be a real-valued function on a compact interval $[a, b]$. Assume that there exists a finite or countable subset E of $[a, b]$ with the following properties:*

(B.1.a) $\liminf_{h\downarrow 0} \frac{f(x+h)-f(x)}{h} \geq 0$ *for all $x \in [a, b[\backslash E$,*

(B.1.b) $\liminf_{h\downarrow 0} f(x + h) \geq f(x)$ *for all $x \in [a, b[$,*

(B.1.c) $\liminf_{h\downarrow 0} f(x - h) \leq f(x)$ *for all $x \in]\,a, b]$.*

Then $f(b) \geq f(a)$.

Proof. Let $\varepsilon > 0$ be arbitrary. We will prove that $f(b) \geq f(a) - \varepsilon$. Let $\varepsilon' = \frac{\varepsilon}{1+b-a}$ and $E = \{x_k : k \in \mathbb{N}\}$.

For each $x \in [a, b]$, let $I(x) = \{k : x_k < x\}$. Define $g : [a, b] \to \mathbb{R}$ by

$$g(x) = \sum_{k\in I(x)} 2^{-k}\varepsilon'.$$

Then g is left-continuous and monotonically nondecreasing.

Let S be the set of all $x \in [a, b]$ such that $f(y) \geq f(a) - (y - a)\varepsilon' - g(y)$ for all $y \in [a, x]$. It is clear that $a \in S$, and also that S is an interval. So S is of the form $[a, c[$ or $[a, c]$, with $c \in [a, b]$.

Suppose $S = [a, c\,[$. Then $c > a$. By (B.1.c), given $\delta > 0$ there is a sequence $\{z_j\}$ of points of $[a, b]$ such that $z_j < c$, $z_j \to c$, and $f(c) \geq f(z_j) - \delta$. Then the z_j belong to S, so the inequalities $f(z_j) \geq f(a) - (z_j - a)\varepsilon' - g(z_j) \geq f(a) - (c-a)\varepsilon' - g(c)$ hold. It then follows that $f(c) \geq f(a) - (c-a)\varepsilon' - g(c) - \delta$. Since δ is arbitrary, we have $f(c) \geq f(a) - (c-a)\varepsilon' - g(c)$, so $c \in S$, which is a contradiction.

Therefore $S = [a, c]$ for some $c \in [a, b]$. We now show that $c = b$. Assume that $c < b$, and consider separately the cases $c \notin E$, $c \in E$.

If $c \notin E$, then (B.1.a) implies that there exists a $c' > c$ such that $f(x) - f(c) \geq -(x-c)\varepsilon'$ for every $x \in [c, c']$. But then, since $f(c) \geq f(a) - (c-a)\varepsilon' - g(c)$, we can conclude that $f(x) \geq f(a) - (x-a)\varepsilon' - g(c) \geq f(a) - (x-a)\varepsilon' - g(x)$ for $x \in [c, c']$. Therefore $c' \in S$, contradicting the fact that $S = [a, c]$.

Now suppose $c \in E$. Then $c = x_k$ for some k, and $x_k \neq b$. By (B.1.b), there exists $h > 0$ such that $c + h \leq b$ and $f(y) - f(c) \geq -2^{-k}\varepsilon'$ for all $y \in [c, c+h]$. If $y \in]\,c, c+h]$, then $k \notin I(c)$, and $I(c) \cup \{k\} \subseteq I(y)$. Therefore $g(y) \geq g(c) + 2^{-k}\varepsilon'$. Since $f(c) \geq f(a) - (c-a)\varepsilon' - g(c)$, we have $f(y) \geq f(c) - 2^{-k}\varepsilon' \geq f(a) - (c-a)\varepsilon' - 2^{-k}\varepsilon' - g(c) \geq f(a) - (y-a)\varepsilon' - g(y)$. So $c + h \in S$, which is a contradiction.

We have therefore proved that $c = b$. Then

$$f(b) \geq f(a) - (b-a)\varepsilon' - g(b) \geq f(a) - (b-a)\varepsilon' - \varepsilon' = f(a) - \varepsilon.$$

Since ε is arbitrary, we have shown that $f(b) \geq f(a)$, as desired. □

Appendix C. A simpler version of Brunovský's stratification condition. We prove that (Br.3.A) *holds if and only if $\mathcal{P}$ is a stratification of S.* It is clear that if $\mathcal{P}$ is a stratification of S, then (Br.3.A) holds. Let us prove the converse. Suppose that (Br.3.A) holds. Then $\mathcal{P}$ is a locally finite partition of S into nonempty connected embedded $\mathcal{C}^1$ submanifolds of S. Let us prove by contradiction that the frontier axiom (FA) holds. Suppose the axiom was violated for some pair (P_1, P_2) of members of $\mathcal{P}$. Of all these "bad" pairs, choose one for which P_1 has the largest possible dimension. Then P_1, P_2 are in $\mathcal{P}$, $P_1 \neq P_2$ (so $P_1 \cap P_2 = \emptyset$), and $P_1 \cap clos(P_2) \neq \emptyset$. Let $\tilde{P}_1 = P_1 \cap clos(P_2)$, so $\tilde{P}_1$ is a nonempty relatively closed subset of P_1. We will show that $\tilde{P}_1 = P_1$, contradicting the fact that (P_1, P_2) is a bad pair. To begin with, we cannot have $P_2 = \{0\}$, for if $P_2 = \{0\}$, then P_2 would be closed, so $P_1 \cap P_2 = P_1 \cap clos(P_2) = \tilde{P}_1 \neq \emptyset$, which is a contradiction. Also, $\dim(P_1) < n$, for if $\dim(P_1) = n$, then P_1 would be open, so the fact that $P_1 \cap clos(P_2) \neq \emptyset$ would imply that $P_1 \cap P_2 \neq \emptyset$, which is a contradiction. Finally, we may assume that $P_1 \neq \{0\}$, because if $P_1 = \{0\}$, then $\tilde{P}_1 = \{0\} = P_1$, because $\tilde{P}_1 \subseteq P_1$ and $\tilde{P}_1 \neq \emptyset$. So from now on we take it for granted that $P_1 \neq \{0\}$, $P_2 \neq \{0\}$, and $\dim(P_1) < n$, so, in particular, $P_1 \in \mathcal{P}'$. Let us first assume that $\dim(P_2) < n$. Then $P_2 \in \mathcal{P}'$. So both P_2 and P_1 belong to $\mathcal{P}'$, and in addition $P_1 \cap clos(P_2) \neq \emptyset$. Since $\mathcal{P}'$ is a stratification of S' by (Br.3.A), it follows that $P_1 \subseteq clos(P_2)$, contradicting the fact that the pair (P_1, P_2) was bad. This excludes the possibility that $\dim(P_2) < n$, and we are left with the case when $\dim(P_2) = n$, so P_2 is open in S. Let $\hat{P}_1 \stackrel{\text{def}}{=} P_1 \backslash \tilde{P}_1$. The fact that (P_1, P_2) is a bad pair implies that $\hat{P}_1 \neq \emptyset$. Since $\tilde{P}_1 \neq \emptyset$, $\tilde{P}_1$ is relatively closed in P_1, and P_1 is connected, it follows that $\hat{P}_1$ is not relatively closed in P_1. So $\tilde{P}_1 \cap clos_{P_1}(\hat{P}_1) \neq \emptyset$. Pick a point $\bar{x} \in \tilde{P}_1 \cap clos_{P_1}(\hat{P}_1)$. Let $m = \dim(P_1)$. We already know that $m < n$. Choose a coordinate chart $\mathbf{x} = (x^1, \ldots, x^n) : N \to \mathbb{R}^n$ that maps an open neighborhood N of $\bar{x}$ diffeomorphically onto the open cube $]-1, 1\,[^{\,n}$ in $\mathbb{R}^n$, in such a way that $\mathbf{x}(\bar{x}) = 0$ and $\mathbf{x}(P_1 \cap N) =]-1, 1\,[^{\,m} \times \{0\}^{n-m}$. For $\delta > 0$, let $N(\delta) = \mathbf{x}^{-1}(]-\delta, \delta\,[^{\,n})$. Since $\mathcal{P}$ is locally finite, if we let $Q(\delta)$ be the set of all $P \in \mathcal{P}$ that intersect $N(\delta)$, then there must exist a $\bar{\delta}$ such that the set $Q = Q(\delta)$ is finite and independent of δ for $\delta \in]\,0, \bar{\delta}]$. Clearly, $P_1 \in Q$ and $P_2 \in Q$. Let $Z(\delta) = clos_{N(\delta)}(P_2 \cap N(\delta))$. Then $(P_2 \cup \tilde{P}_1) \cap N(\delta) \subseteq Z(\delta)$. Let us exclude the possibility that $(P_2 \cup \tilde{P}_1) \cap N(\delta) = Z(\delta)$.

If $(P_2 \cup \tilde{P}_1) \cap N(\delta) = Z(\delta)$, then $P_2 \cap (N(\delta) \backslash P_1)$ is relatively closed in $N(\delta)\backslash P_1$. Since $P_2 \cap (N(\delta)\backslash P_1)$ is also relatively open in $N(\delta)\backslash P_1$ and nonempty, it follows that $P_2 \cap (N(\delta)\backslash P_1)$ must be a union of connected components of $N(\delta)\backslash P_1$. If $m < n-1$, then $N(\delta)\backslash P_1$ is connected, so $P_2 \cap (N(\delta)\backslash P_1) = N(\delta)\backslash P_1$. If $m = n-1$, then $N(\delta)\backslash P_1$ has two connected components, and $P_1 \cap N(\delta)$ is entirely contained in the closure of each one of them. So in both cases it follows that $P_1 \cap N(\delta) \subseteq clos(P_2)$. But then $P_1 \cap N(\delta) \subseteq \tilde{P}_1$, showing that $\tilde{P}_1$ is a relative neighborhood of $\bar{x}$ in P_1, which contradicts our choice of $\bar{x}$ as a limit point in P_1 of $P_1 \backslash \tilde{P}_1$. We now know that $(P_2 \cup \tilde{P}_1) \cap N(\delta)$ is a proper subset of $Z(\delta)$, for each $\delta \in]\,0, \bar{\delta}]$. Fix a sequence $\{\delta_j\}$ such that $0 < \delta_j \leq \bar{\delta}$ for all j and $\delta_j \downarrow 0$. Pick $y_j \in Z(\delta_j)\backslash((P_2 \cup \tilde{P}_1) \cap N(\delta_j))$. Then every y_j belongs to a $P^j \in Q$, but $y_j \notin P_1 \cup P_2$. (It is obvious that $y_j \notin P_2$ and $y_j \notin \tilde{P}_1$, since $y_j \in N(\delta_j)$. On the other hand, $y_j \in clos(P_2)$, so y_j cannot be in P_1, because if it was in P_1 it would belong to $\tilde{P}_1$.) So $P_1 \neq P^j \neq P_2$ for every j. Since Q is finite, we may assume, after passing to a subsequence, that all the P_j's are equal to one and the same $P \in Q$. By construction, $P \cap clos(P_2) \neq \emptyset$, because all the y_j are in $clos(P_2)$. Since $P \neq P_2$, P cannot be open, because $P \in \mathcal{P}$, so $P \cap P_2 = \emptyset$, thanks to the fact that $\mathcal{P}$ is a partition, so if P was open, then $P \cap clos(P_2)$ would be empty. So $\dim(P) < n$. Moreover, $P \neq \{0\}$ because $y_j \neq \bar{x}$ but $y_j \to \bar{x}$ and $y_j \in P$. So $P \in \mathcal{P}'$. Since $\bar{x} \in clos(P) \cap P_1$, and both P and P_1 are in $\mathcal{P}'$, it follows that $P_1 \subseteq clos(P)$ and $\dim(P_1) < \dim(P)$. Since we have chosen (P_1, P_2) to be a bad pair for which $\dim(P_1)$ is maximized, we can infer that (P, P_2) is not a bad pair. Since P and P_2 are in $\mathcal{P}$, and $P \cap clos(P_2) \neq \emptyset$, the inclusion $P \subseteq clos(P_2)$ must hold. But then $clos(P) \subseteq clos(P_2)$ as well, and this implies that $P_1 \subseteq clos(P_2)$, since we know that $P_1 \subseteq clos(P)$. So (P_1, P_2) is not a bad pair after all, and our proof is complete.

Acknowledgments. We want to thank Michael Malisoff for carefully reading the paper and for many useful discussions and suggestions. The final part of the work was carried out between January and June 1998 while the second author author was a visitor at the Institut Henri Poincaré in Paris. He is grateful to the Institut Henri Poincaré for its kind hospitality during this period.

NONPARAMETRIC ESTIMATION AND ADAPTIVE CONTROL OF FUNCTIONAL AUTOREGRESSIVE MODELS[*]

BRUNO PORTIER[†] AND ABDERRAHIM OULIDI[‡]

Abstract. This paper deals with nonparametric estimation and adaptive control of nonlinear systems of the form $X_{n+1} = f(X_n) + U_n + \xi_{n+1}$ ($n \in \mathbb{N}$) where the state X_n is observed, f is an unknown function, and the control U_n is chosen in order to track a given reference trajectory. We estimate the function f using a nonparametric estimator and study two adaptive control laws built from this nonparametric estimator and derived from the self-tuning control. The first one can be used for open-loop stable systems and requires an additional exciting noise. The second one needs some a priori knowledge on function f but allows us to control open-loop unstable systems. We establish some general results on the nonparametric estimator of f like the uniform almost sure convergence over dilating sets and then prove that both adaptive control laws are asymptotically optimal in quadratic mean. In addition, we give a strongly consistent estimator of the covariance matrix of the unobservable white noise ξ_n.

Key words. adaptive control, discrete-time stochastic nonlinear system, nonparametric estimation, optimal adaptive tracking

1. Introduction.

Since Aström and Wittenmark [2] introduced the self-tuning regulator in 1973, the stochastic adaptive tracking problem has drawn much attention from the control community (see, for example, Chen and Guo [7], Caines [6], Chen [8], Duflo [13], and the references therein). For linear models, the ARX and ARMAX models, the difficult problem of identifying unknown parameters and simultaneously tracking a reference signal has been completely solved using both the weighted least squares algorithm (see Bercu [3], [4] and Guo [18]) and a slight modification of the extended least squares algorithm (see Guo and Chen [16], Guo [17]).

Nevertheless, these linear models are not well suited for modelling when the relation between the state and its past is nonlinear. Several authors have proposed interesting methods for adaptive control of nonlinear models: neural networks-based methods, for example, have been increasingly used (see Narendra and Parthasarathy [27], Chen and Khalil [9] and Jagannathan, Lewis, and Pastravanu [22]). But, for these methods, theoretical results are not always proven.

In this paper, we consider the problem of adaptive control of discrete-time nonlinear stochastic systems. We will focus on NARX models on $\mathbb{R}^d$ ($d \in \mathbb{N}^*$) of the form

$$X_{n+1} = f(X_n) + U_n + \xi_{n+1} \quad (n \in \mathbb{N}), \tag{1.1}$$

where X_n, U_n, and ξ_n are the system output, input, and driven noise of the system, respectively. State X_n is observed, driving function f is unknown, ξ_n is an unobservable white noise, and control U_n is chosen in order to track a given deterministic reference trajectory, denoted by $(X_n^*)_{n\geq 1}$.

Clearly, this is quite a small class of models. Indeed, state is observed, time delay is equal to one, both control and state are in the same space ($\mathbb{R}^d$), and the system is always stabilizable. Our work, though, is a first step toward the study of nonlinear stochastic control systems and deals with the problem of unknown function f estimation. It should be noticed, however, that despite its simplicity, model (1.1) has already been used (in a slightly different version) to regulate the output gas flow-rate of an aerobic digestion process by adapting the liquid flow-rate of an influent of industrial wine distillery wastewater (see Hilgert et al. [21]).

In order to estimate function f, we introduce a kernel method-based recursive estimator (see Härdle [19], Devroye and Györfi [11]). We use general results on nonparametric estimation of regression functions. Using nonparametric estimation may come with a price, however. Compared with parametric methods, nonparametric ones have slower convergence rates. This is the counterpart of the flexibility of such nonparametric design. Let us mention that kernel estimation methods are also used in identification problems for nonlinear dynamic systems such as Hammerstein systems (see Greblicki [14], Greblicki and Pawlak [15]).

Nonparametric estimation of regression function has often been studied in a noncontrolled framework, i.e., $U_n \equiv 0$ in model (1.1) (see Collomb [10], Doukhan and Ghindès [12], Ango Nze and Portier [1], Truong and Stone [32], Bosq [5]). Unfortunately, all these papers deal with stationary and mixing processes; therefore, these results and techniques are not suitable for controlled processes: U_n can depend on the current state X_n and on the previous ones. Thus, another approach is necessary.

Duflo [13] and Senoussi [31] have given the first convergence results for $\widehat{f}_n$ in a control framework. For nonadaptive control laws ensuring that model (1.1) is stable (in the sense defined in section 2), they prove that $\forall\, A < \infty$

$$\sup_{\|x\| \leq A} \left\| \widehat{f}_n(x) - f(x) \right\| \xrightarrow[n\to\infty]{a.s.} 0, \tag{1.2}$$

where $\widehat{f}_n$ denotes the nonparametric estimator of function f. Hilgert, Senoussi, and Vila [20] generalize this result for models where the unknown function f depends on time n. In this paper, we extend result (1.2): we establish the uniform almost sure convergence of $\widehat{f}_n$ over dilating sets, i.e.,

$$\sup_{\|x\| \leq v_n} \left\| \widehat{f}_n(x) - f(x) \right\| \xrightarrow[n\to\infty]{a.s.} 0, \tag{1.3}$$

where $(v_n)_{n\geq 0}$ is a sequence of positive numbers increasing to infinity. Such a result allows us to study adaptive control laws built from $\widehat{f}_n$ which was not possible with result (1.2). Indeed, in order to obtain the asymptotic optimality of the tracking, we have to prove that

$$\frac{1}{n} \sum_{k=1}^{n} \left\| \widehat{f}_k(X_k) - f(X_k) \right\|^2 \xrightarrow[n\to\infty]{a.s.} 0 \tag{1.4}$$

and clearly, the uniform almost sure convergence over fixed compact sets is not sufficient.

In order to solve the problem of tracking, we propose two adaptive control laws, based on the certainty-equivalence principle. The first one can be used only when model (1.1) is open-loop stable. It requires an additional exciting term:

$$U_n \;=\; -\widehat{f}_n(X_n) \;+\; X^*_{n+1} \;+\; \gamma_{n+1}\, \eta_{n+1}, \tag{1.5}$$

where $\eta = (\eta_n)_{n\geq 1}$ is a Gaussian white noise and $(\gamma_n)_{n\geq 1}$ a sequence of real numbers decreasing to 0. The second adaptive control law requires some a priori knowledge about function f, but allows us to control open-loop unstable systems:

$$U_n \;=\; -\widehat{f}_n(X_n)\mathbb{1}_{E_n}(X_n) \;-\; f^*(X_n)\mathbb{1}_{\overline{E}_n}(X_n) \;+\; X^*_{n+1}, \tag{1.6}$$

where $\overline{E}_n$ denotes the complementary set of E_n. Function f^* characterizes the a priori knowledge about function f and allows us to compensate the possible lack of observations which disrupts the local estimator $\widehat{f}_n$. Set E_n, which will be specified in section 4.2, is introduced to ensure the closed-loop stability of model (1.1).

For both control laws, we prove that the tracking is asymptotically optimal, i.e.,

$$\frac{1}{n}\sum_{k=1}^{n} \|X_k - X^*_k\|^2 \;\underset{n\to\infty}{\xrightarrow{a.s.}}\; \mathrm{trace}(\Gamma), \tag{1.7}$$

where Γ denotes the covariance matrix of the noise ξ_n.

This paper is organized as follows. Section 2 is devoted to the model assumptions. Section 3 is concerned with the nonparametric estimation of function f. In section 4, we explain the adaptive control problem and we study the properties of control laws (1.5) and (1.6). In addition, the strong consistency of an estimator of Γ is proven. Finally, Appendices A to D contain proofs of the main results.

2. Model assumptions.

Let $(\Omega, \mathcal{A}, P)$ be a probability space with a filtration $\mathcal{F} = (\mathcal{F}_n)_{n\geq 0}$, where $\mathcal{F}_n$ is the σ-algebra generated by events occurring up to time n. We assume that control $U = (U_n)_{n\geq 0}$ and noise $\xi = (\xi_n)_{n\geq 1}$ are adapted to $\mathcal{F}$, and that X_0 and U_0 are $\mathcal{F}_0$-measurable and arbitrarily chosen. Typically, here we have $\mathcal{F}_n = \sigma(X_0, U_0, \xi_1, \ldots, \xi_n)$. Finally, let us assume the following properties for model (1.1).

ASSUMPTION [$A1$] (*about function f*). *Function f is Lipschitz:*

$$\exists\, r_f < \infty,\ \forall\, x \in \mathbb{R}^d,\ \forall\, y \in \mathbb{R}^d,\quad \|f(x) - f(y)\| \;\leq\; r_f\,\|x - y\|\,,$$

where $\|\,.\,\|$ denotes the usual norm on $\mathbb{R}^d$.

ASSUMPTIONS [$A2$] (*about noise ξ*).

- *$\xi = (\xi_n)_{n\geq 1}$ is a sequence of independent and identically distributed random vectors with mean 0 and invertible covariance matrix Γ which is supposed to be unknown.*
- *ξ_n has a finite moment of order $m > 2$ and its distribution is absolutely continuous with respect to the Lebesgue measure. Its probability density function denoted by p is supposed to be C^1-class, p and its gradient are bounded.*

In this paper, the following definition for stability is used.

DEFINITION 2.1. *The process $(X_n)_{n\geq 0}$, defined by (1.1), is said to be stable if there exist constants $\mu > 0$ and $M < \infty$ such that for any initial law (the law of X_0),*

$$\limsup_{n\to\infty} \frac{1}{n}\sum_{k=1}^{n} \|X_k\|^{\mu} \;\leq\; M\,,\ \ a.s.$$

We will see in section 4 that the system driven by control (1.5) or (1.6) is stable with $\mu = m$. Let us now present nonparametric estimator $\widehat{f}_n$ and the uniform almost sure convergence of $\widehat{f}_n$ over dilating sets.

3. Estimation of function f. In order to estimate unknown function f, we use a recursive version of the classical kernel estimator of the regression function (see, for example, Härdle [19]). Let K be a function from $\mathbb{R}^d$ to $\mathbb{R}_+$ satisfying $\int K(y)\,dy = 1$ and let α be a real number in $]0\,,\,1/d[$. Function K is called the kernel and α the bandwidth parameter. For $x \in \mathbb{R}^d$, we estimate $f(x)$ by

$$\widehat{f}_n(x) = \frac{\displaystyle\sum_{i=0}^{n-1} i^{\alpha d} K\Big(i^{\alpha}(X_i - x)\Big)\Big(X_{i+1} - U_i\Big)}{\displaystyle\sum_{i=0}^{n-1} i^{\alpha d} K\Big(i^{\alpha}(X_i - x)\Big)} \tag{3.1}$$

if the denominator of $\widehat{f}_n(x)$ is not equal to 0, and by 0 otherwise.

Let us remark that $\widehat{f}_n(x)$ can be rewritten as $\sum_{i=0}^{n-1} w_i(X_i, x)\,(X_{i+1} - U_i)$, where $w_i(X_i, x) \geq 0$ and $\sum_{i=0}^{n-1} w_i(X_i, x) = 1$. So, $\widehat{f}_n(x)$ appears to be a weighted sum of $(X_{i+1} - U_i)_{0 \leq i \leq n-1}$. The closer X_i is to x, the greater is the weight $w_i(X_i, x)$, thanks to the kernel K and the bandwidth parameter α, and therefore, the greater is the contribution of $(X_{i+1} - U_i)$ to $\widehat{f}_n(x)$.

Nonparametric estimator (3.1) is said to be recursive because for $x \in \mathbb{R}^d$ and $n \geq 0$ we have

$$\begin{aligned} H_n(x) &= H_{n-1}(x) \ + \ n^{\alpha d} K\Big(n^{\alpha}(X_n - x)\Big)\,,\ H_{-1}(x) \ = \ 0, \\ N_n(x) &= N_{n-1}(x) \ + \ n^{\alpha d} K\Big(n^{\alpha}(X_n - x)\Big)\,\Big(X_{n+1} - U_n\Big)\,,\ N_{-1}(x) \ = \ 0, \end{aligned}$$

where $N_{n-1}(x)$ and $H_{n-1}(x)$ denote the numerator and the denominator of $\widehat{f}_n(x)$, respectively. This recursive property is useful in the adaptive control framework. Indeed, as soon as a new observation becomes available, $\widehat{f}_n(x)$ can easily be updated.

The following assumptions are made on kernel K.

Assumptions [$A3$] (*about kernel* K). $K : \mathbb{R}^d \to \mathbb{R}_+^*$ *is a positive bounded function, with a compact support such that*

- $\int K(y)\,dy \ = \ 1$ *and* $\int \|y\|\,K(y)\,dy \ < \infty$.
- $\exists\ r_K < \infty,\ \forall\, x \in \mathbb{R}^d,\ \forall\, y \in \mathbb{R}^d,\ \ \|K(x) - K(y)\| \ \leq \ r_K\ \|x - y\|$.

For example, Epanechnikov's kernel, defined by

$$K(y) = K(y_1, \ldots, y_d) = \prod_{j=1}^{d} (3/4)(1 - y_j)^2 1\!\!1_{\{|y_j| \leq 1\}},$$

satisfies [$A3$].

Now we give convergence results for estimator $\widehat{f}_n$. Part 1 of Theorem 3.1 will be used to study the convergence of $\widehat{f}_n(x)$ with control law (1.5) and part 2 with control law (1.6).

Theorem 3.1. *Assume that* [$A1$], [$A2$], *and* [$A3$] *hold. Let* $\alpha \in\ ]0\,,\,1/2d[$ *and let* $(v_n)_{n\geq 1}$ *be a sequence of positive real numbers increasing to infinity such that* $v_n = O(n^{\nu})$ *with* $\nu > 0$.

1. *If there exists a sequence* $(w_n)_{n\geq 0}$ *of positive real numbers, increasing to infinity, such that for any initial law*

$$\liminf_{n\to\infty} \left(\inf_{\|x\| \leq v_n} \frac{1}{w_n}\ H_{n-1}(x) \right) \ > \ 0,\ \ a.s., \tag{3.2}$$

where $H_{n-1}(x) = \sum_{i=0}^{n-1} i^{\alpha d} K\left(i^{\alpha}(X_i - x)\right)$*, then, for any* $s \in \left]1/2 + \alpha d\,,\, 1\right[$,

$$\sup_{\|x\| \le v_n} \left\| \widehat{f}_n(x) - f(x) \right\| \overset{a.s.}{=} o\left(\frac{n^s}{w_n}\right) + O\left(\frac{n^{1-\alpha}}{w_n}\right). \tag{3.3}$$

2. *More particularly, if the probability density function p is strictly positive and if there exists a finite constant M such that for any initial law*

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} \|X_k\|^2 \le M, \ \ a.s., \tag{3.4}$$

then (3.2) *and* (3.3) *hold with* $w_n = n\,m_n$ *and* $m_n = \inf\{p(z);\ \ \|z\| \le v_n + R\}$ *for some finite constant R.*

Proof. The proof is given in Appendix B. □

Comments. We will say that we have uniform almost sure dilated convergence of $\widehat{f}_n$ to f if and only if there exists a sequence $(v_n)_{n\ge 0}$ of positive real numbers, increasing to infinity, such that

$$\sup_{\|x\| \le v_n} \left\| \widehat{f}_n(x) - f(x) \right\| \xrightarrow[n\to\infty]{a.s.} 0. \tag{3.5}$$

From part 1 of Theorem 3.1, we can observe that the convergence of $\widehat{f}_n$ to f depends only on the behavior of the denominator H_{n-1} of $\widehat{f}_n$. We will see in section 4 (see Theorem 4.1) how to choose sequences (v_n) and (w_n) in order to satisfy condition (3.2) when control law (1.5) is used to drive model (1.1).

Let us make some comments about $H_{n-1}(x)$. The quantity $n^{-1}H_{n-1}(x)$ behaves as a kind of frequency of the past values of the process $(X_i)_{0\le i\le n-1}$ located in a neighborhood of x. Condition (3.2) constrains the asymptotical behavior of $H_{n-1}(x)$, in order to have enough observations in a neighborhood of x, whatever x may be. Let us also mention that, when process (X_n) is asymptotically stationary (see Devroye and Györfi [11]), $n^{-1}H_{n-1}(x)$ is an estimator of the probability density function of the stationary distribution at point x.

When the assumptions of part 2 are fulfilled, result (3.5) is true as soon as

$$m_n^{-1} = \left(\inf\left\{p(z)\ ;\ \|z\| \le v_n + R\right\}\right)^{-1} = \inf\left(o\left(n^{\alpha}\right)\ ,\ O\left(n^{1-s}\right)\right). \tag{3.6}$$

Thus, it is the decrease of the probability density function p and the choice of a well-suited sequence (v_n) which give the rate of the uniform almost sure dilated convergence of $\widehat{f}_n$. If p rapidly decreases to 0, then sequence (v_n) must slowly increase to infinity. There is, however, a well-known property of kernel-based estimation: any new observation improves the estimator only in a neighborhood of this observation. According to the uniform convergence requirement, any heavy tailed noise is better than any Gaussian-type noise. Indeed, for any given n, heavy tailed noises explorate a larger zone than Gaussian-type noises.

The following corollary emphasizes this point. Let us consider the widely used Gaussian noise. In that case, we are able to easily exhibit sequence (v_n) and specify sequence (m_n) and convergence rate of $\widehat{f}_n$.

Corollary 3.2. *Assume that* [A1], [A2], *and* (3.4) *hold, and that* ξ *is a Gaussian white noise with mean zero and invertible covariance matrix* Γ.

1. *For $\alpha = 1/2(d+1)$, any initial law and any $A < \infty$,*

$$\sup_{\|x\| \leq A(\text{loglog } n)^{1/2}} \left\| \widehat{f}_n(x) - f(x) \right\| \overset{a.s.}{=} O\left(n^{-\lambda}\right) , \tag{3.7}$$

with $\lambda \in \,]0\,,\, 1/2(d+1)[$.

2. *For $\alpha \in \,]0\,,\, 1/2d[$, any initial law and any positive constant A such that $A^2/\lambda_{\min}(\Gamma) < \inf(\alpha\,,\, 1-s)$, where $\lambda_{\min}(\Gamma)$ denotes the minimum eigenvalue of the matrix Γ,*

$$\sup_{\|x\| \, \leq \, A(\log \, n)^{1/2}} \left\| \widehat{f}_n(x) - f(x) \right\| \overset{a.s.}{=} O\left(n^{-\lambda}\right) , \tag{3.8}$$

with $\lambda = \inf(\alpha\,,\, 1-s) - A^2/\lambda_{\min}(\Gamma)$.

Proof. Since ξ_n is Gaussian, [*A*2] is fulfilled and the probability density function p is such that

$$\inf\Big\{ p(z) \ ; \ \|z\| \leq v_n + R \Big\} \ \geq \ \text{cte} \exp\left(- \frac{(v_n + R)^2}{2\,\lambda_{\min}(\Gamma)} \right) \ \geq \ \text{cte} \exp\left(- \frac{v_n^2}{\lambda_{\min}(\Gamma)} \right) .$$

Thus, if we take $v_n = A\,(\log\log\, n)^{1/2}$ with $A \in \,]0\,,\, \infty[$, condition (3.6) is verified since $m_n \geq \text{cte}\,(\log n)^{-\delta}$ with $\delta = A^2/\lambda_{\min}(\Gamma)$. The choice $\alpha = 1/2(d+1)$ leads to part 1.

Now, if we choose $v_n = A\,(\log\, n)^{1/2}$ with $A > 0$, then $m_n \geq \text{cte}\, n^{-A^2/\lambda_{\min}(\Gamma)}$ and part 2 is easily derived. □

Prediction errors. In forecasting and adaptive control problems, the behavior of the prediction errors is a natural question to address (the prediction error at time k is defined by $\widehat{f}_k(X_k) - f(X_k)$). The following convergence result can be useful:

$$\frac{1}{n} \sum_{k=1}^{n} \left\| \widehat{f}_k(X_k) - f(X_k) \right\|^2 \overset{a.s.}{=} o(1). \tag{3.9}$$

If we are able to prove that $\sup_{\|x\| \leq v_n} \|\widehat{f}_n(x) - f(x)\| \overset{a.s.}{=} o(1)$, for a sequence $(v_n)_{n\geq 1}$ increasing to infinity, then

$$\frac{1}{n} \sum_{k=1}^{n} \left\| \widehat{f}_k(X_k) - f(X_k) \right\|^2 \mathbb{1}_{\{\, \|X_k\| \, \leq \, v_k\}} \overset{a.s.}{=} o(1).$$

Result (3.9) is then easily derived by establishing a similar result for prediction errors of the form $\|\widehat{f}_k(X_k) - f(X_k)\|^2 \mathbb{1}_{\{\, \|X_k\| \, > \, v_k\}}$. The following theorem deals with this particular point.

Theorem 3.3. *Assume that* [*A*1], [*A*2], *and* [*A*3] *hold and that there exist two constants $\mu > 0$ and $M < \infty$ such that*

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} \|X_k\|^{\mu} \leq M\,, \ \ a.s. \tag{3.10}$$

Let $(v_n)_{n\geq 1}$ be a sequence of positive real numbers increasing to infinity. Let us denote $\xi_n^{\#} = \sup_{k\leq n} \|\xi_k\|$. Then, for any $b \in [\,0\,,\, \mu\,[$,

$$\frac{1}{n} \sum_{k=1}^{n} \left\| \widehat{f}_k(X_k) - f(X_k) \right\|^b \mathbb{1}_{\{\|X_k\| > v_k\}} \overset{a.s.}{=} O\left(\frac{\left(\xi_n^{\#}\right)^b}{n} \sum_{k=1}^{n} v_k^{-\mu} + \frac{1}{n} \sum_{k=1}^{n} v_k^{b-\mu} \right).$$

Proof. First, Lemma B.1 gives

$$\sum_{k=1}^{n} \left\| \widehat{f}_k(X_k) - f(X_k) \right\|^b \, \mathbb{1}_{\{\|X_k\| > v_k\}} \overset{a.s.}{=} O\left(\sum_{k=1}^{n} \left(\|X_k\|^b + 1 + (\xi_k^{\#})^b \right) \mathbb{1}_{\{\|X_k\| > v_k\}} \right).$$

Then, part 2 of Lemma A.1 finishes the proof. □

Example. Let us once again consider the Gaussian white noise case and let us show that the prediction errors converge to 0 in quadratic mean. Assume that we can exhibit a control law ensuring (control law (1.6) is well suited) that there exist $\mu > 2$ and $M < \infty$ such that

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} \|X_k\|^{\mu} \le M, \quad \text{a.s.}$$

Then, since ξ_n is Gaussian, $\xi_n^{\#} \overset{a.s.}{=} O((\log n)^{1/2})$ and taking $v_n = A\,(\log n)^{1/2}$, with $A > 0$ such that $A^2/\lambda_{\min}(\Gamma) < \inf(\alpha\,,\, 1 - s)$, we derive from result (3.8) and Theorem 3.3 that

$$\frac{1}{n} \sum_{k=1}^{n} \left\| \widehat{f}_k(X_k) - f(X_k) \right\|^2 \overset{a.s.}{=} O\Big((\log n)^{2-\mu} \Big).$$

Now we explain the adaptive control problem and give the properties of control laws (1.5) and (1.6). In addition, the strong consistency of an estimator of Γ is obtained.

4. Study of two optimal adaptive control laws. In this section we consider a simple problem of adaptive control: the problem of adaptive tracking. The goal of adaptive tracking is to find a control sequence $U = (U_n)_{n\ge 1}$ which forces the output $X = (X_n)_{n\ge 1}$ to track the given deterministic reference trajectory $X^* = (X_n^*)_{n\ge 1}$.

If function f were known, the control U_n defined by

$$U_n = -f(X_n) + X_{n+1}^* \tag{4.1}$$

would ensure that the tracking is asymptotically optimal in quadratic mean. We have, indeed, the following:

$$\frac{1}{n} \sum_{k=1}^{n} \|X_k - X_k^*\|^2 = \frac{1}{n} \sum_{k=1}^{n} \|\xi_k\|^2 \xrightarrow[n\to\infty]{a.s.} \operatorname{trace}(\Gamma). \tag{4.2}$$

When function f is unknown, we know how to estimate it using the kernel estimator (3.1) and then, we can replace f by $\widehat{f}_n$ in (4.1). Thus, the adaptive tracking control U_n is given by

$$U_n = -\widehat{f}_n(X_n) + X_{n+1}^*. \tag{4.3}$$

Using this control law, the closed-loop system is of the form

$$X_{n+1} - X_{n+1}^* = \Big(f(X_n) - \widehat{f}_n(X_n) \Big) + \xi_{n+1}. \tag{4.4}$$

Let us remember, as seen in section 3, that in order to obtain good properties of convergence for $\widehat{f}_n$, the closed-loop system must be stable. Since the closed-loop properties of system (1.1) driven by (4.3) are unknown, we propose two adaptive control laws which are derived from (4.3) and for which stability properties of the closed-loop system can be obtained by adding some complementary assumptions on model (1.1). Then, for both control laws, we prove that the tracking is asymptotically optimal, i.e.,

$$\frac{1}{n}\sum_{k=1}^{n}\|X_k - X_k^*\|^2 \underset{n\to\infty}{\xrightarrow{a.s.}} \operatorname{trace}(\Gamma) \tag{4.5}$$

and $\widehat{\Gamma}_n$, defined by

$$\widehat{\Gamma}_n = \frac{1}{n}\sum_{k=1}^{n}\left(X_k - X_k^*\right)\left(X_k - X_k^*\right)^T, \tag{4.6}$$

is a strongly consistent estimator of Γ.

4.1. The excited tracking control. In this section, we study the excited tracking control law proposed by Oulidi in [28]. First, let us make the following assumptions for model (1.1).

Assumptions [*A*4] (*about function f and noise ξ*).

- *Function f satisfies* [A1]*with $r_f < 1$.*
- *White noise ξ is bounded and satisfies* [*A*2].

Let us remark that the crucial assumption is the open-loop stability of model (1.1), which is implied by the value of the Lipschitz coefficient. Moreover, from a practical point of view, the noise assumption is not too restrictive.

In order to control model (1.1), we use the excited tracking control defined as follows.

Construction of U_n. Let $(X_n^*)_{n\geq 1}$ and $(\eta_n)_{n\geq 1}$, respectively, be a bounded deterministic reference trajectory and a Gaussian white noise with mean zero and invertible covariance matrix Γ_η, and let $(\gamma_n)_{n\geq 1}$ be the sequence of real numbers defined by

$$\gamma_1 > 0\,, \quad \gamma_n = C_\gamma\left(\log n\right)^{-\gamma} \quad \text{with} \quad C_\gamma < \infty \quad \text{and} \quad \gamma \in \,]0\,,\,1/2[.$$

Besides, $\eta = (\eta_n)_{n\geq 1}$ is supposed to be independent of X_0 and ξ. The excited tracking control, at time n, is given by

$$U_n \;=\; -\widehat{f}_n(X_n) \;+\; X_{n+1}^* \;+\; \gamma_{n+1}\,\eta_{n+1}. \tag{4.7}$$

The addition of an exciting noise in the control law allows us to obtain the uniform strong consistency for $\widehat{f}_n$ over dilating sets, unreachable when ξ is bounded. Besides, we can specify the convergence rate of $\widehat{f}_n$. Similar persistently excited control is used in the ARMAX framework to obtain the consistency of the least squares estimator (see Caines [6]).

Theorem 4.1. *Assume that* [*A*3] *and* [*A*4] *hold.*

1. *Then there exists a finite constant M such that for all initial law and any integer m,*

$$\limsup_{n\to\infty}\frac{1}{n+1}\sum_{k=0}^{n}\|X_k\|^m \;\leq\; M\,, \quad a.s.$$

2. *Let us take* $\alpha \in \,]0\,,\,1/2d[$. *Then, for some finite constant* A, *we have*

$$\liminf_{n\to\infty}\left(\inf_{\|x\|\le\, A(\log n)^{1/2-\gamma}}\ \frac{1}{n^{1-\delta}(\log n)^{\gamma d}}\ H_{n-1}(x)\right) >\ 0,\ \ a.s.,$$

and

$$\sup_{\|x\|\le A(\log n)^{1/2-\gamma}} \left\|\widehat{f}_n(x)-f(x)\right\| \overset{a.s.}{=} o\left(n^{-\delta}\right)$$

with $\delta \in \,]0\,,\,1/2-\alpha d[$. *Moreover, the tracking is asymptotically optimal in quadratic mean*

$$\frac{1}{n}\sum_{k=1}^{n}\|X_k-X_k^*\|^2 \xrightarrow[n\to\infty]{a.s.} \text{trace}(\Gamma),$$

$$\frac{1}{n}\sum_{k=1}^{n}\|X_k-X_k^*-\xi_k\|^2 \overset{a.s.}{=} O\left((\log n)^{-2\gamma}\right)$$

and $\widehat{\Gamma}_n \xrightarrow[n\to\infty]{a.s.} \Gamma\,$.

Proof. The proof is given in Appendix C. The result of almost sure uniform dilated convergence of $\widehat{f}_n$ is obtained using part 1 of Theorem 3.1 in which assumption (3.2) is verified with $v_n = O\left((\log n)^{1/2-\gamma}\right)$ and $w_n = n^{1-\delta}\,(\log n)^{\gamma d}$. □

Now let us study control law (1.6).

4.2. Control with a priori knowledge on the model. In this section, we build a control law similar to the one proposed by Portier [30]. In this reference, an adaptive control algorithm, built on $\widehat{f}_n$ and using a priori knowledge about function f, was studied by simulation. The author shows that its adaptive control law gives very satisfactory results: function f is well estimated in the domain where the observations are clustered and this estimation leads to a good tracking of the given reference trajectory. However, no theoretical results prove that the tracking is optimal, though it appeared through the simulation results (see also Najim, Oppenheim, and Portier [26], Portier and Oppenheim [29]).

Let us introduce the knowledge we need on model (1.1). Assume there is a function f^* such that we have the following.

Assumption [*A*5]. *Function* f^* *is continuous and*

$$\exists\ a_f \in \left[\,0\,,\,1/2\,\right[,\exists\ A_f \in \left]\,0\,,\,\infty\right[,\forall x\in\mathbb{R}^d,\quad \|f(x)-f^*(x)\|\ \le\ a_f\,\|x\| +\ A_f.$$

Then we can build an adaptive control law which first ensures the stability of the closed-loop model and finally possesses the optimality property (4.5).

Construction of U_n. Let $(X_n^*)_{n\ge1}$ be a bounded deterministic given reference trajectory. At time n, the adaptive tracking control with a priori knowledge is given by

$$U_n\ =\ -\widehat{f}_n(X_n)\mathbb{1}_{E_n}(X_n)\ -\ f^*(X_n)\mathbb{1}_{\overline{E}_n}(X_n)\ +\ X_{n+1}^*, \tag{4.8}$$

where E_n is the set $\{x\in\mathbb{R}^d\,;\,\|\,\widehat{f}_n(x)-f^*(x)\,\|\le\, b_f\,\|x\|+B_f\}$ with $b_f \in\,]a_f\,,\,1-a_f[$ and $B_f \in\,]A_f\,,\,\infty[\ ;\ \overline{E}_n$ denotes the complementary set of E_n.

Function f^* and constants a_f and A_f characterize the a priori knowledge we have on model (1.1). From a practical point of view, knowing function f^* is more important (see Portier and Oppenheim [29]) than the assumption on constant a_f (and then on b_f) since the value of B_f can be chosen arbitrarily large. Using control law (4.8) in model (1.1), we obtain the following results.

Theorem 4.2. *Assume that* [*A*1], [*A*2], [*A*3], *and* [*A*5] *hold and that the probability density function* p *is strictly positive.*

1. *Then, there exists a finite constant* M *such that for any initial law,*

$$\limsup_{n\to\infty} \frac{1}{n+1}\sum_{k=0}^{n} \|X_k\|^m \ \leq\ M\,, \quad a.s.$$

2. *Let us take* $\alpha \in \left]0\,,\,1/2d\right[$. *If there is a sequence of positive real numbers* $(v_n)_{n\geq 1}$ *increasing to infinity such that* $v_n = O\left(n^{\nu}\right)$ *with* $\nu > 0$ *and*

$$\left(\inf\left\{p(z)\ ;\ \|z\| \leq v_n + R\right\}\right)^{-1} \ = \ \inf\left(o\left(n^{\alpha}\right)\,,\,O\left(n^{1-s}\right)\right)$$

for some constant $R < \infty$ *and with* $s \in \left]1/2 + \alpha d\,,\,1\right[$, *then we have the optimality of the tracking, i.e.,*

$$\frac{1}{n}\sum_{k=1}^{n} \|X_k - X_k^*\|^2 \ \ \xrightarrow[n\to\infty]{a.s.} \ \ \mathrm{trace}(\Gamma),$$

and $\widehat{\Gamma}_n \xrightarrow[n\to\infty]{a.s.} \Gamma\,.$

Proof. The proof is given in Appendix D. □

When ξ is a Gaussian white noise, we can specify the convergence rate of the optimality.

Corollary 4.3. *Assume that* [*A*1], [*A*3], *and* [*A*5] *hold and that* ξ *is a Gaussian white noise with zero mean and invertible covariance matrix* Γ. *Then, for* $\alpha \in \left]0\,,\,1/2d\right[$, *any initial law and any* $m > 2$,

$$\frac{1}{n}\sum_{k=1}^{n} \|X_k - X_k^* - \xi_k\|^2 \ \overset{a.s.}{=}\ O\left((\log n)^{2-m}\right).$$

Remark. The convergence rate is smaller than the one we have in the ARX framework, which is of (log n)/n (for example, see Lai and Wei [23], [24], Guo [17], and also Bercu [4]).

Proof. Noise ξ_n being Gaussian, [*A*2] is fulfilled and ξ_n has any moment of order m. Thus, part 1 of Theorem 4.2 holds for any m. Besides, part 2 of Corollary 3.2 gives

$$\sup_{\|x\|\,\leq\, A(\log\ n)^{1/2}} \left\|\widehat{f}_n(x) - f(x)\right\| \ \ \overset{a.s.}{=}\ \ O\left(n^{-\lambda}\right), \tag{4.9}$$

where $\lambda = \inf(\alpha\,,\,1-s) - A^2/\lambda_{\min}(\Gamma)$ with $A > 0$ and $A^2/\lambda_{\min}(\Gamma) < \inf(\alpha\,,\,1-s)$. Finally, from (D.13) (see Appendix D)

$$\begin{aligned}\sum_{k=1}^{n} \|X_k - X_k^* - \xi_k\|^2 \overset{a.s.}{=} O\left(\sum_{k=1}^{n-1} v_k^{2-m}\right) \ + \ O\left(n\,v_n^{2-m}\right) \\ + \ O\left(\sum_{k=1}^{n-1}\left(\sup_{\|x\|\,\leq\, v_k}\left\|\widetilde{f}_k(x)\right\|\right)^2\right),\end{aligned} \tag{4.10}$$

and we easily derive the corollary, setting $v_k = A\,(\log\ k)^{1/2}$ in the last equation. □

Appendix A. In this first appendix, we give three useful lemmas and their proofs.

Lemma A.1. *Let $(\phi_n)_{n\geq 1}$ be a sequence of random vectors. Assume that there are $\mu > 0$ and a finite constant M such that $\limsup_{n\to\infty} \frac{1}{n}\sum_{k=1}^{n} \|\phi_k\|^{\mu} \leq M$.*

1. *Then, for R large enough, $\liminf_{n\to\infty} \frac{1}{n}\sum_{k=0}^{n-1} \mathbb{1}_{\{\|\phi_k\|\leq R\}} > 0$.*
2. *Let $(v_n)_{n\geq 1}$ be a sequence of positive real numbers increasing to infinity. Then,*

$$\forall\, b \in [0\,,\, \mu[,\quad \frac{1}{n}\sum_{k=1}^{n} \|\phi_k\|^{b}\, \mathbb{1}_{\{\,\|\phi_k\| > v_k\}} \;=\; O\left(\frac{1}{n}\sum_{k=1}^{n} v_k^{b-\mu}\right) + O\Big(v_n^{b-\mu}\Big).$$

Proof. Let $R > 0$. Since

$$\text{(A.1)}\qquad \frac{1}{n}\sum_{k=1}^{n} \|\phi_k\|^{\mu} \geq \frac{1}{n}\sum_{k=1}^{n} \|\phi_k\|^{\mu}\, \mathbb{1}_{\{\|\phi_k\|>R\}} \;\geq\; \frac{R^{\mu}}{n}\sum_{k=1}^{n} \mathbb{1}_{\{\|\phi_k\|>R\}},$$

we easily deduce that

$$\text{(A.2)}\qquad \frac{1}{n}\sum_{k=1}^{n} \mathbb{1}_{\{\|\phi_k\|\leq R\}} \geq 1 - \frac{M}{R^{\mu}},$$

and part 1 holds for R large enough. Let $b \in [0\,,\,\mu[$. For $k \geq 1$,

$$\|\phi_k\|^{b}\, \mathbb{1}_{\{\,\|\phi_k\| > v_k\}} = \|\phi_k\|^{\mu}\; \|\phi_k\|^{b-\mu}\, \mathbb{1}_{\{\,\|\phi_k\| > v_k\}} \;\leq\; \|\phi_k\|^{\mu}\, v_k^{b-\mu}.$$

Thus, if we set $S_n = \sum_{k=1}^{n} \|\phi_k\|^{\mu}$ and $S_0 = 0$, we obtain that

$$\text{(A.3)}\qquad \begin{aligned} \frac{1}{n}\sum_{k=1}^{n} \|\phi_k\|^{b}\, \mathbb{1}_{\{\|\phi_k\|>v_k\}} &\leq \frac{1}{n}\sum_{k=1}^{n} v_k^{b-\mu}\Big(S_k - S_{k-1}\Big) \\ &= \frac{1}{n}\sum_{k=1}^{n} \Big(v_k^{b-\mu} - v_{k+1}^{b-\mu}\Big)\, S_k \;+\; v_{n+1}^{b-\mu}\,\frac{S_n}{n}. \end{aligned}$$

Then using the lemma's assumption, we derive that

$$\text{(A.4)}\qquad \begin{aligned} \frac{1}{n}\sum_{k=1}^{n} \|\phi_k\|^{b}\, \mathbb{1}_{\{\|\phi_k\|>v_k\}} &= O\Big(\frac{1}{n}\sum_{k=1}^{n} k\,\Big(v_k^{b-\mu} - v_{k+1}^{b-\mu}\Big)\Big) \;+\; O\Big(v_{n+1}^{b-\mu}\Big) \\ &= O\Big(\frac{1}{n}\sum_{k=1}^{n} v_k^{b-\mu}\Big) \;+\; O\Big(v_n^{b-\mu}\Big), \end{aligned}$$

which establishes part 2. □

Now we give a lemma useful for establishing a result of almost sure uniform dilated convergence for the square integrable martingales index-linked by $x \in \mathbb{R}^d$ which appear in the rest of the paper.

Lemma A.2. *For $x \in \mathbb{R}^d$, let us consider*

$$\text{(A.5)}\qquad M_n(x) = \sum_{i=1}^{n} i^{\lambda}\,\Big(K\Big(i^{\alpha}(X_i - x)\Big) \,-\, \mathbb{E}\Big[K\Big(i^{\alpha}(X_i - x)\Big)\,/\,\mathcal{F}_{i-1}\Big]\Big),$$

where $\lambda \in\,]0\,,\,1/2[\,$, $\alpha \in\,]0\,,\,1/2d[\,$, $(X_n)_{n\geq 0}$ is given by model (1.1), and K is the kernel of the nonparametric estimator. Assume that [A2] and [A3] hold. Then, for $A < \infty$, $\nu > 0$, and some $t \in\,]1/2 \,+\, \lambda\,,\,1[$,

$$\text{(A.6)}\qquad \sup_{\|x\|\leq A\, n^{\nu}} \|M_n(x)\| \overset{a.s.}{=} o\left(n^{t}\right).$$

Proof. The proof uses a theorem due to Oulidi that we can find with its proof in Duflo [13, Theorem 6.4.34, p. 220]. For the sake of completeness, we recall this theorem below.

Theorem. *Let us consider a probability space with a filtration $\mathbb{F}$ and a sequence $(M_n(x))_{n\geq 0, x\in\mathbb{R}^d}$ such that $\forall x$, $M_n(x)$ is a square-integrable martingale adapted to $\mathbb{F}$ and $\forall n$, the trajectories $x \to M_n(x)$ are continuous. Suppose there exists a sequence (s_n) adapted to $\mathbb{F}$ which tends a.s. to infinity and is such that, denoting $\Delta_{n+1}(x) = M_{n+1}(x) - M_n(x)$ and $h(x) = (2x \log\log x)^{1/2}$, there exist two constants $0 < \delta < \gamma$ and constants a, b, c, and d with the following properties:*
P1. *a.s., $\langle M(0)\rangle_n \leq a\, s_{n-1}^2$ and $|\Delta_n(0)| \leq b\, s_{n-1}^2\,(h(s_{n-1}^2))^{-1}$;*
P2. *for any pair (x, y), a.s.,*

$$\langle M(x) - M(Y)\rangle_n \leq c\, s_{n-1}^2\, \|x - y\|^\gamma,$$
$$|\Delta_n(x) - \Delta_n(y)| \leq d\, \|x - y\|^\delta\, s_{n-1}^2\,(h(s_{n-1}^2))^{-1}.$$

Then we have the following result. Let v be any function from $\mathbb{R}_+$ to itself which is increasing to infinity and such that for $\theta > 1$, $v\left(\theta^{n+1}\right) = O\left(v(\theta^n)\right)$. Then, for any $\beta > \sup(\delta\,, \gamma - \delta)$, a.s.,

$$\sup_{\|x\|\leq v(s_{n-1}^2)} \|M_n(x)\| = o\Big(v^\beta(s_{n-1}^2)\, h(s_{n-1}^2)\Big)\,. \qquad \square$$

Let us show that $M_n(x)$ defined by (A.5) matches the different assumptions of this theorem. To this aim, let us denote for $n \geq 1$ and $x \in \mathbb{R}^d$, $\Delta_n(x) = M_n(x) - M_{n-1}(x)$, and $\langle M(x)\rangle_n = \sum_{k=1}^n \mathbb{E}\left[\Delta_k^2(x) \,/\, \mathcal{F}_{k-1}\right]$, where $M_0(\,.\,) \equiv 0$. For $x \in \mathbb{R}^d$ and $n \geq 1$, $M_n(x)$ is a square integrable martingale adapted to $\mathcal{F}$. Let us denote $s_n^2 = n^{1+2\lambda+\alpha\delta}$ for some $\delta > 0$. Since K is bounded (cf. Assumption [$A3$]),

$$|\Delta_n(0)| \leq \text{cte } n^\lambda \;\leq\; \text{cte } s_n^2\,(h(s_n^2))^{-1}, \tag{A.7}$$

where $h(x) = (2x\, \log\log\, x)^{1/2}$. In addition, since p is bounded (cf. Assumption [$A2$]),

$$\begin{aligned} \langle M(0)\rangle_n &\leq \sum_{i=1}^n \mathbb{E}\left[i^{2\lambda}\, K^2\left(i^\alpha\, X_i\right) / \mathcal{F}_{i-1}\right] \\ &\leq \sum_{i=1}^n i^{2\lambda-\alpha d} \int K^2(t)\, p\Big(i^{-\alpha}t - f(X_{i-1}) - U_{i-1}\Big)\, dt \\ &\leq \|\, p\,\|_\infty\, \|K\|_\infty \sum_{i=1}^n i^{2\lambda-\alpha d} \;\leq\; \text{cte } n^{1+2\lambda-\alpha d} \;\leq\; \text{cte } s_n^2. \end{aligned} \tag{A.8}$$

Let $x, y \in \mathbb{R}^d$. Since K is bounded and Lipschitz, we have for any $\delta \in\,]0\,,\,1[$,

$$\begin{aligned} |\Delta_n(x) - \Delta_n(y)| &\leq \text{cte } n^{\lambda(1-\delta/2)}\, |\Delta_n(x) - \Delta_n(y)|^{\delta/2} \\ &\leq \text{cte } \|x - y\|^{\delta/2}\, n^{\lambda+\alpha\delta/2} \;\leq\; \text{cte } \|x - y\|^{\delta/2}\, s_n^2\,(h(s_n^2))^{-1}, \end{aligned} \tag{A.9}$$

$$\begin{aligned} \big\langle M(x) - M(y)\big\rangle_n &\leq \sum_{i=1}^n i^{2\lambda}\, \mathbb{E}\left[\Big(K\left(i^\alpha(X_i - x)\right) - K\left(i^\alpha(X_i - y)\right)\Big)^2 / \mathcal{F}_{i-1}\right] \\ &\leq \text{cte } \|x - y\|^\delta\, n^{1+2\lambda+\alpha\delta} \;\leq\; \text{cte } \|x - y\|^\delta\, s_n^2. \end{aligned} \tag{A.10}$$

Then, with (A.7)–(A.10), assumptions of Oulidi's theorem are fulfilled and therefore, for any $\omega > \delta/2 > 0$,

$$\sup_{\|x\| \leq v(\sigma_n^2)} \|M_n(x)\| \overset{a.s.}{=} o\Big(v^{\omega}(s_n^2)\, h(s_n^2)\Big), \tag{A.11}$$

where v is a real valued function increasing to infinity, such that $v\left(\theta^{n+1}\right) = O\left(v(\theta^n)\right)$ for $\theta > 1$. In particular, if we take $v(n) = A\, n^{\nu/(1+2\lambda+\alpha\delta)}$ for $A < \infty$ and $\nu > 0$, we obtain (A.6). This closes the proof. □

Lemma A.3 below collects some classic and sparse results that we can find in Duflo [13] or in Meyn and Tweedie [25]. Part 1 of Lemma A.3 will be used to establish part 1 of Theorems 4.1 and 4.2, and part 2 will ensure that some of martingales we consider are square integrable.

LEMMA A.3. *Let $0 < a < 1$ and $b < \infty$, and let $Z = (Z_n)$ and $\varepsilon = (\varepsilon_n)$ be two positive sequences of random variables. Assume that, for $n \geq 1$,*

$$Z_n \leq a\, Z_{n-1} \;+\; b \;+\; \varepsilon_n. \tag{A.12}$$

1. *If ε is a sequence of independent, identically distributed positive random variables with a moment of order $m \geq 1$, then $\sup_{k \leq n} Z_k \;=\; o(n^{1/m})$, a.s. and there is a finite constant M such that*

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} Z_k^m \;\leq\; M\,, a.s.$$

2. *In addition, if Z_0 has a moment of order m, then $\sup_n \mathbb{E}\left[Z_n^m\right] \;<\; \infty$.*

For the sake of completeness, let us recall a sketch of proof.

Proof. From (A.12), we easily deduce that $Z_n \;\leq\; a^n\, Z_0 \;+\; \text{cte} \;+\; \sum_{k=1}^{n} a^{n-k}\varepsilon_k$. Then, $Z_n \overset{a.s.}{=} O(\sup_{k\leq n} \varepsilon_k)$ and since ε has a moment of order m, then $Z_n \overset{a.s.}{=} o(n^{1/m})$. In addition, for $a < a_1 < 1$, we have $Z_n^m \;\leq\; a_1\, Z_{n-1}^m \;+\; \text{cte} \;+\; \text{cte}\; \varepsilon_n^m$ and we derive that $(1 - a_1) \limsup_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} Z_k^m \;\leq\; \text{cte} \;+\; \text{cte} \limsup_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} \varepsilon_k^m$. Then, with the assumptions on ε, $\limsup_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} \varepsilon_k^m \;\leq\;$ cte and part 1 is established. Part 2 follows from the fact that $Z_n^m \;\leq\; a_1^n\, Z_0^m \;+\; \text{cte} \;+\; \text{cte}\; \sum_{k=1}^{n} a_1^{n-k} \varepsilon_k^m$. □

Appendix B. This appendix is concerned with the proof of Theorem 3.1. Let us denote $\widetilde{f}_n(x) = \widehat{f}_n(x) - f(x)$. Starting from the definition of $\widehat{f}_n(x)$, we can write

$$\widetilde{f}_n(x) \;=\; \frac{M_n(x) + R_{n-1}(x)}{H_{n-1}(x)} \mathbb{1}_{\{H_{n-1}(x) \neq 0\}} \;-\; f(x) \mathbb{1}_{\{H_{n-1}(x) = 0\}} \tag{B.1}$$

$$\text{with} \quad M_n(x) \;=\; \sum_{i=0}^{n-1} i^{\alpha d}\, K\Big(i^{\alpha}(X_i - x)\Big) \xi_{i+1},$$

$$R_{n-1}(x) \;=\; \sum_{i=0}^{n-1} i^{\alpha d}\, K\Big(i^{\alpha}(X_i - x)\Big) \Big(f(X_i) - f(x)\Big),$$

and easily derive that for any $x \in \mathbb{R}^d$,

$$\Big\|\widehat{f}_n(x) - f(x)\Big\| \leq \|f(x)\| \;+\; \sup_{k\leq n} \|\xi_k\| \;+\; \frac{\|R_n(x)\|}{H_{n-1}(x)} \mathbb{1}_{\{H_{n-1}(x) \neq 0\}}. \tag{B.2}$$

The proof of Theorem 3.1 consists of studying separately $M_n(x)$, $R_{n-1}(x)$, and $H_{n-1}(x)$ and then combining the results.

Study of $M_n(x)$. Since process $(\xi_n)_{n\geq 1}$ has a finite moment of order $m > 2$ and since for any x, $y \in \mathbb{R}^d$ and any $\delta \in]0\,,\,1[$,

$$n^{\alpha d}\, \left|K\left(n^{\alpha}(X_n - x)\right)\right| \leq \text{cte } n^{\alpha d}, \tag{B.3}$$

$$n^{\alpha d}\, \left|K\left(n^{\alpha}(X_n - x)\right) - K\left(n^{\alpha}(X_n - y)\right)\right| \leq \text{cte } n^{\alpha d + \alpha\delta}\, \|x - y\|^{\delta}, \tag{B.4}$$

the assumptions of the following corollary, also due to Oulidi [28] and which we can find with its proof in Duflo [13, Corollary 6.4.35, p. 223], are fulfilled with, for instance, $T_n = n^{\alpha d + \alpha\delta}$.

Corollary. *Let (ε_n) be a noise of dimension 1 adapted to a filtration $\mathbb{F} = (\mathcal{F}_n)_{n\geq 0}$ such that, for some $\alpha > 0$, $\sup_n \mathbb{E}[|\varepsilon_{n+1}|^{2+2\alpha} \,/\, \mathcal{F}_n] < \infty$, a.s. We consider a sequence $(Y_n(x))_{n\geq 0, x\in\mathbb{R}^d}$ such that $\forall\, x$, $Y_n(x)$ is adapted to $\mathbb{F}$ and, $\forall\, n$, the process $(Y_n(.))$ is continuous. Finally, we suppose we have a positive sequence (T_n) adapted to $\mathbb{F}$, such that $|T_n(0)| \leq T_n$, a.s., and there exist two constants $\delta > 0$ and $a < \infty$ such that, for any pair (x, y), $|Y_n(x) - Y_n(y)| \leq a\, \|x - y\|^{\delta}\, T_n$, a.s. For $M_n(x) = \sum_{k=1}^n Y_{k-1}(x)\,\varepsilon_k$ and $\tau_n = \sum_{k=0}^n T_k^2$, we assume that, a.s., $\tau_\infty = \infty$ and $\sum T_n^{2+2\alpha}\, (\tau_n)^{-1-\alpha}\, (\log\log\, n)^{\alpha} < \infty$. Then, for $\beta > \delta$ and any function $v : \mathbb{R}_+ \to \mathbb{R}_+$ increasing to infinity and such that for $\theta > 1$, $v\left(\theta^{n+1}\right) = O\left(v(\theta^n)\right)$, we have*

$$\sup_{\|x\|\leq\, v(\tau_{n-1})} \|M_n(x)\| \overset{a.s.}{=} o\Big(v^{\beta}(\tau_{n-1})\, (2\tau_{n-1}\, \log\log\, \tau_{n-1})^{1/2}\Big). \qquad \square$$

Taking $v(n) = A\, n^{\nu/(1+2\alpha\, d + 2\alpha\delta)}$ (for any $A < \infty$ and $\nu > 0$) in the corollary above, we obtain, for $s > 1/2 + \alpha d$

$$\sup_{\|x\|\leq\, A\, n^{\nu}} \|M_n(x)\| \overset{a.s.}{=} o(n^s). \tag{B.5}$$

In addition, let us note that the restriction $\alpha \in\,]0\,,\, 1/2d[$ derives from the fact that in that which follows the real s must be chosen as $s < 1$.

Study of $R_n(x)$. Since function f is Lipschitz-continuous (cf. [$A1$]),

$$\|R_n(x)\| \leq r_f \sum_{i=1}^n i^{\alpha d} K\Big(i^{\alpha}(X_i - x)\Big)\, \|X_i - x\|\,. \tag{B.6}$$

In addition, since K has a compact support (cf. [$A3$]), there exists a finite constant c_K such that $K(y) = 0$ for $\|y\| \geq c_K$. Then

$$\begin{aligned} \|R_n(x)\| \;&\leq\; r_f \sum_{i=1}^n i^{\alpha d - \alpha} K\Big(i^{\alpha}(X_i - x)\Big) i^{\alpha}\, \|X_i - x\|\, \mathbb{1}_{\left\{i^{\alpha}\, \|X_i - x\| \,\leq\, c_K\right\}} \\ &\overset{a.s.}{=} O\Big(T_n(x)\Big) \end{aligned} \tag{B.7}$$

with $T_n(x) = \sum_{i=1}^n i^{\alpha d - \alpha} K\Big(i^{\alpha}(X_i - x)\Big)$. In addition, since $T_n(x) \leq H_n(x)$, there exists a finite constant c_f such that for any $x \in \mathbb{R}^d$,

$$\frac{\|R_n(x)\|}{H_{n-1}(x)} \mathbb{1}_{\{H_{n-1}(x) \neq 0\}} \leq c_f. \tag{B.8}$$

Then, by combining this result with (B.2), we prove the following lemma which gives a first result on $\|\widehat{f}_n(x) - f(x)\|$.

LEMMA B.1. *Assume that* [A1] *and* [A3] *hold. Let us denote* $\xi_n^{\#} = \sup_{k\leq n}\|\xi_k\|$. *Then, there exists* $c_f<\infty$ *such that* $\forall\, x\in\mathbb{R}^d$ *and* $\forall\, n\geq 1$,

$$\left\|\widehat{f}_n(x)-f(x)\right\| \;\leq\; c_f \;+\; \|f(x)\| \;+\; \xi_n^{\#}, \qquad a.s.$$

We are left with the study of $T_n(x)$. Let us write $T_n(x) = M_n^T(x) + T_n^c(x)$ with

$$\begin{aligned} M_n^T(x) &= \sum_{i=1}^n i^{\alpha d-\alpha}\Big(K\Big(i^\alpha(X_i-x)\Big) - \mathbb{E}\left[K\Big(i^\alpha(X_i-x)\Big)/\mathcal{F}_{i-1}\right]\Big),\\ T_n^c(x) &= \sum_{i=1}^n i^{\alpha d-\alpha}\;\mathbb{E}\left[K\Big(i^\alpha(X_i-x)\Big)/\mathcal{F}_{i-1}\right]\\ &= \sum_{i=1}^n i^{-\alpha}\int K(t)\,p\Big(i^{-\alpha}t+x-f(X_{i-1})-U_{i-1}\Big)dt. \end{aligned}$$

Since p is bounded (cf. [$A2$]) and $\int K(t)\,dt=1$ (cf. [$A3$]),

$$\sup_{x\in\mathbb{R}^d}\|T_n^c(x)\| \overset{a.s.}{=} O\left(n^{1-\alpha}\right). \tag{B.9}$$

For $x\in\mathbb{R}^d$ and $n\geq 1$, $M_n^T(x)$ is a square integrable martingale for which we can apply Lemma A.2 with $\lambda=\alpha d-\alpha$. Then, for $A<\infty$, $\nu>0$, and $s'>\frac{1}{2}+\alpha d-\alpha$,

$$\sup_{\|x\|\leq A\,n^\nu}\left\|M_n^T(x)\right\| \overset{a.s.}{=} o\left(n^{s'}\right). \tag{B.10}$$

Moreover, since $\alpha\in\,]0\,,\,1/2d[$, the real s' can be chosen such that $s'<1-\alpha$. Therefore, from (B.9) and (B.10), we obtain that for $A<\infty$ and $\nu>0$

$$\sup_{\|x\|\leq A\,n^\nu}\|T_n(x)\| \overset{a.s.}{=} O\left(n^{1-\alpha}\right), \tag{B.11}$$

and therefore

$$\sup_{\|x\|\leq A\,n^\nu}\|R_n(x)\| \overset{a.s.}{=} O\left(n^{1-\alpha}\right). \tag{B.12}$$

Finally, as soon as $v_n=O(n^\nu)$, by combining result (B.5) and result (B.12) with assumption (3.2), we derive part 1 since

$$\sup_{\|x\|\leq v_n}\frac{\|M_n(x)\|}{H_{n-1}(x)} \overset{a.s.}{=} o\left(\frac{n^s}{w_n}\right), \tag{B.13}$$

$$\sup_{\|x\|\leq v_n}\frac{\|R_{n-1}(x)\|}{H_{n-1}(x)} \overset{a.s.}{=} O\left(\frac{n^{1-\alpha}}{w_n}\right). \tag{B.14}$$

Proof of part 2. To establish part 2, we have only to prove that

$$\liminf_{n\to\infty}\left(\inf_{\|x\|\leq v_n}\frac{1}{n\,m_n}\,H_{n-1}(x)\right) \;>\; 0, \text{ a.s.} \tag{B.15}$$

We study $H_n(x)$ by proceeding as for $T_n(x)$. For $x\in\mathbb{R}^d$, let us set

$$H_n(x) \;=\; M_n^H(x) \;+\; \Big(H_n^c(x) \;-\; J_n(x)\Big) \;+\; J_n(x) \tag{B.16}$$

with

$$\begin{aligned}
M_n^H(x) &= \sum_{i=1}^{n} i^{\alpha d} \left(K\Big(i^\alpha (X_i - x)\Big) \; - \; \mathbb{E}\left[K\Big(i^\alpha (X_i - x)\Big) \,/\, \mathcal{F}_{i-1} \right] \right), \\
H_n^c(x) &= \sum_{i=1}^{n} i^{\alpha d} \; \mathbb{E}\Big[K\left(i^\alpha (X_i - x)\right) / \mathcal{F}_{i-1} \Big] \\
&= \sum_{i=1}^{n} \int K(t)\, p\Big(i^{-\alpha} t + x - f(X_{i-1}) - U_{i-1}\Big)\, dt, \\
J_n(x) &= \sum_{i=1}^{n} \; p\Big(x - f(X_{i-1}) - U_{i-1}\Big).
\end{aligned}$$

For $x \in \mathbb{R}^d$ and $n \geq 1$, $M_n^H(x)$ is a square integrable martingale. Then, by Lemma A.2 with $\lambda = \alpha d$, we derive that for $A < \infty$, $\nu > 0$, and $s'' > \frac{1}{2} + \alpha d$,

$$\text{(B.17)} \qquad \sup_{\|x\| \leq A\, n^\nu} \left\| M_n^H(x) \right\| \; \overset{a.s.}{=} \; o\left(n^{s''} \right).$$

Since $\|Dp\|_\infty < \infty$ (cf. [$A2$]) and $\int \|t\|\, K(t)\, dt < \infty$ (cf. [$A3$]),

$$\text{(B.18)} \qquad \sup_{x \in \mathbb{R}^d} \| H_n^c(x) - J_n(x) \| \; \overset{a.s.}{=} \; O\left(n^{1-\alpha}\right).$$

Let $R < \infty$. For $x \in \mathbb{R}^d$ such that $\|x\| \leq v_n$, we have

$$\text{(B.19)} \qquad \|p\|_\infty \; \geq \; \frac{1}{n}\, J_n(x) \; \geq \; \frac{m_n}{n} \sum_{k=0}^{n-1} \mathbb{1}_{\{\|f(X_k) + U_k\| \leq R\}},$$

where $m_n = \inf\{p(z) \; ; \; \|z\| \leq v_n + R\}$. Since $m > 2$, $\limsup_{n \to \infty} \frac{1}{n} \sum_{k=1}^{n} \|\xi_k\|^2 < \infty$. Combining this last result with assumption (3.4), we derive that

$$\limsup_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} \|f(X_k) + U_k\|^2 < \; \infty,$$

and then by applying part 1 of Lemma A.1, we obtain

$$\text{(B.20)} \qquad \liminf_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} \mathbb{1}_{\{\|f(X_k) + U_k\| \leq R\}} \; > \; 0, \; \text{ a.s.}$$

Then, combining (B.17), (B.18), (B.19), and (B.20) gives (B.15).

Appendix C. This appendix is concerned with the proof of Theorem 4.1.

1. *Stability of* (X_n). Using (4.7) in model (1.1), the following equation holds:

$$\text{(C.1)} \qquad X_{n+1} = -\widetilde{f}_n(X_n) \; + \; X_{n+1}^* \; + \; \xi_{n+1} \; + \; \gamma_{n+1} \eta_{n+1}.$$

Since ξ and $(X_n^*)_{n \geq 1}$ are bounded and f is Lipschitz, we deduce from Lemma B.1 that

$$\text{(C.2)} \qquad \|X_{n+1}\| \leq \; r_f \, \|X_n\| \; + \; A_2 \; + \; \gamma_{n+1} \; \|\eta_{n+1}\|$$

with $A_2 < \infty$. Then part 1 is obtained using Lemma A.3.

2. *Consistency of* $\widehat{f}_n$. To prove the almost sure uniform dilated convergence of $\widehat{f}_n$, we use part 1 of Theorem 3.1. Therefore, we must verify assumption (3.2) and, more precisely, find two sequences $(v_n)_{n\geq 1}$ and $(w_n)_{n\geq 1}$ such that

$$\liminf_{n\to\infty}\left(\inf_{\|x\|\leq v_n}\frac{1}{w_n}\,H_{n-1}(x)\right) > \ 0, \text{ a.s.} \tag{C.3}$$

For $n \geq 0$, let us set $\Pi_n = -\widetilde{f}_n(X_n) + X^*_{n+1}$ and consider the following decomposition:

$$H_n(x) \ = \ M^H_n(x) \ + \ \Big(H^c_n(x) - J_n(x)\Big) \ + \ \Big(J_n(x) - L_n(x)\Big) \ + \ L_n(x) \tag{C.4}$$

with

$$\begin{aligned}
M^H_n(x) &= H_n(x) \ - \ H^c_n(x),\\
H^c_n(x) &= \sum_{i=1}^{n} \ i^{\alpha d}\ \mathbb{E}\left[K\Big(i^{\alpha}\,(X_i - x)\Big)/\mathcal{F}_{i-1}\right]\\
&= \sum_{i=1}^{n} \ i^{\alpha d}\ \mathbb{E}\left[K\Big(i^{\alpha}\,(\Pi_{i-1} + \gamma_i\,\eta_i + \xi_i - x)\Big)/\mathcal{F}_{i-1}\right]\\
&= \sum_{i=1}^{n} \ \gamma_i^{-d}\iint K(v)\,p(u)\,p_\eta\left(\gamma_i^{-1}\left(i^{-\alpha}v + x - \Pi_{i-1} - u\right)\right)du\,dv,\\
J_n(x) &= \sum_{i=1}^{n} \ \gamma_i^{-d}\int p(u)\,p_\eta\left(\gamma_i^{-1}\,(x - \Pi_{i-1} - u)\right)\,du,\\
L_n(x) &= \sum_{i=1}^{n} \ \gamma_i^{-d}p_\eta\left(\gamma_i^{-1}\,(x - \Pi_{i-1})\right).
\end{aligned}$$

In this part, $\mathcal{F}_n = \sigma\,(X_0, U_0, \xi_1, \eta_1, \ldots, \xi_n, \eta_n)$. We now proceed as for $H_n(x)$ in Appendix B. For $x \in \mathbb{R}^d$ and $n \geq 1$, $M^H_n(x)$ is a square integrable martingale adapted to $\mathcal{F}$. Then, by Lemma A.2 with $\lambda = \alpha d$, we obtain that for $A < \infty$, $\nu > 0$, and $s \in \,]1/2 + \alpha d\,,\,1[$,

$$\sup_{\|x\|\leq\,A\,n^{\nu}}\left\|M^H_n(x)\right\| \ \overset{a.s.}{=} \ o\,(n^s)\,. \tag{C.5}$$

Since $\|Dp_\eta\| < \infty$, $\int \|v\|\,K(v)\,dv < \infty$ (cf. [$A3$]), and $\int \|u\|\,p(u)\,du < \infty$,

$$\sup_{x\in\mathbb{R}^d}\|H^c_n(x) - J_n(x)\| \ + \ \sup_{x\in\mathbb{R}^d}\|J_n(x) - L_n(x)\| \overset{a.s.}{=} O\left(\sum_{i=1}^{n}\gamma_i^{-d-1}\right). \tag{C.6}$$

We are left with the study of $L_n(x)$. Let $R > 0$. Using Lemma B.1 and Assumption [$A4$], we deduce that $\|\Pi_n\| \ \leq \ \|X_n\| \ + \ N$, with $N < \infty$. Hence,

$$L_n(x) \ \geq \ \sum_{i=1}^{n} \ \gamma_i^{-d}\inf_{\|y\|\leq N+R}p_\eta\left(\gamma_i^{-1}\,(x - y)\right)\mathbb{1}_{\{\|X_{i-1}\|\leq R\}}. \tag{C.7}$$

Since η is a Gaussian white noise with invertible covariance matrix Γ_η, we have

$$p_\eta\left(\gamma_i^{-1}\,(x - y)\right) \ \geq \ \text{cte}\ \exp\left(-\frac{\gamma_i^{-2}\ \|\,x - y\,\|^2}{2\,\lambda_{\min}(\Gamma_\eta)}\right), \tag{C.8}$$

and since $\gamma_n = C_\gamma (\log n)^{-\gamma}$ with $\gamma \in \,]0\,,\, 1/2[$,

$$\text{(C.9)}\quad \inf\left\{ p_\eta\left(\gamma_n^{-1}\,(x-y)\right)\ ;\ \|x\|^2 \le A\,\gamma_n^2\,\log n\,,\, \|y\|\, \le N+R \right\}\ \ge\ \text{cte}\, n^{-\delta},$$

with $\delta = A/2\,\lambda_{\min}(\Gamma_\eta)$. Finally,

$$\text{(C.10)}\qquad \inf_{\|x\|^2 \le A\,\gamma_n^2\,\log n} L_n(x)\ \ge\ \text{cte}\ \sum_{i=2}^{n} i^{-\delta}\,(\log i)^{-\gamma d}\,\mathbb{1}_{\{\|X_{i-1}\|\,\le\,R\}}.$$

In addition, by part 1 of Theorem 4.1, there exists a finite constant M such that $\limsup_{n\to\infty} \frac{1}{n}\sum_{i=1}^{n}\|X_{i-1}\|^2\ \le\ M$, a.s. Then, from part 1 of Lemma A.1, we deduce that

$$\text{(C.11)}\qquad \liminf_{n\to\infty} \frac{1}{n}\sum_{i=1}^{n} \mathbb{1}_{\{\|X_{i-1}\|\,\le\,R\}} >\ 0,\ \text{a.s.},$$

and therefore

$$\text{(C.12)}\quad \liminf_{n\to\infty}\left(\inf_{\|x\| \le\, (2\,\delta\,\lambda_{\min}(\Gamma_\eta))^{1/2} C_\gamma (\log n)^{1/2-\gamma}} \frac{L_n(x)}{n^{1-\delta}(\log n)^{\gamma d}}\right) >\ 0,\ \text{a.s.}$$

Then, combining (C.5), (C.6), and (C.12), we obtain that for any $\delta \in \,]0\,,\, 1/2 - \alpha d[$

$$\text{(C.13)}\qquad \liminf_{n\to\infty}\left(\inf_{\|x\| \le\, A(\log n)^{1/2-\gamma}} \frac{1}{n^{1-\delta}(\log n)^{\gamma d}}\ H_{n-1}(x)\right) >\ 0,\ \text{a.s.},$$

where $A\ =\ (2\,\delta\,\lambda_{\min}(\Gamma_\eta))^{1/2}\,C_\gamma$. Thus (3.2) is fulfilled and part 2 of Theorem 4.1 is proved.

3. *Optimality of the tracking.* From (C.1), we have

$$\begin{aligned} \left\|X_{n+1} - X_{n+1}^*\right\|^2 &= \left\|\widetilde{f}_n\left(X_n\right)\right\|^2\ 2\left\langle \widetilde{f}_n\left(X_n\right)\,,\, \xi_{n+1} + \gamma_{n+1}\,\eta_{n+1}\right\rangle \\ &\qquad\quad +\ \left\|\xi_{n+1}\right\|^2\ +\ \gamma_{n+1}^2\ \left\|\eta_{n+1}\right\|^2\ +\ 2\,\gamma_{n+1}\left\langle \eta_{n+1}, \xi_{n+1}\right\rangle, \\ \left\|X_n - X_n^* - \xi_n\right\|^2 &\le 2\ \left\|\widetilde{f}_{n-1}\left(X_{n-1}\right)\right\|^2\ +\ 2\,\gamma_n^2\ \left\|\eta_n\right\|^2, \end{aligned}$$

where $\langle\ .\ ,\ .\ \rangle$ denotes the inner product on $\mathbb{R}^d$. Using part 2 of Theorem 4.1, Lemma B.1, and Theorem 3.3, we derive that for any integer m,

$$\text{(C.14)}\quad \frac{1}{n}\sum_{k=1}^{n}\left\|\widetilde{f}_k\left(X_k\right)\right\|^2\ \mathbb{1}_{\left\{\|X_k\|\,\le\, A_\delta(\log k)^{1/2-\gamma}\right\}} \overset{a.s.}{=} o\left(n^{-2\delta}\right),$$

$$\text{(C.15)}\quad \frac{1}{n}\sum_{k=1}^{n}\left\|\widetilde{f}_k\left(X_k\right)\right\|^2\ \mathbb{1}_{\left\{\|X_k\|\,>\, A_\delta(\log k)^{1/2-\gamma}\right\}} \overset{a.s.}{=} O\left((\log n)^{(1/2-\gamma)(2-m)}\right).$$

Hence, for any integer m,

$$\text{(C.16)}\qquad \frac{1}{n}\sum_{k=1}^{n}\left\|\widetilde{f}_k\left(X_k\right)\right\|^2 \overset{a.s.}{=} O\left((\log n)^{-(1/2-\gamma)(m-2)}\right).$$

For $n\ \ge\ 1$, $M_n\ =\ \sum_{k=1}^{n}\langle \widetilde{f}_{k-1}\left(X_{k-1}\right), \gamma_k\,\eta_k + \xi_k\rangle$ is a square integrable martingale. Since $\|\,\langle M\rangle_n\,\| = O(\sum_{k=1}^{n}\|\widetilde{f}_{k-1}\left(X_{k-1}\right)\|^2)$ and $\sum_{k=1}^{n}\|\widetilde{f}_{k-1}\left(X_{k-1}\right)\|^2 \overset{a.s.}{=} o(n)$

by (C.16), we deduce from a strong law of large numbers for the martingales (for example, Duflo [13, Theorem 1.3.15, p. 20]) that for any $\lambda > 0$,

$$\text{(C.17)} \qquad \frac{1}{n}\sum_{k=1}^{n} \langle \widetilde{f}_{k-1}\,(X_{k-1})\ ,\, \gamma_k\,\eta_k + \xi_k\rangle \overset{a.s.}{=} O\left(\frac{(\log n)^{1+\lambda}}{n}\right)^{1/2}.$$

Since η is a Gaussian white noise, $\sum_{k=1}^{n} \|\eta_k\|^2 \overset{a.s.}{=} O(n)$ and then part 2 of Lemma A.1 gives

$$\text{(C.18)} \qquad \frac{1}{n}\sum_{k=1}^{n} \gamma_k^2\,\|\eta_k\|^2 \overset{a.s.}{=} O\left((\log n)^{-2\gamma}\right).$$

To close the proof of Theorem 4.1, we have only to combine all these results and use classical strong law of large numbers for the other terms.

Appendix D. This appendix is concerned with the proof of Theorem 4.2. For $x \in \mathbb{R}^d$, let us denote $\widetilde{f}^*(x) = f(x) - f^*(x)$.

1. *Stability of* (X_n). Let us first rewrite model (1.1) with control (4.8) in the following way:

$$\text{(D.1)} \quad X_{n+1} \;=\; \Big(f^*(X_n) - \widehat{f}_n(X_n)\Big)\,\mathbb{1}_{E_n}(X_n) \;+\; \widetilde{f}^*(X_n) \;+\; X^*_{n+1} + \xi_{n+1}.$$

Then, using Assumption $[A5]$,

$$\text{(D.2)} \qquad \|X_{n+1}\| \;\leq\; \underbrace{(a_f + b_f)}_{<\,1}\|X_n\| \;+\; \underbrace{\left(A_f + B_f + \left\|X^*_{n+1}\right\|\right)}_{<\,\infty} \;+\; \|\xi_{n+1}\|,$$

and applying Lemma A.3 gives part 1 of Theorem 4.2.

2. *Optimality of the control law.* For $k \geq 0$, let us set $\Pi_k = f(X_k) + U_k - X^*_{k+1}$. Then

$$\text{(D.3)} \qquad \left\|X_{k+1} - X^*_{k+1}\right\|^2 = \|\Pi_k\|^2 \;+\; 2\,\Pi_k^T\,\xi_{k+1} \;+\; \|\xi_{k+1}\|^2,$$

where Π_k^T denotes the transpose of Π_k. To prove the optimality, we study the convergence of the sum of each term in the last equation right-hand side.

The study of $(1/n)\sum_{k=0}^{n-1}\|\xi_{k+1}\|^2$ is straightforward. To explore $(1/n)\sum_{k=0}^{n-1}\Pi_k^T \times \xi_{k+1}$, we must face the real difficulty which concerns $(1/n)\sum_{k=0}^{n-1}\|\Pi_k\|^2$.

Step 1: *study of* $(1/n)\sum_{k=0}^{n-1}\|\xi_{k+1}\|^2$. Since ξ has a finite moment of order $m > 2$, we have the regular strong law of large numbers

$$\text{(D.4)} \qquad \frac{1}{n}\sum_{k=0}^{n-1} \|\xi_{k+1}\|^2 \xrightarrow[n\to\infty]{a.s.} \operatorname{trace}(\Gamma).$$

Step 2: *study of* $(1/n)\sum_{k=0}^{n-1}\|\Pi_k\|^2$. To this aim, let us rewrite

$$\begin{aligned}\Pi_k = &\Big(-\widetilde{f}_k(X_k)\mathbb{1}_{E_k}(X_k) + \widetilde{f}^*(X_k)\mathbb{1}_{\overline{E}_k}(X_k)\Big)\,\mathbb{1}_{V_k}(X_k)\\ &+\;\Big(-\widetilde{f}_k(X_k)\mathbb{1}_{E_k}(X_k) + \widetilde{f}^*(X_k)\mathbb{1}_{\overline{E}_k}(X_k)\Big)\,\mathbb{1}_{\overline{V}_k}(X_k),\end{aligned}$$

where V_k denotes the set $\left\{x \in \mathbb{R}^d\,;\, \|x\| \leq v_k\right\}$ and $\overline{V}_k$ its complementary.

- First, using assumption on function f^* (cf. $[A5]$),

$$\text{(D.5)}\sum_{k=1}^{n} \left\|\widetilde{f}^*(X_k)\right\|^2 \mathbb{1}_{\overline{E}_k}(X_k)\mathbb{1}_{\overline{V}_k}(X_k) \overset{a.s.}{=} O\left(\sum_{k=1}^{n}\left(\|X_k\|^2+1\right)\mathbb{1}_{\{\,\|X_k\|\,>\,v_k\}}\right).$$

Moreover, there are two constants c_1, $c_2 > 0$ such that, a.s.,

$$\text{(D.6)}\quad \begin{aligned}\left\|\widetilde{f}_k(X_k)\right\|^2 \mathbb{1}_{E_k}(X_k) &\leq \left\|\widetilde{f}_k(X_k)\right\|^2 \mathbb{1}_{\left\{x\in\mathbb{R}^d\,;\,\|\widetilde{f}_k(x)\|-\|\widetilde{f}^*(x)\|\,\leq\, b_f\|x\|+B_f\right\}}(X_k)\\ &\leq \left\|\widetilde{f}_k(X_k)\right\|^2 \mathbb{1}_{\left\{x\in\mathbb{R}^d\,;\,\|\widetilde{f}_k(x)\|\,\leq\, c_1\|x\|+\ c_2\right\}}(X_k)\\ &\leq \left(c_1\|X_k\|+\ c_2\right)^2\end{aligned}$$

and

$$\text{(D.7)}\quad \sum_{k=1}^{n} \left\|\widetilde{f}_k(X_k)\right\|^2 \mathbb{1}_{E_k}(X_k)\mathbb{1}_{\overline{V}_k}(X_k) \overset{a.s.}{=} O\left(\sum_{k=1}^{n}\left(\|X_k\|^2+1\right)\mathbb{1}_{\{\,\|X_k\|\,>\,v_k\}}\right).$$

Since $\sum_{k=1}^{n}\|X_k\|^m \overset{a.s.}{=} O(n)$ with $m > 2$, part 2 of Lemma A.1 applied to (D.5) and (D.7) leads to

$$\text{(D.8)}\qquad \begin{aligned}&\frac{1}{n}\sum_{k=1}^{n}\left(\left\|\widetilde{f}_k(X_k)\right\|^2\mathbb{1}_{E_k}(X_k)+\left\|\widetilde{f}^*(X_k)\right\|^2\mathbb{1}_{\overline{E}_k}(X_k)\right)\mathbb{1}_{\overline{V}_k}(X_k)\\ &\qquad\overset{a.s.}{=}\ O\left(\frac{1}{n}\sum_{k=1}^{n}v_k^{2-m}\right)\ +\ O\left(v_n^{2-m}\right).\end{aligned}$$

- Using once again Assumption $[A5]$, we derive

$$\text{(D.9)}\sum_{k=1}^{n} \left\|\widetilde{f}^*(X_k)\right\|^2 \mathbb{1}_{\overline{E}_k}(X_k)\mathbb{1}_{V_k}(X_k)$$
$$\overset{a.s.}{=} O\left(\sum_{k=1}^{n}\left(\|X_k\|^2+1\right)\mathbb{1}_{\left\{x\in\mathbb{R}^d\,;\,(b_f-a_f)\|x\|+(B_f-A_f)\leq\|\widetilde{f}_k(x)\|\right\}}(X_k)\ \mathbb{1}_{V_k}(X_k)\right).$$

In addition, for all constants $c_3, c_4 > 0$, there is $c_5 > 0$ such that for $k \geq 1$

$$\text{(D.10)}\qquad \begin{aligned}&\left\|\widetilde{f}_k(X_k)\right\|^2\mathbb{1}_{V_k}(X_k)\\ &\quad\geq\ \left\|\widetilde{f}_k(X_k)\right\|^2\mathbb{1}_{\left\{x\in\mathbb{R}^d\,;\,\|\widetilde{f}_k(x)\|\geq c_3\,\|x\|\,+c_4\right\}}(X_k)\mathbb{1}_{V_k}(X_k)\\ &\quad\geq\ c_5\left(\|X_k\|^2+1\right)\mathbb{1}_{\left\{x\in\mathbb{R}^d\,;\,\|\widetilde{f}_k(x)\|\geq c_3\|x\|\,+c_4\right\}}(X_k)\mathbb{1}_{V_k}(X_k).\end{aligned}$$

Thus, using this result in (D.9), we derive that

$$\text{(D.11)}\quad \sum_{k=1}^{n} \left\|\widetilde{f}^*(X_k)\right\|^2 \mathbb{1}_{\overline{E}_k}(X_k)\mathbb{1}_{V_k}(X_k) \overset{a.s.}{=} O\left(\sum_{k=1}^{n}\left\|\widetilde{f}_k(X_k)\right\|^2\mathbb{1}_{\{\|X_k\|\leq v_k\}}\right)$$

and then

$$\sum_{k=1}^{n}\left(\left\|\widetilde{f}_k(X_k)\right\|^2 \mathbb{1}_{E_k}(X_k)+\left\|\widetilde{f}^*(X_k)\right\|^2 \mathbb{1}_{\overline{E}_k}(X_k)\right)\mathbb{1}_{V_k}(X_k) \overset{a.s.}{=} O\left(\sum_{k=1}^{n}\left(\sup_{\|x\|\le v_k}\left\|\widetilde{f}_k(x)\right\|\right)^2\right). \tag{D.12}$$

Finally, combining (D.8) and (D.12) leads to

$$\frac{1}{n}\sum_{k=1}^{n}\|\Pi_k\|^2 \overset{a.s.}{=} O\left(\frac{1}{n}\sum_{k=1}^{n} v_k^{2-m}\right) + O\left(v_{n+1}^{2-m}\right) + O\left(\frac{1}{n}\sum_{k=1}^{n}\left(\sup_{\|x\|\le v_k}\left\|\widetilde{f}_k(x)\right\|\right)^2\right). \tag{D.13}$$

Since assumptions of part 2 of Theorem 3.1 are satisfied, $\sup_{\|x\|\le v_n}\|\widetilde{f}_n(x)\| \overset{a.s.}{=} o(1)$, and since $m>2$, then $v_n^{2-m}=o(1)$. Therefore, from (D.13), we deduce that

$$\frac{1}{n}\sum_{k=1}^{n}\|\Pi_k\|^2 \overset{a.s.}{=} o(1). \tag{D.14}$$

Step 3: *study of* $(1/n)\sum_{k=0}^{n-1}\Pi_k^T\,\xi_{k+1}$. For $n\ge 1$, $M_n=\sum_{k=0}^{n-1}\Pi_k^T\,\xi_{k+1}$ is a square integrable martingale. Since $\|\langle M\rangle_n\| \le \text{trace}(\Gamma)\sum_{k=0}^{n-1}\|\Pi_k\|^2 \overset{a.s.}{=} o(n)$ (by (D.14)), we deduce from a strong law of large numbers for the martingales (for example, Duflo [13, Theorem 1.3.15, p. 20]), that for any $\delta>0$,

$$\frac{1}{n}\sum_{k=0}^{n-1}\Pi_k^T\,\xi_{k+1} \overset{a.s.}{=} O\left(\frac{(\log n)^{1+\delta}}{n}\right)^{1/2}. \tag{D.15}$$

Finally, results (D.4), (D.14), and (D.15) give the optimality of the tracking.

To finish the proof of Theorem 4.2, let us remark that

$$\left\|\widehat{\Gamma}_n-\Gamma\right\| \overset{a.s.}{=} O\left(\frac{1}{n}\sum_{k=0}^{n-1}\|\Pi_k\|^2\right) + O\left(\left\|\frac{1}{n}\sum_{k=1}^{n}\xi_k\,\xi_k^T-\Gamma\right\|\right). \tag{D.16}$$

Acknowledgments. The authors thank Prof. Marie Duflo, Prof. Georges Oppenheim, and Prof. Jean-Michel Poggi for helpful discussions, as well as the two anonymous referees for their useful comments which allowed us to significantly improve this paper.

CONJUGATE POINTS FOR VARIATIONAL PROBLEMS WITH EQUALITY AND INEQUALITY STATE CONSTRAINTS*

HIDEFUMI KAWASAKI[†] AND VERA ZEIDAN[‡]

Abstract. In this paper, variational problems with equality and inequality state constraints are considered. The theory of conjugate points for these problems is developed, and necessary conditions for weak local optimality are derived in terms of this concept and the Legendre condition. For the case of inequality constraints, the envelope-like effect is taken into consideration in the accessory problem.

Key words. conjugate points, accessory problem, inequality and equality state constraints, Jacobi system, Legendre condition, variational problems, necessary optimality conditions

1. Introduction.

In this paper, we deal with two variational problems. One is the variational problem with inequality state constraints:

$$\text{(VP)} \qquad \text{Minimize} \int_0^T f(t, x(t), \dot{x}(t))dt$$
$$\text{subject to} \quad x(0) = x_0, \quad x(T) = x_T, \quad x \in W^n_{1,\infty}[0, T],$$
$$g(t, x(t)) \leq 0 \ \text{ for all } t \in [0, T];$$

the other is the variational problem with equality state constraints:

$$\text{(VP}_0\text{)} \qquad \text{Minimize} \int_0^T f(t, x(t), \dot{x}(t))dt$$
$$\text{subject to} \quad x(0) = x_0, \quad x(T) = x_T, \quad x \in W^n_{1,\infty}[0, T],$$
$$h(t, x(t)) = 0 \ \text{ for all } t \in [0, T],$$

where $T > 0$ is a fixed time, x_0 and x_T are given points in R^n, and $W^n_{1,\infty}[0,T] := \{x : [0,T] \to R^n \mid x_i \text{ ; absolutely continuous, } ||x|| < \infty\}$ equipped with the norm $||x|| = \max_{t\in[0,T]} ||x(t)|| + \text{esssup}_{t\in[0,T]} ||\dot{x}(t)||$. We assume that $f : R^{2n+1} \to R$, $h : [0,T] \times R^n \to R^l$ and $g : [0,T] \times R^n \to R^m$ are continuous and have continuous partial derivatives with respect to (w.r.t.) x and $\dot{x}$ up to order 2 inclusive.

Since the inception of optimal control theory in the 1960s and its increased applications to modern problems, the study of variational problems with state constraints has been the center of attention for several researchers; see, for instance, [2], [9], [10], [11], [12], [17], [28], [29], [31], [36], [38] and the references provided therein. At this stage, many questions pertaining to the first-order optimality conditions have been satisfactorily answered. Recently, the light has been strongly focusing on the questions concerning second-order optimality conditions. For the case of abstract problems with

[‡]Department of Mathematics, Michigan State University, East Lansing, MI 48824 (zeidan@math.msu.edu).

inequality constraints, it was observed by Kawasaki [18] that a certain envelope-like effect occurs and is manifested by the appearance of an extra term in the second-order necessary condition. Later this phenomenon was also noticed by several authors (Ioffe [15], [16], Cominetti [8], Páles and Zeidan [32], [33], and Penot [36]).

For the case of variational problems with state constraints, (e.g., the problem (VP)), it is shown [32] that an extra term appears in the corresponding accessory problem.

In the context of second-order necessary conditions for weak local minima, the concept of conjugate point plays a crucial role in the history of variational problems with fixed endpoints and no state constraints (e.g., [4], [13], and [30]). This concept is usually given in terms of envelopes and is traditionally used as an effective tool to verify the nonnegativity of the second variation, or equivalently, to verify that the accessory problem has a zero minimum value. Hence, it is an important question to obtain optimality conditions in terms of conjugate points theory. This theory was extended in Zeidan and Zezza [43], [44] to the case when general endpoint conditions are present; this naturally includes the periodic ones.

However, the problem of deriving the conjugate point theory for the case when state constraints are present is a long-standing open question. This is the case even for the calculus of variations setting.

The main purpose of this paper is to develop a theory of conjugate points for the problems (VP) and (VP_0). The second aim is to establish in terms of this notion necessary conditions for optimality in (VP) and (VP_0). Our approach is analytical.

In section 2 we review the resulting envelope-like effect for an abstract infinite dimensional optimization problem. Then, the second variation is derived in Theorem 2.3 for (VP) via a direct proof. This result requires the nonemptiness of the set of second-order admissible variations $K(y)$ (see (2.2)) and, as expected, evokes in the second variation an extra term E (see Definition 2.2).

Since the constraint $K(y) \neq \emptyset$ is neither an equality nor an inequality and since the extra term involving E is so complicated to analyze, then the form of the accessory problem given by Theorem 2.3 is not appropriate to derive the conjugate point theorem. In section 3, we obtain from the second-variation of section 2 a "well-behaved" accessory problem (AP) for (VP) that has quadratic objectives and inequalities. The major results of the paper are given in section 4. There, we consider a quadratic problem (GAP) generalizing the accessory problem (AP) for which we develop necessary conditions for optimality phrased in terms of a certain "Jacobi system." This later inspires the introduction of the "conjugate point" notion for (GAP). As a consequence we obtain that the nonexistence of points in $(0, T)$ conjugate to 0 is necessary for optimality in (VP). In section 5 we obtain the Legendre condition for (VP). Conjugate point theory for (VP_0) is derived in section 6. In the final section we provide two numerical examples that illustrate the utility of the results.

2. Preliminary results. Both (VP) and (VP_0) are formulated as an abstract optimization problem in Banach spaces:

$$\text{(P)} \qquad \begin{array}{ll} \text{Minimize} & F(x) \\ \text{subject to} & G(x) \in K, \quad H(x) = 0, \end{array}$$

where X, V, W are Banach spaces, K is a closed convex *cone* in V with nonempty interior, $F : X \to R$, $G : X \to V$, and $H : X \to W$ are of C^2-class. For instance, to include (VP_0) (equality constraints) one would take $V = \{0\}$.

We first give some notations and definitions. We denote by $\langle \cdot, \cdot \rangle$ the canonical pairing between a Banach space V and its topological dual space V^*. For any $A \subset X$, its *interior*, *closure*, and *conical hull* are denoted by $\mathrm{int}A$, $\bar{A}$, and $\mathrm{cone}A$, respectively. All vectors in R^n except gradient vectors are column vectors. For $a \in R^n$, a^T denotes the transpose of a, and a_i denotes the ith component of a. The polar cone of K is defined by $K^\circ = \{v^* \in V^* | \langle v^*, v \rangle \ \leq 0 \quad \text{for all } v \in K\}$. For any $\hat{K} \subset V$ and $v^* \in V^*$, the support function is defined by $\delta^*(v^*|\hat{K}) = \sup\{\langle v^*, v\rangle | v \in \hat{K}\}$. For any twice continuously differentiable mapping H, we denote by $H'(x)$ and $H''(x)$ the first and second Fréchet differentials, respectively. A feasible function $\bar{x}$ is *regular* if $H'(\bar{x})$ has a closed range. A vector $y \in X$ is called a *critical* direction at $\bar{x}$ if

$$F'(\bar{x})y = 0, \quad H'(\bar{x})y = 0, \quad G'(\bar{x})y \in \overline{\mathrm{cone}}(K - G(\bar{x})). \tag{2.1}$$

For a given $y \in X$, we define the second-order admissible variation set

$$K(y) := \{w \in V | d(\theta^2 G(\bar{x}) + \theta G'(\bar{x})y + w,\, K) \to 0 \text{ as } \theta \to \infty\}, \tag{2.2}$$

where $d(a, K)$ denotes the distance from a point a to the set K; see Kawasaki [18], [20]. The set $K(y)$ is the closure of the set of second-order admissible variations defined in [32].

THEOREM 2.1 (see [32, Theorem 6]). *Let $\bar{x}$ be a regular local minimum of (P). Then, for each critical direction y satisfying $K(y) \neq \emptyset$, there exist $\lambda_0 \geq 0$, $v^* \in K^\circ$, and $w^* \in W^*$ not all zero such that*

$$L'(\bar{x}) = 0, \tag{2.3}$$

$$L''(\bar{x})(y, y) - 2\delta^*(v^*|K(y)) \geq 0, \tag{2.4}$$

$$\langle v^*, G(\bar{x})\rangle = 0, \tag{2.5}$$

where

$$L(x) := \lambda_0 F(x) + \langle v^*, G(x)\rangle + \langle w^*, H(x)\rangle.$$

Remark 2.1. As a consequence of (2.1), (2.3), and $v^* \in K^\circ$, we obtain the second complementary condition

$$\langle v^*, G'(\bar{x})y\rangle = 0. \tag{2.6}$$

Remark 2.2. The additional term $\delta^*(v^*|K(y))$ was first introduced in [18]. It is closely related to the second derivative of an envelope formed by the generalized inequality constraint $G(x) \in K$; see [18], [19], and [20]. Readers may also refer to [3], [5], [8], [15], [16], [21], [22], [23], [24], [25], [26], [32], [33], [35], [36], [39], [41], and [42]. Theorem 2.1 was also derived in [15, Thm. 5.1] under the Mangasarian–Fromovitz condition. In that case $\lambda_0 = 1$.

Now, we derive a second-order necessary optimality condition for the variational problem (VP) with inequality state constraints by applying Theorem 2.1 to (VP). Let $\bar{x}$ be an arbitrary weak minimum for (VP). For the sake of simplicity we use the following abbreviations:

$$\bar{f}(t) = f(t, \bar{x}(t), \dot{\bar{x}}(t)),\ \bar{g}(t) = g(t, \bar{x}(t)), \dots .$$

We shall invoke the *full-rank condition*, that is,

$$\{\bar{g}_{jx}(t)\}_{\bar{g}_j(t)=0} \text{ are linearly independent for any } t \in [0,T].$$

Note that it can be shown that the Mangasarian–Fromovitz condition holds if the full-rank condition holds together with

$$g(0,x_0) < 0, \quad g(T,x_T) < 0. \tag{2.7}$$

In order to apply Theorem 2.1 to (VP), we take $X := W^n_{1,\infty}[0,T]$, $V := (C[0,T])^m$, and $W := R^{2n}$. Furthermore, we take $K := \{v \in (C[0,T])^m \mid v(t) \le 0 \text{ for all } t\}$, $F(x) := \int_0^T f(t,x,\dot{x})dt$, $G(x)(t) := g(t,x(t))$, and $H(x) := (x(0)-x_0, x(T)-x_T)^T$, respectively.

Under the assumptions in section 1, the mappings $F : X \to R$, $G : X \to V$, and $H : X \to R^{2n}$ are twice continuously Fréchet differentiable, and their first and second Fréchet differentials are given by

$$F'(\bar{x})y = \int_0^T \{\bar{f}_x y + \bar{f}_{\dot{x}}\dot{y}\}dt, \tag{2.8}$$

$$F''(\bar{x})(y,y) = \int_0^T \{y^T \bar{f}_{xx} y + 2y^T \bar{f}_{x\dot{x}}\dot{y} + \dot{y}^T \bar{f}_{\dot{x}\dot{x}}\dot{y}\}dt, \tag{2.9}$$

$$G'(\bar{x})y = \bar{g}_x y, \quad G''(\bar{x})(y,y) = y^T \bar{g}_{xx} y, \tag{2.10}$$

$$H'(\bar{x})y = (y(0), y(T))^T, \quad H''(\bar{x})(y,y) = (0,0)^T; \tag{2.11}$$

see, e.g., Girsanov [11] and Ioffe and Tihomirov [14].

The set $K(y)$ in this setting is

$$\begin{aligned} K(y) := \{w \in (C[0,T])^m \mid \exists\ \Delta(\theta) \in (C[0,T])^m \text{ such that } \Delta(\theta) \to 0 \text{ as } \theta \to \infty, \\ \theta^2 \bar{g}(t) + \theta \bar{g}_x(t) y(t) + w(t) + \Delta(\theta)(t) \le 0 \quad \text{for all } t, \quad \text{for all } \theta > 0\}. \end{aligned}$$

In order to deal with the extra term $\delta^*(v^*|K(y))$ in (2.4), we need the function $E(t)$ introduced in [19] and [20]. A function closely related to E was also introduced for this context in [32] and [33].

Definition 2.2. *For any u, $v \in C[0,T]$ that satisfy $u(t) \ge 0$ for all t and $v(t) \ge 0$ for any t such that $u(t) = 0$, we define a function $E : [0,T] \to [-\infty, \infty]$ by*

$$E(t) := \begin{cases} \max\left\{\limsup_{n\to\infty} \dfrac{v(t_n)^2}{4u(t_n)};\ \{t_n\} \text{ satisfies } (2.13)\right\} & \textit{if } t \in T_0, \\ 0 & \textit{if } t \in T_1 \backslash T_0, \\ -\infty & \text{otherwise}, \end{cases} \tag{2.12}$$

where

$$T_0 := \left\{ t \in T \mid {}^{\exists}t_n \to t \text{ s.t. } u(t_n) > 0,\ -\frac{v(t_n)}{u(t_n)} \to +\infty \right\}, \tag{2.13}$$

$$T_1 := \{t \in T \mid u(t) = v(t) = 0\}. \tag{2.14}$$

Furthermore, it is convenient to use the following notation: Let $y(t)$ be critical. For each $j = 1, \ldots, m$, take in Definition 2.2

$$u(t) = -\bar{g}_j(t), \quad v(t) = -\bar{g}_{jx}(t)y(t). \tag{2.15}$$

Then we denote the function $E(t)$ by $E_j(t; y)$, and $(E_1(t; y), \ldots, E_m(t; y))^T$ by $E(t; y)$, respectively. The following second-order necessary optimality condition was essentially obtained in Páles, Zeidan [32, Thm. 6] for a more general problem. Since the problem (VP) is simpler than that considered in [32], a direct and short proof is provided below in order to complete the presentation of this paper.

THEOREM 2.3. *If $\bar{x}$ is a weak minimum for* (VP)*, then for each critical direction $y \in W^n_{1,\infty}[0, T]$ satisfying $K(y) \neq \emptyset$, there exists a constant vector $a \in R^n$, a constant $\lambda_0 \geq 0$, and a nondecreasing function $\lambda : [0, T] \to R^m$ that is right-continuous except at $t = 0$ such that λ_0 and $d\lambda$ are not zero and*

$$\lambda_0 \left(\bar{f}_{\dot{x}}(t) - \int_0^t \bar{f}_x ds \right) - \int_{(0,t]} d\lambda^T \bar{g}_x = a^T \text{ a.e. } t \in [0, T], \tag{2.16}$$

(2.17)
$$\int_0^T \lambda_0 \{y^T \bar{f}_{xx} y + 2y^T \bar{f}_{x\dot{x}} \dot{y} + \dot{y}^T \bar{f}_{\dot{x}\dot{x}} \dot{y}\} dt + \int_{[0,T]} y^T (d\lambda^T \bar{g})_{xx} y + 2 \int_{[0,T]} d\lambda(t)^T E(t; y) \geq 0,$$

and

$$d\lambda_j(t) = 0 \quad \text{on} \quad \{t \mid \bar{g}_j(t) = \bar{g}_{jx}(t)y(t) = 0\}^c, \quad j = 1, \ldots, m. \tag{2.18}$$

If in addition the full-rank condition holds then $\lambda_0 \neq 0$, say $\lambda_0 = 1$, and in this case, λ does not depend on y.

Remark 2.3. Since $y = 0$ is a critical direction and since $0 \in K(0)$, then by Theorem 2.3, $y = 0$ has an associated $\lambda_0 \geq 0$ and λ satisfying (2.16) and (2.20). Under the full-rank condition and (2.7), Theorem 2.3 asserts that this particular λ_0 is nonzero and that when we take $\lambda_0 = 1$, λ is independent of y and is unique up to a constant.

Proof. By Riesz's representation theorem, the Lagrange function $L(x)$ is represented as

$$L(x) = \int_0^T \lambda_0 f dt + \int_{[0,T]} d\lambda^T g + \sum_{k=0,\ T} \nu_k^T (x(k) - x_k), \tag{2.19}$$

where $\nu_0,\ \nu_T \in R^n$ and $\lambda : [0, T] \to R^m$ is a componentwise nondecreasing function; see, e.g., Rudin [40]. For any critical direction y, we get from (2.3), (2.19), and the integration by parts that

$$\begin{aligned} 0 = L'(\bar{x})y &= \int_0^T \lambda_0 \{\bar{f}_x y + \bar{f}_{\dot{x}} \dot{y}\} dt + \int_{[0,T]} d\lambda^T \bar{g}_x y + \sum_{k=0}^{T} \nu_k^T y(k) \\ &= \int_0^T \lambda_0 \left\{ \bar{f}_{\dot{x}} - \int_0^t \bar{f}_x dt - \int_{(0,t]} d\lambda^T \bar{g}_x \right\} \dot{y} dt \end{aligned}$$

for all $y \in W^n_{1,\infty}[0,T]$ satisfying $y(0) = y(T) = 0$. This implies (2.16); see, e.g., [11], [14], and [27]. On the other hand, the complementarity condition (2.5) becomes

$$\int_{[0,T]} d\lambda^T \bar{g} = 0. \tag{2.20}$$

Since λ is nondecreasing and $\bar{g}$ is nonpositive, (2.20) implies that

$$d\lambda_j(t) = 0 \ \text{ if } \ \bar{g}_j(t) < 0. \tag{2.21}$$

Hence the second complementarity condition (2.6) becomes

$$\int_{\bar{g}(t)=0} d\lambda^T \bar{g}_x = 0. \tag{2.22}$$

Since $G'(\bar{x})y \in \overline{\text{cone}}(K - G(\bar{x}))$, it follows from Lemma 6.1 in [18] that

$$\bar{g}_x(t)y(t) \le 0 \ \text{ if } \ \bar{g}(t) = 0. \tag{2.23}$$

Combining (2.4), (2.21), (2.22), and (2.23), we get (2.18). On the other hand, it was shown in [20, p. 222] and [34, Cor. (4.2) (iv)] that

$$\delta^*(v^*|K(y)) = -\int_{[0,T]} d\lambda(t)^T E(t;y). \tag{2.24}$$

Combining (2.9), (2.10), and (2.24), we get (2.17).

Now, assume the full-rank condition. Then, if $\lambda_0 = 0$, (2.16) yields that

$$\int_{(t_1,t_2]} d\lambda^T \bar{g}_x = 0 \qquad \text{for all } \ t_1, t_2 \in [0,T].$$

The right continuity of λ, the full-rank condition, and (2.21) imply that $d\lambda = 0$ on $[0,T]$. Hence a contradiction is obtained. Thus, $\lambda_0 \neq 0$ and can be taken to be 1. Similar arguments show that if λ and μ are two nondecreasing functions that are right continuous except at $t = 0$ and satisfy (2.16) and (2.21), then they must have $d\lambda = d\mu$ on $[0,T]$. □

3. The accessory problem (AP). In this section, we will give an accessory problem (AP) for (VP). Assume in the rest of the paper that the full rank condition and (2.7) hold. By Theorem 2.3 and Remark 2.3, there exist unique (up to a constant) multipliers $\lambda_0 = 1$ and λ such that Theorem 2.3 leads to a prototype of our accessory problem:

$$\begin{aligned}(\text{AP}_0)\ \text{Minimize } & \frac{1}{2}\int_0^T \{y^T \bar{f}_{xx} y + 2y^T \bar{f}_{x\dot{x}} \dot{y} + \dot{y}^T \bar{f}_{\dot{x}\dot{x}} \dot{y}\} dt \\ & + \frac{1}{2}\sum_{j=1}^m \int_{[0,T]} \{y^T \bar{g}_{jxx} y + 2E_j\} d\lambda_j, \\ & \text{subject to } y \ \text{ being critical and } \ K(y) \neq \emptyset.\end{aligned}$$

From Theorem 2.3, it follows that $y(t) \equiv 0$ is a minimum of (AP_0).

Note that when we attempt to give a first-order necessary optimality condition for (AP_0) as well as the classical Jacobi equation, we encounter two difficulties:

(1) The constraint $K(y) \neq \emptyset$ is neither an inequality constraint nor an equality constraint.

(2) The definition of $E(t;y)$ is so complicated that the extra term $\int_{[0,T]} E_j(t;y)d\lambda_j$ is hard to analyze as a function of y.

Hence the key of this section is to overcome these two difficulties. Before solving them, we first deal with critical directions.

Lemma 3.1. *When $\bar{x}(t)$ is a weak minimum for* (VP)*, then a function $y \in W^n_{1,\infty}[0,T]$ is critical if and only if*

$$\int_{[0,T]} d\lambda(t)^T \bar{g}_x(t)y(t) = 0, \tag{3.1}$$

$$\bar{g}_{jx}(t)y(t) \leq 0 \quad \text{if} \quad \bar{g}_j(t) = 0 \tag{3.2}$$

for all j, and

$$y(0) = y(T) = 0. \tag{3.3}$$

Proof. It is evident that $H'(\bar{x})y = 0$ is equivalent to (3.3). As was seen in the proof of Theorem 2.3, the condition $G'(\bar{x})y \in \overline{\text{cone}}(K - G(\bar{x}))$ is equivalent to (3.2). Since the first-order optimality condition (2.3) is satisfied, the condition $F'(\bar{x})y = 0$ is equivalent to $\langle v^*, G'(\bar{x})y\rangle = 0$, which is furthermore equivalent to (3.1). This completes the proof. □

In this result, we characterize the nonemptiness of $K(y)$ in terms of inequalities. Thus, the first difficulty encountered above is circumvented.

Lemma 3.2. *For any critical direction $y(t)$, the necessary and sufficient condition for the nonemptiness of $K(y)$ is that there exists $\beta \in W^m_{1,\infty}[0,T]$ such that*

$$\bar{g}_{jx}(t)y(t) + \sqrt{-2\bar{g}_j(t)}\beta_j(t) \leq 0 \tag{3.4}$$

for all t and $j = 1, \ldots, m$. Furthermore, when $\beta(t)$ satisfies (3.4)*, it holds that*

$$\sum_{j=1}^m \int_{[0,T]} \beta(t)^2 d\lambda_j \geq 2\sum_{j=1}^m \int_{[0,T]} E_j(t;y)d\lambda_j, \tag{3.5}$$

where $\lambda_j(t)$ is the nondecreasing function guaranteed in Theorem 2.3.

Proof. First we note that $K(y)$ is nonempty if and only if $E_j(t;y) < \infty$ for all t and $j = 1, \ldots, m$; see Theorem 2.1 in [19]. Next, for each $j = 1, \ldots, m$, put

$$u_j(t) := -\bar{g}_j(t), \quad v_j(t) := -\bar{g}_{jx}(t)y(t). \tag{3.6}$$

Sufficiency: Let β satisfy (3.4). Then, for any converging sequence $t_n \to t$ satisfying

$$-\frac{v_j(t_n)}{u_j(t_n)} \to \infty, \tag{3.7}$$

we get from (3.4) that

$$0 < \frac{-v_j(t_n)}{\sqrt{2u_j(t_n)}} \leq -\beta_j(t_n). \tag{3.8}$$

Tending $n \to \infty$, we get

$$0 \leq \limsup_{n\to\infty} \frac{v_j(t_n)^2}{2u_j(t_n)} \leq \beta_j(t)^2. \tag{3.9}$$

It follows from the definition of $E_j(t; y)$ that $0 \leq 2E_j(t; y) \leq \beta_j(t)^2 < \infty$. When there is no sequence $t_n \to t$ satisfying (3.7), it is evident from the definition of $E_j(t; y)$ that $2E_j(t; y) \leq 0 \leq \beta_j(t)^2$. Since $d\lambda \geq 0$, we readily get (3.5) from these inequalities.

Necessity: Since $v_j(t) \geq 0$ if $u_j(t) = 0$, condition (3.4) implies that

$$\beta_j(t) \leq \frac{v_j(t)}{\sqrt{2u_j(t)}} \quad \text{if} \quad u_j(t) > 0 \quad \text{for all} \quad j = 1, \ldots, m. \tag{3.10}$$

Since β_j is continuous, this condition yields that

$$-\frac{v_j(t)}{\sqrt{2u_j(t)}} \text{ is bounded above on } \{t : u_j(t) > 0\} \text{ for all } \quad j = 1, \ldots, m. \tag{3.11}$$

Conversely, assume that (3.11) holds for some upper bounds $M_j > 0$. Set $\beta_j(t) = M_j$ on $[0, T]$. The result is that the function $\beta = (\beta_j)$ is in $W^m_{1,\infty}[0, T]$ and satisfies (3.4) on $[0, T]$. Therefore, (3.4) is equivalent to (3.11).

Now, we proceed by contradiction. If (3.11) does not hold, then there exist some j and a sequence t_n such that $u(t_n) > 0$ and

$$\lim_{n\to\infty} \frac{-v_j(t_n)}{\sqrt{2u_j(t_n)}} = \infty. \tag{3.12}$$

Here we may assume that t_n converges to some point $\bar{t}$. Then it is evident that $v_j(t_n) < 0$ for all sufficiently large n,

$$\lim_{n\to\infty} \frac{v_j(t_n)^2}{4u_j(t_n)} = \infty, \tag{3.13}$$

and

$$-\frac{v_j(t_n)}{u_j(t_n)} = \frac{v_j(t_n)^2}{u_j(t_n)} \frac{1}{-v_j(t_n)} \to \infty. \tag{3.14}$$

Therefore $E_j(\bar{t}; y) = \infty$, so that $K(y)$ is empty. This completes the proof. □

Combining Lemmas 3.1 and 3.2, we get another variational problem, which we call the accessory problem for the variational problem (VP):

$$\begin{aligned}
\text{(AP) Minimize } & \frac{1}{2}\int_0^T \{y^T \bar{f}_{xx} y + 2y^T \bar{f}_{x\dot{x}} \dot{y} + \dot{y}^T \bar{f}_{\dot{x}\dot{x}} \dot{y}\} dt \\
& + \frac{1}{2}\sum_{j=1}^m \int_{[0,T]} \{y^T \bar{g}_{jxx} y + \beta_j^2\} d\lambda_j \\
\text{subject to } & y \in W^n_{1,\infty}[0, T], \quad \beta \in W^m_{1,\infty}[0, T], \\
& \bar{g}_{jx}(t) y(t) + \sqrt{-2\bar{g}_j(t)}\beta_j(t) \leq 0 \quad \text{if} \quad d\lambda_j(t) = 0, \\
& \bar{g}_{jx}(t) y(t) + \sqrt{-2\bar{g}_j(t)}\beta_j(t) = 0 \quad \text{if} \quad d\lambda_j(t) > 0, \\
& y(0) = y(T) = 0.
\end{aligned}$$

Theorem 2.3 implies that the objective function of (AP) is nonnegative. Hence, it is evident that $(y(t), \beta(t)) \equiv (0, 0)$ is a minimum of the accessory problem (AP).

4. Conjugate points for the (VP) problem. The goal of this section is to eventually derive necessary conditions for the (VP) problem in terms of conjugate points. In order to achieve this goal, we first derive the conjugate point theory for the general quadratic problem (GAP) below, and then the conjugate points for (VP) will be defined exactly as the conjugate points for its accessory problem (AP), which is quadratic. In this section, we first give a first-order necessary optimality condition (Jacobi system) for the accessory problem (AP). Next, we will define conjugate points by using the Jacobi system, and finally we will prove that the open interval $(0, T)$ includes no points conjugate to 0 for any weak minimum for (VP).

$$\text{(GAP) Minimize } \frac{1}{2}\int_0^T \{y^T P y + 2y^T Q\dot{y} + \dot{y}^T R\dot{y}\}dt + \frac{1}{2}\sum_{j=1}^{m}\int_{[0,T]}\{y^T C_j y + \beta_j^2\}d\lambda_j$$

subject to $y \in W^n_{1,\infty}[0,T], \quad \beta \in W^m_{1,\infty}[0,T],$

$$a_j(t)^T y(t) + \alpha_j(t)\beta_j(t) \le 0 \text{ if } d\lambda_j(t) = 0, \tag{4.1}$$

$$a_j(t)^T y(t) + \alpha_j(t)\beta_j(t) = 0 \quad \text{if } d\lambda_j(t) > 0, \tag{4.2}$$

$$y(0) = y(T) = 0,$$

where R, Q, and P are $n\times n$-matrix-valued essentially bounded measurable functions for $j = 1, \dots, m$, C_j is a continuous $n\times n$-matrix-valued function, $a_j(t)$ in $W^n_{1,\infty}[0,T]$ and $\alpha_j(t)$ in $W_{1,\infty}[0,T]$, and $d\lambda_j$ is a given nonnegative regular Borel measure. We assume that $R(t)$, $P(t)$, and $C_j(t)$ are symmetric, $\alpha_j(0)$ and $\alpha_j(T)$ are positive for all $j = 1, \dots, m$, the measure satisfies

$$\alpha_j(t)d\lambda_j(t) = 0 \quad \text{on} \quad [0,T] \tag{4.3}$$

for all $j = 1, \dots, m$, and $\{a_j^T(t)\}_{\alpha_j(t)=0}$ are linearly independent for all $t \in [0,T]$.

In the following, we use these abbreviations:

$$\alpha(t) := \begin{pmatrix}\alpha_1(t)\\ \vdots \\ \alpha_m(t)\end{pmatrix}, \quad D(\alpha) := \begin{pmatrix}\alpha_1 & & 0\\ & \ddots & \\ 0 & & \alpha_m\end{pmatrix}, \quad A(t) := \begin{pmatrix}a_1(t)^T\\ \vdots \\ a_m(t)^T\end{pmatrix}. \tag{4.4}$$

The following theorem is a first-order necessary optimality condition for the generalized accessory problem (GAP).

THEOREM 4.1. *If* $(y, \beta) \in W^n_{1,\infty}[0,T]\times W^m_{1,\infty}[0,T]$ *is a minimum for the accessory problem* (GAP), *then there exist* $d \in R^n$ *and* $\mu : [0,T] \to R^m$ *with bounded variation that is right-continuous except at* $t = 0$ *such that* $y(0) = y(T) = 0$, *and the Jacobi system holds:*

(J1)

$$Q(t)^T y(t) + R(t)\dot{y}(t) - \int_0^t \{Py + Q\dot{y}\}dt - \sum_{j=1}^{m}\int_{(0,t]} C_j y d\lambda_j - \int_{(0,t]} A^T d\mu = d \quad \text{a.e. } t,$$

$$\beta_j(t)d\lambda_j(t) = \alpha_j(t)d\mu_j(t) = 0, \tag{J2}$$

$$a_j(t)^T y(t) \le 0 \quad \text{if} \quad \alpha_j(t) = 0, \tag{J3}$$

(J4) $$a_j(t)^T y(t) + \alpha_j(t)\beta_j(t) \le 0 \quad \textit{if} \ \ d\lambda_j(t) = 0,$$

(J5) $$a_j(t)^T y(t) d\mu_j(t) = a_j(t)^T y(t) d\lambda_j(t) = 0,$$

and

(J6) $$d\mu_j(t) \ge 0 \quad \textit{if} \ \ d\lambda_j(t) = 0$$

for all $t \in [0, T]$ *and* $j = 1, \ldots, m$.

Proof. For the sake of simplicity, we denote by $F(y, \beta)$ the quadratic objective function of (GAP). Now, let (y, β) be a minimum for (GAP). Then, since all the functions in the constraints are linear w.r.t. (y, β), it is easily seen that there exists no $(z, \gamma) \in W^n_{1,\infty}[0, T] \times W^m_{1,\infty}[0, T]$ such that $F'(y, \beta)(z, \gamma) < 0$, $Az + D(\alpha)\gamma \in K_\lambda$, and $z(0) = z(T) = 0$, where K_λ denotes the set of all $v \in W^m_{1,\infty}[0, T]$ that satisfies

(4.5) $$v_j(t) \le 0 \text{ if } d\lambda_j(t) = 0 \ \text{ and } \ a_j(t)^T y(t) + \alpha_j(t)\beta_j(t) = 0,$$

(4.6) $$v_j(t) \in R \text{ if } d\lambda_j(t) = 0 \ \text{ and } \ a_j(t)^T y(t) + \alpha_j(t)\beta_j(t) < 0,$$

(4.7) $$v_j(t) = 0 \text{ if } d\lambda_j(t) > 0$$

for all $j = 1, \ldots, m$. This implies that the zero-vector in $R \times (C[0, T])^m \times R^{2n}$ does not belong to the following convex cone:

(4.8) $$C := \left\{ \begin{pmatrix} F'(y,\, \beta)(z, \gamma) + p \\ Az + D(\alpha)\gamma - v \\ z(0) \\ z(T) \end{pmatrix} ; \begin{array}{l} p > 0 \\ v \in K_\lambda \\ z \in W^n_{1,\infty}[0, T] \\ \gamma \in W^m_{1,\infty}[0, T] \end{array} \right\}.$$

As we shall later see, C has nonempty interior. Hence, by the separation theorem, there exist $\lambda_0 \in R$, ν_0, $\nu_T \in R^n$, and $\mu : [0, T] \to R^m$ of bounded variations that are right-continuous except at $t = 0$ not all zero such that

(4.9) $$\lambda_0\{F'(y, \beta)(z, \gamma) + p\} + \int_{[0,T]} d\mu^T \{Az + D(\alpha)\gamma - v\} + \nu_0^T z(0) + \nu_T^T z(T) \ge 0$$

for all $p > 0$, $v \in K_\lambda$, $z \in W^n_{1,\infty}[0, T]$, and $\gamma \in W^m_{1,\infty}[0, T]$. We easily get $\lambda_0 \ge 0$. From (4.9) and the definition of K_λ, we obtain

(4.10) $$d\mu_j(t) \ge 0, \quad \text{if} \ \ d\lambda_j(t) = 0 \ \text{ and } \ a_j(t)^T y(t) + \alpha_j(t)\beta_j(t) = 0,$$

and

(4.11) $$d\mu_j(t) = 0, \quad \text{if} \ \ d\lambda_j(t) = 0 \ \text{ and } \ a_j(t)^T y(t) + \alpha_j(t)\beta_j(t) < 0,$$

which yields the last assertion (J6). Tending $p \to +0$ and taking $v = 0$ in (4.9), we have

(4.12) $$\lambda_0 F'(y, \beta)(z, \gamma) + \int_{[0,T]} d\mu^T \{Az + D(\alpha)\gamma\} + \nu_0^T z(0) + \nu_T^T z(T) \ge 0$$

for all $z \in W^n_{1,\infty}[0, T]$ and $\gamma \in W^m_{1,\infty}[0, T]$. Let us show $\lambda_0 > 0$. Suppose that $\lambda_0 = 0$ in (4.12); then we have

(4.13) $$\int_{[0,T]} d\mu^T \{Az + D(\alpha)\gamma\} + \nu_0^T z(0) + \nu_T^T z(T) = 0.$$

Hence, for any (z, γ) satisfying $z(0) = z(T) = 0$, we have, by integration by parts, that

$$\int_0^T \left(\int_{(0,t]} d\mu^T A \right) \dot{z}(t)dt + \int_0^T \left(\int_{[0,t]} d\mu^T D(\alpha) \right) \dot{\gamma}(t)dt = 0. \tag{4.14}$$

Hence both $\int_{(0,t]} d\mu^T A$ and $\int_{(0,t]} d\mu^T D(\alpha)$ are constant, so that $d\mu^T (A, D(\alpha)) = 0$. Since the matrix $(A(t), D(\alpha(t)))$ has full rank, we have $d\mu(t) = 0$. Hence from (4.13) we have $\nu_0 = \nu_T = 0$. This leads to a contradiction. Hence we may assume that $\lambda_0 = 1$, and we get from (4.12) that

$$F'(y, \beta)(z, \gamma) + \int_{[0,T]} d\mu^T \{Az + D(\alpha)\gamma\} = 0 \tag{4.15}$$

for any (z, γ) such that $z(0) = z(T) = 0$. That is,

$$\int_0^T \{y^T Pz + \dot{y}^T Q^T z + y^T Q\dot{z} + \dot{y}^T R\dot{z}\}dt + \sum_{j=1}^m \int_{[0,T]} \{y^T C_j z d\lambda_j + d\lambda^T D(\beta)\gamma\}$$
$$+ \int_{[0,T]} d\mu^T \{Az + D(\alpha)\gamma\} = 0.$$

By integration by parts, we have

$$\int_0^T \dot{z}(t)^T \left\{ Q(t)^T y(t) + R(t)\dot{y}(t) - \int_0^t \{Py + Q\dot{y}\}dt - \sum_{j=1}^m \int_{(0,t]} C_j y d\lambda_j - \int_{(0,t]} A^T d\mu \right\} dt$$

$$- \int_0^T \dot{\gamma}(t)^T \left\{ \int_{(0,t]} D(\beta)d\lambda + \int_{(0,t]} D(\alpha)d\mu \right\} dt = 0. \tag{4.16}$$

From (4.16), we get (J1) and

$$D(\beta(t))d\lambda(t) + D(\alpha(t))d\mu(t) = 0 \quad \text{on} \quad [0, T]. \tag{4.17}$$

Combining (4.3) and (4.17), we get (J2).

From (4.1), (4.2), (4.10), and (4.11) we get (J3), (J4),

$$\{a_j(t)^T y(t) + \alpha_j(t)\beta_j(t)\}d\lambda_j(t) = 0, \tag{4.18}$$

and

$$\{a_j(t)^T y(t) + \alpha_j(t)\beta_j(t)\}d\mu_j(t) = 0. \tag{4.19}$$

Combining (4.18), (4.19), and (J2), we get (J5). Finally, we prove that the convex cone C has nonempty interior. For any $u \in (W_{1,\infty}^+[0, T])^m$, that is, for any nonnegative-valued function in $W_{1,\infty}^m[0, T]$, the full-rank property of $(A, D(\alpha))$ implies the following linear equation has an unique solution $w(t) \in R^m$:

$$(A(t), D(\alpha(t))) \begin{pmatrix} A(t)^T \\ D(\alpha(t)) \end{pmatrix} w(t) = u(t). \tag{4.20}$$

Put

$$z(t) := A(t)^T w(t), \quad \gamma(t) := D(\alpha(t))w(t). \tag{4.21}$$

Then, by Cramer's formula, z in $W^n_{1,\infty}[0,T]$ and γ in $W^m_{1,\infty}[0,T]$. From (4.20), we have

$$A(t)z(t) + D(\alpha(t))\gamma(t) = u(t). \tag{4.22}$$

Since $\alpha(0)$ and $\alpha(T)$ are positive and since α is continuous, there exists $\delta > 0$ such that α is positive on $[0,\delta] \cup [T-\delta, T]$. Next, for any $\xi_0,\ \xi_T \in R^n$, put

$$\bar{z}(t) := \begin{cases} \frac{1}{\delta}\{tz(t) + (\delta - t)\xi_0(t)\} & \text{on } [0,\delta], \\ z(t) & \text{on } [\delta, T-\delta], \\ \frac{1}{\delta}\{(T-t)z(t) + (t-T+\delta)\xi_T(t)\} & \text{on } [T-\delta, T], \end{cases} \tag{4.23}$$

where

$$\xi_0(t) = \frac{1}{\delta}\left[z(\delta)t + (\delta - t)\xi_0\right]$$

and

$$\xi_T(t) = \frac{1}{\delta}\left[z(T-\delta)(T-t) + (t-T+\delta)\xi_T\right].$$

Similarly for a suitable $\eta \in W^m_{1,\infty}[0,T]$, satisfying $\eta(\delta) = \gamma(\delta)$ and $\eta(T-\delta) = \gamma(T-\delta)$, and which we will define later, put

$$\bar{\gamma}(t) := \begin{cases} \frac{1}{\delta}\{t\gamma(t) + (\delta - t)\eta(t)\} & \text{on } [0,\delta], \\ \gamma(t) & \text{on } [\delta, T-\delta], \\ \frac{1}{\delta}\{(T-t)\gamma(t) + (t-T+\delta)\eta(t)\} & \text{on } [T-\delta, T]. \end{cases} \tag{4.24}$$

Then it is evident from (4.22)–(4.24) that

$$\bar{z}(0) = \xi_0, \quad \bar{z}(T) = \xi_T, \ \dot{\bar{z}}(\delta) = \dot{z}(\delta), \quad \text{and} \quad \dot{\bar{z}}(T-\delta) = \dot{z}(T-\delta), \tag{4.25}$$

$\bar{z}$ and $\bar{\gamma}$ are in $W^n_{1,\infty}$ and $W^m_{1,\infty}$, and

$$A(t)\bar{z}(t) + D(\alpha(t))\bar{\gamma}(t) = u(t) \quad \text{on} \quad [\delta, T-\delta]. \tag{4.26}$$

Furthermore, for any $t \in [0,\delta]$, it follows from (4.22)–(4.24) that

(4.27)

$$\begin{aligned} &u(t) - \{A(t)\bar{z}(t) + D(\alpha(t))\bar{\gamma}(t)\} \\ &= A(t)z(t) + D(\alpha(t))\gamma(t) - A(t)\frac{tz(t) + (\delta - t)\xi_0(t)}{\delta} - D(\alpha(t))\frac{t\gamma(t) + (\delta - t)\eta(t)}{\delta} \\ &= \frac{\delta - t}{\delta}\{A(t)(z(t) - \xi_0(t)) + D(\alpha(t))\gamma(t)\} - \frac{\delta - t}{\delta}D(\alpha(t))\eta(t). \end{aligned}$$

We can choose $\eta(t)$ so that the right-hand side of (4.27) is nonnegative for all $t \in [0,\delta]$. Indeed, put $\rho(t) := A(t)(z(t) - \xi_0(t)) + D(\alpha(t))\gamma(t)$. Then the right-hand side of (4.27) is nonnegative if and only if

$$\rho_j(t) \geq \alpha_j(t)\eta_j(t) \ \text{ for all } \ j = 1, \dots, m. \tag{4.28}$$

Since $\alpha_j(t) > 0$ on $[0, \delta]$ and since both ρ and α are in $W^m_{1,\infty}[0, T]$, (4.28) is achieved by a certain function $\eta(t)$ in $W^m_{1,\infty}[0, T]$. This fact together with (4.27) implies that

$$u(t) \geq A(t)\bar{z}(t) + D(\alpha(t))\bar{\gamma}(t) \quad \text{on} \quad [0, \delta]. \tag{4.29}$$

Similarly, we can prove that the inequality in (4.29) also holds on $[T-\delta, T]$ by choosing a suitable $\eta(t)$. Finally, take

$$v(t) := \begin{cases} 0 & \text{on } [\delta, T - \delta], \\ A(t)\bar{z}(t) + D(\alpha(t))\bar{\gamma}(t) - u(t) \leq 0 & \text{on } [0, \delta] \cup [T - \delta, T]. \end{cases} \tag{4.30}$$

Then it is easily seen from assumption (4.3) that $v \in K_\lambda$ and $u = A\bar{z} + D(\alpha)\bar{\gamma} - v$. Therefore the convex cone C contains $[r, \infty) \times (W^+_{1,\infty}[0, T])^m \times R^{2n}$, where r is some real number. This completes the proof. □

Definition 4.2. *A pair $(y, \beta) \in W^n_{1,\infty}[0, T] \times W^m_{1,\infty}[0, T]$ is said to satisfy the Jacobi system for* (GAP) *if there exist a constant vector $d \in R^n$ and $\mu : [0, T] \to R^m$ with bounded variation that is right-continuous except at $t = 0$ such that* (J1)–(J6) *are satisfied.*

Theorem 4.3. *Let c be in $(0, T]$, and let $(y, \beta) \in W^n_{1,\infty}[0, T] \times W^m_{1,\infty}[0, T]$ satisfy the generalized Jacobi system on $[0, c]$ and the end points condition*

$$y(0) = y(c) = 0 \quad \text{and} \quad \beta(c)^T \int_{(c,T]} d\lambda = 0. \tag{4.31}$$

Define $\bar{y}(t)$ and $\bar{\beta}(t)$ by

$$\bar{y}(t) := \begin{cases} y(t) & \text{on } [0, c], \\ 0 & \text{on } [c, T], \end{cases} \qquad \bar{\beta}(t) := \begin{cases} \beta(t) & \text{on } [0, c], \\ \beta(c) & \text{on } [c, T], \end{cases} \tag{4.32}$$

respectively. Then $(\bar{y}, \bar{\beta})$ is also a feasible solution for the generalized accessory problem (GAP)*, and the value of the objective function at $(\bar{y}, \bar{\beta})$ is zero.*

Proof. It is clear that $(\bar{y}, \bar{\beta})$ is a feasible solution for (GAP). It suffices to show that

$$\int_0^c \{y^T P y + 2y^T Q\dot{y} + \dot{y}^T R\dot{y}\}dt + \sum_{j=1}^m \int_{[0,c]} \{y^T C_j y + \beta_j^2\} d\lambda_j = 0. \tag{4.33}$$

By (J2), (J1), and integration by parts, this integration is equal to

$$\int_0^c \left(y(t)^T Q(t) + \dot{y}(t)^T R(t) - \int_0^t y^T P dt - \int_0^c \dot{y}^T Q^T dt - \sum_{j=1}^m \int_{(0,t]} y^T C_j d\lambda_j \right) \dot{y}(t) dt$$

$$= \int_0^c \left(\int_{(0,t]} d\mu^T A \right) \dot{y} dt = \int_{[0,c]} d\mu^T A y = 0,$$

where the first equality follows from the complementarity condition (J5). This completes the proof. □

Definition 4.4. *Let y belong to $W^m_{1,\infty}[0, T]$ and let c be in $(0, T]$. Then we denote by $\dot{y}_{ess}(c - 0)$ the set of all essential cluster points of $\dot{y}(t)$ as $t \to c - 0$, that is, those that persist upon the removal of any set of measure zero; see Clarke* [6, Ex. 2.2.5].

DEFINITION 4.5. *A point $c \in (0,T]$ is said to be conjugate to $t=0$ for* (GAP) *if there exist a pair $(y,\beta) \in W^m_{1,\infty}[0,T] \times W^m_{1,\infty}[0,T]$ and an essential cluster point $\xi \in \dot{y}_{ess}(c-0)$ such that they satisfy, with some μ and d, the Jacobi system* (J1)–(J6) *on $[0,c]$, the end points condition* (4.31),

$$a_j(c)^T\xi \geq 0 \quad \textit{if} \quad \alpha_j(c) = 0 \quad \textit{and} \quad d\lambda_j(c) = 0, \tag{4.34}$$

$$a_j(c)^T\xi = 0 \quad \textit{if} \quad d\lambda_j(c) > 0, \tag{4.35}$$

for all j, and

$$\underset{t\to c-0,\ \dot{y}(t)\to\xi}{\textit{limesssup}}\ \dot{y}(t)^T R(t)\dot{y}(t) > 0. \tag{4.36}$$

In particular, when both $\dot{y}(t)$ and $R(t)$ have the left limits at $t=c$, conditions (4.34), (4.35)*, and* (4.36) *reduce, respectively, to*

$$a_j(c)^T\dot{y}(c-0) \geq 0 \quad \textit{if} \quad \alpha_j(c) = 0 \quad \textit{and} \quad d\lambda_j(c) = 0, \tag{4.37}$$

$$a_j(c)^T\dot{y}(c-0) = 0 \quad \textit{if} \quad d\lambda_j(c) > 0, \tag{4.38}$$

and

$$\dot{y}(c-0)^T R(c-0)\dot{y}(c-0) > 0. \tag{4.39}$$

The following result is a necessary condition in terms of the conjugate point theory for the optimal value of (GAP) to be zero.

THEOREM 4.6. *Assume that* (GAP) *has a minimum value equal to zero. Then the open interval $(0,T)$ contains no points conjugate to $t=0$.*

Remark 4.1. Note that we do not assume that the strengthened Legendre condition holds and thus, $R(c-0)$ need not be positive definite. Hence, Theorem 4.6 is applicable to the shortest path problem in Euclidean space; see Example 7.2 below.

Proof of Theorem 4.6. Let (y,β) satisfy the Jacobi system (J1)–(J6) on $[0,c]$ and the end points condition (4.31). Let $(\bar{y},\bar{\beta})$, defined by (4.32), be the extensions of (y,β). Then, by Theorem 4.3, $(\bar{y},\bar{\beta})$ is a global minimum for the generalized accessory problem (GAP). Hence, by Theorem 4.1, there exist a function $\bar{\mu}(t)$ and a constant $\bar{d}$ that satisfy the Jacobi system (J1)–(J6). In particular, (J1) reduces to

$$Q(t)^Ty(t) + R(t)\dot{y}(t) - \int_0^t \{Py + Q\dot{y}\}dt - \sum_{j=1}^m \int_{(0,t]} \{C_jyd\lambda_j + a_jd\bar{\mu}_j\} = \bar{d} \tag{4.40}$$

a.e. on $[0,c]$, and

$$-\int_0^c \{Py + Q\dot{y}\}dt - \sum_{j=1}^m \int_{(0,c]} \{C_jyd\lambda_j + a_jd\bar{\mu}_j\} = \bar{d}. \tag{4.41}$$

By subtracting (4.41) from (4.40) and multiplying it by $\dot{y}(t)^T$, we get

$$\begin{aligned} &\dot{y}(t)^TQ(t)^Ty(t) + \dot{y}(t)^TR(t)\dot{y}(t) + \dot{y}(t)^T\int_t^c \{Py + Q\dot{y}\}dt \\ &+ \sum_{j=1}^m \dot{y}(t)^T\int_{(t,c]} C_jyd\lambda_j + \sum_{j=1}^m \dot{y}(t)^T\int_{(t,c]} a_jd\bar{\mu}_j = 0 \end{aligned} \tag{4.42}$$

a.e. on $[0,c]$. Here, since $\dot{y}(t)^T Q(t)^T$ is essentially bounded and $y(c)=0$, the first term of (4.42) converges to zero as $t \to c-0$. Similarly, the third and the fourth terms tend to zero. Now, let ξ be the essential cluster point in the definition of conjugate points, and let $t_k \to c-0$ satisfy (4.42) and $\dot{y}(t_k) \to \xi$. Then the last term in (4.42) converges to $\xi^T \sum_{j=1}^m a_j(c) d\bar{\mu}_j(c)$. So we get from (4.42) that

$$\lim_{k\to\infty} \dot{y}(t_k)^T R(t_k)\dot{y}(t_k) + \sum_{j=1}^{m} \xi^T a_j(c) d\bar{\mu}_j(c) = 0. \tag{4.43}$$

Hence it follows from (J2) and (4.35) that

$$\lim_{k\to\infty} \dot{y}(t_k)^T R(t_k)\dot{y}(t_k) + \sum_{\alpha_j(c)=0,\ d\lambda_j(c)=0} \xi^T a_j(c) d\bar{\mu}_j(c) = 0. \tag{4.44}$$

However, for any j satisfying $\alpha_j(c)=0$ and $d\lambda_j(c)=0$, we get from (4.34) and (J6) that $\xi^T a_j(c) d\bar{\mu}_j(c) \geq 0$, so that $\lim_{k\to\infty} \dot{y}(t_k)^T R(t_k)\dot{y}(t_k) \leq 0$, which contradicts (4.36). This completes the proof. □

In the rest of this section, we apply the concept of conjugate points and Theorem 4.6 to the problem (VP).

DEFINITION 4.7. *A point $c \in (0,T]$ is said to be conjugate to $t=0$ for* (VP) *if c is a conjugate point to $t=0$ for* (AP).

The following theorem is a necessary condition for optimality in (VP) in terms of the conjugate point theory. It is an immediate consequence of Theorems 2.3 and 4.6. We assume that $\bar{g}(t) \in W^m_{1,\infty}[0,T]$ and $\bar{g}_{jx}(t) \in W^n_{1,\infty}[0,T]$ for all j and that the full rank condition and (2.7) hold.

THEOREM 4.8 (main theorem). *Let $\bar{x}(t)$ be a weak minimum for the variational problem* (VP). *Then the open interval $(0,T)$ contains no points conjugate to $t=0$.*

5. Legendre condition for (VP). In the definition of conjugate points (Definition 4.5), we used a kind of Legendre condition. In this section, we justify it, that is, we will prove that the usual Legendre condition holds for (VP).

First, let $\bar{x}(t)$ be a weak minimum for (VP). Then there exists $\varepsilon > 0$ such that $F(\bar{x}) \leq F(\bar{x}+\varepsilon y)$ if $\bar{x}+\varepsilon y$ is feasible and $\parallel y \parallel < 1$, where F is the objective function of (VP) and $\parallel y \parallel$ is the norm in $W^n_{1,\infty}[0,T]$.

Hence, by putting $u := \dot{y}$, $(\bar{y}(t), \bar{u}(t)) \equiv (0,0)$ is a global minimum for the following optimal control problem:

$$\begin{aligned}
\text{(OCP) Minimize } & \int_0^T f(t, \bar{x}(t)+\varepsilon y(t), \dot{\bar{x}}(t)+\varepsilon u(t))dt \\
\text{subject to } & y(0)=y(T)=0, \quad (y,u) \in W^n_{1,\infty}[0,T] \times L^n_\infty[0,T], \\
& \dot{y} = u, \\
& g(t, \bar{x}(t)+\varepsilon y(t)) \leq 0 \quad \text{for all } t \in [0,T], \\
& |y(t)| < 1, \quad |u(t)| < 1,
\end{aligned}$$

where $|\cdot|$ designates the Euclidean norm.

THEOREM 5.1. *If $\bar{x}$ is a weak minimum for* (VP), *then $f_{\dot{x}\dot{x}}(t, \bar{x}(t), \dot{\bar{x}}(t))$ is nonnegative definite for a.e. t.*

Proof. By the maximum principle, see, e.g., Clarke [6, Thm. 5.2.1], there exist $\lambda_0 \in \{0,1\}$, m-dimensional vector-valued absolutely continuous p, and a nondecreasing function $\lambda : [0,T] \longrightarrow R^m$ that is right-continuous except $t=0$ such that

$(\lambda_0, p, d\lambda)$ are not all zero,

$$\dot{p}(t) = -H_y\left(t, \bar{y}(t), p(t) + \int_{(0,t]} \bar{g}_x^T d\lambda, \bar{u}(t), \lambda_0\right), \tag{5.1}$$

$$H\left(t, \bar{y}(t), p(t) + \int_{(0,t]} \bar{g}_x^T d\lambda, w, \lambda_0\right) \geq H\left(t, \bar{y}(t), p(t) + \int_{(0,t]} \bar{g}_x^T d\lambda, \bar{u}(t), \lambda_0\right) \tag{5.2}$$

for all $|w| < 1$ and a.e. t, and

$$d\lambda_j(t) = 0 \;\text{ if }\; \bar{g}_j(t) < 0 \tag{5.3}$$

for all j, where

$$H(t, y, q, w, \lambda_0) := q^T u - \lambda_0 f(t, \bar{x}(t) + \varepsilon y, \dot{\bar{x}}(t) + \varepsilon w) \tag{5.4}$$

for $(t, y, q, w, \lambda_0) \in [0, T] \times R^{3n+1}$. Since

$$H\left(t, \bar{y}(t), p(t) + \int_{(0,t]} \bar{g}_x^T d\lambda, w, \lambda_0\right) = \left(p(t) + \int_{(0,t]} \bar{g}_x^T d\lambda\right)^T w - \lambda_0 f(t, \bar{x}(t), \dot{\bar{x}}(t) + \varepsilon w) \tag{5.5}$$

takes the maximum at $w = 0$, we get

$$p(t) + \int_{(0,t]} \bar{g}_x^T d\lambda - \lambda_0 \varepsilon f_{\dot{x}}(t, \bar{x}(t), \dot{\bar{x}}(t)) = 0 \tag{5.6}$$

for a.e. t. Furthermore, by differentiating (5.5) twice w.r.t. w, we see that $\lambda_0 \varepsilon^2 f_{\dot{x}\dot{x}}(t, \bar{x}(t), \dot{\bar{x}}(t))$ is nonnegative definite for a.e. t. Finally, we show that $\lambda_0 \neq 0$. Indeed, if $\lambda_0 = 0$, then from (5.6) we have

$$p(t) + \int_{(0,t]} \bar{g}_x^T d\lambda = 0 \tag{5.7}$$

for a.e. t. For any $t \in [0, T]$, by choosing a suitable sequence t_k converging to t from the left and taking the limit in (5.7), we get

$$p(t) + \int_{(0,t)} \bar{g}_x^T d\lambda = 0, \tag{5.8}$$

where the commutativity of the limit with the integration is guaranteed by Lebesgue's convergence theorem. Similarly, by taking a suitable right limit in (5.7), we see that (5.7) holds for all $t \in [0, T]$. So, from (5.7) and (5.8), we have $\bar{g}_x(t)^T(\lambda(t) - \lambda(t-0)) = 0$ for all t. Since $\{\bar{g}_{jx}(t)\}_{\bar{g}_j(t)=0}$ are linearly independent and $d\lambda_j(t) = 0$ for any j such that $\bar{g}_j(t) < 0$, we see that $\lambda(t)$ does not jump at any point t. On the other hand, it follows from the adjoint equation (5.1) that $\dot{p} = -\lambda_0 \varepsilon \bar{f}_x = 0$. Since $p(0) = 0$, we have $p(t) = 0$. Next, differentiate (5.7). Then we have $\dot{p} + \bar{g}_x^T \dot{\lambda} = 0$. Hence $\bar{g}_x^T \dot{\lambda} = 0$, which implies that $\dot{\lambda} = 0$. This contradicts that $(\lambda_0, p, d\lambda)$ are not all zero. Therefore λ_0 is positive. This completes the proof. □

Remark 5.1. Theorem 5.1 above asserts that the usual Legendre condition holds even if there exists an inequality state constraint. This fact is surprising, because the result is different in the case of an equality state constraint. Namely, when the inequality constraint $g(t, x(t)) \leq 0$ is replaced with $h(t, x(t)) = 0$, we get only

$$\xi^T f_{\dot{x}\dot{x}}(t, \bar{x}(t), \dot{\bar{x}}(t))\xi \geq 0 \;\text{ if }\; h_x(t, \bar{x}(t))\xi = 0; \tag{5.9}$$

see, e.g., Hestenes [13, Thm. 5.1].

6. Conjugate points for ($\mathbf{VP_0}$) problem. In this section, we deal with the variational problem (VP_0) with equality state constraints. Since all the proofs are similar to and far simpler than those of the inequality case, we omit them. Assume that $\bar{h}_x(t)$ has full rank for all t.

THEOREM 6.1. *If $\bar{x}(t)$ is a weak minimum for* (VP_0)*, then there exists a constant vector $a \in R^n$ and a function $\lambda : [0,T] \longrightarrow R^m$ with bounded variation that is right-continuous except at $t = 0$ such that for each critical direction $y \in W^n_{1,\infty}[0,T]$, we have*

$$\bar{f}_{\dot{x}}(t) - \int_0^t \bar{f}_x ds - \int_{(0,t]} d\lambda^T \bar{h}_x = a^T \quad a.e.\ t \in [0,T], \tag{6.1}$$

$$\int_0^T \{y^T \bar{f}_{xx} y + 2y^T \bar{f}_{x\dot{x}} \dot{y} + \dot{y}^T \bar{f}_{\dot{x}\dot{x}} \dot{y}\} dt + \int_{[0,T]} y^T (d\lambda^T \bar{h})_{xx} y \geq 0. \tag{6.2}$$

The accessory problem for (VP_0) is given as follows:

$$(\mathrm{AP}^0)\ \text{Minimize}\ \frac{1}{2} \int_0^T \{y^T \bar{f}_{xx} y + 2y^T \bar{f}_{x\dot{x}} \dot{y} + \dot{y}^T \bar{f}_{\dot{x}\dot{x}} \dot{y}\} dt + \frac{1}{2} \int_{[0,T]} y^T (d\lambda^T \bar{h})_{xx} y$$

$$\text{subject to } y \in W^n_{1,\infty}[0,T], \quad \bar{h}_{jx}(t) y(t) \equiv 0, \quad y(0) = y(T) = 0.$$

THEOREM 6.2. *If y is a weak minimum for* (AP^0)*, then there exist $d \in R^n$ and $\mu : [0,T] \longrightarrow R^m$ of bounded variation that is right-continuous except at $t = 0$ such that the Jacobi system is satisfied, that is, a.e. t,*

($\mathrm{J1}_0$)

$$\bar{f}_{\dot{x}x}(t) y(t) + \bar{f}_{\dot{x}\dot{x}}(t) \dot{y}(t) - \int_0^t \{\bar{f}_{xx} y + \bar{f}_{x\dot{x}} \dot{y}\} dt - \sum_{j=1}^m \int_{(0,t]} \{\bar{h}_{jxx} y d\lambda_j + \bar{h}^T_{jx} d\mu_j\} = d,$$

a.e. t, and

$$\bar{h}_x(t) y(t) \equiv 0. \tag{$\mathrm{J2}_0$}$$

THEOREM 6.3. *Let c be in $(0,T]$, y satisfy* ($\mathrm{J1}_0$) *and* ($\mathrm{J2}_0$) *on $[0,c]$, and c satisfy the end points condition $y(0) = y(c) = 0$. Next, define $\bar{y}(t)$ by $y(t)$ on $[0,c]$, and 0 on $[c,T]$. Then $\bar{y}$ is also a feasible solution for* (AP^0)*, and the value of the objective function at $\bar{y}$ is zero.*

DEFINITION 6.4. *A point $c \in (0,T]$ is said to be conjugate to $t = 0$ if there exist a feasible solution $y \in W^m_{1,\infty}[0,T]$ for* (AP^0) *and an essential cluster point $\xi \in \dot{y}_{ess}(c-0)$ such that they satisfy, for some μ and d, the Jacobi system* ($\mathrm{J1}_0$)*,* ($\mathrm{J2}_0$) *on $[0,c]$, the end points condition $y(0) = y(c) = 0$, $\bar{h}_x(c)\xi = 0$, and $limesssup_{t \to c-0,\ \dot{y}(t) \to \xi}\, \dot{y}(t)^T \bar{f}_{\dot{x}\dot{x}}(t) \dot{y}(t) > 0$.*

THEOREM 6.5. *Let $\bar{x}(t)$ be a weak minimum for the variational problem* (VP_0)*. Then the open interval $(0,T)$ contains no points conjugate to $t = 0$.*

Remark 6.1. Traditionally, it was thought that inequality constraints could be treated in the context of equality constraints by adding a slack variable of the form v^2 (see, e.g., [13, p. 261] or [30, p. 148]). However, this method produces necessary conditions for optimality that are considerably weaker than those obtained via Theorem 2.1. For instance, if we add the slack variable $\frac{v^2}{2}$ to $g(t,x(t))$, the constraint $g(t,x(t)) \leq 0$ reduces to

$$g(t,x(t)) + \frac{v^2}{2}(t) = 0 \qquad \text{for all} \quad t \in [0,T]. \tag{6.3}$$

Now apply the results of this section to (VP), where $g(t,x(t)) \leq 0$ is replaced by (6.3). We obtain that the accessory problem (AP) has a zero minimum over a set of directions $(y,\beta) \in W^n_{1,\infty}[0,T] \times W^m_{1,\infty}[0,T]$ which is a strict subset of the set of critical directions used in section 3. In fact, (y,β) must now satisfy $y(0)=y(T)=0$ and, for all t and for all j,

$$a_j^T(t)y(t) + \alpha_j(t)\beta_j(t) = 0, \tag{6.4}$$

where $a_j^T(t) = \bar{g}_{jx}(t)$ and $\alpha_j(t) = \sqrt{-2\bar{g}_j(t)}$. Furthermore, the Jacobi system associated with (GAP) subject to (6.4) would be (J1), (J2), (J5), (J6), and (6.4). Hence, with this Jacobi system the number of conjugate points is smaller than that obtained by using (J1)–(J6), as in Definition 4.5. Thus, the necessary condition that we would obtain in terms of conjugate points is weaker than that given in Theorems 4.6 and 4.8.

7. Examples. We begin this section by introducing a connection condition. Usually, optimal solutions for (VP) have a couple of phases. For instance, in Figure 7.1 below, $\bar{x}(t)$ has two phases: straight line x_0P and sin-curve Px_T. This fact makes calculation of the Jacobi system, especially (J1), complicated. For example, when we compute the integrations in (J1) for t that correspond to a point in Px_T, we have to divide the interval of integration into two subintervals like $[0,t]=[0,\tau)\cup[\tau,t]$. However, we can avoid this division by introducing a connection condition at the boundary point $t=\tau$.

THEOREM 7.1. *Let y and μ satisfy* (J1), *and let τ be in* $(0,T)$. *Then it holds that*

(7.1)
$$\{Q^T(t)y(t) + R(t)\dot{y}(t)\}|_{t=\tau-0}^{t=\tau+0} = \sum_{j=1}^{m}\{C_j(\tau)y(\tau)\lambda_j(t)|_{t=\tau-0}^{t=\tau} + a_j(\tau)\mu_j(t)|_{t=\tau-0}^{t=\tau}\}.$$

We call (7.1) *the connection condition.*

Proof. Take the left and the right limits at τ in (J1). Then, since $\lambda(t)$ and $\mu(t)$ are right-continuous, we get the desired result by comparing the limits. □

With the connection condition, we do not need to take care of the value of the constant vector $d \in R^n$ in (J1). It suffices to use the fact that the left-hand side of (J1) is constant in each phase; see (7.7) below. Furthermore, we can easily derive another connection condition for the Euler–Lagrange equation (2.16).

$$\bar{f}_{\dot{x}}(t)|_{t=\tau-0}^{t=\tau+0} = \lambda(t)^T|_{t=\tau-0}^{t=\tau}\bar{g}_x(\tau). \tag{7.2}$$

Example 7.1.

$$\text{Minimize} \int_0^T f(t,x,\dot{x})dt = \frac{1}{2}\int_0^T (\dot{x}^2 - x^2)dt$$
$$\text{subject to } x(0)=0, \quad x(T)=-1, \quad x \in W_{1,\infty}[0,T],$$
$$g(t,x(t)) = l(t) - x(t) \leq 0 \quad \text{for all } t \in [0,T],$$

where $\pi \leq \tau < T < 2\pi$ are fixed and

$$l(t) := \min\left\{\frac{t-\pi}{\sin(T-\tau)},\ 0,\ \frac{\tau - t}{\sin(T-\tau)}\right\}.$$

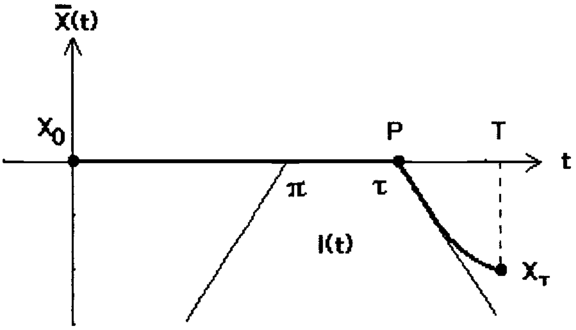

FIG. 7.1.

It is easily seen that the following pair satisfies the boundary condition and the Euler–Lagrange equation (2.16):

$$\bar{x}(t) := \begin{cases} 0 & \text{on } [0,\tau], \\ -\frac{\sin(t-\tau)}{\sin(T-\tau)} & \text{on } [\tau,T], \end{cases} \quad \text{and} \quad \lambda(t) := \begin{cases} 0 & \text{on } [0,\tau), \\ \frac{1}{\sin(T-\tau)} & \text{on } [\tau,T]. \end{cases}$$

Next, since $R(t) = \bar{f}_{\dot{x}\dot{x}}(t) = 1$, $Q(t) = \bar{f}_{x\dot{x}}(t) = 0$, $P(t) = \bar{f}_{xx}(t) = -1$, $C_1(t) = \bar{g}_{xx}(t) = 0$, and $a_1(t) = \bar{g}_x(t)^T = -1$, (J1) reduces to

$$\dot{y} + \int_0^t y\,dt + \mu(t) - \mu(0) = d. \tag{7.3}$$

On the other hand, it follows from (J2) that $d\mu = 0$ on $[0,\pi) \cup (\tau,T]$, so that $\ddot{y}+y = 0$ a.e. on $[0,\pi) \cup (\tau,T]$. Since $y(0) = 0$, we have $y(t) = A\sin t$ on $[0,\pi]$. Let us now see if $t = \pi$ is conjugate to 0 or not. By taking $\beta(t) \equiv 0$, we can easily see that the pair (y,β) satisfies the Jacobi system. Furthermore, $t = \pi$ satisfies (4.39) if $A \neq 0$. Indeed, if $A \neq 0$, then $R(\pi-0)\dot{y}(\pi-0)^2 = A^2 > 0$.

Case 1. In the case of $\tau > \pi$, it holds that $d\lambda(\pi) = 0$, $\bar{g}(\pi) = 0$, and $\bar{g}_x(\pi)\dot{y}(\pi - 0) = A$. Hence, by taking $A > 0$, we see that $t = \pi$ is conjugate to 0, and hence $\bar{x}$ is not a weak minimum for the problem.

Case 2. In the case of $\tau = \pi$, it holds that $d\lambda(\pi) > 0$ and $\bar{g}_x(\pi)\dot{y}(\pi - 0) = A$. Hence, by (4.38), A must be zero if $t = \pi$ is conjugate to 0. However, this contradicts (4.39). Hence $t = \pi$ is not conjugate to 0. Furthermore, since $y(t) = B\sin t$ for some $B \in R$ on $[\pi,T]$, $(\pi,T]$ contains no points conjugate to $t = 0$. Therefore $\bar{x}$ could be optimal.

Example 7.2. The problem is to find the shortest path which does not cross the inside of the unit ball $B \subset R^3$ and which joins two given points x^0, $x^1 \notin B$; see Figure 7.2. That is,

$$\text{Minimize} \int_{t_0}^{T} f(t,x(t),\dot{x}(t))dt = \int_{t_0}^{T} \sqrt{\dot{x}_1(t)^2 + \dot{x}_2(t)^2 + \dot{x}_3(t)^2}dt$$

$$\text{subject to } x(t_0) = x^0, \quad x(T) = x^1, \quad x \in W^n_{1,\infty}[t_0,T],$$

$$g(t,x(t)) = \frac{1}{2}(1 - x_1(t)^2 - x_2(t)^2 - x_3(t)^2) \leq 0 \quad \text{for all } t \in [t_0,T],$$

where $t_0 < 0$, $\frac{\pi}{2} < T$ are fixed.

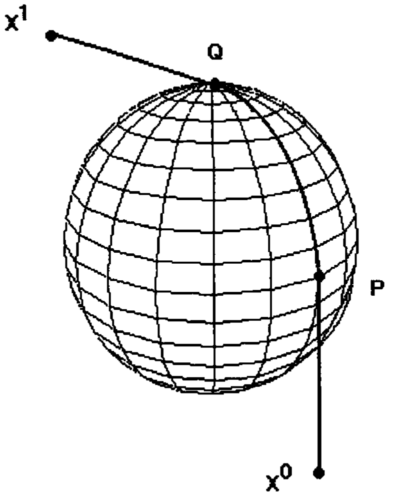

FIG. 7.2.

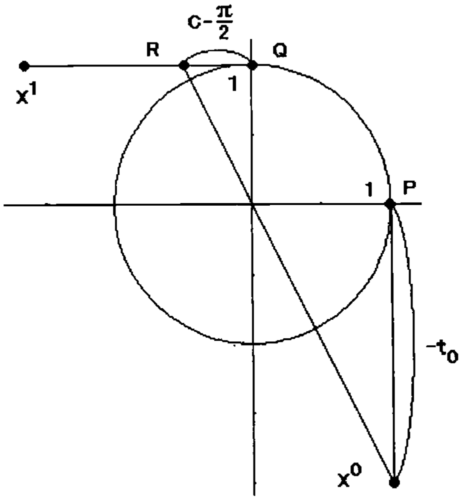

FIG. 7.3.

In this example, we consider the case where the endpoints are given by

$$x^0 = (1, 0, t_0)^T,\ x^1 = \Big(\frac{\pi}{2} - T, 0, 1\Big)^T. \tag{7.4}$$

As a candidate for an optimal solution, let us take

$$\bar{x}(t) := \begin{cases} (1, 0, t)^T & \text{on } t_0 \le t < 0, \\ (\cos t, 0, \sin t)^T & \text{on } 0 \le t < \frac{\pi}{2}, \\ (\frac{\pi}{2} - t, 0, 1)^T & \text{on } \frac{\pi}{2} \le t \le T. \end{cases} \tag{7.5}$$

Then it is easily seen that $\bar{x}(t)$ satisfies the Euler–Lagrange equation by taking

$$\lambda(t) := \begin{cases} 0 & \text{on } t_0 \le t < 0, \\ t & \text{on } 0 \le t < \frac{\pi}{2}, \\ \frac{\pi}{2} & \text{on } \frac{\pi}{2} \le t \le T. \end{cases} \tag{7.6}$$

Now, let us compute the Jacobi system.

Phase 1. $t_0 \le t < 0$. On this interval, it is easily seen that (J1) reduces to

$$\begin{pmatrix} \dot{y}_1(t) \\ \dot{y}_2(t) \\ 0 \end{pmatrix} + \int_{(t_0,t]} \begin{pmatrix} 1 \\ 0 \\ t \end{pmatrix} d\mu = d.$$

Since $y(t_0) = 0$, we see that $d\mu(t) \equiv 0$, $y_1(t) = d_1(t - t_0)$, $y_2(t) = d_2(t - t_0)$, and $y_3(t)$ can be arbitrary except $y_3(t_0) = 0$. Suppose that there exists a point c conjugate to t_0 in this interval. Then both $y_1(t)$ and $y_2(t)$ must vanish, so that $\dot{y}(c-0)^T \bar{f}_{\dot{x}\dot{x}}(c-0)\dot{y}(c-0) = \dot{y}_1(c-0)^2 + \dot{y}_2(c-0)^2 = 0$, which contradicts (4.39). Therefore there is no point conjugate to t_0 in this interval.

Phase 2. $0 \le t < \pi$. It is easily seen that (J1) reduces to

(7.7)
$$\begin{pmatrix} \cos^2 t & 0 & \sin t \cos t \\ 0 & 1 & 0 \\ \sin t \cos t & 0 & \sin^2 t \end{pmatrix} \begin{pmatrix} \dot{y}_1(t) \\ \dot{y}_2(t) \\ \dot{y}_3(t) \end{pmatrix} + \int_{(0,t]} \begin{pmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{pmatrix} dt + \int_{(0,t]} \begin{pmatrix} \cos t \\ 0 \\ \sin t \end{pmatrix} d\mu = c,$$

where $c \in R^3$ is a suitable constant vector. Here we note that the interval of integration is not $(t_0, t]$ but $(0, t]$. On the other hand, it follows from (J5) that $\bar{g}_x y dt = 0$. That is, $y_1(t)\cos t + y_3(t)\sin t = 0$. Hence there exists a real-valued function $\rho(t)$ such that

$$(y_1(t), y_3(t)) = \rho(t)(\sin t, -\cos t). \tag{7.8}$$

Hence $\rho(t)$ is absolutely continuous. Substituting (7.8) into (7.7), we get

$$\rho(t)\cos t + \int_{(0,t]} \rho(t)\sin t\, dt + \int_{(0,t]} \cos t d\mu = c_1 \tag{7.9}$$

and

$$\rho(t)\sin t - \int_{(0,t]} \rho(t)\cos t\, dt + \int_{(0,t]} \sin t d\mu = c_3. \tag{7.10}$$

By differentiating (7.9), we have $(\dot{\rho}(t) + \dot{\mu}(t))\cos t = 0$. Similarly, we get from (7.10) that $(\dot{\rho}(t) + \dot{\mu}(t))\sin t = 0$. Therefore

$$\dot{\rho} + \dot{\mu} = 0. \tag{7.11}$$

On the other hand, it follows from the second component of (7.7) that $\ddot{y}_2 + y_2 = 0$. Hence

$$y_2(t) = A\cos t + B\sin t, \tag{7.12}$$

where A and B are real constants.

Then it is easily seen that the connection condition (7.1) at $t = 0$ reduces to

$$d_1 = \dot{y}_1(0+0) = \rho(0), \quad d_2 = \dot{y}_2(0+0) = B. \tag{7.13}$$

Furthermore, since $y(t)$ is continuous at $t = 0$, we have

$$d_1 = 0, \ A = -d_2 t_0. \tag{7.14}$$

Combining (7.12), (7.13), and (7.14), we get

$$y_2(t) = B(\sin t - t_0 \cos t). \tag{7.15}$$

Now, suppose that there exists a point c conjugate to t_0 in this interval. Then we get from (7.15) that $\tan c = t_0 < 0$, which contradicts that $0 \leq c < \frac{\pi}{2}$. Therefore there is no point conjugate to t_0 in this interval.

Phase 3. $\frac{\pi}{2} \leq t \leq T$. As was the case in Phase 1, it follows from (J1) that $d\mu = 0$, $y_2(t)$ and $y_3(t)$ are straight lines, and $y_1(t)$ is arbitrary. If there exists a point c conjugate to t_0 in $[\frac{\pi}{2}, T]$, then y_2 and y_3 are given by $y_2(t) = b_2(t-c)$ and $y_3(t) = b_3(t-c)$, where b_k's are constants. Furthermore, it follows from the connection condition (7.1) and the continuity of $y(t)$ at $t = \frac{\pi}{2}$ that $b_2 = Bt_0$, $B = b_2(\frac{\pi}{2} - c)$, and $b_3 = 0$. Hence

$$B\left\{t_0\left(\frac{\pi}{2} - c\right) - 1\right\} = 0. \tag{7.16}$$

On the other hand, it follows from (4.39) that $0 < \dot{y}(c-0)^T \bar{f}_{\dot{x}\dot{x}}(c-0)\dot{y}(c-0) = \dot{y}_2^2(c-0)^2 + \dot{y}_3^2(c-0)^2 = b_2^2 = B^2 t_0^2$. Hence we get from (7.16) that

$$t_0\left(\frac{\pi}{2} - c\right) - 1 = 0. \tag{7.17}$$

In Figure 7.3, R indicates the point $\bar{x}(c)$. Since the inequality constraint is inactive at $t = c$, conditions (4.37) and (4.38) are trivially satisfied. Furthermore, it is easily seen that (J2)–(J6) are satisfied by taking $\beta(t) \equiv 0$. Therefore, when $T > \frac{\pi}{2} - \frac{1}{t_0}$, $\bar{x}(t)$ is not a weak minimal solution.

Acknowledgments. The authors would like to thank Michigan State University and the University of Michigan. They also thank Professor John R. Birge for the excellent research opportunity.

ANALYSIS OF NEUMANN BOUNDARY OPTIMAL CONTROL PROBLEMS FOR THE STATIONARY BOUSSINESQ EQUATIONS INCLUDING SOLID MEDIA[*]

HYUNG-CHUN LEE[†] AND O. YU. IMANUVILOV[‡]

Abstract. This article deals with Neumann boundary optimal control problems associated with the Boussinesq equations including solid media. These problems are first put into an appropriate mathematical formulation. Then the existence of optimal solutions is proved. The use of Lagrange multiplier techniques is justified and an optimality system of equations is derived.

Key words. flow control, temperature control, Boussinesq equations, optimization

1. Introduction.

In this article we study boundary optimal control problems for a steady natural convection fluid. The control is heat flux on a portion of the boundary.

We consider the nondimensional Boussinesq equations (including solid media) as follows:

$$-Pr\Delta\mathbf{u}+(\mathbf{u}\cdot\nabla)\mathbf{u}=-\nabla p+Pr\,Ra\,T\mathbf{e}_2+\mathbf{f}\quad\text{in }\Omega_f,\tag{1.1}$$

$$\nabla\cdot\mathbf{u}=0\quad\text{in }\Omega_f,\tag{1.2}$$

$$-\nabla\cdot(\kappa\nabla T)+(\mathbf{u}\cdot\nabla)T=Q,\quad\text{in }\Omega\tag{1.3}$$

with boundary conditions

$$\mathbf{u}=\mathbf{0}\quad\text{on }\partial\Omega_f,\quad\mathbf{u}\equiv\mathbf{0}\quad\text{in }\Omega-\Omega_f=\Omega_s,\tag{1.4}$$

$$T=0\quad\text{on }\Gamma_D,\quad\frac{\partial T}{\partial\mathbf{n}}=g\quad\text{on }\Gamma_C,\tag{1.5}$$

where the regular bounded open set Ω in $\mathbb{R}^2$ is made up of two subdomains Ω_f (fluid domain) and Ω_s (solid domain) separated by a C^∞, connected arc (a regular hypersurface) Σ, with the result that $\Omega=\Omega_f\cup\Sigma\cup\Omega_s$. *Moreover, we assume that* Σ *intersects* $\partial\Omega$ *in two junction points* x_-,x_+ *under nonzero angles. We have, in addition,* $\overline{\partial\Omega_f\cap\partial\Omega_s}=\overline{\Sigma}$. *In* (1.5), $\Gamma_D=\partial\Omega\backslash\Gamma_C$, *where* Γ_C *is a regular open subset of* $\partial\Omega$ *such that* $x_-,x_+\notin\overline{\Gamma}_C$. In (1.1)–(1.5), $\mathbf{u}$, p, and T denote the velocity, pressure, and temperature fields, respectively, with $\mathbf{f}$ a given body force, Q a given heat source, and

control g. The vector $\mathbf{e}_2$ is a unit vector in the direction of gravitational acceleration and κ is a thermal conductivity parameter. In this article, we consider the case of $\kappa \equiv \kappa_f$ in Ω_f and $\kappa \equiv \kappa_s$ in Ω_s, where κ_f and κ_s are positive constants. The vector $\mathbf{n}$ denotes the outward unit normal to Ω, and Pr and Ra denote the Prandtl and Rayleigh numbers, respectively.

Next, we introduce the functionals

$$\mathcal{J}_1(\mathbf{u}, T, p, g) = \frac{1}{2}\int_{\Omega} |T - T_d|^2 \, d\mathbf{x} + \frac{\delta}{2}\int_{\Gamma_C} |g|^2 \, ds \tag{1.6}$$

and

$$\mathcal{J}_2(\mathbf{u}, T, p, g) = \frac{1}{2}\int_{\Omega} |\nabla \times \mathbf{u}|^2 \, d\mathbf{x} + \frac{\delta}{2}\int_{\Gamma_C} |g|^2 \, ds. \tag{1.7}$$

The optimal control problem we consider is to seek state variables $(\mathbf{u}, p, T)$ and a control g such that the functional (1.6) or (1.7) is minimized subject to (1.1)–(1.5), where T_d is some desired temperature distribution. The functional (1.6) effectively measures the difference between the temperature field T and a prescribed field T_d. The real goal of optimization is to minimize the first term appearing in the definition (1.6). The functional (1.7) measures the vorticity of the flow. The control of vorticity has significant applications in science and engineering, such as control of turbulence and control of crystal growth process. The second terms in the cost functionals (1.6) and (1.7) are added to limit the cost of controls. The positive penalty parameter δ can be used to change the relative importance of the two terms appearing in the definition of the functional.

In past years, considerable progress has been made in mathematical analyses and computations of optimal control problems for viscous flows. Optimal control problems for the viscous, incompressible Navier–Stokes equations have been studied very actively during the last ten years (see [8, 9, 10, 13, 14, 15, 21] and references therein). An optimal control problem for the thermally coupled incompressible Navier–Stokes equations by Neumann boundary heat control is considered in [12] in which the Navier–Stokes equations and heat equations are not fully coupled. In [16], an optimal control problem for a coupled solid/fluid temperature control is considered. Linear feedback control of Boussinesq equations is considered in [22]. Also, control problems for the time dependent Boussinesq equations and related problems are considered in [2, 4, 17, 18, 20]. In this article, we consider optimal control problems for the stationary Boussinesq equations including solid media.

The plan of the paper is as follows. In the remainder of this section, we introduce the notation that will be used throughout the paper. Then, in section 2, we give a precise statement of a weak formulation of the Boussinesq equations and prove that a sufficiently smooth solution to the Boussinesq equations exists. In section 3, we give a precise statement of the optimization problem and prove that an optimal solution exists. In section 4, we prove the existence of Lagrange multipliers and then use the method of Lagrange multipliers to derive an optimality system. Some remarks and further discussions are also given.

1.1. Notation. We introduce some function spaces and their norms, along with some related notations used in subsequent sections; for details see [1].

Let Ω be a bounded domain of $\mathbb{R}^2$ with a Lipschitz continuous boundary Γ. Let $L^2(\Omega)$ be the space of real-valued square integrable functions defined on Ω, and let

$\|\cdot\|_{L^2(\Omega)}$ be the norm in this space. We define the Sobolev space $H^m(\Omega)$ for the nonnegative integer m by

$$H^m(\Omega) \overset{def}{=} \left\{u \in L^2(\Omega) \mid D^\alpha u \in L^2(\Omega) \text{ for } 0 \le |\alpha| \le m\right\},$$

where D^α is the weak (or distributional) partial derivative and α is a multi-index. The norm $\|\cdot\|_{H^m(\Omega)}$ associated with $H^m(\Omega)$ is given by

$$\|u\|^2_{H^m(\Omega)} = \sum_{|\alpha|\le m} \|D^\alpha u\|^2_{L^2(\Omega)}.$$

Note that $H^0(\Omega) = L^2(\Omega)$. For the vector-valued functions, we define the Sobolev space $\mathbf{H}^m(\Omega)$ (in all cases, boldface indicates vector-valued) by

$$\mathbf{H}^m(\Omega) \overset{def}{=} \{\mathbf{u} = (u_1, u_2) \mid u_i \in H^m(\Omega) \text{ for } i = 1, 2\},$$

and its associated norm $\|\cdot\|_{\mathbf{H}^m(\Omega)}$ is given by

$$\|\mathbf{u}\|^2_{\mathbf{H}^m(\Omega)} = \sum_{i=1}^{2} \|u_i\|^2_{H^m(\Omega)}.$$

We also define particular subspaces:

$$L^2_0(\Omega) = \left\{f \in L^2(\Omega) : \int_\Omega f \, d\mathbf{x} = 0\right\}, \quad \mathbf{H}^1_0(\Omega) = \left\{\mathbf{u} \in \mathbf{H}^1(\Omega) : \mathbf{u} = \mathbf{0} \text{ on } \Gamma\right\},$$

and

$$H^1_D(\Omega) = \left\{S \in H^1(\Omega) : S = 0 \text{ on } \Gamma_D\right\}.$$

We make use of the well-known space $\mathbf{L}^4(\Omega)$ equipped with the norm $||\cdot||_{\mathbf{L}^4(\Omega)}$.

We also define the solenoidal spaces

$$\mathbf{V} \overset{def}{=} \left\{\mathbf{u} \in \mathbf{H}^1_0(\Omega_f) \,|\, \nabla \cdot \mathbf{u} = 0\right\}.$$

If Ω is bounded and has a Lipschitz continuous boundary (these are kinds of domains under consideration here), Sobolev's embedding theorem yields that $H^1(\Omega) \hookrightarrow\hookrightarrow L^4(\Omega)$, where $\hookrightarrow\hookrightarrow$ denotes compact embedding, i.e., a constant C exists such that

$$||u||_{L^4(\Omega)} \le C||u||_{H^1(\Omega)}. \tag{1.8}$$

Obviously a similar result holds for the spaces $\mathbf{H}^1(\Omega)$ and $\mathbf{L}^4(\Omega)$.

2. A weak formulation of the Boussinesq equations. We introduce the following bilinear and trilinear forms for $\mathbf{u}, \mathbf{v}$ and $\mathbf{w} \in \mathbf{H}^1(\Omega_f)$, $T, S \in H^1(\Omega)$:

$$\begin{aligned}
a_0(\mathbf{u}, \mathbf{v}) &= \int_{\Omega_f} \nabla\mathbf{u} : \nabla\mathbf{v} \, d\mathbf{x} \quad \forall\, \mathbf{u}, \mathbf{v} \in \mathbf{H}^1(\Omega_f),\\
a_1(T, S) &= \int_\Omega \kappa\nabla T \cdot \nabla S \, d\mathbf{x} \quad \forall\, T, S \in H^1(\Omega),\\
b(\mathbf{v}, q) &= -\int_{\Omega_f} q\nabla \cdot \mathbf{v} \, d\mathbf{x} \quad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega_f),\ \forall\, q \in L^2(\Omega_f),\\
c_0(\mathbf{u}, \mathbf{w}, \mathbf{v}) &= \int_{\Omega_f} (\mathbf{u} \cdot \nabla)\mathbf{w} \cdot \mathbf{v} \, d\mathbf{x} \quad \forall\, \mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbf{H}^1(\Omega_f),\\
c_1(\mathbf{u}, T, S) &= \int_{\Omega_f} (\mathbf{u} \cdot \nabla)T\, S \, d\mathbf{x} \quad \forall\, \mathbf{u} \in \mathbf{H}^1(\Omega_f),\ \forall\, T, S \in H^1(\Omega),
\end{aligned}$$

and

$$d(T,\mathbf{v}) = \int_{\Omega_f} T\mathbf{e}_2 \cdot \mathbf{v}\, d\mathbf{x} \quad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega_f),\ \forall\, T \in H^1(\Omega).$$

We first note that the bilinear forms $a_0(\cdot,\cdot)$ and $a_1(\cdot,\cdot)$ are clearly continuous, i.e.,

$$|a_0(\mathbf{u},\mathbf{v})| \leq ||\mathbf{u}||_{\mathbf{H}^1(\Omega_f)}||\mathbf{v}||_{\mathbf{H}^1(\Omega_f)} \tag{2.1}$$

and

$$|a_1(T,S)| \leq \max(\kappa_f,\kappa_s)||T||_{H^1(\Omega)}||S||_{H^1(\Omega)}. \tag{2.2}$$

We have the coercivity relations associated with $a_0(\cdot,\cdot)$ and $a_1(\cdot,\cdot)$:

$$a_0(\mathbf{u},\mathbf{u}) = ||\nabla\mathbf{u}||^2_{L^2(\Omega_f)} \geq C_1||\mathbf{u}||^2_{\mathbf{H}^1(\Omega_f)} \qquad \forall\, \mathbf{u} \in \mathbf{H}^1_0(\Omega_f) \tag{2.3}$$

and

$$a_1(T,T) \geq \min(\kappa_f,\kappa_s)||\nabla T||^2_{L^2(\Omega)} \geq C_2||T||^2_{H^1(\Omega)} \qquad \forall\, T,S \in H^1_D(\Omega), \tag{2.4}$$

which are direct consequences of Poincaré inequality.

2.1. A weak formulation of the equations. The weak form of the constraint equations (1.1)–(1.5) is then given as follows: seek $\mathbf{u} \in \mathbf{H}^1_0(\Omega_f)$, $p \in L^2_0(\Omega_f)$, and $T \in H^1_D(\Omega)$ such that

$$\nu\, a_0(\mathbf{u},\mathbf{v}) + c_0(\mathbf{u},\mathbf{u},\mathbf{v}) + b(\mathbf{v},p) = \alpha\, d(T,\mathbf{v}) + \langle \mathbf{f},\mathbf{v}\rangle \quad \forall\, \mathbf{v} \in \mathbf{H}^1_0(\Omega_f), \tag{2.5}$$

$$b(\mathbf{u},q) = 0 \quad \forall\, q \in L^2_0(\Omega_f), \tag{2.6}$$

and

$$a_1(T,S) + c_1(\mathbf{u},T,S) = \langle Q,S\rangle + \int_{\Gamma_C} \kappa\, g\, S\, ds \quad \forall\, S \in H^1_D(\Omega). \tag{2.7}$$

Throughout the mathematical discussions, for the sake of convenience we set $\nu = Pr$ and $\alpha = Pr \times Ra$, which are not to be confused with the physical quantities such as kinematic viscosity.

LEMMA 2.1. *Suppose* $0 < \min(\kappa_f,\kappa_s) \leq \max(\kappa_f,\kappa_s) < \infty$. *Then, for* $\mathbf{u},\mathbf{v},\mathbf{w} \in \mathbf{H}^1(\Omega_f)$ *and* $T,S \in H^1(\Omega)$ *there are constants* $C_{1,2,3,4}$ *such that*

$$|c_0(\mathbf{u},\mathbf{w},\mathbf{v})| \leq C_1||\mathbf{u}||_{\mathbf{H}^1(\Omega_f)}||\mathbf{v}||_{\mathbf{H}^1(\Omega_f)}||\mathbf{w}||_{\mathbf{H}^1(\Omega_f)}, \tag{2.8}$$

$$c_0(\mathbf{u},\mathbf{v},\mathbf{v}) = 0 \quad \textit{if}\ \mathbf{u} \in \mathbf{V}, \tag{2.9}$$

$$|c_1(\mathbf{u},T,S)| \leq C_2||\mathbf{u}||_{\mathbf{H}^1(\Omega_f)}||T||_{H^1(\Omega)}||S||_{H^1(\Omega)} \quad \forall\, \mathbf{u} \in \mathbf{V}, \tag{2.10}$$

$$c_1(\mathbf{u},T,T) = 0 \quad \textit{if} \quad \mathbf{u} \in \mathbf{V}, \tag{2.11}$$

and

$$|d(T,\mathbf{u})| \leq C_3||T||_{L^2(\Omega)}||\mathbf{u}||_{\mathbf{L}^2(\Omega_f)} \leq C_4||\nabla T||_{L^2(\Omega)}||\nabla\mathbf{u}||_{\mathbf{L}^2(\Omega_f)}. \tag{2.12}$$

Proof. The first and third inequalities follow from the Hölders inequalities and the continuous embeddings of $\mathbf{H}^1$ into $\mathbf{L}^4$ and $\mathbf{L}^2$ and H^1 into L^4 and L^2, respectively. We obtain

$$\begin{aligned}|c_0(\mathbf{u},\mathbf{w},\mathbf{v})| &\leq ||\mathbf{u}||_{\mathbf{L}^4(\Omega_f)}||\nabla\mathbf{v}||_{\mathbf{L}^2(\Omega_f)}||\mathbf{w}||_{\mathbf{L}^4(\Omega_f)}\\ &\leq C_1||\mathbf{u}||_{\mathbf{H}^1(\Omega_f)}||\mathbf{v}||_{\mathbf{H}^1(\Omega_f)}||\mathbf{w}||_{\mathbf{H}^1(\Omega_f)}\end{aligned}$$

and

$$\begin{aligned}|c_1(\mathbf{u},T,S)| &\leq ||\mathbf{u}||_{\mathbf{L}^4(\Omega_f)}||\nabla T||_{L^2(\Omega)}||\nabla S||_{L^2(\Omega)}\\ &\leq C_2||\mathbf{u}||_{\mathbf{H}^1(\Omega_f)}||T||_{H^1(\Omega)}||S||_{H^1(\Omega)}.\end{aligned}$$

The second and fourth equalities follow from Green's formulas

$$c_0(\mathbf{u},\mathbf{v},\mathbf{v}) = \frac{1}{2}(\mathbf{u},\nabla(\mathbf{v}\cdot\mathbf{v})) = \frac{1}{2}(\mathbf{n}\cdot\mathbf{u},\mathbf{v}\cdot\mathbf{v})_{\partial\Omega_f} = 0$$

and

$$c_1(\mathbf{u},T,T) = \frac{1}{2}\int_{\partial\Omega_f}(\mathbf{u}\cdot\mathbf{n})T^2\,ds = 0,$$

provided that $\nabla\cdot\mathbf{u} = 0$ and $\mathbf{u}\in\mathbf{V}$. The last inequality follows from the Cauchy Schwarz inequality. □

We now show that at least one solution always exists for data $g\in L^2(\Gamma_C)$, $Q\in L^2(\Omega)$, and $\mathbf{f}\in\mathbf{L}^2(\Omega_f)$. Further, that solution is unique for either small data or an equivalent restriction on the Rayleigh and Prandtl numbers. Stationary boundary value problems (1.1)–(1.5) were studied by many authors (see [3, 5] and references therein). Here, we adapt and/or extend their results with suitable modifications.

LEMMA 2.2 (Leray–Schauder). *Let E be a Banach space, and let $G:[0,1]\times E\to E$ be a continuous, compact map, such that $G(0,v) = v_0$ is independent of $v\in E$. Suppose that there exists $M<\infty$ such that, for all $(\sigma,x)\in[0,1]\times E$,*

$$G(\sigma,x) = x \implies ||x|| < M.$$

Then the map $G_1 : E\to E$ given by $G_1(v) = G(1,v)$ has a fixed point.

Proof. For the proof, see [7, Theorem 8.1, p. 57]. □

THEOREM 2.3. *For every $g\in L^2(\Gamma_C)$, $Q\in L^2(\Omega)$, and $\mathbf{f}\in\mathbf{L}^2(\Omega_f)$, the Boussinesq equations* (2.5)–(2.7) *have a solution $(\mathbf{u},T,p)\in\mathbf{V}\times H^1(\Omega)\times L^2_0(\Omega_f)$ satisfying the estimate*

$$\begin{aligned}&||\mathbf{u}||_{\mathbf{H}^1(\Omega_f)} + ||p||_{L^2(\Omega_f)} + ||T||_{H^1(\Omega)}\\ &\qquad\leq C\left(||\mathbf{f}||_{\mathbf{L}^2(\Omega_f)} + ||Q||_{L^2(\Omega)} + ||g||_{L^2(\Gamma_C)}\right).\end{aligned} \tag{2.13}$$

Proof. From (2.2), (2.4), (2.10), and (2.11), it follows that for $\mathbf{u}\in\mathbf{V}$, $a_1(\cdot,\cdot) + c_1(\mathbf{u},\cdot,\cdot)$ is a continuous and elliptic bilinear form on $H^1_0(\Omega)\times H^1_0(\Omega)$, and thus on $H^1_D(\Omega)\times H^1_D(\Omega)$. Thus, for given $g\in L^2(\Gamma_C)$ and $Q\in L^2(\Omega)$, by the Lax–Milgram lemma and trace theorems there is a unique solution $T \in H^1_D(\Omega)$ satisfying (2.7) and the estimate

$$||T||_{H^1(\Omega)} + ||T||_{L^2(\Gamma_C)} \leq C \left(||g||_{L^2(\Gamma_C)} + ||Q||_{L^2(\Omega)}\right). \tag{2.14}$$

Thus, we may define a mapping $F : \mathbf{V} \to H^1(\Omega)$ by $F(\mathbf{u}) = T$. The theorem will be proved if one can show that there is at least one $\mathbf{u} \in \mathbf{V}$ such that

$$\nu\, a_0(\mathbf{u}, \mathbf{v}) + c_0(\mathbf{u}, \mathbf{u}, \mathbf{v}) = \alpha\, d(F(\mathbf{u}), \mathbf{v}) + \langle \mathbf{f}, \mathbf{v}\rangle \quad \forall\, \mathbf{v} \in \mathbf{V}. \tag{2.15}$$

From inequality (2.3) it follows that $a_0(\cdot, \cdot)$ is a continuous and elliptic bilinear form on $\mathbf{V} \times \mathbf{V}$ and

$$\begin{aligned} &| - c_0(\mathbf{u}, \mathbf{u}, \mathbf{v}) + d(F(\mathbf{u}), \mathbf{v}) + \langle \mathbf{f}, \mathbf{v}\rangle| \\ &\qquad\qquad \leq (C_2||\mathbf{u}||^2_{\mathbf{H}^1(\Omega_f)} + \alpha\, C_4||F(\mathbf{u})||_{H^1(\Omega)} + ||\mathbf{f}||_{\mathbf{L}^2(\Omega_f)})\; ||\mathbf{v}||_{\mathbf{H}^1(\Omega_f)} \end{aligned}$$

for all $\mathbf{v} \in \mathbf{V}$ follows from (2.10) and (2.12). Thus we may define a mapping $G : \mathbf{V} \to \mathbf{V}$ by

$$\nu\, a_0(G(\mathbf{u}), \mathbf{v}) = -c_0(\mathbf{u}, \mathbf{u}, \mathbf{v}) + \alpha\, d(F(\mathbf{u}), \mathbf{v}) + \langle \mathbf{f}, \mathbf{v}\rangle \quad \forall\, \mathbf{v} \in \mathbf{V}. \tag{2.16}$$

Clearly, $\mathbf{u}$ is a solution of (2.15) if it is a solution of

$$G(\mathbf{u}) = \mathbf{u}. \tag{2.17}$$

Now we may apply the Leray–Schauder Principle to prove the existence of the solution to (2.17). First, we verify the compactness of G. Let $\mathbf{u}_1, \mathbf{u}_2 \in \mathbf{V}$. Set $\mathbf{w} = G(\mathbf{u}_2) - G(\mathbf{u}_1)$. Subtracting the equations obtained from (2.16) by substituting $\mathbf{u}_2$ and $\mathbf{u}_1$ for $\mathbf{u}$ and $\mathbf{w}$ for $\mathbf{v}$, we get

$$\begin{aligned} \nu\, a_0(\mathbf{w}, \mathbf{w}) = &-c_0(\mathbf{u}_2 - \mathbf{u}_1; \mathbf{u}_2, \mathbf{w}) \\ &\qquad + c_0(\mathbf{u}_1; \mathbf{u}_2 - \mathbf{u}_1, \mathbf{w}) + \alpha\, d(F(\mathbf{u}_2) - F(\mathbf{u}_1), \mathbf{w}). \end{aligned} \tag{2.18}$$

Now we estimate $||F(\mathbf{u}_2) - F(\mathbf{u}_1)||_{H^1(\Omega)}$. Substitute $\mathbf{u}_2$ and $\mathbf{u}_1$ in (2.7) and subtract to get

$$\begin{aligned} a_1(F(\mathbf{u}_2) - F(\mathbf{u}_1), S) = &- c_1(\mathbf{u}_2 - \mathbf{u}_1; F(\mathbf{u}_2), S) \\ &- c_1(\mathbf{u}_1; F(\mathbf{u}_2) - F(\mathbf{u}_1), S) \quad \forall\, S \in H^1_D(\Omega). \end{aligned} \tag{2.19}$$

Substituting $F(\mathbf{u}_2) - F(\mathbf{u}_1)$ for S and using (2.4), (2.10), and (2.11), we have

$$||\nabla F(\mathbf{u}_2) - \nabla F(\mathbf{u}_1)||_{L^2(\Omega)} \leq C(||g||_{L^2(\Gamma_C)} + ||Q||_{L^2(\Omega)})\; ||\mathbf{u}_2 - \mathbf{u}_1||_{\mathbf{L}^4(\Omega_f)}. \tag{2.20}$$

Thus

$$\begin{aligned} ||\nabla \mathbf{w}||_{\mathbf{L}^2(\Omega_f)} \leq \nu^{-1}(&||\mathbf{u}_2||_{\mathbf{L}^4(\Omega_f)} + ||\mathbf{u}_1||_{\mathbf{L}^4(\Omega_f)} \\ &+\alpha\, C(||g||_{L^2(\Gamma_C)} + ||Q||_{L^2(\Omega)}))\; ||\mathbf{u}_2 - \mathbf{u}_1||_{\mathbf{L}^4(\Omega_f)} \end{aligned}$$

follows from (2.18) and (2.20) using (2.3), (2.8), and (2.11). Since $\mathbf{H}^1_0(\Omega_f)$ is compactly embedded in $\mathbf{L}^4(\Omega_f)$ and hence so is $\mathbf{V}$, it follows that G is a continuous compact map.

Now we define $G(\sigma, \mathbf{v}) = \sigma G(\mathbf{v})$ for all $(\sigma, \mathbf{v}) \in [0, 1] \times \mathbf{V}$. Clearly, $G(0, \mathbf{v}) = \mathbf{0}$ is independent of $\mathbf{v}$.

Suppose $\sigma \in (0,1]$ and $\mathbf{v} \in \mathbf{V}$ satisfies $\sigma G(\mathbf{v}) = \mathbf{v}$. Then

$$\sigma^{-1}\, \nu\, a_0(\mathbf{v},\mathbf{v}) = -c_0(\mathbf{v};\mathbf{v},\mathbf{v}) + \alpha\, d(F(\mathbf{v}),\mathbf{v}) + \langle \mathbf{f},\mathbf{v}\rangle. \tag{2.21}$$

From the above fact, we have

$$\begin{aligned} ||\nabla \mathbf{v}||_{\mathbf{L}^2(\Omega_f)} &\leq \sigma\, \left(\frac{\alpha}{\nu}\, C_4 ||\nabla F(\mathbf{v})||_{L^2(\Omega)} + ||\mathbf{f}||_{\mathbf{L}^2(\Omega_f)}\right) \\ &\leq C\left(||g||_{L^2(\Gamma_C)} + ||Q||_{L^2(\Omega)} + ||\mathbf{f}||_{\mathbf{L}^2(\Omega_f)}\right), \end{aligned}$$

which completes the proof. □

We now prove a global uniqueness of the Boussinesq equations (2.5)–(2.7) for the case of small data.

THEOREM 2.4. *Let* $\mathbf{u}$ *and* $F(\mathbf{u}) = T$ *be a solution of* (2.5)–(2.7)*, and suppose* $N||\nabla \mathbf{u}||_{\mathbf{L}^2(\Omega_f)}$ $+\alpha\, M < \nu$*, where*

$$N = \sup\left\{c_0(\mathbf{u},\mathbf{v},\mathbf{w}) : ||\nabla \mathbf{u}||_{\mathbf{L}^2(\Omega_f)} = ||\nabla \mathbf{v}||_{\mathbf{L}^2(\Omega_f)} = ||\nabla \mathbf{w}||_{\mathbf{L}^2(\Omega_f)} = 1, \mathbf{u},\mathbf{v},\mathbf{w} \in \mathbf{V}\right\}$$

and

$$M = \sup\left\{\frac{d(F(\mathbf{u}) - F(\mathbf{v}), \mathbf{u}-\mathbf{v})}{||\nabla \mathbf{u} - \nabla \mathbf{v}||^2_{\mathbf{L}^2(\Omega_f)}} : \mathbf{u} \neq \mathbf{v}, \mathbf{u},\mathbf{v} \in \mathbf{V}\right\}.$$

Then $\mathbf{u}$ *and* $F(\mathbf{u}) = T$ *is the unique solution of* (2.5)–(2.7).

Proof. Suppose $(\mathbf{w}, F(\mathbf{w}))$ is a solution of (2.5)–(2.7), where $\mathbf{w} \neq \mathbf{u}$; then

$$\nu\, a_0(\mathbf{u},\mathbf{v}) + c_0(\mathbf{u},\mathbf{u},\mathbf{v}) = \alpha\, d(F(\mathbf{u}),\mathbf{v}) + \langle \mathbf{f},\mathbf{v}\rangle \quad \forall\, \mathbf{v} \in \mathbf{V}$$

and

$$\nu\, a_0(\mathbf{w},\mathbf{v}) + c_0(\mathbf{w},\mathbf{w},\mathbf{v}) = \alpha\, d(F(\mathbf{w}),\mathbf{v}) + \langle \mathbf{f},\mathbf{v}\rangle \quad \forall\, \mathbf{v} \in \mathbf{V}.$$

Subtracting with $\mathbf{v} = \mathbf{u} - \mathbf{w}$ and using the fact that $c_0(\mathbf{w}, \mathbf{u}-\mathbf{w}, \mathbf{u}-\mathbf{w}) = 0$, we have

$$\nu\, a_0(\mathbf{u}-\mathbf{w}, \mathbf{u}-\mathbf{w}) = -c_0(\mathbf{u}-\mathbf{w}, \mathbf{u}, \mathbf{u}-\mathbf{w}) + \alpha\, d\left(F(\mathbf{u}) - F(\mathbf{w}), \mathbf{u}-\mathbf{w}\right).$$

Hence,

$$\begin{aligned} \nu ||\nabla(\mathbf{u}-\mathbf{w})||^2_{\mathbf{L}^2(\Omega)} &\leq \left(N ||\nabla \mathbf{u}||_{\mathbf{L}^2(\Omega)} + \alpha M\right) ||\nabla(\mathbf{u}-\mathbf{w})||^2_{\mathbf{L}^2(\Omega)} \\ &< \nu ||\nabla(\mathbf{u}-\mathbf{w})||^2_{\mathbf{L}^2(\Omega)}, \end{aligned}$$

which is a contradiction. Therefore, $\mathbf{w} = \mathbf{u}$. □

2.2. Regularity of solutions of the Boussinesq equations. We now examine the regularity of solutions of the Boussinesq equations (2.5)–(2.7).

THEOREM 2.5. *Suppose that the given data satisfies* $Q \in L^2(\Omega)$, $\mathbf{f} \in \mathbf{L}^2(\Omega_f)$. *Then if* $(\mathbf{u}, p, T) \in \mathbf{H}^1_0(\Omega_f) \times L^2_0(\Omega_f) \times H^1_D(\Omega)$ *denotes a solution of the problem* (2.5)–(2.7)*, we have that* $(\mathbf{u}, p, T) \in \mathbf{H}^1_0(\Omega_f) \cap \mathbf{H}^2(\Omega_f) \times L^2_0(\Omega_f) \cap H^1(\Omega_f) \times H^1_D(\Omega) \cap H^s(\Omega)$ *for all* $s < \frac{3}{2}$*. Moreover, there exists a continuous function* P_s *for each* s *such that*

$$\begin{aligned} ||\mathbf{u}||_{\mathbf{H}^2(\Omega_f)} + ||p||_{H^1(\Omega_f)} + ||T||_{H^s(\Omega)} & \\ \leq P_s\left(||\mathbf{f}||_{\mathbf{L}^2(\Omega_f)} + ||Q||_{L^2(\Omega)} + ||g||_{L^2(\Gamma_C)}\right). & \end{aligned} \tag{2.22}$$

Proof. First we prove for the temperature T the regularity result and estimate. Since in Theorem 2.3 we already obtained an a priori estimate for $(\mathbf{u}, T)$ in $\mathbf{H}_0^1(\Omega_f) \times H^1(\Omega)$, by a localization argument it suffices to prove an estimate for temperature only in a vicinity of Σ. By our assumption, in the neighborhood of junction points T equals zero on the boundary. Thus locally one can consider our transmission problem as one with zero Dirichlet boundary conditions. Thus by Theorem 5 in [24], we have

$$(2.23) \qquad ||T||_{H^s(\Omega)} \le C(s) \left(||Q||_{L^2(\Omega)} + ||g||_{L^2(\Gamma_C)} + ||\mathbf{f}||_{\mathbf{L}^2(\Omega_f)} + 1\right)^2$$

for all $s \in (0, 3/2)$.

We also note that by assumption the boundary $\partial\Omega_f$ consists of two smooth arcs which intersect two times with anglers $\theta_i \in (0, \pi)$. Then since $T_f \in H^1(\Omega_f)$ and $\mathbf{f} \in \mathbf{L}^2(\Omega_f)$, the regularity of $\mathbf{u}$ and p follows from well-known theories concerning the Navier–Stokes equations in polygons (see Theorem 7.3.3.4 in [11]). By (2.23) and a priori estimates for the Stokes system in a polygon (see [11]) there exists a continuous function P_s for each s such that

$$(2.24) \qquad ||\mathbf{u}||_{\mathbf{H}^2(\Omega_f)} \le P_s \left(||\mathbf{f}||_{\mathbf{L}^2(\Omega_f)} + ||Q||_{L^2(\Omega)} + ||g||_{L^2(\Gamma_C)}\right).$$

Thus, the proof is completed. □

REMARK 2.1. *The regularity of temperature T achieved in the previous theorem is optimal in the sense of scale of Sobolev spaces $H^s(\Omega)$. In fact, even if $\kappa_s = \kappa_f$, in general $T \notin H^{\frac{3}{2}}(\Omega)$ (see [23]).*

3. The optimization problem and the existence of optimal solutions.

3.1. The optimization problems. We state the optimal control problem. We look for a $(\mathbf{u}, T, p, g) \in \mathbf{H}_0^1(\Omega_f) \times H_D^1(\Omega) \times L_0^2(\Omega_f) \times \mathcal{V}$ such that the cost functional

$$(3.1) \qquad \textit{(Problem 1)} \quad \mathcal{J}_1(\mathbf{u}, T, p, g) = \frac{1}{2} \int_\Omega |T - T_d|^2 \, d\mathbf{x} + \frac{\delta}{2} \int_{\Gamma_C} |g|^2 \, ds$$

or

$$(3.2) \qquad \textit{(Problem 2)} \quad \mathcal{J}_2(\mathbf{u}, T, p, g) = \frac{1}{2} \int_\Omega |\nabla \times \mathbf{u}|^2 \, d\mathbf{x} + \frac{\delta}{2} \int_{\Gamma_C} |g|^2 \, ds,$$

subject to the constraints

$$(3.3) \qquad \nu \, a_0(\mathbf{u}, \mathbf{v}) + c_0(\mathbf{u}, \mathbf{u}, \mathbf{v}) + b(\mathbf{v}, p) = \alpha \, d(T, \mathbf{v}) + \langle \mathbf{f}, \mathbf{v} \rangle \ \ \forall\, \mathbf{v} \in \mathbf{H}_0^1(\Omega_f),$$

$$(3.4) \qquad b(\mathbf{u}, q) = 0 \quad \forall\, q \in L_0^2(\Omega_f),$$

and

$$(3.5) \qquad a_1(T, S) + c_1(\mathbf{u}, T, S) = \langle Q, S \rangle - (\kappa g, S)_{\Gamma_C} \quad \forall\, S \in H_D^1(\Omega),$$

where $\mathcal{V}$ is a nonempty, closed, and convex subset of $L^2(\Gamma_C)$.

The *admissibility set* $\mathcal{U}_{ad}$ is defined by

$$(3.6) \qquad \begin{aligned} \mathcal{U}_{ad} = \big\{(\mathbf{u}, T, p, g) \in \mathbf{H}_0^1(\Omega_f) \times H^1(\Omega) \times L_0^2(\Omega_f) \times \mathcal{V} :& \\ \mathcal{J}(\mathbf{u}, T, p, g) < \infty, \quad \text{and (3.3)–(3.5) are satisfied}&\big\}, \end{aligned}$$

where $\mathcal{J}(\mathbf{u},T,p,g)$ is $\mathcal{J}_1(\mathbf{u},T,p,g)$ or $\mathcal{J}_2(\mathbf{u},T,p,g)$ depending on minimization problems. Then $(\mathbf{u},T,p,g)\in\mathcal{U}_{ad}$ is called an optimal solution if there exists $\varepsilon>0$ such that

$$\mathcal{J}(\mathbf{u},T,p,g)\le\mathcal{J}(\mathbf{v},S,q,h)\quad\forall\,(\mathbf{v},S,q,h)\in\mathcal{U}_{ad},\tag{3.7}$$

satisfying

$$\|\mathbf{u}-\mathbf{v}\|_{\mathbf{H}^1(\Omega_f)}+\|T-S\|_{H^1(\Omega)}+\|p-q\|_{L^2(\Omega_f)}+\|g-h\|_{L^2(\Gamma_C)}<\varepsilon\,.\tag{3.8}$$

If for an optimal solution $(\mathbf{u},T,p,g)\in\mathcal{U}_{ad}$ the inequalities (3.7) and (3.8) hold true with $\varepsilon=+\infty$, we say that $(\mathbf{u},T,p,g)$ is the *global minimum.* The optimal control problem can now be formulated as a constrained minimization in a Hilbert space:

$$\min_{(\mathbf{v},S,q,h)\in\mathcal{U}_{ad}}\mathcal{J}(\mathbf{v},S,q,h).\tag{3.9}$$

Problems 1 and 2 can be analyzed in exactly the same manner. In this section, we treat the first problem in detail.

3.2. The existence of an optimal solution. The existence of an optimal solution can be proved based on the a priori estimates (2.13) and standard techniques.

THEOREM 3.1. *Let* $Q\in L^2(\Omega)$ *and* $\mathbf{f}\in\mathbf{L}^2(\Omega_f)$. *Then there is an optimal solution* $(\hat{\mathbf{u}},\hat{T},\hat{p},\,\hat{g})\in\mathcal{U}_{ad}$ *to* (3.9).

Proof. The set $\mathcal{U}_{ad}$ is apparently nonempty because of Lemma 2.2. Thus we may choose a minimizing sequence $\{\mathbf{u}^{(n)},T^{(n)},p^{(n)},g^{(n)}\}$ in $\mathcal{U}_{ad}$ such that

$$\lim_{n\to\infty}\mathcal{J}_1(\mathbf{u}^{(n)},T^{(n)},p^{(n)},g^{(n)})=\inf_{(\mathbf{v},S,q,z)\in\mathcal{U}_{ad}}\mathcal{J}_1(\mathbf{v},S,q,z).\tag{3.10}$$

By the definition of $\mathcal{U}_{ad}$, we have

$$\begin{aligned}\nu\,a_0(\mathbf{u}^{(n)},\mathbf{v})+c_0(\mathbf{u}^{(n)},\mathbf{u}^{(n)},\mathbf{v})+b(\mathbf{v},p^{(n)})&\\ =\alpha\,d(T^{(n)},\mathbf{v})+\langle\mathbf{f},\mathbf{v}\rangle&\quad\forall\,\mathbf{v}\in\mathbf{H}_0^1(\Omega_f),\end{aligned}\tag{3.11}$$

$$b(\mathbf{u}^{(n)},q)=0\quad\forall\,q\in L_0^2(\Omega_f),\tag{3.12}$$

and

$$a_1(T^{(n)},S)+c_1(\mathbf{u}^{(n)},T^{(n)},S)=\langle Q,S\rangle+\kappa_f(g^{(n)},S)\quad\forall\,S\in H_D^1(\Omega).\tag{3.13}$$

From (1.6) and (3.6), we easily see that $\{||g^{(n)}||_{L^2(\Gamma_C)}\}$ is uniformly bounded. Also, by (2.13) we have that the sequences $\{||\mathbf{u}^{(n)}||_{\mathbf{H}^1(\Omega_f)}\}$, $\{||T^{(n)}||_{H^1(\Omega)}\}$ and $\{||p^{(n)}||_{L^2(\Omega_f)}\}$ are uniformly bounded. We may then extract subsequences such that

$$\begin{aligned}g^{(n)}\rightharpoonup\hat{g}&\quad\text{in }L^2(\Gamma_C),\\ \mathbf{u}^{(n)}\rightharpoonup\hat{\mathbf{u}}\quad\text{in }\mathbf{H}_0^1(\Omega_f)&\quad\text{and}\quad\nabla\mathbf{u}^{(n)}\rightharpoonup\nabla\hat{\mathbf{u}}\quad\text{in }\mathbf{L}^2(\Omega_f),\\ T^{(n)}\rightharpoonup\hat{T}\quad\text{in }H_D^1(\Omega)&\quad\text{and}\quad\nabla T^{(n)}\rightharpoonup\nabla\hat{T}\quad\text{in }\mathbf{L}^2(\Omega),\\ p^{(n)}\rightharpoonup\hat{p}&\quad\text{in }L^2(\Omega_f),\\ \mathbf{u}^{(n)}\to\hat{\mathbf{u}}&\quad\text{in }\mathbf{L}^4(\Omega_f)\ \text{ and }\ \mathbf{L}^2(\Omega_f)\end{aligned}$$

for some $(\hat{\mathbf{u}},\hat{T},\hat{p},\hat{g})\in\mathbf{H}_0^1(\Omega_f)\times H_D^1(\Omega)\times L_0^2(\Omega_f)\times L^2(\Gamma_C)$. The last convergence result above follows from the compact embedding $\mathbf{H}^1(\Omega_f)\hookrightarrow\hookrightarrow\mathbf{L}^4(\Omega_f)$ and $\mathbf{H}^1(\Omega_f)\hookrightarrow\hookrightarrow$

$\mathbf{L}^2(\Omega_f)$. We may pass to the limit in (3.11)–(3.13) to determine that $(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g})$ satisfies (3.3)–(3.5). Indeed, the only troublesome term when one passes to the limit is the nonlinearity $c_0(\cdot, \cdot, \cdot)$. However, note that

$$c_0(\mathbf{u}^{(n)}, \mathbf{u}^{(n)}, \mathbf{v}) \\ = \int_{\partial\Omega_f} (\mathbf{u}^{(n)} \cdot \mathbf{n})\mathbf{u}^{(n)} \cdot \mathbf{v}\, ds - \int_{\Omega_f} (\mathbf{u}^{(n)} \cdot \nabla)\mathbf{v} \cdot \mathbf{u}^{(n)}\, d\mathbf{x} \quad \forall\, \mathbf{v} \in \mathcal{D}(\bar{\Omega}_f),$$

where $\mathcal{D}(\bar{\Omega}_f)$ is the space of test functions. Then, since $\mathbf{u}^{(n)} \to \hat{\mathbf{u}}$ in $\mathbf{L}^2(\Omega_f)$ and $\int_{\partial\Omega_f} (\mathbf{u}^{(n)} \cdot \mathbf{n})\mathbf{u}^{(n)} \cdot \mathbf{v}\, ds = 0$ for all n, we have that

$$\lim_{k\to\infty} c_0(\mathbf{u}^{(k)}, \mathbf{u}^{(k)}, \mathbf{v}) = -\int_{\Omega_f} (\hat{\mathbf{u}} \cdot \nabla)\, \mathbf{v} \cdot \hat{\mathbf{u}}\, d\mathbf{x} \qquad \forall\, \mathbf{v} \in \mathcal{D}(\bar{\Omega}_f).$$

Since $\mathcal{D}(\bar{\Omega}_f)$ is dense in $\mathbf{H}^1_0(\Omega_f)$, we have that for each $\hat{\mathbf{u}} \in \mathbf{H}^1_0(\Omega_f)$,

$$\lim_{k\to\infty} c_0(\mathbf{u}^{(k)}, \mathbf{u}^{(k)}, \mathbf{v}) = c_0(\hat{\mathbf{u}}, \hat{\mathbf{u}}, \mathbf{v}) \quad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega_f).$$

Thus we have shown that $(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g})$ indeed satisfies (3.3)–(3.5) so that $(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g}) \in \mathcal{U}_{ad}$.

Finally, it is easy to see that $\mathcal{J}_1(\cdot, \cdot, \cdot, \cdot)$ is weakly lower-semicontinuous so that

$$\mathcal{J}_1(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g}) = \inf_{(\mathbf{v}, S, q, z) \in \mathcal{U}_{ad}} \mathcal{J}_1(\mathbf{v}, S, q, z). \tag{3.14}$$

Thus an optimal solution belonging to $\mathcal{U}_{ad}$ exists. □

4. The existence of Lagrange multipliers and an optimality system. This section is devoted to obtaining an optimality system to (3.9). We wish to use the method of Lagrange multipliers to turn the constrained optimization problem (3.9) into an unconstrained one. We establish also that there exists an open and dense set of initial data such that the Lagrange multiplier with respect to functional (1.6) is not equal to zero. We first show that suitable Lagrange multipliers exist.

THEOREM 4.1. *Let $Q \in L^2(\Omega)$ and $\mathbf{f} \in \mathbf{L}^2(\Omega)$. Assume $(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g}) \in \mathcal{U}_{ad}$ is an optimal solution to minimization problem* (3.9). *Then there exist Lagrange multipliers $(\lambda, \mathbf{w}, R, q) \in \mathbb{R}^1 \times \mathbf{V} \cap \mathbf{H}^2(\Omega_f) \times H^s(\Omega) \times H^1(\Omega_f)$ for all $s < \frac{3}{2}$ such that*

$$(\lambda, \mathbf{w}, R, q) \neq 0\,, \tag{4.1}$$

$$-\nabla \cdot (\kappa \nabla R) - \chi_{\Omega_f}(\hat{\mathbf{u}} \cdot \nabla)R - \alpha\, \chi_{\Omega_f}(\mathbf{w}, \mathbf{e}_2) + \lambda(\hat{T} - T_d) = 0 \ \textit{in}\ \Omega, \tag{4.2}$$

$$\frac{\partial R}{\partial \mathbf{n}}|_{\Gamma_C} = 0, \quad (\lambda\delta\hat{g} - \kappa R, g - \hat{g})_{L^2(\Gamma_C)} \geq 0 \quad \forall\, g \in \mathcal{V}, \quad R|_{\Gamma_D} = 0, \tag{4.3}$$

$$-\nu\Delta\mathbf{w} - (\hat{\mathbf{u}} \cdot \nabla)\mathbf{w} + B(\hat{\mathbf{u}}, \mathbf{w}) + R\nabla\hat{T} = \nabla q \ \ \textit{in}\ \Omega_f, \tag{4.4}$$

and

$$\nabla \cdot \mathbf{w} = 0, \ \ \mathbf{w}|_{\partial\Omega_f} = 0, \tag{4.5}$$

where $B(\hat{\mathbf{u}}, \mathbf{w}) = \big((\mathbf{w}, \frac{\partial\hat{\mathbf{u}}}{\partial x_1}), (\mathbf{w}, \frac{\partial\hat{\mathbf{u}}}{\partial x_2})\big)$. Moreover, if $\lambda = 0$ and $\mathcal{V} = L^2(\Gamma_C)$, then $R \neq 0$.

Proof. To prove the existence of Lagrange multipliers for the constrained minimization problem (3.9), we use the penalty method. Let us consider the auxiliary extremal problem : find $(\mathbf{u}, T, p, g) \in \mathbf{V} \times H^1(\Omega) \times L_0^2(\Omega_f) \times L^2(\Gamma_C)$ which minimizes the functional

$$\begin{aligned} J_\varepsilon(\mathbf{u}, T, p, g) &= \mathcal{J}_1(\mathbf{u}, T, p, g) \\ &+ \frac{1}{2\varepsilon}\| - \nu\Delta\mathbf{u} + (\mathbf{u}\cdot\nabla)\mathbf{u} - \alpha T\mathbf{e}_2 + \nabla p - \mathbf{f}\|^2_{\mathbf{L}^2(\Omega_f)} \\ &+ \frac{1}{2\varepsilon}\| - \nabla\cdot(\kappa\nabla T) + \chi_{\Omega_f}(\mathbf{u}\cdot\nabla)T - Q\|^2_{L^2(\Omega)} \\ &+ \frac{N}{2}\|\mathbf{u} - \hat{\mathbf{u}}\|^2_{\mathbf{L}^2(\Omega_f)} + \frac{N}{2}\|T - \hat{T}\|^2_{L^2(\Omega)} + \frac{N}{2}\|g - \hat{g}\|^2_{L^2(\Gamma_C)} \end{aligned} \tag{4.6}$$

with

$$T|_{\Gamma_D} = 0,\ \frac{\partial T}{\partial \mathbf{n}}|_{\Gamma_C} = g,\ g \in \mathcal{V},\ \mathbf{u}|_{\partial\Omega_f} = 0,\ \nabla\cdot\mathbf{u} = 0, \tag{4.7}$$

where $(\hat{\mathbf{u}}, \hat{p}, \hat{T}, \hat{g}) \in \mathbf{V} \cap \mathbf{H}^2(\Omega_f) \times H^1(\Omega_f) \cap L_0^2(\Omega_f) \times H_D^1(\Omega) \cap H^s(\Omega) \times L^2(\Gamma_C)$ for all $s < \frac{3}{2}$ is a solution to extremal problem (3.9), such that inequality (3.8) holds true with $\varepsilon = \hat{\varepsilon}$ and $N > 0, \varepsilon \in (0, 1)$ as parameters. The existence of this solution $(\hat{\mathbf{u}}, \hat{p}, \hat{T}, \hat{g})$ was established in Theorem 3.1. By a method similar to the one used in the proof of Theorem 3.1, one can prove that there exists a solution of the problem (4.6)–(4.7) $(\hat{\mathbf{u}}_\varepsilon, \hat{T}_\varepsilon, \hat{p}_\varepsilon, \hat{g}_\varepsilon) \in \mathbf{V} \cap \mathbf{H}^2(\Omega_f) \times H_D^1(\Omega) \cap H^s(\Omega) \times H^1(\Omega_f) \cap L_0^2(\Omega_f) \times L^2(\Gamma_C)$ for all $s \in [1, \frac{3}{2})$. Moreover, from the fact that $J_\varepsilon(\hat{\mathbf{u}}_\varepsilon, \hat{T}_\varepsilon, \hat{p}_\varepsilon, \hat{g}_\varepsilon) \leq J_\varepsilon(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g}) = \mathcal{J}_1(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g})$ and the inequality (2.22), we have that

$$\begin{aligned} &\left\{(\hat{\mathbf{u}}_\varepsilon, \hat{T}_\varepsilon, \hat{p}_\varepsilon, \hat{g}_\varepsilon)\right\}_{\varepsilon\in(0,1)} \quad \text{is bounded in} \\ &\qquad\qquad \mathbf{V} \cap \mathbf{H}^2(\Omega_f) \times H_D^1(\Omega) \cap H^s(\Omega) \times L_0^2(\Omega_f) \times L^2(\Gamma_C) \end{aligned} \tag{4.8}$$

for all $s \in [1, \frac{3}{2})$. Thus, from (4.6)–(4.8) for any $\hat{\varepsilon} > 0$, taking parameter N sufficiently large, we obtain

$$\|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|_{\mathbf{L}^2(\Omega_f)} + \|\hat{T}_\varepsilon - \hat{T}\|_{L^2(\Omega)} + \|\hat{g}_\varepsilon - \hat{g}\|_{L^2(\Gamma_C)} \leq \hat{\varepsilon}/2\,. \tag{4.9}$$

Denoting

$$\begin{aligned} \hat{f}_\varepsilon &= -\nu\Delta\hat{\mathbf{u}}_\varepsilon + (\hat{\mathbf{u}}_\varepsilon\cdot\nabla)\hat{\mathbf{u}}_\varepsilon - \alpha\hat{T}_\varepsilon\mathbf{e}_2 + \nabla\hat{p}_\varepsilon - \mathbf{f}, \\ \hat{Q}_\varepsilon &= -\nabla\cdot(\kappa\nabla\hat{T}_\varepsilon) + \chi_{\Omega_f}(\hat{\mathbf{u}}_\varepsilon\cdot\nabla)\hat{T}_\varepsilon - Q, \end{aligned}$$

we obviously have

$$(\hat{f}_\varepsilon, \hat{Q}_\varepsilon) \to (0, 0) \quad \text{in} \quad \mathbf{L}^2(\Omega_f) \times L^2(\Omega). \tag{4.10}$$

By fact (4.8) and the Sobolev imbedding theorem and interpolation theorem, we have

$$\begin{aligned} \|(\hat{\mathbf{u}}_\varepsilon\cdot\nabla)\hat{\mathbf{u}}_\varepsilon &- (\hat{\mathbf{u}}\cdot\nabla)\hat{\mathbf{u}}\|_{\mathbf{L}^2(\Omega_f)} \\ &\leq \|((\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}})\cdot\nabla)\hat{\mathbf{u}}_\varepsilon + (\hat{\mathbf{u}}\cdot\nabla)(\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}})\|_{\mathbf{L}^2(\Omega_f)} \\ &\leq C\|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|_{\mathbf{H}^{\frac{3}{4}}(\Omega_f)}(\|\hat{\mathbf{u}}_\varepsilon\|_{\mathbf{H}^2(\Omega_f)} + \|\hat{\mathbf{u}}\|_{\mathbf{H}^2(\Omega_f)}) \\ &\leq C\|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|^{\frac{1}{4}}_{\mathbf{V}}\|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|^{\frac{3}{4}}_{\mathbf{H}^2(\Omega_f)}(\|\hat{\mathbf{u}}_\varepsilon\|_{\mathbf{H}^2(\Omega_f)} + \|\hat{\mathbf{u}}\|_{\mathbf{H}^2(\Omega_f)}) \\ &\leq C\|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|^{\frac{1}{4}}_{\mathbf{V}}, \end{aligned} \tag{4.11}$$

where C is independent of $\epsilon \in (0,1)$. Note that

$$\begin{aligned}(4.12)\qquad & -\nu\Delta(\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}) + (\hat{\mathbf{u}}_\varepsilon \cdot \nabla)\hat{\mathbf{u}}_\varepsilon - (\hat{\mathbf{u}} \cdot \nabla)\hat{\mathbf{u}} \\ & \qquad - \alpha(\hat{T}_\varepsilon - \hat{T})\mathbf{e}_2 + \nabla(\hat{p}_\varepsilon - \hat{p}) = \hat{f}_\varepsilon \quad \text{in} \quad \Omega_f\end{aligned}$$

and

$$(4.13)\qquad (\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}})|_{\partial\Omega_f} = 0, \quad \nabla \cdot (\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}) = 0.$$

By (4.11) and a priori estimates for the Stokes problem (see [25]), we have

$$\begin{aligned}(4.14)\qquad & \|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|_{\mathbf{H}^2(\Omega_f)} + \|\hat{p}_\varepsilon - \hat{p}\|_{H^1(\Omega_f)} \\ & \qquad \le C(\|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|_{\mathbf{V}}^{\frac{1}{4}} + \|\hat{T}_\varepsilon - \hat{T}\|_{L^2(\Omega)} + \|\hat{f}_\varepsilon\|_{\mathbf{L}^2(\Omega)}).\end{aligned}$$

The inequalities (4.9), (4.10), and (4.14) imply that for any $\hat{\varepsilon} > 0$ there exists a $N(\hat{\varepsilon}) > 0$ such that

$$\begin{aligned}(4.15)\qquad & \|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|_{\mathbf{H}^1(\Omega_f)} + \|\hat{T}_\varepsilon - \hat{T}\|_{H^1(\Omega)} + \|\hat{p}_\varepsilon - \hat{p}\|_{L^2(\Omega_f)} + \|\hat{g}_\varepsilon - \hat{g}\|_{L^2(\Gamma_C)} \le \hat{\varepsilon}, \\ & \qquad \forall \varepsilon \in (0,1).\end{aligned}$$

Therefore, without loss of generality, taking if necessary a subsequence, one can prove that

$$(\hat{\mathbf{u}}_\varepsilon, \hat{T}_\varepsilon, \hat{p}_\varepsilon, \hat{g}_\varepsilon) \rightharpoonup (\tilde{\mathbf{u}}, \tilde{T}, \tilde{p}, \tilde{g}) \quad \text{in } \mathbf{V} \cap \mathbf{H}^2(\Omega_f) \times H^1_D(\Omega) \times H^1(\Omega_f) \cap L^2_0(\Omega_f) \times L^2(\Gamma_C).$$

In the same way, as was done in the proof of Theorem 3.1, one can show that $(\tilde{\mathbf{u}}, \tilde{T}, \tilde{p}, \tilde{g}) \in \mathcal{U}_{ad}$. Moreover, inequality (4.15) and weak lower-semicontinuity of norms in Hilbert spaces imply

$$(4.16)\quad \|\tilde{\mathbf{u}} - \hat{\mathbf{u}}\|_{\mathbf{H}^1(\Omega_f)} + \|\tilde{T} - \hat{T}\|_{H^1(\Omega)} + \|\tilde{p} - \hat{p}\|_{L^2(\Omega_f)} + \|\tilde{g} - \hat{g}\|_{L^2(\Gamma_C)} \le \hat{\varepsilon}.$$

On the other hand, the inequality

$$\mathcal{J}_\varepsilon(\hat{\mathbf{u}}_\varepsilon, \hat{T}_\varepsilon, \hat{p}_\varepsilon, \hat{g}_\varepsilon) \le \mathcal{J}_1(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g})$$

yields

$$(4.17)\qquad \mathcal{J}_1(\hat{\mathbf{u}}_\varepsilon, \hat{T}_\varepsilon, \hat{p}_\varepsilon, \hat{g}_\varepsilon) \le \mathcal{J}_1(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g}).$$

Since the functional $\mathcal{J}_1$ is weak lower-semicontinuous, we have

$$(4.18)\qquad \mathcal{J}_1(\tilde{\mathbf{u}}, \tilde{T}, \tilde{p}, \tilde{g}) \le \mathcal{J}_1(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g}).$$

By (4.16) and (4.18), we have that $(\tilde{\mathbf{u}}, \tilde{T}, \tilde{p}, \tilde{g})$ is a solution of the optimal control problem (3.9).

Now if we assume that $(\tilde{\mathbf{u}}, \tilde{T}, \tilde{p}, \tilde{g}) \neq (\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g})$, then

$$\mathcal{J}_1(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g}) - \mathcal{J}_1(\tilde{\mathbf{u}}, \tilde{T}, \tilde{p}, \tilde{g}) \ge \frac{1}{2}\|\tilde{\mathbf{u}} - \hat{\mathbf{u}}\|^2_{\mathbf{L}^2(\Omega_f)} + \frac{1}{2}\|\tilde{T} - \hat{T}\|^2_{L^2(\Omega)} > 0,$$

which contradicts the fact that $(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g})$ is the solution to problem (3.9). Thus, $(\tilde{\mathbf{u}}, \tilde{T}, \tilde{p}, \tilde{g}) = (\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g})$ and we have

$$(4.19)\quad (\hat{\mathbf{u}}_\varepsilon, \hat{T}_\varepsilon, \hat{p}_\varepsilon, \hat{g}_\varepsilon) \rightharpoonup (\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g}) \text{ in } \mathbf{H^2}(\Omega_f) \times H^1_D(\Omega) \times L^2(\Omega_f) \times L^2(\Gamma_C).$$

Moreover, by (4.18) and (4.19) we have

$$\lim_{\varepsilon\to 0}\mathcal{J}_1(\hat{\mathbf{u}}_\varepsilon,\hat{T}_\varepsilon,\hat{p}_\varepsilon,\hat{g}_\varepsilon)=\mathcal{J}_1(\hat{\mathbf{u}},\hat{T},\hat{p},\hat{g}). \tag{4.20}$$

Hence by (4.19) and (4.20) we have

$$\hat{g}_\varepsilon\to\hat{g}\ \text{ in } L^2(\Gamma_C). \tag{4.21}$$

On the other hand, the facts (4.10), (4.14), (4.19), and (4.21) imply

$$(\hat{\mathbf{u}}_\varepsilon,\hat{T}_\varepsilon,\hat{p}_\varepsilon,\hat{g}_\varepsilon)\to(\hat{\mathbf{u}},\hat{T},\hat{p},\hat{g})\text{ in }\mathbf{H^2}(\Omega_f)\times H^1_D(\Omega)\times L^2(\Omega_f)\times L^2(\Gamma_C) \tag{4.22}$$

and

$$(\hat{\mathbf{u}}_\varepsilon,\hat{p}_\varepsilon,\hat{T}_\varepsilon)\to(\hat{\mathbf{u}},\hat{p},\hat{T})\text{ in }\mathbf{V}\times H^1(\Omega_f)\times H^s(\Omega)\quad\forall s\in\left(1,\frac{3}{2}\right). \tag{4.23}$$

Let $\mathbf{v}\in\mathbf{H}^2(\Omega)\cap\mathbf{V}$, $p\in C^2(\overline{\Omega})$, and $S_1\in H^2(\Omega)$ be arbitrary functions such that $S_1=0$ on Γ_D and $\frac{\partial S_1}{\partial\mathbf{n}}=0$ on Γ_C, and let $S_2\in H^s(\Omega)$ $(s<3/2)$ be the solution of the boundary value problem

$$\begin{gathered}-\nabla\cdot(\kappa\nabla S_2)=0\quad\text{on }\Omega,\\ S_2=0\quad\text{on }\Gamma_D,\quad\frac{\partial S_2}{\partial\mathbf{n}}=g\quad\text{on }\Gamma_C,\end{gathered}$$

where g is an arbitrary element in $\mathcal{V}$.

Now we introduce a function P defined by

$$P(\lambda_1,\lambda_2,\lambda_3)=\mathcal{J}_\epsilon(\hat{\mathbf{u}}_\epsilon+\lambda_1\mathbf{v},\hat{T}_\epsilon+\lambda_2S_1+\lambda_3(S_2-\hat{T}_\epsilon),\hat{p}_\epsilon,\hat{g}_\epsilon+\lambda_3(g-\hat{g}_\epsilon)).$$

Clearly, the function $P\in C^2(\mathbb{R}^3)$ and attains its minimum at $(0,0,0)$ on the set $\{(\lambda_1,\lambda_2,\lambda_3)\in\mathbb{R}^3\mid\lambda_3\in[0,1]\}$. Thus, we have

$$\frac{\partial P}{\partial\lambda_1}(0,0,0)=0,\quad\frac{\partial P}{\partial\lambda_2}(0,0,0)=0,\quad\frac{\partial P}{\partial\lambda_3}(0,0,0)\ge 0. \tag{4.24}$$

From the equations and inequality in (4.24), we obtain the optimality system

$$R_\varepsilon=\frac{1}{\varepsilon}(-\nabla\cdot(\kappa\nabla\hat{T}_\varepsilon)+\chi_{\Omega_f}(\hat{\mathbf{u}}_\varepsilon\cdot\nabla)\hat{T}_\varepsilon-Q), \tag{4.25}$$

$$\mathbf{w}_\varepsilon=\frac{1}{\varepsilon}(-\nu\Delta\hat{\mathbf{u}}_\varepsilon+(\hat{\mathbf{u}}_\varepsilon\cdot\nabla)\hat{\mathbf{u}}_\varepsilon+\nabla\hat{p}_\varepsilon-\alpha\hat{T}_\varepsilon\mathbf{e}_2-\mathbf{f}), \tag{4.26}$$

$$\begin{aligned}-\nabla\cdot(\kappa\nabla R_\varepsilon)-\chi_{\Omega_f}(\hat{\mathbf{u}}_\varepsilon\ \cdot\ \nabla)R_\varepsilon-\alpha\,\chi_{\Omega_f}(\mathbf{w}_\varepsilon,\mathbf{e}_2)&\\ +(\hat{T}_\varepsilon-T_d)+N(\hat{T}_\varepsilon-\hat{T})=0\quad\text{in }\Omega,&\end{aligned} \tag{4.27}$$

$$\begin{gathered}\frac{\partial R_\varepsilon}{\partial\mathbf{n}}|_{\Gamma_C}=0,\quad R_\varepsilon|_{\Gamma_D}=0,\\ (\delta\hat{g}_\varepsilon+N(\hat{g}_\varepsilon-\hat{g})-\kappa R_\varepsilon,\quad g-\hat{g}_\varepsilon)_{L^2(\Gamma_C)}\ge 0\quad\forall\,g\in\mathcal{V},\end{gathered} \tag{4.28}$$

$$-\nu\,\Delta\mathbf{w}_\varepsilon-(\hat{\mathbf{u}}_\varepsilon\cdot\nabla)\mathbf{w}_\varepsilon+B(\hat{\mathbf{u}}_\varepsilon,\mathbf{w}_\varepsilon)+R_\varepsilon\nabla\hat{T}_\varepsilon+N(\hat{\mathbf{u}}_\varepsilon-\hat{\mathbf{u}})=\nabla q_\varepsilon\text{ in }\Omega_f, \tag{4.29}$$

and

$$\nabla\cdot\mathbf{w}_\varepsilon=0,\ \ \mathbf{w}_\varepsilon|_{\partial\Omega_f}=0, \tag{4.30}$$

where the first equality in (4.28) has a sense due to the estimate

$$\left\|\frac{\partial R_\varepsilon}{\partial\mathbf{n}}\right\|_{H^s(\partial\Omega)}\le C(s)\big(\|\nabla\cdot(\kappa\nabla R_\varepsilon)\|_{L^2(\Omega)}+\|R_\varepsilon\|_{H^1(\Omega)}\big)$$

whenever $R_\varepsilon\in H^1_D(\Omega),\ s<0$.

Setting $I_\varepsilon=(\|R_\varepsilon\|^2_{L^2(\Omega)}+\|\mathbf{w}_\varepsilon\|^2_{\mathbf{L}^2(\Omega_f)})^{\frac{1}{2}}$, we consider two cases.

(A) Let $\liminf_{\varepsilon\to+0}I_\varepsilon=+\infty$. Denote $\tilde R_\varepsilon=R_\varepsilon/I_\varepsilon,\tilde{\mathbf{w}}_\varepsilon=\mathbf{w}_\varepsilon/I_\varepsilon,\tilde q=q_\varepsilon/I_\varepsilon$. From (4.25)–(4.30) the triple $(\tilde{\mathbf{w}}_\varepsilon,\tilde R_\varepsilon,\tilde q_\varepsilon)$ satisfies the equations

$$\begin{aligned}-\nabla\cdot(\kappa\nabla\tilde R_\varepsilon)-\chi_{\Omega_f}(\hat{\mathbf{u}}_\varepsilon\cdot\nabla)\tilde R_\varepsilon-\alpha\,\chi_{\Omega_f}(\tilde{\mathbf{w}}_\varepsilon,\mathbf{e}_2)&\\ +\frac{\hat T_\varepsilon-T_d}{I_\varepsilon}+N\frac{\hat T_\varepsilon-\hat T}{I_\varepsilon}&=0\quad\text{in}\quad\Omega,\end{aligned}\tag{4.31}$$

$$\begin{gathered}\frac{\partial\tilde R_\varepsilon}{\partial\mathbf{n}}|_{\Gamma_C}=0,\quad \tilde R_\varepsilon|_{\Gamma_D}=0,\\ \left(\frac{\delta\hat g_\varepsilon+N(\hat g_\varepsilon-\hat g)}{I_\varepsilon}-\kappa\tilde R_\varepsilon,\quad g-\hat g_\varepsilon\right)_{L^2(\Gamma_C)}\ge 0\quad\forall g\in\mathcal{V},\end{gathered}\tag{4.32}$$

$$-\nu\,\Delta\tilde{\mathbf{w}}_\varepsilon-(\hat{\mathbf{u}}_\varepsilon\cdot\nabla)\tilde{\mathbf{w}}_\varepsilon+B(\hat{\mathbf{u}}_\varepsilon,\tilde{\mathbf{w}}_\varepsilon)+\tilde R_\varepsilon\nabla\hat T_\varepsilon+N\frac{\hat{\mathbf{u}}_\varepsilon-\hat{\mathbf{u}}}{I_\varepsilon}=\nabla\tilde q_\varepsilon\ \text{ in }\Omega_f, \tag{4.33}$$

and

$$\nabla\cdot\tilde{\mathbf{w}}_\varepsilon=0,\ \ \tilde{\mathbf{w}}_\varepsilon|_{\partial\Omega_f}=0. \tag{4.34}$$

By the definitions of $\tilde{\mathbf{w}}_\varepsilon$ and $\tilde R_\varepsilon$, we have $\|\tilde{\mathbf{w}}_\varepsilon\|_{\mathbf{L}^2(\Omega_f)}\le 1$ and $\|\tilde R_\varepsilon\|_{L^2(\Omega)}\le 1$. Thus, taking if necessary a subsequence, one can show that

$$(\tilde{\mathbf{w}}_\varepsilon,\tilde R_\varepsilon)\rightharpoonup(\tilde{\mathbf{w}},\tilde R)\quad\text{in }\mathbf{L}^2(\Omega_f)\times L^2(\Omega). \tag{4.35}$$

Taking the inner product of (4.31) with R_ε in $L^2(\Omega)$ and integrating the product by parts, we obtain

$$\begin{aligned}\int_\Omega\kappa|\nabla\tilde R_\varepsilon|^2d\mathbf{x}&\le\|\tilde R_\varepsilon\|^2_{L^2(\Omega)}\\ &+C(\|\hat T_\varepsilon-T_d\|^2_{L^2(\Omega_s)}/I^2_\varepsilon+\|\hat T_\varepsilon-\hat T\|^2_{L^2(\Omega)}/I^2_\varepsilon+\|\tilde{\mathbf{w}}_\varepsilon\|^2_{\mathbf{L}^2(\Omega_f)}).\end{aligned}\tag{4.36}$$

By the fact $\|\tilde R_\varepsilon\|_{L^2(\Omega)}\le 1$ and the inequalities (4.15) and (4.36), we can assume without loss of generality that

$$\|\tilde R_\varepsilon\|_{H^1(\Omega)}\le C, \tag{4.37}$$

where the constant C is independent of ε. Then again taking the inner product of (4.33) with $\tilde{\mathbf{w}}_\varepsilon$ in $\mathbf{L}^2(\Omega)$ and integrating the product by parts, we obtain

$$\begin{aligned}\nu \int_\Omega |\nabla \tilde{\mathbf{w}}_\varepsilon|^2 \, d\mathbf{x} &= -\int_\Omega (\tilde{R}_\varepsilon(\nabla \hat{T}_\varepsilon, \tilde{\mathbf{w}}_\varepsilon) + (\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}, \tilde{\mathbf{w}}_\varepsilon) + (B(\hat{\mathbf{u}}_\varepsilon, \tilde{\mathbf{w}}_\varepsilon), \tilde{\mathbf{w}}_\varepsilon)) \, d\mathbf{x} \\ &\le C\Bigg(\|\nabla \hat{T}_\varepsilon\|_{L^2(\Omega)} \|\tilde{R}_\varepsilon\|_{H^1(\Omega)} \|\tilde{\mathbf{w}}_\varepsilon\|_V + \|\hat{\mathbf{u}}_\varepsilon\|_V \|\tilde{\mathbf{w}}_\varepsilon\|^{\frac{1}{2}}_{\mathbf{L}^2(\Omega_f)} \|\tilde{\mathbf{w}}_\varepsilon\|^{\frac{3}{2}}_V \\ &\qquad + \frac{\|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|_{\mathbf{L}^2(\Omega_f)} \|\tilde{\mathbf{w}}_\varepsilon\|_{\mathbf{L}^2(\Omega_f)}}{I_\varepsilon} \Bigg). \end{aligned} \tag{4.38}$$

By (4.22), (4.35), and (4.37) the above estimate implies immediately

$$\|\tilde{\mathbf{w}}_\varepsilon\|_{\mathbf{V}} \le C, \tag{4.39}$$

where the constant C is independent of ε.

From the facts (4.35), (4.37), and (4.39), again taking if necessary a subsequence, we obtain

$$\begin{aligned} (\tilde{\mathbf{w}}_\varepsilon, \tilde{R}_\varepsilon) &\rightharpoonup (\tilde{\mathbf{w}}, \tilde{R}) \quad \text{in} \quad \mathbf{V} \times H^1(\Omega), \\ (\tilde{\mathbf{w}}_\varepsilon, \tilde{R}_\varepsilon) &\to (\tilde{\mathbf{w}}, \tilde{R}) \quad \text{in} \quad \mathbf{L}^2(\Omega_f) \times L^2(\Omega). \end{aligned} \tag{4.40}$$

Furthermore, by (4.8) and (4.40) the sequence

$$\left\{ -(\hat{\mathbf{u}}_\varepsilon \cdot \nabla)\tilde{\mathbf{w}}_\varepsilon + B(\hat{\mathbf{u}}_\varepsilon, \tilde{\mathbf{w}}_\varepsilon) + \tilde{R}_\varepsilon \nabla \hat{T}_\varepsilon + N \frac{\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}}{I_\varepsilon} \right\}_{\varepsilon \in (0,1)}$$

is bounded in $\mathbf{L}^2(\Omega_f)$, and thus we have

$$\tilde{\mathbf{w}}_\varepsilon \rightharpoonup \tilde{\mathbf{w}} \ \text{ in } \mathbf{H}^2(\Omega_f). \tag{4.41}$$

Once again, since (4.8), (4.40), and (4.41) imply the boundedness of the sequence

$$\left\{ -\chi_{\Omega_f} (\hat{\mathbf{u}} \cdot \nabla)\tilde{R}_\varepsilon - \alpha\, \chi_{\Omega_f} (\tilde{\mathbf{w}}_\varepsilon, \mathbf{e}_2) + \frac{\hat{T}_\varepsilon - T_d}{I_\varepsilon} + \frac{\hat{T}_\varepsilon - \hat{T}}{I_\varepsilon} \right\}_{\varepsilon \in (0,1)}$$

in the space $L^2(\Omega)$, by (4.22) and (4.40) we have (see [24])

$$\tilde{R}_\varepsilon \rightharpoonup \tilde{R} \text{ in } H^s(\Omega) \text{ as } \varepsilon \to 0 \quad \forall s \in \left(1, \frac{3}{2}\right). \tag{4.42}$$

Since $\|(\tilde{\mathbf{w}}_\varepsilon, \tilde{R}_\varepsilon)\|_{\mathbf{L}^2(\Omega_f) \times L^2(\Omega)} = 1$, it follows from (4.40) that

$$\|(\tilde{\mathbf{w}}, \tilde{R})\|_{\mathbf{L}^2(\Omega_f) \times L^2(\Omega)} = 1. \tag{4.43}$$

Thus passing to the limit in (4.31)–(4.34) as $\varepsilon \to +0$, keeping in mind (4.19), (4.41), and (4.42), we obtain the optimality system (4.1)–(4.5) with $\lambda = 0$:

$$-\nabla \cdot (\kappa \nabla \tilde{R}) - \chi_{\Omega_f} (\, \hat{\mathbf{u}} \cdot \nabla)\tilde{R} - \alpha\, \chi_{\Omega_f} (\tilde{\mathbf{w}}, \mathbf{e}_2) = 0 \text{ in } \Omega, \tag{4.44}$$

$$\frac{\partial \tilde{R}}{\partial \mathbf{n}}|_{\Gamma_C} = 0, \quad -(\kappa \tilde{R}, g - \hat{g})|_{L^2(\Gamma_C)} \ge 0 \quad \forall\, g \in \mathcal{V}, \quad \tilde{R}|_{\Gamma_D} = 0, \tag{4.45}$$

$$-\nu \Delta \tilde{\mathbf{w}} - (\hat{\mathbf{u}} \cdot \nabla)\tilde{\mathbf{w}} + B(\hat{\mathbf{u}}, \tilde{\mathbf{w}}) + \tilde{R} \nabla \hat{T} = \nabla \tilde{q} \ \text{ in } \Omega_f, \tag{4.46}$$

and

$$\nabla \cdot \tilde{\mathbf{w}} = 0, \ \ \tilde{\mathbf{w}}|_{\partial\Omega_f} = 0. \tag{4.47}$$

The necessary regularity of Lagrange multipliers follows from (4.22), (4.41), and (4.42).

Now we consider the case $\mathcal{V} = L^2(\Gamma_C)$. In that case the inequality

$$-(\kappa\tilde{R}, g - \hat{g})_{L^2(\Gamma_C)} \geq 0 \quad \forall\, g \in \mathcal{V}$$

implies $\tilde{R}|_{\Gamma_C} = 0$. Then by the uniqueness theorem for the Cauchy problem for the Laplace operator from (4.44) and (4.45) we have

$$\tilde{R} \equiv 0 \quad \text{in } \Omega_s.$$

Now let us show that $\tilde{R} \neq 0$ in Ω_f. If our statement is not true, then (4.44) yields

$$(\tilde{\mathbf{w}}(x), \mathbf{e}_2) = 0 \quad \text{in} \quad \Omega_f.$$

By (4.47) and the above equality there exists a vector $\mathbf{a}$ such that

$$\frac{\partial \tilde{\mathbf{w}}_i}{\partial \mathbf{a}} = 0 \quad \text{in } \Omega_f \ \forall\, i \in \{1,2\}. \tag{4.48}$$

Hence by (4.47) and (4.48) $\tilde{\mathbf{w}} \equiv 0$. But this contradicts (4.43).

(B) Let $\liminf_{\varepsilon\to 0} I_\varepsilon < +\infty$ or, put another way,

$$\|R_\varepsilon\|_{L^2(\Omega)} + \|\mathbf{w}_\varepsilon\|_{\mathbf{L}^2(\Omega_f)} \leq C. \tag{4.49}$$

Taking the inner product of (4.27) with R_ε in $L^2(\Omega)$ and integrating the product by parts, we obtain

$$\begin{aligned}\int_\Omega \kappa|\nabla R_\varepsilon|^2\, d\mathbf{x} \leq{}& \|R_\varepsilon\|^2_{L^2(\Omega)} \\ &+ C(\|\hat{T}_\varepsilon - T_d\|^2_{L^2(\Omega_s)} + \|\hat{T}_\varepsilon - \hat{T}\|^2_{L^2(\Omega)} + \|\mathbf{w}_\varepsilon\|^2_{\mathbf{L}^2(\Omega_f)}).\end{aligned} \tag{4.50}$$

By (4.49) and (4.50) we can assume without loss of generality that

$$R_\varepsilon \rightharpoonup R \quad \text{in } H^1(\Omega). \tag{4.51}$$

Then again taking the inner product of (4.29) with $\mathbf{w}_\varepsilon$ in $\mathbf{L}^2(\Omega)$ and integrating the product by parts, we obtain

$$\begin{aligned}\nu\int_\Omega |\nabla\mathbf{w}_\varepsilon|^2\, d\mathbf{x} &= -\int_\Omega (R_\varepsilon(\nabla\hat{T}_\varepsilon, \mathbf{w}_\varepsilon) + (\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}, \mathbf{w}_\varepsilon) + (B(\hat{\mathbf{u}}_\varepsilon, \mathbf{w}_\varepsilon), \mathbf{w}_\varepsilon))\, d\mathbf{x} \\ &\leq C(\|\nabla\hat{T}_\varepsilon\|_{L^2(\Omega)}\|R_\varepsilon\|_{H^1(\Omega)}\|\mathbf{w}_\varepsilon\|_V + \|\hat{\mathbf{u}}_\varepsilon\|_V\|\mathbf{w}_\varepsilon\|^{\frac{1}{2}}_{\mathbf{L}^2(\Omega_f)}\|\mathbf{w}_\varepsilon\|^{\frac{3}{2}}_V \\ &\qquad + \|\hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}}\|_{\mathbf{L}^2(\Omega_f)}\|\mathbf{w}_\varepsilon\|_{\mathbf{L}^2(\Omega_f)}).\end{aligned} \tag{4.52}$$

By (4.22), (4.49), and (4.51) the above estimate implies immediately

$$\mathbf{w}_\varepsilon \rightharpoonup \mathbf{w} \quad \text{in } \mathbf{V}. \tag{4.53}$$

Once again, using arguments similar to (4.35) and (4.40), we obtain

$$(\mathbf{w}_\varepsilon, R_\varepsilon) \rightharpoonup (\mathbf{w}, R) \quad \text{in} \quad \mathbf{H}^2(\Omega_f) \times H^s(\Omega) \quad \forall s \in \left(1, \frac{3}{2}\right). \tag{4.54}$$

By (4.22), (4.51), (4.53), and (4.54) passing to the limit in (4.27)–(4.30), we obtain optimality system (4.1)–(4.5) with $\lambda = 1$. The relations (4.22), (4.53), (4.54), and the equation (4.4) imply the necessary regularity of Lagrange multipliers. □

Remark 4.1. *If Lagrange multiplier $\lambda \neq 0$ in system (4.1)–(4.5), without loss of generality we can assume that $\lambda = 1$. Instead of $R, \mathbf{w}, q$ one can just introduce the new Lagrange multipliers $\tilde{R} = R/\lambda, \tilde{\mathbf{w}} = \mathbf{w}/\lambda, \tilde{q} = q/\lambda$. Obviously, $\tilde{\mathbf{w}}, \tilde{R}, \tilde{q}$ satisfy the system of equations*

$$(1, \tilde{\mathbf{w}}, \tilde{R}, \tilde{q}) \neq 0, \tag{4.55}$$

$$-\nabla \cdot (\kappa \nabla \tilde{R}) - \chi_{\Omega_f}(\hat{\mathbf{u}} \cdot \nabla)\tilde{R} - \alpha\, \chi_{\Omega_f}(\tilde{\mathbf{w}}, \mathbf{e}_2) + (\hat{T} - T_d) = 0 \ \text{in}\ \Omega, \tag{4.56}$$

$$\frac{\partial \tilde{R}}{\partial \mathbf{n}}|_{\Gamma_C} = 0, \quad (\delta \hat{g} - \kappa \tilde{R}, g - \hat{g})_{L^2(\Gamma_C)} \geq 0 \quad \forall\, g \in \mathcal{V}, \quad \tilde{R}|_{\Gamma_D} = 0, \tag{4.57}$$

$$-\nu \Delta \tilde{\mathbf{w}} - (\hat{\mathbf{u}} \cdot \nabla)\tilde{\mathbf{w}} + B(\hat{\mathbf{u}}, \tilde{\mathbf{w}}) + \tilde{R} \nabla \hat{T} = \nabla \tilde{q} \ \ \text{in} \quad \Omega_f, \tag{4.58}$$

and

$$\nabla \cdot \tilde{\mathbf{w}} = 0, \ \ \tilde{\mathbf{w}}|_{\partial \Omega_f} = 0. \tag{4.59}$$

Naturally, we are interested in the case when the optimality system has the Lagrange multiplier λ not equal to zero. Unfortunately, we could not prove that for an arbitrary $(\mathbf{f}, Q) \in \mathbf{L}^2(\Omega_f) \times L^2(\Omega)$ the optimality system (4.1)–(4.5) holds true with $\lambda \neq 0$. But below we will prove this fact for the dense set of $(\mathbf{f}, Q)$ in $\mathbf{L}^2(\Omega_f) \times L^2(\Omega)$. First, let us introduce the following definition.

Definition 4.1. *We say that pair $(\mathbf{f}, Q) \in \mathbf{L}^2(\Omega_f) \times L^2(\Omega)$ belongs to the set $\mathcal{O}$ if and only if for all global minimums to problem (3.9) (with right-hand sides in (1.1) and (1.3) equal to $\mathbf{f}$ and Q, respectively) the optimality system (4.1)–(4.5) holds true with $\lambda = 1$.*

Theorem 4.2. *The set $\mathcal{O}$ is dense in $\mathbf{L}^2(\Omega_f) \times L^2(\Omega)$.*

Proof. Let us consider the auxiliary extremal problem

$$\begin{aligned} \mathcal{I}_\varepsilon(\mathbf{u}, T, p, g) &= \mathcal{J}_1(\mathbf{u}, T, p, g) \\ &\quad + \frac{1}{2\varepsilon}\| - \nu \Delta \mathbf{u} + (\mathbf{u} \cdot \nabla)\mathbf{u} - \alpha T \mathbf{e}_2 + \nabla p - \mathbf{f}\|^2_{\mathbf{L}^2(\Omega_f)} \\ &\quad + \frac{1}{2\varepsilon}\| - \nabla \cdot (\kappa \nabla T) + \chi_{\Omega_f}(\mathbf{u} \cdot \nabla)T \ - Q\|^2_{L^2(\Omega)} \ \rightarrow \ \inf, \end{aligned} \tag{4.60}$$

and

$$T|_{\Gamma_D} = 0, \ \frac{\partial T}{\partial \mathbf{n}}|_{\Gamma_C} = g \in \mathcal{V}, \ \mathbf{u}|_{\partial \Omega_f} = 0, \ \nabla \cdot \mathbf{u} = 0. \tag{4.61}$$

By arguments similar to one in the proof of Theorem 4.1, one can show that there exists at least one solution $(\hat{\mathbf{u}}_\varepsilon, \hat{T}_\varepsilon, \hat{p}_\varepsilon, \hat{g}_\varepsilon) \in \mathbf{V} \cap \mathbf{H}^2(\Omega_f) \times H^1(\Omega) \times L^2_0(\Omega_f) \times L^2(\Gamma_C)$ to problem (4.60) and (4.61). Let us denote by $(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g})$ a solution to problem (3.9). Since $\mathcal{I}_\varepsilon(\hat{\mathbf{u}}_\varepsilon, \hat{T}_\varepsilon, \hat{p}_\varepsilon, \hat{g}_\varepsilon) \leq \mathcal{I}_\varepsilon(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g}) = \mathcal{J}_1(\hat{\mathbf{u}}, \hat{T}, \hat{p}, \hat{g})$, we have

$$(\varepsilon R_\varepsilon, \varepsilon \mathbf{w}_\varepsilon) \rightarrow (0, 0) \quad \text{in} \quad L^2(\Omega) \times \mathbf{L}^2(\Omega_f), \tag{4.62}$$

where

$$R_\varepsilon = \frac{1}{\varepsilon}(-\nabla \cdot (\kappa \nabla \hat{T}_\varepsilon) + \chi_{\Omega_f}(\hat{\mathbf{u}}_\varepsilon \cdot \nabla)\hat{T}_\varepsilon - Q) \tag{4.63}$$

and

$$\mathbf{w}_\varepsilon = \frac{1}{\varepsilon}(-\nu\Delta\hat{\mathbf{u}}_\varepsilon + (\hat{\mathbf{u}}_\varepsilon \cdot \nabla)\hat{\mathbf{u}}_\varepsilon + \nabla\hat{p}_\varepsilon - \alpha\hat{T}_\varepsilon\mathbf{e}_2 - \mathbf{f}). \tag{4.64}$$

The optimality system to problem (4.60)–(4.61) is as follows:

$$-\nabla \cdot (\kappa\nabla R_\varepsilon) - \chi_{\Omega_f}(\hat{\mathbf{u}}_\varepsilon \cdot \nabla)R_\varepsilon - \alpha\chi_{\Omega_f}(\mathbf{w}_\varepsilon, \mathbf{e}_2) + (\hat{T}_\varepsilon - T_d) = 0 \text{ in } \Omega, \tag{4.65}$$

$$\frac{\partial R_\varepsilon}{\partial \mathbf{n}}|_{\Gamma_C} = 0, \ \ (\delta\hat{g}_\varepsilon - \kappa R_\varepsilon, g - \hat{g}_\varepsilon)_{L^2(\Gamma_C)} \geq 0 \quad \forall\, g \in \mathcal{V}, \ \ R_\varepsilon|_{\Gamma_D} = 0, \tag{4.66}$$

$$-\nu\,\Delta\mathbf{w}_\varepsilon - (\hat{\mathbf{u}}_\varepsilon \cdot \nabla)\mathbf{w}_\varepsilon + B(\hat{\mathbf{u}}_\varepsilon, \mathbf{w}_\varepsilon) + R_\varepsilon\nabla\hat{T}_\varepsilon + \hat{\mathbf{u}}_\varepsilon - \hat{\mathbf{u}} = \nabla q_\varepsilon \ \text{ in } \Omega_f, \tag{4.67}$$

and

$$\nabla \cdot \mathbf{w}_\varepsilon = 0, \ \ \mathbf{w}_\varepsilon|_{\partial\Omega_f} = 0. \tag{4.68}$$

Note that a global minimum to problem (4.60)–(4.61) is simultaneously the global minimum solution to problem (3.9); there, instead of $(Q, \mathbf{f})$, we have $(\varepsilon R_\varepsilon + Q, \varepsilon\mathbf{w}_\varepsilon + \mathbf{f})$. By (4.65)–(4.68) the Lagrange multiplier λ equals 1. On the other hand, let $(\tilde{\mathbf{u}}, \tilde{T}, \tilde{p}, \tilde{g})$ be another global minimum to problem (3.9); there, in the right-hand side of (2.5) and (2.7), instead of $(Q, \mathbf{f})$, we have $(\varepsilon R_\varepsilon + Q, \varepsilon\mathbf{w}_\varepsilon + \mathbf{f})$. Obviously, $(\tilde{\mathbf{u}}, \tilde{T}, \tilde{p}, \tilde{g})$ are also solutions to problem (4.60)–(4.61). Hence the pair $(\varepsilon R_\varepsilon + Q, \varepsilon\mathbf{w}_\varepsilon + \mathbf{f}) \in \mathcal{O}$. Then the statement of the our theorem follows from (4.62). □

Unfortunately, in the general case we cannot prove that the set $\mathcal{O}$ constructed in Theorem 4.2 is open. Below we consider the special case. Let us assume that

$$\mathcal{V} = X \subset L^2(\Gamma_C), \ \text{ where } X \text{ is a linear space, } \dim X < \infty.$$

We start from the following definitions.

Definition 4.2. *Let E and E_0 be Banach spaces and $\Omega \subset E$. The mapping $A : E \to E_0$ is called proper on Ω if the preimage $A^{-1}K \cap \Omega$ of a compact $K \subset E_0$ is compact in Ω for any choice of a compact $K \subset E_0$.*

Definition 4.3. *A linear operator $L : E \to E_0$ is called a Fredholm operator with index k, $k \in \mathbf{Z}$, if the image subspace $L(E) \subset E_0$ is closed and has a finite codimension* $\mathrm{codim} L(E) = \dim(E_0/L(E))$, *and the kernel $Ker\, L \subset E$ has a finite dimension* $\dim Ker\, L$. *The number k is called the index of L : $k = \dim Ker\, L - \mathrm{codim} L(E)$.*

Definition 4.4. *Let A be an operator defined in an open domain $O \subset E$ of a Banach space $E, A : O \to E_0$, where E_0 is another Banach space. It is supposed that A is continuously differentiable on O and $A'(u)$ is a Fredholm operator with the index k for any $u \in O$. Such a mapping is called Fredholm with the index k on O.*

Definition 4.5. *Let $B \subset O$. A point $y \in E_0$ is called a regular value of A on B, where A is the operator defined in Definition* 4.4, *in two cases:*

1. *if $y \notin A(B)$,*
2. *if $y \in A(B)$ and for any $u \in A^{-1}y \cap B$ the differential $A'(u)$ at the point u maps E onto E_0. All the values which are not regular are called critical values.*

The following Sard–Smale theorem was proved in [6].

Theorem 4.3 (Sard–Smale). *Let A be a mapping of class $C^r, r \in \mathbf{N}$, on a domain $O \subset E$. Let A be Fredholm on O with the index $k, r \geq k$. Let $B \subset O$ be a closed set, and let A be proper on B. Then the set D of all regular values of A on B is an open and dense set in E_0.*

The following theorem was proved in [19].

THEOREM 4.4 (Kato). *Let E and E_0 be Banach spaces, and let operator $K = T + S : E \to E_0$ be a sum of continuous linear Fredholm operator T and a compact linear operator S. Then K is the Fredholm operator with $Ind\, K = Ind\, T$.*

Let us introduce the Banach spaces

$$\begin{aligned} E &= \mathbf{V} \cap \mathbf{H}^2(\Omega_f) \times H^1(\Omega_f) \cap L_0^2(\Omega_f) \times Y, \\ \tilde{E} &= \mathbf{V} \cap \mathbf{H}^2(\Omega_f) \times H^1(\Omega_f) \cap L_0^2(\Omega_f) \times \tilde{Y}, \text{ and} \\ E_0 &= \mathbf{L}^2(\Omega_f) \times L^2(\Omega), \end{aligned}$$

where

$$Y = \left\{ T \in H_D^1(\Omega), -\nabla \cdot (\kappa \nabla T) \in L^2(\Omega), \frac{\partial T}{\partial \mathbf{n}} \in X \right\}$$

and

$$\tilde{Y} = \left\{ T \in H_D^1(\Omega), -\nabla \cdot (\kappa \nabla T) \in L^2(\Omega), \frac{\partial T}{\partial \mathbf{n}}|_{\Gamma_C} = 0 \right\}$$

are Banach spaces equipped with the norm

$$\|T\|_Y = \|T\|_{\tilde{Y}} = \|T\|_{H^1(\Omega)} + \|\nabla \cdot (\kappa \nabla T)\|_{L^2(\Omega)} + \left\| \frac{\partial T}{\partial \mathbf{n}} \right\|_{L^2(\Gamma_C)}.$$

We introduce the mapping $A : E \to E_0$ defined by

$$(4.69)\ A(u, p, T) = (-\nu \Delta \mathbf{u} + (\mathbf{u} \cdot \nabla)\mathbf{u} + \nabla p - \alpha T \mathbf{e}_2, -\nabla \cdot (\kappa \nabla T) + (\mathbf{u} \cdot \nabla) T).$$

PROPOSITION 4.5. *The mapping $A \in C^\infty(E, E_0)$ is a Fredholm mapping on E with the index $k = \dim X$. Moreover, for any $r > 0$ the mapping A is proper on $B_r = \{x \in E_0, \|x\|_{E_0} \le r\}$.*

Proof. We can write out the mapping A in the form

$$A(\mathbf{u}, p, T) = A_1(\mathbf{u}, p, T) + A_2(\mathbf{u}, p, T),$$

where $A_1(\mathbf{u}, p, T) = (-\nu \Delta \mathbf{u} + \nabla p - \alpha T \mathbf{e}_2, -\nabla \cdot (\kappa \nabla T)) : E \to E_0$ is the linear continuous operator and

$$A_2(\mathbf{u}, p, T) = ((\mathbf{u} \cdot \nabla)\mathbf{u}, \chi_{\Omega_f} (\mathbf{u} \cdot \nabla) T)$$

is the bilinear operator. By the estimate

$$\|A_2(\mathbf{u}, p, T)\|_{\mathbf{L}^2(\Omega_f)} \le C \left(\|\mathbf{u}\|_{\mathbf{L}^4(\Omega_f)} \|\nabla \mathbf{u}\|_{\mathbf{L}^4(\Omega_f)} + \|\mathbf{u}\|_{\mathbf{L}^\infty(\Omega_f)} \|\nabla T\|_{L^2(\Omega_f)} \right)$$

this bilinear operator is continuous. This implies (see [26]) $A \in C^\infty(E, E_0)$. One can write out the derivative of this operator at the point $(\mathbf{u}_0, p_0, T_0)$ as follows:

$$A_2'(\mathbf{u}_0, p_0, T_0)[\mathbf{u}, p, T] = ((\mathbf{u}_0 \cdot \nabla)\mathbf{u} + (\mathbf{u} \cdot \nabla)\mathbf{u}_0, (\mathbf{u}_0 \cdot \nabla) T + (\mathbf{u} \cdot \nabla) T_0).$$

Also, the estimate

$$\begin{aligned} &\|A_2'(\mathbf{u}_0, p_0, T_0)[\mathbf{u}, p, T]\|_{\mathbf{L}^2(\Omega_f) \times L^2(\Omega)} \\ &\qquad \le C\big(\|\mathbf{u}_0\|_{\mathbf{L}^4(\Omega_f)} \|\nabla \mathbf{u}\|_{\mathbf{L}^4(\Omega_f)} + \|\mathbf{u}\|_{\mathbf{L}^4(\Omega_f)} \|\nabla \mathbf{u}_0\|_{\mathbf{L}^4(\Omega_f)} \\ &\qquad\quad + \|\mathbf{u}\|_{\mathbf{L}^\infty(\Omega_f)} \|\nabla T_0\|_{L^2(\Omega_f)} + \|\mathbf{u}_0\|_{\mathbf{L}^\infty(\Omega_f)} \|\nabla T\|_{L^2(\Omega_f)} \big) \end{aligned}$$

implies that for each $(\mathbf{u}_0, p_0, T_0) \in E$ the derivative $A_2'(\mathbf{u}, p, T)$ is the compact operator. Note that $A'(0)(\mathbf{u}, p, T) = A_1(\mathbf{u}, p, T)$. Since $Im\, A_1 = E_0$, the index of this operator equals $\dim X$. Applying the Theorem 4.4, we obtain that A is a Fredholm mapping with the index $k = \dim X$ as desired.

Now let us prove that the mapping A is proper. Let K be an arbitrary compact set in E_0. Then $A^{-1}K \cap B_r$ is a bounded set in E. On the other hand, $A_2(A^{-1}K \cap B_r)$ is a compact set, and, obviously, $K_1 = K + A_2(A^{-1}K \cap B_r)$ is also a compact set. Then $A^{-1}K \cap B_r \subset A_1^{-1}K_1 \cap B_r \subset M_1 + M_2$, where

$$M_1 = \{(\mathbf{u}, p, T) \in \tilde{E}, A_1(\mathbf{u}, p, T) \in K_1\}$$

and

$$M_2 = \left\{(0, 0, T), T \in B, \nabla \cdot \kappa \nabla T \equiv 0, g \in X, \frac{\partial T}{\partial \mathbf{n}}|_{\Gamma_C} = g, \|g\|_{L^2(\Gamma_C)} \le r\right\}.$$

Since M_2 is a closed finite dimensional set, it is compact. On the other hand, since the operator A_1 is an isomorphism between $\tilde{E}$ and E_0, the set M_1 is also compact. This implies immediately that $M_1 + M_2$ is compact. The proof of the theorem is finished. □

Now we have the following theorem.

THEOREM 4.6. *Let $\mathcal{V}$ be a linear finite dimensional space in $L^2(\Gamma_C)$. Then the set $\mathcal{O}$ contains a set $\mathcal{O}_1$ which is open and dense in $\mathbf{L}^2(\Omega_f) \times L^2(\Omega)$.*

Proof. We prove this theorem by contradiction. Let $\mathrm{M} \subset E_0$ be the set of $(\mathbf{f}, Q) \in \mathbf{L}^2(\Omega_f) \times L^2(\Omega)$ such that there exists a solution of the system (4.1)–(4.5) with $\lambda = 0$ and $\mathbf{Int}\,\overline{\mathrm{M}} \neq \emptyset$. Let us show that M belongs to the set of critical values of the mapping (4.69). By Theorem 2.3, we have that $A(E) = E_0$. But by definition, for all $(\mathbf{f}, Q) \in \mathrm{M}$, there exists $(\hat{\mathbf{u}}, \hat{p}, \hat{T}) \in E$ such that $A(\hat{\mathbf{u}}, \hat{p}, \hat{T}) = (\mathbf{f}, Q)$ and $(\hat{\mathbf{u}}, \hat{p}, \hat{T})$ is a solution to optimal problem (3.9) with the optimality system (4.1)–(4.5) and $\lambda = 0$. Hence $\mathrm{Ker}\, A'^*(\hat{\mathbf{u}}, \hat{p}, \hat{T})(\cdot) \neq \emptyset$ and $\mathrm{Im}\, A'(\hat{\mathbf{u}}, \hat{p}, \hat{T}) \neq E_0$. This implies that M belongs to the set of critical values of the mapping A. On the other hand, by Proposition 4.5, $A \in C^\infty(E, E_0)$ is a Fredholm mapping with index $k = \dim X$. Finally, let $\mathcal{P}$ be an open bounded subset of $\mathbf{Int}\,\overline{\mathrm{M}}$. Then there exists a ball $B_r \subset E$ such that for all $(\mathbf{f}, Q) \in \mathcal{P}$ all global minimum to problem (3.9) belong to B_r. By Proposition 4.5 the mapping A is proper on B_r. Hence, by the Sard–Smale theorem, the set of regular values is dense in E_0. We obtain a contradiction, and thus the proof is completed. □

A NECESSARY AND SUFFICIENT CONDITION FOR BOUNDED-INPUT BOUNDED-STATE STABILITY OF NONLINEAR SYSTEMS*

ANDREA BACCIOTTI† AND LUISA MAZZI†

Abstract. The main purpose of this work is to prove a converse theorem for bounded-input bounded-state stability of nonlinear systems in the framework of Liapunov's second method. The construction gives rise to an upper semicontinuous time-dependent Liapunov function. In certain cases, the monotonicity conditions can be checked by means of contingent directional derivatives.

Key words. Liapunov functions, external stability, nonlinear systems

Introduction. In this work we address the problem of characterizing uniform bounded-input bounded-state (UBIBS) stability for time-varying, continuous time, finite-dimensional nonlinear systems

$$\dot{x} = f(t, x, u), \qquad t \geq 0, \quad x \in \mathbb{R}^n, \quad u \in \mathbb{R}^m, \tag{0.1}$$

in the framework of Liapunov's second method. Roughly speaking, a system is said to be bounded-input bounded-state stable if for each initial pair (t_0, x_0) and each admissible input $u = u(t)$, the corresponding solution $x = \varphi(t)$ of (0.1) remains bounded for all $t \geq t_0$. In order to conceive a more formal and precise definition, we insert a short digression about the time-invariant linear case. First, let us specify some terminology and notation.

Throughout this paper, an *admissible input* is a measurable, essentially bounded function $u = u(t) : [0, +\infty) \to \mathbb{R}^m$. The euclidean norm of a finite-dimensional vector v is denoted by $|v|$. If $u(\cdot)$ is an admissible input, we shall write

$$\|u(\cdot)\| = \operatorname*{ess\,sup}_{t \geq 0} |u(t)|.$$

Let I be an interval, and let $u(\cdot)$ be an admissible input. A (Carathéodory) *solution* of (0.1) on I corresponding to the input $u(\cdot)$ is a function $\varphi(t)$ which is absolutely continuous on every compact subinterval of I and which satisfies the differential equation $\dot{x} = f(t, x, u(t))$ almost everywhere (a.e.) on I. When we want to emphasize the dependence of a solution $\varphi(t)$ on the admissible input $u(\cdot)$ and a given initial pair (t_0, x_0), we write $x = \varphi(t; t_0, x_0, u(\cdot))$.

Let a linear system of the form

$$\dot{x} = Ax + Bu \tag{0.2}$$

be given.

It is well known that A is Hurwitz (if and) only if there exist positive constants γ_1, γ_2, and α such that for each initial state x_0 and each admissible input

$u : [0, +\infty) \to \mathbb{R}^m$ one has

$$|\varphi(t; 0, x_0, u(\cdot))| \leq \gamma_1 |x_0| e^{-\alpha t} + \gamma_2 \cdot \|u(\cdot)\| \tag{0.3}$$

for each $t \geq 0$. In particular, (0.3) implies the weaker condition

$$|\varphi(t; 0, x_0, u(\cdot))| \leq \gamma_1 |x_0| + \gamma_2 \cdot \|u(\cdot)\| \tag{0.4}$$

for each $t \geq 0$. This last condition has a characterization in terms of the Kalman canonical decomposition of (0.2).

Proposition 0.1. *Let the linear system* (0.2) *be given and let A_{11} and A_{22} be, respectively, the controllable part and the uncontrollable part of A which appear in its Kalman decomposition. There exist $\gamma_1, \gamma_2 > 0$ such that* (0.4) *holds for each x_0 and each $u(\cdot)$, if and only if*

(i) *the real part of all the eigenvalues of A_{11} is negative;*

(ii) *the real part of all the eigenvalues of A_{22} is nonpositive and all the eigenvalues with zero real part are simple.*

In fact, if the uncontrollable part is stable, the corresponding solutions remain bounded. Hence, the controllable part can be viewed as a subsystem with Hurwitz matrix and bounded input, so that (0.3) applies.

The estimates (0.3) and (0.4) turn out to be very useful in studying the behavior of the state response of a system with respect to bounded inputs, as classical classroom examples show. Both (0.3) and (0.4) can be extended to nonlinear systems. In this context, it is convenient to introduce the formalism of the so-called functions of class $\mathcal{K}$. Although functions of class $\mathcal{K}$ are a classical tool in stability theory, the details of the definition may vary from author to author. We adopt the following definition.

Definition 0.1. *A real function defined on $[0, +\infty)$ is said to be of class $\mathcal{K}^\infty$ if it is continuous, strictly increasing, $\alpha(0) \geq 0$, and $\lim_{r \to +\infty} \alpha(r) = +\infty$.*

The definitions of class $\mathcal{K}^\infty$ available in the literature often include the requirement $\alpha(0) = 0$. Since in this paper we are interested in the behavior for large x, we also include functions with $\alpha(0) > 0$.

The extension of (0.3) to the nonlinear case gives rise to the well-known notion of *input-to-state stability* introduced by Sontag ([11]; see also [7, p. 501] for a definition in the time-varying setting) and thoroughly studied in the last decade. In particular, it has been proved that at least in the time-invariant case, input-to-state stability can be characterized by means of $\mathcal{C}^\infty$ Liapunov functions which satisfy certain growth conditions and a monotonicity condition expressed in differential form (see [12]).

In this paper we are mainly interested in the extension of (0.4) to the nonlinear case.

Definition 0.2. *We say that system* (0.1) *satisfies the UBIBS stability property if there exist maps $\gamma_1, \gamma_2 \in \mathcal{K}^\infty$ such that, for each initial pair (t_0, x_0), each admissible input $u : [0, +\infty) \to \mathbb{R}^m$, and each $t \geq t_0$,*

$$|\varphi(t; t_0, x_0, u(\cdot))| \leq \gamma_1(|x_0|) + \gamma_2(\|u(\cdot)\|).$$

This definition has several equivalent formulations, reported in the following proposition, whose proof is omitted. (The equivalence between (i) and (ii) is proved in [1] for the time-invariant case; the equivalence between (ii) and (iii) can be obtained by analogous arguments.)

PROPOSITION 0.2. *The following statements are equivalent:*

(i) *System* (0.1) *has the UBIBS stability property.*

(ii) *For each $R > 0$ there exists $S > 0$ such that for each initial pair (t_0, x_0) and each essentially bounded input $u : [0, +\infty) \to \mathbb{R}^m$*

$$|x_0| \leq R, \quad \|u(\cdot)\| \leq R, \quad t \geq t_0 \quad \Longrightarrow \quad |\varphi(t; t_0, x_0, u(\cdot))| \leq S.$$

(iii) *There exists $\Sigma \in \mathcal{K}^\infty$ such that for each $t_0 > 0$, each $R > 0$, each $x_0 \in \mathbb{R}^n$, and each admissible input $u(\cdot) : [0, +\infty) \to \mathbb{R}^m$ one has*

$$|x_0| \leq R, \quad \|u(\cdot)\| \leq R, \quad t \geq t_0 \quad \Longrightarrow \quad |\varphi(t; t_0, x_0, u(\cdot))| \leq \Sigma(R).$$

Remark 0.1. From (ii) it is clear in particular that the term "uniform" in Definition 0.2 is intended to have a double interpretation: the dependence of S on R is affected neither by the choice of x_0 (within the ball of radius R) nor by the choice of t_0.

Notice also that for the map Σ in (iii), we necessarily have $\Sigma(r) \geq r$ for each $r \geq 0$. Indeed from (iii) it follows in particular that

$$|\varphi(t_0; t_0, x_0, u(\cdot))| = |x_0| \leq \Sigma(R)$$

for each $|x_0| \leq R$.

The main contribution of this paper is presented in section 1. We prove that (0.1) is UBIBS stable if and only if there exists a Liapunov function satisfying some suitable uniform growth conditions and the monotonicity condition. Our characterization is valid under very general assumptions. The "if" part is easy and basically known (see, for instance, [4]). The "only if" part is actually a converse Liapunov theorem for UBIBS stability, and it requires a delicate and original procedure. The principal difficulty is the construction of the Liapunov function in the presence of inputs. In section 1, we also point out that in general an UBIBS stable system has no continuous Liapunov function.

At this point, a comparison with some earlier, related results and some comments on the regularity issue are necessary. It is evident that for systems without input, UBIBS stability reduces to *Lagrange stability* (sometimes referred to as *uniform boundedness of solutions*). A characterization of Lagrange stability by means of nonnecessarily continuous Liapunov functions is immediate and can be deduced, for instance, from [15, Ch. V] and [2]. On the other hand, it is well known that continuous Liapunov functions for Lagrange stability may not exist (see [8], [4]). More regular Liapunov functions can be obtained either by strengthening the notion of stability (see again [8], [4]) or for systems with Lipschitz continuous right-hand side [15, Ch. V].

Time-invariant systems deserve a particular mention. In this case, one would expect Liapunov functions independent of t. However, a famous counterexample [5, p. 87] shows that in general continuous time-invariant Liapunov functions for Lagrange stable time-invariant systems do not exist, even if the right-hand side is $\mathcal{C}^\infty$. To this respect, it is worth mentioning Yorke's (rarely quoted) paper [14], where it is proved that for any stable, time-invariant, Lipschitz continuous system there exists a lower semicontinuous Liapunov function.

Keeping in mind this last result, we come back to system (0.1) and UBIBS stability. In section 2, we prove that if a suitable Lipschitz condition is fulfilled, then the Liapunov function constructed in section 1 is upper semicontinuous.

Finally, in section 3 we show that, provided that $V(t,x)$ is upper semicontinuous, it is possible to recognize the monotonicity property by means of a differential inequality involving the so-called generalized contingent directional derivative. In fact, this requires further restrictions on both f and the class of admissible inputs.

Dealing with Liapunov functions and UBIBS stability, it is worth mentioning the pioneering paper [13]: while in the present paper we characterize UBIBS stability by means of a single Liapunov function, in [13] the authors use a whole family $V_a(t,x)$ of them. The parameter a is related to the bound of the input variable.

1. A necessary and sufficient condition. In this section, we need the following hypotheses on (0.1).

Assumption (H). For any admissible input $u(t)$, for any pair $(t_0, x_0) \in \mathbb{R}^+ \times \mathbb{R}^n$, there exists a unique solution $\varphi(t; t_0, x_0, u(\cdot))$, defined for all $t \geq 0$.

We shall systematically employ the reformulation of the UBIBS stability property (iii) of Proposition 0.2. We denote by $H^\eta = \{x \in \mathbb{R}^n \ : \ |x| > \eta\}$ for $\eta > 0$.

THEOREM 1.1. *Assume that* (0.1) *satisfies assumption* (H). *System* (0.1) *has the UBIBS stability property if and only if there exist* $\eta > 0$*, functions* $a, b, \gamma \in \mathcal{K}^\infty$*, and a function* $V(t,x) : [0,+\infty) \times H^\eta \to \mathbb{R}$ *such that*

(i) $a(|x|) \leq V(t,x) \leq b(|x|)$ *for each* $t \geq 0$ *and each* $x \in H^\eta$*;*

(ii) $\gamma(r) \geq r + \eta$ *for each* $r \geq 0$*;*

(iii) *for each* $R > 0$*, for each input* $u(\cdot)$*, and for each solution* $\varphi(t)$ *of* (0.1) *corresponding to the input* $u(\cdot)$*,*

$$t_1 < t_2 \quad \Longrightarrow \quad V(t_1, \varphi(t_1)) \geq V(t_2, \varphi(t_2)) \tag{1.1}$$

provided that $|u(t)| \leq R$ *and* $|\varphi(t)| \geq \gamma(R)$ *for all* $t \in [t_1, t_2]$.

A function $V(t,x)$ satisfying the properties listed above is called a UBIBS-*weak Liapunov function* or, simply, a weak Liapunov function. For the sake of brevity, we shall refer to property (iii) of Theorem 1.1 by saying that V is *decreasing along the solutions* of (0.1).

We remark that the Liapunov function $V(t,x)$ we get in Theorem 1.1 is allowed to be discontinuous.

Proof of the sufficient part. Without loss of generality, we assume that $a(0) = 0$, so that $a^{-1} \in \mathcal{K}^\infty$. We actually show that (iii) of Proposition 0.2 is fulfilled with

$$\Sigma(R) = (a^{-1} \circ b \circ \gamma)(R) + \gamma(R).$$

First, we notice that according to this definition, $\Sigma \in \mathcal{K}^\infty$, and in fact, for each $R > 0$, we have $\Sigma(R) > \gamma(R) > R$.

Now, fix $R > 0$ and take an arbitrary initial instant $t_0 \geq 0$, an initial state x_0 with $|x_0| \leq R$, and an input $u(\cdot) : [t_0, +\infty) \to \mathbb{R}^m$ such that $\|u(\cdot)\| \leq R$. Assume that for some $t_2 > t_0$, it may happen that

$$|\varphi(t_2; t_0, x_0, u(\cdot))| > S = \Sigma(R).$$

Since $\Sigma(R) > \gamma(R) > R$ and $\varphi(t; t_0, x_0, u(\cdot))$ is continuous, there exists an instant $t_1 \in (t_0, t_2)$ such that $|\varphi(t_1; t_0, x_0, u(\cdot))| = \gamma(R)$, while $|\varphi(t; t_0, x_0, u(\cdot))| \geq \gamma(R)$ for $t \in [t_1, t_2]$.

For the sake of simplicity, we set $x_1 = \varphi(t_1; t_0, x_0, u(\cdot))$ and $x_2 = \varphi(t_2; t_0, x_0, u(\cdot))$. Since a is strictly increasing we have

$$a^{-1}(b(\gamma(R))) < \Sigma(R) = S \quad \Longrightarrow \quad b(\gamma(R)) < a(S).$$

In conclusion,

$$V(t_1, x_1) \leq b(|x_1|) = b(\gamma(R)) < a(S) < a(|x_2|) \leq V(t_2, x_2),$$

while $|u(t)| \leq R$ and $|\varphi(t; t_0, x_0, u(\cdot))| \geq \gamma(R)$ for $t \in [t_1, t_2]$. This is a contradiction to (1.1). □

Proof of the necessary part. Of course, the necessary part of Theorem 1.1 is more difficult, since it requires the construction of $V(t, x)$. We begin by introducing some notation and by proving one lemma.

For $t > 0, x \in \mathbb{R}^n$ $(x \neq 0)$, we define a subset of admissible inputs:

$$U(t, x) := \{u(\cdot) : \exists c > 0 \text{ such that } |u(s)| \leq \min_{0 \leq \theta \leq t} |\varphi(\theta; t, x, u(\cdot))| - c \quad \forall s \geq 0\}.$$

The definition of $U(t, x)$ can be extended to the case $t = 0$ by taking $U(0, x) = \{0\}$, where 0 denotes the zero input.

LEMMA 1.1. *Assume that* (0.1) *has the UBIBS property. We set* $\eta = \Sigma(1)$. *Then,* $U(t, x) \neq \emptyset$ *for all* $x \in H^\eta$, *for all* $t \geq 0$.

Proof. We prove that $u(\cdot) \equiv 0 \in U(t, x)$ for all $t > 0$ and $x \in H^\eta$. The case $t = 0$ follows trivially from the definition. When $t \neq 0$, we consider a solution $\varphi(\cdot; t, x, 0)$. Since it is continuous, $|\varphi(\cdot; t, x, 0)|$ has a minimum at a point $\tau \in [0, t]$. Let us assume by contradiction that $\varphi(\tau; t, x, 0) = 0$. By uniqueness of solutions, $x = \varphi(t; \tau, 0, 0)$. Then, according to the UBIBS stability property (applied with $R = 1$), we should have $|x| \leq \Sigma(1)$. But this is impossible, since $|x| > \eta = \Sigma(1)$.

Thus, it follows that $\min_{0 \leq \theta \leq t} |\varphi(\theta; t, x, 0)| > 0$, and there exists $c > 0$ such that $0 \equiv |u(s)| < \min_{0 \leq \theta \leq t} |\varphi(\theta; t, x, 0)| - c$ for each $s \geq 0$. □

We are now ready to define a function $V(t, x)$. As in Lemma 1.1, let $\eta = \Sigma(1)$. For each $t \geq 0$ and each $x \in H^\eta$, we set

$$V(t, x) := \inf_{u(\cdot) \in U(t,x)} \min_{s \in [0,t]} |\varphi(s; t, x, u(\cdot))|. \tag{1.2}$$

The proof that this function actually fulfills all the requirements of Theorem 1.1 will be accomplished through several steps.

Step 1. There exists $b \in \mathcal{K}^\infty$ such that $V(t, x) \leq b(|x|)$ for $x \in H^\eta$.

The proof of Step 1 is obvious: indeed, from (1.2) it turns out immediately that $V(t, x) \leq |x|$.

Step 2. There exists $a \in \mathcal{K}^\infty$ such that $a(|x|) \leq V(t, x)$ for $x \in H^\eta$.

To begin with, we remark that $\Sigma^{-1}(r)$ is defined for $r \in [\Sigma(0), +\infty)$, where $\Sigma(0) < \eta$. Moreover, Σ^{-1} is continuous, strictly increasing on its domain, and $\lim_{r \to +\infty} \Sigma^{-1}(r) = +\infty$. We prove that the inequality

$$\Sigma^{-1}(|x|) \leq V(t, x) \tag{1.3}$$

holds for $x \in H^\eta$. According to (1.2), for $t \geq 0, x \in H^\eta$, and every fixed $\varepsilon > 0$ there exist $u(\cdot) \in U(t, x)$ and $\tau \in [0, t]$ such that

$$|\varphi(\tau; t, x, u(\cdot))| < V(t, x) + \varepsilon.$$

Let $\xi = \varphi(\tau; t, x, u(\cdot))$ and set $R = V(t, x) + \varepsilon$. Therefore

$$\min_{s \in [0,t]} |\varphi(s; t, x, u(\cdot))| < R.$$

Since $u(\cdot) \in U(t,x)$, we have $|u(s)| \leq R$ for each $s \geq 0$ as well. Applying the definition of UBIBS stability, we obtain

$$|x| = |\varphi(t;\tau,\xi,u(\cdot))| \leq \Sigma(R) = \Sigma(V(t,x)+\varepsilon),$$

which yields

$$\Sigma^{-1}(|x|) \leq V(t,x)+\varepsilon.$$

Inequality (1.3) follows since the choice of ε was arbitrary and independent of the pair (t,x). To complete the proof of Step 2, it is sufficient to take any $a \in \mathcal{K}^\infty$ such that $a(r) = \Sigma^{-1}(r)$, for $r > \eta$.

Let us now set $\gamma(r) = \Sigma(r) + \eta$ for $r \geq 0$. By virtue of Remark 0.1, we trivially have the following.

Step 3. γ fulfills (ii) of Theorem 1.1.

Thus, it remains to prove the following step.

Step 4. $V(t,x)$ is decreasing along the trajectories of (0.1).

Let us fix $R > 0$ and let $0 \leq t_1 < t_2$. Pick up any admissible input $u(\cdot)$ such that $|u(t)| \leq R$ for each $t \in [t_1,t_2]$, and let $\varphi(t)$ be any solution of (0.1), defined for $t \in [t_1,t_2]$, corresponding to the input $u(\cdot)$ and lying on the closed region $\overline{H^{\gamma(R)}}$. Finally, we set $x_1 = \varphi(t_1)$ and $x_2 = \varphi(t_2)$. Since $\gamma(R) > \eta$, the values $V(t_1,x_1)$ and $V(t_2,x_2)$ are well defined.

Claim A.

$$V(t_2,x_2) \leq \min_{t_1 \leq t \leq t_2} |\varphi(t)|.$$

We prove only the case $t_1 > 0$, because the case $t_1 = 0$ is a simplified version of this one. Let us consider the admissible input:

$$u_0(t) = \begin{cases} u(t), & t \in [t_1,t_2], \\ 0, & t \notin [t_1,t_2]. \end{cases}$$

Obviously, $|u_0(t)| \leq R$ for each $t \geq 0$. On the other hand,

$$\varphi(t;t_2,x_2,u_0(\cdot)) = \varphi(t)$$

for $t \in [t_1,t_2]$, so that

$$|\varphi(t;t_2,x_2,u_0(\cdot))| \geq \gamma(R) > \Sigma(R) \geq R \tag{1.4}$$

for $t \in [t_1,t_2]$. Assume that there exists $\theta < t_1$ such that

$$|\varphi(\theta;t_2,x_2,u_0(\cdot))| \leq R.$$

According to the UBIBS stability property, this should imply $|x_2| \leq \Sigma(R)$, a contradiction to (1.4). Hence, we see that

$$|\varphi(t;t_2,x_2,u_0(\cdot))| > R$$

even when $t < t_1$.

The minimum of $|\varphi(\cdot;t_2,x_2,u_0(\cdot))|$ on $[0,t_2]$ exists and, of course, it is strictly greater than R. Hence, there exists some $c > 0$ such that

$$|u_0(t)| \leq R < \min_{s \in [0,t_2]} |\varphi(s;t_2,x_2,u_0(\cdot))| - c$$

for $t \geq 0$. This implies that $u_0(\cdot) \in U(t_2,x_2)$.

We are now ready to prove Claim A. Indeed,

$$\begin{aligned}V(t_2,x_2) &= \inf_{u\in U(t_2,x_2)} \min_{0\le t\le t_2} |\varphi(t;t_2,x_2,u(\cdot))|\\ &\le \min_{0\le t\le t_2} |\varphi(t;t_2,x_2,u_0(\cdot))| \le \min_{t_1\le t\le t_2} |\varphi(t)|\end{aligned}$$

as required.

To carry on the proof of Step 4, we shall proceed now by contradiction. Assume that the opposite inequality holds:

$$V(t_1,x_1) < V(t_2,x_2).$$

By definition, there exist $\tau \le t_1$, $u_1(\cdot) \in U(t_1,x_1)$, and $\xi_1 \in \mathbb{R}^n$ such that $\xi_1 = \varphi(\tau;t_1,x_1,u_1(\cdot))$ and

$$V(t_1,x_1) \le |\xi_1| < V(t_2,x_2). \tag{1.5}$$

Claim B.

$$\min_{t\le t_1} |\varphi(t;t_1,x_1,u_1(\cdot))| > R.$$

Otherwise, for some $\tilde t \le t_1$ we should have

$$|\tilde\xi| = |\varphi(\tilde t;t_1,x_1,u_1(\cdot))| \le R.$$

Since $u_1(\cdot)\in U(t_1,x_1)$, we should have

$$|u_1(t)| < |\tilde\xi| \le R$$

for $t \ge 0$, as well. Then, the UBIBS stability property should imply $|x_1| \le \Sigma(R)$, and this is a contradiction (recall that $x_1 = \varphi(t_1) = \varphi(t_1;t_1,x_1,u_1(\cdot)) \in \overline{H^{\gamma(R)}}$ and $\gamma(R) \ge \Sigma(R)$).

Claim B is thus proved. We now define

$$u_2(t) = \begin{cases} u(t), & t\in[t_1,t_2],\\ u_1(t), & t\notin[t_1,t_2].\end{cases}$$

Of course,

$$\varphi(t;t_2,x_2,u_2(\cdot)) = \begin{cases} \varphi(t;t_1,x_1,u_1(\cdot)), & t\in[0,t_1),\\ \varphi(t), & t\in[t_1,t_2].\end{cases}$$

Claim C.

$$u_2(\cdot)\in U(t_2,x_2).$$

We need to show that

$$|u_2(t)| \le \min_{0\le s\le t_2} |\varphi(s;t_2,x_2,u_2(\cdot))| - c$$

for some $c>0$ and $t\ge 0$. From (1.5) and Claim A it follows that

$$\min_{0\le s\le t_1} |\varphi(s;t_1,x_1,u_1(\cdot))| < V(t_2,x_2) \le \min_{t_1\le s\le t_2} |\varphi(s)|.$$

In other words, $|\varphi(\cdot;t_2,x_2,u_2(\cdot))|$ reaches its minimum on the interval $[0,t_1]$. Hence,

$$\min_{0\le s\le t_2}|\varphi(s;t_2,x_2,u_2(\cdot))| = \min_{0\le s\le t_1}|\varphi(s;t_1,x_1,u_1(\cdot))|. \tag{1.6}$$

Since $u_1(\cdot)\in U(t_1,x_1)$, there exists $c_1>0$ such that

$$|u_1(t)|\le \min_{0\le s\le t_1}|\varphi(s;t_1,x_1,u_1(\cdot))|-c_1$$

for all $t\ge 0$. But $u_1(\cdot)$ and $u_2(\cdot)$ coincide for $t<t_1$ and $t>t_2$. Taking into account (1.6) we therefore have

$$|u_2(t)|\le \min_{0\le s\le t_2}|\varphi(s;t_2,x_2,u_2(\cdot))|-c_1 \tag{1.7}$$

for $t<t_1$ and $t>t_2$. On the other hand, for $t\in[t_1,t_2]$ we have $|u_2(t)|=|u(t)|\le R$. According to Claim B and the continuity of solutions, there exists $c_2>0$ such that

$$\min_{0\le s\le t_1}|\varphi(s;t_1,x_1,u_1(\cdot))|-c_2>R$$

or, from (1.6),

$$\min_{0\le s\le t_2}|\varphi(s;t_2,x_2,u_2(\cdot))|-c_2>R\ge|u(t)|.$$

Taking $c=\min\{c_1,c_2\}$, we finally see that (1.7) holds even when $t\in[t_1,t_2]$. This shows that $u_2(\cdot)\in U(t_2,x_2)$ and Claim C is proved.

We can now get the conclusion. Claim C implies that

$$V(t_2,x_2)\le \min_{0\le s\le t_2}|\varphi(s;t_2,x_2,u_2(\cdot))|.$$

On the other hand, it is clear that

$$\xi_1=\varphi(\tau;t_1,x_1,u_1(\cdot))=\varphi(\tau;t_2,x_2,u_2(\cdot))$$

and that $V(t_2,x_2)\le|\xi_1|$. Comparing this last conclusion with (1.5), we obtain a contradiction. The proof of Step 4 and of the necessary part of Theorem 1.1 is completed. □

Remark 1.1. In general, it is not possible to construct a continuous Liapunov function $V(t,x)$ for any UBIBS-stable system (0.1). As a counterexample, we can take the scalar system $\dot{x}=f(x)+bu$, where $f(x)$ is the function defined in [8, p. 269], and $b=0$. It is clear that the system is UBIBS-stable. If $V(t,x)$ is a continuous weak Liapunov function, $V(t,x)$ also should be a continuous Liapunov function for the Lagrange-stable equation $\dot{x}=f(x)$. But it is well known that such a function cannot exist (see [4]).

Remark 1.2. The proof of Theorem 1.1 can be carried out even if the set $U(t,x)$ is replaced by

$$U_0(t,x)=\{u(\cdot)\ \text{ such that } |u(s)|\le \min_{0\le\theta\le t}|\varphi(\theta;t,x,u(\cdot))|\ \forall s\le 0\}$$

(see [3], where a preliminary version of Theorem 1.1 was showed). In this case, Lemma 1.1 becomes obvious and the proof of Step 4 is simplified as well. However, if the function V is defined by means of the set $U_0(t,x)$, the development of the next section becomes impossible. For this reason, we preferred to adopt from the beginning the stronger construction based on the set $U(t,x)$.

Remark 1.3 (time-invariant systems). If we consider a time-invariant system

$$\dot{x} = f(x,u)$$

and we assume the existence and uniqueness of solutions for all $t \in \mathbb{R}$, we are able to obtain a time-invariant Liapunov function $V(x)$ satisfying Theorem 1.1.

In this case we define the set of admissible inputs as

$$U(x) = \Big\{ u(\cdot) \ : \ |u(s)| \le \inf_{\theta \le 0} |\varphi(\theta; x, u(\cdot))| \Big\}.$$

Note that here, according to Remark 1.2, we have taken $c = 0$.

The Liapunov function $V(x)$ can be defined as

$$V(x) = \inf_{u \in U(x)} \ \inf_{\theta \le 0} |\varphi(\theta; x, u(\cdot))|.$$

With these definitions, the proof of Theorem 1.1 works, with minor modifications.

2. An upper semicontinuous Liapunov function. The goal of this section is to prove that, under additional assumptions, the Liapunov function constructed in the previous section is at least semicontinuous. To begin with, the next lemma shows that the definition of the set $U(t,x)$ introduced in the previous section can be reformulated in an apparently stronger form.

LEMMA 2.1. *For any pair* (t,x),

$$\begin{aligned} U(t,x) = \{\ u(\cdot) :\ & \exists\delta > 0,\ \exists c > 0 \text{ such that} \\ & |u(s)| \le \min\nolimits_{0 \le \theta \le t+\delta} |\varphi(\theta; t, x, u(\cdot))| - c \ \ \forall s \ge 0\ \}. \end{aligned}$$

The proof is an easy consequence of continuity of solutions, and it is left to the reader.

As already suggested, in order to proceed we need to strengthen the hypotheses on system (0.1). So, from now on, we shall consider system (0.1) under the following additional assumption.

Assumption (L).

(i) $f(t,x,u)$ is locally bounded.

(ii) $f(t,x,u)$ is locally Lipschitz with respect to x. More precisely, we require that for each initial pair (t_0,x_0) and each admissible input $u(t)$, there exists a compact neighborhood Ω of (t_0,x_0) in $\mathbb{R}^+ \times \mathbb{R}^n$ and a positive function $L(t)$ such that $L(t)$ is integrable and

$$|f(t,x,u(t)) - f(t,y,u(t))| \le L(t)|x-y| \tag{2.1}$$

for each pair $(t,x), (t,y) \in \Omega$.

The main result of this section is based on Lemma 2.2. The arguments of its proof are classical (see, for instance, [9, section 5]). A short sketch of the proof is reported, for the reader's convenience. Let

$$\mathcal{B}_0(\delta) := \{(t,x) \in [0,+\infty) \times \mathbb{R}^n \ : \ |t-t_0| < \delta,\ |x-x_0| < \delta\},$$

where (t_0,x_0) is a fixed point of $[0,+\infty) \times \mathbb{R}^n$.

LEMMA 2.2. *If* (0.1) *satisfies Assumptions* (H) *and* (L), *for any admissible input* $u(\cdot)$ *there exist* $K > 0$, $\rho \in (0,1)$ *such that, for all* $\delta \in (0,\rho)$ *and all* $(t,x) \in \mathcal{B}_0(\delta)$,

$$|\varphi(s;t,x,u(\cdot)) - \varphi(s;t_0,x_0,u(\cdot))| \leq K\delta \quad \forall s \in [0, t_0+1].$$

Proof. Let t_0, x_0, and the admissible input $u(t)$ be fixed. The solution $\varphi(s;t_0,x_0,u(\cdot))$ has compact image I on the interval $[0,t_0+1]$. Let N be the tubular neighborhood of radius 1 of I, and let $L(t)$ be a function such that (2.1) holds for any $(t,x),(t,y) \in N$. Moreover, let M be an upper bound for the norm of $f(t,x,u(t))$ on N. Finally, let ρ be such that

$$\rho \leq \frac{1}{2(1+M)}\ e^{-\int_0^{t_0+1} L(s)ds} < 1$$

and

$$\mathcal{B}_0(\rho) \subseteq N.$$

We claim that for each $(t,x) \in \mathcal{B}_0(\rho)$, $\varphi(s;t,x,u(\cdot)) \in N$ for each $s \in [0,t_0+1]$. We study separately the intervals $[0,t_0]$ and $[t_0,t_0+1]$, and we see the proof in the first case; in the second one, the proof is analogous, and it is left to the reader.

By contradiction, let us assume that there exists $s \in [0,t_0]$ such that $\varphi(s;t,x,u(\cdot)) \notin N$. Let

$$\tau = \sup\{s \in [0,t_0] \ : \ \varphi(s;t,x,u(\cdot)) \notin N\}.$$

Since (2.1) holds in the interval $[\tau,t_0]$, we have

$$\begin{aligned} &|\varphi(\tau;t,x,u(\cdot)) - \varphi(\tau;t_0,x_0,u(\cdot))| \\ &\leq |x-x_0| + \left|\int_t^\tau |f(\theta;\varphi(\theta;t,x,u(\cdot)),u(\theta)) - f(\theta;\varphi(\theta;t_0,x_0,u(\cdot)),u(\theta))|\ d\theta\right| \\ &\quad + \left|\int_{t_0}^t f(\theta;\varphi(\theta;t_0,x_0,u(\cdot)),u(\theta))\ d\theta\right| \\ &\leq |x-x_0| + \left|\int_t^\tau L(\theta)\,|\varphi(\tau;t,x,u(\cdot)) - \varphi(\tau;t_0,x_0,u(\cdot))|\,d\theta\right| + M\,|t-t_0| \end{aligned}$$

since $|x-x_0| + M\,|t-t_0| \leq (1+M)\rho$, and by Gronwall's inequality we have

$$\leq (1+M)\rho e^{\left|\int_t^\tau L(\theta)\ d\theta\right|} \leq (1+M)\rho e^{\int_0^{t_0+1} L(\theta)\ d\theta} \leq \frac{1}{2}.$$

Therefore, $\varphi(\tau;t,x,u(\cdot)) \in N$ together with $\varphi(\tau-s;t,x,u(\cdot))$ for any small enough s, and this is a contradiction to the choice of τ.

Let us now consider any $\delta \in (0,\rho)$. For $(t,x) \in \mathcal{B}_0(\delta)$, the image of the corresponding solution lies in N, so that (2.1) applies, with the same $L(t)$ used before. By repeating the argument based on Gronwall's inequality, we get

$$|\varphi(s;t,x,u(\cdot)) - \varphi(s;t_0,x_0,u(\cdot))| \leq K\delta \quad \forall s \in [0,t_0+1],$$

where $K = (1+M)e^{\int_0^{t_0+1} L(s)ds}$. □

THEOREM 2.1. *If the input system* (0.1) *satisfies the UBIBS property and Assumptions* (H) *and* (L)*, then there exists an UBIBS-weak upper semicontinuous Liapunov function.*

Proof. We show that, under Assumption (L), the Liapunov function defined in Theorem 1.1 is upper semicontinuous.

Step 1. For any pair (t_0, x_0), if $u \in U(t_0, x_0)$, there exists $\delta_0 > 0$ such that $u \in U(t, x)$ for all $(t, x) \in \mathcal{B}_0(\delta_0)$.

By Lemma 2.1, there exist $\delta_1 > 0$, $c > 0$ such that

$$|u(s)| \leq \min_{0 \leq \theta \leq t_0 + \delta_1} |\varphi(\theta; t_0, x_0, u(\cdot))| - c \quad \forall s \geq 0. \tag{2.2}$$

Let $K > 0$ be as in Lemma 2.2. Then, for each $\delta \in (0, \rho)$ we have

$$|\varphi(\theta; t_0, x_0, u(\cdot))| \leq |\varphi(\theta; t, x, u(\cdot))| + K\delta, \qquad \theta \in [0, t_0 + 1] \tag{2.3}$$

for any $(t, x) \in \mathcal{B}_0(\delta)$.

Let us choose $\delta_0 < \min\{\rho, \delta_1, \frac{c}{K}\}$, and let us set $c' = c - K\delta_0 > 0$. By (2.2) and (2.3), if $(t, x) \in \mathcal{B}_0(\delta_0)$, then

$$\begin{aligned}
|u(s)| &\leq \min_{0 \leq \theta \leq t_0 + \delta_1} |\varphi(\theta; t_0, x_0, u(\cdot))| - c \\
&\leq \min_{0 \leq \theta \leq t_0 + \delta_0} |\varphi(\theta; t_0, x_0, u(\cdot))| - c \\
&\leq \min_{0 \leq \theta \leq t_0 + \delta_0} |\varphi(\theta; t, x, u(\cdot))| - c + K\delta_0 \\
&\leq \min_{0 \leq \theta \leq t} |\varphi(\theta; t, x, u(\cdot))| - c + K\delta_0 \\
&\leq \min_{0 \leq \theta \leq t} |\varphi(\theta; t, x, u(\cdot))| - c' \quad \forall s \geq 0.
\end{aligned}$$

This means that $u(s) \in U(t, x)$ for all $(t, x) \in \mathcal{B}_0(\delta_0)$.

Step 2. $V(t, x)$ is upper semicontinuous.

Let V be defined at (t_0, x_0). By construction, for all $\varepsilon > 0$ there exist $v \in U(t_0, x_0)$ and $\tau \in [0, t_0]$ such that

$$|\varphi(\tau; t_0, x_0, v(\cdot))| \leq V(t_0, x_0) + \frac{1}{2}\varepsilon. \tag{2.4}$$

By Step 1, there exists $\delta_0 > 0$ such that $v \in U(t, x)$ for all $(t, x) \in \mathcal{B}_0(\delta_0)$. Therefore, by the definition of $V(t, x)$,

$$V(t, x) \leq |\varphi(\tau; t, x, v(\cdot))| \quad \forall (t, x) \in \mathcal{B}_0(\delta_0). \tag{2.5}$$

By Lemma 2.2, there exists $K = K(v) > 0$ such that, for all $\delta < \delta_0$ and all $(t, x) \in \mathcal{B}_0(\delta)$,

$$|\varphi(\tau; t, x, v(\cdot))| \leq |\varphi(\tau; t_0, x_0, v(\cdot))| + K\delta. \tag{2.6}$$

Summing up (2.4), (2.5), and (2.6) we get

$$\begin{aligned}
V(t, x) \leq |\varphi(\tau; t, x, v(\cdot))| &\leq |\varphi(\tau; t_0, x_0, v(\cdot))| + K\delta \\
&\leq V(t_0, x_0) + \frac{1}{2}\varepsilon + K\delta.
\end{aligned}$$

If we choose $\delta < \min\left(\delta_0, \frac{\varepsilon}{2K}\right)$, we get

$$V(t, x) < V(t_0, x_0) + \varepsilon$$

for all $(t, x) \in \mathcal{B}_0(\delta)$. $\square$

3. Monotonicity and generalized derivatives. As far as Liapunov-like functions are concerned, the regularity issue is strictly related to the monotonicity condition (iii) of Theorem 1.1. For instance, if the function $V(t,x)$ turns out to be differentiable for each $t>0$ and for $x \in H^\eta$, condition (iii) of Theorem 1.1 can be reformulated in the following way:

$$\forall R>0,\ \forall x \in H^\eta,\ \forall u \in \mathbb{R}^m,$$
$$|u| \le R,\ |x| \ge \gamma(R) \Longrightarrow \frac{\partial V}{\partial t}(t,x) + \nabla_x V(t,x)\cdot f(t,x,u) \le 0, \quad \text{a.e. } t \ge 0. \tag{3.1}$$

The obvious advantage of (3.1), with respect to (iii) of Theorem 1.1, is that it can be checked without explicitly solving the differential equation. We are interested in getting some characterization of (iii) in terms of a differential inequality even with the less regular Liapunov function we are able to obtain.

It is well known that when $V(t,x)$ is locally Lipschitz, its monotonicity along a trajectory $x=\varphi(t)$ can be checked by looking at the sign of one of the Dini derivatives of $V(t,\varphi(t))$ (see [15]). Unfortunately, the Liapunov function we get is only upper semicontinuous. Therefore, we need to adjust previous results to our weaker assumptions. We start with the following lemma, which establishes a relation between monotonicity of semicontinuous functions of a single variable and Dini derivatives. The lemma can be obtained as a consequence of [6, Theorem 1.4], or as an easy generalization of the argument used in [10, p. 347].

LEMMA 3.1. *Let $\psi : [a,b] \to \mathbb{R}$ be upper semicontinuous. Then*

(i) *ψ is nonincreasing on $[a,b]$ if and only if $\overline{D^-}\psi(t) \le 0$ for each $t \in [a,b]$;*

(ii) *ψ is nondecreasing on $[a,b]$ if and only if $\underline{D^+}\psi(t) \ge 0$ for each $t \in [a,b]$.*

This result, together with the use of contingent derivatives, allows us to get a characterization of monotonicity of $V(t,x)$ along trajectories by means of a differential inequality. We recall the following definition.

DEFINITION 3.1. *Given a function $g : \mathbb{R}^N \to \mathbb{R}$, the upper left contingent generalized directional derivative of g at z, with respect to $v \in \mathbb{R}^N$, is*

$$\overline{D_K^-}g(z,v) = \limsup_{\substack{h\to 0^- \\ w\to v}} \frac{g(z+hw)-g(z)}{h}.$$

When g is locally Lipschitz, $\overline{D_K^-}g(z,v)$ is equal to the corresponding directional Dini derivative, but in general $\overline{D_K^-}g(z,v)$ is greater than the corresponding Dini derivative.

Since we are interested in the case $N=1+n$, $z=(t,x)$, and $v=(1,w)$, we shall use the notation $\overline{D_K^-}g(t,x,w)$ instead of $\overline{D_K^-}g((t,x),(1,w))$.

In order to state the main result of this section, we introduce appropriate assumptions.

Assumption (C).

(i) $f(t,x,u)$ is continuous.

(ii) The class of admissible inputs is restricted to the one of continuous maps $u : [0,+\infty) \to \mathbb{R}^m$.

Under these hypotheses, any solution $\varphi(t)$ corresponding to an admissible input is a classical solution, and it satisfies (0.1) everywhere on its domain.

THEOREM 3.1. *Let* (0.1) *satisfy Assumption* (C), *and let* $V(t,x)$ *be an upper semicontinuous function satisfying the following property:* $\exists\gamma \in \mathcal{K}^\infty$ *such that,* $\forall R > 0$, $\forall x \in \mathbb{R}^n$, $\forall u \in \mathbb{R}^m$, $\forall t \geq 0$,

$$|u| \leq R,\ |x| \geq \gamma(R) \quad \Longrightarrow \quad \overline{D_k^-} V(t,x,f(t,x,u)) \leq 0.$$

Then V *is decreasing along the solutions of* (0.1)*; that is, condition* (iii) *of Theorem* 1.1 *is fulfilled.*

Proof. Let $\psi(t) = V(t,\varphi(t))$, where $\varphi(t)$ is as in (iii) of Theorem 1.1 and $u(t)$ is the corresponding input. By Lemma 3.1, it is sufficient to prove that $\overline{D^-}\psi(t) \leq 0$ for each $t \in [t_1,t_2]$. We have

$$\begin{aligned}\overline{D^-}\psi(t) &= \limsup_{h\to 0^-} \frac{\psi(t+h)-\psi(t)}{h}\\ &= \limsup_{h\to 0^-} \frac{V(t+h,\varphi(t+h)) - V(t,\varphi(t))}{h}\\ &= \limsup_{h\to 0^-} \frac{V(t+h,\varphi(t)+h\dot\varphi(t)+o(h)) - V(t,\varphi(t))}{h}.\end{aligned}$$

We write $o(h) = h\alpha(h)$, where $\lim_{h\to 0}\alpha(h) = 0$. Then

$$\overline{D^-}\psi(t) = \limsup_{h\to 0^-} \frac{V(t+h,\varphi(t)+h[\dot\varphi(t)+\alpha(h)]) - V(t,\varphi(t))}{h}.$$

Notice that $w(h) = \dot\varphi(t) + \alpha(h) \to \dot\varphi(t)$ for $h \to 0$. Thus, if we set $x = \varphi(t)$ and $v = \dot\varphi(t) = f(t,x,u(t))$, we get

$$\begin{aligned}\overline{D^-}\psi(t) &\leq \limsup_{\substack{h\to 0^-\\ w\to v}} \frac{V(t+h,x+hw) - V(t,x)}{h}\\ &= \overline{D_k^-}V(t,x,v) = \overline{D_k^-}V(t,x,f(t,x,u(t))).\end{aligned}$$

The conclusion is immediate. □

MAXIMAL SOLUTIONS IN DECENTRALIZED SUPERVISORY CONTROL*

ARD OVERKAMP† AND JAN H. VAN SCHUPPEN‡

Abstract. The decentralized supervisory control problem is to construct for a discrete-event system a set of supervisors each observing only part of the system and each controlling only part of the events such that the interconnection of the system and the supervisors meets control objectives of safety and liveness. Definitions are provided of the concepts of a maximal solution, of a Nash equilibrium, and of a strong Nash equilibrium for a set of supervisors with as order relation the inclusion relation on the set of closed-loop languages. The main result is that a set of supervisors is a maximal solution if and only if it is a strong Nash equilibrium. A procedure to determine a Nash equilibrium is described and illustrated by an example. There is no guarantee that the procedure halts in finite time. However, in the case that it halts in finite time, then it is proven that a Nash equilibrium is obtained.

Key words. discrete-event system, decentralized supervisory control, maximal solution, Nash equilibrium

1. Introduction.

The purpose of this paper is to show how the concept of a Nash equilibrium can be used to obtain maximal solutions of supervisors for decentralized control of discrete-event systems.

Decentralized supervisory control problems arise very naturally in protocol design problems for computer and communication networks but also occur in transportation and manufacturing problems. The network may be modeled as a discrete-event system. The physical separation between the sender and the receiver implies that observations of the operation of the network are available only locally. The problem is then to synthesize a set of controllers in a protocol problem—one at the sender end and one at the receiver end of the communication channel. The interconnection of the network with the supervisors has then to meet control objectives of safety and liveness according to a specification.

Decentralized control is a conceptually difficult problem. Results are available mainly for decentralized control of linear systems and of stochastic systems (see the survey [18]). Fundamental results are partly based on the analogy with game, dynamic game, and team problems. The decentralized supervisory control problem was formulated by R. Cieslak et al. (see [2]), in which the alternating bit protocol is used as an example. The authors presented a necessary and sufficient condition for the existence of a controller for which the closed-loop language equals a specified language. A generalization of this result to the closed-loop language was fit between an upper and lower bound, and an analysis of the set of supervisors was derived by K. Rudie and W. M. Wonham (see [14, 17]). These authors also studied the protocol synthesis problem (see [15, 16]). P. Kozak and W. M. Wonham proposed another solution procedure based on projection of the supremal supervisor (see [4]). Recent work on

decentralized supervisory control of nondeterministic systems using prioritized synchronization is presented by R. Kumar and M.A. Shayman (see [5]). The synthesis procedures proposed so far do not satisfy the need of engineering decentralized control problems. The performance of the resulting controllers is in general too conservative.

The approach of this paper is based on an analogy with dynamic game problems. The restriction is imposed to consider a model with only two supervisors. The concept of a maximal solution of a pair of supervisors is defined with respect to the inclusion relation on the set of languages of the closed-loop system. Because the set of pairs of supervisors is a large discrete set, there may be many such pairs. The determination of a maximal pair of supervisors is achieved indirectly. The concept of a strong Nash equilibrium of a pair of supervisors is introduced based on analogy with game theory. It is shown that a pair of supervisors that is a strong Nash equilibrium is also a maximal solution and conversely. A procedure is proposed to compute a strong Nash equilibrium of a pair of supervisors. The procedure is illustrated with an example.

A description of the paper by section follows. Section 2 contains a definition of a discrete-event system that differs slightly from the case usually considered in the literature, the formulation of the decentralized supervisory control problem, and the definition of maximal solution and Nash equilibrium. The result, that a pair of supervisors that is a strong Nash equilibrium is also a maximal solution and conversely, is established in section 3. The procedure for a Nash equilibrium is stated in section 4. Section 5 contains conclusions.

The results of this paper were announced in the conference paper [11] and form part of the thesis [10, Chap. 6] of the first author.

2. Problem formulation.

2.1. Framework.

A simple framework will be introduced that allows us to concentrate on the decentralized aspects of the control problem.

Throughout this paper denote the global set of events by Σ, the global set of controllable events by Σ_{c}, the uncontrolled system by G, and the specification by E. The discrete-event system will be modeled as a finite state automaton with the notation $G = (\Sigma, Q, \delta, q_0)$, with Q the discrete state space, $\delta : \Sigma \times Q \to Q$ the transition function, and q_0 the initial state. For a string $s \in \Sigma^*$ denote by $\bar{s} \subseteq \Sigma^*$ the set of prefixes of this string.

Definition 2.1. *A* supervisor *or* discrete-event controller *is defined by a triple*

$$S = (\Sigma(S),\ \Sigma_{\mathrm{c}}(S),\ \gamma(S)),$$

where

$$\Sigma(S) \subseteq \Sigma, \quad \Sigma_{\mathrm{c}}(S) \subseteq \Sigma(S), \quad \gamma(S) : p_s(\mathrm{L}(G)) \to 2^{\Sigma_{\mathrm{c}}(S)},$$

and p_s is the projection from Σ to $\Sigma(S)$.

Define the controlled language of supervisor S with respect to G or, for short, the language *of S as*

$$\mathrm{L}(S/G) = \{s \in \mathrm{L}(G) : \forall v\sigma \in \bar{s}, \sigma \notin \gamma(S, p_s(v))\}.$$

Note that $\mathrm{L}(S/G) \subseteq \Sigma^*$.

Let $\mathcal{C}(\Sigma_a)$ denote the set of all supervisors S with event set $\Sigma(S) = \Sigma_a$ and controllable event set $\Sigma_c(S) = \Sigma_c \cap \Sigma_a$. The function $\gamma(S)$ will be called the control law *of supervisor S. Note that $\gamma(S, s)$ is defined for all $s \in p_s(\mathrm{L}(G))$.*

The control law $\gamma(S)$ maps each trace $s \in p_s(\mathrm{L}(G))$ onto the set of disabled events. In the literature, often the set of enabled events is specified [13]. Both approaches are equivalent.

In the definition above the set of controllable events is taken to be contained in the set of events observable by the supervisor. In general it is possible that a supervisor can influence events it cannot observe. In [10, Sect. 5.2] it is shown how in this situation a control problem can be remodeled such that all controllable events are observable. As that reference is not widely available, the approach is briefly sketched. The idea is based on flags. Controllable, unobservable events are usually implemented with flags. If a flag is set, then the event can execute. If the flag is cleared, then the event is disabled. The plant is remodelled such that it includes the events that set and clear the flags. These so-called flag events are observable and controllable. In this remodeled plant the original events are no longer controllable as they are enabled and disabled via the flag events. If the flag events are, via projection, removed from the language of the remodeled plant, then the language of the original plant is obtained.

Attention will be focused on the decentralized aspects of the supervisory control problem. Marking, nondeterminism, or failure semantics will not be considered. The argument for a simple framework also justifies the restriction to only two supervisors. The authors are confident that in the future the results can be extended to more general frameworks and more supervisors.

The basic supervisory control problem needs to be redefined for the new framework. Note that supervisors, as stated in Definition 2.1, can disable only controllable events. So they are always complete. It is not necessary to add a completeness requirement as is done in [13].

Definition 2.2. *Consider a discrete-event system and a legal language $L(E) \subset \Sigma^*$. The basic supervisory control problem (BSCP) is to find a supervisor S, such that $\mathrm{L}(S/G) \subseteq \mathrm{L}(E)$.*

Ramadge and Wonham showed that there exists a unique supremal solution to this control problem. This supremal can be effectively computed [13]. It is characterized by a language called the supremal controllable sublanguage contained in $\mathrm{L}(G) \cap \mathrm{L}(E)$. As the notion of controllability will not be used any further, we refer the interested reader to the given reference for more information. The only aspect of controllability that will be used in this chapter is that the supremal controllable language can be effectively computed.

Definition 2.3. *Let $K^\uparrow$ be the supremal controllable sublanguage contained in $\mathrm{L}(G) \cap \mathrm{L}(E)$. The* supremal supervisor*, denoted by $S^\uparrow$, is defined by*

$$\gamma(S^\uparrow, s) = \begin{cases} \{\sigma \in \Sigma_c : s\sigma \in \mathrm{L}(G) \text{ and } s\sigma \notin K^\uparrow\}, & \text{if } s \in K^\uparrow, \\ \emptyset, & \text{otherwise.} \end{cases}$$

It is not difficult to show that $\mathrm{L}(S^\uparrow/G) = K^\uparrow$. As $S^\uparrow$ is supremal it holds for all supervisors S which solve the given BSCP, that $\mathrm{L}(S/G) \subseteq \mathrm{L}(S^\uparrow/G)$.

In this paper it will be assumed that the BSCP is already solved and that the supremal supervisor $S^\uparrow$ is given. It is sufficient to find a supervisor that implements $S^\uparrow$, with respect to the implementation relation defined below. Proposition 2.7 shows that this is a valid approach. A supervisor implements the supremal supervisor if and only if the supervisor solves the BSCP.

Definition 2.4. *Let S_a, S_b be two supervisors such that $\Sigma(S_a) = \Sigma(S_b)$. Supervisor S_a* implements *S_b, denoted by $S_a \sqsubseteq S_b$, if*

$$\gamma(S_b, s) \subseteq \gamma(S_a, s) \quad \forall\, s \in p(\mathrm{L}(S_a/G)),$$

where p is the projection on $\Sigma(S_a) = \Sigma(S_b)$.

Supervisor S_a implements S_b if it disables at least as much as S_b.

LEMMA 2.5. *Let S_a, S_b be two supervisors such that $\Sigma(S_a) = \Sigma(S_b)$.*

$$S_a \sqsubseteq S_b \Rightarrow \mathrm{L}(S_a/G) \subseteq \mathrm{L}(S_b/G).$$

The proof of the preceding lemma and that of Proposition 2.7 are simple and may be found in [10, Chap. 6].

The following example will show why the converse of Lemma 2.5 does not hold.

Example 2.6. Let G be the system such that $\mathrm{L}(G) = \{\varepsilon, \mathtt{a}\}$. Define S_a by $\gamma(S_a, \varepsilon) = \emptyset$ and $\gamma(S_a, \mathtt{a}) = \emptyset$. Define S_b by $\gamma(S_b, \varepsilon) = \emptyset$ and $\gamma(S_a, \mathtt{a}) = \{\mathtt{a}\}$. Then $\mathrm{L}(S_a/G) = \{\varepsilon, \mathtt{a}\} = \mathrm{L}(S_b/G)$, but $\gamma(S_b, \mathtt{a}) \not\subseteq \gamma(S_a, \mathtt{a})$. So $S_a \not\sqsubseteq S_b$. □

In [10, Thm. 2.17] it was shown that in the failure-semantics-based framework a supervisor solves the BSCP if and only if it implements the supremal supervisor. Proposition 2.7 states the same result for the framework of this paper. Because the proof is analogous to that of [10, Thm. 2.17], it is omitted.

PROPOSITION 2.7. *Let the uncontrolled system G, the specification E, and the set of controllable events Σ_c be given. Let $S^\uparrow$ be the supremal supervisor of the BSCP.*

$$\forall S \in \mathcal{C}(\Sigma),\ S \sqsubseteq S^\uparrow \iff \mathrm{L}(S/G) \subseteq \mathrm{L}(S^\uparrow/G) \iff \mathrm{L}(S/G) \subseteq \mathrm{L}(E).$$

In the rest of this paper we will consider control problems that place extra constraints on the supervisor besides the ones given in the BSCP. Proposition 2.7 states that we can first solve the BSCP to get the supremal supervisor $S^\uparrow$. Next we can look for supervisors that satisfy the extra constraints and that implement $S^\uparrow$. In this last step we can concentrate on the extra requirement. As we are mainly interested in the extra requirements imposed by the decentralized nature of the control problem, we will assume that the first step is already solved and that the supremal supervisor $S^\uparrow$ is given.

DEFINITION 2.8. *The* basic supervisory synthesis problem *(BSSP) is to find a supervisor $S \in \mathcal{C}(\Sigma(S^\uparrow))$ such that $S \sqsubseteq S^\uparrow$.*

Often in the literature supervisors are defined as languages instead of control maps. We choose to use control maps as they allow us to divide the control problem into two steps. In the first step the supremal supervisor is synthesized. In this step the controllability condition plays an important role. In the second step we can concentrate on the decentralized aspect of the control problem. Proposition 2.7 shows that we do not have to consider the controllability condition in this step. If supervisors are defined as languages, then also the problem can be divided into two parts. The synthesis problem of the second part is then defined as follows: find a supervisor S such that $\mathrm{L}(S/G) \subseteq \mathrm{L}(S^\uparrow/G)$ and $\mathrm{L}(S/G)$ is controllable. It is necessary to check for controllability, as $\mathrm{L}(S/G) \subseteq \mathrm{L}(S^\uparrow/G)$ does not imply that $\mathrm{L}(S/G)$ is controllable. So in the second step we still have to consider controllability. Using control maps, we can forget about controllability in the second step and concentrate on the decentralized aspects of the control problem. It is not too difficult to adapt the results of this paper to a language-based approach.

2.2. Decentralized supervisory synthesis problem. Up until now we have only looked at supervisors that can observe the whole event set and that enable or disable all controllable events. Now we will look at the decentralized control problem where we have two supervisors, each observing a part of the event set, and each controlling only part of the controllable events (see Figure 1). The two supervisors

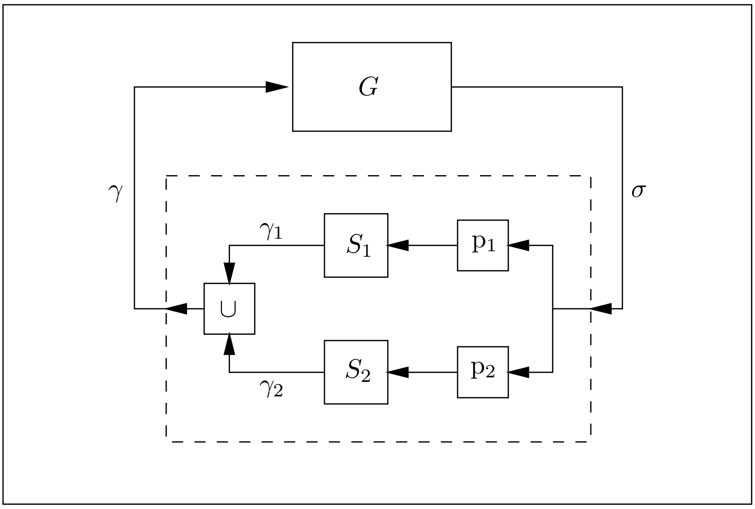

Fig. 1. *The decentralized supervisory control problem.*

together have to control G such that the language of the controlled system is contained in the language of E. Note that the specification is given for the whole controllable system. This is usually referred to as a global specification [14, 17]. If the specification can be decomposed into two local specifications, one for each supervisor, then the decentralized control problem can be reduced to two independent supervisory control problems. In each of these local control problems a single supervisor is synthesized. This control problem has already been solved by F. Lin and W. M. Wonham [7]. In what follows we will assume that the specification is global and cannot be decomposed into local specifications.

As stated before, we will assume the BSCP is already solved and the supremal supervisor $S^{\uparrow}$ is known. By Proposition 2.7 it is sufficient to find a decentralized implementation of $S^{\uparrow}$ to solve the decentralized supervisory control problem.

First it will be defined how two decentralized supervisors co-operate. An event is disabled by the combination of the two supervisors if it is disabled by at least one of them.

Definition 2.9. *Let S_1 and S_2 be two supervisors. The* composition *of S_1 and S_2 is denoted $S_1 \wedge S_2$ and defined by*

$$\begin{aligned}\Sigma(S_1 \wedge S_2) &= \Sigma_1 \cup \Sigma_2,\\ \Sigma_{\mathrm{c}}(S_1 \wedge S_2) &= \Sigma_{\mathrm{c}}(S_1) \cup \Sigma_{\mathrm{c}}(S_2),\\ \gamma(S_1 \wedge S_2, s) &= \gamma(S_1, \mathrm{p}_1(s)) \cup \gamma(S_2, \mathrm{p}_2(s)) \qquad \forall\, s \in \mathrm{p}_{1,2}(\mathrm{L}(G)),\end{aligned}$$

where p_1 *denotes the projection on* $\Sigma(S_1)$, p_2 *denotes the projection on* $\Sigma(S_2)$, *and* $\mathrm{p}_{1,2}$ *denotes the projection on* $\Sigma(S_1 \wedge S_2)$.

Proposition 2.10. $\mathrm{L}(S_1 \wedge S_2/G) \;=\; \mathrm{L}(S_1/G) \cap \mathrm{L}(S_2/G)$.

Proof. The reasoning follows from Definition 2.1.

$$\begin{aligned}& s \in \mathrm{L}(S_1 \wedge S_2/G)\\ &\iff s \in \mathrm{L}(G)\, \forall v\sigma \in \overline{s},\ \sigma \notin \gamma(S_1 \wedge S_2, \mathrm{p}_{1,2}(v))\\ &\iff s \in \mathrm{L}(G)\, \forall v\sigma \in \overline{s},\ \sigma \notin \gamma(S_1, \mathrm{p}_1(v)),\ \sigma \notin \gamma(S_2, \mathrm{p}_2(v))\\ &\iff s \in \mathrm{L}(S_1/G),\ s \in \mathrm{L}(S_2/G)\\ &\iff s \in \mathrm{L}(S_1/G) \cap \mathrm{L}(S_2/G). \qquad \Box\end{aligned}$$

Definition 2.11. *Consider the discrete-event system specified before and a global specification. Let the supremal supervisor $S^{\uparrow}$ be given. Let $\Sigma_1, \Sigma_2 \subseteq \Sigma$ be two event sets such that $\Sigma_1 \cup \Sigma_2 = \Sigma$. The decentralized supervisory synthesis problem (DSSP) is to find a pair of supervisors $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ such that*

$$S_1 \wedge S_2 \sqsubseteq S^{\uparrow}.$$

In this definition we made two important assumptions. The one is that $\Sigma_1 \cup \Sigma_2 = \Sigma$. The other is that, according to the definition of $\mathcal{C}(\Sigma_i)$, the set of controllable events of supervisor S_i, $\Sigma_{\mathrm{c},i}$, is equal to $\Sigma_i \cap \Sigma_{\mathrm{c}}$ for $i = 1, 2$.

Consider the case where $\Sigma_1 \cup \Sigma_2 \subsetneqq \Sigma$. If $\Sigma_{\mathrm{c}} \subseteq \Sigma_1 \cup \Sigma_2$, then we can compute the supremal supervisor under partial observation, with observation alphabet $\Sigma_1 \cup \Sigma_2$. See [2, 6] and section [10, Sect. 5.1]. Equivalently to Proposition 2.7, it can be shown that a supervisor implements this supremal supervisor if and only if it solves the control problem under partial observation. We can assume that this control problem is already solved and that the supremal supervisor under partial observation is given. So this control problem can be reduced to the DSSP.

If $\Sigma_{\mathrm{c}} \nsubseteq \Sigma_1 \cup \Sigma_2$, then the control problem can be remodeled in such a way that all controllable events are observable. See [10, Sect. 5.2].

The other assumption is that $\Sigma_{\mathrm{c},i} = \Sigma_i \cap \Sigma_{\mathrm{c}}$, $i = 1, 2$. That is, the controllable events of supervisor S_i are observable by S_i, and an event that is controllable by $S^{\uparrow}$ and observable by S_i is also controllable by S_i. This is the same constraint as given by Rudie [14, 17] under which decomposability of the closed-loop language is necessary and sufficient for the existence of a decentralized solution. It is argued that in most communication problems these constraints are satisfied. Again, as we want to keep the model simple, we do not consider systems that fail to satisfy this constraint. The authors hope that in the future these constraints can be relaxed.

2.3. Maximal solutions. Traditionally in discrete-event control, supervisors are synthesized that restrict the uncontrolled system as little as possible. A solution is considered optimal if the language of the system controlled by this optimal supervisor is larger than the languages of all other solutions.

Definition 2.12. *Consider the DSSP of Definition* 2.11. *A pair of supervisors* $(S_1^{\uparrow}, S_2^{\uparrow}) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ *is called an* optimal decentralized solution *if it is a solution, i.e.,*

$$S_1^{\uparrow} \wedge S_2^{\uparrow} \sqsubseteq S^{\uparrow}, \tag{1}$$

and for all pairs $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$

$$S_1 \wedge S_2 \sqsubseteq S^{\uparrow} \Rightarrow \mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(S_1^{\uparrow} \wedge S_2^{\uparrow}/G). \tag{2}$$

Recall from [14, 17] the definition of decomposability. A language $K \subseteq \mathrm{L}(G)$ is called *decomposable* if

$$K = \mathrm{p}_1^{-1}(\mathrm{p}_1(K)) \cap \mathrm{p}_2^{-1}(\mathrm{p}_2(K)) \cap \mathrm{L}(G). \tag{3}$$

Rudie showed that, under the given assumptions, there exists a decentralized solution, $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$, such that the language of the controlled system, $\mathrm{L}(S_1 \wedge S_2/G)$, is equal to a given language $K \subseteq \mathrm{L}(G)$ if and only if K is decomposable. The set of decomposable languages is not closed under arbitrary unions. It is therefore not guaranteed that this set contains a unique supremal element. This implies that in general the optimal decentralized solution does not exist. There may exist several, mutually incomparable, maximal solutions.

DEFINITION 2.13. *Consider the DSSP of Definition* 2.11. *A pair of supervisors* $(S_1^{\square}, S_2^{\square}) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ *is called a* maximal decentralized solution *if it is a solution, i.e.,*

$$S_1^{\square} \wedge S_2^{\square} \sqsubseteq S^{\uparrow},$$

and there does not exist a pair $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ *such that*

$$S_1 \wedge S_2 \sqsubseteq S^{\uparrow} \text{ and } \mathrm{L}(S_1^{\square} \wedge S_2^{\square}/G) \subsetneq \mathrm{L}(S_1 \wedge S_2/G).$$

The set of decomposable languages is closed under arbitrary intersections. It therefore contains a unique infimal element. Rudie posed the following control problem. Given lower bound $\mathrm{L}(A) \subseteq \Sigma^*$ and upper bound $\mathrm{L}(E) \subseteq \Sigma^*$, find a pair $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$, such that

$$\mathrm{L}(A) \subseteq \mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(E).$$

She showed there exists a solution to this control problem if and only if the infimal decomposable language containing $\mathrm{L}(A)$ is contained in $\mathrm{L}(E)$. Although this infimal is useful to solve the existence question, it often does not give a satisfactory solution. The following example shows that it is in general not trivial to define the lower bound $\mathrm{L}(A)$.

Example 2.14. Consider the alternating bit protocol [14, 17, 19]. This protocol achieves the reliable transmission of messages across an unreliable connection. To achieve this, the sender attaches to each message an extra bit containing either a zero or a one. The protocol can start with either a zero or a one attached to the first message. Consequently, the message with either a one or a zero attached is disabled initially. If the lower bound allows a zero attached to the first message, then the protocol cannot disable this message. It cannot choose the option where a one is attached to the first message. The lower bound $\mathrm{L}(A)$ should allow for both options. Therefore it cannot contain either of the options as this would exclude the other option. The only lower bound that allows both options is the empty language. Unfortunately the infimal decomposable language derived from the empty language does not give a satisfactory solution. See also [10, Sect. 2.5]. □

Another suggestion presented in [14, 17] was to look for the suboptimal solution characterized by the strong decomposability condition. A language $K \subseteq \mathrm{L}(G)$ is called *strongly decomposable* (with respect to Σ_1 and Σ_2) if

$$K = \left(\mathrm{p}_1^{-1}(\mathrm{p}_1(K)) \cup \mathrm{p}_2^{-1}(\mathrm{p}_2(K))\right) \cap \mathrm{L}(G). \tag{4}$$

This condition is closed under arbitrary unions. So the supremal strongly decomposable language exists. Recall from [6] the definition of normality. A language $K \subseteq \mathrm{L}(G)$ is called *normal* (with respect to $\Sigma_{\mathrm{o}} \subseteq \Sigma$) if

$$K = \mathrm{p}_{\mathrm{o}}^{-1}(\mathrm{p}_{\mathrm{o}}(K)) \cap \mathrm{L}(G). \tag{5}$$

Normality of a language K is a sufficient condition for the existence of supervisor that can observe events in Σ_{o} and that achieves K as language of the controlled system.

PROPOSITION 2.15. *If* $K \subseteq \mathrm{L}(G)$ *is strongly decomposable with respect to* Σ_1 *and* Σ_2*, then* K *is normal with respect to* Σ_1 *and normal with respect to* Σ_2.

Proof. The inclusion $K \subseteq \mathrm{p}_i^{-1}(\mathrm{p}_i(K)) \cap \mathrm{L}(G)$ is satisfied for all languages contained in $\mathrm{L}(G)$. So, it is sufficient to prove $K \supseteq \mathrm{p}_i^{-1}(\mathrm{p}_i(K)) \cap \mathrm{L}(G)$. By the definition of strong decomposability

$$\begin{aligned} K &= \big(\mathrm{p}_1^{-1}(\mathrm{p}_1(K)) \,\cup\, \mathrm{p}_2^{-1}(\mathrm{p}_2(K))\big) \,\cap\, \mathrm{L}(G) \\ &= \big(\mathrm{p}_1^{-1}(\mathrm{p}_1(K)) \,\cap\, \mathrm{L}(G)\big) \,\cup\, \big(\mathrm{p}_2^{-1}(\mathrm{p}_2(K)) \,\cap\, \mathrm{L}(G)\big) \\ &\supseteq \mathrm{p}_i^{-1}(\mathrm{p}_i(K)) \cap \mathrm{L}(G) \text{ for } i = 1, 2. \qquad \square \end{aligned}$$

The consequence of this proposition is that, if language K is strongly decomposable, then one supervisor, either $S_1 \in \mathcal{C}(\Sigma_1)$ or $S_2 \in \mathcal{C}(\Sigma_2)$, can obtain K as language of the controlled system. The other supervisor is not needed. Obviously, strong decomposability is too strong a restriction for decentralized control problems.

It can be concluded that the existing results for decentralized supervisory control problems do not satisfy the needs from control engineering.

In this paper a characterization of maximal solutions for decentralized control problems will be derived. Is it useful to look for maximal solutions? If a solution is maximal, then this does not imply that it is a good solution. For instance, a maximal solution may allow a lot of unimportant traces and disable all important ones. Another solution which allows less unimportant traces but more important ones may be considered a better solution. However, the authors believe there are some good reasons to investigate the characteristics of maximal solutions. The first and most important reason is that it gives us valuable insight into the fundamental properties of decentralized control problems. This insight may be used to derive algorithms that can synthesize "good" (in whatever sense) solutions, whether they are maximal or not.

Another reason why the authors believe maximality is important is that these "good" solutions will probably be maximal. So, although maximality of a solution does not imply that this solution is useful, a solution that is useful (good in some sense) will most likely be maximal. If a characterization of all maximal solutions can be given, then all "good" solutions will satisfy this characterization. So this characterization limits the class of solutions in which the good ones can be found.

Suppose a solution is given, but it is not fully satisfactory. One can ask the question whether the solution can be extended to obtain a better one. This is possible only if the given solution is not yet maximal. So also in this case a characterization of the maximal solutions will be useful.

2.4. Projections. In [4], Kozak and Wonham propose projections of the supremal supervisor as a solution to the decentralized control or synthesis problem.

DEFINITION 2.16. *The* projection of the supremal supervisor *to event set* $\Sigma_a \subseteq \Sigma(S^\uparrow)$ *is denoted by* $\mathrm{proj}(S^\uparrow, \Sigma_a)$. *It is defined for all* $s_a \in \mathrm{p_a}(\mathrm{L}(G))$ *by*

$$\begin{aligned} &\gamma(\mathrm{proj}(S^\uparrow, \Sigma_a), s_a) \\ &\quad = \left\{\sigma \in \Sigma_c \cap \Sigma_a : \exists s \in \mathrm{p}_a^{\text{-}1}(s_a) \cap \mathrm{L}(S^\uparrow/G) \textit{such that } \sigma \in \gamma(S^\uparrow, s)\right\}. \end{aligned}$$

PROPOSITION 2.17 ([4], Lem. 5.1).

$$\mathrm{proj}(S^\uparrow, \Sigma_1) \wedge \mathrm{proj}(S^\uparrow, \Sigma_2) \;\sqsubseteq\; S^\uparrow. \tag{6}$$

Kozak and Wonham call $\mathrm{proj}(S^\uparrow, \Sigma_1) \wedge \mathrm{proj}(S^\uparrow, \Sigma_2)$ the *fully decentralized solution.* In general the infimal decomposable solution of Rudie and the projected solution of Kozak and Wonham are incomparable. However, if the given lower bound, $\mathrm{L}(A)$, is

FIG. 2. *The fully decentralized solution is in general not maximal.*

the empty trace, then the projected solution is larger than the infimal decomposable solution. But, even if $\Sigma_1 \cap \Sigma_2 = \emptyset$, the fully decentralized solution is in general not maximal. Consider the following example.

Example 2.18. Consider the supremal supervisor and the fully decentralized solution given in Figure 2. In this example $\Sigma_1 = \{\mathtt{a}_1, \mathtt{b}_1\}$, $\Sigma_2 = \{\mathtt{a}_2, \mathtt{b}_2\}$, and $\Sigma_c = \{\mathtt{a}_1, \mathtt{a}_2\}$. The pair $(\mathrm{proj}(S^{\uparrow}, \Sigma_1), \mathrm{proj}(S^{\uparrow}, \Sigma_2))$ is not maximal, because the pair (S_1, S_2) results in a strictly larger controlled language.

Supervisor $\mathrm{proj}(S^{\uparrow}, \Sigma_1)$ disables event $\mathtt{a}_1$ because the uncontrolled system can execute event $\mathtt{a}_2$, after which event $\mathtt{a}_1$ must be disabled. However, as supervisor S_2 disables $\mathtt{a}_2$ it is not necessary for supervisor S_1 to disable $\mathtt{a}_1$. The pair of supervisors obtained by projection from the supremal supervisor is in general not maximal because the supervisors only take into account the control actions of the supremal supervisor. They do not consider the control law of the other supervisor. In order to obtain a maximal solution it is necessary that the supervisors take into account the control law of the other supervisor. So, to synthesize supervisor S_1 one should already know the control law of supervisor S_2, and to synthesize S_2 one should already know the control law of supervisor S_1. It is this cyclic dependency that makes the synthesis of decentralized controllers such a hard problem.

3. Nash equilibria and maximal solutions.

Decentralized stochastic control has been studied extensively. It is related to game and team theory (see [1, 3, 8, 12]). In these fields of research a so-called cost function is used. This cost function maps a decentralized control law to a real number. A solution is considered optimal if it has the lowest cost. Using cost functions, all solutions can be compared with each other. In the field of decentralized supervisory control, solutions are compared by the

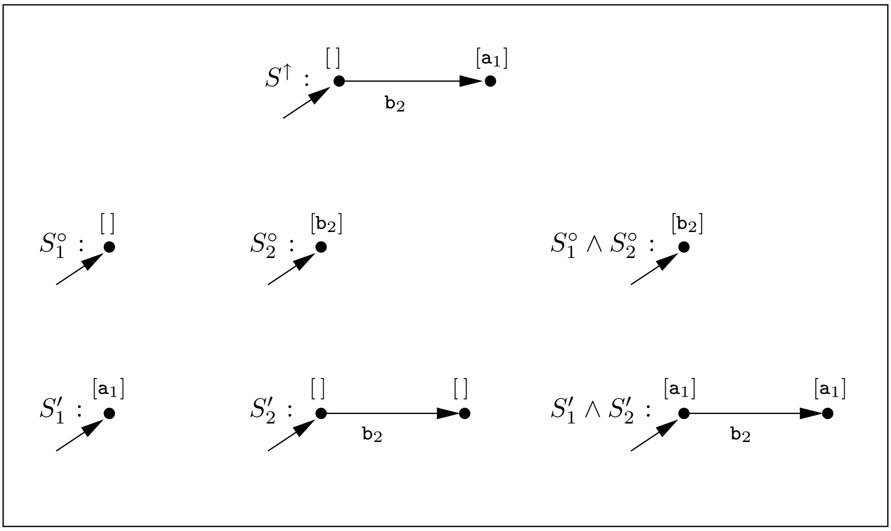

FIG. 3. *The pair* $(S_1^{\circ}, S_2^{\circ})$ *is a Nash equilibrium, yet it is not maximal.*

language of the controlled system. This ordering is not complete. Some solutions may not be comparable.

In game and team theory the notion of Nash equilibrium plays an important role. It will be shown that Nash equilibria are also important for decentralized supervisory control. A pair of supervisors forms a Nash equilibrium if a supervisor cannot improve the controlled language when the other supervisor is kept fixed and conversely.

DEFINITION 3.1. *Consider the DSSP of Definition* 2.11. *A pair of supervisors* $(S_1^{\circ}, S_2^{\circ}) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ *is called a* Nash equilibrium *if it is a solution, i.e.,*

$$S_1^{\circ} \wedge S_2^{\circ} \sqsubseteq S^{\uparrow},$$

and

$$\begin{aligned} &\forall S_2 \in \mathcal{C}(\Sigma_2) S_1^{\circ} \wedge S_2 \sqsubseteq S^{\uparrow} \Rightarrow \ \mathrm{L}(S_1^{\circ} \wedge S_2/G) \subseteq \mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G), \ \textit{and} \\ &\forall S_1 \in \mathcal{C}(\Sigma_1) S_1 \wedge S_2^{\circ} \sqsubseteq S^{\uparrow} \Rightarrow \ \mathrm{L}(S_1 \wedge S_2^{\circ}/G) \subseteq \mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G). \end{aligned}$$

In game theory, controllers have conflicting optimization criteria, whereas in team theory all controllers try to optimize the same cost criterion. Note that in the above definition the closed-loop language is analogous to the cost function in a team or game problem. The notion of Nash equilibrium has been introduced in game theory. In team theory it is also known as a person-by-person optimal solution.

In team theory, under certain convexity conditions, a set of controllers is maximal if and only if it is a Nash equilibrium [12]. This equivalence is quite useful because it is relatively easier to determine a Nash equilibrium than a maximum.

The following example shows that for discrete-event systems the Nash equilibrium condition is not sufficient to guarantee maximality.

Example 3.2. Consider the supremal supervisor $S^{\uparrow}$ and the decentralized implementation $(S_1^{\circ}, S_2^{\circ})$ given in Figure 3. $\Sigma_1 = \{\mathtt{a}_1\}$, $\Sigma_2 = \{\mathtt{b}_2\}$. All events are controllable. It is not difficult to check that the pair $(S_1^{\circ}, S_2^{\circ})$ is a Nash equilibrium. However, it is not maximal, because the pair (S_1', S_2') is a solution with a strictly larger controlled language. □

For discrete-event systems we need the stronger condition of a strong Nash equilibrium to guarantee maximality of a pair of supervisors.

DEFINITION 3.3. *Consider the DSSP of Definition* 2.11. *A pair of supervisors* $(S_1^\circ, S_2^\circ) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ *is called a* strong Nash equilibrium *if it is a Nash equilibrium, and for all* $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$,

$$\mathrm{L}(S_1 \wedge S_2/G) = \mathrm{L}(S_1^\circ \wedge S_2^\circ/G) \Rightarrow (S_1, S_2) \text{ is a Nash equilibrium.} \tag{7}$$

An intuitive interpretation of the need for the concept of a strong Nash equilibrium follows. The aim of the paper is to obtain a characterization of a maximal decentralized solution in terms of a person-by-person characterization as in game and team theory. Example 3.2 shows that there exists a pair of supervisors that is a Nash equilibrium but not a maximal solution. The condition for a pair of supervisors (S_1°, S_2°) to be a Nash equilibrium is phrased solely in terms of the closed-loop language $L(S_1^\circ \wedge S_2^\circ/G)$. Because of this formulation, it appears that it is necessary that any pair of languages that achieves the same closed-loop language is also a Nash equilibrium. If such a pair was not a Nash equilibrium, one would be able to construct a pair of supervisors with a strictly larger closed-loop language. This in turn would contradict maximality. The next theorem shows that the concept of a strong Nash equilibrium is appropriate.

By Proposition 2.7, $\mathrm{L}(S_1 \wedge S_2/G) = \mathrm{L}(S_1^\circ \wedge S_2^\circ/G)$ and $S_1^\circ \wedge S_2^\circ \sqsubseteq S^\uparrow$ together imply that $S_1 \wedge S_2 \sqsubseteq S^\uparrow$.

THEOREM 3.4. *A pair of supervisors* $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ *is maximal if and only if it is a strong Nash equilibrium.*

Proof (strong Nash ⇒ Maximal). Assume $(S_1^\circ, S_2^\circ) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ is strong Nash but not maximal. Then there exists a pair $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ such that $S_1 \wedge S_2 \sqsubseteq S^\uparrow$ and $\mathrm{L}(S_1^\circ \wedge S_2^\circ/G) \subsetneqq \mathrm{L}(S_1 \wedge S_2/G)$. Define $S_1^\square \in \mathcal{C}(\Sigma_1)$ by

$$\gamma(S_1^\square, s_1) = \gamma(S_1^\circ, s_1) \cup \gamma(S_1, s_1) \quad \forall s_1 \in \mathrm{p}_1(\mathrm{L}(G)).$$

We will prove the following points.

1. $\mathrm{L}(S_1^\square/G) = \mathrm{L}(S_1^\circ/G) \cap \mathrm{L}(S_1/G)$,
2. $S_1^\square \wedge S_2^\circ \sqsubseteq S^\uparrow$,
3. $S_1^\square \wedge S_2 \sqsubseteq S^\uparrow$,
4. $\mathrm{L}(S_1^\circ \wedge S_2^\circ/G) = \mathrm{L}(S_1^\square \wedge S_2^\circ/G)$,
5. $\mathrm{L}(S_1^\square \wedge S_2^\circ/G) \subseteq \mathrm{L}(S_1^\square \wedge S_2/G)$.

(Point 1.) This point will be proven by complete induction. The initial step follows from $\varepsilon \in \mathrm{L}(S_1^\square/G)$ and $\varepsilon \in \mathrm{L}(S_1^\circ/G) \cap \mathrm{L}(S_1/G)$. For the inductive step let $s \in \mathrm{L}(S_1^\square/G)$ and $s \in \mathrm{L}(S_1^\circ/G) \cap \mathrm{L}(S_1/G)$. Then

$$\begin{aligned} s\sigma \in \mathrm{L}(S_1^\square/G) &\iff s\sigma \in \mathrm{L}(G),\ \sigma \notin \gamma(S_1^\square, \mathrm{p}_1(s)) \\ &\iff s\sigma \in \mathrm{L}(G),\ \sigma \notin \gamma(S_1^\circ, \mathrm{p}_1(s)),\ \sigma \notin \gamma(S_1, \mathrm{p}_1(s)) \\ &\iff s\sigma \in \mathrm{L}(S_1^\circ/G),\ s\sigma \in \mathrm{L}(S_1/G) \\ &\iff s\sigma \in \mathrm{L}(S_1^\circ/G) \cap \mathrm{L}(S_1/G). \end{aligned}$$

It follows that $\mathrm{L}(S_1^\square/G) = \mathrm{L}(S_1^\circ/G) \cap \mathrm{L}(S_1/G)$.

(Points 2 and 4.) From point 1 and Proposition 2.10, it follows that

$$\begin{aligned}\mathrm{L}(S_1^{\Box} \wedge S_2^{\circ}/G) &= \mathrm{L}(S_1^{\circ}/G) \cap \mathrm{L}(S_1/G) \cap \mathrm{L}(S_2^{\circ}/G)\\ &= \mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G) \cap \mathrm{L}(S_1/G)\\ &= \big[\text{because } \mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G) \subseteq \mathrm{L}(S_1 \wedge S_2/G) \text{ and}\\ &\quad\ \text{by Proposition 2.10 } \mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(S_1/G)\big]\\ &\quad\ \mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G).\end{aligned}$$

This proves point 4. Point 2 follows from $S_1^{\circ} \wedge S_2^{\circ} \sqsubseteq S^{\uparrow}$ and Proposition 2.7.

(Point 3.) From point 1 and Proposition 2.10, it follows that

$$\begin{aligned}\mathrm{L}(S_1^{\Box} \wedge S_2/G) &= \mathrm{L}(S_1^{\circ}/G) \cap \mathrm{L}(S_1/G) \cap \mathrm{L}(S_2/G)\\ &\subseteq \mathrm{L}(S_1/G) \cap \mathrm{L}(S_2/G) = \mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(S^{\uparrow}/G).\end{aligned}$$

So, by Proposition 2.7, $S_1^{\Box} \wedge S_2 \sqsubseteq S^{\uparrow}$.

(Point 5.) From point 4, it follows that

$$\begin{aligned}\mathrm{L}(S_1^{\Box} \wedge S_2^{\circ}/G) &= \mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G)\\ &= \big[\text{because } \mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G) \subseteq \mathrm{L}(S_1 \wedge S_2/G)\big]\\ &\quad\ \mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G) \cap \mathrm{L}(S_1 \wedge S_2/G)\\ &= \mathrm{L}(S_1^{\circ}/G) \cap \mathrm{L}(S_2^{\circ}/G) \cap \mathrm{L}(S_1/G) \cap \mathrm{L}(S_2/G)\\ &\subseteq \mathrm{L}(S_1^{\Box}/G) \cap \mathrm{L}(S_2/G) = \mathrm{L}(S_1^{\Box} \wedge S_2/G).\end{aligned}$$

As the pair $(S_1^{\circ}, S_2^{\circ})$ is strong Nash, it follows from point 4 that $(S_1^{\Box}, S_2^{\circ})$ is Nash. So, by point 3 and the definition of Nash, $\mathrm{L}(S_1^{\Box} \wedge S_2/G) \subseteq \mathrm{L}(S_1^{\Box} \wedge S_2^{\circ}/G)$. Then, from points 4 and 5, $\mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G) = \mathrm{L}(S_1^{\Box} \wedge S_2^{\circ}/G) = \mathrm{L}(S_1^{\Box} \wedge S_2/G)$. As $(S_1^{\circ}, S_2^{\circ})$ is strong Nash, the pair $(S_1^{\Box}, S_2)$ is Nash. So

$$\mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(S_1^{\Box} \wedge S_2/G) = \mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}/G).$$

But this contradicts our assumption that $\mathrm{L}(S_1^{\circ} \wedge S_2^{\circ}) \subsetneqq \mathrm{L}(S_1 \wedge S_2/G)$. We can conclude that if $(S_1^{\circ}, S_2^{\circ})$ is strong Nash, then it is maximal.

(Maximal ⇒ Strong Nash.) Assume $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ is maximal but not strong Nash. Then there exists a pair $(S_1', S_2') \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ such that $\mathrm{L}(S_1' \wedge S_2'/G) = \mathrm{L}(S_1 \wedge S_2/G)$ and (S_1', S_2') is not Nash. So

$$\exists S_1'' \in \mathcal{C}(\Sigma_1) \,\text{such that}\, S_1'' \wedge S_2' \sqsubseteq S^{\uparrow}\text{and } \mathrm{L}(S_1'' \wedge S_2'/G) \not\subseteq \mathrm{L}(S_1' \wedge S_2'/G)$$

or

$$\exists S_2'' \in \mathcal{C}(\Sigma_2) \text{ such that } S_1' \wedge S_2'' \sqsubseteq S^{\uparrow} \text{ and } \mathrm{L}(S_1' \wedge S_2''/G) \not\subseteq \mathrm{L}(S_1' \wedge S_2'/G).$$

Assume, without loss of generality, that such an S_2'' exists. Let $S_2^{\Box} \in \mathcal{C}(\Sigma_2)$ be defined by

$$\gamma(S_2^{\Box}, s_2) = \begin{cases} \gamma(S_2', s_2) \cap \gamma(S_2'', s_2), & \text{if } s_2 \in \mathrm{p}_2(\mathrm{L}(S_2'/G)) \text{ and } s_2 \in \mathrm{p}_2(\mathrm{L}(S_2''/G)),\\ \gamma(S_2', s_2), & \text{if } s_2 \in \mathrm{p}_2(\mathrm{L}(S_2'/G)) \text{ and } s_2 \notin \mathrm{p}_2(\mathrm{L}(S_2''/G)),\\ \gamma(S_2'', s_2), & \text{if } s_2 \notin \mathrm{p}_2(\mathrm{L}(S_2'/G)) \text{ and } s_2 \in \mathrm{p}_2(\mathrm{L}(S_2''/G)),\\ \Sigma_{2,\mathrm{c}}, & \text{otherwise.}\end{cases}$$

We will prove the following points.

1. $\mathrm{L}(S_2^{\square}/G) = \mathrm{L}(S_2'/G) \cup \mathrm{L}(S_2''/G)$,
2. $S_1' \wedge S_2^{\square} \sqsubseteq S^{\uparrow}$,
3. $\mathrm{L}(S_1' \wedge S_2'/G) \subseteq \mathrm{L}(S_1' \wedge S_2^{\square}/G)$,
4. $\mathrm{L}(S_1' \wedge S_2''/G) \subseteq \mathrm{L}(S_1' \wedge S_2^{\square}/G)$.

(Point 1.) This point will be proven by complete induction. The initial step follows from $\varepsilon \in \mathrm{L}(S_2^{\square}/G)$ and $\varepsilon \in \mathrm{L}(S_2'/G) \cup \mathrm{L}(S_2''/G)$. For the inductive step let $s \in \mathrm{L}(S_2^{\square}/G)$ and $s \in \mathrm{L}(S_2'/G) \cup \mathrm{L}(S_2''/G)$. Trace s can be in one of the three sets $\mathrm{L}(S_2'/G) \cap \mathrm{L}(S_2''/G)$, $\mathrm{L}(S_2'/G) - \mathrm{L}(S_2''/G)$, or $\mathrm{L}(S_2''/G) - \mathrm{L}(S_2'/G)$. If $s \in \mathrm{L}(S_2'/G) \cap \mathrm{L}(S_2''/G)$, then

$$\begin{aligned} s\sigma \in \mathrm{L}(S_2^{\square}/G) &\iff s\sigma \in \mathrm{L}(G) \wedge \sigma \notin \gamma(S_2^{\square}, \mathrm{p}_2(s)) \\ &\iff s\sigma \in \mathrm{L}(G) \ \wedge \ \big(\sigma \notin \gamma(S_2', \mathrm{p}_2(s)) \vee \sigma \notin \gamma(S_2'', \mathrm{p}_2(s))\big) \\ &\iff s\sigma \in \mathrm{L}(S_2'/G) \vee s\sigma \in \mathrm{L}(S_2''/G) \\ &\iff s\sigma \in \mathrm{L}(S_2'/G) \cup \mathrm{L}(S_2''/G). \end{aligned}$$

If $s \in \mathrm{L}(S_2'/G)$ but $s \notin \mathrm{L}(S_2''/G)$, then

$$\begin{aligned} s\sigma \in \mathrm{L}(S_2^{\square}/G) &\iff s\sigma \in \mathrm{L}(G) \wedge \sigma \notin \gamma(S_2^{\square}, \mathrm{p}_2(s)) \\ &\iff s\sigma \in \mathrm{L}(G) \wedge \sigma \notin \gamma(S_2', \mathrm{p}_2(s)) \\ &\iff s\sigma \in \mathrm{L}(S_2'/G) \\ &\iff s\sigma \in \mathrm{L}(S_2'/G) \cup \mathrm{L}(S_2''/G). \end{aligned}$$

A similar reasoning holds if $s \in \mathrm{L}(S_2''/G)$ but $s \notin \mathrm{L}(S_2'/G)$. Hence, it follows that $\mathrm{L}(S_2^{\square}/G) = \mathrm{L}(S_2'/G) \cup \mathrm{L}(S_2''/G)$.

(Points 2, 3, and 4.) From point 1 and Proposition 2.10, it follows that

$$\begin{aligned} \mathrm{L}(S_1' \wedge S_2^{\square}/G) &= \mathrm{L}(S_1'/G) \ \cap \ \big(\mathrm{L}(S_2'/G) \cup \mathrm{L}(S_2''/G)\big) \\ &= \big(\mathrm{L}(S_1'/G) \cap \mathrm{L}(S_2'/G)\big) \ \cup \ \big(\mathrm{L}(S_1'/G) \cap \mathrm{L}(S_2''/G)\big) \\ &= \mathrm{L}(S_1' \wedge S_2'/G) \cup \mathrm{L}(S_1' \wedge S_2''/G). \end{aligned}$$

This directly proves points 3 and 4. Point 2 follows from $S_1' \wedge S_2' \sqsubseteq S^{\uparrow}$, $S_1' \wedge S_2'' \sqsubseteq S^{\uparrow}$, and Proposition 2.7.

As (S_1, S_2) is maximal, so is (S_1', S_2'). Then, by point 3, $\mathrm{L}(S_1' \wedge S_2'/G) = \mathrm{L}(S_1' \wedge S_2^{\square}/G)$. From point 4 it follows that $\mathrm{L}(S_1' \wedge S_2''/G) \subseteq \mathrm{L}(S_1' \wedge S_2'/G)$. But this contradicts our assumption that $\mathrm{L}(S_1' \wedge S_2''/G) \nsubseteq \mathrm{L}(S_1' \wedge S_2'/G)$. Hence it can be concluded that if (S_1, S_2) is maximal, then it is strong Nash. $\square$

Consider two pairs of supervisors to be *control equivalent* if their controlled languages are equal, or

$$(S_1, S_2) \equiv (S_3, S_4) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2) \text{ if } L(S_1 \wedge S_2/G) = L(S_3 \wedge S_4/G).$$

Then a pair of supervisors is maximal if and only if all control equivalent pairs are Nash equilibria. Let the *control equivalence class* corresponding with the language $K \subseteq \mathrm{L}(G)$ be the set of pairs for which the controlled language is equal to K. A prefix closed and decomposable language can be considered maximal if and only if all pairs in its corresponding control equivalence class are Nash equilibria.

If the event sets Σ_1 and Σ_2 are disjoint, then a weaker condition can be found to characterize maximal solutions. Define $(\widehat{S}_1, \widehat{S}_2)$ as the pair of most restrictive supervisors in the control equivalence class of (S_1, S_2).

Definition 3.5. *Let $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$. The supervisor $\widehat{S}_1 \in \mathcal{C}(\Sigma_1)$ is defined by*

$$\gamma(\widehat{S}_1, s_1) = \{\sigma \in \Sigma_c(S_1) : s_1\sigma \notin \mathrm{p}_1(\mathrm{L}(S_1 \wedge S_2/G))\} \quad \forall s_1 \in \mathrm{p}_1(\mathrm{L}(G)).$$

The supervisor $\widehat{S}_2 \in \mathcal{C}(\Sigma_2)$ is defined analogously.

Supervisor $\widehat{S}_1$ can be seen as the most restrictive supervisor of all supervisors S_1' for which there exists a supervisor S_2' such that $\mathrm{L}(S_1' \wedge S_2'/G) = \mathrm{L}(S_1 \wedge S_2/G)$. That is, if such an S_1' disables event σ after trace s, then $s\sigma$ is not an element of $\mathrm{L}(S_1'/G) \supseteq \mathrm{L}(S_1' \wedge S_2'/G) = \mathrm{L}(S_1 \wedge S_2/G)$. So $\widehat{S}_1$ will also disable this event.

First it needs to be proven that $(\widehat{S}_1, \widehat{S}_2)$ is a solution and that it is control equivalent with (S_1, S_2).

Proposition 3.6. *Let $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ be a decentralized solution implementing $S^\uparrow$, and let $(\widehat{S}_1, \widehat{S}_2)$ be defined as above. Then*

1. *$\widehat{S}_1 \wedge \widehat{S}_2 \sqsubseteq S^\uparrow$, and*
2. *$\mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G) = \mathrm{L}(S_1 \wedge S_2/G)$.*

Proof (point 2, $\mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G) \subseteq \mathrm{L}(S_1 \wedge S_2/G)$). First we will prove by induction that $\mathrm{L}(\widehat{S}_1/G) \subseteq \mathrm{L}(S_1/G)$. The initial step follows from $\varepsilon \in \mathrm{L}(\widehat{S}_1/G)$ and $\varepsilon \in \mathrm{L}(S_1/G)$. For the inductive step let $s \in \mathrm{L}(\widehat{S}_1/G)$ and $s \in \mathrm{L}(S_1/G)$.

$$\begin{aligned}
s\sigma \in \mathrm{L}(\widehat{S}_1/G) &\Rightarrow s\sigma \in \mathrm{L}(G) \ \wedge \ \sigma \notin \gamma(\widehat{S}_1, \mathrm{p}_1(s)) \\
&\Rightarrow s\sigma \in \mathrm{L}(G) \ \wedge \ \big(\sigma \notin \Sigma_\mathrm{c}(S_1) \vee \mathrm{p}_1(s)\sigma \in \mathrm{p}_1(\mathrm{L}(S_1 \wedge S_2/G))\big) \\
&\Rightarrow \big[\text{because } \mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(S_1/G)\big] \\
&\qquad s\sigma \in \mathrm{L}(G) \ \wedge \ \big(\sigma \notin \Sigma_\mathrm{c}(S_1) \vee \mathrm{p}_1(s)\sigma \in \mathrm{p}_1(\mathrm{L}(S_1/G))\big) \\
&\Rightarrow s\sigma \in \mathrm{L}(G) \ \wedge \ \big(\sigma \notin \Sigma_\mathrm{c}(S_1) \vee \sigma \notin \gamma(S_1, \mathrm{p}_1(s))\big) \\
&\Rightarrow \big[\text{because } \sigma \notin \Sigma_\mathrm{c}(S_1) \Rightarrow \sigma \notin \gamma(S_1, \mathrm{p}_1(s))\big] \\
&\qquad s\sigma \in \mathrm{L}(G) \ \wedge \ \sigma \notin \gamma(S_1, \mathrm{p}_1(s)) \\
&\Rightarrow s\sigma \in \mathrm{L}(S_1/G).
\end{aligned}$$

By symmetry it follows that $\mathrm{L}(\widehat{S}_2/G) \subseteq \mathrm{L}(S_2/G)$. So

$$\mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G) = \mathrm{L}(\widehat{S}_1/G) \cap \mathrm{L}(\widehat{S}_2/G) \subseteq \mathrm{L}(S_1/G) \cap \mathrm{L}(S_2/G) = \mathrm{L}(S_1 \wedge S_2/G).$$

(Point 2, $\mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G)$.) First it will be proven by induction that $\mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(\widehat{S}_1/G)$. The initial step follows from $\varepsilon \in \mathrm{L}(S_1 \wedge S_2/G)$ and $\varepsilon \in \mathrm{L}(\widehat{S}_1/G)$. For the inductive step let $s \in \mathrm{L}(S_1 \wedge S_2/G)$ and $s \in \mathrm{L}(\widehat{S}_1/G)$.

$$\begin{aligned}
&s\sigma \in \mathrm{L}(S_1 \wedge S_2/G) \\
&\Rightarrow \sigma \notin \Sigma_1 \ \vee \ \big(\sigma \in \Sigma_1 \wedge \mathrm{p}_1(s\sigma) = \mathrm{p}_1(s)\sigma \in \mathrm{p}_1(\mathrm{L}(S_1 \wedge S_2/G))\big) \\
&\Rightarrow \big[\text{by construction of } \gamma(\widehat{S}_1, \mathrm{p}_1(s))\big] \\
&\qquad \sigma \notin \Sigma_1 \ \vee \ (\sigma \in \Sigma_1 \wedge \sigma \notin \gamma(\widehat{S}_1, \mathrm{p}_1(s))) \\
&\Rightarrow \big[\text{because } \gamma(\widehat{S}_1, \mathrm{p}_1(s)) \subseteq \Sigma_1\big] \ \ \sigma \notin \gamma(\widehat{S}_1, \mathrm{p}_1(s)) \\
&\Rightarrow \big[\text{because } s \in \mathrm{L}(\widehat{S}_1/G) \text{ and } s\sigma \in \mathrm{L}(G)\big] \ \ s\sigma \in \mathrm{L}(\widehat{S}_1/G).
\end{aligned}$$

By symmetry it follows that $\mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(\widehat{S}_2/G)$. So

$$\mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(\widehat{S}_1/G) \cap \mathrm{L}(\widehat{S}_2/G) = \mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G).$$

(Point 1.) This follows directly from point 2 and Proposition 2.7. □

THEOREM 3.7. *Let* $\Sigma_1 \cap \Sigma_2 = \emptyset$. *Let* $(S_1, S_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$. *Let* $(\widehat{S}_1, \widehat{S}_2) \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ *be defined by Definition* 3.5. *Then* (S_1, S_2) *is maximal if and only if* $(\widehat{S}_1, \widehat{S}_2)$ *is a Nash equilibrium.*

Proof (Maximal $\Rightarrow$ Nash). If (S_1, S_2) is maximal, then by Theorem 3.4 (S_1, S_2) is a strong Nash equilibrium, which by points 1 and 2 of Proposition 3.6 implies that $(\widehat{S}_1, \widehat{S}_2)$ is a Nash equilibrium.

(Nash $\Rightarrow$ Maximal.) Assume $(\widehat{S}_1, \widehat{S}_2)$ is a Nash equilibrium, but (S_1, S_2) is not maximal. Then, by point 2 of Proposition 3.6 $(\widehat{S}_1, \widehat{S}_2)$ is not maximal. There exists a pair $(S_1', S_2') \in \mathcal{C}(\Sigma_1) \times \mathcal{C}(\Sigma_2)$ such that $S_1' \wedge S_2' \sqsubseteq S^{\uparrow}$ and $\mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G) \subsetneqq \mathrm{L}(S_1' \wedge S_2'/G)$. We will first prove that

$$\widehat{S}_1 \wedge S_2' \sqsubseteq S^{\uparrow} \text{ and } S_1' \wedge \widehat{S}_2 \sqsubseteq S^{\uparrow}.$$

It will be proven by induction that $\mathrm{L}(\widehat{S}_1/G) \subseteq \mathrm{L}(S_1'/G)$. The initial step follows from $\varepsilon \in \mathrm{L}(\widehat{S}_1/G)$ and $\varepsilon \in \mathrm{L}(S_1'/G)$. For the inductive step let $s \in \mathrm{L}(\widehat{S}_1/G)$ and $s \in \mathrm{L}(S_1'/G)$.

$$\begin{aligned}
s\sigma \in \mathrm{L}(\widehat{S}_1/G) &\Rightarrow s\sigma \in \mathrm{L}(G) \ \wedge \ \sigma \notin \gamma(\widehat{S}_1, \mathrm{p}_1(s)) \\
&\Rightarrow s\sigma \in \mathrm{L}(G) \ \wedge \ (\sigma \notin \Sigma_{\mathrm{c}}(S_1) \vee \mathrm{p}_1(s)\sigma \in \mathrm{p}_1(\mathrm{L}(S_1 \wedge S_2/G))) \\
&\Rightarrow [\text{because } \mathrm{L}(S_1 \wedge S_2/G) \subseteq \mathrm{L}(S_1' \wedge S_2'/G) \subseteq \mathrm{L}(S_1'/G)] \\
&\quad\ s\sigma \in \mathrm{L}(G) \ \wedge \ (\sigma \notin \Sigma_{\mathrm{c}}(S_1) \vee \mathrm{p}_1(s)\sigma \in \mathrm{p}_1(\mathrm{L}(S_1'/G))) \\
&\Rightarrow s\sigma \in \mathrm{L}(G) \ \wedge \ (\sigma \notin \Sigma_{\mathrm{c}}(S_1) \vee \sigma \notin \gamma(S_1', \mathrm{p}_1(s))) \\
&\Rightarrow [\text{because } \sigma \notin \Sigma_{\mathrm{c}}(S_1) \Rightarrow \sigma \notin \gamma(S_1', \mathrm{p}_1(s))] \\
&\quad\ s\sigma \in \mathrm{L}(G) \ \wedge \ \sigma \notin \gamma(S_1', \mathrm{p}_1(s)) \\
&\Rightarrow s\sigma \in \mathrm{L}(S_1'/G).
\end{aligned}$$

It follows that $\mathrm{L}(\widehat{S}_1/G) \subseteq \mathrm{L}(S_1'/G)$. Now

$$\begin{aligned}
\mathrm{L}(\widehat{S}_1 \wedge S_2'/G) &= \mathrm{L}(\widehat{S}_1/G) \cap \mathrm{L}(S_2'/G) \subseteq \mathrm{L}(S_1'/G) \cap \mathrm{L}(S_2'/G) \\
&= \mathrm{L}(S_1' \wedge S_2'/G) \subseteq \mathrm{L}(S^{\uparrow}/G).
\end{aligned}$$

So, by Proposition 2.7, $\widehat{S}_1 \wedge S_2' \sqsubseteq S^{\uparrow}$. It follows by symmetry that $S_1' \wedge \widehat{S}_2 \sqsubseteq S^{\uparrow}$.

As $\mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G) \subsetneqq \mathrm{L}(S_1' \wedge S_2'/G)$ there exists a trace $s \in \mathrm{L}(S_1' \wedge S_2'/G)$ such that $s \notin \mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G)$. Let $v\sigma$ be the prefix of s such that $\sigma \in \Sigma$, $v \in \mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G)$, and $v\sigma \notin \mathrm{L}(\widehat{S}_1 \wedge \widehat{S}_2/G)$. Assume without loss of generality that $\sigma \in \Sigma_2$. Then, by the assumption that $\Sigma_1 \cap \Sigma_2 = \emptyset$, $\sigma \notin \Sigma_1$. So $\sigma \notin \gamma(\widehat{S}_1, \mathrm{p}_1(v)) \subseteq \Sigma_1$. Thus $v\sigma \in \mathrm{L}(\widehat{S}_1/G)$. As $v\sigma \in \mathrm{L}(S_1' \wedge S_2'/G) \subseteq \mathrm{L}(S_2'/G)$, it follows that $v\sigma \in \mathrm{L}(\widehat{S}_1 \wedge S_2'/G)$. But this contradicts the fact that $(\widehat{S}_1, \widehat{S}_2)$ is a Nash equilibrium. Hence we can conclude that if $(\widehat{S}_1, \widehat{S}_2)$ is a Nash equilibrium, then (S_1, S_2) is maximal. □

A prefix closed and decomposable language $K \subseteq \mathrm{L}(G)$ can be considered maximal if and only if the pair of most restricting supervisors in the control equivalence class corresponding with language K is a Nash equilibrium.

4. Construction of Nash equilibria. Theorems 3.4 and 3.7 give characterizations of the maximal solutions in terms of Nash equilibria. However, they do not state how Nash equilibria can be obtained. For dynamic games in the field of game and team theory, a necessary condition for a Nash equilibrium can be given by the coupled Bellman–Hamilton–Jacobi equations. A solution to these equations is under certain additional conditions also sufficient for a Nash equilibrium. A procedure for the construction of a solution is known [9]. It alternately keeps one of the controllers fixed and tries to optimize the other. At each iteration only one of the controllers is optimized. For dynamic games it is not guaranteed that the procedure converges. And if it converges, it is not guaranteed that it does so in a finite number of steps.

For supervisory control the Bellman–Hamilton–Jacobi equations are not applicable. Yet, the procedure can still be used. At each iteration one of the supervisors is kept fixed and the other is optimized. Only one supervisor is synthesized in each step. This can be seen as a supervisory control problem for a single supervisor. The combination of the fixed supervisor and the uncontrolled system is taken as the uncontrolled system for this control problem. As only one supervisor is synthesized (and all controllable events are observable) a unique optimal solution exists. In the next iteration this optimal supervisor is taken fixed and the other supervisor is optimized. This procedure is repeated until the pair of supervisors remains invariant. Below this procedure is formalized.

Assume without loss of generality that S_1 is the supervisor which is kept fixed. Consider the supervisory control problem with partial observations for the plant S_1/G and with legal language $L(S^{\uparrow})$. Then define

$$K = \sup \left\{ \begin{array}{l} K' \subseteq L(S_1/G) | (1)\ K' \subseteq L(S^{\uparrow}), \\ (2)\ K' \text{ controllable with respect to } (L(S_1/G), \Sigma_c(\Sigma_2)), \\ (3) \text{ and normal with respect to } L(S_1/G) \text{ and } p_2 \end{array} \right\}. \tag{8}$$

The supremal supervisor S_2 with respect to the uncontrolled system S_1/G is defined by

$$\gamma(S_2, s_2) = \{\sigma \in \Sigma_{\rm c}(S_2) : s_2\sigma \notin {\rm p}_2(K)\} \quad \forall s_2 \in {\rm p}_2({\rm L}(G)). \tag{9}$$

If S_2 is kept fixed, then S_1 is computed analogously. The formula for K in this case is obtained from that of (8) by interchanging the indices 1 and 2.

LEMMA 4.1. *Let S_1 be the supervisor which is kept fixed. Let S_2 and K be as defined above. Then* ${\rm L}(S_1 \wedge S_2/G) = K$.

Proof. The proof will be by complete induction. As $\varepsilon \in {\rm L}(S_1 \wedge S_2/G)$ and $\varepsilon \in K$ the initial step is satisfied. For the inductive step let $s \in {\rm L}(S_1 \wedge S_2/G)$ and $s \in K$.

$$\begin{aligned} s\sigma \in {\rm L}(S_1 \wedge S_2/G) &\iff s\sigma \in {\rm L}(S_1/G) \wedge \sigma \notin \gamma(S_2, {\rm p}_2(s)) \\ &\iff s\sigma \in {\rm L}(S_1/G) \ \wedge\ (\sigma \notin \Sigma_{\rm c}(\Sigma_2) \vee {\rm p}_2(s)\sigma \in {\rm p}_2(K)) \\ &\iff [\text{because } s \in K \text{ and } K \text{ is controllable}] \\ &\qquad s\sigma \in {\rm L}(S_1/G) \ \wedge\ (s\sigma \in K \vee {\rm p}_2(s)\sigma \in {\rm p}_2(K)) \\ &\iff [\text{because } K \subseteq {\rm p}_2^{-1}({\rm p}_2(K))] \\ &\qquad s\sigma \in {\rm L}(S_1/G) \wedge s\sigma \in {\rm p}_2^{-1}({\rm p}_2(K)) \\ &\iff \big[\text{because } K \text{ is normal with respect to} {\rm L}(S_1/G)\big] \\ &\qquad s\sigma \in K. \qquad \square \end{aligned}$$

The procedure is described by the following steps.

PROCEDURE 4.2.

1. *Choose a pair of most restrictive supervisors* (S_1^0, S_2^0) *as starting point of the procedure. Take, for instance, the pair of most restrictive supervisors corresponding with the fully decentralized solution. Let* $j = 0$.
2. *If* j *is even, then let* S_2^{j+1} *be the supremal supervisor with respect to uncontrolled system* S_1^j/G *and event set* Σ_2. *Let* $S_1^{j+1} = S_1^j$. *If* j *is odd, then let* S_1^{j+1} *be the supremal supervisor with respect to uncontrolled system* S_2^j/G *and event set* Σ_1. *Let* $S_2^{j+1} = S_2^j$.
3. *If* $(S_1^{j+1}, S_2^{j+1}) \neq (S_1^j, S_2^j)$, *then increment* j *and continue with step* 2.

First it will be shown that all pairs of supervisors (S_1^j, S_2^j) are most restricting.

LEMMA 4.3. *Let* $j \in N$ *and assume that* (S_1^j, S_2^j) *is most restrictive. Then* (S_1^{j+1}, S_2^{j+1}) *obtained in the second step of the procedure is also most restrictive.*

Proof. Assume without loss of generality that j is odd. So $S_2^{j+1} = S_2^j$ and S_1^{j+1} is the supremal supervisor with respect to S_2^j/G. Let $K^j = \mathrm{L}(S_1^j \wedge S_2^j/G)$ and $K^{j+1} = \mathrm{L}(S_1^{j+1} \wedge S_2^{j+1}/G)$. Comparing (9) with Definition 3.5, it is not difficult to see that S_1^{j+1} is most restrictive with respect to K^{j+1}. Supervisor $S_2^{j+1} = S_2^j$ is most restrictive with respect to language K^j. It remains to show that it is most restrictive with respect to K^{j+1}.

$$\begin{aligned} &\sigma \in \gamma(S_2^{j+1}, s_2) = \gamma(S_2^j, s_2) \Rightarrow \sigma \in \Sigma_{\mathrm{c}}(S_2^j) \wedge s_2\sigma \notin \mathrm{L}(S_2^j/G) \\ &\Rightarrow [\text{because } K^{j+1} \subseteq \mathrm{L}(S_2^j/G)]\ \sigma \in \Sigma_{\mathrm{c}}(S_2^j) \wedge s_2\sigma \notin K^{j+1}. \end{aligned}$$

As K^{j+1} is supremal it follows that $K^j \subseteq K^{j+1}$.

$$\begin{aligned} \sigma \notin \gamma(S_2^{j+1}, s_2) = \gamma(S_2^j, s_2) \Rightarrow & \left[\text{because } S_2^j \text{ is most restrictive with respect to} K^j\right] \\ & \sigma \notin \Sigma_{\mathrm{c}}(S_2^j) \vee s_2\sigma \in K^j \\ & \Rightarrow \left[\text{because } K^j \subseteq K^{j+1}\right]\ \sigma \notin \Sigma_{\mathrm{c}}(S_2^j) \vee s_2\sigma \in K^{j+1}. \end{aligned}$$

It follows that S_2^{j+1} is most restrictive with respect to K^{j+1}. And thus (S_1^{j+1}, S_2^{j+1}) is most restrictive. ☐

Next it will be shown that if $(S_1^{j+1}, S_2^{j+1}) = (S_1^j, S_2^j)$, then (S_1^j, S_2^j) forms a Nash equilibrium. So if Σ_1 and Σ_2 are disjoint, then this pair is a maximal solution.

THEOREM 4.4. *Let* $j \in \mathbb{N}$ *and let* $S_1^j, S_2^j, S_1^{j+1}, S_2^{j+1}$ *be constructed by the procedure above. If* $(S_1^{j+1}, S_2^{j+1}) = (S_1^j, S_2^j)$, *then* (S_1^j, S_2^j) *forms a Nash equilibrium.*

Proof. Assume without loss of generality that j is odd. Then, according to the second step of the procedure, $S_2^{j+1} = S_2^j$ and S_1^{j+1} is the supremal supervisor with respect to S_2^j/G. As $S_1^{j+1} = S_1^j$ it follows that S_1^j is optimal if S_2^j is kept fixed. This proves the first part of the Nash equilibrium condition.

From the previous iteration of the procedure it follows that $S_1^j = S_1^{j-1}$ and that S_2^j is the supremal supervisor with respect to S_1^{j-1}/G. In the next iteration supervisor S_2^{j+2} will be synthesized. Supervisor S_2^{j+2} is the optimal solution with respect to $S_1^{j+1}/G = S_1^j/G = S_1^{j-1}/G$. So S_2^{j+2} will be equal to S_2^j. Supervisor S_2^j is optimal if S_1^j is kept fixed. This proves the second part of the Nash equilibrium condition. And thus (S_1^j, S_2^j) is a Nash equilibrium. ☐

Example 4.5. Consider the system described in Example 2.18 and Figure 2. Take the pair of most restrictive supervisors corresponding with the fully decentralized solution as starting point of the procedure. In this case $S_1^0 = \mathrm{proj}(S^{\uparrow}, \Sigma_1)$ and $S_2^0 = \mathrm{proj}(S^{\uparrow}, \Sigma_2)$. Let $\Sigma_1 = \{\mathtt{a}_1, \mathtt{b}_1\}$, $\Sigma_2 = \{\mathtt{a}_2, \mathtt{b}_2\}$, and $\Sigma_{\mathrm{c}} = \{\mathtt{a}_1, \mathtt{a}_2\}$. Note that

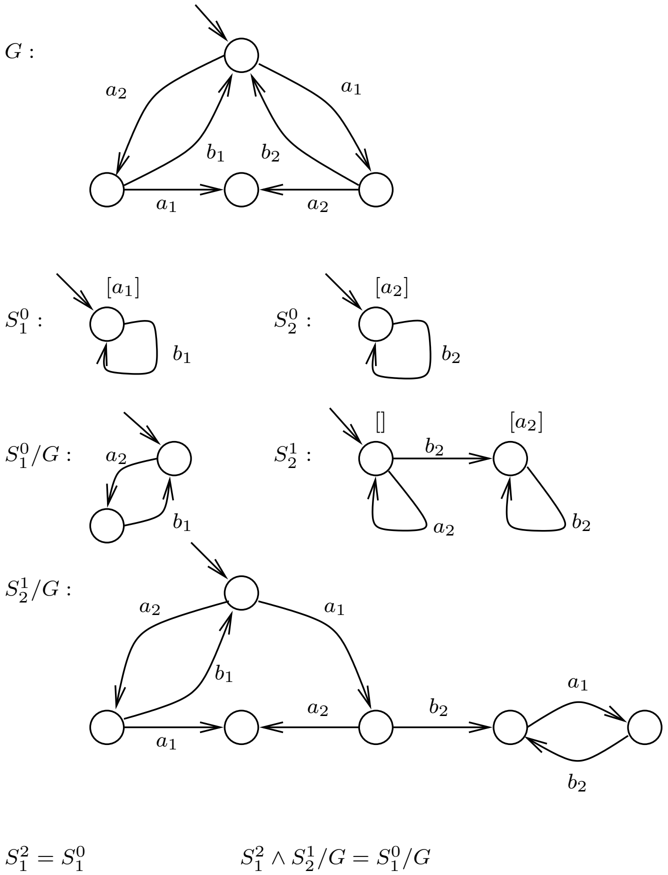

FIG. 4. *Construction of a Nash equilibrium pair of supervisors for Example* 4.5.

the event sets Σ_1 and Σ_2 are disjoint. The construction of the Nash equilibrium is summarized in Figure 4. In this construction use is made of the expression for the control law of (9). First S_1^0 is kept fixed and the optimal supervisor S_2^1 with respect to the uncontrolled system S_1^0/G is derived. Note that $L(S_1^0/G) \subseteq L(S^{\uparrow})$ and thus by (8) $K = L(S_1^0/G)$.

Next, S_2^1 is kept fixed. The language $L(S_2^1/G) \not\subseteq L(S^{\uparrow})$, so K is a proper subset of $L(S_2^1/G)$. The optimal supervisor S_1^2 with respect to the uncontrolled system S_2^1/G is derived. It turns out that $S_1^2 = S_1^0$. In subsequent steps the pair of supervisors remains invariant. The pair (S_1^2, S_2^1) is thus a Nash equilibrium, and therefore, according to Theorem 3.7, a maximal solution. The closed-loop system according to this Nash equilibrium is identical to S_1^0/G.

Example 4.6. Now, consider a slight alteration of the control problem of Example 4.5. Let $\Sigma_c = \Sigma$ and let the rest be unchanged. Take, as before, the pair of most restrictive supervisors corresponding with the fully decentralized solution as a starting point. In this case also the b-events are disabled. The construction of the pair of supervisors is then illustrated in Figure 5.

The procedure will converge to the limit pair (S_1^*, S_2^*). However, this solution will not be obtained in a finite number of steps.

The example shows that a small change in the parameters of the problem may

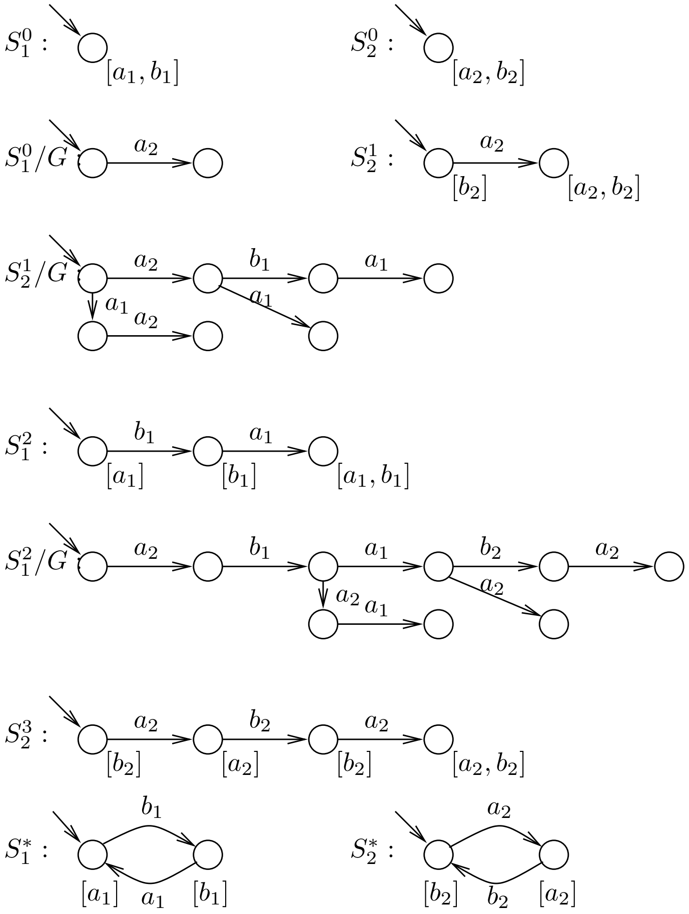

FIG. 5. *Construction of a Nash equilibrium pair of supervisors for Example* 4.6.

lead to a different solution. It may even cause the procedure to become nonhalting.

Up until now these particularities are not fully understood. Further research is needed to adapt the algorithm such that it always converges in a finite number of steps. Also, further research is required to understand the relationship between the initial parameters and the eventual solution. For decentralized control of finite-dimensional linear systems, there is an example for which the procedure does not stop after a finite number of steps and for which a decentralized controller is infinite-dimensional (see [18]). For concrete decentralized supervisory control problems a few steps of the procedure may yield a useful pair of supervisors.

It would be ideal if the procedure could produce a representation of all maximal solutions. It is not certain whether such a representation is finite.

5. Conclusions. For decentralized supervisory control a pair of supervisors is defined to be a maximal solution if there does not exist another such pair with a strictly larger closed-loop language. It has been argued that a maximal solution is of interest to control synthesis of decentralized discrete-event systems. The construction of a maximal solution is handled by analogy with game and team problems. A pair of supervisors is defined to be a Nash equilibrium if, when one supervisor is kept fixed, the other cannot be changed so as to enlarge the closed-loop language and conversely. The main result is then that a pair of supervisors is a strong Nash equilibrium if and only if it is a maximal solution.

A procedure is presented for the construction of a strong Nash equilibrium of a pair of supervisors. The procedure alternatingly keeps one supervisor fixed and solves a supervisory control problem for the other supervisor. The procedure is shown to work on an example. Another example establishes that the procedure may not stop after any finite number of steps.

Major open questions are (1) the classification of all maximal solutions for the decentralized supervisory control problem, and (2) conditions under which Procedure 4.2 stops after a finite number of steps. Experience should be gained with this approach to decentralized supervisory control.

ON THE SYNTHESIS OF OPTIMAL SCHEDULERS IN DISCRETE EVENT CONTROL PROBLEMS WITH MULTIPLE GOALS[*]

HERVÉ MARCHAND[†], OLIVIER BOIVINEAU[‡], AND STÉPHANE LAFORTUNE[‡]

Abstract. This paper deals with a new type of optimal control for discrete event systems. Our control problem extends the theory of [R. Sengupta and S. Lafortune, *SIAM J. Control Optim.*, 36 (1998), pp. 488–541] that is characterized by the presence of uncontrollable events, the notion of occurrence and control costs for events, and a worst-case objective function. A significant difference with [R. Sengupta and S. Lafortune, *SIAM J. Control Optim.*, 36 (1998), pp. 488–541] is that our aim is to make the system evolve through a set of multiple goals, one by one, with no order necessarily prespecified, whereas the previous theory only deals with a single goal. Our solution approach is divided into two steps. In the first step, we use the optimal control theory in [R. Sengupta and S. Lafortune, *SIAM J. Control Optim.*, 36 (1998), pp. 488–541] to synthesize individual controllers for each goal. In the second step, we develop the solution of another optimal control problem, namely, how to modify if necessary and piece together, or schedule, all of the controllers built in the first step in order to visit each of the goals with the least total cost. We solve this problem by defining the notion of a scheduler and then by mapping the problem of finding an optimal scheduler to an instance of the well-known traveling salesman problem (TSP) [E. L. Lawler, J. K. Lenstra, A. H. G. Rinooy Kan, and D. B. Shmoys, *The Traveling Salesman Problem*, John Wiley, 1985]. We finally suggest various strategies to reduce the complexity of the TSP resolution while still preserving global optimality.

Key words. discrete event systems, optimal control, scheduler, traveling salesman problem

1. Introduction and motivation.

We are interested in a new class of optimal control problems for discrete event systems (DES). We adopt the formalism of supervisory control theory [16] and model the system as the regular language generated by a finite state machine (FSM). Our control problem follows the theory in [19, 20, 21] and is characterized by the presence of uncontrollable events, the notion of occurrence and control costs for events, and a worst-case objective function. A significant difference with the work in [21] and with the other works dealing with optimal control of DES [6, 11, 14, 24] is that we wish to make the system evolve through a set of marked states (or multiple goals) one by one, with no order necessarily specified a priori; in contrast, the previous theories only deal with a single marked state.

Our problem formulation is motivated by several application domains such as test objective generation in verification and diagnostics, planning in environments with uncertain results of actions, and routing in communication networks.

- In test objective generation, a given system has been designed to meet some specific requirements. However, it may happen that some of these require-

ments have been overlooked or neglected. Failures can occur as a consequence of negligence. Test objective generation is a way of (ideally exhaustively) checking for inconsistencies in the behavior of the system [1, 3, 17]. The marked states (the states of interest) would be some particular states in which the behavior of the system to be tested is suspected to be flawed. The method that we develop generates a behavior for the system that allows it to reach all these states in an optimal way, with respect to the given occurrence and control cost functions for the events. Each time a state of interest is reached, a behavioral test can be performed on this particular state in order to check if it meets the requirements and conforms to the designed or expected behavior.

- In artificial intelligence (AI), the behavior of an agent is often sought to be optimized with respect to an optimality criterion [5]. Moreover, dealing with multiple goals is an active area of research in AI [13]. The model and the methods that we develop in this work can easily be applied to an agent evolving in an environment where the results of its actions are not always the ones expected. Under certain restrictions, there is a mapping between partial controllability in DES and the notion of a nondeterministic environment[1] in AI [18]. The notion of an optimal scheduler that we define and construct can be used to do planning with multiple goals.
- Broadcasting and multicasting in a communication network is an instance of a multiagent system. Here, the marked states would represent the nodes of the network to which we would want the information to be sent. The uncontrollability of certain events would be interpreted as the uncertainty regarding the actual route that the information would take, since the entire route is not up to the decision of the single sending agent. The solution that we generate can be used to determine the number of duplicated messages that must be sent in parallel through the network in order for all the desired recipients to receive the piece of information.

Our solution approach consists of two steps. The starting point is an FSM which represents the desired behavior of a given system. From this FSM, we can generate a controller that verifies any property that we would wish to associate to it, from the set of acceptable controllers. The desirable property is often taken to minimize a quantitative performance measure. In our case, we generate a controller which verifies a range of properties. This is what has been called the DP-optimality property of an FSM [21]. DP-optimality stands for dynamic programming optimality. This comes from the fact that we use back-propagation from the goal state to generate the controller, based on event cost functions. The controller is represented as an FSM also. The theory of DP-optimal controllers has been developed in the restricted case of one unique marked state [19, 20, 21]. We use the theory in [21] to synthesize a set of optimal controllers corresponding to the different marked states, each treated individually. This yields a set of FSMs that are generated independently from each other. These controllers are synthesized in a manner that gives them an optimal substructure, consistent with the notion of DP-optimality of [21]. The objective function has a worst-case form. The total worst-case computational complexity of the first step is

[1] The notion of a nondeterministic environment in AI is different from the notion of a nondeterministic FSM in control of DES. In AI, a nondeterministic environment is one where the actions undertaken by the agent might not lead to the expected arrival state of the world, whereas in control of DES, a nondeterministic FSM is one in which there are identically labeled transitions that lead from one state to different states.

cubic in the number of states in the systems. At this point, the notion of a DP-optimal controller is replaced by the notion of a stepwise DP-optimal scheduler. By scheduler, we mean a sequence of behaviors that are modeled by FSMs. We develop the solution of a "higher-level" optimal control problem, where we use all the controllers built in the first step in order to visit each of the marked states with least total cost; we call this problem that of finding a "stepwise DP-optimal scheduler." We solve this problem by defining the notion of a scheduler and then by mapping the problem of finding a stepwise DP-optimal scheduler to an instance of the well-known traveling salesman problem (TSP) [8]. We finally suggest different strategies to reduce the computational complexity of this step while still preserving global optimality by taking advantage of some particular properties of the structure of stepwise DP-optimal schedulers.

One of the differences between DP-optimality and stepwise DP-optimality resides in the controller having an FSM structure, whereas the scheduler is a concatenation of FSMs. All the states appear only once in a controller, whereas states can appear several times in a scheduler, but under different circumstances, i.e., in different submachines. Also, another difference between DP-optimal controllers and a stepwise DP-optimal scheduler for an FSM is the existence of a unique maximal DP-optimal controller which contains all the other DP-optimal controllers as submachines, whereas there is no notion of a unique maximal stepwise DP-optimal scheduler.

This paper is organized as follows. In section 2, the necessary notations are introduced. In section 3, we recall the basic definitions and properties of the optimal control theory of DES of [19, 20, 21]. More precisely, we review the notion of a DP-optimal submachine of an FSM G. This definition is used as a springboard to section 4, where we introduce the enlarged problem in the case of multiple marked states. In section 5, we define the notion of an optimal scheduler; such a scheduler ensures that the system will visit each state in a given set of states at least once while minimizing a given cost function over the trajectories of the system. We then suggest possible simplifications that can be made to reduce the overall complexity of the computation of a stepwise DP-optimal scheduler. Section 6 illustrates this new notion of optimality with an example. Section 7 presents some possible applications of the theory that is developed throughout this paper. A conclusion and discussion on future works are presented in section 8.

2. Preliminaries. In this section, the main concepts and notations are defined (more definitions will be made when necessary in the following sections). The system to be controlled is modeled as an FSM defined by a 5-tuple $G = \langle \Sigma, Q, q_0, Q_m, \delta \rangle$, where Σ is the set of events, Q is the (finite) set of states, q_0 is the initial state, Q_m is the set of marked states, and δ is the partial transition function defined over $\Sigma^* \times Q \to Q$. The notation $\delta_G(\sigma, q)!$ means that $\delta_G(\sigma, q)$ is defined, i.e., there is a transition labeled by event σ out of state q in machine G. Likewise, $\delta_G(s, q)$ denotes the state reached by taking the sequence of events defined by trace s from state q in machine G. The behavior of the system is described by the prefix-closed language $\mathcal{L}(G)$ [2], generated by G. $\mathcal{L}(G)$ is a subset of Σ^*, where Σ^* denotes the Kleene closure of the set Σ [4]. Similarly, the language $\mathcal{L}_m(G)$ corresponds to the marked behavior of the FSM G, i.e., the set of trajectories of the system ending in one of the marked states of G.

Some of the events in Σ are uncontrollable, i.e., their occurrence cannot be prevented by a controller, while the others are controllable. In this regard, Σ is partitioned as $\Sigma = \Sigma_c \cup \Sigma_{uc}$, where Σ_c represents the set of controllable events and Σ_{uc} represents the set of uncontrollable events. In what follows, we will only be interested in *trim* FSMs (i.e., FSMs whose states are all accessible from q_0 and coaccessible to Q_m). For explicit mathematical definitions, the reader may refer to [2]. We say that an FSM $A = \langle \Sigma, Q_A, q_{0A}, Q_{mA}, \delta_A \rangle$ is a submachine of G if $\Sigma_A \subseteq \Sigma$, $Q_A \subseteq Q$, $Q_{m_A} \subseteq Q_m$, and $\forall \sigma \in \Sigma_A, q \in Q_A,\quad \delta_A(\sigma, q)! \Rightarrow (\delta_A(\sigma, q) = \delta(\sigma, q))$. The statement $A \subseteq G$ denotes that A is a submachine of G. We also say that A is a submachine of G at q whenever $q_{0A} = q \in Q$ and $A \subseteq G$. For any $q \in Q$, we will use $\mathcal{M}(G, q, Q_m) = \{A \subseteq G : A \text{ is trim with respect to } Q_{m_A} \text{ and } q_{0_A} = q\}$ to represent the set of trim submachines of G at q with respect to Q_m. This set has a maximal element in the sense that this maximal element contains all other elements as submachines. It is denoted as $M(G, q, Q_m)$. For convenience, we write $\mathcal{M}(G, q)$ and $M(G, q)$ when there is only one marked state, i.e., when $Q_m = \{q_m\}$.

As stated in [21], to take into account the numerical aspect of the optimal control problem, costs are associated with each event of Σ. To this effect, we introduce an occurrence cost function $c_e : \Sigma \to \mathbb{R}^+ \cup \{0\}$ and a control cost function $c_c : \Sigma \to \mathbb{R}^+ \cup \{0, \infty\}$. Occurrence cost functions are used to model the cost incurred in executing an event (energy, time, etc.). Control cost functions are used to represent the fact that disabling a transition possibly incurs a cost. The control cost function is infinity for events of Σ_{uc}. These cost functions are then used to introduce a cost on the trajectories of a submachine A of G. To this effect, we first define a projection p_j that, when applied to a trace of events $s = \sigma_1^s \sigma_2^s \dots \sigma_{\|s\|}^s$, gives the subtrace of s of length j starting from σ_1^s ($p_j(s) = \sigma_1^s \sigma_2^s \dots \sigma_j^s$ if $j \le \|s\|$, and is undefined otherwise). We also introduce $\Sigma_d^G(A, q)$ as the set of disabled events at state q for the system to remain in submachine A of G.

Definition 2.1. *Let A be a submachine of G, and let $\mathcal{L}_m(A)$ be the marked language of A. Then the following are defined.*

- *For any state $q \in Q_A$ and string $s = \sigma_1^s \sigma_2^s \dots \sigma_{\|s\|}^s$ such that $\delta_A^*(s, q)$ exists, the cost of the string s is given by*

$$c^g(q, A, s) = \sum_{j=1}^{\|s\|} c_e(\sigma_j^s) \; + \; \sum_{j=1}^{\|s\|} \sum_{\substack{\sigma \in \Sigma_d^G(A, q') \\ q' = \delta_A(p_j(s), q)}} c_c(\sigma). \tag{2.1}$$

- *The objective function denoted as $c_{sup}^g(.)$ is given by*

$$c_{sup}^g(A) = \sup_{s \in \mathcal{L}_m(A)} c^g(q_{0A}, A, s). \tag{2.2}$$

Basically, the cost of a trajectory is the sum of the occurrence costs of the events belonging to this trajectory to which is added the cost of disabling events on the way to remain in A. If an uncontrollable event is disabled, this renders the cost of a trajectory infinite because the second term of (2.1) becomes infinity. The notation $c_{sup}^g(A)$ represents the worst-case behavior that is possible in submachine A.

3. Review of the DP-optimal problem for one final state. In general, the purpose of optimal control is to study the behavioral properties of a system, to take advantage of a particular structure, and to generate a controller which constrains the system to a desired behavior according to quantitative and qualitative aspects. In the basic setup of supervisory control theory (see [15, 16] and Chapter 3 of [2]), optimality is with respect to set inclusion, and thus all legal behaviors are equally good (zero cost) and illegal behaviors are equally bad (infinite cost). The work in [21] enriches this setup by the addition of quantitative measures in the form of occurrence and control cost functions, to capture the fact that some legal behaviors are better than others. The problem is then to synthesize a controller that is not only legal, but also "good" in the sense of given quantitative measures. Some other studies appear in [6, 11, 14, 24]. In this section, we present some results of [21] that are necessary for developing the solution procedure for optimal schedulers. Our aim here is not to describe in detail all the theory, which can be found in [19, 20, 21], but to present the principal notations and results that we use in what follows.

Definition 3.1. *A submachine A of G is said to be controllable if $\forall\ q \in Q_A$, such that there exists $s \in \Sigma^*$ and $\delta(s, q_{o_A}) = q$, the following is satisfied:*

$$\forall\sigma((\sigma \in \Sigma_{uc}) \wedge (\delta(\sigma, q)!)) \Rightarrow \delta_A(\sigma, q)!$$

We now define the optimization problem for a single marked state q_m.

Definition 3.2. *$\forall q \in Q$, $A_o \in \mathcal{M}(G, q)$ is an optimal submachine if*

$$c^g_{\sup}(A_o) = \min_{A\in\mathcal{M}(G,q)} c^g_{\sup}(A) < \infty.$$

For such a submachine A_o, $c^g_{\sup}(A_o)$ represents the optimal cost (in fact, the worst inevitable cost) necessary to reach q_m from q_0. It means that a submachine with a lower cost could not ensure the accessibility of q_m from q_0. The following lemma (Lemma 2.15 in [19]) is stated to note that optimal solutions lie within the class of controllable submachines.

Lemma 3.3. *Let $A \in \mathcal{M}(G, q, Q_m)$. If $c^g_{sup}(A) < \infty$, then A is controllable.*
Theorem 4.2 of [19] gives necessary and sufficient conditions for the existence of optimal submachines as follows.

Theorem 3.4. *An optimal submachine of G exists if and only if there exists a submachine A of G such that A is trim, controllable and $\forall s \in \mathcal{L}(G)$ and $q \in Q$ such that $\delta(s, q) = q$ we have $c^g(q, A, s) = 0$.*

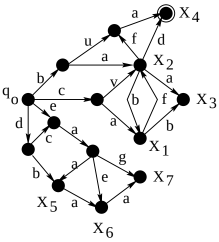
Intuitively, this theorem states that an optimal solution exists when there are controllable submachines of G in which all cycles have a zero cost. The controllability assumption ensures that the positive cost cycles can be broken using controllable events alone. We now introduce the notion of DP-optimal submachines. This kind of submachine will be used intensively in the next sections.

Definition 3.5. *A submachine $A_{DO} \in \mathcal{M}(G, q)$ is DP-optimal if it is optimal and $\forall q' \in Q_{A_{DO}}$, $M(A_{DO}, q')$ is an optimal submachine in $\mathcal{M}(G, q')$.*

If a particular DP-optimal FSM includes all other DP-optimal FSMs as submachines of itself, then we call it the *maximal DP-optimal submachine.* The maximal DP-optimal submachine of a machine G at q with respect to the final marked state q_m will be denoted by $M^o_D(G, q, q_m)$. Note that all DP-optimal submachines are acyclic. The existence of a DP-optimal submachine of G is given by the following theorem (Theorem 4.3 of [19]).

Theorem 3.6. *If an optimal submachine of G exists, then the unique maximal DP-optimal submachine $G^m_{des} = M^o_D(G, q_0, q_m)$ of G with respect to the final state q_m also exists.*

The cyclic DP-optimal algorithm. Consider an FSM $G = \langle\Sigma, Q, q_0, q_m, \delta\rangle$ with a unique initial state q_0 and a unique marked state q_m. Assume that all occurrence costs are strictly positive; then there exists an algorithm [21], named **DP-Opt**, with a worst-case complexity $\mathcal{O}(|Q|^2|\Sigma|\log(|\Sigma|)+|Q|^3|\Sigma|)$ (Theorem 6.10 of [21]), that constructs the desired maximal DP-optimal submachine of the FSM G with respect to q_0 and q_m, that we denote as G^m_{des}. The algorithm also returns the worst inevitable



Event	c_e	Remarks

cost $c^g_{sup}(G^m_{des})$. Moreover, during the computation of the algorithm, we can recover the submachines $M^o_D(G, q, q_m)$ associated with $c^g_{sup}(M^o_D(G, q, q_m))$ for each state visited during the computation. A simplified version of this algorithm can be found in [10] (when the control cost function is reduced to the null function for controllable events).

Example of the DP-optimal problem. We conclude this section by illustrating the DP-optimal problem through an example that is reused in section 6. Let G be an FSM and $\Sigma = \{a, b, c, d, e, f, g, u, v\}$ such that a, b, c, d, e, f, and g are controllable; u and v are uncontrollable. G and the event cost function defined on Σ are as in Figure 3.1. We assume $c_c \in \{0, \infty\}$. Finally, the initial state is q_0 and the final state is X_4.

Using the **DP-Opt** program, we obtain the maximal DP-optimal submachine of G, denoted G^4_{des}, for which the worst inevitable cost is equal to $c^g_{sup}(G^4_{des}) = 6$.

We can observe all the properties of the generated submachine. First, it is controllable, since from any state, there exists a path that leads surely to the goal X_4. Also, it is optimal, since all the paths leading to X_4 have a finite and minimized worst-case cost (notably, no uncontrollable event at state X_4 needs to be disabled). Finally, the DP-optimality property can be observed. From every state q of G^4_{des}, the path from q to X_4 which has the highest cost contains an uncontrollable event u that cannot be disabled.

We have reviewed the optimal control problem and the notion of DP-optimal submachines when only one marked state is present in the system. We now turn our attention to the case of multiple marked states and present our results for this new problem. This will require the introduction of a new, more comprehensive, optimality criterion.

4. The optimal control problem with multiple marked states. In the previous section, we were interested in finding a DP-optimal submachine of G that makes the system evolve from an initial state q_0 to a final state q_m by minimizing a cost function along the various trajectories of the system. Here, our goal is different. We consider an FSM G with a set of multiple marked (or final) states $\mathcal{X} = (X_i)_{i\in[1,\ldots,n]}$. Our aim is now to have the system reach each and every one of the states of $\mathcal{X}$. To account for the fact that it may not be possible to find such a path, we assume in the following the possibility of *resetting* the system to its initial state q_0, when the system has evolved in one of the states of $\mathcal{X}$. The *Reset* event that is added in this section is much more than an artifact for developing the theory. Indeed, many interpretations can be associated with it. First, there are physical systems that can actually be reset to their initial state (like a World Wide Web browser, for example). Second, the *Reset* event can be seen as an event whose occurrence signals the impossibility of visiting all the states of $\mathcal{X}$ without visiting the initial state q_0 more than once. This apparent impossibility can be alleviated by having multiple systems perform in parallel. For example, in the case of a communication network, a message that is sent cannot be brought back to the initial state. However, it can be regenerated, and then the number of *Reset* events can be regarded as an indicator of the number of copies of the message that must be generated and sent in parallel in a broadcast or a multicast (See section 7).

4.1. Stepwise DP-optimality definition. Due to the *Reset* event, the system is now represented by the following FSM $G = \langle \Sigma \cup \{Reset\}, Q, q_0, \mathcal{X}, \delta\rangle$, with $\delta(Reset, X_i) = q_0 \ \forall X_i \in \mathcal{X}$. As in the previous section, we introduce cost functions that take into account the particular *Reset* event: the occurrence cost function $c_e : \Sigma \cup \{Reset\} \to \mathbb{R}^+ \cup \{0\}$ such that $\forall \sigma \in \Sigma, c_e(\sigma) \geq 0$ and $c_e(Reset) = 0$, and the control cost function $c_c : \Sigma \cup \{Reset\} \to \mathbb{R}^+ \cup \{0, \infty\}$ such that $\forall \sigma \in \Sigma, c_c(\sigma) \geq 0$ and $c_c(Reset) = 0$.

DEFINITION 4.1. *Let $s \in \mathcal{L}_m(G)$. The trajectory s is said to be* valid *if there exists at least n prefixes of s, $(s_i)_{i\in[1,\ldots,n]}$, such that $\delta(q_0, s_i) = X_i \in \mathcal{X}$.*

In other words, a trajectory is valid if it makes the system evolve into each of the marked states in $\mathcal{X}$. Note that the definition does not require that the trajectory visit each marked state exactly once. Besides, due to the *Reset* event, the system has the possibility of coming back in its initial state along the trajectory. The set of valid trajectories of the FSM G will be denoted as $\mathcal{S}$.

Given that our primary interest is in the states of $\mathcal{X}$, we introduce the notion of a *valid state trajectory.*

DEFINITION 4.2. *Let s be a valid trajectory in $\mathcal{S}$, such that $s = t_1^s \ldots t_l^s$, with $l > n$ and $\delta(q_0, t_1^s \ldots t_k^s) = X_k^s \in \mathcal{X} \cup \{q_0\}$. We define the function D from $\mathcal{S}$ into $\{q_0\}(\mathcal{X}^*\{q_0\})^*$, such that $D(s) = (X_k^s)_{k\in[1,\ldots,l]}$.*[2] *Such a trajectory is called a* valid state trajectory *with respect to $\mathcal{X}$. We denote as $\mathcal{D}$ the set of valid state trajectories in G, with respect to the set of valid trajectories $\mathcal{S}$: $\mathcal{D} = D(\mathcal{S})$.*

A valid state trajectory $d \in \mathcal{D}$ corresponds to a trajectory in $\{q_0\}(\mathcal{X}^*\{q_0\})^*$ that contains all the states of $\mathcal{X}$ (with possible repetitions).

Since we must deal with a set of marked states rather than with a single marked state, we need to introduce a model that comprises all the states of the set $\mathcal{X}$ and that accounts for the global behavior of the system. It is not possible to use a classical merge operation ($\oplus$, Definition 6.2 in [21]), because states might appear in different submachines in different contexts, i.e., with different partial transition functions associated with them. Therefore, instead of using a merge, we introduce the notion of a scheduler. A scheduler can be thought of as a concatenation of (DP-optimal, in our case) submachines. The role of the scheduler is then to make the system evolve according to one submachine at a time and to account for switching between them at appropriate instants. In what follows, the symbol "$\circ$" will denote the concatenation of two submachines A and A' of G. It is defined in terms of languages. Let $\mathcal{L}_m(A)$ and $\mathcal{L}_m(A')$ be the marked languages of A and A'. Then $\mathcal{L}_m(A \circ A') = \{st \ : \ s \in \mathcal{L}_m(A), \ t \in \mathcal{L}_m(A')\}$. Note that $\mathcal{L}_m(A \circ A') \subseteq \mathcal{L}_m(G)$ if and only if $Q_{m_A} = \{q_{0_{A'}}\}$ and $Q_{m_{A'}} \subseteq Q_{m_G} = \mathcal{X}$. Also note that, due to possible cycles in the FSM G, $A \circ A'$ is in general no longer a submachine of G since some state q of G may be shared by the two submachines A and A' but without the same transitions.

[2] This function allows the "extraction" of the state trajectory in G from the valid trajectory s.

Definition 4.3. *Let $d = (X^d_{k'})_{k' \in [0,\dots,l]} \in \mathcal{D}$ be a valid state trajectory of $\mathcal{X} \cup \{q_0\}$, and let $(A_k)_{k \in [1,\dots,l]}$ such that $l \geq n$ and $A_k \in \mathcal{M}(G, X^d_{k-1}, X^d_k)$ $\forall k \in [1,\dots,l]$; then the structure $A = A_1 \circ A_2 \circ \cdots \circ A_l$ is called a* scheduler *with respect to G and $\mathcal{X}$. The set of schedulers with respect to G and $\mathcal{X}$ is denoted as $\mathcal{M}^{sc}(G, \mathcal{X})$.*

In this particular case, for each submachine of the scheduler, there is only one initial state and one final state. Hence, for two consecutive submachines A_i and A_{i+1}, we have $q_{m_{A_i}} = q_{0_{A_{i+1}}}$. Note that for a scheduler $A = A_1 \circ A_2 \circ \cdots \circ A_l$, some A_k may be simply reduced to the simple FSM $(X^d_k \xrightarrow{Reset} q_0)$. This FSM is clearly a DP-optimal submachine from X^d_k to q_0. Besides, in some cases, $\mathcal{M}^{sc}(G, \mathcal{X})$ can be reduced to $\emptyset$. The cost associated with a scheduler $A = A_1 \circ A_2 \circ \cdots \circ A_l$, denoted as $C^{sc}_{sup}(A)$, is given by

$$C^{sc}_{sup}(A) = \sum_{i=1}^{l} c^g_{sup}(A_i). \tag{4.1}$$

The following definition extends the notion of DP-optimality to the notion of stepwise DP-optimality.

Definition 4.4. *Let $A \in \mathcal{M}^{sc}(G, \mathcal{X})$ be a scheduler, such that A makes the system evolve through a valid state trajectory $d = (X^d_{k'})_{k' \in [0,\dots,l]}$ of $\mathcal{D}$. $A = A_1 \circ A_2 \circ \cdots \circ A_l$ is said to be* stepwise DP-optimal *if each of the submachines $A_k \in \mathcal{M}(G, X^d_{k-1}, X^d_k)$ is DP-optimal with respect to its initial state X^d_{k-1} and final state X^d_k, and if the following condition is satisfied:*

$$C^{sc}_{sup}(A_o) = \min_{A \in \mathcal{M}^{sc}(G,\mathcal{X})} C^{sc}_{sup}(A) < \infty.$$

We wish to draw attention to the following assumption.

Assumption 4.1. From now on, we assume that the DP-optimal submachines under consideration, with the exception of $(X^d_k \xrightarrow{Reset} q_0)$, are maximal. This is done for two main reasons. First, the algorithm **DP-Opt** (see Appendix A of [10]) outputs exactly the maximal DP-optimal submachines. Second, taking the maximal DP-optimal submachines allows the system greater freedom. Indeed, it contains all the other DP-optimal submachines; therefore, it has more possible paths from the initial state to the final marked state. In most applications, it is desirable to lower the probability of taking the worst-case cost path, which is the intent of taking the maximal DP-optimal submachine for $(G^i_{des})_{i \in [1,\dots,n]}$. The more possible paths there are, the less likely it is for the system to take the worst-case cost path. Note that the *Reset* machine $(X^d_k \xrightarrow{Reset} q_0)$ need not be maximal (this can only happen if occurrence costs cannot be equal to zero); in this case, however, given our interpretation of the *Reset* event, we will include the single transition $(X^d_k \xrightarrow{Reset} q_0)$ in the scheduler.

Under this assumption, the following property is a direct consequence of Definition 4.4.

Property 4.2. *Let G be an FSM, and let $\mathcal{X}$ be the set of marked states of G. Let A be a stepwise DP-optimal scheduler, such that $A = A_1 \circ A_2 \circ \cdots \circ A_l$. Let $d = (X^d_k)_{k \in [0,\dots,l]}$ of $\mathcal{D}$ be the associated valid state trajectory. Then $\forall k \in [1,\dots,l]$, $A_k = M^o_D(G, X^d_{k-1}, X^d_k)$. Furthermore, the global cost of the scheduler is*

$$C^{sc}_{sup}(A) = \sum_{k=1}^{l} c^g_{sup}(M^o_D(G, X^d_{k-1}, X^d_k)) < \infty. \tag{4.2}$$

This property states that if a stepwise DP-optimal scheduler exists, then all the submachines constituting this scheduler are the respective $M_D^o(G, X_{k-1}, X_k)$. Moreover the cost of the scheduler is then simply equal to the sum of the costs of these DP-optimal submachines. We will refer to this important result as the *additivity property* of the stepwise DP-optimal scheduler. In what follows, the set of all schedulers A such that all the submachines of A are of the form $M_D^o(G, X_i, Xj)$ for $X_i, X_j \in \mathcal{X} \cup \{q_0\}$, is denoted $\mathcal{M}_D^{sc}(G, \mathcal{X})$.

Now that we have defined the notion of a stepwise DP-optimal scheduler and given some of its properties, we need to give necessary and sufficient conditions for its existence. The next subsection gives these conditions and also proves desirable properties of such a scheduler.

4.2. Existence of a stepwise DP-optimal scheduler. Theorem (4.7) presented below gives necessary and sufficient conditions for the existence of a stepwise DP-optimal scheduler. First we prove the following lemma.

LEMMA 4.5. *If the DP-optimal submachines $M_D^o(G, X_i, X_j)$ and $M_D^o(G, X_j, X_k)$ of G exist, then there exists a DP-optimal submachine $M_D^o(G, X_i, X_k)$. Moreover, we have the following* triangular inequality:

$$c^g_{sup}(M_D^o(G, X_i, X_k)) \le c^g_{sup}(M_D^o(G, X_i, X_j)) + c^g_{sup}(M_D^o(G, X_j, X_k)). \tag{4.3}$$

Proof. Assume the existence of $M_D^o(G, X_i, X_j) = \langle \Sigma_{ij}, Q_{ij}, X_i, X_j, \delta_{ij} \rangle$ and of $M_D^o(G, X_j, X_k) = \langle \Sigma_{jk}, Q_{jk}, X_j, \{X_k\}, \delta_{jk} \rangle$. Consider the intersection of the states of these two submachines as being $Q_{ij} \cap Q_{jk} = \{X_j, q_1, \ldots, q_n\}$. Note that this intersection might be reduced to $\{X_j\}$. We construct a new submachine $G_{ik} = \langle \Sigma_{ik}, Q_{ik}, q_{0_{ik}}, Q_{m_{ik}}, \delta_{ik} \rangle$ from these submachines:

$$G_{ik} = \begin{cases} \Sigma_{ik} & = \quad \Sigma_{ij} \cup \Sigma_{jk}, \;\; Q_{ik} \;\; = \;\; Q_{ij} \cup Q_{jk}, \\ q_{0_{ik}} & = \quad X_i, \qquad\quad Q_{m_{ik}} \;\; = \;\; \{X_k\}, \\ \delta_{ik}(\sigma, q) & = \quad \begin{cases} \delta_{jk}(\sigma, q) \text{ if it exists and } q \in Q_{jk}, \\ \delta_{ij}(\sigma, q) \text{ if it exists and } q \in Q_{ij} - \{X_j, q_1, \ldots, q_n\}, \\ \text{undefined otherwise.} \end{cases} \end{cases}$$

This submachine G_{ik} is well defined. Any possible ambiguity has been eliminated by separately dealing with the states $\{X_j, q_1, \ldots, q_n\}$ in the definition of δ_{ik}. G_{ik} is obtained by always following the partial transition function of $M_D^o(G, X_j, X_k)$ as a default behavior, and following the partial transition function of $M_D^o(G, X_i, X_j)$ otherwise whenever possible. First, the machines $M_D^o(G, X_i, X_j)$ and $M_D^o(G, X_j, X_k)$ are trim. Second, G_{ik} is constructed by forward propagation; therefore, all the states of G_{ik} are accessible with respect to the initial state X_i and are coaccessible with respect to the marked state X_k. Therefore, G_{ik} is trim.

Moreover, G_{ik} is controllable. Indeed, the partial transition function δ_{ik} says that as long as the system has not reached a state of the set $\{X_j, q_1, \ldots, q_n\}$, it follows the partial transition function of δ_{ij}. Due to the DP-optimality of $M_D^o(G, X_i, X_j)$, the system will always reach a state of the set $\{X_j, q_1, \ldots, q_n\}$ with a finite cost. Indeed, if the system never visits a state in $\{q_1, \ldots, q_n\}$, it will eventually reach X_j. Let us call q the first state of the set $\{X_j, q_1, \ldots, q_n\}$ that is visited by the system as it evolves. At this point, the default partial transition function becomes δ_{jk}; therefore, the system will eventually reach the marked state X_k with a finite cost since the submachine $M_D^o(G, X_i, X_j)$ is DP-optimal. Since the cost of reaching X_k from q is finite, the overall cost of reaching X_k is necessarily finite. From Lemma 3.3, G_{ik} is controllable.

Finally, G_{ik} has no positive cost cycles. $M_D^o(G, X_i, X_j)$ and $M_D^o(G, X_i, X_k)$ do not have positive cost cycles (by definition of DP-optimality). As we have described previously, before the system reaches a state of $\{X_j, q_1, \ldots, q_n\}$ for the first time, it will not complete a positive cost cycle (from the DP-optimal nature of $M_D^o(G, X_i, X_j)$). After the system reaches a state of $\{X_j, q_1, \ldots, q_n\}$ for the first time, it will not complete a positive cost cycle either (from the DP-optimal nature of $M_D^o(G, X_j, X_k)$). Therefore, no new cycles have been introduced. The only cycles that may exist in G_{ik} are those of $M_D^o(G, X_i, X_j)$ and $M_D^o(G, X_j, X_k)$.

Given that G_{ik} is trim, controllable, and contains no cycles of positive cost in G, FSM G_{ik} satisfies the preconditions of Theorem (3.4), and there exists an optimal submachine of G_{ik}. Following Theorem 3.6, there also exists a DP-optimal submachine $M_D^o(G, X_i, X_k)$ of G_{ik}.

The proof of the *triangular inequality* relies on what we have said previously. The cost of reaching a state of the set $\{X_j, q_1, \ldots, q_n\}$, from the initial state X_i, is less than $c^g_{sup}(M_D^o(G, X_i, X_j))$ (equality is possible but not necessary when X_j is reached). Once one of the states $\{X_j, q_1, \ldots, q_n\}$ has been reached, the cost for the system to reach the marked state X_k is less than $c^g_{sup}(M_D^o(G, X_j, X_k))$ (equality is possible but not necessary when the system visits X_j) because the corresponding machine is DP-optimal. More formally, let us take a trace s of events that leads from the initial state X_i to the final state X_k, i.e., such that $\delta_{ik}(s, X_i) = X_k$. As seen earlier, s visits at least one state of the set $\{X_j, q_1, \ldots, q_n\}$. Let us call it q again. We can now subdivide s into s_1 and s_2 such that $s = s_1 s_2$, $\delta_{ik}(s_1, X_i) = q$, and $\delta_{ik}(s_2, q) = X_k$. From the DP-optimality of the two submachines $M_D^o(G, X_i, X_j)$ and $M_D^o(G, X_j, X_k) \forall s$ such that $s = s_1 s_2$, $\delta_{ik}(s_1, X_i) = q$, $\delta_{ik}(s_2, q) = X_k$, we can compare

$$\begin{cases} c^g(X_i, M_D^o(G, X_i, X_j), s_1) \leq c^g_{sup}(M_D^o(G, X_i, X_j)), \\ c^g(q, M_D^o(G, X_j, X_k), s_2) \leq c^g_{sup}(M_D^o(G, X_j, X_k)). \end{cases}$$

Since this is true for all traces leading from X_i to X_j, we can deduce the triangular inequality. □

The following corollary uses the construction in the proof of Lemma 4.5 to introduce a necessary condition for the existence of a stepwise DP-optimal scheduler. The proof is straightforward and can be found in [10].

COROLLARY 4.6. *If G^k_{des} does not exist, then there exists no subscheduler that makes the system evolve from q_0 to X_k, should it be indirectly via states of $\mathcal{X}$.*

As a consequence of these results, we can ensure that a state X_k is accessible in an optimal way if and only if G^k_{des} exists. We are now able to give the necessary and sufficient conditions of the existence of a stepwise DP-optimal scheduler. This is stated by Theorem 4.7.

THEOREM 4.7. *There exists a corresponding stepwise DP-optimal scheduler $A \in \mathcal{M}_D^{sc}(G, \mathcal{X})$ if and only if the n DP-optimal submachines G^i_{des} of G exist $\forall X_i \in \mathcal{X}, i \in [1, \ldots, n]$.*

Proof. The necessary condition is given by Corollary 4.6, which states that if there is a state X_i of $\mathcal{X}$ such that there does not exist a DP-optimal submachine G^i_{des}, then there is no way to reach this state with a finite cost (thus in a DP-optimal way) and the goal cannot be achieved. All the states of $\mathcal{X}$ cannot be visited, since one of them cannot be visited. The condition is sufficient since FSM A, such that

$A = G^1_{des} \circ (X_1 \xrightarrow{Reset} q_0) \circ G^2_{des} \circ (X_2 \xrightarrow{Reset} q_0) \circ \cdots \circ G^n_{des} \circ (X_n \xrightarrow{Reset} q_0)$, visits all the states of $\mathcal{X}$. A is then a possible scheduler allowing the achievement of the goal. $\square$

This theorem implies that the stepwise DP-optimal problem has a solution when there exists a DP-optimal submachine for each of the X_i. Besides, if a stepwise DP-optimal solution exists, it need not be unique in general. There is no notion of a maximal stepwise DP-optimal scheduler, as in the DP-optimal problem [21]. The problem of finding one of the optimal schedulers is now explored.

5. Determination of a stepwise DP-optimal scheduler. In this section, we need to assume that the occurrence costs are strictly positive: $\forall \sigma \in \Sigma,\ c_e(\sigma) > 0$. This assumption is necessary when we use the **DP-Opt** algorithm in order to ensure polynomial complexity. We also assume that a DP-optimal submachine exists for all the states $X_i \in \mathcal{X}$. From here on, G^i_{des} will denote the maximal DP-optimal submachine of the particular FSM $G_i = \langle \Sigma, Q, q_0, X_i, \delta \rangle$ output by the **DP-Opt** algorithm. We take advantage of the DP-optimal structure of each of the G^i_{des}. We explore the possibility of starting the system at q_0, reaching a state X_i, and instead of doing a *Reset*, continuing the graph to a state X_j. To do so, we convert the problem to a path-cost minimization problem on a graph equivalent to a TSP.

5.1. Modeling of the problem. In order to convert the stepwise DP-optimal problem into a path-cost minimization problem, we use the **DP-Opt** algorithm. This algorithm computes for each $X_i \in \mathcal{X}$ the DP-optimal submachine G^i_{des}. During this computation, a state X_j belonging to $\mathcal{X}$ may be reached. Due to the DP-optimality definition, the algorithm also gives the DP-optimal submachine between X_j and X_i. The worst inevitable case cost between these two states can be collected as well and placed in a matrix $C \in \mathbb{R}^{n+1} \times \mathbb{R}^{n+1}$ that has the following form (see [10] for the algorithm and further details):

$$\text{(5.1)} \quad \begin{array}{ll} \bullet\ C[i,i] = \infty, & \bullet\ C[i,0] = 0, i \neq 0, \\ \bullet\ C[0,i] = c^g_{sup}(G^i_{des}), i \neq 0, & \bullet\ C[k,i] = \begin{cases} c^g_{sup}(M^o_D(G, X_k, X_i)) \text{ if it exists,} \\ \infty \text{ otherwise.} \end{cases} \end{array}$$

From additivity Property 4.2, the cost of a scheduler $A = A_1 \circ A_2 \circ \cdots \circ A_l$ of $\mathcal{M}^{sc}_D$ is equal to

$$\text{(5.2)}\ C^{sc}_{sup}(A) = \sum_{k=1}^{l} c^g_{sup}(A_k) \ = \ \sum_{k=1}^{l} c^g_{sup}(M^o_D(G, X_{d_{k-1}}, X_{d_k})) \ = \ \sum_{k=1}^{l} C[d_{k-1}, d_k].$$

Considering (5.2), the new optimization problem is now reduced to finding a path with a minimal cost in the directed graph associated with the matrix C. This closely resembles the TSP with the slight difference that multiple visits to states of $\mathcal{X}$ are possible. In this new problem, the "cities" are represented by the set of nodes $\mathcal{X}$, and the "streets" are represented by machines $(G^i_{des})_{i \in [1,\ldots,n]}$ and $M^o_D(G, X_i, X_j)$ when these are available. The costs of these paths are given by the maximum costs for each machine, i.e., the $(c^g_{sup}(G^i_{des}))_{i \in [1,\ldots,n]}$ and the $(c^g_{sup}(M^o_D(G, X_i, X_j)))_{i,j \in [1,\ldots,n]}$. Figure 5.1 illustrates this conversion from the graph of the FSM to the reachability graph.

Note that some elements of C might be equal to ∞ after all G^i_{des} have been computed, which does not mean that the corresponding DP-optimal submachines do not exist. This means that they have not been computed in the algorithm **DP-Opt**.

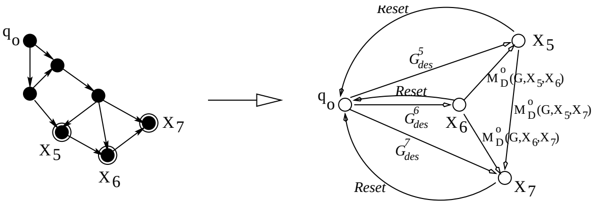

FIG. 5.1. *Conversion from the FSM to a reachability graph on the marked states.*

Indeed, let us suppose that some $M^o_D(G, X_i, X_j)$ has not been computed (and that therefore $C[i, j] = \infty$). It means that it is less costly to perform a *Reset* from state X_i to state q_0, and to reach X_j through G^j_{des}. Another way of seeing this is to look at what the **DP-Opt** algorithm does. It backtracks from the marked state, say X_j. If it reaches X_i before q_0, this means that the cost from X_i to X_j is less than the cost from q_0 to X_j, in which case it is less costly to go directly from X_i to X_j than to reset the system. On the other hand, if state X_i is not reached when the algorithm reaches q_0 during its backtracking, it means that the cost to go from X_i to X_j is greater than the cost of resetting the system (0 in our case) and taking the DP-optimal submachine G^j_{des}. This explains why these paths are not taken into account as possible paths and are directly replaced in the matrix C by an infinite cost.

5.2. Generation of the stepwise DP-optimal scheduler. The problem of finding a stepwise DP-optimal scheduler A_0 has been brought down to solving an instance of the TSP, a classic combinatorial optimization problem. Many methods exist to solve the problem in an acceptable amount of time [8]. We specify once more the conditions in which we solve the TSP. The costs of the paths are all nonnegative. The nodes of $\mathcal{X}$ must be visited *at least once.* One requirement of the TSP is that the salesman come back to the city he started from. This condition does not change anything in our problem since this maps to a *Reset*, which has null cost in our model. Finally, note that the cost matrix C, given in section 5.1, is not necessarily symmetric.

The first step is to transform our modified version of the TSP, where we can visit a node more than once (but at least once), into an ordinary TSP where we must visit each node exactly once. This is typically done by transforming the matrix C into a matrix C', called the all-pairs shortest-paths matrix [8]. Many techniques exist to perform such a computation. Among them is the Floyd–Warshall algorithm [8], which runs in a worst case of $\mathcal{O}(n^3)$, where n represents the number of vertices. Once the all-pairs shortest-paths matrix C' is obtained, we can feed it to a TSP solver.

C and C' have the same dimension but represent different features of the graph. C contains, as noninfinite elements, the costs of the links that actually exist in the graph of the TSP. C' contains the minimum costs necessary to go from one marked state to another, along DP-optimal submachines. C' is a reachability matrix, whereas C is a connectivity matrix. Notably, C' shows if states can be reached by using the *Reset* event. Concretely, to obtain C' from C, one only needs to replace any infinite value in C by the value in the same column in the first line (the cost of the G^i_{des} associated with column i).

Resolution of the TSP. The actual solving of the TSP from matrix C' can be done by using several methods. The most common method is the branch and bound method (see Chapters 9 and 10 of [9] and [12, 7]). An outline of the method can be found in Appendix B of [10]. The worst-case complexity for solving the TSP is

$(n+1)!$. However, the branch and bound method is expected to give a solution to the TSP in a tolerable amount of time. (To give a feel of the time complexity of this method, a 1,000 node fully-connected TSP can be solved in about 20 minutes on a standard workstation.)

The principle of the branch and bound method is quite natural. A branching strategy and a bounding strategy are used alternatively. The branching strategy consists of forcing a supplementary constraint to the system, usually by forcing a set of subpaths in the graph. This allows us to find a solution that is suboptimal in general but that is sometimes optimal. The bounding strategy focuses on finding a lower bound on the cost of the optimal solution by relaxing one of the constraints of the problem (usually by relaxing the constraint that the solution must be a tour). The branching yields a search tree, and the bounding yields a way of quickly finding a suboptimal solution which is close to the optimal solution of the problem. The final solution is optimal.

5.3. Restitution of the stepwise DP-optimal scheduler. From a solution of the TSP, we now build a corresponding stepwise DP-optimal scheduler. The resolution of the TSP provides an optimal solution that gives the ordering in which the states should be visited so as to minimize the worst-case cost. A solution is under the form of a set of $n+1$ pairs (there are $n+1 = |\mathcal{X} \cup \{q_0\}|$ states), in which each state appears exactly once as an initial state and exactly once as a final state of a pair. For pairs (X_i, X_j) that represent a physically existing submachine $M_D^o(G, X_i, X_j)$, i.e., for which $C[i,j] < \infty$, it is sufficient to map these pairs to their associated submachine. As for the pairs (X_i, X_j) that do not map to an existing DP-optimal submachine, i.e., those for which $C[i,j] = \infty$ and $C'[i,j] < \infty$, they are divided into two pairs, namely, (X_i, q_0) and (q_0, X_j). The first is mapped to a *Reset* to the initial state, and the second is mapped to the DP-optimal submachine G_{des}^j.

THEOREM 5.1. *Given a solution of the TSP, by adopting the previous mapping, the obtained scheduler is stepwise DP-optimal.*

Proof. The initial solution of the TSP with respect to the matrix C' is given by a tour of the form $\{(q_0, X_{i_1}); (X_{i_1}, X_{i_2}); \dots (X_{i_j}, X_{i_{j+1}}); \dots; (X_{i_n}, q_0)\}$ with a corresponding cost $TSP(C') = C'[0, i_1] + C'[i_1, i_2] + \cdots + C'[i_j, i_{j+1}] + \cdots + C'[i_n, 0]$. Consider now the transformation previously adopted. If the pair (X_i, X_j) originally exists, i.e., $C[i,j] < \infty$, then the path is admissible in the original problem and we replace the pair by the submachine $M_D^o(G, X_i, X_j)$, where the corresponding cost $c_{sup}^g(M_D^o(G, X_i, X_j))$ is equal to $C[i,j]$. If the pair (X_i, X_j) does not map to an existing DP-optimal submachine, i.e., $C[i,j] = \infty$, then we need to *Reset* the system before directly going to X_j through G_{des}^j. The *triangular inequality* of Lemma (4.5) ensures that in this case, $C'[i,j] = c_{sup}^g(G_{des}^j)$. The pair is then replaced by the subscheduler $(X_i \xrightarrow{Reset} q_0) \circ G_{des}^j$, with the corresponding cost equal to $c_{sup}^g(G_{des}^j)$.

We then obtain a new sequence of pairs, with a cost equal to $TSP(C')$ but for which all the submachines actually exist in the original problem. The DP-optimality of each submachine of the scheduler is given by construction, since we only consider submachines of the form $M_D^o(G, X_i, X_j)$ or G_{des}^j. The minimal cost of the scheduler is ensured by the optimality of the TSP solution and by the fact that the mapping does not add new costs. □

An interesting property is given next. It states that all the submachines that constitute a stepwise DP-optimal scheduler are directly derived from all the DP-optimal submachines built during the computation of the matrix C (see section 5.1 and (5.1)).

PROPOSITION 5.2. *A stepwise DP-optimal scheduler A_o obtained by the TSP solution is composed of exactly n different DP-optimal submachines (not counting the possible Resets of the system). Moreover, all these submachines are obtained from the DP-optimal submachines $(G^i_{des})_{i\in[1,\dots,n]}$ computed during the matrix generation step (see* (5.1)*).*

Proof. The general solution of the TSP for the matrix C' is a tour of the form $\{(q_0, X_{i_1}); (X_{i_1}, X_{i_2}); \dots; (X_{i_j}, X_{i_j}); \dots; (X_{i_n}, q_0)\}$. Note that there are exactly $n+1$ pairs in this tour (but the last pair is a trivial one, i.e., a *Reset*). If a pair (X_i, X_j) originally exists, i.e., if $C[i,j] < \infty$, then the path is in the original problem and it is replaced by the submachine $M^o_D(G, X_i, X_j)$. If not, i.e., if $C[i,j] = \infty$, then the system is reset before directly going to X_j through G^j_{des}. The pair is then replaced by the subscheduler $(X_i \xrightarrow{Reset} q_0) \circ G^j_{des}$. The n pairs are then replaced by either the DP-optimal submachine $M^o_D(G, X_i, X_j) = Trim(G^j_{des}, X_i, X_j)$, or by the subscheduler $(X_i \xrightarrow{Reset} q_0) \circ G^j_{des}$. The final solution of our problem has then exactly n nontrivial submachines that can be obtained from the n DP-optimal submachine $(G^i_{des})_{i=[1,\dots,n]}$ of G, by a trim operation. □

COROLLARY 5.3. *In a stepwise DP-optimal scheduler obtained by the TSP solution, the states of $\mathcal{X}$ are visited exactly once by the stepwise DP-optimal scheduler.*[3]

We wish to draw attention to the following fact. The stepwise DP-optimal scheduler visits each marked state exactly once when it is obtained from the TSP solution. However, the system itself, through its evolution described by the FSM G, may visit a marked state of G more than once. This comes from the fact that the scheduler is constructed on C', whereas the behavior of the system modeled by the FSM G should be observed at a less abstract level, namely at the level of the FSM, G.

Remark 5.1. In [10], we also presented the resolution of the stepwise DP-optimal problem in the case of a nonzero occurrence cost for the *Reset* event (see section 5.3 of [10] for further details).

5.4. Some simplifications of the TSP resolution. In order to solve the stepwise DP-optimal problem, we have to solve the corresponding TSP for the matrix C. The TSP is an NP-complete problem. It is then greatly advantageous to find some simplification methods, taking advantage of the special structure of a stepwise DP-optimal scheduler, in order to reduce the computational complexity of the corresponding TSP without loss of global optimality. Proofs and algorithms are omitted in this section due to lack of space. They can be found in the companion paper [10].

5.4.1. Divide and conquer. In some cases, it is possible to divide the matrix C into several smaller ones. In such cases, it suffices to solve the TSP on each of these submatrices. The following proposition states the necessary and sufficient conditions for this simplification.

PROPOSITION 5.4. *Assume there exists a partition of $\mathcal{X} = \cup_{k\in[1,\dots,l]}(\mathcal{X}_k)$ such that $\forall k_1, k_2 \in [1,\dots,l]$, $\forall X_i \in \mathcal{X}_{k_1}$, and $\forall X_j \in \mathcal{X}_{k_2}$, the submachine $M^o_D(G, X_i, X_j)$ is not defined.*

If A_o is a stepwise DP-optimal scheduler with respect to $\mathcal{X}$, then it is possible to find a set of schedulers $A_{\mathcal{X}_k}$, where each $A_{\mathcal{X}_k}$ is stepwise DP-optimal with respect to $\mathcal{X}_k$ with an optimal cost $c^{sc}_{sup}(A_{\mathcal{X}_k})$ to visit of all the states of $\mathcal{X}_k$, and such that $A_o = \circ^l_{k=1} A_{\mathcal{X}_k}$ with $c^{sc}_{sup}(A_o) = \sum^l_{k=1} c^{sc}_{sup}(A_{\mathcal{X}_k})$.

[3] The proof is omitted and can be found in [10].

In view of Proposition 5.4, the global problem can be solved on each submatrix C_k, $k \in [1,\ldots,l]$, corresponding to the particular set of states $\mathcal{X}_k \cup \{q_0\}$. The necessary computation to find the connected components before applying Proposition 5.4 can be performed in $\mathcal{O}(n+E)$, where E is the number of vertices of the directed graph associated to matrix C (see [10] for details).

5.4.2. Terminal path simplification. We address here a property of the scheduler that can lead to a simplification on the matrix C. This property states that if there exists a kind of "dead-end" in the graph of the matrix, then it is always better to follow this path until the end than to perform a *Reset* and come back to visit the end of this path later.

Proposition 5.5. *Assume that there exists a subset $\mathcal{X}_i = (X_{i_k})_{k\in[1,\ldots,m]}$ of $\mathcal{X}$, with $m < n$ and such that*

1. *$\forall k \in [1,\ldots,m-1]$, $M^o_D(G, X_{i_k}, X_{i_{k+j}})$ exists for $j \in [1,\ldots,m-k]$,*
2. *$\forall k \in [2,\ldots,m]$, $M^o_D(G, X_{i_k}, X_{i_{k-j}})$ does not exist for $j \in [1,\ldots,k-1]$,*
3. *$\forall k \in [1,\ldots,m]$ and $\forall X_l \in \mathcal{X} - \mathcal{X}_i$, $M^o_D(G, X_{i_k}, X_l)$ is not defined.*

Under these assumptions, the submachines $(G^{i_k}_{des})_{k\in[2,\ldots,m]}$ do not belong to the stepwise DP-optimal scheduler A_o.

Proposition 5.5 deals with situations where a dead-end occurs. By dead-end, we mean a set of states $\{q_1,\ldots,q_n\}$ in which $\forall i \in [1,\ldots,n]$, $(q_j)_{j>i}$ are the only states coaccessible from q_i. If there exists a dead-end in the graph of marked states, the system will never enter that dead-end directly through one of the G^i_{des} but will only enter indirectly from the initial state q_0. This means that no direct submachine of the type G^i_{des} will be used by a scheduler to enter a dead-end. Any visit to a state of the dead-end is done via a visit to a state that does not belong to the dead-end.

An algorithm that performs this simplification on the matrix C according to the three assumptions in Proposition 5.5 is presented in [10]. Its complexity is linear in the number of states of $\mathcal{X}$. With this simplification, the paths of the form $q_0 \to X_{i_k}$ do not constitute valid paths any longer and, consequently, will not be taken into account as possible solutions in the corresponding TSP solution. This terminal path simplification can narrow down the search space when solving the TSP.

5.4.3. Predefined partial order for the visit of $\mathcal{X}$. Throughout section 5, we have assumed that we had no prespecified order in which to visit the marked states in $\mathcal{X}$. This may be the case in several applications. However, in other applications, such as test-generation, we may be interested in the path taken by a system more than in the final state it reaches. The designer may want to enforce the system to follow a given path. The path would be characterized by the states it traverses, which would be marked. This would yield an ordering, not on the marked states, but on the subpaths themselves. A possible extension of this predefined partial order assumption would be to consider our problem in a hierarchical setting in the same spirit as in [23, 22].

Let us consider a simple example. Assume that we have the marked states $\{X_1,\ldots,X_{10}\}$ to visit in an optimal way. If we do not prespecify the order in which they should be visited, the TSP will be solved on a 10 × 10 matrix. The designer may want to observe the behavior of the system when it visits states X_1 through X_3 in that order, X_4 through X_7 in that order, and X_7 through X_{10} in that order. This would reduce the TSP to a 3 × 3 matrix, abstracting away from the ten states to four macrostates: $\{q_0\}, \{X_1, X_2.X_3\}, \{X_4, X_5, X_6, X_7\}$, and $\{X_8, X_9, X_10\}$. The solution thus obtained will not be stepwise DP-optimal per se. It will be optimal given the additional constraints imposed by the designer.

(g) $c^g_{sup}(G^7_{des}) = 6$

FIG. 6.2. *The DP-optimal FSMs for the different state of $\mathcal{X}$.*

6. Example. The following example is constructed to illustrate the essential stages of the optimal control problem for multiple marked states to visit. For the sake of simplicity, we have assumed that all control costs have zero cost for controllable events and infinite costs for uncontrollable events. We here consider a system modeled by the FSM G, which represents its legal behavior. In this example, there are seven states denoted $(X_i)_{i\in[1,\dots,7]} = \mathcal{X}$ to visit in no particular order. Some costs are allocated to each of the events of the FSM G. The event costs and their status (controllable or not) are as depicted in Figure 6.1.

Note that in Figure 6.1, the *Reset* events are not represented but exist between each of the $(X_i)_{i\in[1,\dots,7]}$ and the initial state q_0. The first phase of the algorithm consists of computing the various DP-optimal submachines $(G^i_{des})_{i\in[1,\dots,7]}$ for each of the final states of $\mathcal{X}$. This part is performed using the **DP-Opt** algorithm (see Appendix A of [10]). The seven figures given next (Figure 6.2) correspond to the DP-optimal submachines for each of the final states $(X_i)_{i\in[1,\dots,7]}$. We also give the worst inevitable cost for each submachine $(G^i_{des})_{i\in[1,\dots,7]}$.

According to (5.1) in section 5.1, we obtain the matrix C, encoding the worst inevitable cost between two states X_i and X_j.

	q_0	X_1	X_2	X_3	X_4	X_5	X_6	X_7
q_0	∞	**6**	**4**	**5**	**5**	**4**	**5**	**6**
X_2	0	**2**	∞	**1**	**2**	∞	∞	∞
X_3	0	∞	∞	∞	∞	∞	∞	∞
X_4	0	∞	∞	∞	∞	∞	∞	∞
X_5	0	∞	∞	∞	∞	∞	**1**	**2**
X_6	0	∞	∞	∞	∞	∞	∞	**1**
X_7	0	∞	∞	∞	∞	∞	∞	∞

Following Proposition 5.4, we can see that $\mathcal{X}_1 = \{X_1, X_2, X_3, X_4\}$ and $\mathcal{X}_2 = \{X_5, X_6, X_7\}$ form a partition of the set of states $\mathcal{X} = (X_i)_{i\in[1,\dots,7]}$. Moreover, the states of $\mathcal{X}_2$ satisfy Proposition 5.5. Thus, in order to solve the TSP, we can now consider the two following matrices. Note that in the second one, we have replaced $C[0, 6]$ and $C[0, 7]$ by ∞ as stated by Proposition 5.5.

	q_0	X_1	X_2	X_3	X_4
q_0	∞	**6**	**4**	**5**	**5**
X_1	0	∞	**1**	**2**	**3**
X_2	0	**2**	∞	**1**	**2**
X_3	0	∞	∞	∞	∞
X_4	0	∞	∞	∞	∞

	q_0	X_5	X_6	X_7
q_0	∞	**4**	∞	∞
X_5	0	∞	**1**	**2**
X_6	0	∞	∞	**1**
X_7	0	∞	∞	∞

One solution (there are several) of the TSP for each submatrix is

$$\{(q_0, X_4); (X_4, X_1); (X_1, X_2); (X_2, X_3); (X_3, q_0)\},$$
$$\{(q_0, X_5); (X_5, X_6); (X_6, X_7); (X_7, q_0)\}.$$

This is the output of the TSP resolution method run on each of the subproblems. The optimal worst-case costs are 13 and 6, respectively. From Theorem (5.1), there exist two stepwise DP-optimal schedulers A_{0_1} and A_{0_2}. We need to retrieve them from the output of the resolution of the TSP and build a global stepwise DP-optimal scheduler A_0.

We look at each one of the pairs and see if they correspond to a DP-optimal submachine. In this case $(q_0, X_4), (X_1, X_2), (X_2, X_3)$, and (X_3, q_0) correspond to G^4_{des}, $M^o_D(G, X_1, X_2)$, $M^o_D(G, X_2, X_3)$, and $X_3 \overset{Reset}{\longrightarrow} q_0$, respectively. (X_4, X_1) does not have any associated DP-optimal submachine. We decompose it: (X_4, X_1) becomes $(X_4 \overset{Reset}{\longrightarrow} q_0)$ concatenated with G^1_{des}. An optimal DP-optimal scheduler A_{o_1} is the following:

$$A_{o_1} = G^4_{des} \circ (X_4 \overset{Reset}{\longrightarrow} q_0) \circ G^1_{des} \circ M^o_D(G, X_1, X_2) \circ M^o_D(G, X_2, X_3) \circ (X_3 \overset{Reset}{\longrightarrow} q_0).$$

For the second subproblem of the divide and conquer method, we also map the pairs to original DP-optimal submachines, yielding scheduler A_{o_2}.

$$A_{o_2} = G^5_{des} \circ M^o_D(G, X_5, X_6) \circ M^o_D(G, X_6, X_7) \circ (X_7 \overset{Reset}{\longrightarrow} q_0).$$

Note that we use exactly four DP-optimal submachines for the first subproblem and three for the second, as expected from Proposition 5.3. We finally generate the global stepwise DP-optimal scheduler A_o as the concatenation of the two subschedulers A_{o_1} and A_{o_2}, yielding the following scheduler, A_o.

$$\begin{aligned} A_o &= A_{o_1} \circ A_{o_2} \\ &= G^4_{des} \circ (X_4 \xrightarrow{Reset} q_0) \circ G^1_{des} \circ M^o_D(G, X_1, X_2) \circ M^o_D(G, X_2, X_3) \circ (X_3 \xrightarrow{Reset} q_0) \\ &\quad \circ G^5_{des} \circ M^o_D(G, X_5, X_6) \circ M^o_D(G, X_6, X_7) \circ (X_7 \xrightarrow{Reset} q_0). \end{aligned}$$

In fact, this scheduler is actually composed of three different nontrivial subschedulers. The stepwise DP-optimal A_o can be rewritten as

$$\begin{aligned} A_o &= G^4_{des} \circ (X_4 \xrightarrow{Reset} q_0) \circ A_1 \circ (X_3 \xrightarrow{Reset} q_0) \circ A_2 \circ (X_7 \xrightarrow{Reset} q_0). \\ & where \left\{ \begin{array}{lcl} A_1 &=& M^o_D(G, X_1, X_2) \circ M^o_D(G, X_2, X_3), \\ A_2 &=& G^5_{des} \circ M^o_D(G, X_5, X_6) \circ M^o_D(G, X_6, X_7). \end{array} \right. \end{aligned} \tag{6.1}$$

This last expression shows the minimum number of *Reset*s that are necessary to visit all the X_i in an optimal way (three, in this case).

7. Potential applications of the theory. Applications of the theory that we have elaborated cover various fields of engineering. One application that can be developed from the theory is test objective generation. In test objective generation, the goal is to check whether a particular system meets the expectations or the requirements that are associated with it. In this framework, the states of interest may be states in which the system is suspected to behave incoherently or incorrectly, or states in which misbehavior could be dramatic or dangerous. These would be the states that would be marked. The theory that we developed allows us to visit all these states and to test the behavior of the system in each one. Once the system has reached one of the marked states, all the known events can be disabled to check if the system stops or enters a forbidden state. A timeout can be set, for example. If the system has not behaved incoherently after that timeout, we can decide to pursue the visit of the marked states. Other more involved strategies can be applied to determine whether a state is faulty or not. For each state, either the behavior of the system is acceptable, or it is not. In the first case where the state is flawless, the next submachine of the scheduler is activated in order to make the system evolve in the next state of interest to be tested. In the case where a failure has been detected in the state, either we stop since the system is faulty and does not correspond to the awaited specifications, or we proceed to determine other possible faults. To do so, we *reset* the system to its initial state q_0, and go directly to the next state, say X_i, through its direct DP-optimal submachine, namely G^i_{des}, and the process continues.

Another application area is planning in the case of multiple goals in AI. Several search algorithms exist when one unique goal is sought (see part II of [18]). Planning in the case of multiple goals remains challenging and interesting. The framework in which we have developed the theory allows goals to be independent or related. Once again, the *Reset* event has an interesting interpretation in AI. It represents the impossibility to meet all the goals without returning to the initial state. It may represent the possibility of using several agents to achieve the goals, each running in parallel. The number of *Reset* events gives the necessary and sufficient number of agents that are needed to perform the goal of reaching all the subgoals in parallel, without any conflicts. These applications constitute interesting further work.

We give a last potential application example of our theory: routing in a communication network. In the same way that several agents can perform in parallel to achieve different tasks, in a communication network a message can be broadcast by generating multiple copies of it and sending these copies in parallel, along the stepwise DP-optimal paths. These paths are actually the stepwise DP-optimal schedulers seen as stepwise DP-optimal subnetworks. The marked states represent the agents to whom the messages are destined. The costs may be the energy consumed for each transmission between nodes. The uncontrollability of certain events may reflect the possibility of other agents changing the terminal path to certain nodes, based on their own view of the network.

Example 7.1. Consider the example of section 6 as a routing problem in a communication problem. Relation (6.1) (i.e., the solution of the stepwise DP-optimal problem) highlights the manner in which the information would need to be sent through the communication network. Given that there are exactly three *Reset* events, the sender should generate exactly three messages and send them in parallel. For each message, the sender can specify (in each header, for example) the desired route that each message should take, according to the sender's view of the network and calculations. (This routing is actually given by the corresponding stepwise DP-optimal subscheduler.) However, the uncontrollability is represented by the fact that other intermediate routing nodes may have a view of the network that is different from that of the sender, in which case the former might decide on a new route.

8. Conclusion. In this paper, we have introduced a new type of optimal control for DES. Previous work in optimal control deals with numerical performances in supervisory control theory when the goal to achieve is a unique state of interest. In contrast, our goal was to make the system evolve through a set of goals one by one, with no order necessarily specified a priori. The order in which the states are visited was part of the optimization problem since it had an influence on the cost of visiting all the goal states.

The system to be controlled is represented by an FSM with a set of multiple marked states $\mathcal{X} = (X_i)_{i\in[1,\dots,n]}$ representing the states of interest. Our aim was to have the system reach each and every one of the $(X_i)_{i\in[1,\dots,n]}$. To do so, we have introduced the notion of a scheduler. A scheduler can be thought of as a concatenation of submachines. The role of the scheduler is to make the system evolve according to one submachine at a time and account for switching between them at appropriate instants, i.e., when one of the states of interest has been reached. We have then introduced the notion of a stepwise DP-optimal scheduler of an FSM G with respect to the set $\mathcal{X}$. This particular type of scheduler is custom made given the system on which the optimization is to be run. It has the particularity of being composed of DP-optimal submachines which allow optimality from state of interest to state of interest (stepwise). Moreover, the ordering of these DP-optimal submachines allows global optimality in the sense that the total worst-case cost of visiting all the states of $\mathcal{X}$ is minimized.

We gave a necessary and sufficient condition for the existence of a stepwise DP-optimal scheduler, namely, the existence of n DP-optimal submachines between the initial state q_0 and each state of the n states of $\mathcal{X}$. This condition is not very restrictive, since if it does not hold, that means that one of the states is not reachable in a controllable manner, i.e., not surely reachable from the initial state q_0. In such a case, it is obvious that the state in question will never be reachable with a surely finite cost.

From a computational point of view, we showed that our optimal problem could be brought down to an instance of the TSP. The solution of this particular TSP gives a direct access to both the structure of a stepwise DP-optimal scheduler and the worst-case cost for visiting all the states of interest. Considering the high computational complexity of this step, we also gave ways of taking advantage of some particular properties of the structure of a stepwise DP-optimal scheduler, leading to the reduction of the computational complexity of the corresponding TSP without loss of global optimality.

Finally, besides the possible applications briefly presented in section 7, future work will most probably extend the theory to the case of a system where the events are partially observable.

Acknowledgment. The authors wish to thank the reviewers for their relevant comments.

LAW OF THE ITERATED LOGARITHM FOR A CONSTANT-GAIN LINEAR STOCHASTIC GRADIENT ALGORITHM[*]

J. A. JOSLIN[†] and A. J. HEUNIS[‡]

Abstract. We study almost-sure limiting properties, taken as $\varepsilon \searrow 0$, of the finite horizon sequence of random estimates $\{\theta_0^\varepsilon, \theta_1^\varepsilon, \theta_2^\varepsilon, \dots, \theta_{\lfloor T/\varepsilon \rfloor}^\varepsilon\}$ for the linear stochastic gradient algorithm

$$\theta_{n+1}^\varepsilon = \theta_n^\varepsilon + \varepsilon \left[a_{n+1} - (\theta_n^\varepsilon)' X_{n+1} \right] X_{n+1}, \qquad \theta_0^\varepsilon \overset{\triangle}{=} \theta_* \quad \text{nonrandom},$$

where $T \in (0,\infty)$ is an arbitrary constant, $\varepsilon \in (0,1]$ is a (small) adaptation gain, and $\{a_n\}$ and $\{X_n\}$ are data sequences which drive the algorithm. These limiting properties are expressed in the form of a functional law of the iterated logarithm.

Key words. stochastic gradient algorithm, L-mixing processes, functional law of the iterated logarithm

1. Introduction.

A commonly used stochastic gradient algorithm has the following structure:

$$\theta_{n+1}^\varepsilon = \theta_n^\varepsilon + \varepsilon \left[a_{n+1} - (\theta_n^\varepsilon)' X_{n+1} \right] X_{n+1}, \quad \theta_0^\varepsilon \overset{\triangle}{=} \theta_*, \quad \forall\, n = 0, 1, \dots \tag{1.1}$$

Here $\varepsilon \in (0,1]$ is a (small) constant called the *adaptation gain*; $\theta_* \in \Re^d$ is a fixed nonrandom *initial condition*; and $\{a_n,\ n = 1,2,\dots\}$ and $\{X_n,\ n = 1,2,\dots\}$ are, respectively, $\Re$ and $\Re^d$-valued *data processes* which "drive" the algorithm and in turn give rise to the $\Re^d$-valued process of *estimates* $\{\theta_n^\varepsilon,\ n = 0,1,2,\dots\}$.

Within this context one often wants to characterize asymptotic properties of the random sequence $\{\theta_0^\varepsilon, \theta_1^\varepsilon, \theta_2^\varepsilon, \dots, \theta_{\lfloor T\varepsilon^{-1} \rfloor}^\varepsilon\}$ as $\varepsilon \to 0$, where $T \in (0,\infty)$ is a fixed but arbitrary constant called the *horizon.* Such asymptotic properties deal with the *finite horizon* characteristics of (1.1). Perhaps the most basic of these asymptotic properties is given by the so-called *ODE method* which, in the present context, essentially says the following. Under reasonably general conditions on the processes $\{a_n\}$ and $\{X_n\}$, one can relate the sequence of estimates $\{\theta_n^\varepsilon\}$ to the solution $\{\theta^0(\tau),\ \tau \in [0,\infty)\}$ of the ODE

$$\dot{\theta^0}(\tau) = \bar{b} - \bar{R}\theta^0(\tau), \quad \theta^0(0) = \theta_*, \tag{1.2}$$

(where the d-vector $\bar{b}$ and $d \times d$-matrix $\bar{R}$ in (1.2) are typically given by conditions such as (C2) in section 2) by the following *finite horizon weak law of large numbers.* For each $\delta \in (0,\infty)$ and $T \in (0,\infty)$ we have

$$\lim_{\varepsilon \to 0} P \left[\max_{0 \le \tau \le T} |\theta_{\lfloor \tau/\varepsilon \rfloor}^\varepsilon - \theta^0(\tau)| > \delta \right] = 0 \tag{1.3}$$

(see Kushner and Shwartz [19, Theorem 1, p. 178]), where $\lfloor x \rfloor$ denotes the integer part of $x \in [0, \infty)$. The ODE method is comprehensively covered in, for example, the books of Benveniste, Métivier, and Priouret [1], Kumar and Varaiya [17], and Kushner and Yin [18].

In classical probability, the law of large numbers is complemented by Donsker's functional central limit theorem (CLT), which has the following form. Suppose that $\{\xi_k,\ k = 1, 2, \ldots\}$ is an independent and identically distributed (i.i.d.) sequence of random variables with $E\xi_k = 0$, $E\xi_k^2 = 1$. Define the partial sums

$$(1.4) \qquad S_n \overset{\triangle}{=} \sum_{k=1}^{n} \xi_k \qquad \forall\, n = 1, 2, \ldots$$

and, for each $m = 1, 2, \ldots$, let $\{\Xi^m(\tau),\ \tau \in [0, \infty)\}$ be the continuous piecewise-linear process given by

$$(1.5) \qquad \Xi^m(\tau) \overset{\triangle}{=} \begin{cases} 0 & \text{if } \tau = 0, \\ m^{-\frac{1}{2}} S_n & \text{if } \tau = n/m, \quad \forall\, n = 1, 2, \ldots, \\ \text{linear interpolation,} & \text{otherwise.} \end{cases}$$

Then, for each $T \in (0, \infty)$, the process $\{\Xi^m(\tau),\ \tau \in [0, T]\}$ converges weakly to a standard Wiener process $\{W(\tau), \tau \in [0, T]\}$ as $m \to \infty$ (see Theorem 10.1 of Billingsley [2]). An analogous *finite horizon functional CLT* can be established for the random sequence $\{\theta_0^\varepsilon, \theta_1^\varepsilon, \theta_2^\varepsilon, \ldots, \theta_{\lfloor T\varepsilon^{-1} \rfloor}^\varepsilon\}$ obtained from (1.1). For each $\varepsilon \in (0, 1]$ define the $\Re^d$-valued continuous piecewise-linear process $\{\Theta^\varepsilon(\tau),\ \tau \in [0, \infty)\}$ by

$$(1.6) \qquad \Theta^\varepsilon(\tau) \overset{\triangle}{=} \begin{cases} \varepsilon^{-\frac{1}{2}} \left(\theta_{\tau/\varepsilon}^\varepsilon - \theta^0(\tau) \right), & \tau = k\varepsilon, \quad \forall\, k = 0, 1, 2, \ldots, \\ \text{linear interpolation,} & \text{otherwise.} \end{cases}$$

Then, subject to certain regularity conditions on the data sequences $\{a_n\}$ and $\{X_n\}$, for each $T \in (0, \infty)$ the process $\{\Theta^\varepsilon(\tau),\ \tau \in [0, T]\}$ converges weakly in $C[0, T]$ (the space of continuous functions from $[0, T]$ into $\Re^d$) to a limiting Gauss–Markov process $\{\hat{\Theta}(\tau),\ \tau \in [0, T]\}$ as $\varepsilon \to 0$. A precise formulation of this result, pertaining to a general class of algorithms which includes (1.1) as a special case and providing a complete characterization of the Gauss–Markov limit, may be found in [1, Theorem 1, p. 107] and [3, Theorem 2, p. 969]. The Gauss–Markov limit is also discussed further in Remark 3.4.

In the context of a sum of i.i.d. random variables $\{\xi_k,\ k = 1, 2, \ldots\}$ with $E\xi_k = 0$ and $E\xi_k^2 = 1$, Donsker's functional CLT is complemented by another basic result, namely, Strassen's *functional law of the iterated logarithm* (see Theorem 3 of [25]). To see the form of this result, fix some $T \in (0, \infty)$ and put

$$(1.7)\ K_\xi^T \overset{\triangle}{=} \left\{ \phi : [0, T] \to \Re\ : \phi(0) = 0,\ \phi(\cdot) \text{ abs. continuous, } \frac{1}{2} \int_0^T |\dot{\phi}(s)|^2\, ds \le 1 \right\}.$$

It is well known that K_ξ^T is a compact set of continuous functions (with the supremum norm of uniform convergence over $[0, T]$), and Strassen's functional law of the iterated logarithm (LIL) says the following. For P-almost all ω the sequence of continuous functions $\{\Xi^m(\tau, \omega)/\sqrt{2 \log \log m},\ \tau \in [0, T]\}$, indexed by $m = 1, 2, \ldots$, converges towards K_ξ^T as $m \to \infty$, and the set of its accumulation points coincides exactly with K_ξ^T, the sense of convergence being that of uniform convergence over $[0, T]$. This result—called by Williams [26, page 208] a "staggering generalization" of Kolmogorov's classical LIL—can be used as a tool for deriving many subtle fine-structure properties of the sample-paths of the partial-sum sequence $\{S_n\}$. For example, it can be used to show that, with probability one, the quantity

$$\frac{1}{N}\text{cardinality}\left(\left\{1 \le n \le N :\ S_n > \frac{1}{2}\sqrt{2n\log\log n}\right\}\right), \qquad N = 1, 2, \ldots,$$

exceeds 0.99999 for infinitely many values of N, whereas (again with probability one) the same quantity exceeds the slightly larger number 0.999999 for only finitely many N (see Strassen [25] for this as well as other examples of how one can use the functional LIL to analyze the partial sum process).

The preceding discussion suggests the problem of establishing a functional LIL for the random sequence $\{\theta_0^\varepsilon, \theta_1^\varepsilon, \theta_2^\varepsilon, \ldots, \theta_{\lfloor T\varepsilon^{-1}\rfloor}^\varepsilon\}$ arising from (1.1). This should have the same relation to the finite horizon functional CLT indicated previously as Strassen's functional LIL has to Donsker's functional CLT, and therefore should be of the following general form. For each fixed $T \in (0, \infty)$ there is a compact set $K_\Theta^T \subset C[0, T]$ (with a characterization analogous to that of K_ξ^T in (1.7)) and, for P-almost all ω, the family of continuous functions $\{\Theta^\varepsilon(\tau, \omega)/\sqrt{2\log\log\varepsilon^{-1}},\ \tau \in [0, T]\}$, indexed by $\varepsilon \in (0, 1]$, converges towards K_Θ^T (as $\varepsilon \to 0$) and the set of its $C[0, T]$-accumulation points coincides exactly with K_Θ^T. This is a *finite horizon functional LIL* for the sequence of estimates $\{\theta_0^\varepsilon, \theta_1^\varepsilon, \theta_2^\varepsilon, \ldots, \theta_{\lfloor T\varepsilon^{-1}\rfloor}^\varepsilon\}$, and our goal is to establish a result of this kind (see Theorem 3.3 to follow) subject to certain conditions on the data sequences $\{a_n\}$ and $\{X_n\}$ which are set forth in section 2. We choose to concentrate attention on the algorithm (1.1) because there seem to be major technical obstacles to getting this result for the more general classes of fixed-gain algorithms proposed, for example, in [1] and [3], whereas the linear structure of (1.1) simplifies matters considerably.

The usual method for establishing a functional LIL, pioneered by Strassen [25], is to first prove a so-called *strong invariance principle* for the partial-sum sequence $\{S_n\}$. Essentially, this says that one can always construct a Wiener process $\{W_t\}$ on the same probability space on which the S_n of (1.4) are defined (or perhaps on some extension of this space) such that

$$S_{\lfloor t\rfloor} - W_t = o(\sqrt{t\log\log t}) \quad (t \to \infty) \quad \text{almost surely (a.s.).} \tag{1.8}$$

Then one uses (1.8), together with known sample-path properties of the Wiener process, as the basis for establishing Strassen's functional LIL. In the context of stochastic algorithms with *decreasing gain* one can follow a similar approach (see [12] and [24]) but for *constant-gain* algorithms, such as (1.1), it is not at all obvious how to formulate and prove an analogue of (1.8). Accordingly, we shall adopt a different approach, in the spirit of a method pioneered by Chover [5], who showed how to establish Strassen's functional LIL using a CLT with *rate of convergence* in place of the strong invariance principle (1.8). This general approach, which was made to work in [15] for the stochastic averaging principle, will be extended here to work for the algorithm (1.1).

The organization of the paper is as follows: in section 2 we state and discuss conditions on the sequences $\{a_n\}$ and $\{X_n\}$ which drive the algorithm (1.1). In section 3 we establish the main result, namely Theorem 3.3. The proof in section 3 relies on two key technical results, namely an auxiliary LIL (see Theorem 3.5) and an a.s. approximation theorem (see Theorem 3.6). These are established in sections 4 and 5, respectively. Another essential technical result, needed for the proofs in section 4, is a functional CLT with rate of convergence (see Theorem 4.4), and this is proved in section 6. In section 7 we develop a miscellany of subsidiary technical lemmas which are used in the previous sections. In section 8 we restate, in a form best suited to our needs, some results from probability theory which are used in section 3 to section 7. Finally, we define the notation at the beginning of each section where it is first needed.

2. Conditions.

Notation 2.1. We use the following notation: $\Re^d$, $\Re^{d\times r}$ denote the usual vector spaces of real d-dimensional column vectors and real d by r matrices, respectively, with vector norm $|x| \stackrel{\triangle}{=} (\sum_{i=1}^d x_i^2)^{1/2}$ for all $x \in \Re^d$, and matrix operator norm $|A| \stackrel{\triangle}{=} \max_{x\in\Re^r,\ |x|=1} |Ax|$ for all $A \in \Re^{d\times r}$. Write $(B)'$ for the transpose of a matrix B. For an $\Re^d$ or $\Re^{d\times r}$-valued random element X and $p \in [1,\infty)$, put $\|X\|_p \stackrel{\triangle}{=} (E[|X|^p])^{1/p}$. For $x \in [0,\infty)$, $\lfloor x \rfloor$ is the largest integer n such that $n \le x$.

The data sequences $\{a_n,\ n = 1,2,\ldots\}$ and $\{X_n,\ n = 1,2,\ldots\}$ driving the algorithm (1.1) will always be special instances of the class of L-mixing processes introduced by Gerencsér [9], and formulated in a discrete-parameter setting as follows.

Definition 2.2. *Suppose that* $\{\mathcal{F}_n,\ n = 1,2,\ldots\}$ *and* $\{\mathcal{F}_n^+,\ n = 1,2,\ldots\}$ *are sequences of sub-σ-algebras in the probability triple* $(\Omega,\mathcal{F},P)$*, increasing and decreasing, respectively, with* $\mathcal{F}_n$ *and* $\mathcal{F}_n^+$ *independent for each* $n = 1,2,\ldots.$ *An* $\Re^{d\times r}$*-valued random process* $\{z_n,\ n = 1,2,\ldots\}$ *on* $(\Omega,\mathcal{F},P)$ *is L-mixing with respect to the system* $(\mathcal{F}_n,\mathcal{F}_n^+)$ *when* (i) $\{z_n\}$ *is* $\{\mathcal{F}_n\}$*-adapted,* (ii) *for each* $p \in [1,\infty)$ *we have* $\sup_n \|z_n\|_p < \infty$*, and, for*

$$\gamma_p(s) \stackrel{\triangle}{=} \sup_{n>s} \|z_n - E\left[z_n \mid \mathcal{F}_{n-s}^+\right]\|_p \quad \forall\, s = 1,2,\ldots, \quad \textit{we have} \quad \sum_{1\le s<\infty} \gamma_p(s) < \infty.$$

We shall require the following strengthened notion of L-mixing.

Definition 2.3. *Suppose that* $\{\mathcal{F}_n,\ n = 1,2,\ldots\}$ *and* $\{\mathcal{F}_n^+,\ n = 1,2,\ldots\}$ *are sequences of sub-σ-algebras in the probability triple* $(\Omega,\mathcal{F},P)$*, as in Definition* 2.2. *An* $\Re^{d\times r}$*-valued random process* $\{z_n,\ n = 1,2,\ldots\}$ *on* $(\Omega,\mathcal{F},P)$ *is geometrically L-mixing with respect to the system* $(\mathcal{F}_n,\mathcal{F}_n^+)$*, when* (i) $\{z_n\}$ *is* $\{\mathcal{F}_n\}$*-adapted,* (ii) $\sup_n \|z_n\|_p < \infty$ *for each* $p \in [0,\infty)$*,* (iii) *there is a constant* $\lambda \in (0,1)$ *and, for each* $p \in [1,\infty)$*, a constant* $C_p \in [0,\infty)$ *such that*

$$\sup_{n>s} \|z_n - E\left[z_n \mid \mathcal{F}_{n-s}^n\right]\|_p \le C_p\, \lambda^s \qquad \forall\, s = 1,2,\ldots,$$

where

$$\mathcal{F}_m^n \stackrel{\triangle}{=} \mathcal{F}_n \cap \mathcal{F}_m^+, \qquad \textit{when} \qquad 1 \le m < n. \tag{2.1}$$

(Thus, $\mathcal{F}_m^n$ *is the collection of all events which are members of both* $\mathcal{F}_n$ *and* $\mathcal{F}_m^+$*.) The constant* $\lambda \in (0,1)$ *is called a rate of the geometrically L-mixing process.*

Remark 2.4. Notice that conditioning is on the σ-algebra $\mathcal{F}_{n-s}^+$ in Definition 2.2, whereas it is on the smaller σ-algebra $\mathcal{F}_{n-s}^n$ in Definition 2.3 (see Remark 2.5 for more discussion on this). Using the elementary inequality $\|z - E[z \mid \mathcal{H}]\|_p \le 2\|z - E[z \mid \mathcal{G}]\|_p$, which holds for $z \in L_p(\Omega,\mathcal{F},P)$, $p \in [1,\infty)$, and sub-σ-algebras $\mathcal{G} \subset \mathcal{H} \subset \mathcal{F}$, one sees immediately that a geometrically L-mixing process with respect to a given system $(\mathcal{F}_n, \mathcal{F}_n^+)$ is also L-mixing with respect to the system $(\mathcal{F}_n, \mathcal{F}_n^+)$. Besides being motivated by L-mixing, the notion of geometric L-mixing in Definition 2.3 is also closely related to that of *exponential stability* introduced by Ljung [20] and Ljung and Caines [21] (see also Caines [4, p. 488] and Davis and Vinter [6, p. 217]). An important instance of a geometrically L-mixing process is the output of a stable finite-dimensional linear system with the form

$$x_{n+1} = Ax_n + Be_n, \qquad z_n = Cx_n + De_n, \qquad n = 1, 2, \ldots,$$

where $\{e_1, e_2, e_3, \ldots\}$ is a "driving" sequence of independent random vectors, and x_1 and $\sigma\{e_1, e_2, \ldots\}$ are independent, with $\sup_n \|e_n\|_p < \infty$ and $\|x_1\|_p < \infty$ for each $p \in [1, \infty)$. Here one defines

$$\text{(2.2)} \quad \mathcal{F}_n \overset{\triangle}{=} \sigma\{x_1, e_1, e_2, \ldots, e_n\}, \qquad \mathcal{F}_n^+ \overset{\triangle}{=} \sigma\{e_{n+1}, e_{n+2}, \ldots\} \qquad \forall\, n = 1, 2, \ldots,$$

and, by the argument in [4, pages 488-489] it is easily shown that $\{z_n\}$ is geometrically L-mixing with respect to the system $(\mathcal{F}_n, \mathcal{F}_n^+)$. It is this close link to stable linear systems that makes L-mixing a very appropriate model for signals in data communication problems. The L^p-bounds established for L-mixing in [9] and [10] also render this class of processes extremely tractable, and will be used frequently in the arguments that follow.

Remark 2.5. Suppose that $\{\mathcal{F}_n,\ n = 1, 2, \ldots\}$ and $\{\mathcal{F}_n^+,\ n = 1, 2, \ldots\}$ are sequences of sub-σ-algebras in the probability triple $(\Omega, \mathcal{F}, P)$, as in Definitions 2.2 and 2.3, and $\{z_n,\ n = 1, 2, \ldots\}$ is some $\Re^{d\times r}$-valued and geometrically L-mixing process with respect to the system $(\mathcal{F}_n, \mathcal{F}_n^+)$. For each $s = 1, 2, \ldots$, define the process $\{z_n[s], n = 1, 2, \ldots\}$ by

$$\text{(2.3)} \qquad z_n[s] \overset{\triangle}{=} E\left[z_n \mid \mathcal{F}_{n-s}^n\right] \qquad \forall\, n = 1, 2, \ldots,$$

where we put $\mathcal{F}_{n-s}^n \overset{\triangle}{=} \mathcal{F}_1^n$ when $n \leq s$. Observe that, for each $s = 1, 2, \ldots$, the process $\{z_n[s],\ n = 1, 2, \ldots\}$ is s-dependent, since, from (2.3), one has $\sigma\{z_1[s], z_2[s], \ldots, z_m[s]\} \subset \mathcal{F}_m$, while $\sigma\{z_n[s], z_{n+1}[s], \ldots, z_{n+k}[s]\} \subset \mathcal{F}_{n-s}^+$, and the σ-algebras $\mathcal{F}_m$ and $\mathcal{F}_{n-s}^+$ are clearly independent when $n - m > s$. Thus, we see from Definition 2.3 that a geometrically L-mixing process $\{z_n\}$ can be nicely approximated by the s-dependent process $\{z_n[s]\}$. This approximation property was used by Ljung and Caines [21] to establish asymptotic normality in off-line system identification, and will likewise be necessary for proving the main results of this work.

From now on we shall always suppose that the data processes $\{a_n,\ n = 1, 2, \ldots\}$ and $\{X_n,\ n = 1, 2, \ldots\}$, which drive the recursion (1.1), are $\Re$ and $\Re^d$-valued, respectively, defined on a common probability triple $(\Omega, \mathcal{F}, P)$, and subject to the following conditions (C1) to (C4).

(C1) There are sequences $\{\mathcal{F}_n,\ n = 1, 2, \ldots\}$ and $\{\mathcal{F}_n^+,\ n = 1, 2, \ldots\}$ of sub-σ-algebras, as in Definition 2.2, such that $\{a_n\}$ and $\{X_n\}$ are geometrically L-mixing with respect to the system $(\mathcal{F}_n, \mathcal{F}_n^+)$.

(C2) There exists a d-vector $\bar{b}$ and a $d\times d$ matrix $\bar{R}$ such that the limits

$$\text{(2.4)} \quad \bar{b} \overset{\triangle}{=} \lim_{N\to\infty} \frac{1}{N+1} \sum_{n=n_0}^{N+n_0} E[a_n X_n]\,, \quad \bar{R} \overset{\triangle}{=} \lim_{N\to\infty} \frac{1}{N+1} \sum_{n=n_0}^{N+n_0} E[X_n (X_n)']$$

exist uniformly with respect to $n_0 = 1, 2, \ldots$.

To state the remaining conditions we need the following notation:

$$(2.5)\qquad \begin{cases} b_n \stackrel{\triangle}{=} a_n X_n, & \bar{b}_n \stackrel{\triangle}{=} E[b_n]\,, \quad \tilde{b}_n \stackrel{\triangle}{=} b_n - \bar{b}_n, \quad \hat{b}_n \stackrel{\triangle}{=} \bar{b}_n - \bar{b}, \\ R_n \stackrel{\triangle}{=} X_n(X_n)', & \bar{R}_n \stackrel{\triangle}{=} E[R_n]\,, \quad \tilde{R}_n \stackrel{\triangle}{=} R_n - \bar{R}_n, \quad \hat{R}_n \stackrel{\triangle}{=} \bar{R}_n - \bar{R}. \end{cases}$$

Also, recall that $\{\theta^0(\tau),\ \tau \in [0,\infty)\}$ is the (unique) solution of (1.2). The remaining conditions are as follows.

(C3a) For each $T \in (0,\infty)$ there exist constants $C_1(T) \in [0,\infty)$ and $\varepsilon(T) \in (0,1]$ such that

$$\max_{0 \le k \le 1+\lfloor T\varepsilon^{-1}\rfloor} \left| \sum_{j=0}^{k-1} (\hat{b}_{j+1} - \hat{R}_{j+1}\theta^0(\varepsilon j)) \right| \le C_1(T)$$

for each $\varepsilon \in (0, \varepsilon(T)]$.

(C3b) There exist constants $\varepsilon_0 \in (0,1]$, $\alpha \in [0,3/4)$, and $C_2 \in [0,\infty)$ such that

$$\left| \sum_{j=k+1}^{k+N} \hat{R}_{j+1}(I - \varepsilon\bar{R})^j \right| \le C_2 N^\alpha$$

for all $\varepsilon \in (0,\varepsilon_0]$ and all $k, N = 1,2,\ldots$.

(C4) There is a constant $C_3 \in [0,\infty)$ and a function $A : \Re^d \to \Re^{d\times d}$ such that $A(\theta)$ is symmetric positive definite for each $\theta \in \Re^d$, and

$$(2.6)\qquad \left| \frac{1}{N+1}\operatorname{cov}\left(\sum_{n=n_0}^{N+n_0} \tilde{H}_n(\theta) \right) - A(\theta) \right| \le \frac{C_3[1+|\theta|^2]}{N+1}$$

for all $\theta \in \Re^d$ and $N, n_0 = 1,2,3,\ldots$, where

$$(2.7)\qquad \tilde{H}_n(\theta) \stackrel{\triangle}{=} \tilde{b}_n - \tilde{R}_n\theta \quad \forall\, \theta \in \Re^d, \quad \forall\, n = 1,2,\ldots.$$

Remark 2.6. Condition (C2) defines the d-vector $\bar{b}$ and the $d \times d$-matrix $\bar{R}$, which then gives the right side of the ODE (1.2). Conditions (C2), (C3a), and (C3b) control the "amount of nonstationarity" in the data processes $\{a_n\}$ and $\{X_n\}$. (C3a) is the same as the first of the conditions appearing in (3.4) of Khas'minskii [13] but is just rewritten in the context of algorithm (1.1) and plays a role similar to that of its counterpart in [13], while (C3b) is a mild condition which limits fluctuations of $\bar{R}_n \stackrel{\triangle}{=} E[X_n(X_n)']$ about $\bar{R}$ defined in (C2).

Remark 2.7. Suppose the $\Re^{d\times r}$-valued process $\{z_n,\ n = 1,2,\ldots\}$ is geometrically L-mixing with respect to a system $(\mathcal{F}_n, \mathcal{F}_n^+)$. Then it follows at once that the centralized process $\{z_n - Ez_n,\ n = 1,2,\ldots\}$ is geometrically L-mixing with respect to the system $(\mathcal{F}_n, \mathcal{F}_n^+)$. Moreover, if the $\Re^{r\times q}$-valued process $\{y_n,\ n = 1,2,\ldots\}$ is also geometrically L-mixing with respect to the system $(\mathcal{F}_n, \mathcal{F}_n^+)$, then it is easily verified using Definition 2.3 that the $\Re^{d\times q}$-valued process $\{z_n y_n,\ n = 1,2,\ldots\}$ is geometrically L-mixing with respect to system $(\mathcal{F}_n, \mathcal{F}_n^+)$. In view of these observations and condition (C1), it follows that the processes $\{\tilde{b}_n,\ n = 1,2,\ldots\}$ and $\{\tilde{R}_n,\ n = 1,2,\ldots\}$ given by (2.5) are zero-mean and geometrically L-mixing with respect to the system $(\mathcal{F}_n, \mathcal{F}_n^+)$, and $\{\tilde{H}_n(\theta),\ n = 1,2,\ldots\}$ given by (2.7) is zero-mean and geometrically L-mixing for each $\theta \in \Re^d$.

Remark 2.8. Condition (C4) gives the function $A(\cdot)$ which will be used to formulate the limiting set K_Θ^T in the main result (see Theorem 3.3). In some special cases it is possible to give explicit formulae for $A(\theta)$. For example, suppose that the driving data $\{a_n, X_n\}$ is weakly stationary so that, for each θ, we have $E[\tilde{H}_1(\theta)] = E[\tilde{H}_{1+r}(\theta)]$ and $E[\tilde{H}_1(\theta)\tilde{H}_n'(\theta)] = E[\tilde{H}_{1+r}(\theta)\tilde{H}_{n+r}'(\theta)]$ for all $r, n = 1, 2, \ldots$. Then it is easily shown that (C4) follows from (C1) with $A(\theta)$ given by

$$A(\theta) \overset{\triangle}{=} E[\tilde{H}_1(\theta)\tilde{H}_1'(\theta)] + \sum_{n=2}^{\infty} E[\tilde{H}_1(\theta)\tilde{H}_n'(\theta)] + \sum_{n=2}^{\infty} E[\tilde{H}_n(\theta)\tilde{H}_1'(\theta)].$$

For another example, suppose that the driving data is cyclostationary. This implies that there is a positive integer constant P such that, for each θ, we have $E[\tilde{H}_n(\theta)] = E[\tilde{H}_{n+P}(\theta)]$ and, for $\Lambda(\theta, m, n) \overset{\triangle}{=} E[\tilde{H}_m(\theta)\tilde{H}_n'(\theta)]$, we have $\Lambda(\theta, m, n) = \Lambda(\theta, m + P, n + P)$ for all $m, n = 1, 2, \ldots$. With the help of the periodicity relation we can extend $\Lambda(\theta, m, n)$ to all integers $-\infty < m, n < \infty$. By a straightforward adaptation of the argument on page 222 of [13] or page 76 of [14] it may be shown that (C4) follows from (C1) with $A(\theta)$ given by

$$A(\theta) = \frac{1}{P} \sum_{m=1}^{P} \sum_{n=-\infty}^{\infty} \Lambda(\theta, m, n).$$

A property of the mapping $A(\theta)$ in (C4) that will soon be needed is the following lemma.

Lemma 2.9 (proved in section 7). *Suppose conditions* (C1) *and* (C4). *Then the function* $A(\cdot)$ *given by* (2.6) *is locally Lipschitz continuous over* $\Re^d$.

3. The main result.

Notation 3.1. For the results of this and later sections we need the following additional notation. $C[0,T]$ indicates the space of continuous functions $f : [0,T] \to \Re^d$, for some $T \in (0, \infty)$, with norm $\|\cdot\|_C$ defined by $\|f\|_C \overset{\triangle}{=} \sup_{0 \le \tau \le T} |f(\tau)|$, and $AC_0[0,T] \overset{\triangle}{=} \{\psi \in C[0,T] : \ \psi(0) = 0, \ \psi(\cdot) \text{ abs. continuous}\}$. Also, for $x \in C[0,T]$ and $K \subset C[0,T]$, put $\|x - K\|_C \overset{\triangle}{=} \inf_{y \in K} \|x - y\|_C$. If $\{x_m, \ m = 1, 2 \ldots\}$ is a sequence in $C[0,T]$, then $\mathrm{acc}\{x_m\}$ denotes the set of its accumulation points in $C[0,T]$ (if any), and the notation $\{x_m(\tau), \ \tau \in [0,T]\} \twoheadrightarrow K$ for some set $K \subset C[0,T]$ means that (i) $\lim_{m\to\infty} \|x_m - K\|_C = 0$ and (ii) $\mathrm{acc}\{x_m\} = K$. The $\twoheadrightarrow$ symbol (due to Kuelbs [16]) provides a succinct language for expressing Strassen's functional LIL formulated in section 1, namely, for each $T \in (0, T)$ and processes $\{\Xi^m(\tau), \ \tau \in [0,T]\}$ given by (1.5), we have

$$\left\{ \frac{\Xi^m(\tau)}{\sqrt{2 \log\log m}}, \ \tau \in [0,T] \right\} \twoheadrightarrow K_\xi^T \qquad \text{a.s.} \tag{3.1}$$

For the main result of this paper, we must slightly extend this symbolism. If $x_\varepsilon \in C[0,T]$ for all $\varepsilon \in (0,1]$, then $\mathrm{acc}\{x_\varepsilon\}$ denotes the set of accumulation points in $C[0,T]$ (if any) as $\varepsilon \searrow 0$, and the notation $\{x_\varepsilon(\tau), \ \tau \in [0,T]\} \twoheadrightarrow K$ means that (i) $\lim_{\varepsilon \to 0} \|x_\varepsilon - K\|_C = 0$ and (ii) $\mathrm{acc}\{x_\varepsilon\} = K$.

Remark 3.2. From now on we fix an arbitrary finite horizon $T \in (0, \infty)$. Using the $\twoheadrightarrow$ notation of the preceding paragraph, our main result is the following LIL for algorithm (1.1), which characterizes a.s. limiting properties of $\{\Theta^\varepsilon(\tau), \ \tau \in [0,T]\}$, the restriction to $[0,T]$ of the process Θ^ε defined by (1.6).

Theorem 3.3. *Suppose conditions* (C1)–(C4) *of section* 2*, fix some finite horizon* $T \in (0,\infty)$*, and let* $\bar{R}$*,* $A(\cdot)$*,* $\{\theta^0(\tau),\ \tau \in [0,T]\}$ *and* $\{\Theta^\varepsilon(\tau),\ \tau \in [0,T]\}$*, be defined by* (2.4), (2.6), (1.2), and (1.6)*, respectively. Define the mapping* $I_\Theta^T : AC_0[0,T] \to [0,\infty]$ *by*

$$I_\Theta^T(\phi) \overset{\triangle}{=} \frac{1}{2}\int_0^T (\dot{\phi}(s) + \bar{R}\phi(s))' A^{-1}(\theta^0(s))(\dot{\phi}(s) + \bar{R}\phi(s))\, ds, \tag{3.2}$$

and let

$$K_\Theta^T \overset{\triangle}{=} \{\phi \in AC_0[0,T] \colon I_\Theta^T(\phi) \le 1\}. \tag{3.3}$$

Then K_Θ^T *is a compact subset of* $C[0,T]$*, and we have*

$$\left\{ \frac{\Theta^\varepsilon(\tau)}{\sqrt{2\log\log\varepsilon^{-1}}},\ \tau \in [0,T] \right\} \longrightarrow\!\!\!\!\rightarrow K_\Theta^T \quad a.s. \tag{3.4}$$

Remark 3.4. To motivate the proof of Theorem 3.3 we briefly recall how one can establish the functional CLT giving weak convergence of $\{\Theta^\varepsilon(\tau),\ \tau \in [0,T]\}$ to some limiting Gauss–Markov process $\{\hat{\Theta}(\tau),\ \tau \in [0,T]\}$ (see section 1). For each $\varepsilon \in (0,1]$ define the piecewise-linear continuous process $\{W^\varepsilon(\tau),\ \tau \in [0,\infty)\}$ by $W^\varepsilon(0) \overset{\triangle}{=} 0$, and

$$W^\varepsilon(\tau) \overset{\triangle}{=} \begin{cases} \varepsilon^{\frac{1}{2}} \sum_{j=1}^k \tilde{b}_j - \tilde{R}_j\theta^0((j-1)\varepsilon) & \forall\, \tau = k\varepsilon,\ \ k = 1,2,\dots, \\ \text{linear interpolation,} & \text{otherwise.} \end{cases} \tag{3.5}$$

Fix some arbitrary $T \in (0,\infty)$ as in Remark 3.2. For $\varepsilon \in (0,1]$, define the mapping $G^\varepsilon : C[0,T] \to C[0,T]$ as follows. For every $w \in C[0,T]$, let $G^\varepsilon(w)$ be given by the solution $v \in C[0,T]$ of the recursion

$$v(\tau) = \begin{cases} w(0), & \text{if } \tau = 0, \\ w(\tau) - \varepsilon \sum_{j=0}^{k-1} \bar{R}\, v(\varepsilon j), & \text{if } \tau = k\varepsilon,\ \ k = 1,2,\dots, \\ \text{linear interpolation,} & \text{otherwise.} \end{cases} \tag{3.6}$$

By a detailed analysis of the recursion (1.1) (which is not given here) we can show

$$\Theta^\varepsilon(\cdot) \approx G^\varepsilon(W^\varepsilon)(\cdot), \tag{3.7}$$

in the sense that $\{\Theta^\varepsilon(\tau),\ \tau \in [0,T]\}$ and $\{G^\varepsilon(W^\varepsilon)(\tau),\ \tau \in [0,T]\}$ have approximately the same distributions in $C[0,T]$ for small $\varepsilon \in (0,1]$. This suggests that we can get a weak limit for $\{\Theta^\varepsilon(\tau), \tau \in [0,T]\}$ when we establish a weak limit for $\{W^\varepsilon(\tau),\ \tau \in [0,T]\}$ and show that G^ε converges suitably to some limiting mapping $G : C[0,T] \to C[0,T]$ as $\varepsilon \to 0$. Indeed, using the fact that $\{\tilde{b}_j\}$ and $\{\tilde{R}_j\}$ are geometrically L-mixing (see Remark 2.7) and trivially modifying the arguments of [1, pp. 105–106], it can be proved that $\{W^\varepsilon(\tau),\ \tau \in [0,T]\}$ converges weakly in $C[0,T]$ to the restriction to $[0,T]$ of the Gauss–Markov process $\{\hat{W}^0(\tau),\ \tau \in [0,\infty)\}$ given by

$$\hat{W}^0(\tau) \overset{\triangle}{=} \int_0^\tau A^{\frac{1}{2}}(\theta^0(s))\, d\hat{B}(s) \qquad \forall\, \tau \in [0,\infty), \tag{3.8}$$

for some standard $\Re^d$-valued Brownian motion $\hat{B}(\cdot)$ on a probability triple $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$. In addition, it is easily seen from elementary analysis that $G^\varepsilon(\cdot)$ converges uniformly on compact subsets of $C[0,T]$ to the mapping $G : C[0,T] \to C[0,T]$ defined as follows.

For every $w \in C[0,T]$, let $G(w)$ be given by the solution $v \in C[0,T]$ of the linear integral equation

$$v(\tau) = w(\tau) - \int_0^\tau \bar{R}\, v(s)\, ds \quad \forall\, \tau \in [0,T]. \tag{3.9}$$

These facts suggest that $\{G^\varepsilon(W^\varepsilon)(\tau),\ \tau \in [0,T]\}$ converges weakly to the limit $\{G(\hat{W}^0)(\tau),\ \tau \in [0,T]\}$ and thus, in view of (3.7), that the weak limit of $\{\Theta^\varepsilon(\tau),\ \tau \in [0,T]\}$ is likewise the process $\{G(\hat{W}^0)(\tau),\ \tau \in [0,T]\}$ or, equivalently, the process given by the solution of the stochastic differential equation

$$d\hat{\Theta}(\tau) = d\hat{W}^0(\tau) - \bar{R}\hat{\Theta}(\tau)\, d\tau, \quad \hat{\Theta}(0) = 0, \quad \forall\, \tau \in [0,T]. \tag{3.10}$$

In short, one first proves a CLT giving weak convergence of the simpler process $\{W^\varepsilon(\tau),\ \tau \in [0,T]\}$ to the limit $\{\hat{W}^0(\tau),\ \tau \in [0,T]\}$ defined by (3.8), then uses the approximation (3.7) to transfer this result into a CLT giving weak convergence of $\{\Theta^\varepsilon(\tau),\ \tau \in [0,T]\}$ to the limit $\{\hat{\Theta}(\tau),\ \tau \in [0,T]\}$ defined by (3.10). Our strategy for establishing Theorem 3.3 will be based on a very analogous method. First establish a functional LIL for the process $\{W^\varepsilon(\tau),\ \tau \in [0,T]\}$ as follows.

THEOREM 3.5 (proved in section 4). *Suppose conditions* (C1)–(C4) *of section* 2, *and fix some finite horizon* $T \in (0,\infty)$. *Let* $\{\theta^0(\tau),\ \tau \in [0,T]\}$, $\{W^\varepsilon(\tau),\ \tau \in [0,T]\}$, *and* $A(\cdot)$ *be defined by* (1.2), (3.5), and (2.6), *respectively, and write*

$$K_W^T \triangleq \left\{ \phi \in AC_0[0,T] :\ \frac{1}{2}\int_0^T (\dot{\phi}(s))' A^{-1}(\theta^0(s))\dot{\phi}(s)\, ds \le 1 \right\}. \tag{3.11}$$

Then K_W^T *is a compact subset of* $C[0,T]$, *and*

$$\left\{ \frac{W^\varepsilon(\tau)}{\sqrt{2\log\log\varepsilon^{-1}}},\ \tau \in [0,T] \right\} \twoheadrightarrow K_W^T \quad a.s. \tag{3.12}$$

It remains to transfer the LIL of Theorem 3.5 for the process $\{W^\varepsilon(\tau),\ \tau \in [0,T]\}$ into the one given by Theorem 3.3 for the process $\{\Theta^\varepsilon(\tau),\ \tau \in [0,T]\}$. To this end, the following almost-sure version of (3.7) is essential.

THEOREM 3.6 (proved in section 5). *Suppose conditions* (C1)–(C3) *of section* 2, *and fix some finite horizon* $T \in (0,\infty)$. *Then, for the process* $\{W^\varepsilon(\tau),\ \tau \in [0,T]\}$ *and mapping* $G^\varepsilon : C[0,T] \to G^\varepsilon$ *defined by* (3.5) *and* (3.6), *respectively, we have*

$$\lim_{\varepsilon \searrow 0} \|G^\varepsilon(W^\varepsilon) - \Theta^\varepsilon\|_C = 0 \ \ a.s. \tag{3.13}$$

With Theorems 3.5 and 3.6 available, the proof of the main result is easy.

Proof of Theorem 3.3. One sees from (3.6) and (3.9) that $G^\varepsilon(\cdot)$ and $G(\cdot)$ are linear and continuous on $C[0,T]$. Using the Arzela–Ascoli theorem, it is easily seen that $G^\varepsilon(\cdot) \to G(\cdot)$ uniformly on compact subsets of $C[0,T]$ as $\varepsilon \searrow 0$. In view of this fact, if $Y^\varepsilon \in C[0,T]$ for all $\varepsilon \in (0,1]$ is such that $\{Y^\varepsilon(\tau),\ \tau \in [0,T]\} \twoheadrightarrow K$ for some compact $K \subset C[0,T]$, then it follows by easy analysis that $\{G^\varepsilon(Y^\varepsilon),\ \tau \in [0,T]\} \twoheadrightarrow G(K)$. Thus, identifying $Y^\varepsilon(\tau)$ with $W^\varepsilon(\tau)/\sqrt{2\log\log\varepsilon^{-1}}$ and using Theorem 3.5, we get

$$\left\{ \frac{G^\varepsilon(W^\varepsilon)(\tau)}{\sqrt{2\log\log\varepsilon^{-1}}},\ \tau \in [0,T] \right\} \twoheadrightarrow G(K_W^T), \quad \text{a.s.} \tag{3.14}$$

Next, from the definitions of K_Θ^T and K_W^T (see (3.3), (3.11)), and the definition of $G(\cdot)$ given by (3.9), we see that

$$G(K_W^T) = K_\Theta^T. \tag{3.15}$$

Now K_W^T is compact (by Theorem 3.5), thus K_Θ^T is compact, and (3.4) follows from (3.14), (3.15), and Theorem 3.6. □

Remark 3.7. One immediate consequence of Theorem 3.3 is that, subject to conditions (C1)–(C4), we have

$$\max_{0\le\tau\le T} |\theta^\varepsilon_{\lfloor\tau/\varepsilon\rfloor} - \theta^0(\tau)| = O(\varepsilon^{\frac{1}{2}}\sqrt{2\log\log\varepsilon^{-1}}) \quad \text{a.s.} \tag{3.16}$$

for each $T \in (0,\infty)$. We thus complement the finite horizon weak law of large numbers (1.3) with a strong law of large numbers together with an a.s. rate of convergence, which, by an argument identical to that in ([12], page 120), may be seen to be the best possible rate of convergence.

Remark 3.8. The general methodology used for establishing Theorem 3.3 is suggested by an approach developed in [15] for proving a functional LIL for random ODEs. The methods of [15] depend in an essential way on rather restrictive boundedness hypotheses which, when carried over directly into the context of (1.1), entail uniform boundedness of the driving data sequence $\{X_n\}$ with respect to $n = 1, 2, \ldots$ and $\omega \in \Omega$. Although this boundedness may be reasonably acceptable for differential equations, it is not realistic for algorithms, and it is necessary to significantly redesign the overall approach used in [15] for differential equations to suit the system (1.1). In the following sections we shall extensively use (i) nice properties of geometric L-mixing processes, in particular their approximability (see Remark 2.5) by s-dependent processes, (ii) L^p-bounds for sums of L-mixing processes over "triangular" domains (see Theorem 5.2), and (iii) the linear structure of (1.1), in order to deal with the problems caused by unboundedness of the data sequences in (1.1).

4. Proof of Theorem 3.5.

Notation 4.1. For this section we need the following additional notation: If (S, ρ) is a metric space then $\mathcal{B}(S)$ denotes its Borel σ-algebra, and if Y is a $\mathcal{F}/\mathcal{B}(S)$-measurable mapping from a triple $(\Omega, \mathcal{F}, P)$ into (S, ρ), then $\mathcal{L}(Y)$ is the probability measure on $\mathcal{B}(S)$ defined by $\mathcal{L}(Y)(A) \overset{\triangle}{=} P\{\omega : \ Y(\omega) \in A\}$ for all $A \in \mathcal{B}(S)$. For probability measures P_1 and P_2 on the metric space $C[0,T]$ with metric given by the norm $\|\cdot\|_C$ (see Notation 3.1), let $\Pi_C(P_1, P_2)$ denote the Prohorov distance between P_1 and P_2 (see section 8 for a general definition of Prohorov distance). If $\{\alpha_n\}$ and $\{\beta_n\}$ are sequences of real numbers, then the notation $\alpha_n \ll \beta_n$ indicates the existence of a constant $C \in [0,\infty)$ such that $|\alpha_n| \le C|\beta_n|$ for all $n = 1, 2, \ldots$ If α_ε and β_ε are real numbers for each $\varepsilon \in (0,1]$ then $\alpha_\varepsilon \ll \beta_\varepsilon$ indicates the existence of numbers $\varepsilon_0 \in (0,1]$ and $C \in [0,\infty)$ such that $|\alpha_\varepsilon| \le C|\beta_\varepsilon|$ for all $\varepsilon \in (0, \varepsilon_0]$.

The proof of Theorem 3.5 relies on the following result which is an immediate consequence of combining Lemma 2.1(iv) and Theorem 4.3 of Kuelbs [16].

THEOREM 4.2. *Fix some $T \in (0,\infty)$, and suppose that $M : [0,T] \to \Re^{d\times d}$ is continuous with $M(s)$ being positive-definite symmetric for each $s \in [0,T]$. Then the set*

$$K \overset{\triangle}{=} \left\{ \phi \in AC_0[0,T] \colon \frac{1}{2}\int_0^T (\dot{\phi}(s))' M^{-1}(s)\dot{\phi}(s)\, ds \le 1 \right\} \tag{4.1}$$

is a compact subset of $C[0,T]$*. Define a Gaussian process* $\{\hat{Y}(\tau),\ \tau \in [0,T]\}$ *by*

$$\hat{Y}(\tau) \overset{\triangle}{=} \int_0^\tau M^{\frac{1}{2}}(s)\, d\hat{B}(s) \qquad \forall\, \tau \in [0,T], \tag{4.2}$$

where $\hat{B}(\cdot)$ *is a standard* $\Re^d$*-valued Brownian motion on a triple* $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$*, and let* $\{Y_r,\ r = 1,2,\ldots\}$ *be a sequence of* $C[0,T]$*-valued random variables defined on a triple* $(\Omega, \mathcal{F}, P)$*. Then the following hold.* (i) *If*

$$\sum_{r=1}^{\infty} \Pi_C(\mathcal{L}(Y_r), \mathcal{L}(\hat{Y})) < \infty, \tag{4.3}$$

then

$$\lim_{r\to\infty} \left\| \frac{Y_r}{\sqrt{2\log r}} - K \right\|_C = 0, \quad a.s. \tag{4.4}$$

(ii) *If, in addition to* (4.3)*, the sequence* $\{Y_r\}$ *is independent, then*

$$\operatorname{acc}\left\{ \frac{Y_r(\omega)}{\sqrt{2\log r}} \right\} = K, \qquad a.s. \tag{4.5}$$

Remark 4.3. In Theorem 4.2 the set K is defined in terms of the covariance function $M(\cdot)$ of a Gaussian process $\{\hat{Y}(\tau)\}$. The theorem says that if a sequence of $C[0,T]$-valued random functions $\{Y_r\}$ converges fast enough in distribution to the Gaussian limit $\hat{Y}$ (see (4.3)), then all accumulation points of the sequence $\{Y_r(\omega)/\sqrt{2\log r},\ r = 1,2,\ldots\}$ are included *within* the set K for P-almost all ω (see (4.4)), regardless of any dependence which may exist in the sequence $\{Y_r\}$. This is true, in particular, when the Y_r are Gaussian with common distribution equal to that of $\hat{Y}$, for then (4.3) is automatically satisfied. If, in addition, the sequence $\{Y_r\}$ is *independent*, then the set of accumulation points of $\{Y_r(\omega)/\sqrt{2\log r},\ r = 1,2,\ldots\}$ is not only included within K but actually coincides *exactly* with K for P-almost all ω (see (4.5)). Taken together, (4.4) and (4.5) constitute a law of the *noniterated* logarithm. In the present section we shall use Theorem 4.4 (to follow) as a tool for verifying (4.3), and then establish Theorem 3.5 on the basis of the law of the noniterated logarithm resulting from Theorem 4.2.

THEOREM 4.4 (proved in section 6). *Suppose conditions* (C1)–(C4) *of section* 2 *hold and fix some finite horizon* $T \in (0,\infty)$*. Let* $\{\hat{W}^0(\tau),\ \tau \in [0,T]\}$ *be defined by* (3.8)*, and let* $\{W^\varepsilon(\tau),\ \tau \in [0,T]\}$ *be defined by* (3.5)*. Then there is a constant* $\eta \in (0,\infty)$ *such that*

$$\Pi_C(\mathcal{L}(W^\varepsilon), \mathcal{L}(\hat{W}^0)) \ll \varepsilon^\eta.$$

Remark 4.5. Fix an arbitrary finite horizon $T \in (0,\infty)$. For the proofs in this and in later sections we shall need the $\Re^d$-valued process $\{\xi_n^\varepsilon,\ n = 1,2,\ldots\}$ defined for each $\varepsilon \in (0,1]$ by

$$\xi_n^\varepsilon \overset{\triangle}{=} \tilde{H}_n(\theta^0(((n-1)\varepsilon) \wedge T)) \equiv \tilde{b}_n - \tilde{R}_n\theta^0(((n-1)\varepsilon) \wedge T) \quad \forall\, n = 1,2,\ldots \tag{4.6}$$

(recall (2.7) and (2.5)). To simplify the notation, we do not indicate dependence of ξ_n^ε upon the horizon T, which is fixed throughout this work. It follows at once from

(3.5) that we have

$$W^\varepsilon(\tau) = \varepsilon^{\frac{1}{2}} \left(\sum_{\nu=1}^{\lfloor \tau/\varepsilon \rfloor} \xi_\nu^\varepsilon + (\tau/\varepsilon - \lfloor \tau/\varepsilon \rfloor) \xi_{\lfloor \tau/\varepsilon \rfloor + 1}^\varepsilon \right) \qquad \forall\, \tau \in [0, T]. \tag{4.7}$$

Since $\{\tilde{b}_n\}$ and $\{\tilde{R}_n\}$ are zero-mean and geometrically L-mixing (see Remark 2.7), and $\theta^0(((n-1)\varepsilon) \wedge T)$ is uniformly bounded with respect to $\varepsilon \in (0,1]$, $n = 1, 2, \ldots$, and nonrandom, it follows at once that $\{\xi_n^\varepsilon,\ n = 1, 2, \ldots\}$ is zero-mean and geometrically L-mixing. In fact, if

$$\xi_n^\varepsilon[s] \overset{\triangle}{=} E\left[\xi_n^\varepsilon \mid \mathcal{F}_{n-s}^n\right] = \tilde{b}_n[s] - \tilde{R}_n[s]\theta^0((n-1)\varepsilon \wedge T) \qquad \forall\, s, n = 1, 2, \ldots, \tag{4.8}$$

then there is a constant $\lambda \in (0,1)$, and, for each $p \in [1, \infty)$, a constant $C_p \in [0, \infty)$, such that

$$\sup_{n > s} \|\xi_n^\varepsilon - \xi_n^\varepsilon[s]\|_p \le C_p\, \lambda^s \qquad \forall\, s = 1, 2, \ldots, \qquad \forall\, \varepsilon \in (0, 1], \tag{4.9}$$

and it follows from Remark 2.5 that $\{\xi_n^\varepsilon[s],\ n = 1, 2, 3, \ldots\}$ is a zero-mean s-dependent process for each $s = 1, 2, \ldots$ and $\varepsilon \in (0, 1]$. Notice that λ and C_p in (4.9) are *uniform* with respect to $\varepsilon \in (0, 1]$.

Remark 4.6. We can apply Theorem 8.5 separately to the geometrically L-mixing processes $\{\tilde{b}_n\}$ and $\{\tilde{R}_n\}$ in (4.6), and use the uniform boundedness in (ε, n) of $\theta^0(((n-1)\varepsilon) \wedge T)$ to get the following. For each $p \in [2, \infty)$ there is a constant $C_p^1 \in [0, \infty)$ such that for any nonrandom sequence $\{A_n\}$ of $d \times d$-matrices we have

$$\left\| \sum_{n=1}^N A_n \xi_n^\varepsilon \right\|_p \le C_p^1 \left(\sum_{n=1}^N |A_n|^2 \right)^{\frac{1}{2}} \qquad \forall\, N = 1, 2, \ldots, \qquad \forall\, \varepsilon \in (0, 1].$$

Notice that the dependencies of the constants in Theorem 8.5, and uniformity in $\varepsilon \in (0, 1]$ of C_p and λ in (4.9), entail that C_p^1 does not depend on ε, N, or the sequence $\{A_n\}$.

Proof of Theorem 3.5. From Lemma 2.9 we know that $A(\theta^0(s))$ is continuous in $s \in [0, T]$. Upon comparing (3.11) and (4.1), we see from Theorem 4.2 that K_W^T is compact. We now use Theorem 4.2 to show that a.s.

$$\text{(i)}\ \ \lim_{\varepsilon \searrow 0} \left\| \frac{W^\varepsilon}{\sqrt{2 \log\log \varepsilon^{-1}}} - K_W^T \right\|_C = 0, \quad \text{(ii)}\ \ K_W^T = \operatorname{acc}\left\{ \frac{W^\varepsilon}{\sqrt{2 \log\log \varepsilon^{-1}}} \right\}, \tag{4.10}$$

which gives Theorem 3.5.

Proof of (4.10)(i). Without loss of generality take $T = 1$. Fix $\sigma \in [\frac{9}{10}, 1)$ and put

$$\varepsilon_r \overset{\triangle}{=} \exp(-r^\sigma) \qquad \forall\, r = 1, 2, 3, \ldots. \tag{4.11}$$

Then, for each $\varepsilon \in [\varepsilon_{r+1}, \varepsilon_r]$, we have

$$\left\| \frac{W^{\varepsilon}(\cdot)}{\sqrt{2\log\log\varepsilon^{-1}}} - \frac{K_W^T}{\sqrt{\sigma}} \right\|_C \leq \left\| \frac{W^{\varepsilon}(\cdot)}{\sqrt{2\log\log\varepsilon^{-1}}} - \frac{W^{\varepsilon_r}(\cdot)}{\sqrt{2\log\log\varepsilon^{-1}}} \right\|_C$$
$$+ \left\| \frac{W^{\varepsilon_r}(\cdot)}{\sqrt{2\log\log\varepsilon^{-1}}} - \frac{W^{\varepsilon_r}(\cdot)}{\sqrt{2\log\log\varepsilon_r^{-1}}} \right\|_C + \left\| \frac{W^{\varepsilon_r}(\cdot)}{\sqrt{2\log\log\varepsilon_r^{-1}}} - \frac{K_W^T}{\sqrt{\sigma}} \right\|_C ,$$

and thus

$$\text{(4.12)} \qquad \sup_{\varepsilon_{r+1}\leq\varepsilon\leq\varepsilon_r} \left\| \frac{W^{\varepsilon}}{\sqrt{2\log\log\varepsilon^{-1}}} - \frac{K_W^T}{\sqrt{\sigma}} \right\|_C \leq \sup_{\varepsilon_{r+1}\leq\varepsilon\leq\varepsilon_r} \frac{\|W^{\varepsilon} - W^{\varepsilon_r}\|_C}{\sqrt{2\log\log\varepsilon_r^{-1}}}$$
$$+ \left\| \frac{W^{\varepsilon_r}}{\sqrt{2\log\log\varepsilon_r^{-1}}} \right\|_C \left(1 - \sqrt{\frac{\log\log\varepsilon_r^{-1}}{\log\log\varepsilon_{r+1}^{-1}}} \right) + \left\| \frac{W^{\varepsilon_r}}{\sqrt{2\log\log\varepsilon_r^{-1}}} - \frac{K_W^T}{\sqrt{\sigma}} \right\|_C .$$

Remark 4.7. We will show that the three terms on the right of (4.12) go to zero a.s. when $r \to \infty$ for each $\sigma \in [\frac{9}{10}, 1)$. Since we can choose σ arbitrarily close to 1, this gives (4.10)(i). Our choice of the sequence $\{\varepsilon_r\}$ is determined by the following considerations. From (4.7) we see that the number of terms in the sum for $W^{\varepsilon}(\tau)$ increases reciprocally with decreasing ε. Thus, to control the supremum appearing in the first term on the right side of (4.12), we want the difference $(\varepsilon_{r+1}^{-1} - \varepsilon_r^{-1})$ to not be too large, which means that $\{\varepsilon_r\}$ must go to zero quite slowly. On the other hand, in the course of the following proof, we shall need Theorem 4.2(i) to deal with the last term on the right of (4.12), using Theorem 4.4 to verify a bound of the form (4.3) (with $Y_r \triangleq W^{\varepsilon_r}$, $\hat{Y} \triangleq \hat{W}^0$), and for this it is important that $\{\varepsilon_r\}$ not go to zero *too slowly.* Our choice of the sequence $\{\varepsilon_r\}$ turns out to be the right compromise, meeting both of these requirements.

We now deal with the first term on the right of (4.12). For each $\gamma \in [0, \infty)$, define piecewise-constant process $\{S_\gamma(\tau),\ \tau \in [0,1]\}$ by

$$\text{(4.13)} \qquad S_\gamma(\tau) \triangleq \begin{cases} \sum_{j=1}^{\lfloor \tau\gamma \rfloor} \left[\tilde{b}_j - \tilde{R}_j \theta^0((j-1)/\gamma) \right], & \text{when } \ \gamma > 0, \\ 0, & \text{when } \ \gamma = 0, \end{cases}$$

and observe, from (4.7) and (4.13), that

$$\text{(4.14)} \qquad W^{\varepsilon}(\tau) = \varepsilon^{\frac{1}{2}} \{ S_{\varepsilon^{-1}}(\tau) + (\tau/\varepsilon - \lfloor \tau/\varepsilon \rfloor)\, \xi^{\varepsilon}_{\lfloor \tau/\varepsilon \rfloor + 1} \} \qquad \forall\, \tau \in [0,1].$$

Put $N_\varepsilon \triangleq \lfloor \varepsilon^{-1} \rfloor$ for all $\epsilon \in (0,1]$, and observe from (4.14) that

$$\text{(4.15)} \ \|W^{\varepsilon} - W^{\varepsilon_r}\|_C \leq \varepsilon^{\frac{1}{2}} \max_{k=1,\ldots,N_\varepsilon} |\xi_k^{\varepsilon}| + \|\varepsilon^{\frac{1}{2}} S_{\varepsilon^{-1}} - \varepsilon_r^{\frac{1}{2}} S_{\varepsilon_r^{-1}}\|_C + \varepsilon_r^{\frac{1}{2}} \max_{k=1,\ldots,N_{\varepsilon_r}} |\xi_k^{\varepsilon_r}|$$

for all $\epsilon \in [\varepsilon_{r+1}, \varepsilon_r]$. Now we need the following result.

LEMMA 4.8 (proved in section 7). *Suppose that $\{\gamma_n\}$ is a sequence of random variables (either $\Re^d$- or $\Re^{d\times r}$-valued for all n) on a probability space $(\Omega, \mathcal{F}, P)$, such that* $\sup_n \|\gamma_n\|_8 < \infty$. *Then, for almost always (a.a.) ω, there exists some constant $C(\omega) \in [0, \infty)$ such that*

$$\max_{n=1,2,\ldots,N} |\gamma_i(\omega)| \leq C(\omega) N^{\frac{1}{7}} \qquad \forall\, N = 1, 2, \ldots .$$

By (4.6) and Lemma 4.8, for P-a.a. ω there are constants $c_1(\omega), c_2(\omega) \in [0,\infty)$ such that

$$(4.16)\ \varepsilon^{\frac{1}{2}} \max_{k=1,\dots,N_\varepsilon} |\xi_k^\varepsilon(\omega)| \le \varepsilon^{\frac{1}{2}} \left\{ \max_{k=1,2,\dots,N_\varepsilon} |\tilde{b}_k(\omega)| + \max_{k=1,\dots,N_\varepsilon} |\tilde{R}_k(\omega)||\theta^0((k-1)\varepsilon)| \right\}$$

$$\le \varepsilon^{\frac{1}{2}} c_1(\omega) \left(N_\varepsilon^{\frac{1}{7}} + N_\varepsilon^{\frac{1}{7}} \max_{0\le\tau\le 1} |\theta^0(\tau)| \right) \le c_2(\omega)\varepsilon_r^{\frac{5}{14}} \quad \forall\, \varepsilon \in [\varepsilon_{r+1}, \varepsilon_r], \quad \forall\, r = 1,2,3,\dots.$$

For the second term on the right of (4.15), fix some integer $p \ge 3$ and observe that

$$(4.17) \qquad E\left[\sup_{\varepsilon_{r+1}\le\varepsilon\le\varepsilon_r} \|\varepsilon^{\frac{1}{2}} S_{\varepsilon^{-1}} - \varepsilon_r^{\frac{1}{2}} S_{\varepsilon_r^{-1}}\|_C^{2p} \right]$$

$$\le 2^{2p} \left\{ E\left[\sup_{\varepsilon_{r+1}\le\varepsilon\le\varepsilon_r} (|\varepsilon_r^{\frac{1}{2}} - \varepsilon^{\frac{1}{2}}| \|S_{\varepsilon^{-1}}\|_C)^{2p} \right] + E\left[\sup_{\varepsilon_{r+1}\le\varepsilon\le\varepsilon_r} (\varepsilon_r^{\frac{1}{2}} \|S_{\varepsilon^{-1}} - S_{\varepsilon_r^{-1}}\|_C)^{2p} \right] \right\}.$$

To deal with the expectations on the right side of (4.17) we need the next result, which is a slight variant of Lemma 3.7 in [15], and is proved in exactly the same way.

LEMMA 4.9. *Suppose conditions* (C1)–(C2) *of section* 2 *hold, and define* $S_\gamma(\tau)$, $\tau \in [0,1]$, *as in* (4.13) *for each* $\gamma \in [0,\infty)$. *Then, corresponding to each integer* $p \ge 3$, *there exists a constant* $\alpha_p \in (0,\infty)$ *such that*

$$E\left[\sup_{\gamma\le u\le\eta} \|S_u - S_\gamma\|_C^{2p} \right] \le \alpha_p \eta(\eta-\gamma)^{p-1} \qquad \forall\, 0 \le \gamma < \eta < \infty.$$

Since $\sigma < 1$ in (4.11), we see from the mean-value theorem applied to $r \to r^\sigma$ that $\varepsilon_r/\varepsilon_{r+1} \le e^\sigma$. Thus, from Lemma 4.9,

$$(4.18) \quad E\left[\sup_{\varepsilon_{r+1}\le\varepsilon\le\varepsilon_r} (\varepsilon_r^{\frac{1}{2}} \|S_{\varepsilon^{-1}} - S_{\varepsilon_r^{-1}}\|_C)^{2p} \right] = \varepsilon_r^p E\left[\sup_{\varepsilon_r^{-1}\le u\le\varepsilon_{r+1}^{-1}} \|S_u - S_{\varepsilon_r^{-1}}\|_C^{2p} \right]$$

$$\le \alpha_p \varepsilon_r^p \varepsilon_{r+1}^{-1} \left(\varepsilon_{r+1}^{-1} - \varepsilon_r^{-1}\right)^{p-1} \le e^\sigma \alpha_p \{(\varepsilon_r - \varepsilon_{r+1})(\varepsilon_{r+1}^{-1})\}^{p-1} \triangleq e^\sigma \alpha_p B_r^p \qquad \forall\, r = 1,2,\dots.$$

In the same way, one shows that the first expectation on the right side of (4.17) has an identical upper bound, and thus the quantity on the left side of (4.17) is $O(B_r^p)$, where the constant implied by O depends only on p. By applying the mean value theorem to $r \to \exp(-r^\sigma)$, we easily see that $B_r^p \le \{\sigma e^\sigma r^{(\sigma-1)}\}^{(p-1)}$. Then, fixing integer $p > \frac{2-\sigma}{1-\sigma}$, it follows that $r^{(\sigma-1)(p-1)} = O(r^{-\beta-1})$ for some $\beta > 0$, and thus the sequence $\{B_r^p,\ r = 1,2,\dots\}$ is summable. Hence, from (4.17) and the monotone convergence theorem,

$$E\left[\sum_{r\ge 1} \sup_{\varepsilon_{r+1}\le\varepsilon\le\varepsilon_r} \|\varepsilon^{\frac{1}{2}} S_{\varepsilon^{-1}} - \varepsilon_r^{\frac{1}{2}} S_{\varepsilon_r^{-1}}\|_C^{2p} \right] < \infty,$$

which implies

$$(4.19) \qquad \lim_{r\to\infty} \left[\sup_{\varepsilon_{r+1}\le\varepsilon\le\varepsilon_r} \|\varepsilon^{\frac{1}{2}} S_{\varepsilon^{-1}} - \varepsilon_r^{\frac{1}{2}} S_{\varepsilon_r^{-1}}\|_C \right] = 0 \text{ a.s.}$$

Similarly to (4.16), one sees that the third term on the right side of (4.15) is $O(\varepsilon_r^{\frac{5}{14}})$ a.s., and hence using (4.15), (4.16), and (4.19), we get

$$\lim_{r\to\infty}\left\{\sup_{\varepsilon_{r+1}\le\varepsilon\le\varepsilon_r}\|W^\varepsilon - W^{\varepsilon_r}\|_C\right\} = 0 \text{ a.s.} \tag{4.20}$$

This controls the first term on the right of (4.12). As for the third term, use Theorem 4.4 to find some constants $c_1 > 0$, $\eta > 0$ and $r_0 > 0$ such that $\Pi_C(\mathcal{L}(W^{\varepsilon_r}), \mathcal{L}(\hat{W}^0)) \le c_1 \exp(-\eta r^\sigma)$ for all $r \ge r_0$, thus $\sum_r \Pi_C(\mathcal{L}(W^{\varepsilon_r}), \mathcal{L}(\hat{W}^0)) < \infty$. Hence Theorem 4.2(i) (with $M(\tau) \triangleq A(\theta^0(\tau))$, $Y_r(\cdot) \triangleq W^{\varepsilon_r}(\cdot)$, $\hat{Y}(\cdot) \triangleq \hat{W}^0(\cdot)$, and $K \triangleq K_W^T$) establishes the convergence $\lim_{r\to\infty} \|\frac{W^{\varepsilon_r}(\cdot)}{\sqrt{2\log r}} - K_W^T\|_C = 0$ *a.s.* Now $\sigma \log r = \log\log \varepsilon_r^{-1}$ (see (4.11)); therefore,

$$\lim_{r\to\infty}\left\|\frac{W^{\varepsilon_r}}{\sqrt{2\log\log\varepsilon_r^{-1}}} - \frac{K_W^T}{\sqrt{\sigma}}\right\|_C = 0 \quad \text{a.s.} \tag{4.21}$$

As for the second term on the right side of (4.12), clearly $\lim_r \frac{\log\log\varepsilon_r^{-1}}{\log\log\varepsilon_{r+1}^{-1}} = 1$ (by L'Hôpital formula), and thus (4.21) and boundedness of K_W^T in $C[0,1]$ shows that this term goes a.s. to zero with $r \to \infty$. It follows that the quantity on the left side of (4.12) tends a.s. to zero as $r \to \infty$.

Proof of (4.10)(ii). Fix $\sigma \in (1, 3/2)$, and define ε_r as in (4.11).

Remark 4.10. In contrast to the situation of Remark 4.7, where $\sigma < 1$ so that ε_r^{-1} increases quite slowly with r, here we take $\sigma > 1$ in (4.11) so that ε_r^{-1} increases *extremely rapidly* with r. In view of (4.7), this ensures that the sum for $W^{\varepsilon_{r+1}}(\tau)$ involves many more terms than does the sum for $W^{\varepsilon_r}(\tau)$, or, equivalently, the sums for $W^{\varepsilon_{r+1}}(\tau)$ and $W^{\varepsilon_r}(\tau)$ have few terms in common. The geometric L-mixing of $\{\xi_\nu^\varepsilon\}$ then suggests that the sequence $\{W^{\varepsilon_r}(\cdot)\}$ of $C[0,1]$-valued random variables should be approximately independent, and we can then expect to use Theorem 4.2(ii) to obtain (4.10)(ii). Indeed, in the course of the following proof we shall make this intuition rigorous, using the geometric L-mixing of $\{\xi_\nu^\varepsilon\}$ and rapid increase of $\{\varepsilon_r\}$ to construct a sequence $\{W_2^r(\cdot)\}$ of independent $C[0,1]$-valued random variables to which we can apply Theorem 4.2(ii), and which approximates the sequence $\{W^{\varepsilon_r}(\cdot)\}$ in a strong sense (see (4.31)). From this it is easy to deduce (4.10)(ii).

Recalling $\lambda \in (0,1)$ in (4.9), define

$$q(r) \triangleq \left\lfloor \frac{r^2}{2\ln\lambda^{-1}} \right\rfloor, \quad \tau_r \triangleq \varepsilon_r\left(1 + q(r) + \frac{1}{\varepsilon_{r-1}}\right) \ \forall\, r = 1, 2, \ldots, \tag{4.22}$$

$$\zeta_u^\varepsilon \triangleq \xi_{\lfloor u\rfloor+1}^\varepsilon, \quad \zeta_u^\varepsilon[q] \triangleq \xi_{\lfloor u\rfloor+1}^\varepsilon[q] \quad \forall \varepsilon \in (0,1], \quad \forall u \in [0,\infty), \quad \forall q = 1, 2 \ldots \lfloor u\rfloor\,. \tag{4.23}$$

For each $r = 1, 2, \ldots$, define $\{W_1^r(\tau),\ \tau \in [0,1]\}$ and $\{W_2^r(\tau),\ \tau \in [0,1]\}$ by

$$W_1^r(\tau) \triangleq \begin{cases} 0, & \text{if } 0 \le \tau \le \tau_r, \\ \varepsilon_r^{\frac{1}{2}} \displaystyle\int_{\tau_r/\varepsilon_r}^{\tau/\varepsilon_r} \zeta_u^{\varepsilon_r}\, du, & \text{if } \tau_r < \tau \le 1, \end{cases} \tag{4.24}$$

$$W_2^r(\tau) \triangleq \begin{cases} 0, & \text{if } 0 \le \tau \le \tau_r, \\ \varepsilon_r^{\frac{1}{2}} \displaystyle\int_{\tau_r/\varepsilon_r}^{\tau/\varepsilon_r} \zeta_u^{\varepsilon_r}[q(r)]\, du, & \text{if } \tau_r < \tau \le 1. \end{cases} \tag{4.25}$$

We first show that $\{W_2^r(\cdot)\}$ is a sequence of $C[0,1]$-valued *independent* random variables. To this end, observe from (4.22), (4.23), and (4.25) that

$$\mathcal{A}_r \overset{\triangle}{=} \sigma\{W_2^r(\tau),\ 0 \leq \tau \leq 1\} \subset \sigma\{\xi^{\varepsilon_r}_{2+q(r)+\lfloor \varepsilon_{r-1}^{-1} \rfloor}[q(r)], \ldots, \xi^{\varepsilon_r}_{1+\lfloor \varepsilon_r^{-1} \rfloor}[q(r)]\}. \tag{4.26}$$

Now $\xi_j^{\varepsilon_r}[q]$ is $\mathcal{F}_{j-q}^j$-measurable for all $q, j = 1, 2, \ldots$ (see (4.8)), and thus from (4.26) we find

$$\mathcal{A}_r \subset \mathcal{F}_{2+\lfloor \varepsilon_{r-1}^{-1} \rfloor}^{1+\lfloor \varepsilon_r^{-1} \rfloor}, \tag{4.27}$$

where $\mathcal{F}_m^n$ is given by (2.1). Now one sees from Definition 2.3 that the finite collection of σ-algebras $\{\mathcal{F}_{m_1}^{n_1}, \mathcal{F}_{m_2}^{n_2}, \ldots, \mathcal{F}_{m_r}^{n_r}\}$ is independent when $m_1 < n_1 < m_2 < n_2 < \cdots < m_r < n_r$; hence (4.27) shows that $\{W_2^r(\cdot),\ r = 1, 2, \ldots\}$ is a sequence of $C[0,1]$-valued independent random variables. In order to use Theorem 4.2(ii) on this sequence, we next show that

$$\sum_{r=1}^{\infty} \Pi_C(\mathcal{L}(W_2^r), \mathcal{L}(\hat{W}^0)) < \infty, \tag{4.28}$$

where $\{\hat{W}^0(\tau),\ \tau \in [0,1\}$ is defined by (3.8). By the triangle inequality we have

$$\begin{aligned} \Pi_C(\mathcal{L}(W_2^r), \mathcal{L}(\hat{W}^0)) \leq \Pi_C(\mathcal{L}(W_2^r), \mathcal{L}(W_1^r)) &+ \Pi_C(\mathcal{L}(W_1^r), \mathcal{L}(W^{\varepsilon_r})) \\ &+ \Pi_C(\mathcal{L}(W^{\varepsilon_r}), \mathcal{L}(\hat{W}^0)), \end{aligned} \tag{4.29}$$

and it remains to upper-bound the three terms on the right side of (4.29). To this end we require the following lemma.

Lemma 4.11 (proved in section 7). *Suppose the hypotheses of Theorem* 3.5. *Then we have*

$$E\left[\max_{0 \leq \tau \leq 1} |W_1^r(\tau) - W_2^r(\tau)|^4\right] \ll \varepsilon_r.$$

Then, from Lemma 8.6(ii) (with $c \overset{\triangle}{=} 4$) we get $\Pi_C(\mathcal{L}(W_1^r), \mathcal{L}(W_2^r)) \ll (\varepsilon_r^{\frac{1}{4}})^{\frac{4}{5}} = \varepsilon_r^{\frac{1}{5}}$. Next, we need the following lemma.

Lemma 4.12 (proved in section 7). *Suppose the hypotheses of Theorem* 3.5. *Then we have*

$$E\left[\max_{0 \leq \tau \leq 1} |W^{\varepsilon_r}(\tau) - W_1^r(\tau)|^4\right] \ll r^{-10}.$$

By Lemmas 4.12 and 8.6(ii) (with $c \overset{\triangle}{=} 4$) we get $\Pi_C(\mathcal{L}(W_1^r), \mathcal{L}(W^{\varepsilon_r})) \ll (r^{-\frac{5}{2}})^{\frac{4}{5}} = r^{-2}$. By Theorem 4.4 there exists $r_0, \eta \in (0, \infty)$ such that $\Pi_C(\mathcal{L}(W^{\varepsilon_r}), \mathcal{L}(\hat{W}^0)) \ll \varepsilon_r^{\eta}$ for all $r \geq r_0$, and hence by (4.29), we get $\Pi_C(\mathcal{L}(W_2^r), \mathcal{L}(\hat{W}^0)) \ll \varepsilon_r^{\frac{1}{5}} + \varepsilon_r^{\eta} + r^{-2}$, and (4.28) follows. Thus, by independence of the sequence $\{W_2^r(\cdot),\ r = 1, 2, \ldots,\}$ and Theorem 4.2(ii) (with $M(\tau) \overset{\triangle}{=} A(\theta^0(\tau))$, $Y_r(\cdot) \overset{\triangle}{=} W_2^r(\cdot)$, $\hat{Y}(\cdot) \overset{\triangle}{=} \hat{W}^0(\cdot)$, and $K \overset{\triangle}{=} K_W^T$), we get $\mathrm{acc}\{\frac{W_2^r}{\sqrt{2 \log r}}\} = K_W^T$ a.s. Now $\sigma \log r = \log \log \varepsilon_r^{-1}$ (see (4.11)), and hence

$$\mathrm{acc}\left\{\frac{W_2^r}{\sqrt{2 \log \log \varepsilon_r^{-1}}}\right\} = \frac{K_W^T}{\sqrt{\sigma}}. \tag{4.30}$$

From Lemma 4.11 and Borel–Cantelli, we have $\lim_{r\to\infty}\|W_1^r - W_2^r\|_C = 0$ a.s. Similarly, by Lemma 4.12, $\lim_{r\to\infty}\|W_1^r - W^{\varepsilon_r}\|_C = 0$ a.s. Thus, by the triangle inequality,

$$\lim_{r\to\infty}\|W_2^r - W^{\varepsilon_r}\|_C = 0 \text{ a.s.} \tag{4.31}$$

From (4.30), (4.31), and the fact that $\{W^{\varepsilon_r}\}$ is a subnet of $\{W^\varepsilon\}$,

$$\frac{K_W^T}{\sqrt{\sigma}} = \operatorname{acc}\left\{\frac{W^{\varepsilon_r}}{\sqrt{2\log\log\varepsilon_r^{-1}}}\right\} \subset \operatorname{acc}\left\{\frac{W^{\varepsilon}}{\sqrt{2\log\log\varepsilon^{-1}}}\right\} \quad \text{a.s.} \tag{4.32}$$

Since (4.32) holds for σ arbitrarily near 1 with $\sigma > 1$, we have

$$K_W^T \subset \operatorname{acc}\left\{\frac{W^{\varepsilon}}{\sqrt{2\log\log\varepsilon^{-1}}}\right\} \quad \text{a.s.} \tag{4.33}$$

Now (4.10)(i) and (4.33) yield (4.10)(ii) as required. □

5. Proof of Theorem 3.6.

Remark 5.1. For ease of notation put

$$Z^\varepsilon(\tau) \overset{\triangle}{=} G^\varepsilon(W^\varepsilon)(\tau) \quad \forall\, \tau \in [0,T]. \tag{5.1}$$

From (3.6) and (4.7) we see that, for each $\varepsilon \in (0,1]$, the sequence $\{Z^\varepsilon(\varepsilon k)\}$ is given by

$$Z^\varepsilon(\varepsilon(k+1)) = (I - \varepsilon\bar{R})Z^\varepsilon(\varepsilon k) + \varepsilon^{\frac{1}{2}}\xi_{k+1}^\varepsilon, \quad Z^\varepsilon(0) = 0, \tag{5.2}$$

which is a linear system driven by the geometrically L-mixing process $\{\xi_k^\varepsilon\}$. Theorem 3.6 effectively relates $\{\Theta^\varepsilon(\varepsilon k)\}$ to the output of this system.

Without loss of generality we shall take $T = 1$. Put $N_\varepsilon \overset{\triangle}{=} \lfloor\varepsilon^{-1}\rfloor$ for all $\varepsilon \in (0,1]$. From (1.1), (1.2), and (2.5),

$$\theta_k^\varepsilon = \theta_* + \varepsilon\sum_{j=0}^{k-1}\left(b_{j+1} - R_{j+1}\theta_j^\varepsilon\right), \qquad \theta^0(\varepsilon k) = \theta_* + \int_0^{\varepsilon k}\left(\bar{b} - \bar{R}\theta^0(s)\right) ds. \tag{5.3}$$

In view of (1.6) we have $\Theta^\varepsilon(\varepsilon k) \overset{\triangle}{=} \varepsilon^{-\frac{1}{2}}(\theta_k^\varepsilon - \theta^0(\varepsilon k))$, and thus, using (5.3), (3.5), and (2.5),

$$\begin{aligned}
\Theta^\varepsilon(\varepsilon k) &= \varepsilon^{\frac{1}{2}}\sum_{j=0}^{k-1} b_{j+1} - \varepsilon^{\frac{1}{2}}\sum_{j=0}^{k-1} R_{j+1}\theta_j^\varepsilon + \varepsilon^{\frac{1}{2}}\sum_{j=0}^{k-1}(\tilde{b}_{j+1} - \tilde{R}_{j+1}\theta^0(\varepsilon j)) \\
&\quad - \varepsilon^{\frac{1}{2}}\sum_{j=0}^{k-1}((b_{j+1} - \bar{b}_{j+1}) - (R_{j+1} - \bar{R}_{j+1})\theta^0(\varepsilon j)) - k\varepsilon^{\frac{1}{2}}\bar{b} + \varepsilon^{-\frac{1}{2}}\int_0^{\varepsilon k}\bar{R}\theta^0(s)\, ds \\
&= W^\varepsilon(\varepsilon k) - \varepsilon^{\frac{1}{2}}\sum_{j=0}^{k-1} R_{j+1}(\theta_j^\varepsilon - \theta^0(\varepsilon j)) + \varepsilon^{\frac{1}{2}}\sum_{j=0}^{k-1}\left((\bar{b}_{j+1} - \bar{b})\right. \\
&\quad \left. - (\bar{R}_{j+1} - \bar{R})\theta^0(\varepsilon j)\right) + \varepsilon^{-\frac{1}{2}}\left(\int_0^{\varepsilon k}\bar{R}\theta^0(s)\, ds - \varepsilon\sum_{j=0}^{k-1}\bar{R}\theta^0(\varepsilon j)\right),
\end{aligned}$$

and hence, again using (2.5),

$$\Theta^\varepsilon(\varepsilon k) = W^\varepsilon(\varepsilon k) - \varepsilon \sum_{j=0}^{k-1} R_{j+1}\Theta^\varepsilon(\varepsilon j) + \varepsilon^{\frac{1}{2}} \sum_{j=0}^{k-1}(\hat{b}_{j+1} - \hat{R}_{j+1}\theta^0(\varepsilon j)) + \varepsilon^{-\frac{1}{2}}\left(\int_0^{\varepsilon k} \bar{R}\theta^0(s)\,ds - \varepsilon\sum_{j=0}^{k-1}\bar{R}\theta^0(\varepsilon j)\right) \tag{5.4}$$

for all $\varepsilon \in (0,1]$ and $k = 1,2,\ldots,N_\varepsilon$. Define

$$\Delta^\varepsilon(\varepsilon k) \overset{\triangle}{=} \Theta^\varepsilon(\varepsilon k) - Z^\varepsilon(\varepsilon k) \qquad \forall\, k = 0,1,2,\ldots,N_\varepsilon. \tag{5.5}$$

From (2.5) we know that $\bar{R} = R_{j+1} - (\tilde{R}_{j+1} + \hat{R}_{j+1})$, and thus, using (5.1) and (3.6),

$$Z^\varepsilon(\varepsilon k) = W^\varepsilon(\varepsilon k) - \varepsilon \sum_{j=0}^{k-1} R_{j+1} Z^\varepsilon(\varepsilon j) + \varepsilon \sum_{j=0}^{k-1}(\tilde{R}_{j+1} + \hat{R}_{j+1})Z^\varepsilon(\varepsilon j). \tag{5.6}$$

The quantity in brackets in the fourth term on the right side of (5.4) is clearly $O(\varepsilon)$ uniformly with respect to $k = 1,2,\ldots,N_\varepsilon$, while condition (C3a) ensures that the third term on the right side of (5.4) is $O(\varepsilon^{\frac{1}{2}})$ uniformly in $k = 1,2,\ldots,N_\varepsilon$. Subtracting (5.6) from (5.4) and taking magnitudes gives

$$|\Delta^\varepsilon(\varepsilon k)| \le \varepsilon \sum_{j=0}^{k-1} |R_{j+1}|\,|\Delta^\varepsilon(\varepsilon j)| + (|I_k^\varepsilon| + |J_k^\varepsilon| + O(\varepsilon^{\frac{1}{2}})), \tag{5.7}$$

where the constant implied by $O(\varepsilon^{\frac{1}{2}})$ is uniform with respect to $k = 1,2,\ldots,N_\varepsilon$, and

$$I_k^\varepsilon \overset{\triangle}{=} \varepsilon \sum_{j=0}^{k-1} \tilde{R}_{j+1} Z^\varepsilon(\varepsilon j), \quad J_k^\varepsilon \overset{\triangle}{=} \varepsilon \sum_{j=0}^{k-1} \hat{R}_{j+1} Z^\varepsilon(\varepsilon j) \quad \forall\, k = 1,2,\ldots,1+N_\varepsilon. \tag{5.8}$$

By (5.7), the fact that $\Delta^\varepsilon(0) = 0$, and the discrete-parameter version of Gronwall–Bellman's inequality (obtained by taking $\mu(\cdot)$ to be counting measure with weights $\varepsilon|R_{j+1}|$ over the nonnegative integers $j = 0,1,2,\ldots$ in Theorem 5.1 on page 498 of [8]), we get

$$\max_{0\le k\le N_\varepsilon+1} |\Delta^\varepsilon(\varepsilon k)| \le \exp\left(\varepsilon \sum_{j=1}^{N_\varepsilon} |R_j|\right) \max_{1\le k\le N_\varepsilon+1} (|I_k^\varepsilon| + |J_k^\varepsilon| + O(\varepsilon^{\frac{1}{2}})) \tag{5.9}$$

for all $\varepsilon \in (0,1]$. The proof proceeds by showing that, as $\varepsilon \searrow 0$, the right-hand side of (5.9) converges to zero a.s. Since $Z^\varepsilon(\cdot)$ and $\Theta^\varepsilon(\cdot)$ are both linear on intervals of the form $[(k-1)\varepsilon, k\varepsilon)$, $k = 1,2,\ldots,N_\varepsilon$ and continuous, this gives Theorem 3.6. Now products of geometrically L-mixing processes are geometrically L-mixing (see Remark 2.7), and thus one easily sees from condition (C1) and (2.5) that $\{|R_n|^2\}$ is geometrically L-mixing; in view of Theorem 8.5 and a standard use of the Borel–Cantelli lemma, it then follows that

$$\limsup_{\varepsilon\searrow 0} \varepsilon \sum_{j=1}^{N_\varepsilon} |R_j| < \infty, \quad \text{a.s.} \tag{5.10}$$

In light of (5.9) and (5.10), Theorem 3.6 will be established when we show that

$$\text{(5.11)}\quad \limsup_{\varepsilon\searrow 0}\max_{0\le k\le N_\varepsilon+1}|I^\varepsilon_k| = 0 \text{ a.s.} \quad\text{and}\quad \limsup_{\varepsilon\searrow 0}\max_{0\le k\le N_\varepsilon+1}|J^\varepsilon_k| = 0 \text{ a.s.}$$

To establish the first limit of (5.11), note from (5.2) that $Z^\varepsilon(\varepsilon j) = \varepsilon^{\frac{1}{2}}(I-\varepsilon\bar{R})^j\sum_{i=0}^{j-1}(I-\varepsilon\bar{R})^{-i-1}\xi^\varepsilon_{i+1}$ for all $j=0,1,\dots,N_\varepsilon{+}1$, from which we see that I^ε_k in (5.8) can be written as

$$\text{(5.12)}\ I^\varepsilon_k = \varepsilon^{\frac{3}{2}}\sum_{j=0}^{k-1}\tilde{R}_{j+1}(I-\varepsilon\bar{R})^j\Gamma^\varepsilon_j, \quad\text{where}\quad \Gamma^\varepsilon_j \triangleq \sum_{i=1}^{j}(I-\varepsilon\bar{R})^{-i}\xi^\varepsilon_i, \quad \Gamma^\varepsilon_0 \triangleq 0.$$

The following very special case of Theorem 1.1 of Gerencsér [10] is essential for establishing (5.11).

THEOREM 5.2. *Let $\{f_1(i)\}_{i=0}^\infty$ and $\{f_2(i)\}_{i=0}^\infty$ be real-valued nonrandom sequences, and let $\{u_1(i)\}_{i=0}^\infty$ and $\{u_2(i)\}_{i=0}^\infty$ be zero-mean geometrically L-mixing processes with rate $\lambda\in(0,1)$. Then there exists a constant $c\in(0,\infty)$ such that, for $l,k=1,2\dots$, with $l>k$, we have*

$$\left\|\sum_{j=k}^{l-1}\sum_{i=0}^{j-1} f_1(i)u_1(i)f_2(j)u_2(j)\right\|_4 \le c[\psi_1(l,k)+\psi_2(l,k)],$$

where (taking $f_1(i)\triangleq f_2(i)\triangleq 0$ when $i<0$)

$$\text{(5.13)}\qquad \begin{cases} \psi_1(l,k)\triangleq\left(\sum_{i=k}^{l} h(i,l,k)(|f_2(i-1)|+|f_2(i-2)|)\varphi_1^2(i)\right)^{\frac{1}{2}}, \\ \psi_2(l,k)\triangleq\sum_{i=1}^{l} h(i,l,k)|f_1(i-2)|, \end{cases}$$

$$\text{(5.14)}\ \varphi_1(i)\triangleq\left(\sum_{j=0}^{i-1}f_1^2(j)\right)^{\frac{1}{2}}, \qquad h(i,l,k)\triangleq\sum_{j=i\vee k}^{l}|f_2(j-1)|\lambda^{j-i}, \quad i=1,\dots,l.$$

Remark 5.3. The constant c is invariant with respect to $l,k=1,2,\dots$, and the sequences $\{f_1(i)\}$ and $\{f_2(i)\}$, but may depend on the quantities λ, $\sup_{i\ge 0}\|u_1(i)\|_8$ and $\sup_{j\ge 0}\|u_2(j)\|_8$. Theorem 1.1 of [10] is established in a continuous-parameter setting and gives general L^p-bounds on arbitrarily many multiple integrals of L-mixing processes. Theorem 5.2 stated here is a specialization of this result to the discrete-parameter case for an L^4-bound on two summations of geometrically L-mixing processes.

Since we can diagonalize $\bar{R}$ (by condition (C2)) there is no loss of generality in supposing that $d=1$. For each $\varepsilon\in(0,1)$ and $i,j=0,1,2,\dots$, define

$$\text{(5.15)}\qquad u_1(\varepsilon;i)\triangleq\xi^\varepsilon_{i+1} \qquad\text{and}\qquad u_2(j)\triangleq\tilde{R}_{j+1},$$

$$\text{(5.16)}\ f_1(\varepsilon;i)\triangleq\begin{cases}(1-\varepsilon\bar{R})^{-i-1}, & \text{if } i\ge 0,\\ 0, & \text{if } i<0,\end{cases} \qquad f_2(\varepsilon;j)\triangleq\begin{cases}(1-\varepsilon\bar{R})^{j}, & \text{if } j\ge 0,\\ 0, & \text{if } j<0,\end{cases}$$

and note by Remark 4.5 that $u_1(\varepsilon;\cdot)$ and $u_2(\cdot)$ are zero-mean geometrically L-mixing with some rate $\lambda\in(0,1)$. From (5.12), (5.15), and (5.16) we can write

$$E[|I_l^\varepsilon - I_k^\varepsilon|^4] = \varepsilon^6 E\left[\left(\sum_{j=k}^{l-1}\sum_{i=0}^{j-1} f_1(\varepsilon;i)u_1(\varepsilon;i)f_2(\varepsilon;j)u_2(j)\right)^4\right] \tag{5.17}$$

for all $1 \le k < l \le 1 + N_\varepsilon$. Now define $\psi_1(l,k;\varepsilon)$, $\psi_2(l,k;\varepsilon)$, $\varphi_1(i;\varepsilon)$, and $h(i,l,k;\varepsilon)$ exactly as in (5.13) to (5.14), but allowing for the parametrization by ε in (5.15) and (5.16). Put $\varepsilon_0 \overset{\triangle}{=} 1/2$ when $\bar{R} = 0$, and put $\varepsilon_0 \overset{\triangle}{=} 1/(2\bar{R})$ when $\bar{R} > 0$. In view of (5.14) and (5.16), we have $h(i,l,k;\varepsilon) \le \sum_{j=i\vee k}^{l} \lambda^{j-i}$, and clearly $\max_{1\le i\le N_\varepsilon}(1-\varepsilon\bar{R})^{-i} = O(1)$ for all $\varepsilon \in (0,\varepsilon_0]$. Now $\sum_{i=1}^{k}\{\sum_{j=k}^{l}\lambda^{j-i}\} = \{\sum_{i=1}^{k}\lambda^{k-i}\}(1-\lambda^{l-k+1})/(1-\lambda) = O(1-\lambda^{l-k+1}) = O(l-k)$. Thus, from (5.13) and $\lambda \in (0,1)$, there are constants $c_1, c_2 \in (0,\infty)$ such that

$$\psi_2(l,k;\varepsilon) \le c_1\left(\sum_{i=1}^{k}\sum_{j=k}^{l}\lambda^{j-i} + \sum_{i=k+1}^{l}\sum_{j=i}^{l}\lambda^{j-i}\right) \le c_2(l-k) \tag{5.18}$$

for all $\varepsilon \in (0,\varepsilon_0]$, and $1 \le k < l \le 1+N_\varepsilon$. Similarly, from the fact that $\max_{1\le i\le N_\varepsilon}(1-\varepsilon\bar{R})^{-2i} = O(1)$ for all $\varepsilon \in (0,\varepsilon_0]$, and (5.14), we get $\varphi_1^2(i;\varepsilon) \le c_3 i$ for all $\varepsilon \in (0,\varepsilon_0]$, $i = 1,\ldots,N_\varepsilon$. Then, from (5.13), and $h(i,l,k;\varepsilon) \le \sum_{j=i}^{l}\lambda^{j-i}$ (when $i \ge k$),

$$\psi_1^2(l,k;\varepsilon) \le c_4 \sum_{i=k}^{l}\left(\sum_{j=i}^{l}\lambda^{j-i}\right)\varphi_1^2(i;\varepsilon) \le c_5\sum_{i=k}^{l} i \le c_6(l^2-k^2) \tag{5.19}$$

for all $\varepsilon \in (0,\varepsilon_0]$, and $1 \le k < l \le 1 + N_\varepsilon$, where $c_3, c_4, c_5, c_6 \in (0,\infty)$ are constants. Using Theorem 5.2, (5.17), (5.18), and (5.19), we find a constant $c_7 \in (0,\infty)$ such that

$$E[|I_l^\varepsilon - I_k^\varepsilon|^4] \le c_7\varepsilon^6[(l^2-k^2)^2 + (l-k)^4] \le 2c_7\varepsilon^6[l^2-k^2]^2 \tag{5.20}$$

for all $\varepsilon \in (0,1]$, and $1 \le k < l \le 1 + N_\varepsilon$. Since $I_1^\varepsilon = 0$ (see (5.2), (5.8)), from (5.20) and Theorem 8.1(ii) (with $\gamma \overset{\triangle}{=} 2$, $\nu \overset{\triangle}{=} 4$, $h(i,j) \overset{\triangle}{=} j^2 - i^2$, $1 \le i \le j \le 1 + N_\varepsilon$), there are constants $c_8, c_9 \in (0,\infty)$ such that

$$E\left[\max_{1\le k\le N_\varepsilon+1}|I_k^\varepsilon|^4\right] = E\left[\max_{1\le k\le N_\varepsilon+1}|I_k^\varepsilon - I_1^\varepsilon|^4\right] \le c_8\varepsilon^6[h(1,1+N_\varepsilon)]^2 \le c_9\varepsilon^2 \tag{5.21}$$

for all $\varepsilon \in (0,\varepsilon_0]$. From (5.21) (with $\varepsilon \overset{\triangle}{=} 1/n$) and the Borel–Cantelli theorem,

$$\lim_{n\to\infty}\max_{1\le k\le n+1}\left|I_k^{1/n}\right| = 0 \quad \text{a.s.},$$

and thus

$$\lim_{\varepsilon\searrow 0}\max_{1\le k\le N_\varepsilon+1}\left|I_k^{1/N_\varepsilon}\right| = 0 \quad \text{a.s.} \tag{5.22}$$

To get the first limit of (5.11) from (5.22) we must fill the gaps between successive $1/N_\varepsilon$. For this we observe

$$\max_{1\le k\le N_\varepsilon+1}|I_k^\varepsilon| \le \max_{1\le k\le N_\varepsilon+1}\left|I_k^{1/N_\varepsilon}\right| + B_\varepsilon^1 + B_\varepsilon^2, \tag{5.23}$$

which results from the triangle inequality, (5.12), $N_\varepsilon^{\frac{3}{2}}\varepsilon^{\frac{3}{2}} \leq 1$, and the definition of B_ε^1 and B_ε^2 in (5.24) and (5.25). Now we need the following lemma.

Lemma 5.4 (proved in section 7). *Suppose* (C1)–(C3) *of section* 2. *Let* Γ_j^ε *be defined by* (5.12) *and* $N_\varepsilon \overset{\triangle}{=} \lfloor \varepsilon^{-1} \rfloor$. *Then* (a) *we have*

$$(5.24)\quad B_\varepsilon^1 \overset{\triangle}{=} \varepsilon^{\frac{3}{2}} \max_{1\leq k\leq N_\varepsilon+1} \left| \sum_{j=0}^{k-1} \tilde{R}_{j+1}((I-\varepsilon\bar{R})^j - (I-N_\varepsilon^{-1}\bar{R})^j)\Gamma_j^{N_\varepsilon^{-1}} \right| \ll \varepsilon^{\frac{1}{2}},$$

$$(5.25)\quad B_\varepsilon^2 \overset{\triangle}{=} \varepsilon^{\frac{3}{2}} \max_{1\leq k\leq N_\varepsilon+1} \left| \sum_{j=0}^{k-1} \tilde{R}_{j+1}(I-\varepsilon\bar{R})^j(\Gamma_j^\varepsilon - \Gamma_j^{N_\varepsilon^{-1}}) \right| \ll \varepsilon^{\frac{3}{14}},$$

and (b) *we have bounds identical to* (5.24) *and* (5.25)*, but with* $\hat{R}_{j+1}$ *in place of* $\tilde{R}_{j+1}$.

The first limit of (5.11) follows from (5.22), (5.23), and Lemma 5.4 (a). In the same way, using condition (C3b) and Lemma 5.4(b), we can establish the second limit in (5.11) (the proof is similar to, but easier than that of the first limit in (5.11) since the matrices $\hat{R}_{j+1}$ in the definition of J_k^ε are nonrandom, whereas the $\tilde{R}_{j+1}$ in the definition of I_k^ε are random—see (5.8)). □

6. Proof of Theorem 4.4.

Notation 6.1. In this section we shall require the following additional notation: $\mathcal{Z} \overset{\triangle}{=} \{\ldots,-2,-1,0,1,2,\ldots\}$, $\mathcal{Z}_+ \overset{\triangle}{=} \{1,2,\ldots\}$. Also, $\#A$ indicates the cardinality of a finite set A. For positive integer m, let $\Pi_2^m(P_1,P_2)$ denote the Prohorov distance between probability measures P_1 and P_2 on the metric space $\Re^m$ with metric given by the norm $|\cdot|$ (see Notation 2.1), and let $\mathcal{N}_m(b,Q)$ denote the normal distribution in $\Re^m$ with m-dimensional mean vector b and covariance Q.

Remark 6.2. Theorem 4.4 is a functional CLT with rate of convergence for the process $\{W^\varepsilon(\tau),\ \tau\in[0,T]\}$, which is derived from summing the geometrically L-mixing random vectors $\{\xi_n^\varepsilon\}$ (see Remark 4.5), and may be regarded as a generalization to a function-space setting of [11, Lemma A.2.1]. This latter result gives rates of convergence in a classical (i.e., nonfunctional) CLT for a sum of geometrically L-mixing random vectors in terms of bounds on characteristic functions over finite-dimensional Euclidean space. The function-space result is considerably more difficult to establish because the Prohorov distance for probability measures on $C[0,T]$ does not relate nicely to characteristic functions. Theorem 4.4 also extends the result of Yurinskii [27, section 2], which is a functional CLT with rate of convergence for sums of independent random vectors, and bears clear similarities to [14, Lemma A6.1], which is a functional CLT with rate of convergence for a sum of strong mixing random vectors subject to quite stringent boundedness conditions that do not generally apply to algorithms. We emphasize that Theorem 4.4 involves a combination of a *function-space* rate of convergence (as contrasted with the classical rate in [11]) for a sum of *dependent* random vectors (compared with the independent case in [27]), and subject to only weak boundedness (as contrasted with uniform boundedness in [14]). The combination of all these elements presents technical challenges not found in [11], [14], or [27], and is the main reason for the somewhat lengthy proofs of this section.

Without loss of generality we shall prove Theorem 4.4 with $T=1$. For all $k=1,2,\ldots$ and $\varepsilon\in(0,1]$ define the kd-dimensional vectors Ξ_k^ε and $\hat{\Xi}_k^0$ by

$$\Xi_k^\varepsilon \triangleq \begin{bmatrix} W^\varepsilon(\frac{1}{k}) \\ W^\varepsilon(\frac{2}{k}) \\ \vdots \\ W^\varepsilon(1) \end{bmatrix} \quad \text{and} \quad \hat{\Xi}_k^0 \triangleq \begin{bmatrix} \hat{W}^0(\frac{1}{k}) \\ \hat{W}^0(\frac{2}{k}) \\ \vdots \\ \hat{W}^0(1) \end{bmatrix}. \tag{6.1}$$

In order to establish Theorem 4.4 we need the following CLT giving weak convergence of Ξ_k^ε to $\hat{\Xi}_k^0$ as $\varepsilon \to 0$ and $k \to \infty$, where k increases slowly enough that it is much less than ε^{-1} (the slowly increasing k is needed when we establish weak convergence in a function space setting).

THEOREM 6.3. *Let Ξ_k^ε and $\hat{\Xi}_k^0$ be as defined in* (6.1). *Under conditions* (C1)–(C4) *of section* 2, *there are constants $c \in (0,\infty)$ and $\varepsilon_0 \in (0,1)$ such that, for all $\varepsilon \in (0,\varepsilon_0]$ and $k=1,2,\dots,\lfloor \varepsilon^{-\frac{1}{36}} \rfloor$, we have*

$$\Pi_2^{kd}(\mathcal{L}(\Xi_k^\varepsilon), \mathcal{L}(\hat{\Xi}_k^0)) \le c\varepsilon^{\frac{1}{48}}. \tag{6.2}$$

Proof of Theorem 6.3. Fix arbitrary $\varepsilon \in (0,1]$ and $k=1,2,\dots$. Recalling that we take $T=1$ in the proof, we can use (4.7) to write the lth element $W^\varepsilon(l/k)$ of Ξ_k^ε in the form

$$W^\varepsilon(l/k) = \varepsilon^{\frac{1}{2}} \left(\sum_{j=1}^{l} \left[\sum_{\nu \in J_j^{\varepsilon,k}} \xi_\nu^\varepsilon \right] + V_l^{\varepsilon,k} \right) \qquad \forall\, l = 1,2,\dots,k, \tag{6.3}$$

where $V_l^{\varepsilon,k}$ is a small "interpolation term" given by

$$V_l^{\varepsilon,k} \triangleq \left(\frac{l}{\varepsilon k} - \left\lfloor \frac{l}{\varepsilon k} \right\rfloor \right) \xi^\varepsilon_{\lfloor l/(\varepsilon k) \rfloor + 1} \qquad \forall\, l = 1,2,\dots,k, \tag{6.4}$$

and $J_j^{\varepsilon,k}$ is the block of consecutive integers given by

$$J_j^{\varepsilon,k} \triangleq \left\{ 1 + \left\lfloor \frac{j-1}{\varepsilon k} \right\rfloor, \dots, \left\lfloor \frac{j}{\varepsilon k} \right\rfloor \right\} \qquad \forall\, j = 1,2,\dots,k. \tag{6.5}$$

We will call the $J_j^{\varepsilon,k}$ the "basic blocks." We see from (6.3) that the lth row of Ξ_k^ε involves summation over the basic blocks $J_1^{\varepsilon,k}, \dots J_l^{\varepsilon,k}$.

Remark 6.4. The proof is based on the Markov–Bernstein technique of long blocks alternated with short blocks. The basic idea is as follows. If $\sum_{\nu=1}^m \rho_\nu$ is a sum of weakly-dependent random vectors $\{\rho_\nu\}$ (e.g., the elements of a geometric L-mixing sequence), then we can study its asymptotic properties by partitioning the interval of summation $1,2,\dots,m$ into long blocks G_i^m of integers, all of equal length p_m, separated by short blocks H_i^m of integers, likewise of equal length q_m, giving a pattern of adjacent blocks $G_1^m, H_1^m, G_2^m, H_2^m, \dots, G_r^m, H_r^m, H_{r+1}^m$. Here the integer $r \equiv r_m$ is equal to the *maximum* number of long block/short block pairs (of total length $p_m + q_m$) which one can fit completely into the interval of summation $1,2,\dots,m$, and H_{r+1}^m is a "remainder block" whose cardinality is less than that of a long block/short block pair, namely $p_m + q_m$. On the one hand, if the short blocks H_i^m are long enough, then terms of the form $\sum_{\nu \in G_i^m} \rho_\nu$ and $\sum_{\nu \in G_j^m} \rho_\nu$ for $i \ne j$ involve widely separated (hence approximately independent) summands, and are thus themselves almost independent. On the other hand, if the long blocks are much longer than the short blocks then the contribution to the total sum of the ρ_ν for ν belonging to the short blocks H_i^m is negligible, and thus $\sum_{\nu=1}^m \rho_\nu \approx \sum_{i=1}^{r_m}\{\sum_{\nu\in G_i^m}\rho_\nu\}$. We thus have a sum (over $i = 1,2,\dots,r_m$) of almost independent terms on the right-hand side, and we can use this independence to study the limiting properties of the original sum of random vectors.

In our problem matters are slightly more complicated because we do not have a fixed interval of summation. Instead, different entries $W^\varepsilon(l/k)$ of the vector Ξ_k^ε involve different intervals of summation, as may be seen from (6.3). We therefore partition not the overall intervals of summation for $W^\varepsilon(l/k)$, but rather the basic blocks $J_j^{\varepsilon,k}$ in (6.3), into adjacent long and short blocks $G_{i,j}^{\varepsilon,k}$ and $H_{i,j}^{\varepsilon,k}$ of consecutive integers ordered according to the pattern

$$G_{1,j}^{\varepsilon,k},\ H_{1,j}^{\varepsilon,k},\ G_{2,j}^{\varepsilon,k},\ H_{2,j}^{\varepsilon,k},\ G_{3,j}^{\varepsilon,k}, H_{3,j}^{\varepsilon,k},\dots, G_{r,j}^{\varepsilon,k},\ H_{r,j}^{\varepsilon,k},\ H_{r+1,j}^{\varepsilon,k}. \tag{6.6}$$

The blocks $G_{i,j}^{\varepsilon,k}$, $i = 1,2,\dots,r$ have common cardinality $p_{\varepsilon,k}$ and the alternate blocks $H_{i,j}^{\varepsilon,k}$, $i = 1,2,\dots,r$ have common cardinality $q_{\varepsilon,k}$ given by

$$p_{\varepsilon,k} \triangleq \lfloor k^{-1}\varepsilon^{-\frac{1}{3}}\rfloor, \qquad q_{\varepsilon,k} \triangleq \lfloor k^{-1}\varepsilon^{-\frac{1}{9}}\rfloor, \tag{6.7}$$

while r is chosen to completely fit the largest number of consecutive pairs of blocks $G_{i,j}^{\varepsilon,k}, H_{i,j}^{\varepsilon,k}$ (of total length $p_{\varepsilon,k} + q_{\varepsilon,k}$) into $J_j^{\varepsilon,k}$, namely

$$r \equiv r_{\varepsilon,k} \triangleq \lfloor (\# J_j^{\varepsilon,k})/(p_{\varepsilon,k} + q_{\varepsilon,k})\rfloor. \tag{6.8}$$

The $G_{i,j}^{\varepsilon,k}$ are long blocks and the $H_{i,j}^{\varepsilon,k}$ are short blocks for all $i = 1,2,\dots,r$, while the last block $H_{r+1,j}^{\varepsilon,k}$ is a "remainder block" whose cardinality is less than $p_{\varepsilon,k} + q_{\varepsilon,k}$. Thus,

$$\#\left(G_{i,j}^{\varepsilon,k}\right) = p, \quad \#\left(H_{i,j}^{\varepsilon,k}\right) = q, \quad \text{and} \quad 0 \le \#\left(H_{r+1,j}^{\varepsilon,k}\right) < p + q, \tag{6.9}$$

where, for brevity, p and q are now used for $p_{\varepsilon,k}$ and $q_{\varepsilon,k}$, respectively. Denoting the first integer of the block $G_{i,j}^{\varepsilon,k}$ by $b_{i,j}^{\varepsilon,k}$, from (6.6) we see that

$$b_{i,j}^{\varepsilon,k} \triangleq 1 + \left\lfloor \frac{j-1}{k\varepsilon} \right\rfloor + (i-1)(p+q) \qquad \forall\, i = 1,\dots,r+1, \tag{6.10}$$

and, for each $j = 1,2,\dots,k$, we clearly have $G_{i,j}^{\varepsilon,k} = [b_{i,j}^{\varepsilon,k}\ ,\ b_{i,j}^{\varepsilon,k} + p)$ and $H_{i,j}^{\varepsilon,k} = [b_{i,j}^{\varepsilon,k} + p\ ,\ b_{i,j}^{\varepsilon,k} + p + q)$, for all $i = 1,\dots,r$, while $H_{r+1,j}^{\varepsilon,k} = [b_{r,j}^{\varepsilon,k} + p + q\ ,\ j/(k\varepsilon)]$.

Remark 6.5. To summarize, the lth entry $W^\varepsilon(l/k)$ of Ξ_k^ε is partitioned into a sum of ξ_ν^ε over the basic blocks $J_j^{\varepsilon,k}$ indexed by $j = 1,2,\dots,l$ (see (6.3)), and each basic block $J_j^{\varepsilon,k}$ is itself partitioned into a sequence of long block/short block pairs $G_{i,j}^{\varepsilon,k}, H_{i,j}^{\varepsilon,k}$, indexed by $i = 1,2,\dots,r_{\varepsilon,k}$, and a remainder block $H_{r+1,j}^{\varepsilon,k}$ (see (6.6)).

For each $j=1,\dots,k$ and $i=1,\dots,r$, define the d-vectors

$$Y_{i,j}^{\varepsilon,k} \triangleq \sum_{\nu\in G_{i,j}^{\varepsilon,k}} \xi_\nu^\varepsilon, \qquad Z_{i,j}^{\varepsilon,k} \triangleq \sum_{\nu\in H_{i,j}^{\varepsilon,k}} \xi_\nu^\varepsilon, \qquad Z_{r+1,j}^{\varepsilon,k} \triangleq \sum_{\nu\in H_{r+1,j}^{\varepsilon,k}} \xi_\nu^\varepsilon, \tag{6.11}$$

and observe from (6.3) that

$$W^\varepsilon(l/k) = \varepsilon^{\frac{1}{2}} \sum_{j=1}^{l} \left\{ \sum_{i=1}^{r} (Y_{i,j}^{\varepsilon,k} + Z_{i,j}^{\varepsilon,k}) + Z_{r+1,j}^{\varepsilon,k} \right\} + \varepsilon^{\frac{1}{2}} V_l^{\varepsilon,k} \tag{6.12}$$

for all $l = 1, 2, \dots, k$. Next, define the kd-vector $\tilde{Y}^{\varepsilon,k}_{i,j}$ by concatenating the d-dimensional zero vector $(j-1)$ times, and then by joining to this the $(k-j+1)$-fold concatenation of the d-vector $Y^{\varepsilon,k}_{i,j}$, namely, for each $j = 1, 2, \dots, k$ and $i = 1, 2, \dots, r$,

$$\tilde{Y}^{\varepsilon,k}_{i,j} \triangleq (\underbrace{0, 0, \dots, 0}_{d(j-1)\ \text{0's}}, \underbrace{(Y^{\varepsilon,k}_{i,j})', \dots, (Y^{\varepsilon,k}_{i,j})'}_{(k-j+1)\ Y^{\varepsilon,k}_{i,j}\text{'s}})'. \tag{6.13}$$

Likewise, for each $j = 1, 2, \dots, k$ and $i = 1, 2, \dots, r+1$, put

$$\tilde{Z}^{\varepsilon,k}_{i,j} \triangleq (\underbrace{0, 0, \dots, 0}_{d(j-1)\ \text{0's}}, \underbrace{(Z^{\varepsilon,k}_{i,j})', \dots, (Z^{\varepsilon,k}_{i,j})'}_{(k-j+1)\ Z^{\varepsilon,k}_{i,j}\text{'s}})', \tag{6.14}$$

and let $\tilde{V}^{\varepsilon,k}$ be the kd-vector formed by concatenating the d-vectors $V^{\varepsilon,k}_l$, $l = 1, 2, \dots, k$:

$$\tilde{V}^{\varepsilon,k} \triangleq ((V^{\varepsilon,k}_1)', (V^{\varepsilon,k}_2)', \dots, (V^{\varepsilon,k}_k)')'. \tag{6.15}$$

From (6.1), (6.12), and (6.13) to (6.15), we find

$$\Xi^{\varepsilon}_k = \varepsilon^{\frac{1}{2}} \sum_{j=1}^{k} \left\{ \sum_{i=1}^{r} \tilde{Y}^{\varepsilon,k}_{i,j} + \sum_{i=1}^{r+1} \tilde{Z}^{\varepsilon,k}_{i,j} \right\} + \varepsilon^{\frac{1}{2}} \tilde{V}^{\varepsilon,k}. \tag{6.16}$$

Remark 6.6. In the context of summing independent random vectors, Yurinskii [27] introduced the trick of adding a concatenation of zero-vectors to get sums of vectors of common length kd. This motivates the definitions of (6.13) and (6.14). Observe, from (6.11), (6.13), and (6.14), that for all $i = 1, 2, \dots, r$ and $j = 1, 2, \dots, k$, the kd-vectors $\tilde{Y}^{\varepsilon,k}_{i,j}$ and $\tilde{Z}^{\varepsilon,k}_{i,j}$ are derived by effectively summing ξ^{ε}_{ν} over the long blocks $G^{\varepsilon,k}_{i,j}$ and short blocks $H^{\varepsilon,k}_{i,j}$, respectively, while $\tilde{Z}^{\varepsilon,k}_{r+1,j}$ is obtained by summing ξ^{ε}_{ν} over the (infrequent) remainder blocks $H^{\varepsilon,k}_{r+1,j}$. In the light of (6.16), this suggests

$$\Xi^{\varepsilon}_k \approx \varepsilon^{\frac{1}{2}} \sum_{j=1}^{k} \sum_{i=1}^{r} \tilde{Y}^{\varepsilon,k}_{i,j},$$

and, since $G^{\varepsilon,k}_{i,j}$ is separated from $G^{\varepsilon,k}_{i_1,j_1}$ by blocks of length q or more when $(i,j) \neq (i_1, j_1)$, it seems plausible that the $\tilde{Y}^{\varepsilon,k}_{i,j}$ for different (i,j) are approximately independent. For this intuition to help in establishing Theorem 6.3 we must use the fact that $\{\xi^{\varepsilon}_{\nu}\}$ is geometrically L-mixing (see Remark 4.5). To this end, with q given by (6.7), and recalling (4.8), for each $j=1, \dots, k$ and $i=1, \dots, r$, define the d-vectors

$$Y^{\varepsilon,k}_{i,j}[q] \triangleq \sum_{\nu \in G^{\varepsilon,k}_{i,j}} \xi^{\varepsilon}_{\nu}[q], \qquad Z^{\varepsilon,k}_{i,j}[q] \triangleq \sum_{\nu \in H^{\varepsilon,k}_{i,j}} \xi^{\varepsilon}_{\nu}[q], \qquad Z^{\varepsilon,k}_{r+1,j}[q] \triangleq \sum_{\nu \in H^{\varepsilon,k}_{r+1,j}} \xi^{\varepsilon}_{\nu}[q]. \tag{6.17}$$

Motivated by (6.13) to (6.15), for each $j = 1, 2, \dots, k$, put

$$\tilde{Y}^{\varepsilon,k}_{i,j}[q] \triangleq (\underbrace{0, 0, \dots, 0}_{d(j-1)\ \text{0's}}, \underbrace{(Y^{\varepsilon,k}_{i,j}[q])', \dots, (Y^{\varepsilon,k}_{i,j}[q])'}_{(k-j+1) Y^{\varepsilon,k}_{i,j}[q]\text{'s}})' \quad \forall\, i = 1, \dots, r, \tag{6.18}$$

$$\tilde{Z}^{\varepsilon,k}_{i,j}[q] \triangleq (\underbrace{0,0,\dots,0}_{d(j-1)\ \text{0's}}, \underbrace{(Z^{\varepsilon,k}_{i,j}[q])',\dots,(Z^{\varepsilon,k}_{i,j}[q])'}_{(k-j+1) Z^{\varepsilon,k}_{i,j}[q]\text{'s}})' \quad \forall\, i=1,\dots,r+1, \tag{6.19}$$

$$\tilde{V}^{\varepsilon,k}[q] \triangleq ((V^{\varepsilon,k}_1[q])', (V^{\varepsilon,k}_2[q])', \dots, (V^{\varepsilon,k}_k[q])')', \tag{6.20}$$

where (motivated by (6.4)) $V^{\varepsilon,k}_l[q] \triangleq (l/(k\varepsilon) - \lfloor l/(\varepsilon k)\rfloor)\xi^{\varepsilon}_{\lfloor l/(\varepsilon k)\rfloor+1}[q]$ for all $l = 1,2,\dots,k$. Also put

$$\Xi^{\varepsilon}_k[q] \triangleq \varepsilon^{\frac{1}{2}} \sum_{j=1}^{k} \left\{ \sum_{i=1}^{r} \tilde{Y}^{\varepsilon,k}_{i,j}[q] + \sum_{i=1}^{r+1} \tilde{Z}^{\varepsilon,k}_{i,j}[q] \right\} + \varepsilon^{\frac{1}{2}} \tilde{V}^{\varepsilon,k}[q]. \tag{6.21}$$

Using the triangle inequality for the Prohorov metric, we can write

$$\begin{aligned} \Pi^{kd}_2(\mathcal{L}(\Xi^{\varepsilon}_k),\mathcal{L}(\hat{\Xi}^0_k)) \le{}& \Pi^{kd}_2(\mathcal{L}(\Xi^{\varepsilon}_k), \mathcal{L}(\Xi^{\varepsilon}_k[q])) \\ &+ \Pi^{kd}_2\Bigg(\mathcal{L}(\Xi^{\varepsilon}_k[q]),\ \mathcal{L}\Bigg(\varepsilon^{\frac{1}{2}} \sum_{j=1}^{k}\sum_{i=1}^{r} \tilde{Y}^{\varepsilon,k}_{i,j}[q]\Bigg)\Bigg) \\ &+ \Pi^{kd}_2\Bigg(\mathcal{L}\Bigg(\varepsilon^{\frac{1}{2}} \sum_{j=1}^{k}\sum_{i=1}^{r} \tilde{Y}^{\varepsilon,k}_{i,j}[q]\Bigg),\ \mathcal{N}_{kd}\Bigg(0, \varepsilon \sum_{j=1}^{k}\sum_{i=1}^{r} \operatorname{cov}(\tilde{Y}^{\varepsilon,k}_{i,j}[q])\Bigg)\Bigg) \\ &+ \Pi^{kd}_2\Bigg(\mathcal{N}_{kd}\Bigg(0, \varepsilon \sum_{j=1}^{k}\sum_{i=1}^{r} \operatorname{cov}(\tilde{Y}^{\varepsilon,k}_{i,j}[q])\Bigg),\ \mathcal{L}(\hat{\Xi}^0_k)\Bigg). \end{aligned} \tag{6.22}$$

To get Theorem 6.3 we must establish upper bounds for each term on the right-hand side of (6.22). We will write c, c_1, etc. for nonnegative finite constants that may vary from one use to the next.

First term on RHS of (6.22). Define the d-vectors $W^{\varepsilon}_q(l/k) \triangleq \varepsilon^{\frac{1}{2}} \sum_{\nu=1}^{\lfloor l/(k\varepsilon)\rfloor} \xi^{\varepsilon}_{\nu}[q] + V^{\varepsilon,k}_l[q]$ for all $l = 1,2,\dots,k$, (compare (4.7)). Using Cauchy–Schwarz for discrete sums and (4.9), we get constant c such that

$$E[|W^{\varepsilon}(l/k) - W^{\varepsilon}_q(l/k)|^2] \le \varepsilon E\left[\left(1 + \frac{l}{\varepsilon k}\right) \sum_{\nu=1}^{1+\lfloor l/(\varepsilon k)\rfloor} |\xi^{\varepsilon}_{\nu} - \xi^{\varepsilon}_{\nu}[q]|^2\right] \le c\varepsilon^{-1}\lambda^q \tag{6.23}$$

for each $\varepsilon \in (0,1]$, $k = 1,2,\dots$, and $1 \le l \le k$. From (6.21) it follows that $\Xi^{\varepsilon}_k[q]$ is given by the concatenation of the d-vectors $W^{\varepsilon}_q(l/k)$, $l = 1,2,\dots,k$ (in just the same way that Ξ^{ε}_k is given in (6.1) by the concatenation of the d-vectors $W^{\varepsilon}(l/k)$, $l = 1,\dots,k$), and so, from (6.23):

$$\|\Xi^{\varepsilon}_k - \Xi^{\varepsilon}_k[q]\|_2 = \left(\sum_{l=1}^{k} E[|W^{\varepsilon}(l/k) - W^{\varepsilon}_q(l/k)|^2]\right)^{\frac{1}{2}} \le c^{\frac{1}{2}} k^{\frac{1}{2}} \varepsilon^{-\frac{1}{2}} \lambda^{\frac{q}{2}}. \tag{6.24}$$

By (6.24) and Lemma 8.6(ii), for all $\varepsilon \in (0,1]$ and $k = 1,2,\dots$, we get

$$\Pi^{kd}_2(\mathcal{L}(\Xi^{\varepsilon}_k), \mathcal{L}(\Xi^{\varepsilon}_k[q])) \le (c^{\frac{1}{2}} k^{\frac{1}{2}} \varepsilon^{-\frac{1}{2}} \lambda^{\frac{q}{2}})^{\frac{2}{3}} = c^{\frac{1}{3}} k^{\frac{1}{3}} \varepsilon^{-\frac{1}{3}} \lambda^{\frac{q}{3}}. \tag{6.25}$$

Second term on RHS of (6.22). From (6.21), (6.19), and (6.20), one easily verifies that the kd-dimensional vector $(\Xi^{\varepsilon}_k[q] - \varepsilon^{\frac{1}{2}} \sum_{j=1}^{k} \sum_{i=1}^{r} \tilde{Y}^{\varepsilon,k}_{i,j}[q])$ is the concatenation of the sequence of d-dimensional vectors $\varepsilon^{\frac{1}{2}}(\sum_{j=1}^{m} \sum_{i=1}^{r+1} Z^{\varepsilon,k}_{i,j}[q] + V^{\varepsilon,k}_m[q])$ for all $m = 1, 2, \ldots, k$, and thus

$$(6.26)\quad \left\|\Xi_k^\varepsilon[q] - \varepsilon^{\frac{1}{2}} \sum_{j=1}^{k}\sum_{i=1}^{r} \tilde{Y}_{i,j}^{\varepsilon,k}[q]\right\|_2 = \varepsilon^{\frac{1}{2}}\left(\sum_{m=1}^{k}\left\|\sum_{i=1}^{r+1}\sum_{j=1}^{m} Z_{i,j}^{\varepsilon,k}[q] + V_m^{\varepsilon,k}[q]\right\|_2^2\right)^{\frac{1}{2}}$$

$$\leq \varepsilon^{\frac{1}{2}} \sum_{m=1}^{k}\left(\left\|\sum_{i=1}^{r}\sum_{j=1}^{m} Z_{i,j}^{\varepsilon,k}[q]\right\|_2 + \left\|\sum_{j=1}^{m} Z_{r+1,j}^{\varepsilon,k}[q]\right\|_2 + \left\|V_m^{\varepsilon,k}[q]\right\|_2\right),$$

where we have used the inequality $(\sum_{m=1}^{k} a_i^2)^{\frac{1}{2}} \leq \sum_{m=1}^{k} |a_i|$ and then Minkowski's inequality to get the inequality in (6.26). To bound the terms in brackets on the right of (6.26) we shall assume that $d = 1$; the general multivariate case only involves more cumbersome notation. Since $\{\xi_\nu^\varepsilon[q]\}$ is a q-dependent zero-mean process (see Remark 4.5) and distinct blocks $H_{i,j}^{\varepsilon,k}$ are separated by long blocks of cardinality greater than q (recall (6.6) and (6.9)), we see from (6.17) that $Z_{i,j}^{\varepsilon,k}[q]$ and $Z_{i_1,j_1}^{\varepsilon,k}[q]$ are independent zero-mean random variables when $(i, j) \neq (i_1, j_1)$, and thus

$$(6.27)\qquad \left\|\sum_{i=1}^{r}\sum_{j=1}^{m} Z_{i,j}^{\varepsilon,k}[q]\right\|_2 = \left(\sum_{i=1}^{r}\sum_{j=1}^{m} E|Z_{i,j}^{\varepsilon,k}[q]|^2\right)^{1/2}.$$

Now $\{\xi_\nu^\varepsilon\}$ is a geometrically L-mixing zero-mean process; hence Remark 4.6, (6.9), and (6.11) give a constant c such that $\|Z_{i,j}^{\varepsilon,k}\|_2 \leq cq^{\frac{1}{2}}$ for all $\varepsilon \in (0, 1]$, for all $k = 1, 2, \ldots$, for all $i = 1, \ldots, r$, and for all $j = 1, \ldots, k$. Also, from (4.9), (6.11), (6.17), and Minkowski's inequality, we find $\|Z_{i,j}^{\varepsilon,k} - Z_{i,j}^{\varepsilon,k}[q]\|_2 \leq c_1 q\lambda^q$, and thus

$$(6.28)\qquad \|Z_{i,j}^{\varepsilon,k}[q]\|_2 \leq \|Z_{i,j}^{\varepsilon,k}\|_2 + \|Z_{i,j}^{\varepsilon,k}[q] - Z_{i,j}^{\varepsilon,k}\|_2 \leq cq^{\frac{1}{2}} + c_1 q\lambda^q \leq c_2 q^{\frac{1}{2}}$$

for some constants c_1, c_2. Hence, by (6.27), we get $\|\sum_{i=1}^{r}\sum_{j=1}^{m} Z_{i,j}^{\varepsilon,k}[q]\|_2 \leq c_2(rmq)^{\frac{1}{2}}$ for all $\varepsilon \in (0, 1]$, for all $k = 1, 2, \ldots$, and for all $m = 1, \ldots, k$. Similarly, we have $\|\sum_{j=1}^{m} Z_{r+1,j}^{\varepsilon,k}[q]\|_2 \leq c_2(m(p+q))^{\frac{1}{2}}$. Now, from (6.8), (6.7), and $\#J_j^{\varepsilon,k} = \lfloor k^{-1}\varepsilon^{-1}\rfloor$ (see (6.5)), we can find some $\varepsilon_2 \in (0, 1]$ such that

$$(6.29)\qquad r \equiv r_{\varepsilon,k} \leq 2\varepsilon^{-\frac{2}{3}} \qquad \forall\, k = 1, 2, \ldots, \left\lfloor \varepsilon^{-\frac{1}{36}}\right\rfloor, \quad \forall\, \varepsilon \in (0, \varepsilon_2]$$

(e.g., $\varepsilon_2 \overset{\triangle}{=} 1/16$). But clearly $\|V_m^{\varepsilon,k}[q]\|_2 = O(1)$ (uniformly with respect to ε, k, m); thus from (6.26), (6.7),

$$(6.30)\quad \left\|\Xi_k^\varepsilon[q] - \varepsilon^{\frac{1}{2}} \sum_{j=1}^{k}\sum_{i=1}^{r} \tilde{Y}_{i,j}^{\varepsilon,k}[q]\right\|_2 \leq c_3\varepsilon^{\frac{1}{2}} \sum_{m=1}^{k}\{(rmq)^{\frac{1}{2}} + (m(p+q))^{\frac{1}{2}} + O(1)\}$$

$$\leq c_4\varepsilon^{\frac{1}{2}}k\{(\varepsilon^{-\frac{2}{3}}kk^{-1}\varepsilon^{-\frac{1}{9}})^{\frac{1}{2}} + (kk^{-1}\varepsilon^{-\frac{1}{3}})^{\frac{1}{2}} + O(1)\} \leq c_5 k\varepsilon^{\frac{1}{9}}$$

for some constants c_3, c_4, c_5; hence, by Lemma 8.6(ii), for each $\varepsilon \in (0, \varepsilon_2]$ we have

$$(6.31)\qquad \Pi_2^{kd}\left(\mathcal{L}(\Xi_k^\varepsilon[q]), \mathcal{L}\left(\varepsilon^{\frac{1}{2}} \sum_{j=1}^{k}\sum_{i=1}^{r} \tilde{Y}_{i,j}^{\varepsilon,k}[q]\right)\right) \leq (c_5 k\varepsilon^{\frac{1}{9}})^{\frac{2}{3}} = c_5^{\frac{2}{3}} k^{\frac{2}{3}} \varepsilon^{\frac{2}{27}}$$

for all $k = 1, 2, \ldots, \lfloor \varepsilon^{-\frac{1}{36}}\rfloor$.

Third term on RHS of (6.22). Here we shall need the following special case of a finite-dimensional CLT for sums of independent random vectors due to Yurinskii [27, Theorem 1]. Note that the upper-bound we state here is somewhat less precise than the bound given in [27, Theorem 1] but is easier to use.

THEOREM 6.7. *There is a constant* $\gamma \in (0,\infty)$ *with the following property. For all positive integers* m *and finite sequences* $\{u_1, u_2, \dots, u_n\}$ *of zero-mean independent* $\Re^m$*-valued random vectors we have*

$$\Pi_2^m\left(\mathcal{L}\left(\sum_{\alpha=1}^{n} u_\alpha\right), \mathcal{N}_m\left(0, \sum_{\alpha=1}^{n} \operatorname{cov}(u_\alpha)\right)\right) \le \gamma m^{\frac{1}{3}}(\mu_n)^{\frac{2}{9}} \quad \textit{when} \quad \mu_n \overset{\triangle}{=} \sum_{\alpha=1}^{n} E|u_\alpha|^3 < 1.$$

The $\tilde{Y}_{i,j}^{\varepsilon,k}[q]$ given by (6.18) are zero-mean and independent as i and j vary (since $\{\xi_\nu^\varepsilon[q]\}$ is a q-dependent process, and the long blocks $G_{i,j}^{\varepsilon,k}$ are separated by either short blocks $H_{i,j}^{\varepsilon,k}$ or short block/remainder block pairs $H_{r,j}^{\varepsilon,k}, H_{r+1,j}^{\varepsilon,k}$, all of which have length at least q). In Theorem 6.7 we will identify m with kd, n with kr, the summation index α with (i,j) (for $j = 1, \dots, k$ and $i = 1, \dots, r$), u_α with $\varepsilon^{\frac{1}{2}}\tilde{Y}_{i,j}^{\varepsilon,k}[q]$, and μ_n with $\mu_{kr} \overset{\triangle}{=} \sum_{j=1}^{k}\sum_{i=1}^{r} \varepsilon^{\frac{3}{2}} E|\tilde{Y}_{i,j}^{\varepsilon,k}[q]|^3$. From (6.18) we have $|\tilde{Y}_{i,j}^{\varepsilon,k}[q]|^2 = (k - j+1)|Y_{i,j}^{\varepsilon,k}[q]|^2 \le k|Y_{i,j}^{\varepsilon,k}[q]|^2$, and, exactly as for (6.28), we can use Remark 4.6 to find constant c_1 such that $\|Y_{i,j}^{\varepsilon,k}[q]\|_3 \le c_1 p^{\frac{1}{2}}$ for all $\varepsilon \in (0,1]$, for all $k = 1, 2, \dots$, for all $i = 1, \dots, r$, and for all $j = 1, \dots, k$. Thus, from (6.7), we have $E|\tilde{Y}_{i,j}^{\varepsilon,k}[q]|^3 \le c_1^3 k^{\frac{3}{2}} p^{\frac{3}{2}} = c_1^3 \varepsilon^{-\frac{1}{2}}$; hence (6.29) gives $\mu_{kr} = \sum_{j=1}^{k}\sum_{i=1}^{r} \varepsilon^{\frac{3}{2}} E|\tilde{Y}_{i,j}^{\varepsilon,k}[q]|^3 \le 2c_1^3 k \varepsilon^{\frac{1}{3}}$. Define

$$\tilde{T}^{\varepsilon,k} \overset{\triangle}{=} \varepsilon \sum_{j=1}^{k}\sum_{i=1}^{r} \operatorname{cov}(\tilde{Y}_{i,j}^{\varepsilon,k}[q]) \equiv \sum_{\alpha} \operatorname{cov}(u_\alpha), \tag{6.32}$$

and fix some $\varepsilon_3 \in (0, \varepsilon_2]$ such that $2c_1^3 k \varepsilon^{\frac{1}{3}} < 1$ for all $\varepsilon \in (0, \varepsilon_3]$, $k = 1, 2, \dots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$. Then Theorem 6.7 gives a constant c_2 such that, for all $\varepsilon \in (0, \varepsilon_3]$, $k = 1, 2, \dots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$, we have

$$\Pi_2^{kd}\left(\mathcal{L}\left(\varepsilon^{\frac{1}{2}} \sum_{j=1}^{k}\sum_{i=1}^{r} \tilde{Y}_{i,j}^{\varepsilon,k}[q]\right), \mathcal{N}_{kd}(0, \tilde{T}^{\varepsilon,k})\right) \le c_1 (kd)^{\frac{1}{3}} (k\varepsilon^{\frac{1}{3}})^{\frac{2}{9}} = c_2 k^{\frac{5}{9}} \varepsilon^{\frac{2}{27}}. \tag{6.33}$$

Fourth term on RHS of (6.22). To simplify the notation, we use the following convention. If B is a $kd \times kd$ matrix, then $B_{m,n}$ denotes the (m,n)th of the $d \times d$ submatrices into which B can be partitioned for all $m, n = 1, 2, \dots, k$. If v is a kd-vector, then v_m denotes the d-vector consisting of the $(d(m-1)+1)$th to (dm)th elements of v. Fix arbitrary $\varepsilon \in (0,1]$ and $k = 1, 2, \dots$. Define the $kd \times kd$ matrices $\hat{T}^{\varepsilon,k}$ and T^k such that their (m,n)th d-dimensional submatrices are respectively given by

$$\hat{T}_{m,n}^{\varepsilon,k} \overset{\triangle}{=} \varepsilon \sum_{j=1}^{m\wedge n}\sum_{i=1}^{r} \sum_{\nu \in G_{i,j}^{\varepsilon,k}} A(\theta^0((\nu-1)\varepsilon)) \quad \text{and} \quad T_{m,n}^{k} \overset{\triangle}{=} (\operatorname{cov}\hat{\Xi}_k^0)_{m,n} \tag{6.34}$$

for all $m, n = 1, 2, \dots, k$, where $A(\cdot)$ is given by condition (C4). Then, from (6.1) and (3.8), we see that $\mathcal{L}(\hat{\Xi}_k^0) = \mathcal{N}_{kd}(0, T^k)$, so that the fourth term on the right side of (6.22) is bounded as follows:

$$\begin{aligned} \Pi_2^{kd}(\mathcal{N}_{kd}(0, \tilde{T}^{\varepsilon,k}), \mathcal{L}(\hat{\Xi}_k^0)) &\le \Pi_2^{kd}(\mathcal{N}_{kd}(0, \tilde{T}^{\varepsilon,k}), \mathcal{N}_{kd}(0, \hat{T}^{\varepsilon,k})) \\ &\quad + \Pi_2^{kd}(\mathcal{N}_{kd}(0, \hat{T}^{\varepsilon,k}), \mathcal{N}_{kd}(0, T^k)). \end{aligned} \tag{6.35}$$

We will now use Theorem 8.7 to bound each of the terms on the right side of (6.35). In order to deal with the first term we find an expression for $|\tilde{T}^{\varepsilon,k}_{m,n} - \hat{T}^{\varepsilon,k}_{m,n}|$. From (6.18),

$$[\mathrm{cov}(\tilde{Y}^{\varepsilon,k}_{i,j}[q])]_{m,n} = \begin{cases} \mathrm{cov}(Y^{\varepsilon,k}_{i,j}[q]), & \text{when } j \le (m \wedge n), \\ 0, & \text{when } (m \wedge n) < j, \end{cases}$$

and thus, using (6.32),

$$\tilde{T}^{\varepsilon,k}_{m,n} = \varepsilon \sum_{j=1}^{m\wedge n} \sum_{i=1}^{r} \mathrm{cov}(Y^{\varepsilon,k}_{i,j}[q]). \tag{6.36}$$

On combining (6.36), (6.34), and (6.17), we get, for all $m, n = 1, 2, \ldots, k$,

$$|\tilde{T}^{\varepsilon,k}_{m,n} - \hat{T}^{\varepsilon,k}_{m,n}| = \varepsilon \left| \sum_{j=1}^{m\wedge n} \sum_{i=1}^{r} \left[\mathrm{cov}\left(\sum_{\nu \in G^{\varepsilon,k}_{i,j}} \xi^{\varepsilon}_{\nu}[q] \right) - \sum_{\nu \in G^{\varepsilon,k}_{i,j}} A(\theta^0((\nu-1)\varepsilon)) \right] \right|. \tag{6.37}$$

To upper-bound the term in square braces on the right-hand side of (6.37), partition the long block $G^{\varepsilon,k}_{i,j}$ into *adjacent* blocks of integers $Q^{\varepsilon,k}_{\alpha,i,j}$ ordered according to the pattern

$$Q^{\varepsilon,k}_{1,i,j}, Q^{\varepsilon,k}_{2,i,j}, \ldots, Q^{\varepsilon,k}_{l,i,j}, Q^{\varepsilon,k}_{l+1,i,j}, \tag{6.38}$$

where $l \overset{\triangle}{=} \lfloor p/q^2 \rfloor$. The blocks $Q^{\varepsilon,k}_{\alpha,i,j}$, $\alpha = 1, \ldots, l$ have common cardinality q^2, and $Q^{\varepsilon,k}_{l+1,i,j}$ is a "remainder block" whose cardinality is less than q^2. Recalling (6.7), fix some $\varepsilon_{41} \in (0, \varepsilon_3]$ such that

$$l \equiv l_{\varepsilon,k} \overset{\triangle}{=} \lfloor p/q^2 \rfloor \le 2k\varepsilon^{-\frac{1}{9}} \quad \forall\, k = 1, 2, \ldots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor, \quad \forall\, \varepsilon \in (0, \varepsilon_{41}]. \tag{6.39}$$

If $s^{\varepsilon,k}_{\alpha,i,j}$ denotes the first integer of the block $Q^{\varepsilon,k}_{\alpha,i,j}$ then clearly

$$s^{\varepsilon,k}_{\alpha,i,j} \overset{\triangle}{=} b^{\varepsilon,k}_{i,j} + (\alpha-1)q^2 \quad \forall\, \alpha = 1, \ldots, l+1 \tag{6.40}$$

(recall that $b^{\varepsilon,k}_{i,j}$ is the first integer in $G^{\varepsilon,k}_{i,j}$), so that $Q^{\varepsilon,k}_{\alpha,i,j} \overset{\triangle}{=} [s^{\varepsilon,k}_{\alpha,i,j}, s^{\varepsilon,k}_{\alpha,i,j} + q^2)$ for all $\alpha = 1, \ldots, l$, while $Q^{\varepsilon,k}_{l+1,i,j} \overset{\triangle}{=} [s^{\varepsilon,k}_{l+1,i,j}, b^{\varepsilon,k}_{i,j} + p)$. Henceforth, to lighten the notation, we write Q_α for $Q^{\varepsilon,k}_{\alpha,i,j}$ and s_α for $s^{\varepsilon,k}_{\alpha,i,j}$ when convenient. Also, recalling (2.7) and (2.3), put

$$\tilde{H}_n(\theta)[s] \overset{\triangle}{=} E[\tilde{H}_n(\theta)|\mathcal{F}^n_{n-s}] = \tilde{b}_n[s] - \tilde{R}_n[s]\theta \quad \forall\, s, n = 1, 2, \ldots, \quad \theta \in \Re^d, \tag{6.41}$$

and observe from (4.8) that $\xi^{\varepsilon}_{\nu}[q] = \tilde{H}_{\nu}(\theta^0((\nu-1)\varepsilon))[q]$ for all $\nu \in G^{\varepsilon,k}_{i,j}$. One then sees from (6.37) that, for each $m, n = 1, \ldots, k$,

$$|\tilde{T}^{\varepsilon,k}_{m,n} - \hat{T}^{\varepsilon,k}_{m,n}| \le \varepsilon \sum_{j=1}^{m\wedge n} \sum_{i=1}^{r} \{\mathrm{I}^{\varepsilon,k}_{i,j} + \mathrm{II}^{\varepsilon,k}_{i,j} + \mathrm{III}^{\varepsilon,k}_{i,j} + \mathrm{IV}^{\varepsilon,k}_{i,j}\}, \tag{6.42}$$

where

$$\mathrm{I}_{i,j}^{\varepsilon,k} \triangleq \left|\mathrm{cov}\left(\sum_{\nu\in G_{i,j}^{\varepsilon,k}} \xi_\nu^\varepsilon[q]\right) - \sum_{\alpha=1}^{l+1}\mathrm{cov}\left(\sum_{\nu\in Q_\alpha} \xi_\nu^\varepsilon[q]\right)\right|, \tag{6.43}$$

$$\mathrm{II}_{i,j}^{\varepsilon,k} \triangleq \left|\sum_{\alpha=1}^{l+1}\left\{\mathrm{cov}\left(\sum_{\nu\in Q_\alpha} \xi_\nu^\varepsilon[q]\right) - \mathrm{cov}\left(\sum_{\nu\in Q_\alpha} \tilde{H}_\nu(\theta^0(\varepsilon s_\alpha))[q]\right)\right\}\right|, \tag{6.44}$$

$$\mathrm{III}_{i,j}^{\varepsilon,k} \triangleq \left|\sum_{\alpha=1}^{l+1}\left\{\mathrm{cov}\left(\sum_{\nu\in Q_\alpha}\tilde{H}_\nu(\theta^0(\varepsilon s_\alpha))[q]\right) - \left(\#Q_\alpha\right)A(\theta^0(\varepsilon s_\alpha))\right\}\right|, \tag{6.45}$$

$$\mathrm{IV}_{i,j}^{\varepsilon,k} \triangleq \left|\sum_{\alpha=1}^{l+1}(\#Q_\alpha)A(\theta^0(\varepsilon s_\alpha)) - \sum_{\nu\in G_{i,j}^{\varepsilon,k}} A(\theta^0((\nu-1)\varepsilon))\right|. \tag{6.46}$$

Remark 6.8. Our calculation of an upper-bound for $|\tilde{T}_{m,n}^{\varepsilon,k} - \hat{T}_{m,n}^{\varepsilon,k}|$ is closely based on the proof of Lemma 3.1 of Khas'minskii [13], which motivates introduction of the blocks Q_α and the upper-bound (6.42) in terms of the quantities (6.43) to (6.46). The idea is that over the blocks Q_α we "freeze" the time-varying quantity $\theta^0(\varepsilon(\nu-1))$, $\nu \in G_{i,j}^{\varepsilon,k}$, at the value $\theta^0(\varepsilon s_\alpha)$ corresponding to the first member s_α of Q_α. The block Q_α is long enough for the averaging postulated in condition (C4) to come into play (where we identify $\{n_0,\dots,N+n_0\}$ and θ in (2.6) with Q_α and $\theta^0(\varepsilon s_\alpha)$, respectively) and provide an upper bound for (6.45). At the same time, Q_α is short enough to ensure that $\theta^0((\nu-1)\varepsilon) \approx \theta^0(\varepsilon s_\alpha)$, and this will give us upper-bounds for (6.44) and (6.46). Finally, we shall use L-mixing of $\{\xi_\nu^\varepsilon\}$ to bound (6.43). We now proceed to make this intuition precise. For the term in (6.43), put

$$B_{i,j}^{\varepsilon,k} \triangleq (G_{i,j}^{\varepsilon,k} \times G_{i,j}^{\varepsilon,k}) - \bigcup_{\alpha=1}^{l+1}(Q_\alpha \times Q_\alpha) \tag{6.47}$$

(recall that Q_α is short for $Q_{\alpha,i,j}^{\varepsilon,k}$) and let $B_+ \triangleq \{(\nu,\mu) \in B_{i,j}^{\varepsilon,k} : \mu > \nu\}$, $D_\alpha \triangleq \{(\nu,\mu) \in \mathcal{Z}^2 : -\infty < \nu < s_\alpha \le \mu < \infty\}$ for all $\alpha = 2,\dots,l+1$. It follows from (6.47) that

$$B_+ \subset \bigcup_{\alpha=2}^{l+1} D_\alpha. \tag{6.48}$$

By (6.39), (6.48), and Remark 8.4, we have constants $\lambda \in (0,1)$ and c, c_1 with

$$\mathrm{I}_{i,j}^{\varepsilon,k} = \left|\sum_{(\nu,\mu)\in B_{i,j}^{\varepsilon,k}} E\big[(\xi_\nu^\varepsilon[q])(\xi_\mu^\varepsilon[q])'\big]\right| \le c\sum_{(\nu,\mu)\in B_+}\lambda^{\mu-\nu} \tag{6.49}$$

$$\le c\sum_{\alpha=2}^{l+1}\left\{\sum_{(\nu,\mu)\in D_\alpha}\lambda^{\mu-\nu}\right\} \le c\sum_{\alpha=2}^{l+1}\left\{\sum_{n=1}^{\infty} n\lambda^n\right\} \le c_1 l = c_1 l_{\varepsilon,k} \le c_1 k\varepsilon^{-\frac{1}{9}}$$

for all $\varepsilon \in (0,\varepsilon_{41}]$, $k=1,\dots,\lfloor\varepsilon^{-\frac{1}{36}}\rfloor$, $i=1,\dots,r$, $j=1,\dots,k$. Next, we upper-bound the term in (6.44): put $\eta_\nu^1 \triangleq \xi_\nu^\varepsilon[q] \equiv \tilde{H}_\nu(\theta^0((\nu-1)\varepsilon))[q]$ and $\eta_\nu^2 \triangleq \tilde{H}_\nu(\theta^0(\varepsilon s_\alpha))[q]$ for all $\nu \in Q_\alpha$. Then

$$\operatorname{cov}\left(\sum_{\nu\in Q_\alpha} \eta^1_\nu\right) - \operatorname{cov}\left(\sum_{\nu\in Q_\alpha} \eta^2_\nu\right) = \sum_{\nu,\mu\in Q_\alpha} E\left[(\eta^1_\nu - \eta^2_\nu)(\eta^1_\mu)' + (\eta^2_\nu)(\eta^1_\mu - \eta^2_\mu)'\right]. \tag{6.50}$$

Since $\{\theta^0(\tau),\ \tau \in [0,1]\}$ is Lipschitz continuous and $\{\tilde{R}_n[s]\}$, $\{\eta^1_n\}$ are clearly L_2-bounded (uniformly in $s, n = 1, 2, \ldots$), we find constant c such that

$$\left|E\left[(\eta^1_\nu - \eta^2_\nu)(\eta^1_\mu)'\right]\right| \leq \|\tilde{R}_\nu[q]\|_2 \, \|\eta^1_\mu\|_2 |\theta^0(\varepsilon s_\alpha) - \theta^0(\varepsilon(\nu-1))| \leq c\varepsilon(\#Q_\alpha) \tag{6.51}$$

for all $\mu,\ \nu \in Q_\alpha$, with an identical bound for $|E[(\eta^2_\nu)(\eta^1_\mu - \eta^2_\mu)']|$. From (6.39), (6.50), and (6.51), we find

$$\mathrm{II}^{\varepsilon,k}_{i,j} \leq c\varepsilon l(\#Q_\alpha)^3 \leq c\varepsilon(2k\varepsilon^{-\frac{1}{9}})(k^{-2}\varepsilon^{-\frac{2}{9}})^3 \leq c_1\varepsilon^{\frac{2}{9}} \tag{6.52}$$

for all $\varepsilon \in (0, \varepsilon_{41}]$, $k = 1, 2, \ldots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$, $i = 1, \ldots, r$, $j = 1, \ldots, k$. For the term given by (6.45), we need the following lemma.

Lemma 6.9 (proved in section 7). *Suppose conditions* (C1)–(C4) *of section* 2, *and let* $\{\tilde{H}_n(\theta)[s]\}$ *be defined by* (6.41). *Then there are constants* $C \in [0,\infty)$ *and* $\lambda \in (0,1)$ *such that*

$$\left|\operatorname{cov}\left(\sum_{n=n_0}^{N+n_0} \tilde{H}_n(\theta)[s]\right) - A(\theta)(N+1)\right| \leq C[1 + |\theta|^2][1 + (N+1)^2\lambda^s]$$

for all $\theta \in \Re^d$, $s, N, n_0 = 1, 2, 3, \ldots$.

By Lemma 6.9 (identifying θ, s, and the interval $\{n_0, \ldots, n_0 + N\}$ in Lemma 6.9 with $\theta^0(\varepsilon s_\alpha)$, q, and Q_α, respectively), uniform boundedness of $\theta^0(((n-1)\varepsilon) \wedge T)$ (in (ε, n)), and recalling $\#(Q_\alpha) = q^2$, we find constants c, c_1, such that

$$\mathrm{III}^{\varepsilon,k}_{i,j} \leq c\sum_{\alpha=1}^{l+1}[1 + q^4\lambda^q] \leq c_1 l \leq c_1 k\varepsilon^{-\frac{1}{9}} \tag{6.53}$$

for all $\varepsilon \in (0, \varepsilon_{41}]$ and $k = 1, 2, \ldots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$, $i = 1, \ldots, r$, $j = 1, \ldots, k$. Now we bound the term given by (6.46). From Lemma 2.9 we see that $\tau \to A(\theta^0(\tau))$ is globally Lipschitz continuous over the interval $\tau \in [0,1]$, and hence there are constants c, c_1 such that, for all $\varepsilon \in (0, \varepsilon_{41}]$ and $k = 1, 2, \ldots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$,

$$\begin{aligned}\mathrm{IV}^{\varepsilon,k}_{i,j} &\leq c\sum_{\alpha=1}^{l+1}\sum_{\nu\in Q_\alpha} |\varepsilon s_\alpha - (\nu-1)\varepsilon| \leq c_1\varepsilon l\,(\#Q_\alpha)^2 \\ &\leq c_1\varepsilon(k\varepsilon^{-\frac{1}{9}})(k^{-2}\varepsilon^{-\frac{2}{9}})^2 \leq c_1\varepsilon^{\frac{4}{9}}.\end{aligned} \tag{6.54}$$

Combining (6.42), and (6.49) to (6.54), and using (6.29) gives constants c, c_1, such that for all $\varepsilon \in (0, \varepsilon_{41}]$ and all $k = 1, 2, \ldots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$,

$$\begin{aligned}\max_{1\leq m,n\leq k} |\tilde{T}^{\varepsilon,k}_{m,n} - \hat{T}^{\varepsilon,k}_{m,n}| &\leq c\varepsilon\sum_{j=1}^{k}\sum_{i=1}^{r}\{k\varepsilon^{-\frac{1}{9}} + \varepsilon^{\frac{2}{9}} + k\varepsilon^{-\frac{1}{9}} + \varepsilon^{\frac{4}{9}}\} \\ &\leq c_1(\varepsilon kr)(k\varepsilon^{-\frac{1}{9}}) \leq c_1\varepsilon^{\frac{1}{6}}.\end{aligned} \tag{6.55}$$

Thus, there must exist some $\varepsilon_{42} \in (0, \varepsilon_{41}]$ such that $kd^{\frac{1}{2}} \max_{1\le m,n\le k} |\tilde{T}^{\varepsilon,k}_{m,n} - \hat{T}^{\varepsilon,k}_{m,n}| \le c_1\varepsilon^{\frac{1}{6}}kd^{\frac{1}{2}} < 1$ for all $\varepsilon \in (0, \varepsilon_{42}]$ and $k = 1, 2 \dots \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$, and we can use Theorem 8.7 with (6.55) to find a constant c such that

$$\Pi_2^{kd}(\mathcal{N}_{kd}(0, \tilde{T}^{\varepsilon,k}), \mathcal{N}_{kd}(0, \hat{T}^{\varepsilon,k})) \le ck^{\frac{3}{4}}(\varepsilon^{\frac{1}{6}})^{\frac{1}{4}} \le c\varepsilon^{\frac{1}{48}} \tag{6.56}$$

for all $\varepsilon \in (0, \varepsilon_{42}]$ and $k = 1, 2, \dots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$. To bound the second term on the right side of (6.35), fix some $1 \le m, n \le k$. One sees from (3.8) that $\{\hat{W}^0(\tau),\ 0 \le \tau \le 1\}$ is a zero-mean Gaussian process with independent increments and covariance $\int_0^\tau A(\theta^0(s))\,ds$. Thus, from (6.1) and (6.34), we have $T^k_{m,n} = \varepsilon \int_0^{m\wedge n/(k\varepsilon)} A(\theta^0(u\varepsilon))\,du$, and hence

$$\begin{aligned} T^k_{m,n} - \hat{T}^{\varepsilon,k}_{m,n} &= \varepsilon \sum_{j=1}^{m\wedge n} \sum_{i=1}^{r} \sum_{\nu \in H^{\varepsilon,k}_{i,j}} A(\theta^0((\nu - 1)\varepsilon)) \\ &\quad + \varepsilon \left(\int_0^{m\wedge n/(k\varepsilon)} [A(\theta^0(u\varepsilon)) - A(\theta^0(\lfloor u \rfloor \varepsilon))]\,du \right). \end{aligned} \tag{6.57}$$

Now, the last term on the right of (6.57) is clearly $O(\varepsilon)$ uniformly with respect to $1 \le m, n \le k \le \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$ (since Lemma 2.9 ensures that $\tau \to A(\theta^0(\tau))$ is globally Lipschitz continuous over $\tau \in [0, 1]$). Hence, using (6.57), there must be constants c, c_1 such that for $\varepsilon \in (0, \varepsilon_{42}]$ and $k = 1, 2, \dots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$, we have

$$\begin{aligned} \max_{1\le m,n\le k} |\hat{T}^{\varepsilon,k}_{m,n} - T^k_{m,n}| &\le c\varepsilon kr(\# H^{\varepsilon,k}_{i,j}) + O(\varepsilon) \\ &\le c\varepsilon k(2\varepsilon^{-\frac{2}{3}})k^{-1}\varepsilon^{-\frac{1}{9}} + O(\varepsilon) \le c_1\varepsilon^{\frac{2}{9}}. \end{aligned} \tag{6.58}$$

By (6.58) there is clearly some $\varepsilon_{43} \in (0, \varepsilon_{42}]$ such that $kd^{\frac{1}{2}} \max_{1\le m,n\le k} |\hat{T}^{\varepsilon,k}_{m,n} - T^k_{m,n}| < 1$ for all $\varepsilon \in (0, \varepsilon_{43}]$ and $k = 1, 2 \dots \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$, and hence, by Theorem 8.7 and (6.58), we get

$$\Pi_2^{kd}(\mathcal{N}_{kd}(0, \hat{T}^{\varepsilon,k}), \mathcal{N}_{kd}(0, T^k)) \le c_1k^{\frac{3}{4}}(\varepsilon^{\frac{2}{9}})^{\frac{1}{4}} \le c_1\varepsilon^{\frac{5}{144}} \tag{6.59}$$

for all $\varepsilon \in (0, \varepsilon_{43}]$ and $k = 1, 2 \dots \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$. Combining (6.32), (6.35), (6.56), and (6.59), we find a constant c such that

$$\Pi_2^{kd}\left(\mathcal{N}_{kd}\left(0, \varepsilon \sum_{j=1}^{k} \sum_{i=1}^{r} \operatorname{cov} \tilde{Y}^{\varepsilon;k}_{i,j}[q] \right), \mathcal{L}(\hat{\Xi}^0_k) \right) \le c\varepsilon^{\frac{1}{48}} \tag{6.60}$$

for all $\varepsilon \in (0, \varepsilon_{43}]$, $k = 1, 2, \dots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$. Finally, we see that the four terms on the right of (6.22) are upper-bounded by (6.25), (6.31), (6.33), and (6.60), respectively. Since $\lambda \in (0, 1)$ we have $\lambda^{\varepsilon^{-\beta}} = O(\varepsilon^\alpha)$ for constants $\alpha, \beta \in (0, \infty)$. Thus, there must be constants c, c_1, such that

$$\Pi_2^{kd}(\mathcal{L}(\Xi^\varepsilon_k), \mathcal{L}(\hat{\Xi}^0_k)) \le c(k^{\frac{1}{3}}\varepsilon^{-\frac{1}{3}}\lambda^{\frac{q}{3}} + k^{\frac{2}{3}}\varepsilon^{\frac{2}{27}} + k^{\frac{5}{9}}\varepsilon^{\frac{2}{27}} + \varepsilon^{\frac{1}{48}}) \le c_1\varepsilon^{\frac{1}{48}}$$

for all $\varepsilon \in (0, \varepsilon_{43}]$ and $k = 1, 2, \dots, \lfloor \varepsilon^{-\frac{1}{36}} \rfloor$. Now Theorem 6.3 follows with $\varepsilon_0 \overset{\triangle}{=} \varepsilon_{43}$. $\square$

Proof of Theorem 4.4. For each $k = 1, 2, 3, \dots$, $\varepsilon \in (0, 1]$ define continuous process $\{W^\varepsilon_k(\tau),\ \tau \in [0, 1]\}$ by

$$W^\varepsilon_k(\tau) \overset{\triangle}{=} \begin{cases} W^\varepsilon(\tau) & \text{for } \tau = i/k,\ i = 0, 1, \dots, k, \\ \text{linear interpolation,} & \text{otherwise.} \end{cases} \tag{6.61}$$

In the same way, define $\{\hat{W}^0_k(\tau),\ 0\le\tau\le 1\}$ in terms of $\{\hat{W}^0(\tau),\ 0\le\tau\le 1\}$. Also, put $\gamma \triangleq 72$ and $k(\varepsilon)\triangleq\lfloor\varepsilon^{-\frac{1}{\gamma}}\rfloor$ for all $\varepsilon\in(0,1]$. By the triangle inequality we can write

$$(6.62)\quad \begin{aligned}\Pi_C(\mathcal{L}(W^\varepsilon),\mathcal{L}(\hat{W}^0)) \le{}& \Pi_C(\mathcal{L}(W^\varepsilon),\mathcal{L}(W^\varepsilon_{k(\varepsilon)})) + \Pi_C(\mathcal{L}(W^\varepsilon_{k(\varepsilon)}),\mathcal{L}(\hat{W}^0_{k(\varepsilon)}))\\ &+\Pi_C(\mathcal{L}(\hat{W}^0_{k(\varepsilon)}),\mathcal{L}(\hat{W}^0)).\end{aligned}$$

Now upper-bound each term on the right side of (6.62) as follows.

Third term on RHS of (6.62). By the definition of $\{\hat{W}^0_k(\tau),\ 0\le\tau\le 1\}$ (following (6.61)), we have

$$(6.63)\quad \|\hat{W}^0-\hat{W}^0_{k(\varepsilon)}\|_C \le 2\max_{i=0,1,\dots,k(\varepsilon)-1}\left\{\max_{\frac{i}{k(\varepsilon)}\le\tau\le\frac{i+1}{k(\varepsilon)}}\left|\hat{W}^0(\tau)-\hat{W}^0\left(\frac{i}{k(\varepsilon)}\right)\right|\right\},$$

and thus, from the Chebyshev inequality,

$$(6.64)\quad \begin{aligned}&\hat{P}[\|\hat{W}^0-\hat{W}^0_{k(\varepsilon)}\|_C\ge\varepsilon^{\frac{1}{8\gamma}}]\\ &\le\sum_{i=0}^{k(\varepsilon)-1}\hat{P}\left\{\max_{\frac{i}{k(\varepsilon)}\le\tau\le\frac{(i+1)}{k(\varepsilon)}}\left|\hat{W}^0(\tau)-\hat{W}^0\left(\frac{i}{k(\varepsilon)}\right)\right|\ge\frac{1}{2}\varepsilon^{\frac{1}{8\gamma}}\right\}\\ &\le 16\varepsilon^{-\frac{1}{2\gamma}}\sum_{i=0}^{k(\varepsilon)-1}\hat{E}\left\{\max_{\frac{i}{k(\varepsilon)}\le\tau\le\frac{(i+1)}{k(\varepsilon)}}\left|\hat{W}^0(\tau)-\hat{W}^0\left(\frac{i}{k(\varepsilon)}\right)\right|^4\right\}.\end{aligned}$$

By Doob's maximal L_p inequality [8, Proposition 2.16, p. 63] applied to the nonnegative submartingale $\{|\hat{W}^0(\tau)-\hat{W}^0(i/k(\varepsilon))|,\ \tau\in[i/k(\varepsilon),1]\}$, we get

$$(6.65)\quad \begin{aligned}&\hat{E}\left\{\max_{\frac{i}{k(\varepsilon)}\le\tau\le\frac{(i+1)}{k(\varepsilon)}}\left|\hat{W}^0(\tau)-\hat{W}^0\left(\frac{i}{k(\varepsilon)}\right)\right|^4\right\}\\ &\le\left(\frac{4}{3}\right)^4\hat{E}\left|\hat{W}^0\left(\frac{i+1}{k(\varepsilon)}\right)-\hat{W}^0\left(\frac{i}{k(\varepsilon)}\right)\right|^4\ll k^{-2}(\varepsilon).\end{aligned}$$

Combining (6.64) and (6.65) gives

$$\hat{P}[\|\hat{W}^0-\hat{W}^0_{k(\varepsilon)}\|_C\ge\varepsilon^{\frac{1}{8\gamma}}]\ll k^{-1}(\varepsilon)\varepsilon^{-\frac{1}{2\gamma}}\le\varepsilon^{\frac{1}{2\gamma}}\le\varepsilon^{\frac{1}{8\gamma}},$$

and thus, by Lemma 8.6(i), we get

$$(6.66)\quad \Pi_C(\mathcal{L}(\hat{W}^0),\mathcal{L}(\hat{W}^0_{k(\varepsilon)}))\ll\varepsilon^{\frac{1}{8\gamma}}.$$

Second term on RHS of (6.62). We need the next result, which is suggested by the arguments on page 246 of Yurinskii [27].

LEMMA 6.10 (proved in section 7). *For* Ξ^ε_k *and* $\hat{\Xi}^0_k$ *given by* (6.1), *and* W^ε *and* $\hat{W}^0$ *given by* (6.61), *we have*

$$\Pi_C(\mathcal{L}(W^\varepsilon_k),\mathcal{L}(\hat{W}^0_k))\le\Pi_2^{kd}(\mathcal{L}(\Xi^\varepsilon_k),\mathcal{L}(\hat{\Xi}^0_k))\quad\forall\, k=1,2,\dots,\quad\varepsilon\in(0,1].$$

From Lemma 6.10, Theorem 6.3, and the fact that $k(\varepsilon)<\lfloor\varepsilon^{-\frac{1}{36}}\rfloor$,

$$(6.67)\quad \Pi_C(\mathcal{L}(W^\varepsilon_{k(\varepsilon)}),\mathcal{L}(\hat{W}^0_{k(\varepsilon)}))\le\Pi_2^{kd}(\mathcal{L}(\Xi^\varepsilon_{k(\varepsilon)}),\mathcal{L}(\hat{\Xi}^0_{k(\varepsilon)}))\ll\varepsilon^{\frac{1}{48}}.$$

First term on RHS of (6.62). For continuous $\varphi : [0,1] \to \Re$ and $0 \le \tau_1 \le \mu_1 < \mu_2 \le \tau_2 \le 1$ we have $\max_{\mu_1 \le \tau \le \mu_2} |\varphi(\tau) - \varphi(\mu_1)| \le 2 \max_{\tau_1 \le \tau \le \tau_2} |\varphi(\tau) - \varphi(\tau_1)|$. Thus, from (3.5) and (4.6), we get

$$\begin{aligned}
&\max_{\frac{i}{k(\varepsilon)} \le \tau \le \frac{(i+1)}{k(\varepsilon)}} \left| W^\varepsilon(\tau) - W^\varepsilon\left(\frac{i}{k(\varepsilon)}\right)\right| \\
&\quad \le 2 \max_{\lfloor \frac{i}{\varepsilon k(\varepsilon)} \rfloor \le k \le 1 + \lfloor \frac{(i+1)}{\varepsilon k(\varepsilon)} \rfloor} \left| W^\varepsilon(\varepsilon k) - W^\varepsilon\left(\varepsilon \left\lfloor \frac{i}{\varepsilon k(\varepsilon)} \right\rfloor\right)\right| \\
&\quad \le 2 \max_{1 + \lfloor \frac{i}{\varepsilon k(\varepsilon)} \rfloor \le k \le 1 + \lfloor \frac{i+1}{\varepsilon k(\varepsilon)} \rfloor} \varepsilon^{\frac{1}{2}} \left| \sum_{j = 1 + \lfloor i/(\varepsilon k(\varepsilon)) \rfloor}^{k} \xi_j^\varepsilon \right|
\end{aligned} \tag{6.68}$$

for all $i = 0, 1, \ldots, k(\varepsilon) - 1$. Now fix integers M, N with $1 \le M < N$. We see from Remark 4.6 that there is a constant $C_1 \in [0, \infty)$, not depending on the sequence $\{\xi_j^\varepsilon\}$, or M, N, such that $E[|\sum_{j=i}^k \xi_j^\varepsilon|^4] \le C_1[k - i + 1]^2$ for all $M \le i \le k \le N$ and each $\varepsilon \in (0,1]$. Hence, by Theorem 8.1(i) (with $\gamma \overset{\triangle}{=} 2$, $\nu \overset{\triangle}{=} 4$, $g(i,k) \overset{\triangle}{=} k - i + 1$, $M \le i \le k \le N$), there is some constant $A(4,2) \in [0, \infty)$ such that $E[\max_{M \le k \le N} |\sum_{j=M}^k \xi_j^\varepsilon|^4] \le A(4,2)[g(M,N)]^2$ for all $1 \le M < N$ and $\varepsilon \in (0,1]$. Taking $M \overset{\triangle}{=} 1 + \lfloor i/(\varepsilon k(\varepsilon)) \rfloor$, $N \overset{\triangle}{=} 1 + \lfloor (i+1)/(\varepsilon k(\varepsilon)) \rfloor$, we see from (6.68) that there are constants $C_2, C_3 \in [0, \infty)$ such that

$$E\left[\max_{\frac{i}{k(\varepsilon)} \le \tau \le \frac{(i+1)}{k(\varepsilon)}} \left| W^\varepsilon(\tau) - W^\varepsilon\left(\frac{i}{k(\varepsilon)}\right)\right|^4\right] \le \varepsilon^2 C_2 [g(M,N)]^2 \le C_3 k(\varepsilon)^{-2} \tag{6.69}$$

for all $\varepsilon \in (0,1]$. Now (6.63) and (6.64) continue to hold with $\hat{P}$, $\hat{E}$, and $\hat{W}^0$ replaced by P, E, and W^ε, respectively. Thus, we can repeat the argument which gave (6.66), but using (6.69) in place of (6.65), to see

$$\Pi_C(\mathcal{L}(W^\varepsilon), \mathcal{L}(W^\varepsilon_{k(\varepsilon)})) \ll \varepsilon^{\frac{1}{8\gamma}}. \tag{6.70}$$

The conclusion follows from (6.62) and the upper-bounds given by (6.66), (6.67), and (6.70). □

7. Proofs of technical lemmas.

Proof of Lemma 2.9. It is enough to take $d = 1$. From (C4) we have $A(\theta) = \lim_{N \to \infty} \operatorname{cov}(\sum_{\nu=1}^N \tilde{H}_\nu(\theta))$, and thus (see (2.7)),

$$\begin{aligned}
|A(\theta_1) - A(\theta_2)| \le 2 \limsup_{N \to \infty} \frac{1}{N} \sum_{\nu=1}^N \sum_{\nu=1}^N |E[\tilde{b}_\nu \tilde{R}_\mu]|\, |\theta_1 - \theta_2| \\
+ \limsup_{N \to \infty} \frac{1}{N} \sum_{\nu=1}^N \sum_{\nu=1}^N |E[\tilde{R}_\nu \tilde{R}_\mu]|\, |\theta_1^2 - \theta_2^2|.
\end{aligned}$$

From Lemma 8.3(i) it easily follows that the double sums on the right-hand side are $O(N)$, as required for local Lipschitz continuity. □

Proof of Lemma 4.8. Since $P(|\gamma_n| \ge n^{\frac{1}{7}}) \le E\big[|\gamma_n|^8\big]/n^{\frac{8}{7}}$, we must have that $\sum_{n=1}^\infty P(|\gamma_n| \ge n^{\frac{1}{7}}) < \infty$. By Borel–Cantelli, for a.a. ω there exists an integer $L(\omega)$ such that $|\gamma_n(\omega)| \le n^{\frac{1}{7}}$ a.s. for all $n > L(\omega)$. Hence we can find $C(\omega)$ such that $|\gamma_n| \leq C(\omega) n^{\frac{1}{7}}$ for all $n \geq 1$, and the result follows from the monotonicity of $n \to n^{\frac{1}{7}}$. □

Proof of Lemma 4.11. Recall the notation defined in (4.22) to (4.25). Clearly,

$$\max_{0 \leq \tau \leq 1} |W_1^r(\tau) - W_2^r(\tau)| \leq \varepsilon_r^{-\frac{1}{2}} \int_{\tau_r}^{1} |\zeta_{t/\varepsilon_r}^{\varepsilon_r} - \zeta_{t/\varepsilon_r}^{\varepsilon_r}[q(r)]| \, dt.$$

Hence, by Jensen's inequality,

$$\max_{0 \leq \tau \leq 1} |W_1^r(\tau) - W_2^r(\tau)|^4 \leq \varepsilon_r^{-1} \int_0^{1/\varepsilon_r} I[\tau_r/\varepsilon_r, 1/\varepsilon_r](u) \, |\zeta_u^{\varepsilon_r} - \zeta_u^{\varepsilon_r}[q(r)]|^4 \, du.$$

Then, by (4.23), (4.22), (4.9), the fact that $(\tau_r/\varepsilon_r) \geq 1 + q(r)$, and Fubini,

$$E\left[\max_{0 \leq \tau \leq 1} |W_1^r(\tau) - W_2^r(\tau)|^4\right] \ll \varepsilon_r^{-1} \int_0^{1/\varepsilon_r} \lambda^{4q(r)} \, du \ll \exp(2(r^\sigma - r^2)).$$

By the mean value theorem for the mapping $\alpha \to r^\alpha$ (r constant), there exists $\gamma \in [\sigma, 2]$ such that $r^\sigma - r^2 = (\sigma - 2)(\ln r) r^\gamma \leq (\sigma - 2) r^\sigma$, so $\exp\left(2(r^\sigma - r^2)\right) \leq \varepsilon_r^{2(2-\sigma)} \leq \varepsilon_r$ (since $\sigma < 3/2$). □

Proof of Lemma 4.12. Recall the notation defined in (4.22)–(4.25). From (3.5),

$$W^{\varepsilon_r}(\tau) = \varepsilon_r^{\frac{1}{2}} \int_0^{\tau/\varepsilon_r} \zeta_u^{\varepsilon_r} \, du, \quad 0 \leq \tau \leq 1. \tag{7.1}$$

Thus, from (7.1) and (4.24),

$$W^{\varepsilon_r}(\tau) - W_1^r(\tau) = \begin{cases} \varepsilon_r^{\frac{1}{2}} \displaystyle\int_0^{\tau/\varepsilon_r} \zeta_u^{\varepsilon_r} \, du, & \text{if } 0 \leq \tau \leq \tau_r, \\ \varepsilon_r^{\frac{1}{2}} \displaystyle\int_0^{\tau_r/\varepsilon_r} \zeta_u^{\varepsilon_r} \, du, & \text{if } \tau_r \leq \tau \leq 1. \end{cases} \tag{7.2}$$

Therefore, from (7.2) and (4.23) we have

$$\max_{0 \leq \tau \leq 1} |W^{\varepsilon_r}(\tau) - W_1^r(\tau)| = \varepsilon_r^{\frac{1}{2}} \max_{1 \leq k \leq 1 + \lfloor \tau_r/\varepsilon_r \rfloor} \left| \sum_{j=1}^{k} \xi_j^{\varepsilon_r} \right|. \tag{7.3}$$

By Remark 4.6 and Theorem 8.1(i) (with $\nu = 4$, $\gamma = 2$, and $g(i,j) \overset{\triangle}{=} j - i + 1$), we easily see there is a constant $c \in [0, \infty)$, not depending on r, such that

$$E\left[\max_{1 \leq k \leq 1 + \lfloor \tau_r/\varepsilon_r \rfloor} \left| \sum_{j=1}^{k} \xi_j^{\varepsilon_r} \right|^4\right] \leq c \left(\frac{\tau_r}{\varepsilon_r}\right)^2. \tag{7.4}$$

Combining (7.4) with (7.3) and using the fact that $(\tau_r/\varepsilon_r) \ll \varepsilon_{r-1}^{-1}$ gives

$$\begin{aligned} E\left[\max_{0 \leq \tau \leq 1} |W^{\varepsilon_r}(\tau) - W_1^r(\tau)|^4\right] &\ll \varepsilon_r^2 \left(\frac{\tau_r}{\varepsilon_r}\right)^2 \\ &\ll \left(\frac{\varepsilon_r}{\varepsilon_{r-1}}\right)^2 = \exp\left(2(r-1)^\sigma - 2r^\sigma\right). \end{aligned} \tag{7.5}$$

Now $r^\sigma - (r-1)^\sigma = \sigma s^{\sigma-1}$ for some $s \in [r-1, r]$, and hence $\exp(2((r-1)^\sigma - r^\sigma)) \le \exp(-2\sigma(r-1)^{\sigma-1})$. Observe that, since $\sigma > 1$, we have $5\ln r \ll \sigma(r-1)^{\sigma-1}$, or, equivalently, $\exp\left(-\sigma(r-1)^{\sigma-1}\right) \ll r^{-5}$ for all $r \ge 1$. Now the result follows from (7.5). □

Proof of Lemma 5.4. We use the notation defined in the proof of Lemma 3.6. For (5.24) we have

$$\varepsilon^{\frac{3}{2}} \max_{1\le k\le N_\varepsilon+1} \left| \sum_{j=0}^{k-1} \tilde{R}_{j+1} \left((I-\varepsilon\bar{R})^j - (I-N_\varepsilon^{-1}\bar{R})^j\right) \Gamma_j^{N_\varepsilon^{-1}} \right| \tag{7.6}$$

$$\le \varepsilon^{\frac{3}{2}} N_\varepsilon \cdot \max_{0\le j\le N_\varepsilon} |\tilde{R}_{j+1}| \cdot \max_{0\le j\le N_\varepsilon} \left|(I-\varepsilon\bar{R})^j - (I-N_\varepsilon^{-1}\bar{R})^j\right| \cdot \max_{0\le j\le N_\varepsilon} |\Gamma_j^{N_\varepsilon^{-1}}|.$$

We bound the $\max_j |\cdot|$ factors on the right of (7.6). For the third factor, we see from $\max_{1\le i\le n} |I - n^{-1}\bar{R}|^{-2i} = O(1)$ (uniformly in n) and Remark 4.6, that there is a constant $c_1 \in (0,\infty)$ such that

$$E\left[\left|\sum_{k=i}^{j} (I - n^{-1}\bar{R})^{-k} \xi_k^{n^{-1}}\right|^8\right] \le c_1(j-i+1)^4 \quad \forall\, 1\le j\le k\le n. \tag{7.7}$$

From (5.12), (7.7), and Theorem 8.1(i) (with $\nu \overset{\triangle}{=} 8$, $\gamma \overset{\triangle}{=} 4$, $g(i,j) \overset{\triangle}{=} j-i+1$, $1 \le i \le j \le n$), we have

$$E\left[\max_{0\le j\le n} \left|\Gamma_j^{n^{-1}}\right|^8\right] \ll n^4, \tag{7.8}$$

and thus, from Borel–Cantelli,

$$\max_{0\le j\le n} |\Gamma_j^{n^{-1}}| = O(n^{\frac{6}{7}}) \text{ a.s.} \tag{7.9}$$

so that the third $\max_j |\cdot|$ factor on the right of (7.6) is $O(\varepsilon^{-\frac{6}{7}})$ a.s. It follows from Lemma 4.8 that the first $\max_j |\cdot|$ factor on the right of (7.6) is $O(\varepsilon^{-\frac{1}{7}})$ a.s. while the second $\max_j |\cdot|$ factor is easily shown by Taylor's theorem to be $O(\varepsilon)$. Thus, from (7.6), the quantity in (5.24) is a.s. $O(\varepsilon^{\frac{1}{2}}\varepsilon^{-\frac{1}{7}}\varepsilon\varepsilon^{-\frac{6}{7}}) = O(\varepsilon^{\frac{1}{2}})$. The proofs for (5.25) and part (b) are similar and are omitted. □

Proof of Lemma 6.9. From Remark 2.7 we know that $\{\tilde{b}_n\}$ and $\{\tilde{R}_n\}$ are geometrically L-mixing and zero-mean. Thus (recalling (2.7) and (6.41)), there are constants $\lambda \in (0,1)$ and $C_1 \in [0,\infty)$ such that $\|\tilde{H}_n(\theta)\|_2 \le C_1[1+|\theta|]$, $\|\tilde{H}_n(\theta)[s]\|_2 \le C_1[1+|\theta|]$, and $\|\tilde{H}_n(\theta) - \tilde{H}_n(\theta)[s]\|_2 \le C_1[1+|\theta|]\lambda^s$ for all $\theta \in \Re^d$, for all $s, n = 1, 2, \ldots$. Put

$$D^1(n,m,s,\theta) \overset{\triangle}{=} (\tilde{H}_n(\theta) - \tilde{H}_n(\theta)[s])(\tilde{H}_m(\theta))'.$$

By Cauchy–Schwarz and the preceding bounds,

$$|ED^1(n,m,s,\theta)| \le \|\tilde{H}_n(\theta) - \tilde{H}_n(\theta)[s]\|_2 \|\tilde{H}_m(\theta)\|_2 \le C_2[1+|\theta|^2]\lambda^s,$$

and the same upper-bound clearly holds for the expectation of

$$D^2(n,m,s,\theta) \overset{\triangle}{=} \tilde{H}_n(\theta)[s](\tilde{H}_m(\theta) - \tilde{H}_m(\theta)[s])'.$$

Then

$$\begin{aligned}(7.10)\qquad &\left|\operatorname{cov}\left(\sum_{n=n_0}^{N+n_0}\tilde{H}_n(\theta)\right)-\operatorname{cov}\left(\sum_{n=n_0}^{N+n_0}\tilde{H}_n(\theta)[s]\right)\right|\\ &=\left|\sum_{n=n_0}^{N+n_0}\sum_{m=n_0}^{N+n_0}E[D^1(n,m,s,\theta)+D^2(n,m,s,\theta)]\right|\\ &\le 2C_2[1+|\theta|^2](N+1)^2\lambda^s.\end{aligned}$$

The result now follows from condition (C4) and (7.10). □

Proof of Lemma 6.10. Fix some $k=1,2,\ldots$, and let $|\cdot|_\infty$ denote the maximum norm on $\Re^{kd}$ (i.e., $|x|_\infty \overset{\triangle}{=} \max_{1\le i\le kd}|x^i|$). Let $\Pi_\infty^{kd}(P_1,P_2)$ denote Prohorov distance between probability measures P_1 and P_2 on $\Re^{kd}$ with norm $|\cdot|_\infty$, and let $C_k[0,1]$ be the subset of $C[0,1]$ comprising all continuous functions $f:[0,1]\to\Re^d$, with $f(0)=0$, which are piecewise linear with break-points at i/k, $i=1,\ldots,k-1$ (see right-hand side of (6.61)). Then the metric spaces $(\Re^{kd},|\cdot|_\infty)$ and $(C_k[0,1],\|\cdot\|_C)$ are homeomorphic. Since the paths of $\{W_k^\varepsilon(\tau),\ \tau\in[0,1]\}$ and $\{\hat{W}_k^0(\tau),\ \tau\in[0,1]\}$ are in $C_k[0,1]$, it easily follows from (6.1) and (6.61) that $\Pi_C(\mathcal{L}(W_k^\varepsilon),\mathcal{L}(\hat{W}_k^0))=\Pi_\infty^{kd}(\mathcal{L}(\Xi_k^\varepsilon),\mathcal{L}(\hat{\Xi}_k^0))$. Now, for $\eta>0$ and closed $A\subset\Re^{kd}$, put $A^\eta\overset{\triangle}{=}\{x\in\Re^{kd}:|x-a|<\eta$ for some $a\in A\}$ and $A_\infty^\eta\overset{\triangle}{=}\{x\in\Re^{kd}:|x-a|_\infty<\eta$ for some $a\in A\}$. Since $|x|_\infty\le|x|$, we have $A^\eta\subset A_\infty^\eta$, and from this, together with (8.1), we get $\Pi_\infty^{kd}(\mathcal{L}(\Xi_k^\varepsilon),\mathcal{L}(\hat{\Xi}_k^0))\le\Pi_2^{kd}(\mathcal{L}(\Xi_k^\varepsilon),\mathcal{L}(\hat{\Xi}_k^0))$, as required. □

8. Useful results. In this section we collect for easy reference some simple adaptations of results from probability which are used in the previous sections. The following maximal inequalities, due to Móricz [23, Theorem 1] and Longnecker and Serfling [22], are needed for lines (5.21), (6.69), (7.4), and (7.8).

THEOREM 8.1. *Suppose that M and N are integers, $1\le M<N<\infty$, and $\mathcal{Y}$ is a normed vector space with norm $\|\cdot\|$.*

(i) *Let $\{z_k,\ k=M,M+1,\ldots,N\}$ be arbitrary $\mathcal{Y}$-valued random variables. Suppose there are constants $c,\nu\in(0,\infty)$, $\gamma\in(1,\infty)$, and an $\Re$-valued mapping $g(i,j)$ defined for $M\le i\le j\le N$, such that $E[\|\sum_{k=i}^j z_k\|^\nu]\le c[g(i,j)]^\gamma$ for all $M\le i\le j\le N$, and $g(i,j)+g(j+1,k)\le g(i,k)$ for all $M\le i\le j<k\le N$. Then there is a constant $A(\nu,\gamma)\in[0,\infty)$ such that $E[\max_{M\le n\le N}\|\sum_{k=M}^n z_k\|^\nu]\le cA(\nu,\gamma)[g(M,N)]^\gamma$. The constant $A(\nu,\gamma)$ depends on ν and γ only.*

(ii) *Let $\{Q_k,\ k=M,M+1,\ldots,N\}$ be arbitrary $\mathcal{Y}$-valued random variables. Suppose there are constants $c,\nu\in(0,\infty)$, $\gamma\in(1,\infty)$, and an $\Re$-valued mapping $h(i,j)$ defined for $M\le i\le j\le N$, such that $E[\|Q_j-Q_i\|^\nu]\le c[h(i,j)]^\gamma$ for all $M\le i\le j\le N$, and $h(i,j)+h(j,k)\le h(i,k)$ for all $M\le i\le j\le k\le N$. Then, for the constant $A(\nu,\gamma)$ of (i), we have $E[\max_{M\le n\le N}\|Q_n-Q_M\|^\nu]\le cA(\nu,\gamma)[h(M,N)]^\gamma$.*

Remark 8.2. The constant $A(\nu,\gamma)$ has nothing to do with M,N, the random variables $\{z_k\}$, $\{Q_k\}$, or the functions $g(\cdot,\cdot)$, $h(\cdot,\cdot)$ in (i) and (ii). Indeed, (2.1)–(2.3) of [22] give $A(\nu,\gamma)$ explicitly as a function of $\nu>0$ and $\gamma>1$ only. Notice that (ii) follows upon applying (i) of Theorem 8.1 to the sequence $\{z_k,\ k=M,M+1,\ldots,N-1\}$ defined by $z_k\overset{\triangle}{=}Q_{k+1}-Q_k$ for all $k=M,M+1,\ldots,N-1$, with $g(i,j)\overset{\triangle}{=}h(i,j+1)$ for all $M\le i\le j\le N-1$.

By trivially adapting the arguments for Lemma A.1.2(a)(b) of [11], we get the following lemma.

Lemma 8.3. *Suppose that* $\{z_n^1,\ n=1,2,\ldots\}$ *and* $\{z_n^2,\ n=1,2,\ldots\}$ *are* $\Re$*-valued zero-mean geometrically* L*-mixing processes with respect to the system* $(\mathcal{F}_n,\mathcal{F}_n^+)$*. Then there are constants* $C_1,C_2\in[0,\infty)$ *and* $\lambda\in(0,1)$ *such that* (i) $|E\{z_n^1 z_m^2\}|\le C_1\lambda^{|n-m|}$ *for all* $m,n=1,2,\ldots,$ *and* (ii) $|E\{z_n^1[s]z_m^2[s]\}|\le C_2\lambda^{|n-m|}$ *for all* $m,n,s=1,2,\ldots$ *(recall* (2.3)*).*

Remark 8.4. Since $\theta^0((n-1)\varepsilon\wedge T)$ is uniformly bounded (in $\varepsilon\in(0,1]$, $n=1,2,\ldots$) and $\{\tilde{b}_n\}$ and $\{\tilde{R}_n\}$ are zero-mean geometrically L-mixing (by Remark 2.7), we see from (4.8) and Lemma 8.3(ii) that there are constants $C\in[0,\infty)$ and $\lambda\in(0,1)$ such that $|E[(\xi_\nu^\varepsilon[s])(\xi_\mu^\varepsilon[s])']|\le C\ \lambda^{|\mu-\nu|}$ for all $\varepsilon\in(0,1]$, for all $s,\mu,\nu=1,2,\ldots$.

The following result, which is a special case of Theorem 1.1 of Gerencsér [9], is repeatedly used.

Theorem 8.5. *Suppose that* $\{u_j\}$ *is a zero-mean* $\Re^{l\times r}$*-valued geometrically* L*-mixing process, and* $\{A_j\}$ *is a nonrandom sequence of* $d\times l$ *matrices. Then, for each* $p\in[2,\infty)$, $\|\sum_{j=1}^N A_ju_j\|_p\ll(\sum_{j=1}^N|A_j|^2)^{\frac{1}{2}}$*. The constant implied by* $\ll$ *depends only upon* p, $\sup_{j\ge1}\|u_j\|_p$*, and the rate* λ *of the geometrically* L*-mixing process* $\{u_j\}$*, in particular, does NOT depend on* N *or the sequence* $\{A_j\}$*.*

In the remainder of this section we summarize some relevant facts about the *Prohorov metric* for probability measures on a metric space. Suppose that (S,ρ) is a metric space, and let P_1 and P_2 be two probability measures on $(S,\mathcal{B}(S))$. Define the number

$$\Pi(P_1,P_2)\overset{\triangle}{=}\inf\{\eta\in(0,\infty):\ P_1(A)\le P_2(A^\eta)+\eta\ \text{ for all closed } A\subset S\}, \tag{8.1}$$

where $A^\eta\overset{\triangle}{=}\{s\in S:\ \rho(s,a)\le\eta\ \text{ for some } a\in A\}$ for $A\subset S$. All we need to know is that the mapping $\Pi(\cdot,\cdot)$ defined by (8.1) is indeed a metric in the set of all probability measures on $(S,\mathcal{B}(S))$, called the *Prohorov metric*, and when (S,ρ) is a *separable* metric space then $\Pi(\cdot,\cdot)$ is a metric for the topology of weak convergence of probability measures on $(S,\mathcal{B}(S))$. See [8, Theorem 3.1, p. 108]. Thus, one can use the Prohorov metric to quantify *rates* of weak convergence of probability measures. In fact, this is the significance of condition (4.3) in Theorem 4.2. We also make repeated use of the following simple result which is an immediate consequence of (8.1) and the Chebyshev inequality.

Lemma 8.6. *Suppose that* X *and* Y *are random variables defined on* $(\Omega,\mathcal{F},P)$ *with values in a metric space* (S,ρ)*.* (i) *If, for some* $\beta\in(0,\infty)$*, we have* $P\{\rho(X,Y)\ge\beta\}\le\beta$*, then* $\Pi(\mathcal{L}(X),\mathcal{L}(Y))\le\beta$*.* (ii) *If, for some* $\beta\in(0,\infty)$ *and* $c\in[1,\infty)$*, we have* $\|\rho(X,Y)\|_c\le\beta$*, then* $\Pi(\mathcal{L}(X),\mathcal{L}(Y))\le\beta^{\frac{c}{c+1}}$*.*

The next result (used for (6.56) and (6.59)) is a special case of Dehling [7, Theorem 7, p. 400], and upper-bounds the Prohorov distance between Gaussian distributions on Euclidean space.

Theorem 8.7. *There exists a constant* $\beta\in[0,\infty)$ *such that*

$$\Pi_2^{kd}\left(\mathcal{N}_{kd}(0,T),\mathcal{N}_{kd}(0,S)\right)\le\beta k^{\frac{3}{4}}d^{\frac{5}{8}}\left(\max_{1\le m,n\le k}|T_{m,n}-S_{m,n}|\right)^{\frac{1}{4}}$$

for all $k,d=1,2,\ldots,$ *and all* $kd\times kd$ *symmetric positive semidefinite matrices* T *and* S *such that* $kd^{\frac{1}{2}}\max_{1\le m,n\le k}|T_{m,n}-S_{m,n}|<1$*.*

Acknowledgment. Many thanks indeed to the referee for an exceptionally careful and detailed review which led to numerous improvements in this work.

PROPERTIES OF A MULTIVALUED MAPPING ASSOCIATED WITH SOME NONMONOTONE COMPLEMENTARITY PROBLEMS*

YUN-BIN ZHAO† AND GEORGE ISAC‡

Abstract. Using the homotopy invariance property of the degree and a newly introduced concept of the interior-point-ε-exceptional family for continuous functions, we prove an alternative theorem concerning the existence of a certain interior-point of a continuous complementarity problem. Based on this result, we develop several sufficient conditions to assure some desirable properties (nonemptyness, boundedness, and upper-semicontinuity) of a multivalued mapping associated with continuous (nonmonotone) complementarity problems corresponding to semimonotone, $\mathrm{P}(\tau,\alpha,\beta)$-, quasi-$\mathrm{P}_*$-, and exceptionally regular maps. The results proved in this paper generalize well-known results on the existence of central paths in continuous P_0 complementarity problems.

Key words. nonlinear complementarity problems, central path, interior-point-ε-exceptional family, weakly univalent maps, generalized monotonicity

1. Introduction.

Consider the nonlinear complementarity problem (NCP)

$$f(x) \geq 0,\ x \geq 0,\ x^T f(x) = 0,$$

where f is a continuous function from R^n into itself. This problem has now gained much importance because of its many applications in optimization, economics, engineering, etc. (see [8, 12, 16, 18]).

There are several equivalent formulations of the NCP in the form of a nonlinear equation $F(x) = 0$, where F is a continuous function from R^n into R^n. Given such an equation $F(x) = 0$, the most used technique is to perturb F to a certain F_ε, where ε is a positive parameter, and then consider the equation $F_\varepsilon(x) = 0$. If $F_\varepsilon(x) = 0$ has a unique solution denoted by $x(\varepsilon)$ and $x(\varepsilon)$ is continuous in ε, then the solutions $\{x(\varepsilon)\}$ describe, depending on the nature of $F_\varepsilon(x)$, a short path denoted by $\{x(\varepsilon) : \varepsilon \in (0, \bar{\varepsilon}]\}$, or a long path $\{x(\varepsilon) : \varepsilon \in (0, \infty)\}$. If a short path $\{x(\varepsilon) : \varepsilon \in (0, \bar{\varepsilon}]\}$ is bounded, then for any subsequence $\{\varepsilon_k\}$ with $\varepsilon_k \to 0$, the sequence $\{x(\varepsilon_k)\}$ has at least one accumulation point, and by the continuity each of the accumulation points is a solution to the NCP. Thus, a path can be viewed as a certain continuous curve associated with the solution set of the NCP. Based on the path, we may construct various computational methods for solving the NCP, such as interior-point path-following methods (see, e.g., [15, 25, 26, 27, 28, 32, 39]), regularization methods (see [8, 10, 11, 41]), and noninterior path-following methods (see [1, 2, 3, 5, 7, 17, 21]). The most common interior-point path-following method is based on the central path. The curve $\{x(\varepsilon) : \varepsilon \in (0, \infty)\}$ is said to be the central path if for each $\varepsilon > 0$ the vector $x(\varepsilon)$ is the unique solution to the system

$$x(\varepsilon) > 0,\ f(x(\varepsilon)) > 0,\ X(\varepsilon)f(x(\varepsilon)) = \varepsilon e, \tag{1}$$

where $X(\varepsilon) = \operatorname{diag}(x(\varepsilon)), e = (1, \ldots, 1)^T$, and $x(\cdot)$ is continuous on $(0, \infty)$.

In the case when f is a monotone function and the NCP is strictly feasible (i.e., there is a vector $u \in R^n$ such that $u > 0$ and $f(u) > 0$), the existence of the central path is well known (see, for example, [14, 25, 30, 31]). This existence result has been extended to some nonmonotone complementarity problems. Kojima, Mizuno, and Noma [27] proved that the central path exists if f is a uniform-P function. If f is a P_0-function satisfying a properness condition and the NCP is strictly feasible, Kojima, Megiddo, and Noma [25] showed that there exists a class of interior-point trajectories which includes the central path as a special case. If f is a P_0-function and NCP has a nonempty and bounded solution set, Chen, Chen, and Kanzow [4] and Gowda and Tawhid [13] proved that the NCP has a short central path $\{x(\varepsilon) : \varepsilon \in (0, \bar{\varepsilon})\}$. Under a certain properness condition, Gowda and Tawhid [13] showed that the NCP with a P_0-function has a long central path [13, Theorem 9]. It should be pointed out that noninterior-point trajectories have also been extensively studied in the recent literature (see [1, 2, 3, 5, 10, 11, 13, 17, 35, 37]).

However, for a general complementarity problem, the system (1) may have multiple solutions for a given $\varepsilon > 0$, and even if the solution is unique, it is not necessarily continuous in ε. As a result, the existence of the central path is not always guaranteed. We define the (multivalued) mapping $\mathcal{U} : (0, \infty) \to \mathcal{S}(R^n_{++})$ by

$$\mathcal{U}(\varepsilon) = \{x \in R^n_{++} : f(x) > 0, Xf(x) = \varepsilon e\}, \tag{2}$$

where $X = \operatorname{diag}(x)$ and $\mathcal{S}(R^n_{++})$ is the set of all subsets of R^n_{++}, the positive orthant of R^n. The main contribution of this paper is to describe several sufficient conditions which ensure that the multivalued mapping $\mathcal{U}(\varepsilon)$ has the following desirable properties.

(a) $\mathcal{U}(\varepsilon) \neq \emptyset$ *for each* $\varepsilon \in (0, \infty)$.

(b) *For any fixed* $\bar{\varepsilon} > 0$, *the set* $\bigcup_{\varepsilon \in (0, \bar{\varepsilon}]} \mathcal{U}(\varepsilon)$ *is bounded.*

(c) *If* $\mathcal{U}(\varepsilon) \neq \emptyset$, *then* $\mathcal{U}(\varepsilon)$ *is upper-semicontinuous at* ε. *(That is, for any sufficiently small* $\delta > 0$, *we have that* $\emptyset \neq \mathcal{U}(\varepsilon') \subseteq \mathcal{U}(\varepsilon) + \delta B$ *for all* ε' *sufficiently close to* ε, *where* $B = \{x \in R^n : \|x\| < 1\}$ *is the Euclidean unit ball.)*

(d) *If* $\mathcal{U}(\cdot)$ *is single-valued, then* $\mathcal{U}(\varepsilon)$ *is continuous at* ε *provided that* $\mathcal{U}(\varepsilon) \neq \emptyset$.

If the mapping $\mathcal{U}(\cdot)$ satisfies properties (a), (b), and (c), then the set $\bigcup_{\varepsilon \in (0,\infty)} \mathcal{U}(\varepsilon)$ can be viewed as an "interior band" associated with the solution set of the NCP. The "interior band" can be viewed as a generalization of the concept of the central path. Indeed, if $\mathcal{U}(\cdot)$ satisfies properties (a), (b), and (d), then the set $\bigcup_{\varepsilon \in (0,\infty)} \mathcal{U}(\varepsilon)$ coincides with the central path of the NCP.

There exist several ways of generating the central path of the NCP, including maximal monotone methods [14, 30], minimization methods [31], homeomorphism techniques [6, 14, 15, 25, 33], the parameterized Sard theorem [42], and weakly univalent properties of continuous functions [13, 35, 37]. In this paper, we develop a different method for the analysis of the existence of the central path. By means of the homotopy invariance property of the degree and a newly introduced concept of interior-point-ε-exceptional family for continuous functions, we establish an alternative theorem for the nonemptyness of the mapping $\mathcal{U}(\varepsilon)$. For a given $\varepsilon > 0$, the result states that there exists either an interior-point-ε-exceptional family for f or $\mathcal{U}(\varepsilon) \neq \emptyset$. Consequently, to show the nonemptyness of the mapping $\mathcal{U}(\cdot)$, it is sufficient to verify conditions under which the function f possesses no interior-point-ε-exceptional family for any $\varepsilon > 0$. Along with this idea, we provide several sufficient conditions that guarantee the aforementioned desirable properties of the multivalued mapping $\mathcal{U}(\cdot)$.

These sufficient conditions are related to several classes of (nonmonotone) functions such as semimonotone, quasi-P$_*$-, P(τ, α, β)-, and exceptionally regular maps. The results proved in the paper include several known results on the central path as special instances.

This paper is organized as follows. In section 2, we introduce some definitions and some basic results that will be utilized in the paper. In section 3, we show an essential alternative theorem that is useful in later derivations. In section 4, we establish some sufficient conditions to guarantee the nonemptyness, boundedness, and upper-semicontinuity of the map $\mathcal{U}(\varepsilon)$, and the existence of the central path. Some concluding remarks are given in section 5.

Notations: R^n_+ (respectively, R^n_{++}) denotes the space of n-dimensional real vectors with nonnegative components (respectively, positive components), and $R^{n\times n}$ stands for the space of $n \times n$ matrices. For any $x \in R^n$, we denote by $\|x\|$ the Euclidean norm of x, by x_i the ith component of x for $i = 1, \ldots, n$, and by $[x]_+$ the vector whose ith component is $\max\{0, x_i\}$. When $x \in R^n_+(R^n_{++})$, we also write it as $x \geq 0$ $(x > 0)$ for simplicity.

2. Preliminaries. We first introduce the concept of an E$_0$-function, which is a generalization of an E$_0$-matrix, i.e., semimonotone matrix, (see [8]). Recall that an $n \times n$ matrix M is said to be an E$_0$-matrix if for any $0 \neq x \geq 0$, there exists a component $x_i > 0$ such that $(Mx)_i \geq 0$. M is a strictly semimonotone matrix if for any $0 \neq x \geq 0$, there exists a component $x_i > 0$ such that $(Mx)_i > 0$.

DEFINITION 2.1. *A function $f : R^n \to R^n$ is said to be an E_0-function (i.e., semimonotone function) if for any $x \neq y$ and $x \geq y$ in R^n, there exists some i such that $x_i > y_i$ and $f_i(x) \geq f_i(y)$. f is a strictly semimonotone function if for any $x \neq y$ and $x \geq y$ in R^n, there exists some i such that $x_i > y_i$ and $f_i(x) > f_i(y)$.*

It is evident that $f = Mx + q$, where $M \in R^{n\times n}$ and $q \in R^n$, is an E$_0$-function if and only if M is an E$_0$-matrix. We recall that a function f is said to be a P$_0$(P)-function if for any $x \neq y$ in R^n

$$\max_{x_i \neq y_i} (x_i - y_i)(f_i(x) - f_i(y)) \geq 0 (> 0).$$

Clearly, a P$_0$-function is an E$_0$-function. However, the converse is not true (see [8, Example 3.9.2]). Thus the class of E$_0$-functions is larger than that of P$_0$-functions.

DEFINITION 2.2. (D1) [23, 24]. *A map $f : R^n \to R^n$ is said to be quasi monotone if for $x \neq y$ in R^n, $f(y)^T(x - y) > 0$ implies that $f(x)^T(x - y) \geq 0$.*

(D2) [26, 44]. *A map $f : R^n \to R^n$ is said to be a P_*-map if there exists a scalar $\kappa \geq 0$ such that for any $x \neq y$ in R^n we have*

$$(1 + \kappa) \sum_{i \in I_+(x,y)} (x_i - y_i)(f_i(x) - f_i(y)) + \sum_{i \in I_-(x,y)} (x_i - y_i)(f_i(x) - f_i(y)) \geq 0,$$

where

$$I_+(x, y) = \{i : (x_i - y_i)(f_i(x) - f_i(y)) > 0\}, \tag{3}$$

$$I_-(x, y) = \{i : (x_i - y_i)(f_i(x) - f_i(y)) < 0\}.$$

(D3) [26]. *M is said to be a P_*-matrix if there exists a scalar $\kappa \geq 0$ such that*

$$(1 + \kappa) \sum_{i \in I_+} x_i(Mx)_i + \sum_{i \in I_-} x_i(Mx)_i \geq 0,$$

where $I_+ = \{i : x_i(Mx)_i > 0\}$ *and* $I_- = \{i : x_i(Mx)_i < 0\}$.

Clearly, for a linear map $f(x) = Mx + q$, f is a P_*-map if and only if M is a P$_*$-matrix. Väliaho [40] showed that the class of P$_*$-matrices coincides with the class of sufficient matrices [8, 9]. A new equivalent definition of the P$_*$-matrix is given in [46]. The next concept is a generalization of the quasi monotone function and the P$_*$-map.

DEFINITION 2.3. [46] *A function* $f : R^n \to R^n$ *is said to be a quasi-*P_**-map if there exists a constant* $\tau \geq 0$ *such that the following implication holds for all* $x \neq y$ *in* R^n.

$$f(y)^T(x-y) - \tau \sum_{i \in I_+(x,y)} (x_i - y_i)(f_i(x) - f_i(y)) > 0 \Rightarrow f(x)^T(x-y) \geq 0,$$

where $I_+(x,y)$ *is defined by* (3).

From the above definition, it is evident that the class of quasi-P$_*$-maps includes quasi monotone functions and P$_*$-maps. (see [46] for details). The following concept of a $P(\tau, \alpha, \beta)$-map is also a generalization of the P$_*$-map. In [46], it is pointed out that monotone functions and P$_*$-maps are special cases of P(τ, α, β)-maps.

DEFINITION 2.4. [46] *A mapping* $f : R^n \to R^n$ *is said to be a* $P(\tau, \alpha, \beta)$*-map if there exist constants* $\tau \geq 0, \alpha \geq 0,$ *and* $0 \leq \beta < 1$ *such that the following inequality holds for all* $x \neq y$ *in* R^n :

$$(1+\tau) \max_{1 \leq i \leq n} (x_i - y_i)(f_i(x) - f_i(y)) + \min_{1 \leq i \leq n} (x_i - y_i)(f_i(x) - f_i(y)) + \alpha \|x - y\|^\beta \geq 0.$$

The concept of exceptional regularity that we are going to define next has a close relation to such concepts as copositive, R_0-, P$_0$-, and E$_0$-functions. It is shown that the exceptional regularity is a weak sufficient condition for the nonemptyness and the boundedness of the mapping $\mathcal{U}(\varepsilon)$ (see section 4.4 for details).

DEFINITION 2.5. *Let* f *be a function from* R^n *into* R^n. f *is said to be exceptionally regular if, for each* $\beta \geq 0$, *the following complementarity problem has no solution of norm* 1:

$$G(x) + \beta x \geq 0, \ x \geq 0, \ x^T(G(x) + \beta x) = 0,$$

where $G(x) = f(x) - f(0)$.

The following two results are employed to prove the main result of the next section. Let S be an open bounded set of R^n. We denote by $\overline{S}$ and $\partial(S)$ the closure and boundary of S, respectively. Let F be a continuous function from $\overline{S}$ into R^n. For any $y \in R^n$ such that $y \notin F(\partial(S))$, the symbol $\deg(F, S, y)$ denotes the topological degree associated with F, S, and y (see [34]).

LEMMA 2.1. [34] *Let* $S \subset R^n$ *be an open bounded set and* F, G *be two continuous functions from* $\overline{S}$ *into* R^n.

(i) *Let the homotopy* $H(x,t)$ *be defined as*

$$H(x,t) = tG(x) + (1-t)F(x), \ 0 \leq t \leq 1,$$

and let y *be an arbitrary point in* R^n. *If* $y \notin \{H(x,t) : x \in \partial S$ *and* $t \in [0,1]\}$, *then* $deg(G, S, y) = deg(F, S, y)$.

(ii) *If* $deg(F, S, y) \neq 0$, *then the equation* $F(x) = y$ *has a solution in* S.

The following upper-semicontinuity theorem of weakly univalent maps is due to Ravindran and Gowda [35].

LEMMA 2.2. [35] *Let $g : R^n \to R^n$ be weakly univalent; that is, g is continuous and there exist one-to-one continuous functions $g_k : R^n \to R^n$ such that $g_k \to g$ uniformly on every bounded subset of R^n. Suppose that $q^* \in R^n$ such that $g^{-1}(q^*)$ is nonempty and compact. Then for any given scalar $\delta > 0$ there exists a scalar $\gamma > 0$ such that for any weakly univalent function $h : R^n \to R^n$ and for any $q \in R^n$ with*

$$\sup_{\bar{\Omega}} \|h(x) - g(x)\| < \gamma, \ \|q - q^*\| < \gamma,$$

we have

$$\emptyset \neq h^{-1}(q) \subseteq g^{-1}(q^*) + \delta B,$$

where B denotes the open unit ball in R^n and $\Omega = g^{-1}(q^*) + \delta B$.

3. Interior-point-ε-exceptional family and an alternative theorem. We now introduce the concept of the interior-point-ε-exceptional family for a continuous function, which brings us to a new idea, to investigate the properties of the mapping $\mathcal{U}(\varepsilon)$ defined by (2), especially the existence of the central path for NCPs. This concept can be viewed as a variant of the exceptional family of elements which was originally introduced to study the solvability of complementarity problems and variational inequalities [19, 20, 36, 43, 44, 45, 46].

DEFINITION 3.1. *Let $f : R^n \to R^n$ be a continuous function. Given a scalar $\varepsilon > 0$, we say that a sequence $\{x^r\}_{r>0} \subset R^n_{++}$ is an interior-point-ε-exceptional family for f if $\|x^r\| \to \infty$ as $r \to \infty$ and for each x^r there exists a positive number $0 < \mu_r < 1$ such that*

$$f_i(x^r) = \frac{1}{2}\left(\mu_r - \frac{1}{\mu_r}\right) x_i^r + \frac{\varepsilon \mu_r}{x_i^r} \quad \text{for all } i = 1, \ldots, n. \tag{4}$$

Based on the above concept, we can prove the following result which plays a key role in the analysis of the paper.

THEOREM 3.1. *Let f be a continuous function from R^n into R^n. Then for each $\varepsilon > 0$ there exists either a point $x(\varepsilon)$ such that*

$$x(\varepsilon) > 0, \ f(x(\varepsilon)) > 0, \ x_i(\varepsilon) f_i(x(\varepsilon)) = \varepsilon, \ i = 1, \ldots, n \tag{5}$$

or an interior-point-ε-exceptional family for f.

Proof. Let $F(x) = (F_1(x), \ldots, F_n(x))^T$ be the Fischer–Burmeister function of f defined by

$$F_i(x) = x_i + f_i(x) - \sqrt{x_i^2 + f_i^2(x)}, \ i = 1, \ldots, n.$$

It is well known that x solves the NCP if and only if x solves the equation $F(x) = 0$. Given $\varepsilon > 0$, we perturb $F(x)$ to $F_\varepsilon(x)$ given by

$$[F_\varepsilon(x)]_i = x_i + f_i(x) - \sqrt{x_i^2 + f_i^2(x) + 2\varepsilon}, \ i = 1, \ldots, n. \tag{6}$$

It is easy to see that $x(\varepsilon)$ solves the equation $F_\varepsilon(x) = 0$ if and only if $x(\varepsilon)$ satisfies the system (5). We now consider the convex homotopy between the mapping $F_\varepsilon(x)$ and the identity mapping, that is,

$$H(x, t) = tx + (1 - t)F_\varepsilon(x), \ 0 \leq t \leq 1.$$

Let $r > 0$ be an arbitrary positive scalar. Consider the open bounded set $S_r = \{x \in R^n : \|x\| < r\}$. The boundary of S_r is given by $\partial S_r = \{x \in R^n : \|x\| = r\}$. There are only two cases.

Case 1. There exists a number $r > 0$ such that $0 \notin \{H(x,t) : x \in \partial S_r \text{ and } t \in [0,1]\}$. In this case, by (i) of Lemma 2.1, we have that $\deg(I, S_r, 0) = \deg(F_\varepsilon(x), S_r, 0)$, where I is the identity mapping. Since $\deg(I, S_r, 0) = 1$, from the above equation and (ii) of Lemma 2.1, we deduce that the equation $F_\varepsilon(x) = 0$ has a solution, denoted by $x(\varepsilon)$, which satisfies the system (5).

Case 2. For each $r > 0$, there exists some point $x^r \in \partial S_r$ and $t_r \in [0,1]$ such that

$$0 = H(x^r, t_r) = t_r x^r + (1 - t_r)F_\varepsilon(x^r). \tag{7}$$

If $t_r = 0$ for some $r > 0$, then the above equation reduces to $F_\varepsilon(x^r) = 0$, which implies that $x(\varepsilon) := x^r$ satisfies the system (5).

We now verify that $t_r \neq 1$. In fact, if $t_r = 1$ for some $r > 0$, then from (7) we have that $x^r = 0$, which is impossible since $x^r \in \partial S_r$.

Therefore, it is sufficient to consider the case of $0 < t_r < 1$ for all $r > 0$. In this case, it is easy to show that f actually has an interior-point-ε-exceptional family. Indeed, in this case, (7) can be written as

$$x_i^r + (1 - t_r)f_i(x^r) = (1 - t_r)\sqrt{(x_i^r)^2 + f_i^2(x^r) + 2\varepsilon},\ i = 1, \dots, n. \tag{8}$$

Squaring both sides of the above and simplifying, we have

$$x_i^r f_i(x^r) = \frac{1}{2}\left[(1 - t_r) - \frac{1}{1 - t_r}\right](x_i^r)^2 + (1 - t_r)\varepsilon,\ i = 1, \dots, n.$$

Since $t_r \in (0,1)$, the above equation implies that $x_i^r \neq 0$ for all $i = 1, \dots, n$. Denote $\mu_r = 1 - t_r$. We see from the above equation that

$$f_i(x^r) = \frac{1}{2}\left(\mu_r - \frac{1}{\mu_r}\right)x_i^r + \frac{\mu_r \varepsilon}{x_i^r},\ i = 1, \dots, n. \tag{9}$$

We further show that $x^r \in R^n_{++}$. In fact, it follows from (8) that

$$x_i^r + \mu_r f_i(x^r) > \mu_r\sqrt{2\varepsilon} > 0,\ i = 1, \dots, n. \tag{10}$$

On the other hand, by using (9) we obtain

$$x_i^r + \mu_r f_i(x^r) = \frac{1}{2}(\mu_r^2 + 1)x_i^r + \frac{\mu_r^2 \varepsilon}{x_i^r},\ i = 1, \dots, n.$$

Combining (10) and the above equation yields $x^r \in R^n_{++}$. Since $\|x^r\| = r$, it is clear that $\|x^r\| \to \infty$ as $r \to \infty$. Consequently, the sequence $\{x^r\}$ is an interior-point-ε-exceptional family for f. □

The above result shows that if f has no interior-point-ε-exceptional family for each $\varepsilon > 0$, then property (a) of the mapping $\mathcal{U}(\cdot)$ holds. From the result, it is interesting to study various practical conditions under which a continuous function does not possess an interior-point-ε-exceptional family for every $\varepsilon \in (0, \infty)$. In the next section, we provide several such conditions ensuring the aforementioned desirable properties of the mapping $\mathcal{U}(\cdot)$.

4. Sufficient conditions for properties of $\mathcal{U}(\cdot)$.

4.1. E$_0$-function. In this section, we prove that the multivalued mapping $\mathcal{U}(\cdot)$ has properties (a) and (b) if f is a continuous E$_0$-function satisfying a certain properness condition. Moreover, if $F_\varepsilon(x)$ given by (6) is weakly univalent, then property (c) also holds. Applied to P$_0$ complementarity problems, this existence result extends a recent result due to Gowda and Tawhid [13]. The following lemma is quite useful.

Lemma 4.1. *Let $f : R^n \to R^n$ be an E_0-function. Then for any sequence $\{u^k\} \subset R^n_{++}$ with $\|u^k\| \to \infty$, there exist an index i and a subsequence of $\{u^k\}$, denoted by $\{u^{k_j}\}$, such that $u_i^{k_j} \to \infty$ and $f_i(u^{k_j})$ is bounded below.*

Proof. This proof has appeared in several works, see [11, 13, 35, 38]. Let $\{u^k\} \subset R^n_{++}$ be a sequence satisfying $\|u^k\| \to \infty$. Choosing a subsequence if necessary, we may suppose that there exists an index set $I \subseteq \{1, \dots, n\}$ such that $u_i^k \to \infty$ for each $i \in I$, and $\{u_i^k\}$ is bounded for each $i \notin I$. Let $v^k \in R^n$ be a vector constructed as follows:

$$v_i^k = u_i^k \text{ for } i \notin I, \quad v_i^k = 0 \text{ for } i \in I.$$

Thus, $\{v^k\}$ is a bounded sequence. Clearly, $u^k \geq v^k$. Since f is an E$_0$-function, there exist an index $i \in I$ and a subsequence of $\{u^k\}$, denoted by $\{u^{k_j}\}$, such that $u_i^{k_j} > v_i^{k_j}$ and $f_i(u^{k_j}) \geq f_i(v^{k_j})$ for all j. Thus,

$$f_i(u^{k_j}) \geq \inf_j f_i(v^{k_j}).$$

Note that the right-hand side of the above inequality is bounded. The desired result follows. □

To show the main result of this subsection, we will make use of the following assumption which is weaker than several previously known conditions.

Condition 4.1. *For any sequence $\{x^k\}$ satisfying*

(i) *$\{x^k\} \subset R^n_{++}$, $\|x^k\| \to \infty$ and $[-f(x^k)]_+/\|x^k\| \to 0$, and*

(ii) *for each index i with $x_i^k \to \infty$, the corresponding sequence $\{f_i(x^k)\}$ is bounded above, and*

(iii) *there exists at least one index i_0 such that $x_{i_0}^k \to \infty$ and $\{f_{i_0}(x^k)\}$ is bounded, it holds that*

$$\max_{1 \leq i \leq n} x_i^{k_l} f_i(x^{k_l}) \to \infty$$

for some subsequence $\{x^{k_l}\}$.

As we see in the following result the above condition encompasses several particular cases; we omit the details.

Proposition 4.1. *Condition* 4.1 *is satisfied if one of the following conditions holds.*

(C1) *For any positive sequence $\{x^k\} \subset R^n_{++}$ with $\|x^k\| \to \infty$ and $[-f(x^k)]_+/\|x^k\| \to 0$, it holds that $\max_{1\leq i \leq n} x_i^{k_l} f_i(x^{k_l}) \to \infty$ for some subsequence $\{x^{k_l}\}$.*

(C2) *For any sequence $\{x^k\} \subset R^n_{++}$ with $\|x^k\| \to \infty$ and $\min_{1\leq i\leq n} f_i(x^k)/\|x^k\| \to 0$, it holds that $\max_{1\leq i\leq n} x_i^{k_l} f_i(x^{k_l}) \to \infty$ for some subsequence $\{x^{k_l}\}$.*

(C3) [22, 29] *For any sequence $\{x^k\}$ with $\|x^k\| \to \infty$, $[-x^k]_+/\|x^k\| \to 0$, and $[-f(x^k)]_+/\|x^k\| \to 0$, it holds that*

$$\liminf_{k\to\infty} (x^k)^T f(x^k)/\|x^k\| > 0.$$

(C4) [13] *For any sequence* $\{x^k\}$ *with* $\|x^k\| \to \infty$,

$$\liminf_{k\to\infty} \frac{\min_{1\le i\le n} x_i^k}{\|x^k\|} \ge 0, \quad \textit{and} \quad \liminf_{k\to\infty} \frac{\min_{1\le i\le n} f_i(x^k)}{\|x^k\|} \ge 0,$$

there exist an index j *and a subsequence* $\{x^{k_l}\}$ *such that* $x_j^{k_l} f_j(x^{k_l}) \to \infty$.

(C5) [6, 39] f *is a* R_0*-function.*

(C6) [14, 25, 30, 31] f *is monotone and the NCP is strictly feasible.*

(C7) [27] f *is a uniform P-function.*

Remark 4.1. The condition (C1) of the above proposition is weaker than each of the conditions (C2) through (C7). (C2) is weaker than each of the conditions (C4) through (C7). The concept of the R$_0$-function, a generalization of the R_0-matrix [8], was introduced in [39] and later modified in [6].

In what follows, we show under a properness condition that the short "interior band" $\bigcup_{\varepsilon\in(0,\bar\varepsilon]} \mathcal{U}(\varepsilon)$ is bounded for each given $\bar\varepsilon > 0$. The boundedness is important because it implies that the sequence $\{x(\varepsilon_k)\}$, where $x(\varepsilon_k) \in \mathcal{U}(\varepsilon_k)$ and $\varepsilon_k \to 0$, is bounded and each accumulation point of the sequence is a solution to the NCP provided that f is continuous. We impose the following condition on f.

Condition 4.2. *For any positive sequence* $\{x^k\} \subset R^n_{++}$ *such that* $\|x^k\| \to \infty$, $\lim_{k\to\infty}[-f(x^k)]_+ = 0$, *and the sequence* $\{f_i(x^k)\}$ *is bounded for each index* i *with* $x_i^k \to \infty$, *it holds that*

$$\max_{1\le i\le n} x_i^{k_l} f_i(x^{k_l}) \to \infty$$

for some subsequence $\{x^{k_l}\}$.

Clearly, Condition 4.2 is weaker than Condition 4.1 and thereby weaker than all conditions listed in Proposition 4.1. We now prove the boundedness of the short "interior band" under the above condition.

Lemma 4.2. *Suppose that Condition* 4.2 *is satisfied. If* $\mathcal{U}(\varepsilon) \ne \emptyset$ *for each* $\varepsilon > 0$, *then for any* $\bar\varepsilon > 0$ *the set* $\bigcup_{\varepsilon\in(0,\bar\varepsilon]} \mathcal{U}(\varepsilon)$ *is bounded, i.e., property* (b) *holds. Particularly,* $\mathcal{U}(\varepsilon)$ *is bounded for each* $\varepsilon > 0$.

Proof. Suppose that there exists some $\bar\varepsilon > 0$ such that $\bigcup_{\varepsilon\in(0,\bar\varepsilon]} \mathcal{U}(\varepsilon)$ is unbounded. Then there exists a sequence $\{x(\varepsilon_k)\}$, where $\varepsilon_k \in (0, \bar\varepsilon]$, such that $\|x(\varepsilon_k)\| \to \infty$ as $k \to \infty$. Since $x(\varepsilon_k) \in \mathcal{U}(\varepsilon_k)$, we deduce that $[-f(x(\varepsilon_k))]_+ = 0$ for all k, and that

$$0 < f_i(x(\varepsilon_k)) = \frac{\varepsilon_k}{x_i(\varepsilon_k)} < \frac{\bar\varepsilon}{x_i(\varepsilon_k)} \quad \text{for all } i = 1, \dots, n.$$

Thus, for each i such that $x_i(\varepsilon_k) \to \infty$, the sequence $\{f_i(x(\varepsilon_k))\}$ is bounded. By Condition 4.2, we deduce that there exists a subsequence $\{x(\varepsilon_{k_l})\}$ such that

$$\max_{1\le i\le n} x_i(\varepsilon_{k_l}) f_i(x(\varepsilon_{k_l})) \to \infty.$$

This is a contradiction since $x_i(\varepsilon_{k_l}) f_i(x(\varepsilon_{k_l})) = \varepsilon_{k_l} < \bar\varepsilon$ for all $i = 1, \dots, n$. □

The main result on E$_0$-functions is given as follows. Even for P$_0$-functions, this result is new.

Theorem 4.1. *Suppose that* f *is a continuous* E_0*-function and Condition* 4.1 *is satisfied. Then the properties* (a) *and* (b) *of the mapping* $\mathcal{U}(\varepsilon)$ *hold. Moreover, if* $F_\varepsilon(x)$ *defined by* (6) *is weakly univalent in* x, *then the mapping* $\mathcal{U}(\cdot)$ *is upper-semicontinuous, i.e., property* (c) *also holds.*

Proof. To prove property (a), by Theorem 3.1, it suffices to show that there exists no interior-point-ε-exceptional family of f for any $\varepsilon > 0$. Assume to the contrary that for certain $\varepsilon > 0$ the function f has an interior-point-ε-exceptional family $\{x^r\}$. Since $\|x^r\| \to \infty$, $\{x^r\} \subset R^n_{++}$, and f is an E$_0$-function, by Lemma 4.1 there exist some index m and a subsequence $\{x^{r_j}\}$, such that $x^{r_j}_m \to \infty$ and $f_m(x^{r_j})$ is bounded below. From (4), we have

$$0 > \frac{1}{2}\left(\mu_{r_j} - \frac{1}{\mu_{r_j}}\right) x^{r_j}_m = f_m(x^{r_j}) - \frac{\mu_{r_j}\varepsilon}{x^{r_j}_m}.$$

Since $x^{r_j}_m \to \infty$ and $f_m(x^{r_j})$ is bounded below, the right-hand side of the above equation is bounded below. It follows that $\lim_{j\to\infty} \mu_{r_j} = 1$.

On the other hand, we note that for any $0 < \mu < 1$ the function

$$\phi(t) = \frac{1}{2}\left(\mu - \frac{1}{\mu}\right) t + \frac{\mu\varepsilon}{t} \tag{11}$$

is monotonically decreasing with respect to the variable $t \in (0, \infty)$. Passing through a subsequence, we may suppose that there exists an index set $I \subseteq \{1, \dots, n\}$ such that $x^{r_j}_i \to \infty$ for each $i \in I$, and $\{x^{r_j}_i\}$ is bounded for each $i \notin I$.

If $i \notin I$, then there exists some scalar $C > 0$ such that $x^{r_j}_i \le C$ for all j. Since $\phi(t)$ is decreasing and $\mu_{r_j} \to 1$, we have

$$f_i(x^{r_j}) = \frac{1}{2}\left(\mu_{r_j} - \frac{1}{\mu_{r_j}}\right) x^{r_j}_i + \frac{\mu_{r_j}\varepsilon}{x^{r_j}_i} \ge \frac{1}{2}\left(\mu_{r_j} - \frac{1}{\mu_{r_j}}\right) C + \frac{\mu_{r_j}\varepsilon}{C} \to \frac{\varepsilon}{C} > 0.$$

Thus, for all sufficiently large j, we have

$$[-f_i(x^{r_j})]_+ = 0 \ \text{ for all } i \notin I.$$

If $i \in I$, by using (4) and the facts $\mu_{r_j} \to 1$ and $x^{r_j}_i \to \infty$, we have

$$\frac{f_i(x^{r_j})}{\|x^{r_j}\|} = \frac{1}{2}\left(\mu_{r_j} - \frac{1}{\mu_{r_j}}\right) \frac{x^{r_j}_i}{\|x^{r_j}\|} + \frac{\mu_{r_j}\varepsilon}{x^{r_j}_i \|x^{r_j}\|} \to 0,$$

which implies that

$$[-f_i(x^{r_j})]_+/\|x^{r_j}\| \to 0 \ \text{ for all } i \in I.$$

Therefore, $[-f(x^{r_j})]_+/\|x^{r_j}\| \to 0$. Moreover, it follows from (4) that

$$f_i(x^{r_j}) \le \frac{\mu_{r_j}\varepsilon}{x^{r_j}_i} \le \frac{\varepsilon}{x^{r_j}_i} \to 0 \text{ for all } i \in I,$$

which implies that $\{f_i(x^{r_j})\}$ is bounded above for all $i \in I$. Since $m \in I$ and $\{f_m(x^{r_j})\}$ is bounded below, the sequence $\{f_m(x^{r_j})\}$ is indeed bounded. From Condition 4.1, there is a subsequence of $\{x^{r_j}\}$, denoted also by $\{x^{r_j}\}$, such that

$$\max_{1\le i\le n} x^{r_j}_i f_i(x^{r_j}) \to \infty.$$

However, from (4) we have

$$x^{r_j}_i f_i(x^{r_j}) = \frac{1}{2}\left(\mu_{r_j} - \frac{1}{\mu_{r_j}}\right) (x^{r_j}_i)^2 + \mu_{r_j}\varepsilon \le \mu_{r_j}\varepsilon < \varepsilon \tag{12}$$

for all $i \in \{1, \dots, n\}$. This is a contradiction. Property (a) of $\mathcal{U}(\varepsilon)$ follows.

Since Condition 4.1 implies Condition 4.2, the boundedness of the set $\bigcup_{\varepsilon \in (0,\bar{\varepsilon}]} \mathcal{U}(\varepsilon)$ follows immediately from Lemma 4.2. It is known that $x(\varepsilon) \in \mathcal{U}(\varepsilon)$ if and only if $x(\varepsilon)$ is a solution to the equation $F_\varepsilon(x) = 0$, i.e., $\mathcal{U}(\varepsilon) = F_\varepsilon^{-1}(0)$. Since $\mathcal{U}(\varepsilon)$ is bounded, the set $F_\varepsilon^{-1}(0)$ is bounded (in fact, compact, since f is continuous). If $F_\varepsilon(x)$ is weakly univalent in x, by Lemma 2.2, for each scalar $\delta > 0$ there is a $\gamma > 0$ such that for any weakly univalent function $h : R^n \to R^n$ with

$$\sup_{x \in \bar{\Omega}} \|h(x) - F_\varepsilon(x)\| < \gamma, \text{ where } \Omega = F_\varepsilon^{-1}(0) + \delta B, \tag{13}$$

we have

$$\emptyset \neq h^{-1}(0) \subseteq F_\varepsilon^{-1}(0) + \delta B. \tag{14}$$

It is easy to see that for the given $\gamma > 0$ there exists a scalar $\beta > 0$ such that

$$\sup_{x \in \bar{\Omega}} \|F_{\varepsilon'}(x) - F_\varepsilon(x)\| < \gamma \text{ for all } |\varepsilon' - \varepsilon| < \beta.$$

Setting $h(x) := F_{\varepsilon'}(x)$ in (13) and (14), we obtain that $\emptyset \neq F_{\varepsilon'}^{-1}(0) \subseteq F_\varepsilon^{-1}(0) + \delta B$ for all $|\varepsilon' - \varepsilon| < \beta$, i.e., $\mathcal{U}(\varepsilon') \subseteq \mathcal{U}(\varepsilon) + \delta B$ for all ε' sufficiently close to ε. Thus, $\mathcal{U}(\varepsilon)$ is upper-semicontinuous. □

Ravindran and Gowda [35] showed that if f is a P_0-function, then $F_\varepsilon(x)$ given by (6) is a P-function in x, and hence the equation $F_\varepsilon(x) = 0$ has at most one solution $x(\varepsilon)$. In this case, the upper-semicontinuity of $\mathcal{U}(\cdot)$ reduces to the continuity of $x(\varepsilon)$. By the fact that every P_0-function is an E_0-function and is weakly univalent, we have the following result from Theorem 4.1.

COROLLARY 4.1. *Suppose that $f : R^n \to R^n$ is a continuous P_0-function and Condition* 4.1 *is satisfied. Then the central path exists and any slice of it is bounded, i.e., for each $\varepsilon > 0$ there exists a unique $x(\varepsilon)$ satisfying the system* (1)*, $x(\varepsilon)$ is continuous on* $(0, \infty)$*, and the set* $\{x(\varepsilon) : \varepsilon \in (0, \bar{\varepsilon}]\}$ *is bounded for each $\bar{\varepsilon} > 0$.*

When f is a P_0-function, Gowda and Tawhid [13, Theorem 9] showed that the (long) central path exists if condition (C4) of Proposition 4.1 is satisfied. Corollary 4.1 can serve as a generalization of the Gowda and Tawhid result. It is worth noting that the consequences of Corollary 4.1 remain valid if condition (C1) or (C2) of Proposition 4.1 holds.

4.2. Quasi-P_*-maps. The concept of the quasi-P_*-map that is a generalization of the quasi monotone function and the P_*-map was first introduced in [46] to study the solvability of the NCP. Under the strictly feasible assumption as well as the following condition, we can show the nonemptyness and the boundedness of $\mathcal{U}(\cdot)$ if f is a continuous quasi-P_*-map .

CONDITION 4.3. *For any sequence $\{x^k\} \subset R^n_{++}$ such that*

$$\|x^k\| \to \infty, \lim_{k \to \infty} [-f(x^k)]_+ = 0,$$

and $\{f(x^k)\}$ is bounded, it holds that

$$\max_{1 \le i \le n} x_i^{k_l} f_i(x^{k_l}) \to \infty$$

for some subsequence $\{x^{k_l}\}$.

Clearly, the above condition is weaker than Conditions 4.1 and 4.2. It is also weaker than Condition 3.8 in [4] and Condition 1.5(iii) in [25]. The following is the main result of this subsection.

THEOREM 4.2. *Let f be a continuous quasi-P_*-map with the constant $\tau \geq 0$ (see Definition* 2.3*). Suppose that Condition* 4.3 *is satisfied. If the NCP is strictly feasible, then property* (a) *of $\mathcal{U}(\varepsilon)$ holds. Moreover, if Condition* 4.2 *is satisfied, then property* (b) *holds, and if $F_\varepsilon(x)$ is weakly univalent in x, then property* (c) *also holds.*

While the nonemptyness of $\mathcal{U}(\varepsilon)$ is ensured under Condition 4.3, it is not clear if the boundedness of $\mathcal{U}(\varepsilon)$ can follow from this condition. However, from the implications Condition 4.1$\Rightarrow$ Condition 4.2 $\Rightarrow$ Condition 4.3, we have the next consequence.

COROLLARY 4.2. *Suppose that f is a continuous quasi-P_*-map and $F_\varepsilon(x)$ is weakly univalent in x. If the NCP is strictly feasible and Condition* 4.1 *or* 4.2 *is satisfied, then the mapping $\mathcal{U}(\cdot)$ has properties* (a), (b), *and* (c).

The proof of Theorem 4.2 is postponed until we have proved two technical lemmas.

LEMMA 4.3. *Let f satisfy Condition* 4.3*. Assume that $\{x^r\}_{r>0}$ is an interior-point-ε-exceptional family for f. If there exists a subsequence of $\{x^r\}$, denoted by $\{x^{r_k}\}$, such that for some $0 < \gamma < 1$,*

$$\lim_{k\to\infty}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)\|x^{r_k}\|^{1+\gamma} = 0, \tag{15}$$

then we have

$$\lim_{k\to\infty}\left(\min_{1\leq i\leq n} x_i^{r_k}\right) = 0.$$

Proof. Suppose that $\{x^{r_k}\}$ is an arbitrary subsequence of $\{x^r\}$ such that (15) holds. Since $\phi(t)$ defined by (11) is decreasing on $(0,\infty)$, for each $i \in \{1,\dots,n\}$ we have

$$f_i(x^{r_k}) \leq \frac{1}{2}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)\min_{1\leq i\leq n} x_i^{r_k} + \frac{\mu_{r_k}\varepsilon}{\min_{1\leq i\leq n} x_i^{r_k}} \tag{16}$$

and

$$f_i(x^{r_k}) \geq \frac{1}{2}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)\max_{1\leq i\leq n} x_i^{r_k} + \frac{\mu_{r_k}\varepsilon}{\max_{1\leq i\leq n} x_i^{r_k}}. \tag{17}$$

Suppose to the contrary that there exists a subsequence of $\{x^{r_k}\}$, denoted also by $\{x^{r_k}\}$, such that $\min_{1\leq i\leq n} x_i^{r_k} \geq \alpha > 0$ for all $k > 0$, where α is a constant. We derive a contradiction. Indeed, since $\mu_{r_k} - \frac{1}{\mu_{r_k}} < 0$, from (16) we have

$$f_i(x^{r_k}) \leq \frac{\mu_{r_k}\varepsilon}{\min_{1\leq i\leq n} x_i^{r_k}} \leq \frac{\varepsilon}{\alpha} \quad \text{for all } i = 1,\dots,n.$$

From (17) and the above relation, we obtain

$$\frac{\varepsilon}{\alpha} \geq f_i(x^{r_k}) \geq \frac{1}{2}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)\max_{1\leq i\leq n} x_i^{r_k} \quad \text{for all } i = 1,\dots,n. \tag{18}$$

Since $\|x^{r_k}\| \to \infty$, we deduce from (15) that

$$\lim_{k\to\infty}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)\max_{1\leq i\leq n} x_i^{r_k} = 0.$$

Therefore, it follows from (18) that there exists a scalar c such that $c \le f_i(x^{r_k}) \le \varepsilon/\alpha$ for all $i = 1, \ldots, n$ and $\lim_{k\to\infty}[-f_i(x^{r_k})]_+ = 0$. By Condition 4.3, there exists a subsequence of $\{x^{r_k}\}$, denoted still by $\{x^{r_k}\}$, such that $\max_{1\le i\le n} x_i^{r_k} f_i(x^{r_k}) \to \infty$. However, from (12) we have that $x_i^{r_k} f(x_i^{r_k}) \le \mu_{r_k}\varepsilon < \varepsilon$ for all $i = 1, \ldots, n$. This is a contradiction. $\square$

LEMMA 4.4. *Let f satisfy Condition* 4.3. *Assume that $\{x^r\}$ is an interior-point-ε-exceptional family for f. Let $u > 0$ be an arbitrary vector in R^n. Then for any subsequence $\{x^{r_k}\}$ (where $r_k \to \infty$ as $k \to \infty$) there exists a subsequence of $\{x^{r_k}\}$, denoted still by $\{x^{r_k}\}$, such that $f(x^{r_k})^T(x^{r_k} - u) < 0$ for all sufficiently large k.*

Proof. Let $\{x^{r_k}\}$ be an arbitrary subsequence of $\{x^r\}$ (where $r_k \to \infty$ as $k \to \infty$). By using (4) we have

$$\begin{aligned} &f(x^{r_k})^T(x^{r_k} - u) \\ &= \frac{1}{2}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)\|x^{r_k}\|^2 + n\varepsilon\mu_{r_k} - \frac{1}{2}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)(x^{r_k})^T u - \sum_{i=1}^n \frac{\mu_{r_k}\varepsilon u_i}{x_i^{r_k}} \\ &= \frac{1}{2}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)(\|x^{r_k}\|^2 - (x^{r_k})^T u) + \mu_{r_k}\varepsilon\left(n - \sum_{i=1}^n \frac{u_i}{x_i^{r_k}}\right). \end{aligned} \tag{19}$$

We suppose that $f(x^{r_k})^T(x^{r_k} - u) \ge 0$ for all sufficiently large k. We derive a contradiction. From (19), we have

$$0 \le f(x^{r_k})^T(x^{r_k} - u) \le \frac{1}{2}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)(\|x^{r_k}\|^2 - (x^{r_k})^T u) + \mu_{r_k}\varepsilon n.$$

Since $\|x^{r_k}\| \to \infty$, for all sufficiently large k we have

$$0 \le \frac{1}{2}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)(\|x^{r_k}\|^2 - (x^{r_k})^T u) + \mu_{r_k}\varepsilon n \le \mu_{r_k}\varepsilon n,$$

which implies that

$$\begin{aligned} &\lim_{k\to\infty}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)\|x^{r_k}\|^{1+\gamma} \\ &\quad = \lim_{k\to\infty}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)(\|x^{r_k}\|^2 - (x^{r_k})^T u)\frac{\|x^{r_k}\|^{1+\gamma}}{\|x^{r_k}\|^2 - (x^{r_k})^T u} \\ &\quad = 0 \end{aligned}$$

for any scalar $0 < \gamma < 1$. Thus, we see from Lemma 4.3 that

$$\min_{1\le i\le n} x_i^{r_k} \to 0. \tag{20}$$

Notice that

$$\frac{1}{2}\left(\mu_{r_k} - \frac{1}{\mu_{r_k}}\right)(\|x^{r_k}\|^2 - (x^{r_k})^T u) < 0$$

for all sufficiently large k. From (19), (20), and the above inequality, we have

$$f(x^{r_k})^T(x^{r_k} - u) \le \mu_{r_k}\varepsilon\left(n - \sum_{i=1}^n \frac{u_i}{x_i^{r_k}}\right) \le \mu_{r_k}\varepsilon\left(n - \frac{\min_{1\le i\le n} u_i}{\min_{1\le i\le n} x_i^{r_k}}\right) < 0$$

for all sufficiently large k. This is a contradiction. $\square$

We are now ready to prove the results of Theorem 4.2.

Proof of Theorem 4.2. To show property (a) of the mapping $\mathcal{U}(\varepsilon)$, by Theorem 3.1, it suffices to show that f has no interior-point-ε-exceptional family for any $\varepsilon > 0$. Assume to the contrary that there exists an interior-point-ε-exceptional family for f, denoted by $\{x^r\}$. By the strict feasibility of the NCP, there is a vector $u > 0$ such that $f(u) > 0$. Consider two possible cases.

Case (A). There exists a number $r_0 > 0$ such that

$$\max_{1\le i\le n}(x_i^r - u_i)(f_i(x^r) - f_i(u)) < 0 \quad \text{for all } r \ge r_0.$$

In this case, the index set $I_+(x^r, u)$ is empty. Since $f(u) > 0,\ x^r > 0$, and $\|x^r\| \to \infty$, it is easy to see that

$$f(u)^T(x^r - u) > 0$$

for all sufficiently large r. Since f is a quasi-P$_*$-map and $I_+(x^r, u)$ is empty, the above inequality implies that $f(x^r)^T(x^r - u) \ge 0$ for all sufficiently large r. However, by Lemma 4.4 there exists a subsequence of $\{x^r\}$, denoted by $\{x^{r_k}\}$, such that $f(x^{r_k})^T(x^{r_k} - u) < 0$ for all sufficiently large k. This is a contradiction.

Case (B). There exists a subsequence of $\{x^r\}$ denoted by $\{x^{r_j}\}$, where $r_j \to \infty$ as $j \to \infty$, such that

$$\max_{1\le i\le n}(x_i^{r_j} - u_i)(f_i(x^{r_j}) - f_i(u)) \ge 0 \quad \text{for all } j.$$

By using (4), for each i we have

$$\begin{aligned} A_i^{(r_j)} &:= (x_i^{r_j} - u_i)(f_i(x^{r_j}) - f_i(u)) \\ &= (x_i^{r_j} - u_i)\left(-\frac{1}{2}\left(\frac{1}{\mu_{r_j}} - \mu_{r_j}\right)x_i^{r_j} - f_i(u) + \frac{\mu_{r_j}\varepsilon}{x_i^{r_j}}\right). \end{aligned} \tag{21}$$

There exist a subsequence of $\{x^{r_j}\}$, denoted also by $\{x^{r_j}\}$, and a fixed index m such that

$$A_m^{(r_j)} := (x_m^{r_j} - u_m)(f_m(x^{r_j}) - f_m(u)) = \max_{1\le i\le n}(x_i^{r_j} - u_i)(f_i(x^{r_j}) - f_i(u)).$$

For each i such that $x_i^{r_j} \to \infty$, (21) implies that $A_i^{(r_j)} \to -\infty$. Since $A_m^{(r_j)} \ge 0$ for all j, we deduce that $\{x_m^{r_j}\}$ is bounded, i.e., there is a constant $\bar{\delta}$ such that $0 < x_m^{r_j} \le \bar{\delta}$ for all j.

If $x_m^{r_j} \le u_m$, setting $i = m$ in (21), we have

$$\begin{aligned} A_m^{(r_j)} &\le (u_m - x_m^{r_j})\left(\frac{1}{2}\left(\frac{1}{\mu_{r_j}} - \mu_{r_j}\right)x_m^{r_j} + f_m(u)\right) \\ &\le u_m\left(\frac{1}{2}\left(\frac{1}{\mu_{r_j}} - \mu_{r_j}\right)u_m + f_m(u)\right). \end{aligned} \tag{22}$$

If $u_m < x_m^{r_j} \le \bar{\delta}$, setting $i = m$ in (21), we obtain

$$A_m^{(r_j)} \le (x_m^{r_j} - u_m)\frac{\mu_{r_j}\varepsilon}{x_m^{r_j}} \le \mu_{r_j}\varepsilon < \varepsilon. \tag{23}$$

We consider two subcases, choosing a subsequence whenever it is necessary.

Subcase 1. $\mu_{r_j} \to 1$. From (22) and (23), for all sufficiently large j we have

$$A_m^{(r_j)} \leq \max\left\{\varepsilon, u_m\left(f_m(u)+\frac{u_m}{2}\right)\right\}.$$

Thus, for all sufficiently large j, we obtain

$$\begin{aligned} &f(u)^T(x^{r_j}-u)-\tau\max_{1\leq i\leq n}(x_i^{r_j}-u_i)(f_i(x^{r_j})-f_i(u)) \\ &\geq f(u)^T(x^{r_j}-u)-\tau\max\{\varepsilon, u_m(f_m(u)+u_m/2)\} \\ &> 0. \end{aligned}$$

The last inequality above follows from the fact that $f(u)>0, \{x^{r_j}\}\subset R^n_{++}$, and $\|x^{r_j}\|\to\infty$. Since f is a quasi-P$_*$-map, the above inequality implies that $f(x^{r_j})^T(x^{r_j}-u)\geq 0$ for all sufficiently large j, which is impossible according to Lemma 4.4.

Subcase 2. There exists a subsequence of $\{\mu_{r_j}\}$, denoted also by $\{\mu_{r_j}\}$, such that $\mu_{r_j}\leq\delta^*$ for all j, where $0<\delta^*<1$. In this case, from (22) and (23), we have

$$A_m^{(r_j)} \leq \max\left\{\varepsilon, u_m f_m(u)+\frac{u_m^2}{2}\left(\frac{1}{\mu_{r_j}}-\mu_{r_j}\right)\right\}.$$

It follows from (4) that

$$\begin{aligned} T^{(r_j)} &:= f(x^{r_j})^T(u-x^{r_j})-\tau\max_{1\leq i\leq n}(x_i^{r_j}-u_i)(f_i(x^{r_j})-f_i(u)) \\ &= \frac{1}{2}\left(\frac{1}{\mu_{r_j}}-\mu_{r_j}\right)(\|x^{r_j}\|^2-(x^{r_j})^Tu)+\mu_{r_j}\varepsilon\left(\sum_{i=1}^n\frac{u_i}{x_i^{r_j}}-n\right)-\tau A_m^{(r_j)}. \end{aligned}$$

We now show that $T^{(r_j)}>0$ for all sufficiently large j.

If $\varepsilon\leq u_m f_m(u)+\frac{u_m^2}{2}(\frac{1}{\mu_{r_j}}-\mu_{r_j})$, noting that $\mu_{r_j}\leq\delta^*$ and $\|x^{r_j}\|^2-(x^{r_j})^Tu-\tau u_m^2\to\infty$ as $j\to\infty$, we obtain

$$\begin{aligned} T^{(r_j)} &\geq \frac{1}{2}\left(\frac{1}{\mu_{r_j}}-\mu_{r_j}\right)(\|x^{r_j}\|^2-(x^{r_j})^Tu-\tau u_m^2)-\tau u_m f_m(u)-\mu_{r_j}\varepsilon n \\ &\geq \frac{1}{2}\left(\frac{1}{\delta^*}-\delta^*\right)(\|x^{r_j}\|^2-(x^{r_j})^Tu-\tau u_m^2)-\tau u_m f_m(u)-\delta^*\varepsilon n>0. \end{aligned}$$

If $\varepsilon>u_m f_m(u)+\frac{u_m^2}{2}(\frac{1}{\mu_{r_j}}-\mu_{r_j})$, by the same argument as the above, we can show that

$$T^{(r_j)}\geq\frac{1}{2}\left(\frac{1}{\delta^*}-\delta^*\right)(\|x^{r_j}\|^2-(x^{r_j})^Tu)-\delta\varepsilon n-\tau\varepsilon>0$$

for all sufficiently large j. Thus, by the quasi-P$_*$-property of f, we deduce from $T^{(r_j)}>0$ that $f(u)^T(u-x^{r_j})\geq 0$ for all sufficiently large j. It is a contradiction since $\{x^{r_j}\}\subset R^n_{++}, \|x^{r_j}\|\to\infty$, and $f(u)>0$.

The above contradictions show that f has no interior-point-ε-exceptional family for each $\varepsilon>0$. By Theorem 3.1, the set $\mathcal{U}(\varepsilon)\neq\emptyset$ for any $\varepsilon>0$. The boundedness of the short "interior band " follows from Lemma 4.2, and the upper-semicontinuity of $\mathcal{U}(\varepsilon)$ follows easily from Lemma 2.2. $\square$

The class of quasi-P$_*$-maps includes the quasi monotone functions as particular cases. The following result is an immediate consequence of Theorem 4.2.

Corollary 4.3. *Suppose that f is a continuous quasi monotone (in particular, pseudomonotone) function, and the NCP is strictly feasible.*

(i) *If Condition* 4.3 *is satisfied, then property* (a) *of $\mathcal{U}(\varepsilon)$ holds.*

(ii) *If Condition* 4.2 *is satisfied, then properties* (a) *and* (b) *of $\mathcal{U}(\varepsilon)$ hold.*

In the case when $F_\varepsilon(x)$ is univalent (continuous and one-to-one) in x, the equation $F_\varepsilon(x) = 0$ has at most one solution. Combining this fact and Theorem 4.2, we have the following result concerning the existence of the central path of the NCP. To our knowledge, this result can be viewed as the first existence result on the central path for the NCP with a (generalized) quasi monotone function. Up to now, there is no interior-point type algorithms designed for solving (generalized) quasi monotone complementarity problems.

Corollary 4.4. *Let f be a quasi-P_*-map, and $F_\varepsilon(x)$ is univalent in x. If the NCP is strictly feasible and Condition* 4.2 *is satisfied, then the central path exists and the set $\{x(\varepsilon) : \varepsilon \in (0, \bar{\varepsilon}]\}$ is bounded for any given $\bar{\varepsilon} > 0$.*

Particularly, if f is a P$_0$-function, then $F_\varepsilon(x)$ is univalent in x (see [35]). We have the following result.

Corollary 4.5. *Let f be a continuous P_0 and quasi-P_*-map. If the NCP is strictly feasible and Condition* 4.2 *is satisfied, then the conclusions of Corollary* 4.4 *are valid.*

4.3. $P(\tau, \alpha, \beta)$-maps.

It is well known (see [14, 25, 30, 31]) that the monotonicity combined with strict feasibility implies the existence of the central path. In this section, we extend the result to a class of nonmonotone complementarity problems. Our result states that if f is a P(τ, α, β) and P$_0$-map (see Definition 2.4), the central path exists provided that the NCP is strictly feasible. This result gives an answer to the question "What class of nonlinear functions beyond P$_*$-maps can ensure the existence of the central path if the NCP is strictly feasible?" We first show properties of the mapping $\mathcal{U}(\cdot)$ when f is a $P(\tau, \alpha, \beta)$-map.

Theorem 4.3. *Let f be a continuous $P(\tau, \alpha, \beta)$-map. If the NCP is strictly feasible, then properties* (a) *and* (b) *of $\mathcal{U}(\varepsilon)$ hold. Moreover, if $F_\varepsilon(x)$ is weakly univalent in x, property* (c) *also holds.*

Proof. Suppose that there exists a scalar $\varepsilon > 0$ such that f has an interior-point-ε-exceptional family denoted by $\{x^r\}$. Since $\{x^r\} \subset R^n_{++}$ and $\|x^r\| \to \infty$ as $r \to \infty$, there exist some p and a subsequence denoted by $\{x^{r_j}\}$, where $r_k \to \infty$ as $j \to \infty$, such that $\|x^{r_j}\| \to \infty$ and

$$x_p^{r_j} - u_p = \max_{1 \le i \le n} (x_i^{r_j} - u_i).$$

Clearly, $x_p^{r_j} \to \infty$ as $j \to \infty$. On the other hand, there exists a subsequence of $\{x^{r_j}\}$, denoted also by $\{x^{r_j}\}$, such that for some fixed index m and for all j we have

$$(x_m^{r_j} - u_m)(f_m(x^{r_j}) - f_m(u)) = \max_{1 \le i \le n} (x^{r_j} - u_i)(f_i(x^{r_j}) - f_i(u)).$$

By the definition of the P(τ, α, β)-map, we have

$$\begin{aligned}(x_p^{r_j}-u_p)&(f_p(x^{r_j})-f_p(u))\\ &\geq \min_{1\leq i\leq n}(x_i^{r_j}-u_i)(f_i(x^{r_j})-f_i(u))\\ &\geq -(1+\tau)\max_{1\leq i\leq n}(x_i^{r_j}-u_i)(f_i(x^{r_j})-f_i(u))-\alpha\|x^{r_j}-u\|^\beta\\ &= -(1+\tau)(x_m^{r_j}-u_m)(f_m(x^{r_j})-f_m(u))-\alpha\|x^{r_j}-u\|^\beta. \end{aligned} \tag{24}$$

From (4), we have that $f_p(x^{r_j})<\varepsilon/x_p^{r_j}$, and hence

$$B_p^{(r_j)} := \frac{(x_p^{r_j}-u_p)(f_p(x^{r_j})-f_p(u))}{\|x^{r_j}-u\|^\beta} \leq \frac{(x_p^{r_j}-u_p)}{\|x^{r_j}-u\|^\beta}\left(\frac{\varepsilon}{x_p^{r_j}}-f_p(u)\right). \tag{25}$$

It is easy to see that

$$\frac{\|x^{r_j}-u\|^\beta}{x_p^{r_j}-u_p} = \left(\frac{\|x^{r_j}-u\|}{x_p^{r_j}-u_p}\right)^\beta \cdot \frac{1}{(x_p^{r_j}-u_p)^{(1-\beta)}} \leq \frac{n^{\beta/2}}{(x_p^{r_j}-u_p)^{1-\beta}}. \tag{26}$$

Combining (25) and (26) leads to

$$B_p^{(r_j)} \to -\infty \quad \text{as } j\to\infty.$$

From

$$B_p^{(r_j)} \geq B_{min}^{r_j} := \min_{1\leq i\leq n}\frac{(x_i^{r_j}-u_i)(f_i(x^{r_j})-f_i(u))}{\|x^{r_j}-u\|^\beta},$$

we deduce that

$$B_{min}^{r_j} \to -\infty \quad \text{as } j\to\infty. \tag{27}$$

We now show that $\{x_m^{r_j}\}$ is bounded. Assume that there exists a subsequence of $\{x_m^{r_j}\}$, denoted still by $\{x_m^{r_j}\}$, such that $x_m^{r_j}\to\infty$. Then, from (21), we have

$$(x_m^{r_j}-u_m)(f_m(x^{r_j})-f_m(u)) \to -\infty,$$

and hence for all sufficiently large j we have

$$B_m^{(r_j)} := \frac{(x_m^{r_j}-u_m)(f_m(x^{r_j})-f_m(u))}{\|x^{r_j}-u\|^\beta} = \max_{1\leq i\leq n}\frac{(x_i^{r_j}-u_i)(f_i(x^{r_j})-f_i(u))}{\|x^{r_j}-u\|^\beta} < 0.$$

By (27) and the above relation, we obtain

$$(1+\tau)B_m^{(r_j)} + B_{min}^{r_j} \to -\infty \text{ as } j\to\infty. \tag{28}$$

However, since f is a P(τ,α,β)-map, we have

$$(1+\tau)B_m^{(r_j)} + B_{min}^{r_j} \geq -\alpha,$$

which contradicts (28). This contradiction shows that the sequence $\{x_m^{r_j}\}$ is bounded.

By using (4) and (24), we have

$$\begin{aligned}&-(x_p^{r_j}-u_p)\left(\frac{1}{2}\left(\frac{1}{\mu_{r_j}}-\mu_{r_j}\right)x_p^{r_j}+f_p(u)-\frac{\mu_{r_j}\varepsilon}{x_p^{r_j}}\right)\\ &\quad\geq (1+\tau)(x_m^{r_j}-u_m)\left(\frac{1}{2}\left(\frac{1}{\mu_{r_j}}-\mu_{r_j}\right)x_m^{r_j}+f_m(u)-\frac{\mu_{r_j}\varepsilon}{x_m^{r_j}}\right)-\alpha\|x^{r_j}-u\|^\beta.\end{aligned}$$

Multiplying both sides of the above inequality by $1/(x_p^{r_j} - u_p)$, rearranging terms, and using (26), we have

$$\begin{aligned}
&-\frac{1}{2}\left(\frac{1}{\mu_{r_j}} - \mu_{r_j}\right)\left(x_p^{r_j} + \frac{(1+\tau)x_m^{r_j}(x_m^{r_j} - u_m)}{x_p^{r_j} - u_p}\right)\\
&\geq f_p(u) - \frac{\mu_{r_j}\varepsilon}{x_p^{r_j}} + (1+\tau)\left(\frac{f_m(u)(x_m^{r_j} - u_m)}{x_p^{r_j} - u_p} - \frac{\mu_{r_j}\varepsilon(x_m^{r_j} - u_m)}{x_m^{r_j}(x_p^{r_j} - u_p)}\right) - \frac{\alpha\|x^{r_j} - u\|^\beta}{x_p^{r_j} - u_p}\\
&\geq f_p(u) - \frac{\varepsilon}{x_p^{r_j}} - \frac{(1+\tau)f_m(u)u_m}{x_p^{r_j} - u_p} - \frac{(1+\tau)\varepsilon}{x_p^{r_j} - u_p} - \frac{\alpha n^{\beta/2}}{(x_p^{r_j} - u_p)^{1-\beta}}.
\end{aligned}$$

For all sufficiently large j, the left-hand side of the above inequality is negative, but the right-hand side tends to $f_p(u) > 0$ as $j \to \infty$. This is a contradiction. The contradiction shows that f has no interior-point-ε-exceptional family for every $\varepsilon > 0$. By Theorem 3.1, property (a) of $\mathcal{U}(\varepsilon)$ follows. The proof of the boundedness of the set $\bigcup_{\varepsilon\in(0,\bar{\varepsilon}]}\mathcal{U}(\varepsilon)$ is not straightforward. It can be proved by the same argument as the above. Indeed, we suppose that $\{x(\varepsilon_k)\}_{0<\varepsilon_k<\bar{\varepsilon}} \subseteq \bigcup_{\varepsilon\in(0,\bar{\varepsilon}]}\mathcal{U}(\varepsilon)$ is an unbounded sequence. Replacing $\{x^{r_j}\}$ by $\{x(\varepsilon_k)\}$, using

$$f(x(\varepsilon_k)) = \frac{\varepsilon_k}{x(\varepsilon_k)} < \frac{\bar{\varepsilon}}{x(\varepsilon_k)}$$

instead of (4), and repeating the aforementioned proof, we can derive a contradiction. The upper-semicontinuity of $\mathcal{U}(\cdot)$ can be obtained by Lemma 2.2. The proof is complete. □

The class of $\mathrm{P}(\tau,\alpha,\beta)$-maps includes several particular cases such as $P(\tau,\alpha,0)$-, $\mathrm{P}(\tau,0,0)$-, and $\mathrm{P}(0,\alpha,\beta)$-maps. It is shown in [46] that the class of $\mathrm{P}(\tau,0,0)$-maps coincides with the class of P_*-maps. Therefore, f is said to be a P_*-map if and only if there exists a nonnegative scalar $\kappa \geq 0$ such that

$$(1+\kappa)\max_{1\leq i\leq n}(x_i - y_i)(f_i(x) - f_i(y)) + \min_{1\leq i\leq n}(x_i - y_i)(f_i(x) - f_i(y)) \geq 0.$$

Particularly, a matrix $M \in R^{n\times n}$ is a P_*-matrix if and only if there is a constant $\kappa \geq 0$ such that

$$(1+\kappa)\max_{1\leq i\leq n} x_i(Mx)_i + \min_{1\leq i\leq n} x_i(Mx)_i \geq 0.$$

This is an equivalent definition of the concept of a P_*-matrix (sufficient matrix) introduced by Kojima et al. [26] and Cottle, Pang, and Venkateswaran [9]. The following result follows immediately from Theorem 4.3.

Corollary 4.6. *Let f be a continuous P_0 and $P(\tau,\alpha,\beta)$-map. If the NCP is strictly feasible, then the central path exists and any slice of it is bounded.*

It is worth noting that each P_*-map is a P_0 and a $\mathrm{P}(\tau,\alpha,\beta)$-function. The following result is a straightforward consequence of the above corollary.

Corollary 4.7. *Let f be a continuous P_*-map. If the NCP is strictly feasible, then the central path exists and any slice of it is bounded.*

It should be pointed out that P_*-maps are also special instances of quasi-P_*-maps. A result similar to Corollary 4.3 can be stated for P_*-maps. However, as we have shown in Corollary 4.7, the additional conditions such as Conditions 4.1, 4.2, and 4.3 are not necessary for a P_*-map to guarantee the existence of the central path. While P_*-maps and quasi monotone functions are contained in the class of quasi-P_*-maps, Zhao and Isac [46] gave examples to show that a P_*-map, in general, is not a quasi monotone function, and vice versa.

4.4. Exceptionally regular functions. In section 4.1, we study the properties of the mapping $\mathcal{U}(\varepsilon)$ for E_0-functions satisfying a properness condition, i.e., Condition 4.1. In sections 4.2, we show properties of $\mathcal{U}(\varepsilon)$ for quasi-P_*-maps under the strictly feasible condition as well as some properness conditions. In the above section, properness assumptions are removed, and properties of $\mathcal{U}(\varepsilon)$ for $P(\tau, \alpha, \beta)$-maps are proved under the strictly feasible condition only. In this section, removing both the strictly feasible condition and properness conditions, we prove that properties of $\mathcal{U}(\varepsilon)$ hold if f is an exceptionally regular function. The exceptional regularity of a function (see Definition 2.5) was originally introduced in [46] to investigate the existence of a solution to the NCP.

Definition 4.1. [16] *A map $v : R^n \to R^n$ is said to be positively homogeneous of degree $\alpha > 0$ if $v(tx) = t^\alpha v(x)$ for all $x \in R^n$.*

When $\alpha = 1$, the above concept reduces to the standard concept of positive homogeneity. Under the assumption of positively homogeneous of degree $\alpha > 0$, we can show that properties (a) and (b) of $\mathcal{U}(\varepsilon)$ hold if f is exceptionally regular. See the following result.

Theorem 4.4. *Let f be a continuous and exceptionally regular function from R^n into R^n. If $G(x) = f(x) - f(0)$ is positively homogeneous of degree $\alpha > 0$, then properties* (a) *and* (b) *of $\mathcal{U}(\varepsilon)$ hold. Moreover, if $F_\varepsilon(x)$ is weakly univalent, property* (c) *also holds.*

Proof. Suppose that there is a scalar $\varepsilon > 0$ such that f has an interior-point-ε-exceptional family $\{x^r\}$. We derive a contradiction. Indeed, since $G(x)$ is positively homogeneous of degree $\alpha > 0$, we have

$$f(x^r) = f(0) + \|x^r\|^\alpha (f(x^r/\|x^r\|) - f(0)).$$

Without loss of generality, assume that $x^r/\|x^r\| \to \hat{x}$. From the above relation, we have

$$\lim_{r\to\infty} f(x^r)/\|x^r\|^\alpha = f(\hat{x}) - f(0) = G(\hat{x}). \tag{29}$$

From (4), we have

$$\frac{1}{2}\left(\frac{1}{\mu_r} - \mu_r\right) = -\frac{f_i(x^r)}{x_i^r} + \frac{\mu_r \varepsilon}{(x_i^r)^2} \quad \text{for all } i = 1, \dots, n. \tag{30}$$

Let $I_+(\hat{x}) = \{i : \hat{x}_i > 0\}$. Since $\|x^r\| \to \infty$ and $x_i^r/\|x^r\| \to \hat{x}_i$, we deduce that $x_i^r \to \infty$ for each $i \in I_+(\hat{x})$. We now show that

$$\lim_{r\to\infty} \frac{1}{2}\left(\frac{1}{\mu_r} - \mu_r\right) \frac{\|x^r\|}{\|x^r\|^\alpha} = \hat{\mu} \tag{31}$$

for some $\hat{\mu} \geq 0$. It is sufficient to show the existence of the above limit. Indeed, for each $i \in I_+(\hat{x})$, by using (30) and (29) we have

$$\lim_{r\to\infty} \frac{1}{2}\left(\frac{1}{\mu_r} - \mu_r\right) \frac{\|x^r\|}{\|x^r\|^\alpha} = \lim_{r\to\infty} \frac{\|x^r\|}{x_i^r} \left(-\frac{f_i(x^r)}{\|x^r\|^\alpha} + \frac{\mu_r \varepsilon}{x_i^r \|x^r\|^\alpha}\right) = -\frac{G_i(\hat{x})}{\hat{x}_i}.$$

Thus, (31) holds, with

$$\frac{G_i(\hat{x})}{\hat{x}_i} = -\hat{\mu} \quad \text{for all } i \in I_+(\hat{x}). \tag{32}$$

Now, we consider the case of $i \notin I_+(\hat{x})$. In this case, $\hat{x}_i = 0$. By using (4), (31), and (29), we see from $x_i^r/\|x^r\| \to 0$ that

$$\begin{aligned} 0 \le \lim_{r\to\infty} \frac{\mu_r \varepsilon}{x_i^r \|x^r\|^\alpha} &= \lim_{r\to\infty} \left(\frac{f_i(x^r)}{\|x^r\|^\alpha} + \frac{(1/\mu_r - \mu_r)x_i^r}{2\|x^r\|^\alpha} \right) \\ &= \lim_{r\to\infty} \left(\frac{f_i(x^r)}{\|x^r\|^\alpha} + \frac{(1/\mu_r - \mu_r)\|x^r\|}{2\|x^r\|^\alpha} \cdot \frac{x_i^r}{\|x^r\|} \right) \\ &= G_i(\hat{x}), \end{aligned}$$

i.e.,

$$G_i(\hat{x}) \ge 0 \quad \text{for all } i \notin I_+(\hat{x}).$$

Combining (32) and the above relation implies that f is not exceptionally regular. This is a contradiction. The contradiction shows that f has no interior-point-ε-exceptional family for each $\varepsilon > 0$, and hence property (a) of $\mathcal{U}(\varepsilon)$ follows from Theorem 3.1. Property (b) of $\mathcal{U}(\varepsilon)$ can be easily proved. Actually, suppose that there exists a sequence $\{x(\varepsilon_k)\}_{0<\varepsilon_k<\bar{\varepsilon}}$ with $\|x(\varepsilon_k)\| \to \infty$, where $x(\varepsilon_k) \in \mathcal{U}(\varepsilon_k)$. Without loss of generality, let $x(\varepsilon_k)/\|x(\varepsilon_k)\| \to \bar{x}$, where $\|\bar{x}\| = 1$. As in the proof of (29) we have

$$0 \le \lim_{k\to\infty} f(x(\varepsilon_k))/\|x(\varepsilon_k)\|^\alpha = G(\bar{x}).$$

Since $x(\varepsilon_k) \in \mathcal{U}(\varepsilon_k)$, we have that $x_i(\varepsilon_k) f_i(x(\varepsilon_k)) = \varepsilon_k$ for all $i = 1, \ldots, n$. Thus,

$$0 = \lim_{k\to\infty} \frac{x_i(\varepsilon_k) f_i(x(\varepsilon_k))}{\|x(\varepsilon_k)\|^{1+\alpha}} = \bar{x}_i G_i(\bar{x}) \quad \text{for all } i = 1, \ldots, n.$$

Therefore,

$$G_i(\bar{x}) = 0 \quad \text{whenever } \bar{x}_i > 0, \ \text{and } G_i(\bar{x}) \ge 0 \quad \text{whenever } \bar{x}_i = 0,$$

which contradicts the exceptional regularity of $f(x)$. □

It is not difficult to see that a strictly copositive map and a strictly semimonotone function are special cases of exceptionally regular maps. Hence, we have the following result.

COROLLARY 4.8. *Suppose that $G(x) = f(x) - f(0)$ is positively homogeneous of degree $\alpha > 0$. Then conclusions of Theorem 4.4 are valid if one of the following conditions holds.*

(i) *f is an E_0-function, and for each $0 \ne x \ge 0$ there exists an index i such that $x_i > 0$ and $f_i(x) \ne f_i(0)$.*

(ii) *f is strictly copositive, that is, $x^T(f(x) - f(0)) > 0$ for all $0 \ne x \ge 0$.*

(iii) *f is a strictly semimonotone function.*

Proof. Since each of the above conditions implies that $f(x)$ is exceptionally regular, the result follows immediately from Theorem 4.4. □

Motivated by Definition 2.5, we introduce the following concept.

DEFINITION 4.2. *$M \in R^{n\times n}$ is said to be an exceptionally regular matrix if for all $\beta \ge 0, M + \beta I$ is an R_0-matrix.*

It is evident that an exceptionally regular matrix is an R_0-matrix, but the converse is not true. The following result is an immediate consequence of Theorem 4.4 and its corollary.

COROLLARY 4.9. *Let $f = Mx + q$, where $M \in R^{n\times n}$, and q is an arbitrary vector in R^n. If one of the following conditions is satisfied, then properties* (a) *and* (b) *of the mapping $\mathcal{U}(\varepsilon)$ hold:*

(i) *$M \in R^{n\times n}$ is an exceptionally regular matrix.*

(ii) *M is a strictly copositive matrix.*

(iii) *M is a strictly semimonotone matrix.*

(iv) *M is an E_0-matrix, and for each $0 \neq x \geq 0$ there exists an index i such that $x_i > 0$ and $(Mx)_i \neq 0$ (possibly, $(Mx)_i < 0$).*

Furthermore, if M is also a P_0-matrix, then the central path of a linear complementarity problem exists and any slice of it is bounded.

The R_0-property of f has played an important role in the complementarity theory. We close this section by considering this situation. The concept of a nonlinear R_0-function was first introduced by Tseng [38] and later modified by Chen and Harker [6]. We now give a definition of the R_0-function that is different from those in [38] and [6].

Definition 4.3. *$f : R^n \to R^n$ is said to be an R_0-function if $x = 0$ is the unique solution to the following complementarity problem:*

$$G(x) = f(x) - f(0) \geq 0,\ x \geq 0,\ x^T G(x) = 0.$$

This concept is a natural generalization of the R_0-matrix [8]. In fact, for the linear function $f(x) = Mx + q$, it is easy to see that f is an R_0-function if and only if M is an R_0-matrix. In the case when f is an E_0-function, we have shown in Theorem 4.1 that there exists a subsequence $\{\mu_{r_k}\}$ such that $\mu_{r_k} \to 1$. Moreover, if G is positively homogeneous, then from (31) we deduce that $\hat{\mu} = 0$. By using these facts and the above R_0-property and repeating the proof of Theorem 4.4, we have the following result.

Theorem 4.5. *Suppose that $G(tx) = tG(x)$ for each scalar $t \geq 0$ and $x \in R^n$, and that f is an E_0 and R_0-function. Then the conclusions of Theorem* 4.4 *remain valid. Moreover, if f is a P_0 and R_0 -function, the central path exists and any slice of it is bounded.*

5. Conclusions. We introduced the concept of the interior-point-ε-exceptional family for continuous functions, which is important since it strongly pertains to the existence of an interior-point $x(\varepsilon) \in \mathcal{U}(\varepsilon)$ and the central path, even to the solvability of NCPs. By means of this concept, we proved that for every continuous NCP the set $\mathcal{U}(\varepsilon)$ is nonempty for each scalar $\varepsilon > 0$ if there exists no interior-point-ε-exceptional family for f. Based on the result, we established some sufficient conditions for the assurance of some desirable properties of the multivalued mapping $\mathcal{U}(\varepsilon)$ associated with certain nonmonotone complementarity problems. Since properties (a) and (b) of $\mathcal{U}(\varepsilon)$ imply that the NCP has a solution, the argument of this paper based on the interior-point-ε-exceptional family can serve as a new analysis method for the existence of a solution to the NCP.

It is worth noting that any point in $\mathcal{U}(\varepsilon)$ is strictly feasible, i.e., $x(\varepsilon) > 0$ and $f(x(\varepsilon)) > 0$. Therefore, the analysis method in this paper can also be viewed as a tool for investigating the strict feasibility of a complementarity problem. In fact, from Theorems 3.1, 4.1, 4.4, and 4.5, we have the following result.

Theorem 5.1. *Let f be a continuous function. Then the complementarity problem is strictly feasible whenever one of the following conditions holds.*

(i) *There exists a scalar $\varepsilon^* > 0$ such that f has no interior-point-ε^*-exceptional family.*

(ii) *f is an E_0-function and Condition* 4.1 *is satisfied.*

(iii) *$G(x) = f(x) - f(0)$ is positively homogeneous of degree $\alpha > 0$ and f is exceptionally regular.*

(iv) *$f(x) = Mx + q$, where M is an E_0 and R_0-matrix.*

It should be pointed out that the results and the argument of this paper can be easily extended to other interior-point paths. For instance, we can consider the existence of the path

$$(33) \qquad \{(x(\varepsilon), y(\varepsilon)) > 0 : \varepsilon > 0, y(\varepsilon) = f(x(\varepsilon)) + \varepsilon b, x_i(\varepsilon) y_i(\varepsilon) = \varepsilon a_i \text{ for all } i\}$$

(where b and $a > 0$ are fixed vectors in R^n) first studied by Kojima, Megiddo, and Noma [25]. (When $a = \varepsilon e, b = 0$, the above path reduces to the central path). This path can be studied by the concept of interior-point-$\varepsilon(a, b)$-exceptional family. For a continuous function $f : R^n \to R^n$, we say that a sequence $\{x^r\} \subset R^n_{++}$ is an interior-point-$\varepsilon(a, b)$-exceptional family for f if $\|x^r\| \to \infty$ as $r \to \infty$, and for each x^r there exists a positive number $\mu_r \in (0, 1)$ such that for each i

$$f_i(x^r) = -\varepsilon b_i + \frac{1}{2}\left[\mu_r - \frac{1}{\mu_r}\right] x_i^r + \frac{\mu_r \varepsilon a_i}{x_i^r}.$$

Using

$$F_i(x, \varepsilon) = x_i + (f_i(x) + \varepsilon b_i) - \sqrt{x_i^2 + (f_i(x) + \varepsilon b_i)^2 + 2\varepsilon a_i}$$

and arguing as in the same proof of Theorem 3.1, we can show that for any $\varepsilon > 0$ there exists either a point $x(\varepsilon)$ satisfying (33) or an interior-point-$\varepsilon(a, b)$-exceptional family for f. This result enables us to develop some sufficient conditions for the existence of the path (33).

Acknowledgments. The authors would like to thank the referees and Professor Jim Burke for their helpful suggestions and comments on an earlier version of this paper, which helped the authors to correct some mistakes and improve the presentation of the manuscript. They also thank Dr. Mustapha Ait Rami for his valuable comments.

THE VELOCITY TRACKING PROBLEM FOR NAVIER–STOKES FLOWS WITH BOUNDARY CONTROL*

M. D. GUNZBURGER† AND S. MANSERVISI‡

Abstract. We present some systematic approaches to the mathematical formulation and numerical approximation of the time-dependent optimal control problem of tracking the velocity for Navier–Stokes flows in a bounded, two-dimensional domain with boundary control. We study the existence of optimal solutions and derive an optimality system from which optimal solutions may be determined. We also define and analyze semidiscrete-in-time and full space-time discrete approximations of the optimality system and a gradient method for the solution of the fully discrete system. The results of some computational experiments are provided.

Key words. optimal control, Navier–Stokes equations, fluid mechanics

1. Introduction.

In this paper, we study a class of optimal flow control problems for which the fluid motion is controlled by velocity forcing, i.e., injection or suction, along a portion of the boundary and the cost or objective functional is a measure of the discrepancy between the flow velocity and a given target velocity. The fluid motion is constrained to satisfy the time-dependent Navier–Stokes equations for viscous, incompressible flows. In order to regularize the problem, e.g., to limit the size of the control, a quadratic penalization functional depending on the control is added to the cost functional.

Time-dependent optimal flow control problems have been considered by numerous authors, e.g., [1], [4], [5], [6], [7], [13], [14], [15], [16], [22], [23], [24], [25], [26], [27], [29], [30], [31], and [33]. A number of these papers deal with distributed force control in the momentum equation; this type of control is not realizable in most practical situations. Some of these papers only treat questions concerning the existence of optimal solutions and the derivation of optimality systems from which optimal controls and states may be deduced. Others present formal derivations of optimality systems, define algorithms for the approximation of solutions of these systems, and the results of numerical experiments. The objective functionals considered in most of these papers differ from the one considered here, although in many cases, including the one of this paper, the analysis can be extended. Furthermore, in much of the literature, controls are assumed to be separable, i.e., to be the product of a function of time and a function of the space variables; in some cases the second function is assumed known so that control is effected only through a function depending on time. Finally, in some papers, the optimal control problems are set in function spaces that are not practical for numerical approximations.

For example, in [1], partial results about optimal boundary control problems are given. The formulation is not suitable for some applications and the function space proposed for the solution may not allow easy finite element implementations. More consistent are the results in [16] for the drag minimization problem in unbounded domains. In that paper, the method used for the derivation of the optimality system is different from the one used here. Their analyses also apply to bounded domains and the method can be applied with small changes to other cost functionals. However, the function spaces used there are again not useful in practical calculations and no numerical algorithms or numerical analyses are given. In [4], algorithmic issues are discussed and numerical experiments are presented for separable boundary controls, but no numerical analyses are given.

The aim of this paper is to provide a complete and consistent analysis of an optimal boundary control problem for the Navier–Stokes equations and to present the results of some simple numerical experiments. The mathematical framework of this paper, as well as the algorithms developed and analyzed, can be extended to a broad class of practical boundary control problems for partial differential equations in bounded domains.

We now describe the problem of time-dependent boundary control for the Navier–Stokes system that models the velocity tracking problem through a quadratic functional. This problem reflects the desire to steer, over time, a candidate velocity field $\vec{u}$ to a given target velocity field $\vec{U}$ by appropriately controlling the velocity along a portion of the boundary of the flow domain. We consider a two-dimensional flow over the time interval $[0,T]$ in the physical domain Ω with boundary Γ with control effected over $\Gamma_c \subset \Gamma$. The equations considered here are the nondimensional incompressible Navier–Stokes equations

$$(1)\qquad \begin{cases} \vec{u}_t + (\vec{u}\cdot\nabla)\vec{u} - \nu\Delta\vec{u} + \nabla p = \vec{0} & \text{in } (0,T)\times\Omega, \\ \nabla\cdot\vec{u} = 0 \quad \text{in } (0,T)\times\Omega, \\ \vec{u} = \vec{g} \quad \text{on } (0,T)\times\Gamma_c, \\ \vec{u} = \vec{0} \quad \text{on } (0,T)\times(\Gamma\setminus\Gamma_c) \end{cases}$$

with initial velocity $\vec{u}(0,\vec{x}) = \vec{u}_0(\vec{x})$. The vector $\vec{u} = (u_1, u_2)$ denotes the velocity, p the pressure, and ν the constant kinematic viscosity coefficient. We note that for appropriate nondimensionalizations, the Reynolds number is equal to $1/\nu$. The boundary velocity control is denoted by $\vec{g}$ and is required to satisfy the compatibility conditions

$$(2)\qquad \int_{\Gamma_c} \vec{g}\cdot\vec{n}\, d\vec{x} = 0,$$

where $\vec{n}$ denotes the unit outward normal vector along Γ, and

$$(3)\qquad \vec{g}|_{t=0} = \vec{u}_0|_{\Gamma_c}.$$

Thus, the control is required to effect zero mass flow across the boundary and to match, at the initial time, the initial flow $\vec{u}_0$ on the boundary. The first of these is necessary in view of the incompressibility condition and the second in order to obtain the appropriate regularity for the solution of the Navier–Stokes system.

The optimal control problem is formulated as follows:

find a boundary control $\vec{g}$ and a velocity field $\vec{u}$ such that the cost functional

$$\mathcal{J}(\vec{u},\vec{g}) = \frac{\alpha}{2}\int_0^T \int_\Omega |\vec{u}-\vec{U}|^2 \, d\vec{x}dt + \frac{\beta}{2}\int_0^T \int_{\Gamma_c} (|\vec{g}|^2 + \beta_1|\vec{g}_t|^2 + \beta_2|\vec{g}_x|^2) \, d\vec{x}dt \tag{4}$$

is minimized subject to $(\vec{u},\vec{g})$ *satisfying* (1)–(2).

The minimization of the first term involving $(\vec{u}-\vec{U})$ in (4) is the real goal of the velocity tracking problem; the other terms have been introduced in order to bound the control function and to prove the existence of an optimal control. We can effectively limit the size of the control through an appropriate choice of the positive coefficients β, β_1, and β_2.

This paper is organized as follows. In the remainder of this section we introduce some notation and results that will be useful in what follows. In section 2, we give a precise definition of the optimal control problem and prove the existence of optimal solutions. Also, first-order necessary conditions are derived and optimal solutions are characterized as solution of a system of partial differential equations. Semidiscretizations in time and full space-time discretizations are treated in sections 3 and 4, respectively. Issues related to the numerical implementation of the fully discrete algorithms are discussed in section 5 and the results of some computational experiments are presented in section 6.

1.1. Notation and preliminary results.

We introduce the following standard notations over a bounded, connected, open set Ω in $\mathbb{R}^2$ with boundary $\Gamma \in C^2$. Let $\vec{n} = (n_1, n_2)$ and $\vec{\tau}$ denote the unit normal and tangent vectors, respectively. Let $I = (0,T)$, $Q = I \times \Omega$, $S = I \times \Gamma$, and $S_c = I \times \Gamma_c$, where Γ_c denotes the part of the boundary on which control is applied. Also, we denote $\Omega_0 = \Omega \times \{0\}$ and $\Gamma_0 = \Gamma \times \{0\}$.

We shall use the standard notations for the Sobolev spaces (and their vector-valued, i.e., $\mathbb{R}^2$-valued, counterparts) $H^m(\Omega)$ with norm $\|\cdot\|_m$; we also use the notations $L^2(\Omega) = H^0(\Omega)$ with $\|\cdot\| = \|\cdot\|_0$ and $\mathcal{D}(\Omega)$ for the space of distributions. Let $H_0^m(\Omega)$ denote the closure of $C_0^\infty(\Omega)$ under the norm $\|\cdot\|_m$ and $H_0^{-m}(\Omega)$ denote the dual space of $H_0^m(\Omega)$. We introduce the solenoidal spaces $\mathcal{V}(\Omega)$, $V(\Omega)$, and $W(\Omega)$ as

$$\mathcal{V}(\Omega) = \{\vec{u} \in C_0^\infty(\Omega) : \nabla\cdot\vec{u} = 0\},$$
$$V(\Omega) = \{\vec{u} \in H_0^1(\Omega) : \nabla\cdot\vec{u} = 0\},$$
$$W(\Omega) = \{\vec{u} \in L^2(\Omega) : \nabla\cdot\vec{u} = 0\}.$$

The dual space of $V(\Omega)$ is denoted by $V(\Omega)^*$. Also, we define

$$L_0^2(\Omega) = \left\{ p \in L^2(\Omega) : \int_\Omega p \, d\vec{x} = 0 \right\}.$$

Let X be a Banach space and (a,b) an open set of $\mathbb{R}$. We denote by $L^p((a,b);X)$ $(1 \le p < \infty)$ the space of functions $f(t) : (a,b) \to X$ such that f is measurable and

$$\|f\|_{L^p((a,b);X)} = \left(\int_a^b \|f(t)\|_X^p \right)^{1/p}$$

is finite. We also denote by $L^\infty((a,b);X)$ the space of functions f from (a,b) into X such that f is measurable and is bounded almost everywhere (a.e.) over (a,b) and we set

$$\|f\|_{L^\infty((a,b);X)} = \inf_{\|f(t)\| \le M a.e.} (M).$$

We define the following anisotropic Sobolev spaces. Let r and $s \geq 0$ and $Q = (a,b) \times \Omega$. We let

$$H^{r,s}(Q) = L^2((a,b); H^r(\Omega)) \cap H^s((a,b); L^2(\Omega)) \tag{5}$$

with the norm

$$\|u\|_{H^{r,s}} = (\|u\|^2_{L^2((a,b);H^r)} + \|u\|^2_{H^s((a,b);L^2)})^{1/2}.$$

For details about these spaces, see, e.g., [2], [12], [17], [19], and [28].

In order to define a weak form of the Navier–Stokes equations, we introduce two continuous bilinear forms

$$a(\vec{u},\vec{v}) = 2\nu \sum_{i,j=1}^{n} \int_\Omega D_{ij}(\vec{u}) D_{ij}(\vec{v})\, d\vec{x} \qquad \forall\, \vec{u},\, \vec{v} \in H^1(\Omega), \tag{6}$$

$$b(\vec{v},q) = -\int_\Omega q \nabla \cdot \vec{v}\, d\vec{x} \qquad \forall\, q \in L^2(\Omega), \quad \forall\, \vec{v} \in H^1(\Omega), \tag{7}$$

where $D_{ij}(\vec{v}) = \frac{1}{2}(\partial v_i/\partial x_j + \partial v_j/\partial x_i)$, and the continuous trilinear form

$$c(\vec{w};\vec{u},\vec{v}) = \sum_{i,j=1}^{n} \int_\Omega w_j \left(\frac{\partial u_i}{\partial x_j}\right) v_i\, d\vec{x} \qquad \forall\, \vec{w},\, \vec{u},\, \vec{v} \in H^1(\Omega).$$

We will also make use the following operators:

$$\begin{aligned}
&A : H^1(\Omega) \to H^{-1}(\Omega) && (8)\\
&\qquad \langle A\vec{u}, \vec{v}\rangle = a(\vec{u},\vec{v}) \quad \forall\, \vec{u} \in H^1(\Omega), \quad \forall\, \vec{v} \in H^1_0(\Omega), \\
&C : H^1(\Omega) \times H^1(\Omega) \to H^{-1}(\Omega) && (9)\\
&\qquad \langle C(\vec{w})\vec{u}, \vec{v}\rangle = c(\vec{w};\vec{u},\vec{v}) \quad \forall\, \vec{w}, \vec{u} \in H^1(\Omega), \quad \forall\, \vec{v} \in H^1_0(\Omega), \\
&B : H^1(\Omega) \to L^2_0(\Omega) && (10)\\
&\qquad \langle B\vec{u}, p\rangle = b(\vec{u},p) \quad \forall\, p \in L^2_0(\Omega), \quad \forall\, \vec{u} \in H^1(\Omega), \\
&B^* : L^2_0(\Omega) \to H^{-1}(\Omega) && (11)\\
&\qquad \langle \vec{u}, B^* p\rangle = b(\vec{u},p) \quad \forall\, p \in L^2_0(\Omega), \quad \forall\, \vec{u} \in H^1_0(\Omega).
\end{aligned}$$

We will denote by πA and πC the projections of these operators on $V(\Omega)$.

In the rest of the paper, we limit our domain $\Omega \subset \mathbb{R}^2$ to be an open bounded set with simply connected boundary $\Gamma \in C^2$. We define

$$\begin{aligned}
&curl(H^2)(\Omega) = \left\{ \vec{v} \in H^1(\Omega) \ : \ \nabla \cdot \vec{v} = 0, \quad \int_\Gamma \vec{v} \cdot \vec{n}\, d\vec{x} = 0 \right\}, \\
&H^1_n(\Gamma) = \left\{ \vec{g} \in H^1(\Gamma) \ : \ \int_\Gamma \vec{g} \cdot \vec{n}\, d\vec{x} = 0 \right\}, \\
&H^1_{n0}(\Gamma_c) = H^1_0(\Gamma_c) \cap H^1_n(\Gamma_c),
\end{aligned}$$

where Γ_c is part of the boundary Γ. The set $curl(H^2)(\Omega)$ is a closed subspace of $H^1(\Omega)$, and $H^1_n(\Gamma)$ and $H^1_{n0}(\Gamma)$ are closed subspaces of $H^1(\Gamma)$. For details concerning these subspaces, see, e.g., [12]. We remark that the space $H^1(\Gamma)$ can be decomposed in $H^1_n(\Gamma) \oplus (H^1_n(\Gamma))^\perp$, where $(H^1_n(\Gamma))^\perp$ is the space of vectors normal to the surface with constant length. If $\vec{g} \in H^1(\Gamma)$, one can write $\vec{g} = \vec{g}_1 + \vec{g}_2$, where

$$\vec{g}_2 = a\vec{n}, \qquad a = \frac{\int_\Gamma \vec{g} \cdot \vec{n}\, d\vec{x}}{\mu(\Gamma)},$$
$$\vec{g}_1 = \vec{\tau}(\vec{g} \cdot \vec{\tau}) + \vec{n}(\vec{g} \cdot \vec{n} - a),$$

where $\vec{g}_1 \in H^1_n(\Gamma)$ and $\vec{g}_2 \in (H^1_n(\Gamma))^\perp$.

Some useful properties of the trilinear form $c(\vec{u}; \vec{v}, \vec{w})$ can be summarized as follows (see [1] and [29]):

(i)

$$(12) \quad \begin{cases} c(\vec{u};\vec{v},\vec{w}) = -c(\vec{u};\vec{w},\vec{v}) & \forall\, \vec{u} \in V(\Omega), \quad \forall\, \vec{v},\vec{w} \in H^1(\Omega), \\ c(\vec{u};\vec{v},\vec{w}) = -c(\vec{u};\vec{w},\vec{v}) & \forall\, \vec{u} \in curl(H^2)(\Omega), \quad \forall\, \vec{v} \in H^1(\Omega), \quad \forall\, \vec{w} \in H^1_0(\Omega), \end{cases}$$

(ii)

$$(13) \quad \begin{cases} c(\vec{u};\vec{v},\vec{v}) = 0 & \forall\, \vec{u} \in V(\Omega), \quad \forall\, \vec{v} \in H^1(\Omega), \\ c(\vec{u};\vec{v},\vec{v}) = 0 & \forall\, \vec{u} \in curl(H^2)(\Omega), \quad \forall\, \vec{v} \in H^1_0(\Omega), \end{cases}$$

(iii)

$$(14) \quad \begin{cases} |c(\vec{u};\vec{v},\vec{w})| \le \sqrt{2}\|\vec{u}\|^{1/2}\|\nabla\vec{u}\|^{1/2}\|\vec{w}\|^{1/2}\|\nabla\vec{w}\|^{1/2}\|\nabla\vec{v}\| & \forall\, \vec{u},\vec{v},\vec{w} \in H^1(\Omega), \\ |c(\vec{u};\vec{v},\vec{w})| \le C\|\vec{u}\|_1\|\vec{v}\|_1\|\vec{w}\|_1 \quad \forall\, \vec{u},\vec{v},\vec{w} \in H^1(\Omega), \end{cases}$$

where C is independent of the functions $\vec{u}, \vec{v}$, and $\vec{w}$.

We remark that (iii) cannot be extended to a three-dimensional domain. Since we shall make extensive use of this result, all our results will hold only for two-dimensional domains.

The form $c(\vec{u};\vec{u},\vec{w})$ is differentiable in $\vec{u}$ from $V(\Omega)$ into $V(\Omega)^*$. We denote by $c'(\vec{u};\vec{v},\vec{w})$ its variation with respect to a variation $\vec{v}$ in $\vec{u}$ and by $c^*(\vec{u};\vec{v},\vec{w})$ the adjoint of $c(\vec{v};\vec{u},\vec{w})$ for the duality between $V(\Omega)$ and $V(\Omega)^*$. For details about these derived forms, one may refer to [1].

In the rest of the paper we shall use γ and γ_k to denote trace operators, i.e., $\gamma\vec{f} = \gamma_0\vec{f} = \vec{f}_\Gamma$ and $\gamma_0\partial^k_n\vec{f} = \gamma_k\vec{f}$, where $\partial_n\vec{f} = n_1\partial_1\vec{f} + n_2\partial_2\vec{f}$, with $\partial_j\vec{f} = \partial\vec{f}/\partial x_j$.

2. Formulation and analysis of the optimal control problem.

2.1. Weak formulation of the optimal control problem. We consider an open bounded set $\Omega \subset \mathbb{R}^2$ with a boundary $\Gamma \in C^2$. $\vec{U}(t,\vec{x})$ is said to be in the set of *admissible target velocities* U_{ad} if

$$(15) \qquad \begin{cases} \vec{U} = \vec{U}(t,\vec{x}) \in C([0,T];H^1(\Omega)), \\ \vec{F}_{\vec{U}}(t,\vec{x}) \in L^\infty((0,T);L^2(\Omega)), \end{cases}$$

where $\vec{F}_{\vec{U}} = \vec{U}_t - \nu\nabla^2\vec{U} + (\vec{U}\cdot\vec{\nabla})\vec{U}$.

Let $\vec{u} \in L^2((0,T);H^1(\Omega))$ and $p \in L^2((0,T);L^2_0(\Omega))$ denote the state variables, i.e., the velocity and pressure fields, respectively. Let the boundary control $\vec{g}$ belong to $L^2((0,T);H^1_{n0}(\Gamma_c))$ with $\vec{g}_t \in L^2((0,T);L^2(\Gamma_c))$. The state variables are constrained to satisfy the weak form of the Navier–Stokes system (1) for almost all t in $(0,T)$, i.e.,

$$(16)\qquad \begin{cases} \langle \vec{u}_t, \vec{v}\rangle + \nu a(\vec{u},\vec{v}) + c(\vec{u};\vec{u},\vec{v}) + b(\vec{v},p) = 0 \quad \forall\, \vec{v} \in H_0^1(\Omega),\\ b(\vec{u},q) = 0 \quad \forall\, q \in L_0^2(\Omega),\\ (\vec{u},\vec{s})_\Gamma = (\vec{g}(t,\vec{x}),\vec{s})_{\Gamma_c} \quad \forall\, \vec{s} \in H^{-1/2}(\Gamma),\\ \vec{u}(0,\vec{x}) = \vec{u}_0(\vec{x}) \in curl(H^2)(\Omega). \end{cases}$$

More precisely, let $\vec{g} \in H^{1,1}(S_c) \cap L^2((0,T);H^1_{n0}(\Gamma_c))$ and $\vec{u}_0, \in curl(H^2)(\Omega)$. Then, $(\vec{u},p) \in L^2((0,T);H^1(\Omega)) \times L^2((0,T);L^2_0(\Omega))$ is called a *weak solution for the Navier–Stokes equations* if it satisfies (16).

If $\vec{u}$ is a solution of (1), then it is also solution of the weak formulation (16). If $\vec{u}$ is solution of (16), then it satisfies (1) in the sense of distributions on $(0,T)$. If $\vec{g}$, $\vec{u}_0$ are given as above, then we can show that there exists a unique admissible weak solution $(\vec{u},p)$ of (16) such that $\vec{u} \in L^\infty((0,T);W(\Omega)) \cap L^2((0,T);H^1(\Omega))$ and $\vec{u}_t \in L^2((0,T);H^{-1}(\Omega))$; i.e, it is a.e. equal to a continuous function [12].

THEOREM 2.1. *Let $\Omega \subset \mathbb{R}^2$ be an open, bounded domain with boundary Γ of class C^2. Let $\vec{g}(t,\vec{x})$ be a function belonging to $H^{1/2,1}(S)$ satisfying the compatibility conditions*

$$(17)\qquad \int_\Gamma \vec{g}\cdot\vec{n}\, d\Gamma = 0,$$

$$(18)\qquad \vec{g}(0,\vec{x}) = \vec{u}_0|_\Gamma.$$

Then, there exists a unique $\vec{u} \in L^2((0,T);H^1(\Omega)) \cap L^\infty((0,T);L^2(\Omega))$ and $p \in L^2((0,T);L^2_0(\Omega))$ that are the solution of the nonhomogeneous Navier–Stokes problem

$$(19)\qquad \begin{cases} \langle \vec{u}_t, \vec{v}\rangle + \nu\, a(\vec{u},\vec{v}) + c(\vec{u};\vec{u},\vec{v}) + b(\vec{v},p) = 0 \qquad \forall\, \vec{v} \in H_0^1(\Omega),\\ b(\vec{u},q) = 0 \quad \forall\, q \in L_0^2(\Omega),\\ \vec{u} = \vec{g}(t,\vec{x}) \quad \forall\, \vec{x} \in \Gamma,\\ \vec{u}(0,\vec{x}) = \vec{u}_0(\vec{x}) \in curl(H^2)(\Omega) \end{cases}$$

for almost all $t \in (0,T)$. Moreover,

$$(20)\qquad \|\vec{u}\|^2_{L^2((0,T);H^1)} + \|\vec{u}\|^2_{L^\infty((0,T);L^2)} \le K(\|\vec{g}\|^2_{H^{1/2,1}(S)} + \|\vec{u}_0\|^2_{H^{1/2}(\Gamma)}),$$

where K depends on $\vec{g}$.

A proof can be found in [29]. It is worthwhile to recall that that if $\|\vec{g}\|^2_{H^{1/2,1}(S)}$ is uniformly bounded, then also the norms on the left-hand side of (20) are uniformly bounded.

From the previous discussion we can define more precisely the set of admissible solutions which we denote by A_d.

> *Given $T > 0$, $\vec{u}_0 \in curl(H^2)(\Omega)$, and $\vec{U} \in U_{ad}$, then $(\vec{u},p,\vec{g})$ is called an admissible solution for the optimal control problem if $(\vec{u},p,\vec{g}) \in L^2((0,T);H^1(\Omega)) \times L^2((0,T);L^2_0(\Omega)) \times \in H^{1,1}(S_c) \cap L^2(0,T;H^1_{n0}(\Gamma_c))$ is a solution of* (16)*, the control $\vec{g}$ satisfies the compatibility conditions* (17)*–*(18)*, and the functional $\mathcal{J}(\vec{u},\vec{g})$ is bounded.*

The optimal control problem can then be formulated as follows:

given $\vec{u}_0 \in curl(H^2)(\Omega)$ and $\vec{U} \in U_{ad}$, find $(\vec{u}, p, \vec{g}) \in A_d$ such that the control $\vec{g}$ minimizes the cost functional

$$\mathcal{J}(\vec{u}, \vec{g}) = \frac{\alpha}{2} \int_0^T \int_\Omega (\vec{u} - \vec{U})^2 \, d\vec{x}dt + \frac{\beta}{2} \int_0^T \int_{\Gamma_c} (\vec{g}^2 + \beta_1 \vec{g}_x^2 + \beta_2 \vec{g}_t^2) \, d\vec{x}dt \tag{21}$$

with $\alpha, \beta, \beta_1, \beta_2 > 0$.

The first term represents the goal of our optimization and the second term is the penalty term necessary to regularize the solution. The requirement that β must be positive has similarities with the distributed control case; see, e.g., [1] and [22]. The requirement that β_1, β_2 should be different from zero is necessary if we want $\vec{g} \in H^{1,1}(S_c)$.

2.2. Existence of an optimal solution. In this section, we prove that the optimal control problem (21) is well posed and has at least one solution.

THEOREM 2.2. *Given $T > 0$ and $\vec{u}_0 \in curl(H^2)(\Omega)$, then there exists a solution $(\vec{u}, p, \vec{g}) \in A_d$ of the optimal control problem* (21).

Proof. We consider the following equivalent problem. Let $\vec{g} \in H^{1,1}(S_c) \cap L^2(0, T; H^1_{n0}(\Gamma_c))$ and $(\widetilde{u}, \widetilde{p})$ satisfy the linear Stokes equation

$$\begin{cases} \langle \widetilde{u}_t, \vec{v} \rangle + \nu a(\widetilde{u}, \vec{v}) + b(\vec{v}, \widetilde{p}) = 0 \qquad \forall \, \vec{v} \in H^1_0(\Omega), \\ b(\widetilde{u}, q) = 0 \quad \forall \, q \in L^2_0(\Omega), \\ (\widetilde{u}, \vec{s})_\Gamma = (\vec{g}(t, \vec{x}), \vec{s})_{\Gamma_c} \quad \forall \, \vec{s} \in H^{-1/2}(\Gamma), \\ \widetilde{u}(0, \vec{x}) = u_0 \in curl(H^2)(\Omega). \end{cases} \tag{22}$$

The problem is now to find $\widetilde{u}$ and a solution $(\widehat{u}, \widehat{p})$ of the system

$$\begin{cases} \langle \widehat{u}_t, \vec{v} \rangle + \nu a(\widehat{u}, \vec{v}) + c(\widehat{u}; \widehat{u}, \vec{v}) + c(\widetilde{u}; \widetilde{u}, \vec{v}) \\ + c(\widehat{u}; \widetilde{u}, \vec{v}) + c(\widetilde{u}; \widehat{u}, \vec{v}) + b(\vec{v}, \widehat{p}) = 0 \qquad \forall \, \vec{v} \in H^1_0(\Omega), \\ \widehat{u} \in V(\Omega), \end{cases} \tag{23}$$

such that the control $\vec{g}$ minimizes the cost functional

$$\mathcal{J}(\widetilde{u} + \widehat{u}, \vec{g}) = \frac{\alpha}{2} \int_0^T \int_\Omega (\widetilde{u} + \widehat{u} - \vec{U})^2 \, d\vec{x}dt + \frac{\beta}{2} \int_0^T \int_{\Gamma_c} (\vec{g}^2 + \beta_1 \vec{g}_t^2 + \beta_2 \vec{g}_x^2) \, d\vec{x}dt. \tag{24}$$

An admissible solution can be found by solving the above systems with boundary conditions $\vec{g} = \gamma \vec{u}_0$ $\forall t \in [0, T]$. Since the admissible set is not empty and the set of values assumed by the functional is bounded from below, let $\vec{g}_n$ be a minimizing sequence for the problem in (22)–(24) and set $\widetilde{u}_n = \widetilde{u}(\vec{g}_n)$ and $\widehat{u}_n = \widehat{u}(\widetilde{u}_n, \vec{g}_n)$. In the rest of the proof, we denote g_t by g'. The sequences $\{\vec{g}_n\}$ and $\{\vec{g}'_n\}$ are uniformly bounded in $L^2((0, T); H^1_{n0}(\Gamma_c))$ and $L^2((0, T); L^2(\Gamma_c))$, respectively; in fact we can easily choose the sequences such that $\mathcal{J}(\vec{u}_n, \vec{g}_n) \leq M$ $\forall n$, where M is the value of the functional for an admissible solution. The boundary velocity $\widetilde{u}$ is thus uniformly bounded in $L^2((0, T); H^{1/2}_0(\Gamma_c))$ and the corresponding solutions $\widetilde{u}_n$ and $\widehat{u}_n$ are uniformly bounded in the set $L^\infty((0, T); L^2(\Omega)) \cap L^2((0, T); H^1(\Omega))$. Hence, there is a $(\widetilde{u}, \widehat{u}, \vec{g})$ and a subsequence of $(\widetilde{u}_m, \widehat{u}_m, \vec{g}_m)$ that converges weakly to $(\widetilde{u}, \widehat{u}, \vec{g})$. We write

$$\begin{array}{llll} \vec{g}_m & \to \vec{g} & \text{in} & L^2((0,T);H^1_{n0}(\Gamma_c)) & \text{weakly,} \\ \vec{g}'_m & \to \vec{g}' & \text{in} & L^2((0,T);L^2(\Gamma_c)) & \text{weakly,} \\ \widetilde{u}_m & \to \widetilde{u} & \text{in} & L^2((0,T);H^1(\Omega)) & \text{weakly,} \\ \widehat{u}_m & \to \widehat{u} & \text{in} & L^2((0,T);V(\Omega)) & \text{weakly,} \\ \widehat{u}_m & \to \widehat{u} & \text{in} & L^\infty((0,T);W(\Omega)) & *\text{-weakly.} \end{array}$$

Now, $(\widetilde{u},\widehat{u},\vec{g})$ satisfies the system of (22)–(23) and minimizes the functional. In fact, by the lower semicontinuity of the functional (24), we have

$$\mathcal{J}(\widetilde{u}+\widehat{u},\vec{g}) \le \liminf_{m\to\infty} \mathcal{J}(\widetilde{u}_m+\widehat{u}_m,\vec{g}_m).$$

Let $\vec{w}$ be in $\mathcal{V}(\Omega)$ and $\psi(t)$ be a continuously differentiable function on $[0,T]$ with $\psi(T)=0$. We multiply (22) and (23) by $\psi(\tau)\vec{w}$ and then integrate by parts in τ to obtain

$$\begin{aligned} -\int_0^T (\widehat{u}_m,\psi'(\tau)\vec{w})\,d\tau + \nu\int_0^T a(\widehat{u}_m,\psi(\tau)\vec{w})\,d\tau + \int_0^T c(\widehat{u}_m;\widehat{u}_m,\psi(\tau)\vec{w})\,d\tau \\ = \int_0^T (\widehat{f}_m,\psi(\tau)\vec{w})\,d\tau - \int_0^T (\widetilde{u}_m,\psi'(\tau)\vec{w})\,d\tau \\ +\nu\int_0^T a(\widetilde{u}_m,\psi(\tau)\vec{w})\,d\tau = (\vec{u}_0,\psi(0)\vec{w}). \end{aligned}$$

We can pass to the limit inside the linear and the nonlinear terms. In fact, the a priori estimate (see [11] or [32]) for $\widehat{u}$ in a fractional time order Sobolev space yields that $\widehat{u}_m$ converges strongly to $\widehat{u} \in L^2((0,T);V(\Omega))$. If $\psi \in \mathcal{D}((0,T))$, the limit $(\widehat{u},\widetilde{u},\vec{g})$ satisfies the Navier–Stokes equation (22) in the sense of distributions. Since $\mathcal{V}(\Omega)$ is dense in $H^1_0(\Omega)$, this is still true for any $\vec{w} \in H^1_0(\Omega)$ by a continuity argument. □

2.3. First-order necessary conditions. In this section, we derive the first-order necessary conditions. Let G be the set of all $\vec{g} \in H^{1,1}(S) \cap L^2(0,T;H^1_{n0}(\Gamma))$ satisfying the compatibility conditions in (17)–(18). For all $\vec{g} \in G$, the first-order necessary condition is available if the map

$$\vec{u}(\vec{g}) : G \to L^2((0,T);H^1(\Omega))$$

is Gâteaux differentiable. In the following theorem, we state and prove the existence of the Gâteaux derivative for directions $\widetilde{h}$ in $H^{1,1}(S) \cap L^2(0,T;H^1_{n0}(\Gamma))$.

THEOREM 2.3. *Given $\Omega \in C^2$, $\vec{u}_0 \in curl(H^2)$, and $\vec{g} \in G$, the mapping*

$$\vec{u}(\vec{g}) : G \to L^2((0,T);H^1(\Omega))$$

has a Gâteaux derivative $\frac{D\vec{u}}{D\vec{g}} \cdot \widetilde{h}$ in every direction $\widetilde{h} \in H^{1,1}(S) \cap L^2(0,T;H^1_{n0}(\Gamma))$ with $\widetilde{h} = 0$ at $t=0$. Furthermore, $\widetilde{w}(h) = \frac{D\vec{u}}{D\vec{g}} \cdot \widetilde{h}$ is the solution of the problem

$$(25)\quad \begin{cases} \langle \widetilde{w}_t,\vec{v}\rangle + \nu\, a(\widetilde{w},\vec{v}) + c(\vec{u};\widetilde{w},\vec{v}) + c(\vec{w};\widetilde{u},\vec{v}) + b(\vec{v},p) = 0 \quad \forall\, \vec{v} \in H^1_0(\Omega), \\ b(\widetilde{w},q) = 0 \quad \forall\, q \in L^2_0(\Omega), \\ (\widetilde{w}(t,\vec{x}),\vec{s}\,) = (\widetilde{h}(t,\vec{x}),\vec{s}\,) \quad \forall\, \vec{s} \in H^{-1/2}(\Gamma), \\ \widetilde{w}(0,\vec{x}) = 0, \quad \vec{x} \in \Omega, \end{cases}$$

where $\widetilde{w} \in L^\infty((0,T);L^2(\Omega)) \cap L^2((0,T);H^1(\Omega))$.

Proof. Let $\vec{g}$ and $\widetilde{h}$ be given in $H^{1,1}(S) \cap L^2(0,T;H^1_{n0}(\Gamma))$. We need to prove the following result:

$$\lim_{s\to 0}\left(\frac{\|(\vec{u}_{\vec{g}+s\widetilde{h}} - \vec{u}_{\vec{g}}) - s\widetilde{w}(\widetilde{h})\|_{L^2((0,T);H^1)}}{|s|}\right) = 0. \tag{26}$$

We set $\widetilde{u} = (\vec{u}_{\vec{g}+s\widetilde{h}} - \vec{u}_{\vec{g}}) - s\widetilde{w}(\widetilde{h})$ so that $\widetilde{u}$ is the solution of the evolution equation

$$\begin{cases} \dfrac{d\widetilde{u}}{dt} + \nu(\pi A)\widetilde{u} + (\pi C)(\vec{u}_{\vec{g}+s\widetilde{h}})\vec{u}_{\vec{g}+s\widetilde{h}} - (\pi C)(\vec{u}_{\vec{g}})\vec{u}_{\vec{g}} - (\pi C)'(\vec{u}_{\vec{g}})s\widetilde{w} = 0, \\ \widetilde{u} \in V(\Omega), \\ \widetilde{u}(0,\vec{x}) = 0, \quad \vec{x} \in \Omega. \end{cases} \tag{27}$$

If we define the function $\vec{k} \in L^2((0,T);H^{-1}(\Omega))$, as follows,

$$\vec{k} = (\pi C)(\vec{u}_{\vec{g}+s\widetilde{h}})\vec{u}_{\vec{g}+s\widetilde{h}} - (\pi C)(\vec{u}_{\vec{g}})\vec{u}_{\vec{g}} - (\pi C)'(\vec{u}_{\vec{g}})(\vec{u}_{\vec{g}+s\widetilde{h}} - \vec{u}_{\vec{g}}),$$

then (27) becomes

$$\begin{cases} \dfrac{d\widetilde{u}}{dt} + \nu(\pi A)\widetilde{u} + (\pi C)'(\vec{u}_{\vec{g}})\widetilde{u} = \vec{k}, \\ \widetilde{u} \in V(\Omega), \\ \widetilde{u}(t,\vec{x}) = 0, \quad \vec{x} \in \Gamma, \quad t \in (0,T), \\ \widetilde{u}(0,\vec{x}) = 0, \quad \vec{x} \in \Omega. \end{cases} \tag{28}$$

In order to estimate $\|\widetilde{u}\|_1$ we recall the following result, which can be easily found by standard techniques [29]. If $\vec{w}$ is the solution of

$$\begin{cases} \vec{w}_t + \nu(\pi A)\vec{w} + \delta[(\pi C)(\vec{w})\vec{u} + (\pi C)(\vec{u})\vec{w}] + \sigma(\pi C)(\vec{w})\vec{w} = \vec{f}, \\ \vec{w} \in V(\Omega), \end{cases} \tag{29}$$

with initial value $\vec{w}(0,\vec{x}) = 0$ and homogeneous boundary condition, then the solution $\vec{w}$ for all nonnegative real values of δ and σ has the following property: if $\vec{f} \in L^2((0,T);H^{-1}(\Omega))$ and $\vec{u} \in L^\infty((0,T);H^1(\Omega)) \cap L^2((0,T);V(\Omega))$, then the solution $\vec{w} \in L^\infty((0,T);W(\Omega)) \cap L^2((0,T);V(\Omega))$ and

$$\|\vec{w}\|_{L^\infty((0,T);L^2)} \le C_1\|\vec{f}\|_{L^2((0,T);H^{-1})}, \tag{30}$$

$$\|\vec{w}\|_{L^2((0,T);H^1)} \le C_2\|\vec{f}\|_{L^2((0,T);H^{-1})}, \tag{31}$$

where C_1, C_2, given $\vec{u}$, δ, and σ, are constants depending only on Ω and ν.

Using $(\pi C)'(\vec{u}) \cdot \widetilde{u} = (\pi C)(\vec{u})\widetilde{u} + (\pi C)(\widetilde{u})\vec{u}$ and (31) with $\sigma = 0, \delta = 1, \vec{f} = \vec{k} \in L^2((0,T);H^{-1}(\Omega))$, we obtain

$$\int_0^T \|\widetilde{u}\|_1^2 \, d\tau \le C_2 \int_0^T \|\vec{k}\|_{H^{-1}}^2 \, d\tau.$$

Now we need to evaluate the right-hand side term above. From the definition of the norm in $H^{-1}(\Omega)$, we have

$$\|\vec{k}\|_{H^{-1}} = \sup_{\|\vec{v}\|_{H_0^1(\Omega)}\leq 1} \frac{|\langle \vec{k}, \vec{v}\rangle|}{\|\vec{v}\|_1}.$$

The evaluation of the duality pairing on $H^{-1} \times H_0^1$ yields

$$\begin{aligned} |\langle \vec{k}, \vec{v}\rangle| &= |c(\vec{u}_{\vec{g}+s\widetilde{h}}; \vec{u}_{\vec{g}+s\widetilde{h}}, \vec{v}) - c(\vec{u}_{\vec{g}}; \vec{u}_{\vec{g}}, \vec{v}) - c'(\vec{u}_{\vec{g}}; \widehat{u}, \vec{v})| \\ &= |c(\vec{u}_{\vec{g}+s\widetilde{h}}; \vec{u}_{\vec{g}+s\widetilde{h}}, \vec{v}) - c(\vec{u}_{\vec{g}}; \vec{u}_{\vec{g}}, \vec{v}) - c(\vec{u}_{\vec{g}}; \widehat{u}, \vec{v}) - c(\widehat{u}; \vec{u}_{\vec{g}}, \vec{v})| \\ &= |c(\widehat{u}, \vec{u}_{\vec{g}+s\widetilde{h}}, \vec{v}) - c(\widehat{u}; \vec{u}_{\vec{g}}, \vec{v})| = |c(\widehat{u}; \widehat{u}, \vec{v})| \leq K\|\nabla \widehat{u}\|\|\widehat{u}\|\|\nabla \vec{v}\|, \end{aligned} \tag{32}$$

where $\widehat{u} = \vec{u}_{\vec{g}+s\widetilde{h}} - \vec{u}_{\vec{g}}$. Hence, the estimate for $\widetilde{u}$ yields

$$\int_0^T \|\widetilde{u}(t)\|_1^2\, dt \leq KC_2 \int_0^T \|\widehat{u}\|^2\|\widehat{u}\|_1^2\, dt, \tag{33}$$

where $\widehat{u} = \vec{u}_{\vec{g}+s\widetilde{h}} - \vec{u}_{\vec{g}}$ is the solution of the system

$$\begin{cases} \langle \widehat{u}_t, \vec{v}\rangle + \nu a(\widehat{u}, \vec{v}) + c(\vec{u}_{\vec{g}}; \widehat{u}, \vec{v}) + c(\widehat{u}; \vec{u}_{\vec{g}}, \vec{v}) \\ \quad + c(\widehat{u}; \widehat{u}, \vec{v}) + b(\vec{v}, p) = 0 \quad \forall\, \vec{v} \in H^1(\Omega), \\ b(\widehat{u}, q) = 0 \quad \forall\, q \in L_0^2(\Omega), \\ (\widehat{u}(t, \vec{x}), \vec{r}) = (s\widetilde{h}, \vec{r}) \quad \forall\, \vec{r} \in H^{-1/2}(\Gamma), \\ \widehat{u}(0, \vec{x}) = 0, \quad \vec{x} \in \Omega. \end{cases} \tag{34}$$

Again, in order to estimate the norm of $\widehat{u}$ in $L^\infty((0,T); L^2(\Omega))$ and in $L^2((0,T); H^1(\Omega))$, we set $\widehat{u}_2 = \widehat{u} - \widehat{u}_1$ and decompose the nonhomogeneous Navier–Stokes equation into two systems: a linear system defined by the Stokes problem

$$\begin{cases} \langle \widehat{u}_{1t}, \vec{v}\rangle + \nu a(\widehat{u}_1, \vec{v}) + b(\vec{v}, p) = 0 \qquad \forall\, \vec{v} \in H_0^1(\Omega), \\ b(\widehat{u}_1, q) = 0 \quad \forall\, q \in L_0^2(\Omega), \\ (\widehat{u}_1, \vec{r}) = (s\widetilde{h}, \vec{r}) \quad \forall\, \vec{r} \in H^{-1/2}(\Gamma), \\ \widehat{u}_1(0, \vec{x}) = u_0 \in curl(H^2)(\Omega) \end{cases} \tag{35}$$

and the homogeneous Navier–Stokes system

$$\begin{cases} \langle \widehat{u}_{2t}, \vec{v}\rangle + \nu a(\widehat{u}_2, \vec{v}) + c(\vec{u}_{\vec{g}} + \widehat{u}_1; \widehat{u}_2, \vec{v}) + c(\widehat{u}_2; \vec{u}_{\vec{g}} + \widehat{u}_1, \vec{v}) \\ + c(\widehat{u}_2; \widehat{u}_2, \vec{v}) = (\widehat{f}, \vec{v}) \qquad \forall\, \vec{v} \in V(\Omega), \\ \widehat{u}_2 \in V(\Omega), \end{cases} \tag{36}$$

where $\widehat{f} = -c(\widehat{u}_1; \widehat{u}_1, \vec{v})$. From the Stokes system, we have $\widehat{u}_1 \in L^\infty((0,T); L^2(\Omega))$ with $\|\widehat{u}_1\|_{L^\infty((0,T);L^2(\Omega))} \leq sC_3\|\widetilde{h}\|_{H^{1,1}}$ and

$$\int_0^T \|\widehat{u}_1\|_1^2\, dt \leq C_4|s|^2\|\widetilde{h}\|^2_{H^{1,1}(S)}$$

so that $\|\widehat{f}\|_{L^2((0,T);H^{-1})} \le C_5|s|^2\|\widetilde{h}\|^2_{H^{1,1}(S)}$. Also, by using (31) ($\delta = 1$, $\sigma = 1$) to estimate the solution in (36), we have $\|\widehat{u}_2\|_{L^\infty((0,T);L^2(\Omega))} \le sC_6\|\widetilde{h}\|_{H^{1,1}}$ and

$$\int_0^T \|\widehat{u}_2\|_1^2\,dt \le C_7|s|^2\|\widetilde{h}\|^2_{H^{1,1}}.$$

Further details on the above estimates can be found in [29]. Combining the above inequalities we obtain the estimates

$$\|\widehat{u}\|_{L^\infty((0,T);L^2(\Omega))} \le C_8 s\|\widetilde{h}\|_{H^{1,1}}, \tag{37}$$

$$\int_0^T \|\widehat{u}(t)\|_1^2\,dt \le C_9|s|^2\|\widetilde{h}\|^2_{H^{1,1}(S)}.$$

If we use (37) in (33), (26) is satisfied. From the regularity of $\widetilde{h}$, it follows that $\widetilde{w} \in L^\infty((0,T);L^2(\Omega)) \cap L^2((0,T);H^1(\Omega))$. □

The canonical extension $\widetilde{h}_c \to \widetilde{h}$ from $H^1_{n0}(\Gamma_c)$ to $H^1(\Gamma)$, where

$$\widetilde{h} = \begin{cases} \widetilde{h}_c, & \vec{x} \in \Gamma_c, \\ 0, & \vec{x} \in \Gamma \setminus \Gamma_c \end{cases}$$

is a continuous mapping; see [12]. This allows us to take variations in subdomains of the boundary, i.e., $H^1(\Gamma_c)$, and to claim the existence of the Gâteaux derivative for such configurations. For a variation $\widetilde{h}_c \in H^{1,1}(S_c) \cap L^2(0,T;H^1_{n0}(\Gamma_c))$, i.e., $\widetilde{h}_c \in L^2((0,T);H^1_{n0}(\Gamma_c))$ and $\widetilde{h}_{ct} \in L^2((0,T);L^2(\Gamma_c))$, of the control $\vec{g}$, the Gâteaux derivative of the Navier–Stokes system can be written in this following form:

$$\begin{cases} \langle \widetilde{w}_t, \vec{v}\rangle + \nu a(\widetilde{w},\vec{v}) + c(\widetilde{w};\vec{u},\vec{v}) + c(\vec{u};\widetilde{w},\vec{v}) + b(\vec{v},p_1) = 0 \quad \forall\, \vec{v} \in H^1_0(\Omega), \\ b(\widetilde{w},q) = 0 \quad \forall\, q \in L^2_0(\Omega), \\ (\widetilde{w},\vec{s})_\Gamma = (\widetilde{h}_c(t,\vec{x}),\vec{s})_{\Gamma_c} \quad \forall\, \vec{s} \in H^{-1/2}(\Gamma), \\ \widetilde{w}(0,\vec{x}) = 0, \quad \vec{x} \in \Omega. \end{cases} \tag{38}$$

Now, we can show that that the optimal solution must satisfy a first-order necessary condition. If $(\vec{u},\vec{g})$ is an optimal pair, then for every $\widetilde{h} \in H^{1,1}(S_c) \cap L^2(0,T;H^1_{n0}(\Gamma_c))$ and for every $\lambda \in \mathbb{R}$ we have, from the definition of an optimal solution,

$$\mathcal{J}(\vec{g} + \lambda\widetilde{h}) \ge \mathcal{J}(\vec{g}).$$

The above inequality implies

$$\frac{\mathcal{J}(\vec{g}+\lambda\widetilde{h}) - \mathcal{J}(\vec{g})}{\lambda} \ge 0 \quad \text{if} \quad \lambda \ge 0 \quad \text{and} \quad \frac{\mathcal{J}(\vec{g}+\lambda\widetilde{h}) - \mathcal{J}(\vec{g})}{\lambda} \le 0 \quad \text{if} \quad \lambda \le 0.$$

The limit must vanish when λ tends to zero and this leads to the following first-order necessary condition.

THEOREM 2.4. *If $(\vec{u},p,\vec{g})$ is an optimal pair for the problem in* (21), *then the Gâteaux derivative of $\mathcal{J}(\cdot,\cdot)$ vanishes at $(\vec{u},p,\vec{g})$.*

We would like to write the first-order necessary condition in a more explicit form. In order to do this we need this interesting preliminary result.

LEMMA 2.5. *Given $\Omega \in C^2$ and $\vec{u}_0 \in curl(H^2)(\Omega)$. Let $\widetilde{h}_c$ be given in $H^{1,1}(S_c) \cap L^2(0,T;H^1_{n0}(\Gamma_c))$ and let $\widetilde{w}(\widetilde{h}_c)$ be defined by* (38). *Then, for every $\widetilde{h}_2$ belonging to $L^2((0,T);H^1(\Omega))$, we have*

$$\int_0^T \int_\Omega \widetilde{h}_2 \widetilde{w}(\widetilde{h}_c)\, d\vec{x}dt = -\int_0^T \int_{\Gamma_c} \vec{\xi} \cdot \vec{w}\, d\vec{x}dt,$$

where $\vec{w}$ is the solution of the adjoint linearized problem

$$(39) \qquad \begin{cases} -(\vec{w}_t, \vec{v}) + \nu a(\vec{w}, \vec{v}) + c(\vec{v}; \vec{u}, \vec{w}) + c(\vec{u}; \vec{v}, \vec{w}) \\ \quad + b(\vec{v}, \sigma) = (\widetilde{h}_2, \vec{v}) \quad \forall\, \vec{v} \in H^1_0(\Omega), \\ b(\vec{w}, q) = 0 \quad \forall\, q \in L^2_0(\Omega), \\ \vec{w} = 0 \quad \forall\, \vec{x} \in \Gamma, \\ \vec{w}(T, \vec{x}) = 0 \quad \forall\, \vec{x} \in \Omega. \end{cases}$$

The function $\vec{\xi} = (\nu\gamma_1\vec{w} - \sigma\vec{n}) \in L^2((0,T);H^{-1/2}(\Gamma_c))$ is defined by

$$(40) \qquad \int_{\Gamma_c} \vec{\xi} \cdot \vec{v}\, d\vec{x} = -(\vec{w}_t, \vec{v}) + \nu a(\vec{w}, \vec{v}) + c(\vec{v}; \vec{u}, \vec{w}) + c(\vec{u}; \vec{v}, \vec{w}) \\ + b(\vec{v}, \sigma) - (\widetilde{h}_2, \vec{v}) \quad \forall\, \vec{v} \in H^1(\Omega).$$

Proof. We remark that $\widetilde{h}_2 \in L^2((0,T);H^1(\Omega))$; then, (39) has a solution $\vec{w} \in L^\infty((0,T);W(\Omega)) \cap L^2((0,T);V(\Omega))$ and $\sigma \in L^2((0,T);L^2_0(\Omega))$. The definition in (40) makes sense since the weak formulation of the adjoint equation tested against $H^1(\Omega)$ has solution for all $\widetilde{h}_2 \in (H^1)^*(\Omega)$; one can use the same techniques as in [21]. Hence, there exists a $\vec{\xi} \in H^{-1/2}(\Gamma_c)$, defined by (40). We need to evaluate the integral over time of $(\widetilde{w}, \widetilde{h}_2)$. The integral contains $\widetilde{h}_2$, for which we can use (40). We set $\vec{v} = \widetilde{w}$ in that equation and then we integrate by parts with respect to the time variable. We then obtain

$$\int_0^T (\widetilde{h}_2, \widetilde{w})\, dt = \int_0^T [-(\vec{w}_t, \widetilde{w}) + \nu a(\vec{w}, \widetilde{w}) c(\widetilde{w}; \vec{u}; \vec{w}) \\ + c(\vec{u}; \widetilde{w}, \vec{w}) + b(\widetilde{w}, \sigma)]\, dt - \int_0^T \int_{\Gamma_c} \vec{\xi} \cdot \widetilde{h}_c\, d\vec{x}dt \\ = \int_0^T [(\widetilde{w}_t, \vec{w}) + \nu a(\widetilde{w}, \vec{w}) + c(\widetilde{w}; \vec{u}; \vec{w}) + c(\vec{u}; \widetilde{w}, \vec{w})]\, dt - \int_0^T \int_{\Gamma_c} \vec{\xi} \cdot \widetilde{h}_c\, d\vec{x}dt.$$

The result then follows from the fact that the first term vanishes; it satisfies (39), the weak equation for the Gâteaux derivative, with $\vec{v} = \vec{w}$. □

In the next theorem we shall show that if the Gâteaux derivative vanishes, then $\vec{g}$ must be a solution of a differential equation.

THEOREM 2.6. *If $(\vec{u}, \vec{g})$ is an optimal pair for the problem in* (21), *then $\vec{g} \in H^{1,1}(S_c) \cap L^2(0,T;H^1_{n0}(\Gamma_c))$ with $\vec{g}(0, \vec{x}) = \gamma\vec{u}_0$ is solution of*

$$(41) \qquad \int_0^T \int_{\Gamma_c} \left[\vec{g} \cdot \widetilde{h} + \beta_1 \vec{g}_t \cdot \widetilde{h}_t + \beta_2 \partial_s \vec{g} \cdot \partial_s \widetilde{h} - \frac{1}{\beta}(\vec{\xi} \cdot \widetilde{h}) \right] d\vec{x}dt = 0$$

$\forall\, \widetilde{h} \in H^{1,1}(S_c) \cap L^2(0,T; H^1_{n0}(\Gamma_c))$ with $\widetilde{h} = 0$ at $t = 0$. The function $\vec{w} \in L^\infty((0,T); L^2(\Omega)) \cap L^2((0,T); V(\Omega))$ and is the solution of the adjoint linearized problem

$$(42)\qquad \begin{cases} -(\vec{w}_t, \vec{v}) + \nu\, a(\vec{w}, \vec{v}) + c(\vec{u}; \vec{v}, \vec{w}) + c(\vec{v}; \vec{u}, \vec{w}) \\ \quad + b(\vec{v}, \sigma) = \alpha(\vec{u} - \vec{U}, \vec{v}) \quad \forall\, \vec{w} \in H^1_0(\Omega), \\ b(\vec{w}, q) = 0 \quad \forall\, q \in L^2_0(\Omega), \\ \vec{w} = 0 \quad \forall\, \vec{x} \in \Gamma, \\ \vec{w}(T, \vec{x}) = 0 \quad \forall\, \vec{x} \in \Omega \end{cases}$$

and $\vec{\xi} = (\nu\gamma_1\vec{w} - \sigma\vec{n})$ on Γ_c is defined by

$$(43)\qquad \begin{aligned} \int_{\Gamma_c} \vec{\xi} \cdot \vec{v}\, d\vec{x} &= \int_{\Gamma_c} (\nu\gamma_1\vec{w} \cdot \gamma_0\vec{v} - \sigma\gamma_0\vec{v} \cdot \vec{n})\, d\vec{x} \\ &= -(\vec{w}_t, \vec{v}) + \nu\, a(\vec{w}, \vec{v}) + c(\vec{u}; \vec{v}, \vec{w}) \\ &\qquad + c(\vec{v}; \vec{u}, \vec{w}) + b(\vec{v}, \sigma) - \alpha(\vec{u} - \vec{U}, \vec{v}) \quad \forall\, \vec{v} \in H^1(\Omega). \end{aligned}$$

Proof. Let $(\vec{u}, \vec{g})$ be an optimal solution of the problem (21). We compute the Gâteaux derivative of the functional $\mathcal{J}(\vec{u}(\vec{g}), \vec{g})$ in the direction of $\widetilde{h}$ and then Lemma 2.5 completes the proof. We have

$$\begin{aligned} \frac{D\mathcal{J}(\vec{u}, \vec{g})}{D\vec{g}} \cdot \widetilde{h} &= \alpha \int_0^T \int_\Omega (\vec{u} - \vec{U}) \cdot \left(\frac{D\vec{u}}{D\vec{g}} \cdot \widetilde{h} \right) d\vec{x}dt \\ &\quad + \beta \int_0^T \int_{\Gamma_c} [\vec{g} \cdot \widetilde{h} + \beta_1 \vec{g}_t \cdot \widetilde{h}_t + \beta_2 \partial_s \vec{g} \cdot \partial_s \widetilde{h}]\, d\vec{x}dt. \end{aligned}$$

Now, by using Lemma 2.5, we can integrate by parts to obtain

$$\begin{aligned} \frac{D\mathcal{J}(\vec{u}, \vec{g})}{D\vec{g}} \cdot \widetilde{h} &= \alpha \int_0^T \int_\Omega (\vec{u} - \vec{U}) \cdot \vec{w}\, d\vec{x}dt \\ &\quad + \beta \int_0^T \int_{\Gamma_c} [\vec{g} \cdot \widetilde{h} + \beta_1 \vec{g}_t \cdot \widetilde{h}_t + \beta_2 \partial_s \vec{g} \cdot \partial_s \widetilde{h}]\, d\vec{x}dt \\ &= \int_0^T \int_{\Gamma_c} [\beta(\vec{g} \cdot \widetilde{h} + \beta_1 \vec{g}_t \cdot \widetilde{h}_t + \beta_2 \partial_s \vec{g} \cdot \partial_s \widetilde{h}) - (\vec{\xi} \cdot \widetilde{h})]\, d\vec{x}dt, \end{aligned}$$

where $\vec{w}$ is the solution of (42). Now, from Theorem 2.4, if $(\vec{u}, \vec{g})$ is a solution of the optimal control problem, the Gâteaux derivative must vanish. The regularity of $\vec{g}$ follows from the regularity properties shown for $\gamma_1\vec{w}$. □

Equation (41) provides the solution for the boundary control. Since $\widetilde{h} \in H^{1,1}(S_c) \cap L^2(0,T; H^1_{n0}(\Gamma_c))$ with $\widetilde{h}(0, \vec{x}) = 0$, we can take $\widetilde{h} = \psi(t)\vec{r}(\vec{x})$, where $\psi \in \mathcal{D}((0,T))$ with $\psi(0) = 0$ and $\vec{r}(\vec{x})$ in $H^1_{n0}(\Gamma_c)$. After integration by parts, we have

$$(44)\quad \beta_1(\vec{g}_t(T), \vec{r})\psi(T) + \int_0^T \psi(t) \left[(\vec{g}, \vec{r}) - \beta_1(\vec{g}_{tt}, \vec{r}) + \beta_2(\partial_s \vec{g}, \partial_s \vec{r}) - \frac{1}{\beta}(\vec{\xi}, \vec{r}) \right] dt = 0$$

$\forall\, \psi \in \mathcal{D}((0,T))$ with $\psi(0) = 0$ and $\forall \vec{r} \in H^1_{n0}(\Gamma_c)$. In this way, a necessary condition to satisfy (41) is to satisfy the differential equation

$$(45)\qquad (\vec{g}, \vec{r}) - \beta_1(\vec{g}_{tt}, \vec{r}) + \beta_2(\partial_s \vec{g}, \partial_s \vec{r}) - \frac{1}{\beta}(\vec{\xi}, \vec{r}) = 0 \quad \forall\, \vec{r} \in H^1_{n0}(\Gamma_c)$$

with $\vec{g}(0,\vec{x}) = \gamma_0\vec{u}_0(\vec{x})$ and $\vec{g}_t(T,\vec{x}) = 0$. The first of these boundary conditions is imposed on candidate minimizers in order to ensure the regularity of solutions; see (18). The second boundary condition is a result of the minimization process. Now we can use the space $H^1_n(\Gamma_c)$ for the test functions. Because of the orthogonality between $H^1_n(\Gamma_c)$ and $(H^1_n)^\perp(\Gamma_c)$, we can write a weak formulation of (45) with test functions in $H^1(\Gamma_c)$ by adding an arbitrary constant vector in the normal direction. We recall that $H^1(\Gamma_c) = H^1_n(\Gamma_c) \oplus (H^1_n(\Gamma_c))^\perp$ and thus

$$\vec{r} = \vec{r}_1 - \vec{n}\,\frac{\displaystyle\int_{\Gamma_c} \vec{r}_1 \cdot \vec{n}\, d\vec{x}}{\mu(\Gamma_c)},$$

where $\vec{r}_1 \in H^1(\Gamma_c)$. Now, the equation can be tested against $\vec{r}_1 \in H^1_0(\Gamma_c)$ in the following weak form:

$$(46)\quad (\vec{g},\vec{r}_1) - \beta_1(\vec{g}_{tt},\vec{r}_1) + \beta_2(\partial_s\vec{g},\partial_s\vec{r}_1) + k(t)(\vec{n},\vec{r}_1) = \frac{1}{\beta}(\vec{\xi},\vec{r}_1) \quad \forall\,\vec{r}_1 \in H^1_0(\Gamma_c),$$

where $k(t)$ is specified by the constraint

$$\int_\Gamma \vec{g}\cdot\vec{n}d\vec{x} = 0.$$

Finally, in order to obtain the solution of the optimal control problem, we have to solve the Navier–Stokes system

$$(47)\qquad \begin{cases} \langle \vec{u}_t,\vec{v}\rangle + \nu a(\vec{u},\vec{v}) + c(\vec{u};\vec{u},\vec{v}) + b(\vec{v},p) = 0 \quad \forall\,\vec{v}\in H^1_0(\Omega),\\ b(\vec{u},q) = 0 \quad \forall\,q \in L^2_0(\Omega),\\ (\vec{u},\vec{s})_\Gamma = (g(t,\vec{x}),\vec{s})_\Gamma \quad \forall\,\vec{s}\in H^{-1/2}(\Gamma),\\ \vec{u}(0,\vec{x}) = \vec{u}_0(\vec{x}) \in curl(H^2)(\Omega); \end{cases}$$

the adjoint system

$$(48)\qquad \begin{cases} -\langle \vec{w}_t,\vec{v}\rangle + \nu a(\vec{w},\vec{v}) + c(\vec{w};\vec{u},\vec{v}) + c(\vec{u};\vec{w},\vec{v})\\ \quad + b(\vec{v},\sigma) = \alpha(\vec{u}-\vec{U},\vec{v}) \quad \forall\,\vec{v}\in H^1_0(\Omega),\\ b(\vec{w},q) = 0 \quad \forall\,q\in L^2_0(\Omega),\\ \vec{w} = 0 \quad \forall\,\vec{x}\in\Gamma,\\ \vec{w}(T,\vec{x}) = 0 \quad \forall\,\vec{x}\in\Omega; \end{cases}$$

the boundary control equation

$$(49)\qquad \begin{cases} (\vec{g},\vec{r}) - \beta_1(\vec{g}_{tt},\vec{r}) + \beta_2(\partial_s\vec{g},\partial_s\vec{r}) + k(t)(\vec{n},\vec{r})\\ \quad = \dfrac{1}{\beta}[(\gamma_1\vec{w},\vec{r}) - (\vec{n}\sigma,\vec{r})] \quad \forall\,\vec{r}\in H^1_0(\Gamma_c),\\ \vec{g}(0,\vec{x}) = \gamma_0\vec{u}_0 \quad \forall\,\vec{x}\in\Gamma_c,\\ \vec{g}_t(T,\vec{x}) = 0 \quad \forall\,\vec{x}\in\Gamma_c,\\ \vec{g} = 0 \quad \forall\,\vec{x}\in\partial\Gamma_c; \end{cases}$$

and the compatibility condition for the boundary control

$$\int_\Gamma \vec{g} \cdot \vec{n} \, d\Gamma = 0. \tag{50}$$

Equation (50) is needed in order to calculate the variable $k(t)$. If the control is a tangential control, then the adjoint pressure and the term with $k(t)$ can be neglected.

3. Semidiscrete-in-time approximations.

3.1. Formulation of the semidiscrete-in-time optimal control problem.

Let $\sigma_N = \{t_n\}_{n=0}^N$ be a partition of $[0, T]$ into equal intervals $\Delta t = T/N$ with $t_0 = 0$ and $t_N = T$. For each fixed Δt (or N) and for every quantity $q(t, \vec{x})$, we associate the corresponding set $\{q^{(n)}(\vec{x})\}_{n=0}^N$ and a continuous piecewise linear function $q^N = q^N(t, \vec{x})$ such as $q^N(t_n, \vec{x}) = q^{(n)}(\vec{x})$ $\forall$ $n = 0, 1, \dots, N$. We will denote with boldface letter $\mathbf{q}$ the vector $(q^{(1)}, q^{(2)}, \dots, q^{(N)})$ of the discrete time components. Also, the space X^N will be denoted as $\mathbf{X}$. On this partition we define the discrete target velocity as $\vec{U}^{(n)}(\vec{x}) = \vec{U}(t_n, \vec{x})$ for $n = 0, 1, \dots, N$ when $\vec{U} \in U_{ad}$. Let Γ_c be part of the boundary on which we apply the boundary control $\vec{g}$ and

$$H_n^1(\Gamma_c) = \left\{ \vec{g} \in H^1(\Gamma_c) : \int_{\Gamma_c} \vec{g}^{(n)} \cdot \vec{n} \; d\vec{x} = 0 \right\} \quad \text{for } n = 1, 2, \dots, N,$$
