Proof. First let us prove that $E\|x(t)\|$ is uniformly bounded. Let $S(t)$ be the semigroup generated by the optimal closed loop infinitesimal generator $\boldsymbol{A} - \boldsymbol{B}\boldsymbol{B}^{\star}\boldsymbol{R}$, with $\boldsymbol{R}$ the solution of the algebraic Riccati control equation. There exist positive constants M and σ such that $\|S(t)\| \le Me^{-\sigma t}$. It is

$$\begin{aligned} E\|\boldsymbol{x}(t)\| &\le E\|S(t)\boldsymbol{x}(0)\| + E\|\int_0^t S(t-\tau)\boldsymbol{F}\boldsymbol{\omega}(\tau)d\tau\| \\ &\le Me^{-\sigma t}\sqrt{E(\|\boldsymbol{x}(0)\|)^2} + \left(\int_0^t M^2 e^{-2\sigma(t-\tau)}\|\boldsymbol{F}\|^2_{H.S.}\right)^{\frac{1}{2}} \\ &\le M\sqrt{\mathrm{Tr}(\boldsymbol{P}_0)} + \frac{M}{\sqrt{2\sigma}}\|\boldsymbol{F}\|_{H.S.} \end{aligned} \tag{6.6}$$

Consider now the equation

$$\dot{\xi}_{n,T}(t) = (\boldsymbol{A} - \boldsymbol{B}\boldsymbol{B}^\star \boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n)\xi_{n,T}(t). \tag{6.7}$$

It is

$$\xi_{n,T}(t) = S(t)\xi_{n,T}(0) + \int_0^t S(t-\tau)\boldsymbol{B}\boldsymbol{B}^\star(\boldsymbol{R} - \boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n)\xi_{n,T}(\tau)d\tau \tag{6.8}$$

by which it follows that

$$\|\xi_{n,T}(t)\| \le Me^{-\sigma t}\|\xi_{n,T}(0)\| \ + \int_0^t Me^{-\sigma(t-\tau)}\|\boldsymbol{B}\boldsymbol{B}^\star(\boldsymbol{R} - \boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n)\|_{H.S.}\xi_{n,T}(\tau)d\tau \tag{6.9}$$

and by the Gronwall inequality

$$\|\xi_{n,T}(t)\| \le Me^{(-\sigma + M\|\boldsymbol{B}\boldsymbol{B}^\star(\boldsymbol{R}-\boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n)\|_{H.S.}t)}\xi_{n,T}(0). \tag{6.10}$$

Now let $\epsilon > 0$. By Theorem 3.2 in [14] and by the inequality

$$\|\boldsymbol{R} - \boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n\|_{H.S.} \le \|\boldsymbol{\Pi}'_n\boldsymbol{R}\boldsymbol{\Pi}'_n - \boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n\|_{H.S.} + \|\boldsymbol{R} - \boldsymbol{\Pi}'_n\boldsymbol{R}\boldsymbol{\Pi}'_n\|_{H.S.}, \tag{6.11}$$

it follows that there exists T_ϵ such that for every $T > T_\epsilon$ there exists n_T such that for every $n > n_T$

$$\|\boldsymbol{R} - \boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n\|_{H.S.} < \min\left\{\frac{\sigma}{2M\|\boldsymbol{B}\boldsymbol{B}^\star\|}, \frac{\epsilon\sigma}{2M\|\boldsymbol{B}\boldsymbol{B}^\star\| \sup_{\tau\in[-r,\infty)} E\|\boldsymbol{x}(\tau)\|}\right\} \tag{6.12}$$

and so

$$\|\xi_{n,T}(t)\| \le Me^{\frac{-\sigma}{2}t}\xi_{n,T}(0), \tag{6.13}$$

which implies the exponential stability of the closed loop semigroup.

As far as the second part of the thesis is concerned, let

$$e_n(t) = \boldsymbol{x}(t) - \boldsymbol{x}_n(t).$$

It is

$$\dot{e}_n(t) = (\boldsymbol{A} - \boldsymbol{B}\boldsymbol{B}^\star\boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n)e_n(t) + \boldsymbol{B}\boldsymbol{B}^\star(\boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n - \boldsymbol{R})\boldsymbol{x}(t) \tag{6.14}$$

by which, taking into account (6.12),

$$\begin{aligned} E\|e_n(t)\| \le \int_0^t & Me^{(-\sigma+M\|\boldsymbol{B}\boldsymbol{B}^\star(\boldsymbol{R}-\boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n)\|_{H.S.})(t-\tau)} \\ & \cdot\|\boldsymbol{B}\boldsymbol{B}^\star(\boldsymbol{R} - \boldsymbol{R}_n(T)\boldsymbol{\Pi}'_n)\|_{H.S.}E\|\boldsymbol{x}(\tau)\|d\tau < \epsilon. \qquad \square \end{aligned} \tag{6.15}$$

7. Examples. Simulations reported in this section have been performed by MATLAB on a PC using the 3rd order Runge–Kutta integration algorithm.[1]

[1] Simulation programs are available upon request.

Example 1. Consider the following unstable hereditary system:

$$\begin{aligned}\frac{d^2z(t)}{dt^2} &= \frac{dz(t)}{dt} + z(t) + \frac{dz(t-r_1)}{dt} + z(t-r_1)\\ &\quad + \frac{dz(t-r_2)}{dt} + z(t-r_2) + u(t) + \omega_1(t),\\ y(t) &= z(t) + \omega_2(t),\end{aligned} \tag{7.1}$$

where $z(t), u(t), y(t) \in \mathbb{R}$, $\omega_1(t), \omega_2(t) \in \mathbb{R}$ are independent white Gaussian standard noises.

By denoting $Z(t) = \left[\begin{smallmatrix} z(t) \\ \frac{dz(t)}{dt}\end{smallmatrix}\right]$, and $\omega(t) = \left[\begin{smallmatrix}\omega_1(t)\\ \omega_2(t)\end{smallmatrix}\right]$, the system (7.1) can be rewritten as follows:

$$\begin{aligned}\dot{Z}(t) &= \begin{bmatrix} 0 & 1\\ 1 & 1\end{bmatrix} Z(t) + \begin{bmatrix} 0 & 0\\ 1 & 1\end{bmatrix} Z(t-r_1)\\ &\quad + \begin{bmatrix} 0 & 0\\ 1 & 1\end{bmatrix} Z(t-r_2) + \begin{bmatrix} 0\\ 1\end{bmatrix} u(t) + \begin{bmatrix} 0 & 0\\ 1 & 0\end{bmatrix} \omega(t)\\ y(t) &= [1 \quad 0]\, Z(t) + [0 \quad 1]\, \omega(t).\end{aligned} \tag{7.2}$$

The weight matrix in the functional (3.1) has been chosen as

$$\boldsymbol{Q}_0 = \begin{bmatrix} 1000 & 0\\ 0 & 0\end{bmatrix}. \tag{7.3}$$

The time t_f has been chosen equal to 10, and the delays have been chosen as $r_1 = 1.2$ and $r_2 = 2.5$. The initial value of $Z(\vartheta), \vartheta \in [-r_2, 0]$, has been chosen as follows:

$$Z(\vartheta) = \begin{bmatrix} e^{-\vartheta}\\ \cos(10\vartheta)\end{bmatrix},$$

while the initial estimate $\hat{Z}(\vartheta)$ has been set to 0 in the same interval. The covariance operator $\boldsymbol{P}_0$ of the initial state in M_2 has been chosen as follows:

$$\boldsymbol{P}_0 \boldsymbol{x} = (\boldsymbol{x}, \phi)\phi,$$

where $\boldsymbol{x}, \phi \in M_2$, $\phi = \left[\begin{smallmatrix}\phi_0\\ \phi_1\end{smallmatrix}\right]$, $\phi_0 = \phi_1(\vartheta) = \left[\begin{smallmatrix}1\\ 1\end{smallmatrix}\right], \vartheta \in [-r_2, 0]$.

The integration step has been chosen equal to 0.0025.

Figures 2–5 report the first component of the actual $Z(t)$ evolving when the approximated input is applied to the system and of the estimated $\hat{Z}(t)$ for different values of n_1 and n_2. Figures 6–9 report the second component of $Z(t)$ and $\hat{Z}(t)$. In Figures 10–13 the first component and the second one of $Z(t)$ and $\hat{Z}(t)$, the approximated control input and the noisy output, are reported for $n_1 = n_2 = 6$.

Example 2. Consider now the well-known National Transonic Facility [4, 27, 40], the liquid nitrogen wind tunnel at NASA Langley Research Center in Hampton, VA. Here only one of the state variables is measured, the guide vane angle, while no measurement of the mach number nor of the guide vane angle derivative is available. Moreover, we suppose an additive Gaussian noise corrupts the dynamics of the system and the above measure. A simplified model of such a system is given by (see [4] for the

deterministic model)

$$\begin{aligned}\dot{z}(t) &= \begin{bmatrix} -a & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -\bar{\omega}^2 & -2\xi\bar{\omega} \end{bmatrix} z(t) + \begin{bmatrix} 0 & ka & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} z(t-0.33) \\ &\quad + \begin{bmatrix} 0 \\ 0 \\ -\bar{\omega}^2 \end{bmatrix} \boldsymbol{u}(t) + F_0\omega_1(t) \\ \boldsymbol{y}(t) &= [\,0 \quad 1 \quad 0)\,]\, z(t) + G_0\omega_2(t)\end{aligned} \tag{7.4}$$

with $(1/a) = 1.964$, $k = -0.0117$, $\xi = 0.8$, $\bar{\omega} = 6.0$, and $\omega_1(t), \omega_2(t) \in \mathbb{R}$ independent white Gaussian standard noises. As in the LQ problem developed in [4, 27, 40], the matrix $\boldsymbol{Q}_0$ in the functional (3.1) has been chosen as follows:

$$\boldsymbol{Q}_0 = \begin{bmatrix} 10000 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}. \tag{7.5}$$

In simulations we have supposed to know exactly the initial state

$$z(\tau) = \begin{bmatrix} -0.1 \\ 8.547 \\ 0 \end{bmatrix}, \qquad \tau \in [-0.33, 0],$$

and we have used

$$\boldsymbol{F}_0 = \begin{bmatrix} 0 \\ 0 \\ 10 \end{bmatrix}, \qquad \boldsymbol{G} = 1.$$

Figures 14–17 show the three components of the state and the input for $n = 2$. Computed values of the functional

$$J_{10} = \int_0^{10} [\boldsymbol{z}^{\mathrm{T}}(t)\boldsymbol{Q}_0\boldsymbol{z}(t) + \boldsymbol{u}^2(t)]dt \tag{7.6}$$

for different n and the same noise realization are reported in Table 1. The integration step has been chosen equal to $dT = 0.001$, the integral J_{10} has been computed as $dT\sum_{k=0}^{10/dT} \boldsymbol{z}^{\mathrm{T}}(kdT)\boldsymbol{Q}_0\boldsymbol{z}(kdT) + u^2(kdT)$.

We have considered also the infinite horizon LQ problem: this means that we have considered only the Riccati equation for control and evaluated the dynamic approximated Riccati operator in a sufficiently large time. We have stopped integration when the norm of the difference between the Riccati matrix operators evaluated in time kdT and $(k+1)dT$ was less than 10^{-10}.

Tables 2–5 report the values of matrices Π_0^n and of matrices of functions $\Pi_1^n(\vartheta)$ [4, 27, 40] of the approximated, not yet implementable, LQ control law

$$u_n(t) = \Pi_0^n z(t) + \int_{-r}^{0} \Pi_1^n(\theta)z(t+\theta)d\theta. \tag{7.7}$$

ering the approximation scheme [4]. In that approximation scheme Π_1^n is increasingly oscillatory with increasing n, while in our scheme, as in [27, 40], each function in Π_1^n is monotone. This property becomes very important if one wants to implement the approximating feedback law in a real system [27].

In Table 6 the approximations of order $n = 8$ of matrix Π_0, denoted Π_0^8, are reported, computed with approximation schemes in [2, 24, 4, 27, 40] and with the method presented in this paper. Also the exact optimal Π_0 is reported, as computed in [27].

Table 7 reports the values of the functional

$$\int_0^\infty [\boldsymbol{z}^{\mathrm{T}}(t)\boldsymbol{Q}_0\boldsymbol{z}(t) + \boldsymbol{u}^2(t)]dt \tag{7.8}$$

computed using the same approximation schemes for $n = 8$.

The value computed with the method proposed in this paper is obtained by numerical integration of (7.6). The value computed with $t_f = 20$ is quite the same (for $n = 2$ it is $J_{20} = 136.4133$).

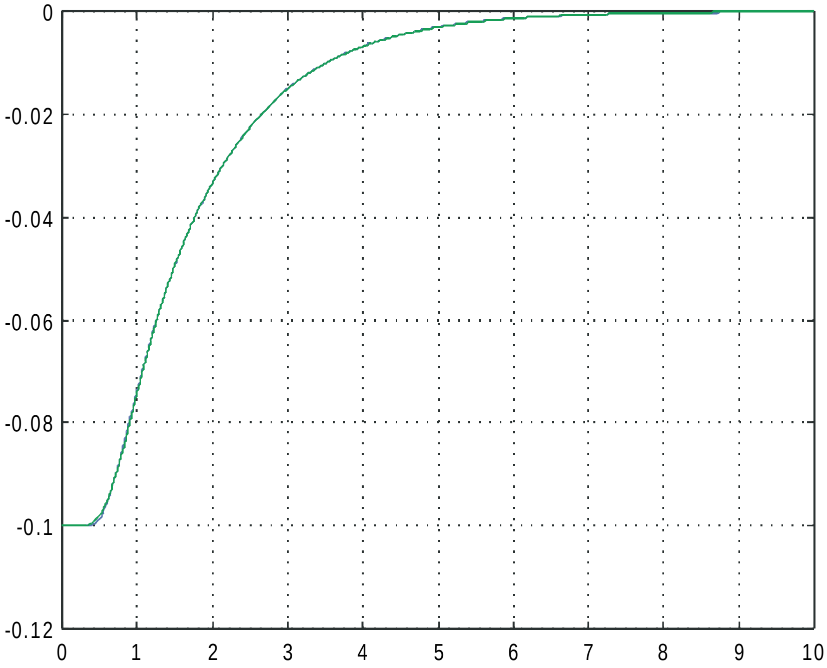

FIG. 18. *Infinite horizon LQG for the wind tunnel. The case of $n = 2$: true and estimated $z_1(t)$ (almost coincident).*

To conclude, the infinite horizon LQG control is considered: the solutions of the approximate algebraic Riccati equations for control and filtering are used in the control scheme. The resulting controller is a dynamic finite dimensional stationary system driven by the noisy output. The values of the index $\int_0^{10}[\boldsymbol{z}^{\mathrm{T}}(t)\boldsymbol{Q}_0\boldsymbol{z}(t)+\boldsymbol{u}^2(t)]dt$, computed for different n and for the same noise realization, are reported in Table 8.

All approximation schemes give, within numerical errors, practically the same value of the cost functional. It is indeed remarkable that the proposed approximation scheme is able to reach such value of the functional starting from noisy output measurements and not, as the other schemes do, starting from noiseless full state information (in a delay interval).

In Figures 18–20 the three components of the state are reported in the infinite horizon case, for $n = 2$. The plots of the input and of the output are reported in Figures 21 and 22.

Comparison with the methods presented in [25, 26] cannot be reported because such papers do not contain numerical results.

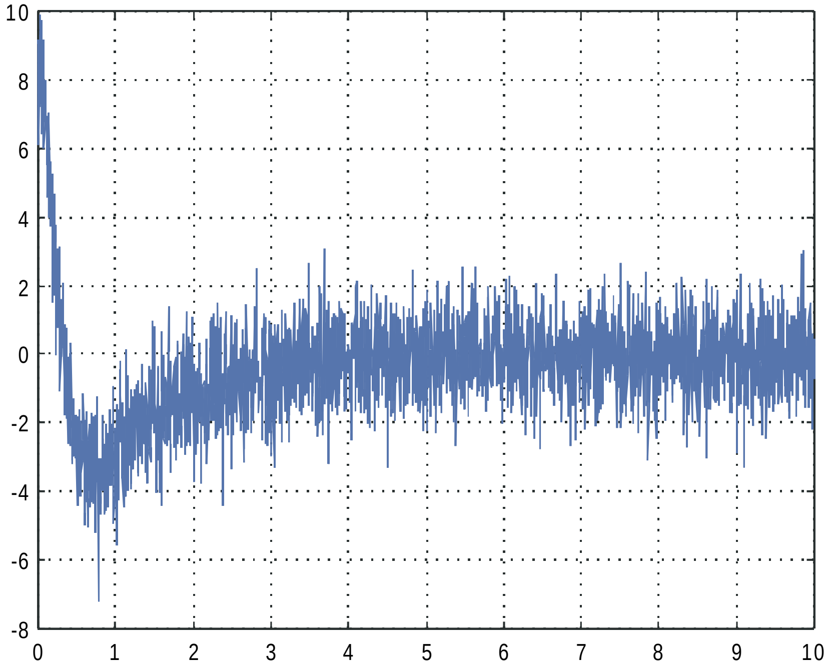

FIG. 22. *Infinite horizon LQG for the wind tunnel. The case of $n = 2$: the noisy output $y(t)$.*

8. Conclusions. In this paper a new spline approximation scheme has been developed for the finite horizon LQG control of general hereditary systems. The approximated LQG controller is a finite dimensional linear system driven by the noisy output. It has been proved that the approximated implementable feedback input and the corresponding state converge to the optimal ones. The approximation scheme makes use of first order splines, introduced by [3] for hereditary systems, suitably adapted to the LQG problem which involves three differential equations, that is, the filter equation and the two Riccati equations required for the computation of the optimal stochastic control. Generally in the literature one of these equations is considered, that is the Riccati equation for the deterministic state feedback optimal control [4, 24, 26, 27, 40]. A methodology with two approximating subspaces has been necessary to apply such spline functions to obtain convergence of the overall LQG problem.

The main feature of the proposed scheme is from a numerical point of view. Indeed our proposal of an implementable LQG controller gives practically the same results of the well-known LQ controller, with a complete knowledge of the infinite dimensional state in a deterministic setting, with reference to an important widely studied case as the NASA National Transonic Facility. The choice of spline environment instead of averaging one is motivated in [4], where its numerical advantages are stressed.

Moreover, the proposed method for choosing splines has the important degree of freedom regarding the possibility of approximating separately the semigroup governing the system and its adjoint. This allows us to use splines of any order [3]. This is very promising for obtaining very good performances in the future.

Future work will involve the infinite horizon LQG problem, which in this paper has been only sketched. For such a problem, the approximation scheme developed here can be used, and convergence of the type in paper [14] can be obtained. As a final remark, we would like to stress that the methodology presented in this paper can involve more than one type of approximation for the three equations governing the LQG stochastic control in order to get the best combination of theoretical and numerical convergences of approximation schemes developed until now [2, 3, 24, 26, 27, 40].

Appendix.

LEMMA A.1. *For any $\boldsymbol{y}_0 \in \mathbb{R}^N$ and for any function $\boldsymbol{f} \in C^0([-r,0];\mathbb{R}^N)$, there exists a unique left-continuous function $\boldsymbol{y}_1 : [-r,0] \mapsto \mathbb{R}^N$ such that*

$$\boldsymbol{y}_1 - \sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{y}_0,\boldsymbol{y}_1)\chi_{[-r,-r_j]} = \boldsymbol{f}, \tag{A.1}$$

where $\boldsymbol{k}_j$ are functions defined in (2.22).

Proof. In the case $\delta = 1$ the summation vanishes and the lemma is trivially true. In the case $\delta > 1$, consider (A.1) in time instants $-r_k$

$$\boldsymbol{y}_1(-r_k) - \sum_{j=1}^{k} \frac{\boldsymbol{y}_1(-r_j) - \boldsymbol{A}_j^{\mathrm{T}}\boldsymbol{y}_0}{\delta - j + 1} = \boldsymbol{f}(-r_k), \quad k = 1,\dots,\delta-1, \tag{A.2}$$

which can be put in matrix form as

$$\begin{bmatrix} \boldsymbol{y}_1(-r_1) \\ \vdots \\ \boldsymbol{y}_1(-r_{\delta-1}) \end{bmatrix} = \begin{bmatrix} \boldsymbol{f}(-r_1) \\ \vdots \\ \boldsymbol{f}(-r_{\delta-1}) \end{bmatrix} + H_{\delta,2} \begin{bmatrix} \boldsymbol{y}_1(-r_1) \\ \vdots \\ \boldsymbol{y}_1(-r_{\delta-1}) \end{bmatrix} - H_{\delta,2} \begin{bmatrix} \boldsymbol{A}_1^{\mathrm{T}} \\ \vdots \\ \boldsymbol{A}_{\delta-1}^{\mathrm{T}} \end{bmatrix} \boldsymbol{y}_0, \tag{A.3}$$

where matrix $H_{\delta,2}$ is defined as follows ($\boldsymbol{I}_N$ is the $N \times N$ identity matrix):

$$\text{(A.4)} \qquad H_{\delta,2} = \begin{bmatrix} \frac{1}{\delta}\boldsymbol{I}_N & 0 & \cdots & 0 & 0 \\ \frac{1}{\delta}\boldsymbol{I}_N & \frac{1}{\delta-1}\boldsymbol{I}_N & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ \frac{1}{\delta}\boldsymbol{I}_N & \frac{1}{\delta-1}\boldsymbol{I}_N & \cdots & \frac{1}{3}\boldsymbol{I}_N & 0 \\ \frac{1}{\delta}\boldsymbol{I}_N & \frac{1}{\delta-1}\boldsymbol{I}_N & \cdots & \frac{1}{3}\boldsymbol{I}_N & \frac{1}{2}\boldsymbol{I}_N \end{bmatrix}.$$

Now, let us define a vector $\boldsymbol{\eta} \in \mathbb{R}^{(\delta-1)N}$ as

$$\text{(A.5)} \qquad \boldsymbol{\eta} = \begin{bmatrix} \boldsymbol{\eta}_1 \\ \vdots \\ \boldsymbol{\eta}_{\delta-1} \end{bmatrix} = (\boldsymbol{I}_{(\delta-1)N} - H_{\delta,2})^{-1} \left(\begin{bmatrix} \boldsymbol{f}(-r_1) \\ \vdots \\ \boldsymbol{f}(-r_{\delta-1}) \end{bmatrix} - H_{\delta,2} \begin{bmatrix} \boldsymbol{A}_1^{\mathrm{T}} \\ \vdots \\ \boldsymbol{A}_{\delta-1}^{\mathrm{T}} \end{bmatrix} \boldsymbol{y}_0 \right)$$

and the left-continuous function

$$\text{(A.6)} \qquad \bar{\boldsymbol{y}}_1(\vartheta) = \begin{cases} \boldsymbol{\eta}_i, & \vartheta = -r_i, \\ \boldsymbol{f}(\vartheta) + \displaystyle\sum_{j=1}^{\delta-1} \frac{\boldsymbol{\eta}_j - \boldsymbol{A}_j^{\mathrm{T}}\boldsymbol{y}_0}{\delta - j + 1} \chi_{[-r,-r_j]}(\vartheta), & \vartheta \neq -r_i, \end{cases}$$

in which $i = 1, \dots, \delta - 1$. It is readily verified that $\bar{\boldsymbol{y}}_1$ satisfies (A.1).

Uniqueness is proved by recognizing that any other function $\tilde{\boldsymbol{y}}_1$ satisfying (A.1) verifies also (A.3), and therefore $\tilde{\boldsymbol{y}}_1(-r_k) = \bar{\boldsymbol{y}}_1(-r_k)$, $k = 1, \dots, \delta - 1$. The difference between expression (A.1) with $\boldsymbol{y}_1 = \bar{\boldsymbol{y}}_1$ and the same expression in which $\boldsymbol{y}_1 = \tilde{\boldsymbol{y}}_1$ is used gives $\bar{\boldsymbol{y}}_1 - \tilde{\boldsymbol{y}}_1 = 0$. This concludes the proof of uniqueness. □

Proof of Proposition 2.2. Only (2.20) and (2.21) require a little mathematics. The case $\delta = 1$ (summations in (2.20) and (2.21) vanish) is a standard result [24, 43]. For the case $\delta > 1$, let $L : \mathcal{D}(L) \mapsto \boldsymbol{M}_2$ be the operator defined as (see (2.20), (2.21))

$$L : \mathcal{D}(L) \mapsto \boldsymbol{M}_2,$$

$$L \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{bmatrix} = \begin{bmatrix} \delta\, \boldsymbol{y}_1(0) + \boldsymbol{A}_0^{\mathrm{T}}\boldsymbol{y}_0 \\ \dfrac{1}{g}\boldsymbol{A}_{01}^{\mathrm{T}}\boldsymbol{y}_0 - \dfrac{d}{d\vartheta}\left(\boldsymbol{y}_1 - \displaystyle\sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{y}_0, \boldsymbol{y}_1)\chi_{[-r,-r_j]} \right) \end{bmatrix},$$

$$\mathcal{D}(L) = \left\{ \begin{bmatrix} \boldsymbol{y}_0 \\ \\ \boldsymbol{y}_1 \end{bmatrix} \,\middle|\, \begin{matrix} \boldsymbol{y}_0 \in \mathbb{R}^N, \quad \boldsymbol{A}_\delta^{\mathrm{T}}\boldsymbol{y}_0 = \boldsymbol{y}_1(-r), \\ \left(\boldsymbol{y}_1 - \displaystyle\sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{y}_0, \boldsymbol{y}_1)\chi_{[-r,-r_j]} \right) \in W^{1,2} \end{matrix} \right\}.$$

We will show that

(a) for every $\boldsymbol{x} \in \mathcal{D}(\boldsymbol{A})$ and every $y \in \mathcal{D}(L)$, it is $(\boldsymbol{y}, \boldsymbol{A}\boldsymbol{x}) - (L\boldsymbol{y}, \boldsymbol{x}) = 0$;

(b) the set $\mathcal{D}(L)$ is dense in M_2.

These two items together state that L is the adjoint of $\boldsymbol{A}$, that is, $\boldsymbol{A}^*$ as defined in (2.20), (2.21).

Let us prove item (a). Take $\boldsymbol{x} \in \mathcal{D}(\boldsymbol{A})$ and $\boldsymbol{y} \in \mathcal{D}(L)$, let us show that $(\boldsymbol{y}, \boldsymbol{A}\boldsymbol{x}) - (L\boldsymbol{y}, \boldsymbol{x}) = 0$:

$$\begin{aligned}(\boldsymbol{y},\boldsymbol{A}\boldsymbol{x}) - (L\boldsymbol{y},\boldsymbol{x}) &= \boldsymbol{y}_0^{\mathrm{T}}\textstyle\sum_{j=1}^{\delta}\boldsymbol{A}_j\boldsymbol{x}_1(-r_j) - \delta\,\boldsymbol{y}_1^{\mathrm{T}}(0)\boldsymbol{x}_0\\ &\quad+ \textstyle\int_{-r}^{0} g(\vartheta)\left[\boldsymbol{y}_1^{\mathrm{T}}(\vartheta)\frac{d}{d\vartheta}\boldsymbol{x}_1(\vartheta) + \frac{d}{d\vartheta}\left(\boldsymbol{y}_1 - \sum_{j=1}^{\delta-1}\boldsymbol{k}_j(\boldsymbol{y}_0,\boldsymbol{y}_1)\chi_{[-r,-r_j]}\right)^{\mathrm{T}}\boldsymbol{x}_1(\vartheta)\right]d\vartheta.\end{aligned}\tag{A.7}$$

$\boldsymbol{y}_1 - \sum_{j=1}^{\delta-1}\boldsymbol{k}_j(\boldsymbol{y}_0,\boldsymbol{y}_1)\chi_{[-r,-r_j]}$ being absolutely continuous, the integral term in (A.7) can be rewritten as

$$\begin{aligned}&\sum_{i=1}^{\delta}\int_{-r_i}^{-r_{i-1}}(\delta-i+1)\frac{d}{d\vartheta}\left[\left(\boldsymbol{y}_1 - \sum_{j=1}^{\delta-1}\boldsymbol{k}_j(\boldsymbol{y}_0,\boldsymbol{y}_1)\chi_{[-r,-r_j]}\right)^{\mathrm{T}}\boldsymbol{x}_1(\vartheta)\right]d\vartheta\\ &\quad+\sum_{i=1}^{\delta}\int_{-r_i}^{-r_{i-1}}(\delta-i+1)\left(\sum_{j=1}^{\delta-1}\boldsymbol{k}_j(\boldsymbol{y}_0,\boldsymbol{y}_1)\chi_{[-r,-r_j]}\right)^{\mathrm{T}}\frac{d}{d\vartheta}\boldsymbol{x}_1(\vartheta)d\vartheta\end{aligned}\tag{A.8}$$

and after a simple computation

$$\begin{aligned}&\sum_{i=1}^{\delta}(\delta-i+1)\left[\left(\boldsymbol{y}_1 - \sum_{j=1}^{\delta-1}\boldsymbol{k}_j(\boldsymbol{y}_0,\boldsymbol{y}_1)\chi_{[-r,-r_j]}\right)^{\mathrm{T}}\boldsymbol{x}_1\right]_{-r_i}^{-r_{i-1}}\\ &\quad+\sum_{i=2}^{\delta}(\delta-i+1)\left(\sum_{h=1}^{i-1}\boldsymbol{k}_h(\boldsymbol{y}_0,\boldsymbol{y}_1)\right)^{\mathrm{T}}[\boldsymbol{x}_1(-r_{i-1}) - \boldsymbol{x}_1(-r_i)]\\ &= \delta\boldsymbol{y}_1^{\mathrm{T}}(0)\,\boldsymbol{x}_1(0) - \boldsymbol{y}_1^{\mathrm{T}}(-r)\,\boldsymbol{x}_1(-r) - \sum_{i=1}^{\delta-1}\boldsymbol{y}_0^{\mathrm{T}}\boldsymbol{A}_i\boldsymbol{x}_1(-r_i).\end{aligned}\tag{A.9}$$

Now, replacing the integral term in (A.7) with the above expression and taking into account that $\boldsymbol{x}_1(0) = \boldsymbol{x}_0$ and $\boldsymbol{y}_1(-r) = \boldsymbol{A}_\delta^{\mathrm{T}}\boldsymbol{y}_0$, it follows that $(\boldsymbol{y},\boldsymbol{A}\boldsymbol{x}) - (L\boldsymbol{y},\boldsymbol{x}) = 0$.

Let us now prove item (b). It is sufficient to prove that $\mathcal{D}(L)$ is dense in $\mathbb{R}^N \times W^{1,2}$. Let $\boldsymbol{y}_0 \in \mathbb{R}^N$, $\boldsymbol{y}_1 \in W^{1,2}$. Consider the following sequence of functions $\boldsymbol{y}_{1,k} \in W^{1,2}$, defined for integers $k > \frac{1}{r-r_{\delta-1}}$:

$$\boldsymbol{y}_{1,k}(\vartheta) = \begin{cases}\boldsymbol{y}_1(\vartheta), & \vartheta \in [-r+\frac{1}{k}, 0],\\ (1-k(\vartheta+r))\boldsymbol{A}_\delta^{\mathrm{T}}\boldsymbol{y}_0 + k(\vartheta+r)\boldsymbol{y}_1(-r+\frac{1}{k}), & \vartheta \in [-r, -r+\frac{1}{k}).\end{cases}\tag{A.10}$$

Being that $-r + 1/k < -r_{\delta-1}$, it is $\boldsymbol{y}_{1,k}(-r_j) = \boldsymbol{y}_1(-r_j)$ for $j = 1,\dots,\delta-1$. As $\boldsymbol{y}_1$ is uniformly bounded in $[-r, 0]$, given any positive ϵ there exists k_ϵ such that

$$\|\boldsymbol{y}_1 - \boldsymbol{y}_{1,k}\|_{L_2} < \frac{\epsilon}{2} \quad \text{for} \quad k > k_\epsilon.\tag{A.11}$$

Note that, since $\boldsymbol{y}_{1,k}(-r) = \boldsymbol{A}_d^{\mathrm{T}}\boldsymbol{y}_0$, if $\delta = 1$, then $\left[\begin{smallmatrix}\boldsymbol{y}_0\\ \boldsymbol{y}_{1,k}\end{smallmatrix}\right] \in \mathcal{D}(\boldsymbol{A}^*)$, and the density of $\mathcal{D}(\boldsymbol{A}^*)$ in $\mathbb{R}^N \times W^{1,2}$ and hence in $\boldsymbol{M}_2$ is proved.

If $\delta > 1$ in general $\left[\begin{smallmatrix}\boldsymbol{y}_0\\ \boldsymbol{y}_{1,k}\end{smallmatrix}\right] \notin \mathcal{D}(\boldsymbol{A}^*)$. For any integer $n > \sup_{j=1,2,\dots,d}\frac{1}{r_j - r_{j-1}}$ it is convenient to define δ functions in $W^{1,2}$ as follows:

$$\chi_j^n(\vartheta) = \begin{cases}\chi_{[-r,-r_j]}(\vartheta), & \vartheta \notin (-r_j, -r_j+\frac{1}{n}),\\ -n(\vartheta + r_j - \frac{1}{n}), & \vartheta \in (-r_j, -r_j+\frac{1}{n}),\end{cases} \quad \text{for} \quad j = 1,\dots,\delta-1,\tag{A.12}$$

are such that

$$\|\chi_j^n - \chi_{[-r,-r_j]}\|_{L_2} = \frac{1}{\sqrt{3n}}, \quad \text{for } j = 1, \dots, \delta - 1. \tag{A.13}$$

By Lemma A.1, for any $n > \sup_{j=1,2,\dots,d} \frac{1}{r_j - r_{j-1}}$, there exists a function $\boldsymbol{y}_{1,k,n}$ such that

$$\boldsymbol{y}_{1,k,n} - \sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{y}_0, \boldsymbol{y}_{1,k,n})\chi_{[-r,-r_j]} = \boldsymbol{y}_{1,k} - \sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{y}_0, \boldsymbol{y}_{1,k})\chi_j^n \tag{A.14}$$

(note that the right-hand side term is in C^0 and therefore Lemma A.1 can be applied).

It can be shown that $\boldsymbol{y}_{1,k,n}(-r_j) = \boldsymbol{y}_{1,k}(-r_j)$, $j = 1, \dots, \delta$, so that $\left[\begin{smallmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_{1,k,n} \end{smallmatrix}\right] \in \mathcal{D}(\boldsymbol{A}^*)$.

Moreover,

$$\begin{aligned} \left\| \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_{1,k} \end{bmatrix} - \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_{1,k,n} \end{bmatrix} \right\|_{\boldsymbol{M}_2} &= \left\| \sum_{j=1}^{\delta-1} \boldsymbol{k}_j(\boldsymbol{y}_0, \boldsymbol{y}_1)(\chi_j^n - \chi_{[-r,-r_j]}) \right\|_{L_2} \\ &\le \sum_{j=1}^{\delta-1} \left\| \boldsymbol{k}_j(\boldsymbol{y}_0, \boldsymbol{y}_1) \right\| \frac{1}{\sqrt{3n}}, \end{aligned} \tag{A.15}$$

where formula (A.13) is used.

Thus, there exists an integer n_ϵ such that for $n > n_\epsilon$ it is

$$\left\| \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_{1,k} \end{bmatrix} - \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_{1,k,n} \end{bmatrix} \right\|_{\boldsymbol{M}_2} < \frac{\epsilon}{2}. \tag{A.16}$$

Finally, for any pair k, n such that $k > k_\epsilon$ and $n > n_\epsilon$ it is

$$\left\| \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_1 \end{bmatrix} - \begin{bmatrix} \boldsymbol{y}_0 \\ \boldsymbol{y}_{1,k,n} \end{bmatrix} \right\|_{\boldsymbol{M}_2} < \epsilon, \tag{A.17}$$

which proves the density of $\mathcal{D}(L)$ in $\boldsymbol{M}_2$. □

Remark A.2 The proof of this proposition concerning the adjoint operator $\boldsymbol{A}^\star$ can also be done by methodology shown in [15]. Using standard Lax–Milgram-type representation theorems, a relationship follows between equivalent inner products, so that an adjoint operator in a given inner product can be found by another one obtained in an equivalent inner product (see [15] and references therein).

LEMMA A.3. *For any nonnegative λ the matrix $H_p(\lambda)$ defined in* (4.59) *is nonsingular.*

Proof. The expression of $H_p(\lambda)$ is here reported for the reader's convenience:

$$H_p(\lambda) = \boldsymbol{I}_{(\delta-1)N} - H_{\delta,2} + \begin{bmatrix} \boldsymbol{I}_N e^{-\lambda(r-r_1)} \\ \vdots \\ \boldsymbol{I}_N e^{-\lambda(r-r_{\delta-1})} \end{bmatrix} h_{\delta,2}. \tag{A.18}$$

As a first step, nonsingularity of matrix $\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2}$ is proved. By the definition of $H_{\delta,2}$ in (A.4) it is

$$\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2} = \begin{bmatrix} \boldsymbol{I}_N - \frac{1}{\delta}\boldsymbol{I}_N & 0 & \cdots & 0 & 0 \\ -\frac{1}{\delta}\boldsymbol{I}_N & \boldsymbol{I}_N - \frac{1}{\delta-1}\boldsymbol{I}_N & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ -\frac{1}{\delta}\boldsymbol{I}_N & -\frac{1}{\delta-1}\boldsymbol{I}_N & \cdots & \boldsymbol{I}_N - \frac{1}{3}\boldsymbol{I}_N & 0 \\ -\frac{1}{\delta}\boldsymbol{I}_N & -\frac{1}{\delta-1}\boldsymbol{I}_N & \cdots & -\frac{1}{3}\boldsymbol{I}_N & \boldsymbol{I}_N - \frac{1}{2}\boldsymbol{I}_N \end{bmatrix}. \tag{A.19}$$

A direct computation shows that the inverse of $\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2}$ is

$$(\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2})^{-1} = \boldsymbol{I}_{N(\delta-1)} + \overline{H}_{\delta,2}, \tag{A.20}$$

where matrix $\overline{H}_{\delta,2}$ is defined as

$$\overline{H}_{\delta,2} = \begin{bmatrix} \frac{1}{\delta-1}\boldsymbol{I}_N & 0 & \cdots & 0 & 0 \\ \frac{1}{\delta-2}\boldsymbol{I}_N & \frac{1}{\delta-2}\boldsymbol{I}_N & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ \frac{1}{2}\boldsymbol{I}_N & \frac{1}{2}\boldsymbol{I}_N & \cdots & \frac{1}{2}\boldsymbol{I}_N & 0 \\ \boldsymbol{I}_N & \boldsymbol{I}_N & \cdots & \boldsymbol{I}_N & \boldsymbol{I}_N \end{bmatrix}. \tag{A.21}$$

The verification can be made writing the following expression for the kth column block of matrix $\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2}$ as

$$\begin{bmatrix} 0 \\ \vdots \\ \boldsymbol{I}_N \\ \vdots \\ 0 \end{bmatrix} - \begin{bmatrix} 0 \\ \vdots \\ \frac{1}{\delta-(k-1)}\boldsymbol{I}_N \\ \vdots \\ \frac{1}{\delta-(k-1)}\boldsymbol{I}_N \end{bmatrix} \tag{A.22}$$

(the first $k-1$ blocks are zero) and the following expression for the jth row block of matrix $\left(\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2}\right)^{-1}$ as

$$[0 \quad \cdots \quad 0 \quad \boldsymbol{I}_N \quad 0 \quad \cdots 0] + \left[\tfrac{1}{\delta-j}\boldsymbol{I}_N \quad \ldots \quad \tfrac{1}{\delta-j}\boldsymbol{I}_N \quad 0 \quad \cdots \quad 0\right] \tag{A.23}$$

(the first j blocks are nonzero). The product when $j < k$ is a sum of zeroes and is trivially zero. It can also be verified that when $j > k$, the product gives zero, and when $j = k$, the product gives $\boldsymbol{I}_N$. This verifies the expression (A.20) for $(\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2})^{-1}$.

Given the invertible matrix $\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2}$, the determinant of $H_p(\lambda)$ can be written as follows:

(A.24)

$$\det(\mathbf{I}_{N(\delta-1)} - H_{\delta,2}) \cdot \det\left(\mathbf{I}_{(\delta-1)N} + (\mathbf{I}_{N(\delta-1)} - H_{\delta,2})^{-1} \begin{bmatrix} \mathbf{I}_N e^{-\lambda(r-r_1)} \\ \vdots \\ \mathbf{I}_N e^{-\lambda(r-r_{\delta-1})} \end{bmatrix} h_{\delta,2}\right).$$

Since for any pair of matrices $A \in \mathbb{R}^{n\times m}$ and $B \in \mathbb{R}^{m\times n}$

$$\det(\boldsymbol{I}_n + A \cdot B) = \det(\boldsymbol{I}_m + B \cdot A), \tag{A.25}$$

the determinant of $H_p(\lambda)$ can also be written as

(A.26)

$$\det(\mathbf{I}_{N(\delta-1)} - H_{\delta,2}) \det\left(\mathbf{I}_{(\delta-1)B} + h_{\delta,2}(\mathbf{I}_{N(\delta-1)} - H_{\delta,2})^{-1} \begin{bmatrix} \mathbf{I}_N e^{-\lambda(r-r_1)} \\ \vdots \\ \mathbf{I}_N e^{-\lambda(r-r_{\delta-1})} \end{bmatrix}\right).$$

Recalling the expression of $h_{\delta,2}$ defined in (4.56) it follows that

$$h_{\delta,2}\left(\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2}\right)^{-1} \begin{bmatrix} \boldsymbol{I}_N e^{-\lambda(r-r_1)} \\ \vdots \\ \boldsymbol{I}_N e^{-\lambda(r-r_{\delta-1})} \end{bmatrix} = c(\lambda)\boldsymbol{I}_N, \tag{A.27}$$

where $c(\lambda)$ is the sum of positive terms that are functions of λ. Therefore it is

$$\det(H_p(\lambda)) = \det(\boldsymbol{I}_{N(\delta-1)} - H_{\delta,2}) \det((1 + c(\lambda))\boldsymbol{I}_N) = \frac{1}{\delta^N}(1 + c(\lambda))^N, \tag{A.28}$$

and this proves the nonsingularity of $H_p(\lambda)$ for any nonnegative λ.

DIFFERENTIAL GAMES AND NONLINEAR $\mathcal{H}_\infty$ CONTROL IN INFINITE DIMENSIONS*

MACIEJ KOCAN† AND PIERPAOLO SORAVIA‡

Abstract. This paper studies the $\mathcal{H}_\infty$ control problem for a nonlinear, unbounded, infinite dimensional system with state constraints. We characterize the solvability of the problem by means of a Hamilton–Jacobi–Isaacs (HJI) equation, proving that the $\mathcal{H}_\infty$ problem can be solved if and only if the HJI equation has a positive definite viscosity supersolution, vanishing and continuous at the origin. In order to do so, the standard definition of the $\mathcal{H}_\infty$ problem has to be relaxed by using the theory of differential games. We apply our results to the one phase Stefan problem.

Key words. viscosity solutions, nonlinear semigroups, accretive operators, dynamic programming, nonlinear $\mathcal{H}_\infty$ control, optimality principles

1. Introduction.

We study the infinite dimensional, controlled dynamical system subject to unknown deterministic disturbances with full state information

$$\left\{\begin{array}{ll} y'(t) + Ay(t) \ni f(y(t)) + Bu(t) + Cw(t) & \text{for } t \geq 0, \\ y(0) = x \in \overline{D(A)}. \end{array}\right. \tag{1.1}$$

The state space H, the control set U, and the disturbance set W are real Hilbert spaces; $A : D(A) \subset H \to H$ is a maximal monotone operator in H, possibly nonlinear and multivalued, with $0 \in \overline{D(A)}$. We will assume that

$$B\colon\ U \to H, \quad C\colon\ W \to H \quad \text{are bounded and linear operators,} \tag{1.2}$$

$$f\colon\ \overline{D(A)} \to H \quad \text{is Lipschitz continuous.} \tag{1.3}$$

For $x \in \overline{D(A)}$, disturbance $w \in L^2_{\text{loc}}(0,+\infty;W)$, and control $u \in L^2_{\text{loc}}(0,+\infty;U)$, it is well known that with the previous assumptions system (1.1) admits a unique trajectory solution $y(\cdot) \equiv y(\cdot,x,u,w) \in C([0,\infty);H)$ in the *mild* sense. For the general theory of nonlinear semigroups and its applications to partial differential equations the reader can consult, for instance, the books by Brézis [8], Barbu [2], [3], Deimling [11], Vrabie [32], and Evans [14]. Since the operators B, C are linear and bounded, our state equation does not apply to systems modeling boundary control problems. However, we put ourselves under assumptions that include large classes of distributed parameter systems, such as, for instance, parabolic variational inequalities describing free boundary parabolic problems. Such systems, in order to be modeled as abstract evolution equations, require the use of a nonlinear, unbounded, and multivalued A.

For explicit examples, the reader can check Barbu [3], Vrabie [32], and [17]. Moreover, in section 2 we recall the abstract setting for the one phase Stefan problem, the prototype of free boundary parabolic problems and well-known model for the melting of ice, and apply our results to that example. We do not seek the most general assumptions on the right-hand side of the differential equation in (1.1) under which our techniques work, in order to reduce some technicalities that might obscure some of the delicate steps of the arguments. For instance, every result could be formulated in the generality of [17].

Our goal is to extend to nonlinear, infinite dimensional systems the equivalence between solvability of the $\mathcal{H}_\infty$ suboptimal control problem for (1.1) and the existence of a nonnegative (positive definite) (super)solution of the corresponding Hamilton–Jacobi–Isaacs (HJI) equation. More precisely, we define the problem as follows. Given $\gamma > 0$ (the disturbance attenuation level) and

$$g\colon \overline{D(A)} \to [0, +\infty] \quad \text{lower semicontinuous}, \quad g(0) = 0, \tag{1.4}$$

we are concerned with existence of a family of *strategies* for the controller $\{\alpha_x[w]\}_{x\in\overline{D(A)}}$, i.e., causal functionals of the disturbance w, which guarantee that the undisturbed system ($w \equiv 0$ in (1.1)) is locally (or locally asymptotically) Lyapunov stable at the origin and such that the following L^2-gain condition is satisfied:

$$\begin{aligned}\int_0^T \left(g(y(t)) + \|\alpha_x[w](t)\|^2\right) dt \quad &\leq \gamma^2 \int_0^T \|w(t)\|^2 dt + K(x) \\ &\text{for all } T > 0,\ w \in L^2_{\mathrm{loc}}(0, \infty; W).\end{aligned} \tag{1.5}$$

In (1.5) we want $K\colon \overline{D(A)} \to [0, +\infty]$, $\mathrm{dom}(K) \equiv \{x\colon\ K(x) \text{ is finite}\} = \overline{\mathrm{dom}(g)} =: \mathcal{K}$, and we require that $K(0) = 0$. The terminology strategy comes from the theory of differential games, in particular from Elliott–Kalton [13] and the references therein. We will denote by Δ the set of strategies, that is, functionals $\alpha\colon L^2_{\mathrm{loc}}(0, +\infty; W) \to L^2_{\mathrm{loc}}(0, +\infty; U)$ characterized by causality, i.e., such that

$$\begin{aligned}w_1 = w_2 \ \text{ almost everywhere (a.e.) in } [0, T],\ T > 0,\ \text{implies} \\ \alpha[w_1] = \alpha[w_2] \ \text{ a.e. in } [0, T].\end{aligned}$$

We note that one can give an equivalent formulation of (1.5) which involves only $w \in L^2(0, \infty; W)$. This is an easy exercise that we leave to the reader. A discontinuous running cost g is often useful in practice, and allowing g to be extended real valued is motivated by state constraints, as we discuss at the beginning of the next section.

The reader will recognize that our definition of the $\mathcal{H}_\infty$ suboptimal problem is nonstandard. The classical one requires that the family of strategies $\{\alpha_x\}$ can be constructed with a feedback control. We need to relax the definition in order to pursue the equivalence between the solvability of the problem and of the HJI equation which is

$$\langle Ax, DV_\gamma\rangle + H(x, DV_\gamma) = g(x) \quad \text{in } \overline{D(A)} \tag{1.6}$$

with Hamiltonian (note that the so-called Isaacs condition holds)

$$\begin{aligned}H(x,p) \ &= \inf_{w\in W} \sup_{u\in U} \left\{-\langle f(x) + Bu + Cw, p\rangle - \|u\|^2 + \gamma^2\|w\|^2\right\} \\ &= \sup_{u\in U} \inf_{w\in W} \left\{-\langle f(x) + Bu + Cw, p\rangle - \|u\|^2 + \gamma^2\|w\|^2\right\} \\ &= -\langle f(x), p\rangle + \frac{1}{4}\|B^*p\|^2 - \frac{1}{4\gamma^2}\|C^*p\|^2.\end{aligned} \tag{1.7}$$

In general, equations like (1.6) do not have smooth (super)solutions, and this is the main problem that arises when studying nonlinear systems. One therefore first needs to interpret solutions of (1.6) in an appropriate weak sense, and we will use the Crandall–Lions theory of viscosity solutions (see [9]). Moreover, nonsmooth solutions make it very difficult to implement the standard *recipe* for the feedback solution of the $\mathcal{H}_\infty$ problem for affine systems, in this case, $u(x) = -\frac{1}{2}B^*DV(x)$. In fact, a continuous feedback solution may not exist in general for a nonlinear system, even though (1.6) has a (nonsmooth) viscosity solution and the $\mathcal{H}_\infty$ problem could be solvable in our weaker sense. This fact gives us the reason for relaxing the definition of the $\mathcal{H}_\infty$ problem. Note that solving the problem in our sense is a necessary condition in order to be able to design a feedback solution; see the statement of Theorem 2.5 below. How far we can go in improving the solution that we characterize in this paper in the quest for a feedback solution of the problem is still an open and intriguing question; see, however, Theorem 2.5 and Corollary 2.6 for possible results in this direction.

In order to achieve our goal, we proceed as follows. We show that checking the gain condition (1.5) is equivalent to checking whether the value function of a differential game

$$(1.8) \qquad V_\gamma(x) = \inf_{\alpha\in\Delta} \sup_{w\in L^2_{\mathrm{loc}}(0,+\infty;W)} \sup_{T\geq 0} \int_0^T \left(g(y(t)) + \|\alpha[w](t)\|^2 - \gamma^2\|w(t)\|^2\right) dt$$

is finite for all $x \in \overline{\mathrm{dom}(g)}$ and vanishes at the origin. Note that in our assumptions V_γ will be discontinuous in general. Note also that since $g \geq 0$, choosing $w(\cdot) \equiv 0 \in L^2(0,\infty;W)$ shows that $V_\gamma \geq 0$; thus $V_\gamma\colon \overline{D(A)} \to [0,+\infty]$. Checking when V_γ is finite is the crucial step of the problem. When the gain condition is obtained, the existence of a solution of the $\mathcal{H}_\infty$ problem is a rather easy consequence of the continuity of V_γ at the origin. Following the ideas of the dynamic programming approach for differential games, the value function V_γ is expected to solve the HJI equation (1.6). (The use of strategies here is essential to implement this approach without smoothness of V_γ.) This fact allows us to characterize the finiteness of the value function V_γ by means of a partial differential equation. We will show that indeed V_γ is a viscosity solution of the HJI equation and it is, in fact, the minimal nonnegative lower semicontinuous supersolution. These facts bear the following consequences: (1) (Theorem 2.3) the L^2-gain condition (1.5) is equivalent to the existence of a finite nonnegative (super)solution, vanishing at the origin, of the HJI equation (1.6); (2) (Theorem 2.4) the existence of a solution of the $\mathcal{H}_\infty$ problem is equivalent to the existence of a positive definite (super)solution of (1.6), vanishing and *continuous* at the origin.

Our results generalize well-known statements holding in the finite dimensional case and for linear systems although, as far as we know, this is the first paper introducing state constraints in the problem; see the beginning of section 2. We extend the current literature even for a linear A in that we never suppose the term g to be continuous. To give a flavor of the difficulties involved, note that solutions of (1.6) are never unique, so classical ideas of viscosity solutions do not apply directly. In general, (1.6) might even have multiple solutions vanishing at the origin. We will use instead versions of the so-called *optimality principles* for solutions of HJI equations without uniqueness that we develop here in an infinite dimensional differential games framework for the first time. Our proofs follow the lines of those in Soravia [23] and [25], where analogous results were proved in the finite dimensional case, but with several additional difficulties, due to the infinite dimensional setting and the unbounded term in the dynamics. Some ideas to deal with state constraints in the infinite dimensional setting were developed in [17] for control systems. In [18] we already studied dissipative systems and the way they are related to the $\mathcal{H}_\infty$ problem. That case turns out to be technically much easier and corresponds to checking the L^2-gain condition (1.5) with a given predetermined Lipschitz continuous feedback $u = u(x)$ in (1.1). Those results can apply here only when (1.6) has a smooth supersolution, and, as a result, the differential games framework is never needed. In general, one should first determine whether the problem is solvable in our sense by solving (1.6) in the viscosity sense, and next try to improve the result and build a (possibly discontinuous) feedback solution.

We recall that the infinite dimensional case of the $\mathcal{H}_\infty$-control problem was previously studied for linear systems with distributed parameters by Van Keulen–Peters–Curtain [29] and Van Keulen [30], in the full information and partial information settings, respectively. Linear abstract systems under assumptions containing boundary control problems were considered by Barbu [5]. The case of nonlinear systems, but with a linear unbounded operator A, was studied by Barbu [4], [6]. The $\mathcal{H}_\infty$ problem in finite dimensions traces back to Zames [33] for linear systems; see also [15], [22], and [12]. For nonlinear-affine systems and smooth solutions of the HJI equation the problem was studied by van der Schaft [28] and Ball–Helton–Walker [1]. For general nonlinear systems and the approach using differential games and viscosity solutions, we refer the reader to the papers by one of the authors [24] and [23]. A general reference to the differential games approach is the book by Basar–Bernhard [7]. The theory of viscosity solutions for HJI equations with nonlinear unbounded terms, see section 2 for the definition, has been developed in works by Tataru [26], [27], Crandall–Lions [10], and Kocan–Soravia [17]. We do emphasize that this theory is quite recent, and to us it seems interesting by itself that the details of a technically complicated problem, such as the $\mathcal{H}_\infty$ suboptimal control problem, can be carried through.

The plan of the paper is as follows. In section 2 we present the main statements and a motivating example. The rest of the paper is devoted to the proofs. In section 3 we study the regularity of the value function V_γ and its relation with the HJI equation (1.6). Section 4 contains technical steps needed in the other proofs: we describe a change of variables for (1.6) which is implemented through an auxiliary problem. Eventually, in section 5 we complete the proofs of the main results.

In this paper $(S(\cdot))_{t\geq 0}$ indicates the nonlinear semigroup generated by $-A$. We denote by $Lip(\Omega)$ the space of all Lipschitz continuous functions on Ω, and, for $\psi \in Lip(\Omega)$, $L(\psi)$ will denote its best Lipschitz constant. If L is a Lipschitz constant for ψ, we say that ψ is L-Lipschitz continuous. We also indicate with P the projection of H onto $\overline{D(A)}$ and, for any normed space X, $B_r^X(x)$ stands for the closed ball in X of radius r centered at x. $USC(X)$ and $LSC(X)$ will stand for the upper and lower semicontinuous extended real-valued functions on X, respectively.

2. Main results, viscosity solutions. We start this section discussing the role of a lower semicontinuous and extended real-valued cost function g. This generality allows us the possibility of introducing state constraints to the system. Note for this purpose that when the left-hand side of (1.5) is finite, then necessarily $g(y(t))$ is finite for a.e. $t \geq 0$, and then

$$y(t) \in \mathcal{K} = \overline{\mathrm{dom}(g)} \quad \text{for all } t \geq 0.$$

Therefore, $\overline{\mathrm{dom}(g)}$ acts as a state constraint on the system. This fact is particularly helpful in the applications, especially in the infinite dimensional setting, where it is even useful to allow $\mathcal{K}$ to have an empty interior relative to $\overline{D(A)}$; see the examples in the paper by the authors [17].

Now we discuss the main assumption on the system. We will impose the following rather natural stability assumption on (1.1).

(2.1)

$$\begin{array}{l}\text{If } u_n \rightharpoonup u \text{ weakly in } L^2(0,T;U) \text{ for some } T>0, \text{ then for every } x \in \overline{D(A)},\\ t \in [0,T] \text{ and } w \in L^2(0,t;W),\ y(t,x,u_n,w) \to y(t,x,u,w) \text{ in } H.\end{array}$$

Remark 1. Condition (2.1), which is the strongest, although natural, assumption that we make on the system, is discussed in detail in Kocan–Soravia [17], and we refer the reader to that paper for additional references. For instance, it turns out that if $-A$ generates a compact semigroup and (1.2) and (1.3) hold, then (2.1) is satisfied; see Proposition 2.7 in [17]. All the statements we prove can also be shown by similar arguments if we assume the following condition instead of (2.1).

$$\left\{\begin{array}{l}\text{If } u_n \rightharpoonup u \text{ weakly in } L^2(0,T;U) \text{ for some } T>0, \text{ then for all } x, x_n \in \overline{D(A)},\\ x_n \rightharpoonup x,\ t \in [0,T] \text{ and } w \in L^2(0,t;W),\ y(t,x_n,u_n,w) \rightharpoonup y(t,x,u,w) \text{ in } H.\end{array}\right.$$

In this case the function g should be also assumed to be weakly lower semicontinuous, and then the weak lower semicontinuity of the value function can be achieved in the statements below. If $-A$ is the linear generator of a semigroup and $f \equiv 0$, then it is well known that the system (1.1) satisfies such a condition. We will not explicitly include this part in the statements for better clarity of the exposition.

We now recall the concept of stability that we require on our system.

DEFINITION 2.1. *We say that the undisturbed system*

$$y' + Ay \ni f(y) + Bu$$

is locally Lyapunov stable at 0, *if for every open neighborhood* $\mathcal{U}$ *of* 0 *in* H *we can find* $\delta > 0$ *such that for* $\|x\| \le \delta$, $x \in \overline{D(A)}$, *there is* $u \in L^2_{\mathrm{loc}}(0,+\infty;U)$ *such that* $y(t,x,u,0) \in \overline{D(A)} \cap \mathcal{U}$ *for all* $t \ge 0$. *If, in addition,*

$$\lim_{t\to+\infty} y(t,x,u,0) = 0,$$

then we say that the system is locally asymptotically stable at 0.

We will also use the following definition below.

DEFINITION 2.2. *We say that a function* $U\colon \overline{D(A)} \to [0,+\infty]$ *is locally positive definite at* 0 *if* $U(0)=0$ *and there is* $\sigma > 0$ *and a continuous, nondecreasing function* $\omega\colon [0,+\infty) \to [0,+\infty)$ *such that* $U(x) \ge \omega(\|x\|)$ *for* $x \in \overline{D(A)}$, $\|x\| \le \sigma$, *and* $\omega(r) = 0$ *if and only if* $r = 0$.

We now state our main results. The precise notion of viscosity solution that we use will be explained at the end of the section. Note that we allow solutions to be extended real valued.

THEOREM 2.3 (characterization of L^2-gain). *Assume that* (1.2), (1.3), (1.4) *and* (2.1) *hold. Then there is a family of strategies* $\{\alpha_x\colon\ x \in \overline{D(A)}\}$ *and a function* $K\colon \overline{D(A)} \to [0,+\infty]$ *satisfying* (1.5), $K(0)=0$, *and* $\overline{\mathrm{dom}(g)} \subset \mathrm{dom}(K)$ *if and only if the HJI equation* (1.6), *where* H *is given in* (1.7), *has a viscosity supersolution* $U\colon \overline{D(A)} \to [0,+\infty]$ *satisfying* $\mathrm{dom}(U) \supset \overline{\mathrm{dom}(g)}$ *and* $U(0)=0$. *In this case, a* *function with these properties is* V_γ, *defined in* (1.8), *and the choice* $K = V_\gamma$ *also gives the best possible estimate in* (1.5) *when choosing a family of optimal strategies for* V_γ.

If, moreover, there is $M > 0$ *such that*

$$V_\gamma(x),\ g(x) \leq M(1 + \|x\|^2), \quad x \in \overline{D(A)},$$

then ${V_\gamma}^*$ *is also a viscosity subsolution of the HJI equation* (1.6) *in* $\{x \in \overline{D(A)}\colon\ {V_\gamma}^*(x) > 0\}$.

The notation ${V_\gamma}^*$ in the statement above refers to the upper semicontinuous envelope of V_γ which is recalled below in (2.8). We recall that ${V_\gamma}^* = V_\gamma$ when the latter is upper semicontinuous.

Theorem 2.4 (characterization of the $\mathcal{H}_\infty$ suboptimal problem). *Assume that* (1.2), (1.3), (1.4), *and* (2.1) *hold. If there is a nonnegative viscosity supersolution* $U\colon \overline{D(A)} \to [0, +\infty]$ *of* (1.6), *locally positive definite at* 0 *and continuous at* 0, *then there exist a family of strategies* $\{\alpha_x\}$ *and a function* $K\colon \overline{D(A)} \to [0, +\infty]$ *continuous at* 0, $K(0) = 0$, *satisfying* (1.5) *and such that the family of controls* $\{\alpha_x[0]\}$ *provides local Lyapunov stability of the undisturbed system at the origin. The system is, moreover, locally asymptotically stable at* 0 *if* g *is locally positive definite at* 0.

If V_γ *is locally positive definite at* 0, *the previous condition is also necessary.*

Sometimes one can really construct smooth supersolutions of the HJI equation (1.6). Then the sufficiency part of Theorem 2.4 can be used to construct in the usual way a feedback solution of the $\mathcal{H}_\infty$ suboptimal control problem. Below we give a specific example where it can be applied. Suppose that $U\colon \overline{D(A)} \to \mathbb{R}$ is a C^1 function, meaning that U is continuously Fréchet differentiable on some open set $\Omega \subset H$ containing $\overline{D(A)}$. As usual, we think of $DU(x)$—the Fréchet differential of U at x—as an element of H, thus identifying H with its dual. We will say that such U is a *classical* supersolution of (1.6) if for every $(x, y) \in A$, i.e., $y \in Ax$, we have

$$\langle y, DU(x)\rangle + H(x, DU(x)) \geq g(x).$$

Classical supersolutions are viscosity supersolutions; see Proposition 6.3 in [19]. Define the feedback control $u(x)\colon = -\frac{1}{2}B^* DU(x)$, and consider the closed loop system

$$y'(t) + Ay(t) \ni f(y(t)) - \frac{1}{2}BB^* DU(y(t)) + Cw(t), \quad y(0) = x. \tag{2.2}$$

Below we will denote by $y(\cdot) = y(\cdot, x, w)$ its mild solution.

Theorem 2.5 (feedback solution). *Assume that* (1.2), (1.3), *and* (1.4) *hold. Suppose that* $U\colon \overline{D(A)} \to \mathbb{R}$ *is a* C^1, *nonnegative, and locally positive definite at* 0 *classical supersolution of* (1.6) *and that* $DU(\cdot)$ *is Lipschitz continuous. Then* $u = u(x)$, *as above, is a feedback solution of the* $\mathcal{H}_\infty$ *suboptimal problem and the family of strategies defined by the position*

$$\alpha_x[w](t) = u(y(t, x, w)), \quad t \geq 0, \tag{2.3}$$

solves the $\mathcal{H}_\infty$ *suboptimal problem in the sense of the definition in the introduction.*

The proof of Theorem 2.5 can be obtained in a straightforward way by observing that U in the statement is a classical supersolution of

$$\begin{aligned}\langle Ax, DU(x)\rangle + \inf\nolimits_{w \in W} \left\{-\langle f(x) + Cw - Bu(x), DU(x)\rangle + \gamma^2 \|w\|^2\right\}\\ \geq \|u(x)\|^2 + g(x) \quad \text{in } \overline{D(A)},\end{aligned}$$

and by using Theorem 2.4 in the case where the control set U is a singleton. We will leave the easy details to the reader.

We pause a little to discuss an example where our framework applies.

Example 1. We consider a simplified version of the one phase Stefan problem, the well-known model for melting ice, see, e.g., Barbu [3]. Let $\Omega \subset \mathbb{R}^N$ be a bounded, open, and smooth set, $N \geq 2$. We want to study the $\mathcal{H}_\infty$ suboptimal problem for the following system, $(t,x) \in (0,+\infty) \times \Omega$,

$$\left\{ \begin{array}{ll} y_t(t,x) - \Delta y(t,x) & \geq f(y(t,x)) + Bu(t) + Cw(t), \\ y_t(t,x) - \Delta y(t,x) & = f(y(t,x)) + Bu(t) + Cw(t) \text{ if } \ y(t,x) > 0, \\ y(t,x) & \geq 0, \quad (t,x) \in (0,+\infty) \times \Omega, \\ \alpha y(t,x) + \beta \frac{\partial y}{\partial n}(t,x) & = 0, \quad (t,x) \in (0,+\infty) \times \partial\Omega, \\ y(0,x) & = y_0(x), \quad x \in \Omega, \end{array} \right. \tag{2.4}$$

where $\alpha,\ \beta \geq 0$ and $\alpha + \beta > 0$. Here we choose as state space $H = L^2(\Omega)$. We can model $-\Delta$ and the boundary conditions with a linear, bounded operator $\tilde{A} \in \mathcal{L}(V, V')$, where $V = H^1(\Omega)$ (or $V = H^1_0(\Omega)$ if $\beta = 0$) which, at least in the case $\beta \neq 0$, is

$$\langle \tilde{A}y, z\rangle = \int_\Omega Dy \cdot Dz \, dx + \frac{\alpha}{\beta} \int_{\partial\Omega} y \cdot z \, d\sigma.$$

To model the variational inequality

$$\min\{y_t - \Delta y - f(y) - Bu - Cw, y\} = 0,$$

which is equivalent to (2.4) except for the boundary conditions, let $\varphi\colon\ H \to \mathbb{R} \cup \{+\infty\}$ be the indicator function of the set $\{y \in V\colon\ \ y \geq 0\}$, i.e.,

$$\varphi(y) = \left\{ \begin{array}{ll} 0, & y \in V,\ y \geq 0, \\ +\infty, & \text{elsewhere}. \end{array} \right.$$

Then define $A = (\tilde{A} + \partial\varphi) \cap (H \times H)$, where $\partial\varphi$ is the subgradient of the convex function φ in the sense of convex analysis; see Rockafellar [31]. It is well known (see Barbu [3]) that then $A = \partial\Phi$, where

$$\Phi(y) = \left\{ \begin{array}{ll} \frac{1}{2}\langle \tilde{A}y, y\rangle, & y \in V,\ y \geq 0, \\ +\infty, & \text{elsewhere}. \end{array} \right.$$

Note that Φ is convex with nontrivial domain, and therefore A is maximal monotone, nonlinear, and multivalued. Moreover, it can be shown that Φ is of compact type, and hence $-A$ generates a compact semigroup. In particular, the assumption (2.1) is satisfied by our results in [17]. System (2.4) is now written in the form (1.1).

For the system modeled in the previous example, let us now consider the running cost g with at most quadratic growth, i.e., $g(x) \leq M\|x\|^2$ for $x \in H$ and some $M > 0$. (We do not add extra state constraints and will only apply Theorem 2.5 for simplicity.) We will suppose that $f(0) = 0$ and show that, at least for sufficiently large values of the disturbance attenuation level γ, (1.6) has a classical supersolution of the form $V(x) = K\|x\|^2$, with a suitable constant $K > 0$. Since A is monotone and $(0,0) \in A$, we have $\langle y, x\rangle \geq 0$ for every $(x,y) \in A$, and thus to verify that V is a classical supersolution of (1.6) it is sufficient to prove the pointwise relation

$$-\langle f(x), DV(x)\rangle + \frac{1}{4}\|B^* DV(x)\|^2 - \frac{1}{4\gamma^2}\|C^* DV(x)\|^2 \geq g(x)$$

for $x \in \overline{D(A)}$. Easy computations, using the fact that f is L-Lipschitz continuous and $f(0) = 0$, show that it is enough to find $K > 0$ satisfying

$$K^2 \left(\inf \left\{ \|B^* x\|^2 \colon \ \|x\| = 1 \right\} - \frac{1}{\gamma^2} \|C^*\|^2 \right) - 2LK - M \geq 0.$$

It is clear that we will succeed for any choice of γ such that

$$\gamma \inf \left\{ \|B^* x\| \colon \ \|x\| = 1 \right\} > \|C^*\|. \tag{2.5}$$

By applying Theorem 2.5 we then get the following result.

Corollary 2.6. *Assume that* (1.2)*,* (1.3)*, and* (1.4) *hold, and that* $f(0) = 0$*. Let* g *have at most quadratic growth. If* $\inf\{\|B^* x\| \colon \ \|x\| = 1\} > 0$*, then for any disturbance attenuation level* γ *satisfying* (2.5) *we can find a constant* $K > 0$ *(which can be explicitly obtained from the computations above) such that the linear feedback law* $u(x) = -KB^* x$ *solves the* $\mathcal{H}_\infty$ *suboptimal problem for the nonlinear system* (2.4)*.*

We resume to say what our plan is for the proof of the main statements. Theorems 2.3 and 2.4 are eventually proved in section 5 and will be achieved through the following series of statements that also have independent interest. The first one refers to the regularity of the value function V_γ. It is proved in section 3.

Proposition 2.7. *Assume that* (1.2), (1.3), (1.4)*, and* (2.1) *hold. Then the value function* V_γ *in* (1.8) *has optimal strategies at any point. In particular,* (1.5) *holds at* $x \in \overline{\mathrm{dom}(g)}$ *for some* $\alpha \in \Delta$ *and* $K(x) < +\infty$ *if and only if* $V_\gamma(x) < +\infty$*. Thus, the* L^2*-gain condition* (1.5) *with* $K(0) = 0$ *can be satisfied if and only if* V_γ *is finite on* $\overline{\mathrm{dom}(g)}$ *and* $V_\gamma(0) = 0$*. Moreover,* V_γ *is lower semicontinuous.*

The next statement concerns the relationships between V_γ and (1.6). It is proved at the end of section 3.

Proposition 2.8. *Assume that* (1.2), (1.3), (1.4)*, and* (2.1) *hold. Then* V_γ *is a viscosity supersolution of* (1.6)*. If, moreover, there is* $M \geq 0$ *such that*

$$V_\gamma(x),\, g(x) \leq M(1 + \|x\|^2) \quad \text{for all} \ \ x \in \overline{D(A)}, \tag{2.6}$$

then ${V_\gamma}^*$ *is a viscosity subsolution of* (1.6) *in* $\{x \in \overline{D(A)} \colon \ {V_\gamma}^*(x) > 0\}$*.*

The next proposition states a representation formula for viscosity solutions (optimality principle). This is the main step of the proof and is proved in section 5.

Proposition 2.9. *Assume that* (1.2), (1.3), (1.4)*, and* (2.1) *hold and suppose that the function* $U \colon \ \overline{D(A)} \to \mathbb{R} \cup \{+\infty\}$ *is a lower semicontinuous, bounded-from-below viscosity supersolution of* (1.6)*. Then for every* $x \in \mathrm{dom}(U)$ *we have*

$$\begin{aligned} U(x) \quad &= \inf_{\alpha \in \Delta} \sup_{w \in L^2_{\mathrm{loc}}(0,+\infty;W)} \sup_{T \geq 0} \left\{ \int_0^T \left(g(y(t)) + \|\alpha[w](t)\|^2 \right) dt \right. \\ &\quad \left. - \int_0^T \gamma^2 \|w(t)\|^2 dt + U(y(T)) \right\}, \end{aligned} \tag{2.7}$$

where $y(\cdot) = y(\cdot, x, \alpha[w], w)$*. In particular, if* U *is nonnegative, then* $U \geq V_\gamma$ *on* $\overline{D(A)}$*.*

We conclude this section with the definition of viscosity solution for first order, nonlinear Hamilton–Jacobi equations with unbounded, nonlinear terms. For a function $\Phi \colon \ \overline{D(A)} \to \mathbb{R}$ and $\hat{x} \in \overline{D(A)}$, let

$$D_A^- \Phi(\hat{x}) = \liminf_{\substack{x \to \hat{x} \\ h \downarrow 0}} \frac{\Phi(x) - \Phi\left(S(h)x\right)}{h}, \quad D_A^+ \Phi(\hat{x}) = \limsup_{\substack{x \to \hat{x} \\ h \downarrow 0}} \frac{\Phi(x) - \Phi\left(S(h)x\right)}{h}.$$

We refer the reader to [10] and [19] for the basic properties of such operators. Given an extended real-valued function u on $\overline{D(A)}$, we denote by u^* and u_* its upper and lower semicontinuous envelopes, respectively, i.e., for $x \in \overline{D(A)}$

$$u^*(x) = \limsup_{\overline{D(A)} \ni y \to x} u(y), \quad u_*(x) = \liminf_{\overline{D(A)} \ni y \to x} u(y). \tag{2.8}$$

Next, we introduce the *test functions* used to define viscosity solutions.

Definition 2.10. *We will say that* $\Phi = \varphi + \psi \in C^1(H) + Lip(H)$ *is a subtest (supertest, resp.) function if*

$$\varphi(Px) \le \ (\ge,\ \textit{resp.})\ \varphi(x) \qquad \textit{and} \ \ \psi(Px) \le \ (\ge)\ \psi(x) \quad \textit{for} \ \ x \in H.$$

We are now ready to define solutions of the equation (1.6).

Definition 2.11. *Assume that* (1.2), (1.3), *and* (1.4) *hold. A possibly extended real-valued function* $U \in USC(\overline{D(A)})$ $(U \in LSC(\overline{D(A)})$, *resp.) is a viscosity subsolution (resp., supersolution) of* (1.6) *if for every subtest (resp., supertest) function* $\Phi = \varphi + \psi \in C^1(H) + Lip(H)$ *and local maximum (resp., minimum)* $\hat{x} \in \mathrm{dom}(U)$ *of* $U - \Phi$ *relative to* $\overline{D(A)}$ *we have*

$$\begin{aligned} D_A^- \Phi(\hat{x}) \quad & + \inf_{w \in W} \sup_{u \in U} \{ -\langle f(\hat{x}) + Bu + Cw, D\varphi(\hat{x}) \rangle \\ & -L(\psi)(\|f(\hat{x})\| + \|Bu\| + \|Cw\|) - \|u\|^2 + \gamma^2 \|w\|^2 \} \le g^*(\hat{x}) \\ \Big(D_A^+ \Phi(\hat{x}) \quad & + \inf_{w \in W} \sup_{u \in U} \{ -\langle f(\hat{x}) + Bu + Cw, D\varphi(\hat{x}) \rangle \\ & +L(\psi)(\|f(\hat{x})\| + \|Bu\| + \|Cw\|) - \|u\|^2 + \gamma^2 \|w\|^2 \} \ge g(\hat{x}), \text{resp.} \Big) \end{aligned}$$

A function U *(not necessarily continuous) defined on* $\overline{D(A)}$ *is a solution of* (1.6) *if* U^* *is a subsolution and* U_* *is a supersolution of* (1.6).

We refer the reader to [10] and to [17] for some more details and discussion of the notion of viscosity solution. Just recall after [17] that without loss of generality one can assume that the test function Φ (equivalently, φ) appearing in Definition 2.11 is globally Lipschitz continuous: $\Phi \in Lip(H)$.

3. Value function and the dynamic programming equation.

In this section we study the value function in (1.8) and prove its relations with the HJI equation (1.6).

First of all, we will obtain some useful estimates concerning the trajectories of the system. Gronwall's inequality immediately shows that for all $x, z \in \overline{D(A)}$, $u \in L^1_{\mathrm{loc}}(0, \infty; U)$, and $w \in L^1_{\mathrm{loc}}(0, \infty; W)$ we have

$$\|y(t, x, u, w) - y(t, z, u, w)\| \le \|x - z\| e^{L(f)\, t} \quad \text{for all} \ \ t \ge 0. \tag{3.1}$$

From (1.2), (1.3), and Hölder's inequality, for all $t \ge 0$ we also have

$$\begin{aligned} \|y(t) - x\| & \le \|S(t)x - x\| + \int_0^t \|f(y(s)) + Bu(s) + Cw(s)\| ds \\ & \le \|S(t)x - x\| + t\|f(x)\| \\ & +K \left(\sqrt{t} \|u\|_{L^2(0,t;U)} + \sqrt{t} \|w\|_{L^2(0,t;W)} + \int_0^t \|y(s) - x\| ds \right) \end{aligned} \tag{3.2}$$

with a constant $K = K(f, B, C)$. Then by Gronwall's inequality, for all $t \geq 0$ we obtain

$$\begin{aligned} \|y(t) - x\| &\leq K\Big(t\|f(x)\| + \sup_{0\leq s\leq t} \|S(s)x - x\| \\ &+\sqrt{t}\|u\|_{L^2(0,t;U)} + \sqrt{t}\|w\|_{L^2(0,t;W)}\Big)e^{Kt}, \end{aligned} \tag{3.3}$$

with a possibly new constant K. In particular, we conclude that for every $x \in \overline{D(A)}$

$$\begin{aligned} &y(t, x, u, w) \to x \ \text{ as } t \downarrow 0, \quad \text{uniformly for } u \text{ and } w \ \text{ bounded in} \\ &L^2(0, t; U) \text{ and } L^2(0, t; W), \quad \text{respectively.} \end{aligned} \tag{3.4}$$

Computations similar to those in (3.2) show that, if f is L-Lipschitz continuous, then for every $t \geq 0$

$$\begin{aligned} \|y(t) - S(t)x\| &\leq \left(\left(L \sup_{0\leq s\leq t} \|S(s)x - x\| + \|f(x)\|\right) t \right. \\ &\left. +\|B\| \int_0^t \|u\| + \|C\| \int_0^t \|w\|\right) e^{Lt}, \end{aligned} \tag{3.5}$$

where $y(\cdot) = y(\cdot, x, u, w)$.

We can now turn to study the value function. The next statement is the superoptimality part of the dynamic programming principle whose proof is standard. (For the suboptimality part, see the final statement in the proof of Proposition 2.8.) In the following for $t > 0$, $x \in \overline{D(A)}$, $u \in L^2(0, t; U)$, and $w \in L^2(0, t; W)$, we put

$$J(t, x, u, w) = \int_0^t \left(g(y(s, x, u, w)) + \|u(s)\|^2 - \gamma^2\|w(s)\|^2\right) ds.$$

PROPOSITION 3.1. *For any $x \in \overline{D(A)}$ and $t \geq 0$*

$$V_\gamma(x) \geq \inf_{\alpha\in\Delta} \sup_{w\in L^2(0,t;W)} \{J(t, x, \alpha[w], w) + V_\gamma(y(t, x, \alpha[w], w))\}. \tag{3.6}$$

COROLLARY 3.2. *Assume* (1.2), (1.3), *and* (1.4), *and suppose that $V_\gamma(x) < +\infty$ and $t \geq 0$. Then for every $w^* \in W$ and $M > \sqrt{V_\gamma(x)}$*

$$V_\gamma(x) \geq \inf \left\{J(t, x, u, w^*) + V_\gamma(y(t, x, u, w^*)) \colon \ u \in B^{L^2(0,t;U)}_{M+\gamma\sqrt{t}\|w^*\|}(0)\right\}.$$

Proof. Fix $x \in \overline{D(A)}$, $w^* \in W$, $t > 0$, and let M be as above. From Proposition 3.1

$$\begin{aligned} V_\gamma(x) &\geq \inf_{\alpha\in\Delta} \{J(t, x, \alpha[w^*], w^*) + V_\gamma(y(t, x, \alpha[w^*], w^*))\} \\ &\geq \inf_{u\in L^2(0,t;U)} \{J(t, x, u, w^*) + V_\gamma(y(t, x, u, w^*))\}. \end{aligned}$$

Suppose that $\|u\|_{L^2(0,t;U)} > \gamma\sqrt{t}\|w^*\| + M$. Since $V_\gamma, g \geq 0$, then

$$J(t, x, u, w^*) + V_\gamma(y(t, x, u, w^*)) \geq \int_0^t \|u(s)\|^2 \, ds - \gamma^2 t\|w^*\|^2 > M^2,$$

and hence the infimum of the left-hand side over all $\|u\|_{L^2(0,t;U)} > \gamma\sqrt{t}\|w^*\| + M$ is at least $M^2 > V_\gamma(x)$. □

To prove that the value function is lower semicontinuous, we will use the following general lemma that constructs optimal strategies in a variety of situations.

LEMMA 3.3. *Suppose that* $g, g_n, \varphi, \varphi_n \in LSC(\overline{D(A)})$, $(\varphi_n)_n$, $(g_n)_n$ *are nondecreasing sequences,* $\sup_n \varphi_n = \varphi$ *and* $\sup_n g_n = g$. *If* (2.1) *holds and*

$$M \equiv \sup_{n\geq 1} \inf_{\alpha\in\Delta} \sup_{w\in L^2_{\mathrm{loc}}} \sup_{t\geq 0} \left\{ \int_0^t \left(g_n(y(s)) + \|\alpha[w](s)\|^2 - \gamma^2\|w(s)\|^2 \right) ds + \varphi_n(y(t)) \right\},$$

where $x \in \overline{D(A)}$ *is fixed and* $y(\cdot) = y(\cdot, x, \alpha[w], w)$, *then there exists* $\alpha^\# \in \Delta$ *such that*

$$\begin{aligned} M = \sup_{w\in L^2_{\mathrm{loc}}} \sup_{t\geq 0} \quad & \left\{ \int_0^t \left(g(y(s,x,\alpha^\#[w],w)) + \|\alpha^\#[w](s)\|^2 \right) ds \right. \\ & \left. -\gamma^2 \int_0^t \|w(s)\|^2 ds + \varphi(y(t,x,\alpha^\#[w],w)) \right\}. \end{aligned} \tag{3.7}$$

Proof. (1) It is clear that M is not bigger than the right-hand side of (3.7) for any choice of $\alpha^\#$. To prove the reverse inequality, we may assume that $M < +\infty$. For every n there exists $\alpha_n \in \Delta$ such that for every $t \geq 0$ and $w \in L^2_{\mathrm{loc}}(0,\infty;W)$ denoting $y_n(\cdot) \equiv y(\cdot, x, \alpha_n[w], w)$, we have

$$\begin{aligned} M + \tfrac{1}{n} \quad & \geq \int_0^t \left(g_n(y_n(s)) + \|\alpha_n[w](s)\|^2 - \gamma^2\|w(s)\|^2 \right) ds + \varphi_n(y_n(t)) \\ & \geq \int_0^t \left(\|\alpha_n[w](s)\|^2 - \gamma^2\|w(s)\|^2 \right) ds. \end{aligned}$$

Hence for all $w \in L^2_{\mathrm{loc}}$ and $t \geq 0$ we have

$$\|\alpha_n[w]\|^2_{L^2(0,t;U)} \leq M + 1 + \gamma^2\|w\|^2_{L^2(0,t;W)}. \tag{3.8}$$

(2) For $T > 0$, every $\alpha \in \Delta$ can be viewed as an element of the product space

$$\left(L^2(0,T;U)\right)^{L^2(0,T;W)}.$$

From (3.8) we have that, up to an obvious identification, $\alpha_n \in \Pi_T$ for all T, n, where

$$\Pi_T = \{\alpha\colon\ L^2(0,T;W) \to L^2(0,T;U)\colon \|\alpha[w]\|^2_{L^2(0,T;U)} \leq M + 1 + \gamma^2\|w\|^2_{L^2(0,T;W)}\}.$$

Since bounded closed balls in $L^2(0,T;U)$ are weakly compact, it follows that Π_T equipped with the product topology is compact. Therefore, for $T = 1$, there is a subnet $\{\alpha^1_\lambda\}_{\lambda\in\Lambda_1}$ of $\{\alpha_n\}$ converging to some $\alpha^1 \in \Pi_1$. Given a positive integer k and a subnet $\{\alpha^k_\lambda\}_{\lambda\in\Lambda_k}$ of $\{\alpha_n\}$ converging to $\alpha^k \in \Pi_k$, there exists a subnet $\{\alpha^{k+1}_\lambda\}_{\lambda\in\Lambda_{k+1}}$ of $\{\alpha^k_\lambda\}_{\lambda\in\Lambda_k}$ converging to $\alpha^{k+1} \in \Pi_{k+1}$. Define $\alpha^\#\colon\ L^2_{\mathrm{loc}}(0,\infty;W) \to L^2_{\mathrm{loc}}(0,\infty;U)$ according to the rule

$$\alpha^\#[w](t) = \alpha^{k+1}[w](t), \quad k \leq t < k+1.$$

It is not difficult to see that nonanticipating strategies form a closed subset of any Π_T, and therefore $\alpha^\# \in \Delta$.

(3) We will finally show that $\alpha^\#$ has the desired property. Let $w \in L^2_{\mathrm{loc}}(0,\infty;W)$ and $t > 0$. By construction there is a subsequence n_k (possibly depending on w and t) such that

$$\alpha_{n_k}[w] \rightharpoonup \alpha^\#[w], \ \text{ weakly in } L^2(0,t;U), \text{ as } k \to \infty. \tag{3.9}$$

By the stability assumption (2.1) the trajectories $y_{n_k}(\cdot)$ converge pointwise to $y^\#(\cdot) \equiv y(\cdot, x, \alpha^\#[w], w)$. Using the lower semicontinuity of φ_n's, g_n's, and the norm, from Fatou's lemma, we deduce

$$\begin{aligned}\liminf_{k\to\infty} \quad & \int_0^t \left(g_{n_k}(y_{n_k}(s)) + \|\alpha_{n_k}[w](s)\|^2 - \gamma^2\|w(s)\|^2\right) ds + \varphi_{n_k}(y_{n_k}(t)) \\ & \geq \int_0^t \left(g(y^\#(s)) + \|\alpha^\#[w](s)\|^2 - \gamma^2\|w(s)\|^2\right) ds + \varphi(y^\#(t)).\end{aligned}$$

Therefore,

$$M \geq \int_0^t \left(g(y^\#(s)) + \|\alpha^\#[w](s)\|^2 - \gamma^2\|w(s)\|^2\right) ds + \varphi(y^\#(t))$$

for every $t \geq 0$ and $w \in L^2_{\text{loc}}(0, \infty; W)$, and hence the conclusion. □

Proof of Proposition 2.7. To prove that for all $x \in \overline{D(A)}$ there are optimal strategies for the value function $V_\gamma(x)$, we need just to apply Lemma 3.3 with $g_n \equiv g$ and $\varphi_n \equiv 0$. The statements concerning the L^2-gain condition then follow trivially. En-passant we note that, using the equivalent definition of V_γ with L^2 disturbances instead of L^2_{loc}, one could simplify this part of the proof by working directly with $L^2(0, \infty; W)$ and $L^2(0, \infty; U)$, which avoids the diagonal argument in the proof of Lemma 3.3.

In order to prove that the value function V_γ is lower semicontinuous, let $x_n \to x$, $x_n, x \in \overline{D(A)}$. Without loss of generality we may assume that $V_\gamma(x_n)$ converges to a finite limit, say, L. Let $\alpha_n \in \Delta$ be an optimal strategy for $V_\gamma(x_n)$, i.e., for every $t \geq 0$ and $w \in L^2(0, t; W)$

$$V_\gamma(x_n) \geq \int_0^t \left(g(y(s, x_n, \alpha_n[w], w)) + \|\alpha_n[w](s)\|^2 - \gamma^2\|w(s)\|^2\right) ds. \tag{3.10}$$

It follows that, if n is sufficiently big, for any $t \geq 0$ and $w \in L^2(0, t; W)$

$$\|\alpha_n[w]\|^2_{L^2(0,t;U)} \leq L + 1 + \gamma^2\|w\|^2_{L^2(0,t;W)}.$$

Arguing as in the proof of Lemma 3.3, there exists $\alpha^\# \in \Delta$ satisfying (3.9). Taking $\liminf$ in (3.10) as $n \to \infty$ as in Lemma 3.3 gives

$$L \geq \int_0^t \left(g(y(s, x, \alpha^\#[w], w)) + \|\alpha^\#[w](s)\|^2 - \gamma^2\|w(s)\|^2\right) ds$$

for every $t \geq 0$ and $w \in L^2(0, t; W)$, which yields $L \geq V_\gamma(x)$, completing the proof of Proposition 2.7. □

We end this section by proving that V_γ solves the HJI equation.

Proof of Proposition 2.8. We start by proving that V_γ is a viscosity supersolution. Recall that, by Proposition 2.7, V_γ is lower semicontinuous. Let $\Phi = \varphi + \psi$ be a Lipschitz continuous supertest function, and assume that $V_\gamma - \Phi$ attains a local minimum at $\hat{x} \in \text{dom}(V_\gamma)$. Note that it is conceivable that $g(\hat{x}) = +\infty$. If $D^+_A\Phi(\hat{x}) = +\infty$, there is nothing to prove. Otherwise, we argue by contradiction. Suppose that there are $\theta > 0$ and $w^* \in W$ such that for every $u \in U$

$$\begin{aligned}D^+_A\Phi(\hat{x}) - \langle f(\hat{x}) \quad & + Bu + Cw^*, D\varphi(\hat{x})\rangle + L(\psi)(\|f(\hat{x})\| + \|Bu\| + \|Cw^*\|) \\ & - \|u\|^2 + \gamma^2\|w^*\|^2 < g(\hat{x}) - 2\theta.\end{aligned} \tag{3.11}$$

First, we will show that

$$D_A^+\Phi(\hat{x}) > -\infty. \tag{3.12}$$

For $t > 0$ choose in the dynamic programming principle, Proposition 3.1, any t-optimal strategy α_t and denote $u_t = \alpha_t[0]$. Since $g \geq 0$, it follows that

$$V_\gamma(\hat{x}) + t \geq \int_0^t \|u_t(s)\|^2 ds + V_\gamma(y(t)), \tag{3.13}$$

where $y(\cdot) = y(\cdot, \hat{x}, u_t, 0)$. Since $V_\gamma \geq 0$, (3.13) yields a uniform bound on $\|u_t\|_{L^2(0,t;U)}$ and by (3.4) the assumption on Φ gives $V_\gamma(\hat{x}) - V_\gamma(y(t)) \leq \Phi(\hat{x}) - \Phi(y(t))$ for all sufficiently small t. From (3.13) and (3.5), for small t we then get

$$\begin{aligned}\Phi(S(t)\hat{x}) - \Phi(\hat{x}) \quad &\leq t - \int_0^t \|u_t\|^2 + \Phi(S(t)\hat{x}) - \Phi(y(t)) \\ &\leq t + L(\Phi)\|y(t) - S(t)\hat{x}\| - \int_0^t \|u_t\|^2 \leq Kt,\end{aligned}$$

where the last inequality also uses the Hölder inequality and an appropriate constant K. Hence $\Phi(S(t)\hat{x}) - \Phi(\hat{x}) \leq O(t)$ as $t \downarrow 0$, which yields (3.12).

Let $M = \sqrt{V_\gamma(\hat{x})} + 1$. Suppose that $\|u\|_{L^2(0,t;U)} \leq M$, $t > 0$, and for $s \in [0,t]$ put $y(s) = y(s, \hat{x}, u, w^*)$. From (3.4), (3.11), the coercivity in u of the left-hand side of (3.11), and the lower semicontinuity of g, it follows that, if t is sufficiently small, then for all $s \in [0,t]$

$$D_A^+\Phi(\hat{x}) - \langle v(s), D\varphi(y(s))\rangle + L(\psi)\|v(s)\| - \|u(s)\|^2 + \gamma^2\|w^*\|^2 < g(y(s)) - \theta,$$

where we denoted $v(s) = f(y(s)) + Bu(s) + Cw^*$. Integrating from 0 to t and using Tataru's result (see [27] and Corollary 4.8 in [19]) yields (note that it works just like formally except for the term $o(t)$)

$$t\theta \leq \int_0^t \left(g(y(s)) + \|u(s)\|^2 - \gamma^2\|w^*\|^2\right) ds + \Phi(y(t)) - \Phi(\hat{x}) + o(t),$$

as $t \to 0$, uniformly for all $\|u\|_{L^2(0,t;U)} \leq M$. By the local minimum property of Φ we obtain

$$t\theta \leq \int_0^t \left(g(y(s)) + \|u(s)\|^2 - \gamma^2\|w^*\|^2\right) ds + V_\gamma(y(t)) - V_\gamma(\hat{x}) + o(t)$$

for all $\|u\|_{L^2(0,t;U)} \leq M$. Then, from Corollary 3.2 (recall the choice of M), we get $t\theta \leq o(t)$ and a contradiction when choosing t sufficiently small.

To prove that, under the additional assumption (2.6), the function ${V_\gamma}^*$ is a subsolution of (1.6) in $\{x \in \overline{D(A)}\colon\ {V_\gamma}^*(x) > 0\}$, we can argue in a similar way as in section 4, where we prove the corresponding result for an auxiliary value function, which is needed in the most delicate step of the proof of Theorem 2.3. Specifically, the suboptimality part of the dynamic programming principle we need follows along the lines of the proof of Proposition 4.6, although adapting this proof requires the assumption (2.6). The fact that ${V_\gamma}^*$ solves the equation can then be adapted from the argument of the proof of Proposition 4.7; see also Proposition 2.4 in [17] for discontinuous value functions. We will therefore omit the details of this part. □

4. The auxiliary problem. Since our problem has unbounded controls and possibly a singular value function, we need to construct a suitable, more regular, auxiliary problem and then use the ideas of the theory of viscosity solutions to compare supersolutions of HJI equations and the corresponding value function. We start by introducing a change of variables. Define $\rho\colon\ \mathbb{R}\cup\{+\infty\}\to(0,\pi]$ as $\rho(t)=\frac{\pi}{2}+\tan^{-1}(t)$, $\rho(+\infty)=\pi$. Note that ρ is strictly increasing and 1-Lipschitz continuous on $\mathbb{R}$. Also, $\rho^{-1}\colon\ (0,\pi]\to\mathbb{R}\cup\{+\infty\}$ is given by $\rho^{-1}(s)=-\cot(s),\ s\in(0,\pi)$.

Let (1.2) and (1.3) hold and let $g\colon\ \overline{D(A)}\to[0,\infty)$ be continuous. Suppose that $U\in LSC(\overline{D(A)})$ is a bounded-from-below supersolution (in the sense of Definition 2.11) of (1.6). Define $W\colon\ \overline{D(A)}\times\mathbb{R}\to(0,\pi]$ according to

$$W(x,r)=\rho(U(x)+r). \tag{4.1}$$

Note that $U(x)=+\infty$ if and only if $W(x,r)=\pi$. Formal computations suggest that W ought to be a supersolution of

$$\begin{aligned}\langle Ax,D_xW\rangle\ &+\inf_{w\in W}\sup_{u\in U}\{-\langle f(x)+Bu+Cw,D_xW\rangle\\ &+\left(\gamma^2\|w\|^2-\|u\|^2-g(x)\right)D_rW\}=0.\end{aligned}\tag{4.2}$$

This is indeed the case if the solutions of (4.2) are meant in an appropriate viscosity sense, modeled on the one introduced in [16] and [21] (equations with separated variables) adapted to differential games in the spirit of Definition 2.11; see also [17]. Note that the Hamiltonian in (4.2) is not necessarily real valued unless $D_rW>0$.

Definition 4.1. *Let $\Omega\subseteq\overline{D(A)}\times\mathbb{R}$. A possibly extended real-valued function $W\in USC(\overline{D(A)}\times\mathbb{R})$ is a viscosity subsolution of* (4.2) *on Ω if for every subtest function Φ as in Definition* 2.10*, $\eta\in C^1(\mathbb{R})$, and local maximum $(\hat{x},\hat{r})\in\Omega\cap\mathrm{dom}(W)$ of $W(x,r)-\Phi(x)-\eta(r)$ relative to Ω, we have*

$$\begin{aligned}&D_A^-\Phi(\hat{x})+\inf_{w\in W}\sup_{u\in U}\{-\langle f(\hat{x})+Bu+Cw,D\varphi(\hat{x})\rangle\\ &-L(\psi)(\|f(\hat{x})\|+\|Bu\|+\|Cw\|)+\left(\gamma^2\|w\|^2-\|u\|^2-g(x)\right)\eta'(\hat{r})\}\le 0.\end{aligned}\tag{4.3}$$

Supersolutions and solutions are defined similarly, following Definition 2.11.

The precise result on the change of variables is the following. Its proof parallels that of Lemmas 3.8 and 3.9 in Kocan–Soravia [17], and we skip it.

Proposition 4.2. *Let $g\colon\ \overline{D(A)}\to[0,\infty)$ be bounded and continuous. Suppose that the function $U\colon\ \overline{D(A)}\to(-\infty,+\infty]$ is a bounded-from-below supersolution (in the sense of Definition* 2.11*) of* (1.6)*. Define $W\colon\ \overline{D(A)}\times\mathbb{R}\to(0,\pi]$ according to* (4.1)*. Then W is a supersolution of* (4.2) *on $\overline{D(A)}\times\mathbb{R}$ in the sense of Definition* 4.1.

At this point we study the auxiliary differential game that corresponds to the change of variables we introduced. Suppose that $g\colon\ \overline{D(A)}\to\mathbb{R}$ and $W\colon\ \overline{D(A)}\times\mathbb{R}\to(0,\infty)$ are bounded. For $\lambda>0$ we will consider an auxiliary value function

$$\begin{aligned}(V_{g,W}^\lambda\equiv)V^\lambda(x,r)\quad&=\inf\nolimits_{\alpha\in\Delta}\sup\nolimits_{w\in L^2_{\mathrm{loc}}(0,\infty;W)}\\ &\quad\sup\nolimits_{t\ge0}e^{-\lambda k(t,\alpha[w],w)}W\left(y(t,x,\alpha[w],w),r+r(t,x,\alpha[w],w)\right),\end{aligned}\tag{4.4}$$

where $(x,r)\in\overline{D(A)}\times\mathbb{R}$ and

$$\begin{aligned}k(t,u,w)\quad&=\int_0^t(1+\|u\|^2+\|w\|^2),\\ r(t,x,u,w)\quad&=\int_0^t\left(g(y(s,x,u,w))+\|u(s)\|^2-\gamma^2\|w(s)\|^2\right)ds.\end{aligned}$$

Choosing $t = 0$ in the definition (4.4) shows that $V^\lambda \geq W > 0$. Moreover, if $U\colon \overline{D(A)} \to \mathbb{R}$ and W is as in (4.1), then $0 < V^\lambda \leq \pi$. Note that for fixed $u \in L^2_{\mathrm{loc}}(0,\infty;U)$ and $w \in L^2_{\mathrm{loc}}(0,\infty;W)$, the function $k(\cdot,u,w)$ is strictly increasing from $[0,+\infty)$ to $[0,+\infty)$ and $t \leq k(t,u,w)$ for all u,w. We will denote by $t = t(\cdot,u,w)$ its inverse function, so, in particular, $k(t(\tau,u,w),u,w) = \tau$, $t(k(t,u,w),u,w) = t$ and $t(\tau,u,w) \leq \tau$; therefore, $t(\tau,u,w) \to 0$ as $\tau \to 0$, uniformly in $u \in L^2_{\mathrm{loc}}$ and $w \in L^2_{\mathrm{loc}}$. We will need to reparametrize the trajectories with the new parameter $\tau = \tau(t,u,w)$, which depends upon the trajectory, in order to get estimates which are uniform on the controls.

We start showing some estimates and regularity of the auxiliary value function.

Lemma 4.3. *Suppose that $g\colon \overline{D(A)} \to [0,\infty)$ and $U\colon \overline{D(A)} \to \mathbb{R}$ are bounded and let W be as in* (4.1). *Then $V^\lambda = V^\lambda_{g,W}$ satisfies*

$$\lim_{r\to-\infty} V^\lambda(x,r) = 0, \quad \textit{uniformly for all } x \in \overline{D(A)}. \tag{4.5}$$

Moreover, for every $M > 0$, $\sup\{V^\lambda(x,r)\colon\ x \in \overline{D(A)},\ r \leq M\} < \pi$.

Proof. Fix any $u^* \in U$. By definition (4.4), choosing $\alpha \equiv u^*$, we have

$$V^\lambda(x,r) \leq \sup_{t\geq 0} e^{-\lambda t}\rho\left(\|U\|_{L^\infty} + r + t(\|g\|_{L^\infty} + \|u^*\|^2)\right), \tag{4.6}$$

and evoking the elementary Lemma 4.4 below, this shows (4.5). If $r < M$, then from (4.6), $V^\lambda(x,r) \leq \rho\left(\|U\|_{L^\infty} + M + \|g\|_{L^\infty} + \|u^*\|^2\right) \vee \pi e^{-\lambda} < \pi$. □

Lemma 4.4. *Let $K,\lambda > 0$. For $r \in \mathbb{R}$ define $h(r) = \sup_{t\geq 0} e^{-\lambda t}\rho(Kt + r)$. Then* $\lim_{r\to-\infty} h(r) = 0$.

Proof. Clearly, $h \geq 0$. Let $\mu = \frac{\lambda}{K} > 0$; by changing variables it follows that $h(r) = e^{\mu r}\sup_{t\geq r} e^{-\mu t}\rho(t)$. Denoting $f(t) = e^{-\mu t}\rho(t)$, we have $f'(t) = e^{-\mu t}(\rho'(t) - \mu\rho(t))$, and since $\lim_{t\to-\infty}\frac{\rho'(t)}{\rho(t)} = 0$, there is t_0 such that $f' < 0$ on $(-\infty,t_0)$. Thus

$$\begin{aligned} h(r) &\leq e^{\mu r}\left(f(r) \vee \sup_{t\geq t_0} f(t)\right) \leq e^{\mu r}\left(e^{-\mu r}\rho(r) \vee \pi e^{-\mu t_0}\right) \\ &\leq \rho(r) \vee \pi e^{\mu(r-t_0)} \to 0 \quad \text{as} \quad r \to -\infty. \qquad \square \end{aligned}$$

Lemma 4.5. *Suppose that $g\colon \overline{D(A)} \to [0,\infty)$ and $U\colon \overline{D(A)} \to \mathbb{R}$ are bounded and Lipschitz continuous, let W be as in* (4.1) *and let $V^\lambda = V^\lambda_{g,W}$.*

(1) *Suppose that $(x_i,r_i) \in \overline{D(A)}\times\mathbb{R}$, $i = 1,2$, and $V^\lambda(x_1,r_1) > V^\lambda(x_2,r_2) > \delta > 0$. Then there exists $M = M(g,U,f,\lambda,\delta) > 0$ such that*

$$V^\lambda(x_1,r_1) - V^\lambda(x_2,r_2) \leq M\|x_1 - x_2\| + r_1 - r_2.$$

(2) *V^λ is Lipschitz continuous in a neighborhood of every point.*

(3) *Suppose that $(\hat{x},\hat{r}) \in \overline{D(A)}\times\mathbb{R}$ is such that $V^\lambda(\hat{x},\hat{r}) > \delta > 0$ and $\hat{r} < 1/\delta$. Then*

$$\liminf_{h\downarrow 0}\frac{V^\lambda(\hat{x},\hat{r}+h) - V^\lambda(\hat{x},\hat{r})}{h} \geq \beta > 0,$$

where $\beta = \beta(g,U,\lambda,\delta)$.

Proof. (1) By definition, for every $\sigma > 0$ there exists $\alpha_\sigma \in \Delta$ such that for all $t \geq 0$ and $w \in L^2(0,t;W)$ we have

$$e^{-\lambda k(t,\alpha_\sigma[w],w)}W\left(y(t,x_2,\alpha_\sigma[w],w), r_2 + r(t,x_2,\alpha_\sigma[w],w)\right) < V^\lambda(x_2,r_2) + \sigma.$$

Given α_σ, there are also $t_\sigma \geq 0$ and $w_\sigma \in L^2(0, t_\sigma; W)$ such that

$$\begin{aligned}&e^{-\lambda k(t_\sigma,\alpha_\sigma[w_\sigma],w_\sigma)} W\left(y(t_\sigma, x_1, \alpha_\sigma[w_\sigma], w_\sigma), r_1 + r(t_\sigma, x_1, \alpha_\sigma[w_\sigma], w_\sigma)\right)\\ &\quad > V^\lambda(x_1, r_1) - \sigma.\end{aligned}$$

Since ρ is bounded, it follows that for every $\sigma < \delta/2$ we have $k(t_\sigma, \alpha_\sigma[w_\sigma], w_\sigma) \leq T = T(\lambda, \delta)$. If for $i = 1, 2$ we denote $y_i(\cdot) = y(\cdot, x_i, \alpha_\sigma[w_\sigma], w_\sigma)$ and $r_i(\cdot) = r_i + r(\cdot, x_i, \alpha_\sigma[w_\sigma], w_\sigma)$, we also have

$$\begin{aligned}&V^\lambda(x_1, r_1) - V^\lambda(x_2, r_2) - 2\sigma\\ &\quad < e^{-\lambda k(t_\sigma,\alpha_\sigma[w_\sigma],w_\sigma)} \left(W(y_1(t_\sigma), r_1(t_\sigma)) - W(y_2(t_\sigma), r_2(t_\sigma))\right).\end{aligned} \tag{4.7}$$

If σ is sufficiently small, then the left-hand side in (4.7) is positive, and then, since ρ is increasing and 1-Lipschitz continuous, the right-hand side is at most $U(y_1(t_\sigma)) + r_1(t_\sigma) - U(y_2(t_\sigma)) - r_2(t_\sigma)$. Therefore, using (3.1), we compute

$$\begin{aligned}&V^\lambda(x_1, r_1) - V^\lambda(x_2, r_2) \leq L(U)\|x_1 - x_2\|e^{L(f)T} + r_1 - r_2\\ &+L(g)\int_0^{t_\sigma} \|y_1(s) - y_2(s)\|ds + 2\sigma\\ &\leq (L(U) + L(g)T)\, e^{L(f)T}\|x_1 - x_2\| + r_1 - r_2 + 2\sigma,\end{aligned}$$

uniformly for σ sufficiently small. Letting $\sigma \downarrow 0$ gives the result.

(2) This follows immediately from (1) since $V^\lambda \geq W > 0$ and W is continuous.

(3) To prove the lower bound on the derivative of the value function V^λ in the last variable we proceed as in the first part of the proof of (1). Let $\hat{x}, \hat{r}$ be given and $V^\lambda(\hat{x}, \hat{r}) \geq \delta > 0$. We fix $\epsilon > 0$ and for $\sigma = \epsilon h$, $r_1 = \hat{r}, r_2 = \hat{r} + h, h > 0$, $x_1 = x_2 = \hat{x}$, we find $\alpha_\sigma, w_\sigma, t_\sigma$ such that, putting $y(\cdot) \equiv y_1(\cdot) \equiv y_2(\cdot)$ and $r(\cdot) = r(\cdot, \hat{x}, \alpha_\sigma[w_\sigma], w_\sigma)$, we have an analogue of (4.7), namely,

$$\begin{aligned}V^\lambda(\hat{x}, \hat{r} + h) &- V^\lambda(\hat{x}, \hat{r}) + 2h\epsilon > e^{-\lambda k(t_\sigma,\alpha_\sigma[w_\sigma],w_\sigma)}(W(y(t_\sigma), \hat{r} + h + r(t_\sigma))\\ &-W(y(t_\sigma), \hat{r} + r(t_\sigma))).\end{aligned} \tag{4.8}$$

Note that, by construction, $\|\alpha_\sigma[w_\sigma]\|^2_{L^2(0,t_\sigma)} \leq k(t_\sigma, \alpha_\sigma[w_\sigma], w_\sigma) \leq T = T(\lambda, \delta)$ for all $\sigma \leq \delta/2$. This implies

$$U(y(t_\sigma)) + \hat{r} + h + r(t_\sigma) \leq \|U\|_\infty + \hat{r} + 1 + (1 + \|g\|_\infty)T$$

for h small enough. Moreover, since for $\sigma < \delta/2$

$$0 < \delta/2 \leq V^\lambda(\hat{x}, \hat{r}) - \sigma < e^{-\lambda k(t_\sigma,\alpha_\sigma[w_\sigma],w_\sigma)} W(y(t_\sigma), \hat{r} + r(t_\sigma)) \leq W(y(t_\sigma), \hat{r} + r(t_\sigma)),$$

we also get

$$U(y(t_\sigma)) + \hat{r} + r(t_\sigma) \geq \rho^{-1}(\delta/2).$$

Then there is $R = R(g, U, \lambda, \delta) > 0$ such that for all h sufficiently small we have

$$U(y(t_\sigma)) + \hat{r} + h + r(t_\sigma) \in [-R, R].$$

Observe that the right-hand side of (4.8) is positive, since ρ is increasing and $h > 0$, and we can now conclude by the mean value theorem that

$$\begin{aligned}&V^\lambda(\hat{x}, \hat{r} + h) - V^\lambda(\hat{x}, \hat{r}) + 2h\epsilon\\ &\quad > e^{-\lambda T}(\rho(U(y(t_\sigma)) + \hat{r} + h + r(t_\sigma)) - \rho(U(y(t_\sigma)) + \hat{r} + r(t_\sigma))) \geq Kh,\end{aligned}$$

where $K = e^{-\lambda T}/(1+R^2)$. Dividing then by h and letting $h \to 0$, we finally obtain

$$\liminf_{h\to 0} \frac{V^\lambda(\hat{x},\hat{r}+h) - V^\lambda(\hat{x},\hat{r})}{h} \geq K - 2\epsilon,$$

and the proof is completed by choosing ϵ sufficiently small. □

We will now obtain a dynamic programming principle for the auxiliary value function.

PROPOSITION 4.6. *Suppose that $g\colon \overline{D(A)} \to [0,\infty)$ and $U\colon \overline{D(A)} \to \mathbb{R}$ are continuous and bounded and let W be as in* (4.1). *Denote $V^\lambda = V^\lambda_{g,W}$ and let $u^* \in U$. If $(V^\lambda)^*(\hat{x},\hat{r}) > W(\hat{x},\hat{r})$, then there is $\epsilon > 0$ such that if $\|x-\hat{x}\|$, $|r-\hat{r}|$, $|V^\lambda(x,r) - (V^\lambda)^*(\hat{x},\hat{r})| < \epsilon$, $t \in (0,\epsilon)$ and $\tau \in (0,\epsilon)$, then*

(4.9)
$$V^\lambda(x,r) \leq e^{-\lambda\tau} \sup_{w\in L^2_{\text{loc}}(0,\infty;W)} V^\lambda\left(y(t(\tau,u^*,w),x,u^*,w), r + r(t(\tau,u^*,w),x,u^*,w)\right),$$

$$V^\lambda(x,r) \leq \sup\{e^{-\lambda k(t,u^*,w)} V^\lambda\left(y(t,x,u^*,w), r + r(t,x,u^*,w)\right) : \ \|w\|_{L^2(0,t;W)} \leq M\}.$$

Proof. (1) To prove (4.9) we argue by contradiction. Suppose that $x_n \to \hat{x}$, $r_n \to \hat{r}$, $\tau_n \downarrow 0$, $V^\lambda(x_n,r_n) \to (V^\lambda)^*(\hat{x},\hat{r})$, and $\epsilon_n > 0$ are such that

$$V^\lambda(x_n,r_n) - \epsilon_n > \sup_{w\in L^2_{\text{loc}}} e^{-\lambda\tau_n} V^\lambda\left(y_n(t_n), r_n(t_n)\right), \tag{4.10}$$

where $y_n(\cdot) = y(\cdot,x_n,u^*,w)$, $r_n(\cdot) = r_n + r(\cdot,x_n,u^*,w)$, and $t_n = t(\tau_n,u^*,w)$.

For a fixed n, first suppose that

$$e^{-\lambda s} W(y_n(t(s,u^*,w)), r_n(t(s,u^*,w))) \leq V^\lambda(x_n,r_n) - \epsilon_n \tag{4.11}$$

for all $s \in [0,\tau_n)$, $w \in L^2(0,t(s,u^*,w);W)$. By definition, for every $\alpha \in \Delta$ there exists $w_\alpha \in L^2_{\text{loc}}$ such that

$$V^\lambda(x_n,r_n) - \frac{\epsilon_n}{2} < \sup_{t\geq 0} e^{-\lambda k(t,\alpha[w_\alpha],w_\alpha)} W\left(y(t,x_n,\alpha[w_\alpha],w_\alpha), r_n + r(t,x_n,\alpha[w_\alpha],w_\alpha)\right).$$

Combining this with (4.11), it follows that for every $\alpha \in \Delta$ with the property that $\alpha[w](t) = u^*$ for all $w \in L^2_{\text{loc}}$ and $t \in [0, t(\tau_n,u^*,w))$, there exists $w_\alpha \in L^2_{\text{loc}}$ such that

$$\begin{aligned} V^\lambda(x_n,r_n) \quad -\tfrac{\epsilon_n}{2} < \sup_{t\geq t(\tau_n,u^*,w_\alpha)} & e^{-\lambda k(t,\alpha[w_\alpha],w_\alpha)} W(y(t,x_n,\alpha[w_\alpha],w_\alpha), r_n \\ & + r(t,x_n,\alpha[w_\alpha],w_\alpha)). \end{aligned} \tag{4.12}$$

By definition, for every $x \in \overline{D(A)}$, $r \in \mathbb{R}$, there exists $\alpha = \alpha(x,r,n) \in \Delta$ such that

$$V^\lambda(x,r) + \frac{\epsilon_n}{2} > \sup_{w\in L^2_{\text{loc}}} \sup_{t\geq 0} e^{-\lambda k(t,\alpha[w],w)} W\left(y(t,x,\alpha[w],w), r + r(t,x,\alpha[w],w)\right).$$

Consider a strategy $\bar{\alpha}$ defined by

$$\bar{\alpha}[w](t) = \begin{cases} u^* & \text{if } 0 \leq t < t_n = t(\tau_n,u^*,w), \\ \alpha_n[w(\cdot - t_n)](t-t_n) & \text{for } t \geq t_n, \end{cases}$$

where $\alpha_n = \alpha(y(t_n, x_n, u^*, w), r_n + r(t_n, x_n, u^*, w), n)$. Observe that $\bar{\alpha}$ is nonanticipating (see Remark 4.2 in Soravia [23]), so $\bar{\alpha} \in \Delta$. There is $\bar{w} = w_{\bar{\alpha}} \in L^2_{\text{loc}}$ as in (4.12), and then by the definition of α_n

$$V^\lambda(x_n, r_n) - \frac{\epsilon_n}{2} < e^{-\lambda k(t_n, \bar{\alpha}[\bar{w}], \bar{w})} \Big(V^\lambda\left(y(t_n, x_n, u^*, \bar{w}), r_n + r(t_n, x_n, u^*, \bar{w})\right) + \frac{\epsilon_n}{2} \Big),$$

which contradicts (4.10).

Hence (4.11) must fail and thus for every n we can find $s_n \in [0, \tau_n)$ and a disturbance $w_n \in L^2(0, t(s_n, u^*, w_n); W)$ such that

$$\begin{aligned} V^\lambda(x_n, r_n) - \epsilon_n < e^{-\lambda s_n} W(y(t(s_n, u^*, w_n), x_n, u^*, w_n), r_n \\ + r(t(s_n, u^*, w_n), x_n, u^*, w_n)). \end{aligned} \tag{4.13}$$

Since $(V^\lambda)^*(\hat{x}, \hat{r}) > W(\hat{x}, \hat{r}) \geq 0$, without loss of generality we may assume that there is $\delta > 0$ such that $V^\lambda(x_n, r_n) - \epsilon_n > \delta$ for all n. From (4.13), since ρ is increasing and $t(s_n, u^*, w_n) \leq s_n$, we get

$$0 < \delta < \rho\left(\|U\|_{L^\infty} + r_n + s_n(\|g\|_{L^\infty} + \|u^*\|^2) - \gamma^2 \int_0^{t(s_n, u^*, w_n)} \|w_n\|^2 \right),$$

and it follows that there is $M > 0$ such that $\int_0^{t(s_n, u^*, w_n)} \|w_n\|^2 \leq M$ for all n. Then from (3.3) we obtain $y(t(s_n, u^*, w_n), x_n, u^*, w_n) \to \hat{x}$ as $n \to \infty$ and, taking $\limsup$ as $n \to \infty$ in (4.13), we conclude

$$\begin{aligned} &(V^\lambda)^*(\hat{x}, \hat{r}) \\ &\leq \limsup_{n\to\infty} \quad \rho\left(U(y(t(s_n, u^*, w_n), x_n, u^*, w_n)) + r_n + s_n(\|g\|_{L^\infty} + \|u^*\|^2)\right) \\ &\qquad\qquad\quad = \rho(U(\hat{x}) + \hat{r}) = W(\hat{x}, \hat{r}), \end{aligned}$$

and we have again a contradiction, completing the proof.

(2) To complete the proof of Proposition 4.6, we first argue as in the proof of (4.9) and show that there is $\epsilon > 0$ such that if $\|x - \hat{x}\|$, $|r - \hat{r}|$, $|V^\lambda(x, r) - (V^\lambda)^*(\hat{x}, \hat{r})| < \epsilon$, and $t \in (0, \epsilon)$ then

$$V^\lambda(x, r) \leq \sup_{w \in L^2(0,t;W)} e^{-\lambda k(t, u^*, w)} V^\lambda\left(y(t, x, u^*, w), r + r(t, x, u^*, w)\right). \tag{4.14}$$

Next, since $(V^\lambda)^*(\hat{x}, \hat{r}) > W(\hat{x}, \hat{r}) \geq 0$, we may assume that ϵ is so small that the left-hand side in (4.14) is always bigger than δ for some fixed $\delta > 0$. Therefore, in the supremum in (4.14) only $w \in L^2(0, t; W)$ satisfying

$$V^\lambda\left(y(t, x, u^*, w), r + r(t, x, u^*, w)\right) > \delta$$

are relevant. From Lemma 4.3 there is $N \in \mathbb{R}$ such that for every such w we have $r + r(t, x, u^*, w) > N$, and hence

$$\begin{aligned} \gamma^2 \int_0^t \|w\|^2 &< r + t(\|g\|_{L^\infty} + \|u^*\|^2) - N \\ &\leq \hat{r} + \epsilon(1 + \|g\|_{L^\infty} + \|u^*\|^2) - N. \qquad \square \end{aligned}$$

Proposition 4.6 enables us to show that the value function V^λ in (4.4) is a subsolution of the quasi-variational inequality

$$\begin{aligned}&\min\Big\{V^\lambda - W,\ \lambda V^\lambda + \langle Ax, D_x V^\lambda\rangle + \sup_{u\in U}\inf_{w\in W}\\ &\qquad\big\{-\langle f(x)+Bu+Cw, D_x V^\lambda\rangle + \big(\gamma^2\|w\|^2 - \|u\|^2 - g(x)\big)\, D_r V^\lambda\big\}\Big\} = 0\end{aligned} \tag{4.15}$$

on $\overline{D(A)}\times\mathbb{R}$. Subsolutions and supersolutions of the equation in separated variables (4.15) are defined by modifying Definition 4.1 in an obvious way. Note that the Hamiltonian in (4.15) may not be real valued unless $D_r V^\lambda > 0$, which by Lemma 4.5 holds in the viscosity sense. The following is a delicate step in our method.

PROPOSITION 4.7. *Suppose that g: $\overline{D(A)}\to[0,\infty)$ and U: $\overline{D(A)}\to\mathbb{R}$ are bounded and Lipschitz continuous; let W be as in* (4.1) *and denote $V^\lambda = V^\lambda_{g,W}$. Then V^λ is a subsolution of* (4.15).

Proof. First, observe that, by Lemma 4.5, the value function V^λ is continuous and that by definition $V^\lambda \ge W$. Let $\Phi = \varphi + \psi$ be a subtest function, which we may assume to be Lipschitz continuous; let $\eta \in C^1(\mathbb{R})$ and $V^\lambda - \Phi - \eta$ have a local maximum equal to 0 at $(\hat x,\hat r)\in\overline{D(A)}\times\mathbb{R}$, where $V^\lambda(\hat x,\hat r) > W(\hat x,\hat r)$. Note that by Lemma 4.5 (3) we have $\eta'(\hat r) > 0$, since $V^\lambda(\hat x,\cdot) - \eta(\cdot)$ has a local maximum point at $\hat r$. By modifying η off a small open interval containing $\hat r$, without loss of generality we may assume that there is $\sigma > 0$ such that

$$\eta'(r) > \sigma \quad \text{for all}\ \ r\in\mathbb{R}. \tag{4.16}$$

By definition of viscosity subsolution, we need to show that

$$\begin{aligned}&\lambda V^\lambda(\hat x,\hat r) + D_A^-\Phi(\hat x) + \sup_{u\in U}\inf_{w\in W}\{-\langle f(\hat x)+Bu+Cw, D\varphi(\hat x)\rangle\\ &-L(\psi)(\|f(\hat x)\| + \|Bu\| + \|Cw\|) + \big(\gamma^2\|w\|^2 - \|u\|^2 - g(\hat x)\big)\,\eta'(\hat r)\} \le 0.\end{aligned} \tag{4.17}$$

(1) If $D_A^-\Phi(\hat x) = -\infty$, there is nothing to do. First, we will prove that

$$D_A^-\Phi(\hat x) < +\infty. \tag{4.18}$$

Choose any $u^*\in U$. From Proposition 4.6 there are $M>0$ and $\epsilon>0$ such that for all $t\in(0,\epsilon)$

$$V^\lambda(\hat x,\hat r) \le \sup\{e^{-\lambda k(t,u^*,w)}V^\lambda(y(t),r(t))\colon\ \|w\|_{L^2(0,t;W)}\le M\}, \tag{4.19}$$

where for given w we wrote $y(\cdot) = y(\cdot,\hat x,u^*,w)$ and $r(\cdot) = \hat r + r(\cdot,\hat x,u^*,w)$. Making ϵ smaller if necessary, we can assume that $\|S(t)\hat x - \hat x\| < 1$ and $V^\lambda(S(t)\hat x,\hat r) > V^\lambda(\hat x,\hat r)/2$ for every $t\in(0,\epsilon)$. Suppose that

$$t\in(0,\epsilon),\quad \|w\|_{L^2(0,t;W)}\le M,\quad \text{and}\ \ V^\lambda(\hat x,\hat r)/2 \le V^\lambda(y(t),r(t)). \tag{4.20}$$

Then, from Lemma 4.5, either $V^\lambda(y(t),r(t)) \le V^\lambda(S(t)\hat x,\hat r)$ or

$$\begin{aligned}V^\lambda(y(t),r(t)) - V^\lambda(S(t)\hat x,\hat r) &\le K\|y(t)-S(t)\hat x\| + r(t) - \hat r\\ &\le K\|y(t)-S(t)\hat x\| + t(\|g\|_{L^\infty} + \|u^*\|^2) - \gamma^2\int_0^t \|w\|^2,\end{aligned}$$

with K depending only on $V^\lambda(\hat{x}, \hat{r})$ and λ. From this, (3.5), and the Hölder inequality we obtain that always

$$V^\lambda(y(t), r(t)) \leq V^\lambda(S(t)\hat{x}, \hat{r}) + Ct \quad \text{as} \quad t \downarrow 0,$$

with a constant C uniform for all t and w. Then from (4.19) it follows that $V^\lambda(\hat{x}, \hat{r}) \leq V^\lambda(S(t)\hat{x}, \hat{r}) + Ct$, and, consequently, $\Phi(\hat{x}) - \Phi(S(t)\hat{x}) \leq Ct$ as $t \downarrow 0$, and we obtain (4.18).

(2) In this step, arguing by contradiction, we will show that

$$\begin{aligned} \lambda V^\lambda(\hat{x}, \hat{r}) \quad &+ \sup_{u \in U} \inf_{w \in W} \{[D_A^- \Phi(\hat{x}) - \langle f(\hat{x}) + Bu + Cw, D\varphi(\hat{x})\rangle \\ &-L(\psi)(\|f(\hat{x})\| + \|Bu\| + \|Cw\|) \\ &+ \left(\gamma^2\|w\|^2 - \|u\|^2 - g(\hat{x})\right) \eta'(\hat{r})]/(1 + \|u\|^2 + \|w\|^2)\} \leq 0. \end{aligned} \tag{4.21}$$

Suppose then that there are $u^* \in U$ and $\theta > 0$ such that for every $w \in W$

$$\begin{aligned} \lambda(\Phi(\hat{x}) \quad &+\eta(\hat{r}))\left(1 + \|u^*\|^2 + \|w\|^2\right) + D_A^-\Phi(\hat{x}) - \langle f(\hat{x}) + Bu^* + Cw, D\varphi(\hat{x})\rangle \\ &-L(\psi)(\|f(\hat{x})\| + \|Bu^*\| + \|Cw\|) \\ &+ \left(\gamma^2\|w\|^2 - \|u^*\|^2 - g(\hat{x})\right) \eta'(\hat{r}) > 2\theta(1 + \|u^*\|^2 + \|w\|^2). \end{aligned} \tag{4.22}$$

Fix $\tau > 0$ and let $w \in L^2_{\text{loc}}(0, \infty; W)$. Denote $y(\cdot) = y(\cdot, \hat{x}, u^*, w)$ and $r(\cdot) = \hat{r} + r(\cdot, \hat{x}, u^*, w)$. Note that

$$t(\tau, u^*, w) + \|w\|^2_{L^2(0, t(\tau, u^*, w); W)} \leq k(t(\tau, u^*, w), u^*, w) = \tau. \tag{4.23}$$

Therefore, from (4.22), (4.16), and (3.4) it follows that if τ is sufficiently small, then for all $s \in [0, t(\tau, u^*, w)]$ (we may suppose $\theta < \sigma\gamma^2$)

$$\begin{aligned} D_A^-\Phi(\hat{x}) \quad &+\lambda\left(\Phi(y(s)) + \eta(r(s))\right)\left(1 + \|u^*\|^2 + \|w(s)\|^2\right) - \langle v(s), D\varphi(y(s))\rangle \\ &\qquad -L(\psi)\|v(s)\| + \left(\gamma^2\|w(s)\|^2 - \|u^*\|^2 - g(y(s))\right)\eta'(r(s)) \\ &> \theta(1 + \|u^*\|^2 + \|w(s)\|^2), \end{aligned} \tag{4.24}$$

with $v(s) = f(y(s)) + Bu^* + Cw(s)$. Multiplying by $e^{-\lambda k(s, u^*, w)}$, integrating from 0 to $t(\tau, u^*, w)$, and using a version of Tataru's result (see Corollaries 4.8 and 4.9 in the paper by the authors and Święch [19]) as in the proof of Proposition 2.8, we obtain

$$\begin{aligned} &\Phi(\hat{x}) + \eta(\hat{r}) - e^{-\lambda\tau}[\Phi(y(t(\tau, u^*, w))) + \eta(r(t(\tau, u^*, w)))] \\ &\geq (1 - e^{-\lambda\tau})\tfrac{\theta}{\lambda} - o(t(\tau, u^*, w)) \geq (1 - e^{-\lambda\tau})\tfrac{\theta}{\lambda} - o(\tau), \end{aligned} \tag{4.25}$$

as $\tau \to 0$, uniformly for all $w \in L^2_{\text{loc}}$. Using (4.23), (3.4), and the maximum property of $\Phi + \eta$, we have

$$\begin{aligned} \sup \quad &\left\{e^{-\lambda\tau}V^\lambda(y(t(\tau, u^*, w)), r(t(\tau, u^*, w))) \colon \ w \in L^2(0, t; W)\right\} \\ &\leq V^\lambda(\hat{x}, \hat{r}) - (1 - e^{-\lambda\tau})\tfrac{\theta}{\lambda} + o(\tau). \end{aligned}$$

Hence by Proposition 4.6, for a sufficiently small $\tau > 0$, this gives $(1 - e^{-\lambda\tau})\theta/\lambda \leq o(\tau)$ and a contradiction when $\tau \downarrow 0$. Thus (4.21) is proved.

(3) Let $\epsilon > 0$. From (4.21) for every $u \in U$ there is $w_u \in W$ such that

$$\begin{aligned} \lambda V^\lambda(\hat{x}, \hat{r}) \quad &(1 + \|u\|^2 + \|w_u\|^2) + D_A^-\Phi(\hat{x}) - \langle f(\hat{x}) + Bu + Cw_u, D\varphi(\hat{x})\rangle \\ &-L(\psi)(\|f(\hat{x})\| + \|Bu\| + \|Cw_u\|) \\ &+ \left(\gamma^2\|w_u\|^2 - \|u\|^2 - g(\hat{x})\right)\eta'(\hat{r}) \leq \epsilon(1 + \|u\|^2 + \|w_u\|^2), \end{aligned} \tag{4.26}$$

and therefore

$$\begin{aligned}(4.27)\quad \|u\|^2 &\big(\lambda V^\lambda(\hat{x},\hat{r})-\eta'(\hat{r})-\epsilon\big)-\langle Bu,D\varphi(\hat{x})\rangle-L(\psi)\|Bu\|\\ &\le \epsilon-D_A^-\Phi(\hat{x})-\lambda V^\lambda(\hat{x},\hat{r})+\langle f(\hat{x}),D\varphi(\hat{x})\rangle+L(\psi)\|f(\hat{x})\|+g(\hat{x})\eta'(\hat{r})\\ &+\|w_u\|^2\big(\epsilon-\lambda V^\lambda(\hat{x},\hat{r})-\gamma^2\eta'(\hat{r})\big)+\langle Cw_u,D\ gf(\hat{x})\rangle+L(\psi)\|Cw_u\|.\end{aligned}$$

If $\epsilon<\sigma\gamma^2$, then the coefficient of $\|w_u\|^2$ on the right-hand side in (4.27) is negative and hence the supremum over all $w_u\in W$ is finite. Then taking the supremum over all $u\in U$ on the left-hand side shows that $\lambda V^\lambda(\hat{x},\hat{r})-\eta'(\hat{r})-\epsilon\le 0$ for every small enough $\epsilon>0$, i.e.,

$$\lambda V^\lambda(\hat{x},\hat{r})\le\eta'(\hat{r}).$$

(4) Using (4.16), it is easy to see that there is $R>0$ such that in the supremum (4.17) it is not restrictive to take $\|u\|\le R$. Now if $\epsilon<\gamma^2\sigma$, then taking the infimum over all $\|u\|\le R$ in (4.27) shows that there is $K=K(R)>0$ independent of ϵ small enough such that $\|w_u\|\le K$ for every $\|u\|\le R$. From (4.26) we then have

$$\begin{aligned}\lambda V^\lambda(\hat{x},\hat{r})\quad &+D_A^-\Phi(\hat{x})+\sup_{u\in U}\inf_{w\in W}\{-\langle f(\hat{x})+Bu+Cw,D\varphi(\hat{x})\rangle\\ &\qquad-L(\psi)(\|f(\hat{x})\|+\|Bu\|+\|Cw\|)+\big(\gamma^2\|w\|^2-\|u\|^2-g(\hat{x})\big)\,\eta'(\hat{r})\}\\ &\le\epsilon(1+K^2+R^2),\end{aligned}$$

and (4.17) follows, as ϵ is arbitrary. □

5. Proofs of the main results. In this section we put everything together to obtain proofs of the main statements. We first deal with the key point of the sufficiency part of our theorems.

Proof of Proposition 2.9. Suppose that $U\in LSC(\overline{D(A)})$ bounded from below is a supersolution of (1.6). Note that we need only to show that U is bigger than the right-hand side of (2.7), by choosing $t=0$. (1) As explained in [17], we can construct two nondecreasing sequences $(g_n)_n$, $g_n\ge 0$, and $(U_n)_n$ of bounded, globally Lipschitz functions defined on H such that on $\overline{D(A)}$ $g=\sup_n g_n$ and $U=\sup_n U_n$. For every n, put $W_n(x,r)=\rho(U_n(x)+r)$, so that $W_n\colon\ H\times\mathbb{R}\to(0,\pi)$ and $W_n\in Lip(H\times\mathbb{R})$. Observe that $W\ge W_n$ for every n. By Proposition 4.2, for every n and $\lambda>0$, $W(x,r)=\rho(U(x)+r)$ is a supersolution of (4.2) on $\overline{D(A)}\times\mathbb{R}$.

(2) Denoting $V_n=V^\lambda_{g_n,W_n}$, by Proposition 4.7 and Lemma 4.5 we know that V_n is a continuous subsolution of

$$\begin{aligned}(5.1)\quad &\min\Big\{V_n-W_n,\ \lambda V_n+\langle Ax,D_xV_n\rangle+\sup_{u\in U}\inf_{w\in W}\\ &\qquad\big\{-\langle f(x)+Bu+Cw,D_xV_n\rangle+\big(\gamma^2\|w\|^2-\|u\|^2-g(x)\big)\,D_rV_n\big\}\Big\}=0\end{aligned}$$

on $\overline{D(A)}\times\mathbb{R}$. We will show that

$$(5.2)\qquad V_n\le W\quad\text{on}\quad\overline{D(A)}\times\mathbb{R}.$$

The proof of (5.2) is adapted from a similar argument of Lemma 5.5 in [17]. We argue by contradiction and suppose that $V_n(\hat{z},\hat{t})-W(\hat{z},\hat{t})\equiv 3\tau>0$ for some $\hat{z}\in\overline{D(A)}$ and $\hat{t}\in\mathbb{R}$. For the sake of simplicity we will assume that $(0,0)\in A$; see step 3 in the proof of Lemma 5.5 in [17] for the small technical modifications necessary in the general case. For $\alpha, \delta, \beta, \kappa > 0$ and $x, y \in \overline{D(A)}$ and $r, s \in \mathbb{R}$ let

$$\Phi(x,y,r,s) = V_n(x,r) - W(y,s) - \frac{\alpha}{2}\|x-y\|^2 - \frac{\beta}{2}(r-s)^2 - \delta(\|x\|^2 + \|y\|^2) - \kappa(r^2+s^2).$$

If δ, κ are sufficiently small, then

$$\sup \Phi \geq V_n(\hat{z},\hat{t}) - W(\hat{z},\hat{t}) - 2\delta\|\hat{z}\|^2 - 2\kappa\hat{t}^2 \geq 2\tau.$$

By the perturbed optimization result of the first author and Święch [20], for every $\epsilon > 0$ one can find $\hat{x}, \hat{y} \in \overline{D(A)}$, $\hat{r}, \hat{s} \in \mathbb{R}$ and $a, b \in \mathbb{R}$ such that $|a|, |b| < \epsilon$, $\Phi(\hat{x},\hat{y},\hat{r},\hat{s}) \geq \sup\Phi - \epsilon$ and the map

$$\Phi(x,y,r,s) - \epsilon d(x,\hat{x}) - \epsilon d(y,\hat{y}) - ar - bs$$

has a strict global maximum at $(\hat{x},\hat{y},\hat{r},\hat{s})$. The function d that we are using above is the so-called Tataru distance

$$d(x,y) = \inf_{t\geq 0}\{t + \|x - S(t)x\|\}.$$

For its properties, besides those mentioned in [20], we refer the reader to [26], [27], [10]. Note that $\Phi(\hat{x},\hat{y},\hat{r},\hat{s}) \geq \sup\Phi - \epsilon \geq 2\tau - \epsilon \geq \tau$ for all sufficiently small ϵ, and then

$$\begin{aligned} V_n(\hat{x},\hat{r}) \geq{}& W(\hat{y},\hat{s}) + \frac{\alpha}{2}\|\hat{x}-\hat{y}\|^2 + \frac{\beta}{2}|\hat{r}-\hat{s}|^2 \\ &+ \delta\left(\|\hat{x}\|^2 + \|\hat{y}\|^2\right) + \kappa\left(|\hat{r}|^2 + |\hat{s}|^2\right) + \tau. \end{aligned} \tag{5.3}$$

In particular, $\hat{y} \in \mathrm{dom}(U)$. Consider two cases. If $V_n(\hat{x},\hat{r}) > W_n(\hat{x},\hat{r})$, then we use (4.2) and (5.1), and from the doubling Theorem 3.1 in Crandall–Lions [10] (see also [16] or [21]; note that our notions of viscosity subsolutions and supersolutions slightly differ from those employed in [10], yet the proof of the doubling theorem can be easily adapted to our setting) we obtain

$$\begin{aligned} &\lambda V_n(\hat{x},\hat{r}) \leq \sup_{u\in U}\inf_{w\in W}\{-\langle f(\hat{y}) + Bu + Cw, \alpha(\hat{x}-\hat{y}) - 2\delta\hat{y}\rangle \\ &+\epsilon\left(\|f(\hat{y})\| + \|Bu\| + \|Cw\|\right) + \left(\gamma^2\|w\|^2 - \|u\|^2 - g_n(\hat{y})\right)\left(\beta(\hat{r}-\hat{s}) - 2\kappa\hat{s} - b\right)\} \\ &- \sup_{u\in U}\inf_{w\in W}\{-\langle f(\hat{x}) + Bu + Cw, \alpha(\hat{x}-\hat{y}) + 2\delta\hat{x}\rangle \\ &-\epsilon\left(\|f(\hat{x})\| + \|Bu\| + \|Cw\|\right) + \left(\gamma^2\|w\|^2 - \|u\|^2 - g_n(\hat{x})\right)\left(\beta(\hat{r}-\hat{s}) + 2\kappa\hat{r} + a\right)\} + 2\epsilon. \end{aligned} \tag{5.4}$$

From (5.3) we obtain that $V_n(\hat{x},\hat{r}) \geq \tau$ and $W(\hat{y},\hat{s}) \leq \pi - \tau$, and Lemma 4.3 and the properties of U and ρ, respectively, give that $\hat{r}$ is bounded from below and $\hat{s}$ is bounded from above, uniformly in all parameters. Also, from (5.3), $\beta|\hat{r}-\hat{s}|^2 \leq 2\pi$, and therefore for any fixed β, $\hat{r}$ and $\hat{s}$ are bounded, uniformly in all other parameters. Now Lemma 4.5 (3) together with the fact that $V_n(\hat{x},r) - \frac{\beta}{2}(r-\hat{s})^2 - \kappa r^2 - ar$ has a maximum at $r = \hat{r}$ yield that

$$\beta(\hat{r}-\hat{s}) + 2\kappa\hat{r} + a \geq \nu = \nu(\beta) > 0. \tag{5.5}$$

From (5.3)

$$\kappa|\hat{r}|, \kappa|\hat{s}| \leq \sqrt{\kappa\pi}, \quad \delta\|\hat{x}\|, \delta\|\hat{y}\| \leq \sqrt{\delta\pi}. \tag{5.6}$$

Also recall that, by standard arguments, see, e.g., Lemma 3.5 in [10], we have

$$\begin{aligned}&\limsup_{\beta\to\infty}\limsup_{\alpha\to\infty}\limsup_{\delta\downarrow 0}\limsup_{\kappa\downarrow 0}\\ &\limsup_{\epsilon\downarrow 0}\left(\alpha\|\hat{x}-\hat{y}\|^2+\delta(\|\hat{x}\|^2+\|\hat{y}\|^2)\right)=0.\end{aligned}\tag{5.7}$$

Equation (5.3) also gives that for α, β fixed, $\alpha(\hat{x}-\hat{y})$ and $\beta(\hat{r}-\hat{s})$ remain bounded, uniformly in other parameters. Hence taking the limit as $\epsilon \downarrow 0$ in (5.4), using (5.5), (5.6), and (5.3) and the estimate on the Hamiltonian as in Lemma 5.4 in [17], we have

$$\begin{aligned}\lambda\tau \le \limsup_{\epsilon\downarrow 0}\{H_n(\hat{y},\quad &\alpha(\hat{x}-\hat{y})-2\delta\hat{y},\beta(\hat{r}-\hat{s})-2\kappa\hat{s})\\ &-H_n(\hat{x},\alpha(\hat{x}-\hat{y})+2\delta\hat{x},\beta(\hat{r}-\hat{s})+2\kappa\hat{r})\},\end{aligned}\tag{5.8}$$

where for $(x,p,v)\in\overline{D(A)}\times H\times(0,+\infty)$ we wrote

$$\begin{aligned}H_n(x,p,v) &= \sup_{u\in U}\inf_{w\in W}\{-\langle f(x)+Bu+Cw,p\rangle\\ &\quad+\left(\gamma^2\|w\|^2-\|u\|^2-g_n(x)\right)v\}\\ &= -\langle f(x),p\rangle-g_n(x)v+\tfrac{1}{4v}\|B^*p\|^2-\tfrac{1}{4v\gamma^2}\|C^*p\|^2.\end{aligned}$$

Note that H_n is uniformly continuous on bounded closed subsets of $\overline{D(A)}\times H\times(0,+\infty)$, and thus using (5.5) and (5.6) while taking the limits gives

$$\begin{aligned}\lambda\tau \le \limsup_{\kappa\downarrow 0}\quad &\limsup_{\delta\downarrow 0}\limsup_{\epsilon\downarrow 0}(\beta L(g_n)|\hat{r}-\hat{s}|\|\hat{x}-\hat{y}\|\\ &+\alpha\|f(\hat{x})-f(\hat{y})\|\|\hat{x}-\hat{y}\|+2\delta\left(|\langle f(\hat{x}),\hat{x}\rangle|+|\langle f(\hat{y}),\hat{y}\rangle|\right))\end{aligned}$$

and then (1.3) and (5.7) yield a contradiction.

The second case applies if $V_n(\hat{x},\hat{r})=W_n(\hat{x},\hat{r})$. Therefore by (5.3) we have

$$\tau\le V_n(\hat{x},\hat{r})-W(\hat{y},\hat{s})\le W_n(\hat{x},\hat{r})-W_n(\hat{y},\hat{s}),\tag{5.9}$$

and then the fact that $W_n\in Lip(H\times\mathbb{R})$ and (5.3) also yield a contradiction as $\alpha,\beta\to\infty$, and thus (5.2) is proved.

(3) So far we proved that for every $\lambda>0$ and $n\ge 1$

$$\begin{aligned}&W(x,r)\ge\inf_{\alpha\in\Delta}\sup_{w\in L^2_{\text{loc}}}\\ &\sup_{t\ge 0}e^{-\lambda k(t,\alpha[w],w)}W_n(y(t,x,\alpha[w],w),r+r(t,x,\alpha[w],w))\\ &=\inf_{\alpha\in\Delta}\sup_{w\in L^2_{\text{loc}}}\sup_{\tau\ge 0}e^{-\lambda\tau}W_n(y(t(\tau,\alpha[w],w)),r+r(t(\tau,\alpha[w],w)))\end{aligned}\tag{5.10}$$

for $x\in\overline{D(A)}$, $U(x)<+\infty$, and $r\in\mathbb{R}$. Fix $x\in\overline{D(A)}$, $U(x)<+\infty$. Letting $\lambda\downarrow 0$ in (5.10), we obtain for every fixed $T>0$

$$\begin{aligned}&W(x,r)=\rho(U(x)+r)\ge\inf_{\alpha\in\Delta}\sup_{w\in L^2_{\text{loc}}(0,\infty;W)}\sup_{\tau\in[0,T]}\\ &\{W_n(y(t(\tau,\alpha[w],w)),r+r(t(\tau,\alpha[w],w)))\}=\rho\Bigg(\inf_{\alpha\in\Delta}\sup_{w\in L^2_{\text{loc}}}\sup_{\tau\in[0,T]}\\ &\left\{\int_0^{t(\tau,\alpha[w],w)}\left(g_n(y(s))+\|\alpha[w](s)\|^2-\gamma^2\|w(s)\|^2\right)ds+r+U_n(y(t(\tau,\alpha[w],w)))\right\}\Bigg),\end{aligned}$$

which implies, since ρ is increasing, for all $n \geq 1$ and $T > 0$

$$(5.11)\quad U(x) \geq \inf_{\alpha\in\Delta} \sup_{w\in L^2_{\text{loc}}} \sup_{\tau\in[0,T]} \left\{ \int_0^{t(\tau,\alpha[w],w)} (g_n(y(s)) + \|\alpha[w](s)\|^2 - \gamma^2\|w(s)\|^2)ds + U_n(y(t(\tau,\alpha[w],w))) \right\}.$$

We can pass to the limit as $n \to \infty$ in (5.11), with an argument similar to the one in Lemma 3.3. Since by definition, for all $\alpha \in \Delta$ and $w \in L^2_{\text{loc}}(0,\infty;W)$, we have $\|\alpha[w]\|^2_{L^2(0,t(T,\alpha[w],w))} \leq T$ and $t(T,\alpha[w],w) \leq T$, in (5.11), we can always limit ourselves to using strategies verifying $\|\alpha[w]\|^2_{L^2(0,\infty)} \leq T$ for all $w \in L^2_{\text{loc}}$. Similarly, we can think here that disturbances $w \in L^2_{\text{loc}}$ satisfy $\|w\|_{L^2(0,\infty)} \leq T$. We can then construct a limit strategy $\alpha^\#$ as in Lemma 3.3, part (2), starting with a family of strategies $\{\alpha_n\}$, where α_n is $1/n$-optimal in (5.11), i.e., satisfies

$$(5.12)\qquad \begin{aligned} U(x) + \frac{1}{n} \geq \int_0^{t(\tau,\alpha_n[w],w)} &(g_n(y(s)) + \|\alpha_n[w](s)\|^2 - \gamma^2\|w(s)\|^2)ds \\ &+ U_n(y(t(\tau,\alpha_n[w],w))), \end{aligned}$$

for all $w(\cdot)$ and $\tau \in [0,T]$. Moreover, the fact that the sequence U_n is uniformly bounded from below (with no loss of generality) gives

$$U(x) + \frac{1}{n} + M \geq \int_0^{t(\tau,\alpha_n[w],w)} (\|\alpha_n[w](s)\|^2 - \gamma^2\|w(s)\|^2)ds;$$

hence, in particular, for $\tau = T$ and allowing only disturbances such that $\|w\|_2^2 \leq C$,

$$t(T,\alpha_n[w],w) + U(x) + \frac{1}{n} + M + (\gamma^2+1)C \geq T.$$

Thus $t_n = t(T,\alpha_n[w],w) \geq 1$ for $T \geq T(U,x,C)$ large enough. From now on we then fix $T \geq T(U,x,C)$. Given $\tau \in [0,T]$, we set

$$\tau_n = k(t(\tau,\alpha^\#,w),\alpha_n,w).$$

Note that $\tau_n \leq k(\tau,\alpha_n[w],w) \leq k(1,\alpha_n[w],w) \leq T$ for $\tau \in [0,1]$ if $t_n \geq 1$, and therefore we can replace τ by τ_n in (5.12) and get

$$\begin{aligned} U(x) + \frac{1}{n} \geq \int_0^{t(\tau,\alpha^\#[w],w)} &\left(g_n(y(s)) + \|\alpha_n[w](s)\|^2 - \gamma^2\|w(s)\|^2\right) ds \\ &+ U_n(y(t(\tau,\alpha^\#[w],w))) \end{aligned}$$

for all $w(\cdot)$, $\|w\|_2^2 \leq C$, and $\tau \in [0,1]$. Using the assumption (2.1) as in Lemma 3.3, part (3), to pass to the limit as $n \to +\infty$ we get that for every $x \in \overline{D(A)}$ and $C > 0$

$$(5.13)\quad U(x) \geq \inf_{\alpha\in\Delta} \sup_{w\in L^2_{loc},\|w\|_2^2\leq C} \sup_{\tau\in[0,1]} \left\{ \int_0^{t(\tau,\alpha[w],w)} \left(g(y(s)) + \|\alpha[w](s)\|^2 - \gamma^2\|w(s)\|^2\right) ds + U(y(t(\tau,\alpha[w],w))) \right\}.$$

A further diagonal argument, again using the machinery of Lemma 3.3 in a similar fashion, is then needed to remove in (5.13) the restriction on the L^2 norm of the disturbances (letting $C \to +\infty$), but we skip the details. In order to take the horizon to ∞ in (5.13) (but with $C = +\infty$), we proceed as follows. For a given $\varepsilon > 0$ and $w \in L^2_{\mathrm{loc}}(0, \infty; W)$, we apply (5.13) and find $\alpha_0 \in \Delta$ (as a matter of fact (5.13) has optimal strategies, and we can even choose α_0 as a function of x) such that, for $x_0 = x$ and $w_0 = w$,

$$\begin{aligned} U(x_0) + \tfrac{\varepsilon}{2} \;\; &\geq \int_0^{t(\tau,\alpha_0[w_0],w_0)} \left(g(y(s, x, \alpha_0[w_0], w_0)) + \|\alpha_0[w_0](s)\|^2 - \gamma^2\|w_0(s)\|^2\right) ds \\ &+U(y(t(\tau, \alpha_0[w_0], w_0))) \end{aligned}$$

for $\tau \in [0, 1]$. Then we apply (5.13) with $C = +\infty$ again at $x_1 = y(1, x, \alpha_0[w_0], w_0)$ and find $\alpha_1 \in \Delta$ such that, for $w_1(\cdot) = w_0(\cdot + 1)$,

$$\begin{aligned} U(x_1) + \tfrac{\varepsilon}{2^2} \;\; &\geq \int_0^{t(\tau,\alpha_1[w_1],w_1)} \left(g(y(s, x_1, \alpha_1[w_1], w_1)) + \|\alpha_1[w_1](s)\|^2 - \gamma^2\|w_1(s)\|^2\right) ds \\ &+U(y(t(\tau, \alpha_1[w_1], w_1), x_1, \alpha_1[w_1], w_1)) \end{aligned}$$

for $\tau \in [0, 1]$, and so forth. We proceed recursively and define the strategy α by the position $\alpha[w] = \overline{u}$, where $\overline{u}$ is the control defined by setting

$$\overline{u}(s) = \begin{cases} \alpha_0[w_0](s), & s \in [0, t(1, \alpha_0[w_0], w_0)), \\ \alpha_1[w_1](s - t(1, \alpha_0[w_0], w_0)), & s \in I_1, \\ \dots . & \end{cases}$$

$I_1 = [t(1, \alpha_0[w_0], w_0), t(1, \alpha_0[w_0], w_0) + t(1, \alpha_1[w_1], w_1))$. The strategy α is a causal functional by construction, since $t(\tau, u, w)$ is a causal functional of the controls for any fixed $\tau > 0$, and, moreover,

$$t(1, \alpha_0[w_0], w_0) + t(1, \alpha_1[w_1], w_1) = t(2, \alpha[w], w),$$

and so forth (see Remark 4.2 in [23] for both statements). Then α satisfies

$$\begin{aligned} U(x) + \varepsilon \;\; &\geq \int_0^{t(\tau,\alpha[w],w)} \left(g(y(s, x, \alpha[w], w)) + \|\alpha[w](s)\|^2 - \gamma^2\|w(s)\|^2\right) ds \\ &+U(y(t(\tau, \alpha[w], w), x, \alpha[w], w)) \end{aligned}$$

for all $\tau \geq 0$ and $w \in L^2_{\mathrm{loc}}(0, \infty; W)$; therefore, in particular, $\alpha[w] \in L^2_{\mathrm{loc}}(0, \infty; U)$ for all $w \in L^2_{\mathrm{loc}}(0, \infty; W)$, since g and U are nonnegative and $t(\tau, u, w) \to +\infty$ as $\tau \to +\infty$. Hence, since ϵ is arbitrary, we obtain for all $x \in \overline{D(A)}$

$$U(x) \geq \inf_{\alpha\in\Delta} \sup_{w\in L^2_{\mathrm{loc}}(0,\infty;W)} \sup_{t\geq 0} \left\{ \int_0^t (g(y(s)) + \|\alpha[w](s)\|^2 - \gamma^2\|w(s)\|^2) ds + U(y(t)) \right\},$$

which concludes the proof since the opposite inequality follows immediately by choosing $t = 0$ in the right-hand side. □

Proof of Theorem 2.4. To prove the Lyapunov stability at 0 of the undisturbed system, let $U\colon \overline{D(A)} \to [0, +\infty]$, $\mathrm{dom}(U) \supset \overline{\mathrm{dom}(g)}$, be a lower semicontinuous supersolution of the HJI equation (1.6), vanishing and continuous at the origin. Suppose that U is locally positive definite at 0 and that σ, $\omega(\cdot)$ are as in Definition 2.2. From

Proposition 2.9, (2.7) holds, and, moreover, the right-hand side of (2.7) has optimal strategies, as it follows applying Lemma 3.3 with $g_n \equiv g$ and $\varphi_n \equiv U$. For all $x \in \operatorname{dom}(U)$ we can then find $\alpha_x \in \Delta$ such that

$$U(x) \geq \int_0^T \left(g(y(t)) + \|\alpha_x[w](t)\|^2 - \gamma^2\|w(t)\|^2\right) dt + U(y(T)) \tag{5.14}$$

for all $T \geq 0$ and $w \in L^2_{\text{loc}}(0, +\infty; W)$. Then (1.5) is satisfied by $\{\alpha_x\}_x$ and $K = U$. By choosing $w \equiv 0$ we then get

$$U(x) \geq U(y(T, x, \alpha_x[0], 0))$$

for all $T \geq 0$, so, in particular, the sublevel sets $\mathcal{V}_\delta = \{x \in \overline{D(A)}\colon\ U(x) < \delta\}$ of U are invariant for the undisturbed system. Moreover, since U is continuous at 0 and $U(0) = 0$, every $\mathcal{V}_\delta$ is a neighborhood (relative to $\overline{D(A)}$) of 0.

Now suppose that $\mathcal{U} = B^H_\epsilon(0) \cap \overline{D(A)}$, where $0 < \epsilon \leq \sigma$. Consider $\mathcal{V} = \mathcal{U} \cap \mathcal{V}_{\omega(\epsilon)}$, a relative neighborhood of 0. If $x \in \mathcal{V}$ and $\|y(t, x, \alpha_x[0], 0)\| = \epsilon$ for some $t > 0$, then $U(y(t, x, \alpha_x[0], 0)) \geq \omega(\epsilon)$, contradicting the invariance of $\mathcal{V}_{\omega(\epsilon)}$. It follows that if $x \in \mathcal{V}$, then $y(t, x, \alpha_x[0], 0) \in \mathcal{V} \subset \mathcal{U}$ for all $t \geq 0$, and the stability at 0 of the undisturbed system follows.

The above argument in fact shows that the family of sets $\mathcal{U}_\epsilon = \{x \in \overline{D(A)}\colon\ \|x\| < \epsilon,\ U(x) < \omega(\epsilon)\}$, $0 < \epsilon \leq \sigma$, is invariant for the undisturbed system and, moreover, is a base of neighborhoods (relative to $\overline{D(A)}$) of 0.

To prove asymptotic stability at 0 when g is locally positive definite at 0, we need a further argument. Let σ, $\omega(\cdot)$ be as in Definition 2.2; it is not restrictive to assume they are the same as above. For $0 < \epsilon \leq \sigma$ put

$$\rho(\epsilon) = \inf\{g(x)\colon\ x \in B^H_\sigma \cap \overline{D(A)} \setminus \mathcal{U}_\epsilon\} > 0.$$

Choosing $w \equiv 0$ in (5.14), we get

$$U(x) \geq \int_0^T g(y(t, x, \alpha_x[0], 0))\, dt$$

for all $T \geq 0$. Suppose that $x \in \mathcal{U}_\sigma$. If $0 < \epsilon < \sigma$ and $y(t, x, \alpha_x[0], 0) \notin \mathcal{U}_\epsilon$ for $t \in [0, T]$, then $T \leq U(x)/\rho(\epsilon)$. Thus $y(t, x, \alpha_x[0], 0) \in \mathcal{U}_\epsilon$ for some $t \geq 0$, and we conclude by the invariance of $\mathcal{U}_\epsilon$. □

CONVEXITY IN HAMILTON–JACOBI THEORY I: DYNAMICS AND DUALITY*

R. TYRRELL ROCKAFELLAR† AND PETER R. WOLENSKI‡

Abstract. Value functions propagated from initial or terminal costs and constraints by way of a differential inclusion, or more broadly through a Lagrangian that may take on ∞, are studied in the case where convexity persists in the state argument. Such value functions, themselves taking on ∞, are shown to satisfy a subgradient form of the Hamilton–Jacobi equation which strongly supports properties of local Lipschitz continuity, semidifferentiability and Clarke regularity. An extended "method of characteristics" is developed which determines them from the Hamiltonian dynamics underlying the given Lagrangian. Close relations with a dual value function are revealed.

Key words. convex value functions, dual value functions, subgradient Hamilton–Jacobi equations, extended method of characteristics, nonsmooth Hamiltonian dynamics, viscosity solutions, variational analysis, optimal control, generalized problems of Bolza

1. Introduction.

Fundamental to optimal control and the calculus of variations are value functions $V : [0,\infty) \times \mathbb{R}^n \to \overline{\mathbb{R}} := [-\infty,\infty]$ of the type

$$(1.1)\; V(\tau,\xi) := \inf\left\{ g\big(x(0)\big) + \int_0^\tau L\big(x(t),\dot{x}(t)\big)dt \,\middle|\, x(\tau)=\xi \right\}, \qquad V(0,\xi) = g(\xi),$$

which propagate an initial cost function $g : \mathbb{R}^n \to \overline{\mathbb{R}}$ forward from time 0 in a manner dictated by a Lagrangian function $L : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$. The possible extended-real-valuedness of g and L serves in the modeling of the constraints and dynamics involved in this propagation, such as restrictions on $x(0)$ and on $\dot{x}(t)$ relative to $x(t)$. The minimization takes place over the arc space $\mathcal{A}^1_n[0,\tau]$, in the general notation that $\mathcal{A}^p_n[\tau_0,\tau_1]$ consists of all absolutely continuous $x(\cdot) : [\tau_0,\tau_1] \to \mathbb{R}^n$ with derivative $\dot{x}(\cdot) \in \mathcal{L}^p_n[\tau_0,\tau_1]$.

Value functions of the "cost-to-go" type, which propagate a terminal cost function backward from a time T, are covered by (1.1) through time reversal; this is the usual setting in optimal control. The fact that problems in optimal control can be treated in terms of an integral functional as in (1.1) for a choice of an extended-real-valued Lagrangian L has been recognized since [1] and has long been the subject of developments in nonsmooth optimization; for more on how control fits in, see, e.g., [2], [3], [4]. This is parallel to, and subsumes, the notion that differential equations with controls can be treated in terms of differential inclusions with the controls suppressed. Value functions are of interest in optimal control especially because of potential connections with feedback rules.

An important issue in Hamilton–Jacobi theory is the extent to which V can be characterized in terms of the Hamiltonian function $H : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ associated with L, as defined through the Legendre–Fenchel transform by

$$H(x, y) := \sup_v \Big\{ \langle v, y\rangle - L(x, v)\Big\}. \tag{1.2}$$

Under the properties of this transform, $H(x, y)$ is sure to be convex in y. When $L(x, v)$ is convex, proper, and lower semicontinuous in v, as is natural for the existence of optimal arcs in (1.1), the reciprocal formula holds that

$$L(x, v) = \sup_y \Big\{ \langle v, y\rangle - H(x, y)\Big\}, \tag{1.3}$$

so L and H are completely dual to each other.

It is well recognized that a function V given by (1.1) can fail to be smooth despite any degree of smoothness of g and L, or for that matter, H. Much of modern Hamilton–Jacobi theory has revolved around this fact, especially in coming up with generalizations of the Hamilton–Jacobi PDE that might pin down V, which of course was the historical motivation for that equation. Except for the case in which H is independent of x, little attention has been paid to ascertaining circumstances in which $V(\tau, \xi)$ is convex in ξ for each $\tau \geq 0$, and to exploring the consequences of such convexity. The convex case merits study for several reasons, however.

Convexity is a crucial marker in classifying optimization problems, and it's often accompanied by interesting phenomena of duality. It can provide powerful support in matters of computation and approximation. Moreover, it has a prospect here of enabling V to be characterized via H in other ways, complementary to the Hamilton–Jacobi PDE, such as versions of the method of characteristics in which convex analysis can be brought to bear. Efforts in the convex case could therefore shed light on topics in nonsmooth Hamilton–Jacobi theory that so far have been overshadowed by PDE extensions.

The convexity of $V(\tau, \xi)$ in ξ entails, for $\tau = 0$, the convexity of the initial function g, but what does it need from the Lagrangian L? The simplest, and in a certain sense the only robust assumption for this is the joint convexity of $L(x, v)$ in x and v, which corresponds under (1.2) and (1.3) to pairing the natural convexity of $H(x, y)$ in y with the concavity of $H(x, y)$ in x. This is what we work with, along with mild conditions of semicontinuity and growth that can readily be dualized.

In optimal control, problems of convex type have roughly the same status within general control theory that linear differential equations have in the general theory of differential equations. They form the backbone for many control applications, covering traditional linear-quadratic control and its modifications to incorporate constraints and penalties (cf. [5]), but also numerous problem models in areas such as economics and operations research.

From the technical standpoint, our convexity assumptions ensure that the optimization problem appearing in (1.1) fits the theory of generalized problems of Bolza of convex type as developed in Rockafellar [1], [6], [7], [8]. That duality theory, dating from the early 1970s and based entirely on convex analysis [6], hasn't previously been utilized in the Hamilton–Jacobi setting. It had to wait for advances toward handling robustly, by means of subgradients, not only the convexity of $V(\tau, \xi)$ in ξ but also its nonconvexity in (τ, ξ). Such advances have since been made through the labor of many researchers, and the time is therefore ripe for investigating the Hamilton–Jacobi aspects of convexity and duality beyond the very special Hopf–Lax case treated in the past, where L and H don't depend on the x argument.

Relying on the background of variational analysis in [10], we make progress in several ways. We demonstrate the existence of a dual value function $\tilde{V}$, propagated by a dual Lagrangian $\tilde{L}$, such that the convex functions $V(\tau, \cdot)$ and $\tilde{V}(\tau, \cdot)$ are conjugate to each other under the Legendre–Fenchel transform for every τ. We use this in particular to derive a subgradient Hamilton–Jacobi equation satisfied directly by V, and a dual one for $\tilde{V}$, despite the unboundedness of these functions and their pervasive ∞ values. At the same time we establish a new subgradient form of the "method of characteristics" for determining these functions from the Hamiltonian H.

Central to our approach is a generalized Hamiltonian ODE associated with H, which is actually a differential inclusion in terms of subgradients instead of gradients. By focusing on $V_\tau = V(\tau, \cdot)$ as a convex function on $\mathbb{R}^n$ that varies with τ, we bring to light the remarkable fact that the graph of the subgradient mapping ∂V_τ evolves through nothing more nor less than its "drift" in the (set-valued) flow in $\mathbb{R}^n \times \mathbb{R}^n$ induced by this generalized Hamiltonian dynamical system.

Our treatment of V, although limited to the convex case, contrasts with other work in Hamilton–Jacobi theory which, in coping with ∞ values, has required $H(x, y)$ to be a special kind of *globally* Lipschitz continuous, convex function of y for each x; see Frankowska [11], [12] and Clarke et al. [13], where ∞ is admitted directly, or Bardi and Capuzzo-Dolcetta [14, Chapter V, section 5], where ∞ is suppressed by nonlinear rescaling (a maneuver incompatible with maintaining convexity). These authors take $H(x, y)$ to be positively homogeneous in y, but a standard trick (passing from Lipschitzian running costs to a Mayer formulation) allows extension to a somewhat broader class of Hamiltonians (of unknown characterization).

While the interior of the set of points where $V < \infty$ could be empty, we prove that if it isn't, then properties of semidifferentiability, Clarke regularity, and local Lipschitz continuity hold for V on that open set under our assumptions. Also, we identify through duality the situations in which coercivity or global finiteness is preserved for all $\tau > 0$.

For simplicity and to illuminate clearly the new features stemming from convexity, we keep to the case of a time-independent Lagrangian L, although extensions of the results to accommodate time dependence ought to be possible.

2. Hypotheses and main results.

In formulating the conditions that will be invoked throughout this paper, we abbreviate lower semicontinuous by "lsc" and refer to an extended-real-valued function as *proper* when it's not the constant function ∞ yet nowhere takes on $-\infty$. Thus, a function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ is proper if and only if its effective domain $\operatorname{dom} f := \{v \mid f(v) < \infty\}$ is nonempty and, on this set, f is finite. Equivalently, f is proper if and only if its epigraph, the set $\operatorname{epi} f := \{(v, s) \mid s \in \mathbb{R},\ f(v) \le s\}$, is nonempty and contains no (entire) vertical lines. Convexity of f corresponds to the convexity of $\operatorname{epi} f$, while lower semicontinuity of f corresponds to the closedness of $\operatorname{epi} f$. Convexity of f implies convexity of $\operatorname{dom} f$, but lower semicontinuity of f need not entail closedness of $\operatorname{dom} f$ (as for instance when $f(v)$ approaches ∞ as v approaches the boundary of $\operatorname{dom} f$ from within).

We denote the Euclidean norm by $|\cdot|$ and call f *coercive* when it is bounded from below and has $f(v)/|v| \to \infty$ as $|v| \to \infty$. Coercivity of a proper nondecreasing function θ on $[0, \infty)$ means that $\theta(s)/s \to \infty$ as $s \to \infty$. For a proper convex function f on $\mathbb{R}^n$, coercivity is equivalent to the finiteness of the conjugate convex function f^* on $\mathbb{R}^n$ under the Legendre–Fenchel transform, $f^*(y) := \sup_v \{\langle v, y\rangle - f(v)\}$.

Basic assumptions (A).

(A0) The initial function g is convex, proper, and lsc on $\mathbb{R}^n$.

(A1) The Lagrangian function L is convex, proper, and lsc on $\mathbb{R}^n \times \mathbb{R}^n$.

(A2) The set $F(x) := \operatorname{dom} L(x, \cdot)$ is nonempty for all x, and there is a constant ρ such that $\operatorname{dist}(0, F(x)) \leq \rho\big(1 + |x|\big)$ for all x.

(A3) There are constants α and β and a coercive, proper, nondecreasing function θ on $[0, \infty)$ such that $L(x, v) \geq \theta\big(\max\{0, |v| - \alpha|x|\}\big) - \beta|x|$ for all x and v.

The joint convexity of L with respect to x and v in (A1) contrasts with the more common assumption of convexity merely with respect to v. It is vital to our duality-based methodology. In combination with the convexity in (A0), it ensures that the functional

$$J_\tau\big(x(\cdot)\big) \;:=\; g\big(x(0)\big) + \int_0^\tau L\big((x(t), \dot{x}(t)\big)dt \tag{2.1}$$

is convex on $\mathcal{A}_n^1[0, \tau]$. It also, as a side benefit, guarantees that J_τ is well defined. That follows because $L(x(t), \dot{x}(t))$ is measurable in t when L is lsc, whereas L majorizes at least one affine function on $\mathbb{R}^n \times \mathbb{R}^n$ through its convexity and properness. Then there exist $(w, y) \in \mathbb{R}^n \times \mathbb{R}^n$ and $c \in \mathbb{R}$ with $L(x(t), \dot{x}(t)) \geq \langle x(t), w\rangle + \langle \dot{x}(t), y\rangle - c$, the expression on the right being summable in t. The integral thus has an unambiguous value in $(-\infty, \infty]$, and so then does $J_\tau(x(\cdot))$.

In (A2), the mapping F gives the differential inclusion that's implicit in the Lagrangian L. Obviously $J_\tau(x(\cdot)) = \infty$ unless the arc $x(\cdot)$ satisfies the constraints

$$\dot{x}(t) \in F(x(t)) \text{ almost everywhere (a.e.) } t, \text{ with } x(0) \in D := \operatorname{dom} g. \tag{2.2}$$

Note that the graph of F, which is the set $\operatorname{dom} L \subset \mathbb{R}^n \times \mathbb{R}^n$, is convex by (A1), although not necessarily closed. Similarly, the initial set D in these implicit constraints is convex by (A0), but need not be closed. Of course, in the special case where L is finite everywhere, the graph of F is all of $\mathbb{R}^n \times \mathbb{R}^n$ and the condition $\dot{x}(t) \in F(x(t))$ trivializes; likewise, if g is finite everywhere, the condition $x(0) \in D$ trivializes.

The nonempty-valuedness of F in (A2) means that there are no state constraints implicitly imposed by L. State constraints are definitely of interest in some applications, but in order to handle them we would have to pass from our duality framework of absolutely continuous trajectories to one in which dual trajectories or perhaps even primal trajectories might have to be merely of bounded variation; cf. [15], [16], [17]. That could be possible, but the technical complications would be more formidable and additional groundwork might have to be laid, so we forgo such an extension for now.

The growth condition in (A2) will be seen to imply that the differential inclusion in (2.2) has no "forced escape time": from any point it provides at least one trajectory over the infinite time interval $[0, \infty)$. The nonemptiness of $F(x)$ didn't really have to be mentioned separately from this growth condition, inasmuch as the distance to $\emptyset$ is ∞.

The function $L(x, \cdot)$ on $\mathbb{R}^n$, which for each x is convex by (A1) and proper by (A2), is coercive under the growth condition in (A3). Note that this growth condition is much weaker than the commonly imposed Tonelli-type condition in which $L(x, v) \geq \theta(|v|)$ for a coercive, proper, nondecreasing function θ. For instance, it covers the case of $L(x, v) = L_0(v - Ax) + L_1(x)$ for coercive L_0 and a function L_1 that does not go down to $-\infty$ at more than a linear rate, whereas the Tonelli-type condition would not do that unless $A = 0$ and L_1 is bounded from below.

The following consequence of our assumptions sets the stage for our analysis of the value function V as giving a "continuously moving" convex function on $\mathbb{R}^n$.

Theorem 2.1 (value function convexity and epi-continuity). *Under* (A), *the function $V_\tau = V(\tau, \cdot)$ is proper, lsc, and convex on $\mathbb{R}^n$ for each $\tau \in [0, \infty)$. Moreover, V_τ depends epi-continuously on τ. In particular, V is proper and lsc as a function on $[0, \infty) \times \mathbb{R}^n$, and V_τ epi-converges to g as $\tau \searrow 0$.*

This theorem will be proved in section 5. The epi-continuity in its statement refers to the continuity of the set-valued mapping $\tau \mapsto \operatorname{epi} V_\tau$ with respect to Painlevé–Kuratowski set convergence. It amounts to the following assertion (here, as elsewhere in this paper, we consistently use superscript $\nu = 1, 2, \ldots \to \infty$ in describing sequences):

$$\text{whenever } \tau^\nu \to \tau \text{ with } \tau^\nu \geq 0, \text{ one has}$$
$$\left\{\begin{array}{ll} \liminf_\nu V(\tau^\nu, \xi^\nu) \geq V(\tau, \xi) & \text{for every sequence } \xi^\nu \to \xi, \\ \limsup_\nu V(\tau^\nu, \xi^\nu) \leq V(\tau, \xi) & \text{for some sequence } \xi^\nu \to \xi, \end{array}\right. \tag{2.3}$$

where the first limit property is the lower semicontinuity of V on $[0, \infty) \times \mathbb{R}^n$. An exposition of the theory of epi-convergence of functions on $\mathbb{R}^n$ is available in Chapter 7 of [10].

Observe that the epi-convergence in Theorem 2.1 answers the question of how the initial condition $V_0 = g$ should be coordinated with the behavior of V when $\tau > 0$. Pointwise convergence of V_τ to V_0 as $\tau \searrow 0$ isn't a suitable property for a context of semicontinuity and extended-real-valuedness.

Epi-convergence has implications also for the subgradients of the functions V_τ. Recall that for a proper convex function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ and a point x, a vector $y \in \mathbb{R}^n$ is a *subgradient in the sense of convex analysis* if

$$f(x') \;\geq\; f(x) + \langle y, \, x' - x \rangle \quad \text{for all } x' \in \mathbb{R}^n. \tag{2.4}$$

The set of such subgradients is denoted by $\partial f(x)$. (This is, in particular, empty when $x \notin \operatorname{dom} f$ but nonempty when $x \in \operatorname{ri} \operatorname{dom} f$, the relative interior of the convex set $\operatorname{dom} f$; see [9], [10].) The *subgradient mapping* $\partial f : x \mapsto \partial f(x)$ has graph

$$\operatorname{gph} \partial f := \big\{ (x, y) \,\big|\, y \in \partial f(x) \big\} \subset \mathbb{R}^n \times \mathbb{R}^n. \tag{2.5}$$

When f is lsc as well as proper and convex, ∂f is a maximal monotone mapping, and $\operatorname{gph} \partial f$ is therefore a globally Lipschitzian manifold of dimension n in $\mathbb{R}^n \times \mathbb{R}^n$; see [10, Chapter 12]. Furthermore, epi-convergence of functions corresponds in this picture to graphical convergence of their subgradient mappings, i.e., Painlevé–Kuratowski set convergence of their graphs; [10, 12.35].

Corollary 2.2 (subgradient manifolds). *Under* (A), *the graph of the subgradient mapping ∂V_τ is, for each $\tau \in [0, \infty)$, a globally Lipschitzian manifold of dimension n in $\mathbb{R}^n \times \mathbb{R}^n$. Moreover this set* $\operatorname{gph} \partial V_\tau$ *depends continuously on τ.*

The epigraphical continuity in the motion of V_τ in Theorem 2.1 thus corresponds to continuity graphically in the motion of ∂V_τ. Not just "continuous" aspects of this motion, but "differential" aspects need to be understood, however. For that purpose the Hamiltonian function H in (1.2) is an indispensable tool.

A better grasp of the nature of H under our assumptions is essential. Because $L(x, \cdot)$ is lsc, proper, and convex under (A1) and (A2), the reciprocal formula in (1.3) does hold, and every property of L must accordingly have some exact counterpart for H. The following fact will be verified in section 3. It describes the class of functions

H such that, when L is defined from H by (1.3), L will be the unique Lagrangian for which (A1), (A2), and (A3) hold, and for which H is the associated Hamiltonian expressed by (1.2).

THEOREM 2.3 (identification of the Hamiltonian class). *A function $H : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ is the Hamiltonian for a Lagrangian L satisfying* (A1), (A2), *and* (A3) *if and only if $H(x, y)$ is everywhere finite, concave in x, convex in y, and the following growth conditions hold, where* (a) *corresponds to* (A3), *and* (b) *corresponds to* (A2)*:*

(a) *There are constants α and β and a finite, convex function φ such that*

$$H(x, y) \ \le \ \varphi(y) + (\alpha|y| + \beta)|x| \quad \textit{for all } x,\ y.$$

(b) *There are constants γ and δ and a finite, concave function ψ such that*

$$H(x, y) \ \ge \ \psi(x) - (\gamma|x| + \delta)|y| \quad \textit{for all } x,\ y.$$

The finite concavity-convexity in Theorem 2.3 implies that H is locally Lipschitz continuous; cf. [9, section 35].

Concave-convex Hamiltonian functions first surfaced as a significant class in connection with generalized problems of Bolza and Lagrange of convex type; cf. [6]. In the study of such problems, a subgradient form of Hamiltonian dynamics turned out to be crucial in characterizing optimality. Only subgradients of convex analysis are needed in expressing such dynamics. The generalized Hamiltonian *system* is

$$\dot{x}(t) \in \partial_y H(x(t), y(t)), \qquad -\dot{y}(t) \in \tilde{\partial}_x H(x(t), y(t)), \tag{2.6}$$

with $\partial_y H(x, y)$ the usual set of "lower" subgradients of the convex function $H(x, \cdot)$ at y, but $\tilde{\partial}_x H(x, y)$ the analogously defined set of "upper" subgradients of the concave function $H(\cdot, y)$ at x. A Hamiltonian *trajectory* over $[\tau_0, \tau_1]$ is an arc $(x(\cdot), y(\cdot)) \in \mathcal{A}^1_{2n}[\tau_0, \tau_1]$ that satisfies (2.6) for almost every t. The associated Hamiltonian *flow* is the one-parameter family of (generally) set-valued mappings S_τ for $\tau \ge 0$ defined by

$$S_\tau(\xi_0, \eta_0) := \big\{(\xi, \eta) \,\big|\, \exists \text{ Hamiltonian trajectory over } [0, \tau] \text{ from } (\xi_0, \eta_0) \text{ to } (\xi, \eta)\big\}. \tag{2.7}$$

Details and alternative expressions of the dynamics in (2.6) will be worked out in section 6. Appropriate extensions to nonsmooth Hamiltonians $H(x, y)$ that aren't concave in x, and thus correspond to Lagrangians $L(x, v)$ that aren't jointly convex in x and v, can be found in [3], [18], [19], and [20]. Hamiltonian trajectories are featured as necessary conditions in these works, but as will be recalled in Theorem 4.1 below, our assumptions yield symmetric relationships between the x and y elements. Here, we confine ourselves to stating how, under our assumptions, the graph of the subgradient mapping ∂V_τ, namely

$$\operatorname{gph} \partial V_\tau := \big\{(\xi, \eta) \,\big|\, \eta \in \partial V_\tau(\xi)\big\} \subset \mathbb{R}^n \times \mathbb{R}^n, \tag{2.8}$$

evolves through such dynamics from the graph of the subgradient mapping $\partial V_0 = \partial g$.

THEOREM 2.4 (Hamiltonian evolution of subgradients). *Under* (A)*, one has $\eta \in \partial V_\tau(\xi)$ if and only if, for some $\eta_0 \in \partial g(\xi_0)$, there is a Hamiltonian trajectory $(x(\cdot), y(\cdot))$ over $[0, \tau]$ with $(x(0), y(0)) = (\xi_0, \eta_0)$ and $(x(\tau), y(\tau)) = (\xi, \eta)$. Thus, the graph of ∂V_τ is the image of the graph of ∂g under the flow mapping S_τ:*

$$\operatorname{gph} \partial V_\tau = S_\tau(\operatorname{gph} \partial g) \quad \textit{for all } \tau \ge 0. \tag{2.9}$$

It will be shown in Theorem 6.3 that in the circumstances of Theorem 2.4, $x(\cdot)$ is an optimal trajectory for the minimization problem defining $V(\tau, \xi)$ in (1.1). At the same time, $y(\cdot)$ is optimal for a certain dual problem, and such optimality of $x(\cdot)$ and $y(\cdot)$ is actually equivalent to the condition in Theorem 2.4.

Theorem 2.4 is the basis for a generalized *method of characteristics* for determining V uniquely from g and H. It will be proved in section 6, where the method will be laid out in full. Especially noteworthy is the global nature of the complete description in Theorem 2.4, which is a by-product of convexity and underscores why the convex case deserves special attention. The classical method of characteristics (which requires the continuous differentiability of g and H) gives an equivalent description of V satisfying the Hamilton–Jacobi equation, but is valid only locally.

Subbotin [21] pioneered a global characteristic method for quite general nonlinear problems by introducing a (nonunique) characteristic *inclusion*, the weak invariance (viability) of which he used to define the concept of a *minimax* solution to the Hamilton–Jacobi equation. In such a general situation, *one* solution of the differential inclusion plays the role of a characteristic trajectory, whereas under our convexity assumptions, *every* solution of (2.6) plays such a role. Further recent work in generalized characteristics for nonlinear first order PDEs can be found in [22] and [23].

To go from the characterization in Theorem 2.4 to a description of the motion of V_τ in terms of a generalized Hamilton–Jacobi PDE, we need to bring in subgradients beyond those of convex analysis. The notation and terminology of the book [10] will be adopted.

Consider any function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ and let x be any point at which $f(x)$ is finite. A vector $y \in \mathbb{R}^n$ is a *regular subgradient* of f at x, written $y \in \hat{\partial} f(x)$, if

$$f(x') \;\geq\; f(x) + \langle y,\, x' - x\rangle + o(|x' - x|). \tag{2.10}$$

It is a (*general*) *subgradient* of f at x, written $y \in \partial f(x)$, if there is a sequence of points $x^\nu \to x$ with $f(x^\nu) \to f(x)$ for which regular subgradients $y^\nu \in \hat{\partial} f(x^\nu)$ exist with $y^\nu \to y$.

These definitions refer to "lower" subgradients, which are usually all that we need. To keep the notation uncluttered, we take "lower" for granted, and in the few situations where "upper" subgradient sets (analogously defined) are called for, we express them by

$$\tilde{\partial} f(x) = -\partial[-f](x), \qquad \tilde{\hat{\partial}} f(x) = -\hat{\partial}[-f](x). \tag{2.11}$$

For a convex function f, $\hat{\partial} f(x)$ and $\partial f(x)$ reduce to the subgradient set defined earlier through (2.4). In the case of the value function V, the "partial subgradient" notation

$$\partial_\xi V(\tau, \xi) = \big\{\eta \,\big|\, \eta \in \partial V_\tau(\xi)\big\} \quad \text{for } V_\tau = V(\tau, \cdot)$$

can thus, through Theorem 2.1, be interpreted equally in any of the senses above.

THEOREM 2.5 (generalized Hamilton–Jacobi equation). *Under* (A)*, the subgradients of V on $(0, \tau) \times \mathbb{R}^n$ have the property that*

$$\begin{aligned} (\sigma, \eta) \in \partial V(\tau, \xi) \quad &\Longleftrightarrow \quad (\sigma, \eta) \in \hat{\partial} V(\tau, \xi) \\ &\Longleftrightarrow \quad \eta \in \partial_\xi V(\tau, \xi), \;\; \sigma = -H(\xi, \eta). \end{aligned} \tag{2.12}$$

In particular, therefore, V satisfies the generalized Hamilton–Jacobi equation

$$\sigma + H(\xi, \eta) = 0 \quad \textit{for all} \quad (\sigma, \eta) \in \partial V(\tau, \xi) \quad \textit{when} \quad \tau > 0. \tag{2.13}$$

This theorem will be proved in section 7. By the first equivalence in (2.12), the equation in (2.13) could be stated with $\hat{\partial}V(\tau,\xi)$ in place of $\partial V(\tau,\xi)$ (or in terms of the proximal subgradients emphasized in the book of Clarke, Ledyaev, Stern, and Wolenski [24]), but we prefer the ∂V version because general subgradients dominate in the variational analysis and subdifferential calculus in [10]. The $\hat{\partial}V$ version would effectively turn (2.13) into the one-sided "viscosity" form of Hamilton–Jacobi equation used for lsc functions by Barron and Jensen [25] and Frankowska [12], in distinction to earlier forms for continuous functions that rested on pairs of inequalities; cf. Crandall, Evans, and Lions [26]. The book of Bardi and Capuzzo-Dolcetta [14] gives a broad view of viscosity theory in its current state, including the relationships between such different forms. A Hamilton–Jacobi equation is called a Hamilton–Jacobi–*Bellman* equation when H is expressed by the max in (1.2).

The extent to which (2.13) (or its viscosity version) and the initial condition on V_0 might suffice to determine V uniquely isn't fully understood yet in the framework of lsc solutions that can take on ∞ when $\tau > 0$. So far, the strongest result directly available in such a framework is the one obtained by Frankowska [12]; for problems satisfying our convexity assumptions, it covers only the case where $L(x,v)$ is the indicator $\delta_C(v-Ax)$ corresponding to a differential inclusion $\dot{x}(t) \in Ax(t)+C$ for some matrix A and nonempty, compact, convex set C. Through a Mayer reformulation, her result could be made to cover the case where a finite, convex function of (x,v) is added to this indicator. How far one could go by such reformulation—and nonlinear rescaling to get rid of ∞—with the results presented by Bardi and Capuzzo-Dolcetta [14, Chapter V, section 5] is unclear.

The arcs $y(\cdot)$ that are paired with the arcs $x(\cdot)$ in the Hamiltonian dynamics are related to the forward propagation of the conjugate initial function g^*, satisfying

$$g^*(y) := \sup_x\Big\{\langle x,y\rangle - g(x)\Big\}, \qquad g(x) := \sup_y\Big\{\langle x,y\rangle - g^*(y)\Big\}, \tag{2.14}$$

with respect to the *dual* Lagrangian $\tilde{L}$, satisfying

$$\begin{aligned} \tilde{L}(y,w) = L^*(w,y) &= \sup_{x,v}\Big\{\langle x,w\rangle + \langle v,y\rangle - L(x,v)\Big\},\\ L(x,v) = \tilde{L}^*(v,x) &= \sup_{y,w}\Big\{\langle x,w\rangle + \langle v,y\rangle - \tilde{L}(y,w)\Big\}. \end{aligned} \tag{2.15}$$

The reciprocal formulas here follow from (A0) and (A1). We'll prove in section 5 that the value function $\tilde{V}$ defined as in (1.1), but with g^* and $\tilde{L}$ in place of g and L, has $\tilde{V}_\tau$ conjugate to V_τ for every τ. This duality will be a workhorse in our analysis of other basic properties.

An advantage of our assumptions (A) is that they carry over symmetrically to the dual setting. Alternative assumptions could fail in that respect. To put this another way, the class of Hamiltonians that we work with, as described in Theorem 2.3, is no accident, but carefully tuned to obtaining the broadest possible results of duality in Hamilton–Jacobi theory (here in the time-independent case).

3. Elaboration of the convexity and growth conditions. Conditions (A1), (A2), and (A3) can be viewed from several different angles, and a better understanding of them is required before we can proceed. Their Hamiltonian translation in Theorem 2.3 has to be verified, but also they will be useful as applied to functions other than L, so a broader, not merely Lagrangian, perspective on them must be attained.

We'll draw on some basic concepts of variational analysis, and convex analysis in particular. For any nonempty subset $C \subset \mathbb{R}^n$, the *horizon cone* is the closed cone

$$C^\infty := \limsup_{\lambda \searrow 0} \lambda C = \big\{ w \in \mathbb{R}^n \,\big|\, \exists\, x^\nu \in C,\, \lambda^\nu \searrow 0, \text{ with } \lambda^\nu x^\nu \to w \big\}.$$

When C is convex, C^∞ is convex and, for any $\bar{x} \in \operatorname{ri} C$ (the relative interior of C) it consists simply of the vectors w such that $\bar{x} + \lambda w \in C$ for all $\lambda > 0$. When C is convex and closed, C^∞ coincides with the "recession cone" of C. See [9, section 6], [10, Chapter 3].

For any function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$, $f \not\equiv \infty$, the *horizon function* f^∞ is the function having as its epigraph the set $(\operatorname{epi} f)^\infty$, where $\operatorname{epi} f$ is the epigraph of f itself. This function is always lsc and positively homogeneous. When f is convex, f^∞ is convex as well and, for any $\bar{x} \in \operatorname{ri}(\operatorname{dom} f)$, is given by $f^\infty(w) = \lim_{\lambda\to\infty} f(\bar{x} + \lambda w)/\lambda$. When f is convex and lsc, f^∞ is the "recession function" of f in convex analysis. Again, see [9, section 6], [10, Chapter 3].

It will be important in the context of conditions (A1), (A2), and (A3) to view L not just as a function on $\mathbb{R}^n \times \mathbb{R}^n$ but in terms of the associated function-valued mapping $x \mapsto L(x,\cdot)$ that assigns to each $x \in \mathbb{R}^n$ the function $L(x,\cdot) : \mathbb{R}^n \to \overline{\mathbb{R}}$. A function-valued mapping is a "bifunction" in the terminology of [9].

DEFINITION 3.1 (regular convex bifunctions). *A function-valued mapping from $\mathbb{R}^n$ to the space of extended-real-valued functions on $\mathbb{R}^n$, as specified in the form $x \mapsto \Lambda(x,\cdot)$ by a function $\Lambda : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$, is called a regular convex bifunction if*

(a1) *Λ is proper, lsc, and convex as a function on $\mathbb{R}^n \times \mathbb{R}^n$;*

(a2) *for each $w \in \mathbb{R}^n$ there is a $z \in \mathbb{R}^n$ with $(w,z) \in (\operatorname{dom}\Lambda)^\infty$;*

(a3) *there is no $z \neq 0$ with $(0,z) \in \operatorname{cl}(\operatorname{dom}\Lambda^\infty)$.*

PROPOSITION 3.2 (bifunction duality). *For $\Lambda : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$, suppose that the mapping $x \mapsto \Lambda(x,\cdot)$ is a regular convex bifunction. Then for the conjugate function $\Lambda^* : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$, the mapping $y \mapsto \Lambda^*(\cdot,y)$ is a regular convex bifunction.*

Indeed, conditions (a2) *and* (a3) *of Definition* 3.1 *are dual to each other in the sense that, under* (a1)*, Λ satisfies* (a2) *if and only if Λ^* satisfies* (a3)*, whereas Λ satisfies* (a3) *if and only if Λ^* satisfies* (a2)*.*

Proof. This was shown as part of Theorem 4 of [8]; for the duality between (a2) and (a3), see the proof of that theorem. □

LEMMA 3.3 (domain selections). *For a function $\Lambda : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ satisfying condition* (a1) *of Definition* 3.1*, condition* (a2) *is equivalent to the existence of a matrix $A \in \mathbb{R}^{n\times n}$ and vectors $a \in \mathbb{R}^n$ and $b \in \mathbb{R}^n$ such that*

$$\big(x,\, Ax + |x|a + b\big) \in \operatorname{ri}(\operatorname{dom}\Lambda) \text{ for all } x \in \mathbb{R}^n. \tag{3.1}$$

Proof. See the first half of the proof of Theorem 5 of [8] for the necessity. The sufficiency is clear because (3.1) implies $\big(x,\, Ax + |x|a\big) \in (\operatorname{dom}\Lambda)^\infty$ for all $x \in \mathbb{R}^n$. □

PROPOSITION 3.4 (Lagrangian growth characterization). *A function $L : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ satisfies* (A1)*,* (A2)*, and* (A3) *if and only if the mapping $x \mapsto L(x,\cdot)$ is a regular convex bifunction. Specifically in the context of Definition* 3.1 *with $\Lambda = L$,* (A1) *corresponds to* (a1)*, and then one has the equivalence of* (A2) *with* (a2) *and that of* (A3) *with* (a3)*.*

Proof. When $\Lambda = L$, (A1) is identical to (a1). Assuming this property now, we argue the other equivalences.

(A2) $\Rightarrow$ (a2). For any $w \in \mathbb{R}^n$ and any integer $\nu > 0$ there exists by (A2) some $v^\nu \in F(\nu w)$ with $|v^\nu| \le \rho(1+\nu|w|)$. Let $x^\nu = \nu w$ and $\lambda^\nu = 1/\nu$. We have $(x^\nu, v^\nu) \in \operatorname{dom} L = \operatorname{dom}\Lambda$ and $\lambda^\nu(x^\nu, v^\nu) = (w, (1/\nu)v^\nu)$ with $(1/\nu)|v^\nu| \le \rho(1+|w|)$. The sequence of pairs $\lambda^\nu(x^\nu, v^\nu)$ is therefore bounded in $\mathbb{R}^n \times \mathbb{R}^n$ and has a cluster point, which necessarily is of the form (w,z) for some $z \in \mathbb{R}^n$. Furthermore $(w,z) \in (\operatorname{dom}\Lambda)^\infty$ by definition. Thus, (a2) is fulfilled.

(a2) $\Rightarrow$ (A2). Applying Lemma 3.3, we get the existence of a matrix A and vectors a and b such that $Ax+|x|a+b \in F(x)$ for all x. Then $\operatorname{dist}(0,F(x)) \le |A||x|+|x||a|+|b|$, so we can get the bound in (A2) by taking $\rho \ge \max\{|b|,\ |A|+|a|\}$.

(A3) $\Rightarrow$ (a3). Let $(\bar{x},\bar{v}) \in \operatorname{ri}(\operatorname{dom} L) = \operatorname{ri}(\operatorname{dom}\Lambda)$. For any (w,z) we have $\Lambda^\infty(w,z) = \lim_{\lambda\to\infty}\Lambda(\bar{x}+\lambda w, \bar{v}+\lambda z)/\lambda$. On the basis of (A3) this yields, in the notation $[s]_+ = \max\{0,s\}$,

$$\begin{aligned}\Lambda^\infty(w,z) &\ge \lim_{\lambda\to\infty} \lambda^{-1}\big[\theta\big([|\bar{v}+\lambda z| - \alpha|\bar{x}+\lambda w|]_+\big) - \beta|\bar{x}+\lambda w|\big]\\ &= \lim_{\lambda\to\infty} \big[\lambda^{-1}\theta\big(\lambda[|\lambda^{-1}\bar{v}+z| - \alpha|\lambda^{-1}\bar{x}+w|]_+\big)\big] - \beta|\lambda^{-1}\bar{x}+w|\big]\\ &= \begin{cases} -\beta|w| & \text{if } [|z|-\alpha|w|]_+ = 0,\\ \infty & \text{if } [|z|-\alpha|w|]_+ > 0.\end{cases}\end{aligned}$$

Hence $\operatorname{dom}\Lambda^\infty \subset \big\{(w,z)\,\big|\,|z| \le \alpha|w|\big\}$. Any $(0,z) \in \operatorname{cl}(\operatorname{dom}\Lambda^\infty)$ then has $|z| \le \alpha|0|$, hence $z=0$, so (a3) holds.

(a3) $\Rightarrow$ (A3). According to Proposition 3.2, condition (a3) on the mapping $x \mapsto \Lambda(x,\cdot)$ is equivalent to condition (a2) on the mapping $y \mapsto \Lambda^*(\cdot,y)$. By Lemma 3.3, the latter provides the existence of a matrix A and vectors a and b such that

$$(Ay+|y|a+b, y) \in \operatorname{ri}(\operatorname{dom}\Lambda^*) \text{ for all } y \in \mathbb{R}^n.$$

Any convex function is continuous over the relative interior of its effective domain, so the function $y \mapsto \Lambda^*(Ay+|y|a+b,y)$ is (finite and) continuous on $\mathbb{R}^n$ (although not necessarily convex). Define the function ψ on $[0,\infty)$ by $\psi(r) = \max\big\{\Lambda^*(Ay+|y|a+b,y)\,\big|\,|y| \le r\big\}$. Then ψ is finite, continuous, and nondecreasing. Because

$$\Lambda(x,v) = \Lambda^{**}(x,v) = \sup\nolimits_{z,y}\Big\{\langle x,z\rangle + \langle v,y\rangle - \Lambda^*(z,y)\Big\}$$

under (a1), we have

$$\begin{aligned}\Lambda(x,v) &\ge \sup\nolimits_y\Big\{\langle x,\ Ay+|y|a+b\rangle + \langle v,y\rangle - \Lambda^*(Ay+|y|a+b,y)\Big\}\\ &\ge \sup\nolimits_y\Big\{-|x|(|A||y|+|y||a|+|b|) + \langle v,y\rangle - \psi(|y|)\Big\}\\ &= \sup\nolimits_y\Big\{-|x||y|(|A|+|a|) - |x||b| + |v||y| - \psi(|y|)\Big\}\\ &= -|x||b| + \sup\nolimits_{r\ge 0}\Big\{r\big[\,|v| - (|A|+|a|)|x|\,\big] - \psi(r)\Big\}\\ &= \psi^*\big([\,|v|-(|A|+|a|)|x|\,]_+\big) - |b||x|,\end{aligned}$$

where again $[s]_+ := \max\{0,s\}$. Let $\alpha = |A|+|a|$, $\beta = |b|$, and $\theta = \psi^*$ on $[0,\infty)$. Then the inequality in (A3) holds for $L = \Lambda$. The function θ has $\theta(0) = -\psi(0)$ (finite) and is the pointwise supremum of a collection of affine functions of the form $s \mapsto rs - \psi(r)$ with $r \ge 0$ and $\psi(r)$ always finite. Hence θ is convex, proper, nondecreasing and in addition has $\lim_{s\to\infty}\theta(s)/s \ge r$ for all $r \ge 0$, which implies coercivity. ∎

PROPOSITION 3.5 (Lagrangian dualization). *If the Lagrangian $L : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ satisfies* (A1), (A2), *and* (A3), *then so too does the dual Lagrangian $\tilde{L} : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ in* (2.15). *Indeed,* (A1) *for L yields* (A1) *for $\tilde{L}$ and the reciprocal formula in* (2.15), *and then* (A2) *for L corresponds to* (A3) *for $\tilde{L}$, whereas* (A3) *for L corresponds to* (A2) *for $\tilde{L}$. Furthermore, the dual Hamiltonian*

$$\tilde{H}(y,x) := \sup_w \Big\{ \langle x, w\rangle - \tilde{L}(y,w) \Big\} \tag{3.2}$$

associated with $\tilde{L}$ is then related to the Hamiltonian H for L by

$$\tilde{H}(y,x) = -H(x,y). \tag{3.3}$$

Proof. Combine Proposition 3.4 with Proposition 3.2 to get the dualization of (A1), (A2), and (A3) to $\tilde{L}$. Note next that since $L(x,\cdot)$ is by (A1), (A2), and (A3) a proper, lsc, convex, and coercive function on $\mathbb{R}^n$, its conjugate function, which is $H(x,\cdot)$, is finite on $\mathbb{R}^n$. The joint convexity of $L(x,v)$ in x and v corresponds to $H(x,y)$ being not just convex in y, as always, but also concave in x; see [9, 33.3] or [10, 11.48]. For the Hamiltonian relationship in (3.3), observe through (2.15) and the formula (1.2) for H that

$$\tilde{L}(y,w) = \sup_{x,v} \Big\{ \langle x, w\rangle + \langle v, z\rangle - L(x,v) \Big\} = \sup_x \Big\{ \langle x, w\rangle + H(x,y) \Big\}. \tag{3.4}$$

Fix any y and let $h(\cdot) = -H(\cdot,y)$, noting that $h(\cdot)$ is a finite convex function on $\mathbb{R}^n$. According to (3.4), we have $\tilde{L}(y,\cdot) = h^*(\cdot)$, and from (3.3) we then have $h^{**}(\cdot) = \tilde{H}(y,\cdot)$. The finiteness and convexity of h ensures that $h^{**} = h$, so that $\tilde{H}(y,\cdot) = -H(\cdot,y)$ as claimed in (3.3). □

Proof of Theorem 2.3. Finite convex functions correspond under the Legendre–Fenchel transform to the proper convex functions that are coercive. Having $H(x,\cdot)$ be a finite convex function on $\mathbb{R}^n$ for each $x \in \mathbb{R}^n$ is equivalent therefore to having H be the Hamiltonian associated by (1.2) with a Lagrangian L such that $L(x,\cdot)$ is, for each $x \in \mathbb{R}^n$, a proper, convex function that is coercive; the function L is recovered from H by (1.3). Concavity of $H(x,y)$ in x corresponds then to joint convexity of $L(x,v)$ in x and v, as already pointed out in the proof of Proposition 3.5; see [9, 33.3] or [10, 11.48].

Thus in particular, any finite, concave-convex function H is the Hamiltonian for some Lagrangian L satisfying (A1), while on the other hand, if L satisfies (A3) along with (A1) (and therefore has $L(x,\cdot)$ always coercive), its Hamiltonian H is finite concave-convex.

It will be demonstrated next that in the case of a Lagrangian L satisfying (A1), condition (A3) is equivalent to the growth condition in (a). This will yield through the duality in Proposition 3.5 the equivalence (A2) with the growth condition in (b), and all claims will thereby be justified. Starting with (a), define $\psi(r) = \max\big\{\varphi(y) \,\big|\, |y| \leq r\big\}$ to get a finite, nondecreasing, convex function ψ on $[0,\infty)$. The inequality in (a) yields $H(x,y) \leq \psi(|y|) + (\alpha|y| + \beta)|x|$ and consequently through (1.3) that

$$\begin{aligned} L(x,v) &\geq \sup_y \Big\{ \langle v, y\rangle - \psi(|y|) - (\alpha|y| + \beta)|x| \Big\} \\ &= \sup_{r\geq 0} \sup_{|y|\leq r} \Big\{ \langle v, y\rangle - \psi(|y|) - (\alpha|y| + \beta)|x| \Big\} \\ &= \sup_{r\geq 0} \Big\{ |v|r - \psi(r) - (\alpha r + \beta)|x| \Big\} = \psi^*\big([\,|v| - \alpha|x|\,]_+\big) - \beta|x|, \end{aligned}$$

where ψ^* is coercive, proper, and nondecreasing on $[0,\infty)$. Taking $\theta = \psi^*$, we get (A3).

Conversely from (A3), where it can be assumed without loss of generality that $\alpha \geq 0$, we can retrace this pattern by estimating through (1.2) that

$$\begin{aligned} H(x,y) &\leq \sup_v \Big\{ \langle v,y\rangle - \theta\big(\big[|v| - \alpha|x|\big]_+\big) + \beta|x| \Big\} \\ &= \sup_{s\geq 0} \sup_{|v|\leq s} \Big\{ \langle v,y\rangle - \theta\big([\,|v| - \alpha|x|\,]_+\big) + \beta|x| \Big\} \\ &= \sup_{s\geq 0} \Big\{ s|y| - \theta\big([s - \alpha|x|\,]_+\big) + \beta|x| \Big\}, \end{aligned}$$

and on changing to the variable $r = s - \alpha|x|$ obtain

$$\begin{aligned} H(x,y) &\leq \sup_{r\geq -\alpha|x|} \Big\{ (r+\alpha|x|)|y| - \theta\big([r]_+\big) + \beta|x| \Big\} \\ &= \sup_{r\geq 0} \Big\{ r|y| - \theta(r) \Big\} + (\alpha|y| + \beta)|x| = \theta^*(|y|) + (\alpha|y|+\beta)|x|, \end{aligned}$$

where θ^* is finite, convex and nondecreasing. The function $\varphi(y) = \theta^*(|y|)$ is then convex on $\mathbb{R}^n$ (see [9, 15.3] or [10, 11.21]). Thus, we have the growth condition in (a). □

4. Consequences for Bolza problem duality.

The properties we have put in place for L and H lead to stronger results about duality for the generalized problems of Bolza of convex type. These improvements, which we lay out next, will be a platform for our investigation of value function duality in section 5.

The duality theory in [1] and [7], as expressed over a fixed interval $[0,\tau]$, centers (in the autonomous case) on a problem of the form

$$(\mathcal{P}) \quad \text{minimize } J\big(x(\cdot)\big) := \int_0^\tau L\big(x(t),\dot{x}(t)\big)dt + l\big(x(0),x(\tau)\big) \text{ over } x(\cdot) \in \mathcal{A}_n^1[0,\tau],$$

where the endpoint function $l : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ is proper, lsc, and convex, and on the corresponding dual problem

$$(\tilde{\mathcal{P}}) \quad \text{minimize } \tilde{J}\big(y(\cdot)\big) := \int_0^\tau \tilde{L}\big(y(t),\dot{y}(t)\big)dt + \tilde{l}\big(y(0),y(\tau)\big) \text{ over } y(\cdot) \in \mathcal{A}_n^1[0,\tau],$$

where the dual endpoint function $\tilde{l} : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ is generated through conjugacy:

$$(4.1) \quad \begin{aligned} \tilde{l}(\eta,\eta') &= l^*(\eta,-\eta') = \sup_{\xi',\xi} \Big\{ \langle \eta,\xi'\rangle - \langle \eta',\xi\rangle - l(\xi',\xi) \Big\}, \\ l(\xi',\xi) &= \tilde{l}^*(\xi',-\xi) = \sup_{\eta,\eta'} \Big\{ \langle \eta,\xi'\rangle - \langle \eta',\xi\rangle - \tilde{l}(\eta',\xi) \Big\}. \end{aligned}$$

A major role in characterizing optimality in the generalized Bolza problems $(\mathcal{P})$ and $(\tilde{\mathcal{P}})$ is played by the *generalized Euler–Lagrange condition*

$$(4.2) \qquad (\dot{y}(t),y(t)) \in \partial L(x(t),\dot{x}(t)) \text{ for a.e. } t,$$

which can also be written in the dual form $(\dot{x}(t),x(t)) \in \partial\tilde{L}(y(t),\dot{y}(t))$ for a.e. t. The Euler–Lagrange conditions are known to be equivalent in turn to the *generalized*

Hamiltonian condition (2.6) being satisfied over the time interval $[0,\tau]$; cf. [6]. They act in combination with the *generalized transversality condition*

$$(y(0),-y(\tau)) \in \partial l(x(0),x(\tau)), \tag{4.3}$$

which likewise has an equivalent dual form, $(x(0),-x(\tau)) \in \partial\tilde{l}(y(0),y(\tau))$. The basic facts about optimality are the following.

THEOREM 4.1 ([1], [6] optimality conditions). *For any functions L and l that are proper, lsc, and convex on $\mathbb{R}^n\times\mathbb{R}^n$, the optimal values in $(\mathcal{P})$ and $(\tilde{\mathcal{P}})$ satisfy* $\inf(\mathcal{P}) \le -\inf(\tilde{\mathcal{P}})$. *Moreover, for arcs $x(\cdot)$ and $y(\cdot)$ in $\mathcal{A}^1_n[0,\tau]$, the following properties are equivalent:*

(a) $(x(\cdot),y(\cdot))$ *is a Hamiltonian trajectory satisfying the transversality condition;*

(b) $x(\cdot)$ *solves* $(\mathcal{P})$, $y(\cdot)$ *solves* $(\tilde{\mathcal{P}})$, *and* $\inf(\mathcal{P}) = -\inf(\tilde{\mathcal{P}})$.

Proof. Basically this is Theorem 5 of [1], but we've used Theorem 1 of [6] to translate the Euler–Lagrange condition to the Hamiltonian condition. □

Theorem 4.1 gives us the sufficiency of the Hamiltonian condition and transversality condition for optimality of arcs in $(\mathcal{P})$ and $(\tilde{\mathcal{P}})$ but not the necessity. We can get that to the extent that we are able to establish that optimal arcs do exist for these problems, and $\inf(\mathcal{P}) = -\inf(\tilde{\mathcal{P}})$. Criteria for that have been furnished in [7] in terms of certain "constraint qualifications," but this is where we can make improvements now in consequence of our working assumptions.

The issue concerns the *fundamental kernel* $E : [0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n \to \overline{\mathbb{R}}$ defined for the Lagrangian L by

$$\begin{aligned} &E(\tau,\xi',\xi) := \inf\left\{ \int_0^\tau L\big(x(t),\dot{x}(t)\big)dt \,\middle|\, x(0)=\xi',\ x(\tau)=\xi \right\}, \\ &E(0,\xi',\xi) := \begin{cases} 0 & \text{if } \xi'=\xi, \\ \infty & \text{if } \xi'\ne\xi, \end{cases} \end{aligned} \tag{4.4}$$

where the minimization is over all arcs $x(\cdot)\in\mathcal{A}^1_n[0,\tau]$ satisfying the initial and terminal conditions. At the same time it concerns the dual fundamental kernel associated with the dual Lagrangian $\tilde{L}$, namely the function $\tilde{E} : [0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n \to \overline{\mathbb{R}}$ defined by

$$\begin{aligned} &\tilde{E}(\tau,\eta',\eta) := \inf\left\{ \int_0^\tau \tilde{L}\big(y(t),\dot{y}(t)\big)dt \,\middle|\, y(0)=\eta',\ y(\tau)=\eta \right\}, \\ &\tilde{E}(0,\eta',\eta) := \begin{cases} 0 & \text{if } \eta'=\eta, \\ \infty & \text{if } \eta'\ne\eta, \end{cases} \end{aligned} \tag{4.5}$$

with the minimization taking place over $y(\cdot)\in\mathcal{A}^1_n[0,\tau]$. The constraint qualifications in [7] are stated in terms of the sets

$$C_\tau := \big\{(\xi',\xi) \,\big|\, E(\tau,\xi',\xi)<\infty\big\}, \qquad \tilde{C}_\tau := \big\{(\eta',\eta) \,\big|\, \tilde{E}(\tau,\eta',\eta)<\infty\big\}. \tag{4.6}$$

They revolve around the overlap between these sets and the sets $\operatorname{dom} l$ and $\operatorname{dom}\tilde{l}$. In this respect the next result provides vital information.

PROPOSITION 4.2 (growth of the fundamental kernel). *Suppose* (A1), (A2), *and* (A3) *hold. Then the following properties of $E(\tau,\cdot,\cdot)$ hold for all $\tau\ge 0$ and guarantee that for all ξ and ξ' the functions $E(\tau,\xi',\cdot)$ and $E(\tau,\cdot,\xi)$ are proper, lsc, convex, and coercive:*

(a) $E(\tau,\cdot,\cdot)$ *is proper, lsc, and convex on* $\mathbb{R}^n\times\mathbb{R}^n$.

(b) *There is a constant* $\rho(\tau) \in (0, \infty)$ *such that*

$$\begin{aligned} \operatorname{dist}\big(0, \operatorname{dom} E(\tau, \xi', \cdot)\big) &\le \rho(\tau)(1 + |\xi'|) \textit{ for all } \xi' \in \mathbb{R}^n, \\ \operatorname{dist}\big(0, \operatorname{dom} E(\tau, \cdot, \xi)\big) &\le \rho(\tau)(1 + |\xi|) \textit{ for all } \xi \in \mathbb{R}^n. \end{aligned}$$

(c) *There are constants* $\alpha(\tau)$*,* $\beta(\tau)$*, and a coercive, proper, nondecreasing function* $\theta(\tau, \cdot)$ *on* $[0, \infty)$ *such that*

$$\left.\begin{aligned} E(\tau, \xi', \xi) &\ge \theta\big(\tau, [\,|\xi| - \alpha(\tau)|\xi'|\,]_+\big) - \beta(\tau)|\xi'| \\ E(\tau, \xi', \xi) &\ge \theta\big(\tau, [\,|\xi'| - \alpha(\tau)|\xi|\,]_+\big) - \beta(\tau)|\xi| \end{aligned}\right\} \textit{ for all } \xi', \xi \in \mathbb{R}^n.$$

Proof. When the mapping $x \mapsto L(x, \cdot)$ is a regular convex bifunction, both of the mappings $\xi' \mapsto E(\tau, \xi', \cdot)$ and $\xi \mapsto E(\tau, \cdot, \xi)$ are regular convex bifunctions as well, for all $\tau \ge 0$. For $\tau > 0$, this was proved as part of Theorem 5 of [8]. For $\tau = 0$, it is obvious from formula (4.5). On this basis we can appeal to Proposition 3.2 for each of the three function-valued mappings. In the conditions in (a) and (b), we get separate constants to work for $E(\tau, \xi', \cdot)$ and $E(\tau, \cdot, \xi)$, but then by taking a max we can get constants that work simultaneously for both, so as to simplify the statements. □

COROLLARY 4.3 (growth of the dual fundamental kernel). *When* L *satisfies* (A1), (A2)*, and* (A3)*, the function* $\tilde{E}$ *likewise has the properties in Proposition* 4.2*.*

Proof. Apply Proposition 4.2 to $\tilde{L}$ instead of L, using the fact from Proposition 3.5 that $\tilde{L}$, like L, satisfies (A1), (A2), and (A3). □

COROLLARY 4.4 (reachable endpoint pairs). *Under* (A1)*,* (A2)*, and* (A3)*, the sets* C_τ *and* $\tilde{C}_\tau$ *in* (4.6) *have the following property for every* $\tau > 0$*:*

(a) *The image of* C_τ *under the projection* $(\xi', \xi) \mapsto \xi'$ *is all of* $\mathbb{R}^n$*. Likewise, the image of* C_τ *under the projection* $(\xi', \xi) \mapsto \xi$ *is all of* $\mathbb{R}^n$*.*

(b) *The image of* $\tilde{C}_\tau$ *under the projection* $(\eta', \eta) \mapsto \eta'$ *is all of* $\mathbb{R}^n$*. Likewise, the image of* $\tilde{C}_\tau$ *under the projection* $(\eta', \eta) \mapsto \eta$ *is all of* $\mathbb{R}^n$*.*

Proof. We get (a) from the property in Proposition 4.2(b). We get (b) then out of the preceding corollary. □

Some generalizations of the conditions in Proposition 4.2 to the case of functions E coming from Lagrangians L that are not fully convex are available in [27].

THEOREM 4.5 (strengthened duality for Bolza problems). *Consider* $(\mathcal{P})$ *and* $(\tilde{\mathcal{P}})$ *under the assumption that the Lagrangian* L *satisfies* (A1)*,* (A2)*, and* (A3)*, whereas the endpoint function* l *is proper, lsc, and convex.*

(a) *If there exists* ξ *such that* $l(\cdot, \xi)$ *is finite, or there exists* ξ' *such that* $l(\xi', \cdot)$ *is finite, then* $\inf(\mathcal{P}) = -\inf(\tilde{\mathcal{P}})$*. This value is not* ∞*, and if it also is not* $-\infty$*, there is an optimal arc* $y(\cdot) \in \mathcal{A}^1_n[0, \tau]$ *for* $(\tilde{\mathcal{P}})$*. In particular the latter holds if an optimal arc* $x(\cdot) \in \mathcal{A}^1_n[0, \tau]$ *exists for* $(\mathcal{P})$*, and in that case both* $x(\cdot)$ *and* $y(\cdot)$ *must actually belong to* $\mathcal{A}^\infty_n[0, \tau]$*.*

(b) *If there exists* η *such that* $\tilde{l}(\eta, \cdot)$ *is finite, or there exists* η' *such that* $\tilde{l}(\cdot, \eta')$ *is finite, then* $\inf(\mathcal{P}) = -\inf(\tilde{\mathcal{P}})$*. This value is not* $-\infty$*, and if it also is not* ∞*, there is an optimal arc* $x(\cdot) \in \mathcal{A}^1_n[0, \tau]$ *for* $(\mathcal{P})$*. In particular the latter holds if an optimal arc* $y(\cdot) \in \mathcal{A}^1_n[0, \tau]$ *exists for* $(\tilde{\mathcal{P}})$*, and in that case both* $x(\cdot)$ *and* $y(\cdot)$ *must actually belong to* $\mathcal{A}^\infty_n[0, \tau]$*.*

Proof. Theorem 1 of [7] will be our vehicle. The conditions referred to as (C_0) and (D_0) in the statement of that result are fulfilled in the case of a finite, time-independent Hamiltonian (cf. p. 11 of [7]), which we have here via Theorem 2.3 (already proved in section 3).

If l satisfies one of the conditions in (a), it is impossible in the face of Corollary 4.4(a) for there to exist a hyperplane that separates the convex sets $\operatorname{dom} l$ and $\operatorname{dom} E(\tau,\cdot,\cdot)$. By separation theory (cf. [9, section 11]), this is equivalent to having $\operatorname{ri} C_\tau \cap \operatorname{ri}\operatorname{dom} l \neq \emptyset$ and $\operatorname{aff} C_\tau \cup \operatorname{dom} l = \mathbb{R}^n \times \mathbb{R}^n$, where "ri" is relative interior as earlier and "aff" denotes affine hull. According to part (b) of Theorem 1 of [7], this pair of conditions guarantees that $\inf(\mathcal{P})$ and $-\inf(\tilde{\mathcal{P}})$ have a common value which is not ∞, and that if this value is also not $-\infty$, then $(\tilde{\mathcal{P}})$ has a solution $y(\cdot) \in \mathcal{A}^1_n[0,\tau]$. We know on the other hand that whenever $\inf(\mathcal{P}) < \infty$ and $(\mathcal{P})$ has a solution $x(\cdot) \in \mathcal{A}^1_n[0,\tau]$, we have $J(x(\cdot))$ finite in $(\mathcal{P})$ (because neither l nor the integral functional in (2.1) can take on $-\infty$), so that $\inf(\mathcal{P})$ is finite. It follows then from Theorem 4.1 that $x(\cdot)$ and $y(\cdot)$ satisfy the generalized Hamiltonian condition, i.e., (2.6). Because H is finite everywhere, this implies by Theorem 2 of [6] that these arcs belong to $\mathcal{A}^\infty_n[0,\tau]$. This proves (a). The claims in (b) are justified in parallel by way of Corollary 4.4(b) and part (a) of Theorem 1 of [7]. □

COROLLARY 4.6 (best-case Bolza duality). *Consider $(\mathcal{P})$ and $(\tilde{\mathcal{P}})$ under the assumption that L satisfies* (A1), (A2), *and* (A3), *whereas l is proper, lsc, and convex. Suppose l has one of the finiteness properties in Theorem* 4.5(a), *while $\tilde{l}$ has one of the finiteness properties in Theorem* 4.5(b). *Then $-\infty < \inf(\mathcal{P}) = -\inf(\tilde{\mathcal{P}}) < \infty$, and optimal arcs $x(\cdot)$ and $y(\cdot)$ exist for $(\mathcal{P})$ and $(\tilde{\mathcal{P}})$. Moreover, any such arcs must belong to $\mathcal{A}^\infty_n[0,\tau]$.*

Proof. This simply combines the conclusions in parts (a) and (b) of Theorem 4.5. □

5. Value function duality. The topic we treat next is the relationship between V and the dual value function $\tilde{V}$ generated by $\tilde{L}$ and g^*:

$$(5.1)\ \tilde{V}(\tau,\eta) := \inf\left\{ g^*\big(y(0)\big) + \int_0^\tau \tilde{L}\big(y(t),\dot{y}(t)\big)dt \,\middle|\, y(\tau)=\eta \right\}, \qquad \tilde{V}(0,\eta) = g^*(\eta),$$

where the minimum is taken over all arcs $y(\cdot) \in \mathcal{A}^1_n[0,\tau]$. Henceforth we assume (A0), (A1), (A2), and (A3) without further mention. Because $\tilde{L}$ and g^* inherit these properties from L and g, everything we prove about V automatically holds in parallel form for $\tilde{V}$.

It will be helpful for our endeavor to note that V can be expressed in terms of E. Indeed, from the definitions of V and E in (1.1) and (4.4) it's easy to deduce the rule that

$$(5.2) \qquad V(\tau,\xi) = \inf_{\xi'}\Big\{V(\tau',\xi') + E(\tau-\tau',\xi',\xi)\Big\} \ \text{ for } 0 \le \tau' \le \tau.$$

By the same token we also have, through (5.1) and (4.5), that

$$(5.3) \qquad \tilde{V}(\tau,\eta) = \inf_{\eta'}\Big\{\tilde{V}(\tau',\eta') + \tilde{E}(\tau-\tau',\eta',\eta)\Big\} \ \text{ for } 0 \le \tau' \le \tau.$$

THEOREM 5.1 (conjugacy). *For each $\tau \ge 0$, the functions $V_\tau := V(\tau,\cdot)$ and $\tilde{V}_\tau := \tilde{V}(\tau,\cdot)$ are proper and conjugate to each other under the Legendre–Fenchel transform*

$$(5.4) \qquad \tilde{V}_\tau(\eta) = \sup_\xi\Big\{\langle\xi,\eta\rangle - V_\tau(\xi)\Big\}, \qquad V_\tau(\xi) = \sup_\eta\Big\{\langle\xi,\eta\rangle - \tilde{V}_\tau(\eta)\Big\}.$$

Hence in particular, the subgradients of these convex functions are related by

$$(5.5) \qquad \eta \in \partial V_\tau(\xi) \iff \xi \in \partial\tilde{V}_\tau(\eta) \iff V_\tau(\xi) + \tilde{V}_\tau(\eta) = \langle\xi,\eta\rangle.$$

Proof. Fix $\tau > 0$ and any vector $\bar\eta \in \mathbb{R}^n$. Let $l(\xi', \xi) = g(\xi') - \langle \xi, \bar\eta\rangle$. The corresponding dual endpoint function $\tilde l$ has $\tilde l(\eta', \eta) = g^*(\eta')$ when $\eta = \bar\eta$, but $\tilde l(\eta', \eta) = \infty$ when $\eta \neq \bar\eta$. In the Bolza problems we then have

$$-\inf(\mathcal{P}) = \sup_\xi\big\{\langle \xi, \bar\eta\rangle - V(\tau, \xi)\big\}, \qquad \inf(\tilde{\mathcal{P}}) = \tilde V(\tau, \bar\eta). \tag{5.6}$$

Because $\operatorname{dom} l$ has the form $C \times \mathbb{R}^n$ for a nonempty convex set C, namely $C = \operatorname{dom} g$, the constraint qualification of Theorem 4.5(a) is satisfied, and we may conclude that $-\inf(\tilde{\mathcal{P}}) = \inf(\mathcal{P}) > -\infty$. This yields the first equation in (5.4)—in the case of $\eta = \bar\eta$—and ensures that $V_\tau \not\equiv \infty$ and $\tilde V_\tau > -\infty$ everywhere. By the symmetry between $(\tilde L, g^*)$ and (L, g), we get the second equation in (5.4) along with $\tilde V_\tau \not\equiv \infty$ and $V_\tau > -\infty$ everywhere.

The subgradient relation translates to this context a property that is known for subgradients of conjugate convex functions in general; cf. [9, 11.3]. □

Proof of Theorem 2.1. Through the conjugacy in Theorem 5.1, we see at once that V_τ is convex and lsc, and of course the same for $\tilde V_\tau$. The remaining task is to demonstrate the epi-continuity property (2.3) of V. It will be expedient to tackle the corresponding property of $\tilde V$ at the same time and appeal to the duality between V and $\tilde V$ in simplifying the arguments. By this approach and by passing to subsequences that tend to τ either from above or from below, we can reduce the challenge to proving that

$$\begin{array}{ll} \text{(a)} & \text{whenever } \tau \geq 0 \text{ and } \tau^\nu \searrow \tau, \text{ one has} \\ & \qquad \begin{cases} \limsup_\nu V(\tau^\nu, \xi^\nu) \leq V(\tau, \xi) & \text{for some sequence } \xi^\nu \to \xi, \\ \liminf_\nu \tilde V(\tau^\nu, \eta^\nu) \geq \tilde V(\tau, \eta) & \text{for every sequence } \eta^\nu \to \eta; \end{cases} \\ \text{(b)} & \text{whenever } \tau > 0 \text{ and } \tau^\nu \nearrow \tau, \text{ one has} \\ & \qquad \begin{cases} \limsup_\nu V(\tau^\nu, \xi^\nu) \leq V(\tau, \xi) & \text{for some sequence } \xi^\nu \to \xi, \\ \liminf_\nu \tilde V(\tau^\nu, \eta^\nu) \geq \tilde V(\tau, \eta) & \text{for every sequence } \eta^\nu \to \eta, \end{cases} \end{array} \tag{5.7}$$

since these "subproperties" yield by duality the corresponding ones with V and $\tilde V$ reversed.

Argument for (a) of (5.7): Fix any $\bar\tau \geq 0$ and $\bar\xi \in \operatorname{dom} V_{\bar\tau}$. We'll verify that the first limit in (a) holds for $(\bar\tau, \bar\xi)$. Take any $\hat\tau > \bar\tau$. By Corollary 4.4(a), the image of the set $C_{\hat\tau - \bar\tau} = \operatorname{dom} E(\hat\tau - \bar\tau, \cdot, \cdot)$ under the projection $(\xi', \xi) \mapsto \xi'$ contains $\bar\xi$. Hence there exists $\hat\xi$ such that $E(\hat\tau - \bar\tau, \bar\xi, \hat\xi) < \infty$. Equivalently, there is an arc $x(\cdot) \in \mathcal{A}^1_n[\bar\tau, \hat\tau]$ such that $\int_{\bar\tau}^{\hat\tau} L(x(t), \dot x(t))dt < \infty$ with $x(\bar\tau) = \bar\xi$ and $x(\hat\tau) = \hat\xi$. Then too for every $\tau \in (\bar\tau, \hat\tau)$ we have $E(\tau - \bar\tau, \bar\xi, x(\tau)) \leq \int_{\bar\tau}^{\tau} L(x(t), \dot x(t))dt < \infty$ and therefore by (5.2) that

$$V(\tau, x(\tau)) \leq V(\bar\tau, \bar\xi) + \alpha(\tau) \text{ for } \alpha(\tau) := \int_{\bar\tau}^{\tau} L(x(t), \dot x(t))dt.$$

Consider any sequence $\tau^\nu \searrow \bar\tau$ in $(\bar\tau, \hat\tau)$. Let $\xi^\nu = x(\tau^\nu)$. Then $\xi^\nu \to \bar\xi$ and we obtain

$$\limsup_\nu V(\tau^\nu, \xi^\nu) \leq \limsup_\nu \big\{V(\bar\tau, \bar\xi) + \alpha(\tau^\nu)\big\} = V(\bar\tau, \bar\xi),$$

as desired. To establish the second limit in (a) as a consequence of this, we note now that the conjugacy in Theorem 5.1 gives $\tilde V(\tau^\nu, \cdot) \geq \langle \xi^\nu, \cdot\rangle - V(\tau^\nu, \xi^\nu)$. For any $\bar\eta$ and sequence $\eta^\nu \to \bar\eta$ this yields

$$\liminf_\nu \tilde V(\tau^\nu, \eta^\nu) \geq \liminf_\nu \big\{\langle \xi^\nu, \eta^\nu\rangle - V(\tau^\nu, \xi^\nu)\big\} \geq \langle \bar\xi, \bar\eta\rangle - V(\bar\tau, \bar\xi). \tag{5.8}$$

But $\bar{\xi}$ was an arbitrary point in $\operatorname{dom} V(\bar{\tau},\cdot)$, so we get the rest of what is needed in (a):

$$\liminf_\nu \tilde{V}(\tau^\nu,\eta^\nu) \;\geq\; \sup_\xi\big\{\langle\xi,\bar{\eta}\rangle - V(\bar{\tau},\xi)\big\} \;=\; \tilde{V}(\bar{\tau},\bar{\eta}). \tag{5.9}$$

Argument for (b) of (5.7): Fix any $\bar{\tau} > 0$ and $\bar{\xi} \in \operatorname{dom} V_{\bar{\tau}}$. We'll verify that the first limit in (a) holds for $(\bar{\tau},\bar{\xi})$. Let $\varepsilon > 0$. Because $V(\bar{\tau},\bar{\xi}) < \infty$, there exists $x(\cdot) \in \mathcal{A}^1_n[0,\bar{\tau}]$ with $x(\bar{\tau}) = \bar{\xi}$ and $g(x(0)) + \int_0^{\bar{\tau}} L(x(t),\dot{x}(t))dt < V(\bar{\tau},\bar{\xi}) + \varepsilon$. Then for all $\tau \in (0,\bar{\tau})$,

$$\begin{aligned} V(\tau,x(\tau)) &\leq g(x(0)) + \int_0^\tau L(x(t),\dot{x}(t))dt \\ &\leq V(\bar{\tau},\bar{\xi}) + \varepsilon - \alpha(\tau) \text{ for } \alpha(\tau) = \int_\tau^{\bar{\tau}} L(x(t),\dot{x}(t))dt. \end{aligned}$$

Consider any sequence $\tau^\nu \nearrow \bar{\tau}$ in $(0,\bar{\tau})$. Let $\xi^\nu = x(\tau^\nu)$. Then $\xi^\nu \to \bar{\xi}$ and we have

$$\limsup_\nu V(\tau^\nu,\xi^\nu) \leq \limsup_\nu\big\{V(\bar{\tau},\bar{\xi}) + \varepsilon - \alpha(\tau^\nu)\big\} \leq V(\bar{\tau},\bar{\xi}) + \varepsilon.$$

We've constructed a sequence with $\xi^\nu \to \bar{\xi}$ with this property for arbitrary ε, so by diagonalization we can get a sequence $\xi^\nu \to \bar{\xi}$ with $\limsup_\nu V(\tau^\nu,\xi^\nu) \leq V(\bar{\tau},\bar{\xi})$, as required. Fixing such a sequence and returning to the inequality $\tilde{V}(\tau^\nu,\cdot) \geq \langle\xi^\nu,\cdot\rangle - V(\tau^\nu,\xi^\nu)$, we obtain now for every sequence $\eta^\nu \to \bar{\eta}$ that (5.8) holds, and hence by the arbitrary choice of $\bar{\xi} \in \operatorname{dom} V_{\bar{\tau}}$ that (5.9) holds as well. □

The duality theory for the Bolza problems in this setting also provides insights into the properties of the optimal arcs associated with V.

THEOREM 5.2 (optimal arcs). *In the minimization problem defining $V_\tau(\xi) = V(\tau,\xi)$, an optimal arc $x(\cdot) \in \mathcal{A}^1_n[0,\tau]$ exists for any $\xi \in \operatorname{dom} V_\tau$. Every such arc $x(\cdot)$ must actually belong to $\mathcal{A}^\infty_n[0,\tau]$ when ξ is such that $\partial V_\tau(\xi) \neq \emptyset$, hence, in particular if $\xi \in \operatorname{ri}\operatorname{dom} V_\tau$.*

Proof. Although the theorem is stated in terms of V alone, its proof will rest on the duality between V and $\tilde{V}$. We'll focus actually on proving the $\tilde{V}$ version, since that ties in better with the foundation already laid in the proof of Theorem 5.1.

Returning to the problems $(\mathcal{P})$ and $(\tilde{P})$ of that proof, we make further use of Theorem 4.5. We showed that our choice of the function l implied $\inf(\tilde{\mathcal{P}}) = -\inf(\mathcal{P}) > -\infty$ in (5.6), but we didn't point out then that it also guarantees through Theorem 4.5(a) that an optimal arc $y(\cdot)$ exists for $(\tilde{\mathcal{P}})$ if, in addition, $\inf(\tilde{P}) < \infty$. Thus, an optimal arc exists for the problem defining $\tilde{V}(\tau,\bar{\eta})$ as long as $\tilde{V}(\tau,\bar{\eta}) < \infty$. Likewise then, an optimal arc exists for the problem defining $V(\tau,\bar{\xi})$ for any $\bar{\xi}$ such that $V(\tau,\bar{\xi}) < \infty$.

Next we use the fact that a vector $\bar{\xi}$ belongs to $\partial\tilde{V}_\tau(\bar{\eta})$ if and only if $\bar{\eta} \in \operatorname{dom}\tilde{V}_\tau$ and $\bar{\xi}$ furnishes the maximum in the expression for $-\inf(\mathcal{P})$ in (5.6). (This is true by (5.4) and (5.5) of Theorem 5.1.) For such a vector $\bar{\xi}$, $V(\tau,\bar{\xi})$ has to be finite, so that there exists, by the argument already furnished, an optimal arc $x(\cdot)$ for the minimizing problem that defined $V(\tau,\bar{\xi})$. That arc $x(\cdot)$ must then be optimal for $(\mathcal{P})$. Theorem 4.5(a) tells us in that case that $x(\cdot)$ and the optimal arc $y(\cdot)$ for $(\tilde{\mathcal{P}})$ are in $\mathcal{A}^\infty_n[0,\tau]$.

To finish up, we merely need to recall that a proper convex function φ has subgradients at every point of $\operatorname{ri}\operatorname{dom}\varphi$, in particular. □

6. Hamiltonian dynamics and method of characteristics. The generalized Hamiltonian ODE in (2.6) now enters the discussion. This dynamical system can be written in the form

$$(\dot{x}(t), \dot{y}(t)) \in G(x(t), y(t)) \quad \text{for a.e. } t \tag{6.1}$$

for the set-valued mapping

$$G : (x, y) \;\mapsto\; \partial_y H(x, y) \times -\tilde{\partial}_x H(x, y), \tag{6.2}$$

which derives from the subgradient mapping $(x, y) \;\mapsto\; \tilde{\partial}_x H(x, y) \times \partial_y H(x, y)$. The latter has traditionally been associated in convex analysis with H as a concave-convex function on $\mathbb{R}^n \times \mathbb{R}^n$. It is known to be nonempty-compact-convex-valued and locally bounded with closed graph (since H is also finite; see [9, section 35]). Hence the same holds for G.

Through these properties of G, the theory of differential inclusions [28] ensures the local existence of a Hamiltonian trajectory through every point. The local boundedness of G makes any trajectory $(x(\cdot), y(\cdot))$ over a time interval $[\tau_0, \tau_1]$ be Lipschitz continuous, i.e., belong to $\mathcal{A}^\infty_n[\tau_0, \tau_1]$. Another aspect of the Hamiltonian dynamics in (2.6), or (6.1)–(6.2), is that $H(x(t), y(t))$ is constant along any trajectory $(x(\cdot), y(\cdot))$. This was proved in [6].

Nowadays there are other concepts of subgradient, beyond those of convex analysis, that can be applied to H without separating it into its concave and convex arguments. The general definition in section 2 directly assigns a subset $\partial H(x, y) \subset \mathbb{R}^n \times \mathbb{R}^n$ to each point $(x, y) \in \mathbb{R}^n \times \mathbb{R}^n$. An earlier definition for this purpose, which was used by Clarke in his work on Hamiltonian conditions for optimality in *nonconvex* problems of Bolza (see [29] and its references), relied on H being locally Lipschitz continuous and utilized what we now recognize as the set $\operatorname{con} \partial H(x, y)$ in such circumstances. (Here "con" designates the convex hull of a set.) A more subtle form of "partial convexification" of $\partial H(x, y)$, involving only the x argument in a special way, has been featured in more recent work on Hamiltonians in nonconvex problems of Bolza; cf. [18], [19], and [20].

As a preliminary to our further analysis of the Hamiltonian dynamics, we provide a clarification of the relationships between these concepts.

PROPOSITION 6.1 (subgradients of the Hamiltonian). *On the basis of $H(x, y)$ being finite, concave in x, and convex in y, one has*

$$\operatorname{con} \partial H(x, y) \;=\; \tilde{\partial}_x H(x, y) \times \partial_y H(x, y), \tag{6.3}$$

this set being nonempty and compact. In terms of the set D consisting of the points (x, y) where H is differentiable (the complement of which is of measure zero), one has

$$\operatorname{con} \partial H(x, y) = \partial H(x, y) = \{\nabla H(x, y)\} \quad \textit{for all} \quad (x, y) \in D. \tag{6.4}$$

The gradient mapping ∇H is continuous relative to D, so that H is strictly differentiable on D. Elsewhere,

$$\operatorname{con} \partial H(x, y) \;=\; \operatorname{con}\Big\{(w, v) \;\Big|\; \exists\, (x^\nu, y^\nu) \to (x, y) \;\; \textit{with} \;\; \nabla H(x^\nu, y^\nu) \to (w, v)\Big\}. \tag{6.5}$$

Proof. Formula (6.5) is well known to hold for the subgradients of any locally Lipschitz continuous function; cf. [10, 9.61]. The special property coming out of the concavity-convexity of H is that the set-valued mapping

$$T_H : (x, y) \;\mapsto\; [-\tilde{\partial}_x H(x, y)] \times \partial_y H(x, y) \;=\; \partial_x[-H](x, y) \times \partial_y H(x, y) \tag{6.6}$$

is maximal monotone; cf. [10, 12.27]. The points (x,y) where T_H is single-valued are the ones where $\tilde{\partial}_x H(x,y)$ and $\partial H_y(x,y)$ both reduce to singletons, a property which corresponds to $H(\cdot,y)$ being differentiable at x while $H(x,\cdot)$ is differentiable at y; then actually H is differentiable (jointly in the two arguments) at (x,y); cf. [9, 35.6]. Thus, the subset of $\mathbb{R}^n \times \mathbb{R}^n$ on which T_H is single-valued is D, and on this set we have $T_H(x,y) = (-\nabla_x H(x,y), \nabla_y H(x,y))$. Then by maximal monotonicity, T_H is continuous on D with

$$T_H(x,y) \;=\; \operatorname{con}\Big\{(-w,v) \,\Big|\, \exists\,(x^\nu,y^\nu) \to (x,y) \text{ with } \nabla H(x^\nu,y^\nu) \to (w,v)\Big\};$$

see [10, 12.63, 12.67]. We thereby obtain (6.3) from (6.5) and at the same time have (6.4), from which H must be strictly differentiable on D by [10, 9.18]. □

COROLLARY 6.2 (single-valuedness in the Hamiltonian system). *The mapping G in the differential inclusion* (6.1)–(6.2) *has the form*

$$G(x,y) = \big\{(v,-w) \,\big|\, (w,v) \in \operatorname{con} \partial H(x,y)\big\} \tag{6.7}$$

and is single-valued a.e. Indeed, $G(x,y) = \big\{(\nabla_y H(x,y), -\nabla_x H(x,y))\big\}$ at all points where the Hamiltonian H is differentiable, whereas in general,

$$\begin{aligned} G(x,y) \;=\; \operatorname{con}\Big\{(v,-w) \,\Big|\, &\exists\,(x^\nu,y^\nu) \to (x,y) \textit{ with} \\ &(\nabla_y H(x^\nu,y^\nu), -\nabla_x H(x^\nu,y^\nu)) \to (v,-w)\Big\}. \end{aligned} \tag{6.8}$$

Despite the typical single-valuedness of G, situations exist in which there can be more than one Hamiltonian trajectory from a given starting point. The flow mappings S_τ for this system, as defined in (2.7), can well have values that are not singleton sets, and indeed, can even be nonconvex sets consisting of more than finitely many points. It's rather surprising, then, that they nonetheless capture with precision the behavior of the Lipschitzian manifolds $\operatorname{gph} \partial V_\tau$ in Corollary 2.2. We're prepared now to prove this fact.

Proof of Theorem 2.4. Fix $\tau > 0$ along with any $\bar{\xi}$ and $\bar{\eta}$. The relation $\bar{\eta} \in \partial V_\tau(\bar{\xi})$ is equivalent by Theorem 5.1 to $\bar{\xi} \in \partial \tilde{V}_\tau(\bar{\eta})$, or to having $\bar{\xi} \in \operatorname{argmax}_\xi \big\{\langle \xi, \bar{\eta}\rangle - V_\tau(\xi)\big\}$. We saw in the proof of Theorem 5.2 that this corresponded further, in terms of the special Bolza problems $(\mathcal{P})$ and $(\tilde{\mathcal{P}})$ introduced in the proof of Theorem 5.1, to the existence of optimal arcs $x(\cdot)$ for $(\mathcal{P})$ and $y(\cdot)$ for $(\tilde{\mathcal{P}})$ such that $x(\tau) = \bar{\xi}$.

On the other hand, because $-\inf(\mathcal{P}) = (\tilde{\mathcal{P}})$ for these problems, we know from Theorem 4.1 that arcs $x(\cdot)$ and $y(\cdot)$ solve these problems, respectively, if and only if $(x(\cdot), y(\cdot))$ is a Hamiltonian trajectory over $[0,\tau]$ satisfying the generalized transversality condition $(y(0), -y(\tau)) \in \partial l(x(0), \bar{\xi})$. Since $l(\xi', \xi) = g(\xi') - \langle \xi, \bar{\eta}\rangle$ by definition in this case, the transversality condition comes down to the relations $y(0) \in \partial g(x(0))$ and $y(\tau) = \bar{\eta}$.

In summary, we have $\bar{\eta} \in \partial V_\tau(\bar{\xi})$ if and only if there is a trajectory $(x(\cdot), y(\cdot))$ over $[0,\tau]$ such that $x(\tau) = \bar{\eta}$, $y(0) \in \partial g(x(0))$, and $y(\tau) = \bar{\eta}$. □

Further details about the evolution of the subgradient mappings $\partial V_\tau = \partial_\xi V(\tau,\cdot)$ can now be recorded. The equivalence in the next theorem came out in the preceding proof.

THEOREM 6.3 (optimality in subgradient evolution). *A pair of arcs $x(\cdot)$ and $y(\cdot)$ gives a Hamiltonian trajectory over $[0,\tau]$ that starts in $\operatorname{gph} \partial g$ and ends at a point $(\xi,\eta) \in \operatorname{gph} \partial V_\tau$ if and only if*

(a) $x(\cdot)$ *is optimal in the minimization problem in* (1.1) *that defines* $V(\tau,\xi)$*, and*
(b) $y(\cdot)$ *is optimal in the minimization problem in* (5.1) *that defines* $\tilde{V}(\tau,\eta)$.

Corollary 6.4 (persistence of subgradient relations). *When a Hamiltonian trajectory* $(x(\cdot),y(\cdot))$ *over* $[0,\tau]$ *has* $y(0)\in\partial g(x(0))$*, it has* $y(t)\in\partial_\xi V(t,x(t))$ *for all* $t\in[0,\tau]$.

We turn now, however, to the task of broadening Theorem 2.4 to cover not only the evolution of subgradients but also that of function values. For this, the graph of ∂V_τ in $\mathbb{R}^n\times\mathbb{R}^n$ has to be replaced by an associated subset of $\mathbb{R}^n\times\mathbb{R}^n\times\mathbb{R}$.

Proposition 6.5 (characteristic manifolds for convex functions). *Let* $f:\mathbb{R}^n\to\overline{\mathbb{R}}$ *be convex, proper, and lsc, and let*

$$M=\big\{(x,y,z)\,\big|\,y\in\partial f(x),\ z=f(x)\big\}\subset\mathbb{R}^n\times\mathbb{R}^n\times\mathbb{R}. \tag{6.9}$$

Then M *is an* n*-dimensional Lipschitzian manifold in the following terms. There is a one-to-one, locally Lipschitz continuous mapping*

$$F:\mathbb{R}^n\to M,\qquad F(u)=(P(u),Q(u),R(u)),$$

whose range is all of M *and whose inverse is Lipschitz continuous as well, in fact with*

$$F^{-1}(x,y,z)=x+y\quad\textit{for }(x,y,z)\in M.$$

The components of F *are given by*

$$P(u)=\mathrm{argmin}_x\Big\{f(x)+\tfrac{1}{2}|x-u|^2\Big\},\qquad Q=I-P,\qquad R=f{\circ}P, \tag{6.10}$$

where P *and* Q*, like* F^{-1}*, are globally Lipschitz continuous with constant* 1*, and* R *is Lipschitz continuous with constant* r *on the ball* $\big\{u\,\big|\,|u|\le r\big\}$ *for each* $r>0$.

Proof. The mapping $u\mapsto(P(u),Q(u))$ is well known to parameterize the graph of ∂f in the manner described; cf. [10, 12.15]. With this parameterization, the component $z=R(u)$ must be $f(P(u))$, so the additional issue is just the claimed Lipschitz property of this expression. According to the formulas for P and Q in (6.10) we have

$$R(u)=p(u)-\tfrac{1}{2}|Q(u)|^2\quad\text{for}\quad p(u):=\min_x\Big\{f(x)+\tfrac{1}{2}|x-u|^2\Big\}. \tag{6.11}$$

The function p is smooth with gradient $\nabla p(u)=Q(u)$; see [10, 2.26]. Hence R is locally Lipschitz continuous, but what can be said about its Lipschitz modulus? Because P and Q are Lipschitz continuous with constant 1 and satisfy $P+Q=I$, they are differentiable at almost every point u, their Jacobian matrices satisfying $\nabla P(u)+\nabla Q(u)=I$ and having norms at most 1. At any such point u, R is differentiable as well, with $\nabla R(u)=Q(u)-\nabla Q(u)Q(u)=\nabla P(u)Q(u)$, so that $|\nabla R(u)|\le|\nabla P(u)||Q(u)|\le|Q(u)|\le|u|$. Thus, $|\nabla R(u)|\le r$ on the ball $\big\{u\,\big|\,|u|\le r\big\}$, and consequently R is Lipschitz continuous with constant r on that ball. □

The set M in (6.9) will be called the (first-order) *characteristic manifold* for f, and the mapping F its *canonical parameterization.*

Proposition 6.6 (recovery of a function from its manifold). *Let* M *be the characteristic manifold of a convex, proper, lsc function* f*. Then* M *uniquely determines* f *as follows:*

(a) *The image* C *of* M *under the projection* $(x,y,z)\mapsto x$*, namely* $C=\mathrm{dom}\,\partial f$*, satisfies* $\mathrm{ri}\,\mathrm{dom}\,f\subset C\subset\mathrm{cl}\,\mathrm{dom}\,f$ *and thus has* $\mathrm{ri}\,C=\mathrm{ri}\,\mathrm{dom}\,f$ *and* $\mathrm{cl}\,C=\mathrm{cl}\,\mathrm{dom}\,f$.

(b) *For every x in C, the vectors $(x,y,z) \in M$ all have the same z, which equals $f(x)$.*

(c) *For every $x \in \operatorname{cl} C \setminus C$ and any $a \in \operatorname{ri} C$, one has $x + \varepsilon(a - x) \in \operatorname{ri} C$ for all $\varepsilon \in (0,1]$ and $f(x + \varepsilon(a-x)) \to f(x)$ as $\varepsilon \searrow 0$.*

(c) *For every $x \notin \operatorname{cl} C$, $f(x) = \infty$.*

Proof. These facts are evident from the definition of M, the well-known existence of subgradients at points of $\operatorname{ri}\operatorname{dom} f$, and the way that f can be recovered fully from its values on $\operatorname{ri}\operatorname{dom} f$; see [9, section 7, section 23]. □

PROPOSITION 6.7 (convergence of characteristic manifolds). *A sequence of convex, proper, lsc functions f^ν on $\mathbb{R}^n$ epi-converges to another such function f if and only if the associated sequence of characteristic manifolds M^ν in $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$ converges (in the Painlevé–Kuratowski sense) to the characteristic manifold M for f.*

Proof. Attouch's theorem on convex functions (cf. [10, 12.35]) says that f^ν epi-converges to f if and only if $\operatorname{gph} \partial f^\nu$ converges to $\operatorname{gph} \partial f$ and, for at least one sequence of points $(x^\nu, y^\nu) \in \operatorname{gph} \partial f^\nu$ converging to a point $(x,y) \in \operatorname{gph} \partial f$, one has $f^\nu(x^\nu) \to f(x)$. On the other hand, epi-convergence of convex functions entails the latter holding for every such sequence of points (x^ν, y^ν). The convergence of the characteristic manifolds is thus hardly more than a restatement of these facts of convex analysis. □

Our goal in these terms is to describe how the characteristic manifold for V_τ evolves from that of g. We introduce the following extension of the Hamiltonian system (6.1)–(6.2), which we speak of as the *characteristic system* associated with H:

$$(\dot{x}(t), \dot{y}(t), \dot{z}(t)) \in \bar{G}(x(t), y(t)) \text{ for a.e. } t \tag{6.12}$$

for the set-valued mapping $\bar{G}$ defined by

$$\bar{G}(x,y) := \big\{ (v,w,u) \,\big|\, (v,w) \in G(x,y),\ u = \langle v, y\rangle - H(x,y) \big\}. \tag{6.13}$$

The trajectories $(x(\cdot), y(\cdot), z(\cdot))$ of this system will be called *characteristic trajectories*. Like G itself, $\bar{G}$ is nonempty-closed-convex-valued and locally bounded with closed graph, so a characteristic trajectory exists, at least locally, through every point of $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$. The corresponding flow mapping for each $\tau \in [0,\infty)$ will be denoted by $\bar{S}_\tau$:

$$\begin{aligned} &\bar{S}_\tau : (\xi_0, \eta_0, \zeta_0) \mapsto \\ &\Big\{ (\xi,\eta,\zeta) \,\Big|\, \exists \text{ characteristic trajectory } (x(\cdot), y(\cdot), z(\cdot)) \text{ over } [0,\tau] \text{ with} \\ &\qquad (x(0), y(0), z(0)) = (\xi_0, \eta_0, \zeta_0),\ (x(\tau), y(\tau), z(\tau)) = (\xi, \eta, \zeta) \Big\}. \end{aligned} \tag{6.14}$$

THEOREM 6.8 (subgradient method of characteristics). *Let M_τ be the characteristic manifold for $V_\tau = V(\tau, \cdot)$, with M_0 the characteristic manifold for $g = V_0$. Then*

$$M_\tau = \bar{S}_\tau(M_0) \quad \text{for all} \quad \tau \geq 0. \tag{6.15}$$

Moreover M_τ, as a closed subset of $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$, depends continuously on τ.

Proof. The continuity of the mapping $\tau \mapsto M_\tau$ is immediate from Proposition 6.7 and the epi-continuity in Theorem 2.1. The evolution of ∂V_τ through the drift of its graph in the underlying system (6.1)–(6.2) has already been verified in Theorem

2.4, so the only issue here is what happens when the z component is added as in (6.12)–(6.13). We have

$$\dot{z}(t) = \langle \dot{x}(t), y(t)\rangle - H(x(t), y(t)) = L(x(t), \dot{x}(t)) \tag{6.16}$$

when $(\dot{x}(t), \dot{y}(t)) \in G(x(t), y(t))$, since that relation entails $\dot{x}(t) \in \partial_y H(x(t), y(t))$, which is equivalent to the second equation in (6.16) because the convex functions $H(x(t), \cdot)$ and $L(x(t), \cdot)$ are conjugate to each other. The arc $x(\cdot)$ is optimal for the minimization problem that defines $V(\tau, \xi)$, so that

$$V(\tau, \xi) = g(x(0)) + \int_0^\tau L(x(t), \dot{x}(t))dt = z(0) + \int_0^\tau \dot{z}(t)dt = z(\tau).$$

The trajectory $(x(\cdot), y(\cdot), z(\cdot))$ does, therefore, carry the point $(x(0), y(0), z(0)) \in M_0$ to the point $(x(\tau), y(\tau), z(\tau)) \in M_\tau$. Conversely, of course, (6.16) is essential for that. □

Theorem 6.8 provides a remarkably global version of the method of characteristics, made possible by convexity. It relies on the one-to-one correspondence between lsc, proper, convex functions and their characteristic manifolds in Proposition 6.5 and on the preservation of such function properties over time, as in Theorem 2.1. By transforming the evolution of functions into the evolution of the associated manifolds, one is able to reduce the function evolution to the drift of those manifolds in the characteristic dynamical system associated with the given Hamiltonian H, or Lagrangian L.

In contrast, the classical method of characteristics requires differentiability at every turn and, in adopting the implicit (or inverse) function theorem as the main tool, is ordinarily limited to local validity. The characteristic manifold M_0 associated with g has to be a smooth manifold, and g must therefore be $\mathcal{C}^2$. The Hamiltonian H has to be $\mathcal{C}^2$ as well, so that the mappings $\bar{S}_\tau$ are single-valued and smooth. But even these assumptions are not enough to guarantee that the characteristic dynamics will carry M_0 into *smooth* manifolds M_τ. The trouble is that the functions V_τ are defined by minimization, and that operation, in its inherent failure to preserve differentiability, simply does not fit well in the framework of classical analysis.

A generalized "method of characteristics" for value functions has also been developed by Subbotin [30], [21], but in a different framework from ours, namely one focused on bounded control dynamics and not convexity, and not revolving around the Hamiltonian function H and its dynamical system. This is also the case in [22] and [23].

7. Hamilton–Jacobi equation and regularity. The time has come to move beyond subgradients of convex analysis and establish properties of the subgradient mapping ∂V as a whole.

Proof of Theorem 2.5. Our first goal is to prove the equivalence of the conditions $\eta \in \partial_\xi V(\tau, \xi)$ and $\sigma = -H(\xi, \eta)$ with having $(\sigma, \eta) \in \hat{\partial} V(\tau, \xi)$ when $\tau > 0$. Here $\partial_\xi V(\tau, \xi)$ is the same as $\hat{\partial}_\xi V(\tau, \xi)$, since the function $V(\tau, \cdot) = V_\tau$ is convex.

Let $\bar{\eta} \in \partial_\xi V(\bar{\tau}, \bar{\xi})$ with $\bar{\tau} > 0$. We need to show that $(-H(\bar{\xi}, \bar{\eta}), \bar{\eta}) \in \hat{\partial} V(\bar{\tau}, \bar{\xi})$, or in other words that

$$V(\tau, \xi) - V(\bar{\tau}, \bar{\xi}) + (\tau - \bar{\tau})H(\bar{\xi}, \bar{\eta}) - \langle \xi - \bar{\xi}, \bar{\eta}\rangle \ \geq\ o\big(|(\tau, \xi) - (\bar{\tau}, \bar{\xi})|\big). \tag{7.1}$$

By Theorem 2.4 there is a Hamiltonian trajectory $(x(\cdot), y(\cdot))$ over $[0, \bar{\tau}]$ that starts in $\operatorname{gph} \partial g$ and goes to $(\bar{\xi}, \bar{\eta})$. Through the local existence property of the Hamiltonian system, this trajectory can be extended to a larger interval $[0, \bar{\tau} + \varepsilon]$, in which case $y(\tau) \in \partial_\xi V(\tau, x(\tau))$ for all $\tau \in [0, \bar{\tau} + \varepsilon]$ by Corollary 6.4, so that

$$(7.2)\ \ V(\tau, \xi) \ \geq \ V(\tau, x(\tau)) + \langle \xi - x(\tau), y(\tau) \rangle \quad \text{for all } \xi \in \mathbb{R}^n \text{ when } \tau \in [0, \bar{\tau} + \varepsilon].$$

We have $V(\tau, x(\tau)) \ = \ g(x(0)) + \int_0^\tau \big[\langle \dot{x}(t), y(t) \big\rangle - H(x(t), y(t))\big] dt$ by Theorem 6.8, where $H(x(t), y(t)) \equiv H(x(\bar{\tau}), y(\bar{\tau}))$ because H is constant along Hamiltonian trajectories. Hence

$$(7.3)\ \ V(\tau, x(\tau)) = V(\bar{\tau}, \bar{\xi}) - (\tau - \bar{\tau}) H(\bar{\xi}, \bar{\eta}) + \int_{\bar{\tau}}^{\tau} \langle \dot{x}(t), y(t) \rangle dt \ \text{ when } \tau \in [0, \bar{\tau} + \varepsilon].$$

Also $\int_{\bar{\tau}}^{\tau} \langle \dot{x}(t), y(t) \rangle dt = \langle x(\tau), y(\tau) \rangle - \langle x(\bar{\tau}), y(\bar{\tau}) \rangle - \int_{\bar{\tau}}^{\tau} \langle x(t), \dot{y}(t) \rangle dt$, so in combining (7.3) with (7.2), we see that the left side of (7.1) is bounded below by the expression

$$\begin{aligned} -\langle \xi - \bar{\xi}, \bar{\eta} \rangle + \langle \xi - x(\tau), y(\tau) \rangle + \langle x(\tau), y(\tau) \rangle - \langle x(\bar{\tau}), y(\bar{\tau}) \rangle - \int_{\bar{\tau}}^{\tau} \langle x(t), \dot{y}(t) \rangle dt& \\ = \langle \xi - \bar{\xi},\, y(\tau) - \bar{\eta} \rangle + \langle \bar{\xi},\, y(\tau) - \bar{\eta} \rangle - \int_{\bar{\tau}}^{\tau} \langle x(t), \dot{y}(t) \rangle dt& \\ = \langle \xi - \bar{\xi},\, y(\tau) - y(\bar{\tau}) \rangle - \int_{\bar{\tau}}^{\tau} \langle x(t) - x(\bar{\tau}), \dot{y}(t) \rangle dt.& \end{aligned}$$

This expression is of type $o\big(|(\tau, \xi) - (\bar{\tau}, \bar{\xi})|\big)$ because $x(\cdot)$ and $y(\cdot)$ are continuous and $\dot{y}(\cdot)$ is essentially bounded on $[0, \bar{\tau} + \varepsilon]$. Thus, $(-H(\bar{\xi}, \bar{\eta}), \bar{\eta}) \in \hat{\partial} V(\bar{\tau}, \bar{\xi})$, as claimed.

To argue the converse implication, we consider now any pair $(\bar{\sigma}, \bar{\eta}) \in \hat{\partial} V(\bar{\tau}, \bar{\xi})$. Such a pair satisfies

$$(7.4) \qquad V(\tau, \xi) \ \geq \ V(\bar{\tau}, \bar{\xi}) + (\tau - \bar{\tau}) \bar{\sigma} + \langle \xi - \bar{\xi}, \bar{\eta} \rangle + o\big(|(\tau, \xi) - (\bar{\tau}, \bar{\xi})|\big).$$

In particular, $\bar{\eta} \in \hat{\partial}_\xi V(\bar{\tau}, \bar{\xi}) = \partial_\xi V(\bar{\tau}, \bar{\xi})$, and we therefore have, as just explained, the existence of a Hamiltonian trajectory $(x(\cdot), y(\cdot))$ for which (7.3) holds. Specializing (7.4) to $\xi = x(\tau)$ and using the expression in (7.3) for $V(\tau, x(\tau))$, we obtain

$$\begin{aligned} V(\bar{\tau}, \bar{\xi}) - &(\tau - \bar{\tau}) H(\bar{\xi}, \bar{\eta}) + \int_{\bar{\tau}}^{\tau} \langle \dot{x}(t), y(t) \rangle dt \\ &\geq \ V(\bar{\tau}, \bar{\xi}) + (\tau - \bar{\tau}) \bar{\sigma} + \langle x(\tau) - x(\bar{\tau}), \bar{\eta} \rangle + o\big(|(\tau, x(\tau)) - (\bar{\tau}, x(\bar{\tau}))|\big), \end{aligned}$$

where the final term is of type $o(|\tau - \bar{\tau}|)$ because $x(\cdot)$ is locally Lipschitz continuous. Then

$$(\tau - \bar{\tau})(\bar{\sigma} + H(\bar{\xi}, \bar{\eta})) \ \leq \ \int_{\bar{\tau}}^{\tau} \langle \dot{x}(t),\, y(t) - y(\bar{\tau}) \rangle dt + o(|\tau - \bar{\tau}|),$$

with the integral term likewise being of type $o(|\tau - \bar{\tau}|)$. Necessarily, then, $\bar{\sigma} + H(\bar{\xi}, \bar{\eta}) = 0$.

We turn now to showing that $\partial V(\tau, \xi) = \hat{\partial} V(\tau, \xi)$ for all ξ when $\tau > 0$. Since $\hat{\partial} V(\tau, \xi) \subset \partial V(\tau, \xi)$ in general, only the opposite inclusion has to be checked. Suppose $(\sigma, \eta) \in \partial V(\tau, \xi)$. By definition, there are sequences $(\tau^\nu, \xi^\nu) \to (\tau, \xi)$ and $(\sigma^\nu, \eta^\nu) \to (\sigma, \nu)$ with $V(\tau^\nu, \xi^\nu) \to V(\tau, \xi)$ and $(\sigma^\nu, \eta^\nu) \in \hat{\partial} V(\tau^\nu, \xi^\nu)$. We have seen that the latter means $\sigma^\nu = -H(\xi^\nu, \eta^\nu)$ and $\eta^\nu \in \partial_\xi V(\tau^\nu, \xi^\nu)$. Then $\sigma = -H(\xi, \eta)$ by the continuity of H.

On the other hand, the sets $C^\nu = \operatorname{gph} \partial_\xi V(\tau^\nu, \cdot)$ converge to $C = \operatorname{gph} \partial_\xi V(\tau, \cdot)$ by Corollary 2.2. Hence from having $\eta^\nu \in \partial_\xi V(\tau^\nu, \xi^\nu)$ we get $\eta \in \partial_\xi V(\tau, \xi)$. The pair (σ, η) thus satisfies the conditions we have identified as describing the elements of $\hat{\partial} V(\tau, \xi)$. □

Through the duality in Theorem 5.1, the statements in Theorem 2.5 are valid equally for the dual value function $\tilde{V}$. From this we obtain the following.

THEOREM 7.1 (dual Hamilton–Jacobi equation). *The dual value function $\tilde{V}$ satisfies*

$$\sigma - H(\xi, \eta) = 0 \quad \textit{for all} \quad (\sigma, \xi) \in \partial \tilde{V}(\tau, \eta) \quad \textit{when} \quad \tau > 0. \tag{7.5}$$

Indeed, for $\tau > 0$ one has $(\sigma, \xi) \in \partial \tilde{V}(\tau, \eta)$ if and only if $(-\sigma, \eta) \in \partial V(\tau, \xi)$.

Proof. In translating Theorem 2.5 to the context of $\tilde{V}$, as justified by Theorem 5.1, we bring into the scene the dual Hamiltonian $\tilde{H}(y, x) = -H(x, y)$ corresponding (in Proposition 3.5) to the dual Lagrangian $\tilde{L}$. The vectors $(\sigma, \xi) \in \partial \tilde{V}(\tau, \eta)$ are characterized by $\xi \in \partial_\eta \tilde{V}(\tau, \eta)$ and $\sigma = -\tilde{H}(\eta, \xi) = H(\xi, \eta)$. Invoking the conjugacy between $V(\tau, \cdot)$ and $\tilde{V}(\tau, \cdot)$ in Theorem 5.1, specifically the relation (5.5), we get the subgradient equivalence. Then (7.5) is immediate from the Hamilton–Jacobi equation already in Theorem 2.5. □

We take up next the issue of what additional properties of continuity, differentiability, etc. the value function V is guaranteed to have beyond the convexity and epi-continuity in Theorem 2.1. We begin with a characterization of the interior of the set

$$\operatorname{dom} V = \big\{ (\tau, \xi) \in [0, \infty) \times \mathbb{R}^n \,\big|\, V(\tau, \xi) < \infty \big\}.$$

PROPOSITION 7.2 (domain interiors). *In terms of $V_\tau = V(\tau, \cdot)$, one has that*

$$(\tau, \xi) \in \operatorname{int} \operatorname{dom} V \quad \Longleftrightarrow \quad \tau > 0, \ \xi \in \operatorname{int} \operatorname{dom} V_\tau.$$

Proof. It's evident that "⇒" holds. We focus therefore on "⇐." Consider $\bar{\tau} > 0$ and $\bar{\xi} \in \operatorname{int} \operatorname{dom} V_{\bar{\tau}}$. The epi-convergence of V_τ to $V_{\bar{\tau}}$ as $\tau \to \bar{\tau}$ in Theorem 2.1 entails through the convexity of these functions that V_τ converges pointwise to $V_{\bar{\tau}}$ uniformly on all compact subsets of $\operatorname{int} \operatorname{dom} V_{\bar{\tau}}$; cf. [10, 7.17]. In particular, this convergence holds on some open neighborhood U of $\bar{x}$ in $\operatorname{dom} V_{\bar{\tau}}$, so for some open interval I around $\bar{\tau}$ we have $U \subset \operatorname{dom} V_\tau$ for all $\tau \in I$. Then $I \times O$ is an open subset of $\operatorname{dom} V$ containing $(\bar{\tau}, \bar{\xi})$, and we conclude that $(\bar{\tau}, \bar{\xi}) \in \operatorname{int} \operatorname{dom} V$. □

The argument just given shows further that V is continuous on the interior of $\operatorname{dom} V$, but we're headed toward showing that V is in fact locally Lipschitz continuous there. The agreement between $\partial V(\tau, \xi)$ and $\hat{\partial} V(\tau, \xi)$ in Theorem 2.5 will have a part in this, and it will yield other strong properties besides.

Recall that a locally Lipschitz continuous function is *subdifferentially regular* (in the sense of Clarke regularity of its epigraph) when all its subgradients are regular subgradients, or equivalently, its subderivatives and regular subderivatives coincide everywhere; for background, see [10, Chapters 8 and 9]. The *subderivative* function for V at a point (τ, ξ) is defined in general by

$$dV(\tau, \xi) : (\tau', \xi') \mapsto dV(\tau, \xi)(\tau', \xi') := \liminf_{\substack{\varepsilon \searrow 0 \\ (\tau'', \xi'') \to (\tau', \xi')}} \frac{V(\tau + \varepsilon \tau'', \, \xi + \varepsilon \xi'') - V(\tau, \xi)}{\varepsilon}.$$

To say that V is *semidifferentiable* at (τ,ξ) is to say that, for all (τ',ξ'), this lower limit exists actually as the full limit

$$\lim_{\substack{\varepsilon\searrow 0\\ (\tau'',\xi'')\to(\tau',\xi')}} \frac{V(\tau+\varepsilon\tau'',\,\xi+\varepsilon\xi'')-V(\tau,\xi)}{\varepsilon}.$$

Then $dV(\tau,\xi)(\tau',\xi')$ must be finite and continuous as a function of (τ',ξ'); cf. [10, 7.21].

THEOREM 7.3 (regularity consequences). *On* $\operatorname{int}\operatorname{dom} V$*, the subgradient mapping* ∂V *is nonempty-compact-convex-valued and locally bounded, and* V *itself is locally Lipschitz continuous and subdifferentially regular, moreover, semidifferentiable with*

$$dV(\tau,\xi)(\tau',\xi') \;=\; \max\Big\{\langle\xi',\eta\rangle-\tau' H(\xi,\eta)\,\Big|\,\eta\in\partial_\xi V(\tau,\xi)\Big\}. \tag{7.6}$$

Indeed, V *is strictly differentiable wherever it is differentiable, which is at almost every point of* $\operatorname{int}\operatorname{dom} V$*, and relative to such points the gradient mapping* ∇V *is continuous.*

Proof. The points $(\tau,\xi)\in\operatorname{int}\operatorname{dom} V$ have been identified in Proposition 7.2 as the ones with $\tau>0$ and $\xi\in\operatorname{int}\operatorname{dom} V(\tau,\cdot)$. Because $V(\tau,\cdot)$ is convex, the mapping $\partial_\xi V(\tau,\cdot)$ is nonempty-compact-valued and locally bounded on $\operatorname{int}\operatorname{dom} V(\tau,\cdot)$, as already known through convex analysis; cf. [6, section 24]. These properties carry over to the behavior of $\partial_\xi V$ on $\operatorname{int}\operatorname{dom} V$ because of the epi-continuous dependence of $V(\tau,\cdot)$ on τ in Theorem 2.1; see [6, section 24] again. The local boundedness of $\partial_\xi V$, when joined with the formula $\sigma=-H(\xi,\eta)$ in Theorem 5.1 and the continuity of H, gives us the nonempty-compact-valuedness and local boundedness of ∂V.

The local boundedness of ∂V on $\operatorname{int}\operatorname{dom} V$ implies that V is Lipschitz continuous there locally; cf. [10, 9.13]. Then from having $\hat{\partial} V(\tau,\xi)=\partial V(\tau,\xi)$ in Theorem 2.5 we get the subdifferential regularity of V on $\operatorname{int}\operatorname{dom} V$ and the convexity of $\partial V(\tau,\xi)$ (because $\hat{\partial} V(\tau,\xi)$ is always convex). Local Lipschitz continuity and subdifferential regularity yield semidifferentiability by [10, 9.16]. Formula (7.6) specializes the semiderivative formula in that result to V by way of the description of $\partial V(\tau,\xi)$ in Theorem 2.5.

By virtue of being locally Lipschitz continuous, V is differentiable a.e. on $\operatorname{int}\operatorname{dom} V$. In the presence of subdifferential regularity, the differentiability is strict and the gradient mapping has the stated continuity property; see [10, 9.20]. □

Elementary examples illustrate the possible nondifferentiability of V. The simplest is to let $H=0$, in which case $V(\tau,\xi)=g(\xi)$, and thus any nondifferentiability in g is propagated forward for all time. A similar effect is provided in the one-dimensional case (n=1) by $H(x,y)=-y$, which yields $V(\tau,\xi)=g(\tau+\xi)$. If g is nondifferentiable at some point $\bar{\xi}$, then V is likewise nondifferentiable at every (τ,ξ) on the line $\tau+\xi=\bar{\xi}$.

To see the trouble from another angle, let $H(x,y)=\psi(x)$, where ψ is any finite concave function. Then, no matter what the choice of convex g, one has $V(\tau,xi)=g(\xi)-\tau\psi(\xi)$. When g is finite, so too is V, but even when g is differentiable, V need not be unless ψ is differentiable. This example underscores that singularities may appear in V even with smooth initial data.

As a complement to Theorem 7.3, we develop further information about $\operatorname{int}\operatorname{dom} V$, utilizing Proposition 7.2 to translate the issue into an investigation of when $\operatorname{int}\operatorname{dom} V_\tau \neq\emptyset$. It will be convenient to work with the calculus of relative interiors and the fact that, for a convex set C in a space $\mathbb{R}^d$, one has $\operatorname{int} C\neq\emptyset$ if and only if $\operatorname{aff} C=\mathbb{R}^d$

(i.e., C isn't included in any hyperplane in $\mathbb{R}^d$), in which case $\operatorname{int} C = \operatorname{ri} C$ (cf. [10, Chapter 2]).

Additional motivation for the following result, besides facilitating use of Theorem 7.3, comes from the fact that the set $\operatorname{dom} V_\tau = \{\xi \mid V(\tau,\xi) < \infty\}$ is the *reachable set* at time τ, giving the points $\xi = x(\tau)$ reached by arcs $x(\cdot) \in \mathcal{A}^1_n[0,\tau]$ that start in $\operatorname{dom} g$ and have finite running cost $\int_0^\tau L(x(t),\dot{x}(t))dt$.

PROPOSITION 7.4 (relative interiors of reachable sets). *For every $\tau \in [0,\infty)$ one has*

$$\emptyset \neq \operatorname{ri}\operatorname{dom} V_\tau = \{\xi \mid \operatorname{ri}\operatorname{dom} g \cap \operatorname{ri}\operatorname{dom} E(\tau,\cdot,\xi) \neq \emptyset\}. \tag{7.7}$$

Here $\operatorname{ri}\operatorname{dom} V_\tau$ *reduces to* $\operatorname{int}\operatorname{dom} V_\tau$ *if and only if there exists $\xi \in \operatorname{dom} V_\tau$ such that* $\operatorname{dom} g \cup \operatorname{dom} E(\tau,\cdot,\xi)$ *does not lie in a hyperplane, that being true then for all $\xi \in \operatorname{dom} V_\tau$.*

Proof. Let $D_\tau = \operatorname{dom} V_\tau$ so $D_0 = \operatorname{dom} g$. Clearly D_τ is the image under $(\xi',\xi) \mapsto \xi$ of $C := \operatorname{dom} E(\tau,\cdot,\cdot) \cap [D_0 \times \mathbb{R}^n]$, all these sets being convex and nonempty. Then, under the same projection mapping, $\operatorname{ri} D_\tau$ is the image of $\operatorname{ri} C$; cf. [10, 2.44]. For each ξ the convex set $\operatorname{dom} E(\tau,\cdot,\xi)$ is nonempty by Corollary 4.4; likewise for each ξ' the convex set $\operatorname{dom} E(\tau,\xi',\cdot)$ is nonempty. The rule for relative interiors in product spaces (cf. [10, 2.43]) says then that

$$\operatorname{ri}\operatorname{dom} E(\tau,\cdot,\cdot) = \{(\xi',\xi) \mid \xi' \in \operatorname{ri}\operatorname{dom} E(\tau,\cdot,\xi)\} = \{(\xi',\xi) \mid \xi \in \operatorname{ri}\operatorname{dom} E(\tau,\xi',\cdot)\}. \tag{7.8}$$

This relative interior meets the set $\operatorname{ri}[D_0 \times \mathbb{R}^n] = \operatorname{ri} D_0 \times \mathbb{R}^n$, as seen from the second of the expressions in (7.8) by taking any $\xi' \in \operatorname{ri} D_0$ and then any $\xi \in \operatorname{ri}\operatorname{dom} E(\tau,\xi',\cdot)$. The rule for relative interiors of intersections (cf. [10, 2.42]) then yields

$$\operatorname{ri} C = [\operatorname{ri}\operatorname{dom} E(\tau,\cdot,\cdot)] \cap [\operatorname{ri} D_0 \times \mathbb{R}^n].$$

Returning to the observation that D_τ is the projection of $\operatorname{ri} C$, and utilizing the first of the expressions in (7.8), we get (7.7).

For the claim about interiors, we have to show that the stated condition on a point $\xi \in D_\tau$ is equivalent to the nonexistence of a hyperplane $M \supset D_\tau$. Fix any $\bar{\xi} \in D_\tau$ and any $\bar{\xi}' \in D_0$ with $(\bar{\xi}',\bar{\xi}) \in \operatorname{dom} E(\tau,\cdot,\cdot)$. A vector ζ gives a hyperplane $M = \{\xi \mid \langle \xi,\zeta\rangle = \alpha\}$ that includes D_τ if and only if $\zeta \neq 0$ and $\pm\zeta \in N_{D_\tau}(\bar{\xi})$, this being the normal cone to D_τ at $\bar{\xi}$. Likewise, a vector ζ' gives a hyperplane $M' = \{\xi' \mid \langle \xi',\zeta'\rangle = \alpha'\}$ that includes both D_0 and $\operatorname{dom} E(\tau,\cdot,\bar{\xi})$ if and only if $\zeta' \neq 0$ and both $\pm\zeta' \in N_{D_0}(\bar{\xi}')$ and $\pm\zeta' \in N_{\operatorname{dom} E(\tau,\cdot,\bar{\xi})}(\bar{\xi}')$. (Here we appeal to the fact that $\bar{\xi}'$ belongs to both D_0 and $\operatorname{dom} E(\tau,\cdot,\bar{\xi})$.) From the calculus of normals to convex sets (cf. [9, section 23], [10, Chapter 6]), the cone $N_{\operatorname{dom} E(\tau,\cdot,\bar{\xi})}(\bar{\xi}')$ is the projection of the cone $N_{\operatorname{dom} E(\tau,\cdot,\cdot)}(\bar{\xi}',\bar{\xi})$:

$$\pm\zeta' \in N_{\operatorname{dom} E(\tau,\cdot,\bar{\xi})}(\bar{\xi}') \iff \exists\,\zeta \text{ with } \pm(\zeta',\zeta) \in N_{\operatorname{dom} E(\tau,\cdot,\cdot)}(\bar{\xi}',\bar{\xi});$$

this relies on the nonemptiness of $\operatorname{dom} E(\tau,\cdot,\xi)$ for all $\xi \in \mathbb{R}^n$ (cf. Corollary 4.4), which in turn ensures that ζ' must be nonzero in this formula when $\zeta \neq 0$. Further calculus, utilizing the set relations that were developed above in determining $\operatorname{ri} D_\tau$, reveals that $\pm\zeta \in N_{D_\tau}(\bar{\xi})$ if and only if $(0,\pm\zeta) \in N_C(\bar{\xi}',\bar{\xi})$, and on the other hand that

$$N_C(\bar{\xi}',\bar{\xi}) = N_{\operatorname{dom} E(\tau,\cdot,\cdot)}(\bar{\xi}',\bar{\xi}) + N_{D_0\times\mathbb{R}^n}(\bar{\xi}',\bar{\xi}),$$
$$\text{where } N_{D_0\times\mathbb{R}^n}(\bar{\xi}',\bar{\xi}) = N_{D_0}(\bar{\xi}') \times \{0\}.$$

Thus, having a $\zeta \neq 0$ such that $\pm\zeta \in N_{D_\tau}(\bar{\xi})$ corresponds to having a $\zeta' \neq 0$ such that $\pm\zeta' \in N_{D_0}(\bar{\xi}')$ and $\pm(\zeta',\zeta) \in N_{\operatorname{dom} E(\tau,\cdot,\cdot)}(\bar{\xi}',\bar{\xi})$. This yields the claimed equivalence. □

Corollary 7.5 (interiors of reachable sets). *If* $\operatorname{int}\operatorname{dom} g \neq \emptyset$*, then for every* $\tau \in [0,\infty)$*,*

$$\emptyset \neq \operatorname{int}\operatorname{dom} V_\tau = \big\{\xi \,\big|\, \operatorname{int}\operatorname{dom} g \cap \operatorname{dom} E(\tau,\cdot,\xi) \neq \emptyset\big\}.$$

Proof. For convex sets C_1 and C_2 with $\operatorname{int} C_2 \neq \emptyset$, one has $\operatorname{ri} C_1 \cap \operatorname{ri} C_2 \neq \emptyset$ if and only if $C_1 \cap \operatorname{int} C_2 \neq \emptyset$. Then too, $C_1 \cup C_2$ cannot lie in a hyperplane. □

Corollary 7.6 (propagation of finiteness).

(a) *If* g *is finite on* $\mathbb{R}^n$*, then* V *is finite on* $[0,\infty) \times \mathbb{R}^n$*.*

(b) *If* L *is finite on* $\mathbb{R}^n \times \mathbb{R}^n$*, then* V *is finite on* $(0,\infty) \times \mathbb{R}^n$*.*

Proof. We get (a) immediately from Corollary 7.5 as the case where $\operatorname{int}\operatorname{dom} g = \mathbb{R}^n$. We get (b) by observing that, for $\tau > 0$, $\operatorname{dom} E(\tau,\cdot,\cdot)$ is all of $\mathbb{R}^n \times \mathbb{R}^n$ when L is finite. □

Corollary 7.7 (propagation of coercivity).

(a) *If* g *is coercive, then* V_τ *is coercive for every* $\tau \in [0,\infty)$*.*

(b) *If* L *is coercive, then* V_τ *is coercive for every* $\tau \in (0,\infty)$*.*

Proof. We rely on the fact that a proper convex function is coercive if and only if its conjugate is finite [10, 11.5]. The claims are justified then by the duality between V_τ and $\tilde{V}$ in Theorem 5.1 and that between L and $\tilde{L}$ in (2.15). □

CONVEXITY IN HAMILTON–JACOBI THEORY II: ENVELOPE REPRESENTATIONS*

R. TYRRELL ROCKAFELLAR† AND PETER R. WOLENSKI‡

Abstract. Upper and lower envelope representations are developed for value functions associated with problems of optimal control and the calculus of variations that are fully convex, in the sense of exhibiting convexity in both the state and the velocity. Such convexity is used in dualizing the upper envelope representations to get the lower ones, which have advantages not previously perceived in such generality and in some situations can be regarded as furnishing, at least for value functions, extended Hopf–Lax formulas that operate beyond the case of state-independent Hamiltonians.

The derivation of the lower envelope representations centers on a new function called the dualizing kernel, which propagates the Legendre–Fenchel envelope formula of convex analysis through the underlying dynamics. This kernel is shown to be characterized by a kind of double Hamilton–Jacobi equation and, despite overall nonsmoothness, to be smooth with respect to time and concave-convex in the primal and dual states. It furnishes a means whereby, in principle, value functions and their subgradients can be determined through optimization without having to deal with a separate, and typically much less favorable, Hamilton–Jacobi equation for each choice of the initial or terminal cost data.

Key words. convex value functions, Hamilton–Jacobi equations, dualizing kernels, fundamental kernels, envelope formulas, Hopf–Lax formulas, viscosity solutions, optimal control

1. Introduction.

A major goal of Hamilton–Jacobi theory is the characterization of value functions that arise from problems of optimal control and the calculus of variations in which endpoints are treated as parameters. The value function $V : [0,\infty) \times \mathbb{R}^n \to \overline{\mathbb{R}} := [-\infty,\infty]$ is defined from a Lagrangian $L : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ and an function $g : \mathbb{R}^n \to \overline{\mathbb{R}}$ by

$$\begin{aligned} V(\tau,\xi) &:= \inf\left\{ g\big(x(0)\big) + \int_0^\tau L\big(x(t),\dot{x}(t)\big)dt \,\middle|\, x(\tau) = \xi \right\} \quad \text{for } \tau > 0, \\ V(0,\xi) &:= g(\xi), \end{aligned} \tag{1.1}$$

with the minimization taking place over all the arcs (i.e., absolutely continuous functions) $x(\cdot) : [0,\tau] \to \mathbb{R}^n$ that reach ξ at time τ. Here $V(\tau,\cdot)$ is viewed as an evolving function on $\mathbb{R}^n$ which starts as g and describes how g is propagated forward to any time τ in a manner dictated by L.

Similarly, value functions can be considered that describe how g is propagated backward from a future time T, and such a "cost-to-go" formulation is common in optimal control. From a theoretical perspective, of course, backward models are equivalent to forward models through time reversal and do not require separate treatment in basic theory. The expression of control problems in terms of a Lagrangian L in

which control parameters do not appear is parallel to the expression of control dynamics in terms of differential inclusions and has generated a substantial literature in nonsmooth optimization, going back to around 1970. More about that can be found in our companion paper [1], which is the springboard for the efforts here.

In the classical context of the calculus of variations, g and L would be smooth (i.e., continuously differentiable). For applications such as in control, however, it is important to allow g and L to be nonsmooth and even to take on ∞ because infinite penalties can systematically be used in incorporating constraints. Under the assumption that g and L are lower semicontinuous (lsc) and proper (i.e., not identically ∞, and nowhere having the value $-\infty$), the integrand $t \mapsto L(x(t), \dot{x}(t))$ is measurable, and the functional $J[x(\cdot)]$ being minimized is well defined. (The usual convention of "inf addition" is followed, in which ∞ dominates in any conflict with $-\infty$.) Then $J[x(\cdot)] = \infty$ unless the arc $x(\cdot)$ satisfies the constraints

$$\begin{aligned} &x(0) \in D, \ \text{ where } D := \big\{ x \,\big|\, g(x) < \infty \big\}, \\ &\dot{x}(t) \in F(x(t)) \ \text{ almost everywhere (a.e.) } t, \ \text{ where } F(x) := \big\{ v \,\big|\, L(x,v) < \infty \big\}. \end{aligned} \tag{1.2}$$

The customary tool for characterizing value functions is the Hamilton–Jacobi PDE in one form or another. It revolves around the Hamiltonian function H associated with L, which is defined through the Legendre–Fenchel transform by

$$H(x,y) := \sup_v \Big\{ \langle v, y \rangle - L(x,v) \Big\}. \tag{1.3}$$

Because V typically lacks smoothness, even when g and L are smooth, various generalizations of the classical PDE have been devised, the foremost being "viscosity" versions. The recent book of Bardi and Capuzzo-Dolcetta [2], with its helpful references, provides broad access to that subject. Viscosity theory is able to characterize V in situations far from classical, and sometimes even when V takes on ∞, but uniqueness results are still lacking in many situations of interest for us here, due to the failure of V to satisfy the continuity, boundedness, or growth conditions that current results demand.

In this paper, instead of working with a generalized Hamilton–Jacobi PDE for V, we develop basic "envelope representations," which characterize V as the pointwise inf or sup of a family of more elementary functions. In cases where a description of V as a unique Hamilton–Jacobi solution of some sort can indeed be furnished, now or in the future, these formulas become PDE solution formulas. For state-independent Hamiltonians, $H(x,y) \equiv H_0(y)$, they reduce to Hopf–Lax formulas. We aim at contributing to Hamilton–Jacobi theory by opening a way for such classical formulas to be extended to state-dependent Hamiltonians, while exploring representations of value functions in their own right, especially as a potential means of determining value functions and their subgradients through optimization without having to deal with a separate Hamilton–Jacobi equation for each choice of the cost function g.

We look at two kinds of envelope formulas: upper and lower. Both kinds have long been known in the Hopf–Lax setting but haven't systematically been sought outside of that. Upper envelope formulas, involving pointwise minimization, are elementary and easy to obtain very generally. However, in order for them to express V on $(0,\infty)$ as the envelope of a family of *finite* functions, not to speak of smooth or subsmooth functions, significant restrictions are necessary. Lower envelope formulas, involving pointwise maximization, arise by dualization and therefore thrive only in the presence of convexity, as with the original Hopf formula itself. In compensation for assumptions of convexity, though, they offer a number of unusual and attractive features.

Our focus will primarily be on lower envelope formulas, because of their special potential, but we will also investigate properties enjoyed by upper envelope formulas under the convexity assumptions we impose.

Convex analysis [3] will be heavily used, but mostly through the results obtained in our preceding paper [1]. To the extent that broader variational analysis is required, we rely on the book [4].

After introducing the duality scheme and deriving the basic envelope formulas in section 2 in terms of the "fundamental kernel" and the "dualizing kernel," we concentrate in section 3 on the dualizing kernel and its characterization by a double Hamilton–Jacobi equation. The lower envelope formula for V in terms of the dualizing kernel and the properties of that kernel developed in section 3 and also in section 4, where connections with subgradients of V are brought out, constitute the paper's main results. To complete the picture, relationships with standard Hopf–Lax formulas are discussed in section 5,

2. Envelopes and convexity. Upper envelope formulas rely on the "double" value function $E : [0,\infty) \times \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ that corresponds to two-endpoint, i.e., Lagrangian, minimization problems for L:

$$\begin{aligned} &E(\tau,\xi',\xi) := \inf\left\{ \int_0^\tau L\big(x(t),\dot{x}(t)\big)dt \,\middle|\, x(0)=\xi',\ x(\tau)=\xi \right\} \quad \text{for } \tau > 0,\\ &E(0,\xi',\xi) := \begin{cases} 0 & \text{if } \xi = \xi',\\ \infty & \text{otherwise,} \end{cases} \end{aligned} \tag{2.1}$$

where the minimization is over all the arcs $x(\cdot)$ that go from ξ' at time 0 to ξ at time τ.

THEOREM 2.1 (upper envelope representation). *The value function V is expressed in terms of E by the formula*

$$V(\tau,\xi) = \inf\nolimits_{\xi'} \Big\{ g(\xi') + E(\tau,\xi',\xi) \Big\} \quad \textit{for } \tau \geq 0. \tag{2.2}$$

Moreover, when $\tau > 0$, an arc $x(\cdot)$ achieves the minimum in the problem defining $V(\tau,\xi)$ in (1.1) *if and only if it achieves the minimum in the problem defining $E(\tau,\xi',\xi)$ in* (2.1) *for some choice of ξ' yielding the minimum in* (2.2).

Proof. Elementary and evident. □

We will call E the *fundamental kernel* associated with L. The "kernel" term comes from the far-reaching analogy between minimizing a sum of functions and integrating a product of functions. Formula (2.2) gives a transform whereby g is converted to $V(\tau,\cdot)$ for $\tau > 0$. It is an "upper envelope" formula because it expresses V as the pointwise infimum of a certain family of functions on $[0,\infty)\times\mathbb{R}^n$, namely the functions $e_{\xi'} : (\tau,\xi) \mapsto g(\xi') + E(\tau,\xi',\xi)$ indexed by $\xi' \in D$, where D is the effective domain of g as in (1.2). In some situations E may be finite or even smooth on $(0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$, and the same then holds for these functions $e_{\xi'}$.

Often E takes on ∞, though, and the upper envelope representation may be difficult to exploit directly. Clearly, $E(\tau,\xi',\xi)$ can't be finite unless there is an arc $x(\cdot)$ that conforms to the differential inclusion in (1.2) and carries ξ' to ξ. Thus, extended-real-valuedness of E is inevitable in applications where the implicit constraints in (1.2) can seriously come into play.

This motivates a search for alternative envelope representations in which troublesome infinite values can be bypassed. Such representations will be generated by way of the function $K : [0,\infty) \times \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ with

$$\begin{aligned} &K(\tau,\xi,\eta) := \inf\left\{ \langle x(0),\eta\rangle + \int_0^\tau L\big(x(t),\dot{x}(t)\big)dt \,\middle|\, x(\tau) = \xi \right\}, \\ &K(0,\xi,\eta) := \langle \xi,\eta\rangle, \end{aligned} \tag{2.3}$$

which we introduce now as the *dualizing kernel* associated with L. The minimization takes place over all arcs $x(\cdot) : [0,\infty) \to \mathbb{R}^n$ that reach ξ at time τ.

For fixed η, $K(\cdot,\cdot,\eta)$ is the value function obtained as in (1.1) but with the linear function $\langle \cdot,\eta\rangle$ in place of g. As a consequence of Theorem 2.1, therefore, we have

$$K(\tau,\xi,\eta) = \inf_{\xi'}\Big\{ \langle \xi',\eta\rangle + E(\tau,\xi',\xi) \Big\}, \tag{2.4}$$

and indeed, this could serve as well as (2.3) in defining K.

Observe that (2.4) dualizes E by employing a variant of the Legendre–Fenchel transform: $-K(\tau,\xi,\eta)$ is calculated by taking the function conjugate to $E(\tau,\cdot,\xi)$ under that transform and evaluating it at $-\eta$. When $E(\tau,\cdot,\xi)$ is lsc, proper, and convex, it can be recovered by the reciprocal formula

$$E(\tau,\xi',\xi) = \sup_\eta \Big\{ K(\tau,\xi,\eta) - \langle \xi',\eta\rangle \Big\}. \tag{2.5}$$

Our strategy is to use such duality between E and K, along with convexity of g, to translate the upper envelope representation in Theorem 2.1 into a lower one involving K and the function g^* conjugate to g. A prerequisite for this, however, is placing assumptions on L that will ensure that E has the properties needed for (2.5) to be valid.

Such assumptions have been identified in our paper [1]. In stating them, we call a function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ *coercive* if f is bounded from below and has $f(v)/|v| \to \infty$ as $|v| \to \infty$ (where $|\cdot|$ is the Euclidean norm). When applied to a proper, nondecreasing function θ on $[0,\infty)$, coercivity means having $\theta(s)/s \to \infty$ as $s \to \infty$.

Basic Assumptions (A).

(A0) The initial function g is convex, proper, and lsc on $\mathbb{R}^n$.

(A1) The Lagrangian function L is convex, proper, and lsc on $\mathbb{R}^n \times \mathbb{R}^n$.

(A2) The mapping F underlying L in (1.2) is nonempty-valued everywhere, and there is a constant ρ such that $\operatorname{dist}(0,F(x)) \le \rho\big(1+|x|\big)$ for all x.

(A3) There are constants α and β and a coercive, proper, nondecreasing function θ on $[0,\infty)$ such that $L(x,v) \ge \theta\big(\max\{0,\, |v| - \alpha|x|\,\}\big) - \beta|x|$ for all x and v.

The meaning of these assumptions has thoroughly been elucidated in [1], so for present purposes we need only to record some key facts and examples.

An immediate consequence of $L(x,v)$ being, by (A1) and (A2), a convex, proper, lsc function of v for each x is that L can be recovered from H by

$$L(x,v) = \sup_y \Big\{ \langle v,y\rangle - H(x,y) \Big\}. \tag{2.6}$$

The correspondence between Lagrangians and Hamiltonians is thus one-to-one under our conditions. For each H of a certain class, the associated L is uniquely determined by (2.6). The Hamiltonian class is described as follows.

PROPOSITION 2.2 (Hamiltonian conditions). *The Hamiltonians for the Lagrangians L satisfying* (A1), (A2), *and* (A3) *are the functions $H : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ such that*

(a) *$H(x,y)$ is finite, concave in x, and convex in y (hence locally Lipschitz continuous).*

(b) *There are constants α and β and a finite, convex function φ such that*

$$H(x,y) \;\le\; \varphi(y) + (\alpha|y| + \beta)|x| \quad \textit{for all } x,\ y.$$

(c) *There are constants γ and δ and a finite, concave function ψ such that*

$$H(x,y) \;\ge\; \psi(x) - (\gamma|x| + \delta)|y| \quad \textit{for all } x,\ y.$$

Proof. This comes from Theorem 2.3 of [1]. Finite concave-convex functions are locally Lipschitz continuous by [3, 35.1]. □

Example 2.3 (subseparable Lagrangians). *Let the Lagrangian have the form*

$$L(x,v) = G(x) + L_0(v - Ax) \tag{2.7}$$

for $A \in \mathbb{R}^{n\times n}$, a finite convex function G on $\mathbb{R}^n$, and a proper convex function L_0 on $\mathbb{R}^n$ that is lsc and coercive. Then L satisfies (A1), (A2), *and* (A3)*, and its Hamiltonian is*

$$H(x,y) = \langle Ax, y\rangle - G(x) + H_0(y), \tag{2.8}$$

where H_0 is a finite convex function on $\mathbb{R}^n$, namely $H_0 = L_0^*$. Conversely, if H has the form (2.8) *for finite convex functions G and H_0, then L has the form* (2.7) *with $L_0 = H_0^*$ and falls in the category described.*

Detail. This is evident from Proposition 2.2 and the conjugacy between finite convex functions (always continuous) and proper convex functions that are lsc and coercive. □

Subseparable Lagrangians illustrate also, in a relatively simple case, the way that our framework of Lagrangians and Hamiltonians connects with control theory. An optimal control problem with linear dynamics $\dot{x}(t) = Ax(t) + Bu(t)$ and running cost integral

$$\int_0^T \big\{G(x(t)) + F(u(t))\big\}dt,$$

with F convex, proper, lsc, and coercive (but possibly taking on ∞) corresponds to the Lagrangian L in (2.7) for

$$L_0(z) = \min\big\{F(u)\,\big|\, Bu = z\big\},$$

and then the Hamiltonian H in (2.8) has $H_0(y) = F^*(B^*y)$, where B^* is the transpose of B and F^* is the convex function conjugate to F, this function being finite because of the coercivity of F. Control constraints are incorporated here through the specification of the set where F is finite. Control formats much more general than this, yet still fully convex and (as may be shown) still fitting with our assumptions, can be found in [5], [6].

Note that if the coercivity condition in (A3) were replaced by a simpler condition like $L(x,v) \ge \theta(|v|)$, Lagrangians of the type in Example 2.3 would have to have $A = 0$, and G would have to be bounded from below.

Of course, there are many more Lagrangians satisfying (A1), (A2), and (A3) than the ones in Example 2.3. An illustration is $L(x,v) = \frac{1}{p}\max\{|x|^p, |v|^p\}$ with $p \in (1,\infty)$, which for q determined by $(1/p) + (1/q) = 1$ has

$$H(x,y) = \begin{cases} \frac{1}{q}|y|^q & \text{when } |y| \geq |x|^{p-1}, \\ |x||y| - \frac{1}{p}|x|^p & \text{when } |y| \leq |x|^{p-1}. \end{cases} \tag{2.9}$$

Proposition 2.4 ([1] convexity of the fundamental kernel). *Under* (A1), (A2), *and* (A3), *$E(\tau,\xi',\xi)$ is a convex, proper, lsc function of (ξ',ξ) for each $\tau \geq 0$. In fact, $E(\tau,\cdot,\xi)$ is proper and coercive for every ξ, and $E(\tau,\xi',\cdot)$ is proper and coercive for every ξ'.*

Proof. This is extracted from Proposition 4.2 and Corollary 4.4 of [1]. □

On the basis of this result we do have the reciprocal formula in (2.5) along with the one in (2.4), and E and K are entirely dual to each other. We are able then to convert the envelope formula in (1.1) into one for functions that are likely to be better behaved. The technique is to apply Fenchel's duality theorem to the minimization problem in (1.1) in order to recast it as a maximization problem.

In the next theorem, and henceforth in this paper, we take assumptions (A) for granted, unless otherwise mentioned.

Theorem 2.5 (lower envelope representation). *The dualizing kernel $K(\tau,\xi,\eta)$ is everywhere finite, convex in ξ, and concave in η. The value function V is expressed in terms of K by the formula*

$$V(\tau,\xi) = \sup_\eta \Big\{K(\tau,\xi,\eta) - g^*(\eta)\Big\}. \tag{2.10}$$

Proof. For any $(\tau,\xi) \in [0,\infty) \times \mathbb{R}^n$, the function $f = E(\tau,\cdot,\xi)$ is lsc, proper, convex, and coercive by Proposition 2.4, so its conjugate f^* is finite. We have $-f^*(-\eta) = K(\tau,\xi,\eta)$ by (2.4), hence $K(\tau,\xi,\eta)$ is finite and concave in η. On the other hand, the convexity of $E(\tau,\xi',\xi)$ in (ξ',ξ) in Proposition 2.4 implies the convexity of $K(\tau,\cdot,\eta)$ by the general principle that when the Legendre–Fenchel transform is applied to one argument of a convex function of two arguments, the result is concave in the residual argument; see [3, 33.3] or [4, 11.48]. (The concavity becomes convexity under the changes of sign.)

To obtain the lower envelope representation, we fix ξ along with τ and view the upper envelope representation in (2.2) as expressing $V(\tau,\xi)$ as the optimal value in the problem of minimizing $g(\xi') + f(\xi')$ for $f = E(\tau,\cdot,\xi)$ as above. By Fenchel's duality theorem (cf. [3, 31.1] or [4, 11.41]), one has

$$\inf_{\xi'}\Big\{g(\xi') + f(\xi')\Big\} = \sup_\eta\Big\{-f^*(-\eta) - g^*(\eta)\Big\} \tag{2.11}$$

if the relative interiors of the convex sets $\{\eta \,|\, -f^*(-\eta) > -\infty\}$ and $\{\eta \,|\, g^*(\eta) < +\infty\}$ have a point in common. That criterion is met through the finiteness of f^*, which makes the first set be all of $\mathbb{R}^n$. Since the inf in (2.11) gives the left side of (2.10) and the sup in (2.11) gives the right side, the equation in (2.10) is confirmed. □

For $\tau = 0$, the lower envelope representation in (2.10) reduces to the Legendre–Fenchel envelope formula

$$g(\xi) = \sup_\eta\Big\{\langle\xi,\eta\rangle - g^*(\eta)\Big\}, \tag{2.12}$$

which expresses the proper, lsc, convex function g as the pointwise supremum of all the affine functions majorized by g. For $\tau > 0$, it can be viewed as extending this formula forward in time through a Hamilton–Jacobi propagation of those affine functions into a different family of functions.

In employing the Fenchel duality rule (2.11) as the tool for passing between upper and lower envelope representations, we are in effect invoking a "minimax principle" in a manner reminiscent in Hamilton–Jacobi theory of the duality seen in classical Hopf–Lax formulas (which will be taken up in section 5). Indeed, our formulas can be recast as follows.

THEOREM 2.6 (envelope formulas in minimax mode). *In terms of the dualizing kernel K, the value function V always has the representation*

$$V(\tau,\xi) = \inf_{\xi'} \sup_{\eta} \Big\{ g(\xi') - \langle \xi', \eta \rangle + K(\tau,\xi,\eta) \Big\}, \tag{2.13}$$

and this even holds for an arbitrary choice of $g : \mathbb{R}^n \to \overline{\mathbb{R}}$. When g is convex, proper, and lsc, however, V also has the representation

$$V(\tau,\xi) = \sup_{\eta} \inf_{\xi'} \Big\{ g(\xi') - \langle \xi', \eta \rangle + K(\tau,\xi,\eta) \Big\}. \tag{2.14}$$

Proof. We get (2.13) by combining the elementary formula (2.2) for V in terms of E with the reciprocal formula (2.5) for E in terms of K, which is valid by Proposition 2.4 under our assumptions. We get (2.14) by combining the representation (2.10) of V in terms of K and g^* with the definition of g^* in terms of g. □

All of duality theory in convex optimization, a very highly developed subject, has the character of a "minimax principle" of course, but there is no single minimax theorem to invoke that would fit all cases. Everything revolves around the precise conditions under which "inf" and "sup" can legitimately be interchanged when the simplest compactness and continuity properties may be absent, as here. Duality of a much deeper kind than in the proof of Theorem 2.5 will be crucial later, for instance, in ascertaining the circumstances in which the supremum in (2.10) is attained and how this can be used in determining the subgradients of V from those of K (cf. Theorem 4.2 and Corollary 4.4 below). Observe that this brings out an important advantage of expressing lower envelope representations as in (2.10) instead of as in (2.14).

The appearance of g^* instead of g in (2.10) shouldn't be regarded as much of a drawback. In many situations g^* can explicitly be determined from g (see [3] and [4, Chapter 11] for the calculus of conjugates), but even if not, there is much that might be made of this formula. Depending on the particular structure of g (in terms of operations like addition and composition), it's common for $g^*(\eta)$ to be expressible as the optimal value in a minimization problem with respect to some other vector, let's call it ζ, in which η is a parameter. When such an expression is substituted into (2.10), one gets a representation of $V(\tau,\xi)$ as the optimal value in a maximization problem involving both η and ζ.

Anyway, as a practical matter, optimization formulas for $V(\tau,\xi)$, whether directly as in (2.10) or with some expansion of the $g^*(\eta)$ term, are generally more favorable for computation than integration formulas, which become intractable numerically in more than a few dimensions. Furthermore, for applications such as to feedback in optimal control the subgradients of V are at least as important as its values. The lower representation in (2.10) affords a much better grip on those than does the upper representation in (2.2), because K is typically far better behaved than E, as will emerge from the results that follow. These better properties suggest that K may be easier to generate than V in a Hamilton–Jacobi context, after which the lower envelope representation in Theorem 2.5 might be used to compute aspects of V as needed, for instance in feedback. Moreover, the same K would be able to serve for every V that relies on the Lagrangian L, no matter what the choice of the initial cost function g.

3. Characterization of the dualizing kernel.

Turning now to the development of properties of K that underpin the lower envelope representation in Theorem 2.5, we begin with a special kind of Hamilton–Jacobi characterization. Only subgradients in the sense of convex analysis are needed in this characterization, but other subgradients will soon enter the discussion too, so we go straight to a review of the full definitions. For background, see [4].

Consider any function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ and let x be any point at which $f(x)$ is finite. A vector $y \in \mathbb{R}^n$ is a *regular subgradient* of f at x, written $y \in \hat{\partial} f(x)$, if

$$f(x') \;\geq\; f(x) + \langle y,\, x' - x\rangle + o(|x' - x|). \tag{3.1}$$

It is a (*general*) *subgradient* of f at x, written $y \in \partial f(x)$, if there is a sequence of points $x^\nu \to x$ with $f(x^\nu) \to f(x)$ for which regular subgradients $y^\nu \in \hat{\partial} f(x^\nu)$ exist with $y^\nu \to y$. (We consistently use superscript ν for sequences; $\nu \to \infty$.) When f is convex, the sets $\hat{\partial} f(x)$ and $\partial f(x)$ are the same and agree with the subgradient set of convex analysis, defined by (3.1) without the "o" term.

These of course are "lower" subgradients, the corresponding regular and general "upper" subgradient sets, defined with the opposite inequality in (3.1) and will be denoted here by $\tilde{\hat{\partial}} f(x)$ and $\tilde{\partial} f(x)$; thus

$$\tilde{\partial} f = -\partial[-f]. \tag{3.2}$$

This notation is expedient because most situations can be couched in terms of lower subgradients alone, cf. [4], although just now we'll have something of an exception.

Regular subgradients have been the mainstay in viscosity theory, but general subgradients are the vehicle for many of the strongest results in variational analysis [4].

In the following theorem, $\partial_\xi K(\tau, \xi, \eta)$ refers to subgradients of the convex function $K(\tau, \cdot, \eta)$, whereas $\tilde{\partial}_\eta K(\tau, \xi, \eta)$ refers to subgradients of the concave function $K(\tau, \xi, \cdot)$.

THEOREM 3.1 (double Hamilton–Jacobi equation). *The kernel $K(\tau, \xi, \eta)$ is continuously differentiable with respect to τ and satisfies, for $\tau \geq 0$,*

$$\begin{aligned} -\frac{\partial K}{\partial \tau}(\tau, \xi, \eta) &= \begin{cases} H(\xi, \eta') & \textit{for all} \quad \eta' \in \partial_\xi K(\tau, \xi, \eta), \\ H(\xi', \eta) & \textit{for all} \quad \xi' \in \tilde{\partial}_\eta K(\tau, \xi, \eta), \end{cases} \\ K(0, \xi, \eta) &= \langle \xi, \eta \rangle, \end{aligned} \tag{3.3}$$

where $\partial K / \partial \tau$ is interpreted as the right partial derivative when $\tau = 0$. Moreover, K is the only such function with $K(\tau, \xi, \eta)$ convex in ξ and concave in η.

The proof of Theorem 3.1 will be furnished later in this section, after some additional developments. The continuous differentiability refers to $(\partial K / \partial \tau)(\tau, \xi, \eta)$ depending continuously on $(\tau, \xi, \eta) \in [0, \infty) \times \mathbb{R}^n \times \mathbb{R}^n$.

The double Hamilton–Jacobi equation in (3.3) has been placed in the elementary picture of subgradients of convex and concave functions and partial derivatives in time, because that seems most conducive to possible uses of the result. What comparison, though, can be made with viscosity versions of Hamilton–Jacobi equations? And why use two equations instead of one?

The double aspect of the characterization comes from the fact that, through duality, K has an alternative expression in which the roles of ξ and η are interchanged.

PROPOSITION 3.2 (alternative formula for the dualizing kernel). *In minimizing over arcs $y(\cdot):[0,\tau]\to\mathbb{R}^n$, one has*

$$-K(\tau,-\xi,\eta)=\inf\Big\{\langle\xi,y(0)\rangle+\int_0^\tau L_*\big(y(t),\dot y(t)\big)dt\,\Big|\,y(\tau)=\eta\Big\},\tag{3.4}$$

where $L_*(y,w)=L^*(-w,y)$. Moreover L_*, like L, satisfies (A1), (A2), *and* (A3), *and its Hamiltonian H_* is given by*

$$H_*(y,x)=\sup\nolimits_w\Big\{\langle w,x\rangle-L_*(y,w)\Big\}=-H(-x,y).\tag{3.5}$$

Proof. The duality theory for convex problems of Bolza [7] will be applied in the form distilled in [1, section 4]. The minimization problem that defines $K(\tau,\xi,\eta)$ in (2.3) is

$$\text{minimize}\ \int_0^\tau L(x(t),\dot x(t))dt+l(x(0),x(\tau))\ \text{ over arcs }\ x(\cdot):[0,\tau]\to\mathbb{R}^n,\tag{$\mathcal{P}$}$$

where $l(a,b)=\langle a,\eta\rangle$ if $b=\xi$ but $l(a,b)=\infty$ if $b\neq\xi$. The duality theory pairs this with

$$\text{minimize}\ \int_0^\tau \tilde L(y(t),\dot y(t))dt+\tilde l(y(0),y(\tau))\ \text{ over arcs }\ y(\cdot):[0,\tau]\to\mathbb{R}^n,\tag{$\tilde{\mathcal{P}}$}$$

where $\tilde L(y,w)=L^*(w,y)$ and $\tilde l(c,d)=l^*(c,-d)$; the latter comes out here as $\tilde l(c,d)=-\langle\xi,d\rangle$ if $c=\eta$ but $\tilde l(c,d)=\infty$ if $c\neq\eta$. Because $l(\cdot,b)$ is finite on $\mathbb{R}^n$ for a certain b, and $\tilde l(c,\cdot)$ is finite on $\mathbb{R}^n$ for a certain c, the optimal values in the two problems are related by $\inf(\mathcal{P})=-\inf(\tilde{\mathcal{P}})$; this holds by [1, Corollary 4.6]. Thus,

$$-K(\tau,\xi,\eta)=\inf\bigg\{\int_0^\tau\tilde L\big(y(t),\dot y(t)\big)dt-\langle\xi,y(\tau)\rangle\,\Big|\,y(0)=\eta\bigg\}.$$

By rewriting in terms of $z(t)=y(\tau-t)$, we can convert this to

$$-K(\tau,\xi,\eta)=\inf\bigg\{\int_0^\tau\tilde L\big(z(t),-\dot z(t)\big)dt-\langle\xi,z(0)\rangle\,\Big|\,z(\tau)=\eta\bigg\}.$$

It remains only to replace ξ by $-\xi$ and the z notation by y again to obtain (3.4).

The fact that L_* again satisfies (A1), (A2), and (A3) comes from the fact that $\tilde L$ inherits these properties from L, as demonstrated in [1, Proposition 3.5]. The expression for the Hamiltonian H_* in terms of H arises similarly from that result, which asserts that the Hamiltonian $\tilde H$ for $\tilde L$ has $\tilde H(y,x)=-H(x,y)$. □

Through results in [1], the value function formulas for K in (2.3) and (3.4) lead to major conclusions about the subgradients of K and in particular to a viscosity version of the double Hamilton–Jacobi equation in Theorem 3.1. This time we use $\partial_{\tau,\xi}K(\tau,\xi,\eta)$ to denote subgradients of the function $K(\cdot,\cdot,\xi)$ on $[0,\infty)\times\mathbb{R}^n$, and so forth.

THEOREM 3.3 (subgradients of the dualizing kernel). *For $\tau>0$, one has*

$$\begin{aligned}(\sigma,\eta')\in\partial_{\tau,\xi}K(\tau,\xi,\eta)\quad&\Longleftrightarrow\quad(\sigma,\eta')\in\hat\partial_{\tau,\xi}K(\tau,\xi,\eta)\\&\Longleftrightarrow\quad\eta'\in\partial_\xi K(\tau,\xi,\eta),\ \ \sigma=-H(\xi,\eta'),\end{aligned}\tag{3.6}$$

and on the other hand

$$\begin{aligned}(\sigma,\xi') \in \tilde{\partial}_{\tau,\eta}K(\tau,\xi,\eta) \quad &\Longleftrightarrow \quad (\sigma,\xi') \in \tilde{\hat{\partial}}_{\tau,\eta}K(\tau,\xi,\eta)\\ &\Longleftrightarrow \quad \xi' \in \tilde{\partial}_{\eta}K(\tau,\xi,\eta),\ \ \sigma = -H(\xi',\eta).\end{aligned} \tag{3.7}$$

Proof. We simply apply [1, Theorem 2.5] first to $K(\cdot,\cdot,\eta)$, which is the value function that propagates $\langle\cdot,\eta\rangle$ under L as in (2.3), and second to $-K(\cdot,-\xi,\cdot)$, which by Proposition 3.2 is the value function that propagates $\langle\xi,\cdot\rangle$ under L_*. □

Corollary 3.4 (double viscosity equation). *For* $\tau > 0$*, one has*

$$\begin{cases}\sigma + H(\xi,\eta') = 0 & \textit{for all} \quad (\sigma,\eta') \in \hat{\partial}_{\tau,\xi}K(\tau,\xi,\eta),\\ \sigma + H(\xi',\eta) = 0 & \textit{for all} \quad (\sigma,\xi') \in \tilde{\hat{\partial}}_{\tau,\eta}K(\tau,\xi,\eta).\end{cases} \tag{3.8}$$

It will be established in the next theorem that K is locally Lipschitz continuous. In view of this, the first of the subgradient equations in (3.8) is equivalent, as shown by Frankowska [8], to $K(\cdot,\cdot,\eta)$ being a Hamilton–Jacobi viscosity solution in the sense of satisfying the upper and lower inequalities of Crandall, Evans, and Lions [9], with initial $K(0,\cdot,\eta) = \langle\cdot,\eta\rangle$. The second equation has a similar viscosity interpretation relative to a switch in the roles of the ξ and η arguments.

It might be hoped that either of these subgradient equations, by itself, would be enough to determine K uniquely. That could be true, but unfortunately the existing results on uniqueness of viscosity solutions are not fully up to the task. The trouble is that H and K need not satisfy the kinds of growth or boundedness conditions assumed in such results. Because of the initial condition $K(\tau,\xi,\eta)$ is certainly neither globally bounded from above nor globally bounded from below, even for fixed ξ or η. One or the other kind of boundedness would be needed to apply the latest uniqueness theorem of Ishii [10], for example. Anyway, the Hamiltonian can grow at rates like those in (2.9), and this can be problematical as well.

Theorem 3.5 (Lipschitz continuity of the dualizing kernel). *The function* K *is locally Lipschitz continuous on* $[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$.

Proof. By [1, Theorem 2.1] the functions $K(\cdot,\cdot,\eta)$ are lsc on $[0,\infty)\times\mathbb{R}^n$ as value functions in the mode of (2.3). Similarly by this result, as applied in the context of Proposition 3.2, the functions $-K(\cdot,-\xi,\cdot)$ are lsc on $[0,\infty)\times\mathbb{R}^n$. Hence the functions $K(\cdot,\xi,\cdot)$ are usc on $[0,\infty)\times\mathbb{R}^n$, and it follows in particular that $K(\tau,\xi,\eta)$ is continuous in $\tau\in[0,\infty)$ for each (ξ,η). Thus, $K(\tau,\cdot,\cdot)$ converges pointwise to $K(\bar{\tau},\cdot,\cdot)$ whenever $\tau\to\bar{\tau}$ in $[0,\infty)$. The functions $K(\tau,\cdot,\cdot)$ are finite and convex-concave by Theorem 2.5, and pointwise convergence of such functions on $\mathbb{R}^n\times\mathbb{R}^n$ implies uniform convergence on bounded sets (see [3, 35.4]). In consequence, K is continuous on $[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$. Furthermore, the convergence implies that the mapping

$$S : (\tau,\xi,\eta) \mapsto \big\{(\eta',\xi') \,\big|\, \eta' \in \partial_{\xi}K(\tau,\xi,\eta),\ \ \xi' \in \tilde{\partial}_{\eta}K(\tau,\xi,\eta)\,\big\} \tag{3.9}$$

is locally bounded on $[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$ and has closed graph (see [3, 35.7]).

This yields through the continuity of H (in Proposition 2.2) the closed graph property and local boundedness on $[0,\infty)\times\mathbb{R}^n$ of the mappings

$$\begin{aligned}(\tau,\xi) &\mapsto \big\{(\sigma,\eta')\,\big|\,\eta' \in \partial_{\xi}K(\tau,\xi,\eta),\ \ \sigma = -H(\xi,\eta')\big\},\\ (\tau,\eta) &\mapsto \big\{(\sigma,\eta')\,\big|\,\eta' \in \tilde{\partial}_{\eta}K(\tau,\xi,\eta),\ \ \sigma = -H(\xi',\eta)\big\}.\end{aligned} \tag{3.10}$$

In general, a function f that is finite and lsc on an open set O in a space $\mathbb{R}^d$ is Lipschitz continuous with constant κ on any set $X \subset O$ such that $|y| \leq \kappa$ for all $y \in \partial f(x)$ when $x \in X$; this holds by [4, 9.2, 9.13]. We invoke this now for $K(\cdot,\cdot,\eta)$ on $(0,\infty)\times\mathbb{R}^n$. From the subgradient characterization in (3.6) of Theorem 3.3 and the local boundedness of the first mapping in (3.10), on $[0,\infty)\times\mathbb{R}^n$ rather than just $(0,\infty)\times\mathbb{R}^n$, we get that $K(\cdot,\cdot,\eta)$ is locally Lipschitz continuous on $(0,\infty)\times\mathbb{R}^n$, and moreover that the Lipschitz constants don't blow up as $\tau \searrow 0$. Since $K(\cdot,\cdot,\eta)$ is anyway continuous on $[0,\infty)\times\mathbb{R}^n$, we conclude it must actually be Lipschitz continuous on $[0,\infty)\times\mathbb{R}^n$.

A parallel argument utilizing the dual formula in Proposition 3.2 shows that the functions $K(\cdot,\xi,\cdot)$ are Lipschitz continuous on $[0,\infty)\times\mathbb{R}^n$. The two properties of Lipschitz continuity combine to give the Lipschitz continuity of K itself on $[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$. □

The subgradient result in Theorem 3.3 will be complemented now by one about subderivatives. These are defined as follows; see [4] for background. For $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ and a point x where $f(x)$ is finite, the *subderivative* of f at x for a vector w is

$$df(x)(w) := \liminf_{\substack{\varepsilon \searrow 0 \\ w' \to w}} \frac{f(x+\varepsilon w') - f(x)}{\varepsilon}. \tag{3.11}$$

If this "liminf" coincides with the associated "limsup" and thus exists as a full limit, f is said to be *semidifferentiable at x for w*, or simply *semidifferentiable at x* if true for all $w \in \mathbb{R}^n$. Semidifferentiability at x corresponds to the difference quotient functions $\Delta_\varepsilon f(x) : w \mapsto [f(x+\varepsilon w) - f(x)]/\varepsilon$ converging uniformly on bounded subsets of $\mathbb{R}^n$, as $\varepsilon \searrow 0$, to a continuous function of w [4, 7.21]. Differentiability is the case where, in addition, the limit function $df(x)$ is linear.

THEOREM 3.6 (subderivatives of the dualizing kernel). *On $(0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$, K is semidifferentiable everywhere, and its subderivative formula is as follows. For any (τ,ξ,η), the quantities $H(\xi,\eta')$ for $\eta' \in \partial_\xi K(\tau,\xi,\eta)$ and $H(\xi',\eta)$ for $\xi' \in \tilde{\partial}_\eta K(\tau,\xi,\eta)$ all have the same value, and in denoting it by $k(\tau,\xi,\eta)$ one has*

$$\begin{aligned} dK(\tau,\xi,\eta)(\theta,\omega,\zeta) = {} & -\theta k(\tau,\xi,\eta) \\ & + \max\bigl\{\langle\eta',\omega\rangle \bigm| \eta' \in \partial_\xi K(\tau,\xi,\eta)\bigr\} \\ & + \min\bigl\{\langle\xi',\zeta\rangle \bigm| \xi' \in \partial_\eta K(\tau,\xi,\eta)\bigr\}. \end{aligned} \tag{3.12}$$

Proof. The first part of the proof, devoted to the existence of the common value $k(\tau,\xi,\eta)$, will be the basis later for knowing that K is continuously differentiable in τ as claimed in Theorem 3.1 but not yet justified.

Let $K_\eta = K(\cdot,\cdot,\eta)$. Since K_η is the value function that propagates a finite convex function under L, namely $\langle\cdot,\eta\rangle$, it is semidifferentiable on $(0,\infty)\times\mathbb{R}^n$ by [1, Theorem 7.3] with the formula

$$dK_\eta(\tau,\xi)(\theta,\omega) = \max\bigl\{\langle\omega,\eta'\rangle - \theta H(\xi,\eta') \bigm| \eta' \in \partial_\xi K_\eta(\tau,\xi)\bigr\}. \tag{3.13}$$

Likewise for $K^\xi = -K(\cdot,-\xi,\cdot)$ in the context of Proposition 3.2, K^ξ is the value function that propagates $\langle\xi,\cdot\rangle$ under L_* and thus is semidifferentiable on $(0,\infty)\times\mathbb{R}^n$ with formula

$$dK^\xi(\tau,\eta)(\theta,\zeta) = \max\bigl\{\langle\xi',\zeta\rangle - \theta H_*(\eta,\xi') \bigm| \xi' \in \partial_\eta K^\xi(\tau,\eta)\bigr\},$$

where $H_*(\eta,\xi') = -H(-\xi',\eta)$. In terms of $\tilde{K}_\xi = K(\cdot,\xi,\cdot)$ the latter can be rewritten as

$$d\tilde{K}_\xi(\tau,\eta)(\theta,\zeta) = \min\bigl\{\langle\xi',\zeta\rangle - \theta H(\xi',\eta) \,\big|\, \xi' \in \tilde{\partial}_\eta \tilde{K}_\xi(\tau,\eta)\bigr\}. \tag{3.14}$$

In particular, K has right and left partial derivatives in τ,

$$\begin{aligned}(\partial^+K/\partial\tau)(\tau,\xi,\eta) &= dK_\eta(\tau,\xi)(1,0) = d\tilde{K}_\xi(\tau,\eta)(1,0),\\ (\partial^-K/\partial\tau)(\tau,\xi,\eta) &= -dK_\eta(\tau,\xi)(-1,0) = -d\tilde{K}_\xi(\tau,\eta)(-1,0),\end{aligned}$$

which by (3.13) must satisfy

$$\begin{aligned}(\partial^-K/\partial\tau)(\tau,\xi,\eta) &= \min\bigl\{-H(\xi,\eta') \,\big|\, \eta' \in \partial_\xi K(\tau,\xi,\eta)\bigr\},\\ (\partial^+K/\partial\tau)(\tau,\xi,\eta) &= \max\bigl\{-H(\xi,\eta') \,\big|\, \eta' \in \partial_\xi K(\tau,\xi,\eta)\bigr\},\end{aligned} \tag{3.15}$$

and on the other hand, by (3.14), must satisfy

$$\begin{aligned}(\partial^-K/\partial\tau)(\tau,\xi,\eta) &= \max\bigl\{-H(\xi',\eta) \,\big|\, \xi' \in \tilde{\partial}_\eta K(\tau,\xi,\eta)\bigr\},\\ (\partial^+K/\partial\tau)(\tau,\xi,\eta) &= \min\bigl\{-H(\xi',\eta) \,\big|\, \xi' \in \tilde{\partial}_\eta K(\tau,\xi,\eta)\bigr\}.\end{aligned} \tag{3.16}$$

We get $(\partial^-K/\partial\tau)(\tau,\xi,\eta) \le (\partial^+K/\partial\tau)(\tau,\xi,\eta)$ from (3.15) but the opposite inequality from (3.16). The partial derivative $(\partial K/\partial\tau)(\tau,\xi,\eta)$ therefore exists and is given by all four expressions on the right in (3.15) and (3.16). In particular, the quantities $H(\xi,\eta')$ and $H(\xi',\eta)$ involved in these expressions must have the same value.

In denoting this common value by $k(\tau,\xi,\eta)$, we have a function that is continuous not only on $(0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$ but has a continuous extension to $[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$. That follows from the closed graph property and local boundedness on $[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$ of the mappings in (3.10), as demonstrated in the proof of Theorem 3.5. Hence $(\partial K/\partial\tau)(\tau,\xi,\eta)$ exists even at $\tau = 0$, when interpreted there as the right partial derivative, and it depends continuously on $(\tau,\xi,\eta)\in[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$.

Henceforth in proceeding with the proof of Theorem 3.6, we argue solely on the basis of $K(\tau,\xi,\eta)$ being continuously differentiable in τ while convex in ξ and concave in η. This will help with something needed eventually in the proof of Theorem 3.1, although a price must be paid in overlaps with arguments already furnished for Theorem 3.5.

Each of the functions $K(\tau,\cdot,\cdot)$, being finite and convex-concave, is locally Lipschitz continuous on $\mathbb{R}^n\times\mathbb{R}^n$ by [3, 35.1]. The differentiability of $K(\tau,\xi,\eta)$ with respect to τ entails continuity in τ. Therefore, whenever $\tau\to\bar{\tau}$ in $[0,\infty)$ the functions $K(\tau,\cdot,\cdot)$ converge pointwise on $\mathbb{R}^n\times\mathbb{R}^n$ to $K(\bar{\tau},\cdot,\cdot)$. We have already seen in the proof of Theorem 3.6 how this convergence implies that the mapping S in (3.9) is locally bounded on $[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$ with closed graph. This guarantees that the local Lipschitz continuity of the functions $K(\tau,\cdot,\cdot)$ is uniform locally with respect to τ (by virtue of [3, 24.7] as applied in the convex and concave arguments separately). In taking this together with the continuity of $\partial K/\partial\tau$, which ensures the local Lipschitz continuity of $K(\tau,\xi,\eta)$ in τ, we deduce that K is locally Lipschitz continuous as a function of $(\tau,\xi,\eta)\in[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$.

We work next with the difference quotient functions concerned in generating the subderivatives of K:

$$\begin{aligned}\Delta_\varepsilon K(\tau,\xi,\eta)(\theta,\omega,\zeta) = {}&\frac{K(\tau+\varepsilon\theta,\,\xi+\varepsilon\omega,\,\eta+\varepsilon\zeta) - K(\tau,\,\xi+\varepsilon\omega,\eta+\varepsilon\zeta)}{\varepsilon}\\ &+\frac{K(\tau,\,\xi+\varepsilon\omega,\,\eta+\varepsilon\zeta) - K(\tau,\xi,\eta)}{\varepsilon}.\end{aligned} \tag{3.17}$$

When $\varepsilon \searrow 0$, the first expression in the sum in (3.17), as a function of (θ, ω, ζ), converges uniformly over bounded sets to the function

$$(\theta, \omega, \zeta) \mapsto (\partial K/\partial \tau)(\tau, \xi, \eta)\theta$$

because of the continuity of $\partial K/\partial \tau$ (through a classical argument using the mean value theorem). The second expression in the sum in (3.17), as a function of (ω, ζ) that is convex-concave, is known from convex analysis [3, 35.6] to converge pointwise to the function

$$(\omega, \zeta) \;\mapsto\; \max_{\eta' \in \partial_\xi K(\tau,\xi,\eta)} \langle \eta', \omega \rangle + \min_{\xi' \in \partial_\eta K(\tau,\xi,\eta)} \langle \xi', \zeta \rangle.$$

The convergence must then be uniform over bounded subsets of $\mathbb{R}^n \times \mathbb{R}^n$ (by [3, 35.4]). Thus, as $\varepsilon \searrow 0$, the functions $\Delta_\varepsilon K(\tau, \xi, \eta)$ do converge uniformly on bounded sets to the function described by the right side of (3.12) with $k = (\partial K/\partial \tau)$. Hence K is semidifferentiable with this as its formula. □

Proof of Theorem 3.1. The continuous differentiability of $K(\tau, \xi, \eta)$ has been demonstrated in the first part of the proof of Theorem 3.6 along with the double formula for $(\partial K/\partial \tau)$ in (3.3), the common value on the right side of (3.3) being the expression $k(\tau, \xi, \eta)$ introduced in the statement of Theorem 3.6. The remaining task is to show the uniqueness in this characterization. Let $J(\tau, \xi, \eta)$ on $[0, \infty) \times \mathbb{R}^n \times \mathbb{R}^n$ be convex in ξ, concave in η, and continuously differentiable in τ, satisfying (3.3). We have to prove that $J = K$.

As a tool in this endeavor, we can use the fact that J, like K, has the subderivative properties in Theorem 3.6, since those properties depend only on the facts now being assumed; see the remark in the middle of the proof of Theorem 3.6 (in the paragraph starting with "Henceforth"). Thus

$$\begin{aligned} dJ(\tau, \xi, \eta)(\theta, \omega, \zeta) = {}& \theta\, (\partial J/\partial \tau)(\tau, \xi, \eta) \\ & + \max\big\{ \langle \eta', \omega \rangle \,\big|\, \eta' \in \partial_\xi J(\tau, \xi, \eta) \big\} \\ & + \min\big\{ \langle \xi', \zeta \rangle \,\big|\, \xi' \in \partial_\eta J(\tau, \xi, \eta) \big\}. \end{aligned} \tag{3.18}$$

In addition we can take J to be locally Lipschitz continuous, because that property was likewise seen there to be a consequence of the current assumptions.

Fix (τ, ξ, η). Certainly $J(\tau, \xi, \eta) = K(\tau, \xi, \eta)$ when $\tau = 0$, so suppose $\tau > 0$. The infimum in the definition (2.3) of $K(\cdot, \cdot, \eta)$ as the value function propagating $\langle \xi, \cdot \rangle$ is attained by an arc $x(\cdot)$ on $[0, \tau]$ which moreover is Lipschitz continuous; this holds by [1, Theorem 5.2], which under our assumptions (A) applies to value functions at interior points (τ, ξ) of their domains. Then too, for any $\tau' \in (0, \tau)$ and the point $\xi' = x(\tau')$, the restriction of $x(\cdot)$ to $[0, \tau']$ is optimal for the minimization problem defining $K(\tau', \xi', \eta)$ (by the "principle of optimality"). Thus

$$K(\tau', x(\tau'), \eta) = \langle x(0), \eta \rangle + \int_0^{\tau'} L\big(x(s), \dot{x}(s)\big) dt \quad \text{for } 0 \le \tau' \le \tau. \tag{3.19}$$

In terms of the functions $\varphi : [0, \tau] \to \mathbb{R}$ and $\psi : [0, \tau] \to \mathbb{R}$ defined by

$$\varphi(t) := K(t, x(t), \eta), \qquad \psi(t) := J(t, x(t), \eta),$$

we have $\varphi(0) = K(0, x(0), \eta) = J(0, x(0), \eta) = \psi(0)$, whereas $\varphi(\tau) = K(\tau, \xi, \eta)$ and $\psi(\tau) = J(\tau, \xi, \eta)$. Furthermore, φ is Lipschitz continuous on $[0, \tau]$, because $x(\cdot)$ has this property and K is locally Lipschitz continuous on $[0,\infty)\times\mathbb{R}^n\times\mathbb{R}^n$. Likewise ψ is Lipschitz continuous on $[0,\tau]$. It follows that φ and ψ are the integrals of their derivatives, which exist a.e. Hence

$$K(\tau,\xi,\eta)-J(\tau,\xi,\eta)=\int_0^\tau \varphi'(t)dt-\int_0^\tau \psi'(t)dt. \tag{3.20}$$

On the basis of (3.19), we have

$$\varphi'(t)=L\big(x(t),\dot{x}(t)\big) \text{ for a.e. } t. \tag{3.21}$$

On the other hand, the semidifferentiability of J in (3.18) yields

$$\psi'(t) \;=\; (\partial J/\partial\tau)(t,x(t),\eta)+\max\big\{\langle\eta',\dot{x}(t)\rangle \,\big|\, \eta'\in\partial_\xi J(t,x(t),\eta)\big\}.$$

For each t let $y(t)$ be a vector ξ' attaining this maximum. Because J satisfies the Hamilton–Jacobi equations in (3.3), we have $(\partial J/\partial\tau)(t,x(t),\eta)=-H(x(t),y(t))$, so that

$$\psi'(t)=-H(x(t),y(t))+\langle y(t),\dot{x}(t)\rangle. \tag{3.22}$$

Since $L(x(t),\cdot)$ and $H(x(t),\cdot)$ are conjugate convex functions, we know from the reciprocal Legendre–Fenchel formula in (2.6) that $\langle y(t),\dot{x}(t)\rangle-H(x(t),y(t))\le L(x(t),\dot{x}(t))$. Therefore $\psi'(t)\le\varphi'(t)$ by (3.22) and (3.21). When this inequality is combined with (3.20), we arrive at the conclusion that $J(\tau,\xi,\eta)\le K(\tau,\xi,\eta)$.

So far, we have established that $J\le K$. To get the opposite inequality, it suffices to show that $-J(\tau,-\xi,\eta)\le -K(\tau,-\xi,\eta)$ for all (τ,ξ,η). But for this we need only to appeal to the alternative value function formula for K in Proposition 3.2 and in such terms reapply the argument just given. □

4. Additional kernel properties and subgradient formulas.

Other facts about the kernels K and E will now be developed, with emphasis on subgradients and regularity. Connections between subgradients of the value function V and those of the dualizing kernel K are featured because of their possible use in applications to feedback in optimal control.

An important role in bringing out such connections is played by the generalized Hamiltonian dynamical system associated with H, which has the form

$$\dot{x}(t)\in\partial_y H(x(t),y(t)), \qquad -\dot{y}(t)\in\tilde{\partial}_x H(x(t),y(t)). \tag{4.1}$$

This dynamical system is the key to characterizing optimality in the theory of generalized problems of Bolza for the Lagrangian L, where it originated in [11]. More on its properties and history can be found in [1] and its references. A Hamiltonian *trajectory* over $[0,\tau]$ is a pair of arcs $x(\cdot)$ and $y(\cdot)$ satisfying (4.1) for almost every t.

THEOREM 4.1 (kernel subgradients and Hamiltonian dynamics). *The following properties are equivalent for any* $\tau\ge 0$:

(a) $\eta'\in\partial_\xi K(\tau,\xi,\eta)$ *and* $\xi'\in\tilde{\partial}_\eta K(\tau,\xi,\eta)$;

(b) $(-\eta,\eta')\in\partial_{\xi',\xi}E(\tau,\xi',\xi)$;

(c) *there is a Hamiltonian trajectory* $(x(\cdot),y(\cdot))$ *over* $[0,\tau]$ *from* (ξ',η) *to* (ξ,η').

Proof. The equivalence between (a) and (b) reflects a general principle about how subgradients behave when partial conjugates are taken, as in the passage between E and K in (2.4) and (2.5); cf. [4, 11.48].

The equivalence between (a) and (c) will come out of a result in [1, Theorem 2.4] about the subgradients of value functions V; more generally, one has $\eta' \in \partial_\xi V(\tau,\xi)$ if and only if there is a Hamiltonian trajectory $(x(\cdot),y(\cdot))$ over $[0,\tau]$ that starts with $y(0) \in \partial g(x(0))$ and ends at (ξ,η'). Since $K(\cdot,\cdot,\eta)$ is the value function that propagates $\langle\cdot,\eta\rangle$, a function with constant subgradient (gradient) η, we deduce that $\eta' \in \partial_\xi K(\tau,\xi,\eta)$ if and only if there is a Hamiltonian trajectory $(x(\cdot),y(\cdot))$ over $[0,\tau]$ that starts with $y(0)=\eta$ (any $x(0)$) and ends at (ξ,η').

For the remainder, we argue in terms of the dual expression in Proposition 3.2, where $-K(\cdot,-\xi,\cdot)$ is the value function that propagates $\langle\xi,\cdot\rangle$ under L_*, a Lagrangian with Hamiltonian H_* given by (3.5). Invoking the same theorem from [1] in this setting, we obtain, after the ± signs settle down and the trajectories are reversed in time, the fact that $\xi' \in \tilde{\partial}_\eta K(\tau,\xi,\eta)$ if and only if there is a Hamiltonian trajectory over $[0,\tau]$ that starts at (ξ',η) and ends with $x(\tau)=\xi$ (any $y(\tau)$). In putting this together with the earlier statement, we arrive at the description in (c). $\square$

THEOREM 4.2 (determination of value function subgradients). *For every $\tau>0$, one has*

$$\text{(4.2)}\qquad \begin{aligned} \partial V(\tau,\xi) &= \bigcup\Big\{\partial_{\tau,\xi}K(\tau,\xi,\eta)\,\Big|\,\eta\in M(\tau,\xi)\Big\},\\ &\textit{where}\ \ M(\tau,\xi) := \operatorname{argmax}_\eta\Big\{K(\tau,\xi,\eta)-g^*(\eta)\Big\}. \end{aligned}$$

Therefore, subgradients of V can be determined from those of K by carrying out the maximization in the lower envelope formula with

$$\text{(4.3)}\qquad (\sigma,\eta')\in\partial V(\tau,\xi) \iff \exists\,\eta\in M(\tau,\xi)\ \textit{with}\ \begin{cases}\eta'\in\partial_\xi K(\tau,\xi,\eta),\\ \sigma=-H(\xi,\eta').\end{cases}$$

Proof. Recall from Theorem 3.3 that the subgradients in $\partial_{\tau,\xi}K(\tau,\xi,\eta)$ are of the form $(-H(\xi,\eta'),\eta')$ for $\eta'\in\partial_\xi K(\tau,\xi,\eta)$. A similar result was obtained in [1, Theorem 2.5] for V; its subgradients have the form $(-H(\xi,\eta'),\eta')$ for $\eta'\in\partial_\xi V(\tau,\xi)$. Further, as already noted in the proof of Theorem 4.1, it was demonstrated in [1, Theorem 2.4] that $\eta'\in\partial_\xi V(\tau,\xi)$ if and only if there is a Hamiltonian trajectory $(x(\cdot),y(\cdot))$ that starts with $y(0)\in\partial g(x(0))$ and ends at (ξ,η').

On the other hand, the condition for η to belong to $M(\tau,\xi)$, i.e., to maximize $K(\tau,\xi,\eta)-g^*(\eta)$, can be expressed in subgradient terms as $0\in\tilde{\partial}_\eta K(\tau,\xi,\eta)-\partial g^*(\eta)$. (This is both necessary and sufficient for optimality because g^* is a convex function while $K(\tau,\xi,\cdot)$ is a finite concave function; see [3, section 31].) Equivalently, there exists some $\xi'\in\tilde{\partial}_\eta K(\tau,\xi,\eta)\cap\partial g^*(\eta)$. But for conjugate convex functions we have $\xi'\in\partial g^*(\eta)$ if and only if $\eta\in\partial g(\xi')$. In view of Theorem 4.1, then, we have $\eta\in M(\tau,\xi)$ if and only if there is a Hamiltonian trajectory $(x(\cdot),y(\cdot))$ that starts with $y(0)\in\partial g(x(0))$ and ends at (ξ,η'). This is the same as the condition derived in terms of V, so we conclude that the subgradient formula in the theorem is correct. $\square$

Theorem 4.2 puts the spotlight on the maximizing set $M(\tau,\xi)$ in the lower envelope formula (1.5) and raises questions about the nature of this subproblem of maximization, in particular whether the maximum is actually attained. We address these questions next.

THEOREM 4.3 (compactness and attainment in the lower envelope formula). *For any $\tau>0$ and ξ, the following properties in the lower envelope formula are equivalent:*

(a) *the set $M(\tau,\xi)=\operatorname{argmax}_\eta\{K(\tau,\xi,\eta)-g^*(\eta)\}$ is nonempty and compact;*

(b) *for every $\beta\in\mathbb{R}$, the upper level set $\{\eta\,|\,K(\tau,\xi,\eta)-g^*(\eta)\geq\beta\}$ is compact;*

(c) $\xi \in \operatorname{int} D(\tau)$ *for the set* $D(\tau) = \big\{\xi \,\big|\, V(\tau,\xi) < \infty\big\}$.

Proof. We return to the proof of Theorem 2.5 and the framework of Fenchel duality in which it was placed, with $f = E(\tau,\cdot,\xi)$ and $-f^*(-\eta) = K(\tau,\xi,\eta)$. It is well known in that theory, in terms of the convex sets $\operatorname{dom} f$ and $\operatorname{dom} g$ (where f and g are finite), that $\operatorname{argmin}_\eta \big\{f^*(-\eta) + g^*(\eta)\big\}$ is nonempty and bounded if and only if $0 \in \operatorname{int}(\operatorname{dom} f - \operatorname{dom} g)$ and the infimum is finite (see, for instance, [4, 11.41, 11.39(b)].) That is in turn equivalent to having $\operatorname{ri} \operatorname{dom} g \cap \operatorname{ri} \operatorname{dom} f \neq \emptyset$ with $\operatorname{dom} g \cup \operatorname{dom} f$ not lying in a hyperplane (cf. [4, 2.45]). In [1, Proposition 7.4] this property has been identified with (c). Thus, (a) is equivalent to (c).

The equivalence between (a) and (b), on the other hand, results from the fact that the function being maximized is concave and upper semicontinuous; cf. [4, 3.27]. □

COROLLARY 4.4 (finite value functions). *When V is finite on $(0,\infty) \times \mathbb{R}^n$, the maximizing set $M(\tau,\xi)$ is nonempty and compact for every $(\tau,\xi) \in (0,\infty) \times \mathbb{R}^n$. In particular this is the case when g is finite on $\mathbb{R}^n$ or on the other hand when L is finite on $\mathbb{R}^n \times \mathbb{R}^n$.*

Proof. The first assertion is justified through condition (c) in Theorem 4.3. The rest cites elementary circumstances in which V is know from [1, Corollary 7.6] to be finite. □

We look further now at the fundamental kernel E, first demonstrating a property of epi-continuity. Epi-continuity, which refers to epigraphs depending continuously on a parameter in the sense of Painléve–Kuratowski set convergence, was established in [1, Theorem 2.1] for the dependence of $V(\tau,\cdot)$ on $\tau \in [0,\infty)$. We'll apply that result to the functions $E(\tau,\cdot,\cdot)$ by way of a reformulation trick.

PROPOSITION 4.5 (fundamental epi-continuity). *The function $E(\tau,\cdot,\cdot) : \mathbb{R}^n \times \mathbb{R}^n \to \overline{\mathbb{R}}$ depends epi-continuously on $\tau \in [0,\infty)$: whenever $\tau^\nu \to \tau$ with $\tau^\nu \geq 0$ one has*

$$\begin{cases} \liminf_\nu E(\tau^\nu,\xi'^\nu,\xi^\nu) \geq E(\tau,\xi',\xi) & \textit{for every sequence } (\xi'^\nu,\xi^\nu) \to (\xi',\xi), \\ \limsup_\nu E(\tau^\nu,\xi'^\nu,\xi^\nu) \leq E(\tau,\xi',\xi) & \textit{for some sequence } (\xi'^\nu,\xi^\nu) \to (\xi',\xi). \end{cases}$$

Proof. Although E seems to fit a different pattern than V, in being generated as a value function in terms of a variable pair (ξ',ξ) of initial and terminal points, instead of an initial function g and a terminal point ξ, we can nonetheless obtain results about E from those for V by an adaptation. The trick is to view E as the value function $V_E : [0,\infty) \times \mathbb{R}^{2n} \to \overline{\mathbb{R}}$ that is generated from the Lagrangian L_E and initial function g_E defined as follows:

$$L_E(x',x,v',v) := \begin{cases} L(x,v) & \text{if } v' = 0, \\ \infty & \text{if } v' \neq 0, \end{cases}$$
$$g_E(x',x) := \begin{cases} 0 & \text{if } x' = x, \\ \infty & \text{if } x' \neq x. \end{cases} \tag{4.4}$$

Indeed, under these definitions $V_E(\tau,\xi',\xi)$ is the infimum of $\int_0^\tau L(x(t),\dot{x}(t))dt$ over all arcs $(x'(\cdot),x(\cdot)) \in \mathcal{A}^1_{2n}[0,\tau]$ such that $x'(0) = x(0)$, $\dot{x}'(t) = 0$ a.e., and $x'(\tau) = \xi'$. The latter conditions obviously force $x(0)$ to be ξ'. Note that g_E and L_E satisfy our blanket assumptions (A) (in higher-dimensional interpretation) because L satisfies (A1)–(A3). By this route, we get justification of our claims through epi-continuity results for value functions in [1, Theorem 2.1]. □

In our next result, we record a basic relationship between certain effective domains, which although convex, could in general have empty interior, namely

$$\begin{aligned} \operatorname{dom} E(\tau,\cdot,\cdot) &= \big\{(\xi',\xi)\,\big|\,E(\tau,\xi',\xi)<\infty\big\},\\ \operatorname{dom} E &= \big\{(\tau,\xi',\xi)\,\big|\,\tau>0,\ E(\tau,\xi',\xi)<\infty\big\}. \end{aligned} \tag{4.5}$$

Proposition 4.6 (domain interior). *The following properties are equivalent:*

(a) $\tau > 0$ *and* $(\xi',\xi)\in \operatorname{int}\operatorname{dom} E(\tau,\cdot,\cdot)$;

(b) $(\tau,\xi',\xi)\in\operatorname{int}\operatorname{dom} E$.

Proof. This is [1, Proposition 7.2] as applied to the value function V_E in the reformulation in the proof of Proposition 4.5. □

In the following theorem, subdifferential regularity is a property that a function has when its epigraph is closed and Clarke regular; see [4].

Theorem 4.7 (regularity of the fundamental kernel). *On* $\operatorname{int}\operatorname{dom} E$, *the subgradient mapping* ∂E *is nonempty-compact-convex-valued and locally bounded, and* E *itself is locally Lipschitz continuous and subdifferentially regular, moreover semidifferentiable with*

$$dE(\tau,\xi',\xi)(\tau',\omega',\omega) \;=\; \max\Big\{\langle\omega,\eta'\rangle-\langle\omega',\eta\rangle-\tau' H(\xi,\eta')\,\Big|\,(-\eta,\eta')\in\partial_{\xi',\xi}E(\tau,\xi',\xi)\Big\},$$

where $H(\xi,\eta')$ *could be replaced by* $H(\xi',\eta)$*. Indeed,* E *is strictly differentiable wherever it is differentiable, which is at almost every point of* $\operatorname{int}\operatorname{dom} E$*, and with respect to such points the gradient mapping* ∇E *is continuous.*

Proof. We apply [1, Theorem 7.3], a result for value functions V in general under our assumptions, to V_E in the pattern of the proof of Proposition 4.6 above. □

Theorem 4.8 (Hamilton–Jacobi equations for the fundamental kernel). *The subgradients of* E *on* $(0,\tau)\times\mathbb{R}^n\times\mathbb{R}^n$ *have the property that*

$$\begin{aligned} (\sigma,-\eta,\eta')\in\partial E(\tau,\xi',\xi) \quad &\Longleftrightarrow \quad (\sigma,-\eta,\eta')\in\hat\partial E(\tau,\xi',\xi)\\ &\Longleftrightarrow \quad (-\eta,\eta')\in\partial_{\xi',\xi}E(\tau,\xi',\xi),\ \ \sigma=-H(\xi,\eta'),\\ &\Longleftrightarrow \quad (-\eta,\eta')\in\partial_{\xi',\xi}E(\tau,\xi',\xi),\ \ \sigma=-H(\xi',\eta). \end{aligned} \tag{4.6}$$

In particular, E *is a solution to the generalized double Hamilton–Jacobi equation:*

$$\left.\begin{aligned} \sigma+H(\xi,\eta')=0\\ \sigma+H(\xi',\eta)=0\end{aligned}\right\}\ \textit{for all}\ \ (\sigma,-\eta,\eta')\in\partial E(\tau,\xi',\xi)\ \ \textit{when}\ \tau>0. \tag{4.7}$$

Proof. We get the equivalence of the first three conditions by applying [1, Theorem 2.5] to V_E, once again following the pattern of reformulation in the proof of Proposition 4.5, but for that purpose it is necessary to know the Hamiltonian H_E for the Lagrangian L_E in (4.4). This calculates out simply to $H_E(x',x,y',y)=H(x,y)$. To add the fourth condition in (4.6), we utilize the subgradient description in Theorem 4.1. Along any Hamiltonian trajectory, H is constant (as proved in [11]), so if the trajectory goes from (ξ',η) to (ξ,η') we must have $H(\xi,\eta')=H(\xi',\eta)$. □

The double Hamilton–Jacobi equation for E isn't surprising in view of the one for K in Theorem 3.1. Indeed, each double equation is essentially equivalent to the other by virtue of the relations in Theorem 4.1. It follows that E is uniquely determined by (4.7) and the initial condition in its definition (2.1). An earlier viscosity version of the double equation for E in simpler cases where E is finite can be seen in the book of Lions [12]. In general cases where E can be discontinuous and take on ∞, however, the Hamilton–Jacobi characterization of K has a major advantage over the one for E in Theorem 4.8, due to the assured finiteness and local Lipschitz continuity of $K(\tau,\xi,\eta)$ (Theorem 3.5), its smoothness in τ (Theorem 3.1), and its semidifferentiability everywhere with respect to all arguments jointly (Theorem 3.6).

5. Application to Hopf–Lax formulas and their generalization. Upper and lower envelope representations of value functions as solutions to Hamilton–Jacobi equations first appeared in works of Hopf [13] and Lax [14] in very particular situations where the Hamiltonian $H(x,y)$ is independent actually of x. We inspect the state-independent case as an example within our framework and then go on to describe how our results cover an extension of the Hopf–Lax formulas beyond that case. The aim is to provide further perspective on how our formulas for value functions tie in with Hamilton–Jacobi theory.

EXAMPLE 5.1 (formulas of classical Hopf–Lax type). *Suppose that $L(x,v) = L_0(v)$ for a coercive, proper, lsc, convex function $L_0 : \mathbb{R}^n \to \overline{\mathbb{R}}$, or that $H(x,y) = H_0(y)$ for a finite convex function $H_0 : \mathbb{R}^n \to \mathbb{R}$, these assumptions being equivalent through the conjugacy relations $H_0 = L_0^*$, $L_0 = H_0^*$. Then the dualizing kernel is given by*

$$K(\tau,\xi,\eta) = \langle \xi,\eta\rangle - \tau H_0(\eta), \tag{5.1}$$

whereas the fundamental kernel is given by

$$E(\tau,\xi',\xi) = \begin{cases} \tau L_0\big(\tau^{-1}[\xi-\xi']\big) & \textit{if } \tau > 0, \\ 0 & \textit{if } \tau = 0,\ \xi-\xi' = 0, \\ \infty & \textit{if } \tau = 0,\ \xi-\xi' \neq 0. \end{cases} \tag{5.2}$$

Thus, for any initial function $g : \mathbb{R}^n \to \overline{\mathbb{R}}$ one has the upper envelope formula

$$V(\tau,\xi) = \inf_{\xi'}\Big\{ g(\xi') + \tau L_0\big(\tau^{-1}[\xi-\xi']\big)\Big\}, \tag{5.3}$$

while if g is convex, proper, and lsc, one also has the lower envelope formula

$$V(\tau,\xi) = \sup_{\eta}\Big\{ \langle \xi,\eta\rangle - \tau H_0(\eta) - g^*(\eta)\Big\}. \tag{5.4}$$

Proof. Conditions (A1), (A2), and (A3) are fulfilled, since this amounts to Example 2.3 with $A = 0$ and $G \equiv 0$. The formula for K in (5.1) follows at once from the second half of the double Hamilton–Jacobi equation in Theorem 3.1, according to which $(\partial K/\partial\tau)(\tau,\xi,\eta) = -H_0(\eta)$. The formula for E in (5.2) then follows from the general one for E in terms of K in (2.5). Finally, we get the upper envelope representation from Theorem 2.1 and the lower envelope representation from Theorem 2.5. □

The duality between the upper and lower envelope representations in this example can also be seen from the angle that (5.4) can be written as

$$V(\tau,\cdot) = (g^* + \tau H_0)^*, \tag{5.5}$$

whereas the right side of (5.3) gives the well known formula of convex analysis for such a conjugate function in terms of the functions $g^{**} = g$ and $H_0^* = L_0$ (see [4, section 11], for instance). In the traditions of Hamilton–Jacobi theory going back to Hopf

[13], g^* and H_0^* don't appear and the formulas for these functions are substituted instead. The upper representation comes out then as

$$V(\tau,\xi) = \inf_{\xi'} \sup_{\eta} \Big\{ g(\xi') + \langle \xi - \xi', \eta \rangle - \tau H_0(\eta) \Big\}, \tag{5.6}$$

while the lower representation becomes

$$V(\tau,\xi) = \sup_{\eta} \inf_{\xi'} \Big\{ g(\xi') + \langle \xi - \xi', \eta \rangle - \tau H_0(\eta) \Big\}. \tag{5.7}$$

Nowadays, though, with the Legendre–Fenchel transform so well understood, there's no reason not to simplify these expressions by writing them with conjugate functions. The equality between the "inf sup" in (5.6) and the "sup inf" in (5.7) falls into the pattern of minimax representations of primal and dual optimization problems of convex type for which there is, by now, an enormous literature; see [3] and [4, Chapter 11]. Generally speaking, such an equality is deeply involved with convexity and requires other qualifications besides. Such qualifications are met here because of our assumptions (A).

Although both (5.6) and (5.7) were proposed by Hopf [13] as possible formulas for solutions to a generalized Hamilton–Jacobi PDE in the mode of

$$u_t(t,x) + H_0(u_x(t,x)) = 0, \qquad u(0,x) = g(x),$$

the first of these is often called the Lax formula because of its appearance in a special case in the earlier paper of Lax [14] on hyperbolic conservation laws.

In work since Hopf, the lecture notes of Lions [12] and Evans [15] have provided further treatment of Hopf–Lax formulas. The paper of Bardi and Evans [16] deserves particular mention. Those authors proved that the upper formula in (5.6), or equivalently (5.3), gives the unique viscosity solution to the Hamilton–Jacobi equation in the case of a finite convex function H_0 and a possibly nonconvex function g that is globally Lipschitz continuous; alternatively by Evans [15], g can be merely continuous if H_0 is coercive. (Coercivity of H_0 corresponds in convex analysis to finiteness of L_0.) In Example 5.1, this formula has been seen to give the value function V regardless of such extra conditions on g or H_0.

Bardi and Evans [16] also showed that the lower formula (5.4), or equivalently (5.7), gives the unique viscosity solution as long as g is convex and globally Lipschitz continuous (which is known in convex analysis to correspond to the effective domain of g^* being bounded). Recently Alvarez, Barron, and Ishii [17] have removed these restrictions: the assertion holds true for all lsc, proper, convex functions g. In the context of Example 5.1, therefore, it follows that the value function V is the unique viscosity solution—in the sense of Barron and Jensen [18] or Frankowska [8], [19] (who employs a subgradient equation in place of a pair of inequalities involving upper as well as lower subgradients).

In the case of the lower envelope formula, Bardi and Evans [16] don't actually assume that H_0 is convex but just that it is continuous, and they still are able then to identify the unique viscosity solution under their strong assumptions on g. Our framework doesn't cover that feature, because the case is not one of optimization and there is no value function V of type (1.1) as a solution candidate.

We demonstrate now that the formulas in Example 5.1 can be extended to a significantly larger class of situations connected with optimal control (in the manner explained after Example 2.3), where the Lagrangian and Hamiltonian *aren't* state-independent, while maintaining their relatively explicit character. Again we emphasize that in the absence of a uniqueness theorem in Hamilton–Jacobi theory capable of handling all the Hamiltonians and value functions in our framework, these formulas, although they uniquely describe value functions, can't yet be claimed to give unique Hamilton–Jacobi solutions.

EXAMPLE 5.2 (extended Hopf–Lax formulas with linear state dependence). *Suppose that $L(x, v) = L_0(v - Ax)$ for a coercive, proper, lsc, convex function $L_0 : \mathbb{R}^n \to \overline{\mathbb{R}}$, or that $H(x, y) = \langle Ax, y\rangle + H_0(y)$ for a finite convex function $H_0 : \mathbb{R}^n \to \mathbb{R}$, these assumptions being equivalent through the conjugacy relations $H_0 = L_0^*$, $L_0 = H_0^*$. Here A is any $n \times n$ matrix. Let A^* be the transpose of A and define $\Psi : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}$ by*

$$\Psi(\tau, \eta) := \int_0^\tau H_0\big(e^{-tA^*}\eta\big)\, dt, \tag{5.8}$$

this expression being finite and convex in η. Then the dualizing kernel is given by

$$K(\tau, \xi, \eta) = \langle e^{-\tau A}\xi, \eta\rangle \tag{5.9}$$

and the fundamental kernel is given by

$$E(\tau, \xi', \xi) = \Phi(\tau, e^{-\tau A}\xi - \xi'), \tag{5.10}$$

where $\Phi(\tau, \zeta) = \sup_\eta \big\{\langle\zeta, \eta\rangle - \Psi(\tau, \eta)\big\}$, or in other words, $\Phi(\tau, \cdot)$ is the convex function conjugate to $\Psi(\tau, \cdot)$. Thus, for any initial function $g : \mathbb{R}^n \to \overline{\mathbb{R}}$ one has the upper envelope representation

$$\begin{aligned} V(\tau, \xi) &= \inf\nolimits_{\xi'} \Big\{g(\xi') + \Phi(\tau, e^{-\tau A}\xi - \xi')\Big\} \\ &= \inf\nolimits_{\xi'} \sup\nolimits_\eta \Big\{g(\xi') + \langle e^{-\tau A}\xi - \xi', \eta\rangle - \Psi(\tau, \eta)\Big\}, \end{aligned} \tag{5.11}$$

while if g is convex, proper, and lsc, one also has the lower envelope representation

$$\begin{aligned} V(\tau, \xi) &= \sup\nolimits_\eta \Big\{\langle e^{-\tau A}\xi, \eta\rangle - \Psi(\tau, \eta) - g^*(\eta)\Big\} \\ &= \sup\nolimits_\eta \inf\nolimits_{\xi'} \Big\{g(\xi') + \langle e^{-\tau A}\xi - \xi', \eta\rangle - \Psi(\tau, \eta)\Big\}. \end{aligned} \tag{5.12}$$

Proof. Fix (τ, ξ, η) and let $k(t) := K(t, \xi, y(t))$ for $y(t) := e^{(t-\tau)A^*}\eta$. From Theorem 3.5, k is Lipschitz continuous on $[0, \tau]$. We have $k(\tau) = K(\tau, \xi, \eta)$ and

$$k(0) = K(0, \xi, y(0)) = \langle\xi, y(0)\rangle = \langle\xi, e^{-\tau A^*}\eta\rangle = \langle e^{-\tau A}\xi, \eta\rangle. \tag{5.13}$$

Furthermore, from the semidifferentiability of K in Theorem 3.6 and its differentiability with respect to τ we have (a.e.)

$$\dot k(t) = (\partial K/\partial\tau)(\tau, \xi, y(t)) + \min\big\{\langle\xi', \dot y(t)\rangle \,\big|\, \xi' \in \tilde\partial_\eta K(t, \xi, y(t))\big\}, \tag{5.14}$$

where $\dot y(t) = A^* y(t)$. For each $t \in [0, \tau]$ let $x(t)$ denote some vector ξ' for which the minimum in (5.14) is attained. Then

$$\begin{aligned} \dot k(t) =& (\partial K/\partial\tau)(\tau, \xi, y(t)) + \langle x(t), \dot y(t)\rangle, \\ &\text{where } \langle x(t), \dot y(t)\rangle = \langle x(t), A^* y(t)\rangle = \langle Ax(t), y(t)\rangle. \end{aligned} \tag{5.15}$$

The second of the Hamilton–Jacobi equations in Theorem 3.1 gives us

$$(5.16)\qquad (\partial K/\partial\tau)(\tau,\xi,y(t)) = -H(x(t),y(t)) = -\langle Ax(t),y(t)\rangle - H_0(y(t)).$$

In combining (5.15) and (5.16) we get $\dot{k}(t) = -H_0(y(t)) = -H_0(e^{(t-\tau)A^*}\eta)$, hence

$$k(\tau) = k(0) - \int_0^\tau H_0\big(e^{(t-\tau)A^*}\eta\big)dt,$$

with the integral equaling $\Psi(\tau,\eta)$ (as seen through time reversal). The desired formula for K in (5.9) comes out now from (5.13) and the fact that $k(\tau) = K(\tau,\xi,\eta)$.

The corresponding formula for E in (5.10) is immediate then from (2.5), and the envelope representations are valid on the basis of Theorems 2.1 and 2.5. □

Example 5.2 may be compared to a recent result of Arisawa and Tourin in [20], extending the upper envelope formula (5.3) to a very special case of state-dependent Hamiltonians of concave-convex type. Those authors take $\mathbb{R}^n$ to be $\mathbb{R}^m \times \mathbb{R}^m$ and treat

$$H(x,y) = H(x_1,x_2;y_1,y_2) = \langle x_2,y_1\rangle + h(y_2)$$

with h a finite *coercive* convex function on $\mathbb{R}^m$ having $\min h = h(0) = 0$. For that case they work out a more detailed expression for the fundamental kernel than the one in (5.10).

The formulas in Example 5.2 reduce to the familiar ones in Example 5.1 when $A = 0$, of course. The big difference is that with $A \neq 0$ they can be applied to optimal control problems with dynamics $\dot{x} = Ax + Bu$ through the connection laid out in section 2 after Example 2.3. Then $H_0(y) = F^*(B^*y)$ for a finite convex conjugate function F^*, hence

$$\Psi(\tau,\eta) := \int_0^\tau F^*(B^*e^{-tA^*}\eta)\,dt.$$

In many situations it could well be possible to generate the values and even subgradients of Ψ numerically. The lower envelope representation of V in (4.12) could then, in light of Theorems 4.2 and 4.3, furnish an effective way of generating subgradients (or approximate subgradients) of V for potential use in feedback rules, through solving real-time optimization subproblems in $\mathbb{R}^n$.

The case in Example 5.2 is still relatively special within our framework. What might be said about value functions that come from state-dependent Hamiltonians more generally under our basic assumptions, as translated through Proposition 2.2? Everything really goes back to Theorem 2.6. The extent to which the basic formulas (2.13) and (2.14) in Theorem 2.6 can be regarded as “explicit” analogs of the classical Hopf–Lax formulas (5.6) and (5.7) hinges on how far one can go in obtaining an “explicit” formula for the dualizing kernel K that we have introduced. This requires an exploration of favorable cases in which the Hamilton–Jacobi characterization of K in Theorem 3.1 can be made to yield an “explicit” expression for K.

Here we have shown that the classical case in Example 5.1, where K is given by (5.1), can be extended with essentially no loss to the case in Example 5.2, where K is given by (5.9). Further research might yield other attractive cases. In the end, though, it must be borne in mind that the notion of what is an explicit expression for a function has evolved considerably in mathematics, and now is more a matter of whether a formula supports insightful analysis tied to modern computational methodology.

QUADRATIC CONTROLLABILITY, STRONG CONTROLLABILITY, AND A RELATED OUTPUT FEEDBACK PROPERTY*

SHAN-MIN SWEI[†], TETSUYA IWASAKI[‡], AND MARTIN CORLESS[§]

Abstract. Quadratic controllability and strong controllability are the two system properties to be discussed for a special class of norm bounded uncertain linear systems. The main contribution of this paper is twofold. First we show that it is possible to reduce the problem of checking quadratic controllability or strong controllability of a given uncertain system to the same problem for a reduced order subsystem, which we call the *essential subsystem*. Then we use this result to examine a related output feedback property. Specifically, for a given uncertain system, we will answer the following question: What condition is necessary and sufficient for the existence of a dynamic output feedback controller such that the states of the closed-loop system converge to the origin with an arbitrarily fast rate? Our aim is to provide an insight and better understanding of uncertain systems through these results.

Key words. quadratic controllability, strong controllability, dynamic output feedback, quadratic feedback minimality

1. Introduction.

The problem of quadratic stabilization of uncertain linear systems has attracted a number of researchers in the past and the results on this subject are abundant; see, for example, [1, 4, 6, 12, 13, 14, 15, 16, 19, 28], just to name a few. In the references [13, 14, 15, 28], the attention was paid to a special class of uncertain linear systems, namely, the systems with (unstructured) norm bounded uncertainties. One important feature of this class of uncertain systems is that the quadratic stabilization problem can be posed as the $\mathcal{H}_\infty$ control problem [8, 17]. Consequently, any standard tool for $\mathcal{H}_\infty$ control (e.g. [2, 3, 7, 22, 23]) can be directly applied to find a quadratically stabilizing controller. Thus, the quadratic stabilization problem has been solved completely for the case of systems with unstructured norm bounded uncertainties.

While the $\mathcal{H}_\infty$ control theory provides a tool for quadratic stabilization, one may lose the insight of the problem by blindly applying such a tool for control design. In this regard, the reference [25] has thoroughly studied the quadratic stabilization problem from a very different perspective in that it exploits the structure of the underlying system. An order reduction process which is similar to the back-stepping [9] was introduced for singular systems and was shown to preserve the quadratic stabilizability property. By repeating the reduction process, the original quadratic stabilization

problem is equivalently transformed to that for a reduced order subsystem, which is much simpler.

In light of this equivalence between the original system and its reduced order subsystem, the notion of quadratic controllability was then introduced in [18]. Quadratic controllability was defined as quadratic stabilizability with an arbitrary rate of convergence. The conditions under which the norm bounded uncertain systems possess such a property were first presented in [24] for a class of scalar input systems and in [18] for more general multi-input systems. Moreover, the equivalence was established [18] in the sense of quadratic controllability between the original system and its reduced order subsystem.

The strong controllability is another important system property which was studied in relation to the (almost) disturbance decoupling problem for linear time-invariant systems, see [5, 10, 11, 20, 21, 22, 23, 26]. This property was defined geometrically in terms of invariant subspaces. The notion of strongly controllable subspace was used in [22, 23] to derive a solution to the singular $\mathcal{H}_\infty$ control problem, by reducing it to the almost disturbance decoupling problem. Roughly speaking, the almost disturbance decoupling problem is solvable if the image of the matrix, through which the disturbance enters the system, is contained in the strongly controllable subspace.

In this paper, we study the quadratic controllability and strong controllability properties through a system reduction process which is similar to but more concise than the one discussed in [18, 25]. Specifically, we give a necessary and sufficient condition for an uncertain linear system to be quadratically controllable or strongly controllable in terms of a reduced order subsystem, and show that strong controllability is stronger than quadratic controllability in general. In the latter half of the paper, we extend the notion of quadratic controllability to the dynamic output feedback case and provide a complete characterization in terms of reduced order subsystems. The matrix inequality solution to the $\mathcal{H}_\infty$ control problem and its connection to the quadratic stabilization will be frequently used in developing many of our results. The essence is briefly outlined as follows.

Let the control input matrix be denoted by B and the direct feedthrough matrix by D. A system order reduction process will be defined when the matrix $B(I-D^+D)$ neither has full row rank nor equals zero, where superscript $+$ denotes the Moore–Penrose inverse. The reduction process is repeated until the matrix "$B(I-D^+D)$" in the reduced order system becomes either a full rank matrix or a zero matrix. We call this resulting reduced order system the *essential subsystem*. Our contribution is to show that the original system is quadratically controllable or strongly controllable if and only if its essential subsystem is so.

A related output feedback property is then discussed for a class of uncertain linear systems. We first define the notion of quadratic feedback minimality of an uncertain system by the existence of a dynamic output feedback controller which quadratically stabilizes the system with any given exponential convergent rate. For systems without uncertainty, this notion can be translated into the property of simultaneous controllability and observability, i.e., the minimality. From this observation, it is tempting to conjecture that an uncertain system is quadratically feedback minimal if both the state feedback problem and its dual problem are quadratically controllable. We show that this conjecture is false. However, it will be shown that an additional orthogonality condition which relates these two problems is needed to make the statement valid.

This paper is organized as follows. In section 2 we review the notions of quadratic controllability and strong controllability, and some important preliminary results are presented for the case where the matrix $B(I - D^+D)$ either has full row rank or is a zero matrix. When the matrix $B(I - D^+D)$ is neither, an order reduction procedure is proposed in section 3 to obtain the reduced order essential subsystem for which the matrix $B(I - D^+D)$ either has full row rank or is a zero matrix. The equivalence in the sense of quadratic controllability or strong controllability is then established between the original system and its essential subsystem. In section 4 our main result shows a necessary and sufficient condition under which the uncertain system possesses the aforementioned quadratic feedback minimality property. We conclude this paper with some remarks in section 5.

We use the following standard notation in this paper. For a matrix A, A^t denotes its (complex conjugate) transpose. A left annihilator of A, denoted by $A^\perp$, is a matrix whose rows form a basis for the null space of A^t. The image and the spectral norm of A are respectively denoted by $\mathrm{Im}(A)$ and $\|A\|$, and $\mathrm{Re}(\cdot)$ means the real part of the argument.

2. Quadratic controllability and strong controllability.

Consider an uncertain system described by

$$\dot{x}(t) = A_\Delta x(t) + B_\Delta u(t), \tag{2.1}$$

where $x(t) \in \boldsymbol{R}^n$ is the state, $u(t) \in \boldsymbol{R}^m$ is the control input. The matrices A_Δ and B_Δ are defined by

$$A_\Delta := A + G\Delta C, \qquad B_\Delta := B + G\Delta D,$$

where $\Delta = \Delta(t, x) \in \boldsymbol{R}^{k\times\ell}$ is a matrix-valued function which may depend on the time and/or the states, and the matrices A, B, G, C, and D are real and known with compatible dimensions. Throughout the paper, we assume that the value of Δ is uncertain but is Lebesgue measurable with respect to the time and continuous with respect to the states. Furthermore, it is assumed that Δ belongs to a *norm bounded set* $\boldsymbol{\Delta}$ defined by

$$\boldsymbol{\Delta} := \{ \ \Delta \in \boldsymbol{R}^{k\times\ell} : \ \|\Delta\| \le 1 \ \}. \tag{2.2}$$

We call the uncertain system described by (2.1) and (2.2) with $\Delta \in \boldsymbol{\Delta}$ a norm bounded uncertain system.

DEFINITION 2.1. *The uncertain system given in* (2.1) *is called* regular *if the matrix* $B(I - D^+D) = 0$ *and is called* simple *if the matrix* $B(I - D^+D)$ *has full row rank.*

The physical implication of Definition 2.1 is that if the control input u is orthogonally decoupled into two parts, namely,

$$\begin{bmatrix} u_1 \\ u_2 \end{bmatrix} := \begin{bmatrix} I - D^+D \\ D^+D \end{bmatrix} u,$$

then with this input description, we will have

$$B_\Delta u = Bu_1 + (B + G\Delta D)u_2, \tag{2.3}$$

which indicates that u_1 is the part of the control input that affects the system without direct influence of the uncertainty Δ, whereas u_2 enters the system through the uncertainty-dependent matrix B_Δ. If a system is regular, then only u_2 is effective, while a simple system receives full control authority through u_1.

Another important observation from Definition 2.1 is that the uncertain system (2.1) is regular if and only if $\mathrm{Im}(B^t) \subseteq \mathrm{Im}(D^t)$, since $D(I - D^+D) = 0$. On the other hand, (2.1) is simple if and only if B has full row rank and $\mathrm{Im}(D^t) \cap \mathrm{Im}(B^t) = \{0\}$.

Definition 2.2. *The uncertain system described in* (2.1) *is said to be* quadratically controllable *(QC) if, for each $\alpha > 0$, there exist a positive definite symmetric matrix $P \in \boldsymbol{R}^{n\times n}$ and a state feedback gain $K \in \boldsymbol{R}^{m\times n}$ such that*

$$P(A_\Delta + B_\Delta K + \alpha I) + (A_\Delta + B_\Delta K + \alpha I)^t P < 0\,,$$

for all $\Delta \in \boldsymbol{\Delta}$.

The notion of quadratic controllability was first introduced in [18]. Basically, it defines that an uncertain system is QC if, for each $\alpha > 0$, it is quadratically stabilizable with the convergent rate α. In other words, it is QC if there exists a state feedback gain K such that the resulting closed-loop system admits a *single* quadratic Lyapunov function (independent of Δ) which proves stability with rate of convergence α against all possible $\Delta \in \boldsymbol{\Delta}$. For systems without uncertainty, i.e., $\dot{x}(t) = Ax(t) + Bu(t)$, the notion of quadratic controllability means the assignability of the closed-loop eigenvalues with arbitrarily large negative real parts, i.e., the controllability of the pair (A,B).

It is important to note that the uncertain system given in (2.1) can be alternatively described as the feedback connection of a nominal system with an uncertain block, which is given by

$$\Sigma: \quad \begin{cases} \dot{x}(t) = Ax(t) + Bu(t) + Gw(t), \\ z(t) = Cx(t) + Du(t), \\ w(t) = \Delta z(t), \end{cases} \tag{2.4}$$

where the two new variables, $w(t) \in \boldsymbol{R}^k$ and $z(t) \in \boldsymbol{R}^\ell$, denote a fictitious disturbance input and a fictitious controlled output, respectively.

The following lemma characterizes QC systems in terms of matrix inequalities.

Lemma 2.3. *Consider the uncertain system Σ described in* (2.4). *The following statements are equivalent.*

(i) *The uncertain system Σ is QC.*

(ii) *For each $\alpha > 0$, there exists $X^t = X > 0$ such that*

$$\begin{bmatrix} B \\ D \end{bmatrix}^\perp \begin{bmatrix} (A+\alpha I)X + X(A+\alpha I)^t + GG^t & XC^t \\ CX & -I \end{bmatrix} \begin{bmatrix} B \\ D \end{bmatrix}^{\perp t} < 0. \tag{2.5}$$

(iii) *For each $\alpha > 0$, there exists $X^t = X > 0$ such that*

$$E^\perp[(\tilde{A} + \alpha I)X + X(\tilde{A} + \alpha I)^t + X\tilde{C}X - \tilde{B}]E^{\perp t} < 0, \tag{2.6}$$

where

$$\begin{aligned} \tilde{A} &:= A - BD^+C, & \tilde{B} &:= B(D^tD)^+B^t - GG^t, \\ \tilde{C} &:= C^t(I - DD^+)C, & E &:= B(I - D^+D). \end{aligned} \tag{2.7}$$

Proof. The equivalence of (i) and (ii) simply follows from the quadratic stabilizability result [8] and the state feedback $\mathcal{H}_\infty$ synthesis result [7]. The equivalence of (ii) and (iii) can be verified by noting that

$$\begin{bmatrix} B \\ D \end{bmatrix}^\perp = \begin{bmatrix} E \\ D \end{bmatrix}^\perp \begin{bmatrix} I & -BD^+ \\ 0 & I \end{bmatrix}$$

and

$$\begin{bmatrix} E \\ D \end{bmatrix}^{\perp} = \left(\begin{bmatrix} E \\ D \end{bmatrix} \begin{bmatrix} E \\ D \end{bmatrix}^t \right)^{\perp} = \begin{bmatrix} EE^t & 0 \\ 0 & DD^t \end{bmatrix}^{\perp} = \begin{bmatrix} E^{\perp} & 0 \\ 0 & D^{\perp} \end{bmatrix}$$

and using the Schur complement. □

Recall that the matrix E in Lemma 2.3 is the uncertainty-free input matrix through which the control input u_1 enters the system as shown in (2.3). If Σ is regular, then $E^{\perp} = I$ and (2.6) becomes a standard Riccati inequality. On the other hand, if Σ is simple, then $E^{\perp}$ becomes trivial; hence (2.6) is trivially satisfied. An immediate consequence of this is that the system Σ in (2.4) is QC if it is simple.

The following lemma shows when an uncertain system is QC. A similar result was obtained in [18, 24]. For completeness, a proof is included.

LEMMA 2.4. *Consider the uncertain system Σ described in* (2.4). *The following statements hold true.*

(a) *If Σ is simple, then it is QC.*

(b) *If Σ is regular, then it is QC if and only if*

$$\tilde{B} \geq 0 \quad \textit{and} \quad (\tilde{A}, \tilde{B}) \ \textit{controllable}, \tag{2.8}$$

where $\tilde{A}$ and $\tilde{B}$ are defined in (2.7).

Proof. Statement (a) is obvious as noted above, and we need only to prove (b).

By the regularity assumption, Lemma 2.3 implies that the uncertain system is QC if and only if, for each $\alpha > 0$, there exists $X^t = X > 0$ such that

$$(\tilde{A} + \alpha I)X + X(\tilde{A} + \alpha I)^t + X\tilde{C}X - \tilde{B} < 0 \tag{2.9}$$

where $\tilde{A}$, $\tilde{B}$, and $\tilde{C} \geq 0$ are defined in (2.7).

Suppose Σ is QC. Then, from Lemma 5.1 in the appendix, we have $\tilde{B} \geq 0$. Suppose $(\tilde{A}$,$\tilde{B})$ is not controllable, then there exist a complex number λ and a nonzero vector v such that

$$v^t(\tilde{A} - \lambda I) = 0, \quad v^t\tilde{B} = 0.$$

Fix such λ and v, and pre- and postmultiply (2.9) by v^t and v, respectively, and we obtain that for each $\alpha > 0$, there exists $X^t = X > 0$ satisfying

$$2[\alpha + \mathrm{Re}(\lambda)]v^tXv + v^tX\tilde{C}Xv < 0\,. \tag{2.10}$$

If we choose $\alpha > 0$ to be sufficiently large such that $\alpha + \mathrm{Re}(\lambda) \geq 0$, then (2.10) implies that $v^tX\tilde{C}Xv < 0$, which contradicts that $\tilde{C} \geq 0$. Hence, $(\tilde{A}$,$\tilde{B})$ must be controllable.

Conversely, suppose $\tilde{B} \geq 0$ and $(\tilde{A}$,$\tilde{B})$ is controllable. Then, for each $\alpha > 0$, there exist a gain matrix K such that $\tilde{A} + \tilde{B}K + \alpha I$ is Hurwitz and a $P^t = P > 0$ satisfying the following Lyapunov inequality:

$$P(\tilde{A} + \tilde{B}K + \alpha I) + (\tilde{A} + \tilde{B}K + \alpha I)^tP + K^t\tilde{B}K + \tilde{C} < 0.$$

Completing the square with respect to K, we obtain

$$P(\tilde{A} + \alpha I) + (\tilde{A} + \alpha I)^tP + \tilde{C} - P\tilde{B}P < -(P+K)^t\tilde{B}(P+K) \leq 0.$$

Now, it is straightforward to verify that $X := P^{-1}$ satisfies (2.9). Thus the system is QC. □

It is easy to derive, under the regularity assumption on Σ, that the first condition in (2.8) is equivalent to the existence of a matrix M, such that

$$G = BM \quad \text{and} \quad \|DM\| \leq 1,$$

which is precisely the *matching condition* obtained in [18]. Intuitively, this condition implies that it is possible to completely compensate the effect of the uncertainty Δ entering the system through G by using the control input through B.

Next we introduce the notion of strong controllability.

DEFINITION 2.5. The strongly controllable subspace *of the uncertain system* (2.1) *is the smallest subspace* $\mathbf{S}$ *of* $\boldsymbol{R}^n$ *for which there exists a matrix* K *such that*

$$(A + KC)\mathbf{S} \subset \mathbf{S}, \qquad \mathrm{Im}(B + KD) \subset \mathbf{S}.$$

The system is said to be strongly controllable *(SC) if its strongly controllable subspace is equal to the whole state space.*

The notion of strong controllability was introduced and studied in the references [5, 10, 11, 20]. It was considered in the context of invariant properties of linear systems, rather than in the robustness analysis context which is our main focus in this paper. It was shown in [26] for the case where $D = 0$ that if Σ is SC, then the problem of almost disturbance decoupling with an arbitrary degree of stability (or rate of convergence) for Σ is solvable. Therefore, the notion of strong controllability is stronger than that of quadratic controllability when $D = 0$.

The following lemma [5, 20] characterizes the strong controllability property in terms of a rank condition.

LEMMA 2.6. *The uncertain system* Σ *is SC if and only if*

$$\mathrm{rank} \begin{bmatrix} A - sI_n & B \\ C & D \end{bmatrix} = n + \mathrm{rank} \begin{bmatrix} C & D \end{bmatrix} \tag{2.11}$$

holds for all $s \in \boldsymbol{C}$.

The characterization of strong controllability given in Lemma 2.6 implies that the system Σ has no finite invariant zeros. If there is no uncertainty in the system, i.e., when $C = 0$ and $D = 0$, then the condition (2.11) reduces to

$$\mathrm{rank} \begin{bmatrix} A - sI_n & B \end{bmatrix} = n \; \forall \, s \in \boldsymbol{C}, \tag{2.12}$$

which is the Popov–Belevitch–Hautus (PBH) rank test for the controllability of the pair (A, B). In this case, strong controllability is equivalent to quadratic controllability and the SC subspace given in Definition 2.5 reduces to the smallest A-invariant subspace containing $\mathrm{Im}(B)$, which is precisely the controllability subspace defined in [27].

The following lemma shows some implications of the uncertain system Σ being simple or regular in relation to the notion of strong controllability.

LEMMA 2.7. *Consider the uncertain system* Σ *described in* (2.4). *The following statements hold true.*

(a) *If* Σ *is simple, then it is SC.*

(b) *If* Σ *is regular, then it is not SC.*

Proof. First we prove (a). Since $B(I - D^+D)$ has full row rank n,

$$\mathrm{rank} \begin{bmatrix} A - sI_n & B \\ C & D \end{bmatrix} = \mathrm{rank} \left(\begin{bmatrix} A - sI_n & B \\ C & D \end{bmatrix} \begin{bmatrix} I & 0 & 0 \\ 0 & D^+D & I - D^+D \end{bmatrix} \right)$$

$$= \operatorname{rank} \begin{bmatrix} A - sI_n & BD^+D & B(I - D^+D) \\ C & D & 0 \end{bmatrix}$$
$$= n + \operatorname{rank} \begin{bmatrix} C & D \end{bmatrix}.$$

To prove (b), we note that since $B = BD^+D$, we have

$$\begin{aligned} \operatorname{rank} \begin{bmatrix} A - sI_n & B \\ C & D \end{bmatrix} &= \operatorname{rank} \left(\begin{bmatrix} I & -BD^+ \\ 0 & I \end{bmatrix} \begin{bmatrix} A - sI_n & BD^+D \\ C & D \end{bmatrix} \right) \\ &= \operatorname{rank} \begin{bmatrix} A - BD^+C - sI_n & 0 \\ C & D \end{bmatrix} \\ &\leq \operatorname{rank}(A - BD^+C - sI_n) + \operatorname{rank} \begin{bmatrix} C & D \end{bmatrix} \\ &< n + \operatorname{rank} \begin{bmatrix} C & D \end{bmatrix}, \end{aligned}$$

where the last strict inequality holds when $s \in \boldsymbol{C}$ is chosen to be an eigenvalue of $A - BD^+C$. □

Note that Lemmas 2.4 and 2.7 completely characterize the QC and SC properties of an uncertain system when it is either simple or regular. However, these results shed little light on uncertain systems which are neither simple nor regular. In the next section, we will introduce the notion of *essential subsystem*, which plays a central role in considering such general cases.

3. Characterization of quadratic controllability and strong controllability via the essential subsystem.

Suppose the uncertain system Σ in (2.4) is neither simple nor regular. In what follows, we will define a reduced order subsystem of Σ which is obtained through state and control input transformations, followed by state truncations. The main features of this subsystem are as follows: (a) it has smaller dimension than the original system, (b) it is either simple or regular, and (c) quadratic controllability or strong controllability of the original system can be verified by checking quadratic controllability or strong controllability of this reduced order subsystem. We call this subsystem of Σ the *essential subsystem*.

3.1. The essential subsystem.

Suppose the system Σ is neither simple nor regular. Let N_0 and R_0 be matrices whose columns form orthonormal bases for the left null space and the range space of $B(I - D^+D)$, respectively. Using the following state and input transformations,

$$\begin{bmatrix} \xi_n \\ \xi_r \end{bmatrix} := \begin{bmatrix} N_0^t \\ R_0^t \end{bmatrix} x, \qquad \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} := \begin{bmatrix} I - D^+D \\ D^+D \end{bmatrix} u,$$

the nominal part of Σ in (2.4) will have the following form:

$$\left\{ \begin{array}{lcl} \dot{\xi}_n &=& A_{nn}\xi_n + A_{nr}\xi_r \qquad\qquad + B_n u_2 + G_n w, \\ \dot{\xi}_r &=& A_{rn}\xi_n + A_{rr}\xi_r + \hat{B}_r u_1 + B_r u_2 + G_r w, \\ z &=& C_n\xi_n + C_r\xi_r \qquad\qquad + D\, u_2, \end{array} \right.$$

where

$$\begin{bmatrix} A_{nn} & A_{nr} \\ A_{rn} & A_{rr} \end{bmatrix} := \begin{bmatrix} N_0^t \\ R_0^t \end{bmatrix} A \begin{bmatrix} N_0 & R_0 \end{bmatrix},$$

$$\begin{bmatrix} 0 & B_n \\ \hat{B}_r & B_r \end{bmatrix} := \begin{bmatrix} N_0^t \\ R_0^t \end{bmatrix} B \begin{bmatrix} I - D^+D & D^+D \end{bmatrix},$$

$$\begin{bmatrix} G_n \\ G_r \end{bmatrix} := \begin{bmatrix} N_0^t \\ R_0^t \end{bmatrix} G, \quad \begin{bmatrix} C_n & C_r \end{bmatrix} := C \begin{bmatrix} N_0 & R_0 \end{bmatrix}.$$

Moreover, $\hat{B}_r$ is a full row rank matrix. It should be noted from the second equation that ξ_r can be fully controlled as desired through u_1, and therefore it can be regarded as part of control input in the first equation. This motivates us to consider the following reduced order subsystem of Σ:

$$\Sigma_1 : \left\{ \begin{array}{rcl} \dot{\zeta}(t) & = & A_1\zeta(t) + B_1 v(t) + G_1 w(t), \\ z(t) & = & C_1\zeta(t) + D_1 v(t), \\ w(t) & = & \Delta z(t), \end{array} \right. \tag{3.1}$$

where $\zeta := \xi_n$ is the state and $v := \begin{bmatrix} \xi_r \\ u_2 \end{bmatrix}$ is the control input, and

$$\begin{aligned} \begin{bmatrix} A_1 & B_1 & G_1 \\ C_1 & D_1 & 0 \end{bmatrix} &:= \left[\begin{array}{c|cc|c} A_{nn} & A_{nr} & B_n & G_n \\ \hline C_n & C_r & D & 0 \end{array} \right] \\ &= \begin{bmatrix} N_0^t & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A & B & G \\ C & D & 0 \end{bmatrix} \begin{bmatrix} N_0 & R_0 & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{bmatrix}. \end{aligned}$$

It is worth noting that $B_n = N_0^t B D^+ D = N_0^t B$, since $N_0^t B(I - D^+ D) = 0$. Clearly, the order of Σ_1 is lower than that of Σ, and it could be either simple or regular. If Σ_1 is neither, the reduction procedure can be applied again to obtain a reduced order subsystem of Σ_1. We may repeat this procedure to generate a sequence of subsystems $\Sigma_1, \ldots, \Sigma_q$ until Σ_q becomes either simple or regular. We call Σ_q the *essential subsystem* of Σ. In the subsequent sections, we show that the quadratic controllability and strong controllability properties are preserved in the reduction process and hence Σ is QC and/or SC if and only if Σ_q is also.

The procedure to obtain Σ_q can be formalized as follows.

Algorithm 1

Given the system Σ, define its essential subsystem Σ_q from the following iteration steps.

Step 0. Let $i = 0$ and set the initial system $\Sigma_0 := \Sigma$, i.e.,

$$\begin{bmatrix} A_0 & B_0 & G_0 \\ C_0 & D_0 & 0 \end{bmatrix} := \begin{bmatrix} A & B & G \\ C & D & 0 \end{bmatrix}.$$

Step 1. If Σ_i is either simple or regular, then go to Step 3; otherwise define the subsystem Σ_{i+1} by

$$\begin{bmatrix} A_{i+1} & B_{i+1} & G_{i+1} \\ C_{i+1} & D_{i+1} & 0 \end{bmatrix} := \begin{bmatrix} N_i^t & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A_i & B_i & G_i \\ C_i & D_i & 0 \end{bmatrix} \left[\begin{array}{c|cc|c} N_i & R_i & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{array} \right],$$

where N_i and R_i are matrices whose columns form orthonormal bases for the left null space and the range space of $B_i(I - D_i^+ D_i)$, respectively.

Step 2. Set $i = i + 1$ and go to Step 1.

Step 3. Let $q := i$ and $\Sigma_q := \Sigma_i$.

Writing down the above iterative process in the closed form, we see that the essential subsystem can be characterized as

$$\begin{bmatrix} A_q & B_q & G_q \\ C_q & D_q & 0 \end{bmatrix} := \begin{bmatrix} N^t & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} A & B & G \\ C & D & 0 \end{bmatrix} \begin{bmatrix} N & * & 0 \\ 0 & * & 0 \\ 0 & 0 & I \end{bmatrix},$$

where $*$ denotes a known entry and

$$N := \begin{cases} I & \text{if } q = 0, \\ N_0 N_1 \cdots N_{q-1} & \text{if } q \geq 1. \end{cases} \tag{3.2}$$

Thus, it can be seen that the essential subsystem Σ_q is obtained through the projection of the original system Σ onto $\mathrm{Im}(N)$. Define a matrix $\mathcal{N}$ by

$$\mathcal{N} := \begin{cases} N & \text{if } \Sigma_q \text{ is regular,} \\ 0 & \text{if } \Sigma_q \text{ is simple.} \end{cases} \tag{3.3}$$

The importance of matrix $\mathcal{N}$ will become eminent when we discuss an output feedback property in section 4.

3.2. Characterization of QC.

The following is the main result of this subsection.

THEOREM 3.1. *Consider the uncertain system Σ described in* (2.4)*. Define the essential subsystem Σ_q by Algorithm* 1*. Then Σ is QC if and only if Σ_q is QC.*

Before we proceed further, some remarks are in order. If Σ_q is simple, then it follows from Lemma 2.4 that Σ_q is QC. On the other hand, if Σ_q is regular, then the matching condition in Lemma 2.4 is necessary (and sufficient) for Σ_q to be QC.

The following lemma is instrumental to the proof of Theorem 3.1, and it shows that the proposed order reduction process preserves the QC property.

LEMMA 3.2. *Consider the uncertain system Σ described in* (2.4) *and its reduced order subsystem Σ_1 defined in* (3.1)*. The system Σ is QC if and only if its subsystem Σ_1 is QC. Moreover, if for each $\alpha > 0$, there exists $X^t = X > 0$ satisfying inequality* (2.6) *for the original system Σ, then $X_1 := N_0^t X N_0$ satisfies the same inequality for the subsystem Σ_1.*

Proof. Note that $U_0 := \begin{bmatrix} N_0 & R_0 \end{bmatrix}$ is an orthogonal matrix and $E^\perp = N_0^t$. Define

$$\begin{bmatrix} \tilde{A}_{nn} & \tilde{A}_{nr} \\ \tilde{A}_{rn} & \tilde{A}_{rr} \end{bmatrix} := U_0^t \tilde{A} U_0, \quad \begin{bmatrix} X_{nn} & X_{nr} \\ X_{nr}^t & X_{rr} \end{bmatrix} := U_0^t X U_0, \tag{3.4a}$$

$$\begin{bmatrix} B_n \\ B_r \end{bmatrix} := U_0^t B, \quad \begin{bmatrix} G_n \\ G_r \end{bmatrix} := U_0^t G, \quad \begin{bmatrix} C_n & C_r \end{bmatrix} := C U_0. \tag{3.4b}$$

Then, after some algebraic manipulations, (2.6) can be rewritten as

$$\begin{aligned} \Phi &:= (\tilde{A}_{nn} X_{nn} + \tilde{A}_{nr} X_{nr}^t) + (\tilde{A}_{nn} X_{nn} + \tilde{A}_{nr} X_{nr}^t)^t + G_n G_n^t - B_n (D^t D)^+ B_n^t \\ &\quad + 2\alpha X_{nn} + (C_n X_{nn} + C_r X_{nr}^t)^t (I - DD^+)(C_n X_{nn} + C_r X_{nr}^t) < 0. \end{aligned} \tag{3.5}$$

Moreover, (3.5) holds if and only if there exists a K such that

$$\Phi + (B_n D^+ + KDD^+)(B_n D^+ + KDD^+)^t < 0.$$

It is straightforward to verify that the above inequality can be equivalently written as

$$\begin{aligned} &\left(A_{nn} X_{nn} + \begin{bmatrix} A_{nr} & B_n D^+ \end{bmatrix} \begin{bmatrix} X_{nr}^t \\ \tilde{K}^t \end{bmatrix}\right) + \left(A_{nn} X_{nn} + \begin{bmatrix} A_{nr} & B_n D^+ \end{bmatrix} \begin{bmatrix} X_{nr}^t \\ \tilde{K}^t \end{bmatrix}\right)^t + G_n G_n^t \\ &+ 2\alpha X_{nn} + \left(C_n X_{nn} + \begin{bmatrix} C_r & DD^+ \end{bmatrix} \begin{bmatrix} X_{nr}^t \\ \tilde{K}^t \end{bmatrix}\right)^t \left(C_n X_{nn} + \begin{bmatrix} C_r & DD^+ \end{bmatrix} \begin{bmatrix} X_{nr}^t \\ \tilde{K}^t \end{bmatrix}\right) < 0, \end{aligned} \tag{3.6}$$

where A_{nn} and A_{nr} are defined similarly to $\tilde{A}_{nn}$ and $\tilde{A}_{nr}$ in that A replaces $\tilde{A}$, and

$$\tilde{K} := K - X_{nn}C_n^t - X_{nr}C_r^t.$$

Taking the Schur complement of (3.6), we obtain

$$\begin{bmatrix} A_{nn}X_{nn} + X_{nn}A_{nn}^t + 2\alpha X_{nn} + G_nG_n^t & X_{nn}C_n^t \\ C_nX_{nn} & -I \end{bmatrix} + \begin{bmatrix} A_{nr} & B_nD^+ \\ C_r & DD^+ \end{bmatrix} \begin{bmatrix} X_{nr}^t \\ \tilde{K}^t \end{bmatrix} \begin{bmatrix} I & 0 \end{bmatrix}$$

$$+ \begin{bmatrix} I \\ 0 \end{bmatrix} \begin{bmatrix} X_{nr} & \tilde{K} \end{bmatrix} \begin{bmatrix} A_{nr} & B_nD^+ \\ C_r & DD^+ \end{bmatrix}^t < 0. \tag{3.7}$$

It then follows from the projection lemma presented in [3, 7] that there exist X_{nr} and $\tilde{K}$ which satisfy the above inequality if and only if

$$\begin{bmatrix} A_{nr} & B_nD^+ \\ C_r & DD^+ \end{bmatrix}^{\perp} \begin{bmatrix} A_{nn}X_{nn} + X_{nn}A_{nn}^t + 2\alpha X_{nn} + G_nG_n^t & X_{nn}C_n^t \\ C_nX_{nn} & -I \end{bmatrix} \begin{bmatrix} A_{nr} & B_nD^+ \\ C_r & DD^+ \end{bmatrix}^{\perp t} < 0.$$

Finally, since

$$\operatorname{Im} \begin{bmatrix} B_n \\ D \end{bmatrix} = \operatorname{Im} \begin{bmatrix} B_nD^+D \\ DD^+D \end{bmatrix} = \operatorname{Im} \begin{bmatrix} B_nD^+ \\ DD^+ \end{bmatrix},$$

we obtain that

$$\begin{bmatrix} A_{nr} & B_nD^+ \\ C_r & DD^+ \end{bmatrix}^{\perp} = \begin{bmatrix} A_{nr} & B_n \\ C_r & D \end{bmatrix}^{\perp}.$$

Hence the above inequality is precisely the condition for the subsystem Σ_1 to be QC. □

We now prove Theorem 3.1.

Proof. In view of Lemma 3.2, the quadratic controllability property is invariant under the proposed order reduction process. Hence the uncertain system Σ is QC if and only if its essential subsystem Σ_q is QC. □

3.3. Characterization of strong controllability. Consider the uncertain system Σ given in (2.4) and its essential subsystem Σ_q. In this subsection, we will establish the equivalence between Σ and Σ_q in the sense of strong controllability. To show this, we rely on the characterization of strong controllability which was given by the rank condition in Lemma 2.6. First, we will examine the strong controllability property of Σ in terms of Σ_1.

LEMMA 3.3. *Consider the uncertain system Σ described in* (2.4) *and its reduced order subsystem Σ_1 defined in* (3.1)*. The rank condition*

$$\operatorname{rank} \begin{bmatrix} A - sI_n & B \\ C & D \end{bmatrix} - n = \operatorname{rank} \begin{bmatrix} A_1 - sI_{n_1} & B_1 \\ C_1 & D_1 \end{bmatrix} - n_1 \tag{3.8}$$

holds for all $s \in \boldsymbol{C}$, where n_1 denotes the dimension of Σ_1.

Proof. Let r be the rank of $B(I - D^+D)$. Since $n = n_1 + r$, we obtain

$$\operatorname{rank} \begin{bmatrix} A - sI_n & B \\ C & D \end{bmatrix} = \operatorname{rank} \left(\begin{bmatrix} N_0^t & 0 \\ 0 & I \\ R_0^t & 0 \end{bmatrix} \begin{bmatrix} A - sI_n & B \\ C & D \end{bmatrix} \left[\begin{array}{c|cc|c} N_0 & R_0 & 0 & 0 \\ 0 & 0 & I & I - D^+D \end{array} \right] \right)$$

$$= \operatorname{rank} \begin{bmatrix} A_1 - sI_{n_1} & B_1 & 0 \\ C_1 & D_1 & 0 \\ * & * & R_0^t B(I - D^+ D) \end{bmatrix}$$

$$= \operatorname{rank} \begin{bmatrix} A_1 - sI_{n_1} & B_1 \\ C_1 & D_1 \end{bmatrix} + n - n_1,$$

where the last equality follows from the fact that the matrix $R_0^t B(I - D^+ D)$ has full row rank $(n - n_1)$. □

It follows readily from the above lemma that $s \in \boldsymbol{C}$ is an invariant zero for the original system Σ if and only if it is an invariant zero for the reduced order subsystem Σ_1. Thus, the invariant zeros of the original system are preserved under the order reduction process and they are the invariant zeros of the essential subsystem Σ_q. Furthermore, by definition, for Σ_q to be SC it must not have finite invariant zeros. This observation is elaborated in the next theorem, which is the main result of this subsection.

THEOREM 3.4. *Consider the uncertain system* Σ *in* (2.4) *and its essential subsystem* Σ_q *defined by Algorithm* 1. *Then* Σ *is SC if and only if* Σ_q *is SC.*

Proof. If Σ is SC, then it follows from Lemma 2.6 that the rank condition (2.11) holds for all $s \in \boldsymbol{C}$. Moreover, from Lemma 3.3, we note that the order reduction process preserves the quantities

$$\operatorname{rank} \begin{bmatrix} A_i - sI_{n_i} & B_i \\ C_i & D_i \end{bmatrix} - n_i \qquad \text{and} \qquad \operatorname{rank} \begin{bmatrix} C_i & D_i \end{bmatrix}, \tag{3.9}$$

where n_i denotes the dimension of subsystem Σ_i. Hence

$$\operatorname{rank} \begin{bmatrix} A_i - sI_{n_i} & B_i \\ C_i & D_i \end{bmatrix} = n_i + \operatorname{rank} \begin{bmatrix} C_i & D_i \end{bmatrix} \ \forall s \in \boldsymbol{C}, \tag{3.10}$$

holds for all $i = 1, \ldots, q$. Thus, from Lemma 2.6, we see that the essential subsystem Σ_q is SC. Conversely, if Σ_q is SC, then it satisfies the rank condition in (3.10) with $i = q$. Again, the quantities in (3.9) are preserved for each $i < q$ and hence Σ must be SC. □

In light of Lemma 2.7 and the fact that Σ_q is either simple or regular, we note that Σ_q is SC if and only if it is simple. It can be inferred from Theorems 3.1 and 3.4 that strong controllability generally implies quadratic controllability, but not vice versa, since an uncertain system can be QC even if its essential subsystem is not simple.

4. A related output feedback property.

We have considered the quadratic controllability property for a class of uncertain linear systems described in (2.1), provided that all the states are available for linear feedback design. This section, however, is concerned with the uncertain systems in which only the measured states are available for feedback, and in addition, they are contaminated by the uncertainties. For this class of uncertain systems, our objective is to determine a necessary and sufficient condition under which there exists a dynamic output feedback controller that will render the closed-loop system which is quadratically stable with any prescribed rate of convergence. We call an uncertain system with such property *quadratically feedback minimal.*

4.1. Notion of quadratic feedback minimality.

Consider the uncertain system described in (2.1) with measured output

$$\begin{cases} \dot{x}(t) &= A_\Delta x(t) + B_\Delta u(t), \\ y(t) &= M_\Delta x(t) + J_\Delta u(t), \end{cases} \tag{4.1}$$

where $y(t) \in \boldsymbol{R}^p$ denotes the measured output, and M_Δ and J_Δ are defined by

$$M_\Delta := M + J\Delta C\,,\ J_\Delta := J\Delta D\,,$$

where the matrices M and J are real and known with compatible dimensions, and Δ belongs to $\boldsymbol{\Delta}$. This uncertain system is to be controlled by a linear, time-invariant, dynamic, output feedback controller of the form

$$\left\{ \begin{array}{rcl} \dot{x}_c(t) & = & A_c x_c(t) + B_c y(t), \\ u(t) & = & C_c x_c(t), \end{array} \right. \tag{4.2}$$

where $x_c(t) \in \boldsymbol{R}^{n_c}$ is the state of the controller, and A_c, B_c, and C_c are real matrices with compatible dimensions. The closed-loop system, which consists of the plant (4.1) and the controller (4.2), is given by $\dot{x}_{c\ell} = \mathcal{A}_\Delta x_{c\ell}$ with

$$x_{c\ell} := \left[\begin{array}{c} x \\ x_c \end{array} \right], \quad \mathcal{A}_\Delta := \left[\begin{array}{cc} A_\Delta & B_\Delta C_c \\ B_c M_\Delta & A_c + B_c J_\Delta C_c \end{array} \right].$$

DEFINITION 4.1. *The uncertain system described in* (4.1) *is said to be* quadratically feedback minimal *(QFM) if for any given $\alpha > 0$, there exist a dynamic controller of the form* (4.2) *and a positive-definite symmetric matrix $P \in \boldsymbol{R}^{(n+n_c)\times(n+n_c)}$ such that*

$$P(\mathcal{A}_\Delta + \alpha I) + (\mathcal{A}_\Delta + \alpha I)^t P < 0 \tag{4.3}$$

for all $\Delta \in \boldsymbol{\Delta}$.

For linear, time-invariant, certain systems (i.e., when Δ is fixed and known), the notion given in Definition 4.1 is equivalent to the assignability (using dynamic output feedback controllers) of the closed-loop eigenvalues with arbitrarily large negative real parts. As is well known, the class of certain systems having such a property coincides with the class of systems that are controllable and observable, i.e., minimal; hence the term QFM. In view of this fact, it is tempting to conjecture that the class of *uncertain* systems having such a property can also be characterized as the class of systems whose state feedback part is QC and its dual part is also QC. However, our result will show that an additional orthogonality condition has to be satisfied.

In view of the uncertain system Σ given in (2.4), we note that the uncertain system (4.1) can be equivalently described by

$$\Sigma_{of}\ :\ \left\{ \begin{array}{rcll} \dot{x}(t) & = & Ax(t) + Bu(t) & +\ Gw(t), \\ y(t) & = & Mx(t) & +\ Jw(t), \\ z(t) & = & Cx(t) + Du(t), & \\ w(t) & = & \Delta z(t). & \end{array} \right. \tag{4.4}$$

Given the system Σ_{of}, we define two auxiliary systems as follows:

$$\Sigma\ :\ \left\{ \begin{array}{rcl} \dot{x}(t) & = & Ax(t) + Bu(t) + Gw(t), \\ z(t) & = & Cx(t) + Du(t), \\ w(t) & = & \Delta z(t) \end{array} \right. \tag{4.5}$$

and

$$\hat{\Sigma}\ :\ \left\{ \begin{array}{rcl} \dot{\hat{x}}(t) & = & \hat{A}\hat{x}(t) + \hat{B}\hat{u}(t) + \hat{G}\hat{w}(t), \\ \hat{z}(t) & = & \hat{C}\hat{x}(t) + \hat{D}\hat{u}(t), \\ \hat{w}(t) & = & \hat{\Delta}\hat{z}(t), \end{array} \right. \tag{4.6}$$

where $(\hat{A}, \hat{B}, \hat{G}, \hat{C}, \hat{D}) := (A^t, M^t, C^t, G^t, J^t)$ and $\hat{\Delta} := \Delta^t$. The system Σ in (4.5) is precisely the system considered in the previous sections, which defines a state feedback problem, whereas the system $\hat{\Sigma}$ defines another state feedback problem which is the dual of the state estimation problem for Σ_{of}. These two systems will play essential roles in developing the main result of this section. In order to facilitate our presentation, we make use of the following notions. For system $\hat{\Sigma}$, we can also apply Algorithm 1 to attain its essential subsystem. Assume that the essential subsystem $\hat{\Sigma}_{\hat{q}}$ is obtained at $i = \hat{q}$.

4.2. QFM systems. The main result of this section is contained in the following theorem.

THEOREM 4.2. *Consider the uncertain system* Σ_{of} *described in* (4.4). *Let the auxiliary systems* Σ *and* $\hat{\Sigma}$ *be given by* (4.5) *and* (4.6). *Define a matrix* $\mathcal{N}$ *for* Σ *as described in* (3.3), *and similarly a matrix* $\hat{\mathcal{N}}$ *for* $\hat{\Sigma}$. *Then,* Σ_{of} *is quadratically feedback minimal if and only if the following conditions hold.*

(a) Σ *is QC*,

(b) $\hat{\Sigma}$ *is QC*, *and*

(c) $\hat{\mathcal{N}}^t\mathcal{N} = 0$.

We will prove this theorem in the next subsection. For now, let us elaborate on the result. For systems without uncertainties, it is well known that Σ_{of} is QFM if and only if both (A,B) and (A^t,C^t) are controllable. For uncertain systems, in view of Theorem 4.2, these conditions are replaced by the quadratic controllability properties of Σ and $\hat{\Sigma}$ as in (a) and (b), and in addition, we have the orthogonality condition (c).

In order to verify the conditions in Theorem 4.2, we need to go through the order reduction process to obtain the essential subsystems for both Σ and $\hat{\Sigma}$, namely, Σ_q and $\hat{\Sigma}_{\hat{q}}$. Depending on whether each of these essential subsystems is simple or regular, we may have to examine four different cases, as shown in Table 4.1, to determine if the system Σ_{of} is QFM.

TABLE 4.1
Four cases resulted from the reduction process.

$\Sigma_q \setminus \hat{\Sigma}_{\hat{q}}$	Simple	Regular
simple	CASE 1	CASE 2
regular	CASE 3	CASE 4

Case 1: Both essential subsystems are simple, and therefore both Σ and $\hat{\Sigma}$ are QC. Moreover, it was defined previously that $\mathcal{N} = 0$ and $\hat{\mathcal{N}} = 0$, and hence condition (c) in Theorem 4.2 is trivially satisfied. Thus, in this case the system Σ_{of} is always QFM. Furthermore, it follows from Theorem 3.4 and Lemma 2.7(a) that both Σ and $\hat{\Sigma}$ are SC, and from Lemma 2.6, for all $s \in \boldsymbol{C}$, we have

$$\begin{aligned} \operatorname{rank}\begin{bmatrix} sI-A & B \\ C & D \end{bmatrix} &= n + \operatorname{rank}\begin{bmatrix} C & D \end{bmatrix}, \\ \operatorname{rank}\begin{bmatrix} sI-A & G \\ M & J \end{bmatrix} &= n + \operatorname{rank}\begin{bmatrix} G \\ J \end{bmatrix}. \end{aligned} \tag{4.7}$$

Cases 2 *and* 3: We consider *Case* 2 only; *Case* 3 can be treated similarly. Since the essential subsystem Σ_q is simple, Σ is QC and $\mathcal{N} = 0$. Hence conditions (a) and

(c) always hold, and Σ_{of} is QFM if and only if condition (b) holds. Since the essential subsystem $\hat{\Sigma}_{\hat{q}}$ is regular, $\hat{\Sigma}$ is QC if and only if $\hat{\Sigma}_{\hat{q}}$ satisfies the matching condition described in Lemma 2.4. In this case, the second equality in (4.7) is replaced with strict inequality ($<$).

Case 4: Both essential subsystems are regular. Conditions (a) and (b) can be checked by utilizing Lemma 2.4. Condition (c) can be verified by direct calculation. In this case, both equalities in (4.7) are replaced with strict inequalities. Finally, it is important to note that Σ_{of} *cannot* be QFM if Σ and $\hat{\Sigma}$ are both regular, since in this case $\mathcal{N} = \hat{\mathcal{N}} = I$ and thus condition (c) can never hold.

4.3. Proof of the main theorem. First, we define two matrix-valued mappings as follows:

$$\begin{aligned} F_\alpha(\Sigma, X) \quad &:= \quad \begin{bmatrix} B \\ D \end{bmatrix}^{\perp} \begin{bmatrix} (A+\alpha I)X + X(A+\alpha I)^t + GG^t & XC^t \\ CX & -I \end{bmatrix} \begin{bmatrix} B \\ D \end{bmatrix}^{\perp t}, \\ S(X,Y,Z) \quad &:= \quad \begin{bmatrix} X & Z^t \\ Z & Y \end{bmatrix}, \end{aligned}$$

where Σ is the system described in (4.5).

The next lemma is essential for proving Theorem 4.2.

LEMMA 4.3. *Consider the uncertain system Σ_{of} described in* (4.4). *The following statements are equivalent.*

(i) *The uncertain system Σ_{of} is QFM.*

(ii) *For each $\alpha > 0$, there exist positive definite symmetric matrices X and Y, such that*

$$F_\alpha(\Sigma, X) < 0, \quad F_\alpha(\hat{\Sigma}, Y) < 0, \quad S(X,Y,I) > 0.$$

Proof. The equivalence follows from the quadratic stabilizability result [8] and the $\mathcal{H}_\infty$ synthesis result [3, 7]. □

In view of Lemma 3.2, next we present a condition which is similar to statement (ii) of Lemma 4.3, but is given in terms of $\hat{\Sigma}$ and a reduced order subsystem of Σ.

LEMMA 4.4. *Consider the uncertain system Σ_{of} in* (4.4) *and define Σ and $\hat{\Sigma}$ as in* (4.5) *and* (4.6). *Suppose that Σ is neither simple nor regular. Then statement* (ii) *of Lemma* 4.3 *holds if and only if the following condition is satisfied.*

(i) *For each $\alpha > 0$, there exist symmetric matrices X_1 and Y such that*

$$F_\alpha(\Sigma_1, X_1) < 0, \quad F_\alpha(\hat{\Sigma}, Y) < 0, \quad S(X_1, Y, N_0) > 0,$$

where Σ_1 is the reduced order subsystem of Σ defined in (3.1) *and N_0 is an orthonormal basis for the left null space of $B(I - D^+D)$.*

Proof. Suppose statement (ii) of Lemma 4.3 holds. From Lemma 3.2, we see that $F_\alpha(\Sigma, X) < 0$ implies that $F_\alpha(\Sigma_1, X_1) < 0$, where $X_1 := N_0^t X N_0$. Note that $S(X,Y,I) > 0$ is equivalent to

$$\begin{bmatrix} U_0^t & 0 \\ 0 & I \end{bmatrix} S(X,Y,I) \begin{bmatrix} U_0 & 0 \\ 0 & I \end{bmatrix} = \begin{bmatrix} X_{nn} & X_{nr} & N_0^t \\ X_{nr}^t & X_{rr} & R_0^t \\ N_0 & R_0 & Y \end{bmatrix} > 0,$$

where U_0 and other matrices are defined in the proof of Lemma 3.2. This implies $S(X_1, Y, N_0) > 0$ and thus the necessity is proved.

Conversely, suppose statement (i) of Lemma 4.4 holds. With $X_{nn} := X_1$, there exists X_{nr} satisfying (3.7) for some $\tilde{K}$ (its existence is guaranteed by $F_\alpha(\Sigma_1, X_1) < 0$). Then X defined by

$$X := U_0 \begin{bmatrix} X_{nn} & X_{nr} \\ X_{nr}^t & X_{rr} \end{bmatrix} U_0^t$$

satisfies $F_\alpha(\Sigma, X) < 0$ for any choice of X_{rr}. Moreover, by choosing $X_{rr} := \gamma I$ with sufficiently large $\gamma > 0$, condition $S(X, Y, I) > 0$ can be met. Thus statement (ii) of Lemma 4.3 holds. □

Applying Lemma 4.4 recursively, a necessary and sufficient condition for the uncertain system Σ_{of} to be QFM can be given in terms of the essential subsystems of Σ and $\hat{\Sigma}$.

LEMMA 4.5. *Consider the uncertain system Σ_{of} and its auxiliary systems Σ and $\hat{\Sigma}$ as given in* (4.5) *and* (4.6). *Let Σ_q and $\hat{\Sigma}_{\hat{q}}$ be the essential subsystems of Σ and $\hat{\Sigma}$, respectively. Then, the following statements are equivalent.*

(i) *The uncertain system Σ_{of} is QFM.*

(ii) *For each $\alpha > 0$, there exist $X_q^t = X_q > 0$ and $Y_{\hat{q}}^t = Y_{\hat{q}} > 0$ such that*

$$F_\alpha(\Sigma_q, X_q) < 0, \quad F_\alpha(\hat{\Sigma}_{\hat{q}}, Y_{\hat{q}}) < 0, \quad S(X_q, Y_{\hat{q}}, \hat{N}^t N) > 0\ ,$$

where N is defined in (3.2) *for Σ and $\hat{N}$ is similarly defined for $\hat{\Sigma}$.*

Proof. Recursively applying Lemma 4.4, we see that statement (i) holds if and only if, for each $\alpha > 0$, there exist $X_q^t = X_q > 0$ and $Y^t = Y > 0$ such that

$$F_\alpha(\Sigma_q, X_q) < 0, \quad F_\alpha(\hat{\Sigma}, Y) < 0, \quad S(X_q, Y, N) > 0.$$

The same argument as described in Lemma 4.4 can be applied for the dual part $\hat{\Sigma}$, leading to the condition in statement (ii). □

Now, we can prove Theorem 4.2.

Proof. We consider the conditions given in Lemma 4.5 for the four cases defined in Table 4.1.

Case 1: Since Σ_q and $\hat{\Sigma}_{\hat{q}}$ are both simple, then it follows from Lemma 2.4(a) that $F_\alpha(\Sigma_q, X_q) < 0$ and $F_\alpha(\hat{\Sigma}_{\hat{q}}, Y_{\hat{q}}) < 0$ are trivially satisfied for any positive definite symmetric X_q and $Y_{\hat{q}}$. Choosing $X_q := \gamma I$ and $Y_{\hat{q}} := \gamma I$ with sufficiently large $\gamma > 0$, the third condition in statement (ii) of Lemma 4.5 can be satisfied. Thus Σ_{of} is QFM.

Cases 2 *and* 3: Consider *Case* 2; *Case* 3 can be shown similarly. Since Σ_q is simple, $F_\alpha(\Sigma_q, X_q) < 0$ holds for any choice of $X_q^t = X_q > 0$. Choosing sufficiently large X_q, the condition $S(X_q, Y_{\hat{q}}, \hat{N}^t N) > 0$ can be met. Thus the system Σ_{of} is QFM if and only if, for each $\alpha > 0$, there exists $Y_{\hat{q}} > 0$ such that $F_\alpha(\hat{\Sigma}_{\hat{q}}, Y_{\hat{q}}) < 0$. This is exactly the condition for $\hat{\Sigma}$ to be QC.

Case 4: Since both Σ_q and $\hat{\Sigma}_{\hat{q}}$ are regular, we have $\hat{\mathcal{N}}^t \mathcal{N} = \hat{N}^t N$. Moreover, it follows from Lemma 5.1 in the appendix that the solutions $X_q(\alpha)$ and $Y_{\hat{q}}(\alpha)$ to $F_\alpha(\Sigma_q, X_q) < 0$ and $F_\alpha(\hat{\Sigma}_{\hat{q}}, Y_{\hat{q}}) < 0$ approach zero when α approaches infinity. Hence, $S(X_q, Y_{\hat{q}}, \hat{N}^t N) > 0$ holds for sufficiently large $\alpha > 0$ only if $\hat{N}^t N = 0$. Conversely, if this is true, condition $S(X_q, Y_{\hat{q}}, 0) > 0$ holds for any positive definite X_q and $Y_{\hat{q}}$, and hence we are left with requirements for Σ_q and $\hat{\Sigma}_{\hat{q}}$ to be QC. □

5. Conclusion. In this paper, we have given complete characterizations of quadratic controllability and strong controllability for a class of norm bounded uncertain linear systems in terms of the essential subsystem. Although the problem of quadratic controllability was already discussed in [18], our approach presented here is straightforward and aimed to include the notion of strong controllability and the case with dynamic output feedback, which are entirely new. The equivalence from the view point of quadratic controllability and strong controllability for the original system and its essential subsystem was derived. A closely related output feedback property was also discussed. Specifically, the necessary and sufficient condition was presented for the existence of a dynamic output feedback controller that quadratically stabilizes the closed-loop system with an arbitrary rate of convergence. However, the geometrical and physical implication of the orthogonal condition given in Theorem 4.2 still needs further investigation.

Appendix: A useful lemma. The following algebraic result is instrumental for proving the main theorems of the paper. A similar result was first used in [24].

LEMMA 5.1. *Let matrices A, $B = B^t$, and $C = C^t \geq 0$ be given. Suppose, for each $\alpha > 0$, there exists $X^t(\alpha) = X(\alpha) > 0$ such that*

$$(A + \alpha I)X(\alpha) + X(\alpha)(A + \alpha I)^t + X(\alpha)CX(\alpha) - B < 0. \tag{5.1}$$

Then,

$$\lim_{\alpha \to \infty} X(\alpha) = 0 \ \textit{ and } \ B \geq 0\,.$$

Proof. It follows readily from (5.1) that, since $C = C^t \geq 0$, we have

$$(A + \alpha I)X(\alpha) + X(\alpha)(A + \alpha I)^t - B < 0\,. \tag{5.2}$$

Suppose $\alpha^* > 0$ is chosen such that $-(A + \alpha I)$ is Hurwitz for all $\alpha \geq \alpha^*$. Then, for each $\alpha \geq \alpha^*$, there exists a unique symmetric solution $Y(\alpha)$ to the following Lyapunov equation:

$$-(A + \alpha I)Y(\alpha) - Y(\alpha)(A + \alpha I)^t + B = 0\,. \tag{5.3}$$

Substituting (5.3) into (5.2), we obtain

$$-(A + \alpha I)[Y(\alpha) - X(\alpha)] - [Y(\alpha) - X(\alpha)](A + \alpha I)^t < 0$$

for all $\alpha \geq \alpha^*$. Since the matrix $-(A + \alpha I)$ is Hurwitz for all $\alpha \geq \alpha^*$, it follows from the Lyapunov stability theory that

$$Y(\alpha) - X(\alpha) > 0 \ \forall \, \alpha \geq \alpha^*\,, \tag{5.4}$$

and this also implies that $Y(\alpha) > 0$ for all $\alpha \geq \alpha^*$. Moreover, we note that $Y(\alpha)$ is monotonically decreasing as α increases. This can be shown by utilizing the fact that $Y(\alpha)$ is analytic in the interval $[\alpha^*, \infty)$ and by taking the derivative of (5.3) with respect to α to obtain

$$-(A + \alpha I)Y^{'}(\alpha) - Y^{'}(\alpha)(A + \alpha I)^t - 2Y(\alpha) = 0\,. \tag{5.5}$$

Since $Y(\alpha) > 0$, (5.5) implies that $Y^{'}(\alpha) := \frac{dY(\alpha)}{d\alpha} < 0$ for $\alpha \geq \alpha^*$. This shows that $Y(\alpha)$ is a monotonically decreasing function; hence $\lim_{\alpha \to \infty} Y(\alpha)$ exists. Moreover, if we rewrite (5.3) as

$$-2\alpha Y(\alpha) = AY(\alpha) + Y(\alpha)A^t - B\,, \tag{5.6}$$

then we observe that since the right-hand side of the above equation has a limit, so must the term on the left-hand side. That is,

$$\Pi_\infty := \lim_{\alpha \to \infty} \alpha Y(\alpha)$$

exists, and this in turn implies that

$$\lim_{\alpha \to \infty} Y(\alpha) = 0 \quad \text{and} \quad \Pi_\infty \geq 0\,. \tag{5.7}$$

Now, it can be readily deduced from (5.4) that

$$\lim_{\alpha \to \infty} X(\alpha) = 0.$$

Furthermore, by taking the limit on both sides of (5.6) and utilizing (5.7), we obtain that $-2\Pi_\infty = -B$, which implies $B \geq 0$. This completes the proof. □

OPTIMAL CONTROL PROBLEMS WITH MIXED CONTROL-STATE CONSTRAINTS*

N. ARADA† AND J.-P. RAYMOND†

Abstract. We consider control problems governed by semilinear parabolic equations in the presence of pointwise mixed control-state constraints. We obtain optimality conditions with finitely additive measures as multipliers associated to the mixed constraints. We study the regularity of the multipliers for different problems. In particular, when a monotonicity or a separation condition is satisfied, we prove that multipliers are bounded measurable functions.

Key words. optimal control, mixed control-state constraints, pointwise constraints, regular multipliers

PII. S0363012999357926

1. Introduction.

This paper deals with control problems governed by parabolic equations in the presence of pointwise constraints on the control and the state variables. We are interested in optimality conditions for these problems, and in regularity properties of Lagrange multipliers associated with mixed control-state constraints. For optimization problems in Banach spaces the regularity of the multipliers is, in general, deduced from the following heuristic statement.

> (HS) The Lagrange multiplier associated with a constraint belongs to the dual space of the space in which the constraint set has a nonempty interior (or a finite codimension).

For bounded controls, pointwise mixed control-state constraints are well posed in an L^∞-space. Thus, according to (HS), the corresponding Lagrange multiplier must belong to a dual space of the form $(L^\infty)'$.

In some situations this heuristic statement does not give the best regularity result for the Lagrange multipliers. Let us give an example. The multiplier corresponding to pointwise state constraints is, in general, a bounded Radon measure [7], [10], [15], [12]. Indeed, pointwise state constraints are well posed in the space of continuous functions. For problems considered in [7], [15], the multiplier associated with a state constraint of the form $y \geq 0$ is a Radon measure. If the previous state constraint is slightly perturbed and is replaced by the control-state constraint $y + \varepsilon v \geq 0$ (with $\varepsilon > 0$ and $v \geq 0$), then the multiplier may be a bounded measurable function (see Corollary 5.6). This is clearly a better regularity result than the one derived from (HS).

This kind of result is known since 1962 for the control of ordinary differential equations, and is stated in [14]. The case of ordinary differential equations is very specific since it is often assumed that optimal controls are piecewise continuous [14], [11]. Even under the assumption of piecewise continuous controls, the "informal" Theorem 4.1 in [11] has not, to the authors' knowledge, been proved fully in the literature (see [11, p. 185]).

The situation is more complicated for partial differential equations. Indeed, in this case, it is not realistic to assume that optimal controls are piecewise continuous. Very recently, using a duality method, Bergounioux and Tröltzsch [5] have proved the existence of regular Lagrange multipliers for a linear control problem with constraints of bottleneck type. An extension to the case of semilinear equations is obtained in [6]. The case of integral control-state constraints is studied in [8].

To our knowledge, there are no general optimality conditions for control problems governed by partial differential equations in the presence of pointwise mixed control-state constraints. In this paper we first prove optimality conditions for control problems with constraints of the form

$$g(y,v) \in \mathcal{C} \subset (L^\infty)^\ell \qquad \text{(mixed control-state constraints)}$$

(in this setting $g = (g_1, \dots, g_\ell)$ is a vector valued function). In section 3, we do not make any particular assumption on mixed state-control constraints, and the corresponding multiplier belongs to a space of the type $((L^\infty)^\ell)'$ (Theorem 3.1). In sections 4 and 5, we prove the existence of regular Lagrange multipliers in the following cases:

- $\ell = 1$ and $(g'_v(y,v))^{-1}$ belongs to L^∞ (Theorem 4.1),
- mixed control-state constraints of the form

$$g_i(y,v) \le 0 \quad \text{for } i = 1, \dots, \ell \qquad \text{(Theorems 5.2, 5.5, 5.7).}$$

Let us denote by $\bar{\zeta}_i$ the multiplier of the constraint $g_i(y,v) \le 0$ corresponding to a solution $(\bar{y},\bar{v})$ of problem $(\mathcal{P})$. (The control problem $(\mathcal{P})$ is defined in section 1.1.) With optimality conditions and the Hahn–Banach extension theorem, we first establish that the sum $\Sigma_{i=1}^{\ell} g'_{iv}(\bar{y},\bar{v})\bar{\zeta}_i$ has the same regularity as the adjoint state.

In section 5.1 we study the case when $\ell = 2$ and when (g_1, g_2) satisfies a separation condition of the form $g_1(\bar{y},\bar{v}) + g_2(\bar{y},\bar{v}) \le -\varepsilon < 0$. We are able to prove that the supports of $\bar{\zeta}_1$ and $\bar{\zeta}_2$ are disjoints. We deduce that each multiplier has the same regularity as the adjoint state, and we use a bootstrap argument to obtain the best regularity result (Theorem 5.2).

In section 5.2 we suppose that g satisfies a monotonicity condition of the form $g'_{iv}(y,v) \le 0$ for $i = 1, \dots, \ell$. We prove that, for $i = 1, \dots, \ell$, the additive measures $g'_{iv}(\bar{y},\bar{v})\bar{\zeta}_i$ are nonnegative. With a decomposition theorem for nonnegative additive measures, we prove that each term $g'_{iv}(\bar{y},\bar{v})\bar{\zeta}_i$ has the same regularity as the adjoint state, and we can conclude with a bootstrap argument (Theorem 5.5).

In section 5.3 we study a problem in which the separation and monotonicity conditions are coupled (Theorem 5.7). These results are applied to examples for which the regularity of multipliers cannot be deduced from results known in the literature.

The separation condition seems to be new (see Remark 5.1). The monotonicity condition is similar to regularity conditions stated for the control of ordinary differential equations (condition (b) in [4]).

For clarity, we consider only the case of a boundary control, but our method can be extended to problems with distributed and boundary controls. Our method is general and may be extended to other problems.

1.1. Setting of the control problem.

Consider the semilinear parabolic equation

$$(1.1)\ \frac{\partial y}{\partial t} + Ay + \Phi(\cdot,y) = 0 \ \text{ in } Q, \quad \frac{\partial y}{\partial n_A} + \Psi(\cdot,y,v) = 0 \ \text{ on } \Sigma, \quad y(0) = y_o \ \text{ in } \Omega,$$

where Ω is a bounded domain in $\mathbb{R}^N$, $Q = \Omega \times]0, T[$, $\Sigma = \Gamma \times]0, T[$, Γ is the boundary of Ω, $T > 0$, $v \in L^\infty(\Sigma)$ is a boundary control, A is a second order elliptic operator, Φ and Ψ are Carathéodory functions (assumptions are specified in section 1.2), and y_o is a fixed function in $C(\overline{\Omega})$. Constraints of the form

$$g(\cdot, y(\cdot), v(\cdot)) \in \mathcal{C} \tag{1.2}$$

are imposed on the pair (y, v), where g is a continuous mapping from $\overline{\Sigma} \times \mathbb{R}^2$ into $\mathbb{R}^\ell$, and $\mathcal{C}$ is a closed convex subset of $(L^\infty(\Sigma))^\ell$ with a nonempty interior in $(L^\infty(\Sigma))^\ell$. The paper is concerned with the control problem

$$(\mathcal{P}) \qquad \inf\{J(y, v) \mid \quad (y, v) \in C(\overline{Q}) \times L^\infty(\Sigma), \quad (y, v) \text{ satisfies (1.1) and (1.2)}\},$$

where the cost functional is given by

$$J(y, v) = \int_Q F(x, t, y)\, dx\, dt + \int_\Sigma G(s, t, y, v)\, ds\, dt + \int_\Omega L(x, y(T))\, dx.$$

Let us give a simple example for which results of the paper may be applied. Consider the state equation

$$\frac{\partial y}{\partial t} - \Delta y = 0 \text{ in } Q, \quad \frac{\partial y}{\partial n} + |y|^3 y = v \text{ on } \Sigma, \quad y(0) = y_o \text{ in } \Omega,$$

with $y_o \geq 0$, $v \geq 0$, and the functional $J(y, v) = \int_\Omega a(x)|y(x, T) - y_d(x)|^2 dx + \int_\Sigma y^4(s, t)\, dsdt$. The nonnegative function a plays the role of a weight, y_d is a desired profile of temperature, and the term $\int_\Sigma y^4(s, t)\, dsdt$ may be interpreted as a term penalizing a too-high temperature on the boundary. In the above radiation boundary condition, the control v corresponds to y^4_{ext}, where y_{ext} is the exterior temperature. In industrial processes it may be important that the difference $y^4_{ext} - y^4$ be bounded from above. Thus a constraint of the form $0 \leq v \leq y^4 + c$ on Σ, with $c > 0$, is meaningful. Setting $g_1(y, v) = v - |y|^3 y - c$, $g_2(y, v) = -v$, the above constraint is equivalent to $g(y, v) = (g_1(y, v), g_2(y, v)) \in \mathcal{C}$, where $\mathcal{C} = \{z \in (L^\infty(\Sigma))^2 \mid z \leq 0\}$ ($z \leq 0$ must be understood componentwise). The existence of solutions for the corresponding problem $(\mathcal{P})$ can be obtained by standard arguments. In Corollary 5.3 we obtain optimality conditions for a class of problems including this example, with multipliers belonging to $L^\infty(\Sigma)$. In our knowledge, the existence of bounded measurable multipliers for this example cannot be deduced from known results in the literature. Examples of constraints for which we obtain the same results are given in section 5. Other examples of equations and functionals satisfying the assumptions of the paper are given in [15].

1.2. Assumptions and notation. We suppose that Ω is of class C^2 (the boundary Γ of Ω is an $(N-1)$-dimensional manifold of class C^2 such that Ω lies locally on one side of Γ). The operator A is of the form

$$Ay(x) = -\sum_{i,j=1}^N D_i(a_{ij}(x) D_j y(x))$$

(D_i denotes the partial derivative with respect to x_i), with coefficient a_{ij} belonging to $C^1(\overline{\Omega})$ and satisfying the conditions

$$a_{ij}(x) = a_{ji}(x) \quad \text{for all } \ i, j \in \{1, \ldots, N\}, \qquad m_0|\xi|^2 \leq \sum_{i,j=1}^N a_{ij}(x)\xi_i\xi_j$$

for every $\xi \in \mathbb{R}^N$ and every $x \in \overline{\Omega}$, with $m_0 > 0$. The conormal derivate of y with respect to A is denoted by $\frac{\partial y}{\partial n_A}$, that is

$$\frac{\partial y}{\partial n_A}(s,t) = \sum_{i,j} a_{ij}(s) D_j y(s,t) n_i(s),$$

where $n = (n_1, \ldots, n_N)$ is the unit normal to Γ outward Ω.

To prove the existence of multipliers in $(L^k(\Sigma))^\ell$ we need some regularity assumptions on the data. They are specified below. Some of them depend on k. Observe that $k = \infty$ is allowed (see (A3)–(A5) below). Throughout the text, the exponent k denotes a given fixed exponent belonging to $]1, \infty]$.

(A1) Φ is a Carathéodory function from $Q \times \mathbb{R}$ into $\mathbb{R}$. For almost every $(x,t) \in Q$, $\Phi(x,t,\cdot)$ is of class C^1. The following estimates hold:

$$|\Phi(x,t,0)| \le \eta(|y|), \qquad C_o \le \Phi'_y(x,t,y) \le \eta(|y|),$$

where $C_o \in \mathbb{R}$ and η is a nondecreasing function from $\mathbb{R}^+$ into $\mathbb{R}^+$.

(A2) Ψ is a Carathéodory function from $\Sigma \times \mathbb{R}^2$ into $\mathbb{R}$. For almost every $(s,t) \in \Sigma$, $\Psi(s,t,\cdot)$ is of class C^1, and it satisfies

$$\begin{aligned} &|\Psi(s,t,0,v)| + |\Psi'_v(s,t,y,v)| \le \eta(|y|)\ \eta(|v|), \\ &C_o \le \Psi'_y(s,t,y,v) \le \eta(|y|)\ \eta(|v|). \end{aligned}$$

(A3) F is a Carathéodory function from $Q \times \mathbb{R}$ into $\mathbb{R}$. For almost all $(x,t) \in Q$, $F(x,t,\cdot)$ is of class C^1. The following estimates hold:

$$|F(x,t,y)| \le F_1(x,t)\eta(|y|), \qquad |F'_y(x,t,y)| \le F_2(x,t)\eta(|y|),$$

where $F_1 \in L^1(Q)$, $F_2 \in L^{k_1}(Q)$, with $k_1 > \frac{(N+2)k}{N+1+2k}$ if $k < \infty$, and $k_1 > \frac{N}{2} + 1$ if $k = \infty$.

(A4) G is a Carathéodory function from $\Sigma \times \mathbb{R}^2$ into $\mathbb{R}$. For almost all $(s,t) \in \Sigma$, $G(s,t,\cdot)$ is of class C^1. The following estimates hold:

$$\begin{aligned} &|G(s,t,y,v)| \le G_1(s,t)\eta(|y|)\eta(|v|), \qquad |G'_v(s,t,y,v)| \le G_2(s,t)\eta(|y|)\eta(|v|), \\ &|G'_y(s,t,y,v)| \le G_3(s,t)\eta(|y|)\eta(|v|), \end{aligned}$$

where $G_1 \in L^1(\Sigma)$, $G_2 \in L^k(\Sigma)$, with $1 < k \le \infty$, $G_3 \in L^{k_2}(\Sigma)$ with $k_2 > \frac{(N+1)k}{N+1+k}$ if $k < \infty$, and $k_2 > N+1$ if $k = \infty$.

(A5) L is a Carathéodory function from $\Omega \times \mathbb{R}$ into $\mathbb{R}$. For almost all $x \in \Omega$, $L(x,\cdot)$ is of class C^1, and

$$|L(x,y)| \le L_1(x)\eta(|y|), \qquad |L'_y(x,y)| \le L_2(x)\eta(|y|),$$

where $L_1 \in L^1(\Omega)$, $L_2 \in L^{k_3}(\Omega)$, with $k_3 > \frac{Nk}{N+1}$ if $k < \infty$, and $k_3 = \infty$ if $k = \infty$.

(A6) g is a function from $\overline{\Sigma} \times \mathbb{R}^2$ into $\mathbb{R}^\ell$. For every $(s,t) \in \overline{\Sigma}$, $g(s,t,\cdot)$ is of class C^1, and for every $y \in \mathbb{R}$, $g(\cdot,y)$ is bounded measurable on Σ. The functions g, g'_y, and g'_v are bounded on compact subsets of $\overline{\Sigma} \times \mathbb{R}^2$.

For simplicity, we often write $g(y,v)$ in place of $g(s,t,y,v)$. We set $\overline{\Omega}_0 = \overline{\Omega} \times \{0\}$, $\overline{\Omega}_T = \overline{\Omega} \times \{T\}$, $\Gamma_T = \Gamma \times \{T\}$. For every $1 \le r \le \infty$, the usual norms in the spaces $L^r(\Omega)$, $L^r(Q)$, $L^r(\Sigma)$ will be denoted by $||\cdot||_{r,\Omega}$, $||\cdot||_{r,Q}$, $||\cdot||_{r,\Sigma}$. The Hilbert space

$W(0,T;H^1(\Omega),(H^1(\Omega))') = \{y \in L^2(0,T;H^1(\Omega)) \mid \frac{dy}{dt} \in L^2(0,T;(H^1(\Omega))')\}$ will be denoted by $W(0,T)$. Throughout what follows, we denote by C a generic constant. If $\mathcal{O}$ is a locally compact subset of $\mathbb{R}^{N+1}$, $C_b(\mathcal{O})$ denotes the space of bounded continuous functions on $\mathcal{O}$, and $C_0(\mathcal{O})$ denotes the space of continuous functions vanishing at infinity. The dual space of $C_0(\mathcal{O})$ will be denoted by $\mathcal{M}_b(\mathcal{O})$ (the space of bounded Radon measures on $\mathcal{O}$). If μ belongs to $\mathcal{M}_b(\mathcal{O})$ and y belongs to $C_b(\mathcal{O})$, we set $\langle \mu, y\rangle_{b,\mathcal{O}} = \int_{\mathcal{O}} y\, d\mu$. For $\sigma > 1$, $k \wedge \sigma$ stands for $\min(k,\sigma)$. For simplicity, $\langle \cdot,\cdot\rangle_{*,\Sigma}$ stands for the duality pairing between the spaces $((L^\infty(\Sigma))^\ell)'$ and $(L^\infty(\Sigma))^\ell$.

2. State and adjoint equations. We begin this section by recalling some existence, uniqueness, and regularity results concerning the state equation (1.1).

DEFINITION 2.1. *A function $y \in L^2(0,T;H^1(\Omega)) \cap C([0,T];L^2(\Omega))$ is a weak solution of* (1.1) *if and only if $\Phi(\cdot,y(\cdot)) \in L^1(Q)$, $\Psi(\cdot,y(\cdot),v(\cdot)) \in L^1(\Sigma)$, and*

$$\int_Q \left(-y\frac{\partial z}{\partial t} + \sum_{i,j=1}^N a_{ij} D_i y D_j z + \Phi(\cdot,y)z \right) dx\,dt - \int_\Omega y_o z(0)\,dx$$
$$= \;-\int_\Sigma \Psi(\cdot,y,v)z\,ds\,dt \qquad \text{for all } z \in C^1(\overline{Q}) \text{ such that } z(T)=0.$$

THEOREM 2.2 (see [16, Theorem 3.1]). *Let us suppose that* (A1)–(A2) *are satisfied. Equation* (1.1) *admits a unique weak solution $y_v \in W(0,T)\cap C(\overline{Q})$ satisfying*

$$\|y_v\|_{C(\overline{Q})} \le C(\|v\|_{\infty,\Sigma} + \|y_o\|_{C(\overline{\Omega})} + 1).$$

Now, let us recall some existence, uniqueness, and regularity results for the adjoint equation. Let (a,b) be in $L^\infty(Q)\times L^\infty(\Sigma)$, and consider the terminal boundary value problem

$$(2.1)\quad \frac{\partial p}{\partial t} + Ap + ap = \mu_Q \quad \text{in } Q, \qquad \frac{\partial p}{\partial n_A} + bp = \mu_\Sigma \quad \text{on } \Sigma, \qquad p(T) = \mu_{\overline{\Omega}_T} \quad \text{on } \overline{\Omega},$$

where $\mu = \mu_Q + \mu_\Sigma + \mu_{\overline{\Omega}_T}$ is a bounded Radon measure on $\overline{Q}\setminus\overline{\Omega}_0$, μ_Q is the restriction of μ to Q, μ_Σ is the restriction of μ to Σ, and $\mu_{\overline{\Omega}_T}$ is the restriction of μ to $\overline{\Omega}_T$.

DEFINITION 2.3. *A function $p \in L^1(0,T;W^{1,1}(\Omega))$ is a weak solution of* (2.1) *if and only if*

$$\int_Q \left(p\frac{\partial z}{\partial t} + \sum_{i,j=1}^N a_{ij} D_j p D_i z + azp \right) dxdt + \int_\Sigma bpz\,dsdt = \langle \mu, z\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0}$$

for all $z \in C^1(\overline{Q})$ satisfying $z(0)=0$ on $\overline{\Omega}$.

We recall an existence theorem for parabolic equations with measures as data.

THEOREM 2.4 (see [15, Theorem 4.1]). *Let (a,b) be in $L^\infty(Q)\times L^\infty(\Sigma)$, and let μ be in $\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)$. Equation* (2.1) *admits a unique solution p in $L^1(0,T;W^{1,1}(\Omega))$. For every (δ,d,β) satisfying $\delta \ge 1$, $d \ge 1$, $\beta \ge 0$, and $\frac{N}{2d} + \frac{1}{\delta} > \frac{N}{2} + \frac{\beta}{2}$, p belongs to $L^\delta(0,T;W^{\beta,d}(\Omega))$ and*

$$||p||_{L^\delta(0,T;W^{\beta,d}(\Omega))} \le C||\mu||_{\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)},$$

where $C \equiv C(\Omega, T, \delta, d, M)$ is a positive constant independent of a and b, and M is an upper bound for $||a||_{\infty,Q} + ||b||_{\infty,\Sigma}$. In particular, the trace of p on Σ satisfies

$$||p_{|\Sigma}||_{L^\sigma(\Sigma)} \leq C||\mu||_{\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)} \qquad \text{for every } 1 \leq \sigma < \frac{N+1}{N}.$$

Moreover, there exists a function in $L^1(\Omega)$, denoted by $p(0)$, such that

$$\int_Q \left(\frac{\partial z}{\partial t} + Az + az\right) p\,dx\,dt + \int_\Sigma \left(\frac{\partial z}{\partial n_A} + bz\right) p\,ds\,dt + \int_\Omega z(0)p(0)\,dx$$
$$= \langle \mu, z\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} \qquad \text{for all } z \in \mathcal{Y},$$

where $\mathcal{Y} = \{y \in W(0,T) \mid \frac{\partial y}{\partial t} + Ay \in L^q(Q),\ \frac{\partial y}{\partial n_A} \in L^\infty(\Sigma),\ y(0) \in C(\overline{\Omega})\}$.

Proposition 2.5. *Set $\Lambda(\mu_Q, \mu_\Sigma, \mu_{\overline{\Omega}_T}) = p_{|\Sigma}$, where p is the solution of* (2.1) *corresponding to $(\mu_Q, \mu_\Sigma, \mu_{\overline{\Omega}_T})$. The mapping $\mu_Q \mapsto \Lambda(\mu_Q, 0, 0)$ is continuous from $L^{\beta_1}(Q)$ into $L^\beta(\Sigma)$, with $\beta_1 > \frac{(N+2)\beta}{N+1+2\beta}$ if $1 \leq \beta < \infty$, and $\beta_1 > \frac{N}{2} + 1$ if $\beta = \infty$. The mapping $\mu_\Sigma \mapsto \Lambda(0, \mu_\Sigma, 0)$ is continuous from $L^{\beta_2}(\Sigma)$ into $L^\beta(\Sigma)$, with $\beta_2 > \frac{(N+1)\beta}{N+1+\beta}$ if $1 \leq \beta < \infty$, and $\beta_2 > N+1$ if $\beta = \infty$.*

The mapping $\mu_{\overline{\Omega}_T} \mapsto \Lambda(0, 0, \mu_{\overline{\Omega}_T})$ is continuous from $L^{\beta_3}(\Omega)$ into $L^\beta(\Sigma)$, with $\beta_3 > \frac{N\beta}{N+1}$ if $1 \leq \beta < \infty$, and $\beta_3 = \infty$ if $\beta = \infty$.

In particular, $p_{|\Sigma}$ belongs to $L^k(\Sigma)$ if $(\mu_Q, \mu_\Sigma, \mu_{\overline{\Omega}_T})$ belongs to $L^{k_1}(Q) \times L^{k_2}(\Sigma) \times L^{k_3}(\Omega)$, where k, k_1, k_2, and k_3 are the exponents in assumptions (A3)–(A5).

Proof. The proof may be performed by using estimates on the analytic semigroup as in [17], Propositions 3.1 and 3.2. □

3. Main results.

Define the Hamiltonian function $\mathcal{H} : \Sigma \times \mathbb{R}^4 \longrightarrow \mathbb{R}$ by

$$\mathcal{H}(s,t,y,v,p,\alpha) = \alpha\ G(s,t,y,v) + p\ \Psi(s,t,y,v).$$

We shall say that $(\bar{y}, \bar{v})$ is regular if there exists $\widehat{v} \in L^\infty(\Sigma)$ such that

$$g(\bar{y},\bar{v}) + g'_y(\bar{y},\bar{v})(z_{\widehat{v}} - z_{\bar{v}}) + g'_v(\bar{y},\bar{v})(\widehat{v} - \bar{v}) \in \text{int } \mathcal{C}, \tag{3.1}$$

where z_v (with $v = \hat{v}$ or $v = \bar{v}$) is the solution of

$$\begin{cases} \dfrac{\partial z}{\partial t} + Az + \Phi'_y(\cdot,\bar{y})z = 0 & \text{in Q}, \\ \dfrac{\partial z}{\partial n_A} + \Psi'_y(\cdot,\bar{y},\bar{v})z = -\Psi'_v(\cdot,\bar{y},\bar{v})\ v & \text{on } \Sigma, \qquad z(0) = 0 \text{ in } \Omega. \end{cases} \tag{3.2}$$

In (3.1) "int" denotes the interior for the topology of $(L^\infty(\Sigma))^\ell$. The qualification condition (3.1) is of Mangasarian–Fromowitz type. It appears in [19, (3.6), p. 20].

Theorem 3.1. *Suppose that* (A1)–(A6) *are fulfilled. If $(\bar{y}, \bar{v})$ is a solution of $(\mathcal{P})$, then there exist $\bar{\alpha} \in [0,1]$, $\bar{\zeta} \in ((L^\infty(\Sigma))^\ell)'$, and $\bar{p} \in L^1(0,T;W^{1,1}(\Omega))$, such that the following conditions hold.*

- *Nontriviality condition* :

$$(\bar{\alpha}, \bar{\zeta}) \neq 0. \tag{3.3}$$

- *Complementarity condition*:

$$\langle \bar{\zeta}, z - g(\bar{y},\bar{v})\rangle_{*,\Sigma} \leq 0 \qquad \text{for all } z \in \mathcal{C}. \tag{3.4}$$

- *Adjoint equation*:

$$(3.5)\qquad \begin{cases} -\dfrac{\partial \bar p}{\partial t} + A\bar p + \Phi'_y(\cdot,\bar y)\bar p = -\bar\alpha F'_y(\cdot,\bar y) & \textit{in } Q,\\[2mm] \dfrac{\partial \bar p}{\partial n_A} + \Psi'_y(\cdot,\bar y,\bar v)\bar p = -\bar\alpha\ G'_y(\cdot,\bar y,\bar v) - [g'_y(\bar y,\bar v)^*\bar\zeta]_{|\Sigma} & \textit{on } \Sigma,\\[2mm] \bar p(T) = -\bar\alpha L'_y(\cdot,\bar y(T)) - [g'_y(\bar y,\bar v)^*\bar\zeta]_{|\Gamma\times\{T\}} & \textit{on } \overline{\Omega}, \end{cases}$$

where $[g'_y(\bar y,\bar v)^*\bar\zeta]_{|\Sigma}$ *is the restriction of* $g'_y(\bar y,\bar v)^*\bar\zeta$ *to* Σ*,* $[g'_y(\bar y,\bar v)^*\bar\zeta]_{|\Gamma\times\{T\}}$ *is the restriction of* $g'_y(\bar y,\bar v)^*\bar\zeta$ *to* $\Gamma\times\{T\}$*, and* $g'_y(\bar y,\bar v)^*\bar\zeta$ *is the bounded Radon measure on* $\Sigma\cup(\Gamma\times\{T\})$ *defined by*

$$\langle g'_y(\bar y,\bar v)^*\bar\zeta, z\rangle_{b,\Sigma\cup\Gamma\times\{T\}} = \langle\bar\zeta, g'_y(\bar y,\bar v)z\rangle_{*,\Sigma} \qquad \textit{for all } z\in C_0(\Sigma\cup(\Gamma\times\{T\})).$$

- *Optimality condition for* $\bar v$:

$$(3.6)\quad \int_\Sigma \mathcal{H}'_v(s,t,\bar y,\bar v,\bar p,\bar\alpha)\chi\,ds\,dt + \langle\bar\zeta, g'_v(\bar y,\bar v)\ \chi\rangle_{*,\Sigma} = 0 \quad \textit{for all}\ \ \chi\in L^\infty(\Sigma).$$

Moreover, if there exists $\widehat v$ *satisfying* (3.1)*, then we can take* $\bar\alpha = 1$.

Remark 3.2. Here $g'_y(\bar y,\bar v)$ is a linear continuous operator from $C_0(\Sigma\cup(\Gamma\times\{T\}))$ into $(L^\infty(\Sigma))^\ell$, and $g'_y(\bar y,\bar v)^*$ denotes the corresponding adjoint operator.

Proof. Let us set

$$\begin{aligned} \mathcal{A} = \{(z,\lambda)\in(L^\infty(\Sigma))^\ell\times\mathbb{R} \mid\ & z = g(\bar y,\bar v) + g'_y(\bar y,\bar v)(z_v - z_{\bar v}) + g'_v(\bar y,\bar v)(v-\bar v),\\ & \lambda = J'_y(\bar y,\bar v)\ (z_v - z_{\bar v}) + J'_v(\bar y,\bar v)(v-\bar v) \ \text{ for some }\ v\in L^\infty(\Sigma)\},\\ \mathcal{B} = \text{int }\mathcal{C}\times&]-\infty,0[, \end{aligned}$$

where $z_{\bar v}$ (respectively, z_v) is the solution of (3.2) corresponding to $\bar v$ (respectively, v). The sets $\mathcal{A}$ and $\mathcal{B}$ are convex, and $\mathcal{B}$ is open. Let us prove that $\mathcal{A}\cap\mathcal{B}=\emptyset$. Argue by contradiction, and suppose that there exists $v_o\in L^\infty(\Sigma)$ such that

$$(3.7)\qquad g(\bar y,\bar v) + g'_y(\bar y,\bar v)(z_{v_o} - z_{\bar v}) + g'_v(\bar y,\bar v)(v_o-\bar v)\in\text{int }\mathcal{C},$$

$$(3.8)\qquad \lambda_o = J'_y(\bar y,\bar v)\ (z_{v_o} - z_{\bar v}) + J'_v(\bar y,\bar v)(v_o-\bar v) < 0.$$

Set $v_\rho = \bar v + \rho(v_o - \bar v)$. Let y_ρ be the solution of (1.1) corresponding to v_ρ, and set $g_\rho = g(\bar y,\bar v) + \frac{1}{\rho}(g(y_\rho,v_\rho) - g(\bar y,\bar v))$. Due to (3.7) and (3.8), there exists $0<\rho_o<1$ such that

$$g_\rho\in\text{int }\mathcal{C} \quad\text{and}\quad \frac{J(y_\rho,v_\rho)-J(\bar y,\bar v)}{\rho} < 0 \quad\text{for all } 0<\rho\le\rho_o<1.$$

Therefore, for every $0<\rho\le\rho_o<1$, we have

$$g(y_\rho,v_\rho) = \rho\ g_\rho + (1-\rho)\ g(\bar y,\bar v)\in\ \text{int }\mathcal{C}\ \text{ and }\ J(y_\rho,v_\rho) < J(\bar y,\bar v) = \inf(\mathcal{P}).$$

The pair (y_ρ,v_ρ) is admissible for $(\mathcal{P})$ and we have a contradiction. Thus, $\mathcal{A}\cap\mathcal{B}=\emptyset$. From a geometric version of the Hahn–Banach theorem (the Eidelheit theorem [18]), there exists $(\bar\alpha,\bar\zeta)\in\mathbb{R}\times((L^\infty(\Sigma))^\ell)'$, such that

$$(3.9)\qquad \bar\alpha\ \lambda_1 + \langle\bar\zeta,z_1\rangle_{*,\Sigma} > \bar\alpha\ \lambda_2 + \langle\bar\zeta,z_2\rangle_{*,\Sigma}\ \text{ for all } (z_1,\lambda_1,z_2,\lambda_2)\in\mathcal{A}\times\mathcal{B},$$

$$\bar\alpha\ \lambda_1 + \langle\bar\zeta, z_1\rangle_{*,\Sigma} \geq \bar\alpha\ \lambda_2 + \langle\bar\zeta, z_2\rangle_{*,\Sigma} \quad \text{for all } (z_1,\lambda_1,z_2,\lambda_2) \in \mathcal{A}\times\overline{\mathcal{B}}. \tag{3.10}$$

- Due to (3.9), $(\bar\alpha,\bar\zeta) \neq 0$. We easily see that $\bar\alpha$ is nonnegative. Indeed if $\bar\alpha < 0$, setting $z_1 = g(\bar y,\bar v)$, $\lambda_1 = 0$, and letting λ_2 tend to $-\infty$, we obtain a contradiction. Thus $\bar\alpha$ is nonnegative. For z fixed in $\mathcal{C}$, by setting $z_1 = g(\bar y,\bar v)$, $z_2 = z$, $\lambda_1 = \lambda_2 = 0$ in (3.10), we establish (3.4).
- Let $v \in L^\infty(\Sigma)$. By setting $z_1 = g(\bar y,\bar v) + g'_y(\bar y,\bar v)(z_v - z_{\bar v}) + g'_v(\bar y,\bar v)(v-\bar v)$, $\lambda_1 = J'_y(\bar y,\bar v)\ (z_v - z_{\bar v}) + J'_v(\bar y,\bar v)(v-\bar v)$, $z_2 = g(\bar y,\bar v)$, and $\lambda_2 = 0$ in (3.10), we obtain

$$\begin{aligned}&\bar\alpha J'_y(\bar y,\bar v)\ (z_v - z_{\bar v}) + \langle g'_y(\bar y,\bar v)^*\bar\zeta, z_v - z_{\bar v}\rangle_{b,\Sigma\cup\Gamma_T}\\ &+ \bar\alpha J'_v(\bar y,\bar v)(v-\bar v) + \langle\bar\zeta, g'_v(\bar y,\bar v)(v-\bar v)\rangle_{*,\Sigma} \geq 0 \quad \text{for all } v \in L^\infty(\Sigma).\end{aligned} \tag{3.11}$$

Since the above inequality is satisfied for all $v \in L^\infty(\Sigma)$, the inequality can be replaced by an equality. Let $\bar p$ be the weak solution of (3.5). With the Green formula of Theorem 2.4, we have

$$\begin{aligned}&\int_Q \bar\alpha\ F'_y(x,t,\bar y)\ (z_v - z_{\bar v})\,dx\,dt + \int_\Omega \bar\alpha\ L'_y(x,\bar y(T))\ (z_v - z_{\bar v})(T)\,dx\\ &+\int_\Sigma \bar\alpha\ G'_y(s,t,\bar y,\bar v)\ (z_v - z_{\bar v})\,ds\,dt + \langle g'_y(\bar y,\bar v)^*\bar\zeta, z_v - z_{\bar v}\rangle_{b,\Sigma\cup\Gamma_T}\\ &= \int_\Sigma \bar p\ \Psi'_v(s,t,\bar y,\bar v)\ (v-\bar v)\,ds\,dt \quad \text{for all } v\in L^\infty(\Sigma).\end{aligned}$$

This equality together with (3.11) gives (3.6).

- Finally, if there exists $\widehat v \in L^\infty(\Sigma)$ such that (3.1) is satisfied, then by setting $z_1 = z_2 = g(\bar y,\bar v) + g'_y(\bar y,\bar v)(z_{\widehat v} - z_{\bar v}) + g'_v(\bar y,\bar v)(\widehat v - \bar v)$ in (3.9), we prove that $\bar\alpha \neq 0$. □

4. Regularity of multipliers for purely mixed constraints. Throughout what follows, $(\bar y,\bar u)$ stands for an optimal solution to $(\mathcal{P})$. In the following two sections, we want to prove that the multiplier $\bar\zeta$ may be identified with $\bar\eta\,dsdt$, where $\bar\eta$ belongs to $(L^k(\Sigma))^\ell$. In this case, (3.3)–(3.6) are rewritten in the form

$$(\bar\alpha,\bar\eta)\neq 0, \qquad \int_\Sigma \bar\eta\ (z - g(\bar y,\bar v))\,ds\,dt \leq 0 \qquad \text{for all } z\in\mathcal{C}, \tag{4.1}$$

$$\begin{cases} -\dfrac{\partial\bar p}{\partial t} + A\bar p + \Phi'_y(\cdot,\bar y)\bar p = -\bar\alpha F'_y(\cdot,\bar y) & \text{in } Q,\\ \dfrac{\partial\bar p}{\partial n_A} + \Psi'_y(\cdot,\bar y,\bar v)\bar p = -\bar\alpha G'_y(\cdot,\bar y,\bar v) - g'_y(\bar y,\bar v)^*\bar\eta & \text{on } \Sigma,\\ \bar p(T) = -\bar\alpha L'_y(\cdot,\bar y(T)) & \text{on } \Omega,\end{cases} \tag{4.2}$$

$$\mathcal{H}'_v(s,t,\bar y(s,t),\bar v(s,t),\bar p(s,t),\bar\alpha) = -g'_v(\bar y,\bar v)^*\bar\eta(s,t) \qquad \text{for almost all } (s,t)\in\Sigma. \tag{4.3}$$

In this section, we consider the control problem $(\mathcal{P})$ when $\ell = 1$ and when the following regularity condition is satisfied.

(A7) $\ell = 1$ and the function $(g'_v(\bar y(\cdot),\bar v(\cdot)))^{-1}$ belongs to $L^\infty(\Sigma)$.

THEOREM 4.1. *Let $(\bar y,\bar v)$ be a solution to $(\mathcal{P})$. Suppose that* (A1)–(A7) *are fulfilled. There exist $\bar\alpha\in[0,1]$, $\bar\eta\in L^k(\Sigma)$ (k is the exponent in assumption* (A3)*),* *and* $\bar{p} \in L^1(0,T;W^{1,1}(\Omega))$*, such that* (4.1)–(4.3) *hold. Moreover, if* (3.1) *is satisfied, then we can take* $\bar{\alpha} = 1$.

Proof. Step 1. Due to Theorem 3.1, there exist $\bar{\alpha} \in [0,1]$, $\bar{\zeta} \in (L^\infty(\Sigma))'$, and $\bar{p} \in L^1(0,T;W^{1,1}(\Omega))$, such that (3.3)–(3.6) hold. From Proposition 2.5, we know that

$$\bar{p}_{|\Sigma} \in L^\sigma(\Sigma) \qquad \text{for all } \sigma < \frac{N+1}{N}. \tag{4.4}$$

Let σ be such that $\sigma < \frac{N+1}{N}$. From (4.4), with assumptions (A2) and (A4), we can easily see that $\mathcal{H}'_v(\cdot,\bar{y},\bar{v},\bar{p},\bar{\alpha})$ belongs to $L^{k\wedge\sigma}(\Sigma)$. Consider the continuous linear operators $\mathcal{S} : L^{(k\wedge\sigma)'}(\Sigma) \mapsto \mathbb{R}$ ($(k\wedge\sigma)'$ is the exponent conjugate to $k\wedge\sigma$) and $\mathcal{K} : L^\infty(\Sigma) \mapsto \mathbb{R}$, defined by

$$\mathcal{S}(\varphi) = -\int_\Sigma \mathcal{H}'_v(s,t,\bar{y},\bar{v},\bar{p},\bar{\alpha})\ \varphi\, ds\, dt \qquad \text{for all } \varphi \in L^{(k\wedge\sigma)'}(\Sigma),$$
$$\mathcal{K}(\chi) = \langle \bar{\zeta}, g'_v(\bar{y},\bar{v})\ \chi\rangle_{*,\Sigma} \qquad \text{for all } \chi \in L^\infty(\Sigma).$$

The optimality condition (3.6) can be rewritten as $\mathcal{S}(\chi) = \mathcal{K}(\chi)$ for all $\chi \in L^\infty(\Sigma)$. Due to the Hahn–Banach extension theorem, there exists $\bar{\mu} \in L^{k\wedge\sigma}(\Sigma)$ such that

$$\int_\Sigma \bar{\mu}\ \chi\, ds\, dt = \langle \bar{\zeta}, g'_v(\bar{y},\bar{v})\ \chi\rangle_{*,\Sigma} \qquad \text{for all } \chi \in L^\infty(\Sigma). \tag{4.5}$$

Moreover, we have

$$\int_\Sigma \bar{\mu}\ \varphi\, ds\, dt = \mathcal{S}(\varphi) \qquad \text{for all } \varphi \in L^{(k\wedge\sigma)'}(\Sigma).$$

If we set $\bar{\eta} = g'_v(\bar{y},\bar{v})^{-1}\ \bar{\mu}$, due to assumption (A7), $\bar{\eta}$ belongs to $L^{k\wedge\sigma}(\Sigma)$, and (4.5) is equivalent to the following equation:

$$\int_\Sigma \bar{\eta}\chi\, ds\, dt = \langle \bar{\zeta}, \chi\rangle_{*,\Sigma} \qquad \text{for all } \chi \in L^\infty(\Sigma). \tag{4.6}$$

The complementarity condition, the adjoint equation, and the optimality condition for $\bar{v}$ follow from (3.4), (3.5), (3.6), and (4.6). Let us prove the nontriviality condition. If $\bar{\alpha} \neq 0$, the proof is complete. If $\bar{\alpha} = 0$, then due to (3.3) we have $\bar{\zeta} \neq 0$, and from (4.6) it follows that $\bar{\eta} \neq 0$.

Step 2. Let us prove that $\bar{\eta}$ belongs to $L^k(\Sigma)$. Let σ_1 be such that $1 < \sigma_1 < \frac{N+1}{N}$. Due to step 1 and assumption (A6) the function $g'_y(\bar{y},\bar{v})\bar{\eta}$ belongs to $L^{k\wedge\sigma_1}(\Sigma)$. From Assumptions (A3)–(A5) and from Proposition 2.5, it follows that $\bar{p}_{|\Sigma}$ belongs to $L^{\sigma_2}(\Sigma)$ for all σ_2 satisfying

$$\sigma_1 < \sigma_2 \qquad \text{and} \qquad \frac{N+1}{2\sigma_1} < \frac{N+1}{2\sigma_2} + \frac{1}{2}. \tag{4.7}$$

Let σ_2 satisfy (4.7). From the regularity of $p_{|\Sigma}$, we deduce that $\mathcal{H}'_v(\cdot,\bar{y},\bar{v},\bar{p},\bar{\alpha})$ belongs to $L^{k\wedge\sigma_2}(\Sigma)$. From (4.3), it follows that $g'_v(\bar{y},\bar{v})\bar{\eta}$ belongs to $L^{k\wedge\sigma_2}(\Sigma)$. With (A7), we deduce that $\bar{\eta}$ belongs to $L^{k\wedge\sigma_2}(\Sigma)$, and with (A6) that $g'_y(\bar{y},\bar{v})\bar{\eta}$ belongs to $L^{k\wedge\sigma_2}(\Sigma)$ for all σ_2 satisfying (4.7). After a finite number of iterations, we can prove that $\bar{\eta}$ belongs to $L^k(\Sigma)$. The proof is complete. □

Remark 4.2. Let us observe that (3.1) can be easily verified when $\mathcal{C} = \{z \in L^\infty(\Sigma) \mid z \le 0\}$, and Ψ is of the form $\Psi(\cdot, y, v) = \psi(\cdot, y) - v$. For $\varepsilon > 0$, let us set $w_\varepsilon = \bar v - \varepsilon g'_v(\bar y, \bar v)^{-1} + g'_v(\bar y, \bar v)^{-1} g'_y(\bar y, \bar v) z_{\bar v}$. Let ξ_ε be the solution to the equation

$$\begin{aligned}
&\frac{\partial \xi}{\partial t} + A\xi + \Phi'_y(\cdot, \bar y)\xi = 0 \quad \text{ in } Q,\\
&\frac{\partial \xi}{\partial n_A} + \psi'_y(\cdot, \bar y)\xi + g'_v(\bar y, \bar v)^{-1} g'_y(\bar y, \bar v)\xi = w_\varepsilon \quad \text{ on } \Sigma, \qquad \xi(0) = 0 \quad \text{ in } \Omega.
\end{aligned}$$

It is clear that ξ_ε is the solution of (3.2) corresponding to $\widehat v = \bar v - \varepsilon g'_v(\bar y, \bar v)^{-1} - g'_v(\bar y, \bar v)^{-1} g'_y(\bar y, \bar v)(\xi_\varepsilon - z_{\bar v})$, which yields to

$$g(\bar y, \bar v) + g'_y(\bar y, \bar v)(z_{\hat v} - z_{\bar v}) + g'_v(\bar y, \bar v)^{-1}(\widehat v - \bar v) = -\varepsilon + g(\bar y, \bar v) \le -\varepsilon.$$

Therefore, the pair $(\widehat v, z_{\hat v})$ satisfies the condition (3.1). In this case, we can set $\bar\alpha = 1$ in the statement of Theorem 4.1.

5. Other regularity results.

In this section, we are concerned with problem $(\mathcal{P})$ when $\mathcal{C} = (\{z \in L^\infty(\Sigma) \mid z \le 0\})^\ell$. In this case, (4.1) is equivalent to

$$(5.1) \qquad (\bar\alpha, \bar\eta) \ne 0, \qquad \bar\eta \ge 0, \qquad \int_\Sigma \bar\eta \; g(\bar y, \bar v)\, ds\, dt = 0.$$

In section 5.1, we suppose that $\ell = 2$ and g satisfies the following separation condition.

(A8) There exists $\varepsilon > 0$ such that $g_1(\bar y, \bar v) + \varepsilon \le -g_2(\bar y, \bar v)$ almost everywhere (a.e.) on Σ. Moreover, we suppose that, for $i = 1, 2$, $(g'_{iv}(\bar y(\cdot), \bar v(\cdot)))^{-1}$ belongs to $L^\infty(\Sigma)$.

Remark 5.1. In examples studied in section 5 (Corollary 5.3 and examples in section 5.3), we are able to verify the qualification condition (3.1) by using both the separation condition and the properties of the state equation. But the separation condition is of a different nature since it gives the regularity of the multipliers (which is not the case of condition (3.1)), and in general it does not give optimality conditions in qualified form (which is the case of condition (3.1)).

With (A8) we are able to prove that the supports of the multipliers associated with the two constraints are disjoint. To prove such a result, we use the isomorphism between $(L^\infty(\Sigma))'$ and the space of bounded Radon measures on $\Sigma^\#$, where $\Sigma^\#$ is a compact Hausdorff space [9].

In section 5.2, we suppose that g satisfies a monotonicity condition of the following form.

(A9) For $i = 1, \ldots, \ell$, $g'_{iv}(\bar y, \bar v) \ge 0$ a.e. on Σ, and $(g'_{iv}(\bar y(\cdot), \bar v(\cdot)))^{-1}$ belongs to $L^\infty(\Sigma)$.

In this case, the regularity of multipliers follows from properties of nonnegative additive measures, and from the Radon–Nikodym theorem.

In section 5.3, we study a problem where the above separation and monotonicity conditions are coupled.

5.1. Regularity of multipliers with a separation assumption.

THEOREM 5.2. *Let* $(\bar y, \bar v)$ *be a solution to* $(\mathcal{P})$. *Suppose that* (A1)–(A6) *and* (A8) *are fulfilled. Then, there exist* $\bar\alpha \in [0, 1]$, $\bar\eta \in (L^k(\Sigma))^2$, *and* $\bar p \in L^1(0, T; W^{1,1}(\Omega))$ *satisfying* (4.2), (4.3), *and* (5.1). *If, in addition,* $\widehat v$ *satisfies* (3.1), *then we can take* $\bar\alpha = 1$.

Recall that k is the exponent introduced in the introduction. It is known that $(L^\infty(\Sigma))'$ can be identified with the space of bounded finitely additive measures vanishing on zero-measure sets [20, Theorem 2.3]. Below we identify $(L^\infty(\Sigma))'$ with $\mathcal{M}(\Sigma^\#)$, the space of Radon measures on $\Sigma^\#$, where $\Sigma^\#$ is a compact Hausdorff space. This identification is useful to characterize the supports of elements of $(L^\infty(\Sigma))'$.

Proof. *Step* 1. Due to Theorem 3.1, there exist $\bar\alpha \in [0,1]$, $\bar\zeta = (\bar\zeta_1, \bar\zeta_2) \in ((L^\infty(\Sigma))')^2$, and $\bar p \in L^1(0,T;W^{1,1}(\Omega))$ such that (3.3)–(3.6) hold. Condition (3.4) may be rewritten as

$$(5.2)\quad \bar\zeta_i \geq 0 \text{ and } \langle \bar\zeta_i, g_i(\bar y, \bar v)\rangle_{*,\Sigma} = \max\ \{\langle \bar\zeta_i, z\rangle_{*,\Sigma} \mid z \in \mathcal{C}\} = 0 \quad \text{for } i = 1,2.$$

Step 2. Let us denote by S_o the closed unit sphere of $(L^\infty(\Sigma))'$ (for the weak-star topology), and let us set

$$\Sigma^\# = \{q \in S_o \mid q \neq 0,\ \langle q, h\rangle_{*,\Sigma} = \langle q, f\rangle_{*,\Sigma}\ \langle q, g\rangle_{*,\Sigma} \ \text{ if } h = g\ f \text{ a.e. on } \Sigma\}.$$

It is well known [9, Theorem 11, p. 445] that $\Sigma^\#$ is a compact Hausdorff space. Moreover, there exists an isometric homomorphism τ from $L^\infty(\Sigma)$ onto $C(\Sigma^\#)$. The isomorphism τ maps nonnegative functions into nonnegative functions and is an algebraic isomorphism in the sense that if $\chi = \chi_1\ \chi_2$ a.e. on Σ, then $\tau(\chi) = \tau(\chi_1)\tau(\chi_2)$. If f is an arbitrary real continuous function, and χ is in $L^\infty(\Sigma)$, then $\tau(f(\chi)) = f(\tau(\chi))$. Hence, for $i = 1,2$, the measure $\bar\zeta_i \in (L^\infty(\Sigma))'$ can be identified with $\widehat{\bar\zeta}_i \in \mathcal{M}(\Sigma^\#)$ (the space of Radon measures on $\Sigma^\#$), via the formula

$$\langle \widehat{\bar\zeta}_i, \psi\rangle_{\Sigma^\#} = \langle \bar\zeta_i, \tau^{-1}(\psi)\rangle_{*,\Sigma} \quad \text{for all} \ \ \psi \in C(\Sigma^\#),$$

where $\langle\cdot,\cdot\rangle_{\Sigma^\#}$ denotes the duality pairing between $\mathcal{M}(\Sigma^\#)$ and $C(\Sigma^\#)$, and where τ^{-1} is the inverse mapping of τ. (For more details see [2].)

Let us prove that under the separation condition (A8), the supports of $\widehat{\bar\zeta}_1$ and $\widehat{\bar\zeta}_2$ (denoted by supp $\widehat{\bar\zeta}_i$) are disjoint. The condition (5.2) is rewritten as

$$\widehat{\bar\zeta}_i \geq 0 \quad \text{and} \quad \langle \widehat{\bar\zeta}_i, \tau(g_i(\bar y, \bar v))\rangle_{\Sigma^\#} = 0 \ \text{ for } i = 1,2.$$

Let us set $\Sigma_i = \{q \in \Sigma^\# \mid \tau(g_i(\bar y, \bar v))(q) = \langle\ q, g_i(\bar y, \bar v)\ \rangle_{*,\Sigma} = 0\}$. Since the mapping $q \mapsto \tau(g_i(\bar y, \bar v))(q)$ is continuous for the weak-star topology of $(L^\infty(\Sigma))'$, Σ_i is closed for this topology. Therefore we have

$$(5.3)\qquad \mathrm{supp}\widehat{\bar\zeta}_i \subset \Sigma_i.$$

On the other hand, due to the positivity property of τ and due to (A8), we have

$$(5.4)\ \tau(g_1(\bar y, \bar v))\ (q) - \varepsilon = \tau(g_1(\bar y, \bar v) - \varepsilon)\ (q) \leq \tau(g_2(\bar y, \bar v))\ (q) \qquad \text{for all } q \in \Sigma^\#.$$

From (5.3) and (5.4), we deduce that supp $\widehat{\bar\zeta}_1 \cap \mathrm{supp}\ \widehat{\bar\zeta}_2 = \emptyset$.

Step 3. Now, let us establish the regularity of $g_v'(\bar y, \bar v)^*\bar\zeta$. First, notice that (3.6) can be stated in the form

$$\int_\Sigma \mathcal{H}_v'(\cdot, \bar y, \bar v, \bar p, \bar\alpha)\chi\, ds\, dt + \langle \widehat{\bar\zeta}_1, \tau(g_{1v}'(\bar y, \bar v))\ \tau(\chi)\rangle_{\Sigma^\#} + \langle \widehat{\bar\zeta}_2, \tau(g_{2v}'(\bar y, \bar v))\ \tau(\chi)\rangle_{\Sigma^\#} = 0$$

for all $\chi \in L^\infty(\Sigma)$. Consider the linear operators $\mathcal{S} : L^{(k\wedge\sigma)'}(\Sigma) \mapsto \mathbb{R}$ and $\mathcal{K} : L^\infty(\Sigma) \mapsto \mathbb{R}$ defined by

$$\mathcal{S}(\varphi) = -\int_\Sigma \mathcal{H}'_v(\cdot, \bar{y}, \bar{v}, \bar{p}, \bar{\alpha})\ \varphi\, ds\, dt \qquad \text{for all } \varphi \in L^{(k\wedge\sigma)'}(\Sigma),$$

$$\mathcal{K}(\chi) = \langle \widehat{\bar{\zeta}}_1, \tau(g'_{1v}(\bar{y}, \bar{v}))\ \tau(\chi)\rangle_{\Sigma^\#} + \langle \widehat{\bar{\zeta}}_2, \tau(g'_{2v}(\bar{y}, \bar{v}))\ \tau(\chi)\rangle_{\Sigma^\#} \quad \text{for all } \chi \in L^\infty(\Sigma).$$

With arguments similar to those of Theorem 4.1, we can prove the existence of a function $\mu \in L^{k\wedge\sigma}(\Sigma)$ satisfying

$$\langle \widehat{\bar{\zeta}}_1, \tau(g'_{1v}(\bar{y}, \bar{v}))\ \tau(\chi)\rangle_{\Sigma^\#} + \langle \widehat{\bar{\zeta}}_2, \tau(g'_{2v}(\bar{y}, \bar{v}))\ \tau(\chi)\rangle_{\Sigma^\#} = \int_\Sigma \mu\ \chi\, ds\, dt \tag{5.5}$$

for all $\chi \in L^\infty(\Sigma)$. Since supp $\widehat{\bar{\zeta}}_1$ and supp $\widehat{\bar{\zeta}}_2$ are two disjoint compact subsets of $\Sigma^\#$, there exists $\psi_o \in C(\Sigma^\#)$, such that

$$0 \le \psi_o \le 1, \quad \psi_o \equiv 1 \quad \text{on supp } \widehat{\bar{\zeta}}_1, \quad \text{and} \quad \psi_o \equiv 0 \quad \text{on supp } \widehat{\bar{\zeta}}_2.$$

Letting $\tilde{\chi}$ be in $L^\infty(\Sigma)$ and setting $\chi_1 = \tau^{-1}(\psi_o)\ \tilde{\chi}$ and $\chi_2 = (1 - \psi_o)\ \tilde{\chi}$ in (5.5), we obtain

$$\langle \bar{\zeta}_i, g'_{iv}(\bar{y}, \bar{v})\tilde{\chi}\rangle_{*,\Sigma} = \langle \widehat{\bar{\zeta}}_i, \tau(g'_{iv}(\bar{y}, \bar{v}))\ \tau(\tilde{\chi})\rangle_{\Sigma^\#} = \int_\Sigma \bar{\mu}_i\ \tilde{\chi}\, ds\, dt \tag{5.6}$$

for $i = 1, 2$, with $\bar{\mu}_1 = \mu\ \tau^{-1}(\psi_o)$ and $\bar{\mu}_2 = \mu\ \tau^{-1}(1 - \psi_o)$. It is clear that $\bar{\mu}_1$ and $\bar{\mu}_2$ belong to $L^{k\wedge\sigma}(\Sigma)$ for all $\sigma < \frac{N+1}{N}$. Let us set $\bar{\eta}_i = (g'_{iv}(\bar{y}, \bar{v}))^{-1}\bar{\mu}_i$ for $i = 1, 2$. We have proved that (4.2), (4.3), and (5.1) are satisfied with $\bar{\eta} = (\bar{\eta}_1, \bar{\eta}_2) \in L^{k\wedge\sigma}(\Sigma)$. We conclude with a bootstrap process as in step 2 of the proof of Theorem 4.1. □

Consider the following example:

$$(\mathcal{P}_1) \qquad \inf\{J(y, v) \mid\ v \in L^\infty(\Sigma),\ (y, v) \text{ satisfies (1.1) and } 0 \le v \le \gamma(y) + c\},$$

where Ψ is of the form $\Psi(\cdot, y, v) = \psi(\cdot, y) - v$. It is a particular case of $(\mathcal{P})$ corresponding to $g_1(s, t, y, v) = v - \gamma(s, t, y) - c(s, t)$ and $g_2(y, v) = -v$. We suppose that c belongs to $L^\infty(\Sigma)$, and γ is defined either by $\gamma(s, t, y) = b(s, t)y$, or by $\gamma(s, t, y) = \phi(y)$, where b belongs to $L^\infty(\Sigma)$, $b \ge 0$, and ϕ is a nondecreasing function of class C^1.

COROLLARY 5.3. *Let $(\bar{y}, \bar{v})$ be a solution of $(\mathcal{P}_1)$, and suppose that* (A1)–(A5) *are fulfilled. Suppose in addition that there exists $\varepsilon > 0$ such that*

$$\gamma(\bar{y}) + c \ge \varepsilon \qquad a.e.\ on\ \Sigma. \tag{5.7}$$

Then, there exist $\bar{\eta} \in (L^k(\Sigma))^2$ and $\bar{p} \in L^1(0, T; W^{1,1}(\Omega))$, such that (4.2), (4.3), *and* (5.1) *are satisfied with $\bar{\alpha} = 1$.*

Remark 5.4. Observe that if $y_o \ge 0$, then $\bar{y} \ge 0$. If ϕ is nonnegative on $\mathbb{R}^+$ and if $c \ge \varepsilon$, then condition (5.7) is satisfied. The case when $\gamma(s, t, y) = b(s, t)y$ is studied in [6]. The proof in [6] is based on duality techniques. Here it is a direct consequence of Theorem 5.2.

Proof. The separation condition (A8) is nothing else than (5.7). Therefore, due to Theorem 5.2, we can state optimality conditions in nonqualified form. To prove the corollary, we have only to check that there exists $\hat{v} \in L^\infty(\Sigma)$ such that (3.1) is satisfied. If $\gamma(s,t,y) = b(s,t)y$, we set $\beta = b$, and if $\gamma(s,t,y) = \phi(y)$, we set $\beta = \phi'(\bar y)$. Therefore $\beta \geq 0$. For $\lambda > 0$, we set $w_\lambda = \bar v - \lambda\varepsilon - \beta z_{\bar v}$. Let ξ_λ be the solution to

$$\frac{\partial \xi}{\partial t} + A\xi + \bar\Phi'_y\,\xi = 0 \ \text{ in } Q, \quad \frac{\partial \xi}{\partial n_A} + \bar\psi'_y\,\xi - \beta\xi = w_\lambda \ \text{ on } \Sigma, \quad \xi(0) = 0 \ \text{ in } \Omega,$$

where $\bar\Phi'_y = \Phi'_y(\cdot,\bar y)$ and $\bar\psi'_y = \psi'_y(\cdot,\bar y)$. Observe that $\xi_\lambda = z_{\tilde v_\lambda}$ is the solution of (3.2) for $\widetilde v_\lambda = \bar v - \lambda\varepsilon + \beta(\xi_\lambda - z_{\bar v})$, and

$$-\beta(z_{\tilde v_\lambda} - z_{\bar v}) + \tilde v_\lambda - \bar v = -\lambda\varepsilon. \tag{5.8}$$

By making the difference between the equation satisfied by $z_{\bar v}$ and the equation satisfied by ξ_λ, we can prove that

$$\xi_\lambda = z_{\tilde v_\lambda} \leq z_{\bar v} \quad \text{and} \quad ||z_{\tilde v_\lambda} - z_{\bar v}||_{C(\overline{Q})} \leq C\lambda\varepsilon. \tag{5.9}$$

By combining (5.9) and (5.8), we prove that there exists a constant $\bar C > 0$ such that

$$||\widetilde v_\lambda - \bar v||_{\infty,\Sigma} \leq \bar C\ \lambda\varepsilon. \tag{5.10}$$

Set $\Sigma_0 = \{(s,t) \in \Sigma \mid \bar v = 0\}$, $\Sigma_\lambda = \{(s,t) \in \Sigma \mid 0 < \bar v \leq 2\bar C\lambda\varepsilon\}$, and let χ_λ (respectively, χ_0) be the characteristic function of Σ_λ (respectively, Σ_0). Set $\widehat v_\lambda = \lambda\varepsilon\chi_0 + (\bar v + \lambda\varepsilon)\chi_\lambda + \widetilde v_\lambda(1 - \chi_0 - \chi_\lambda)$. We claim that the pair $(z_{\hat v_\lambda}, \widehat v_\lambda)$ satisfies (3.1) for λ small enough.

- On $\Sigma_0 \cup \Sigma_\lambda$, we have $\widehat v_\lambda \geq \lambda\varepsilon > 0$. Due to (5.10), on $\Sigma \setminus (\Sigma_0 \cup \Sigma_\lambda)$ we have $\widehat v_\lambda = \widetilde v_\lambda \geq \bar v - |\widetilde v_\lambda - \bar v| \geq \bar C\lambda\varepsilon$. Thus we have $\widehat v_\lambda \geq \min(\lambda\varepsilon, \bar C\lambda\varepsilon)$.
- With (5.10) we obtain

$$||z_{\hat v_\lambda} - z_{\tilde v_\lambda}||_{C(\overline{Q})} \leq C||(\bar v - \widetilde v_\lambda + \lambda\varepsilon)(\chi_\lambda + \chi_0)||_{\infty,\Sigma} \leq C\lambda\varepsilon.$$

Now, from (5.9) we deduce $||z_{\hat v_\lambda} - z_{\bar v}||_{C(\overline{Q})} \leq ||z_{\hat v_\lambda} - z_{\tilde v_\lambda}||_{C(\overline{Q})} + ||z_{\tilde v_\lambda} - z_{\bar v}||_{C(\overline{Q})} \leq C\lambda\varepsilon$. Due to (5.7), we have

$$\bar v - \gamma(\bar y) - c - \beta(z_{\hat v_\lambda} - z_{\bar v}) + (\widehat v_\lambda - \bar v) \leq 2\bar C\lambda\varepsilon - \varepsilon - \beta(z_{\hat v_\lambda} - z_{\bar v}) + \lambda\varepsilon \ \text{ on } \Sigma_0 \cup \Sigma_\lambda.$$

Therefore, we can choose $\lambda > 0$ small enough to have

$$\bar v - \gamma(\bar y) - c - \beta(z_{\hat v_\lambda} - z_{\bar v}) + (\widehat v_\lambda - \bar v) \leq -\frac{\varepsilon}{2} \qquad \text{on } \Sigma_0 \cup \Sigma_\lambda.$$

Since $\tilde v_\lambda = -\lambda\varepsilon + \beta(z_{\tilde v_\lambda} - z_{\bar v}) < 0$ on Σ_0 (because of (5.9)), we have $\widehat v_\lambda - \tilde v_\lambda \geq 0$ on $\Sigma \setminus \Sigma_\lambda$. Hence if ζ_λ is the solution to (3.2) for $v = (\widehat v_\lambda - \tilde v_\lambda)\chi_\lambda = (\bar v + \lambda\varepsilon - \tilde v_\lambda)\chi_\lambda$, we have $z_{\hat v_\lambda} - z_{\tilde v_\lambda} \geq \zeta_\lambda$, and $||\zeta_\lambda||_{C(\overline{Q})} \leq C||(\bar v + \lambda\varepsilon - \tilde v_\lambda)\chi_\lambda||_{r,\Sigma} \leq C\lambda\varepsilon\ \mathcal{L}^N(\Sigma_\lambda)^{\frac{1}{r}}$, with $r > N+1$, and $\mathcal{L}^N(\Sigma_\lambda)$ is the Lebesgue measure of Σ_λ. With (5.8) and the bound for ζ_λ, we have the following estimate on $\Sigma \setminus (\Sigma_0 \cup \Sigma_\lambda)$:

$$\begin{aligned} &\bar v - \gamma(\bar y) - c - \beta(z_{\hat v_\lambda} - z_{\bar v}) + (\widehat v_\lambda - \bar v) \leq -\beta(z_{\tilde v_\lambda} - z_{\bar v}) + (\widetilde v_\lambda - \bar v) - \beta(z_{\hat v_\lambda} - z_{\tilde v_\lambda}) \\ &\leq -\lambda\varepsilon + ||\beta||_{\infty,\Sigma}\ ||\zeta_\lambda||_{\infty,\Sigma} \leq -\lambda\varepsilon + C\lambda\varepsilon\ \mathcal{L}^N(\Sigma_\lambda)^{\frac{1}{r}}. \end{aligned}$$

Since $-\lambda\varepsilon + C\lambda\varepsilon\ \mathcal{L}^N(\Sigma_\lambda)^{\frac{1}{r}} < -\frac{1}{2}\lambda\varepsilon$ for $\lambda > 0$ small enough, the proof is complete. □

5.2. Regularity of multipliers with a monotonicity assumption.

THEOREM 5.5. *Let* $(\bar y, \bar v)$ *be a solution of* $(\mathcal{P})$*. Suppose that* (A1)–(A6) *and* (A9) *are fulfilled. Then, there exist* $\bar\alpha \in [0,1]$, $\bar\eta \in (L^k(\Sigma))^\ell$, *and* $\bar p \in L^1(0,T;W^{1,1}(\Omega))$*), such that conditions* (4.2), (4.3), *and* (5.1) *are satisfied.*

Proof. Due to Theorem 3.1, there exist $\bar\alpha \in [0,1]$, $\bar\zeta = (\bar\zeta_1, \ldots, \bar\zeta_\ell) \in ((L^\infty(\Sigma))^\ell)'$, and $\bar p \in L^1(0,T;W^{1,1}(\Omega))$ such that (3.3)–(3.6) hold. With arguments similar to those of the proof of Theorem 5.2, we show that

$$\bar\zeta_i \geq 0, \quad \langle \bar\zeta_i, g_i(\bar y, \bar v)\rangle_{*,\Sigma} = 0 \qquad \text{for all } i = 1, \ldots, \ell. \tag{5.11}$$

Moreover, as in the proof of Theorem 4.1, with the Hahn–Banach extension theorem, we can establish the existence of a multiplier $\bar\mu$ belonging to $L^{k\wedge\sigma}(\Sigma)$ for all $\sigma < \frac{N+1}{N}$, such that

$$\langle g'_v(\bar y, \bar v)^* \bar\zeta, \chi\rangle_{*,\Sigma} = \int_\Sigma \bar\mu\, \chi\, ds\, dt \qquad \text{for all } \chi \in L^\infty(\Sigma).$$

Due to (A9), for $i = 1, \ldots, \ell$, the additive measures $g'_{iv}(\bar y, \bar v)^* \bar\zeta_i$ are nonnegative. From a decomposition theorem for nonnegative finitely additive measures [9, Theorem 8, p. 163], we deduce that $g'_{iv}(\bar y, \bar v)^* \bar\zeta_i$ admits a unique decomposition

$$g'_{iv}(\bar y, \bar v)^* \bar\zeta_i = \bar\mu_i + \bar\nu_i,$$

where $\bar\mu_i$ are nonnegative countably additive measures, and $\bar\nu_i$ are nonnegative purely finitely additive set functions in $(L^\infty(\Sigma))'$. It follows that

$$g'_v(\bar y, \bar v)^* \bar\zeta = \sum_{i=1}^{\ell} \bar\mu_i + \sum_{i=1}^{\ell} \bar\nu_i = \bar\mu \;\; ds\, dt.$$

Thus, the pair $(\Sigma_{i=1}^{\ell} \bar\mu_i, \Sigma_{i=1}^{\ell} \bar\nu_i)$ is a decomposition of $\bar\mu\, dsdt$ in a nonnegative countably additive measure and a nonnegative purely finitely additive set function. From the uniqueness of this decomposition, we deduce that $\bar\nu_i = 0$. Since $\bar\mu_i \geq 0$ for $i = 1, \ldots, \ell$, $\Sigma_{i=1}^{\ell} \bar\mu_i = \bar\mu\, dsdt$, and $\bar\mu$ belongs to $L^{k\wedge\sigma}(\Sigma)$ for all $\sigma < \frac{N+1}{N}$, there exist nonnegative functions $\xi_i \in L^{k\wedge\sigma}(\Sigma)$ such that $\bar\mu_i = \xi_i\, ds\, dt$ (it is a consequence of the Radon–Nikodym theorem). We set $\bar\eta_i = (g'_{iv}(\bar y, \bar u))^{-1} \xi_i$. We have

$$\langle g'_{iv}(\bar y, \bar v)^* \bar\zeta_i, \chi\rangle_{*,\Sigma} = \int_\Sigma \xi_i\, \chi\, ds\, dt = \int_\Sigma g'_{iv}(\bar y, \bar v) \bar\eta_i\, \chi\, ds\, dt$$

for all $\chi \in L^\infty(\Sigma)$. Thus, (4.2), (4.3), and (5.1) are satisfied with $\bar\eta = (\bar\eta_1, \ldots, \bar\eta_\ell) \in (L^{k\wedge\sigma}(\Sigma))^\ell$. We finish with a bootstrap argument as in the proof of Theorem 4.1. □

Consider the following example.

$$(\mathcal{P}_2) \;\; \inf\{J(y,v) \mid \; v \in L^\infty(\Sigma),\; (y,v) \text{ satisfies (1.1)},\; v \leq \gamma_i(y) + c_i \;\text{ for } i = 1, \ldots, \ell\},$$

where Ψ is of the form $\Psi(\cdot, y, v) = \psi(\cdot, y) - v$. It is a particular case of $(\mathcal{P})$ corresponding to $g_i(y,v) = v - \gamma_i(y) - c_i$ for $i = 1, \ldots, \ell$. We suppose that c_i belongs to $L^\infty(\Sigma)$, and γ_i is defined either by $\gamma_i(s,t,y) = b_i(s,t)y$, or by $\gamma_i(s,t,y) = \phi_i(y)$, where b_i belongs to $L^\infty(\Sigma)$, and ϕ_i is of class C^1.

COROLLARY 5.6. *Let* $(\bar y, \bar v)$ *be a solution of* $(\mathcal{P}_2)$*. Suppose that* (A1)–(A5) *are fulfilled. Then there exist* $\bar\eta \in (L^k(\Sigma))^\ell$ *and* $\bar p \in L^1(0,T;W^{1,1}(\Omega))$*), such that* (4.2), (4.3)*, and* (5.1) *are satisfied with* $\bar\alpha = 1$.

Proof. The assumptions of Theorem 5.5 are clearly satisfied. We have only to check that we can take $\bar{\alpha} = 1$. If $\gamma_i(s,t,y) = b_i(s,t)y$, we set $\beta_i = b_i$, and if $\gamma_i(s,t,y) = \phi_i(y)$, we set $\beta_i = \phi_i'(\bar{y})$. For $\lambda > 0$ and $i = 1, \dots, \ell$, we set $w_{i\lambda} = \bar{v} - \lambda\varepsilon - \beta_i z_{\bar{v}}$. Let ξ_λ be the solution to

$$\begin{aligned} &\frac{\partial \xi}{\partial t} + A\xi + \Phi_y'(\cdot,\bar{y})\xi = 0 && \text{in } Q, \\ &\frac{\partial \xi}{\partial n_A} + \psi_y'(\cdot,\bar{y})\xi = \min_{i=1,\dots,\ell}(w_{i\lambda} + \beta_i \xi) \quad \text{on } \Sigma, && \xi(0) = 0 \text{ in } \Omega. \end{aligned} \tag{5.12}$$

Since the function "min" is Lipschitz with respect to its arguments, the existence of a solution to (5.12) may be proved as in [16] (see also [6] where the same trick is used). Observe that ξ_λ is the solution of (3.2) corresponding to $\widetilde{v}_\lambda = \min_{i=1,\dots,\ell}(w_{i\lambda} + \beta_i\xi)$, that is, $\xi_\lambda = z_{\widetilde{v}_\lambda}$. Moreover,

$$\bar{v} - \gamma_i(\bar{y}) - c_i + (\widetilde{v}_\lambda - \bar{v}) - \beta_i(z_{\widetilde{v}_\lambda} - z_{\bar{v}}) \leq (\widetilde{v}_\lambda - \bar{v}) - \beta_i(z_{\widetilde{v}_\lambda} - z_{\bar{v}}) \leq -\lambda\varepsilon$$

for $i = 1, \dots, \ell$. Thus (3.1) is satisfied by $(\widetilde{v}_\lambda, z_{\widetilde{v}_\lambda})$. □

5.3. Coupling separation and monotonicity conditions. In this section we study a problem for which the monotonicity and separation conditions are coupled. We suppose that $\ell = 3$ and that $g = (g_1, g_2, g_3)$ satisfies the assumption below.

(A10) There exists $\varepsilon > 0$ such that $g_1(\bar{y},\bar{v}) + \varepsilon \leq -g_2(\bar{y},\bar{v})$ and $g_3(\bar{y},\bar{v}) + \varepsilon \leq -g_2(\bar{y},\bar{v})$ a.e. on Σ. The pair $(g_1(\bar{y},\bar{v}), g_3(\bar{y},\bar{v}))$ satisfies the monotonicity condition stated in (A9). The function $(g_{2v}'(\bar{y}(\cdot),\bar{v}(\cdot)))^{-1}$ belongs to $L^\infty(\Sigma)$.

The case of bottleneck type constraints studied in [5], [6] falls into this setting (see Remark 5.8). We prove the existence of regular multipliers when (A10) is fulfilled. At the end of the section we give two examples for which optimality conditions are obtained in qualified form (that is, $\bar{\alpha} = 1$). The existence of regular multipliers for these examples cannot be deduced from [6].

THEOREM 5.7. *Let $(\bar{y},\bar{u})$ be a solution to (P). Suppose that* (A1)–(A6) *and* (A10) *are fulfilled. Then, there exist $\bar{\alpha} \in [0,1]$, $\bar{\eta} \in (L^k(\Sigma))^3$, and $\bar{p} \in L^1(0,T;W^{1,1}(\Omega))$, such that* (4.2), (4.3)*, and* (5.1) *are satisfied. If, in addition, $\widehat{v}$ satisfies* (3.1)*, then we can take $\bar{\alpha} = 1$.*

Proof. Due to Theorem 3.1, there exist $\bar{\alpha} \in [0,1]$, $\bar{\zeta} \in ((L^\infty(\Sigma))^3)'$, and $\bar{p} \in L^1(0,T;W^{1,1}(\Omega))$ such that (3.3)–(3.6) are satisfied. In particular, the condition (3.4) is equivalent to

$$\bar{\zeta}_i \geq 0 \qquad \text{and} \qquad \langle \bar{\zeta}_i, g_i(\bar{y},\bar{v})\rangle_{*,\Sigma} = 0 \tag{5.13}$$

for $i = 1, 2, 3$. As in the proof of Theorem 5.2, we identify the additive measures $\bar{\zeta}_i$ with measures $\widehat{\bar{\zeta}}_i$ belonging to $\mathcal{M}(\Sigma^\#)$ (the space of Radon measures on $\Sigma^\#$), and the optimality condition (3.6) is

$$\int_\Sigma \mathcal{H}_v'(\cdot,\bar{y},\bar{v},\bar{p},\bar{\alpha})\chi \, ds\, dt + \sum_{i=1}^{3} \langle \widehat{\bar{\zeta}}_i, \tau(g_{iv}'(\bar{y},\bar{v}))\ \tau(\chi)\rangle_{\Sigma^\#} = 0$$

for all $\chi \in L^\infty(\Sigma)$. ($\tau$ is the isometric homomorphism used in the proof of Theorem 5.2, and $\langle\cdot,\cdot\rangle_{\Sigma^\#}$ denotes the duality pairing between $\mathcal{M}(\Sigma^\#)$ and $C(\Sigma^\#)$.) With the Hahn–Banach theorem, there exists a function μ belonging to $L^{k\wedge\sigma}(\Sigma)$ for all

$1 < \sigma < \frac{N+1}{N}$, such that

$$\sum_{i=1}^{3} \langle \widehat{\bar{\zeta}}_i, \tau(g'_{iv}(\bar{y}, \bar{v}))\ \tau(\chi) \rangle_{\Sigma^\#} = \int_\Sigma \mu\ \chi\, ds\, dt \qquad \text{for all } \chi \in L^\infty(\Sigma).$$

By using (5.13), and since $(g_1(\bar{y}, \bar{v}), g_2(\bar{y}, \bar{v}))$ and $(g_2(\bar{y}, \bar{v}), g_3(\bar{y}, \bar{v}))$ satisfy the separation condition stated in (A10), we can prove that

$$\text{supp}\ \widehat{\bar{\zeta}}_1 \cap \text{supp}\ \widehat{\bar{\zeta}}_2 = \text{supp}\ \widehat{\bar{\zeta}}_2 \cap \text{supp}\ \widehat{\bar{\zeta}}_3 = \emptyset. \tag{5.14}$$

Since (supp $\widehat{\bar{\zeta}}_1 \cup$ supp $\widehat{\bar{\zeta}}_3$) and supp $\widehat{\bar{\zeta}}_2$ are two disjoint compact subsets of $\Sigma^\#$, by using the same method as in the proof of Theorem 5.2 we deduce that there exist $\bar{\mu}_1$ and $\bar{\mu}_2$ belonging to $L^{k\wedge\sigma}(\Sigma)$ for all $1 < \sigma < \frac{N+1}{N}$, such that

$$\langle \bar{\zeta}_1, g'_{1v}(\bar{y}, \bar{v})\chi \rangle_{*,\Sigma} + \langle \bar{\zeta}_3, g'_{3v}(\bar{y}, \bar{v})\chi \rangle_{*,\Sigma} = \int_\Sigma \bar{\mu}_1\ \chi\, ds\, dt \quad \text{for all } \chi \in L^\infty(\Sigma), \tag{5.15}$$

$$\langle \bar{\zeta}_2, g'_{2v}(\bar{y}, \bar{v})\chi \rangle_{*,\Sigma} = \int_\Sigma \bar{\mu}_2\ \chi\, ds\, dt \qquad \text{for all } \chi \in L^\infty(\Sigma). \tag{5.16}$$

Let us set $\bar{\eta}_2 = (g'_{2v}(\bar{y}, \bar{v}))^{-1}\bar{\mu}_2$. The function $\bar{\eta}_2$ belongs to $L^{k\wedge\sigma}(\Sigma)$ for all $1 < \sigma < \frac{N+1}{N}$. Since $g'_{1v}(\bar{y}, \bar{v})$ and $g'_{3v}(\bar{y}, \bar{v})$ satisfy (A9) with (5.13) and (5.15), as in the proof of Theorem 5.5, we can establish the existence of two nonnegative functions $\bar{\xi}_1 \in L^{k\wedge\sigma}(\Sigma)$ and $\bar{\xi}_3 \in L^{k\wedge\sigma}(\Sigma)$ such that

$$\langle g'_{1v}(\bar{y}, \bar{v})\bar{\zeta}, \chi \rangle_{*,\Sigma} = \int_\Sigma \bar{\xi}_1 \chi\, ds\, dt, \qquad \langle g'_{3v}(\bar{y}, \bar{v})\bar{\zeta}_3, \chi \rangle_{*,\Sigma} = \int_\Sigma \bar{\xi}_3\ \chi\, ds\, dt \tag{5.17}$$

for all $\chi \in L^\infty(\Sigma)$. We set $\bar{\eta}_1 = (g'_{1v}(\bar{y}, \bar{v}))^{-1}\bar{\xi}_1$ and $\bar{\eta}_3 = (g'_{3v}(\bar{y}, \bar{v}))^{-1}\bar{\xi}_3$. The conditions (4.2), (4.3), and (5.1) are satisfied with $\bar{\eta} \in (L^{k\wedge\sigma}(\Sigma))^3$. We can conclude with a bootstrap argument as in the proof of Theorem 4.1. It is clear that if, in addition, $\widehat{v}$ satisfies (3.1), then we can take $\bar{\alpha} = 1$. The proof is complete. □

Finally, consider two examples for which the assumptions of Theorem 5.7 are satisfied.

Example 1. Set $g_1(y, v) = v - \beta_1 y - c_1$, $g_3(y, v) = v - \beta_3 y - c_3$, $g_2(y, v) = -v$, where β_1, β_3, c_1 and c_3 belong to $L^\infty(\Sigma)$, $\beta_1 \geq 0$, $\beta_3 \geq 0$. Suppose that Ψ is of the form $\Psi(\cdot, y, v) = \psi(\cdot, y) - v$. Suppose that there exists $\varepsilon > 0$ such that $\min(\beta_1\bar{y} + c_1, \beta_3\bar{y} + c_3) \geq \varepsilon$. The pairs $(g_1(\bar{y}, \bar{v}), g_2(\bar{y}, \bar{v}))$ and $(g_2(\bar{y}, \bar{v}), g_3(\bar{y}, \bar{v}))$ satisfy the separation condition stated in (A10). The pair $(g_1(\bar{y}, \bar{v}), g_3(\bar{y}, \bar{v}))$ satisfies the monotonicity condition stated in (A9). Thus (A10) is satisfied and Theorem 5.7 can be applied. Moreover, by combining the arguments of the proofs of Corollaries 5.3 and 5.6, we can prove the existence of $\widehat{v}$ obeying (3.1). Thus we can take $\bar{\alpha} = 1$.

Remark 5.8. If we set $\beta_3 = 0$ in the above example, we recover the case of constraints considered in [6].

Example 2. We replace g_1 and g_3 in the above example by $g_1(y, v) = v - \phi_1(y) - c_1$, $g_3(y, v) = v - \phi_3(y) - c_3$, where ϕ_1 and ϕ_3 are nondecreasing functions of class C^1. Suppose that there exists $\varepsilon > 0$ such that $\min(\phi_1(\bar{y}) + c_1, \phi_3(\bar{y}) + c_3) \geq \varepsilon$. Thus (A10) is satisfied and Theorem 5.7 can be applied. As above, we can take $\bar{\alpha} = 1$.

Acknowledgments. The authors wish to thank the anonymous referees for helpful remarks and suggestions that improved the presentation of the paper.

BOUNDEDNESS PROPERTIES FOR TIME-VARYING NONLINEAR SYSTEMS*

JOAN PEUTEMAN[†] [‡], DIRK AEYELS[†], AND RODOLPHE SEPULCHRE[§]

Abstract. A Liapunov theorem guaranteeing uniform boundedness and uniform ultimate boundedness for a time-varying nonlinear system $\dot{x}(t) = f(x(t), t)$ has been established. The study of uniform boundedness and uniform ultimate boundedness of particular classes of time-varying nonlinear systems $\dot{x}(t) = f(x(t), t)$ is reduced to the study of the corresponding time-invariant frozen systems $\dot{x}(t) = f(x(t), \sigma)$ for all $\sigma \in \mathbb{R}$. This approach is illustrated for time-varying homogeneous systems with a positive order, for particular classes of time-varying nonhomogeneous systems and for time-varying Lotka–Volterra equations.

Key words. nonlinear systems, homogeneous systems, uniform boundedness, uniform ultimate boundedness

1. Introduction.

The stability analysis of time-varying systems $\dot{x}(t) = f(x(t), t)$ is, in general, more difficult than the stability analysis of time-invariant systems. For this reason, several approaches have been proposed in the literature to reduce the stability analysis of time-varying systems to the stability analysis of related time-invariant systems.

Averaging is the most popular of these techniques. Exponential stability of the (time-invariant) averaged system $\dot{x}(t) = \bar{f}(x(t))$ implies exponential stability of the original (time-varying) system provided that the time-variation of the original system is sufficiently fast [1, 2, 8]. In contrast, when the time-variation is sufficiently slow, other results have been proposed based on the stability analysis of the familiy of the frozen systems $\dot{x}(t) = f(x(t), \sigma)$ (where σ is treated as a constant parameter) [3, 8, 12, 13, 14, 15].

In the recent paper [11], it has been observed that the fast time-variation hypothesis necessary for averaging results can be replaced by a homogeneity assumption on the vector field $f(x, t)$. Because the homogeneity property affects state but not time, the time-variation of a homogeneous vector field $f(x, t)$ of positive order $\tau > 0$ is inherently fast for $\|x\|$ small and slow for $\|x\|$ large. This fast and slow variation of the vector field is, of course, to be understood relatively to the time-variation of the solutions.

Based on this observation, the main result in [11] concludes local uniform asymptotic stability of the equilibrium point $x = 0$ of the time-varying homogeneous system

from asymptotic stability of the averaged system. This result exploits the inherently *fast* character of homogeneous systems with a positive order *near the origin.*

In the present paper, we exploit the inherently *slow* character of such systems *far from the origin.* We develop a freezing result for homogeneous systems with a positive order: we show that asymptotic stability of each frozen system implies uniform boundedness and uniform ultimate boundedness of the original time-varying system. Boundedness properties rather than asymptotic stability of the equilibrium point follows from the fact that the time-variation is not slow near the origin.

Our result is further extended to systems that are not necessarily homogeneous but that possess a homogeneous approximation for $\|x\|$ sufficiently large. This robustness result is dual to the robustness of local asymptotic stability with respect to higher order perturbations [6, 10].

The paper is organized as follows. In section 2, we formulate a Liapunov result guaranteeing uniform boundedness and uniform ultimate boundedness of a time-varying system $\dot{x}(t) = f(x(t), t)$. We also explain how a Liapunov function can be constructed satisfying the conditions of this Liapunov result. This approach is used in section 3 to prove uniform boundedness and uniform ultimate boundedness of a time-varying homogeneous system with a positive order $\tau > 0$. In section 4, we show that the approach presented in sections 2 and 3 is not restricted to the class of homogeneous systems. In section 5, we illustrate the results by means of a time-varying Lotka–Volterra system defined in the first closed orthant of $\mathbb{R}^n$.

2. Boundedness properties and the freezing technique. We first specify the class of systems under study in the present paper.

Consider

$$\dot{x}(t) = f(x(t), t) \tag{2.1}$$

with $f : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$. We assume that conditions are imposed on (2.1) such that the existence and uniqueness of its solutions are secured for all initial conditions $x_0 \in \mathbb{R}^n$ and for all initial times t_0. The solution of (2.1) at t with initial condition x_0 at t_0 is denoted as $x(t, t_0, x_0)$. These existence and uniqueness conditions are imposed on all the differential equations mentioned in the present paper.

We now introduce the notions of uniform boundedness and uniform ultimate boundedness (see [16, pp. 36–37]).

DEFINITION 2.1. *The system* (2.1) *is* uniformly bounded *when*[1] *for all* $R_1 > 0$, *there exists an* $R_2(R_1) > 0$ *such that for all* $x_0 \in \mathbb{R}^n$, *for all* t_0, *and for all* $t \geq t_0$

$$\|x_0\| \leq R_1 \Rightarrow \|x(t, t_0, x_0)\| \leq R_2(R_1). \tag{2.2}$$

DEFINITION 2.2. *The system* (2.1) *is* uniformly ultimately bounded *when there exists an* $R > 0$ *such that for all* $R_1 > 0$, *there exists a* $T(R_1) > 0$ *such that for all* $x_0 \in \mathbb{R}^n$, *for all* t_0, *and for all* $t \geq t_0 + T(R_1)$

$$\|x_0\| \leq R_1 \Rightarrow \|x(t, t_0, x_0)\| \leq R. \tag{2.3}$$

The classical theorem of Liapunov proves uniform asymptotic stability of the equilibrium point $x = 0$ of a dynamical system $\dot{x}(t) = f(x(t), t)$ when there exists a positive definite and decrescent Liapunov function $V(x, t)$ whose derivative $\dot{V}(x, t)$

[1] In the present paper, we always use—without loss of generality—the Euclidean norm.

along the solutions of the system is negative definite. When there exists an $R_V > 0$ such that the derivative $\dot{V}(x,t)$ along the solutions of the system is negative for x with $\|x\| > R_V > 0$, the following proposition proves uniform boundedness and uniform ultimate boundedness.

Consider the system (2.1). Consider a continuously differentiable function $V : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$.

PROPOSITION 2.3. *Assume that for all $t \in \mathbb{R}$ and for all $x \in \mathbb{R}^n$*

$$\alpha(\|x\|) \leq V(x,t) \leq \beta(\|x\|). \tag{2.4}$$

The functions $\alpha(\cdot) : \mathbb{R}^+ \to \mathbb{R}$ and $\beta(\cdot) : \mathbb{R}^+ \to \mathbb{R}$ are class-$\mathcal{K}_\infty$ functions.[2]

If there exist a class-$\mathcal{K}$ function $\gamma(\cdot) : \mathbb{R}^+ \to \mathbb{R}$ and an $R_V > 0$ such that for all $t \in \mathbb{R}$ and for all $x \in \mathbb{R}^n$ with $\|x\| > R_V$

$$\frac{\partial V}{\partial t}(x,t) + \frac{\partial V}{\partial x}(x,t) f(x,t) \leq -\gamma(\|x\|), \tag{2.5}$$

then (2.1) *is uniformly bounded and uniformly ultimately bounded.*

Proof. The result of the present proposition has been formulated in [16, pp. 39–42]. For completeness, the proof has been included in the appendix. □

The study of uniform boundedness and uniform ultimate boundedness of a time-varying nonlinear system, by means of Proposition 2.3, is, in general, highly nontrivial. Reducing the problem to the study of time-invariant systems may be an important simplification.

Consider the time-varying system (2.1). For each $\sigma \in \mathbb{R}$, define the time-invariant system

$$\dot{x}(t) = f(x(t), \sigma). \tag{2.6}$$

We call the system (2.6) the frozen system of (2.1) at σ. Consider for each $\sigma \in \mathbb{R}$ a continuously differentiable function $V_\sigma : \mathbb{R}^n \to \mathbb{R}$. Define $V : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$ as $V(x,\sigma) := V_\sigma(x)$ for each $\sigma \in \mathbb{R}$ and each $x \in \mathbb{R}^n$.

THEOREM 2.4. *Assume that for all $\sigma \in \mathbb{R}$ and for all $x \in \mathbb{R}^n$*

$$W_1(x) \leq V(x,\sigma) \leq W_2(x). \tag{2.7}$$

The functions $W_1 : \mathbb{R}^n \to \mathbb{R}$ and $W_2 : \mathbb{R}^n \to \mathbb{R}$ are positive definite and radially unbounded.[3]

If there exist an $R_V > 0$ and positive definite functions $W_3 : \mathbb{R}^n \to \mathbb{R}$, $W_4 : \mathbb{R}^n \to \mathbb{R}$, and $W_5 : \mathbb{R}^n \to \mathbb{R}$ such that for all $\sigma \in \mathbb{R}$ and for all $x \in \mathbb{R}^n$ with $\|x\| > R_V$

$$\left| \frac{\partial V}{\partial \sigma}(x,\sigma) \right| \leq W_3(x), \tag{2.8}$$

$$\frac{\partial V}{\partial x}(x,\sigma) f(x,\sigma) \leq -W_4(x), \tag{2.9}$$

[2] A continuous function $\eta : [0,a) \to [0,\infty)$ is said to be a class-$\mathcal{K}$ function if it is strictly increasing and $\eta(0) = 0$. It is said to be a class-$\mathcal{K}_\infty$ function if $a = \infty$ and $\eta(r) \to \infty$ as $r \to \infty$.

[3] A function $W : \mathbb{R}^n \to \mathbb{R}$ is positive definite when W is continuous, $W(0) = 0$, and $W(x) > 0$ for all $x \in \mathbb{R}^n \setminus \{0\}$. In the case when $W(x) \to +\infty$ as $\|x\| \to +\infty$, the positive definite function W is radially unbounded.

$$W_3(x) - W_4(x) \leq -W_5(x), \tag{2.10}$$

then (2.1) *is uniformly bounded and uniformly ultimately bounded.*

Proof. The proof of the present theorem is based on Proposition 2.3. For each $t \in \mathbb{R}$ and for each $x \in \mathbb{R}^n$, define

$$V(x,t) := V(x,\sigma)\Big|_{\sigma=t}. \tag{2.11}$$

By (2.7) and [8, pp. 138–139], (2.4) is satisfied. By (2.8) and (2.9), it is clear that for all $t \in \mathbb{R}$ and for all $x \in \mathbb{R}^n$ with $\|x\| > R_V$

$$\frac{\partial V}{\partial t}(x,t) + \frac{\partial V}{\partial x}(x,t)f(x,t) \leq W_3(x) - W_4(x) \leq -W_5(x) < 0. \tag{2.12}$$

By [8, pp. 138–139], (2.5) is satisfied, and by Proposition 2.3 this implies uniform boundedness and uniform ultimate boundedness for the original time-varying system (2.1). □

Remark 1. It is obvious that the statement of Theorem 2.4 can be relaxed by replacing (2.8) and (2.9) by $\frac{\partial V}{\partial \sigma}(x,\sigma) + \frac{\partial V}{\partial x}(x,\sigma)f(x,\sigma) \leq -W_5(x)$. However, for the purpose we have in mind (see section 3), the present formulation of Theorem 2.4 will be applied.

3. Homogeneous systems.

In the present section, we specialize the result of the previous sections to the class of homogeneous systems.

Given an n-tuple $r = (r_1, \dots, r_n)$ (for all $i \in \{1, \dots, n\} : r_i > 0$), we define the dilation δ to be the map

$$\delta : \mathbb{R}^+ \times \mathbb{R}^n \to \mathbb{R}^n : (s,x) \to \delta(s,x) = (s^{r_1}x_1, \dots, s^{r_n}x_n), \tag{3.1}$$

where $x = (x_1, \dots, x_n)$.

A continuous function $h : \mathbb{R}^n \to \mathbb{R}$ is r-homogeneous of degree $m \geq 0$ if and only if

$$\forall x \in \mathbb{R}^n, \forall s \in \mathbb{R}^+ : h(\delta(s,x)) = s^m h(x). \tag{3.2}$$

A continuous function $f_H : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ is r-homogeneous of order $\tau \geq 0$ if and only if

$$\forall x \in \mathbb{R}^n, \forall t \in \mathbb{R}, \forall s \in \mathbb{R}^+ : f_H(\delta(s,x),t) = s^\tau \delta(s, f_H(x,t)). \tag{3.3}$$

When f_H is r-homogeneous of order $\tau \geq 0$, then for all $p > 0$, f_H is r'-homogeneous of order $\tau' \geq 0$ with $r' = (\frac{r_1}{p}, \dots, \frac{r_n}{p})$ and $\tau' = \frac{\tau}{p}$. When h is r-homogeneous of degree $m \geq 0$, then for all $p > 0$, h is r'-homogeneous of degree $m' \geq 0$ with $r' = (\frac{r_1}{p}, \dots, \frac{r_n}{p})$ and $m' = \frac{m}{p}$. For this reason, taking $0 < r_i < 1$ for all $i \in \{1, \dots, n\}$ is not a restriction in the definition of homogeneity. In what follows, we always take $0 < r_i < 1$ for all $i \in \{1, \dots, n\}$.

An r-homogeneous norm ρ is a continuous function $\rho : \mathbb{R}^n \to \mathbb{R}$ which is positive definite and r-homogeneous of degree 1 ($0 < r_i < 1$: for all $i \in \{1, \dots, n\}$).

In the present paper, we will use the r-homogeneous norm

$$\rho(x) = \sum_{i=1}^{n} |x_i|^{\frac{1}{r_i}}. \tag{3.4}$$

This homogeneous norm is continuously differentiable in $\mathbb{R}^n$ and for all $i \in \{1, \dots, n\}$,

$$\frac{\partial \rho}{\partial x_i}(\delta(s,x)) = s^{1-r_i}\frac{\partial \rho}{\partial x_i}(x)\,. \tag{3.5}$$

Lemma 3.1. *The time-invariant r-homogeneous system $\dot{x}(t) = f_H(x(t))$ of order $\tau > 0$ is asymptotically stable if and only if there exists a $k > 1$ such that for all $x_0 \in \mathbb{R}^n$ and for all $t \geq 0$*

$$\rho(x(t,0,x_0)) \leq \frac{k\rho(x_0)}{(1+t\rho(x_0)^\tau)^{\frac{1}{\tau}}}. \tag{3.6}$$

Proof. The proof is omitted. The reader is referred to [4, pp. 278–284] for a proof when the dilation is the standard dilation. □

3.1. Main result. Consider the r-homogeneous system

$$\dot{x}(t) = f_H(x(t),t) \tag{3.7}$$

with order $\tau > 0$. Consider for each $\sigma \in \mathbb{R}$ the frozen system

$$\dot{x}(t) = f_H(x(t),\sigma). \tag{3.8}$$

The solution of (3.7) at t with initial condition $x_0 \in \mathbb{R}$ at t_0 is denoted as $x_H(t,t_0,x_0)$, and the solution of (3.8) is denoted as $x_{H\sigma}(t,t_0,x_0)$.

Theorem 3.2. *Assume the following.*

- *The equilibrium point $x = 0$ of each frozen system* (3.8) *is asymptotically stable, and the estimate* (3.6) *is uniform, i.e., there exists a $k > 1$ independent of σ such that for all $\sigma \in \mathbb{R}$, for all $x_0 \in \mathbb{R}^n$, and for all $t \geq 0$*

$$\rho(x_{H\sigma}(t,0,x_0)) \leq \frac{k\rho(x_0)}{(1+t\rho(x_0)^\tau)^{\frac{1}{\tau}}}. \tag{3.9}$$

- *$f_H(x,\sigma)$ is continuously differentiable with respect to x and σ.*
- *There exists a $c_f > 0$ such that for all $\sigma \in \mathbb{R}$, for all $y \in \mathbb{R}^n$ with $\rho(y) = 1$, and for all $i,k \in \{1,\dots,n\}$*

$$|f_{Hi}(y,\sigma)| \leq c_f \quad \textit{and} \quad \left|\frac{\partial f_{Hi}}{\partial x_k}(y,\sigma)\right| \leq c_f \quad \textit{and} \quad \left|\frac{\partial f_{Hi}}{\partial \sigma}(y,\sigma)\right| \leq c_f; \tag{3.10}$$

then the time-varying system (3.7) *is uniformly bounded and uniformly ultimately bounded.*

Proof. The proof is based on Theorem 2.4. Define for all $x \in \mathbb{R}^n$ and for all $\sigma \in \mathbb{R}$

$$V(x,\sigma) := \int_0^\infty \rho(x_{H\sigma}(t,0,x))^{m\tau}dt, \tag{3.11}$$

where m will be chosen later on in the proof.

By (3.3), (3.10), and [4, pp. 278–284], there exists a $k' > 0$ such that for all $\sigma \in \mathbb{R}$, for all $x \in \mathbb{R}^n$, and for all $t \geq 0$

$$\rho(x_{H\sigma}(t,0,x)) \geq \frac{k'\rho(x)}{(1+t\rho(x)^\tau)^{\frac{1}{\tau}}}. \tag{3.12}$$

We now prove (2.7), (2.8), and (2.9).

I. By (3.9) and (3.12), there exist a $c_1 > 0$ and a $c_2 > 0$ such that for all $x \in \mathbb{R}^n$ and for all $\sigma \in \mathbb{R}$

$$c_1 \rho(x)^{(m-1)\tau} \le V(x,\sigma) \le c_2 \rho(x)^{(m-1)\tau}. \tag{3.13}$$

This implies that (2.7) is satisfied when $m > 1$.

II. In order to verify (2.8), we calculate $\frac{\partial V}{\partial \sigma}(x,\sigma)$. Notice that

(3.14)
$$\begin{aligned}\frac{\partial V}{\partial \sigma}(x,\sigma) &= m\tau \int_0^\infty \rho(x_{H\sigma}(t,0,x))^{m\tau-1} \frac{\partial}{\partial \sigma}\left(\rho(x_{H\sigma}(t,0,x))\right) dt \\ &= m\tau \int_0^\infty \rho(x_{H\sigma}(t,0,x))^{m\tau-1} \left(\sum_{i=1}^n \frac{\partial \rho}{\partial x_i}(x_{H\sigma}(t,0,x)) \frac{\partial x_{H\sigma i}}{\partial \sigma}(t,0,x)\right) dt.\end{aligned}$$

Here, we assume that $m > \frac{1}{\tau}$. For all $i \in \{1, \dots, n\}$,

$$\begin{aligned}&\frac{\partial \rho}{\partial x_i}(x_{H\sigma}(t,0,x)) \\ &= \frac{\partial \rho}{\partial x_i}\left(\delta(\rho(x_{H\sigma}(t,0,x))^{-1}, x_{H\sigma}(t,0,x))\right) \rho(x_{H\sigma}(t,0,x))^{1-r_i}.\end{aligned} \tag{3.15}$$

The continuity of $\frac{\partial \rho}{\partial x_i}$ on the compact set $\{y : y \in \mathbb{R}^n, \rho(y) = 1\}$ implies the existence of a $c_\rho > 0$ such that $|\frac{\partial \rho}{\partial x_i}(y)| \le c_\rho$ for all $i \in \{1, \dots, n\}$ and for all $y \in \mathbb{R}^n$ with $\rho(y) = 1$. It is clear that[4]

(3.16)
$$\left|\frac{\partial V}{\partial \sigma}(x,\sigma)\right| \le m\tau \int_0^\infty \rho(x_{H\sigma}(t,0,x))^{m\tau-1} c_\rho \left(\sum_{i=1}^n \rho(x_{H\sigma}(t,0,x))^{1-r_i} \left| \frac{\partial x_{H\sigma i}}{\partial \sigma}(t,0,x)\right| \right) dt.$$

In order to obtain an upper bound for the right-hand side of (3.16), we first calculate an appropriate upper bound for

$$\sum_{i=1}^n \rho(x_{H\sigma}(t,0,x))^{1-r_i} \left| \frac{\partial x_{H\sigma i}}{\partial \sigma}(t,0,x)\right|. \tag{3.17}$$

By integrating (3.8), one obtains that for all $x \in \mathbb{R}^n$ and for all $t \ge 0$,

$$x_{H\sigma}(t,0,x) = x + \int_0^t f_H(x_{H\sigma}(s,0,x),\sigma) ds \tag{3.18}$$

and

$$\begin{aligned}\frac{\partial x_{H\sigma i}}{\partial \sigma}(t,0,x) = \int_0^t &\sum_{k=1}^n \frac{\partial f_{Hi}}{\partial x_k}(x_{H\sigma}(s,0,x),\sigma) \frac{\partial x_{H\sigma k}}{\partial \sigma}(s,0,x) \\ &+ \frac{\partial f_{Hi}}{\partial \sigma}(x_{H\sigma}(s,0,x),\sigma) ds.\end{aligned} \tag{3.19}$$

[4] Since $f_H(x,\sigma)$ is continuously differentiable with respect to x and σ, the solution $x_{H\sigma}(t,t_0,x_0)$ is continuously differentiable with respect to σ [5, Theorem 3.3, p. 21].

By multiplying (3.19) with $\rho(x_{H\sigma}(t,0,x))^{1-r_i}$ and invoking the triangle inequality, one obtains that the expression (3.17) is less than or equal to

$$\begin{aligned}(3.20)\qquad &\sum_{i=1}^{n}\rho(x_{H\sigma}(t,0,x))^{1-r_i}\int_0^t\sum_{k=1}^{n}\left|\frac{\partial f_{Hi}}{\partial x_k}(x_{H\sigma}(s,0,x),\sigma)\right|\ \left|\frac{\partial x_{H\sigma k}}{\partial\sigma}(s,0,x)\right|\\ &+\left|\frac{\partial f_{Hi}}{\partial\sigma}(x_{H\sigma}(s,0,x),\sigma)\right|ds.\end{aligned}$$

Notice that

$$\begin{aligned}(3.21)\qquad &\frac{\partial f_{Hi}}{\partial x_k}(x_{H\sigma}(s,0,x),\sigma)\\ &=\ \rho(x_{H\sigma}(s,0,x))^{\tau+r_i-r_k}\frac{\partial f_{Hi}}{\partial x_k}\left(\delta(\rho(x_{H\sigma}(s,0,x))^{-1},x_{H\sigma}(s,0,x)),\sigma\right)\end{aligned}$$

and

$$\begin{aligned}(3.22)\qquad &\frac{\partial f_{Hi}}{\partial\sigma}(x_{H\sigma}(s,0,x),\sigma)\\ &=\ \rho(x_{H\sigma}(s,0,x))^{\tau+r_i}\frac{\partial f_{Hi}}{\partial\sigma}\left(\delta(\rho(x_{H\sigma}(s,0,x))^{-1},x_{H\sigma}(s,0,x)),\sigma\right).\end{aligned}$$

By (3.10) and (3.20), the expression (3.17) is less than or equal to

$$\begin{aligned}(3.23)\qquad &c_f\sum_{i=1}^{n}\rho(x_{H\sigma}(t,0,x))^{1-r_i}\int_0^t\sum_{k=1}^{n}\rho(x_{H\sigma}(s,0,x))^{\tau+r_i-r_k}\left|\frac{\partial x_{H\sigma k}}{\partial\sigma}(s,0,x)\right|\\ &+\rho(x_{H\sigma}(s,0,x))^{\tau+r_i}ds.\end{aligned}$$

By (3.9), $\rho(x_{H\sigma}(\tau,0,x_0))\le k\rho(x_0)$ for all $x_0\in\mathbb{R}^n$ and for all $\tau\ge0$. By setting $x_0=x_{H\sigma}(s,0,x)$ and $\tau=t-s$, one obtains that for all $s\in[0,t]$: $\rho(x_{H\sigma}(t-s,0,x_{H\sigma}(s,0,x)))\le k\rho(x_{H\sigma}(s,0,x))$ such that $\rho(x_{H\sigma}(t,0,x))\le k\rho(x_{H\sigma}(s,0,x))$. This implies by (3.23) that the expression (3.17) is less than or equal to

$$\begin{aligned}&(3.24)\\ &c_f\sum_{i=1}^{n}k^{1-r_i}\int_0^t\rho(x_{H\sigma}(s,0,x))^{1-r_i}\left(\sum_{k=1}^{n}\rho(x_{H\sigma}(s,0,x))^{\tau+r_i-r_k}\left|\frac{\partial x_{H\sigma k}}{\partial\sigma}(s,0,x)\right|\right.\\ &\left.+\ \rho(x_{H\sigma}(s,0,x))^{\tau+r_i}\right)ds.\end{aligned}$$

By (3.9), there exists a $c_3>0$ such that for all $x\in\mathbb{R}^n$ and for all $t\ge0$,

$$(3.25)\qquad \int_0^t\rho(x_{H\sigma}(s,0,x))^{1+\tau}ds\le c_3\rho(x).$$

This implies the existence of a $c_4>0$ and a $c_5>0$ such that the expression (3.17) is less than or equal to

$$\begin{aligned}&(3.26)\\ &c_4\rho(x)+c_5\int_0^t\rho(x_{H\sigma}(s,0,x))^{\tau}\left(\sum_{k=1}^{n}\rho(x_{H\sigma}(s,0,x))^{1-r_k}\left|\frac{\partial x_{H\sigma k}}{\partial\sigma}(s,0,x)\right|\right)ds.\end{aligned}$$

By the Gronwall–Bellman lemma, it is clear that

$$\sum_{i=1}^{n} \rho(x_{H\sigma}(t,0,x))^{1-r_i} \left| \frac{\partial x_{H\sigma i}}{\partial \sigma}(t,0,x) \right| \le c_4 \rho(x) e^{c_5 \int_0^t \rho(x_{H\sigma}(s,0,x))^{\tau} ds}. \tag{3.27}$$

By (3.9), there exists a $c_6 > 0$ such that for all $x \in \mathbb{R}^n$ and for all $t \ge 0$,

$$c_5 \int_0^t \rho(x_{H\sigma}(s,0,x))^{\tau} ds \le c_6 \ln\left(1 + t\rho(x)^{\tau}\right), \tag{3.28}$$

and therefore

$$\sum_{i=1}^{n} \rho(x_{H\sigma}(t,0,x))^{1-r_i} \left| \frac{\partial x_{H\sigma i}}{\partial \sigma}(t,0,x) \right| \le c_4 \rho(x) \left(1 + t\rho(x)^{\tau}\right)^{c_6}. \tag{3.29}$$

This implies by (3.16) and (3.9) the existence of a $c_7 > 0$ such that

$$\left| \frac{\partial V}{\partial \sigma}(x,\sigma) \right| \le c_7 \rho(x)^{m\tau} \int_0^{\infty} \left(1 + t\rho(x)^{\tau}\right)^{c_6 + \frac{1}{\tau} - m} dt. \tag{3.30}$$

Take $m > c_6 + \frac{1}{\tau} + 1$. There exists a $c_8 > 0$ such that for all $\sigma \in \mathbb{R}$ and for all $x \in \mathbb{R}^n$,

$$\left| \frac{\partial V}{\partial \sigma}(x,\sigma) \right| \le c_8 \rho(x)^{(m-1)\tau}. \tag{3.31}$$

III. From the definition (3.11), one obtains that the derivative of $V(x,\sigma)$ along the solutions of (3.8) equals $\dot{V}(x,\sigma) = -\rho(x)^{m\tau}$. This implies that

$$\frac{\partial V}{\partial x}(x,\sigma) f_H(x,\sigma) = \dot{V}(x,\sigma) = -\rho(x)^{m\tau}. \tag{3.32}$$

IV. By (3.31) and (3.32), (2.8) and (2.9) are satisfied with $W_3(x) = c_8 \rho(x)^{(m-1)\tau}$ and $W_4(x) = \rho(x)^{m\tau}$. Since $W_3(x) - W_4(x)$ is a continuous function of x that tends to $-\infty$ as $\|x\|$ tends to $+\infty$, there exist an $R_V > 0$ and a positive definite $W_5 : \mathbb{R}^n \to \mathbb{R}$ such that for all x with $\|x\| > R_V$, $W_3(x) - W_4(x) \le -W_5(x)$. Theorem 2.4 implies uniform boundedness and uniform ultimate boundedness of the system (3.7). □

Remark 2. By taking $V(x,\sigma)$ as defined by (3.11) and by setting $V(x,t) = V(x,\sigma)|_{\sigma=t}$ as in the proof of Theorem 2.4, we not only prove uniform boundedness and uniform ultimate boundedness of (3.7). We also obtain the estimate

$$\rho(x_H(t,t_0,x_0)) \le \frac{k\rho(x_0)}{\left(1 + (t-t_0)\rho(x_0)^{\tau}\right)^{\frac{1}{\tau}}} \tag{3.33}$$

when $\|x_H(\tau,t_0,x_0)\|$ is sufficiently large for all $\tau \in [t_0,t]$. Indeed, by (3.31) and (3.32), the derivative of $V(x,t)$ along the trajectories of (3.7) satisfies the inequality

$$\dot{V}(x_H(t,t_0,x_0),t) \le c_8 \rho(x_H(t,t_0,x_0))^{(m-1)\tau} - \rho(x_H(t,t_0,x_0))^{m\tau}. \tag{3.34}$$

There exists an $R_{V2} > 0$ sufficiently large such that for all $x_H(t,t_0,x_0)$ with $\|x_H(t,t_0,x_0)\| > R_{V2}$, $\dot{V}(x_H(t,t_0,x_0),t) \le -0.5\rho(x_H(t,t_0,x_0))^{m\tau}$. By (3.13), there exist positive constants c_{10} and c_{11} such that

$$\dot{V}(x_H(t,t_0,x_0),t) \le -c_{10} V(x_H(t,t_0,x_0),t)^{\frac{m}{m-1}} \tag{3.35}$$

and by integration

$$V(x_H(t,t_0,x_0),t)^{\frac{1}{1-m}} \ge V(x_0,t_0)^{\frac{1}{1-m}} + c_{11}(t-t_0). \tag{3.36}$$

By (3.13), there exists a $k > 1$ such that for all t_0 and for all $t \ge t_0$ (3.33) is satisfied when $\|x_H(\tau,t_0,x_0)\| > R_{V2}$ for all $\tau \in [t_0,t]$.

3.2. Time-periodicity. For the time-periodic case, the conditions mentioned in Theorem 3.2 can be simplified. When the r-homogeneous system $\dot{x}(t) = f_H(x(t), t)$ with order $\tau > 0$ is time-periodic, it is possible to reformulate the first condition of Theorem 3.2 by simply requiring asymptotic stability for each frozen system $\dot{x}(t) = f_H(x(t), \sigma)$.

THEOREM 3.3. *Consider the system $\dot{x}(t) = f_H(x(t), t)$, where $f_H(x, t)$ is assumed to be time-periodic with period T_f. When $f_H(x, \sigma)$ is continuously differentiable with respect to x and σ and each frozen system $\dot{x}(t) = f_H(x(t), \sigma)$ is assumed to be asymptotically stable, i.e., for each $\sigma \in \mathbb{R}$ there exists a $k(\sigma) > 1$ such that for all $x_0 \in \mathbb{R}^n$ and for all $t \geq 0$*

$$\rho(x_{H\sigma}(t, 0, x_0)) \leq \frac{k(\sigma)\rho(x_0)}{(1 + t\rho(x_0)^\tau)^{\frac{1}{\tau}}}, \tag{3.37}$$

then the time-varying system $\dot{x}(t) = f_H(x(t), t)$ is uniformly bounded and uniformly ultimately bounded.

Proof. The proof is based on Theorem 3.2.

I. First we show that (3.9) is satisfied.

Since $f_H(x, \sigma)$ is continuously differentiable with respect to x and σ, $x_{H\sigma}(T, 0, x)$ is continuously differentiable with respect to σ for all $T > 0$, for all $x \in \mathbb{R}^n$, and for all $\sigma \in [0, T_f]$ [5, Theorem 3.3, p. 21]. This implies that for all $T > 0$, for all $x \in \mathbb{R}^n$, and for all $\sigma \in [0, T_f]$

$$\begin{aligned} &\lim\nolimits_{\sigma' \to \sigma} x_{H\sigma'}(T, 0, x) = x_{H\sigma}(T, 0, x) \quad \text{and} \\ &\lim\nolimits_{\sigma' \to \sigma} \rho(x_{H\sigma'}(T, 0, x)) = \rho(x_{H\sigma}(T, 0, x)). \end{aligned} \tag{3.38}$$

Take an arbitrary $\sigma \in [0, T_f]$. $k(\sigma)$ in (3.37) is not unique, but for each fixed σ, the set of the possible $k(\sigma)$ has an infimum $k_{\inf}(\sigma)$. We will now prove that $k_{\inf}(\sigma)$ is a continuous function of σ. The continuity of $k_{\inf}(\sigma)$ as a function of σ on a compact interval implies the existence of a bounded maximum $\bar{k}_{\inf}$ on $[0, T_f]$. By taking an arbitrary $\epsilon > 0$ and setting $k = \bar{k}_{\inf} + \epsilon$, (3.37) implies that (3.9) is satisfied.

Suppose $k_{\inf}(\sigma)$ as a function of σ has a discontinuity at σ', i.e., there exists an $\epsilon' > 0$ such that for each $\delta' > 0$ there is a $\sigma'' \in]\sigma' - \delta', \sigma' + \delta'[$ for which $|k_{\inf}(\sigma') - k_{\inf}(\sigma'')| > \epsilon'$. This means that $k_{\inf}(\sigma'') < k_{\inf}(\sigma') - \epsilon'$ or that $k_{\inf}(\sigma'') > k_{\inf}(\sigma') + \epsilon'$.

First, suppose that $k_{\inf}(\sigma'') < k_{\inf}(\sigma') - \epsilon'$. For this fixed σ', $k_{\inf}(\sigma')$ is the infimum of all possible $k(\sigma')$. By (3.37), there exist a $T' > 0$ and an $x' \in \mathbb{R}^n$ such that

$$\rho(x_{H\sigma'}(T', 0, x')) > \frac{(k_{\inf}(\sigma') - \frac{\epsilon'}{4})\rho(x')}{(1 + T'\rho(x')^\tau)^{\frac{1}{\tau}}}. \tag{3.39}$$

But by (3.37)

$$\rho(x_{H\sigma''}(T', 0, x')) \leq \frac{(k_{\inf}(\sigma'') + \frac{\epsilon'}{4})\rho(x')}{(1 + T'\rho(x')^\tau)^{\frac{1}{\tau}}} \leq \frac{(k_{\inf}(\sigma') - \frac{3\epsilon'}{4})\rho(x')}{(1 + T'\rho(x')^\tau)^{\frac{1}{\tau}}} \tag{3.40}$$

such that

$$\rho(x_{H\sigma'}(T', 0, x')) - \rho(x_{H\sigma''}(T', 0, x')) > \frac{\epsilon'}{2} \frac{\rho(x')}{(1 + T'\rho(x')^\tau)^{\frac{1}{\tau}}} \tag{3.41}$$

for all $\delta' > 0$ with $\sigma'' \in]\sigma' - \delta', \sigma' + \delta'[$. Since (3.41) contradicts with (3.38), the assumption that $k_{\inf}(\sigma'') < k_{\inf}(\sigma') - \epsilon'$ is false.

Suppose that $k_{\inf}(\sigma'') > k_{\inf}(\sigma') + \epsilon'$. For this fixed σ'', $k_{\inf}(\sigma'')$ is the infimum of all possible $k(\sigma'')$. There exist a $T'' > 0$ and an $x'' \in \mathbb{R}^n$ such that

$$\rho(x_{H\sigma''}(T'', 0, x'')) > \frac{(k_{\inf}(\sigma'') - \frac{\epsilon'}{4})\rho(x'')}{(1 + T''\rho(x'')^{\tau})^{\frac{1}{\tau}}}. \tag{3.42}$$

But by (3.37),

$$\rho(x_{H\sigma'}(T'', 0, x'')) \le \frac{(k_{\inf}(\sigma') + \frac{\epsilon'}{4})\rho(x'')}{(1 + T''\rho(x'')^{\tau})^{\frac{1}{\tau}}} \le \frac{(k_{\inf}(\sigma'') - \frac{3\epsilon'}{4})\rho(x'')}{(1 + T''\rho(x'')^{\tau})^{\frac{1}{\tau}}} \tag{3.43}$$

such that

$$\rho(x_{H\sigma''}(T'', 0, x'')) - \rho(x_{H\sigma'}(T'', 0, x'')) > \frac{\epsilon'}{2} \frac{\rho(x'')}{(1 + T''\rho(x'')^{\tau})^{\frac{1}{\tau}}} \tag{3.44}$$

for all $\delta' > 0$ with $\sigma'' \in]\sigma' - \delta', \sigma' + \delta'[$. Since (3.44) contradicts with (3.38), the assumption that $k_{\inf}(\sigma'') > k_{\inf}(\sigma') + \epsilon'$ is false.

Since the discontinuity assumptions lead to contradictions, $k_{\inf}(\sigma)$ is a continuous function of σ. Therefore, $k_{\inf}(\sigma)$ has a bounded maximum $\bar{k}_{\inf}$ on $[0, T_f]$. By taking an arbitrary $\epsilon > 0$ and setting $k = \bar{k}_{\inf} + \epsilon$, (3.37) implies that (3.9) is satisfied.

II. Since $f_H(x, \sigma)$ is periodic in the second variable and since $f_H(x, \sigma)$ is continuously differentiable with respect to x and σ, (3.10) is satisfied.

III. Theorem 3.2 implies uniform boundedness and uniform ultimate boundedness of the homogeneous system $\dot{x}(t) = f_H(x(t), t)$ with order $\tau > 0$. □

4. Homogeneous approximations far from the origin. In the present section, we generalize the results of section 3. We consider systems that have a dominant homogeneous approximation at infinity, i.e., systems represented as $\dot{x}(t) = f_H(x(t), t) + g(x(t), t)$. Here $f_H : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ is homogeneous with a positive order τ and $g : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ is a perturbation of f_H when $\|x\|$ is sufficiently large.

Consider $g : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$. There exist an $R_g > 0$ and a continuous nonincreasing function $F : \mathbb{R}^+ \to \mathbb{R}$ with $\lim_{s \to \infty} F(s) = 0$ such that for all $x \in \mathbb{R}^n$ with $\rho(x) > R_g$ and for all $t \in \mathbb{R}$

$$\|\delta(\rho(x)^{-1}, g(x, t))\| \le \rho(x)^{\tau} F(\rho(x)). \tag{4.1}$$

A typical example is the case where $g(x, t)$ is the sum of a finite number of homogeneous terms with the same dilation as $f_H(x, t)$ and with orders *smaller* than τ. For x with $\|x\|$ sufficiently large, $g(x, t)$ can be seen as a perturbation which does not affect the uniform boundedness and the uniform ultimately boundedness property.

Consider the system

$$\dot{x}(t) = f_H(x(t), t) + g(x(t), t) \tag{4.2}$$

and the frozen systems

$$\dot{x}(t) = f_H(x(t), \sigma) + g(x(t), \sigma). \tag{4.3}$$

The solution of $\dot{x}(t) = f_H(x(t), t)$ at t with initial condition $x_0 \in \mathbb{R}$ at t_0 is denoted as $x_H(t, t_0, x_0)$, the solution of $\dot{x}(t) = f_H(x(t), \sigma)$ is denoted as $x_{H\sigma}(t, t_0, x_0)$, the solution of (4.2) is denoted as $x(t, t_0, x_0)$, and the solution of (4.3) is denoted as $x_\sigma(t, t_0, x_0)$.

THEOREM 4.1. *Assume that all the conditions of Theorem* 3.2 *are satisfied; then the time-varying system* $\dot{x}(t) = f_H(x(t), t) + g(x(t), t)$ *is uniformly bounded and uniformly ultimately bounded.*

Proof. In order to prove the boundedness properties, consider the Liapunov function $V(x, \sigma)$, defined by (3.11), which satisfies (3.13), (3.31), and (3.32).

I. By making calculations similar to the calculations in part II in the proof of Theorem 3.2 leading to (3.31), one obtains $\frac{\partial V}{\partial x_j}(x, \sigma)$ for all $j \in \{1, \ldots, n\}$ and for all $x \in \mathbb{R}^n$. There exists a $c_9 > 0$ such that for all $j \in \{1, \ldots, n\}$ and for all $x \in \mathbb{R}^n$

$$\left|\frac{\partial V}{\partial x_j}(x, \sigma)\right| \leq c_9 \rho(x)^{(m-1)\tau - r_j} \tag{4.4}$$

when $m > c_6 + \frac{1}{\tau} + 1$.

II. By (4.1), for all $x \in \mathbb{R}^n$ with $\rho(x) > R_g$, for all $t \in \mathbb{R}$, and for all $j \in \{1, \ldots, n\}$

$$|g_j(x, t)| \leq \rho(x)^{r_j + \tau} F(\rho(x)). \tag{4.5}$$

From (3.32), (4.4), and (4.5),

$$\sum_{j=1}^{n} \frac{\partial V}{\partial x_j}(x, \sigma)(f_{Hj}(x, \sigma) + g_j(x, \sigma)) \leq -\rho(x)^{m\tau}(1 - nc_9 F(\rho(x))) \tag{4.6}$$

when $\rho(x) > R_g$. Since $\lim_{s \to \infty} F(s) = 0$, there exists a $\rho_F > R_g$ such that for all $x \in \mathbb{R}^n$ with $\rho(x) > \rho_F$, $F(\rho(x)) < \frac{1}{2nc_9}$. This implies that for all $x \in \mathbb{R}^n$ with $\rho(x) > \rho_F$

$$\frac{\partial V}{\partial x}(x, \sigma)(f_H(x, \sigma) + g(x, \sigma)) < -\frac{1}{2}\rho(x)^{m\tau}. \tag{4.7}$$

III. By (3.31) and (4.7), (2.8) and (2.9) are satisfied with $W_3(x) = c_8 \rho(x)^{(m-1)\tau}$ and $W_4(x) = \frac{1}{2}\rho(x)^{m\tau}$. Since $W_3(x) - W_4(x)$ is a continuous function of x that tends to $-\infty$ as $\|x\|$ tends to $+\infty$, there exist an $R_V > 0$ and a positive definite $W_5 : \mathbb{R}^n \to \mathbb{R}$ such that for all $x \in \mathbb{R}^n$ with $\|x\| > R_V$, $W_3(x) - W_4(x) \leq -W_5(x)$. Theorem 2.4 implies uniform boundedness and uniform ultimate boundedness of the system (4.2). □

The boundedness results of Theorem 4.1 do not require time-periodicity of the system $\dot{x}(t) = f_H(x(t), t)$. In Theorem 4.2, we consider the time-periodic case which allows a simplification of the conditions.

THEOREM 4.2. *Consider the system* $\dot{x}(t) = f_H(x(t), t)$ *with order* $\tau > 0$. *Here,* $f_H(x, t)$ *is assumed to be time-periodic with period* T_f. *When* $f_H(x, \sigma)$ *is continuously differentiable with respect to* x *and* σ *and each frozen system* $\dot{x}(t) = f_H(x(t), \sigma)$ *is assumed to be asymptotically stable, then the time-varying system* $\dot{x}(t) = f_H(x(t), t) + g(x(t), t)$ *is uniformly bounded and uniformly ultimately bounded.*

Proof. All the conditions imposed by Theorem 3.3 are satisfied. The proof of Theorem 3.3 implies that the conditions imposed by Theorem 4.1 (and, equivalently, by Theorem 3.2) are satisfied. This implies uniform boundedness and uniform ultimate boundedness of the time-varying system $\dot{x}(t) = f_H(x(t), t) + g(x(t), t)$. □

The condition that each frozen system $\dot{x}(t) = f_H(x(t), \sigma)$ is asymptotically stable in order to ensure boundedness properties cannot, in general, be relaxed to a stability condition for some frozen systems. This is illustrated by means of a scalar example. Consider the case where $f_H(x,t) = s(t)x^5$ with $s(t) = 0$ when $t \in [0,1)$ and $s(t) = -1$ when $t \in [1,2)$ with $s(t) = s(t+2)$ for all $t \in \mathbb{R}$. When $g(x,t) = x^3$, the system $\dot{x}(t) = s(t)x^5 + x^3$ is not bounded. (The system has a finite escape time since $s(t) = 0$ when $t \in [0,1)$.)

If we specialize the result of Theorem 4.2 to the case where $f_H(x,t) = f_H(x)$ is time-invariant, Theorem 4.2 shows that asymptotic stability of $\dot{x}(t) = f_H(x(t))$ implies uniform boundedness and uniform ultimate boundedness of

$$\dot{x}(t) = f_H(x(t)) + g(x(t),t). \tag{4.8}$$

The boundedness properties are determined by $f_H(x)$ and not by $g(x,t)$. By (4.1), for x with $\|x\|$ sufficiently large, $g(x,t)$ is a perturbation which does not affect the uniform boundedness and the uniform ultimate boundedness property.

On the other hand, for $\|x\|$ sufficiently small, the local asymptotic stability properties of (4.8) are determined by $g(x,t)$ and not by $f_H(x,t)$. By (4.1), $f_H(x,t)$ does not affect the local stability properties. For example, when $f_H(x) = -x^3$ and $g(x,t) = x$, the system $\dot{x}(t) = -x^3(t) + x(t)$ is uniformly bounded and uniformly ultimately bounded, but the origin is not stable.

There is a duality between these boundedness results and the results proved by Hermes [6, Theorem 3.3], the results proved by Morin and Samson ([10, Proposition 2], and the linearization technique [8, pp. 127–132 and pp. 147–148]. Hermes [6] proves that asymptotic stability of $\dot{x}(t) = f_H(x(t))$ implies local asymptotic stability of $\dot{x}(t) = f_H(x(t)) + g(x(t))$ in the case when $g(x)$ is the sum of a finite number of homogeneous terms with the same dilation as $f_H(x)$ and with orders *larger* than τ. This result is valid since for x with $\|x\|$ sufficiently small $g(x)$ can be seen as a perturbation which does not affect the local asymptotic stability property.

5. Example: Lotka–Volterra equations. Theorem 4.2 proves uniform boundedness and uniform ultimate boundedness for systems arising as $\dot{x}(t) = f_H(x(t),t) + g(x(t),t)$ when all the frozen systems $\dot{x}(t) = f_H(x(t),\sigma)$ of order $\tau > 0$ have an asymptotically stable equilibrium point $x = 0$. The verification of this asymptotic stability property is crucial in the application of Theorem 4.2. It is obvious that the verification of this asymptotic stability property becomes much easier when the frozen systems $\dot{x}(t) = f_H(x(t),\sigma)$ belong to a class of systems whose stability properties have been studied in the literature. We illustrate this by means of an example.

Consider the time-varying Lotka–Volterra system

$$\dot{x}_i(t) = x_i(t)\left((A(t)x)_i + r_i(t)\right), \tag{5.1}$$

where $x = (x_1, \dots, x_n)^T$. Here, $A : \mathbb{R} \to \mathbb{R}^{n\times n}$ is periodic with period T_A and for all $i \in \{1, \dots, n\}$, $r_i : \mathbb{R} \to \mathbb{R}$.

The time-varying Lotka–Volterra equation (5.1) is a positive system. A system is positive if its state-components are nonnegative, i.e., the first closed orthant of $\mathbb{R}^n$ is positively invariant. Examples of these systems are found in a variety of applied areas such as biology, chemistry, and sociology [9, 7].

Although the results in the previous sections are formulated for systems defined in $\mathbb{R}^n$, they also allow the study of positive systems defined in the first closed orthant of $\mathbb{R}^n$.

Indeed, if $\dot{x}(t) = f_H(x(t),t)$ is defined in the first orthant of $\mathbb{R}^n$ with the additional condition that this first closed orthant is positively invariant for the original time-varying system and for all the time-invariant frozen systems $\dot{x}(t) = f_H(x(t), \sigma)$, the results of Theorems 3.2 and 3.3 remain valid.

Suppose that $\dot{x}(t) = f_H(x(t), t) + g(x(t), t)$ is defined in the first orthant of $\mathbb{R}^n$ with the additional condition that this first closed orthant is positively invariant for the time-varying systems $\dot{x}(t) = f_H(x(t), t) + g(x(t), t)$ and $\dot{x}(t) = f_H(x(t), t)$. Suppose also that the first closed orthant of $\mathbb{R}^n$ is positively invariant for all the time-invariant frozen systems $\dot{x}(t) = f_H(x(t), \sigma) + g(x(t), \sigma)$ and $\dot{x}(t) = f_H(x(t), \sigma)$; then the results of Theorems 4.1 and 4.2 remain valid.

Example 1. Assume the following.

- Whenever

  $$x_i \left(A(\sigma)x\right)_i = \lambda(\sigma)x_i, \qquad i = 1, \ldots, n, \tag{5.2}$$

  holds for some σ and for some $x \neq 0$ with $x_i \geq 0$ for all $i \in \{1, \ldots, n\}$, then $\lambda(\sigma) < 0$.
- $A(\sigma)$ is continuously differentiable. There exists a $c_A > 0$ such that for all $\sigma \in \mathbb{R}$

  $$\|A(\sigma)\| \leq c_A \quad \text{and} \quad \|\dot{A}(\sigma)\| \leq c_A. \tag{5.3}$$

- There exists a $c_r > 0$ such that for all $\sigma \in \mathbb{R}$ and for all $i \in \{1, \ldots, n\}$

  $$|r_i(\sigma)| \leq c_r; \tag{5.4}$$

then the time-varying system (5.1) is uniformly bounded and uniformly ultimately bounded.

Proof. By [7, pp. 185–187], all the systems

$$\dot{x}_i(t) = x_i(t)(A(\sigma)x(t))_i \tag{5.5}$$

are asymptotically stable. Take an arbitrary $r \in]0, 1[$. All the systems (5.5) are homogeneous with respect to the dilation $(r, \ldots, r)$ with order $\tau = r > 0$. Take $f_H(x, t) = (f_{H1}(x, t), \ldots, f_{Hn}(x, t))^T$ with $f_{Hi}(x, t) = x_i(A(t)x)_i$, and take $g_i(x, t) = r_i(t)x_i$ for all x and for all t. By setting $F(s) = \frac{\sqrt{n}c_r}{s^r}$, (4.1) is satisfied. By the asymptotic stability property of (5.5), by setting $T_f = T_A$, and by (5.3), the conditions required by Theorems 3.3 and 4.2 are satisfied. By Theorem 4.2, we obtain uniform boundedness and uniform ultimate boundedness for the time-varying positive system (5.1). □

6. Conclusions. In the present paper, we have reduced the study of uniform boundedness and uniform ultimate boundedness of a time-varying system to the study of the time-invariant frozen systems.

Appendix A. The appendix contains the proof of Proposition 2.3.

Proof. Take an arbitray $R_1 > 0$. Define $R_2(R_1) := \max\{\alpha^{-1}(\beta(R_V)), \alpha^{-1}(\beta(R_1))\}$. Take an arbitrary $x_0 \in \mathbb{R}^n$ with $\|x_0\| \leq R_1$. In order to prove (2.2), suppose that for some $t_1 > t_0$, $\|x(t_1, t_0, x_0)\| > R_2(R_1)$. Because of continuity of solutions and since $R_2(R_1) \geq \max\{R_1, R_V\}$, there exists a $t_1' \in [t_0, t_1[$ such that $\|x(t_1', t_0, x_0)\| = \max\{R_1, R_V\}$ and $\|x(t, t_0, x_0)\| > \max\{R_1, R_V\}$ for all $t \in]t_1', t_1]$. Since

$$V(x(t_1, t_0, x_0)) = V(x(t_1', t_0, x_0)) + \int_{t_1'}^{t_1} \dot{V}(x(t, t_0, x_0), t)dt \tag{A.1}$$

and by (2.5) $\dot{V}(x(t,t_0,x_0)) \leq -\gamma(\|x(t,t_0,x_0)\|)$ for all $t \in]t_1', t_1]$, it is clear that

$$V(x(t_1,t_0,x_0)) \leq V(x(t_1',t_0,x_0)) \leq \beta(\max\{R_1, R_V\}). \tag{A.2}$$

By (A.2) and (2.4), $\|x(t_1,t_0,x_0)\| \leq \max\{\alpha^{-1}(\beta(R_V)), \alpha^{-1}(\beta(R_1))\} = R_2(R_1)$. This contradicts the assumption that $\|x(t_1,t_0,x_0)\| > R_2(R_1)$. Therefore, $\|x(t,t_0,x_0)\| \leq R_2(R_1)$ for all $t \geq t_0$ and (2.2) follows.

In order to prove (2.3), take $R = \alpha^{-1}(\beta(R_V))$. Take an arbitrary $R_1 > 0$. Take an arbitrary t_0 and $x_0 \in \mathbb{R}^n$ with $\|x_0\| \leq R_1$. The solution $x(t,t_0,x_0)$ exists for all $t \geq t_0$ since by the first part of the proof $\|x(t,t_0,x_0)\| \leq \max\{\alpha^{-1}(\beta(R_V)), \alpha^{-1}(\beta(R_1))\}$. Define

$$T(R_1) = \max\left\{0, \frac{\beta(R_1) - \alpha(\beta^{-1}(\alpha(R)))}{\gamma(R_V)}\right\}. \tag{A.3}$$

Assume that for all $t_1 \in [t_0, t_0 + T(R_1)]$, $\|x(t_1,t_0,x_0)\| > \beta^{-1}(\alpha(R)) = R_V$ such that $\|x(t,t_0,x_0)\| > \beta^{-1}(\alpha(R)) = R_V$ for all $t \in [t_0, t_1]$ and by (2.5), $\dot{V}(x(t,t_0,x_0),t) \leq -\gamma(R_V)$ for all $t \in [t_0,t_1]$. Since for all $t_1 \in [t_0, t_0 + T(R_1)]$,

$$\begin{aligned} V(x(t_1,t_0,x_0),t_1) &= V(x_0,t_0) + \int_{t_0}^{t_1} \dot{V}(x(t,t_0,x_0),t)dt \leq V(x_0,t_0) \\ &- (t_1 - t_0)\gamma(R_V), \end{aligned} \tag{A.4}$$

we also have

$$\begin{aligned} &V(x(t_0 + T(R_1), t_0, x_0), t_0 + T(R_1)) \\ &\leq \beta(R_1) - T(R_1)\gamma(R_V) \leq \alpha(\beta^{-1}(\alpha(R))). \end{aligned} \tag{A.5}$$

This implies by (2.4) that $\|x(t_0 + T(R_1), t_0, x_0)\| \leq \beta^{-1}(\alpha(R))$, which contradicts the assumption that $\|x(t_1,t_0,x_0)\| > \beta^{-1}(\alpha(R))$ for all $t_1 \in [t_0, t_0 + T(R_1)]$. Consequently, there exists a $t_1 \in [t_0, t_0 + T(R_1)]$ such that $\|x(t_1)\| \leq \beta^{-1}(\alpha(R))$. By the first part of the proof, $\|x(t)\| \leq R$ when $t \geq t_1$ and (2.3) follows. □

A FREQUENCY DOMAIN ROBUST STABILITY THEOREM FOR INFINITE DIMENSIONAL SYSTEMS WITH PARAMETRIC UNCERTAINTY*

COLEMAN BROSILOW† AND MARSHALL J. LEITMAN‡

Abstract. A robust stability theorem of non-Kharitonov type for parametric uncertainty is formulated and proved: *A closed loop system depending on a connected set of parameters whose maximum frequency response is bounded is either stable for all the parameters or for none.* Realistic illustrative examples are provided.

Key words. robust stability, process control, H-infinity, closed loop frequency response, Mp-tuning, parametric uncertainty, root locus

1. Introduction.

In this investigation we formulate and prove a frequency domain robust stability theorem for infinite dimensional systems with parametric uncertainty which is not of Kharitonov [7] type. That is, we are not restricted to polynomial functions or to interval parameter uncertainty. We formulate our result in terms of sufficiently regular meromorphic functions and rather arbitrary parameter sets. Although we state and prove our main result for scalar-valued transfer functions, it can be extended to the matrix-valued case without too much modification. Ours is a parametric approach and differs from the gap metric approach introduced by Zames and El-Sakkary [13]. In the context of frequency response measurements, Vinnicombe [10] has proved some sharp gap metric robust stability results.

The importance of our result is that it justifies a relatively simple computational procedure for the design and tuning of control systems for stable or unstable, finite or infinite dimensional processes with uncertain parameters. The tuning procedure, which we call Mp-tuning, adjusts controller parameters to achieve a specified maximum peak of the frequency response of a closed loop transfer function over all processes in the uncertainty set. If the maximum magnitude of the closed loop frequency response is finite over all uncertain processes, our robust stability theorem then ensures that the resulting control system is stable for all processes in the uncertainty set provided it is stable for any one process in the uncertainty set; conversely, if the control system is unstable for any one process in the uncertainty set, then the control system is unstable for all processes in the uncertainty set.

Examples are provided to illustrate the use of our theorem for stable and unstable processes, infinite dimensional systems, and to emphasize the key role played by the requirement that the transfer function of the closed loop control system be a suitable meromorphic function, a condition which is usually easy to assess in practice.

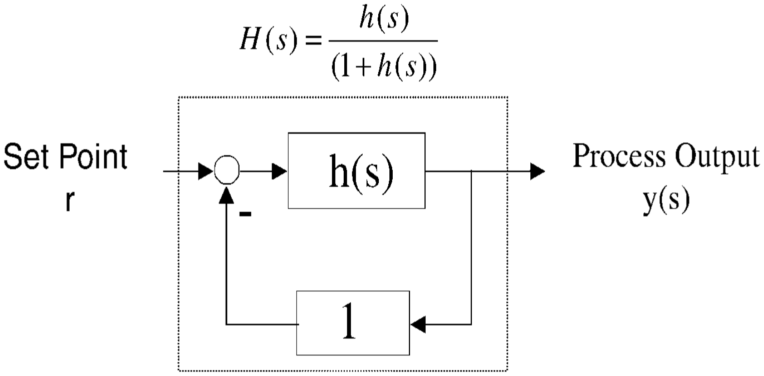

FIG. 1. *A simple feedback system.*

2. Definitions, notation, and hypotheses.

2.1. Transfer functions. An *(open loop) transfer function* is a complex-valued function $(s,p) \mapsto h(s,p)$ of a complex variable s and a parameter p.[1] To the open loop transfer function h we associate the *(closed loop) transfer function* H given by

$$h \mapsto H = \frac{h}{1+h}. \tag{1}$$

The feedback system is shown in Figure 1.

A *parameter* p is an n-dimensional real-valued vector lying in a subset Π of $\mathbb{R}^n$, Euclidean n-space, called the *parameter set* or the *uncertainty set.* If the complex variable s lies on the imaginary axis, we write $s = i\omega$ and call the real number ω the *frequency.* By the *closed loop frequency response (for the parameter* p) we mean the complex-valued function of a real variable given by

$$\omega \mapsto H(i\omega,p) = \frac{h(i\omega,p)}{1+h(i\omega,p)}. \tag{2}$$

To a distinct pair of open loop transfer functions, h and $\widetilde{h}$, we associate a transfer function $\widetilde{H}$ of the form

$$\left(h,\widetilde{h}\right) \mapsto \widetilde{H} = \frac{\widetilde{h}}{1+h}. \tag{3}$$

The corresponding closed loop frequency response is $\omega \longmapsto \widetilde{H}(i\omega,p)$.

2.2. Complex notation and meromorphic functions. The symbol s always denotes a complex number. Complex numbers are represented as points $s = \alpha + i\omega$ in the complex plane, $\mathbb{C}$, or as points on the complex projective sphere (Riemann sphere), $\mathbb{P}$. The complex points at infinity, $s = \infty$, and at zero, $s = 0$, are identified with the north and south poles of the projective sphere, $\mathbb{P}$. If $s \neq \infty$ is in $\mathbb{P}$, we still write $s = \alpha + i\omega$ for some real pair (α,ω). The open complex half-plane $\mathbb{C}^+ = \{s : \Re(s) > 0\} \subset \mathbb{C}$ corresponds to an open hemisphere of $\mathbb{P}$, denoted by $\mathbb{P}^+$. $\overline{\mathbb{C}^+}$ denotes the closed

[1] In this context, for each p, the function $s \mapsto h(s,p)$ may be construed as the Laplace transform of some real-valued function depending on the parameter p.

complex half-plane $\overline{\mathbb{C}^+} = \{s : \Re(s) \geq 0\} \subset \mathbb{C}$. $\overline{\mathbb{P}^+}$ denotes the closure, in $\mathbb{P}$, of the open hemisphere $\mathbb{P}^+$. The real number line, $(-\infty, +\infty)$, is denoted by $\mathbb{R}$, and the extended real number line, $[-\infty, +\infty]$, is denoted by $\overline{\mathbb{R}}$. The topologies of $\mathbb{P}$ and $\mathbb{C}$ are the same provided we identify the neighborhood of infinity $\{s : |s| > M\} \subset \mathbb{C}$ with the north polar cap of $\mathbb{P}$.

A map $(s,p) \to f(s,p)$ on a region in $\mathbb{C}\times\mathbb{C}^n$ is a *holomorphic function* whenever $(s,(p_1,p_2,\ldots,p_n)) \to f(s,(p_1,p_2,\ldots,p_n))$ is holomorphic separately in each of the variables $s, p_1, p_2, \ldots, p_n$. A map $(s,p) \to f(s,p)$ on a region in $\mathbb{C}\times\mathbb{C}^n$ is a *meromorphic function* if, on every neighborhood, $\mathcal{U}_i$, in the region, it is the ratio of two relatively prime holomorphic functions, say, n_i and m_i; that is, $m_i(s,p) f(s,p) = n_i(s,p)$ on $\mathcal{U}_i$. The m's and the n's must agree on overlapping neighborhoods in the sense that $n_i m_j = n_j m_i$ on $\mathcal{U}_i \cap \mathcal{U}_j$. Regarding the *value,* $f(s_0,p_0)$, of a meromorphic function f at a point (s_0,p_0) we have the following important definition.

The values of a meromorphic function.

$$f(s_0,p_0) = \begin{cases} 0 & \text{if} \quad n_i(s_0,p_0) = 0, m_i(s_0,p_0) \neq 0 \quad \text{(zero)}, \\ \frac{n_i(s_0,p_0)}{m_i(s_0,p_0)} & \text{if} \quad n_i(s_0,p_0) \neq 0, m_i(s_0,p_0) \neq 0, \\ \infty & \text{if} \quad n_i(s_0,p_0) \neq 0, m_i(s_0,p_0) = 0 \quad \text{(pole)}, \\ \text{undefined} & \text{if} \quad n_i(s_0,p_0) = 0, m_i(s_0,p_0) = 0. \end{cases} \tag{4}$$

In the first three cases f has a definite value in $\mathbb{P}$ at (s_0,p_0), denoted by $f(s_0,p_0)$; in the last case, the value of f must remain undefined since there is no consistent way to assign a value at such a point.[2] Indeed, for any complex number c, there is a point (s,p), arbitrarily close to (s_0,p_0), at which $f(s,p) = c$.

2.3. Hypotheses on the parameter set and the closed loop transfer function. Regarding the parameter set Π, we always assume the following:

(P) *The parameter set* Π *is an open connected subset of* $\mathbb{R}^n$.

Since Π is *connected,* for any two points $\widehat{p}$ and $\widehat{q}$ in Π, there is a *path* σ *in* Π *from* $\widehat{p}$ *to* $\widehat{q}$; that is, there is a continuous function $\sigma : [0,1] \to \Pi$ such that $\sigma(0) = \widehat{p}$ and $\sigma(1) = \widehat{q}$.

In the following hypotheses, h is a function defined on $\overline{\mathbb{P}^+} \times \Pi$ with values in $\mathbb{P}$; that is, h has a value at every point in $\overline{\mathbb{C}^+} \times \Pi$ and at the points $\{\infty\} \times \Pi$.

(M) *There is a connected open set* $\widehat{\Pi}$ *in* $\mathbb{C}^n$ *such that* $\widehat{\Pi} \cap \mathbb{R}^n = \Pi$ *and the function* $(s,p) \mapsto h(s,p)$ *has a meromorphic extension to* $\mathbb{C}^+ \times \widehat{\Pi}$*, also denoted by* h. (In particular, h has a value at every point in $\mathbb{C}^+ \times \Pi$ in the sense of the definition of the values of a meromorphic function (4).[3])

(S) *For each parameter* $p \in \Pi$*, the function* $s \mapsto h(s,p)$ *is not constant on* $\mathbb{C}^+$.

(R) *For each parameter* $p \in \Pi$*, the function* $s \mapsto h(s,p)$ *is real-valued or* ∞ *on the positive real axis* $\{s : \Re(s) > 0, \Im(s) = 0\}$.

(C) *The function* $(s,p) \mapsto h(s,p)$ *is (jointly) continuous as a function from* $\overline{\mathbb{P}^+} \times \Pi$ *into* $\mathbb{P}$.[4]

[2] See, for example, Hörmander [6, Theorem 6.2.3].

[3] If $(s,p) \mapsto h(s,p)$ is "meromorphic for real parameters p" in the sense of convergent power series expansions, this extension is always possible.

[4] If h, regarded as a map from $\overline{\mathbb{P}^+} \times \widehat{\Pi}$ into $\mathbb{P}$, satisfies (M), then $(s,p) \mapsto h(s,p)$ is always (jointly) continuous at points in $\mathbb{P}^+ \times \Pi$ (since h is meromorphic and has a value at every point in $\mathbb{P}^+ \times \widehat{\Pi}$). Since h has a value at every point in $\overline{\mathbb{P}^+} \times \Pi$, the condition (C) amounts to the additional assumption that h be (jointly) continuous at boundary points of the form $(i\omega, p) \in \overline{\mathbb{P}^+} \times \Pi$ for $\omega \in \mathbb{R}$ or $(\infty, p) \in \overline{\mathbb{P}^+} \times \Pi$.

The hypotheses (M), (S), and (R) are essentially regularity or consistency conditions on h. However, the connectivity of the parameter set, hypothesis (P), and the continuity of h, hypothesis (C), especially at points on the imaginary axis, are structurally necessary for our results to hold. (See Example 4.1.)

If h satisfies any of the hypotheses (M), (S), (R), or (C), so does the function $1 + h$. Furthermore, if h satisfies the hypothesis (M), so does the function H defined by (1) since we can assign H values in a manner consistent with the definition of the values of a meromorphic function (4). If, in addition to (M), h satisfies hypotheses (R) and/or (C), so does H.

We will be concerned with either a single open loop transfer function h and its associated closed loop transfer function H or a distinct pair of open loop transfer functions h and $\widetilde{h}$ together with the associated closed loop transfer function $\widetilde{H}$ defined by (3). In general, if h and $\widetilde{h}$ each satisfy hypotheses (M) and/or (C), it does not follow that $\widetilde{H}$ satisfies (M) and/or (C), for it may not be possible to assign values to $\widetilde{H}$ consistent with definition of the values of a meromorphic function (4) at every point where h and $\widetilde{h}$ have values. In such a case we must add the following compatibility hypothesis.

(D) *The open loop transfer functions h and $\widetilde{h}$ are* compatible *in the sense that each satisfies hypotheses (M) and (C) and the function $\widetilde{H} = \frac{\widetilde{h}}{1+h}$ also satisfies hypotheses (M) and (C).* Clearly, h is always compatible with itself.

For a given open loop transfer function h, the *maximum magnitude of the closed loop frequency response over all parameters* or, succinctly, the *maximum magnitude*, we mean the extended-real-valued function $\mathcal{H} : [-\infty, +\infty] \to [0, +\infty]$ defined by

$$\omega \mapsto \mathcal{H}(\omega) = \sup_{p\in\Pi} |H(i\omega, p)| = \sup_{p\in\Pi} \left| \frac{h(i\omega, p)}{1 + h(i\omega, p)} \right|. \tag{5}$$

Whenever hypothesis (C) holds, $\mathcal{H}$ is well defined on the extended real line $\overline{\mathbb{R}}$. By an *extended*-real-valued function, we mean that the supremum in the definition of $\mathcal{H}$ can be infinite at a given frequency, say, $\widetilde{\omega}$, in which case we write $\mathcal{H}(\widetilde{\omega}) = +\infty$; in particular $\mathcal{H}(\widetilde{\omega}) = +\infty$ whenever $h(i\widetilde{\omega}, \widetilde{p}) + 1 = 0$ for some frequency $\widetilde{\omega}$ and some parameter $\widetilde{p}$. If hypotheses (M), (C), and (R) hold, $h(\overline{s}, p) = \overline{h(s, p)}$ on $\overline{\mathbb{P}^+} \times \Pi$, since $h(s, p)$ is real-valued or ∞ on the positive real axis $\{s : \Re(s) > 0, \Im(s) = 0\}$. In particular, $h(-i\omega, p) = \overline{h(i\omega, p)}$ for all $\omega \in \mathbb{R}$ and each $p \in \Pi$.[5] In this case, the maximum magnitude is an (extended-real-valued) *even* function of the frequency; hence, it is completely determined by its values for $\omega \in [0, \infty]$. Definition (5) and the assertions above remain meaningful and valid mutatis mutandis when we have a distinct pair of compatible transfer functions h and $\widetilde{h}$, in which case we write $\widetilde{\mathcal{H}}$ instead of $\mathcal{H}$.

For a single open loop transfer function h, and a parameter p_0, the corresponding closed loop system is said to be *stable at the parameter* p_0 whenever the function $s \mapsto H(s, p_0) = \frac{h(s,p_0)}{1+h(s,p_0)}$ has no pole ($\neq \infty$) in the *closed* hemisphere $\overline{\mathbb{P}^+}$. This condition is equivalent to the assertion that the function $s \mapsto 1 + h(s, p_0)$ has no zero in the *closed* hemisphere $\overline{\mathbb{P}^+}$. The closed loop system is said to be *unstable at the parameter* p_0 if it is not stable at p_0; that is, $s \mapsto H(s, p_0) = \frac{h(s,p_0)}{1+h(s,p_0)}$ has at least one pole in the *closed* hemisphere $\overline{\mathbb{P}^+}$.

[5] This is a consequence of the reflection principle. Note that $h(\infty, p)$ is real-valued or ∞ for every parameter p.

For a pair of distinct compatible open loop transfer functions h and $\widetilde{h}$, we also say that the corresponding closed loop system is *stable at the parameter* p_0 whenever the transfer function $s \mapsto \widetilde{H}(s,p_0) = \frac{\widetilde{h}(s,p_0)}{1+h(s,p_0)}$ has no pole ($\neq \infty$) in the *closed* hemisphere $\overline{\mathbb{P}^+}$. The closed loop system is again said to be *unstable at the parameter* p_0 if it is not stable at p_0; that is, $s \mapsto \widetilde{H}(s,p_0) = \frac{\widetilde{h}(s,p_0)}{1+h(s,p_0)}$ has at least one pole in the *closed* hemisphere $\overline{\mathbb{P}^+}$. In the case of distinct compatible open loop transfer functions, stability at parameter p_0 is not equivalent to the assertion that the function $s \mapsto 1 + h(s,p_0)$ has no zero in the *closed* hemisphere $\overline{\mathbb{P}^+}$. Indeed, $1 + h(s,p_0)$ could be nonzero at a point where $\widetilde{h}(s,p_0)$ has a pole.

3. Main results and proofs. We now state our main result—*the robust stability theorem (RST)*—for a single open loop transfer function.

Theorem 3.1 (RST: single transfer function). *Assume that the open loop transfer function satisfies hypotheses* (P), (M), (S), (R), *and* (C). *Let the maximum magnitude of the closed loop frequency response over all parameters be bounded. Then, if the closed loop system is stable for* at least one *parameter in the parameter set* Π, *the closed loop system is stable for* all *parameters in the parameter set* Π.

Proof (outline of the proof). Suppose Theorem 3.1 was false under the stated hypotheses. Then there is a parameter q_0 for which the system is stable and another parameter p_0 for which the system is unstable. The parameter set Π is assumed open and connected, so we can choose a path from p_0 to q_0 lying entirely inside the parameter set Π. Since the system is unstable for p_0, there is at least one point, say, s_0, in $\overline{\mathbb{P}^+}$ such that $1+h(s_0,p_0)=0$; and, since the system is stable for q_0, there is no such point corresponding to q_0. We then use a "root locus" or "continuity" argument to conclude that there is a parameter $\widehat{p} \in \Pi$ and a frequency $\widehat{\omega} \in [0,\infty]$ such that $1+h(i\widehat{\omega},\widehat{p})=0$, and, hence, $\mathcal{H}(\widehat{\omega}) = +\infty$. The maximum magnitude is not bounded, which contradicts our hypothesis. □

In order to develop the root locus argument and complete the proof of Theorem 3.1, we establish some preliminary definitions and results. It will be convenient to write g for the function $h+1$. The hypotheses (M), (R), (S), and (C) hold for g if and only if they hold for h. If, for some parameter p_0, $s \longmapsto g(s,p_0)$ has no zero in $\overline{\mathbb{P}^+}$, we say that g is *stable* at p_0. We say g is *unstable* at p_0 if it is not stable at p_0.

We will first be concerned with the zeros of g in the set $\mathbb{P}^+ \times \Pi$; that is, those points $(s_0,p_0) \in \mathbb{P}^+ \times \Pi$ such that $g(s_0,p_0)=0$. Fix such a zero, (s_0,p_0). Henceforth, suppose (M) and (S) hold.[6] Then there is a positive integer k_0 and neighborhood in $\mathbb{P}^+ \times \widehat{\Pi}$ of (s_0,p_0) on which g is holomorphic and satisfies

$$g(s,p_0) = (s-s_0)^{k_0} f(s,p_0) \tag{6}$$

for some function $s \mapsto f(s,p_0)$, holomorphic near s_0, such that $f(s_0,p_0) \neq 0$. We call k_0 the *multiplicity* of the zero (s_0,p_0). We need the following immediate consequence of the Weierstrass preparation theorem (WPT).[7]

Theorem 3.2 (WPT). *Let g satisfy* (M) *and* (S). *Suppose* $g(s_0,p_0)=0$ *at* $(s_0,p_0) \in \mathbb{P}^+ \times \Pi$. *Then there is a neighborhood U_0 in $\mathbb{P}^+ \times \widehat{\Pi}$ of the zero (s_0,p_0) and k_0 functions $p \mapsto \lambda_k(p)$, $\lambda_k(p_0)=0$, $k=0,1,2,3,\ldots,(k_0-1)$, holomorphic on some common neighborhood W_0 in $\widehat{\Pi}$ of p_0, such that the function* $(s,p) \mapsto g(s,p)$

[6] Hypothesis (S) guarantees that the function $s \mapsto g(s,p_0)$ is not identically zero near s_0.

[7] For a complete statement and proof of the Weierstrass preparation theorem, see Hörmander [6].

and the function

$$(s,p)\mapsto (s-s_0)^{k_0}+\sum_{j=0}^{k_0-1}\lambda_j(p)(s-s_0)^j \tag{7}$$

have the same set of zeros on U_0. *This function is called the* Weierstrass polynomial *associated with* g *at the point* (s_0,p_0).

Let p_0 and q_0 be distinct parameters in Π, and let σ be a path in Π from p_0 to q_0. Let (s_0,p_0) be a zero of g such that $s_0\in\mathbb{P}^+$. For each $t\in[0,1]$ define a set $L_0^\sigma(t)\subset\mathbb{C}^+$ by

$$L_0^\sigma(t)=\left\{\widehat{s}\in\mathbb{P}^+ : \exists\varsigma:[0,t]\overset{cont}{\longrightarrow}\mathbb{P}^+,\left\{\begin{array}{l}\varsigma(0)=s_0\\ \varsigma(t)=\widehat{s}\\ \forall\tau\in[0,t],g(\varsigma(\tau),\sigma(\tau))=0\end{array}\right\}\right\}. \tag{8}$$

In other words, $L_0^\sigma(t)$ is the set of those zeros, $\widehat{s}$, of $s\to g(s,\sigma(t))$ in $\mathbb{P}^+$ for which there is a continuous path $\tau\mapsto(\varsigma(\tau),\sigma(\tau))$ on $[0,t]$ into $\mathbb{P}^+\times\Pi$, consisting entirely of zeros of g, connecting the zero (s_0,p_0) to the zero $(\widehat{s},\sigma(t))$. We call $L_0^\sigma(t)$ the *root locus, at* t, *emanating from* s_0 *induced by* σ or, simply, *the root locus emanating from* s_0.

The following three properties of the root locus are implicit in its definition:

(L1) $L_0^\sigma(0)=\{s_0\}$,

(L2) $s\in L_0^\sigma(t)\Rightarrow g(s,\sigma(t))=0$,[8]

(L3) $L_0^\sigma(t)\neq\emptyset\Rightarrow\forall\tau\in[0,t),L_0^\sigma(\tau)\neq\emptyset$.

Thus far, there is no guarantee that $L_0^\sigma(\tau)\neq\emptyset$ for *any* $\tau>0$. The next property of the root locus asserts that there are such τ's.

(L4) *There is an* $\epsilon\in(0,1]$ *such that* $\forall\tau\in[0,\epsilon),L_0^\sigma(\tau)\neq\emptyset$.

This is an immediate consequence of the following lemma, which asserts that the local behavior of the root locus is entirely determined by the Weierstrass polynomial.

LEMMA 3.1 (local root locus lemma). *Let* g *satisfy* (P), (M), *and* (S). *Fix* $\widehat{\tau}\in[0,1]$. *Let* $(\widehat{s},\sigma(\widehat{\tau}))\in\mathbb{P}^+\times\Pi$ *be a zero of* g; *that is,* $g(\widehat{s},\sigma(\widehat{\tau}))=0$. *Suppose this zero has multiplicity* $\widehat{k}$. *Then, for some* $\epsilon>0$, *there are* $\widehat{k}$ *continuous functions* $\tau\mapsto\zeta_l(\tau),l=1,2,3,\ldots,\widehat{k}$, *defined on a common subinterval of* $[0,1]$ *of the form* $[\widehat{\tau},\widehat{\tau}+\epsilon)$ *or* $(\widehat{\tau}-\epsilon,\widehat{\tau}]$, *depending on whether* $\widehat{\tau}\in[0,1)$ *or* $\widehat{\tau}\in(0,1]$, *with values in* $\mathbb{P}^+$, *each of which satisfies* $g(\zeta_l(\tau),\sigma(\tau))=0$ *for all* τ *in the common interval of definition. We say that* $\tau\mapsto(\zeta_l(\tau),\sigma(\tau))$ *is a forward or backward path of zeros of* g *induced by* σ *emanating from* $(\widehat{s},\sigma(\widehat{\tau}))$. *Of course, if* $\hat{\tau}\in(0,1)$, *there are* $\hat{k}$ *forward and* $\hat{k}$ *backward paths of zeros induced by* σ *emanating from* $(\widehat{s},\sigma(\widehat{\tau}))$ *and, hence, as many as* $\hat{k}^2$ *continuous paths of zeros of* g *on* $(\hat{\tau}-\epsilon,\hat{\tau}+\epsilon)$ *containing* $(\widehat{s},\sigma(\widehat{\tau}))$.

Proof. The proof is given for the case $\widehat{\tau}=0$, which yields property (L4). The other cases are similarly proved. Let U_0 and W_0 be the neighborhoods described in the WPT associated with $(\widehat{s},\sigma(\widehat{\tau}))=(s_0,p_0)$. Choose $\epsilon\in(0,1)$ so that $\sigma(\tau)\in W_0$ whenever $\tau\in[0,\epsilon)$. This is clearly possible. For each $\tau\in[0,\epsilon)$, consider the roots of the Weierstrass polynomial associated with g at the given zero:

$$(s-s_0)^{\hat{k}}+\sum_{k=0}^{\hat{k}-1}\lambda_k(\sigma(\tau))(s-s_0)^k. \tag{9}$$

[8] In general, the converse assertion $g(s,\sigma(t))=0\Rightarrow s\in L(t)$ is false.

By the WPT the roots of this polynomial are precisely those of $s \mapsto g(s, \sigma(\tau))$, provided that $(s, \sigma(\tau)) \in U_0$. (Note that the $\hat{k}$ coefficient functions $\tau \mapsto \lambda_k(\sigma(\tau))$, $k = 0, 1, 2, 3, \ldots, (\hat{k} - 1)$, are each continuous and satisfy $\lambda_k(\sigma(0)) = \lambda_k(p_0) = 0$.) It follows that there are $\hat{k}$ continuous complex-valued functions $\tau \mapsto \zeta_l(\tau)$, $l = 1, 2, 3, \ldots, \hat{k}$, on $[0, \epsilon)$ such that each $\zeta_l(0) = s_0$ and

$$(10) \qquad (\zeta_l(\tau) - s_0)^{\hat{k}} + \sum_{k=0}^{\hat{k}-1} \lambda_k(\sigma(\tau))(\zeta_l(\tau) - s_0)^k = 0.$$

The functions $\tau \mapsto (\zeta_l(\tau), \sigma(\tau))$ are paths of zeros of g induced by σ emanating from $(\widehat{s}, \sigma(\widehat{\tau})) = (s_0, p_0)$. Any one of the $\hat{k}$ functions $\tau \mapsto \zeta_l(\tau)$ can serve as a path, or a segment of a path, in the definition of L_0^σ. In particular, $L_0^\sigma(\tau) \neq \emptyset$ for $\tau \in [0, \epsilon)$. □

There is a *maximal* interval of the form $[0, \epsilon_0) \subseteq [0, 1)$ such that $\tau \in [0, \epsilon_0) \Rightarrow L_0^\sigma(\tau) \neq \emptyset$. Indeed, the maximal interval $[0, \epsilon_0)$ can be realized by

$$(11) \qquad [0, \epsilon_0) = \bigcup \{[0, \epsilon) \subseteq [0, 1) : \forall \tau \in [0, \epsilon), L_0^\sigma(\tau) \neq \emptyset\}.$$

Consider the *Ω-limit set,* $\Omega(\sigma)$, of the root locus $t \mapsto L_0^\sigma(t)$ on the maximal interval $[0, \epsilon_0)$. The set $\Omega(\sigma)$ is defined by[9]

$$(12) \qquad \Omega(\sigma) = \bigcap_{\tau \in [0, \epsilon_0)} cl\left(\bigcup_{t \in [\tau, \epsilon_0)} L_0^\sigma(t)\right).$$

By its construction, $\Omega(\sigma)$ is a nonempty, compact subset of $\overline{\mathbb{P}^+}$. We call $\Omega(\sigma)$ *the Ω-limit set (for g) induced by σ emanating from s_0.*

We can now state and prove the following lemma.

Lemma 3.2 (Ω-limit set). *Assume that g satisfies* (P), (M)*, and* (S). *Let p_0 and q_0 be parameters in Π such that g is stable at q_0 and unstable at p_0. For the unstable parameter p_0, let there be a point $s_0 \in \mathbb{P}^+$ such that $g(s_0, p_0) = 0$. Fix a path σ in Π from p_0 to q_0. Let $\Omega(\sigma)$ be the Ω-limit set for g induced by σ emanating from s_0. Then $\Omega(\epsilon_0, \sigma) \bigcap \mathbb{P}^+ = \emptyset$. Equivalently, the Ω-limit set, $\Omega(\sigma)$, regarded as a subset of $\overline{\mathbb{P}^+}$, is a nonempty, compact subset of the extended imaginary axis $\{s : \Re(s) = 0\} \cup \{\infty\}$.*[10]

Proof. Consider the root locus $t \mapsto L_0^\sigma(t)$ of g induced by σ emanating from s_0 and its Ω-limit set $\Omega(\epsilon_0, \sigma)$. Observe that $L_0^\sigma(1) = \emptyset$, since g is stable at q_0. Suppose $\Omega(\sigma) \bigcap \mathbb{P}^+ \neq \emptyset$. Let $\widehat{s} \in \Omega(\sigma) \bigcap \mathbb{P}^+$. Then there is an increasing sequence $t_n \uparrow \epsilon_0$ and a sequence $s_n \in \mathbb{P}^+$ such that $s_n \to \widehat{s}$ and $g(s_n, \sigma(t_n)) = 0$. Now g must be holomorphic in some neighborhood of $(\widehat{s}, \sigma(\epsilon_0))$ in $\mathbb{P}^+ \times \widehat{\Pi}$, since it is defined at $(\widehat{s}, \sigma(\epsilon_0))$; moreover, it vanishes at points arbitrarily close to $(\widehat{s}, \sigma(\epsilon_0))$. Since g is jointly continuous at $(\widehat{s}, \sigma(\epsilon_0))$, it follows that $g(\widehat{s}, \sigma(\epsilon_0)) = 0$. It turns out that $\widehat{s} \in L_0^\sigma(\epsilon_0)$, so $L_0^\sigma(\epsilon_0) \neq \emptyset$. To see this, apply the local root locus Lemma 3.1 at the point $(\widehat{s}, \sigma(\epsilon_0))$. For N sufficiently large there must be a subsequence s_{n_k}, $n_k \geq N$, which lies entirely on one of the paths of zeros of g induced by σ emanating *backward* from $(\widehat{s}, \sigma(\epsilon_0))$ as described in the local root locus Lemma 3.1. This follows since *all* the zeros of $s \mapsto g(s, \sigma(\epsilon_0))$ close to $\hat{s}$ are determined by the corresponding Weierstrass

[9] The function cl( ) denotes topological closure in the complex plane $\mathbb{C}$ or on the projective sphere $\mathbb{P}$.

[10] The extended imaginary axis, $\{s : \Re(s) = 0\} \bigcup \{\infty\}$, should be construed as a great circle on $\mathbb{P}$.

polynomial. For any corresponding t_{n_k}, we have $s_{n_k} \in L_0^\sigma(t_{n_k})$. This implies that $\widehat{s} \in L_0^\sigma(\epsilon_0)$. Since $L_0^\sigma(1) = \emptyset$, we must have $\epsilon_0 < 1$. But then the interval $[0, \epsilon_0)$ is not maximal. Indeed, since $\widehat{s} \in L_0^\sigma(\epsilon_0)$, we can apply the local root locus Lemma (3.1) *forward* at $(\widehat{s}, \sigma(\epsilon_0))$, as we did at $(s_0, \sigma(0))$. Hence, there must be an ϵ_1, $1 \geq \epsilon_1 > \epsilon_0$ such that $L_0^\sigma(t) \neq \emptyset$ for $t \in [\epsilon_0, \epsilon_1)$. The proof is complete. □

Finally, we can prove Theorem (3.1).

Proof (details of the proof). Suppose Theorem 3.1 to be false. If, for the unstable parameter p_0, there is a frequency $\widehat{\omega} \in [0, \infty]$ such that $1 + h(i\widehat{\omega}, p_0) = 0$, then $\mathcal{H}(\widehat{\omega}) = \infty$. This is an immediate contradiction, and the RST follows. Suppose that for the unstable parameter p_0 there is no such point; that is, $1 + h(i\omega, p_0) \neq 0$ for all $\omega \in [0, \infty]$. Then there is at least one point $s_0 \in \mathbb{P}^+$ such that $g(s_0, p_0) = 1 + h(s_0, p_0) = 0$. Fix a path σ in Π from p_0 to q_0. By the Ω-limit set Lemma 3.2, the Ω-limit set $\Omega(\sigma)$ for g induced by σ emanating from s_0 is a subset of the extended imaginary axis $\{s : \Re(s) = 0\} \bigcup \{\infty\}$. Let $\widehat{s} \in \Omega(\sigma)$. Either $\widehat{s} = i\widehat{\omega}$, for some $\widehat{\omega} \in \mathbb{R}$, or $\widehat{s} = \infty$. In either case, there is a sequence $t_n \uparrow \epsilon_0$ and a sequence of points $s_n \in \mathbb{P}^+$ such that $s_n \to \widehat{s}$ and $g(s_n, \sigma(t_n)) = 0$. By the joint continuity assumption (C), we must have $g(\widehat{s}, \widehat{p}) = 0$, where $\widehat{p} = \sigma(\epsilon_0)$. This means that $\mathcal{H}(\widehat{\omega}) = +\infty$ or $\mathcal{H}(\infty) = +\infty$; that is, the maximum magnitude of the closed loop frequency response over all parameters is unbounded, which contradicts our hypothesis. The theorem is proved. □

The RST also holds for a pair of distinct compatible open loop transfer functions. However, the proof requires a bit more care.

Theorem 3.3 (RST: distinct compatible transfer functions). *Assume that the distinct pair of open loop transfer functions satisfy hypotheses* (P), (M), (S), (R), *and* (C), *and are compatible. Let the maximum magnitude of the closed loop frequency response over all parameters be bounded. Then, if the closed loop system is stable for* at least one *parameter in the parameter set* Π, *the closed loop system is stable for* all *parameters in the parameter set* Π.

Proof. The details of the proof are essentially the same as those for Theorem 3.1 once the following observations are made.

If $s \longmapsto \widetilde{H}(s, r_0)$ has a pole at s_0, then $\widetilde{H}$ has a pole at (s_0, r_0). In this case, $\widetilde{H}$ can be represented in a neighborhood of (s_0, r_0) as a ratio of a pair of relatively prime holomorphic functions, say, $\widetilde{m}$ and $\widetilde{n}$ ($\widetilde{H} = \frac{\widetilde{n}}{\widetilde{m}}$), such that $\widetilde{n}(s_0, r_0) \neq 0$ and $\widetilde{m}(s_0, r_0) = 0$. The two lemmas (Lemmas 3.1 and 3.2) and the proof of the theorem remain essentially unchanged, except that we use the $\widetilde{m}$'s locally in place of g. In this case we refer to $\Omega(\sigma)$ as *the* Ω-limit set (for $\widetilde{H}$) induced by σ emanating from s_0.

Suppose Theorem 3.3 to be false. If, for the unstable parameter p_0, there is a frequency $\widehat{\omega} \in [0, \infty]$ such that $\widetilde{H}(i\widehat{\omega}, p_0) = \infty$, then $\widetilde{\mathcal{H}}(\widehat{\omega}) = \infty$. This is an immediate contradiction, and the robust stability Theorem 3.3 follows. Suppose that for the unstable parameter p_0 there is no such point; that is, $\widetilde{H}(i\omega, p_0) \neq \infty$ for all $\omega \in [0, \infty]$. Then there is at least one point $s_0 \in \mathbb{P}^+$ such that $\widetilde{H}(s_0, p_0) = \infty$. Fix a path σ in Π from p_0 to q_0. By the root locus Lemma 3.1, the Ω-limit set $\Omega(\sigma)$ for $\widetilde{H}$ induced by σ emanating from s_0 is a nonempty, compact subset of the extended imaginary axis $\{s : \Re(s) = 0\} \bigcup \{\infty\}$. Let $\widehat{s} \in \Omega(\sigma)$. Either $\widehat{s} = i\widehat{\omega}$, for some $\widehat{\omega} \in \mathbb{R}$, or $\widehat{s} = \infty$. In either case, there is a sequence $t_n \uparrow \epsilon_0$ and a sequence of points $s_n \in \mathbb{P}^+$ such that $s_n \to \widehat{s}$ and $\widetilde{H}(s_n, \sigma(t_n)) = \infty$. By the joint continuity assumption (C), we must have $\widetilde{H}(\widehat{s}, \widehat{p}) = \infty$, where $\widehat{p} = \sigma(\epsilon_0)$. This means that $\widetilde{\mathcal{H}}(\widehat{\omega}) = +\infty$ or $\widetilde{\mathcal{H}}(\infty) = +\infty$; that is, the maximum magnitude of the closed loop frequency response over all parameters is unbounded, which contradicts our hypothesis. The theorem is proved. □

4. Examples. We provide three useful examples. The first, Example 4.1, illustrates the key role played by hypotheses (S) and (C). The second two, Examples 4.2 and 4.3, deal with unstable uncertain processes and illustrate the use of our robust stability Theorem 3.3, for a pair of distinct transfer functions. To deal with such processes, we will use two degree of freedom control structures shown in Figures 2 and 3. Since the configuration of Figure 3 is internally unstable for unstable processes (Morari and Zafiriou [8]), we will use Figure 3 only for design purposes. Actual control system implementation must be by Figure 2, or by algorithms proposed by Berber and Brosilow [1, 2] and Cheng and Brosilow [4], which yield the same input-output transfer functions as in Figure 3 but which are internally stable.

Example 4.1 (the role of hypotheses (P) and (C)). This example[11] illustrates the role of hypotheses (P) and (C) and why they are necessary for our result to hold.

Suppose h is given by

$$h(s,a) = \frac{a(a-s)}{a(1-a)+s(1+a)}, \tag{13}$$

where the parameter set is the open interval $\Pi = \{a : -1 < a < 1\}$. In this case the closed loop transfer function is

$$\frac{h(s,a)}{1+h(s,a)} = a\frac{(a-s)}{a+s}, \tag{14}$$

and the maximum magnitude function, $\mathcal{H}$, is

$$\mathcal{H}(\omega) = \sup_{-1<a<1} \left| \frac{h(s,i\omega)}{1+h(s,i\omega)} \right| = 1. \tag{15}$$

Clearly $\mathcal{H}$ is bounded. On the other hand, for $a < 0$ the system is unstable, while for $a > 0$, the system is stable. This seems to violate the conclusion of our RST! To see that this compelling example is not a counterexample to Theorem 3.1, examine the hypotheses. The parameter set, Π, is just an interval, so it is connected. From the formula above, h is well defined as a meromorphic function for all parameters $a \in \Pi$ and $s \in \mathbb{C}^+$; moreover, h is real-valued for $a \in \Pi$ and $s \in \{s : \Im(s) = 0, \Re(s) > 0\}$. Hence, hypotheses (P), (M), and (R) are satisfied. However, hypothesis (S) requires that, for any $a \in \Pi$, the function $s \to h(s,a)$ not be constant in $\mathbb{C}^+$. However, at $a = 0$, $s \to h(s,0) = 0$ for $s \in \mathbb{C}^+$. More importantly, hypothesis (C) requires that h be well defined on the extended imaginary axis for all parameters $a \in \Pi$ in such a way that it is jointly continuous there. But h cannot be defined at $(s_0, a_0) = (0,0)$ in such a way that it is jointly continuous at that point. In fact, the defining expression (13) for h represents a meromorphic function for all complex s and a which has no value at $s = a = 0$ in the sense of the definition of the values of a meromorphic function (4). An obvious way to avoid violating hypotheses (S) and/or (C) is to exclude $a = 0$ from the parameter set. However, since Π is an interval, this would disconnect the parameter set, violating hypothesis (P).

[11] The authors are indebted to Professor Sebastian Engell, Chemietechnik, Universität Dortmund, for suggesting this example.

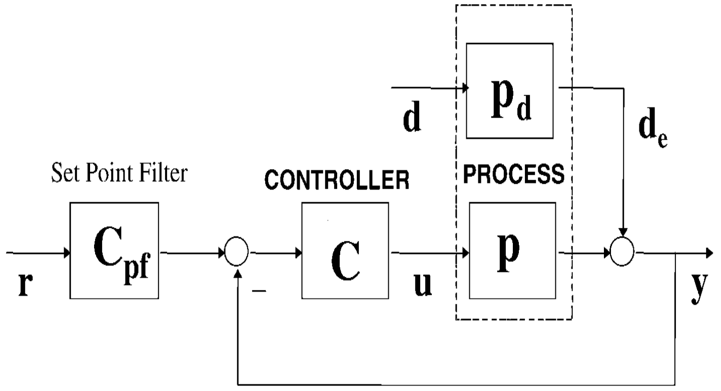

FIG. 2. *Standard feedback two degree of freedom control system.*

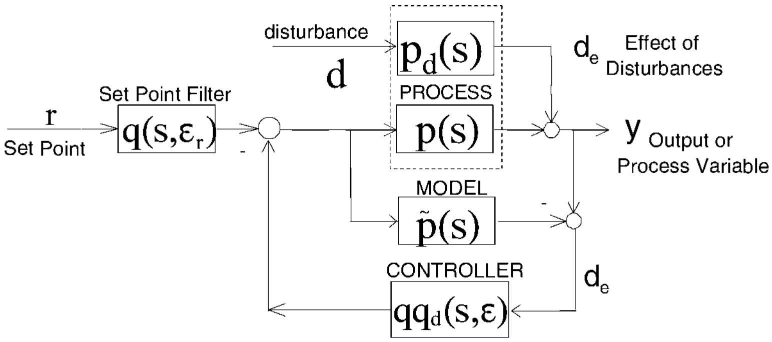

FIG. 3. *IMC form of two degree of freedom control system.*

Example 4.2 (an undamped two-mass spring system). This example presents the solution for an unstable "benchmark" control problem proposed by Wie and Bernstein [11, 12]. It consists of an undamped two-mass spring system modeled by

$$y(s) = p(s)u(s) + p_d(s)d(s), \tag{16}$$

where

$$p(s) = \frac{\frac{1}{2}}{s^2\left(\frac{1}{2k}s^2 + 1\right)}, \tag{17}$$

$$p_d(s) = \frac{\frac{1}{2}\left(\frac{1}{k}s^2 + 1\right)}{s^2\left(\frac{1}{2k}s^2 + 1\right)}, \tag{18}$$

and where

k =process spring constant ($0.5 \le k \le 2$),

u =control effort,

y =position of second mass.

The control objective is to design a robust controller to suppress impulse disturbances for all the plants in the uncertainty set. Further, the "nominal" process is to have a settling time of 15 seconds.

Referring to Figures 2 and 3, the closed transfer functions between the set points and the disturbances and the process are

$$y(s) = \frac{c_{pf}c(s)p(s)r(s) + p_d(s)d(s)}{(1 + c(s)p(s))} \tag{19}$$

for Figure 2 and

$$y(s) = \frac{q(s, \varepsilon_r)p(s)r(s) + (1 - \tilde{p}(s)qq_d(s, \varepsilon))\, p_d(s)d(s)}{(1 + (p(s) - \tilde{p}(s))\, qq_d(s, \varepsilon))} \tag{20}$$

for Figure 3.

The transfer functions given by (19) and (20) are equivalent (in terms of input-output transfer functions) if $c_{pf}(s)$ and $c(s)$ are chosen as

$$c_{pf}(s) = q(s, \varepsilon_r)\, (qq_d(s, \varepsilon))^{-1} \tag{21}$$

and

$$c(s) = \frac{qq_d(s, \varepsilon)}{(1 - \tilde{p}(s)qq_d(s, \varepsilon))}. \tag{22}$$

To design the controller $c(s)$ in (22) we select the controller, $qq_d(s, \varepsilon)$, so that the zeros of $(1 - \tilde{p}(s)qq_d(s, \varepsilon))$ cancel the poles of $\tilde{p}_d(s)$. An easy way of accomplishing this task is to take the controller $qq_d(s, \varepsilon)$ to be the product of two terms, $q(s, \varepsilon)$ and $q_d(s, \varepsilon)$:

$$qq_d(s, \varepsilon) = q(s, \varepsilon)q_d(s, \varepsilon). \tag{23}$$

The term $q(s, \varepsilon)$ is taken as the inverse of the model process as given below:

$$q(s, \varepsilon) = \frac{s^2 \left(\frac{1}{2\tilde{k}}s^2 + 1\right)}{\frac{1}{2}\,(\varepsilon s + 1)^4}, \tag{24}$$

where

$\tilde{k}$=model spring constant,

ε=adjustable controller filter time constant.

The above choice for $q(s, \varepsilon)$ reduces the problem to that of choosing $q_d(s, \varepsilon)$ so that the zeros of $(1 - q_d(s, \varepsilon))\,/\,(\varepsilon s + 1)^4$ cancel the poles of $\tilde{p}_d(s)$. This requires that $q_d(s, \varepsilon)$ be at least of third order as given by

$$q_d(s) = \frac{\tau_3 s^3 + \tau_2 s^2 + \tau_1 s + 1}{(\varepsilon s + 1)^3}. \tag{25}$$

The constants τ_1, τ_2, and τ_3 in (25) are chosen so that the numerator of $(1 - q_d(s, \varepsilon))\,/\,(\varepsilon s + 1)^4$ has zeros at $s = 0$ and at $s = \pm i\sqrt{2\tilde{k}}$. There is automatically an additional zero at $s = 0$ by virtue of the fact that $q_d(0, \varepsilon)$ is one. Equating the coefficients of the requisite polynomials yields

$$\tau_1 = 7\varepsilon, \tag{26}$$

$$\tau_2 = 21\varepsilon^2 - 70\tilde{k}\varepsilon^4 + 28\tilde{k}^2\varepsilon^6, \tag{27}$$

$$\tau_3 = 35\varepsilon^3 - 42\tilde{k}\varepsilon^5 + 4\tilde{k}^2\varepsilon^7. \tag{28}$$

These constants depend on the value of the filter time constant, ε, and the model parameter $\tilde{k}$. The filter time constant, ε, is selected to be $\varepsilon = 1$ so that the nominal plant with $\tilde{k} = 1$ has the desired settling time of about 15 seconds as required in the benchmark problem specifications (Wie and Bernstein [11, 12]). Having thus chosen ε, our only remaining task is to find an optimal value for $\tilde{k}$.

We will choose that value of $\tilde{k}$ that minimizes the maximum peak of $y(i\omega)/d(i\omega)$ from (20). By exploring values of the model spring constant, $\tilde{k}$, between 0.5 and 2, we determined that this minimum peak is obtained by using the model spring constant $\tilde{k} = 0.7$. The controller for this spring constant is given by

$$C_1(s) = \frac{10.8\left(s^3 - 1.88s^2 + 0.93s + 0.13\right)}{s^3 + 7s^2 + 19.6s + 25.2}. \tag{29}$$

Values for $\tilde{k}$ near 0.5 and 2 yield unstable control systems which are indicated by very large peaks of the maximum of $y(i\omega)/d(i\omega)$.

Braatz and Morari [3] solved the above control problem using the D-K iteration method (Doyle [5]) obtaining the following "μ-optimal" controller:

$$C_\mu(s) = \frac{0.443\,(9.402s + 1)\,(-2.697s + 1)\,(0.4789s + 1)}{(0.216s^2 + 0.861s + 1)\,(0.118s^2 + 0.369s + 1)}. \tag{30}$$

For the hypotheses of the robust stability Theorem 3.3, the pair of distinct transfer functions h, $\tilde{h}$, and the associated $\tilde{H}$ are constructed through

$$h(s) = (p(s) - \tilde{p}(s))qq_d(s), \tag{31}$$

$$\tilde{h}(s) = (1 - \tilde{p}(s)qq_d(s)), \tag{32}$$

and, recalling (3),

$$\tilde{H}(s) = \frac{(1 - \tilde{p}(s)qq_d(s))}{1 + (p(s) - \tilde{p}(s))qq_d(s)}. \tag{33}$$

Compare the transfer functions $\tilde{H}(s)$ in (33) and $y(s)$ in (20).

Figure 4 shows that the maximum value of the sensitivity function is bounded for both control systems. Since a separate Nyquist analysis of the control systems for a process with a spring constant of $k = 0.8$ shows that each control system is stable for that value of the spring constant, we conclude from our robust stability Theorem 3.3 that the control system is stable for all values of the spring constant in the uncertainty set. Further, since the maximum of the sensitivity function over all frequencies is smaller for controller $C_1(s)$ than for controller $C_\mu(s)$, we expect that the time responses for the control system using $C_1(s)$ are likely to be less oscillatory than those for $C_\mu(s)$, at least for some values of the spring constant. The time responses in Figures 5 and 6 confirm this expectation.

Example 4.3 (unstable first-order lag plus deadtime process). This example demonstrates the application of our robust stability Theorem 3.3 to an infinite dimensional system. It also points out the need to check the stability of one process which is not equal to the model in order to draw correct conclusions regarding the stability of all processes in the set of uncertain processes. The process is

$$p(s) = \frac{Ke^{-s}}{(-s+1)},\ 0.9 \leq K \leq 1.1. \tag{34}$$

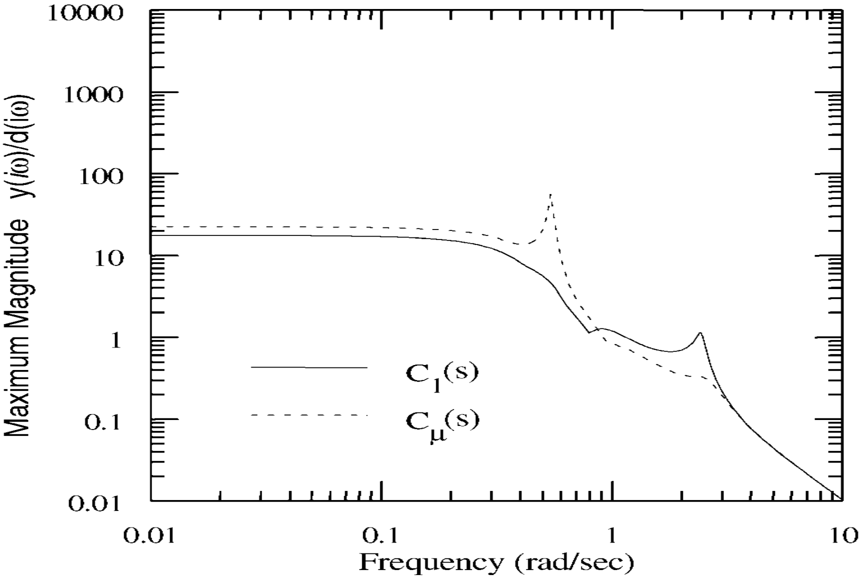

FIG. 4. *Maximum magnitude of the sensitivity function using controllers* $C_1(s)$ *and* $C_\mu(s)$*.*

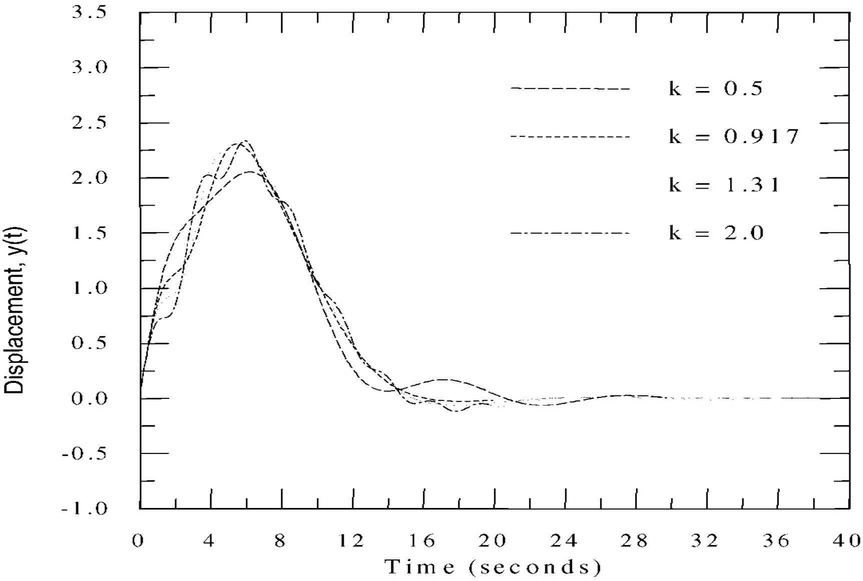

FIG. 5. *Response of body* 2 *position,* $y(t)$*, to an impulse disturbance for different spring constant values using controller* $C_1(s)$*.*

This process is one that is not easy to control, in spite of the relatively small range of uncertain gains, because of the large magnitude of the deadtime to time constant ratio.

The process model is taken as

$$\tilde{p}(s) = \frac{e^{-s}}{(-s+1)}. \tag{35}$$

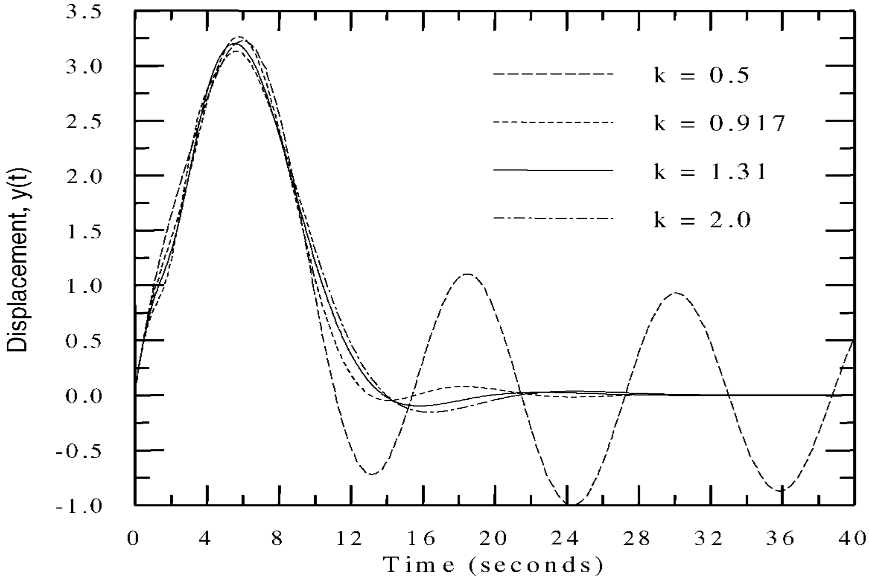

FIG. 6. *Response of body* 2 *position, $y(t)$, to an impulse disturbance for different spring constant values using controller $C_\mu(s)$.*

Selecting a filter time constant, ε, of 0.5 gives

$$qq_d(s, 0.5) = \frac{(-s+1)(5.116s+1)}{(0.5s+1)^2}. \tag{36}$$

Substituting (34), (35), and (36) into (20) and computing the sensitivity function yields Figure 7. For the hypotheses of the robust stability Theorem 3.3, the pair of distinct transfer functions h, $\tilde{h}$, and the associated $\tilde{H}$ are constructed, as in the previous example, through (31), (32), and (33).

Figure 7 indicates that the sensitivity function is finite over all positive frequencies. However, to conclude from this that the control system is stable over all uncertain processes, we must also see if the control system is stable for any single process gain, K, in the range 0.9 to 1.1, but not equal to 1.0. Since the control system given by Figure 3 is internally unstable, a common alternative is to use the control system of Figure 2 with the controller, $C(s)$, given by (22). A Nyquist analysis of this controller with $qq_d(s)$ given by (36) shows that the controller has six right half-plane poles. Further, a Nyquist analysis of the sensitivity function given by (19), using the same controller, shows that the disturbance response is unstable for a process gain of 1.1. Thus, from our robust stability Theorem 3.3, we can conclude that the control system is unstable for all process gains in the uncertainty range.

If the controller filter time constant, ε, is increased to 2.8, then the two degree of freedom IMC controller becomes

$$qq_d(s, 2.8) = \frac{(-s+1)(38.25s+1)}{(2.8s+1)^2}. \tag{37}$$

A Nyquist analysis of the controller found by substituting (37) into (22) shows that the denominator has one right half-plane zero, but this zero is exactly at 1, and so is cancelled by the numerator zero at 1. This cancellation must be enforced so that the

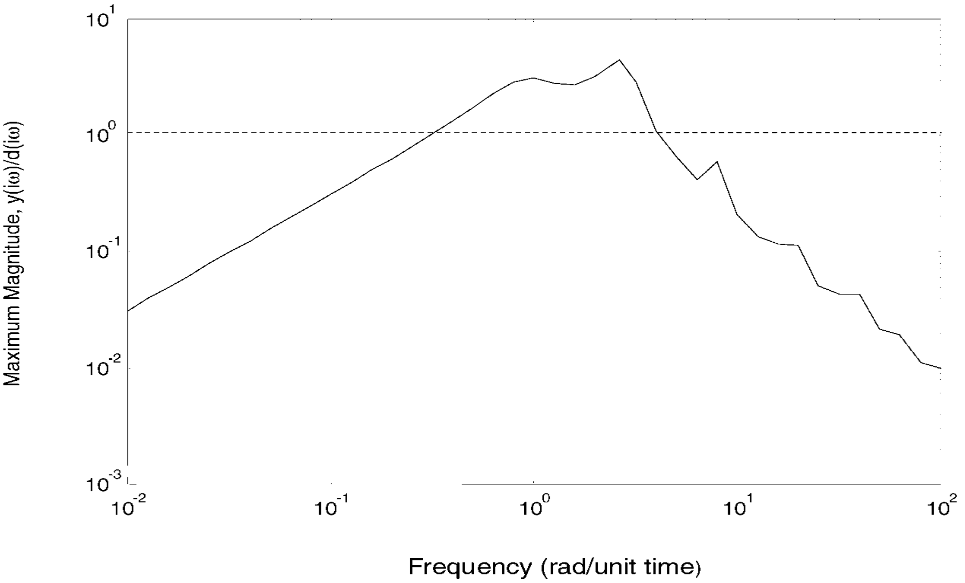

FIG. 7. *Upper bound of sensitivity function when* $\varepsilon = 0.5$.

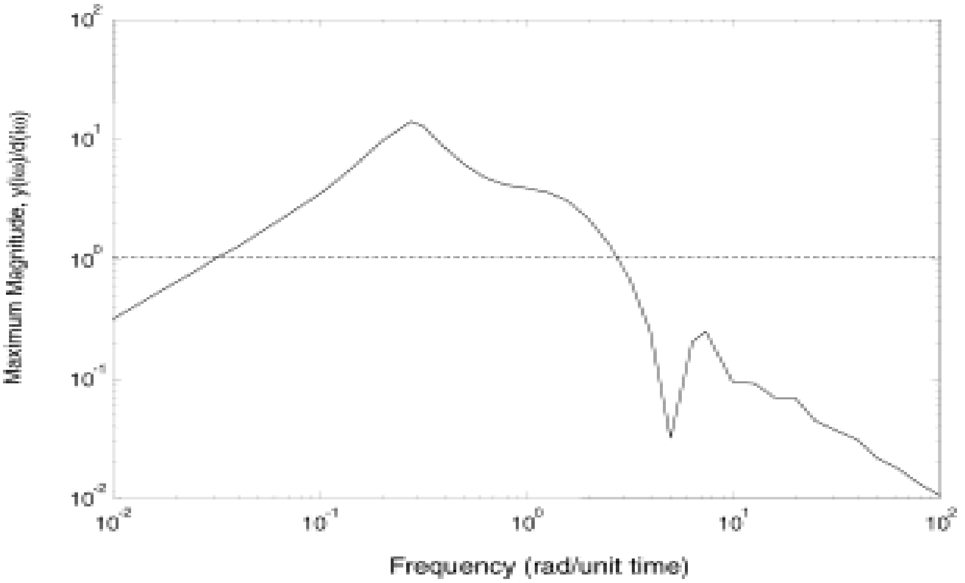

FIG. 8. *Upper bound of sensitivity function when* $\varepsilon = 2.8$.

controller that is actually implemented is stable, except of course for the pole at the origin. The upper bound of the sensitivity function for the control system associated with (37) is shown in Figure 8.

From Figure 8, and our robust stability Theorem 3.3, we conclude that the control system is stable for all process gains between 0.9 and 1.1 because a Nyquist analysis for a gain of 1.1 shows that this control system is stable. The time response for a unit step disturbance and a unit step set point change for the control system with $\varepsilon = 2.8$ and $\varepsilon_r = 2.8$ are shown in Figures 9 and 10.

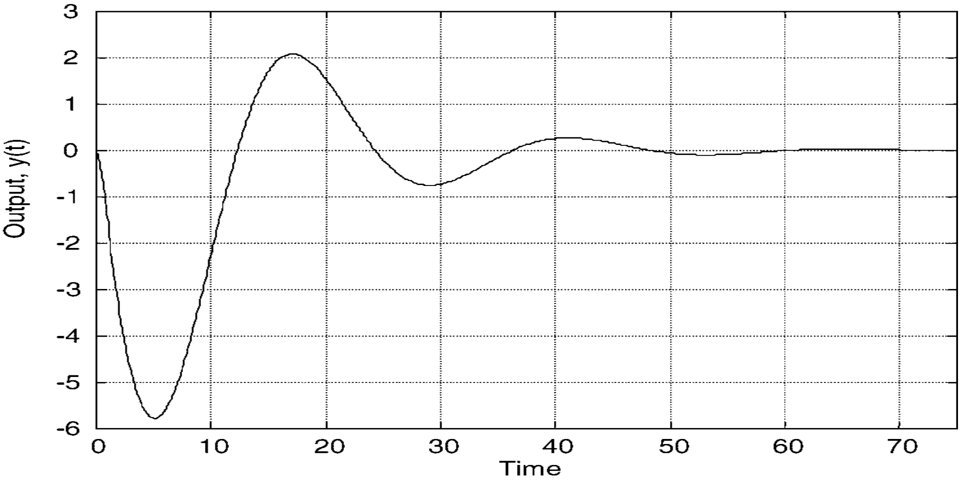

FIG. 9. *Disturbance step response when $\varepsilon_r = 3$ and $\varepsilon = 2.8$.*

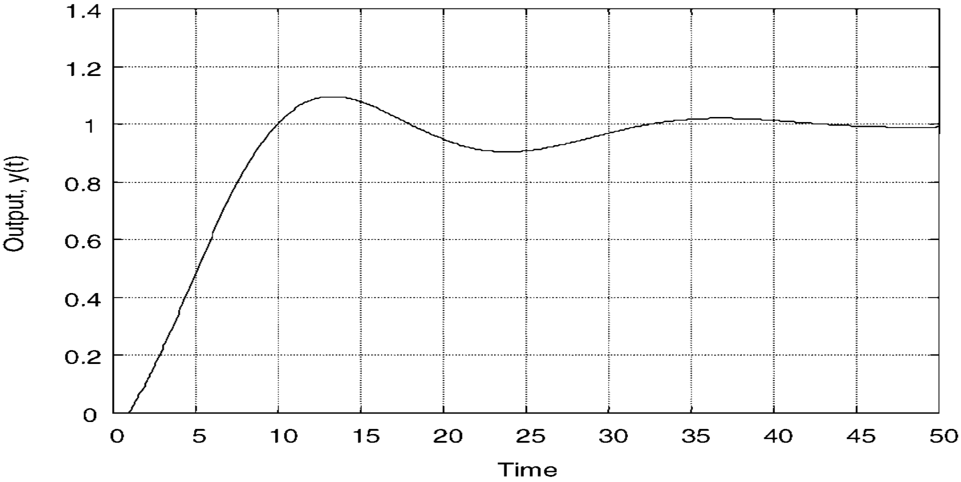

FIG. 10. *Set point step response when $\varepsilon_r = 3$ and $\varepsilon = 2.8$.*

It is instructive to compare the responses of Figures 9 and 10 with those of an internally stable control system such as that proposed by Berber and Brosilow [1, 2]. These responses are given in Figures 11 and 12 for the same process (i.e., $K = 0.9$). Based on the height and position of the peaks in Figures 7 and 8, one would expect the time responses associated with Figure 7 to be faster and less oscillatory than those associated with Figure 8. As can be seen from Figures 11 and 12, this is indeed the case.

5. Computational considerations. From a practical point of view, implementation of our results depends upon our ability to compute efficiently the maximum magnitude function, $\mathcal{H}$, in (5). In Examples 4.2 and 4.3, we used our robust stability results to establish the stability or instability of closed loop systems, and, in Example 4.2, to select an optimal model parameter. This was done with the aid of

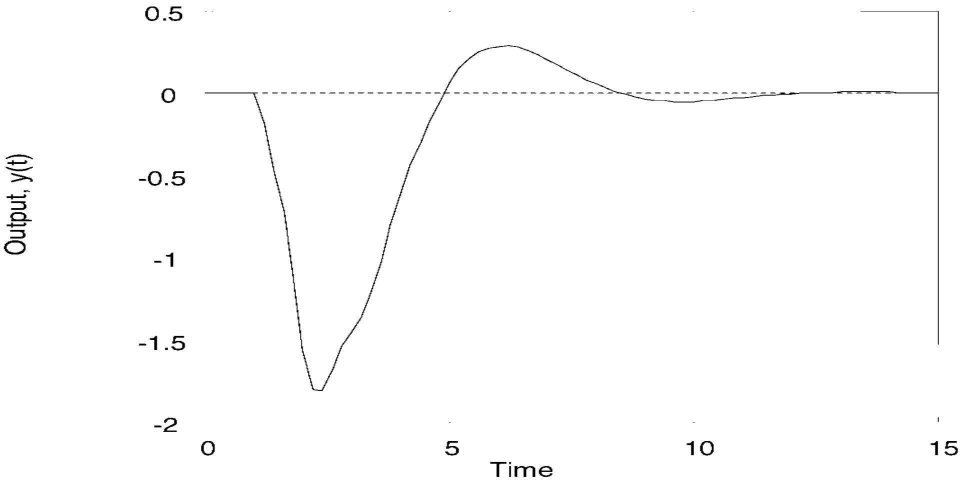

FIG. 11. *Disturbance step response when $\varepsilon_r = 1.3$ and $\varepsilon = 0.5$.*

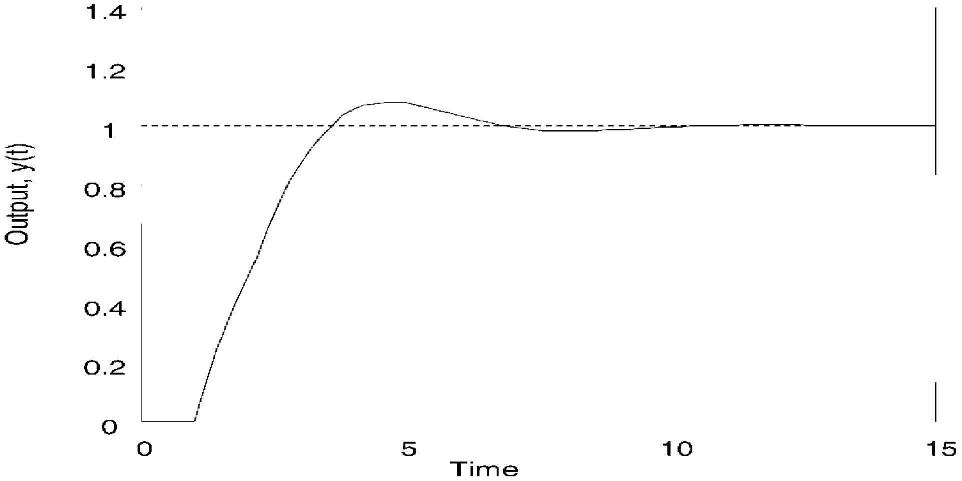

FIG. 12. *Set point step response when $\varepsilon_r = 1.3$ and $\varepsilon = 0.5$.*

MATLAB-based software developed by Strycezk [9].[12] This software uses the following approach to keep the computations tractable. Starting at a very high frequency,[13] the algorithm seeks the maximum magnitude of the specified closed loop transfer function over frequency and all uncertain parameters. The result of this optimization is the highest frequency local (possibly global) maximum. The algorithm then searches for all local maxima between the frequency just found and a frequency below which

[12] This software is available free of charge at the web site http://cheme.cwru.edu/People/Faculty/brosilow/brosilow.htm#brosilow. It requires MATLAB 5.3, or higher, as well as the Control System and Optimization Toolboxes. The user interface makes data input quite comfortable and online help is available. Results of the computations are presented as both graphs and tables. Since URLs tend to change over time, a relatively sure method of arriving at the site containing this software is first to access the home page of Case Western Reserve University (http://www.cwru.edu), and from there proceed to the home page of the Chemical Engineering Department, and finally to the home page of C. Brosilow.

[13] In this case, 1000/ the smallest model, uncertain process, or controller time constant.

the magnitude of the closed loop frequency response is constant (e.g., 1 for integral control systems). The results of these calculations are presented in a graph of magnitude versus frequency. Unstable control systems usually show magnitudes higher than 10^8. However, for practical purposes, closed loop magnitudes higher than 100 times the closed loop gain can be taken as evidence of an effectively unstable control system.

The optimization algorithm used in the above calculation is the constrained optimization algorithm provided by the MATLAB Optimization Toolbox. The optimization algorithm has worked well with less than six uncertain parameters, and we have experience with such processes. The algorithm should also work well with many more than six uncertain parameters, but we do not yet have experience with such problems.

Acknowledgments. One of the authors (M.J.L.) is indebted to his colleagues Professors Alejandro de Acosta, Michael Hurley, Thomas Ivey, and Arthur Obrock, all of Case Western Reserve University, for their valuable comments.

MULTIPLIER RULES UNDER MIXED ASSUMPTIONS OF DIFFERENTIABILITY AND LIPSCHITZ CONTINUITY*

JANE J. YE†

Abstract. In this paper we study nonlinear programming problems with equality, inequality, and abstract constraints where some of the functions are Fréchet differentiable at the optimal solution, some of the functions are Lipschitz near the optimal solution, and the abstract constraint set may be nonconvex. We derive Fritz John type and Karush–Kuhn–Tucker (KKT) type first order necessary optimality conditions for the above problem where Fréchet derivatives are used for the differentiable functions and subdifferentials are used for the Lipschitz continuous functions. Constraint qualifications for the KKT type first order necessary optimality conditions to hold include the generalized Mangasarian–Fromovitz constraint qualification, the no nonzero abnormal multiplier constraint qualification, the metric regularity of the constraint region, and the calmness constraint qualification.

Key words. necessary optimality conditions, Fréchet differentiability, subdifferentials, constraint qualifications, metric regularity, calmness

1. Introduction.

The classical multiplier rule usually requires that the objective function and the inequality constraints be differentiable, the equality constraints be continuously differentiable at the optimal solution, and the abstract constraint set be convex with nonempty interior (e.g., see Bazaraa, Sherali, and Shetty [1] and Mangasarian [14]).

Over the last three decades, the classical multiplier rule was extended under two different assumptions: differentiability and Lipschitz continuity.

On the one hand, the classical multiplier rule was extended in the direction of eliminating the smoothness assumption while keeping the differentiability assumption. In the case where there is no abstract constraint, based on a correction theorem, Halkin [9] proved that the classical multiplier rule holds under the weaker assumption which requires only that the equality constraints be Fréchet differentiable at the optimal solution and continuous in a neighborhood of the optimal solution. Based on a multidimensional intermediate value theorem, Di [7] derived some first order and second order multiplier rules for nonlinear programming problems with equality, inequality, and abstract constraints where all functions are Fréchet differentiable at the optimal solution and continuous in a neighborhood of the optimal solution and the abstract constraint set is convex.

On the other hand, in nonsmooth analysis the classical multiplier rule was generalized in the direction of replacing the differentiability assumption by the Lipschitz continuity assumption. Under the assumption that all functions are Lipschitz near the optimal solution and the abstract constraint set is closed, Clarke [3] derived a generalized multiplier rule involving the Clarke generalized gradient and the Clarke normal

cone. The Clarke generalized gradient of a function would reduce to the usual derivative only when the function is strictly differentiable (for example, when the function is continuously differentiable). Hence, when all functions involved are continuously differentiable and the abstract constraint set is convex, the generalized multiplier rule of Clarke would recover the classical multiplier rule. However, the Clarke generalized gradient of a Lipschitz continuous function may be strictly larger than the set which consists of the usual derivative when the function is Fréchet differentiable but not strictly differentiable. In the case when the abstract set is convex, Ioffe [11] showed that the Clarke generalized multiplier rule can be sharpened by replacing the Clarke generalized gradient by the Michel–Penot subdifferential which coincides with the usual derivative when the function is Gâteaux differentiable. Other results in this direction also include Mordukhovich's combined multiplier rule [16] and the Treiman's multiplier rule [19].

In this paper we study first order necessary optimality conditions for nonlinear programming problems with equality, inequality, and abstract constraints where some of the functions are Fréchet differentiable at the optimal solution, some of the functions are Lipschitz near the optimal solution, and the abstract constraint set may be nonconvex. For the above nonlinear programming problem with mixed assumptions on differentiability and Lipschitz continuity, since a differentiable function may not be Lipschitz continuous, the only applicable necessary optimality conditions in the literature are fuzzy multiplier rules (see, e.g., Borwein and Zhu [2]). Although in a finite dimensional space the fuzzy multiplier rule reduces to an exact multiplier rule, it involves the singular subdifferential of the non-Lipschitz functions. Our purpose is to derive exact (i.e., nonfuzzy) first order multipler rules which do not involve any singular subdifferentials for the above problem where Fréchet derivatives are used for the differentiable functions and subdifferentials are used for the Lipschitz continuous functions.

To be more precise, we consider the following optimization problem:

$$
\begin{array}{lll}
\text{(P)} & \text{minimize} & f(x) \\
& \text{subject to} & g_i(x) \le 0, \quad i = 1, 2, \ldots, I, \\
& & h_j(x) = 0, \quad j = 1, 2, \ldots, J, \\
& & \phi_k(x) \le 0, \quad k = 1, 2, \ldots, K, \\
& & \psi_l(x) = 0, \quad l = 1, 2, \ldots, L, \\
& & x \in \Omega,
\end{array}
$$

where $f, g_i(i = 1, 2, \ldots, I), h_i(j = 1, 2, \ldots, J), \phi_k(k = 1, 2, \ldots, K), \psi_l(l = 1, 2, \ldots, L)$ are the objective function and the constraint functions from a Banach space X to R. Ω is a closed subset of X and I, J, K, L are given integers. Generally one has $I \ge 1, J \ge 1, K \ge 1, L \ge 1$, but we allow I, J, K, or $L = 0$ to signify the case in which there are no explicit constraints of the type.

Let $\bar{x}$ be a local optimal solution to (P). Denote by $I(\bar{x}) := \{i : g_i(\bar{x}) = 0\}$ and $K(\bar{x}) := \{k : \phi_k(\bar{x}) = 0\}$ the index sets of the binding constraints. We always make the following basic assumptions on the constraint functions.

(A) $g_i(i \in I(\bar{x})), h_j(j = 1, 2, \ldots, J)$ are Fréchet differentiable at $\bar{x}$ and $g_i(i \notin I(\bar{x}))$ are continuous at $\bar{x}$. $\phi_k(k \in K(\bar{x})), \psi_l(l = 1, 2, \ldots, L)$ are Lipschitz near $\bar{x}$ and $\phi_k(k \notin K(\bar{x}))$ are continuous at $\bar{x}$.

Our main results include the following multiplier rules.

Theorem 1.1 (Fritz John necessary optimality conditions for the case $L = 0$).

Let $\bar{x}$ be a local optimal solution of (P) *with $L = 0$. Suppose that f is either Fréchet differentiable at $\bar{x}$ or Lipschitz near $\bar{x}$, in addition to assumption* (A), *$h_j (j = 1, 2, \dots, J)$ are continuous in a neighborhood of $\bar{x}$, and there exists a vector that is hypertangent* (*see Definition* 2.4) *to the abstract constraint set Ω at $\bar{x}$. Then there exist scalars $\lambda \geq 0, \alpha_i \geq 0 (i \in I(\bar{x})), \beta_j (j = 1, 2, \dots, J), \gamma_k \geq 0 (k \in K(\bar{x}))$ not all zero such that*

$$0 \in \lambda \partial^{\diamond} f(\bar{x}) + \sum_{i \in I(\bar{x})} \alpha_i \nabla g_i(\bar{x}) + \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) + \sum_{k \in K(\bar{x})} \gamma_k \partial^{\diamond} \phi_k(\bar{x}) + N(\bar{x}, \Omega),$$

where $\partial^{\diamond}$ denotes the Michel–Penot subdifferential, ∇ denotes the Fréchet derivative, and $N(\bar{x}, \Omega)$ denotes the Clarke normal cone to Ω at $\bar{x}$.

Remark 1. Note that in the case where f is Fréchet differentiable at $\bar{x}$, $\partial^{\diamond} f(\bar{x}) = \{\nabla f(\bar{x})\}$ in the above multiplier rule. As it was shown by Fernandez [8], the continuity assumption of the equality constraints h_j in Theorem 1.1 cannot be removed.

THEOREM 1.2 (Fritz John necessary optimality conditions for the case $I = J = 0$). *Let $\bar{x}$ be a local optimal solution of* (P) *with $I = J = 0$. Suppose that the objective function f is Fréchet differentiable at $\bar{x}$, $\phi_k (k \in K(\bar{x})), \psi_l (l = 1, 2, \dots, L)$ are Lipschitz near $\bar{x}$ and $\phi_k (k \notin K(\bar{x}))$ are continuous at $\bar{x}$. Then there exist scalars $\lambda \geq 0, \gamma_k \geq 0 (k \in K(\bar{x})), \eta_l (l = 1, 2, \dots, L)$ not all zero such that*

$$0 \in \lambda \nabla f(\bar{x}) + \sum_{k \in K(\bar{x})} \gamma_k \partial \phi_k(\bar{x}) + \sum_{l=1}^{L} \eta_l \partial \psi_l(\bar{x}) + N(\bar{x}, \Omega),$$

where ∂ denotes the Clarke generalized gradient and $N(x, \Omega)$ denotes the Clarke normal cone to Ω at $\bar{x}$. Moreover, if X is an Asplund space which is a Banach space whose separable subspaces have separable duals (as is the case for reflexive spaces), under the above assumptions, there exist scalars $\lambda \geq 0, \gamma_k \geq 0 (k \in K(\bar{x})), \eta_l (l = 1, 2, \dots, L)$ not all zero such that

$$0 \in \lambda \nabla f(\bar{x}) + \sum_{k \in K(\bar{x})} \gamma_k \hat{\partial} \phi_k(\bar{x}) + \hat{\partial} \left(\sum_{l=1}^{L} \eta_l \psi_l \right) (\bar{x}) + \hat{N}(\bar{x}, \Omega),$$

where $\hat{\partial}$ denotes the limiting subdifferential and $\hat{N}(\bar{x}, \Omega)$ denotes the limiting normal cone to Ω at $\bar{x}$.

As in smooth and Lipschitz optimization we also give constraint qualifications under which the scalar λ in the above theorems is nonzero such as the generalized Mangasarian–Fromovitz constraint qualification (GMFCQ), the no nonzero abnormal multiplier constraint qualification (NNAMCQ), the metric regularity of the constraint region (metric regularity CQ), and the calmness constraint qualification (calmness CQ).

We organize the paper as follows. In the next section we provide preliminaries that will be used in the paper. In section 3, we prove Theorem 1.1, the Fritz John type necessary optimality condition for the case where there are no Lipschitz continuous equality constraints. In section 4, we introduce constraint qualifications, discuss the relationship between the (GMFCQ) and (NNAMCQ), and prove that under constraint qualifications such as the (NNAMCQ), the metric regularity CQ and the calmness CQ, λ in Theorems 1.1 can be taken as 1. An example is given to show that when the objective function is not Lipschitz but only Fréchet differentiable, the metric regularity CQ may not imply the calmness CQ. Hence the well-known relationships between these constraint qualifications may not hold when some of the functions are not Lipschitz but Fréchet differentiable. However, it turns out that the Karush–Kuhn–Tucker (KKT) conditions can usually be derived directly. We prove that unlike the Fritz John type condition (Theorem 1.1), under the metric regularity CQ and the calmness CQ the KKT condition holds even in the case where $L \neq 0$, and the continuity assumption of the Fréchet differentiable equality constraints is not needed. In section 5, we derive KKT type necessary optimality conditions for the case where all constraint functions are Lipschitz continuous and the objective function is Fréchet differentiable under the constraint qualification (NNAMCQ), the metric regularity CQ, and the calmness CQ. Theorem 1.2, the Fritz John type necessary optimality condition, then follows as an easy consequence.

2. Preliminaries.

This section contains some background material on nonsmooth analysis which will be used throughout the paper. We give only concise definitions that will be needed in the paper. For more detailed information on the subject, our references are Clarke [4], Clarke, Ledyaev, Stern, and Wolenski [5], Loewen [13], and Mordukhovich and Shao [17].

We first give the following notations that will be used throughout the paper. For a vector $v \in R^n$, v_i is the ith components of v. For any Banach space X we denote its norm by $\|\cdot\|$ and consider the dual space X^* equipped with the weak-star topology w^*, where $\langle\cdot,\cdot\rangle$ means the canonic pairing. As usual, B and B^* stand for the open unit balls in the space and the dual space in question. Note that intΩ, clΩ, and *co*Ω mean, respectively, the interior, the closure, and the convex hull of an arbitrary nonempty set $\Omega \subset X$, while the notation cl^* is used for the weak-star topological closure in X^*.

For a set-valued map $\Phi : X \rightrightarrows X^*$, we denote by

$$\limsup_{x\to\bar{x}} \Phi(x)$$

the sequential Kuratowski–Painlevé upper limit with respect to the norm topology in X and the weak-star topology in X^*, i.e.,

$$\limsup_{x\to\bar{x}} \Phi(x) := \{x^* \in X^* | \exists \text{ sequences } x_k \to \bar{x}, x_k^* \xrightarrow{w^*} x^*, \\ \text{with } x_k^* \in \Phi(x_k) \forall k = 1, 2, \ldots\}.$$

We now give some concepts for various normal cones.

Definition 2.1. *Let Ω be a nonempty subset of a Banach space X and let $\epsilon \geq 0$.*

(i) *Given $x \in \text{cl}\Omega$, the set*

$$N_\epsilon^F(x,\Omega) := \left\{ x^* \in X^* | \limsup_{x'\to x, x'\in\Omega} \frac{\langle x^*, x'-x\rangle}{\|x'-x\|} \leq \epsilon \right\} \tag{2.1}$$

is called the set of Fréchet ϵ-normals to Ω at x. When $\epsilon = 0$, the set (2.1) is a cone which is called the Fréchet normal cone to Ω at x and is denoted by $N^F(x,\Omega)$.

(ii) *Let $\bar{x} \in \text{cl}\Omega$. The nonempty cone*

$$\hat{N}(\bar{x},\Omega) := \limsup_{x\to\bar{x},\epsilon\downarrow 0} N_\epsilon^F(x,\Omega) \tag{2.2}$$

is called the limiting normal cone to Ω at $\bar{x}$.

Using the definitions for normal cones, we now give definitions for corresponding subdifferentials of a single-valued map.

DEFINITION 2.2. *Let X be a Banach space and $\varphi : X \to R \cup \{+\infty\}$ be l.s.c. (lower semicontinuous) and finite at $x \in X$. The sets*

$$\begin{aligned} \partial^F_\epsilon \varphi(x) &:= \{x^* \in X^* | (x^*, -1) \in N^F_\epsilon((x, \varphi(x)), epi\varphi)\}, \\ \hat{\partial}\varphi(x) &:= \{x^* \in X^* | (x^*, -1) \in \hat{N}((x, \varphi(x)), epi\varphi)\}, \end{aligned} \tag{2.3}$$

where $epi\varphi := \{(x, v) : v \geq \varphi(x)\}$ denotes the epigraph of φ, are called, respectively, the Fréchet ϵ-subdifferential and the limiting subdifferential of φ at x. When $\epsilon = 0$, the set (2.3) *is called the Fréchet subdifferential of φ at x and is denoted by $\partial^F\varphi(x)$.* It is known that the Fréchet subdifferential has the following analytic expression:

$$\partial^F\varphi(x) = \left\{x^* \in X^* | \liminf_{x' \to x} \frac{\varphi(x') - \varphi(x) - \langle x^*, x' - x\rangle}{\|x' - x\|} \geq 0\right\}. \tag{2.4}$$

Let X be any Banach space, $\bar{x} \in X$, and $\varphi : X \to R$ be any continuous function. Then the Michel–Penot directional derivative of φ at $\bar{x}$ in the direction $v \in X$ introduced in [15] is given by

$$\varphi^\square(\bar{x}; v) := \sup_{w \in X} \limsup_{t \downarrow 0} \frac{\varphi(\bar{x} + t(v + w)) - \varphi(\bar{x} + tw)}{t}$$

and the Michel–Penot subdifferential of φ at $\bar{x}$ is given by the set

$$\partial^\diamond\varphi(\bar{x}) := \{x^* \in X^* | \langle x^*, v\rangle \leq \varphi^\square(\bar{x}; v)\ \forall v \in X\}.$$

It is known (see [15, Proposition 1.3]) that when a function φ is Gâteaux differentiable at $\bar{x}$, $\partial^\diamond\varphi(\bar{x}) = \{\nabla\varphi(\bar{x})\}$.

The following properties of the Michel–Penot directional derivatives and the Michel–Penot subdifferentials will be useful.

PROPOSITION 2.3 (see [15, 11]). *Let X be a Banach space, $x \in X$, and f be Lipschitz near x with constant L_f. Then*

(i) *The function $v \to f^\square(x; v)$ is finite, positively homogeneous, and subadditive on X.*

(ii) *As a function of v, $f^\square(x; v)$ is Lipschitz continuous with constant L_f on X.*

(iii) *$\partial^\diamond f(x)$ is a nonempty, convex, weak*-compact subset of X^* and $\|x^*\| \leq L_f$ for every $x^* \in \partial^\diamond f(x)$.*

Let X be any Banach space, $\bar{x} \in X$, and $\varphi : X \to R$ be Lipschitz near $\bar{x}$. Then the Clarke generalized derivative of φ at $\bar{x}$ in the direction $v \in X$ is given by

$$\varphi^0(\bar{x}; v) := \limsup_{x \to \bar{x}, t \downarrow 0} \frac{\varphi(x + tv) - \varphi(x)}{t}$$

and the Clarke generalized gradient of φ at $\bar{x}$ is given by the set

$$\partial\varphi(\bar{x}) := \{x^* \in X^* | \langle x^*, v\rangle \leq \varphi^0(\bar{x}; v)\ \forall v \in X\}.$$

Let Ω be a nonempty subset of a Banach space X and consider its distance function, that is, the function $d_\Omega(\cdot) : X \to R$ defined by

$$d_\Omega(x) = \inf\{\|x - c\| : c \in \Omega\}.$$

The Clarke tangent cone to Ω at $\bar{x}$ is defined by

$$T(\bar{x},\Omega) := \{v \in X \mid d^0_\Omega(\bar{x};v) = 0\}$$

and the Clarke normal cone to Ω at $\bar{x}$ is defined by polarity with $T(\bar{x},\Omega)$:

$$N(\bar{x},\Omega) := \{x^* \in X^* | \langle x^*, v\rangle \le 0 \quad \forall v \in T(\bar{x},\Omega)\}.$$

DEFINITION 2.4 (hypertangent). *Let X be a Banach space. A vector v in X is said to be hypertangent to the set $\Omega \subseteq X$ at the point $x \in \Omega$ if for some $\epsilon > 0$,*

$$y + tw \in \Omega \quad \forall y \in (x+\epsilon B)\cap\Omega, w \in v + \epsilon B, t \in (0,\epsilon).$$

It follows easily that any vector v hypertangent to Ω at x belongs to $T(x,\Omega)$. It is possible to have no hypertangents at all. However, it is clear that when Ω is a convex set with nonempty interior, then any vector $x^* - x$ with $x^* \in \text{int}\Omega$ is hypertangent to Ω at x.

It is known that in any Banach space X and for any $\epsilon \ge 0$

$$N^F_\epsilon(\bar{x},\Omega) \subseteq \hat{N}(\bar{x},\Omega) \subseteq N(\bar{x},\Omega),$$
$$\partial^F_\epsilon \varphi(\bar{x}) \subseteq \hat{\partial}\varphi(\bar{x}) \subseteq \partial^\diamond \varphi(\bar{x}) \subseteq \partial\varphi(\bar{x})$$

and in any Asplund space, the following precise relationships hold [17, Theorems 2.9 and 8.11]:

(i) For any closed set $\Omega \subseteq X$ and $\bar{x} \in \Omega$ one has

$$\hat{N}(\bar{x},\Omega) = \limsup_{x\to\bar{x}} N^F(x,\Omega),$$
$$N(\bar{x};\Omega) = \text{cl}^* co\hat{N}(\bar{x},\Omega).$$

(ii) For any function $\varphi : X \to R$ which is Lipschitz near $\bar{x} \in X$, one has

$$\hat{\partial}\varphi(\bar{x}) = \limsup_{x\to\bar{x}} \partial^F\varphi(x),$$
$$\partial\varphi(\bar{x}) = \text{cl}^* co\hat{\partial}\varphi(\bar{x}).$$

We now summarize the sum rules and chain rules for the various subdifferentials in the literature. For convenience, we do not intend to quote the results under the most general assumptions. Instead, we provide the results under the assumptions we need in our paper. For example, since when Y is finite dimensional, a function $\varphi : X \to Y$ is Lipschitz near $\bar{x} \in X$ is strictly Lipschitzian at $\bar{x}$ in the sense of [17]; Propositions 2.5(ii) and 2.6(ii) are special cases of the results in [17].

PROPOSITION 2.5 (sum rules).

(i) (*See, e.g., the proof of* [6, Lemma 2.2].) *Let X be a Banach space and $\bar{x} \in X$. Let $\varphi_1 : X \to R$ be Fréchet differentiable at $\bar{x}$ and $\varphi_2 \to R \cup \{+\infty\}$ be finite and l.s.c. at $\bar{x}$. Then*

$$\partial^F(\varphi_1 + \varphi_2)(\bar{x}) = \nabla\varphi_1(\bar{x}) + \partial^F\varphi_2(\bar{x}).$$

(ii) (*See* [17, Proposition 2.5 and Theorem 4.1].) *Let X be an Asplund space and $\bar{x} \in X$. Let $\varphi_i : X \to R \cup \{+\infty\}, i = 1,2,$ be l.s.c. at $\bar{x}$ and one of these functions is Lipschitz near $\bar{x}$. Then one has*

$$\hat{\partial}(\varphi_1 + \varphi_2)(\bar{x}) \subseteq \hat{\partial}\varphi_1(\bar{x}) + \hat{\partial}\varphi_2(\bar{x}).$$

(iii) (*See* [4, Proposition 2.3.3].) *Let X be a Banach space and $\bar{x} \in X$. Let $\varphi_i : X \to R, i = 1, 2$, be Lipschitz near $\bar{x}$. Then one has*

$$\partial(\varphi_1 + \varphi_2)(\bar{x}) \subseteq \partial\varphi_1(\bar{x}) + \partial\varphi_2(\bar{x}).$$

Proposition 2.6 (chain rules).

(i) (*See* [5, Theorem 2.5].) *Let X be a Banach space and $\bar{x} \in X$. Suppose that $\varphi : X \to R^n$ is Lipschitz near $\bar{x}$ and $f : R^n \to R$ is Lipschitz near $\varphi(\bar{x})$. Then*

$$\partial(f \circ \varphi)(\bar{x}) \subseteq \mathrm{cl}^* co \cup_{y^* \in \partial f(\varphi(\bar{x}))} \partial\langle y^*, \varphi\rangle(\bar{x}).$$

(ii) (*See* [17, Proposition 2.5 and Corollary 6.3].) *Moreover, if X is an Asplund space, then*

$$\hat{\partial}(f \circ \varphi)(\bar{x}) \subseteq \cup_{y^* \in \hat{\partial} f(\varphi(\bar{x}))} \hat{\partial}\langle y^*, \varphi\rangle(\bar{x}).$$

The following exact penalty results given by Clarke in [4, Proposition 2.4.3] will often be used in the paper.

Proposition 2.7. *Let C be a closed subset of X. Assume that f attains a minimum over C at $\bar{x} \in C$ and f is Lipschitz near $\bar{x}$ with constant $L_f > 0$. Then for all $K \geq L_f$, the function $g(y) = f(y) + K d_C(y)$ also attains a minimum over X at $\bar{x}$.*

3. Proof of Theorem 1.1.

We need only to prove the theorem under the assumption that there do not exist scalars $\alpha_i \geq 0 (i \in I(\bar{x})), \beta_j (j = 1, 2, \ldots, J), \gamma_k \geq 0 (k \in K(\bar{x}))$ not all zero such that

$$0 \in \sum_{i \in I(\bar{x})} \alpha_i \nabla g_i(\bar{x}) + \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) + \sum_{k \in K(\bar{x})} \gamma_k \partial^\diamond \phi_k(\bar{x}) + N(\bar{x}, \Omega). \tag{3.1}$$

Indeed, if (3.1) is satisfied by some scalars $\alpha_i \geq 0 (i \in I(\bar{x})), \beta_j (j = 1, 2, \ldots, J), \gamma_k \geq 0 (k \in K(\bar{x}))$ that are not all zero, then by taking $\lambda = 0$ we obtain the Fritz John condition.

Case 1, $J \neq 0$.

Since $\nabla h_j(\bar{x}) (j = 1, 2, \ldots, J)$ are linearly independent by assumption (3.1), by the correction theorem of Halkin [9, Theorem F], there exist a neighborhood U of $\bar{x}$ and a continuous mapping ζ from U into X such that $\zeta(\bar{x}) = 0, \nabla\zeta(\bar{x}) = 0$ and

$$h_j(x + \zeta(x)) = \langle \nabla h_j(\bar{x}), x - \bar{x}\rangle \quad \forall x \in U, \ j = 1, 2, \ldots, J. \tag{3.2}$$

We shall now prove that there is no $v \in \mathrm{int}T(\bar{x}, \Omega)$ such that

$$f^\square(\bar{x}; v) < 0, \tag{3.3}$$

$$\langle \nabla g_i(\bar{x}), v\rangle < 0, \quad i \in I(\bar{x}), \tag{3.4}$$

$$\langle \nabla h_j(\bar{x}), v\rangle = 0, \quad j = 1, 2, \ldots, J, \tag{3.5}$$

$$\phi_k^\square(\bar{x}; v) < 0, \quad k \in K(\bar{x}). \tag{3.6}$$

By contradiction, we assume that there exists $v^* \in \mathrm{int}T(\bar{x}, \Omega)$ such that (3.3)–(3.6) hold. Let

$$\theta(t) = \bar{x} + tv^* + \zeta(\bar{x} + tv^*) \ \ \forall t \in [0, 1].$$

Then by virtue of (3.2) and (3.5), for all $\tau \in (0,1]$ small enough, $h_j(\theta(\tau)) = 0$ for all $j = 1, 2, \ldots, J$. Since $\theta(0) = \bar{x}, \nabla\theta(0) = v^*$, by the chain rule,

$$\lim_{t \to 0^+} \frac{g_i(\theta(t)) - g_i(\theta(0))}{t} = \langle \nabla g_i(\bar{x}), v^* \rangle \quad \forall i \in I(\bar{x}).$$

Consequently, by virtue of (3.4),

$$\lim_{t \to 0^+} \frac{g_i(\theta(t)) - g_i(\theta(0))}{t} < 0 \quad \forall i \in I(\bar{x}).$$

That is, for all $\tau \in (0,1]$ small enough,

$$g_i(\theta(\tau)) < 0 \quad \forall i \in I(\bar{x}).$$

Since ϕ_k is Lipschitz near $\bar{x}$,

$$\phi_k^\square(\bar{x}; v^*) = \sup_{w \in X} \limsup_{v' \to v^*, t \downarrow 0} \frac{\phi_k(\bar{x} + t(v' + w)) - \phi_k(\bar{x} + tw)}{t} \quad \forall k \in K(\bar{x}).$$

Consequently, by virtue of (3.6), we have for all $\tau \in (0,1]$ small enough,

$$\frac{\phi_k(\bar{x} + \tau v^* + \zeta(\bar{x} + \tau v^*)) - \phi_k(\bar{x})}{\tau} < 0 \quad \forall k \in K(\bar{x}).$$

That is, for all $\tau \in (0,1]$ small enough,

$$\phi_k(\theta(\tau)) < 0 \quad \forall k \in K(\bar{x}).$$

Similarly since $f^\square(\bar{x}, v) = \langle \nabla f(\bar{x}), v \rangle$ when f is Fréchet differentiable, for all $\tau \in (0,1]$ small enough, $f(\theta(\tau)) < f(\bar{x})$ by virtue of (3.3). By assumption, there exists a hypertangent to Ω at $\bar{x}$. By Rockafellar (see [4, Theorem 2.4.8]), the set of all hypertangents to Ω at $\bar{x}$ coincides with the interior of the Clarke tangent cone to Ω at $\bar{x}$. So for all $\tau \in (0,1]$ small enough,

$$\bar{x} + tv^* + \zeta(\bar{x} + \tau v^*) = \bar{x} + \tau \left[v^* + \frac{\zeta(\bar{x} + \tau v^*)}{\tau} \right] \in \Omega.$$

By the continuity assumptions at $\bar{x}$ for $g_i(i \notin I(\bar{x})), \phi_k(k \notin K(\bar{x}))$, for all $\tau \in (0,1]$ small enough,

$$\begin{aligned} &g_i(\theta(\tau)) < 0 \quad \forall i \notin I(\bar{x}), \\ &\phi_k(\theta(\tau)) < 0 \quad \forall k \notin K(\bar{x}). \end{aligned}$$

Hence there exists $\tau \in (0,1]$ such that

$$\begin{aligned} &f(\theta(\tau)) < f(\bar{x}), \\ &g_i(\theta(\tau)) < 0, \qquad i = 1, 2, \ldots, I, \\ &h_j(\theta(\tau)) = 0, \qquad j = 1, 2, \ldots, J, \\ &\phi_k(\theta(\tau)) < 0, \qquad k = 1, 2, \ldots, K, \\ &\theta(\tau) \in \Omega, \end{aligned}$$

which contradicts the fact that $\bar{x}$ is a local optimal solution of (P).

Since $T(\bar{x}, \Omega)$ is a closed convex cone and $f^{\square}(\bar{x}; v), \phi_k^{\square}(\bar{x}; v)$ are continuous in v (see Proposition 2.3), by virtue of nonexistence of $v \in \text{int}T(\bar{x}, \Omega)$ satisfying (3.3)–(3.6), the nonemptyness of $\text{int}T(\bar{x}, \Omega)$, and Proposition 4.4, $v = 0$ is a solution to the following problem:

$$\begin{aligned} \min \quad & f^{\square}(\bar{x}; v) \\ \text{s.t.} \quad & \langle \nabla g_i(\bar{x}), v \rangle \le 0, \quad i \in I(\bar{x}), \\ & \langle \nabla h_j(\bar{x}), v \rangle = 0, \quad j = 1, 2, \ldots, J, \\ & \phi_k^{\square}(\bar{x}; v) \le 0, \quad k \in K(\bar{x}), \\ & v \in T(\bar{x}, \Omega). \end{aligned}$$

Applying the generalized multiplier rule of Clarke [4, Theorem 6.1.1], there exist scalars $\lambda \ge 0, \alpha_i \ge 0 (i \in I(\bar{x})), \beta_j (j = 1, 2, \ldots, J), \gamma_k \ge 0 (k \in K(\bar{x}))$ not all zero such that

$$\begin{aligned} 0 \in \lambda \partial_v f^{\square}(\bar{x}; 0) + \sum_{i \in I(\bar{x})} \alpha_i \nabla g_i(\bar{x}) + \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) \\ + \sum_{k \in K(\bar{x})} \gamma_k \partial_v \phi_k^{\square}(\bar{x}; 0) + N(0, T(\bar{x}, \Omega)), \end{aligned}$$

where ∂_v denotes the generalized gradient with respect to v.

By definition, $\xi \in \partial^{\diamond} f(\bar{x})$ if and only if

$$\langle \xi, v \rangle \le f^{\square}(\bar{x}; v) \ \forall v \in X. \tag{3.7}$$

Since $f^{\square}(\bar{x}; v)$ is a convex function of v (see Proposition 2.3) and obviously $f^{\square}(\bar{x}; 0) = 0$, (3.7) holds if and only if $\xi \in \partial_v f^{\square}(\bar{x}; 0)$. Hence, $\partial_v f^{\square}(\bar{x}; 0) = \partial^{\diamond} f(\bar{x})$. Similarly, $\partial_v \phi_k^{\square}(\bar{x}; 0) = \partial^{\diamond} \phi_k(\bar{x})$. Since $\xi \in N(\bar{x}, \Omega)$ if and only if $\langle \xi, v \rangle \le 0$ for all $v \in T(\bar{x}, \Omega)$,

$$N(0, T(\bar{x}, \Omega)) = N(\bar{x}, \Omega).$$

Hence the Fritz John condition holds in this case.

Case 2, $J = 0, I \ne 0$.

We shall now prove that there is no $v \in \text{int}T_{\Omega}(\bar{x})$ such that

$$f^{\square}(\bar{x}; v) < 0, \tag{3.8}$$

$$\langle \nabla g_i(\bar{x}), v \rangle < 0, \quad i \in I(\bar{x}), \tag{3.9}$$

$$\phi_k^{\square}(\bar{x}; v) < 0, \quad k \in K(\bar{x}). \tag{3.10}$$

By contradiction, we assume that there exists $v^* \in \text{int}T(\bar{x}, \Omega)$ such that (3.8)–(3.10) hold. Since $g_i, i \in I(\bar{x})$ are differentiable at $\bar{x}$, for $t > 0$ small enough,

$$g_i(\bar{x} + tv^*) = g_i(\bar{x}) + t\langle \nabla g_i(\bar{x}), v^* \rangle + \alpha_i(\bar{x}, tv^*) t \|v^*\| \quad \forall i \in I(\bar{x}),$$

where $\lim_{t \to 0} \alpha_i(\bar{x}, tv^*) = 0$ for $i \in I(\bar{x})$.

By virtue of (3.9), for $\tau > 0$ small enough,

$$\langle \nabla g_i(\bar{x}), v^* \rangle + \alpha_i(\bar{x}, \tau v^*) \|v^*\| < 0$$

and hence for $\tau > 0$ small enough,

$$g_i(\bar{x} + \tau v^*) < 0, \quad i = 1, 2, \ldots, I.$$

By virtue of (3.10), we have for all $\tau \in (0,1]$ small enough,

$$\frac{\phi_k(\bar{x}+\tau v^*)-\phi_k(\bar{x})}{\tau} < 0 \quad \forall k \in K(\bar{x}).$$

That is, for all $\tau \in (0,1]$ small enough,

$$\phi_k(\bar{x}+\tau v^*) < 0, \quad k = 1,2,\ldots,K.$$

Similarly, we can prove that for all τ small enough,

$$f(\bar{x}+\tau v^*) < f(\bar{x}).$$

Since v^* is a hypertangent to Ω at $\bar{x}$, $\bar{x}+\tau v^* \in \Omega$ for $\tau > 0$ small enough. Hence there exists $\tau > 0$ such that

$$\begin{aligned}
&f(\bar{x}+\tau v^*) < f(\bar{x}),\\
&g_i(\bar{x}+\tau v^*) < 0, \quad i = 1,2,\ldots,I,\\
&\phi_k(\bar{x}+\tau v^*) < 0, \quad k = 1,2,\ldots,K,\\
&\bar{x}+\tau v^* \in \Omega,
\end{aligned}$$

which contradicts the fact that $\bar{x}$ is a local optimal solution of (P).

The remaining proof is similar to Case 1.

4. Constraint qualifications and the KKT conditions.

In this section we introduce four constraint qualifications which ensure the KKT conditions hold and discuss the relationships among them.

The first constraint qualification for the case $L = 0$ follows naturally from the Fritz John necessary optimality condition as in the following proposition.

THEOREM 4.1 (KKT condition for the case $L = 0$ under the (NNAMCQ)). *In addition to the assumptions of Theorem* 1.1*, assume that there is no nonzero abnormal multiplier, i.e.,*

$$\begin{aligned}
(4.1) \qquad &0 \in \sum_{i \in I(\bar{x})} \alpha_i \nabla g_i(\bar{x}) + \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) + \sum_{k \in K(\bar{x})} \gamma_k \partial^{\diamond} \phi_k(\bar{x}) + N(\bar{x},\Omega),\\
&\alpha_i \geq 0, \ i \in I(\bar{x}),
\end{aligned}$$

implies that $\alpha_i = 0$ for all $i \in I(\bar{x}), \beta_j = 0$ for all $j = 1,2,\ldots,J, \gamma_k = 0$ for all $k \in K(\bar{x})$. Then $\lambda > 0$ in the conclusion of Theorem 1.1.

Proof. By Theorem 1.1, there exist scalars $\lambda \geq 0, \alpha_i \geq 0 (i \in I(\bar{x})), \beta_j (j = 1,2,\ldots,J), \gamma_k \geq 0 (k \in K(\bar{x}))$ not all zero such that

$$(4.2) \quad 0 \in \lambda \partial^{\diamond} f(\bar{x}) + \sum_{i \in I(\bar{x})} \alpha_i \nabla g_i(\bar{x}) + \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) + \sum_{k \in K(\bar{x})} \gamma_k \partial^{\diamond} \phi_k(\bar{x}) + N(\bar{x},\Omega).$$

The case $\lambda = 0$ is impossible. Indeed, if $\lambda = 0$ in the above condition, then the inclusion (4.2) coincides with inclusion (4.1). The assumption then rules out this possibility. □

Motivated by the above KKT condition we define the following constraint qualification for the general problem (P).

DEFINITION 4.2. *We say that* (P) *satisfies the* (NNAMCQ) *if*

$$
\begin{aligned}
&0 \in \sum_{i\in I(\bar{x})} \alpha_i \nabla g_i(\bar{x}) + \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) + \sum_{k\in K(\bar{x})} \gamma_k \partial^{\diamond} \phi_k(\bar{x}) + \sum_{l=1}^{L} \eta_l \partial^{\diamond} \psi_l(\bar{x}) + N(\bar{x}, \Omega),\\
&\alpha_i \geq 0,\ i \in I(\bar{x}), \gamma_k \geq 0,\ k \in K(\bar{x}),
\end{aligned}
$$

implies that $\alpha_i = 0$ *for all* $i \in I(\bar{x}), \beta_j = 0$ *for all* $j = 1, 2, \ldots, J, \gamma_k = 0$ *for all* $k \in K(\bar{x}), \eta_l = 0$ *for all* $l = 1, 2, \ldots, L$.

We now prove that the (NNAMCQ) is closely related to but weaker than the (GMFCQ) defined as follows.

DEFINITION 4.3. *We say that* (P) *satisfies the* (GMFCQ) *at* $\bar{x}$ *if there exists* $d_0 \in \mathrm{int} T(\bar{x}, \Omega)$ *such that*

(i) $\langle \nabla g_i(\bar{x}), d_0 \rangle < 0, \phi_k^{\square}(\bar{x}; d_0) < 0\ \forall i \in I(\bar{x}), k \in K(\bar{x})$,

(ii) $\langle \nabla h_j(\bar{x}), d_0 \rangle = 0, \psi_l^{\square}(\bar{x}; d_0) = 0,\ i = 1, 2, \ldots, J, l = 1, 2, \ldots, L$,

(iii) *for any* $\xi_l \in \partial^{\diamond} \psi_l(\bar{x}), l = 1, \ldots, L$, $\{\nabla h_1(\bar{x}), \ldots, \nabla h_J(\bar{x}), \xi_1, \ldots, \xi_L\}$ *are linearly independent.*

PROPOSITION 4.4. *The* (GMFCQ) *implies* (NNAMCQ). *Under the assumption that* $\mathrm{int} T(\bar{x}, \Omega) \neq \emptyset$, *the* (GMFCQ) *and* (NNAMCQ) *are equivalent.*

Proof. Since the proof of (GMFCQ) implying (NNAMCQ) is exactly similar to the proof in the case $I = J = 0$ [12, Proposition 4.3], we omit the proof.

We now prove the reverse statement under the assumption that $\mathrm{int} T(\bar{x}, \Omega) \neq \emptyset$. Suppose that the (NNAMCQ) holds but not the (GMFCQ). If for some $\xi_l \in \partial^{\diamond} \psi_l(\bar{x}), l = 1, 2, \ldots, L$, $\{\nabla h_1(\bar{x}), \ldots, \nabla h_J(\bar{x}), \xi_1, \ldots, \xi_L\}$ are linearly dependent, then there exist scalars $\beta_j (j = 1, 2, \ldots, J), \eta_l (l = 1, 2, \ldots, L)$ not all zero such that

$$
\begin{aligned}
0 &\in \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) + \sum_{l=1}^{L} \eta_l \partial^{\diamond} \psi_l(\bar{x})\\
&\subseteq \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) + \sum_{l=1}^{L} \eta_l \partial^{\diamond} \psi_l(\bar{x}) + N(\bar{x}, \Omega),
\end{aligned}
$$

which contradicts the fact that there is no nonzero abnormal multiplier for (P). If there is no $d_0 \in \mathrm{int} T(\bar{x}, \Omega)$ satisfying items (i) and (ii), then in the case $I \neq 0$, $d = 0$ must be an optimal solution to the following problem:

$$
\begin{aligned}
\min\quad & \langle \nabla g_{\bar{i}}(\bar{x}), d \rangle\\
\text{s.t.}\quad & \langle \nabla g_i(\bar{x}), d \rangle \leq 0,\ i \in I(\bar{x}) \backslash \{\bar{i}\},\\
& \langle \nabla h_j(\bar{x}), d \rangle = 0,\ j = 1, \ldots, J,\\
& \phi_k^{\square}(\bar{x}; d) \leq 0,\ k \in K(\bar{x}),\\
& \psi_l^{\square}(\bar{x}; d) = 0,\ l = 1, \ldots, L,\\
& d \in T(\bar{x}, \Omega),
\end{aligned}
$$

where $\bar{i} \in I(\bar{x})$ and in the case where $I = 0$ but $K \neq 0$, $d = 0$ must be an optimal solution to the following problem:

$$
\begin{aligned}
\min\quad & \phi_{\bar{k}}^{\square}(\bar{x}; d)\\
\text{s.t.}\quad & \langle \nabla h_j(\bar{x}), d \rangle = 0,\ j = 1, \ldots, J,\\
& \phi_k^{\square}(\bar{x}; d) \leq 0,\ k \in K(\bar{x}) \backslash \{\bar{k}\},
\end{aligned}
$$

$$\psi_l^{\square}(\bar{x}; d) = 0, \ l = 1, \dots, L,$$
$$d \in T(\bar{x}, \Omega),$$

where $\bar{k} \in K(\bar{x})$. Applying the generalized multiplier rule of Clarke completes the proof. □

In Lipschitz optimization, it is well known that the calmness condition is the weakest constraint qualification. We now extend the definition of the calmness condition [4] to our setting.

Definition 4.5 (calmness). *Let $\bar{x}$ be a solution of* (P). (P) *is calm at $\bar{x}$ provided that there exist $\epsilon > 0$ and $\mu > 0$ such that for all $(p, q, u, v) \in \epsilon B_{I+J+K+L}$ and all $x \in \bar{x} + \epsilon B$ satisfying*

$$g(x) + p \leq 0, h(x) + q = 0, \phi(x) + u \leq 0, \psi(x) + v = 0, x \in \Omega \tag{4.3}$$

one has

$$f(\bar{x}) \leq f(x) + \mu \|(p, q, u, v)\|,$$

where B_n denotes the open unit ball in R^n, $g(x) := (g_1(x), g_2(x), \dots, g_I(x))^t$ and $h(x), \phi(x), \psi(x)$ are the vector-valued mappings defined similarly.

We now prove that the calmness condition is also a constraint qualification in our setting. It is interesting to note that unlike the Fritz John type condition (Theorem 1.1) the KKT conditions under either the calmness condition (Theorem 4.2) or the one under the metric regularity condition (Theorems 4.8 and 4.10) hold even for problem (P) with $L \neq 0$. Moreover, under either the calmness condition or the metric regularity condition, the Fréchet differentiable equality constraints do not need to be continuous near the optimal solution.

Theorem 4.6 (KKT condition under calmness CQ). *Let $\bar{x}$ be a solution of* (P). *Suppose that the objective function f is either Fréchet differentiable at $\bar{x}$ or Lipschitz near $\bar{x}$, the constraint functions satisfy assumption* (A), *and there exists a vector that is hypertangent to Ω at $\bar{x}$. If* (P) *is calm at $\bar{x}$, then there exist $\alpha_i \geq 0 (i \in I(\bar{x})), \beta_j (j = 1, 2, \dots, J), \gamma_k \geq 0 (k \in K(\bar{x})), \eta_l (l = 1, 2, \dots, L)$ such that*

$$0 \in \partial^{\diamond} f(\bar{x}) + \sum_{i \in I(\bar{x})} \alpha_i \nabla g_i(\bar{x}) + \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) + \sum_{k \in K(\bar{x})} \gamma_k \partial^{\diamond} \phi_k(\bar{x})$$
$$+ \sum_{l=1}^{L} \eta_l \partial^{\diamond} \psi_l(\bar{x}) + N(\bar{x}, \Omega).$$

Proof. By the definition of calmness, $(x, p, u) = (\bar{x}, 0, 0)$ is a local solution to

$$\begin{aligned} \min \quad & f(x) + \mu(\|(p, u)\| + \sum_{j=1}^{J} |h_j(x)| + \sum_{l=1}^{L} |\psi_l(x)|) \\ \text{s.t.} \quad & g(x) + p \leq 0, \\ & \phi(x) + u \leq 0, \\ & x \in \Omega. \end{aligned}$$

For a function $g_i(x)$, denote by $g_i^+(x) := \max\{g_i(x), 0\}$. Since $g(x) - g^+(x) \leq 0$,$\phi(x) - \phi^+(x) \leq 0$ and $g(\bar{x}) - g^+(\bar{x}) = 0, \phi(\bar{x}) - \phi^+(\bar{x}) = 0$, taking $p = -g^+(x), u = -\phi^+(x)$, by the calmness condition $\bar{x}$ is also a local solution of the following problem:

$$\begin{aligned}\min \quad & f(x)+\mu\Bigg(\sqrt{I+K}\max\{g_1(x),\dots,g_I(x),\phi_1(x),\dots,\phi_K(x),0\} \\ & \qquad\qquad + \sum_{j=1}^{J}|h_j(x)|+\sum_{l=1}^{L}|\psi_l(x)|\Bigg) \\ \text{s.t.} \quad & x\in\Omega.\end{aligned}$$

That is, $(x,r,s,t)=(\bar{x},0,0,0)$ is a local solution of the following problem:

$$\begin{aligned}\min \quad & f(x)+\mu\left(\sqrt{I+K}r+\sum_{j=1}^{J}s_j+\sum_{l=1}^{L}t_l\right) \\ \text{s.t.} \quad & r\ge g_i(x),\ i=1,2,\dots,I, \\ & r\ge \phi_k(x),\ k=1,2,\dots,K, \\ & r\ge 0, \\ & s_j\ge h_j(x),\ j=1,2,\dots,J, \\ & s_j\ge -h_j(x),\ j=1,2,\dots,J, \\ & t_l\ge \psi_l(x),\ l=1,2,\dots,L, \\ & t_l\ge -\psi_l(x),\ l=1,2,\dots,L, \\ & x\in\Omega.\end{aligned}$$

It is straightforward to verify that the (NNAMCQ) for the above problem is satisfied and the Lagrange multiplier rule with $\lambda=1$ for the original problem follows from applying Theorem 4.1 to the above problem. □

We also extend the notion of metric regularity in smooth and Lipschitz optimization to our setting.

DEFINITION 4.7. *Let C denote the constraint region of* (P) *and $\bar{x}\in C$. C is said to be metrically regular at $\bar{x}$ if there exist positive constants μ,ϵ such that for all $(p,q,u,v)\in\epsilon B$ and all $x\in\bar{x}+\epsilon B$ satisfying* (4.3)*, one has*

$$d_C(x)\le\mu\|(p,q,u,v)\|.$$

As in smooth and Lipschitz optimization, the metric regularity is stronger than the calmness condition in our setting when the objective function is Lipschitz continuous.

THEOREM 4.8 (KKT condition under the metric regularity assumption when the objective function is Lipschitz). *Let $\bar{x}$ be a solution of* (P)*. Assume that the objective function f is Lipschitz near $\bar{x}$, the constraint functions satisfy assumption* (A)*, and there exists a vector that is hypertangent to Ω at $\bar{x}$. If the constraint region is metrically regular at $\bar{x}$, then the KKT condition as stated in the conclusion of Theorem* 4.6 *also holds.*

Proof. Since the objective function f is Lipschitz near $\bar{x}$, by virtue of Proposition 2.7, $\bar{x}$ is a local solution to the following problem:

$$\min \quad f(x)+L_f d_C(x),$$

where L_f denotes the Lipschitz constant of f near $\bar{x}$ and C is the constraint region of (P). By the metric regularity, $(x,p,q,u,v)=(\bar{x},0,0,0,0)$ is a local solution to the following problem:

$$\begin{array}{ll} \min & f(x) + L_f\mu\|(p,q,u,v)\| \\ \text{s.t.} & g(x)+p \le 0, h(x)+q \le 0, \phi(x)+u \le 0, \psi(x)+v=0, x \in \Omega. \end{array}$$

That is, the calmness CQ is satisfied at $\bar{x}$ and hence the conclusion of Theorem 4.6 also holds. □

Unlike the case where the objective function is Lipschitz continuous, when the objective function is only differentiable, the metric regularity of a constraint region may not imply the calmness as illustrated by the following example.

Example. Consider the following optimization problem:

$$\begin{array}{ll} \min & f(x) \\ \text{s.t.} & x = 0, \end{array}$$

where

$$f(x) := \begin{cases} x^2 \sin\frac{1}{x^2} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases}$$

It is clear that f is differentiable everywhere with

$$f'(x) := \begin{cases} 2x\sin\frac{1}{x^2} - \frac{2}{x}\cos\frac{1}{x^2} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases}$$

Hence f is differentiable at the optimal solution $\bar{x}=0$ but not Lipschitz near $\bar{x}=0$. The constraint region $\{x : x = 0\}$ is metrically regular since the constraint function is linear. However, the problem is not calm at $\bar{x}=0$ since $\bar{x}=0$ is not a solution to the perturbed problem

$$\min \quad f(x) + \mu\|x\|$$

for any $\mu > 0$.

However, although the metric regularity is not stronger than the calmness condition when the objective function is not Lipschitz, it turns out that the metric regularity is still a constraint qualification when the objective function is Fréchet differentiable. In the remainder of this section, we would like to prove the KKT condition under the metric regularity assumption when the objective function is Fréchet differentiable. First we prove the following formula for the Fréchet normal cone to the feasible region C and then we use the result to derive the multiplier rules.

LEMMA 4.9. *Let $\bar{x}$ be a feasible solution of* (P). *Assume that the constraint functions satisfy assumption* (A) *and there exists a vector that is hypertangent to Ω at $\bar{x}$. If C, the feasible region of* (P), *is metrically regular at $\bar{x}$, then*

$$N^F(\bar{x}, C) \subset \left\{ \sum_{i\in I(\bar{x})} \alpha_i \nabla g_i(\bar{x}) + \sum_{j=1}^{J} \beta_j \nabla h_j(\bar{x}) + \sum_{k \in K(\bar{x})} \gamma_k \partial^\diamond \phi_k(\bar{x}) \right. \\ \left. + \sum_{l=1}^{L} \eta_l \partial^\diamond \psi_l(\bar{x}) + N(\bar{x}, \Omega) : \alpha_i \ge 0, \gamma_k \ge 0, i \in I(\bar{x}), k \in K(\bar{x}) \right\}.$$

Proof. Let ξ be any element in $N^F_C(\bar{x})$. Then for any $\lambda \downarrow 0$ there exists $\delta > 0$ such that

$$\langle \xi, x' - \bar{x} \rangle \le \lambda \|x' - \bar{x}\| \qquad \forall x' \in C \cap (\bar{x} + \delta B).$$

That is, $\bar{x}$ is a local solution to the following problem:

$$\begin{array}{ll} \min & -\langle \xi, x' \rangle + \lambda \|x' - \bar{x}\| \\ \text{s.t.} & x' \in C. \end{array}$$

Since the objective function of the above problem is Lipschitz continuous, by virtue of Proposition 2.7, $\bar{x}$ is a local solution to the following problem:

$$\min \quad -\langle \xi, x' \rangle + \lambda \|x' - \bar{x}\| + L d_C(x'),$$

where $L \geq \|\xi\| + \lambda$ for all $\lambda > 0$. By the metric regularity, $\bar{x}$ is a local solution to the following problem:

$$\begin{array}{lll} (\mathrm{P}') & \min & -\langle \xi, x' \rangle + \lambda \|x' - \bar{x}\| \\ & & +L\mu(\sqrt{I+K} \max\{g_1(x'), \ldots, g_I(x'), \phi_1(x'), \ldots, \phi_K(x'), 0\} \\ & & +\|h(x')\| + \|\psi(x')\|) \\ & \text{s.t.} & x' \in \Omega. \end{array}$$

Or equivalently, $(x', r, s, t) = (\bar{x}, 0, 0, 0)$ is a local solution to the following problem:

$$\begin{array}{ll} \min & -\langle \xi, x' \rangle + \lambda \|x' - \bar{x}\| + M \left(r + \sum_{j=1}^{J} s_j + \sum_{l=1}^{L} t_l \right) \\ \text{s.t.} & r \geq g_i(x'), \quad i = 1, 2, \ldots, I, \\ & r \geq \phi_k(x'), k = 1, 2, \ldots, K, \\ & r \geq 0, \\ & s_j \geq h_j(x'), \quad j = 1, 2, \ldots, J, \\ & s_j \geq -h_j(x'), \quad j = 1, 2, \ldots, J, \\ & t_l \geq \psi_l(x'), \quad l = 1, 2, \ldots, L, \\ & t_l \geq -\psi_l(x'), \quad l = 1, 2, \ldots, L, \\ & x' \in \Omega, \end{array}$$

with $M = L\mu\sqrt{I+K}$. One can easily verify that the (NNAMCQ) for the above problem is satisfied. Applying Theorem 4.1, there exist $\alpha_i^\lambda (i \in I(\bar{x}))$, $\beta_j^\lambda (j = 1, 2, \ldots, J)$, $\gamma_k^\lambda (k \in K(\bar{x}))$, $\eta_l^\lambda (l = 1, 2, \ldots, L)$, such that

$$\begin{aligned} 0 \in -\xi + \lambda B^* + \sum_{i \in I(\bar{x})} \alpha_i^\lambda \nabla g_i(\bar{x}) + \sum_{j=1}^{L} \beta_j^\lambda \nabla h_j(\bar{x}) \\ + \sum_{k \in K(\bar{x})} \gamma_k^\lambda \partial^\diamond \phi_k(\bar{x}) + \sum_{l=1}^{L} \eta_l^\lambda \partial^\diamond \psi_l(\bar{x}) + N(\bar{x}, \Omega). \end{aligned}$$

Since the (NNAMCQ) holds for problem (P'), $\{(\alpha^\lambda, \beta^\lambda, \gamma^\lambda, \eta^\lambda)\}$ must be bounded. Without loss of generality, we may assume that $\{(\alpha^\lambda, \beta^\lambda, \gamma^\lambda, \eta^\lambda)\}$ converges. The proof of the lemma is completed after taking limits as $\lambda \to 0$, by virtue of the weak* compactness of the Michel–Penot subdifferentials (see Proposition 2.3). □

THEOREM 4.10 (KKT condition under the metric regularity CQ when the objective function is Fréchet differentiable). *Let $\bar{x}$ be a local optimal solution of* (P).

Assume that f is Fréchet differentiable at $\bar{x}$, the constraint functions satisfy assumption (A) *, and there exists a vector that is hypertangent to Ω at $\bar{x}$. If C is metrically regular at $\bar{x}$, then there exist scalars $\alpha_i \geq 0 (i \in I(\bar{x})), \beta_j (j = 1, \ldots, J), \gamma_k \geq 0 (k \in K(\bar{x})), \eta_l (l = 1, 2, \ldots, L)$ such that*

$$0 \in \nabla f(\bar{x}) + \sum_{i \in I(\bar{x})} \alpha_i \nabla g_i(\bar{x}) + \sum_{j=1}^{L} \beta_j \nabla h_j(\bar{x}) + \sum_{k \in K(\bar{x})} \gamma_k \partial^{\diamond} \phi_k(\bar{x}) + \sum_{l=1}^{L} \eta_l \partial^{\diamond} \psi_l(\bar{x}) + N(\bar{x}, \Omega).$$

Proof. Since f is Fréchet differentiable at $\bar{x}$, we have

$$\lim_{x \to \bar{x}} \frac{f(x) - f(\bar{x}) - \langle \nabla f(\bar{x}), x - \bar{x} \rangle}{\|x - \bar{x}\|} = 0.$$

Since $\bar{x}$ is a local solution to (P), one has

$$\begin{aligned} \limsup_{x \to \bar{x}, x \in C} \frac{-\langle \nabla f(\bar{x}), x - \bar{x} \rangle}{\|x - \bar{x}\|} &\leq \limsup_{x \to \bar{x}, x \in C} \frac{f(x) - f(\bar{x}) - \langle \nabla f(\bar{x}), x - \bar{x} \rangle}{\|x - \bar{x}\|} \\ &\leq \lim_{x \to \bar{x}} \frac{f(x) - f(\bar{x}) - \langle \nabla f(\bar{x}), x - \bar{x} \rangle}{\|x - \bar{x}\|} \\ &= 0. \end{aligned}$$

That is, $-\nabla f(\bar{x}) \in N^F(\bar{x}, C)$. The proof of the theorem follows by applying Lemma 4.9, the expression of the Fréchet normal cone to the constraint region. □

5. Multiplier rules for the case $I = J = 0$.

In this section we consider problem (P) in the case where all constraint functions are Lipschitz and the objective function f is Fréchet differentiable. Under this assumption, we derive multiplier rules without requiring the existence of a hypertangent to the abstract constraint set Ω. Note that in Asplund space, the results are sharper since the limiting subdifferentials and the limiting normal cones instead of the Clarke generalized gradients and the Clarke normal cones are used.

First we prove the following formula for the Fréchet normal cone to the feasible region with $I = J = 0$ and then we use the result to derive the multiplier rules.

LEMMA 5.1. *Let $\bar{x}$ be a feasible solution of* (P) *with $I = J = 0$. Assume that $\phi_k (k \in K(\bar{x})), \psi_l (l = 1, 2, \ldots, L)$ are Lipschitz near $\bar{x}$ and $\phi_k (k \notin K(\bar{x}))$ are continuous at $\bar{x}$. If C is metrically regular at $\bar{x}$, then*

$$N^F(\bar{x}, C) \subset \left\{ \sum_{k \in K(\bar{x})} \gamma_k \partial \phi_k(\bar{x}) + \sum_{l=1}^{L} \eta_l \partial \psi_k(\bar{x}) + N(\bar{x}, \Omega) : \gamma_k \geq 0, k \in K(\bar{x}) \right\},$$

where C denotes the feasible region of (P) *with $I = J = 0$.*

Moreover, if X is an Asplund space, then

$$N^F(\bar{x}, C) \subset \left\{ \sum_{k=1}^{K} \gamma_k \hat{\partial} \phi_k(\bar{x}) + \hat{\partial} \langle \eta, \psi \rangle(\bar{x}) + \hat{N}(\bar{x}, \Omega) : \gamma_k \geq 0, k \in K(\bar{x}) \right\}.$$

Proof. Let ξ be any element in $N_C^F(\bar{x})$. Then for any $\lambda_\nu \downarrow 0$, there exists $\delta > 0$ such that

$$\langle \xi, x' - \bar{x} \rangle \le \lambda_\nu \|x' - \bar{x}\| \qquad \forall x' \in C \cap (\bar{x} + \delta B).$$

That is, $\bar{x}$ is a local solution to the following problem:

$$\begin{array}{ll} \min & -\langle \xi, x' \rangle + \lambda_\nu \|x' - \bar{x}\| \\ \text{s.t.} & x' \in C. \end{array}$$

Since the objective function of the above problem is Lipschitz continuous, by virtue of Proposition 2.7, $\bar{x}$ is a local solution to the following problem:

$$\min \quad -\langle \xi, x' \rangle + \lambda_\nu \|x' - \bar{x}\| + L d_C(x'),$$

where $L \ge \|\xi\| + \lambda_\nu$ for all $\nu = 1, 2, \ldots$. By metrical regularity, $\bar{x}$ is a local solution to the following problem:

$$\begin{array}{ll} \min & -\langle \xi, x' \rangle + \lambda_\nu \|x' - \bar{x}\| + L\mu \left(\sqrt{K} \max\limits_{k \in K(\bar{x})} \{\phi_k(x'), 0\} + \|\psi(x')\| \right) \\ \text{s.t.} & x' \in \Omega. \end{array}$$

Or equivalently, $\bar{x}$ is a local solution to the following problem:

$$\min -\langle \xi, x' \rangle + \lambda_\nu \|x' - \bar{x}\| + M \left(\max_{k \in K(\bar{x})} \{\phi_k(x'), 0\} + \|\psi(x')\| \right) + \tilde{L} d_\Omega(x'),$$

with $M = L\mu\sqrt{K}$ and $\tilde{L}$ being the Lipschitz constant of the objective function of the previous optimization problem.

If X is an Asplund space, then by the sum rule for limiting subdifferentials (Proposition 2.5(ii)),

$$0 \in -\xi + \lambda_\nu B^* + M \hat{\partial} \varphi \circ (\phi, \psi)(\bar{x}) + \hat{N}(\bar{x}, \Omega),$$

where $\varphi(u, v) = \max_{k \in K(\bar{x})} \{u_k, 0\} + \|v\|$. By the chain rule,

$$\xi \in \lambda_\nu B^* + M \cup_{(\gamma,\eta) \in \hat{\partial}\varphi(\phi(\bar{x}), \psi(\bar{x}))} \hat{\partial} \langle (\gamma, \eta), (\phi, \psi) \rangle (\bar{x}) + \hat{N}(\bar{x}, \Omega).$$

That is, there exists $(\gamma_\nu, \eta_\nu) \in \hat{\partial}\varphi(\phi(\bar{x}), \psi(\bar{x}))$ such that

$$\xi \in \lambda_\nu B^* + M \hat{\partial} \langle (\gamma_\nu, \eta_\nu), (\phi, \psi) \rangle (\bar{x}) + \hat{N}(\bar{x}, \Omega).$$

Since φ is Lipschitz, by virtue of Proposition 2.3, (γ_ν, η_ν) is a bounded sequence in R^{K+L} and one can assume that $(\gamma_\nu, \eta_\nu) \rightarrow (\gamma, \eta)$ for some $(\gamma, \eta) \in \hat{\partial}\varphi(\phi(\bar{x}), \psi(\bar{x}))$. Hence,

$$\begin{aligned} \xi &\in \lambda_\nu B^* + M \hat{\partial} \langle (\gamma_\nu, \eta_\nu), (\phi, \psi) \rangle (\bar{x}) + \hat{N}(\bar{x}, \Omega) \\ &\subseteq \lambda_\nu B^* + M [\hat{\partial} \langle (\gamma, \eta), (\phi, \psi) \rangle (\bar{x}) + \hat{\partial} \langle (\gamma_\nu, \eta_\nu) - (\gamma, \eta), (\phi, \psi) \rangle (\bar{x})] + \hat{N}(\bar{x}, \Omega) \\ &\subseteq \lambda_\nu B^* + M \hat{\partial} \langle (\gamma, \eta), (\phi, \psi) \rangle (\bar{x}) + M \|(\gamma_\nu, \eta_\nu) - (\gamma, \eta)\| L_{(\phi,\psi)} B^* + \hat{N}(\bar{x}, \Omega). \end{aligned}$$

Taking limits as $\nu \to \infty$, by virtue of the weak* sequential closedness of limiting subdifferentials, one has

$$\xi \in M \hat{\partial} \langle (\gamma, \eta), (\phi, \psi) \rangle (\bar{x}) + \hat{N}(\bar{x}, \Omega)$$

for some

$$\begin{aligned}(\gamma,\eta) &\in \hat{\partial}\varphi(\phi(\bar{x}),\psi(\bar{x}))\\ &= \left\{(\gamma,\eta) : \sum_{k\in K(\bar{x})}\gamma_k = 1, \gamma_k \geq 0 k \in K(\bar{x}), \eta \in B_L\right\}.\end{aligned}$$

The case where X is a general Banach space can be proved similarly. □

THEOREM 5.2 (KKT condition when $I = I = 0$ under the metric regularity CQ). *Let $\bar{x}$ be a local optimal solution of* (P) *with $I = J = 0$. Assume that f is Fréchet differentiable at $\bar{x}$, $\phi_k(k \in K(\bar{x})), \psi_l(l = 1, 2, \ldots, L)$ are Lipschitz near $\bar{x}$ and $\phi_k(k \notin K(\bar{x}))$ are continuous at $\bar{x}$. If C is metrically regular at $\bar{x}$, then there exist $\gamma_k \geq 0(k \in K(\bar{x})), \eta_l(l = 1, 2, \ldots, L)$ such that*

$$0 \in \nabla f(\bar{x}) + \sum_{k\in K(\bar{x})} \gamma_k\partial\phi_k(\bar{x}) + \sum_{l=1}^{L} \eta_l\partial\psi_l(\bar{x}) + N(\bar{x}, \Omega).$$

Moreover, if X is a Asplund space and C is metrically regular at $\bar{x}$, then there exist $\gamma_k \geq 0(k \in K(\bar{x})), \eta_l \in R(l = 1, 2, \ldots, L)$ such that

$$0 \in \nabla f(\bar{x}) + \sum_{k\in K(\bar{x})} \gamma_k\hat{\partial}\phi_k(\bar{x}) + \hat{\partial}\langle\eta, \psi\rangle(\bar{x}) + \hat{N}(\bar{x}, \Omega).$$

Proof. Since f is Fréchet differentiable at $\bar{x}$, as in the proof of Theorem 4.10,

$$-\nabla f(\bar{x}) \in N^F(\bar{x}, C).$$

The proof of the theorem follows by applying Lemma 5.1, the expression of the Fréchet normal cone to the constraint region. □

Remark 2. Sufficient conditions for metrical regularity in the case $I = J = 0$ include the following:

(i) (see [10, Theorem 3].) The constraint region is defined by a system of linear equalities and inequalities, i.e.,

$$C := \{x \in X : \langle x_k^*, x\rangle = 0, k = 1, \ldots, K, \langle y_l^*, x\rangle \leq 0 l = 1, \ldots, L\}$$

for some $x_k^* \in X^*(k = 1, \ldots, K), y_l^* \in X^*(l = 1, \ldots, L)$.

(ii) In Banach space [4, Theorem 6.6.1], the (NNAMCQ) in the Clarke generalized gradient form is satisfied, i.e.,

$$\begin{aligned}&0 \in \sum_{k\in K(\bar{x})} \gamma_k\partial\phi_k(\bar{x}) + \sum_{l=1}^{L} \eta_l\partial\psi_k(\bar{x}) + N(\bar{x}, \Omega),\\ &\gamma_k \geq 0 \ \forall k \in K(\bar{x})\end{aligned}$$

implies that $\gamma_k = 0, k \in K(\bar{x}), \eta_l = 0, l = 1, 2, \ldots, L$. In Asplund space [18, Corollary 6.2], the (NNAMCQ) in the limiting subdifferential form is satisfied, i.e.,

$$\begin{aligned}&0 \in \sum_{k\in K(\bar{x})} \gamma_k\hat{\partial}\phi_k(\bar{x}) + \hat{\partial}\langle\eta, \psi\rangle(\bar{x}) + \hat{N}(\bar{x}, \Omega),\\ &\gamma_k \geq 0 \ \forall k \in K(\bar{x})\end{aligned}$$

implies that $\gamma_k = 0, k \in K(\bar{x}), \eta_l = 0, l = 1, 2, \ldots, L$.

THEOREM 5.3 (KKT condition when $I = J = 0$ under the calmness CQ). *Let $\bar{x}$ be a local optimal solution of* (P) *with $I = J = 0$. Assume that f is Fréchet differentiable at $\bar{x}$, $\phi_k(k \in K(\bar{x})), \psi_l(l = 1, 2, \ldots, L)$ are Lipschitz near $\bar{x}$ and $\phi_k(k \notin K(\bar{x}))$ are continuous at $\bar{x}$. If* (P) *is calm at $\bar{x}$, then the conclusions of Theorem* 5.2 *hold.*

Proof. By the definition of calmness, $(x, u) = (\bar{x}, 0)$ is a local solution to

$$\begin{aligned} \min \quad & f(x) + \mu(\|u\| + \|\psi(x)\|) \\ \text{s.t.} \quad & \phi(x) + u \le 0, \\ & x \in \Omega. \end{aligned}$$

Since $\phi(x) - \phi^+(x) \le 0$ and $\phi(\bar{x}) - \phi^+(\bar{x}) = 0$, $\bar{x}$ is also a local solution of the following problem:

$$\begin{aligned} \min \quad & f(x) + \mu\left(\sqrt{K} \max\{\phi_1(x), \ldots, \phi_K(x), 0\} + \|\psi(x)\|\right) \\ \text{s.t.} \quad & x \in \Omega. \end{aligned}$$

Case 1. X is a general Banach space. It is easy to see that $(x, r, s) = (\bar{x}, 0, 0)$ is a local solution to the following problem:

$$\begin{aligned} \min \quad & f(x) + \mu\left(\sqrt{K} r + \sum_{l=1}^{L} s_l\right) \\ \text{s.t.} \quad & r \ge \phi_k(x), \ k = 1, \ldots, K, \\ & r \ge 0, \\ & s_l \ge \psi_l(x), \quad l = 1, 2, \ldots, L, \\ & s_l \ge -\psi_l(x), \quad l = 1, 2, \ldots, L, \\ & x \in \Omega. \end{aligned}$$

It is straightforward to verify that the (NNAMCQ) for the above problem is satisfied and the KKT condition follows from Theorem 5.2 and in Remark 2(ii).

Case 2. X is an Asplund space. Equivalently, $\bar{x}$ is a local solution to the following problem:

$$\min \quad f(x) + \mu\left(\sqrt{K} \max_{k \in K(\bar{x})}\{\phi_k(x), 0\} + \|\psi(x)\|\right) + \delta_\Omega(x),$$

where $\delta_\Omega(x)$ is the indicator function of a set Ω defined by

$$\delta_\Omega(x) := \begin{cases} 0 & \text{if } x \in \Omega, \\ +\infty & \text{if } x \notin \Omega. \end{cases}$$

Since f is Fréchet differentiable and $G(x) := \mu(\sqrt{K} \max_{k \in K(\bar{x})}\{\phi_K(x), 0\} + \|\psi(x)\|)$ is Lipschitz near $\bar{x}$, one has

$$\begin{aligned} 0 &\in \nabla f(\bar{x}) + \partial^F(G + \delta_\Omega)(\bar{x}) \quad \text{(by Proposition 2.5(i))} \\ &\subseteq \nabla f(\bar{x}) + \hat{\partial}(G + \delta_\Omega)(\bar{x}) \\ &\subseteq \nabla f(\bar{x}) + \hat{\partial} G(\bar{x}) + \hat{N}(\bar{x}, \Omega) \quad \text{(Proposition 2.5(ii))}. \end{aligned}$$

The remaining proof follows by using the sum rules and the chain rules as in the proof of Lemma 5.1. □

Proof of Theorem 1.2. Suppose X is a Banach space. If the (NNAMCQ) in the Clarke generalized gradient form does not hold, then the Fritz John condition holds with $\lambda = 0$. Otherwise if the (NNAMCQ) in the Clarke generalized gradient form holds, then by Remark 2 and Theorem 5.2, the Fritz John condition holds with $\lambda = 1$.

Similarly suppose that X is an Asplund space. If the (NNAMCQ) in the limiting subdifferential form as in Remark 2 does not hold, then the required Fritz John condition holds with $\lambda = 0$. Otherwise if the (NNAMCQ) in the limiting subdifferential form holds, then by Remark 2 and Theorem 5.2, the required Fritz John condition holds with $\lambda = 1$.

Acknowledgments. The author would like to thank Jay Treiman for his suggestions on replacing the Clarke generalized gradient by the Michel–Penot subdifferential in Theorem 1.1 and those in section 4 in an earlier version.

THE LOCAL SOLVABILITY OF A HAMILTON–JACOBI–BELLMAN PDE AROUND A NONHYPERBOLIC CRITICAL POINT*

ARTHUR J. KRENER†

Abstract. We show the existence of a local solution to a Hamilton–Jacobi–Bellman (HJB) PDE around a critical point where the corresponding Hamiltonian ODE is not hyperbolic, i.e., it has eigenvalues on the imaginary axis. Such problems arise in nonlinear regulation, disturbance rejection, gain scheduling, and linear parameter varying control. The proof is based on an extension of the center manifold theorem due to Aulbach, Flockerzi, and Knobloch. The method is easily extended to the Hamilton–Jacobi–Isaacs (HJI) PDE. Software is available on the web to compute local approximtate solutions of HJB and HJI PDEs.

Key words. parametrized optimal control, nonlinear regulation, nonlinear disturbance rejection, gain scheduling, linear parameter varying control, H_∞ regulation

1. Introduction.

Consider a smooth optimal control problem of minimizing

$$\frac{1}{2}\int_0^\infty \|e\|^2 + \|u\|^2 dt \tag{1.1}$$

subject to

$$\begin{array}{rcl} \dot{x} & = & f(x,u) = Ax + Bu + O(x,u)^2, \\ e & = & h(x,u) = Cx + Du + O(x,u)^2. \end{array} \tag{1.2}$$

The optimal cost $\pi(x)$ and the optimal feedback $\kappa(x)$ satisfy the Hamiliton–Jacobi–Bellman (HJB) PDE

$$0 = \frac{\partial \pi}{\partial x}(x) f(x, \kappa(x)) + l(x, \kappa(x)), \tag{1.3}$$

$$\kappa(x) = \text{argmin}_u \left\{ \frac{\partial \pi}{\partial x}(x) f(x,u) + l(x,u) \right\}, \tag{1.4}$$

where

$$\begin{aligned} l(x,u) &= \frac{1}{2}(\|e\|^2 + \|u\|^2) \\ &= \frac{1}{2}\left(x'Qx + 2x'Su + u'Ru\right) + O(x,u)^3 \end{aligned} \tag{1.5}$$

and $Q = C'C,\ S = C'D,\ R = I + D'D$.

The HJB PDE may not admit a smooth global solution but under suitable conditions there does exist a viscosity solution. We refer the reader to [10], [11] for details. It is well known [22] that the HJB PDE admits a smooth solution locally around

$x = 0$ under suitable conditions. We briefly review these conditions and the method of proof.

Consider first the linear quadratic part of the above problem, minimizing

$$\tfrac{1}{2}\int_0^\infty (x'Qx + 2x'Su + u'Ru) \tag{1.6}$$

subject to

$$\dot{x} \quad = \quad Ax + Bu. \tag{1.7}$$

If they exist, the optimal cost is quadratic, $\frac{1}{2}x'Px$, and the optimal feedback is linear, $u = Kx$. Moreover, P satisfies the algebraic Riccati equation

$$0 = A'P + PA + Q - (PB + S)R^{-1}(PB + S)'$$

and

$$K = -R^{-1}(PB + S)'.$$

It is well known [3] that if the pair A, B is stabilizable and the pair C, A is detectable, then there is a unique nonnegative definite solution to the algebraic Riccati equation and the resulting feedback is asymptotically stabilizing. If C, A is observable, then P is positive definite.

The $2n$ dimensional Hamiltonian system associated with this problem is linear,

$$\begin{bmatrix} \dot{x} \\ \dot{\lambda}' \end{bmatrix} = \mathbf{H} \begin{bmatrix} x \\ \lambda' \end{bmatrix}, \tag{1.8}$$

where

$$\mathbf{H} = \begin{bmatrix} A - BR^{-1}S' & -BR^{-1}B' \\ -Q + SR^{-1}S' & -A' + SR^{-1}B' \end{bmatrix}. \tag{1.9}$$

If A, B is stabilizable and C, A is detectable, then this system is hyperbolic, i.e., none of the eigenvalues of $\mathbf{H}$ lie on the imaginary axis. Since $\mathbf{H}$ is Hamiltonian, this implies that n eigenvalues lie in the open left half plane and n eigenvalues lie in the open right half plane. In fact, the n dimensional stable subspace of $\mathbf{H}$ is the graph of the gradient of the unique nonnegative definite solution to the algebraic Riccati equation,

$$\lambda = x'P.$$

In other words, the stable subspace is the span of the columns of

$$\begin{bmatrix} I \\ P \end{bmatrix}. \tag{1.10}$$

We return to the nonlinear problem (1.1), (1.2). The associated Hamiltonian system is nonlinear,

$$\begin{aligned} \dot{x}' &= \frac{\partial H}{\partial \lambda}(\lambda, x, \kappa(\lambda, x)), \\ \dot{\lambda} &= -\frac{\partial H}{\partial x}(\lambda, x, \kappa(\lambda, x)), \end{aligned} \tag{1.11}$$

where the Hamiltonian is

$$\begin{array}{rcl} H(\lambda,x,u) & = & \lambda f(x,u)+l(x,u) \\ & = & \lambda\,(Ax+Bu) \\ & & +\frac{1}{2}\,(x'Qx+2x'Su+u'Ru) \\ & & +O(\lambda,x,u)^3 \end{array} \tag{1.12}$$

and the optimal control as determined by the Pontryagin maximum principle satisfies

$$u=\kappa(\lambda,x)=\mathrm{argmin}_u H(\lambda,x,u). \tag{1.13}$$

The linearization of this system (1.11) around the origin is the linear Hamiltonian system above (1.8). Hence if A,B is stabilizable and C,A is detectable, then there is an n dimensional local stable manifold around the origin [15]. Moreover, this submanifold is the graph of the gradient of the optimal cost,

$$\lambda=\frac{\partial\pi}{\partial x}(x).$$

Hence the HJB PDE (1.3), (1.4) is locally solvable. The details can be found in Lukes [22].

In this paper we show that the HJB PDE is locally solvable in certain situations where the linear part of the system is not stabilizable or not detectable. Such systems arise naturally in the problems of nonlinear regulation, disturbance rejection, gain scheduling, and linear parameter varying control. In these problems there tends to be certain modes of the linearized system at the origin which are neutrally stable, uncontrollable, and/or unobservable. But fortunately these modes tend to be sufficiently separated from the others or can be made so by feedforward from the exosystem state so that an extension of the stable manifold theorem can be used to prove the local solvability of the HJB PDE. We proved this extension, which we call the stable and partial center manifold theorem, only to learn that a similar result had already been shown by Aulbach, Flockerzi, and Knobloch [6] and Aulbach and Flockerzi [7]. Since their result is not well known and may not be readily available, we include our proof. We also prove an additional result that the Taylor series of the stable and partial center manifold can be computed term-by-term. This justifies the term-by-term solution of the HJB PDE in these situations in the spirit of Al'brecht [2].

The rest of the paper is organized as follows. In the next section we introduce the problems of nonlinear regulation, disturbance rejection, gain scheduling, and linear parameter varying control and discuss when they can be transformed so that a local solution of the HJB equation exists. In section 4 we state and prove two theorems, the stable and partial center manifold theorem and a theorem on its term-by-term development. In section 5 we show how these theorems can be used to prove the local solvability of the HJB PDE and to construct approximate solutions. In the last section we discuss the local solvability of HJI PDEs and how they arise in H_∞ extensions of the above problems.

2. Nonlinear regulation and related problems.

Consider a smooth nonlinear plant

$$\begin{array}{rcl} \dot{x} & = & f(x,u,\bar{x}) \\ & = & Ax+Bu+F\bar{x} \\ & & +f^{[2]}(x,u,\bar{x})+O(x,u,\bar{x})^3, \\ e & = & h(x,u,\bar{x}) \\ & = & Cx+Du+H\bar{x} \\ & & +h^{[2]}(x,u,\bar{x})+O(x,u,\bar{x})^3 \end{array} \tag{2.1}$$

which is perturbed by a smooth nonlinear exosystem

$$\begin{aligned} \dot{\bar{x}} &= \bar{f}(\bar{x}) \\ &= \bar{A}\bar{x} + \bar{f}^{[2]}(\bar{x}) + O(\bar{x})^3, \end{aligned} \tag{2.2}$$

where superscript $[d]$ denotes terms composed of homogeneous polynomials of degree d. The dimensions of $x, u, \bar{x}, e$ are $n, m, \bar{n}, p$, respectively.

The goal of regulation is to use a combination of feedforward and feedback control $u = \alpha(x, \bar{x})$ so that the output of the plant asymptotically goes to 0,

$$e(t) \longrightarrow 0$$

for every $x(0)$, $\bar{x}(0)$. The plant should also be internally stable.

The exosystem could be a system whose output we wish the plant to track (regulation), a noise source whose disturbances we wish the plant to reject (disturbance rejection), or static and/or dynamic parameters to be used for scheduling the controller of the plant (gain scheduling).

A linear parameter varying (LPV) system,

$$\begin{aligned} \dot{x} &= A(\bar{x})x + B(\bar{x})u \\ &= \left(A^{[0]} + A^{[1]}(\bar{x}) + \cdots\right) x + \left(B^{[0]} + B^{[1]}(\bar{x}) + \cdots\right) u, \\ e &= C(\bar{x})x + D(\bar{x})u \\ &= \left(C^{[0]} + C^{[1]}(\bar{x}) + \cdots\right) x + \left(D^{[0]} + D^{[1]}(\bar{x}) + \cdots\right) u, \end{aligned}$$

falls into the last category.

We make the reasonable assumptions that the linear part of the plant is stabilizable and detectable when $\bar{x} = 0$ and the linear part of the exosystem is stable. Most plants are designed to be linearly stabilizable and detectable. If the exosystem was unstable then it would probably be impossible to overcome its effect on the plant. The combined system (2.1), (2.2) is not linearly stabilizable because we have no control over the stable modes of the exosystem and some of these might not be linearly detectable.

The solution of the regulator problem is in two steps. The first is to use feedforward from the exosystem state to insure exact tracking when the initial conditions of the plant and the exosystem permit this. We are assuming that the state of the exosystem is available for measurement. The more general case, when it is not measurable, was treated in [14] and [8]. Even when the state of the exosystem is not measurable, one must find the feedforward control law that would insure exact tracking if it were measurable. We discuss only the case when x, $\bar{x}$ are measurable.

The linear version of the problem was solved by Francis [12] and its nonlinear generalization is due to Isidori and Byrnes [14]. One seeks $\theta(\bar{x})$, $\beta(\bar{x})$ satisfying the Francis–Byrnes–Isidori (FBI) PDE

$$\begin{aligned} f(\theta(\bar{x}), \beta(\bar{x}), \bar{x}) &= \frac{\partial \theta}{\partial \bar{x}}(\bar{x}) \bar{f}(\bar{x}), \\ h(\theta(\bar{x}), \beta(\bar{x}), \bar{x}) &= 0. \end{aligned} \tag{2.3}$$

If the FBI PDE is solvable, then the control $u = \beta(\bar{x})$ makes $x = \theta(\bar{x})$ an invariant manifold of the combined system consisting of plant and exosystem. On this manifold, exact tracking occurs, $e = 0$.

One can attempt to solve the FBI equations term-by-term. Suppose

$$\theta(\bar{x}) = T\bar{x} + \theta^{[2]}(\bar{x}) + O(\bar{x})^3,$$
$$\beta(\bar{x}) = L\bar{x} + \beta^{[2]}(\bar{x}) + O(\bar{x})^3.$$

The linear part of the FBI equations are the Francis equations

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} T \\ L \end{bmatrix} - \begin{bmatrix} T \\ 0 \end{bmatrix} \bar{A} = - \begin{bmatrix} F \\ H \end{bmatrix}.$$

These equations are solvable for any F, H iff no output zero of the plant is a pole of the exosystem [13, 16, 17]. In other words, the exosystem should not excite those frequencies that the plant cannot produce.

The output zeros of the plant are those complex numbers s for which there exist complex n and p row vectors ξ and ζ such that

$$\begin{bmatrix} \xi & \zeta \end{bmatrix} \begin{bmatrix} A - sI & B \\ C & D \end{bmatrix} = \begin{bmatrix} 0 & 0 \end{bmatrix}.$$

There may be a finite or infinite number of output zeros. For example, if $m = p$, then there are either n zeros or every s is a zero. The poles $\lambda_1, \dots, \lambda_{\bar{n}}$ of the exosystem are the eigenvalues of $\bar{A}$.

If there is a resonance between a pole and zero, the equations will still be solvable for some F, H. The solvability depends on the direction ξ, ζ of the zero and the eigenvector of the pole.

The higher degree equations are linear and depend on the solutions of the lower degree equations. They are solvable for arbitrary higher degree terms iff the harmonics of the exosystem don't resonate with the zeros of the plant [13, 16, 17].

For example, the degree two equations are

$$\begin{aligned} &A\theta^{[2]}(\bar{x}) + B\beta^{[2]}(\bar{x}) - \frac{\partial \theta}{\partial \bar{x}}(\bar{x}) \left(\bar{A}\bar{x}\right) \\ &\qquad = -f^{[2]}(T\bar{x}, L\bar{x}, \bar{x}) + T\bar{f}^{[2]}(\bar{x}), \\ &C\theta^{[2]}(\bar{x}) + D\beta^{[2]}(\bar{x}) \\ &\qquad = -h^{[2]}(T\bar{x}, L\bar{x}, \bar{x}). \end{aligned}$$

These are solvable for arbitrary $f^{[2]}, h^{[2]}$ iff no output zero of the plant equals the sum of two poles of the exosystem, $\lambda_k \neq s_i + s_j$. If there is a resonance, they are solvable for some $f^{[2]}, h^{[2]}$. Matlab-based software is available on the web to compute the solution of the FBI PDE to any degree using the function `fbi.m` of the Nonlinear Systems Toolbox [20].

Now suppose that the FBI equations have been solved. The second step is to use additional feedforward and feedback to insure that the closed loop system converges to the tracking manifold $x = \theta(\bar{x})$ where $e = 0$. This can be achieved locally by linear pole placement techniques [14], but an alternative approach is to use optimal control methods to achieve a nonlinear solution [16, 17]. Define transverse coordinates z, v by

$$\begin{aligned} z &= x - \theta(\bar{x}) = x - T\bar{x} - \theta^{[2]}(\bar{x}) + O(\bar{x})^3, \\ v &= u - \beta(\bar{x}) = u - L\bar{x} - \beta^{[2]}(\bar{x}) + O(\bar{x})^3. \end{aligned} \tag{2.4}$$

In these coordinates the plant and exosystem are of the form

$$\begin{aligned} \dot{z} &= \tilde{f}(z,v,\bar{x}) = Ax + Bu + \tilde{f}^{[2]}(z,v,\bar{x}) + O(z,v,\bar{x})^3, \\ \dot{\bar{x}} &= \bar{f}(\bar{x}) = \bar{A}\bar{x} + \bar{f}^{[2]}(\bar{x}) + O(\bar{x})^3, \\ e &= \tilde{h}(z,v,\bar{x}) = Cz + Dv + \tilde{h}^{[2]}(z,v,\bar{x}) + O(z,v,\bar{x})^3, \end{aligned} \tag{2.5}$$

where

$$\begin{aligned} \tilde{f}(z,v,\bar{x}) &= f(z+\theta(\bar{x}), v+\beta(\bar{x}), \bar{x}) - f(\theta(\bar{x}), \beta(\bar{x}), \bar{x}), \\ \tilde{h}(z,v,\bar{x}) &= h(z+\theta(\bar{x}), v+\beta(\bar{x}), \bar{x}). \end{aligned} \tag{2.6}$$

Notice that the linear part of the z dynamics and the linear part of the output are unaffected by $\bar{x}$. Recall we have assumed that the linear part of the plant is stabilizable and detectable and the linear part of the exosystem is neutrally stable. Furthermore,

$$\begin{aligned} \tilde{f}(0,0,\bar{x}) &= f(\theta(\bar{x}), \beta(\bar{x}), \bar{x}) - f(\theta(\bar{x}), \beta(\bar{x}), \bar{x})) = 0, \\ \tilde{h}(0,0,\bar{x}) &= h(\theta(\bar{x}), \beta(\bar{x}), \bar{x}) = 0. \end{aligned} \tag{2.7}$$

A stabilizing feedback can be found by minimizing

$$\tfrac{1}{2}\textstyle\int_0^\infty \|e\|^2 + \|v\|^2 dt \tag{2.8}$$

subject to the dynamics (2.5). Other cost criterions l can be used as long as they satisfy (2.11). In particular a cost criterion like $x'Qx + u'Ru$ should not be used as then (2.11) will not hold. Intuitively, one should not cost the part of the state and the control that are necessary to achieve exact tracking. Even in the linear case, there is considerable confusion on this point, e.g., [3].

Let $\pi(z,\bar{x})$ denote the optimal cost and $\gamma(z,\bar{x})$ the optimal feedback; then π, γ satisfy the HJB PDE

$$\begin{aligned} 0 &= \frac{\partial \pi}{\partial z}(z,\bar{x})\tilde{f}(z,\gamma(z,\bar{x}),\bar{x}) + \frac{\partial \pi}{\partial \bar{x}}(z,\bar{x})\bar{f}(\bar{x}) \\ &\quad + l(z,\gamma(z,\bar{x}),\bar{x}), \\ 0 &= \frac{\partial \pi}{\partial z}(z,\bar{x})\frac{\partial \tilde{f}}{\partial v}(z,\gamma(z,\bar{x}),\bar{x}) + \frac{\partial l}{\partial v}(z,\gamma(z,\bar{x}),\bar{x}), \end{aligned} \tag{2.9}$$

where

$$\begin{aligned} l(z,v,\bar{x}) &= \tfrac{1}{2}(\|e\|^2 + \|v\|^2) \\ &= \tfrac{1}{2}\left(z'Qz + 2z'Sv + v'Rv\right) \\ &\quad + l^{[3]}(z,v,\bar{x}) + O(z,v,\bar{x})^4 \end{aligned} \tag{2.10}$$

for the matrices $Q = C'C,\ S = C'D,\ R = I + D'D$, and some cubic polynomial $l^{[3]}$.

By generalizing Al'brecht's method [2], we can solve the HJB PDE term-by-term [16]. Since

$$\begin{aligned} \tilde{f}(z,v,\bar{x}) &= O(z,v), \\ \tilde{h}(z,v,\bar{x}) &= O(z,v), \\ l(z,v,\bar{x}) &= O(z,v)^2, \end{aligned} \tag{2.11}$$

we expect that

$$\begin{array}{rcl}\pi(z,\bar{x}) & = & O(z)^2,\\ \gamma(z,\bar{x}) & = & O(z).\end{array} \tag{2.12}$$

In particular, we expect that

$$\begin{aligned}\pi(z,\bar{x}) &= \frac{1}{2}z'Pz + \pi^{[3]}(z,\bar{x}) + O(z,\bar{x})^4,\\ \gamma(z,\bar{x}) &= Kz + \gamma^{[2]}(z,\bar{x}) + O(z,\bar{x})^3.\end{aligned}$$

The lowest degree terms in the HJB equations are the familiar Riccati equation and the formula for the optimal linear feedback

$$\begin{array}{rcl}0 & = & A'P + PA + Q - (PB+S)R^{-1}(PB+S)',\\ K & = & -R^{-1}(PB+S)'.\end{array} \tag{2.13}$$

At each higher degree $d > 1$, the equations are linear in the unknowns $\pi^{[d+1]}$, $\gamma^{[d]}$ and depend on the lower order terms of the solution. They are solvable if the linear part of the plant is stabilizable and the linear part of the exosystem is stable. For example, to find the next terms $\pi^{[3]}(z,\bar{x})$, $\gamma^{[2]}(z,\bar{x})$, one plugs the first two terms of π, γ into HJB equations and collects the next terms (degree 3 from the first HJB equation and degree 2 from the second HJB equation)

$$\begin{aligned}0 = {}&\frac{\partial\pi^{[3]}}{\partial z}(z,\bar{x})(A+BK)z + \frac{\partial\pi^{[3]}}{\partial\bar{x}}(z,\bar{x})(\bar{A}\bar{x})\\ &+z'P\tilde{f}^{[2]}(z,Kz,\bar{x}) + l^{[3]}(z,Kz,\bar{x}),\\ 0 = {}&\frac{\partial\pi^{[3]}}{\partial z}(z,\bar{x})B + z'P\frac{\partial\tilde{f}^{[2]}}{\partial v}(z,Kz,\bar{x})\\ &+\gamma^{[2]}(z,\bar{x})'R + \frac{\partial l^{[3]}}{\partial v}(z,Kz,\bar{x}).\end{aligned} \tag{2.14}$$

Notice that the first equation involves only $\pi^{[3]}$, the other unknown $\gamma^{[2]}$ does not appear. This equation is solvable if $A+BK$ is asymptotically stable and $\bar{A}$ is stable. This follows from the fact that the mapping

$$\pi^{[3]}(z,\bar{x}) \mapsto \frac{\partial\pi^{[3]}}{\partial z}(z,\bar{x})(A+BK)z + \frac{\partial\pi^{[3]}}{\partial\bar{x}}(z,\bar{x})(\bar{A}\bar{x})$$

is a linear operator on cubic polynomials. It is not hard to see that its eigenvalues are the sum of three eigenvalues of $A+BK$ and $\bar{A}$. The operator restricts to a linear operator on the subspace of $\pi^{[3]}(z,\bar{x})$ satisfying (2.12), where its eigenvalues are the sum of three eigenvalues of $A+BK$ or the sum of two eigenvalues of $A+BK$ and one eigenvalue of $\bar{A}$. Since the eigenvalues of $A+BK$ are in the open left half plane and those of $\bar{A}$ are in the closed left half plane, the restricted operator is invertible and the first equation of (2.14) is always solvable. We discuss this further in the proof of Theorem 4.2.

Given the solution $\pi^{[3]}$, we can then solve the second equation for $\gamma^{[2]}$

$$\gamma^{[2]}(z,\bar{x}) = -R^{-1}\left(\frac{\partial\pi^{[3]}}{\partial z}(z,\bar{x})B + z'P\frac{\partial\tilde{f}^{[2]}}{\partial v}(z,Kz,\bar{x}) + \frac{\partial l^{[3]}}{\partial v}(z,Kz,\bar{x})\right)'.$$

The higher degree terms are found in a similar fashion. Matlab-based software is available on the web to compute the solution of the HJB PDE to any degree using the function `hjb.m` in the Nonlinear Systems Toolbox [20]. If one wants to solve the FBI PDE and then the HJB PDE in the transverse coordinates, use the function `mdl_mtch.m`.

Given the solutions of the FBI and HJB equations, the desired feedforward/feedback is

$$\begin{aligned} u &= \alpha(x,\bar{x}) \\ &= \beta(\bar{x}) + \gamma(x-\theta(\bar{x}),\bar{x}). \end{aligned}$$

Of course the above discussion is formal. We shall show using results from [6], [7] that the HJB PDE (2.9) is locally solvable. Furthermore, its Taylor series expansion can be computed term-by-term as described above. To do so we shall use an invariant manifold theorem that we shall discuss in the next section. In section 4 we use this theorem to show the local existence of the solution to the HJB equation (2.9).

Suppose one has computed approximate solutions to the FBI PDE up to degree d and the HJB PDE up to degree $d+1$, and one has the desired $\alpha(x,\bar{x})$ up to degree d. Despite the formal nature of these, one can explicitly verify where it gives the desired solution. The function $\pi(x-\theta(\bar{x},\bar{x}))$ is a potential Lyapunov function for the approximate tracking manifold $x=\theta(\bar{x})$ on which the error $e=O(\bar{x})^{d+1}$. Using this and the true closed loop dynamics, one can estimate the basin of attraction of the approximate tracking manifold.

3. Stable and partial center manifold theorem.

The following theorem was proven by Aulbach, Flockerzi, and Knobloch [6] and Aulbach and Flockerzi [7]. We were unaware of their work and suspected that such a theorem must hold because of the formal discussion of the last section. We present our independent proof because [6] and [7] are not widely known nor readily available. Moreover, Theorem 3.2 is new and its proof depends on the proof of Theorem 3.1.

THEOREM 3.1 (see [6], [7]). *Given an ODE of the form*

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \end{bmatrix} = \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} + \begin{bmatrix} f_1(x) \\ f_2(x) \\ f_3(x) \end{bmatrix}, \tag{3.1}$$

where $x_i \in \mathbf{R}^{\mathbf{n_i}}$, $n=n_1+n_2+n_3$, and $f_i(x)$ is C^k for $k\ge 2$. Suppose that

(3.2) *the eigenvalues of A_1 have negative real part,*

(3.3) *the eigenvalues of A_2 have nonnegative real part,*

(3.4) *the eigenvalues of A_3 have nonpositive real part,*

$$f_i(0,0,0)=0,\ i=1,2,3, \tag{3.5}$$

$$\frac{\partial f_i}{\partial x_j}(0,0,0)=0,\ i,j=1,2,3, \tag{3.6}$$

$$f_i(0,x_2,0)=0,\ i=1,3. \tag{3.7}$$

Then there exists, around $x=(0,0,0)$, a local C^{k-2} invariant manifold

$$x_3=\phi(x_1,x_2), \tag{3.8}$$

where

$$\phi(0,x_2)=0, \tag{3.9}$$

$$\frac{\partial\phi}{\partial x}(0,0)=0 \textit{ if } k>2. \tag{3.10}$$

Remarks. The condition (3.7) implies that $\{x_1=0,\ x_3=0\}$ is an invariant manifold. When the spectrum of A_2 lies on the imaginary axis, we call this a partial center manifold as it corresponds to only some of the eigenvalues on the imaginary axis. We call (3.8) a local stable and partial center manifold because it contains the local stable manifold and part of the local center manifold. The partial center manifold provides the needed gap between the eigenvalues that are associated to the invariant manifold and those that are not. The necessity of the existence of the partial center manifold to the existence of the stable and partial center manifold could be argued as follows. If the stable and partial center manifold exists, then its intersection with the center manifold should yield the partial center manifold. The flaw in this argument is that center manifolds are not necessarily unique and the intersection of manifolds is not necessarily a manifold [5], [9]. Still it is plausible. In the above theorem there is a loss of smoothness, from a C^k dynamics to a C^{k-2} local stable and partial center manifold. This is probably an artifact of the proof. In the stable manifold theorem and the theorem of Aulbach and Flockerzi [7] there is no loss of smoothness, and in the center manifold theorem there is a loss of smoothness from C^k to C^{k-1}.

Proof. The first step to make suitable linear changes of coordinates on each of the three subspaces so that there exist $\alpha\geq 16\beta>0$ such that for all $x_1,\ x_2,\ x_3$

$$\begin{aligned} x_1'A_1x_1 &\leq -\alpha|x_1|^2,\\ x_2'A_2x_2 &\leq \beta|x_2|^2,\\ -x_3'A_3x_3 &\leq \beta|x_3|^2. \end{aligned}$$

This is possible by Lemma 1 of [15].

The next step is to use a cut-off function to redefine f. Let $\nu(x)$ be a scalar valued C^∞ function, $0\leq\nu(x)\leq 1$, $\nu(x)=1$ for $0\leq|x|\leq 1$, and $\nu(x)=0$ for $|x|\geq 2$. For any $\epsilon>0$, define

$$f(x;\epsilon):=f(\nu(x/\epsilon)x).$$

Since $f(x;\epsilon)$ agrees with $f(x)$ for $|x|\leq\epsilon$, it suffices to prove the theorem for some $\epsilon>0$.

Next we show that there exists a continuous function $k(\epsilon)$ with $k(0)=0$ and a constant $K>0$ such that for all $x,\ \bar{x}\in\mathbf{R^n}$ and for $i=1,2,3$

$$|f_i(x;\epsilon)-f_i(\bar{x};\epsilon)|^2\leq k^2(\epsilon)|x-\bar{x}|^2 \tag{3.11}$$

and for $i=1,3$

$$|f_i(x;\epsilon)-f_i(\bar{x};\epsilon)|^2\leq k^2(\epsilon)\left|\begin{array}{c} x_1-\bar{x}_1\\ x_3-\bar{x}_3\end{array}\right|^2+K\left|\begin{array}{c}\bar{x}_1\\ \bar{x}_3\end{array}\right|^2|x_2-\bar{x}_2|^2. \tag{3.12}$$

Note that

$$|f_i(x;\epsilon)-f_i(\bar{x};\epsilon)|^2\leq\left|\frac{\partial f_i}{\partial x}(\xi;\epsilon)\right|^2|x-\bar{x}|^2,$$

where ξ is some point on the line between x and $\bar{x}$. Also for $i = 1, 3$

$$\begin{aligned}|f_i(x;\epsilon) - f_i(\bar{x};\epsilon)|^2 &\le |f_i(x;\epsilon) - f_i(\bar{x}_1, x_2, \bar{x}_3;\epsilon) + f_i(\bar{x}_1, x_2, \bar{x}_3;\epsilon) - f_i(\bar{x};\epsilon)|^2 \\ &\le 2|f_i(x;\epsilon) - f_i(\bar{x}_1, x_2, \bar{x}_3;\epsilon)|^2 + 2|f_i(\bar{x}_1, x_2, \bar{x}_3;\epsilon) - f_i(\bar{x};\epsilon)|^2 \\ &\le 2\left|\frac{\partial f_i}{\partial x}(\xi_1, x_2, \xi_3;\epsilon)\right|^2 \left|\begin{array}{c} x_1 - \bar{x}_1 \\ 0 \\ x_3 - \bar{x}_3 \end{array}\right|^2 \\ &\quad +2\left|\frac{\partial f_i}{\partial x_2}(\bar{x}_1, \xi_2, \bar{x}_3;\epsilon)\right|^2 |x_2 - \bar{x}_2|^2,\end{aligned}$$

where (ξ_1, x_2, ξ_3) is some point on the line between x and $(\bar{x}_1, x_2, \bar{x}_3)$ and $(\bar{x}_1, \xi_2, \bar{x}_3)$ is some point on the line between $(\bar{x}_1, x_2, \bar{x}_3)$ and $\bar{x}$. Furthermore,

$$\left|\frac{\partial f_i}{\partial x_2}(\bar{x}_1, \xi_2, \bar{x}_3;\epsilon)\right|^2 \le \left|\frac{\partial^2 f_i}{\partial x \partial x_2}(\xi;\epsilon)\right|^2 \left|\begin{array}{c} \bar{x}_1 \\ 0 \\ \bar{x}_3 \end{array}\right|^2,$$

where ξ is some point on the line between $(0, \xi_2, 0)$ and $(\bar{x}_1, \xi_2, \bar{x}_3)$.

Now $\nu(x)$ and its partials are continuous functions with compact support so there exists a constant M such that

$$\begin{aligned}\left|\frac{\partial \nu}{\partial x}(x)\right| &\le M, \\ \left|\frac{\partial^2 \nu}{\partial x^2}(x)\right| &\le M\end{aligned}$$

for all x. Since f_i satisfies (3.6) we can choose M large enough so that

$$\begin{aligned}\left|\frac{\partial f_i}{\partial x}(x)\right| &\le M|x|, \\ \left|\frac{\partial^2 f_i}{\partial x^2}(x)\right| &\le M\end{aligned}$$

for all $|x| \le 1$. Then for $0 < \epsilon < 1/2$

$$\begin{aligned}\left|\frac{\partial f_i}{\partial x}(x;\epsilon)\right| &\le \left|\frac{\partial f_i}{\partial x}(\nu(x/\epsilon)x)\right| \left|\nu(x/\epsilon) + \frac{\partial \nu}{\partial x}(x/\epsilon)\frac{x}{\epsilon}\right| \\ &\le 2M(1+2M)\epsilon,\end{aligned}$$

$$\begin{aligned}\left|\frac{\partial^2 f_i}{\partial x^2}(x;\epsilon)\right| &\le \left|\frac{\partial^2 f_i}{\partial x^2}(\nu(x/\epsilon)x)\right| \left|\nu(x/\epsilon) + \frac{\partial \nu}{\partial x}(x/\epsilon)\frac{x}{\epsilon}\right|^2 \\ &\quad + \left|\frac{\partial f_i}{\partial x}(\nu(x/\epsilon)x)\right| \left|\frac{\partial \nu}{\partial x}(x/\epsilon)\frac{2}{\epsilon} + \frac{\partial^2 \nu}{\partial x^2}(x/\epsilon)\frac{x}{\epsilon^2}\right| \\ &\le M(1+2M)^2 + 8M^2.\end{aligned}$$

Let

$$\begin{aligned}k^2(\epsilon) &= 2\left(2M(1+2M)\epsilon\right)^2, \\ K &= 2\left(M(1+2M)^2 + 8M^2\right)^2;\end{aligned}$$

then $k(\epsilon)$ is continuous and goes to 0 as ϵ goes to 0.

Henceforth we suppress the ϵ and write $f(x)$ for $f(x;\epsilon)$.

Let $k_1,\ k_2$ be any positive constants and X denote the space of all Lipschitz continuous functions $\phi(x_1,x_2)$ defined for $|x_1|<\epsilon$ and any x_2 such that

$$\phi(0,x_2)=0, \tag{3.13}$$

$$|\phi(x_1,x_2)-\phi(\bar{x}_1,\bar{x}_2)|^2 \le k_1|x_1-\bar{x}_1|^2+k_2|\bar{x}_1|\,|x_2-\bar{x}_2|^2. \tag{3.14}$$

Taking $\bar{x}_1=0$, these imply that

$$|\phi(x_1,x_2)|^2\le k_1|x_1|^2$$

so we can define

$$\|\phi\|^2=\sup\left\{\frac{|\phi(x_1,x_2)|^2}{|x_1|}:|x_1|<\epsilon\right\}. \tag{3.15}$$

With this norm, X is a complete space.

For $|x_1|<\epsilon,\ x_2\in\mathbf{R^{n_2}}$, and $\phi\in X$, define

$$\xi_i(t)=\xi_i(t;x_1,x_2,\phi)$$

for $i=1,2$ to be the solution of

$$\dot{\xi}_i=A_i\xi_i+f_i(\xi_1,\xi_2,\phi(\xi_1,\xi_2)), \tag{3.16}$$

$$\xi_i(0)=x_i. \tag{3.17}$$

Define a mapping T on X as follows:

$$(T\phi)(x_1,x_2)=\int_\infty^0 e^{-A_3s}f_3(\xi_1(s),\xi_2(s),\phi(\xi_1(s),\xi_2(s)))\,ds. \tag{3.18}$$

We would like to show that for ϵ sufficiently small, T is a contraction on X.

Suppose $x_1=0$; then $\xi_1(t)=0$ because of (3.7) and for the same reason

$$(T\phi)(0,x_2)=0$$

so $T\phi$ satisfies (3.13).

Suppose $\phi,\ \bar{\phi}\in X$; then for any $|x_1|<\epsilon,\ x_2\in\mathbf{R^{n_2}},\ |\bar{x}_1|<\epsilon,\ \bar{x}_2\in\mathbf{R^{n_2}}$, and $x_3=\phi(x_1,x_2),\ \bar{x}_3=\bar{\phi}(\bar{x}_1,\bar{x}_2)$, then by the above for $i=1,2,3$

$$\begin{aligned}|f_i(x)-f_i(\bar{x})|^2&\le 2|f_i(x)-f_i(\bar{x}_1,\bar{x}_2,\phi(\bar{x}_1,\bar{x}_2))|^2\\&\quad+2|f_i(\bar{x}_1,\bar{x}_2,\phi(\bar{x}_1,\bar{x}_2),)-f_i(\bar{x})|^2\\&\le 2k^2(\epsilon)\left((1+k_1)|x_1-\bar{x}_1|^2+(1+k_2\epsilon)\,|x_2-\bar{x}_2|^2+\epsilon\|\phi-\bar{\phi}\|^2\right)\end{aligned} \tag{3.19}$$

and for $i=1,3$

$$\begin{aligned}|f_i(x)-f_i(\bar{x})|^2&\le 2|f_i(x)-f_i(\bar{x}_1,\bar{x}_2,\phi(\bar{x}_1,\bar{x}_2))|^2\\&\quad+2|f_i(\bar{x}_1,\bar{x}_2,\phi(\bar{x}_1,\bar{x}_2))-f_i(\bar{x})|^2\\&\le l_1(\epsilon)|x_1-\bar{x}_1|^2+l_2(\epsilon)|\bar{x}_1|\,|x_2-\bar{x}_2|^2+l_3(\epsilon)|\bar{x}_1|\,\|\phi-\bar{\phi}\|^2,\end{aligned} \tag{3.20}$$

where the functions

$$\begin{aligned} l_1(\epsilon) &= 2k^2(\epsilon)(1+k_1), \\ l_2(\epsilon) &= 2\left(k^2(\epsilon)k_2 + K(1+k_1)\epsilon\right), \\ l_3(\epsilon) &= 2k^2(\epsilon) \end{aligned}$$

go to 0 as $\epsilon \to 0$.

Suppose $\xi_i(t),\ \bar{\xi}_i(t)$ for $i = 1, 2$ are the solutions of

$$\begin{aligned} \dot{\xi}_i &= A_i\xi_i + f_i(\xi_1, \xi_2, \phi(\xi_1, \xi_2)), \\ \xi_i(0) &= x_i, \end{aligned}$$

$$\begin{aligned} \dot{\bar{\xi}}_i &= A_i\bar{\xi}_i + f_i(\bar{\xi}_1, \bar{\xi}_2, \bar{\phi}(\bar{\xi}_1, \bar{\xi}_2)), \\ \bar{\xi}_i(0) &= \bar{x}_i \end{aligned}$$

and $\xi_3(t) = \phi(\xi_1(t), \xi_2(t)),\ \bar{\xi}_3(t) = \bar{\phi}(\bar{\xi}_1(t), \bar{\xi}_2(t))$.

Then since $2ab \le a^2 + b^2$ and $(a+b)^2 \le 2a^2 + 2b^2$

$$\begin{aligned} &\frac{d}{dt}\frac{|\xi_1 - \bar{\xi}_1|^2 + |\xi_2 - \bar{\xi}_2|^2}{2} \\ &\le (\xi_1 - \bar{\xi}_1)'\left(A_1(\xi_1 - \bar{\xi}_1) + f_1(\xi) - f_1(\bar{\xi})\right) \\ &\quad + (\xi_2 - \bar{\xi}_2)'\left(A_2(\xi_2 - \bar{\xi}_2) + f_2(\xi) - f_2(\bar{\xi})\right) \\ &\le -\alpha|\xi_1 - \bar{\xi}_1|^2 + \beta|\xi_2 - \bar{\xi}_2|^2 + k(\epsilon)\left(|\xi_1 - \bar{\xi}_1| + |\xi_2 - \bar{\xi}_2|\right) \\ &\quad \left[2(1+k_1)|\xi_1 - \bar{\xi}_1|^2 + 2(1+k_2\epsilon)|\xi_2 - \bar{\xi}_2|^2 + 2\epsilon\|\phi - \bar{\phi}\|^2\right]^{\frac{1}{2}} \\ &\le \left(-\alpha + k(\epsilon)(2+k_1)\right)|\xi_1 - \bar{\xi}_1|^2 + \left(\beta + k(\epsilon)(2+k_2\epsilon)\right)|\xi_2 - \bar{\xi}_2|^2 \\ &\quad + k(\epsilon)\epsilon\|\phi - \bar{\phi}\|^2. \end{aligned}$$

We assume ϵ is small enough so that

$$\begin{aligned} -\alpha + k(\epsilon)(2+k_1) &\le 2\beta \\ k(\epsilon)(2+k_2\epsilon) &\le \beta \\ k(\epsilon)\epsilon &\le 2\beta; \end{aligned}$$

then

$$\frac{d}{dt}\left(|\xi_1 - \bar{\xi}_1|^2 + |\xi_2 - \bar{\xi}_2|^2\right) \le 4\beta\left(|\xi_1 - \bar{\xi}_1|^2 + |\xi_2 - \bar{\xi}_2|^2 + \|\phi - \bar{\phi}\|^2\right)$$

and by Gronwall's inequality

$$|\xi_1(t) - \xi_1(t)|^2 + |\xi_2(t) - \xi_2(t)|^2 \le e^{4\beta t}\left(|x_1 - \bar{x}_1|^2 + |x_2 - \bar{x}_2|^2 + \|\phi - \bar{\phi}\|^2\right). \tag{3.21}$$

With this inequality in hand we can obtain a stricter one by using (3.20) instead of (3.19).

$$\begin{aligned} \frac{d}{dt}\frac{|\xi_1 - \bar{\xi}_1|^2}{2} &\le -\alpha|\xi_1 - \bar{\xi}_1|^2 + |\xi_1 - \bar{\xi}_1| \\ &\quad \left[l_1(\epsilon)|\xi_1 - \bar{\xi}_1|^2 + l_2(\epsilon)|\bar{\xi}_1|\ |\xi_2 - \bar{\xi}_2|^2 + l_3(\epsilon)|\bar{\xi}_1|\ \|\phi - \bar{\phi}\|^2\right]^{\frac{1}{2}}. \end{aligned} \tag{3.22}$$

Now suppose that $\bar{x}_1 = 0,\ \bar{x}_2 = 0$ so that $\bar{\xi}_1 = 0,\ \bar{\xi}_2 = 0$; then

$$\frac{d}{dt}\frac{|\xi_1|^2}{2} \le \left(-\alpha + l_1^{\frac{1}{2}}(\epsilon)\right)|\xi_1|^2.$$

If ϵ is small enough so that

$$l_1^{\frac{1}{2}}(\epsilon) \le \frac{\alpha}{2},$$

then by Gronwall

$$|\xi_1(t)|^2 \le e^{-\alpha t}|x_1|^2. \tag{3.23}$$

For $a,\ b,\ c \ge 0$ we have $\sqrt{a+b+c} \le \sqrt{a} + \sqrt{b} + \sqrt{c}$ so (3.22) becomes

$$\begin{aligned}\frac{d}{dt}\frac{|\xi_1 - \bar{\xi}_1|^2}{2} &\le \left(-\alpha + l_1^{\frac{1}{2}}(\epsilon)\right)|\xi_1 - \bar{\xi}_1|^2\\ &\quad + l_2^{\frac{1}{2}}(\epsilon)|\xi_1 - \bar{\xi}_1|\ |\bar{\xi}_1|^{\frac{1}{2}}|\xi_2 - \bar{\xi}_2|\\ &\quad + l_2^{\frac{1}{2}}(\epsilon)|\xi_1 - \bar{\xi}_1|\ |\bar{\xi}_1|^{\frac{1}{2}}\|\phi - \bar{\phi}\|\\ &\le \left(-\alpha + l_1^{\frac{1}{2}}(\epsilon) + l_2^{\frac{1}{2}}(\epsilon) + l_3^{\frac{1}{2}}(\epsilon)\right)|\xi_1 - \bar{\xi}_1|^2\\ &\quad + l_2^{\frac{1}{2}}(\epsilon)|\bar{\xi}_1|\ |\xi_2 - \bar{\xi}_2|^2\\ &\quad + l_3^{\frac{1}{2}}(\epsilon)|\bar{\xi}_1|\ \|\phi - \bar{\phi}\|^2.\end{aligned}$$

Assume ϵ is small enough so that

$$l_1^{\frac{1}{2}}(\epsilon) + l_2^{\frac{1}{2}}(\epsilon) + l_3^{\frac{1}{2}}(\epsilon) \le \frac{\alpha}{2},$$

then using (3.23), (3.21), this becomes

$$\begin{aligned}\frac{d}{dt}\frac{|\xi_1 - \bar{\xi}_1|^2}{2} &\le -\frac{\alpha}{2}|\xi_1 - \bar{\xi}_1|^2\\ &\quad + l_2^{\frac{1}{2}}(\epsilon)e^{(4\beta - \frac{\alpha}{2})t}|\bar{x}_1|\left(|x_1 - \bar{x}_1|^2 + |x_2 - \bar{x}_2|^2 + \|\phi - \bar{\phi}\|^2\right)\\ &\quad + l_3^{\frac{1}{2}}(\epsilon)e^{-\frac{\alpha}{2}t}|\bar{x}_1|\ \|\phi - \bar{\phi}\|^2.\end{aligned}$$

Since $16\beta \le \alpha$,

$$\begin{aligned}\frac{d}{dt}|\xi_1 - \bar{\xi}_1|^2 &\le -\alpha|\xi_1 - \bar{\xi}_1|^2\\ &\quad + 2l_2^{\frac{1}{2}}(\epsilon)e^{-\frac{\alpha}{4}t}|\bar{x}_1|\left(|x_1 - \bar{x}_1|^2 + |x_2 - \bar{x}_2|^2\right)\\ &\quad + 2(l_2^{\frac{1}{2}}(\epsilon) + l_3^{\frac{1}{2}}(\epsilon))e^{-\frac{\alpha}{4}t}|\bar{x}_1|\ \|\phi - \bar{\phi}\|^2\end{aligned}$$

so by Gronwall

$$\begin{aligned}|\xi_1(t) - \bar{\xi}_1(t)|^2 &\le e^{-\alpha t}|x_1 - \bar{x}_1|^2\\ &\quad + \frac{8}{3}l_2^{\frac{1}{2}}(\epsilon)e^{-\frac{\alpha}{4}t}|\bar{x}_1|\left(|x_1 - \bar{x}_1|^2 + |x_2 - \bar{x}_2|^2\right)\\ &\quad + \frac{8}{3}(l_2^{\frac{1}{2}}(\epsilon) + l_3^{\frac{1}{2}}(\epsilon))e^{-\frac{\alpha}{4}t}|\bar{x}_1|\ \|\phi - \bar{\phi}\|^2.\end{aligned} \tag{3.24}$$

Next we use (3.20) to estimate

$$\begin{aligned}\left|(T\phi)(x_1,x_2)-(T\bar{\phi})(\bar{x}_1,\bar{x}_2)\right|^2 &= \left|\int_0^\infty e^{-A_3 s}\left(f_3(\xi(s))-f_3(\bar{\xi}(s))\right)\ ds\right|^2\\ &\le \int_0^\infty e^{2\beta s}\left|f_3(\xi(s))-f_3(\bar{\xi}(s))\right|^2\ ds\\ &\le \int_0^\infty e^{2\beta s}\ \big[l_1(\epsilon)|\xi_1(s)-\bar{\xi}_1(s)|^2\\ &\qquad +l_2(\epsilon)|\bar{\xi}_1(s)|\ |\xi_2(s)-\bar{\xi}_2(s)|^2\\ &\qquad +l_3(\epsilon)|\bar{\xi}_1(s)|\ \|\phi-\bar{\phi}\|^2\big]\ ds.\end{aligned}$$

From (3.21), (3.23), (3.24) and $16\beta\le\alpha$

$$\begin{aligned}&\left|(T\phi)(x_1,x_2)-(T\bar{\phi})(\bar{x}_1,\bar{x}_2)\right|^2 \le \int_0^\infty e^{2\beta s}\Big[l_1(\epsilon)\,(\ e^{-\alpha s}|x_1-\bar{x}_1|^2\\ &\quad+\frac{8}{3}l_2^{\frac{1}{2}}(\epsilon)e^{-\frac{\alpha}{4}s}|\bar{x}_1|\left(|x_1-\bar{x}_1|^2+|x_2-\bar{x}_2|^2\right)\\ &\quad+\frac{8}{3}\left(l_2^{\frac{1}{2}}(\epsilon)+l_3^{\frac{1}{2}}(\epsilon)\right)e^{-\frac{\alpha}{4}s}|\bar{x}_1|\ \|\phi-\bar{\phi}\|^2\ )\\ &\quad+l_2(\epsilon)e^{-\frac{\alpha}{2}s}|\bar{x}_1|\ e^{4\beta s}\left(|x_1-\bar{x}_1|^2+|x_2-\bar{x}_2|^2+\|\phi-\bar{\phi}\|^2\right)\\ &\quad+l_3(\epsilon)e^{-\frac{\alpha}{2}s}|\bar{x}_1|\ \|\phi-\bar{\phi}\|^2\Big]\ ds\\ &\quad\le m_1(\epsilon)|x_1-\bar{x}_1|^2+m_2(\epsilon)|\bar{x}_1|\ |x_2-\bar{x}_2|^2\\ &\quad+m_3(\epsilon)|\bar{x}_1|\ \|\phi-\bar{\phi}\|^2,\end{aligned}\tag{3.25}$$

where

$$\begin{aligned}m_1(\epsilon)&=l_1(\epsilon)\left(\frac{8}{7\alpha}+\frac{64}{3\alpha}l_2^{\frac{1}{2}}(\epsilon)\epsilon\right)+\frac{8}{\alpha}l_2(\epsilon)\epsilon,\\ m_2(\epsilon)&=\frac{64}{3\alpha}l_1(\epsilon)l_2^{\frac{1}{2}}(\epsilon)+\frac{8}{\alpha}l_2(\epsilon),\\ m_3(\epsilon)&=\frac{64}{3\alpha}l_1(\epsilon)\left(l_2^{\frac{1}{2}}(\epsilon)+l_3^{\frac{1}{2}}(\epsilon)\right)+\frac{8}{\alpha}l_2(\epsilon)+\frac{8}{3\alpha}l_3(\epsilon).\end{aligned}$$

Notice that $m_i(\epsilon)\to 0$ as $\epsilon\to 0$.

By letting $\bar{\phi}=\phi$ we see that

$$\begin{aligned}\left|(T\phi)(x_1,x_2)-(T\phi)(\bar{x}_1,\bar{x}_2)\right|^2 &\le 2m_1(\epsilon)|x_1-\bar{x}_1|^2\\ &\quad+2m_2(\epsilon)|\bar{x}_1|\ |x_2-\bar{x}_2|^2,\end{aligned}$$

so $(T\phi)(x_1,x_2)$ satisfies (3.14) for ϵ sufficiently small and T maps X to X.

By letting $\bar{x}=x$ we see that

$$\left|(T\phi)(x_1,x_2)-(T\bar{\phi})(x_1,x_2)\right|^2\le m_3(\epsilon)|\bar{x}_1|\ \|\phi-\bar{\phi}\|^2,$$

so $T : X \to X$ is a contraction for ϵ sufficiently small. Hence there exists a unique $\phi \in X$ such that

$$\phi = T\phi.$$

Let $\xi_i(t)$ satisfy (3.16), (3.17) for $i = 1, 2$ and $\xi_3(t) = \phi(\xi_1(t), \xi_2(t))$. By the definition of T (3.18),

$$\begin{aligned} \xi_3(t) &= (T\phi)(\xi_1(t), \xi_2(t)) \\ &= \int_\infty^0 e^{-A_3 s} f_3(\xi(t+s))\, ds \\ &= \int_\infty^t e^{-A_3(t-s)} f_3(\xi(s))\, ds, \end{aligned}$$

so $\xi(t)$ is a solution of the differential equation (3.1) and (3.8) defines a C^0 invariant manifold.

Now suppose $k > 2$. We wish to show that the invariant manifold (3.8) is C^1. Consider the dynamics tangent to (3.1),

$$\begin{bmatrix} \dot{z}_1 \\ \dot{z}_2 \\ \dot{z}_3 \end{bmatrix} = \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix} + \begin{bmatrix} g_1(x,z) \\ g_2(x,z) \\ g_3(x,z) \end{bmatrix}, \tag{3.26}$$

where

$$g_i(x,z) = \frac{\partial f_i}{\partial x}(x) z.$$

The combined system (3.1), (3.26) satisfies the hypothesis of Theorem 3.1, so a C^0 invariant manifold

$$\begin{bmatrix} x_3 \\ z_3 \end{bmatrix} = \begin{bmatrix} \phi(x_1, x_2, z_1, z_2) \\ \psi(x_1, x_2, z_1, z_2) \end{bmatrix} \tag{3.27}$$

can be found by the extension of the above contraction, call it S. Suppose $\phi(x_1, x_2)$ is a C^1 element of X; define

$$\psi(x_1, x_2, z_1, z_2) = \frac{\partial \phi}{\partial(x_1, x_2)}(x_1, x_2) \begin{bmatrix} z_1 \\ z_2 \end{bmatrix}. \tag{3.28}$$

If

$$(\bar{\phi}(x_1, x_2, z_1, z_2), \bar{\psi}(x_1, x_2, z_1, z_2)) = S(\phi(x_1, x_2), \psi(x_1, x_2, z_1, z_2)),$$

then it is straightforward to verify that

$$\bar{\phi}(x_1, x_2, z_1, z_2) = T(\phi(x_1, x_2)),$$

so $\bar{\phi}(x_1, x_2, z_1, z_2) = \bar{\phi}(x_1, x_2) \in X$ and

$$\bar{\psi}(x_1, x_2, z_1, z_2) = \frac{\partial \bar{\phi}}{\partial(x_1, x_2)}(x_1, x_2) \begin{bmatrix} z_1 \\ z_2 \end{bmatrix}.$$

Hence if we start the contraction at $\phi,\ \psi$ satisfying (3.28), it will converge to a $\phi,\ \psi$ satisfying (3.28), so the invariant manifold (3.8) is C^1. By repeated application of this technique we can show it is C^{k-2}.

It remains to verify (3.10) if $k > 2$. Clearly (3.9) implies

$$\frac{\partial \phi}{\partial x_2}(0,0) = 0.$$

Since (3.8) defines a C^{k-2} invariant manifold, we can take its time derivative to obtain the PDE

$$\begin{aligned}&A_3\phi(x_1,x_2) + f_3(x_1,x_2,\phi(x_1,x_2))\\ &= \sum_{j=1}^{2} \frac{\partial \phi_i}{\partial x_j}(x_1,x_2)\left(A_j x_j + f_j(x_1,x_2,\phi(x_1,x_2))\right). \end{aligned} \tag{3.29}$$

Taking the linear terms from both sides, we obtain a homogeneous linear equation

$$A_3\frac{\partial \phi}{\partial x_1}(0,0) - \frac{\partial \phi}{\partial x_1}(0,0)A_1 = 0. \tag{3.30}$$

The eigenvalues of the linear mapping

$$B \mapsto A_3B - BA_1$$

have positive real part because they are of the form $\lambda_3 - \lambda_1$, where $\lambda_3,\ \lambda_1$ are eigenvalues of $A_3,\ A_1$, respectively, and so the real part of $\lambda_3 - \lambda_1$ is positive. Hence (3.30) is nonsingular and

$$\frac{\partial \phi}{\partial x_1}(0,0) = 0. \qquad \square$$

The next theorem gives a term-by-term approximation of the stable and partial center manifold.

Theorem 3.2. *Suppose the hypothesis of Theorem* 3.1 *holds for* $k > 3$ *and let* $\phi(x_1,x_2)$ *define the* C^{k-2} *stable and partial center manifold. Suppose* $\psi(x_1,x_2)$ *is a* C^{k-2} *function satisfying* (3.9) *and the PDE* (3.29) *through terms of degree* $k-3$*,*

$$\begin{aligned}&A_3\psi(x_1,x_2) + f_3(x_1,x_2,\psi(x_1,x_2))\\ &= \sum_{j=1}^{2} \frac{\partial \psi}{\partial x_j}(x_1,x_2)\left(A_j x_j + f_j(x_1,x_2,\psi(x_1,x_2))\right) + O(x_1,x_2)^{k-2}. \end{aligned} \tag{3.31}$$

Then ϕ *and* ψ *agree to degree* $k-3$*,*

$$\psi(x_1,x_2) = \phi(x_1,x_2) + O(x_1,x_2)^{k-2}. \tag{3.32}$$

Proof. The theorem holds because the Taylor series coefficients to degree $k-3$ of any ψ satisfying (3.31) are uniquely determined. To see this we use induction on r. Assume that ϕ and ψ satisfy (3.31) to degree r and their Taylor series coefficients agree up to $r-1$.

Assume that $A_1,\ A_2,\ A_3$ are semisimple so that there exist bases of left and right eigenvectors. If they are not semisimple, the argument is essentially the same involving bases of left and right generalized eigenvectors but the details are messier, and hence are ommitted. Suppose for $j = 1, 2$, $k = 1, \dots, n_i$, and $l = 1, \dots, n_j$

$$w_{j,l}A_j = \lambda_{j,l}w_{j,l}, \tag{3.33}$$

$$A_3 v^{3,k} = \lambda_{3,k}v^{3,k}. \tag{3.34}$$

Let $\psi^{[r]}(x_1, x_2)$ be the part of $\psi(x_1, x_2)$ that is a homogeneous polynomial of degree r. A basis for the n_3-vector fields homogeneous of degree r in x_1, x_2 consists of the vector fields

$$\phi^{3,k}_{j_1,l_1;\dots;j_r,l_r}(x) = v^{3,k}(w_{j_1,l_1}x_{j_1})\dots(w_{j_r,l_r}x_{j_r}), \tag{3.35}$$

where $k = 1, \dots, n_i$, $j_s = 1, 2$, $l_s = 1, \dots, n_{j_s}$ and the pairs $(j_1, l_1) \le \dots \le (j_r, l_r)$ are in lexographic order.

Thus

$$\psi^{[r]}(x_1, x_2) = \sum_{k;j_1,l_1;\dots;j_r,l_r} \gamma^{j_1,l_1;\dots;j_r,l_r}_{3,k} \psi^{3,k}_{j_1,l_1;\dots;j_r,l_r}(x_1, x_2) \tag{3.36}$$

with

$$\gamma^{j_1,l_1;\dots;j_r,l_r}_{3,k} = 0 \tag{3.37}$$

if $j_1 = \dots = j_r = 2$ so that (3.9) is satisfied.

If we extract the degree r terms from (3.31), we obtain

$$A_3\psi^{[r]}3(x_1, x_2) - \sum_{j=1}^{2} \frac{\partial \psi^{[r]}_i}{\partial x_j}(x_1, x_2)A_j x_j = h^{[r]}(x_1, x_2), \tag{3.38}$$

where $h^{[r]}(x_1, x_2)$ depends only on the ODE (3.1) and the lower degree part of $\psi(x_1, x_2)$ which has been determined by (3.31). Now

$$\begin{aligned} A_3\psi^{3,k}_{j_1,l_1;\dots;j_r,l_r}(x_1, x_2) &- \sum_{j=1}^{2} \frac{\partial \psi^{3,k}_{j_1,l_1;\dots;j_r,l_r}(x_1, x_2)}{\partial x_j}(x_1, x_2)A_j x_j \\ &= (\lambda_{3,k} - \lambda_{j_1,l_1} - \dots - \lambda_{j_r,l_r})\, \psi^{3,k}_{j_1,l_1;\dots;j_r,l_r}(x_1, x_2). \end{aligned}$$

The real part of $\lambda_{3,k}$ is nonnegative and the real parts of λ_{j_s,l_s} are negative if $j_s = 1$ and are nonpositive if $j_s = 2$. Because of (3.37), we can restrict our attention to $\psi^{3,k}_{j_1,l_1;\dots;j_r,l_r}$, where at least one $j_s = 1$ so such $\gamma^{j_1,l_1;\dots;j_r,l_r}_{3,k}$ are uniquely determined by (3.38). □

Notice that if (3.7) is not satisfied to degree r, then (3.38) might not be solvable for then $h^{[r]}(x_1, x_2)$ might contain terms of the form $\psi^{3,k}_{j_1,l_1;\dots;j_r,l_r}(x_1, x_2)$, where $j_1 = \dots = j_r = 2$ and $\lambda_{3,k} - \lambda_{2,l_1} - \dots - \lambda_{2,l_r}$ might be zero.

4. Local solvability of the HJB PDE. The principle theorem of this paper is the following.

THEOREM 4.1. *Suppose the plant* (2.1) *and exosystem* (2.2) *are C^k, the linear part of the plant is stabilizable and detectable when $\bar{x} = 0$, the linear part of the exosystem is stable, the FBI PDE* (2.3) *has a C^k solution in some neighborhood of* 0 *in $\bar{x}$ space. Then in some neighborhood of* $0, 0$ *in $x, \bar{x}$ space there exists a C^{k-2} solution to HJB PDE* (2.9) *satisfying* (2.12).

Proof. The proof generalizes the standard approach [22] to showing the existence of local solutions to HJB PDEs. The graph of gradient of the solution π of the HJB PDE (2.9) is an invariant manifold of the associated Hamiltonian system of ODEs. In the standard case, the Hamiltonian ODEs have a hyperbolic fixed point at the origin and the invariant manifold is the stable manifold of this fixed point. But in this case, the Hamiltonian ODEs do not have a hyperbolic fixed point at the origin and the desired invariant manifold is a stable and partial center manifold.

Consider the Hamiltonian associated to the optimal control problem (2.8),

$$\begin{aligned} H(\lambda,\mu,z,\bar{x},v) &= \lambda\tilde{f}(z,v,\bar{x})+\mu\bar{f}(\bar{x})+l(z,v,\bar{x}) \\ &= \lambda\big(Az+Bv+\tilde{f}^{[2]}(z,v,\bar{x})\big) \\ &\quad +\mu\left(\bar{A}\bar{x}+\bar{f}^{[2]}(\bar{x})\right) \\ &\quad +\tfrac{1}{2}\left(z'Qz+2z'Sv+v'Rv\right) \\ &\quad +l^{[3]}(z,v,\bar{x})+O(\lambda,\mu,z,\bar{x},v)^4. \end{aligned} \tag{4.1}$$

The Pontryagin maximum principle asserts that the optimal control is

$$v=\gamma(\lambda,\mu,z,\bar{x})=\arg\min_{v} H(\lambda,\mu,z,\bar{x},v). \tag{4.2}$$

For small $\lambda,\mu,z,\bar{x}$ this is given by solving

$$\frac{\partial H}{\partial v}(\lambda,\mu,z,\bar{x},v)=0,$$

which yields

$$\begin{aligned} \gamma = -R^{-1}&\left(B'\lambda'+S'z+\left(\frac{\partial\tilde{f}^{[2]}}{\partial v}\right)'\lambda'+\left(\frac{\partial\tilde{l}^{[3]}}{\partial v}\right)'\right) \\ &+O(\lambda,\mu,z,\bar{x})^3. \end{aligned}$$

The HJB PDE (2.9) can be expressed in terms of the Hamiltonian as

$$H\left(\frac{\partial\pi}{\partial z},\frac{\partial\pi}{\partial\bar{x}},z,\bar{x},\gamma\left(\frac{\partial\pi}{\partial z},\frac{\partial\pi}{\partial\bar{x}},z,\bar{x}\right)\right)=0. \tag{4.3}$$

The Hamiltonian ODEs are

$$\begin{aligned} \dot{z}' &= \frac{\partial H}{\partial\lambda}(\lambda,\mu,z,\bar{x},\gamma(\lambda,\mu,z,\bar{x})), \\ \dot{\lambda} &= -\frac{\partial H}{\partial z}(\lambda,\mu,z,\bar{x},\gamma(\lambda,\mu,z,\bar{x})), \\ \dot{\bar{x}}' &= \frac{\partial H}{\partial\mu}(\lambda,\mu,z,\bar{x},\gamma(\lambda,\mu,z,\bar{x})), \\ \dot{\mu} &= -\frac{\partial H}{\partial\bar{x}}(\lambda,\mu,z,\bar{x},\gamma(\lambda,\mu,z,\bar{x})) \end{aligned} \tag{4.4}$$

and these are C^{k-1} since the Hamiltonian is C^k.

The linearization of this system around $0,0,0,0$ is

$$\left[\begin{array}{c} \dot{z} \\ \dot{\lambda}' \\ \hline \dot{\bar{x}} \\ \dot{\mu}' \end{array}\right]=\left[\begin{array}{cc} \mathbf{H_{11}} & \mathbf{H_{12}} \\ \mathbf{H_{21}} & \mathbf{H_{22}} \end{array}\right]\left[\begin{array}{c} z \\ \lambda' \\ \hline \bar{x} \\ \mu' \end{array}\right], \tag{4.5}$$

where

$$\mathbf{H} = \left[\begin{array}{cc|cc} A - BR^{-1}S' & -BR^{-1}B' & 0 & 0 \\ -Q + SR^{-1}S' & -A' + SR^{-1}B' & 0 & 0 \\ \hline 0 & 0 & \bar{A} & 0 \\ 0 & 0 & 0 & -\bar{A}' \end{array}\right]. \tag{4.6}$$

The column span of

$$\left[\begin{array}{cc} I_{n\times n} & 0 \\ P & 0 \\ 0 & I_{\bar{n}\times\bar{n}} \\ 0 & 0 \end{array}\right] \tag{4.7}$$

is an $n + \bar{n}$ dimensional stable and partial center subspace of the linear Hamiltonian system (4.5), where P is the unique nonnegative definite solution of the algebraic Riccati equation (2.13). We know that such a solution exists because the linear part of the plant was assumed to be stabilizable and detectable [3]. Half of the eigenvalues of the upper left $2n \times 2n$ block $\mathbf{H_{11}}$ lie in the open left half plane and half lie in the open right half plane. The asymptotically stable subspace is spanned by the first n columns of (4.7). As for the lower right $2\bar{n} \times 2\bar{n}$ block $\mathbf{H_{22}}$, by assumption the eigenvalues of $\bar{A}$ are in the closed left half plane and hence those of $-\bar{A}'$ are in the closed right half plane. A stable subspace is spanned by the last $\bar{n}$ columns of (4.7). Furthermore, the submanifold $z = 0,\ \lambda = 0,\ \mu = 0$ is an invariant submanifold of the nonlinear Hamiltonian system (4.4), so the conditions of the stable and partial center manifold Theorem are satisfied. There exists an $n + \bar{n}$ dimensional stable and partial center manifold in the $2(n + \bar{n})$ dimensional $z, \lambda, \bar{x}, \mu$ space which is tangent to the column span of (4.7) at $0, 0, 0, 0$. Hence this manifold is given by

$$\begin{array}{rcl} \lambda & = & \phi(z, \bar{x}), \\ \mu & = & \psi(z, \bar{x}), \end{array} \tag{4.8}$$

where ϕ, ψ are C^{k-3} and

$$\begin{array}{rcl} \phi(0, \bar{x}) & = & 0, \\ \psi(0, \bar{x}) & = & 0. \end{array} \tag{4.9}$$

This submanifold is Lagrangian, i.e., a maximal dimension submanifold on which the canonical two form

$$\omega = d\lambda\ dz + d\mu\ d\bar{x}$$

vanishes [1], [4]. To see that it vanishes we note that ω is invariant under the Hamiltonian flow (4.4) and this flow is converging to the $\bar{n}$ dimensional submanifold $z = 0,\ \lambda = 0,\ \mu = 0$, where ω clearly vanishes. The submanifold (4.8) is of maximal dimension, $n + \bar{n}$, in $2(n + \bar{n})$ variables.

Hence the one form

$$\phi(z, \bar{x})\ dz + \psi(z, \bar{x})\ d\bar{x}$$

is closed locally around $0, 0$ in $z, \bar{x}$ space and so there exists a C^{k-2} function $\pi(z, \bar{x})$ such that

$$\frac{\partial \pi}{\partial z}(z, \bar{x}) = \phi(z, \bar{x}),$$

$$\begin{aligned}
\frac{\partial \pi}{\partial \bar{x}}(z,\bar{x}) &= \psi(z,\bar{x}),\\
\pi(0,\bar{x}) &= 0,\\
\frac{\partial \pi}{\partial z}(0,\bar{x}) &= 0,\\
\frac{\partial \pi}{\partial \bar{x}}(0,\bar{x}) &= 0.
\end{aligned}$$

Note that π satisfies (2.12).

Differentiating (4.8) with respect to t along the Hamiltonian flow (4.4) yields

$$\begin{aligned}
\frac{\partial H}{\partial \lambda}\frac{\partial^2 \pi}{\partial z^2} + \frac{\partial H}{\partial \mu}\frac{\partial^2 \pi}{\partial z \partial \bar{x}} + \frac{\partial H}{\partial z} &= 0,\\
\frac{\partial H}{\partial \lambda}\frac{\partial^2 \pi}{\partial z \partial \bar{x}} + \frac{\partial H}{\partial \mu}\frac{\partial^2 \pi}{\partial \bar{x}^2} + \frac{\partial H}{\partial z} &= 0
\end{aligned}$$

or equivalently

$$\begin{aligned}
\frac{\partial}{\partial z} H\left(\frac{\partial \pi}{\partial z}, \frac{\partial \pi}{\partial \bar{x}}, z, \bar{x}, \gamma\left(\frac{\partial \pi}{\partial z}, \frac{\partial \pi}{\partial \bar{x}}, z, \bar{x}\right)\right) &= 0,\\
\frac{\partial}{\partial \bar{x}} H\left(\frac{\partial \pi}{\partial z}, \frac{\partial \pi}{\partial \bar{x}}, z, \bar{x}, \gamma\left(\frac{\partial \pi}{\partial z}, \frac{\partial \pi}{\partial \bar{x}}, z, \bar{x}\right)\right) &= 0.
\end{aligned}$$

Clearly π satisfies the HJB PDE (4.3) at $z = 0,\ \bar{x} = 0$, so it satisfies it in a neighborhood of this point. Moreover π is of the form

$$\pi(z,\bar{x}) = \frac{1}{2} z' P z + O(z,\bar{x})^3 \qquad \square \tag{4.10}$$

The next theorem shows that the solution to the HJB PDE (2.9) can be computed term-by-term.

THEOREM 4.2. *Suppose the hypotheses of Theorem* 4.1 *hold for* $k > 3$ *and let* $\pi(z,\bar{x})$ *be the* C^{k-2} *solution of the HJB PDE* (2.9) *satisfying* (2.12). *Suppose* $\phi(x_1,x_2)$ *is a* C^{k-2} *function satisfying the HJB PDE through terms of degree* $k-3$ *and satisfying* (2.12). *Then* π *and* ψ *agree to degree* $k-3$,

$$\pi(z,\bar{x})) = \psi(z,\bar{x}) + O(z,\bar{x})^{k-2} \tag{4.11}$$

Proof (sketch). Clearly $\pi(z,\bar{x})$ satisfies the term-by-term equations, so the result follows if we can show that these equations have unique solutions satisfying (2.12). We showed above that the quadratic terms agree, and as for the cubic terms, consider (2.14). The first equation is a linear equation for $\pi^{[3]}$. For simplicity assume that $A + BK$ and $\bar{A}$ have bases of left eigenvectors

$$\begin{array}{lcll}
\xi_i(A+BK) & = & \lambda_i \xi_i, & i = 1,\ldots,n,\\
\zeta_j \bar{A} & = & \mu_j \xi_i, & j = 1,\ldots,\bar{n},
\end{array} \tag{4.12}$$

otherwise we use bases of generalized eigenvectors. Since the linear part of the plant is stabilizable and detectable, the linear part of the closed loop system is asymptotically stable, Re $\lambda_i < 0$, and by assumption the linear part of the exosystem is stable, Re $\mu_j \leq 0$.

Now any cubic polynomial $\pi^{[3]}(z,\bar{x})$ satisfying (2.12) can be expressed as

$$\begin{aligned}\pi^{[3]}(z,\bar{x}) = &\sum c_{i_1,i_2,i_3}\ \xi_{i_1}z\ \xi_{i_2}z\ \xi_{i_3}z\\ &+\sum d_{i_1,i_2,j_3}\ \xi_{i_1}z\ \xi_{i_2}z\ \zeta_{j_3}\bar{x}\end{aligned}$$

and

$$\begin{aligned}&\frac{\partial\pi^{[3]}}{\partial z}(z,\bar{x})(A+BK)z+\frac{\partial\pi^{[3]}}{\partial\bar{x}}(z,\bar{x})(\bar{A}\bar{x})\\ &=\sum c_{i_1,i_2,i_3}\ \ (\lambda_{i_1}+\lambda_{i_2}+\lambda_{i_3})\,\xi_{i_1}z\ \xi_{i_2}z\ \xi_{i_3}z\\ &\quad+\sum d_{i_1,i_2,j_3}\ \ (\lambda_{i_1}+\lambda_{i_2}+\mu_{j_3})\,\xi_{i_1}z\ \xi_{i_2}z\ \zeta_{j_3}\bar{x}.\end{aligned}$$

It follows from (2.11) that

$$z'P\tilde{f}^{[2]}(z,Kz,\bar{x})+l^{[3]}(z,Kz,\bar{x})=O(z,\bar{x})^2,$$

so

$$\begin{aligned}&z'P\tilde{f}^{[2]}(z,Kz,\bar{x})+l^{[3]}(z,Kz,\bar{x})\\ &\quad=\sum k_{i_1,i_2,i_3}\ \xi_{i_1}z\ \xi_{i_2}z\ \xi_{i_3}z\\ &\qquad+\sum l_{i_1,i_2,j_3}\ \xi_{i_1}z\ \xi_{i_2}z\ \zeta_{j_3}\bar{x}\end{aligned}$$

for some k,l's. Hence there is a unique $\pi^{[3]}$ satisfying (2.14) and (2.12) given by

$$\begin{aligned}c_{i_1,i_2,i_3}&=-\frac{k_{i_1,i_2,i_3}}{\lambda_{i_1}+\lambda_{i_2}+\lambda_{i_3}},\\ d_{i_1,i_2,j_3}&=-\frac{l_{i_1,i_2,j_3}}{\lambda_{i_1}+\lambda_{i_2}+\mu_{j_3}}\end{aligned}$$

because the denominators are not zero, Re $\lambda_i<0$, and Re $\mu_j\le 0$. The higher degree terms are handled in a similar fashion. □

5. H_∞ regulation.

One can also use nonlinear H_∞ control techniques to stabilize the transverse dynamics in a robust fashion. Consider a smooth plant

$$\begin{aligned}\dot{x}&=f(x,u,\bar{x})+g(x,\bar{x},w)\\ &=Ax+Bu+F\bar{x}+Gw\\ &\quad+f^{[2]}(x,u,\bar{x})+g^{[2]}(x,\bar{x},w)+O(x,u,\bar{x},w)^3\\ e&=h(x,u,\bar{x})\\ &=Cx+Du+H\bar{x}\\ &\quad+h^{[2]}(x,u,\bar{x})+O(x,u,\bar{x})^3\end{aligned}\tag{5.1}$$

which is perturbed by an unknown noise $w(t)$ and by a smooth nonlinear exosystem

$$\begin{aligned}\dot{\bar{x}}&=\bar{f}(\bar{x},w)\\ &=\bar{A}\bar{x}+\bar{B}w+\bar{f}^{[2]}(\bar{x},w)+O(\bar{x},w)^3.\end{aligned}\tag{5.2}$$

Notice that there is no direct interaction between the control and the noise in the dynamics and the noise w does not directly affect the error e.

The goal is as before, to find a feedforward and feedback control $u = \alpha(x, \bar{x})$ to drive $e(t)$ as close to zero as possible for any $x(0)$, $\bar{x}(0)$ despite the unknown noise. More precisely, for any choice of α the closed loop system defines a map from the initial conditions $x(0)$, $\bar{x}(0)$ and the noise $w(t)$ to the variables that we want to keep small, $u(t)$, $e(t)$. We would like the gain of this mapping to be as small as possible. This is a very difficult problem to solve directly so we settle for a suboptimal solution. Given an attenuation level $\delta > 0$, we seek an $u = \alpha(x, \bar{x})$ so that the map from $x(0)$, $\bar{x}(0)$, $w(t)$ to $u(t)$, $e(t)$ has gain less than δ. This goal needs to be modified because as before we should not penalize those parts of $x(0)$, $u(t)$ that are necessary for exact tracking.

As before we start by solving the FBI equations (2.3) for exact tracking and transform the combined system into transverse coordinates (2.4) to obtain

$$\begin{aligned}
\dot{z} &= \tilde{f}(z, v, \bar{x}) + \tilde{g}(z, \bar{x}, w)\\
&= Ax + Bv + \tilde{G}w + \tilde{f}^{[2]}(z, v, \bar{x}, w) + \tilde{g}^{[2]}(z, \bar{x}, w) + O(z, v, \bar{x}, w)^3\\
\dot{\bar{x}} &= \bar{f}(\bar{x}) = \bar{A}\bar{x} + \bar{B}w + \bar{f}^{[2]}(\bar{x}, w) + O(\bar{x}, w)^3\\
e &= \tilde{h}(z, v, \bar{x}) = Cz + Dv + \tilde{h}^{[2]}(z, v, \bar{x}) + O(z, v, \bar{x})^3,
\end{aligned} \tag{5.3}$$

where

$$\begin{aligned}
\tilde{f}(z, v, \bar{x}) &= f(z + \theta(\bar{x}), v + \beta(\bar{x}), \bar{x}) - \tfrac{\partial \theta}{\partial \bar{x}}(\bar{x})\bar{f}(\theta(\bar{x}), \bar{x})\\
\tilde{g}(z, \bar{x}, w) &= g(z + \theta(\bar{x}), \bar{x}, w)\\
\tilde{h}(z, v, \bar{x}) &= h(z + \theta(\bar{x}), v + \beta(\bar{x}), \bar{x})\\
\tilde{G} &= G - TB.
\end{aligned} \tag{5.4}$$

We wish to find the control $v = \gamma(z, \bar{x})$ that maximizes

$$\pi(z, \bar{x}) = \inf_{w} \frac{1}{2} \int_0^t \delta^2 |w(s)|^2 - |e(s)|^2 - |v(s)|^2 \, ds, \tag{5.5}$$

where the infimum is over all $t \geq 0$, with $w(s)$ generating a trajectory satisfying $z(0) = 0$, $\bar{x}(0) = 0$, $z(t) = z$, $\bar{x}(t) = \bar{x}$. For any control $v = \gamma(z, \bar{x})$, the function $\pi(z, \bar{x})$ is the minimum required net energy that must be supplied to the combined system to go from the origin $0,\ 0$ to $z,\ \bar{x}$. Energy is supplied to the system at the rate $\frac{\delta^2}{2}|w(s)|^2$ and extracted from the system at the rate $\frac{1}{2}(|e(s)|^2 + |v(s)|^2)$. The goal is to supremize the energy necessary to reach any z, $\bar{x}$. See [23] and [18, 19] for more on nonlinear H_∞ control.

An immediate consequence of the definition of $\pi(z, \bar{x})$ is that along any trajectory of the system

$$\pi(z(s), \bar{x}(s))]_{t_1}^{t_2} \leq \frac{1}{2} \int_{t_1}^{t_2} \delta^2 |w(s)|^2 - |e(s)|^2 - |v(s)|^2 \, ds. \tag{5.6}$$

This is called a dissipation inequality; if we view $\pi(z, \bar{x})$ as the energy stored in the combined system when it is in state z, $\bar{x}$ then the change in stored energy over any time interval is less than or equal to the net energy supplied to the system over that time interval.

If there exists a control $v = \gamma(z, w)$ so that $\pi(z, \bar{x}) \geq 0$, then

$$\frac{1}{2} \int_{t_1}^{t_2} |e(s)|^2 + |v(s)|^2 \, ds \leq \pi(z(t_1), \bar{x}(t_1)) + \frac{\delta^2}{2} \int_{t_1}^{t_2} |w(s)|^2 \, ds. \tag{5.7}$$

If this holds, then the energy of the tracking error plus the energy of the control used to reduce it is less than the energy of the initial mismatch between the plant and exosystem, $\pi(z(t_1), \bar{x}(t_1))$, plus the energy of the disturbance.

We can view (5.5) as the cost criterion of a differential game pitting the control v against the noise w. The optimal $\pi,\ v^*,\ w^*$ satisfy the HJI PDE

$$\begin{aligned}0 &= \frac{\partial \pi}{\partial z}(z,\bar{x})\left(\tilde{f}(z,v,\bar{x}) + \tilde{g}(z,\bar{x},w)\right)\\ &\quad+\frac{\partial \pi}{\partial \bar{x}}(z,\bar{x})\bar{f}(\bar{x},w) + l(z,v,\bar{x},w)\\ v^*, w^* &= \arg\ \min_v \max_w \left\{ \frac{\partial \pi}{\partial z}(z,\bar{x})\left(\tilde{f}(z,v,\bar{x}) + \tilde{g}(z,\bar{x},w)\right)\right.\\ &\quad\left.+\frac{\partial \pi}{\partial \bar{x}}(z,\bar{x})\bar{f}(\bar{x},w) + l(z,v,\bar{x},w)\right\},\end{aligned} \tag{5.8}$$

where

$$\begin{aligned}l(z,v,\bar{x},w)) &= \frac{1}{2}\left(|e|^2 + |v|^2\right) - \frac{\gamma^2}{2}|w|^2\\ &= \frac{1}{2}\left(z'Qz + 2z'Sv + v'Rv\right) - \frac{\gamma^2}{2}|w|^2\\ &\quad+l^{[3]}(z,v,\bar{x}) + O(z,v,\bar{x})^4.\end{aligned}$$

Van der Schaft [23] considered the local solvability of the HJI PDE when the plant is stabilizable and detectable and there is no exosystem (so $x = z,\ u = v,\ G = \tilde{G}$). He showed that a local solution exists if the linear quadratic part of the problem admits a stable solution. That is, there exists a $P \geq 0$ satisfying the Riccati equation

$$\begin{aligned}0 &= A'P + PA + Q + \frac{1}{\gamma^2}P\tilde{G}\tilde{G}'P\\ &\quad-(PB+S)R^{-1}(PB+S)'\end{aligned} \tag{5.9}$$

and such that the closed loop spectrum is in the open left half plane,

$$\sigma\left(A - BR^{-1}(B'P + S') + \frac{1}{\gamma^2}\tilde{G}\tilde{G}'P\right) < 0. \tag{5.10}$$

The optimal linear feedback and worst case noise are

$$\begin{aligned}v^* &= -R^{-1}(B'P + S')z,\\ w^* &= \frac{1}{\gamma^2}\tilde{G}'Pz.\end{aligned}$$

Following the approach described in section 4 using the stable and partial center manifold theorem, one can prove the following theorems.

THEOREM 5.1. *Suppose the plant* (5.1) *and exosystem* (5.2) *are* C^k, *the linear part of the plant is stabilizable and detectable when* $\bar{x} = 0$, *the linear part of the exosystem is stable, and the FBI PDE* (2.3) *has a* C^k *solution in some neighborhood of* 0 *in* $\bar{x}$ *space. If there exists a* $P \geq 0$ *satisfying the Riccati equation* (5.9) *and such that the closed loop spectrum is in the open left half plane* (5.10), *then in some neighborhood of* $0, 0$ *in* $x, \bar{x}$ *space there exists a* C^{k-2} *solution to HJB PDE* (5.8) *satisfying* (2.12).

THEOREM 5.2. *Suppose the hypotheses of Theorem* 5.1 *hold for* $k > 3$ *and let* $\pi(z, \bar{x})$ *be the* C^{k-2} *solution of the HJI PDE* (5.8) *satisfying* (2.12). *Suppose* $\phi(x_1, x_2)$ *is a* C^{k-2} *function satisfying the HJI PDE through terms of degree* $k-3$ *and satisfying* (2.12). *Then* π *and* ψ *agree to degree* $k-3$,

$$\pi(z, \bar{x})) = \psi(z, \bar{x}) + O(z, \bar{x})^{k-2}. \tag{5.11}$$

VALUE-FUNCTIONS FOR DIFFERENTIAL GAMES AND CONTROL SYSTEMS WITH DISCONTINUOUS TERMINAL COST[*]

SŁAWOMIR PLASKACZ[†] AND MARC QUINCAMPOIX[‡]

Abstract. This paper deals with Mayer's problem for control systems and differential games with discontinuous terminal cost. There are two main results in the paper. The first one says that the value function for control systems can be characterized as the unique solution—in suitable sense—to the Hamilton–Jacobi–Bellman equation without any regularity assumptions on the terminal cost. For differential games satisfying Isaacs's minmax condition, the second main result says that the value function is the unique solution to the Hamilton–Jacobi–Isaacs equation when the terminal cost is semicontinuous. This allows to prove the existence of the value under Isaacs's condition. This paper extends some results already well known in the continuous case.

Key words. viscosity solution, Hamilton–Jacobi equations, Mayer's problem

1. Introduction.

We consider a differential game in which dynamics is given by $x'(t) = f(t,x,u,v)$, where the state variable x belongs to $\mathbb{R}^n$, and the controls $u : [t_0,T] \mapsto U$ and $v : [t_0,T] \mapsto V$ are measurable functions. By $x(\cdot;\, t_0,x_0,u,v)$ we denote the solution to the Cauchy problem

$$\left\{ \begin{array}{l} x'(t) = f(t,x(t),u(t),v(t)), \\ x(t_0) = x_0. \end{array} \right. \tag{1}$$

We are interested in a differential game with a terminal cost $g : \mathbb{R}^n \mapsto \mathbb{R}$. Namely, the player acting on the control u tries to minimize the terminal cost $g(x(T))$ while the other player tries to maximize it. These optimal behaviors of the two players are modelized in the framework of nonanticipative strategies introduced by Varayia–Elliot–Kalton–Roxin.

Let us denote by $\mathcal{U}(t_0)$ and $\mathcal{V}(t_0)$ the set of measurable controls on $[t_0,T]$, by $\alpha : \mathcal{V}(t_0) \to \mathcal{U}(t_0)$ a nonanticipative strategy of the first player and by $\beta : \mathcal{U}(t_0) \to \mathcal{V}(t_0)$ a nonanticipative strategy of the second player. The set $\Gamma(t_0)$ (respectively, $\Delta(t_0)$) denotes the set of all nonanticipative strategies of the first (respectively, the second) player.

This leads to the definition of two value functions

$$\left\{ \begin{array}{l} V_g^-(t_0,x_0) := \inf_{\alpha\in\Gamma(t_0)} \sup\{g(x) :\, x \in \mathrm{cl}\ (A_\alpha(t_0,x_0))\}, \\ V_g^+(t_0,x_0) := \sup_{\beta\in\Delta(t_0)} \inf\{g(x) :\, x \in \mathrm{cl}\ (B_\beta(t_0,x_0))\}, \end{array} \right. \tag{2}$$

where cl means closure and $A_\alpha(t_0,x_0) = \{x(T;\, t_0,x_0,\alpha(v),v) :\ v \in \mathcal{V}(t_0)\}$, $B_\beta(t_0,x_0) = \{x(T;\, t_0,x_0,u,\beta(u)) :\ u \in \mathcal{U}(t_0)\}$ denote the reachable sets. Let us notice that when g is continuous, we can skip the closure in the definition (2) of value functions. In this paper we provide an example with a discontinuous g showing that the two

value functions V_g^+ and V_g^- are not equal when we do not take the closure in the definition (2).

The main question we address here is the existence of a value of the game, namely, the question of equality between V_g^+ and V_g^-. This problem has been studied—and solved—in [13] in the case of Lipschitz terminal cost g. The present paper deals with discontinuous terminal cost.

Before explaining how we solve the discontinuous Mayer problem for games, let us recall the approach of Evans and Souganidis [13] in the case of a Lipschitz continuous terminal cost. They prove that the two value functions are the unique continuous viscosity solutions of two Hamilton–Jacobi equations. Under the assumption that the two Hamiltonians coincide—the so-called Isaacs condition—these two value functions are hereby equal. In the context of discontinuous terminal cost, the value functions are discontinuous and standard uniqueness results for viscosity solutions of PDE cannot be used.

Here our approach consists of proposing a definition for solutions to Hamilton–Jacobi equations and to prove a uniqueness result for the Hamilton–Jacobi equations coming from differential games with Isaacs's condition. Our main aim is not to add a new concept to the already numerous notions of generalized solutions of PDEs but to prove the existence of a value of the game in the discontinuous case using the definition of solution.

Our second main interest is optimal control systems with discontinuous end-cost which leads to the following definition of the value function:[1]

$$W_g(t_0, x_0) = \inf_{u \in \mathcal{U}(t)} g(x(T;\, t_0, x_0, u)), \tag{3}$$

where $x(\cdot;\, t_0, x_0, u)$ is solution to the Cauchy problem

$$x'(t) = f(t, x(t), u(t)), \quad x_0 = x(t_0). \tag{4}$$

Our main result for control says that W_g is the unique solution to the corresponding Hamilton–Jacobi–Bellman equation for arbitrary discontinuous terminal cost g.

The proposed definition of solutions of Hamilton–Jacobi equations and our methods of proof are motivated by three already known approaches we described below.

First, Frankowska has observed that some invariance property of the epigraph and/or hypograph of the value function for control can be used to define a notion of solution to some Hamilton–Jacobi equation [14]. The author has used this fact to characterize the value function of the Mayer problem in the lower semicontinuous case in [15]. Such type of monotonicity properties of the value function along trajectories (or equivalently invariance or viability [1] of the epigraph and/or hypograph) has also been studied in the spirit of [15] in some works; among them we quote [6], [7], [8], [9], [10], [11], [16].

Second, we consider the comparison principle [12] and Barles–Perthame stability result [3] for viscosity super- and subsolutions. Since the beginning of the theory where viscosity solutions were (bounded uniformly) continuous, there was, until now, a constant effort to develop notions of discontinuous viscosity solutions. Without doing an exhaustive history of these theories, let us mention the Ishii solution (well exposed in [3]) based on semicontinuous envelopes of functions, Barron–Jensen semicontinuous

[1] One can easily check that the definition (3) of W_g does not require the use of the closure of the reachable set used in (2).

solutions [5], [2] for convex Hamiltonians, and envelope[2] solutions [4] which are related to Subbotin solution.

Third, we consider the minimax solution introduced by Subbotin (cf. [21] and its bibliography; see also [19]). This concept of solution is related to an interpretation of the Hamilton–Jacobi equation through a dynamic game with Isaacs's condition. In [21], the existence and the uniqueness of a semicontinuous minmax solution to the Hamilton–Jacobi–Isaacs equation are proved; this allows us to deduce the existence of the value of the game in the context of positional strategy [17].

The novelty of the results presented here are mainly the existence of the value for differential games with nonanticipative strategies and semicontinuous terminal cost, the characterization of the semicontinuous game value function as the unique solution of the Hamilton–Jacobi–Isaacs equation, and the characterization of "fully" discontinuous value function as the unique solution of the Hamilton–Jacobi–Bellman equation for optimal control.

From the point of view of PDEs, which is not our main topic, one can consider our work as existence and uniqueness results for PDEs with convex Hamiltonian and "fully" discontinuous boundary condition and as existence and uniqueness results for PDEs with nonnecessary convex Hamiltonian and semicontinuous boundary condition. In fact, at the end of the paper [2], there is an illuminating example showing for a PDE with nonconvex Hamiltonian that many Ishii solutions can exist; we discuss this example and prove the existence and uniqueness of solution in the context of the notion of solution used in the present paper. Also our work says that g is a semiresolutive function for the Hamilton–Jacobi–Bellman equation in the meaning of [18].

Let us explain how the paper is organized. In the first section, we introduce some preliminaries and we state a result concerning the discontinuous Mayer problem for control. In the second section, we present our main results concerning games. The last section is devoted to an appendix with the technical proofs of our claims.

2. Preliminaries. Consider the measurable functions $u : [t_0, T] \mapsto U$ and $v : [t_0, T] \mapsto V$. Let U and V be compact metric spaces. Let us denote by $\mathcal{U}(t_0)$ and $\mathcal{V}(t_0)$ the set of such measurable controls. We say that a map $\alpha : \mathcal{V}(t_0) \to \mathcal{U}(t_0)$ is a nonanticipative strategy of the first player if for every control v_1, $v_2 \in \mathcal{V}(t_0)$ such that

$$v_1(s) = v_2(s) \text{ for almost all } s \in [t_0, \tau],$$

we have

$$\alpha(v_1)(s) = \alpha(v_2)(s) \text{ for almost all } s \in [t_0, \tau].$$

We say that a map $\beta : \mathcal{U}(t_0) \to \mathcal{V}(t_0)$ is a nonanticipative strategy of the second player if for every controls u_1, $u_2 \in \mathcal{U}(t_0)$ such that

$$u_1(s) = u_2(s) \text{ for almost all } s \in [t_0, \tau],$$

we have

$$\beta(u_1)(s) = \beta(u_2)(s) \text{ for almost all } s \in [t_0, \tau].$$

[2] We thank the anonymous referee for pointing out that the notion of solution used in the present paper is similar to envelope solution.

Let $\Gamma(t_0)$ $(\Delta(t_0))$ denote the set of all such nonanticipative strategies of the first (second) player. Setting $A_\alpha(t_0,x_0) = \{x(T;\, t_0,x_0,\alpha(v),v) :\ v \in \mathcal{V}(t_0)\}$, $B_\beta(t_0,x_0) = \{x(T;\, t_0,x_0,u,\beta(u)) :\ u \in \mathcal{U}(t_0)\}$ the reachable sets, this enables us to define the value functions V_g^+ and V_g^- by relation (2). We assume that $f : [0,T]\times\mathbb{R}^n\times U\times V \to \mathbb{R}^n$ satisfies the following:

$$(5)\qquad \left\{\begin{array}{l} f(\,\cdot,\,\cdot\,,u,v) \text{ is Lipschitz continuous,}\\ f(t,x,\,\cdot,\,\cdot\,) \text{ is continuous,}\\ f \text{ has a linear growth, i.e.,}\\ \sup_{(t,u,v)} \|f(t,x,u,v)\| \le a(1+\|x\|)\\ \text{for some given } a>0. \end{array}\right.$$

For convenience, we do not repeat the same assumption in the control case viewed as a particular differential game where f does not depend on v.

Let us recall the Isaacs condition

$$(6)\qquad \left\{\begin{array}{c} \min_{u\in U}\max_{v\in V}\langle f(t,x,u,v),p\rangle = \max_{v\in V}\min_{u\in U}\langle f(t,x,u,v),p\rangle\\ \text{for every } t,\ x, \text{ and } p\in\mathbb{R}^n. \end{array}\right.$$

Throughout the paper, we assume that

$$(7)\qquad f(t,x,U,v) \ \text{ is convex for every } t,\ x,\ v$$

and

$$(8)\qquad f(t,x,u,V) \ \text{ is convex for every } t,\ x,\ u$$

hold true.

Let $g : \mathbb{R}^n \mapsto \mathbb{R}$ be a terminal cost.

If the terminal cost g is discontinuous, then so is the value function. To describe the value function as a unique solution to a corresponding Hamilton–Jacobi equation we introduce the following.

Definition 1. *Let $H : [0,T]\times\mathbb{R}^{2n} \to \mathbb{R}$ be a Hamiltonian. The function $(t,x)\mapsto u(t,x)$ is a solution to the following Hamilton–Jacobi equation with terminal condition:*

$$(9)\qquad \left\{\begin{array}{l} \dfrac{\partial u}{\partial t} + H\left(t,x,\dfrac{\partial u}{\partial x}\right) = 0,\\ u(T,x) = g(x),\ x\in\mathbb{R}^n, \end{array}\right.$$

if and only if

$$(10)\qquad \left\{\begin{array}{ll} \text{(i)} & u \textit{ is the supremum on the set of subsolutions}\\ & \phi \textit{ such that } \phi(T,x)\le g(x)\,\forall\, x\in\mathbb{R}^n,\\ \text{(ii)} & u \textit{ is the infimum on the set of supersolutions}\\ & \psi \textit{ such that } \psi(T,x)\ge g(x)\,\forall\, x\in\mathbb{R}^n. \end{array}\right.$$

The above meaning of solution is similar to envelope solution introduced in [4].

Here we call supersolution[3] any lower semicontinuous function $\psi : (0,T]\times\mathbb{R}^n \to \mathbb{R}$ such that

$$\forall (t,x) \in\ (0,T)\times\mathbb{R}^n,\ \forall\ (p_t,p_x)\in\ \partial_-\psi(t,x),\ p_t + H(t,x,p_x) \le 0,$$

[3] The definitions of the subdifferential $\partial_-\psi(t,x)$ and the superdifferential $\partial_+\phi(t,x)$ can be found in the appendix.

and we call subsolution any upper semicontinuous function $\phi : (0,T] \times \mathbb{R}^n \to \mathbb{R}$ such that

$$\forall (t,x) \in \ (0,T) \times \mathbb{R}^n,\ \forall\ (p_t, p_x) \in \partial_+\phi(t,x),\ p_t + H(t,x,p_x) \geq 0.$$

3. Discontinuous Mayer problem for control.

3.1. Main result for control.

We state the result obtained for the control case.

THEOREM 2. *Let $g : \mathbb{R}^n \mapsto \mathbb{R}$ be a bounded function. Assume that $f : [0,T] \times \mathbb{R}^n \times U \to \mathbb{R}^n$ satisfies* (5) *and* (7). *Then the value function $W_g : (0,T] \times \mathbb{R}^n \to \mathbb{R}$ given by*

$$W_g(t,x) = \inf_{u \in \mathcal{U}(t)} g(x(T;\, t,x,u))$$

is the unique generalized solution to the Hamilton–Jacobi–Bellmann equation (18) *where*

$$H(t,x,p) := \min_{u \in\ U} \langle f(t,x,u), p\rangle. \tag{11}$$

To avoid repetition of arguments, we postpone the proof until the appendix and we shall obtain this proof using results stated in the differential game context.

Remark 1. Theorem 2 is in fact the existence and uniqueness result for Hamilton–Jacobi equation (18) with Hamiltonian given by (11) and arbitrary terminal condition g. A uniqueness result in the case of lower semicontinuous g has been obtained in [5], [15] in the framework of different definitions of solutions. If g is lower semicontinuous, then the solutions in the meaning of Definition 1 as well as in the meaning of [5], [15] are equal to the value function W, so they coincide. We give an example of nonsemicontinuous g.

Example 1. Let $g : \mathbb{R} \to \mathbb{R}$ be the characteristic function of rationals. The dynamics $x' = f(t,x)$ of a system is given by a right-hand side that depends neither on u nor on v and satisfies (5). In this case the value $V(t_0,x_0) = g(x(T;\, t_0,x_0))$ is discontinuous at every point. In spite of this, by Theorem 2, V is the unique solution (in the sense of Definition 1) of the corresponding problem (18). Let us remark that the concepts of solution from [15] and [21] do not apply to the example.

3.2. Application to Mayer control problems with state constraints.

Let K be a closed subset of $\mathbb{R}^n$. We are interested in the characterization of the value function $W_g^K : [0,T] \times K \to R$

$$W_g^K(t_0,x_0) = \inf_{\left\{\begin{array}{l} u \in U(t_0), \\ x(t;t_0,x_0,u) \in K \text{ for } t \in [t_0,T) \end{array}\right.} g(x(T)) \tag{12}$$

as a unique solution to a Hamilton–Jacobi equation. In the literature there are many attempts to solve this problem (see [20], [16]). The minimal requirement guaranteeing that the function W_g^K is well defined by (12) is[4]

$$\left\{\begin{array}{l} \text{for any initial condition } (t_0,x_0) \in [0,T] \times K \text{ there exist} \\ \text{a control } u \in U(t_0) \text{ such that the solution } x(t;t_0,x_0,u) \\ \text{remains in set of constraints } K \text{ for every } t \in [t_0,T]. \end{array}\right. \tag{13}$$

[4] Property (12), called the viability property, can also be characterized by a geometrical condition in terms of Bouligand tangent cones (cf. [1]).

We provide a characterization of the value function W_g^K under assumption (13).

PROPOSITION 3. *Let $K \subset \mathbb{R}^n$ be closed and $g : \mathbb{R}^n \mapsto \mathbb{R}$ be a function bounded by $M > 0$. Assume that $f : [0,T] \times \mathbb{R}^n \times U \to \mathbb{R}^n$ satisfies* (5), (7) *and that* (13) *holds true for f, K. Then*

$$W_g^K(t,x) = U(t,x,0) \quad \text{for } x \in K,$$

where $U : [0,T] \times \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$ is the unique solution to

$$\left\{ \begin{array}{l} \frac{\partial U}{\partial t} + \tilde{H}(t,x,y,\frac{\partial U}{\partial x},\frac{\partial U}{\partial y}) = 0, \\ U(T,x,y) = g(x) + (M+1)\chi_{(0,\infty)}(y), \end{array} \right. \tag{14}$$

where $\tilde{H}(t,x,y,p_x,p_y) = \min_{u\in U}\langle f(t,xu),p_x\rangle + d_K(x)p_y$ and $\chi_{(0,\infty)}$ denotes the characteristic function of the open interval $(0,\infty)$.

Proof. We adopt the classical method of adding an extra variable (usually used to reduce a Bolza problem to a Mayer one) and the technique of penalization function. We consider a new control problem

$$\left\{ \begin{array}{l} x'(t) = f(t,x(t),u(t)), \\ y'(t) = d_K(x(t)), \end{array} \right.$$

where $d_K(x)$ denotes the distance from x to K. It is obvious that (5), (7) hold true for the extended control system. By Theorem 2, we obtain that the value function

$$\begin{array}{l} U(t_0,x_0,y_0) \\ = \inf_{u\in U(t_0)} g(x(T;t_0,x_0,u)) + (M+1)\chi_{(0,\infty)}\left(y_0 + \int_{t_0}^T d_K(x(t;t_0,x_0,u))dt\right) \end{array}$$

is the unique generalized solution to (14). On the other hand, just from the very definition, one can easily check that for every $x_0 \in K$ we have

$$W_g^K(t_0,x_0) = U(t_0,x_0,0). \qquad \square$$

4. Mayer problem for differential games.

4.1. First comparison result. Let us state our first result comparing the value functions following.

PROPOSITION 4. *If* (5), (6) *hold true and a terminal cost function g is locally bounded, then*

$$V_g^+(t,x) \le V_g^-(t,x)$$

for every $(t,x) \in [0,T] \times \mathbb{R}^n$.

The proof is a direct conclusion from the following lemma.

LEMMA 5. *Assume that* (5), (6) *hold true. Then*

$$\mathrm{cl}\ (A_\alpha(t_0,x_0)) \cap \mathrm{cl}(B_\beta(t_0,x_0)) \neq \emptyset$$

for each $\alpha \in \Gamma(t_0)$, $\beta \in \Delta(t_0)$.

Proof. Suppose to the contrary that there exist α_0, β_0 such that cl $(A_{\alpha_0}(t_0,x_0)) \cap$ cl $(B_{\beta_0}(t_0,x_0)) = \emptyset$.

Then there exists a Lipschitz continuous function $h : \mathbb{R}^n \to [0,1]$ such that $h(x) = 0$ for $x \in$ cl (A_{α_0}) and $h(x) = 1$ for $x \in$ cl (B_{β_0}). Hence,

$$V_h^-(t_0,x_0) = 0 < 1 = V_h^+(t_0,x_0).$$

This is a contradiction with Theorem 4.1 in [13] stating that if the terminal cost is Lipschitz continuous, then the upper value equals to the lower value. $\square$

To obtain the reverse inequality we shall study more deeply the Isaacs equation.

4.2. Values and Isaacs's equation. In the section we prove that any supersolution to Isaacs's equation is greater than the corresponding upper value and that any subsolution is smaller than the lower value. The main tool in proofs is viability theory (see [1]).

PROPOSITION 6. *Assume that* (5), (7) *hold true. Suppose that* $\psi : (0,T] \times \mathbb{R}^n \to \mathbb{R}$ *is lower semicontinuous and is a supersolution to*

$$\psi_t + H^-(t,x,\psi_x) = 0 \tag{15}$$

on $(0,T) \times \mathbb{R}^n$ *when*

$$H^-(t,x,p) = \max_{v\in V} \min_{u\in U} \langle f(t,x,u,v), p\rangle.$$

Then for every $(t_0, x_0) \in (0,T) \times \mathbb{R}^n$ *there exists a nonanticipative strategy* $\alpha \in \Gamma(t_0)$ *such that*

$$\psi(t_0,x_0) \geq \psi(t, x(t;\, t_0, x_0, \alpha(v), v)) \tag{16}$$

for every $v \in \mathcal{V}(t_0)$ *and* $t \in [t_0, T]$.

The proof of this proposition is postponed until the appendix.

COROLLARY 7. *Under the assumptions of Proposition* 6 *we obtain*

$$\psi(t,x) \geq V_g^-(t,x),$$

where $g(x) := \psi(T,x)$.

Proof. Since g is lower semicontinuous, then for every subset $A \subset \mathbb{R}^n$ we have $\sup\{g(x) :\, x \in A\} = \sup\{g(x) :\, x \in \mathrm{cl}\ (A)\}$. Thus

$$V_g^-(t_0,x_0) = \inf_{\alpha\in\Gamma(t_0)} \sup\{g(x) :\, x \in A_\alpha(t_0,x_0)\}.$$

By Proposition 6 we obtain

$$\psi(t_0,x_0) \geq \inf_{\alpha\in\Gamma(t_0)} \sup\{g(x) :\, x \in A_\alpha(t_0,x_0)\},$$

which gives us the desired inequality. □

PROPOSITION 8. *Assume that* (5), (8) *hold true. Suppose that* $\phi : (0,T] \times \mathbb{R}^n \to \mathbb{R}$ *is upper semicontinuous and is a subsolution to*

$$\phi_t + H^+(t,x,\phi_x) = 0$$

on $(0,T) \times \mathbb{R}^n$ *when*

$$H^+(t,x,p) = \min_{u\in U} \max_{v\in V} \langle f(t,x,u,v), p\rangle.$$

Then for every $(t_0, x_0) \in (0,T) \times \mathbb{R}^n$ *there exists a nonanticipative strategy* $\beta \in \Delta(t_0)$ *such that*

$$\phi(t_0,x_0) \leq \phi(t, x(t;\, t_0, x_0, u, \beta(u)))$$

for every $u \in \mathcal{U}(t_0)$ *and* $t \in [t_0, T]$.

The proof can be done using the same method as in the proof of Proposition 6.

Corollary 9. *Under the assumptions of Proposition* 8 *we obtain*

$$\phi(t,x) \leq V_h^+(t,x),$$

where $h(x) := \phi(T,x)$.

The proof is similar to the proof of Corollary 7.

If Isaacs's condition (6) holds true, then $H^- = H^+ (=: H)$ and previous results can be summarized in the following comparizon result (cf. Théorème d'unicité forte 4.10 in [3])

Proposition 10 (comparison result). *Assume that* (5)–(8) *hold true. Suppose that* $\psi : (0,T] \times \mathbb{R}^n \to \mathbb{R}$ *is lower semicontinuous and is a supersolution to*

$$\psi_t + H(t,x,\psi_x) = 0 \tag{17}$$

on $(0,T) \times \mathbb{R}^n$ *and* $\phi : (0,T] \times \mathbb{R}^n \to \mathbb{R}$ *is upper semicontinuous and is a subsolution to* (17) *on* $(0,T) \times \mathbb{R}^n$. *If* $\psi(T,x) \geq \phi(T,x)$ *for* $x \in \mathbb{R}^n$, *then* $\psi(t,x) \geq \phi(t,x)$ *for* $t \in (0,T]$ *and* $x \in \mathbb{R}^n$.

Proof. By Proposition 4 and Corollaries 7, 9, we have

$$\phi(t,x) \leq V_h^+(t,x) \leq V_h^-(t,x) \leq V_g^-(t,x) \leq \psi(t,x),$$

where $h(x) = \phi(T,x)$ and $g(x) = \psi(T,x)$ for $x \in \mathbb{R}^n$. □

4.3. Main result. In the section we prove the existence of value and characterize it by Isaacs's equation.

Theorem 11. *Assume that* (5)–(8) *hold true and* $g : \mathbb{R}^n \to \mathbb{R}$ *is a locally bounded lower semicontinuous function. Then the game has a value, i.e.,*

$$V_g^+ = V_g^- (=: V).$$

The value function V *is the smallest supersolution to the Hamilton–Jacobi–Isaacs equation*

$$V_t + H(t,x,V_x) = 0 \tag{18}$$

satisfying $V(T,x) \geq g(x)$ *when* $H := H^+ = H^-$.

Moreover, the value function V *is the unique generalized solution to* (18) *satisfying* $V(T,x) = g(x)$.

We have stated the result in the lower semicontinuous case. After typical reformulation it remains valid in the upper semicontinuous case. Before proving this result let us recall—in an adapted version—a result proved in [3] (cf. Theorem 4.1 in [3]), which plays an important role in the proof of our main theorem.

Lemma 12. *Assume that* $H : (0,T) \times \mathbb{R}^{2n} \to \mathbb{R}$ *is a continuous Hamiltonian. If* $w_n : (0,T) \times \mathbb{R}^n \to \mathbb{R}$ *is an increasing sequence of uniformly locally bounded supersolutions of a Hamilton–Jacobi equation*

$$\eta_t + H(t,x,\eta_x) = 0 \tag{19}$$

and $w : (0,T) \times \mathbb{R}^n \to \mathbb{R}$ *is a pointwise limit of* w_n, *then* w *is a supersolution of* (19).

Proof of Theorem 11.[5] We define a sequence $g_n : \mathbb{R}^n \to \mathbb{R}$ by

$$g_n(x) = \inf_{y \in \mathbb{R}^n} g(y) + n\|x-y\|.$$

[5] We would like to thank P. Cardaliaguet, who brought our attention to the inf-convolution method, which simplified the proof.

The inf-convolutions g_n are Lipschitz, $g_n(x) \leq g_{n+1}(x)$ and $\lim_n g_n(x) = g(x)$ for every $x \in \mathbb{R}^n$.

Using Evans–Souganidis characterization of value functions in the case of Lipschitz continuous terminal cost [13, Theorem 4.1], we have $V^+_{g_n} = V^-_{g_n} (:= V_n)$ and V_n is a viscosity solution (i.e., super- and subsolution) to (18).

Denote $W(t,x) = \lim_n V_n(t,x)$. By Lemma 12, W is a supersolution to (18). By Corollary 7, we obtain $W \geq V^-_g$. Since $V^+_g \geq V^+_{g_n}$, we deduce $V^+_g \geq W$. Hence

$$V^+_g \geq V^-_g.$$

Combining it with Proposition 4, we obtain $V^+_g = V^-_g = W$.

If $\psi : (0,T] \times \mathbb{R}^n \to \mathbb{R}$ is a supersolution to (18) and $\psi(T,x) \geq g(x)$, then $\psi \geq V^-_g$. Thus V is the smallest supersolution to (18) satisfying $V(T,x) \geq g(x)$.

Since V_n is a subsolution to (18), $V_n(T,x) \leq g(x)$ and $V = \lim_n V_n$, we obtain that V is a generalized solution to (18), $V(T,\cdot) = g(\cdot)$. □

Remark 2. Due to general properties of monotone approximation, V is also a solution to (18) in the Ishii sense. Namely, upper semicontinuous envelope of V coincides with the upper weak limit of V_n (cf. the exercise on page 91 in [3]), which by Theorem 4.1 in [3] is a subsolution of (18).

The following example with a slight modification is taken from [2]. It served in [2] as a counter-example to uniqueness of discontinuous solution—in the Ishii sense—to a Hamilton–Jacobi equation. Definition 1 is not equivalent to the notion of solution introduced by Ishii. In the example there exists a unique solution in the meaning of Definition 1 and there are several solutions in the Ishii sense [2].

Example 2. Let $U = V = [-1,1]$. We define $f : (-\infty, 0] \times \mathbb{R} \times U \times V \to \mathbb{R}$ by

$$f(t,x,u,v) = \chi_{(x \leq t)}(x-t)v + \chi_{(x \geq t)}(x-t)u.$$

It is easy to check that f satisfies (5)–(8) and the corresponding Hamiltonian is given by

$$H(t,x,p) = (x-t)|p|.$$

To define a terminal cost function $g : \mathbb{R} \to \mathbb{R}$, we fix $t_0 = x_0 < 0$. Let $b = x(0; t_0, x_0, u_1, v)$, $a = x(1; t_0, x_0, u_{-1}, v)$, where $u_1(t) = 1$, $u_{-1}(t) = -1$ for $t \in [t_0, 0]$, v is an arbitrary control. We define

$$g(x) = \begin{cases} 1 & \text{if } x \in (a,b), \\ -1 & \text{elsewhere.} \end{cases}$$

We set the terminal time T to be zero.

By Theorem 11, the value V for this game exists and is the *unique* solution to the corresponding Hamilton–Jacobi equation

$$\begin{cases} V_t + (x-t)|V_x| = 0, \\ V(0,x) = g(x) \text{ for every } x \in \mathbb{R}. \end{cases} \quad \square$$

Remark 3. The assumptions (7) and (8) concerning the convexity of the right-hand side are crucial for obtaining $V^+_g \geq V^-_g$ because we used a viability approach which requires convexity. We recall that thanks to Proposition 4, inequality $V^+_g \leq V^-_g$ holds true.

4.4. On the definition of the values of the game. In the definition of upper and lower values (2) we have used the closure of reachable sets. They can be defined as well without closure:

$$\begin{cases} U_g^-(t_0,x_0) := \inf_{\alpha\in\Gamma(t_0)} \sup\{g(x) : x \in A_\alpha(t_0,x_0)\}, \\ U_g^+(t_0,x_0) := \sup_{\beta\in\Delta(t_0)} \inf\{g(x) : x \in B_\beta(t_0,x_0)\}. \end{cases}$$

We shall exhibit an example where $U_g^- \neq U_g^+$.

Repeating the same arguments we can prove Corollaries 7, 9 for values $U^{+/-}$ instead of $V^{+/-}$ and show that $U_g^+ \geq U_g^-$. To obtain the reverse inequality it would be enough to know that $A_\alpha \cap B_\beta \neq \emptyset$ (see Proposition 4). The following example shows that in general it is not true. Thus we can define a terminal cost function g in such a way that $U_g^+ > U_g^-$.

Example 3. We provide an example of a differential game where $U_g^+ > U_g^-$. For doing this we construct a pair of nonanticipative strategies (α,β) such that

$$A_\alpha \cap B_\beta = \emptyset.$$

(Let us notice that this implies that neither A_α nor B_β are closed by Proposition 4.) We consider the following differential game on $\mathbb{R}^2$:

$$\begin{cases} x'(t) = u, \\ y'(t) = v, \end{cases}$$

where $U = V = [0,1]$. We set $x_0 = 0$, $t_0 = 0$ and $T = 1$. We denote by x_u (y_v) the solution to the Cauchy problem $x'(t) = u(t)$, $x(0) = 0$ (respectively, $y'(t) = v(t)$, $y(0) = 0$). We define the constant controls $u_0(t) = v_0(t) = 0$ and $u_1(t) = v_1(t) = 1$ for $t \in [0,1]$. For measurable functions w, $z : [0,1] \to [0,1]$ we define an (ultrametric) distance

$$\rho(w,z) = 1 - \max\{t \in [0,1] : \ w(s) = z(s) \text{ for almost everywhere } s \in [0,t]\}.$$

(This ultrametric distance has been used in [8] and [11] to prove Lemma 14.)

Set $B = \{u \in \mathcal{U}(0) : \ \rho(u,u_0) < 1\}$ and $S = \{u \in \mathcal{U}(0) : \ \rho(u,u_0) = 1\}$. Define two nonanticipative strategies α, β as follows:

$$\alpha(v) = \begin{cases} u_0 & \text{if} \quad v \in B, \\ u_1 & \text{if} \quad v \in S, \end{cases}$$

$$\beta(u) = \begin{cases} v_1 & \text{if} \quad u \in B, \\ v_0 & \text{if} \quad u \in S. \end{cases}$$

If $u \in S$, then $x_u(1) > 0$. If $p \in (0,1]$, then there exists a control $u \in S$ such that $x_u(1) = p$.

If $u \in B$, then $x_u(1) < 1$. If $p \in [0,1)$, then there exists a control $u \in B$ such that $x_u(1) = p$.

We have

$$\begin{aligned} A_\alpha &= \{(x_{\alpha(v)}(1), y_v(1)) : \ v \in B\} \cup \{(x_{\alpha(v)}(1), y_v(1)) : \ v \in S\} \\ &= \{0\} \times [0,1) \cup \{1\} \times (0,1] \end{aligned}$$

and

$$\begin{aligned} B_\beta &= \{(x_u(1), y_{\beta(u)}(1)) : \ u \in B\} \cup \{(x_u(1), y_{\beta(u)}(1)) : \ u \in S\} \\ &= [0,1) \times \{1\} \cup (0,1] \times \{0\}. \end{aligned}$$

Setting $g = \chi_{B_\beta}$ we obtain $U_g^+(0,0) = 1 > 0 = U_g^-(0,0)$. □

We did not succeed in finding an example where g is semicontinuous. Hence the question of knowing if $U_g^- = U_g^+$ (so, it would be equal to $V_g^- = V_g^+$) for semicontinuous g remains an open problem.

Appendix. We recall some necessary notions and facts from nonsmooth analysis.

Let $K \subset \mathbb{R}^n$ be a nonempty subset and $x_0 \in K$. The contingent cone to K at x_0, $T_K(x_0)$, is defined by

$$v \in T_K(x_0) \iff \liminf_{h \to 0^+} \frac{dist(x_0 + hv, K)}{h} = 0.$$

A polar cone T^- to a subset $T \subset \mathbb{R}^n$ is defined by

$$T^- = \{p \in \mathbb{R}^n : \ \forall v \in T, \ \langle p, v \rangle \leq 0\}.$$

Let $\Omega \subset \mathbb{R}^n$ be an open subset and $w : \Omega \to \mathbb{R}$ be a lower semicontinuous function. The subdifferential of w at $x_0 \in \Omega$ is given by

$$\partial_- w(x_0) = \left\{ p \in \mathbb{R}^n : \ \liminf_{x \to x_0} \frac{w(x) - w(x_0) - \langle p, x - x_0 \rangle}{\|x - x_0\|} \geq 0 \right\}.$$

It is well known that

$$p \in \partial_- w(x_0) \iff (p, -1) \in \left[T_{Epi(w)}(x_0, w(x_0)) \right]^-,$$

where *Epi* stands for the epigraph. For an upper semicontinuous function w we define a superdifferential by

$$\partial_+ w(x_0) = \left\{ p \in \mathbb{R}^n : \ \limsup_{x \to x_0} \frac{w(x) - w(x_0) - \langle p, x - x_0 \rangle}{\|x - x_0\|} \leq 0 \right\}$$

and we have

$$p \in \partial_+ w(x_0) \iff (-p, 1) \in \left[T_{Hypo(w)}(x_0, w(x_0)) \right]^-,$$

where *Hypo* stands for the hypograph.

The following Rockafellar result (see [15]) gives more information about the connection between subgradients and normals to epigraph.

LEMMA 13. *Consider a lower semicontinuous function* $w : \Omega \to \mathbb{R}$ *and* $x_0 \in \Omega$. *If* $(p, 0) \in \left[T_{Epi(w)}(x_0, w(x_0)) \right]^-$, *then there exist* $x_n \to x_0$, $p_n \to p$, $q_n \to 0$, $q_n < 0$ *such that*

$$(p_n, q_n) \in \left[T_{Epi(w)}(x_n, w(x_n)) \right]^-.$$

The following result can be deduced from [8, Theorem 2.1].

LEMMA 14. *Assume that* $f : \mathbb{R}^n \times U \times V \to \mathbb{R}^n$ *satisfies* (5), (7) *and a subset* $D \subset \mathbb{R}^n$ *is closed. If for every* $z \in D$ *we have*

$$\forall p \in \left[T_D(z) \right]^-, \ \max_{v \in V} \min_{u \in U} \langle f(z, u, v), p \rangle \leq 0, \tag{20}$$

then for every $z_0 \in D$, $t_0 < T$, *there exists a nonanticipative strategy* $\alpha : \mathcal{V}(t_0) \to \mathcal{U}(t_0)$ *such that for every* $v \in \mathcal{V}(t_0)$ *we have*

$$z(t; t_0, z_0, \alpha(v), v) \in D$$

for $t \in [t_0, T]$*, where* $z(\cdot;\, t_0, z_0, u, v)$ *denotes the solution to the problem*

$$\left\{ \begin{array}{l} z' = f(z, u(t), v(t)), \\ z(t_0) = z_0. \end{array} \right.$$

Proof of Proposition 6. Fix $t_0 \in (0, T)$. We set

$$D_\psi := \mathrm{cl}(\{(t, x, r) :\, t \in (0, T],\ x \in \mathbb{R}^n,\ r \geq \psi(t, x)\}) \cup [T, +\infty) \times \mathbb{R}^n,$$

$$\tilde{f}(t, x, r, u, v) = \left\{ \begin{array}{lll} 0 & \text{if} & t < 0, \\ \frac{t}{t_0}(1, f(t, x, u, v), 0) & \text{if} & t \in [0, t_0], \\ (1, f(t, x, u, v), 0) & \text{if} & t \in (t_0, T], \\ (1, f(T, x, u, v), 0) & \text{if} & t > T. \end{array} \right.$$

We show that (20) holds true for $\tilde{f}$, D_ψ.

Let $z_0 = (s_0, x_0, r_0) \in D_\psi$. If $s_0 = 0$, then $\tilde{f} = 0$. Obviously, (20) holds true. If $s_0 \geq T$ and $(p_s, p_x, p_r) \in \left[T_{D_\psi}(s_0, x_0, r_0)\right]^-$, then $p_s \leq 0$, $p_x = 0$, $p_r = 0$. Hence, (20) holds true.

It remains to consider the case $s_0 \in (0, T)$. We have $\left[T_{D_\psi}(s_0, x_0, r_0)\right]^- \subset \left[T_{D_\psi}(s_0, x_0 \psi(s_0, x_0))\right]^-$. Let $(p_s, p_x, p_r) \in \left[T_{D_\psi}(s_0, x_0 \psi(s_0, x_0))\right]^-$. If $p_r < 0$, then $(\frac{p_s}{-p_r}, \frac{p_x}{-p_r}) \in \partial_- \psi(s_0, x_0)$. Since ψ is a supersolution to (15) we have

$$\frac{p_s}{-p_r} + \max_{v \in V} \min_{u \in U} \left\langle f(s_0, x_0, u, v), \frac{p_x}{-p_r} \right\rangle \leq 0.$$

Hence,

$$\max_{v \in V} \min_{u \in U} \langle \tilde{f}(s_0, x_0, r_0, u, v), (p_s, p_x, p_r) \rangle \leq 0.$$

Now, we consider the case $p_v = 0$. By Lemma 13, there exist $s_n \to s_0$, $x_n \to x_0$, $p_{sn} \to p_s$, $p_{xn} \to p_x$, $p_{rn} \to 0$, $p_{rn} < 0$ such that

$$(p_{sn}, p_{xn}, p_{rn}) \in \left[T_{Epi(\psi)}(s_n, x_n, \psi(t_n, x_n))\right]^-.$$

Since $p_{rn} < 0$, from what we already have proved, we obtain

$$\max_{v \in V} \min_{u \in U} \langle \tilde{f}(s_n, x_n, \psi(s_n, x_n), u, v), (p_{sn}, p_{xn}, p_{rn} \rangle \leq 0.$$

Since f is continuous and U is compact, we have

$$\max_{v \in V} \min_{u \in U} \langle \tilde{f}(s_0, x_0, r_0, u, v), (p_s, p_x, p_r \rangle \leq 0.$$

By Theorem 14, there exists $\alpha \in \Gamma(t_0)$ such that for every $v \in \mathcal{V}(t_0)$

$$z(s;\, t_0, z_0, \alpha(v), v) \in D_\psi \tag{21}$$

for every $s \in [t_0, T]$, where $z(s;\, t_0, z_0, u, v)$ denotes the solution to the Cauchy problem

$$\left\{ \begin{array}{l} z'(s) = \tilde{f}(z(s), u(s), v(s)), \\ z(t_0) = z_0. \end{array} \right.$$

Let $z(s, t_0, z_0, \alpha(v), v) = (t(s), x(s), r(s))$. By the definition of $\tilde{f}$, we have $t(s) = s$, $x(s) = x(s;\, t_0, x_0, \alpha(v), v)$, $r(s) = \psi(t_0, x_0)$. It yields (16) for $t \in [t_0, T)$. Since ψ is lower semicontinuous, we obtain (16) for $t = T$. $\square$

Let us deduce now our result concerning the control problem.

Proof of Theorem 2. Fix $(t_0, x_0) \in (0, T] \times \mathbb{R}^n$. Let $\varepsilon > 0$. There exists $u_\varepsilon \in \mathcal{U}(t_0)$ such that $g(x(T;\, t_0, x_0, u_\varepsilon)) < W_g(t_0, x_0) + \varepsilon$. We define $h : \mathbb{R}^n \to \mathbb{R}$ by

$$h(x) = \begin{cases} g(x) & \text{for} \quad x = x(T;\, t_0, x_0, u_\varepsilon), \\ M & \text{for} \quad x \neq x(T;\, t_0, x_0, u_\varepsilon), \end{cases}$$

where M is a bound of $\|g\|$. Obviously, h is lower semicontinuous. By Theorem 11, the value W_h is a supersolution to (18). We have $W_h(t_0, x_0) < W_g(t_0, x_0) + \varepsilon$. Hence,

$$W_g(t_0, x_0) = \inf\{\psi(t_0, x_0) : \ \psi \text{ is a supersolution to (18)}, \ \psi(T, \cdot) \geq g(\cdot)\}.$$

We define $l : \mathbb{R}^n \to \mathbb{R}$ by

$$l(x) = \begin{cases} W_g(t_0, x_0) & \text{if} \quad x \in \{x(T;\, t_0, x_0, u) : \ u \in \mathcal{U}(t_0)\}, \\ -M & \text{if} \quad x \notin \{x(T;\, t_0, x_0, u) : \ u \in \mathcal{U}(t_0)\}. \end{cases}$$

By (5), (7), the reachable set $\{x(T;\, t_0, x_0, u) : \ u \in \mathcal{U}(t_0)\}$ is closed. Thus, l is upper semicontinuous. Obviously, we have $W_g(t_0, x_0) = W_l(t_0, x_0)$. By Theorem 11 (in a version for upper semicontinuous terminal cost), we obtain that W_l is a subsolution to (18). Hence,

$$W_g(t_0, x_0) = \sup\{\phi(t_0, x_0) : \ \phi \text{ is a subsolution to (18)}, \ \phi(T, \cdot) \leq g(\cdot)\}. \qquad \square$$

ADAPTIVE LQG CONTROL OF INPUT-OUTPUT SYSTEMS—A COST-BIASED APPROACH*

M. PRANDINI† AND M. C. CAMPI†

Abstract. In this paper, we consider linear systems in input-output form and introduce a new adaptive linear quadratic Gaussian (LQG) control scheme which is shown to be self-optimizing. The identification algorithm incorporates a cost-biasing term, which favors the parameters with smaller LQG optimal cost and a second term that aims at moderating the time-variability of the estimate. The corresponding closed-loop scheme is proven to be stable and to achieve an asymptotic LQG cost equal to the one obtained under complete knowledge of the true system (self-optimization).

The results of this paper extend in a nontrivial way previous results established along the cost-biased approach in other settings.

Key words. LQG adaptive control, least squares identification, cost-biased identification, self-optimality

1. Introduction.

Since the appearance of the original contribution of Aström and Wittenmark [1], the analysis of self-tuning control systems has constituted a challenging topic for theorists working in the area of adaptive control. The first significant convergence results were obtained in the late 1970s for minimum-variance control schemes. In particular, a global convergence result for an adaptive control system based on the stochastic gradient algorithm has been established in [13]. Extensions to the least squares (LS) algorithm are dealt with in [32] by introducing a suitable modification to the standard recursive least squares algorithm. Such a modification is in fact not necessary in order to achieve optimality [20].

The common result of all the above-mentioned contributions is that a minimum-variance self-tuning control system obtains under various operating conditions the same performance as the one achievable under complete knowledge of the true plant (*self-optimization*). It is important, however, to emphasize that the minimum-variance control law calls for the restrictive—and often unrealistic—assumption that the plant is minimum-phase. Extending these results to more general control techniques suitable for nonminimum-phase plants has attracted much attention in the last decade. The corresponding analysis, however, is far more complex.

It is by now well known (see, e.g., [21, 22, 18, 25, 33]) that the self-optimization result does not hold true for general control laws based on the minimization of multistep performance indexes. As a matter of fact, the interplay between identification and control in a certainty equivalence adaptive control scheme may result in the convergence of the parameter estimate to a parameterization different from the true one in absence of suitable excitation conditions (see, e.g., [5, 18, 2, 6]). When a cost criterion other than the output variance is considered, this identifiability problem results in a strictly suboptimal performance. In particular, the identifiability problem

†Dipartimento di Elettronica per l'Automazione, Università degli Studi di Brescia, Via Branze 38, 25123 Brescia, Italy (prandini@ing.unibs.it, campi@ing.unibs.it).

is significant in infinite-horizon linear quadratic Gaussian (LQG) control and, in fact, in [33] it is proven that for a state space system subject to Gaussian noise the set of the parameterizations leading to optimality of LQG control is strictly contained in the set of the potential convergence points.

A first approach to achieve optimality consists of securing the parameter consistency by introducing suitable probing signals in the control system. The probing signals should be sufficiently exciting so that consistency is achieved, and—at the same time—mild enough in order not to degrade the control system performance. In [8, 9, 10, 14, 28], this is obtained by a careful selection of an asymptotically vanishing dither noise. This approach is useful only in the case when noise injection is feasible.

A second approach—adopted in this paper—is based on the so-called *cost-biased method* originally introduced in [21]. In order to better focus on the basic idea underlying this approach and to highlight the main contributions given in the present paper, we proceed as follows: first we introduce the dynamic systems we consider; then we outline the cost-biased approach with specific reference to our class of systems; finally we put our results into perspective with the other existing results obtained along the cost-biased approach.

We consider dynamic systems in input-output form described by the following equation:

$$\mathcal{A}(\vartheta^\circ; q^{-1})\, y_t = \mathcal{B}(\vartheta^\circ; q^{-1})\, u_{t-1} + n_t, \tag{1.1}$$

where $\mathcal{A}(\vartheta^\circ; q^{-1}) = 1 - \sum_{i=1}^{n} a_i^\circ q^{-i}$ and $\mathcal{B}(\vartheta^\circ; q^{-1}) = \sum_{i=1}^{m} b_i^\circ q^{-i+1}$ are polynomials in the unit-delay operator q^{-1} and $\vartheta^\circ = [\,a_1^\circ\ a_2^\circ \dots a_n^\circ\ b_1^\circ\ b_2^\circ \dots b_m^\circ\,]^T$ is the system parameter vector. The control objective is to minimize the quadratic cost

$$\limsup_{N\to\infty} \frac{1}{N} \sum_{t=0}^{N-1} [\, y_t^2 + \beta\, u_t^2], \tag{1.2}$$

where the control weighting coefficient β is strictly positive.

The basic idea of the cost-biased approach can be outlined as follows.

Suppose a standard LS algorithm is used for the identification of system (1.1) and let $\hat{\vartheta}_t^{LS}$ be the corresponding LS estimate at time t. According to the certainty equivalence principle, the control action is obtained by the relation $u_t = u_t^\star(\hat{\vartheta}_t^{LS})$, where $u_t^\star(\vartheta)$ indicates the optimal LQG control law for system (1.1) with parameter ϑ. For ease of reference, let us introduce the symbol $S(\vartheta_1, \vartheta_2)$ for the control system formed by system (1.1) with parameter ϑ_1 with the loop closed by $u_t = u_t^\star(\vartheta_2)$. Since the identification is performed in closed-loop, it is expected that the behavior of $S(\vartheta^\circ, \hat{\vartheta}_t^{LS})$ will be the same, at least in the long run, as the one of $S(\hat{\vartheta}_t^{LS}, \hat{\vartheta}_t^{LS})$. Then, the LQG cost for $S(\vartheta^\circ, \hat{\vartheta}_t^{LS})$—i.e., the incurred cost—will be the same as the LQG cost for $S(\hat{\vartheta}_t^{LS}, \hat{\vartheta}_t^{LS})$. However, one should note that the latter configuration is optimal for the estimated model, whereas the incurred cost obviously cannot be lower than the optimal cost for the true system. From this, one concludes that the least squares algorithm has a natural tendency to return estimates with an optimal cost that is not smaller than the optimal cost associated with the true system and that, when it is strictly larger, the adaptive scheme attains a suboptimal performance.

In the cost-biased approach an extra term that favors parameters with smaller optimal cost is added to the LS identification cost. This extra term is selected with a twofold objective. On the one hand, it should be strong enough so that the optimal LQG cost associated with the estimated model is asymptotically not larger than the optimal cost for the true system. If, on the other hand, it is so mild that the closed-loop identification property $S(\vartheta^\circ, \hat{\vartheta}_t^{LS}) = S(\hat{\vartheta}_t^{LS}, \hat{\vartheta}_t^{LS})$ is preserved, then one still has that the incurred cost is equal to the cost for $S(\hat{\vartheta}_t^{LS}, \hat{\vartheta}_t^{LS})$. From this, optimality of the adaptive control scheme is achieved.

The cost-biased approach has been successfully applied in a number of different settings. Controlled Markov chains with a finite parameter set are considered in [21]. The results of this paper have been extended to Markov chains with an infinite parameter set in [24] and to systems with a general state space but still with a finite parameter set in [19].

Linear systems in a state space representation are dealt with in [18] and [7]. In these papers, the restrictive assumption that the state is fully accessible is made. Moreover, it is assumed that the noise system affects all state variables. This assumption is crucial for the correct functioning of the proposed identification procedure. As a matter of fact, the presence of a full-range noise sheds light on the existing difference between the true system and the estimated model and this helps the identification task. In the paper [7], it is in fact shown that this mechanism is effective enough so as to counteract the biasing effect of the cost-biasing term thus guaranteeing the closed-loop identification property. Unfortunately, the assumption that the noise is full-range is so restrictive that it cannot be applied to many situations of interest. In particular, a state space realization of the input-output system (1.1) does not satisfy this condition.

In the present paper, an optimal adaptive control scheme for system (1.1) still based on the cost-biasing idea is presented. Extending the cost-biased approach to systems as (1.1) is important in that input-output systems are largely used in adaptive control applications. Moreover, assuming only the input and output measurability is much more realistic than assuming full state accessibility. As a side remark we also note that, in contrast with [18] and [7], our approach does not require the noise to be Gaussian.

The paper is organized as follows: in section 2, we describe the cost-biased adaptive LQG control scheme and recall some relevant properties of the standard LS estimates. The study of the cost-biased identification algorithm is presented in section 3. Section 4 is devoted to the analysis of the closed-loop stability and the characterization of the self-tuning LQG control performance. Finally, section 5 presents conclusions and suggestions for future research.

2. The cost-biased adaptive LQG control system.

2.1. The LQG optimal control problem. In this section, we summarize some known facts on infinite-horizon LQG control relevant for the subsequent developments. This is also useful in order to introduce the assumptions and the notations we shall use throughout the paper.

Consider the discrete time single input, single output (SISO) system (1.1) where signal n_t is a stochastic disturbance precisely described in the following.

ASSUMPTION 2.1. *$\{n_t\}$ is a martingale difference sequence with respect to a filtration $\{\mathcal{F}_t\}$, satisfying the following conditions:*

1. $\sup_t E[|n_t|^p/\mathcal{F}_{t-1}] < \infty$ *almost surely (a.s)* $\forall p > 0$;
2. $\lim_{N\to\infty} \frac{1}{N}\sum_{t=0}^{N-1} n_t^2 = \sigma^2 > 0$ *a.s.*

Note that Assumption 2.1 is satisfied when $\{n_t\}$ is an independently and identically distributed (i.i.d.) Gaussian sequence, but it includes many other situations.

We make the assumption on system (1.1) that $n > 0$ (nontrivial autoregressive part). Note that if $n = 0$, the trivial control law $u_t = 0$, $t \geq 0$, is obviously optimal irrespective of the value of ϑ°.

We further assume that system (1.1) belongs to a known set of stabilizable models according to the following.

ASSUMPTION 2.2. *$\vartheta^\circ \in \Theta$, where Θ is a compact set such that $\Theta \subset \{\vartheta \in \Re^{n+m} : q^s\mathcal{A}(\vartheta; q^{-1})$ and $q^{s-1}\mathcal{B}(\vartheta; q^{-1})$ have no unstable pole-zero cancellations$\}$, $s = \max\{n, m\}$ being the order of the system.*

System (1.1) is initialized at time $t = 0$ with $y_t = u_{t-1} = 0$, $t \leq 0$.

For the determination of an optimal control law, it is convenient to represent system (1.1) in a state space form such that the state is accessible and then apply the well-known solution to the optimal LQG control problem for full state accessible state space systems (see, e.g., [10], [3]).

Defining $x_t := [y_t \; y_{t-1} \ldots y_{t-(n-1)} \; u_{t-1} \; u_{t-2} \ldots u_{t-(m-1)}]^T$, system (1.1) can be given the following state space representation of order $\bar{s} := n + m - 1$

$$\left\{ \begin{array}{l} x_{t+1} = A(\vartheta^\circ)x_t + B(\vartheta^\circ)u_t + Cn_{t+1}, \quad x_0 = [0\,0\ldots 0]^T, \\ y_t = Hx_t \end{array} \right. \tag{2.1}$$

with matrices

$$A(\vartheta) = \left[\begin{array}{cccc|cccc} a_1 & \cdots & a_{n-1} & a_n & b_2 & \cdots & b_{m-1} & b_m \\ 1 & 0 & \cdots & & 0 & \cdots & & 0 \\ & \ddots & \ddots & & & \ddots & & 0 \\ & & 1 & 0 & & & & 0 \\ \hline 0 & \cdots & \cdots & 0 & 0 & \cdots & \cdots & 0 \\ 0 & \cdots & \cdots & 0 & 1 & 0 & & \\ & \ddots & \ddots & & & \ddots & \ddots & \\ & & 0 & 0 & & & 1 & 0 \end{array} \right],$$

$$B(\vartheta) = \left[\begin{array}{c} b_1 \\ 0 \\ \vdots \\ 0 \\ \hline 1 \\ 0 \\ \vdots \\ 0 \end{array} \right], \quad C = \left[\begin{array}{c} 1 \\ 0 \\ \vdots \\ 0 \\ \hline 0 \\ 0 \\ \vdots \\ 0 \end{array} \right], \quad H = \left[\begin{array}{cccc|ccc} 1 & 0 & \cdots & 0 & 0 & \cdots & 0 \end{array} \right].$$

In this way, the LQG regulation problem for the system in input-output representation (1.1) is reformulated as a complete state information control problem where the performance index to be minimized is given by $\limsup_{N\to\infty} \frac{1}{N} \sum_{t=0}^{N-1} [x_t^T T x_t + \beta u_t^2]$, where $T = H^T H \geq 0$ and $\beta > 0$.

Note that, in the case when $n > 1$ and $m > 1$, the state space representation (2.1) of system (1.1) is nonminimal (the order of system (1.1) is $s = \max\{n, m\}$, whereas the dimension of matrix $A(\vartheta^\circ)$ is $\bar{s} = n + m - 1$). However, from the block triangular matrix structure of $A(\vartheta^\circ)$ it is easily seen that the added eigenvalues are identically equal to zero. Hence from Assumption 2.2 it follows that $(A(\vartheta^\circ), B(\vartheta^\circ))$

is stabilizable and $(A(\vartheta^\circ), H)$ is detectable and the standard approach based on the solution to a Riccati equation can be used to determine the control law.

Specifically, the solution to the original LQG control problem has the following expression [10]:

$$u_t = \mathcal{S}(\vartheta^\circ; q^{-1})\, y_t + \mathcal{R}(\vartheta^\circ; q^{-1})\, u_t, \tag{2.2}$$

where $\mathcal{S}(\vartheta^\circ; q^{-1}) = \sum_{i=0}^{n-1} s_i(\vartheta^\circ) q^{-i}$ and $\mathcal{R}(\vartheta^\circ; q^{-1}) = \sum_{i=1}^{m-1} r_i(\vartheta^\circ) q^{-i}$, and coefficients $\{s_i(\vartheta^\circ)\}$ and $\{r_i(\vartheta^\circ)\}$ are computed as follows.

Set $L(\vartheta^\circ) := [\, s_0(\vartheta^\circ)\ s_1(\vartheta^\circ) \dots s_{n-1}(\vartheta^\circ)\ r_1(\vartheta^\circ) \dots r_{m-1}(\vartheta^\circ)\,]$. Then

$$L(\vartheta^\circ) = -(B(\vartheta^\circ)^T P(\vartheta^\circ) B(\vartheta^\circ) + \beta)^{-1} B(\vartheta^\circ)^T P(\vartheta^\circ) A(\vartheta^\circ), \tag{2.3}$$

where $P(\vartheta^\circ)$ is the unique positive semidefinite solution to the discrete time algebraic Riccati equation

$$P = A(\vartheta^\circ)^T \left[P - PB(\vartheta^\circ)(B(\vartheta^\circ)^T P B(\vartheta^\circ) + \beta)^{-1} B(\vartheta^\circ)^T P \right] A(\vartheta^\circ) + H^T H.$$

Moreover, the optimal LQG cost is given by $J^\star(\vartheta^\circ) = \sigma^2 trace(P(\vartheta^\circ) C C^T)$, a.s.

Remark 2.3. *Since the positive semidefinite solution $P(\vartheta)$ to*

$$P = A(\vartheta)^T \left[P - PB(\vartheta)(B(\vartheta)^T P B(\vartheta) + \beta)^{-1} B(\vartheta)^T P \right] A(\vartheta) + H^T H \tag{2.4}$$

is analytic as a function of the parameter vector ϑ in the set $\mathcal{C} = \{\vartheta \in \Re^{n+m} : q^s \mathcal{A}(\vartheta; q^{-1})$ and $q^{s-1} \mathcal{B}(\vartheta; q^{-1})$ have no unstable pole-zero cancellations$\}$ (see [12]*), it is easily seen that $s_i(\vartheta)$, $r_i(\vartheta)$, and $J^\star(\vartheta)$ are analytic functions of ϑ, $\vartheta \in \mathcal{C}$, as well.*

2.2. The cost-biased identification algorithm.

Introducing the observation vector $\varphi_t := [\, y_t \dots y_{t-(n-1)}\ u_t \dots u_{t-(m-1)}]^T$, system (1.1) can be given the regression-like form

$$y_t = \varphi_{t-1}^T \vartheta^\circ + n_t, \tag{2.5}$$

and the LS identification index for the estimate of ϑ° is [26]

$$V_t(\vartheta) = \sum_{s=1}^{t} (y_s - \varphi_{s-1}^T \vartheta)^2. \tag{2.6}$$

In the theorem below, we recall a fundamental result for the LS estimate proven in [23, Theorem 1].

Theorem 2.4. *Suppose that u_t is $\mathcal{F}_t$-measurable. Then*

$$(\vartheta^\circ - \hat{\vartheta}_t^{LS})^T \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T (\vartheta^\circ - \hat{\vartheta}_t^{LS}) = O\left(\log \lambda_{max} \left(\sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T \right) \right) \quad a.s. \tag{2.7}$$

In particular, this implies that under the conditions

(i) $\lambda_{min} \left(\sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T \right) \to \infty$ *a.s.,*

(ii) $\log \lambda_{max} \left(\sum_{s=0}^{t} \varphi_{s-1} \varphi_{s-1}^T \right) = o\left(\lambda_{min} \left(\sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T \right) \right)$ *a.s.,* *the LS estimate is consistent.*

In adaptive control, identification is performed in closed-loop. Therefore, one cannot ensure the satisfaction of conditions (i) and (ii) and the true parameter vector is generally not consistently estimated. Nevertheless, property (2.7) still provides a valuable bound on the discrepancy between the estimated parameter and the true parameter. We call this property "closed-loop identification property" to emphasize that it holds even in closed-loop. On the other hand, as discussed in section 1, the LS identification algorithm generally provides estimates with an optimal LQG cost larger than the optimal cost associated with the true system. This is the reason why optimality of an LS-based adaptive control scheme is not guaranteed.

Motivated by these considerations, we introduce a cost-biased identification algorithm with the twofold objective of preserving the LS property (2.7) and forcing the estimates to lie asymptotically in the parameter region with an optimal cost not larger than the optimal cost associated with the true system.

Consider the estimate $\hat{\vartheta}_t$ computed through the following algorithm:

$$\hat{\vartheta}_t = \begin{cases} \arg\min_{\vartheta \in \Theta} D_t(\vartheta) & \text{if } t = t_i,\ i = 0, 1, 2, \dots, \\ \hat{\vartheta}_{t-1} & \text{otherwise,} \end{cases} \tag{2.8}$$

where the time instants $\{t_i\}$ are obtained by the recursive equation $t_{i+1} = t_i + T_i$ initialized with $t_0 = 0$ and the cost-biased identification index $D_t(\vartheta)$ is given by

$$D_t(\vartheta) = V_t(\vartheta) + \alpha_t J^\star(\vartheta) + \gamma_t \|\vartheta - \hat{\vartheta}_{t-1}\|,\ \hat{\vartheta}_{-1} = 0, \tag{2.9}$$

where $V_t(\vartheta)$ is the LS cost (2.6) and $J^\star(\vartheta)$ is the optimal LQG cost for system (1.1) with parameter ϑ. The identification algorithm is completely defined by specifying the sequences of

- freezing time intervals $\{T_i\}$,
- cost-biasing weights $\{\alpha_t\}$,
- friction parameters $\{\gamma_t\}$.

We discuss hereafter the meaning of these parameters, while their actual choice is postponed to the following section.

The freezing parameter T_i is used to ensure stability of the closed-loop system. Since the parameter estimate changes with time and the control law is tuned to such an estimate, the adaptive control system is time-varying. On the other hand, it is well known that guaranteeing a stability property at each time instant for the "frozen dynamics" does not imply that the overall time-varying system has a stable dynamics. This problem can be solved by updating the estimate at a slower rate than the updating of the system variables, and this is achieved by a suitable choice of T_i. This same approach is exploited, for instance, in [17], [27], and [29].

The cost-biasing term $\alpha_t J^\star(\vartheta)$ is introduced with the objective of penalizing those parameterizations with high optimal LQG cost. The weight α_t has to be appropriately selected so as to balance the contrasting objectives of preserving the closed-loop identification property (2.7) and forcing the asymptotic estimate to correspond to a model with value of the optimal LQG performance index not larger than the optimal performance value for the true system.

Finally, the friction term $\gamma_t \|\vartheta - \hat{\vartheta}_{t-1}\|$ is introduced so as to avoid the estimate $\hat{\vartheta}_t$ being subject to undesired jumps in the time instants t_i when it is updated. This is necessary to prove optimality of the adaptive scheme.

3. Selection of $\{\mathbf{T_i}\}$, $\{\alpha_\mathbf{t}\}$, $\{\gamma_\mathbf{t}\}$ and properties of $\hat{\vartheta}_\mathbf{t}$. The adaptive control law is given by the optimal control law (2.2) with the estimate $\hat{\vartheta}_t$ in place of ϑ° (certainty equivalence principle):

$$u_t = \mathcal{S}(\hat{\vartheta}_t; q^{-1})\, y_t + \mathcal{R}(\hat{\vartheta}_t; q^{-1})\, u_t.$$

The system

$$\begin{cases} y_{t+1} = [1 - \mathcal{A}(\hat{\vartheta}_t; q^{-1})]\, y_{t+1} + \mathcal{B}(\hat{\vartheta}_t; q^{-1})\, u_t, \\ u_t = \mathcal{S}(\hat{\vartheta}_t; q^{-1})\, y_t + \mathcal{R}(\hat{\vartheta}_t; q^{-1})\, u_t \end{cases} \tag{3.1}$$

is then given the name of *time-varying estimated system.* We will select T_i so as to stabilize system (3.1) and later on in section 4 we shall see that this leads to the stability of the true closed-loop system. Letting $x_t := [y_t \dots y_{t-(n-1)} u_{t-1} \dots u_{t-(m-1)}]^T$, this system can be given the state space representation

$$x_{t+1} = F(\hat{\vartheta}_t)\, x_t \tag{3.2}$$

with

$$F(\vartheta) = A(\vartheta) + B(\vartheta)L(\vartheta), \tag{3.3}$$

where matrices $A(\vartheta)$, $B(\vartheta)$, and $L(\vartheta)$ have been introduced in section 2.1.

Choose now a constant $\mu < 1$ (*contraction* constant). The time interval T_i is then defined as

$$T_i := \inf\{\tau \in Z_+ : \|F(\hat{\vartheta}_{t_i})^\tau\| \le \mu\} \tag{3.4}$$

(note that such a T_i exists since $\hat{\vartheta}_{t_i}$ belongs to Θ and therefore corresponds to a stabilizable system). In this way, the time-varying system (3.1) is kept constant until its dynamics is contracted by a factor μ, whence guaranteeing its stability. The following proposition makes this precise.

PROPOSITION 3.1. *The autonomous estimated system $x_{t+1} = F(\hat{\vartheta}_t)\, x_t$ is a.s. exponentially stable, uniformly in time.*

Proof. The proof is given in the appendix. □

The choice of $\{\alpha_t\}$ and $\{\gamma_t\}$ is discussed in the next theorem.

THEOREM 3.2. *Suppose that u_t is $\mathcal{F}_t$-measurable. Given $\delta > 0$, select*

$$\alpha_t := \log^{1+\delta} \lambda_{max} \left(\sum_{s=1}^{t} \varphi_{s-1}\varphi_{s-1}^T \right) \tag{3.5}$$

and $\{\gamma_t\}$ to be a positive diverging sequence of real numbers satisfying $\gamma_t = o(\alpha_t)$. Then,

(i) $(\vartheta^\circ - \hat{\vartheta}_{t_i})^T \sum_{s=1}^{t_i} \varphi_{s-1}\varphi_{s-1}^T (\vartheta^\circ - \hat{\vartheta}_{t_i}) = O\left(\log^{1+\delta} \lambda_{max} \left(\sum_{s=1}^{t_i} \varphi_{s-1}\varphi_{s-1}^T \right) \right)$ *a.s.,*

(ii) $\limsup_{t\to\infty} J^\star(\hat{\vartheta}_t) \le J^\star(\vartheta^\circ)$ *a.s.,*

(iii) *if* $\sum_{t=1}^{N} \|\varphi_{t-1}\|^2 = O(N)$ *a.s., then* $\sum_{t=1}^{N} \|\hat{\vartheta}_t - \hat{\vartheta}_{t-1}\| = o(N)$ *a.s.*

Proof. The proof is given in the appendix. □

According to (3.5), $\{\alpha_t\}$ is chosen to be an increasing sequence of real numbers adaptively selected on the basis of the data generated by the controlled system. According to result (ii), this selection is effective in pushing the estimate towards the region where the optimal LQG cost is not larger than $J^\star(\vartheta^\circ)$. In turn, result (i) shows that the closed-loop identification property (2.7) is preserved with two slight differences: (1) the exponent $1+\delta$ appears in the right-hand side, (2) the rate of divergence in point (i) of Theorem 3.2 concerns only the time instants t_i when the estimate $\hat{\vartheta}_t$ is updated, while the original closed-loop identification property refers to all t's.

Before ending this section, we state a proposition regarding the estimation error

$$e_t := \varphi_t^T[\vartheta^\circ - \hat{\vartheta}_t]. \tag{3.6}$$

The technical proof of this proposition is given in the appendix and is obtained by a suitable manipulation of the sole result (i) in Theorem 3.2.

Proposition 3.3. *The estimation error $e_t = \varphi_t^T[\vartheta^\circ - \hat{\vartheta}_t]$ satisfies the following equation:*

$$\sum_{t=0,\ t\notin\mathcal{B}_N}^{N} |e_t|^p = o\left(\sum_{t=0}^{N} \|\varphi_t\|^p + N\right), \quad p \geq 2,\ a.s.,$$

where $\mathcal{B}_N$ is a set of instant points which depends on N, whose cardinality is bounded: $|\mathcal{B}_N| \leq C_{\mathcal{B}}\ \forall N$.

4. Stability and optimality.

The closed-loop system

$$\left\{\begin{array}{l} y_{t+1} = [1-\mathcal{A}(\vartheta^\circ;q^{-1})]\,y_{t+1} + \mathcal{B}(\vartheta^\circ;q^{-1})\,u_t + n_{t+1}, \\ u_t = \mathcal{S}(\hat{\vartheta}_t;q^{-1})\,y_t + \mathcal{R}(\hat{\vartheta}_t;q^{-1})\,u_t \end{array}\right. \tag{4.1}$$

can be represented as a variation system with respect to the so-called estimated system of (3.1) as follows:

$$\left\{\begin{array}{l} y_{t+1} = [1-\mathcal{A}(\hat{\vartheta}_t;q^{-1})]\,y_{t+1} + \mathcal{B}(\hat{\vartheta}_t;q^{-1})\,u_t + n_{t+1} + e_t, \\ u_t = \mathcal{S}(\hat{\vartheta}_t;q^{-1})\,y_t + \mathcal{R}(\hat{\vartheta}_t;q^{-1})\,u_t, \end{array}\right. \tag{4.2}$$

where e_t is defined in (3.6). The uniform stability property of the estimated system (3.1) (Proposition 3.1) and the property of e_t stated in Proposition 3.3 are exploited in the next theorem to prove stability of system (4.1).

Theorem 4.1 (L^p-stability). *The adaptive LQG control scheme*

$$\left\{\begin{array}{l} y_{t+1} = [1-\mathcal{A}(\vartheta^\circ;q^{-1})]\,y_{t+1} + \mathcal{B}(\vartheta^\circ;q^{-1})\,u_t + n_{t+1}, \\ u_t = \mathcal{S}(\hat{\vartheta}_t;q^{-1})\,y_t + \mathcal{R}(\hat{\vartheta}_t;q^{-1})\,u_t \end{array}\right.$$

is L^p-stable: $\limsup_{N\to\infty} \frac{1}{N}\sum_{t=0}^{N-1}[|y_t|^p + |u_t|^p] < \infty$ *a.s.* $\forall p > 0$.

Proof. Fix a time point $N > 0$ and an integer $d \geq 1$.

From Proposition 3.3, there exists a set of instant points $\mathcal{B}_{N-1}$ such that

$$\sum_{t=0,\ t\notin\mathcal{B}_{N-1}}^{N-1} e_t^{2^d} = o\left(\sum_{t=0}^{N-1} \|\varphi_t\|^{2^d} + N\right) \quad \text{a.s.} \tag{4.3}$$

In view of representation (4.2) of system (4.1), it is easily seen that the state vector

$$x_t = [y_t \dots y_{t-(n-1)}\, u_{t-1} \dots u_{t-(m-1)}]^T$$

is governed by the equation

$$\begin{aligned} x_{t+1} &= F^\circ(\hat{\vartheta}_t)\, x_t + C n_{t+1} && (4.4)\\ &= F(\hat{\vartheta}_t)\, x_t + C[e_t + n_{t+1}], && (4.5)\end{aligned}$$

where $F^\circ(\vartheta) = A(\vartheta^\circ) + B(\vartheta^\circ)L(\vartheta)$, $A(\vartheta^\circ)$, $B(\vartheta^\circ)$, $L(\vartheta)$, and C are defined in section 2.1, and $F(\vartheta)$ is given in (3.3).

For the following derivations, it is convenient to use representation (4.4) in the time instants $t \in \mathcal{B}_{N-1}$ and representation (4.5) for $t \notin \mathcal{B}_{N-1}$, thus finally leading to

$$x_{t+1} = \begin{cases} F^\circ(\hat{\vartheta}_t)\, x_t + C n_{t+1}, & t \in \mathcal{B}_{N-1}, \\ F(\hat{\vartheta}_t)\, x_t + C[e_t + n_{t+1}], & t \notin \mathcal{B}_{N-1}. \end{cases} \tag{4.6}$$

Note now that since $\hat{\vartheta}_t$ belongs to the compact set Θ and $F^\circ(\vartheta)$ is a continuous function of ϑ, $\vartheta \in \Theta$, we then have that $\|F^\circ(\hat{\vartheta}_t)\|$ is uniformly bounded. From this fact and the uniform exponential stability of the autonomous system $x_{t+1} = F(\hat{\vartheta}_t)x_t$ (Proposition 3.1), and the fact that $|\mathcal{B}_{N-1}| \leq C_{\mathcal{B}}$ $\forall N$ (see Proposition 3.3), it is easy to show that the state vector x_t generated by system (4.6) can be bounded as follows:

$$\|x_t\| \leq k_1 \left\{ \sum_{i=1}^{t} \nu^{t-i}|n_i| + \sum_{i=0, i\notin\mathcal{B}_{N-1}}^{t-1} \nu^{t-i}|e_i| \right\}, \quad t \leq N,$$

where k_1 and $\nu \in (0,1)$ are suitable constants. We now have

$$\begin{aligned} &\left[k_1 \left\{ \sum_{i=1}^{t} \nu^{t-i}|n_i| + \sum_{i=0, i\notin\mathcal{B}_{N-1}}^{t-1} \nu^{t-i}|e_i| \right\} \right]^{2^d} \\ &\quad \leq k_1^{2^d} \left[\left\{ \sum_{i=1}^{t} \nu^{t-i}|n_i| + \sum_{i=0, i\notin\mathcal{B}_{N-1}}^{t-1} \nu^{t-i}|e_i| \right\}^2 \right]^{2^{d-1}} \\ &\quad \leq k_1^{2^d} \left[2 \left\{ \sum_{i=1}^{t} \nu^{\frac{t-i}{2}} (\nu^{\frac{t-i}{2}}|n_i|) \right\}^2 + 2 \left\{ \sum_{i=0, i\notin\mathcal{B}_{N-1}}^{t-1} \nu^{\frac{t-i}{2}} (\nu^{\frac{t-i}{2}}|e_i|) \right\}^2 \right]^{2^{d-1}} \\ &\quad \leq k_1^{2^d} \left[2 \sum_{i=1}^{t} \nu^{t-i} \sum_{i=1}^{t} \nu^{t-i} n_i^2 + 2 \sum_{i=0, i\notin\mathcal{B}_{N-1}}^{t-1} \nu^{t-i} \sum_{i=0, i\notin\mathcal{B}_{N-1}}^{t-1} \nu^{t-i} e_i^2 \right]^{2^{d-1}} \\ &\quad \leq k_1^{2^d} \left(\frac{2}{1-\nu} \right)^{2^{d-1}} \left[\sum_{i=1}^{t} \nu^{t-i} n_i^2 + \sum_{i=0, i\notin\mathcal{B}_{N-1}}^{t-1} \nu^{t-i} e_i^2 \right]^{2^{d-1}}. \end{aligned}$$

Iterating this same equation d times, we then obtain

$$\|x_t\|^{2^d} \leq k_2 \left\{ \sum_{i=1}^{t} \nu^{t-i} n_i^{2^d} + \sum_{i=0, i\notin\mathcal{B}_{N-1}}^{t-1} \nu^{t-i} e_i^{2^d} \right\}, \quad t \leq N, \tag{4.7}$$

k_2 being a suitable constant, from which we finally get

$$\frac{1}{N}\sum_{t=1}^{N}\|x_t\|^{2^d} \le k_3 \left\{ \frac{1}{N}\sum_{t=1}^{N} n_t^{2^d} + \frac{1}{N}\sum_{t=0,t\notin\mathcal{B}_{N-1}}^{N-1} e_t^{2^d} \right\}, \tag{4.8}$$

where k_3 is a suitable constant, independent of N.

We next bound the two terms in the right-hand side of (4.8).

The term $\frac{1}{N}\sum_{t=1}^{N} n_t^{2^d}$ is handled as follows. Define $v_t := n_t^{2^d} - E[n_t^{2^d}|\mathcal{F}_{t-1}]$. Then $\{v_t\}$ is a martingale difference satisfying

$$\sum_{t=1}^{\infty}\frac{1}{t^2}E[v_t^2|\mathcal{F}_{t-1}] \le \sum_{t=1}^{\infty}\frac{1}{t^2}E[n_t^{2^{d+1}}|\mathcal{F}_{t-1}] < \infty,$$

due to Assumption 2.1. By applying Theorem 2.18 in [16], we then conclude that $\frac{1}{N}\sum_{t=0}^{N-1}[n_t^{2^d} - E[n_t^{2^d}|\mathcal{F}_{t-1}]]$ tends to zero, a.s. Since $\frac{1}{N}\sum_{t=0}^{N-1} E[n_t^{2^d}|\mathcal{F}_{t-1}]$ is bounded by Assumption 2.1, we finally have $\limsup_{N\to\infty}\frac{1}{N}\sum_{t=0}^{N-1} n_t^{2^d} < \infty$, a.s.

The term $\frac{1}{N}\sum_{t=0,t\notin\mathcal{B}_{N-1}}^{N-1} e_t^{2^d}$ is immediately bounded by means of (4.3) and the final bound for $\frac{1}{N}\sum_{t=1}^{N}\|x_t\|^{2^d}$ is obtained

$$\frac{1}{N}\sum_{t=1}^{N}\|x_t\|^{2^d} = O(1) + o\left(\frac{1}{N}\sum_{t=0}^{N-1}\|\varphi_t\|^{2^d}\right) \quad \text{a.s.}$$

Since $\frac{1}{N}\sum_{t=0}^{N-1}\|\varphi_t\|^{2^d} \le \frac{1}{N}\sum_{t=0}^{N}\|x_t\|^{2^d}$, this implies that $\frac{1}{N}\sum_{t=0}^{N-1}\|\varphi_t\|^{2^d}$ remains bounded. Then, the thesis immediately follows from the arbitrariness of d and the fact that $\frac{1}{N}\sum_{t=0}^{N-1}\|\varphi_t\|^{p} \le \frac{1}{N}\sum_{t=0}^{N-1}[\|\varphi_t\|^{2^d}+1]$, $p \le 2^d$. □

In the next theorem we show that the LQG adaptive control scheme is self-optimizing.

THEOREM 4.2 (optimality). *The adaptive LQG control scheme*

$$\begin{cases} y_{t+1} = [1-\mathcal{A}(\vartheta^\circ;q^{-1})]\,y_{t+1} + \mathcal{B}(\vartheta^\circ;q^{-1})\,u_t + n_{t+1}, \\ u_t = \mathcal{S}(\hat{\vartheta}_t;q^{-1})\,y_t + \mathcal{R}(\hat{\vartheta}_t;q^{-1})\,u_t \end{cases}$$

is self-optimizing: $\limsup_{N\to\infty}\frac{1}{N}\sum_{t=0}^{N-1}\left[y_t^2 + \beta\,u_t^2\right] = J^\star(\vartheta^\circ)$ a.s.

Proof. We start by showing that $x_t := [y_t \dots y_{t-(n-1)}\ u_{t-1} \dots u_{t-(m-1)}]^T$ satisfies the following equation:

$$\|x_t\|^p = o(t), \quad \forall p > 0, \quad \text{a.s.} \tag{4.9}$$

This condition will be useful in the subsequent derivations. By contradiction, suppose that there exist $\{t_k\}_{k\ge 0}$ and a real number $\eta > 0$, such that $\|x_{t_k}\| > \eta t_k\ \forall k$. Then

$$\limsup_{N\to\infty}\frac{1}{N}\sum_{t=1}^{N}\|x_t\|^{1+p} \ge \limsup_{k\to\infty}\frac{1}{t_k}\|x_{t_k}\|^{1+p} \ge \limsup_{k\to\infty}\frac{1}{t_k}\eta^{1+p}t_k^{1+p} = \infty,$$

which contradicts Theorem 4.1.

Observe now that the dynamic programming equation for the estimated model $x_{t+1} = A(\hat{\vartheta}_t)x_t + B(\hat{\vartheta}_t)u_t + Cn_{t+1}$ writes

$$\begin{aligned} J^\star(\hat{\vartheta}_t) + x_t^T P(\hat{\vartheta}_t)x_t = x_t^T T x_t + \beta u_t^2 + E\big[&(A(\hat{\vartheta}_t)x_t + B(\hat{\vartheta}_t)u_t + Cn_{t+1})^T \\ &P(\hat{\vartheta}_t)(A(\hat{\vartheta}_t)x_t + B(\hat{\vartheta}_t)u_t + Cn_{t+1})\,|\,\mathcal{F}_t\big], \end{aligned} \tag{4.10}$$

where $P(\vartheta)$ is the solution to the Riccati equation (2.4). By (2.1) and the definition (3.6), x_t can be given the following expression:

$$x_{t+1} = A(\hat{\vartheta}_t)x_t + B(\hat{\vartheta}_t)u_t + Cn_{t+1} + Ce_t. \tag{4.11}$$

Substituting (4.11) in (4.10), we then get

$$J^\star(\hat{\vartheta}_t) + x_t^T P(\hat{\vartheta}_t)x_t = x_t^T T x_t + \beta u_t^2 + E\big[(x_{t+1} - Ce_t)^T P(\hat{\vartheta}_t)(x_{t+1} - Ce_t) \,|\, \mathcal{F}_t\big],$$

from which

$$\begin{aligned}\frac{1}{N}\sum_{t=0}^{N-1} J^\star(\hat{\vartheta}_t) - \frac{1}{N}\sum_{t=0}^{N-1}[x_t^T T x_t + \beta u_t^2]&\\ = -\frac{1}{N}\sum_{t=0}^{N-1}&\Big[x_t^T P(\hat{\vartheta}_t)x_t - E\big[x_{t+1}^T P(\hat{\vartheta}_{t+1})x_{t+1} \,|\, \mathcal{F}_t\big]\Big]\\ +\frac{1}{N}\sum_{t=0}^{N-1}& E\big[x_{t+1}^T(P(\hat{\vartheta}_t) - P(\hat{\vartheta}_{t+1}))x_{t+1} \,|\, \mathcal{F}_t\big]\\ +\frac{1}{N}\sum_{t=0}^{N-1}& E\big[e_t^T C^T P(\hat{\vartheta}_t)Ce_t \,|\, \mathcal{F}_t\big]\\ -2\frac{1}{N}\sum_{t=0}^{N-1}& E\big[x_{t+1}^T P(\hat{\vartheta}_t)Ce_t \,|\, \mathcal{F}_t\big].\end{aligned} \tag{4.12}$$

From property (ii) in Theorem 3.2, we get $\limsup_{N\to\infty} \frac{1}{N}\sum_{t=0}^{N-1} J^\star(\hat{\vartheta}_t) \le J^\star(\vartheta^\circ)$ a.s. Therefore, the thesis will be proved if we show that all the terms in the right-hand side of (4.12) tend to zeros as $N \to \infty$. We shall study each term separately.

First term:

$$\begin{aligned}\frac{1}{N}\sum_{t=0}^{N-1}\Big[x_t^T P(\hat{\vartheta}_t)x_t - E\big[x_{t+1}^T P(\hat{\vartheta}_{t+1})x_{t+1} \,|\, \mathcal{F}_t\big]\Big] &= -\frac{1}{N}x_N^T P(\hat{\vartheta}_N)x_N\\ +\frac{1}{N}x_0^T P(\hat{\vartheta}_0)x_0 + \frac{1}{N}\sum_{t=0}^{N-1}&\Big[x_{t+1}^T P(\hat{\vartheta}_{t+1})x_{t+1} - E\big[x_{t+1}^T P(\hat{\vartheta}_{t+1})x_{t+1} \,|\, \mathcal{F}_t\big]\Big].\end{aligned}$$

The term $\frac{1}{N}x_0^T P(\hat{\vartheta}_0)x_0$ equals zero. As for $\frac{1}{N}x_N^T P(\hat{\vartheta}_N)x_N$, observe that

$$\frac{1}{N}x_N^T P(\hat{\vartheta}_N)x_N \le k_1\frac{1}{N}\|x_N\|^2,$$

k_1 being a suitable constant, since $P(\vartheta)$ is uniformly bounded on the compact set Θ (see Remark 2.3). Therefore, from (4.9) we get

$$\lim_{N\to\infty}\frac{1}{N}x_N^T P(\hat{\vartheta}_N)x_N = 0.$$

Define $w_t := x_{t+1}^T P(\hat{\vartheta}_{t+1})x_{t+1} - E\big[x_{t+1}^T P(\hat{\vartheta}_{t+1})x_{t+1} \,|\, \mathcal{F}_t\big]$. Then $\{w_t\}$ is a martingale difference. Hence, $\frac{1}{N}\sum_{t=0}^{N-1} w_t$ asymptotically vanishes if $\sum_{t=0}^{\infty}\frac{1}{t^2}E[w_{t+1}^2|\mathcal{F}_t] < \infty$ (see Theorem 2.18 in [16]). We have

$$E[w_{t+1}^2|\mathcal{F}_t] \le E\big[(x_{t+1}^T P(\hat{\vartheta}_{t+1})x_{t+1})^2|\, \mathcal{F}_t\big] \le k_2 E\big[\|x_{t+1}\|^4|\, \mathcal{F}_t\big] \le k_3\Big[\|x_t\|^4 + \|u_t\|^4 + 1\Big],$$

k_2, k_3 being suitable constants, since $P(\vartheta)$ is uniformly bounded over Θ and $\{n_t\}$ satisfies point 1 in Assumption 2.1. We then need to prove that $\sum_{t=0}^{\infty}\frac{1}{t^2}[\|x_t\|^4 + \|u_t\|^4] < \infty$. This is easily shown through (4.9) with $p = 8$, which implies $\|x_t\|^4 = o(t^{1/2})$ and $u_t^4 = o(t^{1/2})$, since $\sum_{t=0}^{\infty}\frac{1}{t^2}[\|x_t\|^4 + \|u_t\|^4] = \sum_{t=0}^{\infty}\frac{1}{t^{3/2}}\frac{1}{t^{1/2}}[\|x_t\|^4 + \|u_t\|^4]$, where $\sum_{t=0}^{\infty}\frac{1}{t^{3/2}}$ converges.

Second term:

Observe that $\{v_t\} := \{x_{t+1}^T(P(\hat{\vartheta}_t)-P(\hat{\vartheta}_{t+1}))x_{t+1}-E\big[x_{t+1}^T(P(\hat{\vartheta}_t)-P(\hat{\vartheta}_{t+1}))x_{t+1}|\,\mathcal{F}_t\big]\}$ is a martingale difference. By derivations similar to those for the first term, we can prove that $\frac{1}{N}\sum_{t=0}^{N} v_t \to 0$. Then

$$\lim_{N\to\infty}\frac{1}{N}\sum_{t=0}^{N-1} E\big[x_{t+1}^T(P(\hat{\vartheta}_t) - P(\hat{\vartheta}_{t+1}))x_{t+1}\,|\,\mathcal{F}_t\big] = 0$$

is proven by showing that

$$\lim_{N\to\infty}\frac{1}{N}\sum_{t=0}^{N-1} x_{t+1}^T(P(\hat{\vartheta}_t) - P(\hat{\vartheta}_{t+1}))x_{t+1} = 0. \tag{4.13}$$

To prove (4.13), apply the Schwarz inequality to obtain

$$\begin{aligned}\left|\frac{1}{N}\sum_{t=0}^{N-1} x_{t+1}^T(P(\hat{\vartheta}_t) - P(\hat{\vartheta}_{t+1}))x_{t+1}\right| &\le \frac{1}{N}\sum_{t=0}^{N-1}\|P(\hat{\vartheta}_t) - P(\hat{\vartheta}_{t+1})\|\,\|x_{t+1}\|^2\\ &\le \left(\frac{1}{N}\sum_{t=0}^{N-1}\|P(\hat{\vartheta}_t) - P(\hat{\vartheta}_{t+1})\|^2\right)^{\frac{1}{2}}\left(\frac{1}{N}\sum_{t=0}^{N-1}\|x_{t+1}\|^4\right)^{\frac{1}{2}}.\end{aligned}$$

By Theorem 4.1 $\frac{1}{N}\sum_{t=0}^{N-1}\|x_{t+1}\|^4$ is bounded. Moreover, $\lim_{N\to\infty}\frac{1}{N}\sum_{t=0}^{N-1}\|P(\hat{\vartheta}_t) - P(\hat{\vartheta}_{t+1})\|^2 = 0$ because of property (iii) in Theorem 3.2 and the Lipschitz continuity of $P(\vartheta)$ over Θ ($P(\vartheta)$ is analytic on Θ and Θ is compact). This concludes the proof of (4.13).

Third term:

Since $\hat{\vartheta}_t \in \Theta$ and $P(\vartheta)$ is uniformly bounded on Θ, then

$$0 \le \frac{1}{N}\sum_{t=0}^{N-1} E\big[e_t^T C^T P(\hat{\vartheta}_t)Ce_t\,|\,\mathcal{F}_t\big] = \frac{1}{N}\sum_{t=0}^{N-1} e_t^T C^T P(\hat{\vartheta}_t)Ce_t \le h_1\frac{1}{N}\sum_{t=0}^{N-1} e_t^2,$$

h_1 being a suitable constant. We now show that

$$\lim_{N\to\infty}\frac{1}{N}\sum_{t=0}^{N-1} e_t^2 = 0 \quad \text{a.s.} \tag{4.14}$$

From Proposition 3.3 it follows that there exists a set of instant points $\mathcal{B}_{N-1}$ whose cardinality is upper bounded by a constant $C_{\mathcal{B}} < \infty$ such that $\frac{1}{N}\sum_{t=0,\ t\notin\mathcal{B}_{N-1}}^{N-1} e_t^2 = \frac{1}{N}o(\sum_{t=0}^{N-1}\|\varphi_t\|^2)$ a.s. Then, recalling the definition (3.6) of e_t, we have

$$\frac{1}{N}\sum_{t=0}^{N-1} e_t^2 = \frac{1}{N}o\left(\sum_{t=0}^{N-1}\|\varphi_t\|^2\right) + \frac{1}{N}\sum_{t\in\mathcal{B}_{N-1}}|\varphi_t^T(\vartheta^\circ - \hat{\vartheta}_t)|^2.$$

By Theorem 4.1, the first term tends to zero. As for the second term, we have that it can be upper bounded as follows:

$$\frac{1}{N}\sum_{t\in\mathcal{B}_{N-1}}|\varphi_t^T(\vartheta^\circ-\hat{\vartheta}_t)|^2\le h_2\,C_{\mathcal{B}}\frac{1}{N}\max_{0\le t\le N-1}\|\varphi_t\|^2,\quad h_2=\text{suitable constant,}$$

since $\hat{\vartheta}_t$ is bounded uniformly in time. Noting that $\|\varphi_t\|^2\le\|x_{t+1}\|^2+\|x_t\|^2$, from (4.9) we get

$$\|\varphi_t\|^2=o(t)\quad\text{a.s.,}\tag{4.15}$$

which implies $\frac{1}{N}\max_{0\le t\le N-1}\|\varphi_t\|^2\to 0$.

Fourth term:

$$\begin{aligned}\frac{1}{N}\sum_{t=0}^{N-1}&E\big[x_{t+1}^TP(\hat{\vartheta}_t)Ce_t\,|\,\mathcal{F}_t\big]\\&=\frac{1}{N}\sum_{t=0}^{N-1}E\big[(A(\vartheta^\circ)x_t+B(\vartheta^\circ)u_t+Cn_{t+1})^TP(\hat{\vartheta}_t)Ce_t\,|\,\mathcal{F}_t\big]\\&=\frac{1}{N}\sum_{t=0}^{N-1}x_t^TA(\vartheta^\circ)^TP(\hat{\vartheta}_t)Ce_t+\frac{1}{N}\sum_{t=0}^{N-1}u_t^TB(\vartheta^\circ)^TP(\hat{\vartheta}_t)Ce_t.\end{aligned}$$

We next show that each term on the right-hand side goes to zero as N tends to infinity.

Since $\hat{\vartheta}_t\in\Theta$, with Θ compact, and $P(\vartheta)$ is analytic on Θ, by using Schwarz inequality, we have

$$\left|\frac{1}{N}\sum_{t=0}^{N-1}x_t^TA(\vartheta^\circ)^TP(\hat{\vartheta}_t)Ce_t\right|\le k\left(\frac{1}{N}\sum_{t=0}^{N-1}\|x_t\|^2\right)^{\frac{1}{2}}\left(\frac{1}{N}\sum_{t=0}^{N-1}e_t^2\right)^{\frac{1}{2}}.$$

Then $\lim_{N\to\infty}\frac{1}{N}\sum_{t=0}^{N-1}x_t^TA(\vartheta^\circ)^TP(\hat{\vartheta}_t)Ce_t=0$ a.s. follows from Theorem 4.1 and (4.14).

Similarly, one can prove that $\lim_{N\to\infty}\frac{1}{N}\sum_{t=0}^{N-1}u_t^TB(\vartheta^\circ)^TP(\hat{\vartheta}_t)Ce_t=0$ a.s. □

5. Conclusions. The more commonly adopted strategy for the design of adaptive control laws is the certainty equivalence approach. Although the approach is conceptually simple, working out stability and optimality results for certainty equivalence adaptive control schemes is a difficult task even in the ideal case when the true system belongs to the model class. This is due to the intricate interaction between control and identification in closed-loop, which can cause identifiability problems.

We introduced a new LQG adaptive control scheme based on the certainty equivalence principle able to ensure both stability and optimality results irrespectively of the excitation characteristics of the involved signals by adopting a cost-biased approach.

This paper presents the following limitations:

- *the true system is described as an ARX system subject to white noise.* This hypothesis is necessary mainly for the applicability of the proposed cost-biased LS identification method, whose properties are in fact derived on the basis of the LS estimate properties. As a consequence of this fact, the extension to the ARMAX system case is not straightforward.

- *the proposed identification method is nonrecursive.* The cost-biased identification index has, in general, multiple local minima and its minimization is not straightforward. Therefore, it should be minimized by resorting to some global optimization algorithm (see, e.g., [30, 31, 4, 15]). This limitation must be removed by introducing some recursive way to minimize our performance index so as to retain all the properties relevant to control.

These problems constitute interesting research issues. In particular, inspired by the result obtained for the white noise case, one can conceive of introducing appropriate cost-biased identification algorithms for the colored noise case. In this regard, much work has to be done, but an encouraging starting point is represented by the fact that the extended LS algorithm satisfies closed-loop properties similar to those valid for the LS algorithm (see, e.g., [10]).

Appendix. Proofs of the results in section 3.

Proof of Proposition 3.1. Recall that $\hat{\vartheta}_t \in \Theta$, $t \geq 0$, where Θ is compact and is such that all the parametrizations in Θ correspond to stabilizable models. We start by proving that $T(\vartheta) := \inf\{\tau \in Z_+ : \|F(\vartheta)^\tau\| \leq \mu\}$ is uniformly bounded in the compact set Θ, i.e., $\sup_{\vartheta \in \Theta} T(\vartheta) < \infty$.

Condition $\vartheta \in \Theta$ implies that the system $\mathcal{A}(\vartheta; q^{-1}) y_{t+1} = \mathcal{B}(\vartheta; q^{-1}) u_t$ associated with parameter ϑ is stabilizable and therefore stabilized by the control law $u_t = \mathcal{S}(\vartheta; q^{-1}) y_t + \mathcal{R}(\vartheta; q^{-1}) u_t$. From this it follows that the dynamic matrix $F(\vartheta)$ of the time-invariant system

$$x_{t+1} = F(\vartheta) x_t \tag{A.1}$$

is exponentially stable.

Denote by $\{\lambda_i(\vartheta)\}_{i=1,\ldots,n+m-1}$ the eigenvalues of $F(\vartheta)$.

By the observation that $F(\vartheta)$ is a continuous function of ϑ, $\mathcal{C} = \{\vartheta \in \Re^{n+m} : q^s \mathcal{A}(\vartheta; q^{-1})$ and $q^{s-1} \mathcal{B}(\vartheta; q^{-1})$ have no unstable pole-zero cancellations$\}$, we have that $\bar{\lambda}(\vartheta) := \max_{i \in \{1,\ldots,n+m-1\}} |\lambda_i(\vartheta)|$ is also a continuous function of ϑ, $\vartheta \in \mathcal{C}$. Being Θ compact and included in $\mathcal{C}$, the conclusion is finally drawn that

$$\bar{\lambda} := \max_{\vartheta \in \Theta} \bar{\lambda}(\vartheta) < 1.$$

Fix now a real number $\bar{\nu} \in (\bar{\lambda}, 1)$ and introduce the system

$$w_{t+1} = \frac{1}{\bar{\nu}} F(\vartheta)\, w_t. \tag{A.2}$$

System (A.2) is exponentially stable $\forall \vartheta \in \Theta$, since $|\frac{\lambda_i(\vartheta)}{\bar{\nu}}| \leq \frac{\bar{\lambda}}{\bar{\nu}} < 1$ $\forall i$, $\forall \vartheta \in \Theta$. Hence, the solution $S(\vartheta)$ to the Lyapunov equation associated with matrix $\frac{1}{\bar{\nu}} F(\vartheta)$

$$\frac{1}{\bar{\nu}} F(\vartheta)^T\, S(\vartheta)\, \frac{1}{\bar{\nu}} F(\vartheta) - S(\vartheta) = -I$$

is positive definite. Moreover, it is a standard fact that the state vector w_t of system (A.2) can be bounded as follows in terms of $S(\vartheta)$:

$$\|w_t\| \leq \sqrt{\frac{\lambda_{max}(S(\vartheta))}{\lambda_{min}(S(\vartheta))}}\, \|\, w_{t^\star}\|, \;\; t \geq t^\star \geq 0, \tag{A.3}$$

where $\lambda_{max}(S(\vartheta))$ and $\lambda_{min}(S(\vartheta))$ are, respectively, the maximum and minimum eigenvalues of $S(\vartheta)$. Since $S(\vartheta)$ is continuous in the closed set Θ (see [12]), we can define $c := \max_{\vartheta\in\Theta} \sqrt{\frac{\lambda_{max}(S(\vartheta))}{\lambda_{min}(S(\vartheta))}}$ and rewrite inequality (A.3) as $\|w_t\| \le c\,\|w_{t^\star}\|,\ \ t \ge\ t^\star$ $\forall\,\vartheta \in \Theta$. Setting $w_{t^\star} = x_{t^\star}$, we finally get a bound on the state vector x_t of the time-invariant system (A.1)

$$\|x_t\| \le c\,\bar\nu^{t-t^\star}\|x_{t^\star}\|, \quad t \ge t^\star, \forall\,\vartheta \in \Theta. \tag{A.4}$$

Set $\bar T = \inf\{\tau \in Z_+ : c\,\bar\nu^\tau \le \mu\} < \infty$. Since $\|x_{\bar T+t^\star}\| = \|F(\vartheta)^{\bar T} x_{t^\star}\| \le \mu\|x_{t^\star}\|$ $\forall\,\vartheta \in \Theta$, $\forall\, x_{t^\star}$, then $\|F(\vartheta)^{\bar T}\| = \sup_{\|x\|\neq 0} \frac{\|F(\vartheta)^{\bar T} x\|}{\|x\|} \le \mu\ \forall\,\vartheta \in \Theta$, and therefore $T(\vartheta) = \inf\{\tau \in Z_+ : \|F(\vartheta)^\tau\| \le \mu\}$ satisfies $T(\vartheta) \le \bar T\ \forall\,\vartheta \in \Theta$. This finally implies that

$$\sup_{\vartheta\in\Theta}\{T(\vartheta)\} \le \bar T < \infty. \tag{A.5}$$

Let us turn now to considering the time-varying system $x_{t+1} = F(\hat\vartheta_t)\,x_t$.

Being $\hat\vartheta_t \in \Theta$, $t \ge 0$, from (A.5) it follows that the updating time interval T_i in (3.4) is uniformly bounded:

$$T := \sup_{i\ge 0} T_i < \bar T. \tag{A.6}$$

We are now in a position to establish the uniform exponential stability. We apply (A.4) to the state vector x_t on each finite time interval $[t_i, t_{i+1}]$, thus getting

$$\|x_t\| \le c\,\bar\nu^{t-t^\star}\|x_{t^\star}\|, \ \ t_i \le t^\star \le t \le t_{i+1}. \tag{A.7}$$

If we choose $t^\star = t_i$, we have $\|x_t\| \le c\,\bar\nu^{t-t_i}\|x_{t_i}\|,\ \ t \in [t_i, t_{i+1}]$. From the definition (3.4) of $\{T_k\}$, it follows that $\|x_{t_i}\| \le \mu^{i-j}\|x_{t_j}\|,\ \ j \le i$. By applying (A.7) in the time interval $[t_{j-1}, t_j]$ with $t = t_j$, we get $\|x_{t_j}\| \le c\,\bar\nu^{t_j-t^\star}\|x_{t^\star}\|,\ \ t^\star \in [t_{j-1}, t_j]$. These last three inequalities lead to

$$\|x_t\| \le c\,\bar\nu^{t-t_i}\mu^{i-j}\,c\,\bar\nu^{t_j-t^\star}\|x_{t^\star}\|,\ \ t_{j-1} \le t^\star \le t_j \le t_i \le t \le t_{i+1},\ \ j \le i.$$

By setting $\nu = \max\{\bar\nu, \mu^{\frac{1}{T}}\} < 1$, we have that $\mu \le \nu^{T_k}\ \forall k$ and therefore

$$\begin{aligned}\|x_t\| &\le c^2\,\nu^{t-t_i}\nu^{t_i-t_{i-1}}\dots\nu^{t_{j+1}-t_j}\nu^{t_j-t^\star}\|x_{t^\star}\| \\ &= c^2\,\nu^{t-t^\star}\|x_{t^\star}\|,\ \ t_{j-1} \le t^\star \le t_j \le t_i \le t \le t_{i+1}.\end{aligned}$$

Finally, from this last inequality and inequality (A.7), we get $\|x_t\| \le c^2\,\nu^{t-t^\star}\|x_{t^\star}\|$, $t^\star \le t$, i.e., the thesis.

Proof of Theorem 3.2. Point (i): $D_t(\vartheta) - V_t(\hat\vartheta_t^{LS})$ can be written as follows:

$$\begin{aligned}D_t(\vartheta) - V_t(\hat\vartheta_t^{LS}) &= \sum_{s=1}^t (y_s - \varphi_{s-1}^T\vartheta)^2 + \alpha_t J^\star(\vartheta) + \gamma_t\|\vartheta - \hat\vartheta_{t-1}\| - \sum_{s=1}^t (y_s - \varphi_{s-1}^T\hat\vartheta_t^{LS})^2 \\ &= \vartheta^T\sum_{s=1}^t \varphi_{s-1}\varphi_{s-1}^T\vartheta - 2\vartheta^T\sum_{s=1}^t \varphi_{s-1}y_s + \alpha_t J^\star(\vartheta) + \gamma_t\|\vartheta - \hat\vartheta_{t-1}\| \\ &\quad -(\hat\vartheta_t^{LS})^T\sum_{s=1}^t \varphi_{s-1}\varphi_{s-1}^T\hat\vartheta_t^{LS} + 2(\hat\vartheta_t^{LS})^T\sum_{s=1}^t \varphi_{s-1}y_s.\end{aligned} \tag{A.8}$$

The LS estimate $\hat{\vartheta}_t^{LS}$ minimizing $V_t(\vartheta)$ satisfies the following equality:

$$\sum_{s=1}^{t} \varphi_{s-1} y_s = \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T \hat{\vartheta}_t^{LS}.$$

Substituting this last expression in (A.8), we obtain

$$D_t(\vartheta) - V_t(\hat{\vartheta}_t^{LS}) = (\vartheta - \hat{\vartheta}_t^{LS})^T \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T (\vartheta - \hat{\vartheta}_t^{LS}) + \alpha_t J^\star(\vartheta) + \gamma_t \|\vartheta - \hat{\vartheta}_{t-1}\|. \tag{A.9}$$

Set $\vartheta_t := \arg\min_{\vartheta \in \Theta} D_t(\vartheta)$. By definition of ϑ_t we have

$$D_t(\vartheta_t) - V_t(\hat{\vartheta}_t^{LS}) \leq D_t(\vartheta) - V_t(\hat{\vartheta}_t^{LS}), \quad \vartheta \in \Theta.$$

By choosing $\vartheta = \vartheta^\circ$ and using expression (A.9), we then get

$$\begin{aligned} &(\vartheta_t - \hat{\vartheta}_t^{LS})^T \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T (\vartheta_t - \hat{\vartheta}_t^{LS}) + \alpha_t J^\star(\vartheta_t) + \gamma_t \|\vartheta_t - \hat{\vartheta}_{t-1}\| \\ &\leq (\vartheta^\circ - \hat{\vartheta}_t^{LS})^T \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T (\vartheta^\circ - \hat{\vartheta}_t^{LS}) + \alpha_t J^\star(\vartheta^\circ) + \gamma_t \|\vartheta^\circ - \hat{\vartheta}_{t-1}\| \\ &= O(\alpha_t) \quad \text{a.s.,} \end{aligned} \tag{A.10}$$

where the last equality follows from Theorem 2.4, the definition (3.5) of α_t, the fact that $\|\vartheta^\circ - \hat{\vartheta}_{t-1}\|$ is bounded, and the relation $\gamma_t = o(\alpha_t)$. Since $\alpha_t J^\star(\vartheta_t) + \gamma_t \|\vartheta_t - \hat{\vartheta}_{t-1}\| \geq 0$, we have $(\vartheta_t - \hat{\vartheta}_t^{LS})^T \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T (\vartheta_t - \hat{\vartheta}_t^{LS}) = O(\alpha_t)$ a.s. From definition (3.5) of α_t and Theorem 2.4, we then have

$$\begin{aligned} (\vartheta_t - \vartheta^\circ)^T \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T (\vartheta_t - \vartheta^\circ) &\leq 2\Big[(\vartheta_t - \hat{\vartheta}_t^{LS})^T \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T (\vartheta_t - \hat{\vartheta}_t^{LS}) \\ &\quad + (\hat{\vartheta}_t^{LS} - \vartheta^\circ)^T \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T (\hat{\vartheta}_t^{LS} - \vartheta^\circ)\Big] \\ &= O(\alpha_t) \text{ a.s.,} \end{aligned}$$

thus concluding the proof of point (i), since $\hat{\vartheta}_t = \vartheta_t$, for $t = t_i$, $i = 0, 1, \ldots$.

Point (ii): A simple elaboration of (A.10) shows that

$$\begin{aligned} J^\star(\vartheta_t) &\leq \frac{(\vartheta^\circ - \hat{\vartheta}_t^{LS})^T \sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T (\vartheta^\circ - \hat{\vartheta}_t^{LS})}{\alpha_t} + J^\star(\vartheta^\circ) + \frac{\gamma_t}{\alpha_t} \|\vartheta^\circ - \hat{\vartheta}_{t-1}\| \\ &= \frac{O(\log \lambda_{max}(\sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T))}{\log^{1+\delta} \lambda_{max}(\sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T)} + \frac{o(\alpha_t)}{\alpha_t} + J^\star(\vartheta^\circ) \text{ a.s.,} \end{aligned}$$

where in the second equation we have used the definition of α_t given in equation (3.5) and the fact that $\gamma_t = o(\alpha_t)$. To conclude the proof, it suffices to show that $\lim_{t \to \infty} \log \lambda_{max}(\sum_{s=1}^{t} \varphi_{s-1} \varphi_{s-1}^T) = \infty$. The easy proof of this fact is omitted.

Point (iii): By the definition (2.8) of $\hat{\vartheta}_t$, we have

$$V_t(\hat{\vartheta}_t) + \alpha_t J^\star(\hat{\vartheta}_t) + \gamma_t \|\hat{\vartheta}_t - \hat{\vartheta}_{t-1}\| \leq V_t(\hat{\vartheta}_{t-1}) + \alpha_t J^\star(\hat{\vartheta}_{t-1}),$$

which implies

$$\text{(A.11)} \quad \sum_{t=1}^{N} \gamma_t \|\hat{\vartheta}_t - \hat{\vartheta}_{t-1}\| \leq \sum_{t=1}^{N} [V_t(\hat{\vartheta}_{t-1}) - V_t(\hat{\vartheta}_t)] + \sum_{t=1}^{N} \alpha_t [J^\star(\hat{\vartheta}_{t-1}) - J^\star(\hat{\vartheta}_t)].$$

The first term in the right-hand side of (A.11) can be bounded as follows:

$$\begin{aligned} \sum_{t=1}^{N} [V_t(\hat{\vartheta}_{t-1}) - V_t(\hat{\vartheta}_t)] &\leq V_1(\hat{\vartheta}_0) - V_N(\hat{\vartheta}_N) + \sum_{t=1}^{N-1} [V_{t+1}(\hat{\vartheta}_t) - V_t(\hat{\vartheta}_t)] \\ &\leq V_1(\hat{\vartheta}_0) + \sum_{t=1}^{N-1} [\varphi_t^T(\vartheta^\circ - \hat{\vartheta}_t) + n_{t+1}]^2 \\ &\leq V_1(\hat{\vartheta}_0) + 2\sum_{t=1}^{N-1} [\varphi_t^T(\vartheta^\circ - \hat{\vartheta}_t)]^2 + 2\sum_{t=1}^{N-1} n_{t+1}^2 \\ &\leq k_1 \left[1 + \sum_{t=1}^{N} \|\varphi_{t-1}\|^2 + \sum_{t=1}^{N-1} n_{t+1}^2 \right], \end{aligned}$$

k_1 being a suitable constant, where we used the boundedness of $\hat{\vartheta}_t$.

By Remark 2.3, the second term in the right-hand side of (A.11) can be bounded as follows:

$$\begin{aligned} \sum_{t=1}^{N} \alpha_t [J^\star(\hat{\vartheta}_{t-1}) - J^\star(\hat{\vartheta}_t)] &= \alpha_1 J^\star(\hat{\vartheta}_0) - \alpha_N J^\star(\hat{\vartheta}_N) + \sum_{t=1}^{N-1} (\alpha_{t+1} - \alpha_t) J^\star(\hat{\vartheta}_t) \\ &\leq \alpha_1 J^\star(\hat{\vartheta}_0) + \max_{\vartheta \in \Theta} J^\star(\vartheta) \sum_{t=1}^{N-1} (\alpha_{t+1} - \alpha_t) \\ &= k_2[1 + \alpha_N], \end{aligned}$$

where k_2 is a suitable constant.

Substituting these bounds in (A.11), we then have

$$\text{(A.12)} \quad \frac{1}{N} \sum_{t=1}^{N} \gamma_t \|\hat{\vartheta}_t - \hat{\vartheta}_{t-1}\| \leq \bar{k} \left[\frac{1}{N} + \frac{\alpha_N}{N} + \frac{1}{N} \sum_{t=1}^{N} \|\varphi_{t-1}\|^2 + \frac{1}{N} \sum_{t=1}^{N-1} n_{t+1}^2 \right],$$

with $\bar{k}$ = suitable constant. Observe now that all the terms in the right-hand side of (A.12) are $O(1)$. This, in particular, follows from the assumption of point (iii) in Theorem 3.2 that $\sum_{t=1}^{N} \|\varphi_{t-1}\|^2 = O(N)$ and Assumption 2.1, point 2. Then $\frac{1}{N} \sum_{t=1}^{N} \gamma_t \|\hat{\vartheta}_t - \hat{\vartheta}_{t-1}\| = O(1)$. Since γ_t tends to infinity, this last equation implies $\frac{1}{N} \sum_{t=1}^{N} \|\hat{\vartheta}_t - \hat{\vartheta}_{t-1}\| = o(1)$, that is, the thesis.

Proof of Proposition 3.3. Fix a real number $\epsilon > 0$ and a time instant N. Consider the set of instant points in the interval $[0, N]$ where $\tilde{\vartheta}_t := \vartheta^\circ - \hat{\vartheta}_t$ changes: $t_0, t_1, \ldots, t_{i(N)}$, where $i(N) := \max\{i : t_i \leq N\}$. In these instant points we define a set of subspaces $\{S_{t_i}\}_{i=0}^{i(N)}$ through the following backward recursive procedure:

for $i = i(N) + 1$, set $S_i = \emptyset$,

for $i = i(N), i(N) - 1, \ldots, 0$, set (here and throughout the symbol $\tilde{\vartheta}_{t,S}$ stands for the projection of vector $\tilde{\vartheta}_t$ onto the subspace S)

$$\text{(A.13)} \qquad S_{t_i} = \begin{cases} S_{t_{i+1}} & \text{if } \|\tilde{\vartheta}_{t_i, S_{t_{i+1}}^\perp}\| \leq \epsilon, \\ S_{t_{i+1}} \oplus span\{\tilde{\vartheta}_{t_i}\} & \text{otherwise.} \end{cases}$$

For each $t \in [0, N]$, with the notation $i(t) := \max\{i : t_i \leq t\}$, we have

$$|\varphi_t^T \tilde{\vartheta}_t|^p \leq c_p \, |\varphi^T_{t,S^\perp_{t_{i(t)}}} \tilde{\vartheta}_{t,S^\perp_{t_{i(t)}}}|^p + c_1 \, |\varphi^T_{t,S_{t_{i(t)}}} \tilde{\vartheta}_{t,S_{t_{i(t)}}}|^p, \tag{A.14}$$

where c_p is a suitable constant depending on p. By definition (A.13), the first term in the right-hand side can be upper bounded as follows:

$$|\varphi^T_{t,S^\perp_{t_{i(t)}}} \tilde{\vartheta}_{t,S^\perp_{t_{i(t)}}}|^p \leq \epsilon^p \|\varphi_t\|^p. \tag{A.15}$$

To handle the second term, we first work out a basis in $S_{t_{i(t)}}$. For this purpose, consider the subset $\{\tau_j\}_{j=1}^{dim(S_{t_0})}$ of instant points $\{t_i\}_{i=0}^{i(N)}$ such that subspace S_{t_i} enlarges: $S_{\tau_j} \supset S_{t_i}$, $t_i > \tau_j$. The searched basis is $\{\tilde{\vartheta}_{\tau_j}\}_{j=dim(S_{t_0})-dim(S_{t_{i(t)}})+1}^{dim(S_{t_0})}$.

In view of the uniform boundedness of $\tilde{\vartheta}_t$ and also considering the very definition of subspaces S_{t_i} (equation (A.13)), it is easy to see that vectors $\{\tilde{\vartheta}_{\tau_j}\}$ are spread in subspace $S_{t_{i(t)}}$ in such a way that the angle between each pair of vectors tends to zero only when $\epsilon \to 0$. Consequently, there exists a constant $c(\epsilon)$, depending on ϵ, but independent of N, such that term $|\varphi^T_{t,S_{t_{i(t)}}} \tilde{\vartheta}_{t,S_{t_{i(t)}}}|^p$ in the right-hand side of inequality (A.14) can be bounded as follows:

$$\begin{aligned} |\varphi^T_{t,S_{t_{i(t)}}} \tilde{\vartheta}_{t,S_{t_{i(t)}}}|^p &\leq \Delta^p \|\varphi_{t,S_{t_{i(t)}}}\|^p \\ &\leq \Delta^p c(\epsilon) \sum_{j=dim(S_{t_0})-dim(S_{t_{i(t)}})+1}^{dim(S_{t_0})} \|\varphi_{t,span\{\tilde{\vartheta}_{\tau_j}\}}\|^p, \end{aligned} \tag{A.16}$$

where $\Delta = \max_{\vartheta_1,\vartheta_2 \in \Theta} \|\vartheta_1 - \vartheta_2\|$.

By plugging estimates (A.15) and (A.16) in (A.14), we obtain

$$|\varphi_t^T \tilde{\vartheta}_t|^p \leq c_p \epsilon^p \|\varphi_t\|^p + c_p \, \Delta^p \, c(\epsilon) \sum_{j=dim(S_{t_0})-dim(S_{t_{i(t)}})+1}^{dim(S_{t_0})} \|\varphi_{t,span\{\tilde{\vartheta}_{\tau_j}\}}\|^p.$$

Summing up these relations from time $t = 0$ to $t = N$, we finally have

$$\sum_{t=0}^N |\varphi_t^T \tilde{\vartheta}_t|^p \leq c_p \epsilon^p \sum_{t=0}^N \|\varphi_t\|^p + c_p \, \Delta^p \, c(\epsilon) \sum_{t=0}^N \sum_{j=dim(S_{t_0})-dim(S_{t_{i(t)}})+1}^{dim(S_{t_0})} \|\varphi_{t,span\{\tilde{\vartheta}_{\tau_j}\}}\|^p. \tag{A.17}$$

Introduce now the time-varying set of instant points

$$\mathcal{B}_N := \cup_{j=1}^{dim(S_{t_0})} \{\tau_j, \tau_j + 1, \ldots, \tau_j + T - 1\},$$

where $T := \sup_{i \geq 0} T_i < \infty$ (see (A.6) in the proof of Proposition 3.1). Since $\dim(S_{t_0}) \leq n + m$, we obviously have $|\mathcal{B}_N| \leq T(n + m)$.

Then

$$\sum_{t=0,\, t \notin \mathcal{B}_N}^N \sum_{j=dim(S_{t_0})-dim(S_{t_{i(t)}})+1}^{dim(S_{t_0})} \|\varphi_{t,span\{\tilde{\vartheta}_{\tau_j}\}}\|^p \leq \sum_{j=1}^{dim(S_{t_0})} \sum_{t=0}^{\tau_j - 1} \|\varphi_{t,span\{\tilde{\vartheta}_{\tau_j}\}}\|^p.$$

We now show that

$$\text{(A.18)} \qquad \sum_{t=0}^{t_i-1} |\varphi_t^T \tilde{\vartheta}_{t_i}|^p = o\left(\sum_{t=0}^{t_i-1} \|\varphi_t\|^p\right) \quad \text{a.s.},$$

from which it follows that

$$\sum_{t=0,\ t\not\in\mathcal{B}_N}^{N} \ \sum_{j=dim(S_{t_0})-dim(S_{t_{i(t)}})+1}^{dim(S_{t_0})} \|\varphi_{t,span\{\tilde{\vartheta}_{\tau_j}\}}\|^p \leq \frac{n+m}{\epsilon^p}\left[o\left(\sum_{t=0}^{N}\|\varphi_t\|^p\right) + O(1)\right],$$
(A.19)

where we used the fact that $\dim(S_{t_0}) \leq n+m\ \forall N$.

Observe first that

$$\text{(A.20)} \qquad \sum_{t=0}^{t_i-1} \|\varphi_t\|^2 = O\left(\sum_{t=0}^{t_i-1} \|\varphi_t\|^p\right) \quad \text{a.s.}$$

Indeed, using Jensen's inequality [11, Corollary 1 in section 4.3])

$$\begin{aligned}\sum_{t=0}^{t_i-1} \|\varphi_t\|^2 &= t_i\left[\left(\frac{1}{t_i}\sum_{t=0}^{t_i-1}\|\varphi_t\|^2\right)^{p/2}\right]^{2/p} \\ &\leq t_i\left[\frac{1}{t_i}\sum_{t=0}^{t_i-1}\|\varphi_t\|^p\right]^{2/p} = \sum_{t=0}^{t_i-1}\|\varphi_t\|^p\left[\frac{t_i}{\sum_{t=0}^{t_i-1}\|\varphi_t\|^p}\right]^{1-2/p},\end{aligned}$$

where

$$\text{(A.21)} \qquad \limsup_{i\to\infty} \frac{t_i}{\sum_{t=0}^{t_i-1}\|\varphi_t\|^p} < \infty \quad \text{a.s.}$$

This last equation is easily derived as follows. From the regression-like form $y_t = \varphi_{t-1}^T\vartheta^\circ + n_t$, it follows that $|n_t|^p \leq 2^{p-1}\max\{\|\vartheta^\circ\|,1\}[\,|y_t|^p + \|\varphi_{t-1}\|^p\,]$. Taking into account that the autoregressive part of system is not trivial ($n>0$), this in turn implies that $|n_t|^p \leq h_1[\,\|\varphi_t\|^p + \|\varphi_{t-1}\|^p\,]$, from which it is easily shown that $\sum_{t=1}^{N-1}|n_t|^p \leq h_1\sum_{t=0}^{N-1}\|\varphi_t\|^p$, where h_1 is a suitable constant. Since $\frac{1}{N}\sum_{t=1}^{N-1}|n_t|^p \geq [\frac{1}{N}\sum_{t=0}^{N-1}n_t^2]^{p/2}$ (using Jensen's inequality), from Assumption 2.1, we then get

$$\limsup_{N\to\infty}\frac{1}{N}\sum_{t=0}^{N-1}\|\varphi_t\|^p > 0 \quad \text{a.s.},$$

from which (A.21) follows.

By means of (A.20), we now show that $\sum_{t=0}^{t_i-1}|\varphi_t^T\tilde{\vartheta}_{t_i}|^p = o(\sum_{t=0}^{t_i-1}\|\varphi_t\|^p)$ a.s., which implies (A.18). This equation is easily derived from property (i) in Theorem 3.2

as follows:

$$\begin{aligned}\sum_{t=0}^{t_i-1} |\varphi_t^T \tilde{\vartheta}_{t_i}|^p &\leq \left| \sum_{t=0}^{t_i-1} |\varphi_t^T(\vartheta^\circ - \vartheta_{t_i})|^2 \right|^{p/2} \\ &= o\left(\left(\operatorname{Log} \sum_{t=0}^{t_i-1} \|\varphi_t\| \right)^{p(1+\delta)/2} \right) \qquad \text{(by property (i))} \\ &= o\left(\sum_{t=0}^{t_i-1} \|\varphi_t\|^2 \right) \\ &= o\left(\sum_{t=0}^{t_i-1} \|\varphi_t\|^p \right) \qquad \text{(by (A.20)).}\end{aligned}$$

By using inequality (A.17) and inequality (A.19), we obtain

$$\begin{aligned}\sum_{t=0,\ t\notin \mathcal{B}_N}^{N} |\varphi_t^T \tilde{\vartheta}_t|^p &\leq c_p \epsilon^p \sum_{t=0}^{N} \|\varphi_t\|^p + c_p \Delta^p c(\epsilon) \frac{n+m}{\epsilon^p} \left[o\left(\sum_{t=0}^{N} \|\varphi_t\|^p \right) + O(1) \right] \\ &\leq c_p \epsilon^p O\left(\sum_{t=0}^{N} \|\varphi_t\|^p + N \right) + c_p \Delta^p c(\epsilon) \frac{n+m}{\epsilon^p} o\left(\sum_{t=0}^{N} \|\varphi_t\|^p + N \right),\end{aligned}$$

which finally implies that

$$\limsup_{N\to\infty} \frac{\displaystyle\sum_{t=0,\ t\notin \mathcal{B}_N}^{N} |\varphi_t^T \tilde{\vartheta}_t|^p}{\displaystyle\sum_{t=0}^{N} \|\varphi_t\|^p + N} \leq c_p \epsilon^p.$$

Since ϵ is arbitrarily chosen, the thesis follows.

ZERO-SUM STOCHASTIC GAMES IN BOREL SPACES: AVERAGE PAYOFF CRITERIA*

ONÉSIMO HERNÁNDEZ-LERMA[†] AND JEAN B. LASSERRE[‡]

Abstract. This paper is concerned with two-person zero-sum dynamic stochastic games in Borel spaces, with possibly unbounded payoff function, and several average (or ergodic) payoff criteria. We give conditions under which the long-run *expected average* payoff criterion, the *sample-path average* criterion, the existence of solutions to the average payoff *Shapley equations*, and a certain *"martingale condition"* are all equivalent.

Key words. zero-sum stochastic games, Borel spaces, expected average payoff, sample-path average payoff, Shapley equations

1. Introduction.

In this paper we study noncooperative, discrete-time, two-person zero-sum stochastic games in Borel spaces with possibly unbounded payoff function. We consider three average (or ergodic) payoff criteria: the long-run *expected average payoff* (EAP), the *sample-path average payoff* (SPAP), and the existence of *canonical pairs* of stationary strategies, by which we mean a pair of strategies that satisfy the *Shapley equations* for the average payoff criterion (see Definition 4.3). We give conditions under which these criteria are all equivalent and also equivalent to a certain "martingale condition" (Theorem 5.9(c)).

This equivalence is not obvious at all. For instance, there are well-known counterexamples (e.g., [4]) showing that EAP optimality (Definition 4.1) does *not* imply the existence of solutions to the Shapley equation. Similarly, the comparison—not to mention the *equivalence*—between EAP optimality and SPAP optimality (Definition 4.2) is not quite straightforward, not even in the case of a bounded payoff function or for *Markov control processes* (MCPs), which correspond to the one-player case (see Remark 5.11).

The average payoff criteria have been widely studied for finite or countable state spaces (see, for instance, [1, 3, 6, 24, 26] and their references), but for *uncountable* spaces they are restricted to just a few publications, for instance, [7, 16, 17, 18, 21, 22, 25]. In the latter case, which is the one we are interested in, one can distinguish two main approaches: the "contraction" and the "vanishing discount" approaches. In the former, the idea is to impose conditions to ensure that Fan's minimax operator (see (4.15)) is a contraction map in some norm. This has been done in [7, 22, 25] using the "span" seminorm (see also section 3.3 in [9] for the one-player case), which requires the immediate payoff function to be *bounded*, and in [18] (see also [1, 24]) using the weighted w-norm in (5.2) below. The second, "vanishing discount," approach is used

in [21]. Here we use a *third approach* to obtain the Shapley equation, which is roughly related to the "policy iteration" (or Howard's) algorithm for MCPs.

At any rate, a common feature to all these works and ours is that they all require strong ergodicity conditions. For instance, the hypotheses in [7, 22, 25] guarantee geometric ergodicity in the *total variation* norm, whereas in [1, 18, 21, 24] this kind of ergodicity is with respect to a *weighted* w-*norm* (see (5.3) and (5.4)). This w-norm is of common use to analyze MCPs—see, for example, [8, 11, 12, 13, 14, 19] and their references.

The remainder of the paper is organized as follows. Sections 2 and 3 introduce standard material on stochastic games and strategies, respectively. The optimality criteria we are concerned with are presented in section 4. The core of the paper is contained in section 5: after introducing some assumptions, we present our main results on the *equivalence* of EAP optimality, the existence of "canonical pairs" of strategies (Theorem 5.8), a certain martingale condition (Theorem 5.9), and SPAP optimality (Theorem 5.10). These results are specialized in the obvious manner to MCPs (Corollary 5.12). Finally, after some technical preliminaries in section 6, the proofs of Theorems 5.8, 5.9, and 5.10 are presented in sections 7, 8, and 9, respectively.

2. The game model. In this section we introduce the (discrete-time, time-homogeneous) two-person zero-sum stochastic game model we are interested in. We begin by introducing the following terminology and notation—for further details the reader may refer to Bertsekas and Shreve [2], for instance.

DEFINITION 2.1. (a) *A Borel subset* X *of a complete and separable metric space is called a* Borel space*, and its Borel σ-algebra is denoted by* $\mathcal{B}(\mathrm{X})$*. We deal only with Borel spaces, and so "measurable" (for either sets or functions) always means "Borel-measurable." Given a Borel space* X*, we denote by* $\mathbb{P}(\mathrm{X})$ *the family of probability measures on* X*, endowed with the weak topology* $\sigma(\mathbb{P}(\mathrm{X}), C_b(\mathrm{X}))$*, where* $C_b(\mathrm{X})$ *stands for the space of continuous bounded functions on* X*. In this case,* $\mathbb{P}(\mathrm{X})$ *is a Borel space. Moreover, if* X *is compact, then so is* $\mathbb{P}(\mathrm{X})$*.*

(b) *Let* X *and* Y *be Borel spaces. A measurable function* $\varphi : \mathrm{Y} \to \mathbb{P}(\mathrm{X})$ *is called a* transition probability from Y *to* X *(also known as a* stochastic kernel *on* X *given* Y*), and we denote by* $\mathbb{P}(\mathrm{X}|\mathrm{Y})$ *the family of all those transition probabilities. If* φ *is in* $\mathbb{P}(\mathrm{X}|\mathrm{Y})$*, then we write its values either as* $\varphi(y)(B)$ *or as* $\varphi(B|y)$ *for all* $y \in \mathrm{Y}$ *and* $B \in \mathcal{B}(\mathrm{X})$*. Finally, if* $\mathrm{X} = \mathrm{Y}$*, then* φ *is called a* Markov *transition probability on* X*.*

The stochastic game model. We shall consider the two-person zero-sum game model

$$GM := (\mathrm{X}, A, B, \mathbb{K}_A, \mathbb{K}_B, Q, r), \tag{2.1}$$

where X is the *state space*, and A and B are the *action spaces* for players 1 and 2, respectively. These spaces are all assumed to be Borel spaces. The sets $\mathbb{K}_A \in \mathcal{B}(\mathrm{X}\times A)$ and $\mathbb{K}_B \in \mathcal{B}(\mathrm{X}\times B)$ are the *constraint sets.* That is, for each state $x \in \mathrm{X}$, the x-section in $\mathbb{K}_A$, namely,

$$A(x) := \{a \in A | (x, a) \in \mathbb{K}_A\},$$

represents the set of admissible actions for player 1 in the state x. Similarly, the x-section in $\mathbb{K}_B$,

$$B(x) := \{b \in B | (x, b) \in \mathbb{K}_B\},$$

stands for the family of admissible actions for player 2 in the state x. Let

$$\mathbb{K} := \{(x, a, b) | x \in \mathrm{X}, a \in A(x), b \in B(x)\},$$

which is a Borel subset of $\mathrm{X} \times A \times B$ (see Lemma 1.1 in [20], for instance). Then $Q \in \mathbb{P}(\mathrm{X}|\mathbb{K})$ is the game's *transition law*, and, finally, $r : \mathbb{K} \to \mathbb{R}$ is a measurable function representing the *reward function* for player 1 (or the *cost function* for player 2).

The game is played as follows. At each stage (or time) $t = 0, 1, \dots,$ players 1 and 2 observe the current state $x \in \mathrm{X}$ of the system and then independently choose actions $a \in A(x)$ and $b \in B(x)$, respectively. As a consequence of this, the following happens: (1) player 1 receives an immediate reward $r(x, a, b)$; (2) player 2 incurs a cost $r(x, a, b)$; and (3) the system moves to a new state x' with distribution $Q(\cdot\, |x, a, b)$. Thus, the goal of player 1 is to maximize his/her reward, whereas that of player 2 is to minimize his/her cost.

3. Strategies. Let $H_0 := \mathrm{X}$ and $H_t := \mathbb{K} \times H_{t-1}$ for $t = 1, 2, \dots$. For each t, an element $h_t = (x_0, a_0, b_0, \dots, x_{t-1}, a_{t-1}, b_{t-1}, x_t)$ of H_t represents a "history" of the game up to time t. A *strategy* for player 1 is then defined as a sequence $\pi^1 = \{\pi^1_t, t = 0, 1, \dots\}$ of transition probabilities π^1_t in $\mathbb{P}(A|H_t)$ such that

$$\pi^1_t(A(x_t))|h_t) = 1 \quad \forall h_t \in H_t,\ t = 0, 1, \dots .$$

We denote by Π_1 the family of all strategies for player 1.

Now define $\mathbb{A}(x) := \mathbb{P}(A(x))$ for each state $x \in \mathrm{X}$, and let Φ_1 be the class of all transition probabilities $\varphi \in \mathbb{P}(A|\mathrm{X})$ such that $\varphi(x)$ is in $\mathbb{A}(x)$ for all $x \in \mathrm{X}$. Then a strategy $\pi^1 = \{\pi^1_t\} \in \Pi_1$ is called *stationary* if there exists $\varphi \in \Phi_1$ such that

$$\pi^1_t(\cdot\, |h_t) = \varphi(x_t)(\cdot\,) \quad \forall h_t \in H_t,\ t = 0, 1, \dots .$$

We will identify Φ_1 with the family of stationary strategies for player 1.

The sets of strategies Π_2 and Φ_2 for player 2 are defined similarly, writing $B(x)$ and $\mathbb{B}(x) := \mathbb{P}(B(x))$ in lieu of $A(x)$ and $\mathbb{A}(x)$, respectively.

Let $(\Omega, \mathcal{F})$ be the (canonical) measurable space that consists of the sample space $\Omega := (\mathrm{X} \times A \times B)^\infty$ and its product σ-algebra $\mathcal{F}$. Then for each pair of strategies $(\pi^1, \pi^2) \in \Pi_1 \times \Pi_2$ and each "initial state" $x \in \mathrm{X}$, there exists a probability measure P^{π^1,π^2}_x and an stochastic process $\{(x_t, a_t, b_t), t = 0, 1, \dots\}$ defined on $(\Omega, \mathcal{F})$ in a canonical way, where $x_t, a_t,$ and b_t represent the state and the actions of players 1 and 2, respectively, at each stage $t = 0, 1, \dots$. The expectation operator with respect to P^{π^1,π^2}_x is denoted by E^{π^1,π^2}_x.

Remark 3.1. As was already mentioned at the end of section 2, the players choose their actions *independently.* This means, more precisely, that for any pair of strategies $\pi^i = \{\pi^i_t\} \in \Pi_i$ $(i = 1, 2)$ and any initial state $x \in \mathrm{X}$, the corresponding action processes $\{a_t\}$ and $\{b_t\}$ are *conditionally independent* in the sense that

$$P^{\pi^1,\pi^2}_x(a_t \in C, b_t \in D|h_t) = \pi^1_t(C|h_t)\pi^2_t(D|h_t)$$

for all $C \in \mathcal{B}(A), D \in \mathcal{B}(B), h_t \in H_t,$ and $t = 0, 1, \dots .$

4. Average payoff criteria. For each $n = 1, 2, \dots$ and each history $h_\infty := (x_0, a_0, b_0, x_1, a_1, b_1, \dots)$, let

$$J^0_n(h_\infty) := \sum_{t=0}^{n-1} r(x_t, a_t, b_t) \tag{4.1}$$

be the *n-stage sample-path payoff* when player $i\,(i = 1, 2)$ uses the strategy $\pi^i \in \Pi_i$, given the initial state $x_0 = x$. The corresponding *n-stage expected payoff* is

$$J_n(\pi^1, \pi^2, x) := E_x^{\pi^1,\pi^2}\left[\sum_{t=0}^{n-1} r(x_t, a_t, b_t)\right]. \tag{4.2}$$

We then define the long-run SPAP

$$J^0(h_\infty) := \liminf_{n\to\infty} J_n^0(h_\infty)/n, \tag{4.3}$$

and, similarly, the long-run EAP

$$J(\pi^1, \pi^2, x) := \liminf_{n\to\infty} J_n(\pi^1, \pi^2, x)/n. \tag{4.4}$$

To introduce the optimality criteria we are concerned with we use the following concepts. The functions on X defined as

$$L(x) := \sup_{\pi^1\in\Pi_1} \inf_{\pi^2\in\Pi_2} J(\pi^1, \pi^2, x) \quad \text{and} \quad U(x) := \inf_{\pi^2\in\Pi_2} \sup_{\pi^1\in\Pi_1} J(\pi^1, \pi^2, x) \tag{4.5}$$

are called the *lower value* and the *upper value*, respectively, of the (expected) average payoff game. It is clear that $L(\cdot) \le U(\cdot)$ in general, but if it holds that $L(x) = U(x)$ for all $x \in$ X, then the common function is called the *value* of the game and is denoted by $V(\cdot)$.

DEFINITION 4.1. *Suppose that the game has a value $V(\cdot)$. Then a strategy π^{*1} in Π_1 is said to be* expected average payoff optimal *(briefly, EAP optimal)* for player 1 *if*

$$\inf_{\pi^2\in\Pi_2} J(\pi^{*1}, \pi^2, x) = V(x) \quad \forall x \in \text{X}. \tag{4.6}$$

Similarly, $\pi^{*2} \in \Pi_2$ is EAP optimal for player 2 *if*

$$\sup_{\pi^1\in\Pi_1} J(\pi^1, \pi^{*2}, x) = V(x) \quad \forall x \in \text{X}. \tag{4.7}$$

If $\pi^{*i} \in \Pi_i$ is EAP optimal for player $i\,(i = 1, 2)$, then (π^{*1}, π^{*2}) is called an EAP optimal pair *of strategies (also known as a* saddle point *or as a* noncooperative equilibrium*).*

For the SPAP we introduce a similar optimality criterion. (We use below the usual abbreviation "a.s." for "almost surely.")

DEFINITION 4.2. *Suppose that the game has a value $V(\cdot)$. Then a pair of strategies $(\pi^{*1}, \pi^{*2}) \in \Pi_1 \times \Pi_2$ is said to be* SPAP optimal *if it satisfies that for all $x \in$ X and $\pi^i \in \Pi_i\,(i = 1, 2)$,*

$$J^0(h_\infty) = V(x), \quad P_x^{\pi^{*1},\pi^{*2}} a.s., \tag{4.8}$$

$$J^0(h_\infty) \ge V(x), \quad P_x^{\pi^{*1},\pi^{2}} a.s., \tag{4.9}$$

$$J^0(h_\infty) \le V(x), \quad P_x^{\pi^{1},\pi^{*2}} a.s. \tag{4.10}$$

SPAP optimality is also studied in [3, 7, 24], for instance.

To introduce our last optimality criterion we use the following notation. (Recall that $\mathbb{A}(x) := \mathbb{P}(A(x))$ and $\mathbb{B}(x) := \mathbb{P}(B(x))$; see section 3.) For any given function $f : \mathbb{K} \to \mathbb{R}$ and probability measures $\varphi \in \mathbb{A}(x)$ and $\psi \in \mathbb{B}(x)$, we write

$$f(x, \varphi, \psi) := \int_{A(x)} \int_{B(x)} f(x, a, b)\psi(db)\varphi(da) \tag{4.11}$$

whenever the integrals are well defined. In particular, for r and Q as in (2.1),

$$r(x, \varphi, \psi) := \int_{A(x)} \int_{B(x)} r(x, a, b)\psi(db)\varphi(da)$$

and

$$Q(\cdot\,|x, \varphi, \psi) := \int_{A(x)} \int_{B(x)} Q(\cdot\,|x, a, b)\psi(db)\varphi(da).$$

DEFINITION 4.3. *A four-tuple $(\xi_*, u_*, \varphi_*, \psi_*)$ that consists of a constant $\xi_* \in \mathbb{R}$, a measurable function $u_* : \mathrm{X} \to \mathbb{R}$, and a pair $(\varphi_*, \psi_*) \in \Phi_1 \times \Phi_2$ of stationary strategies is said to be a* canonical four-tuple *if it holds that, for all $x \in \mathrm{X}$,*

$$\xi_* + u_*(x) = r(x, \varphi_*(x), \psi_*(x)) + \int_{\mathrm{X}} u_*(y)Q(dy|x, \varphi_*(x), \psi_*(x)) \tag{4.12}$$

$$= \max_{\varphi\in\mathbb{A}(x)} \left[r(x, \varphi, \psi_*(x)) + \int_{\mathrm{X}} u_*(y)Q(dy|x, \varphi, \psi_*(x)) \right] \tag{4.13}$$

$$= \min_{\psi\in\mathbb{B}(\mathrm{X})} \left[r(x, \varphi_*(x), \psi) + \int_{\mathrm{X}} u_*(y)Q(dy|x, \varphi_*(x), \psi) \right]. \tag{4.14}$$

In this case, it is also said that (φ_*, ψ_*) is a canonical pair of stationary strategies. (Concerning the name "canonical four-tuple," see the second paragraph in section 6.)

Definition 4.3 is of course related to the so-called *Shapley* (or *dynamic programming*) *equation*

$$\xi_* + u_*(x) = Tu_*(x) \quad \forall x \in \mathrm{X},$$

where T is the minimax operator defined by

$$\begin{aligned} Tu_*(x) &:= \max_{\varphi\in\mathbb{A}(x)} \min_{\psi\in\mathbb{B}(\mathrm{X})} \left[r(x, \varphi, \psi) + \int_{\mathrm{X}} u_*(y)Q(dy|x, \varphi, \psi) \right] \\ &= \min_{\psi\in\mathbb{B}(x)} \max_{\varphi\in\mathbb{A}(x)} \left[r(x, \varphi, \psi) + \int_{\mathrm{X}} u_*(y)Q(dy|x, \varphi, \psi) \right]. \end{aligned} \tag{4.15}$$

Our assumptions in section 5 will ensure that the maximum and the minimum in (4.15) are indeed attained and also that the second equality holds.

On the other hand, the relation between Definitions 4.3 and 4.1 is that if u_* satisfies that

$$\lim_{n\to\infty} n^{-1}E_x^{\pi^1,\pi^2} u_*(x_n) = 0 \tag{4.16}$$

for all $x \in \mathrm{X}$ and $\pi^i \in \Pi_i\,(i = 1, 2)$, then one can easily show that ξ_* *is the value* $V(\cdot\,)$ of the game and that *the canonical pair (φ_*, ψ_*) is EAP optimal.* (See the proof of Theorem 5.8 in section 7.) Thus, denoting by $(\Phi_1 \times \Phi_2)_{ca}$ the family of canonical pairs and by $(\Phi_1 \times \Phi_2)_{eap}$ the family of EAP optimal strategies, we have

$$(\Phi_1 \times \Phi_2)_{ca} \subset (\Phi_1 \times \Phi_2)_{eap} \tag{4.17}$$

if (4.16) holds. Moreover, the relation (4.17) is, in general, *strict*; in other words, as shown by well-known counterexamples (for instance, [4]), without suitable hypotheses, an EAP optimal pair is not necessarily canonical. The key fact to note here is that iteration of (4.12) yields

$$n\xi_* + u_*(x) = J_n(\varphi_*, \psi_*, x) + E_x^{\varphi_*,\psi_*} u_*(x_n) \tag{4.18}$$

for all $x \in \mathrm{X}$ and $n = 1, 2, \ldots$. This establishes an explicit relation between the n-stage averages $J_n(\varphi_*, \psi_*, x)/n$ and ξ_*, whereas for an arbitrary EAP optimal pair an expression such as (4.18) is virtually impossible to obtain. However, we show below (Theorem 5.8) that under appropriate assumptions we have *equality* in (4.17), i.e.,

$$(\Phi_1 \times \Phi_2)_{ca} = (\Phi_1 \times \Phi_2)_{eap}, \tag{4.19}$$

and in fact these sets also coincide with the family $(\Phi_1 \times \Phi_2)_{spap}$ of SPAP optimal pairs of stationary strategies (Theorem 5.10).

5. Main results.

As we already mentioned in section 1, our assumptions are an obvious variant of hypotheses previously used to study MCPs and stochastic games [1, 8, 11, 12, 13, 14, 18, 19, 21, 24]. In particular, the following Assumption 5.1 consists of standard continuity-compactness hypotheses, together with a growth condition (5.1) on the reward/cost function r.

Assumption 5.1. (a) For each state $x \in \mathrm{X}$, the (nonempty) sets $A(x)$ and $B(x)$ of admissible actions are compact.

(b) For each (x, a, b) in $\mathbb{K}$, $r(x, \cdot\,, b)$ is upper semicontinuous (u.s.c.) on $A(x)$, and $r(x, a, \cdot\,)$ is lower semicontinuous (l.s.c.) on $B(x)$.

(c) For each (x, a, b) in $\mathbb{K}$ and each bounded measurable function v on X, the functions

$$\int_{\mathrm{X}} v(y)Q(dy|x, \cdot\,, b) \quad \text{and} \quad \int_{\mathrm{X}} v(y)Q(dy|x, a, \cdot\,)$$

are continuous on $A(x)$ and $B(x)$, respectively.

(d) There exists a constant r_1 and a measurable function $w(\cdot\,) \geq 1$ on X such that

$$|r(x, a, b)| \leq r_1 w(x) \quad \forall (x, a, b) \in \mathbb{K}, \tag{5.1}$$

and, in addition, part (c) holds when v is replaced with w.

The next two assumptions are used to guarantee that the state process $\{x_t\}$ is "ergodic" in a suitable sense—see Remark 5.5(b).

Assumption 5.2. There exists a probability measure $\nu \in \mathbb{P}(\mathrm{X})$, a positive number $\alpha < 1$, and a measurable function $\beta : \mathbb{K} \to [0, 1]$ for which the following holds for all (x, a, b) in $\mathbb{K}$ and D in $\mathcal{B}(\mathrm{X})$:

(a) $Q(D|x, a, b) \geq \beta(x, a, b)\nu(D)$.

(b) $\int_{\mathrm{X}} w(y)Q(dy|x, a, b) \leq \alpha w(x) + \beta(x, a, b) \parallel \nu \parallel_w$, where $w(\cdot\,) \geq 1$ is the function in Assumption 5.1(d), and $\parallel \nu \parallel_w := \int w d\nu$.

(c) $\inf \int_{\mathrm{X}} \beta(x, \varphi(x), \psi(x))\nu(dx) > 0$, where the infimum is over all pairs (φ, ψ) in $\Phi_1 \times \Phi_2$.

Assumption 5.3. There exists a σ-finite measure λ on X with respect to which, for each pair (φ, ψ) in $\Phi_1 \times \Phi_2$, the Markov transition probability $Q(\cdot\,|x, \varphi(x), \psi(x))$ is λ-irreducible.

We next introduce some notation and then we mention some important consequences of the above assumptions.

DEFINITION 5.4. $\mathbb{B}_w(\mathrm{X})$ *denotes the linear space of real-valued measurable functions* u *on* X *with a finite* w*-norm, which is defined as*

$$\| u \|_w := \sup_{x \in \mathrm{X}} |u(x)|/w(x), \tag{5.2}$$

and $\mathbb{M}_w(\mathrm{X})$ *stands for the normed linear space of finite signed measures* μ *on* X *such that*

$$\| \mu \|_w := \int_{\mathrm{X}} w d|\mu| < \infty, \tag{5.3}$$

where $|\mu| := \mu^+ + \mu^-$ *denotes the total variation of* μ.

Note that the integral $\int u d\mu$ is finite for each u in $\mathbb{B}_w(\mathrm{X})$ and μ in $\mathbb{M}_w(\mathrm{X})$ because, by (5.2) and (5.3),

$$\left| \int u d\mu \right| \leq \| u \|_w \int w d|\mu| = \| u \|_w \| \mu \|_w < \infty.$$

Remark 5.5. Suppose that Assumptions 5.2 and 5.3 are satisfied. Then we have the following:

(a) For each pair (φ, ψ) in $\Phi_1 \times \Phi_2$ the state (Markov) process $\{x_t\}$ is *positive Harris recurrent*; hence, in particular, the Markov transition probability

$$Q(\cdot\,|x, \varphi(x), \psi(x))$$

admits a unique *invariant probability measure* in $\mathbb{M}_w(\mathrm{X})$, which will be denoted by $q(\varphi, \psi)$; thus

$$q(\varphi, \psi)(D) = \int_{\mathrm{X}} Q(D|x, \varphi(x), \psi(x)) q(\varphi, \psi)(dx) \quad \forall D \in \mathcal{B}(\mathrm{X}).$$

(b) $\{x_t\}$ is w*-geometrically ergodic*, that is, there exist positive constants $\theta < 1$ and M such that

$$\left| \int_{\mathrm{X}} u(y) Q^n(dy|x, \varphi(x), \psi(x)) - \int_{\mathrm{X}} u(y) q(\varphi, \psi)(dy) \right| \leq w(x) \| u \|_w M \theta^n \tag{5.4}$$

for every $u \in \mathbb{B}_w(\mathrm{X}), x \in \mathrm{X}$, and $n = 0, 1, \ldots$, where Q^n denotes the n-step Markov transition probability. This result follows from Lemmas 3.3 and 3.4 in [8], where it was *assumed* the positive Harris recurrence in part (a). However, as noted in Lemma 4.1 of [19], (a) follows from our current Assumptions 5.2 and 5.3.

The w-geometric ergodicity (5.4) was obtained in [8] following ideas from Kartashov [15]. It turns out, however, that (5.4) can be obtained in several different ways; see, for instance, Hordijk and Yushkevich [14], Küenle [18], Nowak [21], or section 7.3.D and section 10.2.C in [11]. For the *countable* case, see [1] or [24], for instance. For geometric ergodicity in the *total variation norm*, which is obtained by taking $w(\cdot) \equiv 1$ in (5.3), see [7], section 3.3 in [9], or the notes to section 7.3 in [11].

It should be noted that all of the examples in [1, 7, 11, section 10.9, 14, 19, 24] satisfy our Assumptions 5.1, 5.2, and 5.3, as well as Assumption 5.7 below (taking γ as the "counting measure" if X is a *countable* set).

Another important consequence of Assumptions 5.2 and 5.3, together with Assumption 5.1 is that, as proved in Theorem 3 of Nowak [21], the set $(\Phi_1 \times \Phi_2)_{eap}$ in (4.17) is nonempty. More precisely, we have the following.

PROPOSITION 5.6 (Nowak [21]). *If Assumptions* 5.1*,* 5.2*, and* 5.3 *are satisfied, then the (expected) average payoff game has a constant value, say, $V(x) = V^*$ for all $x \in \mathrm{X}$, and there exists an EAP optimal pair of stationary strategies.*

The hypotheses C5 and C6 used in [21] to prove Proposition 5.6 are somewhat different from our Assumptions 5.2 and 5.3, but the fact is that they also give the w-geometric ergodicity (5.4), which combined with standard dynamic programming arguments is a key tool to prove Proposition 5.6.

Here we use Proposition 5.6 as our point of departure, and, together with the following assumption, use it to prove our first main result, Theorem 5.8. In fact, Nowak [21] also obtains the Shapley equations, but our proof, in section 7, is quite different from his—see Remark 7.1. Moreover, he does not obtain the *equivalence* stated in Theorem 5.8.

Assumption 5.7. There exists a σ-finite measure γ on X and a strictly positive density function $g(x, a, b, \cdot\,)$ such that

$$Q(D|x, a, b) = \int_D g(x, a, b, y)\gamma(dy)$$

for all $D \in \mathcal{B}(\mathrm{X})$ and $(x, a, b) \in \mathbb{K}$.

Note that *Assumption* 5.7 *implies Assumption* 5.3 *with* $\lambda = \gamma$.

THEOREM 5.8. *If Assumptions* 5.1*,* 5.2*, and* 5.7 *are satisfied, then* (4.19) *holds, that is,*

$$(\Phi_1 \times \Phi_2)_{ca} = (\Phi_1 \times \Phi_2)_{eap}.$$

In fact, there exists a canonical four-tuple $(\xi_*, u_*, \varphi_*, \psi_*)$ with u_* in $\mathbb{B}_w(\mathrm{X})$ and (by Proposition 5.6*) $\xi_* = V^*$.*

In addition to the equivalence between EAP optimality and the existence of canonical four-tuples, the hypotheses of Theorem 5.8 give other characterizations of EAP optimality, as in Theorem 5.9 below, where we use the following notation.

Let $\mathcal{F}_n$ be the σ-algebra generated by (x_t, a_t, b_t) for $t = 0, \dots, n$, that is,

$$\mathcal{F}_n := \sigma\{x_0, a_0, b_0, \dots, x_n, a_n, b_n\}. \tag{5.5}$$

Moreover, let J_n^0 be as in (4.1) and ξ_*, u_* as in Theorem 5.8, and then define the stochastic process

$$M_n(h_\infty) := J_n^0(h_\infty) + u_*(x_n) - n\xi_* \quad \text{for} \quad n = 1, 2, \dots, \tag{5.6}$$

with $M_0(h_\infty) := u_*(x_0)$. Finally, let $\Delta : \mathbb{K} \to \mathbb{R}$ be the so-called *discrepancy function* given by

$$\Delta(x, a, b) := r(x, a, b) + \int_{\mathrm{X}} u_*(y)Q(dy|x, a, b) - u_*(x) - \xi_*. \tag{5.7}$$

From this definition of Δ it is immediate that (5.8), below, is just another way of expressing (4.12)–(4.14). Thus the equivalence of (a) and (b) in the following theorem is a direct consequence of Theorem 5.8.

THEOREM 5.9. *Under the hypotheses of Theorem* 5.8*, the following statements are equivalent:*

(a) *The pair* $(\varphi_*, \psi_*) \in \Phi_1 \times \Phi_2$ *is EAP optimal.*

(b) *For each* $x \in \mathrm{X}$

$$\Delta(x, \varphi_*(x), \psi_*(x)) = \max_{\varphi \in \mathbb{A}(x)} \Delta(x, \varphi, \psi_*(x)) = \min_{\psi \in \mathbb{B}(x)} \Delta(x, \varphi_*(x), \psi) = 0. \tag{5.8}$$

(c) *For each* $x \in \mathrm{X}, \pi^1 \in \Pi_1$*, and* $\pi^2 \in \Pi_2$

(c$_1$) $\{M_n(h_\infty), \mathcal{F}_n\}$ *is a* $P_x^{\varphi_*, \psi_*}$*-martingale,*

(c$_2$) $\{M_n(h_\infty), \mathcal{F}_n\}$ *is a* $P_x^{\varphi_*, \pi^2}$*-submartingale, and*

(c$_3$) $\{M_n(h_\infty), \mathcal{F}_n\}$ *is a* $P_x^{\pi^1, \psi_*}$*-supermartingale.*

On the other hand, if we add the "second order" condition (5.9) to (5.1), it turns out that the sets in (4.19) coincide with $(\Phi_1 \times \Phi_2)_{spap}$. That is, we have the following.

THEOREM 5.10. *Suppose that the hypotheses of Theorem* 5.8 *are satisfied and, in addition, there is a constant* $r_2 \geq 0$ *such that*

$$r^2(x, a, b) \leq r_2 w(x) \quad \forall (x, a, b) \in \mathbb{K}. \tag{5.9}$$

Then a pair of strategies in $\Phi_1 \times \Phi_2$ *is EAP optimal if and only if it is SPAP optimal; hence, by Theorem* 5.8*,*

$$(\Phi_1 \times \Phi_2)_{eap} = (\Phi_1 \times \Phi_2)_{ca} = (\Phi_1 \times \Phi_2)_{spap}. \tag{5.10}$$

To conclude this section and proceed to prove Theorems 5.8, 5.9, and 5.10, we shall specialize these theorems to MCPs or one-player stochastic games. To fix ideas we begin with the following obvious remark.

Remark 5.11. (a) If there is only one player, say player 1, then the game model GM in (2.1) reduces to the *Markov control model*

$$MCM = (\mathrm{X}, A, \mathbb{K}_A, \widehat{Q}, \widehat{r}), \tag{5.11}$$

where X, A, and $\mathbb{K}_A$ are exactly as in (2.1), but the transition law $\widehat{Q}$ and the reward function $\widehat{r}$ are defined on $\mathbb{K}_A$, that is, $\widehat{Q}$ is in $\mathbb{P}(\mathrm{X}|\mathbb{K}_A)$ and $\widehat{r} : \mathbb{K}_A \to \mathbb{R}$.

(b) Another way in which GM reduces to a Markov control model is to assume that one of the players, say player 2, selects a *fixed* stationary strategy ψ in Φ_2. In this case, the corresponding Markov control model is given by (5.11) with

$$\widehat{r}(x, a) := r(x, a, \psi(x)) \quad \text{and} \quad \widehat{Q}(\cdot\,|x, a) := Q(\cdot\,|x, a, \psi(x)) \;\; \forall x \in \mathrm{X}.$$

In either case, the optimality criteria in section 4 reduce in an obvious manner. In particular, the *value* of the MCP becomes

$$\widehat{V}(x) := \sup_{\pi \in \Pi_c} \widehat{J}(\pi, x) \,\text{for}\, x \in \mathrm{X}, \tag{5.12}$$

where Π_c is the set of all control strategies obtained from Π_1 (see section 3).

With this notation, Proposition 5.6 and Theorems 5.8, 5.9, and 5.10 yield the following.

COROLLARY 5.12. *Consider the MCP associated to* (5.11) *and suppose that Assumptions* 5.1, 5.2, *and* 5.3 *are satisfied. Then we have the following:*

(a) *There exists an* expected average reward *(EAR) optimal strategy* φ^* *in* Φ_1*, the set of stationary control strategies, and the value* $\widehat{V}(\cdot)$ *in* (5.12) *satisfies*

$$\widehat{J}(\varphi^*, x) = \widehat{V}(x) = \sup_{\varphi \in \Phi_1} \widehat{J}(\varphi, x) =: \xi^* \quad \forall x \in \mathrm{X}, \quad \textit{and}$$

(b) *there exists a* canonical triplet (ξ^*, h^*, φ^*) *with* $\xi^* \in \mathbb{R}, h^* \in \mathbb{B}_w(\mathrm{X})$*, and* $\varphi^* \in \Phi_1$*, that is (cf. Definition* 4.3*) for all* $x \in \mathrm{X}$*,*

$$\xi^* + h^*(x) = \widehat{r}(x, \varphi^*(x)) + \int_{\mathrm{X}} h^*(y)\widehat{Q}(dy|x, \varphi^*(x)) \tag{5.13}$$
$$= \max_{\varphi \in \mathbb{A}(x)} \left[\widehat{r}(x, \varphi) + \int_{\mathrm{X}} h^*(y)\widehat{Q}(dy|x, \varphi) \right].$$

In this case, φ^* *is said to be a* canonical strategy*.*

Furthermore, if we replace Assumption 5.3 *with Assumption* 5.7*, then the following statements* (c) *to* (f) *are equivalent:*

(c) $\varphi^* \in \Phi_1$ *is EAR optimal.*

(d) $\varphi^* \in \Phi_1$ *is a canonical strategy.*

(e) *For each* $x \in \mathrm{X}$*,*

$$\widehat{\Delta}(x, \varphi^*(x)) = \max_{\varphi \in \mathbb{A}(x)} \widehat{\Delta}(x, \varphi) = 0,$$

where $\widehat{\Delta} : \mathbb{K}_A \to \mathbb{R}$ *is the (average reward) discrepancy function:*

$$\widehat{\Delta}(x, a) := \widehat{r}(x, a) + \int_{\mathrm{X}} h^*(y)\widehat{Q}(dy|x, a) - h^*(x) - \xi^*.$$

(f) *For each* $\pi \in \Pi_c$ *and* $x \in \mathrm{X}$*, the stochastic process (cf.* (5.6)*)*

$$\widehat{M}_n(\widehat{h}_\infty) := \sum_{t=0}^{n-1} \widehat{r}(x_t, a_t) + h^*(x_n) - n\xi^* \quad \textit{for} \quad n = 1, 2, \dots,$$

with $\widehat{M}_0(\widehat{h}_\infty) := h^*(x_0)$ *and* $\widehat{h}_\infty = (x_0, a_0, x_1, a_1, \dots)$*, is a* P_x^π*-supermartingale (with respect to the* σ*-algebra generated by* $\{x_0, a_0, \dots, x_n, a_n\}$*—see* (5.5)*), whereas* $\{\widehat{M}_n(\widehat{h}_\infty), n = 0, 1, \dots\}$ *is a* $P_x^{\varphi^*}$*-martingale. Finally, if in addition* $\widehat{r}(x, a)$ *satisfies* (5.9)*, then each of the statements* (c) *to* (f) *is equivalent to the following:*

(g) $\varphi^* \in \Phi$ *is* sample-path average reward *(SPAR)* optimal*, that is (with* ξ^* *as in* (a) *and the obvious changes in* (4.3)*),*

$$J^0(\widehat{h}_\infty) = \xi^* \quad P_x^{\varphi^*} \, a.s. \ \ \forall x \in \mathrm{X}$$

and

$$J^0(\widehat{h}_\infty) \le \xi^* \quad P_x^\pi \ a.s. \ \ \forall \pi \in \Pi_c, x \in \mathrm{X}.$$

Proof. Parts (a) and (b) are well known—see, for instance, part (a) of Theorem 10.3.6 in [11]. Furthermore, part (b) of the same theorem shows that if $\varphi^* \in \Phi_1$ is EAR optimal, then φ^* satisfies (5.13) for *almost every* $x \in \mathrm{X}$ (with respect to some probability measure on X). However, under Assumption 5.7, it follows from Theorem 5.8 that (5.13) *holds for all* $x \in \mathrm{X}$, which gives the equivalence of (c) and (d). The remaining parts follow from Theorems 5.9 and 5.10. □

The rest of the paper is devoted to proving Theorems 5.8, 5.9, and 5.10 in sections 7, 8, and 9, respectively.

6. Preliminaries. In this section we present some concepts and preliminary results needed to prove the theorems in section 5. Some of these results are well known, but we state them here for completeness and ease of reference.

First of all, let us recall that if $P \in \mathbb{P}(\mathrm{X}|\mathrm{X})$ is a Markov transition probability on X and $c : \mathrm{X} \to \mathbb{R}$ is a given measurable function, then the equation

$$\xi + u(x) = c(x) + \int_{\mathrm{X}} u(y) P(dy|x) \quad \forall x \in \mathrm{X} \tag{6.1}$$

is called the (strictly unichain) *Poisson equation* (P.E.) for P with "charge" c, and the pair $(\xi, u(\cdot))$, with $\xi \in \mathbb{R}$ and $u(\cdot) : \mathrm{X} \to \mathbb{R}$, is called a solution to the P.E. This solution is also known as a *canonical pair*, which partly explains the name of "canonical triplet" for (ξ^*, h^*, φ^*) in (5.13), and of "canonical four-tuple" for $(\xi_*, u_*, \varphi_*, \psi_*)$ in (4.12). Note, in particular, that (4.12) is the P.E. for the Markov transition probability and the charge given by

$$P(\cdot\,|x) := Q(\cdot\,|x, \varphi_*(x), \psi_*(x)) \quad \text{and} \quad c(x) := r(x, \varphi_*(x), \psi_*(x)), \tag{6.2}$$

respectively. The following lemma shows, in particular, how to obtain the P.E. associated to an arbitrary pair of strategies in $\Phi_1 \times \Phi_2$.

LEMMA 6.1. *Suppose that Assumptions* 5.1, 5.2, *and* 5.3 *hold. Then for each pair of stationary strategies* $(\varphi, \psi) \in \Phi_1 \times \Phi_2$ *we have the following:*

(a) *The (finite) constant*

$$j(\varphi, \psi) := \int_{\mathrm{X}} r(x, \varphi(x), \psi(x)) q(\varphi, \psi)(dx),$$

with $q(\varphi, \psi)$ *as in Remark* 5.5(a), *is such that* (4.3) *and* (4.4) *can be written, for all* $x \in \mathrm{X}$, *as*

$$J^0(h_\infty) = \lim_{n\to\infty} J_n^0(h_\infty)/n = j(\varphi, \psi) \quad P_x^{\varphi,\psi} a.s. \tag{6.3}$$

and

$$J(\varphi, \psi, x) = \lim_{n\to\infty} J_n(\varphi, \psi, x)/n = j(\varphi, \psi), \tag{6.4}$$

respectively.

(b) *The function* $h_{\varphi,\psi}$ *defined on* X *as*

$$\begin{aligned} h_{\varphi,\psi}(x) &:= \lim_{n\to\infty} [J_n(\varphi, \psi, x) - nj(\varphi, \psi)] \\ &= \sum_{t=0}^{\infty} E_x^{\varphi,\psi} [r(x_t, \varphi(x_t), \psi(x_t)) - j(\varphi, \psi)] \end{aligned}$$

belongs to $\mathbb{B}_w(\mathrm{X})$ *(the set in Definition* 5.4*), and, moreover, its* w*-norm is independent of* (φ, ψ)*; in fact,*

$$\| h_{\varphi,\psi} \|_w \leq r_1 M/(1-\theta) \quad \forall (\varphi, \psi) \in \Phi_1 \times \Phi_2,$$

with r_1 *as in* (5.1), *and* M *and* θ *as in* (5.4).

(c) *The pair* $(j(\varphi, \psi), h_{\varphi,\psi})$ *in* $\mathbb{R} \times \mathbb{B}_w(\mathrm{X})$ *is the unique solution of the P.E.*

$$j(\varphi, \psi) + h_{\varphi,\psi}(x) = r(x, \varphi(x), \psi(x)) + \int_{\mathrm{X}} h_{\varphi,\psi}(y) Q(dy|x, \varphi(x), \psi(x)) \tag{6.5}$$

(*compare with* (6.1)) *that satisfies the condition*

$$\int_{\mathrm{X}} h_{\varphi,\psi}(x) q(\varphi,\psi)(dx) = 0.$$

Proof. The convergence in (6.3), which is a special case of the strong law of large numbers for Markov chains, follows from the positive Harris recurrence in Remark 5.5(a). (If necessary, for further details see Theorem 11.2.1 and Corollary 11.2.2 in [11], for instance.) The remaining statements in the lemma are part of Proposition 10.2.3 in [11]. □

Following Küenle [18], one can also get the P.E. (6.5) using a "contraction argument."

LEMMA 6.2. *Suppose that Assumptions* 5.2 *and* 5.3 *are satisfied. Let* (φ,ψ) *be an arbitrary pair in* $\Phi_1 \times \Phi_2$*, and define*

$$P(\cdot\,|x) := Q(\cdot\,|x,\varphi(x),\psi(x)) \quad and \quad \mu(\cdot\,) := q(\varphi,\psi)(\cdot\,). \tag{6.6}$$

If a function u *in* $\mathbb{B}_w(\mathrm{X})$ *is* P-subharmonic *(or subinvariant), that is,*

$$u(x) \le \int_{\mathrm{X}} u(y) P(dy|x) \quad \forall x \in \mathrm{X},$$

then $u(\cdot\,)$ *is constant* μ*-a.e.; in fact,*

$$u(\cdot\,) = \inf_{x\in\mathrm{X}} u(x) = \int_{\mathrm{X}} u d\mu \quad \mu\text{-}a.e.$$

(with P *and* μ *as in* (6.6)*). Similarly, if* u *is* P-superharmonic *(or superinvariant), that is,* $u(x) \ge \int u(y)P(dy|x)$ *for all* $x \in \mathrm{X}$*, then*

$$u(\cdot\,) = \sup_{x\in\mathrm{X}} u(x) = \int_{\mathrm{X}} u d\mu \quad \mu\text{-}a.e.$$

Proof. See, for instance, Lemma 7.5.12 in [11]. □

Let μ_1 and μ_2 be two measures on X and recall that, by definition, μ_1 is *absolutely continuous* with respect to μ_2 (in symbols: $\mu_1 \ll \mu_2$) if $\mu_2(D) = 0$, with D in $\mathcal{B}(\mathrm{X})$, implies $\mu_1(D) = 0$. In addition, μ_1 is *equivalent* to μ_2 if $\mu_1 \ll \mu_2$ and $\mu_2 \ll \mu_1$.

LEMMA 6.3. *Suppose that Assumptions* 5.2 *and* 5.7 *hold, and let* γ *be as in the latter assumption. Then, for any pair* (φ,ψ) *in* $\Phi_1 \times \Phi_2$,

(a) γ *is equivalent to the invariant probability measure* $q(\varphi,\psi)$*; hence,*

(b) *if* $q(\varphi,\psi)(D) = 0$*, then* $Q(D|x,a,b) = 0$ *for all* (x,a,b) *in* $\mathbb{K}$.

Proof. (a) If $\gamma(D) = 0$, then (by Assumption 5.7)

$$Q(D|x,a,b) = \int_D g(x,a,b,y)\gamma(dy) = 0 \quad \forall (x,a,b) \in \mathbb{K}. \tag{6.7}$$

Therefore, by the invariance of $q(\varphi,\psi)$ (see Remark 5.5(a)),

$$q(\varphi,\psi)(D) = \int_{\mathrm{X}} Q(D|x,\varphi(x),\psi(x)) q(\varphi,\psi)(dx) = 0;$$

that is, $q(\varphi,\psi) \ll \gamma$.

To prove the converse, we already noted that Assumption 5.7 implies Assumption 5.3 with the irreducibility measure $\lambda = \gamma$. On the other hand, if a Markov chain is λ-irreducible and has an invariant probability measure, say, μ, then $\lambda \ll \mu$. (For a proof of this fact see, for instance, Theorem 7.2 in [23].) Therefore, taking μ as $q(\varphi, \psi)$, we conclude that $\lambda = \gamma$ is absolutely continuous with respect to $q(\varphi, \psi)$.

(b) By part (a), $q(\varphi, \psi)(D) = 0$ implies $\gamma(D) = 0$, which in turn yields (6.7). □

The following result, which in particular gives (4.16), follows from straightforward calculations using (5.2) and the inequality in Assumption 5.2(b); see, for example, [8, 12] or Lemma 10.4.1 in [11].

Lemma 6.4. *Suppose that* (5.1) *and Assumptions* 5.1(a) *and* 5.2(b) *are satisfied, and let* $k := 1 + \| \nu \|_w /(1-\alpha)$. *Then for any* $\pi^i \in \Pi_i$ $(i = 1, 2)$, $x \in \mathrm{X}$, *and* $n = 0, 1, \ldots$

(a) $E_x^{\pi^1,\pi^2} w(x_n) \le k w(x)$, *and*

(b) $E_x^{\pi^1,\pi^2} |r(x_n, a_n, b_n)| \le r_1 k w(x)$.

In particular, by (a) *and* (5.2), *for any function* u *in* $\mathbb{B}_w(\mathrm{X})$ *we have*

(c) $E_x^{\pi^1,\pi^2} |u(x_n)| \le \| u \|_w \, k w(x)$, *and so*

(d) $\lim_{n\to\infty} n^{-1} E_x^{\pi^1,\pi^2} |u(x_n)| = 0$, *and the convergence is uniform on* $\Pi_1 \times \Pi_2$.

Finally, let us consider the minimax operator T in (4.15). Choose an arbitrary function u in $\mathbb{B}_w(\mathrm{X})$ and let

$$H(u; x, a, b) := r(x, a, b) + \int_{\mathrm{X}} u(y) Q(dy|x, a, b) \quad \text{for} \quad (x, a, b) \in \mathbb{K}. \tag{6.8}$$

By Assumptions 5.1(c) and the second part of 5.1(d), the integral in (6.8) is continuous in both $a \in A(x)$ and $b \in B(x)$ (see Lemma 8.3.7(a) in [11], for instance). This fact and Assumption 5.1(b) yield that $H(u; x, \cdot, b)$ is u.s.c. on $A(x)$ and that $H(u; x, a, \cdot)$ is l.s.c. on $B(x)$. Therefore (using the notation in (4.11)), the function $H(u; x, \varphi, \psi)$ is u.s.c. in $\varphi \in \mathbb{A}(x) := \mathbb{P}(A(x))$ and l.s.c. in $\psi \in \mathbb{B}(\mathrm{X}) := \mathbb{P}(B(x))$; see, for example, the "extended Fatou Lemma" 8.3.7(b) and the statement (12.3.37) in [11, p. 225]. Moreover, $H(u; x, \varphi, \psi)$ is concave (as it is linear) in φ and convex in ψ. Thus, by Fan's minimax theorem [5] and well-known minimax measurable selection theorems (see, for instance, [20]), we get the following.

Lemma 6.5. *Suppose that Assumptions* 5.1 *and* 5.2(b) *hold. Then* Tu *is in* $\mathbb{B}_w(\mathrm{X})$ *for each* u *in* $\mathbb{B}_w(\mathrm{X})$, *and there exist stationary strategies* $\varphi^* \in \Phi_1$ *and* $\psi^* \in \Phi_2$ *such that, for all* $x \in \mathrm{X}$,

$$\begin{aligned} Tu(x) &= H(u; x, \varphi^*(x), \psi^*(x)) \\ &= \max_{\varphi \in \mathbb{A}(x)} H(u; x, \varphi, \psi^*(x)) \\ &= \min_{\psi \in \mathbb{B}(\mathrm{X})} H(u; x, \varphi^*(x), \psi). \end{aligned} \tag{6.9}$$

Proof. By the remarks in the previous paragraph, we need only to show that if u is in $\mathbb{B}_w(\mathrm{X})$, then so is Tu. This follows from (5.1), (5.2), and Assumption 5.2(b), which give, for any $(x, a, b) \in \mathbb{K}$,

$$\begin{aligned} |H(u; x, a, b)| &\le r_1 w(x) + \| u \|_w \int_{\mathrm{X}} w(y) Q(dy|x, a, b) \\ &\le (r_1 + \|u\|_w (\alpha + \|\nu\|_w)) w(x) \end{aligned} \tag{6.10}$$

because $0 \le \beta(x, a, b) \le 1$ and $w(\cdot) \ge 1$. Thus, by (6.9) and (6.10), Tu is indeed in $\mathbb{B}_w(\mathrm{X})$. □

7. Proof of Theorem 5.8. We begin with the easiest (in fact, standard) part (4.17). That is, we wish to show that if $(\xi_*, u_*, \varphi_*, \psi_*)$ is a canonical four-tuple with u_* in $\mathbb{B}_w(\mathrm{X})$, then (φ_*, ψ_*) is EAP optimal.

Dividing by n both sides of (4.18) and letting $n \to \infty$, Lemma 6.4(d) and (6.4) give

$$J(\varphi_*, \psi_*, x) = j(\varphi_*, \psi_*) = \xi_* \quad \forall x \in \mathrm{X}. \tag{7.1}$$

Thus, to complete the proof that (φ_*, ψ_*) is EAP optimal it remains only to prove that ξ_* equals the value V^* in Proposition 5.6, i.e.,

$$\xi_* = V^*. \tag{7.2}$$

To prove this let us first note that (4.13) gives

$$\xi_* + u_*(x) \geq r(x, \varphi, \psi_*(x)) + \int_{\mathrm{X}} u_*(y) Q(dy|x, \varphi, \psi_*(x)) \tag{7.3}$$

for all $x \in \mathrm{X}$ and $\varphi \in \mathbb{A}(x)$. Then, by standard dynamic programming arguments (see [1, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, 17, 18, 19]),

$$n\xi_* + u_*(x) \geq J_n(\pi^1, \psi_*, x) + E_x^{\pi^1, \psi_*} u_*(x_n) \tag{7.4}$$

for any $\pi^1 \in \Pi_1, x \in \mathrm{X}$, and $n = 1, 2, \ldots$. Multiplying by $1/n$ both sides of (7.4) and taking the lim inf as $n \to \infty$, it follows from (4.4) and Lemma 6.4(d) that

$$\xi_* \geq J(\pi^1, \psi_*, x) \geq \inf_{\pi^2 \in \Pi_2} J(\pi^1, \pi^2, x) \quad \forall \pi^1 \in \Pi_1, x \in \mathrm{X}. \tag{7.5}$$

This implies that $\xi^* \geq L(x) = V^*$ for all $x \in \mathrm{X}$.

A similar argument, but using now (4.14), gives

$$\xi_* \leq J(\varphi_*, \pi^2, x) \leq \sup_{\pi^1 \in \Pi_1} J(\pi^1, \pi^2, x) \quad \forall \pi^2 \in \Pi_2, x \in \mathrm{X}, \tag{7.6}$$

so that $\xi_* \leq U(x) = V^*$ for all $x \in \mathrm{X}$, and so (7.2) follows. This completes the proof of (4.17).

To prove (4.19), let us now take an EAP optimal pair (φ_*, ψ_*). We wish to prove that (φ_*, ψ_*) is a canonical pair, so that it satisfies (4.12)–(4.14) with $\xi_* = V^*$ and some function u_* in $\mathbb{B}_w(\mathrm{X})$. With this in mind, first note that, by (6.4) and Proposition 5.6, we have

$$J(\varphi_*, \psi_*, x) = j(\varphi_*, \psi_*) = V^* \quad \forall x \in \mathrm{X}. \tag{7.7}$$

Thus, by Lemma 6.1(b), (c), there is a function u_0 in $\mathbb{B}_w(\mathrm{X})$ such that the P.E. (6.5) for (φ_*, ψ_*) can be written as

$$V^* + u_0(x) = r(x, \varphi_*(x), \psi_*(x)) + \int_{\mathrm{X}} u_0(y) Q(dy|x, \varphi_*(x), \psi_*(x)) \tag{7.8}$$

for all $x \in \mathrm{X}$. It follows that

$$V^* + u_0(x) \geq \min_{\psi \in \mathbb{B}(\mathrm{X})} \left[r(x, \varphi_*(x), \psi) + \int_{\mathrm{X}} u_0(y) Q(dy|x, \varphi_*(x), \psi) \right], \tag{7.9}$$

which (by Lemma 6.5) yields

$$V^* + u_0(x) \geq r(x, \varphi_*(x), \psi_0(x)) + \int_X u_0(y) Q(dy|x, \varphi_*(x), \psi_0(x)) \tag{7.10}$$

for all $x \in X$ and some $\psi_0 \in \Phi_2$. On the other hand, iteration of (7.10) gives that (as in (7.3)–(7.5)), for all $x \in X$,

$$V^* \geq J(\varphi_*, \psi_0, x) \geq \inf_{\pi^2 \in \Pi_2} J(\varphi_*, \pi^2, x) = V^*,$$

where the latter equality is due to (4.6). In other words,

$$J(\varphi_*, \psi_0, x) = j(\varphi_*, \psi_0) = V^* \quad \forall x \in X, \tag{7.11}$$

and so ψ_0 is a best reply of player 2 to the EAP optimal strategy φ_* of player 1. Now, write the P.E. for (φ_*, ψ_0) using (7.11). Then, repeating the argument used to obtain (7.8), there is a function u_1 in $\mathbb{B}_w(X)$ such that, for all $x \in X$,

$$V^* + u_1(x) = r(x, \varphi_*(x), \psi_0(x)) + \int_X u_1(x) Q(dy|x, \varphi_*(x), \psi_0(x)). \tag{7.12}$$

If we now subtract (7.12) from (7.10), we see that

$$u_0(x) - u_1(x) \geq \int_X [u_0(y) - u_1(y)] \, Q(dy|x, \varphi_*(x), \psi_0(x)) \quad \forall x \in X,$$

so that $u_0 - u_1$ is superharmonic with respect to the Markov transition probability $Q(\cdot\,|x, \varphi_*(x), \psi_0(x))$. Consequently, by Lemma 6.2, there is a constant k_1 and a Borel set $D_1 \subset X$, with $q(\varphi_*, \psi_0)(D_1) = 1$, such that

$$u_0(x) = u_1(x) + k_1 \quad \forall x \in D_1.$$

Finally, define

$$v_0(\cdot\,) := u_0(\cdot\,) = u_1(\cdot\,) + k_1 \,\text{on}\, D_1$$

and

$$v_0(x) := \min_{\psi \in \mathbb{B}(X)} \left[r(x, \varphi_*(x), \psi) + \int_X u_0(y) Q(dy|x, \varphi_*(x), \psi) \right] - V^* \tag{7.13}$$

for $x \in D_1^c$, where $D_1^c := X \backslash D_1$ denotes the complement of D_1. Then, as

$$q(\varphi_*, \psi_0)(D_1^c) = 0,$$

Lemma 6.3(b) gives that $Q(D_1^c|x, a, b) = 0$ for all (x, a, b) in $\mathbb{K}$, which in turn implies that in the integral in (7.13) we may replace u_0 with v_0. Thus,

$$V^* + v_0(x) = \min_{\psi \in \mathbb{B}(x)} \left[r(x, \varphi_*(x), \psi) + \int_X v_0(y) Q(dy|x, \varphi_*(x), \psi) \right] \tag{7.14}$$

for all $x \in X$.

We now go back to the initial P.E. (7.8), but instead of taking the "minimum" as in (7.9), we now take the "maximum," i.e.,

$$\begin{aligned} V^* + u_0(x) &\le \max_{\varphi \in \mathbb{A}(x)} \left[r(x, \varphi, \psi_*(x)) + \int_{\mathrm{X}} u_0(y) Q(dy|x, \varphi, \psi_*(x)) \right] \\ &= r(x, \varphi_0(x), \psi_*(x)) + \int_{\mathrm{X}} u_0(y) Q(dy|x, \varphi_0(x), \psi_*(x)) \end{aligned}$$

for some $\varphi_0 \in \Phi_1$. Then, with obvious changes, the arguments used in (7.11)–(7.14) give the existence of a Borel set D_2 with $q(\varphi_0, \psi_*)(D_2) = 1$ and a function v_1 in $\mathbb{B}_w(\mathrm{X})$ such that

$$v_1(\cdot\,) = u_0(\cdot\,) \,\text{on}\, D_2, \tag{7.15}$$

and

$$V^* + v_1(x) = \max_{\varphi \in \mathbb{A}(x)} \left[r(x, \varphi, \psi_*(x)) + \int_{\mathrm{X}} v_1(y) Q(dy|x, \varphi, \psi_*(x)) \right] \tag{7.16}$$

for all $x \in \mathrm{X}$.

To conclude, let $D := D_1 \cap D_2$ and define $u_*(\cdot\,) := u_0(\cdot\,)$ on D and

$$u_*(x) := Tu_0(x) - V^* \quad \text{for} \quad x \in D^c. \tag{7.17}$$

By Lemma 6.3(a), we have $\gamma(D_1^c) = \gamma(D_2^c) = 0$, and so $\gamma(D^c) = 0$, which by Assumption 5.7 gives $Q(D^c|x, a, b) = 0$ for all (x, a, b) in $\mathbb{K}$. Hence, instead of (7.17) we may write

$$V^* + u_*(x) = Tu_*(x) \quad \forall x \in \mathrm{X}, \tag{7.18}$$

which together with (7.8), (7.12)–(7.14), and (7.15)–(7.16) gives that $(V^*, u_*, \varphi_*, \psi_*)$ is a canonical four-tuple. □

Remark 7.1. It is interesting to note that the previous proof is quite different from Nowak's [21] "vanishing discount" proof of a solution to the Shapley equations, but still at the last step of his proof he uses an argument such as that in (7.17)–(7.18). Moreover, while we assume a strictly positive density $g(x, a, b, \cdot\,)$ (see Assumption 5.7), he uses a condition on g that implies the continuity of $(a, b) \mapsto Q(\cdot\,|x, a, b)$ in the *total variation norm* for each $x \in \mathrm{X}$; see hypothesis C7 in [21]. Thus, it is unclear (to us, at least) if his hypotheses would allow a proof such as ours, and, conversely, if our assumptions would allow a proof such as his.

8. Proof of Theorem 5.9. It is evident that (5.8) is simply another way of writing (4.12)–(4.14). Therefore, the equivalence of (a) and (b) follows from Theorem 5.8. (For a different way of getting this equivalence see Remark 8.1 below.)

Now choose an arbitrary initial state $x \in \mathrm{X}$ and arbitrary strategies π^i in Π_i ($i = 1, 2$), and let $\mathcal{F}_n$ be as in (5.5). To prove that (b) *implies* (c), first note that

$$E_x^{\pi^1,\pi^2}\left[u_*(x_{n+1})|\mathcal{F}_n\right] = \int_{\mathrm{X}} u_*(y) Q(dy|x_n, a_n, b_n), \tag{8.1}$$

and, therefore, from (5.7),

(8.2)

$$E_x^{\pi^1,\pi^2}\left[\Delta(x_n, a_n, b_n)|\mathcal{F}_n\right] = r(x_n, a_n, b_n) + E_x^{\pi^1,\pi^2}\left[u_*(x_{n+1})|\mathcal{F}_n\right] - u_*(x_n) - \xi_*.$$

Let us now consider the stochastic process in (5.6). From Lemma 6.4(b), (c), it follows that this process is integrable with respect to $P_x^{\pi^1,\pi^2}$, i.e.,

$$E_x^{\pi^1,\pi^2}|M_n(h_\infty)| < \infty \quad \text{for each} \quad n = 0, 1, \ldots .$$

Moreover,

$$M_{n+1}(h_\infty) = M_n(h_\infty) + r(x_n, a_n, b_n) + u_*(x_{n+1}) - u_*(x_n) - \xi_*,$$

so that, by (8.2),

$$E_x^{\pi^1,\pi^2}\left[M_{n+1}(h_\infty)|\mathcal{F}_n\right] = M_n(h_\infty) + E_x^{\pi^1,\pi^2}\left[\Delta(x_n, a_n, b_n)|\mathcal{F}_n\right]. \tag{8.3}$$

This expression immediately yields that (5.8) implies (c). Indeed, if

$$\Delta(x, \varphi_*(x), \psi_*(x)) = 0 \;\; \forall x \in \mathrm{X}, \tag{8.4}$$

then, by (8.3),

$$E_x^{\varphi_*,\psi_*}\left[M_{n+1}(h_\infty)|\mathcal{F}_n\right] = M_n(h_\infty) \;\; \forall n = 0, 1, \ldots, \tag{8.5}$$

and (c$_1$) follows. Similarly, if

$$\min_{\psi \in \mathbb{B}(x)} \Delta(x, \varphi_*(x), \psi) = 0 \;\; \forall x \in \mathrm{X}, \tag{8.6}$$

so that

$$\Delta(x, \varphi_*(x), \psi) \geq 0 \;\; \forall x \in \mathrm{X}, \psi \in \mathbb{B}(x), \tag{8.7}$$

then (8.3) yields

$$E_x^{\varphi_*,\pi^2}\left[M_{n+1}(h_\infty)|\mathcal{F}_n\right] \geq M_n(h_\infty) \;\; \forall n = 0, 1, \ldots, \tag{8.8}$$

and we get (c$_2$). Finally, if

$$\max_{\varphi \in \mathbb{A}(x)} \Delta(x, \varphi, \psi_*(x)) = 0, \tag{8.9}$$

then

$$\Delta(x, \varphi, \psi_*(x)) \leq 0 \;\; \forall x \in \mathrm{X}, \varphi \in \mathbb{A}(x). \tag{8.10}$$

Thus, from (8.3),

$$E_x^{\pi^1,\psi_*}\left[M_{n+1}(h_\infty)|\mathcal{F}_n\right] \leq M_n(h_\infty) \;\; \forall n = 0, 1, \ldots,$$

and (c$_3$) follows.

The converse, (c) *implies* (b), is just as easy; first note that taking expectations in both sides of (8.3) we get

$$E_x^{\pi^1,\pi^2} M_{n+1}(h_\infty) = E_x^{\pi^1,\pi^2} M_n(h_\infty) + E_x^{\pi^1,\pi^2} \Delta(x_n, a_n, b_n). \tag{8.11}$$

Therefore, if (c$_1$) holds, then

$$E_x^{\varphi_*,\psi_*} \Delta(x_n, a_n, b_n) = 0,$$

which for $n = 0$ gives (8.4). Similarly, under (c$_2$), (8.11) gives

$$E_x^{\varphi_*,\pi^2}\Delta(x_n, \varphi_*(x_n), \pi_n^2(h_n)) \geq 0$$

for all $x \in \mathrm{X}, h_n \in H_n$ (see section 3), and $n = 0, 1, \ldots$. In particular, for $n = 0$ we obtain

$$\Delta(x, \varphi_*(x), \pi_0^2(x)) \geq 0 \quad \forall x \in \mathrm{X},$$

and so, as $\pi^2 \in \Pi_2$ was arbitrary, we get (8.7) and (8.6). Finally, from (8.11) and (c$_3$) we deduce (8.10) and (8.9). □

Remark 8.1. Let $J_n(\Delta; \pi^1, \pi^2, x)$ and $J(\Delta; \pi^1, \pi^2, x)$ be the functions in (4.2) and (4.4), respectively, obtained by replacing $r(x, a, b)$ with the discrepancy function $\Delta(x, a, b)$; that is,

$$J_n(\Delta; \pi^1, \pi^2, x) := E_x^{\pi^1,\pi^2}\left[\sum_{t=0}^{n-1}\Delta(x_t, a_t, b_t)\right] \tag{8.12}$$

and

$$J(\Delta; \pi^1, \pi^2, x) := \liminf_{n\to\infty} J_n(\Delta; \pi^1, \pi^2, x)/n. \tag{8.13}$$

Now take expectations on both sides of (8.2) and then sum over n to get

$$J_n(\Delta; \pi^1, \pi^2, x) = J_n(\pi^1, \pi^2, x) + E_x^{\pi^1,\pi^2}u_*(x_n) - u_*(x) - n\xi_*.$$

Thus multiplying by $1/n$ and taking lim inf as $n \to \infty$, Lemma 6.4(d) and (8.13) yield

$$J(\pi^1, \pi^2, x) = \xi_* + J(\Delta; \pi^1, \pi^2, x). \tag{8.14}$$

From this expression we can immediately deduce the equivalence of (a) and (b) in Theorem 5.9. (A similar expression for the SPAP criterion is obtained in (9.5).)

9. Proof of Theorem 5.10. We shall use the notation in (8.12) and (8.13) but for the SPAP criterion, that is,

$$J_n^0(\Delta; h_\infty) := \sum_{t=0}^{n-1}\Delta(x_t, a_t, b_t) \tag{9.1}$$

and

$$J^0(\Delta; h_\infty) := \liminf_{n\to\infty} J_n^0(\Delta; h_\infty)/n,$$

where $x_0 = x \in \mathrm{X}$ and $\pi^i \in \Pi_i$ $(i = 1, 2)$ are arbitrary. Moreover, with $\mathcal{F}_n$ as in (5.5), we consider the stochastic processes

$$\begin{aligned} Y_t(\pi^1, \pi^2) : &= u_*(x_t) - E_x^{\pi^1,\pi^2}\left[u_*(x_t)|\mathcal{F}_{t-1}\right] \\ &= u_*(x_t) - \int_{\mathrm{X}} u_*(y)Q(dy|x_{t-1}, a_{t-1}, b_{t-1}) \end{aligned} \tag{9.2}$$

for $t = 1, 2, \ldots,$ and

$$S_n(\pi^1, \pi^2) := \sum_{t=1}^{n} Y_t(\pi^1, \pi^2). \tag{9.3}$$

From (8.1), (8.2), and (9.1), we can also write the latter process as

$$S_n(\pi^1,\pi^2) = u_*(x_t) - u_*(x_0) - J_n^0(\Delta; h_\infty) + J_n^0(h_\infty) - n\xi_*. \tag{9.4}$$

On the other hand, (9.2), (9.3), and straightforward calculations show that $S_n(\pi^1,\pi^2)$ is a $P_x^{\pi^1,\pi^2}$-martingale with respect to $\mathcal{F}_n$, and, in addition, Lemma 11.3.11 in [11], which is the same as Lemma 4.4 in [13], gives that $P_x^{\pi^1,\pi^2}$ a.s.

$$\lim_{n\to\infty} n^{-1} S_n(\pi^1,\pi^2) = 0 \quad \text{and} \quad \lim_{n\to\infty} n^{-1} u_*(x_n) = 0.$$

Therefore, multiplying both sides of (9.4) by n^{-1} and letting $n \to \infty$ we get

$$J^0(h_\infty) = \xi_* + J^0(\Delta; h_\infty) \quad P_x^{\pi^1,\pi^2}\text{a.s.} \tag{9.5}$$

We next use (9.5) to prove the “only if” part of Theorem 5.10.

Suppose that $(\varphi_*,\psi_*) \in \Phi_1 \times \Phi_2$ is EAP optimal, that is, (φ_*,ψ_*) is in $(\Phi_1 \times \Phi_2)_{eap}$. Then write (5.8) more explicitly, as in (8.4), (8.6)–(8.7), and (8.9)–(8.10), to get the following: (8.4), (9.5), and (6.3) yield (4.8) with $V(\cdot) = \xi_*$, that is,

$$J^0(h_\infty) = \xi_* \quad P_x^{\varphi_*,\psi_*}\text{a.s.} \tag{9.6}$$

Similarly, (9.5) and (8.7) give

$$J^0(h_\infty) \geq \xi_* \quad P_x^{\varphi_*,\pi^2}\text{a.s.}, \tag{9.7}$$

whereas (9.5) and (8.10) give

$$J^0(h_\infty) \leq \xi_* \quad P_x^{\pi^1,\psi_*}\text{a.s.} \tag{9.8}$$

Hence, as $x \in \mathrm{X}, \pi^1 \in \Pi_1$ and $\pi^2 \in \Pi_2$ were arbitrary, we conclude (from Definition 4.2) that (φ_*,ψ_*) is SPAP optimal with the SPAP optimal payoff $V(\cdot) = \xi_*$.

Conversely, suppose that (φ_*,ψ_*) satisfies (9.6)–(9.8) for all $x \in \mathrm{X}$ and $\pi^i \in \Pi_i$ $(i = 1, 2)$. Then, by (9.6), (6.3), and (6.4), we see that (φ_*,ψ_*) satisfies

$$J(\varphi_*,\psi_*,x) = \xi_* \quad \forall x \in \mathrm{X}. \tag{9.9}$$

On the other hand, as (9.8) holds for all $\pi^1 \in \Pi_1 \supset \Phi_1$, using again (6.3) and (6.4) we see that

$$J(\varphi,\psi_*,x) = j(\varphi,\psi_*) \leq \xi_* \quad \forall \varphi \in \Phi_1, x \in \mathrm{X}; \tag{9.10}$$

thus, if we *fix* $\psi_* \in \Phi_2$ as in Remark 5.11(b), then (9.9), (9.10), and Corollary 5.12(a) yield

$$\sup_{\pi^1 \in \Pi_1} J(\pi^1,\psi_*,x) = \xi_* \quad \forall x \in \mathrm{X}. \tag{9.11}$$

In like manner, with the obvious (notational) changes in Remark 5.11(b) and Corollary 5.12(a), we can see that (9.7) implies that

$$\inf_{\pi^2 \in \Pi_2} J(\varphi_*,\pi^2,x) = \xi_* \quad \forall x \in \mathrm{X}. \tag{9.12}$$

Thus, from (9.11) and (9.12), it follows that the pair (φ_*,ψ_*) is EAP optimal. □

PATHWISE OPTIMALITY IN STOCHASTIC CONTROL*

PAOLO DAI PRA†, GIOVANNI B. DI MASI†, AND BARBARA TRIVELLATO†

Abstract. We introduce a notion of pathwise optimality for stochastic control problems over an infinite time horizon, and give sufficient conditions for the existence of pathwise optimal controls. We analyze both diffusion processes and processes with discrete state space.

Key words. stochastic optimal control, Hamilton–Jacobi–Bellman equations, pathwise optimality

AMS subject classification. 93E20

1. Introduction.

Suppose we are given a probability space $(\Omega, \mathcal{F}, P)$ and a family of stochastic processes $x^u = (x_t^u)_{t\in[0,T]}$, indexed by a control parameter u. A stochastic control problem is defined by assigning real valued cost function $J(x^u, u)$ and consists in minimizing its expectation $E(J(x^u, u))$ over the controls.

This approach to optimization is quite appropriate when one deals with a controlled phenomenon that replicates many times, but may lack of reliability for a single trial. Indeed, even if a control u^* that minimizes the expected cost is known, the random variable $J(x^{u^*}, u^*)$ may have large fluctuations about its mean, making the choice of the control u^* a risky one. Various modifications of the performance index $E(J(x^u, u))$ have been proposed, in order to take these fluctuations into account. For example, one may penalize fluctuations around the mean by including in the index higher moments of the cost $J(x^u, u)$. An approach in this direction consists in minimizing over u the index $E\{e^{\mu J(x^u,u)}\}$, where $\mu > 0$ is a *risk* parameter (*risk sensitive control*).

Another point of view consists in looking for controls that are pathwise optimal, in some suitable sense. The most naive aim would be to find a control u^* such that $J(x^{u^*}, u^*) \leq J(x^u, u)$ almost surely (a.s.) for every control u. This exceedingly strong notion of optimality can be weakened by saying that a control u^* is a.s. optimal if for any other control u one can realize on *some* probability space $(\Omega', \mathcal{F}', P')$ the processes X^{u^*}, X^u having the same law of x^{u^*} and x^u, respectively, and such that $J(X^{u^*}, u^*) \leq J(X^u, u)$ P'-a.s. It is clear that any control that is a.s. optimal also minimizes the mean cost. In most interesting cases, however, as shown in [13], there is no optimal control for this notion of optimality.

The picture changes when one considers stochastic control problems over an infinite time horizon. Suppose the processes x^u to be defined in the whole time interval $[0, +\infty)$ and that the controls are themselves stochastic processes $u = (u_t)_{t\geq 0}$. We assign a real valued function $c(x_t^u, u_t)$ representing the running cost, and we let

$$J_T(u) = \int_0^T c(x_t^u, u_t)dt$$

†Dipartimento di Matematica Pura e Applicata, Università di Padova, Via Belzoni 7, 35131 Padova, Italy (daipra@math.unipd.it, dimasi@math.unipd.it, trivellato@math.unipd.it).

(here and in what follows we simply write $J_T(u)$ rather than $J_T(x^u, u)$). For a given nonincreasing function $g : [0, +\infty) \to (0, +\infty)$ with $\lim_{T\to+\infty} g(T) = 0$, we say that a control u^* is g-optimal a.s. (or in probability) if for any other control u the random variables

$$g(T)[J_T(u^*) - J_T(u)]^+$$

go to zero a.s. (or in probability) as $T \to +\infty$. This notion of optimality, which we believe has been first introduced by Rotar, has been studied in special cases in [14, 18, 11, 12, 2, 19, 16, 7, 15, 3].

The purpose of this paper is to give results on almost sure optimality and optimality in probability for rather general nonlinear systems. In particular, we give conditions for the existence of an optimal control. These conditions can be verified in many interesting examples, including the LQG models treated, e.g., in [7], for which we can slightly weaken the assumptions, as well as several nonlinear models.

We begin in section 2 by giving our main definitions. Sections 3 and 5 are devoted to almost sure optimality and optimality in probability for controlled diffusion processes. Several examples are given in section 4. Sections 6 and 7 contain analogous results for point processes. In section 8 we consider controlled Markov chains with finite state space. In this case we can establish the existence of pathwise optimal controls in great generality.

2. Basic definitions.

In this paper we consider stochastic processes with values in $\mathbb{R}^d$ and whose trajectories belong to path space D. Here D is either $\mathcal{C}([0, +\infty), \mathbb{R}^d)$, provided with the topology of uniform convergence on the compact subsets of $[0, +\infty)$ or the set of *cadlag* functions $D = D([0, +\infty), \mathbb{R}^d)$, provided with the Skorohod topology (see, e.g., [5, Chapter 3, section 12]). Whenever the notion of measurability in D will occur, it will be meant with respect to the Borel σ-field associated to the above-mentioned topologies.

Let U be a measurable space. For any $v \in U$ we are given a Markov operator L^v, acting on a suitable domain $\mathcal{D}^v$ of functions from $\mathbb{R}^d$ to $\mathbb{R}$. We assume that there exists a subspace $\mathcal{C}$ of $\mathcal{D}^v$, which does not depend on v, such that the operator L^v is the closure of its restriction $\mathcal{C}$. The set $\mathcal{C}$ is called a *core* for the Markov operators L^v. Progressively measurable processes $u : [0, +\infty) \times D \to U$ are called *controls* (we shall write $u_t(x)$ for the value of u at time t on the path x). Suppose that a nonnegative measurable function $c : \mathbb{R}^d \times U \to [0, +\infty)$ and a probability measure μ on $\mathbb{R}^d$ are given. A control u is said to be *admissible* if the following conditions are satisfied:

1. For every $t \in [0, +\infty)$, the function $u_t : D \to U$ is measurable with respect to the σ-field $\mathcal{F}_t$ generated by the projections $\{\Pi_s : s \leq t\}$, where, for $x \in D$, $\Pi_s(x) = x_s$.
2. There exists a probability measure P^u on D such that for every $f \in \mathcal{C}$ the process

$$z_t = f(x_t) - \int_0^t (L^{u_s} f)(x_s) ds$$

is a P^u-local martingale, and $P^u \circ \Pi_0^{-1} = \mu$.
3. Let

$$J_t(u) = \int_0^t c(x_s, u_s) ds.$$

Then $J_t(u) < +\infty$ P^u-a.s. for all $t > 0$.

The set of admissible controls will be denoted by $\mathcal{U}$. Consider a nonincreasing function $g : [0, +\infty) \to (0, +\infty)$ such that $\lim_{t\to+\infty} g(t) = 0$.

DEFINITION 2.1. *We say that a control $u^* \in \mathcal{U}$ is g-optimal a.s. (respectively, in probability) if for all $u \in \mathcal{U}$ and for all probability measures P^{u,u^*} on $D \times D$ having marginals P^u and P^{u^*} and such that*

$$P^{u,u^*}\{(x, y) \in D \times D : x_0 \neq y_0\} = 0 \tag{2.1}$$

we have

$$\lim_{T\to+\infty} g(T)[J_T(u^*) - J_T(u)]^+ = 0 \qquad P^{u,u^*}\text{-a.s.} \tag{2.2}$$

(respectively, in probability with respect to P^{u,u^*}).

Remark 1. A special and interesting choice for g is $g(t) = 1/t$. Under rather mild assumptions (e.g., uniform integrability of $J_T(u)$) one can show that $1/t$-optimality implies optimality for the average cost per unit time

$$\limsup_{T\to+\infty} T^{-1}E^u(J_T(u)),$$

where E^u denotes expectation with respect to P^u. The results in this paper concern g-optimality for $g(t) = t^{-\alpha}$ for all $\alpha > 1/2$.

Remark 2. We have chosen to introduce our stochastic processes in a weak sense, i.e., as probability measures on the path space. In some cases there is a natural probability space over which all processes corresponding to admissible controls can be realized. This is the case, for instance, when considering diffusion processes, if one chooses to deal with strong solutions. In other cases, however, e.g., for counting processes, it is not so, the reason being that there is no natural "noise" that accounts for the randomness in the system. Thus, in the definition of controlled Markov process, we preferred not to make reference to any given probability space. The notion of g-optimality has been adapted accordingly. Note that our definition is stronger than the one given in previous works on this subject, since we require (2.2) to hold for any "coupling" P^{u,u^*} of P^u and P^{u^*}.

Remark 3. In the examples that we give in sections 4 and 8, where pathwise optimality is actually shown, condition (2.1) on the measures P^{u,u^*} would be irrelevant, so that we obtain an even stronger notion of optimality. In general, however, condition (2.1) is relevant. To see this, let X_1, X_2 be two disjoint subsets of $\mathbb{R}^d$. For $i = 1, 2$ let L_i^v, $v \in U$, be the generator of a controlled Markov process, with initial law μ_i and law P_i^u, u being an admissible control. Assume $P_i^u(x_t \in X_i) = 1$ for any admissible control u, i.e., the process is X_i-valued. Finally, let u_i^* be a g-optimal control, associated to a given running cost function $c_i(x, v)$.

Now consider the $X_1 \cup X_2$-valued process with generator $L^v f(x) = L_i^v f(x)$ if $x \in X_i$, initial condition $(\mu_1 + \mu_2)/2$, and running cost $c(x, v) = c_i(x, v)$ for $x \in X_i$. Clearly the control $u^* = u_i^*$ if $x_0 \in X_i$ is g-optimal for this combined problem.

Suppose now to remove condition (2.1). Then we can construct a coupling P^{u,u^*} satisfying $P^{u,u^*}(x_0 \in X_1, y_0 \in X_2 \text{ or } x_0 \in X_2, y_0 \in X_1) = 1$. In other words, under this P^{u,u^*}, the two process evolve with different generator and different cost function. There is no reason, therefore, for (2.2) to hold.

3. Pathwise optimality for controlled diffusions. In this section we assume the Markov operator L^v to be of the form

$$L^v = \frac{1}{2}\sum_{i,j=1}^{d} a_{ij}(x,v)\frac{\partial^2}{\partial x_i \partial x_j} + \sum_{i=1}^{d} f_i(x,v)\frac{\partial}{\partial x_i},$$

where $a_{ij}, f_i : \mathbb{R}^d \times U \to \mathbb{R}$ are measurable functions and, for each $(x,u) \in \mathbb{R}^d \times U$, the matrix $a(x,u) = (a_{ij}(x,u))_{ij}$ is positive semidefinite.

Suppose $u \in \mathcal{U}$, and let P^u be the probability measure on $D = \mathcal{C}([0,+\infty), \mathbb{R}^d)$ introduced in the previous section. It is well known that P^u is the law of a weak solution of the stochastic differential equation

$$\begin{array}{rcl} dx_t & = & f(x_t,u_t)dt + \sigma(x_t,u_t)dw_t, \\ x_0 & \sim & \mu, \end{array}$$

where σ is a (possibly degenerate) square root of a and w_t is a d-dimensional Brownian motion.

The basic tool for solving the optimal control problem for diffusions is provided by the following partial differential equations, which will be referred to as the Hamilton–Jacobi–Bellman (HJB) equation and the stationary Hamilton–Jacobi–Bellman (SHJB) equation:

$$\text{(HJB)} : \begin{cases} \dfrac{\partial V_T}{\partial t}(t,x) + \inf\limits_{v \in U}[L^v V_T(t,x) + c(x,v)] = 0, \\ V_T(T,x) = 0. \end{cases}$$

$$\text{(SHJB)} : \inf_{v \in U}[L^v \phi(x) + c(x,v)] = \lambda.$$

Note that the (SHJB) equation is an equation for the pair (ϕ, λ), where λ is a real number. For generalities on these equations and their connections to stochastic control we refer the reader to [4].

We now give two different sets of assumptions on the model. We will show in Section 4 that these assumptions are satisfied for various classes of models.

The function g below is a positive, nonincreasing function vanishing at infinity.

Assumption A.

A1. For each $T > 0$ there exists a solution $V_T \in \mathcal{C}^{1,2}([0,T] \times \mathbb{R}^d)$ of (HJB).

A2. There exists a solution (ϕ, λ) of (SHJB), with $\phi \in \mathcal{C}^2(\mathbb{R}^d)$. The "inf" in (SHJB) is attained at $v = k(x)$, and the feedback $u_t^* = k(x_t)$ is an admissible control. Moreover, there exist constants $C, \epsilon > 0$ for which

$$E^{P^{u^*}}\left[\left(\phi^-(x_t)\right)^{2+\epsilon} \right] < C$$

for all $t \geq 0$, where ϕ^- denotes the negative part of ϕ.

A3. The following inequality holds:

$$\limsup_{T \to +\infty} g(T)\Big[\phi(x_0) + \lambda T - V_T(0,x_0)\Big] \leq 0 \quad \mu\text{-a.s.}$$

A4. There is a constant $B > 0$ such that

$$\left\| \frac{\partial V_T}{\partial x}(t,x)\sigma(x,v) \right\|^2 \leq B(c(x,v)+1),$$

uniformly in t, T.

A5. As A4, with ϕ replacing V_T.

Moreover, there exists an integer $m > 0$ such that the following further assumptions hold.

A6. There exists a constant $C > 0$ such that

$$E^{P^{u^*}}\left\{\left[\int_0^T c(x_t, u_t)\, dt\right]^m\right\} \leq CT^m$$

for all $T > 0$.

A7. Define $q(t) = t^{1/2}g(t)$. Then

$$\int_1^{+\infty} q^m(t)dt < +\infty.$$

Assumption B. There exists a solution (ϕ, λ) of (SHJB), with ϕ bounded. Moreover, Assumptions A2, A5, A6, and A7 hold.

We can now state the main results, whose proof is deferred to section 5.

THEOREM 3.1. *Suppose that either Assumption* A *or Assumption* B *holds. Then the feedback u^* is g-optimal a.s.*

THEOREM 3.2. *Suppose that either Assumption* A *or Assumption* B *holds, but in both cases condition* A7 *is weakened to $q(t) = o(1)$. Then the feedback u^* is g-optimal in probability.*

Remark 4. Note that if one can show that A6 holds for *all* m large enough, then one can choose $g(t) = t^{-(1/2+\delta)}$ for any $\delta > 0$.

4. Examples.

4.1. The linear quadratic regulator.

As an application, consider the completely observed stationary linear regulator with quadratic cost. For simplicity we let x_0 be a deterministic vector, i.e., $\mu = \delta_{x_0}$. Such assumption can be easily weakened.

$$dx_t = (Ax_t + Bu_t)\, dt + G\, dw_t, \tag{4.1}$$

$$J_T(u) = \int_0^T (x_t^{'}Qx_t + u_t^{'}Ru_t)\, dt, \tag{4.2}$$

where $x_t \in \mathbf{R}^n$, $u_t \in \mathbf{R}^m$, w is the standard p-dimensional Wiener process, A, B, G, Q, R are constant matrices of appropriate dimensions, Q, R are symmetric and positive definite, and the pair (A, B) is stabilizable. We recall that under the above assumptions, there exists the limit

$$\Pi = \lim_{T\to\infty} \Pi_T(t) \;\text{ for all } t \geq 0, \tag{4.3}$$

where $\Pi_T(t)$ is the solution to the Riccati differential equation on $[0, T]$

$$\frac{d}{dt}\Pi_T(t) + \Pi_T(t)A + A^{'}\Pi_T(t) - \Pi_T(t)BR^{-1}B^{'}\Pi_T(t) + Q = 0,\; \Pi_T(T) = 0, \tag{4.4}$$

and Π is the positive definite solution to the algebraic Riccati equation

$$\Pi A + A^{'}\Pi - \Pi BR^{-1}B^{'}\Pi + Q = 0. \tag{4.5}$$

Moreover, for some positive constants C, K

$$\|\Pi_T(t) - \Pi\| \leq Ce^{-K(T-t)}, \quad 0 \leq t \leq T, \tag{4.6}$$

and the matrix $A - BR^{-1}B^{'}\Pi$ is stable (see [1]).

We now show that Theorems 3.1 and 3.2 hold for this model, Assumption A being satisfied. The solutions to (HJB) and (SHJB) are given by, respectively,

$$V_T(t,x) = \phi_T(t,x) + \int_t^T \lambda_T(s)\,ds \tag{4.7}$$

with

$$\phi_T(t,x) = x^{'}\Pi_T(t)x, \quad \lambda_T(t) = \operatorname{tr}(G^{'}\Pi_T(t)G) \tag{4.8}$$

and

$$\phi(x) = x^{'}\Pi x, \quad \lambda = \operatorname{tr}(G^{'}\Pi G). \tag{4.9}$$

Moreover, the optimal feedback is

$$u_t^* = -R^{-1}B^{'}\Pi x_t, \tag{4.10}$$

which is easily seen to be admissible. Thus Assumptions A1 and A2 are satisfied. Assumption A3 is an immediate consequence of (4.6). Assumptions A4 and A5 are easily checked using the positivity of Q and the fact that

$$\frac{\partial V_T}{\partial x}(t,x)\sigma(x,u) = 2x^{'}\Pi_T(t), \qquad \frac{\partial \phi}{\partial x}(x)\sigma(x,u) = 2x^{'}\Pi.$$

Finally, by (4.10), denoting by x^* the process corresponding to the optimal control u^*, we have

$$c(x_t^*, u_t^*) = x_t^{*'}Qx_t^* + u_t^{*'}Ru_t^* = x_t^{*'}(Q + \Pi BR^{-1}B^{'}\Pi)x_t^* \leq C|x_t^*|^2. \tag{4.11}$$

We know that the matrix $A - BR^{-1}B^{'}\Pi$ is stable, so that the function $t \mapsto E|x_t^*|^2$ is bounded on $[0,\infty)$. As x_t^* is a Gaussian process it turns out that there exists a positive constant C_k such that

$$E|x_t^*|^k \leq C_k \ \text{ for all } t \geq 0, k \geq 2. \tag{4.12}$$

From (4.11), (4.12), and the inequality

$$\|\int_0^T \xi_t\,dt\|_m \leq \int_0^T \|\xi_t\|_m\,dt,$$

where $\|.\|_m$ is the $L^m(\Omega)$ norm, Assumption A6 follows for all $m \geq 1$.

4.2. Uniformly ergodic diffusions. In this section we consider a class of nonlinear controlled diffusions for which Assumption A is satisfied.

Consider diffusions satisfying the following stochastic differential equation:

$$\begin{array}{rcl} dx_t & = & (g(x_t) + u_t)dt + dw_t, \\ x_0 & \sim & \mu, \end{array}$$

where $x_t, u_t \in \mathbb{R}^d$. The cost functional is given by

$$J_T(u) = \int_0^T \left[l(x_t) + \frac{1}{2}\|u_t\|^2 \right] dt.$$

In other words, we are considering models as in section 3 with $U = \mathbb{R}^d$, $f(x,u) = g(x) + u$, $\sigma(x,u) = I$, and $c(x,u) = l(x) + \frac{1}{2}\|u\|^2$. We also make the following further assumptions on the model.

(i) The function $l(\cdot)$ is nonnegative, continuously differentiable, and its first partial derivatives are bounded.

(ii) The function $g(\cdot)$ is twice continuously differentiable, and its first partial derivatives are bounded.

(iii) There exists a constant $c > 0$ such that, for every $x, y \in \mathbb{R}^d$

$$(x-y)\cdot(g(x) - g(y)) \leq -c\|x-y\|^2,$$

where "$\cdot$" is the scalar product in $\mathbb{R}^d$.

PROPOSITION 4.1. *Under* (i), (ii), *and* (iii) *there exists a solution* $V_T \in \mathcal{C}^{1,2}$ *of* (HJB). *The first partial derivatives of* V_T *with respect to* x *are uniformly bounded in all variables. In particular, Assumptions* A1 *and* A4 *are satisfied. Moreover, the "inf" in* (HJB) *determines an admissible feedback control* u^T*; the corresponding process* x^T*, defined for times* $t \in [0,T]$*, is such that all its moments are uniformily bounded in both* t *and* T.

The existence of a regular solution V_T is proved in [9, Theorem 6.2]. The remaining part of Proposition 4.1 is proved in [8, Lemma 4.1 and Appendix A]. Note that in [9, Theorem 6.2], the control is supposed to take values a compact set. In this example, however, this is not a restriction since the "inf" in (HJB) is attained at the feedback $-\nabla_x V_T(t,x)$ that, as stated in Proposition 4.1, is bounded in all variables.

PROPOSITION 4.2. *There exists a solution* (ϕ, λ) *of* (SHJB) *with* $\phi \in \mathcal{C}^2$. *The first partial derivatives of* ϕ *are bounded. Moreover, the "inf" in* (SHJB) *determines an admissible feedback control* u^**; the corresponding process* x_t^* *is such that all its moments are bounded in time. Thus, in particular, Assumptions* A2 *and* A5 *hold, and* A6 *is satisfied for every* $m \geq 1$.

For the proof of Proposition 4.2 see [8, sections 3 and 4].

Thus, we have only to check Assumption A3. Define $W_T(t,x) = \phi(x) + \lambda(T-t)$. By the standard verification theorem of stochastic control (see, e.g., [9, Chapter 4, Theorem 4.1], we have, for all $x \in \mathbb{R}^d$,

$$\begin{aligned} V_T(0,x) &= \inf_{u \in \mathcal{U}} E \int_0^T c(x_t, u_t) dt, \\ W_T(0,x) = \phi(x) + \lambda T &= \inf_{u \in \mathcal{U}} E \left\{ \int_0^T c(x_t, u_t) dt + \phi(x_T) \right\} \\ &= E \left\{ \int_0^T c(x_t^*, u_t^*) dt + \phi(x_T^*) \right\}, \end{aligned}$$

where we have used the fact that the function $W_T(t,x)$ is a solution of (HJB) with final condition $W_T(T,x) = \phi(x)$. It follows that

$$W_T(0,x) \leq V_T(0,x) + E\phi(x_T^T), \tag{4.13}$$

where x^T is the process defined in Proposition 4.1. Note that, since ϕ has bounded gradient, it grows at most linearly. Therefore, by Proposition 4.1, the expectation $E\phi(x_T^T)$ is bounded in T, and Assumption A3 easily follows.

4.3. Diffusions with periodic coefficients. In this section we consider a class of nonlinear controlled diffusions for which Assumption B is satisfied.

We consider stochastic differential equations in $\mathbb{R}^d$ of the type

$$\begin{aligned} dx_t &= f(x_t, u_t)dt + dw_t, \\ x_0 &\sim \mu, \end{aligned}$$

where we assume (i) U is a compact metric space; (ii) f is jointly continuous in (x, u), and it is α-Holder continuous in x uniformly with respect to u, for some $\alpha > 0$; (iii) f is periodic in x. Moreover, the running cost function $c(x, u)$ is also assumed to be periodic in x, jointly continuous in (x, u), and α-Holder continuous in x uniformly with respect to u.

PROPOSITION 4.3. *There exists a solution of* (SHJB) *for the above models, such that $\phi \in \mathcal{C}^2(\mathbb{R}^d)$ and it is periodic.*

Proof. The existence of a periodic solution of (SHJB) in $W^{2,p}((0, \tau)^d)$ (τ is the period) for all $p \geq 2$ comes from [4, Theorem 6.1]. It follows that $\frac{\partial \phi}{\partial x} \in W^{1,p}$ for all large p, and therefore it is Holder continuous (see [6, Theorem IX.14]). Plugging this information into (SHJB), we get that $\Delta\phi$ is Holder continuous. Thus (see, e.g., [20, Theorem 4.1]) $\phi \in \mathcal{C}^2$. □

Note now that boundedness of ϕ follows from Proposition 4.3. Moreover, conditions A5 and A6 are trivially satisfied. As far as A2 is concerned, we have to show that the "inf" in (SHJB) is attained at an admissible feedback control. By continuity of f, c and compactness of U, the "inf" is attained at a feedback $k(x)$. Since the function $b(x) = f(x, k(x))$ is bounded, a weak solution of

$$\begin{aligned} dx_t &= b(x_t)dt + dw_t, \\ x_0 &\sim \mu \end{aligned}$$

can be constructed by a Girsanov transformation [10]. So $u_t^* = k(x_t)$ is admissible. In conclusion Assumption B is satisfied, which guarantees a.s. g-optimality of u^* for all g satisfying A7.

5. Proofs for diffusions.

Proof of Theorem 3.1. In this proof we let $(\Omega, \mathcal{F}, P)$ be any probability space in which stochastic processes $x_\cdot, x^*$, having law P^u and P^{u^*}, respectively, are defined. Without loss of generality (e.g., by using Theorem 4.2 in [10]), we may assume there are Brownian motions $w_\cdot, w_\cdot^*$ such that the equalities

$$\begin{aligned} dx_t &= f(x_t, u_t)dt + \sigma(x_t, u_t)dw_t, \\ dx_t^* &= f(x_t^*, u_t^*)dt + \sigma(x_t^*, u_t^*)dw_t^* \end{aligned}$$

hold in a strong sense.

Let $n = [T]$ be the integer part of $T > 0$. Then

$$\begin{aligned} g(T)[J_T(u^*) - J_T(u)] &= g(T)\left[\int_0^T c(x_t^*, u_t^*)\,dt - \int_0^T c(x_t, u_t)\,dt\right] \\ &\leq g(n)\left[\int_0^{n+1} c(x_t^*, u_t^*)\,dt - \int_0^n c(x_t, u_t)\,dt\right] \\ &= g(n)[J_{n+1}(u^*) - J_n(u)]. \end{aligned}$$

Thus it is sufficient to prove

$$\limsup_{n\to+\infty} g(n)[J_{n+1}(u^*) - J_n(u)] \leq 0 \quad \text{a.s.} \tag{5.1}$$

We first assume that Assumption A holds.

For $\varepsilon > 0$, we define $\Gamma_n = \{g(n)[J_{n+1}(u^*) - J_n(u)] \geq \varepsilon\}$, $\tau_n = \inf\{s : J_s(u) \geq h_n\} \wedge n$, and $h_n = nq(n)^{-1}$. We have

$$\begin{aligned} P(\Gamma_n, \tau_n < n) &= P(g(n)J_{n+1}(u^*) \geq g(n)J_n(u) + \varepsilon, \tau_n < n) \\ &\leq P(g(n)J_{n+1}(u^*) \geq g(n)h_n + \varepsilon) \\ &\leq P(J_{n+1}(u^*) \geq h_n). \end{aligned} \tag{5.2}$$

From the Chebyshev inequality, A6, and the definition of h_n

$$\begin{aligned} P(J_{n+1}(u^*) \geq h_n) &\leq h_n^{-m} E[J_{n+1}(u^*)]^m \\ &\leq C h_n^{-m}(n+1)^m = Cq(n)^m(1 + \tfrac{1}{n})^m, \end{aligned} \tag{5.3}$$

where we denoted by C different constants whose specific values are irrelevant. Condition A7 is equivalent to convergence of $\sum_{n=1}^{+\infty} q(n)^m$ and $\sum_{n=1}^{+\infty} q(n)^m(1 + 1/n)^m$. Thus from (5.2) and (5.3)

$$\sum_{n=1}^{+\infty} P(\Gamma_n, \tau_n < n) < +\infty, \tag{5.4}$$

which implies (5.1) on the set $\{\tau_n < n\}$.

We now deal with the set $\{\tau_n = n\}$. By applying Itô's rule to the solution of (HJB) we get

$$dV_T(t, x_t) = \left[\frac{\partial V_T}{\partial t}(t, x_t) + L^{u_t} V_T(t, x_t)\right] dt + \frac{\partial V_T}{\partial x}(t, x_t)\sigma(x_t, u_t) dw_t.$$

Using (HJB), adding and subtracting $c(x_t, u_t)dt$ to the previous equation, we get

$$J_T(u) = V_T(0, x_0) + \int_0^T \Delta^{V_T}(t, x_t, u_t) dt + M_T^{V_T}(u), \tag{5.5}$$

where

$$\Delta^{V_T}(t, x_t, u_t) = L^{u_t} V_T(t, x_t) + c(x_t, u_t) - \inf_{v \in U}[L^v V_T(t, x_t) + c(x_t, v)] \geq 0$$

and

$$M_T^{V_T}(u) = \int_0^T \frac{\partial V_T}{\partial x}(t, x_t)\sigma(x_t, u_t) dw_t$$

is a continuous local martingale. Similarly, by using the solution of (SHJB) rather than (HJB) we have

$$J_T(u^*) = \phi(x_0) + \lambda T - \phi(x_T^*) + M_T^\phi(u^*), \tag{5.6}$$

where

$$M_T^\phi(u^*) = \int_0^T \frac{\partial \phi}{\partial x}(t, x_t^*)\sigma(x_t^*, u_t^*) dw_t^*.$$

Thus, letting $W_T(t, x) = \phi(x) + \lambda(T - t)$, we obtain

$$g(n)[J_{n+1}(u^*) - J_n(u)] \leq g(n)[W_{n+1}(0,x_0) - V_n(0,x_0)] - g(n)\phi^-(x^*_{n+1})$$

$$+g(n)\int_0^{n+1} \frac{\partial W_{n+1}}{\partial x}(t,x^*_t)\sigma(x^*_t,u^*_t)\,dw^*_t - g(n)\int_0^n \frac{\partial V_n}{\partial x}(t,x_t)\sigma(x_t,u_t)\,dw_t. \tag{5.7}$$

It follows by Assumption A2 and the Borel–Cantelli lemma that

$$\lim_{n\to\infty} g(n)\phi^-(x^*_{n+1}) = 0$$

a.s., and by Assumption A3 that

$$\limsup_{n\to+\infty} g(n)[W_{n+1}(0,x_0) - V_n(0,x_0)] \leq 0 \quad \text{a.s.} \tag{5.8}$$

Now let Γ'_n denote the event where the expression in the second line of (5.7) takes a value greater that ε. Using first Chebyshev and then Burkholder inequality [17], we have

$$\begin{aligned} P(\Gamma'_n, \tau_n = n) &\leq P\left(g(n)\int_0^{n+1} \frac{\partial W_{n+1}}{\partial x}(t,x^*_t)\sigma(x^*_t,u^*_t)\,dw^*_t \geq \frac{\varepsilon}{3}\right) \\ &+P\left(-g(n)\int_0^n \frac{\partial V_n}{\partial x}(t,x_t)\sigma(x_t,u_t)\,dw_t \geq \frac{\varepsilon}{3}, \tau_n = n\right) \\ &\leq Cg(n)^{2m}E\left[\int_0^{n+1}\left|\frac{\partial W_{n+1}}{\partial x}(t,x^*_t)\sigma(x^*_t,u^*_t)\right|^2 dt\right]^m \\ &+Cg(n)^{2m}E\left[\int_0^{\tau_n}\left|\frac{\partial V_n}{\partial x}(t,x_t)\sigma(x_t,u_t)\right|^2 dt\right]^m. \end{aligned} \tag{5.9}$$

Now using Assumptions A5, A6, and the inequality $(a+b)^m \leq 2^m(a^m+b^m)$ we have

$$\begin{aligned} &E\left[\int_0^{n+1}\left|\frac{\partial W_{n+1}}{\partial x}(t,x^*_t)\sigma(x^*_t,u^*_t)\right|^2 dt\right]^m \\ &\leq B2^m\left[(n+1)^m + E\left[\int_0^{n+1} c(x^*_t,u^*_t)\,dt\right]^m\right] \leq B'(n+1)^m. \end{aligned} \tag{5.10}$$

Moreover, by Assumption A4 and the definition of τ_n,

$$\int_0^{\tau_n}\left|\frac{\partial V_n}{\partial x}(t,x_t)\sigma(x_t,u_t)\right|^2 dt \leq B[J_{\tau_n}(u)+n] \leq B[h_n+n]. \tag{5.11}$$

Thus, by (5.9)–(5.11), we obtain, for some constant A

$$P(\Gamma'_n, \tau_n = n) \leq Ag(n)^{2m}[(n+1)^m + (h_n+n)^m] = A\left[q_n^{2m}\left(1+\frac{1}{n}\right)^m + (q_n+q_n^2)^m\right], \tag{5.12}$$

which implies

$$\sum_{n=1}^{+\infty} P(\Gamma'_n, \tau_n = n) < +\infty.$$

This inequality, together with the Borel–Cantelli lemma, (5.4), and (5.8) completes the proof under Assumption A.

Under Assumption B the proof needs a slight modification. In particular, the proof of (5.1) on $\{\tau_n < n\}$ is unchanged. For the case $\{\tau_n = n\}$ we use Itô's rule for both $\phi(x_t)$ and $\phi(x_t^*)$, obtaining

$$g(n)[J_{n+1}(u^*) - J_n(u)] \leq g(n)[\lambda + \phi(x_n) - \phi(x_{n+1}^*)]$$

$$+g(n)\int_0^{n+1} \frac{\partial W_{n+1}}{\partial x}(t, x_t^*)\sigma(x_t^*, u_t^*)\, dw_t^* - g(n)\int_0^n \frac{\partial W_n}{\partial x}(t, x_t)\sigma(x_t, u_t)\, dw_t.$$

Bounds for the martingale terms are obtained as before, while $g(n)[\lambda+\phi(x_n)-\phi(x_{n+1}^*)]$ goes to zero, since ϕ is bounded. □

Proof of Theorem 3.2. Just note that, under the hypothesis of Theorem 3.2, the expressions in (5.3) and (5.12) are infinitesimal, although possibly not summable. □

6. Pathwise optimality for multivariate point processes. In this section we deal with stochastic processes taking value in $\mathbb{N}^d$, $\mathbb{N}$ being the set of positive integers, and generated by the family of operators

$$L^v = \sum_{i=1}^d \lambda^{(i)}(x, v)\nabla_i \tag{6.1}$$

with $x \in \mathbb{N}^d$; here $\nabla_i f(x) = f(x+e_i) - f(x)$, where $e_i = (0, \ldots, 0, 1, 0, \ldots, 0)$, the "1" being in the ith component. The functions $\lambda^{(i)}$ are assumed to be measurable and nonnegative.

Suppose u is an admissible control. Here P^u is meant to be defined on $D = D([0, +\infty), \mathbb{N}^d) \subset D([0, +\infty), \mathbb{R}^d)$. It is well known that, under P^u, the processes

$$M_t^{(i)} = x_t^{(i)} - \int_0^t \lambda^{(i)}(x_s, u_s)ds, \quad i = 1, \ldots, d, \tag{6.2}$$

are orthogonal local martingales. In (6.2), x_t denotes the canonical process.

In this context, the equations (HJB) and (SHJB) have the same form they had for diffusions, once the operator L^v is replaced by the one in (6.1).

As for diffusions, we now state two sets of assumptions.

Assumption A.

A1. For all $T > 0$ there exists a solution V_T of (HJB) that is continuously differentiable in t.

A2. There exists a solution (ϕ, λ) of (SHJB). The "inf" in (SHJB) is attained at $v = k(x)$, and the feedback $u_t^* = k(x_t)$ is an admissible control. Moreover, there exist constants $C, \epsilon > 0$ for which

$$E^{P^{u^*}}\left[\left(\phi^-(x_t)\right)^{2+\epsilon}\right] < C.$$

A3. The following inequality holds:

$$\limsup_{T\to+\infty} g(T)\left[\phi(x_0) + \lambda T - V_T(0, x_0)\right] \leq 0 \qquad \mu\text{-a.s.}$$

Moreover, there is an integer $m > 0$ such that the following further assumptions hold.

A4. There is a constant $B > 0$ such that for all $1 \le r \le 2^m$ and for all $i = 1, \dots, d$

$$|\nabla_i V_T(t,x)|^r \lambda^{(i)}(x,u) \le B(c(x,u)+1). \tag{6.3}$$

(Note that it is enough to check (6.3) for $r = 1$ and $r = 2^m$.)

A5. As A4, with ϕ replacing V_T.

A6. There is a constant $C > 0$ such that

$$E\left\{\left[\int_0^T c(x_t^*, u_t^*)dt\right]^{2^{m-1}}\right\} \le CT^{2^{m-1}}$$

for all $T > 0$.

A7. Define $q(t) = t^{1/2}g(t)$. Then

$$\int_1^{+\infty} q^{2^{m-1}}(t)dt < +\infty.$$

As we shall see later, the reason why these assumptions are slightly more complicated than the ones in section 3 is that it is harder to get good estimates for discontinuous martingales than for continuous ones.

Assumption B. There is a solution (ϕ, λ) of (SHJB), with ϕ bounded. Moreover, Assumptions A2, A5, A6, and A7 hold.

Under either Assumption A or B Theorems 3.1 and 3.2 hold true. Their proof, in the context of point processes, is given in the following section.

7. Proofs for point processes. Theorems 3.1 and 3.2 for point processes are proved using the same argument used for diffusions. We sketch here the proof, stressing the only important modification that is needed. For simplicity of notation we write P for P^{u,u^*}.

We again start by defining $h_n = nq^{-1}(n)$ and $\tau_n = \inf\{s : J_s(u) \ge h_n\} \wedge n$. The proof of

$$\limsup_{n\to\infty} g(n)[J_{n+1}(u^*) - J_n(u)] \le 0 \quad \text{a.s.} \tag{7.1}$$

on the set $\{\tau_n < n\}$ is identical to the one in section 5. For the case $\{\tau_n = n\}$ we need to obtain representations for the cost function J_T that correspond to (5.5) and (5.6). Observe that

$$\begin{aligned} V_T(T,x_T) - V_T(0,x_0) &= -V_T(0,x_0) \\ &= \sum_{0<t\le T}[V_T(t,x_t) - V_T(t,x_{t-})] + \int_0^T \frac{\partial V_T}{\partial t}(t,x_t)dt \\ &= \sum_{i=1}^d \int_0^T \nabla_i V_T(t,x_{t-})dx_t^{(i)} + \int_0^T \frac{\partial V_T}{\partial t}(t,x_t)dt \\ &= \int_0^T \Big(\frac{\partial V_T}{\partial t} + L^{u_t}V_T\Big)(t,x_t)dt + M_T^{V_T}(u), \end{aligned}$$

where

$$M_T^{V_T}(u) = \sum_{i=1}^d \int_0^T \nabla_i V_T(t,x_{t-})dM_t^{(i)},$$

with $M_t^{(i)}$ being the local martingale in (6.2). Thus, similarly to (5.5),

$$J_T(u) = V_T(0, x_0) + \int_0^T \Delta^{V_T}(t, x_t, u_t)dt + M_T^{V_T}(u), \tag{7.2}$$

where

$$\Delta^{V_T}(t, x_t, u_t) = L^{u_t}V_T(t, x_t) + c(x_t, u_t) - \inf_{v \in U}[L^v V_T(t, x_t) + c(x_t, v)] \geq 0.$$

A similar representation for the cost is obtained if one uses the solution of the (SHJB). The key to the proof of Theorem 3.1 is to show that for every $\epsilon > 0$, under Assumption A,

$$\sum_n P\{g(n)|M_n^{V_n}(u)| > \epsilon, \tau_n = n\} < +\infty \tag{7.3}$$

together with the analogous estimate for the martingale with ϕ replacing V_T and u^* replacing u. We prove only (7.3); the rest of the proof is identical to the diffusion case.

We begin by noting that the quadratic variation of the local martingale $M_T^{V_T}(u)$ is given by (see [17, Theorem 22])

$$[M_T^{V_T}(u), M_T^{V_T}(u)] = \sum_{i=1}^d \int_0^T [\nabla_i V_T(t, x_{t-})]^2 dx_t^{(i)}.$$

It follows, by Burkholder inequality, that

$$\begin{aligned} E\left\{|M_n^{V_{\tau_n}}(u)|^{2^m}\right\} &\leq C\sum_{i=1}^d E\left\{\left[\int_0^{\tau_n}[\nabla_i V_n(t, x_{t-})]^2 dx_t^{(i)}\right]^{2^{m-1}}\right\} \\ &\leq C'\sum_{i=1}^d \left(E\left\{\left[\int_0^{\tau_n}[\nabla_i V_{\tau_n}(t, x_{t-})]^2 dM_t^{(i)}\right]^{2^{m-1}}\right\}\right. \\ &\qquad \left. + E\left\{\left[\int_0^{\tau_n}[\nabla_i V_{\tau_n}(t, x_t)]^2 \lambda^{(i)}(x_t, u_t)dt\right]^{2^{m-1}}\right\}\right) \end{aligned}$$

for some constants C, C' depending on m. Now we can apply again Burkholder inequality to the local martingale

$$\int_0^{\tau_n} [\nabla_i V_n(t, x_{t-})]^2 dM_t^{(i)}$$

in order to bound the term

$$E\left\{\left[\int_0^{\tau_n}[\nabla_i V_n(t, x_{t-})]^2 dM_t^{(i)}\right]^{2^{m-1}}\right\}.$$

Iterating this procedure and noting that, for the last iteration

$$E\left\{\int_0^{\tau_n}[\nabla_i V_n(t, x_{t-})]^{2^m} dx_t^{(i)}\right\} = E\left\{\int_0^{\tau_n}[\nabla_i V_n(t, x_{t-})]^{2^m} \lambda^{(i)}(x_t, u_t)dt\right\},$$

we obtain the following estimate:

$$E\Big\{|M^{V_n}_{\tau_n}(u)|^{2^m}\Big\} \le C\sum_{i=1}^{d}\sum_{r=1}^{m} E\left\{\left[\int_0^{\tau_n}[\nabla_i V_{\tau_n}(t,x_{t-})]^{2^r}\lambda^{(i)}(x_t,u_t)dt\right]^{2^{m-r}}\right\}. \tag{7.4}$$

It follows, using Chebyshev's inequality, Assumption A4, and the definition of τ_n that

$$P\{g(n)|M^{V_n}_n(u)| > \epsilon, \tau_n = n\} \le Cg^{2^m}(n)E\Big\{|M^{V_n}_{\tau_n}(u)|^{2^m}\Big\}$$

$$\le Cg^{2^m}(n)\sum_{i=1}^{d}\sum_{r=1}^{m} B[J_{\tau_n}(u)+n]^{2^{m-r}} \le C'g^{2^m}(n)\sum_{r=1}^{m}[h_n+n]^{2^{m-r}}.$$

The summability over n of this last expression is straightforward. The proof of (7.3) is therefore completed.

The modifications needed for the proof of Theorem 3.2 are identical to the case of diffusions. □

8. Pathwise optimality for Markov chains with finite state space. Let X be a finite set and assume U is a compact metric space. For $x, y \in X$, with $x \neq y$, let

$$l_{x,y} : U \to \mathbb{R}^+$$

be strictly positive functions. The X-valued controlled processes we consider in this section correspond to the family of operators L^v, $v \in U$, defined by

$$L^v f(x) = \sum_{y\neq x} l_{x,y}(v)[f(y) - f(x)]. \tag{8.1}$$

To complete the assumptions on the model we assume that the running cost function $c(x, v)$ is continuous in v.

LEMMA 8.1. *There exists a solution* (ϕ, λ) *of* (SHJB).

We have not been able to find a proper reference for Lemma 8.1. Its proof, obtained by adapting that of [4, Theorem 6.1], is given in the appendix. Note that, due to the finiteness of X, compactness of U, and continuity of $l_{x,y}(\cdot), c(x,\cdot)$, there is a feedback $k(x)$ that minimizes the "inf" in (SHJB); moreover, the associated feedback control is admissible.

We can now prove the main result of this section.

THEOREM 8.2. *The control* $u^*(x_t)$ *is g-optimal a.s. for every g satisfying Assumption* A7*, and it is g-optimal in probability if* $g(t)t^{1/2} = o(1)$.

Proof. The proof is a simple modification of the one for point processes. As for both diffusions and point processes, the proof starts by defining the stopping time τ_n, and showing that

$$\limsup_{n\to\infty} g(n)[J_{n+1}(u^*) - J_n(u)] \le 0 \tag{8.2}$$

on the set $\{\tau_n < n\}$, a.s. or in probability according to which assumptions one chooses. For the case $\tau_n = n$ we obtain a representation of the cost function in terms of the solution of (SHJB).

For $y \in X$, let $N_t(y)$ be the process that counts the number of jumps to the state y. It is known that

$$M_t(y) = N_t(y) - \int_0^t l_{x_s,y}(u_s)ds$$

is a P^u-martingale, with quadratic variation $N_t(y)$. Thus, if (ϕ, λ) is the solution of (SHJB), we get

$$\phi(x_T) - \phi(x_0) = \sum_{0 \leq t \leq T} [\phi(x_t) - \phi(x_{t-})]$$

$$= \int_0^T \sum_{y \neq x_{t-}} [\phi(y) - \phi(x_{t-})]dN_t(y) = \int_0^T L^{u_t}\phi(x_t)dt + \int_0^T \sum_{y \neq x_{t-}} [\phi(y) - \phi(x_{t-})]dM_t(y).$$

It follows that

$$g(n)[J_{n+1}(u^*) - J_n(u)] \leq g(n)[\lambda + \phi(x_n)]$$

$$+g(n) \int_0^{n+1} \sum_{y \neq x_{t-}} [\phi(y) - \phi(x^*_{t-})]dM^*_t(y) - g(n) \int_0^n \sum_{y \neq x_{t-}} [\phi(y) - \phi(x_{t-})]dM_t(y). \tag{8.3}$$

Expression (8.3) is estimated as in the proof for point processes. It is clear that here $\phi(x)$ and $l_{x,y}(u)$ are bounded, which makes the proof work as the one for point processes under Assumption B. □

Appendix A.

Proof of Lemma 8.1.

For $\alpha > 0$ define the function

$$V_\alpha(x) = \inf_{u \in \mathcal{U}} E^u_x \left\{ \int_0^{+\infty} e^{-\alpha t} c(x_t, u_t)dt \right\}, \tag{A.1}$$

where E^u_x is the expectation with respect to P^u with initial condition $P^u \circ \Pi_0^{-1} = \delta_x$. It is easy to see that V_α can also be rewritten as

$$V_\alpha(x) = \inf_{u \in \mathcal{U}} E^u_x \left\{ \int_0^T e^{-\alpha t} c(x_t, u_t)dt + e^{-\alpha T} V_\alpha(x_T) \right\}$$

for any $T > 0$. Now define

$$\begin{aligned} V_{\alpha,T}(x,t) = & \inf_{u \in \mathcal{U}} E^u_x \left\{ \int_t^T e^{-\alpha s} c(x_s, u_s)ds + e^{-\alpha T} V_\alpha(x_T) \Big| x_t = x \right\} \\ = & \; e^{-\alpha t} V_\alpha(x). \end{aligned} \tag{A.2}$$

Clearly $V_{\alpha,T}$ is the value function of a stochastic control problem in the finite time horizon $[0, T]$. Thus it satisfies the (HJB) equation

$$\frac{\partial V_{\alpha,T}}{\partial t}(x,t) + \inf_{v \in U} \left[L^v V_{\alpha,T}(x,t) + e^{-\alpha t} c(x,v) \right] = 0$$

that, by (A.2), is equivalent to

$$\inf_{v \in U} \Big[L^v V_\alpha(x) + c(x,v) \Big] = \alpha V_\alpha(x). \tag{A.3}$$

Now let

$$\bar{V_\alpha} = \frac{1}{|X|} \sum_{x \in X} V_\alpha(x),$$

$$\phi_\alpha(x) = V_\alpha(x) - \bar{V_\alpha}.$$

Equation (A.3) can be rewritten in terms of ϕ_α as

$$\inf_{v \in U} \left[\sum_{y \neq x} l_{x,y}(v) \big(\phi_\alpha(y) - \phi_\alpha(x) \big) + c(x,v) \right] = \alpha \phi_\alpha(x) + \alpha \bar{V_\alpha}. \tag{A.4}$$

Let $k_\alpha(x)$ be the feedback that realizes the "inf" in (A.4) (or (A.3)), and let m_α be the invariant measure of the corresponding optimal process. The invariant measure satisfies the equation

$$\sum_{y \neq x} m_\alpha(x) l_{x,y}(k_\alpha(x)) = \sum_{y \neq x} m_\alpha(y) l_{y,x}(k_\alpha(y)) \tag{A.5}$$

from which one easily obtains

$$0 < A \leq m_\alpha(x) \leq B < +\infty \quad \text{for all } \alpha > 0, x \in X, \tag{A.6}$$

where

$$B = \frac{|X| \sup\{l_{x,y}(v) : x,y \in X, v \in U\}}{\inf\{l_{x,y}(v) : x,y \in X, v \in U\}},$$

$$A = \frac{\inf\{l_{x,y}(v) : x,y \in X, v \in U\} \wedge 1}{1 + |X| \sup\{l_{x,y}(v) : x,y \in X, v \in U\}}.$$

In particular, A and B do not depend on α.

Now consider (A.3). After multiplying it by $m_\alpha(x) V_\alpha(x)$, summing over x, and using (A.5), we obtain

$$\begin{aligned} &\frac{1}{2} \sum_x \sum_{y \neq x} m_\alpha(x) l_{x,y}(k_\alpha(x)) [V_\alpha(y) - V_\alpha(x)]^2 \\ &\quad = \sum_x m_\alpha(x) c(x, k_\alpha(x)) V_\alpha(x) - \alpha \sum_x m_\alpha(x) V_\alpha^2(x). \end{aligned} \tag{A.7}$$

On the other hand, if we multiply (A.3) by $m_\alpha(x)$ and sum over x, we get

$$0 = \alpha \sum_x m_\alpha(x) V_\alpha(x) - \sum_x m_\alpha(x) c(x, k_\alpha(x)). \tag{A.8}$$

By (A.7) and (A.8) we obtain

$$\begin{aligned} &\frac{1}{2} \sum_x \sum_{y \neq x} m_\alpha(x) l_{x,y}(k_\alpha(x)) [\phi_\alpha(y) - \phi_\alpha(x)]^2 \\ &\quad = \sum_x m_\alpha(x) c(x, k_\alpha(x)) \phi_\alpha(x) - \alpha \sum_x m_\alpha(x) V_\alpha(x) \phi_\alpha(x). \end{aligned} \tag{A.9}$$

Note now that, by (A.1),

$$\alpha V_\alpha(x) \le \sup_{x,v} c(x,v) < +\infty. \tag{A.10}$$

Thus (A.6), (A.9), and (A.10) yield

$$|\phi_\alpha(y) - \phi_\alpha(x)|^2 \le C \sup_z |\phi_\alpha(z)| \quad \text{for all } x, y \in X \tag{A.11}$$

for some constants $C > 0$. Inequality (A.11) implies that ϕ_α is uniformly bounded in α. Otherwise, for any $M > 0$ there is α, x such that $|\phi_\alpha(x)| > M$. Combining this with (A.11), we get

$$\left| \sum_y \phi_\alpha(y) \right| \ge M - |X|\sqrt{CM}.$$

It cannot be so for M large, since $\sum_y \phi_\alpha(y) = 0$.

Boundedness of both ϕ_α and αV_α guarantees that along some sequence $\alpha_n \to 0$

$$\phi_{\alpha_n} \to \phi, \quad \alpha_n \bar{V}_{\alpha_n} \to \lambda.$$

We may now pass to the limit as $\alpha_n \to 0$ in (A.4), and we see that (ϕ, λ) is a solution to (SHJB).

EXISTENCE AND CHARACTERIZATION OF AN OPTIMAL CONTROL FOR THE PROBLEM OF LONG WAVES IN A SHALLOW-WATER MODEL[*]

AZIZ BELMILOUDI[†]

Abstract. In this paper we present a method of optimal control developed in order to calculate the current corresponding to the observed sea level in a fluid domain Ω and during a time T. The control is the external stress $\underline{f}$. The cost function measures the distance between the observed and computed sea levels. The equations satisfied by the depth and the depth averaged velocity are of nonlinear shallow-water type. The existence and uniqueness of a solution for the direct problem are studied in the case of Dirichlet nonhomogeneous boundary conditions. We prove, by means of minimizing sequences, the existence of an optimal control $(\underline{f}, \underline{u})$ in the case of the small data and a very viscous fluid. To characterize it we build a sequence of problems corresponding to a linearization of the direct problem. We obtain the necessary conditions of optimality. The set of equations and the inequality characterizing the optimal control $(\underline{f}, \underline{u})$ is obtained as the limit of the penalization.

Key words. optimal control, shallow-water equations, nonlinear partial differential equations, minimizing sequences, penalization, altimetric measurements, oceanography

1. Introduction and setting of the problem.

The mathematical method developed in this paper allows us to obtain the circulation in an oceanic domain Ω from satellite measurements which are surface observations. Altimetric measurements give the distance between the satellite and the sea surface. It is now possible to extract from these data the sea level topography with a precision in the order of centimeters. The sea level will act as the observation in our control model.

The phenomenon we are studying derives from the modelization of long waves in shallow-water zones (lochs, lagoons, etc.). In such regions currents are weak but play an important role in the biological and ecological equilibrium. The equations of motion are of Navier–Stokes type. Shallow-water domains are characterized by a small ratio between vertical and horizontal length scales. Then the friction on the bottom is important. Some assumptions of the model are imposed by physical features, such as the Boussinesq approximation: density variations are neglected except in the terms of gravity acceleration. Moreover, we assume that the pressure is hydrostatic, which is justified by the difference between horizontal and vertical scalings: the vertical component of the Navier–Stokes equations is simplified in order to express the balance between the gravity term and the vertical gradient of pressure.

The shallow-water equations are obtained by integrating the Navier–Stokes equations with respect to depth [5]. Moreover, we suppose that the velocity is small enough that $\frac{\partial \underline{\tilde{u}}}{\partial t} \gg (\underline{\tilde{u}}\nabla)\underline{\tilde{u}}$. This assumption is justified for shallow-water domains (see, for example, Pedlosky [17, pp. 67–69]) where currents remain weak, but it presents great variations with time. It allows one to neglect the advection term. Then the equations

verified by the depth averaged motion are the following:

$$\begin{aligned}&\frac{\partial \underline{\tilde{u}}}{\partial t} - \nu_1 \Delta \underline{\tilde{u}} + \frac{C}{D} \mid \underline{\tilde{u}} \mid_2 \underline{\tilde{u}} + \underline{F} \wedge \underline{\tilde{u}} + g\nabla \tilde{h} = \underline{\tilde{f}} \text{ on } \Omega,\\ &\frac{\partial \tilde{h}}{\partial t} - \nu_2 \Delta \tilde{h} + \operatorname{div}(\tilde{h}\underline{\tilde{u}}) = f_0 \text{ on } \Omega,\end{aligned} \tag{1.1}$$

where $\underline{\tilde{u}}: \ \Omega\times]0,T[\longrightarrow \mathbb{R}^2$ is the velocity and $\tilde{h}: \ \Omega\times]0,T[\longrightarrow \mathbb{R}$ is the depth of the studied layer and $\mid . \mid_2$ denotes the euclidean norm in $\mathbb{R}^2$.

The domain $\Omega \in \mathbb{R}^2$ is the projection of the oceanic domain on the horizontal plane. It corresponds to the undisturbed sea surface. Γ denotes its boundary. $\underline{F}$ is the Coriolis force defined by $(0, 0, 2\omega\text{sin}(\phi))$, where ω is the rotation rate of the earth and ϕ the latitude. g denotes the acceleration of gravity. The dissipative term corresponds to Reynolds stresses. ν_1 and ν_2 are eddy viscosity and diffusivity coefficients. C is the Chezy positive constant, D the averaged depth of the layer. The right-hand terms $\underline{\tilde{f}}$ and f_0 represent, respectively, the outside stress and the fluid exchanges (rain, evaporation, etc.). The shear effect on the bottom is represented by the term $\frac{C}{D} \mid \underline{\tilde{u}} \mid_2 \underline{\tilde{u}}$.

The total depth $\tilde{h}$ can be considered as the sum of two terms: the bottom topography $H(x, y)$ which is given and the topography $\xi(x, y, t)$ of the free sea surface. In order to solve (1.1), we have to set boundary and initial conditions:

$$\begin{aligned}&(\underline{\tilde{u}}, \tilde{h}) = (\underline{\tilde{u}}_B, \tilde{h}_B) \text{ on } \Gamma,\\ &(\underline{\tilde{u}}, \tilde{h})(t = 0) = (\underline{\tilde{u}}_0, \tilde{h}_0) \text{ in } \Omega.\end{aligned} \tag{1.2}$$

We are first going to prove that problem (1.1)–(1.2) is equivalent to another nonlinear problem with homogeneous boundary conditions.

Let $\underline{u}_L$ be the solution of the linear problem

$$\begin{aligned}&\frac{\partial \underline{u}_L}{\partial t} - \nu_1 \Delta \underline{u}_L = 0 \text{ in } \Omega,\\ &\underline{u}_L(t = 0) = \underline{u}_1 \text{ in } \Omega,\\ &\underline{u}_L = \underline{\tilde{u}}_B \text{ on } \Gamma\end{aligned} \tag{1.3}$$

and let h_L be the solution of the linear problem

$$\begin{aligned}&\frac{\partial h_L}{\partial t} - \nu_2 \Delta h_L = 0 \text{ in } \Omega,\\ &h_L(t = 0) = h_1 \text{ in } \Omega,\\ &h_L = \tilde{h}_B \text{ on } \Gamma,\end{aligned} \tag{1.4}$$

where $\underline{u}_1 \in H^1(\Omega) \cap L^\infty(\Omega)$, $\underline{\tilde{u}}_B \in L^2(0, T, H^{1/2}(\Gamma)) \cap L^\infty(0, T, L^\infty(\Gamma))$, $h_1 \in H^1(\Omega) \cap L^\infty(\Omega)$, and $\tilde{h}_B \in L^2(0, T, H^{1/2}(\Gamma)) \cap L^\infty(0, T, L^\infty(\Gamma))$.

REMARK 1. (i) *We can choose any* $(\underline{u}_1, h_1) \in H^1(\Omega) \cap L^\infty(\Omega)$. *For example, we can take* $\underline{u}_1 = \underline{\tilde{u}}_0$ *and* $h_1 = \tilde{h}_0$. $(\underline{u}_L, h_L)$ *is a lifting of the boundary conditions.*

(ii) *According to Fabre, Puel, and Zuazua* [7] *the function* $(\underline{u}_L, h_L)$ *solution of the problems* (1.3), (1.4) *will thus satisfy* $(\underline{u}_L, h_L) \in L^2(0, T, (H^1(\Omega))^3) \cap L^\infty(0, T, (L^\infty(\Omega))^3)$. □

Setting $\underline{u} = \underline{\tilde{u}} - \underline{u}_L$, $h = \tilde{h} - h_L$, $f_1 = f_0 - \operatorname{div}(h_L \underline{u}_L)$, $\underline{f} = \underline{\tilde{f}} - g\nabla h_L - \underline{F} \wedge \underline{u}_L$, problem (1.1)–(1.2) can be rewritten as follows:

$$
\begin{aligned}
&\textit{Find } (\underline{u}, h) \textit{ such that}\\
&\frac{\partial \underline{u}}{\partial t} - \nu_1 \Delta \underline{u} + \frac{C}{D} \mid (\underline{u} + \underline{u}_L) \mid_2 (\underline{u} + \underline{u}_L) + \underline{F} \wedge \underline{u} + g \nabla h = \underline{f} \textit{ in } \Omega,\\
&\frac{\partial h}{\partial t} - \nu_2 \Delta h + \operatorname{div}(h\underline{u}) + \operatorname{div}(h_L \underline{u}) + \operatorname{div}(h \underline{u}_L) = f_1 \textit{ in } \Omega,\\
&(\underline{u}, h) = (\underline{0}, 0) \textit{ on } \Gamma,\\
&(\underline{u}, h)(t = 0) = (\underline{u}_0, h_0) \textit{ in } \Omega,
\end{aligned}
\tag{1.5}
$$

where $(\underline{u}_0, h_0) = (\tilde{\underline{u}}_0 - \underline{u}_1, \tilde{h}_0 - h_1)$.

It has to be noted that the two linear problems (1.3), (1.4) do not depend on the forcing $\tilde{\underline{f}}$ but only on the boundary conditions $(\tilde{\underline{u}}_B, \tilde{h}_B)$. These two problems being solved, problem (1.1)–(1.2) is equivalent to the homogeneous problem (1.5).

Our purpose is to develop a control method in order to compute the depth averaged velocity $\tilde{\underline{u}}$. The surface topography $\xi(x, y, t)$ can be deduced from altimetric measurements. Therefore $\tilde{h} = H(x, y) + \xi(x, y, t)$ can be taken as the observation. We assume that the fluid exchanges f_0 are known; the model is then controlled by the external forcing $\tilde{\underline{f}}$.

The previous remark concerning the equivalence between problem (1.1)–(1.2) and problem (1.5) makes it possible to apply the control method to problem (1.5) instead of problem (1.1)–(1.2). Obviously we first have to solve problems (1.3) and (1.4) in order to obtain $(\underline{u}_L, h_L)$. Then $\underline{f}$ acts as the control and the observation is the depth h_{obs}. The optimal control is the forcing minimizing a cost function which measures the distance between the computed depth h and the observation h_{obs}. Precisely we will study the following optimal control problem: find $(\underline{u}, h, \underline{f})$ such that the cost function

$$
J(\underline{f}, \underline{u}) = \frac{1}{4} \parallel h - h_{obs} \parallel^4_{L^4(0,T,L^4(\Omega))} + \frac{\gamma}{2} \parallel \underline{f} \parallel^2_{L^2(0,T,L^2(\Omega))} \qquad (\mathcal{P})
$$

is minimized subject to the problem (1.5), with $\underline{f} \in K_c$, K_c (given) being a convex, closed, nonempty subset of $L^2(0, T, L^2(\Omega))$.

This paper is organized as follows: Section 2 is devoted to the study of problem (1.5). We give sufficient conditions on the surface forcing $\underline{f}$, on the initial situation $(\underline{u}_0, h_0)$, and on $(\underline{u}_L, h_L)$ in order to prove the existence of a solution. These conditions being satisfied, we prove the uniqueness of the solution.

Section 3 is devoted to the control problem associated with (1.5). We first deal with the homogeneous case $\tilde{\underline{u}}_B = \underline{0}$, $\tilde{h}_B = 0$. Then we have $\underline{u}_L = \underline{0}$, $h_L = 0$; problem (1.1)–(1.2) and problem (1.5) are identical. We prove the existence of an optimal control by means of minimizing sequences $(\underline{f}_k, \underline{u}_k)$. In order to characterize this optimal control, we have to introduce a penalized control problem $\mathcal{P}_\epsilon$: the cost function is penalized and adapted to the optimal control $(\underline{f}, \underline{u})$. This type of method was introduced by Lions [12], [14] to control singular distributed systems. More recent works have developed the method of control in mathematical physics and performed variational data assimilation [1], [2], [3], [4], [15], [16].

The specificity of this paper derives from the following features: the direct problem is time-dependent and of shallow-water type, the equations are coupled and nonlinear. Moreover, the altimetric measurements allow us to take the sea level topography as the observation. The penalized control problem $\mathcal{P}_\epsilon$ is defined in such a way that the direct problem is linear. In order to characterize $(\underline{f}_\epsilon, \underline{w}_\epsilon)$, solution of $\mathcal{P}_\epsilon$, we define a suitable adjoint problem. The solution $(\underline{f}, \underline{u})$ of our initial control problem is obtained as the limit of $(\underline{f}_\epsilon, \underline{w}_\epsilon)$ when $\epsilon \to 0$. The set of equations and inequality characterizing $(\underline{f}, \underline{u})$ is obtained by passing to the limit in the characterization of $(\underline{f}_\epsilon, \underline{w}_\epsilon)$. The same technique can be used in the nonhomogeneous case: $\tilde{\underline{u}}_B \neq \underline{0}$, $\tilde{h}_B \neq 0$ because the velocity $\underline{u}_L$ and the depth h_L do not depend on control $\underline{f}$. $(\underline{u}_L, h_L)$ is calculated first. Then the control method is applied to the homogeneous problem (1.5).

The main result of this paper is the following theorem:

> Under the assumptions of Proposition 1, the optimal control problem $(\mathcal{P})$ has at least one solution $(\underline{u}, h, \underline{f})$ such that $\underline{f} \in K_c$ and $(\underline{u}, h)$ is the solution of problem (2.1) with a forcing equal to $\underline{f}$. Moreover, there exists $(\underline{R}, S) \in L^2(0,T,(H^1_0(\Omega))^3) \cap L^\infty(0,T,(L^2(\Omega))^3)$ such that

$$-\left(\frac{\partial \underline{R}}{\partial t}, \underline{v}\right) + a_1(\underline{R}, \underline{v}) + \frac{C}{D}\left(\mid (\underline{u}+\underline{u}_L) \mid_2 \underline{R} + (\underline{u}+\underline{u}_L, \underline{R})_2 \frac{(\underline{u}+\underline{u}_L)}{\mid (\underline{u}+\underline{u}_L) \mid_2}, \underline{v}\right)$$
$$-(\underline{F} \wedge \underline{R}, \underline{v}) - ((h+h_L)\nabla S, \underline{v}) = 0,$$
$$-\left(\frac{\partial S}{\partial t}, \beta\right) + a_2(S,\beta) - (((\underline{u}+\underline{u}_L)\nabla)S, \beta) - g(\mathrm{div}(\underline{R}), \beta) = ((h-h_{obs})^3, \beta),$$
$$(\underline{R}, S)(t=T) = (\underline{0}, 0) \quad \forall(\underline{v}, \beta) \in (H^1_0(\Omega))^3 \quad \text{almost everywhere (a.e.) } t \in (0,T),$$

and

$$(\underline{R} + \gamma \underline{f},\ \underline{g} - \underline{f})_{L^2(0,T,L^2(\Omega))} \geq 0\ \forall \underline{g} \in K_c.$$

2. Existence and uniqueness conditions. Let Ω be a fixed bounded open domain of $\mathbb{R}^2$. Γ denotes its boundary and is supposed to be sufficiently regular.

We introduce the following functional spaces:
$V_1 = (H^1_0(\Omega))^2$, $H_1 = (L^2(\Omega))^2$, $V_2 = H^1_0(\Omega)$, $H_2 = L^2(\Omega), V = V_1 \times V_2$, and $H = H_1 \times H_2$.

The norm and the seminorm defined on $H^1(\Omega)$ are equivalent in V_1, V_2, and V. Then we set $\| \underline{v} \| = \| \underline{v} \|_{V_1}$, $\| \beta \| = \| \beta \|_{V_2}$, and $\| X \| = \| X \|_V$ for $\underline{v} \in V_1, \beta \in V_2$, and $X \in V$. $\mid . \mid$ denotes the norm in $L^2(\Omega)$, $\mid . \mid_2$ denotes the euclidean norm in $\mathbb{R}^2$, and $(.,.)_2$ denotes the scalar product in $\mathbb{R}^2$.

We define

$a_1(\underline{u}, \underline{v}) = \nu_1(\nabla \underline{u}, \nabla \underline{v})$,
$a_2(h, \beta) = \nu_2(\nabla h, \nabla \beta)$,
$a(X,Y) = a_1(\underline{u}, \underline{v}) + a_2(h,\beta)$ with $X = (\underline{u}, h)$ and $Y = (\underline{v}, \beta)$.

a_1, a_2, and a are bilinear continuous coercive forms, respectively, on V_1, V_2, and V and we denote by α the constant of coercivity of a.

We can now write the weak formulation of problem (1.5):

(2.1)
Find $(\underline{u}, h) \in L^2(0,T,V) \cap L^\infty(0,T,H)$ such that

$$\left(\frac{\partial \underline{u}}{\partial t}, \underline{v}\right) + a_1(\underline{u}, \underline{v}) + \frac{C}{D}(\mid (\underline{u}+\underline{u}_L) \mid_2 (\underline{u}+\underline{u}_L), \underline{v}) + (\underline{F} \wedge \underline{u}, \underline{v}) - g(\mathrm{div}(\underline{v}), h) = (\underline{f}, \underline{v}),$$
$$\left(\frac{\partial h}{\partial t}, \beta\right) + a_2(h,\beta) + (\mathrm{div}(h\underline{u}), \beta) + (\mathrm{div}(h_L\underline{u}), \beta) + (\mathrm{div}(h\underline{u}_L), \beta) = (f_1, \beta)\ \forall(\underline{v}, \beta) \in V,$$
$$(\underline{u}, h)(t=0) = (\underline{u}_0, h_0).$$

Before studying the existence and uniqueness conditions, we are first going to prove four lemmas.

Lemma 1. *The operator :* $\underline{u} \longrightarrow | \underline{u} |_2 \, \underline{u}$ *is a monotone operator.*

Proof. Let $(\underline{u}, \underline{v}) \in V_1 \times V_1$,

$$(| \underline{u} |_2 \, \underline{u} - | \underline{v} |_2 \, \underline{v}, \underline{u} - \underline{v}) = (| \underline{u} |_2^2, | \underline{u} |_2) - (| \underline{u} |_2 \, \underline{u}, \underline{v}) - (| \underline{v} |_2 \, \underline{v}, \underline{u}) + (| \underline{v} |_2^2, | \underline{v} |_2).$$

Since $(\underline{u}, \underline{v})_2 \leq | \underline{u} |_2 | \underline{v} |_2$ we have

$$(| \underline{u} |_2 \, \underline{u} - | \underline{v} |_2 \, \underline{v}, \underline{u} - \underline{v}) \geq (| \underline{u} |_2^2 - | \underline{v} |_2^2, | \underline{u} |_2 - | \underline{v} |_2) = ((| \underline{u} |_2 - | \underline{v} |_2)^2, | \underline{u} |_2 + | \underline{v} |_2).$$

This implies that

$$(| \underline{u} |_2 \, \underline{u} - | \underline{v} |_2 \, \underline{v}, \underline{u} - \underline{v}) \geq 0. \qquad \square$$

Lemma 2. *If* $(\underline{u}, \underline{v})$ *is given in* $V_1 \times V_1$, *we have the following results:*

(i) $| \underline{u} |_2 \, \underline{v} \in L^{3/2}(\Omega)$.

(ii) *There exists a positive constant* c *such that* $\| \quad | \underline{u} |_2 \, \underline{v} \|_{V_1'} \leq c \, | \underline{u} | \quad \| \underline{v} \|$.

Proof. (i) Using the Schwarz inequality, we obtain

$$\int_\Omega | \underline{u} |_2^{3/2} | \underline{v} |_2^{3/2} \, d\Omega \leq c \left(\int_\Omega | \underline{u} |_2^2 \, d\Omega \right)^{3/4} \left(\int_\Omega | \underline{v} |_2^6 \, d\Omega \right)^{1/4}.$$

By applying the Sobolev injections ([11], for example), we have $\| | \underline{u} |_2 \, \underline{v} \|_{L^{3/2}(\Omega)} \leq c \, | \underline{u} | \| \underline{v} \|$ and then $| \underline{u} |_2 \, \underline{v} \in L^{3/2}(\Omega)$.

(ii) Setting $\underline{w} \in V_1$, we have $| (| \underline{u} |_2 \, \underline{v}, \underline{w}) | \leq c \, \| | \underline{u} |_2 \, \underline{v} \|_{L^{3/2}(\Omega)} \| \underline{w} \|_{L^3(\Omega)}$. Using result (i), we obtain $| (| \underline{u} |_2 \, \underline{v}, \underline{w}) | \leq c \, | \underline{u} | \| \underline{v} \| \| \underline{w} \|$, from which we can deduce result (ii). $\square$

Lemma 3. (i) *If* $\underline{v} \in V_1$ *or* $h \in V_2$, *then* $| (\mathrm{div}(h\underline{v}), \beta) | \leq c \, \| h \|_{L^4(\Omega)} \| \beta \| \| \underline{v} \|_{L^4(\Omega)}$,

(ii) *If* $(\underline{v}, h) \in V$, *then we have (Gagliardo–Nirenberg's inequality)* $\| \underline{v} \|_{L^4(\Omega)} \leq c \, \| \underline{v} \|^{\frac{1}{2}} | \underline{v} |^{\frac{1}{2}}$ *and* $\| h \|_{L^4(\Omega)} \leq c \, \| h \|^{\frac{1}{2}} | h |^{\frac{1}{2}}$.

Proof. (i) By applying the Green formula and $\underline{v} \in V_1$ (or $h \in V_2$) we obtain $| (\mathrm{div}(h\underline{v}), \beta) | = | ((h\nabla)\beta), \underline{v}) |$. Thus $| (\mathrm{div}(h\underline{v}), \beta) | \leq c \, \| h \|_{L^4(\Omega)} \| \beta \| \| \underline{v} \|_{L^4(\Omega)}$. For the proof of (ii) see, for example, [6], [18], [19].

Lemma 4. *Let* $(\underline{u}_m, h_m)$ *be a sequence converging toward* $(\underline{u}, h)$ *in* $L^2(0, T, H)$ *strongly and in* $L^2(0, T, V)$ *weakly. Then for any vector function* $\varphi(t)(\underline{v}, \beta)$, $\varphi \in C^1([0, T])$ *and* $(\underline{v}, \beta) \in V$, *we have*

(i) $\lim_{m \to \infty} \int_0^T (| \underline{u}_m + \underline{u}_L |_2 \, (\underline{u}_m + \underline{u}_L), \varphi(t)\underline{v}) dt = \int_0^T (| (\underline{u} + \underline{u}_L) |_2 \, (\underline{u} + \underline{u}_L), \varphi(t)\underline{v}) dt$.

(ii) $\lim_{m \to \infty} \int_0^T (\mathrm{div}(\underline{u}_m h_m), \varphi(t)\beta) dt = \int_0^T (\mathrm{div}(\underline{u}h), \varphi(t)\beta) dt$.

Proof. (i) We write

$$\int_0^T (| \underline{u}_m + \underline{u}_L |_2 \, (\underline{u}_m + \underline{u}_L), \varphi(t)\underline{v}) dt = \int_0^T \langle | \underline{u}_m + \underline{u}_L |_2 \, \varphi(t)\underline{v}, \underline{u}_m + \underline{u}_L \rangle_{V_1', V_1} dt$$

and

$$\int_0^T (| \underline{u} + \underline{u}_L |_2 \, (\underline{u} + \underline{u}_L), \varphi(t)\underline{v}) dt = \int_0^T \langle | \underline{u} + \underline{u}_L |_2 \, \varphi(t)\underline{v}, \underline{u} + \underline{u}_L \rangle_{V_1', V_1} dt.$$

Subtracting the previous equalities gives

$$\left| \int_0^T (\mid \underline{u}_m + \underline{u}_L \mid_2 (\underline{u}_m + \underline{u}_L), \varphi(t)\underline{v}) dt - \int_0^T (\mid \underline{u} + \underline{u}_L \mid_2 (\underline{u} + \underline{u}_L), \varphi(t)\underline{v}) dt \right|$$

$$\begin{aligned}
&= \left| \int_0^T \langle \mid \underline{u}_m + \underline{u}_L \mid_2 \varphi(t)\underline{v}, \underline{u}_m + \underline{u}_L \rangle_{V_1', V_1} dt \right. \\
&\qquad \left. - \int_0^T \langle \mid \underline{u} + \underline{u}_L \mid_2 \varphi(t)\underline{v}, \underline{u} + \underline{u}_L \rangle_{V_1', V_1} dt \right| \\
&\leq \left| \int_0^T \langle (\mid \underline{u}_m + \underline{u}_L \mid_2 - \mid \underline{u} + \underline{u}_L \mid_2) \varphi(t)\underline{v}, \underline{u}_m + \underline{u}_L \rangle_{V_1', V_1} dt \right| \\
&\qquad + \left| \int_0^T \langle \mid \underline{u} + \underline{u}_L \mid_2 \varphi(t)\underline{v}, \underline{u}_m - \underline{u} \rangle_{V_1', V_1} dt \right| \\
&\leq \; \parallel (\mid \underline{u}_m - \underline{u} \mid_2) \varphi(t)\underline{v} \parallel_{L^2(0,T,V_1')} \parallel \underline{u}_m + \underline{u}_L \parallel_{L^2(0,T,V_1)} \\
&\qquad + \left| \int_0^T \langle \mid \underline{u} + \underline{u}_L \mid_2 \varphi(t)\underline{v}, \underline{u}_m - \underline{u} \rangle_{V_1', V_1} dt \right|.
\end{aligned}$$

Since $\underline{u}_m$ converges towards $\underline{u}$ strongly in $L^2(0, T, H_1)$ and weakly in $L^2(0, T, V_1)$, since φ is bounded, and by using lemma 2 we obtain result (i).

(ii) By applying the Green formula, we have

$$\begin{aligned}
\int_0^T (\operatorname{div}(\underline{u}_m h_m), \varphi(t)\beta) dt &= - \int_0^T (h_m \varphi(t) \nabla\beta, \underline{u}_m) dt \\
&= - \int_0^T \sum_{i=1}^{i=2} \int_\Omega h_m \varphi(t) \partial_i \beta (u_m)_i d\Omega dt.
\end{aligned}$$

Using Temam [18, Lemma 3.2, p. 289] these integrals converge to

$$- \int_0^T (h\varphi(t)\nabla\beta, \underline{u}) dt = \int_0^T (\operatorname{div}(h\underline{u}), \varphi(t)\beta) dt. \qquad \square$$

We can now state the result of existence and uniqueness.

Proposition 1. *We assume that* $F_{ex} = (\underline{f}, f_1) \in L^2(0, T, H)$, $X_0 = (\underline{u}_0, h_0) \in V \cap (L^\infty(\Omega))^3$, *and* $(\underline{u}_L, h_L) \in L^2(0, T, (H^1(\Omega))^3) \cap L^\infty(0, T, (L^\infty(\Omega))^3)$.
If the following conditions are satisfied,

(i) $K = (2\alpha - C_g - C_L(\parallel \underline{u}_L \parallel_{L^\infty(0,T,L^4(\Omega))} + \parallel h_L \parallel_{L^\infty(0,T,L^4(\Omega))}))/C_0 > 0$,

(ii) $\mid X_0 \mid < K$,

(iii) $\mid X_0 \mid^2 + C_I(\parallel F_{ex} \parallel^2_{L^2(0,T,L^2(\Omega))} + \parallel \underline{u}_L \parallel^3_{L^3(0,T,L^4(\Omega))}) < K^2$,

then problem (2.1) *admits one unique solution* $(\underline{u}, h)$ *in* $L^2(0, T, V) \cap L^\infty(0, T, H)$.

Remark 2. *If* $(\underline{u}_L, h_L) \in L^2(0, T, (H^1(\Omega))^3) \cap L^\infty(0, T, (L^\infty(\Omega))^3)$, *then* $\operatorname{div}(h_L \underline{u}_L) \in L^2(0, T, L^2(\Omega))$. *If* $(\underline{\tilde{f}}, f_0) \in L^2(0, T, H)$, *then* $(\underline{f}, f_1) \in L^2(0, T, H)$. $\square$

Proof of the existence.

Since V is separable, there exists a free and total sequence $(\underline{w}_1, p_1), \ldots, (\underline{w}_m, p_m), \ldots$ in V. We denote by V_m the space generated by $(\underline{w}_1, p_1), \ldots, (\underline{w}_m, p_m)$. For each m

we define an approach problem:

(2.2)

$$\begin{aligned}
&\text{Find } (\underline{u}_m, h_m) \in V_m \text{ such that}\\
&\left(\frac{\partial \underline{u}_m}{\partial t}, \underline{w}_k\right) + a_1(\underline{u}_m, \underline{w}_k) + \frac{C}{D}(\mid \underline{u}_m + \underline{u}_L \mid_2 (\underline{u}_m + \underline{u}_L), \underline{w}_k) + (\underline{F} \wedge \underline{u}_m, \underline{w}_k)\\
&-g(\mathrm{div}(\underline{w}_k), h_m) = (\underline{f}, \underline{w}_k) \ \forall k = 1, m,\\
&\left(\frac{\partial h_m}{\partial t}, p_k\right) + a_2(h_m, p_k) + (\mathrm{div}(h_m \underline{u}_m), p_k) + (\mathrm{div}(h_m \underline{u}_L), p_k)\\
&+(\mathrm{div}(h_L \underline{u}_m), p_k) = (f_1, p_k) \ \forall k = 1, m,\\
&(\underline{u}_m, h_m)(t = 0) = (\underline{u}_{0m}, h_{0m}),
\end{aligned}$$

where, $(\underline{u}_{0m}, h_{0m})$ is the orthogonal projection in H of $(\underline{u}_0, h_0)$ on V_m such that $(\underline{u}_{0m}, h_{0m})$ converges strongly towards $(\underline{u}_0, h_0)$ in H, $\mid \underline{u}_{0m} \mid \leq \mid \underline{u}_0 \mid$, and $\mid h_{0m} \mid \leq \mid h_0 \mid$. Since $(\underline{u}_m, h_m) \in V_m$, we have $(\underline{u}_m, h_m) = (\sum_{k=1}^m g_{km}(t)\underline{w}_k, \sum_{k=1}^m l_{km}(t)p_k)$. (g_{km}, l_{km}) are scalar functions defined on $[0, T]$.

Multiplying the first half of (2.2) by g_{km} and the second half of (2.2) by l_{km} and adding with respect to k, we obtain

$$\begin{aligned}
(2.3)\qquad &\frac{1}{2}\frac{\partial \mid \underline{u}_m \mid^2}{\partial t} + a_1(\underline{u}_m, \underline{u}_m) + \frac{C}{D} \parallel \underline{u}_m + \underline{u}_L \parallel^3_{L^3(\Omega)} - g(\mathrm{div}(\underline{u}_m), h_m)\\
&\qquad -\frac{C}{D}(\mid \underline{u}_m + \underline{u}_L \mid_2 (\underline{u}_m + \underline{u}_L), u_L) = (\underline{f}, \underline{u}_m),\\
&\frac{1}{2}\frac{\partial \mid h_m \mid^2}{\partial t} + a_2(h_m, h_m) + (\mathrm{div}(h_m \underline{u}_m), h_m) + (\mathrm{div}(h_m \underline{u}_L), h_m)\\
&\qquad +(\mathrm{div}(h_L \underline{u}_m), h_m) = (f_1, h_m).
\end{aligned}$$

From these two equations we deduce

$$\begin{aligned}
&\frac{1}{2}\frac{\partial \mid X_m \mid^2}{\partial t} + a(X_m, X_m) + \frac{C}{D} \parallel \underline{u}_m + \underline{u}_L \parallel^3_{L^3(\Omega)} = \frac{C}{D}(\mid \underline{u}_m + \underline{u}_L \mid_2 (\underline{u}_m + \underline{u}_L), \underline{u}_L)\\
&\quad + g(\mathrm{div}(\underline{u}_m), h_m) - (\mathrm{div}(h_m \underline{u}_m), h_m)\\
&\quad - (\mathrm{div}(h_m \underline{u}_L), h_m) - (\mathrm{div}(h_L \underline{u}_m), h_m) + (F_{ex}, X_m),
\end{aligned}$$

where $X_m = (\underline{u}_m, h_m)$ and $F_{ex} = (\underline{f}, f_1)$.

According to Green's formula and Gagliardo–Nirenberg's inequality we have

$$2(\mathrm{div}(h_m \underline{u}_m), h_m) = (h_m^2, \mathrm{div}(\underline{u}_m))$$

and

$$\mid 2(\mathrm{div}(h_m \underline{u}_m), h_m) \mid \leq C \parallel h_m \parallel^2_{L^4(\Omega)} \parallel \underline{u}_m \parallel \leq C_0 \parallel X_m \parallel^2 \mid X_m \mid .$$

According to Lemma 3 we have

$$\begin{aligned}
\mid 2(\mathrm{div}(h_m \underline{u}_L), h_m) \mid &\leq C_L \parallel \underline{u}_L \parallel_{L^4(\Omega)} \parallel X_m \parallel^2,\\
\mid 2(\mathrm{div}(h_L \underline{u}_m), h_m) \mid &\leq C_L \parallel h_L \parallel_{L^4(\Omega)} \parallel X_m \parallel^2 .
\end{aligned}$$

Moreover,

$$\left|\frac{2C}{D}(\mid \underline{u}_m + \underline{u}_L \mid_2 (\underline{u}_m + \underline{u}_L), \underline{u}_L)\right| \leq C_L(\parallel \underline{u}_L \parallel_{L^4(\Omega)} \parallel X_m \parallel^2 + \parallel \underline{u}_L \parallel^3_{L^4(\Omega)})$$

and

$$| g(\mathrm{div}(\underline{u}_m), h_m) | \leq C_g \parallel X_m \parallel^2 .$$

Using the previous inequalities and the coercivity of a we deduce

$$\frac{\partial \mid X_m \mid^2}{\partial t} + \psi_m(t) \parallel X_m \parallel^2 \leq C_I(\mid F_{ex} \mid^2 + \parallel \underline{u}_L \parallel^3_{L^4(\Omega)}), \tag{2.4}$$

where $\psi_m(t) = 2\alpha - C_0 \mid X_m(t) \mid - C_g - C_L(\parallel \underline{u}_L \parallel_{L^\infty(0,T,L^4(\Omega))} + \parallel h_L \parallel_{L^\infty(0,T,L^4(\Omega))})$.

Let us prove that $\psi_m(t) > 0 \ \forall t \in [0,T]$.

According to condition (ii), we have $\psi_m(0) > 0$. Let us suppose that there exists $t \in [0,T]$ such that $\psi_m(t) \leq 0$. Since function ψ_m is continuous, there exists $T_0 \in [0,T[$ such that $\forall t \in [0, T_0[, \psi_m(t) > 0$ and $\psi_m(T_0) = 0$.

Integrating (2.4) from 0 to T_0 we obtain

$$\begin{aligned} &| X_m(T_0) |^2 + \int_0^{T_0} \psi_m(t) \parallel X_m(t) \parallel^2 dt \\ &\quad \leq C_I(\parallel F_{ex} \parallel^2_{L^2(0,T,L^2(\Omega))} + \parallel \underline{u}_L \parallel^3_{L^3(0,T,L^4(\Omega))}) + | X_0 |^2 . \end{aligned}$$

Since $\psi_m > 0$ on $[0, T_0[$ and $\psi_m(T_0) = 0$, we obtain

$$K^2 \leq C_I(\parallel F_{ex} \parallel^2_{L^2(0,T,L^2(\Omega))} + \parallel \underline{u}_L \parallel^3_{L^3(0,T,L^4(\Omega))}) + | X_0 |^2;$$

thus condition (iii) cannot be satisfied and we conclude that

$$\psi_m(t) > 0 \ \forall t \in [0,T].$$

We can now deduce from inequality (2.4) that X_m is uniformly bounded in $L^\infty(0,T,H) \cap L^2(0,T,V)$. This result makes it possible to extract from X_m a sub sequence also denoted by X_m which converges towards X in $L^\infty(0,T,H)$ weakly* and $L^2(0,T,V)$ weakly. By using (2.2), the continuity of the operator a, Hölder's inequality, and Lemma 3, we obtain

$$\left(\frac{\partial X_m}{\partial t}, w \right) \leq c(\parallel X_m \parallel + \parallel X_m \parallel^2 + | F_{ex} | + \parallel \underline{u}_L \parallel^2_{L^4(\Omega)} + \parallel h_L \parallel^2_{L^4(\Omega)}) \parallel w \parallel,$$

where $w = (\underline{v}, \beta)$.

Since X_m is uniformly bounded in $L^2(0,T,V)$, F_{ex} is in $L^2(0,T,L^2(\Omega))$ and $(\underline{u}_L, h_L)$ is in $L^2(0,T,L^4(\Omega))$, we can deduce that $\partial X_m / \partial t$ is uniformly bounded in $L^1(0,T,V')$.

Let us introduce space $Y = \{w \in L^2(0,T,V), \partial w/\partial t \in L^1(0,T,V')\}$. According to Temam [18], [19] the injection of Y into $L^2(0,T,H)$ is compact. Sequence X_m is uniformly bounded in Y. Then we can extract from X_m a subsequence also denoted by X_m and such that

$$\begin{array}{ll} X_m \rightharpoonup X & \text{weakly in } L^2(0,T,V), \\ X_m \longrightarrow X & \text{strongly in } L^2(0,T,H). \end{array}$$

We are going to prove that $X = (\underline{u}, h)$ is solution of problem (2.1).

In order to pass to the limit in (2.2), let us consider $\varphi \in C^1([0,T])$ such that $\varphi(T) = 0$.

Multiplying (2.2) by φ and integrating with respect to time, we obtain

(2.5)

$$\begin{aligned}
&-\int_0^T (\underline{u}_m, \varphi'(t)\underline{w}_k)dt + \int_0^T a_1(\underline{u}_m, \varphi(t)\underline{w}_k)dt + \frac{C}{D}\int_0^T (| \underline{u}_m + \underline{u}_L |_2 (\underline{u}_m + \underline{u}_L), \varphi(t)\underline{w}_k)dt \\
&+\int_0^T (\underline{F} \wedge \underline{u}_m, \varphi(t)\underline{w}_k)dt + g\int_0^T (\nabla h_m, \varphi(t)\underline{w}_k)dt + (u_{0m}, \varphi(0)\underline{w}_k) = \int_0^T (\underline{f}, \varphi(t)\underline{w}_k)dt, \\
&-\int_0^T (h_m, \varphi'(t)p_k)dt + \int_0^T a_2(\underline{u}_m, \varphi(t)p_k)dt + \int_0^T (\mathrm{div}(h_m\underline{u}_m), \varphi(t)p_k)dt + (h_{0m}, \varphi(0)p_k) \\
&+\int_0^T (\mathrm{div}(h_m\underline{u}_L), \varphi(t)p_k)dt + \int_0^T (\mathrm{div}(h_L\underline{u}_m), \varphi(t)p_k)dt = \int_0^T (f_1, \varphi(t)p_k)dt.
\end{aligned}$$

It is easy to pass to the limit in the linear terms. For the nonlinear terms we apply the result of Lemma 4.

Since (u_{0m}, h_{0m}) converges towards $(\underline{u}_0, h_0)$, the limit $(\underline{u}, h)$ verifies the equation

(2.6)

$$\begin{aligned}
&-\int_0^T (\underline{u}, \varphi'(t)\underline{v})dt + \int_0^T a_1(\underline{u}, \varphi(t)\underline{v})dt + \frac{C}{D}\int_0^T (| (\underline{u} + \underline{u}_L) |_2 (\underline{u} + \underline{u}_L), \varphi(t)\underline{v})dt, \\
&+\int_0^T (\underline{F} \wedge \underline{u}, \varphi(t)\underline{v})dt + g\int_0^T (\nabla h, \varphi(t)\underline{v})dt + (\underline{u}_0, \varphi(0)\underline{v}) = \int_0^T (\underline{f}, \varphi(t)\underline{v})dt, \\
&-\int_0^T (h, \varphi'(t)\beta)dt + \int_0^T a_2(h, \varphi(t)\beta)dt + \int_0^T (\mathrm{div}(h\underline{u}), \varphi(t)\beta)dt + (h_0, \varphi(0)\beta) \\
&+\int_0^T (\mathrm{div}(h_L\underline{u}), \varphi(t)\beta)dt + \int_0^T (\mathrm{div}(h\underline{u}_L), \varphi(t)\beta)dt = \int_0^T (f_1, \varphi(t)\beta)dt
\end{aligned}$$

for $\underline{v} = \underline{w}_1, \underline{w}_2, \dots$ and $\beta = p_1, p_2, \dots$. By linearity and a continuity argument this equation holds for any $(\underline{v}, \beta) \in V$.

Assuming $\varphi \in \mathcal{D}(0, T)$, we deduce that $(\underline{u}, h)$ verifies (2.1) in the distribution sense on $(0, T)$.

In order to prove the initial conditions, we multiply (2.1) by a function $\varphi \in C^1([0, T])$ such that $\varphi(T) = 0$. Integrating with respect to t and comparing with (2.7), we obtain

$$\underline{u}(0) = \underline{u}_0 \text{ and } h(0) = h_0.$$

Since $(\underline{u}, h) \in L^2(0, T, V)$ and $(\underline{u}', h') \in L^1(0, T, V')$, we conclude that $(\underline{u}, h)$ is weakly continuous from $[0, T]$ into H [13].

Remark 3. (i) *Since $(\underline{u}, h)$ is in $L^\infty(0, T, H) \cap L^2(0, T, V)$, we obtain that $(\underline{u}, h)$ is in $L^4(0, T, L^4(\Omega))$ by applying result* (ii) *of Lemma* 3.

(ii) *If we a priori impose the regularity $h \in L^4(0, T, L^4(\Omega))$, then we obtain the existence of a solution $(\underline{u}, h)$ without any conditions.*

Proof of the uniqueness.

Let us suppose that problem (2.1) admits two solutions $(\underline{u}_1, h_1)$ and $(\underline{u}_2, h_2)$. Set $\underline{u} = \underline{u}_1 - \underline{u}_2, h = h_1 - h_2$, and $X = (\underline{u}, h)$.

$(\underline{u},h)$ is the solution of the problem

(2.7)

$$\begin{aligned}
&\left(\frac{\partial \underline{u}}{\partial t},\underline{v}\right)+a_1(\underline{u},\underline{v})+\frac{C}{D}(\mid \underline{u}_1+\underline{u}_L \mid_2 (\underline{u}_1+\underline{u}_L)- \mid \underline{u}_2+\underline{u}_L \mid (\underline{u}_2+\underline{u}_L),\underline{v})\\
&+(\underline{F}\wedge \underline{u},\underline{v})-g(\mathrm{div}(\underline{v}),h)=0,\\
&\left(\frac{\partial h}{\partial t},\beta\right)+a_2(h,\beta)+(\mathrm{div}(h_1\underline{u}_1-h_2\underline{u}_2),\beta)+(\mathrm{div}(h_L\underline{u}+h\underline{u}_L),\beta)=0\ \forall(\underline{v},\beta)\in V,\\
&(\underline{u},h)(t=0)=0.
\end{aligned}$$

Setting $(\underline{v},\beta)=(\underline{u},h)$ in (2.7), we obtain

$$\begin{aligned}
\frac{1}{2}\frac{\partial \mid X\mid^2}{\partial t}+a(X,X)+\frac{C}{D}(\mid \underline{u}_1 \mid_2 \underline{u}_1- \mid \underline{u}_2 \mid_2 \underline{u}_2,\underline{u}) &= g(\mathrm{div}(\underline{u}),h)\\
&-(\mathrm{div}((h_1+h_L)\underline{u}),h)-(\mathrm{div}(h(\underline{u}_2+\underline{u}_L)),h).
\end{aligned} \tag{2.8}$$

Using the coercivity of operator a and Lemmas 1, 3 we obtain

$$\begin{aligned}
&\frac{\partial \mid X\mid^2}{\partial t}+2\alpha \parallel X\parallel^2\\
&\quad\le c_1 \mid X \mid\parallel X\parallel +c_2 \mid X\mid^{1/2}\parallel X\parallel^{3/2}(\parallel \underline{u}_2+\underline{u}_L\parallel_{L^4(\Omega)}+\parallel h_1+h_L\parallel_{L^4(\Omega)}).
\end{aligned}$$

By applying Hölder's inequality we have

$$\frac{\partial \mid X\mid^2}{\partial t}+\alpha\parallel X\parallel^2\le c(1+\parallel \underline{u}_2+\underline{u}_L\parallel^4_{L^4(\Omega)}+\parallel h_1+h_L\parallel^4_{L^4(\Omega)})\mid X\mid^2 .$$

The functions $\parallel \underline{u}_2+\underline{u}_L\parallel^4_{L^4(\Omega)}$ and $\parallel h_1+h_L\parallel^4_{L^4(\Omega)}$ being integrable with respect to time, we deduce by applying Gronwall's lemma that

$$\mid X(t)\mid^2\le c\ \mid X(0)\mid^2 \exp\left(\int_0^t(\parallel \underline{u}_2(s)+\underline{u}_L(s)\parallel^4_{L^4(\Omega)}+\parallel h_1(s)+h_L(s)\parallel^4_{L^4(\Omega)})ds\right).$$

Since $\mid X\mid(0)=0$, then $\mid X(t)\mid^2\le 0\ \forall t\in[0,T]$.

Hence

$$\underline{u}_1=\underline{u}_2 \quad\text{and}\quad h_1=h_2. \qquad \square$$

Now we give a physical interpretation of conditions (i) and (iii).

(i) $K=(2\alpha-C_g-C_L(\parallel \underline{u}_L\parallel_{L^\infty(0,T,L^4(\Omega))}+\parallel h_L\parallel_{L^\infty(0,T,L^4(\Omega))}))/C_0>0$, where $\alpha=\min(\nu_1,\nu_2)$.

$(\underline{u}_L,h_L)$ corresponds to a lifting of the boundary conditions $(\underline{\tilde{u}}_B,\tilde{h}_B)$. Therefore condition (i) expresses a relationship between the eddy viscosity coefficients ν_1, ν_2 and the boundary conditions. ν_1 and ν_2 have to be chosen large enough to verify (i).

(iii) $\mid X_0\mid^2+C_I(\parallel F_{ex}\parallel^2_{L^2(0,T,L^2(\Omega))}+\parallel \underline{u}_L\parallel^3_{L^3(0,T,L^4(\Omega))})<K^2$, where $X_0=(\underline{u}_0,h_0)$.

The initial conditions $(\underline{u}_0,h_0)$, the boundary conditions, and the eddy viscosity coefficients being fixed, condition (iii) applies to the variability of the external forcing F_{ex} which has to be small enough. Physically, this condition is realistic and not too restrictive.

3. Existence and characterization of the optimal control.

The problem is controlled by the external stress $\underline{f}$. The depth of the layer is $h = \xi + H - h_L$. The bottom topography H is known and the surface topography ξ can be deduced from altimetric measurements. Therefore h will be the observation for the control model.

Thus $U_c = L^2(0, T, L^2(\Omega))$ will be the control space; we choose $L^4(0, T, L^4(\Omega))$ as the observation space; $h_{obs} \in L^4(0, T, L^4(\Omega))$ denotes the observation. In order to obtain the existence of a solution for the direct problem, we assume that the data are small and the fluid is viscous enough.

The cost function J is defined by

$$J(\underline{g}, \underline{v}) = \frac{1}{4} \parallel h - h_{obs} \parallel^4_{L^4(0,T,L^4(\Omega))} + \frac{1}{2}\gamma \parallel \underline{g} \parallel^2_{U_c} \quad \text{with } \gamma > 0,$$

where $(\underline{v}, h)$ is the solution of the direct problem (2.1), the external forcing being equal to $\underline{g}$.

Let K_c be a convex, closed, nonempty subset of U_c. The optimal control problem can be written as follows:

$$\begin{aligned} &\text{Find } (\underline{f}, \underline{u}) \in U_{ad} \text{ such that} \\ &J(\underline{f}, \underline{u}) = \inf_{(\underline{g},\underline{v}) \in U_{ad}} J(\underline{g}, \underline{v}), \end{aligned} \tag{3.1}$$

$U_{ad} = \{(\underline{g}, \underline{v}) \in K_c \times L^2(0, T, V_1) \cap L^\infty(0, T, H_1)/J(\underline{g}, \underline{v}) < \infty$, and there exists $h \in L^2(0, T, V_2) \cap L^\infty(0, T, H_2)$ such that $(\underline{v}, h, \underline{g})$ is solution of problem (2.1),with a forcing equal to $\underline{g}\}$ is the admissibility set.

REMARK 4. *The space U_{ad} is not empty. Let $\underline{g} = 0$ and then let $(\underline{v}, h) \in L^2(0, T, V) \cap L^\infty(0, T, H)$ be the solution of* (2.1). *According to Proposition* 1 $(\underline{v}, h)$ *exists. Moreover we have $J(0, \underline{v}) \le c(\parallel h \parallel^{1/2}_{L^2(0,T,V_1)} \parallel h \parallel^{1/2}_{L^\infty(0,T,H_1)} + \parallel h_{obs} \parallel_{L^4(0,T,L^4(\Omega))})^4 < \infty$. Thus $(0, \underline{v}, h) \in U_{ad}$.*

3.1. Existence and characterization of an optimal control in the case of homogeneous boundary conditions.

We first deal with the case of homogeneous boundary conditions $\tilde{\underline{u}}_B = \underline{0}, \tilde{h}_B = 0$. Then we have $\underline{u}_L = 0, h_L = 0$ and the initial problem (1.1)–(1.2) is identical to problem (1.5).

THEOREM 1. *Under the assumptions of Proposition* 1, *the optimal control problem* (3.1) *has at least one solution $(\underline{f}, \underline{u}) \in U_{ad}$.*

Proof. Let $(\underline{f}_k, \underline{u}_k)$ be a minimizing sequence in U_{ad} for the function J such that

$$\liminf_{k \to \infty} J(\underline{f}_k, \underline{u}_k) = \inf_{(\underline{g},\underline{v}) \in U_{ad}} J(\underline{g}, \underline{v}).$$

Since $J(\underline{f}_k, \underline{u}_k)$ is bounded for a minimizing sequence $(\underline{f}_k, \underline{u}_k) \in U_{ad}$, then $(\underline{f}_k, h_k)$ is uniformly bounded in $U_c \times L^4(0, T, L^4(\Omega))$ according to the definition of J.

Setting $(\underline{v}, \beta) = (\underline{u}_k, h_k)$ in (2.1) gives

$$\begin{aligned} \frac{1}{2}\frac{\partial \mid \underline{u}_k \mid^2}{\partial t} + a_1(\underline{u}_k, \underline{u}_k) + \frac{C}{D}(\mid \underline{u}_k \mid_2 \underline{u}_k, \underline{u}_k) - g(\mathrm{div}(\underline{u}_k), h_k) &= (\underline{f}_k, \underline{u}_k), \\ \frac{1}{2}\frac{\partial \mid h_k \mid^2}{\partial t} + a_2(h_k, h_k) + (\mathrm{div}(h_k \underline{u}_k), h_k) &= (f_1, h_k). \end{aligned}$$

Adding these two equations, we obtain

$$\frac{1}{2}\frac{\partial \mid X_k \mid^2}{\partial t} + a(X_k, X_k) + \frac{C}{D} \parallel \underline{u}_k \parallel^3_{L^3(\Omega)} - g(\mathrm{div}(\underline{u}_k), h_k) + (\mathrm{div}(h_k \underline{u}_k), h_k) = (\underline{F}_k, X_k),$$

where $X_k = (\underline{u}_k, h_k)$ and $\underline{F}_k = (\underline{f}_k, f_1)$.

According to Green's formula we have $(\mathrm{div}(h_k\underline{u}_k), h_k) = \frac{1}{2}(\mathrm{div}(\underline{u}_k), h_k^2)$ and therefore $\mid (\mathrm{div}(h_k\underline{u}_k), h_k) \mid \leq c \parallel \underline{u}_k \parallel \quad \parallel h_k \parallel^2_{L^4(\Omega)}$.

Applying the coercivity of the bilinear form a and Hölder's inequality, we obtain

$$\frac{1}{2}\frac{\partial \mid X_k \mid^2}{\partial t} + \alpha \parallel X_k \parallel^2 + \frac{C}{D} \parallel \underline{u}_k \parallel^3_{L^3(\Omega)} \leq c_0 \mid \underline{F}_k \mid^2 + c_1 \mid X_k \mid^2 + \frac{\alpha}{2} \parallel X_k \parallel^2 + c_2 \parallel h_k \parallel^4_{L^4(\Omega)}$$

which implies

$$\frac{\partial \mid X_k \mid^2}{\partial t} + \alpha \parallel X_k \parallel^2 \leq 2c_0 \mid \underline{F}_k \mid^2 + 2c_1 \mid X_k \mid^2 + 2c_2 \parallel h_k \parallel^4_{L^4(\Omega).} \tag{3.2}$$

Applying Gronwall's lemma now gives

$$\mid X_k(t) \mid^2 \leq c_4(1 + \parallel \underline{F}_k \parallel^2_{L^2(0,T,H)} + \parallel h_k \parallel^4_{L^4(0,T,L^4(\Omega))}) \ \forall t \in [0,T].$$

Since $(h_k, \underline{f}_k)$ is uniformly bounded in $L^4(0,T,L^4(\Omega)) \times L^2(0,T,L^2(\Omega))$ and f_1 is independent of k, we have

$$\mid X_k(t) \mid^2 \leq c_5 \ \forall t \in [0,T].$$

By integrating inequality (3.2) with respect to time, we now obtain

$$\parallel X_k(t) \parallel^2_{L^2(0,T,V)} \leq c.$$

Hence

$$X_k \text{ is uniformly bounded in } L^2(0,T,V) \cap L^\infty(0,T,H). \tag{3.3}$$

By using (2.1), the continuity of a, Hölder's inequality, and Lemma 3 we obtain

$$\left(\frac{\partial X_k}{\partial t}, \underline{w}\right) \leq c_6(\parallel X_k \parallel + \parallel X_k \parallel^2_{L^4(\Omega)} + \mid \underline{F}_k \mid) \parallel \underline{w} \parallel \tag{3.4}$$

and then, according to the continuous injection of $H^1(\Omega)$ in $L^4(\Omega)$,

$$\left(\frac{\partial X_k}{\partial t}, \underline{w}\right) \leq c_7(\parallel X_k \parallel + \parallel X_k \parallel^2 + \mid \underline{F}_k \mid) \parallel \underline{w} \parallel .$$

Since $\parallel X_k \parallel_{L^2(0,T,V)}$ and $\parallel \underline{F}_k \parallel_{L^2(0,T,H)}$ are uniformly bounded, we can conclude that

$$\frac{\partial X_k}{\partial t} \text{ is uniformly bounded in } L^1(0,T,V'). \tag{3.5}$$

Let us introduce space $Y = \{\underline{w} \in L^2(0,T,V), \partial\underline{w}/\partial t \in L^1(0,T,V')\}$. According to Temam [18], [19] the injection of Y into $L^2(0,T,H)$ is compact. We have proved that X_k is uniformly bounded in Y. $\underline{f}_k$ being uniformly bounded in U_c, we can extract from $(X_k, \underline{F}_k)$ a subsequence also denoted by $(X_k, \underline{F}_k)$ and such that

$$\begin{array}{lc} \underline{f}_k \rightharpoonup \underline{f} & \text{weakly in } U_c, \\ X_k \rightharpoonup X & \text{weakly in } L^2(0,T,V), \\ X_k \longrightarrow X & \text{strongly in } L^2(0,T,H). \end{array}$$

We now have to verify that $X = (\underline{u}, h)$ is the solution of problem (2.1), $\underline{f}$ being the external forcing. For this, we refer to a similar result occurring in the proof of Proposition 1.

Since J is weakly lower semicontinuous, we have

$$J(\underline{f}, \underline{u}) \leq \liminf_{k\to\infty} J(\underline{f}_k, \underline{u}_k),$$

and then $J(\underline{f}, \underline{u}) = \inf_{(\underline{g},\underline{v})\in U_{ad}} J(\underline{g}, \underline{v})$, which achieves the proof. □

Remark 5. *The question of the uniqueness is not treated; in general (in nonlinear problems) the answer is expected to be negative (for the same remark see, for example, Fattorini and Sritharan* [8], [9] *and Lions* [12]*).* □

In order to characterize the optimal control, we introduce a cost function J_ϵ which is a penalization of J corresponding to a linearization of problem (2.1). Then we will study the limit when ϵ tends to 0.

Let $(\underline{f}, \underline{u})$ be the solution of the control problem (3.1). Function J_ϵ is defined by

$$\begin{aligned} J_\epsilon(\underline{g}, \underline{w}) \quad &= \frac{1}{4} \parallel H(\underline{g}, \underline{w}) - h_{obs} \parallel^4_{L^4(0,T,L^4(\Omega))} + \frac{1}{2}\gamma \parallel \underline{g} \parallel^2_{U_c} \\ &\quad + \frac{1}{2\epsilon}\int_0^T a_1(\underline{U}(\underline{g}, \underline{w}) - \underline{w}, \underline{U}(\underline{g}, \underline{w}) - \underline{w})dt \\ &\quad + \frac{1}{2} \parallel \underline{U}(\underline{g}, \underline{w}) - \underline{u} \parallel^2_{L^2(0,T,H_1)} + \frac{1}{2} \parallel \underline{g} - \underline{f} \parallel^2_{U_c}, \end{aligned} \tag{3.6}$$

where $(\underline{U}(\underline{g}, \underline{w}), H(\underline{g}, \underline{w}))$ is the solution of the following problem:

$$\begin{aligned} &\left(\frac{\partial \underline{U}}{\partial t}, \underline{v}\right) + a_1(\underline{U}, \underline{v}) + \frac{C}{D}(\mid \underline{w} \mid_2 \underline{U}, \underline{v}) + (\underline{F} \wedge \underline{U}, \underline{v}) - g(\mathrm{div}(\underline{v}), H) = (\underline{g}, \underline{v}), \\ &\left(\frac{\partial H}{\partial t}, \beta\right) + a_2(H, \beta) + (\mathrm{div}(H\underline{w}), \beta) = (f_1, \beta) \ \forall(\underline{v}, \beta) \in V, \\ &(\underline{U}, H)(t = 0) = (\underline{u}_0, h_0). \end{aligned} \tag{3.7}$$

Lemma 5. *$\underline{U}(\underline{f},\underline{u})=\underline{u}$ and $H(\underline{f},\underline{u})=h$, where $(\underline{u},h)$ is the solution of problem* (2.1)*, the external forcing being equal to $\underline{f}$.*

Proof. Let $\underline{u}_1 = \underline{U}(\underline{f}, \underline{u}) - \underline{u}$ and $h_1 = H(\underline{f}, \underline{u}) - h$.

Subtracting (2.1) from (3.7) gives

$$\begin{aligned} &\left(\frac{\partial \underline{u}_1}{\partial t}, \underline{v}\right) + a_1(\underline{u}_1, \underline{v}) + \frac{C}{D}(\mid \underline{u} \mid_2 \underline{u}_1, \underline{v}) + (\underline{F} \wedge \underline{u}_1, \underline{v}) - g(\mathrm{div}(\underline{v}), h_1) = 0, \\ &\left(\frac{\partial h_1}{\partial t}, \beta\right) + a_2(h_1, \beta) + (\mathrm{div}(h_1\underline{u}), \beta) = 0 \ \forall(\underline{v}, \beta) \in V, \\ &(\underline{u}_1, h_1)(t = 0) = (\underline{0}, 0). \end{aligned} \tag{3.8}$$

Setting $(\underline{v}, \beta) = (\underline{u}_1, h_1)$ in (3.8) and summing the first and second parts of (3.8), we obtain

$$\frac{1}{2}\frac{\partial \mid Y \mid^2}{\partial t} + a(Y, Y) + \frac{C}{D}\int_\Omega \mid \underline{u} \mid_2 \quad \mid \underline{u}_1 \mid_2^2 d\Omega = -(\mathrm{div}(h_1\underline{u}), h_1) + g(\mathrm{div}(\underline{u}_1), h_1),$$

where $Y = (\underline{u}_1, h_1)$.

According to Green's formula we have $(\mathrm{div}(h_1\underline{u}), h_1) = \frac{1}{2}(\mathrm{div}(\underline{u}), h_1^2)$ and therefore

$$\mid (\mathit{div}(h_1\underline{u}), h_1) \mid \leq c \parallel \underline{u} \parallel \quad \parallel h_1 \parallel^2_{L^4(\Omega)}.$$

Using the coercivity of operator a, Gagliardo–Nirenberg's inequality and Hölder's inequality we obtain

$$\frac{\partial \mid Y \mid^2}{\partial t} + \alpha \parallel Y \parallel^2 \leq c(1 + \parallel \underline{u} \parallel^2) \mid Y \mid^2 .$$

By now applying Gronwall's lemma, we can deduce

$$\mid Y(t) \mid^2 \leq c \mid Y(0) \mid^2 \left(\exp \left(\int_0^t \parallel \underline{u} \parallel^2 \, dt \right) \right) \forall t \in [0, T].$$

Since $\mid Y(0) \mid = 0$ we have $Y = 0 \ \forall t$ and then $(\underline{u}_1, h_1) = (\underline{0}, 0)$. □

The control problem associated with direct problem (3.7) and cost function J_ϵ defined by (3.6) is then the following:

$$\text{Find } (\underline{f}_\epsilon, \underline{w}_\epsilon) \in U^\epsilon_{ad} \text{ such that} \tag{3.9}$$
$$J_\epsilon(\underline{f}_\epsilon, \underline{w}_\epsilon) = \inf_{(\underline{g}, \underline{v}) \in U^\epsilon_{ad}} J_\epsilon(\underline{g}, \underline{v}),$$

where the admissibility set is $U^\epsilon_{ad} = K_c \times L^2(0, T, V_1)$ and K_c is a convex, closed, nonempty subset of U_c.

3.1.1. Study of the penalized control problem.

In this section we prove the existence of an optimal control solution of problem (3.9). We then characterize this control by means of direct problem (3.7) and its adjoint.

Proposition 2. *For any $\epsilon > 0$, control problem* (3.9) *has at least one solution $(\underline{f}_\epsilon, \underline{w}_\epsilon)$ in U^ϵ_{ad}.*

Proof. This result is proved in the same way as in Theorem 1. □

From now on, $(\underline{f}_\epsilon, \underline{w}_\epsilon)$ denotes the optimal control solution of problem (3.9). We set $\underline{U}_\epsilon = \underline{U}(\underline{f}_\epsilon, \underline{w}_\epsilon), H_\epsilon = H(\underline{f}_\epsilon, \underline{w}_\epsilon)$. $(\underline{U}_\epsilon, H_\epsilon)$ is the solution of the following problem:

$$\tag{3.10} \begin{aligned} &\left(\frac{\partial \underline{U}_\epsilon}{\partial t}, \underline{v} \right) + a_1(\underline{U}_\epsilon, \underline{v}) + \frac{C}{D}(\mid \underline{w}_\epsilon \mid_2 \underline{U}_\epsilon, \underline{v}) + (\underline{F} \wedge \underline{U}_\epsilon, \underline{v}) - g(\operatorname{div}(\underline{v}), H_\epsilon) = (\underline{f}_\epsilon, \underline{v}), \\ &\left(\frac{\partial H_\epsilon}{\partial t}, \beta \right) + a_2(H_\epsilon, \beta) + (\operatorname{div}(H_\epsilon \underline{w}_\epsilon), \beta) = (f_1, \beta) \ \forall (\underline{v}, \beta) \in V, \\ &(\underline{U}_\epsilon, H_\epsilon)(t = 0) = (\underline{u}_0, h_0). \end{aligned}$$

We are now going to characterize the optimal control $(\underline{f}_\epsilon, \underline{w}_\epsilon)$.

Theorem 2. *Let $(\underline{f}, \underline{u})$ be a solution of control problem* (3.1) *and $(\underline{f}_\epsilon, \underline{w}_\epsilon)$ be a* *solution of control problem* (3.9)*. Then there exists* $(\underline{U}_\epsilon, H_\epsilon)$ *and* $(\underline{R}_\epsilon, S_\epsilon)$ *such that*

$$\begin{aligned}
&\left(\frac{\partial \underline{U}_\epsilon}{\partial t}, \underline{v}\right) + a_1(\underline{U}_\epsilon, \underline{v}) + \frac{C}{D}(\mid \underline{w}_\epsilon \mid_2 \underline{U}_\epsilon, \underline{v}) + (\underline{F} \wedge \underline{U}_\epsilon, \underline{v}) - g(\mathrm{div}(\underline{v}), H_\epsilon) = (\underline{f}_\epsilon, \underline{v}),\\
&\left(\frac{\partial H_\epsilon}{\partial t}, \beta\right) + a_2(H_\epsilon, \beta) + (\mathrm{div}(H_\epsilon \underline{w}_\epsilon), \beta) = (f_1, \beta)\ \forall(\underline{v}, \beta) \in V,\\
&(\underline{U}_\epsilon, H_\epsilon)(t=0) = (\underline{u}_0, h_0),
\end{aligned}$$

$$\begin{aligned}
&\left(-\frac{\partial \underline{R}_\epsilon}{\partial t}, \underline{v}\right) + a_1(\underline{R}_\epsilon, \underline{v}) + \frac{C}{D}(\mid \underline{w}_\epsilon \mid_2 \underline{R}_\epsilon + (\underline{R}_\epsilon, \underline{U}_\epsilon)_2 \frac{\underline{w}_\epsilon}{\mid \underline{w}_\epsilon \mid_2}, \underline{v}) - (\underline{F} \wedge \underline{R}_\epsilon, \underline{v})\\
&-((H_\epsilon \nabla) S_\epsilon, \underline{v}) = (\underline{U}_\epsilon - \underline{u}, \underline{v}),\\
&\left(-\frac{\partial S_\epsilon}{\partial t}, \beta\right) + a_2(S_\epsilon, \beta) + (\mathrm{div}(\beta \underline{w}_\epsilon), S_\epsilon) - g(\mathrm{div}(\underline{R}_\epsilon), \beta) = ((H_\epsilon - h_{obs})^3, \beta)\ \forall(\underline{v}, \beta) \in V,\\
&(\underline{R}_\epsilon, S_\epsilon)(t=T) = (\underline{0}, 0),
\end{aligned}$$

and
$$(\underline{R}_\epsilon + \gamma \underline{f}_\epsilon + \underline{f}_\epsilon - \underline{f},\ \underline{g} - \underline{f}_\epsilon)_{U_c} \geq 0\ \forall \underline{g} \in K_c.$$

Proof. The partial derivative of (3.7), at point $(\underline{f}_\epsilon, \underline{w}_\epsilon)$, with respect to $\underline{g}$ at constant $\underline{w}$ is

(3.11)
$$\begin{aligned}
&\left(\frac{\partial \underline{U}_g}{\partial t}, \underline{v}\right) + a_1(\underline{U}_g, \underline{v}) + \frac{C}{D}(\mid \underline{w}_\epsilon \mid_2 \underline{U}_g, \underline{v}) + (\underline{F} \wedge \underline{U}_g, \underline{v}) - g(\mathrm{div}(\underline{v}), H_g) = (\underline{g}, \underline{v}),\\
&\left(\frac{\partial H_g}{\partial t}, \beta\right) + a_2(H_g, \beta) + (\mathrm{div}(H_g \underline{w}_\epsilon), \beta) = 0\ \forall(\underline{v}, \beta) \in V,\\
&(\underline{U}_g, H_g) = (\underline{0}, 0)
\end{aligned}$$

and the partial derivative of (3.7), at point $(\underline{f}_\epsilon, \underline{w}_\epsilon)$, with respect to $\underline{w}$ at constant $\underline{g}$ is

(3.12)
$$\begin{aligned}
&\left(\frac{\partial \underline{U}_w}{\partial t}, \underline{v}\right) + a_1(\underline{U}_w, \underline{v}) + \frac{C}{D}\left(\mid \underline{w}_\epsilon \mid_2 \underline{U}_w, \underline{v}\right) + \frac{C}{D}\left((\underline{w}, \underline{w}_\epsilon)_2 \frac{\underline{U}_\epsilon}{\mid \underline{w}_\epsilon \mid_2}, \underline{v}\right) + (\underline{F} \wedge \underline{U}_w, \underline{v})\\
&-g(\mathrm{div}(\underline{v}), H_w) = 0,\\
&\left(\frac{\partial H_w}{\partial t}, \beta\right) + a_2(H_w, \beta) + (\mathrm{div}(H_w \underline{w}_\epsilon) + \mathrm{div}(H_\epsilon \underline{w}), \beta) = 0\ \forall(\underline{v}, \beta) \in V,\\
&(\underline{U}_w, H_w) = (\underline{0}, 0).
\end{aligned}$$

The existence of $(\underline{U}_\epsilon, H_\epsilon)$, the solution of the direct problem, follows from the definition of J_ϵ. On the other hand, we have to prove the existence of $(\underline{R}_\epsilon, S_\epsilon)$ verifying the adjoint problem.

First $(\underline{R}_\epsilon, S_\epsilon)$ will denote the solution of the following problem:

$$\begin{aligned}
&\left(-\frac{\partial \underline{R}_\epsilon}{\partial t}, \underline{v}\right) + a_1(\underline{R}_\epsilon, \underline{v}) + \frac{C}{D}(\mid \underline{w}_\epsilon \mid_2 \underline{R}_\epsilon, \underline{v}) - (\underline{F} \wedge \underline{R}_\epsilon, \underline{v}) - ((H_\epsilon \nabla) S_\epsilon, \underline{v}) \\
&= (\underline{U}_\epsilon - \underline{u}, \underline{v}) + \frac{1}{\epsilon} a_1(\underline{U}_\epsilon - \underline{w}_\epsilon, \underline{v}), \\
&\left(-\frac{\partial S_\epsilon}{\partial t}, \beta\right) + a_2(S_\epsilon, \beta) + (\mathrm{div}(\beta \underline{w}_\epsilon), S_\epsilon) - g(\mathrm{div}(\underline{R}_\epsilon), \beta) \\
&= ((H_\epsilon - h_{obs})^3, \beta) \ \forall (\underline{v}, \beta) \in V, \\
&(\underline{R}_\epsilon, S_\epsilon)(t = T) = (\underline{0}, 0).
\end{aligned} \tag{3.13}$$

This linear problem has one unique solution $(\underline{R}_\epsilon, S_\epsilon)$ in $L^2(0, T, V)$.

Setting $(\underline{v}, \beta) = (\underline{R}_\epsilon, S_\epsilon)$ in (3.12) and integrating with respect to time gives

$$\begin{aligned}
&\int_0^T \left(\frac{\partial \underline{U}_w}{\partial t}, \underline{R}_\epsilon\right) dt + \int_0^T a_1(\underline{U}_w, \underline{R}_\epsilon) dt + \frac{C}{D} \int_0^T (\mid \underline{w}_\epsilon \mid_2 \underline{U}_w, \underline{R}_\epsilon) dt \\
&\quad + \quad \frac{C}{D} \int_0^T \left((\underline{w}, \underline{w}_\epsilon)_2 \frac{\underline{U}_\epsilon}{\mid \underline{w}_\epsilon \mid_2}, \underline{R}_\epsilon\right) dt \\
&\quad + \int_0^T (\underline{F} \wedge \underline{U}_w, \underline{R}_\epsilon) dt - g \int_0^T (\mathrm{div}(\underline{R}_\epsilon), H_w) dt = 0, \\
&\int_0^T \left(\frac{\partial H_w}{\partial t}, S_\epsilon\right) dt + \int_0^T a_2(H_w, S_\epsilon) dt + \int_0^T (\mathrm{div}(H_w \underline{w}_\epsilon) + \mathrm{div}(H_\epsilon \underline{w}), S_\epsilon) dt = 0.
\end{aligned}$$

After integration by parts we obtain

$$\begin{aligned}
&-\int_0^T \left(\frac{\partial \underline{R}_\epsilon}{\partial t}, \underline{U}_w\right) dt + \int_0^T a_1(\underline{R}_\epsilon, \underline{U}_w) dt + \frac{C}{D} \int_0^T (\mid \underline{w}_\epsilon \mid_2 \underline{R}_\epsilon, \underline{U}_w) dt \\
&+ \frac{C}{D} \int_0^T \left((\underline{w}, \underline{w}_\epsilon)_2 \frac{\underline{U}_\epsilon}{\mid \underline{w}_\epsilon \mid_2}, \underline{R}_\epsilon\right) dt \\
&- \int_0^T (\underline{F} \wedge \underline{R}_\epsilon, \underline{U}_w) dt - g \int_0^T (\mathrm{div}(\underline{R}_\epsilon), H_w) dt = 0, \\
&- \int_0^T \left(\frac{\partial S_\epsilon}{\partial t}, H_w\right) dt + \int_0^T a_2(S_\epsilon, H_w) dt + \int_0^T (\mathrm{div}(H_w \underline{w}_\epsilon) + \mathrm{div}(H_\epsilon \underline{w}), S_\epsilon) dt = 0.
\end{aligned}$$

Since $(\underline{R}_\epsilon, S_\epsilon)$ verifies (3.13), this implies

$$\begin{aligned}
&\frac{C}{D} \int_0^T \left((\underline{w}, \underline{w}_\epsilon)_2 \frac{\underline{U}_\epsilon}{\mid \underline{w}_\epsilon \mid_2}, \underline{R}_\epsilon\right) dt - g \int_0^T (\mathrm{div}(\underline{R}_\epsilon), H_w) dt + \int_0^T (\underline{U}_\epsilon - \underline{u}, \underline{U}_w) dt \\
&\quad + \frac{1}{\epsilon} \int_0^T a_1(\underline{U}_\epsilon - \underline{w}_\epsilon, \underline{U}_w) dt = 0, \\
&\int_0^T (\mathrm{div}(H_\epsilon \underline{w}), S_\epsilon) dt + g \int_0^T (\mathrm{div}(\underline{R}_\epsilon), H_w) dt + \int_0^T ((H_\epsilon - h_{obs})^3, H_w) dt = 0;
\end{aligned}$$

hence

(3.14)

$$\begin{aligned}&g\int_0^T(\mathrm{div}(\underline{R}_\epsilon),H_w)dt=\frac{C}{D}\int_0^T\left((\underline{U}_\epsilon,\underline{R}_\epsilon)_2\frac{\underline{w}_\epsilon}{\mid\underline{w}_\epsilon\mid_2},\underline{w}\right)dt+\int_0^T(\underline{U}_\epsilon-\underline{u},\underline{U}_w)dt\\&\quad+\frac{1}{\epsilon}\int_0^T a_1(\underline{U}_\epsilon-\underline{w}_\epsilon,\underline{U}_w)dt,\\&g\int_0^T(\mathrm{div}(\underline{R}_\epsilon),H_w)dt=\int_0^T(H_\epsilon\nabla S_\epsilon,\underline{w})dt-\int_0^T((H_\epsilon-h_{obs})^3,H_w)dt.\end{aligned}$$

The partial derivative of J_ϵ, at point $(\underline{f}_\epsilon,\underline{w}_\epsilon)$, with respect to $\underline{w}$ at constant $\underline{g}$ is

$$\frac{\partial J_\epsilon}{\partial\underline{w}}(\underline{f}_\epsilon,\underline{w}_\epsilon).\underline{w}=\int_0^T((H_\epsilon-h_{obs})^3,H_w)dt+\frac{1}{\epsilon}\int_0^T a_1(\underline{U}_\epsilon-\underline{w}_\epsilon,\underline{U}_w-\underline{w})dt+\int_0^T(\underline{U}_\epsilon-\underline{u},\underline{U}_w)dt.$$

Control problem (3.9) includes no constraint concerning $\underline{w}$, so

$$\frac{\partial J_\epsilon}{\partial\underline{w}}(\underline{f}_\epsilon,\underline{w}_\epsilon).\underline{w}=0\ \forall\underline{w}\in L^2(0,T,V_1).$$

From this and (3.14) we deduce

$$\frac{1}{\epsilon}\int_0^T a_1(\underline{U}_\epsilon-\underline{w}_\epsilon,\underline{w})dt=\int_0^T\left(H_\epsilon\nabla S_\epsilon-\frac{C}{D}(\underline{U}_\epsilon,\underline{R}_\epsilon)_2\frac{\underline{w}_\epsilon}{\mid\underline{w}_\epsilon\mid_2},\underline{w}\right)dt\quad\forall\underline{w}\in L^2(0,T,V_1).$$

In particular, we have

$$\begin{gathered}\frac{1}{\epsilon}\int_0^T a_1(\underline{U}_\epsilon-\underline{w}_\epsilon,\varphi(t)\underline{v})dt=\int_0^T\left(H_\epsilon\nabla S_\epsilon-\frac{C}{D}(\underline{U}_\epsilon,\underline{R}_\epsilon)_2\frac{\underline{w}_\epsilon}{\mid\underline{w}_\epsilon\mid_2},\varphi(t)\underline{v}\right)dt\\\forall(\underline{v},\varphi)\in V_1\times\mathcal{D}(0,T).\end{gathered}$$

Thus, in the distribution sense,

$$\frac{1}{\epsilon}a_1(\underline{U}_\epsilon-\underline{w}_\epsilon,\underline{v})=\left(H_\epsilon\nabla S_\epsilon-\frac{C}{D}(\underline{U}_\epsilon,\underline{R}_\epsilon)_2\frac{\underline{w}_\epsilon}{\mid\underline{w}_\epsilon\mid_2},\underline{v}\right)\quad\forall\underline{v}\in V_1.\tag{3.15}$$

Since $(\underline{R}_\epsilon,S_\epsilon)$ is the solution of problem (3.13), we obtain by using (3.15) that $(\underline{R}_\epsilon,S_\epsilon)$ verifies the problem

(3.16)

$$\begin{aligned}&\left(-\frac{\partial\underline{R}_\epsilon}{\partial t},\underline{v}\right)+a_1(\underline{R}_\epsilon,\underline{v})+\frac{C}{D}\left(\mid\underline{w}_\epsilon\mid_2\underline{R}_\epsilon+(\underline{R}_\epsilon,\underline{U}_\epsilon)_2\frac{\underline{w}_\epsilon}{\mid\underline{w}_\epsilon\mid_2},\underline{v}\right)-(\underline{F}\wedge\underline{R}_\epsilon,\underline{v})\\&-((H_\epsilon\nabla)S_\epsilon,\underline{v})=(\underline{U}_\epsilon-\underline{u},\underline{v}),\\&\left(-\frac{\partial S_\epsilon}{\partial t},\beta\right)+a_2(S_\epsilon,\beta)+(\mathrm{div}(\beta\underline{w}_\epsilon),S_\epsilon)-g(\mathrm{div}(\underline{R}_\epsilon),\beta)=((H_\epsilon-h_{obs})^3,\beta)\quad\forall(\underline{v},\beta)\in V,\end{aligned}$$

which is the adjoint problem occuring in Theorem 2.

We now are going to prove the inequality which characterizes the optimal control $\underline{f}_\epsilon$.

Setting $(\underline{v},\beta)=(\underline{R}_\epsilon,S_\epsilon)$ in (3.11) and integrating with respect to time give

$$\int_0^T\left(\frac{\partial\underline{U}_g}{\partial t},\underline{R}_\epsilon\right)dt+\int_0^T a_1(\underline{U}_g,\underline{R}_\epsilon)dt+\int_0^T\frac{C}{D}(\mid\underline{w}_\epsilon\mid_2\underline{U}_g,\underline{R}_\epsilon)dt+\int_0^T(\underline{F}\wedge\underline{U}_g,\underline{R}_\epsilon)dt$$
$$-g\int_0^T(\mathrm{div}(\underline{R}_\epsilon),H_g)dt=\int_0^T(\underline{g},\underline{R}_\epsilon)dt,$$
$$\int_0^T\left(\frac{\partial H_g}{\partial t},S_\epsilon\right)dt+\int_0^T a_2(H_g,S_\epsilon)dt+\int_0^T(\mathrm{div}(H_g\underline{w}_\epsilon),S_\epsilon)dt=0$$

and then

$$-\int_0^T\left(\frac{\partial\underline{R}_\epsilon}{\partial t},\underline{U}_g\right)dt+\int_0^T a_1(\underline{R}_\epsilon,\underline{U}_g)dt+\int_0^T\frac{C}{D}(\mid\underline{w}_\epsilon\mid_2\underline{R}_\epsilon,\underline{U}_g)dt$$
$$-\int_0^T(\underline{F}\wedge\underline{R}_\epsilon,\underline{U}_g)dt$$
$$-g\int_0^T(\mathrm{div}(\underline{R}_\epsilon),H_g)dt=\int_0^T(\underline{g},\underline{R}_\epsilon)dt,$$
$$-\int_0^T\left(\frac{\partial S_\epsilon}{\partial t},H_g\right)dt+\int_0^T a_2(S_\epsilon,H_g)dt+\int_0^T(\mathrm{div}(H_g\underline{w}_\epsilon),S_\epsilon)dt=0.$$

Since $(\underline{R}_\epsilon,S_\epsilon)$ is the solution of problem (3.16), we obtain

$$(3.17)\qquad\begin{aligned}&-\frac{C}{D}\int_0^T\left((\underline{R}_\epsilon,\underline{U}_\epsilon)_2\frac{\underline{w}_\epsilon}{\mid\underline{w}_\epsilon\mid_2},\underline{U}_g\right)dt-g\int_0^T(\mathrm{div}(\underline{R}_\epsilon),H_g)dt\\&+\int_0^T(\underline{U}_\epsilon-\underline{u},\underline{U}_g)dt+\int_0^T(H_\epsilon\nabla S_\epsilon,\underline{U}_g)dt=\int_0^T(\underline{g},\underline{R}_\epsilon)dt,\\&g\int_0^T(\mathrm{div}(\underline{R}_\epsilon),H_g)dt+\int_0^T((H_\epsilon-h_{obs})^3,H_g)dt=0.\end{aligned}$$

The partial derivative of J_ϵ, at point $(\underline{f}_\epsilon,\underline{w}_\epsilon)$, with respect to $\underline{g}$ at constant $\underline{w}$ is

$$\begin{aligned}\frac{\partial J_\epsilon}{\partial\underline{g}}(\underline{f}_\epsilon,\underline{w}_\epsilon).\underline{g}\;&=\;\int_0^T((H_\epsilon-h_{obs})^3,H_g)dt+\gamma(\underline{f}_\epsilon,\underline{g})_{U_c}+(\underline{f}_\epsilon-\underline{f},\underline{g})_{U_c}\\&\quad+\frac{1}{\epsilon}\int_0^T a_1(\underline{U}_\epsilon-\underline{w}_\epsilon,\underline{U}_g)dt+\int_0^T(\underline{U}_\epsilon-\underline{u},\underline{U}_g)dt.\end{aligned}$$

Applying relationship (3.15), we deduce

$$\frac{\partial J_\epsilon}{\partial\underline{g}}(\underline{f}_\epsilon,\underline{w}_\epsilon).\underline{g}=\int_0^T((H_\epsilon-h_{obs})^3,H_g)dt+\gamma(\underline{f}_\epsilon,\underline{g})_{U_c}+(\underline{f}_\epsilon-\underline{f},\underline{g})_{U_c}$$
$$+\int_0^T\left(H_\epsilon\nabla S_\epsilon-\frac{C}{D}(\underline{U}_\epsilon,\underline{R}_\epsilon)_2\frac{\underline{w}_\epsilon}{\mid\underline{w}_\epsilon\mid_2},\underline{U}_g\right)dt+\int_0^T(\underline{U}_\epsilon-\underline{u},\underline{U}_g)dt.$$

$(\underline{R}_\epsilon,S_\epsilon)$ verifies equations (3.17). We then obtain

$$\frac{\partial J_\epsilon}{\partial\underline{g}}(\underline{f}_\epsilon,\underline{w}_\epsilon).\underline{g}=\gamma(\underline{f}_\epsilon,\underline{g})_{U_c}+(\underline{f}_\epsilon-\underline{f},\underline{g})_{U_c}+\int_0^T(\underline{g},\underline{R}_\epsilon)dt.$$

Since $U_c = L^2(0,T,L^2(\Omega))$ we have

$$\frac{\partial J_\epsilon}{\partial \underline{g}}(\underline{f}_\epsilon, \underline{w}_\epsilon).\underline{g} = \int_0^T (\underline{R}_\epsilon + \gamma \underline{f}_\epsilon + \underline{f}_\epsilon - \underline{f}, \underline{g})dt.$$

Control problem (3.9) includes a constraint on $\underline{g}$: $\underline{g} \in K_c \subset U_c$. Therefore the optimal control $\underline{f}_\epsilon$ has to verify the inequality

$$\frac{\partial J_\epsilon}{\partial \underline{g}}(\underline{f}_\epsilon, \underline{w}_\epsilon).(\underline{g} - \underline{f}_\epsilon) \geq 0 \quad \forall \underline{g} \in K_c$$

and we have

$$\int_0^T (\underline{R}_\epsilon + \gamma \underline{f}_\epsilon + \underline{f}_\epsilon - \underline{f}, \underline{g} - \underline{f}_\epsilon)dt \geq 0 \quad \forall \underline{g} \in K_c.$$

This achieves the proof of Theorem 2. □

3.1.2. Characterization of the optimal control. The penalized control problem (3.9) has a solution which is characterized by means of the direct and adjoint penalized equations.

We are now going to characterize the optimal control $(\underline{f}, \underline{u})$, the solution of problem (3.1). $(\underline{u}, h)$ denotes the solution of direct problem (2.1). The adjoint problem is obtained by passing to the limit in the adjoint penalized equations introduced in Theorem 2.

THEOREM 3. *Let* $(\underline{f}_\epsilon, \underline{w}_\epsilon)$ *be a solution of control problem* (3.9). *The following convergence results are verified as* $\epsilon \longrightarrow 0$:

- $\underline{f}_\epsilon$ *converges to* $\underline{f}$ *in* U_c *strongly,*
- $\lim_{\epsilon \longrightarrow 0} \frac{1}{\epsilon} \parallel \underline{U}_\epsilon - \underline{w}_\epsilon \parallel^2_{L^2(0,T,H^1(\Omega))} = 0,$
- $\underline{U}_\epsilon \rightharpoonup \underline{u}$ *weakly in* $L^2(0,T,H^1(\Omega))$,
- $\underline{U}_\epsilon \longrightarrow \underline{u}$ *strongly in* $L^2(0,T,L^2(\Omega))$,
- $H_\epsilon \rightharpoonup h$ *weakly in* $L^2(0,T,H^1(\Omega))$,
- $H_\epsilon \longrightarrow h$ *strongly in* $L^2(0,T,L^2(\Omega))$,
- $\underline{w}_\epsilon \rightharpoonup \underline{u}$ *weakly in* $L^2(0,T,H^1(\Omega))$,
- $J_\epsilon(\underline{w}_\epsilon, \underline{f}_\epsilon)$ *converges to* $J(\underline{u}, \underline{f})$,

Proof. $(\underline{f}, \underline{u}) \in U_{ad}$ denotes a solution of control problem (3.1). $(\underline{f}_\epsilon, \underline{w}_\epsilon) \in U^\epsilon_{ad}$ denotes a solution of the penalized control problem (3.9). Since $J_\epsilon(\underline{f}, \underline{u}) = J(\underline{f}, \underline{u})$ and $U_{ad} \subset U^\epsilon_{ad}$, we have

$$J_\epsilon(\underline{f}_\epsilon, \underline{w}_\epsilon) \leq J(\underline{f}, \underline{u}).$$

According to the definition of J_ϵ, this implies that

$$\begin{array}{ll} & \parallel \underline{f}_\epsilon - \underline{f} \parallel^2_{U_c} \leq 2J(\underline{f}, \underline{u}), \\ (3.18) & \displaystyle\int_0^T a_1(\underline{U}_\epsilon - \underline{w}_\epsilon, \underline{U}_\epsilon - \underline{w}_\epsilon)dt \leq 2\epsilon J(\underline{f}, \underline{u}), \\ & \parallel \underline{U}_\epsilon - \underline{u} \parallel^2_{L^2(0,T,H_1)} \leq 2J(\underline{f}, \underline{u}), \\ & \parallel H_\epsilon - h_{obs} \parallel^4_{L^4(0,T,L^4(\Omega))} \leq 4J(\underline{f}, \underline{u}). \end{array}$$

Using the coercivity of a, we deduce from (3.18) the following results:

$$\begin{array}{ll} & \parallel \underline{f}_\epsilon \parallel^2_{U_c} \leq 2 \parallel \underline{f} \parallel^2_{U_c} + 4J(\underline{u}, \underline{f}), \\ (3.19) & \displaystyle\lim_{\epsilon \rightarrow 0} \parallel \underline{U}_\epsilon - \underline{w}_\epsilon \parallel_{L^2(0,T,H^1(\Omega))} = 0, \\ & \parallel \underline{U}_\epsilon \parallel_{L^2(0,T,H_1)} \leq c, \\ & \parallel H_\epsilon \parallel_{L^4(0,T,L^4(\Omega))} \leq c, \end{array}$$

where c is a positive constant.

Equation (3.19) implies that $\underline{U}_\epsilon$ converges towards $\underline{w}_\epsilon$ strongly in $L^2(0,T,H^1(\Omega))$ and that $(\underline{U}_\epsilon, H_\epsilon)$ is uniformly bounded in $L^2(0,T,L^2(\Omega)) \times L^4(0,T,L^4(\Omega))$. For ϵ sufficiently small, $\| \underline{U}_\epsilon - \underline{w}_\epsilon \|_{L^2(0,T,H^1(\Omega))}$ is uniformly bounded. Therefore there exists a positive constant $c > 0$ independent of ϵ such that

$$\| \underline{w}_\epsilon \|_{L^2(0,T,H^1(\Omega))} \leq c(1 + \| \underline{U}_\epsilon \|_{L^2(0,T,H^1(\Omega))})$$

and

$$\| \underline{w}_\epsilon \|_{L^2(0,T,L^2(\Omega))} \leq c(1 + \| \underline{U}_\epsilon \|_{L^2(0,T,L^2(\Omega))}).$$

Since $\underline{U}_\epsilon$ is uniformly bounded in $L^2(0,T,L^2(\Omega))$, we have

$$\| \underline{w}_\epsilon \|_{L^2(0,T,L^2(\Omega))} \leq c. \tag{3.20}$$

We can now pass to the limit in direct problem (3.10).

Setting $(\underline{v}, \beta) = (\underline{U}_\epsilon, H_\epsilon)$ in (3.10) and adding the first and second parts of (3.10) gives

$$\begin{aligned} \frac{1}{2}\frac{\partial \mid X_\epsilon \mid^2}{\partial t} + a(X_\epsilon, X_\epsilon) + \frac{C}{D}\int_\Omega \mid \underline{w}_\epsilon \mid_2 \mid \underline{U}_\epsilon \mid_2^2 \, d\Omega = (\underline{F}_\epsilon, X_\epsilon) + g(\operatorname{div}(\underline{U}_\epsilon), H_\epsilon) \\ - (\operatorname{div}(H_\epsilon \underline{w}_\epsilon), H_\epsilon), \end{aligned}$$

where $X_\epsilon = (\underline{U}_\epsilon, H_\epsilon)$ et $\underline{F}_\epsilon = (\underline{f}_\epsilon, f_1)$.

According to Green's formula we have $(\operatorname{div}(H_\epsilon \underline{w}_\epsilon), H_\epsilon) = \frac{1}{2}(\operatorname{div}(\underline{w}_\epsilon), H_\epsilon^2)$ and therefore

$$\mid (\operatorname{div}(H_\epsilon \underline{w}_\epsilon), H_\epsilon) \mid \leq c(\| \underline{U}_\epsilon - \underline{w}_\epsilon \| + \| \underline{U}_\epsilon \|) \ \| H_\epsilon \|_{L^4(\Omega)}^2 .$$

Applying the coercivity of a, the positivity of $\int_\Omega \mid \underline{w}_\epsilon \mid_2 \mid \underline{U}_\epsilon \mid_2^2 \, d\Omega$, and Hölder's inequality we obtain

$$\frac{\partial \mid X_\epsilon \mid^2}{\partial t} + \alpha \| X_\epsilon \|^2 \leq c_2 \mid \underline{F}_\epsilon \mid^2 + c_3 \mid X_\epsilon \mid^2 + c_4(\| H_\epsilon \|_{L^4(\Omega)}^4 + \| \underline{U}_\epsilon - \underline{w}_\epsilon \|^2). \tag{3.21}$$

Gronwall's lemma now gives

$$\mid X_\epsilon \mid^2 \leq c(1 + \| \underline{F}_\epsilon \|_{L^2(0,T,L^2(\Omega))}^2 + \| H_\epsilon \|_{L^4(0,T,L^4(\Omega))}^4 + \| \underline{U}_\epsilon - \underline{w}_\epsilon \|_{L^2(0,T,H^1(\Omega))}^2).$$

According to (3.19) and (3.21), we deduce that sequence X_ϵ is uniformly bounded in $L^2(0,T,V) \cap L^\infty(0,T,H)$; $(\underline{f}_\epsilon, \underline{w}_\epsilon)$ being uniformly bounded in $U_c \times L^2(0,T,H^1(\Omega))$, we can extract from $(\underline{f}_\epsilon, X_\epsilon, \underline{w}_\epsilon)$ a subsequence also denoted by $(\underline{f}_\epsilon, X_\epsilon, \underline{w}_\epsilon)$, which verifies

$$\begin{array}{rcl} \underline{f}_\epsilon \rightharpoonup \underline{f}_0 & & \text{weakly in } U_c, \\ X_\epsilon \rightharpoonup X_0 & & \text{weakly in } L^2(0,T,H^1(\Omega)), \\ X_\epsilon \longrightarrow X_0 & & \text{strongly in } L^2(0,T,L^2(\Omega)), \\ \underline{w}_\epsilon \rightharpoonup \underline{U}_0 & & \text{weakly in } L^2(0,T,H^1(\Omega)). \end{array} \tag{3.22}$$

We now have to verify that $X_0 = (\underline{U}_0, H_0)$ is the solution of (2.1), $\underline{f}_0$ being the external forcing. For this, we refer to a similar result occurring in the proof of Proposition 1.

Now applying the property of weak lower semicontinuity of J, we obtain [6]

(3.23)

$J(\underline{f}_0, \underline{U}_0) \leq \liminf_{\epsilon \to 0} J(\underline{f}_\epsilon, \underline{U}_\epsilon)$

and

$\frac{1}{2}(\| \underline{U}_0 - \underline{u} \|^2_{L^2(0,T,L^2(\Omega))} + \| \underline{f}_0 - \underline{f} \|^2_{U_c})$

$\leq \liminf_{\epsilon \to 0} \frac{1}{2}(\| \underline{U}_\epsilon - \underline{u} \|^2_{L^2(0,T,L^2(\Omega))} + \| \underline{f}_\epsilon - \underline{f} \|^2_{U_c})$.

From (3.23), we deduce

$$J(\underline{f}_0, \underline{U}_0) \leq \liminf_{\epsilon \to 0} J_\epsilon(\underline{f}_\epsilon, \underline{w}_\epsilon).$$

Since $(\underline{f}_\epsilon, \underline{w}_\epsilon)$ (resp., $(\underline{f}, \underline{u})$) is the optimal control solution of (3.1) (resp., (3.9)), we thus have

$$J(\underline{f}_0, \underline{U}_0) \leq \liminf_{\epsilon \to 0} J_\epsilon(\underline{f}_\epsilon, \underline{w}_\epsilon) \leq J(\underline{f}, \underline{u}) \leq J(\underline{f}_0, \underline{U}_0).$$

We conclude that

$$J(\underline{f}_0, \underline{U}_0) = J(\underline{f}, \underline{u});$$

$(\underline{f}_0, \underline{U}_0)$ is a solution of control problem (3.1).

Applying Lemma 5, we also have

$$J(\underline{f}, \underline{u}) \leq \liminf_{\epsilon \to 0} J_\epsilon(\underline{f}_\epsilon, \underline{w}_\epsilon) \leq \limsup_{\epsilon \to 0} J_\epsilon(\underline{f}_\epsilon, \underline{w}_\epsilon) \leq J(\underline{f}, \underline{u}),$$

which implies

$$\lim_{\epsilon \to 0} J_\epsilon(\underline{f}_\epsilon, \underline{w}_\epsilon) = J(\underline{f}, \underline{u}) = J(\underline{f}_0, \underline{U}_0).$$

$\underline{U}_\epsilon$ converges towards $\underline{U}_0$ in $L^2(0, T, L^2(\Omega))$ strongly; therefore

$$\begin{aligned} 0 \leq \limsup_{\epsilon \to 0} &\left(\frac{1}{2} \left(\frac{1}{\epsilon} \int_0^T a_1(\underline{U}_\epsilon - \underline{w}_\epsilon - \underline{U}_\epsilon - \underline{w}_\epsilon) dt + \| \underline{f}_\epsilon - \underline{f} \|^2_{U_c} \right) \right) \\ &+ \frac{1}{2} \| \underline{U}_0 - \underline{u} \|^2_{L^2(0,T,L^2(\Omega))} \\ &\leq \limsup_{\epsilon \to 0} J_\epsilon(\underline{f}_\epsilon, \underline{w}_\epsilon) - \liminf_{\epsilon \to 0} J(\underline{f}_\epsilon, \underline{U}_\epsilon). \end{aligned}$$

According to (3.23) this implies

$$\begin{aligned} &\lim_{\epsilon \to 0} \frac{1}{\epsilon} \int_0^T a_1(\underline{U}_\epsilon - \underline{w}_\epsilon, \underline{U}_\epsilon - \underline{w}_\epsilon) dt = 0, \\ &\lim_{\epsilon \to 0} \| \underline{f}_\epsilon - \underline{f} \|^2_{U_c}, \\ &(\underline{U}_0, H_0, \underline{f}_0) = (\underline{u}, h, \underline{f}). \qquad \square \end{aligned}$$

These convergence results will allow us to pass to the limit in the adjoint penalized problem and thus to characterize the optimal control $(\underline{f}, \underline{u})$.

THEOREM 4. *Let $(\underline{f}, \underline{u})$ be a solution of control problem* (3.1) *and* $(\underline{u}, h)$ *be the solution of direct problem* (2.1). *Then there exists* $(\underline{R}, S) \in L^2(0, T, V)$ *such that*

$$\left(-\frac{\partial \underline{R}}{\partial t}, \underline{v}\right) + a_1(\underline{R}, \underline{v}) + \frac{C}{D}\left(\mid \underline{u} \mid_2 \underline{R} + (\underline{R}, \underline{u})_2 \frac{\underline{u}}{\mid \underline{u} \mid_2}, \underline{v}\right) - (\underline{F} \wedge \underline{R}, \underline{v}) - (h\nabla S, \underline{v}) = 0,$$
$$\left(-\frac{\partial S}{\partial t}, \beta\right) + a_2(S, \beta) - ((\underline{u}\nabla)S, \beta) - g(\mathrm{div}(\underline{R}), \beta) = ((h - h_{obs})^3, \beta) \quad \forall(\underline{v}, \beta) \in V,$$
$$(\underline{R}, S)(t = T) = (\underline{0}, 0)$$
and
$$(\underline{R} + \gamma\underline{f},\ \underline{g} - \underline{f})_{U_c} \geq 0\ \forall \underline{g} \in K_c.$$

Proof. $(\underline{R}_\epsilon, S_\epsilon)$ being the solution of the adjoint penalized problem (3.16), we introduce the sequence d_ϵ by setting

$$d_\epsilon = \parallel S_\epsilon \parallel^{-1}_{L^4(0,T,L^4(\Omega))} \text{ if } S_\epsilon \text{ is not uniformly bounded in } L^4(0, T, L^4(\Omega)),$$
$$d_\epsilon = 1 \text{ if } S_\epsilon \text{ is uniformly bounded in } L^4(0, T, L^4(\Omega)).$$

REMARK 6. *Sequence d_ϵ converges towards d with $d = 0$ or 1.*

We multiply (3.16) by d_ϵ and we thus obtain a couple $(\widetilde{\underline{R}_\epsilon}, \widetilde{S}_\epsilon)$ verifying

(3.24)
$$\left(-\frac{\partial \widetilde{\underline{R}_\epsilon}}{\partial t}, \underline{v}\right) + a_1(\widetilde{\underline{R}_\epsilon}, \underline{v}) + \frac{C}{D}\left(\mid \underline{w}_\epsilon \mid_2 \widetilde{\underline{R}_\epsilon} + (\widetilde{\underline{R}_\epsilon}, \underline{U}_\epsilon)_2 \frac{\underline{w}_\epsilon}{\mid \underline{w}_\epsilon \mid_2}, \underline{v}\right) - (\underline{F} \wedge \widetilde{\underline{R}_\epsilon}, \underline{v})$$
$$-((H_\epsilon\nabla)\widetilde{S}_\epsilon, \underline{v}) = d_\epsilon(\underline{U}_\epsilon - \underline{u}, \underline{v}),$$
$$\left(-\frac{\partial \widetilde{S}_\epsilon}{\partial t}, \beta\right) + a_2(\widetilde{S}_\epsilon, \beta) + (\mathrm{div}(\beta\underline{w}_\epsilon), \widetilde{S}_\epsilon) - g(\mathrm{div}(\widetilde{\underline{R}_\epsilon}), \beta) = d_\epsilon((H_\epsilon - h_{obs})^3, \beta)$$
$$\forall(\underline{v}, \beta) \in V,$$
$$(\widetilde{\underline{R}_\epsilon}, \widetilde{S}_\epsilon)(t = T) = (\underline{0}, 0)$$
and the inequality
$$(\widetilde{\underline{R}_\epsilon} + d_\epsilon(\gamma\underline{f}_\epsilon + \underline{f}_\epsilon - \underline{f}), \underline{g} - \underline{f}_\epsilon)_{U_c} \geq 0 \quad \forall\underline{g} \in K_c.$$

Setting $(\underline{v}, \beta) = (\widetilde{\underline{R}_\epsilon}, \widetilde{S}_\epsilon)$ in (3.24), we obtain

$$-\frac{1}{2}\frac{\partial \mid \widetilde{\underline{R}_\epsilon} \mid^2}{\partial t} + a_1(\widetilde{\underline{R}_\epsilon}, \widetilde{\underline{R}_\epsilon}) + \frac{C}{D}\left(\mid \underline{w}_\epsilon \mid_2 \widetilde{\underline{R}_\epsilon} + (\widetilde{\underline{R}_\epsilon}, \underline{U}_\epsilon)_2 \frac{\underline{w}_\epsilon}{\mid \underline{w}_\epsilon \mid_2}, \widetilde{\underline{R}_\epsilon}\right) - ((H_\epsilon\nabla)\widetilde{S}_\epsilon, \widetilde{\underline{R}_\epsilon})$$
$$= d_\epsilon(\underline{U}_\epsilon - \underline{u}, \widetilde{\underline{R}_\epsilon}),$$
$$-\frac{1}{2}\frac{\partial \mid \widetilde{S}_\epsilon \mid^2}{\partial t} + a_2(\widetilde{S}_\epsilon, \widetilde{S}_\epsilon) + (\mathrm{div}(\widetilde{S}_\epsilon\underline{w}_\epsilon), \widetilde{S}_\epsilon) - g(\mathrm{div}(\widetilde{\underline{R}_\epsilon}), \widetilde{S}_\epsilon) = d_\epsilon((H_\epsilon - h_{obs})^3, \widetilde{S}_\epsilon).$$

Adding these two equations gives

$$-\frac{1}{2}\frac{\partial \mid Y_\epsilon \mid^2}{\partial t} + a(Y_\epsilon, Y_\epsilon) + \frac{C}{D}\int_\Omega \mid \underline{w}_\epsilon \mid_2 \quad \mid \widetilde{\underline{R}_\epsilon} \mid_2^2 d\Omega + \frac{C}{D}\int_\Omega (\widetilde{\underline{R}_\epsilon}, \underline{U}_\epsilon)_2 \frac{(\underline{w}_\epsilon, \widetilde{\underline{R}_\epsilon})_2}{\mid \underline{w}_\epsilon \mid_2} d\Omega$$
$$-((H_\epsilon\nabla)\widetilde{S}_\epsilon, \widetilde{\underline{R}_\epsilon}) + (\mathrm{div}(\widetilde{S}_\epsilon\underline{w}_\epsilon), \widetilde{S}_\epsilon) - g(\mathrm{div}(\widetilde{\underline{R}_\epsilon}), \widetilde{S}_\epsilon)$$
$$= d_\epsilon(\underline{U}_\epsilon - \underline{u}, \widetilde{\underline{R}_\epsilon}) + d_\epsilon((H_\epsilon - h_{obs})^3, \widetilde{S}_\epsilon),$$

where $Y_\epsilon = (\widetilde{\underline{R}_\epsilon}, \widetilde{S}_\epsilon)$.

Hölder's inequality implies that

$$d_\epsilon((H_\epsilon - h_{obs})^3, \widetilde{S}_\epsilon) \leq c_0(d_\epsilon^{4/3} \parallel H_\epsilon - h_{obs} \parallel^4_{L^4(\Omega)} + \parallel \widetilde{S}_\epsilon \parallel^4_{L^4(\Omega)}).$$

According to Green's formula we have

$$2(\text{div}(\widetilde{S}_\epsilon \underline{w}_\epsilon), \widetilde{S}_\epsilon) = (\widetilde{S}_\epsilon^{\ 2}, \text{div}(\underline{w}_\epsilon)) \text{ and } \mid 2(\text{div}(\widetilde{S}_\epsilon \underline{w}_\epsilon), \widetilde{S}_\epsilon) \mid \leq c \parallel \widetilde{S}_\epsilon \parallel^2_{L^4(\Omega)} \parallel \underline{w}_\epsilon \parallel.$$

Now applying the coercivity of a and Lemma 3 we obtain

$$\begin{aligned} -\frac{1}{2}\frac{\partial \mid Y_\epsilon \mid^2}{\partial t} + \alpha \parallel Y_\epsilon \parallel^2 + \frac{C}{D}\int_\Omega \mid \underline{w}_\epsilon \mid_2 \quad \mid \widetilde{\underline{R}_\epsilon} \mid_2^2 \, d\Omega \\ \leq \frac{C}{D}\int_\Omega \mid \underline{U}_\epsilon \mid_2 \quad \mid \widetilde{\underline{R}_\epsilon} \mid_2^2 \, d\Omega + c_1 \parallel \widetilde{\underline{R}_\epsilon} \parallel \mid \widetilde{S}_\epsilon \mid \\ + c_2(\parallel H_\epsilon \parallel_{L^4(\Omega)} \parallel \widetilde{\underline{R}_\epsilon} \parallel_{L^4(\Omega)} \parallel \widetilde{S}_\epsilon \parallel + \parallel \widetilde{S}_\epsilon \parallel^2_{L^4(\Omega)} \parallel \underline{w}_\epsilon \parallel) \\ + d_\epsilon \mid \underline{U}_\epsilon - \underline{u} \mid \mid \widetilde{\underline{R}_\epsilon} \mid + c_0(d_\epsilon^{4/3} \parallel H_\epsilon - h_{obs} \parallel^4_{L^4(\Omega)} + \parallel \widetilde{S}_\epsilon \parallel^4_{L^4(\Omega)}), \end{aligned}$$

which implies

$$\begin{aligned} -\frac{1}{2}\frac{\partial \mid Y_\epsilon \mid^2}{\partial t} + \alpha \parallel Y_\epsilon \parallel^2 + \frac{C}{D}\int_\Omega \mid \underline{w}_\epsilon \mid_2 \quad \mid \widetilde{\underline{R}_\epsilon} \mid_2^2 \, d\Omega \leq c_3 \mid \underline{U}_\epsilon \mid \parallel Y_\epsilon \parallel^2_{L^4(\Omega)} \\ + c_4(\parallel H_\epsilon \parallel_{L^4(\Omega)} \parallel Y_\epsilon \parallel_{L^4(\Omega)} \parallel Y_\epsilon \parallel + \parallel \underline{w}_\epsilon \parallel \parallel \widetilde{S}_\epsilon \parallel^2_{L^4(\Omega)}) + c_5 \parallel Y_\epsilon \parallel \mid Y_\epsilon \mid \\ + c_6 d_\epsilon \mid \underline{U}_\epsilon - \underline{u} \mid \mid Y_\epsilon \mid + c_0(d_\epsilon^{4/3} \parallel H_\epsilon - h_{obs} \parallel^4_{L^4(\Omega)} + \parallel \widetilde{S}_\epsilon \parallel^4_{L^4(\Omega)}). \end{aligned}$$

Applying Gagliardo–Nirenberg's inequality, Hölder's inequality, and the boundedness of $\underline{U}_\epsilon - \underline{u}$ and $\underline{U}_\epsilon$ in $L^\infty(0, T, H)$, we obtain

$$\begin{aligned} -\frac{\partial \mid Y_\epsilon \mid^2}{\partial t} + \alpha \parallel Y_\epsilon \parallel^2 + \frac{2C}{D}\int_\Omega \mid \underline{w}_\epsilon \mid_2 \quad \mid \widetilde{\underline{R}_\epsilon} \mid_2^2 \, d\Omega \leq c_7 \mid Y_\epsilon \mid^2 + c_8 \parallel H_\epsilon \parallel^4_{L^4(\Omega)} \\ + c_9 \parallel \underline{w}_\epsilon \parallel^2 + c_{10} d_\epsilon \mid Y_\epsilon \mid + c_{11}(d_\epsilon^{4/3} \parallel H_\epsilon - h_{obs} \parallel^4_{L^4(\Omega)} + \parallel \widetilde{S}_\epsilon \parallel^4_{L^4(\Omega)}). \end{aligned} \tag{3.25}$$

In particular, we have

$$\begin{aligned} -\frac{\partial \mid Y_\epsilon \mid^2}{\partial t} \leq c_{12} \mid Y_\epsilon \mid^2 + c_8 \parallel H_\epsilon \parallel^4_{L^4(\Omega)} + c_9 \parallel \underline{w}_\epsilon \parallel^2 + c_{13} d_\epsilon^2 \\ + c_{10}(d_\epsilon^{4/3} \parallel H_\epsilon - h_{obs} \parallel^4_{L^4(\Omega)} + \parallel \widetilde{S}_\epsilon \parallel^4_{L^4(\Omega)}). \end{aligned}$$

Integrating with respect to time gives

$$\begin{aligned} \mid Y_\epsilon \mid^2 \leq c_{11}\int_t^T \mid Y_\epsilon \mid^2 \, dt + c_8 \parallel H_\epsilon \parallel^4_{L^4(0,T,L^4(\Omega))} + c_9 \parallel \underline{w}_\epsilon \parallel^2_{L^2(0,T,H^1(\Omega))} + c_{12} T d_\epsilon^2 \\ + c_{10}(d_\epsilon^{4/3} \parallel H_\epsilon - h_{obs} \parallel^4_{L^4(0,T,L^4(\Omega))} + \parallel \widetilde{S}_\epsilon \parallel^4_{L^4(0,T,L^4(\Omega))}). \end{aligned}$$

Since $H_\epsilon - h_{obs}$ is uniformly bounded in $L^4(0, T, L^4(\Omega))$, H_ϵ in $L^4(0, T, L^4(\Omega))$, and $\underline{w}_\epsilon$ in $L^2(0, T, H^1(\Omega))$, then by Gagliardo–Nirenberg's inequality we deduce

$$\mid Y_\epsilon \mid^2 \leq c_{11}\int_t^T \mid Y_\epsilon \mid^2 \, dt + c_{13}(1 + d_\epsilon^{4/3} + d_\epsilon^2 + \parallel \widetilde{S}_\epsilon \parallel^4_{L^4(0,T,L^4(\Omega))}).$$

Since d_ϵ is bounded and $\widetilde{S}_\epsilon$ is uniformly bounded in $L^4(0,T,L^4(\Omega))$, by using Gronwall's lemma we prove that Y_ϵ is uniformly bounded in $L^\infty(0,T,L^2(\Omega))$.

From (3.25) we deduce that

$$Y_\epsilon \text{ is uniformly bounded in } L^2(0,T,H^1(\Omega)) \cap L^\infty(0,T,L^2(\Omega)).$$

Using (3.24), we have

$$-\left(\frac{\partial Y_\epsilon}{\partial t}, W\right) = -a(Y_\epsilon, W) - \frac{C}{D}\int_\Omega \mid \underline{w}_\epsilon \mid_2 \ (\underline{\widetilde{R}_\epsilon}, \underline{v})_2 d\Omega - \frac{C}{D}\int_\Omega (\underline{\widetilde{R}_\epsilon}, \underline{U}_\epsilon)_2 \frac{(\underline{w}_\epsilon, \underline{v})_2}{\mid \underline{w}_\epsilon \mid_2} d\Omega$$
$$+((H_\epsilon \nabla)\widetilde{S}_\epsilon, \underline{v}) + ((\widetilde{S}_\epsilon \nabla)\beta, \underline{w}_\epsilon) + g(\mathrm{div}(\underline{\widetilde{R}_\epsilon}), \beta) + d_\epsilon(\underline{U}_\epsilon - \underline{u}, \underline{v}) + d_\epsilon((H_\epsilon - h_{obs})^3, \beta),$$

where $W = (\underline{v}, \beta)$.

According to the continuity of the bilinear form a, Lemma 3, and Hölder's inequality, we obtain

$$\left|\left(\frac{\partial Y_\epsilon}{\partial t}, W\right)\right| \leq c(\parallel Y_\epsilon \parallel + \parallel \underline{w}_\epsilon \parallel_{L^4(\Omega)} \parallel Y_\epsilon \parallel_{L^4(\Omega)} + \parallel \underline{U}_\epsilon \parallel_{L^4(\Omega)} \parallel Y_\epsilon \parallel_{L^4(\Omega)}$$
$$+ \parallel H_\epsilon \parallel_{L^4(\Omega)} \parallel Y_\epsilon \parallel + d_\epsilon \mid \underline{U}_\epsilon - \underline{u} \mid + d_\epsilon \parallel H_\epsilon - h_{obs} \parallel^3_{L^4(\Omega)}) \parallel W \parallel,$$

which implies

$$\left\|\frac{\partial Y_\epsilon}{\partial t}\right\|_{V'} \leq c(\parallel Y_\epsilon \parallel + \parallel \underline{w}_\epsilon \parallel_{L^4(\Omega)} \parallel Y_\epsilon \parallel_{L^4(\Omega)} + \parallel \underline{U}_\epsilon \parallel_{L^4(\Omega)} \parallel Y_\epsilon \parallel_{L^4(\Omega)}$$
$$+ \parallel H_\epsilon \parallel_{L^4(\Omega)} \parallel Y_\epsilon \parallel + d_\epsilon \mid \underline{U}_\epsilon - \underline{u} \mid + d_\epsilon \parallel H_\epsilon - h_{obs} \parallel^3_{L^4(\Omega)}).$$

Integrating with respect to time and using Hölder's inequality, we obtain

$$\left\|\frac{\partial Y_\epsilon}{\partial t}\right\|_{L^1(0,T,V')} \leq c(1 + \parallel Y_\epsilon \parallel^2_{L^2(0,T,H^1(\Omega))} + \parallel \underline{w}_\epsilon \parallel^2_{L^2(0,T,H^1(\Omega))} + \parallel \underline{U}_\epsilon \parallel^2_{L^2(0,T,H^1(\Omega))}$$
$$+ \parallel H_\epsilon \parallel^2_{L^2(0,T,H^1(\Omega))} + d^2_\epsilon + \parallel \underline{U}_\epsilon - \underline{u} \parallel^2_{L^2(0,T,L^2(\Omega))} + d^4_\epsilon + \parallel H_\epsilon - h_{obs} \parallel^4_{L^4(0,T,L^4(\Omega))}).$$

Applying (3.18), (3.19), and the boundedness of Y_ϵ,$\underline{U}_\epsilon$,H_ϵ and $\underline{w}_\epsilon$ in $L^2(0,T,H^1(\Omega))$, we deduce that $\partial Y_\epsilon / \partial t$ is uniformly bounded in $L^1(0,T,V')$.

We can then extract from (Y_ϵ) a subsequence also denoted (Y_ϵ) and such that

$$\begin{aligned} Y_\epsilon &\rightharpoonup Y \quad \text{weakly in } L^2(0,T,H^1(\Omega)), \\ Y_\epsilon &\longrightarrow Y \quad \text{strongly in } L^2(0,T,L^2(\Omega)). \end{aligned}$$

Since $(\underline{F}_\epsilon, \underline{U}_\epsilon, H_\epsilon, \underline{w}_\epsilon)$ verifies the convergence results proved in Theorem 3, we can pass to the limit in (3.24). The method is the same as in the proof of Proposition 1. We thus obtain that $Y = (\underline{R}, S)$ verifies the equations

$$\left(-\frac{\partial \underline{R}}{\partial t}, \underline{v}\right) + a_1(\underline{R}, \underline{v}) + \frac{C}{D}\left(\mid \underline{u} \mid_2 \underline{R} + (\underline{R}, \underline{u})_2 \frac{u}{\mid \underline{u} \mid_2}, \underline{v}\right) - (\underline{F} \wedge \underline{R}, \underline{v})$$
$$-((h\nabla)S, \underline{v}) = 0,$$
$$\left(-\frac{\partial S}{\partial t}, \beta\right) + a_2(S, \beta) + (\mathrm{div}(\beta \underline{u}), S) - g(\mathrm{div}(\underline{R}), \beta) = d((h - h_{obs})^3, \beta) \quad \forall (\underline{v}, \beta) \in V,$$
$$(\underline{R}, S)(T) = (\underline{0}, 0),$$

and

$$\int_0^T (\underline{R} + d\gamma \underline{f},\ \underline{g} - \underline{f}) dt \geq 0 \ \forall \underline{g} \in K_c, \text{where } d = 0 \ \mathit{or} \ 1.$$

We are now going to prove that $d = 1$ in order to achieve the proof of Theorem 4. Let us suppose that $d = 0$; then $(\underline{R}, S)$ verifies the system

$$\begin{aligned}
&\left(-\frac{\partial \underline{R}}{\partial t}, \underline{v}\right) + a_1(\underline{R}, \underline{v}) + \frac{C}{D}\left(|\,\underline{u}\,|_2\ \underline{R} + (\underline{R}, \underline{u})_2 \frac{\underline{u}}{|\,\underline{u}\,|_2}, \underline{v}\right) - (\underline{F} \wedge \underline{R}, \underline{v})\\
&-((h\nabla)S, \underline{v}) = 0,\\
&\left(-\frac{\partial S}{\partial t}, \beta\right) + a_2(S, \beta) + (\mathrm{div}(\beta \underline{u}), S) - g(\mathrm{div}(\underline{R}), \beta) = 0 \quad \forall(\underline{v}, \beta) \in V,\\
&(\underline{R}, S)(T) = (\underline{0}, 0).
\end{aligned} \tag{3.26}$$

Setting $(\underline{v}, \beta) = (\underline{R}, S)$ in (3.26) and adding the first and second parts of (3.26), we obtain

$$\begin{aligned}
&-\frac{1}{2}\frac{\partial\,|\,Y\,|^2}{\partial t} + a(Y, Y) + \frac{C}{D}\int_\Omega |\,\underline{u}\,|_2 \quad |\,\underline{R}\,|_2^2\, d\Omega + \frac{C}{D}\int_\Omega \frac{(\underline{u}, \underline{R})_2^2}{|\,\underline{u}\,|_2} d\Omega\\
&= ((h\nabla)S, \underline{R}) - (\mathrm{div}(S\underline{u}), S) + g(\mathrm{div}(\underline{R}), S),
\end{aligned}$$

where $Y = (\underline{R}, S)$.

By using the coercivity of operator a, Lemma 3, and Hölder's inequality, we obtain

$$-\frac{\partial\,|\,Y\,|^2}{\partial t} + \alpha \parallel Y \parallel^2 \leq c(1 + \parallel h \parallel_{L^4(\Omega)}^4 + \parallel \underline{u} \parallel_{L^4(\Omega)}^4)\,|\,Y\,|^2\ .$$

The functions $\parallel h \parallel_{L^4(\Omega)}^4$ and $\parallel \underline{u} \parallel_{L^4(\Omega)}^4$ are integrable with respect to time, so by applying Gronwall's lemma, we deduce

$$|\,Y\,|^2 \leq c\,|\,Y(T)\,|^2\ exp\left(\int_t^T (\parallel h(s) \parallel_{L^4(\Omega)}^4 + \parallel \underline{u}(s) \parallel_{L^4(\Omega)}^4) ds\right) \quad \forall t \in [0, T].$$

Since $Y(T) = 0$, we thus obtain $Y = 0$.

Since the solution S is the limit with $\epsilon \to 0$ of $\widetilde{S}_\epsilon$ and the sequence $\parallel \widetilde{S}_\epsilon \parallel_{L^4(0,T,L^4(\Omega))}$ is equal to 1, then $\parallel S \parallel_{L^4(0,T,L^4(\Omega))}$ is equal to 1 and we have a contradiction. So we can conclude that $d = 1$.

This achieves the proof of the theorem. □

3.2. Study of the optimal control problem with nonhomogeneous boundary conditions. The results obtained in section 3.1 can easily be extended to the general nonhomogeneous case. Then the first step consists of solving linear problems (1.3) and (1.4) whose solution $(\underline{u}_L, h_L)$ doesn't depend on the control $\underline{f}$. We have proved the equivalence between initial problem (1.1)–(1.2) and homogeneous problem (1.5). Therefore the control method is applied to problem (1.5), the penalization method works in the same way as in section 3.1, and we obtain the two following theorems.

Theorem 5. *Under the assumptions of Proposition* 1, *the optimal control problem* (3.9) *has at least one solution* $(\underline{f}, \underline{u})$ *in* U_{ad}.

THEOREM 6. *Optimal control* $(\underline{f}, \underline{u})$ *is characterized by*

$$\begin{aligned}
&\left(\frac{\partial \underline{u}}{\partial t}, \underline{v}\right) + a_1(\underline{u}, \underline{v}) + \frac{C}{D}(\mid (\underline{u} + \underline{u}_L) \mid_2 (\underline{u} + \underline{u}_L), \underline{v}) + (\underline{F} \wedge \underline{u}, \underline{v}) - g(\mathrm{div}(\underline{v}), h) = (\underline{f}, \underline{v}),\\
&\left(\frac{\partial h}{\partial t}, \beta\right) + a_2(h, \beta) + (\mathrm{div}(h\underline{u}), \beta) + (\mathrm{div}(h_L\underline{u}), \beta) + (\mathrm{div}(h\underline{u}_L), \beta) = (f_1, \beta)\\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \forall(\underline{v}, \beta) \in V,\\
&(\underline{u}, h)(t = 0) = (\underline{u}_0, h_0),
\end{aligned}$$

$$\begin{aligned}
&\left(-\frac{\partial \underline{R}}{\partial t}, \underline{v}\right) + a_1(\underline{R}, \underline{v}) + \frac{C}{D}\left(\mid (\underline{u} + \underline{u}_L) \mid_2 \underline{R} + (\underline{u} + \underline{u}_L, \underline{R})_2 \frac{(\underline{u} + \underline{u}_L)}{\mid (\underline{u} + \underline{u}_L) \mid_2}, \underline{v}\right)\\
&-(\underline{F} \wedge \underline{R}, \underline{v}) - ((h + h_L)\nabla S, \underline{v}) = 0,\\
&\left(-\frac{\partial S}{\partial t}, \beta\right) + a_2(S, \beta) - (((\underline{u} + \underline{u}_L)\nabla)S, \beta) - g(\mathrm{div}(\underline{R}), \beta) = ((h - h_{obs})^3, \beta)\\

\end{aligned}$$

and

$$(\underline{R} + \gamma \underline{f},\ \underline{g} - \underline{f})_{U_c} \geq 0\ \forall \underline{g} \in K_c.$$

4. Conclusion.

We have developed a control method in order to calculate the velocity $\underline{u}$ and the depth h. The sea level, deduced from altimetric measurements, constitutes the observation in our model. The fluid exchanges are supposed to be known; the outside stress $\underline{f}$ is unknown. We take then $\underline{f}$ as the control. $(\underline{u}(\underline{f}), h(\underline{f}))$ are the velocity and depth corresponding to any control $\underline{f}$. The optimal control is defined as the outside stress minimizing a given cost function which measures the distance between the observed depth and the depth $h(\underline{f})$. The observed depth is driven by an outside stress $\underline{f}_r$. $\underline{f}$ is an approximation of the unknown real outside stress $\underline{f}_r$ and then $(\underline{u}(\underline{f}), h(\underline{f}))$ induced by the optimal control $\underline{f}$ has to approach the real circulation $(\underline{u}_r, h_r)$ observed by the satellite.

The existence of optimal control is proved by means of minimizing sequences. The question of the uniqueness is not treated; in general the answer is expected to be negative. To characterize the control, we introduce a family of penalized control problems; we obtain a set of equations characterizing these problems. Finally we demonstrate the convergence of the penalized problems and obtain the optimality conditions from which the solution of the initial nonlinear control problem and states may be determinated.

We can use this theoretical study to develop a numerical scheme: let a fixed ϵ be small enough, we may choose $\underline{f}_1$ and so $(\underline{u}_1, h_1)$ is the solution of the nonlinear shallow-water problem driven by $\underline{f}_1$. Then we solve the linear penalized control problem numerically, for example, by using a quasi-Newton method. We obtain then the solution $(\underline{f}_\epsilon, \underline{w}_\epsilon, \underline{U}_\epsilon, H_\epsilon)$ and we compare $(\underline{f}_\epsilon, \underline{U}_\epsilon, H_\epsilon)$ to $(\underline{f}_1, \underline{u}_1, h_1)$. If the error is not sufficiently small, we initialize the algorithm with $(\underline{f}_\epsilon, \underline{U}_\epsilon, H_\epsilon)$ and we iterate the process. The computed solution $(\underline{f}_\epsilon, \underline{U}_\epsilon, H_\epsilon)$ approximates the solution of the initial nonlinear control problem. The approximate solution $(\underline{f}_\epsilon, \underline{U}_\epsilon, H_\epsilon)$ depends on the small parameter ϵ. The circulation $(\underline{U}_\epsilon, H_\epsilon)$ is driven by the outside stress $\underline{f}_\epsilon$. In order to confirm and to validate numerically the convergence results and the control method, we may compare $(\underline{f}_\epsilon, \underline{U}_\epsilon, H_\epsilon)$ and $(\underline{f}_r, \underline{u}_r, h_r)$ for different values of ϵ.

We can thus compute the velocity and depth in a shallow-water domain Ω, during a time T, from satellite observations of the surface topography.

Acknowledgment. The author is grateful to the referee for many useful comments and suggestions which have improved the presentation of this paper.

GENERIC SIMPLICITY OF THE SPECTRUM AND STABILIZATION FOR A PLATE EQUATION*

JAIME H. ORTEGA† AND ENRIQUE ZUAZUA‡

Abstract. In this work we prove the generic simplicity of the spectrum of the clamped plate equation in a bounded regular domain of $\mathbb{R}^d$. That is, given $\Omega \subset \mathbb{R}^d$, we show that there exists an arbitrarily small deformation of the domain u, such that all the eigenvalues of the plate system in the deformed domain $\Omega + u$ are simple. To prove this result we first prove a nonstandard unique continuation property for this system that also holds generically with respect to the perturbations of the domain. Both the proof of this generic uniqueness result and the generic simplicity of the spectrum use Baire's lemma and shape differentiation. Finally, we show an application of this unique continuation property to a result of generic stabilization for a plate system with one dissipative boundary condition.

Key words. spectral theory, plate equation, unique continuation property, stabilization

1. Introduction and main results.

In this work we are interested in the study of the spectral properties for the plate system

$$
\left\{
\begin{array}{rcll}
\triangle^2 y & = & \lambda y & \text{in } \Omega, \\
y & = & 0 & \text{on } \partial\Omega, \\
\dfrac{\partial y}{\partial n} & = & 0 & \text{on } \partial\Omega,
\end{array}
\right. \tag{1.1}
$$

where $\Omega \subseteq \mathbb{R}^d$ is a bounded domain with boundary of class C^4.

Problem (1.1) admits a sequence of eigenvalues

$$0 < \lambda_1 \le \lambda_2 \le \cdots \le \lambda_n \le \cdots \longrightarrow \infty,$$

which have finite multiplicity. The eigenfunctions $\{y_n\}_n \subset H_0^2(\Omega)$ of (1.1) can be chosen to form an orthonormal basis of $H_0^2(\Omega)$.

On the other hand, it is well known that the eigenvalues of (1.1) are not always simple. For instance, in [8], it is shown that the first eigenvalue is not simple in a suitable annular domain.

The problem of the simplicity of the spectrum arises in many contexts. This is, for instance, the case when analyzing stabilizability and controllability issues for evolution systems. When the spectrum is simple one can often reduce these problems to the analysis of suitable properties of eigenfunctions, which is an easier problem to deal with because of the lack of dependence with respect to time. We refer to J. L.

Lions and E. Zuazua [21] for an example of a control problem where this strategy is successfully applied.

Concerning the simplicity of the spectrum, the problem we address is as follows. *Are there arbitrarily small deformations of the domain* $u \in W^{5,\infty}(\Omega, \mathbb{R}^d)$, *such that the spectrum of* (1.1) *in the deformed domain* $\Omega + u$ *is simple?*

In this paper we give a positive answer to this question. We show that the set of deformations of the domain $u \in W^{5,\infty}(\Omega, \mathbb{R}^d)$, such that the spectrum of the plate system is simple, is a dense subset of $W^{5,\infty}(\Omega, \mathbb{R}^d)$.

The generic simplicity of the spectrum of second order elliptic operators is by now well known. We refer to J. H. Albert [1] for perturbations of the coefficients of the operator and to A. M. Micheletti [22] and K. Uhlenbeck [29] for perturbations of the domain.

The result we prove in this paper and the methods we employ are inspired in [25] by the authors, where a similar result was proved for the $2-D$ Stokes system. The proof combines Baire's lemma and shape differentiation. These two tools reduce the problem to the obtainment of a suitable unique continuation property for the eigenfunctions. In the context of second order problems this uniqueness problem can be dealt with by means of Holmgrem's theorem. However, this is not the case when working with the plate equation. In this case the uniqueness problem cannot be analyzed in the context of the classical Cauchy problems since only three boundary conditions are known to vanish. We then proceed as in [25], showing that the uniqueness property holds generically with respect to the perturbations of the domain. But this turns out to be sufficient to complete the proof of the generic simplicity of the spectrum.

Our generic unique continuation property refers to the following uniqueness problem.

If y *solves* (1.1) *for some* $\lambda > 0$ *and*

$$\frac{\partial^2 y}{\partial n^2} = 0 \qquad \text{on } \Gamma_0,$$

then, necessarily, $y \equiv 0$.

This property will be referred to as *spectral uniqueness.*

THEOREM 1.1. *Let* $\Omega \subset \mathbb{R}^d$ *be a bounded domain with boundary of class* C^4. *Let* Γ_0 *be an open nonempty subset of* $\partial\Omega$.

Then, the set of deformations of the domain $u \in W^{5,\infty}(\Omega, \mathbb{R}^d)$, *such that* $u = 0$ *on* $\partial\Omega \setminus \Gamma_0$ *and for which spectral uniqueness holds when* Ω *and* Γ_0 *are replaced by* $\Omega + u$ *and* $\Gamma_0 + u$, *is residual in*

$$W_0 = \{u \in W^{5,\infty}(\Omega, \mathbb{R}^d) : u = 0 \text{ on } \partial\Omega \backslash \Gamma_0\}.$$

In other words, it is a countable intersection of dense open sets of W_0. *In particular, it is dense in* W_0. □

Remark 1.1. (1) As far as we know, there is no example in the literature of bounded domain Ω and open subset Γ_0 of $\partial\Omega$ for which there exists a nontrivial eigenfunction of (1.1) such that the further condition

$$\frac{\partial^2 y}{\partial n^2} = 0 \quad \text{on } \Gamma_0 \tag{1.2}$$

is satisfied.

However, our result is of a generic nature, and, therefore, it does not apply to any domain Ω and open subset Γ_0 of $\partial\Omega$.

Therefore, whether this unique continuation property holds for any Ω and $\Gamma_0 \subset \partial\Omega$ remains an open problem.

(2) Using multiplier techniques (see Appendix I of [18], [19], and [13]), one can show that this unique continuation holds for any domain Ω provided Γ_0 is a subset of the boundary of the form

$$\Gamma_0 = \Gamma(x_0) = \{x \in \partial\Omega \,:\, (x - x_0) \cdot n(x) > 0\}.$$

In fact, multiplier methods allow us to show that uniqueness holds for the dynamic plate model, but always for subsets of the boundary of this particular form.

Note, however, that these subsets of the boundary are always large. In other words, there are many small subsets of the boundary Γ_0 that cannot be written in this form.

Consequently, our result is, as far we know, the first one that applies to arbitrarily small subsets of boundary, but it is of generic nature.

(3) Note also that the deformations we apply do deform the subset Γ_0 itself. Whether this unique continuation result applies when u preserves Γ_0 or not is an open problem. □

With the aid of this result we prove the main result on the generic simplicity of the spectrum.

THEOREM 1.2. *Let Ω be a bounded domain of $\mathbb{R}^d$ of class C^4. Let Γ_0 be an open nonempty subset of $\partial\Omega$.*

Then the set

$$A = \left\{u \in W^{5,\infty}(\Omega, \mathbb{R}^d) : u = 0 \text{ on } \partial\Omega \setminus \Gamma_0 \text{ and the spectrum of } (1.1) \text{ is simple}\right\}$$

is residual in

$$W_0 = \left\{u \in W^{5,\infty}(\Omega, \mathbb{R}^d) : u = 0 \text{ on } \partial\Omega \setminus \Gamma_0\right\}. \qquad □$$

We also show an application of Theorem 1.1 to the study of the stabilization of the plate system with dissipative boundary conditions.

Let us consider the system

$$(1.3) \qquad \begin{cases} y_{tt} + \triangle^2 y &= 0 & \text{in } \Omega \times (0,\infty), \\ y &= 0 & \text{on } \partial\Omega \times (0,\infty), \\ \dfrac{\partial y}{\partial n} &= 0 & \text{on } \partial\Omega \setminus \Gamma_0 \times (0,\infty), \\ \triangle y &= -\dfrac{\partial y_t}{\partial n} & \text{on } \Gamma_0 \times (0,\infty), \\ y(x,0) &= y_0 & \text{in } \Omega, \\ y_t(x,0) &= y_1 & \text{in } \Omega. \end{cases}$$

It is easy to see that for any $(y_0, y_1) \in X = X_1 \times X_2$ system (1.3) admits a unique solution $y \in C([0,\infty); X_1) \cap C^1([0,\infty); X_2)$. Here and in what follows $X_1 = \{\varphi \in H^2(\Omega) \cap H_0^1(\Omega) : \frac{\partial \varphi}{\partial n} = 0 \text{ on } \partial\Omega \setminus \Gamma_0\}$ and $X_2 = L^2(\Omega)$.

We define the energy of the system as

$$(1.4) \qquad E(t) = \frac{1}{2} \int_\Omega \left[|y_t|^2 + |\triangle y|^2\right].$$

From the dissipative boundary conditions of (1.3) we have that

$$\frac{d}{dt}E(t) = -\int_{\Gamma_0} |\triangle y(x,t)|^2 \, d\Gamma \leq 0. \tag{1.5}$$

Thus, we deduce that the energy decreases for any solution y of (1.3) as $t \to \infty$. Therefore, the following question arises naturally.

Does the energy of any solution of (1.3) *tend to zero as* $t \to \infty$*? In other words, does*

$$E(t) \to 0 \qquad \text{as} \quad t \to \infty \tag{1.6}$$

for every solution of (1.3)*?*

We will see that the stabilization property (1.6) holds generically with respect to the domain Ω, as in the following theorem.

THEOREM 1.3. *Let $\Omega \subset \mathbb{R}^d$ be an open bounded set of class C^4, and let Γ_0 be an open nonempty subset of the boundary, such that the spectral uniqueness property holds.*

Then, every solution of (1.3) *verifies that*

$$E(t) \to 0 \qquad \text{as } t \to +\infty. \qquad \square \tag{1.7}$$

To prove this result we use La Salle's invariance principle, which allows us to reduce our stabilization problem to a unique continuation property. This unique continuation problem turns out to be the one we have solved generically in Theorem 1.1, i.e., the spectral uniqueness problem.

We could also consider system (1.3) with two dissipative boundary conditions instead of one. Consider, for instance,

$$\begin{cases} y = \dfrac{\partial y}{\partial n} = 0 & \text{on } \partial\Omega \setminus \Gamma_0 \times (0,\infty), \\ \triangle y = -\dfrac{\partial y_t}{\partial n} & \text{on } \Gamma_0 \times (0,\infty), \\ \dfrac{\partial \triangle y}{\partial n} = y_t & \text{on } \Gamma_0 \times (0,\infty). \end{cases} \tag{1.8}$$

Then the stabilization result above holds for every domain Ω and for every nonempty open subset $\Gamma_0 \subset \partial\Omega$. In this case, by means of La Salle's invariance principle, we can reduce our problem to a unique continuation one that may be solved by applying the classical uniqueness theorem by Holmgrem. Indeed, in this case, we add the extra boundary conditions $\triangle y = \frac{\partial y}{\partial n} = 0$ on Γ_0 to the solutions of (1.1), in which case we are in the context of the classical Cauchy problem.

Remark 1.2. The methods developed in this paper may be applied to other plate systems, such as when the plate equation is replaced by the one taking into account the rotational inertia term, i.e.,

$$y_{tt} - \gamma \triangle y_{tt} + \triangle^2 y = 0,$$

with $\gamma > 0$. Other boundary conditions may also be considered. For instance, the condition $\frac{\partial y}{\partial n} = 0$ on $\partial\Omega \setminus \Gamma_0$ may be replaced by $\triangle y = 0$ on $\partial\Omega \setminus \Gamma_0$.

The same result applies as well to plate equations with nonlinear monotone boundary damping. $\square$

Remark 1.3. When Γ_0 is a subset of the boundary of the form $\Gamma(x_0)$ we indicated in Remark 1.1, uniform stability properties may be proved for the systems under consideration, i.e.,

$$E(t) \leq Ce^{-\alpha t}E(0)$$

for suitable $C, \alpha > 0$ (see, for instance, [15]). We do not address this problem here. In any case, one does not expect, in general, exponential decay to hold when the dissipative term acts on a small subset of the boundary. □

The rest of this work is organized as follows. In section 2 we present some preliminary results on the variational formulation of the plate equation and shape differentiation. In section 3 we prove a result of existence and regular dependence of the branches of eigenvalues and eigenfunctions of the bilaplacian with respect to the perturbation of the domain. In section 4 we compute the local variations of the eigenvalues and eigenfunctions of the bilaplacian. In section 5 we prove the unique continuation property of Theorem 1.1. In section 6 we prove the simplicity of the spectrum of Theorem 1.2. Finally, in section 7 we prove the stabilization result of Theorem 1.3.

2. Preliminaries.

2.1. Baire's lemma.

First we remember the Baire's lemma, which will be a useful tool.

LEMMA 2.1 (Baire's lemma). *Let X be a complete metric space, and let A_n be an open dense subset of X for all $n \in \mathbb{N}$.*

Then $\cap_{n\in\mathbb{N}} A_n$ is dense in X. □

A direct consequence of Baire's lemma is the following result.

LEMMA 2.2. *Let X be a complete metric space, and let $\{A_n\}_{n\geq 0}$ be a sequence of open subsets of X such that*

1. *$A_0 = X$, and*
2. *A_{n+1} is a dense subset of A_n for all $n \geq 0$.*

Then $\cap_{n=1}^{\infty} A_n$ is dense in X. □

2.2. Variational formulation of the plate system.

The variational formulation of the eigenvalue problem (1.1) is as follows: to find $y \in H_0^2(\Omega)$ and $\lambda \in \mathbb{R}$ such that

$$\int_\Omega \triangle y \triangle \varphi = \lambda \int_\Omega y\varphi \qquad \forall \varphi \in H_0^2(\Omega). \tag{2.1}$$

This variational eigenvalue problem can be handled in a standard way.

It is well known that there exists a positive constant $c > 0$ such that

$$\|f\|^2_{H^2(\Omega)} \leq c \int_\Omega |\triangle f|^2 \quad \forall f \in H_0^2(\Omega). \tag{2.2}$$

Then

$$|f|_2 = \left(\int_\Omega |\triangle f|^2\right)^{\frac{1}{2}} \tag{2.3}$$

defines a norm in $H_0^2(\Omega)$, equivalent to the one induced by the norm of $H^2(\Omega)$.

Thus

$$b : H_0^2(\Omega) \times H_0^2(\Omega) \to \mathbb{R}, \qquad b(\phi,\varphi) = \int_\Omega \triangle\phi\,\triangle\varphi \tag{2.4}$$

is a coercive and continuous bilinear form. Then, for each $f \in H^{-2}(\Omega)$, there exists a unique solution $y \in H_0^2(\Omega)$ of the problem

$$\int_\Omega \triangle y \triangle\varphi = \langle f,\varphi\rangle_{H^{-2}\times H_0^2} \qquad \forall\varphi \in H_0^2(\Omega).$$

This shows the existence and uniqueness of weak solutions of the elliptic problem

$$\begin{cases} \triangle^2 y &= f & \text{in } \Omega, \\ y &= 0 & \text{on } \partial\Omega, \\ \dfrac{\partial y}{\partial n} &= 0 & \text{on } \partial\Omega. \end{cases} \tag{2.5}$$

Using the compactness of the imbedding $H_0^2(\Omega) \hookrightarrow L^2(\Omega)$, one can show that the map $f \in L^2(\Omega) \to y \in L^2(\Omega)$ is compact. It is also easy to see that it is self-adjoint. Applying the classical spectral theory for compact, self-adjoint operators, we deduce that the eigenvalue problem (2.1) admits a sequence of eigenvalues

$$0 < \lambda_1 \le \lambda_2 \le \lambda_3 \le \cdots \to +\infty.$$

Moreover, each eigenvalue has finite multiplicity, and the eigenfunctions $y_i \in H^4(\Omega) \cap H_0^2(\Omega)$ can be chosen to form an orthonormal basis of $L^2(\Omega)$.

2.3. Shape differentiation. An important tool for the study of the generic properties is the *shape differentiation.* For more details about this technique, we refer to [4], [27], [28], and the bibliographies therein.

Given a domain Ω and a function $u : \Omega \to \mathbb{R}^d$, we define the new domain $\Omega + u$ by

$$\Omega + u = \{y \in \mathbb{R}^d : y = x + u(x),\ x \in \Omega\}. \tag{2.6}$$

Let us consider perturbations u in the space $W^{k,\infty}(\Omega,\mathbb{R}^d)$ with norm

$$\|u\|_{k,\infty} = \underset{0\le|\alpha|\le k,\, x\in\Omega}{\text{sup ess}} |D^\alpha u(x)|.$$

The following results are well known.

LEMMA 2.3 (see [28]). *Let $u \in W^{k,\infty}(\Omega,\mathbb{R}^d)$, and let $k \ge 1$ be such that $\|u\|_{k,\infty} \le \frac{1}{2}$. Then the map $(I+u) : \Omega \to \Omega + u$ is invertible. Furthermore, there exists $w \in W^{k,\infty}(\Omega,\mathbb{R}^d)$ such that $(I+u)^{-1} = I + w$ and $\|w\|_{k,\infty} \le C_k \|u\|_{k,\infty}$, where C_k is a constant independent on u.* □

Remark 2.1. According to this result, if Ω is of class C^j, we can choose $k = j+1$ (and therefore the perturbation space $W^{k,\infty}(\Omega,\mathbb{R}^d)$) such that our new domain $\Omega + u$ is also of class C^j. In particular, if Ω is of class C^4, then $\Omega + u$ is also of class C^4, and the solutions of the eigenvalue problem for the bilaplacian in the new domain $\Omega + u$ satisfy $y(u) \in H^4(\Omega+u) \cap H_0^2(\Omega+u)$ for every $u \in W^{5,\infty}(\Omega,\mathbb{R}^d)$ small enough. This is the functional framework we shall work in. □

LEMMA 2.4 (see [28]). *Let $k \geq 1$, and consider the function*

$$\begin{array}{rrcl} \gamma : & W^{k,\infty}(\Omega, \mathbb{R}^d) & \rightarrow & W^{k-1,\infty}(\Omega, \mathbb{R}), \\ & u & \rightarrow & \gamma(u) = Jac\,(I+u) = \left|\det\left[\partial_j\,(I+u)_i\right]\right|. \end{array}$$

This function γ is differentiable at $u = 0$. Furthermore, the directional derivative in the direction w at the point $u = 0$ is $\operatorname{div} w$; *that is,*

$$\langle D\gamma(0), w\rangle = \operatorname{div}\, w \quad \forall\, w \,\in\, W^{k,\infty}(\Omega, \mathbb{R}^d). \qquad \square$$

LEMMA 2.5 (see [28]). *Let $k \geq 1$. The map*

$$\begin{array}{rrcl} \beta : & \mathcal{W} \subset W^{k,\infty}(\Omega, \mathbb{R}^d) & \rightarrow & \mathcal{M}_{d\times d}\left(W^{k-1,\infty}(\Omega, \mathbb{R})\right), \\ & u & \rightarrow & {}^t\left[\partial_j\,(I+u)_i\right]^{-1}, \end{array}$$

where $\mathcal{W}$ is a neighborhood of $u = 0$ on $W^{k,\infty}(\Omega, \mathbb{R}^d)$, is differentiable on $u = 0$. Its directional derivative on $u = 0$ in the direction w is given by the matrix $-^t\left[\partial_j w_i\right]$, where ${}^t\left[\partial_j w_i\right]$ denotes the adjoint of $\left[\partial_j w_i\right]$. In other words,

$${}^t\left[\partial_j\,(I+u)_i\right]^{-1} = [I] -^t \left[\partial_j u_i\right] + \theta(u),$$

where the matrix $\theta(u)$ satisfies

$$\frac{\|\theta(u)\|_{k-1,\infty}}{\|u\|_{k,\infty}} \rightarrow 0 \quad \text{as} \quad \|u\|_{k,\infty} \rightarrow 0. \qquad \square$$

Now, we consider a function

$$\begin{array}{rrcl} v : & W^{k,\infty}(\Omega, \mathbb{R}^d) & \rightarrow & W^{m,r}(\Omega+u), \\ & u & \rightarrow & v(u), \end{array}$$

where $1 \leq r < \infty$ and $m \leq k$ are integer numbers. In practice, $v(u)$ will be the solution of a suitable problem, which depends on the perturbation function u (for instance, a solution of our eigenvalue problem (1.1)).

We are interested in the study of the regularity of the function $v(u)$ with respect to the perturbation parameter u.

DEFINITION 2.1 (see [28]). *Let $k \geq m \geq 1$, $1 \leq r < \infty$. We say that the function $v(u)$ has a first order local variation at $u = 0$ on $W^{m-1,r}_{loc}(\Omega)$ if $v(u) \in W^{m,r}(\Omega+u)$ for all $u \in W^{k,\infty}(\Omega, \mathbb{R}^d)$ and there exists a linear map $v'(\Omega; u)$ defined from $u \in W^{k,\infty}(\Omega, \mathbb{R}^d)$ to $W^{m-1,r}_{loc}(\Omega)$ such that, for each open set $\omega \subset\subset \Omega$,*

$$v(u) = v(0) + v'(\Omega; u) + \widehat{\theta}(u) \ \text{ in } \omega,$$

when $\|u\|_{k,\infty}$ is small enough and

$$\frac{\widehat{\theta}(u)}{\|u\|_{k,\infty}} \rightarrow 0 \quad \text{in } W^{m-1,r}(\omega) \quad \text{as } \|u\|_{k,\infty} \rightarrow 0. \qquad \square$$

Remark 2.2. From Definition 2.1 it follows that the *first local variation* can be defined as

$$v'(\Omega; u) = \lim_{t\rightarrow 0} \frac{v(tu)\,|_{\omega} - v(0)\,|_{\omega}}{t} \quad \text{ in } \ \omega, \tag{2.7}$$

where $\omega \subset\subset \Omega$ and $v(tu)|_{\omega}$, $v(0)|_{\omega}$ are the restrictions of the functions $v(tu)$ and $v(0)$ to ω. □

In what follows, to simplify the notation, we will write $v'(u) = v'(\Omega; u)$.

The following theorem provides sufficient conditions for the existence of the first local variation for functions which depend on the deformation u. Furthermore, it provides an expression for the local variation on the boundary in terms of the normal derivative of $v(0)$.

THEOREM 2.6 (see [28]). *Let Ω be a $C^{0,1}$ domain. Consider a map $u \to v(u) \in W^{m,r}(\Omega + u)$ defined on a neighborhood of $u = 0$ in $W^{k,\infty}(\Omega, \mathbb{R}^d)$, with $k \geq m \geq 1$ and $1 \leq r < \infty$.*

Let us assume that there exists a linear continuous map $u \to \dot{v}(u)$ defined on $W^{k,\infty}(\Omega, \mathbb{R}^d)$ with values in $W^{m,r}(\Omega)$, such that

$$v(u) \circ (I + u) = v(0) + \dot{v}(u) + \theta(u) \quad \text{in } W^{m,r}(\Omega)$$

for all $u \in W^{k,\infty}(\Omega, \mathbb{R}^d)$ small enough, where

$$\frac{\theta(u)}{\|u\|_{k,\infty}} \to 0 \quad \text{on } W^{m,r}(\Omega) \quad \text{as } \|u\|_{k,\infty} \to 0.$$

Furthermore, assume that for each $u \in W^{k,\infty}(\Omega, \mathbb{R}^d)$ small enough,

$$v(u) = 0 \quad \text{on} \quad \partial(\Omega + u).$$

Then, for each $\omega \subset\subset \Omega$, the function $u \to v_\omega(u) = v(u)|_\omega$, defined on a neighborhood of $u = 0$ in $W^{k,\infty}(\Omega, \mathbb{R}^d)$ with values in $W^{m-1,r}(\omega)$, is differentiable at $u = 0$.

Moreover, the map $u \to v(u)$ has a local derivative at $u = 0$ (see Definition 2.1) and the local derivative at $u = 0$, in the direction u, denoted by $v'(u)$, verifies $v'(u) \in W^{m-1,r}(\Omega)$ and

$$v'(u) = -(u \cdot n) \frac{\partial v(0)}{\partial n} \quad \text{on} \quad \partial\Omega,$$

where n is the unit outward normal vector to Ω. □

In what follows we will use the notation

$$\mathcal{W} = \{u \in W^{k,\infty}(\Omega, \mathbb{R}^d) : \|u\|_{k,\infty} < c_\Omega\},$$

where $k \geq 1$ and $c_\Omega < 1/2$ is small enough such that all the previous results hold.

LEMMA 2.7 (see [4, Lemma 9]). *Let $u \in \mathcal{W}$. If $f \in H_0^1(\Omega + u)$, there exists a unique $g \in H_0^1(\Omega)$ such that $f \circ (I + u) = g$. Moreover,*

$$\left(\frac{\partial f}{\partial z_i}\right) \circ (I + u) = \sum_j M_{ij}(u) \frac{\partial g}{\partial x_j} = D_i(u) g, \tag{2.8}$$

where the matrix $M(u)$ is defined as

$$M(u) = [M_{ij}(u)] =^t \left[\frac{\partial}{\partial x_j}(I + u)_i\right]^{-1},$$

and

$$z_i = x_i + u_i(x) \quad \forall\, x \in \Omega. \quad □$$

3. Regularity of the eigenvalues and eigenfunctions.

3.1. Some results of spectral theory. To prove the existence and regularity of the eigenvalues and eigenfunctions of the plate system with respect to the perturbation parameter u, we will use the Lyapunov–Schmidt method (see [30], [7, p. 30]).

LEMMA 3.1 (see [7, Lemma 4.1, p. 31]). *Suppose that X and Z are Hilbert spaces and $A : X \longrightarrow Z$ is a continuous linear operator. Let $U : X \longrightarrow N(A)$, $E : Z \longrightarrow R(A)$ be the orthogonal projections from X and Z on the kernel and range of A, respectively.*

Then, there exists a bounded linear operator $Q : R(A) \longrightarrow N(A)^{\perp}$, called the right inverse of A, such that

$$AQ = I : R(A) \longrightarrow R(A), \qquad QA = I - U : Z \longrightarrow N(A)^{\perp}.$$

Let Λ be a closed subset of a Banach space, such that $Int\Lambda \neq \emptyset$. If $N : \Lambda \times X \longrightarrow Z$ is a continuous operator, then the problem

$$Ax - N(x, \lambda) = 0 \tag{3.1}$$

is equivalent to the equations

$$z - QEN(y + z, \lambda) = 0, \tag{3.2}$$

$$(I - E)N(y + z, \lambda) = 0, \tag{3.3}$$

where $x = y + z$, $y \in N(A)$, and $z \in N(A)^{\perp}$. □

Assume that the operator N verifies that

$$N(0, 0) = 0, \qquad \frac{\partial N}{\partial x}(0, 0) = 0,$$

and consider (3.2) for (x, λ) in a neighborhood of $(0, 0)$ in $X \times \Lambda$. Applying the implicit function theorem to (3.2), we deduce the existence of a neighborhood $V \subset N(A) \times \Lambda$ of $(0, 0)$ and a function $z^* : V \longrightarrow N(A)^{\perp}$ with the same regularity of N providing the solution of (3.1). Therefore, if $\{y_1, \ldots , y_h\}$ is an orthonormal basis of $N(A)$, the solution $x(\lambda)$ of (3.1) satisfies

$$x(\lambda) = \sum_{i=1}^{h} c_i(\lambda) y_i + z^* \left(\sum_{i=1}^{h} c_i(\lambda) y_i, \lambda \right) = 0 \tag{3.4}$$

for suitable coefficients $c_1, \ldots , c_h$. Then, $(x, \lambda) \in V$ satisfy (3.1) iff

$$(I - E)\, N \left(\sum_{i=1}^{h} c_i(\lambda) y_i + z^* \left(\sum_{i=1}^{h} c_i(\lambda) y_i, \lambda \right), \lambda \right) = 0, \tag{3.5}$$

which is a finite dimensional system of equations on the constants $c_1, \ldots , c_h$.

Now we have the following result, which is a slight variation of a theorem due to J. H. Albert [2].

THEOREM 3.2. *Let E be a Hilbert space with inner product $\langle \cdot, \cdot \rangle$, and let Λ be a Banach space. Let $P : D(P) \subset E \to E$ be a self-adjoint operator densely defined* *in E. Assume that λ is an eigenvalue of multiplicity h of P, and let $\phi_1, \ldots, \phi_h$ be the orthonormal eigenfunctions associated to λ. Moreover, assume that there exists a bounded linear operator $Q : E \rightarrow E$, such that $Q\Pi_N = 0$ and $Q(P+\lambda) = I - \Pi_N$, Π_N being the orthogonal projection in $N = \operatorname{Ker}(P+\lambda)$.*

Let $R(u)$ be an analytic self-adjoint map in $B(E,F)$ for every u in a neighborhood of $u = 0$ in Λ, such that $R(0) = 0$ and $P(u) = P + R(u)$.

Then there exist h analytic functions defined in a neighborhood of $u = 0$ in Λ with values in $\mathbb{R}$, $u \rightarrow \lambda_i(u)$, and h analytic functions $u \rightarrow \phi_i(u)$, with values in E, $i = 1, \ldots, h$, defined in a neighborhood of $u = 0$ in Λ, such that the following hold.

1. $\lambda_j(0) = \lambda, \qquad j = 1, \ldots, h.$
2. *For all u small enough, $(\lambda_j(u), \phi_j(u))$ is a solution of the eigenvalue problem $P(u)\phi_j(u) = \lambda_j(u)\phi_j(u)$.*
3. *For all u small enough the set $\{\phi_1(u), \ldots, \phi_h(u)\}$ is orthonormal in E.*
4. *For each interval $I \subset \mathbb{R}$ such that $\overline{I}$ contains only the eigenvalue λ of (P), there exists a neighborhood U of $u = 0$ such that there are exactly h eigenvalues (counting the multiplicity) $\lambda_1(u), \ldots, \lambda_h(u)$ of (P_u) contained on I.* □

Remark 3.1. To prove Theorem 3.2, we prove first that we can find functions $u \rightarrow \lambda(u) \in \mathbb{R}$ and $u \longrightarrow \phi(u)$ such that $\phi(u)$ is an eigenfunction of (P_u) associated to the eigenvalue $\lambda(u)$. To find the other $h-1$ branches of eigenvalues and eigenfunctions, we apply in an iterative form the method described in the following proposition. □

Proposition 3.3. *Under the hypotheses of Theorem* 3.2, *if λ is an eigenvalue of multiplicity h of P and $\phi_1, \ldots, \phi_h$ are orthonormal eigenfunctions associated to λ, there exists at least a function $u \longrightarrow (\lambda(u), \phi(u)) \in \mathbb{R} \times E$ which is analytic in a neighborhood of $u = 0$ in Λ such that*

1. *$\lambda(0) = \lambda$, and*
2. *$\phi(u)$ is an eigenfunction of $P(u)$, associated to the eigenvalue $\lambda(u)$.* □

Proof of Proposition 3.3. Let λ be an eigenvalue of multiplicity h of P, and let $\phi_1, \ldots, \phi_h$ be the orthonormal eigenfunctions associated to λ.

Suppose that the maps $u \rightarrow \lambda(u)$, $u \rightarrow \phi(u)$, such that

$$(P(u) + \lambda(u))\phi(u) = 0, \tag{3.6}$$

do exist. Then

$$\begin{aligned} (P+\lambda)\phi(u) &= (P + \lambda - P(u) - \lambda(u) + P(u) + \lambda(u))\phi(u) \\ &= (-R(u) + \lambda - \lambda(u))\phi(u) \\ &= -(R(u) + \lambda(u) - \lambda)\phi(u). \end{aligned} \tag{3.7}$$

Since $Q(P+\lambda) = I - \Pi_N$, we obtain that

$$\phi(u) = -[Q(R(u) + \lambda(u) - \lambda)]\phi(u) + \psi(u), \tag{3.8}$$

where $\psi(u) \in N = \operatorname{Ker}(P+\lambda)$.

Thus

$$\psi(u) = [I + Q(R(u) + \lambda(u) - \lambda)]\phi(u), \tag{3.9}$$

and therefore

$$\phi(u) = [I + Q(R(u) + \lambda(u) - \lambda)]^{-1}\psi(u). \tag{3.10}$$

Moreover, the map $[I + Q\,(R\,(u) + \lambda\,(u) - \lambda)]$ has an inverse in a neighborhood of $u = 0$ in Λ.

Thus, if we know the functions $u \to \lambda\,(u)$ and $u \to \psi\,(u)$, we can obtain the map $u \to \phi\,(u)$.

Let $\phi_1, \ldots, \phi_h$ be an orthonormal basis of $N = \operatorname{Ker}(P + \lambda)$. We must find constants $c_j(u)$ such that

$$\psi\,(u) = \sum_{j=1}^{h} c_j\,(u)\,\phi_j. \tag{3.11}$$

We can see that

$$[R\,(u) + \lambda\,(u) - \lambda]\,\phi\,(u) \in N^{\perp}, \tag{3.12}$$

because, according to (3.6), we have that $[R\,(u) + \lambda\,(u) - \lambda]\,\phi\,(u) \in R\,(P + \lambda)$.

Thus

$$\begin{aligned} 0 &= \langle [R\,(u) + \lambda\,(u) - \lambda]\,\phi\,(u)\,, \phi_j \rangle \\ &= \langle [R\,(u) + \lambda\,(u) - \lambda]\,\{I + Q\,[R\,(u) + \lambda\,(u) - \lambda]^{-1}\}\psi\,(u)\,, \phi_j \rangle \\ &= \sum_{i=1}^{h} c_j\,(u)\,\langle [R\,(u) + \lambda\,(u) - \lambda]\,\{I + Q\,[R\,(u) + \lambda\,(u) - \lambda]^{-1}\}\phi_i, \phi_j \rangle, \end{aligned} \tag{3.13}$$

which is a linear system of equations on the unknowns $c_j(u)$.

This system has a nontrivial solution iff

$$\det(\langle [R\,(u) + \lambda\,(u) - \lambda]\,\{I + Q\,[R\,(u) + \lambda\,(u) - \lambda]^{-1}\}\phi_i, \phi_j \rangle) = 0. \tag{3.14}$$

Now we show the existence of the constants $c_1\,(u)\,, \ldots, c_h\,(u)$, not all of them being zero simultaneously.

We replace $\lambda(u) - \lambda$ by α, and we define

$$f_{ij}\,(\alpha, u) = \langle [R\,(u) + \alpha]\{I + Q[R\,(u) + \alpha]^{-1}\}\phi_i, \phi_j \rangle \tag{3.15}$$

and

$$F\,(\alpha, u) = \det\,(f_{ij}\,(\alpha, u))\,. \tag{3.16}$$

For u small enough, the map $u \longrightarrow [I + Q\,[R(u) + \alpha])]^{-1}$ is well defined. Indeed, for $\alpha = 0$ and $u = 0$ we have that $[I + QR(0)] = I$, and the map is analytic in a neighborhood of $u = 0$ in Λ. On the other hand, as we mentioned above, if $F(\alpha, u) = 0$, system (3.13) has a nontrivial solution $c_1(u), \ldots, c_h(u)$, and then

$$\lambda(u) = \lambda + \alpha \tag{3.17}$$

is an eigenvalue of $P(u)$.

Moreover, from (3.8) and (3.11) we deduce that

$$\phi(u) = \sum_{j=1}^{h} c_j(u)\,[I + Q\,(R(u) + \lambda(u) - \lambda)]^{-1}\,(v_j, p_j) \tag{3.18}$$

is an eigenfunction of $P(u)$ associated to the eigenvalue $\lambda(u)$.

According to our previous discussion, for these values of $\alpha(u)$ and setting $\lambda(u) = \lambda + \alpha(u)$, system (3.13) admits a solution $c_1(u), \dots, c_h(u)$, not all the components being zero simultaneously. We have that

$$\begin{aligned} f_{ij}(\alpha, 0) &= \langle [R(0)+\alpha]\{I + Q[R(0)+\alpha]\}^{-1}\phi_i, \phi_j\rangle \\ &= \langle \alpha \{I + \alpha Q\}^{-1}\phi_i, \phi_j\rangle \\ &= \alpha\langle \{I + \alpha Q\}^{-1}\phi_i, \phi_j\rangle \\ &= \alpha\delta_{ij}, \end{aligned} \tag{3.19}$$

because $[I + \alpha Q]\phi_i = \phi_i$.

Therefore, we have that $F(\alpha, 0) = \det(\alpha I) = \alpha^h$.

Applying the Weierstrass preparation theorem, we deduce that

$$F(\alpha, u) = \left(\alpha^h + a_1(u)\alpha^{h-1} + \cdots + a_h(u)\right) E(\alpha, u)$$

with $E(\alpha, u) \neq 0$ in a neighborhood of $(0, 0)$. Then for (α, u) small enough we have that $E(\alpha, u) \neq 0$, and functions $a_j(u)$ are analytic in a neighborhood of $u = 0$.

Then, $F(\alpha, u) = 0$ iff

$$\alpha^h + a_1(u)\alpha^{h-1} + \cdots + a_h(u) = 0. \tag{3.20}$$

Let $\alpha_j(u), j = 1, \dots, h$ be the complex roots of (3.20). Then there exist constants $c_1(u), \dots, c_h(u)$, not all vanishing simultaneously, which are the solution of system (3.13).

Thus, from (3.18) we obtain that

$$\phi(u) = \sum_{j=1}^{h} c_j(u)\left[I + Q\left(R(u) + (\lambda(u) - \lambda)\right)\right]^{-1}\phi_j$$

and $\lambda(u) = \lambda + \alpha_1(u)$ constitute an eigenpair.

Notice that if $c_j(u)$ is complex, it is enough to consider the real part $\mathcal{R}c_j(u)$ to get a real eigenfunction. Since the operator $P(u)$ is self-adjoint, we have that $\alpha_j(u)$ is real, which completes the proof of Proposition 3.3. □

Remark 3.2. Proposition 3.3 provides the existence of one branch of eigenpairs associated to the root $\alpha(u)$ of (3.20). We do not use the eigenpairs associated to the other roots α_j by now since, so far, we do not know whether they coincide or not with the eigenpair associated to $\alpha_1(u)$. □

Now we prove Theorem 3.2.

Proof of Theorem 3.2. Using induction on h, we prove the existence of the h analytic functions $u \to (\lambda_i(u), \phi_i(u))$, such that

$$(P(u) + \lambda_i(u))\phi_i(u) = 0. \tag{3.21}$$

From Proposition 3.3, there exists an analytic function $u \to (\lambda_1(u), \phi_1(u))$ defined in a neighborhood of $u = 0$ in Λ with values in $\mathbb{R} \times E$, which verifies (3.21).

Therefore, Theorem 3.2 holds for $h = 1$. We must prove it for $h \geq 2$.

Let $\Pi_1(u) : E \longrightarrow E$ be the orthogonal projection on the eigenspace generated by $\phi_1(u)$. Then we define the map

$$B(u) = P(u) - \Pi_1(u). \tag{3.22}$$

Then

$$B(0)\phi_j = \left(P(0) - \Pi_1(0)\right)\phi_j = \lambda\phi_j - \delta_{1j}\phi_j; \tag{3.23}$$

that is,

$$B(0)\phi_j = \lambda\phi_j, \quad j = 2, \dots, h,$$

and

$$B(0)\phi_1 = (\lambda - 1)\phi_1.$$

Then, λ is an eigenvalue of multiplicity $h-1$ of the operator $B = B(0)$, with eigenfunctions $v_2, \dots, v_h$.

Note that other linearly independent eigenfunctions of B associated to λ do not exist. Indeed, if ϕ is another eigenfunction of B associated to the eigenvalue λ such that $\langle \phi, \phi_j \rangle = 0$, $j = 2, \dots, h$, then $\langle \phi, \phi_1 \rangle = 0$ (since ϕ_1 is an eigenfunction associated to the eigenvalue $\lambda - 1$) and $B\phi = \lambda\phi$. Then

$$P\phi = B\phi + \Pi_1\phi = B\phi + \langle \phi, \phi_1 \rangle v_1 = \lambda\phi;$$

that is, ϕ is an eigenfunction of P associated to λ, and thus λ is an eigenvalue of multiplicity $h+1$, which is impossible because the multiplicity of λ is h.

We can see that $B(u)$ satisfies the hypotheses of Proposition 3.3. This allows us to apply Proposition 3.3 in an iterative form and to obtain $h-1$ analytic functions in a neighborhood of $u = 0$ in Λ, $u \longrightarrow \lambda_i(u)$, and $u \longrightarrow \phi_i(u)$, with $i = 1, \dots, h$ such that

$$B(u)\phi_i(u) = \lambda_i(u)\phi_i(u).$$

Moreover, the functions $\phi_2(u), \dots, \phi_h(u)$ form an orthonormal set in E.

This shows us the existence of the h branches of eigenpairs.

Now we prove the last part of the theorem.

Since the eigenvalues $u \to \lambda_i(u)$ are analytic in a neighborhood of $u = 0$, there exist constants c_i such that

$$\left|\lambda_i(u) - \lambda_i(v)\right| \le c_i \left\|u - v\right\|.$$

Let $\lambda_1 \le \lambda_2 \le \cdots \le \lambda_n \dots$ be the eigenvalues of the P, and assume that

$$\cdots \le \lambda_{n-1} < \lambda = \lambda_n = \cdots = \lambda_{n+h-1} < \lambda_{n+h} \le \cdots.$$

Let $I \subset \mathbb{R}$ be an interval such that λ is the unique eigenvalue contained in I.

Then there exists $\delta > 0$ such that $I \subset (\lambda_{n-1} + \delta, \lambda_{n+h} - \delta)$. Let $u \in B(0, \delta/c)$, with $c = \max\{c_i : i = 1, \dots, n+h\}$. Then

$$|\lambda_{n-1}(u) - \lambda_{n-1}| \le c_{n-1}\|u\| < c_{n-1}\frac{\delta}{c} \le \delta,$$

and

$$|\lambda_{n+h}(u) - \lambda_{n+h}| \le c_{n+h}\|u\| < c_{n+h}\frac{\delta}{c} \le \delta.$$

Therefore, $\lambda_{n-1}(u) \notin \overline{I}$ and $\lambda_{n+h}(u) \notin \overline{I}$; that is, $P(u)$ has at most h eigenvalues contained in $\overline{I}$ counting multiplicity. This completes the proof of Theorem 3.2. $\square$

3.2. Equivalent formulation for the plate system. Now, for each $u \in W^{5,\infty}(\Omega, \mathbb{R}^d)$, we consider the eigenvalue problem for the plate system

$$\left\{ \begin{array}{rll} \triangle^2 y & = \lambda y & \text{in } \Omega + u, \\ y & = 0 & \text{on } \partial\left(\Omega + u\right), \\ \dfrac{\partial y}{\partial n} & = 0 & \text{on } \partial\left(\Omega + u\right). \end{array} \right. \tag{3.24}$$

Let $\{\lambda\left(u\right), y\left(u\right)\}$ be a solution of (3.24), and define the function $Y\left(u\right) = y\left(u\right) \circ \left(I + u\right).$

Thus, our problem is to find $\lambda\left(u\right) \in \mathbb{R}$ and $Y\left(u\right)$ such that

$$\left\{ \begin{array}{rll} D_j^2\left(u\right)\left(Jac\left(I+u\right) D_i^2\left(u\right) Y\left(u\right)\right) & = \lambda\left(u\right) Y\left(u\right) Jac\left(I+u\right) & \text{in } \Omega, \\ Y\left(u\right) & \in H_0^2\left(\Omega\right), & \end{array} \right. \tag{3.25}$$

where

$$D_i\left(u\right) g = \sum_j M_{ij}\left(u\right) \partial_j f,$$

with $M_{ij}\left(u\right)$ defined as in (2.8) and $g = f \circ \left(I + u\right).$

3.3. Regularity of the eigenvalues and eigenfunctions. Now, we will see the existence of the branches of eigenvalues $u \rightarrow \lambda(u)$ and eigenfunctions $u \rightarrow y(u)$ of the plate system.

LEMMA 3.4. *Let $\Omega \subset \mathbb{R}^d$ be an open bounded set of class C^4.*

Then the map

$$P : W^{5,\infty}(\Omega, \mathbb{R}^d) \longrightarrow \mathcal{L}\left(H_0^2\left(\Omega\right); H^{-2}\left(\Omega\right)\right),$$

such that

$$P(u)\phi = \frac{1}{Jac\left(I+u\right)} D_j^2\left(u\right)\left(Jac\left(I+u\right) D_i^2\left(u\right)\phi\right) \tag{3.26}$$

is analytic in a neighborhood of $u = 0$ in $W^{5,\infty}(\Omega, \mathbb{R}^d)$. □

Proof. We can see that $Jac(I + u)$ is a polynomial on the first partial derivatives of u. Then the map $u \longrightarrow Jac(I + u)$ is analytic in a neighborhood of $u = 0$ in $W^{5,\infty}(\Omega, \mathbb{R}^d)$. On the other hand,

$$M_{ij}(u) = \frac{1}{Jac(I+u)}(\delta_{ij} + a_{ij}),$$

where $a_{ij}(u)$ is the minor of the matrix $M^{-1}(u)$ associated to its ijth element, which is also a polynomial of the first partial derivatives of u. Moreover, for u small enough $Jac(I + u) > 0$. Therefore, $u \longrightarrow M(u)$ is analytic in a neighborhood of $u = 0$ in $W^{5,\infty}(\Omega, \mathbb{R}^d)$ as well.

Since $D(u)\varphi = M(u)\nabla\varphi$, from the analyticity of the functions $u \longrightarrow Jac(I + u)$ and $u \longrightarrow M(u)$ we obtain that the map $P(u)$ is analytic in a neighborhood of $u = 0$ on $W^{5,\infty}(\mathbb{R}^d, \mathbb{R}^d)$ with values in $\mathcal{L}\left(H_0^2\left(\Omega\right); H^{-2}\left(\Omega\right)\right)$, and the proof is complete. □

Now, we can apply Theorem 3.2 to the operator $P(u)$ to obtain the existence of the h analytic branches $u \to (\lambda_i(u), y_i(u))$, with $i = 1, \ldots, h$.

From Lemma 3.1 we have that the map $A = P - \lambda I$ has a right inverse operator Q which satisfies the hypotheses of Theorem 3.2. Furthermore, we have that if $u \in W^{5,\infty}(\Omega, \mathbb{R}^d)$, the new domain $\Omega + u$ has a boundary of class C^4, and then, the eigenfunctions satisfy that $y_i \in H^4(\Omega) \cap H_0^2(\Omega)$. Thus we have the following result.

Theorem 3.5. *Let $\Omega \subset \mathbb{R}^d$ be an open bounded domain of class C^4. Let λ be an eigenvalue of multiplicity h of the plate system* (1.1) *for $u = 0$ with associated eigenfunctions $y_1, \ldots, y_h$.*

Then, there exist h analytic functions with values in $\mathbb{R}$, $u \to \lambda_i(u)$, and h analytic functions $u \to y_i(u)$, with values in $H^4(\Omega + u) \cap H_0^2(\Omega + u)$, $i = 1, \ldots, h$, defined in a neighborhood of $u = 0$ in $W^{5,\infty}(\Omega, \mathbb{R}^d)$, such that the following hold.

1. $\lambda_j(0) = \lambda, \qquad j = 1, \ldots, h.$
2. *For all u small enough, $(\lambda_j(u), y_j(u))$ is a solution of the plate system defined in the new domain $\Omega + u$.*
3. *For all u small enough, the set $\{y(u), \ldots, y(u)\}$ is orthonormal in $L^2(\Omega{+}u)$.*
4. *For each interval $I \subset \mathbb{R}$ such that $\overline{I}$ contains only the eigenvalue λ of* (1.1), *there exists a neighborhood U of $u = 0$ such that there are exactly h eigenvalues (counting the multiplicity) $\lambda_1(u), \ldots, \lambda_h(u)$ of (P_u) contained on I.* □

4. Local variations of the eigenvalues and the eigenfunctions. Let $\Omega \subset \mathbb{R}^d$ be a bounded open set with boundary of class C^4. Let λ be an eigenvalue of (1.1) of multiplicity h, and let y_i, $i = 1, \ldots, h$ be the associated eigenfunctions, normalized in $L^2(\Omega)$.

Let $y_i(u) \in H^4(\Omega + u) \cap H_0^2(\Omega + u)$, $i = 1, \ldots, h$, be the eigenfunctions of (3.24) associated to the eigenvalue $\lambda_i(u)$, where $\lambda = \lambda_i(0)$, $y_i(0) = y_i$, $i = 1, \ldots, h$.

According to the results of the previous section, the branches of the eigenvalues $u \longrightarrow \lambda_i(u) \in \mathbb{R}$ and the eigenfunctions $u \longrightarrow y_i(u) \in H^4(\Omega + u) \cap H_0^2(\Omega + u)$ are analytic with respect to the perturbation parameter u in a neighborhood of $u = 0$ in $W^{5,\infty}(\Omega, \mathbb{R}^d)$. The first local variation of the branches solves the system

$$\left\{ \begin{array}{lll} \triangle^2 y_i'(u) & = \lambda_i'(u) y_i + \lambda y_i'(u) & \text{in } \Omega, \\ y_i'(u) & = 0 & \text{on } \partial\Omega, \\ \dfrac{\partial y_i'(u)}{\partial n} & = -(u \cdot n) \dfrac{\partial^2 y}{\partial n^2} & \text{on } \partial\Omega. \end{array} \right. \tag{4.1}$$

The following result provides an identity for the local derivative of the eigenvalues.

Lemma 4.1. *Under the above conditions, the first local derivatives of the eigenvalues verify*

$$\delta_{ij} \lambda_i'(u) = -\int_{\partial\Omega} (u \cdot n) \frac{\partial y_i}{\partial n} \cdot \frac{\partial^2 y_j}{\partial n^2} \quad \forall i, j = 1, \ldots, h. \qquad \square \tag{4.2}$$

Note that here and in what follows, $\lambda_i'(u)$ denotes the derivative of λ_i at $u = 0$ in the direction u.

Proof. Multiplying (4.1) by $w \in H_0^2(\Omega)$, we obtain that

$$\int_\Omega \triangle y_i'(u) \triangle w = \lambda_i'(u) \int_\Omega y_i w + \lambda \int_\Omega y_i'(u) w. \tag{4.3}$$

Taking $w = y_j$ in (4.3), we have that

$$\int_\Omega \triangle y_i'(u) \triangle y_j = \lambda_i'(u) \int_\Omega y_i y_j + \lambda \int_\Omega y_i'(u) y_j.$$

Since $y_i \in H^4(\Omega), i = 1, \dots, h$ (see [10, Theorem 7.1.2]), integrating by parts, we deduce that

$$\int_\Omega \triangle^2 y_j \, y_i'(u) + \int_{\partial\Omega} \frac{\partial y_i'(u)}{\partial n} \triangle y_j(u) = \lambda_i'(u)\,\delta_{ij} + \lambda \int_\Omega y_i'(u)\, y_j.$$

Therefore,

$$\begin{aligned}\delta_{ij}\lambda_i'(u) &= \int_{\partial\Omega} \frac{\partial y_i'(u)}{\partial n} \triangle y_j \\ &= -\int_{\partial\Omega} (u\cdot n)\, \frac{\partial^2 y_i}{\partial n^2} \triangle y_j = -\int_{\partial\Omega} (u \cdot n)\, \frac{\partial^2 y_i}{\partial n^2} \frac{\partial^2 y_j}{\partial n^2}.\end{aligned} \tag{4.4}$$

The proof is complete. □

5. Proof of Theorem 1.1. In this section, we prove the generic unique continuation property stated in Theorem 1.1.

First, we state a unique continuation result for the evolution plate system, which is a consequence of the classical Holmgrem uniqueness theorem and which is needed in the proof. Being more precise, in the proof of Theorem 1.1 we use this result only for the eigenfunctions of the plate system or, more precisely, for the corresponding separated variables solutions of (5.1). However, we state the result for general solutions of the evolution plate system for the sake of completeness.

Lemma 5.1 (see [18, Lemma 3.6, p. 276]). *Let $\Omega \subset \mathbb{R}^d$ be an open bounded domain with boundary of class C^4. Let $\Gamma_0 \subset \partial\Omega$ be a nonempty open set, and let $T > 0$.*

Then, if y solves

$$\begin{cases} y'' + \triangle^2 y &= 0 \quad \text{in } \Omega \times (0,T), \\ y &= 0 \quad \text{on } \partial\Omega \times (0,T), \\ \dfrac{\partial y}{\partial n} &= 0 \quad \text{on } \partial\Omega \times (0,T), \\ \dfrac{\partial^2 y}{\partial n^2} &= 0 \quad \text{on } \Gamma_0 \times (0,T), \\ \dfrac{\partial \triangle y}{\partial n} &= 0 \quad \text{on } \Gamma_0 \times (0,T), \end{cases} \tag{5.1}$$

then, necessarily, $y \equiv 0$. □

Proof of Theorem 1.1. Let $\Gamma_0 \subseteq \partial\Omega$ be an open nonempty set.

Assume that λ is an eigenvalue of (1.1) of multiplicity h, and let $y_i,\ i = 1, \dots, h$, be the associated eigenfunctions.

We define the set

$$A_0 = W_0 = \left\{u \in W^{5,\infty}(\Omega, \mathbb{R}^d) \,:\, u = 0 \text{ on } \partial\Omega \setminus \Gamma_0\right\},$$

and for each $n \in \mathbb{N}$ we consider the set

$$\begin{aligned}A_n = \{u \in W^{5,\infty}(\Omega, \mathbb{R}^d) \,:\, u = 0 \text{ on } \partial\Omega \setminus \Gamma_0 &\text{ and the unique continuation} \\ &\text{property of Theorem 1.1 holds for the first } n \text{ branches of eigenvalues}\}.\end{aligned}$$

Note that $A_{n+1} \subset A_n$ for all $n \geq 0$. We will prove that A_n is an open subset of W_0 and A_{n+1} is a dense subset of A_n for all $n \geq 0$. Thus, by using Baire's lemma (see Lemmas 2.1 and 2.2), we will prove that $\bigcap_{n\in\mathbb{N}} A_n$ is residual in W_0.

Obviously, this completes the proof since $\bigcap_{n\in\mathbb{N}} A_n$ coincides with the set of admissible perturbations of the domain Ω such that the unique continuation property of Theorem 1.1 holds simultaneously for all the branches of eigenvalues.

To apply Baire's lemma, the following properties of the sets A_n are needed.

(i) $\boldsymbol{A_n}$ is open in $\boldsymbol{W_0}$.

It is clear that A_0 is an open set in W_0. To see that each set A_n is open in $W^{5,\infty}(\Omega, \mathbb{R}^d) \cap W_0$ for $n \geq 1$, we argue by contradiction. Suppose that A_n^c is not closed. Then, there exists a sequence of deformations $\{u_k\}_k \subset A_n^c$ such that u_k converges to $\widetilde{u} \in A_n$ as $k \to \infty$.

Since $\{u_k\}_k \subset A_n^c$, there exist $\{\lambda(u_k), y(u_k)\}_k$ such that

$$\begin{cases} \triangle^2 y(u_k) & = \lambda(u_k)\, y(u_k) & \text{in } \Omega + u_k, \\ y(u_k) & = 0 & \text{on } \partial\Omega + u_k, \\ \dfrac{\partial y(u_k)}{\partial n(\Omega + u_k)} & = 0 & \text{on } \partial\Omega + u_k, \\ \displaystyle\int_{\Omega+u_k} |y(u_k)|^2 & = 1, & \end{cases}$$

and

$$\frac{\partial^2 y(u_k)}{\partial n^2(\Omega + u_k)} = 0 \quad \text{on } \Gamma_0 + u_k,$$

$\lambda(u_k)$ belonging to one of the branches $\lambda_1(u), \dots, \lambda_n(u)$ and $y(u_k)$ being the corresponding eigenfunction.

From Theorem 3.5 we have that the branches $u \to \lambda(u)$, $u \to y(u)$ are analytic functions in a neighborhood of $u = 0$ in $W^{5,\infty}(\Omega, \mathbb{R}^d)$ with values in $\mathbb{R}$ and $H^4(\Omega + u) \cap H_0^2(\Omega + u)$, respectively. Thus the eigenpair $(\lambda(\widetilde{u}), y(\widetilde{u}))$ is a solution of the problem

$$\begin{cases} \triangle^2 y(\widetilde{u}) & = \lambda(\widetilde{u})\, y(\widetilde{u}) & \text{in } \Omega + \widetilde{u}, \\ y(\widetilde{u}) & = 0 & \text{on } \partial\Omega + \widetilde{u}, \\ \dfrac{\partial y(\widetilde{u})}{\partial n(\Omega + \widetilde{u})} & = 0 & \text{on } \partial\Omega + \widetilde{u}, \\ \dfrac{\partial^2 y(\widetilde{u})}{\partial n^2(\Omega + \widetilde{u})} & = 0 & \text{on } \Gamma_0 + \widetilde{u}, \\ \displaystyle\int_{\Omega+\widetilde{u}} |y(\widetilde{u})|^2 & = 1 & \end{cases}$$

for some $\lambda(\widetilde{u})$ belonging to one of the first n branches $\lambda_1(\widetilde{u}), \dots, \lambda_h(\widetilde{u})$. But this is impossible, since $\widetilde{u} \in A_n$. This shows that A_n is an open set.

(ii) $\boldsymbol{A_{n+1}}$ is dense in $\boldsymbol{A_n}$.

Now we will see that A_{n+1} is dense in A_n for all $n \geq 0$; in particular, A_1 is dense in $A_0 = W_0$.

Suppose that A_{n+1} is not dense in A_n. Then, there exists $u \in A_n \setminus A_{n+1}$ and a neighborhood $\mathcal{V}$ of u such that $\mathcal{V} \subset A_n \setminus A_{n+1}$. Without lost of generality, we may assume that $u = 0$.

For any $u \in \mathcal{V} \subset A_n \setminus A_{n+1}$ there exists a nontrivial eigenfunction $y\,(u) \in H_0^2\,(\Omega + u)$ associated to the $(n+1)$th eigenvalue $\lambda\,(u) = \lambda_{n+1}\,(u)$ such that

$$\frac{\partial^2 y\,(u)}{\partial^2 n\,(\Omega + u)} = 0 \text{ on } \Gamma_0 + u. \tag{5.2}$$

On the other hand, from Theorem 2.6, the local variations satisfy

$$\left\{\begin{array}{rcll} \triangle^2 y'\,(u) & = & \lambda'\,(u)\, y + \lambda y'\,(u) & \text{in } \Omega, \\ y'\,(u) & = & 0 & \text{on } \partial\Omega, \\ \dfrac{\partial y'\,(u)}{\partial n} & = & 0 & \text{on } \partial\Omega, \\ \dfrac{\partial^2 y'\,(u)}{\partial n^2} & = & -\,(u \cdot n)\, \dfrac{\partial^3 y}{\partial n^3} & \text{on } \Gamma_0 \end{array}\right. \tag{5.3}$$

for all $u \in \mathcal{V}$, where

$$y\,(0) = y, \quad \lambda\,(0) = \lambda.$$

Since $u = 0$ on $\partial\Omega \setminus \Gamma_0$, we have that

$$\lambda'\,(u) = -\int_{\partial\Omega} (u \cdot n) \left| \frac{\partial^2 y}{\partial n^2} \right|^2 = 0,$$

and therefore

$$\left\{\begin{array}{rcll} \triangle^2 y'\,(u) & = & \lambda y'\,(u) & \text{in } \Omega, \\ y'\,(u) & = & 0 & \text{on } \partial\Omega, \\ \dfrac{\partial y'\,(u)}{\partial n} & = & 0 & \text{on } \partial\Omega, \\ \dfrac{\partial^2 y'\,(u)}{\partial^2 n} & = & -\,(u \cdot n)\, \dfrac{\partial^3 y}{\partial n^3} & \text{on } \Gamma_0. \end{array}\right. \tag{5.4}$$

That is, for each $u \in \mathcal{V}$, $y'\,(u)$ is an eigenfunction of the plate system associated to the eigenvalue λ.

We now distinguish two cases.

Case 1. λ is a simple eigenvalue. Since $y'\,(u)$ is an eigenfunction of the plate system associated to the eigenvalue λ, there exists a constant c_u such that $y'\,(u) = c_u y$, and therefore

$$\frac{\partial^2 y'\,(u)}{\partial n^2} = -\,(u \cdot n)\, \frac{\partial^3 y}{\partial n^3} = c_u \frac{\partial^2 y}{\partial n^2} = 0 \text{ on } \Gamma_0.$$

Thus, we obtain that $\frac{\partial^3 y}{\partial n^3} = 0$ on Γ_0 as well.

From Lemma 5.1 we conclude that $y \equiv 0$ in Ω, which is impossible since y is an eigenfunction of the plate system.

Case 2. λ is a multiple eigenvalue. First, we assume that the eigenvalue λ has multiplicity two. Let y_1, y_2 be the associated eigenfunctions.

We will show that there exists a perturbation u, as small as we want, such that the eigenvalue $\lambda(u)$ is simple or the unique continuation property holds for the branch $u \rightarrow y_1(u)$. Notice that the case where $\lambda(u)$ is simple has been addressed in Case 1 above.

We can proceed in an analogous form considering the branch $u \to y_2(u)$.

We argue by contradiction.

We suppose that the eigenvalue $\lambda(u)$ remains of multiplicity two and the corresponding eigenfunction $y_1(u)$ satisfies (5.2) in a neighborhood $\mathcal{V}$ of $u = 0$. If $\lambda(u)$ is simple, we can proceed as in Case 1. In other words,

$$\frac{\partial^2 y_1(u)}{\partial n^2(\Omega + u)} = 0 \quad \text{on } \Gamma_0 + u \ \forall u \in \mathcal{V}.$$

Then, as in the case of simple eigenvalues, the local variation $y_1'(u)$ is an eigenfunction associated to the eigenvalue λ. Then, there exist constants $c_1(u)$, $c_2(u)$ such that $y_1'(u) = c_1(u)\, y_1 + c_2(u)\, y_2$. Thus, from (5.4) we have that

$$\frac{\partial^2 y_1'(u)}{\partial n^2} = -\left(u \cdot n\right) \frac{\partial^3 y_1}{\partial n^3} \text{ on } \Gamma_0$$

and

$$\frac{\partial^2 y_1'(u)}{\partial n^2} = c_1(u) \frac{\partial^2 y_1}{\partial n^2} + c_2(u) \frac{\partial^2 y_2}{\partial n^2} = c_2(u) \frac{\partial^2 y_2}{\partial n^2} \quad \text{on } \Gamma_0.$$

Hence, for every pair of deformations u_1 and u_2 we have that

$$c_2(u_1) \frac{\partial^2 y_2}{\partial n^2} = -\left(u_1 \cdot n\right) \frac{\partial^3 y_1}{\partial n^3} \text{ on } \Gamma_0,$$

$$c_2(u_2) \frac{\partial^2 y_2}{\partial n^2} = -\left(u_2 \cdot n\right) \frac{\partial^3 y_1}{\partial n^3} \text{ on } \Gamma_0.$$

If $\frac{\partial^3 y_1}{\partial n^3} = 0$ on Γ_0, in view of Lemma 5.1 we immediately deduce that $y_1 \equiv 0$, which is a contradiction. Thus, we can assume that $\frac{\partial^3 y_1}{\partial n^3} \not\equiv 0$ on Γ_0 and consequently that $\frac{\partial^2 y_2}{\partial n^2} \not\equiv 0$ on Γ_0 as well.

Then

$$\frac{(u_1 \cdot n)}{(u_2 \cdot n)} = \frac{c_2(u_1) \dfrac{\partial^2 y_2}{\partial n^2}}{c_2(u_2) \dfrac{\partial^2 y_2}{\partial n^2}} = \frac{c_2(u_1)}{c_2(u_2)} = \text{constant}.$$

That is, necessarily $(u_1 \cdot n) = c\,(u_2 \cdot n)$ for a suitable constant c. This is impossible since the functions u_1 and u_2 may be chosen arbitrarily.

Thus we reach a contradiction.

Assume now that λ is an eigenvalue of multiplicity $h > 2$, and let $y_1, \ldots, y_h$ be the associated eigenfunctions normalized in $L^2(\Omega)$.

We claim that there exists a deformation u, arbitrarily small, such that the eigenvalue $\lambda(u)$ has multiplicity at most $h - 1$ or the unique continuation property holds for the branch $y_1(u)$.

To prove this we argue by contradiction. Suppose that $\lambda(u)$ is an eigenvalue of multiplicity h for all $u \in \mathcal{V}$, with associated eigenfunctions $y_1(u), \ldots, y_h(u)$. Moreover, assume that

$$\frac{\partial^2 y_1(u)}{\partial n\,(\Omega + u)^2} = 0 \quad \text{on } \Gamma_0 + u \tag{5.5}$$

for each $u \in \mathcal{V}$.

Then, from (5.3) we have that $y_1'(u)$ is an eigenfunction of the plate system associated to the eigenvalue λ for each $u \in \mathcal{V}$.

Thus, there exist constants $c_1(u), \ldots, c_h(u)$ such that

$$y_1'(u) = c_1(u)\, y_1 + \cdots + c_h(u)\, y_h. \tag{5.6}$$

Therefore,

$$\begin{aligned} \frac{\partial^2 y_1'(u)}{\partial n^2} &= -(u \cdot n)\frac{\partial^3 y_1}{\partial n^3} \\ &= c_1(u)\frac{\partial^2 y_1}{\partial n^2} + \cdots + c_h(u)\frac{\partial^2 y_h}{\partial n^2} \\ &= c_2(u)\frac{\partial^2 y_2}{\partial n^2} + \cdots + c_h(u)\frac{\partial^2 y_h}{\partial n^2} \quad \text{on } \Gamma_0. \end{aligned} \tag{5.7}$$

On the other hand,

$$\lambda_i'(u) = -\int_{\Gamma_0} (u \cdot n)\left|\frac{\partial^2 y_i}{\partial n^2}\right|^2 \quad \forall i = 1, \ldots, h. \tag{5.8}$$

From (5.5) we have that

$$\frac{\partial^2 y_1}{\partial n^2} = 0 \quad \text{on } \Gamma_0. \tag{5.9}$$

Since the multiplicity does not decrease in a neighborhood U of $u = 0$, we obtain that

$$\lambda_1'(u) = \cdots = \lambda_h'(u) \tag{5.10}$$

for all $u \in U$ such that $u = 0$ on $\partial\Omega \setminus \Gamma_0$. Moreover, according to (5.7)–(5.9), we also have that $\lambda_1'(u) = 0$. Therefore,

$$\lambda_1'(u) = \cdots = \lambda_h'(u) = 0.$$

Thus

$$\frac{\partial^2 y_i}{\partial n^2} = 0 \quad \text{on } \Gamma_0 \;\; \forall i = 1, \ldots, h. \tag{5.11}$$

From (5.7) and (5.11), we deduce that

$$\frac{\partial^3 y_1}{\partial n^3} = 0 \quad \text{on } \Gamma_0. \tag{5.12}$$

From Lemma 5.1 we have that $y_1 \equiv 0$ on Ω, which is impossible because y_1 is an eigenfunction.

Therefore, there exists a deformation $\widetilde{u} \in \mathcal{V}$ such that the eigenvalue $\lambda_1(\widetilde{u})$ has multiplicity at most $h - 1$ or the unique continuation property holds for $y_1(\widetilde{u})$.

If the unique continuation property does not hold in the new domain $\Omega + \widetilde{u}$, we can apply the same argument in an iterative way and obtain a deformation $\widehat{u}$, arbitrarily small, such that the eigenvalue $\lambda(\widehat{u})$ is of multiplicity two or the unique continuation property holds. Since the case where the multiplicity is two was solved before, this completes the proof of the density of A_{n+1} on A_n for all $n \geq 0$.

Applying Baire's lemma (see Lemmas 2.1 and 2.2), we complete the proof of Theorem 1.1. □

Remark 5.1. Note that in the proof of Theorem 1.1 above, we consider only deformations u such that $u = 0$ on $\partial\Omega \setminus \Gamma_0$. Consequently, the deformations u we use do deform the subset Γ_0 of the boundary.

If we consider deformations which do not deform the set Γ_0 (that is, such that $u = 0$ on Γ_0), the argument of the proof does not apply. That is because we cannot guarantee anymore that the local variations $y_i'(u)$ are eigenfunctions of (1.1). □

6. Proof of Theorem 1.2. The proof of Theorem 1.2 is similar to the proof of the generic simplicity of the eigenvalues of the Stokes system (see [25]). We apply Baire's lemma for a suitable sequence of sets $\{A_n\}_{n\geq 0}$.

Let $n = 1, 2, \dots$, and define the sets

$$A_0 = W_0 = \left\{u \in W^{5,\infty}(\Omega, \mathbb{R}^d) \ : \ u = 0 \ \text{ on } \ \partial\Omega \setminus \Gamma_0\right\}, \tag{6.1}$$

and

(6.2)
$$A_n = \big\{u \in W^{5,\infty}(\Omega, \mathbb{R}^d) \colon u = 0 \ \text{ on } \partial\Omega \setminus \Gamma_0, \ \text{ and the first } n \text{ branches}$$
$$\lambda_1(u), \dots, \lambda_n(u) \text{ of eigenvalues of (3.24) are simple}\big\}.$$

As in the proof of Theorem 1.1, we need to check that A_n is an open subset of W_0 and $A_{n+1}$is a dense subset of A_n for all $n \geq 0$. Then, applying Lemma 2.2, we conclude the proof.

(a) $\boldsymbol{A_n}$ is an open set in $\boldsymbol{W^{5,\infty}(\Omega, \mathbb{R}^d) \cap W_0}$.

It is clear that A_0 is an open set. Let $u \in A_n$ for $n \geq 1$, and then

$$\lambda_i(u) \neq \lambda_j(u) \quad \forall i, j = 1, \dots, n+1, i \neq j.$$

Let

$$\delta = \min\{|\lambda_i(u) - \lambda_j(u)| : i, j = 1, \dots, n, i \neq j\}.$$

Let $u' \in U$, where

$$U = \left\{w \in \mathcal{W} : \|u - w\|_{5,\infty} < \frac{\delta}{2c}\right\}$$

and c is the maximum of the Lipschitz constants for the functions $u' \to \lambda_i(u+u')$, $i = 1, \dots, n+1$.

Then

$$\begin{array}{rcl} \delta & \leq & |\lambda_i(u) - \lambda_j(u)| \\ & \leq & |\lambda_i(u+u') - \lambda_i(u)| + |\lambda_i(u+u') - \lambda_j(u+u')| \\ & + & |\lambda_j(u+u') - \lambda_j(u)| \\ & < & \delta + |\lambda_i(u+u') - \lambda_j(u+u')|. \end{array}$$

Thus

$$|\lambda_i(u') - \lambda_j(u')| > 0, \quad i, j = 1, \dots, n+1,$$

which proves that $u + u' \in A_n$, and the set A_n is open.

(b) A_{n+1} is dense in A_n for all $n \geq 0$.

Let $w \in A_n \setminus A_{n+1}$. Without loss of generality we can assume that $u = 0$. Then, either λ_{n+1} remains to be of multiplicity h in a neighborhood of $u = 0$, or there exists $u \neq 0$ arbitrarily small such that the multiplicity is at most $h - 1$. (In the case of $n = 0$, we have that the first eigenvalue has multiplicity $h \geq 2$; that is, $\lambda = \lambda_1(u) = \cdots = \lambda_h(u)$.) Iterating this argument, it can be shown that the $(n+1)$th eigenvalue becomes simple for suitable arbitrarily small perturbations u or it remains of constant multiplicity $h \geq 2$ in a neighborhood of $u = 0$. If the eigenvalue becomes simple, the proof of the density of A_{n+1} is concluded.

Thus, we can assume that λ_{n+1} is of constant multiplicity $h \geq 2$; that is,

$$\lambda = \lambda_{n+1}(u) = \cdots = \lambda_{n+h}(u)$$

for any u in a neighborhood of $u = 0$.

Let $y_1(u), \ldots, y_h(u)$ be the eigenfunctions associated to λ normalized in $L^2(\Omega + u)$.

In view of the generic unique continuation result of Theorem 1.1, we can also assume that the spectral uniqueness holds in Ω.

Then, from (4.2) we have that

$$\lambda'_{n+i}(\Omega; u)\,\delta_{ij} = -\int_{\partial\Omega} (u \cdot n) \frac{\partial^2 y_i}{\partial n^2} \frac{\partial^2 y_j}{\partial n^2}. \tag{6.3}$$

We will prove that there exists a deformation u such that

$$\lambda'_{n+i}(\Omega; u) \neq \lambda'_{n+j}(\Omega; u) \quad \forall\, i \neq j. \tag{6.4}$$

Assuming for the moment that this holds, we deduce that

$$\lambda_{n+i}(\varepsilon u) \neq \lambda_{n+j}(\varepsilon u) \quad \forall i, j = 1, \ldots, n+h+1, i \neq j,$$

for $\varepsilon > 0$ small enough and then $\varepsilon u \in A_{n+1}$.

We proceed by contradiction. Suppose that (6.4) does not hold. Then there exist $i \neq j$, $i, j \in \{1, \ldots, h\}$, such that

$$\lambda'_{n+i}(\Omega; u) = \lambda'_{n+j}(\Omega; u) \tag{6.5}$$

for all u in a neighborhood of $u = 0$.

Thus, from (4.2) we have that

$$\int_{\partial\Omega} (u \cdot n) \left[\frac{\partial^2 y_i}{\partial n^2} \frac{\partial^2 y_j}{\partial n^2} \right] = 0,$$

and from (6.3) and (6.5) we have that

$$\int_{\partial\Omega} (u \cdot n) \left[\left| \frac{\partial^2 y_i}{\partial n^2} \right|^2 - \left| \frac{\partial^2 y_j}{\partial n^2} \right|^2 \right] = 0$$

for all u in a neighborhood of $u = 0$.

Since $u = 0$ on $\partial\Omega \setminus \Gamma_0$, we deduce that

$$\frac{\partial^2 y_i}{\partial n^2} \frac{\partial^2 y_j}{\partial n^2} = 0 \quad \text{on } \Gamma_0 \tag{6.6}$$

and

$$\left|\frac{\partial^2 y_i}{\partial n^2}\right| = \left|\frac{\partial^2 y_j}{\partial n^2}\right| \quad \text{on } \Gamma_0. \tag{6.7}$$

Therefore, we obtain that

$$\frac{\partial^2 y_i}{\partial n^2} = \frac{\partial^2 y_j}{\partial n^2} = 0 \quad \text{on } \Gamma_0. \tag{6.8}$$

Since the spectral uniqueness property holds in the domain Ω, we obtain that

$$y_i = y_j = 0 \quad \text{in } \Omega.$$

But this is impossible because y_i and y_j are eigenfunctions of the plate system.

Applying Baire's lemma (see Lemmas 2.1 and 2.2) to the sets A_n on the space W_0, we complete the proof.

7. Proof of Theorem 1.3. In this section we analyze the evolution dissipative plate equation (1.3). First, we prove the existence and uniqueness of solutions. Then we derive a generic unique continuation result in an infinite time interval. Finally, we complete the proof of Theorem 1.3.

7.1. Existence and uniqueness of solutions for the evolution plate system. First, we analyze the variational formulation of system (1.3).

Recall that $X_1 = \{\varphi \in H^2(\Omega) \cap H_0^1(\Omega) \;:\; \frac{\partial\varphi}{\partial n} = 0 \text{ on } \partial\Omega \setminus \Gamma_0,\}$, $X_2 = L^2(\Omega)$, and $X = X_1 \times X_2$. Then $X = X_1 \times X_2$ is a Hilbert space endowed with the norm of $H^2(\Omega) \times L^2(\Omega)$.

We also introduce the space $X_3 = \{\varphi \in X_1 \;:\; \triangle^2\varphi \in L^2(\Omega)\}$.

Let $B : X_1 \to X_1'$ be the map

$$\langle Bz, v\rangle_{X_1', X_1} = \int_{\Gamma_0} \frac{\partial z}{\partial n}\frac{\partial v}{\partial n}. \tag{7.1}$$

We can see that the linear map B is continuous and accretive.

Let $z \in X_1$. Then, multiplying (1.3) by z, we have that

$$\begin{aligned} 0 &= \left\langle y'' + \triangle^2 y, z\right\rangle_{X_1 \times X_1'} \\ &= \int_\Omega (y''z + \triangle y \triangle z) + \int_{\partial\Omega}\left(z\frac{\partial(\triangle y)}{\partial n} - \triangle y\frac{\partial z}{\partial n}\right) \\ &= \int_\Omega (y''z + \triangle y\triangle z) + \int_{\Gamma_0}\frac{\partial y'}{\partial n}\frac{\partial z}{\partial n}. \end{aligned} \tag{7.2}$$

We also define the map $A : X_1 \to X_1'$ as

$$\langle Az, v\rangle_{X_1', X_1} = \int_\Omega \triangle z \triangle v. \tag{7.3}$$

Then, (7.2) is equivalent to

$$\langle y'' + Ay + By', v\rangle_{X_1', X_1} = 0 \; \forall v \in X_1. \tag{7.4}$$

We define the operator $\mathcal{A} : D(\mathcal{A}) \subset X \to X$ by

$$\mathcal{A}U = (-U_2, AU_1 + BU_2), \quad \text{where } U = (U_1, U_2),$$

and $D(\mathcal{A}) = \{(y, z) \in X_3 \times X_1 \;:\; \triangle y = -\frac{\partial z}{\partial n} \text{ on } \Gamma_0\}$.

Thus, the problem (1.3) is equivalent to solve

$$\begin{aligned} U' + \mathcal{A}U &= 0 \qquad\qquad \text{in } \mathbb{R}^+, \\ U(0) &= (y_0, y_1), \end{aligned}$$

with $U = (y, y')$.

Proposition 7.1. *The operator $\mathcal{A}$ is m-accretive.* □

Proof. Let $U, V \in D(\mathcal{A})$. Then

$$\begin{aligned} \langle \mathcal{A}U - \mathcal{A}V, U - V \rangle_X &= \langle V_2 - U_2, U_1 - V_1 \rangle_{X_1} \\ &\quad + \langle AU_1 - AV_1 + BU_2 - BV_2, U_2 - V_2 \rangle_{X_1', X_1} \\ &= \int_\Omega \triangle (V_2 - U_2) \triangle (U_1 - V_1) + \int_\Omega \triangle (U_1 - V_1) \triangle (U_2 - V_2) \\ &= + \int_{\Gamma_0} \frac{\partial (U_2 - U_1)}{\partial n} \frac{(\partial (U_2 - V_2)}{\partial n} \\ &= \int_{\Gamma_0} \left| \frac{\partial (U_2 - V_2)}{\partial n} \right|^2 \geq 0, \end{aligned}$$

which proves that $\mathcal{A}$ is an accretive operator.

We must prove that $I + \mathcal{A} : D(\mathcal{A}) \to X$ is onto.

Let $W = (W_1, W_2) \in X$. We must show that there exists $U = (U_1, U_2) \in D(\mathcal{A})$, such that

$$(U_1 - U_2, U_2 + AU_1 + BU_2) = (W_1, W_2). \tag{7.5}$$

System (7.5) is equivalent to

$$U_2 = U_1 - W_1, \qquad U_1 + AU_1 + BU_1 = W_2 + BW_1 + W_1. \tag{7.6}$$

To prove the existence of a solution of (7.6), it is enough to show that for every $f \in X_1'$, there exists $U_1 \in X_1$ such that

$$(I + A + B) U_1 = f. \tag{7.7}$$

We first observe that

$$\langle (I + A + B) v, v \rangle_{X_1', X_1} = \int_\Omega v^2 + |\triangle v|^2 + \int_{\Gamma_0} \left| \frac{\partial v}{\partial n} \right|^2 \geq \alpha \|v\|_{X_1}^2 \quad \forall v \in X_1, \tag{7.8}$$

which shows that the bilinear form associated to $(I + A + B)$ is coercive.

On the other hand, the embedding $H^2(\Omega) \hookrightarrow H^1(\Gamma_0)$ is continuous. Thus, the bilinear form associated to $(I + A + B)$ is continuous. Therefore, from Lax–Milgram's lemma we have that there exists a unique $U_1 \in X_1$ such that (7.7) holds.

Therefore, there exists $(U_1, U_2) = (U_1, U_1 - W_1,) \in X_1 \times X_1$ which satisfies (7.5). Moreover, $U_1 \in X_3$ and $(U_1, U_2) \in D(A)$.

This proves that the map $I + \mathcal{A}$ is onto, and thus the operator $\mathcal{A}$ is an m-accretive operator on $X_3 \times X_1$. □

Remark 7.1. Note that since the operator $\mathcal{A}$ is m-accretive in X, in view of [5, Proposition VII.1, p. 101], we deduce that $D(\mathcal{A})$ is dense on X. □

We have the following result on the existence, uniqueness, and regularity of solutions of (1.3).

PROPOSITION 7.2. *Let* $(y_0, y_1) \in X$. *Then there exists a unique solution* y *of* (1.3) *which verifies*

$$y \in C_b([0,+\infty[; X_1) \cap C_b^1([0,+\infty[; X_2). \tag{7.9}$$

Furthermore, if $(y_0, y_1) \in D(\mathcal{A})$, *the solution* y *verifies*

$$(y, y_t) \in C_b([0,+\infty[; D(A)). \tag{7.10}$$

Moreover, when $(y_0, y_1) \in D(\mathcal{A})$, *the energy* $E : \mathbb{R}^+ \to \mathbb{R}^+$, *defined as*

$$E(t) = \frac{1}{2}\int_\Omega \left[|y_t(x,t)|^2 + |\triangle y(x,t)|^2 \right] dx,$$

is a decreasing and differentiable function on $\mathbb{R}^+$. □

Remark 7.2. Here and in what follows we denote by $C_b^k([0,+\infty[; X)$ the space of functions $C^k([0,+\infty[; X) \cap W^{k,\infty}(0,+\infty; X)$. □

Proof of Proposition 7.2. Since the operator $\mathcal{A}$ m-accretive in X, from the Hille–Yosida theorem we have the following.

1. If $(y_0, y_1) \in X = X_1 \times X_2$, there exists a unique solution $U = (y, y_t)$ of

$$\begin{cases} \dfrac{dU}{dt} + \mathcal{A}U &= 0 \qquad \text{on } (0,+\infty), \\ \qquad U(0) &= (y_0, y_1), \end{cases} \tag{7.11}$$

such that (see, for instance, [5, Theorem VII.5, p. 111])

$$U \in C_b([0,+\infty[; X). \tag{7.12}$$

2. If $(y_0, y_1) \in D(\mathcal{A})$, there exists a unique solution $U = (y, y_t)$ of (7.11) such that (see, for instance, [5, Theorem VII.4, p. 105])

$$U \in C_b^1([0,+\infty[; X) \cap C_b([0,+\infty[; D(\mathcal{A})). \tag{7.13}$$

On the other hand,

$$\frac{dE}{dt}(t) = \int_\Omega [y_{tt}(x,t)\, y_t(x,t) + \triangle y_t(x,t)\, \triangle y(x,t)]\, dx. \tag{7.14}$$

Taking $z = y_t$ in (7.2) and integrating by parts, we have that

$$\frac{dE}{dt}(t) = -\int_{\Gamma_0} \left| \frac{\partial y_t}{\partial n} \right|^2 \leq 0, \tag{7.15}$$

which shows us that the energy E is decreasing. □

7.2. A generic unique continuation result. In order to prove Theorem 1.3, we need a nonstandard unique continuation result for the evolution plate system. This is the object of the following proposition.

PROPOSITION 7.3. *Let $\Omega \subset \mathbb{R}^d$ be an open bounded set of class C^4, and let $\Gamma_0 \subset \partial\Omega$ be a nonempty open set such that the spectral uniqueness property holds.*

If $(y_0, y_1) \in D(\mathcal{A})$ and the corresponding solution of (1.3) is such that

$$\frac{\partial y_t}{\partial n} = 0 \text{ on } \Gamma_0 \times (0,\infty), \tag{7.16}$$

then necessarily $y \equiv 0$. □

Proof. We set $v = y_t$. Then v is a weak solution of the system

$$\left\{\begin{array}{lll} v_{tt} + \triangle^2 v & = 0 & \text{in } \Omega \times (0,\infty), \\ v & = 0 & \text{on } \partial\Omega \times (0,\infty), \\ \dfrac{\partial v}{\partial n} & = 0 & \text{on } \partial\Omega \times (0,\infty), \\ v(x,0) & = v_0 = y_1 & \text{in } \Omega, \\ v_t(x,0) & = v_1 = -\triangle^2 y_0 & \text{in } \Omega, \end{array}\right. \tag{7.17}$$

with initial datum $(v_0, v_1) \in H_0^2(\Omega) \times L^2(\Omega)$, and, furthermore, satisfies the condition

$$\triangle v = 0 \quad \text{on } \Gamma_0 \times (0,\infty). \tag{7.18}$$

We will see that $v = 0$. Thus $y(x,t) \equiv y(x)$. Therefore, $y(x) = y_0$ solves

$$\left\{\begin{array}{lll} \triangle^2 y & = 0 & \text{in } \Omega, \\ y & = 0 & \text{on } \partial\Omega, \\ \dfrac{\partial y}{\partial n} & = 0 & \text{on } \partial\Omega \setminus \Gamma_0, \\ \triangle y & = 0 & \text{on } \Gamma_0 \times (0,\infty). \end{array}\right. \tag{7.19}$$

Multiplying (7.19) by y and integrating by parts, we deduce that $\int_\Omega |\triangle y|^2 \, dx = 0$; that is, $y \equiv 0$, since $y = 0$ on $\partial\Omega$.

Thus, the problem is reduced to show that

$$v \equiv 0. \tag{7.20}$$

To prove (7.20), first we observe that $(v, v_t) \in C_b([0,+\infty); H_0^2(\Omega) \times L^2(\Omega))$.

This can be proved easily by analyzing the well posedness of the conservative plate system (7.17).

In what follows we shall use the notation $X = H_0^2(\Omega) \times L^2(\Omega)$.

The solution v of (7.17) may be developed in a Fourier series. Indeed, let $\{\lambda_n\}_n$ be the eigenvalues of the bilaplacian operator with clamped boundary conditions, and let w_n be the associated eigenfunctions normalized in $L^2(\Omega)$:

$$\left\{\begin{array}{lll} \triangle^2 w_n & = \lambda_n w_n & \text{in } \Omega, \\ w_n = \dfrac{\partial w_n}{\partial n} & = 0 & \text{on } \partial\Omega. \end{array}\right. \tag{7.21}$$

We decompose the initial data in Fourier series:

$$v_0(x) = \sum_{n=1}^{\infty} a_n w_n, \qquad v_1(x) = \sum_{n=1}^{\infty} b_n w_n. \tag{7.22}$$

It is easy to check that

$$\|v_0\|^2_{H_0^2(\Omega)} = \sum_{n=1}^{\infty} \lambda_n |a_n|^2, \qquad \|v_1\|^2_{L^2(\Omega)} = \sum_{n=1}^{\infty} |b_n|^2. \tag{7.23}$$

The solution v of (7.17) may be written as

$$v(x,t) = \sum_{n=1}^{\infty} \left[a_n \cos\left(\sqrt{\lambda_n} t\right) + \frac{b_n}{\lambda_n} \sin\left(\sqrt{\lambda_n} t\right) \right] w_n(x). \tag{7.24}$$

Let us define

$$\mu_k = \sqrt{\lambda_k}, \quad \mu_{-k} = -\sqrt{\lambda_k}, \quad w_{-k}(x) = w_k(x). \tag{7.25}$$

If we define the complex coefficients

$$c_k = \frac{1}{2}\left(a_k - i\frac{b_k}{\sqrt{\lambda_k}} \right), \quad c_{-k} = \frac{1}{2}\left(a_k + i\frac{b_k}{\sqrt{\lambda_k}} \right), \tag{7.26}$$

we can write

$$v(x,t) = \sum_{k \in \mathbb{Z}} c_k e^{i\mu_k t} w_k(x). \tag{7.27}$$

Taking into account that $\triangle v = 0$ on $\Gamma_0 \times (0, \infty)$ and applying Bohr's transform to $\triangle v(x,t)$ on Γ_0 (see [3]), we deduce that

$$c_k \triangle w_k = 0 \quad \text{ on } \Gamma_0 \ \forall k \geq 1. \tag{7.28}$$

Therefore, for every $k \in \mathbb{Z}$, we have that $c_k = 0$ or w_k is a solution of the problem

$$\begin{cases} \triangle^2 w_k & = \lambda_k^2 w_k & \text{in } \Omega, \\ w_k & = 0 & \text{on } \partial\Omega, \\ \dfrac{\partial w_k}{\partial n} & = 0 & \text{on } \partial\Omega, \\ \triangle w_k & = 0 & \text{on } \Gamma_0. \end{cases} \tag{7.29}$$

Since, by assumption, the spectral uniqueness holds in Ω, (7.29) implies that $w_k = 0$ in Ω, which is a contradiction. Thus $c_k = 0$ for all $k \in \mathbb{Z}$ and consequently $v \equiv 0$.

This completes the proof. □

7.3. Proof of Theorem 1.3. Now we prove the stabilization result for system (1.3).

Proof. We distinguish two cases.

1. $(y_0, y_1) \in D(\mathcal{A})$.
2. $(y_0, y_1) \in X$.

Step 1. Regular initial data.

Let $\{S_t\}_{t\geq 0}$ be the contraction semigroup associated to (1.3). Then, given $(y_0, y_1) \in D(\mathcal{A})$, we have that $(y, y_t) = S_t\,(y_0, y_1)$ and $\|y, y_t\|_{D(\mathcal{A})} \leq \|y_0, y_1\|_{D(\mathcal{A})}$.

Therefore, the trajectory $\{y\,(t)\,, y_t\,(t)\}_{t\geq 0}$ is bounded in $D(\mathcal{A})$, and, according to the compactness of the imbedding $D(\mathcal{A}) \hookrightarrow X$, $\{y\,(t)\,, y_t\,(t)\}_{t\geq 0}$ is relatively compact in X.

Moreover, the energy E is a strict Lyapunov functional for the semigroup $\{S_t\}_{t\geq 0}$. Indeed, suppose that $(y_0, y_1) \in D\,(\mathcal{A})$ is such that $E\,(t)$ is constant for all $t \geq 0$. Then y solves (1.3) with

$$\frac{\partial y_t}{\partial n} = 0 \quad \text{on } \Gamma_0 \times (0, \infty)\,. \tag{7.30}$$

From Proposition 7.3, we have that $y \equiv 0$. Therefore, $(y_0, y_1) = (0, 0)\,,$ which is the unique equilibrium point for system (1.3).

Thus, from the La Salle invariance principle (see [6, Theorem 9.2.3, p. 122]), we deduce that the $\omega-$limit of the trajectory $\{y, y_t\}_{t\geq 0}$ in X has a unique point $(y_0, y_1) = (0, 0)\,.$

Therefore,

$$\lim_{t\to+\infty} E\,(t) = 0. \tag{7.31}$$

Step 2. Initial data in *X*.

Let $(y_0, y_1) \in X$. Since $D\,(\mathcal{A})$ is dense in X, there exists a sequence of initial data $(y_0^n, y_1^n) \in D\,(\mathcal{A})$ which converges to (y_0, y_1) in X as $n \to \infty$.

Let y be the solution of (1.3) with initial datum (y_0, y_1), and let y^n be the solution of (1.3) with initial datum $(y_0^n, y_1^n)\,.$

Let

$$E_y\,(t) = \int_\Omega \left[|y_t|^2 + |\triangle y|^2\right].$$

Then

$$0 \leq E_y\,(t) \leq 2E_{y_n}\,(t) + 2E_{y-y_n}\,(t) \leq 2E_{y_n}\,(t) + 2E_{y-y_n}\,(0)\,.$$

Since $(y_0^n, y_1^n) \to (y_0, y_1)$ in X as $n \to \infty$, for each $\varepsilon > 0$ there exists $n_0 \in \mathbb{N}$ such that

$$E_{y-y_n}\,(0) < \varepsilon \quad \text{for } n \geq n_0.$$

Moreover, since $(y_0^{n_0}, y_1^{n_0}) \in D\,(\mathcal{A})\,,$ according to the result of the first step, there exists $t_0 \geq 0$ such that

$$E_{y_{n_0}}\,(t) < \varepsilon, \quad t \geq t_0.$$

Therefore, if $t \geq t_0$, we have that

$$E_y\,(t) \leq 2E_{y_{n_0}}\,(t) + 2E_{y-y_{n_0}}\,(t) < 4\varepsilon.$$

Thus

$$\lim_{t\to+\infty} E_y\,(t) = 0.$$

This completes the proof of Theorem 1.3. □

PURSUIT DIFFERENTIAL GAMES WITH STATE CONSTRAINTS[*]

PIERRE CARDALIAGUET[†], MARC QUINCAMPOIX[†], AND PATRICK SAINT-PIERRE[‡]

Abstract. We prove the existence of a value for pursuit games with state constraints. We also prove that this value is lower semicontinuous.

Key words. differential games, pursuit games, state constraints

AMS subject classification. 90D25

PII. S0363012998349327

Introduction. In this paper, we intend to prove that two-player differential games with state constraints have a value.

We investigate a differential game where the first player, called Ursula, playing with u, controls a first system

$$y'(t) = g(y(t), u(t)), \quad u(t) \in U, \tag{0.1}$$

and has to ensure that the state constraint $y(t) \in K_U$ is fulfilled, while the second player, called Victor, playing with v, controls a second system

$$z'(t) = h(z(t), v(t)), \quad v(t) \in V, \tag{0.2}$$

and has to ensure the state constraint $z(t) \in K_V$. The first player aims the state of the full system $(y(\cdot), z(\cdot))$ at avoiding a target as long as possible, while the second player aims the state of the system at reaching this target in minimal time.

This game is known as the pursuit game. Most of the examples and results of the early theory for differential games are concerned with this problem. (For several examples and for methods of explicit resolution, see Isaacs [26], Flynn [20], Breakwell [10], and Bernhard [9].)

As usually in differential game theory, one can define two value functions for the game: the upper one and the lower one. The purpose of this paper is to give some conditions on the system under which the pursuit game has a value, i.e., that the upper value function is equal to the lower value function. We have to face two difficulties: the presence of state constraints and the fact that the value functions can be discontinuous. Let us point out that in most examples studied in Isaacs's book [26], one has to face at least one of the difficulties and often both.

In the early '70s, the question of the existence of a value for pursuit games was the aim of several papers (Varaiya [37], Varaiya and Lin [38], Osipov [29], Friedman [23], [24], [25], Elliot and Kalton [16], [17], Fleming [19], Krasovskii and Subbotin [27]). These works are mainly dealing with unconstrained problems (except for [25]), and the value function is always continuous. Related problems, such as notions of

local asymptotics and local and global stabilizations are studied in the article of Yong [39].

More recently, the techniques of viscosity solutions allow Evans and Sougandinis [18] to simplify the proofs of existence of a value and to characterize this value as a unique solution of some Hamilton–Jacobi equation. Pursuit games without state constraints and for continuous value functions are studied by Soravia in [36]. Alziary de Roquefort [1], [2] uses these methods for a particular continuous pursuit game with state constraints (the lion and man game).

In [33], Rozyev and Subbotin prove the existence of a value for a differential game without continuity and with some state constraints for one player (Victor). However, these results couldn't directly be extended to differential games with separate dynamics and with state constraints on both dynamics. Actually, the basic idea of this method—the so-called "extremal aiming" (which gives the strategy)—is not applicable to situations where there are state constraints for both players. Let us also point out that their approach is devoted to games in a context of strategies slightly different from the one used in this paper. This method is adapted to the kind of strategies we use, the nonanticipative strategies, and to the viscosity solution approach by Bardi, Bottacin, and Falcone in [6]. Our definition of value function is (partially) borrowed from this paper.

When this paper was complete, we received a preprint of Bardi, Koike, and Soravia [7] establishing the existence of a value for pursuit games with state constraints when this value is continuous. Let us point out that the constraints in [7] are more general than ours. However, the method developed in [7] heavily relies on the fact that the value function is continuous. For getting this continuity, the authors assume that one of the value functions vanishes at the boundary of the target and is continuous on this boundary, and that each control system (0.1) and (0.2) is locally controllable.

In this paper, we do not make any controllability condition at the boundary of the target, so that the value of the game is, in general, not continuous. However, following Soner [34], [35] we make some restriction on the dynamics at the boundary of the state constraints. Under this restriction, we prove that the pursuit-evasion game has a value. Let us point out that our result can be used in most examples given in the "classical theory" of differential games.

We follow here the method described in [14] for characterizing the value functions of differential game. Namely, we reduce the study of the pursuit game to a qualitative differential game called an "approach-evasion game." The idea of reducing a quantitative game to a qualitative one comes back to Isaacs [26]. Here we use an idea of Frankowska for control problems, which amounts to characterizing the epigraph of the value function (see [21], for instance, or [14] for further references on the subject). So, in a first step, we study this qualitative game (or game of kind, in Isaacs terminology), we give an "alternative result" for that game, and we characterize the victory domains in a geometric way. Then, in a second step, we interpret the pursuit game as a qualitative pursuit-evasion game in order to prove that there is a value to the problem.

1. Existence of a value for the pursuit game.

In this section, we state the main result of this paper, namely, that pursuit games have a value. For doing so, we first introduce some notations and assumptions.

1.1. Notations and assumptions. The dynamics of the system are

$$\begin{cases} y'(t) = g(y(t), u(t)),\ u(t) \in U,\ y(t) \in K_U, \\ z'(t) = h(z(t), v(t)),\ v(t) \in V,\ z(t) \in K_V, \end{cases}$$

with $y \in \mathbb{R}^l$, $z \in \mathbb{R}^m$. We set $x(t) := (y(t), z(t))$, $N := l + m$, and

$$f(x, u, v) := f(y, z, u, v) := \{g(y, u)\} \times \{h(z, v)\}.$$

The first player (Ursula), controlling u, has to ensure that $y(t) \in K_U$, while the second player (Victor), playing with v, has to ensure that $z(t) \in K_V$.

The sets K_U and K_V have smooth boundaries. Moreover, we assume some transversality conditions of the vector fields at the boundary of the state constraints similar to those of Soner [34], [35]. Namely,

$$(1.1) \quad \begin{cases} \text{(i)} & U \text{ and } V \text{ are compact subsets of some finite} \\ & \text{dimensional spaces,} \\ \text{(ii)} & f : \mathbb{R}^N \times U \times V \to \mathbb{R}^N \text{ is continuous and} \\ & \text{Lipschitz continuous (with Lipschitz constant } \ell) \\ & \text{with respect to } x, \\ \text{(iii)} & \bigcup_u f(x, u, v) \text{ and } \bigcup_v f(x, u, v) \text{ are convex for any } x, \\ \text{(iv)} & K_U = \{y \in \mathbb{R}^l,\ \phi_U(y) \le 0\} \text{ with } \phi_U \in \mathcal{C}^2(\mathbb{R}^l; \mathbb{R}), \\ & \nabla\phi_U(y) \ne 0 \text{ if } \phi_U(y) = 0, \\ \text{(v)} & K_V = \{z \in \mathbb{R}^m,\ \phi_V(z) \le 0\} \text{ with } \phi_V \in \mathcal{C}^2(\mathbb{R}^m; \mathbb{R}), \\ & \nabla\phi_V(z) \ne 0 \text{ if } \phi_V(z) = 0, \\ \text{(vi)} & \forall y \in \partial K_U,\ \exists u \in U \text{ with } \langle \nabla\phi_U(y), g(y, u)\rangle \ < \ 0, \\ \text{(vii)} & \forall z \in \partial K_V,\ \exists v \in V \text{ with } \langle \nabla\phi_V(z), h(z, v)\rangle \ < \ 0. \end{cases}$$

For any time-measurable controls $u(\cdot)$ and $v(\cdot)$, we denote by $y[y_0, u(\cdot)]$, $z[z_0, v(\cdot)]$, and $x[x_0, u(\cdot), v(\cdot)]$ the solutions (in the Caratheodory sense) to (0.1), (0.2), and to

$$(1.2) \quad x'(t) = f(x(t), u(t), v(t)),$$

starting, respectively, from y_0, z_0, and $x_0 := (y_0, z_0)$.

The sets of time-measurable controls $u(\cdot) : \mathbb{R}^+ \to U$ and $v(\cdot) : \mathbb{R}^+ \to V$ are denoted, respectively, by $\mathcal{U}$ and $\mathcal{V}$, while the sets of admissible controls are denoted by $\mathcal{U}(y_0)$ and $\mathcal{V}(z_0)$:

$$\begin{cases} \mathcal{U}(y_0) := \{u(\cdot) \in \mathcal{U} \mid y[y_0, u(\cdot)](t) \in K_U\ \forall t \ge 0\}, \\ \mathcal{V}(z_0) := \{v(\cdot) \in \mathcal{V} \mid z[z_0, v(\cdot)](t) \in K_V\ \forall t \ge 0\}. \end{cases}$$

Under condition (1.1), it is well known (see [4]) that the sets $\mathcal{U}(y_0)$ and $\mathcal{V}(z_0)$ are not empty for any $y_0 \in K_U$ and $z_0 \in K_V$. Moreover, according to Arisawa and Lions [3] (see also [28]), the sets $\mathcal{U}(y_0)$ and $\mathcal{V}(z_0)$ are Lipschitz continuous with respect to y_0 and z_0. Namely, (for instance, for y), we have the following lemma.

LEMMA 1.1. *Under assumption* (1.1)*, for any positive constants Q and T, there is some positive $\lambda = \lambda(Q, T, \ell)$ such that, for any y_0, y_1 belonging to K_U, with $\|y_0\| \le Q$ and $\|y_1\| \le Q$, and for any admissible control $u_0(\cdot) \in \mathcal{U}(y_0)$, there is some admissible control $u_1(\cdot) \in \mathcal{U}(y_1)$ such that*

$$\forall t \in [0, T],\ \|y[y_0, u_0(\cdot)](t) - y[y_1, u_1(\cdot)](t)\| \le \|y_0 - y_1\| e^{\lambda t}\ .$$

Remarks on assumptions (1.1).

1. The regularity assumptions on the domains K_U and K_V can also be weakened by using an extension of Lemma 1.1 recently obtained by Frankowska and Rampazzo in [22] for nonsmooth domains. The transversality condition has to be extended in a suitable way. The results of the present paper also hold true (with the exactly the same proof) under the Frankowska–Rampazzo assumption provided that the sets K_U and K_V are sleek in the sense of [4].
2. Following also [22], the convexity assumption (iii) can be avoided. We have preferred not to do so for simplicity. However, if one omits this assumption, one has to modify the transversality assumption in a suitable way as well as the definition of $\vartheta_C^\flat$ (see [22]).

The players play *nonanticipative strategies.* A map $\alpha : \mathcal{V}(z_0) \to \mathcal{U}(y_0)$ is a nonanticipative strategy (for the first player Ursula and for the point $x_0 := (y_0, z_0) \in K_U \times K_V$) if, for any $\tau > 0$ and for any control $v_1(\cdot)$ and $v_2(\cdot)$ belonging to $\mathcal{V}(z_0)$, which coincide almost everywhere (a.e.) on $[0, \tau]$, $\alpha(v_1(\cdot))$ and $\alpha(v_2(\cdot))$ coincide a.e. on $[0, \tau]$. We denote by $S_U(x_0)$ the set of such nonanticipative strategies for Ursula.

The nonanticipative strategies β for the second player Victor are defined symmetrically, and we denote by $S_V(x_0)$ the set of such strategies.

Throughout this paper, B denotes the closed unit ball of $\mathbb{R}^N$ (endowed with the Euclidean norm), and $d_S(x)$ denotes the distance from a point x to a set S. Moreover, if S is a subset of $\mathbb{R}^N$ and ε is positive, we denote by $S + \varepsilon B$ the set

$$S + \varepsilon B = \{x \in \mathbb{R}^N \mid d_S(x) \leq \varepsilon\} \, .$$

1.2. The main theorem. Let $C \subset K_U \times K_V$ be a closed target. The hitting-time of C for a trajectory $x(\cdot) := (y(\cdot), z(\cdot))$ is

$$\theta_C(x(\cdot)) := \min\{t \geq 0 \mid x(t) \in C\}.$$

If $x(t) \notin C$ for every $t \geq 0$, then we set $\theta_C(x(\cdot)) := +\infty$. In the pursuit game, Ursula wants to maximize θ_C, while Victor wants to minimize it.

Definition 1.2 (value functions). *The lower optimal hitting-time function is the map $\vartheta_C^\flat : K_U \times K_V \to \mathbb{R}^+ \cup \{+\infty\}$ defined, for any $x_0 := (y_0, z_0)$, by*

$$\vartheta_C^\flat(x_0) := \inf_{\beta(\cdot) \in S_V(x_0)} \sup_{u(\cdot) \in \mathcal{U}(y_0)} \theta_C\left(x[x_0, u(\cdot), \beta(u(\cdot))]\right).$$

The upper optimal hitting-time function is the map $\vartheta_C^\sharp : K_U \times K_V \to \mathbb{R}^+ \cup \{+\infty\}$ defined, for any $x_0 := (y_0, z_0)$, by

$$\vartheta_C^\sharp(x_0) := \lim_{\varepsilon \to 0^+} \sup_{\alpha(\cdot) \in S_U(x_0)} \inf_{v(\cdot) \in \mathcal{V}(z_0)} \theta_{C + \varepsilon B}\left(x[x_0, \alpha(v(\cdot)), v(\cdot)]\right).$$

By convention, we set $\vartheta_C^\flat(x) = \vartheta_C^\sharp(x) = 0$ on C.

Remarks.

1. Let us point out that the limit in the definition of $\vartheta_C^\sharp$ exists because the quantity

$$\sup_{\alpha(\cdot) \in S_U(x_0)} \inf_{v(\cdot) \in \mathcal{V}(z_0)} \theta_{C + \varepsilon B}\left(x[x_0, \alpha(v(\cdot)), v(\cdot)]\right)$$

is nondecreasing with respect to ε. Such a definition is used, for instance, in [6]. The meaning of such a definition is the following. Whatever strategy α

is played, the second player can ensure the state of the system to go as close as he wants to the target before $\vartheta^\sharp_C(x_0)$ (but the state of the system need not reach the target).

2. The following definition of the upper value function has been used in several papers:

$$\widehat{\vartheta}^\sharp_C(x_0) := \sup_{\alpha(\cdot)\in S_U(x_0)} \inf_{v(\cdot)\in\mathcal{V}(z_0)} \theta_C\left(x[x_0,\alpha(v(\cdot)),v(\cdot)]\right).$$

However, without controllability assumptions on the boundary of the target, we cannot hope to have a value with this definition of upper value function. For instance, if one considers the unconstrained pursuit game where the dynamics is

$$\begin{cases} y'(t) = u(t), \text{ where } u(t) \in U = [-1,1], \\ z_1'(t) = v(t), \text{ where } v(t) \in V = [-1,1], \\ z_2'(t) = 1, \end{cases}$$

and the target is $C = \{(y,z_1,z_2) \in \mathbb{R}^3 \mid y = z_1 \text{ and } z_2 = 1\}$, then

$$\widehat{\vartheta}^\sharp_C(0,0,0) = +\infty,$$

while

$$\vartheta^\flat_C(0,0,0) = \vartheta^\sharp_C(0,0,0) = 1.$$

Proof. We first prove the last equality. Let us notice that $\beta(u(\cdot))(t) = u(t)$ is an optimal strategy for the second player. Hence $\vartheta^\flat_C(0,0,0) = 1$. Equality $\vartheta^\flat_C(0,0,0) = \vartheta^\sharp_C(0,0,0)$ comes from Theorem 1.3 below.

We now prove the first equality. We define the nonanticipative strategy α in the following way. For any control $v(\cdot)$, let $z_1(\cdot)$ be the solution to

$$\begin{cases} z_1'(t) = v(t), \\ z_1(0) = 0. \end{cases}$$

We set $c = \liminf_{h\to 0^+} z_1(h)/h$. Since $v(t) \in [-1,1]$, we have $c \in [-1,1]$. If $c > -1$, we set $\alpha(v(\cdot))(t) = -1$, while, if $c = -1$, we set $\alpha(v(\cdot))(t) = 1$. Let us point out that such a map α is a nonanticipative strategy. We claim that, for any control $v(\cdot)$, the solution $x(\cdot) = x[0,\alpha(v(\cdot)),v(\cdot)]$ never touches the target.

We consider two cases. If, on the one hand, $c > -1$, then there is some $\tau \in (0,1)$ such that

$$\forall t \in (0,\tau],\ z_1(t) \geq \frac{(c-1)}{2}t \ > \ -t = y(t)\ .$$

Hence

$$\forall t \geq \tau,\ z_1(t) \geq \frac{(c-1)}{2}\tau - (t-\tau) \ > \ -t = y(t)\ .$$

Therefore, for any t, $z_1(t) > y(t)$, so that $x(t) \notin C$.

If, on another hand, $c = -1$, there is a sequence $t_n \to 0^+$ such that $\lim_n z_1(t_n)/t_n = -1$. Hence there is some n such that $t_n \in (0, 1)$ and $z_1(t_n) \leq t_n/2$. Then

$$\forall t \geq t_n,\ z_1(t) \leq t_n/2 + (t - t_n) \ < \ t = y(t)\ .$$

Therefore, for any $t \geq t_n$, $z_1(t) < y(t)$, so that $x(t) \notin C$.

3. A natural question is "What happens if one modifies the lower value function in the same way?" We show below that

$$\vartheta^\flat_C(x_0) := \lim_{\varepsilon \to 0^+} \inf_{\beta(\cdot) \in S_V(x_0)} \sup_{u(\cdot) \in \mathcal{U}(y_0)} \theta_{C+\epsilon B}\left(x[x_0, u(\cdot), \beta(u(\cdot))]\right)$$

(see Proposition 3.2).

4. A last remark, which is not really interesting for differential games, might be interesting from a PDE point of view. In the theory of viscosity solutions, one often characterizes the solution through its lower semicontinuous and upper semicontinuous envelope. In the above example we can notice that the lower semicontinuous envelope of $\widehat{\vartheta^\sharp_C}$ *is not equal* to $\vartheta^\sharp_C$.

THEOREM 1.3. *Assume that conditions* (1.1) *are fulfilled. Then the game has a value:*

$$\forall x_0 \in K_U \times K_V,\ \vartheta^\flat_C(x_0) = \vartheta^\sharp_C(x_0).$$

This theorem is proved in section 4 by reducing the pursuit game to a qualitative differential game called the pursuit-evasion game. We deduce from the "alternative theorem" for this qualitative game (see Theorem 2.6, below) the existence of a value for the pursuit game.

Moreover, the proof gives a geometric characterization of the value function. This characterization can be formulated as a Hamilton–Jacobi–Isaacs equation (see [14]). We shall not do so for the sake of brevity. As indicated in [14], we can also derive from this characterization numerical schemes for computing the value function.

2. An alternative theorem for a qualitative differential game with state constraints.

In this section, we study the differential game in which the first player, Ursula, controlling system (0.1), aims the state of the full system at reaching an open target $\mathcal{O}$ while the other player, Victor, controlling system (0.2), aims the state of the system at avoiding $\mathcal{O}$ and—if possible—at reaching some given evasion set $\mathcal{E}$. This game is very close to the approach-evasion game of Krasovskii and Subbotin [27].

2.1. Statement of the qualitative problem.

DEFINITION 2.1. *Let $\mathcal{O} \subset K_U \times K_V$ be an open target, and let $\mathcal{E} \subset K_U \times K_V$ be a closed evasion set. The victory domains of the players are defined as follows.*

- *Victor's victory domain is the set of initial positions $x_0 := (y_0, z_0)$ belonging to $K_U \times K_V$ for which there is an admissible nonanticipative strategy $\beta : \mathcal{U}(y_0) \to \mathcal{V}(z_0)$ such that, for any admissible control $u(\cdot) \in \mathcal{U}(y_0)$, the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ avoids $\mathcal{O}$ as long as it does not reach $\mathcal{E}$ (or avoids $\mathcal{O}$ on $[0, +\infty)$ if it never reaches $\mathcal{E}$).*
- *Ursula's victory domain is the set of initial positions $x_0 := (y_0, z_0)$ belonging to $K_U \times K_V$ for which there are $T \geq 0$, $\varepsilon > 0$, and an admissible nonanticipative strategy $\alpha : \mathcal{V}(z_0) \to \mathcal{U}(y_0)$ such that, for any admissible control $v(\cdot) \in \mathcal{V}(z_0)$, the solution $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ reaches $\mathcal{O}_\varepsilon := \{x \in \mathcal{O} \mid d_{\partial\mathcal{O}}(x) > \varepsilon\}$ at some time $\tau \leq T$ and does not reach $\mathcal{E} + \varepsilon B$ on $[0, \tau]$.*

In this section, we prove the following alternative result: if x belongs to $K_U \times K_V$, then x belongs to one and only one victory domain. Moreover, we give a geometric characterization of the victory domains.

2.2. The discriminating domains. For $x := (y, z) \in \mathbb{R}^N$, we set

$$U(y) := \{u \in U \mid g(y, u) \in T_{K_U}(y)\},$$

where $T_{K_U}(y)$ is the usual tangent half-space to the set with smooth boundary K_U at y. Let us notice that, under assumptions (1.1), the set-valued map $y \to f(y, U(y))$ is lower semicontinuous with convex compact values (see [5]).

Let us introduce the Hamiltonian of our system:

$$(2.1) \qquad H(x,p) := \begin{cases} \inf_{v\in V} \sup_{u\in U(y)} \langle f(x,u,v), p\rangle & \text{if } x \notin \mathcal{E}, \\ \min\{0\ ,\ \inf_{v\in V} \sup_{u\in U(y)} \langle f(x,u,v), p\rangle\} & \text{otherwise,} \end{cases}$$

where $x := (y, z)$ and where

$$\inf_{v\in V} \sup_{u\in U(y)} \langle f(x,u,v), p\rangle = \sup_{u\in U(y)} \langle g(y,u), p_y\rangle + \inf_{v\in V} \langle h(z,v), p_z\rangle.$$

DEFINITION 2.2. *A closed subset D of $K_U \times K_V$ is a discriminating domain for H if and only if*

$$\forall x \in D,\ \forall p \in NP_D(x),\ H(x,p) \le 0,$$

where $NP_D(x)$ denotes the set of proximal normal to D at x, i.e., the set of $p \in \mathbb{R}^N$ such that the distance of $x + p$ to D is equal to $\|p\|$.

For the original definition of discriminating domains, see Aubin [4].

Discriminating domains can be characterized in two different ways.

THEOREM 2.3. *Suppose that assumptions* (1.1) *are fulfilled. A closed subset D of $K_U \times K_V$ is a discriminating domain for H if and only if, for any initial position $x_0 = (y_0, z_0) \in D$, there is a nonanticipative strategy $\beta \in S_V(x_0)$ such that, for any $u(\cdot) \in \mathcal{U}(y_0)$, the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ remains in D until it reaches $\mathcal{E}$ (or remains in D on $[0, +\infty)$ if it never reaches $\mathcal{E}$).*

Remark. This result was proved independently and in the same time by Plaskacz [30] and by the first author [11] when $K_U = \mathbb{R}^l$ and $\mathcal{E} = \emptyset$. For time-measurable dynamics, see also [15]. Theorem 2.3 (in a more general form) was announced in [13].

THEOREM 2.4. *Suppose that assumptions* (1.1) *are fulfilled. A closed set $D \subset K_U \times K_V$ is a discriminating domain for H if and only if, for any initial position $x_0 := (y_0, z_0) \in D$, for any admissible nonanticipative strategy $\alpha : \mathcal{V}(z_0) \to \mathcal{U}(y_0)$, for any $T \ge 0$, and for any $\varepsilon > 0$, there is an admissible control $v(\cdot) \in \mathcal{V}(z_0)$ such that the solution $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ remains in $D + \varepsilon B$ on $[0, T]$ as long as it does not reach $\mathcal{E} + \varepsilon B$. Namely,*

- *either there is some $\tau \le T$ such that $x[x_0, \alpha(v(\cdot)), v(\cdot)](\tau)$ belongs to $\mathcal{E} + \varepsilon B$ and $x[x_0, \alpha(v(\cdot)), v(\cdot)](t) \in D + \varepsilon B$ for $t \in [0, \tau]$,*
- *or $x[x_0, \alpha(v(\cdot)), v(\cdot)](t) \in D + \varepsilon B$ for $t \in [0, T]$.*

Remark. Note that, if $D \subset (K_U \times K_V)\backslash\mathcal{O}$ is a discriminating domain, then D is a subset of Victor's victory domain (according to Theorem 2.3) and has an empty intersection with Ursula's victory domain (according to Theorem 2.4).

The proof of Theorems 2.3 and 2.4, being rather technical, are given in the appendix.

2.3. The alternative theorem. We now characterize Victor's and Ursula's victory domains. For that purpose, we first recall the definition of the discriminating kernel.

PROPOSITION 2.5 (see [12]). *Let $H : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ be a lower semicontinuous map. If K is a subset of $\mathbb{R}^N$, then K contains a largest (for the inclusion)* closed *discriminating domain for H. This set is called the discriminating kernel of K for H and is denoted by $Disc_H(K)$.*

THEOREM 2.6 (alternative theorem). *Let H be defined by* (2.1) *and assume that* (1.1) *is fulfilled. Then,*

- *Victor's victory domain is equal to $Disc_H(\mathcal{K})$, and*
- *Ursula's victory domain is equal to $(K_U \times K_V)\backslash Disc_H(\mathcal{K})$,*

where $\mathcal{K} := (K_U \times K_V)\backslash\mathcal{O}$.

In particular, any point of $(K_U \times K_V)$ belongs either to Victor's victory domain or to Ursula's. When $K_U = K_V = \mathbb{R}^N$, this characterization can be found in [11].

The proof is given in the appendix.

3. Proof of the existence of a value for the pursuit game. We come back to the problem of the existence of a value (see section 1), i.e., to the equality between $\vartheta_C^\flat$ and $\vartheta_C^\sharp$. We are going to prove that their epigraphs are equal. Let us recall that the epigraph of $\vartheta_C^\flat$ (for instance) is a subset of $\mathbb{R}^{N+1}$ defined by

$$\mathcal{E}pi(\vartheta_C^\flat) = \{(x,\rho) \in \mathbb{R}^{N+1} \mid \vartheta_C^\flat(x) \le \rho\}.$$

In what follows, we always denote by (x,ρ) any point of $\mathbb{R}^{N+1}$, where $x \in \mathbb{R}^N$ and $\rho \in \mathbb{R}$.

THEOREM 3.1. *Assume that conditions* (1.1) *are fulfilled. Then we have*

$$\mathcal{E}pi(\vartheta_C^\flat) = Disc_H(\mathcal{K}) = \mathcal{E}pi(\vartheta_C^\sharp), \tag{3.1}$$

where $\mathcal{K} := K_U \times K_V \times \mathbb{R}^+$ and where the Hamiltonian $H : \mathbb{R}^{N+1} \times \mathbb{R}^{N+1} \to \mathbb{R}$ is defined by

$$\begin{aligned}
&\forall (x,\rho) \in \mathbb{R}^{N+1},\ (p_x, p_\rho) \in \mathbb{R}^{N+1},\\
&H(x,\rho,p_x,p_\rho)\\
&\quad := \sup_{u \in U(y)} \inf_{v \in V} \langle f(x,u,v), p_x\rangle - p_\rho \qquad\qquad \textit{if } x \notin C,\\
&\quad := \min\left\{ 0\,;\ \sup_{u \in U(y)} \inf_{v \in V} \langle f(x,u,v), p_x\rangle - p_\rho \right\} \quad \textit{otherwise.}
\end{aligned}$$

Remarks.

- This result proves Theorem 1.3 since the functions $\vartheta_C^\flat$ and $\vartheta_C^\sharp$, having the same hypograph, are equal.
- We can deduce from this result that the map $\vartheta_C^\flat = \vartheta_C^\sharp$ is lower semicontinuous since its epigraph is closed (the set $Disc_H(\mathcal{K})$ being closed from Proposition 2.5).
- We can also derive from the proof of Theorem 3.1 the existence of an optimal strategy for the pursuer (Victor).

Proof of Theorem 3.1. *Proof of the first equality of* (3.1).

Let us introduce the dynamic $\widetilde{f} : \mathbb{R}^N \times \mathbb{R} \times U \times V \to \mathbb{R}^N \times \mathbb{R}$ given by

$$\widetilde{f}(x,\rho,u,v) := \{f(x,u,v)\} \times \{-1\}.$$

Note that the Hamiltonian H defined above is actually of the form of the Hamiltonian H defined by (2.1) for the dynamics $\widetilde{f}$ and for the closed evasion set defined by $\mathcal{E} := C \times \mathbb{R}$.

From Theorem 2.6, the discriminating kernel of $\mathcal{K}$ for $\widetilde{H}$ is the set of initial positions $(x_0, \rho_0) \in \mathcal{K}$ for which there is some nonanticipative strategy $\beta \in S_V(x_0)$ for Victor such that, for any $u(\cdot) \in \mathcal{U}(y_0)$, the solution to

$$\text{(3.2)} \qquad \begin{cases} x'(t) = f(x(t), u(t), \beta(u(\cdot))(t)), \\ \rho'(t) = -1, \\ x(0) = x_0, \qquad \text{and} \qquad \rho(0) = \rho_0 \end{cases}$$

remains in $\mathcal{K}$ until it reaches the set $\mathcal{E}$.

Let (x_0, ρ_0) belong to $Disc_{\widetilde{H}}(\mathcal{K})$, let β be an associated nonanticipative strategy, and let $(x(\cdot), \rho(\cdot))$ be the solution to (3.2). Since the solution $(x(\cdot), \rho(\cdot))$ remains in $\mathcal{K}$ as long as it does not reach $\mathcal{E}$, $\rho(t) = \rho_0 - t \geq 0$ as long as $x(t) \notin C$. Thus the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ reaches C before ρ_0. In particular,

$$\text{(3.3)} \qquad \vartheta_C^\flat(x_0) \leq \sup_{u(\cdot) \in \mathcal{U}} \theta_C(x[x_0, u(\cdot), \beta(u(\cdot))]) \leq \rho_0 \ .$$

So (x_0, ρ_0) belongs to $\mathcal{E}pi(\vartheta_C^\flat(\cdot))$ and $Disc_{\widetilde{H}}(\mathcal{K}) \subset \mathcal{E}pi(\vartheta_C^\flat(\cdot))$.

For proving the converse inclusion, let x_0 belong to the domain of $\vartheta_C^\flat(\cdot)$, and let $\rho_0 > \vartheta_C^\flat(x_0)$. There is some nonanticipative strategy β for Victor such that, for any $u(\cdot) \in \mathcal{U}(y_0)$, the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ reaches C before ρ_0. In particular, the solution $(x(\cdot), \rho(\cdot))$ to (3.2) remains in $\mathcal{K}$ until it reaches $\mathcal{E}$, so that (x_0, ρ_0) belongs to $Disc_{\widetilde{H}}(\mathcal{K})$ from Theorem 2.6. This holds true for any $\rho_0 > \vartheta_C^\flat(x_0)$.

Since the discriminating kernel is a closed set, we have proved that

$$\mathcal{E}pi(\vartheta_C^\flat(\cdot)) \subset Disc_{\widetilde{H}}(\mathcal{K}).$$

Proof of the second equality of (3.1). Let (y_0, z_0, w_0) belong to $Disc_{\widetilde{H}}(\mathcal{K})$. Fix $\varepsilon > 0$, and let $\alpha : \mathcal{V}(z_0) \to \mathcal{U}(y_0)$ be such that

$$\forall v(\cdot) \in \mathcal{V}(z_0), \ \theta_{C+\varepsilon B}(x[x_0, \alpha(v(\cdot)), v(\cdot)]) \geq \vartheta_C^\sharp(y_0, z_0) - \varepsilon \ .$$

From Theorem 2.6, for this nonanticipative strategy α, for this $\varepsilon > 0$, and for $T := w_0 + \varepsilon$, there is a control $v(\cdot) \in \mathcal{V}(z_0)$ such that the solution to

$$\text{(3.4)} \qquad \begin{cases} x'(t) = f(x(t), \alpha(v(\cdot))(t), v(t)), \\ w'(t) = -1, \\ y(0) = y_0, \ z(0) = z_0, \ w(0) = w_0 \end{cases}$$

remains in $\mathcal{K} + \varepsilon B$ on $[0, T]$ as long as it does not reach $(C \times \mathbb{R}) + \varepsilon B$.

Set $\tau := \inf\{\theta_{C+\varepsilon B}((y(\cdot), z(\cdot))); T\}$. Then $w(t) = w_0 - t$ on $[0, \tau]$ and $w(t) \geq -\varepsilon$ for any $t \in [0, \tau]$. So $\tau \leq w_0 + \varepsilon$.

So finally, $w_0 \geq \vartheta_C^\sharp(y_0, z_0) - 2\varepsilon$. Since this holds true for any $\varepsilon > 0$, we have finally proved that $w_0 \geq \vartheta_C^\sharp(y_0, z_0)$. Thus $Disc_{\widetilde{H}}(\mathcal{K})$ is a subset of $\mathcal{E}pi(\vartheta_C^\sharp)$.

Conversely, let $w_0 > \vartheta_C^\sharp(y_0, z_0)$. Then, for any nonanticipative strategy $\alpha : \mathcal{V}(z_0) \to \mathcal{U}(y_0)$, for any positive ε, there is a control $v(\cdot) \in \mathcal{V}(z_0)$ such that

$$\theta_{C+\varepsilon B}(x[x_0, \alpha(v(\cdot)), v(\cdot)]) \leq w_0.$$

Note that the function $t \to (x[x_0, \alpha(v(\cdot)), v(\cdot))](t), w_0 - t)$ is a solution to (3.4). Moreover, this solution remains in $\mathcal{K}$ as long as the solution does not reach $\mathcal{E} + \varepsilon B$ (i.e., on $[0, \theta_{C+\varepsilon B}(x[x_0, \alpha(v(\cdot)), v(\cdot)])])$. So (y_0, z_0, w_0) belongs to $Disc_{\widetilde{H}}(\mathcal{K})$. Since $Disc_{\widetilde{H}}(\mathcal{K})$ is closed, this holds true for any $w_0 \geq \vartheta^\sharp_C(y_0, z_0)$.

This proves the equality between $Disc_{\widetilde{H}}(\mathcal{K})$ and $\mathcal{E}pi(\vartheta^\sharp_C)$.

We can also use the previous theorem in order to prove some stability results. Namely, we have the following proposition.

Proposition 3.2. *Under the assumptions of Theorem* 3.1*,*

$$\vartheta^\flat_C(x_0) := \lim_{\varepsilon \to 0} \inf_{\beta(\cdot) \in S_V(x_0)} \sup_{u(\cdot) \in \mathcal{U}(y_0)} \theta_{C+\epsilon B}\left(x[x_0, u(\cdot), \beta(u(\cdot))]\right).$$

Proof. Let us denote by $\vartheta^\flat_{C+\epsilon B}$ and H_ϵ the value and the Hamiltonian associated with the target $C + \epsilon B$:

$$\begin{array}{l} \forall (x,\rho) \in \mathbb{R}^{N+1},\ (p_x, p_\rho) \in \mathbb{R}^{N+1}, \\ H(x, \rho, p_x, p_\rho) \\ \quad := \displaystyle\sup_{u \in U(y)} \inf_{v \in V} \langle f(x,u,v), p_x\rangle - p_\rho \qquad\qquad\qquad \text{if } x \notin C + \epsilon B, \\ \quad := \min\left\{ 0\ ;\ \displaystyle\sup_{u \in U(y)} \inf_{v \in V} \langle f(x,u,v), p_x\rangle - p_\rho \right\} \quad \text{otherwise.} \end{array}$$

According to Theorem 3.1, we have

$$\mathcal{E}pi(\vartheta^\flat_{C+\epsilon B}) = Disc_{H_\epsilon}(\mathcal{K}),$$

where $\mathcal{K} := K_U \times K_V \times \mathbb{R}^+$. Since $H_\epsilon \leq H$, the following inequality is obvious:

$$Disc_H(\mathcal{K}) \subset Disc_{H_\epsilon}(\mathcal{K})\ .$$

Conversely, since the lower semicontinuous Hamiltonians H_ϵ converge in the sense of Proposition 1.2 of [12], this proposition states that the decreasing limit of $Disc_{H_\epsilon}(\mathcal{K})$ is a discriminating domain for H. Since this limit is contained in $\mathcal{K}$, because so are $Disc_{H_\epsilon}(\mathcal{K})$, it is contained in $Disc_H(\mathcal{K})$. So we have proved that

$$\bigcap_{\epsilon > 0} Disc_{H_\epsilon}(\mathcal{K}) = Disc_H(\mathcal{K})\ ,$$

which is equivalent to saying that

$$\vartheta^\flat_C(x_0) := \lim_{\epsilon \to 0^+} \inf_{\beta(\cdot) \in S_V(x_0)} \sup_{u(\cdot) \in \mathcal{U}(y_0)} \theta_{C+\epsilon B}\left(x[x_0, u(\cdot), \beta(u(\cdot))]\right)\ .$$

4. Appendix.

We now prove Theorems 2.3, 2.4, and 2.6. The proof of these results has the same framework as the proof of Theorems 2.1, 2.2, 2.3, and 2.4 of [11]. However, the key points of the proofs essentially differ because of the presence of the constraints. Hence, for the sake of brevity, we refer to [11] for the framework of the proofs, and we only give the key points.

4.1. Proof of Theorem 2.3. The condition is sufficient.

Assume that D is a discriminating domain. The crucial point of the proof is the following lemma.

Lemma 4.1. *Suppose that the assumptions of Theorem* 2.3 *are fulfilled, and assume that D is a discriminating domain for H. Then for any $x_0 = (y_0, z_0) \in D$*

and for any control $u(\cdot) \in \mathcal{U}(y_0)$, there is a control $v(\cdot) \in \mathcal{V}(z_0)$ such that the solution $x(\cdot) := x[x_0, u(\cdot), v(\cdot)]$ remains in D until it reaches $\mathcal{E}$ (or remains in D forever if it does not reach $\mathcal{E}$).

The sequel of the proof runs as in Theorem 2.1 of [11] or as in [15].

Proof of Lemma 4.1. Let us assume that D is a discriminating domain for H. Let $x_0 \in D$ and $u_0(\cdot) \in \mathcal{U}(y_0)$. It is enough to prove that there is a measurable control $v(\cdot) \in \mathcal{V}$ and a time $T > 0$ such that $x(\cdot) := x[x_0, u_0(\cdot), v(\cdot)]$ remains in D on $[0,T]$ until it reaches $\mathcal{E}$. Let us notice that, if $x_0 \in \mathcal{E}$, then the proof is obvious. We now assume that $x_0 \notin \mathcal{E}$.

We divide the proof in two steps. In the first step we assume that y_0 belongs to the interior of K_U, and in the second step that y_0 belongs to ∂K_U.

First step. We assume that there is some $T > 0$ such that the solution $y(\cdot) := y[y_0, u_0(\cdot)]$ remains in $\text{Int}(K_U)$ on $[0,T]$. Then we are going to prove that there is a control $v(\cdot) \in \mathcal{V}(z_0)$ such that $x[x_0, u(\cdot), v(\cdot)]$ remains in D on $[0,T]$.

Let $\varepsilon > 0$ be such that

$$\forall t \in [0,T], \quad y(t) + \varepsilon B \subset \text{Int}(K_U).$$

Let us introduce the following open set:

$$W := \{(y,z) \in \mathbb{R}^N \mid \exists t \in [0,T],\ \|y(t) - y\| < \varepsilon\} = (y([0,T]) + \varepsilon \overset{o}{B}) \times \mathbb{R}^m.$$

Let us define the set-valued map:

$$F(t,x) := \begin{cases} \bigcup_{v \in V} f(x, u_0(t), v) & \text{if } x \notin \mathcal{E}, \\ \overline{Co}\{\{0\} \cup \bigcup_{v \in V} f(x, u_0(t), v)\} & \text{if } x \in \mathcal{E}. \end{cases}$$

The main point of the proof is to check the assumptions for applying the measurable viability theorem of [21] for the set $W \cap D$ and F.

Let us notice that F is measurable and upper semicontinuous with respect to x. Moreover, F has convex compact values. We claim that the set $W \cap D$ is a locally compact viability domain for F. Indeed, if $x := (y,z) \in W \cap D$, then $y \in \text{Int}(K_U)$, so that $U(y) = U$. Since D is a discriminating domain, $U(y) = U$ on W, and $f(x,u,V)$ is convex, the proximal normal condition can be replaced by the following one (see, for instance, [12]):

$$\forall x \in D \cap W,\ \forall u \in U,\ \exists v \in V \text{ with } f(x,u,v) \in T_D(x).$$

Thus

$$F(t,x) \cap T_D(x) \neq \emptyset \qquad \text{a.e. } t \in [0,T],$$

where $T_D(x) = \{v \in \mathbb{R}^N\ ,\ \liminf_{h \to 0^+} d_D(x + hv)/h = 0\}$. So we have proved that $W \cap D$ is a locally compact viability domain for F on $[0,T]$.

The measurable viability theorem of [21] states that there is a solution $\bar{x}(\cdot)$ to the differential inclusion

$$\begin{cases} \bar{x}'(t) \in F(t, \bar{x}(t)), \\ \bar{x}(0) = x_0, \end{cases}$$

which remains in D as long as it belongs to W. Note that $\bar{x}(t) = (\bar{y}(t), \bar{z}(t))$, where $\bar{y}(\cdot) = y[y_0, u_0(\cdot)] = y(\cdot)$.

In particular, $\bar{x}(t)$ remains in W on $[0,T]$ and thus also in D on $[0,T]$. As long as $\bar{x}(\cdot)$ does not belong to $\mathcal{E}$, $\bar{x}(\cdot)$ is the solution to

$$\bar{x}'(t) \in \bigcup_{v} f(\bar{x}(t), u_0(t), v)\ .$$

Then the measurable selection theorem (Theorem 8.3.1 of [5]) states that there is some control $v(\cdot)$ such that the solution $x[x_0, u_0(\cdot), v(\cdot)]$ is equal to $\bar{x}(\cdot)$ until the solution reaches $\mathcal{E}$. When the solution has reached $\mathcal{E}$, we can set $v(t) = \bar{v}$, where $\bar{v}$ is any element of V. So we have finally defined a control $v(\cdot)$ such that the solution $x[x_0, u_0(\cdot), v(\cdot)]$ remains in D on $[0,T]$ until it reaches $\mathcal{E}$.

Second step. Let us now assume that y_0 belongs to ∂K_U. From assumption (1.1), there is some $\bar{u} \in U(y_0)$ such that $w := g(y_0, \bar{u})$ belongs to $\mathrm{Int}(T_{K_U}(y_0))$.

Fix $\theta > 0$, and define $x_\theta = (y_0 + \theta w, z_0)$ and $y_\theta(\cdot) := y[y_0 + \theta w, u_0(\cdot)]$. Since K_U is smooth, the solution $y_\theta(\cdot)$ remains in $\mathrm{Int}(K_U)$ on some interval $[0,T]$ (with $T > 0$ independent of θ) for any θ sufficiently small.

Thanks to the first step, we know that there is some control $v_\theta(\cdot)$ such that the solution $x_\theta(\cdot) := x[x_\theta, u_0(\cdot), v_\theta(\cdot)]$ remains in D on $[0,T]$ until it reaches $\mathcal{E}$. Since the set-valued map $\bigcup_{v\in V} f(x, u_0(t), v)$ is measurable, upper semicontinuous with respect to x, and has convex compact values, and since $\mathcal{E}$ is closed, there are a sequence $\theta_n \to 0^+$ and a sequence $x_{\theta_n}(\cdot)$ which converge to some $x(\cdot)$ starting from x_0 and remaining in D on $[0,T]$ until it reaches $\mathcal{E}$. Since, as long as the $x(\cdot)$ has not reached $\mathcal{E}$, $x(\cdot)$ is a solution to

$$x'(t) \in \bigcup_{v} f(x(t), u_0(t), v),$$

the measurable selection theorem states that there exists a control $v(\cdot) \in \mathcal{V}(z_0)$ such that $x(\cdot) = x[x_0, u_0(\cdot), v(\cdot)]$ as long as this solution has not reached $\mathcal{E}$. After the solution has reached $\mathcal{E}$, we can set $v(t) = \bar{v}$, where $\bar{v}$ is any element of V.

The condition is necessary. Assume that the closed set D satisfies the property given in Theorem 2.3. Let $\bar{x} = (\bar{y}, \bar{z}) \in D\backslash\mathcal{E}$, $p \in NP_D(\bar{x})$, and $\bar{u} \in U(\bar{y})$. We have to prove that

$$\sup_{u\in U(\bar{y})} \inf_{v\in V} \langle f(\bar{x}, u, v), p\rangle \le 0.$$

Since the set-valued map $y \to g(y, U(y))$ is lower semicontinuous with compact convex values, the Michael selection theorem (see [5]) yields the existence of a continuous selection $\widetilde{w} : K_U \to U$ of this set-valued map, i.e., $\widetilde{w}(y) \in g(y, U(y))$ such that $\widetilde{w}(\bar{y}) = g(\bar{y}, \bar{u})$. Let $y(\cdot)$ be any solution to the differential equation

$$\begin{cases} y'(t) = \widetilde{w}(y(t)),\ y(t) \in K_U, \\ y(0) = \bar{y}. \end{cases}$$

Then from the measurable selection theorem, there is some measurable control $u(\cdot) \in \mathcal{U}(\bar{y})$ with $y(t) = y[\bar{y}, u(\cdot)](t)$. Note that $y'(0) = g(\bar{y}, \bar{u})$.

Let β be a nonanticipative strategy as in Theorem 2.3. Then $x(\cdot) := x[\bar{x}, u(\cdot), \beta(u(\cdot))]$ remains in D and thus in $\overline{\mathbb{R}^N\backslash(\bar{x} + p + \|p\|B)}$. Then from standard arguments, there is a sequence $t_k \to 0^+$ such that $(x(t_k) - \bar{x})/t_k$ converges to some $v = (v_y, v_z)$ with $\langle v, p\rangle \le 0$. From the very construction of $u(\cdot)$, $v_y = g(\bar{y}, \bar{u})$. Since $h(z, V)$ is convex, $v_z \in h(\bar{z}, V)$. Thus

$$\sup_{u\in U(\bar{y})} \inf_{v\in V} \langle f(\bar{x}, u, v), p\rangle \le 0.$$

4.2. Proof of Theorem 2.4. The condition is sufficient. The proof of the sufficient condition follows the proof of Theorem 2.3 in [11] with Lemma 4.2 below instead of Lemma 4.4 of [11]. In Lemma 4.4 of [11], we use a kind of "extremal aiming" method. Extremal aiming [27] amounts to associating with any point $x \notin D$ some projection $\bar{x}$ of x onto D, and to playing for Ursula some $u \in U$ such that $\inf_v \langle f(\bar{x}, u, v), x - \bar{x}\rangle$ is maximum, and for Victor some $v \in V$ such that $\sup_u \langle f(\bar{x}, u, v), x - \bar{x}\rangle$ is minimum. Unfortunately, this method fails here since the players have to play admissible strategies, and the strategies given by the extremal aiming method have no reason to be admissible.

For stating Lemma 4.2, let us fix some notations. Since we are working only on the bounded interval $[0, T]$ and with solutions starting from initial position x_0, we denote by Q a radius such that any solution starting from x_0 remains in QB on $[0, T]$. We denote by M a upper bound of $\|f\|$ on QB.

LEMMA 4.2. *Under the assumptions of Theorem* 2.4*, there are positive constants (depending on Q, T, M, and ℓ) a and b such that, for any $x \in (K_U \times K_V) \cap QB$, with $x \notin D$ but $d_D(x) \leq Q$, for any admissible nonanticipative strategy $\alpha(\cdot) \in S_U(x)$, and for any $\tau \in [0, T]$, there is some admissible control $v(\cdot) \in \mathcal{V}(z)$ such that*

$$d_D^2(x[x, \alpha(v(\cdot)), v(\cdot)](\tau)) \leq d_D^2(x)[1 + a\tau] + b\tau^2.$$

Proof of Lemma 4.2. Let $\bar{x} := (\bar{y}, \bar{z})$ belong to the projection of x onto D. We also set $p = (p_y, p_z) = x - \bar{x}$. Recall that p belongs to $NP_D(\bar{x})$ and $\|p\| \leq Q$. Let us fix $\tau \in (0, T]$.

Let us consider $\widetilde{u}(\cdot) \in \mathcal{U}(y)$ an admissible control such that

$$\langle y[y, \widetilde{u}(\cdot)](\tau), p_y\rangle = \max_{u(\cdot) \in \mathcal{U}(y)} \langle y[y, u(\cdot)](\tau), p_y\rangle.$$

Thanks to Lemma 1.1, there is some control $\bar{u}(\cdot) \in \mathcal{U}(\bar{y})$ such that

$$\|y[\bar{y}, \bar{u}(\cdot)](\tau) - y[y, \widetilde{u}(\cdot)](\tau)\|^2 \leq \|p_y\|^2 e^{2\lambda\tau} .$$

From Lemma 4.1, there is some admissible control $\bar{v}(\cdot) \in \mathcal{V}(\bar{z})$ such that the solution $x[\bar{x}, \bar{u}(\cdot), \bar{v}(\cdot)]$ remains in D. Thanks to Lemma 1.1, there is some control $v(\cdot) \in \mathcal{V}(z)$ such that

$$\|z[\bar{z}, \bar{v}(\cdot)](\tau) - z[z, v(\cdot)](\tau)\|^2 \leq \|p_z\|^2 e^{2\lambda\tau}.$$

Set $u(\cdot) := \alpha(v(\cdot))$. Then

$$\begin{array}{ll} \multicolumn{2}{l}{d_D^2(x[x, u(\cdot), v(\cdot)](\tau))} \\ \leq & \|x[\bar{x}, \bar{u}(\cdot), \bar{v}(\cdot)](\tau) - x[x, u(\cdot), v(\cdot)](\tau)\|^2 \\ \leq & \|p_z\|^2 e^{2\lambda\tau} + \|y[\bar{y}, \bar{u}(\cdot)](\tau) - y[y, u(\cdot)](\tau)\|^2 \\ \leq & (1 + a\tau)\|p_z\|^2 + \|y[\bar{y}, \bar{u}(\cdot)](\tau) - y[y, u(\cdot)](\tau)\|^2. \end{array}$$

If we set $\bar{y}(\cdot) := y[\bar{y}, \bar{u}(\cdot)]$, $y(\cdot) := y[y, u(\cdot)]$, and $\widetilde{y}(\cdot) := y[y, \widetilde{u}(\cdot)]$, we have

$$\begin{aligned} &\|\bar{y}(\tau) - y(\tau)\|^2 \\ &\quad = \|\bar{y}(\tau) - \widetilde{y}(\tau)\|^2 + \|\widetilde{y}(\tau) - y(\tau)\|^2 + 2\langle \bar{y}(\tau) - \widetilde{y}(\tau); \widetilde{y}(\tau) - y(\tau)\rangle \\ &\quad \leq \|p_y\|^2 e^{2\lambda\tau} + 4M^2\tau^2 + 2\langle -p_y; \widetilde{y}(\tau) - y(\tau)\rangle + 4M^2\tau^2 \\ &\quad \leq (1 + a\tau)\|p_y\|^2 + b\tau^2 \end{aligned}$$

for some constants a and b, since

$$\langle p_y ; y[y, \widetilde{u}(\cdot)](\tau)\rangle \;\geq\; \langle p_y ; y[y, u(\cdot)](\tau)\rangle$$

from the very construction of $\widetilde{u}(\cdot)$. Therefore,

$$d_D^2(x[x, u(\cdot), v(\cdot)](\tau)) \leq (1 + a\tau)\|p\|^2 + b\tau^2,$$

which is the desired result since $\|p\| = d_D(x)$.

Necessary condition. Let us assume that D is not a discriminating domain for H. We are going to prove the existence of some point x_0 and of a nonanticipative strategy $\alpha : \mathcal{V}(z_0) \to \mathcal{U}(y_0)$ of positive ε and T such that, for any $v(\cdot) \in \mathcal{V}(z_0)$, the solution $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ leaves $D + \varepsilon B$ before T and avoids $\mathcal{E} + \varepsilon B$ on $[0, T]$.

Let $x_0 = (y_0, z_0) \in \partial D$ be such that the normal condition is not satisfied. Clearly $x_0 \notin \mathcal{E}$, and there is some $p = (p_y, p_z) \in NP_D(x_0)$ and some $\gamma > 0$ such that

$$\inf_{v \in V} \langle h(z_0, v), p_z\rangle + \sup_{u \in U(y_0)} \langle g(y_0, u), p_y\rangle \;\geq\; \gamma\;.$$

Let $\bar{u} \in U(y_0)$, which achieves the maximum of $\langle g(y_0, u), p_y\rangle$. Then, since $y \to g(y, U(y))$ is lower semicontinuous with convex compact values, there is a continuous selection $\widetilde{g}(y)$ of $g(y, U(y))$ such that $\widetilde{g}(y_0) = g(y_0, \bar{u})$ (by the Michael selection theorem in [5] for instance).

Let $y(\cdot)$ be any solution to $y'(t) = \widetilde{g}(y(t))$, $y(0) = y_0$, $y(t) \in K_U$ for any $t \geq 0$ (the Nagumo theorem [4] states that such a solution exists). There is some control $u(\cdot)$ such that $y(\cdot) = y[y_0, u(\cdot)]$ and $u(\cdot) \in \mathcal{U}(y_0)$ since $y(t) \in K_U$ for $t \geq 0$. Moreover, $y'(0) = g(y_0, \bar{u})$. In particular, there is some $\tau > 0$ such that,

$$\forall t \in (0, \tau),\; \langle y(t) - y_0, p_y\rangle \;\geq\; t \max_{u \in U(y_0)} \langle g(y_0, u), p_y\rangle - t\gamma/3.$$

For $\tau > 0$ sufficiently small and for any admissible control $v(\cdot) \in \mathcal{V}(z_0)$, we have

$$\forall t \in (0, \tau),\; \langle z[z_0, v(\cdot)] - z_0, p_z\rangle \;\geq\; t \inf_{v \in V(z_0)} \langle h(z_0, v), p_z\rangle - t\gamma/3.$$

Let $v(\cdot) \in \mathcal{V}(z_0)$ be any admissible control. Then, since p is a proximal normal to D at x_0, for any $t \in (0, \tau)$,

$$d_D(x[x_0, u(\cdot), v(\cdot)](t)) \geq \|p\| - \|x[x_0, u(\cdot), v(\cdot)](t) - x_0 - p\|.$$

Note that

$$\begin{aligned}
&\|x[x_0, u(\cdot), v(\cdot)](t) - x_0 - p\|^2 \\
&\leq \|p\|^2 - 2\langle y[y_0, u(\cdot)](t) - y_0, p_y\rangle - 2\langle z[z_0, v(\cdot)](t) - z_0, p_z\rangle + Ct^2 \\
&\leq \|p\|^2 - 2t(\gamma - 2\gamma/3) + Ct^2
\end{aligned}$$

for some constant C. So

$$d_D(x[x_0, u(\cdot), v(\cdot)](t)) \geq \|p\| - [\|p\|^2 - 2t\gamma/3 + Ct^2]^{1/2},$$

which is positive for any $t \in (0, \tau)$ if $\tau > 0$ is sufficiently small.

In conclusion, the desired nonanticipative strategy $\alpha : \mathcal{V}(z_0) \to \mathcal{U}(y_0)$ is the constant map $\alpha(v(\cdot)) = u(\cdot)$.

4.3. Proof of Theorem 2.6. We first prove that $Disc_H(\mathcal{K})$ is equal to Victor's victory domain. This runs as in the proof of Theorem 2.2 of [11], where we use the following sequence K_n instead of the sequence K_n of [11]:

$$\begin{cases} K_0 = \mathcal{K}, \\ K_{n+1} := \left\{ x = (y,z) \in K_n \mid \begin{array}{c} \forall u(\cdot) \in \mathcal{U}(y),\ \exists v(\cdot) \in \mathcal{V}(z),\ \exists \tau \in [0,+\infty], \\ \text{such that } x[x,u(\cdot),v(\cdot)](\tau) \in \mathcal{E} \text{ if } \tau < +\infty, \text{ and} \\ \forall t \in [0,\tau),\ x[x,u(\cdot),v(\cdot)](t) \in K_n \end{array} \right\}. \end{cases}$$

It is easy to check that $\bigcap_n K_n$ is a discriminating domain. Hence $\bigcap_n K_n \subset Disc_H(\mathcal{K})$. On the other hand, since the K_n contain $Disc_H(\mathcal{K})$, one has $\bigcap_n K_n = Disc_H(\mathcal{K})$. Hence $\bigcap_n K_n = Disc_H(\mathcal{K})$.

For the characterization of Ursula's victory domain, we introduce the complement of Ursula's victory domain:

$$\mathcal{L} := \left\{ x_0 \in \mathcal{K} \mid \begin{array}{c} \forall \alpha(\cdot),\ T \geq 0,\ \varepsilon > 0,\ \exists v(\cdot) \in \mathcal{V}(z_0), \\ \text{such that, if } x(\cdot) := x[x_0, \alpha(v(\cdot)), v(\cdot)], \\ \text{then, either } \forall t \in [0,T], x(t) \in \mathcal{K} + \varepsilon B \\ \text{or } \exists \tau \leq T,\ x(\tau) \in \mathcal{E} + \varepsilon B, \text{ and} \\ x(t) \in \mathcal{K} + \varepsilon B \text{ for } t \in [0,\tau] \end{array} \right\}.$$

Thanks to Theorem 2.4, $Disc_H(\mathcal{K}) \subset \mathcal{L}$. So we have to prove the converse inclusion.

For doing this, the key argument of [11, Lemma 5.1] is replaced by the following lemma.

LEMMA 4.3. *If x_0 belongs to $\mathcal{K}$ but not to $\mathcal{L}$, there are positive η, ε, and T and, for any $x := (y,z) \in (x_0 + \eta B) \cap \mathcal{K}$, a nonanticipative strategy $\alpha : \mathcal{V}(z) \to \mathcal{U}(y)$ such that, for any $v(\cdot) \in \mathcal{V}(z)$, the solution $x[x, \alpha(v(\cdot)), v(\cdot)]$ does not reach $\mathcal{E} + \varepsilon B$ and leaves $\mathcal{K} + \varepsilon B$ before T. Namely, if we set $x(\cdot) := x[x, \alpha(v(\cdot)), v(\cdot)]$,*

$$\exists \tau \in [0,T],\ x(\tau) \notin \mathcal{K} + \varepsilon B,\ \textit{and}\ x(t) \notin \mathcal{E} + \varepsilon B\ \textit{for}\ t \in [0,\tau]\ .$$

Lemma 4.3 states that the ε and T appearing in the definition of Ursula's victory domain are locally uniform.

Proof of Lemma 4.3. From the very definition of $\mathcal{L}$, if x_0 does not belong to $\mathcal{L}$, there is a nonanticipative strategy $\alpha_0(\cdot)$, T and $\varepsilon_0 > 0$ such that for any $v(\cdot) \in \mathcal{V}(z_0)$, if we set $x_0(\cdot) := x[x_0, \alpha_0(v(\cdot)), v(\cdot)]$,

$$\exists \tau \in [0,T],\ x_0(\tau) \notin \mathcal{K} + \varepsilon_0 B \text{ and } x_0(t) \notin \mathcal{E} + \varepsilon_0 B \text{ for } t \in [0,\tau]\ . \tag{4.1}$$

In the proof of Lemma 5.1 of [11], the same strategy $\alpha_0(\cdot)$ gave the desired result for any $x \in (x_0 + \eta B)$—provided that η was sufficiently small. The situation is more complicated here because α_0 is not necessarily an admissible strategy for $x \in (x_0 + \eta B) \cap \mathcal{K}$ because of the constraints. For solving this difficulty, we use the following lemma proved below. Although we shall apply this lemma indifferently to y and to z, we only formulate it for y.

LEMMA 4.4. *Let Q and T be fixed positive constants. There is some $\lambda > 0$ (depending on the constants of the problem on Q and on T) such that, for any y and y_0 belonging to K_U, with $\|y\| \leq Q$ and $\|y_0\| \leq Q$, there is a nonanticipative strategy $\sigma : \mathcal{U}(y) \to \mathcal{U}(y_0)$ with, for any $u(\cdot) \in \mathcal{U}(y)$ and for $t \in [0,T]$,*

$$\|y[y_0, \sigma(u(\cdot))](t) - y[y, u(\cdot)](t)\| \leq \|y - y_0\| e^{\lambda t}\ .$$

Let us complete the proof of Lemma 4.3. We fix a constant Q sufficiently large in such a way that any solution starting from a point of $x_0 + B$ remains in the ball QB on $[0, T]$. Fix $\eta := \varepsilon_0 e^{-\lambda T}/4$, where λ is defined by Lemma 4.4. Let $x := (y, z) \in (x_0 + \eta B)$.

From Lemma 4.4, there is a nonanticipative map $\sigma_1 : \mathcal{V}(z) \to \mathcal{V}(z_0)$ such that, for any $v(\cdot) \in \mathcal{V}(z)$ and for any $t \in [0, T]$,

$$\|z[z, v(\cdot)](t) - z[z_0, \sigma_1(v(\cdot))](t)\| \leq \eta e^{\lambda t} .$$

Then $\alpha_0 \circ \sigma_1 : \mathcal{V}(z) \to \mathcal{U}(y_0)$ is a nonanticipative map. From Lemma 4.4 again, there is a nonanticipative strategy $\sigma_2 : \mathcal{U}(y_0) \to \mathcal{U}(y)$ such that, for $t \in [0, T]$,

$$\|y[y_0, u(\cdot)](t) - y[y, \sigma_2(u(\cdot))](t)\| \leq \eta e^{\lambda t}$$

for any $u(\cdot) \in \mathcal{U}(y)$. Then $\alpha := \sigma_2 \circ \alpha_0 \circ \sigma_1$ is a nonanticipative strategy from $\mathcal{V}(z)$ to $\mathcal{U}(y)$.

Fix some control $v(\cdot) \in \mathcal{V}(z)$. Set $x_0(\cdot) := x[x_0, \alpha_0(\sigma_1(v(\cdot))), \sigma_1(v(\cdot))]$ and $x(\cdot) := x[x, \alpha(v(\cdot)), v(\cdot)]$.

Then, for $\tau \in [0, T]$ defined in formula (4.1),

$$d_{\mathcal{K}}(x(\tau)) \geq d_{\mathcal{K}}(x_0(\tau)) - \|x(\tau) - x_0(\tau)\| \geq \varepsilon_0 - 2\eta e^{\lambda T} \geq \varepsilon_0/2 .$$

In the same way, $d_{\mathcal{E}}(x(t)) \geq \varepsilon_0/2$ on $[0, \tau]$, which completes the proof of Lemma 4.3.

Proof of Lemma 4.4. From Lemma 1.1, there is some $\lambda > 0$ such that, for any $u_0(\cdot) \in \mathcal{U}(y_0)$ and for any $y \in K_U$, there is some control $u(\cdot) \in \mathcal{U}(y)$ with

$$\|y[y, u(\cdot)](t) - y[y_0, u_0(\cdot)](t)\| \leq \|y - y_0\| e^{\lambda t} \tag{4.2}$$

for any $t \in [0, T]$. Let us consider the set-valued map $\Sigma : \mathcal{U}(y_0) \to \mathcal{U}(y)$ defined by

$$\Sigma(u_0(\cdot)) := \{u(\cdot) \in \mathcal{U}(y) \mid (4.2) \text{ is satisfied}\}.$$

It is easy to check that Σ is nonanticipative in the sense of [15], so that, from the Plaskacz lemma (Lemma 2.7 of [15]), it enjoys a nonanticipative selection σ, i.e., σ is nonanticipative and $\sigma(u_0(\cdot)) \in \Sigma(u_0(\cdot))$ for any $u_0 \in \mathcal{U}(y_0)$.

A PROXIMAL POINT METHOD FOR THE VARIATIONAL INEQUALITY PROBLEM IN BANACH SPACES*

REGINA SANDRA BURACHIK[†] AND SUSANA SCHEIMBERG[‡]

Abstract. In this paper we prove well-definedness and weak convergence of the generalized proximal point method when applied to the variational inequality problem in reflexive Banach spaces. The proximal version we consider makes use of Bregman functions, whose original definition for finite dimensional spaces has here been properly extended to our more general framework.

Key words. maximal monotone operators, proximal point algorithm, Banach spaces, convergence, algorithmic scheme

1. Introduction.

Let B be a reflexive Banach space and $\Omega \subset B$ a nonempty closed and convex set. Given $T\colon B \to \mathcal{P}(B^*)$ a maximal monotone operator, we consider the *classical variational inequality problem* for T and Ω, $VIP(T,\Omega)$, defined by

Find $x^* \in \Omega$ such that there exists $y^* \in T(x^*)$ with

$$\langle y^*, x - x^* \rangle \geq 0 \tag{1.1}$$

for all $x \in \Omega$, where $\langle \cdot, \cdot \rangle$ stands for the dual product in B.

In the particular case in which T is a subdifferential, i.e., $T = \partial\varphi$, where $\varphi : B \to \mathbb{R} \cup \{+\infty\}$ is a proper, convex, and lower semicontinuous functional, (1.1) reduces to the nonsmooth constrained optimization problem

$$\min_{x\in\Omega} \varphi(x). \tag{1.2}$$

The following natural hypotheses will be assumed in our study:

H_1: $D(T)^0 \cap \Omega \neq \emptyset$ or $D(T) \cap \Omega^0 \neq \emptyset$.

Our aim is to study the algorithm given by:

1. Take $x^0 \in \Omega \cap D(T)$.
2. Given x^k, define x^{k+1} by the inclusion

$$0 \in (T + N_\Omega + \lambda_k \nabla f)x^{k+1} - \lambda_k \nabla f(x^k), \tag{1.3}$$

where f is a Bregman function (see Definition 2.1 in section 2.1), $\lambda_k > 0$, and $N_\Omega(\cdot)$ is the normality operator associated to Ω.

3. If $x^{k+1} = x^k$, STOP.

When $B = \Omega = H$, for H a Hilbert space, and $f = \frac{1}{2}\|\cdot\|_2^2$, algorithm (1.3) reduces

to the *classical* proximal point method in a Hilbert space [43]. Thus, scheme (1.3) can be seen as an extension to a Banach space of the proximal point method. The intention of this paper is to study existence and convergence of the sequence $\{x^k\}$ given by (1.3).

An important motivation for analyzing the convergence properties of algorithm (1.3) is related to the so-called *mesh independence principle* [2, 1, 28, 32, 35]. The mesh independence principle relies on infinite-dimensional convergence results for predicting the convergence properties of the discretized finite-dimensional method. Furthermore, it provides a theoretical foundation for the justification of refinement strategies and helps to design this refinement process. Since the focus is the infinite-dimensional solution, a fine discretization scheme has to be chosen so that the discrete solution approximates the infinite-dimensional solution appropriately. Many real-world problems in economics and engineering are modeled in infinite-dimensional spaces. These include optimal control problems, shape optimization problems, and the problem of minimal area surface with obstacles, among many others. In many shape optimization problems [35], the function space is only a Banach and not a Hilbert space, motivating an analysis in this more general framework. For solving constrained optimization problems in Banach spaces, the application of (1.3) to the saddle point operator associated with the problem has been proposed in [37]. The connection of these methods with our results will be discussed in section 4.

The family of Bregman functions we consider in this work includes, for instance, $f(x) = \|x\|_p^p$ when $B = L^p$ or $B = l_p$, with $p \in (1, +\infty)$. Hence, the case $f = \frac{1}{2}\|\cdot\|_2^2$ considered in the classical proximal point method can be seen as a particular case of (1.3). A natural question is, Why should we use a generic Bregman function in (1.3) instead of $f = \frac{1}{2}\|\cdot\|^2$? A first answer is that inclusion (1.3) can be substantially simplified by an appropriated choice of f. For instance, if $B = L^p$ or $B = l_p$, with $p \in (1, +\infty)$, then by choosing $f(x) = \|x\|_p^p$, (1.3) is much simpler than its version for $f(x) = \frac{1}{2}\|x\|_p^2$ (see [13]). Second, consider the case in which we have an optimization problem, i.e., $T = \partial\varphi$ in a Banach space contained in a Hilbert space H. Assume that φ can be extended to H. The proximal point method can then be applied in the whole space H, in which case, the generated sequence may (weakly) converge to an element not in B. In this situation, the use of a "proper" Bregman function defined on B makes sense.

Other extensions of the classical proximal point method to Banach spaces can be found in [17] and [36].

The notion of Bregman function has its origin in [5] and this name was first used by Censor and Lent in [19]. Bregman functions have been extensively used for convex optimization algorithms (e.g., [4], [19], [25], [20]) in finite-dimensional spaces. It has also been used for defining "generalized" versions of the proximal point method (e.g., [21], [23], [26], [30], [34] for finite-dimensional spaces, [10] for Hilbert spaces, and [40], [13], [15] for Banach spaces). A useful tool for comparing the Bregman distance with the distance induced by the norm of the Banach space leads to the notions of *modulus of convexity* and *total convexity* of f (the latter introduced in [8]). More material on these concepts can be found in [22] and [11]. The paper is organized as follows. Section 2 contains theoretical preliminaries. In subsection 2.1 we consider the concept of a Bregman function and examples in a Banach space. In subsection 2.2 we give definitions, properties, and examples related to *modulus of convexity* and *total convexity.* In subsection 2.3 we recall some classical material about maximal monotone operators. We also extend to a reflexive Banach space a result known to hold in Hilbert spaces [6, Lemme 1]. This result will ensure existence of the iterates. Section 3 establishes results concerning the existence and convergence of the iterates. Finally, we present in section 4 an application of algorithm (1.3) to the stochastic convex feasibility problem [9].

2. Theoretical preliminaries.

2.1. Bregman distances in Banach spaces.

Let B be a reflexive Banach space and $f : B \to \mathbb{R} \cup \{+\infty\}$ a strictly convex, proper, and lower semicontinuous function with closed domain $\mathcal{D} := dom(f)$. Assume from now on that $\mathcal{D}^\circ \neq \emptyset$ and that f is Gâteaux differentiable on $\mathcal{D}^\circ$.

The *Bregman distance* with respect to f is the function $D_f : \mathcal{D} \times \mathcal{D}^\circ \to \mathbb{R}$ defined by

$$D_f(z,x) := f(z) - f(x) - \langle \nabla f(x), z - x \rangle, \tag{2.1}$$

where $\nabla f(\cdot)$ is the differential of f defined in $\mathcal{D}^\circ$. The function $D_f(\cdot,\cdot)$ is not a distance in the usual sense of the term (in general, it is not symmetric and does not satisfy the triangular inequality). However, there is a "three point property" which takes the place of this inequality in the proofs.

PROPERTY 2.1. *Given $x \in \mathcal{D}$, $y, z \in \mathcal{D}^\circ$, the following equality is straightforward:*

$$\langle \nabla f(y) - \nabla f(z), z - x \rangle = D_f(x,y) - D_f(x,z) - D_f(z,y). \tag{2.2}$$

Consider the following set of assumptions on f:

B_1 : The *right* level sets of $D_f(y,\cdot)$:

$$S_{y,\alpha} := \{z \in \mathcal{D}^\circ \ : \ D_f(y,z) \leq \alpha\}$$

are bounded for all $\alpha \geq 0$ and for all $y \in \mathcal{D}$.

B_2 : If $\{x^k\} \subset \mathcal{D}^\circ$ and $\{y^k\} \subset \mathcal{D}^\circ$, $w - \lim_{k\to\infty} x^k = x$, $w - \lim_{k\to\infty} y^k = x$, and $\lim_{k\to\infty} D_f(x^k, y^k) = 0$, then

$$\lim_{k\to\infty} \left(D_f(x,x^k) - D_f(x,y^k)\right) = 0.$$

B_3 : If $\{x^k\} \subset \mathcal{D}$ is bounded, $\{y^k\} \subset \mathcal{D}^\circ$ is such that $w - \lim_{k\to\infty} y^k = y$ and $\lim_{k\to\infty} D_f(x^k, y^k) = 0$, then $w - \lim_{k\to\infty} x^k = y$.

B_4 : (zone coerciveness)
For every $y \in B^*$, there exists $x \in \mathcal{D}^\circ$ such that $\nabla f(x) = y$.

The following alternative condition will also be considered in our analysis.

B_2^* : If $\{x^k\} \subset \mathcal{D}^\circ$ and $\{y^k\} \subset \mathcal{D}^\circ$ are bounded sequences such that $\lim_{k\to\infty} \|x^k - y^k\| = 0$, then

$$\lim_{k\to\infty} \left(\nabla f(x^k) - \nabla f(y^k)\right) = 0.$$

Remark 2.1.

(i) Condition B_2^* will be used as an optional assumption in our convergent analysis. Examples of auxiliary functions which satisfy this property are relevant. It has been proved in [16] that for the important cases in which $B = \ell_p$ or $B = L_p$, with $p > 1$, condition B_2^* is satisfied for the family of functions $f(x) = \|x\|^s$, $s > 1$.

(ii) When $B = \mathbb{R}^n$, assumption B_2^* implies B_2.

(iii) Condition B_2 has been considered for the first time in [10] for the case in which $B = H$ a Hilbert space. When $B = R^n$, Censor and Lent [19] considered the condition if $\{x^k\} \subset \mathcal{D}^\circ$, $\lim_{k\to\infty} x^k = x$, then $\lim_{k\to\infty} D_f(x, x^k) = 0$. We point out that this assumption is stronger than B_2. Conditions B_1 and B_3 are natural extensions of the ones required in [19].

Definition 2.1. (i) *We say that f is a* Bregman function *if it satisfies B_1–B_3.*
(ii) *The function f is said to be a* coercive *Bregman function if it satisfies B_1–B_4.*

In our study, the following assumption will be made on the Bregman function f:
$H_2 : \Omega \subset \mathcal{D}^\circ$.

2.2. Total convexity. Let $\mathbb{R}_{++} := \{\alpha \in \mathbb{R} \ : \ \alpha > 0\}$ and $\mathbb{R}_{+} := \{\alpha \in \mathbb{R} \ : \ \alpha \geq 0\}$. Let $\mathcal{D} \subset B$ be a closed and convex set, with $\mathcal{D}^\circ \neq 0$ and $f : B \to \mathbb{R} \cup \{+\infty\}$ a convex function which is Gâteaux differentiable in $\mathcal{D}^\circ$. Following [12], we define the *modulus of convexity* of f, $\nu_f : \mathcal{D}^\circ \times \mathbb{R}_+ \to \mathbb{R}_+$ by

$$\nu_f(z,t) := \inf\{D_f(x,z) \ : \ \|x-z\| = t\}, \tag{2.3}$$

where $D_f(\cdot,\cdot)$ is given by (2.1). The function f is said to be *totally convex* in $\mathcal{D}^\circ$ if and only if $\nu_f(z,t) > 0$ for all $z \in \mathcal{D}^\circ$ and $t > 0$. The result below, which will be useful in what follows, has been proved in [12].

Property 2.2. *Let $z \in \mathcal{D}^\circ$. The function $\nu_f(z,\cdot)$ is* increasing *on $\mathbb{R}_{++}$, i.e., if $0 < \alpha < \beta$, then $\nu_f(z,\alpha) < \nu_f(z,\beta)$.*

Totally convex functions are strictly convex, and in finite dimension total convexity is equivalent to strict convexity, but in infinite dimensional Banach spaces (e.g., in ℓ_p) there exist strictly convex functions which are not totally convex (see [12]). On the other hand, total convexity is a weaker condition than uniform convexity (i.e., $\langle \nabla f(x) - \nabla f(y), x - y\rangle \geq \gamma \|x-y\|^p$ for some $\gamma > 0$, $p > 1$). Uniformly convex functions are totally convex (see [12]), but in the spaces L^p and ℓ_p with $1 < p < 2$ the function $f(x) = \|x\|_p^p$ is totally convex (see [12], [16]), while it is not uniformly convex. We will see later on that total convexity also turns out to be a key property in our convergence analysis. We are now ready to present our last assumption on f.

B_5 : (uniform total convexity). The function f is said to be *uniformly totally convex* if for any bounded set $K \subset \mathcal{D}^\circ$, and any $t \in \mathbb{R}_{++}$, it holds that

$$\inf_{x\in K} \nu_f(x,t) > 0 \ . \tag{2.4}$$

Remark 2.2.

(i) This condition is called *sequential consistency* in [11].

(ii) Assumption B_5 will be an alternative requirement on f in our convergence analysis. When $B = \ell_p$ or $B = L^p$, with $p > 1$, the family of functions $f(x) = \|x\|_p^s$, $s > 1$ is uniformly totally convex (see [16]). Moreover, the latter result has been extended in [14], where the authors prove that in any uniformly convex Banach space the function $f(x) = \|x\|_p^s$, $s > 1$ is uniformly totally convex.

(iii) Let $f : B \to \mathbb{R} \cup \{+\infty\}$ be a Gâteaux differentiable function on $\mathcal{D}^\circ$ such that it verifies assumptions B_2^* and B_5. Then condition B_2 holds. Indeed, take two sequences $\{x^k\}, \{y^k\} \subset \mathcal{D}^\circ$, weakly converging (and thus bounded) to the same point x, such that

$$\lim_{k\to\infty} D_f(x^k, y^k) = 0. \tag{2.5}$$

We must prove that

$$\lim_{k\to\infty} \big(D_f(x,x^k) - D_f(x,y^k)\big) = 0. \tag{2.6}$$

First we see that under this condition, it holds that $\lim_{k\to\infty} \|x^k - y^k\| = 0$. If this is not true, there exists a subsequence $\{x^{k_j} - y^{k_j}\}_{j\geq 0}$ and a positive number α such that

$$\|x^{k_j} - y^{k_j}\| > \alpha, \text{ for all } j \geq 0. \tag{2.7}$$

Let C be a bounded set which contains the sequence $\{y^k\}$. We have that

$$\begin{array}{rcl} D_f(x^{k_j}, y^{k_j}) & \geq & \inf\{D_f(z, y^{k_j}) \, : \, \|x^{k_j} - y^{k_j}\| = \|z - y^{k_j}\|\} \\ & = & \nu_f(y^{k_j}, \|x^{k_j} - y^{k_j}\|) \\ & > & \nu_f(y^{k_j}, \alpha) \\ & \geq & \inf_{y\in C} \nu_f(y, \alpha) > 0, \end{array}$$

where we used that the function $\nu_f(z,\cdot)$ is increasing and B_5. This contradicts the fact that $\lim_{k\to\infty} D_f(x^k, y^k) = 0$. Thus it holds that $\lim_{k\to\infty} \|x^k - y^k\| = 0$. By B_2^*, this implies that

$$\lim_{k\to\infty} \|\nabla f(x^k) - \nabla f(y^k)\| = 0. \tag{2.8}$$

By Property 2.1,

$$D_f(x,x^k) - D_f(x,y^k) = \langle \nabla f(y^k) - \nabla f(x^k), x - x^k\rangle - D_f(x^k, y^k).$$

Combining now (2.5) and (2.8), we obtain (2.6).

2.3. Maximal monotone operators in a reflexive Banach space. For an arbitrary point to set operator $A : B \to \mathcal{P}(B^*)$, we recall the following definitions:
domain of A:

- $D(A) := \{y \in B \, : \, A(y) \neq \emptyset\}$,

graph of A:

- $G(A) := \{(y,v) \in B \times B^* \, : \, v \in A(y)\}$,

range of A:

- $R(A) := \{v \in B^* \, : \, v \in A(y) \text{ for some } y \in B\}$.

The operator $T : B \to \mathcal{P}(B^*)$ is *monotone* if

$$\langle u - v, x - y\rangle \geq 0$$

for all $x, y \in B$ and all $u \in T(x), v \in T(y)$. A monotone operator is called *maximal* if for any other monotone operator $\tilde{T}$ with $\tilde{T}(x) \supseteq T(x)$ for all $x \in B$, it holds that $\tilde{T} = T$.

Maximal monotone operators have an important closedness property.

PROPOSITION 2.2 (see [38, p. 105]). *Any maximal monotone operator $S : B \to \mathcal{P}(B^*)$ is* demiclosed*, i.e., the conditions below hold:*

If $\{x^k\}$ converges weakly to x and $\{w^k \in Sx^k\}$ converges strongly to w, then $w \in Sx$.

If $\{x^k\}$ converges strongly to x and $\{w^k \in Sx^k\}$ converges weakly to w, then $w \in Sx$.

The following well-known result is very useful for asserting maximality of the sum of maximal monotone operators.

Proposition 2.3 (see [42, Theorem 1]). *Let B be a reflexive Banach space, and let T_1 and T_2 be maximal monotone operators from B to $\mathcal{P}(B^*)$. If $D(T_1) \cap D(T_2)^0 \neq \emptyset$, then $T_1 + T_2$ is a maximal monotone operator.*

Definition 2.4. *An operator A is said to be* coercive (*see* [38]) *if $D(A)$ is bounded or*

$$\lim_{\substack{(z,v) \in G(A) \\ \|z\| \to +\infty}} \frac{\langle v, z \rangle}{\|z\|} = +\infty. \tag{2.9}$$

The following definition has been introduced in [3] and [6]. It also appears in [39].

Definition 2.5. *An operator $A : B \to \mathcal{P}(B^*)$ is said to be* regular *if*

$$\text{for all } u \in R(A) \text{ and for all } y \in D(A), \quad \sup_{(z,v) \in G(A)} \langle v - u, y - z \rangle < \infty. \tag{2.10}$$

Proposition 2.6 (see [6, p. 167]). *The subdifferential of a proper lower semicontinuous convex function φ is a regular operator.*

Recall that for a nonempty convex and closed set $\Omega \subset B$, the normality operator $N_\Omega : B \to \mathcal{P}(B^*)$ is given by

$$N_\Omega(x) = \begin{cases} \{\phi \in B^* \mid \langle \phi, z - x \rangle \leq 0 \text{ for any } z \in \Omega\} & \text{if } x \in \Omega\,, \\ \emptyset & \text{if } x \notin \Omega\,. \end{cases}$$

It is easy to check that $N_\Omega(\cdot)$ is the subdifferential of the indicator function χ_Ω associated to the set Ω, i.e.,

$$\chi_\Omega(x) = \begin{cases} 0 & \text{if } x \in \Omega\,, \\ +\infty & \text{if } x \notin \Omega\,. \end{cases}$$

The function χ_Ω is proper convex and lower semicontinuous; hence $N_\Omega(\cdot)$ is a maximal monotone operator. For further use we emphasize that $x \in \Omega^0$ if and only if $N_\Omega(x) = 0$.

Recall that the normalized duality mapping $J : B \to \mathcal{P}(B^*)$ is defined by the property $v \in Ju$ if and only if $\|v\|_{B^*}^2 = \|u\|_B^2 = \langle v, u \rangle$ for any $u \in B$, where $\|\cdot\|_X$ means the norm in the space X. The next property, which we introduce here, will allow us to obtain the existence of the iterates in (1.3). It extends to a Banach space a lemma proved in [6] for Hilbert spaces.

Lemma 2.7. *Assume that B is a reflexive Banach space and J its normalized duality mapping. Let $C, T_0 : B \to \mathcal{P}(B^*)$ be maximal monotone operators such that*

(a) *C is regular,*

(b) *$D(T_0) \cap D(C) \neq \emptyset$ and $R(C) = B^*$,*

(c) *$C + T_0$ is maximal monotone.*

Then $R(C + T_0) = B^*$.

Proof. The proof of this lemma consists of two steps.

Step 1.

In this step we prove the following statement: Let T_1 be a maximal monotone operator such that there exists a convex set $F \subset B^*$ with the following condition: for all $u \in F$ there exists an element $y \in B$ such that

$$\sup_{(z,v) \in G(T_1)} \langle v - u, y - z \rangle < \infty, \tag{2.11}$$

then $F^0 \subset R(T_1)$.

Step 2.

In this part of the proof, we apply the statement of Step 1 for the choices $F := R(C) + R(T_0) (= B^*$ by condition (b)) and $T_1 := C + T_0$. Namely, we show here that the set $F = B^*$ satisfies (2.11) for the operator $C + T_0$. Then the conclusion of Step 1 readily gives $R(T_1) = R(T_0 + C) = B^*$.

Step 1.

If $F^0 = \emptyset$, the conclusion trivially holds. Assume now that $F^0 \neq \emptyset$. For any $f \in F$, we can consider the inclusion

$$f \in (T_1 + \varepsilon J)(x_\varepsilon), \;\; \varepsilon > 0, \tag{2.12}$$

where J is the normalized duality mapping in B. We observe that (2.12) has a unique solution thanks to Browder's result (see [7]). Take $v_\varepsilon \in Jx_\varepsilon$ such that $f - \varepsilon v_\varepsilon \in T_1 x_\varepsilon$. Let $a \in B$ be such that (2.11) holds for $y = a$, i.e., there exists $c \in \mathbb{R}$ such that

$$\text{for all } (z, v) \in G(T_1), \; \langle v - f, a - z\rangle \leq c. \tag{2.13}$$

For the choice $(z, v) := (x_\varepsilon, f - \varepsilon v_\varepsilon)$, (2.13) writes

$$\varepsilon\|x_\varepsilon\|^2 \leq \varepsilon\langle v_\varepsilon, a\rangle + c.$$

Using the fact that for any $p, q \in B$, $w \in Jp$ $\|p\|^2 - 2\langle w, q\rangle + \|q\|^2 \geq 0$, the inequality above becomes

$$\frac{\varepsilon}{2}\|x_\varepsilon\|^2 \leq \frac{\varepsilon}{2}\|a\|^2 + c,$$

which gives $\sqrt{\varepsilon}\|x_\varepsilon\| \leq r$ for some $r > 0$ and $\varepsilon > 0$ small enough.

Now let $\tilde{f} \in F^0$ and $\rho > 0$ such that $\tilde{f} + B^*(0, \rho) := \{\tilde{f} + \varphi \in B^* \; : \; \|\varphi\| < \rho\} \subset F$. For any $\varphi \in B^*(0, \rho)$, it holds by (2.11) that there exists $a(\varphi) \in B$ and $c(\varphi) \in \mathbb{R}$ such that

$$\text{for all } (z, v) \in G(T_1), \; \langle v - (\tilde{f} + \varphi), a(\varphi) - z\rangle \leq c(\varphi). \tag{2.14}$$

Take in (2.12) $f = \tilde{f}$ and $x_\varepsilon = \tilde{x}_\varepsilon$. Then choose $(z, v) := (\tilde{x}_\varepsilon, \tilde{f} - \varepsilon\tilde{v}_\varepsilon)$ in (2.14) to get

$$\langle -\varepsilon\tilde{v}_\varepsilon - \varphi, a(\varphi) - \tilde{x}_\varepsilon\rangle \leq c(\varphi).$$

Some rearrangements of the expression above yield

$$\langle \varphi, \tilde{x}_\varepsilon\rangle \leq c(\varphi) + \langle \varphi, a(\varphi)\rangle + \varepsilon\langle \tilde{v}_\varepsilon, a(\varphi)\rangle - \varepsilon\|\tilde{x}_\varepsilon\|^2,$$

which implies

$$\langle \varphi, \tilde{x}_\varepsilon\rangle \leq c(\varphi) + \langle \varphi, a(\varphi)\rangle + \frac{\varepsilon}{2}(\|a(\varphi)\|^2 - \|\tilde{x}_\varepsilon\|^2).$$

Altogether, we conclude

$$\langle \varphi, \tilde{x}_\varepsilon\rangle \leq c(\varphi) + \langle \varphi, a(\varphi)\rangle + \frac{\varepsilon}{2}\|a(\varphi)\|^2,$$

where we are now considering the elements $\tilde{x}_\varepsilon$ as functionals defined in B^*. Taking in the expression above $\varphi = -\psi \in B^*(0, \rho)$, we obtain a bound $K(\varphi)$ such that

$$|\tilde{x}_\varepsilon(\varphi)| \leq K(\varphi), \text{ for all } \varphi \in B^*(0, \rho). \tag{2.15}$$

Take now $\varepsilon = \frac{1}{k}$, and define $x^k := \tilde{x}_{\frac{1}{k}}$ for any k. By (2.15), $|x^k(\varphi)| \leq K(\varphi)$ for any k. Using now Banach–Saks–Steinhauss theorem (see [24]), there exists $\bar{K}$ a constant such that $|x^k(\varphi)| \leq \bar{K}$ for any k and for any $\varphi \in B^*(0,\rho)$. This implies that the sequence $\{x^k\}$ is bounded and hence it has a weakly convergent subsequence. Call $\{x^{k_j}\}$ such a subsequence and $\bar{x}$ its weak limit. Take $v^{k_j} \in Jx^{k_j}$ such that (2.12) holds for $f = \tilde{f}$ and $x_\varepsilon = x^{k_j}$. Observe that J maps bounded sets on bounded sets. Thus, there exists a subsequence of $\{x^{k_j}\}$ (which we still call $\{x^{k_j}\}$ for simplicity) such that

$$\begin{array}{l} w - \lim_{j\to\infty} x^{k_j} = \bar{x}, \\ \tilde{f} - \frac{1}{k_j} v^{k_j} \in T_1(x^{k_j}), \\ w - \lim_{j\to\infty} \tilde{f} - \frac{1}{k_j} v^{k_j} = \tilde{f}. \end{array} \tag{2.16}$$

Using now maximality of T_1, we will show that $\tilde{f} \in T_1(\bar{x})$. Indeed, for any $(z,v) \in G(T_1)$, we have that

$$0 \leq \left\langle \tilde{f} - \frac{1}{k_j} v^{k_j} - v, x^{k_j} - z \right\rangle = \left\langle \tilde{f} - \frac{1}{k_j} v^{k_j}, x^{k_j} - z \right\rangle - \langle v, x^{k_j} - z\rangle.$$

It is clear that $\lim_{j\to\infty}\langle v, x^{k_j} - z\rangle = \langle v, \bar{x} - z\rangle$ and $\lim_{j\to\infty}\langle \tilde{f}, x^{k_j} - z\rangle = \langle \tilde{f}, \bar{x} - z\rangle$. On the other hand,

$$\frac{1}{k_j}|\langle v^{k_j}, x^{k_j} - z\rangle| \leq \frac{1}{k_j}\|v^{k_j}\|\,\|x^{k_j} - z\|,$$

the rightmost term tending to zero because $\{x^{k_j}\}$ and hence $\{v^{k_j}\}$ are bounded, and $k_j \to \infty$. This yields

$$0 \leq \langle \tilde{f} - v, \bar{x} - z\rangle,$$

which implies by maximality that $\tilde{f} \in T_1(\bar{x})$, as we claimed.

Step 2.

We must prove that the set $F = R(C) + R(T_0)$ satisfies (2.11) for the operator $C + T_0$. Let $u \in R(C) + R(T_0)$, $x \in D(C) \cap D(T_0)$, and $w \in T_0(x)$. Then

$$u = w + (u - w).$$

Since $R(C) = B^*$, we can find $y \in B$ such that $(u - w) \in C(y)$. Using now regularity of C, we know that given $(u - w) \in R(C)$ and $x \in D(C)$, there exists some $c \in \mathbb{R}$ with $\sup_{(z,s)\in G(C)}\langle s - (u - w), x - z\rangle \leq c$, which implies that for any $(z,s) \in G(C)$

$$\langle s - (u - w), x - z\rangle \leq c. \tag{2.17}$$

Let $z \in D(T_0) \cap D(C)$ and $v \in T_0(z)$, by monotonicity we get

$$\langle v - w, x - z\rangle \leq 0. \tag{2.18}$$

Adding (2.17) and (2.18) we obtain

$$\langle (s + v) - u, x - z\rangle \leq c$$

for any $s \in C(z)$, $v \in T_0(z)$, i.e., for any $s + v =: t \in (C + T_0)z$. Therefore,

$$\sup_{(z,t)\in G(C+T_0)} \langle t - u, x - z\rangle < \infty.$$

This establishes (2.11) for $F = R(C) + R(T_0)$ and $T_1 = C + T_0$. Now by Step 1 and the fact that $F = B^*$, we obtain that $C + T_0$ is onto. $\square$

Our convergence theorems require two conditions on the operator T, namely para- and pseudomotonicity, which we discuss next. The notion of paramonotonicity was introduced in [18] and further studied in [29]. It is defined as follows. Let $T : B \to \mathcal{P}(B^*)$, and Ω a closed and convex set.

DEFINITION 2.8. *T is paramonotone in Ω if it is monotone and $\langle z-z', w-w'\rangle = 0$ with z, $z' \in \Omega$, $w \in T(z)$, $w' \in T(z')$ implies $w \in T(z'), w' \in T(z)$.*

The next proposition, whose proof can be found in [29], presents the main properties of paramonotone operators.

PROPOSITION 2.9. (i) *If T is the subdifferential ∂f of a convex function $f : B \to \mathbb{R}$, then T is paramonotone in B.*

(ii) *If T is paramonotone in Ω, x^* solves $VIP(T, \Omega)$ and $\bar{x} \in \Omega$ satisfies that there exists an element $\bar{u} \in T(\bar{x})$ such that $\langle \bar{u}, x^* - \bar{x}\rangle \geq 0$, then $\bar{x}$ also solves $VIP(T, \Omega)$.*

(iii) *If T_1 and T_2 are paramonotone in Ω, then $T_1 + T_2$ is paramonotone in Ω.*

Next we recall the definition of pseudomonotonicity, which has been taken from [7], and should not be confused with other uses of the same word, e.g., [31].

DEFINITION 2.10. *Let B be a reflexive Banach space and $T : B \to \mathcal{P}(B^*)$ such that $D(T)$ is closed and convex. T is said to be pseudomonotone if and only if it satisfies the following condition:*

Take any sequence $\{x^k\} \subset D(T)$, converging weakly to an element $x^0 \in D(T)$ and any sequence $\{w^k\} \subset B^*$, with $w^k \in Tx^k$ for all k, such that

$$\limsup_k \langle w^k, x^k - x^0\rangle \leq 0.$$

Then for each $y \in D(T)$ there exists an element $w^0 \in Tx^0$, such that

$$\langle w^0, x^0 - y\rangle \leq \liminf_k \langle w^k, x^k - y\rangle.$$

PROPOSITION 2.11.

(i) *N_C is pseudomonotone for any $C \subset B$, a closed and convex set.*

(ii) *The sum of pseudomonotone operators is pseudomonotone.*

Proof. (i) Consider a sequence $\{(x^k, w^k) \in G(T)\}_k$ in the conditions of Definition 2.10. Call x^0 the weak limit of $\{x^k\}$. As $N_C(\cdot)$ is a closed cone, $0 \in N_C(x^0)$. Take now any $y \in D(N_C) = C$ and $w^0 = 0 \in N_C(x^0)$, then

$$\liminf_k \langle w^k, x^k - y\rangle \geq 0 = \langle w^0, x^0 - y\rangle,$$

which proves our claim.

(ii) See [38, p. 97]. $\square$

3. The variational inequality problem in a Banach space: Existence and convergence analysis. In this section we study first the existence of iterates in algorithm (1.3). It is known that a maximal monotone operator with bounded domain is surjective (see [7]); hence the iterates clearly exist when the domain of $T + N_\Omega + \nabla f$ is bounded. Other classical results due to Browder (see [7]) concerning surjectivity of the sum of maximal monotone operators apply if we assume that $\nabla f(\cdot)$ or T are coercive operators (see Definition 2.4), with no extra assumptions (besides the natural requirement of existence of solutions of the original problem). When $\nabla f(\cdot)$ or T are *not* coercive, what can be said about the existence of the sequence? We answer this question in the case of a coercive Bregman function.

COROLLARY 3.1. *Let f be a coercive Bregman function. Then algorithm* (1.3) *is well defined.*

Proof. Define the operators $T_0 := T + N_\Omega$ and $C := \lambda_k \nabla f$. It holds that

(a) C is regular (since it is the gradient of a proper closed convex function).

(b) $D(T_0) \cap D(C) = D(T) \cap \Omega \cap \mathcal{D}^\circ = D(T) \cap \Omega \neq \emptyset$ (by H_1 and H_2).

(c) $C + T_0$ is maximal monotone (by (b) and Proposition 2.3).

Then by Lemma 2.7, $T_0 + \lambda_k C = T + N_\Omega + \lambda_k \nabla f$ is onto. Hence, given $\lambda_k \nabla f(x^k) \in B^*$ there exists x^{k+1} such that

$$\lambda_k \nabla f(x^k) \in (T + N_\Omega + \lambda_k \nabla f)(x^{k+1}).$$

The uniqueness follows from the strict monotonicity of f. □

Now we analyze the convergence of the sequence given by (1.3) in a reflexive Banach space B. When the solution set is not empty, we get boundedness of the iterates (see Theorem 3.3). Moreover, we establish in Theorem 3.6 that boundedness of the iterates and nonemptyness of X^* are equivalent. Weak convergence of the whole sequence is established when $\nabla f(\cdot)$ is weak-to-weak continuous or when the set X^* of solutions of problem (1.1) is a singleton. Note that the iterative step of algorithm (1.3) can be rewritten in terms of the Bregman distance: given z^k, z^{k+1} solves the inclusion

$$0 \in (T + N_\Omega + \lambda_k \nabla D_f(\cdot, z^k))(z^{k+1}). \tag{3.1}$$

$$\text{If } z^{k+1} = z^k, \textbf{ stop}. \tag{3.2}$$

THEOREM 3.2. *Suppose that the sequence $\{z^k\}$ given by* (1.3) *is well defined and finite. Then the last term is a solution of* (1.1).

Proof. If the sequence is finite, then it must stop at step (3.2). In this case, inclusion (3.1) for $z^{k+1} = z^k$ writes

$$0 \in (T + N_\Omega + \lambda_k \nabla D_f(\cdot, z^k))(z^k) = (T + N_\Omega)(z^k), \tag{3.3}$$

where we used that $\nabla D_f(z^k, z^k) = \nabla f(z^k) - \nabla f(z^k) = 0$. Inclusion (3.3) readily implies that $z^k \in X^*$. □

From now on we assume that the sequence $\{z^k\}$ generated by (1.3) is well defined and infinite.

THEOREM 3.3. *Assume that $X^* \neq \emptyset$. Then it holds that*

(i) *The sequence $\{z^k\}$ generated by* (1.3) *is bounded,*

(ii)$\sum_{k=0}^{\infty} D_f(z^{k+1}, z^k) < \infty$.

Proof. Let $z^* \in X^*$. In order to prove the boundedness of $\{z^k\}$, we will show that the sequence $D_f(z^*, z^k)$ is decreasing, in which case the result will follow from boundedness of the level sets of the function $D_f(z^*, \cdot)$. By the "three point property" we have that

$$\begin{aligned} D_f(z, z^{k+1}) &= D_f(z, z^k) - D_f(z^{k+1}, z^k) \\ &+ \langle \nabla f(z^k) - \nabla f(z^{k+1}), z - z^{k+1} \rangle \end{aligned} \tag{3.4}$$

for any $z \in \Omega$. As we are supposing that the algorithm (1.3) is well defined, there exist $u^{k+1} \in Tz^{k+1}$ and $\varphi_{k+1} \in N_\Omega(z^{k+1})$ such that

$$\frac{1}{\lambda_k}(u^{k+1} + \varphi_{k+1}) = \nabla f(z^k) - \nabla f(z^{k+1}). \tag{3.5}$$

Combining (3.4) with (3.5) and using the definition of normality operator, expression (3.4) for $z = z^*$ becomes

$$D_f(z^*, z^{k+1}) \leq D_f(z^*, z^k) - D_f(z^{k+1}, z^k) - \frac{1}{\lambda_k}\langle u^{k+1}, z^{k+1} - z^*\rangle. \tag{3.6}$$

By definition of X^*, the rightmost term is nonnegative, implying

$$D_f(z^*, z^{k+1}) \leq D_f(z^*, z^k) - D_f(z^{k+1}, z^k). \tag{3.7}$$

Therefore the sequence $D_f(z^*, z^k)$ is decreasing and, as pointed out before, this fact ensures the boundedness of the sequence $\{z^k\}$. Actually, taking $\alpha = D_f(z^*, z^0)$ we have that $\{z^k\} \subset S_{z^*,\alpha}$, which is a bounded set (condition B_1). This completes the proof of (i).

(ii) As the sequence $\{D_f(z^*, z^k)\}$ is also bounded below, it converges to a limit, which we call l^*. By (3.7),

$$D_f(z^{k+1}, z^k) \leq D_f(z^*, z^k) - D_f(z^*, z^{k+1}). \tag{3.8}$$

Summing up inequality (3.8),

$$\sum_{k=0}^{\infty} D_f(z^{k+1}, z^k) \leq \sum_{k=0}^{\infty}(D_f(z^*, z^k) - D_f(z^*, z^{k+1})) = D_f(z^*, z^0) - l^* < \infty,$$

and (ii) is established. □

The theorem above establishes boundedness of the sequence, and thus existence of weak accumulation points. Now we establish below two different hypotheses on the data under which the weak accumulation points are in fact solutions of the original problem (1.1). The first hypothesis is an assumption on the Bregman function f alone, and is the total uniform convexity, together with B_2^* instead of B_2. The second hypothesis is a requirement on the operator T, which we ask to be para- and pseudomonotone.

THEOREM 3.4. *Let X^* be nonempty and $\lambda_k < \lambda$. Suppose further any of the assumptions below:*

A_1: *T is pseudo- and paramonotone with closed domain,*

A_2: *f is a Bregman function with B_2^* instead of B_2, which is also uniformly totally convex.*

Then any weak accumulation point is a solution of the $VIP(T, \Omega)$.

Proof. By (i) of Theorem 3.3, there exists a subsequence $\{z^{k_j}\} \subset \{z^k\}$ which is weakly convergent to a point $\bar{z}$. Using now Theorem 3.3 (ii), $\lim_{j\to\infty} D_f(z^{k_j+1}, z^{k_j}) = 0$. Condition B_3 implies that also $\lim_{j\to\infty} z^{k_j+1} = \bar{z}$.

Case 1: Assume condition A_1. We use B_2 for $x^j = z^{k_j+1}$ and $y^j = z^{k_j}$, which yields

$$\lim_{j\to\infty}(D_f(\bar{z}, z^{k_j+1}) - D_f(\bar{z}, z^{k_j})) = 0. \tag{3.9}$$

Using (3.5), (3.4) for $z =: \bar{z}$, and (3.9) we obtain

$$\begin{aligned} 0 &= \lim\nolimits_{j\to\infty}(D_f(\bar{z}, z^{k_j+1}) - D_f(\bar{z}, z^{k_j}) - D_f(z^{k_j+1}, z^{k_j})) \\ &\leq \liminf\nolimits_{j\to\infty} \tfrac{1}{\lambda_{k_j}}\langle u^{k_j+1}, \bar{z} - z^{k_j+1}\rangle. \end{aligned}$$

By pseudomonotonicity of T, for $z^* \in X^*$, there exists $u \in T(\bar{z})$ with the property

$$\langle u, \bar{z} - z^* \rangle \le \liminf_{j\to\infty} \langle u^{k_j+1}, z^{k_j+1} - z^* \rangle = 0,$$

where the last equality is obtained by (3.6). In fact, for $u^* \in T(z^*)$,

$$\begin{aligned} 0 &\le \langle u^*, z^{k_j+1} - z^* \rangle \le \langle u^{k_j+1}, z^{k_j+1} - z^* \rangle \\ &\le \lambda_{k_j} (D_f(z^*, z^{k_j}) - D_f(z^*, z^{k_j+1}) - D_f(z^{k_j+1}, z^{k_j})), \end{aligned}$$

where we used monotonicity in the second inequality. The claim follows taking limit for $j \to \infty$. By Proposition 2.9(ii), $\bar{z}$ is a solution of $VIP(T, \Omega)$.

Case 2: Consider hypothesis A_2. We follow the same steps as in Remark 2.2(ii) for $\{x^j\} = \{z^{k_j}\}$ and $\{y^j\} = \{z^{k_j+1}\}$. It holds that $\lim_{j\to\infty} \|z^{k_j} - z^{k_j+1}\| = 0$. By B_2^*, we have that $\lim_{j\to\infty}(\nabla f(z^{k_j}) - \nabla f(z^{k_j+1})) = 0$. Now the definition of the algorithm yields $\lim_{j\to\infty} \frac{1}{\lambda_{k_j}}(u^{k_j+1} + \varphi^{k_j+1}) = 0$, for some $u^{k_j+1} \in Tz^{k_j+1}$ and $\varphi^{k_j+1} \in N_\Omega(z^{k_j+1})$. Our hypothesis on λ implies that $\lim_{j\to\infty}(u^{k_j+1} + \varphi^{k_j+1}) = 0$. By demiclosedness of the graph of $T + N_\Omega$ (see Proposition 2.2), we conclude that $0 \in (T + N_\Omega)(\bar{z})$, as we wanted to prove. □

Remark 3.1. The result below establishes conditions under which the whole sequence defined by algorithm (1.3) converges weakly to a solution. A crucial hypothesis is the weak-to-weak continuity of ∇f. This requirement is fulfilled when $X = l^p$ and $f(x) = 1/p\|x\|_p^p$.

THEOREM 3.5. *Consider the same assumptions as in Theorem* 3.4. *If X^* is a singleton or if ∇f is a weak-to-weak continuous mapping, then the whole sequence converges weakly to a solution, i.e., there exists a unique weak accumulation point.*

Proof. The statement is obvious if X^* is a singleton. For the second claim suppose that $\nabla f(\cdot)$ is weak-to-weak continuous. We will show that there exists only one weak accumulation point. Suppose there are two points z_1, z_2, which are weak limits of subsequences of $\{z^k\}$. By Theorems 3.3 and 3.4, we know that z_1 and z_2 belong to X^*. By (3.7), the sequences $\{D_f(z_1, z^k)\}$ and $\{D_f(z_2, z^k)\}$ are convergent. Call l_1 and l_2 their limits. Then

$$\begin{aligned} &\lim_{k\to\infty} \left(D_f(z_1, z^k) - D_f(z_2, z^k)\right) = l_1 - l_2 \\ &= f(z_1) - f(z_2) + \lim_{k\to\infty} \langle \nabla f(z^k), z_2 - z_1 \rangle. \end{aligned} \tag{3.10}$$

Call $l := \lim_{k\to\infty} \langle \nabla f(z^k), z_2 - z_1 \rangle$. If $w - \lim_{j\to\infty} z^{k_j} = z_1$, and $w - \lim_{j\to\infty} z^{l_j} = z_2$, taking $k = k_j$ in (3.10) and using the weak-to-weak continuity of $\nabla f(\cdot)$, we get that $l = \langle \nabla f(z_1), z_2 - z_1 \rangle$. Repeating the same argument with $k = l_j$ in (3.10), we get $l = \langle \nabla f(z_2), z_2 - z_1 \rangle$. Hence, $\langle \nabla f(z_2) - \nabla f(z_1), z_2 - z_1 \rangle = 0$. By strict convexity of f, we conclude that $z_1 = z_2$, which establishes the uniqueness of the weak accumulation point. □

The result below establishes that boundedness of the sequence given by algorithm (1.3) is a sufficient and necessary condition for existence of solutions of problem (1.1).

THEOREM 3.6. *Consider the assumptions A_1 or A_2 of Theorem* 3.4. *If $X^* = \emptyset$, then the sequence is unbounded. Conversely, if $X^* \neq \emptyset$, then the sequence is bounded.*

Proof. The second claim follows from Theorem 3.3(i). We prove the first one. Suppose that $X^* = \emptyset$ and $\{z^k\}$ bounded. Then there are a convex, closed, and bounded set S and a positive number r such that

$$\overline{\{z^k\}}^w \subset B(0, r) \subset S^0, \tag{3.11}$$

where $\overline{X}^w$ stands for the weak closure and $B(0,r) := \{y \in B : \|y\| \leq r\}$ is a (strongly and weakly) closed ball in B. Define the operator $\tilde{T} := T + N_S$, where N_S is the normality operator associated with S. The operator $\tilde{T}$ is maximal monotone by Proposition 2.3 and the fact that $D(T) \cap S^0 \supset \{z^k\} \neq \emptyset$.

Consider the sequence $\{\tilde{z}^k\}$ generated by method (1.3) for $\tilde{T}$. First, we prove that this sequence is well defined. Recall that any maximal monotone operator with bounded domain is onto (see [7]). The operator $\tilde{T}$ has bounded domain, and so the same happens with the operator $T^k(\cdot) := (\tilde{T} + N_\Omega + \lambda_k \nabla f)(\cdot) - \lambda_k \nabla f(z^k)$ used in each iteration. Thus, T^k is onto, and so $\tilde{z}^{k+1}$ exists. The uniqueness of $\tilde{z}^{k+1}$ follows from strict monotonicity of $\nabla f(\cdot)$. Altogether, we have that $\tilde{z}^{k+1}$ is uniquely defined as the solution of the inclusion on y:

$$0 \in (\tilde{T} + N_\Omega + \lambda_k \nabla f)(y) - \lambda_k \nabla f(\tilde{z}^k). \tag{3.12}$$

Thus, we established the well-definedness of the sequence $\{\tilde{z}^k\}$.

Our second step will be to prove by induction that if method (1.3) is applied to $\tilde{T}$ with $\tilde{z}^0 = z^0$, then $\tilde{z}^k = z^k$ for all k. The claim is true for $k = 0$. Suppose that $\tilde{z}^k = z^k$. The point z^{k+1} satisfies

$$0 \in (T + N_\Omega + \lambda_k \nabla f) z^{k+1} - \lambda_k \nabla f(z^k). \tag{3.13}$$

Since z^{k+1} belongs to S^0, we have that $N_S(z^{k+1}) = 0$, which, together with (3.13) and the induction hypothesis, gives

$$0 \in (T + N_S)(z^{k+1}) + N_\Omega(z^{k+1}) + \lambda_k(\nabla f(z^{k+1}) - \nabla f(\tilde{z}^k)).$$

Therefore, z^{k+1} is the unique solution of (3.12), and, as a consequence, $\tilde{z}^{k+1} = z^{k+1}$. The induction step is complete and we conclude that $\tilde{z}^k = z^k$ for all k. Our goal is to prove that any weak accumulation point of $\{z^k\}$ is a solution of $VIP(T, \Omega)$, thus contradicting the hypothesis $X^* = \emptyset$. As $\tilde{z}^k = z^k$ for all k, it will be enough to prove that any weak accumulation point of $\{\tilde{z}^k\}$ is a solution of $VIP(T, \Omega)$. Before we establish this fact, let us observe that if z is a weak accumulation point of $\{\tilde{z}^k\}$ which solves $VIP(\tilde{T}, \Omega)$, then it also solves $VIP(T, \Omega)$. Indeed, let $z \in \overline{\{\tilde{z}^k\}}^w$ be such that there exists $u \in \tilde{T}(z)$ with $\langle u, x - z\rangle \geq 0$ for any $x \in \Omega$. As $z \in \overline{\{\tilde{z}^k\}}^w = \overline{\{z^k\}}^w \subset S^0$, it holds that $\tilde{T}(z) = T(z) + N_S(z) = T(z)$. Hence, there exists $u \in T(z) = \tilde{T}(z)$ such that $\langle u, x - z\rangle \geq 0$ for any $x \in \Omega$. This proves that z solves $VIP(T, \Omega)$. It only remains to prove that any weak accumulation point of $\{\tilde{z}^k\}$ (and hence of $\{z^k\}$) solves $VIP(\tilde{T}, \Omega)$. In order to establish this result, let us check that the requirements of Theorem 3.4 hold for $\tilde{T}$ under conditions A_1 or A_2. In order to do this, let us check first that the set of solutions of $VIP(\tilde{T}, \Omega)$ is not empty. As mentioned above, the elements of this set are the zeroes of $\tilde{T} + N_\Omega = T + N_S + N_\Omega$. Note that $D(\tilde{T} + N_\Omega) = D(T) \cap \Omega \cap S \subset S$. Since S is bounded, $\tilde{T} + N_\Omega$ is onto (see [7]), and therefore it has zeroes. Then $VIP(\tilde{T}, \Omega)$ is not empty.

We prove now that any of the assumptions A_1 or A_2 on the data imply that algorithm (1.3) applied to $\tilde{T}$ generates a sequence whose accumulation points are all solutions of $VIP(\tilde{T}, \Omega)$. This is trivial for hypothesis A_2, which does not depend on the operator.

Assume now hypothesis A_1. Since $\tilde{T} = T + \partial(\chi_S)$, $\tilde{T}$ is paramonotone as a sum of two paramonotone operators (see Proposition 2.9(iii)). It follows from Proposition 2.11(i) that N_S is pseudomonotone. Thus $\tilde{T}$ is the sum of two pseudomonotone operators, and therefore it is pseudomonotone (see Proposition 2.11(ii)). Hence all the requirements of Theorem 3.4 hold for $\tilde{T}$. This implies that any weak accumulation point of $\{\tilde{z}^k\}$ is a solution of $VIP(\tilde{T},\Omega)$.

By boundedness, $\{\tilde{z}^k\}$, and therefore $\{z^k\}$, has weak cluster points and, as proved in Theorem 3.4, all of them are solutions of $VIP(\tilde{T},\Omega)$. As observed above this implies that all this elements are also solutions of $VIP(T,\Omega)$, in contradiction with our hypothesis. We conclude that $\{z^k\}$ is unbounded. □

4. An application: Augmented Lagrangians in Banach spaces. The connection between augmented Lagrangian methods and proximal-type methods in the context of finite dimensional spaces or Hilbert spaces has been the subject of intense investigation since the pioneer work of [44], [43]; see, for example, [27], [26], [34]. In an arbitrary reflexive Banach space, augmented Lagrangians have been studied for the first time in [11], [37], as an application for solving the *stochastic convex feasibility problem* (*SCFP*) (see [9]). This problem is the minimization of a convex function subject to (possibly infinitely many) constraints. In [11], the authors define a Lagrangian and a dual problem for (SCFP). They establish Karush–Khun–Tucker conditions, which, under reasonable circumstances, are necessary and sufficient for a pair to be a primal-dual solution of (SCFP). It is proved in [11] that primal-dual solutions of (SCFP) are the zeroes of a maximal monotone operator $\tilde{T}$, associated to the Lagrangian. Hence, algorithm (1.3) for finding zeroes of monotone operators can be applied to $\tilde{T}$, as long as we find a Bregman function which satisfies conditions B_2^* and B_5 in the primal and dual variables. First we describe briefly (SCFP). Second we present a particular instance of (SCFP) for which a specific Bregman function satisfying conditions B_2^* and B_5 can be given.

Problem (SCFP):

Take X to be a reflexive separable Banach space with dual X^*, $f : X \to \mathbb{R}$ a convex and continuously differentiable function, Λ a nonempty set, and $(\Lambda, \mathcal{A}, \mu)$ a complete probability space. For defining the constraints of the problem, consider $F : X \times \Lambda \to \mathbb{R}$ such that

- $F(\cdot,\lambda) : X \to \mathbb{R}$ is convex and continuously differentiable.
- $F(x,\cdot)$, $\partial_x F(x,\cdot) : \Lambda \to \mathbb{R}$ belong to $\mathcal{L}^p(\Lambda)$, with $p > 1$.

Consider the problem

$$\text{(SCFP)} \qquad \begin{array}{c} \min f(x) \\ \text{subject to } F(x,\lambda) \le 0 \quad \text{a.e. } (\Lambda), \end{array}$$

where the expression "a.e. (Λ)" means that

$$\mu(\{\lambda \in \Lambda \mid F(x,\lambda) \le 0\}) = 1.$$

The Lagrangian $L : X \times \mathcal{L}^q(\Lambda) \to \overline{\mathbb{R}}$ associated with (SCFP) is defined as

$$L(x,y) := \begin{cases} f(x) + \int_\Lambda F(x,\lambda) y(\lambda) d\mu(\lambda) & \text{if } y(\lambda) \ge 0 \ \text{ a.e. } (\Lambda), \\ \\ -\infty & \text{c.c.} \end{cases}$$

Take $q = p/(p-1)$. In a similar way as in [44], define the (maximal monotone) operator $\tilde{T} : X \times \mathcal{L}^q(\Lambda) \to \mathcal{P}(X^* \times \mathcal{L}^p(\Lambda))$ as

$$\tilde{T}(x,y) := (\partial_x L(x,y), -\partial_y L(x,y)).$$

Then the *dual* problem associated with the *primal* problem (SCFP) is find $y \in \mathcal{L}^q(\Lambda)$ such that

$$y \in arg\max\{\varphi(z) \mid z \in \mathcal{L}^q(\Lambda),\ z(\lambda) \ge 0 \quad \text{a.e. } (\Lambda)\},$$

where $\varphi : \mathcal{L}^q(\Lambda) \to [-\infty, \infty)$ is the function

$$\varphi(z) := \inf\{L(x, z) \mid x \in X\}.$$

Karush–Khun–Tucker conditions can be stated in this context, and under mild assumptions a pair (x, y) satisfies these conditions if and only if it is a zero of $\tilde{T}$ [11, Chapter 2]. These are the *primal-dual optimal pairs* associated to (SCFP). In [37], a doubly augmented Lagrangian method is defined. It requires auxiliary Bregman functions g, h in the primal and dual variables, respectively.

Particular instance of (SCFP):

Take $X = \mathcal{L}^s(\Lambda)$, $s > 1$, $g : \mathcal{L}^s(\Lambda) \to \mathbb{R}$, and $h : \mathcal{L}^q(\Lambda) \to \mathbb{R}$ given by

$$g(x) := (1/s)\|x\|_s^s\,, \quad h(y) := (1/q)\|y\|_q^q.$$

The fact that g and h satisfy conditions B_2^* and B_5 has been observed in Remarks 2.1(i) and 2.2(ii), respectively. We can now set in the definition of algorithm (1.3):

$$\begin{aligned} &B := \mathcal{L}^s(\Lambda) \times \mathcal{L}^q(\Lambda),\\ &\Omega := \mathcal{L}^s(\Lambda),\\ &T := \tilde{T},\\ &f(x, y) := g(x) + h(y). \end{aligned} \tag{4.1}$$

As f satisfies A_2 of Theorem 3.4, algorithm (1.3) generates a bounded sequence such that any weak accumulation point is a primal-dual solution of (SCFP), as long as there exist primal-dual solutions of (SCFP). If Λ is denumerable, then by Remark 3.1 and Theorem 3.5, the whole sequence converges weakly to a primal-dual solution.

ERRATUM: HOFFMAN'S ERROR BOUND, LOCAL CONTROLLABILITY, AND SENSITIVITY ANALYSIS[*]

ABDERRAHIM JOURANI[†]

Abstract. The proofs of Lemma 5.2 and Theorem 5.1 in [*SIAM J. Control Optim.,* 38 (2000), pp. 947–970] have a common error which concerns the existence of (locally) Lipschitz selections. Indeed, Lemma 5.2 is true in the case where the multivalued mapping G is convex-valued, and in our case this assumption is not satisfied. So some modifications are needed. The statement of Theorem 5.1 (which does not use Lemma 5.2) is as follows.

PII. S0363012900370466

Theorem 1. *Suppose that the graph GrF of the multivalued mapping F is closed and that*

$$(0, v^*) \in \partial^F_{(u,v)} h(\overline{u}, 0, \overline{y}) \quad \Longrightarrow \quad v^* = 0, \tag{1}$$

where $h(u,v,y) = d(u,v,GrF_y)$ and $F_y : u \to F(u,y)$. Suppose also that the multivalued mapping $y \to F_y(u)$ is pseudo-Lipschitzian around $\overline{y}$ uniformly in u in some neighborhood of $\overline{u}$; that is, there exist $a > 0$ and $r > 0$ such that for all $y, y' \in \overline{y} + rB_Y$, and $u \in \overline{u} + rB_U$

$$F_y(u) \cap rB_V \subset F_{y'}(u) + a\|y - y'\|B_V.$$

Then the multivalued mapping $(y, v) \to F_y^{-1}(v)$ is pseudo-Lipschitzian around $(\overline{y}, 0, \overline{u})$.

This allows us to modify the statement of Corollary 5.4 in [1].

Corollary 2. *Let f be locally Lipschitzian around the point $(\overline{u}, \overline{y})$ solution of*

$$f(u, y) = 0.$$

Suppose that

$$0 \in \partial^F_u (v^* \circ f)(\overline{u}, \overline{y}) \quad \Longrightarrow \quad v^* = 0.$$

Then the multivalued mapping S defined by

$$S(y) = \{x : \quad f(x, y) = 0\}$$

is pseudo-Lipschitzian around $(\overline{y}, \overline{u})$.

Consequently, I am withdrawing Lemma 5.2 and the third remark after it in [1].

VARIATIONAL ANALYSIS OF THE ABSCISSA MAPPING FOR POLYNOMIALS[*]

JAMES V. BURKE[†] AND MICHAEL L. OVERTON[‡]

Abstract. The abscissa mapping on the affine variety $\mathcal{M}_n$ of monic polynomials of degree n is the mapping that takes a monic polynomial to the maximum of the real parts of its roots. This mapping plays a central role in the stability theory of matrices and dynamical systems. It is well known that the abscissa mapping is continuous on $\mathcal{M}_n$, but not Lipschitz continuous. Furthermore, its natural extension to the linear space $\mathcal{P}_n$ of polynomials of degree n or less is not continuous. In our analysis of the abscissa mapping, we use techniques of modern nonsmooth analysis described extensively in Variational Analysis (R. T. Rockafellar and R. J.-B. Wets, Springer-Verlag, Berlin, 1998). Using these tools, we completely characterize the subderivative and the subgradients of the abscissa mapping, and establish that the abscissa mapping is everywhere subdifferentially regular. This regularity permits the application of our results in a broad context through the use of standard chain rules for nonsmooth functions. Our approach is epigraphical, and our key result is that the epigraph of the abscissa map is everywhere Clarke regular.

Key words. nonsmooth analysis, polynomials, stability, subgradient, Clarke regular

PII. S0363012900367655

Let $\mathcal{P}_n$ denote the linear space of complex polynomials of degree n or less, and let $\mathcal{M}_n$ denote the affine variety in $\mathcal{P}_n$ consisting of the monic polynomials of degree n. In this article we study variational properties of the *abscissa mapping*

$$a : \mathcal{M}_n \to \mathbb{R}$$

given by

$$a(p) = \max \{ \operatorname{Re} \zeta \mid p(\zeta) = 0 \} .$$

Our study is partly motivated by the need to provide tools for understanding the variational behavior of the *spectral abscissa mapping* on the n by n complex matrices defined by

$$\alpha(M) = a(\det(\lambda I - M)).$$

Properties of the spectral abscissa are closely tied to stability theory for matrices and dynamical systems. Thus, the variational behavior of the spectral abscissa has important consequences for the sensitivity of the stability properties of such systems under perturbation. In [BO], we apply the variational results obtained in this paper to study the variational behavior of the spectral abscissa map.

The abscissa mapping has a number of characteristics that make it difficult to analyze. It is well known that a is continuous, but not Lipschitz continuous, on

$\mathcal{M}_n$. In addition, the natural extension of a to all of $\mathcal{P}_n$ is not continuous at any point of the subspace $\mathcal{P}_{n-1}$. In this paper, we show that the techniques of modern nonsmooth analysis described in the recent book [RW98] are ideally suited to the study of mappings of this type. Thus, a secondary purpose of this paper is to illustrate the usefulness of the nonsmooth analysis techniques developed by many authors over the last 30 years by applying them to a classical function of great practical importance. Using techniques from nonsmooth analysis, we are able to establish that the abscissa mapping is everywhere *subdifferentially regular*. This remarkable result has major consequences for the development of a calculus for the variational behavior of the abscissa mapping under composition.

It needs to be stated that our analysis owes a great debt to earlier work of Levantovskii [Lev80]. Levantovskii studied the set of stable polynomials, i.e., the set of polynomials whose abscissa is nonpositive, and provided an outline for the derivation of the tangent cone to this set. We generalize this proof technique to establish the key result of section 1 (Theorem 1.2).

The paper is organized as follows; we assume that the reader is familiar with [RW98]. Section 1 is devoted to the derivation of the *subderivative* of a. This is done via an *epigraphical* approach, where we derive the formula for the subderivative from a description of the *tangent cone* to the epigraph of the abscissa mapping a. In addition, we develop some basic tools that relate the prime factorization of a polynomial to a factorization of the tangent cone. The key to this result is the local factorization Lemma 1.4. In section 2, we use the representation of the tangent cone obtained in section 1 to derive a representation for the set of *regular normals* to the epigraph of a. This in turn yields a representation for the set of *regular subgradients* for a at any point in $\mathcal{M}_n$. In section 3, we establish that the abscissa mapping is everywhere subdifferentially regular. The key result is that the epigraph of the abscissa map is Clarke regular.

Most of the notation that we use is introduced as it is required. However, it is useful to briefly describe our conventions for discussing polynomials in their distinct roles as points in the linear space $\mathcal{P}_n$ and as functions over the complex field. One could identify $\mathcal{P}_n$ with $\mathbb{C}^{n+1}$ and attempt to derive the variational properties of a as a mapping on $\mathbb{C}^{n+1}$, but this would completely ignore the very rich underlying algebraic structure of polynomials. Since it is the roots of polynomials that lie at the heart of the mapping a, it is the polynomial perspective that drives our analysis. Given a polynomial $p \in \mathcal{P}_n$, we will always use the Greek letter λ to denote the indeterminant associated with representing the polynomial as a function. Thus we write $p(\lambda)$ as the associated polynomial function. Monomials and shifted monomials play a central role in our analysis. For this reason we give them a special notation so that we can discuss them as points in $\mathcal{P}_n$. We write

$$e_{(\ell,\lambda_0)}(\lambda) = (\lambda - \lambda_0)^\ell.$$

1. The subderivative and the tangent cone.

To apply the tools developed in [RW98], we first extend the definition of a to the entire linear space $\mathcal{P}_n$:

$$a : \mathcal{P}_n \to \mathbb{R}$$

is given by

$$a(p) = \begin{cases} \max\{\operatorname{Re}\zeta \mid p(\zeta) = 0\} & \text{if } p \in \mathcal{M}_n, \\ +\infty & \text{otherwise.} \end{cases}$$

This extension allows us to focus our attention on the set of monic polynomials. In particular, we have $\mathrm{dom}\,(a) = \{p \mid a(p) < +\infty\} = \mathcal{M}_n$. Given $p \in \mathcal{M}_n$, our goal is to derive a formula for $da(p)$, the *subderivative* of the mapping a. Following [RW98, Definition 8.1], the subderivative of a at a point $p \in \mathcal{M}_n$ is the mapping $da(p) : \mathcal{P}_n \to \mathbb{R} \cup \{\pm\infty\}$ given by

$$da(p)(\hat{q}) = \liminf_{\substack{\tau \searrow 0 \\ q \to \hat{q}}} \frac{a(p + \tau q) - a(p)}{\tau},$$

where the parameter τ is understood to be real. Since a is $+\infty$ on $\mathcal{P}_n \backslash \mathcal{M}_n$, we have

$$\mathrm{dom}\,(da(p)) = \{p \mid da(p) < +\infty\} \subset \mathcal{P}_{n-1}.$$

Hence, we restrict our attention to the behavior of $da(p)$ on the subspace $\mathcal{P}_{n-1}$.

We approach the problem of computing $da(p)$ from an epigraphical perspective. The epigraph of a is the set

$$\mathrm{epi}\,(a) = \{(p, \mu) \mid a(p) \leq \mu < +\infty\}.$$

Using this set, we can construct $da(p)$ from the formula

$$\mathrm{epi}\,(da(p)) = T_{\mathrm{epi}\,(a)}(p, a(p)) \tag{1.1}$$

[RW98, Theorem 8.2]. Here $T_{\mathrm{epi}\,(a)}(p, a(p))$ is the *tangent cone* to the set $\mathrm{epi}\,(a)$ at the point $(p, a(p))$. For a subset C of a finite dimensional linear space X, we have

$$T_C(x) = \left\{ d \;\middle|\; \begin{array}{c} \exists\ \{x^k\} \subset C \text{ and } \{t_k\} \subset \mathbb{R}_+ \text{ such that} \\ x^k \to x,\ t_k \searrow 0, \text{ and } t_k^{-1}(x^k - x) \to d \end{array} \right\} \tag{1.2}$$

$$= \left\{ \gamma d \;\middle|\; \begin{array}{c} \gamma \geq 0, \text{ and there exits } \{x^k\} \subset C \\ \text{with } x^k \to x \text{ such that } d = \displaystyle\lim_{k\to\infty} \frac{x^k - x}{\|x^k - x\|} \end{array} \right\}, \tag{1.3}$$

where $\mathbb{R}_+$ is the set of nonnegative real numbers and $\|\cdot\|$ is any norm on X. By considering $\mathcal{P}_{n-1}$ as a subspace of $\mathcal{P}_n$, we have

$$T_{\mathrm{epi}\,(a)}(p, \mu) \subset \mathcal{P}_{n-1} \times \mathbb{R} \qquad \text{for all } \mu \geq a(p), \tag{1.4}$$

since a is $+\infty$ on $\mathcal{P}_n \backslash \mathcal{M}_n$. In particular,

$$T_{\mathrm{epi}\,(a)}(p, \mu) = \mathcal{P}_{n-1} \times \mathbb{R} \qquad \text{whenever } \mu > a(p), \tag{1.5}$$

since a is continuous on $\mathcal{M}_n$.

In our first lemma we show that the tangential geometry of $\mathrm{epi}\,(a)$ remains essentially unchanged under the linear transformations corresponding to a uniform shift of the roots. For each $\lambda_0 \in \mathbb{C}^n$ define the linear transformation $H_{\lambda_0} : \mathcal{P}_n \to \mathcal{P}_n$ by

$$H_{\lambda_0}(p)(\lambda) = p(\lambda - \lambda_0).$$

Lemma 1.1. *Let λ_0 be a given complex number. Then*

$$T_{epi\,(a)}(H_{\lambda_0}(p), \eta + Re\,(\lambda_0)) = \{(H_{\lambda_0}(v), \mu) \,:\, (v, \mu) \in T_{epi\,(a)}(p, \eta)\}\ .$$

Proof. Define the affine transformation $\hat{H}_{\lambda_0} : \mathcal{P}_n \times \mathbb{R} \to \mathcal{P}_n \times \mathbb{R}$ by

$$\hat{H}_{\lambda_0}(p,\mu) = (H_{\lambda_0}(p), \mu + \operatorname{Re}(\lambda_0)).$$

Clearly, the mapping $\hat{H}_{\lambda_0}$ is invertible (indeed, $\hat{H}_{\lambda_0}^{-1} = \hat{H}_{-\lambda_0}$). In addition,

$$\hat{H}_{\lambda_0}^{-1}(\operatorname{epi}(a)) = \operatorname{epi}(a).$$

Therefore, by [RW98, Exercise 6.7] and the invertibility of $\hat{H}_{\lambda_0}$, we have

$$\begin{aligned} T_{\operatorname{epi}(a)}(H_{\lambda_0}(p), \mu + \operatorname{Re}(\lambda_0)) &= T_{\operatorname{epi}(a)}(\hat{H}_{\lambda_0}(p,\mu)) \\ &= \nabla \hat{H}_{\lambda_0}(p,\mu) T_{\operatorname{epi}(a)}(p,\mu) \\ &= \{(H_{\lambda_0}(v), \mu) \,:\, (v,\mu) \in T_{\operatorname{epi}(a)}(p,\eta)\}. \qquad \square \end{aligned}$$

We now derive a formula for the tangent cone to epi (a) at $(e_{(n,0)}, 0)$. All of our subsequent analysis relies on this key result. The proof is rather long and involved. It is based on an outline provided by Levantovskii [Lev80] for deriving a formula for the tangent cone to the set of stable polynomials.

THEOREM 1.2. *We have* $(v,\eta) \in T_{epi\,(a)}(e_{(n,0)}, 0)$, *with*

$$v = \beta_1 e_{(n-1,0)} + \beta_2 e_{(n-2,0)} + \cdots + \beta_n, \tag{1.6}$$

if and only if

$$Re\,\beta_1 \geq -n\eta, \tag{1.7}$$

$$Re\,\beta_2 \geq 0, \tag{1.8}$$

$$Im\,\beta_2 = 0, \text{ and} \tag{1.9}$$

$$\beta_k = 0 \text{ for } k = 3, \ldots, n. \tag{1.10}$$

Therefore, for $v \in \mathcal{P}_{n-1}$ *given by* (1.6), *we have*

$$da(e_{(n,0)})(v) = \begin{cases} -\frac{Re\,\beta_1}{n} & \text{if (1.8)–(1.10) hold, and} \\ +\infty & \text{otherwise.} \end{cases}$$

Proof. We begin by showing that (1.7)–(1.10) and (1.6) imply that (v,η) is an element of the tangent cone $T_{\operatorname{epi}(a)}(e_{(n,0)}, 0)$. This is done by constructing a curve in epi (a) converging to $(e_{(n,0)}, 0)$ and having derivative equal to (v,η). Consider the polynomials having coefficients that are polynomials in ξ and given by

$$\begin{aligned} p(\lambda,\xi) &= \left(\lambda + \frac{\beta_1}{n}\xi\right)^{n-2} \left(\lambda + \sqrt{-1}(\beta_2\xi)^{\frac{1}{2}} + \frac{\beta_1}{n}\xi\right) \left(\lambda - \sqrt{-1}(\beta_2\xi)^{\frac{1}{2}} + \frac{\beta_1}{n}\xi\right) \\ &= \left(\lambda^{n-2} + (n-2)\frac{\beta_1}{n}\xi\lambda^{n-3} + o(\xi)\right) \left(\lambda^2 + 2\frac{\beta_1}{n}\xi\lambda + \beta_2\xi + o(\xi)\right) \\ &= \lambda^n + \beta_1\xi\lambda^{n-1} + \beta_2\xi\lambda^{n-2} + o(\xi) \\ &= \lambda^n + \xi v(\lambda) + o(\xi)\ . \end{aligned}$$

Let ξ be real and positive. Then $a(p(\lambda,\xi)) = -\frac{\operatorname{Re}(\beta_1)}{n}\xi$. Therefore,

$$\lim_{\xi \searrow 0} \frac{a(p(\lambda,\xi)) - a(\lambda^n)}{\xi} = -\frac{\operatorname{Re}(\beta_1)}{n} \leq \eta,$$

which yields the result.

We now show that any element (v,η) in the tangent cone $T_{\mathrm{epi}\,(a)}(e_{(n,0)},0)$ must satisfy (1.7)–(1.10) if v is given the representation (1.6). To this end, we make use of the following norm on $\mathcal{P}_n \times \mathbb{R}$:

$$\left\|(b_0 e_{(n,0)} + b_1 e_{(n-1,0)} + \cdots + b_n, \mu)\right\| = \max\{\,|b_0|\,,\,|b_1|\,,\ldots,\,|b_n|\,,\,|\mu|\,\}\ .$$

Let $(v,\eta) \in T_{\mathrm{epi}\,(a)}(e_{(n,0)},0)$ with v written as in (1.6). By definition there is a sequence $\{(p_k,\mu_k)\} \in \mathrm{epi}\,(a)$ with $(p_k,\mu_k) \to (e_{(n,0)},0)$ and

$$\text{(1.11)} \qquad \frac{((p_k,\mu_k) - (e_{(n,0)},0))}{\left\|(p_k,\mu_k) - (e_{(n,0)},0)\right\|} \to (\gamma v, \gamma\eta)$$

for some $\gamma > 0$.

Given $\epsilon \in \mathbb{C}^n$, define $\sigma_j\ :\ \mathbb{C}^n \to \mathbb{C}$ for $j = 1,2,\ldots,n$ to be the symmetric functions

$$\text{(1.12)}\,\sigma_1(\epsilon) = \sum_{t=1}^{n} \epsilon_t \quad \text{and} \quad \sigma_j(\epsilon) = \sum_{1\le t_1<t_2<\cdots<t_j\le n} \left(\prod_{s=1}^{j} \epsilon_{t_s}\right) \text{ for } j = 2,\ldots,n,$$

and set $\sigma = (\sigma_1,\sigma_2,\cdots,\sigma_n)^T$. For each $k = 1,2,\ldots$ there exist complex numbers $\epsilon^k = (\epsilon_{k1},\ \epsilon_{k2},\ldots,\epsilon_{kn})^T \to 0$ such that $\mathrm{Re}\,(\epsilon_{kj}) \ge -\mu_k$ for $j = 1,2,\ldots,n$ and

$$\text{(1.13)} \qquad p_k(\lambda) = \prod_{j=1}^{n}(\lambda + \epsilon_{kj}) = (\lambda^n + \sigma_1(\epsilon^k)\lambda^{n-1} + \cdots + \sigma_n(\epsilon^k))\ .$$

For each $k = 1,2,\ldots$, set

$$\nu_k = \left\|(p_k,\mu_k) - (e_{(n,0)},0)\right\| = \max\{(\left\|\sigma(\epsilon^k)\right\|_\infty,\,|\mu_k|\,\}.$$

Then the limit (1.11) can be interpreted componentwise as

$$\gamma\beta_j = \lim_{k\to\infty} \frac{\sigma_j(\epsilon^k)}{\nu_k}$$

for $j = 1,2,\ldots,n$. Set $\tilde\sigma_j = \gamma\beta_j$ for $j = 1,2,\ldots,n$. We establish the result by showing that

$$\text{(1.14)} \quad \mathrm{Re}\,\tilde\sigma_1 \ge -n\gamma\eta,\ \ \mathrm{Re}\,\tilde\sigma_2 \ge 0,\ \ \mathrm{Im}\,\tilde\sigma_2 = 0,\ \text{ and } \tilde\sigma_k = 0 \text{ for } k = 3,4,\ldots,n.$$

Clearly, $\mathrm{Re}\,(\tilde\sigma_1) \ge -n\gamma\eta$ since $\mathrm{Re}\,(\sigma_1(\epsilon^k)) = \sum_{j=1}^{n} \mathrm{Re}\,(\epsilon_{kj}) \ge -n\mu_k$ for all $k = 1,2,\ldots$ and $\mu_k/\nu_k \to \gamma\eta$. We now show that $\tilde\sigma_j = 0$ for $j = 3,4,\ldots,n$. First note that

$$\text{(1.15)} \qquad \sigma_j(\epsilon) = o(\|\epsilon\|_\infty^2) \quad \text{for } j = 3,4,\ldots,n.$$

Define

$$\text{(1.16)} \qquad \alpha_{kj} = \mathrm{Re}\,\epsilon_{kj} \quad \text{and} \quad \delta_{kj} = \mathrm{Im}\,\epsilon_{kj}$$

for $j = 1,2,\ldots,n$ and $k = 1,2,\ldots$. Note that $\alpha_{kj} \ge -\mu_k$ for $j = 1,2,\ldots,n$ and $k = 1,2,\ldots$. In addition, it is easily verified that

$$\mathrm{Re}\,\sigma_2(\epsilon^k) = \sum_{s<t}[\alpha_{ks}\alpha_{kt} - \delta_{ks}\delta_{kt}] \text{ and } \mathrm{Im}\,\sigma_2(\epsilon^k) = \left[\sum_{s<t}\alpha_{ks}\delta_{kt} + \sum_{s<t}\delta_{ks}\alpha_{kt}\right].$$

Then, by definition,

$$\begin{aligned}\left|\sigma_1(\epsilon^k)\right|^2 &= \left\|\epsilon^k\right\|_2^2 + 2\sum_{s<t} \operatorname{Re}(\bar{\epsilon}_{ks}\epsilon_{kt}) \\ &= \left\|\epsilon^k\right\|_2^2 + 2\sum_{s<t} \alpha_{ks}\alpha_{kt} + 2\sum_{s<t} \delta_{ks}\delta_{kt} \\ &= \left\|\epsilon^k\right\|_2^2 + 4\sum_{s<t} \alpha_{ks}\alpha_{kt} + 2\sum_{s<t}[\delta_{ks}\delta_{kt} - \alpha_{ks}\alpha_{kt}] \\ &= \left\|\epsilon^k\right\|_2^2 + 4\sum_{s<t} \alpha_{ks}\alpha_{kt} - 2\operatorname{Re}\sigma_2(\epsilon^k) \\ &\geq \left\|\epsilon^k\right\|_\infty^2 - 2n(n-1)\mu_k^2 - 2\operatorname{Re}(\sigma_2(\epsilon^k)) \\ &\geq \left\|\epsilon^k\right\|_\infty^2 - 4n(n-1)\max\{\,|\mu_k|\,,\,\left|\sigma_2(\epsilon^k)\right|\,\}\,,\end{aligned}$$

whenever $|\mu_k| \leq 1$. Hence, if ϵ^k and μ_k are such that $\left|\sigma_1(\epsilon^k)\right| < \frac{\|\epsilon^k\|_\infty}{2}$ and $|\mu_k| \leq 1$, then, for $\Delta = \frac{3}{16n^2}$, we have

$$\max\{\,|\mu_k|\,,\,\left|\sigma_2(\epsilon^k)\right|\,\} > \Delta\left\|\epsilon^k\right\|_\infty^2.$$

On the other hand, if $\left|\sigma_1(\epsilon^k)\right| \geq \frac{\|\epsilon^k\|_\infty}{2}$ and $\left\|\epsilon^k\right\|_\infty \leq 1$, then $\left|\sigma_1(\epsilon^k)\right| \geq \frac{\|\epsilon^k\|_\infty^2}{4}$. Thus, in either case, we have

$$\max(\,|\mu_k|\,,\,\left|\sigma_1(\epsilon^k)\right|,\,\left|\sigma_2(\epsilon^k)\right|\,) \geq \Delta\left\|\epsilon^k\right\|_\infty^2, \tag{1.17}$$

whenever $\left\|\epsilon^k\right\|_\infty \leq 1$ and $|\mu_k| \leq 1$. This implies that

$$\nu_k \geq \Delta\left\|\epsilon^k\right\|_\infty^2 \tag{1.18}$$

for all k sufficiently large. This bound, in conjunction with (1.15), allows us to conclude that

$$\tilde{\sigma}_j = \lim_{k\to\infty}\frac{\sigma_j(\epsilon^k)}{\nu_k} = 0 \qquad \text{for } j = 3, 4, \ldots, n.$$

We now turn our attention to the coefficient $\tilde{\sigma}_2$. If

$$\max\{\,\left|\sigma_1(\epsilon^k)\right|,\,\left|\sigma_2(\epsilon^k)\right|\,\} = o(\nu_k),$$

we are done since then $\tilde{\sigma} = 0$. Hence, we assume that

$$\max\{\,\left|\sigma_1(\epsilon^k)\right|,\,\left|\sigma_2(\epsilon^k)\right|\,\} \neq o(\nu_k)$$

so that

$$\nu_k = \max\{\,\left|\sigma_1(\epsilon^k)\right|,\,\left|\sigma_2(\epsilon^k))\right|,\,|\mu_k|\,\}$$

for all k sufficiently large. Set $\tilde{\nu}_{kj} = \max\{\,\left|\sigma_j(\epsilon^k)\right|,\,|\mu_k|\,\}$ for $j = 1, 2$. Observe that if $\lim_{k\to\infty}\frac{\sigma_2(\epsilon^k)}{\tilde{\nu}_{k1}} = 0$, then we are done since in this case $\nu_k = \tilde{\nu}_{k1}$ for all k sufficiently large which implies that $\tilde{\sigma}_2 = 0$. Hence, with no loss in generality, we can assume that there is a constant $c > 0$ such that

$$\left|\sigma_2(\epsilon^k)\right| \geq c\tilde{\nu}_{k1} \quad \text{for all } k = 1, 2, \ldots. \tag{1.19}$$

Therefore, there is a constant $K > 0$ such that

$$K\left|\sigma_2(\epsilon^k)\right| \geq \nu_k \quad \text{for all } k \text{ sufficiently large.} \tag{1.20}$$

Now observe that

$$|\sigma_2(\epsilon)| = \left|\sum_{s<t} \epsilon_s \epsilon_t\right| \leq \sum_{s<t} |\epsilon_s|\,|\epsilon_t| \leq \frac{n(n-1)}{2}\,\|\epsilon\|_\infty^2 . \tag{1.21}$$

Therefore, for all k sufficiently large,

$$c\left|\operatorname{Re}(\sigma_1(\epsilon^k))\right| \leq c\left|\sigma_1(\epsilon^k)\right| \leq c\tilde{\nu}_{k1} \leq \left|\sigma_2(\epsilon^k)\right| \leq \frac{n(n-1)}{2}\left\|\epsilon^k\right\|_\infty^2 ,$$

and so, from (1.20), we have

$$|\mu_k| \leq \nu_k \leq \frac{Kn(n-1)}{2}\left\|\epsilon^k\right\|_\infty^2 . \tag{1.22}$$

In particular, this implies that

$$\frac{\mu_k}{\|\epsilon^k\|_\infty} \to 0.$$

In addition, since $\alpha_{kj} + \mu_k \geq 0$ for each $j = 1, 2, \ldots, n$ and all $k = 1, 2, \ldots$ and

$$0 \leq \sum_{j=1}^{n} \frac{\alpha_{kj} + \mu_k}{\|\epsilon^k\|_\infty} \leq \frac{\left|\operatorname{Re}(\sigma_1(\epsilon^k))\right| + n\,|\mu_k|}{\|\epsilon^k\|_\infty} \leq \frac{n(n-1)}{2}\left(\frac{1}{c} + Kn\right)\left\|\epsilon^k\right\|_\infty ,$$

for all $k = 1, 2, \ldots$ (recall the definition of the α_{kj}'s from (1.16)), we obtain

$$\lim_{k\to\infty} \frac{\alpha_{kj}}{\|\epsilon^k\|_\infty} = 0 \quad \text{for } j = 1, 2, \ldots, n. \tag{1.23}$$

Putting together the bounds (1.18), (1.20), and (1.22), we obtain the relation

$$\Delta\left\|\epsilon^k\right\|_\infty^2 \leq \nu_k \leq K\left|\sigma_2(\epsilon^k)\right| \leq K\frac{n(n-1)}{2}\left\|\epsilon^k\right\|_\infty^2 , \tag{1.24}$$

for all $k = 1, 2, \ldots$. In addition, the bound (1.19) implies that

$$\frac{\left|\operatorname{Im}(\sigma_1(\epsilon^k))\right|^2}{|\sigma_2(\epsilon^k)|} \leq \frac{\left|\sigma_1(\epsilon^k)\right|^2}{|\sigma_2(\epsilon^k)|} \leq \frac{1}{c^2}\left|\sigma_2(\epsilon^k)\right|$$

so that

$$\frac{\left|\operatorname{Im}(\sigma_1(\epsilon^k))\right|^2}{|\sigma_2(\epsilon^k)|} \to 0.$$

Now since $\left|\operatorname{Im}(\sigma_1(\epsilon^k))\right|^2 = \sum_{j=1}^{n} \delta_{kj}^2 + 2\sum_{s<t} \delta_{ks}\delta_{kt}$, this implies that

$$\lim_{k\to\infty} \sum_{s<t} \frac{\delta_{ks}\delta_{kt}}{|\sigma_2(\epsilon^k)|} \leq 0. \tag{1.25}$$

Finally, recall that

$$\sigma_2(\epsilon^k) = \left[\sum_{s<t} \alpha_{ks}\alpha_{kt} - \sum_{s<t} \delta_{ks}\delta_{kt}\right] + i\left[\sum_{s<t} \alpha_{ks}\delta_{kt} + \sum_{s<t} \delta_{ks}\alpha_{kt}\right].$$

Therefore, by (1.24), (1.25), and (1.23), we see that

$$\mathrm{Re}\,(\tilde{\sigma}_2) = \lim_{k\to\infty} \frac{\mathrm{Re}\,(\sigma_2(\epsilon^k))}{\nu_k} \geq 0.$$

Similarly, from (1.24) and (1.23), we have

$$\begin{aligned} |\,\mathrm{Im}\,(\tilde{\sigma}_2)| &= \lim_{k\to\infty} \frac{\left|\,\mathrm{Im}\,(\sigma_2(\epsilon^k))\right|}{\nu_k} \\ &\leq \Delta^{-1} \lim_{k\to\infty} \sum_{s<t} \left(\frac{|\alpha_{ks}|}{\|\epsilon^k\|_\infty} \frac{|\delta_{kt}|}{\|\epsilon^k\|_\infty} + \frac{|\alpha_{kt}|}{\|\epsilon^k\|_\infty} \frac{|\delta_{ks}|}{\|\epsilon^k\|_\infty} \right) \\ &= 0, \end{aligned}$$

since $\frac{|\delta_{kj}|}{\|\epsilon^k\|_\infty} \leq 1$ for all $j = 1, 2, \ldots, n$ and $k = 1, 2, \ldots$.

The final statement of the theorem concerning the formula for $da(e_{(n,0)})(v)$ now follows immediately from the equivalence of (1.1) and (1.7)–(1.10). □

By combining Lemma 1.1 with Theorem 1.2, we obtain the following corollary.

COROLLARY 1.3. *Given $\lambda_0 \in \mathbb{C}$, we have $(v, \eta) \in T_{epi\,(a)}(e_{(n,\lambda_0)}, Re\,(\lambda_0))$, with*

$$v = \beta_1 e_{(n-1,\lambda_0)} + \beta_2 e_{(n-2,\lambda_0)} + \cdots + \beta_n\ , \tag{1.26}$$

if and only if $\beta_1, \beta_2, \ldots, \beta_n$ satisfy the conditions (1.7)–(1.10). *Therefore, for $v \in \mathcal{P}_{n-1}$ given by* (1.26), *we have*

$$da(e_{(n,\lambda_0)})(v) = \begin{cases} -\frac{Re\,\beta_1}{n} & \textit{if } (1.8)\text{–}(1.10) \textit{ hold,} \\ +\infty & \textit{otherwise.} \end{cases}$$

We now show that the factorization of a polynomial into powers of linear factors (or the *prime factorization*) can be used to obtain a description of the tangent cone to the epigraph of a from Corollary 1.3. We begin by developing a tool that allows us to treat each of the linear factors in the prime factorization separately. We then glue the results for each of the factors back together to obtain a result for the polynomial as a whole. This tool is provided in the next lemma which establishes a local property for factorizations into relatively prime factors.

LEMMA 1.4. *Let $(n_1, n_2, \ldots, n_m)$ be a partition of n, that is, for $j = 1, 2, \ldots, m$ each n_j is a positive integer and $n = \sum_{j=1}^m n_j$. Set*

$$\mathcal{S} = \mathbb{C} \times \mathcal{P}_{n_1-1} \times \mathcal{P}_{n_2-1} \times \cdots \times \mathcal{P}_{n_m-1}$$

and let $p_j \in \mathcal{M}_{n_j}$ for $j = 1, 2, \ldots, m$. Consider the mapping $F : \mathcal{S} \to \mathcal{P}_n$ given by

$$F(v_0, v_1, v_2, \ldots, v_m) = (1 + v_0) \prod_{j=1}^m (p_j + v_j)\ .$$

If the polynomials $p_1, \ldots, p_m$ are relatively prime(i.e., have no common roots), then there exist open neighborhoods U of $0 \in \mathcal{S}$ and W of $F(0) \in \mathcal{P}_n$ such that F is *a homeomorphism between U and W with $\nabla(F^{-1})$ existing, continuous on W, and satisfying $\nabla(F^{-1})(F(u)) = [\nabla F(u)]^{-1}$ for all $u \in U$. Thus, in particular, we have Ran $(\nabla F(0)) = \mathcal{P}_n$; that is, every polynomial $h \in \mathcal{P}_n$ can be written as*

$$h = \nabla F(0)(w_0, w_1, \ldots, w_m) = \sum_{j=0}^{m} r_j w_j \ , \tag{1.27}$$

for some $(w_0, w_1, \ldots, w_m) \in \mathcal{S}$, where

$$r_0 = \prod_{j=1}^{m} p_j \quad \textit{and} \quad r_s = \prod_{j \neq s} p_j \quad \textit{for } s = 1, 2, \ldots, m. \tag{1.28}$$

Proof. Since $\dim(\mathcal{S}) = n + 1 = \dim(\mathcal{P}_n)$, the result follows from the classical inverse function theorem once it is shown that $\ker(\nabla F(0)) = \{0\}$. Let $\mathcal{Z}_j$ denote the set of zeros of the polynomial p_j counting multiplicity, for $j = 1, 2, \ldots, m$, and let $(w_0, w_1, \ldots, w_m) \in \ker(\nabla F(0))$. Since the polynomials $p_1, p_2, \ldots, p_m$ are relatively prime, we have $\mathcal{Z}_j \cap \mathcal{Z}_s = \emptyset$ whenever $j \neq s$. Equations (1.27) and (1.28) and the inclusion $(w_0, w_1, \ldots, w_m) \in \ker(\nabla F(0))$ imply that for each $s = 1, 2, \ldots, m$ the polynomial

$$f_s = r_s w_s$$

has zeros not only at the points $\cup_{j \neq s} \mathcal{Z}_j$ (with the corresponding multiplicities) but also at the points $\mathcal{Z}_s$ (with the corresponding multiplicities). Hence, each f_s is either the zero polynomial or its degree is at least n. However, the degree of each f_s is at most $n-1$, since $w_s \in \mathcal{P}_{n_s - 1}$. Therefore, f_s is the zero polynomial for $s = 1, 2, \ldots, m$. This in turn implies that $w_j = 0$ for $j = 1, 2, \ldots, m$, and finally that $w_0 = 0$. Consequently, $\ker(\nabla F(0)) = \{0\}$. □

As a first application of Lemma 1.4, we show if a polynomial is written as a product of relatively prime factors, then the tangent cone to the epigraph of a at this polynomial is contained within a kind of product of the tangent cones associated with each of the relatively prime factors.

THEOREM 1.5. *Let $(n_1, n_2, \ldots, n_m)$ be a partition of n, and let $p_j \in \mathcal{M}_{n_j}$ for $j = 1, 2, \ldots, m$ be relatively prime. Set $p = \prod_{j=1}^{m} p_j \in \mathcal{M}_n$. Let the space $\mathcal{S}$ and the function $F : \mathcal{S} \to \mathcal{P}_n$ be as given in Lemma* 1.4. *If $(h, \omega) \in T_{epi\,(a)}(p, a(p))$, then there exists $(0, w_1, w_2, \ldots, w_m) \in \mathcal{S}$ such that h is given by* (1.27) *and* (1.28)*, where, for $j = 1, \ldots, m$, $(w_j, \omega) \in T_{epi\,(a_{n_j})}(p_j, a(p))$ and a_{n_j} denotes the abscissa mapping on $\mathcal{P}_{n_j}$.*

Proof. Let (h, ω) be a nonzero element of the tangent cone $T_{\text{epi}\,(a)}(p, a(p))$. Then there is a sequence $\{(q_k, \alpha_k)\} \subset \text{epi}\,(a) \subset \mathcal{M}_n \times \mathbb{R}$ and a scalar $\gamma > 0$ such that

$$(q_k, \alpha_k) \to (p, a(p)) \quad \text{and} \quad \frac{(q_k, \alpha_k) - (p, a(p))}{\|(q_k, \alpha_k) - (p, a(p))\|} \to (\gamma h, \gamma \omega) \ .$$

Let $F : \mathcal{S} \to \mathcal{P}_n$ be as in Lemma 1.4. Then, by trimming finitely many terms from the beginning of the sequence if necessary so that q_k is sufficiently close to p, Lemma 1.4 yields the existence of a sequence $\{(0, v_{k1}, v_{k2}, \ldots, v_{km})\} \subset \mathcal{S}$ such that $(0, v_{k1}, v_{k2}, \ldots, v_{km}) \to 0$ and

$$q_k = F(0, v_{k1}, v_{k2}, \ldots, v_{km}) = \prod_{j=1}^{m} (p_j + v_{kj}) \quad \text{for all } k = 1, 2, \ldots \ ,$$

since $\{q_k\} \subset \mathcal{M}_n = \mathrm{dom}\,(a)$. Since $(q_k, \alpha_k) \in \mathrm{epi}\,(a)$, we have

$$(p_j + v_{kj}, \alpha_k) \in \mathrm{epi}\,(a_{n_j}) \quad \text{for all } j = 1, 2, \ldots, m \text{ and } k = 1, 2, \ldots \tag{1.29}$$

and

$$(p_j + v_{kj}, \alpha_k) \to (p_j, a(p)) \quad \text{for all } j = 1, 2, \ldots, m. \tag{1.30}$$

Set $v^k = (0, v_{k1}, v_{k2}, \ldots, v_{km})$ for $k = 1, 2, \ldots$, and set $\bar{v} = 0$ so that $v^k \to \bar{v}$. Then

$$\begin{aligned} q_k - p &= F(v^k) - F(\bar{v}) \\ &= \nabla F(\bar{v})(v^k - \bar{v}) + o(\|v^k - \bar{v}\|) \, . \end{aligned} \tag{1.31}$$

By Lemma 1.4, $\nabla(F^{-1})$ is continuous in a neighborhood of p so that F^{-1} is Lipschitz continuous near p. Consequently, there is a constant $K > 0$ such that $\|v^k - \bar{v}\| \leq K \|q_k - p\|$ for all $k = 1, 2, \ldots$. This fact, combined with (1.31), yields

$$\begin{aligned} \gamma h &= \lim_{k \to \infty} \frac{q_k - p}{\|(q_k, \alpha_k) - (p, a(p))\|} \\ &= \nabla F(\bar{v}) \lim_{k \to \infty} \frac{v^k - \bar{v}}{\|(q_k, \alpha_k) - (p, a(p))\|} \\ &= \nabla F(0)(0, \hat{w}_1, \hat{w}_2, \ldots, \hat{w}_m), \end{aligned} \tag{1.32}$$

where

$$\hat{w}_j = \lim_{k \to \infty} \frac{v_{kj}}{\|(q_k, \alpha_k) - (p, a(p))\|} \quad \text{for } j = 1, 2, \ldots, m.$$

Equation (1.32) verifies (1.27) with $w_j = \gamma^{-1}\hat{w}_j$ for $j = 1, 2, \ldots, m$. From (1.29), (1.30), and definition (1.2) (here $t_k = \|(q_k, \alpha_k) - (p, a(p))\|$), we have that (w_j, ω) is an element of $T_{\mathrm{epi}\,(a_{n_j})}(p_j, a(p))$, for $j = 1, 2, \ldots, m$, which proves the result. □

We now apply Corollary 1.3, Lemma 1.4, and Theorem 1.5 to obtain a complete representation of the tangent cone to the epigraph of the abscissa mapping at an arbitrary polynomial. This representation involves the prime factorization of the polynomial. For this purpose, and for the application of this result in later sections, it is useful to introduce some more notation.

Let $p \in \mathcal{M}_n$ have prime factorization

$$p = \prod_{j=1}^{m} e_{(n_j, \lambda_j)}, \tag{1.33}$$

where $\lambda_1, \ldots, \lambda_m$ are distinct complex numbers and $(n_1, n_2, \ldots, n_m)$ is a partition of n. Define $\mathcal{S}_p$ to be the product space

$$\mathcal{S}_p = \mathbb{C} \times \mathcal{P}_{n_1 - 1} \times \mathcal{P}_{n_2 - 1} \times \cdots \times \mathcal{P}_{n_m - 1}. \tag{1.34}$$

In conjunction with $\mathcal{S}_p$, we define the mapping $F_p : \mathcal{S}_p \to \mathcal{P}_n$ by

$$F_p(v_0, v_1, \ldots, v_m) = (1 + v_0) \prod_{j=1}^{m} (e_{(n_j, \lambda_j)} + v_j) \quad \text{for all } (v_0, v_1, \ldots, v_m) \in \mathcal{S}_p, \tag{1.35}$$

so that $F_p(0) = p$. By analogy with (1.27), for every $(w_0, w_1, \ldots, w_m) \in \mathcal{S}$, we have

$$\nabla F_p(0)(w_0, w_1, \ldots, w_m) = \sum_{j=0}^{m} r_j w_j \ , \tag{1.36}$$

where

$$r_0 = p \quad \text{and} \quad r_s = \prod_{j \neq s} e_{(n_j, \lambda_j)} \quad \text{for } s = 1, 2, \ldots, m. \tag{1.37}$$

In addition, we define

$$\mathcal{I}(p) = \{ j \in \{1, 2, \ldots, m\} \mid a(p) = \operatorname{Re} \lambda_j \} , \tag{1.38}$$

the set of indices of active roots of p.

We now state and prove the main result of this section.

THEOREM 1.6. *Let $p \in \mathcal{M}_n$ have factorization* (1.33). *Then (h, ω) is an element of $T_{epi\,(a)}(p, a(p))$ if and only if there exists a vector $(w_0, w_1, w_2, \ldots, w_m) \in \mathcal{S}_p$ such that*

$$h = \nabla F_p(0)(w_0, w_1, w_2, \ldots, w_m), \tag{1.39}$$

where $\nabla F_p(0)$ is defined in (1.36)–(1.37),

$$w_0 = 0, \tag{1.40}$$

and

$$(w_j, \omega) \in T_{epi\,(a_{n_j})}(e_{(n_j, \lambda_j)}, a(p)) \quad \textit{for } j = 1, 2, \ldots, m. \tag{1.41}$$

In addition, if for each $j = 1, 2, \ldots, m$, w_j is given the representation

$$w_j = \beta_{j1} e_{(n_j - 1, \lambda_j)} + \beta_{j2} e_{(n_j - 2, \lambda_j)} + \cdots + \beta_{j n_j} \ , \tag{1.42}$$

then, for each $j \in \mathcal{I}(p)$, a necessary and sufficient condition for (1.41) *to hold is that*

$$Re\,\beta_{j1} \geq -n_j \omega, \tag{1.43}$$

$$Re\,\beta_{j2} \geq 0, \tag{1.44}$$

$$Im\,\beta_{j2} = 0, \ \textit{and} \tag{1.45}$$

$$\beta_{js} = 0 \textit{ for } s = 3, 4, \ldots, n_j \ . \tag{1.46}$$

Proof. Let us first assume that $(h, \omega) \in T_{\mathrm{epi}\,(a)}(p, a(p))$ and show that (h, ω) must satisfy (1.39), (1.40), and (1.41). By Lemma 1.4, there must exist a vector $(w_0, w_1, w_2, \ldots, w_m)$ in $\mathcal{S}_p$ such that (1.39) holds. The fact that $w_0 = 0$ follows from (1.4), while (1.41) follows immediately from Theorem 1.5. The conditions (1.43)–(1.46) follow from (1.41) and Corollary 1.3.

Next, let us assume that $(h, \omega) \in \mathcal{P}_{n-1} \times \mathbb{R}$ satisfies (1.39), (1.40), and (1.41). We need to show that $(h, \omega) \in T_{\mathrm{epi}\,(a)}(p, a(p))$. We accomplish this by following the approach taken in Theorem 1.2. That is, we will exhibit a curve in epi (a) passing through $(p, a(p))$ and having the tangent direction (h, ω) at $(p, a(p))$. For $j = 1, 2, \ldots, m$, give each w_j in (1.39) the representation (1.42). Then, by Corollary 1.3, we know that the conditions (1.43)–(1.46) are satisfied for $j \in \mathcal{I}(p)$. For each such $j \in \mathcal{I}(p)$, define

$$\begin{aligned} p_j(\lambda, \xi) &= \left((\lambda - \lambda_j) + \frac{\beta_{j1}}{n_j}\xi \right)^{n_j - 2} \\ &\quad \times \left((\lambda - \lambda_j) + \sqrt{-1}(\beta_{j2}\xi)^{\frac{1}{2}} + \frac{\beta_{j1}}{n_j}\xi \right) \left((\lambda - \lambda_j) - \sqrt{-1}(\beta_{j2}\xi)^{\frac{1}{2}} + \frac{\beta_{j1}}{n_j}\xi \right) \\ &= (\lambda - \lambda_j)^{n_j} + (\beta_{j1}\xi)(\lambda - \lambda_j)^{n_j - 1} + \beta_{j2}\xi(\lambda - \lambda_j)^{n_j - 2} + o(\xi) \\ &= (\lambda - \lambda_j)^{n_j} + \xi w_j(\lambda) + o(\xi), \end{aligned} \tag{1.47}$$

and, for $j \in \{1, 2, \ldots, m\} \backslash \mathcal{I}(p)$, define

$$p_j(\lambda, \xi) = (\lambda - \lambda_j)^{n_j} + \xi w_j(\lambda) \ . \tag{1.48}$$

Set $p(\lambda, \xi) = \prod_{j=1}^{m} p_j(\lambda, \xi)$, so that, from (1.36), (1.37), and (1.39),

$$\begin{aligned} p(\lambda, \xi) &= p(\lambda) + \xi \sum_{j=1}^{m} r_j(\lambda) w_j(\lambda) + o(\xi) \\ &= p(\lambda) + \xi \nabla F_p(0)(0, w_1, \ldots, w_m)(\lambda) + o(\xi) \\ &= p(\lambda) + \xi h(\lambda) + o(\xi). \end{aligned}$$

Then, for all ξ small, positive, and real,

$$\begin{aligned} a(p(\lambda, \xi)) &= \max_{j \in \mathcal{I}(p)} \operatorname{Re} \left(\lambda_j - \frac{\beta_{j1}}{n_j}\xi \right) \\ &\leq a(p) + \xi\omega \end{aligned}$$

so that $(p(\lambda, \xi), a(p) + \xi\omega) \in \operatorname{epi}(a)$ for all ξ small, positive, and real. Therefore, since

$$\lim_{\xi \searrow 0} \frac{(p(\lambda, \xi), a(p) + \xi\omega) - (p(\lambda), a(p))}{\xi} = (h(\lambda), \omega),$$

we have $(h, \omega) \in T_{\operatorname{epi}(a)}(p, a(p))$, completing the proof. □

COROLLARY 1.7. *Let $p \in \mathcal{M}_n$ have factorization* (1.33) *and let $h \in \mathcal{P}_n$. By Lemma* 1.4, *there exists $(w_0, w_1, w_2, \ldots, w_m)$ in $\mathcal{S}_p$ such that* (1.39) *holds, where, for each $j = 1, 2, \ldots, m$, w_j can be written as in* (1.42). *With this representation for h, either $w_0 = 0$ and* (1.44)–(1.46) *hold for $j \in \mathcal{I}(p)$, in which case*

$$da(p)(h) = \max_{j \in \mathcal{I}(p)} \frac{-Re(\beta_{j1})}{n_j} \ ,$$

or

$$da(p)(h) = +\infty.$$

Proof. By Theorem 1.6, we know that $da(p)(h) = +\infty$ if either $w_0 \neq 0$ or the coefficients β_{js}, $s = 1, 2, \ldots, n_j$, do not satisfy one of the conditions in (1.44)–(1.46) for every $j \in \mathcal{I}(p)$. On the other hand, if $w_0 = 0$ and all of the conditions in (1.44)–(1.46) are satisfied for every $j \in \mathcal{I}(p)$, then the inequality (1.43) in Theorem 1.6 implies that $(h, \omega) \in T_{\operatorname{epi}(a)}((p, a(p)))$ if and only if $\omega \geq \frac{-\operatorname{Re}(\beta_{j1})}{n_j}$ for every $j \in \mathcal{I}(p)$. Since $T_{\operatorname{epi}(a)}((p, a(p))) = \operatorname{epi}(da(p))$ [RW98, Theorem 8.2], this proves the corollary. □

2. Regular subgradients and the normal cone. We now turn our attention to the variational objects *dual* to the subderivative and the tangent cone. These are the subgradients and the normal cone. These objects are defined in terms of a duality pairing between the linear space $\mathcal{P}_n$ and its *dual space.* Traditionally the *dual space* is the space of continuous linear functionals on the *primal* space (which in our setting is $\mathcal{P}_n$). The *duality pairing* is then the continuous bilinear functional obtained by evaluating a given linear functional at a given point. However, in general, the dual space may have many possible representations and for each representation there may be any number of bilinear functionals that *pair the spaces in duality.*

In our analysis, we have chosen to regard $\mathcal{P}_n$ as a Hilbert space, in which case the dual of $\mathcal{P}_n$ is itself. However, we will need to consider a whole family of duality pairings, or inner products, on $\mathcal{P}_n$. To describe this family of inner products, recall that for each $\lambda_0 \in \mathbb{C}$, the polynomials

$$e_{(j,\lambda_0)},\ j = 0, 1, \ldots, n, \tag{2.1}$$

form a basis for $\mathcal{P}_n$. Hence, for each $\lambda_0 \in \mathbb{C}$, we can define a real inner product on $\mathcal{P}_n$ associated with the representation in this basis. Given $p = \sum_{j=1}^n a_j e_{(n-j,\lambda_0)}$ and $q = \sum_{j=1}^n b_j e_{(n-j,\lambda_0)}$, define the inner product

$$\langle \cdot\, , \cdot \rangle_{(n,\lambda_0)} : \mathcal{P}_n \times \mathcal{P}_n \to \mathbb{R}$$

by

$$\langle p\, , q \rangle_{(n,\lambda_0)} = \operatorname{Re} \sum_{j=0}^{n} \bar{a}_j b_j. \tag{2.2}$$

Thus, in the case $n = 0$, we recover the real inner product on $\mathbb{C}$. Note that this family of inner products behaves continuously in p, q, and λ_0 in the sense that the mapping

$$(p, q, \lambda) \mapsto \langle p\, , q \rangle_{(n,\lambda)} \tag{2.3}$$

is continuous on $\mathcal{P}_n \times \mathcal{P}_n \times \mathbb{C}$. To see this, note that the expansions of the polynomials p and q in the basis (2.1) are just their Taylor series expansions at λ_0, hence,

$$\langle p\, , q \rangle_{(n,\lambda)} = \operatorname{Re} \left(\sum_{j=0}^{n} \frac{\overline{p^{(j)}(\lambda)}}{j!} \frac{q^{(j)}(\lambda)}{j!} \right),$$

where $f^{(j)}$ denotes the jth derivative of the function f.

By setting $\lambda_0 = 0$ in (2.1), we obtain the *standard basis* for $\mathcal{P}_n$. The inner product (2.2) associated with the standard basis is simply written $\langle \cdot\, , \cdot \rangle$.

The spaces $\mathcal{S}_p$ defined in (1.34) also play a key role in our analysis; therefore, we need an inner product on these spaces as well. We use the inner product

$$\langle (u_0, u_1, \ldots, u_m)\, , (v_0, v_1, \ldots, v_m) \rangle_p = \sum_{s=0}^{m} \langle u_s\, , v_s \rangle_{(n_s - 1, \lambda_s)}\ , \tag{2.4}$$

for every $(u_0, u_1, \ldots, u_m)$ and $(v_0, v_1, \ldots, v_m)$ in $\mathcal{S}_p$, where we define $n_0 = 1$ in this expression and hereafter.

Spaces paired in duality give rise to the notion of the adjoint of a linear transformation. Suppose (X, X^*) and (Y, Y^*) are spaces paired in duality, with the duality pairing between X and X^*, and Y and Y^* given by $\langle \cdot\,,\cdot\rangle_X$ and $\langle \cdot\,,\cdot\rangle_Y$, respectively. If A is a linear transformation mapping X to Y, then the adjoint of A, denoted A^*, is the linear transformation mapping Y^* to X^* defined by the condition that

$$\langle A^*y\,,x\rangle_X = \langle y\,,Ax\rangle_Y \quad \text{for all } x \in X \text{ and } y \in Y^*.$$

The dual variational objects studied in this section are the cone of regular normals and the set of regular subgradients. The cone of regular normal vectors to the epigraph of a at a point $(p,\mu) \in \mathrm{epi}\,(a)$, denoted $\widehat{N}_{\mathrm{epi}\,(a)}(p,\mu)$, is given by

$$\left\{ (z,\eta) \;\middle|\; \begin{array}{c} \langle (z,\eta)\,,(q,\tau)-(p,\mu)\rangle \le o(\|(q,\tau)-(p,\mu)\|) \\ \forall\,(q,\tau)\in \mathrm{epi}\,(a) \end{array} \right\},$$

where $\langle (z,\eta)\,,(q,\tau)\rangle = \eta\tau + \langle z\,,q\rangle$ (note that $\mathrm{epi}\,(a) \subset \mathcal{P}_n \times \mathbb{R}$ so that η and τ are real). The cone of regular normals is defined to be the empty set at points not in the epigraph of a. The set of regular subgradients of a at $p \in \mathrm{dom}\, a = \mathcal{M}_n$ is given by

$$\hat{\partial} a(p) = \{ z \mid a(q) \ge a(p) + \langle z\,,q-p\rangle + o(\|q-p\|)\ \forall\, q \in \mathcal{P}_n \}.$$

If $p \ne \mathcal{M}_n$, we define $\hat{\partial} a(p)$ to be the empty set. By [RW98, Theorem 8.9], we have the following relationship between the cone of regular normals and the set of regular subgradients:

$$\hat{\partial} a(p) = \left\{ z \;\middle|\; (z,-1) \in \widehat{N}_{\mathrm{epi}\,(a)}(p,a(p)) \right\}. \tag{2.5}$$

In addition, [RW98, Proposition 6.5] tells us that the cone of regular normals is the polar of the tangent cone at points $(p,a(p)) \in \mathrm{epi}\,(a)$:

$$\widehat{N}_{\mathrm{epi}\,(a)}(p,a(p)) = T_{\mathrm{epi}\,(a)}(p,a(p))^\circ\ , \tag{2.6}$$

where

$$T_{\mathrm{epi}\,(a)}(p,a(p))^\circ = \left\{ (z,\xi) \;\middle|\; \langle (z,\xi)\,,(h,\omega)\rangle \le 0\ \forall\,(h,\omega) \in T_{\mathrm{epi}\,(a)}(p,a(p)) \right\}.$$

We take a moment to observe two important consequences of the equivalence (2.6). These observations are based on the relations (1.4) and (1.5). By (1.4), we have that the vector $(e_{(n,0)},0)$ is orthogonal to every vector in $T_{\mathrm{epi}\,(a)}(p,a(p))$, regardless of the choice of the polynomial $p \in \mathcal{M}_n$. Therefore, by (2.6),

$$\left\{ (\beta e_{(n,0)},0) \mid \beta \in \mathbb{C} \right\} \subset \widehat{N}_{\mathrm{epi}\,(a)}(p,a(p)) \quad \text{for every } p \in \mathcal{M}_n. \tag{2.7}$$

In addition, (1.5) and (2.6) imply that

$$\left\{ (\beta e_{(n,0)},0) \mid \beta \in \mathbb{C} \right\} = \widehat{N}_{\mathrm{epi}\,(a)}(p,\mu), \quad \text{whenever } \mu > a(p). \tag{2.8}$$

We now proceed to derive an expression for $\widehat{N}_{\mathrm{epi}\,(a)}(p,a(p))$ using (2.6) and Theorem 1.6. We then use the relation (2.5) to determine $\hat{\partial} a(p)$.

THEOREM 2.1. *Let $p \in \mathcal{M}_n$ have factorization* (1.33) *and let $\mathcal{I}(p)$ be as defined in* (1.38). *Then (z,η) is an element of the normal cone $\widehat{N}_{epi\,(a)}(p,a(p))$ if and only if*

$$\eta \le 0 \tag{2.9}$$

and the vector $u \in \mathcal{S}_p$ defined by $u = \nabla F_p(0)^* z$ and given the representation

$$u_j = \sum_{l=1}^{n_j} \mu_{jl} e_{(n_j - l, \lambda_j)} \quad \textit{for } j = 1, \ldots, m \tag{2.10}$$

satisfies

$$u_j = 0 \quad \textit{for } j \notin \mathcal{I}(p) \textit{ and } j \neq 0, \tag{2.11}$$

$$\textit{Re}\,\mu_{j1} \leq 0 \textit{ and } \textit{Im}\,\mu_{j1} = 0 \quad \textit{for } j \in \mathcal{I}(p), \tag{2.12}$$

$$\textit{Re}\,\mu_{j2} \leq 0 \quad \textit{for } j \in \mathcal{I}(p), \quad \textit{and} \tag{2.13}$$

$$\sum_{j \in \mathcal{I}(p)} n_j \mu_{j1} = \eta. \tag{2.14}$$

Proof. Let $(h, \omega) \in T_{\mathrm{epi}\,(a)}(p, a(p))$. By Theorem 1.6, we know that there exists $(0, w_1, w_2, \ldots, w_m) \in \mathcal{S}_p$ such that $h = \nabla F_p(0)(0, w_1, w_2, \ldots, w_m)$, where for $j = 1, 2, \ldots, m$ each w_j has the representation (1.42) with the coefficients β_{js} satisfying (1.43)–(1.46) for $j \in \mathcal{I}(p)$, and, for $j \notin \mathcal{I}(p)$,

$$\beta_{js}, \quad s = 1, 2, \ldots, n_j, \text{ are unrestricted.} \tag{2.15}$$

Now let $(z, \eta) \in \mathcal{P}_n \times \mathbb{R}$ and set $u = (u_0, u_1, \ldots, u_m) = \nabla F_p(0)^* z$, where each u_j, $j = 1, \ldots, m$ is given the representation (2.10). Then, from definition (2.4), we have

$$\begin{aligned} \langle (z, \eta), (h, \omega) \rangle &= \eta\omega + \langle z, h \rangle \\ &= \eta\omega + \langle z, \nabla F_p(0)(0, w_1, w_2, \ldots, w_m) \rangle \\ &= \eta\omega + \langle \nabla F_p(0)^* z, (0, w_1, w_2, \ldots, w_m) \rangle_p \\ &= \eta\omega + \langle (u_0, u_1, \ldots, u_m), (0, w_1, w_2, \ldots, w_m) \rangle_p \\ &= \eta\omega + \sum_{j=1}^{m} \langle u_j, w_j \rangle_{(n_j - 1, \lambda_j)} \\ &= \eta\omega + \sum_{j=1}^{m} \sum_{l=1}^{n_j} \mathrm{Re}\, \bar{\mu}_{jl} \beta_{jl}. \end{aligned} \tag{2.16}$$

Hence, by (2.6), $(z, \eta) \in \widehat{N}_{\mathrm{epi}\,(a)}(p, a(p))$ if and only if

$$\eta\omega + \sum_{j=1}^{m} \sum_{l=1}^{n_j} \mathrm{Re}\, \bar{\mu}_{jl} \beta_{jl} \leq 0 \tag{2.17}$$

for all choices of ω and β_{jl}, $j = 1, \ldots, m$, $l = 1, \ldots, n_j$, satisfying (1.43)–(1.46) for each $j \in \mathcal{I}(p)$.

We first show that any $(z, \eta) \in \mathcal{P}_n \times \mathbb{R}$ for which the associated vector $u = (u_0, u_1, \ldots, u_m) = \nabla F_p(0)^* z$, where each u_j, $j = 1, \ldots, m$, has representation (2.10) and for which η and μ_{jl}, $j = 1, \ldots, m$, $l = 1, \ldots, n_j$, satisfy (2.9) and (2.11)–(2.14) is necessarily an element of the normal cone $\widehat{N}_{\mathrm{epi}\,(a)}(p, a(p))$. For this purpose, suppose that ω and β_{jl}, $j = 1, \ldots, m$, $l = 1, \ldots, n_j$ satisfy (1.43)–(1.46) for each $j \in \mathcal{I}(p)$ so that the corresponding vector (h, ω) is an element of the tangent cone $T_{\mathrm{epi}\,(a)}(p, a(p))$.

Then

$$\begin{aligned}\langle (z,\eta),(h,\omega)\rangle &= \eta\omega + \sum_{j=1}^{m}\sum_{l=1}^{n_j} \operatorname{Re}\bar{\mu}_{jl}\beta_{jl}\\ &= \eta\omega + \sum_{j\in\mathcal{I}(p)} [\mu_{j1}\operatorname{Re}\beta_{j1} + \operatorname{Re}\mu_{j2}\operatorname{Re}\beta_{j2}]\\ &\le \eta\omega - \sum_{j\in\mathcal{I}(p)} n_j\mu_{j1}\left(\frac{-\operatorname{Re}\beta_{j1}}{n_j}\right)\\ &\le \eta\omega - \sum_{j\in\mathcal{I}(p)} n_j\mu_{j1}\omega\\ &= 0,\end{aligned}$$

where the first equality follows from (2.16), the second equality from (2.11), (2.12), (1.45), and (1.46), the first inequality from (2.13) and (1.44), the second inequality from (1.43), and the final equality from (2.14). Therefore, the set of (z,η) satisfying (2.9)–(2.14) is contained in $\widehat{N}_{\operatorname{epi}(a)}(p,a(p))$.

We now show the reverse inclusion. Let $(z,\eta)\in\widehat{N}_{\operatorname{epi}(a)}(p,a(p))$ and set $u=(u_0,u_1,\ldots,u_m)=\nabla F_p(0)^*z$ with each u_j, $j=1,\ldots,m$ given representation (2.10). We show that (z,η) must satisfy the conditions (2.11)–(2.14) by requiring that the inequality (2.17) holds for every (h,ω) in the tangent cone $T_{\operatorname{epi}(a)}(p,a(p))$. To this end, let (h,ω) be any element of the tangent cone $T_{\operatorname{epi}(a)}(p,a(p))$ so that the corresponding vectors w_j, $j=1,\ldots,m$, satisfy (1.43)–(1.46) for each $j\in\mathcal{I}(p)$ and (2.15) for $j\notin\mathcal{I}(p)$. By setting $\omega=1$ and all β_{jl} equal to zero in (2.17), we find that $\eta\le 0$. By (2.15), β_{js} is free for $j\notin\mathcal{I}(p)$, $s=1,2,\ldots,n_j$, so that (2.17) implies that (2.11) holds. Since $\operatorname{Im}\beta_{j1}$ is free whenever $j\in\mathcal{I}(p)$, (2.17) implies that $\operatorname{Im}\mu_{j1}=0$ for all $j\in\mathcal{I}(p)$. In addition, (1.43) and (2.17) imply that $\operatorname{Re}\mu_{j2}\le 0$ for all $j\in\mathcal{I}(p)$. Therefore, (2.9), (2.11), the second half of (2.12) (i.e., the equality), and (2.13) have been verified.

We now establish the first half of (2.12) (i.e., the inequality) and (2.14). By taking $\operatorname{Re}\beta_{j2}=0$ for $j\in\mathcal{I}(p)$, the expression (2.16) can be simplified to

$$\langle (z,\eta),(h,\omega)\rangle = \eta\omega + \sum_{j\in\mathcal{I}(p)} \mu_{j1}\operatorname{Re}\beta_{j1}. \tag{2.18}$$

By combining this with (2.17), we must have

$$\sum_{j\in\mathcal{I}(p)} \mu_{j1}\operatorname{Re}\beta_{j1} \le -\eta\omega \tag{2.19}$$

for all choices of ω and $\operatorname{Re}\beta_{j1}$, $j\in\mathcal{I}(p)$, satisfying (1.43). Observe that (1.43) holds if and only if

$$\omega \ge \max_{j\in\mathcal{I}(p)} \frac{-\operatorname{Re}\beta_{j1}}{n_j}. \tag{2.20}$$

Since $-\eta\ge 0$, we can multiply this inequality through by $-\eta$ to obtain the inequality

$$-\eta\omega \ge -\eta \max_{j\in\mathcal{I}(p)} \frac{-\operatorname{Re}\beta_{j1}}{n_j}. \tag{2.21}$$

Since the right-hand side of this inequality yields the smallest possible value of the product $-\eta\omega$, we find that (1.43) and (2.19) hold if and only if

$$\sum_{j\in\mathcal{I}(p)} \mu_{j1}\operatorname{Re}\beta_{j1} \le (-\eta)\max_{j\in\mathcal{I}(p)} \frac{-\operatorname{Re}\beta_{j1}}{n_j} \qquad \forall \beta_{j1}\in\mathbb{C},\ j\in\mathcal{I}(p). \tag{2.22}$$

Consider two cases: $\eta = 0$ and $\eta < 0$. If $\eta = 0$, then (2.22) implies that $\mu_{j1} = 0$ for all $j \in \mathcal{I}(p)$ so that (2.12) and (2.14) are satisfied. On the other hand, if $\eta < 0$, define $\tilde{\mu}_j = \frac{n_j}{\eta}\mu_{j1}$ and $\tilde{\beta}_j = \frac{-\operatorname{Re}\beta_{j1}}{n_j}$ for $j \in \mathcal{I}(p)$. Substituting into (2.22), we obtain

$$\sum_{j\in\mathcal{I}(p)} \tilde{\mu}_j\tilde{\beta}_j \le \max_{j\in\mathcal{I}(p)} \tilde{\beta}_j \qquad \forall \tilde{\beta}_j\in\mathbb{R}. \tag{2.23}$$

But this holds if and only if $\tilde{\mu}_j \ge 0$ for $j \in \mathcal{I}(p)$ and $\sum_{j\in\mathcal{I}(p)}\tilde{\mu}_j = 1$, or equivalently, (2.12) and (2.14) hold. □

Theorem 2.1 and (2.5) immediately yield the following representation for the set of regular subgradients.

Theorem 2.2. *Let $p \in \mathcal{M}_n$ have factorization* (1.33). *Then $z \in \hat{\partial}a(p)$ if and only if the vector of polynomials*

$$\nabla F_p(0)^* z = (u_0, u_1, \ldots, u_m) \in \mathcal{S}_p,$$

with

$$u_j = \sum_{l=1}^{n_j} \mu_{jl} e_{(n_j-l,\lambda_j)}, \qquad j = 1, 2, \ldots, m,$$

is such that

$$\begin{aligned} u_j &= 0 \quad \textit{for } j \notin \mathcal{I}(p) \textit{ and } j \ne 0,\\ Re\,\mu_{j1} \le 0 \textit{ and } Im\,\mu_{j1} &= 0 \quad \textit{for } j \in \mathcal{I}(p),\\ Re\,\mu_{j2} &\le 0 \quad \textit{for } j \in \mathcal{I}(p), \textit{ and}\\ \sum_{j\in\mathcal{I}(p)} n_j\mu_{j1} &= -1. \end{aligned}$$

A more concise representation for the set of regular subgradients is possible. First note that if $p = e_{(n,\lambda_0)}$, then, for $(h_0, h_1) \in \mathcal{S}_p = \mathbb{C}\times\mathcal{P}_{n-1}$,

$$\nabla F_p(0)(h_0, h_1) = h_0 e_{(n,\lambda_0)} + h_1$$

and

$$\nabla F_p(0)^* \sum_{j=0}^{n} b_j e_{(n-j,\lambda_0)} = \left(b_0, \sum_{j=1}^{n} b_j e_{(n-j,\lambda_0)}\right), \tag{2.24}$$

since

$$\left\langle \sum_{j=0}^{n} b_j e_{(n-j,\lambda_0)}, h_0 e_{(n,\lambda_0)} + h_1 \right\rangle_{(n,\lambda_0)} = \left\langle \left(b_0, \sum_{j=1}^{n} b_j e_{(n-j,\lambda_0)}\right), (h_0, h_1) \right\rangle_p .$$

In this case $\nabla F_p(0)^* = \nabla F_p(0)^{-1}$. Hence, by Theorem 2.2, we have the following formula for the set of regular subgradients of a at $e_{(n,\lambda_0)}$:

$$\hat{\partial} a(e_{(n,\lambda_0)}) = \left\{ z \;\middle|\; \begin{array}{c} z = \sum_{j=0}^n \mu_j e_{(n-j,\lambda_0)}, \\ \text{where } \mu_j \in \mathbb{C},\ j = 0, 1, \ldots, n, \\ \mu_1 = \frac{-1}{n},\ \text{and } \operatorname{Re}(\mu_2) \le 0 \end{array} \right\}. \tag{2.25}$$

In the general case a similar formula can be obtained with the aid of the recession cone of the set $\hat{\partial} a(e_{(n,\lambda_0)})$:

$$\hat{\partial} a(e_{(n,\lambda_0)})^\infty = \left\{ z \;\middle|\; \begin{array}{c} z = \sum_{j=0}^n \mu_j e_{(n-j,\lambda_0)}, \\ \text{where } \mu_j \in \mathbb{C},\ j = 0, 1, \ldots, n, \\ \mu_1 = 0,\ \text{and } \operatorname{Re}(\mu_2) \le 0 \end{array} \right\}. \tag{2.26}$$

Define $\hat{\partial} a(e_{(n,\lambda_0)})^{\tilde{\infty}}$ as the projection of $\hat{\partial} a(e_{(n,\lambda_0)})^\infty$ onto $\mathcal{P}_{n-1}$:

$$\hat{\partial} a(e_{(n,\lambda_0)})^{\tilde{\infty}} = \left\{ z \;\middle|\; \begin{array}{c} z = \sum_{j=1}^n \mu_j e_{(n-j,\lambda_0)}, \\ \text{where } \mu_j \in \mathbb{C},\ j = 1, \ldots, n, \\ \mu_1 = 0,\ \text{and } \operatorname{Re}(\mu_2) \le 0 \end{array} \right\}.$$

Then, given a polynomial $p \in \mathcal{M}_n$ having prime factorization (1.33), the set of regular subgradients of a at p has the form

$$\hat{\partial} a(p) = \nabla F_p(0)^{-*} \left[\operatorname{conv} \{ v_j \mid j \in \mathcal{I}(p) \} + K \right], \tag{2.27}$$

where $v_1, \ldots, v_m \in \mathcal{S}_p$ are given by

$$\begin{aligned} v_1 &= -\frac{1}{n_1}(0, e_{(n_1-1,\lambda_1)}, 0, \ldots, 0), \\ v_2 &= -\frac{1}{n_2}(0, 0, e_{(n_2-1,\lambda_2)}, 0, \ldots, 0), \\ &\vdots \\ v_m &= -\frac{1}{n_m}(0, 0, \ldots, 0, e_{(n_m-1,\lambda_m)}), \end{aligned}$$

and K is the convex cone in $\mathcal{S}_p$ given by

$$K = \mathbb{C} \times \hat{\partial} a(e_{(n_1,\lambda_1)})^{\tilde{\infty}} \times \cdots \times \hat{\partial} a(e_{(n_m-1,\lambda_m)})^{\tilde{\infty}}.$$

Observe that this implies the recession cone of $\hat{\partial} a(p)$ is given by

$$\hat{\partial} a(p)^\infty = \nabla F_p(0)^{-*} K. \tag{2.28}$$

3. Subdifferential regularity.

The set of normal vectors to epi (a) at a point $(p, \mu) \in$ epi (a) is given by

$$N_{\operatorname{epi}(a)}(p, \mu) = \left\{ (z, \omega) \;\middle|\; \begin{array}{c} \exists \{(p_k, \mu_k)\} \subset \operatorname{epi}(a),\ \{(z_k, \omega_k)\} \subset \mathcal{P}_n \times \mathbb{R} \\ \text{with } (z_k, \omega_k) \in \widehat{N}_{\operatorname{epi}(a)}(p_k, \mu_k)\ \forall\, k, \\ \text{such that} \\ (p_k, \mu_k) \to (p, \mu) \text{ and } (z_k, \omega_k) \to (z, \omega) \end{array} \right\}. \tag{3.1}$$

By convention $N_{\mathrm{epi}\,(a)}(p,\mu)=\emptyset$ if $(p,\mu)\notin \mathrm{epi}\,(a)$. The abscissa mapping a is said to be subdifferentially regular at a point $(p,\mu)\in \mathrm{epi}\,(a)$ (equivalently, $\mathrm{epi}\,(a)$ is Clarke regular at (p,μ)) if

$$\widehat{N}_{\mathrm{epi}\,(a)}(p,\mu)=N_{\mathrm{epi}\,(a)}(p,\mu) \tag{3.2}$$

[RW98, Definition 7.25]. The goal of this section is to show that the set $\mathrm{epi}\,(a)$ is everywhere subdifferentially regular.

Some simplification in definition (3.1) is possible due to the continuity of a on its domain $\mathcal{M}_n$. Recall from (2.8) that

$$\widehat{N}_{\mathrm{epi}\,(a)}(p,\mu)=\left\{(\beta e_{(n,0)},0)\mid \beta\in\mathbb{C}\right\}\quad \text{whenever } \mu>a(p).$$

Since this subspace is constant on the set $\{(p,\mu)\mid \mu>a(p)\}$, we find that

$$N_{\mathrm{epi}\,(a)}(p,\mu)=\widehat{N}_{\mathrm{epi}\,(a)}(p,\mu)\quad \text{whenever } \mu>a(p).$$

Therefore, to establish that a is everywhere subdifferentially regular we need only establish the equivalence (3.2) at the points $(p,a(p))$ for $p\in\mathcal{M}_n$. In addition, from (2.7), we have $\left\{(\beta e_{(n,0)},0)\mid \beta\in\mathbb{C}\right\}\subset \widehat{N}_{\mathrm{epi}\,(a)}(p,\mu)$ for all $(p,\mu)\in\mathrm{epi}\,(a)$. Hence, it is always the case that

$$\widehat{N}_{\mathrm{epi}\,(a)}(p,\eta)\subset \widehat{N}_{\mathrm{epi}\,(a)}(p,\mu)\quad \text{whenever } a(p)\le\mu<\eta.$$

Therefore, the representation for the normal cone at the points $(p,a(p))$ for $p\in\mathcal{M}_n$ can be refined to

$$N_{\mathrm{epi}\,(a)}(p,a(p))=\left\{(z,\omega)\;\middle|\;\begin{array}{c}\exists\,\{p_k\}\subset\mathcal{M}_n,\ \{(z_k,\omega_k)\}\subset\mathcal{P}_n\times\mathbb{R}\\ \text{with } (z_k,\omega_k)\in\widehat{N}_{\mathrm{epi}\,(a)}(p_k,a(p_k))\ \forall\,k,\\ \text{such that}\\ p_k\to p \text{ and } (z_k,\omega_k)\to(z,\omega)\end{array}\right\}. \tag{3.3}$$

However, even with this simplification, we are confronted with a significant technical hurdle. Recall from Theorem 2.1 that the regular normals are characterized through the adjoint operator $\nabla F_p(0)^*$. Therefore, we now need to compute limits of these operators along sequences $p_k\to p$. But these adjoints are defined as linear transformations from $\mathcal{P}_n$ to $\mathcal{S}_{p_k}$ and are based on the inner products $\langle\cdot\,,\cdot\rangle_{p_k}$. How can we interpret limits of the adjoints $\nabla F_{p_k}(0)^*$ when the spaces $\mathcal{S}_{p_k}$ and their associated inner products $\langle\cdot\,,\cdot\rangle_{p_k}$ may not even be commensurate? The answer again lies with the local factorization lemma, Lemma 1.4.

Suppose that the polynomial $p\in\mathcal{M}_n$ has prime factorization (1.33) and let $\{p_k\}$ be a sequence of monic polynomials converging to p. Lemma 1.4 says that, by trimming off finitely many elements of the sequence if necessary, we may assume with no loss of generality that each of the polynomials p_k has a factorization of the form

$$p_k=\prod_{j=1}^{m}q_{kj}, \tag{3.4}$$

where the roots of the polynomials q_{kj}, $j=1,\dots,m$, are pairwise disjoint and $q_{kj}\to e_{(n_j,\lambda_j)}$ for each $j=1,\dots,m$. Moreover, since there are only finitely many partitions of n, we may assume with no loss in generality (by extracting a subsequence if necessary) that there exist positive integers ℓ_j, $j = 1, \ldots, m$, and n_{js}, $j = 1, \ldots, m$, $s = 1, \ldots, \ell_j$, with $\sum_{s=1}^{\ell_j} n_{js} = n_j$, such that, for each $k = 1, 2, \ldots$,

$$q_{kj} = \prod_{s=1}^{\ell_j} e_{(n_{js}, \lambda_{kjs})}, \tag{3.5}$$

where the complex numbers λ_{kjs}, $j = 1, \ldots, m$, $s = 1, \ldots, \ell_{kj}$ are distinct and satisfy $\lambda_{kjs} \to \lambda_j$ for $s = 1, \ldots, \ell_j$. Hence, for each $k = 1, 2, \ldots$, we have

$$\mathcal{S}_{p_k} = \mathbb{C} \times \left[\bigtimes_{j=1}^{m} \left(\mathcal{P}_{n_{j1}-1} \times \cdots \times \mathcal{P}_{n_{j\ell_j}-1} \right) \right], \tag{3.6}$$

$$F_{p_k}(v_0, v_{11}, \ldots, v_{1\ell_1}, \ \ldots \ , v_{m1}, \ldots, v_{m\ell_m}) = (1 + v_0) \prod_{j=1}^{m} \prod_{s=1}^{\ell_j} (e_{(n_{js}, \lambda_{kjs})} + v_{js}), \tag{3.7}$$

and

$$\nabla F_{p_k}(0)(h_0, h_{11}, \ldots, h_{1\ell_1}, \ \ldots \ , h_{m1}, \ldots, h_{m\ell_m}) = h_0 r_{k0} + \sum_{j=1}^{m} r_{kj} \left(\sum_{s=1}^{\ell_j} \hat{r}_{kjs} h_{js} \right), \tag{3.8}$$

where

$$r_{k0} = p_k \quad \text{and} \quad r_{kj_0} = \prod_{j \neq j_0} \prod_{s=1}^{\ell_j} e_{(n_{js}, \lambda_{kjs})}, \qquad j_0 = 1, \ldots, m,$$

and

$$\hat{r}_{kj_0 s_0} = \prod_{\substack{s=1 \\ s \neq s_0}}^{\ell_{j_0}} e_{(n_{j_0 s}, \lambda_{kj_0 s})}, \quad j_0 = 1, \ldots, m, \ s_0 = 1, \ldots, \ell_j \ .$$

Let us write $\hat{\mathcal{S}} = \mathcal{S}_{p_k}$, since $\mathcal{S}_{p_k}$ is fixed for all $k = 1, 2, \ldots$. Note that as $k \to \infty$, we have $r_{kj} \to r_j$, where r_j is defined in (1.37), for $j = 0, 1, \ldots, m$, and $\hat{r}_{kjs} \to e_{(\bar{n}_{js}, \lambda_j)}$, where $\bar{n}_{js} = n_j - n_{js}$, for $j = 1, \ldots, m$, $s = 1, \ldots, \ell_j$. Hence, $\nabla F_{p_k}(0) \to \Psi$, where the linear transformation $\Psi : \hat{\mathcal{S}} \to \mathcal{P}_n$ is given by

$$\Psi(h_0, h_{11}, \ldots, h_{1\ell_1}, \ \ldots \ , h_{m1}, \ldots, h_{m\ell_m}) = h_0 r_0 + \sum_{j=1}^{m} r_j \left(\sum_{s=1}^{\ell_j} e_{(\bar{n}_{js}, \lambda_j)} h_{js} \right). \tag{3.9}$$

Observe that the representation of $\nabla F_p(0)$ given in (1.36) and (1.37) enables us to write the operator Ψ as the composition

$$\Psi = \nabla F_p(0) \circ \Xi, \tag{3.10}$$

where the linear operator $\Xi : \hat{\mathcal{S}} \to \mathcal{S}_p$ is given by

$$\begin{aligned} &\Xi(h_0, h_{11}, \ldots, h_{1\ell_1},.,.,h_{m1}, \ldots, h_{m\ell_m}) \\ &\qquad = \left(h_0, \sum_{s=1}^{\ell_1} e_{(\bar{n}_{1s}, \lambda_1)} h_{1s}, \ldots, \sum_{s=1}^{\ell_m} e_{(\bar{n}_{ms}, \lambda_m)} h_{ms} \right). \end{aligned} \tag{3.11}$$

Theorem 2.1 gives us access to the regular normals through the adjoint operators $\nabla F_p(0)^*$. Thus, in order to understand the normal cone, which consists of the limits of the regular normals, we need to come to an understanding of the limit of the adjoints $\nabla F_{p_k}(0)^*$. This limit is an adjoint of the operator Ψ. However, what this means needs clarification since each of the adjoints $\nabla F_{p_k}(0)^*$ arises from a different duality pairing. We need to determine the correct duality pairing for the definition of the adjoint Ψ^* so that it is the limit of the operators $\nabla F_{p_k}(0)^*$.

The duality pairing that we seek is obtained from our earlier observation (2.3) that the mapping $(p, q, \lambda) \mapsto \langle p\,, q\rangle_{(n,\lambda)}$ is continuous. This continuity implies that the pointwise limit of the inner products $\langle\cdot\,,\cdot\rangle_{p_k}$ exists as $k \to \infty$. Indeed, for each

$$u = (u_0, u_{11}, \ldots, u_{1\ell_1}, \ \ldots\ , u_{1\ell_m}, \ldots, u_{m\ell_m})$$

and

$$v = (v_0, v_{11}, \ldots, v_{1\ell_1}, \ \ldots\ , v_{1\ell_m}, \ldots, v_{m\ell_m})$$

in $\hat{\mathcal{S}}$, we have

$$\langle u\,, v\rangle_{p_k} \to \langle u\,, v\rangle_{\infty}\,,$$

where

$$\langle u\,, v\rangle_{\infty} = \langle u_0\,, v_0\rangle + \sum_{j=1}^{m}\sum_{s=1}^{\ell_j} \langle u_{js}\,, v_{js}\rangle_{(n_{js}-1,\lambda_j)}\ . \tag{3.12}$$

Therefore, if we define Ψ^* to be the adjoint of Ψ with respect to the duality pairings $(\mathcal{P}_n, \langle\cdot\,,\cdot\rangle)$ and $(\hat{\mathcal{S}}, \langle\cdot\,,\cdot\rangle_{\infty})$, then

$$\nabla F_{p_k}(0)^* \to \Psi^*. \tag{3.13}$$

Our next task is to derive a representation for the operator Ψ^*. Using the representation for Ψ given in (3.10), this reduces to deriving a representation for the adjoint of the operator Ξ. For this, the following lemma provides the key.

LEMMA 3.1. *Let $\lambda_0 \in \mathbb{C}$ and let $\delta = (n_1, n_2, \ldots, n_m)$ be a partition of n. Define $\mathcal{D}_\delta$ to be the product space*

$$\mathcal{D}_\delta = \mathcal{P}_{(n_1-1)} \times \mathcal{P}_{(n_2-1)} \times \cdots \times \mathcal{P}_{(n_m-1)},$$

endowed with the inner product

$$\langle (u_1, \ldots, u_m)\,, (v_1, \ldots, v_m)\rangle_{(\delta,\lambda_0)} = \sum_{j=1}^{m} \langle u_j\,, v_j\rangle_{(n_j-1,\lambda_0)}\,.$$

For $j = 1, 2, \ldots, m$, define $\bar{n}_j = n - n_j$ and consider the linear transformation $\Phi_{(\delta,\lambda_0)} : \mathcal{D}_\delta \to \mathcal{P}_{n-1}$ given by

$$\Phi_{(\delta,\lambda_0)}(h_1, \ldots, h_m) = \sum_{j=1}^{m} e_{(\bar{n}_j,\lambda_0)} h_j\ .$$

Then the adjoint of $\Phi_{(\delta,\lambda_0)}$ with respect to the duality pairings

$$(\mathcal{P}_{n-1}, \langle\cdot\,,\cdot\rangle_{(n-1,\lambda_0)}) \quad \text{and} \quad (\mathcal{D}_\delta, \langle\cdot\,,\cdot\rangle_{(\delta,\lambda_0)})$$

is given by

$$\Phi^*_{(\delta,\lambda_0)}\left(\sum_{j=1}^{n} b_j e_{(n-j,\lambda_0)}\right) = \left(\sum_{j=1}^{n_1} b_j e_{(n_1-j,\lambda_0)},\ldots,\sum_{j=1}^{n_m} b_j e_{(n_m-j,\lambda_0)}\right).$$

Proof. Define $J_s = \{j \mid n_j \geq s\}$ for $s = 1, 2, \ldots, n$. Note that J_s may be empty for some values of s. For example, if $m \geq 2$, then $J_n = \emptyset$. Let $(h_1, \ldots, h_m) \in \mathcal{D}_\delta$, where each $h_j \in \mathcal{P}_{n_j-1}$ has representation

$$h_j = a_{j1} e_{(n_j-1,\lambda_0)} + a_{j2} e_{(n_j-2,\lambda_0)} + \cdots + a_{jn_j}\ .$$

Given $q \in \mathcal{P}_{n-1}$ with

$$q = b_1 e_{(n-1,\lambda_0)} + \cdots + b_n,$$

we have

$$\begin{aligned}
&\big\langle q\,, \Phi_{(\delta,\lambda_0)}(h_1,\ldots,h_m)\big\rangle_{(n-1,\lambda_0)}\\
&= \Bigg\langle \big(b_1 e_{(n-1,\lambda_0)} + \cdots + b_n\big)\ ,\ \Bigg(e_{(n-1,\lambda_0)}\left(\sum_{j\in J_1} a_{j1}\right)\\
&\qquad\qquad + e_{(n-2,\lambda_0)}\left(\sum_{j\in J_2} a_{j2}\right) + \cdots + \left(\sum_{j\in J_n} a_{jn}\right)\Bigg)\Bigg\rangle_{(n-1,\lambda_0)}\\
&= \operatorname{Re}\left[\bar b_1\left(\sum_{j\in J_1} a_{j1}\right) + \cdots + \bar b_n\left(\sum_{j\in J_n} a_{jn}\right)\right]\\
&= \operatorname{Re}\left[\sum_{s=1}^{n_1} \bar b_s a_{1s} + \sum_{s=1}^{n_2} \bar b_s a_{2s} + \cdots + \sum_{s=1}^{n_m} \bar b_s a_{ms}\right]\\
&= \Bigg\langle \left(\sum_{s=1}^{n_1} b_s e_{(n_1-s,\lambda_0)},\ldots,\sum_{s=1}^{n_m} b_s e_{(n_m-s,\lambda_0)}\right)\ ,\\
&\qquad\qquad \left(\sum_{s=1}^{n_1} a_{1s} e_{(n_1-s,\lambda_0)},\ldots,\sum_{s=1}^{n_m} a_{ms} e_{(n_m-s,\lambda_0)}\right)\Bigg\rangle_{(\delta,\lambda_0)}\\
&= \Bigg\langle \left(\sum_{s=1}^{n_1} b_s e_{(n_1-s,\lambda_0)},\ldots,\sum_{s=1}^{n_m} b_s e_{(n_m-s,\lambda_0)}\right)\ ,(h_1,\ldots,h_m)\Bigg\rangle_{(\delta,\lambda_0)}.
\end{aligned}$$

Since this relation holds for all possible choices of $q \in \mathcal{P}_{n-1}$ and $(h_1, \ldots, h_m) \in \mathcal{D}_\delta$, we have established the result. □

By using the notation developed in Lemma 3.1, we can rewrite the operator $\Xi : \hat{\mathcal{S}} \to \mathcal{S}_p$, defined in (3.11), as

$$\Xi = \big(I, \Phi_{(\delta_1,\lambda_1)}, \ldots, \Phi_{(\delta_m,\lambda_m)}\big)\,, \tag{3.14}$$

where $\delta_j = (n_{j1}, n_{j2}, \ldots, n_{j\ell_j})$ is a partition of n_j for each $j = 1, 2, \ldots, m$. Hence, from (3.10), we have

$$\Psi^* = \Xi^* \circ \nabla F_p(0)^*, \tag{3.15}$$

where $\Xi^* : \mathcal{S}_p \to \hat{\mathcal{S}}$ can be written as

$$\Xi^* = \left(I, \Phi^*_{(\delta_1,\lambda_1)}, \dots, \Phi^*_{(\delta_m,\lambda_m)} \right). \tag{3.16}$$

An explicit representation for the operator Ξ^* can be obtained by applying Lemma 3.1 to each of the operators $\Phi_{(\delta_j,\lambda_j)}$ for $j = 1, 2, \dots, m$.

We now prove the main result of this section.

Theorem 3.2. *The abscissa mapping a is everywhere subdifferentially regular. Equivalently, epi (a) is Clarke regular.*

Proof. Let $p \in \mathcal{P}_n$ have factorization (1.33). Let $(z, \omega) \in N_{\text{epi}\,(a)}(p, a(p))$ so that there exist sequences $\{p_k\} \subset \mathcal{M}_n$ and $\{(z_k, \omega_k)\} \subset \mathcal{P}_n \times \mathbb{R}$ such that $p_k \to p$, $(z_k, \omega_k) \to (z, \omega)$, and $(z_k, \omega_k) \in \widehat{N}_{\text{epi}\,(a)}(p_k, a(p_k))$ for $k = 1, 2, \dots$. We need to show that $(z, \omega) \in \widehat{N}_{\text{epi}\,(a)}(p, a(p))$.

The discussion preceding this theorem shows that we may assume with no loss of generality that (3.4)–(3.16) hold for the sequence $\{p_k\}$. Hence, we make free use of these facts and their associated notations.

Let $\tilde{\mathcal{I}}(p_k) = \{(j, s) \mid a(p_k) = \operatorname{Re} \lambda_{kjs}\}$. Since $(z_k, \omega_k) \in \widehat{N}_{\text{epi}\,(a)}(p_k, a(p_k))$ for $k = 1, 2, \dots$, Theorem 2.1 states that $\omega_k \le 0$ and there exists

$$u_k = (u_{k0}, u_{k11}, \dots, u_{k1\ell_1}, \dots, u_{km1}, \dots, u_{km\ell_m}) \in \hat{\mathcal{S}}$$

with

$$u_{kjs} = \sum_{t=1}^{n_{js}} \mu_{kjst} e_{(n_{js}-t, \lambda_{kjs})}, \qquad \begin{array}{l} k = 1, 2, \dots, \\ j = 1, 2, \dots, m, \\ s = 1, 2, \dots, \ell_j \ , \end{array}$$

such that

$$u_k = \nabla F_{p_k}(0)^* z_k, \tag{3.17}$$

$$u_{kjs} = 0 \quad \text{for } (j, s) \notin \tilde{\mathcal{I}}(p_k), \tag{3.18}$$

$$\operatorname{Re} \mu_{kjs1} \le 0 \text{ and } \operatorname{Im} \mu_{kjs1} = 0 \quad \text{for } (j, s) \in \tilde{\mathcal{I}}(p_k), \tag{3.19}$$

$$\operatorname{Re} \mu_{kjs2} \le 0 \quad \text{for } (j, s) \in \tilde{\mathcal{I}}(p_k), \text{ and} \tag{3.20}$$

$$\sum_{(j,s) \in \tilde{\mathcal{I}}(p_k)} n_{js} \mu_{kjs1} = \omega_k. \tag{3.21}$$

Due to the finiteness of the index sets, we may assume with no loss of generality that $\tilde{\mathcal{I}}(p_k) = \tilde{\mathcal{I}}$ for all $k = 1, 2, \dots$. Define

$$\hat{\mathcal{I}} = \left\{ j \;\middle|\; (j, s) \in \tilde{\mathcal{I}} \text{ for some } s = 1, \dots, \ell_j \right\}.$$

By the continuity of the roots of the monic polynomials (as a multivalued mapping), we have $\hat{\mathcal{I}} \subset \mathcal{I}(p)$, where $\mathcal{I}(p)$ is defined in (1.38).

Using (3.13), let

$$u = \Psi^* z = \lim_{k \to \infty} \nabla F_{p_k}(0)^* z_k = \lim_{k \to \infty} u_k \tag{3.22}$$

and write

$$u = (u_0, u_{11}, \dots, u_{1\ell_1}, \dots, u_{m1}, \dots, u_{m\ell_m}) \in \hat{\mathcal{S}}$$

where

$$u_{js} = \sum_{t=1}^{n_{js}} \mu_{jst} e_{(n_{js}-t,\lambda_j)}, \tag{3.23}$$

with $\mu_{kjst} \to \mu_{jst}$ for $j = 1,\ldots,m,\ s = 1,\ldots,\ell_j,\ t = 1,\ldots,n_{js}$. By (3.22) and (3.17)–(3.21), we have

$$u_{js} = 0 \quad \text{for } (j,s) \notin \tilde{\mathcal{I}}, \tag{3.24}$$

$$\operatorname{Re}\mu_{js1} \le 0 \text{ and } \operatorname{Im}\mu_{js1} = 0 \quad \text{for } (j,s) \in \tilde{\mathcal{I}}, \tag{3.25}$$

$$\operatorname{Re}\mu_{js2} \le 0 \quad \text{for } (j,s) \in \tilde{\mathcal{I}}, \text{ and} \tag{3.26}$$

$$\sum_{(j,s)\in\tilde{\mathcal{I}}} n_{js}\mu_{js1} = \omega. \tag{3.27}$$

Set

$$(w_0, w_1, \ldots, w_m) = \nabla F_p(0)^* z, \tag{3.28}$$

with

$$w_j = \sum_{s=1}^{n_j} b_{js} e_{(n_j-s,\lambda_j)} \qquad \text{for } j = 1,\ldots,m. \tag{3.29}$$

By (3.15), (3.16), (3.22), and (3.28), we have

$$(u_{j1}, u_{j2}, \ldots, u_{j\ell_j}) = \Phi^*_{(\delta_j,\lambda_j)} w_j \qquad \text{for } j = 1,\ldots,m.$$

Consequently, by Lemma 3.1 and (3.23),

$$u_{js} = \sum_{t=1}^{n_{js}} \mu_{jst} e_{(n_{js}-t,\lambda_j)} = \sum_{t=1}^{n_{js}} b_{jt} e_{(n_{js}-t,\lambda_j)}$$

for $j = 1,\ldots,m,\ s = 1,\ldots,\ell_j$, or equivalently,

$$\mu_{jst} = b_{jt} \qquad \text{for } j = 1,\ldots,m,\ s = 1,\ldots,\ell_j,\ t = 1,\ldots,n_{js}. \tag{3.30}$$

Combining this with (3.24) and the definitions (3.23) and (3.29), we find

$$w_j = 0 \quad \text{for } j \notin \hat{\mathcal{I}}, \tag{3.31}$$

and combining (3.30) with (3.25) and (3.26) yields

$$\operatorname{Re} b_{j1} \le 0 \text{ and } \operatorname{Im} b_{j1} = 0 \quad \text{for } j \in \hat{\mathcal{I}} \text{ and} \tag{3.32}$$

$$\operatorname{Re} b_{j2} \le 0 \quad \text{for } j \in \hat{\mathcal{I}}. \tag{3.33}$$

Finally, by combining (3.30) with (3.27), we find

$$\sum_{(j,s)\in\tilde{\mathcal{I}}} n_{js} b_{j1} = \omega. \tag{3.34}$$

Note that the equivalence (3.30) implies that for every $j \in \hat{\mathcal{I}}$ for which $b_{j1} \neq 0$ it must be the case that $\mu_{js1} \neq 0$ for $s = 1, 2, \dots \ell_j$ and so $\{(j1), (j2), \dots, (j\ell_j)\} \subset \tilde{\mathcal{I}}$. Therefore, by (3.27) and (3.34),

$$\omega = \sum_{(j,s)\in\tilde{\mathcal{I}}} n_{js} b_{j1} = \sum_{j\in\hat{\mathcal{I}}} \sum_{s=1}^{\ell_j} b_{j1} n_{js} = \sum_{j\in\hat{\mathcal{I}}} b_{j1} n_j .$$

Consequently, by (3.28), (3.29), (3.31), (3.32), (3.33), the inclusion $\hat{\mathcal{I}} \subset \mathcal{I}(p)$, and Theorem 2.1, we find that $(z, \omega) \in \widehat{N}_{\mathrm{epi}\,(a)}(p, a(p))$, which establishes the result. □

Just as the set of normal vectors is defined to be the set of limits of regular normal vectors, the set of subgradients is defined to be the set of limits of regular subgradients:

$$\partial a(p) = \left\{ q \;\middle|\; \begin{array}{c} \exists\, \{p_k\} \subset \mathrm{dom}\,(a) \text{ and } \{q_k\} \subset \mathcal{P}_n, \\ \text{such that } q_k \in \hat{\partial} a(p_k)\, \forall\, k = 1, 2, \dots, \\ p_k \to p \text{ and } q_k \to q \end{array} \right\}, \tag{3.35}$$

with $\partial a(p) = \emptyset$ if $p \notin \mathrm{dom}\, a = \mathcal{M}_n$. The set of *horizon subgradients*, denoted $\partial^\infty \alpha(p)$, is defined similarly, however, instead of $q_k \to q$ one has $t_k q_k \to q$ for some sequence of positive real numbers $\{t_k\}$ converging to zero. By convention, we have $\partial^\infty a(p) = \{0\}$ if $p \notin \mathrm{dom}\, a$. As in the case of regular subgradients, there is a relationship between these subgradients and the normal cone at a polynomial $p \in \mathcal{M}_n$ [RW98, Theorem 8.9]:

$$\partial a(p) = \left\{ q \;\middle|\; (q, -1) \in N_{\mathrm{epi}\,(a)}(p, a(p)) \right\}$$

and

$$\partial^\infty a(p) = \left\{ q \;\middle|\; (q, 0) \in N_{\mathrm{epi}\,(a)}(p, a(p)) \right\}.$$

Using these relationships, Theorem 3.2 and [RW98, Corollary 8.11] imply that

$$\partial a(p) = \hat{\partial} a(p) \quad \text{and} \quad \partial^\infty a(p) = \hat{\partial} a(p)^\infty \tag{3.36}$$

whenever $p \in \mathcal{M}_n$ (see (2.27) and (2.28)).

The subdifferential regularity of the abscissa mapping implies that it possesses a rich subdifferential calculus. For example, the following chain rule holds.

THEOREM 3.3 (see [RW98, Theorem 10.6]). *Let X be a finite dimensional Euclidean space, and suppose $G : X \to \mathcal{P}_n$ is continuously differentiable in the real sense. Consider the composite mapping $g = a \circ G$. If $x \in X$ is such that $G(x) \in \mathcal{M}_n$ and the only polynomial $q \in \partial^\infty a(G(x))$ with $\nabla G(x)^* q = 0$ is $q = 0$, then*

$$\partial g(x) = \nabla G(x)^* \partial a(G(x)), \qquad \partial^\infty g(x) = \nabla G(x)^* \partial^\infty a(G(x)),$$

and

$$dg(x)(d) = da(G(x))(\nabla G(x) d).$$

To illustrate these results, we apply Theorem 3.3 to the example studied in [BLO]. Let X be $\mathbb{C}^n$ with the standard real inner product, and consider the composition of the abscissa function with the affine mapping $G : \mathbb{C}^n \to \mathcal{P}_n$ given by

$$G(x) = (1 + x_0) e_{(n,0)} + x_1 e_{(n-1,0)} - \sum_{j=2}^{n} x_{j-1} e_{(n-j,0)}.$$

In [BLO, Theorem 2.1], it is shown that $x = 0$ is a strict global minimizer of the function $g = a \circ G$. Since G is affine, we have

$$\nabla G(0)d = d_0 e_{(n,0)} + d_1 e_{(n-1,0)} - \sum_{j=2}^{n} d_{j-1} e_{(n-j,0)},$$

and

$$\nabla G(0)^* \sum_{j=0}^{n} y_j e_{(n-j,0)} = (y_0, y_1 - y_2, -y_3, \ldots, -y_n).$$

The representation for $\partial^\infty a(e_{(n,0)})$ given by (3.36) and (2.26) shows that the only $q \in \partial^\infty a(e_{(n,0)})$ with $\nabla G(0)^* q = 0$ is $q = 0$. Therefore, Theorem 3.3 and the relations (3.36) and (2.25) show that

$$\hat{\partial} g(0) = \partial g(0) = \left\{ \left(z_0, z_1 - \frac{1}{n}, z_2, \ldots, z_{n-1} \right) \mid \operatorname{Re} z_1 \geq 0 \right\}.$$

Finally, observe that since the origin is in the interior of $\hat{\partial} g(0)$, we have, directly from the definition of regular subgradients, that $x = 0$ is a *sharp* minimizer of g in the sense that there exist $\epsilon > 0$ and $\kappa > 0$ such that

$$g(x) \geq g(0) + \kappa \|x\| \qquad \text{whenever} \quad \|x\| \leq \epsilon.$$

Further consequences of these results are explored in [BLO].

Acknowledgment. We gratefully acknowledge a referee for a careful reading of the paper and for several useful suggestions.

ON THE CONTROLLABILITY OF THE LINEARIZED BENJAMIN–BONA–MAHONY EQUATION[*]

SORIN MICU[†]

Abstract. We study the boundary controllability properties of the linearized Benjamin–Bona–Mahony equation

$$\begin{cases} u_t - u_{xxt} + u_x = 0, & x \in (0,1),\, t > 0, \\ u(t,0) = 0,\ u(1,t) = f(t), & t > 0. \end{cases}$$

We show that the equation is approximately controllable but not spectrally controllable (no finite linear combination of eigenfunctions, other than zero, is controllable). Next, we prove a finite controllability result and we estimate the norms of the controls needed in this case.

Key words. boundary control, moments, biorthogonals

1. Introduction.

The Benjamin–Bona–Mahony (BBM) equation

$$u_t + u_x + uu_x - u_{xxt} = 0, \tag{1.1}$$

like the Korteweg-de Vries (KdV) equation

$$u_t + u_x + uu_x + u_{xxx} = 0, \tag{1.2}$$

was originally derived as approximation for surface water waves in a uniform channel (see, for instance, [3], [4], and [5]).

Both (1.1) and (1.2) also cover cases of the following type: surface waves of long wavelength in liquids, acoustic-gravity waves in compressible fluids, hydromagnetic waves in cold plasma, acoustic waves in anharmonic crystals, etc. The wide applicability of these equations is the main reason why, during the last decades, they have attracted so much attention from mathematicians.

The main mathematical difference between KdV and BBM models can be most readily appreciated by comparing the dispersion relation for the respective linearized equations. It can be easily seen that these relations are comparable only for small wave numbers (i.e., long waves) and they generate drastically different responses to short waves (which are irrelevant to its role as a physical model). This is one of the reasons why, whereas existence and regularity theory for the KdV equation is difficult, the theory of the BBM equation is comparatively simple. The computing is also much easier for (1.1) than for (1.2).

The existence, uniqueness, and regularity of the BBM equation have been studied, for instance, in [7] and [18]. The large time behavior of the solutions of (1.1) was also intensively analyzed in the last decade (see, for instance, [1], [2], and [3]).

Although it is generally considered that the BBM equation is easier to deal with than the KdV equation, it seems that, from the controllability point of view, (1.2) offers greater possibilities than (1.1). While important progress has been made in the last years for the KdV (see, for instance, [20], [24], and [21]), very little is known about the BBM. Some interior unique continuation properties for (1.1) and related problems (the linear case included) were studied in [9]. It is well known that, for the linear equation, by using the Hilbert uniqueness method due to J.-L. Lions (see [15]), the unique continuation property implies approximate controllability. Therefore, from [9], some approximate interior controllability results can be obtained for the linearized BBM equation. Nevertheless, the approximate controllability results for the nonlinear case do not seen to be entirely reducible to a unique continuation property and some estimates are needed on the dependence of the control function with respect to the perturbation introduced by the nonlinear term. In [23], (1.1) posed in $\mathbb{R}_+$ with boundary control is studied. It is proved that approximate controllability holds for the corresponding linear equation.

As far as we know there are no results for the controllability of the nonlinear BBM equation.

The present paper is concerned with the boundary controllability properties of the linearized BBM equation in finite domain. More precisely, given $T > 0$ and $u_0 \in H^{-1}(0,1)$ can we find a control function $f \in L^2(0,T)$ such that the solution u of

$$(1.3) \qquad \begin{cases} u_t - u_{xxt} + u_x = 0, & t > 0, \qquad x \in (0,1), \\ u(t,0) = 0,\ u(t,1) = f(t), & t > 0, \\ u(0,x) = u_0(x), & x \in (0,1), \end{cases}$$

satisfies

$$(1.4) \qquad u(T,x) = 0, \quad x \in (0,1)?$$

We shall first show that (1.3) is not spectrally controllable. This means that no finite linear nontrivial combination of eigenvectors can be driven to zero in finite time by using a control $f \in L^2(0,T)$.

Nevertheless, (1.3) is approximately controllable, i.e., the set of reachable states

$$R(T,u_0) = \{u(T,x) \mid f \in L^2(0,T)\}$$

is dense in $L^2(0,1)$ for any $u_0 \in H^{-1}(0,1)$ and $T > 0$. Hence, given $T > 0$, $u_0 \in H^{-1}(0,1)$, $v_0 \in H^{-1}(0,1)$, and $\varepsilon > 0$, there exists a control function $f \in L^2(0,T)$ such that the solution u of (1.3) satisfies $||u(T) - v_0||_{L^2(0,1)} < \varepsilon$.

These two results can be found at the beginning of the last section (Theorems 4.2 and 4.3).

We refer to [19] for similar negative results in the context of the exact controllability of the linear heat equation in a half-line.

Another interesting problem, with practical relevance, is the following finite controllability property: given $T > 0$, $N > 0$, and $u_0 \in H^{-1}(0,1)$, is there a control $f_N \in L^2(0,T)$ such that the projection of the solution of (1.3) over the finite dimensional space generated by the first $2N$ eigenvectors is equal to zero at $t = T$?

We give a positive answer to this question in Theorem 4.6. Moreover, by using some estimates for the corresponding biorthogonal sequences, we analyze how the norms of the controls change with N. We find an upper bound for the norms of the controls and we prove that this is, in some sense, sharp. More precisely, we prove that for any initial data $u_0 \in H^{-1}(0,1)$ there exists a control f_N such that

$$\| f_N \|_{L^2(0,T)} \leq c_1 e^{\gamma_1 N \ln(N)} \| u_0 \|_{H^{-1}(0,1)}, \tag{1.5}$$

where c_1 and γ_1 do not depend on N. Moreover, there are initial data $u_0 \in H_0^1(0,1)$ for which any corresponding control f_N satisfies

$$c_2 e^{\gamma_2 N \ln(N)} \| u_0 \|_{H_0^1(0,1)} \leq \| f_N \|_{L^2(0,T)}, \tag{1.6}$$

where c_2 and γ_2 do not depend on N.

We remark that the norms of the controls f_N may increase very rapidly as N goes to infinity. Hence, the cost needed to drive to zero the first $2N$ eigenmodes can be very high when N is large.

The controllability of the KdV equation has been studied in [20], [21], and [24]. It has been proved that exact controllability holds for the linearized equation with different boundary conditions and number of controls. Hence, a Sobolev space of initial data can be controlled from the boundary. This implies that the linearized KdV equation is not only spectrally controllable but also N-partially controllable with uniformly bounded controls. Therefore the boundary controllability properties of the linearized KdV are much "nicer" than the corresponding ones for the linearized BBM (which is not spectrally controllable and not uniformly N-partially controllable). We also remark that, based on the linear case, local or global controllability results (depending on the number of controls) can be obtained for the nonlinear KdV equation.

The paper is organized in the following way. In the second section we study the differential operator A corresponding to (1.3). We prove that A has a sequence of purely imaginary eigenvalues $(i\lambda_n)_{n\in\mathbb{Z}^*}$ such that $\lim_{|n|\to\infty} \lambda_n = 0$.

In the third section we analyze the biorthogonal sequences to the exponentials family $\{e^{i\lambda_n t}\}_{n\in\mathbb{Z}^*}$ or to a subset of it. First, we prove that there is no full biorthogonal sequence. Next we concentrate our attention on the finite families $\{e^{i\lambda_n t}\}_{\substack{|n|\leq N \\ n\neq 0}}$. In this case various biorthogonal sequences can be constructed. We give an example and we analyze the behavior of the norms of the biorthogonals as N goes to infinity. The techniques used in this section combine classical elements from the theory of analytic functions with constructions specific to our problem.

Finally, in the last section, we use the previous results to solve the controllability problems mentioned above.

2. Linearized BBM equation: Elementary properties.

Let us consider the following equation

$$\begin{cases} u_t - u_{xxt} + u_x = 0, & x \in (0,1), \quad t > 0, \\ u(t,0) = u(t,1) = 0, & t > 0, \\ u(0,x) = u_0(x), & x \in (0,1), \end{cases} \tag{2.1}$$

representing the linearized BBM equation.

In order to put (2.1) in an abstract Cauchy form, we apply the operator $(\mathcal{I}-\partial_x^2)^{-1}$. The following equivalent equation is obtained:

$$\begin{cases} u_t + Au = 0, & x \in (0,1), \quad t > 0, \\ u(0) = u_0, & x \in (0,1), \end{cases} \tag{2.2}$$

where $A : H_0^1(0,1) \to H_0^1(0,1)$ is given by

$$Au = (\mathcal{I} - \partial_x^2)^{-1} \partial_x u. \tag{2.3}$$

Here ∂_x^2 denote the Laplace operator

$$\partial_x^2 : H^2(0,1) \cap H_0^1(0,1) \to L^2(0,1), \quad \partial_x^2 u = u_{xx}.$$

The main properties of the operator A are given in the following proposition.

PROPOSITION 2.1. *A is a compact, skew-adjoint operator in $H_0^1(0,1)$.*

Proof. Due to the regularizing effect of the operator $(\mathcal{I} - \partial_x^2)^{-1}$ it follows immediately that A takes values in $H^2(0,1) \cap H_0^1(0,1)$ which is compactly embedded in $H_0^1(0,1)$. Hence A is compact.

Let us consider in $H_0^1(0,1)$ the inner product given by

$$(u,v) = \int_0^1 \partial_x u \partial_x v + \int_0^1 uv. \tag{2.4}$$

For any $u, v \in H^2(0,1) \cap H_0^1(0,1)$, we obtain

$$(Au,v) = \left(\left(\mathcal{I} - \partial_x^2\right)^{-1} \partial_x u, v \right) = \int_0^1 \partial_x \left[\left(\mathcal{I} - \partial_x^2\right)^{-1} \partial_x u \right] \partial_x v + \int_0^1 \left[\left(\mathcal{I} - \partial_x^2\right)^{-1} \partial_x u \right] v$$

$$= \int_0^1 \left(\mathcal{I} - \partial_x^2\right)^{-1} \left(\partial_x^2 u\right) \partial_x v - \int_0^1 \left[\left(\mathcal{I} - \partial_x^2\right)^{-1} u \right] \partial_x v = - \int_0^1 u(\partial_x v)$$

$$= \int_0^1 (\partial_x u) v = - \int_0^1 \partial_x u \left(\mathcal{I} - \partial_x^2\right)^{-1} \left(\partial_x^2 v\right) + \int_0^1 \partial_x u \left[\left(\mathcal{I} - \partial_x^2\right)^{-1} v \right]$$

$$= - \int_0^1 \partial_x u \partial_x \left[\left(\mathcal{I} - \partial_x^2\right)^{-1} \partial_x v \right] - \int_0^1 u \left[\left(\mathcal{I} - \partial_x^2\right)^{-1} \partial_x v \right] = - \left(u, \left(\mathcal{I} - \partial_x^2\right)^{-1} \partial_x v \right)$$

$$= -(u, Av).$$

By density we obtain that $(Au,v) = -(u,Av) \quad \forall u, v \in H_0^1(0,1)$ and therefore A is skew-adjoint in $H_0^1(0,1)$. □

Since A is compact, (2.2) can be treated like an ordinary differential equation in the Hilbert space $H_0^1(0,1)$. By using Cauchy–Lipschitz–Picard theorem the following properties concerning the solutions of (2.2) are immediate.

PROPOSITION 2.2. *Equation* (2.2) *has a unique solution $u \in C^1\left([0,\infty); H_0^1(0,1)\right)$ which satisfies*

$$\int_0^1 \mid \partial_x u(x,t) \mid^2 + \int_0^1 \mid u(x,t) \mid^2 = \int_0^1 \mid \partial_x u_0 \mid^2 + \int_0^1 \mid u_0 \mid^2 . \tag{2.5}$$

Proof. Since A is a bounded linear operator the existence and uniqueness of solutions follow from Cauchy–Lipschitz–Picard theorem (see [8, p. 104]).

On the other hand, since A is skew-adjoint, we have

$$\frac{1}{2} \frac{d}{dt} \parallel u \parallel_{H_0^1}^2 = Re(u, u_t) = Re(u, -Au) = 0.$$

Hence, the H_0^1 norm of the solution is conserved. □

Remark 2.1. *In fact much more can be said about the regularity of solutions of* (2.2). *Since* (2.2) *is linear and A is a bounded operator we can easily deduce that $u \in C^\omega\left([0,\infty);\, H_0^1(0,1)\right)$, where $C^\omega\left([0,\infty);\, H_0^1(0,1)\right)$ represents the class of analytic functions defined in $[0,\infty)$ with values in $H_0^1(0,1)$. Indeed, for $t_0 \in [0,\infty)$,*

$$\left\|\sum_{n=0}^{\infty} u^{(n)}(t_0)\frac{(t-t_0)^n}{n!}\right\|_{H_0^1} \le \sum_{n=0}^{\infty} \frac{|t-t_0|^n}{n!}\left\|u^{(n)}(t_0)\right\|_{H_0^1}$$

$$\le \sum_{n=0}^{\infty} \frac{|t-t_0|^n}{n!}\,||A||^n\,||u(t_0)||_{H_0^1} < \infty.$$

Hence the series $\sum_{n=0}^{\infty} u^{(n)}(t_0)\frac{(t-t_0)^n}{n!}$ is (absolutely) convergent and

$$u(t) = \exp\left(-A(t-t_0)\right)u(t_0) = \sum_{n=0}^{\infty}(-1)^n\frac{(t-t_0)^n}{n!}A^n u(t_0) = \sum_{n=0}^{\infty}\frac{(t-t_0)^n}{n!}u^{(n)}(t_0).$$

Our next objective is to express the solution u of (2.2) in Fourier series. To do so we need the spectral decomposition of the operator A.

Proposition 2.3. *A has a sequence of purely imaginary eigenvalues $(\mu_n)_{n\in\mathbb{Z}^*}$,*

$$\mu_n = \operatorname{sgn}(n)\frac{i}{2\sqrt{1+n^2\pi^2}}, \quad n \in \mathbb{Z}^*. \tag{2.6}$$

Moreover, to each eigenvalue μ_n corresponds an unique eigenfunction U_n,

$$U_n(x) = \frac{1}{\sqrt{n^2\pi^2+1}}e^{-i\operatorname{sgn}(n)\sqrt{n^2\pi^2+1}x}\sin(n\pi x), \quad n \in \mathbb{Z}^*, \tag{2.7}$$

such that $\| U_n \|_{H_0^1}= 1$. The family $(U_n)_{n\in\mathbb{Z}^*}$ forms an orthonormal basis in $H_0^1(0,1)$.

Proof. We are looking for $\mu \in \mathbb{C}$ and $\tau \in H_0^1(0,1)$ such that $A\tau = \mu\tau$, which is equivalent to

$$\begin{cases} \mu\tau - \mu\tau_{xx} - \tau_x = 0, \\ \tau(0) = \tau(1) = 0. \end{cases} \tag{2.8}$$

Hence, $\tau(x) = c_1 e^{x\frac{-1-\sqrt{1+4\mu^2}}{2\mu}} + c_2 e^{x\frac{-1+\sqrt{1+4\mu^2}}{2\mu}}$.

From the boundary conditions we obtain, from one hand, that $c_1 = -c_2$ and from the other hand, that the eigenvalues of the operator are given by the equation

$$e^{\frac{\sqrt{1+4\mu^2}}{\mu}} = 1. \tag{2.9}$$

It results that the eigenvalues of the operator A are

$$\mu_n = \operatorname{sgn}(n)\frac{i}{2\sqrt{1+n^2\pi^2}}, \quad n \in \mathbb{Z}^*.$$

To each μ_n corresponds an eigenfunction

$$U_n(x) = \frac{1}{\sqrt{n^2\pi^2+1}}e^{-i\operatorname{sgn}(n)\sqrt{1+n^2\pi^2}x}\sin(n\pi x)$$

with $||U_n||_{H_0^1} = 1.$ □

REMARK 2.2. *Let us remark that, for each $n \in \mathbb{Z}^*$,*

$$(U_n)_x(1) = \frac{(-1)^n n\pi}{\sqrt{n^2\pi^2+1}} e^{-i\,\mathrm{sgn}(n)\sqrt{1+n^2\pi^2}} \neq 0$$

and $|(U_n)_x(1)| \sim 1$ as $|n| \to \infty$.

REMARK 2.3. *We have obtained that $\lim_{|n|\to\infty} \lambda_n = 0$. This is due to the compactness of the operator A and will have some very important consequences for the controllability properties of the BBM equation.*

If we consider an initial data, $u_0 \in H_0^1(0,1)$, $u_0 = \sum_{n\in\mathbb{Z}^*} a_n U_n$, the solution of (2.2) corresponding to this initial data can be written as

$$u = \sum_{n\in\mathbb{Z}^*} a_n U_n e^{i\lambda_n t},$$

where $\lambda_n = \frac{\mathrm{sgn}(n)}{2\sqrt{1+n^2\pi^2}}$ and $\mu_n = i\lambda_n$ are the eigenvalues of the operator A found in Proposition 2.3.

3. Biorthogonal sequences.

Let $\lambda_n i$, $n \in \mathbb{Z}^*$, be the eigenvalues of the operator A. In this section we study the sequences biorthogonal to the family of exponentials $\{e^{i\lambda_n t}\}_{n\in\mathbb{Z}^*}$ or to some subset of it. All the results of this section will be used to study the boundary controllability properties of the BBM equation in the last section.

Let us first recall the following definition.

DEFINITION 3.1. *Let $(f_n)_{n\geq 1}$ be a sequence of vectors from a Hilbert space H. The sequence $(g_n)_{n\geq 1} \subset H$ is biorthogonal to $(f_n)_{n\geq 1}$ if and only if $(f_n, g_m) = \delta_{nm}$ $\forall n, m \geq 1$.*

We begin with the following negative result.

THEOREM 3.2. *Let $T > 0$ and $m \in \mathbb{Z}^*$. There is no function $\Theta_m \in L^2(-T,T)$ such that*

$$\int_{-T}^{T} \Theta_m(t) e^{i\lambda_n t} dt = \begin{cases} 0 & \text{if } n \in \mathbb{Z}^*,\ n \neq m, \\ 1 & \text{if } n = m. \end{cases} \tag{3.1}$$

Proof. Let us suppose that there exists a function $\Theta_m \in L^2(-T,T)$ such that (3.1) is satisfied.

We define $F : \mathbb{C} \to \mathbb{C}$ by

$$F(z) = \int_{-T}^{T} \Theta_m(t) e^{izt} dt. \tag{3.2}$$

From the Paley–Wiener theorem, F is an entire function. Moreover, from (3.2) and (3.1) we obtain that

$$F(\lambda_n) = \delta_{nm} \quad \forall n \in \mathbb{Z}^*. \tag{3.3}$$

Since $\lim_{n\to\infty} \lambda_n = 0$, it follows that F is zero on a set with a finite accumulation point. Therefore $F = 0$ which contradicts the fact that $F(\lambda_m) = 1$.

Hence, there is no function $\Theta_m \in L^2(-T,T)$ such that (3.1) is satisfied and the proof ends. □

REMARK 3.1. *From Theorem* 3.2 *the following result of nonobservability can be obtained: there is no sequence* $(\rho_n)_{n\in\mathbb{Z}^*}$ *of positive constants such that the following inequality*

$$\sum_{n\in\mathbb{Z}^*}\rho_n \mid a_n \mid^2 \leq \int_{-T}^{T}\left|\sum_{n\in\mathbb{Z}^*}a_n e^{i\lambda_n t}\right|^2 dt \tag{3.4}$$

is true for any sequence $(a_n)_{n\in\mathbb{Z}^*}$ *with a finite number of nonzero terms.*

This is a direct consequence of Theorem 3.2 *and the following result in moments theory (see* [22, p. 151]*).*

THEOREM A. *Let* H *be a Hilbert space,* $(f_n)_n$ *a vector family from* H*, and* $(c_n)_n$ *a sequence of scalars. In order for a vector* $f\in H$ *to exist such that* $\parallel f \parallel\leq M$ *and* $(f, f_n) = c_n$ $\forall n$*, it is necessary and sufficient that*

$$\left|\sum_n a_n\bar{c}_n\right| \leq M\left\|\sum_n a_n f_n\right\|^2 \tag{3.5}$$

for any finite number of scalars $a_1, a_2, \ldots$.

Let us suppose now that (3.4) *is true. Then, for each* $m\in\mathbb{Z}^*$,

$$|a_m|^2 \leq \frac{1}{\rho_m}\int_{-T}^{T}\left|\sum_{n\in\mathbb{Z}^*}a_n e^{i\lambda_n t}\right|^2 dt$$

for any sequence $(a_n)_{n\in\mathbb{Z}^*}$ *with a finite number of nonzero terms.*

From Theorem A *it follows that there exists* $\Theta_m \in L^2(-T,T)$ *such that* $\int_{-T}^{T}\Theta_m(t)e^{i\lambda_n t}dt = \delta_{mn}$ *which contradicts Theorem* 3.2.

REMARK 3.2. *Theorem* 3.2 *proves that there is no sequence biorthogonal to* $\{e^{i\lambda_n t}\}_{n\in\mathbb{Z}^*}$ *in* $L^2(-T,T)$*. This is related to the fact that* $\lim_{|n|\to\infty}\lambda_n = 0$ *which affects the linear independency of the exponential family* $\{e^{i\lambda_n t}\}_{n\in\mathbb{Z}^*}$ *in* $L^2(-T,T)$*.*

We shall use this result in the last section to prove that no eigenfunction of equation (1.3) *can be driven to zero by using a control function in* $L^2(0,T)$ *(see Theorem* 4.2*).*

Let $N\in\mathbb{N}^*$. We shall pass now to prove the existence of a biorthogonal to the finite family of exponentials $\{e^{i\lambda_n t}\}_{\substack{|n|\leq N\\ n\neq 0}}$.

THEOREM 3.3. *Let* $T > 0$ *and* $N\in\mathbb{N}^*$*. There exists a biorthogonal sequence* $\{\Psi_m\}_{\substack{|n|\leq N\\ n\neq 0}}$ *to the family of exponentials* $\{e^{i\lambda_n t}\}_{\substack{|n|\leq N\\ n\neq 0}}$ *in* $L^2(-T,T)$.

Proof. Let us first prove that there is a constant $C_1(N) > 0$ such that, for any scalars $(a_n)_{\substack{|n|\leq N\\ n\neq 0}}$,

$$C_1(N)\sum_{\substack{|n|\leq N\\ n\neq 0}} \mid a_n \mid^2 \leq \int_{-T}^{T}\left|\sum_{\substack{|n|\leq N\\ n\neq 0}}a_n e^{i\lambda_n t}\right|^2 dt. \tag{3.6}$$

We consider the space generated by $\{e^{i\lambda_n t}\}_{\substack{|n|\leq N\\ n\neq 0}}$,

$$X = \underset{L^2(-T,T)}{\text{Span}}\left\{e^{i\lambda_n t}\right\}_{\substack{|n|\leq N\\ n\neq 0}}.$$

X is a finite-dimensional space of dimension $2N$. Moreover, the application

$$\sum_{\substack{|n|\leq N\\ n\neq 0}} a_n e^{i\lambda_n t}\in X \longrightarrow \sqrt{\sum_{\substack{|n|\leq N\\ n\neq 0}} \mid a_n \mid^2}$$

is a norm in X. Since X is finite dimensional this new norm and the one induced from $L^2(T,T)$ are equivalent. It follows that there is a constant $C_1(N)$ such that (3.6) is satisfied for any scalars (a_n).

Now, for each m, $\mid m \mid\leq N$, $m\neq 0$, we can apply Theorem A from Remark 3.1 by taking $c_n=\delta_{nm}$, $f_n=e^{i\lambda_n t}$, and $H=L^2(-T,T)$. It follows that there exists a function $\Psi_m\in L^2(-T,T)$ such that $\int_{-T}^{T}\Psi_m(t)e^{i\lambda_n t}dt=\delta_{nm}$ $\forall n$, $\mid n\mid\leq N$, $n\neq 0$.

Hence we get a biorthogonal sequence $\{\Psi_m\}_{\substack{|m|\leq N\\ m\neq 0}}\subset L^2(-T,T)$ to the family of exponentials $\{e^{i\lambda_n t}\}_{\substack{|n|\leq N\\ n\neq 0}}$ and the proof finishes. □

REMARK 3.3. *The following inequality is also true:*

$$\int_{-T}^{T}\left|\sum_{\substack{|n|\leq N\\ n\neq 0}} a_n e^{i\lambda_n t}\right|^2 dt\leq 4NT\sum_{\substack{|n|\leq N\\ n\neq 0}}\mid a_n\mid^2 . \tag{3.7}$$

Indeed, from the Cauchy inequality

$$\int_{-T}^{T}\left|\sum_{\substack{|n|\leq N\\ n\neq 0}} a_n e^{i\lambda_n t}\right|^2 dt\leq\int_{-T}^{T}\left(\sum_{\substack{|n|\leq N\\ n\neq 0}}\mid a_n\mid^2\right)\left(\sum_{\substack{|n|\leq N\\ n\neq 0}}\mid e^{i\lambda_n t}\mid^2\right)dt=4NT\sum_{\substack{|n|\leq N\\ n\neq 0}}\mid a_n\mid^2$$

and (3.7) *is proved.*

REMARK 3.4. *The proof of Theorem* 3.3 *shows that there exists at least a biorthogonal sequence to any finite family of exponentials.*

REMARK 3.5. *From Theorem* A *(Remark* 3.1*) we also obtain that the norm of the biorthogonal sequence* $\{\Psi_m\}_{\substack{|m|\leq N\\ m\neq 0}}$ *is bounded by* $C_1(N)$. *Since Theorem* 3.2 *proves that there is no biorthogonal sequence to* $\{e^{i\lambda_n t}\}_{n\in\mathbb{Z}^*}$ *we deduce again from Theorem* A *that* $C_1(N)$ *degenerates when* N *goes to infinity. We shall analyze how this constant changes when* N *increases.*

THEOREM 3.4. *Let* $T>0$ *and* $N\in\mathbb{N}^*$. *There exists a biorthogonal sequence* $\{\Theta\}_{\substack{|n|\leq N\\ n\neq 0}}$ *to the family of exponentials* $\{e^{i\lambda_n t}\}_{\substack{|n|\leq N\\ n\neq 0}}$ *in* $L^2(-T,T)$ *such that*

$$\parallel\Theta_m\parallel^2_{L^2(-T,T)}\leq C_1 e^{\alpha N\ln(N)}, \tag{3.8}$$

where C_1 *and* α *are two constants which do not depend on* N.

Proof. Let us first define, for each m such that $\mid m\mid\leq N$ and $m\neq 0$,

$$\xi_m(z)=\left(\prod_{\substack{|n|\leq N\\ n\neq 0,m}}\frac{z-\lambda_n}{\lambda_m-\lambda_n}\right)\left(\frac{\sin\frac{T(z-\lambda_m)}{2N}}{\frac{T(z-\lambda_m)}{2N}}\right)^{2N}. \tag{3.9}$$

Each function ξ_m has the following properties:

- ξ_m is an entire function,

- $\xi_m(\lambda_n) = \delta_{nm}$,
- $\xi_m(x) \in L^2(-\infty,\infty)$,
- ξ_m is of the exponential type at most T, i.e., there exists a constant $A > 0$ such that $\forall \varepsilon > 0$, we have

$$|\xi_m(z)| \leq Ae^{(T+\varepsilon)|z|} \quad \forall z \in \mathbb{C}.$$

Let us now define

$$\Theta_m(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \xi_m(x) e^{-ixt} dx, \tag{3.10}$$

and we shall show that $\{\Theta_m\}_{\substack{|n|\leq N \\ n\neq 0}}$ is the biorthogonal sequence we are looking for.

From the properties of ξ_m, by using Paley–Wiener theorem, it follows that Θ_m has compact support in $[-T,T]$, it belongs to $L^2(-T,T)$, and

$$\int_{-T}^{T} \Theta_m(t) e^{i\lambda_n t} dt = \xi_m(\lambda_n) = \delta_{nm}.$$

It follows that $(\Theta_m)_{\substack{|m|\leq N \\ m\neq 0}}$ is a biorthogonal sequence to $\{e^{i\lambda_n t}\}_{\substack{|n|\leq N \\ n\neq 0}}$.

Our next objective is to estimate the norm of Θ_m and to see that it satisfies (3.8).

From Plancherel's theorem we have that

$$\| \Theta_m \|_{L^2(-T,T)} = \| \xi_m \|_{L^2(-\infty,\infty)}. \tag{3.11}$$

Let us now estimate $\| \xi_m \|_{L^2(-\infty,\infty)}$.

$$\| \xi_m \|^2_{L^2(-\infty,\infty)} = \int_{-\infty}^{\infty} \left| \left(\prod_{\substack{|n|\leq N \\ n\neq 0,m}} \frac{x-\lambda_n}{\lambda_m-\lambda_n} \right) \left(\frac{\sin \frac{T(x-\lambda_m)}{2N}}{\frac{T(x-\lambda_m)}{2N}} \right)^{2N} \right|^2$$

$$= \left(\prod_{\substack{|n|\leq N \\ n\neq 0,m}} \frac{1}{|\lambda_n-\lambda_m|^2} \right) \int_{-\infty}^{\infty} \left| \left(\prod_{\substack{|n|\leq N \\ n\neq 0,m}} (x-\lambda_n) \right) \left(\frac{\sin \frac{T(x-\lambda_m)}{2N}}{\frac{T(x-\lambda_m)}{2N}} \right)^{2N} \right|^2 dx.$$

Let us first evaluate the constant

$$\gamma_1(N) = \prod_{\substack{|n|\leq N \\ n\neq 0,m}} \frac{1}{|\lambda_m-\lambda_n|^2}.$$

We have

$$\frac{1}{|\lambda_m-\lambda_n|} = \frac{1}{\left| \frac{\operatorname{sgn}(n)}{\sqrt{1+n^2\pi^2}} - \frac{\operatorname{sgn}(m)}{\sqrt{1+m^2\pi^2}} \right|} = \frac{2\sqrt{1+n^2\pi^2}\sqrt{1+m^2\pi^2}}{\left|\operatorname{sgn}(n)\sqrt{1+m^2\pi^2} - \operatorname{sgn}(m)\sqrt{1+n^2\pi^2}\right|}$$

$$\leq \frac{2\sqrt{1+n^2\pi^2}\sqrt{1+m^2\pi^2}}{\left|\sqrt{1+m^2\pi^2}-\sqrt{1+n^2\pi^2}\right|} = \frac{2\sqrt{1+n^2\pi^2}\sqrt{1+m^2\pi^2}\left(\sqrt{1+m^2\pi^2}+\sqrt{1+n^2\pi^2}\right)}{|m^2-n^2|\,\pi^2}$$

$$\leq \frac{2\sqrt{(1+n^2\pi^2)(1+m^2\pi^2)}\left(\frac{\pi^2}{2}m + \frac{\pi^2}{2}n\right)}{|m^2-n^2|\,\pi^2} \leq \sqrt{(1+n^2\pi^2)(1+m^2\pi^2)} \leq (2\pi N)^2.$$

It follows that

$$\gamma_1(N) = \prod_{\substack{|n|\leq N\\ n\neq 0,m}} \frac{1}{\mid \lambda_m - \lambda_n \mid^2} \leq (2\pi N)^{8N-4}. \tag{3.12}$$

Let us now evaluate the integral

$$\gamma_2(N) = \int_{-\infty}^{\infty} \left| \left(\prod_{\substack{|n|\leq N\\ n\neq 0,m}} (x-\lambda_n) \right) \left(\frac{\sin \frac{T(x-\lambda_m)}{2N}}{\frac{T(x-\lambda_m)}{2N}} \right)^{2N} \right|^2 dx.$$

We have

$$\gamma_2(N) = \int_{|x|\leq \frac{1}{2}} \left| \prod_{\substack{|n|\leq N\\ n\neq 0,m}} (x-\lambda_n) \right|^2 \left| \frac{\sin \frac{T(x-\lambda_m)}{2N}}{\frac{T(x-\lambda_m)}{N}} \right|^{4N} dx$$

$$+ \int_{|x|\geq \frac{1}{2}} \left| \prod_{\substack{|n|\leq N\\ n\neq 0,m}} (x-\lambda_n) \right|^2 \left| \frac{\sin \frac{T(x-\lambda_m)}{2N}}{\frac{T(x-\lambda_m)}{2N}} \right|^{4N} dx$$

$$\leq \int_{|x|\leq \frac{1}{2}} \left| \prod_{\substack{|n|\leq N\\ n\neq 0,m}} (x-\lambda_n) \right|^2 dx + \int_{|x|\geq \frac{1}{2}} \left| \prod_{\substack{|n|\leq N\\ n\neq 0,m}} (x-\lambda_n) \right|^2 \left(\frac{2N}{T(x-\lambda_m)} \right)^{4N} dx.$$

However, since $|\lambda_n| < \frac{1}{2}$,

$$\left| \prod_{\substack{|n|\leq N\\ n\neq 0,m}} (x-\lambda_n) \right| \leq \begin{cases} 1 & \text{if } |x| \leq \frac{1}{2}, \\ (2 \mid x \mid)^{2N-1} & \text{if } \mid x \mid \geq \frac{1}{2}. \end{cases}$$

It follows that

$$\gamma_2(N) \leq 1 + \int_{|x|\geq \frac{1}{2}} \frac{2^{4N-2}}{\mid x \mid^2} \left| \frac{x}{x-\lambda_m} \right|^{4N} 2^{4N} \left(\frac{N}{T} \right)^{4N} dx$$

$$\leq 1 + 2^{12N-2} \left(\frac{N}{T} \right)^{4N} \int_{|x|\geq \frac{1}{2}} \frac{1}{\mid x \mid^2} = 1 + 2^{12N} \left(\frac{N}{T} \right)^{4N}.$$

Hence,

$$\gamma_2(N) \leq 1 + 2^{12N} \left(\frac{N}{T} \right)^{4N}. \tag{3.13}$$

From (3.12) and (3.13) it follows that, for N large enough,

$$\parallel \xi_m \parallel_{L^2(-\infty,\infty)} \leq C_1 N^{\alpha N}, \tag{3.14}$$

where $C_1 > 0$ and $\alpha > 3$ are two constants which do not depend on N.

From (3.11) it follows that

$$\| \Theta_m \|_{L^2(-T,T)} \leq C_1 N^{\alpha N}$$

and (3.8) is obtained. □

REMARK 3.6. *In Theorem* 3.4 *we construct an explicit biorthogonal sequence which norm increases as* $\exp(\alpha N \ln(N))$ *as* $N \to \infty$. *Nevertheless, many other biorthogonals can be found. What can be said about the norms of these biorthogonals? We shall prove in the next theorem that the norm of any biorthogonal to* $\{e^{i\lambda_n t}\}_{\substack{|n|\leq N\\ n\neq 0}}$ *is bounded from below by a constant of the type* $\exp(\beta N \ln(N))$. *In this sense,* (3.8) *is sharp.*

THEOREM 3.5. *Let* $(\psi_n)_{\substack{|n|\leq N\\ n\neq 0}}$ *be biorthogonal to* $\{e^{i\lambda_n t}\}_{\substack{|n|\leq N\\ n\neq 0}}$ *in* $L^2(-T,T)$. *Then there exist two positive constants* C_2 *and* ω, *not depending on* N, *such that*

$$\| \psi_m \|_{L^2(-T,T)} \geq C_2 e^{\omega N \ln(N)} \tag{3.15}$$

$\forall m \neq 0$ *such that* $| m | \leq N$.

Proof. In order to prove the theorem some arguments from [11] will be used. We shall give the proof in several steps.

Step 1. Let us define the following sequence of functions:

$$\tau_m(z) = \int_{-T}^{T} \psi_m(t) e^{itz} dt, \quad | m | \leq N, \quad m \neq 0. \tag{3.16}$$

From the Paley–Wiener theorem it follows that τ_m is an entire function of exponential type at most T. Moreover,

$$| \tau_m(x) | \leq \sqrt{2T} \, \| \psi_m \|_{L^2(-T,T)} \quad \forall x \in \mathbb{R}. \tag{3.17}$$

Since τ_m is a function of exponential type it follows from Hadamard's factorization theorem that

$$\tau_m(z) = a z^p e^{bz} \prod_{z_k \in E} \left(1 - \frac{z}{z_k}\right) e^{z/z_k}, \tag{3.18}$$

where E is the set of the zeros z_k of τ_m with $z_k \neq 0$, $E = \{z_k \in \mathbb{C} \mid \tau_m(z_k) = 0, \quad z_k \neq 0\}$.

From the definition of the function τ_m it follows that $\tau_m(\lambda_n) = \delta_{m,n}$. Therefore $\{\lambda_n : | n | \leq N, n \neq 0, n \neq m\} \subseteq E$. Let $E' = \{\lambda_n : | n | \leq N, n \neq 0, n \neq \pm m\}$ and define the polynomial function

$$P_m(z) = \prod_{\substack{|n|\leq N\\ n\neq 0, \pm m}} \frac{\lambda_n - z}{\lambda_n - \lambda_m}. \tag{3.19}$$

Let us now define function $\phi_m(z)$ by

$$\phi_m(z) = \frac{\tau_m(z)}{P_m(z)}. \tag{3.20}$$

The function ϕ_m has the following properties:

- it is an entire function of exponential type at most T,
- $\phi_m(\lambda_m) = 1$,
- $\tau_m(z) = P_m(z)\phi_m(z)$.

Step 2. In this step we shall give some estimates for $\mid P_m(z) \mid$.

$$\mid P_m(z) \mid = \left| \prod_{\substack{|n|\leq N \\ n\neq 0,\pm m}} \frac{\lambda_n - z}{\lambda_n - \lambda_m} \right| = \left(\prod_{\substack{|n|\leq N \\ n\neq 0,\pm m}} \mid \lambda_n - z \mid \right) \left[\prod_{\substack{|n|\leq N \\ n\neq 0,\pm m}} \mid \lambda_n - \lambda_m \mid \right]^{-1}.$$

By taking $z \in \mathbb{C}$ such that $\mid z \mid \geq 2$ we obtain that

$$\prod_{\substack{|n|\leq N \\ n\neq 0,\pm m}} \mid \lambda_n - z \mid \geq (\mid z \mid -1)^{2N-2}. \tag{3.21}$$

On the other hand

$$\prod_{\substack{|n|\leq N \\ n\neq 0,\pm m}} \mid \lambda_n - \lambda_m \mid \leq \prod_{\substack{|n|\leq N \\ n\neq 0,\pm m}} \frac{1}{2}\left(\frac{1}{\sqrt{1+n^2\pi^2}} + \frac{1}{\sqrt{1+m^2\pi^2}} \right) \leq 1. \tag{3.22}$$

From (3.21) and (3.22) we deduce that

$$\mid P_m(z) \mid \geq (\mid z \mid -1)^{2N-2} \quad \forall z \in \mathbb{C},\ \mid z \mid \geq 2. \tag{3.23}$$

Step 3. From (3.17) and (3.23) we obtain that

$$\mid \phi_m(z) \mid = \frac{\mid \tau_m(z) \mid}{\mid P_m(z) \mid} \leq \frac{\sqrt{2T} e^{T \operatorname{Im} z} \parallel \psi_m \parallel_{L^2(-T,T)}}{(|z|-1)^{2N-2}} \quad \forall z \in \mathbb{C},\ |z| \geq 2. \tag{3.24}$$

It follows that

$$\mid \phi_m(x) \mid \leq \sqrt{2T} \parallel \psi_m \parallel_{L^2(-T,T)} \frac{1}{(\mid x \mid -1)^{2N-2}} \quad \forall x \in \mathbb{R},\ \mid x \mid \geq 2. \tag{3.25}$$

We shall show that (3.25) is not possible unless $\parallel \psi_m \parallel$ grows rapidly with N.

Let us first recall the following result (see [14, p. 21] and [6, p. 52]).

THEOREM B. *Let $f(z)$ be holomorphic in the circle $\mid z \mid \leq 2eR$ $(R > 0)$ with $f(0) = 1$ and let $\eta \in (0, \frac{3e}{2})$. Then inside the circle $\mid z \mid \leq R$, but outside of a family of excluded circles the sum of whose radii is not greater than $4\eta R$, we have*

$$\ln(\mid f(z) \mid) > -\left(2 + \ln\left(\frac{3e}{2\eta} \right) \right) \ln(M_f(2eR)), \tag{3.26}$$

where $M_f(2eR) = \max\limits_{|z|=2eR} \mid f(z) \mid$.

We apply this result to our case. Let us define $\varphi_m : \mathbb{C} \to \mathbb{C}, \quad \varphi_m(z) = \phi_m(\lambda_m - z)$.

Evidently, φ_m is an entire function such that $\varphi_m(0) = 1$. Hence, φ_m satisfies the hypothesis of Theorem B. It follows that, $\forall R > 0$ and $\eta \in (0, \frac{3e}{2})$,

$$\ln(\mid \varphi_m(z) \mid) > -2e\left(2 + \ln\left(\frac{3e}{2\eta} \right) \right) \ln(M_{\varphi_m}(2eR)) \quad \forall z \in \mathbb{C},\ \mid z \mid \leq R, \tag{3.27}$$

outside of a set of circles the sum of whose radii is not greater than $4\eta R$.

Let us denote $\delta = 2e(2+\ln(\frac{3e}{2\eta})) > 1$. Also, remark that, from (3.24),

$$M_{\varphi_m}(2eR) \le e^{4eRT}||\psi_m||_{L^2(-T,T)}$$

if $2eR \ge 2$.

Hence, $\forall R > 0$ and $\eta \in (0, \frac{3e}{2})$ such that $2eR \ge 2$,

$$\ln(|\ \varphi_m(z)\ |) > -\delta \ln\left(e^{4eRT}||\psi_m||_{L^2(-T,T)}\right) \quad \forall z \in \mathbb{C},\ |\ z\ |\le R, \tag{3.28}$$

outside of a set of circles the sum of whose radii is not greater than $4\eta R$.

Let us consider $R > 6$ and $\eta \in (0, \frac{1}{8})$.

It follows that there exists $x_0 \in [\frac{R}{2}, R]$ such that

$$\ln(|\ \varphi_m(x_0)\ |) > -\delta \ln\left(e^{4eRT}||\psi_m||_{L^2(-T,T)}\right). \tag{3.29}$$

On the other hand, from (3.25),

$$|\varphi_m(x_0)| = |\phi_m(\lambda_m - x_0)| \le \sqrt{2T}\ \|\ \psi_m\ \|_{L^2(-T,T)}\ \frac{1}{(|\ \lambda_m - x_0\ | -1)^{2N-2}}. \tag{3.30}$$

From (3.30) and (3.29) the following estimate is obtained:

$$\ln\left(\sqrt{2T}\ \|\ \psi_m\ \|_{L^2(-T,T)}\ \frac{1}{(|\ \lambda_m - x_0\ | -1)^{2N-2}}\right) > -\delta \ln\left(e^{4eRT}||\psi_m||_{L^2(-T,T)}\right).$$

Hence

$$(1+\delta)\ln\left(||\psi_m||_{L^2(-T,T)}\right) > -4e\delta TR - \ln(\sqrt{2T}) + (2N-2)\ln(|x_0-\lambda_m|-1). \tag{3.31}$$

Let us now analyze the expression

$$G(N, x_0, R) = (2N-2)\ln(|\ \lambda_m - x_0\ | -1) - 4e\delta TR.$$

Remark that, for $R = N > 6$,

$$\begin{aligned} G(N, x_0, R) &\ge (2N-2)\ln(|\ x_0\ | - |\ \lambda_m\ | -1) - 4e\delta TN \\ &\ge (2N-2)\ln\left(\frac{N}{2}-2\right) - 4e\delta TN \\ &= 2N\left(\frac{N-1}{N}\ln\left(\frac{N}{2}-2\right) - \underbrace{2e\delta T}_{\text{cte}}\right). \end{aligned}$$

It follows that there exists $\omega > 0$, not depending on N, such that

$$G(N, x_0, R) \ge \omega N \ln(N) \tag{3.32}$$

for any N sufficiently large.

From (3.31) it follows that

$$\ln\left(||\psi_m||_{L^2(-T,T)}\right) > -\frac{\ln(\sqrt{2T})}{1+\delta} + \omega N \ln(N)$$

and the proof finishes. □

4. Controllability results. In this section we study some boundary controllability properties of the BBM equation. We begin with the following exact controllability problem: given $T < 0$ and an initial data $u_0 \in H^{-1}(0,1)$ find a control $f \in L^2(0,T)$ such that the solution u of

$$\left\{\begin{array}{lll} u_t - u_{xxt} + u_x = 0, & x \in (0,1), & t > 0, \\ u(t,0) = 0, u(t,1) = f(t), & t > 0, & \\ u(0,x) = u_0(x), & x \in (0,1), & \end{array}\right. \tag{4.1}$$

satisfies

$$u(T,x) = 0, \quad x \in (0,1). \tag{4.2}$$

REMARK 4.1. *Equation* (4.1) *has to be understood in a weak sense. For instance, the solution of* (4.1) *can be defined by transpositions (see* [16], [17]*). Let us briefly recall how can this be done.*

Consider $g \in L^1(0,T,L^2(0,1))$ and v the solution of the adjoint equation

$$\left\{\begin{array}{lll} v_t - v_{xxt} + v_x = g, & x \in (0,1), & t > 0, \\ v(t,0) = v(t,1) = 0, & t > 0, & \\ v(T,x) = 0, & x \in (0,1). & \end{array}\right. \tag{4.3}$$

By multiplying (formally) (4.1) *by v and integrating by parts we obtain*

$$0 = \int_0^T \int_0^1 (u_t - u_{xxt} + u_x)v = \int_0^1 \left(uv|_0^T - u_{xx}v|_0^T\right) + \int_0^T (u_x - uv_x + uv)\,|_0^1$$
$$- \int_0^T \int_0^1 u(v_t - v_{txx} + v_x) = \int_0^1 [-u_0 v(0) + (u_0)_{xx} v(0)] - \int_0^T f v_{tx} - \int_0^T \int_0^1 ug.$$

Therefore we can say that u is the solution of (4.1) *if and only if*

$$\int_0^T \int_0^1 ug + \langle u_0, v(0)\rangle_{H^{-1},H_0^1} = -\int_0^T f(t) v_{tx}(t,1)dt \tag{4.4}$$

$\forall g \in L^1(0,T;L^2(0,1))$ and v the solution of (4.3). *$\langle \cdot, \cdot \rangle$ represents the duality product between H_0^1 and H^{-1}. As in* [16], [17] *it can be proved that* (4.4) *has a unique solution $u \in C([0,T];L^2(0,1))$. On the other hand we have just seen that a classical solution of* (4.1) *is the solution of* (4.4).

Concerning the controllability of (4.1) let us begin with the following result which transforms the control problem into a moments problem.

LEMMA 4.1.

(i) *The initial data $u_0 \in H^{-1}(0,1)$ is controllable to zero in time $T > 0$ with a control $f \in L^2(0,T)$ if and only if*

$$\langle u_0, v(0)\rangle_{H^{-1},H_0^1} = -\int_0^T f(t) v_{tx}(t,1)dt \tag{4.5}$$

for any solution v of the equation

$$\left\{\begin{array}{l} v_t - v_{txx} + v_x = 0, \\ v(t,0) = v(t,1) = 0, \\ v(T,x) = v^T(x) \in H_0^1. \end{array}\right. \tag{4.6}$$

(ii) *The initial data $u_0 \in H^{-1}(0,1)$, $u_0(x) = \sum_{n\in\mathbb{Z}^*} a_n U_n(x)$, is controllable to zero in time $T > 0$ if and only if there exists $f \in L^2(0,T)$ such that*

$$\int_0^T f(t)e^{-i\lambda_n t}dt = \frac{i}{\lambda_n^2 (U_n)_x(1)} a_n \quad \forall n \in \mathbb{Z}^*. \tag{4.7}$$

Proof. (i) Let u be the solution of (4.1) and v the solution of (4.6). It follows that

$$0 = \int_0^T \int_0^1 (u_t - u_{xxt} + u_x)v = -\int_0^T \int_0^1 u(v_t - v_{txx} + v_x)$$

$$+ \int_0^1 (uv - u_{xx}v)\Big|_0^T + \int_0^T (u_x v_t - uv_{xt} + uv)\Big|_0^1 = -\int_0^1 (u_0 v(0) + (u_0)_x v_x)$$

$$+ \int_0^1 (u(T)v(T) + u_x(T)v_x(T)) - \int_0^T f(t)v_{xt}(t,1)dt.$$

We obtain that

$$\int_0^T f(t)v_{xt}(t,1)dt + \langle u_0, v(0)\rangle_{H^{-1},H_0^1} = \langle u(T), v^T\rangle_{H^{-1},H_0^1}$$

$\forall v^T \in H_0^1$.

Hence, u_0 is controllable to zero in time $T > 0$ if and only if (4.5) is satisfied.

(ii) For the second part let us put $v^T = \sum_{n\neq 0} b_n U_n$ and use (4.5). It follows that

$$\sum_{n\neq 0} \frac{1}{\lambda_n} a_n b_n e^{i\lambda_n T} = -\int_0^T f(t) \sum_{n\neq 0} i\lambda_n e^{i\lambda_n(T-t)} b_n (U_n)_x(1)dt$$

which is equivalent to

$$\sum_{n\neq 0} b_n e^{i\lambda_n T}\left[\int_0^T f(t) i\lambda_n e^{-i\lambda_n t}(U_n)_x(1)dt + \frac{1}{\lambda_n}a_n\right] = 0$$

for any $(b_n)_{n\neq 0} \in \ell^2$.

It follows that the control problem is equivalent to finding $f \in L^2(0,T)$ such that

$$\int_0^T f(t)e^{-i\lambda_n t}dt = \frac{i}{(\lambda_n)^2 (U_n)_x(1)} a_n \quad \forall n \in \mathbb{Z}^*. \qquad \square$$

By using Lemma 4.1 and Theorem 3.3 from section 3 the following negative result can be easily proved.

THEOREM 4.2. *No eigenfunction of the operator A can be driven to zero in finite time.*

Proof. The controllability of an eigenfunction U_m is equivalent, by Lemma 4.1, to finding $f \in L^2(0,T)$ such that

$$\int_0^T f(t)e^{-i\lambda_n t} = \begin{cases} 0 & \forall n \in \mathbb{Z}^*, \quad n \neq m, \\ \frac{i}{(\lambda_m)^2 (U_m)_x(1)}, & n = m. \end{cases}$$

Let us suppose that there exists $f \in L^2(0,T)$ with these properties. We define $g \in L^2(-\frac{T}{2}, \frac{T}{2})$ such that $g(t) = f(\frac{T}{2} - t)e^{-\frac{i\lambda_m T}{2}}$ almost everywhere in $(-\frac{T}{2}, \frac{T}{2})$. Then

$$\int_{\frac{T}{2}}^{\frac{T}{2}} g(t)e^{i\lambda_n t}dt = e^{\frac{iT}{2}(\lambda_n - \lambda_m)} \int_0^T f(t)e^{-i\lambda_n t}dt = \begin{cases} 0 & \forall n \in \mathbb{Z}^*, \quad n \neq m, \\ \frac{i}{(\lambda_m)^2 (U_m)_x(1)}, & n = m. \end{cases}$$

However, in Theorem 3.2, we have proved that this is not possible and the proof finishes. □

REMARK 4.2. *From Theorem* 4.2 *it follows that* (4.1) *is not spectrally controllable. This means that no finite linear nontrivial combination of eigenvectors can be driven to zero in finite time by using a control $f \in L^2(0,T)$.*

Let us now study the approximate controllability of (4.1). We recall that (4.1) is approximate controllable in time $T > 0$ if the set of reachable states

$$R(u_0, T) = \{u(T,x) \mid f \in L^2(0,T)\} \tag{4.8}$$

is dense in $L^2(0,1)$ for any $u_0 \in H^{-1}(0,1)$.

In other words, given $T > 0$, $u_0 \in H^{-1}(0,1)$, $v_0 \in L^2(0,1)$, and $\varepsilon > 0$ there exists a control function $f \in L^2(0,T)$ such that the solution u of (4.1) satisfies $||u(T) - v_0||_{L^2(0,1)} < \varepsilon$.

THEOREM 4.3. *Equation* (4.1) *is approximate controllable in any time $T > 0$ with controls in $L^2(0,T)$.*

Proof. From the linearity of (4.1) it follows that it is sufficient to prove that the set $R(0,T)$ is dense in $H_0^1(0,1)$ for any $T > 0$. Therefore we shall consider only the case $u_0 = 0$. Let $u \in C([0,T], H_0^1(0,1))$ be the corresponding solution of (4.1).

Let also v be the solution of the adjoint equation

$$\begin{cases} v_t - v_{txx} + v_x = 0, & x \in (0,1), \quad t < T, \\ v(t,0) = v(t,1) = 0, & t < T, \\ v(T,x) = v^T(x) \in H_0^1(\Omega). \end{cases} \tag{4.9}$$

It follows that

$$\int_0^T f(t) v_{xt}(t,1) dt = (u(T,x), v^T(x))_{H_0^1}. \tag{4.10}$$

Suppose that $R(0,T)$ is not dense in $H_0^1(0,1)$. Hence, there exists $v^T \in H_0^1(0,1)$, $v^T \neq 0$, such that

$$(u(T,x), v^T(x)) = 0 \quad \forall f \in L^2(0,T).$$

From (4.10) it follows that

$$\int_0^T f(t) v_{xt}(t,1) = 0 \quad \forall f \in L^2(0,T).$$

Therefore $v_{xt}(t,1) = 0 \quad \forall t \in (0,T)$. We show now that this contradicts the fact that $v^T \neq 0$. Hence, the problem is reduced to a unique continuation property.

Let us consider the Fourier decomposition of v^T:

$$v^T = \sum_{n \in \mathbb{Z}^*} a_n U_n,$$

where $(a_n)_{n \in \mathbb{Z}^*} \in \ell^2$ and the series converges in $H_0^1(0,1)$.

It follows that the corresponding solution of (4.9) is

$$v(t,x) = \sum_{n \in \mathbb{Z}^*} a_n e^{i\lambda_n (T-t)} U_n(x), \quad t \in (0,T).$$

From the equation v verifies it follows that $v \in C^{\omega}\left([0,\infty);\, H_0^1(0,1)\right)$ (see Remark 2.1).

Hence, from the fact that $v_{xt}(t,1) = 0 \quad \forall t \in (0,T)$, we obtain that $v_{xt}(t,1) = 0 \quad \forall t \in \mathbb{R}$, i.e.,

$$\sum_{n\in\mathbb{Z}^*} a_n e^{i\lambda_n(T-t)}(U_n)_x(1)(-i\lambda_n) = 0 \quad \forall t \in \mathbb{R}.$$

For each $m \in \mathbb{Z}^*$,

$$\begin{aligned} 0 &= \lim_{S\to\infty} \frac{1}{2S}\int_{-S}^{S}\left[\sum_{n\in\mathbb{Z}^*} a_n e^{i\lambda_n(T-t)}(U_n)_x(1)(-i\lambda_n)\right] e^{i\lambda_m t}dt \\ &= a_m(U_m)_x(1)(-i\lambda_m)e^{i\lambda_m T}. \end{aligned}$$

From Remark 2.2 $(U_m)_x(1) \neq 0$. This implies that $a_m = 0 \quad \forall m \in \mathbb{Z}^*$ and therefore $v^T = 0$, which represents a contradiction. Hence, $R(0,T)$ is dense in $H_0^1(0,1)$ and the proof finishes. □

As we have seen in Theorem 4.2 no finite linear combination of eigenfunctions can be driven to zero. In this case the following question arises naturally: can we control to zero at least a part of the solution u of (4.1)? And if we can do this, what is the cost we have to pay?

Therefore we shall now investigate the following special type of controllability.

DEFINITION 4.4. *Equation* (4.1) *is N-partially controllable to zero in time $T > 0$ if, for any $u_0 \in H^{-1}(0,1)$, there exists a control $f \in L^2(0,T)$ such that the projection of the corresponding solution u of* (4.1) *over the space generated by the eigenvectors $(U_n)_{\substack{|n|\leq N\\ n\neq 0}}$ is zero at time $t = T$.*

Let $X_N = \operatorname{Span}\{U_n :| n |\leq N,\, n \neq 0\}$ and let

$$\Pi_N : H^{-1}(0,1) \to X_N, \quad \Pi_N\left(\sum_{n\neq 0} a_n U_n\right) = \sum_{\substack{|n|\leq N\\ n\neq 0}} a_n U_n,$$

be the projection operator.

Evidently, u is N-partially controllable to zero if and only if

$$\Pi_N(u(T)) = 0. \tag{4.11}$$

By using the same argument as in Lemma 4.1, the following result can be obtained immediately.

LEMMA 4.5. *The initial data $u_0 = \sum_{n\neq 0} a_n U_n$ is N-partially controlled to zero in time $T > 0$ if and only if there exists $f \in L^2(0,T)$ such that*

$$\int_0^T f(t)e^{i\lambda_n t}dt = \frac{i}{\lambda_n^2 (U_n)_x(1)} a_n \quad \forall \mid n \mid\leq N, n \neq 0. \tag{4.12}$$

Now, the following theorem can be proved.

THEOREM 4.6. *Any initial data $u_0 \in H^{-1}(0,1)$ can be N-partially controlled to zero in time $T > 0$ by using a control $f_N \in L^2(0,T)$ such that*

$$\| f_N \|_{L^2(0,T)}^2 \leq c_1 \| u_0 \|_{H^{-1}}^2 e^{\alpha_1 N \ln(N)}, \tag{4.13}$$

where c_1 and α_1 are two constants which do not depend on N.

Moreover, there exists initial data $u_0 \in H_0^1(0,1)$ such that any control f_N satisfies

$$\| f_N \|^2_{L^2(0,T)} \geq c_2 \| u_0 \|^2_{H_0^1} e^{\omega_1 N \ln(N)}, \tag{4.14}$$

where c_2 and ω_1 are two constants which do not depend on N.

Proof. Let us consider the initial data $u_0 = \sum_{n\neq 0} a_n U_n$ from $H^{-1}(0,1)$. We prove that there exists a function $f_N \in L^2(0,T)$ such that (4.12) is satisfied. This will be the control we are looking for.

Let $(\Theta_n)_{\substack{n\leq N\\ n\neq 0}}$ be the biorthogonal sequence to $(e^{i\lambda_n t})_{\substack{n\leq N\\ n\neq 0}}$ in $L^2(-\frac{T}{2},\frac{T}{2})$ constructed in Theorem 3.4.

Then we can define

$$f_N(t) = \sum_{\substack{n\neq 0\\ |n|\leq N}} \frac{ia_n}{\lambda_n^2 (U_n)_x(1)} \Theta_n\left(\frac{T}{2} - t\right) e^{\frac{i\lambda_n T}{2}}.$$

Evidently, $f_N \in L^2(0,T)$ and $\int_0^T f_N(t) e^{-i\lambda_n t} dt = \frac{ia_n}{\lambda_n^2 (U_n)_x(1)}$ $\forall \mid n \mid\leq N, n \neq 0$.

From Lemma 4.5 it follows that f_N is the control we are looking for.

By using inequality (3.8) from Theorem 3.4 it follows that

$$\| f_N \|^2_{L^2(0,T)} \leq \sum_{\substack{|n|\leq N\\ n\neq 0}} \frac{\mid a_n \mid^2}{\mid \lambda_n \mid^2 \mid (U_n)_x(1) \mid^2} \sum_{\substack{|n|\leq N\\ n\neq 0}} \| \Theta_n \|^2$$

$$\leq \sum_{\substack{|n|\leq N\\ n\neq 0}} \frac{\mid a_n \mid^2}{\mid \lambda_n \mid^2 \mid (U_n)_x(1) \mid^2} \sum_{\substack{|n|\leq N\\ n\neq 0}} c_1 e^{\alpha N \ln(N)} \leq c_1 \| u_0 \|^2_{H^{-1}} e^{\alpha_1 N \ln(N)}$$

for any $\alpha_1 > \alpha$.

On the other hand let us consider $u_0 = U_m$, $\mid m \mid\leq N$, $m \neq 0$. From Lemma 4.5 u_0 is N-partially controllable to zero in time $T > 0$ if and only if there exists a control $f_N^m \in L^2(0,T)$ such that

$$\int_0^T f_N^m(t) e^{-i\lambda_n t} dt = \begin{cases} 0, & n \neq m, \\ \frac{i}{(\lambda_m)^2 (U_m)_x(1)}, & n = m. \end{cases}$$

We define $g_N^m \in L^2(-\frac{T}{2},\frac{T}{2})$ such that $g_N^m(t) = f_N^m(\frac{T}{2} - t) e^{-\frac{i\lambda_m T}{2}}$ almost everywhere in $(-\frac{T}{2},\frac{T}{2})$. Then

$$\int_{\frac{T}{2}}^{\frac{T}{2}} g_N^m(t) e^{i\lambda_n t} dt = e^{\frac{iT}{2}(\lambda_n - \lambda_m)} \int_0^T f_N^m(t) e^{-i\lambda_n t} dt = \begin{cases} 0 & \forall n \in \mathbb{Z}^*, \quad n \neq m, \\ \frac{i}{(\lambda_m)^2 (U_m)_x(1)}, & n = m. \end{cases}$$

Now, by using Theorem 3.5, it follows that

$$\| f_N^m \|^2_{L^2(0,T)} = \| g_N^m \|^2_{L^2(-\frac{T}{2},\frac{T}{2})} \geq C_2^2 \mid \lambda_m \mid^4 \mid (U_m)_x(1) \mid^2 e^{2\omega N \ln(N)}.$$

It follows that (4.14) is true for any $\omega_1 < 2\omega$ and $c_2 = C_2^2$ and the proof finishes. □

Remark 4.3. *Theorem 4.6 proves that the cost (the norm of the control functions) needed to drive to zero the projection of the solutions of (4.1) over the space generated by the first $2N$ eigenfunctions may increase very rapidly when N goes to infinity. Theorem 4.6 gives an upper bound for these norms (essentially, $e^{\alpha N \ln(N)}$) and shows that there exists a lower bound of the same order.*

5. Comments. As we have mentioned in the introduction, based on the linear case, local or global controllability results (depending on the number of controls) have been obtained for the nonlinear KdV equation in [20], [21], and [24].

The same cannot be said for the nonlinear equation (1.1). In fact, to our knowledge, no result for the controllability of the BBM equation is available. The controllability properties of the nonlinear systems are usually studied by linearizing the problem at an equilibrium state, by proving exact controllability results for this linear problem and by applying next the implicit function theorem. This method was first used in [13] for the ordinary differential equations and next generalized for the nonlinear wave equation (see, for instance, [12]). In [10] and [25] exact and local controllability results were given by using Schauder's fixed point theorem instead of the implicit function theorem. All approaches use the exact controllability result for the linearized equation. Taking into account the negative results (like nonspectral controllability) obtained in this paper for the linearized BBM equation it is not possible to study the controllability properties of (1.1) by using one of the classical techniques mentioned above. Probably, the controllability results for (1.1) are not better than the ones for the corresponding linear case but this is still to be proved.

SINGULAR STOCHASTIC CONTROL, LINEAR DIFFUSIONS, AND OPTIMAL STOPPING: A CLASS OF SOLVABLE PROBLEMS*

LUIS H. R. ALVAREZ†

Abstract. We consider a class of singular stochastic control problems arising frequently in applications of stochastic control. We state a set of conditions under which the optimal policy and its value can be derived in terms of the minimal r-excessive functions of the controlled diffusion, and demonstrate that the optimal policy is of the standard local time type. We then state a set of weak smoothness conditions under which the value function is increasing and concave, and demonstrate that given these conditions increased stochastic fluctuations decrease the value and increase the optimal threshold, thus postponing the exercise of the irreversible policy. In line with previous studies of singular stochastic control, we also establish a connection between singular control and optimal stopping, and show that the marginal value of the singular control problem coincides with the value of the associated stopping problem whenever 0 is not a regular boundary for the controlled diffusion.

Key words. singular stochastic control, linear diffusions, optimal stopping, harvesting, cash flow management

1. Introduction.

Singular stochastic control problems arise quite naturally in many fields applying stochastic control theory. Good examples of such fields are, for example, rational harvesting planning (cf. [1], [5], [6], [15], [24], [25], and [26]) and optimal cash flow management (cf. [3], [19], and [29]). Somewhat surprisingly, while the mathematical literature on singular stochastic control is very extensive (cf. [4], [7], [8], [9], [10], [17], [20], [21], [22], [23], [30], and [31]), it has not been applied yet to its full extent in these applications even though there are many important unanswered questions left. In order to illustrate this argument more precisely, consider a harvester facing the problem of having to determine the harvesting strategy maximizing the expected cumulative yield from the present up to extinction given the form of the underlying stochastic population dynamics. The recent literature on singular stochastic harvesting policies indicates that the depletion and, therefore, the extinction of a harvested population is seldom an optimal policy for a future-oriented harvester and that in most cases a part of the population should be left unharvested in order to be able to harvest in the future as well. Since harvesting is suboptimal as long as the marginal yield accrued from harvesting an extra individual falls short of its opportunity cost (measuring the marginal yield accrued from preserving an extra individual) and the latter factor usually dominates the former at sufficiently low densities, we find that the instantaneous depletion of a population is not optimal. Unfortunately, even though this conclusion is appealing, it has been rigorously proved only for diffusion models with logistic expected growth rates. Similarly, most studies of cash flow management rely on cash flows with affine growth and diffusion parameters (geomet-

ric Brownian motion, Ornstein–Uhlenbeck process, and Brownian motion). Although that assumption is advantageous due to its mathematical simplicity, it overlooks a broad class of processes appearing frequently in reality (for example, *mean reverting diffusions*) and, therefore, leaves unanswered important questions on the nature of the optimal solution and its value in the presence of more complex cash flow processes.

In light of these arguments, we plan to consider the singular stochastic control problem of a regular linear diffusion when the cumulative payoff of the decision-maker depends solely on the implemented policy, and the expected percentage growth rate of the controlled diffusion is decreasing. Thus, the considered problem can be interpreted as the determination of the dividend policy maximizing the expected cumulative present value of the dividends from the present up to the random liquidation date or, alternatively, as the determination of the harvesting strategy maximizing the expected cumulative yield from the present up to the extinction date of the harvested population. By relying on a combination of the classical theory of diffusions and the results of the recent study [4], we show that *the results obtained by relying on logistic growth rates are typically qualitatively robust* in the sense that the optimal policy is to reflect the controlled diffusion at a single threshold satisfying an ordinary first order necessary condition for an optimum in most models subject to decreasing percentage growth rates. In contrast to [4], we are also able to state *a set of very weak sufficient conditions under which the value of the singular stochastic control problem is increasing and concave.* To the best knowledge of the author, these conditions are the weakest under which the value of the singular stochastic control problem has been shown to be concave since no Novikov-type condition is required nor does the drift have to be globally concave. Moreover, the result is shown to be valid independently of the boundary behavior of the controlled diffusion at the lower boundary (for a comparison, see [4]). Given this finding, we show that *increased stochastic fluctuations (i.e., volatility) decrease the value of the singular stochastic control problem and increase the threshold at which the diffusion should optimally be reflected.* Put differently, we demonstrate that *the sign of the relationship between stochasticity and the optimal policy is unambiguously negative*, a result which is in accordance with observations in reality. An economically and biologically important consequence of this finding is that our results support the argument that *increased stochastic fluctuations increase the required exercise premium of an irreversible policy.* We also establish a connection between singular stochastic control and optimal stopping by first demonstrating that the marginal value of the control problem dominates the value of an associated optimal stopping problem. By relying on the classical theory of diffusions, we then prove that these quantities coincide whenever the lower boundary of the state-space of the controlled diffusion is not regular (i.e., when it is either natural, entrance, or exit). This result is of interest since it extends previous results obtained under the assumption that the lower boundary is unattainable for the controlled diffusion (cf. [30] and [31]). In line with recent studies considering singular stochastic control and optimal stopping, we then present an alternative interpretation of the marginal value of the associated stopping problem in terms of the valuation of a perpetual American forward contract and demonstrate that determining the optimal singular stochastic control is closely related to the determination of an optimal irreversible exit policy in the presence of uncertainty.

2. The singular stochastic control problem. Consider the process $\{X(t); t \in [0, \tau(0))\}$, where $\tau(0) = \inf\{t \geq 0 : X(t) \leq 0\}$ denotes the possibly infinite exit date from $\mathbb{R}_+$, defined on a complete filtered probability space $(\Omega, P, \{\mathcal{F}_t\}_{t\geq 0}, \mathcal{F})$ satisfying the usual conditions and described on $\mathbb{R}_+$ by the (Itô-) stochastic differential equation

$$dX(t) = \mu(X(t))X(t)dt + \sigma(X(t))dW(t) - dZ(t), \quad X(0) = x, \tag{1}$$

where the mapping $\mu : \mathbb{R}_+ \mapsto \mathbb{R}$ denotes the expected percentage growth rate of X, $Z(t)$ denotes the implemented control, and $\sigma : \mathbb{R}_+ \mapsto \mathbb{R}_+$ denoting the infinitesimal diffusion coefficient of X is a given Lipschitz-continuous mapping on $\mathbb{R}_+$. We assume throughout this study that the expected percentage growth rate $\mu(x)$ is continuous, decreasing, and satisfies the conditions $\lim_{x\downarrow 0} \mu(x) > 0$, $\lim_{x\downarrow 0} x\mu(x) = 0$, and $\lim_{x\to\infty} \mu(x) < 0$. In other words, (1) describes a dynamic system subject to *pure compensation.* These assumptions imply that the equation $\mu(x) = 0$ has a unique root $K = \mu^{-1}(0)$ and that $\mu(x)x < 0$ for $x > K$ (in mathematical biology, K is known as the *carrying capacity of the environment*; cf. [12], [13], and [14]). For simplicity, we also assume that $\sigma(x) > 0$ on $(0, \infty)$ (this assumption can be relaxed as long as the boundary behavior of the diffusion is specified at the singularities $\{\sigma^{-1}(0)\}$; cf. [4] and [5]). Moreover, in accordance with reality (cf. [1], [5], [6], [24], [25], and [26]), we assume that the upper boundary ∞ of the state-space of X is natural. Thus, even while X may be expected to increase, it is never expected to become infinitely high in finite time. Finally, we call a control Z *admissible* if it is nonnegative, nondecreasing, right-continuous, and $\{\mathcal{F}_t\}$-adapted, and denote the set of admissible controls as Λ.

We observe that when $Z(t) \equiv 0$, X evolves according to a regular linear time homogeneous diffusion with basic characteristics

$$S'(x) = \exp\left(-\int^x \frac{2\mu(y)y}{\sigma^2(y)}dy\right)$$

denoting the density of its scale function S and

$$m'(x) = \frac{2}{\sigma^2(x)S'(x)}$$

denoting the density of its speed measure m. It is worth observing that applying Itô's theorem on the mapping $x \mapsto \ln x$ yields that

$$X(t) = x \exp\left(\int_0^t \mu(X(s))ds\right) M(t), \tag{2}$$

where

$$M(t) = \exp\left(\int_0^t \frac{\sigma(X(s))}{X(s)}dW(s) - \int_0^t \frac{1}{2}\frac{\sigma^2(X(s))}{X^2(s)}ds\right).$$

Thus, if $\sigma(x)/x$ is square-integrable, that is, if

$$E_x \int_0^{t\wedge\tau(0)} \frac{\sigma^2(X(s))}{X^2(s)}ds < \infty,$$

then $M(t)$ is a positive local martingale and, therefore, a supermartingale. In that case, we observe that $0 \leq X(t) \leq xe^{\mu(0)t}M(t)$ almost surely and that $0 \leq E[X(t)] \leq xe^{\mu(0)t}$.

We now define the *net convenience yield accrued from retaining a stock x undistributed* as the mapping $\theta : \mathbb{R}_+ \mapsto \mathbb{R}$ defined in

$$\theta(x) = (\mu(x) - r)x. \tag{3}$$

As is clear intuitively, the mapping $\theta(x)$ measures the net income flow accrued from storing a marginal unit of stock x. In order to guarantee the boundedness of the considered functionals, we assume throughout this study that for all $x \in \mathbb{R}_+$ we have

$$E_x \int_0^{\tau(0)} e^{-rs}\theta(X(s))ds < \infty, \tag{4}$$

where the expectation is taken with respect to the law of the uncontrolled diffusion.

Given the assumptions above, we now plan to consider the stochastic control problem

$$V(x) = \sup_{Z \in \Lambda} E_x \int_0^{\tau(0)} e^{-rs} dZ(s), \tag{5}$$

where $r > 0$ denotes the exogeneously determined discount rate. As in [4], we find by applying the generalized Itô's theorem for semimartingales to the identity map $x \mapsto x$ that

$$V(x) \leq x + \sup_{Z \in \Lambda} E_x \int_0^{\tau(0)} e^{-rs}\theta(X(s))ds \tag{6}$$

for all $x \in \mathbb{R}_+$. Thus, we immediately find the following.

Lemma 1. *If $\mu(0) \leq r$, then the optimal policy is $Z(0) = x$. Under the optimal policy, we have $\tau(0) = 0$ and $V(x) = x$.*

Proof. The assumption $\mu(0) \leq r$ implies that $\theta(x) \leq 0$ for all $x \in \mathbb{R}_+$. The required result is then a straightforward consequence of the inequality (6). □

Lemma 1 states that if the percentage growth rate $\mu(x)$ is smaller than the discount rate r for all x, then waiting is never optimal and the current stock x should be instantaneously depleted since no intertemporal gains can be accrued by postponing the decision into the future. Before proceeding in our analysis, we state the following auxiliary definition.

Definition 2 (see [11, chapter II], [18, section 4.6], and [27, section II.3]). *The Green-kernel $G_r : \mathcal{I}^2 \mapsto \mathbb{R}_+$ of the diffusion X with state-space $\mathcal{I} \subseteq \mathbb{R}$ is defined as*

$$G_r(x,y) = \int_0^\infty e^{-rt} p(t;x,y)dt,$$

where $p(t;x,y)$ is the transition density of X defined with respect to its speed measure m. There are two linearly independent fundamental solutions, $\hat{\psi}(x)$ and $\hat{\varphi}(x)$, with $\hat{\psi}(x)$ increasing and $\hat{\varphi}(x)$ decreasing, spanning the set of solutions of the ordinary differential equation $((\mathcal{A} - r)u)(x) = 0$, where

$$\mathcal{A} = \frac{1}{2}\sigma^2(x)\frac{d^2}{dx^2} + \mu(x)x\frac{d}{dx} \tag{7}$$

is the second order differential operator representing the infinitesimal generator of the underlying diffusion X. The Green-kernel $G_r(x,y)$ can be rewritten in terms of these solutions in the alternative form

$$G_r(x,y) = \begin{cases} B^{-1}\hat{\psi}(x)\hat{\varphi}(y), & x < y, \\ B^{-1}\hat{\psi}(y)\hat{\varphi}(x), & x \geq y, \end{cases}$$

where

$$B = \frac{\hat\psi'(x)}{S'(x)}\hat\varphi(x) - \frac{\hat\varphi'(x)}{S'(x)}\hat\psi(x) > 0$$

is the constant Wronskian determinant of the fundamental solutions.

In order to solve the singular stochastic control problem (5), we now define the auxiliary Markovian functional $F : \mathbb{R}^2_+ \mapsto \mathbb{R}$ as (cf. [1], [4], and [5])

$$F(x,b) = \begin{cases} R(b) - \frac{R'(b)}{\psi'(b)}\psi(b), & x \geq b, \\ R(x) - \frac{R'(b)}{\psi'(b)}\psi(x), & x < b, \end{cases} \tag{8}$$

where

$$\psi(x) = \begin{cases} \hat\psi(x) & \text{if 0 is either natural, exit, or entrance for } X, \\ \hat\psi(x) - \frac{\hat\psi(0)}{\hat\varphi(0)}\hat\varphi(x) & \text{if 0 is regular for } X \end{cases}$$

denotes the increasing fundamental solution of the ordinary differential equation $((\mathcal{A}-r)u)(x) = 0$ defined in the domain of the generator of the diffusion $\{X(t); t \in [0, \tau(0))\}$ and

$$R(x) = B^{-1}\hat\varphi(x)\int_0^x \psi(y)\theta(y)m'(y)dy + B^{-1}\psi(x)\int_x^\infty \hat\varphi(y)\theta(y)m'(y)dy \tag{9}$$

denotes the expected cumulative present value of the future net convenience yields $\theta(x)$ (condition (4) guarantees the convergence of the integrals in (9)). Our first results characterizing the value and optimal policy are now presented in the following (generalizing the results of Theorem 4 in [4]).

Theorem 3. *Assume that $\mu(0) > r$ and that the convenience yield $\theta(x)$ is increasing for $x < x^*$ and decreasing for $x > x^*$, where $x^* = \operatorname{argmax}_{x\in\mathbb{R}_+}\{\theta(x)\} \in (0,\infty)$. Then the optimal policy is*

$$Z(t) = \begin{cases} \mathcal{L}(t, b^*), & t > 0, \\ (x - b^*)^+, & t = 0, \end{cases} \tag{10}$$

where $\mathcal{L}(t,b^*)$ denotes the local time of the process $X(t)$ at the state b^*, and

$$b^* = \operatorname*{argmin}_{x\in\mathbb{R}_+}\left\{\frac{R'(x)}{\psi'(x)}\right\} \in (x^*, \mu^{-1}(r))$$

is the unique interior root of the ordinary first order necessary condition

$$r\int_0^{b^*} \psi(y)\theta(y)m'(y)dy = \theta(b^*)\frac{\psi'(b^*)}{S'(b^*)}. \tag{11}$$

Moreover, the value of the optimal policy is twice continuously differentiable on $\mathbb{R}_+$ and it reads as

$$V(x) = \begin{cases} x + \frac{\theta(b^*)}{r}, & x \geq b^*, \\ x + F(x,b^*), & x < b^*, \end{cases} \tag{12}$$

which can be rewritten alternatively as

$$V(x)=\begin{cases} x+\frac{\theta(b^*)}{r}, & x\geq b^*,\\ \frac{\psi(x)}{\psi'(b^*)}, & x<b^*.\end{cases} \tag{13}$$

Proof. Consider first the Markovian functional

$$\frac{R'(x)}{\psi'(x)}=B^{-1}\frac{\hat{\varphi}'(x)}{\psi'(x)}\int_0^x\psi(y)\theta(y)m'(y)dy+B^{-1}\int_x^\infty\hat{\varphi}(y)\theta(y)m'(y)dy.$$

Standard differentiation yields

$$\frac{d}{dx}\left[\frac{R'(x)}{\psi'(x)}\right]=\frac{2S'(x)}{\sigma^2(x)\psi'^2(x)}\left[r\int_0^x\psi(y)\theta(y)m'(y)dy-\theta(x)\frac{\psi'(x)}{S'(x)}\right].$$

Define now the functional $J:\mathbb{R}_+\mapsto\mathbb{R}$ as

$$J(x)=r\int_0^x\psi(y)\theta(y)m'(y)dy-\theta(x)\frac{\psi'(x)}{S'(x)}. \tag{14}$$

If $z>x>x^*$, the monotonicity of $\theta(x)$ implies that

$$\begin{aligned}\frac{1}{r}\left[J(z)-J(x)\right]&=\int_x^z\psi(y)\theta(y)m'(y)dy-\frac{\theta(z)}{r}\frac{\psi'(z)}{S'(z)}+\frac{\theta(x)}{r}\frac{\psi'(x)}{S'(x)}\\ &>\frac{\theta(z)}{r}\left[\frac{\psi'(z)}{S'(z)}-\frac{\psi'(x)}{S'(x)}\right]-\frac{\theta(z)}{r}\frac{\psi'(z)}{S'(z)}+\frac{\theta(x)}{r}\frac{\psi'(x)}{S'(x)}\\ &=\frac{[\theta(x)-\theta(z)]}{r}\frac{\psi'(x)}{S'(x)}>0,\end{aligned}$$

proving that $I(x)$ is monotonically increasing on (x^*,∞). Similarly, if $z<x<x^*$, the monotonicity of $\theta(x)$ implies that

$$\begin{aligned}\frac{1}{r}\left[J(x)-J(z)\right]&=\int_z^x\psi(y)\theta(y)m'(y)dy-\frac{\theta(x)}{r}\frac{\psi'(x)}{S'(x)}+\frac{\theta(z)}{r}\frac{\psi'(z)}{S'(z)}\\ &<\frac{[\theta(z)-\theta(x)]}{r}\frac{\psi'(z)}{S'(z)}<0,\end{aligned}$$

proving that $I(x)$ is monotonically decreasing on $(0,x^*)$. Moreover, it is clear that the assumption $\mu(0)>r$ and the monotonicity of $\mu(x)$ imply that $\theta(x)>0$ on $(0,\mu^{-1}(r))$. Thus, we find that $J(0)=0$,

$$J(\mu^{-1}(r))=r\int_0^{\mu^{-1}(r)}\psi(y)\theta(y)m'(y)dy,$$

and

$$J(x^*)=\int_0^{x^*}\psi(y)(\theta(y)-\theta(x^*))m'(y)dy-\frac{\theta(x^*)}{r}\frac{\psi'(0)}{S'(0)}<0.$$

Combining this finding with the proven monotonicity and continuity of the functional $J(x)$ implies that there is a unique threshold $b^*\in(x^*,\mu^{-1}(r))$ at which the functional $R'(x)/\psi'(x)$ is minimized and that $R'(x)/\psi'(x)$ is monotonically decreasing for $x<b^*$

and monotonically increasing for $x > b^*$. Given these results, we observe that the proposed value function is twice continuously differentiable on $\mathbb{R}_+$. Moreover, we observe that on $(0, b^*)$ the proposed value function satisfies the inequality

$$V'(x) = 1 + R'(x) - \frac{R'(b^*)}{\psi'(b^*)}\psi'(x) \geq 1,$$

since $\psi'(x) > 0$ and $R'(x)/\psi'(x) \geq R'(b^*)/\psi'(b^*)$ for all $x \in \mathbb{R}_+$. Moreover, we also find that

$$((\mathcal{A} - r)V)(x) = \begin{cases} \theta(x) - \theta(b^*), & x \geq b^* \\ 0, & x < b^* \end{cases} \leq 0,$$

since $((\mathcal{A} - r)R)(x) + \theta(x) = 0$ and b^* is attained on the set where $\theta(x)$ is decreasing. Thus, the proposed value function satisfies the conditions of Lemma 1 in [4] and, therefore, dominates the value of the singular stochastic control problem (5). The rest of the proof is then completed as in the proof of Theorem 4 in [4]. □

Theorem 3 states a set of considerably weak sufficient conditions under which the optimal policy is of the threshold type in the sense that there is a unique optimal threshold at which the control policy should be instantaneously applied at a maximal rate in order to maintain the process below the critical threshold b^*. It is clear that if $\mu(x)$ is continuously differentiable on $\mathbb{R}_+$, then partial integration of (11) implies that the optimal reflection threshold has to satisfy the equivalent condition

$$\int_0^{b^*} \frac{\psi'(y)}{S'(y)}[\mu(y) - r + \mu'(y)y]dy = 0. \tag{15}$$

It is also worth noticing that the optimal threshold b^* is below the equilibrium density $\mu^{-1}(r)$ at which the percentage growth rate is equal to the discount rate, but above the density x^* at which the net convenience yield $\theta(x)$ is maximized. This result is of interest since the difference $b^* - x^*$ measures the *required exercise premium from exercising the irreversible policy*, since x^* is the threshold at which the policy is irreversibly exercised in the absence of stochastic fluctuations (i.e., in the deterministic case).

The results of Theorem 3 are interesting from the point of view of studies considering *rational harvesting planning in the presence of extinction risk*, since it demonstrates that the basic conclusions of models relying on logistic growth remain valid even in models subject to more complex and general per capita growth rates. More specifically, Theorem 3 shows that there is a unique optimal threshold density at which harvesting should be initiated in most models of pure compensation (cf. [5], [6], [24], [25], and [26]). Thus, we find that the *results obtained by relying on logistic models are qualitatively robust*. Similarly, Theorem 3 extends the older results obtained in studies considering the determination of the *rational dividend policy of a firm facing the risk of liquidation* by stating a simple monotonicity condition in terms of the discount rate and the expected growth rate of the cash flow of the firm (cf. [3], [19], and [29]). Moreover, if $\mu(x)$ is assumed to be differentiable, then the result of Theorem 3 is of interest from a *capital theoretic* point of view as well, since it demonstrates that in the presence of stochastic fluctuations we have that $\mu(b^*) + \mu'(b^*)b^* < r$, thus violating the standard *deterministic golden rule of capital accumulation* stating that the marginal yield $\mu(b^*) + \mu'(b^*)b^*$ accrued from retaining yet another marginal unit of stock x should be equal to the interest rate r (cf. [28, pp. 594–595]). In the present case, we find by ordinary differentiation that

$$\mu(b^*) + \mu'(b^*)b^* = r - \frac{1}{2}\sigma^2(b^*)V'''(b^*-).$$

It is also of interest to point out that Theorem 3 demonstrates that on $x < b^*$ the value function satisfies the ordinary differential equation $((\mathcal{A}-r)V)(x) = 0$ subject to the (*Von Neumann-type*) boundary condition $V'(b^*) = 1$ and the variational inequality $V'(x) > 1$. Especially, Theorem 3 shows that the value function $V \in C^2(\mathbb{R}_+)$ is the solution of the quasi-variational inequality

$$\min\{((r-\mathcal{A})V)(x), V'(x) - 1\} = 0.$$

Remark 1. It is worth pointing out that the results of Theorem 3 are also valid in the case where the infinitesimal diffusion coefficient $\sigma(x)$ vanishes at a point $\xi \geq K = \mu^{-1}(0)$ (*independently on the boundary behavior of* X *at* ξ). The reason for this finding is that the analysis in the proof of Theorem 3 is independent of the upper boundary of the state-space of the controlled diffusion as long as this boundary is not below $\mu^{-1}(0)$. This type of diffusion usually appears in studies considering random percentage growth rates, that is, in models of the form (cf. [4], [5], [13], [14], and [26])

$$\frac{dX(t)}{X(t)} = (\alpha dt + \sigma dW(t))\mu(X(t)).$$

A set of sufficient conditions under which the conditions of Theorem 1 are always satisfied are now summarized in the following.

COROLLARY 4. *If $\mu(x)$ is continuously differentiable, $\mu(x)x$ is strictly concave, and $\mu(0) > r$, then the conclusions of Theorem* 3 *are valid.*

Proof. It is sufficient to prove that the net convenience yield satisfies the monotonicity properties of Theorem 3. It is clear that under the assumptions of our corollary, the convenience yield $\theta(x)$ is strictly concave and satisfies the condition $\theta(0) = \theta(\hat{x}) = 0$, where $\hat{x} = \mu^{-1}(r)$. *Rolle's theorem* then implies that there is at least one point $x^* \in (0, \hat{x})$ where the marginal net convenience yield $\theta'(x)$ vanishes. Since $\theta(x)$ is strictly concave, x^* is unique and constitutes a global maximum of $\theta(x)$. Moreover, $\theta'(x) > 0$ on $(0, x^*)$ and $\theta'(x) < 0$ on (x^*, ∞) completing the proof of our corollary. □

Corollary 4 states an usually satisfied concavity condition under which the results of our Theorem 3 are always valid (for example, logistic and Gompertz-type growth). However, it is worth emphasizing that the results of Theorem 3 are more generally valid than the results of Corollary 4, since the concavity of the mapping $\mu(x)x$ is not a necessary condition for the existence of a well-defined global maximum for the net convenience yield $\theta(x)$ (for example, the gamma-response model $\mu(x)x = (x^{-\alpha}e^{-\beta x} - \delta)x$, where $0 < \alpha < 1$, $\beta > 0$, and $\delta > 0$).

In order to describe unambiguously the sign of the relationship between stochastic fluctuations and the optimal policy, we first prove the following important result summarizing the monotonicity and curvature properties of the value.

THEOREM 5. *Assume that $\mu(0) > r$ and that the net convenience yield $\theta(x)$ is increasing for $x < x^*$ and decreasing for $x > x^*$. Then, $V'(x) > 0$ and $V''(x) \leq 0$ for all $x \in \mathbb{R}_+$, and $F(x, b^*)$ is concave on $(0, b^*)$.*

Proof. As was shown in Theorem 3, our assumptions imply that the value is twice continuously differentiable and that it can be written as in (13). Since $\psi(x)$

is increasing, ordinary differentiation of (13) then proves the alleged monotonicity of $V(x)$. Differentiating (13) twice then yields

$$V''(x) = \begin{cases} 0, & x \geq b^*, \\ \frac{\psi''(x)}{\psi'(b^*)}, & x < b^*. \end{cases}$$

Thus, it is sufficient to show that $\psi(x)$ is concave on $(0, b^*)$. To accomplish this task, we first observe that the ordinary differential equation $((\mathcal{A} - r)\psi)(x) = 0$ can be rewritten as

$$\frac{1}{2}\sigma^2(x)\frac{\psi''(x)}{S'(x)} = r\frac{\psi(x)}{S'(x)} - \mu(x)\frac{\psi'(x)}{S'(x)}. \tag{16}$$

Adding and subtracting $rx\psi'(x)/S'(x)$ from (16) then yield that

$$\frac{1}{2}\sigma^2(x)\frac{\psi''(x)}{S'(x)} = r\left[\frac{\psi(x)}{S'(x)} - x\frac{\psi'(x)}{S'(x)}\right] - \theta(x)\frac{\psi'(x)}{S'(x)}.$$

Consider now the mapping

$$g(x) = \frac{\psi(x)}{S'(x)} - x\frac{\psi'(x)}{S'(x)}.$$

Since $0 \leq \lim_{x\downarrow 0} \frac{\psi'(x)}{S'(x)} < \infty$ (cf. [11, p. 19]), we find that the second term on the right-hand side of the equation above vanishes as $x \downarrow 0$. Thus, we observe that

$$\lim_{x\downarrow 0} g(x) = \lim_{x\downarrow 0} \frac{\psi(x)}{S'(x)}.$$

If 0 is either natural, exit, or regular, we find that $\lim_{x\downarrow 0} \frac{\psi(x)}{S'(x)} = 0$ whenever $\lim_{x\downarrow 0} S'(x) > 0$, since $\psi(0) = 0$ (cf. [11, p. 19]). If 0 is entrance, then $\lim_{x\downarrow 0} S'(x) = \infty$ and $\psi(0) \in [0, \infty)$, implying that $\lim_{x\downarrow 0} \frac{\psi(x)}{S'(x)} = 0$ (cf. [11, p. 19]). Thus, it remains to deal with the case when 0 is either natural, exit, or regular and $\lim_{x\downarrow 0} S'(x) = 0$. The latter condition implies that $\frac{\mu(x)x}{\sigma^2(x)}$ has to tend towards infinity as $x \downarrow 0$. L'Hospital's rule then yields that

$$\lim_{x\downarrow 0} g(x) = -\lim_{x\downarrow 0} \frac{\sigma^2(x)}{2\mu(x)x}\frac{\psi'(x)}{S'(x)} = 0,$$

proving that

$$\lim_{x\downarrow 0} g(x) = 0.$$

Ordinary differentiation of $g(x)$ then yields that

$$g'(x) = \theta(x)\psi(x)m'(x),$$

implying that

$$\frac{\psi(x)}{S'(x)} - x\frac{\psi'(x)}{S'(x)} = \int_0^x \theta(y)\psi(y)m'(y)dy.$$

Thus, we have proved that

$$\frac{1}{2}\sigma^2(x)\frac{\psi''(x)}{S'(x)} = r\int_0^x \theta(y)\psi(y)m'(y)dy - \frac{\psi'(x)}{S'(x)}\theta(x). \tag{17}$$

Combining (17) with (11) and the analysis in the proof of Theorem 3 then implies that $\psi''(x) \leq 0$ for all $x \in (0, b^*]$, proving the alleged concavity of both the value $V(x)$ and the cumulative net convenience yields $R(x, b^*)$. □

Theorem 5 states a set of sufficient conditions under which *the marginal value $V'(x)$ is positive but diminishing* as a mapping of the current stock x. It is worth emphasizing that Theorem 5 is valid under a set of very weak conditions, since it does not require a Novikov-type condition, nor does it require concavity or differentiability assumptions on the form of the drift $\mu(x)x$ (for a comparison, see [16]). Thus, Theorem 5 demonstrates that it is only the first order monotonicity properties of the yield $\theta(x)$ which determine both the monotonicity and concavity of the value of the optimal policy. To the best knowledge of the author, the conditions of Theorem 5 are the weakest under which the concavity of the value function has been proven.

Our main results on the effect of increased volatility both on the optimal policy and the value are now summarized in the following.

THEOREM 6. *Assume that the conditions of Theorem* 5 *are met. Then, increased stochastic fluctuations decrease or leave unchanged the value $V(x)$ and increase or leave unchanged the optimal threshold. That is, if $\tilde{\sigma} : \mathbb{R}_+ \mapsto \mathbb{R}$ satisfies the condition $\tilde{\sigma}(x) \geq \sigma(x)$ on $\mathbb{R}_+$, $\tilde{V}(x)$ denotes the value, and $\tilde{b}$ denotes the optimal threshold in the presence of greater stochastic fluctuations, then $\tilde{b} \geq b^*$ and $\tilde{V}(x) \leq V(x)$ on $\mathbb{R}_+$.*

Proof. The alleged result is proved by applying the same technique as in the proof of Theorem 6 in [4]. □

Theorem 6 states a set of usually satisfied conditions under which increased uncertainty has a negative impact on both the value and the optimal policy. As Theorem 6 demonstrates, increased uncertainty increases the optimal threshold and, therefore, postpones the exercise of the singular policy whenever the net convenience yield is increasing below a given point x^* and decreasing above it. It is also worth pointing out that Theorem 6 clearly shows that the value of the associated singular stochastic control problems can be completely ordered in terms of the volatilities of the controlled diffusions whenever the value functions are concave. The result of Theorem 6 is very important from the point of view of applications, since it confirms the intuitively clear argument that *the sign of the relationship between uncertainty and an irreversible policy is unambiguously negative.* Summarizing, we have the following.

COROLLARY 7. *Assume that $\mu(0) > r$ and that the net convenience yield $\theta(x)$ is increasing for $x < x^*$ and decreasing for $x > x^*$. Then, increased stochastic fluctuations increase the required exercise premium $b^* - x^*$.*

Proof. Since x^* is independent of $\sigma(x)$, the conclusion is a straightforward implication of Theorem 6. □

3. Optimal stopping and the marginal value.

It is well known that singular stochastic control is closely related to optimal stopping (cf. [7], [8], [10], [20], [21], [22], [30], and [31]). In order to verify this connection in the present case, we assume throughout this section that both the diffusion coefficient $\sigma(x)$ and the percentage growth rate $\mu(x)$ are continuously differentiable on $\mathbb{R}_+$. Given these extra assumptions, we now plan to consider the optimal stopping problem

$$H(x) = \sup_{\tau < \tilde{\tau}(0)} E_x\left[\exp\left(\int_0^\tau \theta'(\tilde{X}(s))ds\right)\right], \tag{18}$$

where $\tilde{X}(t)$ evolves according to the diffusion described by the stochastic differential equation

$$(19)\quad d\tilde{X}(t) = (\mu(\tilde{X}(t))\tilde{X}(t) + \sigma'(\tilde{X}(t))\sigma(\tilde{X}(t)))dt + \sigma(\tilde{X}(t))dW(t), \quad \tilde{X}(0) = x,$$

and $\tilde{\tau}(0) = \inf\{t \geq 0 : \tilde{X}(t) \leq 0\}$. We can now show the following.

LEMMA 8. *Assume that $\mu(0) > r$ and that the net convenience yield $\theta(x)$ is increasing for $x < x^*$ and decreasing for $x > x^*$. Then, $V'(x) \geq H(x)$ for all $x \in \mathbb{R}_+$.*

Proof. It is clear that $V' \in C^1(\mathbb{R}_+) \cap C^2(\mathbb{R}_+ \backslash \{b^*\})$, that $V'(x) \geq 1$ for all $x \in \mathbb{R}_+$, that $V'''(b^*+) = 0$, and that

$$V'''(b^*-) = -\frac{2\theta'(b^*)}{\sigma^2(b^*)} < \infty.$$

Moreover, since

$$((\mathcal{A} - r)V)(x) = \begin{cases} \theta(x) - \theta(b^*), & x > b^*, \\ 0, & x < b^*, \end{cases}$$

we find that

$$\frac{d}{dx}((\mathcal{A} - r)V)(x) = \frac{1}{2}\sigma^2(x)V'''(x) + (\mu(x)x + \sigma'(x)\sigma(x))V''(x) + \theta'(x)V'(x) \leq 0,$$

since b^* is attained on the set where $\theta(x)$ is decreasing. Thus, the alleged result follows from Theorem 10.4.1 in [32]. □

Lemma 8 demonstrates, by relying on a simple variational argument, that under the assumptions of our paper the marginal value $V'(x)$ of the singular stochastic control problem (5) dominates the value of the associated stopping problem (18). It is, of course, of interest to find out the cases when these two values may coincide in the present case. The main conclusion of this section is now summarized in the following.

THEOREM 9. *Assume that $\mu(0) > r$, that the convenience yield $\theta(x)$ is increasing for $x < x^*$, decreasing for $x > x^*$, and that 0 is either natural, exit, or entrance for the diffusion X. Then, $V'(x) = H(x)$ for all $x \in \mathbb{R}_+$.*

Proof. We know from Lemma 8 that $V'(x) \geq H(x)$ so it is sufficient to show the opposite inequality. Since the stopping time τ in the optimal stopping problem (18) is arbitrary, we observe that

$$H(x) \geq E_x \left[\exp\left(\int_0^{\tau(0,b^*)} \theta'(\tilde{X}(s))ds \right) \right],$$

where $\tau(0, b^*) = \inf\{t \geq 0 : \tilde{X}(t) \notin (0, b^*)\}$. Define now the functional $G(x, a, b^*)$ as

$$G(x, a, b^*) = E_x \left[\exp\left(\int_0^{\tau(a,b^*)} \theta'(\tilde{X}(s))ds \right) \right],$$

where $\tau(a, b^*) = \inf\{t \geq 0 : \tilde{X}(t) \notin (a, b^*)\}$. Since $\hat{\varphi}''(x)\psi'(x) - \psi''(x)\hat{\varphi}'(x) = 2rB\tilde{S}'(x) > 0$, where $\tilde{S}'(x) = S'(x)/\sigma^2(x)$, we observe that the general solution of the ordinary second order differential equation

$$\frac{1}{2}\sigma^2(x)u''(x) + (\mu(x)x + \sigma'(x)\sigma(x))u'(x) + \theta'(x)u(x) = 0$$

is $u(x) = c_1\psi'(x) + c_2\hat{\varphi}'(x)$, where c_1 and c_2 are unknown real constants. It is now an elementary exercise in linear algebra to demonstrate that if $x \in (a, b^*)$, then

$$G(x,a,b^*) = \frac{\hat{\varphi}'(x) - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}\psi'(x)}{\hat{\varphi}'(a) - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}\psi'(a)} + \frac{\psi'(x) - \frac{\psi'(a)}{\hat{\varphi}'(a)}\hat{\varphi}'(x)}{\psi'(b^*) - \frac{\psi'(a)}{\hat{\varphi}'(a)}\hat{\varphi}'(b^*)}. \tag{20}$$

Consider now the second term on the right-hand side of (20). Invoking the alleged boundary behavior of X then implies that (cf. [11, p. 19])

$$\lim_{a\downarrow 0} \frac{\psi'(x) - \frac{\psi'(a)}{\hat{\varphi}'(a)}\hat{\varphi}'(x)}{\psi'(b^*) - \frac{\psi'(a)}{\hat{\varphi}'(a)}\hat{\varphi}'(b^*)} = \lim_{a\downarrow 0} \frac{\psi'(x) - \frac{\psi'(a)/S'(a)}{\hat{\varphi}'(a)/S'(a)}\hat{\varphi}'(x)}{\psi'(b^*) - \frac{\psi'(a)/S'(a)}{\hat{\varphi}'(a)/S'(a)}\hat{\varphi}'(b^*)} = \frac{\psi'(x)}{\psi'(b^*)}.$$

Consider now the first term on the right-hand side of (20). Since $\hat{\varphi}'(x)/\psi'(x)$ is increasing on $\mathbb{R}_+$ and $\psi(x)$ is increasing and concave on $(0, b^*)$, we find that

$$0 \leq \frac{\hat{\varphi}'(x) - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}\psi'(x)}{\hat{\varphi}'(a) - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}\psi'(a)} = \frac{\psi'(x)}{\psi'(a)} \frac{\frac{\hat{\varphi}'(x)}{\psi'(x)} - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}}{\frac{\hat{\varphi}'(a)}{\psi'(a)} - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}} \leq \frac{\frac{\hat{\varphi}'(x)}{\psi'(x)} - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}}{\frac{\hat{\varphi}'(a)}{\psi'(a)} - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}}.$$

Letting $a \downarrow 0$ and invoking again the alleged boundary behavior of X then yields

$$0 \leq \lim_{a\downarrow 0} \frac{\hat{\varphi}'(x) - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}\psi'(x)}{\hat{\varphi}'(a) - \frac{\hat{\varphi}'(b^*)}{\psi'(b^*)}\psi'(a)} \leq 0$$

implying that

$$\lim_{a\downarrow 0} G(x,a,b^*) = \frac{\psi'(x)}{\psi'(b^*)}$$

and, therefore, that

$$H(x) \geq G(x,0,b^*) = V'(x)$$

completing the proof of our theorem. □

Theorem 9 demonstrates, by relying on the classical theory of linear diffusions, that the marginal value $V'(x)$ of the singular stochastic control problem (5) coincides with the value of an associated optimal stopping problem (18) except in the case where the lower boundary is regular. It is worth emphasizing that the result of Theorem 9 is rather general since it is valid also in the case where the lower boundary may be attainable in finite time (exit) for the controlled diffusion X. It is also clear that whenever 0 is regular, we have that $V'(x) \geq H(x)$ and, therefore, that $\{x \in \mathbb{R}_+ : H(x) > 1\} \subseteq \{x \in \mathbb{R}_+ : V'(x) > 1\}$. In other words, the continuation region of the stopping problem (18) is a subset of the do-nothing-region in the associated singular stochastic control problem (5).

Applying now the fundamental theorem of calculus to the mapping $\exp(\int_0^t \theta'(\tilde{X}(s))ds)$ then implies that the value of the optimal stopping problem (18) coincides with the value of a perpetual American-type forward contract (an optimal exit problem; see [2] and references therein, see also [8] for an associated interpretation) of the form

$$H(x) = 1 + \sup_{\tau < \tilde{\tau}(0)} E_x \int_0^\tau \exp\left(\int_0^s \theta'(\tilde{X}(t))dt\right) \theta'(\tilde{X}(s))ds.$$

Thus, we find the following.

COROLLARY 10. *Assume that $\mu(0) > r$, that the convenience yield $\theta(x)$ is increasing for $x < x^*$, decreasing for $x > x^*$, and that 0 is either natural, exit, or entrance for the diffusion X. Then, for all $x \in \mathbb{R}_+$ we have that*

$$V'(x) = 1 + \sup_{\tau<\tilde{\tau}(0)} E_x \int_0^\tau \exp\left(\int_0^s \theta'(\tilde{X}(t))dt\right) \theta'(\tilde{X}(s))ds.$$

Proof. The result is a direct consequence of Theorem 9. □

Corollary 10 presents an interesting result from the point of view of applications. Namely, it states that under the optimal policy (given the conditions of Theorem 9), the marginal expected cumulative present value of the future convenience yields $\theta(x)$ is equal to the expected cumulative present value of the future marginal convenience yields $\theta'(x)$ evaluated from the present up to the Markov time at which the accumulation of the marginal yields is optimally stopped.

AN LMI-BASED ALGORITHM FOR DESIGNING SUBOPTIMAL STATIC $\mathcal{H}_2/\mathcal{H}_\infty$ OUTPUT FEEDBACK CONTROLLERS*

F. LEIBFRITZ[†]

Abstract. We consider the problem of designing a suboptimal $\mathcal{H}_2/\mathcal{H}_\infty$ feedback control law for a linear time-invariant control system when a complete set of state variables is not available. This problem can be necessarily restated as a nonconvex optimization problem with a bilinear, multiobjective functional under suitably chosen linear matrix inequality (LMI) constraints. To solve such a problem, we propose an LMI-based procedure which is a sequential linearization programming approach. The properties and the convergence of the algorithm are discussed in detail. Finally, several numerical examples for static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problems demonstrate the applicability of the considered algorithm and also verify the theoretical results numerically.

Key words. static controllers, output feedback, suboptimal control, robust control, linear systems, linear matrix inequalities, nonconvex programming

1. Introduction.

The static or reduced fixed order dynamic output feedback control problem that meets desired performance and/or robustness specifications is an active research area of the control community. In this paper we consider the computational design of static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controllers. This is an important example of a nonconvex control problem. It consists of determining a static output feedback gain which achieves a certain nominal (suboptimal) performance measure subject to a robustness constraint. The static output feedback problems are important, since it is not always possible to have full access to the state vector and a controller must be used which is based only on the available observations. Moreover, they are important because other problems are reducible to some variations of the static output feedback problem and relevant when a simple controller must be used due to cost and reliability.

During the past decade, control problems with combined $\mathcal{H}_2$ and $\mathcal{H}_\infty$ design criteria have gained a great deal of attention. Concerning continuous-time systems, [7] provides the solution of standard $\mathcal{H}_2$ and $\mathcal{H}_\infty$ control problems in terms of algebraic Riccati equations, where both state feedback and full order compensator-based output feedback are considered. The design of feedback controllers that satisfy both $\mathcal{H}_\infty$ and $\mathcal{H}_2$ specifications is interesting because it offers robust stability and nominal performance. In 1989, Bernstein and Haddad [2] introduced a mixed $\mathcal{H}_2/\mathcal{H}_\infty$ problem. Their approach is to minimize an auxiliary cost subject to an $\mathcal{H}_\infty$ norm constraint, and this cost yields an upper bound on the $\mathcal{H}_2$ norm. The work of [2] is extended in [46] and [6], where another mixed $\mathcal{H}_2/\mathcal{H}_\infty$ problem is addressed. The system considered therein is dual to the Bernstein–Haddad setup (see [45]). Other related works on the design of $\mathcal{H}_2/\mathcal{H}_\infty$ controllers by state or full order output feedback can be found, for example, in [23], [33], [35], [38], and [40]. Only [44] considers a mixed $\mathcal{H}_2/\mathcal{H}_\infty$ problem for the static output feedback case. The solvability conditions and

the algorithms discussed in the above literature are based on coupled Riccati and/or Lyapunov equations. Recently, linear matrix inequalities (LMIs) have attained much attention in control engineering [3], [5], [36], since many control problems can be formulated in terms of LMIs and thus solved via convex programming approaches. For example, this includes $\mathcal{H}_\infty$ [4], [11], [12], [25], $\mathcal{H}_2$ [18], [37], and mixed $\mathcal{H}_2/\mathcal{H}_\infty$ [19], [20], [27], [29], [39]. However, the resulting controllers are state feedback or of order n_x equal to the plant. The difficulties arise if we want to design a static (or reduced fixed order) output feedback controller. Then the problem of determining a static output feedback controller including $\mathcal{H}_2$ and $\mathcal{H}_\infty$ can be restated as a linear algebra problem, which involves two coupled LMIs. In this case, the solution of one should be the inverse of the other. The problem is then no longer convex [12], [25], [31], [30], [42], [43], and finding a solution numerically to these nonconvex problems is a difficult task.

In this paper we will develop an LMI-based computational procedure for solving a mixed $\mathcal{H}_2/\mathcal{H}_\infty$ problem by a static output feedback controller, which is an extension of the algorithm proposed by Leibfritz [31] for the design of stabilizing static $\mathcal{H}_2$ and $\mathcal{H}_\infty$ output feedback gains. The suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem considered in this paper can be necessarily rewritten to a nonconvex, multiobjective programming problem. In particular, this problem consists of minimizing a (nonconvex) functional of the form $\mathcal{J}(P, Q, Y) = \mathrm{Tr}(PQ) + \mathrm{Tr}(Y)$ subject to suitably chosen LMI constraints. Then, using the solution of this problem (if any exists), the existence of a static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback gain F can be tested by solving a suitably chosen LMI feasibility problem in F. Therefore, the problem of finding a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback gain reduces to an optimization problem with a nonconvex objective over a convex set and an LMI feasibility problem.

Similar to Leibfritz [31], we will derive the so-called sequential linear programming matrix method (SLPMM) for solving the resulting nonconvex programming problem. This approach is motivated by successive minimization of a linearization of $\mathcal{J}(P, Q, Y)$ subject to LMI constraints as proposed by [1] for general nonconvex bilinear programming problems. Note that the SLPMM algorithm is closely related to the cone complementarity linearization method developed by [9] for solving the static output feedback stabilization problem. As shown in [31], the theoretical advantages of the SLPMM algorithm over the cone complementarity algorithm are the following. First, the SLPMM algorithm always generates a strictly decreasing sequence of the objective function values which is bounded below by an integer n_x, and thus it is convergent. Second, the sequence of iterates generated by the SLPMM is contained in a compact level set, and therefore it is always bounded. Finally, if a corresponding bilinear matrix problem is nonempty, then every accumulation point of the generated sequence solves this bilinear matrix problem. In this case, it is always possible to reconstruct a static output feedback gain from this solution. On the other hand, if there exists no matrix pair satisfying the bilinear matrix problem, then the SLPMM algorithm always terminates with an objective function value of a bilinear matrix inequality minimization problem which is greater than n_x. This indicates for the considered plant that there exists no static output feedback controller. But in this case, one can construct a reduced fixed order dynamic controller from the computed solution of the bilinear matrix inequality minimization problem. For more details, we refer to Leibfritz [31]. In contrast to these strong theoretical convergence results, the authors in [9] can guarantee only that the sequence of a linear approximation of the objective function values is a monotonically (nonstrict) decreasing sequence, which is bounded below by $2n_x$. Moreover, in the last few years a number of numerical procedures have been proposed for solving static $\mathcal{H}_2$ output feedback problems. For example, the LMI-based methods also include the Min-Max algorithm of Geromel, de Souza, and Skelton [16], [17], the XY-centering algorithm of Iwasaki and Skelton [26], and the alternating projection method of Grigoriadis and Skelton [21], but the convergence of these algorithms is not always guaranteed. Particularly, the Min-Max algorithm guarantees only sequences of upper and lower bounds to the maximal and minimal eigenvalues of PQ, which are strictly decreasing, and increasing sequences under strong technical assumptions. In addition, for ensuring the global convergence of the Min-Max algorithm, they must assume that the generated sequences are contained in a compact set. On the other hand, it may occur that the Min-Max algorithm generates an unbounded sequence even if the bilinear matrix problem is nonempty. In this case the Min-Max method breaks down [9], [17]. Since the XY-centering algorithm is closely related to the Min-Max procedure, the global convergence of this approach can be shown only under similar technical assumptions that are as strong as the ones imposed for the Min-Max algorithm [26, Theorem 2]. Finally, the alternating projection method is guaranteed to converge only locally. These observations motivate us to derive the SLPMM algorithm for more complicated problems such as the static $\mathcal{H}_2/\mathcal{H}_\infty$ problem. For this problem class, we will show that the SLPMM procedure behaves theoretically as well as numerically in a similar way to that described above.

The paper is organized as follows. Section 2 defines the considered system realization and describes the static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem considered in this paper. Section 3 contains the necessary and sufficient conditions for the existence of stabilizing static $\mathcal{H}_\infty$ output feedback controllers. Moreover, the formulation of the LMI-based nonconvex optimization problem, which must be necessarily solvable if the static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem has a solution, can be found therein. Section 3.1 presents the main part of this paper. Therein we motivate the nonconvex multiobjective programming problem, and, similarly as in [31], we derive the SLPMM algorithm for finding a numerical solution of this problem class. Thereafter, we discuss the properties and global convergence of this procedure. Finally, in section 4, we present several examples for the design of suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback control laws, which will demonstrate the applicability of the SLPMM algorithm applied to this problem class. We also verify numerically the theoretical results and demonstrate the design of reduced fixed order dynamic controllers if the algorithm terminates with an optimal value greater than $n_x + \mathrm{Tr}(Y^*)$.

We will use the following notation. I_r denotes the $(r \times r)$ identity matrix. The set of real symmetric $(n \times n)$ matrices is denoted by $\mathcal{S}_n$, and $\mathcal{S}_n^+$ describes the cone of symmetric positive definite $(n \times n)$ matrices. For $A \in \mathcal{S}_n$, $A \succ 0$ $(A \succeq 0)$ means that A is positive definite (semidefinite). Similarly, $A \prec 0$ $(A \preceq 0)$ denotes that A is negative definite (semidefinite). For $A, B \in \mathcal{S}_n$, $A \preceq B$ $(A \succeq B)$ denotes the usual Loewner ordering [24]. The symbol $\mathrm{Tr}(A) = \sum_{i=1}^n a_{ii}$ is the trace operator of a matrix $A \in \mathbb{R}^{n \times n}$. $||A||_F$ is the Frobenius norm of a matrix. Finally, $||T_{zw}||_\infty$ denotes the $\mathcal{H}_\infty$ norm of a proper and real rational stable transfer matrix, i.e., $T_{zw} \in \mathcal{RH}_\infty$ [10], and $||T_{zw}||_{\mathcal{H}_2}$ is the usual $\mathcal{H}_2$ norm of a strictly proper and real rational stable transfer matrix, i.e., $T_{zw} \in \mathcal{RH}_2$ [10].

2. The static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem.

In this section, we focus on the static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem as formulated by Doyle et al. [6] for the full order dynamic output feedback case. However, we take a “suboptimal” approach for designing a static output feedback controller which is similar to [29]. The problem solved by Doyle et al. has been shown to be a dual problem of Bernstein and Haddad [2] in some sense; see, for example, Yeh, Banda, and Chang [45]. Khargonekar and Rotea [29] have obtained a nice solution to the dual problem for a class of suboptimal full order output feedback compensators. For example, a convex optimization approach is proposed to solve the full order output feedback dual problem. However, the static output feedback case considered in this paper is much more difficult, since the problem is then no longer convex.

Consider a finite dimensional linear time–invariant plant Σ_P with the state space realization

$$\Sigma_P \left\{ \begin{array}{rcl} \dot{x}(t) &=& Ax(t) + B_0 w_0(t) + B_1 w_1(t) + B_2 u(t), \quad x(0) = 0, \\ z(t) &=& C_1 x(t) + D_{10} w_0(t) + D_{11} w_1(t) + D_{12} u(t), \\ y(t) &=& C_2 x(t) + D_{20} w_0(t) + D_{21} w_1(t), \end{array} \right.$$

where $x(t) \in \mathbb{R}^{n_x}$ is the state, $w_i(t) \in \mathbb{R}^{n_w}$, $i = 0, 1$, are the disturbance inputs, $u(t) \in \mathbb{R}^{n_u}$ is the control input, $z(t) \in \mathbb{R}^{n_z}$ is the regulated output, and $y(t) \in \mathbb{R}^{n_y}$ is the measured output of the control system. The static output feedback controller Σ_C with the state space realization

$$\Sigma_C \left\{ \begin{array}{rcl} u(t) &=& Fy(t) \end{array} \right.$$

is to be designed, where $F \in \mathbb{R}^{n_u \times n_y}$ denotes the unknown static output feedback gain. Substituting Σ_C into the plant, Σ_P yields the corresponding closed loop system given by

$$\Sigma_{cl} \left\{ \begin{array}{rcl} \dot{x}(t) &=& A_F x(t) + B_{0F} w_0(t) + B_F w_1(t), \quad x(0) = 0, \\ z(t) &=& C_F x(t) + D_{0F} w_0(t) + D_F w_1(t), \end{array} \right.$$

where the closed loop matrices $A_F, B_F, C_F, D_F, B_{0F}$, and D_{0F} are defined as follows:

$$A_F = A + B_2 F C_2,\ B_F = B_1 + B_2 F D_{21},\ C_F = C_1 + D_{12} F C_2,\ D_F = D_{11} + D_{12} F D_{21},$$
$$B_{0F} = B_0 + B_2 F D_{20},\ D_{0F} = D_{10} + D_{12} F D_{20}.$$

Throughout the whole paper, the following assumptions are imposed on the system.

ASSUMPTION 2.1.

(1) *The pair* (A, B_2) *is stabilizable, and the pair* (A, C_2) *is detectable.*

(2) *The data matrices in* Σ_P*, especially the following, are real constant matrices:*

$$A \in \mathbb{R}^{n_x \times n_x}, B_1 \in \mathbb{R}^{n_x \times n_w}, B_2 \in \mathbb{R}^{n_x \times n_u}, C_1 \in \mathbb{R}^{n_z \times n_x}, C_2 \in \mathbb{R}^{n_y \times n_x},$$
$$D_{11} \in \mathbb{R}^{n_z \times n_w}, D_{12} \in \mathbb{R}^{n_z \times n_u}, D_{21} \in \mathbb{R}^{n_y \times n_w}, B_0 \in \mathbb{R}^{n_x \times n_w},$$
$$D_{10} \in \mathbb{R}^{n_z \times n_w}, D_{20} \in \mathbb{R}^{n_y \times n_w}.$$

(3) $F \in \mathbb{R}^{n_u \times n_y}$, $n_u < n_x$, $n_y < n_x$, *and* $\operatorname{rank}(B_2) = n_u$, $\operatorname{rank}(C_2) = n_y$.

We start by considering the analysis problem. Assume the static output feedback law Σ_C is fixed such that the closed loop system Σ_{cl} is internally stable. For example, there exists a static output feedback gain in the set

$$\mathcal{F}_s = \{F \in \mathbb{R}^{n_u \times n_y} \mid A_F \text{ is Hurwitz}\}, \tag{2.1}$$

the so-called stability set. Let $T_{zw_1}(s) = C_F(sI - A_F)^{-1}B_F + D_F$ ($T_{zw_0}(s) = C_F(sI - A_F)^{-1}B_{0F} + D_{0F}$), $s \in \mathbb{C}$, denote the closed loop transfer matrix from w_1 to z (from w_0 to z). The concepts of $\mathcal{H}_\infty$ norm and $\mathcal{H}_2$ norm/cost are well known (cf. [7]). Therefore, we will omit detailed discussion and content ourselves with starting the following definitions for reference. Since all coefficient matrices are assumed to be real and $F \in \mathcal{F}_s$ is fixed, the transfer matrix $T_{zw_1} \in \mathcal{RH}_\infty$ and the $\mathcal{H}_\infty$ norm of T_{zw_1} is defined by

$$||T_{zw_1}||_\infty = \sup_{\omega\in\mathbb{R}} \sigma_{\max}(T_{zw_1}(i\omega)), \tag{2.2}$$

where $\sigma_{\max}(T_{zw_1}(\cdot))$ denotes the largest singular value of T_{zw_1} and i denotes the imaginary unit. Recall that $T_{zw_0} \in \mathcal{RH}_2$ and the $\mathcal{H}_2$ norm of T_{zw_0} is finite, for example, $||T_{zw_0}||_{\mathcal{H}_2} < \infty$, if and only if $D_{0F} \equiv 0$. In this case, if L_o denotes the observability Gramian of the pair (A_F, C_F), the $\mathcal{H}_2$ norm of T_{zw_0} can be computed by

$$||T_{zw_0}||^2_{\mathcal{H}_2} = \operatorname{Tr}(B^T_{0F} L_o B_{0F}); \tag{2.3}$$

for example, L_o satisfies $\operatorname{Lyap}(L_o, F) = A^T_F L_o + L_o A_F + C^T_F C_F = 0$.

Now let the scalar $\gamma > 0$ be given and assume that $||T_{zw_1}||_\infty < \gamma$. Define $R_F = I_{n_w} - \gamma^{-2} D^T_F D_F$, and then it is a standard fact (see, for example, [30], [47]), that there exist a unique real symmetric matrix X and a gain $F \in \mathbb{R}^{n_u \times n_y}$ such that $R_F \succ 0$,

$$\begin{aligned}\operatorname{Ric}(X, F) = {}& A^T_F X + X A_F + \gamma^{-1} C^T_F C_F \\ &+ \gamma^{-1}(X B_F + \gamma^{-1} C^T_F D_F) R^{-1}_F (B^T_F X + \gamma^{-1} D^T_F C_F) = 0,\end{aligned} \tag{2.4}$$

and $A_F + \gamma^{-1} B_F R^{-1}_F (B^T_F X + \gamma^{-1} D^T_F C_F)$ is Hurwitz. Moreover, X satisfies (cf. [2])

$$0 \preceq L_o \preceq X \preceq P,$$

where P fulfills $\operatorname{Ric}(P, F) \preceq 0$. Thus, if the $\mathcal{H}_2$ norm of T_{zw_0} is finite, then we have

$$||T_{zw_0}||^2_{\mathcal{H}_2} = \operatorname{Tr}(B^T_{0F} L_o B_{0F}) \le \operatorname{Tr}(B^T_{0F} X B_{0F}) \le \operatorname{Tr}(B^T_{0F} P B_{0F}). \tag{2.5}$$

Similarly as in [2], [46], [29], or [35], these inequalities motivate us to define the following auxiliary $\mathcal{H}_2/\mathcal{H}_\infty$ cost function for the linear time–invariant closed loop system Σ_{cl}:

$$C_\gamma(P, F) = \operatorname{Tr}(B^T_{0F} P B_{0F}), \tag{2.6}$$

which is an upper bound on $||T_{zw_0}||^2_{\mathcal{H}_2}$ if and only if $D_{0F} \equiv 0$. Moreover, $C_\gamma(P, F) \le \operatorname{Tr}(Y)$ whenever the symmetric matrices $P \succ 0$ and $Y \succeq 0, Y \in \mathbb{R}^{n_w \times n_w}$, satisfy $\operatorname{Ric}(P, F) \prec 0$ and

$$\psi(F, P, Y) := \begin{bmatrix} Y & B^T_{0F} P \\ P B_{0F} & P \end{bmatrix} \succeq 0. \tag{2.7}$$

Note that (2.7) is equivalent to $Y \succeq B^T_{0F} P B_{0F} \succeq 0$ and can be stated also as follows:

$$\begin{bmatrix} Y & B^T_0 P \\ P B_0 & P \end{bmatrix} + \begin{bmatrix} 0 \\ P B_2 \end{bmatrix} F \begin{bmatrix} D_{20} & 0 \end{bmatrix} + \begin{bmatrix} D^T_{20} \\ 0 \end{bmatrix} F^T \begin{bmatrix} 0 & B^T_2 P \end{bmatrix} \succeq 0. \tag{2.8}$$

Thus, for given $P \in \mathcal{S}^+_{n_x}$, the matrix inequality (2.8) is an LMI in Y and F.

By this discussion, it is immediate that $||T_{zw_1}||_\infty < \gamma$ and $||T_{zw_0}||^2_{\mathcal{H}_2} < C_\gamma(P, F)$ if and only if $D_{0F} \equiv 0$. Hence, the Riccati inequality $\operatorname{Ric}(P, F) \prec 0$ leads to an $\mathcal{H}_\infty$ norm bound γ and an $\mathcal{H}_2$ cost upper bound $C_\gamma(P, F)$. If $D_{0F} \neq 0$, then $||T_{zw_0}||^2_{\mathcal{H}_2} = \infty$. In this case, we do not interpret the auxiliary cost function $C_\gamma(P,F)$ as an upper bound on the $\mathcal{H}_2$ cost, but we can interpret it as a robust performance measure similar to the results of [46, Theorem 4] and [6, Theorem 1]. The results concerning the optimization of the auxiliary static $\mathcal{H}_2/\mathcal{H}_\infty$ performance measure over the set of all stabilizing static controller gains F satisfying $||T_{zw_1}||_\infty < \gamma$ can be obtained from the following characterization. The proof of this result is very similar to [29, Lemma 2.1] and is thus omitted (see also [6, Theorems 1, 2]).

Lemma 2.2. *Consider the stable closed loop system Σ_{cl} and let T_{zw_1} (T_{zw_0}) denote the closed loop transfer matrix from w_1 to z (from w_0 to z). Let $\gamma > 0$ be given and suppose that T_{zw_0} is strictly proper, i.e., $D_{0F} \equiv 0$. Let $Ric(\cdot)$ be defined by* (2.4). *Then there exists a gain $F \in \mathbb{R}^{n_u \times n_y}$ satisfying $||T_{zw_1}||_\infty < \gamma$ if and only if there exists a pair (P,F), $F \in \mathbb{R}^{n_u \times n_y}$, $P \in \mathcal{S}^+_{n_x}$, such that $R_F \succ 0$ and $Ric(P,F) \prec 0$. In this case,*

$$C_\gamma(P,F) = \inf\{\mathrm{Tr}(B_{0F}^T P B_{0F}) \mid (P,F) \textit{ satisfy } R_F \succ 0, Ric(P,F) \prec 0, P \succ 0\}. \tag{2.9}$$

With the result of Lemma 2.2, our goal is to minimize the auxiliary static $\mathcal{H}_2/\mathcal{H}_\infty$ performance measure over all stabilizing static output feedback gains F that enforce the $\mathcal{H}_\infty$ constraint. From the previous discussion, this is equivalent to minimizing $\mathrm{Tr}(Y)$ over all matrices F, P, and Y satisfying $\mathrm{Ric}(P,F) \prec 0$, $R_F \succ 0$, $P \succ 0$, $Y \succeq 0$, and $\psi(F,P,Y) \succeq 0$. Thus, we state the suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem considered in this paper as the following nonconvex optimization problem:

$$\begin{array}{lll} \min\ \mathrm{Tr}(Y), & \text{subject to (s.t.)} & P \succ 0,\ R_F \succ 0,\ \mathrm{Ric}(P,F) \prec 0,\ Y \succeq 0, \\ & & \psi(F,P,Y) \succeq 0. \end{array} \tag{2.10}$$

In the following sections, we will discuss a procedure for finding solutions to this problem. Note, a solution (P^*, F^*, Y^*) of (2.10), if any exists, is suboptimal in the sense that

$$\begin{aligned} C_\gamma^{opt}(X,F) &= \min\{\mathrm{Tr}(B_{0F}^T X B_{0F}) \mid X \succeq 0, R_F \succ 0, \mathrm{Ric}(X,F) = 0\} \\ &\le \mathrm{Tr}(B_{0F^*}^T P^* B_{0F^*}) \le \mathrm{Tr}(Y^*), \end{aligned} \tag{2.11}$$

where $C_\gamma^{opt}(X,F)$ denotes the minimal value of the "optimal" static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem.

Finally, note that the results in the following sections can be easily extended to the following static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem formulation:

$$\begin{array}{ll} \min\ \mathrm{Tr}(Y), & \text{s.t. } P \succ 0, R_F \succ 0, \mathrm{Ric}(P,F) \prec 0, Y \succeq 0, \psi(F,P,Y) \succeq 0, \\ & \qquad \mathrm{Lyap}(P,F) \prec 0, D_{0F} = 0. \end{array} \tag{2.12}$$

Here, the goal is to minimize an upper estimate of the optimal static $\mathcal{H}_2$ performance subject to the $\mathcal{H}_\infty$ constraint.

3. Suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback design; LMI approach.

This paragraph is devoted to the computational design of a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controller. For deriving the LMI-based formulation of the static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem, we need the following result which can be found, for example, in [25].

Lemma 3.1. *Let $\mathcal{B} \in \mathbb{R}^{n\times m}, \mathrm{rank}(\mathcal{B}) = m < n$, $\mathcal{C} \in \mathbb{R}^{r\times n}, \mathrm{rank}(\mathcal{C}) = r < n$, and $\Omega \in \mathbb{R}^{n\times n}$ be given. Then there exists $F \in \mathbb{R}^{m\times r}$ satisfying $\mathcal{B}F\mathcal{C} + (\mathcal{B}F\mathcal{C})^T + \Omega \prec 0$ if and only if $N(\mathcal{B}^T)^T \Omega N(\mathcal{B}^T) \prec 0$ and $N(\mathcal{C})^T \Omega N(\mathcal{C}) \prec 0$ hold, where $N(\mathcal{B}^T) \in$*

$\mathbb{R}^{n\times(n-m)}$, $N(\mathcal{C}) \in \mathbb{R}^{n\times(n-r)}$, *denoting any matrices whose columns form orthonormal bases of the null spaces of* $\mathcal{B}^T$, $\mathcal{C}$, *respectively.*

By involving Lemma 3.1 and the strict bounded real lemma [47], the suboptimal static $\mathcal{H}_\infty$ output feedback problem, i.e., find a static output feedback gain F, if any exists, such that A_F is Hurwitz and $||T_{zw_1}||_\infty < \gamma$, can be transformed to a problem of solving two LMIs coupled through a bilinear matrix equation. Similar results can be found, for example, in [12], [25], and [30].

THEOREM 3.2 (existence of static $\mathcal{H}_\infty$ controllers). *Let* $\mathcal{F}_s \neq \emptyset$, $\gamma > 0$ *be given and consider the closed loop system* Σ_{cl} *with* $w_0 = 0$. *Then the following are equivalent.*

(i) *There exists a static output feedback gain* $F \in \mathbb{R}^{n_u\times n_y}$ *such that* A_F *is a Hurwitz matrix and* $||T_{zw_1}||_\infty < \gamma$.

(ii) *There exists a pair* (F, P), $F \in \mathbb{R}^{n_u\times n_y}$, $P \in \mathcal{S}^+_{n_x}$, *satisfying*

$$\mathcal{B}F\mathcal{C} + (\mathcal{B}F\mathcal{C})^T + \Omega \prec 0, \tag{3.1}$$

$$\Omega = \begin{bmatrix} A^TP + PA & PB_1 & C_1^T \\ B_1^TP & -\gamma I_{n_w} & D_{11}^T \\ C_1 & D_{11} & -\gamma I_{n_z} \end{bmatrix}, \mathcal{B} = \begin{bmatrix} PB_2 \\ 0 \\ D_{12} \end{bmatrix}, \mathcal{C} = [C_2 \;\; D_{21} \;\; 0].$$

(iii) *There exist matrices* $P \in \mathcal{S}^+_{n_x}$ *and* $Q \in \mathcal{S}^+_{n_x}$ *satisfying* $PQ = I$ *and*

$$N_Q^T \begin{bmatrix} AQ + QA^T + \gamma^{-1}B_1B_1^T & (C_1Q + \gamma^{-1}D_{11}B_1^T)^T \\ (C_1Q + \gamma^{-1}D_{11}B_1^T) & \gamma^{-1}D_{11}D_{11}^T - \gamma I_{n_z} \end{bmatrix} N_Q \prec 0, \tag{3.2}$$

$$N_P^T \begin{bmatrix} A^TP + PA + \gamma^{-1}C_1^TC_1 & PB_1 + \gamma^{-1}C_1^TD_{11} \\ (PB_1 + \gamma^{-1}C_1^TD_{11})^T & \gamma^{-1}D_{11}^TD_{11} - \gamma I_{n_w} \end{bmatrix} N_P \prec 0, \tag{3.3}$$

where $N_Q := N([B_2^T \;\; D_{12}^T])$ *and* $N_P := N([C_2 \;\; D_{21}])$, *denoting any matrices whose columns form orthonormal bases of the null spaces of* $[B_2^T \;\; D_{12}^T]$ *and* $[C_2 \;\; D_{21}]$, *respectively.*

Proof. Combining the strict bounded real lemma [47], Theorem 3.1, and using a Schur complement argument yields the desired result with $Q = P^{-1}$. □

The inequalities (3.2) and (3.3) are LMIs in Q and P, respectively, and are therefore convex. But finding $P \succ 0$ and $Q \succ 0$ satisfying $PQ = I$, (3.2), and (3.3) together is a difficult task since

$$\Phi_{\mathcal{H}_\infty}(P, Q, \gamma) := \{(P, Q) \in \mathcal{S}^+_{n_x} \mid (P, Q) \text{ satisfying } PQ = I, (3.2), (3.3)\} \tag{3.4}$$

is a nonconvex set, i.e., elements in $\Phi_{\mathcal{H}_\infty}(P, Q, \gamma)$ must be inverse to each other. A numerical algorithm for determining a pair $(P, Q) \in \Phi_{\mathcal{H}_\infty}(P, Q, \gamma)$ can be found, for example, in Leibfritz [31].

Similarly as in Theorem 3.2, we can eliminate the matrix variable F from (2.8) by using [25, Theorem 1], which is a generalization of Lemma 3.1. In particular, we have the following lemma.

LEMMA 3.3. *Let* $Y \in \mathbb{R}^{n_w\times n_w}$, $Y \succeq 0$, $P \in \mathcal{S}^+_{n_x}$, *and* $F \in \mathbb{R}^{n_u\times n_y}$. *Moreover, let* $B_0 \in \mathbb{R}^{n_x\times n_w}$, $B_2 \in \mathbb{R}^{n_x\times n_u}$, *and* $D_{20} \in \mathbb{R}^{n_y\times n_w}$ *be given. Suppose* $[0 \;\; PB_2]^T \in \mathbb{R}^{(n_w+n_x)\times n_u}$, *rank*$([0 \;\; PB_2]^T) \leq n_u$, *and* $[D_{20} \;\; 0] \in \mathbb{R}^{n_y\times(n_w+n_x)}$, *rank*$([D_{20} \;\; 0]) \leq n_y$. *Then the following statements are equivalent.*

(i) *There exists a triple* (F, P, Y) *satisfying* (2.8).

(ii) *There exist matrices* $Y \in \mathbb{R}^{n_w \times n_w}$, $Y \succeq 0$, $P \in \mathcal{S}^+_{n_x}$, *and* $Q \in \mathcal{S}^+_{n_x}$ *satisfying* $PQ = I$ *and*

$$\tilde{\mathcal{Q}}(Q,Y) = N([0\ \ B_2^T])^T \begin{bmatrix} Y & B_0^T \\ B_0 & Q \end{bmatrix} N([0\ \ B_2^T]) \succeq 0, \tag{3.5}$$

$$\tilde{\mathcal{P}}(P,Y) = N([D_{20}\ \ 0])^T \begin{bmatrix} Y & B_0^T P \\ PB_0 & P \end{bmatrix} N([D_{20}\ \ 0]) \succeq 0, \tag{3.6}$$

where $N([0\ \ B_2^T])$ *and* $N([D_{20}\ \ 0])$ *denote any matrices whose columns form orthonormal bases of the null spaces of* $[0\ \ B_2^T]$ *and* $[D_{20}\ \ 0]$, *respectively.*

Proof. Observing that

$$N\left(\begin{bmatrix} 0 \\ PB_2 \end{bmatrix}^T\right) = \begin{bmatrix} I_{n_w} & 0 \\ 0 & P^{-1} \end{bmatrix} N\left(\begin{bmatrix} 0 \\ B_2 \end{bmatrix}^T\right)$$

and using [25, Theorem 1], we obtain the desired result with $Q = P^{-1}$. □

The set

$$\begin{aligned} \tilde{\Phi}(P,Q,Y) := \{(P,Q) \in \mathcal{S}^+_{n_x}, Y \in \mathcal{S}_{n_w} \mid (P,Q,Y) \\ \text{satisfying } Y \succeq 0, PQ = I, (3.5), (3.6)\} \end{aligned} \tag{3.7}$$

is not convex due to the coupling condition $PQ = I$.

Obviously, a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ controller in the sense of the previous section exists if and only if condition (ii) of Theorem 3.2 and (2.8) hold for the same gain matrix F. Assuming that there exist matrices $F, P \in \mathcal{S}^+_{n_x}, Y \in \mathcal{S}_{n_w}$ satisfying (3.1) and (2.8), there exist matrices $(P,Q) \in \mathcal{S}^+_{n_x}$ and $Y \in \mathcal{S}_{n_w}$ satisfying condition (iii) of Theorem 3.2 and condition (ii) of Lemma 3.3. Thus, the static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem can be necessarily transformed to the following bilinear optimization problem:

$$\min\ \mathrm{Tr}(Y), \quad \text{s.t.} \quad (P,Q,Y) \in \Phi_{\mathcal{H}_\infty}(P,Q,\gamma) \cap \tilde{\Phi}(P,Q,Y). \tag{3.8}$$

Now suppose that there exists a solution triple (P^*, Q^*, Y^*) of (3.8) (not necessarily unique); then there exists a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controller if and only if there exists an F satisfying (3.1) and (2.8) for $P = P^*$ and $Y = Y^*$. Note, for given (P^*, Q^*, Y^*), this is an LMI feasibility problem in F. Therefore, the suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ problem is solvable if and only if the bilinear optimization problem (3.8) has a solution and the corresponding LMI feasibility problem in F is nonempty. Hence, these observations lead to the following necessary and sufficient conditions for the existence of static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controllers.

THEOREM 3.4. *Let* $\mathcal{F}_s \neq \emptyset$, $\gamma > 0$ *be given, and consider the closed loop system* Σ_{cl}. *Then the following statements are equivalent.*

(i) *There exists a triple* (F,P,Y), $F \in \mathbb{R}^{n_u \times n_y}$, $P \in \mathcal{S}^+_{n_x}$, $Y \in \mathcal{S}_{n_w}$, *and* $Y \succeq 0$ *satisfying* (3.1) *and* (2.8).

(ii) *There exist matrices* $P \in \mathcal{S}^+_{n_x}$, $Q \in \mathcal{S}^+_{n_x}$, $Y \in \mathcal{S}_{n_w}$, *and* $Y \succeq 0$ *satisfying* $PQ = I$, (3.2), (3.3), (3.5), (3.6), *and, for all such fixed* (P,Y), *there is a matrix* $F \in \mathbb{R}^{n_u \times n_y}$ *satisfying* (3.1) *and* (2.8).

Due to this result, the suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ problem can be solved by first finding a solution of (3.8) which is also a necessary condition for the solvability of (2.10). Secondly, if (3.8) has a solution, the static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback gain, if any exists, can be obtained by solving the corresponding LMI feasibility problem in F. Finally, all gains F which can be reconstructed in this way will be called suboptimal due to the relation $\mathrm{Tr}(Y^*) \geq C_\gamma(P^*, F) \geq C_\gamma^{opt}(X, F)$.

3.1. Bilinear LMI-based algorithm. In this subsection we describe a bilinear, multiobjective LMI-based algorithm for finding a triple (P,Q,Y) satisfying approximatively (3.8). As defined by (3.4) and (3.7), the sets $\Phi_{\mathcal{H}_\infty}(P,Q,\gamma)$ and $\tilde{\Phi}(P,Q,Y)$ are not convex and not closed. To make these sets convex, the coupling constraint $PQ = I$ can be weakened to the following well-known semidefinite programming (SDP)-relaxation:

$$P \succeq Q^{-1} \succ 0 \quad \Longleftrightarrow \quad M(P,Q) := \begin{bmatrix} P & I \\ I & Q \end{bmatrix} \succeq 0. \tag{3.9}$$

Replacing $PQ = I$ in the nonconvex sets $\Phi_{\mathcal{H}_\infty}(P,Q,\gamma)$ and $\tilde{\Phi}(P,Q,Y)$ by $M(P,Q) \succeq 0$ yields a convex approximation of these sets. Moreover, for computational purposes, we prefer to have closed sets. Introducing a positive scalar $\beta > 0$ and replacing the closed loop matrix A_F by $A + \beta I + B_2FC_2$ in Theorem 3.2, we can rewrite the existence conditions of Theorem 3.2 to the following bilinear matrix feasibility problem (cf. Leibfritz [31]).

$$\text{Find } (P,Q) \succ 0, \text{ such that } PQ = I, \quad \mathcal{Q}_\beta(Q,\gamma) \preceq 0, \quad \mathcal{P}_\beta(P,\gamma) \preceq 0, \tag{3.10}$$

where, for given $\beta > 0$ and $\gamma > 0$, we define

$$\mathcal{Q}_\beta(Q,\gamma) = N_Q^T \begin{bmatrix} AQ + QA^T + 2\beta Q + \gamma^{-1}B_1B_1^T & (C_1Q + \gamma^{-1}D_{11}B_1^T)^T \\ C_1Q + \gamma^{-1}D_{11}B_1^T & \gamma^{-1}D_{11}D_{11}^T - \gamma I_{n_z} \end{bmatrix} N_Q, \tag{3.11}$$

$$\mathcal{P}_\beta(P,\gamma) = N_P^T \begin{bmatrix} A^TP + PA + 2\beta P + \gamma^{-1}C_1^TC_1 & PB_1 + \gamma^{-1}C_1^TD_{11} \\ (PB_1 + \gamma^{-1}C_1^TD_{11})^T & \gamma^{-1}D_{11}^TD_{11} - \gamma I_{n_w} \end{bmatrix} N_P, \tag{3.12}$$

and N_Q, N_P are defined as in Theorem 3.2. With these definitions, we replace the nonconvex set $\Phi_{\mathcal{H}_\infty}(P,Q,\gamma)$ by the bilinear approximation

$$\begin{aligned}\bar{\Phi}_{\mathcal{H}_\infty}(P,Q,\gamma,\beta) = \{(P,Q) \in \mathcal{S}_{n_x}^+ \mid (P,Q) \text{ satisfying } PQ = I, \mathcal{Q}_\beta(Q,\gamma) \preceq 0,\\ \mathcal{P}_\beta(P,\gamma) \preceq 0\}\end{aligned} \tag{3.13}$$

and redefine the bilinear optimization problem (3.8) as

$$\min \operatorname{Tr}(Y), \quad \text{s.t.} \quad (P,Q,Y) \in \bar{\Phi}_{\mathcal{H}_\infty}(P,Q,\gamma,\beta) \cap \tilde{\Phi}(P,Q,Y). \tag{3.14}$$

Then, replacing $PQ = I$ by $M(P,Q) \succeq 0$ in (3.7) and (3.13) yields the following closed and linear approximations to the nonconvex and open sets $\bar{\Phi}_{\mathcal{H}_\infty}(P,Q,\gamma)$ and $\tilde{\Phi}(P,Q,Y)$, respectively:

$$\mathcal{X}_\beta(P,Q,\gamma) = \{(P,Q) \in \mathcal{S}_{n_x} \mid M(P,Q) \succeq 0, \mathcal{Q}_\beta(Q,\gamma) \preceq 0, \mathcal{P}_\beta(P,\gamma) \preceq 0\} \tag{3.15}$$

and

$$\begin{aligned}\tilde{\mathcal{X}}(P,Q,Y) = \{(P,Q) \in \mathcal{S}_{n_x}, Y \in \mathcal{S}_{n_w} \mid M(P,Q) \succeq 0, Y \succeq 0, \tilde{\mathcal{Q}}(Q,Y) \succeq 0,\\ \tilde{\mathcal{P}}(P,Y) \succeq 0\}.\end{aligned} \tag{3.16}$$

Observe that the condition $PQ = I$, which is equivalent to $\operatorname{Tr}(PQ) = n_x$, is satisfied if and only if $\operatorname{rank}(M(P,Q)) \equiv n_x$, i.e., the n_x smallest eigenvalues of the positive semidefinite $(2n_x \times 2n_x)$ matrix $M(P,Q)$ are equal to zero. In fact, the constraint $PQ = I$ characterizes the boundary of the set

$$\{(P,Q) \in \mathcal{S}_{n_x} \mid P \succeq Q^{-1} \succ 0\} = \{(P,Q) \in \mathcal{S}_{n_x} \mid M(P,Q) \succeq 0\}.$$

Thus, a feasible matrix triple to the following nonconvex bilinear matrix feasibility problem

$$\begin{gathered} \text{Find } \ (P,Q) \succ 0, Y \succeq 0 \text{ such that} \\ PQ = I,\ \mathcal{Q}_\beta(Q,\gamma) \preceq 0,\ \mathcal{P}_\beta(P,\gamma) \preceq 0,\ \tilde{\mathcal{Q}}(Q,Y) \succeq 0,\ \tilde{\mathcal{P}}(P,Y) \succeq 0 \end{gathered} \tag{3.17}$$

can be obtained by searching for boundary points of the linear and closed set $\mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$, defined by (3.15) and (3.16), respectively. This suggests the following nonconvex bilinear matrix inequality minimization problem:

$$\min\ \mathrm{Tr}(PQ), \quad \text{s.t.} \quad (P,Q,Y) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y). \tag{3.18}$$

Note that there exists a feasible triple (P,Q,Y) satisfying (3.17) if and only if the optimal value of (3.18) is equal to n_x. Since we are interested in a solution triple (P,Q,Y) of the nonconvex problem (3.14), this observation motivates us to define the following bilinear, multiobjective programming problem:

$$\min\ \mathrm{Tr}(PQ) + \mathrm{Tr}(Y), \quad \text{s.t.} \quad (P,Q,Y) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y). \tag{3.19}$$

This problem combines the objective functionals of (3.14) and (3.18). Obviously, minimizing $\mathrm{Tr}(PQ)$ enforces a solution of (3.19) to be close to or on the boundary of the feasible set of (3.19), while minimizing $\mathrm{Tr}(Y)$ drives a solution of (3.19) to be suboptimal for the corresponding static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem.

If the triple (P^*,Q^*,Y^*) is a boundary solution of (3.19) satisfying $P^*Q^* = I$, then we know that (P^*,Q^*,Y^*) is contained in the feasible set of (3.14) and also satisfies

$$n_x + \mathrm{Tr}(Y^*) = \min\{\mathrm{Tr}(PQ) + \mathrm{Tr}(Y) \mid (P,Q,Y) \in \bar{\Phi}_{\mathcal{H}_\infty}(P,Q,\gamma,\beta) \cap \tilde{\Phi}(P,Q,Y)\}.$$

Thus, the optimal value of (3.14) fulfills

$$\begin{aligned} \min\{\mathrm{Tr}(Y) \mid (P,Q,Y) \in \bar{\Phi}_{\mathcal{H}_\infty}(P,Q,\gamma,\beta) \cap \tilde{\Phi}(P,Q,Y)\} - n_x &\leq \mathrm{Tr}(Y^*) - n_x \\ = \ \min\{\mathrm{Tr}(PQ) + \mathrm{Tr}(Y) \mid (P,Q,Y) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)\} &- n_x. \end{aligned}$$

Hence, an optimal solution of (3.19) yields an upper bound to the optimal value of (3.14) and at least a suboptimal solution of (3.14) if and only if the minimal triple (P^*,Q^*,Y^*) of (3.19) satisfies $P^*Q^* = I$. Finally, if and only if $P^*Q^* = I$, then the corresponding suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback gain can be reconstructed from (P^*,Q^*,Y^*) if and only if the following LMI feasibility problem in F is nonempty.

$$\begin{aligned} &\text{Find } F \in \mathbb{R}^{n_u \times n_y}, \text{ such that} \quad \mathcal{B}F\mathcal{C} + (\mathcal{B}F\mathcal{C})^T + \bar{\Omega} \preceq 0 \quad \text{and} \\ &\begin{bmatrix} Y^* & B_0^T P^* \\ P^* B_0 & P^* \end{bmatrix} + \begin{bmatrix} 0 \\ P^* B_2 \end{bmatrix} F \begin{bmatrix} D_{20} & 0 \end{bmatrix} \\ &\qquad + \begin{bmatrix} D_{20}^T \\ 0 \end{bmatrix} F^T \begin{bmatrix} 0 & B_2^T P^* \end{bmatrix} \succeq 0, \end{aligned} \tag{3.20}$$

where

$$\bar{\Omega} = \begin{bmatrix} A^TP^* + P^*A + 2\beta P^* & P^*B_1 & C_1^T \\ B_1^TP^* & -\gamma I_{n_w} & D_{11}^T \\ C_1 & D_{11} & -\gamma I_{n_z} \end{bmatrix}, \mathcal{B} = \begin{bmatrix} P^*B_2 \\ 0 \\ D_{12} \end{bmatrix}, \mathcal{C} = [C_2 \;\; D_{21} \;\; 0].$$

In this case, the discussion in section 3 implies the existence of a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ controller. It also guarantees that A_F is Hurwitz, $||T_{zw_1}||_\infty < \gamma$, and $\mathrm{Tr}(Y^*) \geq \mathrm{Tr}(B_{0F}^TP^*B_{0F}) \geq C_\gamma^{opt}(X,F)$. Thus, such an F is indeed a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback gain.

In what follows we explain a numerical procedure for determining an optimal solution of the bilinear, multiobjective programming problem (3.19). This problem is not convex since the functional $\mathrm{Tr}(PQ)$ is, in general, not convex, but it is bilinear. Therefore, in problem (3.19) we minimize a combination of a bilinear and linear matrix functional over a closed convex set. To solve such a problem, a sequential linearization programming approach as proposed by [1] for general nonconvex bilinear programming problems can be used. In particular, the idea of this approach is very simple. Instead of solving the nonconvex problem (3.19) directly, we linearize the bilinear part of the objective functional. Then we minimize successively the resulting (linearized) LMI constrained semidefinite programming problems.

Algorithm 1 (SLPMM).

For given $\beta > 0$, let $\mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y) \neq \emptyset$.

```
(0) Determine $(P^0, Q^0, Y^0) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$.
    For $k = 0, 1, 2, \ldots$ do
      (1) Determine $(U^k, V^k, Z^k)$ as the unique solution of
          (3.21)  $\min \mathrm{Tr}(PQ^k + P^kQ) + \mathrm{Tr}(Y)$,
                  s.t. $(P,Q,Y) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$.
      (2) If $\mathrm{Tr}(U^kQ^k + P^kV^k) + \mathrm{Tr}(Z^k) = 2\mathrm{Tr}(P^kQ^k) + \mathrm{Tr}(Y^k)$, $\longrightarrow$ Stop.
      (3) Compute $\alpha \in [0,1]$ by solving
          (3.22)  $\min_{\alpha\in[0,1]} \mathrm{Tr}((P^k + \alpha(U^k - P^k))(Q^k + \alpha(V^k - Q^k)))$
                      $+ \mathrm{Tr}(Y^k + \alpha(Z^k - Y^k))$.
      (4) Set $P^{k+1} = (1-\alpha)P^k + \alpha U^k$, $Q^{k+1} = (1-\alpha)Q^k + \alpha V^k$, and $Y^{k+1} =$
          $(1-\alpha)Y^k + \alpha Z^k$.
```

This algorithm is similar to the SLPMM procedure proposed by Leibfritz [31] for the design of stabilizing static $\mathcal{H}_2$ and suboptimal static $\mathcal{H}_\infty$ output feedback controllers. The initialization step of Algorithm 1 is an LMI feasibility problem, and (3.21) is an SDP problem with a linear objective functional under LMI constraints. There are many algorithms available for solving such kinds of problems. For example, interior point methods developed for SDPs can be used (cf. [13]). Algorithm 1 terminates if the first order necessary minimum principle is satisfied at a (local) minimum of (3.19) [34, section 6.1]. For example, define

$$\mathcal{J}(P,Q,Y) := \mathrm{Tr}(PQ) + \mathrm{Tr}(Y). \tag{3.23}$$

Note that $\mathcal{J}(P,Q,Y)$ is continuous and differentiable on the cone of symmetric matrices. Hence,

$$\mathcal{J}'(P,Q,Y)(U,V,Z) = \mathrm{Tr}(UQ + PV) + \mathrm{Tr}(Z),$$
$$\mathcal{J}''(P,Q,Y)(U,V,Z)(H,G,W) = \mathrm{Tr}(HV + UG)$$

for any $U, V, H, G \in \mathcal{S}_{n_x}$ and $Z, W \in \mathcal{S}_{n_w}$. If (P^*, Q^*, Y^*) denotes a local minimum of $\mathcal{J}$ over the closed convex set $\mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$, then for any feasible direction $(P-P^*, Q-Q^*, Y-Y^*) = (\delta P, \delta Q, \delta Y)$ at (P^*, Q^*, Y^*) we obtain

$$\begin{aligned}\mathcal{J}'(P^*,Q^*,Y^*)(\delta P,\delta Q,\delta Y) = \operatorname{Tr}(PQ^*+P^*Q)+\operatorname{Tr}(Y)\\ - 2\operatorname{Tr}(P^*Q^*)-\operatorname{Tr}(Y^*)\geq 0\end{aligned} \tag{3.24}$$

for all $(P,Q,Y) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$ [34, section 6.1, Proposition 1]. Numerically, for a sufficiently small scalar $\varepsilon > 0$, we terminate the algorithm if

$$\tau_k := \operatorname{Tr}(U^kQ^k + P^kV^k) + \operatorname{Tr}(Z^k) - 2\operatorname{Tr}(P^kQ^k) - \operatorname{Tr}(Y^k) \geq -\varepsilon, \quad k \geq 0. \tag{3.25}$$

Moreover, if $(P^k, Q^k, Y^k) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$ and $(U^k, V^k, Z^k) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$ do not satisfy (3.24), we determine a step size parameter $\alpha \in [0,1]$ by minimizing (3.22) with respect to α. Finally, the new iterates $(P^{k+1}, Q^{k+1}, Y^{k+1})$ are convex combinations of (P^k, Q^k, Y^k) and (U^k, V^k, Z^k), respectively, and therefore, they are also contained in $\mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$. Note that the points $(U^k - P^k, V^k - Q^k, Z^k - Y^k)$, $k \geq 0$, are descent directions for $\mathcal{J}$ at (P^k, Q^k, Y^k) unless $\tau_k \geq 0$ for some $k \geq 0$.

For proofing the convergence of Algorithm 1, we need the following result. Suppose for fixed $\beta > 0$ that there exist matrices $(P^0, Q^0, Y^0) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$; then we can define the following level set:

$$\begin{aligned}\Gamma(P^0,Q^0,Y^0) := \{(P,Q,Y) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y) \mid \mathcal{J}(P,Q,Y)\\ \leq \mathcal{J}(P^0,Q^0,Y^0)\}.\end{aligned} \tag{3.26}$$

For this level set, we conclude the following lemma.

LEMMA 3.5. *Let $\beta > 0$ be given, $\mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$ be nonempty, and let $(P^0, Q^0, Y^0) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$ be given. Then the level set $\Gamma(P^0, Q^0, Y^0)$ is compact.*

Proof. Using [24, Theorem 7.4.10], the closeness of $\mathcal{X}_\beta(P,Q,\gamma)$, $\tilde{\mathcal{X}}(P,Q,Y)$, and the definition of $\Gamma(P^0, Q^0, Y^0)$ shows the desired result. □

With the compactness of the level set $\Gamma(P^0, Q^0, Y^0)$, it is straightforward to show the existence of an optimal solution of (3.19) in this level set. In particular, we have the following lemma.

LEMMA 3.6. *Let $\mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y) \neq \emptyset$ and $(P^0, Q^0, Y^0) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$ be given. Then there exists an optimal solution (P^*, Q^*, Y^*) of* (3.19) *in the level set $\Gamma(P^0, Q^0, Y^0)$.*

Proof. By the compactness of $\Gamma(P^0, Q^0, Y^0)$, the continuity of $\mathcal{J}$, and the theorem of Bolzano–Weierstrass, the result follows immediately. □

Thus, Lemma 3.6 ensures the existence of a solution of the multiobjective programming problem (3.19) at least in the compact level set $\Gamma(P^0, Q^0, Y^0)$.

The following lemma is needed in the proof of the Theorem 3.8 given below.

LEMMA 3.7. *Let $a > 0$, $b < 0$, and $c \geq 1$ be given. Then there exists $\rho_* \geq 0$ such that the optimal solution of* $\min_{\alpha \in [0,1]} \, (c + \alpha\, b + (\alpha^2/2)\, a)$ *satisfies*

$$0 < \alpha_* = -\frac{b + \rho_*}{a} \leq 1.$$

Moreover, $\rho_* = 0$ if and only if $a \geq -b$.

Proof. The result can be proven by using the convexity of the objective function and the Karush–Kuhn–Tucker theorem. □

The next result states the basic convergence properties of Algorithm 1. It also justifies the fact that we need only the existence of a solution of (3.19) in $\Gamma(P^0, Q^0, Y^0)$. Before stating these properties, we define the boundary of the set $\mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$, given by

$$\partial\mathcal{X}(P, Q, Y) := \{(P, Q, Y) \in \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y) \mid PQ = I\}. \tag{3.27}$$

Obviously,

$$\partial\mathcal{X}(P, Q, Y) = \bar{\Phi}_{\mathcal{H}_\infty}(P, Q, \gamma, \beta) \cap \tilde{\Phi}(P, Q, Y) \subseteq \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y).$$

Hence, the level set $\Gamma(P^0, Q^0, Y^0)$ also contains all (P, Q, Y) on the boundary of $\mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$. Therefore, similarly as in Lemma 3.6, we can conclude that there also exists an optimal solution of the nonconvex optimization problem (3.14) in the level set $\Gamma(P^0, Q^0, Y^0)$.

THEOREM 3.8. *Let $\beta > 0$ and $(P^0, Q^0, Y^0) \in \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$ be given. Furthermore, assume that $\{(P^k, Q^k, Y^k)\} \subset \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$ is generated by Algorithm* 1. *Then the sequence $\{(P^k, Q^k, Y^k)\}$ is well defined and for all $k \geq 0$, we have*

$$n_x + \mathrm{Tr}(Y^*) \leq n_x + \mathrm{Tr}(Y^{k+1}) \leq \mathcal{J}(P^{k+1}, Q^{k+1}, Y^{k+1}) < \mathcal{J}(P^k, Q^k, Y^k) \tag{3.28}$$

unless $\mathcal{J}'(\cdot)(\cdot) = 0$, where (P^*, Q^*, Y^*) solves (3.19). *Thus, $\{\mathcal{J}(P^k, Q^k, Y^k)\}$ converges to $\hat{\mathcal{J}} \geq n_x + \mathrm{Tr}(Y^*)$ and for all $k \geq 0$, $(P^k, Q^k, Y^k) \in \Gamma(P^0, Q^0, Y^0)$, i.e., $\{(P^k, Q^k, Y^k)\}$ is bounded. Finally, $\mathcal{J}(P^k, Q^k, Y^k) = n_x + \mathrm{Tr}(Y^k)$ if and only if $(P^k, Q^k, Y^k) \in \partial\mathcal{X}(P, Q, Y)$ and $\mathcal{J}'(\cdot)(\cdot) = 0$ for some k.*

Proof. For all $k \geq 0$, we define the following abbreviations:

$$S^k = (P^k, Q^k, Y^k), \quad \delta S^k = (U^k - P^k, V^k - Q^k, Z^k - Y^k), \quad \text{and} \quad T^k = (U^k, V^k, Z^k).$$

If Algorithm 1 terminates at $S^k \in \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$, $k \geq 0$, then

$$\mathcal{J}'(S^k)(S^k) = \mathcal{J}'(S^k)(T^k) = \min_{S \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)} \mathcal{J}'(S^k)(S)$$

and $\mathcal{J}'(P^k, Q^k, Y^k)(P - P^k, Q - Q^k, Y - Y^k) \geq 0$ for all $(P, Q, Y) \in \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$. Thus, if the algorithm does not terminate in step (2), then

$$\mathcal{J}'(S^k)(\delta S^k) = \mathrm{Tr}(U^k Q^k + P^k V^k) + \mathrm{Tr}(Z^k) - 2\mathrm{Tr}(P^k Q^k) - \mathrm{Tr}(Y^k) < 0, \tag{3.29}$$

i.e., δS^k is a descent direction. Using $S^k \in \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$, $T^k \in \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$, and the convexity of $\mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$, steps (3) and (4) of Algorithm 1 imply that

$$(P^{k+1}, Q^{k+1}, Y^{k+1}) \in \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$$

for all $\alpha \in [0, 1]$. Hence, the sequence $\{S^k\} = \{(P^k, Q^k, Y^k)\}$ is well defined by Algorithm 1.

To show the strictly decreasing property of $\{\mathcal{J}(P^k, Q^k, Y^k)\}$, note that for $\alpha \in [0, 1]$, the construction of the algorithm implies

$$\begin{aligned}
\mathcal{J}(S^{k+1}) &= \mathcal{J}(S^k) + \alpha_*\, \mathcal{J}'(S^k)(\delta S^k) + \frac{\alpha_*^2}{2}\mathcal{J}''(S^k)(\delta S^k)(\delta S^k) \\
&\leq \mathcal{J}(S^k) + \alpha\, \mathcal{J}'(S^k)(\delta S^k) + \frac{\alpha^2}{2}\mathcal{J}''(S^k)(\delta S^k)(\delta S^k) \\
&\leq \mathcal{J}(S^k) + \mathcal{J}'(S^k)(\delta S^k) + \frac{1}{2}\mathcal{J}''(S^k)(\delta S^k)(\delta S^k),
\end{aligned} \tag{3.30}$$

where $\alpha_* \in [0, 1]$ denotes the optimal value of (3.22).

Assuming $\mathcal{J}''(S^k)(\delta S^k)(\delta S^k) = 0$ and using (3.29), from (3.30) we obtain $\mathcal{J}(S^{k+1}) < \mathcal{J}(S^k)$ for all $k \geq 0$ unless $\mathcal{J}'(S^k)(\delta S^k) \equiv 0$. Moreover, if $\mathcal{J}''(S^k)(\delta S^k)(\delta S^k) < 0$, then we can conclude that $\mathcal{J}(S^{k+1}) < \mathcal{J}(S^k)$ for all $k \geq 0$. Finally, if $\mathcal{J}''(S^k)(\delta S^k)(\delta S^k) > 0$, then the problem is convex. Defining $a = \mathcal{J}''(\cdot)(\cdot)(\cdot)$, $b = \mathcal{J}'(\cdot)(\cdot)$, and $c = \mathcal{J}(\cdot)$, Lemma 3.7 implies the existence of $\rho_* \geq 0$ such that the solution α_* of (3.22) satisfies

$$0 < \alpha_* = -\frac{\mathcal{J}'(S^k)(\delta S^k) + \rho_*}{\mathcal{J}''(S^k)(\delta S^k)(\delta S^k)} \leq 1.$$

But this implies

$$\frac{1}{2}\alpha_*^2\, \mathcal{J}''(S^k)(\delta S^k)(\delta S^k) = -\frac{1}{2}\alpha_*\, \mathcal{J}'(S^k)(\delta S^k) - \frac{1}{2}\alpha_*\rho_*. \tag{3.31}$$

Using $\alpha_* \in (0, 1]$, $\rho_* \geq 0$, (3.29), (3.30), and (3.31), we obtain $\mathcal{J}(S^{k+1}) < \mathcal{J}(S^k)$ unless $\mathcal{J}'(S^k)(\delta S^k) \equiv 0$ for all $k \geq 0$. Hence, $\{\mathcal{J}(P^k, Q^k, Y^k)\}$ is a strictly decreasing sequence unless $\mathcal{J}'(S^k)(\delta S^k) \equiv 0$. Since $\mathrm{Tr}(Y^k) \geq 0$ and $\mathrm{Tr}(P^k Q^k) \geq n_x$ for all $k \geq 0$, the sequence $\{\mathcal{J}(P^k, Q^k, Y^k)\}$ is also bounded below by $n_x + \mathrm{Tr}(Y^*)$. Therefore, it converges to a limit $\hat{\mathcal{J}} \geq n_x + \mathrm{Tr}(Y^*)$. Moreover, by the definition of the compact level set $\Gamma(P^0, Q^0, Y^0)$, we know that $\{(P^k, Q^k, Y^k)\} \subset \Gamma(P^0, Q^0, Y^0)$, and thus that the generated sequence $\{(P^k, Q^k, Y^k)\}$ is bounded. Finally, assume that $(P^k, Q^k, Y^k) \in \partial\mathcal{X}(P, Q, Y)$ and $\mathcal{J}'(S^k)(\delta S^k) = 0$ for some k. Note that this is fulfilled if and only if $P^k Q^k = I$ and the minimal point T^k of (3.21) satisfy $U^k = P^k$, $V^k = Q^k$, and $Z^k = Y^k$ for some k. Thus, $\mathcal{J}(P^k, Q^k, Y^k) = n_x + \mathrm{Tr}(Y^k) \geq n_x + \mathrm{Tr}(Y^*)$ if and only if $(P^k, Q^k, Y^k) \in \partial\mathcal{X}(P, Q, Y)$ and $\mathcal{J}'(S^k)(\delta S^k) = 0$ for some k. □

Theorem 3.8 ensures that $\{\mathcal{J}(P^k, Q^k, Y^k)\}$ is a strictly decreasing sequence which is bounded below by $n_x + \mathrm{Tr}(Y^*)$ if and only if $(P^k, Q^k, Y^k) \notin \partial\mathcal{X}(P, Q, Y)$ and $\mathcal{J}'(S^k)(\delta S^k) < 0$. On the other hand, $\mathcal{J}(P^k, Q^k, Y^k) = n_x + \mathrm{Tr}(Y^k) \geq n_x + \mathrm{Tr}(Y^*)$ if and only if $(P^k, Q^k, Y^k) \in \partial\mathcal{X}(P, Q, Y)$ and $\mathcal{J}'(S^k)(\delta S^k) = 0$ for some $k \geq 0$. Then we know that $P^k Q^k = I$ and $U^k = P^k$, $V^k = Q^k$, $Z^k = Y^k$ for some k. Hence, in this case, the SLPMM algorithm terminates in step (2) at a point satisfying the coupling condition $PQ = I$.

The SLPMM algorithm may be interpreted as a modified version of the cone complementarity algorithm, expect that in each iteration we must also compute a step size parameter. But this further computational work is essential for the strictly decreasing property of the SLPMM. Indeed, the novel aspect of the SLPMM algorithm is that it always generates a strictly decreasing sequence $\{\mathcal{J}(P^k, Q^k, Y^k)\}$. Moreover, this approach guarantees the boundedness of the iterates (P^k, Q^k, Y^k) for all $k \geq 0$. In contrast to this, the cone complementarity algorithm, the XY-centering algorithm, and other related computational methods in the literature do not share these properties.

The strictness in the inequality (3.28) and the boundedness of $\{(P^k, Q^k, Y^k)\}$ is essential to prove the global convergence of the SLPMM algorithm. The following theorem states the global convergence of our method under rather weak assumptions compared to the existing algorithms in the literature.

Theorem 3.9. *Let $\beta > 0$ and $(P^0, Q^0, Y^0) \in \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$ be given. Furthermore, assume that $\{(P^k, Q^k, Y^k)\} \subset \mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$ is generated by Algorithm* 1. *Then the following hold.*

(i) *The algorithm terminates at some (P^k, Q^k, Y^k) satisfying* (3.24), *or every accumulation point $(\tilde{P}, \tilde{Q}, \tilde{Y})$ of $\{(P^k, Q^k, Y^k)\}$ is stationary, i.e., $(\tilde{P}, \tilde{Q}, \tilde{Y})$ satisfy* (3.24).

(ii) *Every accumulation point* $(\tilde{P},\tilde{Q},\tilde{Y})$ *of* $\{(P^k,Q^k,Y^k)\}$ *satisfies the nonconvex bilinear matrix feasibility problem* (3.17) *and solves the nonconvex optimization problem* (3.14) *if and only if the boundary set* $\partial\mathcal{X}(P,Q,Y)$ *defined in* (3.27) *is nonempty.*

Proof. (i) This result follows immediately by making straightforward modifications to the proof of Leibfritz [31, Theorem 3.7].

(ii) Note that $\partial\mathcal{X}(P,Q,Y)=\bar{\Phi}_{\mathcal{H}_\infty}(P,Q,\gamma,\beta)\cap\tilde{\Phi}(P,Q,Y)\subset\Gamma(P^0,Q^0,Y^0)$ and that $\Gamma(P^0,Q^0,Y^0)$ is compact. Theorem 3.8 implies $\lim_{k\to\infty}\mathcal{J}(P^k,Q^k,Y^k)=\hat{\mathcal{J}}\geq n_x+\mathrm{Tr}(Y^*)=:\mathcal{J}^*$. Since $(P^k,Q^k,Y^k)\in\Gamma(P^0,Q^0,Y^0)$, we also know that the functions $\mathcal{J}(P,Q,Y)=\mathrm{Tr}(PQ)+\mathrm{Tr}(Y)$ and $\tilde{\mathcal{J}}(P,Q,Y)=\mathrm{Tr}(Y)$ attain the (global) minimum values on the compact level set $\Gamma(P^0,Q^0,Y^0)$; i.e., $\mathcal{J}^*=\mathcal{J}(P^*,Q^*,Y^*)\equiv n_x+\mathrm{Tr}(Y^*)$ and $\tilde{\mathcal{J}}^*=\tilde{\mathcal{J}}(P^*,Q^*,Y^*)\equiv\mathrm{Tr}(Y^*)$, respectively.

Suppose $\hat{\mathcal{J}}>\mathcal{J}^*=n_x+\mathrm{Tr}(Y^*)$. From the compactness of $\Gamma(P^0,Q^0,Y^0)\neq\emptyset$ and the continuity of $\mathcal{J}$, it follows that for every $\varepsilon>0$, there exist a $\delta>0$ and a vicinity $U_\delta(P^*,Q^*,Y^*)$ such that $U_\delta(P^*,Q^*,Y^*)\cap\Gamma(P^0,Q^0,Y^0)\neq\emptyset$ and

$$0\leq\mathcal{J}(P,Q,Y)-\mathcal{J}^*<\varepsilon$$

for all $(P,Q,Y)\in U_\delta(P^*,Q^*,Y^*)\cap\Gamma(P^0,Q^0,Y^0)$. Choosing $\varepsilon:=\hat{\mathcal{J}}-n_x-\mathrm{Tr}(Y^*)>0$ implies

$$\mathcal{J}(P,Q,Y)<\varepsilon+n_x+\mathrm{Tr}(Y^*)=\hat{\mathcal{J}}.$$

But this implies the existence of an integer $\hat{k}$ such that for all $k\geq\hat{k}$ and $(P^k,Q^k,Y^k)\in U_\delta(P^*,Q^*,Y^*)\cap\Gamma(P^0,Q^0,Y^0)$ we have $\mathcal{J}(P^k,Q^k,Y^k)<\hat{\mathcal{J}}$, which contradicts that the sequence $\{\mathcal{J}(P^k,Q^k,Y^k)\}$ converges monotonically to $\hat{\mathcal{J}}$. Hence $\hat{\mathcal{J}}=\mathcal{J}^*=n_x+\mathrm{Tr}(Y^*)$; i.e.,

$$\lim_{k\to\infty}\mathcal{J}(P^k,Q^k,Y^k)=\mathcal{J}^*\iff\lim_{k\to\infty}(\mathcal{J}(P^k,Q^k,Y^k)-n_x)=\tilde{\mathcal{J}}^*. \tag{3.32}$$

Since $\{(P^k,Q^k,Y^k)\}\subset\Gamma(P^0,Q^0,Y^0)$ and $\Gamma(P^0,Q^0,Y^0)$ is compact, we conclude the existence of a convergent subsequence of $\{(P^k,Q^k,Y^k)\}$; i.e.,

$$\lim_{j\to\infty}(P^{k_j},Q^{k_j},Y^{k_j})=(\tilde{P},\tilde{Q},\tilde{Y})\in\Gamma(P^0,Q^0,Y^0).$$

Suppose that this accumulation point is not globally optimal. Then $\mathcal{J}(\tilde{P},\tilde{Q},\tilde{Y})>\mathcal{J}^*=n_x+\mathrm{Tr}(Y^*)>\tilde{\mathcal{J}}^*$ and the sequence $\{\mathcal{J}(P^k,Q^k,Y^k)-n_x-\mathrm{Tr}(Y^*)\}$ do not tend to zero. This contradicts (3.32). Hence, $\partial\mathcal{X}(P,Q,Y)\neq\emptyset$ if and only if every accumulation point satisfies (3.17) and solves

$$\begin{aligned}\min\{\mathrm{Tr}(PQ)+\mathrm{Tr}(Y)\mid(P,Q,Y)\in\bar{\Phi}_{\mathcal{H}_\infty}(P,Q,\gamma,\beta)\cap\tilde{\Phi}(P,Q,Y)\}&=n_x+\mathrm{Tr}(Y^*)\\ =n_x+\min\{\mathrm{Tr}(Y)\mid(P,Q,Y)\in\bar{\Phi}_{\mathcal{H}_\infty}(P,Q,\gamma,\beta)\cap\tilde{\Phi}(P,Q,Y)\},&\end{aligned}$$

which in turn is equivalent to the solvability of (3.14). □

From Theorem 3.8, we know that the sequence $\{\mathcal{J}(P^k,Q^k,Y^k)\}$ is strictly decreasing unless $\mathcal{J}'(\cdot)(\cdot)=0$ and is bounded below by $n_x+\mathrm{Tr}(Y^*)$, and hence converges. If in the limit $\mathrm{Tr}(PQ)=n_x$, then $\partial\mathcal{X}(P,Q,Y)\neq\emptyset$. In this case, Theorem 3.9 guarantees the existence of an accumulation point which satisfies the nonconvex bilinear matrix feasibility problem (3.17). Moreover, this point is also a solution of the nonconvex optimization problem (3.14), and therefore, in the limit the necessary condition for the existence of a static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback gain is fulfilled.

Note that for reconstructing such a gain, it is not necessary that the computed solution of the multiobjective problem (3.19) is the global solution of this problem. It suffices that this solution is contained in the boundary set $\partial\mathcal{X}(P,Q,Y)$ defined by (3.27), i.e., it satisfies $PQ = I$. Then, this solution triple is at least an upper bound to the global optimal value of (3.14), and the corresponding gain, if any exists, is at least suboptimal. Thus, if Algorithm 1 terminates with a boundary solution of (3.19), i.e., $\mathcal{J}(P^k, Q^k, Y^k) = n_x + \mathrm{Tr}(Y^k)$ for some $k \geq 0$, then Theorem 3.8 implies $(P^k, Q^k, Y^k) \in \partial\mathcal{X}(P,Q,Y)$ for some k. Moreover, $(P^k, Q^k, Y^k) \in \partial\mathcal{X}(P,Q,Y)$ satisfies

$$\min\{\mathrm{Tr}(Y) \mid (P,Q,Y) \in \bar{\Phi}_{\mathcal{H}_\infty}(P,Q,\gamma,\beta) \cap \tilde{\Phi}(P,Q,Y)\} \leq \mathrm{Tr}(Y^k).$$

Then, using the results of the previous section, a corresponding suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controller exists if and only if the LMI feasibility problem (3.20) in F is nonempty. On the other hand, it may occur that Algorithm 1 terminates at a triple (P^k, Q^k, Y^k) satisfying the first order necessary minimum principle, but $(P^k, Q^k, Y^k) \notin \partial\mathcal{X}(P,Q,Y)$. In this case, we know that $\mathrm{Tr}(P^kQ^k) > n_x$ and a static gain F can not be reconstructed from this triple. But we can reconstruct a reduced dynamic output feedback control law of order $n_c \leq n_x - \max\{n_u, n_y\}$ from this triple by using a well-known system augmentation technique. For more details, we refer the reader, for example, to Leibfritz [31].

4. Numerical examples. In this section, several examples are given for test purposes in order to test the SLPMM approach. We present examples for the design of suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controllers.

The SLPMM algorithm as well as the reconstruction of the controller gain F from the corresponding LMIs have been implemented making use of MATLAB 5.0 facilities. Particularly, for determining a feasible solution $(P^0, Q^0, Y^0) \in \mathcal{X}_\beta(P,Q,\gamma) \cap \tilde{\mathcal{X}}(P,Q,Y)$ in Algorithm 1, step (0), we have used the LMI control toolbox [14] routine FEASP, which finds a solution to a given system of LMIs, if any exists. Moreover, for solving the linearized minimization problem (3.21) of Algorithm 1, step (1), which is a semidefinite programming problem, we have taken the LMI control toolbox procedure MINCX. This solver is an implementation of Nesterov and Nemirovski's projective method for minimizing a linear objective function under LMI constraints as described in [13]. For MINCX we have adjusted the desired relative accuracy on the optimal value to 10^{-12}.

We terminated Algorithm 1 if, for a sufficiently small scalar $\varepsilon > 0$, the condition (3.25) was fulfilled. Moreover for the computation of a step size $\alpha \in [0,1]$ we have used the MATLAB function FMIN.

Finally, we have taken the LMI control toolbox function FEASP applied to the LMI feasibility problem (3.20) for reconstructing the static output feedback controller gain F.

The following data are given in the tables: the iteration counter k of the SLPMM algorithm; if $k = 0$, j denotes the total number of iterations for finding a feasible initial point (P^0, Q^0, Y^0) by FEASP; else j is the total number of iterations for solving the semidefinite programming problem (3.21) by MINCX with relative accuracy of 10^{-12}; the objective function value $\mathcal{J}(P^k, Q^k, Y^k) = \mathrm{Tr}(P^kQ^k) + \mathrm{Tr}(Y^k)$ of the corresponding multiobjective optimization problem (3.19); the function values $\mathrm{Tr}(P^kQ^k)$ and $\mathrm{Tr}(Y^k)$; and τ_k, which indicates if the first order necessary minimum principle is approximatively satisfied.

TABLE 4.1

Convergence behavior of the SLPMM algorithm for the VTOL helicopter model: static $\mathcal{H}_2/\mathcal{H}_\infty$ case.

k	j	$\mathcal{J}(P^k, Q^k, Y^k)$	$\mathrm{Tr}(P^kQ^k)$	$\mathrm{Tr}(Y^k)$	τ_k
0	6	1209.96168	1156.3660285	53.5956538	—
1	53	4.21991536	4.0001534809	0.21976188	$-2.058e+03$
2	45	4.21973458	4.0000000000	0.21973458	$-1.808e-04$
3	18	4.21973458	4.0000000000	0.21973458	$0.000e+00$

For all test examples we have chosen the data matrices B_0, D_{10}, D_{11}, and D_{20} as follows:

$$B_0 = B_1, \quad D_{10} = D_{11} = 0, \quad D_{20} = 0.$$

This choice guarantees $D_{0F} = 0$. Therefore, if a static $\mathcal{H}_2/\mathcal{H}_\infty$ controller gain F exists for the corresponding test problem, it is an upper estimate of $||T_{zw_0}||^2_{\mathcal{H}_2}$ that enforces $||T_{zw_1}||_\infty < \gamma$.

Example 1. A state space model of the longitudinal motion of a VTOL helicopter is considered as in [28]. The dynamic equations of the helicopter model are linearized around a nominal solution where the given dynamic equation is computed for typical loading and flight conditions of the VTOL helicopter at a certain airspeed [41]. The linearization results in a fourth order linear time-invariant state equation with two control and two unknown input components. The data matrices of the linearized model are given by

$$A = \begin{bmatrix} -0.0366 & 0.0271 & 0.0188 & -0.4555 \\ 0.0482 & -1.0100 & 0.0024 & -4.0208 \\ 0.1002 & 0.3681 & -0.7070 & 1.4200 \\ 0 & 0 & 1.0000 & 0 \end{bmatrix}, \; B_1 = \begin{bmatrix} 0.0468 & 0 \\ 0.0457 & 0.0099 \\ 0.0437 & 0.0011 \\ -0.0218 & 0 \end{bmatrix},$$

$$B_2 = \begin{bmatrix} 0.4422 & 0.1761 \\ 3.5446 & -7.5922 \\ -5.5200 & 4.4900 \\ 0 & 0 \end{bmatrix},$$

$$C_1 = \frac{1}{\sqrt{2}} \begin{bmatrix} 2 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}, \; C_2 = \begin{bmatrix} 0 & 1 & 0 & 0 \end{bmatrix}, \; D_{12} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix},$$

$$D_{21} = \begin{bmatrix} 0.00039 & 0.00174 \end{bmatrix}.$$

The goal is to design a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controller Σ_C by the SLPMM Algorithm 1 according to the discussion of the previous sections. In the run of Algorithm 1 we have chosen $\beta = 0.01$, $\gamma = 0.423722$, and $\varepsilon = 10^{-10}$. Table 4.1 demonstrates the convergence behavior of the SLPMM. It illustrates numerically that $\{\mathcal{J}(P^k, Q^k, Y^k)\}$ is a strictly decreasing sequence if $(P^k, Q^k, Y^k) \notin \partial\mathcal{X}(P, Q, Y)$ and $\tau_k < 0$, which converges to $n_x + \mathrm{Tr}(Y^*) = 4 + 0.21973458$. Thus, we have $\partial\mathcal{X}(P, Q, Y) \neq \emptyset$, and equality holds if and only if $(P^k, Q^k, Y^k) \in \partial\mathcal{X}(P, Q, Y)$ and $\tau_k = 0$ for some k according to Theorem 3.8. Moreover, Theorem 3.9 guarantees the existence of an accumulation point of $\{P^k, Q^k, Y^k)\}$ which also solves the nonconvex optimization problem (3.14). Therefore, a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controller exists if and only if the LMI feasibility problem (3.20) in F is nonempty. The resulting static gain matrix which satisfies (3.20) and the closed loop eigenvalues are

$$F = \begin{bmatrix} -0.978987 & 19.43483 \end{bmatrix}^T, \lambda(A_F) = \begin{bmatrix} -152.04 & -0.0989 & -0.2990 \pm 0.949i \end{bmatrix}.$$

Moreover, $||T_{zw_1}||_\infty = 0.2937866 < \gamma$ and $\mathrm{Tr}(B_{0F}^T P B_{0F}) = 0.02869950 \leq \mathrm{Tr}(Y) = 0.21973458$, which shows that F is a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback gain. To compare this solution with the optimal one, we have calculated $C_\gamma^{opt}(X, F) = 0.0231044$ with an algorithm proposed by Leibfritz [32], [30]. This shows, that (3.19) provides a good suboptimal solution to the problem under consideration. As it can be also verified, the sequence $\{(P^k, Q^k, Y^k) \subset \Gamma(P^0, Q^0, Y^0)$ and is thus bounded. For example, we have

$$\begin{aligned} \{||P^k||\} &= \{82.26, 49.82, 49.82, 49.82\}, \\ \{||Q^k||\} &= \{41.16, 1.159, 1.159, 1.159\}, \\ \{||Y^k||\} &= \{26.86, 0.1099, 0.1099, 0.1099\}, \end{aligned}$$

which demonstrates numerically the boundedness of the generated sequence according to Theorem 3.8. The whole computation needs 2.47 CPU seconds on a SUN Ultra 60.

Finally, for this example, we demonstrate numerically that the extended static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem (2.12) can be also solved by the LMI approach as discussed in section 3. The SLPMM terminates after four outer iterations with an approximate solution (P, Q, Y) of the corresponding bilinear programming problem, i.e., $\mathrm{Tr}(PQ) = 4.0000001$. Then, using this solution, the corresponding LMI feasibility problem in F was found to be nonempty. Thus, a static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback gain F satisfying (2.12) exists, and the resulting gain matrix is given by $F = [-0.457876 \;\; 17.38107]^T$.

Example 2 *(transport airplane).* This example studies the longitudinal motion of a modern transport airplane under VMIN flight conditions [15]. The linearized state space model yields the following data matrices:

$$A = \begin{bmatrix} -0.06254 & 0.01888 & 0 & -0.56141 & -0.02751 & 0 & 0.06254 & -0.00123 & 0 \\ 0.01089 & -0.99280 & 0.99795 & 0.00097 & -0.07057 & 0 & -0.01089 & 0.06449 & 0 \\ 0.07743 & 1.67540 & -1.31111 & -0.00030 & -4.25030 & 0 & -0.07743 & -0.10883 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -20.0000 & 20 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -30 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -0.88206 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.88206 & 0.00882 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.00882 & -0.88206 \end{bmatrix},$$

$$B_1 = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1.3282 & 0 & 0 & 0 \\ 0 & 1.62671 & 0 & 0 \\ 0 & -68.75283 & 0 & 0 \end{bmatrix}, B_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 30 \\ 0 \\ 0 \\ 0 \end{bmatrix}, C_1 = \frac{1}{\sqrt{2}} \begin{bmatrix} -0.00519 \\ 0.47604 \\ 0.00098 \\ -0.00031 \\ 0.03378 \\ 0 \\ 0.00519 \\ -0.03086 \\ 0 \end{bmatrix}^T,$$

$$C_2^T = \begin{bmatrix} -0.00519 & 0 \\ 0.47604 & 0 \\ 0.00098 & 0 \\ -0.00031 & 0 \\ 0.03378 & 0 \\ 0 & 0 \\ 0.00519 & 0 \\ -0.03086 & 0 \\ 0 & 0 \end{bmatrix}, D_{21}^T = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 1 \end{bmatrix},$$

and $D_{12} = [1/\sqrt{2}]$. The goal is the design of a robust static control law. Defining $\beta = 10^{-2}$, $\gamma = 0.152032$ and $\varepsilon = 10^{-12}$, Table 4.2 illustrates the convergence behavior of the SLPMM for this example. According to Theorem 3.8, it shows numerically

Table 4.2
Convergence behavior of the SLPMM algorithm for the transport airplane: static $\mathcal{H}_2/\mathcal{H}_\infty$ case.

k	j	$\mathcal{J}(P^k, Q^k, Y^k)$	$\mathrm{Tr}(P^k Q^k)$	$\mathrm{Tr}(Y^k)$	τ_k
0	18	$1.766e+14$	$1.766e+14$	$7.622e+07$	—
1	58	131.706754	83.966174369	47.74057934352	$-3.533e+14$
2	49	9.80419099	9.4602075306	0.343983455585	$-1.689e+02$
3	56	9.39445809	9.0504993630	0.343958730681	$-2.843e-01$
4	86	9.34395876	9.0000000338	0.343958722207	$-4.318e-02$
5	24	9.34395876	9.0000000338	0.343958722207	$0.000e+00$

the strictly decreasing property of the objective function values of (3.19) and the nonemptiness of the boundary of the set $\mathcal{X}_\beta(P, Q, \gamma) \cap \tilde{\mathcal{X}}(P, Q, Y)$, i.e., in the limit we achieve $\mathrm{Tr}(PQ) = n_x$. Thus, $\partial\mathcal{X}(P, Q, Y) \neq \emptyset$ and Theorem 3.9 ensures the existence of an accumulation point of $\{P^k, Q^k, Y^k)\}$ which also solves the nonconvex optimization problem (3.14). Therefore, a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controller exists if and only if the LMI feasibility problem (3.20) in F is nonempty. Solving the LMI feasibility problem (3.20) results in the feasible gain

$$F = \begin{bmatrix} 2.286293 & 0.001023 \end{bmatrix}.$$

The real parts of the closed loop poles range between -0.02686 and -33.4213. Moreover, $||T_{zw_1}||_\infty = 0.08088935$ and $\mathrm{Tr}(B_{0F}^T P B_{0F}) = 0.05135721 \leq \mathrm{Tr}(Y) = 0.34395872$. Once again, comparing this solution with the optimal one, we have calculated $C_\gamma^{opt}(X, F) = 0.0502692$ with the algorithm of [32] for solving the optimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback problem (2.11). Finally, the whole computation needs 53.53 CPU seconds. Again, this example demonstrates numerically the theoretical properties of our algorithm and shows that this approach can be used for the design of a suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback gain.

Example 3 *(Euler–Bernoulli beam).* This example consists of a simple supported Euler–Bernoulli beam as discussed in [22] (see also [18]). Following [22], the state space model is given by Σ_P, with matrices as follows:

$$A = \mathrm{diag}\left\{ \begin{bmatrix} 0 & 1 \\ -r^4 & -0.02\, r^2 \end{bmatrix}, \ r = 1, \dots, 5 \right\},$$

$$B_2^T = C_2 = \begin{bmatrix} 0 & 0.9877 & 0 & -0.309 & 0 & -0.891 & 0 & 0.5878 & 0 & 0.7071 \end{bmatrix}, B_1 = \begin{bmatrix} B_2 & 0_{10\times 1} \end{bmatrix},$$

$$C_1 = \begin{bmatrix} 0.809 & 0 & -0.9511 & 0 & 0.309 & 0 & 0.5878 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

$$D_{12} = \begin{bmatrix} 0 \\ 0.5 \end{bmatrix}, D_{21} = \begin{bmatrix} 0 & 1.9 \end{bmatrix}.$$

Choosing $\beta = 0.01$, $\gamma = 3.59251$, and $\varepsilon = 10^{-10}$, Algorithm 1 terminates after 28.59 CPU seconds, and (3.20) provides the static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controller gain $F = -0.6221049$ with $\mathrm{Tr}(B_{0F}^T P B_{0F}) = 0.5742053 \leq \mathrm{Tr}(Y) = 4.4202$ and $||T_{zw_1}||_\infty = 2.179593$. Moreover, the closed loop poles are

$$\lambda(A_F) = \begin{bmatrix} -0.395 \pm 24.9i & -0.257 \pm 15.9i & -0.326 \pm 8.98i & -0.305 \pm 0.95 & -0.059 \pm 3.99i \end{bmatrix}.$$

Using the algorithm proposed by [30], [32] yields the optimal cost value $C_\gamma^{opt}(X, F) = 0.185282$ of (2.11) with $F_{opt} = -1.036985$ and $||T_{zw_1}||_\infty = 2.14176$.

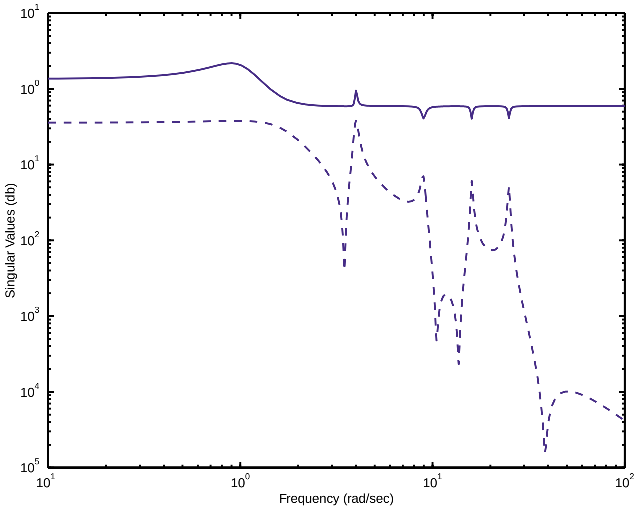

FIG. 4.1. *Singular value plot.*

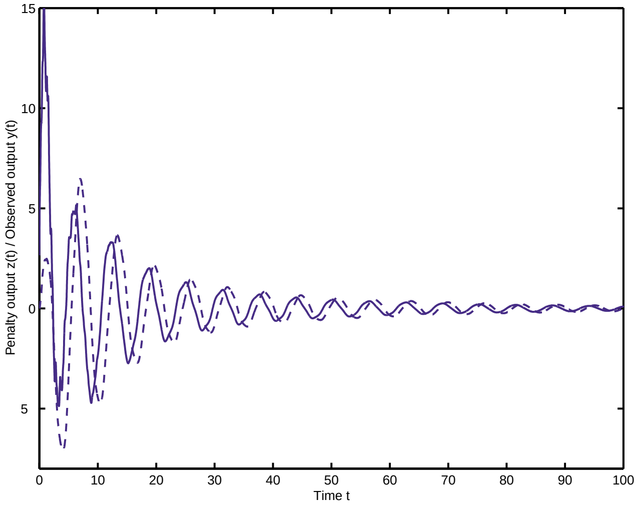

FIG. 4.2. *Phase portraits of the regulated output z (dashed line) and the observed output y (solid line) for the Euler–Bernoulli beam under worst case disturbances: Controlled case.*

The SLPMM algorithm has generated the sequences

$$\{\mathcal{J}(P^k, Q^k, Y^k)\}_{k=0}^4 = \{229.5443, 14.4202522, 14.4202000, 14.4202000, 14.4202000\},$$
$$\{\mathrm{Tr}(P^k Q^k)\}_{k=0}^4 = \{180.32, 10.000029, 10.0000000001, 10.0000000000, 10.0000000000\},$$
$$\{\tau_k\}_{k=1}^4 = \{-3.281 \cdot 10^2, -5.224 \cdot 10^{-5}, -1.278 \cdot 10^{-10}, 0.000\},$$

which underline the theoretical results stated in Theorems 3.8 and 3.9.

Figure 4.1 shows the singular value response of the corresponding closed loop system for the problem under consideration. In Figure 4.2, the phase portraits for the regulated output variable z (dashed line) and the observed output variable y

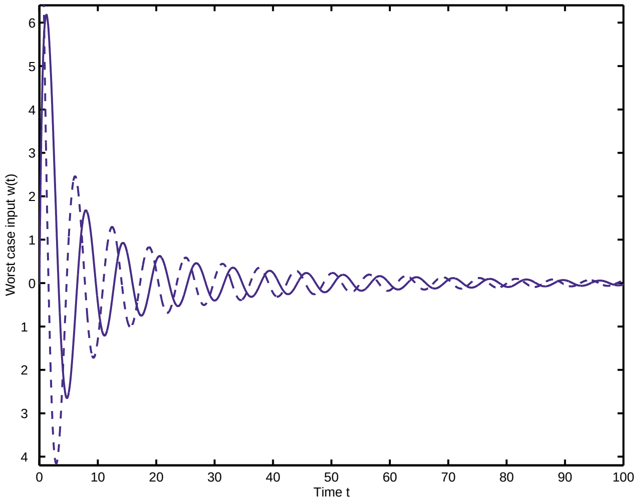

FIG. 4.3. *Worst case disturbances.*

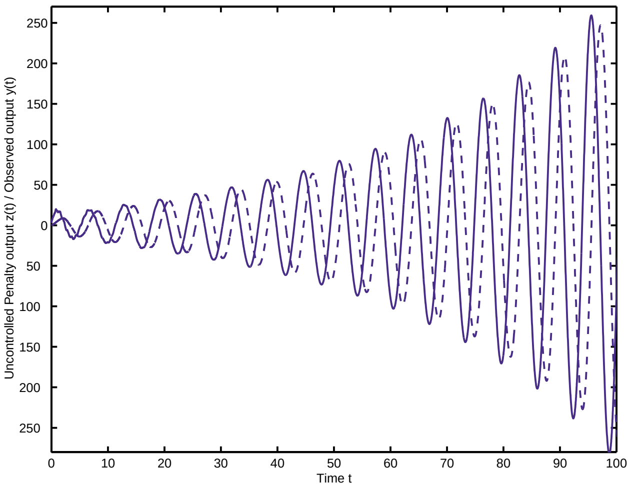

FIG. 4.4. *Phase portraits of the regulated output z (dashed line) and the observed output y (solid line) for the Euler–Bernoulli beam under worst case disturbances: Uncontrolled case.*

(solid line) are displayed for the computed suboptimal static $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback controller under the corresponding worst case inputs w, as illustrated in Figure 4.3. These plots demonstrate that the computed controller gain yields an asymptotically stable closed loop system and satisfies the robustness constraint, even if the worst-case input affects the system. In contrast to this, the uncontrolled system outputs, as shown in Figure 4.4, oscillate away from the stable equilibrium of the system. Especially, the worst case inputs support this behavior and drive the system to be unstable.

Example 4 *(reduced order control).* In this example we consider a three–mass-spring system and illustrate our approach for the design of a reduced order compensator if the SLPMM algorithm terminates at a point (P, Q, Y) satisfying $\mathrm{Tr}(PQ) > n_x$. The system under consideration consists of three unit masses connected by two linear springs with stiffness constant κ. There we have assumed that only the position of the third mass is measured and a control force acts on the first mass. The linear state space realization of this system is given by Σ_P with the following data matrices:

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ -\kappa & 0 & \kappa & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ \kappa & 0 & -2\kappa & 0 & \kappa & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & \kappa & 0 & -\kappa & 0 \end{bmatrix}, B_1 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}, B_2 = \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}, C_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}^T, D_{12} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{bmatrix},$$

$C_1 = [I_6 \;\; 0]^T$, $D_{21} = 0$, and the state components x_i, x_{i+1}, $i = 1, 2, 3$, denote the position and the velocity of the mass i, respectively. It is well known that this linear system is not stabilizable by a static output feedback gain, i.e., $\mathcal{F}_s = \emptyset$, but it is stabilizable by a reduced order controller of order $n_c = 3$, where

$$\Sigma_{CD} \;\{\; \dot{x}_c(t) = A_c x_c(t) + B_c y(t), \quad u(t) = C_c x_c(t) + D_c y(t)$$

denotes the compensator of order $n_c \leq n_x$ with $A_c \in \mathbb{R}^{n_c \times n_c}$, $B_c \in \mathbb{R}^{n_c \times n_y}$, $C_c \in \mathbb{R}^{n_u \times n_c}$, $D_c \in \mathbb{R}^{n_u \times n_y}$, and $x_c(t) \in \mathbb{R}^{n_c}$. Using Algorithm 1 with $\beta = 0.1$, $\gamma = 50.0869$, and $\varepsilon = 10^{-8}$, we can compute a reduced order compensator of the form Σ_{CD} for this example as follows. Since $\mathcal{F}_s = \emptyset$, the SLPMM algorithm provides a solution triple (P, Q, Y) of (3.19) satisfying $\mathrm{Tr}(PQ) > n_x$, i.e., $(P, Q, Y) \notin \partial\mathcal{X}(P, Q, Y)$. In particular, the algorithm has generated the following sequences:

$$\begin{aligned} \{\mathcal{J}(P^k, Q^k, Y^k)\}_{k=0}^5 &= \{10192.8935, 48.3013702, 38.2048006, 37.5019180, 36.7597188, \\ &\quad\; 36.7596674\}, \\ \{\mathrm{Tr}(P^k Q^k)\}_{k=0}^5 &= \{9786.7919, 39.2714948, 30.9417654, 30.8152693, 30.7274670, \\ &\quad\; 30.7274665\}, \\ \{\mathrm{Tr}(Y^k)\}_{k=0}^5 &= \{406.1016, 9.0298754, 7.2630352, 6.6866487, 6.0322518, \\ &\quad\; 6.0322009\}, \\ \{\tau_k\}_{k=1}^5 &= \{-1.84 \cdot 10^4, -9.50, -1.24 \cdot 10^{-2}, -9.12 \cdot 10^{-3}, -3.19 \cdot 10^{-9}\}. \end{aligned}$$

Obviously, $\{\mathcal{J}(P^k, Q^k, Y^k)\}$ is a strictly decreasing sequence which tends to $\mathrm{Tr}(P^5 Q^5)$ $+ \mathrm{Tr}(Y^5) = 30.7274665 + 6.0322009 > n_x + \mathrm{Tr}(Y^*)$, and Algorithm 1 terminates after six iterations satisfying approximatively the first order necessary condition. Since $\partial\mathcal{X}(P, Q, Y) = \emptyset$, we know that there exists no static gain for the problem under consideration. But it is possible to reconstruct a reduced order compensator from the computed solution triple (P, Q, Y) of (3.19). For example, first we compute the eigenvalues of $P - Q^{-1} \succeq 0$. If there are m eigenvalues of $P - Q^{-1}$ which are less than or equal to $\tilde{\varepsilon} > 0$, $\tilde{\varepsilon} \ll 1$, then there exists an n_cth order dynamic output feedback control law of the form Σ_{CD} such that the eigenvalues of the augmented closed loop system matrix $\hat{A}_{\hat{F}} = \hat{A} + \hat{B}_2 \hat{F} \hat{C}_2$ have negative real parts [8, Theorem 3.1], where $n_c = n_x - m$ and the augmented system matrices are defined by [12]:

$$\begin{aligned} &\hat{A} = \begin{bmatrix} A & 0 \\ 0 & 0_{n_c} \end{bmatrix}, \; \hat{B}_1 = \begin{bmatrix} B_1 \\ 0 \end{bmatrix}, \; \hat{B}_2 = \begin{bmatrix} 0 & B_2 \\ I_{n_c} & 0 \end{bmatrix}, \; \hat{C}_1 = [C_1 \;\; 0], \\ &\hat{C}_2 = \begin{bmatrix} 0 & I_{n_c} \\ C_2 & 0 \end{bmatrix}, \; \hat{D}_{12} = [0 \; D_{12}], \; \hat{D}_{21} = \begin{bmatrix} 0 \\ D_{21} \end{bmatrix}, \; \hat{F} = \begin{bmatrix} A_c & B_c \\ C_c & D_c \end{bmatrix}, \end{aligned} \tag{4.1}$$

$\hat{B}_0 = \hat{B}_1$, $\hat{D}_{20} = [0\ 0_{n_y \times n_w}]^T$, and $\hat{D}_{10} = \hat{D}_{11} = D_{11}$. Second, we decompose the positive semidefinite matrix $P - Q^{-1}$ as $UU^T + E$ by a singular value decomposition, where $U \in \mathbb{R}^{n_x \times n_c}$, $E \in \mathbb{R}^{n_x \times n_x}$, $||E|| \leq \tilde{\varepsilon}$, and we define

$$\hat{P} = \left[\begin{array}{cc} P & U \\ U^T & I_{n_c} \end{array} \right], \quad \hat{Y} = Y. \tag{4.2}$$

By [36, Lemma 7.5] we have $\hat{P} \succ 0$. Then, replacing in (3.20) the system matrices by their augmented counterparts, the corresponding LMI feasibility problem in $\hat{F}$ has a solution. Choosing $\tilde{\varepsilon} = 10^{-10}$ yields $m = 3$, $n_c = 3$, and the resulting third order compensator gain

$$\hat{F} = \left[\begin{array}{cc} A_c & B_c \\ C_c & D_c \end{array} \right] = \left[\begin{array}{rrr|r} -0.23619 & -0.59416 & 1.85859 & -2.31612 \\ 0.52718 & -0.14806 & 1.38309 & -1.58075 \\ -0.51506 & -0.91840 & -0.64521 & 2.59614 \\ \hline -0.05706 & -0.01872 & 0.55757 & -1.17127 \end{array} \right].$$

The real parts of closed loop eigenvalues of $\hat{A}_{\hat{F}}$ ranges between -0.00963 and -0.02874. Moreover, $\mathrm{Tr}(\hat{B}_{0\hat{F}}^T \hat{P} \hat{B}_{0\hat{F}}) = 6.032201$ and $||T_{zw_1}||_\infty = 46.46845 < \gamma$, which shows numerically that $\hat{F}$ is a suboptimal third order $\mathcal{H}_2/\mathcal{H}_\infty$ output feedback compensator gain. Summing up, this example demonstrates that we always can construct from the computed solution of Algorithm 1 at least a reduced order compensator gain which satisfies the design criteria. Finally, the whole computation time needs 9.62 CPU seconds on a SUN Ultra 60.

RIESZ BASIS APPROACH TO THE STABILIZATION OF A FLEXIBLE BEAM WITH A TIP MASS*

BAO-ZHU GUO†

Abstract. Using an abstract condition of Riesz basis generation of discrete operators in the Hilbert spaces, we show, in this paper, that a sequence of generalized eigenfunctions of an Euler–Bernoulli beam equation with a tip mass under boundary linear feedback control forms a Riesz basis for the state Hilbert space. In the meanwhile, an asymptotic expression of eigenvalues and the exponential stability are readily obtained. The main results of [*SIAM J. Control Optim.*, 36 (1998), pp. 1962–1986] are concluded as a special case, and the additional conditions imposed there are removed.

Key words. beam equation, boundary control, stability, eigenvalues, Riesz basis

1. Introduction.

When a tip mass is attached to the free end, the vibration of a flexible beam that is clamped at one end and controlled at the free end can be described by the following Euler–Bernoulli beam equation (Conrad and Morgül, 1998):

$$(1)\qquad \begin{cases} y_{tt}(x,t) + y_{xxxx}(x,t) = 0, \quad 0 < x < 1, \quad t > 0, \\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = 0, \quad t \geq 0, \\ -y_{xxx}(1,t) + my_{tt}(1,t) = u(t), \quad t \geq 0, \end{cases}$$

where y is the amplitude of the vibration, m is the tip mass, and u is the boundary control force applied at the free end. In order to achieve uniform stability for this system, one has to employ "higher" derivative controllers. The following linear feedback control law is proposed in Conrad and Morgül (1998):

$$u(t) = -\alpha y_t(1,t) + \beta y_{xxxt}(1,t), \quad t \geq 0,$$

where α and β are real constants. The closed-loop system then becomes

$$(2)\qquad \begin{cases} y_{tt}(x,t) + y_{xxxx}(x,t) = 0, \\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = 0, \\ y_{xxx}(1,t) = \alpha y_t(1,t) + my_{tt}(1,t) - \beta y_{xxxt}(1,t). \end{cases}$$

The energy multiplier method is used in Conrad and Morgül (1998) to show that system (2) is exponentially stable for any $\alpha, \beta > 0$. It is further proved for a special case where $m = \alpha\beta$ that a set of generalized eigenfunctions of system (2) forms a Riesz basis for the state Hilbert space, usually referred to as the Riesz basis (generation) property, and that the spectrum-determined growth condition holds, both for almost

every $\alpha > 0$. Systems with the Riesz basis property are usually referred to as Riesz spectral systems (Xu and Sallet, 1996).

Verification of the Riesz basis property is a very important problem both theoretically and practically. Usually, the property will lead to the establishment of such results as the spectrum-determined growth condition and the exponential stability of the system. However, such verification is usually difficult because the associated system operator is non-self-adjoint. For one-dimensional string equations with general variable coefficients under linear boundary feedback control, successful treatments have been made for the basis property in last two decades; we refer to Cox and Zuazua (1994), Shubov (1996, 1997), and the references therein. The case of a string equation with a tip mass was investigated in Morgül, Conrad, and Rao (1994). An abstract treatment of general Riesz spectral system with one rank perturbation can be found in Sun (1981), Rebarber (1989), and Xu and Sallet (1996), to name just a few. In Rao (1997) and, recently, Li et al. (1999), the beam equations with "low order" perturbations were considered. Since the model of serially connected Euler–Bernoulli beams under joint linear feedback control was proposed in Chen et al. (1987), many efforts have been made to study the asymptotic distribution of the eigenvalues (Chen et al., 1989) and the exponential stability (Rebarber, 1995). However, the spectrum-determined growth condition had not been reported until Conrad (1990), where a cantilevered beam equation was shown to have the Riesz basis property for small feedback gain, and hence the spectrum-determined growth condition is concluded for this special case. The general case for this cantilevered beam equation was resolved partly by Conrad and Morgül (1998).

In these works mentioned above, the verification of Riesz basis generation relies upon Bari's theorem (see, for example, Gohberg and Krein, 1969): if $\{\phi_n\}_1^\infty$ is a Riesz basis for a Hilbert space H, and $\{\psi_n\}_1^\infty$, an ω-linearly independent sequence in H, is quadratically close to $\{\phi_n\}_1^\infty$ in the sense that

$$\sum_{n=1}^{\infty} \parallel \phi_n - \psi_n \parallel^2 < \infty,$$

then $\{\psi_n\}_1^\infty$ is also a Riesz basis itself for H. In order to use Bari's theorem, the following steps are required:

(i) to estimate "high" eigenfrequencies by asymptotic analysis technique;

(ii) to find a sequence of generalized eigenvectors $\{\psi_n\}_{N+1}^\infty$ (where N is a large integer) such that $\{\psi_n\}_{N+1}^\infty$ is quadratically close to a given Riesz basis $\{\phi_n\}_1^\infty$: $\sum_{n=N+1}^{\infty} \parallel \phi_n - \psi_n \parallel^2 < \infty$; and

(iii) to show that the number of linearly independent "low" eigenvectors is exactly N, or, more generally, as in Rao (1997) and Shubov (1996), to show that the root subspace of the system is complete in the state space.

While steps (i) and (ii) are relatively easy, step (iii) has been very difficult, in general, so far. Toward easing this difficulty, Guo (to appear) recently establishes an abstract condition under which steps (i) and (ii) automatically imply step (iii) for discrete operators in general Hilbert spaces. This greatly simplifies the verification of the Riesz basis property in applications. In this paper, we shall use this result (a simplified proof is presented in the appendix of the present paper) to show that a sequence of generalized eigenfunctions of system (2) forms a Riesz basis for the state Hilbert space for any real parameters $\alpha, \beta \neq 0$ and m. This covers the main results of Conrad and Morgül (1998) as a special case and removes the additional conditions imposed there. The exponential stability of the system is then readily established from an asymptotic expression of the eigenvalues, which is also obtained in the process of verification of the Riesz basis generation property.

The paper is organized as follows. In sections 2 and 3, some asymptotic expressions of eigenvalues and eigenfunctions are presented. Section 4 is devoted to the Riesz basis generation. Concluding remarks are given in section 5. Finally, in the appendix, we present a much simplified proof of the abstract result obtained in Guo (to appear) about the Riesz basis property of discrete operators in general Hilbert spaces.

2. Asymptotic expressions of eigenvalues and eigenfunctions. Throughout the paper, we always assume that $\beta \neq 0$. As in Conrad and Morgül (1998), the state Hilbert space for system (2) is $\mathbf{H} = H_E^2(0,1) \times L^2(0,1) \times \mathbb{C}$, where $H_E^2(0,1) = \{f \in H^2(0,1) \mid f(0) = f'(0) = 0\}$, with the inner product induced norm defined as

$$\| (f,g,\eta) \|^2 = \int_0^1 [| f''(x) |^2 + | g(x) |^2] dx + K \mid \eta \mid^2,$$

where $K > 0$ is any constant. Equation (2) can be written as an evolutionary equation in $\mathbf{H}$:

$$\frac{dY(t)}{dt} = \mathcal{A}Y(t), \tag{3}$$

where $Y(t) = (y(\cdot,t), y_t(\cdot,t), -y_{xxx}(1,t) + m\beta^{-1}y_t(1,t))$ and the operator $\mathcal{A} : D(\mathcal{A})(\subset \mathbf{H}) \to \mathbf{H}$ is defined as follows:

$$\begin{cases} \mathcal{A}(f,g,\eta) = (g, -f^{(4)}, -\beta^{-1}\eta - \beta^{-1}(\alpha - m\beta^{-1})g(1)) \quad \forall (f,g,\eta) \in D(\mathcal{A}), \\ D(\mathcal{A}) = \{(f,g,\eta) \in (H^4 \cap H_E^2) \times H_E^2 \times \mathbb{C}, f''(1) = 0, \eta = -f'''(1) + m\beta^{-1}g(1)\}. \end{cases}$$

Now, we present the following lemma on the spectrum of the operator $\mathcal{A}$.

LEMMA 2.1. *$\mathcal{A}^{-1}$ exists and is compact on $\mathbf{H}$. Hence the spectrum $\sigma(\mathcal{A})$ of $\mathcal{A}$ consists of isolated eigenvalues only: $\sigma(\mathcal{A}) = \sigma_p(\mathcal{A})$, where $\sigma_p(\mathcal{A})$ denotes the set of eigenvalues of $\mathcal{A}$. Moreover, each $\lambda = i\tau^2 \in \sigma(\mathcal{A}), \lambda \neq -\beta^{-1}$, is geometrically simple and satisfies the characteristic equation*

$$\tau(i\tau^2 + \beta^{-1})(1 + \cosh\tau\cos\tau) + (m\tau^2 - \alpha i)(\sinh\tau\cos\tau - \cosh\tau\sin\tau) = 0. \tag{4}$$

An eigenfunction (f,g,η) corresponding to $\lambda = i\tau^2 \in \sigma(\mathcal{A})(\lambda \neq -\beta^{-1})$ is given by

$$\begin{cases} f(x) & = \sinh\tau(1-x) - \sin\tau(1-x) - (\sinh\tau\cos\tau x + \sinh\tau x\cos\tau) \\ & \quad +(\cosh\tau x\sin\tau + \cosh\tau\sin\tau x), \\ g & = \lambda f, \\ \eta & = -\dfrac{\lambda\beta^{-1}}{\lambda + \beta^{-1}}(\alpha - m\beta^{-1})f(1). \end{cases} \tag{5}$$

Proof. A simple calculation shows that

$$\mathcal{A}^{-1}(f,g,\eta) = (f_1, g_1, \eta_1) \quad \forall (f,g,\eta) \in \mathbf{H},$$

$$f_1 = \int_x^1 \frac{(x-\tau)^3}{6} g(\tau)d\tau + \int_0^1 \left(\frac{\tau^3}{6} - x\frac{\tau^2}{2}\right) g(\tau)d\tau + \frac{(x-1)^3 - 3x + 1}{6}[\beta\eta + \alpha f(1)],$$

$$g_1 = f, \eta_1 = -\beta\eta - (\alpha - m\beta^{-1})f(1).$$

Since $f_1^{(4)} = -g, g_1 = f, |\eta_1| \leq |\beta||\eta| + |\alpha - m\beta^{-1}|\|f\|_{H^2}$, it follows that

$$\|\mathcal{A}^{-1}(f,g,\eta)\|_{H^4\times H^2\times\mathbb{C}} \leq M\|(f,g,\eta)\|_{\mathbf{H}}$$

for some constant $M > 0$. By the Sobolev embedding theorem, $\mathcal{A}^{-1}$ is compact on $\mathbf{H}$. This is the first part.

Second, for any $\lambda \in \sigma_p(\mathcal{A}), \lambda \neq -\beta^{-1}$, solving eigenvalue problem

$$\mathcal{A}(f,g,\eta) = (g, -f^{(4)}, -\beta^{-1}\eta - \beta^{-1}(\alpha - m\beta^{-1})g(1)) = \lambda(f,g,\eta),$$

one gets

$$g = \lambda f, \eta = -\frac{\lambda\beta^{-1}}{\lambda + \beta^{-1}}(\alpha - m\beta^{-1})f(1),$$

where f satisfies

$$\left\{\begin{array}{l} f^{(4)}(x) + \lambda^2 f(x) = 0, \\ f(0) = f'(0) = f''(1) = 0, \\ (\lambda + \beta^{-1})f'''(1) = \beta^{-1}\lambda(\alpha + m\lambda)f(1). \end{array}\right. \tag{6}$$

If (6) has two linearly independent solutions f_1, f_2, then there are constants c, d ($|c| + |d| \neq 0$) such that $cf_1(1) + df_2(1) = 0$. It follows from (6) that $f = cf_1 + df_2$ satisfies

$$\left\{\begin{array}{l} f^{(4)}(x) + \lambda^2 f(x) = 0, \\ f(0) = f'(0) = f(1) = f''(1) = f'''(1) = 0. \end{array}\right.$$

A simple calculation shows that the above equation has only zero solution. Hence $cf_1 + df_2 \equiv 0$. This contradicts the assumption that f_1, f_2 are linearly independent. Therefore, each $\lambda = i\tau^2 \in \sigma(\mathcal{A}), \lambda \neq -\beta^{-1}$, is geometrically simple.

Now, let $\lambda = i\tau^2$. By the first equation in (6) and the conditions $f(0) = f'(0) = 0$, we have

$$f(x) = c_1(\cosh\tau x - \cos\tau x) + c_2(\sinh\tau x - \sin\tau x),$$

where c_1 and c_2 are constants. Since $f''(1) = 0$, we can set

$$c_1 = \sinh\tau + \sin\tau, c_2 = -\cosh\tau - \cos\tau.$$

Obviously c_1, c_2 can not be zero simultaneously. Hence

$$\begin{aligned} f(x) &= \sinh\tau(1-x) - \sin\tau(1-x) - (\sinh\tau\cos\tau x + \sinh\tau x\cos\tau) \\ &\quad +(\cosh\tau x\sin\tau + \cosh\tau\sin\tau x), \end{aligned}$$

which satisfies

$$\left\{\begin{array}{l} f^{(4)}(x) + \lambda^2 f(x) = 0, \\ f(0) = f'(0) = f''(1) = 0 \end{array}\right. \tag{7}$$

for all $\lambda = i\tau^2$.

Finally, from the last condition $(\lambda + \beta^{-1})f'''(1) = \beta^{-1}\lambda(\alpha + m\lambda)f(1)$, one can obtain (4) (see also Conrad and Morgül, 1998). The proof is complete. □

Lemma 2.2. *There is a family of eigenvalues* $\{\lambda_n, \overline{\lambda}_n\}, \lambda_n = i\tau_n^2$ *of* $\mathcal{A}$ *satisfying*

$$\lambda = \lambda_n = i\tau_n^2 = -2m + i(k\pi)^2 + \mathcal{O}(n^{-1}), \tag{8}$$

where $k = n - 1/2$ *and* n *is a sufficiently large positive integer. An eigenfunction* (f_n, g_n, η_n) *of* $\mathcal{A}$ *corresponding to* λ_n *satisfies*

$$\begin{aligned} F_n(x) &= 2\tau_n^{-2}e^{-\tau_n}\begin{pmatrix} f_n''(x) \\ g_n(x) \\ \eta_n \end{pmatrix}^T \\ &= \begin{pmatrix} e^{-k\pi x} + (-1)^n e^{-k\pi(1-x)} + (\cos k\pi x - \sin k\pi x) \\ i[e^{-k\pi x} + (-1)^n e^{-k\pi(1-x)} - (\cos k\pi x - \sin k\pi x)] \\ 0 \end{pmatrix}^T + \mathcal{O}(n^{-1}), \end{aligned} \tag{9}$$

which holds uniformly for $x \in [0,1]$. *Consequently,*

$$\| F_n(x) \|^2_{L^2\times L^2\times\mathbb{C}} = \| 2\tau_n^{-2}e^{-\tau_n}(f_n, g_n, \eta_n) \|^2_{\mathbf{H}} \to 2 \text{ as } n \to \infty. \tag{10}$$

Proof. Let $k = n - 1/2$, with n as a sufficiently large positive integer. Noting that as $n \to \infty, \|e^{-k\pi x}\|^2_{L^2} \to 0, \|e^{-k\pi(1-x)}\|^2_{L^2} \to 0, \| \cos k\pi x - \sin k\pi x\|^2_{L^2} \to 1$, we can conclude (10) from (9) immediately. So only (9) should be verified. First, in a small neighborhood of $k\pi$, the following estimates are valid uniformly for all $n > 0$:

$$2e^{-\tau}\sinh\tau = 1 + \mathcal{O}(e^{-2|\tau|}), 2e^{-\tau}\cosh\tau = 1 + \mathcal{O}(e^{-2|\tau|}), \sin\tau = \mathcal{O}(1), \cos\tau = \mathcal{O}(1).$$

Second, multiplying $-2i\tau^{-3}e^{-\tau}$ on both sides of (4) yields

$$\cos\tau = \mathcal{O}(| \tau |^{-1}) \text{ or } \cos\tau = \frac{m}{\tau}i(\cos\tau - \sin\tau) + \mathcal{O}(| \tau |^{-2}), \tag{11}$$

which is valid uniformly in a small neighborhood of $k\pi$ for all $n > 0$. Since $\cos k\pi = 0$, we can apply Rouche's theorem to the functions $f(\tau) = \cos\tau$ and $g(\tau) = -\mathcal{O}(| \tau |^{-1})$ in a small neighborhood of $k\pi$ to find a solution to the first equation of (11) to be

$$\tau = \tau_n = k\pi + \mathcal{O}(n^{-1}). \tag{12}$$

Note that

$$\begin{cases} e^{-\tau_n y} = e^{-k\pi y} + \mathcal{O}(n^{-1}), \\ \sin\tau_n x = \sin k\pi x + \mathcal{O}(n^{-1}), \cos\tau_n x = \cos k\pi x + \mathcal{O}(n^{-1}), \end{cases} \tag{13}$$

which holds uniformly for bounded $y > 0$ and $x \in [0,1]$. Upon substituting (12) into the second equation of (11), the term $\mathcal{O}(n^{-1})$ in the expression (12) satisfies

$$-\sin k\pi\mathcal{O}(n^{-1}) = -\frac{mi}{k\pi}\sin k\pi + \mathcal{O}(n^{-2}),$$

so

$$\mathcal{O}(n^{-1}) = \frac{mi}{k\pi} + \mathcal{O}(n^{-2}).$$

This, together with (12), gives

$$\tau_n = k\pi + \frac{mi}{k\pi} + \mathcal{O}(n^{-2}).$$

Then (8) readily follows.

Now let $\tau = \tau_n$ and $(f_n, g_n, \eta_n) = (f, g, \eta)$ be defined by (5). Since

$$\begin{aligned}\tau^{-2} f_n''(x) &= \sinh \tau(1-x) + \sin \tau(1-x) + (\sinh \tau \cos \tau x - \sinh \tau x \cos \tau)\\ &\quad +(\cosh \tau x \sin \tau - \cosh \tau \sin \tau x),\end{aligned}$$

it follows from (13) that

$$\begin{aligned}2\tau^{-2}e^{-\tau} f_n''(x) &= e^{-\tau x} + \cos \tau x - e^{-\tau(1-x)} \cos \tau + e^{-\tau(1-x)} \sin \tau - \sin \tau x + \mathcal{O}(e^{-k\pi})\\ &= e^{-k\pi x} + e^{-k\pi(1-x)} \sin k\pi + \cos k\pi x - \sin k\pi x + \mathcal{O}(n^{-1})\\ &= e^{-k\pi x} + (-1)^n e^{-k\pi(1-x)} + (\cos k\pi x - \sin k\pi x) + \mathcal{O}(n^{-1}),\\ 2\tau^{-2}e^{-\tau} g_n(x) &= ie^{-\tau} f_n(x) = i[e^{-\tau x} - \cos \tau x - e^{-\tau(1-x)} \cos \tau + e^{-\tau(1-x)} \sin \tau\\ &\quad + \sin \tau x] + \mathcal{O}(e^{-k\pi})\\ &= i[e^{-k\pi x} + (-1)^n e^{-k\pi(1-x)} - (\cos k\pi x - \sin k\pi x)] + \mathcal{O}(n^{-1}),\\ 2\tau^{-2}e^{-\tau}\eta_n &= -2\tau^{-2}e^{-\tau} \tfrac{\lambda\beta^{-1}}{\lambda+\beta^{-1}}(\alpha - m\beta^{-1}) f_n(1) = \mathcal{O}(n^{-2}).\end{aligned}$$

The above estimates are valid uniformly for $x \in [0, 1]$. (9) is established. □

It should be pointed out that we are not sure at this stage that (8) is an asymptotic expression for all eigenvalues of $\mathcal{A}$. This will be cleared up after the verification of the Riesz basis generation in section 4.

3. Results of an auxiliary system. In this section, we consider an auxiliary system which is composed of a conservative system and an ordinary differential equation coupled. This system will produce a reference Riesz basis of $\mathbf{H}$, required in Theorem 6.3 in the appendix in verification of basis generation. The principle of constructing this system is based on an observation of the characteristic equation (4) that the "dominant" equation of (4) is $i\tau^3(1+\cosh \tau \cos \tau) = 0$, which can be obtained by letting $\alpha = m = \beta^{-1} = 0$. In this case, system (2) becomes

$$\begin{cases} y_{tt} + y_{xxxx} = 0,\\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = y_{xxxt}(1,t) = 0.\end{cases}$$

Naturally, we consider the well-posed conservative system

$$\begin{cases} y_{tt} + y_{xxxx} = 0,\\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = y_{xxx}(1,t) = 0,\end{cases}$$

which has the same nonzero eigenvalues as that of the system above. In order to get a state space the same as that of the system (2), i.e., $\mathbf{H}$, we complete the conservative system with another ordinary differential equation; then the auxiliary system is obtained, which is described by the following equation:

$$\begin{cases} y_{tt} + y_{xxxx} = 0,\\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = y_{xxx}(1,t) = 0,\\ \dot{\eta}(t) = 0.\end{cases}$$

Alternatively, we can describe the auxiliary system in the form of an evolutionary equation in $\mathbf{H}$,

$$\frac{dY(t)}{dt} = \mathcal{A}_0 Y(t), \tag{14}$$

where the operator $\mathcal{A}_0 : D(\mathcal{A}_0)(\subset \mathbf{H}) \to \mathbf{H}$ is defined as follows:

$$\begin{cases} \mathcal{A}_0(f,g,\eta) = (g, -f^{(4)}, 0) \quad \forall (f,g,\eta) \in D(\mathcal{A}_0), \\ D(\mathcal{A}_0) = \{(f,g,\eta) \in (H^4 \cap H_E^2) \times H_E^2 \times \mathbb{C}, f''(1) = f'''(1) = 0\}. \end{cases}$$

It is easy to show that $1 \in \rho(\mathcal{A}_0), (I - \mathcal{A}_0)^{-1}$ is compact on $\mathcal{H}$ and $\mathcal{A}_0^* = -\mathcal{A}_0$. That is, $\mathcal{A}_0$ is a skew-adjoint operator with compact resolvent on $\mathbf{H}$ (and hence $i\mathcal{A}_0$ is self-adjoint with compact resolvent). It then follows from a well-known result in functional analysis that (i) there is a sequence of normalized eigenfunctions of $\mathcal{A}_0$ which forms an orthonormal basis of $\mathbf{H}$; (ii) for each eigenvalue of $\mathcal{A}_0$, its geometric multiplicity equals its algebraic multiplicity; and (iii) all eigenvalues of $\mathcal{A}_0$ lie on the imaginary axis. (ii) is actually a consequence of (i). (iii) comes directly from the skew-adjointness of $\mathcal{A}_0$. These are advantages of the construction of $\mathcal{A}_0$.

All the analysis of the operator $\mathcal{A}$ in the preceding section is true for the operator $\mathcal{A}_0$. In particular, each $\mu \in \sigma(\mathcal{A}_0), \mu \neq 0$, is geometrically simple and hence algebraically simple. And the characteristic equation for $\mu = i\omega^2 (\neq 0) \in \sigma(\mathcal{A}_0)$ is

(15) $$1 + \cosh\omega \cos\omega = 0.$$

Since all eigenvalues of $\mathcal{A}_0$ lie on the imaginary axis, we need consider only the positive solutions to (15) in order to find all nonzero eigenvalues of $\mathcal{A}_0$.

For $\omega > 0$, writing (15) as $\cos\omega = \mathcal{O}(e^{-\omega})$, we can get the positive solutions of (15) being

(16) $$\omega = \omega_n = k\pi + \mathcal{O}(e^{-k\pi}),$$

where $k = n - 1/2$ for all sufficiently large positive integers n.

Therefore, the spectrum of $\mathcal{A}_0$ consists of all pairs $\{\mu_n, \overline{\mu}_n\}$ together with possibly another finite set, where $\mu_n = i\omega_n^2$ with ω_n given in (16). This is unlike $\mathcal{A}$; $\mu_n = i\omega_n^2 = i(k\pi)^2 + \mathcal{O}(k\pi e^{-k\pi})$ is now indeed an asymptotic expression for all eigenvalues of $\mathcal{A}_0$.

Now, letting $\alpha = m = \beta^{-1} = 0$ and $\tau_n = \omega_n$, in Lemma 2.2, we get an eigenvector (u_n, v_n, ν_n) of $\mathcal{A}_0$ corresponding to $\mu_n = i\omega_n^2 (\neq 0)$ given below:

(17) $$\begin{cases} u_n(x) & = \sinh\omega_n(1-x) - \sin\omega_n(1-x) - (\sinh\omega_n \cos\omega_n x + \sinh\omega_n x \cos\omega_n) \\ & \quad +(\cosh\omega_n x \sin\omega_n + \cosh\omega_n \sin\omega_n x), \\ v_n & = \mu_n u_n, \\ \nu_n & = 0. \end{cases}$$

Clearly, the asymptotic expression (12) is also valid for ω_n defined in (16). Noting that only the expression (12) is used in the proof of Lemma 2.2, we have the following counterpart of Lemma 2.2 for $\mathcal{A}_0$. Similar results were also obtained in Lancaster and Shkalikov (1994).

LEMMA 3.1. *The spectrum of $\mathcal{A}_0$ consists of all $\{\mu_n, \overline{\mu}_n\}$ but possibly a finite number of the other eigenvalues, where $\mu_n = i\omega_n^2, \omega_n$ is determined by* (16). *And the eigenvalues μ_n ($\overline{\mu}_n$) are algebraically simple for all large n. In addition, an eigenfunction (u_n, v_n, ν_n) of $\mathcal{A}_0$ corresponding to μ_n satisfies*

(18) $$\begin{aligned} G_n(x) & = 2\omega_n^{-2} e^{-\omega_n} \begin{pmatrix} u_n''(x) \\ v_n(x) \\ \nu_n \end{pmatrix}^T \\ & = \begin{pmatrix} e^{-k\pi x} + (-1)^n e^{-k\pi(1-x)} + (\cos k\pi x - \sin k\pi x) \\ i[e^{-k\pi x} + (-1)^n e^{-k\pi(1-x)} - (\cos k\pi x - \sin k\pi x)] \\ 0 \end{pmatrix}^T + \mathcal{O}(n^{-1}), \end{aligned}$$

which holds uniformly for all $x \in [0,1]$.

4. Riesz basis generation. In this section, we shall apply Theorem 6.3 in the appendix to get the basis property of $\mathcal{A}$. To do this, we need a reference Riesz basis of $\mathbf{H}$ first. This is accomplished by collecting the eigenfunctions of $\mathcal{A}_0$. As we can conclude from Lemma 3.1 that a "maximal" set (see appendix) of ω-linearly independent eigenfunctions of $\mathcal{A}_0$ consists of all (u_n, v_n, ν_n) defined by (17) but a finite number of the other eigenfunctions, we may assume, without loss of generality, that such a set is

$$\{2\omega_n^{-2}e^{-\omega_n}(u_n, v_n, \nu_n)\}_1^\infty \cup \{\text{their conjugates}\}.$$

Since $\mathcal{A}_0$ is skew-adjoint, the set $\{2\omega_n^{-2}e^{-\omega_n}(u_n, v_n, \nu_n)\}_1^\infty \cup \{\text{their conjugates}\}$ forms an orthogonal basis of $\mathbf{H}$. Because they are approximately normalized (that is, they are upper and lower bounded) according to (10), the set is indeed a Riesz basis of $\mathbf{H}$ by a well-known fact that all approximately normalized Riesz bases in a separate Hilbert space are equivalent.

From (9) and (18), it follows that there is a large positive integer N such that

$$\begin{aligned}
&\sum_{n>N}^{\infty} \parallel 2\tau_n^{-2}e^{-\tau_n}(f_n, g_n, \eta_n) - 2\omega_n^{-2}e^{-\omega_n}(u_n, v_n, \nu_n) \parallel_{\mathbf{H}}^2 \\
&= \sum_{n>N}^{\infty} \parallel F_n - G_n \parallel_{L^2\times L^2\times\mathbb{C}}^2 = \sum_{n>N}^{\infty} \mathcal{O}(n^{-2}) < \infty.
\end{aligned} \tag{19}$$

The same is true for their conjugates. Note that all $\lambda_n = i\tau_n^2$ are different for large n; we can now apply Theorem 6.3 in the appendix to obtain the main results of the present paper.

THEOREM 4.1. *Let the operator $\mathcal{A}$ be defined as in* (3). *Then*

(i) *there is a sequence of generalized eigenfunctions of $\mathcal{A}$ which forms a Riesz basis for the state space* $\mathbf{H}$*;*

(ii) *all of the eigenvalues of $\mathcal{A}$ have the asymptotic expression* (8)*; and*

(iii) *all $\lambda \in \sigma(\mathcal{A})$ with sufficiently large modulus are algebraically simple.*

Therefore, $\mathcal{A}$ generates a C_0-group on $\mathbf{H}$ for any real constants m, α, and β. Moreover, for the semigroup $e^{\mathcal{A}t}$ generated by $\mathcal{A}$, the spectrum-determined growth condition holds. And the growth rate of $e^{\mathcal{A}t}$ is not less than $-2m$.

The stability result for the system (2) is given in the following corollary.

COROLLARY 4.2. *The semigroup $e^{\mathcal{A}t}$ is exponentially stable for any $m, \alpha, \beta > 0$.*

Proof. Taking the inner product of $\mathbf{H}$ as in the beginning of the section 2 with $K = \beta^2/(m + \alpha\beta)$, it is calculated in Conrad and Morgül (1998) that

$$\mathrm{Re}\langle \mathcal{A}Y, Y\rangle = -\frac{K}{\beta} \mid f'''(1) \mid^2 - \frac{Km\alpha}{\beta^2} \mid g(1) \mid^2 \leq 0 \quad \forall\ Y = (f, g, \eta) \in D(\mathcal{A}).$$

That is, $\mathcal{A}$ is dissipative and hence no eigenvalues of $\mathcal{A}$ lie on the open right half complex plane. Now, if $\mathcal{A}Y = \lambda Y$, $Y = (f, g, \eta)$, and $\mathrm{Re}\lambda = 0$, then $f'''(1) = g(1) = 0$. It follows from (6) that

$$\begin{cases} f^{(4)}(x) + \lambda^2 f(x) = 0, \\ f(0) = f'(0) = f''(1) = 0, \\ f'''(1) = f(1) = 0. \end{cases}$$

As it is indicated in the proof of Lemma 2.1, the above equation has a zero solution only. Hence $f \equiv 0$ and so $g = \eta = 0$ by (5). Therefore,

$$\mathrm{Re}\lambda < 0 \quad \forall \lambda \in \sigma(\mathcal{A}). \tag{20}$$

Finally, since $\mathcal{A}$ is of compact resolvent, there are only finitely many eigenvalues of $\mathcal{A}$ in any bounded region of the complex plane, which, together with Theorem 4.1 (ii), shows that there is a constant $\omega > 0$ such that

$$S(\mathcal{A}) = \sup_{\lambda \in \sigma(\mathcal{A})} \mathrm{Re}\lambda < -\omega. \tag{21}$$

The exponential stability then follows from the spectrum-determined growth condition. The proof is complete. □

Before ending the section, we indicate that Theorem 4.1 can be used to obtain the basis property and the spectrum-determined growth condition of a beam equation without tip mass under linear boundary feedback control. Let $\mathcal{A}_1$ be defined by setting $m = \theta\beta$, where θ is real, in the definition of the operator $\mathcal{A}$; that is,

$$\begin{cases} \mathcal{A}_1(f, g, \eta) = (g, -f^{(4)}, -\beta^{-1}\eta - \beta^{-1}(\alpha - \beta^{-1})g(1)) \quad \forall (f, g, \eta) \in D(\mathcal{A}_1), \\ D(\mathcal{A}_1) = \{(f, g, \eta) \in (H^4 \cap H_E^2) \times H_E^2 \times \mathbb{C}, f''(1) = 0, \eta = -f'''(1) + \theta g(1)\}. \end{cases}$$

Then Theorem 4.1 holds true for operator $\mathcal{A}_1$ for any reals β^{-1}, α, and θ. Furthermore, let $\mathcal{A}_2$ be defined by setting $\alpha = \beta^{-1} = 0$ in the definition of $\mathcal{A}_1$. We have

$$\begin{cases} \mathcal{A}_2(f, g, \eta) = (g, -f^{(4)}, 0) \quad \forall (f, g, \eta) \in D(\mathcal{A}_2), \\ D(\mathcal{A}_2) = \{(f, g, \eta) \in (H^4 \cap H_E^2) \times H_E^2 \times \mathbb{C}, f''(1) = 0, \eta = -f'''(1) + \theta g(1)\}. \end{cases}$$

And Theorem 4.1 is also true for operator $\mathcal{A}_2$ for any real θ. However,

$$\frac{dY}{dt} = \mathcal{A}_2 Y(t)$$

is equivalent to

$$\begin{cases} y_{tt}(x,t) + y_{xxxx}(x,t) = 0, \quad 0 < x < 1, \quad t > 0, \\ y(0,t) = y_x(0,t) = y_{xx}(1,t) = 0, \quad t \geq 0, \\ y_{xxx}(1,t) = \theta y_t(1,t), \quad t \geq 0. \end{cases} \tag{22}$$

That is, system (22) is also a Riesz spectral system. This system is just the cantilevered beam equation considered in Conrad (1990), Conrad and Morgül (1998), and Guo (to appear).

Remark 4.3. The conclusion of Corollary 4.2 was proved in Conrad and Morgül (1998) by energy multiplier method. Theorem 4.1 (i) was shown there in the case of $m = \alpha\beta$ for almost every $\alpha > 0$ with other additional conditions. Theorem 4.1 (iii) was also shown there by complex analysis. The Riesz basis property for (22) was obtained there for almost every $\theta > 0$.

5. Concluding remarks. In this paper, an abstract condition for Riesz basis generation of discrete operators in Hilbert spaces is used to show that a sequence of generalized eigenfunctions of an Euler–Bernoulli beam equation with a tip mass under boundary linear feedback control forms a Riesz basis for the state Hilbert space. The stability of the system is also established. This paper greatly improves the work of Conrad and Morgül (1998), where the same results are obtained but for a very special case where $m = \alpha\beta$. Besides these results, the contributions of this paper lie in providing a very simple method which enables us (a) to obtain the asymptotic expressions of eigenvalues and eigenfunctions; (b) to avoid the usual treatment for "low" eigenfrequencies in applying Bari's theorem; and (c) to study potential applications to other problems of beam equations (see Guo and Chan, 2001).

6. Appendix. Abstract result on Riesz basis property. In this appendix, we present the abstract result together with a simplified proof about Riesz basis generation for discrete operators in the Hilbert spaces. This result is crucial to the establishment of the main results of the present paper.

Let us recall that for a closed linear operator A in a Hilbert space H, a nonzero $x \in H$ is called a generalized eigenvector of A, corresponding to an eigenvalue λ (with finite algebraic multiplicity) of A, if there is a positive integer n such that $(\lambda - A)^n x = 0$. Let $\overline{sp}(A)$, the so-called root subspace of A, be the closed subspace spanned by all generalized eigenvectors of A. The following theorem gives a simple characterization of the completeness of $\overline{sp}(A)$; that is, $\overline{sp}(A) = H$.

LEMMA 6.1. *Let A be a densely defined discrete operator (that is, there is a $\lambda \in \rho(A)$ such that $R(\lambda, A) = (\lambda - A)^{-1}$ is compact) in a Hilbert space H. Then $\overline{sp}(A) = H$ if and only if the codimension of $\overline{sp}(A)$ in H is finite.*

Proof. It is well known that the adjoint operator A^* of a densely defined discrete operator A is also a discrete operator. It follows from Lemma 5 on p. 2355 of Dunford and Schwartz (1971) that the following orthogonal decomposition holds:

$$H = \sigma_\infty(A^*) \oplus \overline{sp}(A),$$

where $\sigma_\infty(A^*) = \{x | E(\lambda)x = 0,\ \forall\lambda \in \sigma(A^*)\}, E(\lambda)$ is the eigen-projector of A^* corresponding to λ. Hence $\overline{sp}(A) = H$ if and only if $\sigma_\infty(A^*) = \{0\}$. On the other hand, Lemma 5 on p. 2295 of Dunford and Schwartz (1971) suggests that $\sigma_\infty(A^*)$ is either $\{0\}$ or infinite dimensional. Therefore the codimension of $\overline{sp}(A)$ is finite if and only if $\sigma_\infty(A^*) = \{0\}$. The proof is complete. □

LEMMA 6.2. *Let $\{\phi_n\}_1^\infty$ be a Riesz basis in a Hilbert space H. Let $\{\psi_n\}_{N+1}^\infty$ ($N \geq 0$) be another sequence in H. If*

$$\sum_{n=N+1}^{\infty} \| \phi_n - \psi_n \|^2 < \infty,$$

then there exists an $M \geq N$ such that $\{\phi_n\}_1^M \cup \{\psi_n\}_{M+1}^\infty$ is a Riesz basis of H. In particular, $\{\psi_n\}_{M+1}^\infty$ is ω-linearly independent.

Proof. The proof can follow from Corollary 11.4 on page 374 of Singer (1970).

THEOREM 6.3. *Let A be a densely defined discrete operator in a Hilbert space H. Let $\{\phi_n\}_1^\infty$ be a Riesz basis of H. If there are an integer $N \geq 0$ and a sequence of generalized eigenvectors $\{\psi_n\}_{N+1}^\infty$ of A such that*

$$\sum_{N+1}^{\infty} \|\phi_n - \psi_n\|^2 < \infty,$$

then the following hold.

(i) *There are a constant $M > N$ and generalized eigenvectors $\{\psi_{n0}\}_1^M$ of $\mathcal{A}$ such that $\{\psi_{n0}\}_1^M \cup \{\psi_n\}_{M+1}^\infty$ forms a Riesz basis of H.*

(ii) *Let $\{\psi_{n0}\}_1^M \cup \{\psi_n\}_{M+1}^\infty$ correspond to eigenvalues $\{\sigma_n\}_1^\infty$ of A. Then $\sigma(A) = \{\sigma_n\}_1^\infty$, where σ_n is counted according to its algebraic multiplicity.*

(iii) *If there is an* $M_0 > 0$ *such that* $\sigma_n \neq \sigma_m$ *for all* $m, n > M_0$, *then there is an* $N_0 > M_0$ *such that all* σ_n *are algebraically simple if* $n > N_0$. □

Proof. (ii) and (iii) are consequences of (i). Only proof of (i) is needed. By Lemma 6.2, there is an $M > N$ such that $\{\psi_n\}_{M+1}^{\infty}$ is ω-linearly independent. Let $\{\psi_\alpha\}$ be an arbitrary set such that $\{\psi_n\}_{M+1}^{\infty} \cup \{\psi_\alpha\}$ is a "maximal" ω-linearly independent set of generalized eigenvectors of A; that is, $\{\psi_n\}_{M+1}^{\infty} \cup \{\psi_\alpha\}$ is a ω-linearly independent subset of the set of the generalized eigenvectors of A, and for any generalized eigenvector ψ of A, the extended set $\{\psi_n\}_{M+1}^{\infty} \cup \{\psi_\alpha\} \cup \{\psi\}$ must not be ω-linearly independent anymore. Therefore, $\{\psi_n\}_{M+1}^{\infty} \cup \{\psi_\alpha\}$ spans the root subspace $\overline{sp}(A)$. By the assumption and Bari's theorem, the number of such ψ_α's does not exceed M. Let $\{\psi_\alpha\} = \{\psi_{n0}\}_1^L, L \leq M$. It follows from Theorem 3.2 of Rao (1997) that $\{\psi_{n0}\}_1^L \cup \{\psi_n\}_{M+1}^{\infty}$ forms a Riesz basis of $\overline{sp}(A)$.

On the other hand, by the assumption and Bari's theorem, the number of linearly independent elements in the orthogonal complement of $\overline{sp}(A)$ in H cannot exceed M, and hence the codimension of $\overline{sp}(A)$ is finite. Then from Lemma 6.1, $\overline{sp}(A) = H$.

Therefore, $\{\psi_{n0}\}_1^L \cup \{\psi_n\}_{M+1}^{\infty}$ forms a Riesz basis for the entire space H.

Since a "proper" subset of a basis can not be a basis, it follows from Bari's theorem and the assumption that $L = M$. This is (i). The proof is complete. □

ACHIEVING ARBITRARILY LARGE DECAY IN THE DAMPED WAVE EQUATION*

CARLOS CASTRO[†] AND STEVEN J. COX[‡]

Abstract. We exhibit a sequence of viscous dampings for the fixed string that yields arbitrarily fast attenuation of any and all initial disturbances. The limit case produces extinction of all solutions in finite time.

Key words. damped wave equation, decay rate

AMS subject classifications. 35P15, 35L05

1. Introduction.

The displacement u of a string of unit length, fixed at its ends, and in the presence of viscous damping $2a$, satisfies

$$\begin{aligned} &u_{tt}(x,t) - u_{xx}(x,t) + 2a(x)u_t(x,t) = 0, \quad 0 < x < 1, \quad 0 < t, \\ &u(0,t) = u(1,t) = 0, \quad 0 < t, \end{aligned} \tag{1.1}$$

upon being set in motion by the initial disturbance

$$u(x,0) = u_0(x), \quad u_t(x,0) = v_0(x). \tag{1.2}$$

If $a \in L^\infty(0,1)$ is nonnegative and strictly positive on some subinterval, then the energy

$$E(t) \equiv \int_0^1 u_x^2(x,t) + u_t^2(x,t)\,dx$$

is known to obey $E(t) \le CE(0)e^{2\omega t}$ for some finite $C > 0$ and $\omega < 0$, independent of the initial disturbance. The smallest such ω,

$$\omega(a) \equiv \inf\{\quad \begin{aligned} &\omega : \exists C(\omega) > 0 \text{ such that (s.t.) } E(t) \le CE(0)e^{2\omega t} \\ &\text{for every finite energy solution of (1.1)}\}, \end{aligned}$$

is referred to as the *decay rate* associated with a. If a is to be introduced in order to absorb an initial disturbance, then one naturally wishes to strike upon that a with the least possible (most negative) decay rate. The mathematical attraction here lies in the often noted fact that, with respect to damping, "more is not better." More precisely, for constant a, the decay rate is not a decreasing function of a. Rather, for small a, ω decreases until a reaches π, after which ω rapidly increases to 0. Our aim is to show that there exist nonconstant a that circumvent this phenomena of overdamping and hence that more indeed can be better.

Cox and Zuazua [3, Thm. 6.5] have shown that $a \mapsto \omega(a)$ attains its finite minimum over $\{a \in BV(0,1) : T(a) \leq M\}$, where $T(a)$ denotes the total variation of a. We show here that the total variation constraint is not superfluous. More precisely, we establish the following theorem.

THEOREM 1.1. *If $a_n(x) = 1/(x + 1/n)$, then $\omega(a_n) \to -\infty$ and $T(a_n) \to \infty$ as $n \to \infty$.*

This result is a dramatic improvement over previous attempts to minimize $a \mapsto \omega(a)$. In particular, Cox and Overton [2], based on the study of ω near $a = \pi$, conjectured that $\omega(\pi)$ may indeed be the minimum. Later on, Freitas [4] suggested a negative answer to the conjecture by numerical evidence based on the clever choices $a(x) = \pi(1 + \cos(2\pi x))/2$.

When $n \to \infty$, $a_n(x) \to 1/x \notin BV(0,1)$. In this case the solutions are extinct in finite time.

THEOREM 1.2. *If $a(x) = 1/x$, for any initial data $(u_0, u_1) \in H_0^1(0,1) \times L^2(0,1)$ the solution $u(x,t)$ of (1.1)–(1.2) satisfies*

$$u(x,t) = u_t(x,t) = 0 \qquad \forall t > 2. \tag{1.3}$$

The remainder of the paper is organized as follows. In section 2 we equate the decay rate with the spectral abscissa of the associated damped wave operator and express its shooting function in the case that $a(x) = 1/(x + c)$. In section 3, via simple calculus, we show that all zeros of the shooting function travel arbitrarily far to the left as c is made small. Finally, in section 4 we prove the result for the limit case $a(x) = 1/x$.

2. The shooting function.

For a of finite total variation Benaddi and Rao [1] have shown that $\omega(a)$ coincides with the *spectral abscissa*

$$\mu(a) = \sup\{\Re\lambda : \lambda \in \sigma(a)\},$$

where $\sigma(a)$ denotes the spectrum of the associated damped wave operator

$$\mathcal{A}(a) = \begin{pmatrix} 0 & I \\ d^2/dx^2 & -2a \end{pmatrix}, \qquad D(\mathcal{A}(a)) = (H^2(0,1) \cap H_0^1(0,1)) \times H_0^1(0,1).$$

If $V = [y, z]$ is an eigenvector of $\mathcal{A}(a)$ with eigenvalue λ, then $z = \lambda y$ and $y'' - 2az = \lambda z$, or

$$y'' - \lambda^2 y - 2a\lambda y = 0, \tag{2.1}$$

subject to

$$y(0) = y(1) = 0. \tag{2.2}$$

We adopt the shooting method for the study of (2.1)–(2.2). That is, we denote by $x \mapsto y_2(x, \lambda)$ the function that satisfies (2.1) and the initial conditions

$$y_2(0,\lambda) = 0 \quad \text{and} \quad y_2'(0,\lambda) = 1.$$

The eigenvalues are then simply the roots of $\lambda \mapsto y_2(1,\lambda)$. This gives the exact spectrum when a is constant (in which case y_2 may be obtained in closed form) and asymptotic results in general. In establishing such asymptotic results, Cox and Zuazua

[3, equation 5.3] observed that y_2 could also be simply expressed when the damping was of the particular form

$$a(x) = \frac{1}{x+c} \tag{2.3}$$

for any $c > 0$. In this case,

$$y_2(x,\lambda) = c(x+c)e^{\lambda x} \int_0^x \frac{e^{-2\lambda s}}{(s+c)^2}\, ds.$$

Hence the eigenvalues of $\mathcal{A}(a)$ are the zeros of the *shooting function* $\lambda \mapsto F(\lambda, c)$, where

$$F(\lambda, c) \equiv \int_0^1 \frac{e^{-2\lambda x}}{(x+c)^2}\, dx.$$

One first notices that $F(\cdot, c)$ has no real zeros, and hence the choice (2.3) is not thwarted by overdamping, even for small c. Second, we note that as c becomes small the integrand in F becomes large unless the real part of λ itself becomes quite (negatively) large. We devote the next section to a precise statement of the latter observation and the ensuing proof of Theorem 1.1.

3. Calculus lemmas.

We split F into its real and imaginary parts

$$F(\lambda, c) = \int_0^1 \frac{e^{\alpha x}\cos(\beta x)}{(x+c)^2}\, dx + i\int_0^1 \frac{e^{\alpha x}\sin(\beta x)}{(x+c)^2}\, dx,$$

where $\alpha = -2\Re\lambda$ and $\beta = -2\Im\lambda$, and we attack them separately.

LEMMA 3.1. *If $f \in L^\infty(0,1)$ is nonnegative and decreasing, then*

$$\int_0^1 f(x)\sin(\beta x)\, dx > 0 \qquad \forall\, \beta > 0. \tag{3.1}$$

Proof. For $\beta \le 2\pi$ the result is obvious. For larger β, let K be the greatest integer for which $2\pi K < \beta$, and write

$$\int_0^1 f(x)\sin(\beta x)\, dx = \int_0^{2\pi K/\beta} f(x)\sin(\beta x)\, dx + \int_{2\pi K/\beta}^1 f(x)\sin(\beta x)\, dx \equiv I_1 + I_2.$$

The first integral

$$\begin{aligned} I_1 &= \sum_{k=0}^{K-1} \int_{2\pi k/\beta}^{2\pi(k+1)/\beta} f(x)\sin(\beta x)\, dx \\ &= \sum_{k=0}^{K-1} \left[\int_{2\pi k/\beta}^{\pi(2k+1)/\beta} f(x)\sin(\beta x)\, dx + \int_{\pi(2k+1)/\beta}^{2\pi(k+1)/\beta} f(x)\sin(\beta x)\, dx \right] \\ &= \sum_{k=0}^{K-1} \int_{2\pi k/\beta}^{\pi(2k+1)/\beta} (f(x) - f(x+\pi/\beta))\sin(\beta x)\, dx > 0 \end{aligned}$$

because each integrand is positive.

Concerning I_2, if $(1-2\pi K/\beta) < \pi/\beta$, then the integrand is positive and so $I_2 > 0$. On the other hand, if $(1-2\pi K/\beta) \geq \pi/\beta$, we find

$$\begin{aligned} I_2 &= \int_{2\pi K/\beta}^{\pi(2K+1)/\beta} f(x)\sin(\beta x)\,dx + \int_{\pi(2K+1)/\beta}^{1} f(x)\sin(\beta x)\,dx \\ &= \int_{2\pi K/\beta}^{\pi(2K+1)/\beta} f(x)\sin(\beta x)\,dx - \int_{2\pi K/\beta}^{1-\pi/\beta} f(x+\pi/\beta)\sin(\beta x)\,dx \\ &= \int_{2\pi K/\beta}^{1-\pi/\beta} \{f(x)-f(x+\pi/\beta)\}\sin(\beta x)\,dx + \int_{1-\pi/\beta}^{\pi(2K+1)/\beta} f(x)\sin(\beta x)\,dx > 0. \qquad \square \end{aligned}$$

LEMMA 3.2. *If $\beta > 0$ and $g \in L^\infty(0,1)$ is nonnegative and strictly convex, then*

$$\int_0^{\pi(2J+1)/\beta} g(x)\sin(\beta x)\,dx > 0 \qquad \forall\, J \in \mathbb{N},\ s.t.\ \pi(2J+1) \leq \beta. \tag{3.2}$$

Proof. As g is strictly convex, either (i) g is decreasing, (ii) g is increasing, or (iii) there exists $x_0 \in (0,1)$ such that g is decreasing on $[0,x_0)$ and increasing on $(x_0,1]$.

In case (i) the result follows from Lemma 3.1. In case (ii)

$$\begin{aligned} \int_0^{\pi(2J+1)/\beta} g(x)\sin(\beta x)\,dx &= \int_0^{\pi(2J+1)/\beta} g(\pi(2J+1)/\beta - x)\sin(\pi(2J+1)-\beta x)\,dx \\ &= \int_0^{\pi(2J+1)/\beta} g(\pi(2J+1)/\beta - x)\sin(\beta x)\,dx, \end{aligned}$$

and we can apply again Lemma 3.1, as $f(x) = g(\pi(2J+1)/\beta - x)$ is decreasing. Regarding the third case, we write

$$\begin{aligned} \int_0^{\pi(2J+1)/\beta} g(x)\sin(\beta x)\,dx &= \int_0^{x_0} g(x)\sin(\beta x)\,dx + \int_{x_0}^{\pi(2J+1)/\beta} g(x)\sin(\beta x)\,dx \\ &= \int_0^{x_0} g(x)\sin(\beta x)\,dx + \int_0^{\pi(2J+1)/\beta - x_0} g(\pi(2J+1)/\beta - x)\sin(\beta x)\,dx, \end{aligned}$$

and we note that as g and $x \mapsto g(\pi(2J+1)/\beta - x)$ are decreasing on $(0,x_0)$ and $(0,\pi(2J+1)/\beta - x_0)$, respectively, we may apply the previous lemma to each and conclude positivity of the whole. $\square$

LEMMA 3.3. *Given $A > 0$, there exist $B_1 = B_1(A) > 0$ and $C_1 = C_1(A) > 0$ such that if $0 < \alpha \leq A$, $|\beta| \geq B_1$, and $c \leq C_1$, then*

$$\int_0^1 \frac{e^{\alpha x}\sin(\beta x)}{(x+c)^2}\,dx \neq 0. \tag{3.3}$$

Proof. We assume, without loss of generality, that $\beta > 0$. We decompose

$$\int_0^1 \frac{e^{\alpha x}\sin(\beta x)}{(x+c)^2}\,dx = \int_0^1 \frac{\sin(\beta x)}{(x+c)^2}\,dx + \int_0^1 \frac{(e^{\alpha x}-1)\sin(\beta x)}{(x+c)^2}\,dx \equiv I_1 + I_2$$

and estimate I_2 via

$$I_2 = \int_0^{\pi(2J+1)/\beta} \frac{(e^{\alpha x}-1)\sin(\beta x)}{(x+c)^2}\,dx + \int_{\pi(2J+1)/\beta}^1 \frac{(e^{\alpha x}-1)\sin(\beta x)}{(x+c)^2}\,dx, \tag{3.4}$$

where J is the greatest integer such that $\pi(2J+1) \le \beta$. The first integral in (3.4) is positive, via Lemma 3.2, thanks to the convexity of $x \mapsto (e^{\alpha x}-1)(x+c)^{-2}$ on $[0,1]$ when α and c are positive. Concerning the second integral in (3.4) as

$$\left|\int_{\pi(2J+1)/\beta}^{1} \frac{(e^{\alpha x}-1)\sin(\beta x)}{(x+c)^2}\,dx\right| \le \frac{(1-\pi(2J+1)/\beta)(1+e^{\alpha})}{(\pi(2J+1)/\beta+c)^2} \le \frac{2\pi}{\beta}\frac{(1+e^{\alpha})}{(c+1-2\pi/\beta)^2},$$

it follows that

$$I_2 \ge -\frac{2\pi(1+e^{\alpha})}{\beta(c+1-2\pi/\beta)^2}. \tag{3.5}$$

We now estimate I_1. Integrating by parts, we easily obtain

$$\beta\int_0^1 \frac{\sin(\beta x)}{(x+c)^2}\,dx = \frac{1}{c^2} - \frac{\cos(\beta)}{(1+c)^2} - 2\int_0^1 \frac{\cos(\beta x)}{(x+c)^3}\,dx. \tag{3.6}$$

The third term in this expression can be bounded by

$$-2\int_0^1 \frac{\cos(\beta x)}{(x+c)^3}\,dx > -2\int_0^{\pi/2\beta} \frac{\cos(\beta x)}{(x+c)^3}\,dx \tag{3.7}$$

for

$$-2\int_{\pi/2\beta}^1 \frac{\cos(\beta x)}{(x+c)^3}\,dx = 2\int_0^{1-\pi/2\beta} \frac{\sin(\beta x)}{(x+\pi/2\beta+c)^3}\,dx > 0,$$

thanks to Lemma 3.1 and the decreasing nature of $x \mapsto (x+\pi/2\beta+c)^{-3}$. Returning to (3.7), we find

$$-2\int_0^1 \frac{\cos(\beta x)}{(x+c)^3}\,dx > -2\int_0^{\pi/2\beta} \frac{1}{(x+c)^3}\,dx = \frac{1}{(\pi/2\beta+c)^2} - \frac{1}{c^2}.$$

Using this in (3.6) brings

$$\beta\int_0^1 \frac{\sin(\beta x)}{(x+c)^2}\,dx \ge \frac{1}{(\pi/2\beta+c)^2} - \frac{\cos(\beta)}{(1+c)^2} \ge \frac{1}{(\pi/2\beta+c)^2} - \frac{1}{(1+c)^2}.$$

From this and (3.5) we finally deduce

$$\int_0^1 \frac{e^{\alpha x}\sin(\beta x)}{(x+c)^2}\,dx = I_1 + I_2 \ge \frac{1}{\beta}\left[\frac{1}{(\pi/2\beta+c)^2} - \frac{1}{(1+c)^2} - \frac{2\pi(1+e^{\alpha})}{(c+1-2\pi/\beta)^2}\right].$$

Note that we can choose $C(A)$ and $B_1(A)$ such that the term in the brackets is strictly positive when $0 < c < C(A)$, $\beta \ge B_1(A)$, and $0 < \alpha \le A$. □

Lemma 3.4. *Given positive A and B, there exists a constant $C_2 = C_2(A,B) > 0$ such that if $0 < \alpha \le A$, $|\beta| \le B$, and $c \le C_2$, then*

$$\int_0^1 \frac{e^{\alpha x}\cos(\beta x)}{(x+c)^2}\,dx > 0. \tag{3.8}$$

Proof. Assume that $0 \le \alpha \le A$ and $|\beta| \le B$. Integrating by parts, we obtain

$$\begin{aligned}\int_0^1 \frac{e^{\alpha x}\cos(\beta x)}{(x+c)^2}\,dx &= \frac{1}{c} - \frac{e^{\alpha}\cos(\beta)}{(1+c)} - \beta\int_0^1 \frac{e^{\alpha x}\sin(\beta x)}{(x+c)}\,dx + \alpha\int_0^1 \frac{e^{\alpha x}\cos(\beta x)}{(x+c)}\,dx\\ &= \frac{1}{c} - \frac{e^{\alpha}\cos(\beta)}{(1+c)} - \beta\int_0^1 \frac{e^{\alpha x}\sin(\beta x)}{(x+c)}\,dx\\ &\quad + \alpha\int_0^1 \frac{(e^{\alpha x}-1)\cos(\beta x)}{(x+c)}\,dx + \alpha\int_0^1 \frac{\cos(\beta x)}{(x+c)}\,dx\\ &\equiv M_1 + M_2 + M_3 + M_4 + M_5. \end{aligned} \tag{3.9}$$

Note that the terms $|M_2|, |M_3|$, and $|M_4|$ remain uniformly bounded as $c \to 0$ for all $0 \le \alpha \le A$ and $|\beta| \le B$. Concerning M_5, we have

$$M_5 = \alpha\int_0^1 \frac{\cos(\beta x)}{(x+c)}\,dx = \alpha\left[\cos(\beta)\log(1+c) - \log(c) - \beta\int_0^1 \sin(\beta x)\log(x+c)\,dx\right],$$

which is clearly positive if c is small enough. Therefore, due to the M_1 term, we can choose C sufficiently small so that (3.9) is positive for all $c \le C$. □

Let us now deduce Theorem 1.1 from these last two lemmas. For $A > 0$ we choose

$$C(A) \equiv \min\{C_1(A), C_2(A, B_1)\},$$

where B_1 and C_1 are the constants of Lemma 3.3 and C_2 is the constant of Lemma 3.4. Now, if $0 < \alpha \le A$, then either (3.8) or (3.3) holds, depending on the size of β. As a result, if $c < C(A)$, then all zeros of $\lambda \mapsto F(\lambda, c)$ must lie in the half-space $\Re\lambda \le -A/2$. As A was arbitrary, we may indeed, via (2.3), produce arbitrarily large decay. As A approaches ∞, we note that $C(A)$ decreases to 0 and so the total variation of $1/(x+c)$ approaches ∞.

4. The limit case $a(x) = 1/x$. In this section we prove the extinction result stated in Theorem 1.2. For the sake of simplicity we present here a formal argument. The rigorous proof can be achieved in a standard way.

Consider the limit damped wave equation

$$\begin{cases} u_{tt}(x,t) - u_{xx}(x,t) + \frac{2}{x}u_t(x,t) = 0, \quad 0 < x < 1, \quad t > 0,\\ u(0,t) = u(1,t) = 0,\\ u(x,0) = u_0, \quad u_t(x,0) = u_1. \end{cases} \tag{4.1}$$

We introduce the Laplace transform

$$\mathcal{L}\{u\}(\tau) = U(x,\tau) = \int_0^\infty e^{-\tau t}u(x,t)dt. \tag{4.2}$$

When applying the Laplace transform to (4.1), we obtain

$$\begin{cases} \tau^2 U - U_{xx} + \tau\frac{2}{x}U = \tau u_0(x) + u_1(x) + \frac{2}{x}u_0(x),\\ U(0,\tau) = U(1,\tau) = 0. \end{cases} \tag{4.3}$$

Observe that

$$U(x,\tau) = xe^{\tau x} \tag{4.4}$$

is a solution of the homogeneous equation associated to (4.3):

$$\tau^2 U - U_{xx} + \tau \frac{2}{x} U = 0. \tag{4.5}$$

We look for the solution of (4.3) via reduction of order, i.e., we assume that

$$U(x,\tau) = xe^{\tau x} v(x,\tau). \tag{4.6}$$

Then $v(x,\tau)$ must satisfy

$$\left\{ \begin{array}{l} xv_{xx} + v_x\left(2 + 2\tau x\right) = -e^{-\tau x}\left(\tau u_0 + u_1 + \frac{2u_0}{x}\right), \\ v(1,\tau) = 0, \\ \lim_{x\to 0} |v(x,\tau)| < \infty. \end{array} \right. \tag{4.7}$$

Hence

$$\begin{aligned} (v_x x^2 e^{-2\tau(1-x)})_x &= -xe^{-2\tau(1-x)} e^{-\tau x}\left(\tau u_0 + u_1 + \frac{2u_0}{x}\right), \\ v &= \int_x^1 \frac{1}{r^2} e^{2\tau(1-r)} \int_0^r s e^{-\tau(2-s)} \left(\tau u_0(s) + u_1(s) + \frac{2u_0(s)}{s}\right) ds dr, \end{aligned}$$

$$U = xe^{\tau x} \int_x^1 \frac{1}{r^2} e^{2\tau(1-r)} \int_0^r s e^{-\tau(2-s)} \left(\tau u_0(s) + u_1(s) + \frac{2u_0(s)}{s}\right) ds dr. \tag{4.8}$$

In order to invert the Laplace transform, we simplify the term in the form $\tau e^{\tau\alpha}$. Integrating by parts, we have

$$\begin{aligned} \int_0^r s e^{-\tau(2-s)} \tau u_0(s) ds = \int_0^r s u_0(s) \frac{d}{ds} e^{-\tau(2-s)} ds &= s u_0(s) e^{-\tau(2-s)} \Big]_0^r \\ &\quad - \int_0^r e^{-\tau(2-s)} \left(s u_0' + u_0\right) ds \\ &= r u_0(r) e^{-\tau(2-r)} - \int_0^r e^{-\tau(2-s)} \left(s u_0' + u_0\right) ds. \end{aligned} \tag{4.9}$$

Substituting in (4.8), we have

$$\begin{aligned} U &= xe^{\tau x} \int_x^1 \frac{1}{r} e^{2\tau(1-r)} u_0(r) e^{-\tau(2-r)} dr \\ &\quad + xe^{\tau x} \int_x^1 \frac{1}{r^2} e^{2\tau(1-r)} \int_0^r e^{-\tau(2-s)} \left(-s u_0'(s) + u_0(s) + s u_1(s)\right) ds dr. \end{aligned} \tag{4.10}$$

Now we apply the inverse Laplace transform $\mathcal{L}^{-1}$ to obtain u:

$$\begin{aligned} u(x,t) = \mathcal{L}^{-1}\{U\}(x,t) &= x \int_x^1 \frac{1}{r} u_0(r) \mathcal{L}^{-1}\{e^{\tau(x-r)}\} dr \\ &\quad + x \int_x^1 \frac{1}{r^2} \int_0^r \left(-s u_0'(s) + u_0(s) + s u_1(s)\right) \mathcal{L}^{-1}\{e^{\tau(x-2r+s)}\} ds dr \\ &= x \int_x^1 \frac{1}{r} u_0(r) \delta(t - r + x) dr \\ &\quad + x \int_x^1 \frac{1}{r^2} \int_0^r \left(-s u_0'(s) + u_0(s) + s u_1(s)\right) \delta(t - 2r + x + s) ds dr. \end{aligned} \tag{4.11}$$

Here $\delta(x)$ represents the Dirac delta at $x = 0$.

Once we have an explicit formula for the solution of (4.1), we easily prove the theorem.

Assume that $t > 2$. We have

$$t + x > 1,$$

and the first integral in (4.11) is zero due to the fact that the support of $\delta(t - r + x)$ is not in the domain of the integral. Moreover,

$$2r - x - t < 0$$

(because $r - x < 1$ and $r - t < 1 - 2 = -1$), and the second integral in (4.11) is also zero.

Acknowledgment. The first author is grateful to J. J. L. Velazquez for some fruitful discussions and comments related with this work.

THE TOPOLOGICAL ASYMPTOTIC FOR PDE SYSTEMS: THE ELASTICITY CASE*

STÉPHANE GARREAU[†], PHILIPPE GUILLAUME[‡], AND MOHAMED MASMOUDI[§]

Abstract. The aim of the topological sensitivity analysis is to obtain an asymptotic expansion of a design functional with respect to the creation of a small hole. In this paper, such an expansion is obtained and analyzed in the context of linear elasticity for general functionals and arbitrary shaped holes by using an adaptation of the adjoint method and a domain truncation technique. The method is general and can be easily adapted to other linear PDEs and other types of boundary conditions.

Key words. topological sensitivity, topological derivative, shape optimization, design sensitivity, elasticity, compliance

1. Introduction.

The goal of topological optimization is to find an optimal design with an a priori poor information on the optimal shape of the structure. Unlike the case of classical shape optimization, the topology of the structure may change during the optimization process, as, for example, through the inclusion of holes.

Most of the known results concern structural mechanics. Classical topology optimization involves relaxed formulations and homogenization (see, e.g., [1, 19, 3, 12]). This approach leads us to introduce some microstructures. In the case of compliance (external work) minimization under a volume constraint, a class of laminated materials is exhibited, together with an explicit expression of the optimal material at each point of the structure. Such a method has two drawbacks.

- The optimal solution is not a classical design: it is a quasi-uniform distribution of composite materials. Then some penalization methods must be applied to retrieve a realistic shape.
- Optimization of a criterion like Von Mises stress via homogenization seems to be a difficult task.

For this latter reason, global optimization techniques like genetic algorithms or simulated annealing have been proposed (see, e.g., [22]), but these methods have a high computational cost and can hardly be applied to industrial problems.

Another approach instigated by the work of Schumacher [21] is presented and analyzed in this paper. The shape optimization problem consists in minimizing a functional $j(\Omega) = J(\Omega, u_\Omega)$, where the displacement u_Ω is defined on a variable open and bounded subset Ω of $\mathbb{R}^n$, $n = 2$ or 3. For $\rho > 0$, let $\Omega_\rho = \Omega \backslash \overline{(x_0 + \rho\omega)}$ be the set obtained by removing a small part $x_0 + \rho\omega$ from Ω, where $x_0 \in \Omega$ and $\omega \subset \mathbb{R}^n$ are a fixed open and bounded subset containing the origin. Then, an asymptotic expansion

of the function j can be obtained in the following form:

$$j(\Omega_\rho) = j(\Omega) + f(\rho)g(x_0) + o(f(\rho)), \qquad \lim_{\rho\to 0} f(\rho) = 0, \quad f(\rho) > 0. \tag{1.1}$$

The "topological sensitivity" $g(x_0)$ provides an information for creating a small hole located at x_0. Hence the function g can be used like a descent direction in an optimization process. The physical meaning of creating a hole depends on the boundary condition which is imposed on its boundary.

- A homogeneous Neumann boundary condition means that $x_0 + \rho\omega$ represents a perforation, i.e., a lack of material.
- A homogeneous Dirichlet boundary condition means that $x_0 + \rho\omega$ represents a weld or a rivet. This kind of boundary condition is difficult to handle by classical homogenization methods.

Schumacher [21] introduced the topological sensitivity in the case of compliance minimization. Next, Sokolowski and Żochowski [23] generalized it to a class of functionals in the plane stress case with a homogeneous Neumann condition imposed on the boundary of a circular hole. A topological sensitivity framework using an adaptation of the adjoint method and a truncation technique has been introduced in [17] in the case of a homogeneous Dirichlet condition imposed on the boundary of a circular hole (see also [6]). The fundamental property of an adjoint technique is to provide the variation of a function with respect to a parameter by using a solution u_Ω and an adjoint state v_Ω which do not depend on the chosen parameter. Numerically, it means that only two systems must be solved for obtaining the discrete approximation of $g(x)$ for all $x \in \Omega$. In [10], the topological sensitivity has been derived for a large class of problems, functionals, and boundary conditions on a circular hole $x_0 + \rho\omega$. For example, in linear elasticity the first variation of the function j reads

$$\begin{aligned} j(\Omega_\rho) - j(\Omega) = -\frac{\pi(\lambda+2\mu)}{\mu(9\lambda+14\mu)} &\{20\mu\sigma(u_\Omega) : \varepsilon(v_\Omega) \\ &+(3\lambda-2\mu)\mathrm{tr}\,\sigma(u_\Omega)\,\mathrm{tr}\,\varepsilon(v_\Omega)\}\rho^3 \; + o(\rho^3) \end{aligned} \tag{1.2}$$

for a three-dimensional (3D) Neumann boundary condition on the hole. In the case of a 3D Dirichlet boundary condition, the variation becomes

$$j(\Omega_\rho) - j(\Omega) = \frac{12\pi\mu(\lambda+2\mu)}{2\lambda+5\mu}\, u_\Omega . v_\Omega\, \rho + o(\rho). \tag{1.3}$$

In [23, 14], only variations in $O(\rho^n)$, that is, proportional to the volume of the hole, were considered. One can observe here that other behaviors may occur, depending on the boundary condition which is imposed on the hole.

In this paper is presented the mathematical analysis of the topological sensitivity in the case of general functionals and arbitrary shaped holes. For example, optimization of a criterion like Von Mises stress can be handled by this method. The case of arbitrary shaped holes can be interesting for the identification of cracks. The equations which are here considered are those of linear elasticity, with a Neumann boundary condition on the hole. However, the method is general and can be adapted without any significant modification to many other equations like Stokes or Helmholtz equations. For these equations, the natural boundary condition on the hole is a Dirichlet condition for which the analysis is very similar to the one presented here.

First, an adaptation of the adjoint method to the topological context [17] is developed in section 2. Next, the elasticity problem, the truncation method for simulating the creation of a hole, and the main result are presented in section 3. In the case of a circular or spherical hole, explicit expressions of the topological sensitivity are given for both Dirichlet and Neumann boundary conditions and dimension $n = 2$ or 3. Section 4 is devoted to the proof of the main result presented in section 3. Finally, section 5 describes a topology optimization algorithm illustrated by some numerical examples.

2. A generalized adjoint method.

In this section, the adjoint method [4] is adapted to the topology optimization [17, 10]. Let $\mathcal{V}$ be a fixed Hilbert space. For $\rho \geq 0$, let a_ρ be a bilinear, symmetric, uniformly continuous, and coercive form on $\mathcal{V}$, and let l_ρ be a linear and uniformly continuous form on $\mathcal{V}$. That is, there exist constants $\alpha > 0$, $M > 0$, and $L > 0$ independent of ρ such that for all $\rho \geq 0$,

$$\begin{aligned} a_\rho(u,v) &\leq M\|u\|\,\|v\| \qquad \forall u,\, v \in \mathcal{V}, \\ a_\rho(u,u) &\geq \alpha\|u\|^2 \qquad \forall u \in \mathcal{V}, \\ |l_\rho(v)| &\leq L\|v\| \qquad \forall v \in \mathcal{V}. \end{aligned}$$

We assume in this section that there exist a bilinear and continuous form δ_a, a linear and continuous form δ_l, and a real function $f(\rho) > 0$ defined on $\mathbb{R}_+$ such that

$$\lim_{\rho\to 0} f(\rho) = 0, \tag{2.1}$$

$$\|a_\rho - a_0 - f(\rho)\delta_a\|_{\mathcal{L}_2(\mathcal{V})} = o(f(\rho)), \tag{2.2}$$

$$\|l_\rho - l_0 - f(\rho)\delta_l\|_{\mathcal{L}(\mathcal{V})} = o(f(\rho)), \tag{2.3}$$

where $\mathcal{L}(\mathcal{V})$ (respectively, $\mathcal{L}_2(\mathcal{V})$) denotes the space of continuous and linear (respectively, bilinear) forms on $\mathcal{V}$. It will be shown in section 4 that this assumption is fulfilled in the topology optimization context. The same function f is used here for both asymptotics (2.2)–(2.3). It does not exclude the case where $a_\rho - a_0$ and $l_\rho - l_0$ have different behaviors $O(f_1(\rho))$ and $O(f_2(\rho))$, in which case f is chosen to be the "slowest" between f_1 and f_2; that is, $f_i(\rho) = O(f(\rho))$, $i = 1, 2$.

For $\rho \geq 0$, let u_ρ be the solution to the problem: find $u_\rho \in \mathcal{V}$ such that

$$a_\rho(u_\rho, v) = l_\rho(v) \qquad \forall v \in \mathcal{V}. \tag{2.4}$$

LEMMA 2.1. *For $\rho \geq 0$, this problem has a unique solution u_ρ, and*

$$\|u_\rho - u_0\| = O(f(\rho)).$$

Proof. It follows from the coercivity of a_ρ that

$$\alpha\|u_\rho - u_0\|^2 \leq a_\rho(u_\rho - u_0, u_\rho - u_0), \tag{2.5}$$

which implies

$$\begin{aligned} \alpha\|u_\rho - u_0\|^2 &\leq a_\rho(u_\rho, u_\rho - u_0) - a_\rho(u_0, u_\rho - u_0) \\ &= l_\rho(u_\rho - u_0) - a_\rho(u_0, u_\rho - u_0) \\ &= l_0(u_\rho - u_0) + (l_\rho - l_0)(u_\rho - u_0) - a_\rho(u_0, u_\rho - u_0) \\ &= a_0(u_0, u_\rho - u_0) - a_\rho(u_0, u_\rho - u_0) + (l_\rho - l_0)(u_\rho - u_0) \\ &= f(\rho)(\delta_a(u_0, u_\rho - u_0) + \delta_l(u_\rho - u_0)) + (\|u_0\| + 1)\,\|u_\rho - u_0\|\,o(f(\rho)). \qquad \square \end{aligned}$$

Now consider a function $j(\rho) = J_\rho(u_\rho)$, where J_0 is differentiable with respect to u, its derivative being denoted by $DJ(u)$. Moreover, we suppose that there exists a function δ_J defined on $\mathcal{V}$ such that

$$J_\rho(v) - J_0(u) = DJ(u)(v-u) + f(\rho)\delta_J(u) + o(\|v-u\| + f(\rho)). \tag{2.6}$$

This expression looks like a first order derivative and would be, in fact, the first order derivative of the function $\mathcal{J}(s,u)$ defined by $\mathcal{J}(s,u) := J_{f^{-1}(s)}(v) - J_0(u)$ with the change of variable $s = f(\rho)$.

Next, the Lagrangian $\mathcal{L}$ [4] is defined by

$$\mathcal{L}_\rho(u,v) = J_\rho(\,u) + a_\rho(u,v) - l_\rho(v) \qquad \forall u,v \in \mathcal{V}. \tag{2.7}$$

Its variation with respect to ρ is given by

$$\delta_{\mathcal{L}}(u,v) = \delta_J(u) + \delta_a(u,v) - \delta_l(v),$$

and we have

$$\mathcal{L}_\rho(u,v) - \mathcal{L}_0(u,v) = f(\rho)\delta_{\mathcal{L}}(u,v) + o(f(\rho)).$$

THEOREM 2.2. *The function j has the asymptotic expansion*

$$j(\rho) = j(0) + f(\rho)\delta_{\mathcal{L}}(u_0,v_0) + o(f(\rho)), \tag{2.8}$$

where v_0 is the solution to the adjoint problem: find $v_0 \in \mathcal{V}$ such that

$$a_0(w,v_0) = -DJ(u_0)w \qquad \forall w \in \mathcal{V}. \tag{2.9}$$

Proof. For all $v \in \mathcal{V}$, one has

$$j(\rho) = \mathcal{L}_\rho(u_\rho, v).$$

Hence

$$\begin{aligned} j(\rho) - j(0) &= \mathcal{L}_\rho(u_\rho,v) - \mathcal{L}_0(u_0,v),\\ &= a_\rho(u_\rho,v) - a_0(u_0,v) + J_\rho(u_\rho) - J_0(u_0) - l_\rho(v) + l_0(v). \end{aligned}$$

It follows from (2.6) and Lemma 2.1 that

$$J_\rho(\,u_\rho) - J_0(u_0) = DJ(u_0)(u_\rho - u_0) + f(\rho)\delta_J(u_0) + o(f(\rho)).$$

Next, choosing v_0 as the solution to (2.9), we obtain with (2.3)

$$\begin{aligned} j(\rho) - j(0) &= a_\rho(u_\rho,v_0) - a_0(u_0,v_0) + DJ(u_0)(u_\rho - u_0)\\ &\quad + f(\rho)(\delta_J(u_0) - \delta_l(v_0)) + o(f(\rho))\\ &= a_\rho(u_\rho,v_0) - a_0(u_\rho,v_0) + a_0(u_\rho - u_0, v_0) + DJ(u_0)(u_\rho - u_0)\\ &\quad + f(\rho)(\delta_J(u_0) - \delta_l(v_0)) + o(f(\rho))\\ &= a_\rho(u_\rho,v_0) - a_0(u_\rho,v_0) + f(\rho)(\delta_J(u_0) - \delta_l(v_0)) + o(f(\rho)). \end{aligned}$$

Then, it follows from (2.1), (2.2), and Lemma 2.1 (with $||u_\rho||$ bounded) that

$$\begin{aligned} j(\rho) - j(0) &= f(\rho)\delta_a(u_\rho,v_0) + f(\rho)(\delta_J(u_0) - \delta_l(v_0)) + o(f(\rho))\\ &= f(\rho)(\delta_a(u_0,v_0) + \delta_a(u_\rho - u_0, v_0)) + f(\rho)(\delta_J(u_0) - \delta_l(v_0)) + o(f(\rho))\\ &= f(\rho)\delta_{\mathcal{L}}(u_0,v_0) + o(f(\rho)). \qquad \square \end{aligned}$$

3. The elasticity problem.

Let Ω be an open and bounded subset of $\mathbb{R}^n$, $n = 2$ or 3. The linear elasticity problem [7, 13] is the following: find u_Ω such that

$$\left\{\begin{array}{rcll} -\mathrm{div}\,\sigma(u_\Omega) & = & 0 & \text{in } \Omega, \\ \sigma(u_\Omega)\mathbf{n} & = & F & \text{on } \Gamma_N, \\ u_\Omega & = & 0 & \text{on } \Gamma_D, \end{array}\right. \tag{3.1}$$

where the strain tensor ε and the stress tensor σ are given by

$$\begin{aligned} \sigma_{ij}(u) &= \lambda \mathrm{div}\, u\, \delta_{ij} + 2\mu\varepsilon_{ij}(u), \\ \varepsilon_{ij}(u) &= \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right), \qquad 1 \le i, \quad j \le n. \end{aligned}$$

Here δ_{ij} is the Kronecker symbol, and $\mathbf{n}$ denotes the outward normal to the boundary $\Gamma = \Gamma_D \cup \Gamma_N$, where Γ_D and Γ_N have both a nonnegative Lebesgue measure and $\Gamma_D \cap \Gamma_N = \emptyset$. More general stress tensors of the form $\sigma_{ij}(u) = H_{ij}^{kl}\varepsilon_{kl}(u)$ could be considered without any major modifications. Equations (3.1) describe the displacement u_Ω of an isotropic solid which is loaded by a surface traction F on Γ_N and which is clamped on Γ_D. For simplicity, no volume forces are considered.

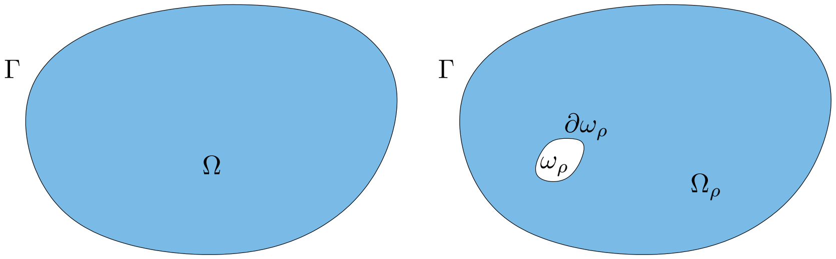

FIG. 3.1. *The initial domain and the same domain after the perforation.*

For a given $x_0 \in \Omega$, consider the perforated open set $\Omega_\rho = \Omega \backslash \overline{\omega_\rho}$, $\omega_\rho = x_0 + \rho\omega$, where $\omega \subset \mathbb{R}^n$ is a fixed open and bounded set containing the origin ($\omega_\rho = \emptyset$ if $\rho = 0$), whose boundary $\partial\omega$ is connected and piecewise of class $\mathcal{C}^1$ (see Figure 3.1). The new displacement u_{Ω_ρ} is the solution to the problem: find u_{Ω_ρ} such that

$$\left\{\begin{array}{rcll} -\mathrm{div}\,\sigma(u_{\Omega_\rho}) & = & 0 & \text{in } \Omega_\rho, \\ \sigma(u_{\Omega_\rho})\mathbf{n} & = & F & \text{on } \Gamma_N, \\ u_{\Omega_\rho} & = & 0 & \text{on } \Gamma_D, \\ \sigma(u_{\Omega_\rho})\mathbf{n} & = & 0 & \text{on } \partial\omega_\rho. \end{array}\right. \tag{3.2}$$

Note that for $\rho = 0$, one has $u_{\Omega_0} = u_\Omega$.

In the context of identification of conductivity imperfections, the asymptotic behavior of a voltage potential $u_{\Omega_\rho} - u_\Omega$ has been studied in [24, 25] for the Laplace equation. In that context, a new variation of u_Ω is computed for each new location of a hole. This method is usually referred to as the direct method. An alternative to this method is to use the adjoint technique. In this case, it is not necessary to compute the variation of u_Ω in order to obtain the variation of a cost function; only an adjoint state must be evaluated, which is independent of the location of the hole.

The displacement u_{Ω_ρ} is defined on the variable domain Ω_ρ; thus it belongs to a functional space which depends on ρ. Hence if we want to derive the asymptotic expansion of a function of the form

$$j(\rho) = \widetilde{J}(u_{\Omega_\rho}), \tag{3.3}$$

we cannot apply directly the tools of section 2, which require a fixed functional space.

In classical shape optimization, this requirement can be satisfied with the help of a domain parameterization technique [18, 16, 11]. This technique involves a fixed domain and a bi-Lipshitz map between this domain and the modified one. In the topology optimization context, such a map does not exist between Ω and Ω_ρ. However, a functional space independent of ρ can be constructed by using a domain truncation technique. Let $R > 0$ be such that the open ball $B(x_0, R)$ is included in Ω. Then the truncated open set Ω_R (see Figure 3.2) is defined by

$$\Omega_R = \Omega \setminus \overline{B(x_0, R)}.$$

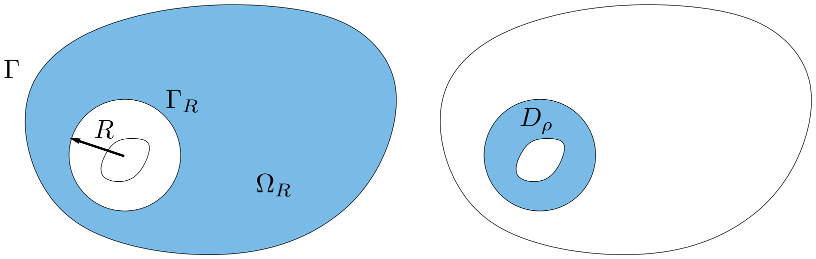

Fig. 3.2. *The truncated domain.*

In section 3.1 are defined

- a Hilbert space $\mathcal{V}_R$ independent of ρ,
- a $\mathcal{V}_R$-elliptic bilinear and continuous form a_ρ, and
- a linear and continuous form l,

such that the solution u_ρ to the equation

$$a_\rho(u_\rho, v) = l(v) \qquad \forall v \in \mathcal{V}_R$$

is equal to the restriction of u_{Ω_ρ} to Ω_R. A bilinear form δ_a satisfying (2.2) will be obtained in section 4, from which the asymptotic expansion of the cost function will be derived by using the framework described in section 2. As no volume forces are considered, we have $\delta_l \equiv 0$. The main result is presented in section 3.2, and the particular case of a spherical hole is detailed in section 3.3.

3.1. Truncation. The open set $B(x_0, R) \setminus \overline{\omega_\rho}$ is denoted by D_ρ (see Figure 3.2). For $\varphi \in H^{1/2}(\Gamma_R)^n$ and $\rho > 0$, let u_ρ^φ be the solution to the problem: find u_ρ^φ such that

$$\left\{ \begin{array}{rcll} -\operatorname{div} \sigma(u_\rho^\varphi) & = & 0 & \text{in } D_\rho, \\ u_\rho^\varphi & = & \varphi & \text{on } \Gamma_R, \\ \sigma(u_\rho^\varphi)\mathbf{n} & = & 0 & \text{on } \partial\omega_\rho, \end{array} \right. \tag{3.4}$$

where Γ_R is the boundary of $B(x_0, R)$. The normal $\mathbf{n}$ is chosen outward to D_ρ on $\partial\omega_\rho$ and Γ_R, regardless of whether D_ρ or Ω_R are considered. For $\rho = 0$, the function u_0^φ is the solution to

$$\left\{ \begin{array}{rcll} -\operatorname{div} \sigma(u_0^\varphi) & = & 0 & \text{in } B(x_0, R), \\ u_0^\varphi & = & \varphi & \text{on } \Gamma_R. \end{array} \right. \tag{3.5}$$

For $\rho \geq 0$, the Dirichlet-to-Neumann operator T_ρ is defined by

$$\begin{array}{rcl} T_\rho : H^{1/2}(\Gamma_R)^n & \longrightarrow & H^{-1/2}(\Gamma_R)^n, \\ \varphi & \longmapsto & T_\rho \varphi = \sigma(u_\rho^\varphi)\mathbf{n}. \end{array}$$

One can observe that the null space of T_ρ consists in the constant functions. Finally, the displacement u_ρ is defined for $\rho \geq 0$ as the solution to the truncated problem: find u_ρ such that

$$\left\{ \begin{array}{rcll} -\operatorname{div} \sigma(u_\rho) & = & 0 & \text{in } \Omega_R, \\ \sigma(u_\rho)\mathbf{n} & = & F & \text{on } \Gamma_N, \\ u_\rho & = & 0 & \text{on } \Gamma_D, \\ \sigma(u_\rho)\mathbf{n} & = & T_\rho u_\rho & \text{on } \Gamma_R. \end{array} \right. \tag{3.6}$$

The variational formulation associated to problem (3.6) is the following: find $u_\rho \in \mathcal{V}_R$ such that

$$a_\rho(u_\rho, v) = l(v) \qquad \forall v \in \mathcal{V}_R,$$

where the functional space $\mathcal{V}_R$, the bilinear form a_ρ, and the linear form l are defined by

$$\begin{aligned} \mathcal{V}_R &= \left\{ u \in H^1(\Omega_R)^n,\ u = 0 \text{ on } \Gamma_D \right\}, \\ a_\rho(u, v) &= \int_{\Omega_R} \sigma(u) : \varepsilon(v)\, dx + \int_{\Gamma_R} T_\rho u.v \, d\gamma(x), \\ l(v) &= \int_{\Gamma_N} F.v \, d\gamma(x). \end{aligned} \tag{3.7}$$

Here $x.y$ denotes the usual dot product of $\mathbb{R}^n$, $\sigma : \varepsilon = \sum_{i,j=1}^n \sigma_{ij}\varepsilon_{ij}$, and $d\gamma(x)$ is the Lebesgue measure on the boundary. Symmetry, continuity, and coercivity of a_ρ follow directly from

$$\int_{\Gamma_R} T_\rho \varphi.\psi \, d\gamma(x) = \int_{D_\rho} \sigma(u_\rho^\varphi) : \varepsilon(u_\rho^\psi)\, dx.$$

The following result is standard in PDE theory.

Proposition 3.1. *Problems* (3.2) *and* (3.6) *have a unique solution. Moreover, the restriction to* Ω_R *of the solution* u_{Ω_ρ} *to problem* (3.2) *is the solution* u_ρ *to problem* (3.6).

We have now at our disposal the fixed Hilbert space $\mathcal{V}_R$ required by section 2. Function (3.3) can be redefined in the following way: for $u \in \mathcal{V}_R$, let $\widetilde{u} \in H^1(\Omega_\rho)^n$ be the extension of u which coincides with u on Ω_R and Γ_R and which satisfies $\operatorname{div} \sigma(\widetilde{u}) = 0$ on D_ρ, $\sigma(\widetilde{u})\mathbf{n} = 0$ on $\partial\omega_\rho$. Then a function J_ρ can be defined on $\mathcal{V}_R$ by

$$J_\rho(u) = \widetilde{J}(\widetilde{u}). \tag{3.8}$$

In particular, it follows from the previous proposition that

$$j(\rho) = \widetilde{J}(u_{\Omega_\rho}) = J_\rho(u_\rho). \tag{3.9}$$

Notice that $J_\rho(u_\rho)$ is independent of the choice of R. For example, if $\widetilde{J}(u_{\Omega_\rho}) = \int_{\Omega_\rho} |u_{\Omega_\rho}|^2 dx$, then we have

$$J_\rho(u) = \int_{\Omega_R} |u|^2 dx + \int_{D_\rho} |u_\rho^\varphi|^2 dx, \quad u \in \mathcal{V}_R \text{ and } \varphi = u \text{ on } \Gamma_R.$$

3.2. The main result. Possibly changing the coordinate system, we can suppose for convenience that $x_0 = 0$. Let v_ω be the solution to the problem

$$\left\{ \begin{array}{rcll} -\operatorname{div}\sigma(v_\omega) & = & 0 & \text{in } \mathbb{R}^n\backslash\overline{\omega}, \\ v_\omega & = & 0 & \text{at } \infty, \\ \sigma(v_\omega)\mathbf{n} & = & \sigma(u_\Omega)(x_0)\mathbf{n} & \text{on } \partial\omega. \end{array} \right. \tag{3.10}$$

In order to be consistent with previous notations, the normal $\mathbf{n}$ is chosen outward to $\mathbb{R}^n\backslash\overline{\omega}$ on $\partial\omega$. This function v_ω can be expressed by a single layer potential on $\partial\omega$ in the following way. Let

$$E(y) = \frac{1}{r}\left(\beta I + \gamma \mathrm{e}_r \mathrm{e}_r^T\right) \quad \text{if } n = 3, \tag{3.11}$$

$$E(y) = \beta \log r\, I + \gamma \mathrm{e}_r \mathrm{e}_r^T \quad \text{if } n = 2,$$

where I is the $n \times n$ identity matrix, $r = ||y||$, $\mathrm{e}_r = y/r$, e_r^T is the transposed vector of e_r, and

$$\beta = \frac{\lambda + 3\mu}{8\pi\mu(\lambda + 2\mu)}, \quad \gamma = \frac{\lambda + \mu}{8\pi\mu(\lambda + 2\mu)} \quad \text{for } n = 3,$$

$$\beta = -\frac{\lambda + 3\mu}{4\pi\mu(\lambda + 2\mu)}, \quad \gamma = \frac{\lambda + \mu}{4\pi\mu(\lambda + 2\mu)} \quad \text{for } n = 2 \text{ (plain strain).}$$

For two-dimensional (2D) plain stress, $\lambda^* = 2\mu\lambda/(\lambda + 2\mu)$ must be substituted for λ. The matrix distribution $E \in \mathcal{D}'(\mathbb{R}^n, \mathbb{R}^{n\times n})$ is a fundamental solution for the elasticity problem in $\mathbb{R}^n$; that is, each column E_j is a solution to

$$-\operatorname{div}\sigma(E_j) = \delta \mathrm{e}_j \quad \text{in } \mathbb{R}^n,$$

where δ is the Dirac distribution and $(\mathrm{e}_j)_{j=1,n}$ is the canonical basis of $\mathbb{R}^n$. Then function v_ω reads

$$v_\omega(y) = \int_{\partial\omega} E(y - x)p(x)\, d\gamma(x), \quad y \in \mathbb{R}^n\backslash\overline{\omega},$$

where $p \in H^{-1/2}(\partial\omega)^n$ is the solution to boundary integral equation [8, 9]

$$\frac{p(y)}{2} + \int_{\partial\omega} \sigma_y(E(y - x)p(x))\mathbf{n}(y)\, d\gamma(x) = \sigma(u_\Omega)(x_0)\mathbf{n}(y) \quad \forall y \in \partial\omega, \tag{3.12}$$

the subscript y in σ_y denoting a differentiation with respect to the variable y. Moreover, due to

$$\int_{\partial\omega} \sigma(u_\Omega)(x_0)\mathbf{n}(x)\ d\gamma(x) = 0,$$

$$\int_{\partial\omega} \sigma_y(E_j(y - x))\mathbf{n}(y)\, d\gamma(y) = \frac{1}{2}\mathrm{e}_j \quad \text{if } x \in \partial\omega, \quad \partial\omega \text{ of class } \mathcal{C}^1 \text{ at } x,$$

multiplying (3.12) by e_i and integrating over $\partial\omega$ yield

$$\begin{aligned} 0 &= \frac{1}{2}\int_{\partial\omega} p_i(y)\, d\gamma(y) + \int_{\partial\omega} p_j(x) \int_{\partial\omega} \sigma_y(E_j(y - x))\mathbf{n}(y)\, d\gamma(y).\mathrm{e}_i\, d\gamma(x) \\ &= \frac{1}{2}\int_{\partial\omega} p_i(y)\, d\gamma(y) + \frac{1}{2}\int_{\partial\omega} p_j(x)\delta_{ij}\, d\gamma(x) \\ &= \int_{\partial\omega} p_i(y)\, d\gamma(y), \end{aligned}$$

where Einstein's summation convention on repeated indices is used throughout this paper. Hence we have

$$\int_{\partial\omega} p(x)\, d\gamma(x) = 0, \tag{3.13}$$

and, using the first order Taylor expansion of E at the point $y \neq x$ for x bounded

$$E(y-x) = E(y) - DE(y)x + O\left(\frac{1}{r^n}\right),$$

we obtain the following asymptotic expansion at infinity of the function v_ω:

$$\begin{aligned} v_\omega(y) &= \int_{\partial\omega} E(y)p(x) \ - (DE(y)x)p(x)\, d\gamma(x) + O\left(\frac{1}{r^n}\right) \\ &= 0 - \int_{\partial\omega} (DE(y)x)p(x)\, d\gamma(x) + O\left(\frac{1}{r^n}\right). \end{aligned}$$

The dominant part $P_\omega(y)$ of v_ω is given by

$$v_\omega(y) = P_\omega(y) + W_\omega(y), \tag{3.14}$$

$$P_\omega(y) = -\int_{\partial\omega} (DE(y)x)p(x)\, d\gamma(x), \quad W_\omega(y) = O\left(\frac{1}{r^n}\right), \tag{3.15}$$

where the function $r^{n-1}P_\omega(y)$ is homogeneous of degree 0; that is, for all $y \neq 0$,

$$P_\omega(y) = \rho^{n-1}P_\omega(\rho y) \quad \forall \rho > 0. \tag{3.16}$$

Moreover, it can easily be checked that

$$-\operatorname{div}\sigma(P_\omega) = 0 \quad \text{in } \mathbb{R}^n\backslash\{0\}. \tag{3.17}$$

Next we consider the solution Q_ω to the problem

$$\left\{ \begin{array}{rcll} -\operatorname{div}\sigma(Q_\omega) & = & 0 & \text{in } D_0, \\ Q_\omega & = & P_\omega & \text{on } \Gamma_R. \end{array} \right. \tag{3.18}$$

The main result is the following, which will be proved in section 4.

THEOREM 3.2. *Let $j(\rho) = J_\rho(u_\rho)$ be a cost function such that for all $v \in \mathcal{V}_R$ and $\rho > 0$,*

$$J_\rho(v) - J_0(u_0) = DJ(u_0)(v - u_0) + \delta_J(u_0)\rho^n + o(\|v - u_0\|_{\mathcal{V}_R} + \rho^n),$$

where $DJ(u_0)$ is continuous and linear on $\mathcal{V}_R$. Let $v_0 \in \mathcal{V}_R$ be the solution to the adjoint equation

$$a_0(w, v_0) = -DJ(u_0)w \quad \forall w \in \mathcal{V}_R, \tag{3.19}$$

and let

$$\delta_a(u_0, v_0) := \int_{\Gamma_R} \sigma(Q_\omega - P_\omega)\mathbf{n}.v_0\, d\gamma(x). \tag{3.20}$$

Then the function j has the following asymptotic expansion:

$$j(\rho) = j(0) + \{\delta_a(u_0, v_0) + \delta_J(u_0)\}\,\rho^n + o(\rho^n). \tag{3.21}$$

The expression $g(x_0) := \delta_a(u_0, v_0) + \delta_J(u_0)$ is called the "topological sensitivity." It is also called the "topological gradient." Moreover, as $g(x_0)$ is independent of ρ, it follows from the uniqueness of an asymptotic expansion that $g(x_0)$ is also independent of R.

Practically, what is computed is the solution u_Ω to (3.1) and the solution v_Ω to

$$\int_\Omega \sigma(w) : \varepsilon(v_\Omega)\, dx = -D\widetilde{J}(u_\Omega)w \quad \forall w \in \mathcal{V}_0. \tag{3.22}$$

As observed in Proposition 3.1, u_0 is the restriction to Ω_R of u_Ω. The same property holds for v_0 and v_Ω. This can easily be seen by observing that for $w \in \mathcal{V}_0$ such that $\operatorname{div} \sigma(\omega) = 0$ in D_0, and denoting by v_R and w_R the restrictions of v_Ω and w to Ω_R, on the one hand, we have

$$\begin{aligned} a_0(w_R, v_R) &= \int_{\Omega_R} \sigma(w_R) : \varepsilon(v_R)\, dx + \int_{\Gamma_R} T_0 w_R . v_R \, d\gamma(x) \\ &= \int_\Omega \sigma(w) : \varepsilon(v_\Omega)\, dx + 0, \end{aligned} \tag{3.23}$$

and on the other hand, due to (3.8), we have $\widetilde{J}(u) = J_0(u_R)$ for all $u \in \mathcal{V}_0$ such that $\operatorname{div} \sigma(u) = 0$ in D_0. Hence

$$D\widetilde{J}(u_\Omega)w = DJ(u_0)w_R. \tag{3.24}$$

Then, gathering (3.23), (3.22), and (3.24), we obtain

$$a_0(w_R, v_R) = -DJ(u_0)w_R \quad \forall w_R \in \mathcal{V}_R,$$

which proves that v_R is the solution to (3.19); that is, v_0 is the restriction to Ω_R of v_Ω.

The basic property of an adjoint technique is also satisfied here, in that the displacement u_Ω (or u_0) and the adjoint state v_Ω (or v_0) do not depend on x_0. Hence only two systems have to be solved in order to compute the topological sensitivity $g(x)$ for all $x \in \Omega$. This plays a crucial role in the efficiency of the optimization algorithm described in section 5.

Thanks to Green's formula and $P_\omega = Q_\omega$ on Γ_R, (3.20)–(3.21) reads also

$$\begin{aligned} j(\rho) = j(0) + \Bigg\{ &\int_{\Gamma_R} \sigma(v_\Omega)\mathbf{n}.P_\omega - \sigma(P_\omega)\mathbf{n}.v_\Omega \, d\gamma(x) \\ &- \int_{D_0} \operatorname{div} \sigma(v_\Omega).Q_\omega \, dx + \delta_J(u_0) \Bigg\} \rho^n + o(\rho^n). \end{aligned} \tag{3.25}$$

In particular, we have the following result, which can be used when the function J does not depend on ρ. The tensor $-A$ is known as the mass matrix; see, e.g., [14].

COROLLARY 3.3. *Let p be defined by* (3.12)*, and*

$$A_{ik}(\sigma(u_\Omega)(x_0)) = \int_{\partial\omega} p_i(x) x_k \, d\gamma(x) \tag{3.26}$$

with $p = (p_i)_{1 \le i \le n}$, $x = (x_k)_{1 \le k \le n}$. Under the assumptions of Theorem 3.2*, if* $\operatorname{div} \sigma(v_\Omega) = 0$ *in* D_0*, then*

$$\delta_a(u_\Omega, v_\Omega) = A(\sigma(u_\Omega)(x_0)) : \varepsilon(v_\Omega)(x_0),$$

and the function j has the following asymptotic expansion:

$$j(\rho) = j(0) + \delta_a(u_\Omega, v_\Omega)\rho^n + o(\rho^n).$$

Moreover, the matrix $A(\sigma(u_\Omega)(x_0)) \in \mathbb{R}^{n\times n}$ is symmetric, is linear with respect to $\sigma(u_\Omega)(x_0)$, and depends only on $\sigma(u_\Omega)(x_0)$ and ω, and the tensor A is symmetric in the following sense:

$$A(\sigma(u_\Omega)(x_0)) : \varepsilon(v_\Omega)(x_0) = A(\sigma(v_\Omega)(x_0)) : \varepsilon(u_\Omega)(x_0).$$

Proof. Due to $\operatorname{div}\sigma(v_\Omega) = 0$, the function v_Ω is analytical around x_0, and through a regularization and localization technique, it can easily be shown that (3.26) becomes

$$j(\rho) = j(0) - \rho^n \left\langle \operatorname{div}\sigma(P_\omega), \varphi v_\Omega \right\rangle_{\mathcal{D}'(D_0),\mathcal{D}(D_0)} + o(\rho^n), \tag{3.27}$$

where $\varphi \in \mathcal{D}(D_0)$ satisfies $\varphi(x) = 1$ on a neighborhood of x_0. For legibility, A_{ik} may stand for $A_{ik}(\sigma(u_\Omega)(x_0))$. It follows from (3.15) that

$$P_\omega(y) = -A_{ik}\partial_k E_i(y).$$

Hence

$$-\operatorname{div}\sigma(P_\omega)(y) = A_{ik}\partial_k \operatorname{div}\sigma(E_i(y)) = -A_{ik}\partial_k\delta \mathrm{e}_i,$$

and

$$\begin{aligned} -\left\langle \operatorname{div}\sigma(P_\omega)(y), \varphi v_\Omega(y)\right\rangle &= \left\langle A_{ik}\delta\mathrm{e}_i, \partial_k(\varphi v_\Omega)(y)\right\rangle \\ &= A_{ik}(\partial_k v_\Omega)_i(x_0) \\ &= A(\sigma(u_\Omega)(x_0)) : Dv_\Omega(x_0). \end{aligned}$$

Function p is the jump of $\sigma(v_\omega)\mathbf{n}$ across $\partial\omega$ if v_ω, defined by (3.10), is extended in ω by $-\operatorname{div}\sigma(v_\omega) = 0$ in ω and v_ω is continuous across $\partial\omega$. Thus

$$A_{ik} = \int_{\partial\omega} [\sigma(v_\omega)\mathbf{n}].(\mathrm{e}_i x_k)\, d\gamma(x),$$

and $A_{ik} = A_{ki}$ follows from Green's formula and $\sigma_{ik}(v_\omega) = \sigma_{ki}(v_\omega)$. Finally, the symmetry of the tensor A is a straightforward consequence of the symmetry of a_ρ for all $\rho \geq 0$. □

3.3. Case of a spherical hole.

Computing the coefficients

$$A_{ik}(\sigma(u_\Omega)(x_0)) = \int_{\partial\omega} p_i(x) x_k\, d\gamma(x)$$

requires solving integral equation (3.12) which is here recalled:

$$\frac{p(y)}{2} + \int_{\partial\omega} \sigma_y(E(y-x)p(x))\mathbf{n}(y)\, d\gamma(x) = \sigma(u_\Omega)(x_0)\mathbf{n}(y) \quad \forall y \in \partial\omega.$$

However, using Saint-Venant's principle, a good approximation of p can be obtained by computing the displacement u_{ext} on $\Omega\backslash\omega$ and the displacement u_{int} on ω with the Dirichlet boundary condition $u_{int} = u_{ext}$ on $\partial\omega$. Then p is approximately equal to the jump $\sigma(u_{ext})\mathbf{n}-\sigma(u_{int})\mathbf{n}$ on $\partial\omega$. When ω is the unit ball $B(0,1)$, then v_ω (and thus P and A) can be computed explicitly with the help of symbolic calculus: with $\sigma_0 := \sigma(u)(0)$, the solution v to

$$\left\{\begin{array}{rcll} -\operatorname{div}\sigma(v) & = & 0 & \text{in } \mathbb{R}^n \setminus \overline{B(0,1)}, \\ \sigma(v)\mathbf{n} & = & \sigma_0\mathbf{n} & \text{on } \partial B(0,1), \\ v & = & 0 & \text{at } \infty, \end{array}\right.$$

is given for $n = 2$ by

$$v_i = \frac{\pi(\mu+\eta)}{2\eta\mu}\left\{4\mu\sigma_0 \colon \varepsilon(E_i) + (\eta - 2\mu)\operatorname{tr}\sigma_0 \operatorname{tr}\varepsilon(E_i) + \frac{\mu+2\eta}{6}\sigma_0 : \varepsilon(\Delta E_i)\right\}, \quad i = 1,2, \tag{3.28}$$

and for $n = 3$ by

$$v_i = \frac{\pi(\lambda+2\mu)}{\mu(9\lambda+14\mu)}\left\{20\mu\sigma_0 \colon \varepsilon(E_i) + (3\lambda - 2\mu)\operatorname{tr}\sigma_0 \operatorname{tr}\varepsilon(E_i) + 2\mu\sigma_0 : \varepsilon(\Delta E_i)\right\}, \quad i = 1,2,3, \tag{3.29}$$

where the constant η is defined by

$$\eta = \left\{\begin{array}{ll} \frac{\mu(3\lambda+2\mu)}{\lambda+2\mu} & \text{plane stress}, \\ \lambda + \mu & \text{plane strain}, \end{array}\right.$$

and $\operatorname{tr}\sigma = \sum_i \sigma_{ii}$ is the usual trace operator.

Also, some similar results can be obtained for a homogeneous Dirichlet boundary condition on $\partial\omega_\rho$. The main difference is the asymptotic behavior at infinity of the solution to the exterior problem corresponding to (3.10):

$$\left\{\begin{array}{rcll} -\operatorname{div}\sigma(v_\omega) & = & 0 & \text{in } \mathbb{R}^n \backslash \overline{\omega}, \\ v_\omega & = & u_\Omega(x_0) & \text{on } \partial\omega, \end{array}\right.$$

that is, $O(1/r)$ for $n = 3$ and $O(\log(r))$ for $n = 2$ instead of $O(1/r^{n-1})$ for the Neumann case (see (3.15)). The solution v_ω to this exterior problem involves E and ΔE, instead of DE and $D(\Delta E)$.

Table 3.1 reports the different expressions of the topological sensitivity for the Dirichlet and Neumann boundary condition in two and three dimensions. For the Neumann boundary condition, they are obtained by simply keeping the principal part P_ω in (3.30) and (3.29) (that is, by removing the terms containing ΔE_i), and by substituting $-v_\Omega$ for E_i. That follows from a direct computation of (3.27) using (3.2), similar to the proof of Corollary 3.3. In particular, we retrieve the expression given by Sokolowski and Żochowski [23] in plane stress elasticity with a Neumann boundary condition.

One can observe that in both cases $\delta_a(u_\Omega, v_\Omega) \neq \sigma(u_\Omega) : \varepsilon(v_\Omega)$; that is, the topological sensitivity is not obtained by considering the limit when $\rho \to 0$ of the classical shape optimization expression of the derivative with respect to $\rho > 0$ (here for the Neumann case):

$$Dj(\rho) = -\int_{\partial\omega_\rho} \sigma(u_\Omega) : \varepsilon(v_\Omega)\, d\gamma(x).$$

Table 3.1
Expressions of the topological sensitivity.

Boundary condition on $\partial\omega_\rho$	$f(\rho)$	$\delta_a(u_\Omega, v_\Omega)$
2D Dirichlet	$\dfrac{1}{\log(\rho)}$	$-\dfrac{4\pi\mu(\mu+\eta)}{2\mu+\eta} u_\Omega . v_\Omega$
3D Dirichlet	ρ	$\dfrac{12\pi\mu(\lambda+2\mu)}{2\lambda+5\mu} u_\Omega . v_\Omega$
2D Neumann	ρ^2	$-\dfrac{\pi(\mu+\eta)}{2\eta\mu}\{4\mu\sigma(u_\Omega):\varepsilon(v_\Omega)+(\eta-2\mu)\mathrm{tr}\,\sigma(u_\Omega)\,\mathrm{tr}\,\varepsilon(v_\Omega)\}$
3D Neumann	ρ^3	$-\dfrac{\pi(\lambda+2\mu)}{\mu(9\lambda+14\mu)}\{20\mu\sigma(u_\Omega):\varepsilon(v_\Omega)+(3\lambda-2\mu)\mathrm{tr}\,\sigma(u_\Omega)\,\mathrm{tr}\,\varepsilon(v_\Omega)\}$

4. Proof of the main result. This section consists in the proof of Theorem 3.2. The variation of the bilinear form a_ρ (see (3.7)) reads

$$a_\rho(u,v) - a_0(u,v) = \int_{\Gamma_R} (T_\rho - T_0)u.v \, d\gamma(x). \tag{4.1}$$

Hence, the problem reduces to the analysis of $(T_\rho - T_0)\varphi$ for $\varphi \in H^{1/2}(\Gamma_R)^n$. More precisely, it will be shown that there exists an operator $\delta_T \in \mathcal{L}(H^{1/2}(\Gamma_R)^n; H^{-1/2}(\Gamma_R)^n)$ such that

$$\|T_\rho - T_0 - \rho^n \delta_T\|_{\mathcal{L}(H^{1/2}(\Gamma_R)^n;\, H^{-1/2}(\Gamma_R)^n)} = O(\rho^{n+1}). \tag{4.2}$$

Then defining δ_a by

$$\delta_a(u,v) = \int_{\Gamma_R} \delta_T u.v \, d\gamma(x), \quad u,\, v \in \mathcal{V}_R,$$

will yield straightforwardly

$$\|a_\rho - a_0 - \rho^n \delta_a\|_{\mathcal{L}_2(\mathcal{V})} = O(\rho^{n+1}).$$

In order to derive (4.2), first we need some definitions and preliminary lemmas.

4.1. Definitions. For convenience, the following norms and seminorms are chosen for the functional spaces which will be used.

- For a bounded, connected, and open subset $\mathcal{O} \subset \mathbb{R}^n$ with a Lipschitz continuous boundary, the Sobolev space $H^1(\mathcal{O})^n$ is equipped with the norm

  $$\|u\|^2_{1,\mathcal{O}} := \int_{\mathcal{O}} \sigma(u) : \varepsilon(u) + u.v \, dx,$$

  which, due to Korn's inequality [20], is equivalent to the usual norm. We will also need the seminorm defined by

  $$|u|^2_{1,\mathcal{O}} := \int_{\mathcal{O}} \sigma(u) : \varepsilon(u) \, dx. \tag{4.3}$$

  This seminorm is equivalent to the previous one on the subspace orthogonal to the constants $\{u \in H^1(\mathcal{O})^n;\ \int_{\mathcal{O}} u \, dx = 0\}$.

- For a given $\rho > 0$, the fractional Sobolev space $H^{1/2}(\Gamma_{R/\rho})^n$ is equipped with the following norm which is equivalent to the usual norm:

  $$\|v\|_{1/2,\Gamma_{R/\rho}} = \inf\left\{\|u\|_{1,C(R/(2\rho),R/\rho)}; \quad u = v \quad \text{on} \quad \Gamma_{R/\rho}\right\},$$

  where $C(r, r') := \{x \in \mathbb{R}^n; \quad r < ||x|| < r'\}$. We will also need the seminorm

  $$|v|_{1/2,\Gamma_{R/\rho}} = \inf\{|u|_{1,C(R/(2\rho),R/\rho)}\,; \quad u = v \quad \text{on} \quad \Gamma_{R/\rho}\}. \tag{4.4}$$

  The introduction of this seminorm is related to the fact that the null space of T_ρ consists in the constant functions.
- The dual space $H^{-1/2}(\Gamma_{R/\rho})^n$ is equipped with the natural norm

  $$\|w\|_{-1/2,\Gamma_{R/\rho}} = \sup\{\langle w, v\rangle_{-1/2,1/2}\,; \quad v \in H^{1/2}(\Gamma_{R/\rho})^n,\ \|v\|_{1/2,\Gamma_{R/\rho}} = 1\}.$$

  It can easily be checked that if $\psi \in H^1(C(R/2, R))^n$ with $\operatorname{div}\sigma(\psi) = 0$ in $C(R/2, R)$, then

  $$\|\sigma(\psi)\mathbf{n}\|_{-1/2,\Gamma_R} \leq c\,|\psi|_{1,C(R/2,R)}\,. \tag{4.5}$$

Here and in what follows, c is a positive constant independent of the data (e.g., of ρ).

4.2. Preliminary lemmas. Recall that $x_0 = 0$. We will use intensively the following change of variable: for a given function u defined on a set $\mathcal{O}$, function $\widetilde{u}$ is defined on $\widetilde{\mathcal{O}} := \mathcal{O}/\rho$ by

$$\widetilde{u}(y) = u(x), \quad y = x/\rho.$$

Unless otherwise specified, the derivation in the operators σ and ε will be considered with respect to the current variable; that is, $\varepsilon_{ij}(u)(x) = (\partial u_i(x)/\partial x_j + \partial u_j(x)/\partial x_i)/2$, $\varepsilon_{ij}(\widetilde{u})(y) = (\partial\widetilde{u}_i(y)/\partial y_j + \partial\widetilde{u}_j(y)/\partial y_i)/2$, etc. Due to $Du(x) = D\widetilde{u}(y)/\rho$ and to (4.3), we have

$$|u|^2_{1,\mathcal{O}} = \int_{\mathcal{O}} \sigma(u) : \varepsilon(u)\,dx = \frac{1}{\rho^2}\int_{\widetilde{\mathcal{O}}} \sigma(\widetilde{u}) : \varepsilon(\widetilde{u})\,\rho^n dy.$$

Hence

$$|u|_{1,\mathcal{O}} = \rho^{(n-2)/2}\,|\widetilde{u}|_{1,\widetilde{\mathcal{O}}}\,. \tag{4.6}$$

Similarly, we have

$$\begin{aligned}|v|_{1/2,\Gamma_R} &= \inf\{|u|_{1,C(R/2,R)}\,; \quad u = v \quad \text{on} \quad \Gamma_R\}\\ &= \inf\{\rho^{(n-2)/2}\,|\widetilde{u}|_{1,C(R/(2\rho),R/\rho)}\,; \quad \widetilde{u} = \widetilde{v} \quad \text{on} \quad \Gamma_{R/\rho}\}.\end{aligned}$$

Hence

$$|v|_{1/2,\Gamma_R} = \rho^{(n-2)/2}\,|\widetilde{v}|_{1/2,\Gamma_{R/\rho}}\,. \tag{4.7}$$

LEMMA 4.1. *For $\varphi \in H^{-1/2}(\partial\omega)^n$ such that*

$$\int_{\partial\omega} \varphi\,d\gamma(x) = 0,$$

let v be the solution to the problem

$$\left\{\begin{array}{rcl} -\operatorname{div}\sigma(v) & = & 0 \quad \text{in } \mathbb{R}^n\backslash\overline{\omega}, \\ v & = & 0 \quad \text{at } \infty, \\ \sigma(v)\mathbf{n} & = & \varphi \quad \text{on } \partial\omega. \end{array}\right. \tag{4.8}$$

The function v is split into

$$v(y) = V(y) + W(y),$$
$$V(y) = -\int_{\partial\omega} (DE(y)x)p(x)\, d\gamma(x),$$

where E is defined in (3.11)*. There exists $c > 0$ such that*

$$|V|_{1,C(R/(2\rho),R/\rho)} \leq c\rho^{n/2}\|\varphi\|_{-1/2,\partial\omega}, \tag{4.9}$$
$$|W|_{1,C(R/(2\rho),R/\rho)} \leq c\rho^{n/2+1}\|\varphi\|_{-1/2,\partial\omega}.$$

Proof. With the help of a single layer potential representation, the function v reads

$$v(y) = \int_{\partial\omega} E(y-x)p(x)\, d\gamma(x), \quad y \in \mathbb{R}^n\backslash\overline{\omega},$$

where (see also (3.13))

$$\frac{p(y)}{2} + \int_{\partial\omega} \sigma_y(E(y-x)p(x))\mathbf{n}(y)\, d\gamma(x) = -\varphi(y) \quad \forall y \in \partial\omega, \tag{4.10}$$

$$\int_{\partial\omega} p(x)\, d\gamma(x) = 0. \tag{4.11}$$

Using a Taylor expansion of E computed at the point y, (4.11), and the well-posedness of (4.10) [8], we have

$$||DV(y)|| \leq \frac{c}{|y|^n}\|\varphi\|_{-1/2,\partial\omega}, \quad ||DW(y)|| \leq \frac{c}{|y|^{n+1}}\|\varphi\|_{-1/2,\partial\omega},$$

from which (4.9) follows straightforwardly. □

LEMMA 4.2. *For $\varphi \in H^{1/2}(\Gamma_R)^n$, let v_ρ be the solution to the problem*

$$\left\{\begin{array}{rcl} -\operatorname{div}\sigma(v_\rho) & = & 0 \quad \text{in } D_\rho, \\ v_\rho & = & \varphi \quad \text{on } \Gamma_R, \\ \sigma(v_\rho)\mathbf{n} & = & 0 \quad \text{on } \partial\omega_\rho. \end{array}\right. \tag{4.12}$$

There exist a constant $c > 0$ (independent of φ and ρ) and $\rho_1 > 0$ such that for all $0 < \rho < \rho_1$,

$$|v_\rho|_{1,D_\rho} \leq c\,|\varphi|_{1/2,\Gamma_R}.$$

Proof. Let w solve the problem

$$\left\{\begin{array}{rcl} -\operatorname{div}\sigma(w) & = & 0 \quad \text{in } C(R/2,R), \\ w & = & \varphi \quad \text{on } \Gamma_R, \\ \sigma(w)\mathbf{n} & = & 0 \quad \text{on } \Gamma_{R/2}, \end{array}\right.$$

and let $w = w_0 + \gamma$, where the constant γ is such that $\int_{C(R/2,R)} w_0\,dx = 0$. For $\rho = 0$, (4.12) is well-posed, and there exists a constant c such that

$$|v_0|_{1,D_0} = |v_0 - \gamma|_{1,D_0} \le c\,\|\varphi - \gamma\|_{1/2,\Gamma_R} \le c\,\|w_0\|_{1/2,\partial C(R/2,R)} \le c\,\|w_0\|_{1,C(R/2,R)}\,,$$

where the last inequality follows from the trace theorem. On the subspace of $H^1(C(R/2,R))$ consisting in the functions u such that $\int_{C(R/2,R)} u\,dx = 0$, the semi-norm $|u|_1$ is equivalent to the norm $\|u\|_1$. Hence, using (4.4), we deduce that

$$|v_0|_{1,D_0} \le c\,|w_0|_{1,C(R/2,R)} = c\,|w|_{1,C(R/2,R)} = c\,|\varphi|_{1/2,\Gamma_R}\,.$$

Then let $\rho_1 > 0$ be such that $\omega_\rho \subset D_0$ for all $\rho < \rho_1$. The function v_ρ minimizes $|v|_{1,D_\rho}$ over the affine space $\left\{v \in H^1(D_\rho)^n;\ v = \varphi \text{ on } \Gamma_R\right\}$. Hence, if $\widehat{v_0}$ denotes the restriction of v_0 to D_ρ, we have

$$|v_\rho|_{1,D_\rho} \le |\widehat{v_0}|_{1,D_\rho} \le |v_0|_{1,D_0} \le c\,|\varphi|_{1/2,\Gamma_R}\,. \qquad \square$$

LEMMA 4.3. *For $\rho > 0$ and $\psi \in H^1(D_0)^n$ such that*

$$\operatorname{div}\sigma(\psi) = 0 \quad \text{in } D_0,$$

let u_ρ be the solution to the problem

$$\left\{\begin{array}{rcll} -\operatorname{div}\sigma(u_\rho) & = & 0 & \text{in } D_\rho, \\ u_\rho & = & 0 & \text{on } \Gamma_R, \\ \sigma(u_\rho)\mathbf{n} & = & \sigma(\psi)\mathbf{n} & \text{on } \partial\omega_\rho. \end{array}\right. \tag{4.13}$$

There exist a constant $c > 0$ (independent of ψ and ρ) and $\rho_1 > 0$ such that for all $0 < \rho < \rho_1$,

$$|u_\rho|_{1,C(R/2,R)} \le c\rho^n \|\sigma(\psi)(\rho y)\mathbf{n}\|_{-1/2,\partial\omega}.$$

Proof. First we note that

$$\int_{\partial\omega} \sigma(\psi)(\rho x)\mathbf{n}\,d\gamma(x) = \frac{1}{\rho^{n-1}} \int_{\partial\omega_\rho} \sigma(\psi)(x)\mathbf{n}\,d\gamma(x) = \frac{1}{\rho^{n-1}} \int_{\omega_\rho} \operatorname{div}\sigma(\psi)\,d\gamma(x) = 0.$$

Hence we can define the solution $\widetilde{v_\rho}$ to the problem

$$\left\{\begin{array}{rcll} -\operatorname{div}\sigma(\widetilde{v_\rho}) & = & 0 & \text{in } \mathbb{R}^n\backslash\overline{\omega}, \\ \widetilde{v_\rho} & = & 0 & \text{at } \infty, \\ \sigma(\widetilde{v_\rho})\mathbf{n} & = & \rho\sigma(\psi)(\rho y)\mathbf{n} & \text{on } \partial\omega. \end{array}\right.$$

The function u_ρ can be written

$$u_\rho = v_\rho - w_\rho,$$

where $v_\rho(x) = \widetilde{v_\rho}(x/\rho)$. The function w_ρ itself is the solution to

$$\left\{\begin{array}{rcll} -\operatorname{div}\sigma(w_\rho) & = & 0 & \text{in } D_\rho, \\ w_\rho & = & v_\rho & \text{on } \Gamma_R, \\ \sigma(w_\rho)\mathbf{n} & = & 0 & \text{on } \partial\omega_\rho. \end{array}\right.$$

It follows from Lemma 4.2 that there exist $c > 0$ and $\rho_1 > 0$ such that for all $0 < \rho < \rho_1$,

$$|w_\rho|_{1,D_\rho} \leq c\,|v_\rho|_{1/2,\Gamma_R}\,. \tag{4.14}$$

Using (4.7), (4.4), and Lemma 4.1, we have

$$\begin{aligned} |v_\rho|_{1/2,\Gamma_R} &= \rho^{(n-2)/2}\,|\widetilde{v_\rho}|_{1/2,\Gamma_{R/\rho}} \leq \rho^{(n-2)/2}\,|\widetilde{v_\rho}|_{1,C(R/(2\rho),R/\rho)} \\ &\leq \rho^{(n-2)/2} c\rho^{n/2}\|\rho\sigma(\psi)(\rho y)\mathbf{n}\|_{-1/2,\partial\omega} = c\rho^n\|\sigma(\psi)(\rho y)\mathbf{n}\|_{-1/2,\partial\omega}. \end{aligned} \tag{4.15}$$

Again using Lemma 4.1, we also have

$$\begin{aligned} |v_\rho|_{1,C(R/2,R)} &= \rho^{(n-2)/2}\,|\widetilde{v_\rho}|_{1,C(R/(2\rho),R/\rho)} \\ &\leq c\rho^n\|\sigma(\psi)(\rho y)\mathbf{n}\|_{-1/2,\partial\omega}. \end{aligned} \tag{4.16}$$

Hence, gathering together (4.14), (4.15), and (4.16), we obtain

$$\begin{aligned} |u_\rho|_{1,C(R/2,R)} &= |v_\rho - w_\rho|_{1,C(R/2,R)} \leq |v_\rho|_{1,C(R/2,R)} + |w_\rho|_{1,D_\rho} \\ &\leq c\rho^n\|\sigma(\psi)(\rho y)\mathbf{n}\|_{-1/2,\partial\omega}. \qquad \square \end{aligned}$$

Lemmas 4.2 and 4.3 are summarized in the following lemma.

Lemma 4.4. *Let v_ρ be the solution to the problem*

$$\left\{\begin{array}{rcll} -\operatorname{div}\sigma(v_\rho) &=& 0 & \text{in } D_\rho, \\ v_\rho &=& \varphi & \text{on } \Gamma_R, \\ \sigma(v_\rho)\mathbf{n} &=& \sigma(\psi)\mathbf{n} & \text{on } \partial\omega_\rho, \end{array}\right.$$

where $\varphi \in H^{1/2}(\Gamma_R)^n$ and $\psi \in H^1(D_0)^n$ with

$$\operatorname{div}\sigma(\psi) = 0 \quad \text{in } D_0.$$

There exist a constant $c > 0$ (independent of φ, ψ and ρ) and $\rho_1 > 0$ such that for all $0 < \rho < \rho_1$,

$$|v_\rho|_{1,C(R/2,R)} \leq c\,|\varphi|_{1/2,\Gamma_R} + c\rho^n\|\sigma(\psi)(\rho y)\mathbf{n}\|_{-1/2,\partial\omega}.$$

4.3. Variation of the boundary operator. The linear operator δ_T (independent of ρ) is defined as follows:

$$\begin{array}{rcl} \delta_T : H^{1/2}(\Gamma_R)^n & \longrightarrow & H^{-1/2}(\Gamma_R)^n, \\ \varphi & \longmapsto & \delta_T\varphi := \sigma(Q_w - P_\omega)\mathbf{n}, \end{array} \tag{4.17}$$

where P_ω and Q_w are defined by (3.15) and (3.18), with $\sigma(u_0^\varphi)(0)$ substituted for $\sigma(u_\Omega)(0)$ in (3.10), the function u_0^φ being the solution to (3.4). (We are interested in $\delta_T u_0$, and in that case there is no substitution to do.)

Proposition 4.5. *The asymptotic expansion of T_ρ is*

$$\|T_\rho - T_0 - \rho^n\delta_T\|_{\mathcal{L}(H^{1/2}(\Gamma_R)^n;\,H^{-1/2}(\Gamma_R)^n)} = O(\rho^{n+1}). \tag{4.18}$$

Proof. Let $\varphi \in H^{1/2}(\Gamma_R)^n$, and denote $u_\rho = u_\rho^\varphi$, $u_0 = u_0^\varphi$ as the solutions to (3.4) and (3.5). The function v_ω is defined by (3.10) (with $\sigma(u_0)(0)$ substituted for

$\sigma(u_\Omega)(0)$). For $y = x/\rho$, recall ((3.14)–(3.16)) that $v_\omega(y) = P_\omega(y) + W_\omega(y)$ with $P_\omega(x/\rho) = \rho^{n-1}P_\omega(x)$ and $W_\omega(y) = O(1/||y||^n)$. Let

$$\psi_\rho(x) = (T_\rho - T_0 - \rho^n \delta_T)\varphi(x).$$

We have

$$\begin{aligned} \psi_\rho(x) &= \sigma(u_\rho(x) - u_0(x) + \rho^n P_\omega(x) - \rho^n Q_\omega(x))\mathbf{n} \\ &= \sigma(w_\rho(x) - \rho W_\omega(x/\rho))\mathbf{n}, \end{aligned}$$

where w_ρ is defined by

$$w_\rho(x) = u_\rho(x) - u_0(x) + \rho v_\omega(x/\rho) - \rho^n Q_\omega(x).$$

The function w_ρ is the solution to

$$\left\{ \begin{array}{rcll} -\operatorname{div}\sigma(w_\rho) &=& 0 & \text{in } D_\rho, \\ w_\rho &=& \rho v_\omega(x/\rho) - \rho^n Q_\omega(x) & \text{on } \Gamma_R, \\ \sigma(w_\rho)\mathbf{n} &=& \sigma(-u_0(x) + \rho v_\omega(x/\rho) - \rho^n Q_\omega(x))\mathbf{n} & \text{on } \partial\omega_\rho. \end{array} \right.$$

In order to apply Lemma 4.4, we have to estimate the two right-hand sides.

On Γ_R, due to (3.18), (3.16), and (3.14), we have

$$\rho v_\omega(x/\rho) - \rho^n Q_\omega(x) = \rho W_\omega(x/\rho).$$

Using (4.7), (4.4), Lemma 4.1, and the elliptic regularity of problem (3.4), we have

$$\begin{aligned} |\rho v_\omega(x/\rho) - \rho^n Q_\omega(x)|_{1/2,\Gamma_R} &= |\rho W_\omega(x/\rho)|_{1/2,\Gamma_R} \\ &= \rho^{n/2}\,|W_\omega(y)|_{1/2,\Gamma_{R/\rho}} \\ &\le \rho^{n/2}\,|W_\omega|_{1,C(R/(2\rho),R/\rho)} \\ &\le c\rho^{n+1}\|\sigma(u_0)(0)\mathbf{n}\|_{-1/2,\partial\omega} \\ &\le c\rho^{n+1}\|\varphi\|_{1/2,\Gamma_R}. \end{aligned} \tag{4.19}$$

On $\partial\omega_\rho$, due to the definition (3.10) of v_ω, we have

$$\sigma_x(\rho v_\omega(x/\rho))\mathbf{n} = \sigma_y(v_\omega(y))\mathbf{n} = \sigma_x(u_0)(0)\mathbf{n},$$

where the subscript in σ denotes the differentiated variable. Hence, using $\sigma(\varepsilon(u_0)(0)x) = \sigma(u_0)(0)$ for all x, we have on $\partial\omega_\rho$

$$\begin{aligned} \sigma(w_\rho)(x)\mathbf{n} &= \sigma(-u_0(x) + \rho v_\omega(x/\rho) - \rho^n Q_\omega(x))\mathbf{n} \\ &= \sigma(-u_0(x) + \varepsilon(u_0)(0)x - \rho^n Q_\omega(x))\mathbf{n} \\ &= \rho\sigma(\theta_\rho)\mathbf{n}, \end{aligned}$$

where the function $\theta_\rho := (-u_0(x) + \varepsilon(u_0)(0)x - \rho^n Q_\omega(x))/\rho$ satisfies $\operatorname{div}\sigma(\theta_\rho) = 0$ in D_0. Applying Lemma 4.4 and using (4.19), we obtain

$$\begin{aligned} |w_\rho|_{1,C(R/2,R)} &\le c\,|\rho v_\omega(x/\rho) - \rho^n Q_\omega(x)|_{1/2,\Gamma_R} + c\rho^n\|\rho\sigma(\theta_\rho)(\rho y)\mathbf{n}\|_{-1/2,\partial\omega} \\ &\le c\rho^{n+1}(\|\varphi\|_{1/2,\Gamma_R} + \|\sigma(\theta_\rho)(\rho y)\mathbf{n}\|_{-1/2,\partial\omega}). \end{aligned}$$

The analyticity of $\sigma(\theta_\rho)(\rho y) = (-\sigma(u_0)(\rho y) + \sigma(u_0)(0))/\rho - \rho^{n-1}\varepsilon(Q_\omega)(\rho y)$ (u_0 and Q_ω are analytical in D_0) and the elliptic regularity of problems (3.4) and (3.18) [15] yield for small ρ

$$\begin{aligned}\|\sigma(\theta_\rho)(\rho y)\mathbf{n}\|_{-1/2,\partial\omega} &\le c\|\sigma(\theta_\rho)(\rho y)\mathbf{n}\|_{L^\infty(\partial\omega)}\\ &\le c\|u_0\|_{W^{2,\infty}(B(0,R/2))} + c\|Q_\omega\|_{W^{1,\infty}(B(0,R/2))}\\ &\le c\|\varphi\|_{1/2,\Gamma_R}.\end{aligned}$$

Hence

$$|w_\rho|_{1,C(R/2,R)} \le c\rho^{n+1}\|\varphi\|_{1/2,\Gamma_R}. \tag{4.20}$$

We have $\operatorname{div}\sigma(w_\rho) = 0$, and $\operatorname{div}\sigma(W_\omega(x/\rho)) = 0$ follows from (3.17); thus using (4.5) and (4.6) yields

$$\begin{aligned}\|\psi_\rho\|_{-1/2,\Gamma_R} &= \|\sigma(w_\rho(x) - \rho W_\omega(x/\rho))\mathbf{n}\|_{-1/2,\Gamma_R}\\ &\le |w_\rho|_{1,C(R/2,R)} + |\rho W_\omega(x/\rho)|_{1,C(R/2,R)}\\ &\le |w_\rho|_{1,C(R/2,R)} + \rho^{n/2}\,|W_\omega|_{1,C(R/(2\rho),R/\rho)}\,,\end{aligned}$$

and we conclude by using (4.20) and (4.19) once more. □

4.4. Variation of the bilinear form. The asymptotic expansion of the bilinear form a_ρ is a direct consequence of Proposition 4.5.

PROPOSITION 4.6. *Let*

$$\delta_a(u,v) = \int_{\Gamma_R} \delta_T u.v \; d\gamma(x), \quad u,\, v \in \mathcal{V}_R.$$

The asymptotic expansion of the bilinear form a_ρ with respect to ρ is

$$\|a_\rho - a_0 - \rho^n\delta_a\|_{\mathcal{L}_2(\mathcal{V})} = O(\rho^{n+1}).$$

Hence the fundamental assumption (2.2) is satisfied, and it follows from Theorem 2.2 that

$$\begin{aligned}j(\rho) &= j(0) + \rho^n g(x_0) + o(\rho^n),\\ g(x_0) &= \delta_a(u_0,v_0) + \delta_J(u_0),\end{aligned} \tag{4.21}$$

which achieves the proof of Theorem 3.2.

5. Numerical results. According to (4.21), the topological sensitivity gives an information on the opportunity of creating a small hole around x_0. Suppose that the function j has to be minimized. Then creating a hole where $g(x) < 0$ may decrease the function j. Following the presentation of Céa, Gioan, and Michel in [5], (4.21) leads to the following optimality condition:

$$g(x) \ge 0 \quad \forall x \in \ \Omega.$$

This condition may be used in the following way to derive a topology optimization algorithm.

5.1. Algorithm (see [5]). Consider an initial domain Ω_0 which represents the design domain. The optimal domain is sought in $\{\Omega' \subset \Omega_0;\ \Omega' \text{ is open}\}$. Let $(m_k)_{k\geq 0}$ be a decreasing sequence of volume constraints with $m_0 = \text{meas}(\Omega_0)$. For example, a geometrical sequence may be chosen. At the kth iteration, the topological sensitivity is denoted by $g_k(x)$, and c_{k+1} is chosen in such a way that

$$\begin{cases} \Omega_{k+1} = \{x \in \Omega_k,\ g_k(x) \geq c_{k+1}\}, \\ \text{meas}(\Omega_{k+1}) = m_{k+1}. \end{cases}$$

The process stops when a target such as a volume constraint (or a constraint on the maximum of the Von Mises stress) is reached. Hence the algorithm is the following.

```
ALGORITHM: TOPOLOGY OPTIMIZATION WITH VOLUME CONSTRAINT.
• Initialization: chose the initial domain $\Omega_0$, and set $k = 0$.
• Repeat
    1. solve the linear elasticity problem in $\Omega_k$,
    2. compute the topological sensitivity $g_k$,
    3. set $\Omega_{k+1} = \{x \in \Omega_k,\ g_k(x) \geq c_{k+1}\}$, where $c_{k+1}$ is chosen such that
       $\text{meas}(\Omega_{k+1}) = m_{k+1}$,
    4. $k \leftarrow k + 1$.
• until target is reached.
```

The topological sensitivity is computed on each element. Then the elements are sorted with respect to this sensitivity. The lowest elements are removed. The number of elements removed at each step is given by the volume ratio (volume of elements removed) / (volume of the previous structure). In the following examples, this volume ratio is taken between 5% and 10%. At each iteration, most of the computational time is required for solving the elasticity problem. As only a few iterations are needed, this method is not expensive in terms of computational cost.

5.2. Applications. The following examples are taken from [12].

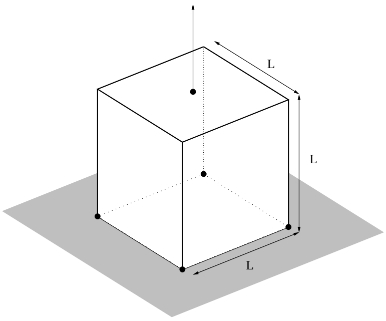

FIG. 5.1. *The design domain and boundary conditions for the first example.*

In the first example, the initial design domain Ω_0 is a cube (see Figure 5.1). The four vertices of the bottom face can slide in the horizontal plan, and the vertical displacement is zero at those latter points. A load is applied on the center of the top face. Fifty iterations were computed, and 9% of the material was removed at each step. Figure 5.2 shows several intermediate designs obtained during the optimization process. The mesh was refined after 25 iterations.

When the four bottom corners are clamped (homogeneous Dirichlet condition), the horizontal lattices between the four supports disappear, and the optimal design consists in four rods joined in a pyramidal structure.

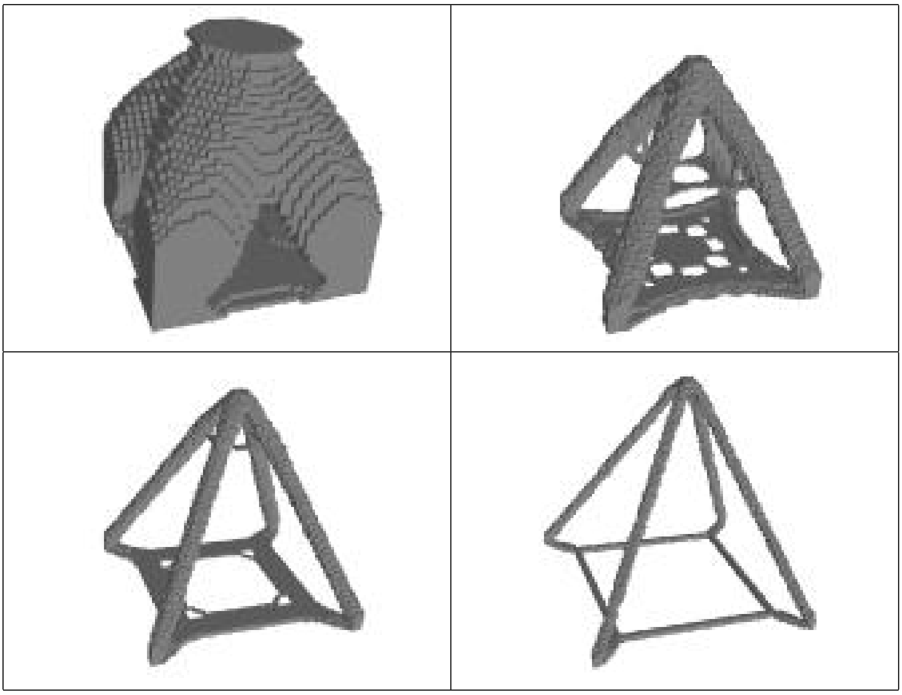

FIG. 5.2. *The pyramids obtained after* 8, 28, 37, *and* 50 *iterations. Volumes represent, respectively,* 50%, 7%, 3%, *and* 1% *of the initial volume.*

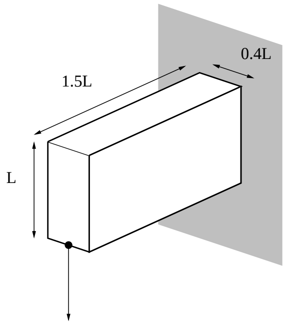

FIG. 5.3. *The design domain and boundary conditions for the slender cantilever beam.*

The second example is a slender cantilever beam (see Figure 5.3). The initial domain Ω_0 is a thin hexahedron with one face clamped, i.e., a homogeneous Dirichlet boundary condition is imposed on the whole face, and a pointwise load is applied at the lower edge of the opposite face. In that case, the minimization of the maximum of the Von Mises stress is also considered. Here 7% of the material is removed at each step. The optimal domains (see Figure 5.4) are obtained after 20 iterations. The results shown on Figure 5.4 recalls the 2D case (see, e.g., [2]); in fact, one dimension is very small with respect to the two others. One can observe that the structures obtained by minimization of the compliance and minimization of the maximum Von Mises stress are slightly different.

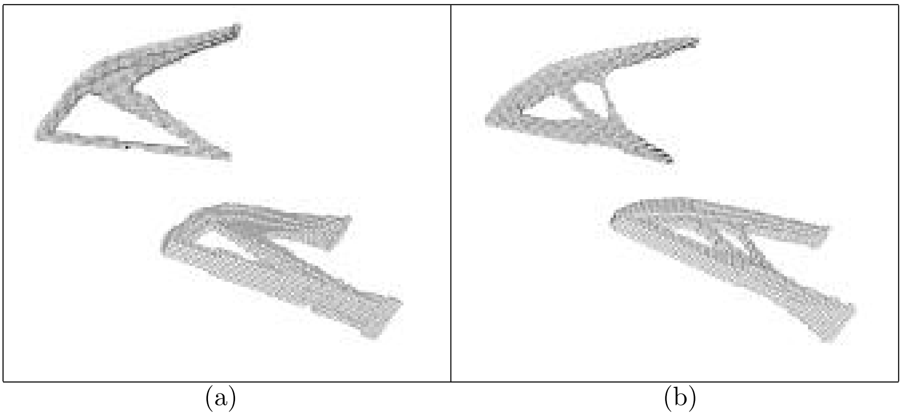

FIG. 5.4. *The slender cantilever beam for a volume equal to* 20% *of the initial volume, after* 20 *iterations. The compliance case is shown in* (a)*, and the Von Mises case is shown in* (b)*.*

6. Conclusion. Using the mathematical framework presented in this paper, it is possible to write an asymptotic expansion of a general functional with respect to the creation of a small hole. This approach is general and can be adapted to various equations and boundary conditions. Moreover, as the topological sensitivity involves only the direct solution and possibly the adjoint state, its computation is cheap, and efficient topology optimization algorithms can be implemented.

Acknowledgment. The authors are grateful to the referees for their thorough reading and their suggestions concerning the presentation.

OPTIMAL CONTROL PROBLEMS FOR STOCHASTIC REACTION-DIFFUSION SYSTEMS WITH NON-LIPSCHITZ COEFFICIENTS[*]

SANDRA CERRAI[†]

Abstract. By using the dynamic programming approach, we study a control problem for a class of stochastic reaction-diffusion systems with coefficients having polynomial growth. In the cost functional a non-Lipschitz term appears, and this allows us to treat the quadratic case, which is of interest in the applications. The corresponding Hamilton–Jacobi–Bellman equation is first resolved by a fixed point argument in a small time interval and then is extended to arbitrary time intervals by suitable a priori estimates. The main ingredient in the proof is the smoothing effect of the transition semigroup associated with the uncontrolled system.

Key words. stochastic reaction-diffusion systems, Hamilton–Jacobi–Bellman equations in infinite dimension, stochastic optimal control problems

1. Introduction.

In this paper we consider the following class of stochastic reaction-diffusion systems with distributed parameter controls in bounded domains $\mathcal{O}$ of $\mathbb{R}^d$, with $d \leq 3$:

$$\tag{1.1} \left\{ \begin{array}{l} \dfrac{\partial y_k}{\partial s}(s,\xi) = \mathcal{A}_k\, y_k(s,\xi) + f_k(\xi, y_1(s,\xi),\dots,y_r(s,\xi)) + z_k(s,\xi) + Q_k \dfrac{\partial^2 w_k}{\partial s \partial \xi}(s,\xi), \\[2ex] y_k(t,\xi) = x_k(\xi), \quad 0 \leq t < s \leq T, \quad \xi \in \overline{\mathcal{O}}, \\[2ex] \mathcal{B}_k\, y_k(s,\xi) = 0, \qquad \xi \in \partial\mathcal{O}, \qquad k = 1,\dots,r. \end{array} \right.$$

Here $\mathcal{A} = (\mathcal{A}_1,\dots,\mathcal{A}_r)$ is a uniformly elliptic second order differential operator with regular real coefficients, and $\mathcal{B} = (\mathcal{B}_1,\dots,\mathcal{B}_r)$ is a first order differential operator acting on the boundary of $\mathcal{O}$. The reaction term $f = (f_1,\dots,f_r) : \overline{\mathcal{O}} \times \mathbb{R}^r \to \mathbb{R}^r$ is continuous, and $f(\xi,\cdot) : \mathbb{R}^r \to \mathbb{R}^r$ is twice differentiable, has polynomial growth together with its derivatives, and fulfills appropriate dissipativity conditions. $Q = (Q_1,\dots,Q_r)$ is a nonnegative bounded linear operator from $H = L^2(\mathcal{O};\mathbb{R}^r)$ into itself, and $\partial^2 w_k/\partial t\,\partial\xi$ are independent space-time white noises defined on a stochastic basis $(\Omega,\mathcal{F},\mathcal{F}_t,\mathbf{P})$. The control $z = (z_1,\dots,z_r)$ is taken in the set of adapted processes of $L^2(\Omega;L^2(0,T;H))$. We remark that the dimension d is taken less than or equal to 3 because the noise should be, in a sense, nondegenerate, and the solution of the system (1.1) has to take value in $E = C(\mathcal{O};\mathbb{R}^r)$.

We are here concerned with the *cost functional*

$$\tag{1.2} J(t,x;z) = \mathbf{E}\,\varphi(y(T)) + \int_t^T \mathbf{E}\,(g(y(s)) + k(z(s)))\,ds,$$

[†]Dipartimento di Matematica per le Decisioni, Università di Firenze, Via Lombroso 6/17, 50134 Firenze, Italy (cerrai@cibs.sns.it).

where $y(s) = y(s,t;x,z)$ is the solution of the problem (1.1), φ and g are bounded and Lipschitz continuous functions from H into $\mathbb{R}$, and $k : H \to]-\infty, +\infty]$ is a measurable function which fulfills suitable conditions. Our aim is to prove that the *value function* corresponding to the cost functional (1.2), which is defined by

$$V(t,x) = \inf \left\{ J(t,x;z)\,;\, z \in L^2(\Omega; L^2(0,T;H))\,\text{adapted} \right\},$$

satisfies the Hamilton–Jacobi–Bellman equation

$$\left\{ \begin{array}{l} \dfrac{\partial u}{\partial t}(t,x) + \mathcal{L}u(t,x) - K(Du(t,x)) + g(x) = 0, \\[2ex] u(T,x) = \varphi(x), \end{array} \right. \tag{1.3}$$

where $\mathcal{L}$ is the differential operator

$$\mathcal{L}\psi(x) = \frac{1}{2}\mathrm{Tr}\,\left[Q^2 D^2 u(t,x)\right] + \langle \mathcal{A}x + f(\cdot;x), Du(t,x)\rangle_H$$

and K is the Legendre transform of k. Notice that the hamiltonian K is not assumed to be Lipschitz continuous so that we can cover the important case of quadratic hamiltonians. Moreover, it is important to stress that in the present paper we are only able to treat the case when data φ and g are Lipschitz continuous.

After proving in the first part that there exists a unique mild solution $u(t,x)$ for (1.3), we show that for any adapted control $z \in L^2(\Omega; L^2(0,T;H))$ and for any $x \in H$ and $t \in [0,T]$ the following identity holds:

$$\begin{aligned} &J(t,x;z) = u(t,x) \\ &+ \int_t^T \mathbf{E}\,\left[K(Du(s,y(s))) + \langle z(s), Du(s,y(s))\rangle_H + k(z(s))\right]\,ds. \end{aligned}$$

Thus, in particular, we have $V(t,x) \geq u(t,x)$. Now if we could prove the existence of a solution $y^\star(t)$ for the *closed loop* equation

$$dy(t) = (\mathcal{A}y(t) + f(\cdot;y(t)) - DK(Du(t,y(t))))\,dt + Q\,dw(t), \qquad y(0) = x, \tag{1.4}$$

then $z^\star(t) = -DK(Du(t,y^\star(t)))$ would be an optimal control for the minimizing problem related to the functional (1.2). But unfortunately here we are only able to prove C^1 regularity for the solution of the Hamilton–Jacobi–Bellman equation (1.3), so that we cannot prove the existence of a solution for (1.4) which is adapted to the filtration $\mathcal{F}_t$. Actually, as the solution of (1.3) is only C^1, the *closed loop* equation (1.4) admits only martingale solutions, and hence there is no reason why the optimal control which we could get from it is adapted to the filtration we fixed at the beginning. Thus at present we restrict ourselves to the proof of the verification theorem. In the future it will be interesting to check if, by introducing the notion of *relaxed controls* (see [17] and [29] for the definition), it will be possible to prove the existence of an optimal control. However, in dimension $d = 1$ we are able to show that under some additional assumptions, the closed loop equation has a unique solution so that there exists a unique optimal control.

In order to prove the opposite inequality $V(t,x) \leq u(t,x)$, we introduce an approximating cost functional $J_\alpha(t,x;z)$, and we prove that it satisfies a verification theorem and admits a unique optimal control for each $\alpha > 0$. Due to suitable a priori estimates, we show that there exists a subset $\mathcal{M}_R$ of the space of adapted processes in $L^2(\Omega; L^2(0,T;H))$ such that for any $\alpha > 0$

$$V_\alpha(t,x) = \inf\left\{ J_\alpha(t,x;z)\ ;\ z \in \mathcal{M}^2_R(T) \right\}.$$

Moreover, we show that for any $x \in C(\overline{\mathcal{O}};\mathbb{R}^r)$ the functional $J_\alpha(t,x;z)$ converges to $J(t,x;z)$ as α goes to zero, uniformly for $z \in \mathcal{M}_R$, so that

$$\lim_{\alpha\to 0} V_\alpha(t,x) \geq V(t,x).$$

Thus, by showing that

$$\lim_{\alpha\to 0} V_\alpha(t,x) = u(t,x),$$

we have that $u(t,x) \geq V(t,x)$, and the verification theorem holds for $x \in C(\overline{\mathcal{O}};\mathbb{R}^r)$. The general case $x \in H$ follows by further approximation arguments.

Hamilton–Jacobi–Bellman equations in infinite dimensional spaces have been studied by several authors by using both semigroup techniques and the approach of viscosity solutions (see [3], [4], [12], [13], [20], [21], [23], [24], [25], and all references quoted therein). In particular, in [20] and [21] abstract semilinear stochastic problems are studied, and the nonlinear term f is assumed to be Lipschitz continuous. Instead, in the present paper we are able to skip the condition of Lipschitz continuity for f, and we can consider the case of reaction terms which have polynomial growth (and hence are not well defined in H).

In order to solve the problem (1.3), we introduce the transition semigroup P_t associated with the system (1.1) by setting for any bounded Borel function φ from H into $\mathbb{R}$ and for any $x \in H$

$$P_t\varphi(x) = \mathbf{E}\,\varphi(y(t;x)), \qquad t \geq 0,$$

where $y(t;x)$ is the solution of the uncontrolled system (1.1) starting from x at time zero. Due to Itô's formula and the variation of constants formula, we write (1.3) in the mild form

$$u(t,x) = P_t\varphi(x) - \int_0^t P_{t-s}K(Du(s,\cdot))(x)\,ds + \int_0^t P_{t-s}g(x)\,ds,$$

and by using a fixed point argument we show that for any $\varphi, g \in C^1_b(H)$ there exists a unique differentiable solution $u(t,x)$ which is defined only in a small time interval $[0,T_0]$, as K is only locally Lipschitz continuous. We want to emphasize that the crucial point in our argument is given by the smoothing effect of the semigroup P_t. Actually, P_t maps the space of bounded Borel functions defined on H into the space of differentiable functions, and the estimate

$$\sup_{x\in H} |D(P_t\varphi)(x)| \leq c(t\wedge 1)^{-\frac{1+\epsilon}{2}} \sup_{x\in H} |\varphi(x)|$$

holds for some constant $\epsilon < 1$ depending on the dimension $d \leq 3$ (see [7] for the proof). In order to have a global solution we need to obtain some a priori estimates. To this purpose we first approximate the reaction term f by a Lipschitz continuous sequence $\{f_\alpha\}_{\alpha>0}$, and then we consider the approximating Hamilton–Jacobi–Bellman equation, with the nonlinear term f replaced by f_α. By a Galerkin argument we prove some a priori estimates for the corresponding solutions $u_\alpha(t,x)$, and, by taking the limit as α goes to zero, we get the good estimates for $u(t,x)$.

2. Notations and preliminary results. Let $\mathcal{O}$ be a bounded regular open set of $\mathbb{R}^d$, with $d \leq 3$, having a regular boundary. Here and in what follows we denote by H the Hilbert space $L^2(\mathcal{O};\mathbb{R}^r)$, endowed with the scalar product $\langle\cdot,\cdot\rangle_H$ and the norm $|\cdot|_H$. For any $p \geq 1$, $p \neq 2$, we denote by $|\cdot|_p$ the norm in $L^p(\mathcal{O};\mathbb{R}^r)$. Moreover, we denote by E the Banach space $C(\overline{\mathcal{O}};\mathbb{R}^r)$ endowed with the *sup-norm* and the duality pairing $\langle\cdot,\cdot\rangle_E$ in $E \times E^\star$.

If X and Y are two separable Banach spaces, $B_b(X;Y)$ is the Banach space of all bounded Borel functions $\varphi : X \to Y$ endowed with the *sup-norm*

$$\|\varphi\|_0^X = \sup_{x\in X} |\varphi(x)|_Y.$$

$C_b(X;Y)$ is the subspace of uniformly continuous functions. For any integer $k \geq 1$, we denote by $C_b^k(X;Y)$ the subspace of k-times Fréchet differentiable functions, having bounded and uniformly continuous derivatives, up to the kth order. If we set for any $j = 1,\dots,k$

$$[\varphi]_j^X = \sup_{x\in X} |D^j\varphi(x)|_{\mathcal{L}^j(X;Y)},$$

we have that $C_b^k(X;Y)$ is a Banach space endowed with the norm

$$\|\varphi\|_k^X = \|\varphi\|_0^X + \sum_{j=1}^k [\varphi]_j^X.$$

We denote by $\mathrm{Lip}_b(X;Y)$ the subspace of functions $\varphi \in C_b(X;Y)$ such that

$$[\varphi]_{\mathrm{Lip}}^X = \sup_{\substack{x,y\in X\\ x\neq y}} \frac{|\varphi(x)-\varphi(y)|_Y}{|x-y|_X} < \infty.$$

$\mathrm{Lip}_b(X;Y)$ is a Banach space endowed with the norm

$$\|\varphi\|_{\mathrm{Lip}}^X = \|\varphi\|_0^X + [\varphi]_{\mathrm{Lip}}^X.$$

When $Y = \mathbb{R}$, we denote $B_b(X;Y)$, $C_b(X;Y)$, $C_b^k(X;Y)$, and $\mathrm{Lip}_b(X;Y)$, respectively, by $B_b(X)$, $C_b(X)$, $C_b^k(X)$, and $\mathrm{Lip}_b(X)$.

2.1. The Nemytskii operator. We assume that for any $k = 1,\dots,r$ there exist two continuous functions $g_k : \overline{\mathcal{O}} \times \mathbb{R} \to \mathbb{R}$ and $h_k : \overline{\mathcal{O}} \times \mathbb{R}^r \to \mathbb{R}$ such that for any $\xi \in \overline{\mathcal{O}}$ and $\sigma = (\sigma_1,\dots,\sigma_r) \in \mathbb{R}^r$ it holds that

$$f_k(\xi,\sigma_1,\dots,\sigma_r) = g_k(\xi,\sigma_k) + h_k(\xi,\sigma_1,\dots,\sigma_r).$$

The functions g_k and h_k are assumed to enjoy the following conditions.

Hypothesis 1.

1. *For any $\xi \in \overline{\mathcal{O}}$ the function $h_k(\xi,\cdot)$ is of class C^2 and has bounded derivatives, uniformly with respect to $\xi \in \overline{\mathcal{O}}$. Moreover, the mapping $D^j_\sigma h_k : \overline{\mathcal{O}} \times \mathbb{R}^r \to \mathcal{L}^j(\mathbb{R}^r)$ is continuous for $j = 1, 2$.*
2. *For any $\xi \in \overline{\mathcal{O}}$, the function $g_k(\xi,\cdot)$ is of class C^2, and there exists $m \geq 0$ such that*
$$\sup_{\xi\in\overline{\mathcal{O}}} \sup_{t\in\mathbb{R}} \frac{|D^j_t g_k(\xi,t)|}{1+|t|^{2m+1-j}} < \infty.$$
Moreover, the mapping $D^j_t g_k : \overline{\mathcal{O}} \times \mathbb{R}^r \to \mathbb{R}$ is continuous for $j = 1, 2$.
3. *There exist $a > 0$ and $c \in \mathbb{R}$ such that*
$$\sup_{\xi\in\overline{\mathcal{O}}} D_t g_k(\xi,t) \leq -a\, t^{2m} + c, \qquad t \in \mathbb{R}. \tag{2.1}$$

The Nemytskii operator F associated with the function $(\xi,\sigma) \mapsto f(\xi,\sigma)$ is defined as
$$F(x)(\xi) = f(\xi, x(\xi)), \quad \xi \in \mathcal{O}.$$
If we denote
$$p_\star = 2m+2, \qquad q_\star = \frac{2m+2}{2m+1},$$
it is possible to show that if $m \geq 1$, then F is twice Fréchet differentiable from $L^{p_\star}(\mathcal{O};\mathbb{R}^r)$ into $L^{q_\star}(\mathcal{O};\mathbb{R}^r)$, and it holds that
$$|D^j F(x)|_{\mathcal{L}^j(L^{p_\star},\, L^{q_\star})} \leq c\left(1+|x|^{2m+1-j}_{p_\star}\right), \qquad x \in L^{p_\star}(\mathcal{O};\mathbb{R}^r).$$
From (2.1) we obtain that for any $x, h \in L^{p_\star}(\mathcal{O};\mathbb{R}^r)$
$$\langle DF(x)h, h\rangle_H \leq -a|x^m h|^2_H + c|h|^2_H,$$
and, in particular,
$$\langle DF(x)h, h\rangle_H \leq c\,|h|^2_H.$$
Moreover, from (2.1) it follows that for any $\sigma, \rho \in \mathbb{R}^r$
$$\sup_{\xi\in\overline{\mathcal{O}}} \langle f(\xi,\sigma+\rho) - f(\xi,\rho), \sigma\rangle_{\mathbb{R}^r} \leq -a|\sigma|^{2m+2} + c\left(1+|\rho|^{2m+1}\right)$$
for some constants $a > 0$ and $c \in \mathbb{R}$, possibly different from those introduced in (2.1). This implies that
$$\langle F(x+h) - F(x), h\rangle_H \leq -a\,|h|^{p^\star}_{p_\star} + c\left(1+|x|^{p_\star}_{p_\star}\right).$$

By using similar arguments, it is immediate to prove that $F : E \to E$ is twice differentiable, and
$$|D^j F(x)|_{\mathcal{L}^j(E)} \leq c\left(1+|x|^{2m+1-j}_E\right), \qquad x \in E. \tag{2.2}$$

For any $h, y \in E$ we define

$$\langle \delta_h, y \rangle_E = \begin{cases} \dfrac{1}{|h|_E} \displaystyle\sum_{k=1}^r y_k(\xi_k) h_k(\xi_k) & \text{if } h \neq 0, \\ \delta_0 & \text{if } h = 0, \end{cases} \tag{2.3}$$

where $|h_k(\xi_k)| = |h_k|_{C(\overline{\mathcal{O}})}$ for any $k = 1, \ldots, r$, and δ_0 is any element of the unitary ball of $E^\star$. It is possible to show that $\delta_h \in \partial\, |h|_E$ (see [11] and [6] for more details), and for any $x, h \in E$

$$\langle F(x+h) - F(x), \delta_h \rangle_E \leq c\, |h|_E.$$

Remark 2.1. For any $k = 1, \ldots, r$, let us define

$$g_k(\xi, t) = -c_k(\xi) t^{2m+1} + \sum_{j=0}^{2m} c_{kj}(\xi) t^j,$$

where c_k, c_{kj} are bounded continuous functions from $\overline{\mathcal{O}}$ into $\mathbb{R}$. If we assume that

$$\inf_{\xi \in \overline{\mathcal{O}}} c_k(\xi) > 0,$$

then it is possible to check that g_k fulfills parts 2 and 3 of Hypothesis 1.

Due to Hypothesis 1, there exists $c \in \mathbb{R}$ such that the mapping $\gamma(\xi, \cdot) = f(\xi, \cdot) - cI$ is dissipative for any $\xi \in \overline{\mathcal{O}}$. Then for any $\alpha > 0$ we can define the function

$$\gamma_\alpha : \overline{\mathcal{O}} \times \mathbb{R}^r \to \mathbb{R}^r, \qquad (\xi, \sigma) \mapsto \gamma(\xi, J_\alpha(\xi, \sigma)),$$

where

$$J_\alpha(\xi, \sigma) = (I - \alpha \gamma(\xi, \cdot))^{-1}(\sigma), \qquad \sigma \in \mathbb{R}^r.$$

As proved in [9, appendix A], the function $J_\alpha(\xi, \cdot)$ is of class C^2 for any fixed $\xi \in \overline{\mathcal{O}}$. Now if we set

$$f_\alpha(\xi, \sigma) = \gamma_\alpha(\xi, \sigma) + c J_\alpha(\xi, \sigma),$$

we have that $f_\alpha(\xi, \cdot)$ is Lipschitz continuous, uniformly with respect to $\xi \in \overline{\mathcal{O}}$, is twice differentiable, and

$$\sup_{\xi \in \overline{\mathcal{O}}} \langle f_\alpha(\xi, \sigma + \rho) - f_\alpha(\xi, \sigma), \rho \rangle_{\mathbb{R}^r} \leq c\, |\rho|^2 \tag{2.4}$$

for some constant c independent of α. Moreover, by using well-known properties of the function $J_\alpha(\xi, \sigma)$ (see [11] for the definitions and main results and see [9, chapter 9, appendix A],

$$\sup_{\xi \in \overline{\mathcal{O}}} |f_\alpha(\xi, \sigma) - f(\xi, \sigma)| \leq \alpha\, c(1 + |\sigma|^{4m+1}). \tag{2.5}$$

For any fixed $\xi \in \overline{\mathcal{O}}$ the function $f_\alpha(\xi, \cdot)$ is of class C^2, and for any $R > 0$

$$\lim_{\alpha \to 0} \sup_{\xi \in \overline{\mathcal{O}}} \sup_{|\sigma| \leq R} |D^j_\sigma f_\alpha(\xi, \sigma) - D^j_\sigma f(\xi, \sigma)| = 0. \tag{2.6}$$

Moreover, it is possible to show that

$$\sup_{\xi \in \overline{\mathcal{O}}} \frac{|D^j_\sigma f_\alpha(\xi,\sigma)|}{1+|\sigma|^{2m+1-j}} \leq c < \infty \tag{2.7}$$

for a constant c independent of α.

For each $\alpha > 0$, let F_α be the Nemytskii operator associated with the function f_α. Clearly F_α is Lipschitz continuous both as an operator in E and as an operator in H and is twice Fréchet differentiable in E, and, thanks to (2.4), there exists a constant c independent of α such that if $x, y \in H$,

$$\langle F_\alpha(x) - F_\alpha(y), x-y\rangle_H \leq c\,|x-y|^2_H, \tag{2.8}$$

and if $x, y \in E$,

$$\langle F_\alpha(x) - F_\alpha(y), \delta_{x-y}\rangle_E \leq c\,|x-y|_E, \tag{2.9}$$

where δ_{x-y} is the element in $\partial\,|x-y|_E$ introduced in (2.3). Furthermore, due to (2.6), for each $j = 0, 1, 2$ it holds that

$$\lim_{\alpha\to 0} \sup_{|x|_E \leq R} |D^j F_\alpha(x) - D^j F(x)|_{\mathcal{L}^j(E)} = 0 \tag{2.10}$$

for any $R > 0$, and due to (2.7)

$$|D^j F_\alpha(x)|_{\mathcal{L}^j(E)} \leq c\left(1 + |x|_E^{2m+1-j}\right), \qquad x \in E. \tag{2.11}$$

2.2. The operators A and Q and the stochastic convolution. We shall denote by $\mathcal{A}$ the second order differential operator defined for each $x \in H$ by $\mathcal{A}x = (\mathcal{A}_1 x_1, \ldots, \mathcal{A}_r x_r)$. For any $k = 1, \ldots, r$ we have

$$\mathcal{A}_k(\xi, D) = \sum_{i,j=1}^d a^{ij}_k(\xi) \frac{\partial^2}{\partial\xi_i \partial\xi_j} + \sum_{i=1}^d b^i_k(\xi)\frac{\partial}{\partial\xi_i}, \qquad \xi \in \overline{\mathcal{O}}.$$

The coefficients a^{ij}_k and b^i_k are assumed to be of class $C^1(\overline{\mathcal{O}})$, and for any $\xi \in \overline{\mathcal{O}}$ the matrix $[a^{ij}_k(\xi)]$ is symmetric and satisfies the uniform ellipticity condition

$$\inf_{\xi \in \overline{\mathcal{O}}} \sum_{i,j=1}^d a^{ij}_k(\xi) h_i h_j \geq \nu |h|^2, \quad h \in \mathbb{R}^d,$$

for some $\nu > 0$. The boundary operator $\mathcal{B}$ is defined by $\mathcal{B}x = (\mathcal{B}_1 x_1, \ldots, \mathcal{B}_r x_r)$, and for each $k = 1, \ldots, r$ we have

$$\mathcal{B}_k(\xi, D) = I \quad \text{or} \quad \mathcal{B}_k(\xi, D) = \sum_{i,j=1}^d a^{ij}_k(\xi)\nu_j(\xi)\frac{\partial}{\partial\xi_i}, \qquad \xi \in \ \partial\,\mathcal{O}. \tag{2.12}$$

We denote by A the realization in H of the elliptic operator $\mathcal{A}$, with the boundary conditions given by $\mathcal{B}$, that is,

$$D(A) = \left\{\, x \in\ H\ :\ \mathcal{A}x \in\ H,\ \mathcal{B}x_{|_{\partial D}} = 0\ \right\}, \quad Ax = \mathcal{A}x,\ x \in\ D(A).$$

The operator A generates an analytic semigroup e^{tA}. The semigroup e^{tA} is also analytic in each $L^p(\mathcal{O};\mathbb{R}^r)$, for $p \in (1,+\infty]$ (see [26, chapter 3] for all details).

In what follows it will not be restrictive to assume that for any $p \in [2,\infty]$

$$|e^{tA}x|_p \leq M|x|_p$$

for some constant $M > 0$ independent of p (see also [9, chapter 4]). In particular, we will have

$$\langle Ax, x\rangle_H \leq 0, \qquad x \in H. \tag{2.13}$$

Finally, if we denote by A the realization in E of the operator $\mathcal{A}$ with the boundary conditions given by $\mathcal{B}$, we have that A generates an analytic semigroup $e^{t\,A}$ of negative type; that is, for any $x \in E$ and $\delta_x \in \partial\,|x|_E$ defined as in (2.3)

$$\langle Ax, \delta_x\rangle_E \leq 0. \tag{2.14}$$

Now for any $k = 1,\dots,r$ we define

$$\mathcal{G}_k(\xi, D) = \sum_{i=1}^{d}\left(b_k^i(\xi) - \sum_{j=1}^{d}\frac{\partial a_k^{ij}}{\partial \xi_j}(\xi)\right)\frac{\partial}{\partial \xi_i}, \qquad \xi \in \mathcal{O},$$

and by difference we define $\mathcal{C}_k = \mathcal{A}_k - \mathcal{G}_k$. The second order elliptic operators $\mathcal{C} = (\mathcal{C}_1,\dots,\mathcal{C}_r)$, generate a negative analytic semigroup e^{tC} in each $L^p(\mathcal{O};\mathbb{R}^r)$ for any $p \in (1,\infty]$ and in E. The semigroup e^{tC} enjoys the same properties as $e^{t\,A}$ and, due to the boundary conditions (2.12), is self-adjoint in H. Moreover, for any $\delta \in \mathbb{R}$ we have that $D((-A)^\delta) = D((-C)^\delta)$ and

$$c_1\,|(-A)^\delta x|_H \leq |(-C)^\delta x|_H \leq c_2\,|(-A)^\delta x|_H \tag{2.15}$$

for suitable positive constants c_1 and c_2 depending only on δ.

Concerning the realization of the operator $\mathcal{G}$, as the coefficients a_k^{ij} and b_k^i are assumed to be smooth, it is easy to check that $D(G^\star) \subset D((-C)^{1/2})$ and

$$|G^\star x|_H \leq c\,|(-C)^{1/2}x|_H, \qquad x \in D(G^\star). \tag{2.16}$$

Finally, we denote by Q the bounded linear operator of components $(Q_1,\dots,Q_r)$. In what follows we shall assume that the operators Q and C fulfill the following conditions.

Hypothesis 2.

1. *There exists a complete orthonormal basis $\{e_k\}$ in H which diagonalizes C such that* $\sup_{k\in\mathbb{N}}|e_k|_E < \infty$. *The corresponding set of eigenvalues is denoted by $\{-\alpha_k\}$.*
2. *The bounded linear operator $Q : H \to H$ is nonnegative and diagonal with respect to the complete orthonormal basis $\{e_k\}$ which diagonalizes C. Moreover, if $\{\lambda_k\}$ is the corresponding set of eigenvalues, we have*

$$\sum_{k=1}^{\infty}\frac{\lambda_k^2}{\alpha_k^{1-\gamma}} < +\infty$$

for some $\gamma > 0$.

3. *There exists* $\epsilon < 1$ *such that*

$$D((-C)^{\frac{\epsilon}{2}}) \subset D(Q^{-1}). \tag{2.17}$$

Remark 2.2. It is known (see, for example, the book by Agmon [1]) that when the elliptic operator $\mathcal{A}$ with the boundary conditions $\mathcal{B}$ is smooth enough, then

$$\alpha_k \asymp k^{2/d}.$$

In this case, it is possible to prove that if $d \leq 3$, then there exists an operator Q which fulfills the conditions of parts 2 and 3 of Hypothesis 2.

Actually, if we assume that

$$\lambda_k \asymp \alpha_k^{-\rho}$$

for some $\rho > (d-2)/4$, then

$$\frac{\lambda_k^2}{\alpha_k^{1-\gamma}} \asymp \alpha_k^{-(1-\gamma+2\rho)} \asymp k^{-\frac{2(1-\gamma+2\rho)}{d}}.$$

As $1+2\rho > d/2$, we can fix $\gamma > 0$ such that $1-\gamma+2\rho > d/2$, and this implies that

$$\sum_{k=1}^{\infty} \frac{\lambda_k^2}{\alpha_k^{1-\gamma}} \asymp \sum_{k=1}^{\infty} k^{-\frac{2(1-\gamma+2\rho)}{d}} < \infty.$$

On the other hand, if $\rho \leq \epsilon/2$, then (2.17) holds. This means that if $d \leq 3$, it is possible to find ρ such that Q enjoys conditions 2 and 3 in Hypothesis 2. Notice that in dimension $d = 1$ one can take $\epsilon = 0$.

Let $\{w_k(t)\}$ be a sequence of mutually independent real-valued Brownian motions defined on a stochastic basis $(\Omega, \mathcal{F}, \mathcal{F}_t, \mathbf{P})$ and adapted to the nonanticipative filtration $\mathcal{F}_t$, $t \geq 0$. We define the cylindrical Wiener process $w(t)$ as

$$w(t) = \sum_{k=1}^{\infty} e_k w_k(t),$$

where $\{e_k\}$ is the complete orthonormal system of H introduced in part 1 of Hypothesis 2. The series above defining $w(t)$ does not converge in H, but it is convergent in any Hilbert space U such that the embedding $H \subset U$ is Hilbert–Schmidt (see [15, chapter 4]).

Now we consider the Ornstein–Uhlenbeck problem associated with the system (1.1)

$$dv(t) = Av(t)\,dt + Q\,dw(t), \qquad v(s) = 0,$$

for $0 \leq s \leq t \leq T$. Due to parts 1 and 2 of Hypothesis 2, such a problem admits a unique solution $w^A(t,s)$, which is the mean-square Gaussian process with values in H given by

$$w^A(t,s) = \int_s^t e^{(t-r)\,A} Q\,dw(r) \tag{2.18}$$

(see, e.g., [15] for a proof). Moreover, as shown in [8], $w^A(\cdot,s) \in C([s,T]\times\overline{\mathcal{O}})$, $\mathbf{P}$-almost surely (a.s.), and for any $p \geq 1$ it holds that

$$\mathbf{E}\,|w^A(\cdot,s)|^p_{C([s,T];E)} < \infty. \tag{2.19}$$

For any $n \in \mathbb{N}$ we define

$$A_n = P_n A P_n, \qquad C_n = C P_n, \qquad G_n = P_n G P_n, \qquad Q_n = Q P_n,$$

where P_n is the projection of H onto the finite dimensional space H_n generated by the eigenfunctions $\{e_1,\dots,e_n\}$. If we denote by $w^A_n(t,s)$ the solution of the problem

$$dv(t) = A_n v(t)\,dt + Q_n\,dw(t), \qquad v(s)=0,$$

by using a factorization argument (see [15]) it is not difficult to prove that for any $p \geq 1$

$$\lim_{n\to+\infty} \mathbf{E}\,|w^A(\cdot,s) - w^A_n(\cdot,s)|^p_{C([s,T];H)} = 0.$$

3. The state equation. By using the notations introduced in the previous section, the controlled system (1.1) can be rewritten in the abstract form

$$dy(t) = (Ay(t) + F(y(t)) + z(t))\;dt + Q\,dw(t), \qquad y(s) = x, \tag{3.1}$$

for $0 \leq s \leq t \leq T$.

Definition 3.1.

1. *Let us fix an adapted process $z \in L^2(\Omega; L^2(0,T;E))$ and $x \in E$. An E-valued predictable process $y(t) = y(t,s;x,z)$ is a* mild *solution for the problem* (3.1) *if*

$$y(t) = e^{(t-s)\,A}x + \int_s^t e^{(t-r)\,A}\,(F(y(r)) + z(r))\;dr + w^A(t,s),$$

where the process $w^A(t,s)$ is given by (2.18).

2. *Let us fix an adapted process $z \in L^2(\Omega; L^2(0,T;H))$ and $x \in H$. A H-valued process $y(t,s;x,z)$ is a* generalized *solution for the problem* (3.1) *if, for any sequences $\{x_n\} \subset E$ converging to x in H and $\{z_n\} \subset L^2(\Omega;L^2(0,T;E))$ converging to z in $L^2(\Omega;L^2(0,T;H))$, the corresponding sequence of mild solutions $\{y(\cdot,s;x_n,z_n)\}$ converges to $y(\cdot,s;x,z)$ in $C([s,T];H)$, $\mathbf{P}$-a.s.*

In [15] (see also [6] and [7]) the following existence and uniqueness result is proved for the uncontrolled system. When $z \neq 0$, the proof is analogous, and we do not repeat it.

Theorem 3.2. *Assume Hypotheses* 1 *and* 2, *and fix $0 \leq s \leq T$.*

1. *For any $z \in L^2(\Omega; L^p(s,T;H))$ with $p > 4/(4-d)$ and for any $x \in E$, the problem* (3.1) *admits a unique mild solution $y(\cdot,s;x,z) \in L^2(\Omega; C((s,T];E) \cap L^\infty(s,T;E))$ such that*

$$|y(t,s;x,z)|_E \leq c_T\Big(|x|_E + |z|^{2m+1}_{L^p(s,t;H)} + \sup_{r\in\,[s,t]} |w^A(r,s)|^{2m+1}_E\Big), \qquad \mathbf{P} - a.s. \tag{3.2}$$

2. *For any $z \in L^2(\Omega; L^2(s,T;H))$ and $x \in H$, the problem* (3.1) *admits a unique generalized solution $y(\cdot, s; x, z) \in L^2(\Omega; C([s,T]; H))$ such that*

$$|y(t,s;x,z)|_H \leq c_T\Big(|x|_H + |z|^{2m+1}_{L^2(s,T;H)} + \sup_{r\in [s,t]} |w^A(r,s)|^{2m+1}_E\Big), \qquad \mathbf{P} - a.s. \tag{3.3}$$

3. *The unique generalized solution $y(\cdot, s; x, z)$ belongs to $L^{p_\star}(t,T; L^{p_\star}(\mathcal{O}))$, $\mathbf{P}$-a.s., and*

$$y(t,s;x,z) = e^{(t-s)\,A}x + \int_s^t e^{(t-r)\,A}\left(F(y(r,s;x,z)) + z(r)\right) dr + w^A(t,s).$$

4. *For any $x_1, x_2 \in H$ and $z_1, z_2 \in L^2(\Omega; L^2(s,T;H))$, we have*

$$|y(t,s;x_1,z_1) - y(t,s;x_2,z_2)|_H \leq c_T\left(|x_1 - x_2|_H + |z_1 - z_2|_{L^2(s,T;H)}\right). \tag{3.4}$$

For any $\alpha > 0$ we consider the approximating problem

$$dy(t) = (Ay(t) + F_\alpha(y(t)) + z(t))\,dt + Q\,dw(t), \qquad y(s) = x, \tag{3.5}$$

$s \leq t \leq T$. Clearly an existence theorem analogous to Theorem 3.2 holds for (3.5). Actually, for each $x \in E$ and $z \in L^2(\Omega; L^p(0,T;H))$, with $p > 4/(4-d)$, there exists a unique mild solution $y_\alpha(\cdot, s; x, z)$ in $L^2(\Omega; C((s,T]; E) \cap L^\infty(s,T;E))$, and for each $x \in H$ and $z \in L^2(\Omega; L^2(0,T;H))$ there exists a unique generalized solution $y_\alpha(\cdot, s; x, z)$ which belongs to $L^2(\Omega; C([s,T]; H))$. Moreover, estimates analogous to (3.2) and (3.3) hold for every $\alpha > 0$.

LEMMA 3.3. *Under Hypotheses* 1 *and* 2, *if $x \in E$ and $z \in L^p(\Omega; L^\infty(0,T;H))$ for p sufficiently large, then for any fixed $q \geq 1$*

$$\lim_{\alpha\to 0} \mathbf{E}\,|y_\alpha(t,s;x,z) - y(t,s;x,z)|^q_E = 0, \tag{3.6}$$

uniformly with respect to $t \in [0,T]$, x in bounded subsets of E and z in the set

$$\mathcal{M}_R = \Big\{\, z \in L^2(\Omega; L^2(0,T;H))\ ;\ \sup_{t\in [0,T]} |z(t)|_H \leq R,\ \mathbf{P} - a.s. \Big\}$$

for any $R > 0$.

Proof. If we set $v_\alpha(t) = y_\alpha(t) - y(t)$, we have that v_α is the unique solution of the problem

$$\frac{dv}{dt}(t) = Av(t) + F_\alpha(y_\alpha(t)) - F(y(t)), \qquad v(s) = 0.$$

Thus, by using classical properties of the subdifferential of the norm in E introduced in (2.3) (see [11] for all properties), if $\delta_{v_\alpha(t)} \in \partial\,|v_\alpha(t)|_E$, we have

$$\frac{d}{dt}^{-}|v_\alpha(t)|_E \leq \left\langle Av_\alpha(t), \delta_{v_\alpha(t)}\right\rangle_E + \left\langle F_\alpha(y_\alpha(t)) - F(y(t)), \delta_{v_\alpha(t)}\right\rangle_E.$$

From (2.9) and (2.14) this easily implies that

$$\frac{d}{dt}^{-}|v_\alpha(t)|_E \leq c\,|v_\alpha(t)|_E + |F_\alpha(y(t)) - F(y(t))|_E$$

so that, due to the Gronwall lemma and (2.5), we have

$$|v_\alpha(t)|_E \leq \alpha\, c \int_s^t e^{c(t-r)} \left(1 + |y(r)|_E^{4m+1}\right) dr.$$

This implies (3.6), as from (2.19) and (3.2) for any $q \geq 1$ we have

$$\sup_{z \in \mathcal{M}_R} \mathbf{E}\, |y(\cdot, s; x, z)|^q_{C([s,T];E)} < \infty. \qquad \square \tag{3.7}$$

Next, for any $n \in \mathbb{N}$ and $\alpha > 0$ we define

$$F_{\alpha,n}(x) = P_n F_\alpha(P_n x), \qquad x \in H.$$

It is immediate to check that for any $x, y \in H$ it holds that

$$\langle F_{\alpha,n}(x) - F_{\alpha,n}(y), x - y \rangle_H \leq c\, |x - y|_H^2 \tag{3.8}$$

for a constant c independent of n and α. Moreover,

$$|F_{\alpha,n}(x) - F_{\alpha,n}(y)|_H \leq c_\alpha\, |x - y|_H \tag{3.9}$$

for some constant c_α independent of n. In correspondence with each $n \in \mathbb{N}$, $\alpha > 0$, and $0 \leq s \leq T$, we consider the approximating problem

$$dy(t) = (A_n y(t) + F_{\alpha,n}(y(t)) + z_n(t))\, dt + Q_n\, dw(t), \qquad y(s) = P_n x, \tag{3.10}$$

where $z_n(t) = P_n z(t)$ and z is an adapted process in $L^2(\Omega; L^2(s,T;H))$. Such a problem is a finite dimensional problem with Lipschitz coefficients. Thus for any $x \in H$ there exists a unique strong solution $y_{\alpha,n}(\cdot, s; x, z) \in L^2(\Omega; C([s,T];H))$.

LEMMA 3.4. *Let z be an adapted process in $L^2(\Omega; L^2(s,T;H))$. If $y_{\alpha,n}(\cdot, s; x, z)$ is the unique solution of the approximating problem* (3.10), *it holds that*

$$\lim_{n \to +\infty} y_{\alpha,n}(\cdot, s; x, z) = y_\alpha(\cdot, s; x, z) \qquad \text{in } L^2(\Omega; C([s,T];H)), \tag{3.11}$$

uniformly for x in bounded subsets of H.

Proof. For each $n, k \in \mathbb{N}$, we consider the problem

$$dy(t) = (A_n y(t) + F_{\alpha,n}(y(t)) + z_{n \wedge k}(t))\, dt + Q_{k \wedge n}\, dw(t), \qquad y(0) = P_n x. \tag{3.12}$$

By using a factorization argument, we have that for any $p \geq 1$

$$\lim_{k \to +\infty} \sup_{n \in \mathbb{N}} \mathbf{E} \sup_{t \in [s,T]} |w^A_{n,k}(t,s)|_H^p = 0,$$

and, since $z \in L^2(\Omega; L^2(s,T;H))$, we have

$$\lim_{k \to +\infty} \sup_{n \in \mathbb{N}} \mathbf{E}\, |z_n - z_{n \wedge k}|^2_{L^2(s,T;H)} = 0.$$

Thus, by some calculations, if we denote by $y^k_{\alpha,n}(t)$ the solution of (3.12), we have

$$\lim_{k \to +\infty} \sup_{n \in \mathbb{N}} |y^k_{\alpha,n}(\cdot, s; x, z) - y_{\alpha,n}(\cdot, s; x, z)|_{L^2(\Omega; C([s,T];H))} = 0. \tag{3.13}$$

Now for any $k \in \mathbb{N}$ we consider the problem

$$dy(t) = (Ay(t) + F_\alpha(y(t)) + z_k(t))\, dt + Q_k\, dw(t), \qquad y(s) = x.$$

It is immediate to check that $w_k^A \in L^p(\Omega, C((s,T]; D((-A)^\delta)))$ for any $\delta \in \mathbb{R}$ and $p \geq 1$. Hence, by straightforward computations, thanks to (2.15) we have that such a problem admits a unique mild solution $y_\alpha^k(\cdot, s; x, z)$ such that

$$\begin{aligned} & |y_\alpha^k(t)|_H^2 + \int_0^t |(-C)^{1/2} y_\alpha^k(s)|_H^2\, ds \\ & \leq c_T \Big(|x|_H^2 + \sup_{t \in [s,T]} |w_k^A(t,s)|^2_{D((-A)^{1/2})} + |z|^2_{L^2(s,T;H)} \Big). \end{aligned} \tag{3.14}$$

Moreover, it is possible to show that for any fixed $k \in \mathbb{N}$

$$\lim_{n \to +\infty} y_{\alpha,n}^k(\cdot, s; x, z) = y_\alpha^k(\cdot, s; x, z) \qquad \text{in } L^2(\Omega; C([s,T]; H)). \tag{3.15}$$

Finally, we have that

$$\lim_{k \to +\infty} y_\alpha^k(\cdot, s; x, z) = y_\alpha(\cdot, s; x, z) \qquad \text{in } L^2(\Omega; C([s,T]; H)). \tag{3.16}$$

Indeed, if we define $v_\alpha^k(t) = y_\alpha(t) - y_\alpha^k(t) - w^A(t,s) + w_k^A(t,s)$, we have that $v_\alpha^k(t)$ is the unique solution for the problem

$$\frac{dv}{dt}(t) = Av(t) + F_\alpha(y_\alpha(t)) - F_\alpha(y_\alpha^k(t)) + z(t) - z_k(t), \qquad v(s) = 0.$$

Thus, by multiplying each side by $v_\alpha^k(t)$, we have

$$\begin{aligned} & \frac{1}{2}\frac{d}{dt}|v_\alpha^k(t)|_H^2 + |(-A)^{1/2} v_\alpha^k(t)|_H^2 \\ & = \left\langle F_\alpha(y_\alpha(t)) - F_\alpha(y_\alpha^k(t)), v_\alpha^k(t) \right\rangle_H + \left\langle z(t) - z_k(t), v_\alpha^k(t) \right\rangle_H \end{aligned}$$

so that, as F_α is Lipschitz continuous, we easily get

$$\frac{1}{2}\frac{d}{dt}|v_\alpha^k(t)|_H^2 \leq c_\alpha\, |v_\alpha^k(t)|_H^2 + c_\alpha\, |w^A(t,s) - w_k^A(t,s)|_H^2 + c\, |z(t) - z_k(t)|_H^2.$$

By applying the Gronwall lemma, by taking the supremum over $t \in [s,T]$, and, finally, by taking the expectation, we get

$$\mathbf{E} \sup_{t \in [s,T]} |v_\alpha^k(t)|_H^2 \leq c_{\alpha,T} \int_s^T \mathbf{E} \left(|w^A(t,s) - w_k^A(t,s)|_H^2 + |z(t) - z_k(t)|_H^2 \right) dt,$$

and this immediately implies (3.16).

Now we can conclude. Actually, due to (3.13) and (3.16), for any $\epsilon > 0$ there exists $k_\epsilon \in \mathbb{N}$ such that for any $n \in \mathbb{N}$ it holds that

$$\mathbf{E} \sup_{t \in [s,T]} \left(|y_{\alpha,n}^{k_\epsilon}(t) - y_{\alpha,n}(t)|_H^2 + |y_\alpha^{k_\epsilon}(t) - y_\alpha(t)|_H^2 \right) < \epsilon/2.$$

Besides, due to (3.15) there exists $n_\epsilon \in \mathbb{N}$ such that

$$\mathbf{E} \sup_{t \in [s,T]} |y_{\alpha,n}^{k_\epsilon}(t) - y_\alpha^{k_\epsilon}(t)|_H^2 < \epsilon/2$$

for any $n \geq n_\epsilon$ so that (3.11) follows. $\square$

4. The first variation equation. Here and in what follows, we shall denote, respectively, by $y(t;x)$, $y_\alpha(t;x)$ and $y_{\alpha,n}(t;x)$ the mild solutions of the problems (3.1), (3.5), and (3.10) when $z=0$ and $s=0$.

In the present section we study the first variation equation associated with the problem (3.1):

$$\frac{dv}{dt}(t) = Av(t) + DF(y(t;x))v(t), \qquad v(0)=h. \tag{4.1}$$

In [6, Theorem 4.2] we have proved that for any $x,h \in E$ there exists a unique mild solution for the problem (4.1), and for any $t \geq 0$ and $x,h \in E$ such a solution is given by $Dy(t;x)h$, the Fréchet derivative of the mapping

$$E \to L^2(\Omega;E), \qquad x \mapsto y(t;x),$$

along the direction h. Moreover, in [7, Proposition 4.1] we have proved that if $x,h \in H$, then the problem (4.1) admits a unique generalized solution $v(x,h)$.

As proved in [5], under Hypotheses 1 and 2 the solution $y_\alpha(t;x)$ is twice mean-square differentiable with respect to $x \in H$. Moreover, the first derivative $Dy_\alpha(t;x)h$ is the unique solution of the first variation equation corresponding to the problem (3.5), which is

$$\frac{dv}{dt}(t) = Av(t) + DF_\alpha(y_\alpha(t))v(t), \qquad v(0)=h.$$

We have the following approximation result.

Lemma 4.1. *Under Hypotheses* 1 *and* 2, *for any $x \in E$ and $t \geq 0$, it holds that*

$$\lim_{\alpha\to 0} \mathbf{E} \sup_{|h|_H \leq 1} |Dy_\alpha(\cdot;x)h - Dy(\cdot;x)h)|^2_{L^\infty(0,T;H)\cap L^2(0,T;D((-A)^{1/2}))} = 0, \tag{4.2}$$

uniformly for x in bounded sets of E.

Proof. As proved in [6], for any $h \in H$

$$\sup_{x\in H}\left(|Dy(t;x)h|^2_H + \int_0^t |(-A)^{1/2}Dy(s;x)h|^2_H\right) \leq c_T|h|^2_H, \qquad \mathbf{P}-\text{a.s.} \tag{4.3}$$

If we define $v_\alpha(t) = Dy_\alpha(t;x)h - Dy(t;x)h$, we have that $v_\alpha(t)$ is the unique solution to the problem

$$\frac{dv}{dt}(t) = Av(t) + DF_\alpha(y_\alpha(t;x))Dy_\alpha(t;x)h - DF(y(t;x))Dy(t;x)h, \quad v(0)=0.$$

Thus we have

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|v_\alpha(t)|^2_H + |(-A)^{1/2}v_\alpha(t)|^2_H \\
&= \langle DF_\alpha(y_\alpha(t))v_\alpha(t), v_\alpha(t)\rangle_H + \langle\left(DF_\alpha(y_\alpha(t)) - DF(y(t))\right)Dy(t;x)h, v_\alpha(t)\rangle_H \\
&\leq c\,|v_\alpha(t)|^2_H + c\,e^{cT}\,|DF_\alpha(y_\alpha(t)) - DF(y(t))|^2_E|h|^2_H,
\end{aligned}$$

the last inequality following from (2.8), (4.3), and the Young inequality. Since F_α verifies the estimate (2.11), for any $x,y \in E$ we have

$$\begin{aligned}
&|DF_\alpha(x) - DF(y)|_E \leq |DF_\alpha(x) - DF_\alpha(y)|_E + |DF_\alpha(y) - DF(y)|_E \\
&\leq c\left(1 + |x|^{2m-1}_E + |y|^{2m-1}_E\right)|x-y|_E + |DF_\alpha(y) - DF(y)|_E.
\end{aligned}$$

Therefore, thanks to the Gronwall lemma and the above inequality, we have

$$|v_\alpha(t)|_H^2 \leq c_T \int_0^t \left(1+|y_\alpha(s)|_E^{4m-2}+|y(s)|_E^{4m-2}\right)|y_\alpha(s)-y(s)|_E^2\,ds|h|_H^2$$

$$+c_T\int_0^t |DF_\alpha(y(s))-DF(y(s))|_E\,ds|h|_H^2.$$

Due to (2.9) it is immediate to check that

$$\sup_{\alpha>0}|y_\alpha(t;x)|_E \leq c_T\Big(|x|_E+\sup_{t\in\,[0,T]}|w^A(t,0)|_E\Big), \qquad \mathbf{P}-\text{a.s.}, \tag{4.4}$$

and hence, by using (2.10), (3.2), and (3.6), we have

$$\lim_{\alpha\to 0}\mathbf{E}\sup_{|h|_H\leq 1}|v_\alpha(t)|_H^2=0.$$

This immediately yields

$$\lim_{\alpha\to 0}\mathbf{E}\sup_{|h|_H\leq 1}\int_0^t|(-A)^{1/2}v_\alpha(s)|_H^2\,ds=0,$$

and (4.2) holds true. □

Due to part 2 of Hypothesis 2, and the closed graph theorem, we have that the operator $\Gamma_\epsilon = Q^{-1}(-A)^{-\epsilon/2}$ is bounded in H. Thus, for any $x\in D((-A)^{1/2})$, by interpolation we get

$$|Q^{-1}x|_H \leq c\,|(-A)^{1/2}x|_H^\epsilon\,|x|_H^{1-\epsilon}. \tag{4.5}$$

Therefore, from (4.2) we get

$$\lim_{\alpha\to 0}\mathbf{E}\sup_{|h|_H\leq 1}\int_0^t|Q^{-1}(Dy_\alpha(s;x)h-Dy(s;x)h)|_H^2\,ds=0, \tag{4.6}$$

uniformly for x in bounded sets of E.

For each $n\in\mathbb{N}$ and $\alpha>0$, the solution of (3.10) is twice mean-square differentiable with respect to $x\in H$. In the next lemma we show that we can approximate in a suitable sense $Dy_\alpha(t;x)h$ by means of $Dy_{\alpha,n}(t;x)h$.

Lemma 4.2. *Assume that Hypotheses* 1 *and* 2 *hold. Then*

$$\lim_{n\to+\infty}\mathbf{E}\sup_{|h|_H\leq 1}|Dy_{\alpha,n}(\cdot;x)h-Dy_\alpha(\cdot;x)P_nh|^2_{L^\infty(0,T;H)\cap L^2(0,T;D((-A)^{1/2}))}=0, \tag{4.7}$$

uniformly for x in bounded subsets of H.

Proof. If we set $v_{\alpha,n}(t)=Dy_{\alpha,n}(t;x)h-Dy_\alpha(t;x)P_nh$, we have that $v_{\alpha,n}(t)$ is the unique solution of the problem

$$\frac{dv}{dt}(t)=Cv(t)+G_nDy_{\alpha,n}(t)h-GDy_\alpha(t)P_nh$$

$$+DF_{\alpha,n}(y_{\alpha,n}(t;x))Dy_{\alpha,n}(t)h-DF_\alpha(y_\alpha(t;x))Dy_\alpha(t)P_nh, \qquad v(0)=0.$$

By using (2.15), (2.16), and (3.9) by some computations, we get

$$\tag{4.8}\begin{aligned}&\frac{d}{dt}|v_{\alpha,n}(t)|_H^2+|(-C)^{1/2}v_{\alpha,n}(t)|_H^2\le c_\alpha\,|v_{\alpha,n}(t)|_H^2\\&+c_{\alpha,T}\left(\|P_n-I\|^2_{\mathcal{L}(D((-C)^{1/2});H)}+|y_{\alpha,n}-y_\alpha|^2_{C([0,T];H)}\right)|Dy_\alpha(t;x)P_nh|^2_{D((-A)^{1/2})}.\end{aligned}$$

In [6] it is proved that for each $h\in H$

$$\sup_{x\in H}\int_0^t|Dy_\alpha(s;x)h|^2_{D((-A)^{1/2})}\,ds\le c_T\,|h|_H^2,\qquad \mathbf{P}-\text{a.s.},$$

and then, by using the Gronwall lemma, this yields

$$|v_{\alpha,n}(t)|_H^2\le c_{\alpha,T}\left(\|P_n-I\|^2_{\mathcal{L}(D((-C)^{1/2});H)}+|y_{\alpha,n}-y_\alpha|^2_{C([0,T];H)}\right)|h|_H^2.$$

Thus, as

$$\lim_{n\to+\infty}\|P_n-I\|_{\mathcal{L}(D((-C)^{1/2});H)}=0,$$

from Lemma 3.4 we get

$$\lim_{n\to+\infty}\mathbf{E}\sup_{|h|_H\le1}\sup_{t\in[0,T]}|Dy_{\alpha,n}(t;x)h-Dy_\alpha(t;x)P_nh|_H^2=0.$$

Thanks to (4.8), from the limit above we get

$$\lim_{n\to+\infty}\mathbf{E}\sup_{|h|_H\le1}\int_0^t|(-A)^{1/2}(Dy_{\alpha,n}(s;x)h-Dy_\alpha(s;x)P_nh)|_H^2\,ds=0$$

so that (4.7) follows. □

By using the interpolation inequality (4.5), we get

$$\tag{4.9}\lim_{n\to+\infty}\mathbf{E}\sup_{|h|_H\le1}\int_0^t\left|Q^{-1}\left(Dy_{\alpha,n}(s;x)h-Dy_\alpha(s;x)P_nh\right)\right|_H^2\,ds=0.$$

5. The transition semigroup. The transition semigroup P_t associated with the system (1.1) is defined for any $\varphi\in B_b(H)$ and $x\in H$ by

$$P_t\varphi(x)=\mathbf{E}\,\varphi(y(t;x)),\qquad t\ge0,$$

where $y(t;x)$ is the solution of the problem (1.1), with $z=0$, starting from x at time zero.

As proved in [7], P_t is a contraction semigroup on $C_b(H)$. In general, P_t is not strongly continuous in $C_b(H)$. Nevertheless, $y(\cdot;x)\in L^2(\Omega;C([0,T];H))$ for any fixed $x\in H$ so that the mapping

$$[0,+\infty)\to\mathbb{R},\qquad t\mapsto P_t\varphi(x),$$

is continuous for any $\varphi\in C_b(H)$.

In [7, Theorem 5.1] we have also proved that P_t has a smoothing effect. Namely, we have shown that $P_t : B_b(H) \to C_b^1(H)$ for any $t > 0$, and if ϵ is the constant introduced in part 3 of Hypothesis 2.

$$\|P_t\varphi\|_j^H \leq c_0\,(t \wedge 1)^{-\frac{(j-i)(1+\epsilon)}{2}}\,\|\varphi\|_i^H, \qquad i \leq j \leq 0, 1, \tag{5.1}$$

for some constant $c_0 > 0$. Moreover, if $\varphi \in C_b(H)$, for any $x, h \in H$ it holds that

$$\langle D(P_t\varphi)(x), h\rangle_H = \frac{1}{t}\,\mathbf{E}\,\varphi(y(t;x)) \int_0^t \left\langle Q^{-1}v(s;x,h), dw(s)\right\rangle_H, \tag{5.2}$$

where $v(s;x,h)$ is the unique generalized solution of the problem (4.1). The formula above is a generalization to the degenerate case of the Bismut–Elworthy formula (see [2] and [16] for the finite dimension and [27] for the infinite dimension).

Now for any $\alpha > 0$ we define P_t^α as the transition semigroup corresponding to the approximating problem (3.5) with $z = 0$. As proved in [5], the semigroup P_t^α maps $B_b(H)$ into $C_b^2(H)$ for any $t > 0$, and if $\varphi \in C_b(H)$, it holds that

$$\langle D(P_t^\alpha\varphi)(x), h\rangle_H = \frac{1}{t}\,\mathbf{E}\,\varphi(y_\alpha(t;x)) \int_0^t \left\langle Q^{-1}Dy_\alpha(s;x)h, dw(s)\right\rangle_H$$

for all $x, h \in H$. Moreover, for $i \leq j = 0, 1, 2$

$$\|P_t^\alpha\varphi\|_j^H \leq c_\alpha\,(t \wedge 1)^{-\frac{(j-i)(1+\epsilon)}{2}}\,\|\varphi\|_i^H. \tag{5.3}$$

Due to (2.8), by proceeding as in [6] it is possible to show that

$$\sup_{x \in H}\left(|Dy_\alpha(t;x)h|_H^2 + \int_0^t |(-A)^{1/2}Dy_\alpha(s;x)h|_H^2\right) \leq c_T|h|_H^2, \qquad \mathbf{P}-\text{a.s.}, \tag{5.4}$$

for a constant c_T independent of α. Thus if $j = 1$, for each $i = 0, 1$ we have

$$\|P_t^\alpha\varphi\|_1^H \leq c\,(t \wedge 1)^{-\frac{(1-i)(1+\epsilon)}{2}}\,\|\varphi\|_i^H, \tag{5.5}$$

and the constant c is independent of α.

From Lemma 3.3, we easily have that for any $\varphi \in C_b(H)$ it holds that

$$\lim_{\alpha \to 0} P_t^\alpha\varphi(x) = P_t\varphi(x), \tag{5.6}$$

uniformly with respect to $t \in [0, T]$ and x in bounded subsets of E. Moreover, from Lemma 4.1, we have that

$$\lim_{\alpha \to 0} |D(P_t^\alpha\varphi)(x) - D(P_t\varphi)(x)|_H = 0, \qquad t > 0, \tag{5.7}$$

uniformly for x in bounded sets of E. Actually, for each $\alpha > 0$ it holds that

$$\langle D(P_t^\alpha\varphi)(x), h\rangle_H = \frac{1}{t}\mathbf{E}\,\varphi(y_\alpha(t;x)) \int_0^t \left\langle Q^{-1}Dy_\alpha(s;x)h, dw(s)\right\rangle_H,$$

and then by easy calculations we obtain

$$\begin{aligned}
&|\langle D(P_t^\alpha\varphi)(x) - D(P_t\varphi)(x), h\rangle_H| \\
&\leq \frac{\|\varphi\|_1^H}{t}\left(\mathbf{E}\,|y_\alpha(t,x) - y(t;x)|_H^2\right)^{1/2}\left(\mathbf{E}\int_0^t |Q^{-1}Dy_\alpha(s;x)h|_H^2\,ds\right)^{1/2} \\
&+\frac{\|\varphi\|_1^H}{t}\left(\mathbf{E}\int_0^t |Q^{-1}(Dy_\alpha(s;x)h - Dy(s;x)h)|_H^2\,ds\right)^{1/2}.
\end{aligned}$$

Thus (5.7) follows from (3.6) and (4.6).

In correspondence of each $n \in \mathbb{N}$, we can introduce the transition semigroup $P_t^{\alpha,n}$ associated with the system (3.10). The semigroup $P_t^{\alpha,n}$ fulfills all the regularizing properties described above for P_t^α. In particular, due to (3.9) it is not difficult to check that for $i = 0, 1$

$$\|P_t^{\alpha,n}\|_1^H \leq c\,(t \wedge 1)^{-\frac{(1-i)(1+\epsilon)}{2}}\,\|\varphi\|_i^H, \qquad t > 0, \tag{5.8}$$

for a constant c which does not depend on n and α. In the next theorem we prove that it is possible to approximate $P_t^\alpha \varphi$ and its first derivative by means of $P_t^{\alpha,n}$ and its first derivative.

Proposition 5.1. *Under Hypotheses* 1 and 2, *for any $\varphi \in C_b(H)$ we have*

$$\lim_{n \to +\infty} P_t^{\alpha,n}\varphi(x) = P_t^\alpha \varphi(x), \tag{5.9}$$

uniformly for x in bounded sets of H and $t \in [0, T]$. Moreover,

$$\lim_{n \to +\infty} |D(P_t^{\alpha,n}\varphi)(x) - D(P_t^\alpha \varphi)(x)|_H = 0, \tag{5.10}$$

uniformly for x in bounded sets of H and $t \in [\delta, T]$, with $\delta > 0$.

Proof. The limit (5.9) follows directly from Lemma 3.4. As far as the limit (5.10) is concerned, we have

$$\begin{aligned}
&\langle D(P_t^\alpha \varphi)(x) - D(P_t^{\alpha,n}\varphi)(x), P_n h\rangle_H \\
&= \frac{1}{t}\mathbf{E}\left(\varphi(y_\alpha(t;x)) - \varphi(y_{\alpha,n}(t;x))\right)\int_0^t \left\langle Q^{-1} D y_\alpha(s;x) P_n h, dw(s)\right\rangle_H \\
&+ \frac{1}{t}\mathbf{E}\,\varphi(y_{\alpha,n}(t;x))\int_0^t \left\langle Q^{-1}(D y_\alpha(s;x) P_n h - D y_{\alpha,n}(s;x)h), dw(s)\right\rangle_H .
\end{aligned}$$

Thus we get

$$\begin{aligned}
&|\langle D(P_t^\alpha \varphi)(x) - D(P_t^{\alpha,n}\varphi)(x), P_n h\rangle_H|^2 \\
&\leq \frac{2}{t^2}\mathbf{E}\,|\varphi(y_\alpha(t;x)) - \varphi(y_{\alpha,n}(t;x))|^2\,\mathbf{E}\int_0^t |Q^{-1} D y_\alpha(s;x) P_n h|_H^2\,ds \\
&+ \frac{2}{t^2}\|\varphi\|_0^2\,\mathbf{E}\int_0^t |Q^{-1}(D y_\alpha(s;x) P_n h - Dx y_{\alpha,n}(s;x)h)|_H^2\,ds.
\end{aligned}$$

By taking the supremum over $|h|_H \leq 1$, due to (3.11), (4.6), and (5.4), it follows that

$$\lim_{n \to +\infty} |P_n D(P_t^\alpha \varphi)(x) - D(P_t^{\alpha,n}\varphi)(x)|_H = 0,$$

and, as

$$\lim_{n \to +\infty} |P_n D(P_t^\alpha \varphi)(x) - D(P_t^\alpha \varphi)(x)|_H = 0,$$

we obtain (5.10). □

6. The Hamilton–Jacobi–Bellman equation. We are here concerned with the infinite dimensional Cauchy problem

$$\frac{\partial u}{\partial t}(t,x) = \mathcal{L}u(t,x) - K(Du(t,x)) + g(x), \qquad u(0,x) = \varphi(x), \tag{6.1}$$

where $\mathcal{L}$ is the differential operator defined by

$$\mathcal{L}\psi(x) = \frac{1}{2}\mathrm{Tr}\,[Q^2 D^2\psi(x)] + \langle Ax + F(x), D\psi(x)\rangle_H\,, \qquad x \in D(A) \cap D(F).$$

In addition to Hypotheses 1 and 2, the following condition shall be assumed.

HYPOTHESIS 3. *The hamiltonian $K : H \to \mathbb{R}$ is Fréchet differentiable and locally Lipschitz continuous together with its derivative. Moreover, $K(0) = 0$.*

Notice that the requirement $K(0) = 0$ is not restrictive, as we can substitute g by $g - K(0)$.

The problem (6.1) can be rewritten in the *mild* form

$$u(t,x) = P_t\varphi(x) - \int_0^t P_{t-s}\left(K(Du(s,\cdot))\right)(x)\,ds + \int_0^t P_{t-s}g(x)\,ds. \tag{6.2}$$

As we noticed in the previous section, the semigroup P_t is not strongly continuous in $C_b(H)$ in general. Nevertheless, the mapping

$$[0,+\infty) \to \mathbb{R}, \qquad t \mapsto P_t\varphi(x)$$

is continuous for any fixed $\varphi \in C_b(H)$ and $x \in H$. Thus the integrals in the formula (6.2) have a meaning only for fixed $x \in H$.

We define $\mathcal{V}^1_T$ as the space of all continuous and bounded functions $u : [0,T]\times H \to \mathbb{R}$, such that $u(t,\cdot) \in C^1_b(H)$ for all $t \in (0,T]$, and the mapping

$$(0,T] \times H \to H, \qquad (t,x) \mapsto Du(t,x)$$

is bounded and measurable. It is easy to check that $\mathcal{V}^1_T$, endowed with the norm

$$\|u\|_{\mathcal{V}^1_T} = \sup_{t\in[0,T]} \|u(t,\cdot)\|_0^H + \sup_{t\in(0,T]} \|Du(t,\cdot)\|_0^H,$$

is a Banach space.

Moreover, we define $\mathcal{Z}^1_T$ as the space of bounded continuous functions $y : [0,T] \times H \to \mathbb{R}$, such that $y(t,\cdot) \in C^1_b(H)$ for all $t \in (0,T]$, and the mapping

$$(0,T] \times H \to H, \qquad (t,x) \mapsto t^{\frac{1+\epsilon}{2}} Dy(t,x)$$

is bounded and measurable. It is easy to check that $\mathcal{Z}^1_T$, endowed with the norm

$$\|u\|_{\mathcal{Z}^1_T} = \sup_{t\in[0,T]} \|y(t,\cdot)\|_0^H + \sup_{t\in(0,T]} (t\wedge 1)^{\frac{1+\epsilon}{2}} \|Dy(t,\cdot)\|_0^H,$$

is a Banach space.

Finally, we say that a function $y \in \mathcal{V}^1_T$ belongs to the space $\mathcal{Z}^2_T$ if $y(0,\cdot) \in C^1_b(H)$, the function $y(t,\cdot)$ is in $C^2_b(H)$ for any $t > 0$, and the mapping

$$(0,T] \times H \to \mathcal{L}(H), \qquad (t,x) \mapsto (t\wedge 1)^{\frac{1+\epsilon}{2}} D^2 y(t;x)$$

is bounded and measurable. $\mathcal{Z}^2_T$, endowed with the norm

$$\|u\|_{\mathcal{Z}^2_T} = \sup_{t\in\,[0,T]} \|y(t,\cdot)\|_1^H + \sup_{t\in\,(0,T]} (t\wedge 1)^{\frac{1+\epsilon}{2}} \|D^2 y(t,\cdot)\|_0^H,$$

is a Banach space.

A proof of the following lemma, in the case when $F = 0$, can be found in [20, Lemmas 4.8 and 4.12]. Such a proof completely adapts to our case where $F \neq 0$; thus we do not repeat it.

LEMMA 6.1. *Let us fix $T > 0$, and, for $\psi : [0,T]\times H \to \mathbb{R}$ bounded and measurable, let us define*

$$\lambda(\psi)(t,x) = \int_0^t P_{t-s}\psi(s,\cdot)(x)\,ds.$$

Then $\lambda(\psi)$ is continuous and bounded, $\lambda(\psi)(t,\cdot)\in C^1_b(H)$ for any $t\geq 0$, and

$$\sup_{t\in\,[0,T]} \|\lambda(\psi)(t,\cdot)\|_1^H < \infty.$$

It is immediate to check that Lemma 6.1 adapts to the approximating semigroups P^α_t and $P^{\alpha,n}_t$.

For each $\alpha > 0$, we consider the approximating problem

$$\frac{\partial u}{\partial t}(t,x) = \mathcal{L}_\alpha u(t,x) - K(Du(t,x)) + g(x), \qquad u(0,x) = \varphi(x),$$

where

$$\mathcal{L}_\alpha\psi(x) = \frac{1}{2}\mathrm{Tr}\,[Q^2 D^2\psi(x)] + \langle Ax + F_\alpha(x), D\psi(x)\rangle_H\,.$$

In mild form it can be rewritten as

$$u(t,x) = P^\alpha_t\varphi(x) - \int_0^t P^\alpha_{t-s}\left(K(Du(s,\cdot))\right)(x)\,ds + \int_0^t P^\alpha_{t-s} g(x)\,ds. \tag{6.3}$$

The first part of the following theorem was proved in [7], under the assumption of Lipschitz continuity for the hamiltonian K. Here the proof is more delicate, as K is only locally Lipschitz.

THEOREM 6.2. *Assume that Hypotheses* 1, 2, *and* 3 *hold, and fix $T > 0$. Then for any $\varphi, g\in \mathrm{Lip}_b(H)$,* (6.2) *admits a unique solution $u(t,x)$ in $\mathcal{V}^1_T$.*

If $u_\alpha(t,x)$ denotes the unique mild solution for the approximating problem (6.3), *we have*

$$\lim_{\alpha\to 0} |u_\alpha(t,x) - u(t,x)| + |Du_\alpha(t,x) - Du(t,x)|_H = 0, \tag{6.4}$$

uniformly for t in compact subsets of $(0,T]$ and for x in bounded subsets of E. Moreover, if $\varphi, g\in C^1_b(H)$, then the limit (6.4) *is uniform for $t\in[0,T]$ and for x in bounded subsets of E.*

We first prove some preliminary results.

LEMMA 6.3. *Fix $\varphi, g \in C^1_b(H)$ and $R\geq 2c_0\,\|\varphi\|_1^H$, where c_0 is the constant introduced in* (5.1). *Then the problem* (6.2) *admits a unique local solution $u(t,x)$ in $[0,\tau_R]$ for some constant*

$$\tau_R = \tau_R\left(\|\varphi\|_1^H, \|g\|_0^H, \|K\|_1^{B_R^H}\right).$$

Proof. For any $\tau > 0$, we define $\Lambda_R(\tau)$ as the set of all bounded continuous functions $u : [0,\tau] \times H \to \mathbb{R}$ such that $u(t,\cdot) \in C_b^1(H)$ for all $t \in [0,\tau]$, the mapping

$$[0,\tau] \times H \to H, \qquad (t,x) \mapsto Du(t,x)$$

is bounded and measurable, and

$$\sup_{t \in [0,\tau]} \|u(t,\cdot)\|_1^H \leq R.$$

We claim that for some τ_R sufficiently small, the operator Γ defined by

$$\Gamma(v)(t,x) = P_t\varphi(x) - \int_0^t P_{t-s}\left(K(Dv(s,\cdot))\right)(x)\,ds + \int_0^t P_{t-s}g(x)\,ds$$

maps $\Lambda_R(\tau_R)$ into itself as a contraction. Due to Lemma 6.1, $\Gamma(v)(t,x)$ is well defined for any x and t. Due to (5.1) we have

$$\|P_t\varphi\|_1^H \leq c_0\,\|\varphi\|_1^H \leq \frac{R}{2}.$$

Moreover, if we set

$$\Gamma_1(v)(t,x) = -\int_0^t P_{t-s}\left(K(Dv(s,\cdot))\right)(x)\,ds + \int_0^t P_{t-s}g(x)\,ds,$$

we have

$$\|\Gamma_1(v)(t,\cdot)\|_0^H \leq \int_0^t \|K(Dv(s,\cdot))\|_0^H\,ds + t\|g\|_0^H \leq \tau\Big(\sup_{x \in B_R^H} |K(x)| + \|g\|_0^H\Big).$$

Concerning the derivative, due to the estimate (5.1) it holds that

$$\|D(\Gamma_1(v))(t,\cdot)\|_0^H \leq c_0 \int_0^t (t-s)^{-\frac{1+\epsilon}{2}}(\|K(Dv(s,\cdot))\|_0^H + \|g\|_0^H)\,ds$$

$$\leq c_0\,\tau^{\frac{1-\epsilon}{2}}\Big(\sup_{x \in B_R^H} |K(x)| + \|g\|_0^H\Big).$$

This implies that

$$\sup_{t \in [0,\tau]} \|\Gamma(v)(t,\cdot)\|_1^H \leq \frac{R}{2} + c\left(\tau + \tau^{\frac{1-\epsilon}{2}}\right)\Big(\sup_{x \in B_R^H} |K(x)| + \|g\|_0^H\Big)$$

so that it is possible to find $\bar{\tau}_R$ sufficiently small such that

$$\sup_{t \in [0,\bar{\tau}_R]} \|\Gamma(v)(t,\cdot)\|_1^H \leq R.$$

In a completely analogous way it is possible to show that Γ is a contraction on $\Lambda_R(\tau_R)$ for some $\tau_R \leq \bar{\tau}_R$. This allows us to conclude that there exists a unique fixed point u for Γ in $\Lambda_R(\tau_R)$, which is the unique solution of (6.2) in $[0,\tau_R]$. □

Remark 6.4. In an identical way it is possible to prove that for each $\alpha > 0$ the mapping

$$\Gamma_\alpha(v)(t,x) = P_t^\alpha\varphi(x) - \int_0^t P_{t-s}^\alpha\left(K(Dv(s,\cdot))\right)(x)\,ds + \int_0^t P_{t-s}^\alpha g(x)\,ds$$

is a contraction in $\Lambda_R(\tau_R)$, where τ_R is the same as in Lemma 6.3. This implies that there exists a unique solution $u_\alpha(t,x)$ for the problem (6.3).

Moreover, it is useful to remark that thanks to (5.5) the contraction constant of Γ_α in $\Lambda_R(\tau_R)$ can be taken as the same for all $\alpha > 0$.

LEMMA 6.5. *If $u(t,x)$ and $u_\alpha(t,x)$ are, respectively, the solutions of the problems* (6.2) *and* (6.3) *with $\varphi, g \in C_b^1(H)$, we have*

$$\lim_{\alpha\to 0} |u_\alpha(t,x) - u(t,x)| + |Du_\alpha(t,x) - Du(t,x)|_H = 0, \tag{6.5}$$

uniformly for t in $[0,\tau_R]$ and for x in bounded subsets of E.

Proof. In order to prove the existence of the solutions $u(t,x)$ and $u_\alpha(t,x)$ for the problems (6.2) and (6.3), we have applied a contraction theorem. Hence, due to Lemma 6.3 and Remark 6.4, for each $\epsilon > 0$ there exists $k_\epsilon \in \mathbb{N}$ such that

$$\sup_{t\in\,[0,\tau_R]} \left(\|u_\alpha(t,\cdot) - \Gamma_\alpha^{k_\epsilon}(0)(t,\cdot)\|_1^H + \|u(t,\cdot) - \Gamma^{k_\epsilon}(0)(t,\cdot)\|_1^H \right) \leq \epsilon/2 \tag{6.6}$$

for each $\alpha > 0$. Now, from Proposition 5.1, by using an induction argument we can prove that for each $k \in \mathbb{N}$

$$\lim_{\alpha\to 0} \left|\Gamma_\alpha^k(0)(t,x) - \Gamma^k(0)(t,x)\right| + \left|D\Gamma_\alpha^k(0)(t,x) - D\Gamma^k(0)(t,x)\right|_H = 0, \tag{6.7}$$

uniformly for (t,x) in bounded subsets of $[0,\tau_R]\times E$. Actually, for $k = 1$, (6.7) follows directly from (5.6) and (5.7). Now assume that (6.7) holds for some $k \geq 1$. We have

$$\Gamma_\alpha^{k+1}(0)(t,x) - \Gamma^{k+1}(0)(t,x) = \Gamma_\alpha(\Gamma_\alpha^k(0))(t,x) - \Gamma(\Gamma^k(0))(t,x)$$

$$= P_t^\alpha\varphi(x) - P_t\varphi(x) + \int_0^t \left(P_{t-s}^\alpha g(x) - P_{t-s}g(x)\right) ds$$

$$- \int_0^t \left(P_{t-s}^\alpha \left[K(D(\Gamma_\alpha^k(0))(s,\cdot))\right](x) - P_{t-s}\left[K(D(\Gamma^k(0))(s,\cdot))\right](x)\right) ds.$$

Since $\Gamma_\alpha^k(0)$ and $\Gamma^k(0)$ belong to $\Lambda_R(\tau_R)$ and (6.7) holds for k, by using (5.6) and the boundedness of K on bounded subsets of H, from the dominated convergence theorem it follows that

$$\lim_{\alpha\to 0} \int_0^t \left(P_{t-s}^\alpha \left[K(D(\Gamma_\alpha^k(0))(s,\cdot))\right](x) - P_{t-s}\left[K(D(\Gamma^k(0))(s,\cdot))\right](x)\right) ds = 0,$$

uniformly on bounded sets of $[0,\tau_R]\times E$. By using (5.6) once more, we have

$$\lim_{\alpha\to 0} P_t^\alpha\varphi(x) - P_t\varphi(x) + \int_0^t \left(P_{t-s}^\alpha g(x) - P_{t-s}g(x)\right) ds = 0,$$

uniformly on bounded sets of $[0,\tau_R]\times E$, so that we get

$$\lim_{\alpha\to 0} \Gamma_\alpha^{k+1}(0)(t,x) - \Gamma^{k+1}(0)(t,x) = 0.$$

The second part of the limit (6.7) for $k+1$ follows by analogous arguments. By induction we can conclude that (6.7) holds for any $k \in \mathbb{N}$.

Now, from (6.6) we have that

$$|u_\alpha(t,x)-u(t,x)|+|Du_\alpha(t,x)-Du(t,x)|_H$$

$$\leq \sup_{t\in\,[0,\tau_R]}\|u_\alpha(t,\cdot)-\Gamma^{k_\epsilon}_\alpha(0)(t,\cdot)\|_1^H+|\Gamma^{k_\epsilon}_\alpha(0)(t,x)-\Gamma^{k_\epsilon}(0)(t,x)|$$

$$+|D\Gamma^{k_\epsilon}_\alpha(0)(t,x)-D\Gamma^{k_\epsilon}(0)(t,x)|_H+\sup_{t\in\,[0,\tau_R]}\|u(t,\cdot)-\Gamma^{k_\epsilon}(0)(t,\cdot)\|_1^H$$

$$\leq \epsilon/2+|\Gamma^{k_\epsilon}_\alpha(0)(t,x)-\Gamma^{k_\epsilon}(0)(t,x)|+\left|D\Gamma^{k_\epsilon}_\alpha(0)(t,x)-D\Gamma^{k_\epsilon}(0)(t,x)\right|_H,$$

and due to (6.7) we can conclude that (6.5) holds. □

Proof of Theorem 6.2. Let us fix $T>0$ and $\varphi,g\in C^1_b(H)$, and let us define

$$R=2c\,(1+T)\,e^{c\,T}\left((1+2c_0)\|\varphi\|_1^H+\|g\|_1^H\right).$$

Due to Lemma 6.3, there exists a mild solution $u(t,x)$ defined for $t\in\,[0,\tau_R]$. Moreover, from Lemma 6.5 we have that (6.4) holds, uniformly with respect to $t\in\,[0,\tau_R]$ and x in bounded sets of E.

From Proposition A.3, we have that

$$\sup_{t\in\,[0,\tau_\star]}\|u_\alpha(t,\cdot)\|_1^H\leq c\,(1+T)e^{c\,T}\left(\|\varphi\|_1^H+\|g\|_1^H\right).$$

According to Lemma 6.5, this implies that for any $t\in\,[0,\tau_\star]$ and $x\in\,E$

$$|u(t,x)|+|Du(t,x)|_H\leq c\,(1+T)e^{c\,T}\left(\|\varphi\|_1^H+\|g\|_1^H\right),$$

and, since $u(t,\cdot)\in\,C^1_b(H)$ for $t\in\,[0,\tau_\star]$, we have

$$\sup_{t\in\,[0,\tau_\star]}\|u(t,\cdot)\|_1^H\leq c\,(1+T)e^{c\,T}\left(\|\varphi\|_1^H+\|g\|_1^H\right). \tag{6.8}$$

In particular, due to the definition of R we have that

$$\|u(\tau_\star,\cdot)\|_1^H\leq\frac{R}{2}.$$

This allows us to repeat all of the same arguments we have been using until now in the intervals $[\tau_\star,2\tau_\star]$, $[2\tau_\star,3\tau_\star]$, and so on, up to time T, and hence to get a global solution.

Now, assume that $\varphi,g\in\,\mathrm{Lip}_b(H)$. It is possible to find two bounded sequences $\{\varphi_k\}$ and $\{g_k\}$ in $C^1_b(H)$ converging, respectively, to φ and g in $C_b(H)$. In correspondence with each k, there exists a unique solution $u_k(t,x)$ to the problem

$$u_k(t,x)=P_t\varphi_k(x)-\int_0^t P_{t-s}\left(K(Du_k(s,\cdot))\right)(x)\,ds+\int_0^t P_{t-s}g_k(x)\,ds.$$

Our aim is to show that $\{u_k\}$ is a Cauchy sequence in $\mathcal{Z}^1_T$ and that the limit u fulfills (6.2).

For each $k,n\in\,\mathbb{N}$ we have

$$u_k(t,x)-u_h(t,x)=P_t\left(\varphi_k-\varphi_h\right)(x)$$

$$-\int_0^t P_{t-s}\left(K(Du_k(s,\cdot))-K(Du_h(s,\cdot))\right)(x)\,ds+\int_0^t P_{t-s}\left(g_k-g_h\right)(x)\,ds.$$

Due to (6.8) we easily have

$$\sup_{k\in\mathbb{N}}\sup_{t\in[0,T]}\|Du_k(t,\cdot)\|_1^H\leq c\,(1+T)e^{c\,T}\sup_{k\in\mathbb{N}}\left(\|\varphi_k\|_1+\|g_k\|_1^H\right)=c_T. \tag{6.9}$$

If M is the Lipschitz constant of K in $B^H_{c_T}$, we have

$$\begin{aligned}&\|u_k(t,\cdot)-u_h(t,\cdot)\|_0^H\leq\|\varphi_k-\varphi_h\|_0^H\\&+M\int_0^t\|Du_k(s,\cdot)-Du_h(s,\cdot)\|_0^H\,ds+t\,\|g_k-g_h\|_0.\end{aligned} \tag{6.10}$$

Moreover, we have

$$\begin{aligned}&Du_k(t,x)-Du_h(t,x)=DP_t(\varphi_k-\varphi_h)(x)\\&-\int_0^t DP_{t-s}\left(K(Du_k(s,\cdot))-K(Du_h(s,\cdot))\right)(x)\,ds+\int_0^t DP_{t-s}(g_k-g_h)(x)\,ds,\end{aligned}$$

so that, thanks to (5.1), we get

$$\begin{aligned}&\|Du_k(t,\cdot)-Du_h(t,\cdot)\|_0^H\leq c\,t^{-\frac{1+\epsilon}{2}}\|\varphi_k-\varphi_h\|_0^H\\&+c\,M\int_0^t(t-s)^{-\frac{1+\epsilon}{2}}\|Du_k(s,\cdot)-Du_h(s,\cdot)\|_0^H\,ds+c\int_0^t(t-s)^{-\frac{1+\epsilon}{2}}\,ds\|g_k-g_h\|_0^H.\end{aligned}$$

This implies that

$$\begin{aligned}&t^{\frac{1+\epsilon}{2}}\|Du_k(t,\cdot)-Du_h(t,\cdot)\|_0^H\leq c\,\|\varphi_k-\varphi_h\|_0^H\\&+c\,Mt^{\frac{1+\epsilon}{2}}\int_0^t(t-s)^{-\frac{1+\epsilon}{2}}\|Du_k(s,\cdot)-Du_h(s,\cdot)\|_0^H\,ds+c\,t\,\|g_k-g_h\|_0^H.\end{aligned} \tag{6.11}$$

By combining (6.10) and (6.11), we conclude that

$$\begin{aligned}&\|u_k(t,\cdot)-u_h(t,\cdot)\|_0^H+t^{\frac{1+\epsilon}{2}}\|Du_k(t,\cdot)-Du_h(t,\cdot)\|_0^H\\&\leq c\left(\|\varphi_k-\varphi_h\|_0^H+T\|g_k-g_h\|_0^H\right)+M(1+c\,T^{\frac{1+\epsilon}{2}})\int_0^t s^{-\frac{1+\epsilon}{2}}\left((t-s)^{-\frac{1+\epsilon}{2}}+1\right)\\&\left(\|u_k(s,\cdot)-u_h(s,\cdot)\|_0^H+s^{\frac{1+\epsilon}{2}}\|Du_k(s,\cdot)-Du_h(s,\cdot)\|_0^H\right)\,ds.\end{aligned}$$

Thus, from a generalization of the Gronwall lemma, we can say that

$$\|u_k-u_h\|_{\mathcal{Z}^1_T}\leq c_T\left(\|\varphi_k-\varphi_h\|_0^H+T\|g_k-g_h\|_0^H\right) \tag{6.12}$$

for some constant c_T independent of k and h. This implies that $\{u_k\}$ is a Cauchy sequence in $\mathcal{Z}^1_T$, and hence it converges to a limit $u\in\mathcal{Z}^1_T$. Moreover, from (6.9) we have that

$$\sup_{t\in[0,T]}\|Du(t,\cdot)\|_0^H<+\infty,$$

so that $u \in \mathcal{V}_T^1$.

Now, we show that u is the mild solution of the problem (6.2). Actually, for any $s > 0$ and $x \in H$

$$\lim_{k \to +\infty} K(Du_k(s,x)) = K(Du(s,x)).$$

Due to (6.9) we can apply the dominated convergence theorem, and we get

$$\lim_{k \to +\infty} \int_0^t P_{t-s} K(Du_k(s,\cdot))(x)\,ds = \int_0^t P_{t-s} K(Du(s,\cdot))(x)\,ds.$$

Therefore, since

$$\lim_{k \to +\infty} P_t \varphi_k(x) = P_t \varphi(x)$$

and

$$\lim_{k \to +\infty} \int_0^t P_{t-s} g_k(x)\,ds = \int_0^t P_{t-s} g(x)\,ds,$$

we conclude that u is a solution of (6.2).

Finally, uniqueness follows from the Gronwall lemma and local Lipschitzianity of K. Indeed, if u_1 and u_2 are two solutions in $\mathcal{V}_T^1$, we have

$$u_1(t,x) - u_2(t,x) = -\int_0^t P_{t-s} \left(K(Du_1(s,\cdot)) - K(Du_2(s,\cdot)) \right)(x)\,ds,$$

and then, if M is the Lipschitz constant of K in $B^H_{c_T}$, where

$$c_T = \|u_1\|_{\mathcal{V}_T^1} + \|u_2\|_{\mathcal{V}_T^1},$$

we have

$$\|u_1 - u_2\|_{\mathcal{V}_T^1} \leq M \int_0^t \left(1 + (t-s)^{-\frac{1+\epsilon}{2}} \right) ds \|u_1 - u_2\|_{\mathcal{V}_T^1}.$$

This implies that $u_1 = u_2$. □

7. Application to control. We apply here the results proved in the previous section to a stochastic control problem. Let $k : H \to]-\infty, +\infty]$ be a convex lower semicontinuous function, and let K be its Legendre transform; that is,

$$K(x) = \sup_{z \in H} \left\{ -\langle x, z \rangle_H - k(z) \right\}, \qquad x \in H.$$

We assume that k is such that K fulfills Hypothesis 3. We consider here the cost functional

$$J(t,x;z) = \mathbf{E} \int_t^T \left(g(y(s)) + k(z(s)) \right) ds + \mathbf{E}\, \varphi(y(T)),$$

where $y(s) = y(s,t;x,z)$ is the unique solution of the controlled system (1.1) at time s, starting from x at time t. We want to minimize the functional J over all adapted controls $z \in L^2(\Omega; L^2([0,T];H))$.

The *value function* corresponding to the cost functional J is defined by

$$V(t,x) = \inf \left\{ J(t,x;z) \,:\, z \in L^2(\Omega; L^2([0,T];H)) \text{ adapted} \right\}$$

and is related to the Hamilton–Jacobi–Bellman equation (6.1). Namely, we are showing that for every $t \in [0,T]$ and $x \in H$

$$V(t,x) = u(T-t,x),$$

where $u(t,x)$ is the unique mild solution of the problem (6.1).

For any $\alpha > 0$ we introduce the approximating cost functional

$$J_\alpha(t,x;z) = \mathbf{E} \int_t^T (g(y_\alpha(s)) + k(z(s)))\, ds + \mathbf{E}\, \varphi(y_\alpha(T)), \tag{7.1}$$

where $y_\alpha(s) = y_\alpha(s,t;x,z)$ is the unique solution to the problem (3.5). In what follows we will denote by $V_\alpha(t,x)$ the corresponding value function.

LEMMA 7.1. *Assume Hypotheses* 1, 2, *and* 3, *and assume that* $\varphi, g \in \mathrm{Lip}_b(H)$. *If* u *is the mild solution of the problem* (6.2), *for any control* $z \in L^2(\Omega; L^2([0,T];H))$, $x \in H$, *and* $t \in [0,T]$, *the following identity holds:*

$$\begin{aligned} &J(t,x;z) = u(T-t,x) \\ &+ \int_t^T \mathbf{E}\, (K(Du(T-s,y(s))) + \langle z(s), Du(T-s,y(s))\rangle_H + k(z(s)))\, ds, \end{aligned} \tag{7.2}$$

where $y(s) = y(s,t;x,z)$ *is the solution of the problem* (3.1).

Moreover, the same identity holds with $J(t,x;z)$, $u(t,x)$, $Du(t,x)$, *and* $y(t)$ *replaced, respectively, by* $J_\alpha(t,x;z)$, $u_\alpha(t,x)$, $Du_\alpha(t,x)$, *and* $y_\alpha(t)$.

Proof. We first assume that $\varphi, g \in C_b^1(H)$. Let $u_{\alpha,n}(t,x)$ be the solution of (A.2), and let $y_{\alpha,n}(s) = y_{\alpha,n}(s,t;x,z)$ be the solution to the problem (3.10). Since $u_{\alpha,n}$ is smooth (in fact, $u_{\alpha,n} \in Z^2(T)$) and $y_{\alpha,n}$ is a strong solution, we can apply Itô's formula to the function $s \mapsto u_{\alpha,n}(T-s, y_{\alpha,n}(s))$ for $t \leq s \leq T$, and we get

$$\begin{aligned} du_{\alpha,n}(T-s,y_{\alpha,n}(s)) &= \langle dy_{\alpha,n}(s), Du_{\alpha,n}(T-s,y_{\alpha,n}(s))\rangle_H \\ &+ \left(\frac{1}{2} \mathrm{Tr}\, \left[Q_n^2 D^2 u_{\alpha,n}(T-s,y_{\alpha,n}(s)) \right] - \frac{\partial u_{\alpha,n}}{\partial t}(T-s,y_{\alpha,n}(s)) \right) ds. \end{aligned}$$

By integrating with respect to $s \in [t,T]$ and by taking the expectation, we get

$$\begin{aligned} \mathbf{E}\, \varphi(y_{\alpha,n}(T)) - u_{\alpha,n}(T-t,x) &= \mathbf{E} \int_t^T (K(Du_{\alpha,n}(T-s,y_{\alpha,n}(s))) \\ &+ \langle z(s), Du_{\alpha,n}(T-s,y_{\alpha,n}(s))\rangle_H - g(y_{\alpha,n}(s)))\, ds. \end{aligned} \tag{7.3}$$

Now, due to Lemma 3.4 and (A.3), we can take the limit as n goes to $+\infty$ in each side of (7.3), and, rearranging all terms, we get

$$\begin{aligned} &\mathbf{E}\, \varphi(y_\alpha(T)) + \mathbf{E} \int_t^T g(y_\alpha(s))\, ds \\ &= u_\alpha(T-t,x) + \mathbf{E} \int_t^T (K(Du_\alpha(T-s,y_\alpha(s))) + \langle z(s), Du_\alpha(T-s,y_\alpha(s))\rangle_H)\, ds. \end{aligned} \tag{7.4}$$

This implies (7.2).

Now, let $\varphi, g \in \mathrm{Lip}_b(H)$. As in the proof of Theorem 6.2, let $\{\varphi_k\}$ and $\{g_k\}$ be two bounded sequences in $C^1_b(H)$ converging, respectively, to φ and g in $C_b(H)$. If we denote by $u^k_\alpha(t,x)$ the solutions of the problem (6.2) corresponding to φ_k and g_k, we have

$$\mathbf{E}\,\varphi_k(y_\alpha(T)) + \mathbf{E}\int_t^T g_k(y_\alpha(s))\,ds = u^k_\alpha(T-t,x)$$

$$+\mathbf{E}\int_t^T \left(K(Du^k_\alpha(T-s,y_\alpha(s))) + \left\langle z(s), Du^k_\alpha(T-s,y_\alpha(s))\right\rangle_H\right)\,ds.$$

It is immediate to check that the sequence $\{u^k_\alpha\}$ fulfills an estimate analogous to (6.12), and then the sequence $\{u^k_\alpha\}$ converges to u_α in $\mathcal{Z}^1_T$, as k goes to infinity. Moreover, due to (2.19), (3.3), and (6.9), we can apply the dominated convergence theorem and, by taking the limit for k going to $+\infty$, we get (7.4) for any $\varphi, g \in \mathrm{Lip}_b(H)$.

Now, if $x \in E$, then $y_\alpha(s) \in E$ and (4.4) holds. Thus, due to (3.11) and (6.4), we can take the limit as α goes to zero in each side of (7.4), and we get (7.2) for $x \in E$. Finally, if $x \in H$, we fix a sequence $\{x_n\} \subset E$ converging to x in H. Thanks to (3.4) we have that $y(s,t;x_n,z)$ converges to $y(s,t;x,z)$ in H, and then, as $u(t,\cdot) \in C^1_b(H)$, we easily get (7.2) for any $x \in H$. □

Now we can conclude by giving the main result of this section.

THEOREM 7.2. *Under Hypotheses* 1, 2, *and* 3, *for any* $\varphi, g \in \mathrm{Lip}_b(H)$ *the value function* $V(t,x)$ *coincides with* $u(T-t,x)$, *where* $u(t,x)$ *is the solution of the problem* (6.2). *Moreover,*

$$V(t,x) = \lim_{\alpha\to 0}\, \min\,\left\{ J_\alpha(t,x;z),\ z \in L^2(\Omega; L^2(0,T;H)),\ \textit{adapted}\right\},$$

where $J_\alpha(t,x;z)$ *is the cost functional defined in* (7.1).

Proof. From (7.2) we immediately have that $J(t,x;z) \geq u(T-t,x)$ for any $z \in L^2(\Omega; L^2(0,T;H))$, so that $V(t,x) \geq u(T-t,x)$. Now we prove the opposite inequality.

Since J_α fulfills a formula analogous to (7.2), we have $V_\alpha(t,x) \geq u_\alpha(T-t,x)$. In fact, it holds that $V_\alpha(t,x) = u_\alpha(T-t,x)$. Actually, by a general property of the Legendre transform, for each $t \in [0,T]$ the mapping

$$H \to \mathbb{R}, \qquad z \mapsto \langle z, Du_\alpha(T-t,y(t))\rangle_H + k(z),$$

attains its maximum for

$$z_\alpha(t) = -DK(Du_\alpha(T-t,y(t))), \qquad t \in [0,T].$$

Thus, if we prove that the *closed loop* equation

(7.5)
$$dy(t) = (Ay(t) + F_\alpha(y(t)) - DK(Du_\alpha(T-t,y(t))))\,dt + Q\,dw(t), \qquad y(0) = x,$$

admits a unique solution $y^\star_\alpha(t)$, and if we define

$$z^\star_\alpha(t) = -DK(Du_\alpha(T-t,y^\star_\alpha(t))),$$

due to (7.2) for J_α we have that $J_\alpha(t,x;z^\star_\alpha) = u(T-t,x)$, so that $y^\star_\alpha(t)$ and $z^\star_\alpha(t)$ are, respectively, the unique optimal state and the unique optimal control for the minimizing problem corresponding to the functional J_α.

Assume that $\varphi, g \in C_b^1(H)$. Due to (5.3) it is possible to show that the solution u_α of the problem (6.3) belongs to $Z^2(T)$ and

$$\|u_\alpha\|_{Z^2(T)} \leq c_{\alpha,T} \left(\|\varphi\|_1^H + T\,\|g\|_1^H\right). \tag{7.6}$$

Thus, if we define for $(t,x) \in [0,T] \times H$

$$U_\alpha(t,x) = -DK(Du_\alpha(t,x)),$$

we have that the function U_α fulfills the conditions of Lemma A.1, so that there exists a unique solution $y_\alpha^\star(t)$ for the closed loop equation (7.5).

Now, assume that $\varphi, g \in \mathrm{Lip}_b(H)$. As in the proofs of Theorem 6.2 and of Lemma 7.1, we approximate them in $C_b(H)$ by two bounded sequences $\{\varphi_k\}$ and $\{g_k\}$ in $C_b^1(H)$. For each k there exists a unique solution $u_{\alpha,k}$ for the problem (6.3), with data φ_k and g_k. Thus, as proved above, in correspondence with each $u_{\alpha,k}$ there exists a unique solution $y_{\alpha,k}^\star(t)$ for the problem (7.5). Let us define $v_{h,k}^\alpha(t) = y_{\alpha,k}^\star(t) - y_{\alpha,h}^\star(t)$. We have that $v_{h,k}^\alpha(t)$ is the unique solution of the problem

$$\begin{aligned}\frac{dv}{dt}(t) = \quad & Av(t) + F_\alpha(y_{\alpha,k}^\star(t)) - F_\alpha(y_{\alpha,h}^\star(t)) - DK(Du_{\alpha,k}(T-t, y_{\alpha,k}^\star(t))) \\ & +DK(Du_{\alpha,h}(T-t, y_{\alpha,h}^\star(t))), \qquad v(0) = 0.\end{aligned}$$

Thus, by multiplying each side by $v_{h,k}^\alpha(t)$, due to the Lipschitz continuity of F_α and (2.13) we get

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}|v_{h,k}^\alpha(t)|_H^2 \leq c_\alpha\,|v_{h,k}^\alpha(t)|_H^2 \\ &+|DK(Du_{\alpha,k}(T-t, y_{\alpha,k}^\star(t))) - DK(Du_{\alpha,h}(T-t, y_{\alpha,h}^\star(t)))|_H |v_{h,k}^\alpha(t)|_H.\end{aligned} \tag{7.7}$$

Since Proposition A.3 holds, the sequences $\{\varphi_k\}$ and $\{g_k\}$ are bounded in $C_b^1(H)$, and DK is locally Lipschitz continuous, there exists $c > 0$ such that

$$\begin{aligned}&|DK(Du_{\alpha,k}(T-t, y_{\alpha,k}^\star(t))) - DK(Du_{\alpha,h}(T-t, y_{\alpha,h}^\star(t)))|_H \\ &\leq c\,|Du_{\alpha,k}(T-t, y_{\alpha,k}^\star(t)) - Du_{\alpha,h}(T-t, y_{\alpha,h}^\star(t))|_H.\end{aligned}$$

Now, for any $t > 0$ and $x, y \in H$, due to (7.6) we have

$$\begin{aligned}&|Du_{\alpha,k}(t,x) - Du_{\alpha,k}(t,y)|_H \\ &\leq c_{\alpha,T} t^{-\frac{1+\epsilon}{2}} \left(\|\varphi_k\|_1^H + T\,\|g_k\|_1^H\right) |x-y|_H \leq c_{\alpha,T} t^{-\frac{1+\epsilon}{2}} |x-y|_H\end{aligned}$$

for some constant independent of k. Moreover, we can repeat all arguments used in the proof of Theorem 6.2, and we have

$$|Du_{\alpha,k}(t,y) - Du_{\alpha,h}(t,y)|_H \leq c_{\alpha,T} t^{-\frac{1+\epsilon}{2}} \left(\|\varphi_k - \varphi_h\|_0^H + T\|g_k - g_h\|_0^H\right).$$

Therefore, we get

$$\begin{aligned}&\left|K(Du_{\alpha,k}(T-t, y_{\alpha,k}^\star(t))) - DK(Du_{\alpha,h}(T-t, y_{\alpha,h}^\star(t)))\right|_H \\ &\leq c_{\alpha,T}(T-t)^{-\frac{1+\epsilon}{2}} \left(|v_{h,k}^\alpha(t)|_H + \|\varphi_k - \varphi_h\|_0^H + T\|g_k - g_h\|_0^H\right),\end{aligned}$$

so that, from (7.7) we conclude

$$\frac{d}{dt}|v^\alpha_{h,k}(t)|^2_H \leq c_{\alpha,T}\left(1+(T-t)^{-\frac{1+\epsilon}{2}}\right)|v^\alpha_{h,k}(t)|^2_H$$

$$+c_{\alpha,T}(T-t)^{-\frac{1+\epsilon}{2}}\left(\|\varphi_k-\varphi_h\|^H_0+T\|g_k-g_h\|^H_0\right)^2.$$

Due to the Gronwall lemma this yields

$$|y^\star_{\alpha,k}(t)-y^\star_{\alpha,h}(t)|^2_H \leq c_{\alpha,T}\left(\|\varphi_k-\varphi_h\|^H_0+T\|g_k-g_h\|^H_0\right)^2,$$

and the sequence $\{y^\star_{\alpha,k}\}$ converges to some $y^\star_\alpha$ in $C([0,T];H)$, $\mathbf{P}$-a.s. and in mean-square, and clearly $y^\star_\alpha$ is the unique solution of the closed loop (7.5).

Since $z^\star_\alpha(t)=-DK(Du_\alpha(T-t,y^\star_\alpha(t)))$, then due to (7.6) there exists a constant R such that

$$\sup_{\alpha>0}\sup_{t\in[0,T]}|z^\star_\alpha(t)|_H=R,\qquad \mathbf{P}-\text{a.s.}$$

This means that if we define the set $\mathcal{M}_R$ as in the Lemma 3.3, then for any $\alpha>0$

$$V_\alpha(t,x)=\inf\{\,J_\alpha(t,x;z)\;;\;z\in\mathcal{M}_R\,\}. \tag{7.8}$$

By using (6.4) we have that if $\varphi,g\in C^1_b(H)$, then for any $t\in[0,T]$ and $x\in E$

$$\lim_{\alpha\to 0}V_\alpha(t,x)=u(T-t,x).$$

Moreover,

$$|J_\alpha(t,x;z)-J(t,x;z)|\leq\|\varphi\|^H_1\mathbf{E}\,|y_\alpha(T)-y(T)|_E+\|g\|^H_1\int_0^t\mathbf{E}\,|y_\alpha(s)-y(s)|_E\,ds,$$

so that, due to Lemma (3.3) we have

$$\lim_{\alpha\to 0}\sup_{z\in\mathcal{M}_R}|J_\alpha(t,x;z)-J(t,x;z)|=0.$$

Due to (7.8) we have that

$$u(T-t,x)=\lim_{\alpha\to 0}V_\alpha(t,x)=\inf\{\,J(t,x;z)\;;\;z\in\mathcal{M}_R\,\}\geq V(t,x),$$

and since $u(T-t,x)\leq V(t,x)$, we conclude that $u(T-t,x)=V(t,x)$ for $\varphi,g\in C^1_b(H)$ and $x\in E$.

Now, if $x\in H$ and $\{x_n\}$ is a sequence in E converging to x in H, by using (3.4) we can prove that

$$\lim_{n\to+\infty}\sup_{z\in\mathcal{M}_R}|J(t,x_n;z)-J(t,x;z)|=0.$$

Therefore, since $u(t,x_n)$ converges to $u(t,x)$, we get the theorem for any $x\in H$. Finally, if $\varphi,g\in\text{Lip}_b(H)$, let $\{\varphi_k\}$ and $\{g_k\}$ be two bounded sequences in $C^1_b(H)$, converging, respectively, to φ and g in $C_b(H)$. We have

$$\lim_{k\to+\infty}\mathbf{E}\,\varphi_k(y(T))+\mathbf{E}\int_0^t(g_k(y(s))+k(z(s)))\,ds=J(t,x;z),$$

uniformly with respect to z, and then, thanks to (6.12), the theorem holds for any $\varphi, g \in \mathrm{Lip}_b(H)$. □

In some particular cases the closed loop equation admits a unique solution, and then there exist a unique optimal control and a unique state for the control problem.

THEOREM 7.3. *Assume the hypotheses of Theorem 7.2, and take the space dimension $d = 1$.*

1. *If the constant m in Hypothesis 1 is less than 2, then for any $\varphi, g \in Lip_b(H)$, and $x \in H$ there exists a unique optimal control for the minimizing problem associated with the functional J. Furthermore, the optimal control $z^\star$ is related to the corresponding optimal state $y^\star$ by the feedback formula*
$$z^\star(t) = -DK(D_x V(T-t, y^\star(t))), \qquad t \in [0,T].$$
2. *If DK can be extended as a Lipschitz continuous mapping from $E^\star$ into itself, then the same conclusion of 1 holds for any $x \in E$.*

Proof. We first prove 1. As we have seen in the proof of the previous theorem, the only thing we have to show is that for any $\varphi, g \in C_b^1(H)$ the derivative with respect to x of the solution u of the problem (6.1) is Lipschitz continuous, and for any $x, y \in H$

$$|Du(t,x) - Du(t,y)|_H \leq c_T\,(t \wedge 1)^{-\frac{1+\epsilon}{2}}\,\left(\|\varphi\|_1^H + T\,\|g\|_1^H\right)|x-y|_H. \tag{7.9}$$

Actually, if we define for $(t,x) \in [0,T] \times H$
$$U(t,x) = -DK(Du(T-t,x)),$$
the function U verifies the conditions of Lemma A.1, and then there exists a unique solution $y^\star(t)$ for the closed loop equation. Thanks to Lemma 7.1 this implies the existence of a unique optimal control and state. Finally, as in the proof of the previous theorem, the general case of $\varphi, g \in \mathrm{Lip}_b(H)$ follows by approximation.

We have seen that u is the unique solution of (6.2) in $C_b^1(H)$ and
$$\|u\|_1^H \leq c_T\,\left(\|\varphi\|_1^H + T\,\|g\|_1^H\right).$$
Clearly, if we show that the function $D(P_t\varphi)$ is Lipschitz continuous for any $\varphi \in C_b^1(H)$ and $t > 0$ and

$$|D(P_t\varphi)(x) - D(P_t\varphi)(y)|_H \leq c\,(t \wedge 1)^{-\frac{1+\epsilon}{2}}\,\|\varphi\|_1^H|x-y|_H, \tag{7.10}$$

then, by using the same arguments of section 6, we have that $u(t,\cdot) \in C_b^1(H)$ and
$$|Du(t,x) - Du(t,y)|_H \leq c\,(t \wedge 1)^{-\frac{1+\epsilon}{2}}\,|x-y|_H,$$
where the constant c depends only on g, φ, and T. Since $D(P_t\varphi)$ is given by the formula (5.2), (7.10) immediately follows once one proves that for any $x, y \in E$ it holds that

$$|v(t;x,h) - v(t;y,h)|_H^2 + \int_0^t |Q^{-1}v(s;x,h) - v(s;y,h)|_H^2 \leq c_T|h|_H^2|x-y|_H^2, \tag{7.11}$$

P-a.s. Let us define $z(t) = v(t;x,h) - v(t;y,h)$. We have that z is the unique solution of the problem

$$\left\{\begin{array}{ll} \dfrac{dz}{dt}(t) = & (Az(t) + DF(y(t;x))z(t))\,dt \\[2ex] & + \left(DF(y(t;x)) - DF(y(t;y))\right)v(t;y,h)\,dt, \qquad z(0) = 0. \end{array}\right.$$

Thus we have

$$\frac{1}{2}\frac{d}{dt}|z(t)|_H^2 + |z(t)|^2_{D((-A)^{1/2})} \leq c\,|z(t)|_H^2$$

$$+\,|\langle (DF(y(t;x)) - DF(y(t;y)))\,v(t;y,h), z(t)\rangle_H|\,.$$

Due to the Sobolev embedding theorem, for any $\delta > 0$ we have

$$|\langle (DF(y(t;x)) - DF(y(t;y)))\,v(t;y,h), z(t)\rangle_H|$$

$$\leq |z(t)|_{D\left((-A)^{(1+\delta)/4}\right)}\,|(DF(y(t;x)) - DF(y(t;y)))\,v(t;y,h)|_1\,.$$

In [6] it is proved that

$$\sup_{x\in\,E} |y(t;x)|_E \leq k(t)(t\wedge 1)^{-\frac{1}{2m}}, \qquad \mathbf{P}-\text{a.s.},$$

for some process $k(t)$ having all moments finite. Thus, since

$$\sup_{x\in\,H} |v(t;x,h)|_H \leq c(t)|h|_H,$$

for some continuous increasing function $c(t)$, by interpolation we get

$$|\langle (DF(y(t;x)) - DF(y(t;y)))\,v(t;y,h), z(t)\rangle_H|$$

$$\leq |z(t)|^{(1+\delta)/2}_{D\left((-A)^{1/2}\right)}|z(t)|_H^{(1-\delta)/2}|x-y|_H|h|_H\,c(t)\,(t\wedge 1)^{-(2m-1)/2m}.$$

As we can write

$$(t\wedge 1)^{-(2m-1)/2m} = (t\wedge 1)^{-(1-\delta)/2}(t\wedge 1)^{-\frac{1}{2}(1+\delta-1/m)},$$

thanks to the Young inequality we get

$$\frac{1}{2}\frac{d}{dt}|z(t)|_H^2 + |z(t)|^2_{D((-A)^{1/2})} \leq c\,|z(t)|_H^2 + \frac{1}{2}|z(t)|^2_{D\left((-A)^{1/2}\right)}$$

$$+c\,|x-y|_H^2|h|_H^2(t\wedge 1)^{-(1-\delta)} + c(t)\,(t\wedge 1)^{-2(1+\delta-1/m)/(1-\delta)}\,|z(t)|_H^2,$$

where $c(t)$ is a process having all moments finite. Now, if $m < 2$, it is possible to find some $\delta \in (0,1)$ such that

$$2(1+\delta-1/m)/(1-\delta) < 1,$$

and then, by using the Gronwall lemma, (7.11) follows.

Concerning the proof of 2, we recall that in [6] it has been proved that for any $\varphi \in C_b^1(E) \supset C_b^1(H)$ and $t > 0$ it holds that

$$|D(P_t\varphi)(x) - D(P_t\varphi)(y)|_{E^\star} \leq c\,(t\wedge 1)^{-\frac{1+\epsilon}{2}}\,\|\varphi\|_1^E|x-y|_E, \qquad x,y \in\ E.$$

Then as before we have that $u(t,\cdot) \in C_b^1(E)$ and

$$|Du(t,x) - Du(t,y)|_{E^\star} \leq c\,(t\wedge 1)^{-\frac{1+\epsilon}{2}}\,|x-y|_E, \tag{7.12}$$

where the constant c depends only on g, φ, and T. This makes it possible to prove that the closed loop equation admits a unique mild solution. Actually, due to the Sobolev embedding theorem, as the dimension d equals 1, for any $\epsilon > 0$ we have that $D((-C)^{1/4+\epsilon})$ is continuously embedded into E, and then

$$\begin{aligned}
&\left|\int_0^t e^{(t-s)C} DK(u(T-s,y(s;x)))\,ds\right|_E \\
&\leq c\int_0^t \left|e^{(t-s)C} DK(u(T-s,y(s;x)))\right|_{D((-C)^{1/4+\epsilon})}\,ds \\
&\leq c\int_0^t (t-s)^{-1/2-2\epsilon}\,|DK(u(T-s,y(s;x)))|_{\left(D((-C)^{1/4+\epsilon})\right)^\star} \\
&\leq c\int_0^t (t-s)^{-1/2-2\epsilon}\,|DK(u(T-s,y(s;x)))|_{E^\star}\,.
\end{aligned}$$

Therefore, as DK is Lipschitz continuous on $E^\star$ and (7.12) holds, it is easy to show that the closed loop equation admits a unique mild solution. □

Notice that if $K(x) = |x|_H^2$, then $DK(x) = x$, so that DK can be extended as a Lipschitz continuous mapping from $E^\star$ into itself.

Appendix A. An a priori estimate.

We prove here an a priori C^1 estimate for the solution u_α of the approximating problem (6.3). As in [21] we represent u_α and Du_α by means of the transition semigroups associated with suitable stochastic problems. This allows us to have a maximum principle both for u_α and Du_α.

LEMMA A.1. *Let $U : [0,T]\times H \to H$ be a bounded and measurable mapping, such that $U(t,\cdot)$ is Lipschitz continuous for any $t > 0$ and*

$$\sup_{t\in[\epsilon,T]} \|U(t,\cdot)\|_{\mathrm{Lip}}^H < \infty$$

for any $\epsilon > 0$. Then, for any $\alpha > 0$ the stochastic problem

$$dy(t) = (Ay(t) + F_\alpha(y(t)) + U(T-t,y(t)))\,dt + Q\,dw(t), \qquad y(r) = x,$$

admits a unique solution $y_\alpha(t,r;x) \in L^2(\Omega; C([r,T];H)\cap L^\infty(r,T;H))$.

Proof. For any $\epsilon > 0$ the function $U(T-t,\cdot)$ is Lipschitz continuous, uniformly for $t \in [0,T-\epsilon]$, and then there exists a unique solution $y_\alpha(t)$ in the interval $[0,T-\epsilon]$ for any $\epsilon > 0$. If we define $v_\alpha(t) = y_\alpha(t) - w^A(t,r)$, we have that $v_\alpha(t)$ is the unique solution of the problem

$$\frac{dv}{dt}(t) = Av(t) + F_\alpha(y_\alpha(t)) + U(T-t,y_\alpha(t)), \qquad v(r) = x. \tag{A.1}$$

Thus, by multiplying each side of (A.1) by $v_\alpha(t)$, we get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|v_\alpha(t)|_H^2 + |(-A)^{1/2}v_\alpha(t)|_H^2 = \left\langle F_\alpha(v_\alpha(t)+w^A(t,r)) - F_\alpha(w^A(t,r)), v_\alpha(t)\right\rangle_H \\
&+ \left\langle F_\alpha(w^A(t,r)), v_\alpha(t)\right\rangle_H + \langle U(T-t,y_\alpha(t)), v_\alpha(t)\rangle_H\,.
\end{aligned}$$

Due to the Lipschitz continuity of F_α and the boundedness of U, this implies that

$$\frac{1}{2}\frac{d}{dt}|v_\alpha(t)|_H^2 \leq c_\alpha\,|v_\alpha(t)|_H^2 + c_\alpha\left(|w^A(t,r)|_H^2 + 1\right).$$

Therefore, by integrating with respect to t, by taking the supremum for $t \in [r, T-\epsilon]$, and, finally, by taking the expectation, due to the Gronwall lemma we have

$$\mathbf{E}\sup_{t\in\,[r,T-\epsilon]}|v_\alpha(t)|_H^2 \leq c_{\alpha,T}\Big(|x|_H^2 + \mathbf{E}\sup_{t\in\,[r,T]}|w^A(t,r)|_H^2\Big).$$

Thanks to the regularity of $w^A(t,r)$, this allows us to conclude that

$$\mathbf{E}\sup_{t\in\,[r,T-\epsilon]}|y_\alpha(t)|_H^2 \leq 2\sup_{t\in\,[r,T-\epsilon]}\left(|v_\alpha(t)|_H^2 + |w^A(t,r)|_H^2\right) \leq c_{\alpha,T}\left(|x|_H^2+1\right).$$

As the constant $c_{\alpha,T}$ does not depend on ϵ, by a uniqueness argument we have that the solution $y_\alpha(t)$ is defined for any $t \in [r,T)$ and $y_\alpha(t,r;x) \in L^2(\Omega; C([r,T);H) \cap L^\infty(r,T;H))$. □

For each $\alpha > 0$ and $n \in \mathbb{N}$, we introduce the approximating Hamilton–Jacobi–Bellman equation

$$\text{(A.2)}\qquad \frac{\partial u}{\partial t}(t,x) = \mathcal{L}_{\alpha,n}u(t,x) - K_n(Du(t,x)) + g_n(x), \qquad u(0,x) = \varphi_n(x),$$

where

$$\mathcal{L}_{\alpha,n}\psi(x) = \frac{1}{2}\mathrm{Tr}\,\left[Q_n^2 D^2\psi(x)\right] + \langle A_n x + F_{\alpha,n}(x), D\psi(x)\rangle_H\,.$$

By arguing as for the problem (6.3) (see Remark 6.4), if $\varphi, g \in \mathrm{Lip}_b(H)$, the problem (A.2) admits a unique local solution $u_{\alpha,n}$ in $\Lambda_R(\tau_R)$. The solution $u_{\alpha,n}$ is the unique fixed point for the functional

$$\Gamma_{\alpha,n}(v)(t,x) = P_t^{\alpha,n}\varphi(x) - \int_0^t P_{t-s}^{\alpha,n}K(Dv(s,\cdot))(x)\,ds + \int_0^t P_{t-s}^{\alpha,n}g(x)\,ds,$$

and due to (5.8) the contraction constant of $\Gamma_{\alpha,n}$ is independent of n and α. Thus we can proceed as in the proof of Lemma 6.5, and thanks to Proposition 5.1 we conclude that for any $\alpha > 0$

$$\text{(A.3)}\qquad \lim_{n\to+\infty}|u_{\alpha,n}(t,x) - u_\alpha(t,x)| + |Du_{\alpha,n}(t,x) - Du_\alpha(t,x)|_H = 0,$$

uniformly for $t \in [0,\tau_R]$ and for x in bounded sets of H.

According to (5.3) it is possible to show that u_α and $u_{\alpha,n}$ have a stronger regularity.

Lemma A.2. *If $\varphi, g \in C_b^1(H)$, then the solutions u_α and $u_{\alpha,n}$ of the problems* (6.2) *and* (6.3) *belong to $\mathcal{Z}^2_{\tau_\star}$ for some $\tau_\star = \tau_\star(\alpha) \leq T$, which can be taken independent of n.* For a proof we refer to [9, chapter 9].

Proposition A.3. *Let us fix $\varphi, g \in C_b^1(H)$, and assume that u_α is the unique solution of the problem* (6.3) *in $\mathcal{Z}^2_{\tau_\star}$, with $\tau_\star = \tau_\star(\alpha) \leq T$. Then, under Hypotheses* 1, 2, *and* 3, *we have*

$$\sup_{\alpha>0}\Big(\sup_{t\in\,[0,\tau_\star]}\|u_\alpha(t,\cdot)\|_1^H\Big) \leq c\,(1+T)e^{c\,T}\left(\|\varphi\|_1^H + \|g\|_1^H\right).$$

Proof. If we define

$$U_{\alpha,n}(t,x)=\int_0^1 DK_n(\lambda Du_{\alpha,n}(t,x))\,d\lambda, \tag{A.4}$$

the problem (A.2) can be rewritten as

$$\begin{cases} \dfrac{\partial u}{\partial t}(t,x)=\dfrac{1}{2}\mathrm{Tr}\,[Q_n^2D^2u(t,x)]+\langle A_nx+F_{\alpha,n}(x)+U_{\alpha,n}(t,x),Du(t,x)\rangle+g_n(x),\\[2ex] u(0,x)=\varphi_n(x). \end{cases}$$

Since $\varphi,g\in C_b^1(H)$, we have that the solution $u_{\alpha,n}\in\mathcal{Z}^2_{\tau_\star}$ and then $U_{\alpha,n}:[0,\tau_\star]\times H\to H_n$ is continuous and bounded. Moreover, since DK is locally Lipschitz continuous, if we define $M_{\alpha,n}$ as the Lipschitz constant of DK in the ball $\{\,x\in H\ ;\ |x|_H\leq\|u_{\alpha,n}\|_{\mathcal{Z}^2_{\tau_\star}}\,\}$ for any $x,y\in H$ and $t>0$, we have that

$$|U_{\alpha,n}(t,x)-U_{\alpha,n}(t,y)|_H\leq\int_0^1|DK_n(\lambda Du_{\alpha,n}(t,x))-DK_n(\lambda Du_{\alpha,n}(t,y))|_H\,d\lambda$$

$$\leq M_{\alpha,n}\,|Du_{\alpha,n}(t,x)-Du_{\alpha,n}(t,y)|_H\leq c\,M_{\alpha,n}\sup_{z\in H}|D^2u_{\alpha,n}(t,z)||x-y|_H$$

$$\leq c\,M_{\alpha,n}\,t^{-\frac{1+\epsilon}{2}}\|u_{\alpha,n}\|_{\mathcal{Z}^2_{\tau_\star}}|x-y|_H.$$

This means that the function $U_{\alpha,n}$ fulfills the hypotheses of Lemma A.1 so that for each $0\leq r<T$ the stochastic problem

$$dy(t)=(A_ny(y)+F_{\alpha,n}(y(t))+U_{\alpha,n}(t,y(t)))\,dt+Q_ndw(t),\qquad y(r)=P_nx, \tag{A.5}$$

admits a unique strong solution $y_{\alpha,n}(t,r;x)\in L^2(\Omega;C([r,\tau_\star);H)\cap L^\infty(r,\tau_\star;H))$.

If we denote by $R^{\alpha,n}_{s,t}$ the corresponding transition semigroup, that is,

$$R^{\alpha,n}_{s,t}\varphi(x)=\mathbf{E}\,\varphi(y_{\alpha,n}(t,s;x)),\qquad 0\leq s\leq t\leq\tau_\star,$$

for $\varphi\in B_b(H)$ and $x\in H$, we have

$$u_{\alpha,n}(t,x)=R^{\alpha,n}_{\tau_\star-t,\tau_\star}\varphi(x)+\int_0^t R^{\alpha,n}_{\tau_\star-t,\tau_\star-s}g(x)\,ds. \tag{A.6}$$

Indeed, since $y_{\alpha,n}(t)$ is a strong solution and $u_{\alpha,n}(t,x)$ is regular, we can apply Itô's formula to the function $s\mapsto u_{\alpha,n}(\tau_\star-s,y_{\alpha,n}(s,\tau_\star-t;x))$, and by integrating with respect to $s\in[\tau_\star-t,\tau_\star]$ and by taking the expectation, we get

$$u_{\alpha,n}(t,x)=\mathbf{E}\,\varphi(y_{\alpha,n}(\tau_\star,\tau_\star-t;x))+\int_0^t\mathbf{E}\,g(y_{\alpha,n}(\tau_\star-s,\tau_\star-t;x))\,ds,$$

which coincides with (A.6). As an immediate consequence this yields

$$\sup_{t\in[0,\tau_\star]}\|u_{\alpha,n}(t,\cdot)\|_0^H\leq\|\varphi\|_0^H+T\|g\|_0^H. \tag{A.7}$$

The proof of the analogous estimate for the derivative of $u_{\alpha,n}(t,x)$ is more complicated but is based on similar arguments.

The problem (A.2) can be rewritten as

$$(\mathrm{A.8})\quad \begin{cases} \dfrac{\partial u}{\partial t}(t,x) = & \dfrac{1}{2}\displaystyle\sum_{k=1}^{n}\lambda_k^2 D_k^2 u(t,x) + \sum_{k,h=1}^{n} a_{k,h}x_h D_k u(t,x) - K_n(Du(t,x)) \\ & +\displaystyle\sum_{k=1}^{n}\left\langle F_{\alpha,n}(x), e_k\right\rangle_H D_k u(t,x) + g_n(x), \\ u(0,x) = & \varphi_n(x), \end{cases}$$

where for each $k,h \in \mathbb{N}$ we denote $D_k u = \langle Du, e_k\rangle$ and $a_{k,h} = \langle Ae_k, e_h\rangle$. By differentiating each side of (A.8) with respect to x_j and by setting $v_j = D_j u$, we get

$$\frac{\partial v_j}{\partial t} = \frac{1}{2}\sum_{k=1}^{n}\lambda_k^2 D_k^2 v_j + \sum_{k=1}^{n} a_{k,h}x_h D_k v_j + \sum_{k=1}^{n} a_{k,j}v_k + \sum_{k=1}^{n}\langle F_{\alpha,n}(x), e_k\rangle D_k v_j$$

$$+\sum_{k=1}^{n}\langle DF_{\alpha,n}(x)e_j, e_k\rangle v_k - \sum_{k=1}^{n}\langle DK_n(Du_{\alpha,n}), e_k\rangle D_k v_j + \langle Dg_n(x), e_j\rangle .$$

By multiplying each side by v_j and by summing up on j, we obtain

$$\frac{1}{2}\frac{\partial}{\partial t}\sum_{j=1}^{n} v_j^2 = \frac{1}{2}\sum_{k,j=1}^{n}\lambda_k^2 v_j D_k^2 v_j + \sum_{k,h,j=1}^{n} a_{k,h}x_h v_j D_k v_j + \sum_{k,j=1}^{n} a_{k,j}v_k v_j$$

$$+\sum_{k,j=1}^{n}\langle F_{\alpha,n}(x), e_k\rangle v_j D_k v_j + \sum_{k,j=1}^{n}\langle DF_{\alpha,n}(x)v_j e_j, v_k e_k\rangle$$

$$-\sum_{k,j=1}^{n}\langle DK_n(Du_{\alpha,n}(t,x)), e_k\rangle v_j D_k v_j + \sum_{j=1}^{n}\langle Dg_n(x), v_j e_j\rangle .$$

Now, if we define $2z_{\alpha,n}(t,x) = |Du_{\alpha,n}(t,x)|_H^2$, it holds that

$$\sum_{k,j=1}^{n}\lambda_k^2 v_j D_k^2 v_j = \sum_{k=1}^{n}\lambda_k^2 D_k^2 z_{\alpha,n} - \sum_{k,j=1}^{n}\lambda_k^2 (D_k v_j)^2,$$

$$\sum_{k,h,j=1}^{n} a_{k,h}x_h v_j D_k v_j + \sum_{k,j=1}^{n} a_{k,j}v_k v_j = \langle A_n x, Dz_{\alpha,n}\rangle + \langle A_n Du_{\alpha,n}, Du_{\alpha,n}\rangle ,$$

$$\sum_{k,j=1}^{n}\langle F_{\alpha,n}(x), e_k\rangle v_j D_k v_j = \langle F_{\alpha,n}(x), Dz_{\alpha,n}\rangle ,$$

$$\sum_{k,j=1}^{n}\langle DK_n(Du_{\alpha,n}), e_k\rangle v_j D_k v_j = \langle DK_n(Du_{\alpha,n}), Dz_{\alpha,n}\rangle .$$

Moreover, we have

$$\sum_{k,j=1}^{n} \langle DF_{\alpha,n}(x)v_j e_j, v_k e_k\rangle = \langle DF_{\alpha,n}(x)Du_{\alpha,n}, Du_{\alpha,n}\rangle,$$

$$\sum_{j=1}^{n} \langle Dg_n, v_j e_j\rangle = \langle Dg_n, Du_{\alpha,n}\rangle\,.$$

Thus, by substituting and by taking into account of (2.13) and (3.8), we can conclude that

$$\frac{\partial z_{\alpha,n}}{\partial t}(t,x) \leq \mathcal{M}_{\alpha,n} z_{\alpha,n}(t,x) + c\, z_{\alpha,n}(t,x) + |Dg_n|_H^2,$$

where the differential operator $\mathcal{M}_{\alpha,n}$ is defined by

$$\mathcal{M}_{\alpha,n}\psi(x) = \frac{1}{2}\mathrm{Tr}\,[Q_n^2 D^2\psi(x)] + \langle A_n x + F_{\alpha,n}(x) - DK_n(Du_{\alpha,n}(t,x)), D\psi(x)\rangle_H\,.$$

Now we define

$$V_{\alpha,n}(t,x) = -DK_n(Du_{\alpha,n}(t,x)).$$

By arguing as above for the function $U_{\alpha,n}(t,x)$ defined in (A.4), we have that $V_{\alpha,n} : [0,\tau_\star]\times H \to H$ satisfies the hypotheses of Lemma A.1 so that the stochastic problem

$$\text{(A.9)}\quad dy(t) = (A_n y(t) + F_{\alpha,n}(y(t)) + V_{\alpha,n}(t,y(t)))\,dt + Q_n dw(t), \qquad y(r) = P_n x,$$

admits a unique strong solution $y_{\alpha,n}(t,r;x)$ for any $0 \leq r \leq \tau_\star$. If we denote by $S_{s,t}^{\alpha,n}$ the transition semigroup associated with (A.9), by arguing as before for the semigroup associated with the problem (A.5), we have that the solution of the problem

$$\frac{\partial v}{\partial t}(t,x) = \mathcal{M}_{\alpha,n} v(t,x) + cv(t,x) + |Dg_n(x)|_H^2, \qquad v(0,x) = |D\varphi_n(x)|_H^2,$$

is given by

$$v_{\alpha,n}(t,x) = e^{c\,t} S^{\alpha,n}_{\tau_\star - t,\tau_\star}|D\varphi_n|_H^2(x) + \int_0^t e^{c(t-s)} S^{\alpha,n}_{\tau_\star-t,\tau_\star-s}|Dg_n|_H^2(x)\,ds.$$

This yields

$$\sup_{t\in\,[0,\tau_\star]} \|v_{\alpha,n}(t,\cdot)\|_0^H \leq c\,(1+T)\,e^{c\,T}\left(\|\varphi\|_1^H + \|g\|_1^H\right)^2$$

so that by a comparison argument we conclude

$$\text{(A.10)}\quad \sup_{t\in\,[0,\tau_\star]} \|Du_{\alpha,n}(t,\cdot)\|_0^H \leq 2 \sup_{t\in\,[0,T]} \|z_{\alpha,n}(t,\cdot)\|_0^H \leq c\,(1+\sqrt{T})\,e^T\left(\|\varphi\|_1^H + \|g\|_1^H\right).$$

From (A.7) and (A.10), due to (A.3), we conclude that our statement holds. □

Acknowledgments. The author wishes to thank Arnaud Debussche and Fausto Gozzi for many useful discussions she had with them.

THE LATTICE STRUCTURE OF BEHAVIORS[*]

SHIVA SHANKAR[†]

For Professor J. C. Willems, on the occasion of his sixtieth birthday.

Abstract. If a linear, continuous, shift invariant distributed system is considered as a (dynamical) system converting input signals to output signals, then this information is encapsulated in the impulse response or the transfer function of the system. The set of all transfer functions has the structure of a ring, corresponding to the operations of parallel and cascade connections of two systems. However, in the behavioral theory of Willems, a system is not described in terms of its input-output transformation property. Indeed, the concept of a behavior does not even need the notions of inputs and outputs and is therefore more fundamental than the classical concept of a system given by its transfer function. The question then arises as to what is the structure of the set of all behaviors. This paper argues that the relevant structure here is that of a modular lattice.

Key words. distributed systems, systems of partial differential equations, modular lattice

1. Introduction.

The purpose of this paper is to explain the algebraic structure of the set of all linear (distributed) behaviors.

In the previous algebraic theory, where the focus was more on the discrete version of a distributed system, i.e., linear multidimensional systems described by difference equations in several indeterminates (see Bose [2] for the 2-D case and Shankar and Sule [10] and Sule [12] for the general n-D case), the point of view adopted was to consider a plant as a (nonautonomous) dynamical system, transferring input signals into output signals. The system being linear, continuous, and shift invariant, the relationship between inputs and outputs could be encapsulated in the impulse response or the transfer function of the system. The transfer function of such a system was a rational function (in several indeterminates). Now two such multidimensional input-output systems could be connected either in parallel or in cascade. The transfer function of the resulting input-output system was then the sum or the product of the transfer functions of the individual systems. The set of all these systems, or more accurately their transfer functions, with these two operations had then the structure of a ring. It was this structure that was the foundation for the theory developed in [10], which described the set of all stabilizing controllers of a plant and which described the topology of robust stabilization, etc. It was this same algebraic structure that was crucial for the characterization of the obstruction to the problem of simultaneously stabilizing two plants by a single controller (or equivalently the problem of stabilizing a plant by a stable controller); see [6] and Ying [16]. This was of course hardly surprising, for any solution of a problem which required one to consider, a priori, the set of all plants should have to take into account, and indeed rely on, the structure of the set of all plants.

More recently, J. C. Willems has in a series of fundamental papers, summarized in [14, 15], transformed the stage in which control problems had been formulated and

solved. In his far-reaching theory, which goes beyond the description of a plant as something that transforms inputs to outputs, indeed which goes beyond notions of inputs and outputs altogether, the central object is the *behavior* of an autoregressive (AR) system (more generally the behavior of an autoregressive moving average (ARMA) system, but the "elimination theorem" allows one to reduce such a behavior to the behavior of an AR system)—formal definitions appear in the next section. This behavior is the set of all homogeneous solutions of a system of differential equations in some appropriate function or distribution space. (By a system I mean here a matrix, each entry of which is a differential operator.) While Willems and his coworkers have in the large concentrated in formulating and solving control problems, both old and new, for lumped systems (i.e., where the differential operators are ordinary)—see Trentelman [13] for a recent exposition—this theory has also been carried over effectively to distributed systems, i.e., the case of partial differential operators, in Oberst [4], in Pillai and Shankar [5], and in [7, 8, 9].

One of the important features of Willems's behavioral theory, and arguably the principal reason for its success, is the algebraic nature of the theory—in fact the algebraic structure of the set of homogeneous solutions of a matrix of differential operators is known in mathematics as a $\mathcal{D}$-module. This algebraic structure is especially crucial in the study of distributed systems for the following reason. Classically, one studied a distributed system in the framework of semigroups of transformations of some infinite dimensional space. These methods of study were function theoretic, necessarily of infinite dimensional objects, and hence rarely effective (in the sense of a finite computable procedure). On the other hand, in the behavioral theory, one associates to a distributed behavior a submodule of a free module of finite rank over the ring of constant coefficient partial differential operators (with coefficients in $\mathbb{R}$ or $\mathbb{C}$), and one studies properties of the behavior in terms of this submodule. As this ring is Noetherian, submodules of free modules of finite rank are *finitely generated.* This enables one, often, to reduce matters to the calculation of *finitely generated* objects such as torsion submodules, Ext modules, etc. (see [4, 5, 7]). Moreover, the availability of computational techniques from commutative algebra (Gröbner basis, etc.) makes the behavioral theory a *practical* one, and I foresee not long from now effective procedures to calculate stabilizing controllers for distributed systems and other such problems.

The question now arises, as in the previous theory of transfer functions, as to what is the structure underlying the set of all behaviors. As remarked earlier, a behavior does not come with a priori notions of inputs and outputs—it is possible to impose an input-output structure for hyperbolic systems (see [8])—but the general notion of a behavior does not depend upon this possibility. Thus it does not make sense, in general, to connect two behaviors in parallel or in cascade, and it is not the structure of a ring that is the right notion here. Instead, this paper argues, the relevant structure here is that of a lattice. The set of behaviors is partially ordered by inclusion, and any collection of behaviors has a least upper bound and a greatest lower bound. This much is straightforward. However, there are two other lattices that are in the picture here. One is the lattice of all submodules of the free module of fixed (finite) rank, each summand some function or distribution space, in which these behaviors are located. A behavior is such a submodule, and furthermore of a very special kind—viz., one that is a $\mathcal{D}$-module, i.e., the kernel of a system of differential operators—and the lattice of behaviors is a subset of this lattice of all submodules. The other is the lattice of all submodules of the free module (of the same rank as above) over the ring of differential operators. The question then arises as to what is the relationship between these three lattices, and the answer to it is the subject of this paper. In relating these structures there are several problems that have to be overcome. For one, distinct submodules of the free module over the ring of differential operators could determine the same behavior. For another, the sum of two behaviors need not be a behavior. It turns out that the notion of a Willems submodule (or the more general notion of closure introduced in this paper) is crucial in overcoming these problems. The importance of a Willems submodule has already been demonstrated in [5] and [7] from both the control as well as the "pure" mathematical points of view (it is the analogue of a radical ideal when a polynomial is considered as a partial differential operator). The results of those papers play a crucial role here, and in turn the results of this paper justify further this notion.

The paper is organized as follows. In the next section I establish a calculus whose final intent is to prove the differential analogue of the fact that the radical of a finite intersection of ideals is the intersection of the individual radicals (Corollary 2.3). To prove this I need results from [4] and [7]. This corollary is of crucial importance in understanding the relationship between the lattices described above, and this is the subject of section 3. The final section concerns the structure of stable and stabilizable behaviors. Stability here is a notion generalizing bounded input–bounded output (BIBO) stability of lumped behaviors that was introduced in [5] and [8], and is fundamental to control. I therefore also include a result describing necessary and sufficient conditions for the stabilizability of a behavior. The paper also includes several examples (or pathologies) which explain when things go wrong and why. It concludes with a result on determinantal ideals, an example of the reverse direction, where the theory of behaviors is used to conclude facts in algebra and in geometry.

2. The calculus of Willems submodules.

In this section I collect some preliminary definitions and results that I need in what follows.

As explained in the introduction, the central object of study in control theory, as it has emerged in recent years, is the behavior of an AR system, which I define first (see [14, 15, 4, 5]).

Let $\mathcal{D}'$ be the space of all distributions on $\mathbb{R}^n$. Let $\mathcal{A} = K[\partial_1, \dots, \partial_n]$, $K = \mathbb{R}$ or $\mathbb{C}$, be the polynomial ring in the n indeterminates $\partial_1, \dots, \partial_n$, with coefficients in K, where ∂_i is partial differentiation in the ith coordinate direction x_i (and thus an element $p(\partial)$ in $\mathcal{A}$ is a (constant coefficient) partial differential operator). The ring $\mathcal{A}$ acts on $\mathcal{D}'$ by differentiation and makes $\mathcal{D}'$ an $\mathcal{A}$-module. Given any $\mathcal{A}$-submodule $\mathcal{W}$ of $\mathcal{D}'$, the map

$$\begin{array}{rccc} p(\partial): & \mathcal{W} & \longrightarrow & \mathcal{W}, \\ & w & \mapsto & p(\partial)w \end{array}$$

is an $\mathcal{A}$-module morphism. The kernel of $p(\partial)$, which is an $\mathcal{A}$-submodule of $\mathcal{W}$, is the *behavior* of $p(\partial)$ in $\mathcal{W}$ (or the $\mathcal{W}$-behavior of $p(\partial)$), and is denoted by $\mathrm{Ker}_{\mathcal{W}}(p(\partial))$. Given an ideal $\mathcal{I}$ in $\mathcal{A}$, the $\mathcal{A}$-submodule $\bigcap_{p(\partial)\in\mathcal{I}} \mathrm{Ker}_{\mathcal{W}}(p(\partial))$ of $\mathcal{W}$ is called the $\mathcal{W}$-behavior of $\mathcal{I}$, and is denoted by $\mathrm{Ker}_{\mathcal{W}}(\mathcal{I})$.

More generally, given an element $r(\partial) = (p_1(\partial), \dots, p_k(\partial))$ in the free module $\mathcal{A}^k$, the map

$$\begin{array}{rccc} r(\partial): & \mathcal{W}^k & \longrightarrow & \mathcal{W}, \\ & w = (w_1, \dots, w_k) & \mapsto & r(\partial)w = \sum_{i=1}^k p_i(\partial)w_i \end{array}$$

is an $\mathcal{A}$-module morphism. Its kernel, denoted $\mathrm{Ker}_{\mathcal{W}}(r(\partial))$, is an $\mathcal{A}$-submodule of $\mathcal{W}^k$, and is called the $\mathcal{W}$-behavior of $r(\partial)$. Given a submodule $\mathcal{R}$ of $\mathcal{A}^k$, let $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$

denote the $\mathcal{A}$-submodule of $\mathcal{W}^k$ given by $\bigcap_{r(\partial)\in\mathcal{R}} \mathrm{Ker}_{\mathcal{W}}(r(\partial))$. Call it the $\mathcal{W}$-behavior of $\mathcal{R}$. As $\mathcal{A}$ is Noetherian, $\mathcal{R}$ is finitely generated, say, by $r_1(\partial),\ldots,r_l(\partial)$. Clearly then $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ is the kernel of the morphism

$$\begin{array}{cccc} R(\partial): & \mathcal{W}^k & \longrightarrow & \mathcal{W}^l, \\ & w & \mapsto & (r_1(\partial)w,\ldots,r_l(\partial)w). \end{array}$$

If $r_i(\partial) = (r_{i1}(\partial),\ldots,r_{ik}(\partial)), i = 1,\ldots,l$, then $R(\partial)$ can be represented, in the usual way, by the following matrix:

$$R(\partial) = \begin{pmatrix} r_{11}(\partial) & \ldots & r_{1k}(\partial) \\ \cdot & \cdots & \cdot \\ \cdot & \cdots & \cdot \\ r_{l1}(\partial) & \ldots & r_{lk}(\partial) \end{pmatrix}. \tag{1}$$

Thus the $\mathcal{W}$-behavior of a submodule of $\mathcal{A}^k$ is the set of homogeneous solutions in the space $\mathcal{W}^k$ of a system (i.e., matrix) of differential operators. If these differential operators are ordinary, i.e., if $n = 1$, then the behavior is said to be lumped; otherwise it is a distributed behavior. Formally, one has the following.

Definition. *Let $\mathcal{W}$ be any $\mathcal{A}$-submodule of $\mathcal{D}'$. A behavior in $\mathcal{W}^k$ (or a $\mathcal{W}$-behavior) is an $\mathcal{A}$-submodule of $\mathcal{W}^k$ of the type* $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$*, for some $\mathcal{A}$-submodule $\mathcal{R}$ of $\mathcal{A}^k$.*

It is an observation of Malgrange that

$$\mathrm{Hom}_{\mathcal{A}}(\mathcal{A}^k/\mathcal{R},\mathcal{W}) \simeq \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}),$$

where the isomorphism is given by

$$\phi \mapsto (\phi(\overline{e_1}),\ldots,\phi(\overline{e_k})),$$

$\overline{e_i}$ is the image of $e_i = (0,\ldots,1,\ldots,0)$ (1 in the ith position) in $\mathcal{A}^k/\mathcal{R}$. This isomorphism which was studied in [4] and [7] plays a central role in this paper.

On the other hand, given a behavior $\mathcal{B}$ in $\mathcal{W}^k$, i.e., an $\mathcal{A}$-submodule of $\mathcal{W}^k$ of the kind $\mathcal{B} = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ for some submodule $\mathcal{R}$ of $\mathcal{A}^k$, let $\mathcal{M}(\mathcal{B}) = \mathcal{M}(\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}))$ be the submodule of $\mathcal{A}^k$ consisting of all the elements in $\mathcal{A}^k$ that map to zero every element in $\mathcal{B}$. Clearly $\mathcal{R} \subset \mathcal{M}(\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}))$. Thus there are two assignments $\mathrm{Ker}_{\mathcal{W}}$ and $\mathcal{M}$ which are both inclusion reversing, i.e., $\mathcal{R}_1 \subset \mathcal{R}_2$ implies $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2) \subset \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1)$ and $\mathcal{B}_1 \subset \mathcal{B}_2$ implies $\mathcal{M}(\mathcal{B}_2) \subset \mathcal{M}(\mathcal{B}_1)$. In other words $\mathrm{Ker}_{\mathcal{W}}$ and $\mathcal{M}$ define a Galois connection between the partially ordered sets of submodules of $\mathcal{A}^k$ and behaviors in $\mathcal{W}^k$. The primary purpose of this paper is to study this Galois connection from the viewpoint of lattice theory.

Lemma 2.1. *Let $\{\mathcal{R}_i\}$ (respectively, $\{\mathcal{B}_i\}$) be any collection of submodules of $\mathcal{A}^k$ (respectively, behaviors in $\mathcal{W}^k$). Then*

(i) $\mathrm{Ker}_{\mathcal{W}}(\sum_i \mathcal{R}_i) = \bigcap_i \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$,

(ii) $\sum_i \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i) \subset \mathrm{Ker}_{\mathcal{W}}(\bigcap_i \mathcal{R}_i)$,

(iii) $\mathcal{M}(\sum_i \mathcal{B}_i) = \bigcap_i \mathcal{M}(\mathcal{B}_i)$,

(iv) $\sum_i \mathcal{M}(\mathcal{B}_i) \subset \mathcal{M}(\bigcap_i \mathcal{B}_i)$.

Proof. Elementary. □

Lemma 2.2. $\mathrm{Ker}_{\mathcal{W}} \circ \mathcal{M}$ *is the identity map on behaviors for any $\mathcal{A}$-submodule $\mathcal{W}$ of $\mathcal{D}'$, i.e.,* $\mathrm{Ker}_{\mathcal{W}} \circ \mathcal{M}(\mathcal{B}) = \mathcal{B}$ *for all $\mathcal{W}$-behaviors $\mathcal{B}$.*

Proof. Clearly $\mathcal{B} \subset \mathrm{Ker}_{\mathcal{W}} \circ \mathcal{M}(\mathcal{B})$. But $\mathcal{B}$ by definition is $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ for some submodule $\mathcal{R}$ of $\mathcal{A}^k$ (for some k). Hence $\mathcal{R} \subset \mathcal{M}(\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})) = \mathcal{M}(\mathcal{B})$. Then $\mathrm{Ker}_{\mathcal{W}} \circ \mathcal{M}(\mathcal{B}) \subset \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}) = \mathcal{B}$. □

COROLLARY 2.1. *The correspondence $\mathcal{B} \to \mathcal{M}(\mathcal{B})$ (between behaviors in $\mathcal{W}^k$ and submodules of $\mathcal{A}^k$) is injective for all $\mathcal{A}$-submodules $\mathcal{W}$ of $\mathcal{D}'$.*

Proof. Suppose $\mathcal{M}(\mathcal{B}_1) = \mathcal{M}(\mathcal{B}_2)$. Then $\mathcal{B}_1 = \mathrm{Ker}_{\mathcal{W}} \circ \mathcal{M}(\mathcal{B}_1) = \mathrm{Ker}_{\mathcal{W}} \circ \mathcal{M}(\mathcal{B}_2) = \mathcal{B}_2$. □

The correspondence $\mathcal{R} \to \mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ is not in general injective, i.e., in general $\mathcal{M}(\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}))$ may strictly contain $\mathcal{R}$ (for instance if $\mathcal{W}$ is the 0 submodule of $\mathcal{D}'$, then $\mathcal{M}(\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})) = \mathcal{A}^k$ for every submodule $\mathcal{R}$ of $\mathcal{A}^k$). This prompts the following definition (see also [5] and [7]).

DEFINITION. *The submodule $\mathcal{M}(\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}))$ is called the Willems closure of $\mathcal{R}$ with respect to $\mathcal{W}$. If $\mathcal{R}$ is equal to $\mathcal{M}(\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}))$, i.e., if $\mathcal{R}$ is equal to its Willems closure with respect to $\mathcal{W}$, then the submodule $\mathcal{R}$ is called a Willems submodule with respect to $\mathcal{W}$.*

The analogy between this definition and the classical definition of a radical ideal was the subject of [7]. This analogy further motivates the following results.

LEMMA 2.3. *The Willems closure of $\mathcal{R}$ with respect to $\mathcal{W}$ is Willems with respect to $\mathcal{W}$. It is maximal amongst all submodules with the same $\mathcal{W}$-behavior as $\mathcal{R}$.*

Proof. The first statement follows from

$$\mathcal{M}(\mathrm{Ker}_{\mathcal{W}}(\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}))) = \mathcal{M}(\mathrm{Ker}_{\mathcal{W}} \circ \mathcal{M})\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}) = \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}).$$

For the second, $\mathrm{Ker}_{\mathcal{W}}(\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$; thus the $\mathcal{W}$-behavior of $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ equals the $\mathcal{W}$-behavior of $\mathcal{R}$. If also $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$, then $\mathcal{R}_1 \subset \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1) = \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$. □

LEMMA 2.4. *Let $\{\mathcal{B}_i\}$ be a collection of $\mathcal{W}$-behaviors. Then the Willems closure of $\sum_i \mathcal{M}(\mathcal{B}_i)$ with respect to $\mathcal{W}$ is $\mathcal{M}(\bigcap_i \mathcal{B}_i)$.*

Proof. Lemma 2.1 implies that $\mathrm{Ker}_{\mathcal{W}}(\sum_i \mathcal{M}(\mathcal{B}_i)) =\bigcap_i \mathrm{Ker}_{\mathcal{W}}(\mathcal{M}(\mathcal{B}_i))$, and this in turn equals $\bigcap_i \mathcal{B}_i = \mathrm{Ker}_{\mathcal{W}}\mathcal{M}(\bigcap_i \mathcal{B}_i)$. Hence the behavior of $\sum_i \mathcal{M}(\mathcal{B}_i)$ is equal to the behavior of the submodule $\mathcal{M}(\bigcap_i \mathcal{B}_i)$ which is Willems. □

LEMMA 2.5. *If $\{\mathcal{R}_i\}$ is any collection of submodules of $\mathcal{A}^k$, each Willems with respect to $\mathcal{W}$, then $\bigcap_i \mathcal{R}_i$ is also Willems with respect to $\mathcal{W}$.*

Proof. By assumption $\mathcal{M}(\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)) = \mathcal{R}_i$ for each i. Hence

$$\bigcap_i \mathcal{R}_i \subset \mathcal{M}\mathrm{Ker}_{\mathcal{W}}\left(\bigcap_i \mathcal{R}_i\right) \subset \mathcal{M}\left(\sum_i \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)\right) = \bigcap_i \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i) = \bigcap_i \mathcal{R}_i,$$

where the second inclusion follows from Lemma 2.1(ii) and the inclusion reversing nature of the assignment $\mathcal{M}$. This implies equality everywhere, and thus that $\bigcap_i \mathcal{R}_i = \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\bigcap_i \mathcal{R}_i)$. □

A question more general than the above lemma, which is of crucial importance in the next section, is whether $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\bigcap_i \mathcal{R}_i)$ equals $\bigcap_i \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$ for an arbitrary collection of submodules $\{\mathcal{R}_i\}$ of $\mathcal{A}^k$. In other words, is the Willems closure of an intersection equal to the intersection of the Willems closures? Of course as $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i) \subset \mathrm{Ker}_{\mathcal{W}}(\bigcap_i \mathcal{R}_i)$ it follows that, always,

$$\mathcal{M}\mathrm{Ker}_{\mathcal{W}}\left(\bigcap_i \mathcal{R}_i\right) \subset \bigcap_i \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i). \tag{2}$$

The other inclusion is not in general true for an arbitrary collection of submodules, as the following "pathology" demonstrates.

Pathology 1. Let $\mathcal{A} = \mathbb{C}[\frac{d}{dt}]$, and let $\mathcal{I}$ be any nonzero proper ideal of $\mathcal{A}$. Let $\mathcal{R}_i = \mathcal{I}^i, i \geq 0$, and consider the behaviors of $\mathcal{R}_i$ in $\mathcal{D}$, the space of compactly supported, complex valued, smooth functions on $\mathbb{R}$. As each $\mathcal{R}_i$ is a nonzero ideal, $\text{Ker}_{\mathcal{D}}(\mathcal{R}_i)$ consists of just the 0 function alone (no nonzero differential operator admits a compactly supported homogeneous solution by the Paley–Wiener theorem). Thus each $\mathcal{M}\text{Ker}_{\mathcal{D}}(\mathcal{R}_i) = \mathcal{A}$ and hence $\bigcap_i \mathcal{M}\text{Ker}_{\mathcal{D}}(\mathcal{R}_i) = \mathcal{A}$. On the other hand $\bigcap_i \mathcal{R}_i = 0$ by Krull's theorem ($\mathcal{A}$ is an integral domain, so its $\mathcal{I}$-adic completion is Hausdorff). Thus $\text{Ker}_{\mathcal{D}}(\bigcap_i \mathcal{R}_i) = \mathcal{D}$, and as the 0 ideal is the only ideal whose behavior is all of $\mathcal{D}$, it follows that $\mathcal{M}\text{Ker}_{\mathcal{D}}(\bigcap_i \mathcal{R}_i) = 0$. □

The question therefore is whether the above is true for finite intersections, i.e., does $\mathcal{M}\text{Ker}_{\mathcal{W}}(\bigcap_{i=1}^m \mathcal{R}_i) = \bigcap_{i=1}^m \mathcal{M}\text{Ker}_{\mathcal{W}}(\mathcal{R}_i)$ hold? (This is the differential analogue of the fact that the radical of a finite intersection of ideals equals the intersection of the individual radicals.) While it may possibly be true for any $\mathcal{A}$-submodule $\mathcal{W}$ of $\mathcal{D}'$, I show below that it is indeed true for the "classical" spaces by using the characterization of Willems submodules with respect to these spaces established in [4] and [7]. As this paper restricts attention to these spaces, I highlight them in the following definition.

Definition. *An $\mathcal{A}$-submodule $\mathcal{W}$ of $\mathcal{D}'$ is said to be a classical space if it is one of the following:*

(i) *$\mathcal{D}'$, the space of all distributions on $\mathbb{R}^n$,*
(ii) *$\mathcal{C}^\infty$, the space of all (complex valued) smooth functions on $\mathbb{R}^n$,*
(iii) *$\mathcal{S}'$, the space of temperate distributions on $\mathbb{R}^n$,*
(iv) *$\mathcal{S}$, the Schwartz space of rapidly decreasing functions on $\mathbb{R}^n$,*
(v) *$\mathcal{E}'$, the space of compactly supported distributions on $\mathbb{R}^n$,*
(vi) *$\mathcal{D}$, the space of compactly supported smooth functions on $\mathbb{R}^n$.*

In the following theorem, I collect results on the Willems closure of a submodule $\mathcal{R}$ of $\mathcal{A}^k$ with respect to the classical spaces from [4] and [7]. Following this I prove a stronger result on the Willems closure with respect to $\mathcal{S}'$ than the one in [7] (this stronger version is more convenient for the purposes of this paper and is used below). To state them, I employ the following notation. Given the submodule $\mathcal{R}$ of $\mathcal{A}^k$, represent $\mathcal{R}$ by an $l \times k$ matrix (whose entries are elements of $\mathcal{A}$), where the l rows (as elements of $\mathcal{A}^k$) generate $\mathcal{R}$, viz., the matrix in (1) above. Consider the kth determinantal ideal of this matrix, i.e., the ideal generated by the determinants of all the $k \times k$ submatrices. Clearly this ideal depends only on the submodule $\mathcal{R}$ and not on the choice of the matrix representing it, i.e., it is independent of the choice of the generators of $\mathcal{R}$. Denote this determinantal ideal by $I_k(\mathcal{R})$ and call it the characteristic ideal of $\mathcal{R}$. (Note that if $l < k$, then $I_k(\mathcal{R}) = 0$.) The affine variety of this ideal in $\mathbb{C}^n$, $\mathcal{V}(I_k(\mathcal{R}))$, is called the characteristic variety of $\mathcal{R}$ (i.e., considering the elements of $\mathcal{A}$ as polynomials). Let $\Im\mathcal{V}(I_k(\mathcal{R}))$ denote the set of purely imaginary points on $\mathcal{V}(I_k(\mathcal{R}))$, i.e., $\Im\mathcal{V}(I_k(\mathcal{R})) = \mathcal{V}(I_k(\mathcal{R})) \cap \imath\mathbb{R}^n$.

Theorem 2.1. (i) *Every submodule $\mathcal{R}$ of $\mathcal{A}^k$ is Willems with respect to $\mathcal{D}'$ or $\mathcal{C}^\infty$.*

(ii) *Let $\mathcal{R} = \bigcap_{i=1}^t \mathcal{Q}_i$ be an irredundant primary decomposition of $\mathcal{R}$ in $\mathcal{A}^k$, where $\mathcal{Q}_i$ is $\mathcal{P}_i$-primary. Suppose that the affine varieties in $\mathbb{C}^n$ of $\mathcal{P}_1, \ldots, \mathcal{P}_r$ intersect $\Im\mathcal{V}(I_k(\mathcal{R}))$, and that of the varieties of $\mathcal{P}_{r+1}, \ldots, \mathcal{P}_t$ do not. Then the Willems closure $\mathcal{M}\text{Ker}_{\mathcal{S}'}(\mathcal{R})$ of $\mathcal{R}$ with respect to $\mathcal{S}'$ is $\bigcap_{i=1}^r \mathcal{Q}_i$, so that $\mathcal{R}$ is Willems with respect to $\mathcal{S}'$ if and only if the variety of every $\mathcal{P}_i$ intersects $\Im\mathcal{V}(I_k(\mathcal{R}))$. In other words $\mathcal{R}$ is*

Willems with respect to $\mathcal{S}'$ if and only if the variety of every associated prime of $\mathcal{A}^k/\mathcal{R}$ intersects $\Im\mathcal{V}(I_k(\mathcal{R}))$.

(iii) *Let $\pi : \mathcal{A}^k \to \mathcal{A}^k/\mathcal{R}$ be the canonical projection. Then the Willems closure of $\mathcal{R}$ with respect to $\mathcal{S}$, $\mathcal{E}'$, or $\mathcal{D}$ is $\pi^{-1}(T(\mathcal{A}^k/\mathcal{R}))$, where $T(\mathcal{A}^k/\mathcal{R})$ is the submodule of torsion elements of $\mathcal{A}^k/\mathcal{R}$, so that $\mathcal{R}$ is Willems with respect to $\mathcal{S}$, $\mathcal{E}'$, or $\mathcal{D}$ if and only if $\mathcal{A}^k/\mathcal{R}$ is torsion-free (or equivalently if and only if $\mathcal{R}$ is 0-primary).* □

Remark. (i) The first part of the above result is a consequence of two deep theorems about $\mathcal{D}'$ and $\mathcal{C}^\infty$. Ehrenpreis, Malgrange, and Palamodov prove that these two spaces are injective $\mathcal{A}$-modules, i.e., that $\mathrm{Hom}_{\mathcal{A}}(-, \mathcal{D}')$ and $\mathrm{Hom}_{\mathcal{A}}(-, \mathcal{C}^\infty)$ are exact (contravariant) functors (see Hörmander [3]). Furthermore, Oberst in [4] proves that $\mathcal{D}'$ and $\mathcal{C}^\infty$ are cogenerators, i.e., that $\mathrm{Hom}_{\mathcal{A}}(\mathcal{X}, \mathcal{D}')$ and $\mathrm{Hom}_{\mathcal{A}}(\mathcal{X}, \mathcal{C}^\infty)$ are equal to 0 if and only if the $\mathcal{A}$-module $\mathcal{X}$ is 0. I use these results in the next section.

The following is now immediate from Lemma 2.4.

COROLLARY 2.2. *Let $\mathcal{B}_i$ be any collection of $\mathcal{D}'$ or $\mathcal{C}^\infty$-behaviors. Then $\sum_i \mathcal{M}(\mathcal{B}_i) = \mathcal{M}(\bigcap_i \mathcal{B}_i)$.*

(ii) It is an easy fact that the Willems closure of $\mathcal{R}$ with respect to $\mathcal{S}'$ described above is independent of the primary decomposition of $\mathcal{R}$ in $\mathcal{A}^k$ (see [7]). Below I establish a stronger and more convenient version of this result.

(iii) The Willems closure of a submodule $\mathcal{R}$ of $\mathcal{A}^k$ with respect to $\mathcal{S}$ is thus equal to its Willems closure with respect to $\mathcal{E}'$ or $\mathcal{D}$ [7].

The following result is a strengthening of the second part of the above theorem.

THEOREM 2.2. *Let $\mathcal{R} = \bigcap_{i=1}^t \mathcal{Q}_i$ be an irredundant primary decomposition of the submodule $\mathcal{R}$ in $\mathcal{A}^k$, where $\mathcal{Q}_i$ is $\mathcal{P}_i$-primary. Suppose that the affine varieties in $\mathbb{C}^n$ of $\mathcal{P}_1, \ldots, \mathcal{P}_r$ contain purely imaginary points (i.e., intersect $\imath\mathbb{R}^n$) and that of $\mathcal{P}_{r+1}, \ldots, \mathcal{P}_t$ do not. Then the Willems closure $\mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R})$ of $\mathcal{R}$ with respect to $\mathcal{S}'$ is $\bigcap_{i=1}^r \mathcal{Q}_i$, so that $\mathcal{R}$ is Willems with respect to $\mathcal{S}'$ if and only if the variety of every associated prime of $\mathcal{A}^k/\mathcal{R}$ contains purely imaginary points.*

Proof. I show that if $\mathcal{R} = \bigcap_{i=1}^t \mathcal{Q}_i$ is an irredundant primary decomposition of $\mathcal{R}$ in $\mathcal{A}^k$, where $\mathcal{Q}_i$ is $\mathcal{P}_i$-primary, then $\bigcup_{i=1}^t \mathcal{V}(\mathcal{P}_i)$ is contained in $\mathcal{V}(I_k(\mathcal{R}))$. This theorem now follows from Theorem 2.1(ii) above, as then the purely imaginary points on $\mathcal{V}(\mathcal{P}_i)$ are exactly those that are the intersection of $\mathcal{V}(\mathcal{P}_i)$ with $\Im\mathcal{V}(I_k(\mathcal{R}))$.

Assume first that $\mathcal{R}$ itself is a $\mathcal{P}$-primary submodule of $\mathcal{A}^k$. I need to show that the determinantal ideal $I_k(\mathcal{R})$ is contained in $\mathcal{P}$, so that $\mathcal{V}(\mathcal{P})$ is then contained in $\mathcal{V}(I_k(\mathcal{R}))$. Thus let d in $I_k(\mathcal{R})$ be the determinant of some $k \times k$ matrix, say D, with entries in $\mathcal{A}$, all of whose rows, considered as elements of $\mathcal{A}^k$, are in $\mathcal{R}$—by definition every generator of $I_k(\mathcal{R})$ occurs in this way. Let D' be the matrix adjoint to D, so that $D'D$ is the $k \times k$ diagonal matrix with the diagonal elements each equal to d. But (matrix) multiplying D on the left by any row, i.e., by an element of $\mathcal{A}^k$, is equivalent to taking an $\mathcal{A}$-linear combination of the rows of D. Thus each row of $D'D$ is an element of $\mathcal{R}$ (as each row of D is an element of $\mathcal{R}$). But as these rows are $d \cdot e_i$, $i = 1, \ldots, k$, $e_i = (0, \ldots, 1, \ldots, 0)$—1 in the ith place—it follows that d is in $ann(\mathcal{A}^k/\mathcal{R})$. As $\mathcal{R}$ is $\mathcal{P}$-primary, $\mathcal{P}$ is the radical of $ann(\mathcal{A}^k/\mathcal{R})$, and thus it further follows that d is in $\mathcal{P}$. This shows that $I_k(\mathcal{R})$ is contained in $\mathcal{P}$, so that $\mathcal{V}(\mathcal{P})$ is contained in $\mathcal{V}(I_k(\mathcal{R}))$.

If now $\mathcal{R} = \bigcap_{i=1}^t \mathcal{Q}_i$, where $\mathcal{Q}_i$ is $\mathcal{P}_i$-primary, then $I_k(\mathcal{R})$ is contained in each $I_k(\mathcal{Q}_i)$ and hence, by the above, that it is in fact contained in each $\mathcal{P}_i$ and hence in $\bigcap_{i=1}^t \mathcal{P}_i$. Then again $\bigcup_{i=1}^t \mathcal{V}(\mathcal{P}_i)$ is contained in $\mathcal{V}(I_k(\mathcal{R}))$. This proves the theorem. □

Remark. The above description of the Willems closure of a submodule with respect to the classical spaces can also be described in terms of localization in a uniform manner. Recollect that if U is a multiplicatively closed subset of $\mathcal{A}$, then one can form rings and modules of fractions in the usual way. Thus $U^{-1}\mathcal{A}^k$ is a $U^{-1}\mathcal{A}$ module, and $\phi : \mathcal{A}^k \to U^{-1}\mathcal{A}^k$, mapping x in $\mathcal{A}^k$ to $\frac{x}{1}$, is an $\mathcal{A}$-module morphism. It is an easy fact that if $\mathcal{R}$ is a submodule of $\mathcal{A}^k$, and if $U^{-1}\mathcal{R}$ is its extension in $U^{-1}\mathcal{A}^k$, then its contraction $\phi^{-1}(U^{-1}\mathcal{R})$ is given by $\cup_{u\in U}(\mathcal{R} : u)$. In this language the above results can be described as follows.

(i) If U_1 is the set of units of $\mathcal{A}$, then $U_1^{-1}\mathcal{A}$ is equal to $\mathcal{A}$, the map ϕ above is the identity, and the Willems closure of $\mathcal{R}$ with respect to $\mathcal{D}'$ or $\mathcal{C}^\infty$ equals $\phi^{-1}(U_1^{-1}\mathcal{R})$, which is of course just equal to $\mathcal{R}$.

(ii) Let U_2 be the multiplicatively closed subset of $\mathcal{A}$ consisting of those polynomials whose affine varieties *do not* contain purely imaginary points. Then an easy check shows that $\mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R})$ is equal to $\phi^{-1}(U_2^{-1}\mathcal{R})$.

(iii) Let U_3 be the multiplicatively closed subset of $\mathcal{A}$ consisting of all the nonzero elements. Then the Willems closure of $\mathcal{R}$ with respect to $\mathcal{S}$, $\mathcal{E}'$, or $\mathcal{D}$ is $\phi^{-1}(U_3^{-1}\mathcal{R})$.

The description of the lattice structure of behaviors in the next section is based on the following corollary to the above theorems. This corollary is, as observed above, the differential analogue of the fact that the radical of a finite intersection of ideals is the intersection of the individual radicals.

COROLLARY 2.3. *Let $\mathcal{R}_i, i = 1, \dots, m$, be submodules of $\mathcal{A}^k$, and let $\mathcal{W}$ be any of the classical spaces. Then*

$$\mathcal{M}\mathrm{Ker}_{\mathcal{W}}\left(\bigcap_{i=1}^{m}\mathcal{R}_i\right) = \bigcap_{i=1}^{m}\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i). \tag{3}$$

Thus in a classical space, the Willems closure of a finite intersection equals the intersection of the individual Willems closures.

Proof. By induction it suffices to prove the above when $m = 2$.

(i) In the case when $\mathcal{W}$ is either $\mathcal{D}'$ or $\mathcal{C}^\infty$, the statement is trivial, as then every submodule is Willems. Thus each side of (3) equals $\mathcal{R}_1 \cap \mathcal{R}_2$.

(ii) Because of the inclusion (2) observed earlier, it is sufficient to prove the other inclusion, viz., that $\mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R}_1) \cap \mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R}_2) \subset \mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R}_1 \cap \mathcal{R}_2)$. Thus let $\mathcal{R}_1 = \bigcap_{i=1}^{t_1}\mathcal{Q}_i$ and $\mathcal{R}_2 = \bigcap_{j=1}^{t_2}\mathcal{Q}'_j$ be irredundant primary decompositions of $\mathcal{R}_1$ and $\mathcal{R}_2$ in $\mathcal{A}^k$, where $\mathcal{Q}_i$ and $\mathcal{Q}'_j$ are $\mathcal{P}_i$-primary and $\mathcal{P}'_j$-primary, respectively, $i = 1, \dots, t_1, j = 1, \dots, t_2$. Suppose that the varieties of $\mathcal{P}_1, \dots, \mathcal{P}_{r_1}$ contain purely imaginary points, whereas those of $\mathcal{P}_{r_1+1}, \dots, \mathcal{P}_{t_1}$ do not. Similarly suppose that the varieties of $\mathcal{P}'_1, \dots, \mathcal{P}'_{r_2}$, and not those of $\mathcal{P}'_{r_2+1}, \dots, \mathcal{P}'_{t_2}$, contain purely imaginary points. Then by the above theorem

$$\mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R}_1) \cap \mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R}_2) = \left(\bigcap_{i=1}^{r_1}\mathcal{Q}_i\right) \cap \left(\bigcap_{j=1}^{r_2}\mathcal{Q}'_j\right).$$

On the other hand $(\bigcap_{i=1}^{t_1}\mathcal{Q}_i) \cap (\bigcap_{j=1}^{t_2}\mathcal{Q}'_j)$ is a primary decomposition of $\mathcal{R}_1 \cap \mathcal{R}_2$ in $\mathcal{A}^k$, though perhaps not irredundant. An irredundant primary decomposition can, however, be obtained from it by omitting (if necessary) some of the $\mathcal{Q}_i$ or $\mathcal{Q}'_j$. Thus the set of associated primes of $\mathcal{R}_1 \cap \mathcal{R}_2$ is a subset of $\{\mathcal{P}_1, \dots, \mathcal{P}_{t_1}, \mathcal{P}'_1, \dots, \mathcal{P}'_{t_2}\}$. This implies that those associated primes of $\mathcal{R}_1 \cap \mathcal{R}_2$ whose varieties contain purely imaginary points are a subset of $\{\mathcal{P}_1, \dots, \mathcal{P}_{r_1},\ P'_1, \dots, \mathcal{P}'_{r_2}\}$. Clearly then this implies (by the above theorem) that $\mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R}_1) \cap \mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R}_2) \subset \mathcal{M}\mathrm{Ker}_{\mathcal{S}'}(\mathcal{R}_1 \cap \mathcal{R}_2)$, and thus that (3) holds when $\mathcal{W}$ is $\mathcal{S}'$.

(iii) Suppose $\mathcal{W}$ is $\mathcal{S}$, $\mathcal{E}'$, or $\mathcal{D}$. Then the Willems closure of $\mathcal{R}_1 \cap \mathcal{R}_2$ (with respect to such a $\mathcal{W}$) is by the above theorem $\pi^{-1}(T(\mathcal{A}^k/\mathcal{R}_1 \cap \mathcal{R}_2))$, where $\pi : \mathcal{A}^k \to \mathcal{A}^k/\mathcal{R}_1 \cap \mathcal{R}_2$ is the canonical projection. But an element x in $\mathcal{A}^k$ such that ax is in $\mathcal{R}_1 \cap \mathcal{R}_2$, for some nonzero a in $\mathcal{A}$, implies that the residue class of x in $\mathcal{A}^k/\mathcal{R}_1$ and in $\mathcal{A}^k/\mathcal{R}_2$ is a torsion element of $\mathcal{A}^k/\mathcal{R}_1$ and $\mathcal{A}^k/\mathcal{R}_2$, respectively. Conversely, let x be an element of $\mathcal{A}^k$ whose residue class in $\mathcal{A}^k/\mathcal{R}_1$ and in $\mathcal{A}^k/\mathcal{R}_2$ is a torsion element of $\mathcal{A}^k/\mathcal{R}_1$ and $\mathcal{A}^k/\mathcal{R}_2$, respectively. So let a_1x and a_2x (a_1 and a_2 nonzero) belong to $\mathcal{R}_1$ and $\mathcal{R}_2$, respectively. This implies that a_1a_2x belongs to $\mathcal{R}_1 \cap \mathcal{R}_2$. As $\mathcal{A}$ is an integral domain, a_1a_2 is nonzero, so that the residue class of x in $\mathcal{A}^k/\mathcal{R}_1 \cap \mathcal{R}_2$ is a torsion element. Thus when $\mathcal{W}$ is $\mathcal{S}$, $\mathcal{E}'$, or $\mathcal{D}$, it again follows that $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1 \cap \mathcal{R}_2) = \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1) \cap \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2)$, so that (3) holds for these classical spaces as well. □

These results permit the description of the lattice structure of behaviors in the classical spaces in the next section. The calculus of behaviors is further developed in [11].

Remark. In view of the fact that inclusion (2) holds for any $\mathcal{A}$-submodule $\mathcal{W}$ of $\mathcal{D}'$, it is tempting to conjecture that the reverse inclusion (for finite intersections because of Pathology 1), and hence equality (3), also holds for any $\mathcal{W}$. It is not clear to me how to even proceed to prove this general statement. The proof of (3) for the classical spaces depends upon the description of the Willems closures of modules, a description that is not available for a general $\mathcal{W}$. Relevant here is the following warning. As observed earlier, the concept of a Willems closure is the generalization to analysis of the algebraic notion of the radical of an ideal (via the Hilbert Nullstellensatz). The proof of the algebraic fact corresponding to (3), viz., that the radical of a finite intersection equals the intersection of the individual radicals, also depends upon a concrete description of a radical ideal.

3. The structure of behaviors. The starting point of this paper, as explained in the introduction, is the elementary observation that the set $\mathbf{L}$ of all submodules of $\mathcal{A}^k$, partially ordered by inclusion, is a complete modular lattice under the operations of module sum and intersection. Recollect (from Birkhoff [1]) that to say $\mathbf{L}$ is a complete lattice is to say that any collection $\{\mathcal{R}_i\}$, not necessarily finite, of submodules of $\mathcal{A}^k$ has a least upper bound (l.u.b.), or join, given by $\sum_i \mathcal{R}_i$, and a greatest lower bound (g.l.b.) or meet given by $\bigcap_i \mathcal{R}_i$, and to say $\mathbf{L}$ is modular is to say that if $\mathcal{R}_2 \subset \mathcal{R}_1$, then $\mathcal{R}_1 \cap (\mathcal{R}_2 + \mathcal{R}_3) = \mathcal{R}_2 + (\mathcal{R}_1 \cap \mathcal{R}_3)$ for any submodule $\mathcal{R}_3$. Recollect also that $\mathbf{L}$ is not, however, a distributive lattice; standard examples show that $\mathcal{R}_1 \cap (\mathcal{R}_2 + \mathcal{R}_3)$ is *not* always equal to $(\mathcal{R}_1 \cap \mathcal{R}_2) + (\mathcal{R}_1 \cap \mathcal{R}_3)$.

Now let $\mathcal{W}$ be any $\mathcal{A}$-submodule of $\mathcal{D}'$. Each fact noted above about the set $\mathbf{L}$ is of course also true about the set $\mathbf{W}$ of all $\mathcal{A}$-submodules of $\mathcal{W}^k$. Thus $\mathbf{W}$, partially ordered by inclusion, is also a complete modular lattice. Consider now the contravariant functor $\mathrm{Ker}_{\mathcal{W}}$ described in the previous section. Let $\mathbf{B}(\mathcal{W}) = \{\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}) \mid \mathcal{R} \in \mathbf{L}\}$ be the set of all behaviors in $\mathcal{W}^k$, also partially ordered by inclusion. I claim that this partially ordered set is also, trivially, a lattice. For suppose that $\{\mathcal{B}_i\}$ is any collection of elements in $\mathbf{B}(\mathcal{W})$. Then its g.l.b. is $\bigcap_i \mathcal{B}_i$ (this intersection is a behavior by Lemma 2.1(i)). This collection also has an l.u.b.; in fact let $\{\mathcal{B}_\alpha\}$ be the collection of all behaviors that contain every $\mathcal{B}_i$—this collection is clearly nonempty as it contains the behavior $\mathcal{W}^k$. Then $\bigcap_\alpha \mathcal{B}_\alpha$ is a behavior (again by Lemma 2.1(i)) which is clearly the smallest behavior that contains every $\mathcal{B}_i$ and is therefore its l.u.b.

Thus there are three lattices in picture here, viz., $\mathbf{L}$, $\mathbf{W}$, and its subset $\mathbf{B}(\mathcal{W})$, and the question arises as to what is the relationship between them. I show below that if $\mathcal{W}$ is a classical space, then $\mathbf{B}(\mathcal{W})$ is anti-isomorphic to a homomorphic image of $\mathbf{L}$ (anti-isomorphic means that the map between these lattices is inclusion reversing, so that g.l.b.'s go to l.u.b.'s and vice versa). This implies then that $\mathbf{B}(\mathcal{W})$ is modular. Furthermore, if $\mathcal{W}$ is $\mathcal{D}'$, $\mathcal{C}^\infty$, or $\mathcal{S}'$, then $\mathbf{B}(\mathcal{W})$ is a sublattice of $\mathbf{W}$. These are the central results of this paper.

PROPOSITION 3.1. *Let $\mathcal{W}$ be a classical space and let $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i), i = 1,\dots,m$, be any finite set of behaviors in $\mathcal{W}^k$. Then $\mathrm{Ker}_{\mathcal{W}}(\sum_{i=1}^m \mathcal{R}_i)$ is the largest $\mathcal{W}$-behavior contained in every $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$, and $\mathrm{Ker}_{\mathcal{W}}(\bigcap_{i=1}^m \mathcal{R}_i)$ is the smallest $\mathcal{W}$-behavior containing every $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$.*

Proof. The first part of the statement follows from Lemma 2.1(i). For the second part, suppose $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ contains $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i), i = 1,\dots,m$. Then $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ is contained in each $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$, and hence in $\bigcap_{i=1}^m \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$. But this intersection is by Corollary 2.3 (i.e., by (3)) equal to $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\bigcap_{i=1}^m \mathcal{R}_i)$ (as $\mathcal{W}$ is by assumption a classical space). It now follows that

$$\mathrm{Ker}_{\mathcal{W}}\left(\bigcap_{i=1}^m \mathcal{R}_i\right) = \mathrm{Ker}_{\mathcal{W}}\mathcal{M}\mathrm{Ker}_{\mathcal{W}}\left(\bigcap_{i=1}^m \mathcal{R}_i\right) \subset \mathrm{Ker}_{\mathcal{W}}\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}).$$

As clearly $\mathrm{Ker}_{\mathcal{W}}(\bigcap_{i=1}^m \mathcal{R}_i)$ contains every $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$, it follows that it is in fact the smallest behavior containing every $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$. □

The converse is also true, viz., the following.

PROPOSITION 3.2. *Suppose that $\mathrm{Ker}_{\mathcal{W}}(\bigcap_{i=1}^m \mathcal{R}_i)$ is the smallest $\mathcal{W}$-behavior containing every $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$. Then (3) holds.*

Proof. Suppose that $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ contains every $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$. Then by assumption $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ contains $\mathrm{Ker}_{\mathcal{W}}(\bigcap_{i=1}^m \mathcal{R}_i)$. In other words, if $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ is contained in $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$ for each i, then $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ is contained in $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\bigcap_{i=1}^m \mathcal{R}_i)$. Hence as $\bigcap_{i=1}^m \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$ is contained in $\mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i)$ for each i, it follows that

$$\bigcap_{i=1}^m \mathcal{M}\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i) \subset \mathcal{M}\mathrm{Ker}_{\mathcal{W}}\left(\bigcap_{i=1}^m \mathcal{R}_i\right),$$

which together with (2) implies (3). □

In essence what Proposition 3.1 establishes (via Corollary 2.3) is that if $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R})$ contains $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i), i = 1,\dots,m$, then it also contains $\mathrm{Ker}_{\mathcal{W}}(\bigcap_{i=1}^m \mathcal{R}_i)$. This statement is not true if i ranges over an infinite set for the same reasons that in this case Corollary 2.3 does not hold.

Pathology 2. Consider again the situation of Pathology 1. Let $\mathcal{R} = \mathcal{I}$ be any nonzero proper ideal of $\mathbb{C}[\frac{d}{dt}]$, and let $\mathcal{R}_i = \mathcal{I}^i, i \geq 1$. Then $\mathrm{Ker}_{\mathcal{D}}(\mathcal{R}) = \mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_i) = 0$, whereas $\mathrm{Ker}_{\mathcal{D}}(\bigcap_i \mathcal{R}_i) = \mathrm{Ker}_{\mathcal{D}}(0) = \mathcal{D}$. □

By Proposition 3.1 it follows that the lattice structure of $\mathbf{B}(\mathcal{W})$ described in the beginning of this section is in fact given by defining the g.l.b. of any finite set of behaviors $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i), i = 1,\dots,m$, to be $\mathrm{Ker}_{\mathcal{W}}(\sum_{i=1}^m \mathcal{R}_i)$ and its l.u.b. to be $\mathrm{Ker}_{\mathcal{W}}(\bigcap_{i=1}^m \mathcal{R}_i)$. This lattice structure is inherited from the lattice structure of $\mathbf{L}$ in the following manner. Consider the equivalence relation $\sim$ on $\mathbf{L}$ given by

$$\mathcal{R} \sim \mathcal{R}' \quad \text{if} \quad \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}').$$

In other words, $\mathcal{R}$ is equivalent to $\mathcal{R}'$ if their Willems closures in $\mathcal{W}$ are equal. Then if $\mathcal{R}_1 \sim \mathcal{R}_1'$ and $\mathcal{R}_2 \sim \mathcal{R}_2'$, it follows (by Lemma 2.1) that $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1+\mathcal{R}_2) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1)\cap$

$\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}'_1) \cap \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}'_2) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}'_1 + \mathcal{R}'_2)$, and thus that $\mathcal{R}_1 + \mathcal{R}_2 \sim \mathcal{R}'_1 + \mathcal{R}'_2$. It also follows that $\mathcal{R}_1 \cap \mathcal{R}_2 \sim \mathcal{R}'_1 \cap \mathcal{R}'_2$, that is, that $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1 \cap \mathcal{R}_2) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}'_1 \cap \mathcal{R}'_2)$, for these two behaviors are, by the above proposition, the l.u.b.'s of $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1) + \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2)$ and $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}'_1) + \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}'_2)$, respectively, and these two sums are equal by assumption. Thus $\sim$ is a congruence relation on $\mathbf{L}$, and quotienting $\mathbf{L}$ by it gives a lattice homomorphic to $\mathbf{L}$. One therefore obtains the following theorem.

THEOREM 3.1. *Let $\mathcal{W}$ be a classical space. Then $\mathbf{B}(\mathcal{W})$, the lattice of all behaviors in $\mathcal{W}^k$, is anti-isomorphic to a homomorphic image of the lattice $\mathbf{L}$ of all submodules of $\mathcal{A}^k$. It follows therefore that $\mathbf{B}(\mathcal{W})$ is a modular lattice.*

Proof. It only remains to observe that a homomorphic image of a modular lattice is itself modular [1, Ex. 5, p. 66]). □

On the other hand, as observed earlier, the set $\mathbf{W}$ of all $\mathcal{A}$-submodules of $\mathcal{W}^k$, partially ordered by inclusion, is a complete modular lattice. The lattice $\mathbf{B}(\mathcal{W})$ of all behaviors in $\mathcal{W}^k$ is a subset of $\mathbf{W}$, and the question then arises as to whether $\mathbf{B}(\mathcal{W})$ is a sublattice of $\mathbf{W}$. This will indeed be so if the sum of two behaviors (and hence of a finite number of behaviors) is not just an $\mathcal{A}$-submodule of $\mathcal{W}^k$, but is itself a behavior—the intersection of behaviors is of course always a behavior (Lemma 2.1(i)). As $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1 \cap \mathcal{R}_2)$ is the smallest $\mathcal{W}$-behavior containing $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1) + \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2)$ (by Proposition 3.1), the question therefore reduces to whether $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1) + \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2)$ equals $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1 \cap \mathcal{R}_2)$. More generally, when is the inclusion in Lemma 2.1(ii) an equality?

Pathology 3. Consider once more the situation of Pathologies 1 and 2; i.e., let $\mathcal{A} = \mathbb{C}[\frac{d}{dt}]$. Let $\mathcal{R}_1$ and $\mathcal{R}_2$ be cyclic submodules of $\mathcal{A}^2$ generated by $(1, 0)$ and $(1, -\frac{d}{dt})$, respectively. Then $\mathcal{R}_1 \cap \mathcal{R}_2$ is the 0 submodule, so that $\mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_1 \cap \mathcal{R}_2)$ is all of $\mathcal{D}^2$. On the other hand, $\mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_1) = \{(0, f) \mid f \in \mathcal{D}\}$ and $\mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_2) = \{(\frac{dg}{dt}, g) \mid g \in \mathcal{D}\}$. Thus an element (u, v) in $\mathcal{D}^2$ is in $\mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_1) + \mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_2)$ only if $u = \frac{dg}{dt}, v = f + g$, where f and g are arbitrary elements in $\mathcal{D}$. Let now u be any (nonzero) *nonnegative* compactly supported smooth function. Then $(u, 0)$, which is in $\mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_1 \cap \mathcal{R}_2)$, is, however, not in $\mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_1) + \mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_2)$, as $g(t) = \int_{-\infty}^{t} dg = \int_{-\infty}^{t} u dt$ is not compactly supported.

Hence $\mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_1) + \mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_2)$ can be strictly contained in $\mathrm{Ker}_{\mathcal{D}}(\mathcal{R}_1 \cap \mathcal{R}_2)$, and thus the lattice structure of $\mathbf{B}(\mathcal{D})$ described by the theorem above does not make it a sublattice of the lattice of all $\mathbb{C}[\frac{d}{dt}]$-submodules of $\mathcal{D}^2$. □

The situation is, however, different if $\mathcal{W}$ is $\mathcal{D}'$, $\mathcal{C}^\infty$, or $\mathcal{S}'$.

THEOREM 3.2. *Let $\mathcal{A} = K[\partial_1, \ldots, \partial_n]$, $K = \mathbb{R}$ or $\mathbb{C}$, and let $\mathcal{R}_1$ and $\mathcal{R}_2$ be submodules of $\mathcal{A}^k$. Then $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1) + \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1 \cap \mathcal{R}_2)$ if $\mathcal{W}$ is an injective $\mathcal{A}$-module.*

Proof. Because of Lemma 2.1(ii), it suffices to prove that $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1 \cap \mathcal{R}_2) \subset \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1) + \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2)$. Thus given an element f in $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1 \cap \mathcal{R}_2)$, one needs to show that it can be written as $f_1 + f_2$, f_i in $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_i), i = 1, 2$, when $\mathcal{W}$ is an injective $\mathcal{A}$-module.

Recollect from the previous section the isomorphism of Malgrange, viz., that $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}) \simeq \mathrm{Hom}_{\mathcal{A}}(\mathcal{A}^k/\mathcal{R}, \mathcal{W})$ for any submodule $\mathcal{R}$ of $\mathcal{A}^k$. Thus given an element f in $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1 \cap \mathcal{R}_2)$, consider it as an $\mathcal{A}$-module morphism

$$f : \mathcal{A}^k/\mathcal{R}_1 \cap \mathcal{R}_2 \longrightarrow \mathcal{W}.$$

Define

$$\begin{array}{cccccc} g: & \mathcal{R}_1 & + & \mathcal{R}_2 & \longrightarrow & \mathcal{W}, \\ & x_1 & + & x_2 & \mapsto & g(x_1 + x_2) = f([x_2]), \end{array}$$

where $[x_2]$ is the residue class of x_2 in $\mathcal{A}^k/\mathcal{R}_1\cap\mathcal{R}_2$. This morphism g is well defined, for if $x_1+x_2 = x_1'+x_2'$ (x_i, x_i' in $\mathcal{R}_i$), then $x_1-x_1' = x_2'-x_2$ is in $\mathcal{R}_1\cap\mathcal{R}_2$. This implies that $f([x_2'-x_2]) = 0$, i.e., that $f([x_2]) = f([x_2'])$, and hence that $g(x_1+x_2) = g(x_1'+x_2')$. By definition, g restricted to $\mathcal{R}_1$ is the zero morphism, and so it induces a morphism

$$h : (\mathcal{R}_1 + \mathcal{R}_2)/\mathcal{R}_1 \longrightarrow \mathcal{W}.$$

Let $\pi : (\mathcal{R}_1+\mathcal{R}_2)/\mathcal{R}_1\cap\mathcal{R}_2 \to (\mathcal{R}_1+\mathcal{R}_2)/\mathcal{R}_1$ be the canonical projection. Let h_1 be the morphism obtained by composing π with h, i.e., let

$$h_1 = h\circ\pi : (\mathcal{R}_1+\mathcal{R}_2)/\mathcal{R}_1\cap\mathcal{R}_2 \longrightarrow \mathcal{W}.$$

Now $(\mathcal{R}_1+\mathcal{R}_2/\mathcal{R}_1)$ is canonically isomorphic to $\mathcal{R}_2/\mathcal{R}_1\cap\mathcal{R}_2$, a submodule of $(\mathcal{R}_1+\mathcal{R}_2)/\mathcal{R}_1\cap\mathcal{R}_2$. By construction h_1 is equal to f on this submodule and equal to the zero morphism on the submodule $\mathcal{R}_1/\mathcal{R}_1\cap\mathcal{R}_2$. As $\mathcal{W}$ is an injective $\mathcal{A}$-module (by assumption), there exists a morphism $f_1 : \mathcal{A}^k/\mathcal{R}_1\cap\mathcal{R}_2 \to \mathcal{W}$ so that the following diagram commutes:

$$\begin{tikzcd}
0 \arrow[r] & (\mathcal{R}_1+\mathcal{R}_2)/\mathcal{R}_1\cap\mathcal{R}_2 \arrow[r] \arrow[d, "h_1"'] & \mathcal{A}^k/\mathcal{R}_1\cap\mathcal{R}_2 \arrow[dl, "f_1"] \\
 & \mathcal{W} &
\end{tikzcd}.$$

As f_1 restricts to the zero morphism on $\mathcal{R}_1/\mathcal{R}_1\cap\mathcal{R}_2$, one can consider f_1 as an element in $\mathrm{Hom}_{\mathcal{A}}(\mathcal{A}^k/\mathcal{R}_1, \mathcal{W})$, i.e., f_1 is in the behavior $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1)$.

Next consider the morphism $f_2 = f - f_1 : \mathcal{A}^k/\mathcal{R}_1\cap\mathcal{R}_2 \to \mathcal{W}$. As f_1 equals f on $\mathcal{R}_2/\mathcal{R}_1\cap\mathcal{R}_2$, f_2 is identically zero on this submodule and can therefore be considered as an element in $\mathrm{Hom}_{\mathcal{A}}(\mathcal{A}^k/\mathcal{R}_2, \mathcal{W})$, i.e., in $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2)$.

Thus $\mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1\cap\mathcal{R}_2) = \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_1) + \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}_2)$. □

COROLLARY 3.1. *Let $\mathcal{W}$ be $\mathcal{D}'$, $\mathcal{C}^\infty$, or $\mathcal{S}'$. Then $\mathbf{B}(\mathcal{W})$, the lattice of all behaviors in $\mathcal{W}^k$, is a sublattice of $\mathbf{W}$, the lattice of all $\mathcal{A}$-submodules of $\mathcal{W}^k$.*

Proof. By the theorem of Ehrenpreis–Malgrange–Palamodov (Remark (i) following Theorem 2.1), $\mathcal{D}'$ and $\mathcal{C}^\infty$ are injective $\mathcal{A}$-modules. It is a result in [9] that $\mathcal{S}'$ is also an injective $\mathcal{A}$-module. □

COROLLARY 3.2. *The lattice $\mathbf{W}$, when $\mathcal{W}$ is either $\mathcal{D}'$ or $\mathcal{C}^\infty$, contains a sublattice anti-isomorphic to $\mathbf{L}$.*

Proof. Consider the map

$$\begin{array}{cccc} \phi : & \mathbf{L} & \longrightarrow & \mathbf{W}, \\ & \mathcal{R} & \mapsto & \mathrm{Ker}_{\mathcal{W}}(\mathcal{R}), \end{array}$$

where $\mathcal{W}$ is either $\mathcal{D}'$ or $\mathcal{C}^\infty$. By Oberst (again Remark (i) following Theorem 2.1), these two $\mathcal{A}$-modules are cogenerators, hence ϕ is an injective map. The corollary now follows from Theorem 3.1 and Corollary 3.1 above. □

While $\mathbf{W}$ is a complete lattice (i.e., arbitrary collections of elements in $\mathbf{W}$ have l.u.b.'s and g.l.b.'s), the lattices $\mathbf{B}(\mathcal{D}')$ and $\mathbf{B}(\mathcal{C}^\infty)$ (which are also complete) are, however, not complete as sublattices of $\mathbf{W}$ as the following pathology demonstrates. Thus the map ϕ in the proof of the above corollary is not a morphism of *complete* lattices.

Pathology 4. Let $\mathcal{A} = \mathbb{C}[\frac{d}{dt}]$, $\mathcal{I} = (\frac{d}{dt})$, and $\mathcal{R}_i = \mathcal{I}^i, i \geq 0$. Consider the collection of $\mathcal{C}^\infty$-behaviors $\{\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_i)\}$. As elements of $\mathbf{W}$, i.e., as $\mathbb{C}[\frac{d}{dt}]$-submodules of $\mathcal{C}^\infty$, this collection has an l.u.b., viz., $\sum_i \mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_i)$. I claim, however, that $\sum_i \mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_i)$

is not a behavior, so that $\sum_i \mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_i)$ is not the l.u.b. of $\{\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_i)\}$ in $\mathbf{B}(\mathcal{C}^\infty)$. For suppose that this sum is a behavior, say, equal to $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$. Then as every submodule now is Willems (Theorem 2.1(i)), it follows that

$$\mathcal{R} = \mathcal{M}\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}) = \mathcal{M}\left(\sum_i \mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_i)\right) = \bigcap_i \mathcal{M}\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_i) = \bigcap_i \mathcal{R}_i,$$

where the third equality follows from Lemma 2.1(iii). But as before, by Krull's theorem, $\bigcap_i \mathcal{R}_i = 0$, so that $\sum_i \mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_i)$ must equal all of $\mathcal{C}^\infty$. This is of course absurd since $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_i)$ equals the $\mathbb{C}$-vector space of polynomials of degree less than i, and which therefore implies that the above sum of behaviors is only the vector space of all polynomials. This shows that $\mathbf{B}(\mathcal{C}^\infty)$ is not complete as a sublattice of $\mathbf{W}$. □

In the next section I study how this structure is inherited by the class of stable behaviors.

4. The structure of stable behaviors. I consider now, in the context of the lattice structure developed in the previous section, an important subclass of (smooth) behaviors, viz., the stable ones. Indeed, the fundamental problem in control theory is to stabilize an a priori unstable mechanism using a controller. The notion of stability that I consider here is a generalization of BIBO stability of lumped systems introduced in [5] and [8], where the growth of the elements in a behavior is specified along certain directions. For the sake of completeness, I quickly review this notion below.

DEFINITION. *The directions of stability is a proper closed convex cone C in $\mathbb{R}^n$ (with vertex at the origin). A $\mathcal{C}^\infty$-behavior is said to be stable with respect to C if every element in it tends to* 0 *along every half line in C.*

Given the cone C of stable directions, define the subset $C_<$ of $\mathbb{R}^n$ as consisting of those points x in $\mathbb{R}^n$ such that $\langle x, y\rangle < 0$ for every nonzero y in C. As the cone C is proper, i.e., as it does not contain a full line, $C_<$ is nonempty and in fact has nonempty interior.

The stability of a behavior is determined by its characteristic variety $\mathcal{V}(I_k(\mathcal{R}))$ (defined above Theorem 2.1), The reason for this is the following. If $R(\partial)$ is any matrix representing $\mathcal{R}$ (as in (1)), then let $R(x)$ be the matrix obtained by replacing the entries of $R(\partial)$ by corresponding polynomials (in the n indeterminates $x_1, \dots, x_n$). Substituting for x any point ξ in $\mathcal{V}(I_k(\mathcal{R}))$ results in a matrix $R(\xi)$ with entries in $\mathbb{C}$ whose column rank is less than k. This implies that there is a nonzero element, say, $c = (c_1, \dots, c_k)$ in $\mathbb{C}^k$, which is in the kernel of the linear map determined by $R(\xi)$. An easy check now shows that then $(c_1 e^{\langle x,\xi\rangle}, \dots, c_k e^{\langle x,\xi\rangle})$ is in the $\mathcal{C}^\infty$-behavior of $\mathcal{R}$. (Here $\langle x, \xi\rangle = \sum_{i=1}^n x_i \xi_i$.) Thus there are such exponential elements in the behavior corresponding to every point in $\mathcal{V}(I_k(\mathcal{R}))$.

Conversely, suppose that $w = (c_1 e^{\langle x,\xi\rangle}, \dots, c_k e^{\langle x,\xi\rangle})$ is in the $\mathcal{C}^\infty$-behavior of $\mathcal{R}$ or equivalently in the kernel of the morphism given by the matrix $R(\partial)$ of (1). As in the proof of Theorem 2.2, let $D(\partial)$ be any $k \times k$ submatrix of $R(\partial)$, so that the w above is also in the behavior of the submodule generated by the rows of $D(\partial)$. Let $d(\partial)$ be the determinant of $D(\partial)$. This $d(\partial)$ is in $I_k(\mathcal{R})$; in fact $I_k(\mathcal{R})$ is generated by such $d(\partial)$. Multiplying $D(\partial)$ on the left by its adjoint $D'(\partial)$ results in a diagonal matrix all of whose entries are $d(\partial)$. It now follows that every component of w is a homogeneous solution of $d(\partial)$. But it is an easy check that $e^{\langle x,\xi\rangle}$ is a homogeneous solution of $d(\partial)$ if and only if ξ lies in the variety of d (now considered as a polynomial). As this is true for every generator of $I_k(\mathcal{R})$, it follows that ξ must lie in $\mathcal{V}(I_k(\mathcal{R}))$. More generally, call an element $(p_1(x)e^{\langle x,\xi\rangle}, \dots, p_k(x)e^{\langle x,\xi\rangle})$ in a behavior, where $p_1, \dots, p_k$

are polynomials, an *exponential element.* Just as above, these exponential elements in $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$ arise from exactly all the points of $\mathcal{V}(I_k(\mathcal{R}))$. It is a theorem of Ehrenpreis, Malgrange, and Palamodov that the closed linear hull of such exponential elements in the $\mathcal{C}^\infty$-behavior of a submodule equals its entire $\mathcal{C}^\infty$-behavior (viz., Theorem 7.6.14 in Hörmander [3]). This enables one to reduce the study of the stability of a behavior to algebraic criteria.

I quote from [5] and [8] a result on stable behaviors that I need at the very end of this section. I use in it, and further below, the following terminology from [3]. Given a subset X of $\mathbb{R}^n$, the *tube* over X is the set of points z in $\mathbb{C}^n$ such that $\Re z$, the real part of z, is in X.

THEOREM 4.1. *If the $\mathcal{C}^\infty$-behavior of a submodule $\mathcal{R}$ is stable with respect to C, then the characteristic variety $\mathcal{V}(I_k(\mathcal{R}))$ is contained in the tube over $C_<$. On the other hand, suppose that the characteristic ideal $I_k(\mathcal{R})$ of $\mathcal{R}$ contains a polynomial without multiple factors (for instance, if this ideal were a radical ideal). Then if $\mathcal{V}(I_k(\mathcal{R}))$ is contained in the tube over $C_<$ and if its distance from the boundary of this tube is strictly positive, then* $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$ *is stable with respect to $C_<$.*

DEFINITION. *A behavior* $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$ *is said to be stabilizable with respect to the cone C if it contains a nontrivial sub-behavior stable with respect to C.*

Restricting such a behavior to a stable sub-behavior is the process of *control.* Suppose that $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}')$ is a sub-behavior of $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$ stable with respect to C. As every submodule of $\mathcal{A}^k$ is Willems with respect to $\mathcal{C}^\infty$, it follows that $\mathcal{R} \subset \mathcal{R}'$. Let $\mathcal{R}_1$ be any submodule of $\mathcal{A}^k$ such that $\mathcal{R} + \mathcal{R}_1 = \mathcal{R}'$. Then as $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}') = \mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}) \cap \mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_1)$ is stable with respect to C (by supposition), the behavior $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_1)$ is said to be a stabilizing controller. If $\mathcal{R}$ and $\mathcal{R}_1$ are represented by matrices $R(\partial)$ and $R_1(\partial)$ (as in (1)), then the above process amounts to appending the rows of $R_1(\partial)$ to the rows of $R(\partial)$. This formulation of control, which does not require any notions of inputs and outputs, is one of Willems' fundamental contributions.

THEOREM 4.2. *A behavior* $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$ *is stabilizable with respect to the cone C if and only if $\mathcal{V}(I_k(\mathcal{R}))$, the characteristic variety of $\mathcal{R}$, intersects the tube over $C_<$.*

Proof. Suppose that $\mathcal{V}(I_k(\mathcal{R}))$ does not intersect the tube over $C_<$. Then any exponential element in $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$, corresponding to some point $\mathcal{V}(I_k(\mathcal{R}))$, will not tend to 0 along some half line in C. As $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$, as also every nontrivial sub-behavior of it, is a closed linear hull of such exponentials (Theorem 7.6.14 in [3]), it follows that $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$ is not stabilizable with respect to C.

Conversely suppose that $\mathcal{V}(I_k(\mathcal{R}))$ intersects the tube over $C_<$. Let ξ be some point in this intersection. Then the element $w = (c_1 e^{\langle x,\xi\rangle}, \dots, c_k e^{\langle x,\xi\rangle}), c_1, \dots, c_k$ arbitrary, is in the behavior of the submodule $\mathcal{R}_1$ of $\mathcal{A}^k$ generated by the rows of

$$R_1(\partial) = \begin{pmatrix} \partial_1 - \xi_1 & 0 & \dots & 0 \\ \partial_2 - \xi_2 & 0 & \dots & 0 \\ . & . & \dots & . \\ \partial_n - \xi_n & 0 & \dots & 0 \\ 0 & \partial_1 - \xi_1 & \dots & 0 \\ . & . & \dots & . \\ 0 & \partial_n - \xi_n & \dots & 0 \\ . & . & \dots & . \\ . & . & \dots & . \\ 0 & 0 & \dots & \partial_1 - \xi_1 \\ . & . & \dots & . \\ 0 & 0 & \dots & \partial_n - \xi_n \end{pmatrix}.$$

In fact every exponential solution of this behavior is of the above form. However, as observed earlier, there is a choice of the $c_1, \ldots, c_k$ such that the corresponding exponential element w, as above, is also in $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$. Indeed, these are the only kind of exponential elements that are in $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}) \cap \mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_1)$. As such exponentials tend to 0 uniformly along every half line in C, it follows, once again by Theorem 7.6.14 in [3], that $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$ is stabilizable with respect to C, and that $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_1)$ is a stabilizing controller. $\square$

Recollect from [1] the definitions of an ideal in a lattice and that of a meet homomorphism. An ideal in a lattice is a subset such that (i) the l.u.b. of any two elements of the subset is in it, and (ii) the g.l.b. of an element in the subset and any element in the lattice is also in the subset. A meet homomorphism between two lattices is an order preserving map such that the image of the g.l.b. of any two elements equals the g.l.b. of the images of the two elements.

THEOREM 4.3. *The set of $\mathcal{C}^\infty$-behaviors, stable with respect to a cone C, is an ideal in the lattice of all behaviors. Given a stabilizable behavior, the set of its stabilizing controllers is the inverse image of this ideal under a meet homomorphism.*

Proof. Let $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_1)$ and $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R}_2)$ be two behaviors stable with respect to C. Then by Theorem 3.2, the l.u.b. of these two behaviors is their sum, which is clearly also stable with respect to C. Moreover, if $\mathrm{Ker}_{\mathcal{C}^\infty}(\mathcal{R})$ is any behavior, the g.l.b. of this behavior and a stable behavior, being a sub-behavior of both, is also stable. This shows that this set of behaviors, stable with respect to C, is an ideal, say $\mathcal{J}$ of $\mathbf{B}(\mathcal{C}^\infty)$.

Let $\mathcal{B}_0$ be a stabilizable behavior. Consider the following map from the lattice of $\mathcal{C}^\infty$-behaviors to itself:

$$\begin{array}{rccc} \phi: & \mathbf{B}(\mathcal{C}^\infty) & \longrightarrow & \mathbf{B}(\mathcal{C}^\infty), \\ & \mathcal{B} & \mapsto & \mathcal{B} \cap \mathcal{B}_0. \end{array}$$

This map is clearly order preserving. As $\phi(\mathcal{B}_1 \cap \mathcal{B}_2) = (\mathcal{B}_1 \cap \mathcal{B}_2) \cap \mathcal{B}_0 = \phi(\mathcal{B}_1) \cap \phi(\mathcal{B}_2)$, it is a meet homomorphism. The set of behaviors that stabilize $\mathcal{B}_0$ are those that are mapped by ϕ into the ideal $\mathcal{J}$ of stable behaviors, i.e., $\phi^{-1}(\mathcal{J})$. $\square$

I conclude with a curious geometric consequence of the above results.

COROLLARY 4.1. *Let $\mathcal{R}_1$ and $\mathcal{R}_2$ be two submodules of $\mathcal{A}^k$ such that both the determinantal ideals $I_k(\mathcal{R}_1)$ and $I_k(\mathcal{R}_2)$ contain elements without multiple factors. Suppose also that both the varieties $\mathcal{V}(I_k(\mathcal{R}_1))$ and $\mathcal{V}(I_k(\mathcal{R}_2))$ are contained in the tube over $C_<$. Then the variety $\mathcal{V}(I_k(\mathcal{R}_1 \cap \mathcal{R}_2))$ is also contained in the tube over $C_<$.*

Proof. Let C' be any cone contained in the interior of C, so that $C_<$ is contained in the interior of $C'_<$. By Theorem 4.1, the $\mathcal{C}^\infty$-behaviors of $\mathcal{R}_1$ and $\mathcal{R}_2$ are both stable with respect to C'. Thus by the above, the sum of these behaviors, which is the behavior of $\mathcal{R}_1 \cap \mathcal{R}_2$, is also stable with respect to C'. Theorem 4.1 now implies that $\mathcal{V}(I_k(\mathcal{R}_1 \cap \mathcal{R}_2))$ is contained in the tube over $C'_<$. As the intersection of all such $C'_<$ is the cone $C_<$, the corollary follows. $\square$

STABILIZABILITY OF SYSTEMS OF ONE-DIMENSIONAL WAVE EQUATIONS BY ONE INTERNAL OR BOUNDARY CONTROL FORCE*

FARID AMMAR KHODJA† AND AHMED BADER†

Abstract. We study the internal and boundary stabilizability of a system of wave equations by one control force. We prove that the "classical" internal damping applied to only one of the equations never gives exponential stability if the wave speeds are different and, if the wave speeds are the same, we give explicit necessary and sufficient conditions for the stability to occur. We also study the simultaneous boundary stabilization of the same system.

1. Introduction.

The starting point of this work was the study of the stabilizability of two coupled abstract second order equations in Hilbert spaces using only one control force. More precisely, let us consider the system

$$\begin{cases} u''(t) = & -Au(t) + Bv'(t) \qquad \text{in } H, \\ v''(t) = & -B^*u'(t) - Cv(t) - Dv'(t) \quad \text{in } G, \end{cases}$$

where H and G are Hilbert spaces. The question then is to characterize the widest classes of operators A, B, C, and D for which the uniform stability of the semigroup associated with this system (once the conditions for its existence are ensured) holds. A general answer seems to be difficult but some results are given, with rather restrictive assumptions, by Afilal and Khodja [1] (see also [3], [5], and [7] for abstract thermoelastic systems which correspond to this system by neglecting v''). In this last paper, it was pointed out that there was a "gap" between the cases $A = C$ and $A \neq C$ in that it is easier to find a stabilizing operator D in the first case ($A = C$) than in the second ($A \neq C$); see [1] for more details.

In this paper, keeping in mind the abstract approach we have just described, we will confine ourselves to the study of one-dimensional hyperbolic systems which are close to the Timoshenko beam equations (see, for instance, [11]).

The first problem we consider is the following.

$$(1.1) \quad \begin{cases} u_{tt} = u_{xx} + b(x)v_t \ + f \qquad\qquad \text{in } (0,\infty)\times(0,1), \\[2ex] v_{tt} = \eta^2 v_{xx} - b(x)u_t + g \quad \text{in } (0,\infty)\times(0,1), \\[2ex] u(t,0) = v(t,0) = u(t,1) = v(t,1) = 0, \quad t \in (0,\infty), \\[2ex] u(0,x) = u_0(x),\ u_t(0,x) = u_1(x),\ v(0,x) = v_0(x),\ v_t(0,x) = v_1(x), \end{cases}$$

†Université de Franche-Comté, Département de Mathématiques et UMR 6623, 16 route de Gray, 25030 Besançon cedex, France (ammar@math.univ-fcomte.fr, bader@math.univ-fcomte.fr).

where $\eta \in \mathbb{R}$, $b \in C([0,1])$ and f and g are two control forces. Our aim here is to study the exponential stability of (1.1) whenever we choose

$$f \equiv 0,\ g = -a(x)v_t, \tag{1.2}$$

where $a \in C([0,1])$. Our system then writes

$$\begin{cases} u_{tt} = u_{xx} + b(x)v_t & \text{in } (0,\infty)\times(0,1), \\ v_{tt} = \eta^2 v_{xx} - b(x)u_t \ - a(x)v_t & \text{in } (0,\infty)\times(0,1), \\ u(t,0) = v(t,0) = u(t,1) = v(t,1) = 0, \quad t \in (0,\infty), \\ u(0,x) = u_0(x),\ u_t(0,x) = u_1(x), v(0,x) = v_0(x), v_t(0,x) = v_1(x). \end{cases} \tag{1.3}$$

The natural energy associated with (1.3) is

$$E(t) = \int_0^1 \left(\mid u_t \mid^2 + \mid u_x \mid^2 + \mid v_t \mid^2 + \eta^2 \mid v_x \mid^2\right) dx. \tag{1.4}$$

Let us recall that (1.3) is *exponentially stable* if there exist $\omega > 0$ and $M > 0$ such that

$$E(t) \leq Me^{-\omega t}E(0) \qquad \forall t > 0 \tag{1.5}$$

holds for any initial data (u_0, u_1, v_0, v_1) with finite energy. It is said to be *strongly stable* if for any initial data (u_0, u_1, v_0, v_1) with finite energy

$$\lim_{t\to\infty} E(t) = 0. \tag{1.6}$$

Our result is then the following.

THEOREM 1.1. *Assume that $a, b \in C([0,1])$.*

(i) *If $\eta \neq 1$, then* (1.5) *does not hold.*

(ii) *If $\eta = 1$, assume moreover that a and b have* disjoint supports. *Then* (1.5) *holds if and only if* (1.3) *is strongly stable and*

$$\overline{a} := \int_0^1 a(x)dx > 0,\ \overline{b} := \int_0^1 b(x)dx \notin \pi\mathbb{Z}. \tag{1.7}$$

Remark 1.2. We will see that under the condition (1.7), the exponential stability holds up in an invariant subspace of the energy space of finite codimension.

If a and b have *disjoint supports,* we are not able to prove strong stability even in the dissipative case ($a \geq 0$ on $(0,1)$). If a and b have *the same support,* the strong stability follows from Kapitonov's result [6] in the dissipative case (see the next remark).

Remark 1.3. The technique we use allows us to deal with systems with more than two wave equations. This is what is done by Kapitonov [6] in higher dimensions. His assumptions amount to taking a, b with the same support assuming that $a > 0$ on its support, and using the multiplier technique, he proves the exponential stability under additional geometrical assumptions (which are easily verified in the one-dimensional case).

With a slight modification of Kapitonov's proof, it is possible, in the one-dimensional case, to prove the exponential stability by assuming only that the supports of a and b contain a common interval.

N. Burq (lecture given at an international conference on control theory, Nancy, France, March 1999), has generalized our result to higher dimension using the microlocal defect measures of P. Gérard and L. Tartar.

The second problem we deal with is

$$\begin{cases} u_{tt} = u_{xx} + b(x)v_t & \text{in } (0,\infty)\times(0,1), \\ v_{tt} = \eta^2 v_{xx} - b(x)u_t & \text{in } (0,\infty)\times(0,1), \\ u(t,0) = v(t,0) = 0, \\ u(t,1) = f(t), \quad \eta^2 v_x(t,1) = g(t), \quad t\in(0,\infty), \\ u(0,x) = u_0(x),\ u_t(0,x) = u_1(x),\ v(0,x) = v_0(x),\ v_t(0,x) = v_1(x). \end{cases}$$

Following Lions [8], we would like to stabilize *simultaneously* this system by two boundary control forces which are related by the relation

$$f' = g \qquad \text{on } (0,\infty).$$

A natural choice of the force g which makes our system dissipative (i.e., $E'(t) \le 0$ for $t > 0$) is

$$g(t) = -\alpha\left(u_x(t,1) + v_t(t,1)\right), \ \ \alpha > 0.$$

We then get the system

$$(1.8) \quad \begin{cases} u_{tt} = u_{xx} + b(x)v_t & \text{in } (0,\infty)\times(0,1), \\ v_{tt} = \eta^2 v_{xx} - b(x)u_t & \text{in } (0,\infty)\times(0,1), \\ u(t,0) = v(t,0) = 0, \\ \quad \eta^2 v_x(t,1) = u_t(t,1) = -\alpha\left(u_x(t,1) + v_t(t,1)\right), \quad t\in(0,\infty), \\ u(0,x) = u_0(x),\ u_t(0,x) = u_1(x),\ v(0,x) = v_0(x),\ v_t(0,x) = v_1(x). \end{cases}$$

The energy associated with this system is again given by (1.4). Our result for system (1.8) is the following.

THEOREM 1.4. *Assume that* $b \in C([0,1])$ *and* $\alpha > 0$. *Then*

(i) *if* $\eta \neq 1$, (1.5) *holds if and only if* (1.8) *is strongly stable and*

$$\eta = \frac{2p+1}{q} \ \ \textit{for some } (p,q) \in \mathbb{Z}\times\mathbb{Z}^*;$$

(ii) *if* $\eta = 1$, (1.5) *holds if and only if* (1.8) *is strongly stable and*

$$\bar{b} := \int_0^1 b(x)dx \neq (2k+1)\frac{\pi}{2} \qquad \textit{for any} \ \ k\in\mathbb{Z}.$$

A related work which deals with simultaneous controllability of a system of one-dimensional wave equations can be found in Avodin and Tucsnak [4].

Remark 1.5. As for the previous system, we will show that exponential stability holds up in an invariant subspace of the energy space of finite codimension.

If $b \equiv 0$, it is easy to verify that strong stability holds. However, if $b \neq 0$, it seems to be difficult to find conditions on b which imply the strong stability.

The paper is organized as follows. In the second section, we begin by stating and proving a lemma extending a result of Neves, Ribeiro, and Lopes [9]. We prove Theorems 1.1 and 1.4 in the third section.

Some of the results of this paper were already announced in [2].

2. A lemma. We consider a one-dimensional hyperbolic system written in the form

$$(2.1)\quad \begin{cases} \dfrac{\partial}{\partial t}\begin{pmatrix} u \\ v \end{pmatrix} = -M(x)\dfrac{\partial}{\partial x}\begin{pmatrix} u \\ v \end{pmatrix} - N(x)\begin{pmatrix} u \\ v \end{pmatrix} \qquad \text{on } [0,T]\times\,]0,l[, \\[2ex] \dfrac{d}{dt}\left[v(t,l) - Du(t,l)\right] = Fu(t,l) + Gv(t,l), \\[2ex] u(t,0) = Ev(t,0), \end{cases}$$

where

(i) *$N(x)$ is an $n \times n$ matrix whose entries n_{ij} are continuous complex valued functions of x in $[0,l]$,*

(ii) *$M(x)$ is a diagonal matrix satisfying*

$$M(x) = \operatorname{diag}\left([M_{ii}(x)]_{i=1}^{r}, [M_{jj}(x)]_{j=r+1}^{q}\right),$$

where M_{ii} (resp., M_{jj}) are diagonal matrices such that

$$\begin{aligned} M_{ii}(t,x) &= \lambda_i(x) I_{m_i}, \qquad & i &= 1,\dots,r, \\ M_{jj}(t,x) &= \mu_j(x) I_{m_j}, \qquad & j &= r+1,\dots,q, \end{aligned}$$

and where I_{m_i} is the identity matrix of size m_i and

$$\sum_{i=1}^{r} m_i = p; \quad \sum_{j=r+1}^{q} m_j = n - p.$$

We suppose also that the entries of $M(x)$ are real valued C^1 functions in x with

$$\lambda_i(x) > 0 \text{ and } \mu_j(x) < 0 \quad \forall\, i,j \text{ and } \forall\, x \in [0,l],$$

(iii) *$u(t,x) = (u_i(t,x))_{i=1}^{p}$ and $v(t,x) = (v_i(t,x))_{j=p+1}^{n}$,*

(iv) *$D, E, F,$ and G are matrices of appropriate sizes.*

With system (2.1), we consider the reduced system

$$(2.2)\quad \begin{cases} \dfrac{\partial}{\partial t}\begin{pmatrix} u \\ v \end{pmatrix} = -M(x)\dfrac{\partial}{\partial x}\begin{pmatrix} u \\ v \end{pmatrix} - N_0(x)\begin{pmatrix} u \\ v \end{pmatrix} \qquad \text{on } (0,T)\times\,]0,l[, \\[2ex] u(t,0) = Ev(t,0)\ \ ,\ \ v(t,l) = Du(t,l), \end{cases}$$

where

(v) $N_0(x) = \mathrm{diag}(N_{11}(x), N_{22}(x), \ldots, N_{qq}(x))$ *is a diagonal matrix per block whose elements* $N_{\eta\eta}(x)$ $(1 \leq \eta \leq q)$ *are* $m_\eta \times m_\eta$ *matrices* (m_η *is the algebraic multiplicity of the eigenvalue* $\lambda_\eta(x)$ (*or* $\mu_\eta(x)$)) *and each matrix* $N_{\eta\eta}(x)$ *is a block of the matrix* $N(x)$ *such that*

$$N_{\eta\eta}(x) = (n_{k,\,l})_{S_{\eta-1} \leq k,l \leq S_\eta} \qquad \textit{with } \; S_0 = 1, \; \textit{and} \;\; S_\eta = \sum_{d=1}^{\eta} m_d.$$

To illustrate this last assumption, if, for example, $M = \mathrm{diag}(1, 1, 2, -3, -3)$ and $N = (n_{ij})_{1 \leq i,j \leq 5}$, then the corresponding reduced matrix N_0 is given by

$$N_0 = \begin{pmatrix} n_{11} & n_{12} & 0 & 0 & 0 \\ n_{21} & n_{22} & 0 & 0 & 0 \\ 0 & 0 & n_{33} & 0 & 0 \\ 0 & 0 & 0 & n_{44} & n_{45} \\ 0 & 0 & 0 & n_{54} & n_{55} \end{pmatrix}.$$

In this study we prove that the two systems (2.1) and (2.2) have the same essential spectral radius.

Before giving the main result of this section, we need to recall some definitions and properties that may be found in Van Neerven [12, pp. 106–111].

Definition 2.1. (i) *If* L *is a linear bounded operator in a Banach space, the essential spectral radius of* L *is*

$$r_{ess}(L) := \inf \{ r > 0 : \lambda \in \sigma(L), |\lambda| \geq r; \; \textit{implies} \\ \lambda \textit{ is an isolated eigenvalue of finite multiplicity} \},$$

where $\sigma(L)$ *is the spectrum of* L.

(ii) *The type (or growth bound)* $\omega(T)$ *of a* C_0*-semigroup* $(T(t))$ *generated by* A *is*

$$\omega(T) := \inf \left\{ \omega \in \mathbb{R}, \, \exists M_\omega > 0, \; \|T(t)\| \leq M_\omega e^{\omega t} \quad \forall \, t \geq 0 \right\}.$$

A well-known result is that there exists a real number $\omega_{ess}(T)$ (the *essential type* of $T(t)$) such that

$$\omega_{ess}(T) := \frac{\ln [r_{ess}(T(t))]}{t}, \;\; t > 0.$$

The property below will play a significant role in our study:

$$r_{ess}(L + K) = r_{ess}(L) \quad \text{for any compact operator } K. \tag{2.3}$$

We recall also (see [12, pp. 106–111]) that the type $\omega(T)$ of a semigroup $(T(t))$ is given by

$$\omega(T) = \max \left[s(A)\, ; \, \omega_{ess}(T) \right],$$

where $s(A)$ is the spectral abscissa of A:

$$s(A) := \sup \{ \mathrm{Re}\, \lambda ; \lambda \in \sigma(A) \}.$$

Returning to our problem, let us introduce the new variable:

$$z(t) = v(t, l) - Du(t, l)$$

and define, on the energy space $H = \left[L^2([0,l])\right]^n \times \mathbb{C}^{n-p}$, the following operators:

$$A_1 \begin{pmatrix} u \\ v \\ z \end{pmatrix} = \left(\left[-M(x)\frac{\partial}{\partial x} - N(x)\right]\begin{pmatrix} u \\ v \end{pmatrix}, Fu(t,l) + Gv(t,l)\right) \tag{2.4}$$

and

$$A_4 \begin{pmatrix} u \\ v \end{pmatrix} = \left[-M(x)\frac{\partial}{\partial x} - N_0(x)\right]\begin{pmatrix} u \\ v \end{pmatrix} \tag{2.5}$$

whose domains are, respectively,

$$\begin{aligned} D(A_1) = \{(u,v,z) \in H\ ; (u,v) \in \left[W^{1,2}(0,l)\right]^n\ ; \\ u(0) = E\,v(0),\ z = v(l) - Du(l)\} \end{aligned} \tag{2.6}$$

and

$$\begin{aligned} D(A_4) = \{(u,v) \in H\ ; (u,v) \in \left[W^{1,2}(0,l)\right]^n\ ; \\ u(0) = E\,v(0),\ v(l) = Du(l)\}\,. \end{aligned} \tag{2.7}$$

Equations (2.1) and (2.2) can be viewed as abstract systems

$$Y_t = A_1 Y \quad \text{in } H,$$

$$Z_t = A_4 Z \quad \text{in } \tilde{H},$$

where $\tilde{H} := \{(u,v,z) \in H;\ z \equiv 0\}$ and

$$A_1 = \begin{pmatrix} -M\dfrac{\partial}{\partial x} - N & 0 \\ 0 & R \end{pmatrix}, \qquad A_4 := -M\frac{\partial}{\partial x} - N_0$$

with $R : \mathbb{C}^{n-p} \longrightarrow \mathbb{C}$ and $Rz(t) = Fu(t,l) + Gv(t,l)$.

As in [9], under the assumptions (i)–(v), A_1 (resp., A_4) defined by (2.4) and (2.6) (resp., by (2.5) and (2.7)) generates a C_0-semigroup $T_1(t)$ on H (resp., ($T_4(t)$ on $\tilde{H}$).

Our main ingredient is the following.

LEMMA 2.2. *Suppose that the assumptions* (i)–(v) *hold; then the difference of the two semigroups $T_1(t)$ and $T_4(t)$ is a compact operator. In particular,*

$$r_{ess}(T_1(t)) = r_{ess}(T_4(t)).$$

Consequently,

$$\omega_{ess}(T_1) = \omega_{ess}(T_4).$$

Remark 2.3. This lemma has been proved by Neves, Ribeiro, and Lopes [9] in the case where the eigenvalues $\lambda_i(x)$ and $\mu_j(x)$ of the diagonal matrix $M(x)$ are all distinct (i.e., $m_i = 1$ for $i = 1, \dots, q$). In this case, these authors showed also that $\omega_{ess}(T_4) = s(A_4)$.

For the proof of Lemma 2.2, we use the same techniques as Neves, Ribeiro, and Lopes [9]. Note that the proof we propose for Lemma 2.2 works in the nonautonomous case as well.

Proof of Lemma 2.2. To simplify, we will prove Lemma 2.2 in the following situation:

- $M(x) = \mathrm{diag}(\lambda(x), \lambda(x), \mu(x))$; with $\lambda(x) > 0$ and $\mu(x) < 0$ for any x in$[0, l]$.
- $N(x) = (n_{ij}(x))_{1\leq i,j\leq 3}$.
- $D = \begin{pmatrix} d_1 & 0 \\ 0 & d_2 \end{pmatrix}$, $F = \begin{pmatrix} f_1 & 0 \\ 0 & f_2 \end{pmatrix}$, $G = g$, and $E = \begin{pmatrix} e_1 \\ e_2 \end{pmatrix}$, where d_1, d_2, f_1, f_2, g, e_1, and e_2 are real or complex constants.

We introduce two intermediate reduced systems:

$$(2.8) \qquad \begin{cases} \dfrac{\partial}{\partial t}\begin{pmatrix} u \\ v \\ w \end{pmatrix} = -M(x)\dfrac{\partial}{\partial x}\begin{pmatrix} u \\ v \\ w \end{pmatrix} - N_0(x)\begin{pmatrix} u \\ v \\ w \end{pmatrix} \qquad \text{on }]0, l[, \\ \\ \dfrac{d}{dt}\left[w(t,l) - d_1u(t,l) - d_2v(t,l)\right] = f_1u(t,l) + f_2v(t,l) + gw(t,l), \\ \\ u(t,0) = e_1w(t,0), \quad v(t,0) = e_2w(t,0), \end{cases}$$

$$(2.9) \qquad \begin{cases} \dfrac{\partial}{\partial t}\begin{pmatrix} u \\ v \\ w \end{pmatrix} = -M(x)\dfrac{\partial}{\partial x}\begin{pmatrix} u \\ v \\ w \end{pmatrix} - N_0(x)\begin{pmatrix} u \\ v \\ w \end{pmatrix} \qquad \text{on }]0, l[, \\ \\ \dfrac{d}{dt}\left[w(t,l) - d_1u(t,l) - d_2v(t,l)\right] = 0, \\ \\ u(t,0) = e_1w(t,0), \; v(t,0) = e_2w(t,0). \end{cases}$$

Denote by A_2 (resp., A_3) the associated operator of system (2.8) (resp., (2.9)). These two operators are defined on the same energy space and have the same domain as A_1. A_2 and A_3 generate, respectively, two C_0-semigroups which we will denote by $T_2(t)$ and $T_3(t)$.

We introduce the space $\bar{H} := \{(u, v, w, z) \in H \; ; \; z = 0\}$ and we define the orthogonal projection P of H on $\bar{H}$:

$$\begin{aligned} P : \qquad & H \longrightarrow \bar{H}, \\ (u, v, w, z) & \longmapsto (u, v, w, 0). \end{aligned}$$

We can identify $T_4(t)$ with $T_4(t)P$ which is an operator on H. It is enough to show that : $(T_1(t) - T_4(t)P)$ is compact.

We write

$$T_1(t) - T_4(t)P = (T_1(t) - T_2(t)) + (T_2(t) - T_3(t)) + (T_3(t) - T_4(t)P)\,.$$

We will show that each term of the right-hand side member is a compact operator.

Step 1. $(T_2(t) - T_3(t))$ *is a compact operator.*

To compute explicitly the semigroups $T_2(t)$ and $T_3(t)$, we follow [9] using the characteristics method. Taking the initial data $Y_0 = ((u_0, v_0), w_0, z_0)$ in H, we put $U = (u, v)$ and $(u_0, v_0) = U_0$. Denote by $z(t) = w(t,l) - d_1u(t,l) - d_2v(t,l)$ the new variable and by $[(u, v), w, z]$ the unique solution of system (2.2) with initial data Y_0.

Given a fixed point (t, x) in $(0, T)\times]0, l[$, let $\varphi(., t, x)$ (resp., $\psi(., t, x)$) be the unique solution of

$$\begin{cases} \dfrac{dx}{ds} = \lambda(x(s)), \\ x(t) = x, \end{cases} \qquad \text{resp.,} \begin{cases} \dfrac{dx}{ds} = \mu(x(s)), \\ x(t) = x. \end{cases}$$

We define the maps

$$\begin{aligned} \tau_i : [0,T] \times [0,l] &\longrightarrow \mathbb{R}, \\ (t,x) &\longrightarrow \tau_i(t,x) \quad i = 1,2, \\ \text{such that } \ \varphi(\tau_1(t,x),t,x) = 0 \ &\text{ and } \ \psi(\tau_2(t,x),t,x) = l. \end{aligned}$$

Denote by $R(t,y,x)$ the fundamental matrix associated with

$$\frac{d}{dt} Y(t) = N_0^{11}(x(t))Y(t),$$

where

$$N_0^{11}(x) = \begin{pmatrix} n_{11}(x) & n_{12}(x) \\ n_{21}(x) & n_{22}(x) \end{pmatrix} \ \text{ and } \ N_0(x) = \begin{pmatrix} N_0^{11}(x) & 0 \\ 0 & n_{33}(x) \end{pmatrix}.$$

Using the corresponding boundary conditions, the solution (U,w,z) is given by the following:

- If $0 \le x \le \varphi(t,0,0)$, then

$$\begin{aligned} U(t,x) = \exp\left[- \int_0^{\tau_1(t,x)} n_{33}(\psi(s,\tau_1(t,x),0))ds \right] R(t,\tau_1(t,x),x) \\ \times \begin{pmatrix} e_1 \\ e_2 \end{pmatrix} w_0(\psi(0,\tau_1(t,x),0)). \end{aligned}$$

- If $\varphi(t,0,0) \le x \le l$, then

$$U(t,x) = R(t,0,x) \times U_0(\varphi(0,t,x)).$$

- If $0 \le x \le \psi(t,0,l)$, then

$$w(t,x) = \exp\left[- \int_0^t n_{33}(\psi(s,t,x))ds \right] w_0(\psi(0,t,x)).$$

- If $\psi(t,0,l) \le x \le l$, then

$$\begin{aligned} w(t,x) = \exp\left(- \int_{\tau_2(t,x)}^t n_{33}(\psi(s,t,x))ds \right) \\ \times \left[z(\tau_2(t,x)) \ + \ [d_1,d_2]R(\tau_2(t,x),0,l)U_0(\varphi(0,\tau_2(t,x),l)) \right]. \end{aligned}$$

- For any t in the interval $J = [0,T]$, we have

$$\begin{aligned} z(t) &= \int_0^t e^{gt-s}(gd_1 + f_1)u(t,l) + (gd_2 + f_2)v(t,l)ds + e^{tg}z_0 \\ &= \int_0^t e^{gt-s}(GD + F)U(s,l)ds + e^{tg}z_0. \end{aligned}$$

Consequently, $T_3(t)Y_0$ is obtained by cancelling the constants f_1, f_2, and g.

Thus

$$(T_2(t) - T_3(t))\left((u_0,v_0),w_0,z_0\right) = (0,\bar{w}(t,x),\bar{z}(t)),$$

where $\bar{w}$ and $\bar{z}$ are given by the following:

- If $0 \leq x \leq \psi(t,0,l)$, then

$$\bar{w}(t,x) = 0.$$

- If $\psi(t,0,l) \leq x \leq l$, then

$$\bar{w}(t,x) = \exp\left(- \int_{\tau_2(t,x)}^{t} n_{33}(\psi(s,t,x))ds \right) \bar{z}(\tau_2(t,x)).$$

- And for all $t \in J$, we have

$$\bar{z}(t) = \int_0^t e^{tg-s}(GD+F)R(s,0,l)U_0(\varphi(0,s,l))ds + (e^{tg}-1)z_0.$$

To prove the compactness of the difference $T_2(t) - T_3(t)$, it is sufficient to show that each component of $(0, \overline{w}, \overline{z}) = (T_2(t) - T_3(t))\, Y_0$ is a compact operator. Remark that the first component is null and that the operator defined by $z_0 \longrightarrow (e^{gt}-1)z_0$ is compact for any $t \in J = [0,T]$. In addition, in view of Lemma 4 in [9], the operator

$$\begin{aligned} U_0 \longrightarrow & \int_0^t \underbrace{e^{tg-s}\left[GD+F\right]R(s,0,l)}_{L(t,s)} U_0(\varphi(0,s,l))ds \\ = & \int_0^t L(t,s)U_0(\varphi(0,s,l))ds \end{aligned}$$

is compact since $L = (L_{ij})_{1 \leq i,j \leq 2}$ is such that the L_{ij} $(1 \leq i,j \leq 2)$ are continuous functions of their arguments and

$$U_0(\varphi(0,s,l)) = \begin{pmatrix} u_0(\varphi(0,s,l)) \\ \\ v_0(\varphi(0,s,l)) \end{pmatrix}$$

$$\text{since} \quad : \frac{d}{ds}(\varphi(0,s,l)) = -\frac{\partial \varphi}{\partial x}(0,s,l)\,\lambda(l) \neq 0.$$

Consequently, $T_2(t) - T_3(t)$ is a compact operator for all t in the compact interval J.

Step 2. *$(T_1(t) - T_2(t))$ is a compact operator.*

For this we write, for a given initial data $Y_0 = ((u_0, v_0), w_0, z_0)$, the differential equation corresponding with system (2.1) in the form

$$\frac{\partial}{\partial t}Y(t) = A_1 Y(t) = A_2 Y(t) + BY(t),$$

where

$$B = \begin{pmatrix} N - N_0 & 0 \\ 0 & 0 \end{pmatrix}.$$

Then we have

$$Y(t) = T_1(t)Y_0 = T_2(t)Y_0 + \int_0^t T_2(t-s)BY(s)ds.$$

Consequently,

$$\begin{aligned}(T_1(t)-T_2(t))Y_0 &= \int_0^t T_2(t-s)BT_1(s)Y_0ds\\ &= \int_0^t T_2(t-s)BT_2(s)Y_0ds + \int_0^t T_2(t-s)B(T_1(s)-T_2(s))Y_0ds.\end{aligned}$$

Lemma 2.4 (see [9, Lemma 3]). *Suppose that $\int_0^t T_2(t-s)BT_2(s)ds$ is a compact operator for all $t \in J$; then $(T_1(t)-T_2(t))$ is a compact operator for all t in J. In fact, $\{(T_1(t)-T_2(t))\,Y;\ \|Y\|_H \le 1,\ t\in J\}$ is precompact.*

To show that $\{(T_1(t)-T_2(t))\,Y; \|Y\|_H \le 1, t\in J\}$ is precompact, it is enough, according to Lemma 2.4, to prove that $\int_0^t T_2(t-s)BT_2(s)ds$ is a compact operator. However, we know that

$$\begin{aligned}T_2(t-s)BT_2(s) = T_3(t-s)BT_3(s) + \left[T_2(t-s)-T_3(t-s)\right]BT_3(s)\\ +T_2(t-s)B\left[T_2(s)-T_3(s)\right]\end{aligned}$$

As $T_2(t)-T_3(t)$ is a compact operator, $\int_0^t T_2(t-s)BT_2(s)ds$ is compact if $\int_0^t T_3(t-s)BT_3(s)ds$ is. For this, we are going to use Lemma 4 of [9]. Let $Y_0 = ((u_0,v_0),w_0,z_0) = (U_0,w_0,z_0)$ be in H. We wish to prove that each integral component of $\int_0^t T_3(t-s)BT_3(s)Y_0ds$ defines a compact operator. Note that the third component $\bar{z}$ defines an operator of finite dimensional range; thus it is compact. We can write

$$\int_0^t T_3(t-s)BT_3(s)Y_0ds = \int_0^t \begin{pmatrix}\bar{U}(t,s,x)\\ \bar{w}(t,s,x)\\ \bar{z}(t,s,x)\end{pmatrix} ds.$$

We deduce that $\bar{U}(t,s)$ is the first component of $\bar{Y}(t,s)$ which is the unique solution of the following Cauchy problem:

$$\begin{cases}\dfrac{d}{dt}Y(t) = A_3Y(t),\\ \\ Y(s)=\tilde{Y}(s).\end{cases}$$

For $\boldsymbol{0 \le x \le \varphi(t,0,0)}$.

We have

$$\int_0^t \bar{U}(t,s,x)ds = \int_0^{\tau_1(t,x)} \bar{U}(t,s,x)ds + \int_{\tau_1(t,x)}^t \bar{U}(t,s,x)ds$$

In the same way as [9], we find

$$\begin{aligned}\int_0^{\tau_1(t,x)} \bar{U}(t,s,x)ds = \int_0^{s_1} \xi_1(t,s,x)\ U_0(\varphi(0,s,x_\psi))ds + \int_{s_1}^{\tau_1(t,x)}\\ \left[\xi_2(t,s,x)\begin{pmatrix}e_1\\ e_2\end{pmatrix} w_0(\psi(0,\tau_1(s,x_\psi),0))ds\right].\end{aligned}$$

And

$$\begin{aligned}\int_{\tau_1(t,x)}^t \bar{U}(t,s,x)ds = \int_{\tau_1(t,x)}^{s_2} \xi_3(t,s,x)\begin{pmatrix}n_{13}\\ n_{23}\end{pmatrix} w_0(\psi(0,s,x_\varphi))ds\\ +\int_{s_2}^t \xi_4(t,s,x)U_0(\varphi(0,\tau_2(s,x_\varphi),l))ds,\end{aligned}$$

where s_1 and s_2 are the two reals satisfying

$$\begin{cases} \varphi(s_1, 0, 0) = \psi(s_1, \tau_1(t, x), 0) := x_\psi, \\ \\ \psi(s_2, 0, l) = \varphi(s_2, t, x) := x_\varphi \end{cases}$$

and $(\xi_i)_{i=1}^4$ are continuous functions of their arguments.

For $\boldsymbol{\varphi(t, 0, 0) \leq x \leq l}$.

It is easy to see that it is a particular case of that previously treated ($0 \leq x \leq \varphi(t, 0, 0)$).

To conclude, we have

$$\begin{aligned} \frac{d\varphi}{ds}(0, s, x_\psi) &= \frac{\partial\varphi}{\partial s}(0, s, x_\psi) + \frac{\partial\varphi}{\partial x}(0, s, x_\psi)\frac{\partial x_\psi}{\partial s} \\ &= \frac{\partial\varphi}{\partial x}(0, s, x_\psi)\ [\mu(x_\psi) - \lambda(x_\psi)]\,. \end{aligned}$$

However, $\mu(x_\psi) < 0$ and $\lambda(x_\psi) > 0$, thus

$$\frac{d\varphi}{ds}(0, s, x_\psi) \neq 0.$$

In addition we have

$$\frac{d\psi}{ds}(0, \tau_1(s, x_\psi), 0) = \frac{\partial\psi}{\partial\tau_1}(0, \tau_1(s, x_\psi), 0) \times \left[\frac{\partial\tau_1}{\partial s}(s, x_\psi) + \frac{\partial\tau_1}{\partial s}(s, x_\psi)\frac{\partial x_\psi}{\partial s}\right].$$

However,

$$\frac{\partial\psi}{\partial\tau_1}(0, \tau_1(s, x_\psi), 0) = -\frac{\partial\psi}{\partial x}(0, \tau_1(s, x_\psi), 0)\,\mu(0) \quad \text{and} \quad \frac{\partial x_\psi}{\partial s} = \mu(x_\psi).$$

Finally,

$$\begin{aligned} \frac{d\psi}{ds}(0, \tau_1(s, x_\psi), 0) = &-\frac{\mu(0)}{\lambda(x_\psi)}\frac{\partial\psi}{\partial x}(0, \tau_1(s, x_\psi), 0) \times \frac{\partial\varphi}{\partial x}(\tau_1(s, x_\psi), s, x_\psi) \\ &\times [\lambda(x_\psi) - \mu(x_\psi)]\,. \end{aligned}$$

In particular,

$$\frac{d\psi}{ds}(0, \tau_1(s, x_\psi), 0) \neq 0.$$

In the same way, we get

$$\frac{d\psi}{ds}(0, s, x_\varphi) \neq 0 \quad \text{and} \quad \frac{d\varphi}{ds}(0, \tau_2(s, x_\varphi), l) \neq 0.$$

We can, according to Lemma 4 of [9], conclude that $\int_0^t \bar{U}(t, s, x)ds$ defines a compact operator.

The second integral component $\int_0^t \bar{w}(t, s, x)ds$ can be treated by similar techniques. Hence $\int_0^t T_2(t-s)BT_2(s)ds$ is compact for any $t \in J$. Thus, from Lemma 2.4, we deduce that $(T_1(t) - T_2(t))$ is a compact operator for any $t \in J$ and that $\{(T_1(t) - T_2(t))Y,\ \|Y\|_H \leq 1,\ t \in J\}$ is precompact.

Finally, $(T_3(t) - T_4(t)P)$ is compact. Indeed, we have

$$T_4(t)P = T_3(t)P \text{ since } A_3 = (A_4, 0).$$

Then $(T_3(t) - T_4(t)P) = T_3(t)(I - P)$ is an operator of finite dimensional range, thus it is compact. Moreover, $\{(T_3(t) - T_4(t)P)Y,\ \|Y\|_H \leq 1,\ t \in J\}$ is precompact.

Hence, Lemma 2.2 is proved. □

Remark 2.5. Lemma 2.2 holds also in the case where the matrices M, N, D, E, F, and G are dependent on the time.

3. Proofs. To prove our two theorems, we introduce the following new variables:

$$\left\{ \begin{array}{ll} p = u_t - u_x; & q = u_t + u_x, \\ & \\ r = v_t - \eta v_x; & s = v_t + \eta v_x. \end{array} \right. \tag{3.1}$$

Our system becomes

$$\frac{\partial}{\partial t}\begin{pmatrix} U \\ V \end{pmatrix} + M\frac{\partial}{\partial x}\begin{pmatrix} U \\ V \end{pmatrix} + N(x)\begin{pmatrix} U \\ V \end{pmatrix} = 0, \tag{3.2}$$

where

$$U = \begin{pmatrix} p \\ r \end{pmatrix}; V = \begin{pmatrix} q \\ s \end{pmatrix} \text{ and } M = \text{diag}(1, \eta; -1, -\eta) \text{ with}$$

$$N(x) = \frac{1}{2}\begin{pmatrix} 0 & -b(x) & 0 & -b(x) \\ b(x) & a(x) & b(x) & a(x) \\ 0 & -b(x) & 0 & -b(x) \\ b(x) & a(x) & b(x) & a(x) \end{pmatrix}. \tag{3.3}$$

Now the boundary conditions in (1.3) transform into

$$U(t,0) = -V(t,0), \quad U(t,1) = -V(t,1), \qquad t > 0, \tag{3.4}$$

and the boundary conditions in (1.8) into

$$U(t,0) = -V(t,0),$$

$$\begin{pmatrix} 1 & \eta \\ \alpha & \eta - \alpha \end{pmatrix} U(t,1) = \begin{pmatrix} -1 & \eta \\ \alpha & \eta - \alpha \end{pmatrix} V(t,1), \tag{3.5}$$

and (3.2) will represent system (1.8) if we set $a \equiv 0$ in (3.3). The equivalence of the transformed systems with our initial systems clearly holds.

In view of the proof of Lemma 2.2, we will set

$$A_1 = -M\frac{\partial}{\partial x} - N(x)$$

with, for the proof of Theorem 1.1, the associated boundary conditions

$$U(0) = -V(0), \quad U(1) = -V(1) \tag{3.6}$$

and, for the proof of Theorem 1.4, the associated boundary conditions

$$U(0) = -V(0),$$

$$\begin{pmatrix} 1 & \eta \\ \alpha & \eta - \alpha \end{pmatrix} U(1) = \begin{pmatrix} -1 & \eta \\ \alpha & \eta - \alpha \end{pmatrix} V(1). \tag{3.7}$$

(Note that in this system, $a \equiv 0$.)

Proof of Theorem 1.1. Assume first that $\eta \neq 1$. According to Lemma 2.2 (see also [9]), the semigroup associated with (3.2), (3.4) has the same essential type as the semigroup associated with the system

$$\begin{gathered} \frac{\partial}{\partial t}\begin{pmatrix} U \\ V \end{pmatrix} + M\frac{\partial}{\partial x}\begin{pmatrix} U \\ V \end{pmatrix} + \widetilde{N}(x)\begin{pmatrix} U \\ V \end{pmatrix} = 0, \\ U(t,0) = -V(t,0), \quad U(t,1) = -V(t,1), \qquad t > 0, \end{gathered} \tag{3.8}$$

with $\widetilde{N}(x) = \operatorname{diag}(0, a(x), 0, a(x))$. We set

$$A_4 = -M\frac{\partial}{\partial x} - \widetilde{N}(x)$$

with the associated boundary conditions (3.6). It is sufficient (see Remark 2.3) to prove that the spectral abscissa $s(A_4)$ is 0. So, let us consider the system

$$(\lambda - A_4)\begin{pmatrix} U \\ V \end{pmatrix} = 0,$$

$$U(0) = -V(0), \qquad U(1) = -V(1).$$

Computing the solutions of this last system, it is easy to prove that λ is an eigenvalue if and only if it satisfies

$$\left(e^{2\lambda} - 1\right)\left(e^{\frac{2}{\eta}(\lambda + \overline{a})} - 1\right) = 0.$$

Thus, the eigenvalues are

$$\begin{aligned} &\lambda = ik\pi, \ k \in \mathbb{Z}^*, \\ &\lambda = -\overline{a} + ik\eta\pi, \qquad k \in \mathbb{Z}, \end{aligned}$$

where $\overline{a} = \int_0^1 a(x)dx$. This proves that $s(A_4) = 0$ and concludes the proof of (i).

Let us now consider the case $\eta = 1$. We set for simplicity $\{x, a(x) \neq 0\} = [\alpha, \beta]$ and $\{x, b(x) \neq 0\} = [\delta, \gamma]$ with $\beta < \delta$ and $(\alpha, \beta, \delta, \gamma) \in ([0,1])^4$.

According to Lemma 2.2, let $A_4 = -M\frac{\partial}{\partial x} - N_0(x)$ be the reduced operator associated with A_1, where

$$N_0(x) = \frac{1}{2}\begin{pmatrix} 0 & -b(x) & 0 & 0 \\ b(x) & a(x) & 0 & 0 \\ 0 & 0 & 0 & -b(x) \\ 0 & 0 & b(x) & a(x) \end{pmatrix}. \tag{3.9}$$

We denote by $T_4(t)$ the C_0-semigroup generated by A_4.

Lemma 2.2 implies that

$$\omega_{ess}(T_1) = \omega_{ess}(T_4).$$

Now we compute $s(A_4)$. Given $Y = (U, V) \in D(A_4)$,

$$(\lambda I - A_4)\begin{pmatrix} U \\ V \end{pmatrix} = 0$$

or

$$\begin{cases} \dfrac{dU}{dx}(x) = -(\lambda I + N_{11}(x))U(x), \\[2ex] \dfrac{dV}{dx}(x) = (\lambda I + N_{11}(x))V(x), \end{cases}$$

where

$$N_{11}(x) = \frac{1}{2}\begin{pmatrix} 0 & -b(x \\ b(x) & a(x) \end{pmatrix}.$$

Solving the differential system above and taking into account the boundary conditions leads to

$$P(\lambda)V(0) := \begin{pmatrix} (e^{-\lambda} - e^{\lambda})\cos\frac{\bar{b}}{2} & (e^{-\lambda-\frac{\bar{a}}{2}} + e^{\lambda+\frac{\bar{a}}{2}})\sin\frac{\bar{b}}{2} \\[2ex] -(e^{-\lambda} + e^{\lambda})\sin\frac{\bar{b}}{2} & (e^{-\lambda-\frac{\bar{a}}{2}} + e^{\lambda+\frac{\bar{a}}{2}})\cos\frac{\bar{b}}{2} \end{pmatrix} V(0) = 0.$$

Consequently, it is clear that

$$\begin{aligned} &\lambda \in \sigma(A_4) \Leftrightarrow \det P(\lambda) = 0, \\ &\quad \Leftrightarrow e^{4\lambda} - (e^{-\bar{a}} + 1)\cos\left(\bar{b}\right)\, e^{2\lambda} + e^{-\bar{a}} = 0. \end{aligned}$$

Let $\delta = (e^{-\bar{a}} + 1)^2 \cos^2\left(\bar{b}\right) - 4e^{-\bar{a}}$. Thus, if we put

$$\begin{cases} x_1 = \frac{1}{2}(e^{-\bar{a}} + 1)\cos\left(\bar{b}\right) + \dfrac{\sqrt{\delta}}{2}, \\[2ex] x_2 = \frac{1}{2}(e^{-\bar{a}} + 1)\cos\left(\bar{b}\right) - \dfrac{\sqrt{\delta}}{2}, \end{cases}$$

then we have

$$s(A_4) = \begin{cases} \left.\begin{array}{ll} \frac{1}{2}\ln x_1 & \text{if } \cos\left(\bar{b}\right) \geq 0, \\[2ex] \frac{1}{2}\ln(-x_2) & \text{if } \cos\left(\bar{b}\right) \leq 0 \end{array}\right\} \text{ if } \delta \geq 0, \\[3ex] -\frac{1}{4}\bar{a} = -\frac{1}{4}\int_0^1 a(t)dt \qquad\qquad \text{if } \delta < 0. \end{cases}$$

Remark that if $\bar{a} \leq 0$, then $s(A_4) \geq 0$ and we deduce the following.

If $\bar{a} > 0$, then $s(A_4) \leq 0$ and $s(A_4) = 0$ if and only if $\cos\left(\bar{b}\right) = \pm 1$, that is, if and only if $\bar{b} \in \pi\mathbb{Z}$.

A simple computation shows that the eigenvalues of A_4 are distributed on at most two vertical axes.

We conclude with the help of the following result.

LEMMA 3.1 (Renardy [10, Theorem 1, p. 1300]). *Let H be a Hilbert space and let $L = L_0 + B$ be the infinitesimal generator of a C_0-semigroup of operators in H. Assume that L_0 is normal and B is bounded. Assume that there exists a number $M > 0$ and an integer n such that the following hold:*

(a) *If $\lambda \in \sigma(L_0)$ and $\mid \lambda \mid > M - 1$, then λ is an isolated eigenvalue of finite multiplicity.*

(b) *If $\mid z \mid > M$, then the number of eigenvalues of L_0 in the unit disk centered at z (counted by multiplicity) does not exceed n.*

Then $\omega_{ess}(e^{Lt}) \leq s(L)$.

We apply this lemma with $L = A_4$ (defined by (2.5) and (2.7)), $L_0 = -M\frac{\partial}{\partial x}$ with $D(L_0) = D(A_4)$ and $B = N_0$. Since M is a constant matrix, it is easy to see that L_0 is normal. Its eigenvalues are $\lambda_k = ik\pi, k \in \mathbb{Z}$, and their (algebraic and geometric) multiplicities are equal to 2. We can then take $n = 2$ and since $\mid \lambda_{k+1} - \lambda_k \mid = \pi$, assertion (b) in Lemma 3.1 is satisfied. Thus, $\omega_{ess}(T_4) \leq s(A_4) < 0$. Note that, according to the definition of the essential spectral radius and the previous inequality, one deduces that $s(A_4) = \omega_{ess}(T_4)$. □

Proof of Theorem 1.4. (i) Assume first that $\eta = \frac{2p+1}{q}$ for some $(p, q) \in \mathbb{Z} \times \mathbb{Z}^*$ with $\eta \neq 1$.

As in the previous proof, computing the essential type amounts to computing the eigenvalues λ of the reduced system, namely,

$$\lambda \begin{pmatrix} U \\ V \end{pmatrix} + M\frac{\partial}{\partial x}\begin{pmatrix} U \\ V \end{pmatrix} = 0$$

with the boundary conditions

$$U(0) = -V(0),$$

$$\begin{pmatrix} 1 & \eta \\ \alpha & \eta - \alpha \end{pmatrix} U(1) = \begin{pmatrix} -1 & \eta \\ \alpha & \eta - \alpha \end{pmatrix} V(1).$$

It is then easy to see that λ is an eigenvalue if and only if it satisfies the equation

$$\alpha \sinh \lambda \sinh \frac{\lambda}{\eta} + \eta \sinh \lambda \cosh \frac{\lambda}{\eta} + \alpha\eta \cosh \lambda \cosh \frac{\lambda}{\eta} = 0. \tag{3.10}$$

To prove the assertion of the theorem, we proceed by contradiction. Assume that there exists a sequence (λ_n) of eigenvalues such that

$$\lim_{n\to\infty} \operatorname{Re} \lambda_n = 0. \tag{3.11}$$

Let us set $\lambda_n = x_n + iy_n$. Using the relations

$$\sinh(a + ib) = \sinh a \cos b + i \cosh a \sin b,$$
$$\cosh(a + ib) = \cosh a \cos b + i \sinh a \sin b,$$

(3.10), and (3.11), we get

$$-\alpha \sin y_n \sin \frac{y_n}{\eta} + i\eta \sin y_n \cos \frac{y_n}{\eta} + \alpha\eta \cos y_n \cos \frac{y_n}{\eta} \underset{n\to\infty}{\to} 0.$$

This last condition is equivalent to

$$\sin y_n \cos \frac{y_n}{\eta} \underset{n\to\infty}{\longrightarrow} 0 \tag{3.12}$$

and

$$\eta \cos y_n \cos \frac{y_n}{\eta} - \sin y_n \sin \frac{y_n}{\eta} \underset{n\to\infty}{\longrightarrow} 0. \tag{3.13}$$

From (3.12), it follows that either $\underset{n\to\infty}{\longrightarrow} 0$ or $\cos \frac{y_n}{\eta} \underset{n\to\infty}{\longrightarrow} 0$. If one of the alternatives holds, (3.13) will imply the second one. We deduce that (3.12)–(3.13) are equivalent to

$$\sin y_n \underset{n\to\infty}{\longrightarrow} 0 \text{ and } \cos \frac{y_n}{\eta} \underset{n\to\infty}{\longrightarrow} 0. \tag{3.14}$$

Now, if (y_n) is bounded, there exists a subsequence that converges to y such that

$$\sin y = 0 \text{ and } \cos \frac{y}{\eta} = 0.$$

But this is possible if and only if there exists $(k, j) \in \mathbb{Z}^2$ such that $\eta = \frac{2k}{2j+1}$. This contradicts our assumption on η. It follows that (y_n) is unbounded and we may assume that $\mid y_n \mid \underset{n\to\infty}{\longrightarrow} \infty$. In this case, (3.14) is equivalent to the existence of a sequence $(k_n, j_n)_n \subset \mathbb{Z} \times \mathbb{Z}$ such that

$$k_n - \eta \left(j_n + \frac{1}{2} \right) \to 0 \text{ as } n \to \infty$$

or equivalently

$$k_n - \eta j_n \to \frac{\eta}{2} \text{ as } n \to \infty. \tag{3.15}$$

Let us consider the set

$$G = \left\{ k - \eta j, (k, j) \in \mathbb{Z}^2 \right\}. \tag{3.16}$$

It is an additive subgroup of $\mathbb{R}$. A well-known result of algebra asserts that either there exists a real number $a > 0$ such that $G = a\mathbb{Z}$ or $\overline{G} = \mathbb{R}$.

The first alternative holds if and only if $a \in \mathbb{Q}$ since $\mathbb{Z} \subset G$. On the other hand, G is closed in $\mathbb{R}$ and (3.15) holds if and only if $\frac{\eta}{2} \in G$. This means that there exists $j \in \mathbb{Z}$ such that $\eta = 2aj = \frac{2p}{q}$ for some $(p, q) \in \mathbb{Z} \times \mathbb{Z}^*$. But this contradicts the form of η.

The second alternative holds if and only if $\eta \in \mathbb{R} \backslash \mathbb{Q}$. So the sufficiency part is proved.

Assume now that $\eta \neq \frac{2p+1}{q}$ for all $(p, q) \in \mathbb{Z} \times \mathbb{Z}^*$. Equation (3.10) rewrites

$$(\alpha + \eta + \alpha\eta) e^{2\lambda(1+\frac{1}{\eta})} - (\alpha + \eta - \alpha\eta) e^{2\frac{\lambda}{\eta}} - (\alpha - \eta - \alpha\eta) e^{2\lambda} + \alpha - \eta + \alpha\eta = 0.$$

We set

$$\begin{aligned} f(\lambda) &= a_0 e^{2\lambda(1+\frac{1}{\eta})} - a_1 e^{2\frac{\lambda}{\eta}} - a_2 e^{2\lambda} + a_3, \quad \lambda \in \mathbb{C}, \\ a_0 &= \alpha + \eta + \alpha\eta, \quad a_1 = \alpha + \eta - \alpha\eta, \\ a_2 &= \alpha - \eta - \alpha\eta, \quad a_3 = \alpha - \eta + \alpha\eta. \end{aligned}$$

We will apply Rouché's theorem to f to prove that there exists a sequence of eigenvalues such that (3.11) holds true. According to the previous computations, there exists a sequence $(k_n, j_n) \in \mathbb{Z}^2$ such that

$$\varepsilon_n := (2k_n - (2j_n + 1)\eta)\,\frac{\pi}{2} \underset{n\to\infty}{\to} 0. \tag{3.17}$$

Let us set $\lambda_n = ik_n\pi$. To achieve our goal, it suffices to prove that there exists a sequence of positive numbers r_n such that $\lim_{n\to\infty} r_n = 0$ and

$$|f(\lambda) - f'(\lambda_n)(\lambda - \lambda_n)| < |f'(\lambda_n)(\lambda - \lambda_n)| \text{ if } |\lambda - \lambda_n| = r_n. \tag{3.18}$$

To estimate the left-hand term in the previous inequality, we have from Taylor's formula

$$|f(\lambda) - f'(\lambda_n)(\lambda - \lambda_n)| \le |f(\lambda_n)| + \sum_{p\ge 2} \frac{\left|f^{(p)}(\lambda_n)\right|}{p!}\,|\lambda - \lambda_n|^p\,. \tag{3.19}$$

We first have, using (3.17) and noting that $a_0 - a_1 = -\ a_2 + a_3 = 2\alpha\eta$

$$\begin{aligned} |f(\lambda_n)| &= \left|(a_0 - a_1)e^{2i\frac{\varepsilon_n}{\eta}} + a_2 - a_3\right| \\ &= 2\alpha\eta\left|e^{2i\frac{\varepsilon_n}{\eta}} - 1\right| \le 4\alpha\,|\varepsilon_n|\,. \end{aligned} \tag{3.20}$$

Moreover, for $p \ge 1$

$$f^{(p)}(\lambda_n) = -2^p\left[\left(a_0\left(1 + \frac{1}{\eta}\right)^p - \frac{a_1}{\eta^p}\right)e^{2i\frac{\varepsilon_n}{\eta}\pi} + a_2\right] \tag{3.21}$$

and for any $p \ge 2$

$$\begin{aligned} \left|f^{(p)}(\lambda_n)\right| &= 2^p\left|\left(a_0\left(1 + \frac{1}{\eta}\right)^p - \frac{a_1}{\eta^p}\right)e^{2i\frac{\varepsilon_n}{\eta}\pi} + a_2\right| \\ &\le 2^p\left(|a_0|\left(1 + \frac{1}{\eta}\right)^p + \frac{|a_1|}{\eta^p} + |a_2|\right). \end{aligned} \tag{3.22}$$

Thus (3.19), (3.20), and (3.22) imply

$$\begin{aligned} |f(\lambda) - f'(\lambda_n)(\lambda - \lambda_n)| &\le |a_0|\left(e^{2r_n(1+\frac{1}{\eta})} - 2r_n\left(1 + \frac{1}{\eta}\right) - 1\right) \\ &\quad + |a_1|\left(e^{2\frac{r_n}{\eta}} - 2\frac{r_n}{\eta} - 1\right) + |a_2|\left(e^{2r_n} - 2r_n - 1\right) \\ &\le 4\left(\left(1 + \frac{1}{\eta}\right)^2|a_0| + \frac{|a_1|}{\eta^2} + |a_2|\right)r_n^2 \quad \text{for } n \ge n_0. \end{aligned}$$

On the other hand, it is easy to see, using the definition of the a_i, that

$$\begin{aligned} |f'(\lambda_n)(\lambda - \lambda_n)| &= 2\Bigg[\left(\frac{a_1 - a_0}{\eta} - a_0\right)^2 - 2a_2\left(\frac{a_1 - a_0}{\eta} - a_0\right)\cos\left(2\frac{\varepsilon_n}{\eta}\right) \\ &\qquad + a_2^2\Bigg]^{1/2} r_n \\ &\ge 2\alpha r_n. \end{aligned}$$

We then need, in order to satisfy (3.18), to find r_n such that, for n sufficiently large

$$4\alpha\left|\varepsilon_n\right| + 4\left(\left(1+\frac{1}{\eta}\right)^2 |a_0| + \frac{|a_1|}{\eta^2} + |a_2|\right) r_n^2 < 2\alpha r_n.$$

Choosing $r_n = \sqrt{|\varepsilon_n|}$, there will exist $N \in \mathbb{N}$ such that for all $n \geq N$

$$|f(\lambda) - f'(\lambda_n)(\lambda-\lambda_n)| < |f'(\lambda_n)(\lambda-\lambda_n)| \quad \text{for} \quad |\,\lambda - \lambda_n| = \sqrt{|\varepsilon_n|}\,.$$

This ends the proof of the point (i) in Theorem 1.4.

(ii) Assume that $\eta = 1$.

As in the previous proof, computing the essential type amounts to computing the eigenvalues λ of the reduced system, namely,

$$\lambda\begin{pmatrix} U \\ V \end{pmatrix} + M\frac{\partial}{\partial x}\begin{pmatrix} U \\ V \end{pmatrix} + N_0\begin{pmatrix} U \\ V \end{pmatrix} = 0$$

with the boundary conditions

$$U(0) = -V(0),$$
$$\begin{pmatrix} 1 & 1 \\ \alpha & 1-\alpha \end{pmatrix} U(1) = \begin{pmatrix} -1 & 1 \\ \alpha & 1-\alpha \end{pmatrix} V(1).$$

Here

$$N_0(x) = \frac{1}{2}\begin{pmatrix} 0 & -b(x) & 0 & 0 \\ b(x) & 0 & 0 & 0 \\ 0 & 0 & 0 & -b(x) \\ 0 & 0 & b(x) & 0 \end{pmatrix}.$$

The eigenvalues satisfy the equation

$$e^{4\lambda} + \frac{4\alpha}{2\alpha+1}\sin(\bar{b})e^{2\lambda} + \frac{2\alpha-1}{2\alpha+1} = 0.$$

Let $\delta = \frac{4\alpha^2}{(1+2\alpha)^2}\sin^2(\bar{b}) - \frac{2\alpha-1}{2\alpha+1}$. Then we have the following.

- If $\delta < 0$, then all solutions satisfy $e^{2\operatorname{Re}\lambda} = \left|e^{2\lambda}\right| = \frac{2\alpha-1}{2\alpha+1}$. It follows that $\operatorname{Re}\lambda = \frac{1}{2}\ln\frac{2\alpha-1}{2\alpha+1} < 0$.
- If $\delta \geq 0$, then $e^{2\operatorname{Re}\lambda} = |e^{2\lambda}| = |-\frac{2\alpha}{2\alpha+1}\sin(\bar{b}) \pm \sqrt{\delta}|$. Thus

$$\operatorname{Re}\lambda = \frac{1}{2}\ln\left|-\frac{2\alpha}{2\alpha+1}\sin(\bar{b}) \pm \sqrt{\delta}\right| \leq 0.$$

Consequently,

$$s(A_4) = \begin{cases} \left.\begin{array}{ll} \frac{1}{2}\ln(-\frac{2\alpha}{2\alpha+1}\sin(\bar{b}) + \sqrt{\delta}) & \text{if } \sin(\bar{b}) \leq 0 \\ \frac{1}{2}\ln(\frac{2\alpha}{2\alpha+1}\sin(\bar{b}) + \sqrt{\delta}) & \text{if } \sin(\bar{b}) \geq 0 \end{array}\right. & \text{if } \delta \geq 0, \\ \frac{1}{2}\ln\frac{2\alpha-1}{2\alpha+1} & \text{if } \delta < 0. \end{cases}$$

A simple computation shows that

$$s(A_4) = 0 \text{ if and only if } \sin(\bar{b}) = \pm 1.$$

We deduce that

$$s(A_4) < 0 \text{ if and only if } \bar{b} \neq (2k+1)\frac{\pi}{2} \quad \forall\ k \in \mathbb{Z}.$$

Next we use Lemma 3.1 and the definition of essential spectral radius; we get (in the same way as in the proof of Theorem 1.1)

$$\omega_{ess}(T_1) = \omega_{ess}(T_4) = s(A_4).$$

We conclude that the semigroup $T_1(t)$ is exponentially stable in an invariant subspace of finite codimension.

VARIATIONAL INEQUALITY PROBLEMS WITH A CONTINUUM OF SOLUTIONS: EXISTENCE AND COMPUTATION*

P. JEAN-JACQUES HERINGS†, DOLF TALMAN‡, AND ZAIFU YANG§

Abstract. In this paper three sufficient conditions are provided under each of which an upper semicontinuous point-to-set mapping defined on an arbitrary polytope has a connected set of zero points that connect two distinct faces of the polytope. Furthermore, we obtain an existence theorem of a connected set of solutions to a nonlinear variational inequality problem over arbitrary polytopes. These results follow in a constructive way by designing a new simplicial algorithm. The algorithm operates on a triangulation of the polytope and generates a piecewise linear path of points connecting two distinct faces of the polytope. Each point on the path is an approximate zero point. As the mesh size of the triangulation goes to zero, the path converges to a connected set of zero points linking the two distinct faces. As a consequence, our results generalize Browder's fixed point theorem [*Summa Brasiliensis Mathematicae*, 4 (1960), pp. 183–191] and an earlier result by the authors [*Math. Oper. Res.*, 21 (1996), pp. 675–696] on the n-dimensional unit cube. An application in economics and some numerical examples are also discussed.

1. Introduction.

Whenever a mathematical model of some phenomenon is constructed, for instance, in engineering or in economics, the first question to ask is whether a solution to the model exists. A very powerful tool that is used to this end is Brouwer's fixed point theorem; see Brouwer [3]. When the model is not a system of equations but a system of correspondences, Kakutani's fixed point theorem [16] is invoked. An alternative to fixed point theorems consists of using intersection theorems on polytopes, with the KKM theorem of Knaster, Kuratowski, and Mazurkiewicz [17] perhaps the most prominent example. It is well known that there is a close relationship between fixed point theorems and intersection theorems. Yet another alternative consists of results that claim the existence of solutions to variational inequality problems, the existence of stationary points, or the existence of zero points.

For certain models, it is not only important to know that there exists at least one solution, but one would like to show the existence of a continuum of solutions. In economics the existence of a continuum of solutions leads to difficulties in expectation formation of agents, and as a consequence provides scope for endogenously generated fluctuations. A particular example comes from general equilibrium theory with price rigidities, where a continuum of solutions on the unit cube as a polytope is shown to

exist in Herings [13]. It is therefore important to have generally applicable tools that guarantee the existence of a continuum of zero points to a certain system of equations.

This leads us to the following problem: Given a point-to-set mapping $\varphi : P \Longrightarrow \mathbb{R}^n$, with P an arbitrary polytope, *what reasonable conditions can guarantee the existence of a continuum of solutions x to the system*

$$0^n \in \varphi(x),$$

where 0^n denotes the n-dimensional vector of zeros? Our approach to show the existence of a continuum of solutions is to show that there is a connected subset of solutions that links together at least two distinct points, thereby guaranteeing the continuum. In this paper we will show that any upper semicontinuous point-to-set mapping with some mild (boundary) conditions will have a connected set of zero points linking together two distinct faces of the polytope P.

It is well known that under certain conditions a point-to-set mapping defined on a polytope has a solution to the variational inequality problem. We generalize the variational inequality problem and define a parametric variational inequality problem. In this paper we show that under similar conditions a point-to-set mapping defined on a polytope P has a connected set of solutions to the parametric variational inequality problem, called parametrized stationary points. The set of parametrized stationary points connects two distinct faces of P. With respect to some given nonzero vector c, on one of these faces, denoted by F^-, the value $c^\top x$ is minimized for $x \in P$, while on the other face, denoted by F^+, the value $c^\top x$ is maximized for $x \in P$. A special case occurs when both F^- and F^+ are vertices of P and the set of parametrized stationary points contains both these vertices. Under the three different conditions the set of parametrized stationary points is a connected set of zero points linking the two distinct faces F^- and F^+ of P.

We prove the existence results by designing a simplicial variable dimension algorithm on a polytope. This type of algorithm was initiated by Scarf [22]. Simplicial homotopy methods were developed by Eaves [8]. The simplicial restart variable dimension algorithm was introduced by van der Laan and Talman [18] to compute a fixed point of a continuous function from the unit simplex into itself. Such an algorithm generates a unique sequence of simplices of varying dimension in a simplicial subdivision of the set and connects the arbitrarily chosen starting point with an approximate solution. For other recent developments, we refer to Talman and Yamamoto [24], Yamamoto [26], Brown, DeMarzo, and Eaves [5], DeMarzo and Eaves [6], Yang [27, 28], and van der Laan, Talman, and Yang [19]. Allgower and Georg [1], Todd [25], and Yang [28] provide comprehensive treatments of simplicial algorithms.

In this paper a simplicial algorithm is proposed which generates within a simplicial subdivision of P a finite sequence of simplices of varying dimension. This sequence connects two different simplices, one simplex lying in the face F^- of P and the other lying in the face F^+ of P. The sequence of simplices connecting these two simplices is generated by the algorithm through a sequence of semilexicographic pivot steps in a linear system of equations. In case the face F^- is not a vertex of P, the algorithm starts by finding a suitable simplex in F^-. Next it generates a sequence of simplices of varying dimension in P. It is possible that the algorithm returns to F^-. Then it generates a third simplex in F^- from where a sequence of adjacent simplices in P is generated. It is shown that the algorithm eventually finds a simplex in F^- from which a sequence of adjacent simplices reaching F^+ is generated.

Induced by the sequence of adjacent simplices, the algorithm yields a piecewise linear path of parametrized stationary points of a piecewise linear approximation of the underlying mapping. When the mesh size of the simplicial subdivision of P goes to zero the sequence (or at least a subsequence) of piecewise linear paths converges to a connected set of parametrized stationary points of the original mapping. This set has points in common with both faces F^- and F^+.

The results in the paper generalize earlier results of Browder [4], Mas-Colell [20], and Herings, Talman, and Yang [15]. In the case of Browder's theorem the polytope is the Cartesian product of a polytope of one dimension less and the unit interval $[0,1]$, while c is the unit vector with the one on the last position. Mas-Colell's result is an extension of Browder's result to deal with correspondences. Both Browder and Mas-Colell proved their results via a rather sophisticated machinery. Since our approach here is constructive, we therefore also obtain an alternative but constructive proof for their results. In Herings, Talman, and Yang [15] the polytope equals the unit cube and the vector c is the vector of ones. In both Browder's and Mas-Colell's theorems, a connected set of fixed points is obtained connecting the levels 0 and 1, whereas the result on the unit cube yields a connected set of zero points connecting the vector of zeros and the vector of ones.

Intersection theorems with a continuum of intersection points can be found in Freidenfelds [9] and Herings and Talman [14]. Although Freidenfelds's intersection theorem typically has a continuum of intersection points, this is not necessarily the case. Freidenfelds's result generalizes the intersection theorem of Scarf [22]. Herings and Talman's results generalize a number of intersection theorems on the unit simplex, including the Scarf-result and the KKM-result, to intersection theorems on the unit cube and show the existence of a continuum of intersection points. The reader should be aware that compared with a large amount of existence results for a single fixed or zero point, existence results for a continuum of fixed or zero points are very rare.

This paper is organized as follows. In section 2 we state the problem and in section 3 we give three sufficient conditions for the existence of a connected set of zero points of an upper semicontinuous point-to-set mapping over an arbitrary polytope which link together two distinct faces of the polytope. An example is also given. In section 4 we introduce the algorithm, prove its convergence, and illustrate the algorithm by an example. In section 5 we analyze the accuracy of the approximation of zero points and prove the existence theorems. In section 6 we discuss a more general case. In section 7 we derive as special cases Browder's and Mas-Colell's theorems and an earlier result of the authors on the unit cube, and we also give an interesting economic application.

2. The problem.

Let I_m denote the set of the first m positive integers. Consider an arbitrary full-dimensional polytope P that has the following representation as a polyhedron:

$$P = \{x \in \mathbb{R}^n \mid {a^i}^\top x \leq b_i \, \forall i \in I_m\}.$$

For each subset I of I_m, define

$$F(I) = \{x \in P \mid {a^i}^\top x = b_i \, \forall i \in I\}.$$

Then $F(I)$ is called a *face* of P unless it is empty. Note that $F(\emptyset) = P$. Let

$$\mathcal{I} = \{I \subset I_m \mid F(I) \text{ is a face of } P\}.$$

A face F of the set $F(I)$ of dimension one lower than the dimension of $F(I)$ is called a *facet* of $F(I)$. The polytope P is said to be *simple* if the dimension of any face $F(I)$ of P is equal to $n - |I|$. Throughout the paper, whenever we use a polytope

P, it is assumed that P is simple and that its representation as a polyhedron has no redundant constraints.

We have the following observations.

(i) For each face F of P, the set $I \in \mathcal{I}$ with $F = F(I)$ is unique and is given by the set $\{i \in I_m \mid a^{i\top} x = b_i \ \forall x \in F\}$.

(ii) The set $F(I)$ is a vertex of P if and only if $I \in \mathcal{I}$ with $|I| = n$.

(iii) If $I \in \mathcal{I}$, then $I \setminus \{i\} \in \mathcal{I}$ for any $i \in I$.

(iv) For some $I \in \mathcal{I}$, F is a facet of $F(I)$ if and only if $F = F(I \cup \{i\})$ for some $i \notin I$ with $I \cup \{i\} \in \mathcal{I}$.

(v) For any $I \in \mathcal{I}$, the vectors a^i with $i \in I$ are linearly independent.

Let c be an arbitrary nonzero vector in $\mathbb{R}^n$. Then F^+ will denote the face of P such that for each $x^+ \in F^+$ it holds that $c^\top x^+ = \max_{x \in P} c^\top x$, and F^- will denote the face of P such that for each $x^- \in F^-$ it holds that $c^\top x^- = \min_{x \in P} c^\top x$. Let $t^+ = c^\top x^+$ for $x^+ \in F^+$ and $t^- = c^\top x^-$ for $x^- \in F^-$. Since P is full-dimensional, it follows that $t^- < t^+$ and therefore $F^- \cap F^+ = \emptyset$. We define

$$I^+ = \{i \in I_m \mid a^{i\top} x = b_i \ \forall x \in F^+\},$$
$$I^- = \{i \in I_m \mid a^{i\top} x = b_i \ \forall x \in F^-\}.$$

So $F^+ = F(I^+)$ and $F^- = F(I^-)$.

We need some further notation. For each $I \in \mathcal{I}$, we define

$$A(I) = \left\{ y \in \mathbb{R}^n \mid y = \sum_{i \in I} \mu_i a^i + \beta c,\ \mu_i \geq 0 \ \forall i \in I, \text{ and } \beta \in \mathbb{R} \right\},$$

$$A_0(I) = \left\{ y \in \mathbb{R}^n \mid y = \sum_{i \in I} \mu_i a^i,\ \mu_i \geq 0 \ \forall i \in I \right\},$$

$$A^*(I) = \{x \in \mathbb{R}^n \mid x^\top y \leq 0 \ \forall y \in A(I)\},$$
$$A_0^*(I) = \{x \in \mathbb{R}^n \mid x^\top y \leq 0 \ \forall y \in A_0(I)\}.$$

Note that $A(\emptyset) = \{y \in \mathbb{R}^n \mid y = \beta c,\ \beta \in \mathbb{R}\}$, $A_0(\emptyset) = \{0^n\}$, $A^*(\emptyset) = \{x \in \mathbb{R}^n \mid x^\top c = 0\}$, and $A_0^*(\emptyset) = \mathbb{R}^n$. Moreover, for any $I \in \mathcal{I}$ we have that $A_0(I) \subset A(I)$, $A^*(I) \subset A_0^*(I)$, $A^*(I) \cap A(I) = \{0^n\}$, and $A_0^*(I) \cap A_0(I) = \{0^n\}$. We may interpret $A(I)$ and $A_0(I)$ as normal cones to the boundary of P and $A^*(I)$ and $A_0^*(I)$ as tangent cones. The pairs $(A(I), A^*(I))$ and $(A_0(I), A_0^*(I))$ may be viewed as primal and dual pairs as well; see, e.g., Aubin [2].

Let $\varphi : P \Longrightarrow \mathbb{R}^n$ be a correspondence that satisfies the following assumption.

ASSUMPTION 2.1. *The correspondence $\varphi : P \Longrightarrow \mathbb{R}^n$ is nonempty valued, compact valued, convex valued, and upper semicontinuous.*

For an arbitrary function $f : P \to \mathbb{R}^n$, the *stationary point* (or *variational inequality*) *problem* for f on the polytope P is to find a point $x^* \in P$ such that

$$(x^* - x)^\top f(x^*) \geq 0 \ \forall x \in P.$$

Such a point x^* is called a *stationary point* of f on P. It is well known that a continuous function on a convex compact set has a stationary point; see Hartman and Stampacchia [11] and Eaves [8].

In the following we give the definition of a stationary point of a correspondence on the polytope P with respect to the vector c.

Definition 2.2. *A point $x^* \in P$ is a stationary point of a correspondence φ on the polytope P with respect to the nonzero vector c if there exists $f \in \varphi(x^*)$ such that $(x^* - x)^\top f \geq 0 \forall x \in P$ satisfying $c^\top x = c^\top x^*$.*

We call the problem of finding a stationary point with respect to a nonzero vector c a *parametric variational inequality problem.* A solution to it is called a *parametrized stationary point.* Now we have the following simple but important observation.

Lemma 2.3. *A point $x^* \in P$ is a parametrized stationary point of the mapping φ on P with respect to c if and only if for some $I \in \mathcal{I}$ it holds that $x^* \in F(I)$ and $\varphi(x^*) \cap A(I) \neq \emptyset$.*

Proof. Let x^* be a parametrized stationary point of φ on P with respect to c. Hence there exists $f \in \varphi(x^*)$ such that $(x^* - x)^\top f \geq 0 \forall x \in P$ satisfying $c^\top x = c^\top x^*$; i.e., x^* maximizes $x^\top f$ subject to ${a^i}^\top x \leq b_i, i \in I_m$, and $c^\top x = c^\top x^*$. Therefore, there exist $\mu_i \geq 0, i \in I_m$, and $\beta \in \mathbb{R}$ satisfying

$$f = \sum_{i \in I_m} \mu_i a^i + \beta c,$$

and $\mu_i = 0$ if ${a^i}^\top x^* < b_i$. Let $I = \{i \in I_m \mid {a^i}^\top x^* = b_i\}$. Then $x^* \in F(I)$ and $f \in A(I) \cap \varphi(x^*)$.

Next let $x^* \in P$ be such that $x^* \in F(I)$ and $A(I) \cap \varphi(x^*) \neq \emptyset$ for some $I \in \mathcal{I}$. Take any $f \in A(I) \cap \varphi(x^*)$. Then $f \in \varphi(x^*)$ and there exists $\mu_i \geq 0, i \in I$, and $\beta \in \mathbb{R}$ satisfying

$$f = \sum_{i \in I} \mu_i a^i + \beta c.$$

Note that ${a^i}^\top x^* = b_i \forall i \in I$, and for any $x \in P$, ${a^i}^\top x \leq b_i \forall i \in I$. Thus ${x^*}^\top f = \sum_{i \in I} \mu_i b_i + \beta c^\top x^* \geq x^\top f$ for all $x \in P$ with $x^\top c = {x^*}^\top c$. By definition, x^* is a stationary point of φ on P with respect to c. □

We show the existence of a continuum of parametrized stationary points of the correspondence φ with respect to the vector c. A point $x^* \in P$ is called a *zero point* of the mapping φ if $0^n \in \varphi(x^*)$. Any zero point of φ is a parametrized stationary point. The main purpose of this paper is to find conditions on φ which enable us to guarantee the existence and the computation of a continuum of zero points of a correspondence φ on P such that it contains points of both F^- and F^+.

3. Existence conditions.

The first result is on the existence of parametrized stationary points.

Theorem 3.1. *Let $\varphi : P \Longrightarrow \mathbb{R}^n$ be any correspondence satisfying Assumption* 2.1 *and let $c \in \mathbb{R}^n \setminus \{0^n\}$ be given. Then there exists a connected set C of parametrized stationary points of φ on P with respect to c such that $C \cap F^- \neq \emptyset$ and $C \cap F^+ \neq \emptyset$.*

The theorem makes clear that there are many parametrized stationary points. To be more precise, there exists a continuum of them with a special topological structure. The set of parametrized stationary points has a connected subset that links the two faces F^- and F^+.

In order to obtain the existence of a continuum of zero points, we need to impose certain conditions on the correspondence φ. The following three results list sufficient conditions for the existence of a continuum of zero points of φ.

Theorem 3.2. *Let $\varphi : P \Longrightarrow \mathbb{R}^n$ be any correspondence satisfying Assumption* 2.1 *and let $c \in \mathbb{R}^n \setminus \{0^n\}$. If for any $x \in F(I), I \in \mathcal{I}$, it holds that $\varphi(x) \cap A(I) \subset \{0^n\}$, then there exists a connected set C of zero points of φ such that $C \cap F^- \neq \emptyset$ and $C \cap F^+ \neq \emptyset$.*

The condition in the theorem states that for any x in the face $F(I)$ of P the image $\varphi(x)$ may not have nonzero elements in common with $A(I)$.

THEOREM 3.3. *Let $\varphi : P \Longrightarrow \mathbb{R}^n$ be any correspondence satisfying Assumption* 2.1 *and let $c \in \mathbb{R}^n \setminus \{0^n\}$. If for any $x \in F(I), I \in \mathcal{I}$, it holds that*

(i) $\varphi(x) \cap A_0^*(I) \cap A(I) \subset \{0^n\}$,

(ii) $\varphi(x) \cap A_0^*(I) \neq \emptyset$,

then there exists a connected set C of zero points of φ such that $C \cap F^- \neq \emptyset$ and $C \cap F^+ \neq \emptyset$.

The conditions in the theorem imply that for any x in the face $F(I)$ of P the image $\varphi(x)$ may not have nonzero elements in common with $A(I) \cap A_0^*(I)$ and that at least one element of $\varphi(x)$ lies in $A_0^*(I)$.

THEOREM 3.4. *Let $\varphi : P \Longrightarrow \mathbb{R}^n$ be any correspondence satisfying Assumption* 2.1*, and let $c \in \mathbb{R}^n \setminus \{0^n\}$. If for any $x \in F(I), I \in \mathcal{I}$, it holds that*

$$\varphi(x) \cap A^*(I) \neq \emptyset,$$

then there exists a connected set C of zero points of φ such that $C \cap F^- \neq \emptyset$ and $C \cap F^+ \neq \emptyset$.

The condition in the theorem says that for any x in the face $F(I)$ of P at least one element of $\varphi(x)$ lies in $A^*(I)$.

The three theorems state different conditions for which a continuum of zero points can be shown to exist. Moreover, there is a logical order in these sufficient conditions. Theorem 3.2 states a weak condition, but one that holds for all elements of $\varphi(x)$. Theorem 3.4 gives a strong condition but requires this condition to hold for only one element in $\varphi(x)$. Theorem 3.3 is in between: it gives a very weak condition for all elements in $\varphi(x)$ together with a rather weak condition for some element in $\varphi(x)$.

The following result claims that for the special case where φ is a function f, Theorem 3.2 is the strongest and Theorem 3.4 the weakest. Note that Assumption 2.1 implies that the function f is continuous.

THEOREM 3.5. *Let P be any polytope and let $c \in \mathbb{R}^n \setminus \{0^n\}$. The collection of functions satisfying the conditions of Theorem* 3.2 *contains the collection of functions satisfying the conditions of Theorem* 3.3*, which contains the collection of functions satisfying the conditions of Theorem* 3.4.

Proof. Suppose that a function f from P to $\mathbb{R}^n$ satisfies the conditions of Theorem 3.4. Take any x in $F(I)$, so $f(x) \in A^*(I)$. Since $A^*(I) \subset A_0^*(I)$ and $A(I) \cap A^*(I) = \{0^n\}$ we obtain that $f(x) \in A_0^*(I)$ and $f(x)$ not in $A(I)$ unless $f(x) = 0^n$. Hence the conditions of Theorem 3.3 are satisfied. Suppose now that a function satisfies the conditions of Theorem 3.3. Again take any x in $F(I)$, so $f(x) \in A_0^*(I)$ and $f(x)$ not in $A(I) \cap A_0^*(I)$ unless $f(x) = 0^n$. Hence $f(x)$ not in $A(I)$ unless $f(x) = 0^n$. □

That Theorems 3.2, 3.3, and 3.4 are mutually exclusive for correspondences follows from the fact that in case of correspondences the image $\varphi(x)$ of any point x in P might consist of more than one element. For example, for a point x in the face $F(I)$ of P it is required in Theorem 3.2 that no nonzero element of $\varphi(x)$ lies in $A(I)$ which does not imply that at least one such element should lie in $A^*(I)$ as required in the conditions of Theorem 3.4. On the other hand if for an x in $F(I)$ it holds that some nonzero element $f \in \varphi(x)$ lies in $A^*(I)$, as in the conditions of Theorem 3.4, then this implies that f indeed does not lie in $A(I)$ but not necessarily that all the other elements of $\varphi(x)$ also do not lie in $A(I)$ as required in Theorem 3.2. Similar remarks can be made when comparing the conditions of Theorem 3.3 with the conditions in the other two theorems.

FIG. 3.1. *The set of zero points of f on P in Example* 3.1 *linking F^- and F^+.*

The theorems above will be proved in a constructive manner in the following sections. Their applications will be discussed in section 7. To conclude this section we will give a numerical example to illustrate the existence of a connected set of zero points on a two-dimensional diamond and then we will illustrate the algorithm with this example in the next section.

Example 3.1. Let the polytope P, illustrated in Figure 3.1, be given by

$$P = \{x \in \mathbb{R}^2 \mid |x_2| \leq 1/2,\ |x_1| + |x_2| \leq 1\}.$$

The vector c and the function f on P are given by $c = (1,0)^\top$ and

$$f(x) = \left(2 - x_1^2 - (x_2+1)^2, \sqrt{2 - x_1^2} - x_2 - 1\right)^\top.$$

Clearly, F^- and F^+ correspond to $(-1,0)^\top$, $(1,0)^\top$, vertices of P, respectively. Furthermore, if x lies on the boundary of P, then $f_1(x) > 0$ and $f_2(x) > 0$ when $x_2 < 0$, and $f_1(x) < 0$ and $f_2(x) < 0$ when $x_2 > 0$. Also, $f_1(x) = 0$ whenever $f_2(x) = 0$. Note that P can be rewritten as

$$\begin{aligned} P = \{x \in \mathbb{R}^2 \quad | \quad & x_1 + x_2 \leq 1,\ x_2 \leq 1/2,\ -x_1 + x_2 \leq 1, \\ & -x_1 - x_2 \leq 1,\ -x_2 \leq 1/2,\ x_1 - x_2 \leq 1\}. \end{aligned}$$

One can easily verify that f is continuous and satisfies the condition of Theorem 3.2. So it follows that there exists a connected set of zero points of f on P linking both $(-1,0)^\top$ and $(1,0)^\top$. In fact this set equals the circle segment $\{x \in P \mid x_1^2+(x_2+1)^2 = 2\}$; see Figure 3.1.

4. The algorithm and its convergence proof. In this section we describe an algorithm on the polytope P that generates a piecewise linear path of parametrized stationary points, with respect to the given nonzero vector c, of a piecewise linear approximation of the mapping φ. The piecewise linear approximation is taken with respect to some simplicial subdivision of the set P. In this and the following sections we assume that the faces F^- and F^+ are vertices of P, denoted by x^- and x^+, respectively. In that case the piecewise linear path generated by the algorithm contains both x^- and x^+ and can be traced by a sequence of semilexicographic pivot steps in a system of linear equations. The general case is discussed in section 6.

For a nonnegative integer t, a t-dimensional simplex or t-simplex, denoted by σ, is defined by the convex hull of $t+1$ affinely independent points $x^1, \ldots, x^{t+1}$ in $\mathbb{R}^n$. We often write $\sigma = \sigma(x^1, \ldots, x^{t+1})$ and call $x^1, \ldots, x^{t+1}$ the vertices of σ. A $(t-1)$-simplex being the convex hull of t vertices of σ is said to be a facet of σ. The facet $\tau(x^1, \ldots, x^{i-1}, x^{i+1}, \ldots, x^{t+1})$ is called the facet of $\sigma(x^1, \ldots, x^{t+1})$ opposite to the vertex x^i. For k, $0 \le k \le t$, a k-simplex being the convex hull of $k+1$ vertices of σ is said to be a k-face or face of σ. A finite collection $\mathcal{T}$ of n-simplices is a triangulation of the polytope P if

(i) P is the union of all simplices in $\mathcal{T}$;

(ii) the intersection of any two simplices of $\mathcal{T}$ is either the empty set or a common face of both.

Let $\mathcal{T}$ be any triangulation of P. Then every face $F(I)$ of P is subdivided into t-simplices, where $t = n - |I|$. For example we can take the V-triangulation of Talman and Yamamoto [24]. Since $\mathcal{T}$ is finite and P is compact, every facet τ of an $(n-|I|)$-simplex σ in $F(I)$ either lies in the boundary of $F(I)$ and is only a facet of σ or is a facet of exactly one other $(n-|I|)$-simplex in $F(I)$. Let f be a simplicial approximation of φ with respect to $\mathcal{T}$. This means that $f(x) \in \varphi(x)$ for each vertex of $\mathcal{T}$ and f is affine on each simplex of $\mathcal{T}$.

A row vector is *lexicopositive* if it is a nonzero vector and its first nonzero entry is positive. A matrix is said to be *lexicopositive* if all its rows are lexicopositive. A matrix is said to be *semilexicopositive* if each row except possibly the last row is lexicopositive.

Definition 4.1. *Let $\tau(x^1, \ldots, x^t)$ be a $(t-1)$-simplex in $F(I)$, where $I \in \mathcal{I}$ with $I = \{i_{t+1}, \ldots, i_n\}$, $t = n - |I|$. The $(n+1) \times (n+1)$ matrix*

$$A_{\tau,I} = \begin{bmatrix} 1 & \cdots & 1 & 0 & \cdots & 0 & 0 \\ -f(x^1) & \cdots & -f(x^t) & a^{i_{t+1}} & \cdots & a^{i_n} & c \end{bmatrix}$$

is the label matrix of τ with respect to I. The simplex τ is I-complete if $A_{\tau,I}^{-1}$ exists and is semilexicopositive; i.e., the first nonzero entry in every row, except possibly the last one, is positive.

Notice that if for an I-complete simplex τ we change the ordering of the first n columns of the matrix $A_{\tau,I}$, the inverse of the resulting matrix still exists and is semilexicopositive. Clearly, if, for some $I \in \mathcal{I}$, a $(t-1)$-simplex $\tau(x^1, \ldots, x^t)$ is an I-complete facet of a simplex $\sigma(x^1, \ldots, x^{t+1})$ in some face $F(I)$, then the system of $n+1$ linear equations with $n+2$ variables

$$\sum_{j=1}^{t+1} \lambda_j \begin{pmatrix} 1 \\ -f(x^j) \end{pmatrix} + \sum_{i \in I} \mu_i \begin{pmatrix} 0 \\ a^i \end{pmatrix} + \beta \begin{pmatrix} 0 \\ c \end{pmatrix} = \begin{pmatrix} 1 \\ 0^n \end{pmatrix} \tag{$*$}$$

has a solution $(\lambda, \mu, \beta) = (\lambda_1, \ldots, \lambda_{t+1}, (\mu_i)_{i \in I}, \beta)$ satisfying $\lambda_j \ge 0$ for $j \in I_{t+1}$ and $\mu_i \ge 0$ for $i \in I$, with $\lambda_{t+1} = 0$. Let x be defined by $x = \sum_{j=1}^{t+1} \lambda_j x^j$ at a solution (λ, μ, β) of $(*)$; then x lies in σ and is a parametrized stationary point of f with respect to c.

The following result is a special case of Theorem 2.6 in Fujishige and Yang [10] and will be used later. This result has been proved in a constructive way.

Theorem 4.2. *Consider any polytope* Q *given by* $\mathrm{Q} = \{x \in \mathbb{R}^n \mid c^{i\top} x \le d_i,\ i \in I_n$ *and* $c^{0\top} x = d_0\}$. *Assume that* Q *is an $(n-1)$-dimensional simple polytope with no redundant constraints. For any $g \in \mathbb{R}^n$, there exists a unique subset $I = \{j_1, \ldots, j_{n-1}\}$*

of I_n with $|I| = n-1$ such that the matrix

$$B^{-1} = \left[\begin{array}{cccccc} 1 & 0 & 0 & \cdots & 0 & 0 \\ g & c^{j_1} & c^{j_2} & \cdots & c^{j_{n-1}} & c^0 \end{array} \right]^{-1}$$

exists and is semilexicopositive.

We now show that each of the two 0-simplices $\{x^-\}$ and $\{x^+\}$ is I-complete in the face $F(I)$ for a unique index set $I \in \mathcal{I}$ containing $n-1$ indices.

Lemma 4.3. *Let $x^1 = x^-$ and $\tau = \{x^1\}$. Then there exists a unique subset $I = \{j_1, \ldots, j_{n-1}\}$ of I^- with $|I| = n-1$ such that τ is an I-complete 0-simplex in $F(I)$.*

Proof. Recall that x^- is a unique solution to the problem

$$\min c^\top x \text{ s.t. } x \in P.$$

By duality theory there exists a unique solution $\lambda_i > 0 \forall i \in I^-$ such that $-c = \sum_{i \in I^-} \lambda_i a^i$. In other words, the vectors c and a^i, $i \in I^-$, are affinely independent. Consider the following polyhedron:

$$W = \{x \in \mathbb{R}^n \mid {a^i}^\top x \leq 1, i \in I^-, c^\top x \leq 1\}.$$

It is easy to see that W is bounded and contains 0^n in its interior and therefore is an n-dimensional polytope. Then the set

$$Q = \{x \in \mathbb{R}^n \mid {a^i}^\top x \leq 1, i \in I^-, c^\top x = 1\}$$

is an $(n-1)$-dimensional polytope. Let $g = -f(x^-)$. Now all the conditions of Theorem 4.2 are satisfied. So there exists a unique subset $I = \{j_1, \ldots, j_{n-1}\}$ of I^- with $|I| = n-1$ such that the matrix

$$B^{-1} = \left[\begin{array}{cccccc} 1 & 0 & 0 & \cdots & 0 & 0 \\ -f(x^-) & a^{j_1} & a^{j_2} & \cdots & a^{j_{n-1}} & c \end{array} \right]^{-1}$$

exists and is semilexicopositive. This means that τ is I-complete. Clearly, τ lies in $F(I)$ since $F(I^-)$ is a subset of $F(I)$ and $\tau = F(I^-)$. □

Lemma 4.4. *Let $x^1 = x^+$ and $\tau = \{x^1\}$. Then there exists a unique subset $I = \{j_1, \ldots, j_{n-1}\}$ of I^+ with $|I| = n-1$ such that τ is an I-complete 0-simplex in $F(I)$.*

Proof. Notice that x^+ is the unique solution to the problem

$$\max c^\top x \text{ s.t. } x \in P.$$

By duality theory there exists a unique solution $\lambda_i > 0 \forall i \in I^+$ such that $c = \sum_{i \in I^+} \lambda_i a^i$. In other words, the vectors $-c$ and a^i, $i \in I^+$, are affinely independent. Consider the following polyhedron:

$$W = \{x \in \mathbb{R}^n \mid {a^i}^\top x \leq 1, i \in I^+, -c^\top x \leq 1\}.$$

It is easy to see that W is an n-dimensional polytope. Then the set

$$Q = \{x \in \mathbb{R}^n \mid {a^i}^\top x \leq 1, i \in I^+, c^\top x = -1\}$$

is an $(n-1)$-dimensional polytope. Let $g = -f(x^+)$. Now all the conditions of Theorem 4.2 are satisfied. So there exists a unique subset $I = \{j_1, \ldots, j_{n-1}\}$ of I^+ with $|I| = n-1$ such that the matrix

$$B^{-1} = \begin{bmatrix} 1 & 0 & 0 & \cdots & 0 & 0 \\ -f(x^+) & a^{j_1} & a^{j_2} & \cdots & a^{j_{n-1}} & c \end{bmatrix}^{-1}$$

exists and is semilexicopositive. This means that τ is I-complete. Clearly, τ lies in $F(I)$ since $F(I^+)$ is a subset of $F(I)$ and τ lies in $F(I^+)$. □

The following lemma is well known in linear programming theory and can easily be proved. We will invoke it later. Let B be a matrix. We denote its ith row by $B_{i.}$ and its jth column by $B_{.j}$.

Lemma 4.5. *Let $B = (B_{.1}, \ldots, B_{.n+1})$ be any nonsingular $(n+1)\times(n+1)$ matrix and let x be any vector in $\mathbb{R}^{n+1}$. Let $k \in I_{n+1}$ and*

$$\bar{B} = (B_{.1}, \ldots, B_{.k-1}, x, B_{.k+1}, \ldots, B_{.n+1}).$$

Then either $(B^{-1}x)_k = 0$ and $\bar{B}$ is singular, or $(B^{-1}x)_k \neq 0$, $\bar{B}$ is nonsingular, and $\bar{B}^{-1}$ is given by

$$\bar{B}^{-1} = \begin{bmatrix} (B^{-1})_{1.} - \frac{(B^{-1}x)_1}{(B^{-1}x)_k}(B^{-1})_{k.} \\ \vdots \\ (B^{-1})_{k-1.} - \frac{(B^{-1}x)_{k-1}}{(B^{-1}x)_k}(B^{-1})_{k.} \\ \frac{1}{(B^{-1}x)_k}(B^{-1})_{k.} \\ (B^{-1})_{k+1.} - \frac{(B^{-1}x)_{k+1}}{(B^{-1}x)_k}(B^{-1})_{k.} \\ \vdots \\ (B^{-1})_{n+1.} - \frac{(B^{-1}x)_{n+1}}{(B^{-1}x)_k}(B^{-1})_{k.} \end{bmatrix}.$$

Lemma 4.6. *Let σ be a t-simplex in $F(I)$, where $I \in \mathcal{I}$, $t = n - |I|$, and $I = \{i_{t+1}, \ldots, i_n\}$. If σ has an I-complete facet τ, then exactly one of the following two cases occurs:*

1. *The simplex σ is an $\bar{I}$-complete simplex in $F(\bar{I})$, where $\bar{I} = I\backslash\{i\}$ for precisely one index $i \in I$.*
2. *The simplex σ has exactly one other I-complete facet $\bar{\tau}$.*

Proof. Let x^{t+1} be the vertex of σ opposite to τ, and let $y = A_{\tau,I}^{-1}(1, -f(x^{t+1})^\top)^\top$. Notice that $y \neq 0^{n+1}$. Let $K = \{i \in I_n \mid y_i > 0\}$. We first prove $|K| > 0$. Since $A_{\tau,I}y = (1, -f(x^{t+1})^\top)^\top$, we have $\sum_{i=1}^t y_i = 1$. This implies that there exists at least one index $i \in I_t$ such that $y_i > 0$. Hence K is nonempty.

Consider the ratio vectors $(1/y_j)(A_{\tau,I}^{-1})_{j.} \forall j \in K$. Choose $k \in K$ such that the kth ratio vector is the minimum in the lexicographic order over all such ratio vectors. Since $A_{\tau,I}^{-1}$ is regular, k is uniquely determined. Now, we consider the following two cases.

(1) If $k \in I_n \backslash I_t$, then let $l = i_k$ and $\bar{I} = I\backslash\{l\}$. Clearly, $\bar{I} \in \mathcal{I}$ and σ is in $F(\bar{I})$. Let B be the matrix obtained from $A_{\tau,I}$ by replacing its kth column by $(1, -f(x^{t+1})^\top)^\top$. It follows from Lemma 4.5 that B^{-1} exists and is semilexicopositive. By reordering the columns of B we get $A_{\sigma,\bar{I}}$ whose inverse exists and is semilexicopositive. So σ is $\bar{I}$-complete.

(2) If $k \in I_t$, then let $\bar{\tau}$ be the facet of σ opposite to the vertex x^k. Using Lemma 4.5, it follows from the choice of k that $A^{-1}_{\bar{\tau},I}$ exists and is semilexicopositive. Hence $\bar{\tau}$ is an I-complete $(t-1)$-simplex in $F(I)$.

It follows immediately from Lemma 4.5 that if any column other than the kth column is replaced, then the inverse of the resulting matrix is not semilexicopositive. □

In Lemma 4.8 we consider the analogous case of making a lexicographic pivot step with a column $(1, a^{i\top})^\top$. First we need the next lemma.

LEMMA 4.7. *For any set $I \in \mathcal{I}$ with $I \neq I^-$ and $I \neq I^+$, there exist no solutions λ_0, λ_i, $i \in I$, to $\sum_{i\in I} \lambda_i a^i = \lambda_0 c$ such that $\lambda_i \leq 0 \forall i \in I$ and $\sum_{i\in I} \lambda_i < 0$.*

Proof. We need to consider the following three cases:

Case (1). If $\lambda_0 = 0$, then $\sum_{i\in I} \lambda_i a^i = \lambda_0 c = 0^n$ contradicts the fact that all vectors a^i, $i \in I$, are linearly independent.

Case (2). If $\lambda_0 < 0$, then by duality theory $\sum_{i\in I} \lambda_i a^i = \lambda_0 c$ and $I \neq I^+$ contradicts the fact that

$$c^\top x^+ = \max_{x\in P} c^\top x.$$

Case (3). If $\lambda_0 > 0$, then by duality theory $\sum_{i\in I} \lambda_i a^i = \lambda_0 c$ and $I \neq I^-$ contradicts the fact that

$$c^\top x^- = \min_{x\in P} c^\top x. \qquad \square$$

LEMMA 4.8. *Let σ be an I-complete $(t-1)$-simplex in $F(I)$, where $I \in \mathcal{I}$, $t = n - |I|$, and $I = \{i_{t+1}, \ldots, i_n\}$. If σ is in $F(\bar{I})$ and $\bar{I} \neq I^-$ or $\bar{I} \neq I^+$, where $\bar{I} = I \cup \{l\} \in \mathcal{I}$ for some $l \in I_m \setminus I$, then exactly one of the following two cases occurs:*

(1) *There exists a unique set $J \in \mathcal{I}$ with $|J| = |I|$ and $J \neq I$ so that σ is in $F(J)$ and is J-complete.*

(2) *There exists exactly one facet τ of σ which is in $F(\bar{I})$ and is $\bar{I}$-complete.*

Proof. Let $x = (0, a^{l\top})^\top$ and $y = A^{-1}_{\sigma,I} x$. Note that $y \neq 0^{n+1}$. Let $K = \{i \in I_n \mid y_i > 0\}$. Note that $A_{\sigma,I} y = (0, a^{l\top})^\top$. We need to consider the following two cases.

Case (i). If there exists an index $j \in I_t$ such that $y_j < 0$, then there must exist an index $i \in I_t$ such that $y_i > 0$ since $\sum_{k=1}^t y_i = 0$. Hence K is nonempty.

Case (ii). Suppose that $y_i = 0 \forall i \in I_t$. If $y_i \leq 0 \forall i = t+1, t+2, \ldots, n$, then we have that $a^l = \sum_{i=t+1}^n y_i a^{j_{i-t}} + y_{n+1} c$. By Lemma 4.7 it is impossible since $\bar{I}$ is neither equal to I^- nor equal to I^+. Hence there exists at least one index $i \in I_n \setminus I_t$ such that $y_i > 0$. Again K is nonempty.

Consider the ratio vectors $(1/y_j)(A^{-1}_{\sigma,I})_{j\cdot} \forall j \in K$. Choose $k \in K$ such that the kth ratio vector is the minimum in the lexicographic order over all such ratio vectors. Since $A^{-1}_{\tau,I}$ is regular, k is uniquely determined. Now, we consider the following two cases.

(1) If $k \in I_n \setminus I_t$, then let $p = i_k$ and $J = I \cup \{l\} \setminus \{p\}$. Clearly, $J \in \mathcal{I}$, $J \neq I$, $|J| = |I|$, and σ is in $F(J)$. Let B be the matrix obtained from $A_{\sigma,I}$ by replacing its kth column by x. It follows from Lemma 4.5 that B^{-1} exists and is semilexicopositive. It is clear that $A_{\sigma,J} = B$. Thus σ is a J-complete $(t-1)$-simplex in $F(J)$.

(2) If $k \in I_t$, then let τ be the facet of σ opposite to the vertex x^k. Clearly, τ is a $(t-2)$-simplex in $F(\bar{I})$. Let B be the matrix obtained from $A_{\sigma,I}$ by replacing its kth column by x. It follows from Lemma 4.5 that B^{-1} exists and is semilexicopositive. By reordering the columns of B we get $A_{\tau,\bar{I}}$, whose inverse also exists and is semilexicopositive. So τ is an $\bar{I}$-complete $(t-2)$-simplex in $F(\bar{I})$.

Again it follows from Lemma 4.5 that if any other column is replaced, then the new matrix is no longer semilexicopositive. ∎

We construct a graph $G = (\mathcal{V}, \mathcal{A})$, where $\mathcal{V}$ denotes the set of nodes and $\mathcal{A}$ denotes the set of edges. Each I-complete $(n - |I| - 1)$-simplex is a *node* in $\mathcal{V}$. An I-complete $(n - |I| - 1)$-simplex τ^1 in $F(I)$ and a J-complete $(n - |J| - 1)$-simplex τ^2 in $F(J)$ are said to be *adjacent* complete simplices if $I = J = L$ and τ^1 and τ^2 are both facets of an $(n - |L|)$-simplex σ in $F(L)$, or τ^1 is a facet of τ^2 and τ^2 is an $(n - |I|)$-simplex in $F(I)$, or τ^2 is a facet of τ^1 and τ^1 is an $(n - |J|)$-simplex in $F(J)$. Two adjacent complete simplices τ^1 and τ^2 are connected by an edge $e = \{\tau^1, \tau^2\} \in \mathcal{A}$. The degree of a node τ in G is defined to be the number of nodes connected with it, denoted by $deg(\tau)$. A path in G from node $\tau^0 = \{x^-\}$ to node τ^l is defined as a sequence of the form $(\tau^0, e_1, \tau^1, \dots, e_l, \tau^l)$, where τ^0, τ^1,…, τ^l are nodes and e_1, …, e_l are edges such that $e_i = \{\tau^{i-1}, \tau^i\}$ for $i \in I_l$. A path is simple if all its nodes and edges are different.

Theorem 4.9. *Let $\mathcal{T}$ be a triangulation of P. Starting at the vertex x^-, the algorithm generates a finite sequence of adjacent J-complete simplices for varying $J \in \mathcal{I}$ which leads to the vertex x^+.*

Proof. By Lemma 4.6, $\{x^-\}$ is an I-complete 0-simplex in $F(I)$ for some unique set $I \in \mathcal{I}$ with $|I| = n - 1$. Since $\{x^-\}$ lies in the boundary of $F(I)$, there exists a unique 1-simplex σ in $F(I)$ having $\{x^-\}$ as its facet. By Lemma 4.6, either σ is an $\bar{I}$-complete simplex in $F(\bar{I})$, where $\bar{I} = I \setminus \{i\}$ for some unique $i \in I$, or σ has exactly one other I-complete facet $\bar{\tau}$. Hence there exists a unique adjacent complete simplex to $\{x^-\}$. That is, $deg(\{x^-\}) = 1$. Similarly, by using Lemmas 4.6 and 4.8, we can prove $deg(\{x^+\}) = 1$.

In all other cases, we prove that if τ is an I-complete $(n - |I| - 1)$-simplex in $F(I)$ for some $I \in \mathcal{I}$, τ has exactly two adjacent complete simplices. There are two possibilities: either τ lies in the interior of $F(I)$ or τ lies in the boundary of $F(I)$. If τ lies in the interior of $F(I)$, then τ is a facet of exactly two $(n - |I|)$-simplices in $F(I)$. It follows from Lemma 4.8 that τ is adjacent to exactly two complete simplices. If τ lies in the boundary of $F(I)$, then there exists exactly one $(n - |I|)$-simplex σ in $F(I)$ having τ as its facet. By Lemma 4.8 either σ is an $\bar{I}$-complete $(n - |\bar{I}| - 1)$-simplex in $F(\bar{I})$ for some unique $\bar{I} \in \mathcal{I}$ with $|\bar{I}| = |I| - 1$ and has no other I-complete facets, or σ has exactly one other I-complete facet. This yields one adjacent complete simplex to τ. On the other hand, since τ lies in the boundary of $F(I)$, τ lies in $F(\tilde{I})$ for some unique set $\tilde{I} \in \mathcal{I}$ with $|\tilde{I}| = |I| + 1$. By Lemma 4.8 either τ is J-complete for some unique set $J \in \mathcal{I}$ with $|J| = |I|$ and $J \neq I$, or τ has exactly one $\tilde{I}$-complete facet. In the former case, τ lies in $F(\tilde{I})$ and hence there exists exactly one simplex $\bar{\sigma}$ in $F(\tilde{I})$ having τ as its facet. It follows again from Lemma 4.8 that there exists exactly one other complete simplex adjacent to τ. This concludes that τ has exactly two adjacent complete simplices. In other words, we have $deg(\tau) = 2$.

As shown above, the degree of each node in the graph $G = (\mathcal{V}, \mathcal{A})$ is at most two. Exactly two nodes have degree equal to one. Since the number of simplices in P is finite, the number of nodes in G must be finite, too. Since $deg(\{x^-\}) = 1$, it is easy to see that there exists a simple finite path starting from $\{x^-\}$. The end node of this path must be a node τ of degree one and different from x^-. The only possibility is that τ is equal to $\{x^+\}$. ∎

In what follows, if a column of $A_{\tau,I}$ corresponds to a vertex x^i, we call it a vertex column; if it corresponds to a constraint vector a^j, we call it an index column. Now we summarize the steps of the algorithm.

FIG. 4.1. *The triangulation of P in Example* 3.1 *underlying the algorithm.*

ALGORITHM.

Step 0 : Take any triangulation of the polytope P. Let $j := 0,\ t := 1,\ x^1 := x^-,\ \tau^j := \tau(x^1)$, and let x^{t+1} be the unique vertex of the simplex in $F(I)$ having τ^j as a facet opposite to it, where I is a set with $n-1$ elements as determined in Lemma 4.3. Go to Step 1.

Step 1 : Let σ be equal to the convex hull of x^{t+1} and τ^j. Pivot $(1, -f(x^{t+1})^\top)^\top$ lexicographically into matrix $A_{\tau^j,I}$. As described in Lemma 4.6, a unique column k from the first n columns of $A_{\tau^j,I}$ will be replaced. If the column k is an index column, then go to Step 3. Otherwise, go to Step 2.

Step 2 : Set $j := j+1$ and let τ^j be the facet of σ opposite the vertex x^k. If $\tau^j = \langle x^+\rangle$, then the algorithm terminates. If τ^j lies in $F(\bar{I})$, where $\bar{I} = I \cup \{l\}$ for some $l \in I_m \setminus I$, then go to Step 4. Otherwise there is exactly another simplex $\widetilde{\sigma}$ in $F(I)$ having τ^j as its facet. Go to Step 1 with x^{t+1} as the unique vertex in $\widetilde{\sigma}$ opposite to the facet τ^j.

Step 3 : Let $i \in I$ be the index corresponding to the column k. Set $I := I\setminus\{i\}$. There is a unique simplex $\widetilde{\sigma}$ in $F(I)$ having σ as a facet. Set $j := j+1,\ t := t+1$, and go to Step 1 with x^{t+1} as the unique vertex in $\widetilde{\sigma}$ opposite to σ, and $\tau^j := \sigma$.

Step 4 : Set $\sigma := \tau^j$. Pivot $(0, a^{l\top})^\top$ lexicographically into matrix $A_{\tau^j,I}$. By Lemma 4.8 there is a unique column k of the first n columns of $A_{\tau^j,I}$ which has to be replaced. If the column k is an index column, then go to Step 3. Otherwise go to Step 2 with $t := t-1$ and $I := \bar{I}$.

It is worth mentioning that the algorithm can also start with the simplex $\langle x^+\rangle$ and terminates with the simplex $\langle x^-\rangle$. Following the above description, it is fairly easy to implement the algorithm on a computer.

From Theorem 4.9 and the system of equations $(*)$ we see that every simplex from $\langle x^-\rangle$ to $\langle x^+\rangle$ contains a parametrized stationary point of the piecewise linear approximation f of φ with respect to $\mathcal{T}$. By taking the straight line segments between the parametrized stationary points of any two adjacent simplices, we obtain a piecewise linear path of parametrized stationary points of f connecting the points x^- and x^+.

COROLLARY 4.10. *Let $\mathcal{T}$ be any triangulation of P. Then with respect to the vector c there is a piecewise linear path of parametrized stationary points of the piecewise linear approximation f of φ with respect to $\mathcal{T}$ and this path connects x^-*

and x^+*.*

Now we will illustrate the algorithm with Example 3.1. To implement the algorithm, we take the triangulation depicted in Figure 4.1. Note that this triangulation is very coarse. The piecewise linear path generated by the algorithm is given by the sequence of line segments $[(-1,0)^\top,(-a,a)^\top]$, $[(-a,a)^\top,(0,b)^\top]$, $[(0,b)^\top,(a,a)^\top]$, and $[(a,a)^\top,(1,0)^\top]$, where $a=(5-\sqrt{7})^{-1}$ and $b=(5-2\sqrt{2})^{-1}$; see Figure 4.2. As we see from Figure 4.2 the path of approximate zero points generated by the algorithm and the set of the actual zero points of f are quite close. The finer the triangulation is the more accurate the approximation will be. In this figure $A=(-a,a)^\top$, $B=(0,b)^\top$, $C=(a,a)^\top$, $D=(-d,d)^\top$, $E=(0,e)^\top$, and $F=(d,d)^\top$ with $d=\sqrt{3}/2-1/2$ and $e=\sqrt{2}-1$.

5. Proofs for the existence theorems. In this section we still assume that x^- and x^+ are unique. First it will be argued in Theorems 5.1 and 5.2 that the points lying on the path given in Corollary 4.10 indeed all correspond to approximate parametrized stationary or zero points of the mapping φ. To show this, a sequence of triangulations $\mathcal{T}^r$ with mesh size converging to zero is taken. This yields, according to Corollary 4.10, for every $r\in\mathbb{N}$, a continuous piecewise linear function $\pi^r:[0,1]\to P$ with image set $\pi^r([0,1])$ connecting x^- and x^+. It will be shown that if q^r is an arbitrary point in $\pi^r([0,1])$ and the sequence $(q^r)_{r\in\mathbb{N}}$ converges to q, then q is a parametrized stationary point of $\varphi(q)$ with respect to c. Under the conditions of Theorems 3.2, 3.3, and 3.4, the piecewise linear approximation can be chosen in such a way that q is a zero point of φ. Furthermore, it will be shown in Theorem 5.4 by a limiting argument that there exists a connected set of zero points of φ, containing both x^- and x^+, that is being approximated.

THEOREM 5.1. *Let $\varphi:P\Longrightarrow\mathbb{R}^n$ be a correspondence satisfying Assumption* 2.1 *and let $c\in\mathbb{R}^n\setminus\{0^n\}$. For $r\in\mathbb{N}$, let $\mathcal{T}^r$ be a triangulation of P with mesh size smaller than $\frac{1}{r}$, let $f^r:P\to\mathbb{R}^n$ be a piecewise linear approximation of φ with respect to $\mathcal{T}^r$, and let $\pi^r:[0,1]\to P$ be the corresponding continuous function with image set connecting x^- and x^+. Let $(q^r)_{r\in\mathbb{N}}$ be an arbitrary convergent sequence of points in P with limit q^* where $q^r\in\pi^r([0,1])$. Then q^* is a parametrized stationary point of φ*

with respect to c.

Proof. Let $(\lambda_1^r, \dots, \lambda_{n+1}^r, x^{1^r}, \dots, x^{n+1^r}, s^{1^r}, \dots, s^{n+1^r})_{r\in\mathbb{N}}$ be a sequence of points in $\mathbb{R}_+^{n+1} \times \prod_{i=1}^{n+1} P \times \prod_{i=1}^{n+1} \mathbb{R}^n$ satisfying that $\sum_{j=1}^{n+1} \lambda_j^r = 1$, $\sigma^r(x^{1^r}, \dots, x^{n+1^r})$ is a simplex of $\mathcal{T}^r$, $q^r = \sum_{j=1}^{n+1} \lambda_j^r x^{j^r} \in \pi^r([0,1])$, and $s^{j^r} = f^r(x^{j^r})$. Notice that it may happen that $\lambda_j^r = 0$ for some $j \in I_{n+1}$. By definition, $f^r(q^r) = \sum_{j=1}^{n+1} \lambda_j^r s^{j^r}$. Define $s^r = f^r(q^r)$; then $s^r = \beta^r c + \sum_{j\in I^r} \mu_j^r a^j$ for some $\beta^r \in \mathbb{R}$ for some $\mu_j^r \geq 0\ \forall j \in I^r$, and for some $I^r \in \mathcal{I}$ satisfying that q^r lies in $F(I^r)$. Since $\cup_{q\in P}\varphi(q)$ is bounded, the sequence given above remains in a compact set, and without loss of generality it can be assumed to converge to an element $(\lambda_1^*, \dots, \lambda_{n+1}^*, x^{*1}, \dots, x^{*n+1}, s^{*1}, \dots, s^{*n+1})$. Define $s^* = \sum_{j=1}^{n+1} \lambda_j^* s^{*j}$. Clearly, it holds that $s^r \to s^*$. Since for every $r \in \mathbb{N}$ the mesh size of $\mathcal{T}^r$ is smaller than $\frac{1}{r}$, it holds for every $j \in I_{n+1}$ that $x^{*j} = q^*$. Using that φ is upper semicontinuous this implies that for every $j \in I_{n+1}$, $s^{*j} \in \varphi(q^*)$. Moreover, $\beta^r \to \beta^*$ for some number β^*, without loss of generality $I^r = I^* \forall r$ for some $I^* \in \mathcal{I}$, and $\mu_j^r \to \mu_j^* \forall j \in I^*$ for some nonnegative μ_j^*. Since φ is convex valued, $\sum_{j=1}^{n+1} \lambda_j^* = 1$ and $\lambda_j^* \geq 0\ \forall j \in I_{n+1}$, it holds that $s^* \in \varphi(q^*)$. Moreover, $q^* \in F(I^*)$ and $s^* = \beta^* c + \sum_{j\in I^*} \mu_j^* a^j \in A(I^*)$. Hence, according to Lemma 2.3, q^* is a parametrized stationary point of φ with respect to c. □

In order to give a constructive proof of Theorems 3.2, 3.3, and 3.4, the piecewise linear approximation f of φ with respect to a triangulation $\mathcal{T}$ should be chosen as follows. We call such a piecewise linear approximation a proper one. In case of Theorem 3.2 any piecewise linear approximation of φ with respect to $\mathcal{T}$ can be chosen. Next consider Theorem 3.3. If a point x in the (relative) interior of a face $F(I)$ is a vertex of a simplex of the triangulation, this implies that at least one element in $\varphi(x)$ lies in the set $A_0^*(I)$, and this element is assigned to the piecewise linear approximation at x. In the case of Theorem 3.4 an element of the set $A^*(I)$ in $\varphi(x)$ is assigned to a vertex x of a simplex if x lies in (the interior of) $F(I)$.

THEOREM 5.2. *Let $\varphi : P \Longrightarrow \mathbb{R}^n$ be a correspondence satisfying the conditions in one of Theorems* 3.2, 3.3, *or* 3.4. *For $r \in \mathbb{N}$, let $\mathcal{T}^r$ be a triangulation of P with mesh size smaller than $\frac{1}{r}$ and let $f^r : P \to \mathbb{R}^n$ be a proper piecewise linear approximation of φ with respect to $\mathcal{T}^r$. Let $(q^r)_{r\in\mathbb{N}}$ be an arbitrary convergent sequence of points in P with limit q^* such that for any $r \in \mathbb{N}$ it holds that $q^r \in \pi^r([0,1])$. Then q^* is a zero point of φ.*

Proof. First consider Theorem 3.2. Following the proof of Theorem 5.1 the limit point $s^* \in \varphi(q^*)$ is an element of $A(I^*)$, whereas q^* is an element of $F(I^*)$. The latter property implies that s^* is not an element of $A(I^*)$, unless $s^* = 0^n$. Hence, $s^* = 0^n$. Next consider Theorem 3.3. Consider again the convergent sequence of simplices σ^r in $F(I^*)$ mentioned in the proof of Theorem 5.1. Then the vertex x^{j^r} of σ^r lies in some face $F(I^{j^r})$ of P with $I^* \subset I^{j^r}$. Hence, we have that $A_0^*(I^{j^r}) \subset A_0^*(I^*)$, and so $s^r \in A_0^*(I^*) \forall r$ because of the properness of f^r. Consequently, $s^* \in A_0^*(I^*)$ and therefore $s^* \in A_0^*(I^*) \cap A(I^*) \subset \{0^n\}$, i.e., $s^* = 0^n$. In the case of Theorem 3.4, following a similar argument as in the previous case we obtain that $s^* \in A^*(I^*) \cap A(I^*)$. Since the latter intersection consists of only the zero vector, we obtain again that $s^* = 0^n$. □

From Theorem 5.2 the next result follows immediately.

COROLLARY 5.3. *Let $\varphi : P \Longrightarrow \mathbb{R}^n$ be a correspondence satisfying the conditions in one of Theorems* 3.2, 3.3, *or* 3.4. *For $r \in \mathbb{N}$, let $\mathcal{T}^r$ be a triangulation of P with mesh size smaller than $\frac{1}{r}$ and let $f^r : P \to \mathbb{R}^n$ be a proper piecewise linear approximation of φ with respect to $\mathcal{T}^r$. Then for every $\varepsilon > 0$ there exists an $R \in \mathbb{N}$*

such that for every $r \geq R$ it holds that $q^r \in \pi^r([0,1])$ implies $\|f^r(q^r)\|_\infty < \varepsilon$.

Proof. Suppose that a sequence $(q^r, f^r(q^r))_{r\in\mathbb{N}}$ exists with $q^r \in \pi^r([0,1])$ and $\|f^r(q^r)\|_\infty \geq \varepsilon$ for every $r \in \mathbb{N}$. Since P and $\cup_{q\in P}\varphi(q)$ are compact, there exists a converging subsequence $(q^{r^s}, f^{r^s}(q^{r^s}))_{s\in\mathbb{N}}$, with limit say (q^*, s^*), where $\|s^*\|_\infty \geq \varepsilon > 0$. As in the proof of Theorem 5.2 it can be shown that $s^* = 0^n$, yielding a contradiction. □

Using Theorem 4.9 and Theorem 5.2 it will be shown that there exists a connected set C in P such that $x^- \in C$, $x^+ \in C$, and $0^n \in \varphi(q)\ \forall q \in C$. Hence, there is a continuum of zero points of φ being approximated by the algorithm of section 4. For a nonempty, compact set $S \subset \mathbb{R}^n$, define the continuous function $d_S : \mathbb{R}^n \to \mathbb{R}$ by $d_S(x) = \min\{\|x-y\|_\infty \mid y \in S\}$.

THEOREM 5.4. *Let $\varphi : P \Longrightarrow \mathbb{R}^n$ be a correspondence satisfying the conditions in one of Theorems* 3.2, 3.3, *or* 3.4. *Then there exists a connected set C of points in P such that $x^- \in C$, $x^+ \in C$, and $0^n \in \varphi(q)\ \forall q \in C$.*

Proof. Define $Q = \{q \in P \mid 0^n \in \varphi(q)\}$. From the conditions of the theorems it immediately follows that $x^- \in Q$, $x^+ \in Q$, and Q is compact. Suppose the theorem is false. Then x^+ is not an element of the component of Q containing x^-. By Munkres [21, p. 235] it holds for every compact set X in some Euclidean space and for every element $x \in X$ that the component of X containing x equals the intersection of all sets containing x which are both open and closed in X. Hence, there exists a set Q^0, which is open and closed in Q, such that $x^- \in Q^0$ and $x^+ \notin Q^0$. Define $Q^1 = Q \setminus Q^0$. Then Q^1 is open and closed in Q, $x^- \notin Q^1$, and $x^+ \in Q^1$. Since Q is compact, it follows that Q^0 and Q^1 are disjoint, compact sets. Hence, there exists $\varepsilon > 0$ such that $\min\{\|q^0 - q^1\|_\infty \mid q^0 \in Q^0,\ q^1 \in Q^1\} \geq \varepsilon$. For every $r \in \mathbb{N}$, let $\mathcal{T}^r$ be a triangulation of P with mesh size smaller than $\frac{1}{r}$, let $f^r : P \to \mathbb{R}^n$ be a proper piecewise linear approximation of φ with respect to $\mathcal{T}^r$, and let $\pi^r : [0,1] \to P$ be the corresponding continuous function with image set connecting x^- and x^+. Define $g^r : [0,1] \to \mathbb{R}$ by

$$g^r(t) = d_{Q^0}(\pi^r(t)) - d_{Q^1}(\pi^r(t))\ \forall t \in [0,1].$$

Since g^r is continuous, $g^r(0) \leq -\varepsilon$, and $g^r(1) \geq \varepsilon$, there exists a point $t^r \in [0,1]$ such that $g^r(t^r) = 0$. Hence, $d_{Q^0}(\pi^r(t^r)) = d_{Q^1}(\pi^r(t^r)) = d_Q(\pi^r(t^r)) \geq \frac{1}{2}\varepsilon$. Without loss of generality, it can be assumed that $(\pi^r(t^r))_{r\in\mathbb{N}}$ converges to a point $q^* \in P$. Hence,

$$d_Q(q^*) = d_Q\left(\lim_{r\to\infty} \pi^r(t^r)\right) = \lim_{r\to\infty} d_Q(\pi^r(t^r)) \geq \frac{1}{2}\varepsilon > 0.$$

However, by Theorem 5.2, $d_Q(q^*) = 0$, yielding a contradiction. □

Similarly, one can easily show that in the case of Theorem 3.1 there exists a connected set C of parametrized stationary points in P with respect to c such that $x^- \in C$ and $x^+ \in C$.

6. The general case. The algorithm proposed in the previous section can be adapted for computing a continuum of parametrized stationary points or zero points of φ on P in case the faces F^- and F^+ are not vertices of P. First we take any point v in the interior of F^- and a triangulation of P such that the face F^- itself is being triangulated according to the V-triangulation of Talman and Yamamoto [24]. For $J \in \mathcal{I}$ such that $I^- \subset J$, let $VF(J) = \{x \in F^- | x = \lambda v + (1-\lambda)y, 0 \leq \lambda \leq 1, y \in F(J)\}$. The V-triangulation subdivides any such set $VF(J)$ into $(n - |J| + 1)$-simplices.

Then we apply the algorithm of Talman and Yamamoto [24] to find a parametrized stationary point x^- in F^- of the piecewise linear approximation f of the correspondence φ on P with respect to c. To initiate the algorithm, we solve $\max x^\top f(v)$

subject to $x \in F^-$, which yields, by using Theorem 2.6 of Fujishige and Yang [10] for its dual, a uniquely determined vertex $F(I_0)$ of F^- as a solution, with $|I_0| = n$ and $I^- \subset I_0$. Then starting with the 0-simplex $\{v\}$ and I equal to I_0 the algorithm generates a sequence of adjacent simplices in $VF(I)$ for varying $I \in \mathcal{I}$ such that $I^- \subset I$, and the common facets $\tau(x^1, \dots, x^t)$ satisfy that the system of equations

$$\sum_{j=1}^{t} \lambda_j \begin{pmatrix} 1 \\ -f(x^j) \end{pmatrix} + \sum_{i \in I} \mu_i \begin{pmatrix} 0 \\ a^i \end{pmatrix} = \begin{pmatrix} 1 \\ 0^n \end{pmatrix}$$

has a solution (λ, μ) satisfying $\lambda_j \geq 0, j \in I_t, \mu_i \geq 0$ for $i \in I \backslash I^-$. Notice that $I^- \subset I$ and that we allow I to be equal to I^-.

The algorithm of Talman and Yamamoto stops as soon as a $(t-1)$-simplex $\tau^-(x^1, \dots, x^t)$ in $F(I)$ for some I containing I^- is generated for which the system has a solution (λ, μ). Then $x = \sum_{j=1}^{t} \lambda_j x^j$ is a parametrized stationary point in $F(I^-)$ with respect to c of the piecewise linear approximation f of φ. Next the vector $(c^\top, 0)$ is pivoted semilexicographically into the system, making any $\mu_i, i \in I$, nonnegative. Since $-c = \sum_{i \in I^-} \lambda_i a^i$ for unique $\lambda_i > 0$, one of the μ_i's, say μ_{i_0}, for some $i_0 \in I^-$, will leave the basis. Now the algorithm continues in $F(I \backslash \{i_0\})$ with the unique t-simplex σ in $F(I \backslash \{i_0\})$ having τ^- as a facet and a semilexicographic pivot step is made with $(1, -f^\top(x^{t+1}))^\top$ where x^{t+1} is the vertex of σ opposite to τ, and so on.

In this way the algorithm generates for varying $I \in \mathcal{I}$ by semilexicographic pivoting a unique sequence of adjacent simplices in $F(I)$ with common I-complete facets until a facet τ being a simplex in $F(H)$ for some H containing I^- or a complete facet τ^+ being a simplex in $F(J)$ for some J containing I^+ is generated. In the former case the algorithm continues in the subset $VF(H)$ of $F(I^-)$ as above until again an I-complete simplex in $F(I)$ for some I containing I^- is found, and so on. In the latter case the point $x^+ = \sum_{j=1}^{t} \lambda_j x^j$ at the solution (λ, μ, β) lies in τ^+ and is a parametrized stationary point in F^+ of f with respect to c.

Letting x^- be the last point being generated in F^-, the algorithm generates a piecewise linear path of parametrized stationary points of f with respect to the vector c. This path connects the point x^- in the face F^- with a point x^+ in the face F^+. Taking a sequence of triangulations of P with mesh tending to zero, in the limit a connected set of parametrized stationary points of φ is obtained with respect to c connecting the faces F^- and F^+. In case the correspondence φ satisfies the conditions of Theorems 3.2, 3.3, or 3.4 and the piecewise linear approximations are chosen in an appropriate way, there exists a connected set of zero points of φ connecting F^- and F^+.

Notice that if a sequence of triangulations with mesh tending to zero is taken, for any triangulation in this sequence the points x^- in F^- and x^+ in F^+ being connected through the piecewise linear path generated by the algorithm may differ. In the limit these points converge on a subsequence to two different zero points of φ, one lying in F^- and the other lying in F^+.

7. Examples. In this section we will derive three existing existence theorems from Theorems 3.2, 3.3, and 3.4.

The first example is derived from general equilibrium theory with price rigidities. Let $U^n = \{x \in \mathbb{R}^n \mid 0 \leq x_i \leq 1 \; \forall i \in I_n\}$ be the n-dimensional unit cube. Let 1^n denote the n-vector of ones and for $i \in I_n$ let $e(i)$ denote the ith unit vector in $\mathbb{R}^n$. Under standard assumptions on economic primitives (see, e.g., Herings [12] for details), it can be derived that the total excess demand function of an economy with completely fixed prices $p \in \mathbb{R}^n_{++}$ is a continuous function $f : U^n \to \mathbb{R}^n$ with the following properties:

(A) for every $x \in U^n$, for every $j \in I_n$, $x_j = 0$ implies $f_j(x) \geq 0$, and $x_j = 1$ implies $f_j(x) \leq 0$;

(B) for every $x \in U^n$, $p^\top f(x) = 0$.

THEOREM 7.1. *Let $f : U^n \to \mathbb{R}^n$ be the excess demand function of an economy with completely fixed prices $p \in \mathbb{R}^n_{++}$. Then there exists a connected set C of zero points of f such that $0^n \in C$ and $1^n \in C$.*

Proof. We can rewrite the set U^n as

$$U^n = \{x \in \mathbb{R}^n \mid a^{i\top} x \leq b_i \ \ \forall\, i \in I_{2n}\},$$

where $a^i = e(i)$, $b_i = 1$, $a^{n+i} = -e(i)$, and $b_{n+i} = 0 \forall i \in I_n$. We can partition any $I \in \mathcal{I}$ into two disjoint subsets I^1 and I^2 with $I^1 \subset I_n$ and $I^2 \subset I_{2n} \setminus I_n$. Notice that $i \in I^1$ implies $i + n \notin I^2$, and $i \in I^2$ implies $i - n \notin I^1$.

Let $c = p$. Clearly, $x^- = 0^n$ and $x^+ = 1^n$. We check the condition of Theorem 3.2. Suppose $0^n \neq f(x) \in A(I)$ for some $I \in \mathcal{I}$, so $f(x) = \sum_{i \in I^1} \mu_i e(i) - \sum_{i \in I^2} \mu_i e(i - n) + \beta p$, where $\mu_i \geq 0\ \forall i \in I$, and $\beta \in \mathbb{R}$, and some μ_i or β nonzero. Conditions (A) and (B) imply that $f(0^n) = 0^n$ and $f(1^n) = 0^n$, so $I \neq I_n$ and $I \neq I_{2n} \setminus I_n$. If $I = \emptyset$, then $0 = p^\top f(x) = p^\top \beta p \neq 0$, a contradiction. Take any nonempty set $I \in \mathcal{I}$ not equal to I_n or $I_{2n} \setminus I_n$.

If $I^1 \neq \emptyset$ and $I^2 \neq \emptyset$, then $p_i(\beta + \mu_i) \leq 0$, for $i \in I^1$, and $p_{i-n}(\beta - \mu_i) \geq 0$, for $i \in I^2$, so $\beta = 0$ and $\mu_i = 0 \forall i \in I$, a contradiction.

If $I^1 = \emptyset$, then $I^2 \neq \emptyset$, so $\beta > 0$, but then $f(x) > 0^n$, a contradiction to $0 = p^\top f(x)$.

If $I^2 = \emptyset$, then $I^1 \neq \emptyset$, so $\beta < 0$, but then $f(x) < 0^n$, a contradiction to $0 = p^\top f(x)$. Consequently, Theorem 3.2 holds. □

The proof of Theorem 7.1 shows that our results apply to economies with completely fixed prices $p \in \mathbb{R}^n_{++}$. Since the results apply to all such economies, that is, for all possible specifications of utility functions and initial endowments, it also shows that our results satisfy a certain kind of robustness. The above theorem can also be derived from Theorems 3.3 and 3.4.

The following result is obtained by Herings, Talman, and Yang [15, Theorem 4.3, p. 690] which generalizes Theorem 7.1. It is therefore also related to economies with price rigidities, and it applies even under somewhat weaker assumptions on the economic primitives. We will show that this theorem is a special case of Theorem 3.3.

THEOREM 7.2. *Let $\varphi : U^n \Longrightarrow \mathbb{R}^n$ be any correspondence satisfying Assumption 2.1. Moreover, it holds that*

(A) *for every $x \in U^n$, there exists $f \in \varphi(x)$ such that, for every $j \in I_n$, $x_j = 0$ implies $f_j \geq 0$, and $x_j = 1$ implies $f_j \leq 0$;*

(B) *for every $x \in U^n$, for every $f \in \varphi(x)$, there exists some $p \in \mathbb{R}^n_{++}$ such that $p^\top f = 0$.*

Then there exists a connected set C of zero points of φ such that $0^n \in C$ and $1^n \in C$.

Proof. Rewrite the set U^n as in the proof of Theorem 7.1. Let $c = 1^n$. Clearly, $x^- = 0^n$ and $x^+ = 1^n$. Moreover, it is easy to verify that condition (ii) of Theorem 3.3 is satisfied by condition (A). We have to check condition (i). For $I = \emptyset$, condition (i) is trivially satisfied. Now take any nonempty set I from $\mathcal{I}$. We partition I into two disjoint subsets I^1 and I^2 as in the proof of Theorem 7.1. Suppose there is some $x \in F(I)$ and some $f \in \varphi(x)$ such that $f \in (A_0^*(I) \cap A(I)) \setminus \{0^n\}$. This implies that there exist $\mu_i \geq 0 \; \forall \; i \in I$ and $\beta \in \mathbb{R}$ such that

$$\begin{array}{rcl} f & = & \sum_{i \in I} \mu_i a^i + \beta c, \\ f^\top a^i & \leq & 0 \quad \forall \; i \in I, \\ f & \neq & 0^n. \end{array}$$

Equivalently,

$$\begin{array}{rcl} f & = & \sum_{i \in I^1} \mu_i e(i) - \sum_{i \in I^2} \mu_i e(i-n) + \beta c, \\ f_i & \leq & 0 \quad \forall \; i \in I^1, \\ f_i & \geq & 0 \quad \forall \; n + i \in I^2, \\ f & \neq & 0^n. \end{array}$$

This implies that

$$\begin{array}{rcl} \beta & \geq & \max_{i \in I^2} \mu_i, \\ \beta & \leq & -\max_{i \in I^1} \mu_i. \end{array} \tag{7.1}$$

In case $I^2 = \emptyset$, we have $f < 0^n$. This contradicts condition (B). In case $I^1 = \emptyset$, we have $f > 0^n$, again contradicting condition (B). In cases $I^1 \neq \emptyset$ and $I^2 \neq \emptyset$, without loss of generality there exist $i \in I^1$ and $j \in I^2$ such that $\mu_i > 0$ and $\mu_j > 0$. This would mean both $\beta > 0$ and $\beta < 0$ from (7.1) which is impossible. Hence condition (i) is satisfied. □

Now we use Theorem 3.4 to show that there is a continuum of constrained equilibria in a pure exchange economy with general price rigidities; see, e.g., Schalk and Talman [23] for details. Price vectors in such an economy with n commodities are restricted to an n-dimensional simple polytope

$$P = \{p \in \mathbb{R}^n_+ \mid t^- \leq p^\top c \leq t^+, \; {a^i}^\top p \leq b_i, \; i \in I_m\}$$

for some strictly positive vector c with length 1, $0 < t^- < t^+$, ${a^i}^\top c = 0 \; \forall i \in I_m$. We also assume that there are no redundant constraints and that P is a subset of $\mathbb{R}^n_{++}$. We define

$$Q = \{q \in \mathbb{R}^n \mid t^- \leq q^\top c \leq t^+, \; a^{i\top} q \leq b_i + \varepsilon \; \forall i \in I_m\}$$

for some $\varepsilon > 0$. For ε small enough, $F(I)$, $I \subset I_m$, is a face of Q if and only if $\{x \in P \mid a^i x = b_i, \; i \in I\}$ is a face of P. For any q in Q, let $p(q)$ be the orthogonal projection of q on P and let $I(q)$ be such that $p(q)$ is in the interior of the face $F(I(q))$ of P. Then there exist unique nonnegative numbers $\mu^i(q), i \in I(q)$, such that $q = p(q) + \sum_{i \in I(q)} \mu_i(q) a^i$.

At $q \in Q$ define the price vector by $p(q)$ and a continuous rationing scheme $(r^i(q), d_i(q))$, $i \in I_m$, such that $r^i(q) = a^i$, $d_i(q) = 0$ if $\mu_i(q) = 1$ and $d_i(q) = M$ if $\mu_i(q) = 0$ or i not in $I(q)$, for sufficiently large $M > 0$. This rationing scheme determines the constraints on the net-supply of the consumers. Given a utility function u^h and initial endowment w^h, consumer $h \in H$ maximizes his utility $u^h(x)$ over his budget constraint given by $p(q)^\top x \leq p(q)^\top w^h$ and rationing constraints $r^i(q)^\top (x - w^h) \leq d_i(q), i \in I_m$. The solution set $x^h(q)$ yields the constraint excess demand set $z^h(q) = x^h(q) - \{w^h\}$ of consumer $h \in H$ at q. Adding up these sets over all consumers in H gives the total constraint excess demand correspondence $\zeta : Q \to \mathbb{R}^n$. Under certain standard economic conditions, the correspondence ζ satisfies Assumption 2.1 and $p(q)^\top z = 0$ for any $z \in \zeta(q)$, $q \in Q$.

A constrained equilibrium is obtained if $q \in P$ is such that $0^n \in \zeta(q)$. At such an equilibrium, $p(q)^\top a^i = b_i$ if the ith rationing scheme is binding.

Let F^- be the face of Q on which $c^\top x$ is minimized on Q and let F^+ be the face of Q on which $c^\top x$ is maximized on Q. Notice that $F^- = \{q \in Q \mid q^\top c = t^-\}$ and $F^+ = \{q \in Q \mid q^\top c = t^+\}$.

To see that there is a connected set of constrained equilibria linking F^- and F^+, define the mapping φ on Q by $\varphi(q) = \{y | y = z - (c^\top z)c, z \in \zeta(q)\}, q \in Q$. We will show that $\varphi(q) \subset A^*(I)$ when q lies in the interior of the face $F(I)$ of Q. Clearly, $c^\top y = 0$ for any $y \in \varphi(q)$. Moreover, for any $y = z - (c^\top z)c \in \varphi(q)$ and $i \in I(q) \cap I_m$ it holds that ${a^i}^\top y = {a^i}^\top z - ({a^i}^\top c)c^\top z = {r^i(q)}^\top z \leq 0$. Therefore, any $y \in \varphi(q)$ is an element of $A^*(I)$, and hence $\varphi(q) \subset A^*(I)$ if $q \in F(I)$. According to Theorem 3.4 there exists a connected set C in Q intersecting both F^- and F^+ such that every point $q \in C$ is a zero point of φ, i.e., $0^n \in \varphi(q)$. For such a q it holds that there is $z \in \zeta(q)$ satisfying $z - (c^\top z)c = 0^n$. Because $p(q)^\top z = 0$, we obtain that $(c^\top z)(p(q)^\top c) = 0$. Hence, $c^\top z = 0$, since $p(q)^\top c > 0$. This implies that $z = 0^n$ and therefore $0^n \in \zeta(q)$, inducing a constrained equilibrium. Consequently there exists a connected set of constrained equilibria linking the two faces F^- and F^+.

Finally, we show that the fundamental fixed point theorems of Browder [4] and Mas-Colell [20] can also be derived from Theorem 3.4. Browder proved the continuous function case and Mas-Colell extended the result to the upper semicontinuous correspondence case.

THEOREM 7.3. *Let P be an n-dimensional polytope and let $\varphi : P \times [0,1] \Longrightarrow P$ be any correspondence satisfying Assumption* 2.1. *Then the set*

$$D = \{(x,t) \in P \times [0,1] \mid x \in \varphi(x,t)\}$$

contains a connected set C such that

$$C \cap (\mathrm{P} \times \{0\}) \neq \emptyset \quad \textit{and} \quad C \cap (\mathrm{P} \times \{1\}) \neq \emptyset.$$

Proof. We can rewrite the set $P \times [0,1]$ as

$$\begin{aligned} W = \{(x,t) \in \mathbb{R}^{n+1} \quad | \quad & ({a^i}^\top, 0)(x^\top, t)^\top \leq b_i \quad \forall i \in I_m, \\ & (0, \ldots, 0, -1)(x^\top, t)^\top \leq 0, \\ & (0, \ldots, 0, 1)(x^\top, t)^\top \leq 1\}. \end{aligned}$$

Let $c = (0, \ldots, 0, 1)^\top \in \mathbb{R}^{n+1}$. Obviously, W is simple and no constraint is redundant. Moreover, $F^+ = \{(x,t) \in W \mid t = 1\}$ and $F^- = \{(x,t) \in W \mid t = 0\}$.

Construct the correspondence $\psi : W \Longrightarrow \mathbb{R}^{n+1}$ as

$$\psi(x,t) = (\varphi(x,t) - \{x\}) \times \{0\}.$$

We will show that for any $I \in \mathcal{I}$ and any $(x,t) \in F(I)$, we have $\psi(x,t) \subset A^*(I)$. For $I = \emptyset$, $\psi(x,t) \subset A^*(\emptyset)$ since $c^\top z = 0$ for any $z \in \psi(x,t)$. Now take any nonempty set I from $\mathcal{I}$. We have to consider the following two cases:

(1) In case $I \subset I_m$, take any (x,t) in the face $F(I)$ of W and any z in $\psi(x,t)$. We have

$${a^i}^\top x = b_i \ \forall i \in I; \ z = ((k-x)^\top, 0)^\top$$

for some $k \in P$. Take any $y \in A(I)$. That is,

$$y = \sum_{i \in I} \lambda_i ({a^i}^\top, 0)^\top + \beta c$$

for some $\lambda_i \geq 0$ and $\beta \in \mathbb{R}$. Thus, we have

$$z^\top y = \sum_{i \in I} \lambda_i (k - x)^\top a^i.$$

Since $k \in P$, we have $a^{i\top} k \leq b_i$ for $i \in I_m$. Since $a^{i\top} x = b_i$ for $i \in I$, we have $z^\top y \leq 0$. This means that $\psi(x, t)$ is a subset of $A^*(I)$.

(2) If $I \not\subset I_m$, either $m + 1$ or $m + 2$ is contained in I. For example, suppose that $m + 2$ is in I, i.e., $t = 1$. The case $m + 1 \in I$ follows the same argument. Take any (x, t) in the face $F(I)$ of W and any z in $\psi(x, t)$. We have

$$a^{i\top} x = b_i \ \forall i \in I \setminus \{m + 2\}; \ t = 1; \ z = ((k - x)^\top, 0)^\top$$

for some $k \in P$. Take any $y \in A(I)$. That is,

$$y = \sum_{i \in I \setminus \{m+2\}} \lambda_i (a^{i\top}, 0)^\top + \beta c$$

for some $\lambda_i \geq 0$ and $\beta \in \mathbb{R}$. Thus, we have

$$z^\top y = \sum_{i \in I \setminus \{m+2\}} \lambda_i (k - x)^\top a^i.$$

Since $k \in P$, we have $a^{i\top} k \leq b_i$ for $i \in I_m$. Since $a^{i\top} x = b_i$ for $i \in I \setminus \{m + 2\}$, we have $z^\top y \leq 0$. This means that $\psi(x, t)$ is again a subset of $A^*(I)$. By Theorem 3.4 there exists a connected set C in W such that

$$0^{n+1} \in \psi(x, t) \quad \forall (x, t) \in C; \ F^+ \cap C \neq \emptyset; \ F^- \cap C \neq \emptyset.$$

Clearly, $x \in \varphi(x, t)$ for each $(x, t) \in C$. □

We remark that the above theorem can also be derived from Theorem 3.2 or Theorem 3.3.

INPUT-OUTPUT-TO-STATE STABILITY*

MIKHAIL KRICHMAN[†], EDUARDO D. SONTAG[‡], AND YUAN WANG[§]

Abstract. This work explores Lyapunov characterizations of the input-output-to-state stability (IOSS) property for nonlinear systems. The notion of IOSS is a natural generalization of the standard zero-detectability property used in the linear case. The main contribution of this work is to establish a complete equivalence between the IOSS property and the existence of a certain type of smooth Lyapunov function. As corollaries, one shows the existence of "norm-estimators," and obtains characterizations of nonlinear detectability in terms of relative stability and of finite-energy estimates.

Key words. nonlinear stability, Lyapunov function techniques, input-output-to-state stability, input-to-state stability, observers, detectability

1. Introduction.

This paper concerns itself with the following question, for dynamical systems: *is it possible to estimate, on the basis of external information provided by past input and output signals, the magnitude of the internal state $x(t)$ at time t?* The rest of this introduction will explain, in very informal and intuitive terms, the motivation for this question, closely related to the "zero-detectability" problem, sketching the issues that arise and the main results. Precise definitions are provided in the next section.

State estimation is central to control theory. It arises in signal processing applications (Kalman filters), as well as in stabilization based on partial information (observers). By and large, the theory of state estimation is well understood for linear systems, but it is still poorly developed for more general classes of systems, such as finite dimensional deterministic systems, with which this paper is concerned. An outstanding open question is the derivation of useful necessary and sufficient conditions for the existence of observers, i.e., "algorithms" (dynamical systems) which converge to an estimate $\hat{x}(t)$ of the state $x(t)$ of the system of interest, using the information provided by $\{u(s), s \leq t\}$, the set of past input values, and by $\{y(s), s \leq t\}$, the set of past output measurements. In the context of stabilization to an equilibrium, let us say to the zero state $x = 0$ if we are working in a Euclidean space, a weaker type of estimate is sometimes enough: it may suffice to have a norm-estimate, that is to say, an upper bound $\hat{x}(t)$ on the *magnitude* (norm) $|x(t)|$ of the state $x(t)$. Indeed, it is often the case (cf. [32] and Assumption UEC (73) in [18]) that norm-estimates suffice for control applications. To be more precise, one wishes that $\hat{x}(t)$ eventually becomes

an upper bound on $|x(t)|$ as $t \to \infty$. We are thus interested in *norm-estimators* which, when driven by the input/output data generated by the system, produce such an upper bound $\hat{x}(t)$; cf. Figure 1.1.

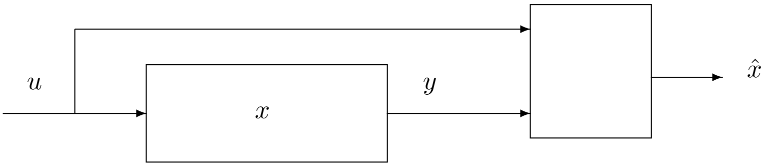

FIG. 1.1. *Norm-estimator.*

In order to understand the issues that arise, let us start by considering the very special case when the external data (inputs u and outputs y) vanish identically. The obvious estimate (assuming, as we will, that everything is normalized so that the zero state is an equilibrium for the unforced system, and the output is zero when $x = 0$) is $\hat{x}(t) \equiv 0$. However, the only way that this estimate fulfills the goal of upper bounding the norm of the true state as $t \to \infty$ is if $x(t) \to 0$. In other words, one obvious necessary property for the possibility of norm-estimation is that the origin must be a globally asymptotically stable state with respect to the "subsystem" consisting of those states for which the input $u \equiv 0$ produces the output $y \equiv 0$. One says in this case that the original system is *zero-detectable.* For *linear systems*, zero-detectability is equivalent to detectability, that is to say, the property that if any two trajectories produce the same output, then they approach each other. Zero-detectability is a central property in the general theory of nonlinear stabilization on the basis of output measurements; see, for instance, among many other references, [34, 17, 50, 10, 16]. Our work can be seen as a contribution toward the better characterization and understanding of this fundamental concept.

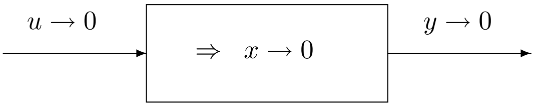

FIG. 1.2. *State converges to zero if external data does.*

However, zero-detectability by itself is far from being sufficient for our purposes, since it fails to be "well-posed" enough. One easily sees that, at the least, one should ask that, when inputs and outputs are small, states should also be small, and if inputs and outputs converge to zero as $t \to \infty$, states do too; cf. Figure 1.2. Moreover, when formally defining the notion of norm-estimator and the natural necessary and sufficient conditions for its existence, other requirements appear: the existence of asymptotic bounds on states, as a function of bounds on input/output data, and the need to describe the "overshoot" (transient behavior) of the state.

One way to approach the formal definition, so as to incorporate all the above characteristics in a simple manner, is to look at the analogous questions for the stability problem, which, for linear systems, is known to be technically dual to detectability. This leads one to the area which deals precisely with this circle of ideas: *input-to-state stability* (ISS).

ISS was introduced in [35] and has proved to be a very useful paradigm in the study of nonlinear stability; see, for instance, the textbooks [16, 20, 22, 23], and the papers [7, 14, 15, 19, 28, 11, 32, 33, 44, 42, 49, 48], as well as its variants such as integral ISS (cf. [2, 4, 24, 38]) and input/output stability (cf. [35, 46, 47]). The notion of ISS takes into account the effect of initial states in a manner fully compatible with Lyapunov stability, and incorporates naturally the idea of "nonlinear gain" functions; the reader may wish to consult [37] and [41] for expositions, as well as [44] for the proofs of several of the main characterizations. Roughly speaking, a system is ISS provided that, no matter what is the initial state, if the inputs are small, then the state must eventually be small. Dualizing this definition one arrives at the notion of detectability which is the main subject of study of this paper: *input-output-to-state stability* (IOSS). (The terminology "IOSS" is not to be confused with the totally different concept called input/output stability (IOS)—cf. [35, 46, 47]—which refers instead to stability of outputs, rather than to detectability.)

A system $\dot{x} = f(x, u)$ with measurement ("output") map $y = h(x)$ is IOSS if there are some functions $\beta \in \mathcal{KL}$ and $\gamma_1, \gamma_2 \in \mathcal{K}_\infty$ such that the estimate

$$|x(t)| \leq \max\left\{\beta(|x(0)|, t), \gamma_1\left(\left\|u|_{[0,t]}\right\|\right), \gamma_2\left(\left\|y|_{[0,t]}\right\|\right)\right\}$$

holds for any initial state $x(0)$ and any input $u(\cdot)$, where $x(\cdot)$ is the ensuing trajectory and $y(t) = h(x(t))$ the respective output function. (States $x(t)$, input values $u(t)$, and output values $y(t)$ lie in appropriate Euclidean spaces. We use $|\cdot|$ to denote Euclidean norm and $\|\cdot\|$ for supremum norm. Precise definitions and technical assumptions are discussed later.) The terminology IOSS is self-explanatory: formally, there is "stability from the input/output data to the state." The term was introduced in the paper [45], but the same notion had appeared before: it represents a natural combination of the notions of "strong" observability (cf. [35]) and ISS, and was called simply "detectability" in [36] (where it is phrased in input/output, as opposed to state space, terms and applied to questions of parameterization of controllers) and was called "strong unboundedness observability" in [19] (more precisely, this last notion also allows an additive nonnegative constant in the right-hand side of the estimate). In [45], two of the authors described relationships between the existence of full state observers and the IOSS property, or more precisely, a property which we called "incremental IOSS." The use of ISS-like formalism for studying observers, and hence implicitly the IOSS property, has also appeared several times in other authors' work, such as the papers [31, 26].

One of the main results of this paper is that a system is IOSS if and only if it admits a norm-estimator (in a sense also to be made precise). This result is in turn a consequence of a necessary and sufficient characterization of the IOSS property in terms of smooth dissipation functions, namely, there is a proper (radially unbounded) and positive definite smooth function V of states (a "storage function" in the language of dissipative systems introduced by Willems [52] and further developed by Hill and Moylan [12, 13] and others) such that a *dissipation inequality*

$$\frac{d}{dt}V(x(t)) \;\leq\; -\sigma_1(|x(t)|) + \sigma_2(|y(t)|) + \sigma_3(|u(t)|) \tag{1.1}$$

holds along all trajectories, with the functions σ_i of class $\mathcal{K}_\infty$. This provides an "infinitesimal" description of IOSS, and a norm-observer is easily built from V. Such a characterization in dissipation terms was conjectured in [45], and we provide here a complete solution to the problem. (The paper [45] also explains how the existence of V links the IOSS property to "passivity" of systems.)

It is worth pointing out that several authors have independently suggested that one should *define* "detectability" in dissipation terms. For example, in [27, eq. 15], one finds detectability defined by the requirement that there should exist a differentiable storage function V satisfying our dissipation inequality but with the special choice $\sigma_2(r) := r^2$ (there were no inputs in the class of systems considered there). A variation of this is to weaken the dissipation inequality, to merely require

$$x \neq 0 \;\Rightarrow\; \frac{d}{dt}V(x(t)) < \sigma_2(|y(t)|)$$

(again, with no inputs), as done, for instance, in the definition of detectability given in [30]. Observe that this represents a slight weakening of our property, in so far as there is no "margin" of stability $-\sigma_1(|x(t)|)$. One of our contributions is to show that such alternative definitions (when posed in the right generality) are in fact equivalent to IOSS.

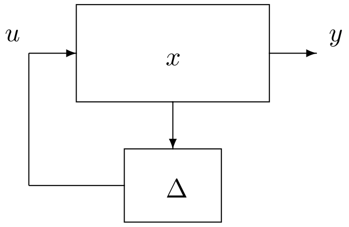

FIG. 1.3. *Robust detectability.*

A key preliminary step in the construction of V, just as it was for the analogous result for the ISS property obtained in [42], is the characterization of the IOSS property in robustness terms, by means of a "small gain" argument. The IOSS property is shown to be equivalent to the existence of a "robustness margin" $\rho \in \mathcal{K}_\infty$. This means that every system obtained by closing the loop with a feedback law Δ (even dynamic and/or time-varying) for which $|\Delta(t)| \leq \rho(|x(t)|)$ for all t (cf. Figure 1.3) is OSS (i.e., is IOSS as a system with no inputs). In order to formulate precisely this notion of robust detectability, we need to consider auxiliary "systems with disturbances." Since such systems must be introduced anyhow, we decided to present all our results (and definitions, even of IOSS) for systems with disturbances, in the process gaining extra generality in our results.

The core of the paper is, thus, the construction of V for "robustly detectable" (more precisely, "robust IOSS") systems $\dot{x} = g(x, d)$ which are obtained by substituting $u = d\rho(|x|)$ in the original system, and letting $d = d(\cdot)$ be an arbitrary measurable function taking values in a unit ball. The function V must satisfy a differential inequality of the form $\dot{V}(x(t)) \leq -\sigma_1(|x(t)|) + \sigma_2(|y(t)|)$ along all trajectories, that is to say, the following partial differential inequality:

$$\nabla V(x) \cdot g(x, d) \;\leq\; -\sigma_1(|x|) + \sigma_2(|y|)$$

for some functions σ_1 and σ_2 of class $\mathcal{K}_\infty$. But one last reduction consists of turning this problem into one of building Lyapunov functions for "relatively asymptotically stable" systems. Indeed, one observes that the main property needed for V is that it should *decrease along trajectories as long as $y(t)$ is sufficiently smaller than $x(t)$*. This leads us to the notion of "global asymptotic stability modulo outputs" and its Lyapunov-theoretic characterization.

The construction of V relies upon the solution of an appropriate optimal control problem, for which V is the value function. This problem is obtained by "fuzzifying" the dynamics near the set where $y \ll x$, so as to obtain a problem whose value function is continuous. Several elementary facts about relaxed controls are used in deriving the conclusions. The last major ingredient is the use of techniques from nonsmooth analysis, and in particular inf-convolutions, in order to obtain a Lipschitz, and from there by a standard regularization argument, a smooth, function V, starting from the continuous V that was obtained from the optimal control problem.

Finally, we will also discuss a version of detectability which relies upon "energy" estimates instead of uniform estimates. Such versions of detectability are fairly standard in control theory; see, for instance, [10], which defined "L^2-detectability" by a requirement that the state trajectory should be in L^2 if the observations are. The corresponding "integral to integral" notion uses a very interesting concept introduced in [29], that of "unboundedness observability" (UO), which amounts to a "relative (modulo outputs) forward completeness" property. It is shown that, for systems with no controls, the integral variant of OSS is equivalent to the conjunction of OSS and UO.

It is worth remarking that the main result in this paper amounts to providing necessary and sufficient conditions for the existence of a smooth (and proper and positive definite) solution V to a partial differential inequality which is equivalent to asking that (1.1) holds along all trajectories, namely,

$$\max_{u\in\mathbf{R}^m} \left\{\nabla V(x)\cdot f(x,u) + \sigma_1(|x|) - \sigma_2(|h(x)|) - \sigma_3(|u|)\right\} \;\leq\; 0\,. \tag{1.2}$$

It is a consequence of our results that if there is an (even just) lower semicontinuous such solution (when "solution" is interpreted in a weak sense, for example, in terms of viscosity or proximal subdifferentials), then there is also a smooth solution (usually, however, with different comparison functions σ_i's). This is because the existence of a weak solution is already equivalent to IOSS, as shown in [21]. It is a routine observation that the above partial differential inequality can be posed in an equivalent way as a *Hamilton–Jacobi inequality (HJI)*, in the special case of quadratic input "cost" $\sigma_3(r) = r^2$ and for systems $\dot{x} = f(x,u)$ which are affine in controls, i.e., systems of the form

$$\dot{x} \;=\; g_0(x) \;+\; \sum_{i=1}^{m} u_i\, g_i(x) \tag{1.3}$$

(we are denoting by u_i the ith component of u). Indeed, one need only replace the expression in (1.2) by its maximum value obtained at $u_i = (1/2)\nabla V(x)\cdot g_i(x)$, $i = 1,\dots,m$, thereby obtaining the following HJI:

$$\nabla V(x)\cdot g_0(x) + \frac{1}{4}\sum_{i=1}^{m}(\nabla V(x)\cdot g_i(x))^2 + \sigma_1(|x|) - \sigma_2(|h(x)|) \;\leq\; 0\,. \tag{1.4}$$

2. Definitions and statements of the main results.

2.1. Systems of interest.

We study a system whose dynamics depend on two types of inputs, which we respectively call *controls* and *disturbances*:

$$\dot{x}(t) = f(x(t),\mathbf{u}(t),\mathbf{w}(t)), \quad y(t) = h(x(t)). \tag{2.1}$$

Here, states evolve in $\mathbf{X} = \mathbf{R}^n$, controls are measurable, essentially bounded functions $\mathbf{u}$ on $\mathcal{I} = \mathbf{R}_{\geq 0}$ with values in $\mathbb{U} := \mathbf{R}^{m_u}$, and disturbances are measurable functions

$\mathbf{w} : \mathcal{I} \to \Gamma$ with values in Γ, which is a compact, convex subset of $\mathbf{R}^{m_w}$. We will denote the set of all such functions by $\mathcal{M}_\Gamma$. In those cases when a different interval $\mathcal{I} \subset \mathbf{R}_{\geq 0}$ of definition for a control $\mathbf{u}$ is specified, we always apply the definitions to the extension of $\mathbf{u}$ to $\mathbf{R}_{\geq 0}$, using $\mathbf{u} \equiv 0$ on $\mathbf{R}_{\geq 0} \setminus \mathcal{I}$. The function $f : \mathbf{X} \times \mathbb{U} \times \Gamma \to \mathbf{X}$ is locally Lipschitz in (x, u) uniformly on w, jointly continuous in x, u, and w, and such that $f(0, 0, w) = 0$ for any $w \in \Gamma$; and $h : \mathbf{X} \to \mathcal{Y} := \mathbf{R}^p$ is smooth (C^1) and vanishes at 0.

A function $\alpha : \mathbf{R}_{\geq 0} \to \mathbf{R}_{\geq 0}$ is *of class* $\mathcal{K}$ if it is continuous, positive definite, and strictly increasing, and is *of class* $\mathcal{K}_\infty$ if it is also unbounded. A function $\beta : \mathbf{R}_{\geq 0} \times \mathbf{R}_{\geq 0} \to \mathbf{R}_{\geq 0}$ is said to be *of class* $\mathcal{KL}$ if for each fixed $t \geq 0$, $\beta(\cdot, t)$ is of class $\mathcal{K}$, and for each fixed $s \geq 0$, $\beta(s, t)$ decreases to 0 as $t \to \infty$. Let $z(\cdot)$ be a measurable function.

The L_∞ (essential supremum) norm of the restriction of z to the interval $[t_1, t_2]$ is denoted by $\left\| z|_{[t_1,t_2]} \right\|$.

Given a state $\xi \in \mathbf{X}$, for each pair $(\mathbf{u}, \mathbf{w})$ denote by $x(t, \xi, \mathbf{u}, \mathbf{w})$ the unique maximal solution of the system (2.1), which is defined on some maximal interval $[0, t_{\max}(\xi, \mathbf{u}, \mathbf{w}))$. We will use the notation $y(t, \xi, \mathbf{u}, \mathbf{w}) := h(x(t, \xi, \mathbf{u}, \mathbf{w}))$, and, when unimportant or clear from the context, we will write $t_{\max}$ instead of $t_{\max}(\xi, \mathbf{u}, \mathbf{w})$, $x(t)$ instead of $x(t, \xi, \mathbf{u}, \mathbf{w})$, and $y(t)$ instead of $y(t, \xi, \mathbf{u}, \mathbf{w})$.

2.2. Notions of "uniform detectability" and dissipation functions.

DEFINITION 2.1. *A system of type* (2.1) *is said to be* uniformly input-output-to-state stable (UIOSS) *if there exist functions $\beta \in \mathcal{KL}$ and $\gamma_1, \gamma_2 \in \mathcal{K}$ such that the estimate*

$$|x(t, \xi, \mathbf{u}, \mathbf{w})| \leq \max\left\{\beta(|\xi|, t), \gamma_1\left(\left\|\mathbf{u}|_{[0,t]}\right\|\right), \gamma_2\left(\left\|y|_{[0,t]}\right\|\right)\right\} \tag{2.2}$$

holds for any initial state $\xi \in \mathbf{X}$, control $\mathbf{u}$, disturbance $\mathbf{w}$, and $t \in [0, t_{\max}(\xi, \mathbf{u}, \mathbf{w}))$.

DEFINITION 2.2. *A smooth (C^∞) function $V : \mathbf{X} \to \mathbf{R}_{\geq 0}$ is a UIOSS-Lyapunov function for system* (2.1) *if*

- *there exist $\mathcal{K}_\infty$-functions α_1, α_2 such that*

$$\alpha_1(|\xi|) \leq V(\xi) \leq \alpha_2(|\xi|) \tag{2.3}$$

  holds for all ξ in $\mathbf{X}$, and
- *there exists a $\mathcal{K}_\infty$-function α and $\mathcal{K}$-functions σ_1, σ_2 such that*

$$\nabla V(\xi) \cdot f(\xi, u, w) \leq -\alpha(|\xi|) + \sigma_1(|u|) + \sigma_2(|h(\xi)|) \tag{2.4}$$

  for all ξ in $\mathbf{X}$, for all control values $u \in \mathbb{U}$, and for all disturbance values $w \in \Gamma$. □

Property (2.3) amounts to positive definiteness and properness of V; requiring the existence of an upper bound α_2 is redundant, as it follows from the fact that V is continuous and satisfies $V(0) = 0$. However, it is convenient to specify this bound explicitly, as it will be used in various estimates. Condition (2.4) is a *dissipation inequality* in the sense of [52].

Remark 2.1. A smooth function $V : \mathbf{X} \to \mathbf{R}_{\geq 0}$, satisfying (2.3) on $\mathbf{X}$ with some α_1, α_2 of class $\mathcal{K}_\infty$, is a UIOSS-Lyapunov function for a system (2.1) if and only if there exist functions α_3 of class $\mathcal{K}_\infty$, and γ and χ_1 of class $\mathcal{K}$ such that

$$\nabla V(\xi) \cdot f(\xi, u, w) \leq -\alpha_3(|\xi|) + \gamma(|h(\xi)|) \tag{2.5}$$

for any $\xi \in \mathbf{X}$, $w \in \Gamma$, and $u \in \mathbb{U}$ such that $|\xi| \geq \chi_1(|u|)$.

Indeed, clearly (2.4) implies (2.5) with $\alpha_3(\cdot) := \alpha(\cdot)/2$, $\gamma \equiv \sigma_2$, and $\chi_1 := \alpha^{-1} \circ (2\sigma_1)$. To prove the other implication, assume now that (2.5) holds with some $\alpha_3 \in \mathcal{K}_\infty$ and γ, $\chi_1 \in \mathcal{K}$. Define $\sigma_1(\cdot) = \max\{0, \hat{\sigma_1}(\cdot)\}$, where

$$\hat{\sigma_1}(r) := \max\left\{\nabla V(\xi) \cdot f(\xi, u, w) + \alpha_3(\chi_1(|u|)) : |u| \leq r,\ |\xi| \leq \chi_1(r), w \in \Gamma\right\}.$$

Then σ_1 is continuous, $\sigma_1(0) = 0$, and one can assume that σ_1 is a $\mathcal{K}_\infty$-function (majorize it by one if it is not). We claim that (2.4) holds with $\alpha \equiv \alpha_3$ and $\sigma_2 \equiv \gamma$. Indeed, if $|\xi| \geq \chi_1(|u|)$, then (2.5) holds, from which (2.4) trivially follows. If $|\xi| < \chi_1(|u|)$, then, by definition of σ_1,

$$\sigma_1(|u|) \geq \nabla V(\xi) \cdot f(\xi, u, w) + \alpha_3(\chi_1(|u|))$$

for every w, which, in turn, implies (2.4).

A few particular cases of the UIOSS property have been studied in the literature. If the system (2.1) in consideration has no outputs and no disturbances, UIOSS reduces to the well-known ISS property, whose Lyapunov characterization was obtained in [42]. In case (2.1) is autonomous, UIOSS becomes OSS. This property was introduced in [43] where Lyapunov-type necessary and sufficient conditions were obtained. Finally, for systems with no disturbances, UIOSS is just IOSS. This property was introduced in [45], where it was conjectured that any IOSS control system admits a smooth IOSS-Lyapunov function. This conjecture will be proven here in a more general setting, for systems forced by both controls and disturbances. A few interesting applications of this Lyapunov characterization were also discussed in [45], one of them to be defined next.

2.3. Norm-estimators.

DEFINITION 2.3. *A* state-norm-estimator *(or* state-norm-observer*) for a system Σ of type* (2.1) *is a pair $(\Sigma_{n.o}, k(\cdot,\cdot))$, where $k : \mathbf{R}^\ell \times \mathcal{Y} \to \mathbf{R}$, and $\Sigma_{n.o}$ is a system*

$$\dot{p} = g(p, u, y) \tag{2.6}$$

evolving in $\mathbf{R}^\ell$ and driven by the controls and outputs of Σ, such that the following conditions are satisfied.

- *There exist $\mathcal{K}$-functions $\hat{\gamma}_1$ and $\hat{\gamma}_2$ and a $\mathcal{KL}$-function $\hat{\beta}$ such that for any initial state $\zeta \in \mathbf{R}^\ell$, all inputs $\mathbf{u}$ and $\mathbf{y}$, and any t in the interval of definition of the solution $p(\cdot, \zeta, \mathbf{u}, \mathbf{y})$, the following inequality holds:*

  $$|k(p(t, \zeta, \mathbf{u}, \mathbf{y}), \mathbf{y}(t))| \leq \hat{\beta}(|\zeta|, t) + \hat{\gamma}_1\left(\left\|\mathbf{u}|_{[0,t]}\right\|\right) + \hat{\gamma}_2\left(\left\|\mathbf{y}|_{[0,t]}\right\|\right) \tag{2.7}$$

  (in other words, the system (2.6) *is IOS with respect to the inputs u and y and output k).*
- *There are functions $\rho \in \mathcal{K}$ and $\beta \in \mathcal{KL}$ so that, for any pair of initial states ξ and ζ of systems* (2.1) *and* (2.6)*, respectively, any control $\mathbf{u} : \mathbf{R}_{\geq 0} \to \mathbb{U}$ and any disturbance $\mathbf{w} \in \mathcal{M}_\Gamma$, we have*

  $$|x(t, \xi, \mathbf{u}, \mathbf{w})| \leq \beta(|\xi| + |\zeta|, t) + \rho(|k(p(t, \zeta, \mathbf{u}, \mathbf{y}_{\xi,\mathbf{u},\mathbf{w}}), \mathbf{y}_{\xi,\mathbf{u},\mathbf{w}}(t))|) \tag{2.8}$$

  for all $t \in [0, t_{\max}(\xi, \mathbf{u}, \mathbf{w}))$. (Here $\mathbf{y}_{\xi,\mathbf{u},\mathbf{w}}$ denotes the output trajectory of Σ, that is, $\mathbf{y}_{\xi,\mathbf{u},\mathbf{w}}(t) = y(t, \xi, \mathbf{u}, \mathbf{w})$.)

2.4. Statement of the main result. The main theorem to be proved in this paper, summarizing the equivalent characterizations of UIOSS, will be as follows.

THEOREM 2.4. *Let* Σ *be a system of type* (2.1). *Then the following are equivalent:*

1. Σ *is UIOSS.*
2. Σ *admits a UIOSS-Lyapunov function.*
3. *There is a state-norm-estimator for* Σ.

The main contribution is in showing that 1 implies 2; the remaining implications are much easier.

2.5. Example: Linear systems. A particular class of systems (2.1) is as follows. A *linear*, time-invariant system Σ_{lin} with outputs is one for which f and h are linear, that is,

$$\begin{aligned} \dot{x} &= \mathbf{A}x + \mathbf{B}u, \\ y &= \mathbf{C}x, \end{aligned} \tag{2.9}$$

where $\mathbf{A} \in \mathbf{R}^{n\times n}$, $\mathbf{B} \in \mathbf{R}^{n\times m}$, and $\mathbf{C} \in \mathbf{R}^{p\times n}$. (We assume that $m_w = 0$.)

Recall the following definition.

DEFINITION 2.5. *A linear, time-invariant system* (2.9) *is* detectable*, or* asymptotically observable*, if the implication*

$$\mathbf{C}x(t) \equiv 0 \implies x(t) \to 0 \tag{2.10}$$

holds for any trajectory $x(t)$ *of* (2.9)*, corresponding to the zero control* $\mathbf{u} \equiv 0$.

The following result is a totally routine linear systems theory fact, but we include the proof as a motivation for the nonlinear material to follow.

PROPOSITION 2.6. *If a linear system* (2.9) *is detectable, then it is IOSS.*

Proof. It is a well-known fact (see, for example, [39]) that if a system (2.9) is detectable, then there exists a matrix $\mathbf{L} \in \mathbf{R}^{n\times p}$, such that the matrix $\mathbf{A} + \mathbf{LC}$ is Hurwitz, and, furthermore, the system

$$\dot{z}(t) = \mathbf{A}z(t) + \mathbf{B}\mathbf{u}(t) + \mathbf{L}(\mathbf{C}z(t) - y(t)), \tag{2.11}$$

referred to as an *observer* and driven by the controls and outputs of (2.9), has the property that if $x(t)$ and $z(t)$ are any solutions of (2.9) and (2.11), respectively, then $|x(t) - z(t)| \to 0$, and, in particular, if $x(0) = z(0)$, then $x(t) = z(t)$ for all nonnegative t. Fix an initial state ξ and a control $\mathbf{u}$. Then the solution $x(t, \xi, \mathbf{u})$ of (2.9) is also the solution of (2.11) with $z(0) = \xi$, so that

$$x(t, \xi, \mathbf{u}) = e^{t(\mathbf{A}+\mathbf{LC})}\xi + \int_0^t e^{s(\mathbf{A}+\mathbf{LC})}[\mathbf{B}\mathbf{u}(t-s) - \mathbf{L}y(t-s)]ds.$$

Choose two positive numbers δ' and δ so that $\Re\lambda \leq -\delta' < -\delta$ for every eigenvalue λ of $\mathbf{A} + \mathbf{LC}$. Then there exists a polynomial $P(\cdot)$ and, consequently, a constant K such that

$$\begin{aligned} |x(t, \xi, \mathbf{u})| &\leq P(t)e^{-\delta' t}|\xi| + \int_0^t P(s)e^{-\delta' s}\left[\|\mathbf{B}\|\,|\mathbf{u}(t-s)| + \|\mathbf{L}\|\,|y(t-s)|\right]ds \\ &\leq Ke^{-\delta t}|\xi| + K\frac{\|\mathbf{B}\|}{\delta}\left\|\mathbf{u}|_{[0,t]}\right\| + K\frac{\|\mathbf{L}\|}{\delta}\left\|y|_{[0,t]}\right\|. \end{aligned} \tag{2.12}$$

Thus, the IOSS estimate (2.2) holds for (2.9) with the linear gains $\beta(r, t) := Ke^{-\delta t}r$ and $\gamma_1(r) = \gamma_2(r) := K\frac{\|\mathbf{B}\|}{\delta}r$. □

To see this, first note that the solution $z(\cdot,\zeta,\mathbf{u},\mathbf{y})$ of (2.11) satisfies the estimate

$$|z(t,\zeta,\mathbf{u},\mathbf{y})| \leq Ke^{-\delta t}\,|\xi| + K\frac{\|\mathbf{B}\|}{\delta}\left\|\mathbf{u}|_{[0,t]}\right\| + K\frac{\|\mathbf{L}\|}{\delta}\left\|y|_{[0,t]}\right\|,$$

where K,δ are the same as in (2.12). Also, with $e := x - z$, we have

$$\dot{e}(t) = (A + LC)e(t).$$

From this we see that, along any trajectory $(x(t), z(t))$ of (2.9) and (2.11),

$$|x(t)| \leq K\,|\xi - \zeta|\,e^{-\delta t} + |z(t)|$$

for all $t \geq 0$, where K,δ are again as in (2.12).

To find an IOSS-Lyapunov function for system (2.9), take any symmetric matrix $\mathbf{P} \in \mathbf{R}^{n\times n}$ such that

$$\mathbf{P}(\mathbf{A}+\mathbf{LC}) + (\mathbf{A}+\mathbf{LC})'\mathbf{P} = -I$$

(such a matrix $\mathbf{P}$ exists, because $\mathbf{A}+\mathbf{LC}$ is Hurwitz). Define

$$V(x) := x'\mathbf{P}x. \tag{2.13}$$

Notice that, since $\mathbf{P}(\mathbf{A}+\mathbf{LC}) = ((\mathbf{A}+\mathbf{LC})'\mathbf{P})'$, we have $x'\mathbf{P}(\mathbf{A}+\mathbf{LC})x = x'(\mathbf{A}+\mathbf{LC})'\mathbf{P}x$. Therefore

$$\begin{aligned}
\nabla V(x)\cdot f(x,u) &= 2x'\mathbf{P}\,(\mathbf{A}x + \mathbf{B}u)\\
&= 2x'\mathbf{P}\,((\mathbf{A}+\mathbf{LC})x + \mathbf{B}u - \mathbf{L}y)\\
&= 2x'\mathbf{P}(\mathbf{A}+\mathbf{LC})x + 2x'\mathbf{PB}u - 2x'\mathbf{PL}y\\
&= x'(\mathbf{P}(\mathbf{A}+\mathbf{LC}) + (\mathbf{A}+\mathbf{LC})'\mathbf{P})x + 2x'\mathbf{PB}u - 2x'\mathbf{PL}y\\
&\leq -|x|^2 + 2\,\|\mathbf{P}\|\,\|\mathbf{B}\|\,|u|\,|x| + 2\,\|\mathbf{P}\|\,\|\mathbf{L}\|\,|y|\,|x|\\
&\leq -|x|^2 + |x|^2/4 + 4\,\|\mathbf{P}\|^2\,\|\mathbf{B}\|^2\,|u|^2 + |x|^2/4 + 4\,\|\mathbf{P}\|^2\,\|\mathbf{L}\|^2\,|y|^2\\
&\leq -|x|^2/2 + 4\,\|\mathbf{P}\|^2\,\|\mathbf{B}\|^2\,|u|^2 + 4\,\|\mathbf{P}\|^2\,\|\mathbf{L}\|^2\,|y|^2.
\end{aligned}$$

So, the UIOSS dissipation inequality holds for V with gains defined by $\alpha(r) = r/2$, $\sigma_1(r) = 4\,\|\mathbf{P}\|^2\,\|\mathbf{B}\|^2\,r^2$, $\sigma_2(r) = 4\,\|\mathbf{P}\|^2\,\|\mathbf{L}\|^2\,r^2$.

2.6. Systems without controls. Let Ω be a compact metric space (which is always assumed to be of the form $[-1,1]^m$ unless specified otherwise). Consider systems of the type

$$\dot{x} = f(x(t),\mathbf{d}(t)), \quad y(t) = h(x(t)), \tag{2.14}$$

where $f : \mathbf{X}\times\Omega$ is locally Lipschitz in x uniformly on d and jointly continuous in x and d, and $f(0,d) = 0$ for any $d \in \Omega$. The inputs are measurable functions $\mathbf{d} : \mathcal{I} \to \Omega$, and we use the term *disturbances* to refer to such Ω-valued inputs. We will use $\mathcal{M}_\Omega$ to denote the collection of all such functions.

This system can be seen as a particular case of (2.1) that eschews controls and is driven only by disturbances. However, it will play an important role in our studies; therefore for convenience we will define the corresponding stability property and dissipation inequality for this system separately from the main Definition 2.1.

Definition 2.7. *A system* (2.14) *is UOSS (uniformly output-to-state stable) if there exist some $\beta \in \mathcal{KL}$ and $\gamma_2 \in \mathcal{K}$ such that*

$$|x(t,\xi,\mathbf{d})| \leq \max\left\{\beta(|\xi|,t), \gamma_2\left(\left\|y|_{[0,t]}\right\|\right)\right\} \tag{2.15}$$

for any disturbance $\mathbf{d}$*, initial state* $\xi \in \mathbf{X}$*, and* $t \in [0, t_{\max})$.

Definition 2.8. *A UOSS-Lyapunov function for system* (2.14) *is a smooth function* $V : \mathbf{X} \to \mathbf{R}_{\geq 0}$ *satisfying* (2.3) *and*

$$\nabla V(x) \cdot f(x,d) \leq -\alpha_3(|x|) + \gamma(|h(x)|) \quad \forall\, x \in \mathbf{X},\ \forall\, d \in \Omega, \tag{2.16}$$

with some class $\mathcal{K}_\infty$ functions α_i and a $\mathcal{K}$ function γ. For systems with no disturbances we simply say that V is an OSS-Lyapunov function.

2.6.1. "Modulo outputs" relative stability.

Recall the classical notion of uniform global asymptotic stability for systems of type (2.14), ensuring that every solution of the system tends to the equilibrium and never goes too far from it. Suppose now that it does not matter how the system behaves when the information provided by the output is adequate, that is, the norm of the output dominates the norm of the current state. On the other hand, we want the system to decay nicely when the output does not help in determining how large the state is. This motivates the following "modulo output" definition of stability.

Definition 2.9. *A system of type* (2.14) *satisfies the GASMO (global asymptotic stability modulo output) property if there exist a function ρ of class $\mathcal{K}_\infty$ and a function λ of class $\mathcal{KL}$ such that, for all $\xi \in \mathbf{X}$, $\mathbf{d} \in \mathcal{M}_\Omega$, and any $T < t_{\max}(\xi,\mathbf{d})$, if*

$$|x(t,\xi,\mathbf{d})| \geq \rho(|h(x(t,\xi,\mathbf{d}))|) \quad \forall\, 0 \leq t \leq T,$$

then the estimate

$$|x(t,\xi,\mathbf{d})| \leq \lambda(|\xi|,t) \quad \forall\, 0 \leq t \leq T \tag{2.17}$$

holds.

Remark 2.2. If a system in consideration has no outputs, then the GASMO property becomes global asymptotic stability (GAS).

The following proposition provides an "ε-δ" characterization of the GASMO property.

Proposition 2.10. *A system of type* (2.14) *satisfies the GASMO property if and only if there exists a $\mathcal{K}_\infty$-function ρ so that the following two properties hold.*

1. *For any $\varepsilon > 0$ and any $r > 0$, there exists some $T_{r,\varepsilon}$ such that for any $|\xi| \leq r$, any $\mathbf{d}$, and any $T \in [0, t_{\max}(\xi,\mathbf{d}))$ such that $T \geq T_{r,\varepsilon}$, if*

$$|x(t,\xi,\mathbf{d})| \ \geq\ \rho(|y(t,\ \xi,\mathbf{d})|)\ \forall\, 0 \leq t \leq T\,,$$

then

$$|x(t,\ \xi,\mathbf{d})|\ <\ \varepsilon\ \ \forall\, t \in [T_{r,\varepsilon}, T]\,.$$

2. *There exists a $\mathcal{K}$-function ϑ such that for any $\xi \in \mathbf{X}$, any disturbance $\mathbf{d}$, and any $T < t_{\max}(\xi,\mathbf{d})$ such that*

$$|x(t,\xi,\mathbf{d})|\ \geq\ \rho(|y(t,\xi,\mathbf{d})|)\ \forall\, 0 \leq t \leq T\,,$$

the following "bounded overshoot" estimate holds:

$$|x(T,\xi,\mathbf{d})|\ \leq\ \vartheta(|\xi|)\,.$$

The necessity part is obvious. To prove the sufficiency, we need the following lemma, proved in section 3 of [25], although not explicitly stated in this form.

LEMMA 2.11. *Let* $\Phi(r,t) : (\mathbf{R}_{\geq 0})^2 \to \mathbf{R}_{\geq 0}$ *be a map such that*

1. *for all* $\varepsilon > 0$ *and for all* $R > 0$ *there exists* T *such that* $\Phi(r,t) < \varepsilon$ *for all* $0 \leq r \leq R$ *and for all* $t \geq T$,
2. *for all* $\varepsilon > 0$ *there exists* $\delta > 0$ *such that if* $r \leq \delta$, *then* $\Phi(r,t) < \varepsilon$ *for all* $t > 0$.

Then Φ *can be majorized by a* $\mathcal{KL}$*-function.*

Proof of sufficiency for Proposition 2.10. Consider the function

$$\Phi(r,t) := \sup\left\{|x(t,\xi,\mathbf{d})| : \ |\xi| \leq r,\, \mathbf{d} \in \mathcal{M}_\Omega,\ |x(s,\xi,\mathbf{d})| \geq \rho(|y(s,\xi,\mathbf{d})|)\ \forall\, s \in [0,t]\right\}.$$

Then the conditions 1 and 2 of Lemma 2.11 follow from the assumptions 1 and 2 of the proposition, so that one can majorize Φ by a $\mathcal{KL}$-function λ. □

2.6.2. Integral variants. The UOSS property gives uniform estimates on states as a function of uniform bounds on outputs. There is a "finite energy output implies finite energy state" version as well.

DEFINITION 2.12. *A system of type* (2.14) *is* integral-to-integral uniformly output-to-state stable (iiUOSS) *if there exist functions* γ, κ *of class* $\mathcal{K}$, *and* $\chi \in \mathcal{K}_\infty$ *such that*

$$\int_0^t \chi(|x(s,\xi,\mathbf{d})|)\, ds \ \leq\ \kappa(|\xi|) + \int_0^t \gamma(|h(x(s,\xi,\mathbf{d}))|)\, ds \tag{2.18}$$

for any initial state ξ, *any disturbance* $\mathbf{d} \in \mathcal{M}_\Omega$, *and any time* $t \in [0, t_{\max}(\xi,\mathbf{d}))$.

Without loss of generality, γ and κ can be assumed to be of class $\mathcal{K}_\infty$.

DEFINITION 2.13. *A system* (2.1) *is called* forward complete *if for every initial condition* ξ, *every input signal* $\mathbf{u}$, *and every disturbance* $\mathbf{d}$ *defined on* $[0,+\infty)$, *the corresponding trajectory* $x(t,\xi,\mathbf{u},\mathbf{d})$ *is defined for all* $t \geq 0$, *i.e.,* $t_{\max}(\xi,\mathbf{u},\mathbf{d}) = +\infty$.

The following property, which is strictly weaker than forward completeness, was introduced in [29].

DEFINITION 2.14. *A system* (2.14) *has the* unboundedness observability *property (UO) if*

$$\limsup_{t \nearrow t_{\max}(\xi,\mathbf{d})} |y(t,\xi,\mathbf{d})| = +\infty \tag{2.19}$$

holds for each initial state ξ *and disturbance* $\mathbf{d}$ *with* $t_{\max}(\xi,\mathbf{d}) < \infty$.

The following useful characterization of UO was provided in [3].

PROPOSITION 2.15. *A system* (2.14) *has the UO property if and only if there exist class* $\mathcal{K}$ *functions* ρ_1, χ_1, χ_2, *and a constant* c, *such that the following implication holds:*

$$\begin{aligned} &|h(x(t,\xi,\mathbf{d}))| \leq \rho_1(|x(t,\xi,\mathbf{d})|) \quad \forall\, t \in [0,T] \\ &\Rightarrow |x(t,\xi,\mathbf{d})| \leq \chi_1(t) + \chi_2(|\xi|) + c \quad \forall t \in [0,T] \end{aligned} \tag{2.20}$$

for all $\xi \in \mathbf{X}$, $\mathbf{d} \in \mathcal{M}_\Omega$, *and all* $T \in [0, t_{\max}(\xi,\mathbf{d}))$.

This proposition provides a uniform bound on all the states that can be reached by a UO system in given time from a given bounded set via a trajectory *not dominated by the output.* Notice that *for systems with disturbances* (2.14), *the UOSS property implies the UO property.*

2.6.3. Statement of the main result for the case of no controls.

THEOREM 2.16. *Let Σ be a system of type* (2.14). *Then the following are equivalent:*

1. Σ *is UOSS.*
2. Σ *is GASMO.*
3. Σ *is iiUOSS and UO.*
4. Σ *admits a UOSS-Lyapunov function.*

2.7. Organization of the paper. Implications 2 ⇒ 3 ⇒ 1 of Theorem 2.4 are proven in section 5. The part of Theorem 2.4 most difficult to prove is the implication 1 ⇒ 2. The main technical result needed for this proof is implication 2 ⇒ 4 of Theorem 2.16. This is proven in section 4. The construction of a UIOSS-Lyapunov function for an original system (2.1) is reduced, via a small gain argument, to the construction of a UOSS-Lyapunov function for a special system (2.14) related to the original system (2.1). This reduction is done in section 3.1, and section 3.2 completes the construction of UIOSS-Lyapunov functions.

Finally, implications 3 ⇒ 2, 1 ⇒ 2, and 4 ⇒ 3 of Theorem 2.16 are proven in section 3.3, and 4 ⇒ 1 follows from Theorem 2.4.

3. Reduction to the case of no controls.

In this part we show how to reduce our main result to the particular case of systems with no controls. Let $\mathbb{U}_1$ denote a closed unit ball $\{u \in \mathbb{U} : |u| \leq 1\}$ in $\mathbb{U}$.

3.1. Robust output-to-state stability.

DEFINITION 3.1. *System* (2.1) *is said to be* robustly output-to-state stable (ROSS) *if there exists a locally Lipschitz $\mathcal{K}_\infty$-function φ, called a* stability margin, *such that the system*

$$\dot{x}(t) = g(x(t), \mathbf{d}(t)) := f(x(t), \mathbf{d}_u(t)\varphi(|x(t)|), \mathbf{w}(t)) \tag{3.1}$$

with disturbances $d := [d_u, w] \in \mathbb{U}_1 \times \Gamma$ and outputs $y = h(x)$ is UOSS.

Notice that the set $\mathbb{U}_1 \times \Gamma$ is a compact, convex subset of $\mathbf{R}^{m_u+m_w}$. We will denote it by Ω in this section. Observe also that the dynamics g of system (3.1) are locally Lipschitz in x uniformly in d, and also $g(0, d) = 0$ for all $d \in \Omega$.

LEMMA 3.2. *If a system* (2.1) *is UIOSS, then it is ROSS.*

The proof will follow from a few preliminary lemmas.

Let $\beta \in \mathcal{KL}$ and γ_1, $\gamma_2 \in \mathcal{K}_\infty$ be as in (2.2). Let $\vartheta(r) = \beta(r, 0)$. Without loss of generality, we may assume that ϑ is $\mathcal{K}_\infty$ and $\vartheta(r) \geq r$ (so that $\vartheta^{-1}(r) \leq r$).

Define $\varphi(r)$ to be a locally Lipschitz $\mathcal{K}_\infty$-function, which minorizes ${\gamma_1}^{-1}(\frac{1}{4}\vartheta^{-1}(r))$ and can be extended as a Lipschitz function to a neighborhood of $[0, \infty)$. To prove the lemma we will show that φ is a stability margin for (2.1).

PROPOSITION 3.3. *Fix a $\xi \in \mathbf{X}$, a control $\mathbf{u}$, and a disturbance $\mathbf{w}$, and let $x(\cdot) := x(\cdot, \xi, \mathbf{u}, \mathbf{w})$ be the corresponding solution of the system* (2.1). *Let $T \in [0, t_{\max}(\xi, \mathbf{u}, \mathbf{w}))$. Then if $|\mathbf{u}(t)| \leq \varphi(|x(t)|)$ for almost all $t \in [0, T]$, the estimate*

$$|x(t)| \leq \max\left\{\beta(|\xi|, t),\ \gamma_2(\|y|_{[0,t]}\|),\ \frac{|\xi|}{4}\right\} \tag{3.2}$$

holds for all $t \in [0, T]$.

Proof.

Claim 1. Suppose $T < t_{\max}(\xi, \mathbf{u}, \mathbf{w})$. If

$$|\mathbf{u}(t)| \leq \varphi(|x(t)|) \text{ for almost all } t \in [0, T), \tag{3.3}$$

then, for all $t \in [0, T)$,

$$|x(t)| \le \max\left\{\vartheta(|\xi|), 2\gamma_2(\left\|y|_{[0,t]}\right\|)\right\}. \tag{3.4}$$

Proof of the claim. Suppose first that $\xi = 0$. In this case $x(t) \equiv 0$. Indeed, define $\mathbf{d}_u(\cdot)$ on $[0, t_{\max}(\xi, \mathbf{u}, \mathbf{w}))$ by

$$\mathbf{d}_u(t) = \begin{cases} 0 & \text{if } x(t) = 0, \\ \mathbf{u}(t)/\varphi(|x(t)|) & \text{if } x(t) \ne 0. \end{cases}$$

Then (3.3) implies that $\mathbf{d}_u \in \mathcal{M}_{\mathbb{U}_1}$ and that $x(\cdot)$ is the solution of (3.1) with $\xi = 0$, $\mathbf{w}$ as we picked, and $\mathbf{d}_u(\cdot)$ as we defined. Noticing that the constant function equal to 0 is also a solution of this system, with the same initial state and the same disturbance, we conclude by uniqueness of solutions that $x(t) = 0$ for all nonnegative t, so that (3.4) trivially holds.

Suppose now that $\xi \ne 0$. Fix ε, such that $1 < \varepsilon < 2$. We will first show that if $|\mathbf{u}(t)| \le \varphi(|x(t)|)$ for almost all $t < T$, then the estimate

$$|x(t)| \le \max\left\{\varepsilon\vartheta(|\xi|), 2\gamma_2(\left\|y|_{[0,t]}\right\|)\right\} \tag{3.5}$$

holds for all $t \in [0, T)$. Indeed, notice that (3.5) is true as a strict inequality at $t = 0$ because $|\xi| \le \vartheta(|\xi|) < \varepsilon\vartheta(|\xi|)$. If (3.5) fails at some $t \in [0, T)$, then there exists a

$$t_0 = \min\left\{t < T \ : \ x(t) = \max\left\{\varepsilon\vartheta(|\xi|), 2\gamma_2(\left\|y|_{[0,t]}\right\|)\right\}\right\}.$$

Note that $t_0 > 0$ because at $t = 0$ we have a strict inequality in (3.5). So, (3.5) holds for all $t \in [0, t_0)$ and $x(t_0) = \max\left\{\varepsilon\vartheta(|\xi|), 2\gamma_2(\left\|y|_{[0,t_0]}\right\|)\right\}$. Therefore for almost all $t \in [0, t_0)$ we have

$$\begin{aligned}
&\gamma_1(\left\|\mathbf{u}|_{[0,t]}\right\|) \le \gamma_1(\left\|\varphi(|x(\cdot)|)|_{[0,t]}\right\|) \\
&\le \max\left\{\frac{1}{4}\vartheta^{-1}(\varepsilon\vartheta(|\xi|)), \frac{1}{4}\vartheta^{-1}(2\gamma_2(\left\|y|_{[0,t]}\right\|))\right\} \\
&\le \max\left\{\frac{1}{4}\varepsilon\vartheta(|\xi|), \frac{1}{4}2\gamma_2(\left\|y|_{[0,t]}\right\|)\right\} \\
&\le \max\left\{\vartheta(|\xi|), \gamma_2(\left\|y|_{[0,t]}\right\|)\right\}.
\end{aligned}$$

Then, since our system is UIOSS and $x(\cdot)$ is continuous, for all $t \in [0, t_0]$ we have

$$\begin{aligned}
|x(t)| &\le \max\left\{\vartheta(|\xi|), \gamma_1(\left\|\mathbf{u}|_{[0,t]}\right\|), \gamma_2(\left\|y|_{[0,t]}\right\|)\right\} \\
&= \max\left\{\vartheta(|\xi|), \gamma_2(\left\|y|_{[0,t]}\right\|)\right\}.
\end{aligned}$$

On the other hand, $|x(t_0)| = \max\left\{\varepsilon\vartheta(|\xi|), 2\gamma_2(\left\|y|_{[0,t_0]}\right\|)\right\}$ by definition of t_0. The contradiction proves the estimate (3.5). Letting ε tend to 1, we conclude that estimate (3.4) holds for all $t \in [0, T)$, completing the proof of Claim 1.

Hence, under the assumption of Claim 1, we have

$$\begin{aligned}
\gamma_1\left(\left\|\mathbf{u}|_{[0,t]}\right\|\right) &\le \gamma_1\left(\left\|\varphi(|x(\cdot)|)|_{[0,t]}\right\|\right) \\
&\le \max\left\{\frac{|\xi|}{4}, \frac{1}{4}\vartheta^{-1}\left(2\gamma_2\left(\left\|y|_{[0,t]}\right\|\right)\right)\right\}
\end{aligned}$$

for all t in $[0, t_{\max})$. So,

$$|x(t)| \le \max\left\{\beta(|\xi|, t),\ \gamma_2\left(\left\|y|_{[0,t]}\right\|\right),\ \frac{|\xi|}{4},\ \frac{1}{4}\vartheta^{-1}\left(2\gamma_2\left(\left\|y|_{[0,t]}\right\|\right)\right)\right\}$$

for all $t \in [0, t_{\max})$. Noticing that

$$\frac{1}{4}\vartheta^{-1}\left(2\gamma_2\left(\|y|_{[0,t]}\|\right)\right) \leq \gamma_2\left(\|y|_{[0,t]}\|\right)$$

(because $\vartheta^{-1}(r) \leq r$), we arrive at (3.2). □

LEMMA 3.4. *Given any $\mathcal{KL}$-function $\hat{\beta}$, there exists a $\mathcal{KL}$-function β and a $\mathcal{K}_\infty$-function ν such that for any $\tau > 0$, any continuous function $\mu : [0,\tau] \to \mathbf{R}_{\geq 0}$, and any nonnegative constant C, the following implication holds:*

$$\forall t_1, t_2,\ \ 0 \leq t_1 < t_2 \leq \tau,\quad \mu(t_2) \leq \max\left\{\hat{\beta}(\mu(t_1), t_2 - t_1),\ \frac{\mu(t_1)}{2},\ C\right\} \tag{3.6}$$

implies

$$\mu(\tau) \leq \max\left\{\beta(\mu(0),\tau),\ \ \nu(C)\right\}. \tag{3.7}$$

Proof. By Proposition 7 in [38], there exist μ_1 and $\mu_2 \in \mathcal{K}_\infty$ such that

$$\hat{\beta}(r,t) \leq \mu_1(\mu_2(r)e^{-t}),$$

so, by majorizing $\hat{\beta}$ as above if necessary, we can assume without loss of generality that $\hat{\beta}$ is continuous in its second variable, and $\hat{\beta}(r,0) \geq r$ for all r. For any $r > 0$ define T_r to be the first time when $\hat{\beta}(r, T_r) = r/2$. By replacing $\hat{\beta}$ with the $\mathcal{KL}$-function $\widetilde{\beta}$, defined by

$$\widetilde{\beta}(r,t) := \max\left\{\hat{\beta}(r,t),\ \hat{\beta}(r,0)e^{-t}\right\},$$

we can assume without loss of generality that the series $\sum_{i=0}^{\infty} T_{\frac{r}{2^i}}$ diverges for every $r > 0$.

Define a function $\phi : \mathbf{R}_{\geq 0} \times \mathbf{R}_{\geq 0} \to \mathbf{R}_{\geq 0}$ as follows:

$$\phi(r,t) = \begin{cases} \hat{\beta}(r,t) & \text{for } t \in [0, T_r), \\ \hat{\beta}\left(\frac{r}{2^k}, t - \sum_{i=0}^{k-1} T_{\frac{r}{2^i}}\right) & \text{for } \ t \in \left[\sum_{i=0}^{k-1} T_{\frac{r}{2^i}}, \sum_{i=0}^{k} T_{\frac{r}{2^i}}\right),\ \ k = 1,2,3\dots. \end{cases}$$

Notice that the following two conditions hold for ϕ.

(1) For every R, $\varepsilon > 0$, there exists $\widetilde{t} > 0$ such that $\phi(r,t) \leq \varepsilon$ for all $r < R$ and $t > \widetilde{t}$.

Indeed, fix positive R and ε and find $k \in \mathbb{Z}$ such that $\hat{\beta}(R/2^k, 0) < \varepsilon$. Next, by continuity of $\hat{\beta}$ and by compactness of $[0,R]$ we can find a $\widetilde{t}$, such that $\sum_{i=0}^{k-1} T_{\frac{r}{2^i}} < \widetilde{t}$ for all positive $r < R$. Then, if $r < R$ and $t > \widetilde{t}$, then

$$\phi(r,t) = \hat{\beta}\left(\frac{r}{2^k}, t - \sum_{i=0}^{k-1} T_{\frac{r}{2^i}}\right) < \hat{\beta}\left(\frac{r}{2^k}, 0\right) < \varepsilon.$$

(2) For all $\varepsilon > 0$ there exists $\delta > 0$ such that if $r \leq \delta$, then $\phi(r,t) < \varepsilon$ for all $t \geq 0$.

Indeed, for all r and t, $\phi(r,t) \leq \hat{\beta}_0(r) := \hat{\beta}(r,0)$. For any positive ε, take $\delta = \delta(\varepsilon) := \hat{\beta}_0^{-1}(\varepsilon)$. Then, for all $t \geq 0$ we have

$$\phi(r,t) \leq \hat{\beta}\left(\hat{\beta}_0^{-1}(\varepsilon), 0\right) \leq \varepsilon.$$

Therefore, by Lemma 2.11, ϕ can be majorized by a $\mathcal{KL}$-function β.

Let $\nu(r) = \hat{\beta}(2r, 0)$.

Now pick any μ, C, and τ satisfying (3.6). Define $T = \min\{t : \mu(t) \leq 2C\}$ and $T = \tau$ if $\mu(t) > 2C$ for all $t \geq 0$.

For any t_1 and t_2 in $[0, \tau]$ such that $0 \leq t_1 \leq t_2 \leq T$, we have $\mu(t_1) > 2C$, so that $\mu(t_1)/2 > C$, hence

$$\mu(t_2) \leq \max\left\{\hat{\beta}(\mu(t_1), t_2 - t_1), \mu(t_1)/2\right\}. \tag{3.8}$$

Suppose now that $\tau = T$. If $0 \leq \tau < T_{\mu(0)}$, then (3.8) with $t_1 = 0$, $t_2 = \tau$ yields

$$\mu(\tau) \leq \max\left\{\hat{\beta}(\mu(0), \tau), \frac{\mu(0)}{2}\right\} = \hat{\beta}(\mu(0), \tau),$$

where the equality follows from the definition of $T_{\mu(0)}$. Likewise, if

$$\tau \in \left[\sum_{i=0}^{k-1} T_{\frac{\mu(0)}{2^i}}, \sum_{i=0}^{k} T_{\frac{\mu(0)}{2^i}}\right),$$

then

$$\begin{aligned}\mu(\tau) &\leq \max\left\{\hat{\beta}\left(2^{-k}\mu(0), \tau - \sum_{i=0}^{k-1} T_{\frac{\mu(0)}{2^i}}\right), 2^{-(k+1)}\mu(0)\right\} \\ &= \hat{\beta}\left(2^{-k}\mu(0), \tau - \sum_{i=0}^{k-1} T_{\frac{\mu(0)}{2^i}}\right),\end{aligned}$$

where the inequality follows from (3.8) and the equality is implied by the definition of $T_{\frac{\mu(0)}{2^k}}$. Therefore we have

$$\mu(\tau) \leq \phi(\mu(0), \tau). \tag{3.9}$$

In case $\tau > T$, inequality (3.6) implies

$$\begin{aligned}\mu(\tau) &\leq \max\left\{\hat{\beta}(2C, \tau - T), \mu(T)/2, C\right\} \\ &= \max\left\{\hat{\beta}(2C, \tau - T), C, C\right\} \leq \hat{\beta}(2C, 0) = \nu(C).\end{aligned} \tag{3.10}$$

Combining (3.9) and (3.10) we obtain

$$\mu(\tau) \leq \max\{\phi(\mu(0), \tau), \nu(C)\} \leq \max\{\beta(\mu(0), \tau), \nu(C)\}. \qquad \square$$

Proof of Lemma 3.2. We need to show that the system (3.1), corresponding to our system (2.1) with the stability margin φ we have defined, is UOSS. Apply Lemma 3.4 to the $\mathcal{KL}$-function $\hat{\beta} := \beta$ to find appropriate functions $\beta_1 \in \mathcal{KL}$ and $\nu \in \mathcal{K}$. Assume given any initial state ξ and disturbance $\mathbf{d} = [\mathbf{d}_u, \mathbf{w}]$, and let $x(t) := x(t, \xi, \mathbf{d}_u, \mathbf{w})$ be the corresponding solution. Fix any positive $t < t_{\max}(\xi, \mathbf{d})$, and define $\mathbf{u}$ by

$$\mathbf{u}(s) := \begin{cases} \varphi(|x(s)|)\mathbf{d}_u(s), & s \leq t \\ 0, & s > t. \end{cases}$$

Then, for all $s \le t$ we have $x(s) = x(s, \xi, \mathbf{u}, \mathbf{w})$, where the latter is the solution of the original system (2.1) with control $\mathbf{u}$ and disturbance $\mathbf{w}$. Let $C = \gamma_2(\left\|y|_{[0,t]}\right\|)$. Then, for any t_1 and t_2 in $[0, t]$ we have $C \ge \gamma_2(\left\|y|_{[t_1,t_2]}\right\|)$. So, since $|\mathbf{u}(s)| \le \varphi(|x(s)|)$ for all $s \in [0, t]$, Proposition 3.3 will imply that

$$|x(t_2)| \le \max\left\{\beta(|x(t_1)|, t_2 - t_1),\ \frac{|x(t_1)|}{2},\ C\right\}.$$

By the choice of β_1 and ν we then have

$$|x(t)| \le \max\left\{\beta_1(|\xi|, t), \nu(\gamma_2(\left\|y|_{[0,t]}\right\|))\right\},$$

proving the UOSS property for system (3.1) corresponding to the original UIOSS system. Thus, φ is indeed a stability margin for the original system, and the proof of Lemma 3.2 is now complete. □

3.2. A UIOSS system admits a UIOSS-Lyapunov function. We show now how the main implication of Theorem 2.4 follows from Theorem 2.16.

LEMMA 3.5 (see Lemma 2.13 in [42]). *Suppose a system* Σ *of type* (2.1) *is ROSS. Let* V *be a UOSS-Lyapunov function for the system* (3.1) *associated with* Σ*. Then* V *is a UIOSS-Lyapunov function for* Σ*.*

Proof. Let φ be a stability margin for Σ. Since V is a UOSS-Lyapunov function for (3.1), inequalities (2.3) and (2.16) hold with some α_1, α_2, α_3, and γ. Pick a state $\xi \in \mathbf{X}$ and disturbance value $w \in \Gamma$. For any control value $u \in \mathbb{U}$ with $|u| \le \varphi(|\xi|)$ we can find a $d_u \in \mathbb{U}_1$ such that $u = d_u \varphi(|\xi|)$, so that by the dissipation inequality (2.16) for V (applied with $d := [d_u, w]$) we have

$$\nabla V(\xi) \cdot f(\xi, u, w) = \nabla V(\xi) \cdot g(\xi, d) \le -\alpha_3(|\xi|) + \gamma(|h(\xi)|),$$

proving (2.5) for V. So, the condition as in Remark 2.1 is satisfied for V with $\chi_1 = \varphi^{-1}$, and α_i and γ as before. Thus, V is a UIOSS-Lyapunov function for Σ. □

By Theorem 2.16, the system (3.1) admits a UOSS-Lyapunov function V. Hence the following corollary follows.

COROLLARY 3.6. *If a system* (2.1) *is ROSS, then it admits a UIOSS-Lyapunov function.*

By Lemma 3.2, every UIOSS system is also ROSS, hence the implication 1 ⇒ 2 of Theorem 2.4 follows.

3.3. UOSS and iiUOSS imply the GASMO property.

LEMMA 3.7. *A UOSS system of type* (2.14) *satisfies the GASMO property.*

Proof. Assume that system (2.14) is UOSS. Without loss of generality, we may assume that γ_2 in (2.15) is of class $\mathcal{K}_\infty$.

Let $\vartheta(s) = \beta(s, 0)$. Recall that we have assumed that $\vartheta(s) > s$ for all $s > 0$. Now let ρ be any $\mathcal{K}_\infty$-function satisfying the inequality $\rho(s) > \vartheta(4\gamma_2(s))$ for all $s > 0$.

Claim. For any $\xi \in \mathbf{X}$, any $\mathbf{d} \in \mathcal{M}_\Omega$, and any $\tau \in [0, t_{\max}(\xi, \mathbf{d}))$, if

$$|x(t, \xi, \mathbf{d})| \ge \rho(|y(t, \xi, \mathbf{d})|)\ \forall\ 0 \le t \le \tau,$$

then

$$\gamma_2(|y(t, \xi, \mathbf{d})|) \le |\xi| / 2\ \forall\ 0 \le t \le \tau,$$

and hence

$$|x(t, \xi, \mathbf{d})| \le \beta(|\xi|, 0) = \vartheta(|\xi|)\ \forall\ 0 \le t \le \tau.$$

In particular, if $|x(t,\ \xi,\mathbf{d})| \geq \rho(|y(t,\xi,\mathbf{d})|)$ for all $t \in [0, t_{\max}(\xi,\mathbf{d}))$, then $t_{\max}(\xi,\mathbf{d}) = \infty$.

Proof of the claim. If $\xi = 0$, the result is clear. Pick any $\xi \neq 0$, $\mathbf{d} \in \mathcal{M}_\Omega$ and assume that $|x(t,\xi,\mathbf{d})| \geq \rho(|y(t,\xi,\mathbf{d})|)$ for all $0 \leq t \leq \tau$ for some $\tau \in (0,\ t_{\max}(\xi,\mathbf{d}))$. Then, at $t = 0$,

$$\gamma_2(|y(0,\xi,\mathbf{d})|) \leq \gamma_2(\rho^{-1}(|\xi|)) \leq \gamma_2(\rho^{-1}(\vartheta(|\xi|))) < |\xi|/4.$$

Hence, $\gamma_2(|y(t,\xi,\mathbf{d})|) < |\xi|/4$ for all $t \in [0,\delta)$ for some $\delta > 0$. Let

$$t_1 = \inf\left\{t > 0 : \gamma_2(|y(t,\xi,\mathbf{d})|) \geq |\xi|/2\right\}.$$

Then $t_1 > 0$. Assume now that $t_1 \leq \tau$. Then

$$\gamma_2(|y(t_1,\xi,\mathbf{d})|) = |\xi|/2 \quad\text{and}\quad \gamma_2(|y(t,\xi,\mathbf{d})|) < |\xi|/2$$

for each $t \in [0,\ t_1)$, and hence for such t, $|x(t,\xi,d)| \leq \vartheta(|\xi|)$. Then, for each $0 \leq t \leq t_1$,

$$\gamma_2(|y(t,\xi,\mathbf{d})|) \leq \gamma_2(\rho^{-1}(|x(t,\xi,\mathbf{d})|)) \leq \gamma_2(\rho^{-1}(\vartheta(|\xi|))) < |\xi|/4.$$

By continuity, $\gamma_2(|y(t_1,\xi,\mathbf{d})|) \leq |\xi|/4$, contradicting the definition of t_1. This shows that it is impossible to have $t_1 \leq \tau$, and the proof of the claim is complete.

For each $r > 0$ let T_r be any nonnegative number so that $\beta(r,t) < r/2$ for all $t \geq T_r$. Now, given any $r > 0$ and any $\varepsilon > 0$, for each $i = 1, 2, \ldots$, let $r_i := 2^{1-i}r$, and let $k(\varepsilon)$ be any positive integer so that $2^{-k(\varepsilon)}r < \varepsilon$ and define $T_{r,\varepsilon}$ as $T_{r_1} + T_{r_2} + \cdots + T_{r_{k(\varepsilon)}}$.

Pick any trajectory $x(t,\xi,\mathbf{d})$ as in the statement of Proposition 2.10, defined on an interval of the form $[0,T]$, with $T \geq T_{r,\varepsilon}$, with initial condition $|\xi| \leq r$, and disturbance $\mathbf{d} \in \mathcal{M}_\Omega$, satisfying $|x(t,\xi,\mathbf{d})| \geq \rho(|y(t,\xi,\mathbf{d})|)$ for all $t \in [0,T]$. Then, the above claim implies that $\gamma_2(|y(t,\xi,\mathbf{d})|) < |\xi|/2$ for all such t. Therefore, for any $t > T_{r_1} = T_r$,

$$\begin{aligned}|x(t,\xi,\mathbf{d})| &\leq \max\left\{\beta(|\xi|,t),\ |\xi|/2\right\}\\ &\leq \max\left\{\beta(r,t),\ r/2\right\} \leq r/2.\end{aligned}$$

Consider now the restriction of the trajectory to the interval $[T_{r_1}, T]$. This is the same as the trajectory that starts from the state $x(T_{r_1},\xi,\mathbf{d})$, which has norm less than r_1, so by the same argument and the definition of T_{r_2} we have that $|x(t,\xi,d)| \leq r/4$ for all $t \geq T_{r_2}$. Repeating on each interval $[T_{r_i}, T_{r_{i+1}}]$, we conclude that $|x(t,\xi,d)| < \varepsilon$ for all $T_{r,\varepsilon} \leq t \leq T$. □

LEMMA 3.8. *Suppose a system of type* (2.14) *is iiUOSS and UO. Then it satisfies the GASMO property with* $\rho(\cdot) := \max\left\{\chi^{-1}(2\gamma(\cdot)), \rho_1^{-1}(\cdot)\right\}$, *where* χ *and* γ *are as in the definition of iiUOSS and* ρ_1 *is as in Proposition* 2.15.

To prove this lemma, we need the following elementary observation, which is a variant of what is usually referred to as "Barbălat's lemma."

PROPOSITION 3.9. *Let* $\mathcal{X} := \{x_\alpha,\ \alpha \in \mathcal{A}\}$ *be a family of absolutely continuous curves in* $\mathbf{X}$, *each of which is defined on an interval* $\mathcal{I}_\alpha$, *either half-open* ($\mathcal{I}_\alpha = [0,\lambda_\alpha)$) *or closed* ($\mathcal{I}_\alpha = [0,\lambda_\alpha]$). *Suppose the following.*

- $\mathcal{X}$ *is closed with respect to shifts, that is, for all* $\alpha \in \mathcal{A}$ *and* $T \in \mathcal{I}_\alpha$, *there exists an* $\alpha' \in \mathcal{A}$ *such that* $x_{\alpha'} \equiv x_{\alpha T}$, *where* $x_{\alpha T}$ *is defined by* $x_{\alpha T}(t) := x_\alpha(t+T)$, *and* $\lambda_{\alpha'} = \lambda_\alpha - T$.
- *There exists a nonnegative, increasing function* ν_3 *such that*

$$|\dot{x}_\alpha(t)| \leq \nu_3(|x_\alpha(t)|)\ \ \forall\, \alpha \in \mathcal{A} \quad \textit{for almost all } t \in \mathcal{I}_\alpha.$$

- *There exist functions κ and χ of class $\mathcal{K}_\infty$ such that*

$$\kappa(|x_\alpha(0)|) \geq \int_0^t \chi(|x_\alpha(s)|)\,ds \quad \forall\, \alpha \in \mathcal{A},\ t \in \mathcal{I}_\alpha.$$

Then for any two positive numbers r and ε there exists a $T_{r,\varepsilon}$, such that for all $\alpha \in \mathcal{A}$ and $t \in \mathcal{I}_\alpha$ the following holds:

$$t \geq T_{r,\varepsilon} \text{ and } |x_\alpha(0)| \leq r \Rightarrow |x_\alpha(t)| < \varepsilon.$$

Proof.

Claim 1. Given any $\varepsilon > 0$, there exists $\delta = \delta(\varepsilon)$ such that if $|x_\alpha(0)| \leq \delta$, then $|x_\alpha(t)| < \varepsilon$ for all $t \in I_\alpha$.

Proof of Claim 1. Fix a positive ε, and set

$$\delta(\varepsilon) = \min\left\{\frac{\varepsilon}{2}, \kappa^{-1}\left(\frac{\varepsilon\chi(\varepsilon/2)}{2\nu_3(\varepsilon)}\right)\right\}.$$

Pick any $\alpha \in \mathcal{A}$ such that $|x_\alpha(0)| \leq \delta$.

Suppose $\left|x_\alpha(\widetilde{t}_2)\right| \geq \varepsilon$ for some $\widetilde{t}_2 \in \mathcal{I}_\alpha$. Then there exist t_1 and t_2 with $t_1 < t_2 \leq \widetilde{t}_2$ such that $|x_\alpha(t_1)| = \varepsilon/2$ and $\varepsilon/2 < |x_\alpha(t)| < \varepsilon$ for all $t \in (t_1, t_2)$. Then

$$\frac{\varepsilon}{2} = |x_\alpha(t_2)| - |x_\alpha(t_1)| \leq |x_\alpha(t_2) - x_\alpha(t_1)| \leq \sup_{t_1 \leq t \leq t_2} |\dot{x}_\alpha(t)|\,(t_2 - t_1) \leq \nu_3(\varepsilon)(t_2 - t_1).$$

So,

$$\kappa(\delta) \geq \kappa(|\xi|) \ \geq \ \int_{t_1}^{t_2} \chi(|x_\alpha(s)|)\,ds > \frac{1}{2}\chi\left(\frac{\varepsilon}{2}\right)(t_2 - t_1) \geq \frac{\varepsilon\chi(\varepsilon/2)}{2\nu_3(\varepsilon)} \geq \kappa(\delta).$$

The obtained contradiction proves the claim.

Claim 2. Given positive numbers r and δ, there exists a time $\tau(r,\delta)$ such that if $|x_\alpha(0)| \leq r$ and $\tau(r,\delta) \in \mathcal{I}_\alpha$, then $\exists t_0 < \tau(r,\delta)$ such that $|x(t_0, \xi, \mathbf{d})| \leq \delta$.

Proof of Claim 2. Take $\tau(r,\delta) = \frac{2\kappa(r)}{\chi(\delta)}$. Then, if $\tau(r,\delta) \in I_\alpha$ and $|x_\alpha(t)| > \delta$ for all $t \in [0, \tau(r,\delta))$, then we have

$$\kappa(r) \geq \kappa(|x_\alpha(0)|) \geq \int_0^{\tau(r,\delta)} \chi(|x_\alpha(s)|)\,ds > \chi(\delta)\frac{\kappa(r)}{\chi(\delta)} = \kappa(r).$$

The obtained contradiction proves the claim.

Fix arbitrary positive r and ε. By Claim 1, find $\delta(\varepsilon)$ such that if $|x_\alpha(0)| < \delta(\varepsilon)$, then $|x_\alpha(t)| \leq \varepsilon$ for all $t \in [0, \lambda_\alpha)$. Define $T_{r,\varepsilon} := \tau(r, \delta(\varepsilon))$, where $\tau(r,\delta(\varepsilon))$ is furnished by Claim 2. If $|x_\alpha(0)| < r$, then, by Claim 2, there is a $t_0 < \tau(r,\delta(\varepsilon))$ with $|x_\alpha(t_0)| < \delta(\varepsilon)$. Consider now a function $x_{\alpha'}(\cdot) := x_\alpha(t_0 + \cdot)$ (it belongs to $\mathcal{X}$ by assumption). Since $|x_{\alpha'}| \leq \delta(\varepsilon)$, Claim 1 ensures that

$$|x_\alpha(t)| = |x_{\alpha'}(t - t_0)| \leq \varepsilon \quad \forall\, t \geq t_0 \geq T_{r,\varepsilon}.$$

This shows that $T_{r,\varepsilon}$ satisfies the conclusion of the proposition. □

We now return to the proof of Lemma 3.8.

Proof. Recall that we have defined $\lambda_{\xi,\mathbf{d}} := \inf\{t \in [0, t_{\max}(\xi,\mathbf{d})) : |x(t,\xi,\mathbf{d})| \leq \rho(|y(t,\xi,\mathbf{d})|)\}$, and let $\lambda_{\xi,\mathbf{d}} = t_{\max}$ if $|x(t,\xi,d)| > \rho(|y(t,\xi,\mathbf{d})|)$ for all $t \in [0, t_{\max})$.

Note that, given ξ and $\mathbf{d}$, for all $t < \lambda_{\xi,\mathbf{d}}$ we have $\chi(|x(t,\xi,\mathbf{d})|) > 2\gamma(|h(x(t,\xi,\mathbf{d}))|)$ so that

$$\kappa(|\xi|) \geq \int_0^t (\chi(|x(s,\xi,\mathbf{d})|) - \gamma(|h(x(s,\xi,\mathbf{d}))|))\, ds > \frac{1}{2}\int_0^t \chi(|x(s,\xi,\mathbf{d})|)\, ds. \tag{3.11}$$

Let ν_3 be a $\mathcal{K}$-function such that $\max_{d\in\Omega}|f(x,d)| \leq \nu_3(|x|)$. Write $x_{\xi,\mathbf{d}}(\cdot) := x(\cdot,\xi,\mathbf{d})$. Notice that the family $\{x_{\xi,\mathbf{d}}(\cdot),\ \xi \in \mathbf{X},\ \mathbf{d} \in \mathcal{M}_\Omega\}$ with $\mathcal{I}_{\xi,\mathbf{d}} := [0, \lambda_{\xi,\mathbf{d}})$ satisfies all the assumptions of Proposition 3.9 (with "κ" $= 2\kappa$). Given any positive r, ε, Proposition 3.9 furnishes $T_{r,\varepsilon}$. This $T_{r,\varepsilon}$ obviously fits the first condition in the characterization of the GASMO property, provided by Proposition 2.10.

To find a function ϑ to ensure that the second part of Proposition 2.10 is satisfied, recall that, by Proposition 2.15, if a system (2.14) has the UO property, then there exist class $\mathcal{K}_\infty$-functions ρ_1, μ_1, μ_2, and a constant $c > 0$ such that the following implication holds for all $\xi \in \mathbf{X}$, all $\mathbf{d} \in \mathcal{M}_\Omega$, and all $T \in [0, t_{\max}(\xi,\mathbf{d}))$:

$$\begin{aligned}|h(x(t,\xi,\mathbf{d}))| \ &\leq \ \rho_1(|x(t,\xi,\mathbf{d})|) \ \ \forall t \in [0,T] \\ &\Rightarrow |x(t,\xi,\mathbf{d})| \leq \mu_1(t) + \mu_2(|\xi|) + c \ \ \forall t \in [0,T].\end{aligned}$$

Therefore, if $|\xi| \leq r$ and $T_{r,r/2}$ is as defined above, then for all $t \in [0, \lambda_{\xi,\mathbf{d}})$ we have

$$|x(t,\xi,\mathbf{d})| \leq \mu_1(T_{r,r/2}) + \mu_2(r) + c \ \text{ if } t < T_{r,r/2}$$

and

$$|x(t,\xi,\mathbf{d})| \leq r/2 \ \text{ if } t \geq T_{r,r/2}.$$

Thus, the following estimate holds for all such t:

$$|x(t,\xi,\mathbf{d})| \leq \widetilde{\vartheta}(|\xi|) := \max\left\{|\xi|/2,\ \mu_1(T_{|\xi|,|\xi|/2}) + \mu_2(|\xi|) + c\right\}.$$

Next, take a sequence $\{\varepsilon_k\}$, $k = 0, 1, 2, \ldots$, strictly decreasing to 0, with $\varepsilon_0 = 1$. For each ε_k, find $\delta_k = \delta(\varepsilon_k)$ as in the proof of Claim 1. Since $\delta_k \leq \varepsilon_k/2$, the sequence $\{\delta_k\}$ converges to 0 as well. Find a function ϑ of class $\mathcal{K}$, such that

(1) $\vartheta(\delta_{k+1}) > \varepsilon_k \ \ \forall k > 0$,
(this will ensure that $|x(t,\xi,\mathbf{d})| \leq \vartheta(|\xi|)$ for all ξ with $|\xi| < \delta_0$, for all $t \in [0, \lambda_{\xi,\mathbf{d}}]$)
(2) $\vartheta(s) \geq \widetilde{\vartheta}(s) \ \ \forall s > \delta_0$.

Then ϑ satisfies the second condition in the Proposition 2.10. This completes the proof. □

Remark 3.1. The unboundedness observability assumption is crucial in proving the last lemma. The following example illustrates a disturbance-free integral-to-integral output-to-state stable (iiOSS) system which fails to be OSS (and, equivalently, fails to be GASMO).

Let $1_A(\cdot)$ denote the indicator function of a set A, and let ϕ_ε be a C^∞-bump function with support in $(-\varepsilon, \varepsilon)$:

$$\phi_\varepsilon(\xi) := \begin{cases} e^{-\frac{|\xi|^2}{\varepsilon^2 - |\xi|^2}}, & |\xi| < \varepsilon, \\ 0, & |\xi| \geq \varepsilon. \end{cases} \tag{3.12}$$

Fix an arbitrary positive $\varepsilon < 0.25$ and consider a one dimensional autonomous system

$$\Sigma: \qquad \dot{x} = f(x), \quad y = h(x),$$

where

$$\begin{aligned} f(x) = x^3 & \left[1_{(-\infty,-1]}(x)(1-\phi_\varepsilon(x+1)) + 1_{[1,+\infty)}(x)(1-\phi_\varepsilon(x-1))\right] \\ & -x\left[1_{(-1,1)}(x)(1-\phi_\varepsilon(x+1))(1-\phi_\varepsilon(x-1))\right], \end{aligned}$$

and h is a smooth function such that $h(x) = x$ for all x in $[-2, 2]$, and $h(x) = 0$ if $|x| \geq 3$.

Claim 1. The system Σ is iiOSS.

Proof. Note that Σ has a stable equilibrium at $x = 0$ and two unstable ones at 1 and -1. If $|x| < 1$, then $\text{sign}(x) = -\text{sign}(f(x))$, so, if $|\xi| \leq 1$, then $|x(t,\xi)| \leq 1$ for any nonnegative t. Therefore, if $\xi \in [-1, 1]$, then for all $t \geq 0$ we have

$$\int_0^t |x(s,\xi)|\,ds = \int_0^t |h(x(s,\xi))|\,ds, \tag{3.13}$$

so, estimate (2.18) trivially follows for all $\xi \in [-1, 1]$ and all $t \in t_{\max}(\xi)$ with $\gamma = Id$ and any $\kappa \in \mathcal{K}$.

If $|\xi| \geq 1 + \varepsilon$, then $f(x) = x^3$, so that

$$x(t,\xi) = \frac{\text{sign}(\xi)}{\sqrt{\xi^{-2} - 2t}}.$$

Thus, in this case the solution $x(t,\xi)$ is defined for all nonnegative $t < t_{\max}(\xi) = \xi^{-2}/2$ and

$$\int_0^t |x(s,\xi)|\,ds \leq \int_0^{t_{\max}(\xi)} |x(s,\xi)|\,ds = \frac{1}{\xi} \leq \frac{1}{1+\varepsilon}.$$

Let κ be any $\mathcal{K}$-function such that $\kappa(1) \geq (1+\varepsilon)^{-1}$. Suppose $1 < |\xi| < 1 + \varepsilon$. Let $\hat{t}$ be the time when $\left|x(\hat{t},\xi)\right| = 1 + \varepsilon$. Then $t_{\max}(\xi) = \hat{t} + (1+\varepsilon)^{-2}/2$. Also, $x(s,\xi) = h(x(s,\xi))$ for all $s \in [0,\hat{t}]$, so, in particular, equality (3.13) holds for all $t < \hat{t}$, which, again, trivially implies (2.18) with $\gamma = Id$ and any $\kappa \in \mathcal{K}$.

If $t > \hat{t}$, then

$$\begin{aligned} \int_0^t |x(s,\xi)|\,ds &= \int_0^{\hat{t}} |x(s,\xi)|\,ds + \int_{\hat{t}}^t |x(s,\xi)|\,ds \\ &\leq \int_0^{\hat{t}} |x(s,\xi)|\,ds + \int_{\hat{t}}^{t_{\max}(\xi)} |x(s,\xi)|\,ds \\ &= \int_0^{\hat{t}} |h(x(s,\xi))|\,ds + \int_0^{t_{\max}(1+\varepsilon)} |x(s,1+\varepsilon)|\,ds \\ &\leq \int_0^{\hat{t}} |h(x(s,\xi))|\,ds + \kappa(\xi) \\ &\leq \int_0^{t} |h(x(s,\xi))|\,ds + \kappa(\xi). \end{aligned}$$

This shows that Σ is iiOSS, as estimate (2.18) holds for Σ with the κ that we constructed and $\gamma = Id$. □

Claim 2. System Σ is not OSS.

Proof. Indeed, pick any initial state ξ of large enough magnitude so that $h(\xi) = 0$. Then $h(x(t,\xi)) = 0$ for all $t < t_{\max}(\xi) = \xi^{-2}/2$. If Σ were OSS, then there would exist some $\mathcal{KL}$-function β such that $|x(t,\xi)| \le \beta(|\xi|, t)$, but $|x(t,\xi)|$ tends to ∞ as $t \to t_{\max}(\xi)$, whereas $\beta(|\xi|, t) \le \beta(|\xi|, 0)$. This contradiction proves the claim. □

We now prove implication 4 ⇒ 3 of Theorem 2.16.

Proof. Suppose a system Σ of type (2.14) is UOSS. We have already remarked that Σ is UO, so we must show that it is iiUOSS. By assumption there exists a smooth function V satisfying (2.16) and (2.3) with some α_1, α_2, α_3, and γ. Pick any ξ, $\mathbf{d}$, and $t \in [0, t_{\max}(\xi, \mathbf{d}))$. Integrating inequality (2.16) along the trajectory $x(\cdot, \xi, \mathbf{d})$ over $[0, t]$ we get

$$\begin{aligned}\int_0^t \alpha_3(|x(t,\xi,\mathbf{d})|)dt &\le V(x(0,\xi,\mathbf{d})) - V(x(t,\xi,\mathbf{d})) + \int_0^t \gamma(|h(x(t,\xi,\mathbf{d}))|)\, dt \\ &\le \alpha_2(|\xi|) + \int_0^t \gamma(|h(x(t,\xi,\mathbf{d}))|)\, dt,\end{aligned}$$

proving inequality (2.18) for system Σ, with $\chi = \alpha_3$ and $\kappa = \alpha_2$. □

With Lemma 3.7 in mind we conclude that the only step missing in establishing the Lyapunov characterization for UOSS is proving the implication 2.16 ⇒ 2.16 in Theorem 2.16.

3.4. A remark on the GASMO ⇒ UOSS implication.

Remark 3.2. Once the Lyapunov characterization for UOSS is proven, the implication 2 ⇒ 1 of Theorem 2.16 will automatically follow by appealing to the converse Lyapunov theorem (2 ⇒ 4 ⇒ 1). However, it is worth mentioning that GASMO ⇒ UOSS implication can easily be proven directly without this intermediate step.

Indeed, fix $\xi \in \mathbf{X}$ and $\mathbf{d} \in \mathcal{M}_\Omega$. Take any $t \in [0, t_{\max}(\xi, \mathbf{d}))$. If $t \le \lambda_{\xi,\mathbf{d}}$, then the GASMO property provides the estimate

$$|x(t,\xi,\mathbf{d})| \le \lambda(|\xi|, t). \tag{3.14}$$

Suppose now that $t > \lambda_{\xi,\mathbf{d}}$. Obviously, at least one of the two following conditions must be satisfied:

(1) $|x(t,\xi,\mathbf{d})| > 2\rho(|h(x(t,\xi,\mathbf{d}))|)$,

(2) $|x(t,\xi,\mathbf{d})| \le 3\rho(|h(x(t,\xi,\mathbf{d}))|)$.

If condition (2) applies, then we have a bound

$$|x(t,\xi,\mathbf{d})| \le 3\rho(|h(x(t,\xi,\mathbf{d}))|) \le 3\rho(\left\|y|_{[0,t]}\right\|). \tag{3.15}$$

In case condition (1) holds, let

$$\widetilde{t} := \max\left\{s,\ \lambda_{\xi,\mathbf{d}} < s < t \ : \ |x(s,\xi,\mathbf{d})| = 2\rho(|h(x(s,\xi,\mathbf{d}))|)\right\}.$$

Then, again by the GASMO property applied with initial state $x(\widetilde{t}, \xi, \mathbf{d})$, we have

$$\begin{aligned}|x(t,\xi,\mathbf{d})| &\le \lambda(\left|x(\widetilde{t},\xi,\mathbf{d})\right|, t - \widetilde{t}) \\ &\le \lambda(2\rho(\left|y(\widetilde{t},\xi,\mathbf{d})\right|), 0) \le \lambda(2\rho(\left\|y|_{[0,t]}\right\|), 0).\end{aligned} \tag{3.16}$$

Combining estimates (3.14), (3.15), and (3.16), we conclude that inequality (2.15) holds for Σ with $\beta(\cdot) := \lambda(\cdot)$ and $\gamma_2(\cdot) := \max\{\lambda(2\rho(\cdot), 0),\ 3\rho(\cdot)\}$.

4. The case of no controls.

4.1. Setup. Suppose a system Σ of type (2.14) satisfies the GASMO property with some $\mathcal{K}_\infty$ function ρ. By majorizing ρ with another $\mathcal{K}_\infty$-function if necessary, we will assume that ρ is smooth when restricted to $s > 0$ and also $\rho(s) > s$ for all positive s. We let

$$\mathcal{D} := \{\xi \in \mathbf{X}\colon\ |\xi| \le \rho(|h(\xi)|)\}\ ,$$

$$\mathcal{E} := \mathbf{X} \backslash \mathcal{D}\,,$$

and

$$\mathcal{E}_1 := \{\xi \in \mathbf{X} : |\xi| > 2\rho(|h(\xi)|)\}\ .$$

For each $\mathbf{d} \in \mathcal{M}_\Omega$ and $\xi \in \mathcal{E}$, define

$$\lambda_{\xi,\mathbf{d}} = \inf\{t \in [0, t_{\max}) : x(t, \xi, \mathbf{d}) \in \mathcal{D}\}\,, \tag{4.1}$$

with the convention $\lambda_{\xi,\mathbf{d}} = t_{\max}(\xi, \mathbf{d})$ if the trajectory never enters $\mathcal{D}$. If $\mathcal{D} = \mathbf{X}$, then any proper, smooth, and positive definite function $V : \mathbf{X} \to \mathbf{R}$ is a UOSS-Lyapunov function for (2.14). Indeed, because it is proper and finite, V obviously satisfies (2.3) for some α_1 and α_2. Since V is smooth, $|\nabla V(\xi)|$ is bounded above by a nondecreasing continuous function $\nu(|\xi|)$ and

$$\frac{d}{dt}V(x(t)) \;=\; \nabla V(x(t)) \cdot f(x(t), \mathbf{d}(t)) \;\le\; \nu(|x(t)|)\nu_3(|x(t)|),$$

where $\nu_3(|\cdot|)$ is a $\mathcal{K}$-function majorizing $f(\cdot, d)$ for all $d \in \Omega$. Then, since $|x| \le \rho(|h(x)|)$ for all $x \in \mathbf{X}$, we have

$$\frac{d}{dt}V(x(t)) \;\le\; -\nu(|x(t)|)\nu_3(|x(t)|) \;+\; 2\nu(\rho(|h(x(t))|))\nu_3(\rho(|h(x(t))|))\,.$$

So, V satisfies inequality

$$\nabla V(x) \cdot f(x, d) \le -\alpha_3(|x|) + \gamma(|h(x)|) \quad \forall\, x \in \mathbf{X},\ \forall\, d \in \Omega$$

(with $\alpha_3(\cdot) = \nu(\cdot)\nu_3(\cdot)$ and $\gamma(\cdot) = [2\nu \circ \rho(\cdot)][\nu_3 \circ \rho(\cdot)]$), which is the same as (2.4) for systems of type (2.14).

Suppose now that $\mathcal{D} \ne \mathbf{X}$. Recall that we have defined, for each $\xi \notin \mathcal{D}$ and $d \in \mathcal{M}_\Omega$, $\lambda_{\xi,\mathbf{d}} = \inf\{t \in [0, t_{\max}) : x(t, \xi, \mathbf{d}) \in \mathcal{D}\}$, with the convention $\lambda_{\xi,\mathbf{d}} = t_{\max}(\xi, \mathbf{d})$ if the trajectory never enters $\mathcal{D}$.

The GASMO property then implies

$$|x(t, \xi, \mathbf{d})| \le \lambda(|\xi|\,, t) \qquad \forall\, \xi \in \mathcal{E},\ \forall\, \mathbf{d} \in \mathcal{M}_\Omega,\ \forall\, t \in [0, \lambda_{\xi,\mathbf{d}}) \tag{4.2}$$

for some $\lambda \in \mathcal{KL}$.

Note that, because of property (4.2), the system cannot have any equilibrium in $\mathcal{E}$, that is,

$$f(\xi, d) \ne 0$$

for every $\xi \in \mathcal{E}$ and every $d \in \Omega$. Moreover, replacing $\rho(s)$ by $c\rho(s)$ for some $c > 1$ if necessary, one may also assume that $f(\xi, d) \ne 0$ for all $\xi \in \partial\mathcal{D} \setminus \{0\}$ and all $d \in \Omega$.

We introduce an auxiliary system $\hat{\Sigma}$ which slows down the motions of the original one:

$$\dot{z} \;=\; \widehat{f}(z,d) \;=\; \frac{1}{1+|f(z,d)|^2+\kappa(z)}f(z,d), \tag{4.3}$$

where κ is any smooth function $\mathbf{X} \to [0,\infty)$ with the property that

$$\kappa(\xi) \;\geq\; 2\max_{d\in\Omega} |\nabla(\rho\circ|h|)(\xi)\cdot f(\xi,d)| \tag{4.4}$$

whenever $|h(\xi)| \geq 1$. (Recall that ρ was assumed, without loss of generality, to be smooth for positive arguments.) For each disturbance $\hat{\mathbf{d}}$ (defined on $\mathbf{R}_{\geq 0}$) denote by

$$z(s,\xi,\hat{\mathbf{d}})$$

the value at time s of the solution of the equation $\dot{z} = \widehat{f}(z,\hat{\mathbf{d}})$ with initial state ξ. Observe that, as $\widehat{f}$ is bounded, this solution exists for all nonnegative s.

Claim 1. For each ξ and each $\mathbf{d}$,

$$x(t,\xi,\mathbf{d}) = z(\sigma_{\xi,\mathbf{d}}(t),\xi,\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1}) \qquad \forall\, t\in[0,t_{\max}(\xi,\mathbf{d})), \tag{4.5}$$

where $\sigma_{\xi,\mathbf{d}} : [0,t_{\max}(\xi,\mathbf{d})) \to \mathbf{R}_{\geq 0}$ is defined by

$$\sigma_{\xi,\mathbf{d}}(t) = \int_0^t \Big[1+|f(x(s,\xi,\mathbf{d}),\mathbf{d}(s))|^2+\kappa(x(s,\xi,\mathbf{d}))\Big]\,ds.$$

Moreover, $\sigma_{\xi,\mathbf{d}}(t)\to\infty$ as $t\to t_{\max}(\xi,\mathbf{d})$, so, we can define $\sigma_{\xi,\mathbf{d}}(t_{\max}(\xi,\mathbf{d})) := +\infty$ for convenience.

Proof of Claim 1. Indeed, writing $s=\sigma_{\xi,\mathbf{d}}(t)$ and computing the derivative of $x({\sigma_{\xi,\mathbf{d}}}^{-1}(s),\xi,\mathbf{d})$ with respect to s, one has

$$\begin{aligned} f(x(t,\xi,\mathbf{d}),\mathbf{d}(t)) = \frac{d}{dt}x(t,\xi,\mathbf{d}) &= \frac{d}{dt}x({\sigma_{\xi,\mathbf{d}}}^{-1}\circ\sigma_{\xi,\mathbf{d}}(t),\xi,\mathbf{d})\\ &= \frac{d}{ds}x\left({\sigma_{\xi,\mathbf{d}}}^{-1}(s),\xi,\mathbf{d}\right)\cdot\frac{d}{dt}\sigma_{\xi,\mathbf{d}}(t)\\ &= \frac{d}{ds}x({\sigma_{\xi,\mathbf{d}}}^{-1}(s),\xi,\mathbf{d})\Big[1+|f(x(t,\xi,\mathbf{d}),\mathbf{d}(t))|^2+\kappa(x(t,\xi,\mathbf{d}))\Big]. \end{aligned}$$

Therefore

$$\begin{aligned} \frac{d}{ds}x({\sigma_{\xi,\mathbf{d}}}^{-1}(s),\xi,\mathbf{d}) &= \frac{f(x(t,\xi,\mathbf{d}),\mathbf{d}(t))}{1+|f(x(t,\xi,\mathbf{d}),\mathbf{d}(t))|^2+\kappa(x(t,\xi,\mathbf{d}))}\\ &= \frac{f\left(x({\sigma_{\xi,\mathbf{d}}}^{-1}(s),\xi,\mathbf{d}),\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1}(s)\right)}{1+|f\left(x({\sigma_{\xi,\mathbf{d}}}^{-1}(s),\xi,\mathbf{d}),\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1}(s)\right)|^2+\kappa\left(x\left({\sigma_{\xi,\mathbf{d}}}^{-1}(s),\xi,\mathbf{d}\right)\right)}\\ &= \widehat{f}\left(x\left({\sigma_{\xi,\mathbf{d}}}^{-1}(s),\xi,\mathbf{d}\right),\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1}(s)\right) \qquad \forall\, 0\leq s<\sigma_{\xi,\mathbf{d}}(t_{\max}(\xi,\mathbf{d})). \end{aligned}$$

Thus, the functions $z(s,\xi,\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1})$ and $x({\sigma_{\xi,\mathbf{d}}}^{-1}(s),\xi,\mathbf{d})$ satisfy the same differential equation (4.3) with initial state ξ on $[0,\ \sigma_{\xi,\mathbf{d}}(t_{\max}(\xi,\mathbf{d})))$, therefore they coincide on $[0,\ \sigma_{\xi,\mathbf{d}}(t_{\max}(\xi,\mathbf{d})))$.

To show the limit property of $\sigma_{\xi,\mathbf{d}}$, suppose

$$\lim_{t\to t_{\max}(\xi,\mathbf{d})} \sigma_{\xi,\mathbf{d}}(t) = b < \infty$$

(note that the limit exists because $\sigma_{\xi,\mathbf{d}}(\cdot)$ is increasing). Let

$$K = \{z(s,\xi,\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1}) : 0 \le s < b\}.$$

Then K is bounded, so $\bar{K}$ is compact, and by (4.5), $x(t,\xi,\mathbf{d}) \in K \subseteq \bar{K}$ for all $t \in [0, t_{\max}(\xi,\mathbf{d}))$, contradicting the maximality of $t_{\max}(\xi,\mathbf{d})$. □

For each initial state ξ and each disturbance function $\mathbf{d}$, define

$$\theta_{\xi,\mathbf{d}} = \inf\{t \ge 0 : \; z(t,\xi,\mathbf{d}) \in \mathcal{D}\}\,, \tag{4.6}$$

where $\theta_{\xi,\mathbf{d}} = \infty$ if $z(t,\xi,\mathbf{d}) \notin \mathcal{D}$ for all $t \ge 0$. Note that $\theta_{\xi,\mathbf{d}} > 0$ for all $\mathbf{d} \in \mathcal{M}_\Omega$ and all $\xi \in \mathcal{E}$ because $\mathcal{E}$ is open. Observe also that if $\mathbf{d}_1 = \mathbf{d}\circ\sigma_{\xi,\mathbf{d}}$,

$$\theta_{\xi,\mathbf{d}} = \sigma_{\xi,\mathbf{d}_1}(\lambda_{\xi,\mathbf{d}_1}).$$

Claim 2. System $\hat{\Sigma}$ satisfies the GASMO property.

Proof. According to (4.2) and (4.5), we have, for every $\xi \in \mathcal{E}$ and each $\mathbf{d}$,

$$\begin{aligned}|z(t,\xi,\mathbf{d})| &= \left|x({\sigma_{\xi,\mathbf{d}_1}}^{-1}(t),\xi,\mathbf{d}_1)\right| \\ &\le \lambda(|\xi|\,, {\sigma_{\xi,\mathbf{d}_1}}^{-1}(t)) \le \vartheta(|\xi|),\end{aligned}$$

for all $t \in [0,\theta_{\xi,\mathbf{d}})$, where $\vartheta(s) = \lambda(s,0)$, and $\mathbf{d}_1$ is such that $\mathbf{d} = \mathbf{d}_1 \circ {\sigma_{\xi,\mathbf{d}_1}}^{-1}$. Let

$$M_r = 1 + \max_{d\in\Omega, |\xi|\le\vartheta(r)} |f(\xi,d)|^2 + \max_{|\xi|\le\vartheta(r)} \kappa(\xi).$$

Then, for any $\xi \in \mathcal{E}$ with $|\xi| \le r$, it holds that

$$\sigma_{\xi,\mathbf{d}_1}(t) = \int_0^t \Big[1 + |f(x(s,\xi,\mathbf{d}_1),\mathbf{d}_1(s))|^2 + \kappa(x(s,\xi,\mathbf{d}_1))\Big]\, ds \;\le\; M_r t$$

for all $t \in [0,\lambda_{\xi,\mathbf{d}_1})$, and hence, ${\sigma_{\xi,\mathbf{d}_1}}^{-1}(t) \ge \frac{t}{M_r}$ for all $|\xi| \le r$, $t \in [0,\theta_{\xi,\mathbf{d}})$. Consequently, we have

$$|z(t,\xi,\mathbf{d})| \le \hat{\lambda}(|\xi|\,,t) \qquad \forall\, t \in [0,\theta_{\xi,\mathbf{d}}), \tag{4.7}$$

where $\hat{\lambda}(s,t) = \lambda(s, \frac{t}{M_s})$ is clearly of class $\mathcal{KL}$. Therefore, this shows that system $\hat{\Sigma}$ is GASMO. □

From now on, we let the function λ of class $\mathcal{KL}$ be as in Definition 2.9 for the system $\hat{\Sigma}$, that is, the following estimate holds for system (4.3):

$$|z(t,\xi,\mathbf{d})| \le \lambda(|\xi|\,,t) \qquad \forall\, t \in [0,\theta_{\xi,\mathbf{d}}), \tag{4.8}$$

for all $\xi \in \mathcal{E}$, and all $\mathbf{d} \in \mathcal{M}_\Omega$.

According to Proposition 7 in [38], there exist $\mathcal{K}_\infty$-functions μ_1 and μ_2 such that

$$\lambda(r,t) \le \mu_1(\mu_2(r)e^{-t}) \qquad \forall\, r,\; t \ge 0. \tag{4.9}$$

Define

$$\Xi(s) := \mu_1^{-1}(s). \tag{4.10}$$

The proof will now develop as follows. We first construct a continuous Lyapunov-like function V_0, defined on the set $\mathcal{E}_1$. Next V_0 is approximated by a Lipschitz continuous function (by the methods of nonsmooth analysis). The resulting function is then approximated by a smooth function V_1. Finally we extend V_1 to the rest of the state space, obtaining a Lyapunov-like function, smooth away from the origin, which is then approximated by a smooth Lyapunov function.

4.2. Definitions and basic facts on relaxed controls. Recall that our disturbances $\mathbf{d}$ are measurable functions $\mathbf{R}_{\geq 0} \to \Omega$, a compact, convex subset of $\mathbf{R}^m$.

Let $\mathcal{P}(\Omega)$ be the set of all Radon probability measures on Ω. Bishop's theorem furnishes a weak norm on $\mathcal{P}(\Omega)$, whose corresponding metric topology coincides with the weak star topology on $\mathcal{P}(\Omega)$ (see [51, pp. 40 and 267]).

For any $T > 0$, we define $\mathcal{S}_T$ to be the set of all measurable functions from $[0,T]$ to $\mathcal{P}(\Omega)$, and $\mathcal{S}$ to be the set of all measurable functions from $\mathbf{R}_{\geq 0}$ to $\mathcal{P}(\Omega)$. We topologize $\mathcal{S}_T$ by weak convergence: $\{\nu_k(\cdot)\} \to \nu(\cdot)$ in $\mathcal{S}_T$ if and only if

$$\int_0^T \int_\Omega g(t,\omega) d[\nu_k(t)](\omega)\, dt \to \int_0^T \int_\Omega g(t,\omega) d[\nu(t)](\omega)\, dt$$

for all functions $g : [0,T] \times \Omega \to \mathbf{R}$ which are continuous in ω, measurable in t, and such that

$$\max\{|g(t,\omega)|\,,\ \omega \in \Omega\}$$

is integrable on $[0,T]$. We say that $\{\nu_k\} \to \nu$ weakly in $\mathcal{S}$ if, for every $T > 0$, the sequence $\left\{\nu_k|_{[0,T]}\right\}$ of restrictions of ν_k to $[0,T]$ converges to $\nu|_{[0,T]}$ in $\mathcal{S}_T$.

Notice that, since every element of Ω can be identified with the δ-measure, concentrated in it, Ω can be embedded into $\mathcal{P}(\Omega)$, $\mathcal{M}_\Omega$ into $\mathcal{S}$, and $\mathcal{M}_\Omega^T$ into $\mathcal{S}_T$ in the obvious way, where $\mathcal{M}_\Omega^T$ is the set of functions in $\mathcal{M}_\Omega$ restricted to $[0,T]$.

For each $\nu \in \mathcal{P}(\Omega)$, we denote

$$f(x,\nu) \;=\; \int_\Omega f(x,r)\, d\nu(r)\,. \tag{4.11}$$

Notice that for any relaxed control $\nu(\cdot)$, the function $f(\cdot,\nu(\cdot)) : (x,t) \to f(x,\nu(t))$ is Lipschitz in x and measurable in t. Moreover, as for all $x \in \mathbf{X}$ and all $\nu \in \mathcal{P}(\Omega)$, we have a bound

$$|f(x,\nu)| \leq \max_{d\in\Omega} |f(x,d)|\,,$$

the solution of the "system" $\dot{x}(t) = f(x(t),\nu(t))$ exists for any initial condition ξ and relaxed control ν on some maximal interval $[0, t_{\max}(\xi,\nu))$. Write $x(\cdot,\xi,\nu)$ to denote this solution. Just as in the case with ordinary controls, we will define

$$\lambda_{\xi,\nu} := \inf\{t \leq t_{\max}\ :\ x(s,\xi,\nu) \in \mathcal{D}\}\,. \tag{4.12}$$

The basic three facts we will be using in the next section are as follows.

Fact 1. For any $T > 0$, the space $\mathcal{S}_T$ is sequentially compact (see [51, Thm IV.2.1, p. 272]). Consequently, $\mathcal{S}$ is sequentially compact by a diagonalization argument.

Fact 2. For any $T > 0$, the set $\mathcal{M}_\Omega^T$ of ordinary controls on $[0,T]$ is dense in $\mathcal{S}_T$ (see [5, p. 691], also [51]). Consequently, $\mathcal{M}_\Omega$ is dense in $\mathcal{S}$. The topology of $\mathcal{S}$

induces a topology on the subspace $\mathcal{M}_\Omega$. This topology is stronger than the topology of L^p for any positive p: in fact, $\{\mathbf{d}_k(t)\} \to \mathbf{d}$ would imply

$$\int_0^T g(\mathbf{d}_k(t))dt \to \int_0^T g(\mathbf{d}(t))\,dt$$

for any continuous function $g : \mathbb{U} \to \mathbf{R}$ and any positive T.

Fact 3. For any $T > 0$, the mapping $(t, \xi, \nu(\cdot)) \mapsto z(t, \xi, \nu)$ is continuous on $[0, T] \times \mathbf{X} \times \mathcal{S}_T$ (see [1, Lemma 3.12]).

Some relevant immediate consequences of Facts 1, 2, and 3 are as follows.

Claim 1. The function $(\xi, \nu) \to \lambda_{\xi,\nu}$, mapping initial states and disturbances to the first hitting times as defined in (4.12), is lower semicontinuous on both ν and ξ. (This easily follows from continuous dependence on initial conditions and control, and from the fact that the set $\mathcal{D}$ is closed.)

Claim 2. If system (2.14) is GASMO, then, for any initial value $\xi \in \mathcal{E}$, a relaxed disturbance $\nu \in \mathcal{S}$, and time $T \leq \lambda_{\xi,\nu}$ we have an estimate

$$x(T, \xi, \nu) \leq \lambda(|\xi|, T).$$

Proof. Pick $\xi \in \mathbf{X}$ and $\nu \in \mathcal{S}$. Let $\{\mathbf{d}_k\}$ be a sequence of ordinary disturbances, converging to ν in $\mathcal{S}$. Then, for large enough k we have $t_{\max}(\xi, \mathbf{d}_k) > T$, and $x(\cdot, \xi, \mathbf{d}_k)$ converge to $x(\cdot, \xi, \nu)$ uniformly on $[0, T]$. Also, by Claim 1, $\liminf_{k\to\infty} \lambda_{\xi,\mathbf{d}_k} \geq \lambda_{\xi,\nu}$. Since we assume the system to be GASMO, the estimate (2.17) holds for $\mathbf{d} := \mathbf{d}_k$ for all large enough k and for all $t \leq T$, so the claim follows. □

With the previous claim in mind, we can say that the system (2.14) with $d \in \mathcal{S}$ is GASMO (this is a slight abuse of terminology because, strictly speaking, (2.14) with relaxed disturbances is not really a "system," as that would mean, by definition, that disturbances take values in a finite dimensional space). Consequently, the auxiliary system (4.3) is also GASMO for $\mathbf{d} \in \mathcal{S}$. Thus, we can assume that (4.8) holds for all $\xi \in \mathcal{E}$ and all $\mathbf{d} \in \mathcal{S}$.

4.3. Constructing a continuous Lyapunov-like function on $\mathcal{E}_1$. In section 4.1 we introduced the system $\hat{\Sigma} : \dot{z} = \hat{f}(z, d) := \frac{f(z,d)}{1+|f(z,d)|^2+\kappa(z)}$, which slows down the motions of the original system Σ. Recall also that $\mathcal{D} := \{\xi : |\xi| \leq \rho(|h(\xi)|)\}$, and define the set

$$\mathcal{B} := \{\xi : \rho(|h(\xi)|) \leq |\xi| \leq 1.5\rho(|h(\xi)|)\}.$$

Let $f_0 : \mathbf{X} \to \mathbf{R}$ be defined by

$$f_0(\xi) = \max_{\mathrm{d}\in\Omega} \left|\widehat{f}(\xi, \mathrm{d})\right|.$$

Note that f_0 is locally Lipschitz, and recall that we have assumed with no loss of generality that Σ has no equilibria on the set $\{x \in \mathbf{X} : |x| \geq \rho(|h(x)|)\}$ (otherwise replace $\rho(\cdot)$ by $c\rho(\cdot)$, where $c > 1$). In particular, $f_0(\xi) \neq 0$ for any $\xi \in \partial\mathcal{D} \setminus \{0\}$. Let $\phi : \mathbf{X} \setminus \{0\} \to [0, 1]$ be smooth and

$$\phi(x) = \begin{cases} 1, & x \in \mathcal{D}, \\ 0, & x \in \mathbf{X} \setminus (\mathcal{D} \cup \mathcal{B}). \end{cases}$$

Now introduce another system, on the state space $\mathbf{X} \setminus \{0\}$,

$$\widetilde{\Sigma} : \quad \dot{z} = \widetilde{f}(z, d, v),$$

where disturbances d are as before, and auxiliary controls $\mathbf{v}$ are measurable functions of time, taking values in $[-1,1]^n$ (note that the dimension of the control set for v's is the same as that of $\mathbf{X}$), where, for each $i = 1, 2, \ldots, n$,

$$\widetilde{f}_i(z, d, v) := \widehat{f}_i(z, d) + 2\phi(z) f_0(z) v_i.$$

For each $T > 0$, let $\mathcal{W}_T$ denote the set of the auxiliary controls defined on $[0, T]$ (i.e., measurable functions $\mathbf{v} : [0, T] \to [-1, 1]^n$) equipped with the weak convergence topology; that is, "$\{\mathbf{v}_k\}$ converges weakly to $\mathbf{v}$ in $\mathcal{W}_T$" means

$$\int_0^T \varphi(s)\mathbf{v}_k(s)\, ds \;\to \int_0^T \varphi(s)\mathbf{v}(s)\, ds$$

for all functions φ that are integrable over $[0, T]$. With the weak topology, $\mathcal{W}_T$ is sequentially compact (cf. [39, Proposition 10.1.5]). Consequently, given any sequence $\{\mathbf{v}_k\}$ of controls defined on $[0, \infty)$, there exist some control $\mathbf{v}$ and a subsequence $\{\mathbf{v}_{k_j}\}$ such that $\mathbf{v}_{k_j} \to \mathbf{v}$ weakly on every interval $[0, T]$.

We denote the set of the auxiliary controls defined on $[0, \infty)$ by $\mathcal{W}$. Let $\{\mathbf{v}_k\} \subset \mathcal{W}$ and $\mathbf{v} \in \mathcal{W}$. We say that $\{\mathbf{v}_k\}$ weakly converges to $\mathbf{v}$ if, for every $T > 0$, the sequence of restrictions $\{\mathbf{v}_k|_{[0,T]}\}$ weakly converges to $\mathbf{v}|_{[0,T]}$ in $\mathcal{W}_T$.

Recall that $z(t, \xi, \mathbf{d})$ denotes the solution of $\hat{\Sigma}$. Write $z(t, \xi, \mathbf{d}, \mathbf{v})$ for the value at time t of the solution of $\widetilde{\Sigma}$ with initial state $\xi \neq 0$, disturbance $\mathbf{d} \in \mathcal{M}_\Omega$, and auxiliary control $\mathbf{v} \in \mathcal{W}$.

Observe the following.

- $\widetilde{\Sigma}$ is affine in v.
- since for any $\xi \in \mathbf{X}$ and $d \in [-1, 1]^m$, $|\hat{f}(\xi, d)| \le 1$, we have $|\widetilde{f}(\xi, d, v)| \le 3$ for any ξ, d and v. In particular, this implies that $\widetilde{\Sigma}$ is forward complete.
- Suppose $\xi \notin \mathcal{D} \cup \mathcal{B}$ and pick $\mathbf{d} \in \mathcal{M}_\Omega$ and $\mathbf{v} \in \mathcal{W}$. Then there is some $t_0 > 0$ such that $z(t, \xi, \mathbf{d}) \notin \mathcal{D} \cup \mathcal{B}$ for all $t \in [0, t_0]$, and $z(t, \xi, \mathbf{d}, \mathbf{v}) \equiv z(t, \xi, \mathbf{d})$ on $[0, t_0]$.

To extend the definition of $z(t, \xi, \mathbf{d}, \mathbf{v})$ to the case when $\mathbf{d} \in \mathcal{S}$, we let, for a fixed $\mathbf{d} \in \mathcal{S}$ and $\mathbf{v} \in \mathcal{W}$,

$$g_{\mathbf{d},\mathbf{v}}(z, t) := \hat{f}(z, \mathbf{d}(t)) + 2\phi(z) f_0(z)\mathbf{v}(t)$$

(where $f(z, \mathbf{d}(t))$ is as defined in (4.11) for $\nu := \mathbf{d}(t) \in \mathcal{P}(\Omega)$). Then $g_{\mathbf{d},\mathbf{v}} : \mathbf{X} \setminus \{0\} \times \mathbf{R}_{\ge 0} \to \mathbf{X}$ is locally Lipschitz in its first variable, and $|g_{\mathbf{d},\mathbf{v}}(z, t)| \le 3$ for all $(z, t) \in \mathbf{X} \setminus \{0\} \times \mathbf{R}_{\ge 0}$. Hence, the solution of

$$\begin{aligned} \dot{z}(t) &= g_{\mathbf{d},\mathbf{v}}(z, t), \\ z(0) &= \xi \end{aligned}$$

exists for all $\xi \in \mathbf{X} \setminus \{0\}$ and $t \ge 0$. We will denote it by $z(t, \xi, \mathbf{d}, \mathbf{v})$.

Observe that $\widetilde{f} : \mathbf{X} \setminus \{0\} \times \Omega \times [-1, 1]^n \to \mathbf{R}^n$ is continuous, and $\widetilde{f}(z, d, v)$ is locally Lipschitz in z on $\mathbf{X} \setminus \{0\}$ uniformly on $(d, v) \in \Omega \times [-1, 1]^n$. The system $\widetilde{\Sigma}$ evolves in the state space $\mathbf{X} \setminus \{0\}$. As $|\widetilde{f}| \le 3$ everywhere, trajectories are defined and unique for each initial value $\xi \in \mathbf{X} \setminus \{0\}$ and each pair of inputs $\mathbf{d}, \mathbf{v}$. Moreover, if $z(\cdot)$ is a maximal such trajectory, then either $z(t)$ is defined for all $t \ge 0$, or there is some $T > 0$ such that $\lim_{t \to T} z(t) = 0$. We prove next that this last case cannot happen.

Lemma 4.1. *For every ball U around 0, there is a constant c such that for any $\xi \in U$, $\xi \neq 0$, $\mathbf{d} \in \mathcal{S}$, $\mathbf{v} \in \mathcal{W}$, and $t \geq 0$, we have a lower bound*

$$|z(t, \xi, \mathbf{d}, \mathbf{v})| > \frac{1}{2} |\xi| \, e^{-ct}. \tag{4.13}$$

Proof. Since $\hat{f}$ is locally Lipschitz in x uniformly in d, and $\hat{f}(0, d) = 0$ for all d, we can find a positive constant c, such that $|\hat{f}(z, d)| \leq c|z|/3$ for all $z \in U$ and all $d \in \Omega$. Then also $|f_0(z)| \leq c|z|/3$; therefore

$$\left|\widetilde{f}(z, d, v)\right| \leq \left|\hat{f}(z, d)\right| + 2 \, |f_0(z)| \leq c|z|$$

for all $v \in [-1, 1]^n$, all $d \in \Omega$, and hence, all $d \in \mathcal{P}(\Omega)$. Now fix $\xi \in U \setminus \{0\}$, $\mathbf{d} \in \mathcal{S}$, and $\mathbf{v} \in \mathcal{W}$, and write $z(t) := z(t, \xi, \mathbf{d}, \mathbf{v})$. Note that the inequality (4.13) holds for $t = 0$; therefore it holds for all small enough $t > 0$. Suppose that (4.13) fails at some $t_2 > 0$, so that

$$|z(t_2)| \leq \frac{1}{2} |\xi| \, e^{-ct_2} < |\xi| \, . \tag{4.14}$$

Then there exists a $t_1 < t_2$ such that $|z(t_1)| = |\xi|$ and $|z(t)| \leq |\xi|$ for all $t \in [t_1, t_2]$. Let

$$w(t) := |z(t)|^2 /2.$$

Then, for almost all $t \in [t_1, t_2]$

$$|\dot{w}(t)| = |z(t) \cdot \dot{z}(t)| \leq c \, |z(t)|^2 = 2cw(t).$$

In particular, this implies that $\dot{w}(t) + 2cw(t) \geq 0$. So, for all $t \in [t_1, t_2]$ we have

$$0 \leq e^{2ct}(\dot{w}(t) + 2cw(t)) = \frac{d(e^{2ct}w(t))}{dt},$$

implying that $e^{2ct}w(t) \geq e^{2ct_1}w(t_1)$ for all $t \in [t_1, t_2]$. Thus,

$$\frac{1}{2} |z(t_2)|^2 = w(t_2) \geq e^{2ct_1}w(t_1)e^{-2ct_2} = \frac{1}{2} |z(t_1)|^2 e^{-2c(t_2 - t_1)} \geq \frac{1}{2} |\xi|^2 e^{-2ct_2},$$

so that $|z(t_2)| \geq e^{-ct_2} |\xi|$, contradicting (4.14). □

Corollary 4.2. *For every $r > 0$ and $T > 0$ there is a $\sigma = \sigma(r, T) > 0$ such that for any $\mathbf{d} \in \mathcal{S}$, $\mathbf{v} \in \mathcal{W}$, $|\xi| \geq r$, and $t \leq T$ we have*

$$|z(t, \xi, \mathbf{d}, \mathbf{v})| \geq \sigma.$$

Lemma 4.3. *For each $\mathbf{d} \in \mathcal{S}_T$ and each $\mathbf{v} \in \mathcal{W}_T$, if $\xi_k \to \xi$ in $\mathbf{X} \setminus \{0\}$, $\mathbf{d}_k \to \mathbf{d}$ in $\mathcal{S}_T$, and $\mathbf{v}_k \to \mathbf{v}$ in $\mathcal{W}_T$, $\{z(t, \xi_k, \mathbf{d}_k, \mathbf{v}_k)\}$ converges to $z(t, \xi, \mathbf{d}, \mathbf{v})$ uniformly on $[0, T]$.*

Proof. Assume without loss of generality that $\xi_k \in U := B_{\frac{|\xi|}{2}}(\xi)$. Since $|\widetilde{f} \leq 3|$ and by Corollary 4.2, $\mathcal{R}_T\,(U) \subseteq B_{1.5|\xi|+3T}(0) \setminus B_\sigma(0)$, where $\sigma = \sigma(|\xi|\,/2, T)$ is as in Corollary 4.2. Let M_1 and M_2 be Lipschitz constants for $\hat{f}(\cdot, d)$ (uniformly for

$d \in \Omega$) and $2f_0\,\phi$, respectively, on $B_{1.5|\xi|+3T}(0) \setminus B_\sigma(0)$. Write $z(t) := z(t,\xi,\mathbf{d},\mathbf{v})$, and $z_k(t) := z(t,\xi_k,\mathbf{d}_k,\mathbf{v}_k)$. Now, for all $t \in [0,T]$ we have

$$\begin{align}
|z(t)-z_k(t)| &= \left|\xi_k - \xi + \int_0^t \left(\widetilde{f}(z_k(t),\mathbf{d}_k(t),\mathbf{v}_k(t)) - \widetilde{f}(z(t),\mathbf{d}(t),\mathbf{v}(t))\right) dt\right| \notag\\
&\le |\xi_k - \xi| + \left|\int_0^t \left(\widetilde{f}(z(t),\mathbf{d}_k(t),\mathbf{v}_k(t)) - \widetilde{f}(z(t),\mathbf{d}(t),\mathbf{v}(t))\right) dt\right| \notag\\
&\qquad + \int_0^t \left|\widetilde{f}(z_k(t),\mathbf{d}_k(t),\mathbf{v}_k(t)) - \widetilde{f}(z(t),\mathbf{d}_k(t),\mathbf{v}_k(t))\right| dt \notag\\
&\le |\xi_k - \xi| + \left|\int_0^t \left(\hat{f}(z(t),\mathbf{d}_k(t)) - \hat{f}(z(t),\mathbf{d}(t))\right) dt\right| \tag{4.15}\\
&\qquad +2\left|\int_0^t \left(f_0(z(t))\phi(z(t))\mathbf{v}_k(t) - f_0(z(t))\phi(z(t))\mathbf{v}(t)\right) dt\right| \tag{4.16}\\
&\qquad + \int_0^t (M_1+M_2)\,|z_k(t)-z(t)|\,dt. \notag
\end{align}$$

The integrals in (4.15) and (4.16) tend to 0 because of the convergence of $\{\mathbf{d}_k(\cdot)\}$ to $\mathbf{d}$ in $\mathcal{S}$ and the weak convergence of $\mathbf{v}_k$ to $\mathbf{v}$. So, for any $\varepsilon > 0$ we can find a K such that, for all $k \ge K$,

$$\begin{aligned}
|\xi_k - \xi| &+ \left|\int_0^T \left(\hat{f}(z(t),\mathbf{d}_k(t)) - \hat{f}(z(t),\mathbf{d}(t))\right) dt\right| \\
&+ 2\left|\int_0^t \left(f_0(z(t))\phi(z(t))\mathbf{v}_k(t) - f_0(z(t))\phi(z(t))\mathbf{v}(t)\right) dt\right| \le \varepsilon e^{-(M_1+M_2)T}.
\end{aligned}$$

Then, for all $k \ge K$ and $t \in [0,T]$ we have, by the Gronwall inequality,

$$|z(t)-z_k(t)| \le \varepsilon e^{-(M_1+M_2)T}\, e^{(M_1+M_2)t} \le \varepsilon.$$

As ε was arbitrary, this proves uniform convergence. □

Also, since for any $\xi \in \partial D \setminus \{0\}$, $f_0(\xi) \ne 0$, and $f_0(\xi) \ge |\hat{f}(\xi,d)|$ for any $d \in \Omega$, we have the following controllability property on $\partial\mathcal{D} \setminus \{0\}$.

LEMMA 4.4. *Let $\xi \ne 0$ be on $\partial\mathcal{D}$. Then, for each $\tau > 0$, there exists a neighborhood U of ξ, such that for any $\eta \in U$ and any $\mathbf{d} \in \mathcal{M}_\Omega$, there is some control $\mathbf{v}$, and some $0 \le t_1 \le \tau$, such that $z(t_1,\eta,\mathbf{d},\mathbf{v}) = \xi$ and $z(t,\eta,\mathbf{d},\mathbf{v}) \in U$ for all $0 \le t \le t_1$.*

Proof. Since $\phi(\xi)\,f_0(\xi) \ne 0$ and the function $\phi(\cdot)\,f_0(\cdot)$ is continuous, we can find a ball U_1 centered at ξ and a constant c_1 such that $\phi(z)f_0(z) > c_1$ for every $z \in U_1$. Since $\phi(\xi) = 1$ and ϕ is continuous, one could also find a ball $U_2 \subseteq U_1$ centered at ξ, so that

$$\left|\widehat{f}(z,d)\right| \le 1.5\phi(z)f_0(z) \quad \forall z \in U_2,\ d \in \Omega.$$

Fix $\tau > 0$ and let $B(\xi)$ be the ball of radius $\tau c_1/2$ centered at ξ. Define $U := B(\xi) \cap U_2$. Pick a point $\eta \in U$. Then $|\xi - \eta| < \tau c_1/2$, so,

$$\bar{v}_2 := \frac{2(\xi-\eta)}{\tau c_1}$$

has norm smaller than 1. Consider the "feedback law"

$$k(z,d) = \frac{1}{2}(1.5k_1(z,d) + 0.5\bar{v}_2),$$

where

$$k_1(z,d) := -\frac{\widehat{f}(z,d)}{1.5\phi(z)f_0(z)}.$$

Notice that for all $z \in U$ and $d \in \Omega$ we have $|k_1(z,d)| \leq 1$ and

$$\begin{aligned}\widetilde{f}(z,d,k(z,d)) &= \widehat{f}(z,d) + 2\phi(z)f_0(z)k(z,d)\\ &= \widehat{f}(z,d) + 1.5\phi(z)f_0(z)k_1(z,d) + 0.5\phi(z)f_0(z)\bar{v}_2\\ &= 0.5\phi(z)f_0(z)\bar{v}_2 = \frac{(\xi-\eta)\phi(z)f_0(z)}{\tau c_1}.\end{aligned}$$

Thus, with any initial condition $\eta \in U$ and disturbance $\mathbf{d} \in \mathcal{M}_\Omega$, if the control $v(t) := k(z(t), d(t))$ is applied, then the trajectory of the system $\widetilde{\Sigma}$ will be the line segment, connecting ξ and η, transversed with a velocity greater than $(\xi - \eta)/\tau$. So, there exists a $t_0 \leq \tau$ such that $z(t_0, \eta, \mathbf{d}, \mathbf{v}) = \xi$ and, since U is convex, $z(t, \eta, \mathbf{d}, \mathbf{v}) \in U$ for all $t \geq t_0$. □

For each $\mathbf{d} \in \mathcal{S}$, let

$$\theta_{\mathbf{d}}(\xi, \mathbf{v}) = \inf\{t \geq 0 : z(t, \xi, \mathbf{d}, \mathbf{v}) \in \mathcal{D}\},$$

where as before, $\theta_{\mathbf{d}}(\xi, \mathbf{v}) = \infty$ if the trajectory never reaches $\mathcal{D}$.

LEMMA 4.5. *The map* $(\xi, \mathbf{v}, \mathbf{d}) \mapsto \theta_{\mathbf{d}}(\cdot,\cdot)$ *is lower semicontinuous on* $\mathcal{E} \times \mathcal{W} \times \mathcal{S}$.

Proof. Let $\{\xi_k\} \subset \mathcal{E}$, $\{\mathbf{v}_k\} \subset \mathcal{W}$ and $\{\mathbf{d}_k\} \subset \mathcal{S}$ be such that $\xi_k \to \xi, \mathbf{v}_k \to \mathbf{v}$, and $\mathbf{d}_k \to \mathbf{d}$ for some $\xi \in \mathcal{E}$, $\mathbf{v} \in \mathcal{W}$, and $\mathbf{d} \in \mathcal{S}$. We need to show that

$$\theta_{\mathbf{d}}(\xi, \mathbf{v}) \leq \liminf_{k\to\infty} \theta_{\mathbf{d}_k}(\xi_k, \mathbf{v}_k). \tag{4.17}$$

Let $\theta_k = \theta_{\mathbf{d}_k}(\xi_k, \mathbf{v}_k)$. Without loss of generality, we may assume that

$$\liminf_{k\to\infty} \theta_k = \theta_0 < \infty.$$

Passing to a subsequence if necessary, we assume that $\theta_k \to \theta_0$. Thus, there exists some K such that $\theta_k \leq \theta_0 + 1$ for all $k \geq K$. Since $\{z(t, \xi_k, \mathbf{d}_k, \mathbf{v}_k)\}$ converges to $z(t, \xi, \mathbf{d}, \mathbf{v})$ uniformly on $[0, \theta_0 + 1]$, it follows that

$$z(\theta_0, \xi, \mathbf{d}, \mathbf{v}) = \lim_{k\to\infty} z(\theta_k, \xi_k, \mathbf{d}_k, \mathbf{v}_k).$$

Since $\mathcal{D}$ is closed and $z(\theta_k, \xi_k, \mathbf{d}_k, \mathbf{v}_k) \in \mathcal{D}$ for each k, we know that $z(\theta_0, \xi, \mathbf{d}, \mathbf{v}) \in \mathcal{D}$, and hence, $\theta_{\mathbf{d}}(\xi, \mathbf{v}) \leq \theta_0$. □

Define, for $\xi \in \mathcal{E}, \mathbf{d} \in \mathcal{S}$, and $\mathbf{v} \in \mathcal{W}$,

$$V_{\mathbf{v}}(\xi, \mathbf{d}) := \int_0^{\theta_{\mathbf{d}}(\xi,\mathbf{v})} \Xi(|z(t, \xi, \mathbf{d}, \mathbf{v})|)\, dt$$

(where Ξ is as in (4.10)) and, for $\xi \in \mathcal{E}$ and $\mathbf{d} \in \mathcal{S}$,

$$\widetilde{V}_0(\xi, \mathbf{d}) := \inf_{\mathbf{v}\in\mathcal{W}} V_{\mathbf{v}}(\xi, \mathbf{d}).$$

Note that for some $\mathbf{v}$ and $\mathbf{d}$, $V_{\mathbf{v}}(\xi, \mathbf{d})$ may take ∞ as its value, but $\widetilde{V}_0(\xi, \mathbf{d})$ is always finite, since

$$\widetilde{V}_0(\xi, \mathbf{d}) \leq V_O(\xi, \mathbf{d}), \tag{4.18}$$

where $O(\cdot)$ is the control identically equal to 0. Recall that by definition of Ξ we have then, for all $\xi \in \mathcal{E}_1$ and $\mathbf{d} \in \mathcal{S}$,

$$
\begin{aligned}
V_O(\xi, \mathbf{d}) &= \int_0^{\theta_{\mathbf{d}}(\xi, O)} \Xi(|z(t, \xi, \mathbf{d}, O)|)\, dt \\
&= \int_0^{\theta_{\mathbf{d}}(\xi, O)} \Xi(|z(t, \xi, \mathbf{d})|)\, dt \leq \int_0^{\infty} \Xi(\mu_1(\mu_2(|\xi|)e^{-t}))dt \leq \mu_2(|\xi|), \qquad (4.19)
\end{aligned}
$$

where μ_1 and μ_2 are as in (4.9).

LEMMA 4.6. *The function $V_{(\cdot)}(\cdot, \cdot) : \mathcal{E} \times \mathcal{S} \times \mathcal{W} \to \mathbf{R}_{\geq 0}$ is lower semicontinuous.*

Proof. Let $(\xi, \mathbf{d}, \mathbf{v}) \in \mathcal{E} \times \mathcal{S} \times \mathcal{W}$, and let $\{\xi_k\} \to \xi$, $\{\mathbf{d}_k\} \to \mathbf{d}$ and $\{\mathbf{v}_k\} \to \mathbf{v}$, where $\xi_k \in \mathcal{E}$ for all k.

Case 1. $V_{\mathbf{v}}(\xi, \mathbf{d}) < \infty$. In this case, for any $\varepsilon > 0$, there exists some $0 < T < \theta_{\mathbf{d}}(\xi, \mathbf{v})$ such that

$$
V_{\mathbf{v}}(\xi, \mathbf{d}) \ = \ \int_0^{\theta_{\mathbf{d}}(\xi, \mathbf{v})} \Xi(|z(t, \xi, \mathbf{d}, \mathbf{v})|)\, dt \ \leq \ \int_0^{T} \Xi(|z(t, \xi, \mathbf{d}, \mathbf{v})|)\, dt + \varepsilon.
$$

Without loss of generality we can assume that all ξ_k are within the unit distance from ξ. Recall that the reachable set from the unit ball around ξ is bounded. Since $z(t, \xi_k, \mathbf{d}_k, \mathbf{v}_k)$ converges to $z(t, \xi, \mathbf{d}, \mathbf{v})$ uniformly on $[0, T]$, and $\Xi(\cdot)$ is uniformly continuous on compacts, there exists some $K > 0$ such that

$$
|\Xi(|z(t, \xi, \mathbf{d}, \mathbf{v})|) - \Xi(|z(t, \xi_k, \mathbf{d}_k, \mathbf{v}_k)|)| < \frac{\varepsilon}{1+T} \ \ \forall k > K, \ \forall t \in [0, T].
$$

This implies that

$$
\int_0^{T} \Xi(|z(t, \xi_k, \mathbf{d}_k, \mathbf{v}_k)|)\, dt \ \geq \ \int_0^{T} \Xi(|z(t, \xi, \mathbf{d}, \mathbf{v})|)\, dt - \varepsilon
$$

for all $k \geq K$. By Lemma 4.5, there exists some $K_1 \geq K$ such that $\theta_{\mathbf{d}_k}(\xi_k, \mathbf{v}_k) > T$ for all $k \geq K_1$. Thus, for all $k \geq K_1$,

$$
\begin{aligned}
V_{\mathbf{v}_k}(\xi_k, \mathbf{d}_k) &\geq \int_0^{T} \Xi(|z(t, \xi_k, \mathbf{d}_k, \mathbf{v}_k)|)\, dt \\
&\geq \int_0^{T} \Xi(|z(t, \xi, \mathbf{d}, \mathbf{v})|)\, dt - \varepsilon \ \geq \ V_{\mathbf{v}}(\xi, \mathbf{d}) - 2\varepsilon.
\end{aligned}
$$

As ε was arbitrary, we conclude that

$$
V_{\mathbf{v}}(\xi, \mathbf{d}) \leq \liminf V_{\mathbf{v}_k}(\xi_k, \mathbf{d}_k).
$$

Case 2. $V_{\mathbf{v}}(\xi, \mathbf{d}) = \infty$.

In this case, $\theta_{\mathbf{d}}(\xi, \mathbf{v}) = \infty$. Fix an integer $k \geq 0$. There exists some T_k such that

$$
\int_0^{T_k} \Xi(|z(t, \xi, \mathbf{d}, \mathbf{v})|)\, dt \geq k.
$$

Repeating the same argument used above, one sees that

$$
\int_0^{T_k} \Xi(|z(t, \xi_l, \mathbf{d}_l, \mathbf{v}_l)|)\, dt \geq k - 1
$$

for all $l \geq L_0$ for some L_0. By Lemma 4.5, there is some $L_1 \geq L_0$ such that $\theta_{\mathbf{d}_l}(\xi_l, \mathbf{v}_l) \geq T_k$ for all $l \geq L_1$. Consequently, for all $l \geq L_1$,

$$V_{\mathbf{v}_l}(\xi_l, \mathbf{d}_l) \geq \int_0^{T_k} \Xi(|z(t, \xi_l, \mathbf{d}_l, \mathbf{v}_l)|)\, dt \geq k - 1.$$

Since $k > 0$ can be picked arbitrarily, it follows that

$$\liminf V_{\mathbf{v}_l}(\xi_l, \mathbf{d}_l) = \infty.$$

In both cases, we have shown that $\liminf V_{\mathbf{v}_l}(\xi_l, \mathbf{d}_l) \geq V_{\mathbf{v}}(\xi, \mathbf{d})$. The lower semicontinuity property follows readily. □

LEMMA 4.7. *For every $\xi \in \mathcal{E}$, $\mathbf{d} \in \mathcal{S}$, there exists a control $\bar{\mathbf{v}}$ such that*

$$V_{\bar{\mathbf{v}}}(\xi, \mathbf{d}) = \widetilde{V}_0(\xi, \mathbf{d}). \tag{4.20}$$

Proof. Let $\mathbf{v}_k$ be a sequence of controls such that $V_{\mathbf{v}_k}(\xi, \mathbf{d}) \searrow \widetilde{V}_0(\xi, \mathbf{d})$. Without loss of generality we are assuming that all these controls are defined for all positive t (by letting them equal to 0 where they are not defined). Extract from $\{\mathbf{v}_k\}$ a subsequence $\{\mathbf{v}_{k_l}\}$ converging weakly to some limit $\bar{v}$ in $\mathcal{W}$. Without relabeling, we assume that $\mathbf{v}_k \to \bar{\mathbf{v}}$. By Lemma 4.6,

$$V_{\bar{\mathbf{v}}}(\xi, \mathbf{d}) \leq \lim_{k\to\infty} V_{\mathbf{v}_k}(\xi, \mathbf{d}) = \widetilde{V}_0(\xi, \mathbf{d}).$$

Combining this with the fact that $\widetilde{V}_0(\xi, \mathbf{d}) \leq V_{\mathbf{v}}(\xi, \mathbf{d})$ for all $\mathbf{v} \in \mathcal{W}$, one thus proves (4.20). □

COROLLARY 4.8. *For any $\xi \in \mathcal{E}, \mathbf{d} \in \mathcal{S}, \mathbf{v} \in \mathcal{W}$, and $0 \leq T < \theta_{\mathbf{d}}(\xi, \mathbf{v})$, it holds that*

$$\widetilde{V}_0(\xi, \mathbf{d}) \;\leq\; \int_0^T \Xi(|z(s, \xi, \mathbf{d}, \mathbf{v})|)\, ds + \widetilde{V}_0(z(T, \xi, \mathbf{d}, \mathbf{v}), \mathbf{d}_T), \tag{4.21}$$

where $\mathbf{d}_T(t) = \mathbf{d}(t + T)$ for all $t \geq 0$.

Proof. Suppose the assertion is not true. Then there exist $\xi \in \mathcal{E}$, $T > 0$, $\mathbf{v} \in \mathcal{W}$, and $\mathbf{d} \in \mathcal{S}$ such that (4.21) fails. By Lemma 4.7, one can find a control $\mathbf{v}_1$ such that $\widetilde{V}_0(z(T, \xi, \mathbf{d}, \mathbf{v}), \mathbf{d}_T) = V_{\mathbf{v}_1}(z(T, \xi, \mathbf{d}, \mathbf{v}), \mathbf{d}_T)$. Define $\bar{\mathbf{v}}$ to be the concatenation of $\mathbf{v}$ and $\mathbf{v}_1$. Then, letting $\theta := \theta_{\mathbf{d}_T}(z(T, \xi, \mathbf{d}, \mathbf{v}), \mathbf{v}_1)$ and noticing that $\theta_{\mathbf{d}}(\xi, \bar{\mathbf{v}}) = \theta + T$, we get, by our assumption,

$$\begin{aligned}
\widetilde{V}_0(\xi, \mathbf{d}) &> \int_0^T \Xi(|z(s, \xi, \mathbf{d}, \mathbf{v})|)\, ds + \widetilde{V}_0(z(T, \xi, \mathbf{d}, \mathbf{v}), \mathbf{d}_T) \\
&= \int_0^T \Xi(|z(s, \xi, \mathbf{d}, \mathbf{v})|)\, ds + \int_0^\theta \Xi(|z(t, z(T, \xi, \mathbf{d}, \mathbf{v}), \mathbf{d}_T, \mathbf{v}_1)|)\, dt \\
&= \int_0^{\theta+T} \Xi(|z(s, \xi, \mathbf{d}, \bar{\mathbf{v}})|)\, ds,
\end{aligned}$$

which contradicts with the minimality of $\widetilde{V}_0(\xi, \mathbf{d})$. □

LEMMA 4.9. *For each $\xi \in \partial\mathcal{D}$, the following holds:*

$$\lim_{\eta\to\xi} \widetilde{V}_0(\eta, \mathbf{d}) = 0 \tag{4.22}$$

uniformly in $\mathbf{d} \in \mathcal{S}$*, that is, for any* $\varepsilon > 0$*, there is a neighborhood* U *of* ξ *such that* $\widetilde{V}_0(\eta, \mathbf{d}) < \varepsilon$ *for all* $\eta \in U \cap \mathcal{E}$ *and all* $\mathbf{d} \in \mathcal{S}$*.*

Proof. If $\xi = 0$, the result follows from (4.18) and (4.19). Suppose now that $\xi \neq 0$.

Let $\varepsilon > 0$ be given. Let $\tau = \frac{\varepsilon}{\Xi(|\xi|+1)}$. Find a neighborhood U of ξ as in Lemma 4.4. Shrinking U if necessary, we assume that $|\xi - \eta| \leq 1$ for all $\eta \in U$.

Suppose $\eta \in U \cap \mathcal{E}$ and $\mathbf{d} \in \mathcal{M}_\Omega$. By the controllability property, there is some control v such that $z(t_1, \eta, \mathbf{d}, \mathbf{v}) = \xi \in \partial\mathcal{D}$ for some $t_1 \in [0, \tau]$, and that $z(t, \eta, \mathbf{d}, \mathbf{v}) \in U$ for all $t \in [0, t_1]$. Thus,

$$V_{\mathbf{v}}(\eta, \mathbf{d}) \leq \int_0^{t_1} \Xi(|z(s, \eta, \mathbf{d}, \mathbf{v})|)\, ds \leq \tau \cdot \Xi(|\xi| + 1) \leq \varepsilon,$$

from which it follows that $\widetilde{V}_0(\eta, \mathbf{d}) \leq \varepsilon$.

The above shows that $\widetilde{V}_0(\eta, \mathbf{d}) \leq \varepsilon$ for all nonrelaxed $\mathbf{d} \in \mathcal{M}_\Omega$, $\eta \in U \cap \mathcal{E}$. Pick a relaxed $\mathbf{d} \in \mathcal{S}$. Then there exists a sequence $\{\mathbf{d}_k\} \subset \mathcal{M}_\Omega$ such that $\mathbf{d}_k \to \mathbf{d}$ in the topology of relaxed controls. Let $\eta \in U \cap \mathcal{E}$. Let $\mathbf{v}_k$ be such that $\widetilde{V}_0(\eta, \mathbf{d}_k) = V_{\mathbf{v}_k}(\eta, \mathbf{d}_k)$. By weak sequential compactness of $\mathcal{W}$, one may assume, after taking a subsequence, that $\mathbf{v}_k \to \bar{\mathbf{v}}$ for some $\bar{\mathbf{v}}$. By Lemma 4.6,

$$V_{\bar{\mathbf{v}}}(\eta, \mathbf{d}) \leq \liminf_{k \to \infty} V_{\mathbf{v}_k}(\eta, \mathbf{d}_k) \leq \varepsilon,$$

and consequently, $\widetilde{V}_0(\eta, \mathbf{d}) \leq \varepsilon$. This shows that $\widetilde{V}_0(\eta, \mathbf{d}) \leq \varepsilon$ for all $\eta \in U \cap \mathcal{E}$ and all $d \in \mathcal{S}$. □

To prove the continuity of $\widetilde{V}_0$, we also need the following result.

LEMMA 4.10. *Suppose for some* $\xi \in \mathcal{E}$*,* $\mathbf{d} \in \mathcal{S}$*, and* $\mathbf{v} \in \mathcal{W}$*,* $V_{\mathbf{v}}(\xi, \mathbf{d}) < \infty$*. Then there exists some* $\xi_0 \in \partial\mathcal{D}$ *such that*

$$\lim_{t \to \theta_{\mathbf{d}}(\xi, \mathbf{v})} z(t, \xi, \mathbf{d}, \mathbf{v}) = \xi_0. \tag{4.23}$$

Proof. Suppose $V_{\mathbf{v}}(\xi, \nu) < \infty$. This means that

$$\int_0^{\theta_\nu(\xi, \mathbf{v})} \Xi(|z(s, \xi, \nu, \mathbf{v})|)\, ds < \infty. \tag{4.24}$$

If $\theta_{\mathbf{d}}(\xi, \mathbf{v}) < \infty$, then (4.23) follows from the continuity of $z(\cdot, \xi, \nu, \mathbf{v})$ with $\xi_0 = z(\theta_{\mathbf{d}}(\xi, \mathbf{v}))$.

Suppose now that $\theta_{\mathbf{d}}(\xi, \mathbf{v}) = \infty$. Since the integral in (4.24) converges, it follows that

$$\int_t^\infty \Xi(|z(s, \xi, \mathbf{d}, \mathbf{v})|)\, ds \to 0 \quad \text{as} \quad t \to \infty.$$

Consider the family of functions $\{x_t(\cdot),\ t > 0\}$, defined by $x_t(s) := z(t + s, \xi, \mathbf{d}, \mathbf{v})$, $\mathcal{I}_t = [0, \infty)$. By Lemma 4.1, the trajectory $z(s, \xi, \mathbf{d}, \mathbf{v})$ does not reach the origin in finite time, hence, there exists a positive, strictly decreasing function φ such that $\varphi(s) < |z(s, \xi, \mathbf{d}, \mathbf{v})|$ for all $s > 0$. Find a $\mathcal{K}_\infty$-function κ such that

$$\kappa(\varphi(t)) > \int_t^\infty \Xi(|z(s, \xi, \mathbf{d}, \mathbf{v})|)\, ds = \int_0^\infty \Xi(|x_t(s)|)\, ds.$$

Then the family $\{x_t(\cdot),\ t > 0\}$ satisfies all the conditions of Proposition 3.9 (with $\chi := \Xi$). Take $r := |\xi|$. Then, for any $\varepsilon > 0$, $|z(t, \xi, \mathbf{d}, \mathbf{v})| < \varepsilon$ for all $t > T_{r,\varepsilon}$. So, the conclusion of the lemma follows. □

Proposition 4.11. *The function* $\widetilde{V}_0 : \mathcal{E} \times \mathcal{S} \to \mathbf{R}$ *is continuous.*

Proof. Fix $\xi \in \mathcal{E}$, $\mathbf{d} \in \mathcal{S}$. Suppose $\xi_k \to \xi, \mathbf{d}_k \to \mathbf{d}$, where $\xi_k \in \mathcal{E}$. Let $\{k_j\}$ be a subsequence of $\{k\}$ such that

$$\lim_{j\to\infty} \widetilde{V}_0(\xi_{k_j}, \mathbf{d}_{k_j}) = \liminf_{k\to\infty} \widetilde{V}_0(\xi_k, \mathbf{d}_k). \tag{4.25}$$

For each k, let $\mathbf{v}_k$ be such that $\widetilde{V}_0(\xi_k, \mathbf{d}_k) = V_{\mathbf{v}_k}(\xi_k, \mathbf{d}_k)$. Notice that $\lim_{k\to\infty} V_{\mathbf{v}_k}(\xi_k, \mathbf{d}_k)$ exists, because of (4.25).

By sequential compactness of $\mathcal{W}$, there exists a subsequence of $\{\mathbf{v}_{k_j}\}$ converging to some $\bar{\mathbf{v}} \in \mathcal{W}$. Without relabeling, we assume that $\mathbf{v}_{k_j} \to \bar{\mathbf{v}}$. It then follows from Lemma 4.6 that

$$V_{\bar{\mathbf{v}}}(\xi, \mathbf{d}) \leq \lim\, V_{\mathbf{v}_{k_j}}(\xi_{k_j}, \mathbf{d}_{k_j}) = \liminf\, \widetilde{V}_0(\xi_k, \mathbf{d}_k).$$

Consequently, $\widetilde{V}_0(\xi, \mathbf{d}) \leq \liminf\, \widetilde{V}_0(\xi_k, \mathbf{d}_k)$. To complete the proof, we will show that

$$\widetilde{V}_0(\xi, \mathbf{d}) \geq \limsup_{k\to\infty} \widetilde{V}_0(\xi_k, \mathbf{d}_k). \tag{4.26}$$

Let $\mathbf{v}$ be a control such that $\widetilde{V}_0(\xi, \mathbf{d}) = V_{\mathbf{v}}(\xi, \mathbf{d})$. Let $\varepsilon > 0$ be given. By Lemma 4.10, there is some $\xi_0 \in \partial\mathcal{D}$ such that (4.23) holds. By Lemma 4.9, there is a neighborhood U of ξ_0 such that

$$\widetilde{V}_0(\eta, \nu) < \varepsilon/4 \ \ \forall \eta \in U \cap \mathcal{E},\ \forall \nu \in \mathcal{S}. \tag{4.27}$$

Let $0 < T < \theta_{\mathbf{d}}(\xi, \mathbf{v})$ be such that $z(T, \xi, \mathbf{d}, \mathbf{v}) \in U$. Then, since $\{z(t, \xi_k, \mathbf{d}_k, \mathbf{v})\}$ converges to $z(t, \xi, \mathbf{d}, \mathbf{v})$ uniformly on $[0, T]$, it follows that $z(T, \xi_k, \mathbf{d}_k, \mathbf{v}) \in U$ for $k \geq K_1$ for some K_1. By Lemma 4.5, one may assume that $T < \theta_{\mathbf{d}_k}(\xi_k, \mathbf{v})$ for all $k \geq K_1$. Consequently, $\eta = z(T, \xi_k, \mathbf{d}_k, \mathbf{v})$ is also in $\mathcal{E}$, so, applying (4.27) with $\nu = (\mathbf{d}_k)_T$, we have

$$\widetilde{V}_0(z(T, \xi_k, \mathbf{d}_k, \mathbf{v}), (\mathbf{d}_k)_T) < \varepsilon/4 \qquad \forall\, k \geq K_1,$$

where $(\mathbf{d}_k)_T(t) = \mathbf{d}_k(T+t)$. By the uniform convergence property of $\{z(t, \xi_k, \mathbf{d}_k, \mathbf{v})\}$, it follows that there is some compact set $\mathcal{K}$ such that $z(t, \xi_k, \mathbf{d}_k, \mathbf{v}) \in \mathcal{K}$ for all k and all $t \in [0, T]$. Using also the uniform continuity of $\Xi(\cdot)$ on compacts, one sees that there is some $K_2 \geq K_1$ such that

$$\int_0^T \Xi(|z(s, \xi_k, \mathbf{d}_k, \mathbf{v})|)\, ds \ \leq\ \int_0^T \Xi(|z(s, \xi, \mathbf{d}, \mathbf{v})|)\, ds + \varepsilon/2$$

for all $k \geq K_2$. Thus, (4.21) implies

$$\begin{aligned}\widetilde{V}_0(\xi_k, \mathbf{d}_k) &\leq \int_0^T \Xi(|z(s, \xi_k, \mathbf{d}_k, \mathbf{v})|)\, ds + \widetilde{V}_0(z(T, \xi_k, \mathbf{d}_k, \mathbf{v}), (\mathbf{d}_k)_T)\\ &\leq V_{\mathbf{v}}(\xi, \mathbf{d}) + \varepsilon/2 + \varepsilon/2 \ =\ \widetilde{V}_0(\xi, \mathbf{d}) + \varepsilon\end{aligned}$$

for all $k \geq K_2$. From this it follows that

$$\widetilde{V}_0(\xi, \mathbf{d}) \geq \limsup\, \widetilde{V}_0(\xi_k, \mathbf{d}_k) - \varepsilon.$$

Letting $\varepsilon \to 0$, one proves (4.26). □

For each $\xi \in \mathcal{E}$, define

$$V_0(\xi) := \sup_{\mathbf{d}\in\mathcal{M}_\Omega} \widetilde{V}_0(\xi,\mathbf{d}). \tag{4.28}$$

Note that the supremum is finite for each $\xi \in \mathcal{E}$; in fact, by (4.18) and (4.19), we have the upper bound

$$V_0(\xi) \le \mu_2(|\xi|) \qquad \forall\, \xi \in \mathcal{E}, \tag{4.29}$$

where μ_2 is as in inequality (4.9). Also observe that the same function V_0 results if the supremum in (4.28) is taken over the set $\mathcal{S}$. This follows from the fact that $\mathcal{M}_\Omega$ is dense in $\mathcal{S}$ and the continuity property of $\widetilde{V}_0$.

By sequential compactness of $\mathcal{S}$ and by continuity of $\widetilde{V}_0$, we get the following.

Corollary 4.12. *For any ξ in $\mathcal{E}$ there exists a (possibly relaxed) disturbance* $\mathbf{d}$ *such that $V_0(\xi) = \widetilde{V}_0(\xi,\mathbf{d})$, that is, $V_0(\xi) = \max_{\bar{\mathbf{d}}\in\mathcal{S}} \widetilde{V}_0(\xi,\bar{\mathbf{d}})$. Moreover, $V_0 : \mathcal{E} \to \mathbf{R}$ is continuous.*

Proof. Fix $\xi \in \mathcal{E}$. By definition of V_0, there exists a sequence of disturbances $\{\mathbf{d}_k(\cdot)\}$ such that $\widetilde{V}_0(\xi,\mathbf{d}_k) \nearrow V_0(\xi)$. By sequential compactness of $\mathcal{S}$, we can extract a subsequence $\{\mathbf{d}_{k_i}\}$, converging in $\mathcal{S}$ to some $\mathbf{d}$. By continuity of $\widetilde{V}_0$,

$$V_0(\xi) = \lim_{i\to\infty} \widetilde{V}_0(\xi,\mathbf{d}_{k_i}) = \widetilde{V}_0(\xi,\mathbf{d}),$$

proving the first statement of the corollary.

Now fix $\xi \in \mathcal{E}$. Take any sequence $\{\xi_k\} \in \mathcal{E}$, converging to ξ and such that the sequence $\{V_0(\xi_k)\}$ converges. Let $\mathbf{d}_k(\cdot)$ and $\mathbf{d} \in \mathcal{S}$ be maximizing disturbances for ξ_k and ξ, respectively, that is,

$$V_0(\xi_k) = \widetilde{V}_0(\xi_k,\mathbf{d}_k) \text{ and } V_0(\xi) = \widetilde{V}_0(\xi,\mathbf{d}).$$

Extracting a subsequence if necessary, let $\hat{\mathbf{d}}$ be a limit of $\{\mathbf{d}_k\}$ in $\mathcal{S}$. Then, by continuity of $\widetilde{V}_0$ and by definition of V_0, we have

$$V_0(\xi) \;\ge\; \widetilde{V}_0(\xi,\hat{\mathbf{d}}) \;=\; \lim_{k\to\infty} \widetilde{V}_0(\xi_k,\mathbf{d}_k) \;=\; \lim_{k\to\infty} V_0(\xi_k).$$

Consequently, if $\{\xi_i\} \subset \mathcal{E}$ is any sequence, converging to ξ, then

$$V_0(\xi) \;\ge\; \limsup_{i\to\infty} V_0(\xi_i),$$

proving upper semicontinuity of V_0.

On the other hand, again by continuity of $\widetilde{V}_0$, we have

$$\liminf_{k\to\infty} V_0(\xi_k) \ge \lim_{k\to\infty} \widetilde{V}_0(\xi_k,\mathbf{d}) = V_0(\xi),$$

showing the lower semicontinuity of V_0. Thus we conclude that V_0 is continuous on $\mathcal{E}$. □

Lemma 4.13. *There exists a $\mathcal{K}_\infty$-function $\underline{\alpha}$ such that*

$$\underline{\alpha}(|\xi|) \le V_0(\xi)$$

for all $\xi \in \mathcal{E}_1$.

Notice that if $|\xi| \ge 1.6\rho(|h(\xi)|)$ and $\xi \ne 0$, then $\xi \in \mathcal{E}$, because $|\xi| > |\xi|/1.6 \ge \rho(|h(\xi)|)$. To prove Lemma 4.13, we first prove a technical lemma.

Lemma 4.14. *Suppose $\Sigma : \dot{z} = g(z,d)$, $y = h(z)$ is a system of type* (2.14)*, and $p(\cdot)$ is a smooth function of class $\mathcal{K}_\infty$, such that the following conditions hold:*

- *$|g(\xi, d)| \leq 1$ for all $\xi \in \mathbf{X}$ and $d \in \Omega$,*
- *$|\nabla(p \circ |h|)(\xi) \cdot g(\xi, d)| \leq 1$ for all $d \in \Omega$ and all ξ with $|h(\xi)| \geq 1$,*
- *$p(s) \geq s$ for all $s > 0$.*

Pick any constant $a > 0$ and define $K_0 = p(1) + (2+a)/a + 1$. Then for each $\xi \in \mathbf{X}$ such that

$$|\xi| \geq (1+a)p(|h(\xi)|) \text{ and } |\xi| \geq K_0,$$

it holds that

$$|z(t, \xi, \mathbf{d})| > p(|h(z(t, \xi, \mathbf{d}))|)$$

for all $t \in [0, 1)$ and any $\mathbf{d} \in \mathcal{M}_\Omega$.

Proof. Fix a, ξ, and $\mathbf{d}$ as in the formulation of the lemma, and define

$$\theta := \min\{t \,:\, |z(t, \xi, \mathbf{d})| \leq p(|h(z(t, \xi, \mathbf{d}))|)\}$$

with the convention $\theta = +\infty$ if the inequality never holds for $t \geq 0$. Assume the lemma is false, so that $\theta < 1$.

Let $\eta = z(\theta, \xi, \mathbf{d})$, and let $\hat{\mathbf{d}}$ be the shift of $\mathbf{d}$ by θ, that is, $\hat{\mathbf{d}}(t) = \mathbf{d}(t + \theta)$. Since $|g(z, d)| \leq 1$ for all $z \in \mathbf{X}$ and all $d \in \Omega$, it holds that $|\eta| \geq |\xi| - \theta \geq K_0 - 1$. By the definitions of η and θ, one has

$$p(|h(\eta)|) = |\eta| \geq K_0 - 1, \tag{4.30}$$

so also $|h(\eta)| \geq p^{-1}(K_0 - 1) > 1$. Thus, $|h(z(s, \eta, \hat{\mathbf{d}}))| > 1$ for all s near zero.

Claim. $|h(z(s, \eta, \hat{\mathbf{d}}))| > 1$ for all $s \in [-1,\, 0]$.

Assume the claim is false. Then there must exist some $-1 \leq s_0 < 0$ so that

$$s_0 = \max\left\{s \leq 0 :\ |h(z(s, \eta, \hat{\mathbf{d}}))| \leq 1\right\}.$$

We have that for each $s \in (s_0,\, 0]$, $|h(z(s, \eta, \hat{\mathbf{d}}))| > 1$.

Recall that $|\nabla(p \circ |h|)(z) f(z, d)| \leq 1$ for all z with $|h(z)| \geq 1$ and all $d \in \Omega$.

Thus

$$\left|\frac{d}{ds} p\left(\left|h(z(s, \eta, \hat{\mathbf{d}}))\right|\right)\right| \leq 1 \quad \forall\, s \in (s_0,\, 0].$$

This, in turn, implies that

$$p\left(\left|h(z(s_0, \eta, \hat{d}))\right|\right) \geq p(|h(\eta)|) + s_0 \geq K_0 + s_0 - 1 > p(1),$$

and so, since p is strictly increasing, $|h(z(s_0, \eta, \hat{\mathbf{d}}))| > 1$, thus contradicting the definition of s_0. This proves the claim.

It follows from the claim that $|h(z(s, \xi, \mathbf{d}))| > 1$ for all $s \in [0, \theta]$. Thus,

$$\begin{aligned} p(|h(\eta)|) = |\eta| \ &\geq\ |\xi| - \theta \\ &\geq (1+a)p(|h(\xi)|) - \theta \geq (1+a)p(|h(\eta)|) - (1+a)\theta - \theta. \end{aligned}$$

(The last inequality used the fact that $\left|\frac{d}{ds} p(|h(z(s, \xi, \mathbf{d}))|)\right| \leq 1$ for all $s \in [0, \theta]$.) It follows that $p(|h(\eta)|) \leq \frac{2+a}{a}\theta$, so from (4.30) we know that

$$K_0 \leq 1 + p(|h(\eta)|) \leq 1 + \frac{2+a}{a}\theta,$$

contradicting the choice of K_0. This shows that it is impossible to have $\theta < 1$. □

Proof of Lemma 4.13. Recall that if $\xi \notin \mathcal{D} \cup \mathcal{B}$, then $\widetilde{f}(\xi, d, v) = \hat{f}(\xi, d)$ for any d and v, so that

$$\left|\nabla(1.5\rho \circ |h|)(\xi) \cdot \widetilde{f}(\xi, d, v)\right| = \frac{1.5\,|\nabla(\rho \circ |h|)(\xi) \cdot f(\xi, d)|}{1 + |f(\xi, d)|^2 + \kappa(\xi)} \leq 1,$$

where the last inequality follows from (4.4). Therefore the assumptions of Lemma 4.14 are satisfied with $p := 1.5\rho$ and $f(\xi, d) := \widetilde{f}(\xi, d, v) = \widehat{f}(\xi, d)$. By Lemma 4.14, we can find a constant K_0 such that if $|\xi| > K_0$ and $|\xi| \geq 1.6\rho(|h(\xi)|)$, then $z(t, \xi, \mathbf{d}, v) \notin \mathcal{D} \cup \mathcal{B}$ for all $t \in [0, 1)$. In particular, for such a ξ we will have $\theta_{\mathbf{d}}(\xi, \mathbf{v}) > 1$ and $|z(t, \xi, \mathbf{d}, \mathbf{v})| > |\xi| - 1$ for all positive $t < 1$. Hence, the inequality

$$\Xi(|z(t, \xi, \mathbf{d}, \mathbf{v})|) > \Xi(|\xi| - 1) \quad \forall t \in [0, 1)$$

holds for any $\mathbf{d} \in \mathcal{M}_\Omega$, $\mathbf{v} \in \mathcal{W}$, and any ξ such that

$$|\xi| > \max\{K_0 + 1,\ 1.6\rho(|h(\xi)|)\}\,. \tag{4.31}$$

Therefore, for any ξ as in (4.31) and any $\mathbf{d} \in \mathcal{M}_\Omega$, the following estimate holds:

$$V_0(\xi) \ \geq\ \widetilde{V}_0(\xi, \mathbf{d}) \ \geq\ \int_0^1 \Xi(|z(t, \xi, \mathbf{d}, \mathbf{v})|)dt \ \geq\ \Xi(|\xi| - 1).$$

Next, notice that V_0 is strictly positive on $\mathcal{E}$. Indeed, $|\widetilde{f}(\xi, d, v)| \leq 3$ for any $\xi \in \mathcal{E}$, $d \in \Omega$, and $v \in [-1, 1]^n$, so that

$$|z(s, \xi, \mathbf{d}, \mathbf{v}) - \xi| \leq \frac{1}{2}\text{dist}(\xi, \mathcal{D}) \quad \forall\, s \leq \frac{\frac{1}{2}\text{dist}(\xi, \mathcal{D})}{3},\ \mathbf{d} \in \mathcal{M}_\Omega,\ \mathbf{v} \in \mathcal{W}.$$

Therefore $\theta_{\mathbf{d}}(\xi, \mathbf{v}) \geq \frac{1}{6}\text{dist}(\xi, \mathcal{D})$ and $|z(s, \xi, \mathbf{d}, \mathbf{v})| \geq \xi - \frac{1}{2}\text{dist}(\xi, \mathcal{D})$ for all $s \leq \frac{1}{6}\text{dist}(\xi, \mathcal{D})$, all $\mathbf{d} \in \mathcal{M}_\Omega$, and $\mathbf{v} \in \mathcal{W}$. So, we have

$$V_{\mathbf{v}}(\xi, \mathbf{d}) \ \geq\ \int_0^{\text{dist}(\xi,\mathcal{D})/6} \Xi\left(|z(s, \xi, \mathbf{d}, \mathbf{v})|\right) ds \ \geq\ \frac{\text{dist}(\xi, \mathcal{D})}{6}\, \Xi(|\xi| - \text{dist}(\xi, \mathcal{D})/2).$$

This shows that

$$\inf_{\mathbf{d} \in \mathcal{M}_\Omega} \inf_{v \in \mathcal{W}} V_{\mathbf{v}}(\xi, \mathbf{d}) \geq \frac{\text{dist}(\xi, \mathcal{D})}{6}\, \Xi\!\left(|\xi| - \frac{\text{dist}(\xi, \mathcal{D})}{2}\right). \tag{4.32}$$

Thus also the $\sup_{\mathbf{d} \in \mathcal{M}_\Omega} \inf_{v \in \mathcal{W}} V_{\mathbf{v}}(\xi, \mathbf{d})$ satisfies (4.32), and hence the same inequality holds for V_0.

Since V_0 is lower semicontinuous, it attains its minimum on any compact set. For each positive l define

$$r_l := \frac{1}{l}\max\{K_0 + 1,\ 1.6\rho(|h(\xi)|)\} \quad \text{and} \quad m_l = \inf\{V_0(z)\ :\ z \in \mathcal{E}_1,\ r_l \leq |z| \leq r_1\}\ .$$

Since the sequence $\{m_l\}$ is nonincreasing and positive, and Ξ is of class $\mathcal{K}_\infty$, we can find a $\mathcal{K}_\infty$-function $\underline{\alpha}$ such that

$$\underline{\alpha}(s) < m_l \ \ \forall\, s \in [r_l, r_{l-1}],\ \forall\, l > 1$$

and

$$\underline{\alpha}(s) < \Xi(s-1) \forall\, s \geq \max\left\{K_0 + 1,\ 1.6\rho(|h(\xi)|)\right\}.$$

By construction, $\underline{\alpha}$ will be a lower bound for V_0 on $\mathcal{E}_1$. □

Combining Lemma 4.13 with (4.29), we get the following, using $\bar{\alpha} := \mu_2$:

$$\underline{\alpha}(|\xi|) \leq V_0(\xi) \leq \bar{\alpha}(|\xi|) \qquad \forall\, \xi \in \mathcal{E}_1. \tag{4.33}$$

The following lemma and corollary summarize the dissipation properties for V_0.

LEMMA 4.15. *For any $\xi \in \mathbf{X} \setminus (\mathcal{D} \cup \mathcal{B})$ and $\mathbf{d} \in \mathcal{M}_\Omega$, and any t_0 such that $z(t, \xi, \mathbf{d}) \notin \mathcal{D} \cup \mathcal{B}$ for all $t \in [0, t_0]$, the following dissipation inequality holds:*

$$V_0(z(t, \xi, \mathbf{d})) - V_0(\xi) \leq -\int_0^{t_0} \Xi(|z(t, \xi, \mathbf{d})|)\, dt.$$

Proof. Fix $\xi \in \mathbf{X} \setminus (\mathcal{D} \cup \mathcal{B})$, $\mathbf{d} \in \mathcal{M}_\Omega$, and any positive t_0 as in the formulation of the lemma. Let $\varepsilon > 0$ be given. Find $\mathbf{d}_1$ such that

$$V_0(z(t_0, \xi, \mathbf{d})) - \widetilde{V}_0(z(t_0, \xi, \mathbf{d}), \mathbf{d}_1) < \varepsilon,$$

and let $\mathbf{v}_1 \in \mathcal{W}$ be a control such that $\widetilde{V}_0(z(t_0, \xi, \mathbf{d}), \mathbf{d}_1) = V_{\mathbf{v}_1}(z(t_0, \xi, \mathbf{d}), \mathbf{d}_1)$. Let $\widetilde{\mathbf{d}}$ be defined by

$$\widetilde{\mathbf{d}}(t) = \begin{cases} \mathbf{d}(t) & \text{if } 0 \leq t \leq t_0, \\ \mathbf{d}_1(t - t_0) & \text{if } t > t_0. \end{cases}$$

Then $z(t, z(t_0, \xi, \mathbf{d}), \mathbf{d}_1, \mathbf{v}_1) = z(t + t_0, \xi, \widetilde{\mathbf{d}}, \widetilde{\mathbf{v}})$ for all $t \geq 0$. By assumption,

$$z(t, \xi, \mathbf{d}) \notin \mathcal{D} \cup \mathcal{B} \qquad \forall\, t \in [0, t_0],$$

and therefore we have

$$z(t, \xi, \mathbf{d}) = z(t, \xi, \mathbf{d}, \mathbf{v}) \qquad \forall\, t \in [0, t_0], \quad \forall\, \mathbf{v} \in \mathcal{W}. \tag{4.34}$$

Notice also that (4.34) implies that $\theta_{\widetilde{\mathbf{d}}}(\xi, \mathbf{v}) > t_0$ for all $\mathbf{v} \in \mathcal{W}$ and

$$\begin{aligned} \widetilde{V}_0(\xi, \widetilde{\mathbf{d}}) &= \min_{\mathbf{v} \in \mathcal{W}} \int_{t_0}^{\theta_{\widetilde{\mathbf{d}}}(\xi, \mathbf{v})} \Xi\left(\left|z(s, \xi, \widetilde{\mathbf{d}}, \mathbf{v})\right|\right) ds \\ &= \int_0^{t_0} \Xi\left(\left|z(s, \xi, \widetilde{\mathbf{d}})\right|\right) ds + \min_{\mathbf{v} \in \mathcal{W}} \int_{t_0}^{\theta_{\widetilde{\mathbf{d}}}(\xi, \mathbf{v})} \Xi\left(\left|z(s, \xi, \widetilde{\mathbf{d}}, \mathbf{v})\right|\right) ds \\ &= \int_0^{t_0} \Xi(|z(s, \xi, \mathbf{d})|) ds + \min_{\mathbf{v} \in \mathcal{W}} \int_0^{\theta_{\mathbf{d}_1}(z(t_0, \xi, \mathbf{d}), \mathbf{v})} \Xi(|z(s, z(t_0, \xi, \mathbf{d}), \mathbf{d}_1, \mathbf{v})|) ds \\ &= \int_0^{t_0} \Xi(|z(s, \xi, \mathbf{d})|) ds + \widetilde{V}_0(z(t_0, \xi, \mathbf{d}), \mathbf{d}_1). \end{aligned}$$

Consequently, one has

$$\widetilde{V}_0(z(t_0, \xi, \mathbf{d}), \mathbf{d}_1) = \widetilde{V}_0(\xi, \widetilde{\mathbf{d}}) - \int_0^{t_0} \Xi\left(|z(s, \xi, \mathbf{d})|\right) ds.$$

Thus,

$$\begin{aligned} V_0(z(t_0,\xi,\mathbf{d})) &\le \widetilde{V}_0(z(t_0,\xi,\mathbf{d}),\mathbf{d}_1)+\varepsilon \\ &= \widetilde{V}_0(\xi,\widetilde{\mathbf{d}}) - \int_0^{t_0} \Xi(|z(s,\xi,\mathbf{d})|)\,ds + \varepsilon \\ &\le V_0(\xi) - \int_0^{t_0} \Xi(|z(s,\xi,\mathbf{d})|)\,ds + \varepsilon. \end{aligned}$$

Letting $\varepsilon \to 0$, we get the desired inequality. □

Thus, we have proven that the UOSS dissipation inequality holds for V_0 along the trajectories of the slower system $\hat{\Sigma}$ which are entirely contained in $\mathbf{X}\setminus(\mathcal{D}\cup\mathcal{B})$. It follows immediately that the same estimate holds along the trajectories of the original system Σ.

Corollary 4.16. *For any $\xi\in\mathbf{X}\setminus(\mathcal{D}\cup\mathcal{B})$ and $\mathbf{d}\in\mathcal{M}_\Omega$, and any t_0 such that $x(t,\xi,\mathbf{d})\notin\mathcal{D}\cup\mathcal{B}$ for all $t\in[0,t_0]$, the following dissipation inequality holds:*

$$V_0(x(t,\xi,\mathbf{d})) - V_0(\xi) \le -\int_0^{t_0} \Xi(|x(t,\xi,\mathbf{d})|)\,dt. \tag{4.35}$$

Proof. Pick an initial state $\xi\in\mathbf{X}\setminus(\mathcal{D}\cup\mathcal{B})$, a disturbance $\mathbf{d}\in\mathcal{M}_\Omega$, and an appropriate t_0. Then

$$\begin{aligned} &V_0(x(t_0,\xi,\mathbf{d})) - V_0(x(\xi)) \\ &= V_0(z(\sigma_{\xi,\mathbf{d}}(t_0),\xi,\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1})) - V_0(z(\sigma_{\xi,\mathbf{d}}(t_1),\xi,\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1})) \\ &\le -\int_0^{\sigma_{\xi,\mathbf{d}}(t_0)} \Xi\left(\left|z(s,\xi,\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1})\right|\right)ds \\ &= -\int_0^{t_0} \Xi\left(\left|z(\sigma_{\xi,\mathbf{d}}(t),\xi,\mathbf{d}\circ{\sigma_{\xi,\mathbf{d}}}^{-1})\right|\right)d\sigma_{\xi,\mathbf{d}}(t) \\ &= -\int_0^{t_0} \Xi(|x(t,\xi,\mathbf{d})|)\,\frac{d}{dt}\sigma_{\xi,\mathbf{d}}(t)\,dt \\ &= -\int_0^{t_0} \Xi(|x(t,\xi,\mathbf{d})|)[1+|f(x(t,\xi,\mathbf{d}),\mathbf{d}(t))|^2+\kappa(x(s,\xi,\mathbf{d}))]\,dt \\ &\le -\int_0^{t_0} \Xi(|x(t,\xi,\mathbf{d})|)\,dt. \qquad \square \end{aligned}$$

4.4. Some definitions and facts from nonsmooth analysis.

Definition 4.17. *A vector $\zeta\in\mathbf{R}^n$ is a* proximal subgradient *(respectively,* proximal supergradient*) of the function $V:\mathbf{R}^n\to(-\infty,+\infty]$ at x if there exists some positive σ such that, for all x' in some neighborhood of x,*

$$V(x') \ge V(x) + \zeta\cdot(x'-x) - \sigma|x'-x|^2 \tag{4.36}$$

$$(\textit{correspondingly, } V(x') \le V(x) + \zeta\cdot(x'-x) + \sigma|x'-x|^2). \tag{4.37}$$

The (possibly empty) set of all proximal subgradients (respectively, supergradients) of V at x is called the proximal subdifferential *and is denoted $\partial_P V(x)$ (respectively,* proximal superdifferential*, denoted $\partial^P V(x)$). Note that the definitions imply that if* *the function V is differentiable at x, then both the subdifferential and superdifferential sets must be subsets of the $\{\nabla V(x)\}$.*

LEMMA 4.18. *Let Σ be a system of type* (2.14)*, ξ be a vector in $\mathbf{X}$, $\bar{d} \in \Omega$, and $V : \mathbf{X} \to \mathbf{R}$. Then, if there exist some continuous $\alpha_\xi : \mathbf{R}_{\geq 0} \to \mathbf{R}$ and $\varepsilon > 0$ such that the following inequality holds for all $\tau < \varepsilon$,*

$$V(x(\tau,\xi,\mathbf{d})) - V(\xi) \;\leq\; \int_0^\tau \alpha_\xi(t)dt \tag{4.38}$$

(where $\mathbf{d}$ is the constant disturbance equal to $\bar{d}$), then for any $\zeta \in \partial_P V(\xi)$ the proximal form of inequality (4.38) *holds:*

$$\zeta \cdot f(\xi,\bar{d}) \leq \alpha_\xi(0). \tag{4.39}$$

Proof. It follows from (4.36) and (4.38) that, for all τ close enough to 0 we have

$$\int_0^\tau \alpha_\xi(t)dt \;\geq\; V(x(\tau,\xi,\mathbf{d})) - V(\xi) \;\geq\; \zeta \cdot (x(\tau,\xi,\mathbf{d}) - \xi) - \sigma|x(\tau,\xi,\mathbf{d}) - \xi|^2.$$

Dividing by τ and passing to the limit as τ tends to 0, we get (4.39). □

4.5. Smoothing out a continuous Lyapunov function. The next result shows how to approximate a continuous function V by a locally Lipschitz one in a weak C^1 sense. The function V is assumed to be bounded below, or up to a translation by a constant, nonnegative.

LEMMA 4.19. *Let $\Sigma : \dot{x} = f(x,d)$ be a system, with $x \in \mathbf{X} = \mathbf{R}^n$ and $d \in \Omega$, a compact metric space, so that $f(x,d)$ is locally Lipschitz in x uniformly on d and jointly continuous in x and d. Assume that we are given*

- *an open subset $\mathcal{O}$ of $\mathbf{X}$;*
- *a continuous, nonnegative function $V : \mathcal{O} \to \mathbf{R}$ satisfying*

  $$\zeta \cdot f(x,d) \leq \Theta(x,d) \;\; \forall x \in \mathcal{O},\; \zeta \in \partial_P V(x),\; d \in \Omega \tag{4.40}$$

  with some continuous function $\Theta : \mathcal{O} \times \Omega \to \mathbf{R}$;
- *two positive, continuous functions Υ_1 and Υ_2 on $\mathcal{O}$.*

Then there exists a function $\widetilde{V} : \mathcal{O} \to \mathbf{R}$, locally Lipschitz on $\mathcal{O}$, such that

$$0 \leq V(x) - \widetilde{V}(x) \leq \Upsilon_1(x) \;\; \forall x \in \mathcal{O} \tag{4.41}$$

and

$$L_{f_d}\widetilde{V}(x) \leq \Theta(x,d) + \Upsilon_2(x) \quad \forall d \in \Omega \text{ and for almost all } x \in \mathcal{O}, \tag{4.42}$$

where f_d is the vector field defined by $f_d = f(\cdot,d)$.

Note that, by Rademacher's theorem, the directional derivative $L_{f_d}\widetilde{V}(x)$, given by $\nabla V(x) \cdot f(x,d)$, is defined for almost all x because $\widetilde{V}$ is locally Lipschitz. The proof will follow closely along the lines of the proof of the similar result for CLFs, found in [9] or [40].

We will first prove a "local" version of the result. For any K which is a compact subset of $\mathcal{O}$ and $r > 0$, we introduce the following notations:

- $\bar{B}_r(K) := \{x \in \mathbf{X} : \exists \xi \in K \text{ with } |x - \xi| \leq r\}$, the closed r-fattening of K, for $r > 0$,
- $\beta(K) := \sup_{x \in K} V(x)$,

- $m_K := \frac{1}{4} \min \{\Upsilon_2(x) : x \in K\}$,
- $\ell_K :=$ a Lipschitz constant for f with respect to x in K, that is,

$$|f(x, d) - f(x', d)| \leq \ell_K |x - x'| \;\; \forall d \in \Omega, \; \forall x \in K,$$

- $\omega_K(\cdot) :=$ the modulus of continuity of V on K, that is,

$$\omega_K(\delta) := \sup \{V(x) - V(x') \; : \; |x - x'| \leq \delta; x, x' \in K\},$$

- $\pi_K(\cdot) :=$ the modulus of continuity of Θ on $K \times \Omega$, that is,

$$\begin{aligned}\pi_K(\delta) := \sup\{\Theta(x, d) - \Theta(x', d') \; : \; &|x - x'| + \operatorname{dist}(d, d') \leq \delta;\\ &x, x' \in K, d, d' \in \Omega\}.\end{aligned}$$

To approximate the given continuous function V by a locally Lipschitz one, we would like to use the notion of "Iosida–Moreau inf-convolution," well known in convex analysis. Fix a parameter $\alpha \in (0, 1]$. Suppose for the moment that V is defined on the whole $\mathbf{X}$. Define

$$V_\alpha(x) := \min_{y \in \mathbf{X}} \left[V(y) + \frac{1}{2\alpha^2} |y - x|^2 \right].$$

For each fixed x, the set of points y where the minimum is attained is nonempty because V is bounded below. Denote one of them by $y_\alpha(x)$.

Fix a compact K and $\alpha \in (0, 1]$, let

$$K_\alpha := \bar{B}_{\alpha\sqrt{2\beta(K)}}(K).$$

The following four claims summarize some of the useful properties of V_α, proven in [9], [40] (or see the primary sources such as [8]).

Claim 1. For all $x \in K$,

$$|y_\alpha(x) - x|^2 \; \leq \; \min \left\{ 2\alpha^2 \beta(K), \; 2\alpha^2 \omega_{K_\alpha} \left(\alpha \sqrt{2\beta(K)} \right) \right\}.$$

Proof of Claim 1. By definition of V_α and $\beta(K)$, we have

$$\frac{1}{2\alpha^2} \, |y_\alpha(x) - x|^2 \leq V(x) - V(y_\alpha(x)) \leq V(x) \leq \beta(K), \tag{4.43}$$

so that $|y_\alpha(x) - x|^2 \leq 2\alpha^2 \beta(K)$. On the other hand, the first inequality in (4.43) implies also that

$$\begin{aligned}|y_\alpha(x) - x|^2 &\leq 2\alpha^2 (V(x) - V(y_\alpha(x)))\\ &\leq 2\alpha^2 \omega_{K_\alpha} (|y_\alpha(x) - x|) \; \leq \; 2\alpha^2 \omega_{K_\alpha} \left(\alpha \sqrt{2\beta(K)} \right),\end{aligned}$$

proving the claim.

Let

$$\zeta_\alpha(x) = \frac{x - y_\alpha(x)}{\alpha^2}.$$

Claim 2. For any $x \in \mathbf{X}$,

$$\zeta_\alpha(x) \in \partial_P V(y_\alpha(x)) \;\text{ and} \tag{4.44}$$

$$\zeta_\alpha(x) \in \partial^P V_\alpha(x). \tag{4.45}$$

Claim 3. For any $x \in K$,

$$V_\alpha(x) \le V(x) \le V_\alpha(x) + \omega_{K_\alpha}\left(\alpha\sqrt{2\beta(K)}\right).$$

Claim 4. V_α is locally Lipschitz.

Now recall that, in our setting, V is defined on an open subset $\mathcal{O}$ of $\mathbf{X}$, so, we can't minimize the expression in the definition of V_α over the whole state space. However, for any compact subset K of $\mathcal{O}$ we can choose α small enough so that

$$K_\alpha \subset \mathcal{O},$$

hence, for any x in K we could define V_α minimizing over $y \in \mathcal{O}$, and the same function V_α results on K.

LEMMA 4.20. *Assume that* V *satisfies* (4.40), *a compact* K *is fixed, and* $\alpha \in (0,1]$ *is chosen to satisfy*

- $K_\alpha = \bar{B}_{\alpha\sqrt{2\beta(K)}}(K) \subset \mathcal{O}$,
- $\pi_{K_\alpha}\left(\alpha\sqrt{2\beta(K)}\right) \le m_K$, *and*
- $2\ell_{K_\alpha}\omega_{K_\alpha}\left(\alpha\sqrt{2\beta(K)}\right) \le m_K$.

Then the function

$$V_\alpha(x) := \inf_{y\in\mathcal{O}}\left[V(y) + \frac{1}{2\alpha^2}|y-x|^2\right] \tag{4.46}$$

will possess the following property:

$\forall\ x \in K, \forall\ d \in \Omega$, *and* $\forall\ \zeta \in \partial_P V_\alpha(x)$,

$$\zeta \cdot f(x,d) \le \Theta(x,d) + 2m_K.$$

Proof. Fix any $x \in K$. The choice of α ensures that the infimum in (4.46) is a minimum, and it is achieved at some $y_\alpha(x) \in K_\alpha$. The definition of $\zeta_\alpha(x)$ and Claim 1 imply that

$$|\zeta_\alpha(x)||y_\alpha(x)-x| = \frac{|y_\alpha(x)-x|^2}{\alpha^2} \le 2\omega_{K_\alpha}\left(\alpha\sqrt{2\beta(K)}\right). \tag{4.47}$$

Using again the fact that $y_\alpha(x) \in K_\alpha$,

$$|f(x,d) - f(y_\alpha(x),d)| \le \ell_{K_\alpha}|x - y_\alpha(x)|.$$

Combining the last inequality with (4.47) we obtain

$$|\zeta_\alpha(x)||f(x,d) - f(y_\alpha(x),d)| \le 2\ell_{K_\alpha}\omega_{K_\alpha}\left(\alpha\sqrt{2\beta(K)}\right). \tag{4.48}$$

Now, by Claim 2, $\zeta_\alpha(x) \in \partial_P V(y_\alpha(x))$. Hence,

$$\begin{aligned}\zeta_\alpha(x)\cdot f(y_\alpha(x),d) &\le \Theta(y_\alpha(x),d)\\ &\le \Theta(x,d) + \pi_{K_\alpha}(|x-y_\alpha(x)|)\\ &\le \Theta(x,d) + \pi_{K_\alpha}\left(\alpha\sqrt{2\beta(K)}\right)\\ &\le \Theta(x,d) + m_K.\end{aligned}$$

So, by the last inequality, (4.48), and the choice of α, we have

$$\begin{aligned}\zeta_\alpha(x)\cdot f(x,d) &= \zeta_\alpha(x)\cdot f(y_\alpha(x),d)+\zeta_\alpha(x)\cdot(f(x,d)-f(y_\alpha(x),d))\\ &\le \Theta(x,d)+m_K+m_K.\end{aligned} \tag{4.49}$$

Next, we show that $\partial_P V_\alpha(x)\subseteq\{\zeta_\alpha\}$ for all $x\in K$. Pick any $\zeta\in\partial_P V_\alpha(x)$. By definition of the proximal subgradient, the inequality

$$\zeta\cdot(y-x)\le V_\alpha(y)-V_\alpha(x)+o(|y-x|) \tag{4.50}$$

holds for all y near x. Since $\zeta_\alpha(x)$ is a proximal supergradient of V_α at x, we also have

$$-\zeta_\alpha(x)\cdot(y-x)\le -V_\alpha(y)+V_\alpha(x)+o(|y-x|). \tag{4.51}$$

Adding (4.50) and (4.51), we get

$$(\zeta-\zeta_\alpha(x))\cdot(y-x)\le o(|y-x|) \tag{4.52}$$

for all y sufficiently close to x. Substituting $y=x+h(\zeta-\zeta_\alpha(x))$ in (4.52) and letting h tend to 0, we arrive at $\zeta=\zeta_\alpha(x)$. □

Now we are ready to prove the main lemma of the section.

Proof of Lemma 4.19. For every $x\in\mathcal{O}$ find an $r_x>0$ small enough so that $\bar{B}_{r_x}(x)\subset\mathcal{O}$. Then the collection of open balls $\{B_{r_x}(x),\, x\in\mathcal{O}\}$ forms an open covering of $\mathcal{O}$. By paracompactness of $\mathcal{O}$ we can find a locally finite refinement $\{B_i, i\in\mathbb{N}\}$ of $\{B_{r_x}(x),\, x\in\mathcal{O}\}$ (cf. [6, Lemma 4.1]). Moreover, since $\cup_{x\in\mathcal{O}}B_{r_x}=\mathcal{O}$, we also have $\cup_i B_i=\mathcal{O}$. Let $\{\varphi_i, i\in\mathbb{N}\}$ be a partition of unity, subordinate to $\{B_i\}$. For each index i, let

$$\mathcal{J}_i=\{j\in\mathbb{N}\,:\,B_i\cap B_j\ne\emptyset\}\,.$$

Notice that $\mathcal{J}_i$ is finite for all i, because of local finiteness of the covering $\{B_i\}$. For every $i\in\mathbb{N}$ define

$$M_i:=\sup|\nabla\varphi_i(x)||f(x,d)|,$$

where the supremum is taken over all $x\in\cup_{j\in\mathcal{J}_i}\bar{B}_j$ and all $d\in\Omega$; and

$$N_i=\max_{j\in\mathcal{J}_i}\operatorname{card}(\mathcal{J}_j),$$

that is, N_i denotes the maximum cardinality of $\mathcal{J}_j$ for j such that B_j intersects B_i. Next, for each compact $K=\bar{B}_i$, $i\in\mathbb{N}$, choose an α_i as in the formulation of Lemma 4.20, satisfying the following two additional conditions:

$$N_i\,\omega_{K_{\alpha_i}}\left(\alpha_i\sqrt{2\beta(\bar{B}_i)}\right)M_i<\frac{1}{2}\inf_{x\in\bar{B}_i}\Upsilon_2(x) \tag{4.53}$$

and

$$\omega_{K_{\alpha_i}}\left(\alpha_i\sqrt{2\beta(\bar{B}_i)}\right)<\frac{1}{2}\inf_{x\in\bar{B}_i}\Upsilon_1(x) \tag{4.54}$$

(where K_{α_i} denotes $B_{\alpha_i\sqrt{2\beta(\bar{B}_i)}}(\bar{B}_i)$).

Next, for each $i \in \mathbb{N}$, define V_{α_i} on $\bar{B}_i$ as in (4.46) (this can be done, because, by the choice of α_i, $K_{\alpha_i} \subseteq \mathcal{O}$). Since V_{α_i} is locally Lipschitz, it is differentiable almost everywhere by Rademacher's theorem. Lemma 4.20 implies that for almost all $x \in \bar{B}_i$ and all $d \in \Omega$

$$L_{f_d} V_{\alpha_i}(x) \leq \Theta(x,d) + \Upsilon_2(x)/2.$$

Define

$$\widetilde{V} := \sum_{i=1}^{+\infty} V_{\alpha_i} \varphi_i.$$

Strictly speaking, this does not make sense, because V_{α_i} is not defined outside $\bar{B}_i$, but that does not matter because φ_i vanishes outside B_i anyway.

Since each $V_{\alpha_i}(x) \leq V(x)$ for all $x \in B_i$ and φ_i's add up to 1, the definition of $\widetilde{V}$ shows that $\widetilde{V}(x) \leq V(x)$ for all $x \in \mathcal{O}$. It is also clear from the definition of $\widetilde{V}$ that $\widetilde{V}$ is locally Lipschitz on $\mathcal{O}$.

We claim that for almost all $x \in \mathcal{O}$ and all $d \in \Omega$ the following hold:

1. $0 \leq V(x) - \widetilde{V}(x) \leq \Upsilon_1(x)$;
2. $\nabla \widetilde{V}(x) \cdot f(x,d) \leq \Theta(x,d) + \Upsilon_2(x)$.

Take any $x \in \mathcal{O}$ and find $i \in \mathbb{N}$ such that $x \in B_i$. Define also $\mathcal{J}_x := \{j \in \mathbb{N} : x \in B_j\}$. Note that $\mathcal{J}_x \subseteq \mathcal{J}_i$ and that $\widetilde{V}(x) := \sum_{j \in J_x} V_{\alpha_j}(x)\varphi_j(x)$. Then Claim 3 and the choice of α_j (condition (4.54)) imply

$$V(x) - V_{\alpha_j}(x) \leq \omega_{K_{\alpha_j}} \left(\alpha_j \sqrt{2\beta(\bar{B}_j)} \right) \leq \Upsilon_1(x)/2$$

for all $j \in \mathcal{J}_x$. Thus,

$$\begin{aligned} V(x) - \widetilde{V}(x) &= V(x) - \sum_{j=1}^{+\infty} V_{\alpha_j} \varphi_j \\ &= V(x) - \sum_{j \in \mathcal{J}_i} V_{\alpha_j} \varphi_j \\ &\leq V(x) - \min_{j \in \mathcal{J}_x} \left\{ V_{\alpha_j}(x) \right\} \left(\sum_{j \in \mathcal{J}_x} \varphi_j(x) \right) \\ &= V(x) - \min_{j \in \mathcal{J}_x} \left\{ V_{\alpha_j}(x) \right\} \\ &\leq \frac{\Upsilon_1(x)}{2}, \end{aligned}$$

proving the first statement.

To prove the second statement, write

$$\begin{aligned} L_{f_d} \widetilde{V}(x) &= \sum_{j \in \mathcal{J}_x} L_{f_d} V_{\alpha_j}(x) \, \varphi_j(x) + \sum_{j \in \mathcal{J}_x} V_{\alpha_j}(x) \, L_{f_d} \varphi_j(x) \\ &= \sum_{j \in \mathcal{J}_x} L_{f_d} V_{\alpha_j}(x) \, \varphi_j(x) + \sum_{j \in \mathcal{J}_x} V_{\alpha_j}(x) \, L_{f_d} \varphi_j(x) - V(x) \sum_{j \in \mathcal{J}_x} L_{f_d} \varphi_j(x) \qquad (4.55) \\ &\leq \max_{j \in \mathcal{J}_x} L_{f_d} V_{\alpha_j}(x) \sum_{j \in \mathcal{J}_x} \varphi_j(x) + \sum_{j \in \mathcal{J}_x} \left(V_{\alpha_j}(x) - V(x) \right) \, L_{f_d} \varphi_j(x) \end{aligned}$$

$$\le \Theta(x,d) + \Upsilon_2(x)/2 + \sum_{j\in\mathcal{J}_i} \left|V_{\alpha_j}(x) - V(x)\right| |L_{f_d}\varphi_j(x)|$$

$$\le \Theta(x,d) + \Upsilon_2(x)/2 + \sum_{j\in\mathcal{J}_i} M_j \omega_{K_{\alpha_j}}\left(\alpha_j\sqrt{2\beta(\bar{B}_j)}\right) \tag{4.56}$$

$$\le \Theta(x,d) + \Upsilon_2(x)/2 + \sum_{j\in\mathcal{J}_i} \frac{\Upsilon_2(x)}{2N_j} \tag{4.57}$$

$$\le \Theta(x,d) + \Upsilon_2(x)/2 + \Upsilon_2(x)/2 \tag{4.58}$$

$$\le \Theta(x,d) + \Upsilon_2(x),$$

where the equality (4.55) follows from the fact that $\sum_{j\in\mathcal{J}_x} L_{f_d}\varphi_j(x) = 0$, inequality (4.56) follows from Lemma 4.20 and Claim 3; inequality (4.57) follows from the choice of α_i (condition (4.53)); and (4.58) is implied by the fact that

$$\operatorname{card}\mathcal{J}_i \le N_j \quad \forall j \in \mathcal{J}_i.$$

This completes the proof of the lemma. □

The lemma we have just proved will provide the "continuous ⇒ locally Lipschitz away from zero" step in the smoothing process. To obtain a smooth Lyapunov function, we will use the following simple smoothing result. The proof is given, for the special case when α does not depend on d, in [25], but the general case (α depends on d) is proved in exactly the same manner, so we omit the proof here.

Lemma 4.21. *Let $\mathcal{O}$ be an open subset of $\mathbf{R}^n$, and let Ω be a compact subset of $\mathbf{R}^l$, and assume the following as given:*

- *a locally Lipschitz function $\Phi : \mathcal{O} \to \mathbf{R}$;*
- *a continuous map $f : \mathbf{R}^n \times \Omega \to \mathbf{R}^n$, $(x, d) \mapsto f(x, d)$ which is locally Lipschitz on x uniformly on d;*
- *a continuous function $\alpha : \mathcal{O} \times \Omega \to \mathbf{R}$ and continuous functions $\mu, \nu : \mathcal{O} \to \mathbf{R}_{>0}$*

such that for each $d \in \Omega$,

$$L_{f_d}\Phi(\xi) \le \alpha(\xi, d) \quad \textit{almost everywhere } \xi \in \mathcal{O}, \tag{4.59}$$

where f_d is the vector field defined by $f_d = f(\cdot, d)$ (recall that $\nabla\Phi$ is defined almost everywhere, since Φ is locally Lipschitz by Rademacher's theorem). Then there exists a smooth function $\Psi : \mathcal{O} \to \mathbf{R}$ such that

$$|\Phi(\xi) - \Psi(\xi)| < \mu(\xi) \quad \forall \xi \in \mathcal{O}$$

and for each $d \in \Omega$,

$$L_{f_d}\Psi(\xi) \le \alpha(\xi, d) + \nu(\xi) \quad \forall \xi \in \mathcal{O}.$$

The next result immediately follows by Lemma 4.21.

Corollary 4.22. *Under the assumptions of Lemma 4.19 there also exists a smooth function $\hat{V}$ on $\mathcal{O}$, satisfying inequalities*

$$\left|V(x) - \hat{V}(x)\right| \le \Upsilon_1(x) \ \forall x \in \mathcal{O} \tag{4.60}$$

and

$$L_{f_d}\hat{V}(x) \le \Theta(x,d) + \Upsilon_2(x) \quad \forall d \in \Omega, \ \forall x \in \mathcal{O}. \tag{4.61}$$

Proof. Suppose that $\mathcal{O}$, V, Υ_1, Υ_2 are given and the assumptions of Lemma 4.19 hold. Replacing Υ_1 by $\Upsilon_1/2$ and Υ_2 by $\Upsilon_2/2$, and applying Lemma 4.19, we can find a locally Lipschitz function $\widetilde{V}$, defined on $\mathcal{O}$ and satisfying (4.41) and (4.61) with $\Upsilon_1/2$ and $\Upsilon_2/2$ instead of Υ_1 and Υ_2. Next, Lemma 4.21, applied with the same $\mathcal{O}$ and with $\Phi := \widetilde{V}$, $\alpha := \Theta + \Upsilon_2/2$, $\mu := \Upsilon_1/2$, and $\nu := \Upsilon_2/4$, furnishes a smooth function $\hat{V} := \Psi$ as needed. □

In section 4.3 we have constructed a function V_0, satisfying inequalities (4.33) on $\mathcal{E}_1$ and (4.35) along all trajectories of Σ, contained in $\mathcal{E}_1$. Therefore, by Lemma 4.18, the proximal inequality (4.39) holds for V_0 at any interior point of $\mathcal{E}_1$. Then Corollary 4.22, applied with $\mathcal{O} := \text{int } \mathcal{E}_1$, $\Upsilon_1(\cdot) := \underline{\alpha}(|\cdot|)/2$, $\Upsilon_2(\cdot) := \Xi(|\cdot|)/2$, $\Theta(x,d) := \Xi(|x|)$, provides a smooth function

$$V_1 : \text{int } \mathcal{E}_1 \to \mathbf{R}_{>0}; \quad V_1 := \hat{V}_0,$$

satisfying the following two conditions for all $\xi \in \text{int } \mathcal{E}_1$:

$$\underline{\alpha}(|\xi|)/2 \le V_1(\xi) \le \bar{\alpha}(|\xi|) + \underline{\alpha}(|\xi|)/2$$

(we will replace $\underline{\alpha}(|\cdot|)/2$ by $\underline{\alpha}(\cdot)$ and $\bar{\alpha}(|\cdot|) + \underline{\alpha}(|\cdot|)/2$ by $\bar{\alpha}(|\cdot|)$ from now on to avoid cluttering the notation),

$$L_{f_d} V_1(\xi) \le -\Xi_1(|\xi|) \quad \forall d \in \Omega, \tag{4.62}$$

where $\Xi_1(\cdot) \equiv \Xi(\cdot)/2$.

4.6. Extending to the rest of X and smoothing at the origin. To construct a UOSS-Lyapunov-like function defined on the whole $\mathbf{X}$, we must "patch" V_1 with some smooth, proper, and positive definite function such that the dissipation inequality still holds.

LEMMA 4.23. *Suppose Σ is a system of type* (2.14), *and ρ is a function of class $\mathcal{K}_\infty$. Define $\mathcal{E}_1 := \{x \in \mathbf{X} : |x| > 2\rho(|h(x)|)\}$ and suppose that $V_1 : \mathcal{E}_1 \to \mathbf{R}_{\ge 0}$ is a smooth function satisfying, with some suitable $\mathcal{K}_\infty$ functions, the inequality*

$$\underline{\alpha}(|\xi|) \le V_1(\xi) \le \bar{\alpha}(|\xi|) \tag{4.63}$$

and inequality (4.62) *on $\mathcal{E}_1$. Then there exist a Lyapunov-like function V_2 for Σ, smooth away from the origin, and a class $\mathcal{K}_\infty$ function Φ, such that*

$$V_2(x) = \Phi \circ V_1(x) \quad \forall\, x \text{ such that } |x| > 3\rho(|h(x)|),$$

and the following dissipation inequality holds with some $\check{\alpha}_3 \in \mathcal{K}_\infty$, $\check{\gamma} \in \mathcal{K}$:

$$\nabla V_2(\xi) \cdot f(\xi, d) \le -\check{\alpha}_3(|\xi|) + \check{\gamma}(|h(\xi)|) \qquad \forall \xi \ne 0, \quad \forall d \in \Omega. \tag{4.64}$$

Proof. Let

$$\mathcal{E}_2 := \{\xi : |\xi| > 3\rho(|h(\xi)|)\}.$$

Since the sets $\{\xi : |\xi| \ge 3\rho(|h(\xi)|)\}$ and $\{\xi : |\xi| \le 2\rho(|h(\xi)|)\}$ are disjoint and closed in the topology of $\mathbf{X} \setminus \{0\}$, one can find a smooth function $\phi : \mathbf{X} \setminus \{0\} \to [0,1]$ with the property that

$$\phi(\xi) = \begin{cases} 1 & \text{if } |\xi| \ge 3\rho(|h(\xi)|), \\ 0 & \text{if } |\xi| \le 2\rho(|h(\xi)|) \end{cases}$$

and ϕ is nonzero elsewhere. It is easy to see that $|\nabla\phi(x)|$ is bounded above by a $\mathcal{K}$-function ν_2 of $|x|$ outside the unit ball centered at 0. One can also find a smooth, strictly increasing function $\nu_1 : [0,1] \to \mathbf{R}_{\geq 0}$, such that $\nu_1(0) = 0$ and $|\nabla\phi(x)| \leq \frac{1}{\nu_1(|x|)}$ for all x such that $0 < |x| \leq 1$.

Let ν_3 be a $\mathcal{K}$-function such that $\max_{d\in\Omega} |f(\xi,d)| \leq \nu_3(|\xi|)$. Take any smooth function $\pi_1 \colon [0,\bar{\alpha}(1)] \to \mathbf{R}_{\geq 0}$ with $\pi_1'(s) > 0$ for all $s \in (0,\bar{\alpha}(1))$, such that

$$\frac{\pi_1(\bar{\alpha}(r))}{\nu_1(r)} < s(r), \quad \frac{\pi_1(r^2)}{\nu_1(r)} < s(r)$$

for some $\mathcal{K}$-function s and all $0 < r \leq 1$. Let π_2 be any $\mathcal{K}$-function such that $\pi_2(r) \leq \pi_1'(r)$ for all nonnegative $r \leq 1$.

Let $\Phi(r) = \int_0^r \pi_2(r_1)dr_1$. Then $\Phi(r) \leq \pi_1(r)$ for all $r \leq 1$, so that $\frac{\Phi(\bar{\alpha}(r))}{\nu_1(r)} < s(r)$ and $\frac{\Phi(r^2)}{\nu_1(r)} < s(r)$ for all $r \in (0,1]$.

Now let

$$V_2(\xi) = \phi(\xi)\Phi(V_1(\xi)) + (1-\phi(\xi))\Phi(|\xi|^2). \tag{4.65}$$

If $|\xi| > 3\rho(|h(\xi)|)$, then $V_2 \equiv \Phi\circ V_1$ in a neighborhood of ξ, so that, for all $d \in \Omega$,

$$\nabla V_2(\xi)\cdot f(\xi,d) = \Phi'(V_1(\xi))[\nabla V_1(\xi)\cdot f(\xi,d)] \leq -\pi_2(\underline{\alpha}(|\xi|))\Xi_1(|\xi|). \tag{4.66}$$

On the other hand, if $|\xi| \leq 3\rho(|h(\xi)|)$, then

$$\begin{aligned}\nabla V_2(\xi)\cdot f(\xi,d) = {} & [\nabla\phi(\xi)\cdot f(\xi,d)]\,\Phi(V_1(\xi)) + \phi(\xi)\,\Phi'(V_1(\xi))\,[\nabla V_1(\xi)\cdot f(\xi,d)] \\ & -[\nabla\phi(\xi)\cdot f(\xi,d)]\,\Phi(|\xi|^2) + (1-\phi(\xi))\,2\Phi'(|\xi|^2)\,[\xi\cdot f(\xi,d)] \\ \leq {} & |\nabla\phi(\xi)|\,|f(\xi,d)|\;\Phi(V_1(\xi)) + |\nabla\phi(\xi)|\,|f(\xi,d)|\;\Phi(|\xi|^2) \\ & + 2\,|(1-\phi(\xi))|\;\Phi'(|\xi|^2)\;|\xi|\,|f(\xi,d)| \\ \leq {} & |\nabla\phi(\xi)|\,|f(\xi,d)|\;\Phi(\bar{\alpha}(|\xi|)) + |\nabla\phi(\xi)|\,|f(\xi,d)|\;\Phi(|\xi|^2) \\ & +2\Phi'(|\xi|^2)\;|\xi|\,|f(\xi,d)|\,,\end{aligned}$$

where the first inequality follows from the fact that $\phi(\xi)\,\Phi'(V_1(\xi))\,[\nabla V_1(\xi)\cdot f(\xi,d)] \leq 0$. Next, the definition of Φ provides the following bounds for the three terms in the right-hand side of the last inequality:

$$\Phi(\bar{\alpha}(|\xi|))\,|\nabla\phi(\xi)|\,|f(\xi,d)| \leq \max\{s(|\xi|), \Phi(\bar{\alpha}(|\xi|))\nu_2(|\xi|)\}\,\nu_3(|\xi|),$$

$$2\Phi'(|\xi|^2)[|\xi|\,|f(\xi,d)|] \leq 2\pi_2(|\xi|^2)\,|\xi|\,\nu_3(|\xi|),$$

$$\Phi(|\xi|^2)\,|\nabla\phi(\xi)|\,|f(\xi,d)| \leq \max\left\{s(|\xi|), \Phi(|\xi|^2)\nu_2(|\xi|)\right\}\nu_3(|\xi|).$$

Define $\breve{\alpha}_3$, $\breve{\gamma}$, $\breve{\alpha}_1$, and $\breve{\alpha}_2$ by

$$\breve{\alpha}_3(r) := \pi_2(\underline{\alpha}(r))\Xi_1(r),$$

$$\begin{aligned}\breve{\gamma}(r) := {} & 2\pi_2((3\rho(r))^2)3\rho(r)\nu_3(3\rho(r)) \\ & + \max\left\{s(3\rho(r)), \Phi((3\rho(r))^2)\nu_2(3\rho(r))\right\}\nu_3(3\rho(r)) + \breve{\alpha}_3(3\rho(r)),\end{aligned}$$

$$\check{\alpha}_1(r) = \min\left\{\Phi(r^2), \Phi \circ \underline{\alpha}(r)\right\},$$

and

$$\check{\alpha}_2(r) = \max\left\{\Phi(r^2), \Phi \circ \bar{\alpha}(r)\right\}.$$

Then inequalities

$$\check{\alpha}_1(|x|) \le V_2(x) \le \check{\alpha}_2(|x|) \quad \forall\, x \neq 0 \tag{4.67}$$

and (4.64) hold for V_2. Define $V_2(0) := 0$. Then inequality (2.3) holds for V_2 with $\alpha_1 := \check{\alpha}_1$, $\alpha_2 := \check{\alpha}_2$ on $\mathbf{X}$, and in particular implies that V_2 is continuous as 0. Then, V_2 is a UOSS-Lyapunov-like function for Σ, smooth away from the origin. □

Recall that $V_2(\xi) \equiv \Phi(V_1(\xi))$ for all ξ with $|\xi| > 3\rho(|h(\xi)|)$. Therefore inequality (4.62) implies that

$$\nabla V_2 \cdot f(\xi, d) \le -\alpha_3(|\xi|)\ \forall\, |\xi| > 3\rho(|h(\xi)|),\ \forall d \in \Omega. \tag{4.68}$$

Proposition 4.24. *Suppose that a system Σ of type* (2.14) *admits a continuous UOSS-Lyapunov-like function V_2, smooth away from* 0 *and satisfying inequalities* (4.67), (4.64)*, and* (4.68)*. Then Σ admits a UOSS-Lyapunov function.*

The basic idea used to obtain a Lyapunov function, smooth on the whole $\mathbf{X}$, is composing V_2 with some appropriately chosen $\mathcal{K}_\infty$-function β. This technique was previously utilized in [25]. We will need the following generalization of Lemma 4.3 from [25], where this function β is constructed. In our setting we also need the derivative of β to be of class $\mathcal{K}_\infty$, which was not required in [25]. The proof is only a slight modification of the proof of the mentioned lemma.

Lemma 4.25. *Assume that $V : \mathbf{R}^n \longrightarrow \mathbf{R}_{\ge 0}$ is C^0, positive definite, and the restriction $V|_{\mathbf{R}^n\setminus\{0\}}$ is C^∞.*

Then, given any $m \in \mathbb{N}$ there exists a $\mathcal{K}_\infty$-function β_m, smooth on $(0,\infty)$, satisfying the following conditions:

- *$\beta_m^{(i)}(t) \to 0$ as $t \to 0^+$ for each $i = 0, 1, \ldots$,*
- *$\beta_m^{(i)} \in \mathcal{K}_\infty\ \forall i \le m$,*
- *$W_m := \beta \circ V$ is a C^∞ function on all of $\mathbf{R}^n$.*

We now return to the proof of Proposition 4.24.

Proof. Take the function V_2, and apply Lemma 4.25 to get a function β_1, with derivative in class $\mathcal{K}$, such that

$$V_3 := \beta_1 \circ V_2$$

is smooth on $\mathbf{X}$. Let $\alpha_1(\cdot) := \beta_1(\check{\alpha}_1(\cdot)/2)$, $\alpha_2(\cdot) := \beta_1(\check{\alpha}_2(\cdot) + \check{\alpha}_1(\cdot)/2)$. Then $\alpha_i \in \mathcal{K}_\infty$ and

$$\alpha_1(|x|) \le V_3(x) \le \alpha_2(|x|).$$

Furthermore, for any $x \in \mathbf{X} \setminus \{0\}$ we have

$$\begin{aligned} L_{f_d} V_3(x) &= \beta_1'(V_2(x))\,[L_{f_d} V_2]\,(x) \\ &\le \beta_1'(V_2(x))\,(-\alpha_3(|x|)/2 + \check{\gamma}(|h(x)|)) \\ &\le -\beta_1'(\check{\alpha}_1(|x|)/2)\check{\alpha}_3(|x|)/2 + \beta_1'(\check{\alpha}_2(|x|) + \check{\alpha}_1(|x|)/2)\check{\gamma}(|h(x)|). \end{aligned}$$

Recall that, because of (4.68), the $\check{\gamma}$ term in the last estimate can be dropped if $|x| > 3\rho(|h(x)|)$, so that we can write

$$L_{f_d} V_3(x) \leq -\beta_1'(\check{\alpha}_1(|x|)/2)\check{\alpha}_3(|x|)/2 + \beta_1'(\check{\alpha}_2(3\rho(|h(x)|)) + \check{\alpha}_1(3\rho(|h(x)|))/2)\check{\gamma}(|h(x)|).$$

Thus V_3 is a smooth UOSS-Lyapunov function, satisfying the dissipation inequality with

$$\alpha_3(\cdot) := \beta_1'(\check{\alpha}_1(\cdot)/2)\,\check{\alpha}_3(\cdot)/2$$

and

$$\gamma(\cdot) := \beta_1'(\check{\alpha}_2(3\rho(\cdot)) + \check{\alpha}_1(3\rho(\cdot))/2)\,\check{\gamma}(\cdot).$$

This completes the construction. □

5. Norm-observers.

As conjectured in [45] and proved in this presentation, every IOSS system admits an IOSS-Lyapunov function. One of the main motivations for the notion of IOSS, and for deriving Lyapunov characterizations, is the fact that a Lyapunov function enables us to get insights into the behavior of control systems. In particular, it may be useful to have an estimate of how far the system is from the equilibrium at any given time, and in some situations this "norm-estimate" is sufficient for the design of a stabilizer. We next provide a construction for a norm-observer in the most general case—for systems of type (2.1), assuming that we have a smooth UIOSS-Lyapunov function at our disposal.

5.1. Exponential decay Lyapunov functions.

DEFINITION 5.1. *Let Σ be a system of type* (2.1). *A C^1-function $V : \mathbf{X} \to \mathbf{R}_{\geq 0}$ is an* exponential decay UIOSS-Lyapunov function *for Σ if it satisfies* (2.3) *with some α_1 and α_2, and the following version of inequality* (2.4)*:*

$$\text{(5.1)}\quad \nabla V(x) \cdot f(x,u,w) \leq -V(x) + \sigma_1(|u|) + \sigma_2(|h(x)|) \quad \forall x \in \mathbf{X},\ u \in \mathbb{U},\ w \in \Gamma$$

holds with some σ_1 and $\sigma_2 \in \mathcal{K}$.

LEMMA 5.2. *Suppose V is a UIOSS-Lyapunov function for a system Σ of type* (2.1), *satisfying inequality* (2.4). *Then there exists a $\mathcal{K}_\infty$-function ρ such that a function $W := \rho \circ V$ is an exponential decay UIOSS-Lyapunov function for Σ.*

Proof. Assume that system (2.1) admits a UIOSS-Lyapunov function with α_i ($i = 1, 2$) as in (2.3) and with $\alpha, \sigma_1, \sigma_2$ as in (2.4). Replacing α by $\alpha \circ \alpha_2^{-1}$, we have

$$\text{(5.2)}\qquad \frac{d}{dt}V(x(t,\xi,\mathbf{u})) \;\leq\; -\alpha(V(x(t,\xi,\mathbf{u}))) + \sigma_1(|\mathbf{u}(t)|) + \sigma_2(|y(t,\xi,\mathbf{u})|)$$

for almost all $t \in [0,\ t_{\max}(\xi, u))$. According to Lemma 12 in [32], there exists some function $\rho \in \mathcal{K}_\infty$ which can be extended as a C^1-function to a neighborhood of $[0, \infty)$ such that $\rho'(r)\frac{\alpha(r)}{2} \geq \rho(r)$ for all $r \geq 0$. Consider the function $W(\xi) := \rho(V(\xi))$. Observe that W is again proper and positive definite. Along any trajectory $x(t) := x(t,\xi,\mathbf{u})$ (with $y(t) := y(t,\xi,\mathbf{u})$), at any point where (2.4) holds, one has that $\frac{d}{dt}W(x(t)) = \rho'(V(x(t)))\frac{d}{dt}V(x(t))$ is upper bounded by

$$-\rho'(V(x(t)))\frac{\alpha(V(x(t)))}{2} + \rho'(V(x(t)))\left(-\frac{\alpha(V(x(t)))}{2} + \sigma_1(|\mathbf{u}(t)|) + \sigma_2(|y(t)|)\right),$$

which in turn is bounded by

$$-\rho(V(x(t)) + \rho'(V(x(t)))\left(-\frac{\alpha(V(x(t)))}{2} + \sigma_1(|\mathbf{u}(t)|) + \sigma_2(|y(t)|)\right). \tag{5.3}$$

Observe that when $V(x(t)) \geq \alpha^{-1}(2\sigma_1(|\mathbf{u}(t)|) + 2\sigma_2(|y(t)|))$ it holds that

$$\rho'(V(x(t)))\left(-\frac{\alpha(V(x(t)))}{2} + \sigma_1(|\mathbf{u}(t)|) + \sigma_2(|y(t)|)\right) \leq 0, \tag{5.4}$$

while if instead $V(x(t)) \leq \alpha^{-1}(2\sigma_1(|\mathbf{u}(t)|) + 2\sigma_2(|y(t)|))$, then

$$\rho'(V(x(t)))\,(\sigma_1(|\mathbf{u}(t)|) + \sigma_2(|y(t)|)) \;\leq\; \hat{\sigma_1}(|\mathbf{u}(t)|) + \hat{\sigma_2}(|y(t)|) \tag{5.5}$$

for some $\mathcal{K}_\infty$-functions $\hat{\sigma_1}$ and $\hat{\sigma_2}$ (using here the fact that $\rho'(s)$ is a continuous function). Combining (5.4) and (5.5), one concludes from the estimate (5.3) on $\frac{d}{dt}W(x(t))$ that

$$\frac{d}{dt}W(x(t)) \;\leq\; -W(x(t)) + \hat{\sigma_1}(|\mathbf{u}(t)|) + \hat{\sigma_2}(|y(t)|)$$

for almost all $t \in [0, t_{\max})$. □

5.2. Construction of a norm-observer.

PROPOSITION 5.3. *Suppose that a system Σ admits an exponential decay UIOSS-Lyapunov function V. Then the pair $(\Sigma_{n.o}, k)$, where*

$$\Sigma_{n.o}: \quad \dot{p} = -p + \sigma_1(|u|) + \sigma_2(|y|), \tag{5.6}$$

with σ_1 and σ_2 as in (5.1) *and $k(\cdot,\cdot)$ defined by $k(s,r) = s$, is a norm-estimator for Σ.*

Proof. Assume without loss of generality that the function α_2 in the definition of V satisfies $r \leq \alpha_2(r)$ for all nonnegative r.

The system (5.6) is ISS with respect to u and y, since it can be seen as an asymptotically stable linear system driven by the input $(\sigma_1(|u|), \sigma_2(|y|))$, so, inequality (2.7) obviously holds. Pick any initial states ξ, ζ of Σ and (5.6), respectively, any control $\mathbf{u}$, and any disturbance $\mathbf{w}$. Consider the resulting trajectory $(x(t), p(t))$ of the composite system. Property (5.1) implies that

$$\frac{d}{dt}(V(x(t)) - p(t)) \leq -(V(x(t)) - p(t)) \tag{5.7}$$

for almost all $t \in [0, t_{\max}(\xi, \mathbf{u}, \mathbf{w}))$. Thus

$$V(x(t)) \;\leq\; p(t) + e^{-t}(V(\xi) - \zeta) \;\leq\; |p(t)| + 2e^{-t}\alpha_2(|\xi| + |\zeta|)$$

(using $r \leq \alpha_2(r)$). This can be written as (2.8) with $\rho := \alpha_1^{-1}(2(\cdot))$ and $\beta(s,t) := \alpha_1^{-1}(4e^{-t}\alpha_2(s))$. □

Implication 2 ⇒ 3 of Theorem 2.4 now follows from Lemma 5.2 and Proposition 5.3.

We now turn to the proof of implication 3 ⇒ 1 of Theorem 2.4.

Proof. Assume that $(\Sigma_{n.o}, k)$ is some norm-estimator for Σ. Choose any initial state ξ for Σ, any input $\mathbf{u}$, disturbance $\mathbf{w}$, and the special initial state $\zeta = 0$ for $\Sigma_{n.o}$. Then inequality (2.7) becomes

$$|k(p(t, 0, \mathbf{u}, \mathbf{y}_{\xi,\mathbf{u},\mathbf{w}}), y(t, \xi, \mathbf{u}, \mathbf{w}))| \;\leq\; \hat{\gamma}_1\left(\left\|\mathbf{u}|_{[0,t]}\right\|\right) + \hat{\gamma}_2\left(\left\|\mathbf{y}_{\xi,\mathbf{u},\mathbf{w}}|_{[0,t]}\right\|\right) \tag{5.8}$$

for all $t \in [0, t_{\max})$, with some class-$\mathcal{K}$ functions $\hat{\gamma}_1$ and $\hat{\gamma}_2$ (the $\mathcal{KL}$-term vanishes because $\zeta = 0$). Then, combining (5.8) with the estimate (2.8) we get

$$\begin{aligned} |x(t,\xi,\mathbf{u},\mathbf{w})| &\le \beta(|\xi|,t) + \rho(|k(p(t,0,\mathbf{u},\mathbf{y}_{\xi,\mathbf{u},\mathbf{w}}), y(t,\xi,\mathbf{u},\mathbf{w}))|) \\ &\le \max\left\{2\beta(|\xi|,t),\, 4\rho(\hat{\gamma}_1(\left\|\mathbf{u}|_{[0,t]}\right\|)),\, 4\rho(\hat{\gamma}_1(\left\|y_{\xi,\mathbf{u},\mathbf{w}}|_{[0,t]}\right\|))\right\}. \end{aligned}$$

This proves the UIOSS property for Σ. □

6. Pointers for future research.

6.1. Integral variants of UIOSS. The UIOSS property gives uniform estimates of the states in terms of the uniform bounds on outputs and essential bounds on controls. A natural question to ask is what property will result if instead of the uniform (or essential) bounds we use other "finite energy" concepts, such as, for example, L^γ-type norms (defined by $\left\|g|_{[\sigma,\tau]}\right\|_\gamma = \int_\sigma^\tau \gamma(|g(t)|)dt$) of inputs and/or outputs, where the "γ's" for inputs and outputs are some appropriately chosen functions of class $\mathcal{K}_\infty$, which depend on the system. For systems without controls, the iiUOSS property provides a "finite energy outputs ⇒ finite energy state" characterization, which is "almost" equivalent to UOSS (see Theorem 2.16). Searching for the *uniform* estimate of the states in terms of L^γ-norms of inputs and outputs leads to the following definition.

DEFINITION 6.1. *A system of type* (2.1) *is* uniformly integral input-output-to-state stable *(UiIOSS) if there exist functions $\alpha_x \in \mathcal{K}_\infty$, $\beta \in \mathcal{KL}$, γ_1, and $\gamma_2 \in \mathcal{K}$ such that*

$$\alpha_x\left(|x(t,\xi,\mathbf{w},\mathbf{u})|\right) \le \beta(|\xi|,t) + \int_0^t \left(\gamma_1(|\mathbf{u}(s)|) + \gamma_2\left(|y(s,\xi,\mathbf{w},\mathbf{u})|\right)\right) ds \tag{6.1}$$

for all $\xi \in \mathbf{X}$, all $\mathbf{w}$ and $\mathbf{u}$, and all $t \in [0, t_{\max}(\xi,\mathbf{u},\mathbf{w}))$.

This general definition may be adjusted in obvious manners to all the particular cases of system (2.1).

Remark 6.1. It is easy to see that estimate (6.1) is equivalent to the following estimate (with different bounding functions, of course):

$$\begin{aligned} |x(t,\xi,\mathbf{w},\mathbf{u})| \le \max\Bigg\{&\beta(|\xi|,t),\, \gamma\left(\int_0^t (\gamma_1(|\mathbf{u}(s)|))ds\right), \\ &\gamma\left(\int_0^t \gamma_2(|y(s,\xi,\mathbf{w},\mathbf{u})|)ds\right)\Bigg\}, \end{aligned} \tag{6.2}$$

In the particular case of systems without outputs and disturbances, a Lyapunov characterization of the UiIOSS property, reduced to integral input-to-state stability (iISS), was obtained in [4]. By repeating the proof of the implication 1 ⇒ 2 of Theorem 1 in [4] one can show that a system of type (2.1) will be UiIOSS if it admits a smooth, proper Lyapunov function $V : \mathbf{X} \to R_{\ge 0}$, satisfying inequality (2.4) with some σ_1 and σ_2 of class $\mathcal{K}$, and a *positive definite* function α. Whether or not this sufficient condition is also necessary for UiIOSS is not known. Notice, however, that this condition is weaker than the corresponding property for UIOSS, as the dissipation condition for a UIOSS-Lyapunov function requires α to be of class $\mathcal{K}_\infty$. Thus, any UIOSS system will also be UiIOSS. The converse implication is not true, as demonstrated in the following example.

Example 6.2. The construction is similar to the one used in Remark 3.1, so, we recall that $\phi_\varepsilon(\cdot)$ denotes a C^∞-bump function as in (3.12), and $1_A(\cdot)$ is the indicator function of a set A.

Choose $\varepsilon_f = 0.1$ and any $\varepsilon_h < (1-\varepsilon_f)e^{-1}$, and consider the autonomous system

$$\Sigma_1 : \quad \dot{x} = f(x); \quad y = h(x)$$

with

$$f_1(x) = x\left[1_{(-\infty,-1]}(x)(1-\phi_{\varepsilon_f}(x+1)) + 1_{[1,+\infty)}(x)(1-\phi_{\varepsilon_f}(x-1))\right] \\ -x\left[1_{(-1,1)}(x)(1-\phi_{\varepsilon_f}(x+1))(1-\phi_{\varepsilon_f}(x-1))\right],$$

and

$$h_1(x) = 1 - \phi_{\varepsilon_h}(x)$$

evolving in $\mathbf{X} = \mathbf{R}$. We claim that Σ_1 is iOSS but not OSS.

Consider also an autonomous system Σ_2 on $\mathbf{R}$ with

$$f_2(x) = x; \qquad h_2(x) \equiv 1. \tag{6.3}$$

This system cannot serve as a counterexample, because $h_2(0) \neq 0$. However, its behavior away from 0 is identical to that of Σ_1, so that considering it will simplify the presentation.

Let $x_i(t,\xi)$, $i = 1,2$, denote the solutions of Σ_i, starting at ξ, and let $y_i(t,\xi)$ denote the corresponding output trajectories. It is easy to see that both Σ_1 and Σ_2 are forward complete.

Since the dynamics of Σ_1 and Σ_2 are odd functions and outputs are even (but only the magnitudes of outputs are involved in the estimates), we need only to consider trajectories starting from the positive initial states, as the same estimates will work for trajectories contained in the other half-line.

Since $f_1(x) < f_2(x)$ for all $x \in (0, 1+\varepsilon_f)$ and $f_1(x) = f_2(x)$ for $x \geq 1+\varepsilon_f$, we have, for all $t > 0$, $x_1(t,\xi) < x_2(t,\xi)$ for any $\xi \in (0, 1+\varepsilon_f)$, and $x_1(t,\xi) = x_2(t,\xi) = \xi e^t$ if $|\xi| \geq 1+\varepsilon_f$. In particular, this shows that Σ_1 is not OSS, because the trajectory diverges to $+\infty$, but $h_1(\xi e^t)$ is bounded.

However, observe that when $t \leq |\xi|$,

$$|x_2(t,\xi)| \leq |\xi|\, e^{|\xi|} \leq e^{2|\xi|}\, |\xi|\, e^{-\frac{t}{1+|\xi|}},$$

whereas when $t > |\xi|$, we have

$$|x_2(t,\xi)| \leq te^t.$$

Letting

$$\beta(r,t) := re^{2r-\frac{t}{1+r}}; \quad \gamma_2 := Id; \quad \gamma(t) := te^t,$$

and noticing that

$$\int_0^t \gamma_2(|y_2(s,\xi)|)ds = t,$$

we conclude $x_2(t,\xi)$ satisfies estimate (6.2).

Now observe that

- If $\xi \geq 1$, then $1 \leq x_1(t,\xi) \leq x_2(t,\xi)$ for all $t \geq 0$, so that $y_1(t,\xi) = y_2(t,\xi) = 1$ and $x_1(t,\xi)$ satisfies (6.2).

- If $\xi \in [0, 1 - \varepsilon_f]$, then

$$x_1(t, \xi) = \xi e^{-t} \leq \beta(|\xi|, t).$$

- Finally, if $\xi \in (1 - \varepsilon_f, 1)$, then
  - for all $t \geq 0$ it holds that $|x_1(t, \xi)| < 1$;
  - for all $t \in [0, 1]$ it holds that $|x_1(t, \xi)| > (1 - \varepsilon_f)e^{-1} > \varepsilon_h$, so that $y_1(t, \xi) = 1 = y_2(t, \xi)$.

  Therefore $x_1(t, \xi)$ satisfies (6.2) for all $t \leq 1$ and

$$\int_0^t \gamma_2(|y_2(s, \xi)|)ds \geq 1 \geq x_1(t, \xi) \quad \forall\, t \geq 1.$$

This shows that $x_1(t, \xi)$ satisfies (6.2) for all ξ and $t \geq 0$, thus, Σ_1 is, indeed, iOSS.

It could also be of interest to consider yet another property, providing a uniform estimate for the state in terms of the uniform norm of the output and L^γ-norm of the input.

Definition 6.2. *A system of type* (2.1) *satisfies the U(iI)OSS property if there exist functions $\alpha_x \in \mathcal{K}_\infty$, $\beta \in \mathcal{KL}$, γ_1, and $\gamma_2 \in \mathcal{K}$ such that*

$$\alpha_x\left(|x(t, \xi, \mathbf{w}, \mathbf{u})|\right) \leq \beta(|\xi|, t) + \int_0^t \gamma_1(|\mathbf{u}(s)|)ds + \gamma_2\left(\left\|y_{\xi,\mathbf{w},\mathbf{u}}|_{[0,t]}\right\|\right) \tag{6.4}$$

for all $\xi \in \mathbf{X}$, all $\mathbf{w}$ and $\mathbf{u}$, and all $t \in [0, t_{\max}(\xi, \mathbf{u}, \mathbf{w}))$.

Deriving a Lyapunov characterization for this property may be a challenge. It would be logical to expect that a good candidate for a U(iI)OSS-Lyapunov function can be a proper function $V : \mathbf{X} \to \mathbf{R}_{\geq 0}$, satisfying inequality (2.4) with α being either positive definite or class $\mathcal{K}_\infty$. However, we can see right away that neither of these two possibilities is the right guess. Indeed, notice that both OSS and iISS are particular cases of the U(iI)OSS property. If a U(iI)OSS-Lyapunov function would satisfy (2.4) with α of class $\mathcal{K}_\infty$ (as required by OSS), it would follow that every disturbance-free U(iI)OSS system without outputs is ISS, which is not true (see [4] for an example of an iISS system, which is not ISS). On the other hand, if a U(iI)OSS-Lyapunov function satisfied (2.4) with α positive definite (as required by iISS), it would imply that having such a dissipation function is sufficient for OSS, which is not so, because this would mean that every iOSS system is OSS.

6.2. Incremental IOSS. As mentioned in the introduction, the detectability property for nonlinear systems is not equivalent to zero-detectability. In searching for a correct notion for nonlinear detectability one could think of the following generalization of UIOSS.

Definition 6.3. *A system* (2.1) *is incrementally uniformly input-output to state stable (ΔUIOSS) if there exists some $\beta \in \mathcal{KL}$ and $\gamma_1, \gamma_2 \in \mathcal{K}$ such that, for every two initial states ξ_1 and ξ_2, any two controls $\mathbf{u}_1$ and $\mathbf{u}_2$, and any disturbance $\mathbf{w}$,*

$$\begin{aligned} |x(t, \xi_1, \mathbf{u}_1, \mathbf{w}) - x(t, \xi_2, \mathbf{u}_2, \mathbf{w})| \leq \max\big\{&\beta(|\xi_1 - \xi_2|, t), \\ &\gamma_1\left(\left\|(\mathbf{u}_1 - \mathbf{u}_2)|_{[0,t]}\right\|\right), \gamma_2\left(\left\|(\mathbf{y}_{\xi_1,\mathbf{u}_1,\mathbf{w}} - \mathbf{y}_{\xi_2,\mathbf{u}_2,\mathbf{w}})|_{[0,t]}\right\|\right)\big\} \end{aligned} \tag{6.5}$$

for all t in the common domain of definition.

Deriving a right Lyapunov characterization for this property may lead to a construction of a full-order observer.

RELATIVE FLATNESS AND FLATNESS OF IMPLICIT SYSTEMS*

PAULO SÉRGIO PEREIRA DA SILVA† AND CARLOS CORRÊA FILHO‡

Abstract. In this work we define the concept of *relative flatness* of a system with respect to a subsystem. The subsystem associated to a set of outputs of a system is constructed, and called here *output subsystem.* It is shown that the relative flatness of a system with respect to the output subsystem implies the flatness of the corresponding implicit system obtained by setting these outputs to zero. A sufficient condition of relative flatness based on a *relative derived flag* is presented. Based on these results, a sufficient condition for the flatness of a class of nonlinear implicit systems is obtained.

Key words. nonlinear systems, implicit systems, time-varying systems, flatness, relative flatness, feedback linearization

AMS subject classifications. 93C05, 93B18, 93B29.

1. Introduction and motivation.

The aim of this paper is to present the notion of *relative flatness* with respect to a subsystem. We show that this concept may be useful for control systems theory, in particular for studying the structure of nonlinear implicit systems. Our approach is based on the infinite dimensional geometric setting recently introduced in control theory [17, 40, 19] in combination with the ideas presented in [50, 48, 53]. Our sufficient conditions for flatness of implicit systems may be regarded as a generalization of the conditions obtained in [50] for explicit systems. Our setting has some connections with the ideas of [47], which has considered a different class of implicit systems.

Feedback linearization is an important problem in nonlinear control theory. This problem was completely solved in the static-state feedback case [25, 23] but necessary and sufficient conditions for feedback linearizability by dynamic state feedback are not yet known (see [5, 48, 6, 20, 51, 53, 1, 44, 52, 22, 41, 54]).

The notion of differential flatness was introduced by Fliess et al. [16, 18] and is strongly related to the problem of feedback linearization. This concept corresponds to a complete and finite parametrization of all solutions of a control system by a differentially independent family of functions called flat output.

Linear *singular* (or implicit) systems are an important class of control systems and many papers and books on this subject are found in the literature [4, 31].[1] Solvability of nonlinear implicit differential equations is considered in [2, 43]. Other problems like controllability [29], stabilization [32, 7], canonical forms [45], and feedback control [8] have already been considered.

[1] Note that the *module theoretic* approach of [15] is also valid for implicit systems.

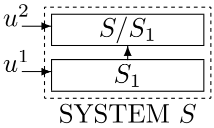

FIG. 1.1. *Structure of a system S with respect to a subsystem S_1.*

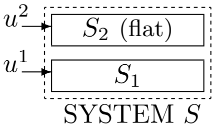

FIG. 1.2. *Structure of a system S that is relatively flat with respect to a subsystem S_1. Note that S_2 is flat.*

Feedback linearization of implicit systems has been studied for instance in [30, 26]. These works consider the problem of finding a state transformation and a state feedback such that the closed loop system is a linear singular system. In this work we tackle the problem of finding sufficient conditions for flatness of a class of time-varying implicit systems of the form[2]

$$\dot{x}(t) = f(t, x(t), u(t)), \tag{1.1a}$$

$$y(t) = h(t, x(t), u(t)) = 0, \tag{1.1b}$$

where $x(t) \in \mathbb{R}^n$, $y(t) \in \mathbb{R}^p$, $u(t) \in \mathbb{R}^m$ and all the components of $f(x)$ and $g(x)$ are analytical functions of x. We stress that a set of implicit differential equations of arbitrary order can be put into the form (1.1a)–(1.1b) [39].

We now present, without being precise, a summary of the ideas and the results of this paper. Roughly speaking, a subsystem S_1 of a system S is some part of S that may be considered as a system by itself. Note that S_1 may affect the "quotient system" S/S_1, but it is not affected by S/S_1 as depicted in Figure 1.1.

Remark 1.1. We stress that, in Figure 1.1, S/S_1 is not a subsystem.

Recall that a system is *flat* if and only if there exists a differentially independent set of functions $y = (y_1, \ldots, y_m)$, called the *flat output*, such that every variable of the system is a function of the flat output and its derivatives. A system S is said to be *relatively flat with respect to a given subsystem* S_1 if, after a convenient *endogenous feedback*, S is decomposed into two independent subsystems S_1 and S_2 such that S_2 is a flat system[3] (see Figure 1.2). We stress that the fact that the system is decomposed into two independent subsystems is not artificial since the same structure occurs for the algebraic counterpart of this definition (see Remark 5.1).

In this paper, a sufficient condition for relative flatness is given (see Theorem 8.2). One can easily conclude that a system S that is relatively flat with respect to a flat subsystem is also flat,[4] leading to a sufficient condition of flatness of system S.

Now, let y be the output (not necessarily a flat output) of system S. We will show that one can construct a subsystem Y of S such that Y contains only the "information" of time and of y and its derivatives $y^{(k)}, k \in \mathbb{N}$ (see Theorem 4.3). Subsystem Y will be called *output subsystem.*

[2] This class is more general than the one considered by [30, 26].

[3] See Definition 5.1 for a precise statement of *relative flatness.*

[4] See Proposition 5.2 for a precise statement of this idea.

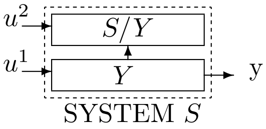

FIG. 1.3. *Structure of a system S with respect to the output subsystem Y.*

The structure of the implicit system obtained from S by setting y to be equal to zero (see Figure 1.3) is directly related to the properties of S with respect to the output subsystem Y. Under some regularity assumptions, if S is relatively flat with respect to Y, then the implicit system obtained from S by including the constraint $y = 0$ is also flat.[5]

The paper is organized as follows. In section 2 the notation and some mathematical background are presented. The infinite dimensional differential geometric approach of [19] is briefly summarized in section 3. The notion of *subsystem* is presented in section 4. The existence and some properties of local *output* subsystems are also discussed in section 4. The concept of *relative flatness* is discussed in section 5. In section 6 it is shown that, under regularity assumptions, an implicit system (1.1a)–(1.1b) may be considered as a system that is immersed in the explicit system (1.1a). In section 7, the results of the previous sections are used to derive a sufficient condition for flatness of implicit systems. A sufficient condition for relative flatness based on *relative derived flags* is developed in section 8. Some examples are discussed in section 9. Finally, some auxiliary results and proofs are presented in Appendices A and B.

2. Preliminaries and notation. The field of real numbers is denoted by $\mathbb{R}$ and $\mathbb{N}$ stands for the set natural numbers (including zero). The subset $\{1, \ldots, k\}$ of $\mathbb{N}$ is denoted by $\lfloor k \rceil$. Given a set W, then card W stands for the cardinality of W. We adopt the standard notations of differential geometry and exterior algebra in the finite and infinite dimensional case [55, 57]. Let us briefly recall the main definitions of the infinite dimension setting introduced in control systems theory [17, 40, 19]. This approach is mainly based on the differential geometry of jets and prolongations (see, for instance, [27, 57]), whereas the approach of [24] and [34] is based on finite dimensional differential geometry [55].

Let A be a countable set. Denote by $\mathbb{R}^A$ the set of functions from A to $\mathbb{R}$. One may define the coordinate function $x_i : \mathbb{R}^A \to \mathbb{R}$ by $x_i(\xi) = \xi(i), i \in A$. This set can be endowed with the Fréchet topology (i.e., an *inverse limit* topology [57]). A basis of this topology is given by the subsets of the form $\mathcal{B} = \{\xi \in \mathbb{R}^A \mid |x_i(\xi) - \delta_i| < \epsilon_i, i \in F\}$, where F is a finite subset of A, $\delta_i \in \mathbb{R}$, and ϵ_i is a positive real number for $i \in F$. A function $\phi : \mathbb{R}^A \to \mathbb{R}$ is smooth if $\phi = \psi(x_{i_1}, \ldots, x_{i_s})$, where $\psi : \mathbb{R}^s \to \mathbb{R}$ is a smooth function. Only the dependence on a finite number of coordinates is allowed.

From this notion of smoothness, one can easily state the notions of vector fields and differential forms[6] on $\mathbb{R}^A$ and smooth mappings from $\mathbb{R}^A$ to $\mathbb{R}^B$. The notion of an $\mathbb{R}^A$-manifold can be also established easily as in the finitely dimensional case [57].

[5] See Theorem 7.2 for a precise statement of this sufficient condition of flatness.

[6] We stress that the forms are finite combinations of the form $\sum_i a_{I_i} dx_{I_i}$, where I_i is the multi-index $(j_{i,1}, \ldots, j_{i,r_i})$, the a_{I_i} are smooth functions, $dx_{I_i} = dx_{j_{i,1}} \wedge \cdots \wedge dx_{j_{i,r_i}}$. On the other hand, the fields are (possibly) infinite sums of the form $\sum_{i \in A} a_i \frac{\partial}{\partial x_i}$.

Given an $\mathbb{R}^A$-manifold $\mathcal{P}$, $C^\infty(\mathcal{P})$ denotes the set of smooth maps from $\mathcal{P}$ to $\mathbb{R}$. Let $\mathcal{Q}$ be an $\mathbb{R}^B$-manifold and let $\phi : \mathcal{P} \to \mathcal{Q}$ be a smooth mapping. The corresponding tangent and cotangent mapping will be denoted, respectively, by $\phi_* : T_p\mathcal{P} \to T_{\phi(p)}\mathcal{Q}$ and $\phi^* : T^*_{\phi(p)}\mathcal{Q} \to T^*_p\mathcal{P}$.

The map $\phi : \mathcal{P} \to \mathcal{Q}$ is called an *immersion* if, around every $\xi \in \mathcal{P}$ and $\phi(\xi) \in \mathcal{Q}$, there exist local charts of $\mathcal{P}$ and $\mathcal{Q}$ such that, in these coordinates, $\phi(x) = (x, 0)$. The map ϕ is called a *submersion* if, around every $\xi \in \mathcal{P}$ and $\phi(\xi) \in \mathcal{Q}$, there exist local charts of $\mathcal{P}$ and $\mathcal{Q}$ such that, in these coordinates, $\phi(x, y) = x$.

In the finite dimensional case, immersion and submersions are locally characterized, respectively, by the injectivity and surjectivity of the tangent mappings. However, in the infinite dimensional case this is no longer true. Moreover, the inverse function theorem and the classical Frobenius theorem (for distributions) do not hold and a field does not admit a flow in general [57].

Given two forms η and ξ in $\Lambda(\mathcal{P})$, then $\eta \wedge \xi$ denotes their *wedge* multiplication. The *exterior derivative* of $\eta \in \Lambda(\mathcal{P})$ will be denoted by $d\eta$. Note that the graded algebra $\Lambda(\mathcal{P})$, as well as its homogeneous elements $\Lambda_k(\mathcal{P})$ of degree k, have a structure of $C^\infty(\mathcal{P})$-module. See [55, 3] for details. Given a family $\nu = (\nu_1, \ldots, \nu_k)$ of a $C^\infty(\mathcal{P})$-module, then span $\{\nu_1, \ldots, \nu_k\}$ stands for the span over $C^\infty(\mathcal{P})$.

Given a field f and a 1-form ω on $\mathcal{P}$, we denote $\omega(f)$ by $\langle \omega, f \rangle$. The set of smooth k-forms on $\mathcal{P}$ will be denoted by $\Lambda_k(\mathcal{P})$ and $\Lambda(\mathcal{P}) = \cup_{k\in\mathbb{N}}\Lambda_k(\mathcal{P})$.

The following useful result of finite dimensional differential geometry is known as the "Cartan lemma" [55, Ex. 16, p. 80]. Let $\{\omega_1, \ldots, \omega_r\} \subset \Lambda_1(\mathcal{P})$ be independent pointwise. Assume that there exist 1-forms $\eta_1, \ldots, \eta_r$ such that $\sum_{i=1}^r \eta_i \wedge \omega_i = 0$. Then there exist functions $a_{ij} \in C^\infty(\mathcal{P})$, with $a_{ij} = a_{ji}$, such that $\eta_i = \sum_{j=1}^r a_{ij}\omega_j \quad (i = 1, \ldots, r)$. The same result is also valid pointwise, i.e., $\sum_{i=1}^r \eta_i \wedge \omega_i|_p = 0$ implies that $\eta_i(p) = \sum_{j=1}^r a_{ij}\omega_j(p) \quad (i = 1, \ldots, r)$ for convenient $a_{ij} = a_{ji} \in \mathbb{R}$.

A smooth codistribution J is a $C^\infty(\mathcal{P})$-submodule $J \subset T^*\mathcal{P}$. Given a submodule S of $\Lambda(\mathcal{P})$ and $p \in \mathcal{P}$, then $S(p)$ denotes the $\mathbb{R}$-linear subspace of $\Lambda_1(\mathcal{P})|_p$ given by $\operatorname{span}_\mathbb{R} \{\zeta(p) |\ \zeta \in S\}$. In particular, if J is a codistribution, then $J(p)$ denotes the subspace of $T^*_p\mathcal{P}$ given by $\operatorname{span}_\mathbb{R} \{\omega(p) |\ \omega \in J\}$.[7]

Assume that a codistribution I is locally generated by $\eta_1, \ldots, \eta_k$ and that $\Psi = \{x_i |\ i \in A\}$ is a local coordinate system around some open set $U \subset \mathcal{P}$. Then one may apply to I the standard techniques of differential geometry, for instance, the Frobenius theorem, by "pulling back" the results that hold on the finite dimensional case (see [40] and [36, section 2]).

3. Diffieties and systems. In this section we recall the main concepts of the infinite dimensional geometric setting of [17, 40, 19]. We have chosen to present a simplified exposition. For a more complete and intrinsic presentation the reader may refer to the cited literature.

3.1. Diffieties. A *diffiety* M is an $\mathbb{R}^A$-manifold equipped with a distribution Δ of finite dimension r, called *Cartan distribution.* A section of the Cartan distribution is called a *Cartan field.* An *ordinary diffiety* is a diffiety for which $\dim \Delta = 1$ and a Cartan field ∂_M is distinguished and called *the Cartan field.* In this paper we will consider only ordinary diffieties, which will be called simply by *diffieties.*

A Lie–Bäcklund mapping $\phi : M \to N$ between diffieties is a smooth mapping that is compatible with the Cartan fields, i.e., $\phi_*\partial_M = \partial_N \circ \phi$. A *Lie–Bäcklund*

[7] One can also define a codistribution as a map $p \mapsto J(p)$, where $J(p)$ is a subspace of $T^*_p\mathcal{P}$.

immersion (resp., *submersion*) is a Lie–Bäcklund mapping that is an immersion (resp., submersion). A Lie–Bäcklund isomorphism between two diffieties is a diffeomorphism that is a Lie–Bäcklund mapping.

Context permitting, we will denote the Cartan field of an ordinary diffiety M simply by $\frac{d}{dt}$. Given a smooth object ϕ defined on M (a smooth function, field, or form), then $L_{\frac{d}{dt}}(\phi)$ will be denoted by $\dot{\phi}$ and $L^n_{\frac{d}{dt}}(\phi)$ by $\phi^{(n)}, n \in \mathbb{N}$. In particular, if ω is a 1-form given by $\omega = \sum_{\text{finite}} \alpha_i dx_i$, then $\dot{\omega} = \sum_{\text{finite}}(\dot{\alpha}_i dx_i + \alpha_i d\dot{x}_i)$.

3.2. Systems. The set of real numbers $\mathbb{R}$ has a trivial diffiety structure with the Cartan field defined by the operation of differentiation of smooth functions. A *system* is a triple $(S, \mathbb{R}, \tau)$ where S is a diffiety equipped with Cartan field $\frac{d}{dt}$, the mapping $\tau : S \to \mathbb{R}$ is a Lie–Bäcklund submersion, and $\frac{d}{dt}(\tau) = 1$. The function τ represents *time* that is chosen once and for all. Context permitting, the system $(S, \mathbb{R}, \tau)$ is denoted simply by S. A *Lie–Bäcklund mapping between two systems* $(S, \mathbb{R}, \tau)$ and $(S', \mathbb{R}, \tau')$ is a *time-respecting* Lie–Bäcklund mapping $\phi : S \to S'$, i.e., $\tau' = \tau \circ \phi$. The previous condition means that the notion of time of both systems coincide. This notion of system is *time-varying*, as will be explained below.

3.3. State representation. We present a simplified definition of state representation that introduces the state and the input and its derivatives as a local coordinate system (see [17, 19] for a more intrinsic presentation).

A local state representation of a system $(S, \mathbb{R}, \tau)$ is a local coordinate system $\psi = \{t, x, U\}$, where $x = \{x_i, i \in \lfloor n \rceil\}$, $U = \{u_j^{(k)} | \; j \in \lfloor m \rceil, k \in \mathbb{N}\}$, where $u_j^{(k)} = L^k_{\frac{d}{dt}} u_j$, and $\tau = t$. The set of functions $x = (x_1, \ldots, x_n)$ is called state and $u = (u_1, \ldots, u_m)$ is called input. In these coordinates the Cartan field is locally written by

$$\frac{d}{dt} = \frac{\partial}{\partial t} + \sum_{i=1}^{n} f_i \frac{\partial}{\partial x_i} + \sum_{k \in \mathbb{N}} \sum_{j \in \lfloor m \rceil} u_j^{(k+1)} \frac{\partial}{\partial u_j^{(k)}}. \tag{3.1}$$

Note that f_i may depend on t, x, and a finite number of elements of U. In this sense, the state representation defined here is said to be generalized, since one accepts that f_i may depend on the derivatives of the input. If the functions f_i depend only on $\{t, x, u\}$ for $i \in \lfloor n \rceil$, then the state representation is said to be *classical*. A state representation of a system S is completely determined by the choice of the state x and the input u and will be denoted by (x, u). A state representation is said to be *analytic* if the f_i are all analytic.[8]

3.4. Output. An output y of a system S is a set $y = (y_1, \ldots, y_p)$ of smooth functions defined on S. If (x, u) is a state representation of S, then it is clear that

$$y_j = y_j(t, x, u, \ldots, u^{(\alpha_j)}), \; j \in \lfloor p \rceil. \tag{3.2}$$

If the y_j depend only on $\{t, x, u\}$ for $j \in \lfloor p \rceil$, then the output is said to be *classical* with respect to the state representation (x, u). A state representation (x, u) with output y is said to be *analytic* if the functions f_i and the y_j are all analytic with respect to its arguments x and $\{u^{(j)} \mid j \in \mathbb{N}\}$.

[8] This definition is coordinate dependent since only smooth atlases are considered on diffieties [57].

3.5. System associated to differential equations. Now assume that a control system is defined by a set of equations

$$\begin{aligned} \dot{t} &= 1, \\ \dot{x}_i &= f_i(t, x, u, \dots, u^{(\alpha_i)}),\ i \in \lfloor n \rceil, \\ y_j &= y_j(t, x, u, \dots, u^{(\beta_j)}),\ j \in \lfloor p \rceil. \end{aligned} \tag{3.3}$$

One can always associate to these equations a diffiety S of global coordinates $\psi = \{t, x, U\}$ and Cartan field given by (3.1).

3.6. Flatness. We present now a simple definition of flatness in terms of coordinates.[9] A system S equipped with Cartan field $\frac{d}{dt}$ and time function $t = \tau$ is locally flat around $\xi \in S$ if there exists a set of smooth functions $y = (y_1, \dots, y_m)$, called *flat output*, such that the set $\{t, y_i^{(j)} |\ i \in \lfloor m \rceil, j \in \mathbb{N}\}$ is a (local) coordinate system of S around $\xi \in S$, where $y_i^{(j)} = L^j_{\frac{d}{dt}} y_i$. Note that the Cartan field is locally given by

$$\frac{d}{dt} = \frac{\partial}{\partial t} + \sum_{j \in \mathbb{N}} \sum_{i \in \lfloor m \rceil} y_i^{(j+1)} \frac{\partial}{\partial y_i^{(j)}}.$$

Let $\Psi : S \to T$ be a Lie–Bäcklund isomorphism between two systems. Then S is flat if and only if T is flat also. If $y = (y_1, \dots, y_m)$ is a flat output of T, then $\{y_1 \circ \Psi, \dots, y_m \circ \Psi\}$ is a flat output of S.

3.7. Endogenous feedback and coordinate changes. Since a local state representation (x, u) is by definition a local coordinate system, a new local state representation (z, v) induces a coordinate change from $\{t, x, (u^{(i)} : i \in \mathbb{N})\}$ to $\{t, z, (v^{(j)} : i \in \mathbb{N})\}$. The coordinate changes of this kind are called *endogenous feedbacks*.[10]

An example of endogenous feedback is static-state feedback. Two state representations (x, u) and (z, v) defined around $\xi \in S$ are said to be linked by (time-varying) static-state feedback if we locally have

$$\operatorname{span}\{dt, dx\} = \operatorname{span}\{dt, dz\}, \tag{3.4a}$$

$$\operatorname{span}\{dt, dx, du\} = \operatorname{span}\{dt, dz, dv\}. \tag{3.4b}$$

Let (x, u) be a classical state representation and let z and v be family of smooth functions such that card x = card z and card u = card v. Then it is easy to show that, if (3.4) locally holds, then (z, v) is a local state representation that is linked to (x, u) by static-state feedback [36, Prop. 3.2].

Another example of endogenous feedback is putting integrators in series with the first k inputs of the system (3.3). This procedure induces a local state representation (z, v) of the system S, where $z = (x_1, \dots, x_n, u_1, \dots, u_k)$ and $v = (\dot{u}_1, \dots, \dot{u}_k, u_{k+1}, \dots, u_m)$, called *dynamic extension* of the state.

4. Subsystems.

A (local) *subsystem* S_a of a given system S is a system S_a such that there exists a surjective[11] Lie–Bäcklund submersion $\pi : U \subset S \to S_a$, where U is an open subset of S. A (local) subsystem will be denoted by (S_a, π) or simply by S_a.

[9] For more intrinsic definitions and some variations, see [17, 19].

[10] See [17] for a definition of endogenous feedback that considers an equivalence relation between systems.

[11] Since submersions are open maps, one can always consider that $S_a = \pi(U)$ by restricting S_a to the image of π.

4.1. State equations adapted to subsystems. Assume that there exists a local classical state representation (x, u) of a system S of the form

$$\dot{x}_a = f_a(t, x_a, u_a), \tag{4.1a}$$

$$\dot{x}_b = f_b(t, x_a, x_b, u_a, u_b), \tag{4.1b}$$

where $x = (x_a, x_b)$ and $u = (u_a, u_b)$. Assume that (4.1a) represents the state equations of a subsystem S_a and $\pi : S \to S_a$ is such that $\pi(t, x, U) = (t, x_a, U_a)$, where U denotes the set $(u^{(j)}|\ j \in \mathbb{N})$ and U_a denotes the set $({u_a}^{(j)}|\ j \in \mathbb{N})$. A state representation of S the form (4.1a)–(4.1b) is said to be adapted to the subsystem S_a. In the end of this section we show that state equations adapted to a subsystem can be generically constructed (see Proposition 4.4).

4.2. Relative static-state feedback. We will consider now a special case of endogenous feedback that will be called by *relative static-state feedback*. Consider that $((x_a, x_b), (u_a, u_b))$ is a local state representation for system S such that the state equations are of the form (4.1a)–(4.1b). A relative state feedback is a new state representation $((x_a, z_b), (u_a, v_b))$ such that

$$\begin{aligned} z_b &= z_b(t, x_b,\, x_a, u_a, \dots, {u_a}^{(r)}),\\ v_b &= v_b(t, x_b, u_b, x_a, u_a, \dots, {u_a}^{(r+1)}), \end{aligned} \tag{4.2}$$

where r is a convenient integer and similar equations do exist for x_b, u_b as functions of $x_a, z_b,\, u_a, v_b$ and the derivatives of u_a. In other words, this is an invertible time-varying feedback. The next definition renders this notion more intrinsic.

DEFINITION 4.1. *Let S be a system and let (π, S_a) be a (local) subsystem of S. Let (x, u) and (z, v) be two (local) state representations of S. Let Σ be the codistribution defined by the pull-back*[12] $\Sigma = \pi^*(T^* S_a)$*. Then (x, u) and (z, v) are linked by a* relative static-state feedback *with respect to the subsystem S_a if* $\operatorname{span}\{dx\} + \Sigma = \operatorname{span}\{dz\} + \Sigma$ *and* $\operatorname{span}\{dx, du\} + \Sigma = \operatorname{span}\{dz, dv\} + \Sigma$.

PROPOSITION 4.2. *Let S be a system with local state representation (x, u) defined on $V_\xi \subset S$, where $x = (x_a, x_b)$, and $u = (u_a, u_b)$ are such that the state equations are of the form* (4.1a)*–*(4.1b)*. Let S_a be the (local) subsystem associated to equation* (4.1a)*. Consider the set of smooth functions $z = (x_a, z_b)$ and $v = (u_a, v_b)$ defined on V_ξ, where* $\operatorname{card} x = \operatorname{card} z = n$ *and* $\operatorname{card} u = \operatorname{card} v = m$*. Then the following statements are equivalent:*

(i) *(z, v) is a local state representation around ξ and (x, u) and (z, v) are linked by relative static-state feedback.*

(ii) $\operatorname{span}\{dx\} + \Sigma = \operatorname{span}\{dz\} + \Sigma$ *and* $\operatorname{span}\{dx, du\} + \Sigma = \operatorname{span}\{dz, dv\} + \Sigma$.

Proof. See [39]. □

Remark 4.1. The proof of the Proposition 4.2 shows that (i) implies that condition (4.2) is satisfied for a subsystem S_a defined by (4.1a). It will be shown (see Proposition 4.4) that all subsystems admit adapted state equations of the form (4.1a)–(4.1b), up to relative static-state feedbacks.

4.3. Output subsystem. Given a system S with output y, a (local) *output subsystem* is a (local) subsystem $\pi : U \subset S \to Y$ such that $\pi^*(T^*_{\pi(\xi)} Y) = \operatorname{span}\left\{dt, dy^{(k)} : k \in \mathbb{N}\right\}|_\xi, \xi \in U$.

[12] Note that $\operatorname{span}\{dt\} \subset \Sigma$.

4.4. Existence of local output subsystems. Without loss of generality, assume that (x, u) is a classic state representation with output y. If it is not the case, we can add integrators in series with the input until the required properties are fulfilled. The next theorem shows that local output subsystems can be constructed generically and they admit adapted state equations up to relative static-state feedback. Furthermore, they are unique up to Lie–Bäcklund isomorphisms.

Theorem 4.3 (existence and uniqueness of output subsystems). *Let S be a system and let (x, u) be a classical* analytical *state representation defined on an open neighborhood $W \subset S$. Let y be a classical output of S. Let $n =$ card x. Let $U \subset W$ be the set of regular points of the codistributions $Y_k, \mathcal{Y}_k, k \in \lfloor n \rceil$, where $Y_k = \operatorname{span}\left\{dt, dy, \dots, dy^{(k)}\right\}$ and $\mathcal{Y}_k = \operatorname{span}\left\{dt, dx, dy, \dots, dy^{(k)}\right\}$. Then, around any $\xi \in U$, there exists an open neighborhood V_ξ of ξ and a local* classical *state representation $(z, v) = ((z_a, z_b), (v_a, v_b))$ of the system S, defined on V_ξ, such that:*

(i) *The (local) state equations are*

$$\dot{z}_a = f_a(t, z_a, v_a), \tag{4.3a}$$

$$\dot{z}_b = f_b(t, z_a, z_b, v_a, v_b). \tag{4.3b}$$

(ii) *Let Y be the local subsystem associated to* (4.3a) *and let $\pi : V_\xi \to Y$ be the corresponding Lie–Bäcklund submersion. We have $\pi^*(T^*Y) = \operatorname{span}$ $\{dt,\ dz_a,\ (dv_a^{(k)} : k \in \mathbb{N})\} = \operatorname{span}\left\{dt, dy^{(k)} : k \in \mathbb{N}\right\}$. In particular, Y is an output subsystem of S. Let $\mathcal{Z} = \{z_a, (v_a^{(k)} : k \in \mathbb{N})\}$ and $\mathcal{Y} = \{y_j^{(k)} : j \in \lfloor p \rceil, k \in \mathbb{N}\}$. Then $\mathcal{Z} \subset \mathcal{Y}$.*

(iii) *The state representations (x, u) and (z, v) are linked by relative static-state feedback with respect to the subsystem Y associated to* (4.3a).

Furthermore, two local output subsystems around any $\xi \in S$ are (locally) Lie–Bäcklund isomorphic.

Proof. See Appendix A.1. □

We state now the result that assures that a subsystem can be generically represented by state equations of the form (4.1a)–(4.1b).

Proposition 4.4. *Assume that S_a is a subsystem of S and that there exist local state representations for S_a and S around every point of S_a and S. Then, generically, there exists local state representations of S of the form* (4.1a)–(4.1b) *in a way that* (4.1a) *is a state representation of S_a.*

Proof. Let $\pi : S \to S_a$ be the corresponding Lie–Bäcklund submersion. Take a local state representation (z_a, e_a) of S_a around $\pi(\xi) \in S_a$. We abuse notation and denote $z_a \circ \pi$ and $e_a \circ \pi$, respectively, by z_a and e_a. Now, consider system S with output $y = (z_a, e_a)$ and construct, possibly by extending the state with derivatives of the input, a classical state representation of S such that y is a classical output. The result follows easily from the application of Theorem 4.3 and the fact that $T^*S_a = \operatorname{span}\{dt, dz_a^{(k)}, de_a^{(k)}, k \in \mathbb{N}\}$. □

If the outputs are differentially independent, the next result shows that local output subsystems are generically flat.

Proposition 4.5. *Let U be the open and dense subset of Theorem* 4.3. *Assume that the (explicit) system* (1.1a) *with output $y = h(t, x, u)$ is right-invertible, i.e., the output rank ρ is equal to the number of output components.*[13] *Let $\pi : V_\xi \subset S \to Y$ be a local output subsystem with $V_\xi \subset U$. Then Y is (locally) flat with flat output y.*

Proof. See [39]. □

[13] See Appendix B for the definition of the output rank ρ.

5. Relative flatness.

5. Relative flatness. We now state the concept of *relative flatness.*

DEFINITION 5.1. *Let S be a system and (π_1, S_1) and (π_2, S_2) be two subsystems of S. The system S is said to be locally* decomposed by *S_1 and S_2 if, around $\xi \in S$, there exists local coordinates (t, x^1) for S_1, (t, x^2) for S_2, and (t, x^1, x^2) for*[14] *S such that $\pi_i(t, x^1, x^2) = (t, x^i), i = 1, 2$. A system S is said to be (locally)* relatively flat *with respect to a subsystem S_1 if there exists a flat subsystem S_2 such that S is (locally) decomposed by S_1 and S_2.*

The next proposition states a sufficient condition for flatness. It can be shown that it is not a necessary condition [39].

PROPOSITION 5.2. *Let S_1 be a (locally) flat subsystem of a system S. Assume that S is relatively flat with respect to S_1. Then S is (locally) flat.*

Proof. The union of flat outputs of S_1 and S_2 is a flat output of S. $\square$

Remark 5.1. In the differential algebraic approach of [14] (see also [21]) one can define a subsystem of a system K/k as a field extension L/k such that L is a subfield of K. Then a system K/k is relatively flat with respect to L if the system K/L is flat, considering L as the ground field (see [11] for a result similar to Proposition 5.2.). However, these algebraic notions are not suitable for our purposes because integrability conditions are not available in this algebraic context.

It can be shown that, if K/k is relatively flat with respect to L, then K/k can be decomposed into two independent subsystems L/k and F/k, where F/k is flat (see [56]). In this sense, the assumption that the system is decomposed into two independent subsystems in the definition of relative flatness is not restrictive with respect to the algebraic definition (see also [35] for similar facts that occur when L corresponds to the noncontrollable subsystem.)

The following proposition is a necessary and sufficient condition for completing a given output y into a flat output (see [42] for related results).

PROPOSITION 5.3. *Let S be a system and let S_1 be a flat subsystem of S. Let y be a (local) flat output for S_1. Then there exists a set z of smooth functions such that S is locally flat with flat output (y, z) if and only if S is relatively flat with respect to the subsystem S_1.*

Proof. The necessity is obvious. The sufficiency follows from the proof of Proposition 5.2. $\square$

6. Implicit systems regarded as Lie–Bäcklund immersions.

6. Implicit systems regarded as Lie–Bäcklund immersions. Let S be the nonconstrained system defined by (1.1a). We show that, under some regularity assumptions, (1.1a)–(1.1b) may be regarded as a system that is immersed in S. We construct a system Γ and a Lie–Bäcklund immersion $\iota : \Gamma \to S$ such that every integral curve $\sigma(t)$ of the Cartan field of S, respecting the constraints $y(t) \equiv 0$, is of the form $\sigma(t) = \iota \circ \gamma(t)$ for a suitable integral curve $\gamma(t)$ of the Cartan field of Γ.

Consider the explicit (nonconstrained) system S defined by (1.1a) with output $y = h(t, x, u)$, global coordinates $\{t, x, (u_i^{(j)} : i \in \lfloor m \rceil; j \in \mathbb{N})\}$, and Cartan field (3.1). Consider now the following assumptions.

A1. Existence and regularity assumption. *Let $\Gamma = \{\xi \in S \mid y^{(k)}(\xi) = 0$ for all $k \in \mathbb{N}\}$. Assume that $\Gamma \neq \emptyset$ and furthermore, $\Gamma \subset U$, where U is the open and dense subset of the system S such that the statement of Theorem* 4.3 *holds.*[15] *In other words, around every point $\xi \in \Gamma$, we can construct a local output subsystem.*

[14] We abuse notation and denote $x^i \circ \pi_i$ simply by x^i.

[15] Note that in this case the state representation (1.1a) is globally defined. According the proof of Theorem 4.3 we have that U is the open and dense set of regular points of the codistributions $Y_k = \text{span}\left\{dt, dy, \dots, dy^{(k)}\right\}$ and $\mathcal{Y}_k = \text{span}\left\{dt, dx, dy, \dots, dy^{(k)}\right\}$ for $k \in \{0, 1, \dots, n\}$.

A2. Time interval assumption. *For every $\xi \in \Gamma$ and every open neighborhood $U \subset S$ of ξ, there exists some $\epsilon \geq 0$ such that $\tau(\Gamma \cap U)$ contains an open interval $(\tau(\xi) - \epsilon, \tau(\xi) + \epsilon)$.*

Remark 6.1. Note that assumption A2 means that Γ "does exist" during an interval of time. If the system is time-invariant it is easy to verify that assumption A2 is not needed. Note also that the set Γ may be empty, and in this case the implicit system has no solution. For instance, let $y_1 = x_1 + 1$ and $y_2 = x_1^2 + 2$. Then $y_1 = 0$ implies that $y_2 \neq 0$. A problem of this nature may occur with output derivatives.

When the assumptions A1, A2 hold, the set $\Gamma \subset S$ may be endowed with the structure of an immersed Fréchet manifold by choosing the subset topology, as shown by the following proposition.

PROPOSITION 6.1. *Suppose that assumptions* A1 *and* A2 *are satisfied for system S. Then the subset $\Gamma \subset S$ has a structure of immersed manifold in S. Let $\iota : \Gamma \to S$ be the canonical insertion. We can define a Cartan field ∂_Γ on Γ by the equation $\iota_* \partial_\Gamma(\gamma) = \frac{d}{dt} \circ \iota(\gamma), \gamma \in \Gamma$. Equipped with this Cartan field, Γ is a system such that ι is a Lie–Bäcklund immersion. Furthermore, all the solutions $\xi(t)$ of* (1.1a) *obeying the restriction* (1.1b) *are of the form $\xi(t) = \iota \circ \nu(t)$, where $\nu(t)$ is a solution of* Γ.

Proof. We show first that Γ is an immersed manifold. For this, consider the topological subspace $\Gamma \subset S$ with the subset topology. For each point $\xi \in \Gamma$, Theorem 4.3 gives local charts $\phi : \hat{U} \to \tilde{U} \subset \mathbb{R}^A$, where $\phi = \{t, z_a, V_a, z_b, V_b\}$, $V_a = \{v_a^{(k)} : k \in \mathbb{N}\}$, $V_b = \{v_b^{(k)} : k \in \mathbb{N}\}$, and we have span $\{dt, dz_a, dV_a\}$ = span $\{dt, dy^{(k)} : k \in \mathbb{N}\}$. This local chart is adapted to a local output subsystem $\pi : \hat{U} \to Y$, and is such that $\pi(t, z_a, V_a, z_b, V_b) = (t, z_a, V_a)$. Furthermore, by part (ii) of Theorem 4.3, the functions of the set $\mathcal{Z} = \{z_a, V_a\}$ are such that $\mathcal{Z} \subset \mathcal{Y}$, where $\mathcal{Y} = \{y^{(k)} : k \in \mathbb{N}\}$. By construction, if $\nu \in \hat{U} \cap \Gamma$, then $y^{(k)}(\nu) = 0$ for all $k \in \mathbb{N}$. This implies that all the components of $\mathcal{Z}$ are also null in ν. If we show that the functions in $\mathcal{W} = \mathcal{Y} - \mathcal{Z}$ are also null in $\nu \in \Gamma \cap \hat{U}$, we will show that a point ν is in $\Gamma \cap \hat{U}$ if and only if $z_a = 0$ and $V_a = 0$ in ν. In fact, note first that, since span $\{dt, d\mathcal{Z}\}$ = span $\{dt, d\mathcal{Y}\}$, all the functions θ in $\mathcal{Y}$ can be locally written in the form $\theta = \theta(t, z_a, V_a)$. By assumption A2, if we restrict $\tilde{U}$ to a basic open set of the form $I_{\tau(\xi)} \times W$, where $I_{\tau(\xi)} = (\tau(\xi) - \epsilon, \tau(\xi) + \epsilon)$, we may assume that, for every $\bar{t} \in I_{\tau(\xi)}$, then $\hat{U} \cap \Gamma$ contains a point $\xi_{\bar{t}} = (\bar{t}, z_a, V_a, z_b, V_b) = (\bar{t}, 0, 0, z_b, V_b)$. For any fixed $\bar{t} \in I_{\tau(\xi)}$, since $\xi_{\bar{t}} \in \Gamma \cap \hat{U}$, we have that $\theta(\xi_{\bar{t}}) = \theta(\bar{t}, 0, 0) = 0$. Since this is true for all $\bar{t} \in I_{\tau(\xi)}$, we have shown our claim.

Now consider the map $\mu : \Gamma \cap \hat{U} \to \mu(\Gamma \cap \hat{U}) \subset \mathbb{R}^B$ such that $\mu(t, 0, 0, z_b, V_b) = (t, z_b, V_b)$. We shall show that these maps form a smooth atlas of Γ. By construction it is clear that these maps are homeomorphisms. Hence it suffices to show that these charts are C^∞ compatible. For convenience denote the functions of the chart ϕ by $\{t, X, Z\}$ and the functions of the chart μ by $\{t, Z\}$, where $X = \{z_a, V_a\}$ and $Z = \{z_b, V_b\}$.

Now let $\mu_i : \Gamma \cap U_i \to \tilde{V}_i$, $i = 1, 2$, be two local charts constructed in that way, based, respectively, on the local charts of S given by $\phi_i = \{t, X_i, Z_i\}$, $i = 1, 2$. In particular, it follows that $\mu_i \circ \phi_i(t, 0, Z_i) = (t, Z_i)$, $i = 1, 2$. Without loss of generality, assume that $U_1 = U_2$. Consider the local coordinate change $(t, X_1, Z_1) = \phi_1 \circ \phi_2^{-1}(t, X_2, Z_2)$. Note that the map $\theta : \tilde{V}_2 \to \tilde{V}_1$ such that $(t, Z_1) \mapsto (t, Z_2)$ defined by $(t, 0, Z_1) = \phi_1 \circ \phi_2^{-1}(t, 0, Z_2)$ is a local diffeomorphism with inverse defined by $(t, 0, Z_2) = \phi_2 \circ \phi_1^{-1}(t, 0, Z_1)$. Since $\theta = \mu_1 \circ \mu_2^{-1}$, we conclude that such charts are C^∞ compatible.

Now let $\iota : \Gamma \to S$ be the insertion map. In the coordinates ϕ and μ previously constructed, we have $\iota(t, Z) = (t, 0, Z)$. In particular, ι is an immersion between $\mathbb{R}^A$-manifolds and so $\iota_*(\zeta)$ is injective for all $\zeta \in \Gamma$. Remember that any function η of the set $X = \{z_a, V_a\} \subset \mathcal{Y}$ is such that $\dot{\eta}|_\nu = 0$ for every $\nu \in \Gamma \cap \hat{U}$. In particular, we have that the image of $\iota_*(\nu)$ contains $\frac{d}{dt}(\iota(\nu))$ for every $\nu \in \Gamma \cap \hat{U}$. So we can define ∂_Γ by the rule $\iota_*\partial_\Gamma = \frac{d}{dt} \circ \iota$. By definition, it follows that ι is a Lie–Bäcklund immersion.

The last affirmation of the statement is a consequence of the first one. □

Remark 6.2. Let $\phi = (t, x_a, V_a, x_b, V_b)$ and $\mu = (t, x_b, V_b)$ be, respectively, the coordinates of S and Γ constructed above. In this coordinates we have

$$\partial_\Gamma = \frac{\partial}{\partial t} + \sum_{i=1}^{n_b} f_{b_i}(t, 0, 0, x_b, V_b) \frac{\partial}{\partial x_{b_i}} + \sum_{i=1}^{m_b} \sum_{j \in \mathbb{N}} u_{b_i}^{(j+1)} \frac{\partial}{\partial u_{b_i}^{(j)}}, \tag{6.1}$$

where $f_{b_i} = \frac{d}{dt}(x_{b_i}) = f_{b_i}(t, x_a, V_a, x_b, V_b)$, $i \in \lfloor n_b \rceil$. In other words, (x_b, u_b) is a state representation of Γ.

It is easy to show that the pull-back (by ι) of a relative static-state feedback for S with respect to a local output subsystem Y induces a static-state feedback for Γ if one considers the state representation $((x_a, x_b), (u_a, u_b))$ for S and (x_b, u_b) for Γ.

7. Flatness of implicit systems. In this section we will derive a sufficient condition for flatness of implicit systems. Let us begin with an auxiliary result.

Proposition 7.1. *Let Γ, S, and Y be systems, where Γ is immersed in S and Y is a subsystem of S. Let $\iota : \Gamma \to S$ and $\pi : S \to Y$ be, respectively, the corresponding Lie–Bäcklund immersion and submersion. Assume that there exist local coordinates (t, γ) of Γ, (t, γ, y) of S, and (t, y) of Y such that $\iota(t, \gamma) = (t, \gamma, 0)$ and*[16] *$\pi(t, \gamma, y) = (t, y)$. Assume that S is relatively flat with respect to Y. Then Γ is (locally) flat.*

Proof. Let S_2 be a flat subsystem of S such that S_2 and Y decomposes S (see Definition 5.1). Let $\pi_2 : S \to S_2$ be the corresponding Lie–Bäcklund submersion. Recall that there exists coordinates $(t, z, \tilde{y})$ of S, $(t, \tilde{y})$ of Y, and (t, z) of S_2 such that $\pi_2 : (t, z, \tilde{y}) = (t, z)$ and $\pi : (t, z, \tilde{y}) = (t, \tilde{y})$. Since the coordinate change map $(t, y) \to (t, \tilde{y})$ is a local diffeomorphism, we may assume without loss of generality that $\tilde{y} = y$. With a possible restriction of domains, we can consider the coordinate change mapping $\phi(t, \gamma, y) = (t, z, y)$. Note that the map $\phi_0(t, \gamma) = (t, z)$ such that $\phi(t, \gamma, 0) = (\phi_0(t, \gamma), 0) = (t, z, 0)$ is a local diffeomorphism. Let $\Psi : \Gamma \to S_2$ be such that $\Psi = \pi_2 \circ \iota$. By definition, Ψ is a Lie–Bäcklund mapping since it is a composition of Lie–Bäcklund mappings. In the coordinates (t, z) for S_2 and (t, γ) for Γ we have $\Psi(t, \gamma) = \phi_0(t, \gamma)$. Hence Ψ is a local Lie–Bäcklund isomorphism and so Γ is flat. In particular if θ is a flat output of S_2, then $\theta \circ \Psi$ is a flat output of Γ. □

The following result is a sufficient condition for flatness of an implicit system. It can be shown that it is not a necessary condition [39].

Theorem 7.2. *Let S be the explicit system defined by* (1.1a). *Let $y = h(t, x, u)$ be an output for system S and let Y be the corresponding output subsystem of S. Suppose that assumptions* A1–A2 *of the previous section hold for the system* (1.1a) *with the constraints* (1.1b). *According to Proposition* 6.1, (1.1a)–(1.1b) *define a system Γ that is immersed in S. Assume that the explicit system* (1.1a) *is (locally) relatively flat with respect to the subsystem Y. Then the implicit system Γ is locally flat around all $\xi \in \Gamma$.*

Proof. Let $\iota : \Gamma \to S$ be the insertion map and let $\pi : U \subset S \to Y$ be the canonical submersion onto the local output subsystem Y. According to the proof of Proposition

[16] We assume that (t, y) is inside the domain of our local chart of Y for $y = 0$.

6.1, we can define local charts $\phi = (t, X, Z)$ of S, $\mu = (t, Z)$ of Γ and $\Psi = (t, X)$ of Y such that $\iota(t, X) = (t, 0, Z)$ and $\pi(t, X, Z) = (t, X)$. Hence, by Proposition 7.1 (for $\gamma = Z$ and $y = X$) the result follows. $\square$

Let (1.1a) be a flat (explicit) system and assume that the output y of (1.1b) is part of the flat output of the explicit system (1.1a). Then next result shows that the implicit system (1.1a)–(1.1b) is flat.

COROLLARY 7.3. *Assume that S is locally flat with flat output $y = (y_1, \ldots, y_m)$. Assume that the local coordinate system $\{t, y_i^{(j)} : i \in \lfloor m \rceil, j \in \mathbb{N}\}$ is defined on open set V whose image is a basic open set $\tilde{V}$.*[17] *Let $\Gamma \subset V$ defined by $\{\xi \in V \mid y_i^{(j)}(\xi) = 0, i \in \lfloor r \rceil, j \in \mathbb{N}\}$. Assume that Γ is nonempty. Then Γ is an immersed system in $V \subset S$. Furthermore, Γ is (locally) flat with flat output $y_{r+1}, \ldots, y_m$.*

Proof. Consider system S with output $\tilde{y} = (y_{r+1}, \ldots, y_m)$. Let $\tilde{x} = \emptyset$ and $\tilde{u} = (\tilde{y}_1, \ldots, \tilde{y}_m)$. Then $(\tilde{x}, \tilde{u})$ is a local state representation of S. Let $\tilde{Y}_r = \text{span}\ \{dt,\ dy,\ \ldots,\ dy^{(k)}\}$ and $\mathcal{Y}_r = \text{span}\ \{dt,\ d\tilde{x},\ dy,\ \ldots,\ dy^{(k)}\}$. Then $\tilde{Y}_r = \mathcal{Y}_r$ are nonsingular codistributions on S for $r \in \mathbb{N}$ and hence assumption A1 of section 6 holds. Since $\tilde{V}$ is a basic open set, it is also clear that assumption A2 holds. By Theorem 4.3, the output subsystem $\tilde{Y}$ is well defined, and by Proposition 4.5, it follows that $\tilde{Y}$ is locally flat. By Proposition 5.3, S is relatively flat with respect to $\tilde{Y}$. The desired result follows from Theorem 7.2. $\square$

8. A sufficient condition for relative flatness.

Consider a system S and a subsystem S_1 of S given by (4.1a)–(4.1b), where (4.1a) represents S_1. Let $\dim x_a = n_a$, $\dim x_b = n_b$, $\dim u_a = m_a$, and $\dim u_b = m_b$. For this system one can define the *relative derived flag* as follows.

DEFINITION 8.1. *The relative derived flag of the system* (4.1a)–(4.1b) *is the sequence of codistributions $I^{(k)}$ defined by $I^{(-1)} = \text{span}\{(dx_b - f_b dt), (du_b - \dot{u}_b dt)\}$, and $I^{(k)}(p) = \text{span}\{\omega(p) \mid \ \omega \in I^{(k-1)},\ d\omega(p) \bmod\ (I^{(k-1)} + J)|_p \equiv 0\}$, $k \in \mathbb{N}$, where*

$$J \;=\; \text{span}\left\{(dx_a - \dot{x}_a dt), (du_a{}^{(j)} - u_a{}^{(j+1)}dt)|\ \ j \in \mathbb{N}\right\}. \tag{8.1}$$

Remark 8.1. In the proof of Proposition 8.3 it is shown that if $I^{(k)}$ is nonsingular, then it is smooth (otherwise $I^{(k+1)}$ is not well defined). The 1-forms in span $\left\{\frac{d}{dt}\right\}^{\perp}$ are called *contact forms* [40]. Let $\pi : S \to S_a$ be the Lie–Bäcklund submersion of S onto subsystem S_a (see section 4.1). Then it is easy to show that J is the codistribution generated by the contact forms of S_a, i.e., $J = \pi^*(T^*S_a) \cap \text{span}\left\{\frac{d}{dt}\right\}^{\perp}$. It follows that J is invariant by coordinate changes, and in particular, it is invariant by endogenous feedback. In [39] it is shown that

$$I^{(0)} = \text{span}\left\{dx_b - \dot{x}_b dt\right\}. \tag{8.2}$$

By construction we have $\dim I^{(-1)} = n_b + m_b$ and $\dim I^{(0)} = n_b$. Note also that $I^{(k)} + J \subset I^{(-1)} + J \subset \text{span}\left\{\frac{d}{dt}\right\}^{\perp}, k \in \mathbb{N}$. We will show that the relative derived flag carries an intrinsic structural information, at least if one restricts the class of transformations to *relative static-state feedback* (see Corollary 8.4).

THEOREM 8.2. *Assume that the codistributions* span $\left\{I^{(k)}, dt, J\right\}$ *are involutive, that $I^{(k)}$ are nonsingular for all $k \in \mathbb{N}$, and that $I^{(N)} = 0$ for N big enough. Then the system S is (locally) relatively flat with respect to S_1.*

[17] Recall that a basic open set is of the form $\tilde{V} = \{\xi \in S \mid |y_i^{(j)}(\xi) - \bar{y}_i^{(j)}| < \epsilon_{ij}, (i,j) \in \Delta\}$, where Δ is a finite subset of $\lfloor m \rceil \times \mathbb{N}$, $\bar{y}_i^{(j)} \in \mathbb{R}$, and $\epsilon_{ij} \in \mathbb{R}^+$.

Remark 8.2. It is easy to verify that J is involutive, i.e., that $d\omega \bmod J \equiv 0$ for all 1-forms $\omega \in J$. Furthermore, the codistribution span $\left\{I^{(k)}, dt, J\right\}$ is involutive if and only if span $\left\{I^{(k)}, dt, J_{\rho_k}\right\}$ is involutive for ρ_k big enough, where

$$J_l = \operatorname{span}\left\{(dx_a - f_a dt), (d{u_a}^{(j)} - {u_a}^{(j+1)}dt) \mid j \in \lfloor l \rceil\right\}. \tag{8.3}$$

To prove Theorem 8.2 we need the following auxiliary result whose proof is deferred to Appendix A.2.

PROPOSITION 8.3. *Assume that the conditions of the Theorem* 8.2 *are satisfied on an open neighborhood V_ξ of ξ in S. Then, for every $p \in V_\xi$ and $k \in \mathbb{N}$ we have* $\dim(I^{(k)} + J)|_p / J(p) = \dim I^{(k)}(p)$. *Assume that $I^{(k-1)} + J$ has a local basis $B = \bar{B} \cup B_J$, where B_J is a local basis of J and $\bar{B}$ is of the form*

$$\bar{B} = \left\{\omega_i^{(j)} : i \in \lfloor s \rceil, j \in \{0, \ldots, r_i\}\right\}, \tag{8.4}$$

where $\omega_i = d\theta_i - \dot{\theta}_i dt$, $\theta_i \in C^\infty(S)$, $i \in \lfloor s \rceil$ (or $\bar{B} = \emptyset$). Assume that the subset $\{\omega_i^{(r_i)} : i \in \lfloor s \rceil\}$ is linearly independent mod $\{I^{(k)} + J\}$. *Let $\dot{B} = \{\omega_i^{(r_i+1)} : i \in \lfloor s \rceil\}$. Then we may complete the set $B \cup \dot{B}$ with a set $\hat{B} = \{\omega_i, i = s+1, \ldots, \sigma\}$, where $\omega_i = d\theta_i - \dot{\theta}_i dt$ in a way that $B \cup \dot{B} \cup \hat{B}$ is a basis of $I^{(k-2)} + J$ such that $\dot{B} \cup \hat{B}$ is linearly independent* mod $\{I^{(k-1)} + J\}$.

Proof (of Theorem 8.2*).*[18] Let $N \in \mathbb{N}$ be the smallest integer such that $I^{(k)} = I^{(k+1)} = 0$ for all $k \geq N$. Let $\mathcal{B}_N$ be a basis for $J = I^{(N)} + J$ given by $\mathcal{B}_N = \{\eta, \mu_l \mid\ l \in \mathbb{N}\}$, where $\eta = (dx_a - \dot{x}_a dt)$ and $\mu_l = (d{u_a}^{(l)} - {u_a}^{(l+1)}dt), l \in \mathbb{N}$. Since span $\left\{I^{(N-1)}, J, dt\right\}$ is involutive and $I^{(N-1)}$ is nonsingular, by Proposition 8.3 with $\bar{B} = \emptyset$, we can construct a local basis $\mathcal{B}_{N-1}$ of $I^{(N-1)} + J$ of the form $\mathcal{B}_{N-1} = A_{N-1} \cup \mathcal{B}_N$, where $A_{N-1} = \{(d\theta_{1,i_1} - \frac{d}{dt}\theta_{1,i_1}dt) \mid i_1 \in \lfloor s_{N-1} \rceil\}$. Let $\dot{A}_{N-1} = \{(d\theta_{1,i_1}^{(1)} - \theta_{1,i_1}^{(2)}dt), i_1 \in \lfloor s_{N-1} \rceil\}$. By Proposition 8.3, we may construct a set $\hat{A}_{N-1} = \{(d\theta_{2,i_2} - \frac{d}{dt}\theta_{2,i_2}dt) \mid i_2 \in \lfloor s_{N-2} \rceil\}$ in a way that $\mathcal{B}_{N-2} = A_{N-2} \cup \mathcal{B}_N$ is a basis of $I^{(N-2)} + J$, where $A_{N-2} = \hat{A}_{N-1} \cup \dot{A}_{N-1} \cup A_{N-1} = \{(d\theta_{k,i_k}^{(j-1)} - \theta_{k,i_k}^{(j)}dt) \mid k \in \lfloor 2 \rceil, i_k \in \lfloor s_{N-k} \rceil, j \in \lfloor 2-k+1 \rceil\}$. Note also that, by Proposition 8.3, it follows that the set $\hat{A}_{N-1} \cup \dot{A}_{N-1} = \{(d\theta_{k,i_k}^{(2-k)} - \theta_{k,i_k}^{(2-k+1)}dt) \mid k \in \lfloor 2 \rceil, i_k \in \lfloor s_{N-k} \rceil\}$ is linearly independent mod $I^{(N-1)} + J$.

Continuing in this way, using Proposition 8.3, we may construct in the rth step, a basis for $I^{(N-r)} + J$ of the form

$$\mathcal{B}_{N-r} = A_{N-r} \cup \mathcal{B}_N, \tag{8.5}$$

where $A_{N-r} = \hat{A}_{N-r+1} \cup \dot{A}_{N-r+1} \cup A_{N-r+1}$ and

$$\begin{aligned} A_{N-r+1} &= \{(d\theta_{k,i_k}^{(j-1)} - \theta_{k,i_k}^{(j)}dt) \mid k \in \lfloor r-1 \rceil, i_k \in \lfloor s_{N-k} \rceil, j \in \lfloor r-k \rceil\} \\ \hat{A}_{N-r+1} \cup \dot{A}_{N-r+1} &= \{(d\theta_{k,i_k}^{(r-k)} - \theta_{k,i_k}^{(r-k+1)}dt) \mid k \in \lfloor r \rceil, i_k \in \lfloor s_{N-k} \rceil\} \end{aligned} \tag{8.6}$$

and where $\hat{A}_{N-r+1} \cup \dot{A}_{N-r+1}$ is linearly independent mod $\{I^{(N-r+1)} + J\}$ for $r \in \lfloor N+1 \rceil$. From Proposition 8.3, note that $\dim(I^{(k)}(p) + J(p))/J(p) = \dim I^{(k)}(p)$, $k \in \mathbb{N}$.

[18] Most of the techniques that are necessary for the proof of our sufficient condition of relative flatness are very similar to the techniques of the proof of the main result of [35].

Taking $r = N+1$ in (8.6) we obtain a basis $\mathcal{B}_{-1} = A_{-1} \cup B_N$, where $A_{-1} = \hat{A}_0 \cup \dot{A}_0 \cup A_0$ and

$$\begin{aligned} A_0 &= \{(d\theta_{k,i_k}^{(j-1)} - \theta_{k,i_k}^{(j)} dt) \mid k \in \lfloor N \rceil, i_k \in \lfloor s_{N-k} \rceil, j \in \lfloor N-k+1 \rceil\}, \\ \hat{A}_0 \cup \dot{A}_0 &= \{(d\theta_{k,i_k}^{(N-k+1)} - \theta_{k,i_k}^{(N-k+2)} dt) \mid k \in \lfloor N+1 \rceil, i_k \in \lfloor s_{N-k} \rceil\}, \end{aligned} \tag{8.7}$$

where the set $\hat{A}_0 \cup \dot{A}_0$ is independent mod $I^{(0)} + J$. Since $\dim I^{(0)} = n_b$ and $\dim I^{(-1)} = n_b + m_b$ we have card $\hat{A}_0 \cup \dot{A}_0 = m_b$. Now define the set w of n_b (state) functions and the set v of m_b (input) functions given by

$$\begin{aligned} w &= \{w_{k,i_k}^l \mid w_{k,i_k}^l = \theta_{k,i_k}^{(l-1)} : k \in \lfloor N \rceil, i_k \in \lfloor s_{N-k} \rceil, l \in \lfloor N-k+1 \rceil\}, \\ v &= \{v_{k,i_k} \mid v_{k,i_k} = \theta_{k,i_k}^{(N-k+1)} : k \in \lfloor N+1 \rceil, i_k \in \lfloor s_{N-k} \rceil\}. \end{aligned}$$

By construction of $\mathcal{B}_0$ and $\mathcal{B}_{-1}$ it is clear that $I^{(0)} + J + \operatorname{span}\{dt\} = \operatorname{span}\{dt, dx_a, dw\} + J = \operatorname{span}\{dt, dx_a, dx_b\} + J$ and $I^{(-1)} + J + \operatorname{span}\{dt\} = \operatorname{span}\{dt, dx_a, dw, du_a, dv\} = \operatorname{span}\{dt, dx_a, dx_b, du_a, du_b\} + J$. Since card $x_b =$ card w and card $v_b =$ card v then, by Proposition 4.2 we conclude that $((x_a, w), (u_a, v))$ is a state representation that is linked to $((x_a, x_b), (u_a, u_b))$ by relative static-state feedback. Since $I^{(k)} \subset \operatorname{span}\left\{\frac{d}{dt}\right\}^{\perp}$, the equations $\langle (d\theta_{k,i_k}^{(j)} - \theta_{k,i_k}^{(j+1)} dt), \frac{d}{dt} \rangle = 0$, $k \in \lfloor N \rceil$, $i_k \in \lfloor s_{N-k} \rceil$, $j \in \lfloor N-k+1 \rceil$, imply the following closed loop state equations:

$$\begin{aligned} &\dot{t} = 1, \\ &\dot{x}_a = f_a(x_a, u_a) \\ &\left\{ \begin{aligned} \dot{w}_{k,i_k}^1 &= w_{k,i_k}^2, \\ \dot{w}_{k,i_k}^2 &= w_{k,i_k}^3, \\ &\vdots \\ \dot{w}_{k,i_k}^{N-k+1} &= v_{k,i_k}, \end{aligned} \right. \qquad k \in \lfloor N \rceil,\ i_k \in \lfloor s_{N-k} \rceil. \end{aligned} \tag{8.8}$$ □

Remark 8.3. Note that, if $s_{-1} > 0$, then the inputs $\{v_{k,i_k} \mid k = N+1, i_k \in \lfloor s_{-1} \rceil\}$ are completely decoupled from the state of system (8.8), i.e., (8.8) is not well formed in this case [46]. Note also that, if one restricts the coordinate transformations to the class of *relative static-state feedback* (see Definition 4.1), then the conditions of Theorem 8.2 are necessary and sufficient. This follows from the invariance of the relative derived flag with respect to relative static-state feedback (see Corollary 8.4) and after (tedious) calculations of the relative derived flag of a system of the form (8.8).

COROLLARY 8.4. *Consider the system S of equations* (4.1a)–(4.1b). *Let $x = (x_a, x_b)$ and J be defined by* (8.1). *Let $\widehat{I}^{(-1)} = \operatorname{span}\{dx - \dot{x}dt, du - \dot{u}dt\} + J$ and $\widehat{I}^{(k)}(p) = \operatorname{span}\{\omega(p) \mid \omega \in \widehat{I}^{(k-1)},\ d\omega(p) \bmod \widehat{I}^{(k-1)}|_p \equiv 0\}$ for $k \in \mathbb{N}$. Assume that the codistributions $\operatorname{span}\{\widehat{I}^{(k)}, dt\}$ are involutive, $\dim \widehat{I}^{(k)}(q)/J(q)$ is (locally) constant for $k \in \mathbb{N}$, and that $\widehat{I}^{(N)} = J$ for N big enough. Then the system S is (locally) relatively flat with respect to S_1. Furthermore, the codistributions $\widehat{I}^{(k)}$, $k \in \mathbb{N}$, are invariant by relative static-state feedback with respect to the subsystem defined by* (4.1a).

Proof. We show first that $\widehat{I}^{(k)} = I^{(k)} + J$ for $k \in \{-1\} \cup \mathbb{N}$. This is obviously true for $k = -1$. Assume that this is true for $k-1$ and let $\hat{\omega} \in \widehat{I}^{(k-1)}$. Then $\hat{\omega} = \omega + \mu$, where $\omega \in I^{(k-1)}$ and $\mu \in J$. As J is involutive, then $d\hat{\omega} \bmod \widehat{I}^{(k-1)} \equiv 0$ if and only if $d\omega \bmod (I^{(k-1)} + J) \equiv 0$. In particular, $\hat\omega \in \widehat{I}^{(k)}$ if and only if $\omega \in I^{(k)}$. It follows that $\widehat{I}^{(k)} = I^{(k)} + J$, showing our claim. Hence, the first affirmation follows easily from Theorem 8.2. To show the invariance of the flag $\widehat{I}^{(k)}$, let $(\tilde x, \tilde u)$ be a state representation of S that is linked to (x, u) by relative static-state feedback. Let $\widetilde{I}^{(-1)} = \text{span}\,\{d\tilde x - \dot{\tilde x}dt,\, d\tilde u - \dot{\tilde u}dt\} + J$. Since $J + \text{span}\,\{dt\} = \Sigma = \pi^*(T^*S_a)$, by Definition 4.1 it follows $\widetilde{I}^{(-1)} + \text{span}\,\{dt\} = \widehat{I}^{(-1)} + \text{span}\,\{dt\}$. Hence, $\tilde\omega \in \widetilde{I}^{(-1)}$ if and only if $\tilde\omega = \hat\omega + \beta dt$, where $\hat\omega \in \widehat{I}^{(-1)}$. Now note that $\widetilde{I}^{(-1)}$ and $\widehat{I}^{(-1)}$ are both contained in span $\left\{\frac{d}{dt}\right\}^{\perp}$. In particular, $\langle\tilde\omega, \frac{d}{dt}\rangle = \langle\hat\omega, \frac{d}{dt}\rangle = 0$ implies that $\beta = 0$. We conclude that $\widetilde{I}^{(-1)} = \widehat{I}^{(-1)}$. Since the computation of $\widetilde{I}^{(k)}$ follows the same rule as the computation $\widehat{I}^{(k)}$ and J is invariant by endogenous feedback (see Remark 8.1), we conclude that $\widetilde{I}^{(k)} = \widehat{I}^{(k)}, k \in \mathbb{N}$. □

Remark 8.4. Let $\mathcal{U} = \text{span}\,\{dx\}^{\perp}$ and $H = J^{\perp}$. Let $G_0 = \mathcal{U} \cap H$ and let $G_{k+1} = G_k + [\frac{d}{dt}, G_k]$. It can be shown [9] that the conditions of Theorem 8.2 for time-invariant systems are equivalent to the involutivity of the distributions G_i and the existence of k such that $G_i = H$ for all $i \geq k$.

8.1. Flatness and local output subsystems.

8.1. Flatness and local output subsystems. Theorem 8.5 is a sufficient condition for relative flatness with respect to a local output subsystem.

THEOREM 8.5. *Let S be the explicit system* (1.1a) *with state representation* (x, u) *and output $y = h(t, x, u)$. Let U be the open and dense set where Theorem* 4.3 *holds. Let* $\widehat{I}^{(0)} = \text{span}\,\{dx - \dot x dt\} + J$, *where* $J = \text{span}\{dy^{(k-1)} - y^{(k)}dt : k \in \mathbb{N}\}$. *Consider the relative derived flag* $\widehat{I}^{(i)}(p) = \text{span}\{\omega(p) \mid \omega \in \widehat{I}^{(i-1)},\, d\omega(p) \bmod \widehat{I}^{(i-1)}(p) \equiv 0\}$. *Assume that, in U, the codistributions* $\text{span}\{\widehat{I}^{(k)}, dt\}$ *are involutive, and that* $\dim \widehat{I}^{(k)}(q)/J(q)$ *is (locally) constant dimensional for $k \in \mathbb{N}$ and $\widehat{I}^{(N)} = J$ for N big enough. Then S is (locally) relatively flat* with respect to *the output subsystem Y around every $\xi \in U$.*

Proof. By Theorem 4.3 there exists a local output subsystem Y of S and new state representation $((z_a, z_b), (v_a, v_b))$ linked to (x, u) by a relative static-state feedback, such that the closed loop state equations are given by (4.3a)–(4.3b), where $\text{span}\{dt, dz_a, dv_a^{(k)} : k \in \mathbb{N}\} = \text{span}\,\left\{dt, dy^{(k)} : k \in \mathbb{N}\right\} = J + \text{span}\,\{dt\}$. Let $\tilde J = \text{span}\{(dz_a - \dot z_a), (dv_a^{(k)} - v_a^{(k+1)}) : k \in \mathbb{N}\}$. It follows easily that $\tilde J + \text{span}\,\{dt\} = J + \text{span}\,\{dt\}$. Using the fact that $J \subset \text{span}\,\left\{\frac{d}{dt}\right\}^{\perp}$ and $\tilde J \subset \text{span}\,\left\{\frac{d}{dt}\right\}^{\perp}$ (see the arguments of the proof of Corollary 8.4), it follows that $\tilde J = J$. Then the result follows from Corollary 8.4. □

9. Examples.

9.1. An academic example.

9.1. An academic example. Consider the implicit system

$$\dot x_1 = \frac{x_2^2}{(1 + x_3^2)^2} + e^{x_3}u_1, \quad \dot x_2 = (1 + x_3^2)u_1 + \frac{2x_2x_3}{(1 + x_3^2)}u_2, \quad \dot x_3 = u_2, \tag{9.1a}$$

$$y = x_1 = 0. \tag{9.1b}$$

Let S be the (explicit) system (9.1a) with output $y = x_1$. It is easy to verify that the codistributions $\mathcal{Y}_k = \text{span}\,\left\{dt, dy, \ldots, dy^{(k)}\right\}$ and $Y_k = \text{span}\{dt, dx, dy, \ldots, dy^{(k)}\}$ of Lemma B.1 are nonsingular everywhere for $k \in \mathbb{N}$, and $\sigma_k = 1, k \geq 1$. Note also that $\Gamma = \{\xi \in S \mid y^{(k)}(\xi) = 0\}$ is nonempty because Γ contains the point $\xi \in S$ defined by $x_1(\xi) = x_2(\xi) = x_3(\xi) = u_1^{(k)}(\xi) = u_2^{(k)}(\xi) = 0$, $k \in \mathbb{N}$ (for any t). Since the system is time-invariant then the assumptions A1 and A2 of section 6 are satisfied.

By Proposition 6.1, the implicit system is an immersed system in the nonconstrained system. Let $J = \text{span}\{dy^{(k)} - y^{(k+1)}dt : k \in \mathbb{N}\}$ and let $\widehat{I}^{(0)} = \text{span}\,\{dx - \dot{x}dt\} + J$. Using condition (A.3), some calculations show that[19] $\widehat{I}^{(1)} = \text{span}\{\eta - \langle \eta, \frac{d}{dt}\rangle dt\} + J$, where $\eta = dx_2 - \frac{2x_2x_3}{(1+x_3^2)}dx_3$ and $\widehat{I}^{(2)} = J$. Since $d\eta = \frac{2x_3}{(1+x_3^2)}(\eta \wedge dz_3)$, it follows from Theorem 8.5, for every local output subsystem Y, that the explicit system S is relatively flat with respect to Y. By Theorem 7.2, the implicit system Γ defined by (9.1a)–(9.1b) is locally flat around every point $\xi \in \Gamma$. By the proof of Theorem 8.2 and the construction of Γ in section 6, a flat output of the implicit system can be constructed by finding a function ψ such that $d\phi = \alpha\eta$. A possible solution is $\psi = \frac{x_2}{(1+x_3^2)}$.

By Propositions 4.5 and 5.3, one may complete the output y into a flat output (y, z) for system S. In this case one may take $z = \psi$.

9.2. Constrained robots. Constrained robots are robots whose movement is restricted by some physical contact surfaces. Such restrictions can be represented by adding r holonomic constraints $\phi_i(q) = 0 \ \ (i = 1, \ldots, r)$ to its original equations.

The following model can be obtained by taking into account the contact forces [28]:

$$\text{(9.2a)} \qquad \frac{d}{dt}\begin{pmatrix} q \\ \dot{q} \end{pmatrix} = \begin{pmatrix} \dot{q} \\ -M^{-1}H \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ M^{-1}(J\phi)^T & M^{-1} \end{pmatrix}\begin{pmatrix} \lambda \\ \tau \end{pmatrix},$$

$$\text{(9.2b)} \qquad 0 = \phi_i(q),\ i = 1, \ldots, r,$$

where $q \in \mathbb{R}^n$, $J\phi(q) = \partial\phi/\partial q$, $\lambda = (\lambda_1, \ldots, \lambda_r)^T$ is a vector corresponding to the contact forces, $M(q)$ is the symmetric positive definite mass matrix, and $H(q, \dot{q})$ corresponds to Coriolis and gravity forces. We will assume that $\partial\phi/\partial q$ has rank r for all q in the operation region of the robot. Note that system (9.2a)–(9.2b) is in the form (1.1a)–(1.1b).

Let $\psi = (\psi_1, \ldots, \psi_{n-r})$ be chosen in a way that map $q \mapsto (\phi, \psi)$ is a local diffeomorphism. Considering only the explicit system S defined by (9.2a), it is easy to show that (q, λ) is a flat output for S. In particular, (ϕ, ψ, λ) is also a flat output for S. From Corollary 7.3, it follows that (ψ, λ) is a flat output for the constrained robot. Note now that ψ are local coordinates of the constraint surface. In particular, the simultaneous tracking of the position along the constraint surface and the contact forces are possible. The reader may refer to [38] for details and the presentation of the design of a flatness based control, including the underactuated case. Another approach for the solution of this problem is considered, for instance, in [28].

10. Conclusions. In this paper we show that the concept of relative flatness, introduced here, is directly related to the flatness of implicit systems. Sufficient conditions of relative flatness are provided (see Theorem 8.5). This result can be combined with Theorem 7.2 in order to study flatness of implicit systems (1.1a)–(1.1b), as illustrated in the example of section 9.1.

We show, under regularity assumptions, that an implicit system (1.1a)–(1.1b) defines a system Γ (in the sense of section 3.2) that admits state space representations and is immersed in the (explicit) system S defined by (1.1a) (Proposition 6.1). This immersion is in fact an embedding since the topology of the immersed system is the

[19] The application of part (ii) of Lemma A.2 is the easiest way for computing relative derived flags, and lead to linear equations with coefficients that are functions defined on S as shown in the proof of Lemma A.2.

subset topology. This result may be regarded as a generalization of the fact that equation $f(x) = 0$, where $f : \mathbb{R}^n \to \mathbb{R}^p$, defines implicitly an embedded submanifold of $\mathbb{R}^n$ when the Jacobian matrix $Jf(x)$ has constant rank in the solutions of $f(x) = 0$.

Although it is assumed that system (1.1a)–(1.1b) is analytic, this hypothesis is only needed to assure that the output rank ρ of the explicit system (1.1a) with output $y = h(x, u, t)$ is a global invariant, at least in the subset $U \subset S$ of nonsingular points of the codistributions Y_k and $\mathcal{Y}_k$ for $k = 0, \dots, n$ (see Lemma B.1). Note that the differential dimension[20] of the implicit system Γ defined by (1.1a)–(1.1b) is $\tilde{m} = m - \rho$, where $m = \operatorname{card} u$. Hence the assumption of analyticity implies that $\tilde{m}$ is an invariant. All the results of this paper could be rewritten in the smooth case (see [36, Lemma 6.2] for a smooth version of Lemma B.1), but in this case the differential dimension of Γ may depend on the working point. In the same way, it is easy to restrict our results to the time-invariant case (see [36, Lemma 8.1]).

All the definitions and results of this paper are local (note that the time-varying notions are also local in time). The only exception is the construction of the system Γ in section 6 (see Proposition 6.1), that is, a "global" construction.

Appendix A. Proof of auxiliary results.

A.1. Proof of Theorem 4.3. In this proof we use the results and the notations of Lemma B.1. Let $n = \dim x$. By that lemma, around $\xi \in U$, there exists a local state representation (x_n, u_n) defined in V_ξ such that

$$\operatorname{span}\{dt, dx_n\} = \operatorname{span}\left\{dt, dx, dy, \dots, dy^{(n)}\right\}, \tag{A.1a}$$

$$\operatorname{span}\{dt, dx_n, du_n\} = \operatorname{span}\left\{dt, dx, du, dy, \dots, dy^{(n+1)}\right\}, \tag{A.1b}$$

and where $u_n = (\bar{y}_n^{(n+1)}, \hat{u}_n)$. Now choose a subset z_a of $\{y, \dots, y^{(n)}\}$ in a way that $\{dt, dz_a\}$ is a local basis of $\operatorname{span}\left\{dt, dy, \dots, dy^{(n)}\right\}$ and choose z_b in a way that $\{dt, dz_a, dz_b\}$ is a local basis of $\operatorname{span}\left\{dt, dx, dy, \dots, dy^{(n)}\right\}$ around ξ. Let $u_a = \bar{y}_n^{(n+1)}$ and $u_b = \hat{u}_n$. By construction, $((z_a, z_b), (u_a, u_b))$ is a local state-representation of S around ξ, since it is linked to (x_n, u_n) by local static-state feedback (see (3.4)).

By Lemma B.1 part 8, it follows that $\operatorname{span}\{d\dot{z}_a\} \subset \operatorname{span}\{t, z_a, u_a\}$ and that (i) and (ii) hold. Now note that (iii) follows easily from Definition 4.1 and conditions (A.1).

To show that two output subsystems are Lie–Bäcklund isomorphic, let $\pi_i : V_\xi^i \to Y_i$ be local output subsystems for $i = 1, 2$. Assume that $V_\xi^1 \cap V_\xi^2 \neq \emptyset$. We will show that there exist a local Lie–Bäcklund isomorphism $\delta : W_1 \to W_2$, where H is some open neighborhood of ξ for which $H \subset V_\xi^1 \cap V_\xi^2$ and $W_i = \pi_i(H), i = 1, 2$.

Since the π_i are Lie–Bäcklund submersions for $i = 1, 2$, there exists local charts of $\phi_i = (t, X_i, Z_i)$, $i = 1, 2$, defined in some $H \subset S$ and local charts $\psi_i = (t, X_i)$, of Y_i, $i = 1, 2$, defined on $W_i = \pi_i(H)$ such that, in these coordinates $\phi_i \circ \pi_i^{-1} \circ \psi_i(t, X_i, Z_i) = (t, X_i)$, $i = 1, 2$. Since Y_1 and Y_2 are both local subsystems we have $\operatorname{span}\{dt, dX_i\} = \operatorname{span}\left\{dt, dy^{(k)} : k \in \lfloor \mathbb{N} \rceil\right\}$, for $i = 1, 2$. In particular, it follows that the local coordinate change $(t, X_1, Z_1) = \phi_1 \circ \phi_2^{-1}(t, X_2, Z_2)$ is such that $X_1 = \theta(t, X_2)$ and $X_2 = \tilde{\theta}(t, X_1)$. So the map μ defined by $(t, X_2) \mapsto (t, \theta(t, X_2))$ is a local

[20] The local differential dimension is the cardinal of the input of a local state representation. Note that a differential dimension $\tilde{m}$ of a connected smooth system that admits a local state representation around every point is a global invariant [17], [36, Corollary 7.2].

diffeomorphism.[21] Let $\delta : W_2 \subset Y_2 \to W_1 \subset Y_1$ be the local diffeomorphism defined by $\delta = \psi_1^{-1} \circ \mu \circ \psi_2$. To complete the proof it suffices to show that δ is Lie–Bäcklund. For this, we show first that $\delta \circ \pi_2|_H = \pi_1|_H$. In fact, note that

$$\begin{aligned} &\psi_1 \circ (\delta \circ \pi_2) \circ \phi_1^{-1}(t, X_1, Z_1) = \psi_1 \circ (\delta \circ \pi_2 \circ \phi_2^{-1}) \circ (\phi_2 \circ \phi_1^{-1})(t, X_1, Z_1) \\ = \;& (\psi_1 \circ \delta) \circ \pi_2 \circ \phi_2^{-1}(t, X_2, Z_2) = (\mu \circ \psi_2) \circ \pi_2 \circ \phi_2^{-1}(t, X_2, Z_2) \\ = \;& \mu \circ (\psi_2 \circ \pi_2 \circ \phi_2^{-1})(t, X_2, Z_2) = \mu(t, X_2) \\ & \qquad = \; (t, X_1) = \psi_1 \circ \pi_1 \circ \phi_1^{-1}(t, X_1, Z_1). \end{aligned}$$

From the first and the last terms above, we have that $\delta \circ \pi_2|_H = \pi_1|_H$. Denote by ∂_i the Cartan fields, respectively, of Y_i for $i = 1, 2$. By definition, $\pi_i^* \frac{d}{dt} = \partial_i \circ \pi_i$. In particular, $\partial_1 \circ \delta \circ \pi_2 = \partial_1 \circ \pi_1 = (\pi_1) * \frac{d}{dt} = (\delta \circ \pi_2)_* \frac{d}{dt} = \delta_* (\pi_2)_* \frac{d}{dt} = \delta_* \partial_2 \circ \pi_2$. As π_2 is surjective it follows that $\partial_1 \circ \delta = \delta_* \partial_2$, showing that δ is Lie–Bäcklund. □

A.2. Proof of Proposition 8.3. In order to prove Proposition 8.3 we need the following lemmas.

LEMMA A.1. *For all integers $k \geq 0$, $r \geq 0$ and for every point $p \in S$, we have*

(i) $\left(I^{(k)} + J_r + \operatorname{span}\{dt\}\right)\big|_p \cap \operatorname{span}\left\{\frac{d}{dt}\right\}^{\perp} \subset I^{(k)}(p) + J_r$. *The same result also holds when replacing J_r by J;*

(ii) $\operatorname{span}\left\{I^{(k)}, J, dt\right\}|_p = I^{(k)}(p) \oplus J(p) \oplus \operatorname{span}\{dt\}(p)$.

Proof. See [39]. □

LEMMA A.2. *Assume that the conditions of Theorem* 8.2 *are satisfied on an open neighborhood V_ξ of ξ in S. Then $I^{(k)}, k \in \mathbb{N}$, is a smooth codistribution and for every $p \in V_\xi$ and $k \in \mathbb{N}$ we have the following:*

(i) *For all $k \in \mathbb{N}$ there exists a set of covector fields $\Omega = \{\omega_1, \ldots, \omega_{r_k}\} \subset I^{(k)} + J$, where $r_k = \dim I^{(k)}$, $\omega_i = (d\theta_i - \dot{\theta}_i dt)$, with $\theta_i \in C^\infty(S)$, and an open neighborhood V of ξ such that the canonical projections of the elements of $\Omega(\nu)$ form a basis for $(I^{(k)}(\nu) + J(\nu))$ mod $J(\nu)$ for all ν in V.*

(ii) *If ω is of the form $(d\theta - \dot{\theta}dt)$ for a function $\theta \in C^\infty(S)$, then $\omega \in I^{(k+1)} + J$ if and only if $\dot{\omega} \in I^{(k)} + J$. In particular, $I^{(k)} + J \supset I^{(k+1)} + \frac{d}{dt} I^{(k+1)} + J$.*

(iii) *Let $\{\omega_1, \ldots, \omega_r\} \subset I^{(k-1)} + J$ be a set of 1-forms such that $\omega_i = (d\theta_i - \dot{\theta}_i dt)$, where $\theta_i \in C^\infty(S)$. Assume that the set $\{\omega_1(p), \ldots, \omega_r(p)\}$ is linearly independent*[22] mod $I^{(k)}(p) + J(p)$. *Then $\{\dot{\omega}_1(p), \ldots, \dot{\omega}_r(p)\} \subset (I^{(k-2)}(p) + J(p))$ is linearly independent* mod $(I^{(k-1)} + J + \operatorname{span}\{dt\})|_p$.

Proof. Assume by induction that $I^{(j)}, j = -1, 0, \ldots, k$ is smooth. We will show first that (i) and (ii) holds.

(i) We now show that, for an integer l_k big enough, $\operatorname{span}\left\{I^{(k)}, J_{l_k}, dt\right\}$ is involutive (see (8.3)). In fact, since $I^{(k)}$ is nonsingular and finite dimensional, there exist a local basis $\{\tilde{\omega}_i : i \in \lfloor r_k \rceil\}$ of $I^{(k)}$. By part (ii) of Lemma A.1, it follows that the set $\{(\tilde{\omega}_i : i \in \lfloor r_k \rceil), dx_a, du_a, \ldots, du_a^{(l_k)}, dt\}$ is a local basis of $I^{(k)} + J_{l_k} + \operatorname{span}\{dt\}$. Since the codistribution $\operatorname{span}\left\{I^{(k)}, J, dt\right\}$ is involutive, then $d\tilde{\omega}_i = \sum_{j=1}^{r_k} \eta_{ij} \wedge \nu_{ij}$ for convenient 1-forms η_{ij}, ν_{ij} with $\nu_{ij} \in \operatorname{span}\left\{I^{(k)}, J, dt\right\}$. Hence $\nu_{ij} \in \operatorname{span}\{(\tilde{\omega}_i : i \in \lfloor r_k \rceil), dx_a, du_a, \ldots, du_a^{(s_{ij})}, dt\}$. Let $l_k^* = \max_{i,j}\{s_{ij}\}$. Then $\operatorname{span}\left\{I^{(k)}, J_{l_k}, dt\right\}$ is involutive for every $l_k \geq l_k^*$. By the Frobenius theorem and part

[21] We stress that we are not using the inverse function theorem, but only the existence of the inverse of the coordinate change map.

[22] The linear independence of the set $\{\omega_1(p), \ldots, \omega_r(p)\}$ mod $(I^{(k)}(p) + J)$ for some $p \in S$ means that $\left(\sum_{i=1}^{r} \alpha_i \omega_i(p) + \omega(p)\right)\big|_p = 0$ for $\omega \in I^{(k)} + J$ and $\alpha_i \in \mathbb{R}$ implies that $\omega(p) = 0$ and $\alpha_i = 0$.

(ii) of Lemma A.1, we see that span $\left\{I^{(k)}, J_{l_k}, dt\right\}$ is spanned by linearly independent 1-forms $\{d\theta_1, \dots d\theta_{r_k}, dx_a, du_a, \dots, du_a{}^{(l_k)}, dt\}$, where $\dim I^{(k)} = r_k$. Now note that $\omega_i = (d\theta_i - \dot{\theta}_i dt) \in \text{span}\left\{\frac{d}{dt}\right\}^{\perp}$. Since $\omega_i \in \text{span}\left\{I^{(k)}, J_{l_k}, dt\right\}$, by Lemma A.1 part (i) it follows that $\omega_i \in I^{(k)} + J_{l_k}$. Let $K = \text{span}\,\{J_{l_k}, dt\}\,|_p$ and $L = \text{span}\,\{J, dt\}_p$. By construction the canonical projection of the set $\{\omega_i, i \in \lfloor r_k \rceil\}$ on $(I^{(k)}(p) + K)/K$ forms a basis of $(I^{(k)}(p) + K)/K$. By part (ii) of Lemma A.1, it is easy to see that the map $\Psi : (I^{(k)}(p) + K)/K \to (I^{(k)}(p) + L)/L$ such that $\omega(p) \bmod K \mapsto \omega(p) \bmod L$ is an isomorphism. In particular, the canonical projections of the ω_i on $(I^{(k)}(p) + L)/L$ also form a basis.

(ii) It is easy to verify by direct computation that (see [39])

$$d\omega(p) \bmod (I^{(k)}(p) + J(p)) \equiv - \left.\dot{\omega} \wedge dt\right|_p \bmod (I^{(k)}(p) + J(p)) \tag{A.2}$$

for all $p \in S$.

Now we will show that, for all $p \in S$ and $\omega \in I^{(k)}$, we have

$$\omega(p) \in I^{(k+1)}(p) \;\Leftrightarrow\; \dot{\omega}(p) \in \text{span}\left\{I^{(k)}, J, dt\right\}(p). \tag{A.3}$$

Let $\{dt, (\omega_i : i \in \lfloor r_k \rceil), \eta, (\mu_j : j \in \lfloor l_k \rceil)\}$ be a basis for span $\left\{I^{(k)}, J_{l_k}, dt\right\}$. Notice that $\left.\dot{\omega} \wedge dt\right|_p \bmod (I^{(k)}(p) + J(p)) \equiv 0$ means that $\left.\dot{\omega} \wedge dt\right|_p + \sum_{i=1}^{r_k} \left.\zeta_i \wedge \omega_i\right|_p + \left.\xi \wedge \eta\right|_p + \sum_{j=i}^{l_k} \rho_j \wedge \mu_j|_p = 0$ for convenient 1-forms ζ_i, ξ, ρ_j. From the Cartan lemma (see section 2), we conclude that $\dot{\omega}(p) \in \text{span}\left\{I^{(k)}, J_{l_k}, dt\right\}(p)$. Then, (A.3) follows from (A.2) and Definition 8.1. It is easy to show that the same arguments and the fact that J is involutive imply that

$$\omega(p) \in I^{(k+1)}(p) + J(p) \;\Leftrightarrow\; \dot{\omega}(p) \in \text{span}\left\{I^{(k)}, J, dt\right\}(p). \tag{A.4}$$

If $\omega = d\theta - \dot{\theta}dt$ then $\dot{\omega} \in \text{span}\left\{\frac{d}{dt}\right\}^{\perp}$. By (A.4) and from Lemma A.1 part (i), it follows that $\dot{\omega} \in I^{(k)} + J$. Now note that, by (i), $I^{(k+1)} + J$ has a basis for this particular form. This completes the proof of (ii). We show now that our induction hypothesis (i.e., that $I^{(j)}$ is smooth for $j = -1, 0, \dots, k$) implies that $I^{(k+1)}$ is smooth. In fact, by the proof of (i), given a local basis $\{\tilde{\omega}_i : i \in \lfloor r_k \rceil\}$ of $I^{(k)}$, there exists a local basis $\{(\tilde{\omega}_i : i \in \lfloor r_k \rceil), dx_a, (du_a^{(k)} : k \in \mathbb{N}), dt\}$ of $W_k = \text{span}\left\{I^{(k)}, J, dt\right\}$. Note that $W_k \subset W_0 = \text{span}\,\{dx_b, J, dt\}$. In particular, we have $\tilde{\omega}_i = \hat{\omega}_i + \gamma_i$, where $\hat{\omega}_i \in \text{span}\,\{dx_b\}$ and $\gamma_i \in \text{span}\,\{J, dt\} = T^*S_a$. Note that $\mu_i = \dot{\gamma}_i \in \text{span}\,\{J, dt\}$ and we may replace $\tilde{\omega}_i$ by $\hat{\omega}_i$ in the basis of W_k , obtaining another basis of W_k. Note also that there exists a subset $\hat{x}_b$ of x_b such that $\{d\hat{x}_b, du_b, (\tilde{\omega}_i : i \in \lfloor r_k \rceil), dx_a, (du_a^{(k)} : k \in \mathbb{N}), dt\}$ is a basis of W_{-1}. Let $z = (\hat{x}_b, u_b)$. Let $\dot{\tilde{\omega}}_i = \dot{\hat{\omega}}_i + \dot{\gamma}_i = \sum_j a_{ij} dz_j + \mu_i$, where $\mu_i \in \text{span}\,\{J, dt\}$. Denote the matrix formed by the functions a_{ij} by A. By (A.3), $\omega(p) = \sum_j \alpha_i \tilde{\omega}_i \in I^{(k+1)}(p)$ if and only if $\sum_j (\dot{\alpha}_i \tilde{\omega}_i + \alpha_i \dot{\tilde{\omega}}_i)|_p \in W_k(p)$. Denoting by α the column vector with components α_i, then $\omega(p) \in I^{(k+1)}(p)$ if and only if $A(p)\alpha(p) = 0$. Then $I^{(k+1)}$ is nonsingular if and only if $A(p)$ has (locally) constant rank and in this case it is clear that $I^{(k)}$ is smooth.[23]

(iii) To prove (iii), assume that there exists ω in $I^{(k-1)} + J$ and functions $\alpha_i \in C^\infty(S)$ such that for $p \in S$, then $\left.(\omega + \alpha_0 dt + \sum_{i=1}^{r} \alpha_i \dot{\omega}_i)\right|_p = 0$. Hence, $\left.\{[\omega - \sum_{i=1}^{r} (\dot{\alpha}_i)\omega_i] + \alpha_0 dt + \frac{d}{dt}(\sum_{i=1}^{r} \alpha_i \omega_i)\}\right|_p = 0$. Since $[\omega - \sum_{i=1}^{r} (\dot{\alpha}_i)\omega_i](p) \in I^{(k-1)}(p) + J(p)$, it follows that $\left.\frac{d}{dt}(\sum_{i=1}^{r} \alpha_i \omega_i)\right|_p \in \text{span}\left\{I^{(k-1)}, J, dt\right\}(p)$. It follows

[23] This proof also shows that one may compute the relative derived flag by solving linear equations.

from (A.4) that $(\sum_{i=1}^{r}\alpha_i\omega_i)(p) \in I^{(k)}(p) + J(p)$ and hence the set $\{\omega_1, \dots, \omega_r\}$ is not linearly independent mod $I^{(k)} + J(p)$ in $p \in S$. □

Proof (of Proposition 8.3*).* Since $\omega_i = d\theta_i - \dot{\theta}_i dt$, $i \in \lfloor s\rceil$, by part (ii) of Lemma A.1, the set $\mathcal{B} = \{(d\theta_i^{(j)}, j \in \{0, \dots, r_i\}, i \in \lfloor s\rceil), dx_a, du_a, \dots, du_a^{(l_{k-1})}, dt\}$ is a local basis of $I^{(k-1)} + J_{l_{k-1}} + \operatorname{span}\{dt\}$ for any $l_{k-1} > l^*_{k-1}$ for some l^*_{k-1}.

By part (iii) of Lemma A.2, $\dot{B}$ is linearly independent mod $\{I^{(k-1)} + J + \operatorname{span}\{dt\}\}$. Hence $\mathcal{B} \cup \dot{\mathcal{B}} = \{(d\theta_i^{(j)}, j \in \{0, \dots, r_i + 1\}, i \in \lfloor s\rceil), dx_a, du_a, \dots, du_a^{(l_{k-1})}, dt\}$ is linearly independent for all l_{k-1}.

From the proof of part (i) of Lemma A.2, we also have that there exists a local basis $\{(\tilde{\theta}_i : i \in \lfloor r\rceil), dx_a, du_a, \dots, du_a^{(l_{k-2})}, dt\}$ of $I^{(k-2)} + J_{l_{k-2}} + \operatorname{span}\{dt\}$ for every $l_{k-2} \geq l^*_{k-2}$. Let $l_{k-1} = l_{k-2} = \max\{l^*_{k-1}, l^*_{k-2}\}$.

As $I^{(k-1)} \subset I^{(k-2)}$, we may complete $\mathcal{B} \cup \dot{\mathcal{B}}$ with a subset $\hat{\mathcal{B}} = \{\theta_i, i = s+1, \dots, \sigma\}$ of $\{\tilde{\theta}_i : i \in \lfloor r\rceil\}$ in order to form a basis of $I^{(k-2)} + J_{l_{k-2}} + \operatorname{span}\{dt\}$. By the same reasoning of the end of the proof of part (i) of Lemma A.2, it follows that $B \cup \dot{B} \cup \hat{B}$ is a basis of $I^{(k-2)} + J$. The fact that $\dot{\mathcal{B}} \cup \hat{\mathcal{B}}$ is linearly independent mod $(I^{(k-1)} + J + \operatorname{span}\{dt\})$ implies that $\dot{B} \cup \hat{B}$ is also linearly independent mod $(I^{(k-1)} + J)$. □

Appendix B. Geometric interpretation of the dynamic extension algorithm.

In [13] it was shown, using an algebraic approach, that the output rank (the number of differentially independent outputs [14]) can be computed by the *structure algorithm* [49] and the *dynamic extension algorithm* [12, 33]. This interpretation was developed further in [10] in order to study control synthesis problems by quasi-static state feedback. In [36], the algebraic results of [13, 10] are translated to the differential geometric approach of [19], giving the following lemma.

Lemma B.1 (see [36, Lemma 8.2]). *Consider the analytic (explicit) system S defined by* (1.1a) *with analytic output $y = h(t, x, u)$. Let S_k be the open and dense set of regular points of the codistributions $Y_i = \operatorname{span}\{dt, dy, \dots, dy^{(i)}\}$ and $\mathcal{Y}_i =$ span $\{dt, dx, dy, \dots, dy^{(i)}\}$. In the kth step of the dynamic extension algorithm, one may construct a partition*[24] *$y = (\bar{y}_k, \hat{y}_k)$ and a new local classical state representation (x_k, u_k) of the system S with state $x_k = (x, \bar{y}_0^{(0)}, \dots, \bar{y}_k^{(k)})$ and input $u_k = (\bar{y}_k^{(k+1)}, \hat{u}_k)$, defined in an open neighbourhood V_ξ of $\xi \in S_k$, such that*

1. $\operatorname{span}\{dt, dx_k\} = \operatorname{span}\{dt, dx, dy, \dots, dy^{(k)}\}$.
2. $\operatorname{span}\{dt, dx_k, du_k\} = \operatorname{span}\{dt, dx, dy, \dots, dy^{(k+1)}, du\}$.
3. *It is always possible to choose $\bar{y}_{k+1}^{(k+1)}$ in a way that $\bar{y}_k^{(k+1)} \subset \bar{y}_{k+1}^{(k+1)}$.*
4. *It is always possible to choose $\hat{u}_{k+1} \subset \hat{u}_k$.*
5. *Let $\mathcal{D}(\mathcal{C})$ denote the generic dimension of a codistribution $\mathcal{C}$ generated by the differentials of a finite set of analytic functions. The sequence $\sigma_k = \mathcal{D}(\mathcal{Y}_k) - \mathcal{D}(\mathcal{Y}_{k-1})$ is nondecreasing, the sequence $\rho_k = \mathcal{D}(Y_k) - \mathcal{D}(Y_{k-1})$ is nonincreasing, and both sequences converge to the same integer ρ, called the* output rank, *for some $k^* \leq n =$* $\dim x$.
6. *$S_k = S_{k^*}$ for $k \geq k^*$.*
7. *$Y_k \cap \operatorname{span}\{dx\}|_\nu = Y_{k^*-1} \cap \operatorname{span}\{dx\}|_\nu$ for every $\nu \in S_{k^*}$ and $k \geq k^*$.*
8. *Around $\xi \in U_k$, one may choose, $\bar{y}_k = \bar{y}_{k^*}$ for $k \geq k^*$. Furthermore, $Y_{k+1} =$* $Y_k + \operatorname{span}\{\bar{y}_k^{(k+1)}\}$ *for $k \geq k^*$.*

[24] Including a possible reordering of the outputs.

Proof. A complete proof of this result can be found in [36] (see [13, Theorem 2.5] and [10, Lemma 4.1.6] for similar results in algebraic contexts). □

FEEDBACK STABILIZATION OVER COMMUTATIVE RINGS: FURTHER STUDY OF THE COORDINATE-FREE APPROACH[*]

KAZUYOSHI MORI[†][‡] AND KENICHI ABE[†]

Abstract. This paper is concerned with the coordinate-free approach to control systems. The coordinate-free approach is a factorization approach but does not require the coprime factorizations of the plant. We present two criteria for feedback stabilizability for multi-input multi-output (MIMO) systems in which transfer functions belong to the total rings of fractions of commutative rings. Both of them are generalizations of Sule's results in [*SIAM J. Control Optim.*, 32 (1994), pp. 1675–1695]. The first criterion is expressed in terms of modules generated from a causal plant and does not require the plant to be strictly causal. It shows that if the plant is stabilizable, the modules are projective. The other criterion is expressed in terms of ideals called generalized elementary factors. This gives the stabilizability of a causal plant in terms of the coprimeness of the generalized elementary factors. As an example, a discrete finite-time delay system is considered.

Key words. linear systems, feedback stabilization, coprime factorization over commutative rings

1. Introduction.

In this paper we are concerned with the coordinate-free approach to control systems. This approach is a factorization approach but does not require the coprime factorizations of the plant.

The factorization approach to control systems has the advantage that it embraces, within a single framework, numerous linear systems such as continuous-time as well as discrete-time systems, lumped as well as distributed systems, one-dimensional as well as n-dimensional systems, etc. [14]. This factorization approach was patterned after Desoer et al. [3] and Vidyasagar, Schneider, and Francis [14]. In this approach, when problems such as feedback stabilization are studied, one can focus on the key aspects of the problem under study rather than be distracted by the special features of a particular class of linear systems. A transfer function of this approach is given as the ratio of two stable causal transfer functions, and the set of stable causal transfer functions is a commutative ring. For a long time, the theory of the factorization approach had been founded on the coprime factorizability of transfer matrices, which is satisfied in the case where the set of stable causal transfer functions is such a commutative ring as a Euclidean domain, a principal ideal, or a Bézout domain. However, Anantharam in [1] showed that there exist models in which some stabilizable plants do not have right-/left-coprime factorizations.

Recently, Shankar and Sule in [10] have presented a theory of feedback stabilization for single-input single-output (SISO) transfer functions having fractions over general integral domains. Moreover, Sule in [11, 12] has presented a theory of the

feedback stabilization of strictly causal plants for multi-input multi-output (MIMO) transfer matrices, in which transfer functions belong to the total rings of fractions of commutative rings, with some restrictions. Their approach to the control systems is called a "coordinate-free approach" [10, p. 15] in the sense that they do not require the coprime factorizability of transfer matrices. Our objective in this paper is to decrease the restrictions in order to make further comprehensive theory of the coordinate-free approach, so that the theory can be applied to more and more linear control models including ones not yet well understood.

The main contribution of this paper consists of providing two criteria for feedback stabilizability for MIMO systems in which transfer functions belong to the total rings of fractions of commutative rings: the first criterion is expressed in terms of modules ((ii) of Theorem 3.3) and the other in terms of ideals called generalized elementary factors ((iii) of Theorem 3.3). They are more general than Sule's results in the following sense: (i) our results do not require that plants are strictly causal; (ii) we do not employ the restriction of commutative rings. Further, we will not use the theory of algebraic geometry.

The paper is organized as follows. In section 2, we give mathematical preliminaries, set up the feedback stabilization problem, present the previous results, and define the causality of the transfer functions. In section 3, we state our main results. As a preface to our main results, we also introduce there the notion of the generalized elementary factor of a plant. In section 4, we give intermediate results which we will utilize in the proof of the main theorem. In section 5, we prove our main theorem. In section 6, we discuss the causality of the stabilizing controllers. Also, in order to make the contents clear, we present examples concerning a discrete finite-time delay system in sections 3, 4, and 5 consecutively.

2. Preliminaries.

In the following we begin by introducing the notations of commutative rings, matrices, and modules commonly used in this paper. Then we give the formulation of the feedback stabilization problem and the previous results.

2.1. Notations.

Commutative rings. In this paper, we consider that any commutative ring has the identity 1 different from zero. Let $\mathcal{R}$ denote a commutative ring. A *zerodivisor* in $\mathcal{R}$ is an element x for which there exists a nonzero y such that $xy = 0$. In particular, a zerodivisor x is said to be *nilpotent* if $x^n = 0$ for some positive integer n. The set of all nilpotent elements in $\mathcal{R}$, which is an ideal, is called the *nilradical* of $\mathcal{R}$. A *nonzerodivisor* in $\mathcal{R}$ is an element which is not a zerodivisor. The total ring of fractions of $\mathcal{R}$ is denoted by $\mathcal{F}(\mathcal{R})$.

The set of all prime ideals of $\mathcal{R}$ is called the *prime spectrum* of $\mathcal{R}$ and is denoted by $\operatorname{Spec}\mathcal{R}$. The prime spectrum of $\mathcal{R}$ is said to be *irreducible* as a topological space if every nonempty open set is dense in $\operatorname{Spec}\mathcal{R}$.

We will consider that the set of stable causal transfer functions is a commutative ring, denoted by $\mathcal{A}$. From the sense of the transfer functions we consider that the commutative ring $\mathcal{A}$ satisfies the invariant basis property (cf. [6]). In addition to $\mathcal{A}$, we will use the following three kinds of rings of fractions:

(i) The first one appears as the total ring of fractions of $\mathcal{A}$, which is denoted by $\mathcal{F}(\mathcal{A})$ or simply by $\mathcal{F}$; that is, $\mathcal{F} = \{n/d \mid n, d \in \mathcal{A},\ d \text{ is a nonzerodivisor}\}$. This will be considered to be the set of all possible transfer functions. If the commutative ring $\mathcal{A}$ is an integral domain, $\mathcal{F}$ becomes a field of fractions of $\mathcal{A}$. However, if $\mathcal{A}$ is not an integral domain, then $\mathcal{F}$ is not a field, because any zerodivisor of $\mathcal{F}$ is not a unit.

(ii) The second one is associated with the set of powers of a nonzero element of $\mathcal{A}$. Suppose that f denotes a nonzero element of $\mathcal{A}$. Given a set $S_f = \{1, f, f^2, \ldots\}$, which is a multiplicative subset of $\mathcal{A}$, we denote by $\mathcal{A}_f$ the ring of fractions of $\mathcal{A}$ with respect to the multiplicative subset S_f; that is, $\mathcal{A}_f = \{n/d \,|\, n \in \mathcal{A},\ d \in S_f\}$. We point out two facts here: (a) In the case where f is nilpotent, $\mathcal{A}_f$ becomes isomorphic to $\{0\}$. (b) In the case where f is a zerodivisor, even if the equality $a/1 = b/1$ holds over $\mathcal{A}_f$ with $a, b \in \mathcal{A}$, we cannot say in general that $a = b$ over $\mathcal{A}$; alternatively, $a = b + z$ over $\mathcal{A}$ holds with some zerodivisor z of $\mathcal{A}$ such that $zf^\omega = 0$ with a sufficiently large integer ω.

(iii) The last one is the total ring of fractions of $\mathcal{A}_f$, which is denoted by $\mathcal{F}(\mathcal{A}_f)$; that is, $\mathcal{F}(\mathcal{A}_f) = \{n/d \,|\, n, d \in \mathcal{A}_f,\ d \text{ is a nonzerodivisor of } \mathcal{A}_f\}$. If f is a nonzerodivisor of $\mathcal{A}$, $\mathcal{F}(\mathcal{A}_f)$ coincides with the total ring of fractions of $\mathcal{A}$. Otherwise, they may not coincide.

The reader is referred to Chapter 3 of [2] for the ring of fractions and to Chapter 1 of [2] for the prime spectrum.

In the rest of the paper, we will use $\mathcal{R}$ as an unspecified commutative ring and mainly suppose that $\mathcal{R}$ denotes either $\mathcal{A}$ or $\mathcal{A}_f$.

Matrices. Suppose that x and y denote sizes of matrices.

The set of matrices over $\mathcal{R}$ of size $x \times y$ is denoted by $\mathcal{R}^{x\times y}$. In particular, the set of square matrices over $\mathcal{R}$ of size x is denoted by $(\mathcal{R})_x$. A square matrix is called *singular* over $\mathcal{R}$ if its determinant is a zerodivisor of $\mathcal{R}$ and *nonsingular* otherwise. The identity and the zero matrices are denoted by E_x and $O_{x\times y}$, respectively, if the sizes are required, otherwise they are denoted simply by E and O. For a matrix A over $\mathcal{R}$, the inverse matrix of A is denoted by A^{-1} provided that $\det(A)$ is a unit of $\mathcal{F}(\mathcal{R})$. The ideal generated by $\mathcal{R}$-linear combination of all minors of size m of a matrix A is denoted by $I_{m\mathcal{R}}(A)$.

Matrices A and B over $\mathcal{R}$ are *right-coprime over* $\mathcal{R}$ if there exist matrices $\widetilde{X}$ and $\widetilde{Y}$ over $\mathcal{R}$ such that $\widetilde{X}A + \widetilde{Y}B = E$. Analogously, matrices $\widetilde{A}$ and $\widetilde{B}$ over $\mathcal{R}$ are *left-coprime over* $\mathcal{R}$ if there exist matrices X and Y over $\mathcal{R}$ such that $\widetilde{A}X + \widetilde{B}Y = E$. Note that, in the sense of the above definition, even if two matrices have no common right-(left-)divisors except invertible matrices, they may not be right-(left-)coprime over $\mathcal{R}$. (For example, two matrices $[\,z_1\,]$ and $[\,z_2\,]$ of size 1×1 over the bivariate polynomial ring $\mathbb{R}[z_1, z_2]$ over the real field $\mathbb{R}$ are neither right- nor left-coprime over $\mathbb{R}[z_1, z_2]$ in our setting.) Further, a pair (N, D) of matrices N and D is said to be a *right-coprime factorization of P over $\mathcal{R}$* if (i) the matrix D is nonsingular over $\mathcal{R}$, (ii) $P = ND^{-1}$ over $\mathcal{F}(\mathcal{R})$, and (iii) N and D are right-coprime over $\mathcal{R}$. Also, a pair $(\widetilde{N}, \widetilde{D})$ of matrices $\widetilde{N}$ and $\widetilde{D}$ is said to be a *left-coprime factorization of P over $\mathcal{R}$* if (i) $\widetilde{D}$ is nonsingular over $\mathcal{R}$, (ii) $P = \widetilde{D}^{-1}\widetilde{N}$ over $\mathcal{F}(\mathcal{R})$, and (iii) $\widetilde{N}$ and $\widetilde{D}$ are left-coprime over $\mathcal{R}$. As we have seen, in the case where a matrix is potentially used to express *left* fractional form and/or *left* coprimeness, we usually attach a tilde "$\widetilde{\ }$" to a symbol; for example $\widetilde{N}$, $\widetilde{D}$ for $P = \widetilde{D}^{-1}\widetilde{N}$ and $\widetilde{Y}$, $\widetilde{X}$ for $\widetilde{Y}N + \widetilde{X}D = E$.

Modules. For a matrix A over $\mathcal{R}$, we denote by $M_r(A)$ $(M_c(A))$ the $\mathcal{R}$-module generated by rows (columns) of A.

Suppose that A, B, $\widetilde{A}$, $\widetilde{B}$ are matrices over $\mathcal{R}$ and X is a matrix over $\mathcal{F}(\mathcal{R})$ such that $X = AB^{-1} = \widetilde{B}^{-1}\widetilde{A}$ with B and $\widetilde{B}$ being nonsingular. Then the $\mathcal{R}$-module $M_r([\,A^t \quad B^t\,]^t)$ $(M_c([\,\widetilde{A} \quad \widetilde{B}\,]))$ is uniquely determined up to isomorphism with respect to any choice of fractions AB^{-1} $(\widetilde{B}^{-1}\widetilde{A})$ of X as shown in Lemma 2.1 below. Thus for a matrix X over $\mathcal{F}(\mathcal{R})$, we denote by $\mathcal{T}_{X,\mathcal{R}}$ and $\mathcal{W}_{X,\mathcal{R}}$ the mod-

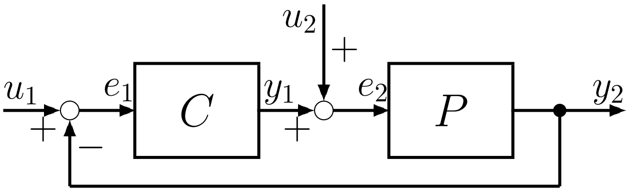

FIG. 2.1. *Feedback system* Σ.

ules $M_r([\,A^t \quad B^t\,]^t)$ and $M_c([\,\widetilde{A} \quad \widetilde{B}\,])$, respectively. If $\mathcal{R} = \mathcal{A}$, we write simply $\mathcal{T}_X$ and $\mathcal{W}_X$ for $\mathcal{T}_{X,\mathcal{A}}$ and $\mathcal{W}_{X,\mathcal{A}}$, respectively. We will use, for example, the notations $\mathcal{T}_P$, $\mathcal{W}_P$, $\mathcal{T}_C$, and $\mathcal{W}_C$ for the matrices P and C over $\mathcal{F}$.

An $\mathcal{R}$-module M is called *free* if it has a basis, that is, a linearly independent system of generators. The *rank* of a free $\mathcal{R}$-module M is equal to the cardinality of a basis of M, which is independent of the basis chosen. An $\mathcal{R}$-module M is called *projective* if it is a direct summand of a free $\mathcal{R}$-module, that is, there is a module N such that $M \oplus N$ is free. The reader is referred to Chapter 2 of [2] for the module theory.

LEMMA 2.1. *Suppose that X is a matrix over $\mathcal{F}(\mathcal{R})$ and is expressed in the form of a fraction $X = AB^{-1} = \widetilde{B}^{-1}\widetilde{A}$ with some matrices A, B, $\widetilde{A}$, $\widetilde{B}$ over $\mathcal{R}$. Then the $\mathcal{R}$-module $M_r([\,A^t \quad B^t\,]^t)$ $(M_c([\,\widetilde{A} \quad \widetilde{B}\,]))$ is uniquely determined up to isomorphism with respect to any choice of fractions AB^{-1} $(\widetilde{B}^{-1}\widetilde{A})$ of X.*

Proof. Without loss of generality, it is sufficient to show that $M_r([\,A_1^t \quad b_1E\,]^t) \simeq M_r([\,A_2^t \quad B_2^t\,]^t)$, where $b_1 \in \mathcal{R}$ and $A_1(b_1E)^{-1} = A_2B_2^{-1}$. Since b_1 is a nonzerodivisor and B_2 is nonsingular, we have $M_r([\,A_1^t \quad b_1E\,]^t) \simeq M_r([\,A_1^t \quad b_1E\,]^t B_2) \simeq M_r([\,A_2^t \quad B_2^t\,]^t b_1E) \simeq M_r([\,A_2^t \quad B_2^t\,]^t)$. The other isomorphism can be proved analogously. □

2.2. Feedback stabilization problem. The stabilization problem considered in this paper follows that of Sule in [11], who considers the feedback system Σ [13, Chapter 5, Figure 5.1] as in Figure 2.1. For further details, see [13]. Let a commutative ring $\mathcal{A}$ represent the set of *stable causal* transfer functions. The total ring of fractions of $\mathcal{A}$, denoted by $\mathcal{F}$, consists of *all* possible transfer functions. The set of matrices of size $x \times y$ over $\mathcal{A}$, denoted by $\mathcal{A}^{x\times y}$, coincides with the set of stable causal transfer matrices of size $x \times y$. Also the set of matrices of size $x \times y$ over $\mathcal{F}$, denoted by $\mathcal{F}^{x\times y}$, coincides with all possible transfer matrices of size $x \times y$. Throughout the paper, the plant we consider has m inputs and n outputs, and its transfer matrix, which itself is also called simply a *plant*, is denoted by P and belongs to $\mathcal{F}^{n\times m}$. We will occasionally consider matrices over $\mathcal{A}$ $(\mathcal{F})$ as ones over $\mathcal{A}_f$ or $\mathcal{F}$ $(\mathcal{F}(\mathcal{A}_f))$ by natural mapping.

DEFINITION 2.2. *Define $\widehat{F}_{\mathrm{ad}}$ by*

$$\widehat{F}_{\mathrm{ad}} = \{(X,Y) \in \mathcal{F}^{x\times y} \times \mathcal{F}^{y\times x} \mid \ \det(E_x + XY) \text{ is a unit of } \mathcal{F}, \\ x \text{ and } y \text{ are positive integers}\}.$$

For $P \in \mathcal{F}^{n\times m}$ and $C \in \mathcal{F}^{m\times n}$, the matrix $H(P,C) \in (\mathcal{F})_{m+n}$ is defined by

$$H(P,C) = \begin{bmatrix} (E_n + PC)^{-1} & -P(E_m + CP)^{-1} \\ C(E_n + PC)^{-1} & (E_m + CP)^{-1} \end{bmatrix} \tag{2.1}$$

provided $(P, C) \in \widehat{F}_{\mathrm{ad}}$. *This* $H(P, C)$ *is the transfer matrix from* $[\, u_1^t \quad u_2^t \,]^t$ *to* $[\, e_1^t \quad e_2^t \,]^t$ *of the feedback system* Σ. *If* (i) $(P, C) \in \widehat{F}_{\mathrm{ad}}$ *and* (ii) $H(P, C) \in (\mathcal{A})_{m+n}$, *then we say that the plant* P *is* stabilizable, P *is* stabilized *by* C, *and* C *is a* stabilizing controller *of* P.

Here we define the causality of transfer functions, which is an important physical constraint, used in this paper. We employ the definition of causality from Vidyasagar, Schneider, and Francis [14, Definition 3.1] and introduce two terminologies later used frequently.

Definition 2.3. *Let* $\mathcal{Z}$ *be a prime ideal of* $\mathcal{A}$, *with* $\mathcal{Z} \neq \mathcal{A}$, *including all zerodivisors. Define the subsets* $\mathcal{P}$ *and* $\mathcal{P}_S$ *of* $\mathcal{F}$ *as follows:*

$$\mathcal{P} = \{n/d \in \mathcal{F} \,|\, n \in \mathcal{A},\ d \in \mathcal{A}\backslash\mathcal{Z}\}, \quad \mathcal{P}_S = \{n/d \in \mathcal{F} \,|\, n \in \mathcal{Z},\ d \in \mathcal{A}\backslash\mathcal{Z}\}.$$

A transfer function in $\mathcal{P}$ $(\mathcal{P}_S)$ *is called* causal (strictly causal). *Similarly, if every entry of a transfer matrix over* $\mathcal{F}$ *is in* $\mathcal{P}$ $(\mathcal{P}_S)$, *the transfer matrix is called* causal (strictly causal). *A transfer matrix is said to be* $\mathcal{Z}$-nonsingular *if the determinant is in* $\mathcal{A}\backslash\mathcal{Z}$ *and to be* $\mathcal{Z}$-singular *otherwise.*

In [14], the ideal $\mathcal{Z}$ is not restricted to a prime ideal in general. On the other hand, in [11], the set of the denominators of causal transfer functions is a multiplicatively closed subset of $\mathcal{A}$. This property is natural since the multiplication of two causal transfer functions should be considered as causal one. Note that this multiplicativity is equivalent to $\mathcal{Z}$ being prime provided that $\mathcal{Z}$ is an ideal. By following the multiplicativity, we consider in this paper that $\mathcal{Z}$ is prime.

In this paper, we do not assume that the prime spectrum of $\mathcal{A}$ is irreducible and the plant P is strictly causal as in [11]. Alternatively, in the rest of the paper we assume only the following:

Assumption 2.4. The given plant is causal in the sense of Definition 2.3.

One can represent a causal plant P in the form of fractions $P = ND^{-1} = \widetilde{D}^{-1}\widetilde{N}$, where the matrices N, D, $\widetilde{N}$, $\widetilde{D}$ are over $\mathcal{A}$, and the matrices D, $\widetilde{D}$ are $\mathcal{Z}$-nonsingular.

It should be noted that when using "a stabilizing controller," we do not guarantee the causality. However, in the classical case of the factorization approach, once we restrict ourselves to strictly proper plants, it is known that any stabilizing controller of strictly causal plant is causal (cf. Corollary 5.2.20 of [13], Theorem 4.1 of [14]). One can see, in fact, that many practical systems are strictly causal. On the other hand, including noncausal stabilizing controllers seems to make the theory easy and simple from the mathematical viewpoint. From these observations, we have accepted the possibility of the noncausality of stabilizing controllers.

In our case, the fact "any stabilizing controller of strictly causal plant is causal" still holds (Proposition 6.2). Further we will show that for any causal plant there exists a causal stabilizing controller (Proposition 6.1).

2.3. Previous results. In [11] Sule gave the results of the feedback stabilizability. We show them after introducing the notion of the elementary factor which is used to state his results.

Definition 2.5 (elementary factors [11, p. 1689]). *Assume that* $\mathcal{A}$ *is a unique factorization domain. Denote by* T *the matrix* $[\, N^t \quad dE_m \,]^t$ *and by* W *the matrix* $[\, N \quad dE_n \,]$ *over* $\mathcal{A}$, *where* $P = Nd^{-1}$ *with* $N \in \mathcal{A}^{n \times m}$, $d \in \mathcal{A}$. *Let* $\{T_1, T_2, \ldots, T_r\}$ *be the family of all nonsingular* $m \times m$ *submatrices of the matrix* T, *and for each index* i, *let* f_i *be the radical of the least common multiple of all the denominators of* TT_i^{-1}. *The family* $F = \{f_1, f_2, \ldots, f_r\}$ *is called the family of* elementary factors of the matrix T. *Analogously let* $\{W_1, W_2, \ldots, W_r\}$ *be the family of all nonsingular*

$n \times n$ submatrices of the matrix W, and for each index j let g_j be the radical of the least common multiple of all the denominators of $W_j^{-1}W$. Let $G = \{g_1, g_2, \ldots, g_l\}$ denote the family of elementary factors of the transposed matrix W^t. *Now let $H = \{f_i g_j \,|\, i = 1, \ldots, r,\ j = 1, \ldots, l\}$. This family H is called the* elementary factor of the transfer matrix P.

Then, Sule's two elegant results can be rewritten as follows. The first result assumes that the prime spectrum of $\mathcal{A}$ is irreducible. The second one assumes that $\mathcal{A}$ is a unique factorization domain.

Theorem 2.6 (see [11, Theorem 1]). *Suppose that the prime spectrum of $\mathcal{A}$ is irreducible. Further suppose that a plant P of size $n \times m$ is strictly causal, where the notion of the strictly causal is defined as in* [12] *(rather than* [11]*). Then the plant P is stabilizable if and only if the following conditions are satisfied:*

(i) *The module $\mathcal{T}_P$ is projective of rank m.*

(ii) *The module $\mathcal{W}_P$ is projective of rank n.* □

Recall that for a matrix X over $\mathcal{F}$ we use the notations $\mathcal{T}_X$ and $\mathcal{W}_X$ to denote $\mathcal{A}$-modules generated by using the matrix X. Further it should be noted that the definitions of $\mathcal{T}_P$ and $\mathcal{W}_P$ in [11] are slightly different from those of this paper. Nevertheless this is not a problem by virtue of Lemma 2.1.

Theorem 2.7 (see [11, Theorem 4]). *Suppose that $\mathcal{A}$ is a unique factorization domain. The plant P is stabilizable if and only if the elementary factors of P are coprime, that is, $\sum_{h \in H}(h) = \mathcal{A}$.* □

3. Main results.

To state our results precisely we define the notion of generalized elementary factors, which is a generalization of the elementary factors in Definition 2.5. Then the main theorem will be presented.

Generalized elementary factors. Originally, the elementary factors have been defined over unique factorization domains as in Definition 2.5. We enlarge this concept in the case of commutative rings.

Before stating the definition, we introduce several symbols used in the definition and widely in the rest of this paper. The symbol $\mathcal{I}$ denotes the set of all sets of m distinct integers between 1 and $m+n$ (recall that m and n are the numbers of the inputs and the outputs, respectively). Normally, an element of $\mathcal{I}$ will be denoted by I, possibly with suffixes such as integers. We will use an element of $\mathcal{I}$ as a suffix as well as a set. For $I \in \mathcal{I}$, if $i_1, \ldots, i_m$ are elements of I in ascending order, that is, $i_a < i_b$ if $a < b$, then the symbol Δ_I denotes the $m \times (m+n)$ matrix whose (k, i_k)-entry is 1 for $i_k \in I$ and zero otherwise.

Definition 3.1 (generalized elementary factors). *Let $P \in \mathcal{F}^{n \times m}$, and N and D are matrices over $\mathcal{A}$ with $P = ND^{-1}$. Denote by T the matrix $[\,N^t \quad D^t\,]^t$. For each $I \in \mathcal{I}$, define the ideal Λ_{PI} of $\mathcal{A}$ by*

$$\Lambda_{PI} = \{\lambda \in \mathcal{A} \,|\, \exists K \in \mathcal{A}^{(m+n)\times m} \ \lambda T = K \Delta_I T\}.$$

We call the ideal Λ_{PI} the generalized elementary factor *of the plant P with respect to I.*

Whenever we use the symbol Λ with some suffix, it will denote a generalized elementary factor. We will also frequently use the symbols λ and λ_I with $I \in \mathcal{I}$ as particular elements of Λ_{PI}. Note that in Definitions 2.5 and 3.1, the matrices represented by T are different in general. However this difference is not a problem since the generalized elementary factors are independent of the choice of the fractions ND^{-1} as shown below.

Lemma 3.2. *For any $I \in \mathcal{I}$, the generalized elementary factor of the plant P with respect to I is independent of the choice of matrices N and D over $\mathcal{A}$ satisfying $P = ND^{-1}$.*

Proof. Let N, N', D be matrices over $\mathcal{A}$ and d' be a scalar of $\mathcal{A}$ such that $P = ND^{-1} = N'{d'}^{-1}$ hold. Further, let

$$\begin{aligned}\Lambda_{PI1} &= \{\lambda \in \mathcal{A} \,|\, \exists K \in \mathcal{A}^{(m+n)\times m}\ \lambda\,[\,N^t \quad D^t\,]^t = K\Delta_I\,[\,N^t \quad D^t\,]^t\},\\ \Lambda_{PI2} &= \{\lambda \in \mathcal{A} \,|\, \exists K \in \mathcal{A}^{(m+n)\times m}\ \lambda\,[\,{N'}^t \quad d'E_m\,]^t = K\Delta_I\,[\,{N'}^t \quad d'E_m\,]^t\}.\end{aligned}$$

In order to prove this lemma it is sufficient to show that the ideals Λ_{PI1} and Λ_{PI2} are equal. Suppose that λ is an element of Λ_{PI1}. Then there exists a matrix K such that $\lambda\,[\,N^t \quad D^t\,]^t = K\Delta_I\,[\,N^t \quad D^t\,]^t$. Multiplying $d'E_m$ on the right of both sides, we have $\lambda\,[\,{N'}^t \quad d'E_m\,]^t\,D = K\Delta_I\,[\,{N'}^t \quad d'E_m\,]^t\,D$. Since the matrix D is nonsingular, we have $\lambda\,[\,{N'}^t \quad d'E_m\,]^t = K\Delta_I\,[\,N^t \quad d'E_m\,]^t$, so that $\lambda \in \Lambda_{PI2}$, which means that $\Lambda_{PI1} \subset \Lambda_{PI2}$. The opposite inclusion relation $\Lambda_{PI1} \supset \Lambda_{PI2}$ can be proved analogously. □

Note also that for every I in $\mathcal{I}$, the generalized elementary factor of the plant with respect to I is not empty since it contains at least zero. In the case where the set of stable causal transfer functions is a unique factorization domain, the generalized elementary factor of the plant with the matrix $\Delta_I T$ being nonsingular becomes a principal ideal and the generator of its radical an elementary factor of the matrix T (in Definition 2.5) up to a unit multiple. Analogously, the elementary factor of the matrix W (in Definition 2.5) corresponds to the generalized elementary factor of the transposed plant P^t.

Main results. We are now in position to state our main results.

Theorem 3.3. *Consider a causal plant P. Then the following statements are equivalent:*

(i) *The plant P is stabilizable.*

(ii) *The $\mathcal{A}$-modules $\mathcal{T}_P$ and $\mathcal{W}_P$ are projective.*

(iii) *The set of all generalized elementary factors of P generates $\mathcal{A}$; that is,*

$$\sum_{I\in\mathcal{I}} \Lambda_{PI} = \mathcal{A}. \tag{3.1}$$

In the theorem, (ii) and (iii) are criteria for feedback stabilizability. Comparing the theorem above with Theorems 2.6 and 2.7, we observe the following: (ii) and (iii) can be considered as generalizations of Theorems 2.6 and 2.7, respectively. For (ii), we do not assume as mentioned earlier that the prime spectrum of $\mathcal{A}$ is irreducible and the plant P is strictly causal. The rank conditions of $\mathcal{T}_P$ and $\mathcal{W}_P$ are deleted. For (iii), the commutative ring $\mathcal{A}$ is not restricted to a unique factorization domain. The elementary factors are replaced by the generalized elementary factors. Although two matrices T and W in Definition 2.5 are used to state Theorem 2.7, only one matrix T in Definition 3.1 is used in (iii).

We will present the proof of the theorem in section 5.

To make the notion of the generalized elementary factors familiar, we present here an example of the generalized elementary factors.

Example 3.4. Some synchronous high-speed electronic circuits such as computer memory devices often cannot have nonzero small delays (see [5], for example). We suppose here that the system cannot have the unit delay as a nonzero small delay. Further we suppose that the impulse response of a transfer function being stable is finitely terminated. Thus the set $\mathcal{A}$ becomes the set of polynomials generated by z^2 and z^3, that is, $\mathcal{A} = \mathbb{R}[z^2, z^3]$, where z denotes the unit delay operator. Then $\mathcal{A}$ is not a unique factorization domain but a Noetherian domain. The total field $\mathcal{F}$ of fractions of $\mathcal{A}$ is $\mathbb{R}(z^2, z^3)$, which is equal to $\mathbb{R}(z)$. The ideal $\mathcal{Z}$ used to define the causality is given as the set of polynomials in $\mathbb{R}[z^2, z^3]$ whose constant terms are zero; that is, $\mathcal{Z} = z^2\mathcal{A} + z^3\mathcal{A} = \{az^2 + bz^3 \mid a, b \in \mathcal{A}\}$. Thus the set of causal transfer functions $\mathcal{P}$ is given as n/d, where n, d are in $\mathcal{A}$ and the constant term of d is nonzero; that is, $\mathcal{P} = \{n/(a + bz^2 + cz^3) \mid n \in \mathcal{A},\ \ a \in \mathbb{R}\backslash\{0\},\ \ b, c \in \mathcal{A}\}$. Further the set of strictly causal transfer functions $\mathcal{P}_{\rm S}$ is given as $\mathcal{P}_{\rm S} = \{(a_1z^2 + b_1z^3)/(a_2 + b_2z^2 + c_2z^3) \mid a_2 \in \mathbb{R}\backslash\{0\},\ \ a_1, b_1, b_2, c_2 \in \mathcal{A}\}$.

Since some factorized polynomials are sometimes expressed more compactly and are thus easier to understand than the expanded ones, we here introduce the following notation: a polynomial in $\mathbb{R}[z]$ surrounded by "$\langle$" and "$\rangle$" indicates that it is in $\mathcal{A}$ as well as in $\mathbb{R}[z]$ even though some factors between "$\langle$" and "$\rangle$" may not be in $\mathcal{A}$.

Let us consider the plant below:

$$P := \begin{bmatrix} (1-z^3)/(1-z^2) \\ (1-8z^3)/(1-4z^2) \end{bmatrix} \in \mathcal{P}^{2\times 1}. \tag{3.2}$$

The representation of the plant is not unique. For example, the (1,1)-entry of the plant has an alternative form $(1 + z^2 + z^4)/(1 + z^3)$ different from the expression in (3.2). Consider parameterizing the representation of the plant. To do so we consider the plant P over $\mathbb{R}(z)$ rather than over $\mathcal{F}$. Thus P can be expressed as

$$P = \begin{bmatrix} (1+z+z^2)/(1+z) \\ (1+2z+4z^2)/(1+2z) \end{bmatrix} \quad \text{over } \mathbb{R}(z). \tag{3.3}$$

However, the coefficients of all numerators and denominators in (3.3) of z with degree 1 are not zero. To make them zero, we should multiply them by $(a_1(1-z)+b_1z^2+c_1z^3)$ or $(a_2(1-2z)+b_2z^2+c_2z^3)$ with $a_1, b_1, c_1, a_2, b_2, c_2 \in \mathcal{A}$ as follows:

$$P = \begin{bmatrix} \frac{\langle(1+z+z^2)(a_1(1-z)+b_1z^2+c_1z^3)\rangle}{\langle(1+z)(a_1(1-z)+b_1z^2+c_1z^3)\rangle} \\ \frac{\langle(1+2z+4z^2)(a_2(1-2z)+b_2z^2+c_2z^3)\rangle}{\langle(1+2z)(a_2(1-2z)+b_2z^2+c_2z^3)\rangle} \end{bmatrix}. \tag{3.4}$$

Every expression of the plant is given in the form of (3.4) with $a_1, b_1, c_1, a_2, b_2, c_2$ in $\mathcal{A}$ provided that the denominators are not zero. From this, we have two observations. One is that the plant P does not have its right- and left-coprime factorizations over $\mathcal{A}$ (even so, it will be shown later that the plant is stabilizable). The other is that the elementary factor of this plant cannot be consistently defined over $\mathcal{A}$. Thus we employ the notion of the generalized elementary factor.

In the following, we calculate the generalized elementary factors of the plant. We choose the following matrices as N, D, and T used in Definition 3.1:

$$\begin{bmatrix} n_1 \\ n_2 \end{bmatrix} := N := \begin{bmatrix} (1-z^3)(1-4z^2) \\ (1-8z^3)(1-z^2) \end{bmatrix},$$
$$[\,d\,] := D := [\,(1-z^2)(1-4z^2)\,], \quad T := [\,N^t \quad D^t\,]^t.$$

Since $m = 1$ (the number of inputs) and $n = 2$ (the number of outputs), the set $\mathcal{I}$ is given as $\mathcal{I} = \{\{1\}, \{2\}, \{3\}\}$ and we let $I_1 = \{1\}$, $I_2 = \{2\}$, $I_3 = \{3\}$.

Let us calculate the generalized elementary factor Λ_{PI_1}. Let $i_1 = 1$ so that $I_1 = \{i_1\}$. Then the $(1, i_1)$-entry of the matrix Δ_{I_1} is 1 and the other entries are zero.

Thus we have $\Delta_{I_1} = [\,1 \quad 0 \quad 0\,]$. The generalized elementary factor Λ_{PI_1} is originally given as follows:

$$\begin{aligned} \Lambda_{PI_1} &= \{\lambda \in \mathcal{A} \,|\, \exists K \in \mathcal{A}^{(m+n)\times m} \;\; \lambda T = K \Delta_{I_1} T\} \\ &= \{\lambda \in \mathcal{A} \,|\, \exists k_1, k_2 \in \mathcal{A} \;\; \lambda\,[\,n_2 \quad d\,]^t = n_1\,[\,k_1 \quad k_2\,]^t\}. \end{aligned} \tag{3.5}$$

Consider (3.5) over $\mathbb{R}[z]$ instead of $\mathcal{A}$. Then the matrix equation in the set of (3.5) can be expressed as

$$\begin{aligned} \lambda \begin{bmatrix} (1-z)(1+z)(1-2z)(1+2z+4z^2) \\ (1-z)(1+z)(1-2z)(1+2z) \end{bmatrix} &= \\ (1-z)(1-2z)(1+2z)(1+z+z^2) \begin{bmatrix} k_1 \\ k_2 \end{bmatrix}&. \end{aligned} \tag{3.6}$$

The set of λ's such that there exist $k_1, k_2 \in \mathbb{R}[z]$ satisfying (3.6) is given as $\{(1+2z)(1+z+z^2)a \mid a \in \mathbb{R}[z]\}$, denoted by L_1. Then the intersection of L_1 and $\mathcal{A}$ is given as follows:

$$L_1 \cap \mathcal{A} = \{\langle (1+2z)(1+z+z^2)(a(1-3z)+bz^2+cz^3)\rangle \in \mathcal{A} \mid a,b,c \in \mathcal{A}\}. \tag{3.7}$$

This is equal to Λ_{PI_1} as shown below. First it is obvious that $L_1 \cap \mathcal{A} \supset \Lambda_{PI_1}$. For each $(1+2z)(1+z+z^2)(a(1-3z)+bz^2+cz^3)$ with $a,b,c \in \mathcal{A}$, we have k_1 and k_2 as follows from (3.6):

$$\begin{aligned} k_1 &= (1+z)(1+2z+4z^2)(a(1-3z)+bz^2+cz^3), \\ k_2 &= (1+z)(1+2z)(a(1-3z)+bz^2+cz^3). \end{aligned}$$

Both k_1 and k_2 are in $\mathcal{A}$. Hence $L_1 \cap \mathcal{A} \subset \Lambda_{PI_1}$ and so $L_1 \cap \mathcal{A} = \Lambda_{PI_1}$. By (3.7), we can also consider that Λ_{PI_1} is generated by $\langle (1+2z)(1+z+z^2)(1-3z)\rangle$, $\langle (1+2z)(1+z+z^2)z^2\rangle$, and $\langle (1+2z)(1+z+z^2)z^3\rangle$.

Analogously, we can calculate the generalized elementary factors Λ_{PI_2} and Λ_{PI_3} of the plant with respect to I_2 and I_3 as follows:

$$\begin{aligned} \Lambda_{PI_2} &= \{\langle (1+z)(1+2z+4z^2)(a(1-3z)+bz^2+cz^3)\rangle \in \mathcal{A} \mid a,b,c \in \mathcal{A}\}, \\ \Lambda_{PI_3} &= \{\langle (1+z)(1+2z)(a(1-3z)+bz^2+cz^3)\rangle \in \mathcal{A} \mid a,b,c \in \mathcal{A}\}. \end{aligned}$$

Observe now that

$$\begin{aligned} \Lambda_{PI_1} &\ni \langle (1+2z)(1-3z)(1+z+z^2)\rangle =: \lambda_{0I_1}, \\ \Lambda_{PI_2} &\ni \langle (1+z)(1+2z+4z^2)(1-3z+z^2)\rangle =: \lambda_{0I_2} \end{aligned}$$

and further

$$\alpha_{I_1}\lambda_{0I_1} + \alpha_{I_2}\lambda_{0I_2} = 1,$$

where

$$\begin{aligned} \alpha_{I_1} &= \tfrac{-4233-23646z^2-39836z^3-201780z^4-113016z^5+75344z^6}{5852} \in \mathcal{A}, \\ \alpha_{I_2} &= \tfrac{10085+18418z^2+121140z^3+131852z^4+113016z^5}{5852} \in \mathcal{A}. \end{aligned}$$

Now let

$$\lambda_{I_1} := \alpha_{I_1}\lambda_{0I_1} \in \Lambda_{PI_1}, \quad \lambda_{I_2} := \alpha_{I_2}\lambda_{0I_2} \in \Lambda_{PI_2}. \tag{3.8}$$

Thus $\Lambda_{PI_1} + \Lambda_{PI_2} = \mathcal{A}$ and $\lambda_{I_1} + \lambda_{I_2} = 1$. Hence by Theorem 3.3, the plant P is stabilizable. $\square$

4. Intermediate results. In this section we provide intermediate results which will be used in the proof of our main theorem stated in the preceding section. This section consists of three parts. We first show that a number of modules generated from plants, controllers, and feedback systems are isomorphic to one another. Next we develop the results which will help to show the existence of a well-defined stabilizing controller. We then give the coprime factorizability of the plant over $\mathcal{A}_f$, where f is an element of the generalized elementary factor of the plant.

Relationship in terms of modules between transfer matrices P, C, and $H(P,C)$. The first intermediate result is the relations, expressed in terms of modules, among the matrices P, C, and $H(P,C)$ as well as their transposed matrices. A number of modules are isomorphic to one another as follows.

PROPOSITION 4.1. *Suppose that P and C are matrices over $\mathcal{F}(\mathcal{R})$. Suppose further that $\det(E_n + PC)$ is a unit of $\mathcal{F}(\mathcal{R})$.*

(i) *The following $\mathcal{R}$-modules are isomorphic to one another:* $\mathcal{T}_{P,\mathcal{R}} \oplus \mathcal{T}_{C,\mathcal{R}}$, $\mathcal{T}_{H(P,C),\mathcal{R}}$, $\mathcal{T}_{H(P^t,C^t)^t,\mathcal{R}}$, $\mathcal{W}_{H(P^t,C^t),\mathcal{R}}$, $\mathcal{T}_{H(C,P),\mathcal{R}}$.

(ii) *The following $\mathcal{R}$-modules are isomorphic to one another:* $\mathcal{W}_{P,\mathcal{R}} \oplus \mathcal{W}_{C,\mathcal{R}}$, $\mathcal{W}_{H(P,C),\mathcal{R}}$, $\mathcal{W}_{H(P^t,C^t)^t,\mathcal{R}}$, $\mathcal{T}_{H(P^t,C^t),\mathcal{R}}$, $\mathcal{W}_{H(C,P),\mathcal{R}}$.

Further for a matrix X over $\mathcal{F}(\mathcal{R})$,

(iii) $\mathcal{T}_{X,\mathcal{R}} \simeq \mathcal{W}_{X^t,\mathcal{R}}$ *and* $\mathcal{W}_{X,\mathcal{R}} \simeq \mathcal{T}_{X^t,\mathcal{R}}$.

Note here that in the proposition above, the controller C need not be a stabilizing controller. For the case where C is a stabilizing controller, see Lemma 2 of [11].

We can consider that the proposition above, especially the relations $\mathcal{T}_{P,\mathcal{R}} \oplus \mathcal{T}_{C,\mathcal{R}} \simeq \mathcal{T}_{H(P,C),\mathcal{R}} \simeq \mathcal{T}_{H(C,P),\mathcal{R}}$, gives an interpretation of the structure of the feedback system in the sense that the module generated by the feedback system is given as the direct sum of the modules generated by the plant and the controller. In the proof ((i)→(ii)) of Theorem 3.3, this proposition will play a key role.

Proof. We first prove (iii). Let A and B be matrices over $\mathcal{R}$ with $X = AB^{-1}$. Then we have $\mathcal{T}_{X,\mathcal{R}} \simeq M_r([\,A^t \quad B^t\,]^t) \simeq M_c([\,A^t \quad B^t\,]) \simeq \mathcal{W}_{(B^{-1})^t A^t,\mathcal{R}} \simeq \mathcal{W}_{X^t,\mathcal{R}}$. The other relation $\mathcal{W}_{X,\mathcal{R}} \simeq \mathcal{T}_{X^t,\mathcal{R}}$ can be proved in a similar way.

Next we prove (i). Suppose that $\det(E_n + PC)$ is a unit of $\mathcal{F}(\mathcal{R})$. We prove the following relations in order: (a) $\mathcal{T}_{P,\mathcal{R}} \oplus \mathcal{T}_{C,\mathcal{R}} \simeq \mathcal{T}_{H(P,C),\mathcal{R}}$, (b) $\mathcal{T}_{H(P,C),\mathcal{R}} \simeq \mathcal{T}_{H(P^t,C^t)^t,\mathcal{R}}$, (c) $\mathcal{T}_{H(P^t,C^t)^t,\mathcal{R}} \simeq \mathcal{W}_{H(P^t,C^t),\mathcal{R}}$, (d) $\mathcal{T}_{H(P,C),\mathcal{R}} \simeq \mathcal{T}_{H(C,P),\mathcal{R}}$.

(a) of (i). The proof of (a) follows mainly the proof of Lemma 2 in [11]. By virtue of Lemma 2.1, it is sufficient to show the relation $\mathcal{T}_{P,\mathcal{R}} \oplus \mathcal{T}_{C,\mathcal{R}} \simeq M_r([\,N_H^t \quad d_H E_{m+n}\,]^t)$ with $N_H \in (\mathcal{R})_{m+n}$, $d_H \in \mathcal{R}$, where $H(P,C) = N_H d_H^{-1}$. Let N, N_C be matrices over $\mathcal{R}$ and d, d_C be in $\mathcal{R}$ with $P = Nd^{-1}$ and $C = N_C d_C^{-1}$. Further, let

$$Q = \begin{bmatrix} d_C E_n & N \\ -N_C & dE_m \end{bmatrix}, \quad S = \begin{bmatrix} d_C E_n & O \\ O & dE_m \end{bmatrix}.$$

From these we have $\mathcal{T}_{P,\mathcal{R}} \oplus \mathcal{T}_{C,\mathcal{R}} \simeq M_r([\,Q^t \quad S^t\,]^t)$. In addition, since $\det(E_n + PC)$ is a unit of $\mathcal{F}(\mathcal{R})$, the matrix N_H is nonsingular so that $M_r([\,Q^t \quad S^t\,]^t) \simeq M_r([\,Q^t \quad S^t\,]^t (\det(N_H)E_{m+n}))$ holds. A simple calculation shows that

$$\begin{bmatrix} Q \\ S \end{bmatrix} (\det(N_H)E_{m+n}) = \begin{bmatrix} d_H E_{m+n} \\ N_H \end{bmatrix} \operatorname{adj}(N_H) S.$$

Because both matrices S and $\operatorname{adj}(N_H)$ are nonsingular, we finally have that

$$\begin{aligned}\mathcal{T}_{P,\mathcal{R}} \oplus \mathcal{T}_{C,\mathcal{R}} &\simeq M_r\left(\begin{bmatrix} Q \\ S \end{bmatrix}\right) \simeq M_r\left(\begin{bmatrix} Q \\ S \end{bmatrix}(\det(N_H)E_{m+n})\right) \\ &\simeq M_r\left(\begin{bmatrix} d_H E_{m+n} \\ N_H \end{bmatrix}\right) \simeq \mathcal{T}_{H(P,C),\mathcal{R}}.\end{aligned}$$

(b) of (i). Observe that the following relation holds:

$$H(P^t, C^t)^t = \begin{bmatrix} O & E_m \\ E_n & O \end{bmatrix} H(P,C) \begin{bmatrix} O & E_n \\ E_m & O \end{bmatrix}. \tag{4.1}$$

Let N_H and d_H be a matrix over $\mathcal{R}$ and a scalar of $\mathcal{R}$, respectively, with $H(P,C) = N_H d_H^{-1}$. Then (4.1) can be rewritten as follows:

$$H(P^t, C^t)^t = \begin{bmatrix} O & E_m \\ E_n & O \end{bmatrix} N_H \left(\begin{bmatrix} O & E_m \\ E_n & O \end{bmatrix} d_H\right)^{-1}.$$

Hence, we have matrices A and B over $\mathcal{R}$ with $H(P^t, C^t)^t = AB^{-1}$ such that

$$A = \begin{bmatrix} O & E_m \\ E_n & O \end{bmatrix} N_H, \quad B = \begin{bmatrix} O & E_m \\ E_n & O \end{bmatrix} d_H.$$

This gives the relation $\mathcal{T}_{H(P,C),\mathcal{R}} \simeq \mathcal{T}_{H(P^t,C^t)^t,\mathcal{R}}$.

(c) of (i). This is directly obtained by applying (iii) to the matrix $H(P^t, C^t)^t$.

(d) of (i). Between the matrices $H(P,C)$ and $H(C,P)$, the following relation holds:

$$H(C,P) = \begin{bmatrix} O & -E_m \\ E_n & O \end{bmatrix} H(P,C) \begin{bmatrix} O & E_n \\ -E_m & O \end{bmatrix}.$$

Letting N_H and d_H be a matrix over $\mathcal{R}$ and a scalar of $\mathcal{R}$ with $H(P,C) = N_H d_H^{-1}$ as in (b), we have matrices N_H' and D_H' over $\mathcal{R}$ such that

$$\begin{bmatrix} N_H' \\ D_H' \end{bmatrix} = \begin{bmatrix} \begin{matrix} O & -E_m \\ E_n & O \end{matrix} & O \\ O & \begin{matrix} O & -E_m \\ E_n & O \end{matrix} \end{bmatrix} \begin{bmatrix} N_H \\ d_H E_{m+n} \end{bmatrix}$$

holds. Since $H(C,P) = N_H' {D_H'}^{-1}$ holds and the first matrix of the right-hand side of the equation above is invertible, the relation $\mathcal{T}_{H(P,C),\mathcal{R}} \simeq \mathcal{T}_{H(C,P),\mathcal{R}}$ holds.

Finally, arguments similar to (i) prove (ii). □

Before moving to the next intermediate result, we prove an easy lemma useful to give results for the transposed plants.

LEMMA 4.2. *A plant P is stabilizable if and only if its transposed plant P^t is stabilizable. Moreover, in the case where the plant P is stabilizable, C is a stabilizing controller of P if and only if C^t is a stabilizing controller of the transposed plant P^t.*

Proof. (Only If) Suppose that a plant P is stabilizable. Let C be a stabilizing controller of P. First, (P^t, C^t) is in $\widehat{F}_{\mathrm{ad}}$, since $(P,C) \in \widehat{F}_{\mathrm{ad}}$ and $\det(E_n + PC) = \det(E_m + P^t C^t)$. From (4.1) in the proof of Proposition 4.1, if $H(P,C) \in (\mathcal{A})_{m+n}$, then $H(P^t, C^t) \in (\mathcal{A})_{m+n}$.

(If) Because $(P^t)^t = P$, the "If" part can be proved analogously. □

$\mathcal{Z}$-nonsingularity of transfer matrices. In order to prove the stabilizability of the given causal plant, which will be necessary in the proof of the main theorem (Theorem 3.3), we should show the existence of the stabilizing controller. To do so, we will need to show that the denominator matrix of the stabilizing controller is nonsingular. The following result will help.

LEMMA 4.3. *Suppose that there exist matrices A, B, C_1, C_2 over $\mathcal{A}$ such that the following square matrix is $\mathcal{Z}$-nonsingular:*

$$\begin{bmatrix} A & C_1 \\ B & C_2 \end{bmatrix}, \tag{4.2}$$

where the matrix A is square and the matrices A and B have same number of columns. Then there exists a matrix R over $\mathcal{A}$ such that the matrix $A + RB$ is $\mathcal{Z}$-nonsingular.

Before starting the proof, it is worth reviewing some easy facts about the prime ideal $\mathcal{Z}$.

Remark 4.4. (i) If a is in $\mathcal{A}\backslash\mathcal{Z}$ and expressed as $a = b + c$ with $b, c \in \mathcal{A}$, then at least one of b and c is in $\mathcal{A}\backslash\mathcal{Z}$. (ii) If a is in $\mathcal{A}\backslash\mathcal{Z}$ and b is in $\mathcal{Z}$, then the sum $a + b$ is in $\mathcal{A}\backslash\mathcal{Z}$. (iii) Every factor in $\mathcal{A}$ of an element of $\mathcal{A}\backslash\mathcal{Z}$ belongs to $\mathcal{A}\backslash\mathcal{Z}$ (that is, if $a, b \in \mathcal{A}$ and $ab \in \mathcal{A}\backslash\mathcal{Z}$, then $a, b \in \mathcal{A}\backslash\mathcal{Z}$).

They will be used in the proofs of Lemma 4.3 and Theorem 3.3.

Proof of Lemma 4.3. This proof mainly follows that of Lemma 4.4.21 of [13].

If the matrix A itself is $\mathcal{Z}$-nonsingular, then we can select the zero matrix as R. Hence we assume in the following that A is $\mathcal{Z}$-singular.

Since (4.2) is $\mathcal{Z}$-nonsingular, there exists a full-size minor of $[\,A^t \quad B^t\,]^t$ in $\mathcal{A}\backslash\mathcal{Z}$ by Laplace's expansion of (4.2) and Remark 4.4(i), (iii). Let a be such a $\mathcal{Z}$-nonsingular full-size minor of $[\,A^t \quad B^t\,]^t$ having as few rows from B as possible.

We here construct a matrix R such that $\det(A + RB) = \pm a + z$ with $z \in \mathcal{Z}$. Since A is $\mathcal{Z}$-singular, the full-size minor a must contain at least one row of B from the matrix $[\,A^t \quad B^t\,]^t$. Suppose that a is obtained by excluding the rows $i_1, \dots, i_k$ of A and including the rows $j_1, \dots, j_k$ of B, where both $i_1, \dots, i_k$ and $j_1, \dots, j_k$ are in ascending order. Now define $R = (r_{ij})$ by $r_{i_1 j_1} = \cdots = r_{i_k j_k} = 1$ and $r_{ij} = 0$ for all other i, j. Observe that $\det(A + RB)$ is expanded in terms of full-size minors of the matrices $[\,E \quad R\,]$ and $[\,A^t \quad B^t\,]^t$ from the factorization $A + RB = [\,E \quad R\,][\,A^t \quad B^t\,]^t$ by the Binet–Cauchy formula. Every minor of $[\,E \quad R\,]$ containing more than k columns of R is zero. By the method of choosing the rows from $[\,A^t \quad B^t\,]^t$ for the full-size minor a, every full-size minor of $[\,A^t \quad B^t\,]^t$ having less than k rows of B is in $\mathcal{Z}$. There is only one nonzero minor of $[\,E \quad R\,]$ containing exactly k columns of R, which is obtained by excluding the columns $i_1, \dots, i_k$ of the identity matrix E and including the columns $j_1, \dots, j_k$ of R; it is equal to ± 1. From the Binet–Cauchy formula, the corresponding minor of $[\,A^t \quad B^t\,]^t$ is a. As a result, $\det(A + RB)$ is given as a sum of $\pm a$ and elements in $\mathcal{Z}$. By Remark 4.4(ii), the sum is in $\mathcal{A}\backslash\mathcal{Z}$ and so is $\det(A + RB)$. The matrix $A + RB$ is now $\mathcal{Z}$-nonsingular. □

Coprimeness and generalized elementary factors. We present here that for each nonnilpotent element λ of the generalized elementary factors, the plant has a right-coprime factorization over $\mathcal{A}_\lambda$. This will be independent of the stabilizability of the plant.

LEMMA 4.5 (cf. Proposition 2.2 of [9]). *Let Λ_{PI} be the generalized elementary factor of the plant P with respect to $I \in \mathcal{I}$ and further let $\sqrt{\Lambda_{PI}}$ denote the radical of Λ_{PI} (as an ideal). Suppose that λ is in $\sqrt{\Lambda_{PI}}$ but not nilpotent. Then, the $\mathcal{A}_\lambda$-module $\mathcal{T}_{P,\mathcal{A}_\lambda}$ is free of rank m.*

Proof. Let T, N, D be the matrices over $\mathcal{A}$ as in Definition 3.1. Recall that $\mathcal{T}_{P,\mathcal{A}_\lambda}$ denotes the $\mathcal{A}_\lambda$-module generated by rows of the matrix T. By Definition 3.1, there exists a matrix K over $\mathcal{A}$ such that $\lambda^r T = K\Delta_I T$ holds for some positive integer r. Then we have a factorization of the matrix T over $\mathcal{A}_\lambda$ as $T = (\lambda^{-r}K)(\Delta_I T)$, where all entries of the matrix $\lambda^{-r}K$ are in $\mathcal{A}_\lambda$. In order to show that the $\mathcal{A}_\lambda$-module $\mathcal{T}_{P,\mathcal{A}_\lambda}$ is free of rank m, provided that λ is not nilpotent, it is sufficient to prove the following two facts: (i) The matrix $\Delta_I T$ is nonsingular over $\mathcal{A}_\lambda$. (ii) There is a matrix X such that the matrix $[\,\lambda^{-r}K \quad X\,]$ is invertible over $\mathcal{A}_\lambda$ and the matrix equation $T = [\,\lambda^{-r}K \quad X\,]\,[\,(\Delta_I T)^t \quad O\,]^t$ holds.

(i). Observe that the matrix D is nonsingular over $\mathcal{A}_\lambda$ as well as over $\mathcal{A}$. Since $D = \Delta_{\{n+1,\ldots,m+n\}}T = (\lambda^{-r}\Delta_{\{n+1,\ldots,m+n\}}K)(\Delta_I T)$ holds (note that the suffix of the symbol Δ is an ordered set of m distinct integers between 1 and $m+n$ as before Definition 3.1), the matrix $\Delta_I T$ is also nonsingular over $\mathcal{A}_\lambda$ provided that λ is not nilpotent.

(ii). Let $\overline{i_1}, \ldots, \overline{i_n}$ be n distinct integers in ascending order between 1 and $m+n$ excluding the integers in I. Then let X be the matrix whose $(\overline{i_k}, k)$-entry is 1 for each $\overline{i_k}$ and zero otherwise. Then the determinant of $[\,\lambda^{-r}K \quad X\,]$ becomes ±1 since the matrix $\lambda^{-r}\Delta_I K$ is the identity matrix of $(\mathcal{A}_\lambda)_m$. □

The lemma below will be used in the proof ((ii)→(iii)) of the main theorem by letting $\mathcal{R} = \mathcal{A}_f$, where f is an element of the generalized elementary factor of the plant but not nilpotent.

LEMMA 4.6. *If $\mathcal{R}$-module $\mathcal{T}_{P,\mathcal{R}}$ $(\mathcal{W}_{P,\mathcal{R}})$ is free of rank m (n), there exist matrices A and B ($\widetilde{A}$ and $\widetilde{B}$) over $\mathcal{R}$ such that (A, B) is a right-coprime factorization ($(\widetilde{A}, \widetilde{B})$ is a left-coprime factorization) of the plant P $(\in \mathcal{F}(\mathcal{R})^{n\times m})$ over $\mathcal{R}$.*

Proof. This lemma is an analogy of the result given in the proof of Lemma 3 of [11]. See this proof. □

Example 4.7. Here we continue Example 3.4. Let us follow Lemmas 4.5 and 4.6 with the plant of (3.2). Let the notation be as in Example 3.4.

First we proceed along the proof of Lemma 4.5. As an example, we pick $I_1 \in \mathcal{I}$ as I and $\lambda_{I_1} \in \Lambda_{PI_1}$ as λ in the proof of Lemma 4.5. Recall that for each $\lambda \in \Lambda_{PI}$, there exists a matrix K such that $\lambda T = K\Delta_I T$ holds. In the case of $\lambda_{I_1} \in \Lambda_{PI_1}$, the matrix K is given as

$$K = \begin{bmatrix} k_1 \\ k_2 \\ k_3 \end{bmatrix} = \begin{bmatrix} \lambda_{I_1} \\ \alpha_{I_1}\langle(1+z)(1-3z)(1+2z+4z^2)\rangle \\ \alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle \end{bmatrix}. \tag{4.3}$$

Thus we have the factorization $T = (\lambda^{-r}K)(\Delta_{I_1}T)$:

$$\begin{bmatrix} (1-z^3)(1-4z^2) \\ (1-8z^3)(1-z^2) \\ (1-z^2)(1-4z^2) \end{bmatrix} = \begin{bmatrix} 1 \\ \lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1-3z)(1+2z+4z^2)\rangle \\ \lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle \end{bmatrix} [\,(1-z^3)(1-4z^2)\,],$$

where $r = 1$ and $\Delta_{I_1}T = [\,(1-z^3)(1-4z^2)\,]$. As shown in part (i) of the proof of Lemma 4.5, $\Delta_{I_1}T = [\,(1-z^3)(1-4z^2)\,]$ is nonsingular.

The matrix X in part (ii) of the proof of Lemma 4.5 is given as $X = \left[\begin{smallmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \end{smallmatrix}\right]^t$ by letting $\overline{i}_1 = 2$ and $\overline{i}_2 = 3$ according to $I_1 = \{1\}$. We can see that the matrix

$$[\,\lambda^{-1}K \quad X\,] = \begin{bmatrix} 1 & 0 & 0 \\ \lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1-3z)(1+2z+4z^2)\rangle & 1 & 0 \\ \lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle & 0 & 1 \end{bmatrix} \tag{4.4}$$

is invertible. Therefore the $\mathcal{A}_{\lambda_{I_1}}$-module $\mathcal{T}_{P,\mathcal{A}_{\lambda_{I_1}}}$ is free and its rank is 1. (However, we will see that the $\mathcal{A}$-module $\mathcal{T}_P$ is not free. See Example 5.2.)

From (4.4) and the matrix equation $T = [\,\lambda^{-r}K \quad X\,]\,[\,(\Delta_{I_1}T)^t \quad O\,]^t$, we let

$$\begin{bmatrix} N_{I_1} \\ D_{I_1} \end{bmatrix} := \begin{bmatrix} 1 \\ \lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1-3z)(1+2z+4z^2)\rangle \\ \lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle \end{bmatrix} = \lambda_{I_1}^{-1}K, \tag{4.5}$$

$$\begin{aligned} \begin{bmatrix} \widetilde{Y}_{I_1} & \widetilde{X}_{I_1} \\ \times & \times \end{bmatrix} &:= \begin{bmatrix} 1 & 0 & 0 \\ -\lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1-3z)(1+2z+4z^2)\rangle & 1 & 0 \\ -\lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle & 0 & 1 \end{bmatrix}, \\ &= [\,\lambda_{I_1}^{-1}K \quad X\,]^{-1}, \end{aligned} \tag{4.6}$$

where $N_{I_1} \in \mathcal{A}_{\lambda_{I_1}}^{2\times 1}$, $\widetilde{Y}_{I_1} \in \mathcal{A}_{\lambda_{I_1}}^{1\times 2}$, $D_{I_1}, \widetilde{X}_{I_1} \in (\mathcal{A}_{\lambda_{I_1}})_1$, and × denotes some matrix. Then (N_{I_1}, D_{I_1}) is a right-coprime factorization of the plant over $\mathcal{A}_{\lambda_{I_1}}$ with $\widetilde{Y}_{I_1}N_{I_1} + \widetilde{X}_{I_1}D_{I_1} = E_1$, which is consistent with Lemma 4.6.

5. Proof of main results.

Now we give the proof of the main theorem.

Proof of Theorem 3.3. We prove the following relations in order: (a) "(i)→(ii)," (b) "(ii)→(iii)," and (c) "(iii)→(i)."

(a) "(i)→(ii)": Suppose that C is a stabilizing controller of the plant P. Then, the $\mathcal{A}$-module $\mathcal{T}_{H(P,C)}$ is obviously free. By the relation $\mathcal{T}_{P,\mathcal{R}} \oplus \mathcal{T}_{C,\mathcal{R}} \simeq \mathcal{T}_{H(P,C),\mathcal{R}}$ in Proposition 4.1(i), we have that the $\mathcal{A}$-module $\mathcal{T}_P$ is projective. By using Proposition 4.1(iii) and Lemma 4.2, the projectivity of the $\mathcal{A}$-module $\mathcal{W}_P$ can be proved analogously.

(b) "(ii)→(iii)": Suppose that (ii) holds, that is, the modules $\mathcal{T}_P$ and $\mathcal{W}_P$ are projective. We let T, N, D be the matrices over $\mathcal{A}$ as in Definition 3.1. According to Theorem IV.32 of [7, p. 295], there exist finite sets F_1 and F_2 such that (1) each of them generates $\mathcal{A}$, and (2) for any $f \in F_1$ ($f \in F_2$) the $\mathcal{A}_f$-module $\mathcal{T}_{P,\mathcal{A}_f}$ ($\mathcal{W}_{P,\mathcal{A}_f}$) is free. Let F be the set of all $f_1 f_2$'s with $f_1 \in F_1$ and $f_2 \in F_2$. Then F generates $\mathcal{A}$ again, and the $\mathcal{A}_f$-modules $\mathcal{T}_{P,\mathcal{A}_f}$ and $\mathcal{W}_{P,\mathcal{A}_f}$ are free for every $f \in F$. We suppose without loss of generality that the sets F_1, F_2, and F do not contain any nilpotent element because $1 + x$ is a unit of $\mathcal{A}$ for any nilpotent x (cf. [2, p. 10]). (However, we note that other zerodivisors cannot be excluded from the set F.) The rank of the free $\mathcal{A}_f$-module $\mathcal{T}_{P,\mathcal{A}_f}$ is m, since m rows of the denominator matrix D are independent over $\mathcal{A}_f$ as well as over $\mathcal{A}$. Analogously the rank of $\mathcal{W}_{P,\mathcal{A}_f}$ is n.

In order to show that (iii) holds, it suffices to show that the relation $\sum_{f\in F}(f^\xi) \subset \sum_{I\in\mathcal{I}} \Lambda_{PI}$ holds for a sufficiently large integer ξ. Once this relation is obtained, since $\sum_{f\in F}(f^\xi) = \mathcal{A}$ holds, we have $\sum_{I\in\mathcal{I}} \Lambda_{PI} = \mathcal{A}$.

Let f be an arbitrary but fixed element of F. Let V_f be a square matrix of size m whose rows are m distinct generators of the $\mathcal{A}_f$-module $M_r([\,N^t \quad D^t\,]^t)$ ($\simeq \mathcal{T}_{P,\mathcal{A}_f}$). We assume without loss of generality that V_f is over $\mathcal{A}$, that is, the denominators of all entries of V_f are 1. Otherwise if V_f is over $\mathcal{A}_f$ but not over $\mathcal{A}$, V_f multiplied by f^x, with a sufficiently large integer x, will be over $\mathcal{A}$, so that we can consider such $V_f f^x$ as "V_f." Thus the following matrix equation holds over $\mathcal{A}$:

$$f^\nu T = K_f V_f \tag{5.1}$$

with a nonnegative integer ν and a matrix $K_f \in \mathcal{A}^{(m+n)\times m}$.

In order to prove the relation $\sum_{f\in F}(f^{\xi}) \subset \sum_{I\in\mathcal{I}} \Lambda_{PI}$, we will first show the relation

$$I_{m\mathcal{A}}(f^{\nu}K_f) \subset \sum_{I\in\mathcal{I}} \Lambda_{PI} \tag{5.2}$$

and then

$$(f^{\xi}) \subset I_{m\mathcal{A}}(f^{\nu}K_f). \tag{5.3}$$

Observe first that $\det(f^{\nu}\Delta_I K_f) \in \Lambda_{PI}$ because

$$\det(f^{\nu}\Delta_I K_f)T = f^{m\nu}K_f \operatorname{adj}(\Delta_I K_f)\Delta_I T.$$

Since every element of $I_{m\mathcal{A}}(f^{\nu}K_f)$ is an $\mathcal{A}$-linear combination of $\det(f^{\nu}\Delta_I K_f)$'s for all $I \in \mathcal{I}$, we have (5.2).

We next present (5.3). Let N_0 and D_0 be matrices with $K_f = [\,N_0^t \quad D_0^t\,]^t$. Since each row of V_f is generated by rows of $[\,N^t \quad D^t\,]^t$ over $\mathcal{A}_f$, there exist matrices $\widetilde{Y}_0$ and $\widetilde{X}_0$ over $\mathcal{A}_f$ such that $V_f = \left[\,\widetilde{Y}_0 f^{\nu} \quad \widetilde{X}_0 f^{\nu}\,\right][\,N^t \quad D^t\,]^t$. Thus, since V_f is nonsingular over $\mathcal{A}_f$, we have $\left[\,\widetilde{Y}_0 \quad \widetilde{X}_0\,\right][\,N_0^t \quad D_0^t\,]^t = E_m$, which implies that (N_0, D_0) is a right-coprime factorization of the plant P over $\mathcal{A}_f$. Recall here that $\mathcal{W}_{P,\mathcal{A}_f}$ is free of rank n. Thus by Lemma 4.6 there exist matrices $\widetilde{N}_0$ and $\widetilde{D}_0$ such that $(\widetilde{N}_0, \widetilde{D}_0)$ is a left-coprime factorization of the plant P over $\mathcal{A}_f$. Let Y_0 and X_0 be matrices over $\mathcal{A}_f$ such that $\widetilde{N}_0 Y_0 + \widetilde{D}_0 X_0 = E_n$ holds. Then we have the following matrix equation:

$$\begin{bmatrix} \widetilde{Y}_0 & \widetilde{X}_0 \\ -\widetilde{D}_0 & \widetilde{N}_0 \end{bmatrix} \begin{bmatrix} N_0 & -X_0 \\ D_0 & Y_0 \end{bmatrix} = \begin{bmatrix} E_m & -\widetilde{Y}_0 X_0 + \widetilde{X}_0 Y_0 \\ O & E_n \end{bmatrix}. \tag{5.4}$$

Denote by R the matrix $[\,-X_0^t \quad Y_0^t\,]^t$. Then the matrix $[\,K_f \quad R\,]$ is invertible over $\mathcal{A}_f$ since the right-hand side of (5.4) is invertible. For each $I \in \mathcal{I}$, let $\overline{I}$ be the ordered set of n distinct integers between 1 and $m+n$ excluding m integers in I and let $\overline{i_1}, \ldots, \overline{i_n}$ be elements of $\overline{I}$ in ascending order. Let $\Delta_{\overline{I}} \in \mathcal{A}^{m\times(m+n)}$ denote the matrix whose $(k, \overline{i_k})$-entry is 1 for $\overline{i_k} \in \overline{I}$ and zero otherwise. Then, by using Laplace's expansion, the following holds:

$$\det([\,K_f \quad R\,]) = \sum_{I\in\mathcal{I}} (\pm \det(\Delta_I K_f)\det(\Delta_{\overline{I}} R)),$$

which is a unit of $\mathcal{A}_f$. From this and since the ideal $I_{m\mathcal{A}_f}(K_f)$ is generated by $\det(\Delta_I K_f)$'s for all $I \in \mathcal{I}$, we have $I_{m\mathcal{A}_f}(K_f) = \mathcal{A}_f$. This equality over $\mathcal{A}_f$ gives (5.3) for a sufficiently large integer ξ.

From (5.2) and (5.3), the relation $\sum_{f\in F}(f^{\xi}) \subset \sum_{I\in\mathcal{I}} \Lambda_{PI}$ holds. Therefore we conclude that the relation $\sum_{I\in\mathcal{I}} \Lambda_{PI} = \mathcal{A}$ holds.

(c) "(iii)→(i)": To prove the stabilizability, we will construct a stabilizing controller of the causal plant P from right-coprime factorizations over $\mathcal{A}_f$ with some f's in $\mathcal{A}$. Let N and D be matrices over $\mathcal{A}$ such that $P = ND^{-1}$ and D is $\mathcal{Z}$-nonsingular. From (3.1), there exist λ_I's such that $\sum \lambda_I = 1$, where λ_I is an element of generalized elementary factor Λ_{PI} of the plant P with respect to I in $\mathcal{I}$; that is, $\lambda_I \in \Lambda_{PI}$. Now let these λ_I's be fixed. Further, let $\mathcal{I}^{\sharp}$ be the set of I's of these nonzero λ_I's; that is, $\sum_{I\in\mathcal{I}^{\sharp}} \lambda_I = 1$. As in (b), we can consider without loss of generality that for every

$I \in \mathcal{I}^\sharp$, λ_I is not a nilpotent element of $\mathcal{A}$. For each $I \in \mathcal{I}^\sharp$, the $\mathcal{A}_{\lambda_I}$-module $\mathcal{T}_{P,\mathcal{A}_{\lambda_I}}$ is free of rank m by Lemma 4.5. As in (b) again, let V_{λ_I} be a square matrix of size m whose rows are m distinct generators of the $\mathcal{A}_{\lambda_I}$-module $M_r([\,N^t \quad D^t\,]^t)$ ($\simeq \mathcal{T}_{P,\mathcal{A}_{\lambda_I}}$) and assume without loss of generality that V_{λ_I} is over $\mathcal{A}$. Then there exist matrices $\widetilde{X}_I$, $\widetilde{Y}_I$, N_I, D_I over $\mathcal{A}_{\lambda_I}$ such that

$$\begin{gathered}[\,N^t \quad D^t\,]^t = [\,N_I^t \quad D_I^t\,]^t V_{\lambda_I}, \quad \left[\widetilde{Y}_I \quad \widetilde{X}_I\right][\,N^t \quad D^t\,]^t = V_{\lambda_I}, \\ \widetilde{Y}_I N_I + \widetilde{X}_I D_I = E_m \end{gathered} \tag{5.5}$$

with $P = N_I D_I^{-1}$ over $\mathcal{F}(\mathcal{A}_{\lambda_I})$.

We here present a formula of a stabilizing controller which is constructed from the matrices $\widetilde{X}_I$ and $\widetilde{Y}_I$. For any positive integer ω, there are coefficients a_I's in $\mathcal{A}$ with $\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega = 1$. Let ω be a sufficiently large integer. Thus the matrices $\lambda_I^\omega D_I \widetilde{X}_I$ and $\lambda_I^\omega D_I \widetilde{Y}_I$ are over $\mathcal{A}$ for every $I \in \mathcal{I}^\sharp$. The stabilizing controller we will construct has the form

$$C = \left(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I\right)^{-1} \left(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{Y}_I\right). \tag{5.6}$$

In the following we first consider that the matrix $(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I)$ is $\mathcal{Z}$-nonsingular and show that the plant is stabilized by the matrix C of (5.6). After showing it, we will be concerned with the case where the matrix $(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I)$ is $\mathcal{Z}$-singular.

Suppose that the matrix $(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I)$ is $\mathcal{Z}$-nonsingular. To prove that C is a stabilizing controller of P, it is sufficient to show that $(P, C) \in \widehat{F}_{\mathrm{ad}}$ and that four blocks of (2.1) are over $\mathcal{A}$.

We first show that $(P, C) \in \widehat{F}_{\mathrm{ad}}$. The following matrix equation holds:

$$\begin{aligned} E_m + CP &= E_m + \left(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I\right)^{-1} \left(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{Y}_I\right) N D^{-1} \\ &= \left(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I\right)^{-1} \\ &\qquad \left(\left(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I\right) D + \left(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{Y}_I\right) N\right) D^{-1}. \end{aligned}$$

By the (1,1)-block of (5.8), we have

$$E_m + CP = \left(\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I\right)^{-1}. \tag{5.7}$$

This shows that $\det(E_m + CP)$ is a unit of $\mathcal{F}$ so that $(P, C) \in \widehat{F}_{\mathrm{ad}}$.

Next we show that four blocks of (2.1) are over $\mathcal{A}$. The $(2, 2)$-block is the inverse of (5.7):

$$(E_m + CP)^{-1} = \sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I.$$

Similarly, simple calculations show that other blocks are also over $\mathcal{A}$ as follows:
$(2,1)$-block:

$$C(E_n+PC)^{-1}=\sum_{I\in\mathcal{I}^\sharp}a_I\lambda_I^\omega D_I\widetilde{Y}_I,$$

$(1,1)$-block:

$$(E_n+PC)^{-1}=E_n-\sum_{I\in\mathcal{I}^\sharp}a_I\lambda_I^\omega N_I\widetilde{Y}_I,$$

$(1,2)$-block:

$$-P(E_m+CP)^{-1}=-\sum_{I\in\mathcal{I}^\sharp}a_I\lambda_I^\omega N_I\widetilde{X}_I.$$

To finish the proof, we proceed to deal with the case where the matrix $(\sum_{I\in\mathcal{I}^\sharp}a_I\lambda_I^\omega D_I\widetilde{X}_I)$ is $\mathcal{Z}$-singular. To make the matrix $\mathcal{Z}$-nonsingular, we reconstruct the matrices $\widetilde{X}_I$ and $\widetilde{Y}_I$ with an $I\in\mathcal{I}^\sharp$.

Since the sum of $a_I\lambda_I^\omega$'s for $I\in\mathcal{I}^\sharp$ is equal to 1, by Remark 4.4(i, iii) there exists at least one summand, say, $a_{I_0}\lambda_{I_0}^\omega$ with an $I_0\in\mathcal{I}^\sharp$, such that both a_{I_0} and λ_{I_0} belong to $\mathcal{A}\backslash\mathcal{Z}$. Let R_{I_0} be a parameter matrix of $\mathcal{A}_{\lambda_{I_0}}^{m\times n}$. Then the following matrix equation holds over $\mathcal{A}_{\lambda_{I_0}}$:

$$(\widetilde{Y}_{I_0}+R_{I_0}\widetilde{D}_{I_0})N_{I_0}+(\widetilde{X}_{I_0}-R_{I_0}\widetilde{N}_{I_0})D_{I_0}=E_m,$$

where $\widetilde{D}_{I_0}=\det(\lambda_{I_0}^\omega D_{I_0})E_n$ and $\widetilde{N}_{I_0}=\lambda_{I_0}^\omega N_{I_0}\operatorname{adj}(\lambda_{I_0}^\omega D_{I_0})$. Since ω is a sufficiently large integer, the following matrix equation is over $\mathcal{A}$:

$$\begin{aligned}&\big(\lambda_{I_0}^\omega(\widetilde{Y}_{I_0}+R_{I_0}\widetilde{D}_{I_0})\big)\big(\lambda_{I_0}^\omega N_{I_0}\big)\\&\qquad+\big(\lambda_{I_0}^\omega(\widetilde{X}_{I_0}-R_{I_0}\widetilde{N}_{I_0})\big)\big(\lambda_{I_0}^\omega D_{I_0}\big)=\lambda_{I_0}^{2\omega}E_m,\end{aligned}$$

where the matrices surrounded by "$\big($" and "$\big)$" in the left-hand side are over $\mathcal{A}$. From the first matrix equation of (5.5), $\det(D)=\det(D_I)\det(V_{\lambda_I})$ over $\mathcal{A}_{\lambda_I}$ for every $I\in\mathcal{I}^\sharp$. Thus by Remark 4.4(iii) the matrix $\lambda_{I_0}^\omega D_{I_0}$ is $\mathcal{Z}$-nonsingular and so is the matrix $\widetilde{D}_{I_0}$ $(=\det(\lambda_{I_0}^\omega D_{I_0})E_n)$.

Consider now the following matrix equation over $\mathcal{A}$:

$$\begin{aligned}&\begin{bmatrix}\sum_{I\in\mathcal{I}^\sharp}a_I\lambda_I^\omega D_I\widetilde{X}_I & \sum_{I\in\mathcal{I}^\sharp}a_I\lambda_I^\omega D_I\widetilde{Y}_I\\ -a_{I_0}\lambda_{I_0}^\omega\det(\lambda_{I_0}^\omega D_{I_0})\widetilde{N}_{I_0} & a_{I_0}\lambda_{I_0}^\omega\det(\lambda_{I_0}^\omega D_{I_0})\widetilde{D}_{I_0}\end{bmatrix}\begin{bmatrix}D & O\\ N & E_n\end{bmatrix}\\&\qquad=\begin{bmatrix}D & \sum_{I\in\mathcal{I}^\sharp}a_I\lambda_I^\omega D_I\widetilde{Y}_I\\ O & a_{I_0}\lambda_{I_0}^\omega\det(\lambda_{I_0}^\omega D_{I_0})\widetilde{D}_{I_0}\end{bmatrix}.\end{aligned}\tag{5.8}$$

The $(1,1)$-block of (5.8) can be understood in the following way. From the last matrix equation in (5.5) we have the following matrix equation over $\mathcal{A}_{\lambda_I}$:

$$D_I\widetilde{Y}_IN+D_I\widetilde{X}_ID=D.$$

Considering the above equation multiplied by $a_I\lambda_I^\omega$ over $\mathcal{A}$, we have the following equation over $\mathcal{A}$:

$$a_I\lambda_I^\omega D_I\widetilde{Y}_IN+a_I\lambda_I^\omega D_I\widetilde{X}_ID=a_I\lambda_I^\omega D+a_I\lambda_I^\omega Z,\tag{5.9}$$

where Z is a matrix over $\mathcal{A}$ such that $\lambda_I^x Z$ is the zero matrix for some positive integer x. Since ω is a large positive integer, we can consider that the matrix $a_I \lambda_I^\omega Z$ in (5.9) becomes the zero matrix. Therefore, the $(1,1)$-block of (5.8) holds. Then the matrix of the right-hand side of (5.8) is $\mathcal{Z}$-nonsingular since both of the matrices D and $a_{I_0}\lambda_{I_0}^\omega \det(\lambda_{I_0}^\omega D_{I_0})\widetilde{D}_{I_0}$ in the right-hand side of (5.8) are $\mathcal{Z}$-nonsingular. Hence the first matrix of (5.8) is also $\mathcal{Z}$-nonsingular by Remark 4.4(iii). By Lemma 4.3 and (5.8), there exists a matrix R'_{I_0} of $\mathcal{A}^{m\times n}$ such that the following matrix is $\mathcal{Z}$-nonsingular:

$$\sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I - a_{I_0}\lambda_{I_0}^{2\omega} D_{I_0} \operatorname{adj}(\lambda_{I_0}^\omega D_{I_0}) R'_{I_0} \widetilde{N}_{I_0}. \tag{5.10}$$

Now let $R_{I_0} := \lambda_{I_0}^\omega \operatorname{adj}(\lambda_{I_0}^\omega D_{I_0}) R'_{I_0}$, $\widetilde{X}_{I_0} := \widetilde{X}_{I_0} - R_{I_0}\widetilde{N}_{I_0}$, and $\widetilde{Y}_{I_0} := \widetilde{Y}_{I_0} + R_{I_0}\widetilde{D}_{I_0}$. Then the matrix $\sum_{I\in\mathcal{I}^\sharp} a_I\lambda_I^\omega D_I \widetilde{X}_I$ becomes equal to (5.10) and $\mathcal{Z}$-nonsingular. □

Remark 5.1. From the proof above, if (i) we can check (3.1) and if (ii) we can construct the right-coprime factorizations of the given causal plant over $\mathcal{A}_{\lambda_I}$ for every $I \in \mathcal{I}^\sharp$, then we can construct stabilizing controllers of the plant, where λ_I is an element of the generalized elementary factor of the plant. For (i), if we can compute, for example, the Gröbner basis [4] over $\mathcal{A}$ and if the generalized elementary factors of the plant are finitely generated, (3.1) can be checked. For (ii), it is already known by Lemmas 4.5 and 4.6 that there exist the right-coprime factorizations of the plant over $\mathcal{A}_{\lambda_I}$.

Let us give an example concerning the Gröbner basis. Consider the generalized elementary factors of Example 3.4. They are expressed as

$$\begin{aligned}
\Lambda_{PI_1} &= (\langle(1+2z)(1+z+z^2)(1-3z)\rangle) + (\langle(1+2z)(1+z+z^2)z^2\rangle)\\
&\qquad +(\langle(1+2z)(1+z+z^2)z^3\rangle),\\
\Lambda_{PI_2} &= (\langle(1+z)(1+2z+4z^2)(1-3z)\rangle) + (\langle(1+z)(1+2z+4z^2)z^2\rangle)\\
&\qquad +(\langle(1+z)(1+2z+4z^2)z^3\rangle),\\
\Lambda_{PI_3} &= (\langle(1+z)(1+2z)(1-3z)\rangle) + (\langle(1+z)(1+2z)z^2\rangle)\\
&\qquad +(\langle(1+z)(1+2z)z^3\rangle).
\end{aligned}$$

Hence each of them has three generators and so is finitely generated. Suppose here that we can calculate the Gröbner basis over $\mathcal{A}$ (of Example 3.4). Then as above the plant is stabilizable if and only if the Gröbner basis of the nine generators contains 1.

In the following two examples we follow the proof of Theorem 3.3. In the first one, we construct a stabilizing controller with part (c). In the other example, we follow part (b). On the other hand we do not follow part (a) since it can be followed easily with part (a) of (i) in the proof of Proposition 4.1.

Example 5.2. We continue Example 3.4 (and 4.7) and construct a stabilizing controller of the plant as in (iii)→(i) of the proof above. Let the notation be as in Examples 3.4 and 4.7.

Since, in this example, $\Lambda_{PI_1} + \Lambda_{PI_2} = \mathcal{A}$ holds, $\mathcal{I}^\sharp = \{I_1, I_2\}$. For $I_1 \in \mathcal{I}^\sharp$, the matrices N_{I_1}, D_{I_1}, $\widetilde{X}_{I_1}$, and $\widetilde{Y}_{I_1}$ of (5.5) over $\mathcal{A}_{\lambda_{I_1}}$ have been calculated as (4.5) and (4.6). For $I_2 \in \mathcal{I}^\sharp$, the matrices N_{I_2}, D_{I_2}, $\widetilde{X}_{I_2}$, and $\widetilde{Y}_{I_2}$ of (5.5) over $\mathcal{A}_{\lambda_{I_2}}$ can be calculated analogously as follows:

$$\begin{aligned}
N_{I_2} &= \begin{bmatrix} \lambda_{I_2}^{-1}\alpha_{I_2}\langle(1+2z)(1-3z+z^2)(1+z+z^2)\rangle \\ 1 \end{bmatrix},\\
D_{I_2} &= [\,\lambda_{I_2}^{-1}\alpha_{I_2}\langle(1+z)(1+2z)(1-3z+z^2)\rangle\,],
\end{aligned}$$

$$\widetilde{Y}_{I_2} = [\,0 \quad 1\,]\,, \widetilde{X}_{I_2} = [\,0\,]\,.$$

Then the following matrices are over $\mathcal{A}$:

$$\begin{aligned}
&\lambda_{I_1} D_{I_1} \widetilde{X}_{I_1} = [\,0\,]\,, \quad \lambda_{I_1} D_{I_1} \widetilde{Y}_{I_1} = [\,\alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle \quad 0\,]\,,\\
&\lambda_{I_2} D_{I_2} \widetilde{X}_{I_2} = [\,0\,]\,, \quad \lambda_{I_2} D_{I_2} \widetilde{Y}_{I_2} = [\,0 \quad \alpha_{I_2}\langle(1+z)(1+2z)(1-3z+z^2)\rangle\,]\,.
\end{aligned}$$

Hence in this example, we can let $\omega = 1$ as a sufficiently large integer and $a_I = 1$ for all $I \in \mathcal{I}^\sharp$ (since $\sum_{I\in\mathcal{I}^\sharp} \lambda_I^\omega = 1$).

Note here that the matrix $\lambda_{I_1} D_{I_1} \widetilde{X}_{I_1} + \lambda_{I_2} D_{I_2} \widetilde{X}_{I_2}$ is $\mathcal{Z}$-singular. Hence we should reconstruct the matrices $\widetilde{Y}_{I_i}$ and $\widetilde{X}_{I_i}$ with i being either 1 or 2 as in the proof of Theorem 3.3. Since, in this example, both λ_{I_1} and λ_{I_2} are nonzerodivisors, we can choose each of 1 and 2. This example proceeds by reconstructing the matrices $\widetilde{Y}_{I_1}$ and $\widetilde{X}_{I_1}$, which means that I_1 is used as I_0 in the proof of Theorem 3.3. The actual reconstruction is done by following the proof of Lemma 4.3.

Consider the first matrix of (5.8). Recall that $\widetilde{N}_{I_0} = \lambda_{I_0}^\omega N_{I_0} \operatorname{adj}(\lambda_{I_0}^\omega D_{I_0})$ and $\widetilde{D}_{I_0} = \det(\lambda_{I_0}^\omega D_{I_0}) E_n$. In this example, they are given as

$$\begin{aligned}
\widetilde{N}_{I_1} &= (\widetilde{N}_{I_0} =) \begin{bmatrix} \lambda_{I_1} \\ \alpha_{I_1}\langle(1+z)(1-3z)(1+2z+4z^2)\rangle \end{bmatrix},\\
\widetilde{D}_{I_1} &= (\widetilde{D}_{I_0} =) \alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle E_2.
\end{aligned}$$

One can check that the first matrix of (5.8) is $\mathcal{Z}$-nonsingular. Then we construct a matrix R'_{I_0} of $\mathcal{A}^{1\times 2}$ such that (5.10) is $\mathcal{Z}$-nonsingular. To do so, we follow temporarily the proof of the Lemma 4.3.

Consider the first matrix of (5.8) as the matrix of (4.2), that is,

$$\begin{aligned}
A &= \sum_{I\in\mathcal{I}^\sharp} a_I \lambda_I^\omega D_I \widetilde{X}_I = [\,0\,]\,,\\
B &= -a_{I_0} \lambda_{I_0}^\omega \det(\lambda_{I_0}^\omega D_{I_0}) \widetilde{N}_{I_0}\\
&= -\alpha_{I_1} \lambda_{I_1} \langle(1+z)(1+2z)(1-3z)\rangle \begin{bmatrix} \lambda_{I_1} \\ \alpha_{I_1}\langle(1+z)(1-3z)(1+2z+4z^2)\rangle \end{bmatrix}.
\end{aligned}$$

Then we choose a full-size a minor of $[\,A^t \quad B^t\,]^t$ having as few rows from B as possible. In this example, we can choose both entries in B. Here we choose the $(1,1)$-entry of B, so that

$$a = -\alpha_{I_1} \lambda_{I_1}^2 \langle(1+z)(1+2z)(1-3z)\rangle. \tag{5.11}$$

Thus we have $k = 1$, $i_1 = 1$, and $j_1 = 1$, where the notations $k, i_1, \ldots, i_k$, and $j_1, \ldots, j_k$ are as in the proof of Lemma 4.3. Hence R in the proof is given as $R = [\,1 \quad 0\,]$. We can confirm that $A + RB = [\,a\,]$ which is $\mathcal{Z}$-nonsingular by observing that every factor of the right-hand side of (5.11) has a nonzero constant term.

From here on we proceed with following again the proof of Theorem 3.3. The notation R used above corresponds to the notation R'_{I_0} in the proof of Theorem 3.3 (that is, $R'_{I_0} = [\,1 \quad 0\,]$). The matrix R_{I_1} is given as follows:

$$R_{I_1} = (R_{I_0} =) \lambda_{I_1}^\omega \operatorname{adj}(\lambda_{I_1}^\omega D_{I_1}) R'_{I_1} = \lambda_{I_1} [\,1 \quad 0\,]\,.$$

Then new $\widetilde{X}_{I_1}$ and $\widetilde{Y}_{I_1}$ are given as follows:

$$\begin{aligned}\widetilde{X}_{I_1} &:= \widetilde{X}_{I_1} - R_{I_1}\widetilde{N}_{I_1} = [\,-\lambda_{I_1}^2\,],\\ \widetilde{Y}_{I_1} &:= \widetilde{Y}_{I_1} + R_{I_1}\widetilde{D}_{I_1} = [\,1+\alpha_{I_1}\lambda_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle \quad 0\,].\end{aligned}$$

Therefore, a stabilizing controller C of the form (5.6) is obtained as

$$\begin{aligned}C &= (\lambda_{I_1}D_{I_1}\widetilde{X}_{I_1} + \lambda_{I_2}D_{I_2}\widetilde{X}_{I_2})^{-1}(\lambda_{I_1}D_{I_1}\widetilde{Y}_{I_1} + \lambda_{I_2}D_{I_2}\widetilde{Y}_{I_2})\\ &= \frac{-1}{\alpha_{I_1}\lambda_{I_1}^2\langle(1+z)(1+2z)(1-3z)\rangle}\\ &\qquad \begin{bmatrix}\alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle(1+\alpha_{I_1}\lambda_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle)\\ \alpha_{I_2}\langle(1+z)(1+2z)(1-3z+z^2)\rangle\end{bmatrix}^t.\end{aligned}$$

The matrix $H(P,C)$ over $\mathcal{A}$ with the stabilizing controller C above is expressed as follows:

$$H(P,C) = \begin{bmatrix}h_{11} & h_{12} & h_{13}\\ h_{21} & h_{22} & h_{23}\\ h_{31} & h_{32} & h_{33}\end{bmatrix},$$

where

$$\begin{aligned}h_{11} &= -\alpha_{I_1}\lambda_{I_1}^2\langle(1+z)(1+2z)(1-3z)\rangle\\ &\qquad\qquad +\alpha_{I_2}\langle(1+z)(1-3z+z^2)(1+2z+4z^2)\rangle,\\ h_{12} &= -\alpha_{I_2}\langle(1+2z)(1+z+z^2)(1-3z+z^2)\rangle,\\ h_{13} &= \lambda_{I_1}^3,\\ h_{21} &= -\alpha_{I_1}\langle(1+z)(1-3z)(1+2z+4z^2)\rangle\\ &\qquad\qquad (1+\lambda_{I_1}\alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle),\\ h_{22} &= \alpha_{I_1}(\langle(1+2z)(1-3z)(1+z+z^2)\rangle(1+\alpha_{I_1}\lambda_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle)\\ &\qquad\qquad -\lambda_{I_1}^2\langle(1+z)(1+2z)(1-3z)\rangle),\\ h_{23} &= \alpha_{I_1}\lambda_{I_1}^2\langle(1+z)(1-3z)(1+2z+4z^2)\rangle,\\ h_{31} &= \alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle(1+\alpha_{I_1}\lambda_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle),\\ h_{32} &= \alpha_{I_2}\langle(1+z)(1+2z)(1-3z+z^2)\rangle,\\ h_{33} &= -\alpha_{I_1}\lambda_{I_1}^2\langle(1+z)(1+2z)(1-3z)\rangle.\end{aligned}$$

Before finishing this example, let us show that the $\mathcal{A}$-module $\mathcal{T}_P$ is *not* free. We show it by contradiction. Suppose that $\mathcal{T}_P$ is free. Then the $\mathcal{A}$-module $M_r(T)$ is also free. Since the matrix D, a part of T, is nonsingular, the rank of $M_r(T)$ is m. Let V be a matrix in $(\mathcal{A})_m$ whose rows are m distinct generators of $M_r(T)$. As in (5.5), we have matrices $\widetilde{Y}$, $\widetilde{X}$, N', D' over $\mathcal{A}$ such that

$$[\,N^t \quad D^t\,]^t = [\,N'^t \quad D'^t\,]^t V,\quad \begin{bmatrix}\widetilde{Y} & \widetilde{X}\end{bmatrix}[\,N^t \quad D^t\,]^t = V,\quad \widetilde{Y}'N' + \widetilde{X}'D' = E_1.$$

However, the last matrix equation is inconsistent with the fact that the plant P does not have coprime factorization. Therefore, $\mathcal{T}_P$ is not free. Nevertheless we note that $\mathcal{T}_P$ is projective by Theorem 3.3. □

Example 5.3. Let us follow part (b) in the proof of Theorem 3.3. Suppose that (i) of Theorem 3.3 holds, that is, the modules $\mathcal{T}_P$ and $\mathcal{W}_P$ are projective.

Consider again the plant P of (3.2). Let $F_1 = \{\lambda_{I_1}, \lambda_{I_2}\}$, where λ_{I_1} and λ_{I_2} are given as in (3.8). Then we have known that $\Sigma_{f\in F_1} f = 1$ and that there exists a right-coprime factorization of the plant over $\mathcal{A}_f$ for every $f \in F_1$. By Lemma 4.2, the transposed plant P^t is stabilizable. We can construct its stabilizing controller by analogy to Example 5.2. Further we see that for both λ_{I_1} and λ_{I_2}, the transposed plant P^t has right-coprime factorizations over $\mathcal{A}_{\lambda_{I_1}}$ and $\mathcal{A}_{\lambda_{I_2}}$; that is, P has left-coprime factorizations over $\mathcal{A}_{\lambda_{I_1}}$ and $\mathcal{A}_{\lambda_{I_2}}$. Thus let $F_2 = \{\lambda_{I_1}, \lambda_{I_2}\}$. For $\lambda_{I_1} \in F_2$, we have the matrices $\widetilde{N}_{I_1}$ $\widetilde{D}_{I_1}$, Y_{I_1}, X_{I_1} over $\mathcal{A}_{\lambda_{I_1}}$ such that $\widetilde{N}_{I_1} Y_{I_1} + \widetilde{N}_{I_1} X_{I_1} = E_2$ and

$$\begin{aligned}
\widetilde{N}_{I_1} &= \left[\begin{smallmatrix}1\\0\end{smallmatrix}\right], \quad Y_{I_1} = [\,1 \quad 0\,], \quad X_{I_1} = \left[\begin{smallmatrix}0&0\\0&1\end{smallmatrix}\right],\\
\widetilde{D}_{I_1} &= \begin{bmatrix} \lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1+2z)(1-3z)\rangle & 0 \\ \lambda_{I_1}^{-1}\alpha_{I_1}\langle(1+z)(1-3z)(1+2z+4z^2)\rangle & 1 \end{bmatrix}.
\end{aligned}$$

On the other hand, for $\lambda_{I_2} \in F_2$, we have the matrices $\widetilde{N}_{I_2}$ $\widetilde{D}_{I_2}$, Y_{I_2}, X_{I_2} over $\mathcal{A}_{\lambda_{I_2}}$ such that $\widetilde{N}_{I_2} Y_{I_2} + \widetilde{N}_{I_2} X_{I_2} = E_2$ and

$$\begin{aligned}
\widetilde{N}_{I_2} &= \left[\begin{smallmatrix}1\\0\end{smallmatrix}\right], \quad Y_{I_2} = [\,1 \quad 0\,], \quad X_{I_2} = \left[\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right],\\
\widetilde{D}_{I_2} &= \begin{bmatrix} 0 & \lambda_{I_2}^{-1}\alpha_{I_2}\langle(1+z)(1+2z)(1-3z+z^2)\rangle \\ 1 & -\lambda_{I_2}^{-1}\alpha_{I_2}\langle(1+2z)(1+z+z^2)(1-3z+z^2)\rangle \end{bmatrix}.
\end{aligned}$$

Now we let $F = \{\lambda_{I_1}^2, \lambda_{I_1}\lambda_{I_2}, \lambda_{I_2}^2\}$ $(= \{f_1 f_2 \,|\, f_1 \in F_1, f_2 \in F_2\})$. Then F still generates $\mathcal{A}$ since $\lambda_{I_1}^2 + 2\lambda_{I_1}\lambda_{I_2} + \lambda_{I_2}^2 = 1$.

In the following we consider the case $f = \lambda_{I_1}^2$. Then using the matrix K of (4.3), we have (5.1) with $\nu = 1$, $K_f = K$, and $V_f = \lambda_{I_1}\Delta_{I_1}T$.

Then the ideal $I_{m\mathcal{A}}(f^\nu K_f)$ is generated by

$$\lambda_{I_1}^3, \quad \alpha_{I_1}\lambda_{I_1}^2\langle(1+z)(1-3z)(1+2z+4z^2)\rangle, \quad \alpha_{I_1}\lambda_{I_1}^2\langle(1+z)(1+2z)(1-3z)\rangle.$$

Thus since each of them is in Λ_{PI_1}, (5.2) holds. Further we can observe that for any integer ξ greater than 1, (5.3) holds since $\lambda_{I_1}^3 \in I_{m\mathcal{A}}(f^\nu K_f)$.

For the other cases $f = \lambda_{I_1}\lambda_{I_2}$ and $f = \lambda_{I_2}^2$, we can follow the relations of (5.2) and (5.3) analogously. Details are left to interested readers.

Remark 5.4. Since Anantharam's example in [1] is artificial, we do not present here the construction of a stabilizing controller. However, we can construct it as part (c) in the proof of Theorem 3.3 (Since Anantharam in [1] did not consider the causality, we let $\mathcal{Z} = \{0\}$ so that $\mathcal{P} = \mathcal{F}$.)

6. Causality of stabilizing controllers.

In this section, we present two facts: (i) for a stabilizable causal plant, there exists at least one stabilizing causal controller and (ii) the stabilizing controller of the strictly causal plant is causal, which inherits Theorem 4.1 in section III of [14, p. 888] and Proposition 1 of [11].

PROPOSITION 6.1. *For every stabilizable causal plant, there exists at least one stabilizing causal controller of the plant.*

Proof. In the construction of the stabilizing controller in part (c) of the proof of Theorem 3.3, the denominator matrix of (5.6) is $\mathcal{Z}$-nonsingular. Suppose that the obtained stabilizing controller is expressed as $\widetilde{B}^{-1}\widetilde{A}$ with the matrices $\widetilde{A}$ and $\widetilde{B}$ over $\mathcal{A}$ such that $\widetilde{B}$ is $\mathcal{Z}$-nonsingular. Then since the relation $\widetilde{B}^{-1}\widetilde{A} = (\det(\widetilde{B})E_m)^{-1}(\mathrm{adj}(\widetilde{B})\widetilde{A})$ holds, every entry of $\widetilde{B}^{-1}\widetilde{A}$ is causal. $\square$

Proposition 6.2. *For every stabilizable strictly causal plant, all stabilizing controllers of the plant must be causal.*

Proof. Suppose that the plant P is stabilizable and strictly causal. Suppose further that C is a stabilizing controller of P. We employ the notation from part (c) of the proof of Theorem 3.3. Thus $a_{I_0}, \lambda_{I_0} \in \mathcal{A}\backslash\mathcal{Z}$ and $\widetilde{Y}_{I_0}N_{I_0} + \widetilde{X}_{I_0}D_{I_0} = E_m$ with $P = N_{I_0}D_{I_0}^{-1} \in \mathcal{F}(\mathcal{A}_{\lambda_{I_0}})$ from (5.5). Let $\mathcal{Z}_{\lambda_{I_0}} = \{z/1 \cdot u \in \mathcal{A}_{\lambda_{I_0}} \mid z \in \mathcal{Z}, u \text{ is a unit of } \mathcal{A}_{\lambda_{I_0}}\}$. Then this $\mathcal{Z}_{\lambda_{I_0}}$ is again a principal ideal of $\mathcal{A}_{\lambda_{I_0}}$.

Observe here that Lemma 8.3.2 of [13] and its proof hold even over a general commutative ring. According to its proof, there exist matrices $\widetilde{A}$ and $\widetilde{B}$ over $\mathcal{A}_{\lambda_{I_0}}$ such that $C = \widetilde{B}^{-1}\widetilde{A}$ and $\widetilde{A}N_{I_0} + \widetilde{B}D_{I_0} = E_m$ ($\widetilde{A}$ and $\widetilde{B}$ correspond to T and S, respectively, in the proof of Lemma 8.3.2 of [13]). Observe also that every entry of N_{I_0} is in $\mathcal{Z}_{\lambda_{I_0}}$. Thus reviewing the proof of Lemma 3.5 of [14], in which the calligraphic H and K in [14] correspond to $\mathcal{A}_{\lambda_{I_0}}$ and $\mathcal{Z}_{\lambda_{I_0}}$, respectively, we have $\det \widetilde{B} \in \mathcal{A}_{\lambda_{I_0}} \backslash \mathcal{Z}_{\lambda_{I_0}}$. This implies that $\widetilde{B}^{-1}\widetilde{A} \in \mathcal{P}^{m\times n}$ by noting that $\lambda_{I_0} \in \mathcal{A}\backslash\mathcal{Z}$. Thus C is causal. □

7. Further work. In this paper we have presented criteria for feedback stabilizability. We have also presented a construction of a stabilizing controller to which Sule's method cannot be applied. Recently the first author [8] has developed a parameterization of stabilizing controllers, which is based on the results of this paper and which does not require coprime factorizability. This can be applied to models to which Youla parameterization cannot be applied.
